(Received 4 April 2001; accepted for publication 9 October 2001)

A transient model for one-dimensional charge transport in an open quantum system is proposed. In the semiclassical limit, it reduces to the inflow boundary value problem for the classical transport equation. On this basis, the coupling of classical and quantum transport models through an interface is investigated. Suitable interface conditions are derived through asymptotic formulas involving the quantum reflection–transmission coefficients and time delays. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421635]

I. INTRODUCTION

In this work, we propose and analyze a method for coupling classical and quantum transport models in a one-dimensional time-dependent setting. This paper is the followup of a previous work of one of the authors,[1] where the one-dimensional stationary case was investigated. We shall see that the account of the time dependence increases the complexity of the coupling methodology to a large extent.

The problem can be formulated as follows. We consider a particle system (such as certain semiconductor devices, e.g., Resonant Tunnelling Diodes), which consists of a small localized portion (denoted by Q), where the dynamics of the particles is quantum and a large area (denoted by C), where the behavior of the particles can be well approximated by classical mechanics. For computational efficiency, it is desirable to use a classical mechanics model for the particles as long as they are in region C and to shift to a quantum model only when they cross the border between the C and Q regions. Similarly, when a particle leaves the Q region, one should be able to shift back to a classical model.

The problems posed by this procedure are twofold. First, independently of the consideration of the classical region, the quantum region is an open quantum system, which may gain or lose particles. Boundary conditions for open quantum systems are not easily derived. Such boundary conditions were proposed and analyzed in Refs. 2, 3 in the one-dimensional stationary case and in Refs. 4, 5 for the multidimensional stationary case (numerical studies of such boundary conditions can be found in Refs. 6–9, . . .). Approximate boundary conditions for the time-dependent case can be found in Refs. 10–12. In the present paper, we shall present an alternative approach to the search for boundary conditions: the *a priori* construction of density matrices that are exact solutions of the quantum von-Neumann equation, and that are consistent with the statistics of the particles coming into the quantum region.

However, there is not a unique such construction. This is due to the necessary ''delocalization'' of the classical particles when they enter the quantum region. Indeed, the quantum-mechanical picture of a particle is a wave packet. If there is only one classical limit of a given

[a]Electronic mail: naoufel@mip.ups-tlse.fr
[b]Electronic mail: degond@mip.ups-tlse.fr
[c]Electronic mail: gamba@math.utexas.edu

quantum wave packet, the reciprocal is obviously untrue. A given classical particle may be the classical limit of many different wave packets. Therefore, when a classical particle crosses the border of the quantum region, one has to choose into which wave packet it will be transformed. Consequently, the construction depends on this arbitrarily chosen wave packet.

In this work, the construction is restricted to the case of a time-independent potential. This is because it makes a large use of the scattering states of the quantum structure, which are well defined only for time-independent potentials. This restriction will be waived in future work.

So far, we have discussed the problem of finding the correct solution of the quantum von-Neumann equation, given the statistics of the incoming particles. Now, we have to examine the reverse question, i.e., how the quantum behavior of the particles in the Q region affects the dynamics in the C region.

For that purpose, we consider the Wigner transform of the density matrix in the Q region and perform a semiclassical limit $\hbar \to 0$. We show that the formal limit of the Wigner distribution function satisfies the usual boundary value problem for the classical transport equation in Q with prescribed incoming data. Furthermore, the outgoing Wigner distribution function at the Q region boundary can be expressed in terms of the incoming data by means of quantum reflection–transmission probabilities and time delays. Since the incoming distribution in the Q region is the outgoing one of the C region and *vice versa*, we can assign similar reflection–transmission conditions to the classical distribution function at the $C-Q$ interface. These conditions only depend on the scattering probabilities and time delays of the quantum structure, but not on the expression of the density matrix in the Q region. Therefore, they lead to a self-contained problem for the classical distribution function, decoupled from that of the quantum region.

In this paper, we first give a general presentation and justification of the above described procedure. Then, we concentrate on the quantum region Q and perform the semiclassical analysis of the Wigner distribution function. Finally, we shall discuss questions regarding current continuity through the interface. We shall only develop formal arguments, and will defer rigorous proofs to a forthcoming paper.[13] A summary of the present approach can be found in Ref. 14.

II. THE COUPLING METHODOLOGY: FORMAL APPROACH

A. Setting of the problem

We consider a one-dimensional system consisting of a large number of independent particles moving along the whole real line. In the sequel, we shall consider electrons, since one of the potential application of the present work is to quantum semiconductor devices. However, the procedure would apply equally well to any other kind of particles. The electrons are subject to a given time-independent potential $V(x)$. We suppose that the gradients of the potential are small apart in a tiny localized region contained in the interval $[a, b]$, where they are large. Therefore, we can consider that the dynamics is classical in the region $C=\mathbb{R}\backslash[a,b]$ and quantum in the region $Q=[a,b]$. What is the precise meaning of small and large in terms of dimensionless parameters and an asymptotic analysis will be the subject of future work. In the present one, we shall take this for granted. Our aim is to find a procedure that couples a classical kinetic description of the particle system in the C region to a quantum statistical model in the Q region.

In $C=\mathbb{R}\backslash[a,b]$, the system is described by the classical particle distribution function $f(x,p,t)$, which is a function of position $x\in\mathbb{R}$, momentum $p\in\mathbb{R}$, and time $t>0$. It is a solution of the one-dimensional collisionless transport (or Vlasov) equation:

$$\partial_t f + v\,\partial_x f + e\frac{\partial V}{\partial x}\partial_p f = 0, \quad x\in\mathbb{R}\backslash[a,b], \quad v=\frac{p}{m}, \tag{1}$$

where m and e are, respectively, the mass and charge, and v, the velocity. At the boundary $\partial C=\{a,b\}$, inflow boundary conditions must be prescribed. At $x=a$ (resp., $x=b$), an inflow velocity for C is such that $v<0$ (resp., $v>0$). We therefore prescribe the boundary conditions

$$f(a,p,t)=f_a(p,t), p<0; \quad f(b,p,t)=f_b(p,t), \quad p>0, \tag{2}$$

where f_a and f_b obviously depend on the dynamics of the Q region.

In $Q=[a,b]$, the system is modeled by the density matrix $\rho(x,x',t)$, which is a solution of the von Neumann equation. However, instead of prescribing boundary conditions for the von Neumann equation at the boundary of the quantum region Q, we take another route. We choose to solve the von Neumann equation on the whole real line, but with a modified potential $\tilde{V}$ that coincides with V in Q and that is constant in C:

$$\tilde{V}(x)=\begin{cases} V_a:=V(a), & x\leqslant a,\\ V(x), & a\leqslant x\leqslant b,\\ V_b:=V(b), & x\geqslant b. \end{cases} \tag{3}$$

Therefore, the von Neumaann equation for ρ reads as

$$i\hbar\rho_t=(\tilde{H}_x-\tilde{H}_{x'})\rho, \quad (x,x',t)\in\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}, \tag{4}$$

where

$$\tilde{H}=-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2}-e\tilde{V}(x)$$

is the modified particle Hamiltonian in the potential $\tilde{V}$ and $\tilde{H}_x$, $\tilde{H}_{x'}$ are, respectively, the actions of $\tilde{H}$ on the x and x' variables. Now, which solution of the von Neumann equation we must consider, of course, depends of the distribution function in the C region. Therefore, the coupling problem can be summarized as follows: how f_a and f_b are linked with ρ and reciprocally how ρ is linked with f?

We first note that we are not going to consider initial value problems for Eqs. (1) and (4), but solutions for all times $t\in\mathbb{R}$ (so-called eternal solutions). The reason is the following. When entering the Q region, a classical particle must be delocalized into a wave packet. However, a wave packet has a finite extension in space and is in fact very unlikely to be compactly supported. In other words, even very far from the Q region, a classical particle interacts with it because of the tiny but nonzero tail of its wave packet representation. Therefore, the interaction of a classical particle with the Q region is nonlocal in time and actually extends infinitely in the past and in the future.

Now, to understand our coupling methodology, it is illuminating to first consider a classical dynamics in the Q region and derive a classical–classical coupling methodology. Of course, this strange question (why not just use the same classical model everywhere) is investigated just for a clearer exposition of the true classical–quantum coupling.

B. Classical–classical coupling

In this section, we suppose that, in the Q region, the system is described by a classical distribution function g, solution of the Vlasov equation,

$$\partial_t g+v\,\partial_x g+e\frac{\partial V}{\partial x}\partial_p g=0, \quad x\in[a,b], \quad v=\frac{p}{m}. \tag{5}$$

Of course, the boundary ∂Q of Q is $\partial Q=\partial C=\{a,b\}$. However, the incoming velocities for the domain Q at a (resp., b) are now such that $v>0$ (resp., $v<0$). Obviously, the boundary conditions for g at a and b must be

$$g(a,p,t)=g_a(p,t):=f(a,p,t), \quad p>0; \quad g(b,p,t)=g_b(p,t):=f(b,p,t), \quad p<0, \tag{6}$$

where $f(a,p,t)$ (for $p>0$) and $f(b,p,t)$ (for $p<0$) are supposedly known from the resolution of f in the C region. Reciprocally, the boundary conditions (2) for f must obviously be completed by the condition that

$$f_a(p,t) := g(a,p,t), \quad p<0; \quad f_b(p,t) := g(b,p,t), \quad p>0. \tag{7}$$

Now, we introduce the characteristic equations of (5):

$$\frac{dX}{dt} = \frac{P(t)}{m}; \quad \frac{dP}{dt} = e\frac{dV}{dx}(X(t)),$$

which are supposed to be uniquely solvable for a given set of initial conditions. This is certainly true, provided that the potential is smooth, which we shall assume from now on. We consider maximal solutions, which exist until the position X reaches one of the boundaries a or b of the domain. We denote by $(X,P)_{(t;x,p)}$; the solution at time t such that $(X,P)(0)=(x,p)$. Now, it is readily seen that

$$\phi_{(a,p_0,t_0)}(x,p,t) = \delta((x,p)-(X,P)_{(t-t_0;a,p_0)}),$$

is the unique measure solution of (5) that satisfies the boundary condition

$$v\,\phi_{(a,p_0,t_0)}(a,p,t) = \delta(p-p_0)\,\delta(t-t_0).$$

Here and in the remainder of the paper, δ denotes the Dirac delta measure. Writing g_a as a superposition of such elementary distributions:

$$\begin{aligned} g_a(p,t) &= \int_{t_0\in\mathbb{R}} \int_{p_0\in\mathbb{R}^+} g_a(p_0,t_0)\,\delta(p-p_0)\,\delta(t-t_0)dt_0\,dp_0 \\ &= \int_{t_0\in\mathbb{R}} \int_{p_0\in\mathbb{R}^+} (v_0 g_a(p_0,t_0))(v_0^{-1}\delta(p-p_0)\,\delta(t-t_0))dt_0\,dp_0 \end{aligned}$$

(with $v_0=p_0/m$), and similarly for g_b:

$$g_b(p,t) = \int_{t_0\in\mathbb{R}} \int_{p_0\in\mathbb{R}^-} (|v_0|g_b(p_0,t_0))(|v_0|^{-1}\delta(p-p_0)\,\delta(t-t_0))dt_0\,dp_0,$$

we can exactly represent g by the integral formula

$$\begin{aligned} g(x,p,t) = &\int_{t_0\in\mathbb{R}} \int_{p_0\in\mathbb{R}^+} (v_0 g_a(p_0,t_0))\phi_{(a,p_0,t_0)}(x,p,t)dt_0\,dp_0 \\ &+ \int_{t_0\in\mathbb{R}} \int_{p_0\in\mathbb{R}^-} (|v_0|g_b(p_0,t_0))\phi_{(b,p_0,t_0)}(x,p,t)dt_0\,dp_0. \end{aligned} \tag{8}$$

The measures $\phi_{(a,p_0,t_0)}$ (resp., $\phi_{(b,p_0,t_0)}$) are elementary distributions that describe particles entering the Q region at time t_0 through point a with momentum $p_0>0$ (resp., through point b and momentum $p_0<0$).

Now, (8) can be used to compute the outgoing traces of g on ∂Q as functions of its incoming traces g_a and g_b, i.e., [by (6)], of the outgoing traces of f (with respect to C). On the other hand, outgoing traces of g on ∂Q are also incoming traces of f on ∂C by virtue of (7). Therefore, this operation will ultimately give us an expression of the incoming traces of f as functions of its

outgoing traces, which will lead to a self-contained problem for f. Then, knowing f and, in particular, its outgoing traces by the resolution of this problem, we will find g by means of formula (8). We are now going to detail this program.

We start with the computation of the outgoing traces of $\phi_{(a,p_0,t_0)}$ and $\phi_{(b,p_0,t_0)}$. Again, using the smoothness of the potential that rules out any pathology of the trajectories, the characteristic $(X,P)_{(t;a,p_0)}$ with $p_0>0$ exits the domain Q after a certain time $\tau(p_0)$ either by point a with momentum $-p_0$ (in which case, we say that the particle is reflected) or by point b with momentum,

$$p_b(p_0)=\mathrm{sgn}(p_0)\sqrt{p_0^2+2me(V_b-V_a)} \tag{9}$$

(then, the particle is transmitted). The expression (9) obviously follows from the energy conservation, itself a consequence of the time independence of the potential. If the expression inside the square root defining $p_b(p_0)$ is negative, then reflection occurs certainly and the quantity $p_b(p_0)$ needs not be defined. We define reflection and transmission coefficients $R(p_0),T(p_0)$ in such a way that

$$R(p_0)=1-T(p_0)=\begin{cases}1, & \text{in the case of a reflection}\\ 0, & \text{in the case of a transmission.}\end{cases}$$

Then we can write

$$v\,\phi_{(a,p_0,t_0)}(a,p,t)=R(p_0)\,\delta(p+p_0)\,\delta((t-t_0)-\tau(p_0)),\quad p<0, \tag{10}$$

$$v\,\phi_{(a,p_0,t_0)}(b,p,t)=T(p_0)\,\delta(p-p_b(p_0))\,\delta((t-t_0)-\tau(p_0)),\quad p>0. \tag{11}$$

Similar definitions can, of course, be given for characteristics starting from b with momentum $p_0<0$. In particular, we define

$$p_a(p_0)=\mathrm{sgn}(p_0)\sqrt{p_0^2-2me(V_b-V_a)}.$$

This leads to the following expressions:

$$v\,\phi_{(b,p_0,t_0)}(b,p,t)=R(p_0)\,\delta(p+p_0)\,\delta((t-t_0)-\tau(p_0)),\quad p>0, \tag{12}$$

$$v\,\phi_{(b,p_0,t_0)}(a,p,t)=T(p_0)\,\delta(p-p_a(p_0))\,\delta((t-t_0)-\tau(p_0)),\quad p<0. \tag{13}$$

Now, from (10)–(13), we deduce, for $p<0$,

$$\begin{aligned}g(a,p,t)=&\int_{t_0\in\mathbb{R}}\int_{p_0\in\mathbb{R}^+}g_a(p_0,t_0)R(p_0)\,\delta(p+p_0)\,\delta((t-t_0)-\tau(p_0))dt_0\,dp_0\\&+\int_{t_0\in\mathbb{R}}\int_{p_0\in\mathbb{R}^-}\frac{|p_0|}{|p_a(p_0)|}g_b(p_0,t_0)T(p_0)\,\delta(p-p_a(p_0))\,\delta((t-t_0)-\tau(p_0))dt_0\,dp_0,\end{aligned}$$

or, after performing the integrations and noting that $p_0'=p_a(p_0)\Leftrightarrow p_0=p_b(p_0')$,

$$g(a,p,t)=R(-p)g_a(-p,t-\tau(-p))+T(p_b(p))g_b(p_b(p),t-\tau(p_b(p))).$$

Similarly, for $p>0$, we have

$$g(b,p,t)=\int_{t_0\in\mathbb{R}}\int_{p_0\in\mathbb{R}^-} g_b(p_0,t_0)R(p_0)\,\delta(p+p_0)\,\delta((t-t_0)-\tau(p_0))dt_0\,dp_0$$
$$+\int_{t_0\in\mathbb{R}}\int_{p_0\in\mathbb{R}^+}\frac{p_0}{p_b(p_0)}g_a(p_0,t_0)T(p_0)\,\delta(p-p_b(p_0))\,\delta((t-t_0)-\tau(p_0))dt_0\,dp_0,$$

or

$$g(b,p,t)=R(-p)g_b(-p,t-\tau(-p))+T(p_a(p))g_a(p_a(p),t-\tau(p_a(p))).$$

We note that, by time reversibility, $T(p_a(p))=T(-p)$ and $\tau(p_a(p))=\tau(-p)$ [for $p>0$ and when $p_a(p)$ is defined]. Similarly, $T(p_b(p))=T(-p)$ and $\tau(p_b(p))=\tau(-p)$ [for $p<0$ and when $p_b(p)$ is defined]. This finally leads to

$$g(a,p,t)=R(-p)g_a(-p,t-\tau(-p))+T(-p)g_b(p_b(p),t-\tau(-p)),\quad p<0, \tag{14}$$

$$g(b,p,t)=R(-p)g_b(-p,t-\tau(-p))+T(-p)g_a(p_a(p),t-\tau(-p)),\quad p>0. \tag{15}$$

Now, eliminating g by (6) and (7), we use (14) and (15) to set up a self-contained reflection–transmission problem for f:

$$f(a,p,t)=R(-p)f(a,-p,t-\tau(-p))+T(-p)f(b,p_b(p),t-\tau(-p)),\quad p<0, \tag{16}$$

$$f(b,p,t)=R(-p)f(b,-p,t-\tau(-p))+T(-p)f(a,p_a(p),t-\tau(-p)),\quad p>0. \tag{17}$$

These boundary conditions express the incoming traces of f as functions of its outgoing traces. They are very likely to lead to a well-posed problem for f in C (the existence of solutions for similar kinds of boundary conditions can be found in Refs. 15,16). With these boundary conditions, the Vlasov equation (1) can be solved in C without any reference to the distribution function in Q. Of course, via the reflection–transmission coefficients R, T and time delays τ, f depends on the potential in Q. Then, once f is found in C, formula (8) allows us to represent the solution in Q as an integral involving the boundary values of f at a and b.

We are going to duplicate the same methodology for the classical–quantum coupling in the next section.

C. Classical–quantum coupling

The first and nonobvious point is to define the analogs of the elementary distributions $\phi_{(a,p_0,t_0)}$ and $\phi_{(b,p_0,t_0)}$ that characterize particles entering the Q region at time t_0 and point a with momentum $p_0>0$ (resp., at point b and momentum $p_0<0$). We start by recalling the definition of the scattering states of the potential $\tilde{V}$. These are solutions ψ of the stationary Schrödinger equation:

$$\tilde{H}\psi=\mathcal{E}\psi \tag{18}$$

(where $\mathcal{E}$ is the energy) that are bounded on the real line but not square integrable. Elementary analysis[17] shows that for a given energy $\mathcal{E}$, the space of such solutions is of dimension zero, one or two according to the relative position of $\mathcal{E}$ with respect to V_a and V_b. A convenient basis of the solution space is provided by wave functions describing the diffusion of a plane wave coming from infinity by the potential inhomogeneity. These are given by the solutions of the following boundary value problem in the interval $[a,b]$:[2]

$$
\begin{aligned}
&-\frac{\hbar^2}{2m}\psi_p''-eV\psi_p=\left(\frac{p^2}{2m}-eV_a\right)\psi_p,\\
\text{for } p>0,\quad &\hbar\psi_p'(a)+ip\psi_p(a)=2ip,\\
&\hbar\psi_p'(b)=ip_b(p)\psi_p(b);
\end{aligned}
\tag{19}
$$

$$
\begin{aligned}
&-\frac{\hbar^2}{2m}\psi_p''-eV\psi_p=\left(\frac{p^2}{2m}-eV_b\right)\psi_p,\\
\text{for } p<0,\quad &\hbar\psi_p'(a)=-ip_a(p)\psi_p(a),\\
&\hbar\psi_p'(b)+ip\psi_p(b)=2ip.
\end{aligned}
\tag{20}
$$

Let us suppose, to fix the ideas, that $V_b>V_a$. Then $p_b(p)$ is always well defined. On the other hand, $p_a(p)$ is well defined only if $|p|\geqslant\sqrt{2em(V_b-V_a)}$. For $p>0$, the two solutions ψ_p and $\psi_{-p_b(p)}$ form a basis of the solution space of (18) associated with the energy $\mathcal{E}=p^2/2m-eV_a=p_b(p)^2/2m-eV_b$, which is therefore of dimension 2. ψ_p describes the scattering of a plane wave coming from $-\infty$ by the potential inhomogeneity, while $\psi_{-p_b(p)}$ describes the scattering of a plane wave coming from $+\infty$. For $p<0$ and $|p|\leqslant\sqrt{2em(V_b-V_a)}$, then $p_a(p)$ in formula (20) has to be defined as a complex square root: $p_a(p)=\pm i\sqrt{2me(V_b-V_a)-p^2}$. Which sign must be chosen in this definition is unimportant because the solution space is of dimension 1 and the two solutions are then proportional. In this case, the solution (20) represents the pure quantum reflection of a plane wave by a potential barrier.

The boundary conditions appearing in (19),(20) are consequences of the following explicit formula for ψ_p outside $[a,b]$ (this is because the potential $\tilde{V}$ is assumed constant in $\mathbb{R}\backslash[a,b]$):

$$
\text{for } p>0,\quad
\begin{aligned}
&\psi_p(x)=e^{ip[(x-a)/\hbar]}+A(p)e^{-ip[(x-a)/\hbar]},\quad x<a,\\
&\psi_p(x)=B(p)e^{ip_b(p)[(x-b)/\hbar]},\quad x>b;
\end{aligned}
\tag{21}
$$

where

$$
A(p)=\psi_p(a)-1:\quad B(p)=\psi_p(b),\quad p>0;
\tag{22}
$$

and

$$
\text{for } p<0,\quad
\begin{aligned}
&\psi_p(x)=B(p)e^{i[(x-a)/\hbar]p_a(p)},\quad x<a,\\
&\psi_p(x)=e^{i[(x-b)/\hbar]p}+A(p)e^{-ip[(x-b)/\hbar]},\quad x>b;
\end{aligned}
\tag{23}
$$

where

$$
A(p)=\psi_p(b)-1;\quad B(p)=\psi_p(a),\quad p<0.
\tag{24}
$$

In the above formulas, $A(p)$ is the coefficient of the reflected wave (reflection amplitude) whereas $B(p)$ is that of the transmitted wave (transmission amplitude) and the factor in front of the incoming wave ensures that it has amplitude 1. If $p<0$ and $|p|\leqslant\sqrt{2em(V_b-V_a)}$ (again assuming that $V_b>V_a$ to fix the idea), it must be noted that $p_a(p)$ in formula (23) is purely imaginary, so that the wave is evanescent in the region $x<a$.

We recall that the corresponding reflection and transmission coefficients,

$$
R(p)=|A(p)|^2,\quad T(p)=\frac{\Re(p_{a,b}(p))}{p}|B(p)|^2,
\tag{25}
$$

[where $p_{a,b}(p)$ stands for p_a (resp., p_b) when $p<0$ (resp., $p>0$) and $\mathcal{R}$, $\mathcal{T}$ for the real and imaginary parts] satisfy

$$R(p)+T(p)=1, \tag{26}$$

and the reciprocity identity

$$T(p)=T(-p_{a,b}(p)), \quad \text{for all } p\in\mathbb{R} \text{ such that } p_{a,b}(p)\in\mathbb{R}. \tag{27}$$

To any scattering state $\psi_p(x)$ corresponds a time-dependent wave function,

$$\Psi_p(x,t)=\psi_p(x)e^{-i[\mathcal{E}(p)t/\hbar]},$$

where we denote by $\mathcal{E}(p)$ the energy associated with ψ_p:

$$\mathcal{E}(p)=\frac{p^2}{2m}-eV_a, \quad \text{for } p>0 \quad \text{and} \quad \mathcal{E}(p)=\frac{p^2}{2m}-eV_b, \quad \text{for } p<0.$$

However, the probability density $|\Psi_p|^2$ associated with Ψ_p is time independent (which is the definition of a stationary solution of the Schrödinger equation). Therefore, such a wave function is unable to represent a dynamical process such as the motion of an isolated particle.

To do so, one has to call for the concept of a wave packet. Let $\Phi_\hbar(p_0,p_1)$ be a ''localizing function'' that can be viewed as the typical shape of the wave packet. This function is arbitrary, provided it satisfies a certain number of constraints that will be listed below. Let us think of $\Phi_\hbar$ as a non-negative real-valued function, which ''gets peaked'' about $p_0=p_1$ as $\hbar$ tends to zero. We shall make this definition more precise later on. We represent an electron coming into the domain Q at time t_0 with momentum p_0 by the following wave packet:

$$\Psi_{p_0,t_0}(x,t)=\int_{\mathbb{R}}\Phi_\hbar(p_0,p_1)\psi_{p_1}(x)\exp\left(-\frac{i(t-t_0)\mathcal{E}(p_1)}{\hbar}\right)dp_1. \tag{28}$$

An important example of the wave packet profile is the Gaussian wave packet,

$$\Phi_\hbar(p_0,p_1)=\sqrt{C_\hbar}\exp\left(-\frac{(p_0-p_1)^2}{4\sigma_\hbar}\right), \tag{29}$$

where $C_\hbar$ is a normalization constant about which we shall come back below and $\sigma_\hbar$ is the momentum variance of the wave packet. Throughout the paper, $\Phi_\hbar$ will be assumed real-valued.

Although the above formula mixes states corresponding to incoming plane waves from either the left ($p_1>0$) or the right ($p_1<0$), a semiclassical analysis shows that Ψ_{p_0,t_0} corresponds to a particle entering Q at time t_0 through a and moving to the right if $p_0>0$ and entering Q through b and moving to the left if $p_0<0$. More specifically, applying the stationary phase theorem, a formal analysis[17] yields, for $p_0>0$,

$$\Psi_{p_0,t_0}\sim\begin{cases}\Psi^I_{p_0,t_0}+\Psi^R_{p_0,t_0}, & x<a,\\ \Psi^T_{p_0,t_0}, & x>b,\end{cases}$$

where the incident $\Psi^I_{p_0,t_0}$, reflected $\Psi^R_{p_0,t_0}$ and transmitted $\Psi^T_{p_0,t_0}$ wave packets, respectively, represent classical particles moving according to the equations

$$x_I(t)=a+v_0(t-t_0), \quad x<a \quad \text{(incident wave)},$$

$$x_R(t)=a-v_0((t-t_0)-\tau_R(p_0)), \quad x<a \quad \text{(reflected wave)},$$

$$x_T(t)=a+v_0((t-t_0)-\tau_T(p_0)),\quad x>b\quad \text{(trasmitted wave)}.$$

Therefore, up to a limit $\hbar\to 0$, the incident wave packet hits the boundary a at time t_0 coming from the left with momentum p_0. It gives rise to a reflected wave packet that departs from a at time $t_0+\tau_R(p_0)$ where $\tau_R(p_0)$ is a quantum reflection time delay, and to a transmitted wave packet that departs from b at time $t_0+\tau_T(p_0)$ with $\tau_T(p_0)$ is the transmission time delay. These delays are given by the following formula (see also Ref. 17):

$$\tau_R(p)=\frac{1}{v}\frac{dS_R(p)}{dp},\quad \tau_T(p)=\frac{1}{v}\frac{dS_T(p)}{dp},\tag{30}$$

where $S_R(p)$ and $S_T(p)$ are smooth realizations of the complex phases of the scattering amplitudes:

$$A(p)=\sqrt{R(p)}e^{i[S_R(p)/\hbar]},\quad B(p)=\sqrt{\frac{p}{\Re(p_{a,b}(p))}T(p)}\,e^{i[S_T(p)/\hbar]}.$$

In this paper, we shall give a more rigorous meaning to these statements.

The wave packet Ψ_{p_0,t_0} is obviously a solution of the time-dependent Schrödinger equation,

$$i\hbar\frac{\partial\Psi}{\partial t}=\tilde{H}\Psi.\tag{31}$$

From these wave packets, we construct a density matrix that is the quantum analog of the elementary distributions $\phi_{(a,p_0,t_0)}$ or $\phi_{(b,p_0,t_0)}$. It is defined by

$$\begin{aligned}\rho_{q_0,t_0}(x,x',t)&=\Psi_{q_0,t_0}(x,t)\overline{\Psi_{q_0,t_0}(x',t)}\\&=\int_{\mathbb{R}^2}\Phi_\hbar(q_0,p_1)\Phi_\hbar(q_0,q_2)\psi_{p_1}(x)\overline{\psi_{p_2}(x')}\\&\quad\times\exp\left(-\frac{i}{\hbar}(t-t_0)(\mathcal{E}(p_1)-\mathcal{E}(p_2))\right)dp_1\,dp_2,\end{aligned}\tag{32}$$

and represents a particle entering Q at time t_0 through point a if $q_0>0$ (resp., through point b if $q_0<0$). ρ_{q_0,t_0} is a truly time-dependent solution of the von Neumann equation (4).

Of course, for ρ_{q_0,t_0} to represent a physically admissible density matrix, it has to be of trace unity. We recall that the trace of a density matrix $\rho(x,x')$ is given by

$$\mathrm{Tr}\,\rho=\int_{\mathbb{R}}\rho(x,x)dx,$$

while $\rho(x,x)dx$ represents the probability density associated with ρ. In order to compute the trace of (32), it is convenient to highlight its relation with the scattering transform.

First, we recall that the definition of the Fourier transform of a function $g(p)$ is defined by

$$\mathcal{F}g(\eta)=\frac{1}{2\pi}\int e^{i\eta p}g(p)dp,\tag{33}$$

while the inverse Fourier transform of a function $G(x)$ is given by

$$\mathcal{F}^{-1}G(p)=\int e^{-i\eta p}G(\eta)d\eta.\tag{34}$$

The Plancherel identity states that

$$\int \overline{\mathcal{F}g(\eta)}\mathcal{F}f(\eta)d\eta = \frac{1}{2\pi}\int \overline{g}f\,dp. \tag{35}$$

The scattering transform can be viewed as a Fourier transform in which the scattering states $\psi_p(x)$ are used instead of the exponentials e^{ipx}. In particular, it reduces to the Fourier transform (up to a change of variables) in the case of a constant potential. More precisely, we define the scattering transform $\mathcal{G}(g)$ according to

$$\mathcal{G}g(x) = \frac{1}{2\pi\hbar}\int_{\mathbb{R}} g(p)\psi_p(x)dp,$$

and the inverse scattering transform:

$$\mathcal{G}^{-1}G(p) = \int_{\mathbb{R}} G(x)\overline{\psi_p(x)}dx.$$

It is immediately seen that, in the case of a constant potential, the scattering and Fourier transforms are related by

$$\mathcal{G}g(x) = \frac{1}{\hbar}\mathcal{F}g\left(\frac{x}{\hbar}\right) = \mathcal{F}[g(\hbar\cdot)](x),$$

$$\mathcal{G}^{-1}G(p) = \mathcal{F}^{-1}G\left(\frac{p}{\hbar}\right) = \hbar\mathcal{F}^{-1}[G(\hbar\cdot)](p).$$

In the general case, $\mathcal{G}^{-1}$ is an isomorphism of Hilbert spaces between L^2_{ac} onto $L^2(\mathbb{R})$, and $\mathcal{G}$ is the inverse isomorphism, where L^2_{ac} denotes the absolutely continuous subspace of $L^2(\mathbb{R})$ associated with the operator $\tilde{H}$. Therefore, we have the analog of Plancherel's formula:

$$\int \overline{\mathcal{G}g(x)}\mathcal{G}f(x)dx = \frac{1}{2\pi\hbar}\int \overline{g}f\,dp. \tag{36}$$

The definition and properties of the scattering transform can be found in Ref. 18.

Now, in view of the scattering transform, Ψ_{p_0,t_0} can be written as

$$\Psi_{p_0,t_0}(x,t) = 2\pi\hbar\mathcal{G}_{p_1}\left[\Phi_\hbar(p_0,p_1)\exp\left(-\frac{i(t-t_0)\mathcal{E}(p_1)}{\hbar}\right)\right](x), \tag{37}$$

where $\mathcal{G}_{p_1}$ indicates that we take the scattering transform with respect to p_1. Then, using (36), we compute

$$\begin{aligned}
\mathrm{Tr}\,\rho_{q_0,t_0}(t) &= \int_{\mathbb{R}} |\Psi_{q_0,t_0}(x,t)|^2\,dx \\
&= (2\pi\hbar)^2\int_{\mathbb{R}}\left|\mathcal{G}_{p_1}\left[\Phi_\hbar(p_0,p_1)\exp\left(-\frac{i(t-t_0)\mathcal{E}(p_1)}{\hbar}\right)\right](x)\right|^2 dx \\
&= 2\pi\hbar\int_{\mathbb{R}}\left|\Phi_\hbar(q_0,p_1)\exp\left(-\frac{i(t-t_0)\mathcal{E}(p_1)}{\hbar}\right)\right|^2 dp_1 = 2\pi\hbar\int_{\mathbb{R}}|\Phi_\hbar(q_0,p_1)|^2\,dp_1.
\end{aligned}$$

Therefore, the density matrix $\rho_{q_0,t_0}(\cdot,\cdot,t)$ is of trace unity if and only if the wave packet function $\Phi_\hbar$ satisfies the normalization condition

$$2\pi\hbar\int_{\mathbb{R}}|\Phi_\hbar(p,q)|^2\,dq=1, \tag{38}$$

which we shall assume satisfied from now on. We note that this normalization condition allows us to define the probability density $P_\hbar(p,q)dq$ according to

$$P_\hbar(p,q)dq=2\pi\hbar|\Phi_\hbar(p,q)|^2\,dq. \tag{39}$$

We also complete the definition of the Gaussian wave packet (29) by giving the expression of the normalizing constant, which, according to (38), must be equal to $C_\hbar=((2\pi)^{3/2}\hbar\sqrt{\sigma_\hbar})^{-1}$.

Now, we recall that Q is an open quantum system where the statistics of incoming particles is described by two distribution functions $g_a(p,t)(p>0)$ and $g_b(p,t)(p<0)$. For simplicity, we define the boundary data $\mathbf{g}$ according to

$$\mathbf{g}(p,t)=g_a(p,t)\quad\text{for } p>0\quad\text{and}\quad\mathbf{g}(p,t)=g_b(p,t)\quad\text{for } p<0. \tag{40}$$

We postulate that the state of the quantum region Q is formed by the superposition of the elementary density matrices ρ_{q_0,t_0}, weighted by the statistics of incoming particles $\mathbf{g}(q_0,t_0)$. We therefore reproduce formula (8) and define the density matrix in Q by the formula

$$\begin{aligned}\rho(x,x',t)&=\int_{\mathbb{R}^2}\frac{|q_0|}{m}\mathbf{g}(q_0,t_0)\rho_{q_0,t_0}(x,x',t)dt_0\,dq_0\\&=\int\frac{|q_0|}{m}\mathbf{g}(q_0,t_0)\Phi_\hbar(q_0,q_1)\Phi_\hbar(q_0,q_2)\psi_{q_1}(x)\overline{\psi_{q_2}}(x')\\&\quad\times\exp\left(-\frac{i}{\hbar}(t-t_0)(\mathcal{E}(q_1)-\mathcal{E}(q_2))\right)dt_0\,dq_0\,dq_1\,dq_2.\end{aligned} \tag{41}$$

This defines how the state of the quantum region Q is computed as a function of the inflow statistics g_a and g_b. Now, we turn to the classical distribution function f in the region C. Of course, it is understood that the inflow statistics for the quantum region Q coincides with the outgoing trace of f, i.e., relation (6) is still valid:

$$g_a(p,t)=f(a,p,t),\quad p>0;\quad g_b(p,t)=f(b,p,t),\quad p<0. \tag{42}$$

The problem is now to find the analog of relation (7). Again, we take our inspiration from the classical case and, more precisely, from the reflection–transmission boundary condition for f, as given by (16) and (17). To use this relation in the quantum–classical coupling case, it is tempting to just replace the classical reflection–transmission coefficients and time delays by the quantum ones. However, this procedure is not current-conservative (see Sec. V). Furthermore, it does not take into account the fact that the quantum delocalization of a particle into a wave packet mixes states of different momenta (or different energies).

In the remainder of this section, we make the following simplifying hypothesis:

$$\Phi_\hbar(p,q)=0,\quad\text{if } p \text{ and } q \text{ have opposite signs.} \tag{43}$$

Under this hypothesis, we specify the following reflection–transmission condition for f at the interface between C and Q:

$$|p|f(a,p,t)=\int_{q>0}P_\hbar(q,-p)R_\hbar(-p)f(a,q,t-\tau_R^\hbar(-p))|q|dq$$
$$+\int_{q<0}P_\hbar(q,p_b(p))T_\hbar(p_b(p))\frac{p}{p_b(p)}f(b,q,t-\tau_T^\hbar(p_b(p)))|q|dq,\quad p<0, \tag{44}$$

$$|p|f(b,p,t)=\int_{q<0}P_\hbar(q,-p)R_\hbar(-p)f(b,q,t-\tau_R^\hbar(-p))|q|dq$$
$$+\int_{q>0}P_\hbar(q,p_a(p))T_\hbar(p_a(p))\frac{p}{p_a(p)}f(a,q,t-\tau_T^\hbar(p_a(p)))|q|dq,\quad p>0. \tag{45}$$

In these formulas, $P_\hbar(q,p)$ is the probability density defined by (39) and $(R_\hbar,T_\hbar)$, $(\tau_R^\hbar,\tau_T^\hbar)$ are the quantum reflection–transmission coefficients and time delays. Note that hypothesis (43) implies that $P_\hbar(q,p)=0$ if p and q have opposite signs. We also remark that the quantum time delays for reflection and transmission are not equal. In the classical formulas (16) and (17), only one of these times is relevant since, for a given value of p, reflection and transmission never occur simultaneously. The probabilistic nature of quantum mechanics, however, makes reflection and transmission occur simultaneously and the associated time delays are different.

We now explain the physics behind these conditions. For instance, let us examine (44), the discussion being obviously identical for (45). It expresses that the particles going out of the quantum zone Q through a (i.e., with momentum $p<0$) originate from particles having entered Q at an earlier time, either through a (i.e., with momentum $-p>0$) or through b [i.e., with momentum $p_b(p)<0$]. However, the entering particles are transformed into wave packets as they cross the border of the Q region, by means of $\Phi_\hbar$. Each entering particle through say a with momentum $q>0$ "excites" a quantum wave of momentum $-p>0$ according to the probability density $P_\hbar(q,-p)$. Therefore the intensity of the wave entering at time t with momentum $-p>0$ per unit time is proportional to

$$\int_{q>0}P_\hbar(q,-p)f(a,q,t)|q|dq.$$

Only the fraction $R(-p)$ will be reflected back to a, the remaining part will be transmitted to b. Furthermore, for the wave to "arrive" at a at time t, it needs to have entered Q at time $t-\tau_R^\hbar(-p)$. Collecting all these remarks leads to the flux of particles exiting Q through a at time t, originating from particles having entered Q through the same point; hence the first integral. The same analysis is valid for the second integral considering waves entering into Q through b and transmitted to a. Simply, the change of p to $p_b(p)$ (if $V_a\neq V_b$) has to be taken into account. The ratio $p/p_b(p)$ takes into account the change of volume in momentum space in the map $p\to p_b(p)$.

Conditions (44), (45) maintain the positivity (i.e., if the outgoing distribution is positive, the incoming one is also positive). Note, however, that the Gaussian wave packet (29) does not satisfy hypothesis (43). It is worth mentioning that quantum time delays may be non positive. Analytical computations for specially unsmooth potentials like delta potentials indicate that time delays may become negative.[19] Nevertheless, for smooth enough potentials, we shall assume that time delays are positive; otherwise the well-posedness of the kinetic problem in C would not be guaranteed.

To summarize our coupling methodology, we first solve the self-contained problem (1) with the reflection–transmission boundary conditions (44) and (45) for f in the classical region C

(provided that the quantum time delays are positive). Then, once f and its boundary values $f(a,p,t)$ (for $p>0$), $f(b,p,t)$ (for $p<0$) are known, we construct the density matrix in the quantum region Q according to (41), where $\mathbf{g}$ is given by (40) and (42).

D. Classical–quantum coupling: Summary of results

We now outline how we can give a rigorous foundation to the above described coupling methodology. The main tool we will use is the Wigner transform.[20] The Wigner transform of the density matrix (41) is defined according to

$$W^{\hbar}(x,p,t)=\frac{1}{2\pi}\int_{\mathbb{R}} e^{i\eta p}\rho\left(x-\frac{\hbar}{2}\eta,x+\frac{\hbar}{2}\eta,t\right)d\eta.$$

Since the wave packets Ψ_{q_0,t_0} are solutions of the Schrödinger equation (31), $W^{\hbar}$ is a solution of the Wigner equation:

$$\partial_t W^{\hbar}+\frac{p}{m}\partial_x W^{\hbar}+\theta_{\hbar}[\tilde{V}]\cdot W^{\hbar}=0,$$

where the pseudodifferential operator $\theta_{\hbar}$ is given by

$$\theta_{\hbar}[\tilde{V}]W^{\hbar}(x,p)=-\frac{ie}{2\pi}\int_{\mathbb{R}} e^{i\eta p}\delta_{\hbar}[\tilde{V}](x,\eta)\mathcal{F}_p^{-1}W^{\hbar}(x,\eta)d\eta,$$

with

$$\delta_{\hbar}[\tilde{V}](x,\eta)=\frac{\tilde{V}\left(x+\frac{\hbar}{2}\eta\right)-\tilde{V}\left(x-\frac{\hbar}{2}\eta\right)}{\hbar},$$

and $\mathcal{F}_p^{-1}$ denotes the inverse Fourier transform (34).

In the remainder of the paper, our goal is to prove that, in the semiclassical limit $\hbar\to 0$, $W^{\hbar}$ converges to a solution $g=g(x,p,t)$ of the Vlasov equation (5) in Q with the inflow boundary conditions (6) at a and b, namely,

$$g(a,p,t)=g_a(p,t),\quad p>0;\quad g(b,p,t)=g_b(p,t),\quad p<0. \tag{46}$$

More precisely, we shall prove the following.

Main Result: Assuming that $\Phi_{\hbar}$ is real, we introduce $\Lambda_{\hbar}$, according to:

$$\Lambda_{\hbar}(p,q,q')=2\pi\hbar\,\Phi_{\hbar}\left(p,q+\frac{\hbar}{2}q'\right)\Phi_{\hbar}\left(p,q-\frac{\hbar}{2}q'\right). \tag{47}$$

We note that

$$\Lambda_{\hbar}(p,q,0)=2\pi\hbar|\Phi_{\hbar}(p,q)|^2=P_{\hbar}(p,q),\quad \int_{\mathbb{R}}\Lambda_{\hbar}(p,q,0)dq=1. \tag{48}$$

We assume additionally that $\Lambda_{\hbar}$ satisfies

$$\lim_{\hbar\to 0}\Lambda_{\hbar}(p,q,q')=\delta(p-q). \tag{49}$$

Then $W^{\hbar}$ formally converges as $\hbar\to 0$ toward g, the solution of

$$\partial_t g + \frac{p}{m}\partial_x g + e\frac{dV}{dx}\partial_p g = 0,$$

$$g(a,p,t) = g_a(p,t), \quad p>0,$$

$$g(b,p,t) = g_b(p,t), \quad p<0.$$

Moreover, we have asymptotically,

$$W^\hbar(a,-p,t) = R_\hbar(p)W^\hbar(a,p,t-\tau_R^\hbar(p)) + T_\hbar(p)W^\hbar(b,p_b(p),t-\tau_T^\hbar(p)), \quad p>0, \tag{50}$$

$$W^\hbar(b,-p,t) = R_\hbar(p)W^\hbar(b,p,t-\tau_R^\hbar(p)) + T_\hbar(p)W^\hbar(a,p_a(p),t-\tau_T^\hbar(p)), \quad p<0, \tag{51}$$

where $R_\hbar(p)$, $T_\hbar(p)$ are the reflection–transmission coefficients (25) and $\tau_R^\hbar(p)$, $\tau_T^\hbar(p)$ are the time delays (30).

Condition (49) guarantees that, in the semiclassical limit, the wave packet gets more and more localized in both position and momentum. For instance, in the case of the Gaussian wave packet (29), we have

$$\Lambda_\hbar(p,q,q') = \frac{1}{2\pi\sigma_\hbar}\exp-\frac{(p-q)^2}{2\sigma_\hbar}\exp-\frac{\hbar^2 q'^2}{8\sigma_\hbar}.$$

Therefore, condition (49) is fulfilled as soon as we simultaneously have

$$\sigma_\hbar \to 0 \quad \text{and} \quad \frac{\hbar^2}{\sigma_\hbar} \to 0, \quad \text{as} \quad \hbar \to 0.$$

For instance, $\sigma_h = O(\hbar)$ as $\hbar \to 0$ is convenient.

This ''formal'' theorem justifies our methodology in that the Wigner transformed density matrix (41) converges in the semiclassical limit toward the solution of the inflow boundary value problem for the Vlasov equation in the region Q. In particular, as $\hbar \to 0$, the trace of the Wigner function at the boundary ∂Q satisfies the dual reflection–transmission problem to that imposed to the classical distribution function f. Indeed, substituting $f(a,p,t)$ to $W^\hbar(a,-p,t)$ and similarly at point b transforms (50), (51) into (16), (17). Therefore, our definition of the density matrix seems established on a solid basis, in spite of the arbitrariness of the wave packet function $\Phi_\hbar$.

The remainder of the paper is organized as follows. In Sec. III we develop the proof of Theorem 2.4 in the case $V_a = V_b$. Then, in Sec. IV, the extension of the result to the case $V_a \neq V_b$ will be outlined. In Sec. V, we prove that the reflection–transmission conditions (44), (45) satisfy the time-integrated current conservation principle. Finally, in Sec. VI, we specialize to the stationary state in order to bridge the gap with earlier work of one of the authors.[1]

III. PROOF OF THE MAIN RESULT IN THE CASE $V_a = V_b$

A. Preliminaries

First, we introduce some notations. We shall need to distinguish between the density matrices $\rho^{(a)}$ and $\rho^{(b)}$ of electrons injected at the boundaries a and b, respectively:

$$\rho^{(a)}(x,x',t) = \int_{\mathbb{R}^+} dq_0 \int_{\mathbb{R}} dt_0 \frac{|q_0|}{m} g_a(q_0,t_0)\Psi_{q_0,t_0}(x,t)\overline{\Psi_{q_0,t_0}(x',t)}, \tag{52}$$

$$\rho^{(b)}(x,x',t) = \int_{\mathbb{R}^-} dq_0 \int_{\mathbb{R}} dt_0 \frac{|q_0|}{m} g_b(q_0,t_0)\Psi_{q_0,t_0}(x,t)\overline{\Psi_{q_0,t_0}(x',t)}, \tag{53}$$

so that $\rho = \rho^{(a)} + \rho^{(b)}$. We also decompose $W^\hbar = W_a^\hbar + W_b^\hbar$ with

$$W^{\hbar}_{a,b}(x,p,t)=\frac{1}{2\pi}\int_{\mathbb{R}} e^{i\eta p}\rho^{(a,b)}\left(x-\frac{\hbar}{2}\eta,x+\frac{\hbar}{2}\eta,t\right)d\eta. \tag{54}$$

The major part of the computation concerns boundary conditions. Indeed, let $\theta(x,p,t)$ be a test function in $\mathcal{D}(\mathbb{R}_x\times\mathbb{R}_p\times\mathbb{R}_t)$. We have the following identity obtained by a simple integration by parts:

$$\int_{(x,p,t)\in[a,b]\times\mathbb{R}^2}\theta\left[\partial_t W^{\hbar}+\frac{p}{m}\partial_x W^{\hbar}+e\frac{dV}{dx}\partial_p W^{\hbar}\right]dx\,dp\,dt=I^{\hbar}_b-I^{\hbar}_a-I^{\hbar}_{ab},$$

where

$$I^{\hbar}_{ab}=\int_{(x,p,t)\in[a,b]\times\mathbb{R}^2}W^{\hbar}\left[\partial_t\theta+\frac{p}{m}\partial_x\theta+e\frac{dV}{dx}\partial_p\theta\right]dx\,dp\,dt,$$

$$I^{\hbar}_b=\int_{\mathbb{R}^2}\frac{p}{m}\theta(b,p,t)W^{\hbar}(b,p,t)dp\,dt,$$

$$I^{\hbar}_a=\int_{\mathbb{R}^2}\frac{p}{m}\theta(a,p,t)W^{\hbar}(a,p,t)dp\,dt.$$

Standard results on semiclassical limits (see, e.g., Refs. 21, 22, 23, 24, 25, etc.) allow us to perform the $\hbar\to 0$ limit in the interior of the interval $[a,b]$, so that

$$\lim_{\hbar\to 0}-I^{\hbar}_{ab}+I^{\hbar}_b-I^{\hbar}_a=0. \tag{55}$$

In particular, we have the following.

Lemma 3.1:

$$\lim_{\hbar\to 0}I^{\hbar}_{ab}=\int_{(x,p,t)\in[a,b]\times\mathbb{R}^2}g\left[\partial_t\theta+\frac{p}{m}\partial_x\theta+e\frac{dV}{dx}\partial_p\theta\right]dx\,dp\,dt. \tag{56}$$

Next, we need to calculate the $\hbar\to 0$ limit of the left boundary term $I^{\hbar}_a$. The right boundary term $I^{\hbar}_b$ can be treated analogously. To this aim, we introduce

$$U(p,t)=\frac{p}{m}\theta(a,p,t), \tag{57}$$

and we remark that $U(0,t)=0$ for all $t\in\mathbb{R}$. We compute

$$I^{\hbar}_a=\int_{\mathbb{R}^2}U(p,t)W^{\hbar}(a,p,t)dp\,dt=\int_{\mathbb{R}^2}U(p,t)W^{\hbar}_a(a,p,t)dp\,dt+\int_{\mathbb{R}^2}U(p,t)W^{\hbar}_b(a,p,t)dp\,dt,$$

where $W^{\hbar}_a$ and $W^{\hbar}_b$ are defined at (54). Let us denote by J^h_a the first integral and K^h_a the second one. We have

$$J_a^\hbar = \int U(p,t) W_a^\hbar(a,p,t)\,dp\,dt$$
$$= \frac{1}{2\pi}\int_{\mathbb{R}^4} dp\,d\eta\,dt_0\,dt \int_{\mathbb{R}^+} dq_0\, e^{i\eta p} U(p,t)\,\frac{|q_0|}{m}\, g_a(q_0,t_0)\,\overline{\Psi_{q_0,t_0}}\left(a+\frac{\hbar}{2}\eta,t\right)$$
$$\times \Psi_{q_0,t_0}\left(a-\frac{\hbar}{2}\eta,t\right). \tag{58}$$

On the other hand, we have

$$\overline{\Psi_{q_0,t_0}}\left(a+\frac{\hbar}{2}\eta,t\right)\Psi_{q_0,t_0}\left(a-\frac{\hbar}{2}\eta,t\right) = \int_{\mathbb{R}^2} \Phi_\hbar(q_0,q_1)\Phi_\hbar(q_0,q_2)\,\overline{\psi_{q_1}}\left(a+\frac{\hbar}{2}\eta\right)\psi_{q_2}\left(a-\frac{\hbar}{2}\eta\right)$$
$$\times \exp\left[i\,\frac{q_1^2-q_2^2}{2m\hbar}(t-t_0)\right] dq_1\,dq_2. \tag{59}$$

Before analyzing (58), we claim that the behavior of the right-hand side of (59) as $\hbar$ tends to zero is left unchanged if we replace the integration set by $\mathbb{R}^2_+$:

$$\overline{\Psi_{q_0,t_0}}\left(a+\frac{\hbar}{2}\eta,t\right)\Psi_{q_0,t_0}\left(a-\frac{\hbar}{2}\eta,t\right) \simeq \int_{\mathbb{R}^2_+} \Phi_\hbar(q_0,q_1)\Phi_\hbar(q_0,q_2)\,\overline{\psi_{q1}}\left(a+\frac{\hbar}{2}\eta\right)\psi_{q_2}\left(a-\frac{\hbar}{2}\eta\right)$$
$$\times \exp\left[i\,\frac{q_1^2-q_2^2}{2m\hbar}(t-t_0)\right] dq_1\,dq_2. \tag{60}$$

This is a consequence of the fact that the wave packet ''is peaked'' around q_0 and q_0 is positive. This claim can be rigorously proven by applying the dominated convergence theorem and will be developed in Ref. 13.

B. First approximation: using the asymptotics of ψ_q in the neighborhood of the boundary

A simple rescaling of the Schrödinger equation (19) leads to

$$\lim_{\hbar\to 0} \psi_q^\hbar\left(a+\frac{\hbar}{2}\eta\right) - e^{i(q/2)\eta} - A(q)e^{-i(q/2)\eta} = 0, \quad \text{for } q>0, \tag{61}$$

uniformly with respect to $\eta \in]-\infty, M]\,(\forall M>0)$. In what follows, we shall forget the subscripts $\hbar$ in the reflection–transmission coefficients and time delays for clarity. Replacing $\psi_q[a+(\hbar/2)\eta]$ by $e^{i(q/2)\eta}+A(q)e^{-iq\eta}$ in (59) leads to the following approximate formula:

$$\overline{\Psi_{q_0,t_0}}\left(a+\frac{\hbar}{2}\eta,t\right)\Psi_{q_0,t_0}\left(a-\frac{\hbar}{2}\eta,t\right) \approx \mathrm{I}_\hbar + \mathrm{II}_\hbar + \mathrm{III}_\hbar + \mathrm{IV}_\hbar, \tag{62}$$

where

$$\mathrm{I}_\hbar = \int_{\mathbb{R}^2} \Phi_\hbar(q_0,q_1)\Phi_\hbar(q_0,q_2) e^{-i([q_1+q_2]/2)\eta} e^{i[(q_1^2-q_2^2)/2m\hbar](t-t_0)} dq_1\,dq_2, \tag{63}$$

$$\mathrm{II}_\hbar = \int_{\mathbb{R}^2} \Phi_\hbar(q_0,q_1)\Phi_\hbar(q_0,q_2)\overline{A(q_1)}A(q_2) e^{i[(q_1+q_2)/2]\eta} e^{i[(q_1^2-q_2^2)/2m\hbar](t-t_0)} dq_1\,dq_2, \tag{64}$$

$$\mathrm{III}_\hbar = \int_{\mathbb{R}^2} \Phi_\hbar(q_0,q_1)\Phi_\hbar(q_0,q_2)\overline{A}(q_1)e^{i[(q_1-q_2)/2]\eta}e^{i[(q_1^2-q_2^2)/2m\hbar](t-t_0)}dq_1\,dq_2, \tag{65}$$

$$\mathrm{IV}_\hbar = \int_{\mathbb{R}^2} \Phi_\hbar(q_0,q_1)\Phi_\hbar(q_0,q_2)A(q_2)e^{i[(q_2-q_1)/2]\eta}e^{i[(q_1^2-q_2^2)/2m\hbar](t-t_0)}dq_1\,dq_2. \tag{66}$$

The first two terms correspond to the contributions of the two plane waves (corresponding to q_1 and q_2) traveling in the same direction, while the last two ones correspond to contributions of opposite traveling waves. We shall see later on that, because of the assumption (49) on the wave packet function $\Phi_\hbar$, the last two integrals have vanishing $\hbar\to 0$ limits.

In order to compute these limits, we perform the change of variables,

$$(z,y)=\left(\frac{q_1+q_2}{2},\frac{q_1-q_2}{\hbar}\right),\quad (q_1,q_2)=\left(z+\frac{\hbar}{2}y,z-\frac{\hbar}{2}y\right),\quad \frac{q_1^2-q_2^2}{2m\hbar}=\frac{yz}{m}, \tag{67}$$

in (63)–(66). Introducing $\Lambda_\hbar$ according to (47), this leads to

$$\mathrm{I}_\hbar=\frac{1}{2\pi}\int \Lambda_\hbar(q_0,z,y)e^{-iz\eta}e^{i(yz/m)(t-t_0)}\,dz\,dy, \tag{68}$$

$$\mathrm{II}_\hbar=\frac{1}{2\pi}\int \Lambda_\hbar(q_0,z,y)\overline{A}\left(z+\frac{\hbar}{2}y\right)A\left(z-\frac{\hbar}{2}y\right)e^{iz\eta}e^{i(yz/m)(t-t_0)}\,dz\,dy, \tag{69}$$

$$\mathrm{III}_\hbar=\frac{1}{2\pi}\int \Lambda_\hbar(q_0,z,y)\overline{A}\left(z+\frac{\hbar}{2}y\right)e^{iy\hbar\eta}e^{i(yz/m)(t-t_0)}\,dz\,dy, \tag{70}$$

$$\mathrm{IV}_\hbar=\frac{1}{2\pi}\int \Lambda_\hbar(q_0,z,y)A\left(z-\frac{\hbar}{2}y\right)e^{-iy\hbar\eta}e^{i(yz/m)(t-t_0)}\,dz\,dy. \tag{71}$$

We deduce from (58) that

$$J_a^\hbar\simeq\frac{1}{2\pi}\int e^{i\eta p}U(p,t)\frac{q_0}{m}g_a(q_0,t_0)[(\mathrm{I}_\hbar+\mathrm{II}_\hbar+\mathrm{III}_\hbar+\mathrm{IV}_\hbar)(q_0,t_0,\eta,t)]dp\,d\eta\,dt_0\,dt\,dq_0.$$

We first integrate with respect to p. This gives

$$J_a^\hbar=\int \mathcal{F}_pU(\eta,t)\frac{q_0}{m}g_a(q_0,t_0)[(\mathrm{I}_\hbar+\mathrm{II}_\hbar+\mathrm{II}_\hbar+\mathrm{IV}_\hbar)(q_0,t_0,\eta,t)]dq_0\,dt_0\,d\eta\,dt. \tag{72}$$

C. Second approximation: Using the asymptotics of the reflection amplitude

Let us now work on $\mathrm{II}_\hbar$. We first recall that the reflection coefficient R and the phase S_R of the reflection amplitude are given by

$$A(z)=\sqrt{R(z)}e^{i[s_R(z)/\hbar]}.$$

We suppose that S is a smooth (at least differentiable) determination of the phase and that it converges smoothly when $\hbar\to 0$. We then have

$$\overline{A}\left(z+\frac{\hbar}{2}y\right)A\left(z-\frac{\hbar}{2}y\right)=R(z)e^{-iS_R'(z)y}+O(\hbar),$$

where

$$S_R'(z)=\frac{d}{dz}S_R(z).$$

This finally leads to

$$\mathrm{II}_\hbar \simeq \frac{1}{2\pi}\int \Lambda_\hbar(q_0,z,y)R(z)e^{i\eta z}e^{-iS_R'(z)y}e^{i(yz/m)(t-t_0)}\,dy\,dz.$$

Now, going back to (72), we notice that t appears in $\mathrm{I}_\hbar$, $\mathrm{II}_\hbar$, $\mathrm{III}_\hbar$, $\mathrm{IV}_\hbar$ only through complex exponentials. Therefore, by integrating first with respect to t, we obtain Fourier transforms of U with respect to the time variable. We finally end up with the following formulas:

$$J_a^\hbar = \mathrm{I}_\hbar' + \mathrm{II}_\hbar' + \mathrm{III}_\hbar' + \mathrm{IV}_\hbar',$$

where

$$\mathrm{I}_\hbar' = \int \mathcal{F}_{p,t}U\left(\eta,\frac{yz}{m}\right)\frac{q_0}{m}g_a(q_0,t_0)\Lambda_\hbar(q_0,z,y)e^{-i\eta z}e^{-i(yz/m)t_0}\,dy\,dz\,dt_0\,dq_0\,d\eta,$$

$$\mathrm{II}_\hbar' = \int \mathcal{F}_{p,t}U\left(\eta,\frac{yz}{m}\right)\frac{q_0}{m}g_a(q_0,t_0)\Lambda_\hbar(q_0,z,y)R(z)e^{i\eta z}e^{-iS_R'(z)y}e^{-i(yz/m)t_0}\,dy\,dz\,dt_0\,dq_0\,d\eta,$$

$$\mathrm{III}_\hbar' = \int \mathcal{F}_{p,t}U\left(\eta,\frac{yz}{m}\right)\frac{q_0}{m}g_a(q_0,t_0)\Lambda_\hbar(q_0,z,y)\overline{A}\left(z+\frac{\hbar}{2}\eta\right)e^{iy\hbar\eta}e^{-i(yz/m)t_0}\,dy\,dz\,dt_0\,dq_0\,d\eta,$$

$$\mathrm{IV}_\hbar' = \int \mathcal{F}_{p,t}U\left(\eta,\frac{yz}{m}\right)\frac{q_0}{m}g_a(q_0,t_0)\Lambda_\hbar(q_0,z,y)A\left(z-\frac{\hbar}{2}\eta\right)e^{-iy\hbar\eta}e^{-i(yz/m)t_0}\,dy\,dz\,dt_0\,dq_0\,d\eta,$$

where the integration domain is $\mathbb{R}$ except for the variable q_0, where it is $\mathbb{R}_+$.

D. Third approximation: Using the assumption (49) on the wave packets

Formally, using (49), $\mathrm{I}_\hbar'$ converges in the sense of measures to

$$\mathrm{I}_\hbar' = \frac{2\pi}{m}\int \mathcal{F}_{p,t}U\left(\eta,\frac{yz}{m}\right)z\overline{\mathcal{F}_t g_a\left(z,\frac{yz}{m}\right)}e^{-i\eta z}\mathbf{1}_{z>0}\,dy\,dz\,d\eta,$$

and the other terms are approximated by

$$\mathrm{II}_\hbar' \simeq \frac{2\pi}{m}\int \mathcal{F}_{p,t}U\left(\eta,\frac{yz}{m}\right)z\overline{\mathcal{F}_t g_a\left(z,\frac{yz}{m}\right)}e^{i\eta z}R(z)e^{-iS_R'(z)y}\mathbf{1}_{z>0}\,dy\,dz\,d\eta,$$

$$\mathrm{III}_\hbar' \simeq \frac{2\pi}{m}\int \mathcal{F}_{p,t}U\left(\eta,\frac{yz}{m}\right)z\overline{\mathcal{F}_t g_a\left(z,\frac{yz}{m}\right)}\overline{A}\left(z+\frac{\hbar}{2}y\right)e^{iy\hbar\eta}\mathbf{1}_{z>0}\,dy\,dz\,d\eta,$$

where $\mathbf{1}_{z>0}$ denotes the characteristic function of the set $\{z>0\}$. The estimate for $\mathrm{IV}_\hbar'$ is similar as for $\mathrm{III}_\hbar'$.

Next, letting z fixed and integrating with respect to y leads, in view of the Parseval identity, to

$$\mathrm{I}_\hbar' = \int_{(z,\eta,t)\in\mathbb{R}^+\times\mathbb{R}^2}\mathcal{F}_p U(\eta,t)g_a(z,t)e^{-i\eta z}\,dz\,d\eta\,dt = \int_{(z,t)\in\mathbb{R}^+\times\mathbb{R}}U(z,t)g_a(z,t)dt\,dz.$$

For $\mathrm{II}_\hbar'$, using the same computations, we get

$$\mathrm{II}'_\hbar \simeq \int_{(z,t)\in\mathbb{R}^+\times\mathbb{R}} U(-z,t)g_a(z,t-\tau_R(z))R(z)dt\,dz,$$

where the reflection time delay $\tau_R(z)$ is given by (30).

Next, we claim that $\mathrm{III}'_\hbar$ tends to zero when $\hbar\to 0$. Indeed, integrating first with respect to η in the formula for $\mathrm{III}'_\hbar$; gives

$$\mathrm{III}'_\hbar = \frac{2\pi}{m}\int_{(z,y)\in\mathbb{R}^+\times\mathbb{R}} \mathcal{F}_t U\left(-\hbar y,\frac{yz}{m}\right) z\overline{\mathcal{F}_t g_a\left(z,\frac{yz}{m}\right)A\left(z+\frac{\hbar}{2}y\right)}dy\,dz.$$

We just notice now that $|\overline{A}|\leqslant 1$, and that

$$\mathcal{F}_t U\left(-\hbar y,\frac{yz}{m}\right)\underset{h\to 0}{\to}\mathcal{F}_t U\left(0,\frac{yz}{m}\right)=0,$$

since $U(0,t)=0$. Since $\mathcal{F}_t U$, $\mathcal{F}_t g_a$ are smooth and sufficiently decaying at ∞, the dominated convergence theorem implies $\lim_{\hbar\to 0}\mathrm{III}'_\hbar=0$. Therefore it follows that

$$J_a^\hbar = \int_{\mathbb{R}^2} U(p,t)W_a^\hbar(a,p,t)dp\,dt \simeq \int_{(p,t)\in\mathbb{R}^+\times\mathbb{R}} U(p,t)g_a(p,t)dp\,dt + \int_{(p,t)\in\mathbb{R}^+\times\mathbb{R}} U(-p,t)g_a(p,t-\tau_R(p))R(p)dp\,dt.$$

Proceeding analogously for K_a^h, we find

$$K_a^H = \int_{\mathbb{R}^2} U(p,t)W_b^\hbar(a,p,t)dp\,dt \simeq \int_{(p,t)\in\mathbb{R}^-\times\mathbb{R}} T(p)U(p,t)g_b(p,t-\tau_T(p))dp\,dt,$$

where the transmission time delay $\tau_T(z)$ is given by (30). This leads to the following asymptotic formulas, restoring the dependence with respect to $\hbar$:

$$W_a^\hbar(a,p,t)=g_a(p,t):\quad W_a^\hbar(a,-p,t)=R_\hbar(p)g_a(p,t-\tau_R^\hbar(p)),$$

$$W_b^\hbar(a,p,t)=0:\quad W_b^\hbar(a,-p,t)=T_\hbar(-p)g_a(-p,t-\tau_T^\hbar(-p)),\quad \text{for } p>0. \tag{73}$$

Analogously, we have the following asymptotic formulas:

$$W_b^h(b,p,t)=g_b(p,t);\quad W_b^\hbar(b,-p,t)=R_\hbar(p)g_b(p,t-\tau_R^\hbar(p)),$$

$$W_a^\hbar(b,p,t)=0;\quad W_a^\hbar(b,-p,t)=T_\hbar(-p)g_a(-p,t-\tau_T^\hbar(-p)),\quad \text{for } p<0.$$

Summing the asymptotic formulas for W_a^h and $W_b^\hbar$, we obtain relations (50) and (51), which concludes the proof of Theorem 2.4 in the case $V_a=V_b$.

IV. THE CASE $V_a\neq V_b$

In this section, we briefly describe how the proof should be adapted to the case $V_a\neq V_b$. The asymptotic analysis of $J_a^\hbar$ is unchanged while that of $K_a^\hbar$ needs to be adapted. We recall that

$$K_a^h=\int_{\mathbb{R}^2} U(p,t)W_b^\hbar(a,p,t)dp\,dt,$$

and is given by (58), in which g_a is replaced by g_b and the integration domain of the variable q_0 is $\mathbb{R}_-$. Besides, we can use (60) in which the integration domain is $\mathbb{R}_-^2$ for exactly the same

reasons as those developed in the case $V_a = V_b$. Note that the phase factor $[i(q_1^2 - q_2^2)/2m\hbar](t - t_0)$ is left unchanged since the energy $\mathcal{E}(q_1)$ and $\mathcal{E}(q_2)$ are shifted by the same amount, q_1 and q_2 having the same sign.

Next, we claim that the contribution of terms for which $p_a(q_1)$ [or $p_a(q_2)$] are imaginary is exponentially small as stated in Lemma B.3 of Ref. 1 (again a rigorous proof developed in Ref. 13 relies on the dominated convergence theorem). Now, using the asymptotic expansion

$$\psi_q\left(a + \frac{\hbar}{2}\eta\right) = B(q)e^{+i[pa(q)/2]\eta} + O(\hbar),$$

leads to the asymptotic approximation [an analog of (72)]:

$$K_a^\hbar \simeq \int \mathcal{F}_p U(\eta, f)\frac{|q_0|}{m} g_b(q_0, t_0)\mathrm{I}_\hbar(q_0, t_0, \eta, t)dq_0\, dt_0\, d\eta\, dt,$$

where the integration domain is $\mathbb{R}$ for all variables except for q_0, where it is $\mathbb{R}_-$. The term $\mathrm{I}_\hbar$ is given by

$$\mathrm{I}_\hbar = \frac{1}{2\pi}\int_{\mathbb{R}^2_\hbar} \Lambda_\hbar(q_0, z, y)\overline{B}\left(z + \frac{\hbar}{2}y\right)B\left(z - \frac{\hbar}{2}y\right)e^{-i\,p_a(z+\hbar/2y) + p_a(z-\hbar/2y)/2\eta}e^{i(yz/m)(t-t_0)}\,dz\,dy,$$

where

$$\mathbb{R}^2_\hbar = \left\{(z,y)\in\mathbb{R}^2, \quad s.t.\left(z \pm \frac{\hbar}{2}y\right) < 0, \quad p_a\left(z \pm \frac{\hbar}{2}y\right)\in\mathbb{R}\right\}$$

Using the asymptotics of the transmission amplitude in the same way as in Sec. III C, we find the asymptotic expression for $\mathrm{I}_\hbar$,

$$\mathrm{I}_\hbar \simeq \int_{y\in\mathbb{R}}\int_{z<0, s.t. p_a(z)\in\mathbb{R}} \Lambda_\hbar(q_0, z, y)T(z)\frac{z}{p_a(z)}e^{-ip_a(z)\eta}e^{-i(z/m)\tau_T(z)y}e^{i(yz/m)(t-t_0)}\,dz\,dy.$$

This leads to

$$K_\hbar^a \simeq \int_{z<0, s.t. p_a(z)\in\mathbb{R}}\int_{(t,\eta)\in\mathbb{R}^2} \mathcal{F}_p U(\eta, t)g_b(z, t-\tau_T(z))T(z)\frac{z}{p_a(z)}e^{-i\eta p_a(z)}\,dz\,d\eta\,dt.$$

Letting $z' = p_a(z)$, which yields $z = p_b(z')$ and $z\,dz = z'\,dz'$, we obtain

$$K_\hbar^a \simeq \int_{(z',t,\eta)\in\mathbb{R}_-\times\mathbb{R}^2} \mathcal{F}_p U(\eta, t)g_b(p_b(z'), t-\tau_T(p_b(z')))T(p_b(z'))e^{-i\eta z'}\,dz'\,d\eta\,dt.$$

The integration domain in z' is $\mathbb{R}_-$ because of the following:

(i) if $V_a \leqslant V_b$, the set $\{z<0, p_a(z)\in\mathbb{R}\}$ is nothing but $(-\infty, -\sqrt{2me(V_b - V_a)})$, which leads to $\mathbb{R}_-$ after the change of variable $z' = p_b(z)$;

(ii) if $V_a \geqslant V_b$, then $\{z<0,\ p_a(z)\in\mathbb{R}\} = \mathbb{R}_-$, and the integration interval in z' should be $(-\infty, -\sqrt{2me(V_a - V_b)})$. Integrating on the whole half-line $\mathbb{R}_-$ does not change the result since $T(p_b(z')) = 0$ whenever $z' \in (-\sqrt{2me(V_a - V_b)}, 0)$.

Finally, making use of the reciprocity identities

$$T(p_p(p)) = T(-p), \quad \tau_T(p_b(p)) = \tau_T(-p),$$

as well as the Parseval identity, we obtain

$$K_\hbar^q \simeq \int_{(p,t)\in \mathbb{R}_+\times\mathbb{R}} U(-p,t)T(-p_b(p))g_b(-p_b(p),t-\tau_T(-p_b(p)))dp\,dt,$$

which is the desired asymptotic result.

V. TIME-INTEGRATED CURRENT CONSERVATION

In this section, we go back to the coupling methodology defined by Eqs. (41)–(45). An important criterion for the validity of the coupling methodology is that it is current conservative, i.e., that there is no net creation or destruction of particles. Here, we show that our coupling approach is current conservative, in a time-integrated form. Instantaneous current conservation cannot be obtained because it would violate the time-energy uncertainty principle. Indeed, the quantum wave packet description of a particle implies a certain time delocalization (which is at least equal to $\hbar$ over the energy delocalization). Therefore, it is not possible to *a priori* know how much of a given wave packet has crossed the border between the C and Q region (or vice versa) at a given time. However, we must be certain that, once an infinite time has elapsed, the whole wave packet has crossed the border; hence a current conservation in time-integrated form.

Let us denote by $J_C(a,t)$ and $J_Q(a,t)$ the classical and quantum currents flowing through point a at time t. They are, respectively, defined by

$$J_Q(a,t)=\frac{\hbar}{m}\mathcal{T}\left(\frac{\partial\rho}{\partial x}(a,a,t)\right)=\frac{\hbar}{m}\int_{\mathbb{R}^2}\frac{|q_0|}{m}\mathbf{g}(q_0,t_0)\mathcal{T}[\overline{\Psi_{q_0,t_0}}(a,t)\Psi'_{q_0,t_0}(a,t)]dq_0\,dt_0, \quad (74)$$

$$J_C(a,t)=\int_{\mathbb{R}}\frac{p}{m}f(a,p,t)dp, \quad (75)$$

with **g** defined by (40) and (42). Then we have the following.

Lemma 5.1: Under hypothesis (43), we have

$$\int_{\mathbb{R}}J_Q(a,t)dt=\int_{\mathbb{R}}J_C(a,t)dt, \quad \int_{\mathbb{R}}J_Q(b,t)dt=\int_{\mathbb{R}}J_C(b,t)dt. \quad (76)$$

Proof: We prove the first relation (76). The proof of the second one obviously follows the same method. We start with the computation of $J_Q(a,t)$. Inserting formula (28) in (74) and performing the change of variables $q_1=z+(\hbar/2)y$, $q_2=z-(\hbar/2)y$, we get

$$\begin{aligned}&\int_{\mathbb{R}}J_Q(a,t)dt\\ &=\mathcal{T}\left\{\frac{\hbar}{m^2}\int|q_0|\overline{\mathcal{F}_t\mathbf{g}\left(q_0,\frac{yz}{m}\right)}\Lambda_\hbar(q_0,z,y)\overline{\psi_{z+(\hbar/2)y}(a)}\psi'_{z-(\hbar/2)y}(a)e^{i(yz/m)t}\,dt\,dz\,dy\,dq_0\right\}\\ &=\mathcal{T}\left\{\frac{2\pi\hbar}{m}\int\frac{|q_0|}{|z|}\overline{\mathcal{F}_t\mathbf{g}(q_0,0)}\Lambda_\hbar(q_0,z,0)\overline{\psi_z(a)}\psi'_z(a)dq_0\,dz\right\}.\end{aligned}$$

Since

$$\mathcal{T}(\overline{\psi_z}(a)\psi'_z(a))=\frac{z}{\hbar}(1-R(z))=\frac{z}{\hbar}T(z) \quad (z>0); \quad \mathcal{T}(\overline{\psi_z}(a)\psi'_z(a))=\frac{z}{\hbar}T(z) \quad (z<0),$$

we deduce, with (48),

$$\int_{\mathbb{R}}J_Q(a,t)dt=\int_{\mathbb{R}}\frac{q_0}{m}\tilde{T}_\hbar(q_0)\mathcal{F}_t\mathbf{g}(q_0,0)dq_0=\int_{\mathbb{R}^2}\frac{p}{m}\tilde{T}_\hbar(p)\mathbf{g}(p,t)dp\,dt,$$

where

$$\tilde{T}_\hbar(p)=\int P_\hbar(p,z)T_\hbar(z)dz, \quad \tilde{R}_\hbar(p)=\int P_\hbar(p,z)R_\hbar(z)dz. \tag{77}$$

Now, we turn to the computation of $J_C(a,t)$. Introducing

$$F(x,p)=\int_{\mathbb{R}} f(x,p,t)dt, \tag{78}$$

we have, with (44), (45), and dropping the indices $\hbar$ for simplicity,

$$\begin{aligned}\int_{\mathbb{R}} J_C(a,t)dt &= \int_{p>0} p[F(a,p)-F(a,-p)]dp \\ &= \int_{p>0} pF(a,p)dp - \left\{ \int_{p>0}\int_{q>0} P(q,p)R(p)F(a,q)|q|dq\,dp \right. \\ &\quad \left. + \int_{p>0}\int_{q<0} P(q,-p_b(p))T(-p_b(p))\frac{p}{p_b(p)}F(b,q)|q|dq\,dp \right\}. \end{aligned} \tag{79}$$

By exchanging the p and q variables in the integrals inside the curly brackets, we are led to

$$\begin{aligned}\int_{\mathbb{R}} J_C(a,t)dt &= \int_{p>0}|p|F(a,p)dp - \int_{p>0}F(a,p)|p|\left(\int_{q>0} P(p,q)R(q)dq \right)dp \\ &\quad - \int_{p<0}F(b,p)|p|\left(\int_{q>0} P(p,-p_b(q))T(-p_b(q))\frac{q}{p_b(q)}dq \right)dp. \end{aligned} \tag{80}$$

Now, we have, using the normalization condition (38) together with relation (26),

$$1-\int_{q>0} P(p,q)R(q)dq = \int_{q>0} P(p,q)T(q)dq = \tilde{T}(p), \quad p>0,$$

$$\int_{q>0} P(p,-p_b(q))T(-p_b(q))\frac{q}{p_b(q)}dq = \int_{q>0} P(p,-q)T(-q)dq = \tilde{T}(p), \quad p<0,$$

and therefore, (80) leads to

$$\int_{\mathbb{R}} J_C(a,t)dt = \int_{p>0}|p|\tilde{T}(p)F(a,p)dp - \int_{p<0}|p|\tilde{T}(p)F(b,p)dp.$$

But, with (78) and the fact that the outgoing trace of f coincides with the incoming trace of g [see Eq. (42)], we deduce that

$$\int_{\mathbb{R}} J_C(a,t)dt = \int_{\mathbb{R}^2} \tilde{T}(p)\mathbf{g}(p,t)p\,dp = \int_{\mathbb{R}} J_Q(a,t)dt,$$

which completes the proof.

VI. CLASSICAL–QUANTUM COUPLING IN THE STATIONARY CASE

In the present section, we specialize our method for the stationary case in order to bridge the gap with previous work.[1] We first state the following lemma.

Lemma 6.1: Assume that the function $\mathbf{g}$ *does not depend on time and that hypothesis* (43) *holds true. Then the density matrix* ρ *defined by* (41) *does not depend on time and is given by*

$$\rho(x,x')=\int \tilde{g}(q)\psi_q(x)\overline{\psi_q}(x')dq, \tag{81}$$

with

$$\tilde{g}(p)=2\pi\hbar\int_{\mathbb{R}}\frac{|q|}{|p|}|\Phi_\hbar(q,p)|^2\mathbf{g}(q)dq=\int_{\mathbb{R}}P(q,p)\frac{|q|}{|p|}\mathbf{g}(q)dq. \tag{82}$$

In a previous work, one of the authors[1] proposed a method for the stationary case based on (81) with $\mathbf{g}$ instead of $\tilde{g}$. We have seen that, given the conditions (49) on $\Phi_\hbar(q,p)$, $\tilde{g}$ is close to $\mathbf{g}$ in the limit $\hbar\to 0$. Therefore, these two constructions are consistent.

Proof: Performing the changes of variables $t_1=t_0-t$ and $(q_1,q_2)\to(z,y)$ [defined by (67)] in the expression (41) (in which $\mathbf{g}$ is now independent of t), we obtain

$$\rho(x,x',t)=\frac{1}{2\pi}\int\frac{|q_0|}{m}\boldsymbol{g}(q_0)\Lambda_\hbar(q_0,z,y)\psi_{z+(\hbar/2)y}(x)\overline{\psi_{z-(\hbar/2)y}(x')}\exp\left(it_1\frac{yz}{m}\right)dt_1\,dq_0\,dy\,dz,$$

which ensures that ρ does not depend on time. The integrations with respect to t_1 and y are, respectively, performed and lead to

$$\rho(x,x')=\int\frac{|q_0|}{|z|}\mathbf{g}(q_0)P(q_0,z)\psi_z(x)\overline{\psi_z(x')}dq_0\,dz=\int\tilde{g}(z)\psi_z(x)\overline{\psi_z(x')}dz,$$

which leads to the result.

Geometric amplitude, adiabatic invariants, quantization, and strong stability of Hamiltonian systems

K. Yu. Bliokh[a)]
Institute of Radio Astronomy, 4, Krasnoznamyonnaya st., 61002, Kharkov, Ukraine

(Received 20 May 2001; accepted for publication 27 September 2001)

Considered is a linear set of ordinary differential equations with a matrix depending on a set of adiabatically varying parameters. Asymptotic solutions have been constructed. As has been shown, an important characteristic determining the qualitative portrait of the system is the real part of Berry's complex geometric phase, which we call the geometric amplitude. For systems with purely imaginary eigenvalues the equivalence has been proven in the adiabatic approximation of system sets without geometric amplitude, Hamiltonian systems, quantizable systems, and strongly stable systems. Classification of the systems without geometric amplitude is given with respect to the kind of matrix of the initial system. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1418718]

I. INTRODUCTION

The interest toward the problem of adiabatic evolution of the dynamic system that seemed to have been solved long ago has increased sharply after the papers by Berry and Hannay.[1–3] They noticed certain unusual properties of some terms in the phase of the well-known adiabatic solutions. These terms can be represented as contour integrals of the nonpotential field in the system parameter space. As a result, they do not depend explicitly on the parameter time dependence, but depend only on the geometry of the contour that the representative point moves along through the parameter space. For this reason, the part of the phase described by these terms has been named geometric. Soon thereafter the geometric phases were measured experimentally and found numerous applications, as an intrinsic part of the adiabatic theory, in diverse areas of modern physics.[4]

In view of the general complex representation of adiabatic solutions to linear systems with slowly varying parameters, it is natural to assume that the geometric phase can be complex as well, i.e., it can change the amplitude of solutions in addition to changing the phase.[5,6] The real part of Berry's complex phase, which is responsible for amplitude variations, will be called the *geometric amplitude*. The complex Berry phases were first considered in Ref. 5. Yet, in that paper, as well as in, for instance, Ref. 6, the geometric amplitude appeared in a system characterized by a nonzero real part of its eigenvalues, i.e., against the background of a far greater real component of the conventional dynamic phase, and hence could not affect the qualitative behavior of the solution. As was shown later, the geometric amplitude can appear in oscillatory systems (i.e., in such systems that have purely imaginary eigenvalues) as well where the real part of the dynamic phase is zero.[7] The example below illustrates the significance of the geometric amplitude in this case. Let the system parameters vary in such a way that the system's representative point moves along a closed contour in the parameter space. In the case of a conventional oscillator the amplitude of the adiabatic solution returns to its initial value together with the parameter values. But if a geometric amplitude is present in the oscillatory system, then the corresponding integral of a nonpotential field along the closed contour in the parameter space assumes a nonzero value, and the system does not return to its initial state. Moreover, if the system's representative point performs a continuous motion along a bounded closed contour (i.e., the variation of the systems parameters is finite), then the system might deviate infinitely far from its initial state.

a)Electronic mail: kostya@bliokh.kharkiv.com

Thus, the presence of a geometric amplitude implies instability of the oscillator system. This kind of instability was treated with the use the WKB formalism for such dynamic systems that are described by ordinary differential equations of order n.[7] The unusual properties of geometric instability make it essentially different from the known parametric resonances. First, the geometric instability is independent of the relationship between the phases of parameter variation and phases of the solution. Second, the geometric instability is present with an arbitrary temporal dependence of the system parameters (not necessarily periodic, however, if periodic, then of an arbitrary small frequency) for any nondegenerate contour described by the system in the parameter space. Finally, the geometric instability is physically reversible, in the sense that it would be sufficient to vary the parameters in such a way as to have the representative point move along the same contour in the opposite direction, for the instability to be replaced by damping.

These properties suggest that the geometric amplitude can play an important role in dynamic systems. Meanwhile, in Ref. 7 the author put forward a hypothesis of the absence of geometric amplitude in Hamiltonian and other systems possessing a certain symmetry, and formulated the problem of identifying classes of systems with the geometric amplitude. The same paper indicated the direct connection between the geometric amplitude and the possibility of constructing adiabatic invariants, namely that adiabatic invariants can only be constructed if the geometric amplitude is absent.

In this paper the author has discovered and investigated the close connection relating the geometric amplitude to adiabatic invariants, Hamiltonian formalism, the quantization problem, and strong stability of the system. We create a classification of the systems without geometric amplitudes, in which the central role belongs to Hamiltonian systems. Considered are the dynamic systems with adiabatically varying parameters, that are described by nondegenerate sets of ordinary linear differential equations with different eigenvalues. Instead of the cumbersome WKB formalism for the nth-order equations, we offer a more convenient and natural formalism of the first-order vector equation. While in the conventional Hamiltonian theory a complex structure is introduced as an auxiliary one after the quadratic Hamiltonian has been brought to the normal form, we assume a complex structure to be specified in the initial equation. After that, the problem of determining whether the system is Hamiltonian is formulated. As a result, the general formalism of the problem is simplified.

II. GENERAL FORMALISM

Let us consider the linear system described by an n-dimensional vector equation in $\mathbf{C}^n$:

$$\mathbf{x}' = \mathbf{A}(\bar{\mu})\mathbf{x}, \tag{1}$$

where $\mathbf{x}=(x_1,\ldots,x_n)$ is the vector function to be found (its components will be called coordinates); the prime stands for differentiation with respect to the independent variable t (known further as time); $\mathbf{A}(\bar{\mu})$ is the linear operator specified by a square nondegenerate matrix that is a smooth function without singularities of the set of s adiabatically varying parameters $\bar{\mu}=(\mu_1,\ldots,\mu_s)$, i.e., of the vector in $\mathbf{R}^s$. (Let us note that all the main results of this paper are nearly identically obtainable for the initial system in $\mathbf{R}^{2n}$ as well.) The system parameters are subject to an arbitrary (though nonresonance) adiabatic variation with time:

$$\bar{\mu}=\bar{\mu}(\varepsilon t), \quad \varepsilon \ll 1. \tag{2}$$

Here, ε is the adiabaticity parameter. The matrix $\mathbf{A}(\bar{\mu})$ is assumed to be nondegenerate with all the values of the parameters, and all of its eigenvalues are separated sufficiently far for permitting use of the independent adiabatic solutions of (1).

The adiabatic solutions of the system (1) are obtainable through the standard asymptotic techniques,[8] however we are going to use the following idea (it was proposed by Neistadt and is mentioned in Ref. 9).

Let us bring the matrix $\mathbf{A}(\overline{\mu})$ to a diagonal form by applying a parameter-dependent linear substitution of coordinates. In terms of the new coordinates, the matrix of the transformed system will be only slightly nondiagonal, with the off-diagonal terms being proportional to the first-order time derivatives and having the order of ε. Let us further diagonalize the matrix obtained to first order in ε via another linear substitution of coordinates. In these coordinates the off-diagonal matrix elements will be second order ε^2 values, being proportional to the second-order time derivatives. This procedure can be similarly reiterated. This way, the initial equation can be brought for any finite order of ε approximation to a diagonal form, for which exact solutions can be easily written. In this paper we are interested only in the first approximation diagonalization, which corresponds to either the adiabatic approximation or the averaging method (the applicability of adiabatic solutions is discussed in Appendix A).

Let $\mathbf{D}(\overline{\mu})$ be the transition matrix toward the new coordinates $\mathbf{y}$ where $\mathbf{A}(\overline{\mu})$ is diagonal. Then,

$$\mathbf{x}=\mathbf{D}(\overline{\mu})\mathbf{y}, \quad \mathbf{D}^{-1}(\overline{\mu})\mathbf{A}(\overline{\mu})\mathbf{D}(\overline{\mu})=\mathbf{\Lambda}(\overline{\mu})\equiv\mathrm{diag}(\lambda_1,\ldots,\lambda_n), \tag{3}$$

where $\lambda_j=\lambda_j(\overline{\mu})$ are current eigenvalues of the matrix $\mathbf{A}(\overline{\mu})$. Using the substitution (3), Eq. (1) is reduced to the form

$$\mathbf{y}'=(\mathbf{\Lambda}-\mathbf{D}^{-1}\mathbf{D}')\mathbf{y}. \tag{4}$$

From here on, wherever it is unambiguous, the functional arguments are omitted for brevity. The matrix of Eq. (4) consists of two components, namely the diagonal matrix $\mathbf{\Lambda}$ of order ε^0, and the nondiagonal matrix $\mathbf{D}^{-1}\mathbf{D}'$, whose order is ε^1, as its elements are proportional to the time derivatives of the parameters, viz., $\mathbf{D}'=(d\mathbf{D}/d\overline{\mu})\overline{\mu}'$. In the meantime, the diagonal terms of the matrix $\mathbf{D}^{-1}\mathbf{D}'$ make a linear contribution in ε to the magnitudes of eigenvalues of the matrix of (4). At the same time, the contribution of the off-diagonal elements of $\mathbf{D}^{-1}\mathbf{D}'$ to the eigenvalues is of higher orders, and in the linear approximation they can always be reduced to zero via a minor basis correction, i.e., substitution:

$$\mathbf{y}=(\mathbf{I}+\mathbf{\Delta})\tilde{\mathbf{y}};$$

$$\mathbf{\Delta}_{ij}=\frac{(\mathbf{D}^{-1}\mathbf{D}')_{ij}}{\lambda_j-\lambda_i}, \quad i\neq j; \quad \mathbf{\Delta}_{ii}=0, \tag{5}$$

where $\mathbf{I}$ is the unit matrix, $|\mathbf{\Delta}|\sim\varepsilon$. As a result of the substitution (5), we obtain, instead of Eq. (4):

$$\tilde{\mathbf{y}}'=[\mathbf{\Lambda}-\mathrm{dg}(\mathbf{D}^{-1}\mathbf{D}')+O(\varepsilon^2)]\tilde{\mathbf{y}}. \tag{6}$$

Here and further on, the operator dg denotes making the off-diagonal components of the matrix vanish. The sought-for approximate solutions of Eq. (6) will be as follows:

$$\tilde{\mathbf{y}}(t)\approx\tilde{\mathbf{y}}(0)\exp\left\{\int_0^t\left[\mathbf{\Lambda}(\overline{\mu}(\varepsilon\tau))-\mathrm{dg}\left(\mathbf{D}^{-1}(\overline{\mu}(\varepsilon\tau))\frac{d}{d\tau}\mathbf{D}(\overline{\mu}(\varepsilon\tau))\right)\right]d\tau\right\}, \tag{7}$$

where the symbol $\approx$ stands for asymptotic equivalence at $\varepsilon\to 0$ [in our case, to an accuracy up to $O(\varepsilon^2)$]. Using the substitution $(d/d\tau)\mathbf{D}(\overline{\mu}(\varepsilon\tau))d\tau=(d/d\overline{\mu})\mathbf{D}(\overline{\mu})d\overline{\mu}$, the second term in (7) can be transformed into a contour integral in the space of parameters, with the solutions being

$$\tilde{\mathbf{y}}(t)\approx\tilde{\mathbf{y}}(0)\exp\left\{\int_0^t\mathbf{\Lambda}(\overline{\mu}(\varepsilon\tau))d\tau+\int_l\overline{\mathbf{\Omega}}(\overline{\mu})d\overline{\mu}\right\}, \tag{8}$$

where

$$\overline{\mathbf{\Omega}}(\overline{\mu})=-\mathrm{dg}\left(\mathbf{D}^{-1}(\overline{\mu})\frac{d\mathbf{D}(\overline{\mu})}{d\overline{\mu}}\right) \tag{9}$$

is the s-dimensional field of the diagonal matrices over the $\overline{\mu}$ space; l is the contour in which the representative point moves. From here on, the integration contour is assumed to lie in a certain finite, simply connected region of $\mathbf{R}^s$, being sufficiently far removed from the singularities of field (9) (turning points) that are known to correspond to the eigenvalues merger points λ_j;[10] in our case those are $(s-1)$-dimensional hypersurfaces.

We have reduced the initial set (1) to a nearly diagonal form, and in the adiabatic approximation Eq. (6) and its solutions (8) break down into n independent components (degrees of freedom) over each dimension y_j. To make things simpler, all further derivations will be made for the jth component, the extension to the entire system being trivial. Equation (6) and its solutions (8) take the form

$$\tilde{y}_j'=(\lambda_j-\overline{\omega_j}\overline{\mu}')\tilde{y}_j+O(\varepsilon^2), \tag{10}$$

$$\tilde{y}_j(t)\approx\tilde{y}_j(0)\exp\left\{\int_0^t\lambda_j(\overline{\mu}(\varepsilon\tau))d\tau+\int_l\overline{\omega_j}(\overline{\mu}_j)d\overline{\mu}\right\}, \tag{11}$$

where

$$\overline{\omega_j}(\overline{\mu})=\overline{\mathbf{\Omega}}_{jj}(\overline{\mu})=-\left(\mathbf{D}^{-1}(\overline{\mu})\frac{d\mathbf{D}(\overline{\mu})}{d\overline{\mu}}\right)_{jj} \tag{12}$$

is the jth element of the diagonal field matrix (9), and $O(\varepsilon^2)$ contains terms proportional to different y_k. We have taken into account that $-\mathrm{dg}(\mathbf{D}^{-1}\mathbf{D}')=\overline{\mathbf{\Omega}}\overline{\mu}'$ in (6).

The first term in the exponent (11) is the standard ''fast,'' or dynamic, phase that depends explicitly on time, following the evolution of the initial matrix eigenvalues. The second ''slow'' term is of order ε, as compared to the first one. It does not depend explicitly on time, being dependent only on the representative point trajectory in the space of parameters.

Let us extract the potential component of the field $\overline{\omega_j}(\overline{\mu})$:

$$\overline{\omega_j}(\overline{\mu})=\mathrm{grad}(\varphi_j(\overline{\mu}))+\overline{\omega_j^{(c)}}(\overline{\mu}), \tag{13}$$

where $\varphi_j(\overline{\mu})$ is a scalar function, while $\overline{\omega_j^{(c)}}(\overline{\mu})$ is the nonpotential component of $\overline{\omega_j}(\overline{\mu})$. By substituting (13) in (11), we obtain

$$\tilde{y}_j(t)\approx\tilde{y}_j(0)\exp\left\{\int_0^t\lambda_j(\overline{\mu}(\varepsilon\tau))d\tau+\varphi_j(\overline{\mu}(t))-\varphi_j(\overline{\mu}(0))+\int_l\overline{\omega_j^{(c)}}(\overline{\mu})d\overline{\mu}\right\}. \tag{14}$$

The contribution of the potential field component $\overline{\omega_j}(\overline{\mu})$ to the solutions (14) is determined only by the boundary parametric values, being independent, as it is, of the integration contour in the $\overline{\mu}$ space. Therefore, it is the component that determines the connection of the slow solution amplitude to *current* parameter values, and is responsible for the construction of adiabatic invariants.

The contribution of the nonpotential component, $\overline{\omega_j^{(c)}}(\overline{\mu})$, quite to the contrary, depends considerably on the contour geometry l (i.e., on all *prior* values of the parameters), being nonzero even at cyclic parametric variations that correspond to closed contours in the $\overline{\mu}$ space. The last term in the exponent (14) is Berry's complex geometric phase.

For the convenience of our further argumentation we will separate the real and imaginary parts of Berry's complex phase. Its imaginary part will be called the geometric phase proper:

$$\psi_j(l)=\mathrm{Im}\int_l\overline{\omega_j^{(c)}}(\overline{\mu})d\overline{\mu}, \tag{15}$$

while its real part will become the geometric amplitude:

$$\gamma_j(l)=\mathrm{Re}\int_l \overline{\omega}_j^{(c)}(\overline{\mu})d\overline{\mu}, \tag{16}$$

since it is exactly its increment that entails the solution amplitude variations.

Proposition: *The geometric terms, along with the current eigenvalues* λ_j *determine the qualitative portrait of a linear adiabatic system.*

Really, the behavior of the linear system (1) is determined, at constant parameters, by the eigenvalue set λ_j. Those eigenvalues can also be used to describe the system (1) with parameters that vary adiabatically over small times $t\ll\varepsilon^{-1}$ (the values λ_j change little over this time). To describe the adiabatic behavior of the system (1) over large times $t\gg\varepsilon^{-1}$, let us determine the effective eigenvalues that correspond to the solutions (14) over a given time:

$$\lambda_j^{\mathrm{eff}}(t)=\frac{\ln\tilde{y}_j(t)-\ln\tilde{y}_j(0)}{t}. \tag{17}$$

By substituting the solutions (14) into (17), we shall obtain

$$\lambda_j^{\mathrm{eff}}=\langle\lambda_j\rangle_t+\frac{\gamma_j+i\psi_j}{t}+O(t^{-1}), \tag{18}$$

where $\langle\lambda_j\rangle_t\equiv(1/t)\int_0^t\lambda_j(\overline{\mu}(\varepsilon\tau))d\tau$ are average values of the current eigenvalues. The second term in (18) has the order ε and, generally speaking, does not tend to zero together with t^{-1}, since during continuous circulation of the representative point in the $\overline{\mu}$ space the geometric terms grow without bound. If there is a bound $\tilde{\lambda}_j^{\mathrm{eff}}=\lim_{t\to\infty}\lambda_j^{\mathrm{eff}}(t)$, then the solution behavior over large times [strictly speaking, over times so large that the value of $\lambda_j^{\mathrm{eff}}(t)$ does not leave the small vicinity of its limit] can be ''roughly'' (i.e., neglecting the local deviations) described by the formula $\tilde{y}_j(t)\approx\tilde{y}_j(0)\exp(\tilde{\lambda}_j^{\mathrm{eff}}t)$. For example, at periodic parametric variations with the period $T\sim\varepsilon^{-1}$, the value $\lambda_j^{\mathrm{eff}}(t)$ tends asymptotically to the limit $\tilde{\lambda}_j^{\mathrm{eff}}=\langle\lambda_j\rangle_T+[\gamma_j(l_T)+i\psi_j(l_T)]/T$, where l_T is the closed contour corresponding to one period. The role of the effective eigenvalues can be illustrated by the geometric instability.[7] That paper considered systems with purely imaginary current eigenvalues, $\mathrm{Re}\,\lambda_j=0$ (in the sequel, such systems will be called *oscillatory*). There the solutions demonstrated an exponential growth at the effective rate $\mathrm{Re}\,\tilde{\lambda}_j^{\mathrm{eff}}=\gamma_j(l_T)/T$.

Thus, to qualitatively describe the behavior of a system with adiabatically varying parameters one has to know the effective eigenvalues that are determined by the local eigenvalues $\lambda_j(\overline{\mu})$ and geometric terms [fields $\overline{\omega}_j^{(c)}(\overline{\mu})$]. It is natural that the geometric terms and local eigenvalues are invariant with respect to local coordinate substitutions that depend on the current values of the parameters and their derivatives and can only change the potentials $\varphi_j(\overline{\mu})$ (see Appendix B). All of the above argumentation provide grounds for listing the geometric phases and amplitudes together with such ''basic'' characteristics of a system as eigenvalues λ_j.

III. ADIABATIC INVARIANT CONSTRUCTION, POINCARÉ'S INTEGRAL INVARIANTS, AND THE LIOUVILLE THEOREM

As noted above, the potentials $\varphi_j(\overline{\mu})$ in the solutions (14) depend on the choice of a coordinate system. In particular, we can always transit to such coordinates in which the potentials $\varphi_j(\overline{\mu})$ vanish. Transition to these coordinates in the case of the Hamiltonian systems corresponds to the transition to the canonical action variables. Let us make the substitution

$$z_j=\tilde{y}_j\exp(-\varphi_j(\overline{\mu})).$$

Then, the equations (10) and their solutions (14), considering (13), (15), and (16), will take on the following form:

$$z_j' = (\lambda_j + \overline{\omega}_j^{(c)}\overline{\mu}')z_j + O(\varepsilon^2); \tag{19}$$

$$z_j(t) \approx z_j(0)\exp\left\{\int_0^t \lambda_j(\overline{\mu}(\varepsilon\tau))d\tau + \gamma_j(l) + i\psi_j(l)\right\}. \tag{20}$$

If in the **z** space the solution absolute values should be approximately constant:

$$I_j(t) \equiv |z_j(t)|^2 \approx \text{const}, \tag{21}$$

then they are known as adiabatic invariants of action I_j. In the initial coordinates, they determine, under given initial conditions, the unambiguous connection between the approximate solution amplitude and current parametric values. The following is obvious.

Statement I: *A given degree of freedom possesses an adiabatic invariant of action if and only if*

$$\begin{gathered} \operatorname{Re}\lambda_j = 0, \\ \gamma_j = 0. \end{gathered} \tag{22}$$

Note that the conditions (22) are equivalent to the requirement that the real part of the effective eigenvalue λ_j^{eff}, introduced in the preceding section, be equal to zero. In other words, it should be equivalent to the requirement of conservation of the oscillatory nature of the motion over large times and under adiabatically varying parameters.

The expressions (21) and the conditions (22) correspond to the conservation of the phase flux of the jth degree of freedom in the **z** space. [Since we consider the general case for a complex equation in $\mathbf{C}^n$, each degree of freedom corresponds to one dimension z_j, with the phase flux of one degree of freedom corresponding to the phase flux of the complex plane z_j. It is rather easy to extend all the results given here to the case of real initial system (1) in $\mathbf{R^{2n}}$, where, after diagonalization of the equations, each degree of freedom corresponds to two complex conjugated equations.] Indeed, from (20) and (21) it is easy to see that the time dependence of the area of a z_j-plane element:

$$S_j(t) \equiv \int dz_j \wedge dz_j^* \approx S_j(0)\exp\left\{2\int_0^t \operatorname{Re}\lambda_j\, d\tau + 2\gamma_j\right\},$$

coincides with the values $I_j(t)$ to insignificant factors (the asterisk stands for complex conjugation, while integration of the 2-form is done over the selected area element of the phase z_j plane at a fixed time). When the geometric amplitude $\gamma_j \neq 0$ is present in the oscillatory system the phase flux is not conserved and gets changed by a factor of $\exp(2\gamma_j)$.

We will define Poincaré's kth ($k \leqslant n$) integral invariant through the statement as follows: The area of an arbitrary k-dimensional hypersurface of the kind

$$S^{(k)}(t) = \int \sum_{a_1 < \ldots < a_k} dz_{a_1} \wedge dz_{a_1}^* \wedge \cdots \wedge dz_{a_k} \wedge dz_{a_k}^*,$$

is conserved in the course of time evolution: $S^{(k)}(t) = \text{const}$. (Here, one has to make an important remark. The Poincare's integral invariants are an attribute of Hamiltonian systems. With this in mind, the considered complex invariant structure can be introduced only for the Hamiltonian systems with purely imaginary current eigenvalues. However, Hamiltonian systems may possess eigenvalues of two other kinds as well, namely pairs of opposite real numbers and quadruples with opposite real and imaginary parts.[16] Those two cases of eigenvalue pairs and quadruples are not considered here. Formally speaking, we can leave them out by requiring that the imaginary parts of eigenvalues λ_j be different.) Poincaré's first integral invariant represents a sum of projection areas on the plane z_j:

$$S^{(1)}=\int \sum_{j=1}^{n} dz_j\wedge dz_j^*=\int \sum_{j=1}^{n} dS_j=\text{const.}$$

Statement II: *In the considered adiabatic approximation (when the degrees of freedom z_j are assumed independent) the existence of Poincaré's first integral invariant is equivalent to the presence of n adiabatic invariants $S_j\approx$ const, i.e., for its existence it is necessary and sufficient that the conditions (22) hold for all degrees of freedom.*

Let us consider also changes in the *n*-dimensional phase volume of the system:

$$S^{(n)}\equiv V(t)\equiv\int dz_1\wedge dz_1^*\wedge\cdots\wedge dz_n\wedge dz_n^*\approx V(0)\exp\left\{2\sum_{j=1}^{n}\left(\int_0^t \mathrm{Re}\,\lambda_j\,d\tau+\gamma_j\right)\right\}.$$

Statement III: *The necessary and sufficient conditions for the phase volume of a system to be conserved, $V(t)\approx$ const (Poincaré's nth integral invariant, or Liouville's theorem) are*

$$\sum_{j=1}^{n}\mathrm{Re}\,\lambda_j=0,\qquad \sum_{j=1}^{n}\gamma_j=0. \tag{23}$$

Thus, Liouville's theorem of conservation of the phase volume of a system imposes restrictions on the geometric amplitudes without forbidding their existence. Should one require conservation of the phase areas for each degree of freedom (adiabatic invariants) or conservation of the phase volume for manifolds of dimension less than *n* (Poincaré's integral invariants), that would only be possible if all geometric amplitudes were identical zeros.

IV. HAMILTONIAN FORMALISM

It is known that a system has Poincaré's first integral invariant only when the system is Hamiltonian.[11,12] In this way, it follows from the results of the preceding section [condition (22)] that the absence of geometric amplitudes is necessary and sufficient for an oscillatory system to be Hamiltonian in the approximation considered. We will produce direct proof for this assertion.

In an oscillatory system without geometric amplitudes, the Hamiltonian formalism is naturally introduced when the diagonalized equations are realificated. Indeed, carrying out the realification of (19) and introducing the variables

$$p_j=\mathrm{Re}\,z_j,\quad q_j=\mathrm{Im}\,z_j,$$

we obtain

$$\begin{aligned}p_j'&=\mathrm{Re}(\lambda_j+\overline{\omega}_j^{(c)}\overline{\mu}')p_j-\mathrm{Im}(\lambda_j+\overline{\omega}_j^{(c)}\overline{\mu}')q_j+O(\varepsilon^2)\\ q_j'&=\mathrm{Im}(\lambda_j+\overline{\omega}_j^{(c)}\overline{\mu}')p_j+\mathrm{Re}(\lambda_j+\overline{\omega}_j^{(c)}\overline{\mu}')q_j+O(\varepsilon^2).\end{aligned} \tag{24}$$

Taking into account the conditions (22) and neglecting ε-quadratic components, we find that $2n$ real equations (24) correspond to the canonical equations with a Hamiltonian:

$$H(p,q)=\frac{1}{2}\sum_{j=1}^{n}\mathrm{Im}(\lambda_j+\overline{\omega}_j^{(c)}\overline{\mu}')(p_j^2+q_j^2), \tag{25}$$

where $p\equiv(p_1,\ldots,p_n)$; $q\equiv(q_1,\ldots,q_n)$.

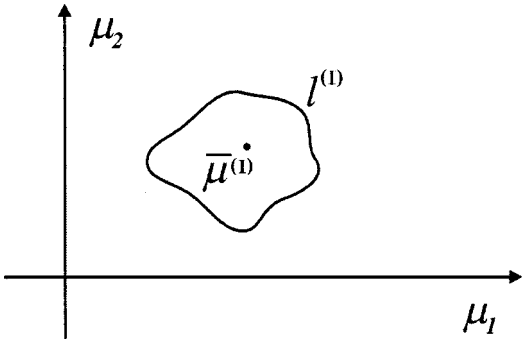

FIG. 1. To the proof of Theorem I. The nonperturbed system realization corresponds to the zero contour at point $\bar{\mu}^{(I)}$, the perturbed one corresponds to the closed contour $l^{(I)}$ around $\bar{\mu}^{(I)}$. Here and in the following figures, for the sake of clearness, we present the case of two-dimensional parameter space: $\bar{\mu}=(\mu_1,\mu_2)$.

Thus, an oscillatory system without geometric amplitudes is a canonical one with a Hamiltonian (25). Let us now prove the opposite: an arbitrary oscillatory Hamiltonian system has no geometric amplitudes.

Let us consider a Hamiltonian system with different imaginary eigenvalues, $\mathrm{Re}\,\lambda_j=0$. We will call a *realization* of a system the system with a certain given time dependence $\bar{\mu}(\varepsilon t)$. As the initial realization we will take the one with arbitrary constant values of the parameters $\bar{\mu}=\bar{\mu}^{(I)}$. It is obvious that the geometric phases and amplitudes of this realization of the system are zero. As the perturbed realization we will consider the realization of the same system where the parameters change in such a way that the representative point is moving along a small closed contour $l^{(I)}$ in the vicinity of the point $\bar{\mu}^{(I)}$ in the parameter space (Fig. 1). The perturbed realization of the system will now possess certain nonzero geometric terms. Their values are independent of a specific parameter-on-time dependence and depend only on the contour $l^{(I)}$ shape. For this reason, without loss of generality, we can assume that in the perturbed realization the parameters depend on time periodically with an arbitrary nonresonance period $T\sim\varepsilon^{-1}$.

Recall that the systems where parameters depend on time periodically are characterized by *multiplicators*, namely the coefficients of eigensolution transformation over one period. Using the explicit form of the solutions (20), we obtain that the system multiplicators in the adiabatic approximation are as follows:

$$\rho_j(l)=\exp\left\{\int_0^T \lambda_j\,dt+\gamma_j(l)+i\psi_j(l)\right\}. \tag{26}$$

In the initial realization $|\rho_j(0)|=1$, i.e., its multiplicators lie on a unit circle. According to the theorem on the strong stability of Hamiltonian systems whose Hamiltonian depends periodically on time,[13] if the perturbation is small enough (i.e., the contour $l^{(I)}$ lies in a sufficiently small vicinity of the point $\bar{\mu}^{(I)}$); then the multiplicators of the perturbed system realization also belong to the unit circle: $|\rho_j(l^{(I)})|=1$. Hence, using (26) for the perturbed realization, we obtain $\gamma_j(l^{(I)})=0$. This proves that the system's geometric amplitudes are equal to zero for an arbitrary small contour in the vicinity of an arbitrary point in the considered region of $\bar{\mu}$ space. Therefore the geometric amplitudes in a Hamiltonian system with $\mathrm{Re}\,\lambda_j=0$ are identical zeros.

This result can be interpreted as the conservation of the oscillatory nature of a Hamiltonian system motion under adiabatic parametric variations. Hence, in particular, it follows [compare (19), (24), (25), taking into account (22)] that a Hamiltonian system with different imaginary eigenvalues and slow varying parameters, similar to a system with constant parameters, is reduced in the adiabatic approximation to the normal form[14] with a Hamiltonian:

$$H(p,q)=\sum_{j=1}^{n} H_j(p_j,q_j)=\frac{1}{2}\sum_{j=1}^{n} w_j(p_j^2+q_j^2), \tag{27}$$

where $iw_j=\lambda_j+\overline{\omega}_j^{(c)}\overline{\mu}'$.

So, we demonstrate that the oscillatory systems have no geometric amplitudes if and only if the system is Hamiltonian. In other words, the following theorem is true.

Theorem I: *Among the system (1) with different imaginary current eigenvalues the sets of Hamiltonian systems and those without geometric amplitudes are, within the adiabatic approximation, coincident. The Hamiltonians of these systems can be reduced to the normal form (27), namely to that of a sum of independent oscillators.*

It should be emphasized that it is exactly in the oscillatory Hamiltonian systems that geometric amplitudes are absent, although they may be present in Hamiltonian systems with a nonzero real part of the current eigenvalues.[5,6] Indeed, the simplest example of such a system may well be the generalized Hannay oscillator[3] with the following Hamiltonian: $H=\frac{1}{2}(\mu_1 p^2+2\mu_2 pq+\mu_3 q^2)$. If one considers the Hannay oscillator in the parametric region $\mu_1\mu_3-\mu_2^2<0$ (corresponding to its eigenvalues being real and its phase portrait being hyperbolic), then the known geometric phase in this system becomes its geometric amplitude. It should be noted that the typical growth rates associated with the geometric amplitude will at all times be much smaller than the typical real part of the system eigenvalues.[7]

V. SYSTEM QUANTIZATION

In this section, we will try to answer the question whether the system (1) can be quantized and what conditions are required for that. As in the preceding section, we will deal with oscillatory systems. We call the spectrum of the jth degree of freedom σ_j the range of $|z_j|^2$ for fixed values of the parameters:

$$\sigma_j(\overline{\mu})=\{|z_j|^2\}|_{\overline{\mu}=\text{const}}.$$

The system quantization will be understood as follows. Let the system (1) with purely imaginary eigenvalues correspond to a certain classical system. It is quite obvious that its spectra are continuous: $\sigma_j=[0,+\infty)$. During quantization we correspond this system to the quantum one so that its dynamic variables z_j satisfy the same differential equations (19), but spectra $\sigma_j(\overline{\mu})$ are discrete and unambiguously determined by the fixed parametric values $\overline{\mu}$.

It is quite clear that the known quantization rules for oscillatory Hamiltonian systems satisfy our requirements (see, for instance, the oscillator quantization in Ref. 15). Indeed, for a Hamiltonian oscillatory system under constant values of parameters σ_j's are, to constant multipliers, spectra of Hamiltonians (27) H_j of independent linear oscillators. We are going to prove that the non-Hamiltonian oscillatory system is unquantizable in principle, and the reason for that can be attributed to the presence of geometric amplitudes.

Consider a realization of a non-Hamiltonian oscillatory system, in which the time dependence of parameters is like shown in Fig. 2. Up to a certain moment of time the parameters preserve certain constant values: $\overline{\mu}=\overline{\mu}^{(II)}$ at $t\in(-\infty,t_1]$; afterward in the finite segment $t\in[t_1,t_2]$ the parameters undergo a single cyclic change, corresponding to the closed contour $l^{(II)}$ with its beginning and end being in the point $\overline{\mu}^{(II)}$; after that the parameter values are equal to the initial ones and remain constant in the sequel: $\overline{\mu}=\overline{\mu}^{(II)}$ at $t\in[t_2,+\infty)$. Let us consider the spectra transformation of this realization in the range $t\in[t_1,t_2]$.

On one hand, in the ranges $t\in(-\infty,t_1]$ and $t\in[t_2,+\infty)$ the considered realization is described by the same differential equations with the same constant parameter values $\overline{\mu}^{(II)}$. That is why its phase portraits in these ranges must coincide:

$$\sigma_j|_{t>t_2}=\sigma_j|_{t<t_1}=\sigma_j(\overline{\mu}^{(II)}).$$

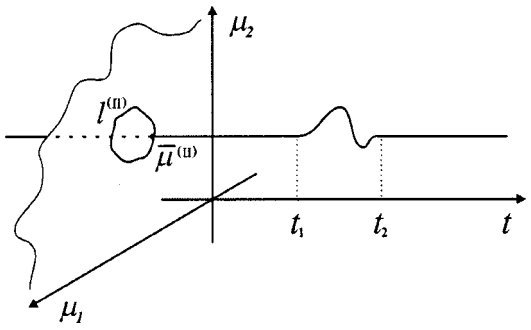

FIG. 2. To the proof of Theorem II. The $\overline{\mu}(t)$ dependence and its projection on the $\overline{\mu}$ space: closed contour $l^{(II)}$ with its beginning and end at point $\overline{\mu}^{(II)}$.

On the other hand, due to the non-Hamiltonian nature of the system, in the range $t\in[t_1,t_2]$ the solution gains geometric amplitudes $\gamma_j^{(II)}=\gamma_j(l^{(II)})$, and, as was shown in Sec. III, the values of $|z_j|^2$ (which are proportional to the phase fluxes of different degrees of freedom) get changed by the factor of $\exp(2\gamma_j^{(II)})$. This means that the spectra of a given system realization undergo the same kind of extension:

$$\sigma_j|_{t>t_2}=\exp(2\gamma_j^{(II)})\sigma_j|_{t<t_1}.$$

Comparing the above assertions, we can avoid a contradiction only if the phase portrait of the system with the constant parameters and its spectra are self-similar with the coefficients $\exp(2\gamma_j^{(II)})$ in each dimension:

$$\sigma_j(\overline{\mu}^{(II)})=\exp(2\gamma_j^{(II)})\sigma_j(\overline{\mu}^{(II)}).$$

Hence an oscillatory system with a nonzero geometric amplitude is unquantizable. Indeed, by choosing different contours $l^{(II)}$ in the considered simply connected region of the $\overline{\mu}$ space, we will obtain that the possible values $\gamma_j^{(II)}=\gamma_j(l^{(II)})$ continuously fill up a certain segment of the real axis. The values of similarity coefficients $\exp(2\gamma_j^{(II)})$ will also continuously fill up the appropriate segment. In particular, by constricting the contour $l^{(II)}$ to the point $\overline{\mu}^{(II)}$ we can make $\gamma_j^{(II)}$ arbitrarily small, with the similarity coefficients being arbitrarily close to one. The classical continuous spectrum $\sigma_j=[0,+\infty)$ is always self-similar with any coefficient. Assume that the quantum discrete spectrum can be self-similar. But in this case the similarity coefficients' values will represent the discrete set, being determined by the interlevel distances. In particular, the quantum spectrum similarity coefficient cannot be made arbitrarily close to one, as this fact would mean that the interlevel distance is arbitrarily small, i.e., the spectrum is continuous. This proves that a non-Hamiltonian system cannot possess a discrete spectrum.

In the Hamiltonian system the phase space is not extended over $t\in[t_1,t_2]$, hence we do not need to require that the spectrum is self-similar. For this reason, the Hamiltonian system spectrum may be discrete.

Thus, the following theorem is true.

Theorem II: *Among the system (1) with different imaginary current eigenvalues the set of quantizable systems coincides, within the adiabatic approximation, with the set of systems without geometric amplitudes (or, according to Theorem I, with the set of Hamiltonian systems).*

The result obtained can be interpreted as yet another confirmation of the so-called Ehrenfest hypothesis.[16,12] According to this hypothesis, during the classical system quantization the quantum numbers correspond to adiabatic invariants. When geometric amplitudes are present, there are no adiabatic invariants in the system, and we cannot correspond a set of certain fixed numbers to each its solution. [Yet, this result does not mean that the system (1) with the geometric amplitudes

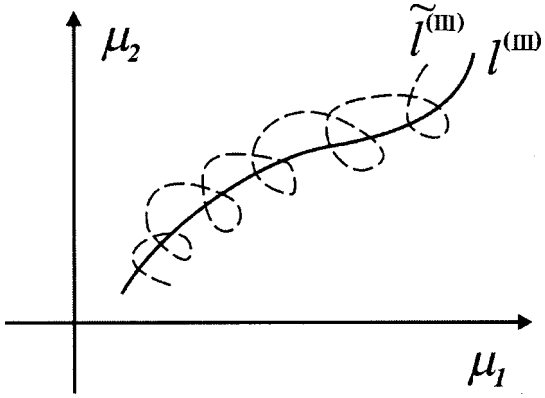

FIG. 3. To the proof of Theorem III. Contour $l^{(III)}$ of the nonperturbed system realization and its corresponding contour $\tilde{l}^{(III)}$ of the perturbed system realization in the space of parameters.

cannot describe a quantum system. Equation (1) can, for example, correspond to the Schrödinger equation of a certain system. We only mean that if the system (1) is classical, then its dependent variables cannot be quantized in the non-Hamiltonian case.]

VI. SYSTEM STRONG STABILITY

In the preceding two sections we established that for oscillatory systems the classes of systems without geometric amplitude, Hamiltonian systems, and quantizable ones are equivalent. In this section, we are going to demonstrate that this class of systems can be regarded as a set of oscillatory systems possessing the property of strong stability.

Let's define the strong stability in the following way.

Definition: *Let a realization of the system (1) with the matrix* $\mathbf{A}=\mathbf{A}_0(\overline{\mu})$ *from a certain class and the dependence* $\overline{\mu}=\overline{\mu}_0(\varepsilon t)$ *be stable, i.e., all of its solutions bounded. If there exists a* $\delta>0$, *such that any perturbed realization of the system (1) with the matrix* $\mathbf{A}=\mathbf{A}_1(\overline{\mu})$ *from the same class and the dependence* $\overline{\mu}=\overline{\mu}_1(\varepsilon t)$, *satisfying the inequality*

$$\|\mathbf{A}_1(\overline{\mu}_1(\varepsilon t))-\mathbf{A}_0(\overline{\mu}_0(\varepsilon t))\|<\delta, \quad \forall t, \tag{28}$$

is also stable, then the initial realization of the system is called strongly stable.

The system is strongly stable if all of its realizations are strongly stable.

Let us demonstrate first that a strongly stable oscillatory system does not have geometric amplitudes, i.e., it is Hamiltonian in the approximation considered. Indeed, let a certain realization of an oscillatory system with nonzero geometric amplitudes be stable. Then, we will select as a perturbed realization, the realization of the same system, in which the representative point would circulate in a certain direction in the $\overline{\mu}$ space around the trajectory of the initial realization (Fig. 3). The trajectories of the representative points for the initial and the perturbed realizations can be done arbitrarily close to each other, such that the condition (28) can be satisfied for arbitrarily small δ. By properly selecting the circulation direction and shape it is always possible to make the geometric amplitude (together with the solution amplitude) grow infinitely, and thus perturbed relization becomes unstable (see the Introduction, Sec. II, Ref. 7). Consequently, a strongly stable oscillatory system must not have geometric amplitude, and it is Hamiltonian in the approximation under consideration.

Now, let us prove the opposite: An oscillatory system of the Hamiltonian class is strongly stable in the approximation considered. This follows directly from the explicit form of the independent solutions (20). Indeed, the oscillatory system eigenvalues are purely imaginary, with the geometric amplitudes in the Hamiltonian systems being identically zero. In this way, the exponent in (20) is purely imaginary for any realization of a Hamiltonian system, and its solutions are

bounded. Since the perturbed system must belong to the same class, in accordance with the above definition, i.e., it must be Hamiltonian, solutions of any of its realization will also be bounded. This concludes the proof of the strong stability of Hamiltonian systems.

The above assertions demonstrate that an oscillatory system with different eigenvalues is strongly stable if and only if the system is Hamiltonian. In other words, the following theorem is true.

Theorem III: *Among the systems (1) with different imaginary eigenvalues, the set of systems with the property of strong stability, in the sense of the above definition, coincides in the adiabatic approximation with the set of Hamiltonian systems (or, in accordance with Theorem I, with the set of systems without geometric amplitudes, or, in accordance with Theorem II, with the set of quantizable systems).*

VII. SYSTEM CLASSIFICATION

As was shown in Sec. II, solutions of a system (1) in the general form possess geometric amplitudes. For this reason, it is natural to perform a classification of such systems that have no geometric amplitudes. This classification will be performed from the standpoint of the matrix type of the initial problem (1). Some of the results to be obtained in this section are well known, and they are given here for the sake of completeness and coherence. Here belong the results concerning the matrix of a Hamiltonian system in the canonical coordinates and in the coordinates connected to the canonical ones via time-independent substitutions.[12,13]

A. Oscillatory systems

In Sec. IV we describe a complete class of oscillatory systems without geometric amplitudes; that turned out to be the set of Hamiltonian systems with different imaginary eigenvalues. In the employed complex canonical $\mathbf{z}$ coordinates the Hamiltonian system has the following form [see (19), taking into account (22)]:

$$\mathbf{z}' = i\tilde{\mathbf{\Lambda}}(\overline{\mu},\overline{\mu}')\mathbf{z} + O(\varepsilon^2), \tag{29}$$

where $\tilde{\mathbf{\Lambda}}(\overline{\mu},\overline{\mu}') = \mathrm{diag}(\lambda_1 + \overline{\omega}_1^{(c)}\overline{\mu}', \ldots, \lambda_n + \overline{\omega}_n^{(c)}\overline{\mu}') \equiv \mathbf{\Lambda}(\overline{\mu}) + \overline{\mathbf{\Omega}}^{(c)}(\overline{\mu})\overline{\mu}'$ is a diagonal real matrix. The initial system (1) is specified, generally speaking, in arbitrary $\mathbf{x}$ coordinates. Let the $\mathbf{x}$ and $\mathbf{z}$ coordinates be connected through a certain transition matrix $\tilde{\mathbf{D}}(\overline{\mu},\overline{\mu}')$ [the dependence on $\overline{\mu}'$ is contained in the substitution (5)]:

$$\mathbf{x} = \tilde{\mathbf{D}}(\overline{\mu},\overline{\mu}')\mathbf{z}. \tag{30}$$

Then the matrix $\mathbf{A}$ of the initial system (1) will be

$$\mathbf{A} = i\tilde{\mathbf{D}}\tilde{\mathbf{\Lambda}}\tilde{\mathbf{D}}^{-1} - \tilde{\mathbf{D}}\tilde{\mathbf{D}}^{-1\prime} + O(\varepsilon^2). \tag{31}$$

Thus, *a set* K *of oscillatory systems (1) without geometric amplitudes is a set of systems (1) with the matrix* $\mathbf{A}(\overline{\mu})$*, representable as (31), where* $\tilde{\mathbf{D}} = \tilde{\mathbf{D}}(\overline{\mu},\overline{\mu}')$ *is an arbitrary complex nondegenerate matrix, while* $\tilde{\mathbf{\Lambda}} = \tilde{\mathbf{\Lambda}}(\overline{\mu},\overline{\mu}')$ *is an arbitrary real diagonal matrix.*

Let us isolate in this set the subsets that may be of special interest. To that end, let us write the system (29) as

$$\mathbf{z}' = \mathbf{J}\mathbf{H}(\overline{\mu},\overline{\mu}')\mathbf{z} + O(\varepsilon^2), \tag{32}$$

where $\mathbf{J} = i\mathbf{I}$ ($\mathbf{I}$ is a unit matrix of order n), while $\mathbf{H}(\overline{\mu},\overline{\mu}') = \tilde{\mathbf{\Lambda}}(\overline{\mu},\overline{\mu}')$ is a Hermitian diagonal matrix. Under realification the matrix $\mathbf{J}$ turns into a unit antisymmetrical matrix of the order $2n$, which defines the symplectic structure, while the matrix $\mathbf{H}(\overline{\mu},\overline{\mu}')$ turns into a real symmetrical matrix Hamiltonian.[12–14]

As is known, canonical substitutions are those that preserve the form of a symplectic structure (while, generally speaking, changing the Hamiltonian) in the new coordinates. In our case, this fact means that the matrix $\mathbf{J}$ turns into itself during canonical substitution of the variables, while Eq. (32) preserves its form with some other Hermitian matrix $\tilde{\mathbf{H}}(\overline{\mu},\overline{\mu}')$ instead of $\mathbf{H}(\overline{\mu},\overline{\mu}')$. It is easy to demonstrate that in the formalism under consideration the set of linear canonical substitutions is represented by the substitutions (30) with the unitary matrix $\tilde{\mathbf{D}}^*(\overline{\mu},\overline{\mu}')=\tilde{\mathbf{D}}^{-1}(\overline{\mu},\overline{\mu}')$ (compare the correspondence of unitary transformations in the quantum mechanics to canonical ones in the classical mechanics).[15,17] After the unitary substitution (30) Eq. (32) turns into

$$\mathbf{x}'=\mathbf{J}\tilde{\mathbf{H}}(\overline{\mu},\overline{\mu}')\mathbf{x}+O(\varepsilon^2),$$

where

$$\tilde{\mathbf{H}}=\tilde{\mathbf{D}}\tilde{\Lambda}\tilde{\mathbf{D}}^{-1}+i\tilde{\mathbf{D}}\tilde{\mathbf{D}}^{-1'}.$$

One can easily see that due to the matrix $\tilde{\mathbf{D}}$ being unitary the matrix $\tilde{\mathbf{H}}$ is Hermitian.

The subset $K_1\subset K$ *of all oscillatory Hamiltonian systems (1), written in the canonical variables, represents the set of systems (1) with the matrix* $\mathbf{A}(\overline{\mu})=\mathbf{J}\tilde{\mathbf{H}}(\overline{\mu})$, *where* $\mathbf{J}=i\mathbf{I}$, *while* $\tilde{\mathbf{H}}(\overline{\mu})$ *is an arbitrary nondegenerate complex Hermitian matrix with different real eigenvalues*.[12,13]

Let us also consider the subset of all systems, associated with the system (32) via substitution of the kind (30), where the matrix is constant $\tilde{\mathbf{D}}(\overline{\mu},\overline{\mu}')=\tilde{\mathbf{D}}=\text{const}$. In this case Eq. (32) turns into the equation

$$\mathbf{x}'=\mathbf{G}\tilde{\tilde{\mathbf{H}}}(\overline{\mu},\overline{\mu}')\mathbf{x}+O(\varepsilon^2),$$

where $\mathbf{G}=i\tilde{\mathbf{D}}\tilde{\mathbf{D}}^*$ is a constant anti-Hermitian matrix, which under the realification defines a new form of the symplectic structure. $\tilde{\tilde{\mathbf{H}}}(\overline{\mu},\overline{\mu}')=\tilde{\mathbf{D}}^{*-1}\tilde{\Lambda}(\overline{\mu},\overline{\mu}')\tilde{\mathbf{D}}^{-1}$ is the Hermitian matrix specifying the matrix Hamiltonian under the realification.

The subset $K_2\subset K$ *of oscillatory Hamiltonian systems (1), represented in arbitrary coordinates and connected with the canonical ones via a constant substitution, is a set of systems (1) with the matrix* $\mathbf{A}(\overline{\mu})=\mathbf{G}\tilde{\tilde{\mathbf{H}}}(\overline{\mu})$. *Here,* $\mathbf{G}$ *is an arbitrary constant nondegenerate complex anti-Hermitian matrix, while* $\tilde{\tilde{\mathbf{H}}}(\overline{\mu})$ *is an arbitrary nondegenerate complex Hermitian matrix, with their product having different purely imaginary eigenvalues*.[12,13]

Evidently, $K_1\subset K_2$.

B. General case

Consider now the general case for nonoscillatory systems when $\operatorname{Re}\mathbf{\Lambda}\neq 0$. Let us make a substitution:

$$\tilde{\mathbf{z}}=\mathbf{z}\exp\left(-\int_0^t \operatorname{Re}\mathbf{\Lambda}(\overline{\mu}(\varepsilon\tau))d\tau\right), \tag{33}$$

which evidently does not affect the geometric terms in the solutions (20) (see Appendix B). Let us assume, as we did before, that the initial $\mathbf{x}$ and $\mathbf{z}$ coordinates are connected through a certain nondegenerate substitution (30). The substitution (33) is equivalent to the transition $\mathbf{\Lambda}\to i\operatorname{Im}\mathbf{\Lambda}$. Therefore, upon the inverse substitution to (30), bringing the equations back to the original $\mathbf{x}$ space we obtain [compare to (1), (3)]:

$$\tilde{\mathbf{x}}'=\tilde{\mathbf{A}}\tilde{\mathbf{x}},\quad \tilde{\mathbf{A}}=i\mathbf{D}\operatorname{Im}\mathbf{\Lambda}\mathbf{D}^{-1}. \tag{34}$$

This equation has purely imaginary current eigenvalues $\tilde{\lambda}_j = i\,\mathrm{Im}\,\lambda_j$ and the same geometric terms in the solutions as the initial equation (1). Thereby the problem has been reduced to the preceding one, and the system has no geometric amplitudes if and only if the system (34) belongs to the above set K of oscillatory Hamiltonian systems. Using (3) and (34), we can write

$$\mathbf{A} = \tilde{\mathbf{A}} + \mathbf{D}\,\mathrm{Re}\,\Lambda\mathbf{D}^{-1}. \tag{35}$$

Thus, *in the general case the complete set* $\mathrm{M} \supset \mathrm{K}$ *of the systems (1) without geometric amplitudes is the set of systems (1) with a matrix representable as (35), where* $\tilde{\mathbf{A}} = \tilde{\mathbf{A}}(\overline{\mu})$ *is an arbitrary matrix from* K; $\mathrm{Re}\,\mathbf{\Lambda}(\overline{\mu})$ *an arbitrary real diagonal matrix and* $\mathbf{D} = \mathbf{D}(\overline{\mu})$ *is the transition matrix bringing* $\tilde{\mathbf{A}}(\overline{\mu})$ *to a diagonal form*.

We will also describe the subsets that may be of special interest.

Lemma: *If the matrix* $\mathbf{A}(\overline{\mu})$ *of the system (1) can be brought to a diagonal form with the unitary matrix* $\mathbf{D}^*(\overline{\mu}) = \mathbf{D}^{-1}(\overline{\mu})$, *then the system has no geometric amplitudes*.

Proof: The geometric terms in the solutions of the system (1) arise from nonpotential components of the matrix field (9) $\overline{\mathbf{\Omega}}(\overline{\mu})$. The condition for the existence of geometric terms is the nonpotentiality of that field:

$$(\mathrm{rot}\,\overline{\mathbf{\Omega}})_{\alpha\beta} \equiv \frac{\partial \mathbf{\Omega}_\alpha}{\partial u_\beta} - \frac{\partial \mathbf{\Omega}_\beta}{\partial \mu_\alpha} \neq 0. \tag{36}$$

Here, the Greek indices relate to the $\overline{\mu}$ space. By substituting (9) into (36), we obtain

$$(\mathrm{rot}\,\overline{\mathbf{\Omega}})_{\alpha\beta} = \mathrm{dg}\left(\frac{\partial \mathbf{D}^{-1}}{\partial \mu_\beta}\frac{\partial \mathbf{D}}{\partial \mu_\alpha} - \frac{\partial \mathbf{D}^{-1}}{\partial \mu_\alpha}\frac{\partial \mathbf{D}}{\partial \mu_\beta} \right) \neq 0.$$

(We recall that the operator dg eliminates off-diagonal matrix components.) Since $\mathbf{D}$ is unitary, it is easy to obtain

$$(\mathrm{rot}\,\overline{\mathbf{\Omega}})_{\alpha\beta} = \mathrm{diag}\left(\frac{\partial \mathbf{D}^*}{\partial \mu_\beta}\frac{\partial \mathbf{D}}{\partial \mu_\alpha} - \frac{\partial \mathbf{D}^*}{\partial \mu_\alpha}\frac{\partial \mathbf{D}}{\partial \mu_\beta} \right) = 2i\,\mathrm{Im}\left(\mathrm{diag}\left(\frac{\partial \mathbf{D}^*}{\partial \mu_\beta}\frac{\partial \mathbf{D}}{\partial \mu_\alpha} \right) \right) \neq 0.$$

Thus, the nonpotential component of the field (9) can only be imaginary, which infers that the solutions can possess a geometric phase, but never an amplitude.

The lemma has been proven.

The set of systems (1) with the matrix $\mathbf{A} = \mathbf{D}\mathbf{\Lambda}\mathbf{D}^{-1}$, *where* $\mathbf{D} = \mathbf{D}(\overline{\mu})$ *is an arbitrary complex unitary matrix, while* $\mathbf{\Lambda} = \mathbf{\Lambda}(\overline{\mu})$ *is an arbitrary complex diagonal matrix, forms the subset* $\mathrm{M}_1 \subset \mathrm{M}$.

The subset M_1 contains, in particular, the subsets of systems (1) with Hermitian, anti-Hermitian, and unitary matrices $\mathbf{A}(\overline{\mu})$. The subset of systems with anti-Hermitian matrices apparently is the subset K_1 described above of oscillatory Hamiltonian systems in the canonical variables.

VIII. CONCLUSIONS

In the paper we considered a linear dynamic system of the general kind, which is described by the complex vector equation with a nondegenerate matrix possessing different eigenvalues. The system matrix is assumed to depend on a set of parameters varying adiabatically. The principal results reported in this paper are as follows.

(1) Adiabatic solutions (8), (11), (14), (20) have been constructed that demonstrate the presence, in the general case of geometric phases and amplitudes.

(2) The geometric terms have been shown to be as important system characteristics as the eigenvalues. Together they determine the qualitative portrait of the system (effective eigenvalues), being invariant with respect to the local coordinate substitutions.

(3) The necessary and sufficient conditions (22) for construction of an adiabatic invariant for one degree of freedom have been formulated. They are the absence of a geometric amplitude and a zero value for the real part of the current eigenvalue of the given degree of freedom.

(4) We analyzed the condition for the existence Poincaré's integral invariants in the system and fulfilment of the Liouville theorem. The Poincaré's first integral invariant is shown to be equivalent, in the adiabatic approximation, to the complete set of n adiabatic invariants. In other words, the conditions for its existence are an oscillatory nature of the system and zero values for all geometric amplitudes. At the same time, the conditions of the Liouville theorem (23), generally speaking, permit the presence of geometric amplitudes in the system (an example of the physical system satisfying the Liouville theorem and containing geometric amplitudes may be the ''beam–plasma system.'' [7]

(5) The main results of this paper can be viewed as the following equivalence relationships. For oscillatory systems in the adiabatic approximation, the equivalence has been shown of classes of systems without geometric amplitudes, Hamiltonian systems, quantizable systems, and strongly stable systems (Theorems I–III):

$$\begin{pmatrix}\text{systems without}\\ \text{geometric amplitudes}\end{pmatrix}\approx\begin{pmatrix}\text{Hamiltonian}\\ \text{systems}\end{pmatrix}\approx\begin{pmatrix}\text{quantizable}\\ \text{systems}\end{pmatrix}\approx\begin{pmatrix}\text{strongly stable}\\ \text{systems}\end{pmatrix}.$$

It might be interesting to compare the equivalence of Hamiltonian and strongly stable systems with the known theorems on strong stability of oscillatory Hamiltonian systems with a time-independent Hamiltonian and with the periodically dependent Hamiltonian.[13,14] The nonlinear counterparts of these theorems are the simplest consequences of the KAM (Kolmogorov–Arnold–Moser) theorem.[12,14] First, the theorems proved in this paper somewhat broaden (in the adiabatic approximation) the class of strongly stable systems to include oscillatory Hamiltonian systems with *an arbitrary* time dependence of parameters. Second, the Hamiltonian nature of systems is not only a sufficient, but also *necessary* condition for the system strong stability in the theorems proved.

(6) Finally, based on the results obtained in this paper, a rather complete classification has been made of the systems without geometric amplitudes from the standpoint of the form of matrix of the initial system. We give a description of the set of all systems without a geometric amplitude, and indicate several subsets that are easily described and may represent special interest.

We have been able to obtain the above results of sufficient generality due to the use of the simplifying assumptions (equation linearity and adiabaticity), as well as to the following important circumstance. Note that the problem of whether a system is Hamiltonian and possesses strong stability was studied many times in the *temporal* statement:

$$\mathbf{x}'=\mathbf{A}(t)\mathbf{x},$$

where the system matrix is an explicit function of time. One can apply to such a problem statement the Birkhoff's remark that in the vicinity of a nonsingular point there should always be coordinate substitution leading the equation up to the trivial Hamiltonian system.[18] We, however, considered the problem of evolution of a nonautonomous system in the *functional* statement: the matrix of the system (1) is time dependent via arbitrary parameter functions $\mathbf{A}=\mathbf{A}(\bar{\mu}(t))$.[19] Note that in the physical problems this statement is more natural. For the system matrix, the difference between the temporal and functional problem statement is not important, since it is simply a composite function of time. However, this circumstance plays an important role when we deal with coordinate substitutions. In the temporal statement all substitutions are simply functions of time, and thus they belong to the same class. Yet, in the functional problem statement the coordinate substitutions are functional of parameters $\bar{\mu}$, which allows us to distinguish between local (the functional is a function of the current value of $\bar{\mu}$) and integral substitutions (the substitution is an integral functional of $\bar{\mu}$ containing the system's prior history) (Appendix B). It is only the local substitutions that leave the eigenvalues and geometric terms invariant. Consequently, if we intend to transform the system without distorting its global qualitative portrait, we must restrict ourselves to

the local variable substitutions. In such a functional problem statement the Birkhoff result does not hold: His proposed substitution may be nonlocal. Therefore the problem of determination of whether a system is Hamiltonian in the vicinity of a nonsingular point becomes nontrivial.

We defined a set of the Hamiltonian systems in the considered approximation, making essential use of the functionality of the problem statement in the proofs of all the theorems.

Our objective in this work is to describe adequately the linear adiabatic systems mainly from the standpoint of mathematical physics. At the same time, we would rather have our attention focused as well on the geometric amplitude in oscillatory systems as a possible physical phenomenon. The linear oscillatory physical systems may be described by equations of a non-Hamiltonian kind and contain geometric amplitudes that promote the development of a geometric instability in the system.[7] In case this phenomenon is discovered in real systems, the geometric amplitude may play an important role due to its unusual properties, which makes it natural to continue the studies in this area. It is hoped that this paper will facilitate the search for systems with geometric amplitude, and if they are discovered, it will help to describe their behavior.

ACKNOWLEDGMENTS

Sincere thanks are due to Yu. A. Kuperin, M. G. Lyubarsky, A. I. Neistadt, and Yu. P. Stepanovsky for their helpful discussions and invaluable advice that brought this research to its present form. The work on this paper was supported in part by INTAS Grant No. 00-00292.

APPENDIX A: LIMITS OF VALIDITY FOR ADIABATIC SOLUTIONS

By employing the technique of consecutive Neistadt diagonalization, as proposed in Sec. II, we obtain the solutions of Eq. (1) after kth diagonalization in the form of

$$\mathbf{x}(t)=\left(\sum_{j=1}^{k}\mathbf{D}^{(i)}(t)+O_1(\varepsilon^k)\right)\exp\left\{\int_0^t\left(\sum_{j=1}^{k}\mathbf{\Lambda}^{(j)}(\tau)+O_2(\varepsilon^k)\right)d\tau\right\}\mathbf{y}^{(k)}(0), \tag{A1}$$

where $\mathbf{y^{(k)}}(0)$ is the initial conditions vector in the kth basis, the matrices $\mathbf{D}^{(j)}$, and diagonal matrices $\mathbf{\Lambda}^{(j)}$ are proportional to ε^{j-1}, while the correction terms $O(\varepsilon^k)$ are written in a form that provide for inductive transition $k\to k+1$. Here consecutive approximations of the factor before the exponent in (37) correspond to the basis corrections as the solution eigenvectors rotate. The diagonal matrices $\mathbf{\Lambda}^{(j)}$ in the exponent approximate the effective eigenvalues of the solution. The properties of the asymptotic solution (A1), strict conditions of the series convergence and estimation of their residual terms can be found in the standard courses on asymptotic methods,[8] while here we will do simple qualitative estimations.

Comparing the formula (A1) with the substitutions (3), (5) and solutions (8), it is easy to see the correspondence:

$$\mathbf{y^{(1)}}\equiv\mathbf{y},\quad \mathbf{y^{(2)}}\equiv\tilde{\mathbf{y}},\quad \mathbf{D^{(1)}}\equiv\mathbf{D},\quad \mathbf{D^{(2)}}\equiv\mathbf{\Delta},\quad \mathbf{\Lambda^{(1)}}\equiv\mathbf{\Lambda},\quad \mathbf{\Lambda^{(2)}}\equiv\overline{\mathbf{\Omega}}\overline{\mu'},$$

and write the adiabatic solutions used in the article as

$$\mathbf{x}(t)=\left(\sum_{j=1}^{2}\mathbf{D^{(j)}}(t)+O_1(\varepsilon^2)\right)\exp\left\{\int_0^t\left(\sum_{j=1}^{2}\mathbf{\Lambda^{(j)}}(\tau)+O_2(\varepsilon^2)\right)d\tau\right\}\mathbf{y^{(2)}}(0). \tag{A2}$$

At the same time, the transition from the $\tilde{\mathbf{y}}$ coordinates to $\mathbf{z}$ coordinates in Sec. III is associated with ambiguity of the diagonalization matrix choice $\mathbf{D^{(1)}}\equiv\mathbf{D}$. It is simply a choice of the certain most convenient matrix $\mathbf{D^{(1)}}$.

Due to the terms $O_2(\varepsilon^2)$ in the time integral, the solutions (A2) are applicable in the time intervals $t\ll t_{\max}=\varepsilon^{-2}$. At that, the considered in this paper small values $\mathbf{\Lambda}^{(2)}$ are integrated over time and can largely determine the value $\mathbf{x}(t)$ only in the range $t\geqslant t_{\min}=\varepsilon^{-1}$.

Let us now derive the conditions, under which one can neglect the terms $O_1(\varepsilon^2)$. We will consider first the most important for the geometric amplitude effect case of an oscillatory system, i.e., $\mathrm{Re}\,\mathbf{\Lambda^{(1)}}=0$.

In the absence of the geometric amplitude the solutions (A2) are bounded (their Lyapunov indices being zero in the adiabatic approximation) and small corrections to the rotation of solution eigenvectors are insignificant, i.e., the contribution of the values $O_1(\varepsilon^2)$ and even $\mathbf{D^{(2)}}$ to the solutions is small at all times $t \ll t_{\max}$. When the geometric amplitude is present, various solutions (A2) may grow exponentially with time at various growth rates on the order ε. The system is said to have an exponential solution splitting.[20] In this case, even a small error in the projections of solution eigenvectors may result in a large error in the solution. In this case, the condition, under which one can neglect the terms $O_1(\varepsilon^2)$, will be $t \ll t_{\max 1}=\varepsilon^{-1}\ln\varepsilon^{-1}$. Note that $t_{\min} \ll t_{\max 1} \ll t_{\max}$.

If the system has the exponential splitting even in the zero approximation: $\mathrm{Re}\,\mathbf{\Lambda}^{(1)} \neq 0$, then, similarly, the small corrections defining projections of eigenvectors will be essential. The condition, under which one can neglect the terms $O_1(\varepsilon^2)$ is $t \ll t_{\max 2}=\ln\varepsilon^{-1}$. Here $t_{\max 2} \ll t_{\min}$, i.e., within these limits of validity the eigenvalue corrections $\mathbf{\Lambda}^{(2)}$ always provide a small contribution to the solutions. In order to derive the solutions applicable in the time range $t \sim t_{\min}$ and usable for the geometric amplitude research, one has to take into account the eigenvector rotations $\mathbf{D^{(k)}}$ up to $k > \varepsilon^{-1}/\ln\varepsilon^{-1}$. Yet, if one assumes that $\tilde{\mathbf{y}} \equiv \mathbf{y^{(k)}}$ in Eq. (6) and below, then all conclusions of this paper remain true, because the values of the geometric terms in the kth basis are still determined only by the matrix $\mathbf{D^{(1)}}$.

APPENDIX B: NOTE ON THE COORDINATE SUBSTITUTIONS CONSIDERED

Throughout this paper [except for the substitution (33)] we consider *local* linear coordinate substitutions, whose transition matrix depends only on the *current* parameter values and their derivatives. The point is that the set of systems associated with such substitutions can be considered to be qualitatively equivalent.

Contrary to local substitutions, let us consider *integral* ones, which contain information about *prior* parameter values and their derivatives. Substitutions of the kind

$$\tilde{y}_j \to \tilde{y}_j \exp\left(\int_0^t f_j(\overline{\mu}(\varepsilon\tau))d\tau \right), \tag{B1}$$

are equivalent to a change of the current eigenvalues of the system: $\lambda_j \to \lambda_j - f_j$. While substitutions of the kind

$$\tilde{y}_j \to \tilde{y}_j \exp\left(\int_l \overline{g}_j(\overline{\mu})d\overline{\mu} \right), \tag{B2}$$

where $\overline{g}_j(\overline{\mu})$ is the nonpotential field, are equivalent to a change of the geometric terms: $\overline{\omega}_j^{(c)} \to \overline{\omega}_j^{(c)} - \overline{g}_j$ [see solutions (14)]. As shown in Sec. II, with the current eigenvalues and geometric terms determine the qualitative portrait of the system. In particular, using the integral substitutions (B1) and (B2) with $f_j=\lambda_j$, $\overline{g}_j=\overline{\omega}_j^{(c)}$, we can always reduce the system, in the adiabatic approximation, to its trivial form: $\tilde{y}_j'=0$.

Note that local variable substitutions correspond to correction of the current basis, and it is obvious that they cannot change the eigenvalues and geometric phases and amplitudes. For this reason, we can say that the systems connected by local substitutions are equivalent qualitatively.

(Received 31 July 2001; accepted for publication 26 September 2001)

The Dirac equation for an electron in two spatial dimensions in the Coulomb and homogeneous magnetic fields is an example of the so-called quasi-exactly solvable models. The solvable parts of its spectrum were previously solved from the recursion relations. In this work we present a purely algebraic solution based on the Bethe ansatz equations. It is realized that, unlike the corresponding problems in the Schrödinger and the Klein–Gordon cases, here the unknown parameters to be solved for in the Bethe ansatz equations include not only the roots of the wave function assumed, but also a parameter from the relevant operator. We also show that the quasi-exactly solvable differential equation does not belong to the classes based on the algebra sl_2. © *2002 American Institute of Physics.*

I. INTRODUCTION

Recently a new type of spectral problem, the so-called quasi-exactly solvable model (QESM), was discovered by physicists and mathematicians.[1–8] This is a special class of quantum-mechanical problems for which analytical solutions are possible only for parts of the energy spectra and for particular values of the fundamental parameters. The reason for such quasi-exactly solvability is usually the existence of a hidden Lie-algebraic structure.[2–6] More precisely, a quasi-exactly solvable (QES) Hamiltonian can be reduced to a quadratic combination of the generators of a Lie group with finite-dimensional representations.

The first physical example of QESM in atomic physics is the system of two electrons moving in an external oscillator potential discussed in Refs. 9 and 10. The authors of these works apparently were unaware of the mathematical development in QESM. Later, several physical QESMs were discovered, which include the two-dimensional Schrödinger,[11] the Klein–Gordon,[12] and the Dirac equations[13] of an electron moving in an attractive/repulsive Coulomb field and a homogeneous magnetic field. The essential features shared by all these above examples are as follows. The differential equations are solved according to the standard procedure. After separating out the asymptotic behaviors of the system, one obtains an equation for the part which can be expanded as a power series of the basic variable. But instead of the two-step recursion relations for the coefficients of power series so often encountered in exactly solvable problems, one gets three-step recursion relations. The complexity of the recursion relations does not allow one to determine the energy spectrum exactly from the normalizability of the eigenfunctions. However, one can impose a sufficient condition for normalizability by terminating the series at a certain order of power of the variable; i.e., by choosing a polynomial. By doing so one could obtain exact solutions to the original problem, but only for certain energies and for specific values of the parameters of the problem. These parameters, namely, are the frequency of the oscillator potential and the external magnetic fields.

In Ref. 14 a systematic and unified algebraic treatment was given to the above-mentioned systems, with the exception of the Dirac case. This was made possible by realizing that these

systems are governed essentially by the same basic equation, which is quasi-exactly solvable owing to the existence of a hidden sl_2 algebraic structure. This algebraic structure was first realized by Turbiner for the case of two electrons in an oscillator potential.[15] In this algebraic approach, analytic expressions of the solvable parts of the energy spectrum and the allowed parameters were expressible in terms of the roots of a set of Bethe ansatz equations.

In this article we would like to extend the method of Ref. 14 to the planar Dirac equation of an electron in the Coulomb and magnetic fields. It turns out that a set of Bethe ansatz equations can also be set up in this case. However, unlike the systems considered in Ref. 14, here the unknown variables in the Bethe ansatz equations involved not only the roots of the wave functions assumed, but also a parameter from the relevant operator. We also demonstrate that the Bethe ansatz approach yields the same spectrum as that obtained by solving recursion relations. Finally, we show that the quasi-exactly solvability of this system is not related to the sl_2 algebra.

II. THE DIRAC EQUATION

In $2+1$ dimensions the Dirac algebra

$$\{\gamma^\mu,\gamma^\nu\}=2g^{\mu\nu},\quad g^{\mu\nu}=\mathrm{diag}(1,-1,-1) \tag{1}$$

may be represented in terms of the Pauli matrices as $\gamma^0=\sigma_3$, $\gamma^k=i\sigma_k$ or, equivalently, the matrices $(\alpha_1,\alpha_2)=\gamma^0(\gamma^1,\gamma^2)=(-\sigma_2,\sigma_1)$ and $\beta=\gamma^0$. Then the Dirac equation for an electron minimally coupled to an external electromagnetic field has the form (we set $c=\hbar=1$)

$$(i\partial_t-H_D)\Psi(t,\mathbf{r})=0, \tag{2}$$

where

$$H_D=\alpha\mathbf{P}+\beta m-eA^0\equiv\sigma_1P_2-\sigma_2P_1+\sigma_3m-eA^0 \tag{3}$$

is the Dirac Hamiltonian, $P_k=-i\partial_k+eA_k$ is the operator of generalized momentum of the electron, A_μ is the vector potential of the external electromagnetic field, m is the rest mass of the electron, and $-e$ $(e>0)$ is its electric charge. The Dirac wave function $\Psi(t,\mathbf{r})$ is a two-component function. In an external Coulomb field and a constant homogeneous magnetic field $B>0$ along the z direction, the potential A_μ assumes the following forms in the symmetric gauge

$$A^0(r)=Ze/r\ \ (e>0),\quad A_x=-By/2,\quad A_y=Bx/2. \tag{4}$$

We assume the wave functions to have the form

$$\Psi(t,\mathbf{x})=\frac{1}{\sqrt{r}}\exp(-iEt)\,\psi_l(r,\varphi), \tag{5}$$

where E is the energy of the electron, and

$$\psi_l(r,\varphi)=\begin{pmatrix}F(r)e^{il\varphi}\\ G(r)e^{i(l+1)\varphi}\end{pmatrix} \tag{6}$$

with integral number l. The function $\psi_l(r,\varphi)$ is an eigenfunction of the conserved total angular momentum $J_z=L_z+S_z=-i\partial/\partial\varphi+\sigma_3/2$ with eigenvalue $j=l+\frac{1}{2}$. It should be reminded that l is not a good quantum number. Only the eigenvalues j of the conserved total angular momentum J_z are physically meaningful.

By putting Eqs. (5) and (6) into (2), and taking into account the equations

$$P_x\pm iP_y=-ie^{\pm i\varphi}\left(\frac{\partial}{\partial r}\pm\left(\frac{i}{r}\frac{\partial}{\partial\varphi}-\frac{eBr}{2}\right)\right), \tag{7}$$

we obtain

$$\frac{dF}{dr}-\left(l+\frac{1}{2}+\frac{eBr}{2}\right)F+\left(E+m+\frac{Z\alpha}{r}\right)G=0, \tag{8}$$

$$\frac{dG}{dr}+\left(l+\frac{1}{2}+\frac{eBr}{2}\right)G-\left(E-m+\frac{Z\alpha}{r}\right)F=0, \tag{9}$$

where $\alpha\equiv e^2=\frac{1}{137}$ is the fine structure constant. In a strong magnetic field the asymptotic solutions of $F(r)$ and $G(r)$ have the forms $\exp(-eBr^2/4)$ at large r, and r^{γ} with $\gamma=\sqrt{(l+1/2)^2-(Z\alpha)^2}$ for small r. One must have $Z\alpha<\frac{1}{2}$, otherwise the wave function will oscillate as $r\to 0$ when $l=0$ and $l=-1$.

Let us assume

$$F(r)=r^{\gamma}\exp(-eBr^2/4)Q(r),\quad G(r)=r^{\gamma}\exp(-eBr^2/4)P(r). \tag{10}$$

In Ref. 13 we showed that parts of the spectrum could be analytically solved for by imposing the sufficient condition that $Q(r)$ and $P(r)$ be polynomials, thus showing that the system belongs to the QESM. The spectrum was solved in Ref. 13 from the recursion relations for the coefficients in the series expansion in Q and P. In this article, we will show that the same spectrum can also be obtained in a purely algebraic way. This is achieved by the method of factorization which leads to a set of Bethe ansatz equations.[13,14]

Substituting Eq. (10) into Eqs. (8) and (9) and eliminating $P(r)$ from the coupled equations, we have

$$\left\{\frac{d^2}{dr^2}+\left[\frac{2\gamma}{r}-eBr+\frac{Z\alpha/r^2}{E+m+Z\alpha/r}\right]\frac{d}{dr}+E^2-m^2+\frac{2EZ\alpha}{r}+\frac{l+\frac{1}{2}}{r^2}-\frac{\gamma}{r^2}-eB(\Gamma+1)\right.$$
$$\left.+\frac{Z\alpha/r^2}{E+m+Z\alpha/r}\left[\frac{\gamma}{r}-eBr-\frac{l+\frac{1}{2}}{r}\right]\right\}\ Q(r)=0, \tag{11}$$

where $\Gamma=l+\frac{1}{2}+\gamma$. Once $Q(r)$ is solved, the form of $P(r)$ is obtainable from Eqs. (8) and (10). If we let $x=r/l_B$, $l_B=1/\sqrt{eB}$, Eq. (11) becomes

$$\left\{\frac{d^2}{dx^2}+\left[\frac{2\gamma}{x}-x+\frac{Z\alpha}{x((E+m)l_Bx+Z\alpha)}\right]\frac{d}{dx}+(E^2-m^2)l_B^2+\frac{2EZl_B\alpha}{x}+\frac{(l+\frac{1}{2}-\gamma)}{x^2}-(\Gamma+1)\right.$$
$$\left.-\frac{Z\alpha(l+\frac{1}{2}-\gamma)}{x^2[(E+m)l_Bx+Z\alpha]}-\frac{Z\alpha}{(E+m)l_Bx+Z\alpha}\right\}\ Q(x)=0. \tag{12}$$

Equation (12) can be rewritten as

$$\left\{\frac{d^2}{dx^2}+\left[\frac{2\beta}{x}-x-\frac{1}{x+x_0}\right]\frac{d}{dx}+\epsilon+\frac{b}{x}-\frac{c}{x+x_0}\right\}\ Q(x)=0. \tag{13}$$

Here $\beta=\gamma+\frac{1}{2}$, $x_0=Z\alpha/[(E+m)l_B]$, $\epsilon=(E^2-m^2)l_B^2-(\Gamma+1)$, $b=b_0+L/x_0$, $b_0=2EZ\alpha l_B$, $L=(l+\frac{1}{2}-\gamma)$, and $c=x_0+L/x_0$. On expressing l_B in the expression of ϵ in terms of x_0, we get

$$\epsilon=\frac{E-m}{E+m}\left(\frac{Z\alpha}{x_0}\right)^2-(\Gamma+1). \tag{14}$$

It is obvious that the energy E is determined once we know the values of ϵ and x_0. The corresponding value of the magnetic field B is then obtainable from the expression $l_B = Z\alpha/[(E+m)x_0]$. Solution of x_0 is achieved below by means of the Bethe ansatz equations.

III. THE BETHE ANSATZ EQUATIONS FOR $Q(x)$

We observe that the problem of finding the spectrum for Eq. (13) is equivalent to determining the eigenvalues of the operator

$$D = -\frac{d^2}{dx^2} - \left(\frac{2\beta}{x} - x - \frac{1}{x+x_0}\right)\frac{d}{dx} - \frac{b}{x} + \frac{c}{x+x_0}. \tag{15}$$

We want to factorize the operator (15) in the form

$$D = a^+ a + \epsilon. \tag{16}$$

The eigenfunctions of the operator D at $\epsilon = 0$ must satisfy the equation

$$aQ(x) = 0. \tag{17}$$

Suppose polynomial solutions exist for Eq. (13), say Q equals a nonvanishing constant, or $Q = \Pi_{k=1}^{n}(x - x_k)$, where x_k are the zeros of Q, and n is the degree of Q. In the case where Q is a constant (which may be viewed as corresponding to $n = 0$), the operators a and a^+ have the form

$$a = \frac{d}{dx}, \quad a^+ = -\frac{d}{dx} - \left(\frac{2\beta}{x} - x - \frac{1}{x+x_0}\right). \tag{18}$$

If $Q = \Pi_{k=1}^{n}(x - x_k)$, a and a^+ will assume the form

$$a = \frac{d}{dx} - \sum_{k=1}^{n} \frac{1}{x - x_k} \tag{19}$$

and

$$a^+ = -\frac{d}{dx} - \left(\frac{2\beta}{x} - x - \frac{1}{x+x_0}\right) - \sum_{k=1}^{n} \frac{1}{x - x_k}. \tag{20}$$

We now substitute the forms of a and a^+ into Eq. (16) and compare the result with Eq. (15). This leads to conditions that must be satisfied by the various parameters and the roots x_k's. For constant $Q\,(n = 0)$, one has

$$\epsilon = b = c = 0. \tag{21}$$

The fact that $c = 0$ implies

$$x_0^2 = -L. \tag{22}$$

For $n \geqslant 1$, one gets

$$b_0 + \frac{L}{x_0} = 2\beta \sum_{k=1}^{n} \frac{1}{x_k}, \quad \epsilon = n, \tag{23}$$

$$x_0 + \frac{L}{x_0} = \sum_{k=1}^{n} \frac{1}{x_k + x_0}, \tag{24}$$

$$\frac{2\beta}{x_k}-x_k-\frac{1}{x_k+x_0}-2\sum_{j\neq k}^{n}\frac{1}{x_j-x_k}=0,\quad k=1,\ldots,n. \tag{25}$$

Equations (22), (24), and (25) constitute the set of $n+1$ Bethe ansatz equations relevant to this Dirac system, which involve $n+1$ unknown parameters $\{x_0,x_1,\ldots,x_n\}$. It is worthwhile to note that, unlike the corresponding equations in the Schrödinger and the Klein–Gordon cases discussed in Ref. 14, this set of Bethe ansatz equations involved not only the roots x_k, but also a parameter x_0 from D. Summing Eq. (25) over k leads to the expression $b_0=x_0+\Sigma_{k=1}^{n}x_k$, i.e., b_0 is simply the sum of all the roots of the Bethe ansatz equations. From the second equation in Eq. (23) we get

$$E^2-m^2=\frac{1}{l_B^2}(\Gamma+n+1). \tag{26}$$

Since $-\frac{1}{2}\leqslant\Gamma\leqslant 0$ for $Z\alpha<\frac{1}{2}$,[13] we see from Eq. (26) that the solvable parts of the spectrum must satisfy $|E|\geqslant m$.

So we see that the solution of the solvable parts of the spectrum E boils down to solving the Bethe ansatz equations for x_0 in the differential operator, and the roots $x_k(k=1,\ldots,n)$ of $Q(x)$. Once the value of x_0 for each order $n=\epsilon$ is known, the energy E is given by Eq. (14). The corresponding magnetic field B is then determined from the definition of b_0, or from Eq. (26). The Bethe ansatz equations thus provide a systematic solutions of the QES spectrum. Of course, as the order of the degree of Q increases, analytical solutions of the Bethe ansatz equations becomes difficult, and one must resort to numerical methods.

IV. SOLUTIONS FOR $n=0,1$, and 2

In what follows we shall show the consistency of the solutions by the Bethe ansatz approach and that by the recursion relations presented in Ref. 13 for the first three lowest orders ($n=0,1,2$) in Q. Instead of solving for x_0, our strategy is to eliminate it in Eq. (14) by means of Eqs. (22)–(25) so as to obtain an equation obeyed by E for each order of Q. This equation is then compared with the corresponding equation obtained from the recursion relations as presented in Ref. 13.

From Eqs. (21) and (22) we have $x_0^2=-L$ and $\epsilon=0$ when Q is a constant. Substitute these values of x_0 and ϵ into Eq. (14), and using the fact that $\Gamma L=(Z\alpha)^2$, we obtain the corresponding value of E as

$$E=-\frac{m}{2(l+\gamma+1)}. \tag{27}$$

This is the result presented in Ref. 13. The corresponding allowed value of the magnetic field B is then obtained from Eqs. (26) and (27). The fact that x_0 is real leads to $L<0$, which in turn implies that the energy levels given by Eq. (27) are only possible for $l<0$. This is consistent with the conclusion obtained by the method of recursion relations.[13]

For $n=1$, we find from Eqs. (14), (23), (24), and (25) that

$$\Gamma+2=\frac{E-m}{E+m}\frac{(Z\alpha)^2}{x_0^2}, \tag{28}$$

$$b_0+\frac{L}{x_0}=\frac{2\beta}{x_1}, \tag{29}$$

$$\frac{1}{x_1+x_0}=x_0+\frac{L}{x_0}, \tag{30}$$

$$\frac{2\beta}{x_1}-x_1-\frac{1}{x_1+x_0}=0. \tag{31}$$

Equations (29)–(31) imply $x_1=b_0-x_0$. Substituting x_1 into Eq. (30), we obtain

$$x_0^2=L\left[\frac{E+m}{2E(Z\alpha)^2}-1\right]^{-1}. \tag{32}$$

Then from Eqs. (32) and (28), we get

$$\left[4(\Gamma+1)-\frac{\Gamma}{Z^2\alpha^2}\right]E^2+4Em+\frac{\Gamma}{(Z\alpha)^2}m^2=0. \tag{33}$$

The energy E can be solved from Eq. (33) by the standard formula, after which the magnetic field is determined from Eq. (26). Equation (33) does not resemble the one obtained from the recursion relation in Ref. 13. However, on multiplying Eq. (33) by $\Gamma+1$ and making use of the fact that $(Z\alpha)^2=\Gamma(\Gamma-2\gamma)$, we can show, after some algebra, that Eq. (33) is equivalent to the corresponding equation given in Ref. 13.

Finally we consider the case for $n=2$. We have Eq. (14) with $\epsilon=2$, together with Eqs. (23)–(25) in the forms

$$\Gamma+3=\frac{E-m}{E+m}\frac{(Z\alpha)^2}{x_0^2}, \tag{34}$$

$$b_0+\frac{L}{x_0}=\frac{2\beta}{x_1}+\frac{2\beta}{x_2}, \tag{35}$$

$$\frac{1}{x_1+x_0}+\frac{1}{x_2+x_0}=x_0+\frac{L}{x_0}, \tag{36}$$

$$\frac{2\beta}{x_1}-x_1-\frac{1}{x_1+x_0}-\frac{2}{x_2-x_1}=0, \tag{37}$$

$$\frac{2\beta}{x_2}-x_2-\frac{1}{x_2+x_0}-\frac{2}{x_1-x_2}=0. \tag{38}$$

From these equations we find $x_1+x_2=b_0-x_0$ and $x_1x_2=2\beta x_0(b_0-x_0)/(b_0x_0+L)$. Putting these expressions into Eq. (36) and using the fact that $\Gamma=2\beta+L-1$, we arrive at

$$(b_0^2-2\beta)x_0^2+b_0\Gamma x_0+[b_0^2(L-1)-L(2\beta+1)]+\frac{b_0\Gamma L}{x_0}=0. \tag{39}$$

Now multiplying Eq. (39) by Γ, using $\Gamma L=(Z\alpha)^2$, and expressing b_0, l_B, and $1/x_0^2$ in terms of E, we get finally

$$\left\{4(2\Gamma+3)-\frac{1}{(Z\alpha)^2}\left[6\Gamma+2(\gamma+1)+\frac{(2\gamma+1)\Gamma}{\Gamma+3}\right]\right\}\ E^3$$
$$+\left\{12-\frac{1}{(Z\alpha)^2}\left[2(\gamma+1)-\frac{(2\gamma+1)\Gamma}{\Gamma+3}\right]\right\}\ E^2m$$
$$+\frac{1}{(Z\alpha)^2}\left[6\Gamma+2(\gamma+1)+\frac{(2\gamma+1)\Gamma}{\Gamma+3}\right]Em^2+\frac{1}{(Z\alpha)^2}\left[2(\gamma+1)-\frac{(2\gamma+1)\Gamma}{\Gamma+3}\right]m^3=0. \tag{40}$$

Again, this equation does not look the same as that obtained from the recursion relations. But we can show they are in fact equivalent as they differ only by a multiplicative factor $(\Gamma+1)(\Gamma+2)$.

V. THE BETHE ANSATZ EQUATIONS FOR $P(x)$

One may as well solve the QES energy spectrum of the problem from the differential equation of $P(x)$ instead of $Q(x)$. The analysis proceeds in exactly the same way as we did for $Q(x)$. We shall only give the outline below in order to show the similarity and differences between the two sets of Bethe ansatz equations.

The equation for $P(x)$ can be cast into the following form:

$$\left\{\frac{d^2}{dx^2}+\left[\frac{2\beta}{x}-x-\frac{1}{x+x_0'}\right]\frac{d}{dx}+\epsilon'+\frac{b'}{x}-\frac{c'}{x+x_0'}\right\}\ P(x)=0. \tag{41}$$

Here $x_0'=Z\alpha/[(E-m)l_B]$, $\epsilon'=(E^2-m^2)l_B^2-\Gamma$, $b'=b_0+c'$, and $c'=-\Gamma/x_0'$. Other parameters are as defined previously. Instead of Eq. (14) we now have

$$\epsilon'=\frac{E+m}{E-m}\left(\frac{Z\alpha}{x_0'}\right)^2-\Gamma. \tag{42}$$

We note here the sign difference before the mass terms in Eqs. (14) and (42). It is obvious that Eq. (41) is in the same form as Eq. (13), and hence is also quasi-exactly solvable. Suppose $P(x)$ has the factorized form $P(x)=\Pi_{k=1}^{n'}(x-x_k')$. Then the set of Bethe ansatz equations for the parameters $\{x_0',x_1',\ldots,x_{n'}'\}$ is given by

$$-\frac{\Gamma}{x_0'}=\sum_{k=1}^{n'}\frac{1}{x_k'+x_0'}, \tag{43}$$

$$\frac{2\beta}{x_k'}-x_k'-\frac{1}{x_k'+x_0'}-2\sum_{j\neq k}^{n'}\frac{1}{x_j'-x_k'}=0,\quad k=1,\ldots,n'. \tag{44}$$

In place of Eq. (23) we have

$$b_0-\frac{\Gamma}{x_0'}=2\beta\sum_{k=1}^{n'}\frac{1}{x_k'},$$

$$\epsilon'=n',\quad n'=1,2.\ldots \tag{45}$$

Summing Eq. (44) over k gives $b_0=\Sigma_{k=1}^{n'}x_k'$. For any given integral value of $\epsilon'=n'$ the QES part of the energy E is determined from Eq. (42) once the values of x_0' are obtained from the Bethe ansatz equations. The corresponding value of the magnetic field B is then obtainable from the expression $l_B=Z\alpha/[(E-m)x_0']$.

We note here that since the two sets of Bethe ansatz Eqs. (22), (24) and (25), and (43) and (44) give the same spectrum of the QES energy E and the corresponding B, we have, from the values of ϵ, ϵ' and b_0, the following necessary conditions:

$$n'=n+1, \tag{46}$$

$$b_0=x_0+\sum_{k=1}^{n}x_k=\sum_{k=1}^{n+1}x_k'. \tag{47}$$

Conversely, one can easily show that Eqs. (46) and (47) are also the sufficient conditions for the two sets of Bethe ansatz equations to give the same QES energy spectrum and magnetic field. The condition (46) implies that the degree of the polynomial $P(x)$ is of one order higher than that of $Q(x)$, which is in complete agreement with the result obtained in Ref. 13.

VI. NON-sl_2-BASED QUASI-EXACTLY SOLVABILITY

We now demonstrate that the QES Eqs. (13) and (41) cannot be represented as a bilinear combination of the generators of the sl_2 algebra. The question of whether there exists non-sl_2-based one-dimensional QESM was first posed in Ref. 2 in which all sl_2-based QESM are classified. The first example of such a kind was given in Ref. 16, which presents a potential arising in the context of the stability analysis around the kink solution for ϕ^4-type field theory in $1+1$ dimensions.

We shall show that Eq. (13) is not generated by the sl_2 algebra. The same conclusion applies immediately to Eq. (41), since both equations have the same form. Let us rewrite Eq. (13) as

$$\left\{-(x^2+x_0x)\frac{d^2}{dx^2}+[x^3+x_0x^2+(1-2\beta)x-2\beta x_0]\frac{d}{dx}-\epsilon x^2+(c-b-\epsilon x_0)x-bx_0\right\}Q(x)=0. \tag{48}$$

Turbiner[2] has shown that all sl_2-based second order QES differential equations can be cast into the form

$$-P_4(x)\frac{d^2Q}{dx^2}+P_3(x)\frac{dQ}{dx}+(P_2(x)-\lambda)Q=0, \tag{49}$$

where

$$\begin{aligned}P_4(x)&=a_{++}x^4+a_{+0}x^3+(a_{+-}+a_{00})x^2+a_{0-}x+a_{--},\\ P_3(x)&=2(2j-1)a_{++}x^3+[(3j-1)a_{+0}+b_+]x^2+[2j(a_{+-}+a_{00})+a_{00}+b_0]x+ja_{0-}+b_-,\\ P_2(x)&=2j(2j-1)a_{++}x^2+2j(ja_{+0}+b_+)x+a_{00}j^2+b_0j.\end{aligned} \tag{50}$$

Here a_{kl}'s and b_k's $(k,l=+,0,-)$ are constants, and j is a non-negative integer or half-integer. Equation (49) corresponds to the eigenvalue problem

$$HQ=\lambda Q, \quad H=-\sum_{\substack{k,l=+,0,-\\ k\geqslant l}}a_{kl}J^kJ^l+\sum_{k=+,0,-}b_kJ^k, \tag{51}$$

which has a polynomial solution of power $2j$ in x. Here J^k's are the generators of sl_2:

$$J^+ = x^2 \frac{d}{dx} - 2jx, \quad J^0 = x \frac{d}{dx} - j, \quad J^- = \frac{d}{dx}. \tag{52}$$

Comparing Eqs. (48) and (49) we find that the two equations are inconsistent with each other. For instance, the coefficient of x^4 in P_4 requires $a_{++} = 0$, whereas the coefficient of x^3 in P_3 implies $2(2j-1)a_{++} = 1$, which gives a nonvanishing a_{++} for positive integral and half-integral values of j. This shows that Eq. (13) is not sl_2-based.

VII. CONCLUSIONS

In conclusion, we have given an algebraic solution to the planar Dirac equation of an electron in the Coulomb and magnetic fields. The relevant Bethe ansatz equations are presented. Unlike the corresponding equations in the Schrödinger and the Klein-Gordon case discussed in Ref. 14, the unknown variables in this set of Bethe ansatz equations include not only the roots of the polynomial assumed, but also a parameter from the QES differential operator. Equivalence between this approach and that by the recursion relations is demonstrated. Finally, we show that the QES equation for this problem does not belong to any of the classes based on the sl_2 algebra.

Noncommuting limits in homogenization theory of electromagnetic crystals

D. Felbacq

(Received 11 June 2001; accepted for publication 24 September 2001)

We study the homogeneous properties of metallic 2D photonic crystals. We give a rigorous proof that the limits when the ratio period over wavelength tends to zero and the conductivity tends to infinity do not commute. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1418013]

I. INTRODUCTION

This article concerns the homogenization of 2D dielectric photonic crystals and the fact that the limits $k\to 0$ (k is the Bloch vector) and $\varepsilon\to+\infty$ do not commute for p-polarized waves (it is not the case for s-polarized waves, which is a straightforward case). This result has been claimed by Nicorovici *et al.* in a series of papers[1–3] and it has been claimed to be false by Krokhin *et al.* in a comment.[4] The point of this article is to make the situation clear once and for all, that is, to give a mathematically clean derivation of the result by Nicorovici and to prove that it is right.

II. HOMOGENIZATION RESULT

Rather than letting the Bloch vector tend to zero, we use the following homogenization scheme: We deal with a finite-size photonic crystal, contained in a bounded domain Ω, with period η (the period is a contracted cell ηY, where $Y=[0,1[^2$ and θ is the filling ratio in Y, see Fig. 1 for notations) and a fixed wavenumber k_0 in which case for an incident field u^i the total field u_η satisfies in p-polarization: $\mathrm{div}(\varepsilon_\eta^{-1}\nabla u_\eta)+k_0^2 u_\eta=0$ and $u_\eta-u^i$ satisfies a radiation condition. Function ε_η is defined by

$$\varepsilon_\eta=\begin{cases}\varepsilon\left(\dfrac{x}{\eta}\right) & \text{in } \Omega,\\ 1 & \text{in } \mathbb{R}^2\backslash\Omega,\end{cases}$$

where $y\in Y\to\varepsilon(y)$ represents the relative permittivity inside the basic cell. It is extended to $\mathbb{R}^2$ by periodization. The relative permittivity of one rod is equal to ε_s and the rest of the cell has relative permittivity ε_Ω. We study the limit of u_η when $\eta\to 0$.

It is known that by standard homogenization theory[5,6] u_η tends, in $L^2_{\mathrm{loc}}(\mathbb{R}^2)$, to u_0 satisfying $\mathrm{div}(\varepsilon_{\mathrm{hom}}^{-1}\nabla u_0)+k_0^2 u_0=0$ where

$$\varepsilon_{\mathrm{hom}}^{-1}=\begin{pmatrix}(1-\theta)\varepsilon_\Omega^{-1}+\theta\varepsilon_s^{-1}+\phi_{11}^{\varepsilon_s} & \phi_{12}^{\varepsilon_s}\\ \phi_{21}^{\varepsilon_s} & (1-\theta)\varepsilon_\Omega^{-1}+\theta\varepsilon_s^{-1}+\phi_{22}^{\varepsilon_s}\end{pmatrix}$$

in Ω and $(\varepsilon_{\mathrm{hom}})^{-1}=1$ in $\mathbb{R}^2\backslash\Omega$. The matrix $(\phi_{ij}^{\varepsilon_s})$ is defined in Ref. 5. If we let ε_s formally tend to infinity we get

$$\varepsilon_{\mathrm{hom}}^{-1}\to\begin{pmatrix}(1-\theta)\varepsilon_\Omega^{-1}+\phi_{11}^{\infty} & \phi_{12}^{\infty}\\ \phi_{21}^{\infty} & (1-\theta)\varepsilon_\Omega^{-1}+\phi_{22}^{\infty}\end{pmatrix}, \tag{1}$$

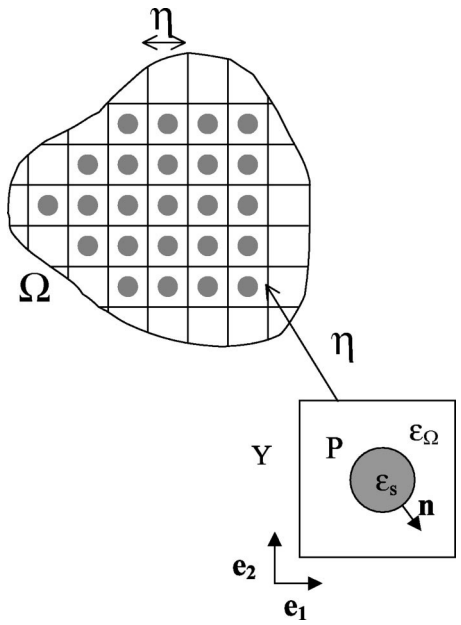

FIG. 1. Sketch of the homogenization problem.

where $\phi_{ij}^{\infty}=\langle \partial w_j/\partial y_i \rangle_Y$, w_j being the unique Y-periodic solution, with null mean, of the following problem

$$\begin{aligned} \Delta w_j &= 0 \quad \text{in } Y\backslash P, \\ \frac{\partial w_j}{\partial n} &= -\mathbf{n}.\mathbf{e_j} \quad \text{on } \partial P, \end{aligned} \tag{2}$$

and $\langle . \rangle_Y$ denotes averaging over Y. For convenience, w_j is extended by 0 on P.

Now let us deal directly with the infinitely conducting crystal; the set of rods is denoted T_η. At step η, the field satisfies $\mathrm{div}(\varepsilon_\eta^{-1}\nabla u_\eta)+k_0^2 u_\eta=0$ in the complementary of the rods with

$$\varepsilon_\eta = \begin{cases} \varepsilon_\Omega \text{ in } \Omega\backslash T_\eta, \\ 1 \text{ in } \mathbb{R}^2\backslash\Omega, \end{cases}$$

and $\partial u_\eta/\partial n=0$ on ∂T_η. Our result is the following.

Theorem: *When* η *tends to* 0, u_η *tends in* L^2_{loc} *to* u_0 *satisfying* $\mathrm{div}(\varepsilon_\infty^{-1}\nabla u_0)+k_0^2 u_0=0$ *in* $\Omega\backslash\partial\Omega$ *where*

$$\begin{aligned} \varepsilon_\infty^{-1} &= \frac{1}{1-\theta}\begin{pmatrix} (1-\theta)\varepsilon_\Omega^{-1}+\phi_{11}^{\infty} & \phi_{12}^{\infty} \\ \phi_{21}^{\infty} & (1-\theta)\varepsilon_\Omega^{-1}+\phi_{22}^{\infty} \end{pmatrix} \quad \text{in } \Omega \\ &= 1 \quad \text{outside } \Omega, \end{aligned}$$

and the following transmission conditions hold on the boundary of $\partial\Omega$:

$$u_0^- = (1-\theta)u_0^+,$$

$$(\varepsilon_\infty^{-1}\nabla u_0^-).\mathbf{n} = \nabla u_0^+.\mathbf{n}.$$

A simple comparison with (1) leads to the following evident conclusion.

Corollary: The limits $\eta\to 0$ *and* $\varepsilon_s\to+\infty$ *do not commute.*

Proof: Step 1: We assume that (u_η) is bounded in $L^2(\Omega)$.

The field u_η is null inside the rods but we can define a function $\tilde{u}_\eta$ such that $u_\eta=\tilde{u}_\eta$ outside T_η and $\tilde{u}_\eta$ belongs to the Sobolev space $H^1_{\mathrm{loc}}(\mathbb{R}^2)$ (see Ref. 6 for a proof), so that $(1-1_{T_\eta})\tilde{u}_\eta=u_\eta$ and $(\tilde{u}_\eta)$ is bounded in $H^1(\Omega)$. Using now a test function ϕ in the Schwartz space $\mathcal{D}(\Omega)$, we find

$$-\int_\Omega 1_{\Omega_\eta}\nabla\tilde{u}_\eta\nabla\phi\, d^2x+k_0^2\varepsilon_\Omega\int_\Omega(1-1_{T_\eta})\tilde{u}_\eta\phi\, d^2x=0.$$

By Rellich–Kondratov theorem, we deduce that up to the extraction of a subsequence we have the following points:

(1) $\tilde{u}_\eta\to\tilde{u}_0$ strongly in $L^2(\Omega)$,
(2) $u_0=(1-1_\Omega\theta)\tilde{u}_0$,
(3) $\chi_\eta=1_{\Omega_\eta}\nabla\tilde{u}_\eta\rightharpoonup\chi_0$ weakly in $L^2(\Omega)$,

so that

$$-\int_\Omega\chi_0\nabla\phi d^2x+k_0^2\int_\Omega u_0\phi\, d^2x=0$$

or equivalently $\mathrm{div}(\chi_0)+k_0^2u_0=0$. We then have to find an expression for χ_0. We set $w_i=w_\eta+x_i$, where $w_\eta=\eta w(x/\eta)$ [note that $w_i\overset{L^2}{\rightharpoonup}x_i$ strongly in $L^2(\Omega)$]. We have

$$\begin{aligned}0&=\int_\Omega[-1_{\Omega_\eta}\nabla\tilde{u}_\eta\nabla(\phi w_i)+k_0^2u_\eta\phi w_i]d^2x\\&=-\int_\Omega\chi_\eta\nabla\phi w_i d^2x+\int_\Omega\nabla\phi\nabla w_i\tilde{u}_\eta d^2x+k_0^2\int_\Omega u_\eta\phi w_i d^2x.\end{aligned}$$

Then letting η tend to 0 in the last expression, we obtain

$$\int_\Omega[-\chi_0x_i+\langle\nabla w_i\rangle_Y.\mathbf{e}_i\tilde{u}_0]\nabla\phi d^2x+k_0^2\int_\Omega u_0\phi x_i d^2x=0.$$

This shows that $\chi_0.\mathbf{e}_i=(\langle\nabla w\rangle_Y+(1-\theta)\mathbf{e}_i).\nabla\tilde{u}_0$ from which we get the following equation, valid in $\mathbb{R}^2$,

$$\mathrm{div}(\varepsilon_\infty^{-1}\nabla\tilde{u}_0)+k_0^2u_0=0.$$

It implies that the following transmission conditions hold on the boundary of Ω:

(1) $u_0^-=(1-\theta)u_0^+$.
(2) $(\varepsilon_{\mathrm{hom}}^{-1}\nabla u_0^-).\mathbf{n}=\nabla u_0^+.\mathbf{n}$.

Step 2: Assuming that the hypothesis of step 1 is false, there is a subsequence, still denoted (u_n), such that $\|u_n\|_\Omega$ diverges to infinity. Let us then deal with the same scattering problem, but with incident field $u^i/\|u_n\|_\Omega$. We can apply the above result to the rescaled field $u_n/\|u_n\|_\Omega$. The uniqueness of the limit problem implies that $\lim_{\eta\to0}u_n/\|u_n\|_\Omega=0$ and a contradiction. The theorem and corollary follow.

A numerical discussion of the theorem and of the unusual transmission conditions is given in Ref. 7.

As a conclusion, we might suggest that a clear mathematical approach should make it possible to avoid any polemical discussion over these issues.

(Received 28 June 2001; accepted for publication 30 August 2001)

We provide geometric quantization of the vertical cotangent bundle $V^*Q\to Q\to\mathbf{R}$, equipped with the canonical Poisson structure and treated as a momentum phase space of nonrelativistic time-dependent mechanics. We show that this quantization is equivalent to fiberwise quantization of symplectic fibers of $V^*Q\to\mathbf{R}$ and that the quantum algebra of time-dependent mechanics is an instantwise algebra. Quantization of the classical evolution equation defines a connection on this instantwise algebra and describes quantum evolution in time-dependent mechanics as a parallel transport. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1412597]

I. INTRODUCTION

We study the covariant (frame-independent) geometric quantization of nonrelativistic mechanics, subject to time-dependent transformations. Its configuration space is a fiber bundle $Q\to\mathbf{R}$ equipped with bundle coordinates (t,q^k), $k=1,\ldots,m$, where t is a fixed Cartesian coordinate on the time axis $\mathbf{R}$. The corresponding momentum phase space is the vertical cotangent bundle V^*Q of $Q\to\mathbf{R}$.[1,2] It is endowed with holonomic bundle coordinates (t,q^k,p_k), subject to time-dependent transition functions

$$q'^k=q'^k(t,q^i),\quad p'_k=\frac{\partial q^j(t,q'^i)}{\partial q'^k}p_j. \tag{1}$$

Of course, all fiber bundles over $\mathbf{R}$ are trivial, but different trivializations,

$$Q\cong\mathbf{R}\times M,\quad V^*Q\cong\mathbf{R}\times T^*M, \tag{2}$$

correspond to different nonrelativistic reference frames. Given such a trivialization, the associated bundle coordinates on V^*Q have time-independent transition functions.

In contrast with the existent quantizations of nonrelativistic mechanics,[3,4] we do not fix a trivialization (2). The key point is that, in this case, the evolution equation is not reduced to the Poisson bracket on V^*Q, but can be expressed into the Poisson bracket on the cotangent bundle T^*Q of Q.[5] Therefore, covariant geometric quantization of time-dependent mechanics on a configuration bundle $Q\to\mathbf{R}$ requires compatible geometric quantization both of the cotangent bundle T^*Q and the vertical cotangent bundle V^*Q of Q.

[a]Electronic mail: giachetta@campus.unicam.it
[b]Electronic mail: mangiaro@camserv.unicam.it
[c]Electronic mail: sard@grav.phys.msu.su

The cotangent bundle T^*Q plays the role of the homogeneous momentum phase space of time-dependent mechanics. It is provided with holonomic coordinates $(q^0=t,q^k,p_0=p,p_k)$, where the fiber coordinate p has the affine transformation law

$$p'=p+\frac{\partial q^k(t,q'^i)}{\partial t}p_k. \tag{3}$$

The cotangent bundle T^*Q is equipped with the canonical Liouville form $\Xi=p_\lambda dq^\lambda$, the canonical symplectic form $\Omega=d\Xi$, and the corresponding Poisson bracket

$$\{f,f'\}_T=\partial^\lambda f\partial_\lambda f'-\partial_\lambda f\partial^\lambda f', \quad f,f'\in C^\infty(T^*Q).$$

There is the canonical one-dimensional affine fiber bundle

$$\zeta: T^*Q\to V^*Q, \tag{4}$$

whose kernel is the annihilator of the vertical tangent bundle $VQ\subset TQ$. The fibration (4) provides the vertical cotangent bundle V^*Q with the canonical Poisson structure $\{,\}_V$ such that

$$\zeta^*\{f,f'\}_V=\{\zeta^*f,\zeta^*f'\}_T, \tag{5}$$

$$\{f,f'\}_V=\partial^k f\partial_k f'-\partial_k f\partial^k f', \tag{6}$$

for all $f,f'\in C^\infty(V^*Q)$.[1,6] The corresponding symplectic foliation coincides with the fibration $V^*Q\to\mathbf{R}$.

The relation (5) defines the monomorphism of Poisson algebras

$$\zeta^*:(C^\infty(V^*Q),\{,\}_V)\to(C^\infty(T^*Q),\{,\}_T). \tag{7}$$

Therefore, a compatibility of geometric quantizations of T^*Q and V^*Q implies that this monomorphism is prolonged to a monomorphism of quantum algebras of V^*Q and T^*Q.

Of course, it seems natural to quantize $C^\infty(V^*Q)$ as a subalgebra (7) of the Poisson algebra $C^\infty(T^*Q)$. However, geometric quantization of the Poisson algebra $(C^\infty(T^*Q),\{,\}_T)$ need not imply that of its Poisson subalgebra $\zeta^*C^\infty(V^*Q)$.

Recall that geometric quantization of a symplectic manifold $(Z,\Omega,\{,\})$ provides a representation

$$\pi: f\to i\hat{f}, \quad [\hat{f},\hat{f}']=-i\widehat{\{f,f'\}}, \tag{8}$$

of a certain subalgebra $\mathcal{A}$ of the Poisson algebra $C^\infty(Z)$ by Hermitian operators $\hat{f}$ in a Hilbert space. The geometric quantization procedure falls into three steps: prequantization, polarization and metaplectic correction.[3,4,7] The first one associates to each element f of the Poisson algebra $C^\infty(Z)$ a first order differential operator $\hat{f}$ on sections of a complex line bundle $C\to Z$ such that the Dirac condition (8) holds. Polarization of a symplectic manifold (Z,Ω) is defined as a maximal (regular) involutive distribution $\mathbf{T}\subset TZ$ on Z such that

$$\Omega(u,v)=0, \quad \forall u,v\in\mathbf{T}_z, \quad z\in Z. \tag{9}$$

Given the Lie algebra $\mathbf{T}(Z)$ of $\mathbf{T}$-subordinate vector fields on Z, let $\mathcal{A}\subset C^\infty(Z)$ be the subalgebra of functions f whose Hamiltonian vector fields u_f fulfill the condition

$$[u_f,\mathbf{T}(Z)]\subset\mathbf{T}(Z).$$

Only elements of this algebra are quantized. After metaplectic correction, the quantum algebra $\mathcal{A}$ is represented by operators in a certain subspace of sections of the tensor product $C\otimes\mathcal{D}_{1/2}$ of the prequantization line bundle $C\to Z$ and the fiber bundle $\mathcal{D}_{1/2}\to Z$ of complex half-forms on Z. We will also appeal to geometric quantization of Poisson manifolds.[6,8]

We show that the standard prequantization of the cotangent bundle T^*Q yields the compatible prequantization of the Poisson manifold V^*Q such that the monomorphism ζ^* (7) is prolonged to a monomorphism of prequantum algebras. However, polarization of T^*Q need not induce any polarization of V^*Q, unless it contains the vertical cotangent bundle $V_\zeta T^*Q$ of the fiber bundle ζ (4) spanned by vectors ∂^0 (see Sec. III). A unique canonical real polarization of T^*Q, satisfying the above condition

$$V_\zeta T^*Q\subset\mathbf{T}, \tag{10}$$

is the vertical tangent bundle VT^*Q of $T^*Q\to Q$. The associated quantum algebra $\mathcal{A}_T$ consists of functions on T^*Q which are affine in momenta p_λ. We show that this vertical polarization of T^*Q yields the polarization of the Poisson manifold V^*Q such that the corresponding quantum algebra $\mathcal{A}_V$ consists of functions on V^*Q which are affine in momenta p_k. It follows that $\mathcal{A}_V$ is a subalgebra of $\mathcal{A}_T$ under the monomorphism (7). After metaplectic correction, the compatible Schrödinger representations of $\mathcal{A}_T$ and $\mathcal{A}_V$ by operators on complex half-forms on Q are obtained.

The physical relevance of the Schrödinger quantization of T^*Q, however, is open to question. The scalar product of half-forms on Q implies integration over time, though the time plays the role of a classical evolution parameter in quantum mechanics, based on Schrödinger and Heisenberg equations. At the same time, the Schrödinger quantization of V^*Q provides instantwise quantization of nonrelativistic mechanics. Indeed, a glance at the Poisson bracket (6) shows that the Poisson algebra $C^\infty(V^*Q)$ is a Lie algebra over the ring $C^\infty(\mathbf{R})$ of functions of time alone, where algebraic operations, in fact, are instantwise operations depending on time as a parameter. We show that the Schrödinger quantization of the Poisson manifold V^*Q induces geometric quantization of its symplectic fibers V_t^*Q, $t\in\mathbf{R}$, such that the quantum algebra $\mathcal{A}_t$ of V_t^*Q consists of elements $f\in\mathcal{A}_V$ restricted to V_t^*Q. This agrees with the instantwise quantization of symplectic fibers $\{t\}\times T^*M$ of the direct product (2) in Ref. 3. Moreover, the induced geometric quantization of fibers V_t^*Q, by construction, is determined by their injection to V^*Q, but not projection of V^*Q. Therefore, it is independent of a trivialization (2), and defines frame-independent instantwise quantization of nonrelativistic mechanics.

Turn now to quantization of the evolution equation in time-dependent mechanics. The problem is that the Poisson structure (6) fails to provide any dynamic equation on the momentum phase space V^*Q because all Hamiltonian vector fields

$$u_f=\partial^k f\partial_k-\partial_k f\partial^k,\quad u_f\rfloor df'=\{f,f'\}_V,\quad \forall f'\in C^\infty(V^*Q),$$

for functions f on V^*Q are vertical. Hamiltonian dynamics of time-dependent mechanics is described in a different way as a particular Hamiltonian dynamics on fiber bundles.[9,10]

A Hamiltonian on the momentum phase space $V^*Q\to\mathbf{R}$ of time-dependent mechanics is defined as a global section

$$h:V^*Q\to T^*Q,\quad p\circ h=-\mathcal{H}(t,q^j,p_j), \tag{11}$$

of the affine bundle ζ (4).[1,2] Of course, it is not an element of the Poisson algebra $C^\infty(V^*Q)$. Every Hamiltonian h (11) yields the pull-back Hamiltonian form

$$H=h^*\Xi=p_k dq^k-\mathcal{H}dt \tag{12}$$

on V^*Q. Given a trivialization (2), the form H is the well-known integral invariant of Poincaré–Cartan, where $\mathcal{H}$ is a familiar (frame-dependent) Hamiltonian. For any Hamiltonian form H (12), there exists a unique vector field γ_H on V^*Q such that $\gamma_H\rfloor dt=1$ and

$$\gamma_H \rfloor dH = 0. \tag{13}$$

This vector field defines the Hamilton equations on V^*Q.

Let us consider the Lie derivative

$$\mathbf{L}_{\gamma_H} f = \gamma_H \rfloor df \tag{14}$$

of a function $f \in C^\infty(V^*Q)$ along γ_H. It is the evolution equation in time-dependent Hamiltonian mechanics. If $\mathbf{L}_{\gamma_H} f = 0$, a function f is constant on a solution of the Hamilton equations. Given a trivialization (2), the evolution equation (14) can be written as

$$\mathbf{L}_{\gamma_H} f = \partial_t f + \{\mathcal{H}, f\}_V.$$

However, taken separately, the terms on its right-hand side are ill-behaved under time-dependent transformations. In order to express the evolution equation into a Poisson bracket, let us consider the pull-back $\zeta^* H$ of the Hamiltonian form $H = h^* \Xi$ onto the cotangent bundle T^*Q. It is readily observed that the difference $\Xi - \zeta^* h^* \Xi$ is a horizontal one-form on $T^*Q \to \mathbf{R}$ and that

$$\mathcal{H}^* = \partial_t \rfloor (\Xi - \zeta^* h^* \Xi) = p + \mathcal{H} \tag{15}$$

is a function on T^*Q which we agree to call a covariant (frame-independent) Hamiltonian. Then the evolution equation (14) is brought into the form

$$\zeta^*(\mathbf{L}_{\gamma_H} f) = \{\mathcal{H}^*, \zeta^* f\}_T, \tag{16}$$

adapted for quantization.

The problem is that the covariant Hamiltonian $\mathcal{H}^*$ (15) does not belong to the algebra $\mathcal{A}_T$, unless it is affine in momenta. Let us assume that $\mathcal{H}^*$ is a polynomial of momenta. This is the case of all physical models. Then one can show (see Sec. V) that $\mathcal{H}^*$ can be represented by a finite sum of products of elements of $\mathcal{A}_T$, though this representation by no means is unique. Thereby, it can be quantized as an element of the enveloping algebra $\overline{\mathcal{A}}_T$ of the Lie algebra $\mathcal{A}_T$.

Remark 1: An ambiguity of the operator representation of a classical Hamiltonian is a well-known technical problem of Schrödinger quantization as well as any geometric quantization scheme, where a Hamiltonian does not preserve a polarization (see Ref. 3 for a general, but rather sophisticated, analysis of such Hamiltonians). One can include the covariant Hamiltonian $\mathcal{H}^*$ (15) in a quantum algebra by choosing polarization of T^*Q which contains the Hamiltonian vector field of $\mathcal{H}^*$. This polarization always exists, but does not satisfy the condition (10) and, therefore, does not define any polarization of the Poisson manifold V^*Q (see Sec. VI). Note that, given a trivialization (2), symplectic fibers V_t^*Q, $t \in \mathbf{R}$, of the Poisson bundle $V^*Q \to \mathbf{R}$ can be provided with the instantwise polarization spanned by vectors

$$(\partial_1 \mathcal{H} \partial^1 - \partial^1 \mathcal{H} \partial_1, \ldots, \partial_m \mathcal{H} \partial^m - \partial^m \mathcal{H} \partial_m).$$

However, this polarization need not be regular and, by construction, is frame-dependent. It is a standard polarization in conservative Hamiltonian mechanics of one-dimensional systems, but it requires an exclusive analysis of each physical model.

Given a covariant Hamiltonian $\mathcal{H}^*$ (15) and its representative $\overline{\mathcal{H}}^*$ in $\overline{\mathcal{A}}_T$, the map

$$\nabla : f \to \{\overline{\mathcal{H}}^*, f\}_T$$

is a derivation of the enveloping algebra $\overline{\mathcal{A}}_V \subset \overline{\mathcal{A}}_T$ of the Lie algebra $\mathcal{A}_V$. Moreover, this derivation obeys the Leibniz rule

$$\nabla(rf) = \partial_t r f + r \nabla f, \quad \forall r \in C^\infty(\mathbf{R}),$$

and, consequently, is a connection on the instantwise algebra $\overline{\mathcal{A}}_V$.[11] This property is preserved under quantization. Therefore, the quantized evolution equation describes quantum evolution in nonrelativistic mechanics as a parallel transport along time. The corresponding evolution operator is constructed. It is different for different reference frames.

II. PREQUANTIZATION

We start from the standard prequantization of the cotangent bundle T^*Q.[3,4,7] Since the symplectic form Ω on T^*Q is exact and, consequently, belongs to the zero de Rham cohomology class, a prequantization bundle is the trivial complex line bundle

$$C=T^*Q\times\mathbf{C}\to T^*Q \tag{17}$$

of zero Chern class. Coordinated by (q^λ,p_λ,c), this bundle is provided with the admissible linear connection

$$A=dp_\lambda\otimes\partial^\lambda+dq^\lambda\otimes(\partial_\lambda+ip_\lambda c\partial_c) \tag{18}$$

whose strength form equals $i\Omega$. The A-invariant Hermitian fiber metric on $C\to Q$ is $g(c,c)=c\overline{c}$. The covariant derivative of sections s of the prequantization bundle C (17) relative to the connection A (18) along the vector field u on T^*Q reads

$$\nabla_u s=u^\lambda(\partial_\lambda-ip_\lambda)s+u_\lambda\partial^\lambda s. \tag{19}$$

Given a function $f\in C^\infty(T^*Q)$ and its Hamiltonian vector field

$$u_f=\partial^\lambda f\partial_\lambda-\partial_\lambda f\partial^\lambda,\quad u_f\rfloor\Omega=-df,$$

the covariant derivative (19) along u_f is

$$\nabla_{u_f}s=\partial^\lambda f(\partial_\lambda-ip_\lambda)s-\partial_\lambda f\partial^\lambda s.$$

Then, in order to satisfy the Dirac condition (8), one assigns to each function $f\in C^\infty(T^*Q)$ the first order differential operator

$$\hat{f}(s)=-i(\nabla_{u_f}+if)s=[-i(\partial^\lambda f\partial_\lambda-\partial_\lambda f\partial^\lambda)+(f-p_\lambda\partial^\lambda f)]s \tag{20}$$

on sections s of the prequantization bundle C (17). The prequantum operators (20) for elements f of the Poisson subalgebra $\zeta^*C^\infty(V^*Q)\subset C^\infty(T^*Q)$ read

$$\hat{f}(s)=[-i(\partial^k f\partial_k-\partial_\lambda f\partial^\lambda)+(f-p_k\partial^k f)]s. \tag{21}$$

Turn now to prequantization of the Poisson manifold $(V^*Q,\{,\}_V)$. The Poisson bivector w of the Poisson structure (6) on V^*Q is

$$w=\partial^k\wedge\partial_k=-[w,\vartheta]_{\mathrm{SN}}, \tag{22}$$

where $[,]_{\mathrm{SN}}$ is the Schouten–Nijenhuis bracket and $\vartheta=p_k\partial^k$ is the Liouville vector field on the vertical cotangent bundle $V^*Q\to Q$. The relation (22) shows that the Poisson bivector w is exact and, consequently, has the zero Lichnerowicz–Poisson cohomology class.[1,6] Therefore, let us consider the trivial complex line bundle

$$C_V=V^*Q\times\mathbf{C}\to V^*Q \tag{23}$$

of zero Chern class. Since the line bundles C (17) and C_V (23) are trivial, C can be seen as the pull-back ζ^*C_V of C_V, while C_V is isomorphic to the pull-back h^*C of C with respect to a

section h (11) of the affine bundle (4). Since $C_V=h^*C$ and since the covariant derivative of the connection A (18) along the fibers of ζ (4) is trivial, let us consider the pull-back

$$h^*A=dp_k\otimes\partial^k+dq^k\otimes(\partial_k+ip_kc\partial_c)+dt\otimes(\partial_t-i\mathcal{H}c\partial_c) \tag{24}$$

of the connection A (18) onto $C_V\to V^*Q$.[11] This connection defines the contravariant derivative

$$\nabla_\phi s_V=\nabla_{w^\sharp\phi}s_V \tag{25}$$

of sections s_V of $C_V\to V^*Q$ along one-forms ϕ on V^*Q. This contravariant derivative corresponds to a contravariant connection A_V on the line bundle $C_V\to V^*Q$.[6] Since the vector fields $w^\sharp\phi=\phi^k\partial_k-\phi_k\partial^k$ are vertical on $V^*Q\to\mathbf{R}$, this contravariant connection does not depend on the choice of a section h. By virtue of the relation (25), the curvature bivector of A_V is equal to iw,[12] i.e., A_V is an admissible connection for the Poisson structure on V^*Q. Then the Kostant-Souriau formula

$$\begin{gathered}\hat f(s_V)=(-i\nabla_{u_f}+f)s_V=[-i(\partial^kf\partial_k-\partial_kf\partial^k)+(f-p_k\partial^kf)]s_V,\\ u_f=w^\sharp df=\partial^kf\partial_k-\partial_kf\partial^k,\end{gathered} \tag{26}$$

defines prequantization of the Poisson manifold V^*Q. In particular, the prequantum operators of functions $r\in C^\infty(\mathbf{R})$ of time alone are reduced to multiplication $\hat r s_V=rs_V$. Consequently, the prequantum algebra of V^*Q inherits the structure of a $C^\infty(\mathbf{R})$-algebra.

It is immediately observed that the prequantum operator $\hat f$ (26) coincides with the prequantum operator $\widehat{\zeta^*f}$ (21) restricted to the pull-back sections $s=\zeta^*s_V$. Thus, the above prequantization of the Poisson algebra $C^\infty(V^*Q)$ is equivalent to its prequantization as a subalgebra of the Poisson algebra $C^\infty(T^*Q)$.

Note that, since the complex line bundles C (17) and C_V (23) are trivial, their sections are simply smooth complex functions on T^*Q and V^*Q, respectively. Then the prequantum operators (20) and (26) can be written in the form

$$\hat f=-i\mathbf{L}_{u_f}+(f-\mathbf{L}_\vartheta f), \tag{27}$$

where ϑ denotes the Liouville vector field on $T^*Q\to Q$ or $V^*Q\to Q$, respectively.

III. QUANTIZATION

Given compatible prequantizations of the cotangent bundle T^*Q and the vertical cotangent bundle V^*Q, let us now construct their compatible polarizations and quantizations. We assume that Q is an oriented manifold and that the cohomology group $H^2(Q,\mathbf{Z}_2)$ is trivial.

Recall that polarization of a Poisson manifold $(Z,\{,\})$ is defined as a sheaf $\mathbf{T}^*$ of germs of complex functions on Z whose stalks $\mathbf{T}^*_z$, $z\in Z$, are Abelian algebras with respect to the Poisson bracket $\{,\}$.[12] Let $\mathbf{T}^*(Z)$ be the structure algebra of global sections of the sheaf $\mathbf{T}^*$; it is also called a Poisson polarization.[6,8] A quantum algebra $\mathcal{A}$ associated to the Poisson polarization $\mathbf{T}^*$ is defined as a subalgebra of the Poisson algebra $C^\infty(Z)$ which consists of functions f such that

$$\{f,\mathbf{T}^*(Z)\}\subset\mathbf{T}^*(Z).$$

Polarization of a symplectic manifold yields its Poisson one.

Let $\mathbf{T}^*$ be a polarization of the Poisson manifold $(T^*Q,\{,\}_T)$. Its direct image in V^*Q with respect to the fibration ζ (4) is polarization of the Poisson manifold $(V^*Q,\{,\}_V)$ if the germs of $\mathbf{T}^*$ are constant along the fibers of ζ,[12] i.e., are germs of functions independent of the momentum coordinate p. It follows that the corresponding symplectic polarization $\mathbf{T}$ of T^*Q is vertical with respect to the fibration $T^*Q\to V^*Q$.

The vertical polarization $\mathbf{T}=VT^*Q$ of T^*Q obeys this condition. The associated quantum algebra $\mathcal{A}_T \subset C^\infty(T^*Q)$ consists of functions which are affine in momenta p_λ. The algebra $\mathcal{A}_T$ acts by operators (27) on the space of smooth complex functions s on T^*Q which fulfill the relation $\nabla_u s=0$ for any $\mathbf{T}$-valued (i.e., vertical) vector field $u=u_\lambda \partial^\lambda$ on the cotangent bundle $T^*Q\to Q$. Clearly, these functions are the pull-back of complex functions on Q with respect to the fibration $T^*Q\to Q$. Following the general metaplectic technique, we come to complex half-forms on Q which are sections of the complex line bundle $\mathcal{D}_{1/2}\to Q$ with the transition functions $c'=Sc$ such that $S\overline{S}$ is the Jacobian of coordinate transition functions on Q. Then the formula (27), where $\mathbf{L}_{u_f}$ is the Lie derivative of half-forms, defines the Schrödinger representation of the Lie algebra $\mathcal{A}_T$ by operators

$$\hat{f}\rho=(-i\mathbf{L}_{a^\lambda\partial_\lambda}+b)\rho=\left(-ia^\lambda\partial_\lambda-\frac{i}{2}\partial_\lambda a^\lambda+b\right)\rho, \quad f=a^\lambda(q^\mu)p_\lambda+b(q^\mu)\in\mathcal{A}_T, \tag{28}$$

in the space $\mathcal{D}_{1/2}(Q)$ of complex half-forms ρ on Q. From now on, we assume that a coordinate atlas of Q and a bundle atlas of $\mathcal{D}_{1/2}\to Q$ are defined on the same covering of Q, e.g., by contractible open sets. Let $E\subset\mathcal{D}_{1/2}(Q)$ consist of half-forms of compact support, and let $\overline{E}$ be its completion with respect to the nondegenerate Hermitian form

$$\langle\rho|\rho'\rangle=\left(\frac{1}{2\pi}\right)^m\int_Q\rho\overline{\rho'}. \tag{29}$$

The (unbounded) operators (28) on the domain E in the Hilbert space $\overline{E}$ are Hermitian.

The vertical polarization of T^*Q defines the polarization $\mathbf{T}^*_V$ of the Poisson manifold V^*Q which contains the germs of functions, constant on the fibers of $V^*Q\to Q$. The associated quantum algebra $\mathcal{A}_V$ consists of functions on V^*Q which are affine in momenta. It is a $C^\infty(\mathbf{R})$-algebra. This algebra acts by operators (27) on the space of smooth complex functions s_V on V^*Q which fulfill the relation $\nabla_u s_V=0$ for any vertical vector field $u=u_k\partial^k$ on $V^*Q\to Q$. These functions are also the pull-back of complex functions on Q with respect to the fibration $V^*Q\to Q$. Similarly to the case of $\mathcal{A}_T$, we obtain the Schrödinger representation of the Lie algebra $\mathcal{A}_V$ by the operators

$$\hat{f}\rho=(-i\mathbf{L}_{a^k\partial_k}+b)\rho=\left(-ia^k\partial_k-\frac{i}{2}\partial_k a^k+b\right)\rho, \quad f=a^k(q^\mu)p_k+b(q^\mu)\in\mathcal{A}_V, \tag{30}$$

on half-forms on Q and in the above Hilbert space $\overline{E}$. Moreover, a glance at the expressions (28) and (30) shows that (30) is the representation of $\mathcal{A}_V$ as a subalgebra of the Lie algebra $\mathcal{A}_T$.

It should be emphasized that, written in the coordinate form, the operators (28) and (30) are defined independently of the choice of a coordinate chart, and their coordinate expressions (28) and (30) are maintained under coordinate transformations (1) and (3).

IV. INSTANTWISE QUANTIZATION

As was mentioned earlier, the physical relevance of the space of half-forms on Q with the scalar product (29) is open to question. At the same time, the representation (30) preserves the structure of $\mathcal{A}_V$ as a $C^\infty(\mathbf{R})$-algebra. Therefore, let us show that this representation defines the instantwise quantization of $\mathcal{A}_V$.

First, the prequantization (26) of the Poisson manifold V^*Q yields prequantization of its symplectic leaves V^*_tQ, $t\in\mathbf{R}$, as follows. The symplectic structure on V^*_tQ is

$$\Omega_t=(h\circ i_t)^*\Omega=dp_k\wedge dq^k, \tag{31}$$

where h is an arbitrary section of the fiber bundle ζ (4) and $i_t: V^*_t Q \to V^*Q$ is the natural imbedding. Since $w^\sharp \phi$ is a vertical vector field on $V^*Q \to \mathbf{R}$ for any one-form ϕ on V^*Q, the contravariant derivative (25) defines a connection along each fiber $V^*_t Q$, $t \in \mathbf{R}$, of the Poisson bundle $V^*Q \to \mathbf{R}$. It is the pull-back

$$A_t = i_t^* h^* A = dp_k \otimes \partial^k + dq^k \otimes (\partial_k + i p_k c \partial_c)$$

of the connection h^*A (24) onto the trivial pull-back line bundle

$$i_t^* C_V = V^*_t Q \times \mathbf{C} \to V^*_t Q.$$

It is readily observed that this connection is admissible for the symplectic structure (31) on $V^*_t Q$, and provides prequantization of the symplectic manifold $(V^*_t Q, \Omega_t)$ by the formula

$$\hat{f}_t = -i\mathbf{L}_{u_{f_t}} + (f_t - \mathbf{L}_{\vartheta_t}) = -i(\partial^k f_t \partial_k - \partial_k f_t \partial^k) + (f_t - p_k \partial^k f_t), \tag{32}$$

where $u_{f_t} = \partial^k f_t \partial_k - \partial_k f_t \partial^k$ is the Hamiltonian vector field of a function f_t on $V^*_t Q$ with respect to the symplectic form Ω_t (31). The operators (32) act on smooth complex functions s_t on $V^*_t Q$. In particular, let f_t, s_t and $(\hat{f}s)_t$ be the restriction to $V^*_t Q$ of a real function f and complex functions s and $\hat{f}(s)$ on V^*Q, respectively. We obtain from the formulas (26) and (32) that

$$(\hat{f}s)_t = \hat{f}_t s_t .$$

This equality shows that the prequantization (26) of the Poisson manifold V^*Q is a leafwise prequantization.[12]

Let $\mathbf{T}^*_V$ be the above polarization of the Poisson manifold V^*Q. It yields the pull-back polarization $\mathbf{T}^*_t = i_t^* \mathbf{T}^*_V$ of a fiber $V^*_t Q$ with respect to the Poisson morphism $i_t: V^*_t Q \to V^*Q$. The corresponding distribution $\mathbf{T}_t$ coincides with the vertical tangent bundle of the fiber bundle $V^*_t Q \to Q_t$. The associated quantum algebra $\mathcal{A}_t$ consists of functions on V^*Q_t which are affine in momenta. In particular, the restriction to $V^*_t Q$ of any element of the quantum algebra $\mathcal{A}_V$ of V^*Q obeys this condition and, consequently, belongs $\mathcal{A}_t$. Conversely, any element of $\mathcal{A}_t$ is of this type. For instance, using a trivialization (2) and the corresponding surjection $\pi_t: V^*Q \to V^*_t Q$, one can define the pull-back $\pi_t^* f_t$ of a function $f_t \in \mathcal{A}_t$ which belongs to the quantum algebra $\mathcal{A}_V$ and $f_t = i_t^*(\pi_t^* f_t)$. Thus, $\mathcal{A}_t = i^* \mathcal{A}_V$ and, therefore, the polarization $\mathbf{T}^*_V$ of the Poisson bundle $V^*Q \to \mathbf{R}$ is a fiberwise polarization.

To provide metaplectic correction and to complete geometric quantization of symplectic fibers of the Poisson bundle $V^*Q \to \mathbf{R}$, one can use the following fact.

Any atlas $\{(U; t, q^k)\}$ of bundle coordinates on the fiber bundle $Q \to \mathbf{R}$ induces a coordinate atlas $\{(Q_t \cap U; q^k)\}$ of its fiber Q_t, $t \in \mathbf{R}$. Since

$$\det \begin{pmatrix} 1 & \partial_t q'^k \\ 0 & (\partial_i q'^k) \end{pmatrix} = \det(\partial_i q'^k),$$

the Jacobian J of the transition function between coordinate charts $(U; t, q^k)$ and $(U'; t, q'^k)$ on Q coincides with the Jacobian J_t of the transition function between coordinate charts $(Q_t \cap U; q^k)$ and $(Q_t \cap U'; q'^k)$ on Q_t at points of $Q_t \cap U \cap U'$. It follows that, for any fiber Q_t of Q, the pull-back $i_t^* \mathcal{D} \to Q_t$ of the complex line bundle $\mathcal{D} \to Q$ of complex densities on Q with transition functions $c' = Jc$ is the complex line bundle of complex densities on Q_t with transition functions $J_t = J|_{Q_t}$. Accordingly, any density L on Q yields the pull-back section $L_t = L \circ i_t$ of the line bundle $i^* \mathcal{D} \to Q_t$, i.e., L_t is a density on Q_t. The pull-back $L \to L_t$ takes the coordinate form

$$L = \mathcal{L}(t, q^k) d^m q \wedge dt \to L_t = \mathcal{L}(t, q^k) d^m q|_{t=\text{const}} = \mathcal{L}(t, q^k) \overline{d^m} q,$$

where $\{\overline{dq}^k\}$ are holonomic fiber bases for V^*Q. It is maintained under transformations of bundle coordinates on Q.

Let now $\mathcal{D}_{1/2}\to Q$ be a complex line bundle of complex half-forms on Q with transition functions S such that $S\overline{S}=J$ on $U\cap U'$. Its pull-back $i_t^*\mathcal{D}_{1/2}$ is a complex line bundle over a fiber Q_t, $t\in\mathbf{R}$, with transition functions $S_t=S|_{Q_t}$. These transition functions obey the relation

$$S_t\overline{S}_t=J|_{Q_t}=J_t,$$

i.e., $i_t^*\mathcal{D}_{1/2}\to Q_t$ is the fiber bundle of half-forms on Q_t. Then the formula (32) defines the Schrödinger representation of the quantum algebra $\mathcal{A}_t$ of the symplectic fiber Q_t by (unbounded) Hermitian operators

$$\hat{f}_t\rho_t=(-i\mathbf{L}_{a^k\partial_k}+b)\rho_t=\left(-ia^k\partial_k-\frac{i}{2}\partial_k a^k+b\right)\rho_t,\quad f_t=a^k(q^i)p_k+b(q^i)\in\mathcal{A}_t, \tag{33}$$

in the Hilbert space $\overline{E_t}$ which is the completion of the pre-Hilbert space E_t of half-forms on Q_t of compact support with respect to the scalar product

$$\langle\rho_t|\rho_t'\rangle=\left(\frac{1}{2\pi}\right)^m\int_{Q_t}\rho_t\overline{\rho_t'}.$$

If Q_t is compact, the operators (33) in $\overline{E_t}$ are self-adjoint. Pre-Hilbert spaces E_t constitute a trivial bundle E_R over $\mathbf{R}$.

As in the above case of densities, any half-form ρ on Q yields the section $\rho\circ i_t$ of the pull-back bundle $i_t^*\mathcal{D}_{1/2}\to Q_t$, i.e., a half-form on Q_t. Given an element $f\in\mathcal{A}_V$ and its pull-back $f_t=i_t^*f\in\mathcal{A}_t$, we obtain from the formulas (30) and (33) that

$$\hat{f}\rho\circ i_t=\hat{f}_t(\rho\circ i_t).$$

This equality shows that the Schrödinger quantization of the Poisson manifold V^*Q can be seen as the instantwise quantization. Following this interpretation, let us choose the representation space $E_R(\mathbf{R})$ for $\mathcal{A}_V$ which consists of complex half-forms ρ on Q such that, for any $t\in\mathbf{R}$, the half-form $\rho\circ i_t$ on Q_t is of compact support. It is a pre-Hilbert $C^\infty(\mathbf{R})$-module. The $E_R(\mathbf{R})$ is also the carrier space for the Lie algebra $\mathcal{A}_T$, but its action on $E_R(\mathbf{R})$ is not instantwise.

V. THE QUANTUM EVOLUTION EQUATION

Turn now to quantization of the evolution equation (16). As was mentioned earlier, the problem is that, in the framework of the Schrödinger quantization, the covariant Hamiltonian $\mathcal{H}^*$ (15) does not belong to the quantum algebra $\mathcal{A}_T$, unless it is affine in momenta. Let us restrict our consideration to the physically relevant case of $\mathcal{H}^*$, polynomial in momenta. We aim to show that such $\mathcal{H}^*$ is decomposed in a finite sum of products of elements of the algebra $\mathcal{A}_T$.

Let f be a smooth function on T^*Q which is a polynomial of momenta p_λ. A glance at the transformation laws (1) and (3) shows that it is a sum of homogeneous polynomials of fixed degree in momenta. Therefore, it suffices to justify a desired decomposition of an arbitrary homogeneous polynomial F of degree $k>1$ on T^*Q. We use the fact that the cotangent bundle T^*Q admits a finite bundle atlas.[13] Let $\{U_\xi\}$, $\xi=1,\ldots,r$, be the corresponding open cover of Q and $\{f_\xi\}$ a smooth partition of unity subordinate to this cover. Put

$$l_\xi=f_\xi(f_1^k+\cdots+f_r^k)^{-1/k}.$$

It is readily observed that $\{l_\xi^k\}$ is also a partition of unity subordinate to $\{U_i\}$. Let us consider the local polynomials

$$F_\xi = F|_{U_\xi} = \sum_{(\alpha_1 \dots \alpha_k)} a_\xi^{\alpha_1 \dots \alpha_k}(q) p_{\alpha_1} \cdots p_{\alpha_k}, \quad q \in U_\xi.$$

Then we obtain a desired decomposition

$$F = \sum_\xi l_\xi^k F_\xi = \sum_\xi \sum_{(\alpha_1 \dots \alpha_k)} [l_\xi a_\xi^{\alpha_1 \dots \alpha_k} p_{\alpha_1}][l_\xi p_{\alpha_2}] \cdots [l_\xi p_{\alpha_k}], \tag{34}$$

where all terms $l_\xi a_\xi^{\alpha_1 \dots \alpha_k} p_{\alpha_1}$ and $l_\xi p_\alpha$ are smooth functions on T^*Q. Clearly, the decomposition (34) by no means is unique.

The decomposition (34) shows that one can associate to a polynomial covariant Hamiltonian $\mathcal{H}^*$ an element $\overline{\mathcal{H}}^*$ of the enveloping algebra $\overline{\mathcal{A}_T}$ of the Lie algebra $\mathcal{A}_T$. Recall that $\overline{\mathcal{A}}$ consists of finite sums of tensor products of elements of $\mathcal{A}_T$ modulo the relations

$$f \otimes f' - f' \otimes f - \{f, f'\}_T = 0.$$

To be more precise, a representative $\overline{\mathcal{H}}^*$ belongs to $\mathcal{A}_T + \overline{\mathcal{A}_V}$, where $\overline{\mathcal{A}_V}$ is the enveloping algebra of the Lie algebra $\mathcal{A}_V \subset \mathcal{A}_T$ [see the decomposition (42)]. The enveloping algebra $\overline{\mathcal{A}_V}$ is provided with the anti-automorphism

$$*: f_1 \otimes \cdots \otimes f_k \to (-1)^k f_k \otimes \cdots \otimes f_1,$$

and one can always make a representative $\overline{\mathcal{H}}^*$ Hermitian.

Since the Dirac condition (8) holds, the Schrödinger representation of the Lie algebras $\mathcal{A}_T$ and $\mathcal{A}_V$ is naturally extended to their enveloping algebras $\overline{\mathcal{A}_T}$ and $\overline{\mathcal{A}_V}$, and provides the quantization $\hat{\mathcal{H}}^*$ of a covariant Hamiltonian $\mathcal{H}^*$.

Given an operator $\hat{\mathcal{H}}^*$, the bracket

$$\nabla \hat{f} = i[\hat{\mathcal{H}}^*, \hat{f}] \tag{35}$$

defines a derivation of the quantum algebra $\overline{\mathcal{A}_V}$. Moreover, since $\hat{p} = -i\partial_t$, the derivation (35) obeys the Leibniz rule

$$\nabla(r\hat{f}) = \partial_t r \hat{f} + r \nabla \hat{f}, \quad r \in C^\infty(\mathbf{R}).$$

Therefore, it is a connection on the instantwise algebra $\overline{\mathcal{A}_V}$, which enables one to treat quantum evolution of $\overline{\mathcal{A}_V}$ as a parallel transport along time.[11,14] In particular, $\hat{f}$ is parallel with respect to the connection (35) if

$$[\hat{\mathcal{H}}^*, \hat{f}] = 0. \tag{36}$$

One can think of this equality as being the Heisenberg equation in time-dependent mechanics, while the quantum constraint

$$\hat{\mathcal{H}}^* \rho = 0, \quad \rho \in E_R(\mathbf{R}), \tag{37}$$

plays a role of the Schrödinger equation. It is readily observed that an operator $\hat{f}$ is a solution of the Heisenberg equation (36) iff it preserves the subspaces of solutions of the Schrödinger equation (37).

Given a trivialization (2) and the corresponding decomposition of a covariant Hamiltonian

$$\hat{\mathcal{H}}^* = -i\partial_t + \hat{\mathcal{H}}, \tag{38}$$

one can introduce the evolution operator U for the connection (35). It obeys the equation

$$\hat{\mathcal{H}}^* \circ U = -iU \circ \partial_t, \tag{39}$$

and can be written as the formal time-ordered exponent

$$U = T \exp\left[-i\int_0^t \hat{\mathcal{H}}\, dt'\right]. \tag{40}$$

In particular, if an element $\rho_0 \in E_R(\mathbf{R})$ obeys the relation $\partial_t \rho_0 = 0$, then $U\rho_0$ is a solution of the Schrödinger equation (37).

The evolution operator U can be brought into the frame-covariant form as follows. By definition, any connection

$$\Gamma = (dq^k - \Gamma^k dt) \otimes \partial_k$$

on the configuration bundle $Q \to \mathbf{R}$ yields a section

$$h_\Gamma : V^*Q \ni \sigma \to \Gamma \rfloor \sigma = p_k(dq^k - \Gamma^k dt) \in T^*Q, \quad p \circ h_\Gamma = -\mathcal{H}_\Gamma = -p_k\Gamma^k,$$

of the affine bundle (4). Then any Hamiltonian is split as

$$h = h_\Gamma - \mathcal{H}^0_\Gamma, \quad \mathcal{H} = \mathcal{H}_\Gamma + \mathcal{H}^0_\Gamma, \tag{41}$$

where $\mathcal{H}^0_\Gamma$ is a function on V^*Q. The physical meaning of this splitting becomes clear due to the fact that every trivialization (2) of $Q \to \mathbf{R}$ yields a complete connection Γ on $Q \to \mathbf{R}$ such that $\Gamma^k = 0$ relative to the corresponding coordinates, and *vice versa*. It follows that such a connection is associated to a nonrelativistic reference frame.[1,11]

With the splitting (41), we have the corresponding decomposition of classical and quantum covariant Hamiltonians

$$\mathcal{H}^* = \mathcal{H}^*_\Gamma + \mathcal{H}^0_\Gamma, \quad \hat{\mathcal{H}}^* = \hat{\mathcal{H}}^*_\Gamma + \hat{\mathcal{H}}^0_\Gamma, \tag{42}$$

where function $\mathcal{H}^*_\Gamma$ belongs to the algebra $\mathcal{A}_T$. In particular, let Γ be a complete connection associated to some trivialization of the configuration bundle $Q \to \mathbf{R}$. Under this trivialization, the decomposition (42) takes the coordinate form (38) where $\mathcal{H} = \mathcal{H}^0_\Gamma$. Then the equation (39) for the evolution operator is easily brought into the frame-covariant form

$$\hat{\mathcal{H}}^* \circ U_\Gamma = U_\Gamma \circ \hat{\mathcal{H}}^*_\Gamma.$$

One can think of the operator U_Γ in this equation as describing quantum evolution with respect to the reference frame Γ. It can be written as the time-ordered exponent (40) where $\mathcal{H}$ is replaced with $\mathcal{H}^0_\Gamma$.

In particular, let an element $\rho_\Gamma \in E_R(\mathbf{R})$ obey the equation

$$\hat{\mathcal{H}}^*_\Gamma \rho_\Gamma = 0. \tag{43}$$

Then $U_\Gamma \rho_\Gamma$ is a solution of the Schrödinger equation (37). One can think of ρ_Γ in the equation (43) as being a stationary state relative to the reference frame Γ. Let Γ' be another reference frames. Then the operator

$$U = T \exp\left[-i\int_0^t (\hat{\mathcal{H}}_\Gamma - \hat{\mathcal{H}}_{\Gamma'})dt'\right], \quad \hat{\mathcal{H}}^*_\Gamma \circ U = U \circ \hat{\mathcal{H}}^*_{\Gamma'},$$

defines an isomorphism between the spaces of stationary states relative to the reference frames Γ and Γ'.

APPENDIX: PRESYMPLECTIC QUANTIZATION

In comparison with the previous geometric quantization of the Poisson manifold $(V^*Q,\{,\}_V)$, its presymplectic quantization that follows enables one to include any covariant Hamiltonian $\mathcal{H}^*$ (15) in the quantum algebra.

A glance at the equation (13) shows that one can think of the vector field γ_H as being the Hamiltonian vector field of a zero Hamiltonian with respect to the presymplectic form dH on V^*Q. Therefore, one can examine geometric quantization of the presymplectic manifold (V^*Q,dH). Given a trivialization (2), this quantization has been studied in Ref. 4.

Geometric quantization is not applied directly to a presymplectic manifold (Z,ω), but to its symplectic realization (Z',ω') such that the presymplectic form ω is a pull-back of a symplectic form ω'. The following two possibilities are usually considered: (i) (Z',ω') is a reduction of (Z,ω) along the leaves of the characteristic distribution of the presymplectic form ω of constant rank,[15,16] and (ii) there is a coisotropic imbedding of (Z,ω) to (Z',ω').[17,18]

In application to (V^*Q,dH), the reduction procedure leads to quantization along classical solutions as follows. The kernel of dH is spanned by the vector field γ_H and, consequently, the presymplectic form dH is of constant rank. Its characteristic foliation is made up by integral curves of this vector field, i.e., solutions of Hamilton equations. If the vector field γ_H is complete, this foliation is simple, i.e., is a fibration of V^*Q over a symplectic manifold N of initial values. In this case, we come to the instantwise quantization when functions on V^*Q at a given instant $t\in\mathbf{R}$ are quantized as functions on N.

The second variant of geometric quantization of the presymplectic manifold (V^*Q,dH) is based on the fact that the image $N_h=h(V^*Q)$ of any section h (11) is a one-codimensional imbedded submanifold and, consequently, is coisotropic. It is given by the constraint

$$\mathcal{H}^*=p+\mathcal{H}(t,q^k,p_k)=0.$$

Then the geometric quantization of the presymplectic manifold (V^*Q,dH) consists in geometric quantization of the cotangent bundle T^*Q and setting the quantum constraint condition

$$\hat{\mathcal{H}}^*\psi=0$$

on physically admissible quantum states. This condition implies that $\hat{\mathcal{H}}^*$ belongs to the quantum algebra of T^*Q. It takes place if one uses polarization of T^*Q which contains the Hamiltonian vector field

$$u_{\mathcal{H}^*}=\partial_t+\partial^k\mathcal{H}\partial_k-\partial_k\mathcal{H}\partial^k. \tag{44}$$

Such a polarization of T^*Q always exists. Indeed, any section h (11) of the affine bundle ζ (4) defines the splitting

$$a_\lambda\partial^\lambda=a_k(\partial^k-\partial^k\mathcal{H}\partial^0)+(a_0+a_k\partial^k\mathcal{H})\partial^0$$

of the vertical tangent bundle VT^*Q of $T^*Q\to Q$. Then elements $(\partial^k-\partial^k\mathcal{H}\partial^0)$ together with the Hamiltonian vector field (44) obey the polarization condition (9) and generate a polarization of T^*Q. Clearly, this polarization does not satisfy the condition (10), and does not define any polarization of the Poisson manifold V^*Q.

(Received 10 August 2001; accepted for publication 16 October 2001)

In this paper, we provide a representation theory for the Feynman operator calculus. This allows us to solve the general initial-value problem and construct the Dyson series. We show that the series is asymptotic, thus proving Dyson's second conjecture for quantum electrodynamics. In addition, we show that the expansion may be considered exact to any finite order by producing the remainder term. This implies that every nonperturbative solution has a perturbative expansion. Using a physical analysis of information from experiment versus that implied by our models, we reformulate our theory as a sum over paths. This allows us to relate our theory to Feynman's path integral, and to prove Dyson's first conjecture that the divergences are in part due to a violation of Heisenberg's uncertainly relations. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1425080]

I. INTRODUCTION

Following Dirac's quantization of the electromagnetic field in 1927,[1] and his relativistic electron theory in 1928,[2] the equations for quantum electrodynamics (QED) were developed by Heisenberg and Pauli[3,4] in the years 1929–30 (see Miller[5] and Schweber[6]). From the beginning, when researchers attempted to use the straightforward and physically intuitive time-dependent perturbation expansion to compute physical observerables, a number of divergent expressions appeared. Although it was known that the same problems also existed in classical electrodynamics, it was noted by Oppenheimer[7] that there was a fundamental difference in the quantum problem as compared to the classical one. (Dirac[8] had shown that, in the classical case, one could account for the problem of radiation reaction without directly dealing with the self-energy divergence by using both advanced and retarded fields and a particular limiting procedure.)

Early attempts to develop subtraction procedures for the divergent expressions were very discouraging because they depended on both the gauge and the Lorentz frame, making them appear ambiguous. Although the equations of QED were both Lorentz and gauge covariant, it was generally believed that, in a strict sense, they had no solutions expandable in powers of the charge. The thinking of the times was clearly expressed by Oppenheimer[9] in his 1948 report to the Solvay Conference, ''If one wishes to explore these solutions, bearing in mind that certain infinite terms will, in a later theory, no longer be infinite, one needs a covariant way of identifying these terms; and for that, not merely the field equations themselves, but the whole method of approximation and solution must at all stages preserve covariance.''

The solution to the problem posed by Oppenheimer was made (independently) by Tomonaga,[10] Schwinger,[11] and Feynman.[12,13] (These papers may be found in Schwinger.[14]) To-

a)Electronic mail: tgill@howard.edu

monaga introduced what is now known as the interaction representation and showed how the approximation process could be carried out in a covariant manner. Schwinger developed the general theory and applied it to many of the important problems. Feynman took a holistic view of physical reality in his development. He suggested that we view a physical event as occurring on a film which exposes more and more of the outcome as the film unfolds. His idea was to deal directly with the solutions to the equations describing the physical system, rather than the equations themselves. In addition to solving the problem posed by Oppenheimer, Feynman's approach led to a new perturbation series, which provided an easy, intuitive, and computationally simple method to study interacting particles while giving physical meaning to each term in his expansion.

Since Feynman's method and approach was so different, it was not clear how it related to that of Schwinger and Tomonaga. Dyson,[15,16] made a major contribution. Dyson realized that Feynman and Schwinger were both dealing with different versions of Heisenberg's S-matrix. He then formally introduced time-ordering and provided a unified approach by demonstrating the equivalence of the Feynman and Schwinger–Tomonaga theories. This approach also allowed him to show how the Schwinger theory could be greatly simplified and extended to all orders of the perturbation expansion. Dyson's time-ordering idea was actually obtained from discussions with Feynman, who later explored and fully developed it into his time-ordered operator calculus.[17]

A. Background

After the problem proposed by Oppenheimer was resolved, attitudes toward the renormalization program and quantum field theory could be classified into three basic groups. The first group consisted of those who were totally dissatisfied with the renormalization program. The second group considered the renormalization program an interim step and believed that the divergences were an indication of additional physics, which could not be reached by present formulations. The first two groups will not be extensively discussed in this paper. However, we can associate the names of Dirac and Landau with the first group, and Sakata and Schwinger with the second. (See Dirac,[18] Sakata,[19] Schwinger,[20] and also Schweber.[6])

The third group was more positive, and directed its attention toward investigating the mathematical foundations of quantum field theory with the hope of providing a more orderly approach to the renormalization program (assuming that the theory proved consistent). This direction was clearly justified since part of the problem had been consistently blamed on a mathematical issue, the perturbation expansion. Indeed, the whole renormalization program critically depended on the expansion of the S-matrix in powers of the coupling constant. This concern was further supported since attempts to use the expansion when the coupling constant was large led to meaningless results. Additional unease could be attributed to the fact that, at that time, not much was actually known about the physically important cases where one was dealing with unbounded operator-valued functions (distributions).

Researchers working on the mathematical foundations of quantum electrodynamics and quantum field theory adopted the name axiomatic field theory starting in the 1950s. These researchers focused on trying to find out what could be learned about the existence of local relativistic quantum field theories based on certain natural assumptions which included the postulates of quantum mechanics, locality, Poincaré invariance, and a reasonable spectrum. This approach was initiated by the work of Wightman,[21] and Lehmann, Symanzik, and Zimmermann.[22,23] Here, the quantized field is interpreted mathematically as an operator-valued Schwartz distribution. Explicit use of the theory of distributions was a major step, which helped to partially make the theory (mathematically) sound by smoothing out the fields locally. (The recent paper by Wightman[24] provides an inspired introduction to the history of Heisenberg's early observations on the latter concept and its relationship to the divergences.[25])

The axiomatic approach proved very fruitful, providing the first rigorous proofs of a number of important general results, and attracted many able researchers. The favored name today is algebraic quantum field theory. The books by Jost,[26] Streater and Wightman,[27] and Bogolubov and Shirkov[28] are the classics, while more recent work can be found in Haag.[29] (See also the book by Bogolubov, Logunov, and Todorov,[30] and the recent review paper by Buchholz.[31])

For a number of reasons, most notably a lack of nontrivial examples, the axiomatic approach evolved in a number of directions. One major direction is called ''constructive'' quantum field theory. Here, one focuses on attempts to directly construct solutions of various model field theories, which either have exact (nonperturbative) solutions, or have an asymptotic perturbative expansion which can be summed to the exact solution. In this approach, instead of formulating the theory in Minkowski space–time, one passes to imaginary time and formulates it in Euclidean space (an idea which first appeared in Dyson[15]). This leads to a formulation in terms of ''Schwinger functions,'' also known as Euclidean Green's functions. The advantage of this approach is that hyperbolic equations are transformed to elliptic ones, and Gaussian kernels, for which a very rich set of analytic tools has been developed, replace Feynman kernels. The output of this enterprise is truly impressive. Constructive solutions have been obtained for a number of important models. Furthermore, this approach has given us a clearer picture of the problems associated with the rigorous construction of a relativistic quantum field theory and provided new mathematical methods. An early summary of this approach may be found in the lecture notes,[32] while more recent progress is contained in the lecture notes,[33] both edited by Velo and Wightman (see also Refs. 34 and 6). The books by Glimm and Jaffe[35] and Simon[36] give a different flavor and point of departure.

Although a great deal of work has been done in constructive field theory over the last 30 years, many difficult problems still remain. For example, the appearance of difficulties with the constructive approach to polynomial types of field theories is discussed in the paper by Sokal.[37] He conjectured that the $\lambda\varphi^4_{\geqslant 4}$ theory ($\lambda\varphi^4$ in four or more space–time dimensions) is a generalized free field, where λ is the coupling constant. This theory represents a self-interacting boson field. The conjecture was proven by Aizenman and Graham[38] and Fröhlich.[39] Three years later, Gawedzki and Kupiainen[40] proved that, if we change the sign of the coupling constant, the solution exists (as a tempered distribution) and the perturbation expansion is asymptotic to the solution. This state of affairs led Wightman (Ref. 33, p. 1) to lament that, ''We do not know whether the lack of an existence theorem for solutions with the 'right' sign reflects the nonexistence of solutions or merely the lack of a technique to construct them.'' Things are further complicated by the fact that the $\lambda\varphi^4_4$ theory has a perturbative solution! This led Gallavotti[41] to suggest that constructive approaches other than the ferromagnetic lattice approximation, used by Aizenman and Graham, and Fröhlich, may be required.

The most well-known method for quantum field theory calculations is perturbative renormalization theory. This approach is discussed in most standard texts on quantum field theory and has an interesting history that is best told by Wightman.[42] (The first book to include Dyson's reformulation of the Feynman–Schwinger–Tomonaga theory is the classic by Jauch and Rohrlich.[43]) Early work in the perturbative approach focused on the development of different renormalization methods with the hope of identifying those for which rigorous mathematical methods could be used. The methods generally consisted of two parts. First, the Green's functions were regularized in a relativistically and gauge invariant manner[28,34,42,44] to yield well-defined tempered distributions, even on the light cone. Then appropriate counter-terms were introduced so that, in the limit, when the regularization was removed, the various divergences of the S-matrix were also removed. It was found that all renormalization procedures are equivalent up to a finite renormalization (cf. Refs. 42 and 34). Today, theories are classified as ''renormalizable'' or ''unrenormalizable'' according to whether the number of renormalizable constants is finite or infinite, respectively.

Some model theories in less than four space–time dimensions considered in constructive field theory belong to a special subclass of renormalizable theories called ''super renormalizable,'' for which the renormalization process can be carried out without using perturbation theory.[32,33,35,36] For these theories, the renormalized perturbation series can be shown to be Borel summable to the exact nonperturbative solution. A nice summary of these developments was given by Glimm and Jaffe.[35] On the other hand, constructive models of the Gross–Neveu type are renormalizable but not super renormalizable (see Ref. 33).

Feldman *et al.*[45] have studied the mathematical foundations of quantum electrodynamics from the perturbative point of view (see also Rosen in Ref. 33, p. 201). Here, a renormalized formal

power series (renormalized tree expansion) is obtained for a measure on the space of fields within the Euclidean formulation of QED. (The tree expansion method is an outgrowth of Wilson's[46] renormalization group approach as distilled by Gallavotti[41] and co-workers.) It is then shown that QED in four (Euclidean) dimensions is locally Borel summable. Their work is truly remarkable and represents the first (formal) proof that (Euclidean) quantum electrodynamics can be renormalized using gauge invariant counterterms. However, in general, it is a nontrivial problem to return from the Euclidean regime to Minkowski space. The return trip requires application of the Osterwalder–Schrader reconstruction theorem (see Ref. 32). This theorem places conditions on the Euclidean Green's functions which guarantee analytic continuation back to the real-time vacuum expectation values. When these conditions are fulfilled, the Lehmann, Symanzik, and Zimmermann[22,23,32] reduction formulas may then be used to obtain the S-matrix. For technical reasons, they were not able to directly apply the Osterwalder–Schrader theorem. They could still get back to QED in Minkowski space–time by following the methods of Hepp[44] and Lowenstein and Speer.[47] However, nothing could be said about the convergence properties of their series.

B. Purpose

It is clear that Dyson's use of time ordering was the fundamental conceptual tool which allowed him to relate the Feynman and Schwinger–Tomonaga theories. This tool has now become a natural part of almost every branch of physics and is even used in parts of engineering. Its importance to the foundations of quantum field theory led Segal[48] to suggest that the identification of mathematical meaning for Feynman's time-ordered operator calculus is one of the major problems. A number of investigators have attempted to solve this problem. Miranker and Weiss[49] showed how the Feynman ordering process could be done formally using the theory of Banach algebras. Nelson[50] used Banach algebras to developed a theory of ''operants'' as an alternate (formal) approach. Araki,[51] motivated by the work of Fujiwara, used Banach algebras to develop yet another formal approach. (Fujiwara[52] had earlier suggested that the Feynman program could be implemented if one used a sheet of unit operators at every point except at time t, where the true operator should be placed.) Maslov[53] used the idea of a T-product to formally order operators and developed an operational theory. Another important approach to this problem via the idea of an index may be found in the works of Johnson and Lapidus,[54–56] see also Johnson, Lapidus, and DeFacio.[57]

This paper is part of a new investigation into the physical and mathematical foundations of relativistic quantum theory. Our overall goal is to construct a self-consistent relativistic quantum theory of particles and fields. For this paper, we have two specific objectives. Our first (and major) objective is to construct a physically simple and computationally useful representation theory for the Feynman time-ordered operator calculus.

A correct formulation and representation theory for the Feynman time-ordered operator calculus should at least have the following desirable features:

(1) It should provide a transparent generalization of current analytic methods without sacrificing the physically intuitive and computationally useful ideas of Feynman.
(2) It should provide a clear approach to some of the mathematical problems of relativistic quantum theory.
(3) It should explain the connection with path integrals.

In the course of his analysis, unification, and simplification of the Feynman–Schwinger–Tomonaga theory, Dyson made two important suggestions (conjectures). The first conjecture concerned the divergences in QED, while the second was concerned with the convergence of the renormalized perturbation series. In addressing the problem of divergences, Dyson conjectured that they may be due to an idealized conception of measurability resulting from the infinitely precise knowledge of the space–time positions of particles (implied by our Hamiltonian formula-

tion) which leads to a violation of the Heisenberg uncertainty principle. This point of view can be traced directly to the Bohr–Rosenfeld theory of measurability for field operators and, according to Schweber,[6] is an outgrowth of Dyson's discussions with Oppenheimer.

In addressing the renormalized S-matrix,[16] Dyson suggested that it might be more reasonable to expect the expansion to be asymptotic rather than convergent and gave physical arguments to support his claim. The lack of a clear mathematical framework made it impossible to formulate and investigate his suggestions.

Schweber[6] notes that Dyson made two other well-known conjectures. The ''overlapping divergences'' conjecture was proved by Salam,[58] Ward,[59] Mills and Yang,[60] and Hepp.[61] Dyson's conjecture that a certain Feynman integral converges, necessary for showing that the ultraviolet divergences cancel to all orders, was proved by Weinberg.[62]

Our second objective is to provide proofs of the above two conjectures under general conditions that should apply to any formulation of quantum field theory which does not abandon Hamiltonian generators for unitary solution operators. The proof of the first conjecture is, to some extent expected, and is a partial vindication of our belief in the consistency of quantum electrodynamics in the sense that the ultraviolet problem is caused by an effect that is basically ''simple.'' Such a result is partly anticipated since the effect can be made to disappear via appropriate cutoffs. We also identify (special) conditions under which the renormalized perturbation series may actually converge. A proof of the above-mentioned conjectures is implicit in, and is one of the major achievements of, constructive field theory for the models studied. In fact, these theories verify a stronger version of the second conjecture since, as noted earlier, the renormalized perturbation series is summable to the true solution.

The work in this paper is both a generalization and simplification of earlier work[63–65] that is easier and requires the weakest known conditions. We construct a new representation Hilbert space and von Neumann algebra for the Feynman (time-ordered) operator calculus. In order to make the theory applicable to other areas, we develop it using semigroups of contractions and the Riemann integral. A contraction semigroup on a Hilbert space $\mathcal{H}$ can always be extended to a unitary group on a larger space $\mathcal{H}'$. Thus, for quantum theory we may replace the semigroups by unitary groups and assume that our space is $\mathcal{H}'$ without any loss in understanding.

The Riemann integral can be easily replaced by the operator-valued Riemann-complete integral of Henstock[66] and Kurzweil,[67] which generalizes the Bochner and Pettis integrals (see Gill[63]). This integral is easier to understand (and learn) compared to the Lebesgue or Bochner integrals, and provides useful variants of the same theorems that have made those integrals so important. Furthermore, it arises from a simple (transparent) generalization of the Riemann integral that was taught in elementary calculus. Its usefulness in the construction of Feynman path integrals was first shown by Henstock,[68] and has been further explored in the recent book by Muldowney.[69]

In Sec. I D we provide a brief review of the necessary operator theory in order to make the paper self-contained. In Sec. II we construct an infinite tensor product Hilbert space and define what we mean by time ordering. In Sec. III we construct time-ordered integrals and evolution operators and prove that they have the expected properties. In Sec. IV we define what is meant by the phase ''asymptotic in the sense of Poincaré'' for operators, and use it to prove Dyson's second conjecture for contraction semigroups. We then discuss conditions under which the perturbation series may be expected to converge.

In Sec. V we take a photograph of a track left by an elementary particle in a bubble chamber as a prototype to conduct a physical analysis of what is actually known from experiment. This approach is used to rederive our time-ordered evolution operator as the limit of a probabilistic sum over paths. We use it to briefly discuss our theory in relationship to the Feynman path integral, and show that it provides a general and natural definition for the path integral that is independent of measure theory and the space of continuous paths.

The results from Sec. V are applied to the S-matrix expansion in Sec. VI to provide a formulation and proof of Dyson's first conjecture. In particular, we show that, within our formulation, the assumption of precise time information over a particle's trajectory introduces an infinite amount of energy into the system at each point in time. We use Dyson's original notation partly for

reasons of nostalgia, but also to point out what we are not able to explain within our framework. Also, since all renormalization procedures are equivalent, there is no loss.

C. Operator theory

In this section we establish notation and quote some results from operator theory used in the paper. Let $\mathcal{H}$ denote a separable Hilbert space over **C** (complex numbers), $\mathbf{B}(\mathcal{H})$ the set of bounded linear operators, and $\mathbf{C}(\mathcal{H})$ the set of closed densely defined linear operators on $\mathcal{H}$.

Definition 1.0: A family of bounded linear operators $\{U(t,0),\, 0\leqslant t<\infty\}$ defined on $\mathcal{H}$ is a *strongly continuous semigroup (or C_0-semigroup)* if

(1) $U(0,0)=I$, (2) $U(t+s,0)=U(t,0)U(s,0)$, and (3) $\lim_{t\to 0} U(t,0)\varphi=\varphi, \forall\, \varphi\in\mathcal{H}$.

$U(t,0)$ is a contraction semigroup in case $\|U(t,0)\|\leqslant 1$. If we replace (2) by (2′) $U(t,\tau)=U(t,s)U(s,\tau)$, $0\leqslant\tau\leqslant s\leqslant t<\infty$, then we call $U(t,\tau)$ a *strongly continuous evolution family*.

Definition 1.2: A densely defined operator H is said to be *maximal dissipative* if $\mathrm{Re}\langle H\varphi,\varphi\rangle\leqslant 0$, $\forall\,\varphi\in D(H)$, and $\mathrm{Ran}\,(I-H)=\mathcal{H}$ [range of $(I-H)$].

The following results may be found in Goldstein[70] or Pazy.[71]

Theorem 1.2: *Let $U(t,0)$ be a C_0-semigroup of contraction operators on $\mathcal{H}$. Then*

(1) $H\varphi=\lim_{t\to 0}(U(t,0)\varphi-\varphi)/t$ *exists for* φ *in a dense set.*
(2) $R(z,H)=(zI-H)^{-1}$ *exists for* $z>0$ *and* $\|R(z,H)\|\leqslant 1/z$.

Theorem 1.3: *Suppose H is a maximal dissipative operator. Then H generates a unique C_0-semigroup $\{U(t,0)|0\leqslant t<\infty\}$ of contraction operators on $\mathcal{H}$.*

Theorem 1.4: *If H is densely defined with both H and H* dissipative, then H is maximal dissipative.*

II. INFINITE TENSOR PRODUCT VON NEUMANN ALGEBRAS

In this section we define time-ordered operators and construct the representation space which will be used in Sec. III to develop our theory of time-ordered integrals and evolution operators. Much of the material in this section was developed by von Neumann[72] for other purposes, but is perfectly suited for our program. In order to see how natural our approach is, let $\mathcal{H}_\otimes=\hat{\otimes}_s\mathcal{H}(s)$denote the infinite tensor product Hilbert space of von Neumann, where $\mathcal{H}(s)=\mathcal{H}$ for $s\in[a,b]$ and $\hat{\otimes}$ denotes closure. If $\mathbf{B}(\mathcal{H}_\otimes)$ is the set of bounded operators on $\mathcal{H}_\otimes$, define $\mathbf{B}(\mathcal{H}(t))\subset\mathbf{B}(\mathcal{H}_\otimes)$ by

$$\mathbf{B}(\mathcal{H}(t))=\{\mathbf{H}(t)|\mathbf{H}(t)=\hat{\otimes}_{a\geqslant s>t}I_s\otimes H(t)\otimes(\otimes_{t>s\geqslant -a}I_s),\forall H(t)\in\mathbf{B}(\mathcal{H})\},\tag{2.1a}$$

where I_s denotes an identity operator, and let $\mathbf{B}^{\#}(\mathcal{H}_\otimes)$ be the uniform closure of the von Neumann algebra generated by the family $\{\mathbf{B}(\mathcal{H}(t)),|t\in E\}$. If the family $\{H(t)|t\in E\}$ is in $\mathbf{B}(\mathcal{H})$, then the corresponding operators $\{\mathbf{H}(t)|t\in E\}\in\mathbf{B}^{\#}(\mathcal{H}_\otimes)$commute when acting at different times: $t\neq s\Rightarrow$

$$\mathbf{H}(t)\mathbf{H}(s)=\mathbf{H}(s)\mathbf{H}(t).\tag{2.1b}$$

Definition 2.0: The smallest space $\mathcal{FD}_\otimes\subseteq\mathcal{H}_\otimes$ which leaves the family $\{\mathbf{H}(t)|t\in E\}$ invariant is called a Feynman–Dyson space for the family. (This is the film.)

We need the following results about operators on $\mathcal{H}_\otimes$.

Theorem 2.1: [von Neumann (Ref. 72)] *The mapping $\mathbf{T}^t_\theta$: $\mathbf{B}(\mathcal{H})\to\mathbf{B}(\mathcal{H}(t))$ is an isometric isomorphism of algebras.* (*We call $\mathbf{T}^t_\theta$ the time-ordering morphism.*)

Definition 2.2: The vector $\Phi=\otimes_s\phi_s$ is said to be equivalent to $\Psi=\otimes_s\psi_s$ and we write $\Phi\approx\Psi$, if and only if

$$\sum_s |\langle\phi_s,\psi_s\rangle_s-1|<\infty.\tag{2.2}$$

Here, $\langle\cdot,\cdot\rangle_s$ is the inner product on $\mathcal{H}(s)$, and it is understood that the sum is meaningful only if at most a countable number of terms are different from zero.

Let $\mathcal{H}_\Phi=\mathrm{cl}\{\Psi|\Psi=\Sigma_{i=1}^n\Psi_i,\Psi_i\approx\Phi,n\in\mathbf{N}\}$ (closure), $\Phi\in\mathcal{H}_\otimes$, and let $\mathbf{P}_\Phi$ denote the projection from $\mathcal{H}_\otimes$ onto $\mathcal{H}_\Phi$. The space $\mathcal{H}_\Phi$ is known as the *incomplete tensor product generated by* Φ. The details on incomplete tensor product spaces as well as proofs of the next two theorems may be found in von Neumann.[72]

Theorem 2.3: *The above-defined relation is an equivalence relation on* $\mathcal{H}_\otimes$ *and*

(1) *if* Ψ *is not equivalent to* Φ, *then* $\mathcal{H}_\Phi\cap\mathcal{H}_\Psi=\{0\}$ *(i.e.,* $\mathcal{H}_\Phi\perp\mathcal{H}_\Psi$*)*;
(2) *if* $\psi_s\neq\phi_s$ *occurs for at most a finite number of* s, *then* $\Phi=\otimes_s\phi_s\approx\Psi=\otimes_s\psi_s$;
(3) *if* $\mathbf{T}\in\mathbf{B}^\#(\mathcal{H}_\otimes)$, *then* $\mathbf{P}_\Phi\mathbf{T}=\mathbf{T}\mathbf{P}_\Phi$ *so that* $\mathbf{P}_\Phi\mathbf{T}\in\mathbf{B}^\#(\mathcal{H}_\Phi)$.

The second condition in Theorem 2.3 implies that, for each fixed $\Phi=\otimes_s\phi_s$, there is an uncountable number of $\Psi=\otimes_s\psi_s$ equivalent to Φ, while the third condition implies that every bounded linear operator on $\mathcal{H}_\otimes$ restricts to a bounded linear operator on $\mathcal{H}_\Phi$ for each Φ.

We can now construct our film $\mathcal{FD}_\otimes$. Let $\{e^i|\mathbf{i}\in\mathbf{N}\}$ denote an arbitrary ordered complete orthonormal basis (c.o.b) for $\mathcal{H}$. For each $t\in\mathbf{E},\mathbf{i}\in\mathbf{N}$, let $e_t^i=e^i$, $E^i=\otimes_{t\in E}e_t^i$, and define $\mathcal{FD}^i$ to be the incomplete tensor product generated by the vector E^i. Setting $\mathcal{FD}_\otimes=\oplus_{i=1}^\infty\mathcal{FD}^i$, it will be clear in Sec. III that $\mathcal{FD}_\otimes$ is (one of an infinite number of) the natural representation space(s) for Feynman's time-ordered operator theory. It should be noted that $\mathcal{FD}_\otimes$ is a nonseparable Hilbert (space) bundle over $[a,b]$. However, it is not hard to see that each fiber is isomorphic to $\mathcal{H}$.

In order to facilitate the proofs in Sec. III, we need an explicit basis for each $\mathcal{FD}^i$. To construct it, fix i and let f^i denote the set of all functions $\{j(t)|t\in E\}$ mapping $E\to\mathbf{N}\cup\{0\}$ such that $j(t)$ is zero for all but a finite number of t. Let $I(j)=\{j(t)|t\in E\}$ denote the function j and set $E_{I(j)}^i=\otimes_{t\in E}e_{t,j(t)}^i$ with $e_{t,0}^i=e^i$ and $j(t)=k\Rightarrow e_{t,k}^i=e^k$.

Theorem 2.4: *The set* $\{E_{I(j)}^i|I(j)\in f^i\}$ *is a (c.o.b) for each* $\mathcal{FD}^i$.

For each $\Phi^i,\Psi^i\in F^i$, set $a_{I(j)}^i=\langle\Phi^i,E_{I(j)}^i\rangle$, $b_{I(j)}^i=\langle\Psi^i,E_{I(j)}^i\rangle$, so that

$$\Phi^i=\sum_{I(j)\in F^i}a_{I(j)}^iE_{I(j)}^i,\Psi^i=\sum_{I(j)\in F^i}b_{I(j)}^iE_{I(j)}^i\ \text{ and }\ \langle\Phi^i,\Psi^i\rangle=\sum_{I(j)\in F^i}a_{I(j)}^i\overline{b_{I(k)}^i}\langle E_{I(j)}^i,E_{I(k)}^i\rangle.$$

Now,

$$\langle E_{I(j)}^i,E_{I(k)}^i\rangle=\prod_t\langle e_{t,I(j)}^i,e_{t,I(k)}^i\rangle=0,$$

unless $j(t)=k(t)$, $\forall t\in E$, so that

$$\langle\Phi^i,\Psi^i\rangle=\sum_{I(j)\in F^i}a_{I(j)}^i\overline{b_{I(j)}^i}.$$

We need the notion of an exchange operator. (Theorem 2.6 is in Ref. 63.)

Definition 2.5: An exchange operator $\mathbf{E}[t,t']$ *is a linear map defined for pairs* $t,t'\in[a,b]$ *such that*:

(1) $\mathbf{E}[t,t']:\mathbf{B}(\mathcal{H}(t))\to\mathbf{B}(\mathcal{H}(t'))$ *onto,*
(2) $\mathbf{E}[t,s]\mathbf{E}[s,t']=\mathbf{E}[t,t']$,
(3) $\mathbf{E}[t,t']\mathbf{E}[t',t]=1$,
(4) *if* $s\neq t,t'$, *then* $\mathbf{E}[t,t']\mathbf{H}(s)=\mathbf{H}(s),\forall\mathbf{H}(s)\in\mathbf{B}(\mathcal{H}(s))$.

Theorem 2.6:

(1) $\mathbf{E}[\cdot,\cdot]$ exists and is a Banach algebra isomorphism on $\mathbf{B}^\#(\mathcal{H}_\otimes)$.
(2) $\mathbf{E}[s,s']\mathbf{E}[t,t']=\mathbf{E}[t,t']\mathbf{E}[s,s']$ for distinct pairs (s,s') and (t,t') in E.

III. TIME-ORDERED INTEGRALS

In this section we construct time-ordered integrals and evolution operators for a fixed family $\{H(t)|t\in E\}\subset \mathbf{C}(\mathcal{H})$ of generators of contraction semigroups on $\mathcal{H}$. We assume that, for each t, $H(t)$ and $H^*(t)$ are dissipative (so that the family is maximal dissipative for each t). In the following discussion we adopt the notation: (e.o.v.): ''except for at most one s value;'' (e.f.n.v.) ''except for an at most finite number of s values;'' and (a.s.c.): ''almost surely and the exceptional set is at most countable.''

The s value referred to is in our fixed interval E.

For the given family $\{H(t)|t\in E\}\subset \mathbf{C}(\mathcal{H})$, define $\exp\{\tau\mathbf{H}(t)\}$ by

$$\exp\{\tau\mathbf{H}(t)\}=\hat{\otimes}_{s\in[b,t)} I_s\otimes(\exp\{\tau H(t)\})\otimes(\otimes_{s\in(t,a]} I_s), \tag{3.1}$$

and set $\mathbf{H}_z(t)=z\mathbf{H}(t)\mathbf{R}(z,\mathbf{H}(t))$, $z>0$, where $\mathbf{R}(z,\mathbf{H}(t))=(zI_\otimes-\mathbf{H}(t))^{-1}$ is the resolvent of $\mathbf{H}(t)$. It is known that $H_z(t)$ generates a uniformly bounded contraction semigroup and $\lim_{z\to\infty}H_z(t)\phi=H(t)\phi$ for $\phi\in D(H(t))$.

Theorem 3.1: *Suppose for each t, $\{H(t)|t\in E\}\subset \mathbf{C}(\mathcal{H})$ generates a strongly continuous contraction semigroup on $\mathcal{H}$. Then $\mathbf{H}(t)\mathbf{H}_z(t)\Phi=\mathbf{H}_z(t)\mathbf{H}(t)\Phi, \Phi\in D$, (where D denotes the domain of the family $\{\mathbf{H}(t)|t\in E\}$), and*

(1) *The family $\{\mathbf{H}_z(t)|t\in E\}$ generates a uniformly bounded contraction semigroup on $\mathcal{FD}_\otimes$ for each t and $\lim_{z\to\infty}\mathbf{H}_z(t)\Phi=\mathbf{H}(t)\Phi, \Phi\in D$.*
(2) *The family $\{\mathbf{H}(t)|t\in E\}\subset \mathbf{C}(\mathcal{H}_\otimes)$ generates a strongly continuous contraction semigroup on $\mathcal{FD}_\otimes$ (so that $\{\mathbf{H}(t)|t\in E\}\subset \mathbf{C}(\mathcal{FD}_\otimes)$).*

Proof: The proof of (1) is standard. Note that $\mathbf{H}_z(t)=z^2\mathbf{R}(z,\mathbf{H}(t))-zI_\otimes$ and $\|\mathbf{R}(z,\mathbf{H}(t))\|_\otimes \leqslant 1/z$, so $\|\exp\{s\mathbf{H}_z(t)\}\|_\otimes=\|\exp\{-sz\}\exp\{sz^2\mathbf{R}(z,\mathbf{H}(t))\}\|_\otimes\leqslant 1$. Now recall that $\lim_{z\to\infty}\{z\mathbf{R}(z,\mathbf{H}(t))\Phi\}=\Phi, \Phi\in\mathcal{FD}_\otimes$, so that, for $\Phi\in D$, we have that $\lim_{z\to\infty}\mathbf{H}_z(t)\Phi=\lim_{z\to\infty}\{z\mathbf{H}(t)\mathbf{R}(z,\mathbf{H}(t))\Phi\}=\lim_{z\to\infty}\{z\mathbf{R}(z,\mathbf{H}(t))\}\mathbf{H}(t)\Phi=\mathbf{H}(t)\Phi$.

To prove (2), first recall (Gill[73]) that a tensor product norm, $\|\cdot\|_\otimes$, is uniform if, for $\hat{\otimes}_{s\in E}T_s\in\mathbf{B}(\mathcal{H}_\otimes)$,

$$\|\hat{\otimes}_{s\in E} T_s\|_\otimes\leqslant\prod_{s\in E}\|T_s\|. \tag{3.2}$$

Using the uniform property of the (Hilbert space) tensor product norm, it is easy to see that $\exp\{\tau\mathbf{H}(t)\}$ is a contraction semigroup.

To prove strong continuity, we need to identify a dense core for the family $\{\mathbf{H}(t)|t\in E\}\subset\mathbf{C}(\mathcal{FD}_\otimes)$. Let D_1 denote the ordered tensor product of the domains of the family $\{H(t)|t\in E\}\subset\mathbf{C}(\mathcal{H})$, (so that $D_1\subset D$)

$$D_1=\otimes_{s\in E} D(H(s))=\left\{\sum_{i=1}^{n}\otimes_s\varphi_s^i\,|\,\varphi_s^i\in D(H(s)), s\in E\right\}. \tag{3.3}$$

It is clear that D_1 is a dense core in $\mathcal{H}_\otimes$, so $D_0=D_1\cap\mathcal{FD}_\otimes$ is a dense core in $\mathcal{FD}_\otimes$. Using our standard basis, if

$$\Phi,\Psi\in D_0,\quad \Phi=\sum_i\sum_{I(j)}a^i_{I(j)}E^i_{I(j)},\quad \Psi=\sum_i\sum_{I(k)}b^i_{I(k)}E^i_{I(k)};$$

then, since $(\exp\{\tau\mathbf{H}(t)\}-I_\otimes)$ is invariant on $\mathcal{FD}^i$ and $I_\otimes$ is the identity on $\mathcal{FD}_\otimes$, we have

$$\langle(\exp\{\tau\mathbf{H}(t)\}-I_\otimes)\Phi,\Psi\rangle=\sum_i\sum_{I(j)}\sum_{I(k)}a^i_{I(j)}\overline{b^i_{I(k)}}\langle(\exp\{\tau\mathbf{H}(t)\}-I_\otimes)E^i_{I(j)},E^i_{I(k)}\rangle, \tag{3.4a}$$

and

$$\langle(\exp\{\tau\mathbf{H}(t)\}-I_{\otimes})E^i_{I(j)},E^i_{I(k)}\rangle=\prod_{s\neq t}\langle e^i_{s,j(s)},e^i_{s,k(s)}\rangle\langle(\exp\{\tau H(t)\}-I)e^i_{t,j(t)},e^i_{t,k(t)}\rangle$$

$$=\langle(\exp\{\tau H(t)\}-I)e^i_{t,j(t)},e^i_{t,j(t)}\rangle(\text{e.o.v.})$$

$$=\langle(\exp\{\tau H(t)\}-I)e^i,e^i\rangle(\text{e.f.n.v.}), \tag{3.4b}$$

$$\Rightarrow\langle(\exp\{\tau\mathbf{H}(t)\}-I_{\otimes})\Phi,\Psi\rangle$$

$$=\sum_i\sum_{I(j)}a^i_{I(j)}\overline{b^i_{I(j)}}\langle(\exp\{\tau H(t)\}-I)e^i,e^i\rangle(\text{a.s.c.}). \tag{3.4c}$$

Since all sums are finite, we have

$$\lim_{\tau\to 0}\langle(\exp\{\tau\mathbf{H}(t)\}-I_{\otimes})\Phi,\Psi\rangle=\sum_i\sum_{I(j)}a^i_{I(j)}\overline{b^i_{I(j)}}\left\{\lim_{\tau\to 0}\langle(\exp\{\tau H(t)\}-I)e^i,e^i\rangle\right\}=0(\text{a.s.c.}). \tag{3.4d}$$

The if and only if part is now clear. Since $\exp\{\tau\mathbf{H}(t)\}$ is bounded on $\mathcal{H}_{\otimes}$ and the above-mentioned limit exists on D_0 (which is dense in $\mathcal{FD}_{\otimes}$), we see that $\exp\{\tau\mathbf{H}(t)\}$ extends to a contraction semigroup on $\mathcal{FD}_{\otimes}$. Now use the fact that, if a bounded semigroup converges weakly to the identity, it converges strongly (see Pazy,[71] p. 44).

We now assume that the family $\{H(t)|t\in E\}\subset\mathbf{C}(\mathcal{H})$ has a weak Riemann integral $Q=\int_a^b H(t)\mathrm{d}t\in\mathbf{C}(\mathcal{H})$. It follows that the family $\{H_z(t)|t\in E\}\subset\mathbf{B}(\mathcal{H})$ also has a weak Riemann integral $Q_z=\int_a^b H_z(t)\mathrm{d}t\in\mathbf{B}(\mathcal{H})$. Let P_n be a sequence of partitions (of E) so that the mesh $\mu(P_n)\to 0$ as $n\to\infty$. Set

$$Q_{z,n}=\sum_{l=1}^{n}H_z(\overline{t_l})\Delta t_l,\quad Q_{z,m}=\sum_{q=1}^{m}H_z(\overline{s_q})\Delta s_q,\quad \mathbf{Q}_{z,n}=\sum_{l=1}^{n}\mathbf{H}_z(\overline{t_l})\Delta t_l,$$

$$\mathbf{Q}_{z,m}=\sum_{q=1}^{m}\mathbf{H}_z(\overline{s_q})\Delta s_q,\quad \text{and}\ \Delta Q_z=Q_{z,n}-Q_{z,m},\quad \Delta\mathbf{Q}_z=\mathbf{Q}_{z,n}-\mathbf{Q}_{z,m}$$

Let

$$\Phi,\Psi\in D_0;\quad \Phi=\sum_i^J\Phi^i=\sum_i^J\sum_{I(j)}^K a^i_{I(j)}E^i_{I(j)},\quad \Psi=\sum_i^L\Psi^i=\sum_i^L\sum_{I(k)}^M b^i_{I(k)}E^i_{I(k)}.$$

Then we have:

Theorem 3.2 (first fundamental theorem for time-ordered integrals):

$$\langle\Delta\mathbf{Q}_z\Phi,\Psi\rangle=\sum_i^J\sum_{I(j)}^K a^i_{I(j)}\overline{b^i_{I(j)}}\langle\Delta Q_z e^i,e^i\rangle(\text{a.s.c.}). \tag{3.5}$$

Note: The form of (3.5) is quite general since $\Delta\mathbf{Q}_z$ can be replaced by other terms which also give a true relationship. For example, it is easy to show that the family $\{\mathbf{H}_z(t)|t\in E\}$ is weakly measurable, weakly continuous, weakly differentiable, etc., if and only if the same is true for the family $\{H_z(t)|t\in E\}$.

Proof:

$$\langle\Delta\mathbf{Q}_z\Phi,\Psi\rangle=\sum_i\sum_{I(j)}\sum_{I(k)}a^i_{I(j)}\overline{b^i_{I(k)}}\langle\Delta\mathbf{Q}_z E^i_{I(j)},E^i_{I(k)}\rangle$$

(we omit the upper limit). Now

$$\langle \Delta \mathbf{Q}_z E^i_{I(j)}, E^i_{I(k)}\rangle = \sum_{l=1}^{n} \Delta t_l \langle \mathbf{H}_z(\overline{t_l}) E^i_{I(j)}, E^i_{I(k)}\rangle - \sum_{q=1}^{m} \Delta s_q \langle \mathbf{H}_z(\overline{s_q}) E^i_{I(j)}, E^i_{I(k)}\rangle$$

$$= \sum_{l=1}^{n} \Delta t_l \prod_{t\neq \overline{t_l}} \langle e^i_{t,j(t)}, e^i_{t,k(t)}\rangle \langle H_z(\overline{t_l}) e^i_{\overline{t_l}, j(\overline{t_l})}, e^i_{\overline{t_l}, k(\overline{t_l})}\rangle$$

$$- \sum_{q=1}^{m} \Delta s_q \prod_{t\neq \overline{s_q}} \langle e^i_{t,j(t)}, e^i_{t,k(t)}\rangle \langle H_z(\overline{s_q}) e^i_{\overline{s_q}, j(\overline{s_q})}, e^i_{\overline{s_q}, k(\overline{s_q})}\rangle$$

$$= \sum_{l=1}^{n} \Delta t_l \langle H_z(\overline{t_l}) e^i_{\overline{t_l}, j(\overline{t_l})}, e^i_{\overline{t_l}, j(\overline{t_l})}\rangle - \sum_{q=1}^{m} \Delta s_q \langle H_z(\overline{s_q}) e^i_{\overline{s_q}, j(\overline{s_q})}, e^i_{\overline{s_q}, j(\overline{s_q})}\rangle$$

$$= \langle \Delta Q_z e^i, e^i\rangle \text{(e.f.n.v.)}.$$

This result leads to (3.5).

Theorem 3.3 (second fundamental theorem for time-ordered integrals): *If the family* $\{H_z(t)|t\in E\}$ *has a weak Riemann (Riemann-complete) integral, then*

(1) *the family* $\{\mathbf{H}_z(t)|t\in E\}\subset \mathbf{B}^{\#}(\mathcal{FD}_{\otimes})$ *has a weak Riemann (Riemann-complete) integral.*

(2) *If, in addition, we assume that for each* Φ *with* $\|\Phi\|=1$,

$$\sup_{t\in E}\left| \int_a^t (\|\mathbf{H}_z(s)\Phi\|^2 - |\langle \mathbf{H}_z(s)\Phi,\Phi\rangle|^2)\mathrm{d}s\right| < \infty, \tag{3.6}$$

then the family $\{\mathbf{H}_z(t)|t\in E\}$ *has a strong integral* $\mathbf{Q}_z[t,a]=\int_a^t \mathbf{H}_z(s)\mathrm{d}s$ *which generates a uniformly continuous contraction semigroup on* $\mathcal{FD}_{\otimes}$.

Notes:

(1) It is sufficient that $\sup_{t\in E}|\int_a^t(\|\mathbf{H}_z(s)E^i\|^2-|\langle \mathbf{H}_z(s)E^i,E^i\rangle|^2)\mathrm{d}s|<\infty$ for each i.
(2) Condition (3.6) is satisfied if $\|\mathbf{H}_z(s)E^i\|^2$ is Lebesgue integrable for each i. In this case, we replace the Riemann integral by the Riemann-complete integral.
(3) In general, the family $\{\mathbf{H}_z(t)|t\in E\}$ need not be a Bochner or Pettis integral, as it is not required that $\|\mathbf{H}_z(t)\Phi\|, \langle \mathbf{H}_z(t)\Phi,\Phi\rangle$ be (square) Lebesgue integrable. It is possible that $\int_a^b\|\mathbf{H}_z(t)\Phi\|^2\mathrm{d}t=\infty$ and $\int_a^b|\langle \mathbf{H}_z(t)\Phi,\Phi\rangle|^2\mathrm{d}t=\infty$, while (3.6) is zero.

For example, let $f(t)$ be any nonabsolutely (square) integrable function and set $\mathbf{H}_z(t)=f(t)I_{\otimes}$. Then the above-mentioned possibility holds while $\int_a^t(\|\mathbf{H}_z(s)\Phi\|^2-|\langle \mathbf{H}_z(s)\Phi,\Phi\rangle|^2)\mathrm{d}s\equiv 0$ for all t in E.

Proof: The proof of (1) is easy and follows from (3.5). To see that (3.6) makes $\mathbf{Q}_z$ a strong limit, let $\Phi\in D_0$. Then

$$\langle \mathbf{Q}_{z,n}\Phi, \mathbf{Q}_{z,n}\Phi\rangle = \sum_i^J \sum_{I(j),I(h)}^K a^i_{I(j)}\overline{a}^i_{I(h)}\left(\sum_{k,m}^n \Delta t_k \Delta t_m \langle H_z(s_k)E^i_{I(j)}, H_z(s_m)E^i_{I(h)}\rangle\right)$$

$$= \sum_i^J \sum_{I(j)}^K |a^i_{I(j)}|^2\left(\sum_{k\neq m}^n \Delta t_k\Delta t_m \langle H_z(s_k)e^i_{s_k,j(s_k)}, e^i_{s_k,j(s_k)}\rangle \right.$$

$$\left. \times \langle e^i_{s_m,j(s_m)}, H_z(s_m)e^i_{s_m,j(s_k)}\rangle\right)$$

$$+ \sum_i^J \sum_{I(j)}^K |a^i_{I(j)}|^2\left(\sum_k^n (\Delta t_k)^2 \langle H_z(s_k)e^i_{s_k,j(s_k)}, H_z(s_k)e^i_{s_k,j(s_k)}\rangle\right). \tag{3.7}$$

This can be rewritten as

$$\|\mathbf{Q}_{z,n}\Phi\|_{\otimes}^2=\sum_i^J\sum_{I(j)}^K|a^i_{I(j)}|^2\left\{|\langle Q_{z,n}e^i,e^i\rangle|^2+\sum_k^n(\Delta t_k)^2(\|H_z(s_k)e^i\|^2-|\langle H_z(s_k)e^i,e^i\rangle|^2)\right\}(\text{a.s.c.}). \tag{3.8}$$

The last term can be written as

$$\left|\sum_{k,}^n(\Delta t_k)^2(\|H_z(s_k)e^i\|^2-|\langle H_z(s_k)e^i,e^i\rangle|^2)\right|\leqslant\mu_n M\sup_{t\in E}\left|\int_a^t(\|H_z(s)e^i\|^2-|\langle H_z(s)e^i,e^i\rangle|^2)\mathrm{ds}\right|,$$

where M is a constant and μ_n is the mesh of P_n, with $\mu_n\to 0$ as $n\to\infty$. Now note that $\|\mathbf{H}_z(t)E^i\|_{\otimes}=\|H_z(t)e^i\|$ and $\langle\mathbf{H}_z(t)E^i,E^i\rangle=\langle H_z(t)e^i,e^i\rangle$ (e.o.v) so that

$$\sup_{t\in E}\left|\int_a^t(\|H_z(s)e^i\|^2-|\langle H_z(s)e^i,e^i\rangle|^2)\mathrm{ds}\right|$$

$$=\sup_{t\in E}\left|\int_a^t(\|\mathbf{H}_z(s)E^i\|^2-|\langle\mathbf{H}_z(s)E^i,E^i\rangle|^2)\mathrm{ds}\right|(\text{a.s.c.}).$$

We can now use (3.6) to get

$$\|\mathbf{Q}_{z,n}\Phi\|_{\otimes}^2\leqslant\sum_i^J\sum_{I(j)}^K|a^i_{I(j)}|^2\left\{|\langle Q_{z,n}e^i,e^i\rangle|^2+\mu_n M\sup_t\left|\int_a^t(\|\mathbf{H}_z(t)E^i\|^2-|\langle\mathbf{H}_z(t)E^i,E^i\rangle|^2)\mathrm{ds}\right|.\right\}$$

$$(\text{a.s.c.}).$$

Thus, $\mathbf{Q}_{z,n}\Phi$ converges strongly to $\mathbf{Q}_z\Phi$ on D_0 and hence has a strong limit on $\mathcal{FD}_{\otimes}$. To show that $\mathbf{Q}_z[t,a]$ generates a uniformly continuous contraction, it suffices to show that $Q_z[t,a]$ and $Q_z^*[t,a]$ are dissipative. Let Φ be in D_0, then

$$\langle\mathbf{Q}_z[t,a]\Phi,\Phi\rangle=\sum_i^J\sum_{I(j)}^K a^i_{I(j)}\overline{b^i_{I(j)}}\langle Q_ze^i,e^i\rangle(\text{a.s.c.})$$

and, since $Q_{z,n}[t,a]$ is disspative for each n, we have

$$\langle Q_z[t,a]e^i,e^i\rangle=\langle Q_{z,n}[t,a]e^i,e^i\rangle+\langle[Q_z[t,a]-Q_{z,n}[t,a]]e^i,e^i\rangle\leqslant\langle[Q_z[t,a]-Q_{z,n}[t,a]]e^i,e^i\rangle.$$

Letting $n\to\infty$, we get $\langle Q_z[t,a]e^i,e^i\rangle\leqslant 0$, so that $\langle\mathbf{Q}_z[t,a]\Phi,\Phi\rangle\leqslant 0$. The same argument applies to $\mathbf{Q}_z^*[t,a]$. Since $\mathbf{Q}_z[t,a]$ is dissipative and densely defined, it has a (bounded) dissipative closure on $\mathcal{FD}_{\otimes}$.

It should be noted that the theorem is still true if we allow the approximating sums for condition (3.6) to diverge but at an order less than $\mu_n^{-1+\delta}$, $0<\delta<1$, that is,

$$\sup_t\left|\int_a^t(\|\mathbf{H}_z(t)E^i\|^2-|\langle\mathbf{H}_z(t)E^i,E^i\rangle|^2)\mathrm{ds}\right|=\infty,$$

with

$$\left|\sum_{k,}^n(\Delta t_k)^2(\|H_z(s_k)e^i\|^2-|\langle H_z(s_k)e^i,e^i\rangle|^2)\right|\leqslant M\mu_n^{\delta}.$$

We also note that

$$\|\mathbf{Q}_z[t,a]\Phi\|_{\otimes}^2=\sum_i^J\sum_{I(j)}^K|a^i_{I(j)}|^2|\langle Q_ze^i,e^i\rangle|^2(\text{a.s.c.}) \tag{3.9}$$

in either of the above cases. This representation makes it easy to prove the next theorem.

Theorem 3.4:

(1) $\mathbf{Q}_z[t,s]+\mathbf{Q}_z[s,a]=\mathbf{Q}_z[t,a]$(a.s.c.),
(2) $s-\lim_{h\to 0}(\mathbf{Q}_z[t+h,a]-\mathbf{Q}_z[t,a])/h=s-\lim_{h\to 0}(\mathbf{Q}_z[t+h,t])/h=\mathbf{H}_z(t)$(a.s.c.),
(3) $s-\lim_{h\to 0}\mathbf{Q}_z[t+h,t]=0$ (a.s.c.),
(4) $s-\lim_{h\to 0}\exp\{\tau\mathbf{Q}_z[t+h,t]\}=I_\otimes$ (a.s.c.), $\tau\geqslant 0$.

Proof: In each case, it suffices to prove the result for $\Phi\in D_0$. To prove (1), use

$$\|[\mathbf{Q}_z[t,s]+\mathbf{Q}_z[s,a]]\Phi\|_\otimes^2=\sum_i^J\sum_{I(j)}^K|a^i_{I(j)}|^2|\langle[Q_z[t,s]+Q_z[s,a]]e^i,e^i\rangle|^2\text{(a.s.c.)}$$
$$=\sum_i^J\sum_{I(j)}^K|a^i_{I(j)}|^2|\langle Q_z[t,a]e^i,e^i\rangle|^2=\|\mathbf{Q}_z[t,a]\Phi\|_\otimes^2\text{(a.s.c.)}.$$

To prove (2), use (1) to get $\mathbf{Q}_z[t+h,a]-\mathbf{Q}_z[t,a]=\mathbf{Q}_z[t+h,t]$(a.s.c.), so that

$$\lim_{h\to 0}\left\|\frac{\mathbf{Q}_z[t+h,t]}{h}\Phi\right\|_\otimes^2=\sum_i^J\sum_{I(j)}^K|a^i_{I(j)}|^2\lim_{h\to 0}\left|\left\langle\frac{Q_z[t+h,t]}{h}e^i,e^i\right\rangle\right|^2=\|\mathbf{H}_z(t)\Phi\|_\otimes^2\text{(a.s.c.)}.$$

The proof of (3) follows from (2), and the proof of (4) follows from (3).

Theorem 3.5: *Suppose that* $\lim_{z\to\infty}\langle Q_z[t,a]\phi,\psi\rangle=\langle Q[t,a]\phi,\psi\rangle$ *exists for* ϕ *in a dense set* $\forall\psi\in\mathcal{H}$ *(weak convergence). Then*:

(1) $Q[t,a]$ generates a strongly continuous contraction semigroup on $\mathcal{H}$,
(2) $\lim_{z\to\infty}\mathbf{Q}_z[t,a]\Phi=\mathbf{Q}[t,a]\Phi$ for $\Phi\in D_0$ and $\mathbf{Q}[t,a]$ is the generator of a strongly continuous contraction semigroup on $\mathcal{FD}_\otimes$,
(3) $\mathbf{Q}[t,s]+\mathbf{Q}[s,a]=\mathbf{Q}[t,a]$(a.s.c.),
(4) $\lim_{h\to 0}[(\mathbf{Q}[t+h,a]-\mathbf{Q}[t,a])/h]\Phi=\lim_{h\to 0}[(\mathbf{Q}[t+h,t])/h]\Phi=\mathbf{H}(t)\Phi$ (a.s.c.),
(5) $\lim_{h\to 0}\mathbf{Q}[t+h,t]\Phi=0$ (a.s.c.), and
(6) $\lim_{h\to 0}\exp\{\tau\mathbf{Q}[t+h,t]\}\Phi=\Phi$(a.s.c.), $\tau\geqslant 0$.

Proof: The proofs are easy. For (1), first note that $Q[t,a]$ is closable and use $\langle Q[t,a]\phi,\phi\rangle=\langle Q_z[t,a]\phi,\phi\rangle+\langle[Q[t,a]-Q_z[t,a]]\phi,\phi\rangle\leqslant\langle[Q[t,a]-Q_z[t,a]]\phi,\phi\rangle$ and let $z\to\infty$. Then do likewise for $\langle\phi,Q^*[t,a]\phi\rangle$ to get that $Q[t,a]$ is maximal dissipative. To prove (2), use (3.9) in the form

$$\|[\mathbf{Q}_z[t,a]-\mathbf{Q}_{z'}[t,a]]\Phi\|_\otimes^2=\sum_i^J\sum_{I(j))}^K|a^i_{I(j)}|^2|\langle[Q_z[t,a]-Q_{z'}[t,a]]e^i,e^i\rangle|^2\text{(a.s.c.)}.$$

This proves that $\mathbf{Q}_z[t,a]\overset{s}{\to}\mathbf{Q}[t,a]$. Since $\mathbf{Q}[t,a]$ is densely defined, it is closable. The same method as above shows that it is maximal dissipative. Proofs of the other results follow the methods of the previous theorem.

Since $\mathbf{Q}[t,a]$ and $\mathbf{Q}_z[t,a]$ generate contraction semigroups, set $\mathbf{U}[t,a]=\exp\{\mathbf{Q}[t,a]\}$, $\mathbf{U}_z[t,a]=\exp\{\mathbf{Q}_z[t,a]\}$, for $t\in E$. They are evolution operators and the following theorem is a slight modification of a result due to Hille and Phillips,[74] known as the second exponential formula.

Theorem 3.6: *If* $\mathbf{Q}'[t,a]=w\mathbf{Q}[t,a]$ *is the generator of a strongly continuous contraction semigroup, and* $\mathbf{U}^w[t,a]=\exp\{w\mathbf{Q}[t,a]\}$, *then, for each n and* $\Phi\in D[(\mathbf{Q}[t,a])^{n+1}]$, *we have (where w is a parameter)*

$$\mathbf{U}^w[t,a]\Phi=\left\{I_\otimes+\sum_{k=1}^{n}\frac{(w\mathbf{Q}[t,a])^n}{n!}+\frac{1}{n!}\int_0^w(w-\xi)^n\mathbf{Q}[t,a]^{n+1}\mathbf{U}^\xi[t,a]\mathrm{d}\xi\right\}\Phi. \tag{3.10}$$

Proof: The proof is easy. Start with $[\mathbf{U}_z^w[t,a]\Phi-I_\otimes]\Phi=\int_0^w\mathbf{Q}_z[t,a]\mathbf{U}_z^\xi[t,a]\mathrm{d}\xi\Phi$ and use integration by parts to get that

$$[\mathbf{U}_z^w[t,a]\Phi-I_\otimes]\Phi=w\mathbf{Q}_z[t,a]\Phi+\int_0^w(w-\xi)[\mathbf{Q}_z[t,a]]^2\mathbf{U}_z^\xi[t,a]\mathrm{d}\xi\Phi.$$

It is clear how to get the nth term. Finally, let $z\to\infty$ to get (3.10).

Theorem 3.7. *If* $a<t<b$,

(1) $\lim_{z\to\infty}\mathbf{U}_z[t,a]\Phi=\mathbf{U}[t,a]\Phi,\quad\Phi\in\mathcal{FD}_\otimes$,
(2) $\partial/\partial t\,\mathbf{U}_z[t,a]\Phi=\mathbf{H}_z(t)\mathbf{U}_z[t,a]\Phi=\mathbf{U}_z[t,a]\mathbf{H}_z(t)\Phi,\quad\Phi\in\mathcal{FD}_\otimes$, and
(3) $\partial/\partial t\,\mathbf{U}[t,a]\Phi=\mathbf{H}(t)\mathbf{U}[t,a]\Phi=\mathbf{U}[t,a]\mathbf{H}(t)\Phi,\quad\Phi\in D(\mathbf{Q}[b,a])\supset D_0$.

Proof: To prove (1), use the fact that $\mathbf{H}_z(t)$ and $\mathbf{H}(t)$ commute along with

$$\begin{aligned}\mathbf{U}[t,a]\Phi-\mathbf{U}_z[t,a]\Phi&=\int_0^1(\mathrm{d}/\mathrm{ds})(e^{s\mathbf{Q}[t,a]}e^{(1-s)\mathbf{Q}_z[t,a]})\Phi\,\mathrm{ds}\\&=\int_0^1 s(e^{s\mathbf{Q}[t,a]}e^{(1-s)\mathbf{Q}_z[t,a]})(\mathbf{Q}[t,a]-\mathbf{Q}_z[t,a])\Phi\,\mathrm{ds},\end{aligned}$$

so that

$$\|\mathbf{U}[t,a]\Phi-\mathbf{U}_z[t,a]\Phi\|\leqslant\|\mathbf{Q}[t,a]\Phi-\mathbf{Q}_z[t,a]\Phi\|.$$

To prove (2), use

$$\mathbf{U}_z[t+h,a]-\mathbf{U}_z[t,a]=\mathbf{U}_z[t,a](\mathbf{U}_z[t+h,t]-I)=(\mathbf{U}_z[t+h,t]-I)\mathbf{U}_z[t,a],$$

so that,

$$\frac{(\mathbf{U}_z[t+h,a]-\mathbf{U}_z[t,a])}{h}=\mathbf{U}_z[t,a]\frac{(\mathbf{U}_z[t+h,t]-I)}{h}.$$

Now set $\Phi_z^t=\mathbf{U}_z[t,a]\Phi$ and use (3.10) with $n=1$ and $w=1$ to get:

$$\mathbf{U}_z[t+h,t]\Phi_z^t=\left\{I_\otimes+\mathbf{Q}_z[t+h,t]+\int_0^1(1-\xi)\mathbf{U}_z^\xi[t+h,t]\mathbf{Q}_z[t+h,t]^2\mathrm{d}\xi\right\}\Phi_z^t,$$

so that

$$\begin{aligned}\frac{(\mathbf{U}_z[t+h,t]-I)}{h}\Phi_z^t-\mathbf{H}_z(t)\Phi_z^t&=\frac{\mathbf{Q}_z[t+h,t]}{h}\Phi_z^t-\mathbf{H}_z(t)\Phi_z^t\\&\quad+\int_0^1(1-\xi)\mathbf{U}_z^\xi[t+h,t]\frac{\mathbf{Q}_z[t+h,t]^2}{h}\Phi_z^t\,\mathrm{d}\xi.\end{aligned}$$

It follows that

$$\left\|\frac{(\mathbf{U}_z[t+h,t]-I)}{h}\Phi_z^t-\mathbf{H}_z(t)\Phi_z^t\right\|_\otimes\leqslant\left\|\frac{\mathbf{Q}_z[t+h,t]}{h}\Phi_z^t-\mathbf{H}_z(t)\Phi_z^t\right\|_\otimes+\frac{1}{2}\left\|\frac{\mathbf{Q}_z[t+h,t]_2}{h}\Phi_z^t\right\|_\otimes.$$

The result now follows from Theorem (3.4)—(2) and (3).

To prove (3), note that $\mathbf{H}_z(t)\Phi=\mathbf{H}(t)\{z\mathbf{R}(z,\mathbf{H}(t))\}\Phi=\{z\mathbf{R}(z,\mathbf{H}(t))\}\mathbf{H}(t)\Phi$, so that $\{z\mathbf{R}(z,\mathbf{H}(t))\}$ commutes with $\mathbf{U}[t,a]$ and $\mathbf{H}(t)$. Now show that

$$\|\mathbf{H}_z(t)\mathbf{U}_z[t,a]\Phi-\mathbf{H}_{z'}(t)\mathbf{U}_{z'}[t,a]\Phi\|\leqslant\|[\mathbf{U}_z[t,a]\Phi-\mathbf{U}_{z'}[t,a]]\mathbf{H}(t)\Phi\|+\|[z\mathbf{R}(z,\mathbf{H}(t))\Phi - z'\mathbf{R}(z',\mathbf{H}(t))]\mathbf{H}(t)\Phi\|\to 0,\quad z,z'\to\infty,$$

so that, for

$$\Phi\in D(\mathbf{Q}[b,a]),\ \ \mathbf{H}_z(t)\mathbf{U}_z[t,a]\Phi\to\mathbf{H}(t)\mathbf{U}[t,a]\Phi=\frac{\partial}{\partial t}\mathbf{U}[t,a]\Phi.$$

The previous theorems form the core of our approach to the Feynman operator calculus. Our theory applies to both hyperbolic and parabolic equations. In the conventional approach, these two cases require different methods (see Pazy[71]). It is not hard to show that the requirements imposed in these cases are stronger than (our condition of) weak integral. This will be discussed in a later paper devoted to the general problem on Banach spaces.

IV. PERTURBATION THEORY

Definition 4.1: The evolution operator $\mathbf{U}^w[t,a]=\exp\{w\mathbf{Q}[t,a]\}$ is said to be *asymptotic in the sense of Poincaré* if, for each n and each $\Phi_a\in D[(\mathbf{Q}[t,a])^{n+1}]$, we have

$$\lim_{w\to 0} w^{-(n+1)}\left\{\mathbf{U}^w[t,a]-\sum_{k=1}^{n}\frac{(w\mathbf{Q}[t,a])^k}{k!}\right\}\Phi_a=\frac{\mathbf{Q}[t,a]^{n+1}}{(n+1)!}\Phi_a. \tag{4.1}$$

This is the operator version of an asymptotic expansion in the classical sense, but here $\mathbf{Q}[t,a]$ is an unbounded operator.

As noted earlier, Dyson[16] analyzed the (renormalized) perturbation expansion for quantum electrodynamics and suggested that it actually diverges. He concluded that we could, at best, hope that the series is asymptotic. His arguments were based on (not completely convincing) physical considerations, but no precise formulation of the problem was possible at that time. However, the calculations of Hurst,[75] Thirring,[76] Peterman,[77] and Jaffe[78] for specific models all support Dyson's contention that the renormalized perturbation series diverges. In his recent book[79] (pp. 13–16), Dyson's views on the perturbation series and renormalization are reiterated: ''... in spite of all the successes of the new physics, the two questions that defeated me in 1951 remain unsolved.'' Here, he is referring to the question of mathematical consistency for the whole renormalization program, and our ability to (reliably) calculate nuclear processes in quantum chromodynamics. (For other details and references to additional works, see Schweber,[6,80] Wightman,[81] and Zinn-Justin.[82])

The general construction of a physically simple and mathematically satisfactory formulation of quantum electrodynamics is still an open problem. The next theorem establishes Dyson's (second) conjecture under conditions that would apply to any (future) theory that does not require a radical departure from the present foundations of quantum theory (unitary solution operators). It also applies to the renormalized expansions in some areas of condensed matter physics where the solution operators are contraction semigroups.

Theorem 4.2: *Suppose the conditions for Theorem 3.5 are satisfied. Then:*

(1) $\mathbf{U}^w[t,a]=\exp\{w\mathbf{Q}[t,a]\}$ *is asymptotic in the sense of Poincaré.*

(2) *For each n and each* $\Phi_a\in D[(\mathbf{Q}[t,a])^{n+1}]$, *we have*

$$\Phi(t)=\Phi_a+\sum_{k=1}^{n} w^k\int_a^t \mathrm{d}s_1\int_a^{s_1}\mathrm{d}s_2\cdots\int_a^{s_{k-1}}\mathrm{d}s_k\mathbf{H}(s_1)\mathbf{H}(s_2)\cdots\mathbf{H}(s_k)\Phi_a$$
$$+\int_0^w(w-\xi)^n\mathrm{d}\xi\int_a^t\mathrm{d}s_1\int_a^{s_1}\mathrm{d}s_2\cdots\int_a^{s_n}\mathrm{d}s_{n+1}\mathbf{H}(s_1)\mathbf{H}(s_2)\cdots\mathbf{H}(s_{n+1})\mathbf{U}^{\xi}[s_{n+1},a]\Phi_a, \tag{4.2}$$

where $\Phi(t)=\mathbf{U}^w[t,a]\Phi_a$.

Proof: From (3.10), we have

$$\mathbf{U}^w[t,a]\Phi=\left\{\sum_{k=0}^{n}\frac{(w\mathbf{Q}[t,a])^n}{n!}+\frac{1}{n!}\int_0^w(w-\xi)^n\mathbf{Q}[t,a]^{n+1}\mathbf{U}^{\xi}[t,a]\mathrm{d}\xi\right\}\Phi,$$

so that

$$w^{-(n+1)}\left\{\mathbf{U}^w[t,a]\Phi_a-\sum_{k=0}^{n}\frac{(w\mathbf{Q}[t,a])^k}{k!}\Phi_a\right\}$$
$$=+\frac{(n+1)}{(n+1)!}w^{-(n+1)}\int_0^w(w-\xi)^n\mathrm{d}\xi\,\mathbf{U}^{\xi}[t,a]\mathbf{Q}[t,a]^{n+1}\Phi_a.$$

Replace the right-hand side by

$$I=\frac{(n+1)}{(n+1)!}w^{-(n+1)}\int_0^w(w-\xi)^n\mathrm{d}\xi\{\mathbf{U}_z^{\xi}[t,a]+[\mathbf{U}^{\xi}[t,a]-\mathbf{U}_z^{\xi}[t,a]]\}\mathbf{Q}[t,a]^{n+1}\Phi_a.$$

Now, expand the term $\mathbf{U}_z^{\xi}[t,a]$ in a two-term Taylor series about zero to get

$$\mathbf{U}_z^{\xi}[t,a]=I_{\otimes}+\xi\mathbf{Q}_z[t,a]+R_z^{\xi}.$$

Put the above in I, compute the elementary integrals showing that only the $I_{\otimes}$ term gives a nonzero value (of $1/(n+1)$) when $w\to 0$. Then let $z\to\infty$ to get

$$\lim_{w\to 0}(n+1)w^{-(n+1)}\int_0^w\mathrm{d}\xi(w-\xi)^n\mathbf{U}^{\xi}[t,a]\mathbf{Q}[t,a]^{n+1}\Phi_a=\mathbf{Q}[t,a]^{n+1}\Phi_a.$$

This proves that $\mathbf{U}[t,a]=\exp\{\mathbf{Q}[t,a]\}$ is asymptotic in the sense of Poincaré. To prove (4.2), let $\Phi_a\in D[(\mathbf{Q}[t,a])^{n+1}]$ for each $k\leqslant n+1$, and use the fact that (Dollard and Friedman[83])

$$(\mathbf{Q}_z[t,a])^k\Phi_a=\left(\int_a^t\mathbf{H}_z(s)\mathrm{d}s\right)^k\Phi_a=(k!)\int_a^t\mathrm{d}s_1\int_a^{s_1}\mathrm{d}s_2\cdots\int_a^{s_{k-1}}\mathrm{d}s_n\mathbf{H}_z(s_1)\mathbf{H}_z(s_2)\cdots\mathbf{H}_z(s_k)\Phi_a. \tag{4.3}$$

Letting $z\to\infty$ gives the result.

Our conditions are very weak. For example, the recent work of Tang and Li[84] required that $\|H(t)\|$ be Lebesgue integrable.

There are well-known special cases in which the perturbation series may actually converge to the solution. This can happen, for example, if the generator is bounded or if it is analytic in some sector. More generally, when the generator is of the form $\mathbf{H}(t)=\mathbf{H}_0(t)+\mathbf{H}_i(t)$, where $\mathbf{H}_0(t)$ is analytic and $\mathbf{H}_i(t)$ is some reasonable perturbation, which need not be bounded, there are conditions that allow the interaction representation to have a convergent Dyson expansion. These results can be formulated and proven in our formalism. However, the proofs are essentially the same as in the standard case so we will present them in a later paper devoted to the operator calculus on Banach spaces. The recent book by Engel and Nagel[85] provides some new results in this general area.

There are also cases where the (renormalized) series may diverge, but still respond to some summability method. This phenomenon is well-known in classical analysis. In field theory, things can be much more complicated. A good discussion, with references, can be found in the review by Wightman[81] and the book by Glimm and Jaffe.[35]

V. SUM OVER PATHS

In this section we first review and make a distinction between what is actually known and what we think we know about the foundations for our physical view of the micro-world. The objective is to provide the background for a number of physically motivated postulates that will be used to develop a theory of measurement for the micro-world (sufficient for our purposes). This will allow us to relate the theory of Secs. III and IV to Feynman's sum over paths approach and prove Dyson's second conjecture. This section differs from the previous ones in that we shift the orientation and perspective from that of mathematical physics to that of theoretical physics.

In spite of the enormous successes of the physical sciences in the past century, our information and understanding about the micro-world is still rather meager. In the macro-world we are quite comfortable with the view that physical systems evolve continuously in time and our results justify this view. Indeed, the success of continuum physics is the basis for a large part of our technical advances in the twentieth century. On the other hand, the same view is also held at the micro-level and, in this case, our position is not very secure. The ability to measure physical events continuously in time at the micro-level must be considered a belief which, although convenient, has no place in science as an *a priori* constraint.

In order to establish perspective, let us consider this belief within the context of a satisfactory, and well-justified theory, Brownian motion. This theory lies at the interface between the macro- and the micro-worlds. Some presentations of this theory (the careful ones) make a distinction between the mathematical and the physical foundations of Brownian motion and that distinction is important for our discussion.

When Einstein[86] began his investigation of the physical issues associated with this phenomenon, he was forced to assume that physical information about the state of a Brownian particle (position, velocity, etc.) can only be known in time intervals that are large compared with the mean time between molecular collisions. (It is known that, under normal physical conditions, a Brownian particle receives about 10^{21} collisions per second.) Wiener took the mathematical step and assumed that this mean time (between collisions) could be made zero, thus providing a mathematical Brownian particle. This corresponds physically to the assumption that the ratio of the mass of the particle to the friction of the fluid is zero in the limit (see Wiener *et al.*[87]).

From the physical point of view, use of Wiener's idealization of the Einstein model was not satisfactory since it led to problems of unbounded path length and nondifferentiability at all points. The first problem is physically impossible while the second is physically unreasonable. Of course, the idealization has turned out to be quite satisfactory in areas where the information required need not be detailed, such as large parts of electrical engineering, chemistry, and the biological sciences. Ornstein and Uhlenbeck[88] later constructed a model that gives the Einstein view asymptotically but, in small-time regions, is equivalent to the assumption that the particle travels a linear path between collisions. This model provides finite path length and differentiability. (The theory was later idealized by Doob.[89]) What we do know is that the very nature of the liquid state implies collective behavior among the molecules. *This means that we do not know what path the particle travels in between collisions*. However, since the tools and methods of analysis require some form of continuity, some such (in between observation) assumptions must be made. It is clear that the need for these assumptions is imposed by the available mathematical structures within which we must represent physical reality as a model.

Theoretical science concerns itself with the construction of mathematical representations of certain restricted portions of physical reality. Various trends and philosophies that are prevalent at the time temper these constructs. A consistent theme has been the quest for simplicity. This requirement is born out of the natural need to restrict models to the minimum number of variables, relationships, constraints, etc., which give a satisfactory account of known experimental results

and possibly allow the prediction of heretofore unknown consequences. One important outcome of this approach has been to implicitly eliminate all reference to the background within which physical systems evolve. In the micro-world, such an action cannot be justified without prior investigation. We propose to replace the use of mathematical coordinate systems by ''physical coordinate systems'' in order to (partially) remedy this problem.

We denote a physical coordinate system at time t by $\mathbf{R}_p^3(t)$. This coordinate system is attached to an observer (including measuring devices) and is envisioned as $\mathbf{R}^3$ plus any background effects, either local or distant, which affect the observer's ability to obtain precise (ideal) experimental information about physical reality. This in turn affects our observer's ability to construct precise (ideal) representations and make precise predictions about physical reality (in the micro-world).

More specifically, consider the evolution of some micro-system on the interval $E=[a,b]$. Physically this evolution manifests itself as a curve on $\mathbf{X}$, where

$$\prod_{t\in E} \mathbf{R}_p^3(t)=\mathbf{X}.$$

Thus, true physical events occur on $\mathbf{X}$ where actual experimental information is modified by fluctuations in $\mathbf{R}_p^3(t)$, and by the interaction of the micro-system with the measuring equipment. Based on the success of our models, we know that such small changes are in the noise region, and they have no effect on our predictions for macro-systems. However, there is no (physical) reason to believe that the effects will be small on micro-systems.

In terms of our theoretical representations, we are forced to model the evolution of physical systems in terms of wave functions, amplitudes, and/or operator-valued distributions, etc. There are thus two spaces, the physical space of evolution for the micro-system and the observer's space of obtainable information concerning this evolution. The lack of distinction between these two spaces seems to be the cause for some of the confusion and lack of physical clarity. For example, it may be perfectly correct to assume that a particle travels a continuous path on $\mathbf{X}$. However, the assumption that the observer's space of obtainable information includes infinitesimal space–time knowledge of this path is completely unfounded. This leads to our first postulate:

Postulate 1: Physical reality is a continuous process in time.

We thus take this view, fully recognizing that experiment does not provide continuous information about physical reality, and that there is no reason to believe that our mathematical representations contain precise information about the continuous space–time behavior of physical processes at this level.

Since the advent of the special theory of relativity, there has been much discussion about events, which generally means a point in $\mathbf{R}^4$ with the Minkowski metric. In terms of real physics, this is a fiction which is frequently useful for reasons of presentation but so widely used that, to avoid confusion, it is appropriate to define what we mean by a *physical event*.

Definition 5.1: A physical event is a set of physical changes in a given system that can be verified directly by experiment or indirectly via subsequent changes, where conclusions are based on an a priori agreed-upon model of the physical process.

This definition corresponds more closely to what is meant by physical events. It explicitly recognizes the evolution of scientific inference and the need for general agreement about what is being observed (based on specific models).

Before continuing, it will be helpful to have a particular physical picture in mind that makes the above-presented discussion explicit. For this purpose, we take this picture to be a photograph showing the track left by a π-meson in a bubble chamber (and take seriously the amount of information available). In particular, we assume that the following reaction occurs:

$$\pi^+ \rightarrow \mu^+ + \nu.$$

We further assume that the orientation of our photograph is such that the π-meson enters on the left at time $t=0$ and the tracks left by the μ-meson disappear on the right at time $t=T$, where

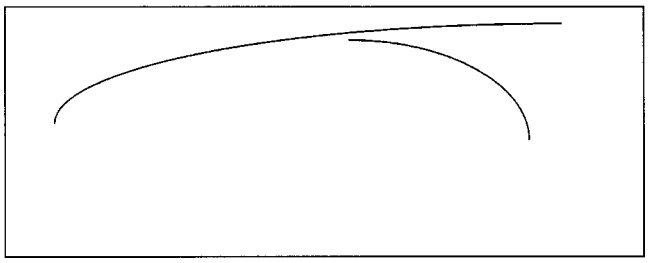

FIG. 1. Ideal picture of the reaction $\pi^+ \to \mu^+ + \nu$.

T is of the order of 10^{-3} s, the time exposure for photographic film. Although the neutrino does not appear in the photograph, we also include a track for it. In Fig. 1 we present a simplified picture of this photograph.

We have drawn the photograph as if we continuously see the particles in the picture. However, experiment only provides us individual bubbles, which do not necessarily overlap, from which we must extract physical information. A more accurate (though still not realistic) depiction is given in Fig. 2.

Let us assume that we have magnified a portion of our photograph to the extent that we may distinguish the individual bubbles created by the π-meson as it passes through the chamber. In Fig. 3, we present a simplified model of adjacent bubbles.

Postulate 2: We assume that the center of each bubble represents the average knowable effect of the particle in a symmetric time interval about the center.

By average knowable effect, we mean the average of the physical observables. In Fig. 3, we consider the existence of a bubble at time τ_j to be caused by the average of the physical observables over the time interval $[t_{j-1}, t_j]$, where $t_{j-1} = (1/2)[\tau_{j-1} + \tau_j]$ and $t_j = (1/2)[\tau_j + \tau_{j+1}]$. This postulate requires some justification. In general, the resolution of film and the relaxation time for distinct bubbles in the chamber vapor are limited. This means that if the π-meson creates two bubbles that are closely spaced in time, the bubbles may coalesce and appear as one. If this does not occur, it is still possible that the film will record the event as one bubble because of its inability to resolve events is such small time intervals.

Let us now recognize that we are dealing with one photograph so that, in order to obtain all available information, we must analyze a large number of photographs of the same reaction obtained under similar conditions (pre-prepared states). It is clear that the number of bubbles and the time placement of the bubbles will vary (independently of each other) from photograph to photograph. Let λ^{-1} denote the average time for the appearance of a bubble in the film.

Postulate 3: We assume that the number of bubbles in any film is a random variable.

Postulate 4: We assume that, given that n bubbles have appeared on a film, the time positions of the centers of the bubbles are uniformly distributed.

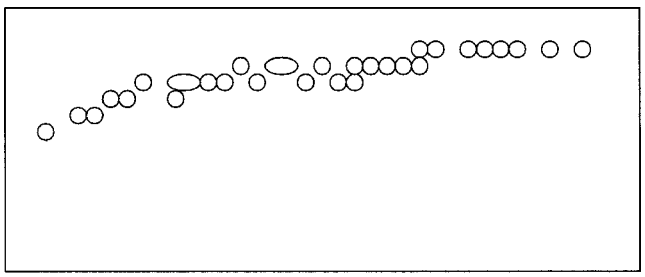

FIG. 2. More accurate picture of the reaction $\pi^+ \to \mu^+ + \nu$.

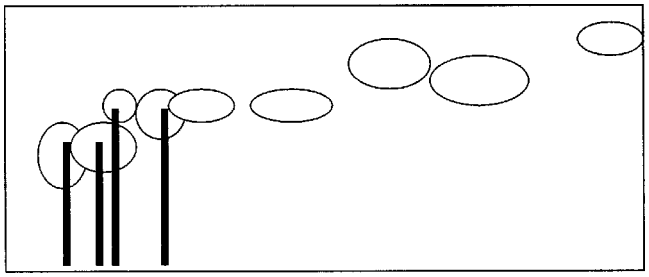

FIG. 3. Highly magnified view showing individual bubbles.

Postulate 5: We assume that $N(t)$, the number of bubbles up to time t in a given film, is a Poisson-distributed random variable with parameter λ.

To motivate Postulate 5, recall that τ_j is the time center of the jth bubble and λ^{-1} is the average (experimentally determined) time between bubbles. The following results can be found in Ross.[90]

Theorem 5.1: *The random variables $\Delta\tau_j=\tau_j-\tau_{j-1}(\tau_0=0)$ are independent identically distributed random variables of exponential type with mean λ^{-1}, for $1\leqslant j\leqslant n$.*

The arrival times $\tau_1,\tau_2,\ldots,\tau_n$ are not independent, but their density function can be computed from

$$\text{Prob}[\tau_1,\tau_2,\ldots,\tau_n]=\text{Prob}[\tau_1]\text{Prob}[\tau_2|\tau_1]\cdots\text{Prob}[\tau_n|\tau_1,\tau_2,\ldots,\tau_{n-1}]. \tag{5.1a}$$

We now use Theorem 5.1 to conclude that, for $k\geqslant 1$,

$$\text{Prob}[\tau_k|\tau_1,\tau_2,\ldots,\tau_{k-1}]=\text{Prob}[\tau_k|\tau_{k-1}]. \tag{5.1b}$$

We do not know this conditional probability. However, the natural assumption is that, given that n bubbles appear, they are equally (uniformly) distributed on the interval. We can now construct what we call the experimental evolution operator. Assume that the conditions for Theorem 3.5 are satisfied and that the family $\{\tau_1,\tau_2,\ldots,\tau_n\}$ represents the time positions of the centers of n bubbles in our film of Fig. 3. Set $a=0$ and define $\mathbf{Q}_E[\tau_1,\tau_2,\ldots,\tau_n]$ by

$$\mathbf{Q}_E[\tau_1,\tau_2,\ldots,\tau_n]=\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}E[\tau_j,s]\mathbf{H}(s)\text{ds}. \tag{5.2a}$$

Here, $t_0=\tau_0=0$, $t_j=(1/2)[\tau_j+\tau_{j+1}]$ (for $1\leqslant j\leqslant n$), and $E[\tau_j,s]$ is the exchange operator defined in Sec. II. The effect of our exchange operator $E[\tau_j,s]$ is to concentrate all information contained in $[t_{j-1},t_j]$ at τ_j. This is how we implement our postulate that the known physical event of the bubble at time τ_j is due to an average of physical effects over $[t_{j-1},t_j]$ with information concentrated at τ_j. We can rewrite $\mathbf{Q}_E[\tau_1,\tau_2,\ldots,\tau_n]$ as

$$\mathbf{Q}_E[\tau_1,\tau_2,\ldots,\tau_n]=\sum_{j=1}^{n}\Delta t_j\left[\frac{1}{\Delta t_j}\int_{t_{j-1}}^{t_j}E[\tau_j,s]\mathbf{H}(s)\text{ds}\right]. \tag{5.2b}$$

Thus, we indeed have an average as required by Postulate 2. The evolution operator is given by

$$U[\tau_1,\tau_2,\ldots,\tau_n]=\exp\left\{\sum_{j=1}^{n}\Delta t_j\left[\frac{1}{\Delta t_j}\int_{t_{j-1}}^{t_j}E[\tau_j,s]\mathbf{H}(s)\text{ds}\right]\right\}. \tag{5.3a}$$

For $\Phi\in\mathcal{FD}_{\otimes}$, we define the function $\mathbf{U}[N(t),0]\Phi$ by

$$\mathbf{U}[N(t),0]\Phi = U[\tau_1,\tau_2,\ldots,\tau_{N(t)}]\Phi. \tag{5.3b}$$

The function $\mathbf{U}[N(t),0]\Phi$ is an $\mathcal{FD}_{\otimes}$-valued random variable, which represents the distribution of the number of bubbles that may appear on our film up to time t. In order to relate $\mathbf{U}[N(t),0]\Phi$ to actual experimental results, we must compute its expected value. Using Postulates 3, 4, and 5, we have

$$\overline{\mathbf{U}}_\lambda[t,0]\Phi = \mathcal{E}[\mathbf{U}[N(t),0]\Phi] = \sum_{n=0}^{\infty} \mathcal{E}\{\mathbf{U}[N(t),0]\Phi | N(t)=n\}\text{Prob}[N(t)=n], \tag{5.4a}$$

$$\mathcal{E}\{\mathbf{U}[N(t),0]\Phi | N(t)=n\} = \int_0^t \frac{d\tau_1}{t}\int_{\tau_1}^t \frac{d\tau_2}{t-\tau_1}\cdots\int_{\tau_{n-1}}^t \frac{d\tau_n}{t-\tau_{n-1}}\mathbf{U}[\tau_n,\ldots,\tau_1]\Phi = \overline{\mathbf{U}}_n[t,0]\Phi, \tag{5.5a}$$

and

$$\text{Prob}[N(t)=n] = \frac{(\lambda t)^n}{n!}\exp\{-\lambda t\}. \tag{5.6}$$

The integral in (5.4a) acts to distribute uniformly the time positions τ_j over the successive intervals $[t,\tau_{j-1}]$, $1\leqslant j\leqslant n$, given that τ_{j-1} has been determined. This is a natural result given our lack of knowledge.

The integral (5.4a) is of theoretical value but is not easy to compute. Since we are only interested in what happens when $\lambda\to\infty$, and as the mean number of bubbles in the film at time t is λt, we can take $\tau_j=(jt/n)$, $1\leqslant j\leqslant n$ ($\Delta t_j = t/n$ for each n). We can now replace $\overline{\mathbf{U}}_n[t,0]\Phi$ by $\mathbf{U}_n[t,0]\Phi$, and with this understanding, we continue to use τ_j, so that

$$\mathbf{U}_n[t,0]\Phi = \exp\left\{\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j} E[\tau_j,s]\mathbf{H}(s)ds\right\}\Phi. \tag{5.5b}$$

We define our experimental evolution operator $\mathbf{U}_\lambda[t,0]\Phi$ by

$$\mathbf{U}_\lambda[t,0]\Phi = \sum_{n=0}^{\infty}\frac{(\lambda t)^n}{n!}\exp\{-\lambda t\}\mathbf{U}_n[t,0]\Phi. \tag{5.4b}$$

We now have the following result, which is a consequence of the fact that Borel summability is regular.

Theorem 5.4: *Assume that the conditions for Theorem 3.5 are satisfied. Then*

$$\lim_{\lambda\to\infty}\overline{\mathbf{U}}_\lambda[t,0]\Phi = \lim_{\lambda\to\infty}\mathbf{U}_\lambda[t,0]\Phi = \mathbf{U}[t,0]\Phi. \tag{5.7}$$

Since $\lambda\to\infty\Rightarrow\lambda^{-1}\to 0$, this means that the average time between bubbles is zero (in the limit) so that we get a continuous path. It should be observed that this continuous path arises from averaging the sum over an infinite number of (discrete) paths. The first term in (5.4b) corresponds to the path of a π-meson that created no bubbles (i.e., the photograph is blank). This event has probability $\exp\{-\lambda t\}$ (which approaches zero as $\lambda\to\infty$). The nth term corresponds to the path of a π-meson that created n bubbles, (with probability $[(\lambda t)^n/n!]\exp\{-\lambda t\}$), etc. Before deriving a physical relationship, let $P[t;s,\lambda]=0$ if $s\leqslant 0$ and, for $0<s<\infty$, define it as

$$P[t;s,\lambda]=e^{-\lambda t}\sum_{k=0}^{\lceil \lambda s\rceil}\frac{(\lambda t)^k}{k!}, \tag{5.8}$$

where $n=\lceil \lambda s\rceil$ is the greatest integer $\leqslant \lambda s$. We can now write $\mathbf{U}[t,0]\Phi$ as

$$\mathbf{U}[t,0]\Phi=\lim_{\lambda\to\infty}\int_0^\infty d_s P[t;s,\lambda]\mathbf{U}_{\lceil \lambda s\rceil}[s,0]\Phi,$$

$$\mathbf{U}_{\lceil \lambda s\rceil}[s,0]\Phi=\exp\left\{\sum_{j=1}^{\lceil \lambda s\rceil}\int_{t_{j-1}}^{t_j}E[\tau_j,u]\mathbf{H}(u)\mathrm{d}u\right\}\Phi. \tag{5.9}$$

Equation (5.9) means that we get both a sum over paths and a probability interpretation for our formalism. This allows us to give a new definition for path integrals.

Suppose the evolution operator $\mathbf{U}[t,0]$ has a kernel, $\mathbf{K}[\mathbf{x}(t),t;\mathbf{x}(0),0]$, such that

(1) $\mathbf{K}[\mathbf{x}(t),t;\mathbf{x}(s),s]=\int_{\mathbf{R}^3}\mathbf{K}[\mathbf{x}(t),t;\mathbf{x}(s),s]\mathbf{K}[\mathbf{x}(s),s;\mathbf{x}(0),0]\mathrm{d}\mathbf{x}(s)$, and
(2) $\mathbf{U}[t,0]\Phi=\int_{\mathbf{R}^3}\mathbf{K}[\mathbf{x}(t),t;\mathbf{x}(0),0]\mathrm{d}\mathbf{x}(0)$.

Then, from Eq. (5.9), we have that

$$\mathbf{U}[t,0]\Phi=\lim_{\lambda\to\infty}\int_0^\infty d_s P[t;s,\lambda]\left\{\prod_{j=1}^{\lceil \lambda s\rceil}\int_{\mathbf{R}^3}\mathbf{K}[\mathbf{x}(t_j),t_j;\mathbf{x}(t_{j-1}),t_{j-1}]_j\prod_{j=1}^{\lceil \lambda s\rceil}\mathrm{d}\mathbf{x}(t_{j-1})\Phi(0)\right\}.$$

Thus, whenever we can associate a kernel with our evolution operator, the time-ordered version always provides a well-defined path-integral as a sum over paths. The definition does not (directly) depend on the space of continuous paths and is independent of a theory of measure on infinite dimensional spaces. Feynman suggested that the operator calculus was more general, in his book with Hibbs[91] (see pp. 355–356).

VI. THE *S*-MATRIX

The objective of this section is to provide a formulation of the S-matrix that will allow us to investigate the sense in which we can believe Dyson's first conjecture. At the end of his second paper on the relationship between the Feynman and Schwinger–Tomonaga theories, he explored the difference between the divergent Hamiltonian formalism that one must begin with and the finite S-matrix that results from renormalization. He takes the view that it is a contrast between a real observer and a fictitious (ideal) observer. The real observer can only determine particle positions with limited accuracy and always gets finite results from his measurements. Dyson then suggests that ''... The ideal observer, however, using non-atomic apparatus whose location in space and time is known with infinite precision, is imagined to be able to disentangle a single field from its interactions with others, and to measure the interaction. In conformity with the Heisenberg uncertainty principle, it can perhaps be considered a physical consequence of the infinitely precise knowledge of (particle) location allowed to the ideal observer, that the value obtained when he measures (the interaction) is infinite.'' He goes on to remark that, if his analysis is correct, the problem of divergences is attributable to an idealized concept of measurability.

In order to explore this idea, we work in the interaction representation with obvious notation. Replace the interval $[t,0]$ by $[T,-T]$, $\mathbf{H}(t)$ by $(-i/\hbar)\mathbf{H}_I(t)$, and our experimental evolution operator $\mathbf{U}_\lambda[T,-T]\Phi$ by the experimental scattering operator $\mathbf{S}_\lambda[T,-T]\Phi$, where

$$\mathbf{S}_\lambda[T,-T]\Phi=\sum_{n=0}^{\infty}\frac{(2\lambda T)^n}{n!}\exp[-2\lambda T]\mathbf{S}_n[T,-T]\Phi, \tag{6.1}$$

$$\mathbf{S}_n[T,-T]\Phi=\exp\left\{(-i/\hbar)\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}E[\tau_j,s]\mathbf{H}_I(s)\mathrm{d}s\right\}\Phi, \tag{6.2}$$

and $\mathbf{H}_I(t)=\int_{\mathbf{R}^3}\mathbf{H}_I(\mathbf{x}(t),t)\mathrm{d}\mathbf{x}(t)$ is the interaction energy. We follow Dyson for consistency (see also the discussion), so that δmc^2 is the mass counter-term designed to cancel the self-energy divergence, and

$$\mathbf{H}_I(\mathbf{x}(t),t)=-ie\mathbf{A}_\mu(\mathbf{x}(t),t)\overline{\psi}(\mathbf{x}(t),t)\gamma_\mu\psi(\mathbf{x}(t),t)-\delta mc^2\overline{\psi}(\mathbf{x}(t),t)\psi(\mathbf{x}(t),t). \tag{6.3}$$

We now give a physical interpretation of our formalism. Rewrite Eq. (6.1) as

$$\mathbf{S}_\lambda[T,-T]\Phi=\sum_{n=0}^{\infty}\frac{(2\lambda T)^n}{n!}\exp\left\{(-i/\hbar)\sum_{j=1}^{n}\int_{t_{j-1}}^{t_j}[E[\tau_j,s]\mathbf{H}_I(s)-i\lambda\hbar I_\otimes]\mathrm{d}s\right\}\Phi. \tag{6.4}$$

In this form, it is clear that the term $-i\lambda\hbar I_\otimes$ has a physical interpretation as the absorption of photon energy of amount $\lambda\hbar$ in each subinterval $[t_j,t_{j-1}]$ (cf. Mott and Massey[92]). When we compute the limit, we get the standard S-matrix (on $[T,-T]$). It follows that we must add an infinite amount of photon energy to the mathematical description of the experimental picture (at each point in time) in order to obtain the standard scattering operator. This is the ultraviolet divergence and shows explicitly that the transition from the experimental to the ideal scattering operator requires that we illuminate the particle throughout its entire path. Thus, it appears that we have, indeed, violated the uncertainty relation. This is further supported if we look at the form of the standard S-matrix:

$$\mathbf{S}[T,-T]\Phi=\exp\left\{(-i/\hbar)\int_{-T}^{T}\mathbf{H}_I(s)\mathrm{d}s\right\}\Phi, \tag{6.5}$$

and note that the differential ds in the exponent implies perfect infinitesimal time knowledge at each point, strongly suggesting that the energy should be totally undetermined. If violation of the Heisenberg uncertainty relation is the cause for the ultraviolet divergence then, as it is a variance relation, it will not appear in first order (perturbation) but should show up in all higher-order terms. On the other hand, if we eliminate the divergent terms in second order, we would expect our method to prevent them from appearing in any higher order term of the expansion. The fact that this is precisely the case in quantum electrodynamics is a clear verification of Dyson's conjecture.

If we allow T to become infinite, we once again introduce an infinite amount of energy into the mathematical description of the experimental picture, as this is also equivalent to precise time knowledge (at infinity). Of course, this is the well-known infrared divergence and can be eliminated by keeping T finite (see Dahmen *et al.*[93]) or introducing a small mass for the photon (see Feynman,[12] p. 769). If we hold λ fixed while letting T become infinite, the experimental S-matrix takes the form:

$$\begin{gathered}\mathbf{S}_\lambda[\infty,-\infty]\Phi=\exp\left\{(-i/\hbar)\sum_{j=1}^{\infty}\int_{t_{j-1}}^{t_j}E[\tau_j,s]\mathbf{H}_I(s)\mathrm{d}s\right\}\Phi,\\ \bigcup_{j=1}^{\infty}[t_{j-1},t_j]=(-\infty,\infty),\quad \Delta t_j=\lambda^{-1}.\end{gathered} \tag{6.6}$$

This form is interesting since it shows how a minimal time eliminates the ultraviolet divergence. Of course, this is not unexpected, and has been known at least since Heisenberg[94] introduced his fundamental length as a way around the divergences. This was a prelude to the various lattice approximation methods. The review by Lee[95] is interesting in this regard.

In closing this section, we record our exact expansion for the S-matrix to any finite order. With $\Phi(-\infty)\in D[(\mathbf{Q}[\infty,-\infty])^{n+1}]$, we have

$$\mathbf{S}[\infty,-\infty]\Phi(-\infty)=\sum_{k=0}^{n}\left(\frac{-i}{\hbar}\right)^{k}\int_{-\infty}^{\infty}ds_1\int_{-\infty}^{s_1}ds_2\cdots\int_{-\infty}^{s_{k-1}}ds_k\mathbf{H}_I(s_1)\mathbf{H}_I(s_2)\cdots\mathbf{H}_I(s_k)\Phi(-\infty)$$
$$+\left(\frac{-i}{\hbar}\right)^{n+1}\int_0^1(1-\xi)^n d\xi\int_{-\infty}^{\infty}ds_1\int_{-\infty}^{s_1}ds_2\cdots\int_{-\infty}^{s_n}ds_{n+1}\mathbf{H}_I(s_1)$$
$$\times\mathbf{H}_I(s_2)\cdots\mathbf{H}_I(s_{n+1})\mathbf{S}^{\xi}[s_{n+1},-\infty]\Phi(-\infty). \tag{6.7}$$

It follows that (in a theoretical sense) we can consider the standard S-matrix expansion to be exact, when truncated at any order, by adding the last term of Eq. (6.7) to give the remainder. This result also means that, whenever we can construct an exact nonperturbative solution, it always implies the existence of a perturbative solution valid to any order. However, in general, only in particular cases can we know if the series at some n (without the remainder) approximates the solution.

VII. CONCLUSION

In this paper we have shown how to construct a natural representation Hilbert space for Feynman's time-ordered operator calculus. This space allows us to construct the time-ordered integral and evolution operator (propagator) under the weakest known conditions. Using the theory, we have shown that the perturbation expansion relevant to quantum theory is asymptotic in the sense of Poincaré. This provides a precise formulation and proof of Dyson's second conjecture[16] that, in general, we can only expect the expansion to be asymptotic.

Our investigation into the extent that our continuous models for the micro-world faithfully represent the amount of information available from experiment has led to a derivation of the time-ordered evolution operator in a more physical way. This approach made it possible to prove that the ultraviolet divergence is caused by a violation of the Heisenberg uncertainty relation at each point in time, thus partially confirming Dyson's first conjecture.

We used Dyson's original notation so as to explicitly exhibit the counter-term necessary to eliminate the self-energy divergence that occurs in QED. This divergence is not accounted for and is outside the scope of the current investigation. Thus, within our present framework, we cannot say that all the divergences arise from our disregard of some simple physics, and are not the result of deeper problems. Thus, Dyson's concerns about the mathematical consistency of quantum electrodynamics, and quantum field theory in general, is still an open problem.

Although we are not working in the framework of axiomatic field theory, our approach may make some uneasy since Haag's theorem suggests that the interaction representation does not exist (see Streater and Wightman,[27] p. 161). (Haag's theorem assumes, among other things, that the equal time commutation relations for the canonical variables of a interacting field are equivalent to those of a free field.) In trying to explain this unfortunate result, these authors point out that (see p. 168) ''... What is even more likely in physically interesting quantum field theories is that equal time commutation relations will make no sense at all; the field might not be an operator unless smeared in time as well as space.'' The work in Secs. V and VI of this paper strongly suggests that there is no physical basis to assume that we know anything about canonical variables at one instant in time (see postulate 2 and the following paragraph). Thus, our approach actually confirms the above-mentioned comments of Streater and Wightman.

(Received 25 July 2001; accepted for publication 25 September 2001)

A complete variational treatment is provided for a family of spiked-harmonic oscillator Hamiltonians $H=-\mathrm{d}^2/\mathrm{d}x^2+Bx^2+\lambda/x^\alpha (B>0,\lambda>0)$, for arbitrary $\alpha>0$. A compact topological proof is presented that the set $S=\{\psi_n\}$ of known exact solutions for $\alpha=2$ constitutes an orthonormal basis of the Hilbert space $L_2(0,\infty)$. Closed-form expressions are derived for the matrix elements of H with respect to S. These analytical results, and the inclusion of a further free parameter, facilitate optimized variational estimation of the eigenvalues of H to high accuracy. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1418247]

I. INTRODUCTION

A family of quantum Hamiltonians known as spiked harmonic oscillators is given by the general Hamiltonian operator

$$H=-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+x^2+\frac{\lambda}{x^\alpha}, \tag{1.1}$$

acting in the Hilbert space $L_2(0,\infty)$. Eigenfunctions $\psi\in L_2(0,\infty)$ of H satisfy the Schrödinger equation

$$-\psi''+\left\{x^2+\frac{\lambda}{x^\alpha}\right\}\psi=E\psi \quad \text{with} \quad \psi(0)=0. \tag{1.2}$$

The function ψ is an eigenfunction corresponding to the eigenvalue E and the condition $\psi(0)=0$ is called a *Dirichlet boundary condition*. The name of the operator derives from the graphical shape of the full potential[1] $V(x)=x^2+\lambda/x^\alpha$, which shows a pronounced peak near the origin for $\lambda>0$. Further, the Hamiltonian Eq. (1.1) is characterized by means of two parameters,[1] namely λ playing the role of a coupling constant and $\alpha\geqslant 0$ determining the degree of the singularity of the potential at the origin. Therefore, it has been regarded as a two parameter (α,λ) problem. Recently however, the present authors[2] have studied a more general family of Hamiltonians, known as generalized spiked harmonic oscillators, determined by

$$H=H_0+\frac{\lambda}{x^\alpha}, \quad H_0=-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+Bx^2+\frac{A}{x^2} \quad (B>0,\ A\geqslant 0) \tag{1.3}$$

a)Electronic mail: rhall@mathstat.concordia.ca

as an operator in $L_2(0,\infty)$. They argued[2–5] that the basis, constructed from the exact solutions of the singular Gol'dman and Krivchenkov Hamiltonian H_0 in Eq. (1.3), forms a more effective starting point for a perturbative variational treatment of the Hamiltonian (1.1) than the basis of the ordinary harmonic oscillator, as used, for example, in earlier works of Aguilera-Navarro *et al.*[6,7] The objective of the present article is the demonstration of this contention, as well as the establishment of a single variational method suitable for the *complete* set of eigenvalues of the Schrödinger equation (1.2). ''Suitable'' means that, regardless of the values of the parameters λ and α, the presented variational treatment remains valid for all discrete energy eigenvalues E_n, $n=0,1,2,...$ and further, is also valid in the N-dimensional case with an arbitrary angular-momentum quantum number l.

The article is essentially self-contained, providing verification of the most relevant results concerning the generalized spiked harmonic oscillators (1.3). The proof we here give for the completeness of the set $S=\{\psi_n\}$ of eigenfunctions of H_0 is topological in nature and compact. However, the principal advances of the present work over Ref. 2 are twofold. First, we have managed now to derive closed forms for the infinite sums representing the matrix elements of H with respect to S; this, in turn, has allowed us to use these matrices to find accurate energy upper bounds quickly. Second, we have included a free parameter A in the perturbation (1.3) and consequently a final minimization of the matrix eigenvalues over A generates even more accurate eigenvalue approximations, or allows us to determine the eigenvalues to a given accuracy with the use of matrices having smaller dimension D. In Sec. II, we give a brief history of the spiked harmonic oscillator problem and indicate its relevance. Thereafter we present in Sec. III the Gol'dman and Krivchenkov potential[2] as an exactly solvable model of singular type, and prove that the exact solutions of its Schrödinger equation form a complete orthonormal basis of the Hilbert space $L_2(0,\infty)$. This topological fact is accomplished by means of using abscissas of plain convergence, absolute convergence, as well as of holomorphy of the Laplace transform, which abscissas are well discussed in the book of Gustav Doetsch. We further develop in Sec. IV explicit expressions for the matrix elements of the Hamiltonian (1.3) for arbitrary values of α subjected to the restriction $\gamma>\alpha/2$ with special attention given to $\alpha=2$, 4, and 6, for which we have the most complete analytic results. Herein $\gamma=1+\frac{1}{2}\sqrt{1+4A}$ arises out of the energy expressions for the exact solutions of the Gol'dman and Krivchenkov Hamiltonian H_0, whereas $\gamma>\alpha/2$ follows from the necessity of taking inner products of functions of type $f(x)=x^{\gamma-(\alpha+1)/2}\exp(-\beta x^2/2)P(x)$ with one another in the Hilbert space $L_2(0,\infty)$, where $P(x)$ is an arbitrary polynomial. This is followed by our variational treatment in Sec. V, wherein we compare in detail our method with that of the variational approach of Aguliera-Navarro *et al.*[6,7] An extension to the N-dimensional case with arbitrary angular momentum number $l=0,1,2,...$ is provided in Sec. VI. Finally, numerical results with detailed comparisons to previous work, accompanied by concluding remarks, are given in Sec. VII. The difficulty concerning convergence of the eigenvalues approximations calculated from the truncated matrix, in particular the slowness of convergence of the eigenvalues, is looked at in depth for the case of $\alpha=4$. It is proved that there is a critical value $\lambda_c=5/4$ such that convergence is slow when $\lambda<\lambda_c$ and rapid when $\lambda>\lambda_c$.

II. BACKGROUND AND BRIEF HISTORY

There are several reasons for the interest in the spiked harmonic oscillator Hamiltonian.[1–42] First, it represents the simplest model of certain realistic interaction potentials in atomic, molecular, and nuclear physics, and second, its interesting intrinsic properties from the viewpoint of mathematical physics. The potential $V(x)=x^2+\lambda/x^\alpha$ gives rise to a notably long-ago recognized surprise, i.e., no dominance of either of the two interaction potentials x^2 and λ/x^α takes place. Thus, for all values of $\lambda>0$, the term λ/x^α always adds an infinite repulsive barrier near the origin and on the other hand, one can never neglect the x^2 term because its absence demolishes the existence of the ground-state energy.[43,44] Consequently,[7] the potential $x^2+\lambda/x^\alpha$ is like a wide valley extending to ∞. Further, the study for small λ reveals the presence of two different behaviors depending on the value of α. When $\alpha<5/2$, the ground state energy has a power series

expansion[7] in terms of λ. For $\alpha \geqslant 5/2$, the regular perturbation theory fails badly for this kind of (*supersingular*) potential. Another interesting observation is that after the perturbation $\lambda x^{-\alpha}$ is shut off $(\lambda \to 0)$, permanent and irreversible (vestigial) effects of the interaction remain.[5] The latter effect was first noted by Klauder,[8–10] who discussed this remarkable phenomenon in connection with nonrenormalizable covariant quantum field theories. In particular, potentials V, which are sufficiently singular, cannot be smoothly turned off $(\lambda \to 0)$ in the Hamiltonian $H = H_0 + \lambda V$ to restore the free Hamiltonian H_0. This is now know as Klauder's phenomenon.[11–13] Indeed, an obvious approach to obtain information about the spectrum of the Hamiltonian equation (1.1) is to regard the potential $x^{-\alpha}$ as a perturbation of the well-known harmonic oscillator Hamiltonian. By means of the exact solutions u_n of the harmonic oscillator, one attempts to investigate the behavior of the spectrum in terms of the unperturbed eigenfunctions u_n of H_0. Detwiler and Klauder[14] realized that the normal perturbation theory already fails badly for the first correction of the ground-state energy $(n=0)$ for $\alpha \geqslant 3$. Examining the asymptotic behavior of the lowest eigenvalues of H by means of variational arguments, they were able to predict the kind of dependence the ground state energy $E = E(\lambda)$ has on the coupling λ for λ sufficiently small.

Due to the failure of the Rayleigh–Schrödinger series, a modified perturbation theory was required, especially to ascertain the higher-order expressions in the energy expansion in terms of powers of λ. Harrell[1] modified the Rayleigh–Schrödinger series by utilizing the standard (Wentzel–Kramers–Brillouin)-approximation technique for the lowest few orders. This proving to be quite successful, he continued to develop a special perturbation theory, now know as singular perturbation theory, and thereby obtained the first few terms of the perturbed λ-expansion for different values of α. This turned out to be a nonpower series expansion and in fact was of exactly the same order as of Detwiler and Klauder.[14] Its drawback is however, that it is valid only for sufficiently small value of the coupling λ, i.e., for $\lambda \ll 1$.

Since the early work of Detwiler and Klauder and Harrell, spiked harmonic-oscillator Hamiltonian equations (1.1) have become the subject of intensive study lasting over three decades.[2–42] Aguilera-Navarro *et al.*[6] managed to obtain a strong coupling perturbative expansion $(\lambda \gg 2)$ for the ground state energy. Shortly after, Aguilera-Navarro and Guardiola[7] attempted to find a path leading from the weak-coupling regime due to Harrell[1] to the strong coupling regime.[6] Nonetheless, they failed to give a general constructive method to relate the two perturbative regimes for arbitrary values of the exponent α. Special attention was given to certain values of α. Aguilera-Navarro *et al.*[17] analyzed the Hamiltonian (1.1) for $\alpha = 1$ around the three regions $\lambda \to -\infty$, $\lambda \to 0$, and $\lambda \to \infty$ via Rayleigh–Ritz large-order perturbative expansions. Aguilera-Navarro *et al.*[18] studied the particular case of $\alpha = 4$ by using a non-orthonormal set satisfying the correct boundary conditions at $x \to \infty$ and $x \to 0$. Exact and approximate (variational) solutions of the ground state energy of the spiked harmonic oscillator problem have also been reported for particular parameter values in the perturbation potential. Aside from these results, special methods have been developed to compute the eigenvalues numerically with high precision.[30–39]

Most of these results however, concern themselves with different approximation techniques for the ground-state energy for the problem in one spatial dimension. Recently, the N-dimensional case has began to attract the attention of many researchers.[3–5,41,42] In earlier work[2–5] we have pointed out the advantages of basing our variational analysis on an exactly soluble model, which itself has a singular potential term.[2] We examine a family of generalized spiked harmonic-oscillator Hamiltonians (1.1) in terms of a one-dimensional space variable $x\,(0 \leqslant x < \infty)$ with eigenfunctions satisfying Dirichlet boundary condition as stated in Eq. (1.3), that is to say, with wave functions vanishing at the boundaries. The singular orthonormal basis, consisting of the set of exact solutions of H_0, serves as a better starting point for the analysis of the Hamiltonian equation (1.1). In this paper we use these exact solutions of H_0 to provide systematic variational solutions of the spiked harmonic oscillator Hamiltonians (1.1). We first discuss the tools we implement herein, namely the Gol'dman and Krivchenkov orthonormal basis.

III. ORTHONORMALITY OF CONFLUENT HYPERGEOMETRIC SERIES AND SINGULAR POTENTIALS

The purpose of the section is to develop the necessary tools for the variational approach we shall present later. Specifically, we derive in this section the orthonormal basis most suitable for dealing with the Hamiltonian equation (1.3). Although the variational method does not *per se* require the use of a complete orthonormal basis, one can employ in some situations an orthogonal, or even a nonorthogonal,[18] set of sufficiently smooth functions to attain very effective results. In such cases, however, the variational method shall only have meaning for the particular set of chosen functions,[18] and the slightest modification of the original problem shall immediately necessitate a new set of functions or at least some modifications. Since we are interested in a set of basis functions admissible for the entire parameter range of α and λ in Eqs. (1.1) and (1.3) for our variational method, we develop our solution by using the solution of an exactly solvable singular potential whose singularity coincides with that of the spiked harmonic oscillator. Therefore, we use an exactly solvable singular Hamiltonian known as the Gol'dman and Krivchenkov Hamiltonian,[45,46]

$$-\psi''+V_0\left(\frac{a}{x}-\frac{x}{a}\right)^2\psi=E_n\psi, \quad x\in[0,\infty) \quad \text{with} \quad \psi(0)=0, \tag{3.1}$$

namely ψ satisfies the Dirichlet boundary condition. The energy spectrum in terms of the parameters V_0 and a is given by[45]

$$E_n=\frac{4}{a}\sqrt{V_0}\left\{n+\frac{1}{2}+\frac{1}{4}\left(\sqrt{1+4V_0a^2}-2a\sqrt{V_0}\right)\right\}, \tag{3.2}$$

whereas the exact wave functions take the form

$$\psi_n(x)=C_nx^{\nu}\exp\left(-\frac{1}{2}\frac{\sqrt{V_0}}{a}x^2\right){}_1F_1\left(-n,\nu+\frac{1}{2}\frac{\sqrt{V_0}}{a}x^2\right) \tag{3.3}$$

with $\nu=\frac{1}{2}(1+\sqrt{1+4V_0a^2})$. In terms of the Pochhammer symbols,

$$(a)_0=1, \quad (a)_k=a(a+1)(a+2)\ldots(a+k-1)=\frac{\Gamma(a+k)}{\Gamma(a)}, \quad k=1,2,...,$$

expressed in terms of the gamma function Γ, the previous function ${}_1F_1$, known as the confluent hypergeometric function,[47] is defined by

$${}_1F_1(-n;b;z)=\sum_{k=0}^{n}\frac{(-n)_kz^k}{(b)_kk!}. \tag{3.4}$$

To simplify the notation, we introduce parameters $B=V_0a^{-2}$ and $A=V_0a^2$, and thereby obtain an exact solution to the one-dimensional Schrödinger equation with the singular potential

$$V(x)=Bx^2+\frac{A}{x^2}, \quad B>0, A\geqslant 0, \tag{3.5}$$

whose energy spectrum is now given in terms of parameters A and B by

$$E_n=2\beta(2n+\gamma), \quad n=0,1,2,..., \tag{3.6}$$

wherein $\beta=\sqrt{B}$ and $\gamma=1+\frac{1}{2}\sqrt{1+4A}$. The wave functions in this case have the form

$$\psi_n(x)=C_nx^{\gamma-1/2}e^{-(1/2)\beta x^2}\,{}_1F_1(-n;\gamma;\beta x^2) \quad \text{for} \quad n=0,1,2,\ldots. \tag{3.7}$$

The constant C_n in Eq. (3.7) is determined from the normalization condition

$$\int_0^\infty \psi_n^2(x)\mathrm{d}x = 1. \tag{3.8}$$

In order to compute this integral, we need the following lemma, which is a generalization of formula f6 in the appendix of the book *Quantum Mechanics* by Landau and Lifshitz.[46]

Lemma 1: For $\gamma > 0$, and $m,n = 0,1,2,...,$

$$\int_0^\infty x^{2\gamma-1} e^{-\beta x^2}\, {}_1F_1(-n;\gamma;\beta x^2)\, {}_1F_1(-m;\gamma;\beta x^2)\mathrm{d}x = \frac{1}{2}\frac{n!\Gamma(\gamma)}{\beta^\gamma(\gamma)_n}\delta_{mn}, \tag{3.9}$$

where $\delta_{mn} = 0$ for $m \neq n$ and 1 for $m = n$.

Proof: We denote the indefinite integral of the left-hand side of Eq. (3.9) by I_{mn} and have by means of the series representation Eq. (3.4) of the confluent hypergeometric function ${}_1F_1$ that

$$I_{mn} = \sum_{k=0}^{m}\sum_{l=0}^{n}\frac{(-m)_k(-n)_l}{(\gamma)_k(\gamma)_l}\frac{\beta^{k+l}}{k!l!}\int_0^\infty x^{2\gamma+2k+2l-1}e^{-\beta x^2}\mathrm{d}x.$$

Further, after resorting to the integral representation of the gamma function

$$\Gamma(x) = \int_0^\infty e^{-t}t^{x-1}\,\mathrm{d}t, \quad x > 0,$$

and a change of variables, we obtain for $2\gamma + 2k + 2l - 1 > 0$ that

$$I_{mn} = \frac{1}{2\beta^\gamma}\sum_{k=0}^{n}\sum_{l=0}^{m}\frac{(-n)_k(-m)_l}{(\gamma)_k(\gamma)_l}\frac{\Gamma(\gamma+k+l)}{k!l!} = \frac{1}{2\beta^\gamma}\sum_{k=0}^{n}\left[\sum_{l=0}^{m}\frac{(-m)_l(\gamma+k)_l}{(\gamma)_l l!}\right]\frac{(-n)_k\Gamma(\gamma+k)}{(\gamma)_k k!}.$$

The finite sum inside the square brackets is just the series representation of the terminated hypergeometric function ${}_2F_1$, and therefore

$$I_{mn} = \frac{1}{2\beta^\gamma}\sum_{k=0}^{n}{}_2F_1(-m,\gamma+k;\gamma;1)\frac{(-n)_k\Gamma(\gamma+k)}{(\gamma)_k k!}.$$

Applying Chu-Vandermonde's theorem[48] on summing the series ${}_2F_1$ with unit argument, we get

$$I_{mn} = \frac{\Gamma(\gamma)}{2\beta^\gamma(\gamma)_m}\sum_{k=0}^{n}\frac{(-k)_m(-n)_k}{k!}, \tag{3.10}$$

wherein we have invoked the identity

$$(-k)_n = \begin{cases} \dfrac{(-1)^n k!}{(k-n)!} & \text{if } 0 \leqslant n \leqslant k \\ 0 & \text{if } n > k. \end{cases} \tag{3.11}$$

On account of Eq. (3.11), the product $(-k)_m(-n)_k$ in Eq. (3.10) differs from zero only for $n = k = m$, and thus

$$\sum_{k=0}^{n}\frac{(-k)_m(-n)_k}{k!} = n!$$

if $n = m$ or 0 if $n \neq m$, which terminates the proof of our lemma. ■

The reader should realize at this point the connection between the above-mentioned lemma and the orthonormality relation of Laguerre polynomials. In fact, because of the relation[47]

$$ {}_1F_1(-n;\gamma+1;x)=\frac{n!}{(\gamma+1)_n}L_n^{(\gamma)}(x), $$

Eq. (3.9) is just another form of the orthonormality condition for Laguerre ploynomials. Thus the normalization constants C_n of Eq. (3.7) can now be determined via Lemma 1 and the normalization condition Eq. (3.8), and this entails

$$ C_n^{-2}=\frac{1}{2}\frac{n!\Gamma(\gamma)}{\beta^{\gamma}(\gamma)_n}, \tag{3.12} $$

and the normalized wave function equation (3.7) now reads as follows:

$$ \psi_n(x)=(-1)^n\sqrt{\frac{2\beta^{\gamma}(\gamma)_n}{n!\Gamma(\gamma)}}x^{\gamma-1/2}e^{-(1/2)\beta x^2}\,{}_1F_1(-n;\gamma;\beta x^2). \tag{3.13} $$

The alternating coefficients $(-1)^n$ were introduced in the definition of $\psi_n(x)$ to guarantee a smooth transition by means of the identity

$$ {}_1F_1\left(-n,\frac{3}{2},x^2\right)=\frac{(-1)^n}{2x}\frac{n!}{(2n+1)!}H_{2n+1}(x) \tag{3.14} $$

to the odd solutions of the harmonic oscillator problem, namely the case $A=0$ in Eq. (3.7). From the immediately preceeding we arrive at

Theorem 1: For $\psi_n(x)$ defined by Eq. (3.13), the following orthonormality relations

$$ \int_0^{\infty}\psi_n(x)\psi_m(x)\mathrm{d}x=\delta_{mn}, \quad m,n=0,1,2,... $$

hold in $L_2(0,\infty)$.

It may seem that the Hamiltonian H_0 is self-adjoint, whence we could assume the completeness of the normalized eigenfunctions $\{\psi_n(x)\}_{n=0}^{\infty}$ from the general theory of self-adjoint operators. However, we are inhibited from doing this because of the domain of definition of H_0. The Hamiltonian operator H_0 in the Hilbert space $L_2(0,\infty)$ cannot have all of $L_2(0,\infty)$ as its domain of definition on account of the presence of the second derivative in H_0. Consequently, the totality $C_0^{\infty}(0,\infty)$ of infinitely differentiable complex valued functions on $(0,\infty)$ with compact support is initially assumed to be the domain of definition of H_0. $C_0^{\infty}(0,\infty)$ lies dense in $L_2(0,\infty)$ and H_0 is formally adjoint to itself, but not necessarily self-adjoint. To make H_0 self-adjoint, we invoke its Friedrichs extension,[49,50] which is a self-adjoint and exists in principle. If we consider H_0 to stand for its Friedrichs extension, then we need to know its spectrum $\sigma(H_0)=\sigma_d(H_0)\cup\sigma_e(H_0)$, i.e., the disjoint union of its discrete and essential spectrums. $L_2(0,\infty)$ is the direct sum of the eigenspaces of H_0 if and only if the essential spectrum is empty.[51,52] We establish $\sigma_e(H_0)=\varnothing$ by demonstrating completeness for the system $\{\psi_n(x)\}_{n=0}^{\infty}$ in the Hilbert space $L_2(0,\infty)$ of all square integrable functions over the interval $(0,\infty)$ for H_0 in its Friedrichs extension form, by means of the well-known Hahn–Banach theorem.

Theorem 2: The set of $L_2(0,\infty)$-functions $\{\psi_n(x)\}_{n=0}^{\infty}$, defined by Eq. (3.13), is a complete orthonormal basis for the Hilbert space $L_2(0,\infty)$.

Proof: The orthonormality of $\{\psi_n(x)\}_{n=0}^{\infty}$ follows from Theorem 1. To prove completeness, we proceed as follows. On account of the definition (3.13) of $\psi_n(x)$ in terms of the hypergeometric function

$$ {}_1F_1(-n,\gamma,\beta x^2)=\sum_{k=0}^{n}\binom{n}{k}\frac{(-\beta)^{n-k}\Gamma(\beta)}{\Gamma(\gamma+n-k)}x^{2(n-k)} $$

we can express each of the functions ${}_1F_1(-n,\gamma,\beta x^2)(n\geqslant 0)$ uniquely as a finite linear combination of $x^{2n}(n\geqslant 0)$ as well as conversely. This in terms of the span, which we denote by $(L.H.)$, means that $(L.H.)({}_1F_1(-n,\gamma,\beta x^2)(n\geqslant 0))=(L.H.)(x^{2n}(n\geqslant 0))$. We multiply each member of these two sets by $x^{\gamma-1/2}\exp(-\beta x^2/2)$, and thereby obtain a linear subspace of the Hilbert space $L_2(0,\infty)$, whose topological closure satifies

$$ \overline{(L.H.)(\cdot^{\gamma-1/2}\,{}_1F_1(-n,\gamma,\beta\cdot^2)\exp(-\beta\cdot^2/2)(n\geqslant 0))}=\overline{(L.H.)(\cdot^{\gamma-1/2+2n}\exp(-\beta\cdot^2/2)(n\geqslant 0))}, $$

and further, orthogonal complementation yields

$$ \begin{aligned}&[(L.H.)(\cdot^{\gamma-1/2}{}_1F_1(-n,\gamma,\beta^2)\exp(-\beta\cdot^2/2)(n\geqslant 0))]^{\perp}\\ &\quad=[(L.H.)(\cdot^{\gamma-1/2+2n}\exp(-\beta\cdot^2/2)(n\geqslant 0))]^{\perp}.\end{aligned} $$

Now we turn to demonstrating that $[(L.H.)(\cdot^{\gamma-1/2}\,{}_1F_1(-n,\gamma,\beta\cdot^2)\exp(-\beta\cdot^2/2)(n\geqslant 0))]^{\perp}=0$, in other words $\{C_n\cdot^{\gamma-1/2}{}_1F_1(-n,\gamma,\beta\cdot^2)\exp(-\beta\cdot^2/2)\}_{n=0}^{\infty}$ constitutes an orthonormal basis of the Hilbert space $L_2(0,\infty)$ with C_n's given by (3.12). Assuming that $\Phi\in L_2(0,\infty)$ with $\Phi\perp(L.H.)(\cdot^{\gamma-1/2}{}_1F_1(-n,\gamma,\beta\cdot^2)\exp(-\beta\cdot^2/2)(n\geqslant 0))$ leads directly to

$$ \langle\cdot^{\gamma-1/2+2n}\exp(-\beta\cdot^2/2)|\Phi\rangle=\int_0^{\infty}x^{\gamma-1/2+2n}\exp(-\beta x^2/2)\overline{\Phi(x)}\,dx=0\quad(n\geqslant 0). $$

We define

$$ f(s)\equiv\int_0^{\infty}x^{\gamma-1/2}\exp(-sx^2/2)\overline{\Phi(x)}\,dx=\int_0^{\infty}e^{-st}F(t)\,dt, $$

where $F(t)\equiv t^{\gamma/2-3/4}\overline{\Phi(\sqrt{t})}/2$.

Out of the fact that $\Phi\in L_2(0,\infty)$ follows

$$ \begin{aligned}\int_0^{\infty}|e^{-st}F(t)|\,dt&=\int_0^{\infty}1/2t^{\gamma/2-3/4}|\Phi(\sqrt{t})|\exp(-(\Re s)t)\,dt\\ &=\sqrt{2}\int_0^{\infty}t^{\gamma/2-1/2}\exp(-(\Re s)t)|\Phi(\sqrt{t})|\,\frac{1}{\sqrt{2}}t^{-1/4}\,dt\\ &\leqslant\sqrt{2}\sqrt{\int_0^{\infty}|t^{\gamma/2-1/2}\exp(-(\Re s)t)|^2\,dt}\sqrt{\int_0^{\infty}|\Phi(\sqrt{t})|^2\,dt}\\ &=\sqrt{2}\sqrt{\int_0^{\infty}\exp(-2(\Re s)t)t^{\gamma-1}\,dt}\sqrt{\int_0^{\infty}|\Phi(x)|^2\,dx}\\ &=\sqrt{2}\sqrt{\frac{1}{(2\Re s)^{\gamma}}\int_0^{\infty}e^{-t}t^{\gamma-1}\,dt}\|\Phi\|_{L_2(0,\infty)}\\ &=\sqrt{2(\Re s)^{-\gamma}\Gamma(\gamma)}\|\Phi\|_{L_2(0,\infty)}\\ &<\infty.\end{aligned} $$

Herewith the abscissa $\tilde{\alpha}$ of absolute convergence[53] of the Laplace integral $f(s)=\mathcal{L}\{F\}$, namely the smallest real number $\tilde{\alpha}$, such that $\int_0^\infty |e^{-st}F(t)|\mathrm{d}t<\infty$ for all $\Re s>\tilde{\alpha}$, has the property that $\tilde{\alpha}\leqslant 0$. In consequence of our substitution $x=\sqrt{t}$, we have further that

$$\langle \cdot^{\gamma-1/2+2n}\exp(-\beta^2/2)|\Phi\rangle=(-1)^n\int_0^\infty (-t)^n e^{-(\beta/2)t}F(t)\mathrm{d}t=f^{(n)}(\beta/2)=0 \quad (n\geqslant 0). \tag{3.15}$$

Since $f(s)$ is definitely holomorphic in the half-plane $\Re s>0$, because the abscissa of holomorphy $\tilde{\chi}$ satisfies $\tilde{\chi}\leqslant\tilde{\beta}\leqslant\tilde{\alpha}$ ($\tilde{\beta}$ being the abscissa of ordinary convergence of the Laplace Integral[53] $\mathcal{L}\{F\}$), $f(s)$ shall clearly have a Taylor series expansion

$$f(s)=\sum_{n=0}^{\infty}(n!)^{-1}f^{(n)}(\beta/2)(s-\beta/2)^n=0 \quad (|s-\beta/2|<\beta/2) \tag{3.16}$$

in terms of Eq. (3.15) about the point $\beta/2>0$. The radius of convergence of this Taylor series is at least a big as $\beta/2$, since it may happen that the abscissa of holomorphy[53] $\tilde{\chi}$ of the Laplace integral $f(s)=\mathcal{L}\{F\}$ is definitely less than the abscissa $\tilde{\beta}$ of ordinary convergence, not to mention that of absolute convergence $\tilde{\alpha}$. Thus we have that $f(s)\equiv 0$ in the open disk $|s-\beta/2|<\beta/2$ of the s complex plane. By means of the identity theorem of holomorphic functions,[54] we have that the Laplace integral $f(s)=\mathcal{L}\{F\}\equiv 0$ in the half-plane of holomorphy $\Re s>\tilde{\chi}$; and more so in the holomorphy domain of f, which contains its half-plane of holomorphy. The uniqueness of the Laplace-transform implies that $F(t)\equiv 1/2t^{\gamma/2-3/4}\Phi(\sqrt{t})=0$ a.e. in t on the interval $[0,\infty)$. Hence, $\int_0^\infty|\Phi(\sqrt{t})|^2(2\sqrt{t})^{-1}\mathrm{d}t=\int_0^\infty|\Phi(x)|^2\,\mathrm{d}x=0$, namely $\Phi=0$ a.e. on $(0,\infty)$, which is to say that $\{C_n\cdot^{\gamma-1/2}{}_1F_1(-n,\gamma;\beta\cdot^2)\}_{n=0}^\infty$ constitutes a complete orthonormal basis of the Hilbert space $L_2(0,\infty)$. ■

IV. THE MATRIX ELEMENTS FOR SINGULAR POTENTIALS

It is well known that the Schrödinger equation, even in the one-dimensional case, rarely possesses an exact (analytic) solution. Consequently, a multitude of arduous numerical techniques have been implemented to ascertain its energy eigenvalues over several decades; from among these, we mention matrix diagonalization. Our primary aim in this section is to find the matrix elements of the Hamiltonian equation (1.3), whose calculation is achieved by means of

Lemma 2: If $2\gamma-\alpha>0$, then for all pairs of non-negative integers and m and n we have that

$$\int_0^\infty x^{2\gamma-\alpha-1}e^{-\beta x^2}{}_1F_1(-n,\gamma,\beta x^2){}_1F_1(-m,\gamma,\beta x^2)\mathrm{d}x$$

$$=\frac{\beta^{\alpha/2-\gamma}}{2}\frac{\left(\frac{\alpha}{2}\right)_n\Gamma\left(\gamma-\frac{\alpha}{2}\right)}{(\gamma)_n}{}_3F_2\left(-m,\gamma-\frac{\alpha}{2},1-\frac{\alpha}{2};\gamma,1-\frac{\alpha}{2}-n;1\right). \tag{4.1}$$

Proof: Let I_{mn} denote the infinite integral on the left-hand side of Eq. (4.1). Using the series representation equation (3.4) of the confluent hypergeometric function ${}_1F_1$ yields

$$I_{mn}=\sum_{k=0}^{m}\sum_{l=0}^{n}\frac{(-m)_k(-n)_l}{(\gamma)_k(\gamma)_l}\frac{\beta^{k+l}}{k!l!}\int_0^\infty x^{-\alpha+2\gamma+2k+2l-1}e^{-\beta x^2}\,\mathrm{d}x. \tag{4.2}$$

By resorting to the integral representation of gamma function, we obtain under the condition $-\alpha/2+\gamma+k+l>0$ that

$$I_{mn}=\frac{1}{2}\sum_{k=0}^{m}\sum_{l=0}^{n}\frac{(-m)_k(-n)_l}{(\gamma)_k(\gamma)_l}\frac{\beta^{\alpha/2-\gamma}}{k!l!}\Gamma\left(-\frac{\alpha}{2}+\gamma+k-l\right)$$

$$=\frac{1}{2}\beta^{\alpha/2-\gamma}\sum_{k=0}^{m}\left[\sum_{l=0}^{n}\frac{(-n)_l\Gamma\left(-\frac{\alpha}{2}+\gamma+k+l\right)}{(\gamma)_l l!}\right]\frac{(-m)_k}{(\gamma)_k}\frac{1}{k!}. \tag{4.3}$$

This relation we rewrite in terms of the Pochhammer symbols, use $\Gamma(-\alpha/2+\gamma+k+l)=(-\alpha/2+\gamma+k)_l\Gamma(-\alpha/2+\gamma+k)$, invoke Chu–Vandermonde's theorem, and thus write

$$\sum_{l=0}^{n}\frac{(-n)_l\Gamma\left(-\frac{\alpha}{2}+\gamma+k+l\right)}{(\gamma)_l l!}=\sum_{l=0}^{n}\frac{(-n)_l\left(-\frac{\alpha}{2}+\gamma+k\right)_l}{(\gamma)_l l!}\Gamma\left(-\frac{\alpha}{2}+\gamma+k\right)$$

$$=\Gamma\left(-\frac{\alpha}{2}+\gamma+k\right)\,{}_2F_1\left(-n-\frac{\alpha}{2}+\gamma+k;\gamma;1\right)$$

$$=\Gamma\left(-\frac{\alpha}{2}+\gamma+k\right)\frac{\left(\frac{\alpha}{2}-k\right)_n}{(\gamma)_n} \tag{4.4}$$

for the finite sum inside the square brackets of Eq. (4.3). Consequently, we arrive at

$$I_{mm}=\frac{1}{2}\beta^{\alpha/2-\gamma}\sum_{k=0}^{m}\Gamma\left(-\frac{\alpha}{2}+\gamma+k\right)\frac{\left(\frac{\alpha}{2}-k\right)_n}{(\gamma)_n}\frac{(-m)_k}{(\gamma)_k}\frac{1}{k!}$$

$$=\frac{1}{2}\beta^{\alpha/2-\gamma}\frac{\Gamma(\gamma)}{(\gamma)_n}\sum_{k=0}^{m}(-1)^k\binom{m}{k}\frac{\Gamma\left(\frac{\alpha}{2}+n-k\right)\Gamma\left(-\frac{\alpha}{2}+\gamma+k\right)}{\Gamma(\gamma+k)\Gamma\left(\frac{\alpha}{2}-k\right)}, \tag{4.5}$$

wherein we have used the identity $(-m)_k/k!=(-1)^k\binom{m}{k}$. We further simplify expression (4.5) by taking note of

$$(a-k)_n=\frac{(1-a)_k(a)_n}{(1-a-n)_k}$$

in order to justify the relation

$$I_{mn}=\frac{1}{2}\beta^{\alpha/2-\gamma}\frac{\Gamma\left(\gamma-\frac{\alpha}{2}\right)\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n}\sum_{k=0}^{m}\frac{(-m)_k\left(\gamma-\frac{\alpha}{2}\right)_k\left(1-\frac{\alpha}{2}\right)_k}{(\gamma)_k\left(1-\frac{\alpha}{2}-n\right)_k k!}=\frac{1}{2}\beta^{\alpha/2-\gamma}\frac{\Gamma\left(\gamma-\frac{\alpha}{2}\right)\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n}\,{}_3F_2$$

$$\left(-m,\gamma-\frac{\alpha}{2},1-\frac{\alpha}{2};\gamma,1-\frac{\alpha}{2}-n;1\right), \tag{4.6}$$

which is valid for all values of α and γ such that $\gamma-\alpha/2>0$. This completes the proof of the lemma. ■

It should be noted that Eq. (4.1) is a generalization of Eq. (3.9), and under the limit process of $\alpha\to 0^+$ Eq. (4.1) reduced to Eq. (3.9). In order to prove this, we proceed by proving

$$\lim_{\alpha\to 0^+}\left(\frac{\alpha}{2}\right)_n {}_3F_2\left(-m,\gamma-\frac{\alpha}{2},1-\frac{\alpha}{2};\gamma,1-\frac{\alpha}{2}-n;1\right)=n!\,\delta_{mn}. \tag{4.7}$$

This can be demonstrated by bringing in the series representation of the terminated hypergeometric function ${}_3F_2$, which leads to

$$\left(\frac{\alpha}{2}\right)_n {}_3F_2\left(-m,\gamma-\frac{\alpha}{2},1-\frac{\alpha}{2};\gamma,1-\frac{\alpha}{2}-n;1\right)=\sum_{k=0}^{m}\frac{(-m)_k\left(\gamma-\frac{\alpha}{2}\right)_k\left(1-\frac{\alpha}{2}\right)_k(-1)^n\Gamma\left(1-\frac{\alpha}{2}\right)}{k!(\gamma)_k\Gamma\left(1-\frac{\alpha}{2}-n+k\right)}$$

by means of the identities

$$\left(1-\frac{\alpha}{2}-n\right)_k=\frac{\Gamma\left(1-\frac{\alpha}{2}-n+k\right)}{\left(1-\frac{\alpha}{2}\right)_{-n}\Gamma\left(1-\frac{\alpha}{2}\right)}=(-1)^n\frac{\left(\frac{\alpha}{2}\right)_n\Gamma\left(1-\frac{\alpha}{2}-n+k\right)}{\Gamma\left(1-\frac{\alpha}{2}\right)}.$$

Therefore, by taking the limit as $\alpha\to 0^+$, we can easily see that

$$\lim_{a\to 0^+}\left(\frac{\alpha}{2}\right)_n {}_3F_2\left(-m,\gamma-\frac{\alpha}{2},1-\frac{\alpha}{2};\gamma,1-\frac{\alpha}{2}-n;1\right)=\sum_{k=0}^{m}\frac{(-m)_k(-1)^n}{\Gamma(1-n+k)}=\sum_{k=0}^{m}\frac{(-m)_k(-k)_n}{k!},$$

where we have made use of the relation $(1+k)_{-n}=(-1)^n/(-k)_n$. Again, the product $(-m)_k(-k)_n$ leads to the fact that the sum

$$\sum_{k=0}^{m}\frac{(-m)_k(-k)_n}{k!}$$

collapses to $n!$, for the case of $m=k=n$, and 0 otherwise.

The matrix elements of the Hamiltonian (1.3) are now given by means of Lemma 3 in terms of the infinite integral

$$x_{mn}^{-\alpha}=\langle\psi_m|x^{-\alpha}|\psi_n\rangle=C_mC_n\int_0^\infty x^{2\gamma-\alpha-1}e^{-\beta x^2}\,{}_1F_1(-n,\gamma,\beta x^2)\,{}_1F_1(-m,\gamma,\beta x^2)\mathrm{d}x. \tag{4.8}$$

Therefore, as a consequence of Lemma 2 and Eq. (3.12), the matrix elements now assume the explicit forms

$$x_{mn}^{-\alpha}=(-1)^{n+m}\beta^{\alpha/2}\frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n}\frac{\Gamma\left(\gamma-\frac{\alpha}{2}\right)}{\Gamma(\gamma)}\sqrt{\frac{(\gamma)_n(\gamma)_m}{n!m!}}\,{}_3F_2\left(-m,\gamma-\frac{\alpha}{2},1-\frac{\alpha}{2};\gamma,1-n-\frac{\alpha}{2};1\right); \tag{4.9}$$

among which the following is of particular interest

$$x_{0n}^{-\alpha}=(-1)^n\beta^{\alpha/2}\frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n}\frac{\Gamma\left(\gamma-\frac{\alpha}{2}\right)}{\Gamma(\gamma)}\sqrt{\frac{(\gamma)_n}{n!}}. \tag{4.10}$$

In the case of α being a non-negative even number ($\alpha=2,4,6,...$), the hypergeometric function ${}_3F_2$ in Eq. (4.9) may be looked upon as a terminated polynomial of degree $1-\alpha/2$ instead of an m-degree polynomial; thus for $n\geqslant m$ and $\alpha=2,4,6,...$ we have that

$${}_3F_2\left(-\left(\frac{\alpha}{2}-1\right),\gamma-\frac{\alpha}{2},-m;\gamma,1-n-\frac{\alpha}{2};1\right)=\sum_{s=0}^{[\alpha/2-1]}\frac{(-m)_s\left(\gamma-\frac{\alpha}{2}\right)_s\left(1-\frac{\alpha}{2}\right)_s}{s!(\gamma)_s\left(1-\frac{\alpha}{2}-n\right)_s}. \tag{4.11}$$

As a result hereof, the matrix elements (4.9) further simplify into the closed form expressions immediately appearing. These are most suitable for computational purposes as for the case of $\gamma>0$ and $\alpha=0$, we indeed shall have

$$x_{mn}^{0}=\begin{cases}1 & \text{if } n=m\\ 0 & \text{if } n\neq m\end{cases} \tag{4.12}$$

after using Eq. (4.7); as it should have been expected in this specific case. For the case of $\gamma>1$ and $\alpha=2$, we have from Eq. (4.9) that

$$x_{mn}^{-2}=\begin{cases}(-1)^{m+n}\beta\dfrac{\Gamma(\gamma-1)}{\Gamma(\gamma)}\sqrt{\dfrac{n!(\gamma)_m}{m!(\gamma)_n}} & \text{if } n\geqslant m\\ (-1)^{m+n}\beta\dfrac{\Gamma(\gamma-1)}{\Gamma(\gamma)}\sqrt{\dfrac{m!(\gamma)_n}{n!(\gamma)_m}} & \text{if } m\geqslant n.\end{cases} \tag{4.13}$$

On the other hand, if the case is $\gamma>2$ and $\alpha=4$, we then have from Eqs. (4.9) and (4.11) that

$$x_{mn}^{-4}=\begin{cases}(-1)^{m+m}\beta^2\dfrac{\Gamma(\gamma-2)}{\Gamma(\gamma+1)}\sqrt{\dfrac{n!(\gamma)_m}{m!(\gamma)_n}}[\gamma(n-m+1)+2m] & \text{if } n\geqslant m\\ (-1)^{m+n}\beta^2\dfrac{\Gamma(\gamma-2)}{\Gamma(\gamma+1)}\sqrt{\dfrac{m!(\gamma)_n}{n!(\gamma)_m}}[\gamma(m-n+1)+2n] & \text{if } m\geqslant n.\end{cases} \tag{4.14}$$

As a final case that we illustrate, namely $\gamma>3$ and $\alpha=6$, we point to the fact that Eq. (4.9) lets us deduce

$$x_{mn}^{-6}=\begin{cases}(-1)^{m+n}\dfrac{\beta^3}{2}\dfrac{\Gamma(\gamma-3)}{\Gamma(\gamma+2)}\sqrt{\dfrac{n!(\gamma)_m}{m!(\gamma)_n}}[(2+n)(1+n)\gamma(\gamma+1)-2m(1+n)\\ \quad\times(\gamma-3)(\gamma+1)-m(1-m)(\gamma-2)(\gamma-3)] & \text{if } n\geqslant m\\ (-1)^{m+n}\dfrac{\beta^3}{2}\dfrac{\Gamma(\gamma-3)}{\Gamma(\gamma+2)}\sqrt{\dfrac{m!(\gamma)_n}{n!(\gamma)_m}}[(2+m)(1+m)\gamma(\gamma+1)-2n(1+m)\\ \quad\times(\gamma-3)(\gamma+1)-n(1-n)(\gamma-2)(\gamma-3) & \text{if } m\geqslant n.\end{cases} \tag{4.15}$$

Actually, we can derive similar expressions for all even integers beyond 6, i.e., $\alpha=8,10,...$. We point to the cases where $m\geqslant n$, where the derivation is achieved by interchanging the order of the

summation of Eq. (4.2) and applying thereafter Eq. (4.11) in reversed order. The particular case of $A=0$ (or $\gamma=\frac{3}{2}$) and $B=1$, that is, allows us, of course, to recover the result of Aguilera-Navarro *et al.*[6] as a special case.

V. VARIATIONAL APPROACH

In this section we implement the results developed in Sec. IV to calculate the matrix elements of $x^{-\alpha}$ by means of a complete orthonormal basis. Thereby we shall be able to introduce a variational treatment of the spiked harmonic oscillator Hamiltonian given by Eq. (1.1). The principle idea is the representation of the Hamiltonian equation (1.1) as

$$H=-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+Bx^2+\frac{\lambda}{x^\alpha}=-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+Bx^2+\frac{A}{x^2}+\left(\frac{\lambda}{x^\alpha}-\frac{A}{x^2}\right), \tag{5.1}$$

where, at a later point, $A(\neq 0)$ plays the role of an extra degree of freedom, which shall be determined through a minimization procedure. Although the idea is not complicated, it has many advantages and we mention just a few. First, the range of α is no longer restricted and it can be extended as one pleases, provided the condition $2\gamma>\alpha$ or more explicitly $A>\frac{1}{4}(\alpha-2)^2-\frac{1}{4}$ is satisfied. Second, it substantially reduces the number of basis elements required for the computation of the eigenvalues of the Hamiltonian equation (1.1), even for the intermediate region $\lambda \approx 1$. Third, it be can be adapted effectively and allows easy handling by means of symbolic software such as Mathematica. Fourth, the approach of Aguilera-Navarro *et al.* now becomes a special case, namely set $A=0$ and $B=1$. Fifth, it can be easily extended to the case of N dimensions, where the orbital angular momentum number l is arbitrary, with minor modifications only, as we shall see in Sec. VI.

Let $\psi(x)$ be a *trial function* for Hamiltonian H given by Eq. (5.1), and let us suppose that $\psi(x)$ is expandable as finite linear combinations of the basis functions $\psi_n(x)$ as given by Eq. (3.13), i.e.,

$$\psi(x)=\sum_{n=0}^{D-1} a_n\psi_n(x). \tag{5.2}$$

The problem now is to minimize the eigenenergies of Eq. (5.2) with respect to the variational parameters a_n, $n=0,1,...,D-1$ in the finite dimensional subspace H_D spanned by the D functions ψ_0, $\psi_1,\ldots,\psi_{D-1}$. However, this is equivalent to diagonalizing the Hamiltonian in Eq. (5.2) in the subspace H_D. By separating the Hamiltonian equation (5.1) into two contributions $H_0=-\mathrm{d}^2/\mathrm{d}x^2+Bx^2+Ax^{-2}$ and $H_I=\lambda x^{-\alpha}-Ax^{-2}$, we have

$$H_{mn}=\int_0^\infty \psi_m(x)H\psi_n(x)\mathrm{d}x\equiv\langle\psi_m|H_0|\psi_n\rangle+\langle\psi_m|H_I|\psi_n\rangle,\quad m,n=0,1,2,...,D-1. \tag{5.3}$$

Since the matrix representation of H_0 is diagonal in the basis $\{\psi_n\}_0^\infty$, the first term on the right-hand side of Eq. (5.3) yields the exact solution of Gol'dman and Krivchenkov potential equation (3.6), i.e.,

$$\langle\psi_m|H_0|\psi_n\rangle=2\beta(2n+\gamma)\delta_{mn}\quad(\beta=\sqrt{B},\gamma=1+\tfrac{1}{2}\sqrt{1+4A}),$$

and the second term on the right-hand side of Eq. (5.3) is given by

$$\langle\psi_m|H_I|\psi_n\rangle=\lambda\langle\psi_m|x^{-\alpha}|\psi_n\rangle-A\langle\psi_m|x^{-2}|\psi_n\rangle,$$

where $\langle\psi_m|x^{-\alpha}|\psi_n\rangle$ and $\langle\psi_m|x^{-2}|\psi_n\rangle$ are given by Eqs. (4.9) and (4.13), respectively.

Two important observations follow from these results. First, the matrix elements of the Hamiltonian (5.1) in terms of the Gol'dman and Krivchenkov basis equation (3.13) are given explicitly by $(m,n=0,1,2,...,D-1,n\geqslant m)$

$$H_{mn}=2\beta(2n+\gamma)\delta_{nm}+(-1)^{n+m}\lambda\beta^{\alpha/2}\frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n}\frac{\Gamma\left(\gamma-\frac{\alpha}{2}\right)}{\Gamma(\gamma)}\sqrt{\frac{(\gamma)_n(\gamma)_m}{n!m!}}$$
$$\times {}_3F_2\left(-m,\gamma-\frac{\alpha}{2},1-\frac{\alpha}{2};\gamma,1-n-\frac{\alpha}{2};1\right)-(-1)^{m+n}\frac{A\beta}{\gamma-1}\sqrt{\frac{n!(\gamma)_m}{m!(\gamma)_n}} \tag{5.4}$$

taken over the D-dimensional subspace spanned by basis (3.13). The expressions in Eq. (5.4) are highly suitable for the systematic computer-aided calculations of the energy eigenvalues via diagonalization and subsequent minimization of the matrix

$$\min_A \operatorname{diag}\begin{pmatrix} H_{00} & H_{10} & \cdots & H_{1D-1} \\ H_{10} & H_{11} & \cdots & H_{1D-1} \\ \cdots & \cdots & \cdots & \cdots \\ H_{D-10} & H_{D-11} & \cdots & H_{D-1D-1} \end{pmatrix}. \tag{5.5}$$

Second, by increasing the matrix dimension D, we can always improve these upper energy bounds. In the variational analysis of the ground state energy of the singular potential $V(x)=x^2+\lambda x^{-\alpha}$, Aguilera-Navarro *et al.*[6] utilized an orthonormal basis of harmonic oscillator eigenfunctions on the interval $(0,\infty)$, i.e., the set of Hermite functions generated by the nonsingular harmonic-oscillator potential x^2. This is equivalent to our basis functions for the case $B=1$ and $A=0$, as mentioned earlier. The shortcomings of their approach, however, are as follows. First, validity only holds for $\alpha<3$. Second, a huge set of the basis elements is needed to obtain reasonably accurate eigenvalues, and this even for the intermediate region $(\lambda\approx 1)$.

VI. THE *N*-DIMENSIONAL CASE

In order to extended the scope of our variational analysis to the N-dimensional spiked harmonic oscillator Hamiltonian equation (1.1), we first determine the exact solutions of the N-dimensional Schrödinger equation with a Gol'dman and Krivchenkov potential equation (3.5). To do this, we notice that the A term of the Gol'dman and Krivchenkov potential has the dimensions of kinetic energy, such as the term that appears in higher-dimensional systems. We therefore may replace A in Eq. (3.5) with

$$A\to A+\Lambda(\Lambda+1),\quad \Lambda=l+\tfrac{1}{2}(N-3),\quad N\geqslant 2, \tag{6.1}$$

and thereby obtain an exact solutions of N-dimensional radial Schrödinger equation

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+\frac{\Lambda(\Lambda+1)}{x^2}+Bx^2+\frac{A}{x^2}\right)\psi_{nl}=E^N_{nl}\psi_{nl}. \tag{6.2}$$

Such exact solutions are generated from the well-known solutions of harmonic oscillator potential by two simple transformations. We first replace the angular momentum l in the harmonic oscillator energy expression $\beta(4n+2l+3)$, $n=0,1,2,...$ by $-\frac{1}{2}+\sqrt{A+(l+\frac{1}{2})^2}$, and subsequently replace l with Λ. Thus, the exact eigenvalues of N-dimensional Schrödinger equation with a Gol'dman and Krivchenkov potential are

$$E^N_{nl}=2\beta(2n+\gamma_N),\quad n,l=0,1,2,..., \tag{6.3}$$

where $\beta=\sqrt{B}$ and $\gamma_N=1+\sqrt{A+(\Lambda+\frac{1}{2})^2}$, while the exact eigenfunctions are given by

$$\psi_{nl}(x)=(-1)^n\sqrt{\frac{2\beta^{\gamma_N}(\gamma_N)_n}{n!\Gamma(\gamma_N)}}x^{\gamma_N-1/2}e^{-(1/2)\beta x^2}\,{}_1F_1(-n;\gamma_N;\beta x^2). \tag{6.4}$$

TABLE I. The rate of convergency for the upper bound of the ground state energy E_0 of the Schrödinger equation $(-\Delta+x^2+\lambda/x^{0.5})\psi=E_0\psi$ for $\lambda=0.1$ and $\lambda=1000$. $E_0^{A=0}$ obtained by diagonalization of the $D\times D$ matrix elements, E_0^A obtained by diagonalization of the $D\times D$ matrix elements then minimizing with respect to the parameter A.

	$\lambda=0.1$		$\lambda=1000$	
$D\times D$	$E_0^{A=0}$	E_0^A	$E_0^{A=0}$	E_0^A
1×1	3.102 277	3.102 185	1025.765 672	415.934 312
2×2	3.102 167	3.102 149	746.081 846	415.932 051
3×3	3.102 151	3.102 143	642.417 430	145.890 659
5×5	3.102 143	3.102 141	549.825 333	415.889 798
10×10	3.102 140	3.102 139 (Exact)	461.349 666	415.889 785 (Exact)

The matrix elements in this case turn out to be

$$\langle\psi_{ml}|x^{-\alpha}|\psi_{nl}\rangle=(-1)^{n+m}\beta^{\alpha/2}\frac{\left(\frac{\alpha}{2}\right)_n}{(\gamma)_n}\frac{\Gamma\left(\gamma_N-\frac{\alpha}{2}\right)}{\Gamma(\gamma_N)}\sqrt{\frac{(\gamma_N)_n(\gamma_N)_m}{n!m!}}$$
$$\times{}_3F_2\left(-m,\gamma_N-\frac{\alpha}{2},1-\frac{\alpha}{2};\gamma_N,1-n-\frac{\alpha}{2};1\right)\quad N\geqslant2. \tag{6.5}$$

Matrix elements for the special cases of $\alpha=2,4,6,...$ are obtained by substituting in Eqs. (4.13)–(4.15) for γ the expression γ_N, where $\gamma_N=1+\sqrt{A+(\Lambda+\frac{1}{2})^2}$. The matrix elements of the Hamiltonian equation (6.2) now turn out to be very similar to those in Eq. (5.4), namely

$$H_{mn}=2\beta(2n+\gamma_N)\delta_{mn}+\lambda\langle\psi_{ml}|x^{-\alpha}|\psi_{nl}\rangle-A\langle\psi_{ml}|x^{-2}|\psi_{nl}\rangle,\quad N\geqslant2. \tag{6.6}$$

Since the purpose of the present work is to consider the variational analysis of the eigenvalues of the Hamiltonian equation (1.1) with Dirichlet boundary condition, we restricted ourselves to the case of $N\geqslant2$ in order to avoid problems stemming from the degeneracy of the spectrum in the case of $N=1$. The one-dimensional case Eq. (5.4) on $L_2(0,\infty)$ is recovered by setting $D=3$ and $l=0$. Further, the recovery of the results of Aguilera-Navarro *et al.* is achieved by substituting $A=0$, $B=1$, $D=3$, and $l=0$ in Eq. (6.6).

VII. NUMERICAL RESULTS

Although the variational method has been used earlier in one form or another, the special form it takes in the present article has a specific purpose. First, the demonstration of the validity of an accurate and uniform approximation not only for the ground state energy of Eq. (1.1), but also for the entire spectrum in arbitrary dimensions with arbitrary angular-momentum number. And second, its applicability to general values of the parameters (α, λ) of the potential, subjected to the restriction $\alpha<2\gamma$. The achievement of these purposes is due to the closed forms we have been able to obtain for the matrix-elements Eq. (4.9). At this point we note that the variational results are upper bounds to the energy levels, in accordance with the variational theorem.

For $\alpha<2$ the variational method gives excellent results for arbitrary value of the coupling λ. The advantage of the minimization process with respect to parameter A is shown in Table I. Herein we compare the numerical values obtained by diagonalization for $\alpha=0.5$ for different dimensions of the matrix equation (5.5) with numerical values obtained by the process of diagonalization and minimization with respect to A. There is an interesting observation, which must be noted here. For given $\alpha<2$, the dimension of the matrix required for obtaining results of a given accuracy depends on the behavior of the coupling λ. For the case where λ is small, however, we can get away with a matrix equation (5.5) of smaller dimension as compared to the case where λ is large. To further

TABLE II. A comparison between the results E^{RP} by means of Ricccati–Padé (Ref. 17) and E^R by means of renomalized series (Ref. 17) and the result of the present work E (correct to seven digits shown) for $\alpha=1$ and various values of the coupling λ.

λ	E^{RP}	E^R	E
0.001	3.001 128	3.001 143	3.001 128
0.01	3.011 276	3.011 417	3.011 276
0.1	3.110 9	3.113 386	3.112 068
1	4.057 906	4.064 649	4.057 888
10	10.577 483	10.577 825	10.577 485

illustrate this point, a one-dimension subspace (1×1 matrix) is adequate for calculating the eigenvalue 3.001 128 (exact to the accuracy quoted) for $\lambda=0.001$ when $\alpha=1$; but for $\lambda=10$, on the other hand, a matrix at least of size 80×80 is necessary to obtain the eigenvalue 10.577 48. In the case of $\alpha=1$, we present in Table II a comparison of our numerical results to some previous work.[17] For $\alpha>2$, the situation is completely reversed.

For $\alpha=2$, the first variational approximation (subspace of dimension one) to the ground state eigenvalues of the spiked harmonic oscillator Hamiltonian is

$$E_0(\alpha=2)=2\beta\gamma+\frac{\lambda\beta}{\gamma-1}-\frac{A\beta}{\gamma-1},\quad \gamma=1+\frac{1}{2}\sqrt{1+4A}. \tag{7.1}$$

The minimization of this expression with respect to the parameter A can be easily performed and leads to $A=\lambda$. On substituting this back into Eq. (7.1) we get $E_0=2\beta(1+\frac{1}{2}\sqrt{1+4A})$, which is the exact result quoted in Eq. (3.6) for $n=0$.

For arbitrary α, the first variational approximation (subspace of dimension 1) of the ground state eigenvalues of the Hamiltonian equation (1.1) is

$$\epsilon_0=\min_A E_0=\min_A\left\{2\beta\gamma+\lambda\beta^{\alpha/2}\frac{\Gamma\left(\gamma-\frac{\alpha}{2}\right)}{\Gamma(\gamma)}-\frac{A\beta}{\gamma-1}\right\},\quad \gamma=1+\frac{1}{2}\sqrt{1+4A}. \tag{7.2}$$

When $D=2$, i.e., subspace of dimension 2, the diagonalization can also be performed analytically via the secular equation, that is to say by means of the expression

$$\epsilon_\pm=\min_A E_\pm=\min_A\{\tfrac{1}{2}[(H_{00}+H_{11})\pm\sqrt{(H_{00}-H_{11})^2+(2H_{01})^2}]\}. \tag{7.3}$$

where $\epsilon_0=\epsilon_-$ and $\epsilon_1=\epsilon_+$. Moreover, one can obtain analytic expressions for upper bound eigenvalues[4] in this case.

Because of the simple formulas for the matrix elements in the cases of $\alpha=4$ and $\alpha=6$ given by (4.14) and (4.15), respectively, the determination of the energy values to any desired accuracy has now been reduced to an easy task. A heuristic scheme for ascertaining the eigenvalues to any required number of digits is as follows. The eigenvalues obtained from successive levels, such as $(1\times1,2\times2,\ldots)$, of the truncated matrix (5.5) are compared, and the calculation ceases when the successive eigenvalues agree with each other up to the prescribed decimal place. It is sufficient, therefore, to use the N-dimensional case for the matrix elements equation (6.5) for calculation purposes. To recover the one-dimensional case, we may set $D=3$ and $l=0$, and to recover the results of Aguilera-Navarro *et al.*, we set $A=0$, $B=1$, $D=3$, and $l=0$. Table III illustrates the use of this procedure for the case of $\alpha=4$ and $\lambda=1000$ in the dimensions $N=2-10$.

Another advantage of the variational approach presented herein is the amount of information that we get about the spectrum of the Hamiltonian equation (1.1) every time we compute the eigenvalues via the diagonalization and minimization. Indeed, we obtain for an arbitrary matrix

TABLE III. Upper bounds E^U for $H=-\Delta+x^2+1000/x^4$ for dimension $N=2-10$, obtained by diagonalization then minimization of the 30×30 matrix elements. The "exact" values E were obtained by direct numerical integration of Schrödinger's equation.

(5.5) of size D a set of upper bounds for the eigenvalues $E_0, E_l, \ldots, E_{D-1}$. Each can be improved by either an increase in the dimension of the matrix, or by extracting the desired level through the diagonalization and thereafter minimizing with respect to parameter A, which is illustrated in Table V.

For $\alpha>2$ and small values of λ, the variational method is still applicable, however the eigenvalues converge very slowly, and an immense number of matrix elements are needed in order to obtain accurate results. In principle, the method is still effective as we see from Table V, but at the expense of using a huge number of matrix elements. On the other hand, we obtained accurate eigenvalues with the use of a modest number of matrix elements for λ varying between 1000 and 0.01, as Table VI indicates. An interesting explanation of this lies in the following comment. Let us look at the perturbed Hamiltonian

$$H=-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+x^2+\frac{A}{x^2}+\epsilon\left(\frac{\lambda}{x^\alpha}-\frac{A}{x^2}\right) \tag{7.4}$$

instead of the one given by Eq. (5.1), and solve the matrix eigenvalue problem by expanding the determinant in powers of ϵ up to and including ϵ^2. It is well known[6] that we shall end up with the perturbation-like formula (after setting $\epsilon=1$)

$$E=E_0+\lambda\langle\psi_0|x^{-\alpha}|\psi_0\rangle-A\langle\psi_0|x^{-2}|\psi_0\rangle-\sum_{n\neq0}^{D}\frac{|\langle\psi_0|\lambda x^{-\alpha}-Ax^{-2}|\psi_n\rangle|^2}{E_n-E_0}, \tag{7.5}$$

where the summation on the right-hand side is finite and D is the number of the basis functions used. By analyzing this sum, we shall come to understand the slow convergence of the eigenvalues calculated by means of the variational approach. For the sake of simplicity, let us restrict ourselves to the case of $\alpha=4$. With the aid of Eqs. (4.13) and (4.14), the sum in Eq. (7.5) becomes

TABLE IV. For arbitrary size $D\times D$ of the matrix (5.5) for $H=-\Delta+x^2+1000/x^4$, a set of upper bounds for the eigenvalues $E_0, E_1, \ldots, E_{D-1}$ that can improve by increasing the size D.

[a]From Ref. 14.
[b]From Ref. 1.
[c]From Ref. 32. Richardson extrapolation. Correct to the six digits shown.
[d]From Padé approximant technique (see Ref. 23).
[e]From the Lanczos/grid method (see Ref. 23). Correct to the six digits shown.
[f]From the present work.

$$\sum_{n\neq 0}^{D}\frac{|\langle\psi_0|\lambda x^{-4}-Ax^{-2}|\psi_n\rangle|^2}{E_n-E_0}=\frac{1}{4}\frac{\Gamma^2(\gamma-2)}{\Gamma^2(\gamma)}\left[\lambda^2\sum_{n=1}^{D}\frac{(n+1)!}{(\gamma)_n}+2\lambda(\lambda-A(\gamma-2))\sum_{n=1}^{D}\frac{(n+1)!}{n(\gamma)_n}+(\lambda-A(\lambda-2))^2\sum_{n=1}^{D}\frac{(n+1)!}{n^2(\gamma)_n}\right] \tag{7.6}$$

in this case. For $D\to\infty$, the sums on the right-hand side of Eq. (7.6) have closed-form expressions in terms of hypergeometric functions, particularly

$$\sum_{n\neq 0}^{\infty}\frac{|\langle\psi_0|\lambda x^{-4}-Ax^{-2}|\psi_n\rangle|^2}{E_n-E_0}=\frac{1}{2\gamma}\frac{\Gamma^2(\gamma-2)}{\Gamma^2(\gamma)}[\lambda^2\,{}_2F_1(3,1;\gamma+1;1)+2\lambda(\lambda-A(\gamma-2))\,{}_3F_2(3,1,1;2,\gamma+1;1)+(\lambda-A(\gamma-2))^2\,{}_4F_3(3,1,1,1;2,2,\gamma+1;1)]. \tag{7.7}$$

Herein the conditions of the convergence of hypergeometric functions[48] guarantee that the function ${}_2F_1$ converges for $\gamma>3$, the function ${}_3F_2$ converges for $\gamma>2$, and ${}_4F_3$ converges for $\gamma>1$. Thus, Eq. (7.7) holds for $\gamma>3$ or $A>3.75$ in general, but for $\alpha=4$, the matrix *elements* equation (4.9) holds for $\gamma>2$ or $A>0.75$. This demonstrates the difficulties one encounters with the variational method for small value of λ. To understand this further, we note the relation between λ and the parameter A. Thus for λ that is small, A is small; on the other hand, λ large implies that A is large. This is evident from the first variational approximation, namely Eq. (7.2) yields

TABLE VI. A comparison between the results E^F of Fernández (Ref. 24), and the results E^{HS} of Hall *et al.* (Ref. 29) and the result of the present work E^{HSK} (correct to seven digits shown) for $\alpha=4$ and $\alpha=6$ and various values of the coupling λ.

	$\alpha=4$			$\alpha=6$		
λ	E_0^F	E_0^{HS}	E_0^{HSK}	E_0^F	E_0^{HS}	E_0^{HSK}
1000	21.384 46	21.370 26	21.369 462	12.737 60	12.725 65	12.718 617
100	11.292 41	11.265 86	11.265 080	8.422 60	8.420 96	8.413 358
10	6.649 78	6.609 66	6.606 622	6.016 40	6.014 94	6.003 209
1	4.548 79	4.504 16	4.494 179	4.676 88	4.684 97	4.659 940
0.1	3.626 44	3.600 44	3.575 557	4.019 15	4.042 84	3.915 665
0.01	3.237 75	3.249 80	3.205 486	3.524 93	3.580 70	3.505 492

$$\epsilon_0 = \min_A \left\{ 2\gamma + \frac{\lambda}{(\gamma-1)(\gamma-2)} - \frac{A}{\gamma-1} \right\}, \quad \gamma = 1 + \frac{1}{2}\sqrt{1+4A}. \tag{7.8}$$

After differentiating Eq. (7.8) with respect to A, it can be shown that the relation between A and λ is implicitly given by

$$\lambda = \frac{(\gamma-2)^2(4(\gamma-1)^2-1)}{4(2\gamma-3)}, \tag{7.9}$$

from which it is quite easy to see that λ is an increasing function of γ for all $\gamma > 2$. Thus for Eq. (7.7) to converge, we must have $\gamma > 3$, i.e., $\lambda > 1.25$. This demonstrates that for $\lambda < 1.25$, the accuracy of the eigenvalue calculations by means of the variational method necessitates a matrix of very large order.

VIII. CONCLUSION

In this paper we have carried our study of the spiked harmonic-oscillator problem further by expressing the Hamiltonian H given by Eq. (1.1) as the perturbation of the singular Gol'dman and Krivchenkov Hamiltonian $H_0 = -\mathrm{d}^2/\mathrm{d}x^2 + Bx^2 + A/x^2$, where the expression $\lambda x^{-\alpha} - Ax^{-2}$ is looked upon as the perturbation term. We have provided a compact proof of the fact that the eigenfunctions of order 0 generated by H_0 form a suitable singularity-adapted basis for the appropriate Hilbert space of the full problem. Our principal results are fourfold: (1) the proof of the completeness of the orthogonal set of normalized eigenvalues of H_0 by means of the domains of convergence, absolute convergence, holomorphy of the Laplace transform; (2) the derivation of the compact closed form (1.3) for the matrix elements $x_{mn}^{-\alpha}$ via infinite integrals of products of two confluent hypergeometric functions; (3) a variational method applied to our perturbation of the Hamiltonian H_0, which proves to be very effective for accurate calculation of the eigenvalues of the spiked harmonic oscillator, as the accompanying numerical calculations verify; (4) we show that this variational approach is applicable to the entire discrete spectrum for the spiked harmonic oscillator in N dimensions.

The noncommutative harmonic oscillator in more than one dimension

Agapitos Hatzinikitas[a] and Ioannis Smyrnakis[b]
University of Crete, Department of Applied Mathematics, L. Knosou-Ambelokipi, 71409 Iraklio Crete, Greece

(Received 22 June 2001; accepted for publication 18 September 2001)

The noncommutative harmonic oscillator, with noncommutativity not only in position space but also in phase space, in arbitrary dimension is examined. It is shown that the $\star$-genvalue problem, which replaces the Schrödinger problem in this case, can be decomposed into separate harmonic oscillator equations for each dimension. The two-dimensional noncommutative harmonic oscillator (four noncommutative phase-space dimensions) is investigated in greater detail. The requirement of the existence of rotationally symmetric solutions leads to a two parameter harmonic oscillator which is completely solved in this case. The angular momentum operator is derived and its $\star$-genvalue problem is shown to be equivalent to the usual eigenvalue problem of the $\star$-genfunction related wave function. The $\star$-genvalues of the angular momentum are found to depend on the energy difference of the oscillations in the two dimensions. Furthermore two examples of a symmetric noncommutative harmonic oscillators are analyzed. The first is the noncommutative two-dimensional Landau problem with harmonic oscillator potential, which shows degeneracy in the energy levels for certain critical values of the noncommutativity parameters, and the second is the three-dimensional harmonic oscillator with noncommuting coordinates and momenta. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1416196]

I. INTRODUCTION

Deformation quantization,[1] through $\star$-product (originally discovered by Groenewold),[2] has recently been receiving increasing attention in field theories on R^d, string theories, and M theory.[3–6]

Recently, in string theory it was realized[7] that the introduction of a constant B field gives rise to noncommutative open string end points, which in turn generate noncommutative D-brane configuration spaces.

The appearance of noncommutative spaces helped to revive the deformation quantization technique of Moyal.[7] This technique was elucidated further in Refs. 8 and 9. In this setup the ordinary product was replaced by the pivotal associative noncommutative $\star$-product, which is essentially unique in flat space.[10] The one-dimensional Schrödinger equation was replaced by the $\star$-genvalue equation, while the wave functions became Wigner functions. The advantage of this approach with respect to the formalism developed in Ref. 11 is that it allows noncommutativity to be introduced in phase space and not just in configuration space.

In the present work we consider the $\star$-genvalue problem for the n-dimensional noncommutative harmonic oscillator ($2n$ phase-space dimensions) with phase-space noncommutativity (the commutative n-dimensional harmonic oscillator with a general quadratic Hamiltonian was studied in Ref. 12). It is again shown that the $\star$-genvalue problem is equivalent to the Schrödinger problem in a suitable representation of the algebra, stemming from the Heisenberg algebra repre-

[a]Electronic mail: ahatzini@tem.uoc.gr
[b]Electronic mail: smyrnaki@tem.uoc.gr

sentation of transformed phase-space variables. The energy eigenvalues and eigenfunctions are determined as functions of the noncommutativity parameters.

The case of the two-dimensional harmonic oscillator is examined thoroughly. The angular momentum operator is derived in the rotationally symmetric case. It is shown that the $\star$-genvalues for the function corresponding to this operator contain, apart from the usual angular momentum eigenvalues, a term that depends on the energy difference of the oscillations in the two dimensions.

In the asymmetric two-dimensional case critical values of the noncommutativity parameters arise. For these values the energy spectrum becomes infinitely degenerate at every level. This problem can be identified with the noncommutative Landau problem in harmonic oscillator potential.

The main motivation for studying so extensively the noncommutative harmonic oscillator is its importance in the noncommutative quantization of field theory, as explored in Ref. 13.

The paper is organized as follows.

In Sec. II we summarize known results, namely the definition of the Moyal product of functions in phase space through the Weyl ordering prescription and the equivalence of the stationary $\star$-genvalue problem in one-dimension to the corresponding Schrödinger problem.

Section III is dedicated to the study of the two-dimensional harmonic oscillator $\star$-genvalue equation for a simple case of nontrivial commutation relations. The $\star$-genvalues and functions are determined for the corresponding Hamiltonian by solving the imaginary and real part equations of the $\star$-genvalue equation.

In Sec. IV the $\star$-genvalue problem for the Hamiltonian and the angular momentum, in the two-dimensional problem of Sec. III, is investigated further. The Hamiltonian $\star$-genvalue problem is shown to be equivalent to the Schrödinger eigenvalue problem for an appropriate action of the position and momentum operators on the space of functions (see Ref. 14). The $\star$-genvalue problem for the angular momentum is also shown to be equivalent to the eigenvalue problem of the corresponding operator for the above-mentioned action of position and momentum operators. Finally, the $\star$-genvalues of the angular momentum are shown to depend also on the energy difference of the oscillations in the two dimensions.

In Sec. V the existence of rotationally symmetric $\star$-genfunctions imposes constraints on the possible commutation relations of the n-dimensional harmonic oscillator. In two dimensions these constraints are solved explicitly, leading to commutation relations that depend on two parameters, and the $\star$-genvalue problem for the corresponding noncommutative Hamiltonian is solved. The angular momentum, which is the generator of rotations, is constructed again and its $\star$-genvalues are computed.

Finally Sec. VI copes with the most general phase-space commutation relations. We show that it is possible, through orthogonal transformations, to bring the matrix realizing the commutation relations into a standard symplectic form. In this way we can compute the energy levels, $\star$-genfunctions and the $\star$-commutation relation of creation and annihilation operator-related functions for the n-dimensional harmonic oscillator. As a first application we consider the physically interesting Landau problem of a charged particle in the noncommutative plane in the presence of a constant magnetic field with a harmonic oscillator potential.[15] We find a critical point for the magnetic field at which the energy levels are infinitely degenerate. As a second application the three-dimensional noncommutative harmonic oscillator (in six phase-space dimensions) is considered.

II. OVERVIEW OF THE WIGNER FUNCTIONS AND THE ★-GENVALUE PROBLEM

Let us start with a classical Hamiltonian $H(q,p)=p^2/2m+V(q)$ in one dimension. Upon quantization the canonical variables q,p become operators $\hat{q},\hat{p}$ satisfying the canonical commutation relations $[\hat{q},\hat{p}]=i\hbar$. One way to define the $\star$-product is via the Weyl map, which is a linear map from the classical phase-space functions to quantum operators. Thus we now consider monomials of the form $q^m p^n$ with m,n positive integers. To define the corresponding operator product it is possible to use the Weyl ordering prescription:[16]

$$\hat{W}(q^m p^n)=\frac{1}{2^n}\sum_{k=0}^{n}\binom{n}{k}\hat{p}^{n-k}\hat{q}^m\hat{p}^k \tag{1}$$

according to which the $\hat{W}(q^m p^n)$ operator is symmetrized in $\hat{q}$ and $\hat{p}$ by use of Heisenberg's commutation relation. This regularization scheme can be extended to act on arbitrary power series functions $f(q,p)$ through linearity. Thus, Weyl ordering is an invertible map from the space of functions on the phase space to the space of quantum operators. We can now use Weyl ordering to define a new product between functions on the phase space:[8,16]

$$\begin{aligned} f(q,p)\star g(q,p)&=\hat{W}^{-1}(\hat{W}(f)\hat{W}(g))\\ &=f(q,p)e^{i(\hbar/2)(\overleftarrow{\partial}_q\overrightarrow{\partial}_p-\overleftarrow{\partial}_p\overrightarrow{\partial}_q)}g(q,p)\\ &=f\left(q+i\frac{\hbar}{2}\overrightarrow{\partial}_p,p-i\frac{\hbar}{2}\overrightarrow{\partial}_q\right)g(q,p). \end{aligned} \tag{2}$$

This is the celebrated $\star$-product which enjoys the properties of noncommutativity, associativity, and uniqueness.

In phase space one can define Wigner quasidistribution functions to calculate matrix elements of observables. The time-independent Wigner function corresponding to a pair of eigenstates $|\psi_n\rangle,|\psi_m\rangle$ of the Schrödinger problem, $\hat{H}|\psi_n\rangle=E_n|\psi_n\rangle$, is represented in two phase-space dimensions by[7]

$$f_{mn}(q,p)=\frac{1}{2\pi}\int \mathrm{d}y\, e^{-iyp}\left\langle q-\frac{\hbar}{2}y\middle|\psi_n\right\rangle\left\langle\psi_m\middle|q+\frac{\hbar}{2}y\right\rangle=f^*_{nm}(q,p), \tag{3}$$

where an asterisk stands for complex conjugation. In this case, one can show by employing the Schrödinger equation and the definition of the star product (2) that Wigner functions obey the $\star$-genvalue equations:[9]

$$H(q,p)\star f_{mn}(q,p)=E_n f_{mn}(q,p),\quad f_{mn}(q,p)\star H(q,p)=E_m f_{mn}(q,p). \tag{4}$$

In (3) for complete sets $|\psi_n\rangle$ one can also derive the completeness relation:

$$\sum_{m,n} f_{mn}(q,p)f^*_{mn}(q',p')=\frac{1}{2\pi\hbar}\,\delta(q-q')\,\delta(p-p'), \tag{5}$$

which enables the construction of arbitrary phase-space functions in terms of $f_{mn}(q,p)$.

For the diagonal case [$m=n$ in (3)] one can prove that the Wigner functions satisfy the diagonal $\star$-genvalue equation:

$$H(q,p)\star f_n(q,p)=f_n(q,p)\star H(q,p)=E_n f_n(q,p) \tag{6}$$

and the orthogonality relation:

$$f_m\star f_n=\frac{1}{2\pi\hbar}\,\delta_{m,n}f_m\,. \tag{7}$$

Furthermore, the real solutions of (6) are required to be of the Wigner type for the wave functions of $\hat{H}|\psi_n\rangle=E_n|\psi_n\rangle$.[8] So, instead of solving the one-dimensional Schrödinger equation one can try to solve the $\star$-genvalue equation to determine directly the diagonal Wigner functions and the corresponding energy spectrum.

III. A TWO-DIMENSIONAL HARMONIC OSCILLATOR

In this case we have four coordinates (q_i,p_j), with $i,j=1,2$, in phase space. The classical Hamiltonian for this model is

$$H(q_i,p_j)=\frac{1}{2}\sum_{i=1}^{2}(q_i^2+p_i^2), \tag{8}$$

where, without loss of generality, parameters have been absorbed in the phase-space variables. Quantum mechanically, the position and momentum operators satisfy the Heisenberg commutation relations. Here we will extend this realization to include nontrivial commutation relations for $\hat{q}_1$, $\hat{q}_2$ and $\hat{p}_1$, $\hat{p}_2$:

$$[\hat{q}_i,\hat{p}_j]=i\hbar\,\delta_{ij},\quad [\hat{q}_1,\hat{q}_2]=i\theta,\quad [\hat{p}_1,\hat{p}_2]=-i\theta, \tag{9}$$

where θ is a real constant. The related star product takes the form:

$$\star=\exp\left[\frac{i}{2}(\overleftarrow{\partial}_{q_1},\overleftarrow{\partial}_{p_1},\overleftarrow{\partial}_{q_2},\overleftarrow{\partial}_{p_2})\begin{pmatrix}0&\hbar&\theta&0\\-\hbar&0&0&-\theta\\-\theta&0&0&\hbar\\0&\theta&-\hbar&0\end{pmatrix}\begin{pmatrix}\vec{\partial}_{q_1}\\\vec{\partial}_{p_1}\\\vec{\partial}_{q_2}\\\vec{\partial}_{p_2}\end{pmatrix}\right]. \tag{10}$$

The resulting $\star$-genvalue equation is

$$\left[\left(q_1+\frac{i\hbar}{2}\partial_{p_1}+\frac{i\theta}{2}\partial_{q_2}\right)^2+\left(p_1-\frac{i\hbar}{2}\partial_{q_1}-\frac{i\theta}{2}\partial_{p_2}\right)^2+\left(q_2+\frac{i\hbar}{2}\partial_{p_2}-\frac{i\theta}{2}\partial_{q_1}\right)^2+\left(p_2-\frac{i\hbar}{2}\partial_{q_2}+\frac{i\theta}{2}\partial_{p_1}\right)^2\right]f(q_1,p_1,q_2,p_2)=2Ef(q_1,p_1,q_2,p_2). \tag{11}$$

Equation (11) splits into an equation for the imaginary part,

$$[\hbar(p_1\partial_{q_1}-q_1\partial_{p_1})+\hbar(p_2\partial_{q_2}-q_2\partial_{p_2})+\theta(q_2\partial_{q_1}-q_1\partial_{q_2})+\theta(p_1\partial_{p_2}-p_2\partial_{p_1})]f=0 \tag{12}$$

and an equation for the real part:

$$\left[(q_1^2+p_1^2+q_2^2+p_2^2)-\frac{(\hbar^2+\theta^2)}{4}(\partial_{q_1}^2+\partial_{p_1}^2+\partial_{q_2}^2+\partial_{p_2}^2)\right]f=2Ef. \tag{13}$$

Equation (12) admits a solution of the form $f(z)$ with $z=2(q_1^2+p_1^2+q_2^2+p_2^2)=4H$. The real part-equation (13) transforms to the ordinary differential equation:

$$\left[z\partial_z^2+2\partial_z+\frac{1}{(\hbar^2+\theta^2)}\left(E-\frac{z}{4}\right)\right]f(z)=0. \tag{14}$$

The problem with this reduction is the inconsistency underlying the number of degrees of freedom. We started with the two-dimensional harmonic oscillator and we ended up with one oscillation equation. So we need to search for a set of transformations that will preserve the number of degrees of freedom. An appropriate set of transformations is

$$\overline{q}_1=q_1,\quad \overline{p}_1=\frac{1}{\sqrt{\hbar^2+\theta^2}}(\hbar_{p_1}+\theta_{q_2}), \tag{15}$$

$$\overline{q_2}=\frac{1}{\sqrt{\hbar^2+\theta^2}}(\hbar q_2-\theta p_1),\quad \overline{p_2}=p_2.$$

The imaginary part equation is then written as

$$[(\overline{p_1}\partial_{\overline{q_1}}-\overline{q_1}\partial_{\overline{p_1}})+(\overline{p_2}\partial_{\overline{q_2}}-\overline{q_2}\partial_{\overline{p_2}})]f=0. \tag{16}$$

This implies that f is a function of $z_1=2(\overline{q_1}^2+\overline{p_1}^2)$ and $z_2=2(\overline{q_2}^2+\overline{p_2}^2)$. The real part equation transforms under the new variables into

$$\left[z_1\partial_{z_1}^2+\partial_{z_1}+z_2\partial_{z_2}^2+\partial_{z_2}+\frac{1}{(\hbar^2+\theta^2)}\left(E-\frac{(z_1+z_2)}{4}\right)\right]f(z_1,z_2)=0. \tag{17}$$

The diagonal $\star$-genfunctions $f_{nm}(z_1,z_2)$ (not to be confused with the nondiagonal Wigner functions in one dimension) associated with this equation are determined through products of Laguerre polynomials:

$$f_{nm}(\tilde{z}_1,\tilde{z}_2)=e^{-(1/2)(\tilde{z}_1+\tilde{z}_2)}L_n(\tilde{z}_1)L_m(\tilde{z}_2), \tag{18}$$

where

$$L_m(\tilde{z}_i)=\frac{1}{m!}e^{\tilde{z}_i}\frac{d^m}{d^m\tilde{z}_i}(e^{-\tilde{z}_i}\tilde{z}_i^m) \tag{19}$$

and $L_0(\tilde{z}_i)=1$, $L_1(\tilde{z}_i)=1-\tilde{z}_i$, $L_2(\tilde{z}_i)=1-2\tilde{z}_i+\tilde{z}_i^2/2$,... with $\tilde{z}_i=z_i/\sqrt{\hbar^2+\theta^2}$. The energies corresponding to these $\star$-genfunctions are

$$E_{nm}=\sqrt{\hbar^2+\theta^2}(n+m+1). \tag{20}$$

The functions corresponding to the annihilation and creation operators are given in terms of the transformed variables as

$$a_i=\frac{1}{\sqrt{2}}(\overline{q_i}+i\overline{p_i}),\quad a_i^\dagger=\frac{1}{\sqrt{2}}(\overline{q_i}-i\overline{p_i}). \tag{21}$$

It is possible to express these functions in terms of the original phase-space variables by reversing our transformations. They satisfy the following modified commutation relations:

$$a_i\star a_j^\dagger-a_j^\dagger\star a_i=\delta_{ij}\sqrt{\hbar^2+\theta^2} \tag{22}$$

and $a_i\star f_{00}(\overline{q_i},\overline{p_i})=0$. They generate the $\star$-Fock space of states as follows:

$$f_{nm}\propto a_1^{\dagger n}a_2^{\dagger m}\star f_{00}\star a_2^m a_1^n. \tag{23}$$

The Hamiltonian takes the following form:

$$H=\sum_{i=1}^{2}\left(a_i^\dagger\star a_i+\frac{\sqrt{\hbar^2+\theta^2}}{2}\right). \tag{24}$$

This completes the solution of the two-dimensional harmonic oscillator $\star$-genvalue problem for the commutation relations we started with.

IV. RELATION TO SCHRÖDINGER EQUATION

In the one-dimensional case the $\star$-genvalue equation is equivalent to the Schrödinger equation, as was shown in Ref. 8. However, in the two-dimensional case one has to search for a suitable representation of the commutation relations before writing down a Schrödinger equation. This problem can be overcome for the harmonic oscillator of Sec. III by using the transformations (15), to transform the commutation relations to two sets of Heisenberg commutation relations with $\hbar$ replaced by $\sqrt{\hbar^2+\theta^2}$, and using the usual representation of the Heisenberg commutation relations in the Hamiltonian. The Schrödinger equation with respect to the new variables becomes

$$\frac{1}{2}\sum_{i=1}^{2}(\hat{\overline{q}}_i^2+\hat{\overline{p}}_i^2)\Psi(\overline{q}_i)=E\Psi(\overline{q}_i) \tag{25}$$

and its eigenfunctions are given by

$$\Psi_{nm}(\overline{q}_i)=\Psi_n(\overline{q}_1)\Psi_m(\overline{q}_2), \tag{26}$$

where Ψ_n are the usual eigenfunctions of the one-dimensional harmonic oscillator. This equation splits into two one-dimensional harmonic oscillator equations. Making use of the one-dimensional equivalence of the Schrödinger problem to the $\star$-genvalue problem we obtain that Eq. (25) (with $\hbar$ replaced by $\sqrt{\hbar^2+\theta^2}$) is equivalent to

$$H(\overline{q}_i,\overline{p}_i)\overline{\star}\overline{f}(\overline{q}_i,\overline{p}_i)=\overline{f}(\overline{q}_i,\overline{p}_i)\overline{\star}H(\overline{q}_i,\overline{p}_i)=E\overline{f}(\overline{q}_i,\overline{p}_i), \tag{27}$$

where

$$\begin{aligned}\overline{f}(\overline{q}_i,\overline{p}_j)&=\overline{f}(\overline{q}_1,\overline{p}_1)\overline{f}\overline{f}(\overline{q}_2,\overline{p}_2)\\&=\frac{1}{(2\pi)^2}\int\int \mathrm{d}y_1\,\mathrm{d}y_2\,e^{-iy_1\overline{p}_1}e^{-iy_2\overline{p}_2}\\&\quad\times\prod_{i=1}^{2}\Psi_i^*\left(\overline{q}_i-\frac{1}{2}\sqrt{\hbar^2+\theta^2}y_i\right)\Psi_i\left(\overline{q}_i+\frac{1}{2}\sqrt{\hbar^2+\theta^2}y_i\right)\\&\equiv\frac{1}{(2\pi)^2}\int\int \mathrm{d}y_1\,\mathrm{d}y_2\,e^{-iy_1\overline{p}_1}e^{-iy_2\overline{p}_2}\prod_{i=1}^{2}\Psi_i^*\Psi_i\,.\end{aligned} \tag{28}$$

The $\overline{\star}$-product, which is the transformed version of the $\star$-product defined in (10), is

$$\overline{\star}=\exp\left[\frac{i}{2}\sqrt{\hbar^2+\theta^2}\sum_{i=1}^{2}(\overleftarrow{\partial}_{\overline{q}_i}\overrightarrow{\partial}_{\overline{p}_i}-\overleftarrow{\partial}_{\overline{\mu}_i}\overrightarrow{\partial}_{\overline{q}_i})\right]. \tag{29}$$

So we have shown that the Schrödinger problem, in the representation of $\hat{q}^i,\hat{p}^j$ defined by the Heisenberg representation of $\hat{\overline{q}}^i,\hat{\overline{p}}^j$, is equivalent to the $\star$-genvalue problem (11).

Next let us investigate what happens with the angular momentum. The phase-space function corresponding to the operator that commutes with the Hamiltonian and generates rotations in the original variables is

$$L=\frac{\hbar}{\hbar^2+\theta^2}\left[\hbar(q_1p_2-q_2p_1)+\frac{\theta}{2}(p_1^2-q_1^2+p_2^2-q_2^2)\right]. \tag{30}$$

Transforming this to the new variables (15) gives

$$\overline{L}(\overline{q}_i,\overline{p}_j)=\frac{\hbar}{\hbar^2+\theta^2}\left[\hbar(\overline{q}_1\overline{p}_2-\overline{q}_2\overline{p}_1)+\frac{\theta}{2}(\overline{q}_2^2+\overline{p}_2^2-\overline{q}_1^2-\overline{p}_1^2)\right]. \tag{31}$$

The angular momentum $\star$-genvalue equation becomes

$$\begin{aligned}
&L(q_i,p_i)\star f(q_i,p_i)\\
&\quad=\overline{L}(\overline{q}_i,\overline{p}_i)\star\overline{f}(\overline{q}_i,\overline{p}_i)\\
&\quad=\frac{1}{(2\pi)^2}\frac{\hbar}{(\hbar^2+\theta^2)}\left[\hbar\left[\overline{q}_1\left(\overline{p}_2-\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_2}\right)-\overline{q}_2\left(\overline{p}_1-\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_1}\right)\right]\right.\\
&\qquad\left.+\frac{\theta}{2}\left[\overline{q}_2^2+\left(\overline{p}_2-\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_2}\right)^2-\overline{q}_1^2-\left(\overline{p}_1-\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_1}\right)^2\right]\right]\\
&\qquad\times\int \mathrm{d}y_1\,\mathrm{d}y_2\exp\left(-iy_1\left(\overline{p}_1+\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_1}\right)\right)\\
&\qquad\times\exp\left(-iy_2\left(\overline{p}_2+\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_2}\right)\right)\prod_{i=1}^{2}\Psi_i^*\Psi_i\\
&\quad=\frac{1}{(2\pi)^2}\frac{\hbar}{(\hbar^2+\theta^2)}\int\int \mathrm{d}y_1\,\mathrm{d}y_2\,e^{-iy_1\overline{p}_1}e^{-iy_2\overline{p}_2}\\
&\qquad\times\left[\hbar\left[\left(\overline{q}_1+\frac{1}{2}\sqrt{\hbar^2+\theta^2}y_1\right)\left(-i\partial_{y_2}-\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_2}\right)\right.\right.\\
&\qquad\left.-\left(\overline{q}_2+\frac{1}{2}\sqrt{\hbar^2+\theta^2}y_2\right)\left(-i\partial_{y_1}-\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_1}\right)\right]\\
&\qquad+\frac{\theta}{2}\left[\left(\overline{q}_2+\frac{1}{2}\sqrt{\hbar^2+\theta^2}y_2\right)^2+\left(-i\partial_{y_2}-\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_2}\right)^2-\left(\overline{q}_1+\frac{1}{2}\sqrt{\hbar^2+\theta^2}y_1\right)^2\right.\\
&\qquad\left.\left.-\left(-i\partial_{y_1}-\frac{i}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_1}\right)^2\right]\right]\prod_{i=1}^{2}\Psi_i^*\Psi_i\\
&\quad=\frac{\hbar}{(\hbar+\theta^2)}[\hbar\sqrt{\hbar^2+\theta^2}m_z+\theta(E_2-E_1)]\overline{f}(\overline{q}_i,\overline{p}_j).
\end{aligned}\tag{32}$$

Here we have used $\overline{p}_ie^{-iy_i\overline{p}_i}=i\partial_{yi}e^{-iy_i\overline{p}_i}$ and partial integration has been performed. Note that

$$\left(\partial_{y_i}+\frac{1}{2}\sqrt{\hbar^2+\theta^2}\vec{\partial}_{\overline{q}_i}\right)\Psi^*\left(\overline{q}_i-\frac{\sqrt{\hbar^2+\theta^2}}{2}y_i\right)=0.$$

The discrete values m_z are the eigenvalues of the angular momentum for the commutative two dimensional harmonic oscillator:

$$\hat{L}\Psi(\overline{q}_i)=(\hat{\overline{q}}_1\hat{\overline{p}}_2-\hat{\overline{q}}_2\hat{\overline{p}}_1)\Psi(\overline{q}_i)=\sqrt{\hbar^2+\theta^2}m_z\Psi(\overline{q}_i). \tag{33}$$

What we have essentially proven is that the solution of the $\star$-genvalue problem for the angular momentum is equivalent to the solution of the eigenvalue problem for the angular momentum operator in the representation we began with. We observe that we pick an extra new term that depends on the energy difference of the two oscillations and is linear in the noncommutativity parameter θ.

V. ROTATIONALLY SYMMETRIC CASE

Up to this point we have considered only the case where $\hat{q}_i$ commute with $\hat{p}_j$, for $i \neq j$, and the $\hat{q}_i, \hat{p}_j$ behave symmetrically, that is $[\hat{q}_1, \hat{q}_2] = -[\hat{p}_1, \hat{p}_2]$. Let us consider the more general situation where the commutation relations are governed by a general antisymmetric matrix M in $2n$ phase-space dimensions. In this case the $\star$-product reads:

$$\star = \exp \frac{i}{2} [\overleftarrow{\partial}_I^T M_{IJ} \vec{\partial}_J], \tag{34}$$

where $\partial_I^T = (\partial_{q_I}, \partial_{p_I})$, and $M_{IJ} = -M_{JI}^T$ are 2×2 matrix blocks. Here the summation convention is assumed. The imaginary part of the $\star$-genvalue equation, generalizing (12) now becomes

$$X_I^T M_{IJ} \partial_J f = 0, \tag{35}$$

where $X_I^T = (q_I, p_I)$. If f is rotationally symmetric, that is $f \equiv f(X_I^T X_I)$, then this equation is satisfied provided that M is antisymmetric. Interestingly enough, if one starts with the $\star$-genvalue problem for this f, ignoring the commutation relations, Eq. (35) would require that the matrix M be antisymmetric.

The real part equation becomes

$$[X_I^T X_I - \tfrac{1}{4} (M_{IK_1} \partial_{K_1})^T (M_{IK_2} \partial_{K_2})] f = 2Ef. \tag{36}$$

Again demanding $f = f(X_I^T X_I)$ to be a solution of (36) we are led to

$$X_I^T X_I f(X_I^T X_I) - \tfrac{1}{2} \mathrm{tr}(M_{IK}^T M_{IK}) f'(X_I^T X_I) - X_{K_1}^T M_{IK_1}^T M_{IK_2} X_{K_2} f''(X_I^T X_I) = 2E f(X_I^T X_I). \tag{37}$$

If this equation is to be satisfied we need

$$M_{IK_1}^T M_{IK_2} = \alpha \delta_{K_1 K_2} I \tag{38}$$

with I the identity matrix. So (38) is the condition for the problem to admit rotational symmetric solutions.

Condition (38) can be solved explicitly in the case of four phase-space dimensions. The most general matrix M that admits rotationally symmetric $\star$-genfunctions is given by

$$M_{11} = \pm M_{22} = \begin{pmatrix} 0 & \hbar \\ -\hbar & 0 \end{pmatrix}, \quad M_{12} = -M_{21} = \begin{pmatrix} \theta & \phi \\ \pm \phi & \mp \theta \end{pmatrix}, \tag{39}$$

where the two signs correspond to the two possible solutions that exist. We are going to more closely examine the first case, since the second can be treated on equal footing. In the present case a transformation that leads to the Heisenberg commutation relations is $\overline{X} = R^T X$, where R is given by

$$R = \begin{pmatrix} \dfrac{\sqrt{\hbar^2 + \phi^2}}{\sqrt{\hbar^2 + \theta^2 + \phi^2}} & 0 & 0 & -\dfrac{\theta}{\sqrt{\hbar^2 + \theta^2 + \phi^2}} \\ -\dfrac{\theta \phi}{\sqrt{\hbar^2 + \theta^2 + \phi^2}\sqrt{\hbar^2 + \phi^2}} & \dfrac{\hbar}{\sqrt{\hbar^2 + \phi^2}} & 0 & -\dfrac{\phi}{\sqrt{\hbar^2 + \theta^2 + \phi^2}} \\ 0 & 0 & 1 & 0 \\ \dfrac{\hbar \theta}{\sqrt{\hbar^2 + \theta^2 + \phi^2}\sqrt{\hbar^2 + \phi^2}} & \dfrac{\phi}{\sqrt{\hbar^2 + \phi^2}} & 0 & \dfrac{\hbar}{\sqrt{\hbar^2 + \theta^2 + \phi^2}} \end{pmatrix}. \tag{40}$$

Certainly this transformation is not unique. It is defined up to symplectic rotations which preserve both the Hamiltonian and the commutation relations in the transformed variables.

The angular momentum, as the generator of rotations, is found to be

$$L=\frac{\hbar}{\hbar^2+\theta^2+\phi^2}\left[\hbar(q_1p_2-q_2p_1)+\frac{\theta}{2}(p_1^2-q_1^2+p_2^2-q_2^2)-\phi(p_1q_1+p_2q_2)\right] \tag{41}$$

and in the transformed variables is reexpressed as

$$\overline{L}=\frac{\hbar}{\hbar^2+\theta^2+\phi^2}\left[\sqrt{\hbar^2+\phi^2}(\overline{q}_1\overline{p}_2-\overline{q}_2\overline{p}_1)+\frac{\theta}{2}(\overline{q}_1^2+\overline{p}_1^2-\overline{q}_2^2-\overline{p}_2^2)\right]. \tag{42}$$

Again the $\star$-genvalue problem for the Hamiltonian is the same as the Schrödinger problem with $\star$-genvalues $E_{n_1,n_2}=\sqrt{\hbar^2+\theta^2+\phi^2}(n_1+n_2+1)$. The same equivalence is valid for the angular momentum $\star$-genvalue problem producing the $\star$-genvalues

$$\frac{\hbar}{(\hbar+\theta^2+\phi^2)}[\sqrt{\hbar^2\phi^2}\sqrt{\hbar^2+\theta^2+\phi^2}m_z+\theta(E_1-E_2)].$$

In the limit $\theta,\phi\to 0$ we can recover from these expressions the usual ones. This solves the general two-dimensional phase-space noncommutative harmonic oscillator that admits rotationally symmetric solutions.

VI. GENERAL CASE

Let us now discard the condition that there exist rotationally symmetric solutions. The matrix M used to define the commutation relations is a general antisymmetric matrix. The following lemma holds:[17]

Lemma 1: Let (V,ω) *be a symplectic vector space and* $g:V\times V\to R$ *be an inner product. Then there exists a basis* $u_1,\ldots,u_n,v_1,\ldots,v_n$ *of* V *which is both g-orthogonal and* ω*-standard. Moreover, this basis can be chosen such that* $g(u_j,u_j)=g(v_j,v_j)$ *for all* j.

This means that it is possible, by rescaling, to find an orthogonal transformation R so that

$$R^TMR=J(M), \tag{43}$$

where

$$J(M)_{IJ}=\alpha_I(M)\,\delta_{IJ}\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}. \tag{44}$$

From (34) we see that if we make the transformation $\overline{X}=R^TX$, then the matrix M in the $\star$-product is replaced by $J(M)$ and the Hamiltonian remains invariant because the transformation is orthogonal. So the $\star$-genvalue problem now becomes

$$\overline{H}\overline{\star}\overline{f}=E\overline{f}, \tag{45}$$

where $\overline{\star}$ is

$$\overline{\star}=\exp\left[\frac{i}{2}\overleftarrow{\partial}_I^T J(M)_{IK}\overrightarrow{\partial}_K\right]. \tag{46}$$

The imaginary part equation (35) becomes

$$\sum_i \alpha_i(\overline{q}_i\partial_{\overline{p}_i}-\overline{p}_i\partial_{\overline{q}_i})\overline{f}(\overline{q}_i,\overline{p}_i)=0, \tag{47}$$

where $\alpha_i=\alpha_I(M)$. This equation is satisfied by $\overline{f}\equiv f(z_i)$ where $z_i=2(\overline{q_i^2}+\overline{p_i^2})$. For this $\overline{f}$, the real part equation takes the form:

$$\sum_i \left[z_i\partial_{z_i}^2+\partial_{z_i}-\frac{1}{\alpha_i^2}\left(\frac{z_i}{4}-E_i\right)\right] f(z_i)=0 \tag{48}$$

and the energy is $E=\Sigma_i E_i$. This equation can be separated into a set of equations for each z_i. Solving these equations we get the eigenvalues $E_i=\alpha_i(n_i+1/2)$ and the eigenfunctions:

$$f_{n_i}(z_i)=e^{-(1/2\alpha_i)z_i}L_{n_i}(z_i/\alpha_i). \tag{49}$$

The overall eigenfunctions are products of the $f_{n_i}(z_i)$. The functions corresponding to annihilation and creation operators again take the form (21). They satisfy the following modified commutation relations:

$$\alpha_i\star a_j^\dagger-a_j^\dagger\star a_i=\alpha_i\delta_{ij} \tag{50}$$

and the Hamiltonian becomes

$$H=\sum_i \left(a_i^\dagger\star a_i+\frac{\alpha_i}{2}\right). \tag{51}$$

Again, the $\star$-genvalue problem is equivalent to the Schrödinger problem in the transformed variables. This means that it is also equivalent in the original variables, if one uses the representation for the original variables that result from the usual representation of the transformed ones (the operators corresponding to the transformed variables satisfy the Heisenberg commutation relations).

As an example that does not admit rotationally symmetric solutions we consider the noncommutative Landau problem in harmonic oscillator potential in two dimensions. Assume for convenience that $\hbar=1$. Here the commutation relations are

$$[\hat{q}_i,\hat{p}_j]=i\delta_{ij},\quad [\hat{q}_1,\hat{q}_2]=i\theta,\quad [\hat{p}_1,\hat{p}_2]=iB. \tag{52}$$

The latter commutation relation results from the presence of magnetic field, while the middle one from the noncommutativity of space. The star product is

$$\star=\exp\left[\frac{i}{2}(\overleftarrow{\partial}_{q_1},\overleftarrow{\partial}_{p_1},\overleftarrow{\partial}_{q_2},\overleftarrow{\partial}_{p_2})\begin{pmatrix}0&1&\theta&0\\-1&0&0&B\\-\theta&0&0&1\\0&-B&-1&0\end{pmatrix}\begin{pmatrix}\vec{\partial}_{q_1}\\\vec{\partial}_{p_1}\\\vec{\partial}_{q_2}\\\vec{\partial}_{p_2}\end{pmatrix}\right]. \tag{53}$$

The α_I take the form:

$$\alpha_\pm=\tfrac{1}{2}(\sqrt{(\theta-B)^2+4}\pm(\theta+B). \tag{54}$$

These $\alpha_\pm$ correspond to the frequencies of the Landau harmonic oscillator in the two dimensions. In this case there is no degeneracy in the $\alpha_\pm$ as opposed to the previous cases.

A transformation matrix R that leads to the Heisenberg commutation relations is

$$R=\begin{pmatrix} -\dfrac{\alpha_-(1+B\tilde{\alpha}_-)}{\sqrt{(1-B\theta)^2+\alpha_-^2(1+\beta\tilde{\alpha}_-)^2}} & 0 & -\dfrac{\alpha_+(1-B\tilde{\alpha}_+)}{\sqrt{(1-B\theta)^2+\alpha_+^2(1-B\tilde{\alpha}_+)^2}} & 0 \\ 0 & \dfrac{1}{\sqrt{1+\tilde{\alpha}_-^2}} & 0 & \dfrac{1}{\sqrt{1+\tilde{\alpha}_+^2}} \\ 0 & -\dfrac{\tilde{\alpha}_-}{\sqrt{1+\tilde{\alpha}_-^2}} & 0 & \dfrac{\tilde{\alpha}_+}{\sqrt{1+\tilde{\alpha}_+^2}} \\ -\dfrac{1-B\theta}{\sqrt{(1-B\theta)^2+\alpha_-^2(1+B\tilde{\alpha}_-)^2}} & 0 & \dfrac{1-B\theta}{\sqrt{(1-B\theta)^2+\alpha_+^2(1-B\tilde{\alpha}_+)^2}} & 0 \end{pmatrix}, \tag{55}$$

where we have assumed that $B\theta<1$ and

$$\tilde{\alpha}_\pm=\tfrac{1}{2}(\sqrt{(\theta-B)^2+4}\pm(\theta-B)). \tag{56}$$

Note that if $B\theta=1$ then the fourth row in the transformation matrix becomes zero, so the transformation becomes degenerate, which is not permitted. So there is a critical value for the magnetic field $B_0=1/\theta$. At B_0 the frequency $\alpha_-=0$, so there is an infinite degeneracy at the energy levels, corresponding to the excitations of the α_- oscillator. This problem was solved through a series of transformations in Ref. 15, without resorting to the $\star$-genvalue formalism.

As a further example consider the case of the noncommutative Landau problem with the additional commutation relations $[\hat{q}_1,\hat{p}_2]=i\phi_1$ and $[\hat{p}_1,\hat{q}_2]=i\phi_2$. In this case the frequencies become

$$\alpha_\pm=\tfrac{1}{2}(\sqrt{(B-\theta)^2+4+(\phi_1+\phi_2)^2}\pm\sqrt{(B+\theta)^2+(\phi_1-\phi_2)^2}) \tag{57}$$

and a degeneracy is produced provided that

$$B\theta-\phi_1\phi_2=1. \tag{58}$$

Note that in this case the matrix M in the $\star$-product becomes degenerate again.

As a final example consider the six phase-space dimensional case. The commutation relations we consider are

$$[\hat{q}_i,\hat{p}_j]=i\delta_{ij},\quad [\hat{q}_1,\hat{q}_2]=i\theta_3,\quad [\hat{q}_1,\hat{q}_3]=-i\theta_2,\quad [\hat{q}_2,\hat{q}_3]=i\theta_1. \tag{59}$$

All other commutation relations are trivial. Now the frequencies α_i are

$$\alpha_{1,2}=\sqrt{1+\theta_1^2+\theta_2^2+\theta_3^2},\quad \alpha_3=1. \tag{60}$$

There is twofold degeneracy for the first frequency. The transformation matrix in this case is

$$R=\begin{pmatrix} -\frac{\theta_1\theta_3}{\alpha\beta} & \frac{\theta_2}{\beta} & 0 & \frac{\theta_1\theta_3}{\alpha\beta\gamma} & 0 & -\frac{\theta_1}{\gamma} \\ -\frac{\theta_2}{\alpha\beta} & 0 & -\frac{\theta_1\theta_3}{\beta\gamma} & -\frac{\theta_2\gamma}{\alpha\beta} & \frac{\theta_1}{\gamma} & 0 \\ -\frac{\theta_2\theta_3}{\alpha\beta} & -\frac{\theta_1}{\beta} & 0 & \frac{\theta_2\theta_3}{\alpha\beta\gamma} & 0 & -\frac{\theta_2}{\gamma} \\ \frac{\theta_1}{\alpha\beta} & 0 & -\frac{\theta_2\theta_3}{\beta\gamma} & \frac{\theta_1\gamma}{\alpha\beta} & \frac{\theta_2}{\gamma} & 0 \\ \frac{\beta}{\alpha} & 0 & 0 & -\frac{\beta}{\alpha\gamma} & 0 & -\frac{\theta_3}{\gamma} \\ 0 & 0 & \frac{\beta}{\gamma} & 0 & \frac{\theta_3}{\gamma} & 0 \end{pmatrix}, \tag{61}$$

where

$$\alpha=\sqrt{1+\theta_1^2+\theta_2^2+\theta_3^2},$$

$$\beta=\sqrt{\theta_1^2+\theta_2^2},$$

$$\gamma=\sqrt{\theta_1^2+\theta_2^2+\theta_3^2}.$$

To summarize, we have shown in the present section how to treat in general the $2n$-dimensional phase-space noncommutative harmonic oscillator. We have seen that in the case the matrix M is degenerate there is a zero eigenvalue and also an infinite degeneracy in the energy levels corresponding to excitations of the zero frequency oscillator.

The supersymmetric technique for random-matrix ensembles with zero eigenvalues

D. A. Ivanov
Institut für Theoretische Physik, ETH-Hönggerberg, CH-8093 Zürich, Switzerland

(Received 13 July 2001; accepted for publication 11 October 2001)

The supersymmetric technique is applied to computing the average spectral density near zero energy in the large-N limit of the random-matrix ensembles with zero eigenvalues: B, DIII-odd, and the chiral ensembles (classes AIII, BDI, and CII). The supersymmetric calculations reproduce the existing results obtained by other methods. The effect of zero eigenvalues may be interpreted as reducing the symmetry of the zero-energy supersymmetric action by breaking a certain Abelian symmetry. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1423765]

I. INTRODUCTION

There exists a remarkable correspondence between large families of random-matrix ensembles and symmetric superspaces. It has been shown by Zirnbauer that in the large-N limit (N is the matrix dimension) correlation functions in random-matrix ensembles may be represented as integrals over appropriate Riemannian symmetric superspaces (with dimensions independent of N).[1] This relation to symmetric superspaces is based on Efetov's supersymmetric technique introducing auxiliary anticommuting (Grassmann) variables in order to directly average correlation functions over the statistical ensemble.[2]

At the same time, the random-matrix ensembles are known to be in one-to-one correspondence with symmetric spaces (Cartan symmetry classes).[3,4] The classification of Zirnbauer thus establishes a correspondence between large families of symmetric spaces and Riemannian symmetric superspaces.[1] The random-matrix ensembles with zero eigenvalues were not included in the original classification, and later it became apparent that the zero eigenvalues in random-matrix ensembles are related to the reducibility of the corresponding symmetric superspaces.[5–7]

In this paper, I study this relation by explicitly calculating the average density of states in all random-matrix ensembles with zero eigenvalues. There are five such ensembles (Table I): class B [so(N) matrices at odd N], class DIII-odd [so($2N$)/u(N) matrices at odd N], and the three chiral ensembles: unitary AIII, orthogonal BDI, and symplectic CII. In a physical context, the ensembles B and DIII-odd appear in vortices in superconductors with odd pairing,[5,8] the chiral classes—in QCD.[9,10] The zero levels in these ensembles occur as a consequence of the symmetry inverting energy ($E \to -E$) combined with the odd dimension (for classes B and DIII-odd) or with the dimensional imbalance between the two chiral sectors (for the chiral classes). Table I also lists the values of the parameters α and β appearing in the joint probability distribution for energy levels ω_i,

$$dP(\omega_1, \ldots, \omega_n) \propto \prod_{i<j} |\omega_i^2 - \omega_j^2|^\beta \prod_i \omega_i^\alpha d\omega_i \tag{1}$$

(β determines the strength of repulsion between levels, α—the strength of repulsion from zero).

Previously, a supersymmetric calculation of the misroscopic spectral density for the chiral unitary case was done in Ref. 6, and the case of class B was studied in Ref. 5 (in the context of class BD, which is the average of classes B and D). I include these cases for completeness in the corresponding sections.

TABLE I. Random-matrix ensembles with zero eigenvalues.

Cartan class	Symmetric space (compact type)	β	α	Number of zero eigenvalues m
$B-D$	$\mathrm{SO}(N)$	2	$2m$	$m=0$, even N
DIII	$\mathrm{SO}(2N)/\mathrm{U}(N)$	4	$1+4m$	$m=1$, odd N
AIII	$\mathrm{SU}(p+q)/\mathrm{S}(\mathrm{U}(p)\times\mathrm{U}(q))$	2	$1+2m$	$m=\lvert p-q\rvert$
BDI	$\mathrm{SO}(p+q)/\mathrm{SO}(p)\times\mathrm{SO}(q)$	1	m	
CII	$\mathrm{Sp}(p+q)/\mathrm{Sp}(p)\times\mathrm{Sp}(q)$	4	$3+4m$	

From the supersymmetric calculations for the five random-matrix ensembles, we find that zero levels in random-matrix ensembles manifest themselves in reducing the symmetry of the supersymmetric action at zero energy. In the absence of zero levels, this action (a function of the supermatrix Q in Efetov's technique[2]) is invariant with respect to the full supergroup preserving the linear constraints on Q (latter being determined by the symmetries of random matrices). For ensembles with zero levels, the zero-energy action is invariant with respect to only a normal subgroup of this supergroup, but breaks the remaining abelian symmetry. In the large-N limit, the integral over Q is dominated by the saddle-point manifold. This manifold is a Riemannian symmetric superspace,[1] and for ensembles admitting zero levels it is not irreducible: it may be split into orbits of the normal subgroup of the full symmetry (super) group. The quotient by this normal subgroup is an abelian (conventional, not super) group [Z_2 for classes $B-D$ and DIII, and GL(1) for the chiral classes]. If the random-matrix ensemble contains zero levels, the action is not invariant with respect to this residual abelian group, but transforms according to one of its one-dimensional representations.

The paper is organized as follows: In Sec. II, I review the results for the average spectral density in the random-matrix ensembles with zero levels. Next, I describe the details of the supersymmetric calculations for each of the five random-matrix ensembles. The calculation for the ensemble $B-D$ is presented in somewhat more detail, and in the subsequent sections the repeating steps of the derivations are described only briefly. In the last section I discuss common features of these calculations specific for ensembles with zero levels.

II. SPECTRAL DENSITY IN RANDOM-MATRIX ENSEMBLES WITH ZERO LEVELS

In this section I review the results for the average spectral density in the vicinity of the zero eigenvalue. All these results are known and were previously derived by other methods. The reader may use this section as a quick reference.

In what follows we consider zero-curvature random-matrix ensembles and treat them as quantum-mechanical Hamiltonians. Accordingly we use quantum-mechanical terminology such as ''energy levels,'' ''interlevel spacing,'' etc.

In an ensemble of random matrices of size N, with a fixed dispersion of matrix elements, the interlevel spacing in the middle of the spectrum scales as $N^{-1/2}$ for large N. If we measure the energy E in the units of this interlevel spacing Δ, the correlation functions in the vicinity of zero energy (middle of the spectrum) have a finite and universal limit as $N\to\infty$. In this paper I am interested in the average density of states $\rho(x)$ as a function of dimensionless energy $x=E/\Delta$. This function gives the average number of energy levels in any interval $[a;b]$,

$$\langle n\rangle_{[a;b]}=\int_a^b \rho(x)dx. \tag{2}$$

(In the case of $\beta=4$ ensembles DIII and CII, all energy levels are doubly degenerate, and for counting purposes every degenerate pair of states will be counted as a single level.) The function

$\rho(x)$ is symmetric $\rho(x)=\rho(-x)$ and has the normalization $\lim_{x\to\infty}\rho(x)=1$. For an ensemble with m zero levels, $\rho(x)$ has a δ-functional contribution at $x=0$: $\rho(x)=m\,\delta(x)+\tilde{\rho}(x)$, where $\tilde{\rho}(x)$ is continuous at $x=0$.

The results for the average density of states $\rho(x)$ in the ensembles studied in this paper are the following (defining $y=2\pi|x|$, m is the number of zero levels in the chiral ensembles):

Class D:

$$1+\frac{\sin y}{y}, \tag{3}$$

Class B:

$$1-\frac{\sin y}{y}+\delta(x), \tag{4}$$

Class DIII-even:

$$\frac{\pi}{2}y[J_1'(y)J_0(y)+J_1^2(y)]+\frac{\pi}{2}J_1(y), \tag{5}$$

Class DIII-odd:

$$\frac{\pi}{2}y[J_1'(y)J_0(y)+J_1^2(y)]-\frac{\pi}{2}J_1(y)+\delta(x), \tag{6}$$

Class AIII (chiral unitary):

$$\frac{\pi}{4}y\left[J_m^2\left(\frac{y}{2}\right)-J_{m-1}\left(\frac{y}{2}\right)J_{m+1}\left(\frac{y}{2}\right)\right]+m\,\delta(x), \tag{7}$$

Class BDI (chiral orthogonal):

$$\frac{\pi}{2}\left(\frac{y}{2}\left[J_m^2\left(\frac{y}{2}\right)-J_{m-1}\left(\frac{y}{2}\right)J_{m+1}\left(\frac{y}{2}\right)\right]+J_m\left(\frac{y}{2}\right)R_m\left(\frac{y}{2}\right)\right)+m\,\delta(x), \tag{8}$$

Class CII (chiral symplectic):

$$\frac{\pi}{2}(y[J_{2m}^2(y)-J_{2m-1}(y)J_{2m+1}(y)]-J_{2m}(y)\tilde{R}_{2m}(y))+m\,\delta(x), \tag{9}$$

where the functions R_n and $\tilde{R}_n$ are defined as

$$\tilde{R}_n(z)=1-R_n(z)=\int_0^z J_n(z')dz'. \tag{10}$$

These results were previously derived by other methods. The results (3) and (4) are presented in the book of Mehta.[11] They are also straightforward to obtain from mapping of level statistics onto free fermions. A supersymmetric approach to classes B and D was developed in Ref. 5. The result (5) was found by Nagao and Slevin[12] and by Altland and Zirnbauer[13] (contrary to their claim, their result is identical to the result of Nagao and Slevin after some algebraic manipulations with Bessel functions). The result (7) was obtained in the works of Verbaarschot and Zahed,[14] Nagao and Slevin,[15] and Forrester.[16] Also, a supersymmetric calculation of (7) at $m=0$ was reported in Ref. 17, and then at arbitrary m in Ref. 6. To make this paper self-contained, I repeat the derivation of Ref. 6 in the corresponding section. The particular case of formula (8) at m

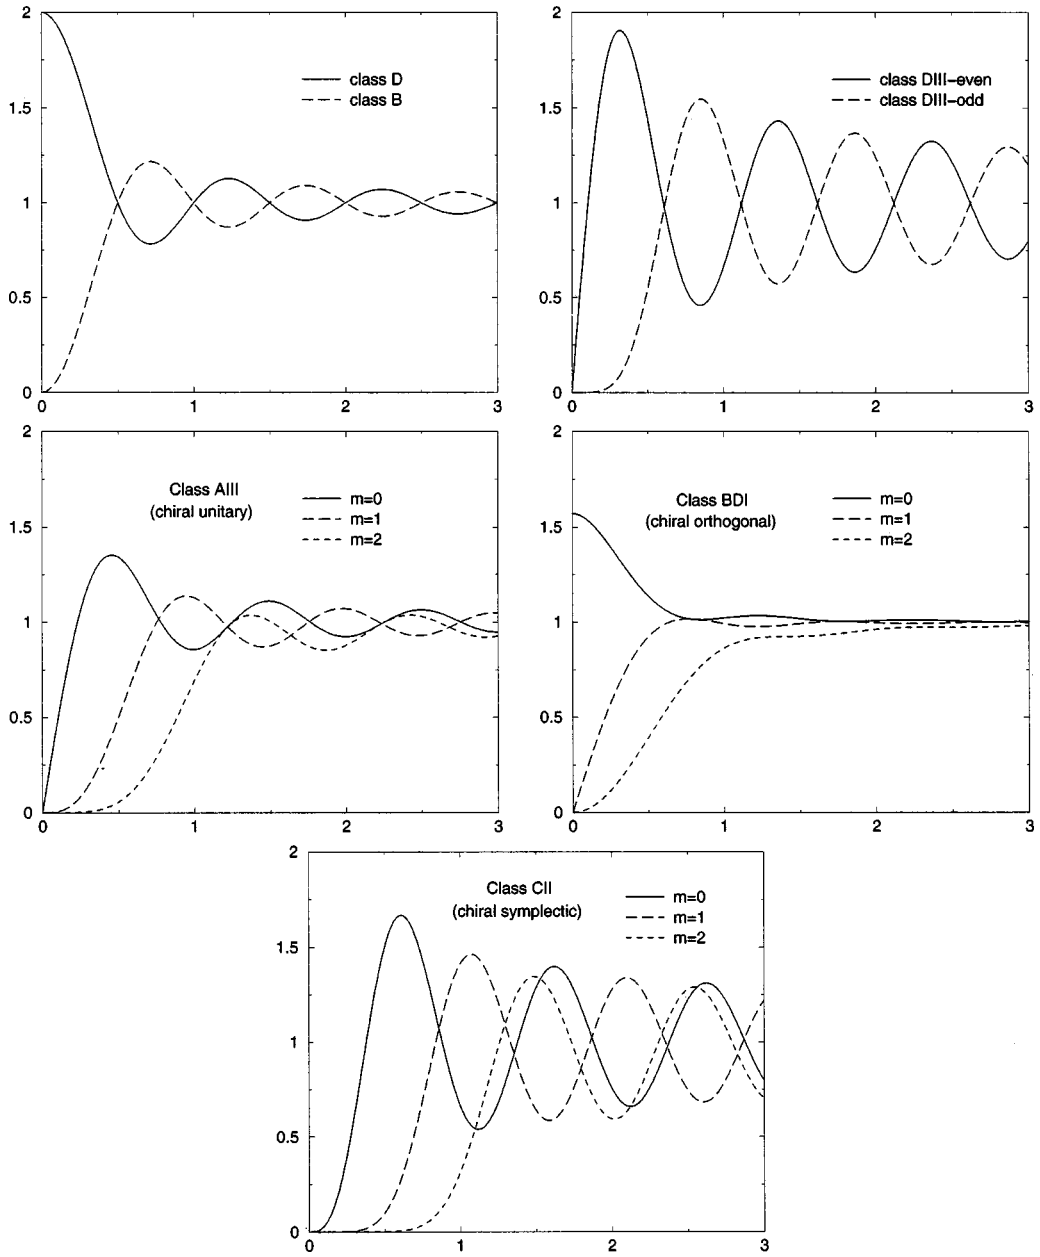

FIG. 1. The average spectral density $\rho(x)$ for ensembles B–D, DIII, AIII, BDI, and CII.

$=1$ can be found in Ref. 12. The case of arbitrary m was treated in Refs. 18 and 19. The latter work also contains the answer for the ensemble CII. The results of Refs. 18 and 19 are presented in the form of complicated integrals. The simple formulas (8) and (9) were later reported in Refs. 20, 21, 22.

The average spectral densities (3)–(9) are plotted in Fig. 1.

III. REMARKS ABOUT NOTATION, SUPERGROUPS, AND SUPERSPACES

In this section I explain some notational conventions used in the subsequent sections. The calculations involve supermatrices acting in a superspace which has the structure $\mathbb{C}^2 \otimes \mathbb{C}^2$ or $\mathbb{C}^2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2$, depending on the symmetry class. One of the $\mathbb{C}^2$ factors refers to the Fermi–Bose (FB)

sectors and defines the supersymmetric grading. The one or two remaining $\mathbb{C}^2$ factors are either produced by additionally doubling the dimension to take into account the symmetries of the random-matrix ensemble (in classes $B-D$, DIII, and BDI) or are originally present in the matrix structure in the random-matrix ensemble (in class DIII and in the three chiral classes). These $\mathbb{C}^2$ will be labeled to as ''particle–hole'' (PH) or ''1–2'' sectors, without stressing the physical meaning of this terminology. In supermatrices, the FB sectors will be graphically divided by solid lines [see, for example, Eq. (12)], with the BB sector in the upper left corner, and the FF sector in the lower right corner. When the matrices also act in the PH or 1–2 spaces, in order to avoid confusion, these spaces will be explicitly mentioned as a subscript, from the outermost division to the innermost subdivision [see, for example, Eqs. (58)–(60)]. The empty spaces in matrices denote zeros.

The supergroups $\mathrm{GL}(n|m)$ and $\mathrm{OSp}(n|2m)$ appearing in our supersymmetric constructions are defined as follows. The complex supergroup $\mathrm{GL}(n|m)$ consists of all invertible supermatrices of dimension $n+m$. The complex supergroup $\mathrm{OSp}(n|2m)$ is the subgroup of $\mathrm{GL}(n|2m)$ obeying the relation,

$$g^{-1}=\gamma g^{T}\gamma^{-1}, \tag{11}$$

where

$$\gamma=\left(\begin{array}{c|cc} 1_n & & \\ \hline & 0 & 1_m \\ & -1_m & 0 \end{array}\right). \tag{12}$$

Its support is the direct product of $\mathrm{O}(n)$ and $\mathrm{Sp}(m)$. More details about these supergroups may be found in Refs. 23, 1. The reader may also refer to Ref. 2 for conventions regarding manipulations with supermatrices. The Lie superalgebras of $\mathrm{OSp}(n|2m)$ and $\mathrm{GL}(n|m)$ are denoted as $\mathrm{osp}(n|2m)$ and $\mathrm{gl}(n|m)$.

To distinguish between fermionic and bosonic sectors [which is important when performing integration, either compact or noncompact, see below], we shall reserve the notation $\mathrm{OSp}(n|2m)$ for the supergroup with $\mathrm{O}(n)$ in the bosonic and $\mathrm{Sp}(m)$ in the fermionic sector. The same supergroup with $\mathrm{O}(n)$ in the fermionic and $\mathrm{Sp}(m)$ in the bosonic sector we denote as $\mathrm{SpO}(n|2m)$. Also, we use the notation $\mathrm{SpSO}(n|2m)$ for the connected component of $\mathrm{SpO}(n|2m)$ [with the unit superdeterminant].

The notation $\mathrm{Sp}(m)$ in this paper refers to the symplectic group of $2m\times 2m$ matrices. This notation agrees with Refs. 1, 3, 8, but differs from Ref. 23, where the same group is denoted $\mathrm{Sp}(2m)$.

IV. CLASSES *B* AND *D*

In this section we use the supersymmetric technique to compute the density of states for the $\mathrm{so}(N)$ random matrices (class D for even N, class B for odd N). This is the simplest of the five examples considered in this paper, and we describe it in more detail to demonstrate the technique of the calculation. The calculation follows the prescription described in detail by Zirnbauer.[1]

The random-matrix ensembles $B-D$ is unitary (with $\beta=2$). The supermatrix Q used in the calculation of the average density of states has dimension $2+2$ (2 bosonic and 2 fermionic dimensions), is parameterized by $4+4$ independent variables and is an element of $\mathrm{osp}(2|2)$ Lie superalgebra. The saddle-point manifold has dimension $2+2$, and thus the density of states in the large-N limit is computed as an integral over two commuting and two Grassmann variables.

The random-matrix ensemble $B-D$ consists of purely imaginary antisymmetric matrices H,

$$H_{ab}=H_{ba}^{*}=-H_{ba}, \quad a,b=1,\ldots,N. \tag{13}$$

The matrix elements have independent Gaussian distributions,

$$dP(H)\propto\prod_{a>b}\ \exp\left(-\frac{|H_{ab}|^2}{2v^2}\right)dH_{ab}, \tag{14}$$

so that the averages of any number of matrix elements are given by the Wick rule together with the pair average,

$$\langle H_{ab}H_{a'b'}\rangle=v^2(\delta_{ab'}\delta_{ba'}-\delta_{aa'}\delta_{bb'}). \tag{15}$$

From the calculation below we shall see that the energy unit defined as

$$\Delta=\frac{\pi v}{\sqrt{N}} \tag{16}$$

plays the role of the average level spacing near zero energy.

The average density of states can be found by differentiating the generating function,

$$Z(\omega_B,\omega_F)=\int dP(H)\,\frac{\det(H-\omega_F\Delta)}{\det(H-\omega_B\Delta)}, \tag{17}$$

where the integration is performed over the ensemble of random matrices H; ω_B and ω_F are auxiliary variables (complex numbers). We included the energy scale Δ in the definition (17) to make ω_B and ω_F dimensionless.

The ensembles considered in this paper have an $E\to -E$ symmetry, which leads to the symmetry of the generating function,

$$Z(\omega_B,\omega_F)=Z(-\omega_B,-\omega_F)=(-1)^m Z(-\omega_B,\omega_F), \tag{18}$$

where m is the number of zero levels. In the supersymmetric calculation below we neglect the overall sign of $Z(\omega_B,\omega_F)$, but restore it at the end of the calculation from the condition $Z(\omega,\omega)=1$ and from positiveness of the density of states.

The two determinants in (17) may be written as Gaussian integrals over bosonic and fermionic variables (auxiliary fields). Introducing the $(N+N)$-component supervector $\psi_a=(\psi_{Ba},\psi_{Fa})$, $a=1,\ldots,N$, and performing the integration over $dP(H)$, we arrive at the partition function for interacting superfields [the common energy scale v drops out already at this step, thanks to our including Δ in (17)],

$$Z(\omega_B,\omega_F)=\int D(\psi^{\dagger},\psi)\exp\left(-\frac{i\pi\omega_\mu}{\sqrt{N}}\psi_{\mu a}^{\dagger}\psi_{\mu a}-\frac{1}{2}[(\psi_{\mu a}^{\dagger}\psi_{\mu b})(\psi_{\nu b}^{\dagger}\psi_{\nu a})-(\psi_{\mu a}^{\dagger}\psi_{\mu b})(\psi_{\nu a}^{\dagger}\psi_{\nu b})]\right), \tag{19}$$

where μ, ν are fermion-boson indices. In the integral, the Grassmann components in ψ and $\psi^{\dagger}$ are treated as independent variables (total $2N$ Grassmann variables). The integral over bosonic components of ψ and $\psi^{\dagger}$ is taken over the $2N$-dimensional real submanifold $(\psi^{\dagger})_{Ba}=(\psi_{Ba})^{*}$.

To decouple the interaction with the Q-matrix, it is necessary to double the dimension of vector ψ. Combine the old superfields $\psi_{\mu a}$ into the new ones,

$$\Psi_a=\begin{pmatrix}\psi_B\\ \psi_B^\dagger\\ \psi_F\\ \psi_F^\dagger\end{pmatrix}_a, \quad \overline{\Psi}_a=\begin{pmatrix}\psi_B^\dagger\\ -\psi_B\\ \psi_F^\dagger\\ \psi_F\end{pmatrix}_a^T, \tag{20}$$

so that

$$\overline{\Psi}=(\gamma\Psi)^T, \tag{21}$$

where

$$\gamma=\left(\begin{array}{cc|cc}0&1&&\\-1&0&&\\\hline&&0&1\\&&1&0\end{array}\right). \tag{22}$$

In terms of the supervectors Ψ and $\overline{\Psi}$, the partition function may be rewritten as

$$Z(\omega_B,\omega_F)=\int D\Psi\,\exp\left(-\frac{1}{2}\mathrm{STr}\left[\frac{i\pi}{\sqrt{N}}\Psi_a\overline{\Psi}_a\hat{\omega}+\frac{1}{2}(\Psi_a\overline{\Psi}_a)^2\right]\right), \tag{23}$$

where

$$\hat{\omega}=\left(\begin{array}{cc|c}\omega_B&&\\&&\\\hline&&\omega_F\end{array}\right)\otimes\begin{pmatrix}1&0\\0&-1\end{pmatrix}. \tag{24}$$

[With this definition of $\hat{\omega}$ we in fact change the sign of ω_F, which may result in the change of sign of $Z(\omega_B,\omega_F)$, according to (18). We shall not control the overall sign of $Z(\omega_B,\omega_F)$, but restore the correct sign at the end of the calculation.]

The matrix $(\Psi_a\overline{\Psi}_a)$ has the explicit form,

$$\Psi_a\overline{\Psi}_a=\left(\begin{array}{cc|cc}Q_B&-X&\sigma&\rho\\\bar{X}&-Q_B&\bar{\rho}&\bar{\sigma}\\\hline\bar{\sigma}&-\rho&Q_F&0\\\bar{\rho}&-\sigma&0&-Q_F\end{array}\right). \tag{25}$$

This is also the form of the supermatrix Q used to decouple the interaction via Hubbard–Stratonovich transformation,

$$Z(\omega_B,\omega_F)=\int DQ\int D\Psi\exp\left(-\frac{1}{2}\mathrm{STr}\left[\frac{N}{2}Q^2+i\sqrt{N}\left(Q-\frac{\pi}{N}\hat{\omega}\right)\Psi_a\overline{\Psi}_a\right]\right). \tag{26}$$

The integration is performed in the space of matrices Q of the form (25) which is equivalent to the linear constraint,

$$\gamma Q\gamma^{-1}=-Q^T. \tag{27}$$

More precisely, the integral is taken along the real subspace in the complex space (27) where Q_B is real, Q_F is purely imaginary, and $\overline{X}=X^*$ (for convergence of the integral).

After integrating in Ψ, we arrive at

$$Z(\omega_B,\omega_F)=\int DQ\left[\mathrm{SDet}\left(Q-\frac{\pi}{N}\hat{\omega}\right)\right]^{-N/2}\exp\left(-\frac{N}{2}\mathrm{STr}\frac{Q^2}{2}\right). \tag{28}$$

Since we are interested in small energy scales (of the order of several level spacings from zero), we can expand the action to terms linear in ω and obtain

$$Z(\omega_B,\omega_F)=\int DQ\exp\left(-\frac{N}{2}\mathrm{STr}\left[\frac{Q^2}{2}+\ln Q\right]+\mathrm{STr}\frac{\pi}{2}\hat{\omega}Q^{-1}\right). \tag{29}$$

At large N, the integral is determined by the saddle points of the action,

$$S_0(Q)=\mathrm{STr}\left(\frac{Q^2}{2}+\ln Q\right). \tag{30}$$

By varying the action, the equation of the saddle-point manifold is

$$Q^2=-1. \tag{31}$$

By deforming the integration contour onto the saddle-point manifold, the integral reduces to

$$Z(\omega_B,\omega_F)=\int_\Gamma DQ\exp\left(-\frac{N}{2}S_0(Q)-\mathrm{STr}\frac{\pi}{2}\hat{\omega}Q\right) \tag{32}$$

(the transversal directions do not contribute to the integral because of the supersymmetry).

The contour of integration Γ on the saddle-point manifold should be determined from the condition that the original contour of integration can be deformed onto it without making integrals divergent (see also discussion of this procedure in Ref. 1). For the convergence of the integral (19) over the bosonic components of ψ and $\psi^\dagger$, the energy ω_B must have an infinitesimal imaginary part $\mathrm{Im}\,\omega_B<0$. Then, for the convergence of the integral (32), the matrix Q must satisfy $\mathrm{Im}\,Q_B>0$ at infinity on the contour Γ [Q_B is the bosonic diagonal element, as shown in (25)]. Besides, the contour Γ must be compact in the fermionic and noncompact in the bosonic sector (see, e.g., Refs. 1, 2, 24). It is shown in Ref. 1 that Γ is the Riemannian symmetric superspace SpO(2|2)/GL(1|1) (class $CI|DIII$).

The key observation, important for taking into account the parity of N, is that the saddle-point manifold Γ consists of two connected components, which are the images of the two components of the symmetry group SpO(2|2) acting on Γ. This symmetry group acts on Q by conjugation: $Q\mapsto UQU^{-1}$. Explicitly, the two connected pieces of Γ may be obtained by rotating by the connected component of the symmetry group SpSO(2|2) the two representative matrices,

$$Q_1 = \left(\begin{array}{cc|cc} i & & & \\ & -i & & \\ \hline & & -i & \\ & & & i \end{array}\right), \qquad Q_2 = \left(\begin{array}{cc|cc} i & & & \\ & -i & & \\ \hline & & i & \\ & & & -i \end{array}\right). \tag{33}$$

The action (30) is invariant with respect to SpSO(2|2), but acquires an additional shift by $2\pi i$ between the two connected components of the saddle-point manifold.

It is this property of the supersymmetric action that allows to distinguish between odd and even N in the large-N limit: In the even-N case (class D, no zero levels), the contributions from the two pieces of the saddle-point manifold come with equal signs, and in the odd-N case (class B, one zero level)—with opposite signs,

$$Z(\omega_B,\omega_F)=Z_1(\omega_B,\omega_F)+(-1)^N Z_2(\omega_B,\omega_F). \tag{34}$$

The average spectral density $\rho(\omega)$ may be found as

$$\rho(\omega)=-\frac{1}{\pi}\mathrm{Im}\frac{\partial Z(\omega_B,\omega_F)}{\partial \omega_B}\bigg|_{\omega_B=\omega_F=\omega-i0}=\frac{1}{\pi}\mathrm{Im}\frac{\partial Z(\omega_B,\omega_F)}{\partial \omega_F}\bigg|_{\omega_B=\omega_F=\omega-i0}. \tag{35}$$

To take the integral over Γ, we need to parameterize the integration contour: In this section, the parameterization involves the two commuting parameters x,ϕ and the two anticommuting ξ and $\overline{\xi}$ (we never use complex conjugation of anticommuting variables in this paper, and so ξ and $\overline{\xi}$ should be treated as independent variables). The expressions for $\rho(\omega)$ in coordinates takes the form,

$$\rho(\omega)=\mathrm{Im}\int DQ\, Q_F \exp[-\pi\omega(Q_B-Q_F)], \tag{36}$$

where $Q_B(x,\phi,\xi,\overline{\xi})$ and $Q_F(x,\phi,\xi,\overline{\xi})$ are diagonal matrix elements of Q in a particular parameterization, and the measure of integration DQ is

$$DQ=\frac{1}{2\pi}J(x,\phi,\xi,\overline{\xi})dx\,d\phi\,d\xi\,d\overline{\xi}. \tag{37}$$

The Jacobian $J(x,\phi,\xi,\overline{\xi})$ may be found from expressing the invariant metric $\mathrm{STr}(dQ)^2$ in coordinates,

$$\mathrm{STr}(dQ)^2=g^{ij}dx_i dx_j \tag{38}$$

and taking its superdeterminant

$$J(\{x_i\})=(\mathrm{SDet}\, g^{ij})^{1/2}. \tag{39}$$

In parameterizing the saddle-point manifold we use the usual trick of splitting the rotation of the supermatrix Q_i into the two rotations by even and odd generators of the supergroup.[2] Namely, we parameterize

$$Q=U_\xi Q_z U_\xi^{-1}, \tag{40}$$

where Q_z is obtained from Q_1 or Q_2 by even rotations parameterized by x and ϕ (and without mixing between boson–bosonic and fermion–fermionic blocks), and

$$U_\xi = \exp(A), \tag{41}$$

where A is an odd infinitesimal rotation linear in ξ and $\overline{\xi}$.

Supersymmetric calculations of this sort often lead to singularities in superintegrals which need to be resolved by properly taking into account boundary terms (see e.g. Refs. 2, 1). In this paper I avoid such singularities by an appropriate choice of parameterization of the odd rotation U_ξ.

We shall also employ the symmetry relating the two components of the saddle-point manifold. Namely, conjugation by the matrix,

$$T = \left(\begin{array}{cc|cc} 1 & 0 & & \\ 0 & 1 & & \\ \hline & & 0 & 1 \\ & & 1 & 0 \end{array}\right), \tag{42}$$

transforms Q_1 into Q_2 ($Q_2 = T^{-1} Q_1 T$) and the two components of the saddle-point manifold into each other.

Thus we first parameterize the component generated by Q_1, and then the parameterization of the other component may be obtained by applying the operator T.

The even rotations of Q_1 may be parameterized as

$$Q_z = i \cdot \left(\begin{array}{cc|cc} \cosh x & -e^{i\phi}\sinh x & & \\ e^{-i\phi}\sinh x & -\cosh x & & \\ \hline & & -1 & 0 \\ & & 0 & 1 \end{array}\right) \tag{43}$$

(with $x \in [0; +\infty)$, $\phi \in [0; 2\pi]$).

The symmetry (27) of the matrix Q imposes a similar symmetry constraint on the matrix A in (41). The latter constraint admits four independent parameters in the boson-fermion and fermion-boson sectors of A. However, when acting on Q_z, only two of them are independent. At this stage we have a freedom of choosing two of the four infinitesimal rotations for our parameterization. The final result does not depend on our choice [provided the Jacobian (39) is nondegenerate], but a good choice of parameterization may considerably simplify the calculation.

We choose

$$A=\left(\begin{array}{cc|cc} & & \xi & 0 \\ & & 0 & \bar{\xi} \\ \hline \bar{\xi} & 0 & & \\ 0 & -\xi & & \end{array}\right) \tag{44}$$

which leads to

$$U_\xi=\left(\begin{array}{cc|cc} 1-\frac{1}{2}\bar{\xi}\xi & 0 & \xi & 0 \\ 0 & 1-\frac{1}{2}\bar{\xi}\xi & 0 & \bar{\xi} \\ \hline \bar{\xi} & 0 & 1+\frac{1}{2}\bar{\xi}\xi & 0 \\ 0 & -\xi & 0 & 1+\frac{1}{2}\bar{\xi}\xi \end{array}\right). \tag{45}$$

The Jacobian calculation may be simplified using the simple algebraic identity,[2]

$$ds^2=\tfrac{1}{2}\mathrm{STr}(dQ)^2=\tfrac{1}{2}\mathrm{STr}(dQ_z)^2+\tfrac{1}{2}\mathrm{STr}[Q_z,\delta U_\xi]^2+\mathrm{STr}(\delta U_\xi[Q_z,dQ_z]), \tag{46}$$

where $\delta U_\xi=U_\xi^{-1}dU_\xi$.

After some calculation, we find for the parameterization chosen

$$ds^2=dx^2+\sinh^2 x\,d\phi^2-[4(\cosh x+1)+2\sinh^2 x\,\bar{\xi}\xi]d\bar{\xi}\,d\xi+2i\sinh^2 x(\bar{\xi}\,d\xi+\xi\,d\bar{\xi})d\phi \tag{47}$$

and

$$J(x,\phi,\xi,\bar{\xi})=\frac{1}{2}\tanh\frac{x}{2}. \tag{48}$$

Also, by a direct calculation,

$$\begin{aligned} Q_{B1}&=i[\cosh x-(\cosh x+1)\bar{\xi}\xi], \\ Q_{F1}&=i[1+(\cosh x+1)\bar{\xi}\xi]. \end{aligned} \tag{49}$$

Using the operator T to relate the two connected components of the saddle-point manifold, we find for the second component,

$$Q_{B2}=Q_{B1},\quad Q_{F2}=-Q_{F1}, \tag{50}$$

and the Jacobian obviously remains the same (48).

As a consistency check, one may verify that

$$Z_{\pm}(\omega,\omega)=\int \frac{1}{2\pi}\, J(x,\phi,\xi,\bar{\xi})dx\, d\phi\, d\bar{\xi}\, d\xi\, (\exp[-\pi\omega(Q_{B1}-Q_{F1})]\pm\exp[-\pi\omega(Q_{B1}+Q_{F1})])$$
$$=1 \tag{51}$$

(up to a sign).

Now the calculation of the integral (36) is easily done,

$$\rho_1(\omega)=\mathrm{Re}\int_0^\infty dx\int_0^{2\pi} d\phi\int d\bar{\xi}\, d\xi\, \frac{1}{4\pi}\tanh\frac{x}{2}[1+(\cosh x+1)\bar{\xi}\xi]$$
$$\times\exp(-i\pi\omega[(\cosh x-1)-2(\cosh x+1)\bar{\xi}\xi])=\tfrac{1}{2}\,\delta(x)+1, \tag{52}$$

$$\rho_2(\omega)=\mathrm{Re}\int_0^\infty dx\int_0^{2\pi} d\phi\int d\bar{\xi}\, d\xi\, \frac{1}{4\pi}\tanh\frac{x}{2}[1+(\cosh x+1)\bar{\xi}\xi]\exp(-i\pi\omega[\cosh x+1])$$
$$=\frac{1}{2}\,\delta(x)-\frac{\sin(2\pi\omega)}{2\pi\omega} \tag{53}$$

(all the calculations are performed up to an overall sign). The δ-function terms are obtained from imaginary $1/i\omega$ terms by shifting ω to the lower half-plane $\omega\to\omega-i0$.

Combining these results with proper signs, we arrive at the final expressions (3) and (4). The asymptotic value $\rho(\omega\to\infty)=1$ proves that Δ given by (16) is indeed the average level spacing.

Note that $\rho_1(\omega)$ appeared in Ref. 5 as the spectral density in class BD (which is the average of B and D).

V. CLASSES *D*III-EVEN AND *D*III-ODD

For classes DIII-even and DIII-odd, the calculation is similar to that of the previous section. The saddle-point manifold again consists of two connected components, and taking their contributions with different signs distinguishes between odd and even matrix dimension.

The ensembles DIII-even and DIII-odd have $\beta=4$. In the calculation of the average spectral density in these ensembles, the matrix Q has dimension $4+4$ and belongs to a $(8+8)$-dimensional linear space. The saddle-point manifold is $(4+4)$-dimensional.

The ensembles DIII are defined as consisting of $2N\times 2N$ matrices,

$$H=i\begin{pmatrix} H_1 & H_2 \\ H_2 & -H_1 \end{pmatrix}, \tag{54}$$

where H_1 and H_2 are real $N\times N$ antisymmetric matrices ($H_1^T=-H_1$, $H_2^T=-H_2$). Depending on whether N is even or odd, this defines the ensemble DIII-even or DIII-odd, respectively. The matrix elements of H_1 and H_2 are assumed to be distributed independently with a Gaussian distribution, and produce the following pair correlation function for the matrix elements of H:

$$\langle H_{ai,bj}H_{a'i',b'j'}\rangle=v^2(\delta_{ii'}\delta_{jj'}-(-1)^{i+j}\bar{\delta}_{ii'}\bar{\delta}_{jj'})(\delta_{ab'}\delta_{ba'}-\delta_{aa'}\delta_{bb'}), \tag{55}$$

where the indices i, j take values 1 or 2 and distinguish between the two N-dimensional sectors in the $2N$-dimensional linear space, and $\bar{\delta}=\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$ in this "1–2" space.

We express energy in the units

$$\Delta=\frac{\sqrt{2}\,\pi v}{\sqrt{N}} \tag{56}$$

(as the result of the calculation, this is the average level spacing).

The space of Ψ-vectors needs to be doubled. Instead of a single vector Ψ_a we introduce a pair of vectors Ψ_{1a} and Ψ_{2a} (here a takes values $1,\ldots,N$),

$$\Psi_{1a}=\begin{pmatrix}\psi_{1B}\\ \psi_{2B}\\ \psi_{1B}^{\dagger}\\ \psi_{2B}^{\dagger}\\ \psi_{1F}\\ \psi_{2F}\\ \psi_{1F}^{\dagger}\\ \psi_{2F}^{\dagger}\end{pmatrix}_a,\quad \Psi_{2a}=\begin{pmatrix}\psi_{2B}\\ -\psi_{1B}\\ \psi_{2B}^{\dagger}\\ -\psi_{1B}^{\dagger}\\ \psi_{2F}\\ -\psi_{1F}\\ \psi_{2F}^{\dagger}\\ -\psi_{1F}^{\dagger}\end{pmatrix}_a,\quad \bar{\Psi}_{1a}=\begin{pmatrix}\psi_{1B}^{\dagger}\\ -\psi_{2B}^{\dagger}\\ -\psi_{1B}\\ \psi_{2B}\\ \psi_{1F}^{\dagger}\\ -\psi_{2F}^{\dagger}\\ \psi_{1F}\\ -\psi_{2F}\end{pmatrix}_a^T,\quad \bar{\Psi}_{2a}=\begin{pmatrix}\psi_{2B}^{\dagger}\\ \psi_{1B}^{\dagger}\\ -\psi_{2B}\\ -\psi_{1B}\\ \psi_{2F}^{\dagger}\\ \psi_{1F}^{\dagger}\\ \psi_{2F}\\ \psi_{1F}\end{pmatrix}_a^T. \tag{57}$$

The two sets of vectors Ψ, $\bar{\Psi}$ are necessary to reproduce the four terms in the interaction induced by (55).

The corresponding supermatrix Q has the form,

$$Q=\left(\begin{array}{cccc|cccc}
Q_B & X_B & -Y_B & 0 & \bar{\sigma}_1 & -\bar{\sigma}_2 & \rho_1 & -\rho_2\\
X_B & -Q_B & 0 & Y_B & -\bar{\sigma}_2 & -\bar{\sigma}_1 & -\rho_2 & -\rho_1\\
\bar{Y}_B & 0 & -Q_B & X_B & \bar{\rho}_1 & -\bar{\rho}_2 & \sigma_1 & -\sigma_2\\
0 & -\bar{Y}_B & X_B & Q_B & -\bar{\rho}_2 & -\bar{\rho}_1 & -\sigma_2 & -\sigma_1\\
\hline
\sigma_1 & \sigma_2 & -\rho_1 & -\rho_2 & -Q_F & -X_F & 0 & -Y_F\\
\sigma_2 & -\sigma_1 & -\rho_2 & \rho_1 & -X_F & Q_F & -Y_F & 0\\
\bar{\rho}_1 & \bar{\rho}_2 & -\bar{\sigma}_1 & -\bar{\sigma}_2 & 0 & -\bar{Y}_F & Q_F & -X_F\\
\bar{\rho}_2 & -\bar{\rho}_1 & -\bar{\sigma}_2 & \bar{\sigma}_1 & -\bar{Y}_F & 0 & -X_F & -Q_F
\end{array}\right)_{FB,PH,12} \tag{58}$$

Equivalently, Q may be described as obeying the two linear constraints,

$$\gamma_{12}Q\gamma_{12}^{-1}=-Q,\quad \gamma_{12}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}_{12}, \tag{59}$$

and

$$\gamma_{PH} Q \gamma_{PH}^{-1} = Q^T, \qquad \gamma_{PH} = \gamma = \left(\begin{array}{cc|cc} 0 & 1 & & \\ -1 & 0 & & \\ \hline & & 0 & 1 \\ & & 1 & 0 \end{array}\right)_{FB,PH} \otimes \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}_{12}, \tag{60}$$

where FB and PH indices specifies that the operator acts in the Fermi–Bose and ''particle–hole'' spaces (the doubling of dimension by combining ψ and $\psi^\dagger$ in a single vector Ψ), and ''1–2'' denotes the space corresponding to the two N-dimensional sectors in the original Hamiltonian (54).

Similarly to the previous section, we find for the generating function $Z(\omega_B, \omega_F)$,

$$\begin{aligned} Z(\omega_B,\omega_F) &= \int D\Psi \exp\left(-\frac{1}{4}\mathrm{STr}\left[i\pi \frac{\sqrt{2}}{\sqrt{N}} \Psi_{ia}\overline{\Psi}_{ia}\hat{\omega} + \frac{1}{2}(\Psi_{ia}\overline{\Psi}_{ia})^2 \right] \right) \\ &= \int DQ \int D\Psi \exp\left(-\frac{1}{2}\mathrm{STr}\left[\frac{N}{2}Q^2 + i\sqrt{\frac{N}{2}}\left(Q - \frac{\pi}{N}\hat{\omega} \right)\Psi_{ia}\overline{\Psi}_{ia} \right] \right) \\ &= \int DQ \left[\mathrm{SDet}\left(Q - \frac{\pi}{N}\hat{\omega} \right) \right]^{-N/2} \exp\left(-\frac{N}{2}\mathrm{STr}\,\frac{Q^2}{2} \right), \end{aligned} \tag{61}$$

where

$$\hat{\omega} = \begin{pmatrix} \omega_B & \\ & \omega_F \end{pmatrix} \otimes \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}_{\mathrm{PH}} \otimes \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}_{12}. \tag{62}$$

At small energies ω_B, ω_F this leads to the formulas (29)–(32), albeit with the new definitions of Q and $\hat{\omega}$.

The saddle-point manifold consists of the two connected pieces represented by

$$Q_1 = \left(\begin{array}{ccccc|ccccc} i & & & & & & & & & \\ & -i & & & & & & & & \\ & & -i & & & & & & & \\ & & & i & & & & & & \\ & & & & i & & & & & \\ \hline & & & & & -i & & & & \\ & & & & & & i & & & \\ & & & & & & & i & & \\ & & & & & & & & -i & \\ & & & & & & & & & -i \end{array}\right), \qquad Q_2 = \left(\begin{array}{ccccc|ccccc} i & & & & & & & & & \\ & -i & & & & & & & & \\ & & -i & & & & & & & \\ & & & i & & & & & & \\ & & & & i & & & & & \\ \hline & & & & & -i & & & & \\ & & & & & & -i & & & \\ & & & & & & & -i & & \\ & & & & & & & & -i & \\ & & & & & & & & & -i \end{array}\right). \tag{63}$$

Similarly to the procedure described in the previous section, first the supermatrices Q_1, Q_2 are rotated by even symmetry-group generators. These rotations do not mix bosonic and fermionic components, i.e., the matrix Q_z contains only boson–boson and fermion–fermion blocks,

$$Q_z = \left(\begin{array}{c|c} Q_z^{(BB)} & \\ \hline & Q_z^{(FF)} \end{array} \right). \tag{64}$$

We shall use the following parameterization of these blocks:

$$Q_z^{(\mathrm{BB})} = \begin{pmatrix} i\cosh\theta_B & n_1\sinh\theta_B & (n_2-in_3)\sinh\theta_B & 0 \\ n_1\sinh\theta_B & -i\cosh\theta_B & 0 & -(n_2-in_3)\sinh\theta_B \\ (n_2+in_3)\sinh\theta_B & 0 & -i\cosh\theta_B & n_1\sinh\theta_B \\ 0 & -(n_2+in_3)\sinh\theta_B & n_1\sinh\theta_B & i\cosh\theta_B \end{pmatrix}_{\mathrm{PH},12}, \tag{65}$$

where (n_1,n_2,n_3) is a vector of a real two-dimensional unit sphere $(n_1^2+n_2^2+n_3^2=1)$. The boson–boson block is the same for the two sectors of the saddle-point manifold.

The fermion–fermion blocks for the two components of the saddle-point manifold are

$$Q_{z1}^{(\mathrm{FF})} = \begin{pmatrix} 0 & 0 & 0 & -ie^{i\theta_F} \\ 0 & 0 & -ie^{i\theta_F} & 0 \\ 0 & -ie^{-i\theta_F} & 0 & 0 \\ -ie^{-i\theta_F} & 0 & 0 & 0 \end{pmatrix}, \tag{66}$$

$$Q_{z2}^{(\mathrm{FF})} = \begin{pmatrix} -i\cos\theta_F & -i\sin\theta_F & 0 & 0 \\ -i\sin\theta_F & i\cos\theta_F & 0 & 0 \\ 0 & 0 & i\cos\theta_F & -i\sin\theta_F \\ 0 & 0 & -i\sin\theta_F & -i\cos\theta_F \end{pmatrix}. \tag{66}$$

The parameter range is $\theta_B\in[0;+\infty)$, $\theta_F\in[0;2\pi]$, and the vector $\mathbf{n}$ runs over the two-dimensional unit sphere S^2.

Like in the previous section, we first do the calculation in the first component of the saddle-point manifold, and then obtain the answers for the second component by using the symmetry operator T mapping one component (generated by Q_1) onto the other (generated by Q_2). One possible choice of such a matrix T is

$$T=\left(\begin{array}{cccc|cccc} 1 & & & & & & & \\ & 1 & & & & & & \\ & & 1 & & & & & \\ & & & 1 & & & & \\ \hline & & & & 1/2 & -i/2 & -i/2 & 1/2 \\ & & & & -i/2 & -1/2 & 1/2 & i/2 \\ & & & & -i/2 & 1/2 & -1/2 & i/2 \\ & & & & 1/2 & i/2 & i/2 & 1/2 \end{array}\right)_{FB,PH,12}. \tag{67}$$

Returning to the parameterization for the first component of the saddle-point manifold, the matrix A involved in the odd rotation (40), (41) is chosen as follows:

$$A=\left(\begin{array}{cccc|cccc} & & & & \xi & \nu & 0 & 0 \\ & & & & -\nu & \xi & 0 & 0 \\ & & & & \bar{\nu} & \bar{\xi} & 0 & 0 \\ & & & & -\bar{\xi} & \bar{\nu} & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & & & & \\ 0 & 0 & 0 & 0 & & & & \\ \bar{\nu} & \bar{\xi} & -\xi & -\nu & & & & \\ -\bar{\xi} & \bar{\nu} & \nu & -\xi & & & & \end{array}\right)_{FB,PH,12}. \tag{68}$$

This matrix satisfies the *flatness* condition $[A,dA]=0$, and this leads to $\delta U_\xi = U_\xi^{-1} dU_\xi = dA$. Using the algebraic identity (46), together with (38), (39), and

$$DQ=\frac{1}{(2\pi)^2} J(\theta_B,\theta_F,\mathbf{n},\xi,\overline{\xi},\nu,\overline{\nu})\, d\theta_B\, d\theta_F\, d^2\mathbf{n}\, d\xi\, d\overline{\xi}\, d\nu\, d\overline{\nu}, \tag{69}$$

one finds after some calculation the explicit form for the invariant measure in the coordinates chosen,

$$DQ=\frac{1}{16\pi^2} e^{-2i\theta_F} \sinh^2\theta_B\, d\theta_B\, d\theta_B\, d\theta_F\, d^2\mathbf{n}\, d\xi\, d\overline{\xi}\, d\nu\, d\overline{\nu} \tag{70}$$

(here $d^2\mathbf{n}$ is the integration over the solid angle on the unit sphere).

The explicit expressions for the diagonal entries of the Q-matrix Q_B and Q_F are found to be

$$Q_{B1}=i[\cosh\theta_B+e^{i\theta_F}(\bar{\xi}\xi-\bar{\nu}\nu)],\quad Q_{F1}=-ie^{i\theta_F}(\bar{\xi}\xi+\bar{\nu}\nu). \tag{71}$$

Using the operator T defined in (67), for the second component of the saddle-point manifold we find

$$\begin{aligned} Q_{B2}&=Q_{B1},\\ Q_{F2}&=i[\cos\theta_F+2\bar{\xi}\xi\bar{\nu}\nu e^{i\theta_F}+\cosh\theta_B(\bar{\nu}\nu-\bar{\xi}\xi)\\ &\quad+in_1\sinh\theta_B(\nu\bar{\xi}-\bar{\nu}\xi)-(n_2+in_3)\bar{\nu}\bar{\xi}\sinh\theta_B+(n_2-in_3)\nu\xi\sinh\theta_B]. \end{aligned} \tag{72}$$

After some calculation, one verifies the normalization:

$$\begin{aligned} Z_1(\omega,\pm\omega)&=\int dQ\,\exp[-2\pi\omega(Q_{B1}\mp Q_{F1})]=0,\\ Z_2(\omega,\pm\omega)&=\int dQ\,\exp[-2\pi\omega(Q_{B2}\mp Q_{F2})]=1. \end{aligned} \tag{73}$$

The density of states is found in terms of Bessel functions,

$$\rho_1(\omega)=\mathrm{Im}\int dQ\,Q_{F1}\exp[-2\pi\omega(Q_{B1}-Q_{F1})]=\frac{1}{2}\delta(\omega)-\frac{\pi}{2}J_1(2\pi\omega) \tag{74}$$

in the first sector, and

$$\rho_2(\omega)=\mathrm{Im}\int dQ\,Q_{B2}\exp[-2\pi\omega(Q_{B2}-Q_{F2})]=\frac{1}{2}\delta(\omega)+\pi^2\omega[J_1'(2\pi\omega)J_0(2\pi\omega)+J_1^2(2\pi\omega)], \tag{75}$$

where in (74) and (75) we assumed $\omega>0$ and are careless about the overall sign of the answers.

Taking these contributions with proper signs, we obtain the answers (5) and (6). Remarkably, in (6), the contributions of $\rho_1(\omega)$ and of $\rho_2(\omega)$ cancel each other to the third order at small ω, producing the correct behavior of the total density of states $\rho(\omega)\propto\omega^5$.

VI. CLASS *A*III (CHIRAL UNITARY)

The supersymmetric calculations for the three chiral random-matrix ensembles differ from those for classes B–D and DIII in that the broken symmetry of the saddle-point manifold is not the discrete Z_2, but the continuous GL(1). The representations of GL(1) are enumerated by the integer winding number whose absolute value equals the number of zero levels in the random-matrix ensemble.

The chiral unitary ensemble considered in this section has $\beta=2$ (unitary bulk statistics). In the calculation of the average density of states, the supermatrix Q has the block form (in the "1–2" space)

$$Q=\begin{pmatrix} 0 & Q_1\\ Q_2 & 0\end{pmatrix}, \tag{76}$$

where Q_1 and Q_2 are $(1+1)$-dimensional supermatrices without linear constraints. Thus the linear space of matrices Q is $4+4$-dimensional, and the saddle-point manifold has dimension $2+2$.

The (Gaussian) chiral unitary ensemble (class AIII in Cartan notation) consists of the matrices of the form,

$$H=\begin{pmatrix} 0 & \tilde{H} \\ \tilde{H}^\dagger & 0 \end{pmatrix}, \tag{77}$$

where $\tilde{H}$ is a rectangular matrix $p\times q$ with complex matrix elements. The matrix elements of $\tilde{H}$ have independent Gaussian distributions,

$$dP(H)\propto\prod_{a,b}\ \exp\left(-\frac{|\tilde{H}_{ab}|^2}{v^2}\right)d\,\mathrm{Re}\,\tilde{H}_{ab}d\,\mathrm{Im}\,\tilde{H}_{ab}\,. \tag{78}$$

The spectrum of such a matrix H consist of $N=\min(p,q)$ pairs of eigenvalues $\pm E_i$ and of $m=|p-q|$ zero eigenvalues. In this paper we are interested in the average density of states near zero in the limit of large matrices $N\to\infty$ while keeping the number of zero levels m fixed. The average level spacing near zero in the large-N limit is

$$\Delta=\frac{\pi v}{2\sqrt{N}}. \tag{79}$$

Following the standard procedure, we introduce p-component superfields Ψ_1 and $\overline{\Psi}_1$, and q-component superfields Ψ_2 and $\overline{\Psi}_2$,

$$\Psi_{1a}=\begin{pmatrix}\psi_{1B}\\ \psi_{1F}\end{pmatrix}_a,\quad \overline{\Psi}_{1a}=\begin{pmatrix}\psi^\dagger_{1B}\\ \psi^\dagger_{1F}\end{pmatrix}^T_a,\quad a=1,\ldots,p, \tag{80}$$

$$\Psi_{2b}=\begin{pmatrix}\psi_{2B}\\ \psi_{2F}\end{pmatrix}_b,\quad \overline{\Psi}_{2b}=\begin{pmatrix}\psi^\dagger_{2B}\\ \psi^\dagger_{2F}\end{pmatrix}^T_b,\quad b=1,\ldots,q. \tag{81}$$

The generating function (17) takes the form,

$$\begin{aligned} Z(\omega_B,\omega_F)&=\int D\Psi\,\exp\left(-\mathrm{STr}\left[\frac{i\pi}{2\sqrt{N}}(\Psi_{1a}\overline{\Psi}_{1a}+\Psi_{2b}\overline{\Psi}_{2b})\hat{\omega}+(\Psi_{1a}\overline{\Psi}_{1a})(\Psi_{2b}\overline{\Psi}_{2b})\right]\right)\\ &=\int D(Q_1,Q_2)\int D\Psi\,\exp\left(-\mathrm{STr}\left[NQ_1Q_2+i\sqrt{N}\left(Q_1-\frac{\pi}{2N}\hat{\omega}\right)\Psi_{2b}\overline{\Psi}_{2b}\right.\right.\\ &\quad\left.\left.+i\sqrt{N}\left(Q_2-\frac{\pi}{2N}\hat{\omega}\right)\Psi_{1a}\overline{\Psi}_{1a}\right]\right)\\ &=\int D(Q_1,Q_2)\left[\mathrm{SDet}\left(Q_1-\frac{\pi}{2N}\hat{\omega}\right)\right]^{-q}\left[\mathrm{SDet}\left(Q_2-\frac{\pi}{2N}\hat{\omega}\right)\right]^{-p}\\ &\quad\times\exp(-N\,\mathrm{STr}\,Q_1Q_2), \end{aligned} \tag{82}$$

where the original integration contour in Q is at $Q_2=Q_1^\dagger$, and

$$\hat{\omega} = \left(\begin{array}{c|c} \omega_B & \\ \hline & \omega_F \end{array}\right). \tag{83}$$

At small energies, expanding the supersymmetric action to terms linear in $\omega_{B,F}$, we find

$$Z(\omega_B,\omega_F) = \int DQ\,[\mathrm{SDet}\,Q_1]^m \exp\left[-NS_0(Q_1,Q_2) + \frac{\pi}{2}\mathrm{STr}\,\hat{\omega}(Q_1^{-1}+Q_2^{-1})\right] \tag{84}$$

with

$$S_0(Q_1,Q_2) = \mathrm{STr}(Q_1Q_2 + \ln Q_1 + \ln Q_2). \tag{85}$$

If Q_1 and Q_2 are combined into a single supermatrix Q according to (76), this action coincides with the standard form (30). The saddle-point manifold Γ is given by the condition,

$$Q_1Q_2 = -1 \tag{86}$$

(which is equivalent to $Q^2=-1$), and the generating function may be written as the integral over the saddle-point manifold,

$$Z_m(\omega_B,\omega_F) = \int_\Gamma DQ\,[\mathrm{SDet}\,Q_1]^m \exp\left[-\frac{\pi}{2}\mathrm{STr}\,\hat{\omega}(Q_1+Q_2)\right]. \tag{87}$$

A parameterization and the calculation of the integral was previously performed in Ref. 6, and I outline their calculation here for completeness. The matrices Q_1 and Q_2 are parameterized as

$$Q_1 = -Q_2^{-1} = \left(\begin{array}{c|c} ie^x & 0 \\ \hline 0 & ie^{i\phi} \end{array}\right) \exp\left(\begin{array}{c|c} 0 & \xi \\ \hline \bar{\xi} & 0 \end{array}\right). \tag{88}$$

The invariant measure deduced from the metric $ds^2=\mathrm{STr}(Q_1Q_2)$ leads to the trivial Jacobian $J=1$ and to the integration measure

$$DQ = \frac{1}{2\pi}dx\,d\phi\,d\xi\,d\bar{\xi}. \tag{89}$$

From the parameterization (88), the diagonal elements of the matrices Q_1 and Q_2 are easily computed. The generating function (87) involves the average of the diagonal elements of Q_1 and Q_2,

$$\begin{aligned} Q_{\mathrm{BB}} &= \tfrac{1}{2}[(Q_1)_{\mathrm{BB}} + (Q_2)_{\mathrm{BB}}] = i\cosh x\,[1-\tfrac{1}{2}\bar{\xi}\xi], \\ Q_{\mathrm{FF}} &= \tfrac{1}{2}[(Q_1)_{\mathrm{FF}} + (Q_2)_{\mathrm{FF}}] = i\cos\phi\,[1+\tfrac{1}{2}\bar{\xi}\xi]. \end{aligned} \tag{90}$$

Also, the m-dependent prefactor in (87) is a plane wave generated by

$$\mathrm{SDet}\,Q_1 = e^{x-i\phi}. \tag{91}$$

The normalization can be verified by computing the integral,

$$Z_m(\omega,\omega)=\int \frac{1}{2\pi}dx\,d\phi\,d\xi\,d\bar{\xi}\,e^{m(x-i\phi)}\exp\left[-i\pi\omega\left(\cosh x\left[1-\frac{1}{2}\bar{\xi}\xi\right]+\cos\phi\left[1+\frac{1}{2}\bar{\xi}\xi\right]\right)\right]$$
$$=\pm 1. \tag{92}$$

The average spectral density is calculated from (35) as the integral (again, up to an overall sign),

$$\rho_m(\omega)=\mathrm{Re}\int \frac{1}{2\pi}dx\,d\phi\,d\xi\,d\bar{\xi}\,e^{m(x-i\phi)}\cosh x\left[1-\frac{1}{2}\bar{\xi}\xi\right]$$
$$\times\exp[-i\pi\omega(\cosh x[1-\tfrac{1}{2}\bar{\xi}\xi]+\cos\phi[1+\tfrac{1}{2}\bar{\xi}\xi])] \tag{93}$$

which after some algebra produces the result (7).

VII. CLASS *BD*I (CHIRAL ORTHOGONAL)

Similarly to the three Wigner–Dyson random-matrix ensembles, the chiral ensembles form the three classes: unitary, orthogonal, and symplectic, depending on the structure of the matrix $\tilde{H}$ in the block form (77). In the chiral orthogonal ensemble (class *BD*I in Cartan notation), the matrix $\tilde{H}$ is real. In this ensemble, the bulk repulsion of the levels corresponds to the orthogonal regime: $\beta=1$. The supermatrix Q involved in the calculation of the average spectral density has the block form (76), but now the matrices Q_1 and Q_2 have dimensions $2+2$ each, with one linear constraint, so the dimension of the linear space of all the matrices Q is $8+8$. The saddle-point equation selects the saddle-point manifold of dimension $4+4$.

The entries of the matrix $\tilde{H}$ in (77) are assumed to be real, with independent Gaussian distributions,

$$dP(H)\propto\prod_{a,b}\ \exp\left(-\frac{|\tilde{H}_{ab}|^2}{2v^2}\right)d\tilde{H}_{ab}\,. \tag{94}$$

As in the chiral unitary ensemble, the spectrum consists of N pairs of opposite energies, and of $m=|p-q|$ zero-energy levels. The average level spacing is given by the same expression (79) [note however a difference between the definitions of v in (78) and in (94), depending on whether $\tilde{H}_{ab}$ are complex or real].

To account for the matrix elements $\tilde{H}_{ab}$ being real, we need to double the dimensions of the superfields Ψ_i and $\bar{\Psi}_i$. The p-component superfields Ψ_1 and $\bar{\Psi}_1$ are defined as

$$\Psi_{1a}=\begin{pmatrix}\psi_{1B}\\ \psi_{1B}^\dagger\\ \psi_{1F}\\ \psi_{1F}^\dagger\end{pmatrix}_a,\quad \bar{\Psi}_{1a}=\begin{pmatrix}\psi_{1B}^\dagger\\ \psi_{1B}\\ \psi_{1F}^\dagger\\ -\psi_{1F}\end{pmatrix}^T_a,\quad a=1,\ldots,p, \tag{95}$$

and similarly, the q-component superfields Ψ_2 and $\bar{\Psi}_2$,

$$\Psi_{2b}=\begin{pmatrix}\psi_{2B}\\ \psi_{2B}^\dagger\\ \psi_{2F}\\ \psi_{2F}^\dagger\end{pmatrix}_b,\quad \bar{\Psi}_{2b}=\begin{pmatrix}\psi_{2B}^\dagger\\ \psi_{2B}\\ \psi_{2F}^\dagger\\ -\psi_{2F}\end{pmatrix}^T_b,\quad b=1,\ldots,q. \tag{96}$$

Repeating the steps of the derivation (82), we arrive at the following expression for the generating function [in place of (84)]:

$$Z_m(\omega_B,\omega_F)=\int DQ\,[\mathrm{SDet}\,Q_1]^{m/2}\exp\left[-\frac{N}{2}S_0(Q_1,Q_2)+\frac{\pi}{4}\mathrm{STr}\,\hat{\omega}(Q_1^{-1}+Q_2^{-1})\right], \tag{97}$$

where $\hat{\omega}$ and $S_0(Q_1,Q_2)$ are given by the old expressions (83) and (85). However, the matrices Q_1 and Q_2 are now two times bigger. Each of them has the explicit form,

$$Q_i=\left(\begin{array}{cc|cc} Q_{Bi} & -X_i & \sigma_i & -\rho_i \\ \bar{X}_i & Q_{Bi} & \bar{\rho}_i & -\bar{\sigma}_i \\ \hline \bar{\sigma}_i & \rho_i & Q_{Fi} & 0 \\ \bar{\rho}_i & \sigma_i & 0 & Q_{Fi} \end{array}\right). \tag{98}$$

Equivalently, this form of the matrices Q_i may be described by the linear constraints,

$$\gamma Q_i \gamma^{-1}=Q_i^T, \tag{99}$$

where

$$\gamma=\left(\begin{array}{cc|cc} 0 & 1 & & \\ 1 & 0 & & \\ \hline & & 0 & 1 \\ & & -1 & 0 \end{array}\right). \tag{100}$$

The saddle-point manifold Γ is determined by the condition (86), and the generating function is expressed as

$$Z_m(\omega_B,\omega_F)=\int_\Gamma DQ\,[\mathrm{SDet}\,Q_1]^{m/2}\exp\left[-\frac{\pi}{4}\mathrm{STr}\,\hat{\omega}(Q_1+Q_2)\right]. \tag{101}$$

In the present section we choose a slightly different form of parameterization than in the previous one. Namely, parameterize

$$Q_1=U_1Q_{z1}U_2^{-1},\quad Q_2=U_2Q_{z2}U_1^{-1}, \tag{102}$$

where the matrices Q_{z1} and Q_{z2} contain only boson–boson and fermion–fermion blocks (contain only even rotations), and the matrices U_1 and U_2 contain only odd rotations. The explicit form of this parameterization is as follows:

$$Q_{z1} = i\left(\begin{array}{cc|cc} e^{x}\cosh\theta & e^{x+iy}\sinh\theta & & \\ e^{x-iy}\sinh\theta & e^{x}\cosh\theta & & \\ \hline & & e^{i\phi} & 0 \\ & & 0 & e^{i\phi} \end{array}\right),$$

$$Q_{z2} = i\left(\begin{array}{cc|cc} e^{-x}\cosh\theta & -e^{-x+iy}\sinh\theta & & \\ -e^{-x-iy}\sinh\theta & e^{-x}\cosh\theta & & \\ \hline & & e^{-i\phi} & 0 \\ & & 0 & e^{-i\phi} \end{array}\right), \tag{103}$$

$$U_1 = \exp(A_1), \qquad U_2 = \exp(A_2), \tag{104}$$

$$A_1 = \left(\begin{array}{cc|cc} & & -\xi & \lambda \\ & & -\bar{\lambda} & \bar{\xi} \\ \hline & & & \\ & & & \end{array}\right), \qquad A_2 = \left(\begin{array}{cc|cc} & & & \\ & & & \\ \hline \bar{\xi} & \lambda & & \\ \bar{\lambda} & \xi & & \end{array}\right). \tag{105}$$

After some calculation, the Jacobian is found to be

$$J = \sinh\theta e^{2(x-i\phi)}, \tag{106}$$

and therefore the measure of integration is

$$DQ = \frac{1}{(2\pi)^2}\sinh\theta\, e^{2(x-i\phi)}\, dx\, dy\, d\theta\, d\phi\, d\bar{\xi}\, d\xi\, d\bar{\lambda}\, d\lambda. \tag{107}$$

Finally, from the explicit calculation of the diagonal elements of Q_1 and Q_2,

$$\begin{aligned} Q_{\mathrm{BB}} &= \tfrac{1}{2}[(Q_1)_{\mathrm{BB}} + (Q_2)_{\mathrm{BB}}] = i[\cosh x\cosh\theta - \tfrac{1}{2}e^{i\phi}(\bar{\xi}\xi - \bar{\lambda}\lambda)], \\ Q_{\mathrm{FF}} &= \tfrac{1}{2}[(Q_1)_{\mathrm{FF}} + (Q_2)_{\mathrm{FF}}] = i[\cos\phi + \tfrac{1}{2}e^{-x}(\cosh\theta[\bar{\xi}\xi - \bar{\lambda}\lambda] - \sinh\theta[e^{iy}\bar{\xi}\bar{\lambda} + e^{-iy}\lambda\xi])]. \end{aligned} \tag{108}$$

Now, after verifying the normalization,

$$Z_m(\omega, \pm\omega) = \int DQ\, e^{m(x-i\phi)}\exp[-\pi\omega(Q_{\mathrm{BB}} \pm Q_{\mathrm{FF}})] = 1, \tag{109}$$

we compute the average density of states as the following integral:

$$\rho_m(\omega)=\mathrm{Re}\int DQ\, e^{m(x-i\phi)}\, Q_{\mathrm{BB}} \exp[-\pi\omega(Q_{\mathrm{BB}}+Q_{\mathrm{FF}})] \tag{110}$$

[where DQ, Q_{BB}, and Q_{FF} are defined in (107) and (108)]. After some algebra and manipulations with Bessel functions, this produces the result (8).

VIII. CLASS *C*II (CHIRAL SYMPLECTIC)

The last symmetry class considered in this paper is *C*II in Cartan notation: the chiral symplectic one. It consists of the matrices H of the block form (77), where the matrix $\tilde{H}$ has an internal 2×2 structure,

$$\tilde{H}=\begin{pmatrix} a & b \\ -b^* & a^* \end{pmatrix}, \tag{111}$$

where a and b are rectangular $p\times q$ matrices [the matrix $\tilde{H}$ thus has the dimensions $2p\times 2q$, and the Hamiltonian (77) has the dimension $2(p+q)$]. The spectrum of such a Hamiltonian consists of the $N=\min(p,q)$ pairs of doubly degenerate levels at opposite energies $\pm E_i$, and of $2m=2|p-q|$ zero-energy levels. Since each level has degeneracy two (or a multiple of two), we divide the density of states by two for the purpose of level counting, and count each degenerate level as a single one.

As in the two previous sections, the supermatrix Q is of the form (76). Similarly to the chiral orthogonal case, the matrices Q_1 and Q_2 in this calculation have dimension $2+2$, with one linear constraint. The dimension of the linear space of matrices Q is thus $8+8$, and the dimension of the saddle-point manifold is $4+4$.

The entries of the matrix (111) are assumed to be normalized as

$$dP(A)\propto\prod_{a,b}\ \exp\left(-\frac{|a_{ab}|^2}{v^2}\right) d\,\mathrm{Re}\,a_{ab}\, d\,\mathrm{Im}\,a_{ab}\prod_{a,b}\ \exp\left(-\frac{|b_{ab}|^2}{v^2}\right) d\,\mathrm{Re}\,b_{ab}\, d\,\mathrm{Im}\,b_{ab}\,. \tag{112}$$

With this normalization, the average level spacing is

$$\Delta=\frac{\pi v}{\sqrt{2N}}. \tag{113}$$

Similarly to the *D*III ensemble discussed before, we need to additionally double the set of the superfields to account for the symplectic matrix structure. Namely, in addition to the ''1–2'' sector, distinguishing between the size-p and size-q blocks in (77), we introduce the ''particle–hole'' (PH) sector referring to the two sectors inside the matrix A (111). Thus we arrive to the four pairs of superfields Ψ_{P1}, $\overline{\Psi}_{P1}$, Ψ_{P2}, $\overline{\Psi}_{P2}$, Ψ_{H1}, $\overline{\Psi}_{H1}$, Ψ_{H2}, $\overline{\Psi}_{H2}$,

$$\Psi_{P1a}=\begin{pmatrix} \psi^\dagger_{P1B} \\ \psi_{H1B} \\ \psi^\dagger_{P1F} \\ \psi_{H1F} \end{pmatrix}_a, \quad \overline{\Psi}_{P1a}=\begin{pmatrix} \psi_{P1B} \\ \psi^\dagger_{H1B} \\ -\psi_{P1F} \\ \psi^\dagger_{H1F} \end{pmatrix}^T_a, \quad \Psi_{H1a}=\begin{pmatrix} \psi^\dagger_{H1B} \\ -\psi_{P1B} \\ \psi^\dagger_{H1F} \\ -\psi_{P1F} \end{pmatrix}_a,$$
$$\overline{\Psi}_{H1a}=\begin{pmatrix} \psi_{H1B} \\ -\psi^\dagger_{P1B} \\ -\psi_{H1F} \\ -\psi^\dagger_{P1F} \end{pmatrix}^T_a, \quad a=1,\ldots,p, \tag{114}$$

and similarly for the sector-2 fields Ψ_{P2}, $\overline{\Psi}_{P2}$, Ψ_{H2}, $\overline{\Psi}_{H2}$.

This results in the following form of matrices Q_i:

$$Q_i = \left(\begin{array}{cc|cc} Q_{Bi} & 0 & -\sigma_i & \bar{\rho}_i \\ 0 & Q_{Bi} & \rho_i & \bar{\sigma}_i \\ \hline \bar{\sigma}_i & -\bar{\rho}_i & Q_{Fi} & \bar{X}_i \\ \rho_i & \sigma_i & X_i & Q_{Fi} \end{array}\right)_{FB,PH}, \tag{115}$$

which differs from the chiral orthogonal ensemble by interchanging the bosonic and fermionic sectors (this duality was already described in Ref. 1).

Performing the standard steps of the derivation [similarly to (82)], we arrive at the following answer in the saddle-point approximation:

$$Z_m(\omega_B,\omega_F)=\int_\Gamma DQ\,[\mathrm{SDet}\,Q_1]^m \exp\left[-\frac{\pi}{2}\mathrm{STr}\,\hat{\omega}(Q_1+Q_2)\right] \tag{116}$$

[note the differences from the orthogonal result (101)!].

Finally, the calculation may be performed using the parameterization obtained from that of the previous section by interchanging bosonic and fermionic sectors. Note that under this interchange, the compact variables become noncompact and vice versa. Explicitly, Eqs. (103), (105)–(107) are replaced by

$$Q_{z1} = i\left(\begin{array}{cc|cc} e^{x} & 0 & & \\ 0 & e^{x} & & \\ \hline & & e^{i\phi}\cos\theta & e^{i(\phi+y)}\sin\theta \\ & & -e^{i(\phi-y)}\sin\theta & e^{i\phi}\cos\theta \end{array}\right), \tag{117}$$

$$Q_{z2} = i\left(\begin{array}{cc|cc} e^{-x} & 0 & & \\ 0 & e^{-x} & & \\ \hline & & e^{-i\phi}\cos\theta & -e^{-i(\phi-y)}\sin\theta \\ & & e^{-i(\phi+y)}\sin\theta & e^{-i\phi}\cos\theta \end{array}\right),$$

$$A_1 = \left(\begin{array}{c|cc} & \xi & \lambda \\ \hline & -\bar{\lambda} & -\bar{\xi} \\ & & \end{array}\right), \qquad A_2 = \left(\begin{array}{c|cc} & & \\ \hline & \bar{\xi} & \lambda \\ & \bar{\lambda} & \xi \end{array}\right). \tag{118}$$

$$DQ = \frac{1}{(2\pi)^2} \sin\theta\, e^{2(x-i\phi)}\, dx\, dy\, d\theta\, d\phi\, d\bar{\xi}\, d\xi\, d\bar{\lambda}\, d\lambda. \tag{119}$$

Equation (108) is replaced by

$$\begin{gathered} Q_{\mathrm{BB}} = \tfrac{1}{2}[(Q_1)_{\mathrm{BB}} + (Q_2)_{\mathrm{BB}}] = i[\cosh x + \tfrac{1}{2} e^{i\phi}(\cos\theta[\bar{\xi}\xi + \bar{\lambda}\lambda] + \sin\theta[e^{iy}\bar{\lambda}\xi + e^{-iy}\lambda\bar{\xi}])], \\ Q_{\mathrm{FF}} = \tfrac{1}{2}[(Q_1)_{\mathrm{FF}} + (Q_2)_{\mathrm{FF}}] = i[\cos\phi\cos\theta - \tfrac{1}{2} e^{-x}(\bar{\xi}\xi + \bar{\lambda}\lambda)]. \end{gathered} \tag{120}$$

Taking the integral

$$\rho_m(\omega) = \mathrm{Re} \int DQ\, e^{2m(x-i\phi)}\, Q_{\mathrm{BB}} \exp[-2\pi\omega(Q_{\mathrm{BB}} + Q_{\mathrm{FF}})], \tag{121}$$

we obtain the final result (9). [Note that in (121) we divided the density of states by two to prevent double counting of the doubly degenerate states.]

IX. ZERO LEVELS AND REDUCED SUPERSYMMETRY OF THE ACTION

After presenting the calculations of the average density of states in the five random-matrix ensembles with zero levels, in this section we discuss the specifics of the supersymmetric method due to the zero levels. I do not present here a consistent mathematical analysis of this problem, leaving it for future study. Instead I only summarize the common features of the above calculations specific for the ensembles with zero levels.

The standard supersymmetric procedure to calculate spectral correlation functions in any random-matrix ensemble starts with introducing bosonic and fermionic fields ψ_B and ψ_F.[1,2] Integrating over the Gaussian disorder produces a four-term interaction. This interaction is then decoupled via Hubbard–Stratonovich transformation by a supermatrix Q whose dimension is independent on the matrix size N in the original random-matrix ensemble. Integrating over the superfields (ψ_B, ψ_F), one arrives at an effective action for the supermatrix Q. The supermatrix Q obeys certain linear symmetry relations and thus belongs to a linear superspace L depending on the symmetries of the original random-matrix ensemble. In the superspace L, there acts a supergroup G inherited from the supersymmetry mixing the bosonic and fermionic fields ψ_B and ψ_F. Namely, an element $g \in G$ is a supermatrix acting on Q by conjugation,

$$g: Q \mapsto g Q g^{-1}. \tag{122}$$

The group G then depends on the symmetries of the matrix Q and hence on the symmetry of the random-matrix ensemble.

The effective action $S(Q)$ may, at small energies ω, be expanded to the linear in ω term,

$$S(Q) = S_{\omega=0}(Q) + \omega\, \mathrm{STr}\, \Lambda Q^{-1}, \tag{123}$$

where $\Lambda \in L$ is a particular supermatrix with $\Lambda^2 = 1$.

TABLE II. Supergroups and superspaces involved in the spectral density calculations.

Class	L	G	H	$\Gamma = G/H$	G_0	G/G_0
$B-D$	osp(2|2)	SpO(2|2)	GL(1|1)	SpO(2|2)/GL(1|1)	SpSO(2|2)	Z_2
DIII	osp(4|4)/osp(2|2)$\oplus$osp(2|2)	SpO(2|2)$\times$SpO(2|2)	SpO(2|2)[a]	SpO(2|2)	S[SpO(2|2)$\times$SpO(2|2)][b]	Z_2
AIII	gl(1|1)$\oplus$gl(1|1)	GL(1|1)$\times$GL(1|1)	GL(1|1)[a]	GL(1|1)	S[GL(1|1)$\times$GL(1|1)][b]	GL(1)
BDI	[gl(2|2)/osp(2|2)]$\oplus$[gl(2|2)/osp(2|2)]	GL(2|2)	OSp(2|2)	GL(2|2)/OSp(2|2)	SL(2|2)[c]	GL(1)
CII	[gl(2|2)/osp(2|2)]$\oplus$[gl(2|2)/osp(2|2)]	GL(2|2)	SpO(2|2)	GL(2|2)/SpO(2|2)	$SL_2(2\|2)$[c]	GL(1)

[a] H is diagonal in G: $H=\{(g,g)\}$ in classes DIII and AIII.
[b] S$[H\times H]$ denotes here the subgroup $\{(g_1,g_2)|S\ \mathrm{Det}\ g_1 = S\ \mathrm{Det}\ g_2\}$.
[c] $SL(2|2)=\{g\in GL(2|2)|S\ \mathrm{Det}\ g=1\}$; $SL_2(2|2)=\{g\in GL(2|2)|S\ \mathrm{Det}\ g=\pm 1\}$.

In ensembles without zero eigenvalues, the zero-energy action $S_{\omega=0}(Q)$ is invariant with respect to the supergroup G. The zero-energy action $S_{\omega=0}(N)$ scales linearly with N, and in the large-N limit the integral over Q is determined by the saddle points of $S_{\omega=0}(Q)$. The saddle-point equation, with the appropriate normalization, reads

$$Q^2=-1. \tag{124}$$

This equation is solved by $Q=i\Lambda$, as well as by any matrix obtained from $i\Lambda$ by G-rotations (122). The matrix Λ is invariant under a subgroup $H\subset G$, and the saddle-point manifold Γ is the quotient G/H.

More precisely, Γ is a Riemannian (real) supermanifold in G/H, which makes it a Riemannian symmetric superspace as defined in Ref. 1. This real submanifold should be determined geometrically from deforming the real integration subspace in L while keeping the integral convergent. A good geometric understanding of this contour deformation still needs to be developed, but the rule of thumb for choosing the real integration manifold in Γ is to take the bosonic sector noncompact and the fermionic one compact [this choice also provides a metric of a definite sign on Γ].

For the random-matrix ensembles with zero eigenvalues, the invariance properties of the effective action $S_{\omega=0}(Q)$ are modified. In this case, $S_{\omega=0}(Q)$ is invariant with respect not to the whole supergroup G, but only with respect to its normal subgroup G_0. The subgroup G_0 must contain H, and the factor group G/G_0 is an abelian group (an ordinary group, not a supergroup). The exponent $\exp[S_{\omega=0}(Q)]$ transforms according to one of its (one-dimensional) representations. The degree of this representation equals the number of zero eigenvalues in the random-matrix ensemble.

In the ensembles $B-D$ and DIII, the group G/G_0 is discrete Z_2, and the two representations of Z_2 correspond to the ensembles with and without zero eigenvalues (odd N and even N, respectively). Specifically, the action $S_{\omega=0}(Q)$ has the form,

$$S_{\omega=0}(Q)=NS_0(Q), \tag{125}$$

where $S_0(Q)$ gets incremented by $i\pi$ under the action of the generator of $G/G_0=Z_2$. Hence, $\exp[S_{\omega=0}(Q)]$ transforms according to the even/odd representation of Z_2 for even/odd N.

In the chiral random-matrix ensembles AIII, BDI, and CII, the group G/G_0 is the continuous GL(1), with its representations labeled by the integer ''winding number'' m. The absolute value of m equals the number of zero eigenvalues in the random-matrix ensemble. The action $S_{\omega=0}(Q)$ in the chiral ensembles [which includes the logarithm of the pre-exponent in (87), (101), (116)] is of the form

$$S_{\omega=0}(Q)=NS_0(Q)+mS_1(Q), \tag{126}$$

where $S_0(Q)$ is invariant under G, and $S_1(Q)$ produces phase shifts under $G/G_0=\mathrm{GL}(1)$. The exponent $\exp[S_{\omega=0}(Q)]$ then transforms as the representation of GL(1) of degree m.

The summary of the ''building blocks'' of the supersymmetric calculations in this paper (the calculation of the average spectral density) is presented in Table II. This table is compiled using the results of Ref. 1 and the calculations in the previous sections. The definitions of the supergroups involved in this table may be found in Sec. III. To keep track of the bosonic (noncompact) and fermionic (compact) sectors of the supergroups, we use the notation OSp for the orthosymplectic supergroup with the orthogonal part in the bosonic, and the symplectic part in the fermionic sectors. In the opposite case of orthogonal fermionic and symplectic bosonic sector, we denote the same supergroup SpO. It is important for reducing the action symmetry in ensembles $B-D$ and DIII, that $\mathrm{SpO}(2n|2n)$ has two disconnected components with superdeterminants 1 and -1 [the former of them denoted as $\mathrm{SpSO}(2n|2n)$]. Incidentally, in the ensembles C and CI, dual to $B-D$ and DIII by interchanging fermionic and bosonic sectors, in the supergroup $\mathrm{OSp}(2n|2n)$, with the non-compact orthogonal sector, the second component (with $S\,\mathrm{Det}=-1$) plays no role and should be disregarded as it always corresponds to a divergent integral. The supergroup $\mathrm{GL}(n|n)$ is not

simple either. First, it has a one-dimensional center consisting of scalar matrices. Second, it has a normal subgroup $\mathrm{SL}(n|n)$ consisting of matrices with unit superdeterminant. This latter reduction of the supergroup $\mathrm{GL}(n|n)$ is crucial for the symmetry classification in the case of the chiral ensembles (the last three lines in Table II).

Finally, it is worth mentioning that the conclusion about the reduced supersymmetry of the zero-energy effective action $S_{\omega=0}(Q)$ may be extended to higher-order correlation functions involving averaging several Green's functions (the average spectral density requires averaging only one Green's function). In Ref. 1 a general procedure of calculating correlation functions of arbitrary order (with the number of zero levels $m=0$) was described, and the saddle-point manifold (a Riemannian symmetric superspace) Γ was found to be always reducible for ensembles admitting zero levels. Thus the extension of the calculation of the present paper to higher-order correlations is straightforward (however, explicit parameterization and integral evaluation immediately becomes much more complicated).

(Received 26 March 2001; accepted for publication 8 October 2001)

In this article we study the construction of supersymmetric spin networks, which has a direct interpretation in context of the representation theory of the superalgebra. In particular we analyze a special kind of spin network associated with superalgebra $\mathrm{Osp}(1|2n)$. It turns out that the set of corresponding spin network states forms an orthogonal basis of the Hilbert space $\mathcal{L}^2(\mathcal{A}/\mathcal{G})$, and this argument holds even in the q-deformed case. The $\mathrm{Osp}(n|2)$ spin networks are also discussed briefly. We expect they could provide useful techniques to quantum supergravity and gauge field theories from the point of nonperturbative view. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421423]

I. INTRODUCTION

The notion of spin networks originally was advocated by Roger Penrose in the 1970s when he tried to give a quantum mechanical description of the geometry of space.[1] In his opinion, the final version of quantum geometry should be a combinatorial theory in which we consider the different combinations and permutations of objects such that we could derive the discrete spectra of observables in the quantum mechanical level. After that the idea of spin networks was introduced to many areas, including lattice gauge theory[2] and topological field theory.[3] In the middle of the 1990s, the spin networks were introduced in loop quantum gravity in a quite different way.[4,5] It was exploited to construct the Hilbert space of kinematical quantum states and consequently the discrete spectra of the area and volume of the space were obtained.[6] Later the dynamics of the spin networks were also considered and its evolution gives rise to a casual set of spin networks[7] or spin foams.[8]

It is evident to see the importance of spin networks if we list some basic features they contain. First spin networks are a very general notion in quantum field theory in which gauge fields are involved. In particular, they are gauge invariant objects, in the sense that the corresponding spin network states will be solutions to the Gauss constraint naturally if we take the standard Dirac procedures to quantize the theory. As a result, it would be much easier to find the physically related subspace in Hilbert space. In path integral formulation, we can consider the functional integration on the modular space since a well-defined measure theory can be established in context of spin networks. In loop quantum gravity, they are background independent and nonperturbative objects as well.

Until now we mainly focus on SU(2) spin networks since it has important application to quantum general relativity.[6,8,9] However, in principle we could construct the spin networks associated to other groups or supergroups. More importantly, we have a belief that they could be applied to quantum supergravity and gauge theories as well. Based on this motivation, the supersymmetric spin networks first were introduced in Ref. 10 and then developed in Ref. 11. In Ref. 10 by virtue of supersymmetric spin networks, we carry out a nonperturbative quantization of simple supergravity. In particular, we find the spectrum of area operator taking a discrete form,

a)Electronic mail: ling@phys.psu.edu

$$\hat{A}|\Gamma^{sg},e_i,v_j\rangle=\sum_i l_p^2\sqrt{j_i\left(j_i+\frac{1}{2}\right)}|\Gamma^{sg},e_i,v_j\rangle, \tag{1}$$

where l_p is the Planck length and $j_i=e_i/2$.

In this article we develop the construction of supersymmetric spin networks. After giving an overview on some general features of spin networks in Sec. II, we study a special kind of super spin network which has superalgebras $\mathrm{Osp}(1|2n)$ in the consequent section, and $\mathrm{Osp}(N|2)$ spin networks are also discussed briefly in Sec. IV. In Sec. V we discuss some possible applications of super spin networks.

II. AN OVERVIEW

A spin network is a graph, $\Gamma(e_i,v_j)$, embedded in a three dimensional manifold M. It is composed of edges (or links) and vertices (either nodes or joints). To each edge, we assign the color, e_i, which is related to the labels of the irreducible representation of groups, and to each vertex we assign an intertwiner operator, v_j, which maps the incoming irreducible representations to the outcoming ones at the vertex. We adopt the convention that the vertex is called a k-valent one if there are k edges meeting at this vertex.

The construction of spin networks has a direct interpretation in representation theory of groups. In spin networks, each edge e labeled by the representation could be understood as a parallel propagator or holonomy of the connection A, $U_e(A)$, along the edge in connection representation. In matrix notation of group theory, it also corresponds to the higher dimensional irreducible representation of the group element. In SU(2) spin networks, we also think of the edge as the combination of many *ropes*, each of which corresponds to the fundamental representation of the group. Therefore, the reason that each edge can be decomposed into many ropes stems from the fact that every higher dimensional irreducible representation of the group can be obtained by employing the symmetrization or antisymmetrization procedures from the fundamental representations. It is this fact that we can decompose the spin network into multi-loop graphs by permuting and connecting all the ropes to form loops, and finally we are able to establish the transformation between spin network states and loop states in the corresponding Hilbert space.

Intertwiner operators associated with every vertex in spin network can be understood as the different ways that we could carry out to connect the ropes when edges meet at the same vertex. Correspondingly, in the language of representation theory of groups, it corresponds to the fact that tensor products of several irreducible representations can be completely decomposed into the direct sum of the irreducible representations. Hence, they are invariant tensors in irreducible representations of groups and given by standard Clebsch–Gordan (CG) theory. In the case of SU(2) spin networks, when the vertex is a tri-valent one, the decomposition of the tensor product is unique. If the edges are more than three, we then can divide the multi-valent vertex into the tri-valent vertices by making use of the intertwiner operator. At the same time, restricted by the expansion of Clebsch–Gordan series, the colors associated with edges which meet at the same vertex must satisfy some conditions consistent with these CG series. We call them admissible conditions. For instance, consider three valences with colors (a,b,c) meet at the same vertex in ordinary SU(2) spin networks. Then they have to satisfy the triangle inequality and the sum of them has to be even numbers; however, in the case of $\mathrm{Osp}(1|2)$, then the sum can be any positive integer.

Associated with each spin network, we can obtain one number by taking the trace of the corresponding matrix product of the propagators along edges in representation space, which is called the evaluation of spin networks. It has very important applications to quantum gravity. In particular, when we consider the action of operators such as area and volume observables on the spin network states, it provides us a practical way to work out the spectra of these observables. In cases of SU(2) and $\mathrm{Osp}(1|2)$, the evaluations of spin networks, in particular the theta graphs, are discussed respectively in Refs. 12 and 10, where $6j$ symbols and recoupling theories play important roles.

Based on the spin network $\Gamma(e_i, v_j)$, we can define a spin network state, $\Phi_{f_\Gamma}(A)$, by means of the cylindrical function with the form

$$\Phi_{f_\Gamma}(A) := f_\Gamma(U_{e_1}(A), \ldots, U_{e_n}(A)), \tag{2}$$

where cylindrical function f_Γ refers to taking the holonomy along each edge and then contracting the holonomy matrix with the intertwiners at each vertex where edges meet. Spin network states have more advantages than loop states since they are linear independent and do form a basis of the Hilbert space, rather than loop states the space of which is over completed and contains some identities. To show the spin network states form a basis in the Hilbert space, we need solve two key problems. One is the definition of inner product of the spin network state, consequently we can show any two different spin network states are orthogonal and linear independent; the other one is the completeness of the spin network states, namely any state in Hilbert space can be expressed in terms of spin network states. In the case of SU(2), these two problems are solved successfully mainly by virtue of the Haar measure and Peter–Weyl theorem in group theory, respectively.[4–6] As a result, SU(2) spin networks play a key role to form a linear independent basis of the Hilbert space in loop quantum gravity.

When we try to extend the notion of spin networks to the supersymmetric case, we need to construct the graphs and find the rules which must be completely consistent with the representation theory of superalgebras. Following constructions of SU(2) and Osp$(1|2)$ spin networks,[4,10] which has been recalled above, let us list some basic procedures that we have to take into account in this article.

(i) The definition of supersymmetric spin networks. At the first sight, it is simple to define the supersymmetric spin networks. We only need to change the representations associated to edges to the corresponding representations of the supergroups and label the vertex by intertwiner operator appropriately. But after that, to make the spin network well defined, we need to consider the following related questions.

(ii) What are the admissible conditions associated with the tri-valent vertex? Or, equivalently, can any tensor product of the irreducible representations be decomposed into the direct sum of the irreducible representations? Due to the features of superalgebras on their own, we will face some troubles at once, because, unlike the Lie algebra, *the tensor products of many kinds of superalgebras are not completely reducible into the irreducible ones*. We could see this trouble elsewhere when we construct the Osp$(2|2)$ spin networks.[11]

(iii) Could we find a way to evaluate the graphs such that we could consider the action of the operators on the corresponding spin network states and then calculate the spectra of the operators? More explicitly, can every edge be decomposed into ropes, as we do in the case of SU(2)? Namely, can any irreducible representation of the supergroups be constructed from the fundamental representation? We will also see only some special sorts of superalgebras have such features. Furthermore, is it possible to carry out a graphic representation of computing the enclosure of edges?

(iv) Does the set of the corresponding spin network states form a basis for the Hilbert space? To show this, first we need to show that any different spin network states are orthogonal and linear independent, and, second, any states in the space can be decomposed into the sum of the spin network states.

To answer these questions, in this article we extend the strategy in SU(2) spin networks to a special kind of supersymmetric spin network which is equipped with superalgebra Osp$(1|2n)$. The analysis of this special one will lead to some general comments on the construction of supersymmetric spin networks with other superalgbras.

But, before we do that, let us recall some basic facts related to superalgebras in the last part of this section. Superalgebras and supergroups were proposed in physics to construct the supersymmetric model in which bosons and fermions are placed in the same supermultiplet and they could change into each other under the supersymmetric transformation. In fact, every superalgebra

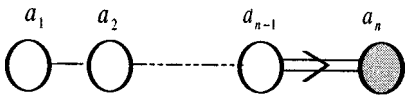

FIG. 1. Dynkin diagram of Osp$(1|2n)$.

or graded algebra contains two kinds of generators. One is even, which is the bosonic part, and the other is odd corresponding to the fermionic part. Contrasting to the ordinary algebras, the even generators of the superalgebra are associated with the *anti*commuting parameters while the odd ones are associated with the *anti*commuting parameters. A special kind of superalgebra is a classical simple Lie superalgebra, whose odd part is completely reducible into one or two irreducible subspaces. Its classification and representation are given in the fundamental paper by Kac.[13] Furthermore, if classical superalgebras admit a nondegenerate metric tensor, they are called basic superalgebras, which is the closest one to simple Lie algebra. All irreducible representations of basic superalgebras are obtainable from a highest weight and the Schur lemma holds under the usual way. However, unlike the ordinary Lie algebras, normally superalgebras have two kinds of representations. One is typical, and the other one is atypical. The typical representations are irreducible and more like the ordinary representations of the Lie algebra, however the atypical ones are in many respects degenerate. In particular, the atypical representations may not be *completely* reducible, for example, if they occur as the semidirect sums of several irreducible atypical representations.

Many kinds of Lie superalgebras do not have properties similar to those of Lie algebras. For example, the complete reducibility is not valid for all the simple Lie superalgebras any more, even for basic ones. Finite reducible but indecomposable representations may appear if we consider the tensor products of irreducible representations. However, the representations of Osp$(1|2n)$ have all the nice properties of those of semisimple Lie algebras. For example, all its reducible representations are fully reducible and therefore a generalized Wigner–Eckhart theorem holds.

The Lie supergroups are obtained by exponentiating Lie superalgebras. Particularly for supergroups SU$(N|M)$ and Osp$(N|2M)$, it is known that all the representations constructable can be obtained from the direct product of fundamental representations.

III. Osp$(1|2n)$ SPIN NETWORKS

A. Definition

First let us concentrate on a special kind of spin network with superalgebra Osp$(1|2n)$ $=B(0,n)$,[14] which is a subset of the orthosympletic Lie superalgebras Osp$(M|2n)$.[15] Its even part is $O(1)\otimes Sp(2n)$ and the Dynkin diagram is shown in Fig.1.

The finite dimensional irreducible representation is characterized by its highest weight Λ $=(a_1,a_2,\ldots,a_n)$, which takes the form

$$\Lambda=a_1\omega_1+a_2\omega_2+\cdots+a_n\omega_n, \tag{3}$$

where $\omega_i(i=1,\ldots,n)$ is the fundamental weight and the coordinate $a_i(i=1,\ldots,n)$ has to be nonnegative integer. The Sp$(2n)$ representation contained in the representation can be read out from the diagram directly by replacing the odd root a_n by $b_n=\frac{1}{2}a_n$. Correspondingly, the edge in Osp$(1|2n)$ spin networks is labeled by e_i, which is defined as a partition of $(a_1,\ldots,a_n)$. In the language of spin networks we also call the weight coordinates colors of the edge. In the simplest case of $n=1$, we see the representation of superalgebra is labeled by only one integer $e_1=2j_1$, and the corresponding spin networks are discussed in detail in Ref. 10.

B. Elements: Edges and vertices

As we mentioned earlier, in general there are two kinds of representations of the superalgebra. One is typical, and the other one is atypical. However, superalgebra Osp$(1|2n)$ has a remarkable

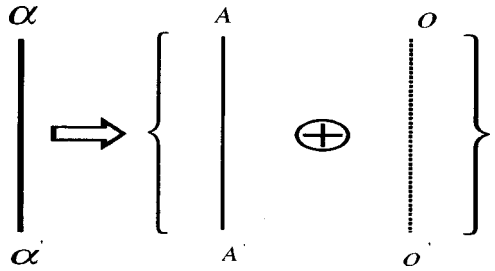

FIG. 2. Composition of unit element with color $(1,0,\ldots,0)$.

feature. It has only typical representation. The fundamental representation is labeled by weight coordinates $(1,0,\ldots,0)$, and the basis vector of the representation is $2n+1$ dimensional and contains one boson and $2n$ fermions,

$$\xi_\alpha = \begin{pmatrix} \psi_A \\ \phi_o \end{pmatrix}, \tag{4}$$

where ψ_A is the fermionic part of the representation and $A=(1,\ldots,2n)$ is the spinor index of $\mathrm{Sp}(2n)$, while ϕ_o is the bosonic part which is only one dimensional. Then the unit element in the fundamental representation can be illustrated as in Fig. 2, in which we denote the $\mathrm{Sp}(2n)$ element by the thin line and the single bosonic part by the dotted line.

The higher finite dimensional representations of the superalgebra can be obtained by symmetrizing and antisymmetrizing the fundamental representations.[16] Note that in the simplest case of $n=1$, we only need to take the symmetrization procedures since the anti-symmetrization of two spinor indices will be identical to the trivial representation. In context of Young tableaus, we have only one row of boxes. However, for $n\geqslant 2$, we need to take both symmetrization and antisymmetrization procedures to obtain all the finite dimensional irreducible representations. For instance, we consider the tensor products of two fundamental representations. We can symmetrize two basis vectors, which is defined as[17]

$$\xi_{(\alpha\beta)} = \xi^1_\alpha \xi^2_\beta + (-)^{g(\alpha)\cdot g(\beta)} \xi^1_\beta \xi^2_\alpha . \tag{5}$$

Also we can antisymmetrize them as

$$\xi_{(\alpha\beta)} = \xi^1_\alpha \xi^2_\beta - (-)^{g(\alpha)\cdot g(\beta)} \xi^1_\beta \xi^2_\alpha , \tag{6}$$

where $g(\alpha)$ is the grade of the index. For fermionic indices, it is one and for bosonic it is zero. If we denote the symmetrization by the square box in the graph, and antisymmetrization by a circle labeled by the number of ropes under consideration, then the unit elements of the supergroup under these representations are illustrated in Fig. 3.

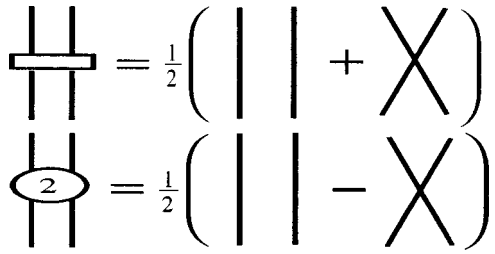

FIG. 3. Symmetrization and antisymmetrization of fundamental representation.

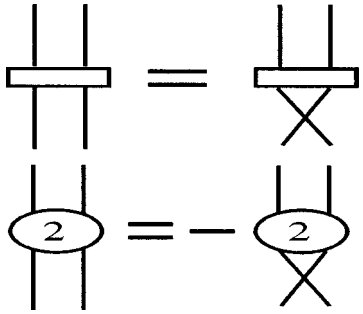

FIG. 4. Property I.

Their weight coordinates are (2,0,...,0) and (0,1,0,...,0), respectively. We also call the unit element symmetrizer in which ropes are symmetrized and antisymmetrizer in which ropes are antisymmetrized. Unlike the symmetrization, we can derive the following properties of the antisymmetrization in graphic representations (see Figs. 4–6).

These properties are easily proved by using the definition of symmetrizers and antisymmetrizers shown in (3). For instance in Fig. 5, when two lines are both symmetrized and antisymmetrized at the same time, then obviously they vanish.

Also, when one graph involves both boxes and circles, we find the order is also important now. For instance, the graphs shown in Fig. 7 are not equivalent.

Continuously taking the antisymmetrization procedures on fundamental representations, we will find it has to be terminated as far as more than $2n$ fundamental representations are involved, since with antisymmetrizing the same index vanishes. To simplify the notation, we only show one line but label the number of ropes which are antisymmetrized in the circle. We draw it as in Fig. 8.

To construct the graphical representation for any highest weight irreducible representation, we need make use of the Young supertableaux. For $\mathrm{Osp}(1|2n)$, the construction of Young supertableaux is simple since it has the same shape as the usual Young tableaus of $\mathrm{Sp}(2n)$ representation $(a_1,a_2,\ldots,a_{n-1},1/2\,a_n)$. The Young tableau associated to $\mathrm{Sp}(2n)$ representation $(a_1,a_2,\ldots,a_{n-1},1/2a_n)$ is defined as a graph with λ_i boxes in the ith row where λ_i is related to the Dynkin labels by

$$\lambda_i=a_i+\lambda_{j+1},\quad \lambda_n=\tfrac{1}{2}a_n, \tag{7}$$

which satisfies $\lambda_1\geqslant\lambda_2\geqslant\cdots\geqslant\lambda_n\geqslant 0$.

Replacing each box in the Young supertableaux by a vertical straight rope and putting them in parallel from left to right, then we define a decomposition of the edge by symmetrizing or antisymmetrizing them corresponding to their positions in Young supertableaux. As a result, if an irreducible representation is obtained by taking both symmetrization and antisymmetrization pro-

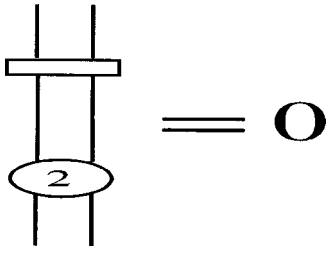

FIG. 5. Property II.

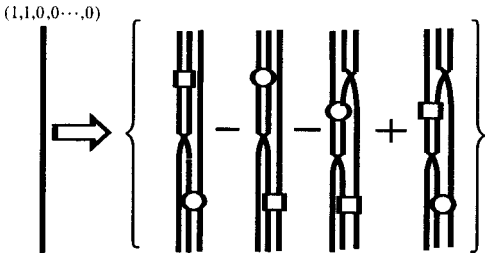

FIG. 9. The graphic representation of $(1,1,0,\ldots,0)$.

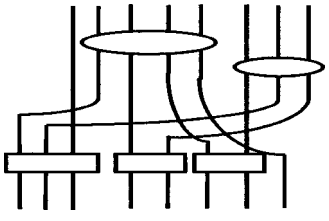

FIG. 10. The rope components of general edges.

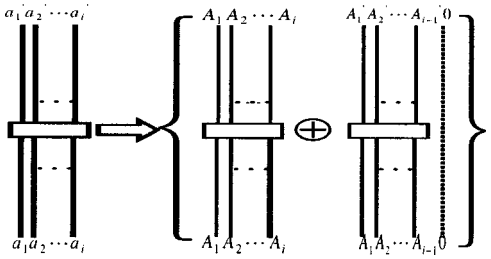

FIG. 11. The rope components of general edges.

cedures, we find there are several inequivalent graphic representations. For example, the representation $(1,1,0,0,\ldots,0)$ could be realized by graphs illustrated in Fig. 9.

In conclusion, we find the edge in spin networks can be decomposed into some components which are the combination of some symmetrized or antisymmetrized ropes. An example of the decomposition is shown in Fig. 10.

Next we consider the vertex and intertwiners in spin networks. In the context of representation theory, it is equivalent to considering the tensor product of irreducible representations. We note that the only Lie superalgebras for which all finite dimensional representations are completely reducible are the direct products of $\mathrm{Osp}(1|2n)$ superalgebras and semi-simple Lie algebras (Djoković–Hochschild theorem[18]). In the context of spin networks, we will have no trouble connecting the edges together at the same vertex. We only need to find out the appropriate admissible conditions and label the vertex by the correct intertwiners, which corresponds to finding the Clebsch–Gordan series for the tensor products of the irreducible representations. To be able to do that, the possible way is to decompose the edge into the direct sum of ones in ordinary $\mathrm{Sp}(2n)$ spin networks since the tensor product of two $\mathrm{Sp}(2n)$ representations is discussed and the CG coefficients are computable.[19] Next, let us go back to consider the decomposition of super edges into the ordinary $\mathrm{Sp}(2n)$ edges. In the case that only symmetrizations are involved, the edge will decomposed into two components, which is illustrated in Fig. 11.

However, if both symmetrization and antisymmetrizations are involved, then we would find the terms will be more than two, and the specific calculation is possible to carry out. Normally we have the following strategy to obtain all the terms in ordinary $\mathrm{Sp}(2n)$ spin networks. The first term in $\mathrm{Sp}(2n)$ spin networks has the same shape as the super one. Then we divide the ropes into symmetrized groups in which each rope is symmetrized with one another. Then we pick out *at most* one rope from each symmetrized group in turn and replace them by the dotted lines such that we will get all the graphs in terms of the ordinary $\mathrm{Sp}(2n)$ spin networks. Finally, we still need to read off any graph which contains at least two dotted but *antisymmetrized* lines since it vanishes. Among all the graphs remaining, we also have to identify some equivalent graphs and maybe it is a little complicated work. However, in context of Young supertableaux, the procedure is simple. We find the supertableaux of $\mathrm{Osp}(1|2n)$ can be decompsed into the direct sum of ordinary tableaux by removing at most one box from each row. So maybe another practical way is to do the

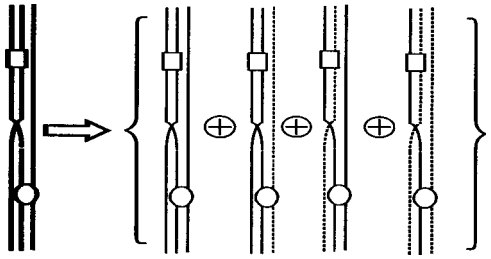

FIG. 12. Decomposition of super spin network into ordinary $\mathrm{Sp}(2n)$ ones.

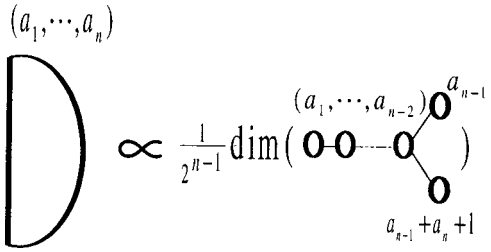

FIG. 13. Closure of the edges.

decomposition in the context of Young tableaux and then transform the Young diagram into edges of the spin networks. For example, the super one $(1,1,0,\ldots,0)$ can be decomposed into four $\mathrm{Sp}(2n)$ terms as shown in Fig. 12.

Then the tensor product of two edges in super spin networks will correspondingly be decomposed to the direct sum of the tensor products of edges in $\mathrm{Sp}(2n)$ spin networks.

C. Evaluation

In this article we have not carried out a specific calculation for the evaluation of $\mathrm{Osp}(1|2n)$ spin networks yet. However, based on the following analysis, we would like to claim that it is definitely possible to do so due to the features of the $\mathrm{Osp}(1|2n)$ superalgebra. Basically we have two ways to evaluate such super spin networks. One way is to decompose the super one into the ordinary $\mathrm{Sp}(2n)$ spin networks, as we argued above; the other way is given as follows. Reference 20 shows that there is a one-to-one correspondence between the graded representation of $\mathrm{Osp}(1|2n)$ and the nonspinorial representations of $\mathrm{O}(2n+1)$. First, if a graded irreducible representation of $\mathrm{Osp}(1|2n)$ and a nonspinorial irreducible representation of $\mathrm{O}(2n+1)$ have the same highest weight, one has

$$\dim(\rho^{\mathrm{osp}(1|2n)}(a_1,\ldots,a_n))=\dim(\rho'^{\mathrm{O}(2n+1)}(a_1,\ldots,a_n)). \tag{8}$$

Moreover, the multiplicity of any weight is the same for both representations. As a direct application of the argument, consider the tensor products of both irreducible representations having the same highest weights. Then we can see the Clebsch–Gordan (CG) series coincide; in particular, since the tensor products are completely reducible, their CG series can be obtained by counting the multiplicities of their weights.

So far, the one-to-one correspondence also gives us an alternative practical way to evaluate the $\mathrm{Osp}(1|2n)$ spin networks by studying the $\mathrm{O}(2n+1)$ spin networks, which should be easy to carry out at first.

In the last part of this section, we conjecture some examples that could be worked out in the future. One is the closure of any edge, namely, the supertrace of the unit element of supergroup $\mathrm{Osp}(1|2n)$ in such finite irreducible representation. Note that the supertrace of supergroups is defined as

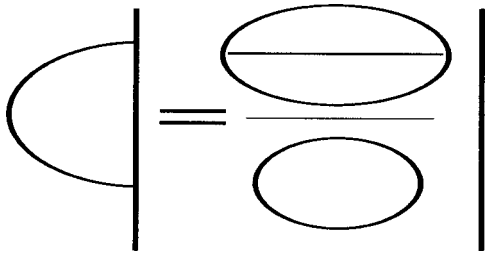

FIG. 14. Identity.

$$\mathrm{Str}(U^{\alpha}_{\beta}) := \mathrm{Tr}(A) - \mathrm{Tr}(D), \tag{9}$$

where we suppose the matrix representation of the supergroup has a structure

$$U = \begin{pmatrix} A & B \\ C & D \end{pmatrix}. \tag{10}$$

This can be done by calculating the dimensions of the Lie algebra $\mathrm{O}(2n+1)$ shown in Fig. 13.

We find the closure of the edge is a nonzero number. Thus we could expect the identity drawn in Fig. 14 to be evident.

They would also be applied to the nonperturbative quantization of eleven dimensional supergravity when we consider the actions of the operators. For instance, we may consider the quadratic Casimir operators and their eigenvalues. In loop quantum gravity, this kind of operator is related to the area observable:

$$C_k(\Lambda) = \frac{1}{4n+2}(\Lambda|\Lambda + 2\rho), \tag{11}$$

where $(|)$ is defined as the inner product of the weights and ρ is defined as

$$\rho = \omega_1 + \omega_2 + \cdots + \omega_n . \tag{12}$$

The supertrace not being zero has more important meaning when we define super spin network states and form the Hilbert space. This good feature will allow us to define generalized ''Ashtekar–Lewandowski'' (AL) measure on the space, moreover, to show the spin network states form a basis of the space.

D. Hilbert space

In this section we begin with the integration theory on the supergroup manifold, and then apply it to spin network states.

Given a manifold M, we define a Lie superalgebra $\mathrm{Osp}(1|2n)$ valued connection one-form A. For instance, in eleven dimensional space–time, we can define the $\mathrm{Osp}(1|32)$ connection as follows,

$$A =: A_{\mu}(x)dx^{\mu} = A^{a}_{\mu}(x)P_a dx^{\mu} + A^{ab}_{\mu}(x)J_{ab}dx^{\mu} + A^{a_1\cdots a_5}_{\mu}(x)Z_{a_1\cdots a_5}dx^{\mu} + \Psi^{\alpha}_{\mu}(x)Q_{\alpha}dx^{\mu}, \tag{13}$$

where $x=(x_0,\ldots,x_{10})$ are local coordinates on M, μ is the space–time index and a,b are internal indices. α is spinor index. $P_a, J_{ab}, Z_{a_1\cdots a_5}$, and Q_{α} are $\mathrm{Osp}(1|2n)$ generators while J_{ab} and $Z_{a_1\cdots a_5}$ are skew symmetric. In (13) we can think of all the components of connection A as the smooth function on the manifold M. Let us denote the space of smooth connections on M as $\mathcal{A}$. Then we define the space of continuous functionals on $\mathcal{A}$ as $\mathrm{Fun}(\mathcal{A})$. Now based on the linear vector space, we want to define a Hilbert space, $\mathcal{L}^2(\mathcal{A})$. Namely, we need introduce some inner product of the quantum states which is the element in $\mathrm{Fun}(\mathcal{A})$, and then consider the completion of $\mathrm{Fun}(\mathcal{A})$. In loop quantum gravity, we carry out all the procedures by introducing a special kind of function of the connection, which is called a cylindrical function. They are defined as the functions of holonomies of the connection. Therefore they are functions of group manifold as well. Then the inner products can be defined by means of taking the integration on the group manifold; as we know, a unique, both left- and right-invariant measure can be defined on it.

Now we extend all the construction mentioned earlier to the supersymmetric case of $\mathrm{Osp}(1|2n)$. First, note the super loop variables can be defined by means of the holonomy of super connections $\mathcal{A}$. For details we refer to Ref. 21:

$$U[\mathcal{A},\gamma](s) := \mathcal{P}\exp\int_{\gamma} ds\,\gamma^{\mu}A_{\mu}(\gamma(s)). \tag{14}$$

Note that U is an element of supergroup $\mathrm{Osp}(1|2n)$. The loop states can be defined as

$$\Psi_{\gamma}(A) := \mathrm{Str}U[A,\gamma], \tag{15}$$

where γ is a loop in the space–time manifold with $\gamma(0)=\gamma(1)$. Though the holonomy is not gauge invariant, their supertrace is gauge invariant indeed.

It is well known that there is a probability measure, the Haar measure, for the compact Lie groups such that we could define a unique normalized both left- and right-invariant integration, namely,

$$\int_G dg = 1, \quad \int dg f(g) = \int dg f(g_0 g g_1) = \int dg f(g^{-1}), \tag{16}$$

where g_0, g_1 are any group elements and $f(g)$ is also an arbitrary function of g. The generalization of the Haar integral for Lie supergroups was discussed in Ref. 22. We refer to that paper for more details on the integration theory on supermanifold. Here we point out that in particular case of $\mathrm{Osp}(1|2n)$, we can also define a generalized Haar measure on the space of functions on the supergroup which are both left- and right-invariant.[23] Therefore it is possible to develop a positive integration theory on the space of connection, $\mathcal{A}$. Here we define the generalized Haar measure on supergroup $\mathrm{Osp}(1|2n)$ as

$$\int_G dg = 1, \quad \int_G g^{(\rho)}_{\alpha\beta} dg = 0, \ \ \rho \neq 0. \tag{17}$$

Next we consider the definition of inner product of spin network states. Associate to every spin network, we can define a corresponding spin network state in the Hilbert space. To show that the set of spin network states does form a basis for the state space in the case of $\mathrm{Osp}(1|2n)$, we carry out the following procedures. In spin networks we know a connection is simply to assign a group element, U_e, to each edge of the graph e by taking the holonomy of the connection A in the irreducible representation ρ_e along the edge. Hence, the space of connections in context of spin networks is

$$\mathcal{A} \cong \bigotimes_{e_i} G^{e_i}, \tag{18}$$

which is the finite product of group G and the measure is defined as

$$\mathcal{D}\mathcal{A} = \bigotimes_{e_i} dU_{e_i}. \tag{19}$$

We call this measure the generalized Ashtekar–Lewandowski measure. Now we could define the inner product of two spin network states by means of cylindrical functions.

Consider a spin network $\Gamma(e_i, v_j)$. We define the cylindrical functions, Φ_{f_Γ}, which only depend on the holonomies of the connection A. Using the generalized Haar measure on $[G]^n$, we then define the scalar product of two cylindrical functions as

$$\langle \Phi_{f_\Gamma} | \Phi_{g_\Gamma} \rangle := \int_{G^n} dU_1 \cdots dU_i \ \overline{f_\Gamma(U_1,\ldots,U_i)} g_\Gamma(U_1,\ldots,U_i). \tag{20}$$

The Hilbert space on which ρ_l is defined can be denoted as $\mathcal{H}_{\rho_l}$. Hence the total Hilbert space associated to the spin networks can be defined as the tensor product of these spaces,

$$\mathcal{H}=\bigotimes_{v_j}\mathcal{H}^{v_j}=\bigotimes_{v_j}\Big(\bigotimes_{e_i}\mathcal{H}_{e_i}\Big)^{v_j}, \tag{21}$$

where e_i are edges meeting at the same vertex v_j. In the case of Osp$(1|2n)$, since any products of finite dimensional irreducible representations are completely reducible, namely,

$$\rho_1\otimes\ldots\otimes\rho_i=\bigoplus_j v^j\rho_j, \tag{22}$$

correspondingly we find the tensor products of the Hilbert spaces can be decomposed into the direct sum of Hilbert spaces on which the irreducible representations of Osp$(1|2n)$ are defined,

$$\mathcal{H}_{e_1}\otimes\ldots\otimes\mathcal{H}_{e_i}=\bigoplus_{\rho_j}K^j\mathcal{H}_{\rho_j}. \tag{23}$$

Furthermore, we can decompose the Hilbert space as the direct sum of the functions on all the irreducible representations and its conjugate:

$$\mathcal{L}^2(\mathcal{A}/\mathcal{G})=\bigoplus_j V_j\otimes V_j^*. \tag{24}$$

Next, to show that the spin network states are orthogonal and linear independent, we exploit the generalized Peter–Weyl theorem:

Theorem: Let ρ be the irreducible representation of Osp$(1|2n)$ with the highest weights ρ^i, and let $U^{\rho}_{\alpha\beta}$, $\alpha,\beta=1,2,\ldots,d_i(d_i=dim\rho^i)$, be the matrix element of ρ^i, Then:

$$\mathrm{Fun}(A)=\bigoplus_i\bigoplus_{\alpha,\beta=1}^{d_i}U^i_{\alpha\beta}, \tag{25}$$

$$\int U^i_{\alpha\beta}\tilde{U}^j_{\gamma\sigma}(-1)^{\beta\gamma+\alpha+\beta}=\delta_{\alpha\gamma}\delta_{ij}\frac{U^i_{\sigma\beta}}{S\dim(i)}, \tag{26}$$

$$\int U^i_{\alpha\beta}\tilde{U}^j_{\gamma\sigma}(-1)^{\beta\gamma}=\delta_{\beta\sigma}\delta_{ij}\frac{U^i_{\alpha\gamma}}{S\dim(i)}. \tag{27}$$

From the formula above, we note that the nonzero supertrace plays an important role. However, for the supergroups whose supertrace vanishes, then we would maybe have some trouble finding the generalized Peter–Weyl theorem.

Now making use of Eqs. (26) and (27) in the generalized Peter–Weyl theorem, and following the procedures in Ref. 4, it is straightforward to show the Osp$(1|2n)$ spin states are orthogonal,

$$\langle\Gamma,e^i,v_j|\Gamma',e^{i'},v_{j'}\rangle=\delta_{\Gamma\Gamma'}\delta_{ii'}\delta_{jj'}. \tag{28}$$

At the same time, using the equation (25) we can show the set of spin network states is completed such that any state in the Hilbert space can be expressed as the sum of the Osp$(1|2n)$ spin network states,

$$|\Phi\rangle=\sum_i C_i|\Gamma_i\rangle. \tag{29}$$

Therefore, the spin network states do form a basis for the Hilbert space $\mathcal{L}^2(\mathcal{A}/\mathcal{G})$.

Finally, we point out that in the case of quantum deformed superalgebra, we could also construct the q-deformed spin networks and the corresponding spin network states, which will have important application when we study the casual evolution of the spin networks and super-

symmetric spin foams. In the q-deformed case, the ordinary sum of two superspins J_1+J_2 cannot give a third superspin any more when q is not equal to one. The notion of coproduct has to be introduced. The generalized Peter–Weyl theorem for $U_q(\mathrm{osp}(1|2n))$ is given in Ref. 24.

In the class of $\mathrm{Osp}(1|2n)$ spin networks, we are particularly interested in the case of $n=16$, namely $\mathrm{Osp}(1|32)$, since this superalgebra is related to the eleven dimensional supergravity[25–27] and M theory.[28] As we know, in eleven dimensional supergravity, the super-Poincare algebras with two- and five-form central charges are obtained by taking an Inonu–Wigner contraction of $\mathrm{Osp}(1|32)$. This superalgebra has many facets in different dimensions, which are studied in Ref. 29. As a result, we expect the $\mathrm{Osp}(1|32)$ spin networks will have its own advantages when we try to carry out a background independent and nonperturbative quantization of the eleven dimensional supergravity and M theory.

IV. Osp($N|2$) SPIN NETWORKS

In previous section we have described $\mathrm{Osp}(1|2n)$ spin networks following the proposal we gave in overview. In this section we will discuss $\mathrm{Osp}(N|2)$ spin networks briefly. We are interested in this kind of spin network because it is related to the chiral supergravities.[30] But in this class the case of $N=2$ is different from the others since the even part of this superalgebra is $\mathrm{SO}(2)\times\mathrm{Sp}(2)$ such that the first number a_1 of Dynkin labels can be any complex number; however, for the others it has to be a non-negative integer. Its construction and application to supergravity are studies in Refs. 11 and 31. Here we consider the general case when N is larger than two.

The basis vectors of the fundamental representation of $\mathrm{Osp}(N|2)$ span a $N+2$ dimensional vector space. Similar to the case of $\mathrm{Osp}(1|2n)$, its higher finite dimensional irreducible representations can be obtained by standard symmetrization and antisymmetrization procedures on fundamental representation. Therefore, in the context of spin networks, we can decompose the edge into ropes.

In fact, any representation of basic Lie superalgebra can be decomposed into the direct sum of irreducible representations of the even subalgebra, which means any edge in super spin networks can be decomposed into the sum of normal edges which are labeled by the irreducible representations of the even subalgebra. In the case of $\mathrm{Osp}(N|2)$, we can decompose the $\mathrm{Osp}(N|2)$ spin networks into the direct sum of the ordinary spin networks with $\mathrm{SO}(N)\otimes\mathrm{Sp}(2)$. In particular, if only the symmetrization procedures are considered, we have simple decompositions. Figure 15 illustrates the basic one which has the color $(2,0,\ldots,0)$.

Since the $\mathrm{SO}(N)$ indices are antisymmetrized, the decomposition of the graphs terminate at the term which contains N dotted lines (see Fig. 16).

However, unlike the case of $\mathrm{Osp}(1|2n)$, some questions arise in the $\mathrm{Osp}(N|2)$ case as we try to construct the Hilbert space based on spin network states. As we mentioned before, both typical and atypical representations are present for other superalgebras except $\mathrm{Osp}(1|2n)$. The key difference of these two types of representations is that all the typical representation is either irreducible or completely reducible; however, the atypical one maybe is not completely reducible (i.e., reducible but not decomposable). In group theory, there is a simple meaning of complete reduc-

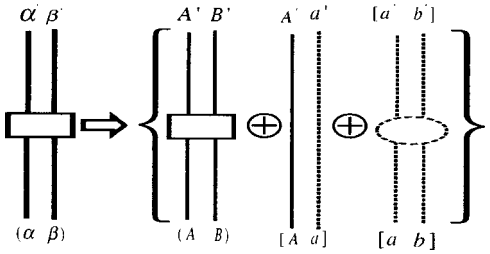

FIG. 15. Symmetrizer with color two.

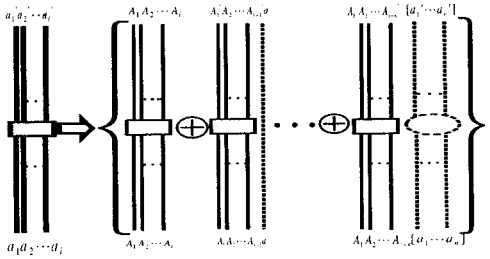

FIG. 16. Symmetrizer with color $(i,0,\ldots,0)$.

ibility, namely the representation space should be a Hilbert space and the representation should be unitary. Correspondingly, in the context of spin networks we will meet some serious problems to show the corresponding spin network states form a basis for the Hilbert space. In this case, we do not know there exists some kind of generalized Peter–Weyl theorem, though the left-invariant Haar integral for such supergroups is also discussed in Ref. 22. But let us note there are some classes, which are called star representations and graded star representations in irreducible representations of the superalgebras.[14,32] Inside each class the complete reducibility is reserved indeed and the CG series can be given also. Thus, spanning spin network states in such subspaces, we still expect they could be well defined to form a basis for such Hilbert spaces. Note that in quantum gravity, only the *physical* Hilbert space is what we want finally. So, it is quite interesting to find some self-consistent subset of spin networks which are well defined and investigate the possible applications to quantum theory.

In the end of this section, let us make a summation by listing the correspondence between the construction of spin networks and the representation theory of the superalgebra.

Spin networks	Representation theory of superalgebra
Edges	Irreducible representation
Vertex	Intertwiner operator
Ropes	Fundamental representations
Admissible conditions	Clebsch–Gordan series
Closure of edges	Supertrace of the unit element
Spin network states	Cylindrical functions
Inner product of spin network states	Generalized Haar measure
Orthogonality and linear independence of states	Generalized Peter–Weyl theorem

V. DISCUSSIONS

In this article we have presented a general introduction to the construction of supersymmetric spin networks. All the strategy in ordinary SU(2) spin networks can be employed in the case of Osp$(1|2n)$ spin networks. In particular, the spin network states form a basis for the Hilbert space $\mathcal{L}^2(\mathcal{A}/\mathcal{G})$. But normally it is becoming more complicated to carry out a practical way to evaluate the spin network graphs, as in general both symmetrization and antisymmetrization procedures are involved in higher finite dimensional irreducible representations. However, it is definitely plausible to give a specific calculation on evaluation of graphs in the future by following strategies given in present article. On the other hand, due to the properties of the superalgebra, it is unclear if we could construct spin network states as the basis of Hilbert space based on any kind of superalgebra. Here we only discussed the Osp$(N|2)$ spin networks briefly and found this problem should be considered seriously.

To apply spin network techniques to quantum supergravities and Yang–Mills theory is very promising and important. At root they are powerful tools to quantize gauge theories along the nonperturbative and background independent approach.

First we expect the corresponding spin network states would be applied to construct the Hilbert space of quantum supergravities. In this framework we could find a practical way to consider the action of the operators, and calculate the spectra of the observables. In Ref. 10, we have made a first step to calculate the spectrum of area operator in $N=1$ Chiral supergravity, and the extension to the case of $N=2$ is also done in Ref. 11.

Second, we propose the holographic hypothesis[33,34] can be tested in the framework of nonperturbative quantum supergravities. This conjecture has been tested in $N=1$ and $N=2$ supergravity, respectively.[31,35] It is the supersymmetric spin networks that make it possible to count the number of degrees of freedom on the boundary such that we find the relations between the area of the boundary and the number of the states do satisfy Bekenstein's conditions.

Until now we only take into account the finite dimensional representation of the superalgebra. It is worth studying what role the spin networks will play if we consider the infinite dimensional representation of the superalgebra.

ACKNOWLEDGMENTS

I am very grateful to my advisor, Professor Lee Smolin, for his contribution and encouragement during the course of this work. Also, I would like to thank Laurent Freidel, Marcus Gaul, Yongge Ma, and Daniele Oriti for their continuous interests in this subject and communication. I am also grateful to the theoretical physics group at Imperial College for hospitality when part of this work was done there. This work was supported by the NSF through Grant No. PHY95-14240 and a gift from the Jesse Phillips Foundation.

[15] The classification of superalgebra was established in Ref. 13. There are three kinds of orthosympletic algebras $\mathrm{Osp}(M|2n)$: $B(m,n)=\mathrm{Osp}(2m+1|2n)$; $C(n)=\mathrm{Osp}(2|2n-2),(n\geqslant 2)$ and $D(m,n)=\mathrm{Osp}(2m|2n),(m,n\geqslant 2)$.
[16] A. Balantekin and I. Bars, J. Math. Phys. **22**, 1149 (1981); **22**, 1810 (1981).
[17] Strictly speaking, unlike the superalgebra $\mathrm{SU}(N|M)$, the symmetrized basis $\xi_{(\alpha\beta)}$ need to shift a little bit by the

condition $G_{\alpha\beta}\xi_{(\alpha\beta)}=0$ (Ref. 16), where $G_{\alpha\beta}$ is the invariant bilinear form taking the form

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & I_n \\ 0 & -I_n & 0 \end{pmatrix}.$$

However, this shift will not affect our construction of the unit element of the supergroups. We just ignore this shift in this article.

(Received 23 February 2001; accepted for publication 25 September 2001)

The mean value of a quantity in an equally weighted wave packet was recently found in the classical limit to be the Fejér average of partial sums of Fourier series expansion of the classical quantity, and the number of stationary states in it is equal to that of partial sums. The incompleteness of the Fejér average in representing a classical quantity enables us to define a classical uncertainty relation which turns out to be the counterpart of the quantum one. In this paper, two typical quantum systems, a harmonic oscillator and a particle in an infinite square well, are used to illustrate the above-mentioned points. © *2002 American Institute of Physics.*

I. INTRODUCTION

During the past few years, the dynamics of wave packets has become a very active field of research—for a review, see Ref. 1. Intensive theoretical and experimental studies show that only the short-term, one or two periods to be precise, behaviors of an initially localized wave packet prove to be similar to those of an appropriate ensemble of classical orbits. Its long-term behaviors such as collapse, (super-)revival, etc., are inevitable and of purely quantum mechanical origin.[1] However, an outstanding problem remains open: In what sense can or cannot the quantum mechanics recover the classical mechanics for a single orbit in the classical limit?

As stated in a standard textbook,[2] in order to obtain a definite classical orbit in the classical limit, we must start from a quasiclassical wave packet of a particular form $|\psi(t)\rangle=\Sigma_m c_m\psi_m$, where the coefficients c_m are noticeably different from zero only in some range δm of values of the quantum number n such that $1\ll\delta m\ll n$; the numbers n are supposed large and the superimposed stationary states ψ_m in the wave packet $|\psi(t)\rangle$ have nearly the same energy E_n.[2] As believed, the mean value of a quantity in such a wave packet must become, in the classical limit, simply the classical value of the quantity; and the mean value was ''proved'' to have a Fourier series form.[2] In fact, the proof given in Ref. 2 is not rigorous in mathematics, as recently pointed out in Ref. 3.

The wave packet we study takes the following simplest form:

$$|\psi(t)\rangle=\frac{1}{\sqrt{2N+1}}\sum_{m=-N}^{N}\psi_{n+m}(x)\exp\left(\frac{-iE_{n+m}t}{\hbar}\right)\quad(N\leqslant n). \tag{1}$$

a)Electronic mail: qhuiliu@cs.hn.cn

It is an equally weighted wave packet (EWWP) which is constructed by superposition of $2N+1$ successive stationary states centered at the nth with an equal weight $1/\sqrt{2N+1}$. Q.H.L. has recently proven in a Letter[3] that in the constraint classical limit;

$$n\to\infty,\hbar\to 0,n\hbar=an\ \ appropriate\ \ classical\ \ action, \tag{2}$$

the quantum mechanical mean value of a quantity in the EWWP goes over to the classical quantity, but the form is Fejér average of partial sums of Fourier series of the classical quantity rather than the Fourier series itself.[3] Let the nth partial sum of Fourier series expansion of a classical quantity f be f_n,

$$f_n=\sum_{k=-n}^{n} c_k \exp\left(\frac{i2k\pi t}{T}\right). \tag{3}$$

The Fejér average $F\langle f\rangle$ of $2N+1$ partial sums is then

$$F\langle f\rangle=\frac{f_0+f_1+f_2+\cdots f_{2N}}{2N+1}. \tag{4}$$

What was proven in Ref. 3 means in the quasiclassical sense that the number $2N+1$ of the stationary states in EWWP (1) is nothing but the number of the partial sums in the Fejér average $F\langle f\rangle$ (4), and

$$\overline{f}=\langle\psi(t)|f|\psi(t)\rangle\approx F\langle f\rangle. \tag{5}$$

We are impressed by the fact that the Fejér average is initially an intellectual creation in pure mathematics to study the convergence of Fourier series. Its existence in physics may reflect the harmony of mind world of mankind and material structure of nature. Since the Fejér average is not familiar to some readers, we give a brief introduction to it in the Appendix.

The Fejér average $F\langle f\rangle$ (4) of a classical quantity can contain an arbitrary number of partial sums for N, which can be an arbitrary integer ranging from 0 to ∞. However, from Eq. (1), quantum mechanics puts an upper bound to N, $N\leqslant n$. In fact, we have $N\ll n$ in the quasiclassical sense as will be shown shortly. Moreover, the minimum of the uncertainty relation $\Delta x\Delta p$ singles out a critical $N=N_c$, for the uncertainty relation cannot be minimized with the number of stationary states being more or less than it. The relation between N_c and n can be reasonably assumed to be given by an exponent equation,

$$N_c\approx n^m,\quad m<1, \tag{6}$$

where m is a constant exponent depending on the form of the potential, and can be called the critical exponent. In this paper, calculations give $m=2/3$ for a harmonic oscillator (HO), and $m=1/2$ for an infinite square well (ISW) potential.

There is no uncertainty associated with a classical quantity; but the representation of Fejér average $F\langle f\rangle$ (4) of the classical quantity is not complete unless $N\to\infty$ (cf. the Appendix). Because of this incompleteness, a classical uncertainty $\Delta_c f$ can be defined by

$$\Delta_c f=\sqrt{F\langle f^2\rangle-(F\langle f\rangle)^2}, \tag{7}$$

which approaches zero as $N\to\infty$. It is the counterpart of the quantum uncertainty Δf for the correspondence relation (5) implies in the semiclassical sense,

$$\Delta_c f\approx\Delta f. \tag{8}$$

Note that in each case in this paper, to compare a classical mechanical result with a quantum mechanical one, the classical quantity takes its semiclassical form.

As a systematic illustration of how the Fejér average relates to the mean value of a quantity in the EWWP, a single HO and a particle in the ISW are studied in Secs. II and III, respectively. Why these two systems are chosen is based on both physical and mathematical considerations. In physics, they are two fundamental models in quantum mechanics and insights into the dynamics exhibited in them speak immediately to a wide range of physical systems.[4] In mathematics, the classical position $x(t)$ and momentum $p(t)$ for a single HO contain only the fundamental frequency terms $\cos(\omega t)$ and $\sin(\omega t)$, respectively; whereas for a particle in the ISW they give the sawtooth and square wave, respectively, which are indispensable in an elementary discussion of Fourier analyses relevant to Fejér average[5–8] that offers the base of our exact treatment. A brief conclusion is given in Sec. IV.

II. FEJÉR AVERAGE AND A SINGLE ONE-DIMENSIONAL HO

A single one-dimensional HO is of great importance in quantum mechanics as well as in classical physics, since it can be used to approximate a single particle moving in an arbitrary continuous potential in the vicinity of a stable equilibrium position. Furthermore, it is analytically calculable throughout. We like to use it to illustrate various aspects of our theory. This section starts with the calculation of mean values of quantities in the EWWP for the HO, from which the Fejér average comes out as a natural result. Next with the minimum of the uncertainty relation $\Delta x \Delta p$, the critical exponent m is obtained. Then the classical uncertainty relation can be defined and found to be in a semiclassical sense comparable to the quantum one. Section II D presents a brief summary.

A. Mean values of quantities in the EWWP for a single HO

For a single one-dimensional HO with mass μ and intrinsic frequency ω, the mean values for the quantities H, H^2, x, x^2, p, p^2 in the EWWP (1) are given by

$$\langle \psi(t)|H|\psi(t)\rangle = (n+\tfrac{1}{2})\hbar\omega, \tag{9}$$

$$\langle \psi(t)|H^2|\psi(t)\rangle = \left[\left(n+\frac{1}{2}\right)\hbar\omega\right]^2 + (n\hbar\omega)^2\frac{N(N+1)}{3n^2}, \tag{10}$$

$$\langle \psi(t)|x|\psi(t)\rangle = \left(\frac{2}{2N+1}\sqrt{\frac{\hbar}{2\mu\omega}}\sum_{m=-N+1}^{N}\sqrt{n+m}\right)\cos\omega t = f(n,N)\left(\frac{2N}{2N+1}\sqrt{\frac{2n\hbar}{\mu\omega}}\right)\cos\omega t, \tag{11}$$

$$\begin{aligned}\langle \psi(t)|x^2|\psi(t)\rangle &= \left(n+\frac{1}{2}\right)\left(\frac{\hbar}{\mu\omega}\right) + \left(\frac{\hbar}{\mu\omega}\right)\frac{1}{2N+1}\sum_{m=-N+2}^{N}\sqrt{(n+m)(n+m-1)}\cos 2\omega t \\ &= \left(n+\frac{1}{2}\right)\left(\frac{\hbar}{\mu\omega}\right) + \left(\frac{n\hbar}{\mu\omega}\right)\frac{2N-1}{2N+1}g(n,N)\cos 2\omega t,\end{aligned} \tag{12}$$

$$\begin{aligned}\langle \psi(t)|p|\psi(t)\rangle &= -\left(\frac{2}{2N+1}\sqrt{\frac{\hbar\mu\omega}{2}}\sum_{m=-N+1}^{N}\sqrt{n+m}\right)\sin\omega t \\ &= -f(n,N)\left(\frac{2N}{2N+1}\sqrt{2\mu n\hbar\omega}\right)\sin\omega t,\end{aligned} \tag{13}$$

$$\begin{aligned}\langle \psi(t)|p^2|\psi(t)\rangle &= \left(n+\frac{1}{2}\right)\mu\hbar\omega - \mu\hbar\omega\frac{1}{2N+1}\sum_{m=-N+2}^{N}\sqrt{(n+m)(n+m-1)}\cos 2\omega t \\ &= \left(n+\frac{1}{2}\right)\mu\hbar\omega - \mu n\hbar\omega\frac{2N-1}{2N+1}g(n,N)\cos 2\omega t,\end{aligned} \tag{14}$$

where $f(n,N)$ and $g(n,N)$ are

$$f(n,N)=\frac{1}{2N}\sum_{m=-N+1}^{N}\sqrt{1+\frac{m}{n}},\ g(n,N)=\frac{1}{2N-1}\sum_{m=-N+2}^{N}\sqrt{\left(1+\frac{m}{n}\right)\left(1+\frac{m-1}{n}\right)}. \quad (15)$$

Since we have $N<n$, $f(n,N)$ and $g(n,N)$ satisfy

$$\sqrt{1+\frac{-N+1}{n}}<f(n,N)<\sqrt{1+\frac{N}{n}}, \quad (16)$$

$$\sqrt{\left(1+\frac{-N+2}{n}\right)\left(1+\frac{-N+1}{n}\right)}<g(n,N)<\sqrt{\left(1+\frac{N}{n}\right)\left(1+\frac{N-1}{n}\right)}. \quad (17)$$

As a consequence, both $f(n,N)$ and $g(n,N)$ approach unity in the following limit;

$$N\to\infty,\quad N/n\to 0. \quad (18)$$

Upon looking more closely, we can find two relations after neglect of terms higher than $O(1/n)$,

$$\frac{2N}{2N+1}f(n,N)=1-\frac{1}{2N}+O\left(\frac{1}{n}\right)\approx\frac{2N}{2N+1}, \quad (19)$$

and

$$\frac{2N-1}{2N+1}g(n,N)=1-\frac{1}{N}+O\left(\frac{1}{n}\right)\approx\frac{2N-1}{2N+1}. \quad (20)$$

Thus, in the classical limit (2) in conjunction with the limit (18), after neglect of the terms higher than $O(1/n)$, results (9)–(14) become the following quantities, respectively:

$$\langle\psi(t)|H|\psi(t)\rangle\approx E, \quad (21)$$

$$\langle\psi(t)|H^2|\psi(t)\rangle\approx E^2, \quad (22)$$

$$\langle\psi(t)|x|\psi(t)\rangle\approx\frac{2N}{2N+1}\sqrt{\frac{2E}{\mu\omega^2}}\cos(\omega t), \quad (23)$$

$$\langle\psi(t)|p|\psi(t)\rangle\approx-\frac{2N}{2N+1}\sqrt{2\mu E}\sin(\omega t), \quad (24)$$

$$\langle\psi(t)|x^2|\psi(t)\rangle\approx\frac{E}{\mu\omega^2}+\frac{2N-1}{2N+1}\frac{E}{\mu\omega^2}\cos(2\omega t)\approx(\langle\psi(t)|x|\psi(t)\rangle)^2, \quad (25)$$

$$\langle\psi(t)|p^2|\psi(t)\rangle\approx\mu E-\frac{2N-1}{2N+1}\mu E\cos(2\omega t)\approx(\langle\psi(t)|p|\psi(t)\rangle)^2. \quad (26)$$

All results on the right-hand side of Eqs. (21)–(26) are the classical quantities in terms of the Fejér average of $(2N+1)$ partial sums of Fourier series. In other words, the mean value of a quantity in the EWWP converges to the Fejér average of the classical quantity in the classical limit. In Sec. II C, the Fejér average of classical quantities will be discussed in more detail.

B. The relation between *N* and *n* determined by minimizing the uncertainty relation

The square of usual uncertainties of x and p as $\langle\psi(t)|x^2|\psi(t)\rangle-(\langle\psi(t)|x|\psi(t)\rangle)^2$ and $\langle\psi(t)|p^2|\psi(t)\rangle-(\langle\psi(t)|p|\psi(t)\rangle)^2$ are time dependent. Because the time average of them over a period suffices to characterize the deviation of quantum mechanics from the classical one, in this subsection we use the following uncertainties:

$$\Delta x=\left(\left(n+\frac{1}{2}\right)-\left(\frac{1}{2N+1}\sum_{m=-N+1}^{N}\sqrt{n+m}\right)^2\right)^{1/2}\left(\frac{\hbar}{\mu\omega}\right)^{1/2}, \tag{27}$$

$$\Delta p=\left(\left(n+\frac{1}{2}\right)-\left(\frac{1}{2N+1}\sum_{m=-N+1}^{N}\sqrt{n+m}\right)^2\right)^{1/2}(\mu\omega\hbar)^{1/2}. \tag{28}$$

The minimum of their product $\Delta x\Delta p$ means to minimize the quantity $(n+1/2)-(\Sigma_{m=-N+1}^{N}\sqrt{n+m}/(2N+1))^2$ at a fixed n. In the quasiclassical case where $N\ll n$ is satisfied, the square root of $\sqrt{n+m}$ can be expanded up to $(m/n)^3$ as (the numerical work will confirm that expansion to this order is accurate enough),

$$\sqrt{n}\left(1+\frac{m}{2n}-\frac{m^2}{8n^2}+\frac{m^3}{16n^3}\right). \tag{29}$$

Then, the summation $\Sigma_{m=-N+1}^{N}\sqrt{n+m}/(2N+1)$ is approximately

$$\begin{aligned}\frac{1}{2N+1}\sum_{m=-N+1}^{N}\sqrt{n+m}&\approx\frac{1}{2N+1}\sum_{m=-N+1}^{N}\sqrt{n}\left(1+\frac{m}{2n}-\frac{m^2}{8n^2}+\frac{m^3}{16n^3}\right)\\&=\frac{N^3-2N(1+2N^2)n/3+8Nn^2+32Nn^3}{16(1+2N)n^{5/2}}.\end{aligned} \tag{30}$$

Treating N as a continuous variable, the zeros of the equation obtained from the derivative of Eq. (30) with respect to N would minimize the uncertainty relation $\Delta x\Delta p$. The only meaningful root is

$$N_c=-\frac{1}{4}+\frac{3\,(-3+4\,n)}{2*2^{2/3}y^{1/3}}+\frac{y^{1/3}}{12*2^{1/3}(-3+4\,n)}, \tag{31}$$

where

$$\begin{aligned}y=&-54\,(-3+4\,n)^3+864\,n\,(-3+4\,n)^2\,(-1+12\,n+48\,n^2)+216\,\sqrt{6}\,\sqrt{n}\,(-3\\&+4\,n)^2\,\sqrt{-1+16\,n-32\,n^2+64\,n^3+3072\,n^4+6144\,n^5}.\end{aligned} \tag{32}$$

When $n\gg 1$, we have approximately, with $[x]$ standing for the integral part of positive number x,

$$N_c\approx[6^{1/3}n^{2/3}]. \tag{33}$$

A comparison of this relation to the numerically exact one, as shown in Fig. 1, shows that this relation is unbelievably accurate in whole range of $n\geqslant 1$. Then the uncertainty relation $\Delta x\Delta p$ is, after simplification,

$$\Delta x\Delta p\approx\frac{\hbar}{2}\frac{3^{2/3}}{2^{1/3}}n^{1/3}=\hbar^{2/3}\left(\frac{3^2}{2^4}\right)^{1/3}(n\hbar)^{1/3}. \tag{34}$$

In the following, we will give its counterpart in classical mechanics.

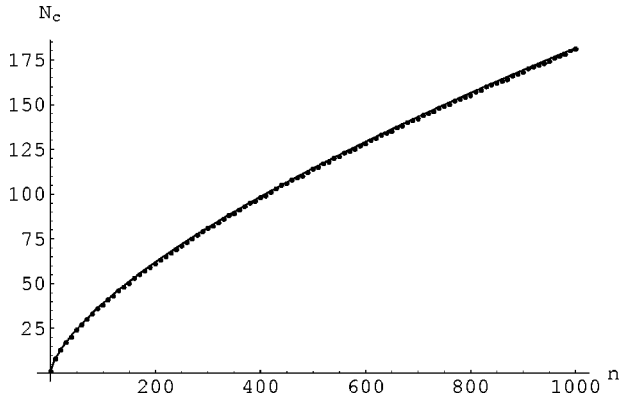

FIG. 1. Comparison of the numerical result of N_c (dotted line) and the approximately analytical one (solid line) $6^{1/3}n^{2/3}$; both are obtained from minimizing of the uncertainty $\Delta x\Delta p$ at each n. These two results coincides with each other in whole range $n\geqslant 1$.

C. Another derivation of the uncertainty relation (34) from the Fejér average approximation of the semiclassical quantities

By definition,[3,5–8] the Fejér averages of the first $(2N+1)$ partial sums of the Fourier series of x, x^2, p, and p^2 are with $N>1$,

$$F\langle x\rangle=\frac{2N}{2N+1}\sqrt{\frac{2E}{\mu\omega^2}}\cos(\omega t), \tag{35}$$

$$F\langle x^2\rangle=\frac{E}{\mu\omega^2}+\frac{2N-1}{2N+1}\frac{E}{\mu\omega^2}\cos(2\omega t), \tag{36}$$

$$F\langle p\rangle=-\frac{2N}{2N+1}\sqrt{2\mu E}\cos(\omega t), \tag{37}$$

$$F\langle p^2\rangle=\mu E-\frac{2N-1}{2N+1}\mu E\cos(2\omega t). \tag{38}$$

The larger the number N, the more accurate are the Fejér average approximations. Analogous to the definition of quantum uncertainties given by Eqs. (27) and (28), the classical uncertainties $\Delta_c x$ and $\Delta_c p$ are defined by

$$\Delta_c x=(\overline{F\langle x^2\rangle-(F\langle x\rangle)^2})^{1/2}=\left(\frac{E}{\mu\omega^2}\left(1-\left(\frac{2N}{2N+1}\right)^2\right)\right)^{1/2}, \tag{39}$$

$$\Delta_c p=(\overline{F\langle p^2\rangle-(F\langle p\rangle)^2})^{1/2}=\left(\mu E\left(1-\left(\frac{2N}{2N+1}\right)^2\right)\right)^{1/2}, \tag{40}$$

where $\overline{f(t)}$ means the time average of the quantity $f(t)$ over a period. The product of $\Delta_c x$ and $\Delta_c p$ is

$$\Delta_c x\Delta_c p=\frac{E}{\omega}\frac{4N+1}{(2N+1)^2}, \tag{41}$$

which reduces to, when $N\gg 1$,

$$\Delta_c x \Delta_c p \approx \frac{E}{N\omega}. \tag{42}$$

We see that the classical uncertainty vanishes only in the limit of N approaching infinity. However, using the relations $N_c \approx [6^{1/3} n^{2/3}]$ and $E \approx n\hbar\omega$, the classical uncertainty relation (42) is in semiclassical form,

$$\Delta_c x \Delta_c p \approx \left\langle \frac{n\hbar}{N_c} \right\rangle \approx 6^{-1/3} \hbar^{2/3} (n\hbar)^{1/3}, \tag{44}$$

which differs from the purely quantum one (34) only in a numerical factor 3/2. Equation (44) can be called a semiclassical uncertainty relation.

D. A brief summary of results obtained by EWWP description of a single HO

(1) For a single one-dimensional HO, analytical calculations give the critical exponent $m=2/3$ and a relation $N_c \approx [6^{1/3} n^{2/3}]$.
(2) The classical uncertainty relation $\Delta_c x \Delta_c p$ is definable, and this uncertainty relation comes from the incompleteness of the Fejér average representation of a classical quantity. After rewriting it into its semiclassical form, we see $\Delta_c x \Delta_c p \approx \Delta x \Delta p$.

III. FEJÉR AVERAGE AND A SINGLE PARTICLE IN AN ISW

A single particle in an ISW is the simplest quantum system whose energy level is not equally spaced, and the wave packet dynamics exhibited in it is essentially the same as that in more complicated system.[4] Since the long-term behaviors of EWWP such as collapse, revival, etc., do not have any analog in classical mechanics, only the first two period behaviors are examined in the following. In Sec. III A, the analytical expressions of mean values x, x^2, p, p^2 in the EWWP for a single particle in an ISW are given. In Sec. III B, the critical exponent $m=1/2$ is numerically determined. In Sec. III C, we show that the inequality of energy level spacing is responsible for the small difference between $\langle f \rangle$ and $F\langle f \rangle$ for $f=x$ and p, respectively. Section IV D presents a brief summary.

A. Mean values of quantities in the EWWP for a single particle in an ISW

For the quantum motion of a particle of mass μ in a one-dimensional ISW with width a, the normalized stationary state function is $\psi_n(x)\exp(-iE_n t/\hbar) = (2/a)^{1/2} \sin(k_n x)\exp(-ip_n^2 t/(2\mu\hbar))$, where $k_n = n\pi/a$, $E_n = p_n^2/(2\mu)$ is the energy and the momenta $p_n = \pm \hbar k_n$ is equally probable. In classical mechanics, the particle moves to and fro within the two impenetrable walls. The classical position x is

$$x = \begin{cases} p_c t/\mu = a\omega t/\pi, & 0 < t < T/2 \\ 2a - a\omega t/\pi \quad T//2 < t < T, \end{cases} \tag{45}$$

where $T = 2a\mu/p_c$ is the time of one period, p_c is the magnitude of momentum, and $\omega = 2\pi/T$ is the frequency. The derivative of position x with respect to time t gives the velocity $p/\mu = \pm p_c/\mu$. The mth partial sum of its Fourier series representing x is given by x_m,

$$x_m = \frac{a}{2} - \frac{4a}{\pi^2} \sum_{r=0}^{m} \frac{\cos[(2r+1)\omega t]}{(2r+1)^2}. \tag{46}$$

Its Fejér average $F\langle x \rangle$ is

$$F\langle x \rangle = \frac{a}{2} - \frac{8a}{\pi^2} \frac{1}{(2N+1)} \sum_{l=0}^{N-1} \sum_{r=0}^{l} \frac{\cos[(2r+1)\omega t]}{(2r+1)^2}. \tag{47}$$

Similarly, we have $F\langle f\rangle$ for $f=x^2,\ p,\ p^2$ [cf. Eqs. (54)–(56)]. Note that there is the famous Gibb's phenomenon when using truncated Fourier series to approximate the classical momentum p, while $F\langle p\rangle$ does not have such a phenomenon.[6–8] The calculation of $\langle f\rangle$ in the EWWP for $f=x,\ x^2,\ p,\ p^2$ is straightforward:

$$\langle x\rangle=\frac{a}{2}+\frac{4a}{\pi^2}\frac{1}{2N+1}\sum_{l=0}^{N-1}\sum_{r=0}^{l}\left\{\left(\frac{1}{(2n+2N-4l+2r-1)^2}-\frac{1}{(2r+1)^2}\right)\right.$$
$$\times\cos\left((2r+1)\left(1+\frac{2N-4l+2r-1}{2n}\right)\omega_n t\right)+\left(\frac{1}{(2n+2N-4l+2r-3)^2}-\frac{1}{(2r+1)^2}\right)$$
$$\left.\times\cos\left((2r+1)\left(1+\frac{2N-4l+2r-3}{2n}\right)\omega_n t\right)\right\}, \tag{48}$$

$$\langle x^2\rangle=\frac{a^2}{3}-\frac{1}{2N+1}\frac{a^2}{2\pi^2}\sum_{m=-N}^{N}\frac{1}{(n+m)^2}+\frac{4a^2}{\pi^2}\frac{1}{2N+1}\sum_{l=1}^{2N}\sum_{r=1}^{l}(-1)^r$$
$$\times\left(\frac{1}{r^2}-\frac{1}{(2n-2N+2l-r)^2}\right)\cos\left(r\left(1-\frac{2N-2l+r}{2n}\right)\omega_n t\right), \tag{49}$$

$$\langle p\rangle=\mu\frac{\mathrm{d}}{\mathrm{d}t}\langle x\rangle, \tag{50}$$

$$\langle p^2\rangle=\frac{1}{2N+1}\left(\frac{\pi\hbar}{a}\right)^2\sum_{m=-N}^{N}(n+m)^2=\left(\frac{n\pi\hbar}{a}\right)^2\left(1+\frac{N+N^2}{3n^2}\right)=p_n^2\left(1+\frac{N+N^2}{3n^2}\right), \tag{51}$$

where $\omega_n=\pi p_n/(\mu a)=n\hbar\pi^2/(\mu a^2)$. The following set of classical limits;

$$n\to\infty,\quad N\to\infty,\quad N/n\to 0,\quad n\hbar\to p_c a/\pi=\omega\mu(a/\pi)^2\quad(\text{i.e., }|p_n|\to p_c,\ \text{or, }\omega_n\to\omega). \tag{52}$$

constitutes the necessary and sufficient condition to ensure the quantum mechanical averages (48)–(51) to be equal to the following Fejér averages;

$$\langle x\rangle\approx F\langle x\rangle=\frac{a}{2}-\frac{8a}{\pi^2}\frac{1}{2N+1}\sum_{l=1}^{N-1}\sum_{r=1}^{l}\frac{\cos[(2r+1)\omega t]}{(2r+1)^2}, \tag{53}$$

$$\langle x^2\rangle\approx F\langle x^2\rangle=\frac{a^2}{3}+\frac{4a^2}{\pi^2}\frac{1}{2N+1}\sum_{l=1}^{2N}\sum_{r=1}^{l}(-1)^r\frac{\cos(r\omega t)}{r^2}, \tag{54}$$

$$\langle p\rangle\approx F\langle p\rangle=\mu\frac{\mathrm{d}}{\mathrm{d}t}F\langle x\rangle, \tag{55}$$

$$\langle p^2\rangle\approx p_c^2. \tag{56}$$

B. The relation between *N* and *n* determined by minimizing the uncertainty relation

The mean value $\langle p\rangle$ is a continuous function of t; it is zero when the center of EWWP starts to return from either wall of the well. Since the mean value of p^2 is a constant of time, $\Delta p=\sqrt{\langle p^2\rangle}$ when $\langle p\rangle=0$. At this instant, minimizing $\Delta x\Delta p$ amounts to minimizing Δx. The numerical result as given in Fig. 2 shows that $N_c\approx[\sqrt{n}]$, e.g., $N_c=23$ when $n=500$. In all numerical calculations hereafter, the natural units are used in which $a=\mu=\hbar=1$.

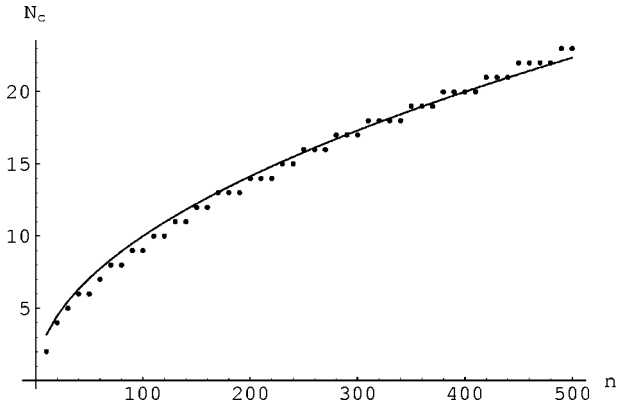

FIG. 2. Corresponding to each n ranging from 10 to 500, there is a unique value of N_c (dotted curve) minimizing the uncertainty $\Delta x \Delta p$. The smooth curve is $\sqrt{n}$. Since $N_c = [\sqrt{n}] \pm 1$ with $[x]$ denoting the integral part of x, $N_c \approx \sqrt{n}$ gives a nice fit.

C. $\langle f \rangle$ and $F\langle f \rangle$ when $n = 500$

When $n = 500$, $N_c = 23$, $p_n = \pm p_c = \pm 500\pi$, and $T = 0.001\,27$, $\langle f \rangle$ and $F\langle f \rangle$ when $f = x$, p are plotted in Fig. 3. The difference between them is small. Is the inequality of the energy level spacing the principal origin of the small difference? In order to examine this problem, we magnify the difference by introducing the reduced uncertainty δf and reduced classical uncertainty $\delta_c f$,

$$\delta f = \sqrt{1 - (\langle f \rangle)^2 / \langle f^2 \rangle}, \quad \delta_c f = \sqrt{1 - (F\langle f \rangle)^2 / F\langle f^2 \rangle}. \tag{57}$$

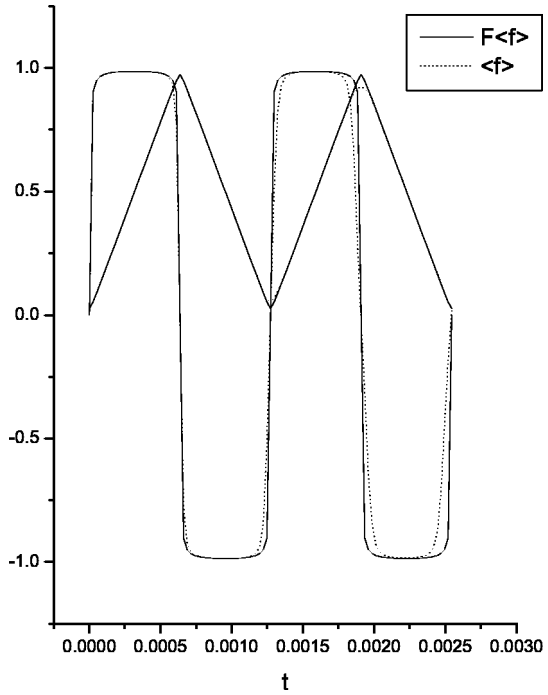

FIG. 3. When $N_c = 23$, $p_n = \pm p_c = \pm 500\pi$, i.e., $n = 500$, and taking 500π as the unit of the momentum, the Fejér averages $F\langle x \rangle$ (solid sawtooth wave), $F\langle p \rangle$ (solid square wave), and the quantum mechanical averages $\langle x \rangle$ (dotted sawtooth curve), and $\langle p \rangle$ (dotted square curve) in the EWWP. In the first period, $\langle x \rangle$ and $F\langle x \rangle$ are almost the same, and so are $\langle p \rangle$ and $F\langle p \rangle$. In some intervals two curves completely coincide, only one curve is possibly visible.

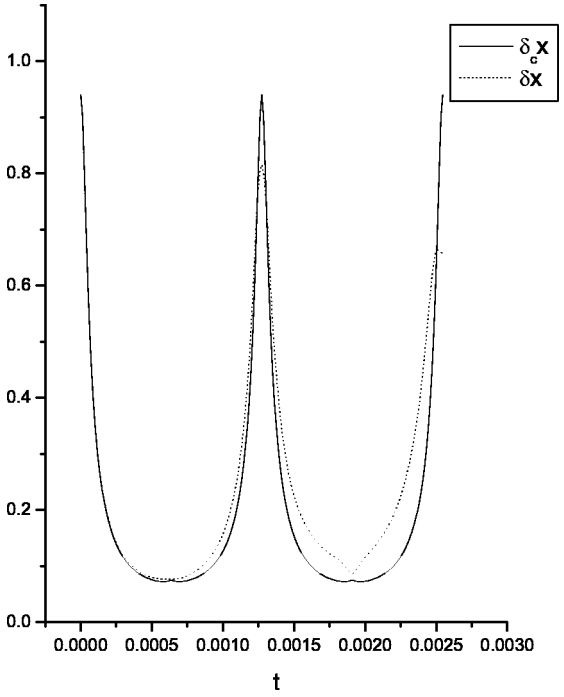

FIG. 4. The difference between $\langle x\rangle$ and $F\langle x\rangle$ viewed from the reduced uncertainty δx (dotted curve) and the classical one $\delta_c x$ (solid curve). The difference between $\langle x\rangle$ and $F\langle x\rangle$ comes from the inequality of energy level spacing. Both curves are entirely different from the classical result $\delta x=0$ $(x\neq 0)$.

In Figs. 4 and 5, we compare the behaviors of δf and $\delta_c f$ for $f=x$, p, respectively. We use solid lines to plot the reduced classical uncertainties $\delta_c f$, and the dotted for either the pure quantum mechanical quantities δf or the semiquantum mechanical ones. By the semiquantum mechanical quantities, we mean those constructed from the pure quantum mechanical ones in which the quantum mechanical matrix elements $f_{n+r,n}=\int_0^a \psi_{n+r}(x) f \psi_n(x)\mathrm{d}x$ are replaced with the rth Fourier amplitudes f_r of the classical quantity f, while the time factors $\exp\{(E_{n+r}-E_n)t/\hbar\}$ remain unchanged. From Eqs. (48) to (50), the pure quantum mechanical quantities and the semi-ones have little difference when n is large and t is small, e.g., $n=500$, $t\leqslant 0.0025$. Therefore when we speak of one of them, both are practically referred to. It is then clear that the difference between solid and dotted lines comes from the inequality of energy level spacing. The longer the time evolves, the more the quantum mechanics deviates from the classical mechanics.

D. A brief summary of results obtained by EWWP description of a single particle in an ISW

(1) For a single particle in an ISW, numerical calculations give a critical exponent $m=1/2$, and relation $N_c\approx\sqrt{n}$.
(2) The small difference between the $\langle f\rangle$ and $F\langle f\rangle$ principally results from the inequality of energy level spacing.

IV. CONCLUSION

Though it is first an intellectual creation in pure mathematics, the Fejér average turns out to be rooted in physics that reflects the objective structure of nature. The quantum mechanical average of a quantity in the EWWP in the quasiclassical sense goes over to the Fejér average of partial sums of Fourier series expansion of the semiclassical quantity, rather than the Fourier series itself as widely accepted.

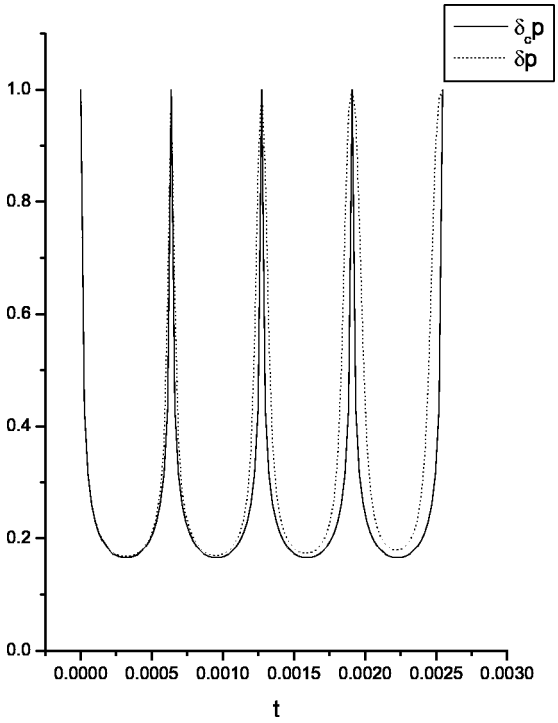

FIG. 5. The difference between $\langle p\rangle$ and $F\langle p\rangle$ viewed from the reduced uncertainty δp (dotted curve) and the reduced classical one $\delta_c p$ (solid curve). Both are entirely different from classical result $\delta p=0$ $(p\neq 0)$.

Two critical exponents $m=1/2,\ 2/3$ are obtained for a single HO and a particle in an ISW, respectively. The critical exponent of the Keplerian motion is of interest and will be studied in the near future.

Because of incompleteness of Fejér average in representing a classical quantity, a classical uncertainty relation $\Delta_c x\Delta_c p$ is definable, which proves to be comparable to the quantum one. This uncertainty is entirely different from the standard deviation associated with an ensemble of classical orbits.[1] In current statistical interpretation of quantum mechanics, the quantum uncertainty is usually interpreted to have a statistical origin.[9]

APPENDIX: A BRIEF INTRODUCTION TO THE FEJÉR AVERAGE

The Fourier series had not come to mathematicians as a reliable and convenient tool until the discovery of the convergence of the Fejér average of its partial sums in 1900. Fejér's theorem is as follows. The Fejér average of the partial sums of the Fourier series $f_n=\Sigma_{k=-n}^{n} c_k \exp(i2k\pi t/T)$ as $\sigma_n=(f_0+f_1+f_2+\cdots f_{n-1})/n$ approximates the given function $f(t)$ at each point where $f(t+0)$ and $f(t-0)$ exist and $f(t)=\frac{1}{2}[f(t+0)+f(t-0)]$, and uniformly converges to the function $f(t)$ when $f(t)$ is continuous on the circle. Note that the truncated Fourier series f_n of $f(t)$ converges *in the mean* to the function. As a profound consequence, the Gibbs phenomenon of Fourier series does not occur with the Fejér average. On its history, see Ref. 5. On its fundamentals, see, for example, Ref. 6. On its applications, see Ref. 7. On its modern developments, see a recent review.[8]

(Received 23 April 2001; accepted for publication 24 September 2001)

We compute the metric associated with noncommutative spaces described by a tensor product of spectral triples. Well-known results of the two-sheets model (distance on a sheet, distance between the sheets) are extended to any product of two spectral triples. The distance between different points on different fibers is investigated. When one of the triples describes a manifold, one finds a Pythagorean theorem as soon as the direct sum of the internal states (viewed as projections) commutes with the internal Dirac operator. Scalar fluctuations yield a discrete Kaluza–Klein model in which the extra component of the metric is given by the internal part of the geometry. In the standard model, this extra component comes from the Higgs field. © *2002 American Institute of Physics*.

I. INTRODUCTION

In the noncommutative approach to the standard model of elementary particles,[1] space–time appears as the product (in the sense of fiber bundles) of a continuous manifold by a discrete space. In previous papers, we have studied the metric aspect of several classes of discrete spaces,[2] and the metric of the continuum has been approached from a Lie-algebraic approach.[3] Here, within the framework of noncommutative geometry, we investigate how the distance in the continuum evolves when the space–time of Euclidean general relativity is tensorized by an internal space. We find that in many cases the relevant picture is the two-sheets model.[4,5] Indeed, under precise conditions, the metric aspect of ''continuum$\times$discrete'' spaces reduces to the simple picture of two copies of the manifold. It was known[6,7] that the distance on each copy is the geodesic distance while the distance between the copies—the distance on the fiber—is a constant. But this does not give a complete description of the geometry, in particular the distance between different points on different copies. In this paper we show that this distance coincides with the geodesic distance within a $(4+1)$-dimensional manifold whose fifth component comes from the internal part of the geometry. This component is a constant in the simplest cases and becomes a function of the manifold when the metric fluctuates. Restricting ourselves to scalar fluctuations of the metric, which correspond to the Higgs sector in the standard model, it appears that the Higgs field describes the internal part of the metric in terms of a discrete Kaluza–Klein model.

The aim of this paper is to investigate the metric aspect of the standard model geometry. This goal is only partially achieved because we focus on scalar fluctuations and we mention only very briefly mathematical aspects such as the Gromov distance. For a comprehensive approach to these questions, the reader is invited to consult Ref. 8. Other works on distance in noncommutative geometry mainly concern lattices[9–12] and finite spaces. A larger bibliography can be found in Ref.

2. Naturally, using a Kaluza–Klein picture in noncommutative geometry is not a new idea and one can refer to Refs. 13 and 14 for instance as well as the textbook.[15] In particular, that the distance between the sheets depends on the manifold has been shown in Refs. 16 and 17. Last but not least, for a comprehensive approach to the subject, the most recent and complete reference is Ref. 17.

The paper is written for a four-dimensional manifold but generalization to higher dimension should be straightforward. Sections II and III introduce classical notions of distance in noncommutative geometry and a simple proof that, on a manifold, this distance coincides with the geodesic distance. Section IV extends known results of the two-sheets model—distance on each copy, distance between the copies—to the product of any two spaces (not necessarily a manifold$\times$a discrete space). In Sec. V we show that, under conditions on the internal part of the Dirac operator, a large number of examples actually reduce to a two points fiber space. In the simplest case the internal space is orthogonal to the continuum in the sense of the Pythagorean theorem (in finite spaces, the Pythagorean theorem has already been mentioned by Ref. 18). Section VI studies the scalar fluctuations (terminology is made precise there) of this metric. Section VII presents examples, among them the standard model, and makes precise the link between the Higgs field and the metric.

II. THE DISTANCE FORMULA

Let $\mathcal{A}$ be a unital C^*-algebra represented over a complex Hilbert space $\mathcal{H}$ equipped with a scalar product $\langle .,. \rangle$ defining the norm $\|\psi\|_{\mathcal{H}}^2 \doteq |\langle \psi, \psi \rangle|$ for $\psi \in \mathcal{H}$. The C^*-norm of $\mathcal{A}$ is the operator norm in $\mathcal{H}$,

$$\|a\|_{\mathcal{A}} \doteq \sup_{\psi \in \mathcal{H}} \frac{\|\pi(a)(\psi)\|_{\mathcal{H}}}{\|\psi\|_{\mathcal{H}}},$$

where π is the representation. The so-called Dirac operator D is a self-adjoint operator in $\mathcal{H}$, possibly unbounded. When the spectral dimension is even,[4] the chirality χ is a Hermitean operator which anticommutes with D and commutes with $\pi(\mathcal{A})$. The set $(\mathcal{A},\mathcal{H},D,\pi,\chi)$ is called a spectral triple. The terminology is justified because π is usually infered in the notation $\mathcal{H}$, and once given $(\mathcal{A},\mathcal{H},D)$, χ—if it exists—is uniquely determined by the axioms of noncommutative geometry.[1] Since the algebra appears through its representation, we can, without loss of generality, replace $\mathcal{A}$ by $\mathcal{A}/\ker(\pi)$ and assume that π is faithful. To improve the readability we omit the symbol π unless necessary.

We denote by $\mathcal{P}(\mathcal{A})$ the set of pure states of $\mathcal{A}$. The distance d between two of its elements ω_1, ω_2 is

$$d(\omega_1,\omega_2) \doteq \sup_{a \in \mathcal{A}} \{|\omega_1(a) - \omega_2(a)| / \|[D,a]\| \leqslant 1\},$$

where $\|.\|$ is the operator norm in $\mathcal{H}$ (we do not write $\|[D,a]\|_{\mathcal{A}}$ because $[D,a]$ may not be the representation of an element of $\mathcal{A}$). This supremum is reached[2] by a positive element such that $\|[D,\pi(a)]\| = 1$:

$$d(\omega_1,\omega_2) = \sup_{a \in \mathcal{A}_+} \{|\omega_1(a) - \omega_2(a)| / \|[D,a]\| = 1\}. \tag{1}$$

This formula is invariant under several transformations, including unitary transformation and projection. First, a unitary element u of $\mathcal{A}$ defines both an automorphism of the algebra $\alpha_u(a) \doteq uau^*$ and a *unitary equivalent* triple $(\mathcal{A},\mathcal{H},uDu^*,\pi \circ \alpha_u)$. Obviously distances are not changed under such a transformation because $\|[D,a]\| = \|[uDu^*, \alpha_u(a)]\|$. More interesting is the action of a projection $e \in \mathcal{A}$ $(e^2 = e^* = e)$ given by

$$\alpha_e(a) \doteq eae,$$

which defines the *restricted* spectral triple

$$(\mathcal{A}_e \doteq \alpha_e(\mathcal{A}), \quad \mathcal{H}_e \doteq e\mathcal{H} \doteq \operatorname{ran} e, \quad D_e \doteq eDe|_{\mathcal{H}_e}, \quad \pi_e \doteq \pi|_{\mathcal{H}_e})$$

whose corresponding distance is denoted by d_e. α_e being not injective, for a pure state $\omega \in \mathcal{P}(\mathcal{A})$ the linear form $\omega \circ \alpha_e$ is not necessarily a state of $\mathcal{A}$ (for instance if e is in the kernel of ω). However it is a pure state of the subalgebra $\mathcal{A}_e$. Conversely, any pure state ω_e of $\mathcal{A}_e$ is made a pure state of $\mathcal{A}$ by writing $\omega_e \circ \alpha_e$. In other words, $\mathcal{P}(\mathcal{A}_e) = \mathcal{P}(\mathcal{A}) \circ \alpha_e \subset \mathcal{P}(\mathcal{A})$.

Lemma 1: If a projection e is such that $[D,e]=0$, *the distance between two pure states* ω_1, ω_2 *of* $\mathcal{A}_e$ *is invariant by projection*: $d_e(\omega_1,\omega_2) = d(\omega_1 \circ \alpha_e, \omega_2 \circ \alpha_e)$.

Proof: For $a_e \in \mathcal{A}_e$, $\|[D_e, \pi_e(a_e)]\| = \|[\pi(e)D\pi(e), \pi(a_e)]\| = \|[D, \pi(a_e)]\|$ therefore

$$\begin{aligned} d_e(\omega_1,\omega_2) &= \sup_{a_e \in \mathcal{A}_e} \{|(\omega_1 - \omega_2)(a_e)| / \|[D,\pi(a_e)]\| \leqslant 1\}, \\ &\leqslant \sup_{a \in \mathcal{A}} \{|(\omega_1 \circ \alpha_e - \omega_2 \circ \alpha_e)(a)| / \|[D,\pi(a)]\| \leqslant 1\} \\ &= d(\omega_1 \circ \alpha_e, \omega_2 \circ \alpha_e). \end{aligned}$$

This upper bound is reached by $\alpha_e(a)$ where $a \in \mathcal{A}$ reaches the supremum for the distance d, namely $\|[D,\pi(a)]\| = 1$ and $d(\omega_1 \circ \alpha_e, \omega_2 \circ \alpha_e) = \omega_1 \circ \alpha_e(a) - \omega_2 \circ \alpha_e(a)$. ■

III. DISTANCE IN A MANIFOLD

The spectral triple of a Riemannian spin manifold $\mathcal{M}$ of dimension four with a metric g is

$$\mathcal{A} = C^\infty(\mathcal{M}), \quad \mathcal{H} = L_2(\mathcal{M},S), \quad D = i\gamma^\mu \partial_\mu = i\partial\!\!\!/, \tag{2}$$

where $L_2(\mathcal{M},S)$ is the set of square integrable spinors on $\mathcal{M}$. The Riemannian gamma matrices $\gamma^\mu = \gamma^{\mu *} = e_a^\mu \gamma^a$ are obtained via the vierbein field e_a^μ from the Euclidean gamma matrices γ^a of the associated Clifford algebra. Using $\delta^{ab} e_a^\mu e_b^\nu = g^{\mu\nu}$ and $\gamma^a\gamma^b + \gamma^b\gamma^a = 2\delta^{ab}\mathbb{I}$ one has $\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}\mathbb{I}$. The spectral dimension is the dimension of the manifold, so there is a chirality $\gamma^5 = \gamma^0\gamma^1\gamma^2\gamma^3$ made of the Euclidean γ^a's. The scalar product of $\mathcal{H}$ is $\langle \psi, \phi \rangle \doteq \int_{\mathcal{M}} \overline{\psi}(x)\phi(x)\,\mathrm{d}x$ and an element $f \in \mathcal{A}$ is represented over $\mathcal{H}$ by the pointwise multiplication, $\pi(f) \doteq f\mathbb{I}$, so that

$$\|f\|_{\mathcal{A}} = \sup_{\psi \in \mathcal{H}} \left(\frac{\int_{\mathcal{M}} (\overline{f\psi})(x)(f\psi)(x)\mathrm{d}x}{\int_{\mathcal{M}} \overline{\psi}(x)\psi(x)\mathrm{d}x} \right)^{1/2} = \sup_{x \in \mathcal{M}} |f(x)|.$$

By Gelfand transform, $\mathcal{P}(\mathcal{A}) \simeq \mathcal{M}$. The isomorphism $x \in \mathcal{M} \leftrightarrow \omega_x \in \mathcal{P}(\mathcal{A})$ is defined by $\omega_x(f) \doteq f(x)$. The noncommutative distance (1),

$$d(x,y) = \sup_{f \in C^\infty(\mathcal{M})} \{|f(x) - f(y)| / \|[i\partial\!\!\!/, f\mathbb{I}]\| \leqslant 1\},$$

coincides with the geodesic distance $L(x,y)$ between points x,y of $\mathcal{M}$. This is a classical result[4] but the proof introduces ideas and notations important for further presentation so that we shall give it in detail (this version of the proof comes from Ref. 19).

The supremum is reached on $\mathcal{A}_+$, so f is real. For $\psi \in \mathcal{H}$, $[i\partial\!\!\!/, f\mathbb{I}]\psi = i(\partial\!\!\!/ f)\psi$, so

$$\|[i\partial\!\!\!/, f\mathbb{I}]\|^2 = \|(i\partial\!\!\!/ f)^* i\partial\!\!\!/ f\| = \|\gamma^\mu \partial_\mu f \gamma^\nu \partial_\nu f\| = \|g^{\mu\nu}\partial_\mu f \partial_\nu f \mathbb{I}\| = \sup_{q \in \mathcal{M}} \{g^{\mu\nu}(q)\partial_\mu f(q)\partial_\nu f(q)\}.$$

The gradient $\vec{\nabla}$ in the usual sense is the exterior derivative d (not to be confused with the distance) which maps zero-forms (i.e., smooth functions over $\mathcal{M}$) to one-forms:

$$\vec{\nabla} f \doteq (\partial_\mu f)\mathrm{d}x^\mu \in T^*\mathcal{M}.$$

By definition[20] g defines an inner product (thus, a norm) in each cotangent space $T_q^*\mathcal{M}$ in such a manner that

$$\|\vec{\nabla} f(q)\|^2_{T_q^*\mathcal{M}} = g^{\mu\nu}(q)\partial_\mu f(q)\partial_\nu f(q).$$

Omitting the index $T_q^*\mathcal{M}$, one writes

$$\|[i\not{b}, f\mathbb{I}]\| = \sup_{q\in\mathcal{M}} \|\vec{\nabla} f(q)\|.$$

Now, let $c: t\in[0,1]\to\mathcal{M}$ be the minimal geodesic between x and y and let $\cdot$ denote the total derivative with respect to t. For any $f\in C^\infty(\mathcal{M})$,

$$f(x)-f(y) = \int_0^1 \dot{f}(c(t))\mathrm{d}t = \int_0^1 \partial_\mu f(p)\dot{c}^\mu(t)\mathrm{d}t,$$

where $p\doteq c(t)$. The metric defines an isomorphism $T_p\mathcal{M}\simeq T_p^*\mathcal{M}$ such that

$$\partial_\mu f(p)\dot{c}^\mu(t) = g^{\mu\nu}(p)\partial_\mu f(p)\dot{c}_\nu(t) = \langle \vec{\nabla} f(p), \dot{c}_\nu(t)\mathrm{d}x^\nu\rangle,$$

thus, by Cauchy–Schwarz, $|\partial_\mu f(p)\dot{c}^\mu(t)| \leqslant \|\vec{\nabla} f(p)\|\|\dot{c}_\nu(t)\mathrm{d}x^\nu\|$. Assuming that f reaches the supremum, one has $\|\vec{\nabla} f\|\leqslant 1$, so

$$\mathrm{d}(x,y) = |f(x)-f(y)| \leqslant \int_0^1 \|\dot{c}_\nu(t)\mathrm{d}x^\nu\|\mathrm{d}t = L(x,y).$$

This upper bound is reached by the function

$$L: q\mapsto L(q,y). \tag{3}$$

Indeed, $L(x)-L(y)=L(x,y)$ and

$$\sup_{q\in\mathcal{M}} \|\vec{\nabla} L(q)\| \leqslant 1. \tag{4}$$

To prove (4), take $q,q'\in\mathcal{M}$ with coordinates q^μ, q'^μ in a given chart such that q' comes from q by the infinitesimal transformation $\sigma(\epsilon)$, $\epsilon\leqslant 1$, where σ is the flow generated by the vector field $g^{\mu\nu}(\partial_\nu L)\partial_\mu$ with initial condition $\sigma(0)=q$. Then, writing $\mathrm{d}q^\mu \doteq q'^\mu - q^\mu$,

$$q^\mu + \mathrm{d}q^\mu = q'^\mu = \sigma^\mu(\epsilon) = \sigma^\mu(0) + \epsilon\frac{\mathrm{d}\sigma^\mu}{\mathrm{d}t}(0) + \mathcal{O}(\epsilon^2) = q^\mu + \epsilon\, g^{\mu\nu}(q)\partial_\nu L(q) + \mathcal{O}(\epsilon^2),$$

which means that

$$\mathrm{d}q^\mu = \epsilon\, g^{\mu\nu}(q)\partial_\nu L(q) + \mathcal{O}(\epsilon^2). \tag{5}$$

As $L(q',y)$ is the shortest length from q' to y, $L(q',y)\leqslant L(q',q)+L(q,y)$, and one has

$$L(q+\mathrm{d}q) \leqslant L(q',q) + L(q). \tag{6}$$

Using (5),

$$L(q',q) \doteq \sqrt{g_{\lambda\rho}(q)\mathrm{d}q^\lambda dq^\rho} = \sqrt{\epsilon^2 g_{\lambda\rho}(q) g^{\lambda\mu}(q)\partial_\mu L(q)\, g^{\rho\nu}(q)\partial_\nu L(q)} = \epsilon\sqrt{g^{\mu\nu}\partial_\mu L(q)\ \partial_\nu L(q)}.$$

Inserting into the right-hand side of (6) whose left-hand side is developed with respect to ϵ yields

$$L(q)+\partial_\mu L(q)\,\mathrm{d}q^\mu = L(q)+\epsilon\, g^{\mu\nu}(q)\partial_\mu L(q)\partial_\nu L(q)+\mathcal{O}(\epsilon^2)$$
$$\leqslant \epsilon\sqrt{g^{\mu\nu}\partial_\mu L(q)\,\partial_\nu L(q)}+L(q)+\mathcal{O}(\epsilon^2),$$

which is true for all q, hence (4) and finally $\mathrm{d}(x,y)=L(x,y)$.

Note that L is not smooth at y but only continuous. As smooth functions are dense in continuous functions, one may exhibit a sequence of smooth functions converging to L and satisfying the commutator norm condition. One may also define the distance as the supremum over the continuous functions of expression (1), see Ref. 17 for details.

IV. TENSOR PRODUCT OF SPECTRAL TRIPLES

The tensor product of an even spectral triple $T_I=(\mathcal{A}_I,\mathcal{H}_I,D_I,\pi_I)$ with chirality χ_I by the spectral triple $T_E=(\mathcal{A}_E,\mathcal{H}_E,D_E,\pi_E)$ is the spectral triple $T_I\otimes T_E\doteq(\mathcal{A}',\mathcal{H}',D')$ defined by

$$\mathcal{A}'\doteq\mathcal{A}_I\otimes\mathcal{A}_E,\quad \mathcal{H}'\doteq\mathcal{H}_I\otimes\mathcal{H}_E,\quad D'\doteq D_I\otimes\mathbb{I}_E+\chi_I\otimes D_E,$$

where the representation of $\mathcal{A}'$ is $\pi'\doteq\pi_I\otimes\pi_E$. The notation $T_I\otimes T_E$ is a matter of convention for spectral triples do not form a vector space. The product of spectral triples is commutative in the sense that when T_E is even with chirality χ_E, then $T_E\otimes T_I\doteq(\mathcal{A},\mathcal{H},D)$ is well defined by permutation of factors,

$$\mathcal{A}\doteq\mathcal{A}_E\otimes\mathcal{A}_I,\quad \mathcal{H}\doteq\mathcal{H}_E\otimes\mathcal{H}_I,\quad D\doteq D_E\otimes\mathbb{I}_I+\chi_E\otimes D_I, \tag{7}$$

$\pi=\pi_E\otimes\pi_I$, and is equivalent to $T_I\otimes T_E$ up to the unitary operator

$$U\doteq\left(\frac{\mathbb{I}_I+\chi_I}{2}\otimes\mathbb{I}_E+\frac{\mathbb{I}_I-\chi_I}{2}\otimes\chi_E\right).$$

For physics it is interesting to take for this tensor product the product of the continuum by the discrete, namely to study the geometry of the four-dimensional space–time of Euclidean general relativity together with an internal discrete space. In the standard model, the internal space describes the electroweak and strong interactions and is defined by a spectral triple T_I in which the algebra $\mathcal{A}_I$ is chosen such that its unitarities are related to the gauge group of interactions while $\mathcal{H}_I$ is the space of fermions. Both $\mathcal{A}_I$ and $\mathcal{H}_I$ are finite dimensional, so T_I is a finite spectral triple[21] and T_E is the usual spectral triple (2) of a manifold. The spectral dimension of a finite spectral triple is 0 and $\dim(T_E)=\dim(\mathcal{M})=4$: both T_E and T_I are even therefore both $T_E\otimes T_I$ and $T_I\otimes T_E$ are defined.

In this section, we give general results that do not require either T_E to be the spectral triple of a manifold or T_I to be finite. To fix notations we simply assume that T_E is even so that we work with $T_E\otimes T_I$. To study the metric of a noncommutative space, the first goal is to make explicit the set of pure states of the associated algebra. For ω_E and ω_I being pure states of $\mathcal{A}_E$ and $\mathcal{A}_I$, the pair (ω_E,ω_I) is a state of $\mathcal{A}$ which acts as $\omega_E\otimes\omega_I$ (that $\mathbb{I}$ maps to 1 is obvious, the positivity can be seen in Ref. 22 for instance) but this is not necessarily a pure state. Moreover there can be pure states of $\mathcal{A}$ that cannot be written as tensor products. However, as soon as one of the algebras is Abelian, one obtains[23] that $\mathcal{P}(\mathcal{A}_E\otimes\mathcal{A}_I)\simeq\mathcal{P}(\mathcal{A}_E)\times\mathcal{P}(\mathcal{A}_I)$ and any pure state ω of $\mathcal{A}$ writes $\omega=\omega_E\otimes\omega_I$.

In the two-sheets model $\mathcal{A}=C^\infty(\mathcal{M})\otimes\mathbb{C}^2$, therefore any pure state is $\omega_x\otimes\omega_i$ where ω_i, $i=1,2$, is a pure state of $\mathbb{C}^2$ and labels the sheets. It is known[4] that $d(\omega_x\otimes\omega_i,\omega_y\otimes\omega_i)$ is the geodesic distance $L(x,y)$ while $d(\omega_x\otimes\omega_i,\omega_x\otimes\omega_j)$ is a constant. This extends to any product of spectral triples. Once fixed a pure state ω_E, $d(\omega_E\otimes\omega_I,\omega_E\otimes\omega_I')$ depends only on the spectral triple T_I and, similarly, $d(\omega_E\otimes\omega_I,\omega_E'\otimes\omega_I)$ depends only on T_E. This is true even when none of the algebra is commutative: the distance is then defined between states that may be not pure.

Theorem 2: Let d_E, d_I, d be the distance in T_E, T_I, $T_E\otimes T_I$, respectively. For ω_E, ω_E' in $\mathcal{P}(\mathcal{A}_E)$ and ω_I, ω_I' in $\mathcal{P}(\mathcal{A}_I)$,

$$d(\omega_E\otimes\omega_I,\omega_E\otimes\omega_I')=d_I(\omega_I,\omega_I'),$$

$$d(\omega_E\otimes\omega_I,\omega_E'\otimes\omega_I)=d_E(\omega_E,\omega_E').$$

Proof: Let f_j denote the elements of $\mathcal{A}_E$ and m_i those of $\mathcal{A}_I$. A generic element of $\mathcal{A}$ is $a=f^i\otimes m_i$, where the summation index i runs over a finite subset of $\mathbb{N}$. Definition (7) yields

$$[D,a]=[D_E,f^i]\otimes m_i+f^i\chi_E\otimes[D_I,m_i].$$

Multiplying this formula from the left and the right by the unitary operator $\chi_E\otimes\mathbb{I}_I$ allows one to write

$$\|[D_E,f^i]\otimes m_i+f^i\chi_E\otimes[D_I,m_i]\|=\|-[D_E,f^i]\otimes m_i+f^i\chi_E\otimes[D_I,m_i]\|,$$

where we use that $\chi_E=\chi_E^*$ commutes with f^i and anticommutes with D_E. For u,v in a normed space, $2\|u\|\leqslant\|u+v\|+\|u-v\|$, thus

$$\|[D_E,f^i]\otimes m_i\|\leqslant\|[D,a]\|, \tag{8}$$

and $\|f^i\chi_E\otimes[D_I,m_i]\|\leqslant\|[D,a]\|$. One can factorize the left-hand side of Eq. (8) by $\chi_E\otimes\mathbb{I}_I$ in order to have

$$\|f^i\otimes[D_I,m_i]\|\leqslant\|[D,a]\|. \tag{9}$$

For any $\omega_E\in\mathcal{P}(\mathcal{A}_E)$ and $a\in\mathcal{A}_+$, let us define $a_E\in\mathcal{A}_I$ by

$$a_E\doteq\omega_E(f^i)m_i.$$

a_E is self-adjoint. Indeed, positivity of a, i.e., $a=(f^{p^*}\otimes m_p^*)(f^q\otimes m_q)=\frac{1}{2}(f^{pq}\otimes m_{pq}+f^{pq^*}\otimes m_{pq}^*)$ where $f^{pq}\doteq f^{p^*}f^q$ and $m_{pq}=m_p^*m_q$, yields

$$a_E=\tfrac{1}{2}(\omega_E(f^{pq})m_{pq}+\omega_E(f^{pq*})m_{pq}^*)=a_E^*.$$

Thus

$$i[D_I,a_E]=i(\omega_E\otimes\mathbb{I}_I)(f^i\otimes[D_I,m_I])$$

in $\mathcal{B}(\mathcal{H}_I)$ is normal. One knows[23] that for any normal element a of a C^*-algebra, $\|a\|=\sup_{\tau\in\mathcal{S}}|\tau(a)|$, where $\mathcal{S}$ is the set of states. Thus, with $\mathcal{S}_I$ the set of states of $\mathcal{B}(\mathcal{H}_I)$,

$$\begin{aligned}\|[D_I,a_E]\|&=\sup_{\tau_I\in\mathcal{S}_I}|\tau_I([D_I,a_E])|\\&\leqslant\sup_{(\tilde{\omega}_E,\tau_I)\in\mathcal{P}(\mathcal{A}_E)\times\mathcal{S}_I}|(\tilde{\omega}_E\otimes\tau_I)(f^i\otimes[D_I,m_i])|\\&\leqslant\sup_{(\tau_E,\tau_I)\in\mathcal{S}_E\times\mathcal{S}_I}|(\tau_E\otimes\tau_I)(f^i\otimes[D_I,m_i])|\\&=\|f^i\otimes[D_I,m_i]\|,\end{aligned}$$

where we use that $if^i\otimes[D_I,m_i]\in\mathcal{B}(\mathcal{H})$ is also normal. Together with (9),

$$\|[D_I,a_E]\|\leqslant\|[D,a]\|.$$

Since $(\omega_E\otimes\omega_I)(a)-(\omega_E\otimes\omega_I')(a)=\omega_I(a_E)-\omega_I'(a_E)$,

$$d(\omega_E\otimes\omega_I,\omega_E\otimes\omega_I')\leqslant d_I(\omega_I,\omega_I').$$

This upper bound is reached by $\mathbb{I}_E\otimes a_I$ where $a_I\in\mathcal{A}_I$ reaches the supremum for T_I alone, namely $d_I(\omega_I,\omega_I')\doteq|(\omega_I-\omega_I')(a_I)|$ and $1=\|[D_I,\pi_I(a_I)]\|$.

The proof for $d(\omega_E\otimes\omega_I,\omega_E'\otimes\omega_I)$ is similar, using (8) instead of (9). ■

V. METRIC IN THE CONTINUUM×DISCRETE

The key points of Theorem 2 are Eqs. (8) and (9). The first one allows one to forget about the internal part of the commutator and makes sense for states of $\mathcal{A}$ defined by different pure states on $\mathcal{A}_E$ but the same pure state on $\mathcal{A}_I$. When T_E is the spectral triple of a manifold and T_I a finite spectral triple, the noncommutative space described by $T_E\times T_I$ is a fiber bundle over the manifold with a discrete fiber. This can also be seen as the union of several copies of the manifold, indexed by the element of the fiber. Theorem 2 simply says that each of the copies is endowed with the metric of the base. Note that the discussion about the Gromov distance between manifolds with distinct metrics in Ref. 4 may not be transposed here because such manifolds are not described by a tensor product of spectral triples.

In contrast, (9) does not take into account the external part of the commutator and is sufficient to determine the distance between states defined by the same pure state on $\mathcal{A}_I$ (i.e., points on the same fiber within the picture of a continuum×discrete space). Of course the mixed case $d(\omega_E\otimes\omega_I,\omega_E{}'\otimes\omega_I')$—the distance between different points on different copies of the manifold—requires one to take into account both the internal and the external part of the commutator. This makes the computation more difficult. However, for continuum×discrete spaces, some of these distances have a nice interpretation in terms of a discrete Kaluza–Klein model: although the internal space is discrete, the distance appears as the geodesic distance in a ''virtual'' $(4+1)$-dimensional manifold (''virtual'' means that the points between the sheets are not part of the geometry, the embedding into a higher dimensional continuum space is a practical intermediate).

Let us first give a semigeneral result which does not require T_E to be the spectral triple of a manifold (T_E is just supposed to be even to fix notations) but which assumes

$$\mathcal{A}_I\doteq\bigoplus_k\mathcal{A}_k,$$

where k runs over a finite subset of $\mathbb{N}$ and the $\mathcal{A}_k$'s are von Neumann algebras on $\mathbb{C}$. Note that a pure state of a direct sum of algebras is a pure state of one of the algebras, that is

$$\mathcal{P}(A_I)=\bigcup_k\mathcal{P}(\mathcal{A}_k).$$

The reason why we restrict ourselves to von Neumann algebras is that to any normal state[24] ω of $\mathcal{A}_k$ corresponds a projection $\rho\in\mathcal{A}_k$, the so-called support of the state, such that

$$\alpha_\rho(a)\doteq\rho a\rho=\omega(a)\rho. \tag{10}$$

We let $\mathcal{P}(\mathcal{A}_k)_*$ denote the set of normal pure states of $\mathcal{A}_k$. Strictly speaking, the support is defined for normal states of complex algebras. However in the standard model, we shall explicitly exhibit such a projection for the real internal algebra so that, in the following, we deal with an algebra over $\mathbb{K}$ where $\mathbb{K}=\mathbb{C}$ or $\mathbb{R}$. Typically, in physical examples, the $\mathcal{A}_k$ are matrix algebras for which it is known that all states are normal; ρ is nothing but a density matrix. When normal pure states of different components $\mathcal{A}_k$ are involved and D_I commutes with the direct sum of their support, one obtains as an immediate consequence of Lemma 1 that $\mathcal{A}_I$ reduces to $\mathbb{K}^2$.

Proposition 3: Let ρ, ρ' *be the supports of two distinct normal pure states* $\omega_k, \omega_{k'} \in \mathcal{P}(\mathcal{A}_k)_*$, *and let* $p \doteq \rho \oplus \rho'$. *If* $[D_I, p] = 0$ *then, for any* $\omega_E, \omega'_E \in \mathcal{P}(\mathcal{A}_E)$,

$$d(\omega_E \otimes \omega_k, \omega'_E \otimes \omega_{k'}) = d_e(\omega_E \otimes \omega_1, \omega'_E \otimes \omega_2),$$

where ω_1, ω_2 *are the pure states of* $\mathbb{K}^2$ *and* d_e *is the distance associated with* $T_e \doteq T_E \otimes T_r$ *with*

$$\mathcal{A}_r \doteq \mathbb{K}^2, \quad \mathcal{H}_r \doteq p\mathcal{H}_I, \quad D_r \doteq pD_I p|_{\mathcal{H}_r}.$$

Proof: The projection $e \doteq \mathbb{I}_E \otimes p \in \mathcal{A}$ defines the restricted triple $T_e \doteq (\mathcal{A}_e, \mathcal{H}_e, D_e)$ in which

$$\mathcal{A}_e \doteq \alpha_e(\mathcal{A}) = \mathcal{A}_E \otimes \alpha_p(\mathcal{A}_I).$$

Since ρ and ρ' correspond to different components of $\mathcal{A}_I$ they are orthogonal, therefore

$$\alpha_p(\mathcal{A}_I) = \alpha_\rho(\mathcal{A}_k) \oplus \alpha_{\rho'}(\mathcal{A}_{k'}) = \omega_k(\mathcal{A}_k)\rho \oplus \omega_{k'}(\mathcal{A}_{k'})\rho'$$

by (10). $\omega_k, \omega_{k'}$ being surjective on $\mathbb{K}$, $\omega_k(\mathcal{A}_k)\rho$ and $\omega_{k'}(\mathcal{A}_{k'})\rho'$ are isomorphic to $\mathbb{K}$. Hence

$$\mathcal{A}_e = \mathcal{A}_E \otimes \mathbb{K}^2.$$

The state $\omega_i \in \mathcal{P}(\mathbb{K}^2)$ extracts the ith component of a pair of elements of $\mathbb{K}$. In detail, for $a_I \in \mathcal{A}_I$,

$$\alpha_p(a_I) = \omega_k(a_I)\rho \oplus \omega_{k'}(a_I)\rho', \tag{11}$$

so that $\omega_1 \circ \alpha_p(a_I) = \omega_k(a_I)$. Since e acts like the identity on $\mathcal{A}_E$,

$$(\omega_E \otimes \omega_1) \circ \alpha_e = \omega_E \otimes (\omega_1 \circ \alpha_p) = \omega_E \otimes \omega_k,$$

and $(\omega'_E \otimes \omega_2) \circ \alpha_e = \omega'_E \otimes \omega_{k'}$. By hypothesis $[D, e] = \chi_E \otimes [D_I, p] = 0$ so Lemma 1 yields

$$d(\omega_E \otimes \omega_k, \omega'_E \otimes \omega_{k'}) = d_e(\omega_E \otimes \omega_1, \omega'_E \otimes \omega_2).$$

$\mathcal{H}_r$ and D_r are given by Lemma 1. ■

To explicitly compute d_e, we now focus on the case of a continuum$\times$discrete space and we take for T_E the spectral triple of a manifold (2). To simplify the notations, the pure state $\omega_x \otimes \omega_k$ is denoted by x_k. The main result of this section is that the internal space is orthogonal to the manifold, in the sense of the Pythagorean theorem, as soon as the Dirac operator commutes with the sum of the density matrices.

Theorem 4: *Let* $\omega_k, \omega_{k'} \in \mathcal{P}(\mathcal{A}_k)_*, \mathcal{P}(\mathcal{A}_{k'})_*$, $k \neq k'$. *Let* ρ, ρ' *be their supports and* $p \doteq \rho \oplus \rho'$. *If* $[D_I, p] = 0$, *then for any points* x, y *in* $\mathcal{M}$,

$$d(x_k, y_{k'})^2 = d(x_k, y_k)^2 + d(y_k, y_{k'})^2.$$

Proof: The proof consists of three steps. First the problem is reduced to a two-sheets model. Then the distance is shown to be the geodesic distance within a $(4+1)$-dimensional Riemannian manifold which, third, satisfies the Pythagorean theorem.

(1) With notations of Proposition 3,

$$d(x_k, y_{k'}) = d_e(x_1, y_2). \tag{12}$$

Let us be more explicit on $\mathcal{H}_r$, π_r, and D_r,

$$\mathcal{H}_r \doteq p\mathcal{H}_I = \mathcal{H}_k \oplus \mathcal{H}_{k'}, \tag{13}$$

where $\mathcal{H}_k \doteq \rho\mathcal{H}_I$ and $\mathcal{H}_{k'} \doteq \rho'\mathcal{H}_I$. Following (11), one lets $a_r = \omega_k(a_I)\rho \oplus \omega_{k'}(a_I)\rho'$ denote a generic element of $\mathcal{A}_r$. Clearly $\pi_r(\rho) = \mathbb{I}_k$ so

$$\pi_r(a_r) = \omega_k(a_I)\mathbb{I}_k \oplus \omega_{k'}(a_I)\mathbb{I}_{k'}. \tag{14}$$

D_r is the restriction to $\mathcal{H}_r$ of the projection of D_I on $\mathcal{H}_r$, namely

$$D_r \doteq \begin{pmatrix} V & M \\ M^* & W \end{pmatrix}, \tag{15}$$

where M is a linear map from $\mathcal{H}_k$ to $\mathcal{H}_{k'}$, and V, W are endomorphisms of $\mathcal{H}_k$, $\mathcal{H}_{k'}$, respectively. M is supposed to be nonzero for the contrary makes D_r commuting with π_r, that is all states of $\mathcal{A}$ defined by ω_k are at infinite distance from any states defined by $\omega_{k'}$.

Equations (13)–(15) associated with (11) fully determine the triple T_r, and thus T_e. Omitting ρ and ρ' appearing in (11), a generic element of $\mathcal{A}_e$ writes

$$a = f^i \otimes \omega_k(m_i) \oplus f^i \otimes \omega_{k'}(m_i) = f \oplus g,$$

where $m_i \in \mathcal{A}_I$ and $f^i, f \doteq f^i\omega_k(m_i), g \doteq f^i\omega_{k'}(m_i) \in C^\infty(\mathcal{M})$. In accordance with (1), we assume that $f \oplus g$ is positive, i.e., f and g are real functions. x_1 and y_2 act as

$$x_1(a) = f(x), \quad y_2(a) = g(y).$$

a is represented by

$$f\mathbb{I}_E \otimes \mathbb{I}_k \oplus g\mathbb{I}_E \otimes \mathbb{I}_{k'}$$

and the Dirac operator $D_e = i\partial\!\!\!/ \otimes \mathbb{I}_I + \gamma^5 \otimes D_r$ is such that

$$[D_e, a] = \begin{pmatrix} i\partial\!\!\!/ f \otimes \mathbb{I}_k & (g-f)\gamma^5 \otimes M \\ \overline{(f-g)}\gamma^5 \otimes M^* & i\partial\!\!\!/ \otimes \mathbb{I}_{k'} \end{pmatrix}. \tag{16}$$

(2) Let us show that d_e coincides with the geodesic distance on the compact manifold

$$\mathcal{M}' \doteq [0,1] \times \mathcal{M},$$

with coordinates $x'^a = (t, x^\mu)$, equipped with the metric

$$\{g^{ab}(x')\} \doteq \begin{pmatrix} \|M\|^2 & 0 \\ 0 & g^{\mu\nu}(x) \end{pmatrix},$$

and made a spin manifold by adding to the previous γ-matrices

$$\gamma^t = \|M\|\gamma^5.$$

Thanks to Sec. III, it is enough to show that d_e coincides with the distance L' of the triple

$$\mathcal{A}' = C^\infty(\mathcal{M}'), \quad \mathcal{H}' = L_2(\mathcal{M}', S), \quad D' = i\gamma^a\partial_a = i\gamma^t\partial_t + i\partial\!\!\!/.$$

To proceed, let $\mathcal{A}''$ be the subset of $\mathcal{A}'_+$ consisting of all functions

$$\phi(t,x) \doteq (1-t)g(x) + tf(x),$$

where f and g are any real functions on $\mathcal{M}$. Then

$$\|[D',\phi]\|^2=\|\gamma^a\partial_a\phi\|^2=\sup_{(t,x)\in\mathcal{M}'}\{g^{ab}(t,x)\,\partial_a\phi(t,x)\,\partial_b\phi(t,x)\}$$
$$\leqslant\sup_{x\in\mathcal{M}}\{\,|(f-g)(x)|^2\|M\|^2+\sup_{t\in[0,1]}P(t,x)\,\},$$

where

$$P(t,x)\doteq t^2\|\vec{\nabla}(f-g)(x)\|^2+2tg^{\mu\nu}(x)\,\partial_\mu(f-g)(x)\,\partial_\nu g(x)+\|\vec{\nabla}g(x)\|^2$$

is a parabola in t of positive leading coefficient, i.e., which reaches its maximum for $t=0$ or 1. Note that

$$P(0,x)=\|\vec{\nabla}g(x)\|^2,\quad P(1,x)=\|\vec{\nabla}f(x)\|^2$$

and, thanks to (16),

$$\left\|\begin{pmatrix}\mathbb{I}_E\otimes\mathbb{I}_k & 0\\ 0 & 0\end{pmatrix}[D_e,a]\begin{pmatrix}\mathbb{I}_E\otimes\mathbb{I}_k & 0\\ 0 & \gamma^5\otimes\mathbb{I}_{k'}\end{pmatrix}\right\|^2=\left\|\begin{pmatrix}i\not{\partial}f\otimes\mathbb{I}_k & (g-f)\mathbb{I}_E\otimes M\\ 0 & 0\end{pmatrix}\right\|^2$$
$$=\sup_{x\in\mathcal{M}}\{\,\|\vec{\nabla}f(x)\|^2+|f(x)-g(x)|^2\|M\|^2\,\}$$
$$\leqslant\|[D_e,a]\|^2.$$

Similarly, one has $\sup_{x\in\mathcal{M}}\{\|\vec{\nabla}g(x)\|^2+|f(x)-g(x)|^2\|M\|^2\}\leqslant\|[D_e,a]\|^2$, hence

$$\|[D',\phi]\|\leqslant\|[D_e,a]\|.$$

Consequently, since $x_1(a)-y_2(a)=\phi(0,x)-\phi(1,y)$,

$$d_e(x_1,y_2)\leqslant\sup_{\phi\in\mathcal{A}''}\{|\phi(0,x)-\phi(1,y)|/\|[D',\phi]\leqslant1\|\}\leqslant L'((0,x),(1,y)).\tag{17}$$

Proving the converse inequality calls for more precision on the geometry of $\mathcal{M}'$. Because $\{g^{ab}(x')\}$ is block diagonal and does not depend on t, the coefficients of the Levi-Civita connection are

$$\Gamma^t_{t\mu}=\Gamma^t_{\mu t}=\tfrac{1}{2}g^{tt}\partial_\mu g_{tt},\quad \Gamma^\mu_{tt}=-\tfrac{1}{2}g^{\mu\nu}\partial_\nu g_{tt},\quad \Gamma^\mu_{t\nu}=\Gamma^\mu_{\nu t}=\Gamma^t_{tt}=\Gamma^t_{\mu\nu}=0,$$

where $g_{tt}=(g^{tt})^{-1}=\|M\|^{-2}$. The geodesic equations read

$$\frac{\mathrm{d}^2t}{\mathrm{d}\tau^2}+g^{tt}(\partial_\mu g_{tt})\frac{\mathrm{d}t}{\mathrm{d}\tau}\frac{\mathrm{d}x^\mu}{\mathrm{d}\tau}=0,\tag{18}$$

$$\frac{\mathrm{d}^2x^\mu}{\mathrm{d}\tau^2}-\frac{1}{2}g^{\mu\nu}(\partial_\nu g_{tt})\frac{\mathrm{d}t}{\mathrm{d}\tau}\frac{\mathrm{d}t}{\mathrm{d}\tau}+\Gamma^\mu_{\lambda\rho}\frac{\mathrm{d}x^\lambda}{\mathrm{d}\tau}\frac{\mathrm{d}x^\rho}{\mathrm{d}\tau}=0,\tag{19}$$

and, because g_{tt} does not depend on x^μ, reduce to

$$\frac{\mathrm{d}t}{\mathrm{d}\tau}=\text{constant}\doteq g^{tt}K,\quad\text{and}\quad\frac{\mathrm{d}^2x^\mu}{\mathrm{d}\tau^2}+\Gamma^\mu_{\lambda\rho}\frac{\mathrm{d}x^\lambda}{\mathrm{d}\tau}\frac{\mathrm{d}x^\rho}{\mathrm{d}\tau}=0\,,\tag{20}$$

where K is a real constant. In other terms, the projection to $\mathcal{M}$ of a geodesic $\mathcal{G}'$ of $\mathcal{M}'$ is a geodesic $\mathcal{G}$ of $\mathcal{M}$, and the projection of $\mathcal{G}'$ to the submanifold $[0,1]\times\mathcal{G}$ is a straight line (i.e., a geodesic of the submanifold). Let $\{x^a(\tau)\}$ be a geodesic in $\mathcal{M}'$ parametrized by its length element $\mathrm{d}\tau$. Note that, using (20),

$$1=\frac{\mathrm{d}\tau^2}{\mathrm{d}\tau^2}=g_{\mu\nu}\frac{\mathrm{d}x^\mu}{\mathrm{d}\tau}\frac{\mathrm{d}x^\nu}{\mathrm{d}\tau}+g^{tt}K^2. \tag{21}$$

Let $\mathrm{d}s$ be the line element of $\mathcal{M}$. Assuming that $g^{tt}K^2\neq 1$ (this will be discussed later),

$$\mathrm{d}\tau^2=\frac{\mathrm{d}s^2}{1-g^{tt}K^2},\quad \mathrm{d}t=\frac{\mathrm{d}t}{\mathrm{d}\tau}\mathrm{d}\tau=\frac{g^{tt}K\,\mathrm{d}s}{\sqrt{1-g^{tt}K^2}}. \tag{22}$$

For q in $\mathcal{M}$, let $\mathcal{G}'_q$ be the minimum geodesic of $\mathcal{M}'$ between $(0,q)$ and $(1,y)$, and $\mathcal{G}_q$ its projection on $\mathcal{M}$. Let us define the continuous function over $\mathcal{M}$,

$$f_0(q)=\sqrt{1-g^{tt}K^2}L(q)=\sqrt{1-g^{tt}K^2}\int_{\mathcal{G}_q}\mathrm{d}s,$$

where L has been defined in (3). Take $a_0=(f_0,g_0)$, where $g_0=f_0-K$. Then

$$x_1(a_0)-y_2(a_0)=f_0(x)-g_0(y)=f_0(x)+K. \tag{23}$$

But the second equation in (22) gives

$$1=\int_{\mathcal{G}'_x}\mathrm{d}t=\frac{g^{tt}K}{\sqrt{1-g^{tt}K^2}}\int_{\mathcal{G}_x}\mathrm{d}s,$$

inserted in (23) as $K1$,

$$x_1(a_0)-y_2(a_0)=\sqrt{1-g^{tt}K^2}\int_{\mathcal{G}_x}\mathrm{d}s+\frac{g^{tt}K^2}{\sqrt{1-g^{tt}K^2}}\int_{\mathcal{G}_x}\mathrm{d}s=\frac{1}{\sqrt{1-g^{tt}K^2}}\int_{\mathcal{G}_x}\mathrm{d}s.$$

Using the first equation in (22) one obtains

$$x_1(a_0)-y_2(a_0)=\int_{\mathcal{G}'_x}\mathrm{d}\tau=L'((0,x),(1,y)). \tag{24}$$

Moreover, $\not\partial f_0=\not\partial g_0$ and $\partial_\mu f_0=\sqrt{1-g^{tt}K^2}\partial_\mu L$, so (16) yields

$$\|[D_e,a_0]\|^2=\sup_{q\in\mathcal{M}}\{g^{\mu\nu}(q)\partial_\mu f_0(q)\partial_\nu f_0(q)+g^{tt}K^2\}=\sup_{q\in\mathcal{M}}\{(1-g^{tt}K^2)\|\vec{\nabla}L(q)\|^2+g^{tt}K^2\}.$$

Recalling (4), this gives $\|[D_e,a_0]\|\leqslant 1$ so, with (24) (and the same remark as the one at the end of Sec. III, concerning the nonsmoothness of f_0 at y),

$$d_e(x_1,y_2)\geqslant L'((0,x),(1,y)).$$

Together with (17) and (12),

$$d(x_k,y_{k'})=L'((0,x),(1,y)). \tag{25}$$

This result holds as long as $g^{tt}K^2 \neq 1$. If this is not true, then $U \doteq (\mathrm{d}x^\mu/\mathrm{d}\tau)\partial_\mu \in TM$ is zero for (21) indicates that $g(U,U)=0$ and $\mathcal{M}$ is Riemannian. In other words, $x^\mu(\tau)$ is a constant. This cannot be the equation of $\mathcal{G}'_x$ unless $x=y$. As a conclusion, (25) holds as soon as $x \neq y$.

When $x=y$, (12) gives $d(y_k,y_{k'})=d_e(y_1,y_2)$. With d_r denoting the distance associated with the triple T_r alone, Proposition (2) yields $d_e(y_1,y_2)=d_r(\omega_1,\omega_2)$, which is nothing but the distance of the simplest two-points space and equals[4] $1/\|M\|$. Thus

$$d(y_k,y_{k'})=\frac{1}{\|M\|}. \tag{26}$$

The projection $\mathcal{G}_y$ of the geodesic $\mathcal{G}'_x=\mathcal{G}'_y$ is, by (19), a geodesic between y and y, that is to say a point. $\mathcal{G}'_y$ reduces to a straight line in the hyperplane. Thus $\mathrm{d}\tau^2=g_{tt}\,\mathrm{d}t^2$ and

$$L'((0,y),(1,y))=\sqrt{g_{tt}}\int_{\mathcal{G}'_y}\mathrm{d}t=\sqrt{g_{tt}}=\frac{1}{\|M\|}.$$

Consequently $d(y_k,y_{k'})=L'((0,y),(1,y))$ and (25) holds even if $x=y$.

(3) The last step is to show that (25) satisfies the Pythagorean equality. g^{tt} being a constant, Eq. (22) indicates that $\mathrm{d}\tau$ and $\mathrm{d}s$ are equal up to a constant factor. In this way, one may parametrize a geodesic of $\mathcal{M}'$ by $\mathrm{d}s$ rather than $\mathrm{d}\tau$ and obtains, thanks to the geodesic equations,

$$\mathrm{d}t=g^{tt}K'\,\mathrm{d}s,$$

where K' is a real constant. Then

$$\mathrm{d}\tau^2=g_{tt}\,\mathrm{d}t^2+\mathrm{d}s^2=\mathrm{d}s^2(1+g^{tt}K'^2).$$

Thus

$$L'((0,x),(1,y))=\sqrt{1+g^{tt}K'^2}\int_{\mathcal{G}'_x}\mathrm{d}s=\sqrt{1+g^{tt}K'^2}L(x,y)=\sqrt{L(x,y)^2+g^{tt}K'^2L(x,y)^2}. \tag{27}$$

On one side, Theorem 2 gives $L(x,y)=d(x_k,y_k)$. On the other side,

$$g^{tt}K'^2L(x,y)^2=g_{tt}\left(\int_{\mathcal{G}'_x}g^{tt}K'\,\mathrm{d}s\right)^2=g_{tt}\left(\int_{\mathcal{G}'_x}\mathrm{d}t\right)^2=g_{tt}=\frac{1}{\|M\|^2}=d^2(y_k,y_{k'})$$

by (26). Together with (25) and (27),

$$d(x_k,y_{k'})^2=d(x_k,y_k)^2+d^2(y_k,y_{k'}).$$

■

VI. FLUCTUATIONS OF THE METRIC

For a complete presentation of the material of this section and a justification of the terminology, see Refs. 4 and 1. To a triple $(\mathcal{A},\mathcal{H},D)$, the axiom of reality adds an operator J, called the real structure, such that $[JaJ^{-1},b]=0$ for any $a,b\in\mathcal{A}$. This allows one to define a right action of $\mathcal{A}$ over $\mathcal{H}$ which makes sense because of the noncommutativity of the algebra. To define a notion of unitarily equivalent spectral triples preserving the operator J, a unitary element u of $\mathcal{A}$ is implemented by the operator $U\doteq uJuJ^{-1}$ rather than the operator u. Then the action of u defines the *gauge transformed* triple $(\mathcal{A},\mathcal{H},D_A)$ where

$$D_A\doteq UDU^*=D+A+JAJ^{-1} \tag{28}$$

with

$$A \doteq u[D,u^{-1}].$$

The self-adjoint operator A governs the failure of invariance of D under a gauge transformation.[4] Under a gauge transformation, A transforms like a usual vector potential. Since in electrodynamics the vector potential is a one-form, one defines the space Ω^1 of one-form of the noncommutative space $(\mathcal{A},\mathcal{H},D)$ as the set of elements

$$a^i[D,b_i],$$

where $a^i,b_i \in \mathcal{A}$. Note that we use the simplifying notation Ω^1 rather than Ω^1_D, more common in the literature, because we only deal with zero-forms and one-forms (Ω^n_D differs from Ω^n for $n \geqslant 2$). Since A is self-adjoint, the set of vector potentials is simply the subset of self-adjoint elements of Ω^1. For any vector potential A, D_A defined by (28) is called the covariant Dirac operator.

The distance is not invariant under a gauge transformation and the metric is said to fluctuate. To study such fluctuations, one has to replace D by D_A everywhere in the preceding sections. A well-known result makes this replacement less studious than it seems.

Lemma 5: $[a,J\omega J^{-1}]=0, \forall\, \omega \in \Omega^1, a \in \mathcal{A}$.

Proof: $[J^{-1}aJ,[D,b_i]]=0$ (first order axiom) and $[a,Ja^iJ^{-1}]=0$ (axiom of reality) yield

$$\begin{aligned}[a,J\omega J^{-1}] &= [a,Ja^i[D,b_i]J^{-1}] \\ &= aJa^iJ^{-1}J[D,b_i]J^{-1} - Ja^i[D,b_i]J^{-1}a \\ &= Ja^i[D,b_i]J^{-1}a - Ja^i[D,b_i]J^{-1}a = 0.\end{aligned}$$

■

As an immediate consequence,

$$[D_A,a]=[D+A,a]. \tag{29}$$

Let us now work out the one-forms of a tensor product triple $T_E \otimes T_I$. In Refs. 25 and 26 it is shown that

$$\Omega^1 = \Omega^1_E \otimes \Omega^0_I + \chi_E \Omega^0_E \otimes \Omega^1_I,$$

where $\Omega^0_E = \mathcal{A}_E$ is the set of zero-forms of $\mathcal{A}_E$, and similar definitions for the other terms. When T_E is the spectral triple of a manifold,

$$\Omega^1_E \ni f^j[i\not{\partial},g_j\mathbb{I}_E] = if^j(\gamma^\mu \partial_\mu g_j) = i\gamma^\mu f_\mu,$$

where $f^j,g_j,f_\mu \doteq f^j\partial_\mu g_j \in C^\infty(\mathcal{M})$. A one-form of the total spectral triple is

$$\Omega^1 \ni i\gamma^\mu f^i_\mu \otimes a_i + \gamma^5 h^j \otimes m_j,$$

where $a_i \in \mathcal{A}_I$, $h^j \in C^\infty(\mathcal{M})$, $m_j \in \Omega^1_I$. A vector potential is

$$A = i\gamma^\mu \otimes A_\mu + \gamma^5 \otimes H \tag{30}$$

with $A_\mu \doteq f^i{}_\mu a_i$ an $\mathcal{A}_I$-valued skew-adjoint vector field (over $\mathcal{M}$) and $H \doteq h^j m_j$ a Ω^1_I-valued self-adjoint scalar field. For a matrix algebra (or a direct sum of matrix algebras), the skew-adjoint elements form the Lie algebra of the Lie group of unitarities. This Lie group represents the gauge group of the theory, thus A_μ is a gauge potential. In Ref. 1 a formula is given for the fluctuations of the metrics due to A_μ with a zero H. This involves the holonomy of the gauge connexion. Here, we focus on the fluctuations coming from the scalar field H, and for simplicity we assume that $A_\mu = 0$. Then (29) becomes

$$[D_A,a]=[D+\gamma^5\otimes H,a]. \tag{31}$$

From now on, we write $D_A\doteq D+\gamma^5\otimes H$. For simplicity, d still denotes the distance associated with the triple $(\mathcal{A},\mathcal{H},D_A)$. Remembering definition (7), a scalar fluctuation substitutes

$$D_H\doteq D_I+H$$

for D_I. The main difference is that the internal Dirac operator D_H now depends on x so that each point x of the manifold defines an internal triple

$$T_I^x\doteq(\mathcal{A}_I,\mathcal{H}_I,D_H(x)).$$

This interpretation of scalar fluctuations perfectly fits to the adaptation of Theorem 2.

Theorem 2′: *Let L be the geodesic distance in $\mathcal{M}$ and d_x the distance of the spectral triple T_I^x alone. For $x,y\in\mathcal{M}$ and $\omega_k,\omega_{k'}\in\mathcal{P}(\mathcal{A}_I)_*$,*

$$d(x_k,x_{k'})=d_x(\omega_k,\omega_{k'}),$$

$$d(x_k,y_k)=L(x,y).$$

Proof: The adaptation of the proof of Theorem 2 is straightforward. Notations are similar except that ω_E is now ω_x so that a_E is replaced by a_x. With $H=h^j m_j$,

$$\begin{aligned}[D_H(x),a_x]=[D_I+\omega_x(h^j)m_j,\omega_x(f^i)m_i]&=\omega_x(f^i)[D_I,m_i]+\omega_x(h^j)\omega_x(f^i)[m_j,m_i]\\&=(\omega_x\otimes\mathbb{I}_I)(f^i\otimes[D_I,m_i]+h^jf^i\otimes[m_j,m_i])\\&=(\omega_x\otimes\mathbb{I}_I)(f^i\otimes[D_H,m_i]).\end{aligned} \tag{32}$$

Then, $i[D_H(x),a_x]$ being normal,

$$\begin{aligned}\|[D_H(x),a_x]\|=\sup_{\tau_I\in\mathcal{S}_I}|\tau_I([D_H(x),a_x])|&=\sup_{\tau_I\in\mathcal{S}_I}|(\omega_x\otimes\tau_I)(f^i\otimes[D_H,m_i])|\\&\leqslant\sup_{\tilde\omega_E\otimes\tau_I\in\mathcal{P}(\mathcal{A}_E)\otimes\mathcal{S}_I}|(\tilde\omega_E\otimes\omega_I)(f^i\otimes[D_H,m_i])|\\&\leqslant\|f^i\otimes[D_H,m_i]\|.\end{aligned}$$

Equation (9) being replaced by $\|f^i\otimes[D_H,m_i]\|\leqslant\|[D_A,a]\|$, one obtains

$$\|[D_H(x),a_x]\|\leqslant\|[D_A,a]\|.$$

The rest of the proof is then similar as in Theorem 2. ■

Note that in (32) we use that ω_x is a character, i.e., that $\mathcal{A}_E$ is Abelian.

Applied to the two-sheets model, Theorem 2′ simply says that the distance between the sheets is encoded by a scalar field, as has already been shown in Ref. 16 [see also Ref. 7 for a $M_2(\mathbb{C})\oplus\mathbb{C}$ model]. Theorem 4 is modified in a more serious way for the fluctuation introduces an x-dependence for the coefficients of the Kaluza–Klein metric.

Theorem 4′: *Let $\omega_k,\omega_{k'}\in\mathcal{P}(\mathcal{A}_k)_*,\mathcal{P}(\mathcal{A}_{k'})_*$, $k\neq k'$. Let ρ,ρ' be the associated projections and $p\doteq\rho\oplus\rho'$. If $[D_H,p]=0$ for any points of $\mathcal{M}$, then for any points $x,y\in\mathcal{M}$,*

$$d(x_k,y_{k'})=L'((0,x),(1,y)),$$

where L' is the geodesic distance of the spin manifold $\mathcal{M}'\doteq[0,1]\times\mathcal{M}$ equipped with the metric

$$\begin{pmatrix}\|M(x)\|^2 & 0\\ 0 & g^{\mu\nu}(x)\end{pmatrix}$$

in which $g^{\mu\nu}$ is the metric of $\mathcal{M}$ and M is the restriction to the representation of $\mathcal{A}_{k'}$ of the projection of D_H on the representation of $\mathcal{A}_k$.

Proof: Unless otherwise made precise, notations are similar to Theorem 4. The first part of the proof is hardly modified. Let $\psi^r \otimes \xi_r \in \mathcal{H}$. Recalling (31) and the definition (30) of H,

$$[D_A, a]\psi^r \otimes \xi_r = \gamma^5 \psi_r \otimes [D_I, p]\xi_r + \gamma^5 h^j \psi_r \otimes [m_j, p]\xi_r \in \mathcal{H}.$$

Evaluated at $x \in \mathcal{M}$, the above expression yields

$$[D_A, a]\psi^r(x) \otimes \xi_r = \gamma^5 \psi_r(x) \otimes [D_I + H(x), p]\xi_r = 0$$

by hypothesis, which means that $[D_A, a]$ is the zero endomorphism of $\mathcal{H}$ so that Lemma 3 applies and

$$d(x_k, y_{k'}) = d_e(x_1, y_2).$$

The only difference with Theorem 4 is that D_r now depends on x. For instance when $\mathcal{A}_I$ is finite dimensional then M is a matrix whose entries are scalar fields on $\mathcal{M}$.

Now $g^{tt}(x) \doteq \|M(x)\|^2$ depends on x but is still independent with respect to t. The geodesic equations (18) and (19) no longer reduce to (20) but

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}\tau}\left(g_{tt}\frac{\mathrm{d}t}{\mathrm{d}\tau}\right) &= \left(\frac{\mathrm{d}}{\mathrm{d}\tau}g_{tt}\right)\frac{\mathrm{d}t}{\mathrm{d}\tau} + g_{tt}\frac{\mathrm{d}}{\mathrm{d}\tau}\left(\frac{dt}{d\tau}\right) \\
&= (\partial_\mu g_{tt})\frac{\mathrm{d}t}{\mathrm{d}\tau}\frac{\mathrm{d}x^\mu}{\mathrm{d}\tau} + g_{tt}\frac{\mathrm{d}^2 t}{\mathrm{d}\tau^2} \\
&= g_{tt}\left(g^{tt}(\partial_\mu g_{tt})\frac{\mathrm{d}t}{\mathrm{d}\tau}\frac{\mathrm{d}x^\mu}{\mathrm{d}\tau} + \frac{\mathrm{d}^2 t}{\mathrm{d}\tau^2}\right) \\
&= 0
\end{aligned}$$

by (18). Thus $g_{tt}(\mathrm{d}t/\mathrm{d}\tau) = K$ is a constant. This is almost the first equation in (20), except that

$$\frac{\mathrm{d}t}{\mathrm{d}\tau} = K g^{tt}(x) \tag{33}$$

now depends on x. $a_0 = (f_0, g_0)$ is defined by

$$f_0(q) \doteq \int_{\mathcal{G}_q} \sqrt{1 - K^2 g^{tt}}\,\mathrm{d}s, \quad g_0 \doteq f_0 - K, \tag{34}$$

where $\mathcal{G}'_q$ is the minimal geodesics from $(0,q)$ to the fixed point $(1,y)$ and $\mathcal{G}_q$ its projection to $\mathcal{M}$ (note that $\mathcal{G}_q$ is no longer a geodesic of $\mathcal{M}$). Assuming that

$$K^2 g^{tt}(p) \neq 1 \tag{35}$$

for any $p \in \mathcal{G}_q$ allows one to write

$$\mathrm{d}\tau = \frac{\mathrm{d}s}{\sqrt{1 - K^2 g^{tt}}}$$

and then

$$1=\int_{\mathcal{G}'_q}\mathrm{d}t=\int_{\mathcal{G}'_q}\frac{\mathrm{d}t}{\mathrm{d}\tau}\mathrm{d}\tau=\int_{\mathcal{G}_q}\frac{Kg^{tt}}{\sqrt{1-K^2g^{tt}}}\mathrm{d}s. \tag{36}$$

If (35) does not hold, we call G the set of points p of $\mathcal{G}_q$ for which $1-K^2g^{tt}(p)=0$. G' is the corresponding subset of $\mathcal{G}'_q$. For any $p'\in\mathcal{G}'_q$, (33) yields

$$\frac{\mathrm{d}t}{\mathrm{d}\tau}\mathrm{d}\tau=K^{-1}\,\mathrm{d}\tau,$$

and (36) is replaced by

$$1=\int_{\mathcal{G}_q/G}\frac{Kg^{tt}}{\sqrt{1-K^2g^{tt}}}\mathrm{d}s+\int_{G'}K^{-1}\,\mathrm{d}\tau.$$

Inserted as $K1$ in $x_1(a_0)-y_2(a_0)=f_0(x)+K$, this gives

$$\begin{aligned}x_1(a_0)-y_2(a_0)&=\int_{\mathcal{G}_x}\sqrt{1-K^2g^{tt}}\,\mathrm{d}s+\int_{\mathcal{G}_x/G}\frac{K^2g^{tt}}{\sqrt{1-K^2g^{tt}(x)}}\mathrm{d}s+\int_{G'}\mathrm{d}\tau\\&=\int_{G}\sqrt{1-K^2g^{tt}}\,\mathrm{d}s+\int_{\mathcal{G}_x/G}\frac{\mathrm{d}s}{\sqrt{1-K^2g^{tt}(x)}}+\int_{G'}\mathrm{d}\tau\\&=\int_{\mathcal{G}'_x/G'}\mathrm{d}\tau+\int_{G'}\mathrm{d}\tau\\&=L'((0,x),(1,y)).\end{aligned}$$

The function $f_0(q)$ is in the vicinity of q by definition (34) constant on a codimension 1 hypersurface through q. Choosing an adapted reference frame with $\{x^1,x^2,x^3\}$ being the coordinates in the hypersurface and x^0 the normal coordinate, one has $\mathrm{d}s(q)=\sqrt{g_{00}(q)}\mathrm{d}x^0$ and $\partial_\mu f_0(q)=\delta^0_\mu\partial_0 f_0(q)$, giving

$$\partial_\mu f_0(q)=\delta^0_\mu\sqrt{1-K^2g^{tt}(q)}\sqrt{g_{00}(q)},$$

$$g^{\mu\nu}(q)\partial_\mu f_0(q)\partial_\nu f_0(q)=g^{00}(1-g^{tt}K^2)g_{00}=1-g^{tt}K^2,$$

which leads to $\|[D_e,a_0]\|=1$. Hence the result. ■

A few comments about this theorem. First, since all the coefficients of the metric depend on x, there is no way that the geodesic distance satisfies the Pythagorean theorem. Second, a metric is nondegenerate by definition, and we implicitly assume that $M(x)$ never cancels. This was assumed in Theorem 4 to make the distance finite. Here the point is more subtle for the field M may be zero for some points x. Let $\ker(M)\subset\mathcal{M}$ be the set of such points. For any $q\in\ker(M)$, $d((0,q),(1,q))=+\infty$ by Proposition 2′. Moreover,

$$\begin{aligned}d((0,q),(1,q))&\leqslant d((0,q),(0,x))+d((0,x),(1,y))+d((1,y),(1,q))\\&\leqslant L(p,x)+d((0,x),(1,y))+L(y,q),\end{aligned}$$

so $d((0,x),(1,y))=+\infty$ for any $x,y\in\mathcal{M}$, which contradicts Theorem 4′ if $x=y\notin\ker(M)$. One solution is to assume that any point (t,q) with $q\in\ker(M)$ is at infinite distance from any other point, and define $\mathcal{M}'$ as $[0,1]\times\mathcal{M}/\ker(M)$. If any path between x and y crosses $\ker(M)$, this operation splits $\mathcal{M}'$ into disconnected parts. A better solution is to take into account the nonscalar part A_μ of the fluctuation. [In physical models, $M(x)$ is the representation of the Higgs field in the unbroken phase. Then, at $M=0$ the Higgs potential reaches its local maximum. Neglecting the

gauge potential A_μ, the Faddeev–Popov determinant of the t'Hooft gauge-fixing condition is zero at the maximum of the Higgs potential. This leads to a Gribov problem and questions a quantum treatment of $M(x)$ without gauge field. (observation by Helmuth Hüffel)] This goes beyond the aim of this paper and the reader should consult Ref. 1. ker M is the set of points where fermions have no mass. It could be interesting to link the degeneracy of the metric to singularities when passing from massive to massless fermions.

VII. THE STANDARD MODEL AND OTHER EXAMPLES

We shall investigate the metric of spaces whose internal part is one of those described in Ref. 2. We also give some indications on the distance in the standard model.

A. Commutative spaces

We call commutative space a spectral triple whose internal algebra is $\mathbb{C}^k$, $k\in\mathbb{N}$. Any k-tuple of complex numbers $a=(a^1,\ldots,a^k)$ is represented by a diagonal matrix. For two pure states $\omega_u,\omega_v (u,v\in[1,k])$, $\rho_u\oplus\rho_v$ is the matrix with null coefficients except 1 on the uth and vth elements of the diagonal. Within the graphical framework of Ref. 2, one shows that the internal distance only depends on points that are on some path between u and v. In other terms

$$d_I(u,v)=\tilde{d}_I(u,v),$$

where $\tilde{d}_I$ denotes the distance computed with the Dirac operator $\tilde{D}_I=\rho D_I\rho$ in which

$$\rho\doteq\bigoplus_{i\in P\cup Q}\rho_i,$$

with P the set of points that are not connected to u or v, and Q the set of points that are connected either to u or to v by one and only one path. Note that, for any internal one-form,

$$\rho a_i[D_I,b^i]\rho=a_i[\tilde{D},b^i]$$

so that the tilde operation is coherent with the scalar fluctuation. At any point x of the manifold

$$d_x(\omega_u,\omega_v)=\tilde{d}_x(\omega_u,\omega_v)$$

therefore, to apply Theorem 2, it is enough to check that $[\tilde{D}_H,\rho]=0$. One verifies that whenever a component of the internal Dirac operator is zero, the corresponding component of any internal one-form is also zero, so that $[\tilde{D}_H,\rho_I]=0$ as soon as $[\tilde{D}_I,\rho_I]=0$.

This means that the only path between u and v is the link $u-v$ itself. The simplest case, $k=2$, endows the two-sheets model with a cylindrical metric. The other examples of commutative spaces given in Ref. 2 do not fit the required condition and our next examples will be noncommutative.

B. Two-points space

Let $\mathcal{A}_I=M_n(\mathbb{C})\oplus\mathbb{C}$ be represented over $\mathbb{C}^{n+1}$ by

$$\begin{pmatrix} m & 0\\ 0 & c\end{pmatrix}, \tag{37}$$

where $m\in M_n(\mathbb{C})$ and $c\in\mathbb{C}$. Possible chirality K and Dirac operator Δ are

$$K=\begin{pmatrix}\mathbb{I}_n & 0\\ 0 & -1\end{pmatrix},\quad \Delta=\begin{pmatrix}0 & M\\ M^* & 0\end{pmatrix},$$

where $M \in \mathbb{C}^n$. But there is no operator J to fluctuate the metric. A solution is to make (37) acting over $\mathcal{H}_I = M_{n+1}(\mathbb{C})$ and define

$$D\psi \doteq \Delta\psi + \psi\Delta, \quad \chi_I\psi \doteq K\psi + \psi K, \quad J\psi \doteq \psi^*$$

for any $\psi \in \mathcal{H}_I$. Since $J\Delta J^{-1}\psi = J\Delta\psi^* = (\Delta\psi^*)^* = \psi\Delta$, one has $D\psi = \Delta\psi + J\Delta J^{-1}\psi$. Moreover, for any $a \in \mathcal{A}_I$, $[J\Delta J^{-1}, a]\psi = a\psi\Delta - a\psi\Delta = 0$, so $[D_I, a] = [\Delta, a]$. Note that this result comes directly from Lemma 5 as soon as one knows that Δ is a one-form.[21] Since the operator norm over $\mathbb{C}^n$ is equal to the operator norm over $M_n(\mathbb{C})$,

$$\|[D,a]\| = \|[\Delta,a]\|$$

and the distance is in fact the same as the one computed with the spectral triple $(\mathcal{A}_I, \mathbb{C}^{n+1}, \Delta)$. Note that this point is assumed in Ref. 27.

Let ρ_1 be the density matrix associated with a pure state ω_1 of $M_n(\mathbb{C})$ and ρ_0 the one corresponding to the pure state ω_0 of $\mathbb{C}$. Then

$$\rho_1 \oplus \rho_0 = \begin{pmatrix} \rho_1 & 0 \\ 0 & 1 \end{pmatrix}$$

so that $[D_I, \rho_1 \oplus \rho_0] = 0$ is equivalent to $\rho_1 M = M$. In other terms, M is collinear to the range of ρ_1. A happy coincidence makes that this is precisely the condition under which the internal distance $d_I(\omega_1, \omega_0) = 1/\|M\|$ is finite.[2] Theorem 4 is true for any Dirac operator—$d_I(\omega_0, \omega_1) = +\infty$ makes $d(x_0, y_1) = +\infty$ for any x, y in $\mathcal{M}$—so

$$d(x_0, y_1) = \sqrt{L(x,y)^2 + \frac{1}{\|M\|^2}}$$

when M is in the range of ρ_1, is infinite otherwise.

C. The standard model

The spectral triple of the standard model (see Refs. 4, 1, and 28 and Refs. 29 and 30 for a physical expectation of the Higgs mass) is the tensor product of the usual spectral triple of a manifold T_E by an internal triple in which

$$\mathcal{A}_I = \mathbb{H} \oplus \mathbb{C} \oplus M_3(\mathbb{C})$$

($\mathbb{H}$ is the real algebra of quaternions) is represented over

$$\mathcal{H}_I = \mathbb{C}^{90} = \mathcal{H}^P \oplus \mathcal{H}^A = \mathcal{H}_L^P \oplus \mathcal{H}_R^P \oplus \mathcal{H}_L^A \oplus \mathcal{H}_R^A.$$

The basis of $\mathcal{H}_L^P = \mathbb{C}^{24}$ consists of the left-handed fermions

$$\begin{pmatrix} u \\ d \end{pmatrix}_L, \quad \begin{pmatrix} c \\ s \end{pmatrix}_L, \quad \begin{pmatrix} t \\ b \end{pmatrix}_L, \quad \begin{pmatrix} \nu_e \\ e \end{pmatrix}_L, \quad \begin{pmatrix} \nu_\mu \\ \mu \end{pmatrix}_L, \quad \begin{pmatrix} \mu_\tau \\ \tau \end{pmatrix}_L,$$

and the basis of $\mathcal{H}_R^P = \mathbb{C}^{21}$ is labeled by the right-handed fermions u_R, d_r, c_R, s_R, t_R, b_R and e_R, μ_R, τ_R (the model assumes massless neutrinos). The color index for the quarks has been omitted. $\mathcal{H}_R^A$ and $\mathcal{H}_L^A$ correspond to the antiparticles. ($a \in \mathbb{H}$, $b \in \mathbb{C}$, $c \in M_3(\mathbb{C})$) is represented by

$$\pi_I(a,b,c) \doteq \pi^P(a,b) \oplus \pi^A(b,c) \doteq \pi_L^P(a) \oplus \pi_R^P(b) \oplus \pi_L^A(b,c) \oplus \pi_R^A(b,c)$$

where, writing $B \doteq \left(\begin{smallmatrix} b & 0 \\ 0 & \bar{b} \end{smallmatrix}\right) \in \mathbb{H}$ and $N = 3$ for the number of fermion generations,

$$\pi_L^P(a)\doteq a\otimes\mathbb{I}_N\otimes\mathbb{I}_3\oplus a\otimes\mathbb{I}_N,\quad \pi_R^P(b)\doteq B\otimes\mathbb{I}_N\otimes\mathbb{I}_3\oplus\overline{b}\otimes\mathbb{I}_N,$$

$$\pi_L^A(b,c)\doteq\mathbb{I}_2\otimes\mathbb{I}_N\otimes c\oplus\overline{b}\mathbb{I}_2\otimes\mathbb{I}_N,\quad \pi_R^A(b,c)\doteq\mathbb{I}_2\otimes\mathbb{I}_N\otimes c\oplus\overline{b}\mathbb{I}_n.$$

One defines a real structure

$$J_I=\begin{pmatrix}0 & \mathbb{I}_{15N}\\ \mathbb{I}_{15N} & 0\end{pmatrix}\circ^{-},$$

where $^{-}$ denotes the complex conjugation, and an internal Dirac operator

$$D_I\doteq\begin{pmatrix}D_P & 0\\ 0 & \overline{D_P}\end{pmatrix}=\begin{pmatrix}D_P & 0\\ 0 & 0\end{pmatrix}+J_I\begin{pmatrix}D_P & 0\\ 0 & 0\end{pmatrix}J_I^{-1}$$

whose diagonal blocks are $15N\times 15N$ matrices

$$D_P\doteq\begin{pmatrix}0 & M\\ M^* & 0\end{pmatrix},$$

with M an $8N\times 7N$ matrix

$$M\doteq\begin{pmatrix}(e_{11}\otimes M_u+e_{22}\otimes M_d)\otimes\mathbb{I}_3 & 0\\ 0 & e_2\otimes M_e\end{pmatrix}. \tag{38}$$

Here, $\{e_{ij}\}$ and $\{e_i\}$ denote the canonical basis of $M_2(\mathbb{C})$ and $\mathbb{C}^2$, respectively. M_u, M_d, M_e are the mass matrices

$$M_u=\begin{pmatrix}m_u & 0 & 0\\ 0 & m_c & 0\\ 0 & 0 & m_t\end{pmatrix},\quad M_d=C_{KM}\begin{pmatrix}m_d & 0 & 0\\ 0 & m_s & 0\\ 0 & 0 & m_b\end{pmatrix},\quad M_e=\begin{pmatrix}m_e & 0 & 0\\ 0 & m_\mu & 0\\ 0 & 0 & m_\tau\end{pmatrix}$$

whose coefficients are the masses of the elementary fermions, pondered by the unitary Cabibbo–Kobayashi–Maskawa matrix. The chirality, last element of the spectral triple, is

$$\chi_I=(-\mathbb{I}_{8N})\oplus\mathbb{I}_{7N}\oplus(-\mathbb{I}_{8N})\oplus\mathbb{I}_{7N}.$$

The presence of the conjugate representation $\overline{b}$ in π_I requires one to view $\mathbb{C}$ as a real algebra. Therefore, the pure state ω_0 of $\mathbb{C}$ is no longer the identity but an $\mathbb{R}$-linear function with value in $\mathbb{R}$ which maps 1 to 1. In other words, ω_0 is the real part: $\omega_0(b)=\mathrm{Re}(b)$. As a quaternionic algebra, $\mathbb{H}$ has a single pure state and this remains true for $\mathbb{H}$ seen as a real algebra.

Lemma 6: The single pure state ω_1 of $\mathbb{H}$ is $\omega_1(a)=\frac{1}{2}\mathrm{Tr}(\mathbb{I}_{\mathbb{H}}a)$.

Proof: The representation of $\mathbb{H}$ over the four-dimensional real vector space with basis $\{1,i,j,k\}$ such that $i^2=j^2=k^2=-1$, $ij=-ji=k$, $jk=-kj=i$, and $ki=-ik=j$, is

$$a=\alpha+\beta i+\gamma j+\delta k,$$

where $\alpha,\beta,\gamma,\delta\in\mathbb{R}$. Since $\overline{a}\doteq\alpha-\beta i-\gamma j-\delta k$, $a\overline{a}\in\mathbb{R}^+$ so any $\mathbb{R}$-linear form is positive. Therefore a state is any $\mathbb{R}$-linear form that maps $\mathbb{I}_{\mathbb{H}}=1$ to 1. Let ω be such a state. By linearity,

$$\omega(a)=\alpha+\beta\omega(i)+\gamma\omega(j)+\delta\omega(k),$$

so ω is uniquely determined by its values on i,j,k. Let $\omega_{\omega(i)}$ be the linear form defined by $\omega_{\omega(i)}(i)=\omega(i)$, $\omega_{\omega(i)}(1)=\omega_{\omega(i)}(j)=\omega_{\omega(i)}(k)=0$. Define similarly $\omega_{\omega(1)},\omega_{\omega(j)},\omega_{\omega(k)}$. Then

$$\omega=\omega_{\omega(1)}+\omega_{\omega(i)}+\omega_{\omega(j)}+\omega_{\omega(k)}$$
$$=\lambda(\omega_{\omega(1)}+\omega_{\kappa\omega(i)}+\omega_{\kappa\omega(j)}+\omega_{\kappa\omega(k)})+(1-\lambda)(\omega_{\omega(1)}+\omega_{\kappa'\omega(i)}+\omega_{\kappa'\omega(j)}+\omega_{\kappa'\omega(k)}), \quad (39)$$

where $\lambda,\kappa\in\mathbb{R}/\{1\}$ and $\kappa'\doteq(1-\lambda\kappa)/(1-\lambda)$. Both factors of the right-hand side of (39) map 1 to 1, so they are states and ω is not pure unless $\omega(i)=\omega(j)=\omega(k)=0$. Hence the only pure state of $\mathbb{H}$ is $\omega_1\doteq\omega_{\omega(1)}$.

The quaternion a can also be represented over $\mathbb{C}^2$ by $\left(\begin{smallmatrix}\theta & \rho\\ -\bar{\rho} & \bar{\theta}\end{smallmatrix}\right)$ where $\theta\doteq\alpha+i\beta$. Then $\mathrm{Tr}(a)\doteq 2\,\mathrm{Re}(\theta)=2\alpha=2\omega_1(a)$, that is $\omega_1(a)=\mathrm{Tr}(\frac{1}{2}\mathbb{I}_H a)$. ■

With regard to $\mathcal{P}(M_3(\mathbb{C}))$, we shall only need the following well-known lemma:

Lemma 7: Let $\omega,\omega'\in\mathcal{P}(\mathcal{A}_I)$. Then $\omega=\omega'$ if and only if $\ker(\omega)=\ker(\omega')$.

Proof: Pure states are linear forms, so if they have the same kernel they are proportional. Since they coincide on the identity, they are equal. ■

Noncommutative geometry gives an interpretation of the Higgs field as a one-form of the internal space. By scalar fluctuation, one-forms closely interfere with the metric. Thus the Higgs field has an interpretation in terms of an internal metric. The conclusive result of this paper is a precision of this link between Higgs and metric when the gauge field A_μ is neglected.

Proposition 8: The finite part of the geometry of the standard model with scalar fluctuations of the metric consists of a two-sheets model labeled by the single states of $\mathbb{C}$ and $\mathbb{H}$. Each of the sheets is a copy of the Riemannian four-dimensional space–time endowed with its metric. The fifth component of the metric, corresponding to the discrete dimension, is

$$g^{tt}(x)=(|1+h_1(x)|^2+|h_2(x)|^2)m_t^2$$

where $\left(\begin{smallmatrix}h_1\\ h_2\end{smallmatrix}\right)$ is the Higgs doublet and m_t the mass of the quark top.

Proof: π_I stands for $\pi_I(a,b,c)$ and $\Delta\doteq\left(\begin{smallmatrix}D_P & 0\\ 0 & 0\end{smallmatrix}\right)$ so that $D_I=\Delta+J\Delta J^{-1}$. Since Δ is a one-form,[21] Lemma 5 yields $[J_I\Delta J_I^{-1},\pi_I]=0$, so that we can take $D_H=\Delta+H$. By explicit calculation,[31]

$$H=\begin{pmatrix}0 & \pi_L^P(h)M & 0 & 0\\ M^*\pi_L^P(h^*) & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\end{pmatrix},$$

where h is a quaternion-valued scalar field. Thus

$$D_H=\begin{pmatrix}0 & \Phi M & 0 & 0\\ M^*\Phi^* & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\end{pmatrix}, \quad (40)$$

where

$$\Phi\doteq(h+\mathbb{I}_{\mathbb{H}})\otimes\mathbb{I}_{4N}=\begin{pmatrix}1+h_1 & h_2\\ -\bar{h}_2 & 1+\bar{h}_1\end{pmatrix}\otimes\mathbb{I}_{4N},$$

with h_1 and h_2 being two complex scalar fields.

By (1), the metric of the standard model is identical to the metric associated with the triple $(\mathcal{A}_s,\mathcal{H},D)$, where $\mathcal{A}_s=C^\infty(\mathcal{M})_s\otimes\mathcal{A}_{Is}$ is the subalgebra of self-adjoint elements of $\mathcal{A}$, with

$$\mathcal{A}_{Is}=\mathbb{C}_s\oplus\mathbb{H}_s\oplus M_3(\mathbb{C})_s=\mathbb{R}\oplus\mathbb{R}\oplus M_3(\mathbb{C})_s.$$

The representation π_s associated with this triple coincides with the restriction of π to $\mathcal{A}_s$. Concerning the quaternion, π_s substitutes

$$\begin{pmatrix} \theta & 0 \\ 0 & \theta \end{pmatrix} \quad \text{to} \quad \begin{pmatrix} \theta & \overrightarrow{\rho} \\ -\overrightarrow{\rho} & \overline{\theta} \end{pmatrix}.$$

In other words, to each representation of $\mathbb{H}$ there corresponds the direct sum of twice the fundamental representation of $\mathbb{R}=\mathbb{H}_s$. Now ω_1 seen as a pure state of $\mathbb{H}_s$ is nothing but the identity. The associated projection $\rho_1 \in \mathbb{H}_s$ is nothing but the real number 1 which obviously satisfies (10). The same is true for ω_0 seen as a pure state of $\mathbb{R}=\mathbb{C}_s$. Hence

$$\pi_s(\rho_0 \oplus \rho_1) = \begin{pmatrix} \mathbb{I}_{15N} & & & 0 \\ & 0_{6N} & & \\ & & \mathbb{I}_{2N} & \\ 0 & & & 0_{6N} \\ & & & & \mathbb{I}_N \end{pmatrix}$$

commutes with D_H defined in (40). Proposition 4′ applies to the distance between pure states of $\mathcal{A}$ defined by ω_0 and ω_1. Here

$$\pi_s(\operatorname{ran}\rho_1) = \mathcal{H}_L^P \quad \text{and} \quad \pi_s(\operatorname{ran}\rho_0) = \mathcal{H}_R^P \oplus \mathcal{H}_{\text{lep}}^A,$$

where $\mathcal{H}_{\text{lep}}^A = \mathbb{C}^{3N}$ is the subset of $\mathcal{H}^A$ generated by the antileptons. Thus the extra metric component is

$$g^{tt}(x) = \|\Phi(x)M\|^2.$$

Note that, as desired, ΦM is a $2\alpha^{\mathbb{H}} \times (\alpha^{\mathbb{C}} + \overline{\alpha^{\mathbb{C}}})$ matrix, where $\alpha^{\mathbb{H}} = 4N$ is the degeneracy of the representation of $\mathbb{H}_s$ in π_L^P, and $\alpha^{\mathbb{C}} = 3N$, $\overline{\alpha^{\mathbb{C}}} = 4N$ are defined as well. Using the explicit form (38),

$$\begin{aligned} \|\Phi(x)M\|^2 &= \max\{\|(\Phi(x)\otimes \mathbb{I}_3)(e_{11}\otimes M_u + e_{22}\otimes M_d)\|^2, \|(\Phi(x)\otimes \mathbb{I}_3)(e_2 \otimes M_e)\|^2\} \\ &= (|1+h_1(x)|^2 + |h_2(x)|^2)\max\{m_t^2, m_\tau^2\} = (|1+h_1(x)|^2 + |h_2(x)|^2)m_t^2. \end{aligned}$$

The other distances, involving the pure states of $M_3(\mathbb{C})$, are not finite. Indeed,

$$\|[D_H, \pi_I(a,b,c)]\| = \left\| \left[\begin{pmatrix} 0 & \Phi M \\ M^*\Phi^* & 0 \end{pmatrix}, \pi^P(a,b) \right] \right\|$$

does not put any constraint on c, thus for $\omega_2 \in \mathcal{P}(M_3(\mathbb{C}))$ and $\omega \in \mathcal{P}(\mathcal{A}_I)$,

$$d_I(\omega_2, \omega) \geqslant \sup_{c \in M_3(\mathbb{C})} |\omega_2(c) - \omega(c)|.$$

For $\omega = \omega_0$, $c = \lambda \mathbb{I}_3$ with $\lambda \to \infty$ makes the distance $d_I(\omega_2, \omega_0)$ infinite. Then

$$d_I(\omega_2, \omega_0) = d(x_2, x_0) \leqslant d(x_2, y_0) + d(y_0, x_0) \leqslant d(x_2, y_0) + L(x,y)$$

by Theorem 4′, so that $d(x_2, y_0) = +\infty$. The same is true for $\omega = \omega_1$. The same is also true when $\omega \in \mathcal{P}(M_3(\mathbb{C}))$ because, by Lemma 7, there exists $c' \in ker(\omega_2)$, $c' \notin ker(\omega)$ which makes $d_I(\omega_2, \omega)$ infinite. ■

VIII. CONCLUSION

Noncommutative geometry intrinsically links the Higgs field with the metric structure of space–time. We have not considered the gauge field A_μ so it is not clear whether or not the interpretation of the Higgs as an extra metric component has a direct physical meaning. It is important to study the influence of the gauge fluctuation together with a Higgs field, and see how it probably makes the metric of the strong interaction part finite.

Since $\mathbb{H}$ has only one pure state, the problem of the distance between states defined by distinct pure states of the same component of the internal algebra is not questioned here. One may be tempted to consider states τ of $\mathbb{H}$ that are not pure. But asking $\tau(\overline{q}) = \overline{\tau}(q)$—which is part of the definition of a real state[32] and does not come as a consequence like in the complex case—precisely means that $\tau = \omega_1$. To extend the field of investigation, one can consider states that do not preserve the conjugation—then the supremum is no longer reached by a positive element—but this contradicts the spirit of density matrices in quantum mechanics. More interesting is probably to take into account complexified states, that is real linear functions with value in $\mathbb{C}$.

The reduction of $\mathcal{A}_I$ to $\mathbb{K}^2$ (Proposition 3) is made possible by the orthogonality of the projections. When the two internal pure states are no longer orthogonal, there is no reason why the relevant picture should remain the two-sheets model. The same is true for two orthogonal states whose sum of the projections does not commute with the Dirac operator. In this sense, if these cases do not support a simple ''classical'' picture (such as being the geodesic distance of a discrete Kaluza–Klein manifold), they reflect a purely noncommutative aspect of space–time.

Note that the result—before fluctuation—concerning states defined by the same pure state of one of the algebras (Theorem 2), as well as the reduction from $\mathcal{A}_I$ to $\mathbb{K}^2$, do not assume that $\mathcal{A}_E$ is Abelian. It is only later, to establish the orthogonality between the internal and the external spaces, that T_E is taken as the spectral triple of a manifold. It would be interesting to clarify the importance, or the unimportance, of the commutativity regarding the Pythagorean theorem.

(Received 9 July 2001; accepted for publication 25 September 2001)

We introduce the notion of *pseudo-Hermiticity* and show that every Hamiltonian with a real spectrum is pseudo-Hermitian. We point out that all the PT-symmetric non-Hermitian Hamiltonians studied in the literature belong to the class of pseudo-Hermitian Hamiltonians, and argue that the basic structure responsible for the particular spectral properties of these Hamiltonians is their pseudo-Hermiticity. We explore the basic properties of general pseudo-Hermitian Hamiltonians, develop *pseudosupersymmetric quantum mechanics*, and study some concrete examples, namely the Hamiltonian of the two-component Wheeler–DeWitt equation for the FRW-models coupled to a real massive scalar field and a class of pseudo-Hermitian Hamiltonians with a real spectrum. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1418246]

I. INTRODUCTION

The past three years have witnessed a growing interest in non-Hermitian Hamiltonians with real spectra.[1–23] Based on the results of various numerical studies, Bender and collaborators[1,4] found certain examples of one-dimensional non-Hermitian Hamiltonians that possessed real spectra. Because these Hamiltonians were invariant under PT transformation, their spectral properties were linked with their PT symmetry. The purpose of this article is to explore the basic structure responsible for the reality of the spectrum of a non-Hermitian Hamiltonian.

By definition, a PT-symmetric Hamiltonian H satisfies

$$PTH(PT)^{-1}=PTHPT=H, \tag{1}$$

where P and T are, respectively, the operators of parity and time-reversal transformations. These are defined according to

$$P\,x\,P=-x, \quad P\,p\,P=T\,p\,T=-p, \quad T\,i1\,T=-i1, \tag{2}$$

where x, p, and 1 are, respectively, the position, momentum, and identity operators acting on the Hilbert space $\mathcal{H}=L^2(\mathbb{R})$ and $i:=\sqrt{-1}$. Note that Eq. (2) applies only for the systems whose classical position x and momentum p are real. In this article we shall only be concerned with these systems.

As we mentioned previously, the only reason for relating the concept of PT-symmetry and non-Hermitian Hamiltonians with a real spectrum is that most of the known examples of the latter satisfy Eq. (1). Certainly there are Hermitian Hamiltonians with a real spectrum that are not PT-symmetric and there are PT-symmetric Hamiltonians that do not have a real spectrum. Therefore, PT-symmetry is neither a necessary nor a sufficient condition for a Hamiltonian to have a real spectrum. This raises the possibility that the PT-symmetry of a Hamiltonian may have

a)Electronic mail: amostafazadeh@ku.edu.tr

nothing to do with the reality of its spectrum. The interest in PT-symmetry seems to be mostly because of the lack of an alternative framework replacing the Hermiticity of the Hamiltonian in ordinary (unitary) quantum mechanics. Much of the published work on the subject concerns the study of various examples and the extension of the concepts developed for Hermitian Hamiltonians to the PT-symmetric ones.[1–20] Recently, Znojil,[21] Japaridze,[22] and Kretschmer and Szymanowski[23] have addressed some of the more fundamental issues regarding the mathematical structure and the interpretation of the PT-symmetric quantum mechanics.

Among the common properties of all the PT-symmetric Hamiltonians that have so far been studied are the following.

(1) Either the spectrum of the Hamiltonian is real (PT-symmetry is exact) or there are complex-conjugate pairs of complex eigenvalues (PT-symmetry is broken).[1,4,10,12]

(2) The indefinite inner-product $\langle\langle\,|\,\rangle\rangle$ defined by

$$\langle\langle\psi_1|\psi_2\rangle\rangle := \langle\psi_1|P|\psi_2\rangle, \quad \forall|\psi_1\rangle,|\psi_2\rangle\in\mathcal{H}, \tag{3}$$

is invariant under the time-translation generated by the Hamiltonian.[21,22]

The main motivation for the present investigation is the remarkable fact that there is no evidence that PT-symmetry is the basic structure responsible for these properties. For example, in Ref. 3, the authors construct a class of non-PT-symmetric Hamiltonians with a real spectrum. Another example of a non-Hermitian Hamiltonian with similar properties is the Hamiltonian describing the evolution of the solutions of the two-component Wheeler–DeWitt equation for FRW-models coupled with a real massive scalar field.[24] This Hamiltonian is explicitly ''time dependent,'' ''parity-invariant,'' and non-Hermitian (with respect to the relevant L^2-$norm$ on the space of two-component wave functions), but the corresponding invariant indefinite inner-product does not involve P.

The organization of the article is as follows. In Sec. II, we introduce the concept of a *pseudo-Hermitian* operator and derive the basic spectral properties of pseudo-Hermitian Hamiltonians. These coincide with Properties 1 and 2 (with P replaced with a Hermitian invertible linear operator η). In Sec. III, we consider the class of pseudo-Hermitian Hamiltonians that have a complete biorthonormal eigenbasis and show that the pseudo-Hermiticity is a necessary condition for having a real spectrum. In Sec. IV, we explore the pseudo-Hermitian Hamiltonian of the two-component Wheeler–DeWitt equation for FRW-models coupled with a real massive scalar field. In Sec. V, we develop pseudosupersymmetric quantum mechanics. In Sec. VI, we use pseudosupersymmetry to construct a large class of pseudo-Hermitian Hamiltonians with a real spectrum. In Sec. VII, we present our concluding remarks.

II. PSEUDO-HERMITIAN HAMILTONIANS

We first give a few definitions. Throughout this paper we will assume that all the inner product spaces are complex. The generalization to real inner product spaces is straightforward.

Definition 1: Let $V_\pm$ be two inner product spaces endowed with Hermitian linear automorphisms $\eta_\pm$ (invertible operators mapping $V_\pm$ to itself and satisfying)

$$\forall v_\pm, w_\pm \in V_\pm, \quad (v_\pm, \eta_\pm w_\pm)_\pm = (\eta_\pm v_\pm, w_\pm)_\pm,$$

where $(,)_\pm$ stands for the inner product of $V_\pm$) and $O: V_+ \to V_-$ be a linear operator. Then the $\eta_\pm$-pseudo-Hermitian adjoint $O^\sharp: V_- \to V_+$ of O is defined by $O^\sharp := \eta_+^{-1} O^\dagger \eta_-$. In particular, for $V_\pm = V$ and $\eta_\pm = \eta$, the operator O is said to be η-pseudo-Hermitian if $O^\sharp = O$.

Definition 2: Let V be an inner product space. Then a linear operator $O: V \to V$ is said to be pseudo-Hermitian, if there is a Hermitian linear automorphism η such that O is η-pseudo-Hermitian.

Now, consider a quantum system with a possibly non-Hermitian and time-dependent Hamiltonian $H=H(t)$ and a Hilbert space $\mathcal{H}$ which is endowed with a Hermitian linear automorphism η.

Proposition 1: The Hermitian indefinite inner product $\langle\langle|\rangle\rangle_\eta$ defined by η, i.e.,

$$\langle\langle\psi_1|\psi_2\rangle\rangle_\eta := \langle\psi_1|\eta|\psi_2\rangle, \quad \forall|\psi_1\rangle,|\psi_2\rangle\in\mathcal{H}, \tag{4}$$

is invariant under the time-translation generated by the Hamiltonian H if and only if H is η-pseudo-Hermitian.

Proof: First note that the η-pseudo-Hermiticity of H is equivalent to the condition

$$H^\dagger = \eta\, H\, \eta^{-1}. \tag{5}$$

Now, using the Schrödinger equation

$$i\frac{\mathrm{d}}{\mathrm{d}t}|\psi(t)\rangle = H|\psi(t)\rangle, \tag{6}$$

its adjoint, and Eq. (4), one has for any two evolving state vectors $|\psi_1(t)\rangle$ and $|\psi_2(t)\rangle$:

$$i\frac{\mathrm{d}}{\mathrm{d}t}\langle\langle\psi_1(t)|\psi_2(t)\rangle\rangle_\eta = \langle\psi_1(t)|(\eta H - H^\dagger\eta)|\psi_2(t)\rangle.$$

Therefore, $\langle\langle\psi_1(t)|\psi_2(t)\rangle\rangle_\eta$ is a constant if and only if (5) holds. □

Note that choosing $\eta=1$ reduces Eq. (5) to the condition of the Hermiticity of the Hamiltonian. Hence *pseudo-Hermiticity is a generalization of Hermiticity*. Furthermore, observe that a typical PT-symmetric Hamiltonian defined on a real phase space $((x,p)\in\mathbb{R}^2)$ has the form $H=p^2/(2m)+V(x)$ where the potential $V(x)=V_+(x)+iV_-(x)$ has an even real part $V_+(x)$ and an odd imaginary part $V_-(x)$, i.e., $V_\pm(\pm x)=\pm V_\pm(x)$. It is not difficult to see that such a PT-symmetric Hamiltonian satisfies

$$H^\dagger = \frac{p^2}{2m}+V_+(x)-iV_-(x) = \frac{p^2}{2m}+V_+(-x)+iV_-(-x) = P\,H\,P = P\,H\,P^{-1}.$$

Hence it is P-pseudo-Hermitian. In contrast, consider the non-Hermitian Hamiltonians

$$H_1 := p^2+x^2p, \quad H_2 := p^2+i(x^2p+p\,x^2).$$

Clearly, H_1 is PT symmetric, but not P-pseudo-Hermitian, whereas H_2 is P-pseudo-Hermitian and not PT symmetric. Therefore, PT symmetry and P-pseudo-Hermiticity are distinct properties. Note, however, that H_1 may be pseudo-Hermitian with respect to another Hermitian automorphism η. We shall explore the relationship between PT-symmetry and pseudo-Hermiticity in Sec. III.

The defining condition (5) may also be expressed as the intertwining relation

$$\eta\, H = H^\dagger\, \eta. \tag{7}$$

Using this equation together with the eigenvalue equation for the Hamiltonian, namely $H|E_i\rangle = E_i|E_i\rangle$, and its adjoint, we can easily show that any two eigenvectors $|E_i\rangle$ and $|E_j\rangle$ of H satisfy

$$(E_i^*-E_j)\langle\langle E_i|E_j\rangle\rangle_\eta = 0. \tag{8}$$

A direct implication of this equation is the following Proposition.

Proposition 2: An η-pseudo-Hermitian Hamiltonian has the following properties.

(a) The eigenvectors with a nonreal eigenvalue have vanishing η-semi-norm, i.e.,

$$E_i\notin\mathbb{R} \quad \text{implies} \quad \||E_i\rangle\|_\eta^2 := \langle\langle E_i|E_i\rangle\rangle_\eta = 0. \tag{9}$$

(b) Any two eigenvectors are η-orthogonal unless their eigenvalues are complex conjugates, i.e.,

$$E_i \neq E_j^* \quad \text{implies} \quad \langle\langle E_i | E_j \rangle\rangle_\eta = 0. \tag{10}$$

In particular, the eigenvectors with distinct real eigenvalues are η-orthogonal.

In the remainder of this section, we list a number of simple but remarkable consequences of pseudo-Hermiticity.

Proposition 3: Let V be an inner product space endowed with a Hermitian linear automorphism η, $1: V \to V$ denote the identity operator, $O_1, O_2: V \to V$ be linear operators, and $z_1, z_2 \in \mathbb{C}$. Then,

(a) $1^\sharp = 1$;
(b) $(O_1^\sharp)^\sharp = O_1$;
(c) $(z_1 O_1 + z_2 O_2)^\sharp = z_1^* O_1^\sharp + z_2^* O_2^\sharp$,

where z_i^* stands for the complex conjugate of z_i.

Proof: (a) and (b) are trivial consequences of the definition of $\sharp$ and the Hermiticity of η. (c) follows from this definition and the linearity of η and η^{-1}:

$$(z_1 O_1 + z_2 O_2)^\sharp = \eta^{-1}(z_1 O_1 + z_2 O_2)^\dagger \eta = z_1^* \eta^{-1} O_1^\dagger \eta + z_2^* \eta^{-1} O_2^\dagger \eta = z_1^* O_1^\sharp + z_2^* O_2^\sharp.$$

□

Proposition 4: Let V_ℓ, with $\ell \in \{1,2,3\}$, be inner product spaces endowed with Hermitian linear automorphisms η_ℓ and $O_1: V_1 \to V_2$ and $O_2: V_2 \to V_3$ be linear operators. Then $(O_2 O_1)^\sharp = O_1^\sharp O_2^\sharp$.

Proof: This relation follows from the following simple calculation:

$$(O_2 O_1)^\sharp = \eta_1^{-1}(O_2 O_1)^\dagger \eta_3 = \eta_1^{-1} O_1^\dagger \eta_2 \eta_2^{-1} O_2^\dagger \eta_3 = O_1^\sharp O_2^\sharp.$$

□

Corollary: Pseudo-Hermitian conjugation ($O \to O^\sharp$) is a $*$-operation.

Proof: According to Propositions 3 and 4, $\sharp$ has all the properties of a $*$-operation. □

Proposition 5: Let V be an inner product space endowed with a Hermitian linear automorphism η, $U: V \to V$ be a unitary operator, and $O: V \to V$ be a linear operator. Then $\eta_U := U^\dagger \eta U$ is a Hermitian linear automorphism, and O is η-pseudo-Hermitian if and only if $O_U := U^\dagger O U$ is η_U-pseudo-Hermitian. In other words, the notion of pseudo-Hermiticity is unitary-invariant.

Proof: First we recall that because U is unitary, η_U is both Hermitian and invertible. Furthermore, we have

$$\eta_U^{-1} O_U^\dagger \eta_U = U^\dagger \eta^{-1} U U^\dagger O^\dagger U U^\dagger \eta U = U^\dagger (\eta^{-1} O^\dagger \eta) U.$$

□

Proposition 6: Let V be an inner product space, η_1 and η_2 be Hermitian linear automorphisms, and $O: V \to V$ be a linear operator. Then the η_1-pseudo-Hermitian adjoint of O coincides with its η_2-pseudo-Hermitian adjoint if and only if $\eta_2^{-1}\eta_1$ commutes with O.

Proof: This statement holds because $\eta_1^{-1} O^\dagger \eta_1 = \eta_2^{-1} O^\dagger \eta_2$ implies $O^\dagger \eta_1 \eta_2^{-1} = \eta_1 \eta_2^{-1} O^\dagger$. Taking the Hermitian adjoint of this relation yields $[O, \eta_2^{-1}\eta_1] = 0$. □

Corollary: If the Hamiltonian H of a quantum system is pseudo-Hermitian with respect to two different Hermitian linear automorphisms η_1 and η_2 of the Hilbert space, then $\eta_2^{-1}\eta_1$ is a symmetry of the system. Conversely, let η be a Hermitian linear automorphism of the Hilbert space, G be a symmetry group of the system whose elements g are represented by invertible linear operators. Then ηg is a Hermitian linear automorphism and H is ηg-pseudo-Hermitian provided that $g^\dagger \eta g = \eta$.

Proof: This is a direct implication of Proposition 6 and the definition of the symmetry, namely $[g, H] = 0$ or equivalently $g^{-1} H g = H$.[25]

III. PSEUDO-HERMITIAN HAMILTONIANS WITH A COMPLETE BIORTHONORNAL EIGENBASIS

Let H be an η-pseudo-Hermitian Hamiltonian with a complete biorthonormal eigenbasis $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ and a discrete spectrum.[26] Then, by definition,

$$H|\psi_n,a\rangle=E_n|\psi_n,a\rangle,\quad H^\dagger|\phi_n,a\rangle=E_n^*|\phi_n,a\rangle, \tag{11}$$

$$\langle\phi_m,b|\psi_n,a\rangle=\delta_{mn}\delta_{ab}, \tag{12}$$

$$\sum_n\sum_{a=1}^{d_n}|\phi_n,a\rangle\langle\psi_n,a|=\sum_n\sum_{a=1}^{d_n}|\psi_n,a\rangle\langle\phi_n,a|=1, \tag{13}$$

where d_n is the multiplicity (degree of degeneracy) of the eigenvalue E_n, and a and b are degeneracy labels.

Proposition 7: Let H be a pseudo-Hermitian Hamiltonian with these properties. Then the nonreal eigenvalues of H come in complex conjugate pairs with the same multiplicity.

Proof: According to Eqs. (5) and (11),

$$H(\eta^{-1}|\phi_n,a\rangle)=\eta^{-1}H^\dagger|\phi_n,a\rangle=E_n^*(\eta^{-1}|\phi_n,a\rangle). \tag{14}$$

Because η^{-1} is invertible, $\eta^{-1}|\phi_n,a\rangle\neq 0$ is an eigenvector of H with eigenvalue E_n^*. More generally, η^{-1} maps the eigensubspace associated with E_n to that associated with E_n^*. Again, because η^{-1} is invertible, E_n and E_n^* have the same multiplicity. □

Next, we use the subscript "$_0$" to denote real eigenvalues and the corresponding basis eigenvectors and the subscript "$_\pm$" to denote the complex eigenvalues with $\pm$ imaginary part and the corresponding basis eigenvectors. Then in view of Eqs. (11)–(14), we have

$$1=\sum_{n_0}\sum_{a=1}^{d_{n_0}}|\psi_{n_0},a\rangle\langle\phi_{n_0},a|+\sum_{n_+}\sum_{\alpha=1}^{d_{n_+}}(|\psi_{n_+},\alpha\rangle\langle\phi_{n_+},\alpha|+|\psi_{n_-},\alpha\rangle\langle\phi_{n_-},\alpha|), \tag{15}$$

$$H=\sum_{n_0}\sum_{a=1}^{d_{n_0}}E_{n_0}|\psi_{n_0},a\rangle\langle\phi_{n_0},a|+\sum_{n_+}\sum_{\alpha=1}^{d_{n_+}}(E_{n_+}|\psi_{n_+},\alpha\rangle\langle\phi_{n_+},\alpha|+E_{n_+}^*|\psi_{n_-},\alpha\rangle\langle\phi_{n_-},\alpha|). \tag{16}$$

Repeating the calculation leading to Eq. (14), we find

$$\eta^{-1}|\phi_{n_0},a\rangle=\sum_{b=1}^{d_{n_0}}c_{ba}^{(n_0)}|\psi_{n_0},b\rangle,\quad c_{ab}^{(n_0)}:=\langle\phi_{n_0},a|\eta^{-1}|\phi_{n_0},b\rangle, \tag{17}$$

$$\eta^{-1}|\phi_{n_+},\alpha\rangle=\sum_{\beta=1}^{d_{n_+}}c_{\beta\alpha}^{(n_+)}|\psi_{n_-},\beta\rangle,\quad c_{\alpha\beta}^{(n_+)}:=\langle\phi_{n_-},\alpha|\eta^{-1}|\phi_{n_+},\beta\rangle, \tag{18}$$

$$\eta^{-1}|\phi_{n_-},\alpha\rangle=\sum_{\beta=1}^{d_{n_+}}c_{\beta\alpha}^{(n_-)}|\psi_{n_+},\beta\rangle,\quad c_{\alpha\beta}^{(n_-)}:=\langle\phi_{n_+},\alpha|\eta^{-1}|\phi_{n_-},\beta\rangle, \tag{19}$$

where $c_{ab}^{(n_0)}$ and $c_{\alpha\beta}^{(n_\pm)}$ are complex coefficients. The latter may be viewed as entries of complex matrices $c^{(n_0)}$ and $c^{(n_\pm)}$, respectively. Because η and consequently η^{-1} are Hermitian operators, so are the matrices $c^{(n_0)}$ and $c^{(n_\pm)}$. In particular, we can make a unitary transformation of the Hilbert space to map the biorthonormal system of eigenbasis vectors of the Hamiltonian to a new system in which these matrices are diagonal. We can further rescale the basis vectors so that $c^{(n_0)}$

and $c^{(n_\pm)}$ become identity matrices. In the following we shall assume, without loss of generality, that such a transformation has been performed. Then, Eqs. (17)–(19) take the form

$$|\phi_{n_0},a\rangle=\eta|\psi_{n_0},a\rangle,\quad |\phi_{n_\pm},\alpha\rangle=\eta|\psi_{n_\mp},\alpha\rangle. \tag{20}$$

In particular, combining this result with Eq. (12), we have the following η-orthonormalization of the eigenvectors of H

$$\langle\!\langle\psi_{n_0},a|\psi_{m_0},b\rangle\!\rangle_\eta=\delta_{n_0,m_0}\delta_{ab},\quad \langle\!\langle\psi_{n_\pm},\alpha|\psi_{m_\mp},\beta\rangle\!\rangle_\eta=\delta_{n_\pm,m_\mp}\delta_{\alpha\beta}. \tag{21}$$

Next, we solve Eq. (20) for $|\psi_{n_0}\rangle$ and $|\psi_{n_\pm}\rangle$ and substitute the result in Eq. (15). This leads to an explicit expression for η that can be easily inverted to yield η^{-1}. The result is

$$\eta=\sum_{n_0}\sum_{a=1}^{d_{n_0}}|\phi_{n_0},a\rangle\langle\phi_{n_0},a|+\sum_{n_+}\sum_{\alpha=1}^{d_{n_+}}(|\phi_{n_-},\alpha\rangle\langle\phi_{n_+},\alpha|+|\phi_{n_+},\alpha\rangle\langle\phi_{n_-},\alpha|), \tag{22}$$

$$\eta^{-1}=\sum_{n_0}\sum_{a=1}^{d_{n_0}}|\psi_{n_0},a\rangle\langle\psi_{n_0},a|+\sum_{n_+}\sum_{\alpha=1}^{d_{n_+}}(|\psi_{n_-},\alpha\rangle\langle\psi_{n_+},\alpha|+|\psi_{n_+},\alpha\rangle\langle\psi_{n_-},\alpha|). \tag{23}$$

One can easily check that the Hamiltonian H and the operators η and η^{-1} as given by Eqs. (16), (22), and (23) satisfy the η-pseudo-Hermiticity condition (5).

The above-mentioned analysis provides the following necessary and sufficient condition for pseudo-Hermiticity.

Theorem: Let H be a non-Hermitian Hamiltonian with a discrete spectrum and a complete biorthonormal system of eigenbasis vectors $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$. Then H is pseudo-Hermitian if and only if one of the following conditions hold

(1) The spectrum of H is real.
(2) The complex eigenvalues come in complex conjugate pairs and the multiplicity of complex conjugate eigenvalues are the same.

Proof: We have already shown in Proposition 7 that pseudo-Hermiticity of H implies at least one of these conditions. To prove that these conditions are sufficient for the pseudo-Hermiticity of H, we use $\{|\psi_n,a\rangle,|\phi_n,a\rangle\}$ to express H in the form (16) and construct η according to Eq. (22). Then, by construction, H and η satisfy (5). □

This theorem reveals the relevance of the concept of pseudo-Hermiticity to the spectral properties of the PT-symmetric Hamiltonians considered in the literature. To the best of our knowledge, an analogue of this theorem that would apply to arbitrary PT-symmetric Hamiltonians does not exist. A direct implication of this theorem is the following corollary.

Corollary 1: Every non-Hermitian Hamiltonian with a discrete real spectrum and a complete biorthonormal system of eigenbasis vectors is pseudo-Hermitian.

Note that, in general, a non-Hermitian Hamiltonian may not admit a complete biorthonormal system of eigenvectors. The preceding Theorem and Corollary 1 may not apply for these non-Hermitian Hamiltonians.

Corollary 2: Every PT-symmetric Hamiltonian with a discrete spectrum and a complete biorthonormal system of eigenbasis vectors is pseudo-Hermitian.

Proof: This statement follows from the above-presented Theorem and fact that the eigenvalues of every PT-symmetric Hamiltonian with a complete biorthonormal system of eigenbasis vectors come in complex conjugate pairs. To see this, let $|E\rangle$ be an eigenvector of H with eigenvalue E, i.e., $H|E\rangle=E|E\rangle$, and $|E\rangle'\coloneqq PT|E\rangle$. Then

$$H|E\rangle' = H(PT)|E\rangle = (PT)H|E\rangle = (PT)E|E\rangle = E^*(PT)|E\rangle = E^*|E\rangle',$$

where we have made use of the linearlity of P and the antilinearlity of T. □

IV. PSEUDO-HERMITICITY IN MINISUPERSPACE QUANTUM COSMOLOGY

The Wheeler–DeWitt equation (with a particularly simple factor ordering prescription) for a Freedman–Robertson–Walker (FRW) model coupled to a massive real scalar field has the form

$$\left[-\frac{\partial^2}{\partial\alpha^2}+\frac{\partial^2}{\partial\phi^2}+\kappa\, e^{4\alpha}-m^2e^{6\alpha}\phi^2\right]\psi(\alpha,\phi)=0, \tag{24}$$

where $\alpha=\ln a$, a is the scale factor, ϕ is the scalar field, m is the mass of ϕ, and $\kappa=-1,0$, or 1 depending on whether the universe is open, flat, or closed.[27] In the two-component representation developed in Ref. 24, this equation takes the form of the Schrödinger equation: $i\dot\Psi=H(\alpha)\Psi$ where a dot stands for a derivative with respect to α and

$$\Psi=\frac{1}{\sqrt2}\begin{pmatrix}\psi+i\dot\psi\\ \psi-i\dot\psi\end{pmatrix},\quad H=\frac{1}{2}\begin{pmatrix}1+\mathcal{D} & -1+\mathcal{D}\\ 1-\mathcal{D} & -1-\mathcal{D}\end{pmatrix}, \tag{25}$$

$$\mathcal{D}:=-\frac{\partial^2}{\partial\phi^2}+V(\phi,\alpha),\quad V(\phi,\alpha):=m^2e^{6\alpha}\phi^2-\kappa\, e^{4\alpha}. \tag{26}$$

As seen from these equations $\mathcal{D}/2$, up to an unimportant additive scalar, is the Hamiltonian of a ''time-dependent'' simple harmonic oscillator with unit ''mass'' and ''frequency'' $\omega=m\,e^{3\alpha}$, where α and ϕ play the roles of time t and position x, respectively.

It is not difficult to check that the two-component Hamiltonian H is not Hermitian with respect to the L^2-inner product on the space of two-component state vectors Ψ. However, its eigenvalue problem can be solved exactly.[24] For an open or flat FRW universe ($\kappa=-1,0$) the eigenvalues of H are real. For a closed FRW model, there is a range of values of α for which all the eigenvalues are real. Outside this range they come in complex conjugate imaginary pairs. This suggests that H is a pseudo-Hermitian Hamiltonian. In fact, we can easily check that H is an η-pseudo Hermitian Hamiltonian for

$$\eta=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{27}$$

The indefinite inner product corresponding to (27) is nothing but the Klein–Gordon inner product that is invariant under the ''time-translation'' generated by H.

V. PSEUDOSUPERSYMMETRIC QUANTUM MECHANICS

The application of the ideas of supersymmetric quantum mechanics[28] in constructing non-Hermitian PT-symmetric Hamiltonians has been considered in Refs. 3, 7, 13, 17, and 19 and a formulation of PT-symmetric supersymmetry has been outlined in Refs. 14 and 20. In this section, we develop a straightforward generalization of supersymmetric quantum mechanics that applies for pseudo-Hermitian Hamiltonians.

Definition 3: Consider a $\mathbb{Z}_2$-graded quantum system[29] with the Hilbert space $\mathcal{H}_+\oplus\mathcal{H}_-$ and the involution or grading operator τ satisfying

$$\tau=\tau^\dagger=\tau^{-1}\quad\text{and}\quad\forall|\psi_\pm\rangle\in\mathcal{H}_\pm,\quad\tau|\psi_\pm\rangle=\pm|\psi_\pm\rangle. \tag{28}$$

Let η be an even Hermitian linear automorphism (i.e., $[\eta,\tau]=0$) and suppose that the Hamiltonian H of the system is η-pseudo-Hermitian. Then H (alternatively the system) is said to have a pseudo-supersymmetry generated by an odd linear operator $\mathcal{Q}$ $(i.e.,\{\mathcal{Q},\tau\}=0)$ if H and $\mathcal{Q}$ satisfy the pseudosuperalgebra

$$\mathcal{Q}^2=\mathcal{Q}^{\sharp 2}=0, \quad \{\mathcal{Q},\mathcal{Q}^\sharp\}=2H. \tag{29}$$

A simple realization of pseudosupersymmetry is obtained using the two-component representation of the Hilbert space where the state vectors $|\psi\rangle$ are identified by the column vector $\binom{|\psi_+\rangle}{|\psi_-\rangle}$ of their components $|\psi_\pm\rangle$ belonging to $\mathcal{H}_\pm$. In this representation, one can satisfy the η-pseudo-Hermiticity of the Hamiltonian H, [i.e., Eq. (5)] and the pseudosuperalgebra (29) by setting

$$\tau=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, \quad \eta=\begin{pmatrix}\eta_+ & 0\\ 0 & \eta_-\end{pmatrix}, \tag{30}$$

$$\mathcal{Q}=\begin{pmatrix}0 & 0\\ D & 0\end{pmatrix}, \quad H=\begin{pmatrix}H_+ & 0\\ 0 & H_-\end{pmatrix}, \tag{31}$$

where $\eta_\pm$ is a Hermitian linear automorphism of $\mathcal{H}_\pm$, $D:\mathcal{H}_+\to\mathcal{H}_-$ is a linear operator, and

$$H_+ := \tfrac{1}{2}D^\sharp D, \quad H_- := \tfrac{1}{2}D\,D^\sharp. \tag{32}$$

Note that, by definition, $\mathcal{Q}^\sharp=\eta^{-1}\mathcal{Q}^\dagger\eta$,

$$D^\sharp=\eta_+^{-1}D^\dagger\eta_-, \tag{33}$$

and that $H_\pm:\mathcal{H}_\pm\to\mathcal{H}_\pm$ are $\eta_\pm$-pseudo-Hermitian Hamiltonians satisfying the intertwining relations

$$D\,H_+=H_-D, \quad D^\sharp H_-=H_+D^\sharp. \tag{34}$$

As a consequence, H_+ and H_- are isospectral, D maps the eigenvectors of H_+ to those of H_-, and $D^\sharp$ does the converse, except for those eigenvectors that are eliminated by these operators. More specifically, suppose that $H_\pm$ has a complete biorthonormal eigenbasis $\{|\psi_n^\pm,a\rangle,|\phi_n^\pm,a\rangle\}$ satisfying

$$H_\pm|\psi_n^\pm,a\rangle=E_n^\pm|\psi_n^\pm,a\rangle, \quad H_\pm^\dagger|\phi_n^\pm,a\rangle=E_n^{\pm *}|\phi_n^\pm,a\rangle.$$

Then, $D|\psi_n^+,a\rangle$ is either zero in which case $E_n^+=0$, or it is an eigenvector of H_- with eigenvalue E_n^+; $D^\sharp|\psi_n^-,a\rangle$ is either zero in which case $E_n^-=0$, or it is an eigenvector of H_+ with eigenvalue E_n^-. Similarly $D^\dagger$ and $D^{\sharp\dagger}$ relate the eigenvectors $|\phi_n^\pm,a\rangle$ of $H_\pm^\dagger$.

An interesting situation arises when one of the automorphisms $\eta_\pm$ is trivial, e.g., $\eta_+=1$. In this case, H_+ is a Hermitian Hamiltonian with a real spectrum, and pseudosupersymmetry implies that the pseudo-Hermitian Hamiltonian H_-—which is generally non-Hermitian—must have a real spectrum as well. This is not the only way to generate non-Hermitian Hamiltonians with a real spectrum. In the next section we shall use pseudo-supersymmetry to construct a class of non-Hermitian Hamiltonians that have a real spectrum.

VI. A CLASS OF NON-HERMITIAN HAMILTONIANS WITH A REAL SPECTRUM

Consider the class of pseudosupersymmetric systems corresponding to the choices:

$$\mathcal{H}_\pm=\mathcal{H}=L^2(\mathbb{R}), \quad \eta_\pm=\pm P, \tag{35}$$

$$D=p+f(x)+ig(x), \tag{36}$$

where f and g are real-valued functions. We can express these functions in the form

$$f(x)=f_+(x)+f_-(x),\quad g(x)=g_-(x)+g_+(x), \tag{37}$$

where f_+ and g_+ are even functions of x, and f_- and g_- are odd functions. In view of Eqs. (35)–(37), (33), and (32), we have

$$D^\sharp=p-f_+(x)+f_-(x)+i[g_+(x)-g_-(x)], \tag{38}$$

$$H_\pm=\tfrac{1}{2}([p+f_-(x)]^2+g'_-(x)\pm g_-^2-f_+^2-i[2g_-(x)f_+(x)\pm f'_+(x)]+K), \tag{39}$$

$$K:=i\{g_+(x),p\}+g_+(x)[2if_-(x)-g_+(x)], \tag{40}$$

where a prime means a derivative and {,} stands for the anticommutator.

Next, we demand that H_+ is a Hermitian Hamiltonian. The necessary and sufficient condition for the Hermiticity of H_+ and non-Hermiticity of H_- is

$$g_+(x)=0,\quad g_-(x)=-\frac{f'_+(x)}{2f_+(x)}. \tag{41}$$

Introducing the even function $\xi(x):=\ln|f_+(x)/\lambda|$ for some $\lambda\in\mathbb{R}-\{0\}$, and using Eqs. (39)–(41), we have

$$H_+=\tfrac{1}{2}([p+f_-(x)]^2+\tfrac{1}{4}\xi'(x)^2-\tfrac{1}{2}\xi''(x)-\lambda^2e^{2\xi(x)}), \tag{42}$$

$$H_-=\tfrac{1}{2}([p+f_-(x)]^2-\tfrac{1}{4}\xi'(x)^2-\tfrac{1}{2}\xi''(x)-\lambda^2e^{2\xi(x)}+2i\lambda e^{\xi(x)}\xi'(x)). \tag{43}$$

By construction, $H_\pm$ are pseudo-Hermitian pseudo-supersymmetric partners. In particular, they are isospectral. H_+ happens to be a Hermitian operator. This implies that the eigenvalues of both H_+ and H_- are real. Furthermore, for $f_-(x)\neq 0$, H_- is not PT-invariant. This is a concrete example of a non-Hermitian Hamiltonian with a real spectrum that fails to be PT-symmetric.

Equation (43) provides a large class of non-Hermitian Hamiltonians with a real spectrum whose members are determined by the choice of functions f_- and ξ. This class includes Hamiltonians with a discrete spectrum. For example let $\xi(x)=-(x/\ell)^{2n}$, where n is a positive integer and ℓ is a positive real parameter with the dimension of length. Then

$$H_\pm=\tfrac{1}{2}[p+f_-(x)]^2+V_\pm(x),$$

$$V_+=\tfrac{1}{2}(n^2\ell^{-4n}x^{4n-2}+n(2n-1)\ell^{-2n}x^{2n-2}-\lambda^2e^{-2\ell^{-2n}x^{2n}}),$$

$$V_-=\tfrac{1}{2}(-n^2\ell^{-4n}x^{4n-2}+n(2n-1)\ell^{-2n}x^{2n-2}-\lambda^2e^{-2\ell^{-2n}x^{2n}}-4i\lambda n\ell^{-2n}x^{2n-1}e^{-\ell^{-2n}x^{2n}}).$$

It is not difficult to see that H_+ is a Hermitian Hamiltonian with a discrete spectrum. Therefore, H_- has a real discrete spectrum as well.

VII. CONCLUSION

In this article, we have introduced the concept of a pseudo-Hermitian operator and showed that the desirable spectral properties attributed to PT-symmetry are in fact consequences of pseudo-Hermiticity of the corresponding Hamiltonians. We have derived various properties of pseudo-Hermitian conjugation and pseudo-Hermitian operators. In particular, we showed how the defining automorphism η is linked to the eigenvectors of an η-pseudo Hermitian Hamiltonian H with a complete biorthonormal eigenbasis. As the corresponding eigenbasis is subject to gauge transformations, the automorphism with respect to which H is pseudo-Hermitian is not unique. This raises the question of the classification of the equivalence classes of automorphisms that lead

to the same notion of pseudo-Hermiticity for a given Hamiltonian. We have given a brief discussion of this problem and showed its connection with symmetries of the Hamiltonian. We have also developed a generalization of supersymmetry that would apply for general pseudo-Hermitian Hamiltonians, and used it to construct a class of pseudo-Hermitian Hamiltonians with a real spectrum.

A particularly interesting result of our investigations is that all the PT-symmetric Hamiltonians that admit a complete biorthonormal eigenbasis are pseudo-Hermitian. In this sense, pseudo-Hermiticity is a generalization of PT-symmetry.

For a PT-symmetric Hamiltonian, the exactness of PT-symmetry implies the reality of the spectrum. More specifically, if an eigenvector $|E\rangle$ is PT-invariant, $PT|E\rangle=|E\rangle$, then the corresponding eigenvalue E is real. A similar condition for a general pseudo-Hermitian Hamiltonian is not known. Pseudo-Hermiticity is only a necessary condition for the reality of the spectrum, not a sufficient condition. In contrast, PT-symmetry is neither necessary nor sufficient. The exact PT-symmetry is a sufficient condition. But for a given PT-symmetric Hamiltonian it is not easy to determine the exactness of PT-symmetry without actually solving the corresponding eigenvalue problem.

We hope that the concepts developed in this article provide the material for a more rigorous study of the foundation of pseudounitary quantum mechanics.

Asymptotics of bound states and bands for laterally coupled waveguides and layers

I. Yu. Popov[a)]
Department of Higher Mathematics, Leningrad Institute of Fine Mechanics and Optics, 14 Sablinskaya, St.-Petersburg 197101, Russia

(Received 2 June 2000; accepted for publication 16 October 2001)

The asymptotics (in the width of windows) of eigenvalues and bands for two-dimensional waveguides and three-dimensional layers coupled through small windows is obtained. The technique is matching of asymptotic expansions of the solutions of boundary value problems. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1425081]

I. INTRODUCTION

The recent development of nanoelectronics allows physicists to create different mesoscopic structures. It stimulates remarkable progress in semiconductor physics. At the same time this progress has brought interesting mathematical problems with direct relevance to physics. The description of ballistic electron transport in many mesoscopic quantum systems reduces to the description of electron wave propagation in a system of waveguides or layers (see, e.g., Refs. 1–5). The problem of bound states for laterally coupled waveguides recently attracted a new wave of interest. This paper deals with different systems of two-dimensional waveguides and three-dimensional layers coupled through small apertures. First, we consider a system of two waveguides Ω_+, Ω_- of widths d_+, d_- coupled laterally through a small window of width $2a$. It has been proved in Ref. 6 that the Dirichlet Laplacian for this system has an eigenvalue λ_a closed to the threshold and it can be estimated as

$$c_1 a^4 \leqslant \frac{\pi^2}{d_+^2} - \lambda_a \leqslant c_2 a^4 \tag{1}$$

for sufficiently small a (the order of this term was found in Ref. 7 on physical level of rigor). Here c_1, c_2 are some constants, $d_+ > d_-$. The authors used variational technique and obtained only estimates and not asymptotics. Analogous estimates were obtained for the case of n coupling windows.[8] The asymptotics of the eigenvalue in question was obtained in Refs. 9 and 10. Some further results are in Ref. 11 (the asymptotics of resonances close to the Nth threshold) and Ref. 12 (the asymptotics of eigenvalues and resonances for curved coupled waveguides). A method of matching the asymptotic expansions (in a) for the corresponding solutions was used. The scheme of matching was a modification of that suggested in Refs. 13 and 14. One can see that there is some correlation between the result and known weak-coupling asymptotics for Schrödinger operators.[15]

In the beginning of the first part of the present paper we describe briefly the procedure and the results of Ref. 10. The result is in good correlation with estimates in Ref. 8. The case of periodic system of coupling openings is considered. In this situation the matching procedure has some new features. The key idea is that it is necessary to consider each fiber (each value of the quasimomentum) separately and to seek the asymptotic expansion not for the eigenvalue but for some function of the eigenvalue of the operator for fixed fiber. The choice of this function is related to

a)Electronic mail: popov@mail.ifmo.ru

the behavior of the Green function for spectral parameter tending to the threshold. The asymptotics of edges of the band which tends to the threshold for $a \to 0$ is obtained.

Then, we consider a coupled two-dimensional quantum waveguide and resonator in the presence of a magnetic field. The quantum mechanical Hamiltonian of a free two-dimensional charged particle in a homogeneous magnetic field that is perpendicular to the plane of confinement of the particle is given in Landau's gauge by the following differential expression:

$$h = -\left(\frac{\partial}{\partial x_1} + Bx_2\right)^2 - \frac{\partial^2}{\partial x_2^2}. \tag{2}$$

More precisely, the aforementioned Hamiltonian H is a self-adjoint operator in $L^2(\mathbf{R}^2)$ which is the closure of the symmetric operator h with domain $C_0^\infty(\mathbf{R}^2)$.[16] In (2) B is the magnetic induction, the system of units is chosen so that the charge of the particle and the physical constants c and $\hbar$ are equal to unity, and the mass of the particle is 1/2. We shall deal with the Hamiltonian in the strip and bounded domain with the Dirichlet boundary condition coupled through a small window. The structure of the spectrum of the Schrödinger operator with magnetic field in a single strip was considered in Ref. 17. A shift of the eigenvalue for the resonator caused by coupling is considered.

In the second part of the paper we deal with a system of two layers Ω_+, Ω_- of widths d_+, d_-,

$$\Omega_\pm = \{(x_1, x_2, x_3) \in \mathbf{R}^2 \times [0, \pm d_\pm]\},$$

coupled laterally through small windows. The problem for the case of one coupling aperture ω_a of the diameter $2a$, $\omega_a = a\omega$, was considered in Ref. 8. It has been proved that the Dirichlet Laplacian for this system has an eigenvalue λ_a close to the threshold and there exist positive constants c_1, c_2, such that

$$e^{-c_1 a^{-3}} \leqslant \frac{\pi^2}{d_+^2} - \lambda_a \leqslant e^{-c_2 a^{-3}} \tag{3}$$

for sufficiently small a, $d_+ > d_-$. The authors used a variational technique.

In the present paper we consider the case of finite and infinite (periodic) systems of coupling windows and obtain the asymptotics of the ground state (for N windows) and the asymptotics of the band (for periodic system of windows). Singly periodic and doubly periodic lattices are considered in the case when there are several window centers in the primitive cell of the lattice. The method of matching of the asymptotic expansions (in a) for the corresponding solutions is used. The scheme of matching described previously is modified. The key idea of the improvement is that one should seek the asymptotic expansion not for the eigenvalue in question but for some function of it. The choice of the function is related to the behavior of the Green function (as a function of spectral parameter) near the threshold. This function changes when we come to the case of periodic system of windows. The case of $d_+ = d_-$ is considered too. It is interesting that in this case the asymptotics is not a limit of that for $d_+ \to d_-$, $d_+ > d_-$ (an additional factor appears). An analogous situation was in the case of waveguides (see previous text). The result (for $N = 1$) is compared with estimates in Ref. 8.

II. COUPLED WAVEGUIDES: SINGLE WINDOW AND FINITE NUMBER OF WINDOWS

Let us describe the procedure of the construction of the asymptotic series for the eigenvalue in the simplest case—two waveguides coupled through a single window. The small parameter a is the halfwidth of the opening. Consider the case when $d_+ > d_-$. Let $\lambda_a = k_a^2$ be the eigenvalue in question. We shall seek the asymptotic series of the following form:

$$\left(\frac{\pi^2}{d_+^2} - k_a^2\right)^{1/2} = \sum_{j=2}^{\infty} \sum_{i=0}^{\infty} k_{ji} a^j (\log a)^i. \tag{4}$$

For the corresponding eigenfunction $\psi_a(x)$ the asymptotic series is the following:

$$\psi_a(x)=\left(\frac{\pi^2}{d_+^2}-k_a^2\right)^{1/2}\sum_{j=0}^{\infty} a^j P_{j+1}(D_y,\log a)G^-(x,y,k)\big|_{y=0}, \quad x\in\Omega^- - S_{a^{1/2}}, \tag{5}$$

$$\psi_a(x)=\sum_{j=1}^{\infty}\sum_{i=0}^{[(j-1)/2]} v_{ji}(x/a)a^j(\log a)^i, \quad x\in S_{2a^{1/2}}, \tag{6}$$

$$\psi_a(x)=-\left(\frac{\pi^2}{d_+^2}-k_a^2\right)^{1/2}\sum_{j=0}^{\infty} a^j P_{j+1}(D_y,\log a)G^+(x,y,k)\big|_{y=0}, \quad x\in\Omega^+ - S_{a^{1/2}}, \tag{7}$$

where S_t is the sphere of radius t with the center at the center of the opening,

$$v_{ji}\in W^1_{2,\mathrm{loc}}(\Omega^+\cup\Omega^-), \quad P_1(D_y,\log a)=a^{(1)}_{10}\frac{\partial}{\partial n_y},$$

$P_m(D_y,\log a)$ are some polynomials in normal and tangential derivatives (in respect to y):

$$P_m(D_y,\log a)=\sum_{q=1}^{m-1}\sum_{i=0}^{[q/2]-1} a^{(m)}_{qi}(\log a)^i D_y^{m-q+1}, \quad m\geqslant 2. \tag{8}$$

$G^{\pm}$ are the Green functions for the waveguides $\Omega^{\pm}$. It is known that its derivatives can be represented in close proximity of the point π^2/d_+^2 in the form

$$\begin{aligned} D_y^j G^+(x,0,k)&=\frac{1}{d_+}\sin\frac{\pi x_2}{d_+}D_x^j\left(\sin\frac{\pi x_2}{d_+}\right)\Bigg|_{x_2=0}\left(\frac{\pi^2}{d_+^2}-k_a^2\right)^{-1/2}+\Phi_j(x,k)\log r+g_j^+(x,k)\\ &\quad+\sum_{i=0}^{[j/2]}\sum_{t=0}^{j-2i-1} b^{(j)}_{it}(k)r^{-j+2(i+t)}\sin(j-2i)\theta,\\ D_y^j G^-(x,0,k)&=\Phi_j(x,k)\log r+g_j^-(x,k)+\sum_{i=0}^{[j/2]}\sum_{t=0}^{j-2i-1} b^{(j)}_{it}(k)r^{-j+2(i+t)}\sin(j-2i)\theta, \end{aligned} \tag{9}$$

where (r,θ) are polar coordinates. Terms $b^{(j)}_{it}(k)$, $\Phi_j(x,k)$, $g_j^-(x,k)$ are analytic in respect to k in some neighborhood of the point π/d_+, $\Phi_j\in C^\infty(\mathbf{R}^2)$ and is antisymmetric with respect to x_2, $g_j^{\pm}\in C^\infty(\Omega^{\pm})$,

$$b^{(j)}_{00}=(-1)^{[(j+1)/2]}(j-1)!/\pi, b^{(3)}_{10}=k^2/(2\pi), \Phi_{1n}(0,k)=-k^2/(2\pi). \tag{10}$$

Boundary problems for the coefficients of the series (6) are obtained by the following way. One substitutes the series (6) and (4) [more precisely, not only (4), but also the corresponding series for k_a] into the Helmholtz equation (for $k=k_a$) with the Dirichlet boundary condition. Then one changes the variables: $\xi=x/a$. The coefficients in the terms with identical powers of a and $\log a$ should be equal. Hence, one obtains the following problems:

$$\begin{aligned} \Delta_\xi v_{ji}&=-\sum_{p=0}^{j-3}\sum_{q=0}^{[p/2]-1}\Lambda_{pq}v_{j-p-2,i-q}, \quad \xi\in\mathbf{R}^2\backslash\Gamma,\\ v_{ji}&=0, \quad \xi\in\Gamma, \end{aligned} \tag{11}$$

where

$$\Gamma=\{\xi:\xi_2=0,\xi_1\in(-\infty,-1]\cup[1,\infty)\},$$

Λ_{pq} are the coefficients of the series

$$k_a^2=\sum_p\sum_q\Lambda_{pq}a^p(\log a)^q.$$

Let $\psi_a^{\pm}(x,k)$ be the series (5), (7), $P_m^{(N)}(D_y,\log a)$ the sums of type (8) where the summation limit $m-1$ is replaced by $\min(m-1,N)$, $\Psi_{a,N}^{\pm}$ the series $\psi_a^{\pm}(x,k)$ in which P_j is replaced by $P_j^{(N)}$, $\hat{\psi}_a^{\pm}(x,k)$, $\hat{k}_N(a)$, $\hat{v}_N(\xi,a)$ the partial sums of the corresponding series. Note that Nth finite sums of the series $\psi_a^{\pm}(x,k)$ and $\Psi_{a,N}^{\pm}(x,k)$ coincide because of the definition of $P_j^{(N)}$. Let us define the operator M_{pq} for the sums $U(x,a)$ of the type (5), (7) (for $k=k_a$) in the following manner: decompose the coefficients of $U(x,a)$ in the asymptotic series for $r\to0$, replace the variables ($\xi=x/a$) and, simultaneously, replace $\log r$ by $\log\rho+\log a$, $\rho=|\xi|$. Mark as $M_{pq}(U)$ the sum of all terms of the type $a^p(\log a)^q\phi(\xi)$. Let

$$M_p=\sum_q M_{pq}. \tag{12}$$

Lemma 1: Let k_a have asymptotics given by (4). Define $L_N(\Psi_{a,N}^{\pm}(x,k_a))$ in the following way:

$$L_1(\Psi_{a,1}^{\pm}(x,k_a))=M_1(\Psi_{a,1}^{\pm}(x,k_a)).$$

$$L_N(\Psi_{a,N}^{\pm}(x,k_a))=L_{N-1}(\Psi_{a,N-1}^{\pm}(x,k_a))+M_N(\Psi_{a,N}^{\pm}(x,k_a)).$$

Then for $N\geqslant1$ the following correlations take place:

$$L_N(\Psi_{a,N}^{\pm}(x,k_a))=\sum_{j=1}^{N}\sum_{i=0}^{[(j-1)/2]}V_{ji}^{\pm}(\xi)a^j(\log a)^i,$$

$$L_N(\Psi_{a,N}^{\pm}(x,k_a))-L_N(\hat{\psi}_{a,N}^{\pm}(x,\hat{k}_N(a)))=O(a\rho^{-N}+a^N(\log a)^N\rho^{-1}),$$

$$(L_N(\Psi_{a,N}^{\pm}(x,k_a))-L_N(\hat{\psi}_{a,N}^{\pm}(x,\hat{k}_N(a))))_{\xi_i}=O(a\rho^{-N-1}+a^N(\log a)^N\rho^{-2}),$$

$$\hat{\psi}_{a,N}^{\pm}(x,\hat{k}_N(a))-L_N(\hat{\psi}_{a,N}^{\pm}(x,\hat{k}_N(a)))=O(r^{N+1}+a^{N+1}(\log a)^N),$$

$$(\hat{\psi}_{a,N}^{\pm}(x,\hat{k}_N(a)))_{x_i}-(L_N(\hat{\psi}_{a,N}^{\pm}(x,\hat{k}_N(a))))_{x_i}=O(r^N+a^{N+1}(\log a)^N/r),$$

for $\rho\to\infty,r\to0$, respectively. Series $V_{ji}^{\pm}(\xi)$ does not depend on N, is the asymptotic solution of (11) for $\rho\to\infty$, and $v_{qm}=V_{qm}^{\pm}(\xi)$ in the right-hand side of (11) has a structure:

$$V_{ji}^{\pm}(\xi)=\sum_{q=-p}^{\infty}\rho^{-q}f_{jiq}^{\pm}(\theta)+\log\rho\sum_{q=1}^{p-2}\rho^qF_{jiq}^{\pm}(\theta), \tag{13}$$

where $p=j-2i$, $F_{jiq}^{\pm}(\theta)$, $f_{jiq}^{\pm}(\theta)$ are linear combinations of $\sin m\theta$, and their sums $V_{ji}^{-}(\xi)+V_{ji}^{+}(\xi)$ are polynomials of $j-2i$ order. Series $V_{Ni}^{\pm}(\xi)$ has a form

$$V_{Ni}^{\pm}(\xi)=\hat{V}_{Ni}^{\pm}(\xi)+k_{N+1,i}k_{20}^{-1}(V_{10}^{\pm}(\xi)\pm\widetilde{V_{10}^{\pm}}(\xi))\pm\frac{k_{20}}{\pi}\sum_{i=0}^{[(N-1)/2]}\sum_{j=2}^{\infty}a_{Nl}^{N-1+p}(-1)^{[(j+1)/2]}$$

$$\times(j-1)!\rho^{-j}\sin j\theta,$$

where $\hat{V}^{\pm}_{Ni}(\xi)$ does not depend on $k_{q+1,p}, a^{(m)}_{qp}$ for $q \geqslant N$,

$$\widetilde{V^{\pm}_{10}}(\xi) = \begin{cases} 0, & \xi_2 > 0, \\ \xi_2, & \xi_2 < 0. \end{cases}$$

The proof consists of direct calculations using asymptotics (9) and (10). Thus, to achieve matching it is necessary to show that there exist values k_{ji}, polynomials P_j, and functions v_{ji} being solutions of (11) such that asymptotics of $v_{ji}, \rho \to \infty$, $\xi_2 > 0 (\xi_2 < 0)$, coincides with the series $V^{+}_{ji}(\xi)(V^{-}_{ji}(\xi))$, correspondingly. We confine our attention in the following to the first term k_{20} only.

Using the described procedure, we obtain the following theorem:

Theorem 1: The leading term of the asymptotics of the eigenvalue λ_a which tends to the lower bound of the continuous spectrum is

$$\lambda_a = \begin{cases} \pi^2/d_+^2 - \left(\dfrac{\pi^3}{4d_+^3}\right)^2 a^4 + o(a^4), & d_+ > d_-, \\ \pi^2/d^2 - \left(\dfrac{\pi^3}{2d^3}\right)^2 a^4 + o(a^4), & d_+ = d_- = d. \end{cases} \tag{14}$$

Remark: The case of coupled curved waveguides is considered in Ref. 12.

The procedure is analogous for the case when there are n coupling windows with the centers at the points $(x_q, 0)$, $q = 1, \ldots, n$, of widths $2a_q = 2a\omega_q$, correspondingly. Let $d_+ > d_-$. Formulas (5)–(7) now have the form:

$$\psi_a(x) = \left(\frac{\pi^2}{d_+^2} - k_a^2\right)^{1/2} \sum_{j=0}^{\infty} \sum_{q=1}^{n} a^j P^q_{j+1}(D_y, \log a) G^{-}(x, y, k)\big|_{y=(x_q,0)}, \quad x \in \Omega^{-} \setminus \cup_q S^q_{a^{1/2}}, \tag{15}$$

$$\psi_a(x) = \sum_{j=1}^{\infty} \sum_{i=0}^{[(j-1)/2]} v^q_{ji}(x/a) a^j (\log a)^i, \quad x \in S^q_{2a^{1/2}}, \tag{16}$$

$$\psi_a(x) = -\left(\frac{\pi^2}{d_+^2} - k_a^2\right)^{1/2} \sum_{j=0}^{\infty} \sum_{q=1}^{n} a^j P^q_{j+1}(D_y, \log a) G^{+}(x, y, k)\big|_{y=(x_q,0)}, \quad x \in \Omega^{+} \setminus \cup_q S^q_{a^{1/2}}, \tag{17}$$

where S^q_t is the corresponding sphere with the center at $(x_q, 0)$. Let us choose

$$P^q_1(D_y, \log a) = \alpha_q \frac{d_+}{\pi} \frac{\partial}{\partial n_y},$$

then, we have

$$a^{-1} M^q_1 (\pi^2/d_+^2 - k_a^2)^{1/2} \sum_{p=1}^{n} P^p_1 G^{+}(x, (x_p, 0), k_a) = -\alpha_q \frac{d_+}{\pi^2} k_{20} \xi_2 \rho_q^{-2} - \sum_{p=1}^{n} \alpha_p \frac{\pi}{d_+^2} \xi_2, \tag{18}$$

$$a^{-1} M^q_1 (\pi^2/d_+^2 - k_a^2)^{1/2} \sum_{p=1}^{n} P^p_1 G^{-}(x, (x_p, 0), k_a) = \alpha_q \frac{d_+}{\pi^2} k_{20} \xi_2 \rho_q^{-2}, \tag{19}$$

where ρ_q is the distance from the center of the qth window, M^q_1 is the expression (12) corresponding to the point $(x_q, 0)$. To construct $v^q_{ji}(x/a)$ we use a harmonic function having the following asymptotics:

$$\hat{Y}_1(\xi)=\begin{cases}\sum_{q=1}^{n}\alpha_q\xi_2+\sum_{j=1}^{\infty}c_{1j}^{q}\rho_q^{-j}\sin j\theta_q, & \xi_2>0,\\ -\sum_{j=1}^{\infty}c_{1j}^{q}\rho_q^{-j}\sin j\theta_q, & \xi_2<0.\end{cases} \tag{20}$$

Here the coefficients

$$c_{11}^{q}=\sum_{p=1}^{n}\alpha_p c_{\omega_q},$$

where c_{ω_q} is the harmonic capacity of the corresponding segment in $\mathbf{R}^2$. It is known (Ref. 18) that it is the following:

$$c_{\omega_q}=(\omega_q/2)^2.$$

Making matching of terms of order $\rho_q^{-1}\sin\theta_q$ in neighborhoods of each opening, we obtain the following system for the determination of α_q:

$$\sum_{q=1}^{n}\alpha_q c_{\omega_{qi}}=\frac{d_+^3}{\pi^3}k_{20}\alpha_i, \quad i=1,2,\ldots,n. \tag{21}$$

The condition of nontrivial solvability of (21) is

$$\det\begin{pmatrix} c_{\omega_1}-\beta & c_{\omega_1} & \ldots & c_{\omega_1}\\ c_{\omega_2} & c_{\omega_2}-\beta & \ldots & c_{\omega_2}\\ . & . & . & .\\ c_{\omega_n} & c_{\omega_n} & \ldots & c_{\omega_n}-\beta\end{pmatrix}=0.$$

Here

$$\beta=\frac{d_+^3}{\pi^3}k_{20}.$$

Simple calculations lead to the value of k_{20}:

$$k_{20}=\frac{\pi^3}{d_+^3}\sum_{i=1}^{n}c_{\omega_i}. \tag{22}$$

Other $n-1$ roots of the equation give us $k_{20}=0$. It means that the terms of such order in the asymptotic series do not give us information about other eigenvalues. The obtained value is the leading term of the asymptotics in a of the ground state only. It was shown in Ref. 8 that for sufficiently small a the discrete spectrum contains only one simple eigenvalue. The case of two identical waveguides can be considered in the analogous way. The result is the following theorem.

Theorem 2: The leading term of the asymptotics of the eigenvalue λ_a which tends to the lower bound of the continuous spectrum for the case of n coupling windows is

$$\lambda_a=\begin{cases} \pi^2/d_+^2-\left(\dfrac{\pi^3}{d_+^3}\displaystyle\sum_{i=1}^{n} c_{\omega_i}\right)^2 a^4+o(a^4), & d_+>d_-, \\ \pi^2/d^2-\left(\dfrac{2\pi^3}{d^3}\displaystyle\sum_{i=1}^{n} c_{\omega_i}\right)^2 a^4+o(a^4), & d_+=d_-=d. \end{cases} \tag{23}$$

Remark: Here we deal with the eigenvalue only. That is why we confine our attention to the lower bound of the continuous spectrum only. There are resonances (quasibound states) near other thresholds (lower bounds of other branches of the continuous spectrum). To obtain its asymptotics it is necessary to construct additional terms of the asymptotic expansions. This problem was analyzed in Ref. 11. In the present work we deal with the Dirichlet boundary condition because it is more natural for quantum waveguide. But the suggested approach can be applied to the case of Neumann or Robin boundary conditions too.

III. COUPLED WAVEGUIDES: PERIODIC SYSTEM OF WINDOWS

Consider waveguides coupled through periodic system of windows ($x^q=qL$). In this case consideration has essentially new features. We shall describe these differences and the result. First, we must replace $(\pi^2 d_+^{-2}-k_a^2)^{1/2}$ in (4), (15), and (17) by another function $f(k_a)$ (see the following). Expressions (15) and (17) should be modified in the following way:

$$\psi_a(x)=\pm f(k_a)\sum_{q=-\infty}^{\infty}\alpha_q\frac{\partial}{\partial n_y}G^{\mp}(x,y,k)\big|_{y=(x^q,0)}+o(a^0), \quad x\in\Omega^{\mp}-\cup_q S_{a^{1/2}}^q, \tag{24}$$

Periodicity leads to the Bloch condition, i.e., $\alpha_q=\exp(i\theta Lq)\alpha_0$, where θ is quasimomentum, $-\pi L^{-1}\leqslant\theta\leqslant\pi L^{-1}$. We shall construct the asymptotics in each fiber, i.e., for fixed value of the quasimomentum (the operator for particular fiber has an eigenvalue). Then by varying θ, we shall obtain band parameters. Matching procedure in a neighborhood of each window is analogous to that for the previous case. The sum on the right-hand side of (18) for $q=0$ is replaced by the series

$$\alpha_0\sum_{q=-\infty}^{\infty}\exp(iqL\theta-\gamma L|\theta|)=(\gamma(\cosh(\gamma L)-\cos(\theta L)))^{-1}\sinh(\gamma L)\alpha_0.$$

Due to this fact we choose the function $f(k_a)$ in the following form:

$$f(k_a)=\gamma(\cosh(\gamma L)-\cos(\theta L))(\sinh(\gamma L))^{-1}.$$

The first terms of the asymptotic expansion (in a) of $f(k_a)$ is sought in the form [compare with (4)]:

$$f(k_a)=L^{-1}(1-\cos(\theta L))+k_{20}a^2+o(a^2). \tag{25}$$

Note that the asymptotics of k_a^2 depends on θ, i.e., we seek asymptotics in each fiber separately.

Matching of terms of order a^{-1} is evident, because one has from (24) and (25) only the following terms of this order:

$$\pm(\pi L)^{-1}(1-\cos(\theta L))\alpha_0\xi_2\rho^{-2}, \quad \xi_2>0(\xi_2<0).$$

As for terms of order a, one gets [instead of (18) and (19)]:

$$a^{-1}M_1^0\left(f(k_a)\sum_{p=-\infty}^{\infty}\alpha_p\frac{\partial G^+}{\partial n_y}(x,(x^p,0),k_a)\right)=-\alpha_0\frac{k_{20}}{\pi}\xi_2\rho_q^{-2}-\alpha_0\frac{\pi^2}{d_+^3}\xi_2,$$

$$a^{-1}M_1^0\left(f(k_a)\sum_{p=-\infty}^{\infty}\alpha_p\frac{\partial G^-}{\partial n_y}(x,(x^p,0),k_a)\right)=\alpha_0\frac{k_{20}}{\pi}\xi_2\rho_q^{-2}.$$

Hence, to match increasing at infinity terms we choose the function v_{10}^0 in the form: $v_{10}^0=-\pi^2 d_+^{-3}\alpha_0 Y_1$. Making equal terms of order $\xi_2\rho_q^{-2}$, one gets $k_{20}=\pi^2 d_+^{-3}/4$. Consequently, the leading term of the asymptotics of the eigenvalue in a fiber is obtained from

$$\gamma(\cosh(\gamma L)-\cos(\theta L))(\sinh(\gamma L))^{-1}=\pi^2 d_+^{-3}a^2/4+o(a^2),\quad \gamma=(\pi^2 d_+^{-2}-k_a^2)^{1/2}.$$

To get a band one should vary the quasimomentum θ, $-\pi L^{-1}\leqslant\theta\leqslant\pi L^{-1}$. To estimate the band edges for small a one can replace the function $\cosh(\gamma L)$ [and $\sinh(\gamma L)$] by the first two terms of its Taylor's series. Changes for the case of two identical waveguides are the same as earlier. The result is the following theorem.

Theorem 3: The asymptotics of the edges of the band which tends to the lower bound of the continuous spectrum for the case of periodic system of coupling windows is as follows:

$$\frac{\pi^2}{d_+^2}-\frac{3\pi^3}{2Ld_+^3}a^2+o(a^2)\leqslant\lambda_a\leqslant\frac{\pi^2}{d_+^2}-\frac{\pi^3}{2Ld_+^3}a^2+o(a^2),\quad d_+>d_-,$$

$$\frac{\pi^2}{d^2}-\frac{3\pi^3}{Ld^3}a^2+o(a^2)\leqslant\lambda_a\leqslant\frac{\pi^2}{d^2}-\frac{\pi^3}{Ld^3}a^2+o(a^2),\quad d_+=d_-=d.$$

Remark: One can see that there is a gap in the spectrum for sufficiently small a.

IV. RESONATOR COUPLED WITH A WAVEGUIDE IN A MAGNETIC FIELD

Consider a system of resonator Ω^{in} coupled through small window ω_a of width $2a$ with a waveguide Ω^{ex}. Let λ_0^{in} be an eigenvalue of the Schrödinger operator with a magnetic field in Ω^{in} (without opening) with the Dirichlet boundary condition and ψ_0 be the corresponding eigenfunction. Let λ_0^{in} be less than the threshold for Ω^{ex}. Then, for sufficiently small a one has a perturbed eigenvalue λ_a^{in} for the system of coupled resonator and waveguide. We seek the asymptotics (the main terms) of k_a^{in}, $k_a^{\text{in}}=\sqrt{\lambda_a^{\text{in}}}$ in the form:

$$k_a^{\text{in}}=k_0+k_{20}a^2+o(a^2),\quad k_0=\sqrt{\lambda_0^{in}}. \tag{26}$$

The asymptotic expansion for the corresponding eigenfunction is as follows:

$$\psi_a(x)=\pm(k^2-k_0^2)\alpha\frac{\partial}{\partial n_y}G^{\text{in,ex}}(x,y,k)\big|_{y=(0,0)}+o(a^0),\quad x\in\Omega^{\text{in,ex}}\setminus S_{a^{1/2}}, \tag{27}$$

$$\psi_a(x)=v_{10}(x/a)a+o(a),\quad x\in S_{2a^{1/2}}, \tag{28}$$

where $G^{\text{in,ex}}$ are the Green functions for $\Omega^{\text{in,ex}}$.

The procedure is analogous to that for coupled waveguides. The difference is that for the Green function of the resonator one has another asymptotics:[20]

$$\frac{\partial G^{\text{in}}}{\partial n_y}(x,(0,0),k)=\frac{\psi_{0n}(0)\psi_0(x)}{k^2-k_0^2}-\pi^{-1}r^{-1}\sin\theta+\Phi_1(x,k)\log r+g_1^{\text{in}}(x,k),$$

$$\frac{\partial G^{\text{ex}}}{\partial n_y}(x,(0,0),k)=-\pi^{-1}r^{-1}\sin\theta+\Phi_1(x,k)\log r+g_1^{ex}(x,k),$$

where ψ_{0n} is the normal derivative of ψ_0.

Boundary problems for the coefficients of the asymptotic series (28) (in our case for one term v_{10}) are obtained in the following way. One substitutes the series (26)–(28) into the following equation (for $k=k_a$) [see (2)] (with the Dirichlet boundary condition):

$$-\Delta u-2iB\left(x_2\frac{\partial u}{\partial x_1}+\frac{\partial(x_2u)}{\partial x_2}\right)+(B^2x_2^2-k^2)u=0.$$

Then, one changes the variables: $\xi=x/a$, and obtains

$$-a^{-1}\Delta v_{10}(\xi)-a2iB\xi_2\frac{\partial v_{10}(\xi)}{\partial\xi_1}+(-E_0^+ +a^2B^2\xi_2^2+\cdots)v_{10}(\xi)+\cdots=0.$$

The coefficients in the terms with identical powers of a (and $\log a$ for the next terms) should be equal. Hence, one obtains the following problem for v_{10} (terms of order a^{-1} in the equation):

$$\Delta_\xi v_{10}=0,\quad \xi\in\mathbf{R}^2\backslash\Gamma,\quad v_{10}=0,\quad \xi\in\Gamma, \tag{29}$$

where $\Gamma=\{\xi:\xi_2=0,\xi_1\in(-\infty,-1]\cup[1,\infty)\}$.

Matching of terms of the asymptotic expansions gives one the value of k_{20}:

$$k_{20}=-\frac{\pi|\psi_{0n}(0)|^2}{8k_0}.$$

The result is as follows.

Theorem 4: The leading term of the asymptotics of the perturbed eigenvalue λ_a^{in} has the following asymptotics

$$\lambda_a^{\text{in}}=\lambda_0^{\text{in}}-\frac{\pi|\psi_{0n}(0)|^2}{4}a^2+o(a^2).$$

Remark: The dependence on B is due to the term ψ_{0n}.

Example: Consider circular resonator Ω^{in}. For this case one can find ψ_{0n} explicitly. Let us deal with physical units in the example: m,e are the mass and charge of an electron, respectively, c is the speed of light, $\hbar$ is Planck's constant, $\mathbf{p}=-i\hbar\nabla$, $\mathbf{A}=2^{-1}\mathbf{B}\times\mathbf{r}$. Then the Schrödinger operator with a magnetic field (the Landau operator) is

$$H=\frac{1}{2m}\left(\mathbf{p}-\frac{e}{c}\mathbf{A}\right)^2.$$

Let Ω^{in} be a disk $\Omega^{\text{in}}=\{(r,\varphi):r\leqslant r_0\}$. Introduce the following notation:

$$\omega=\frac{|e\mathbf{B}|}{cm},\quad \lambda=\left(\frac{\hbar c}{|e\mathbf{B}|}\right)^{1/2},\quad x_0=\frac{r_0}{2\lambda^2}.$$

The spectrum of the operator H with the Dirichlet boundary conditions consists of the eigenvalues E_{st},

$$E_{st}=\hbar\omega(2^{-1}(s+|s|+1)-\epsilon_{st}),\quad s=0,\pm1,\pm2,\ldots,\quad t=1,2,\ldots,$$

ϵ_{st} is a root of the equation $\Phi(\epsilon,|s|+1,x_0)=0$. Here $\Phi(a,c,x)=M(a,c,x)$ is the Kummer function. The corresponding eigenfunction $\psi_{(st)}$ is

$$\psi_{(st)}(r,\varphi)=\left(\frac{m\omega}{2\pi\hbar c_{st}}\right)^{1/2}\frac{r^{|s|}}{(2\lambda^2)^{|s|/2}}\exp\left(is\varphi-\frac{r^2}{4\pi\lambda^2}\right)\Phi\left(\epsilon_{st},|s|+1,\frac{r^2}{2\lambda^2}\right),$$

where c_{st} is normalization constant,

$$c_{st}=\int_0^{x_0}\exp(-x)x^{|s|}(\Phi(\epsilon_{st},|s|+1,x))^2\,dx.$$

The Green function has a form

$$G^{\text{in}}(r,\varphi,r',\varphi';\zeta)=\frac{m\omega}{2\pi\hbar}\exp\left(-\frac{r^2+r'^2}{4\lambda^2}\right)\sum_{s=-\infty}^{\infty}\frac{(rr')^{|s|}}{(2\lambda^2)^{|s|}}\exp is(\varphi-\varphi')$$
$$\times\sum_{t=1}^{\infty}\frac{\Phi\left(\epsilon_{st},|s|+1,\frac{r^2}{2\lambda^2}\right)\Phi\left(\epsilon_{st},|s|+1,\frac{r'^2}{2\lambda^2}\right)}{c_{st}(E_{st}-\zeta)}.$$

One sum can be calculated. Let

$$F_s(q,v,\zeta)=\begin{cases}\Phi(\zeta,|s|+1,q)(\Psi(\zeta,|s|+1,v)-\beta\Phi(\zeta,|s|+1,v)), & q\leqslant v\\ \Phi(\zeta,|s|+1,v)(\Psi(\zeta,|s|+1,q)-\beta\Phi(\zeta,|s|+1,q)), & v\leqslant q.\end{cases}$$

Here

$$\beta=\frac{\Psi(\zeta,|s|+1,x_0)}{\Phi(\zeta,|s|+1,x_0)},\quad \zeta\neq\epsilon_{st},$$

$\Psi(a,c,x)$ is the Trikomi function. Then the Green function takes the form

$$G^{\text{in}}(r,\varphi,r',\varphi';\zeta)=\frac{m\omega}{2\pi\hbar}\exp\left(-\frac{r^2+r'^2}{4\lambda^2}\right)\sum_{s=-\infty}^{\infty}\frac{(rr')^{|s|}}{(2\lambda^2)^{|s|}}\exp is(\varphi-\varphi')$$
$$\times\Gamma\left(\frac{1+s+|s|}{2}-\frac{\zeta}{\hbar\omega}\right)F_s\left(\frac{r^2}{2\lambda^2},\frac{r'^2}{2\lambda^2},\frac{1+s+|s|}{2}-\frac{\zeta}{\hbar\omega}\right).$$

V. COUPLED LAYERS: FINITE NUMBER OF WINDOWS

It is proved in Ref. 8 that for the case of one coupling window there exists an eigenvalue which tends to the threshold when $a\to 0$. Consider the case when there are n coupling windows ω_q^a with centers at the points $x^q,x^q\in\{(x_1,x_2,0),x_i\in\mathbf{R}\}$, $q=1,\ldots,n$, $\omega_q^a=a\omega_q$. We assume that the distances between apertures are of order $|\omega_q|^{1/2}$, i.e., a^0. Let $d_+>d_-$. For n windows there are, generally speaking, n eigenvalues in question. Let us construct the asymptotic series for the ground state (minimal eigenvalue). We shall follow the scheme described previously (for coupled waveguides). The difference is that we start from another form of the asymptotic series. Let $\lambda_a=k_a^2$ be the eigenvalue in question. As for the asymptotic series, it is more convenient to seek the series not for λ_a but for some function of it (the reason will be clear later):

$$(\log(\pi^2-k_a^2d_+^2)^{1/2})^{-1}=\sum_{j=3}^{\infty}k_ja^j. \tag{30}$$

In the paper we shall deal with the first term of the series only (it is sufficient to describe the ground state). For the corresponding eigenfunction $\psi_a(x)$ the asymptotic series is as follows:

$$\psi_a(x)=\pm(\log(\pi^2-k_a^2d_+^2)^{1/2})^{-1}\sum_{j=0}^{\infty}\sum_{q=1}^{n}a^j(P_{j+1}^q(D_y)G^{\pm}(x,y,k_a))\big|_{y=(x_q,0,0)},$$

$$x\in\Omega^{\pm}\setminus\cup_q S_{a^{1/2}}^q, \tag{31}$$

$$\psi_a(x)=\sum_{j=1}^{\infty}v_j^q(x/a)a^j,\quad x\in S_{2a^{1/2}}^q, \tag{32}$$

where S_t^q is the sphere of radius t with the center at x^q,

$$v_j^q\in W_{2,\mathrm{loc}}^1(\Omega^+\cup\Omega^-),\quad P_1^q(D_y)=\alpha_q\frac{\partial}{\partial n_y},$$

$P_m^q(D_y)$ is some polynomial in normal and tangential derivatives (in respect to y):

$$P_m^q(D_y)=\sum_{p=1}^{m-1}a_{pq}^{(m)}D_y^{m-q+1},\quad m\geqslant 2. \tag{33}$$

$G^{\pm}$ are the Green functions for the layers $\Omega^{\pm}$. To find the leading term of the asymptotics of the eigenvalue we need the asymptotics of the derivative of the Green function near the point (0) of the boundary for values of spectral parameter in close proximity of the point π^2/d_+^2:

$$\frac{\partial}{\partial n_y}G^+(x,0,k)=\frac{1}{d_+^2}\sin\frac{\pi x_3}{d_+}\log(\pi^2-k_a^2d_+^2)^{1/2}-\frac{x_3}{2\pi r^3}+g^+(x,k), \tag{34}$$

$$\frac{\partial}{\partial n_y}G^-(x,0,k)=\frac{x_3}{2\pi r^3}+g^-(x,k),\quad r=|x|. \tag{35}$$

Here $g^{\pm}(x,k)$ satisfies the Dirichlet boundary condition and is analytic in k in a neighborhood of $\pi^2d_+^{-2}$. The first term of (34) is obtained from the well-known series for the Dirichlet Green function for the layer

$$G^{\pm}(x,y,k)=\sum_{n=1}^{\infty}\frac{2}{d_{\pm}^2}\sin\frac{\pi nx_3}{d_{\pm}}\sin\frac{\pi ny_3}{d_{\pm}}\frac{i}{4}H_0^{(1)}(i(\pi^2n^2d_{\pm}^{-2}-k^2)^{1/2}((x_1-y_1)^2+(x_2-y_2)^2)^{1/2}).$$

Coefficients v_j^q of the series (32) satisfy boundary problems which are obtained during the process of matching in a neighborhood of the qth window in the following way. One substitutes the series (32), (30) and the corresponding series for k_a into the Helmholtz equation (for $k=k_a$) with the Dirichlet boundary condition. Than one changes the variables (in $S_{2a^{1/2}}^q$): $\xi=x/a$. The coefficients in the terms with identical powers of a should be equal. Hence, one obtains the following problems:

$$\begin{gathered}\Delta_{\xi}v_j^q=-\sum_{p=0}^{j-2}\Lambda_pv_{j-p-2}^q,\quad \xi\in\mathbf{R}^3\setminus\gamma,\\ v_j^q=0,\quad \xi\in\gamma,\end{gathered} \tag{36}$$

where

$$\gamma=\{\xi:\xi_3=0,(\xi_1,\xi_2,0)\in\omega_q\},$$

Λ_p are the coefficients of the series

$$k_a^2=\sum_p \Lambda_p a^p.$$

The definition of $M_p^q(U)$ for a neighborhood of the point x^q is analogous to the definition of $M_p(U)$ for the case of waveguides (see previous text). We need M_1^0 because we deal with the leading terms only.

Thus, to achieve matching it is necessary to show that there exist values k_j, polynomials P_j^q, and functions v_j^q being solutions of (36) such that asymptotics of v_j^q, $\rho\to\infty$, $\xi_2>0(\xi_2<0)$, coincides with the corresponding sums obtained from $\psi_a^{\pm}(x,k)$. We confine our attention in the following to the first term k_3 only.

Taking into account the asymptotics of the Green function (34) in a neighborhood of pth window, one obtains

$$\lim_{k\to\pi/d_+} (\log(\pi^2-k^2d_+^2)^{1/2})^{-1}P_1^qG^+(x,x^q,k)=\frac{\alpha_q}{d_+^2}\sin\pi x_3/d_+,$$

$$\lim_{k\to\pi/d_+} (\log(\pi^2-k^2d_+^2)^{1/2})^{-1}P_1^qG^-(x,x^q,k)=0.$$

Taking into account (30), one has ($M_1=M_1^p$):

$$a^{-1}M_1\left((\log(\pi^2-k_a^2d_+^2)^{1/2})^{-1}\sum_{q=1}^n P_1^qG^+(x,x^q,k_a)\right)=-\frac{1}{2\pi}\alpha_pk_3\xi_3\rho_p^{-3}+\sum_{q=1}^n\frac{\pi}{d_+^3}\alpha_q\xi_3, \tag{37}$$

$$a^{-1}M_1\left((\log(\pi^2-k_a^2d_+^2)^{1/2})^{-1}\sum_{q=1}^n P_1^qG^-(x,x^q,k_a)\right)=\frac{1}{2\pi}\alpha_pk_3\xi_3\rho_p^{-3}, \tag{38}$$

where ρ_p is the distance of a point from the center of the pth window.

Boundary problems for v_1^p,v_2^p have homogeneous right-hand sides. To match the increasing term in (37) it is necessary to choose v_1^p as a harmonic function with the corresponding asymptotics. It is known[21,22] that there exists a harmonic function $Y_1^p(\xi)$, satisfying the boundary condition and having the following asymptotics for $\rho_p\to\infty$:

$$Y_1^p(\xi)=\begin{cases}\xi_3+\frac{3}{2}b_{\omega_p}\xi_3\rho_p^{-3}, & \xi_3>0,\\ -\frac{3}{2}b_{\omega_p}\xi_3\rho_p^{-3}, & \xi_3<0.\end{cases} \tag{39}$$

Here b_{ω_p} is average virtual mass for ω_p. We choose v_1^p in the form:

$$v_1^p(\xi)=\frac{\pi}{d_+^3}\sum_{q=1}^n\alpha_qY_1^p(\xi).$$

Achieving matching of terms of order $\rho_p^{-3}\xi_3$ in neighborhoods of each opening, we obtain the following system for the determination of α_q:

$$\frac{3\pi}{2d_+^3}\sum_{q=1}^n\alpha_qb_{\omega_p}=-\frac{k_3}{2\pi}\alpha_p,\quad p=1,2,\ldots,n. \tag{40}$$

The condition of nontrivial solvability of (40) is

$$\det\begin{pmatrix} b_{\omega_1}+\beta & b_{\omega_1} & \dots & b_{\omega_1} \\ b_{\omega_2} & b_{\omega_2}+\beta & \dots & b_{\omega_2} \\ . & . & . & . \\ b_{\omega_n} & b_{\omega_n} & \dots & b_{\omega_n}+\beta \end{pmatrix}=0. \tag{41}$$

Here

$$\beta=\frac{d_+^3}{3\pi^2}k_3.$$

Summing all the rows, and making simple calculations, we get the value of the determinant (41):

$$(-\beta)^{n-1}\left(\sum_{i=1}^{n} b_{\omega_i}+\beta\right).$$

Hence,

$$-\sum_{i=1}^{n} b_{\omega_i}=\frac{d_+^3}{3\pi^2}k_3,$$

and we get, immediately, the value of k_3:

$$k_3=-\frac{3\pi^2}{d_+^3}\sum_{i=1}^{n} b_{\omega_i}. \tag{42}$$

Other $n-1$ roots ($\beta=0$) of Eq. (42) give us $k_3=0$. It means that the terms of such order in the asymptotic series do not give us information about other eigenvalues. The obtained value is the leading term of the asymptotics in a of the ground state only. The situation is analogous to that for coupled waveguides.

In the case of two identical layers $d_+=d_-=d$ we must make some changes. First, the asymptotics (35) for G^- is now similar to that of G^+ (34). As a result, we obtain

$$a^{-1}M_1^p\left((\log(\pi^2-k_a^2d_+^2)^{1/2})^{-1}\sum_{q=1}^{n} P_1^qG^{\pm}(x,x^q,k_a)\right)=\mp\frac{1}{2\pi}\alpha_pk_3\xi_3\rho_p^{-3}\pm\sum_{q=1}^{n}\frac{\pi}{d_+^3}\alpha_q\xi_3, \tag{43}$$

instead of (37) and (38). Hence, we now need a harmonic function $\tilde{Y}_1^p(\xi)$ with another asymptotics then $Y_1^p(\xi)$ in $\rho_p,\rho_p\to\infty$:

$$\tilde{Y}_1^p(\xi)=\begin{cases}\xi_3+3b_\omega\xi_3\rho_p^{-3}, & \xi_3>0,\\ -\xi_3-3b_\omega\xi_3\rho_p^{-3}, & \xi_3<0.\end{cases} \tag{44}$$

Such function exists. One can see that it is related with Y_1^p in a simple way (in terms of complex variables):

$$\tilde{Y}_1^p(z)=Y_1^p(z)+Y_1^p(-z).$$

Making matching as earlier, we obtain

$$k_3=-\frac{6\pi^2}{d^3}\sum_{i=1}^{n} b_{\omega_i}. \tag{45}$$

Remark: The result is not a formal limit of that for two different layers (as in the case of waveguides). From the point of view of physics the effect is related to the fact that for different layers if energy is slightly greater than the threshold there is only one way to go to infinity, and for identical layers there are simultaneously two ways.

Finally, incorporating (41) and (45), we obtain the result:

Theorem 5: The leading term of the asymptotics of the minimal eigenvalue λ_a which tends to the lower bound of the continuous spectrum for the case of n coupling windows is equal to

$$\lambda_a=\begin{cases}\pi^2/d_+^2-\dfrac{1}{d_+^2}\exp\left(-\dfrac{2d_+^3}{3\pi^2}\left(\displaystyle\sum_{i=1}^{n} b_{\omega_i}\right)^{-1}a^{-3}(1+o(1))\right), & d_+>d_-,\\ \pi^2/d^2-\dfrac{1}{d^2}\exp\left(-\dfrac{d^3}{3\pi^2}\left(\displaystyle\sum_{i=1}^{n} b_{\omega_i}\right)^{-1}a^{-3}(1+o(1))\right), & d_+=d_-=d.\end{cases} \tag{46}$$

For the case of circular window ω of radius R the value of average virtual mass is known:[23]

$$b_\omega=\frac{4}{9\pi}R^3.$$

Hence, one obtains the following corollary:

Corollary 1: The leading term of the asymptotics of the minimal eigenvalue λ_a which tends to the lower bound of the continuous spectrum for the case of n coupling circular windows is equal to

$$\lambda_a=\begin{cases}\pi^2/d_+^2-\dfrac{1}{d_+^2}\exp\left(-\dfrac{3d_+^3}{2\pi^2}\left(\displaystyle\sum_{i=1}^{n} a_i^3\right)^{-1}(1+o(1))\right), & d_+>d_-,\\ \pi^2/d^2-\dfrac{1}{d^2}\exp\left(-\dfrac{3d^3}{4\pi^2}\left(\displaystyle\sum_{i=1}^{n} a_i^3\right)^{-1}(1+o(1))\right), & d_+=d_-=d,\end{cases}$$

where a_i is the radius of the disk ω_i^a.

Corollary 2: The leading term of the asymptotics of the eigenvalue λ_a which tends to the lower bound of the continuous spectrum for the case of one coupling window is equal to

$$\lambda_a=\begin{cases}\pi^2/d_+^2-\dfrac{1}{d_+^2}\exp\left(-\dfrac{2d_+^3}{3\pi^2}a^{-3}b_\omega^{-1}(1+o(1))\right), & d_+>d_-,\\ \pi^2/d^2-\dfrac{1}{d^2}\exp\left(-\dfrac{d^3}{3\pi^2}a^{-3}b_\omega^{-1}(1+o(1))\right), & d_+=d_-=d.\end{cases} \tag{47}$$

Remark: One can compare (47) with estimates in Ref. 8 (3).

VI. LAYERS COUPLED THROUGH PERIODIC SYSTEM OF WINDOWS: SINGLY PERIODIC SYSTEM OF WINDOWS

Consider a case when windows form a singly periodic system. Namely, let Λ_1, $\Lambda_1=\{x,x=(qL,0,0),\ q\in\mathbf{Z}\}$ be the corresponding Bravais lattice, and the primitive cell contains the set Z, $Z=\{z^j,\ j=1,2,\ldots,n\}$, $Z^q=\{z^{j,q}=(z_1^j+qL,z_2,z_3),\ q\in\mathbf{Z},\ j=1,2,\ldots,n\}$, of the windows $(\omega_{q,i}^a)$ centers. The windows are $\omega_{q,i}^a=a\,\omega_{q,i}$, $\omega_{0,i}=\omega_i$. Here we have a band instead of an eigenvalue for a single window. Let us construct the asymptotics of its edges.

Due to periodicity the corresponding solution ψ_a satisfies the Bloch condition:

$$\psi_a(x+L)=e^{i\theta L}\psi_a(x),$$

where θ is a quasimomentum ($-\pi L^{-1}\leqslant\theta\leqslant\pi L^{-1}$). For fixed value of the quasimomentum we have an eigenvalue of the corresponding operator in this fiber. We shall construct the asymptotic expansion of the eigenvalues λ_a^θ in each fiber separately, and then by varying θ, we shall get parameters of the band. Let us seek the asymptotic expansion for the following function f_{Λ_1} of $\lambda_a^\theta=k_{a,\theta}^2$:

$$f_{\Lambda_1}(k_{a,\theta})=L\sqrt{\pi^2-k_{a,\theta}^2d_+^2+\theta^2d_+^2}=k_3^\theta a^3+o(a^3). \tag{48}$$

The asymptotic expansion for the corresponding eigenfunction is as follows:

$$\psi_a(x)=\pm f_{\Lambda_1}(k_{a,\theta})\sum_{p=0}^{\infty}\sum_{q=-\infty}^{\infty}\sum_{z^{j,q}\in Z^q}a^j(P_{p+1}^{q,j}(D_y)G^{\pm}(x,y,k_{a,\theta}))\big|_{y=z^{j,q}},\quad x\in\Omega^{\pm}\setminus\cup_q S_{a^{1/2}}^q, \tag{49}$$

$$\psi_a(x)=\sum_{j=1}^{\infty}v_j^q(x/a)a^j,\quad x\in S_{2a^{1/2}}^q, \tag{50}$$

where $P_1^{q,j}(D_y)=\alpha_q^j(\partial/\partial n_y)$ (the Bloch condition leads to the relation: $\alpha_q^j=e^{i\theta Lq}\alpha_0^j$). Following the above-mentioned procedure of matching (see Sec. V), one obtains for the window $\omega_0^{j'}$ ($\rho=\rho_0^{j'}$):

$$a^{-1}M_1\left(f_{\Lambda_1}(k_{a,\theta})\sum_{q=-\infty}^{\infty}\sum_{z^{j,q}\in Z^q}(P_1^{q,j}(D_y)G^-(x,y,k_{a,\theta}))\bigg|_{y=z^{j,q}}\right)=\frac{1}{2\pi}\alpha_0^jk_3^\theta\xi_3\rho^{-3}, \tag{51}$$

$$\begin{aligned}&a^{-1}M_1\left(f_{\Lambda_1}(k_{a,\theta})\sum_{q=-\infty}^{\infty}\sum_{z^{j,q}\in Z^q}(P_1^{q,j}(D_y)G^+(x,y,k_{a,\theta}))\bigg|_{y=z^{j,q}}\right)\\&\quad=-\frac{1}{2\pi}\alpha_0^jk_3^\theta\xi_3\rho^{-3}+\frac{2\pi^2}{d_+^3}a^{-1}M_1\Bigg(f_{\Lambda_1}(k_{a,\theta})\Bigg(-\frac{1}{2\pi}\alpha_0^{j'}\log\sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2}\\&\qquad+\sum_{z^{j,0}\in Z^0,j\neq j'}\alpha_0^j\frac{i}{4}H_0^{(1)}\left(i|z^{j,0}|\sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2}\right)\\&\qquad+\sum_{q=1}^{\infty}\sum_{z^{j,q}\in Z^q}\alpha_0^j\cos(q\theta L)\frac{i}{4}H_0^{(1)}\left(i|z^{j,q}|\sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2}\right)\Bigg)x_3\Bigg).\end{aligned} \tag{52}$$

Let us take into account the following formula:[24]

$$H_0^{(1)}(mR)=J_0(m\rho)H_0^{(1)}(mr)+2\sum_{n=1}^{\infty}J_n(m\rho)H_n^{(1)}(mr)\cos(n\varphi),\quad \rho<r,\quad m\in\mathbf{C},$$

where φ is the angle between the sides ρ and r in the triangle ρ,r,R. We use this relation with $\rho=|z^0|$, $r=|qL|$, $R=|z^q|$,

$$m=i\sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2}.$$

Then, we use known formula[24]

$$\sum_{n=1}^{\infty}\cos(nb)K_0(nz)=\frac{\pi}{2\sqrt{z^2+b^2}}+\left(C+\log\frac{z}{4\pi}\right)\Big/\,2+\frac{\pi}{2}\sum_{n=1}^{\infty}\left(\frac{1}{\sqrt{(2n\pi-b)^2+z^2}}-\frac{1}{2n\pi}\right)+\frac{\pi}{2}\sum_{n=1}^{\infty}\left(\frac{1}{\sqrt{(2n\pi+b)^2+z^2}}-\frac{1}{2n\pi}\right).$$

One chooses for our case

$$z=L\sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2},\quad b=L\theta,$$

and taking into account the correlations

$$K_0(z)=\frac{\pi i}{2}H_0^{(1)}(iz),z>0,\quad I_0(z)=J_0(iz),\quad \sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2}=i\theta+o(a^0),$$

one transforms (52) to the form:

$$a^{-1}M_1\left(f_{\Lambda_1}(k_{a,\theta})\sum_{q=-\infty}^{\infty}\sum_{z^{j,q}\in Z^q}(P_1^{q,j}(D_y)G^+(x,y,k_{a,\theta}))\Big|_{y=z^{j,q}}\right)$$
$$=-\frac{1}{2\pi}\alpha_0^{j'}k_3^{\theta}\xi_3\rho^{-3}+\frac{\pi^2}{2d_+^2}\sum_{z^{j,0}\in Z^0}\alpha_0^jI_0(i\theta|z^{j,0}|)\xi_3. \tag{53}$$

To match the increasing terms in (51) and (53) we choose $v_1^0(\xi)$ in the following form:

$$v_1^0(\xi)=\frac{\pi^2}{2d_+^2}\sum_{z^{j,0}\in Z^0}\alpha_0^jI_0(i\theta|z^{j,0}|)Y_1(\xi). \tag{54}$$

Matching of terms of order $\xi_3\rho^{-3}$, one gets the following system for α_0^j:

$$\frac{k_3^{\theta}}{2\pi}\alpha_0^{j'}=\frac{\pi^2}{2d_+^2}b_{\omega^{j'}}\sum_{z^{j,0}\in Z^0}\alpha_0^jI_0(i\theta|z^{j,0}|),\quad j'=1,\ldots,n. \tag{55}$$

It is analogous to the system (40). The condition of nontrivial solvability of (55) is

$$\det\begin{pmatrix}\beta_1b_{\omega_1}+\beta & \beta_1b_{\omega_1} & \ldots & \beta_1b_{\omega_1}\\ \beta_1b_{\omega_2} & \beta_1b_{\omega_2}+\beta & \ldots & \beta_1b_{\omega_2}\\ . & . & . & .\\ \beta_1b_{\omega_n} & \beta_1b_{\omega_n} & \ldots & \beta_1b_{\omega_n}+\beta\end{pmatrix}=0. \tag{56}$$

Here

$$\beta=-\frac{d_+^2}{\pi^3}k_3^{\theta},\quad \beta_1=\sum_{z^{j,0}\in Z^0}I_0(i\theta|z^{j,0}|).$$

Summing all the rows, and making simple calculations, we get the value of the determinant (56):

$$(-\beta)^{n-1}\left(\beta_1\sum_{i=1}^{n}b_{\omega_i}+\beta\right).$$

Hence,

$$k_3^{\theta}=\frac{\pi^3}{d_+^2}\sum_{z^{j,0}\in Z^0}\sum_{i=1}^{n} I_0(i\theta|z^{j,0}|)b_{\omega_0^i}.$$

For the eigenvalue in a fiber we have

$$\lambda_a^{\theta}=k_{a,\theta}^2=\frac{\pi^2}{d_+^2}+\theta^2-\frac{\pi^6}{d_+^6L^2}\left(\sum_{z^{j,0}\in Z^0}\sum_{i=1}^{n} I_0(i\theta|z^{j,0}|)b_{\omega_0^i}\right)^2 a^6+o(a^6). \tag{57}$$

It is a dispersion relation. To get a band one must vary θ from $-\pi/L$ to π/L. Due to smallness of a one comes to the conclusion that there is no gap ($b_\omega^2\pi^4 d_+^{-6}a^6<1$). But windows cause a shift of the lower bound of the continuous spectrum:

$$\lambda_{\min,a}=\frac{\pi^2}{d_+^2}-\frac{\pi^6}{d_+^6L^2}\left(\sum_{i=1}^{n} nb_{\omega_0^i}\right)^2 a^6+o(a^6). \tag{58}$$

For the case of two identical layers ($d_-=d_+=d$) it is necessary to change the scheme in the same way as for the case of n coupling windows (see previous text). Formally, it means that in (54) Y_1 should be replaced by $\tilde{Y}_1$ and in (57) and (58) b_ω by $2b_\omega$. The following theorem results.

Theorem 6: The lower bound of the continuous spectrum of Dirichlet Laplacian for layers coupled through singly periodic system of windows is as follows:

$$\lambda_{\min,a}=\begin{cases}\dfrac{\pi^2}{d_+^2}-\dfrac{\pi^6n^2}{d_+^6L^2}\left(\displaystyle\sum_{i=1}^{n} b_{\omega_0^i}\right)^2 a^6+o(a^6), & d_+>d_-,\\[2ex] \dfrac{\pi^2}{d^2}-\dfrac{4\pi^6n^2}{d^6L^2}\left(\displaystyle\sum_{i=1}^{n} b_{\omega_0^i}\right)^2 a^6+o(a^6), & d_+=d_-=d.\end{cases}$$

Corollary 3: The lower bound of the continuous spectrum of the Dirichlet Laplacian for layers coupled through singly periodic system of circular windows $\omega_{q,i}^a$ is as follows:

$$\lambda_{\min,a}=\begin{cases}\dfrac{\pi^2}{d_+^2}-\dfrac{16\pi^4n^2}{81d_+^6L^2}\left(\displaystyle\sum_{i=1}^{n} R_i^3\right)^2 a^6+o(a^6), & d_+>d_-,\\[2ex] \dfrac{\pi^2}{d^2}-\dfrac{64\pi^4n^2}{81d^6L^2}\left(\displaystyle\sum_{i=1}^{n} R_i^3\right)^2 a^6+o(a^6), & d_+=d_-=d.\end{cases}$$

Here R_i is the radius of the circle ω_i.

Note that R_i is dimensionless.

VII. LAYERS COUPLED THROUGH PERIODIC SYSTEM OF WINDOWS: DOUBLY PERIODIC SYSTEM OF WINDOWS

Consider the case of doubly periodic system of windows. Namely, we assume that centers of windows form a two-dimensional lattice. Let Λ_2 be the corresponding Bravais lattice

$$\Lambda_2=\{n_1a_1+n_2a_2\in\mathbf{R}^2|(n_1,n_2)\in\mathbf{Z}^2\},$$

where a_1,a_2 are linearly independent vectors in $\mathbf{R}^2$. The reciprocal lattice Γ_2, the Wigner–Seitz cell $\hat{\Gamma}_2$, and the Brillouin zone $\hat{\Lambda}_2$ are, correspondingly,

$$\Gamma_2=\{n_1b_1+n_2b_2\in\mathbf{R}^2|(n_1,n_2)\in\mathbf{Z}^2\},\quad a_jb_{j'}=2\pi\delta_{jj'},\quad j,j'=1,2,$$

$$\hat{\Gamma}_2=\{s_1a_1+s_2a_2\in\mathbf{R}^2|s_j\in[-1/2,1/2),\quad j=1,2\},$$

$$\hat{\Lambda}_2=\{s_1b_1+s_2b_2\in\mathbf{R}^2|s_j\in[-1/2,1/2),\quad j=1,2\}.$$

The scheme of construction of the main term of the asymptotics of the eigenvalue in a fixed fiber (for fixed quasimomentum) is the same as for one-dimensional lattice Λ_1. That is why we shall not describe here the procedure in detail and shall stress only points that differ from that in Sec. VI.

First, we must replace the function $f_{\Lambda_1}(k_{a,\theta})$ for which the asymptotic expansion is sought (48) by another one $f_{\Lambda_2}(k_{a,\theta})$. Let us describe the choice of this function. The form of $f_{\Lambda_1}(k_{a,\theta})$ is related to the behavior of the sum on the right-hand side of (52) for the values of $k_{a,\theta}$ close to the lower bound of the continuous spectrum of the operator in the fiber $(\pi^2/d_+^2+\theta^2)$. In the case of Λ_1 it is as follows:

$$\frac{d_+}{2L\sqrt{\pi^2-k_{a,\theta}^2d_+^2+\theta^2d_+^2}}.$$

That is why we choose $f_{\Lambda_1}(k_{a,\theta})$ in the form:

$$f_{\Lambda_1}(k_{a,})=L\sqrt{\pi^2-k_{a,\infty}^2d_+^2+\theta^2d_+^2}.$$

For two-dimensional lattice we have double series over Λ_2 on the right-hand side of (52), i.e., (52)is replaced by

$$\begin{aligned}
&a^{-1}M_1\left(f_{\Lambda_2}(k_{a,\theta})\sum_{\lambda\in\Lambda_2}a^j(P_1^\lambda(D_y)G^+(x,y,k_{a,\theta}))\Big|_{y=\lambda}\right)\\
&\quad=-\frac{1}{2\pi}\alpha_0k_3^\theta\xi_3\rho^{-3}+\frac{\pi^2}{d_+^3}a^{-1}M_1\left(f_{\Lambda_2}(k_{a,\theta})\left(-\frac{1}{2\pi}\alpha_0^0\log\sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2}\right.\right.\\
&\qquad\left.\left.+\sum_{\lambda\in\Lambda_2}\sum_{z^{j,q}\in Z^q}\alpha_0^j\frac{i}{4}H_0^{(1)}\left(i|z^{j,q}+\lambda|\sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2}\right)\right)\exp(i(\theta,\lambda))x_3\right).
\end{aligned}\tag{59}$$

Here θ, λ are two-dimensional vectors, and (θ,λ) is scalar product. The sum of such type appears in the theory of two-dimensional crystals. It can be transformed by Poisson summation formula to the form:[25]

$$\sum_{\gamma\in\Gamma_2}\frac{|\hat{\Lambda}_2|}{4\pi^2(|\gamma+\theta|^2+\pi^2d_+^{-2}-k_{a,\theta}^2)}\sum_{z^{j,0}\in Z^0}\alpha_0^jI_0\left(\sqrt{\frac{\pi^2}{d_+^2}-k_{a,\theta}^2}|z^{j,0}|\right),$$

where $|\hat{\Lambda}_2|$ is the square of the Brillouin zone $\hat{\Lambda}_2$ for Λ_2, $\theta\in\hat{\Lambda}_2$. Hence, we choose the function $f_{\Lambda_2}(k_{a,\theta})$ in the form

$$\begin{aligned}
f_{\Lambda_2}(k_{a,\theta})&=|\hat{\Lambda}_2|^{-1}4\pi^2(|\gamma_\theta+\theta|^2+\pi^2d_+^{-2}-k_{a,\theta}^2),\\
|\gamma_\theta+\theta|^2&=\min_{\gamma\in\Gamma_2}|\gamma+\theta|^2.
\end{aligned}\tag{60}$$

Correspondingly, we seek asymptotic expansion of $f_{\Lambda_2}(k_{a,\theta})$,

$$f_{\Lambda_2}(k_{a,\theta})=k_{3,\theta}^{\Lambda_2}a^3+o(a^3).\tag{61}$$

In (49) $f_{\Lambda_1}(k_{a,\theta})$ is replaced by $f_{\Lambda_2}(k_{a,\theta})$. Then, following the same procedure as for singly periodic lattice (see previous text), one comes to the following expression for $k^{\Lambda_2}_{3,\theta}$:

$$k^{\Lambda_2}_{3,\theta}=\frac{2\pi^3}{d_+^3}\sum_{z^{j,0}\in Z^0} I_0(i\sqrt{|\hat{\Lambda}_2|^{-1}}2\pi|\gamma_\theta+\theta||z^{j,0}|)\sum_{i=1}^{n} b_{\omega_0^i}.$$

Consequently, in accordance with (60) and (61) one gets

$$k^2_{a,\theta}=|\gamma_\theta+\theta|^2+\pi^2 d_+^{-2}-|\hat{\Lambda}_2|\frac{\pi^3}{2d_+^3}\sum_{z^{j,0}\in Z^0} I_0(i\sqrt{|\hat{\Lambda}_2|^{-1}}2\pi|\gamma_\theta+\theta||z^{j,0}|)\sum_{i=1}^{n} b_{\omega_0^i}a^3+o(a^3). \tag{62}$$

Varying the quasimomentum θ, $\theta\in\hat{\Lambda}_2$, one gets a band. One can see that due to smallness of a there is no gap. As a result, we come to the following theorem (the result for two identical layers is obtained in the same way as earlier).

Theorem 7: The lower bound of the continuous spectrum of the Dirichlet Laplacian for layers coupled through doubly periodic system of windows is as follows:

$$\lambda_{\min,a}=\begin{cases}\dfrac{\pi^2}{d_+^2}-|\hat{\Lambda}_2|\dfrac{\pi n}{2d_+^3}\displaystyle\sum_{i=1}^{n} b_{\omega_0^i}a^3+o(a^3), & d_+>d_-,\\[2ex] \dfrac{\pi^2}{d^2}-|\hat{\Lambda}_2|\dfrac{\pi n}{d^3}\displaystyle\sum_{i=1}^{n} b_{\omega_0^i}a^3+o(a^3), & d_+=d_-=d.\end{cases}$$

Corollary 3: The lower bound of the continuous spectrum of the Dirichlet Laplacian for layers coupled through doubly periodic system of circular windows $\omega^a_{q,i}$ is as follows:

$$\lambda_{\min,a}=\begin{cases}\dfrac{\pi^2}{d_+^2}-|\hat{\Lambda}_2|\dfrac{2n}{9d_+^3}\displaystyle\sum_{i=1}^{n} R_i^3a^3+o(a^3), & d_+>d_-,\\[2ex] \dfrac{\pi^2}{d^2}-|\hat{\Lambda}_2|\dfrac{4n}{9d^3}\displaystyle\sum_{i=1}^{n} R_i^3a^3+o(a^3), & d_+=d_-=d.\end{cases}$$

Here R_i is the radius of the circle ω_i.

We have investigated the lattice Green's function for the Glasser cubic lattice. Expressions for its density of states, phase shift, and scattering cross section in terms of complete elliptic integrals of the first kind are derived. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421063]

I. INTRODUCTION

The lattice Green's function is defined as

$$G(E)=\frac{\Omega}{(2\pi)^d}\int_{1\mathrm{BZ}}\frac{F(\vec{K})}{E-E(\vec{K})}\vec{\mathrm{d}}k, \tag{1.1}$$

where $E(\vec{k})$ represents a dispersion relation, $F(\vec{k})$ is an appropriate function, Ω denotes the volume of the crystal in the real space, d is the dimension, and 1BZ indicates that the integration is carried over the first Brillouin zone.

In this paper we report on the lattice Green's function and the article is organized as follows. Section II is devoted to the general definition of the diagonal lattice Green's function and its form, inside and outside the band, for the cubic lattice in terms of the first kind elliptic integrals. This section also contains the formulas for the density of states, the phase shift, and the cross section for a point defect case. In Sec. III we present the results and discussion. Finally, the details of the Green's function derivation inside the band are given in the Appendix.

II. LATTICE GREEN'S FUNCTION

The Green's function for the Glasser cubic lattice is defined as[1–5]

$$G^0(E)=\frac{1}{\pi^3}\int_0^{\pi}\int_0^{\pi}\int_0^{\pi}\frac{\mathrm{d}k_x\,\mathrm{d}k_y\,\mathrm{d}k_z}{E-E(k_x,k_y,k_z)}, \tag{2.1}$$

where

$$E(k_x,k_y,k_z)=\cos k_x+\cos k_y+\cos k_z+\cos k_x\cos k_y+\cos k_x\cos k_z+\cos k_y\cos k_z+\cos k_x\cos k_y\cos k_z\,.$$

This case is of practical interest in studying the properties of a Heisenberg ferromagnet with axial anisotropy,[1,6]

[a)]Author to whom all correspondence should be addressed; electronic mail: jkalifa@sci.ju.edu.jo

$$G^0(E)=\frac{4}{\pi^2(E+1)}K^2(k), \tag{2.2}$$

where

$$k^2=\frac{1}{2}\left[1-\frac{(E-7)^{1/2}}{(E+1)^{1/2}}\right], \tag{2.3}$$

and $K(k)$ is the complete elliptic integral of the first kind.

The Green's function inside and outside the band can be written as[7] (some mathematical manipulations are given in the appendix)

$$G^0(E)=\begin{cases}\dfrac{4}{\pi^2(E+1)}K^2(k), & |E|>7\\ \dfrac{\sqrt{2}}{\pi^2\sqrt{E+1}}K(k_+)K(k_-)+i\dfrac{1}{\sqrt{2}\pi^2\sqrt{E+1}}[K^2(k_+)-K^2(k_-)], & -1<E<7.\end{cases} \tag{2.4}$$

Therefore, the density of states is

$$\mathrm{DOS}^0(E)=\frac{1}{\sqrt{2}\pi^3\sqrt{E+1}}[K^2(k_+)-K^2(k_-)], \tag{2.5}$$

where

$$k_{\pm}^2=\tfrac{1}{2}(1\pm((7-E)/8)^{1/2}). \tag{2.6}$$

We consider the case where perfect periodicity is destroyed by modifying just one site (the L site). The situation can be thought of physically as arising by substituting the host atom at the L site by a foreign atom,[8] i.e., a localized zero-range potential of strength ε' is introduced. In the tight-binding model, ε' is proportional to the charge difference between the impurity outer electrons and those of the host atom. Thus our Green's function for this single impurity is[7,9,10]

$$G(L,E)=\begin{cases}\dfrac{4K^2(k)}{(E+1)\pi^2-4\varepsilon' K^2(k)}, & |E|>7\\ \dfrac{2\sqrt{2}\pi^2(E+1)^{1/2}K(k_+)K(k_-)-2\varepsilon' K^2(k_+)K^2(k_-)-\varepsilon'[(K^4(k_+)+K^4(k_-))]+i\pi^2((E+1)2)^{1/2}[K^2(k_+)-K^2(k_-)]}{[\sqrt{2}\pi^2(E+1)^{1/2}-2\varepsilon' K(k_+)K(k_-)]^2+\varepsilon'^2[(K^2(k_+)-K^2(k_-))]^2}, & |E|<7\end{cases}. \tag{2.7}$$

The density of states can be written as[7,9,10]

$$\mathrm{DOS}^0(E)=\frac{\sqrt{2}\pi(E+1)^{1/2}[K^2(k_+)-K^2(k_-)]}{[\sqrt{2}\pi^2(E+1)^{1/2}-2\varepsilon' K(k_+)K(k_-)]^2+\varepsilon'^2[K^2(k_+)-K^2(k_-)]^2}. \tag{2.8}$$

The S-wave phase shift, δ_0, is defined as[7,9,10]

$$\tan\delta_0=\frac{\pi\mathrm{DOS}^0(E)}{\dfrac{1}{\varepsilon'}-\mathrm{Re}\,G^0(E)}. \tag{2.9}$$

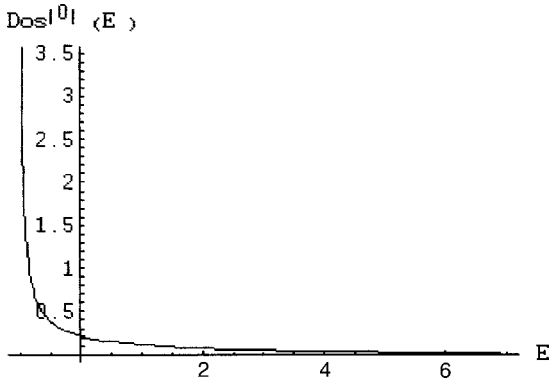

FIG. 1. The density of states (DOS) for the perfect Glasser lattice.

Here, $\mathrm{Re}\,G^0(E)$ refers to the real part of Green's function inside the band. After some mathematical manipulations, we obtain:

$$\tan\delta_0=\frac{K^2(k_+)-K^2(k_-)}{\sqrt{2}(E+1)^{1/2}\pi^2/\varepsilon'-2K(k_+)K(k_-)}. \tag{2.10}$$

The cross section, σ, is defined as[7,9,10]

$$\sigma=\frac{4\pi}{P^2}\frac{\pi^2[\mathrm{DOS}^0(E)]^2}{\left[\mathrm{Re}\,G^0(E)-\dfrac{1}{\varepsilon'}\right]^2+\pi^2[\mathrm{DOS}^0(E)]^2}. \tag{2.11}$$

Here, P refers to the electron momentum.
Therefore, the cross section becomes

$$\sigma=\frac{4\pi}{P^2}\frac{(K^2(k_+)-K^2(k_-))^2}{2\pi^4\left(\dfrac{\sqrt{2}}{\pi^2}K(k_+)K(k_-)-\dfrac{\sqrt{E+1}}{\varepsilon'}\right)^2+(K^2(k_+)-K^2(k_-))^2}. \tag{2.12}$$

III. RESULTS AND DISCUSSION

The results for the Glasser cubic lattice are shown in Figs. 1–8. Figure 1 shows the density of states for the perfect Glasser lattice. It diverges as E goes to minus one and falls off exponentially as expected from Eq. (2.5). The real and imaginary parts of Green's function for the perfect lattice are displayed in Fig. 2, they have the same behavior as noted previously. Figure 3 gives the density

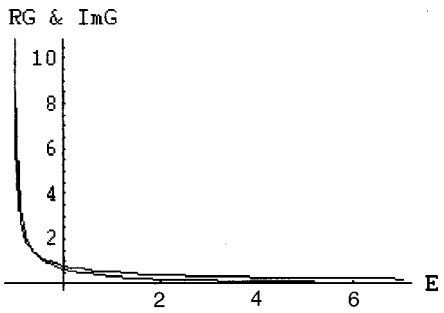

FIG. 2. Real and imaginary parts of Green's function for the perfect Glasser lattice.

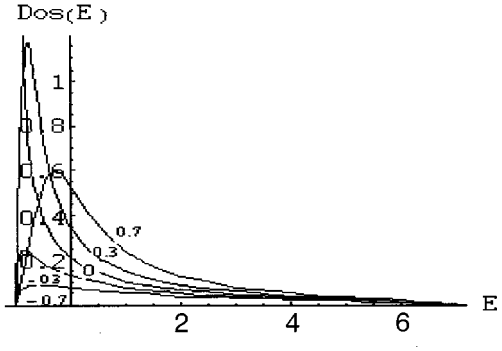

FIG. 3. The DOS for the Glasser lattice with single impurity for different potential strengths ε' (-0.7, -0.3, 0.0, 0.3, and 0.7).

of states for the Glasser lattice with a single impurity potential with strength ε' (-0.7, -0.3, 0.0, 0.3, and 0.7). For $\varepsilon'=0.0$ and 0.3 (in arbitrary units), the density of states diverges as E goes to minus one (as previously) and falls off exponentially. The peak value varies with the potential strength and reaches its maximum at $\varepsilon'=0.7$. Figure 4 shows the density of states (DOS) in three dimensions with one axis representing the potential strength ε' varying between -1 and 1 (arbitrary units) whereas the second axis is the energy scale varying between -1 and 7 as indicated in the formalism.

The phase shift, δ_0, is defined as the shift in the phase of the wave function due to the presence of the impurity potential. Figure 5 displays δ_0 for the Glasser lattice with single impurity for different potential strengths ε'. If an attractive potential is turned on, then it gives rise to a positive phase shift and vice versa. That is, a point defect just to the left of the host in the periodic table leads to positive δ_0. The curves are mirror images of each other. The phase shift vanishes as the potential is turned off (perfect lattice); this behavior is clear from the definition of δ_0. In Fig. 6 we have a more general case of the phase shift, δ_0, for the Glasser lattice with single impurity for potential strengths ε' varying between -1 and 1 (arbitrary units).

The cross section, σ, can be defined as the area an impurity atom presents to the incident electron. It is related to some physical quantities such as the conductivity in metals. Figure 7 shows the cross section, σ, for the Glasser lattice with single impurity for different potential strengths ε'. The values are all positive since σ can be viewed as a sort of probability. The cross

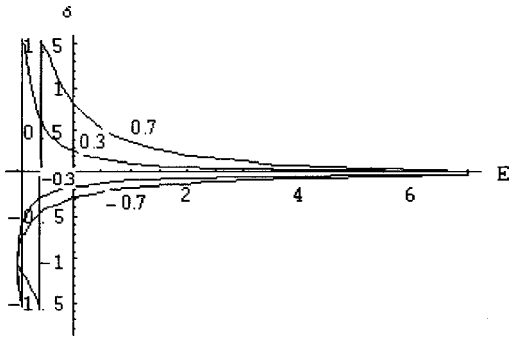

FIG. 5. The phase shift for the Glasser lattice with single impurity for different potential strengths ε' (-0.7, -0.3, 0.0, 0.3, and 0.7).

section vanishes for a perfect lattice as expected. Figure 8 displays the cross section, σ, in three dimensions for the Glasser lattice with single impurity for potential strengths ε' varying between -1 and 1 (arbitrary units).

APPENDIX: DERIVATION OF GREEN'S FUNCTION FOR THE GLASSER LATTICE

In this Appendix we derive an expression for Green's function inside the band in terms of complete elliptic integral of the first kind.

Green's function for the Glasser lattice outside the band is given by[3,4,7]

$$G^0(E)=\frac{4K^2(k)}{\pi^2(E+1)}, \tag{A1}$$

where

$$k=\sqrt{\frac{1}{2}[1-\sqrt{1-\beta^{-1}}]}, \quad \beta=\frac{E+1}{8}<1.$$

The complete elliptic integral of the first kind is expressed as

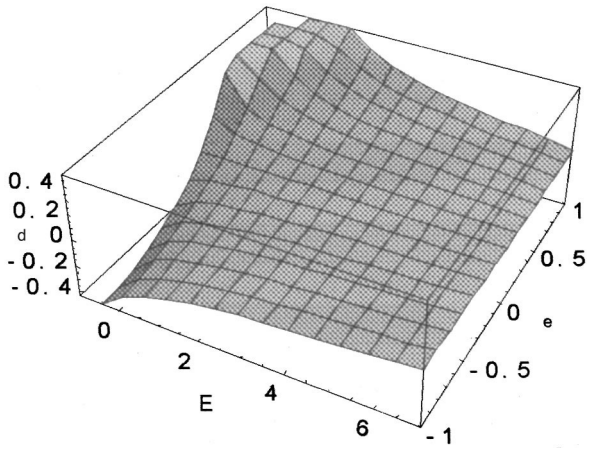

FIG. 6. The phase shift, δ_0, for the Glasser lattice with single impurity for potential strengths ε' varying between -1 and 1 (arbitrary units).

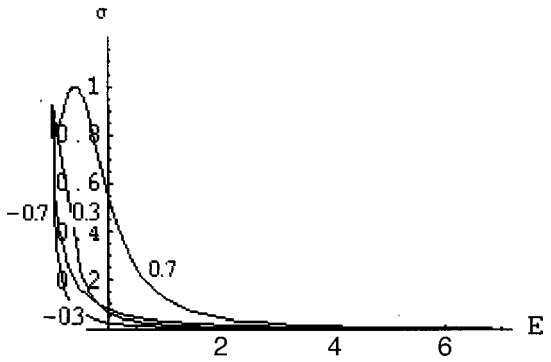

FIG. 7. The cross section, σ, for the Glasser lattice with single impurity for different potential strengths ε' (-0.7, -0.3, 0.0, 0.3, and 0.7).

$$K(k)=\frac{\pi}{2}{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;k^2\right), \tag{A2}$$

where
${}_2F_1(\frac{1}{2},\frac{1}{2};1;k^2)$ is the Gauss hypergeometric function.

Kummer's identity is[11]

$${}_2F_1(\tfrac{1}{4},\tfrac{1}{4};1;\beta^{-1})={}_2F_1(\tfrac{1}{2},\tfrac{1}{2};1;\tfrac{1}{2}(1-\sqrt{1-\beta^{-1}})). \tag{A3}$$

Substituting (A3) in (A1) we have

$$G^0(E)=\frac{({}_2F_1(\frac{1}{4},\frac{1}{4};1;\beta^{-1}))^2}{(E+1)}. \tag{A4}$$

Using the following transformations:[12]

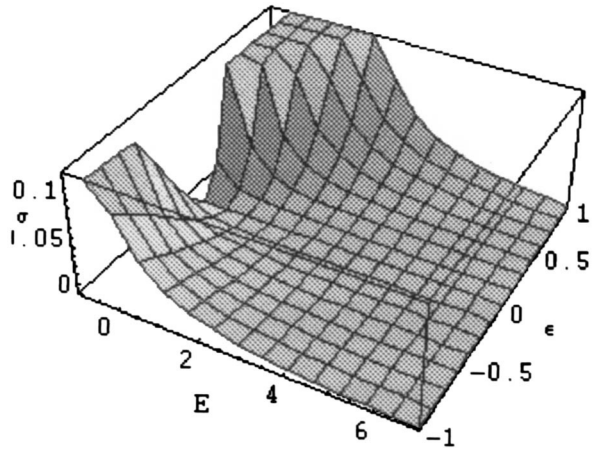

FIG. 8. The cross section, σ, in three dimensions for the Glasser lattice with single impurity for potential strengths ε' varying between -1 and 1 (arbitrary units).

$$ {}_2F_1\left(\frac{1}{4},\frac{1}{4};1;\beta^{-1}\right)=\beta^{1/4}\left(\frac{(\Gamma(\frac{1}{4}))^2}{2\pi^{3/2}}\,{}_2F_1\left(\frac{1}{4},\frac{1}{4};\frac{1}{2};1-\beta\right)+2\pi^{1/2}\frac{\sqrt{\beta-1}}{(\Gamma(\frac{1}{4}))^2}\,{}_2F_1\left(\frac{3}{4},\frac{3}{4};\frac{3}{2};1-\beta\right)\right), \tag{A5} $$

with

$$ \frac{(\Gamma(\frac{1}{4}))^2}{\pi^{3/2}}\,{}_2F_1\left(\frac{1}{4},\frac{1}{4};\frac{1}{2};1-\beta\right)={}_2F_1\left(\frac{1}{2},\frac{1}{2};1;\frac{1}{2}(1+\sqrt{1-\beta})\right)+{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;\frac{1}{2}(1-\sqrt{1-\beta})\right), \tag{A6} $$

and

$$ \frac{4\pi^{1/2}\sqrt{1-\beta}}{(\Gamma(\frac{1}{4}))^2}\,{}_2F_1\left(\frac{3}{4},\frac{3}{4};\frac{3}{2};1-\beta\right)={}_2F_1\left(\frac{1}{2},\frac{1}{2};1;\frac{1}{2}(1-\sqrt{1-\beta})\right) $$
$$ -{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;\frac{1}{2}(1+\sqrt{1-\beta})\right), \tag{A7} $$

in (A5) we obtain

$$ {}_2F_1\left(\frac{1}{4},\frac{1}{4};1;\beta^{-1}\right)=\frac{\beta^{1/4}}{2}\left((1+i)\,{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;\frac{1}{2}(1+\sqrt{1-\beta})\right)\right. $$
$$ \left.+(1-i)\,{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;\frac{1}{2}(1-\sqrt{1-\beta})\right)\right), \tag{A8} $$

or in terms of complete elliptic integral of the first kind

$$ {}_2F_1\left(\frac{1}{4},\frac{1}{4};1;\beta^{-1}\right)=\frac{\beta^{1/4}}{\pi}((1+i)K(k_+)+(1-i)K(k_-)), \tag{A9} $$

where

$$ k_{\pm}^2=\frac{1}{2}(1\pm\sqrt{1-\beta}). $$

Substituting (A9), in (A4) then we obtain

$$ G^0(E)=\frac{\beta^{1/2}}{\pi^2(E+1)}((1+i)K(k_+)+(1-i)K(k_-))^2, \tag{A10} $$

then

$$ G^0(E)=\frac{1}{\sqrt{2}\pi^2\sqrt{E+1}}(2K(k_+)K(k_-)+i(K^2(k_+)-K^2(k_-))). \tag{A11} $$

If a single impurity characterized by a localized potential is introduced in the perfect lattice, then according to Dyson's equation Green's function is defined as[8]

$$ G(L,E)=\frac{G^0(E)}{1-\varepsilon' G^0(E)}. \tag{A12} $$

After some mathematical manipulation Eq. (A12) becomes.

$$G(L,E)$$
$$= \frac{2\pi^2\sqrt{2(E+1)}K(k_+)K(k_-) - 2\varepsilon' K^2(k_+)K^2(k_-) + i\pi^2\sqrt{2(E+1)}(K^2(k_+) - K^2(k_-)) - \varepsilon'[K^4(k_+) + K^4(k_-)]}{(\pi^2\sqrt{2(E+1)} - 2\varepsilon' K(k_+)K(k_-))^2 + \varepsilon'^2(K^2(k_+) - K^2(k_-))^2}. \tag{A13}$$

Thus, the *S*-phase shift and scattering cross section can be evaluated in terms of complete elliptic integrals of the first kind as shown in the text.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 1 JANUARY 2002

Infinite infrared regularization and a state space for the Heisenberg algebra

Andreas U. Schmidt[a)]
Fachbereich Mathematik, Johann Wolfgang Goethe-Universität, 60054 Frankfurt am Main, Germany

(Received 15 June 2001; accepted for publication 17 October 2001)

We present a method for the construction of a Krein space completion for spaces of test functions, equipped with an indefinite inner product induced by a kernel which is more singular than a distribution of finite order. This generalizes a regularization method for infrared singularities in quantum field theory, introduced by Morchio and Strocchi, to the case of singularities of infinite order. We give conditions for the possibility of this procedure in terms of local differential operators and the Gelfand–Shilov test function spaces, as well as an abstract sufficient condition. As a model case we construct a maximally positive definite state space for the Heisenberg algebra in the presence of an infinite infrared singularity. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1425427]

I. INTRODUCTION

A notable case in which some of the abundant singularities of quantum field theory can be treated rigorously is presented by the method of infrared regularization of Morchio and Strocchi.[1,2] There, the first-order singularity of the two-point function of the massless scalar field in $1+1$-dimensional space–time manifests itself in the nonpositivity of the Wightman inner product on the one-particle space. In momentum space, this two-point function appears as a singular integral kernel which is regularized in the distributional sense as a Cauchy principal value. Since this regularization involves subtraction of values of the test functions at $p=0$, the Wightman inner product induced by the two-point function is clearly no longer positive definite. It turns out that, if the usual positivity axiom of Wightman theory, see Ref. 3, is replaced by a weaker Hilbert space structure condition, the construction of a suitable physical state space is still possible. The one-particle space becomes a Krein space, the natural analogon of a Hilbert space in the case of an indefinite inner product, and it is maximal in the sense that there is no larger Krein space closure of the test function space (we refer to Appendix B, where some basic notions of, and results on, indefinite inner product spaces are gathered). Thus, no physical information gets lost and one can identify a positive definite physical Hilbert subspace. In fact, in the case treated in Refs. 1 and 2 the rank of negativity is one, and thus the Krein space is actually a Pontryagin space. In Ref. 4, we have cast this procedure in abstract form, yielding a method by which every quasipositive space, i.e., a space with finite rank of negativity, can be completed to a Pontryagin space. By this, we generalized the infrared regularization method to singularities of the type of finite order distributions. On the other hand it is by now well known that constructive approaches to interacting quantum fields generically involve much more singular objects, see Refs. 5 and 6, namely ultradistributions and even Fourier hyperfunctions.[7,8] Thus, it is natural to look for a further generalization of the procedure for finding a maximal Krein space closure starting from a space of test functions with an indefinite inner product induced by a singular kernel, to the case of nondistributional infinite order singularities, and therefore to the case of an infinite number of negative degrees of freedom. This is what we will present in the following.

We illustrate the regularization method by a neat (yet unphysical) model in which infinite

[a)]Current address: Dipartimento di Fisica E. Fermi, Università di Pisa, via Buonarroti 2, Ed. B, 56127 Pisa PI, Italy; electronic mail: aschmidt@math.uni-frankfurt.de

order singularities appear naturally, at least on a heuristic level. (We tend to denote the whole process of defining an indefinite inner product by a generalized function *and* the construction of a maximal Krein space closure as ''regularization.'' The first step, which is the traditional regularization of a singular integral, means going only half way toward a physically conclusive result.) Namely, we will consider the Schrödinger representation of the Heisenberg algebra on a test function space over $\mathbb{R}$ in the presence of a singularity concentrated at $p=0$. This model will be informally described in Sec. II, where also some notions needed subsequently are introduced. Further, we will state the main result, which is that the regularization procedure yields a maximal Krein space and in it a largest possible, positive definite, closed subspace, which can sensibly be considered as the ''physical state space'' for the Heisenberg algebra of ''observables.''

Section III contains the regularization procedure proper. It shows in particular that there is a certain balance that has to be kept between the singularity of the inner product, measured in terms of infinite order (local) differential operators, and the choice of test function space, which we express in terms of the Gelfand–Shilov scheme of spaces, see Ref. 9, Chap. IV. The method itself is, however, general enough to be applied to a much wider class of singularities than infrared ones, and for a lot of other test function spaces.

In Sec. IV, we formulate abstractly a sufficient condition under which the regularization is guaranteed to work. The conditions we give are not the most general and abstract ones possible, since they reflect the limitations of the procedure of Sec. III. Therefore they present no sharp criterion to decide whether an indefinite space admits the construction of a maximal majorant topology by our construction of a Hilbert majorant. Nevertheless, they capture the essential points that enable our construction, and therefore are at least useful to explain the mechanism behind it. Furthermore, our conditions are simple enough to be effective in many concrete cases. We discuss possible further generalizations at the end of Sec. IV.

Appendix A contains a simple, concrete construction of certain neutral elements, i.e., vectors with vanishing inner product, which play an important role in the regularization procedure in Sec. III. Appendix B compiles some basics about indefinite inner product spaces mainly taken from Ref. 10.

II. THE MODEL

Recently, a comprehensive abstract classification of representations of the Heisenberg algebra on an indefinite inner product space has been worked out by Mnatsakanova *et al.* in Ref. 11. There, it was pointed out that this issue is somewhat more difficult to handle than in the positive definite case, which is covered by the Stone–von Neumann uniqueness theorem, see Ref. 12, Chap. IV. Especially, domain questions appear and the notion of irreducibility has to be reconsidered. Here, we take a different approach in considering a very concrete example where the Heisenberg representation is from the beginning assumed to be the quantum mechanical Schrödinger representation

$$\hat{q} \overset{\text{def}}{=} x\cdot, \qquad \hat{p} \overset{\text{def}}{=} -i\frac{d}{dx},$$

on a function space over $\mathbb{R}$.

The following discussion will take place in momentum space, and we will notoriously denote the Fourier transforms of functions with *f, g,* etc., and the variable by *p*. Consider the indefinite inner product

$$\langle f,g\rangle \overset{\text{def}}{=} (f,g)_{L^2} - \sum_{k=0}^{\infty} c_k^2 \overline{f^{(k)}}(0) g^{(k)}(0), \tag{1}$$

with real coefficients c_k (this will turn out to pose no essential restriction in our case, see the following). It can be formally interpreted as being induced by a generalized function (a kernel) on $\mathbb{R}^2$ in the following way:

$$\langle f,g\rangle = (\delta(p-p')-J(\partial_p\partial_{p'})\delta(p)\delta(p'),\overline{f}(p)g(p')). \tag{2}$$

Here, the infinite order differential operator J is given by its symbol

$$J(\xi)\overset{\text{def}}{=}\sum_{k=0}^{\infty} c_k^2\xi^k.$$

The singularity in $\langle .,.\rangle$ can be characterized by the following notion, where we have already adapted the conventional notation a bit, so as to conform with our application in Sec. III:

Definition and Remark 2.1 (Ref. 9, 159 pp.): An entire function $J(\xi)$ in the complex variable ξ is called *infraexponential of order* $1/(2\delta)$ if it fulfills for every $\varepsilon>0$ an estimate

$$|J(\xi)|\leqslant C_\varepsilon e^{\varepsilon|\xi|^{1/(2\delta)}}$$

for some $C_\varepsilon>0$. In this case, the coefficients c_k^2 of the Taylor series of J satisfy the following upper bounds: For every $D>0$ exists a $\theta\in(0,1)$ and a $C>0$ such that

$$|c_k^2|\leqslant C\frac{\theta^k}{D^k e^{2k\delta}k^{2k\delta}}. \tag{3}$$

Now, our first concern is on which test function space the inner product can be defined. To this end, we use the Gelfand–Shilov scheme for the classification of spaces of smooth functions, see Ref. 9, Chap. IV. For $0\leqslant\alpha,\ \beta\leqslant\infty$ the space $\mathscr{S}_\alpha^\beta(\mathbb{R})$ consists of smooth functions f on $\mathbb{R}$ satisfying estimates

$$|p^q f^{(k)}(p)|\leqslant CA^qB^kq^{q\alpha}k^{k\beta}.$$

We need in fact only consider the regularity of the functions in $\mathscr{S}_\alpha^\beta(\mathbb{R})$ at the origin, which is expressed in the following basic estimate: There exists a $B>0$ such that for all $\rho>0$ and a constant C_f depending on f we have

$$|f^{(k)}(0)|\leqslant C_f(B+\rho)^k k^{k\beta}. \tag{4}$$

It is apparent from (3) and (4) that the indefinite inner product is well-defined on $\mathscr{S}_\alpha^\beta$ by (1) as the distribution (2), whenever J is infraexponential of order $\leqslant 1/(2\beta)$. We denoted by $\mathcal{V}=\mathcal{V}_J(\alpha,\beta;\rho)$ a space $\mathscr{S}_\alpha^\beta$ equipped with an indefinite inner product (1) defined by an infraexponential symbol J of order $1/(2\delta)$ for any $\delta\leqslant\beta$.

Further constraints on the choice of test function space now come from the intended Schrödinger representation of the Heisenberg algebra. As the Heisenberg generators act in momentum space by multiplication with p and differentiation id/dp, it is clear that they will not be symmetric operators with respect to the indefinite inner product $\langle .,.\rangle$ on the whole space. A representation on a subspace of $\mathcal{V}$ acts by symmetric operators only if this subspace consists of functions f such that all derivatives of f vanish at $p=0$. This subspace is at the same time also positive definite. In order that it is also maximal in the sense that there is no larger positive definite subspace in $\mathcal{V}$, one has in fact to assume that the coefficients c_k^2 in Eq. (1) are strictly positive, i.e., $c_k\in\mathbb{R}\backslash\{0\}$ for all k, which we do from now on. In turn, this implies that $J(\partial_p\partial_p')$ is a properly infinite differential operator and thus the singularity in (2) must be stronger than a finite order distribution. This excludes as test function space any space $\mathscr{S}_\alpha^\infty$ which allows only distributions of finite order, and thus in particular the Schwartz space $\mathscr{S}=\mathscr{S}_\infty^\infty$. On the other hand, the very strong singularity of

an analytic functional is also excluded: Since for $\beta=1$ the test functions in $\mathcal{V}$ are all analytic in a strip neighborhood of the real axis, the requirement $f^{(k)}(0)=0$ for all k would lead to the trivial subspace.

After these heuristics, we are ready to state our main result, whose proof will follow in the following section. We will characterize the complete, positive definite representation subspace for the Heisenberg algebra by the Fourier transformation. For that, we need another definition.

Definition 2.2: The space of functions $L^2_0(\mathbb{R})$ is defined as

$$L^2_0(\mathbb{R}) \overset{\text{def}}{=} \{f \in L^2(\mathbb{R}) | \mu^k(f)=0, \ \forall k \in \mathbb{N}_0\},$$

where the *k-th moment* $\mu^k(f)$ of a function $f \in L^2(\mathbb{R})$ is given by

$$\mu^k(f) \overset{\text{def}}{=} \int_{\mathbb{R}} x^k f(x) dx,$$

if it exists for a $k \in \mathbb{N}_0$.

Theorem 2.3: *Let* $0 \leqslant \alpha \leqslant \infty$, $1 < \beta < \infty$. *Assume* $\delta > \beta$, *and let J be infraexponential of order* $1/(2\delta)$ *with strictly positive Taylor coefficients. Then, the space* $\mathcal{V}=\mathcal{V}_J(\alpha,\beta;(2\delta)^{-1})$ *admits a maximal completion to a Krein space* $\mathcal{K}$ *with countably infinite rank of negativity. The maximal positive definite subspace of* $\mathcal{K}$, *invariant under the action of the Heisenberg algebra in the Schrödinger representation by self-adjoint operators on it, is the Fourier transform* $\mathcal{F}L^2_0(\mathbb{R})$ *of* $L^2_0(\mathbb{R})$.

The appearance of $\delta > \beta$ results from technicalities of the infrared regularization process, as will become clear in the following. This leaves room for improvement. It should be stressed that the diagonal form $\delta(p-p')$ of (2) outisde the singularity $p=p'=0$ was chosen to allow for a symmetric action of the Heisenberg generators. The regularization procedure itself is nonetheless rather independent of the structure of the kernel outside the singular points. On the other hand, the discussion at the beginning of this section also points to a principal limitation of the regularization method. If the singularity in a certain point p_0 is that of a proper analytic functional, i.e., $\delta \leqslant 1$, and the rank of indefiniteness is infinite, regularization is impossible since the positive subspace would be trivial in that case.

The somewhat exotic representation of the Heisenberg algebra mentioned previously does not fit into the classification of Ref. 11, see also Ref. 13. Rather it corresponds to the ''counterexample'' in the appendix of Ref. 11. As explained there, $L^2_0(\mathbb{R})$ naturally decomposes into two irreducible subspaces of ''left-'' and ''right-movers'' i.e., states with support, respectively, on the negative, and positive half-axis in momentum space, by closure of the two domains $\mathcal{V}_\pm = \{f \in \mathcal{V} | f(p)=0 \text{ for } p \lessgtr 0\}$ in the Krein topology.

III. INFINITE INFRARED REGULARIZATION

In this section we present the proper method for the construction of a Krein space from $\mathcal{V}$. The general strategy is close in spirit to the well-known method for closing a Hilbert space with respect to the action of a given positive bilinear form on it (see Ref. 14, Appendix A.2). The construction of a maximal majorant Hilbert topology for $\mathcal{V}$ leading to a Krein space closure of it, relies mainly on two ingredients: first, the existence of neutral elements within $\mathcal{V}$ which separate the negative degrees of freedom from the rest of the space. Second, there is some ''air'' left between the decay of the coefficients c_k^2 defining $\langle .,. \rangle$ via (1), and the growth of the Taylor coefficients of the functions in $\mathcal{V}$. This is expressed in Eq. (3), the assumption $\delta > \beta$ of Theorem 2.3, and (4). To make use of that margin, we define the ''damping coefficients'' γ_k by

$$\gamma_k \overset{\text{def}}{=} k^{k\delta}. \tag{5}$$

The neutral decomposition elements will be constructed in Appendix A to fulfill the following demands:

Lemma 3.1: Let $0\leqslant\alpha\leqslant\infty$ *and* $1<\beta<\infty$. *Let there be given a sequence of numbers* c_k *satisfying* (3), *and let* γ_k *be as in* (5). *Then there exists a sequence of functions* $\{\chi_k\}_{k\in\mathbb{N}_0}\subset\mathscr{S}^{\beta}_{\alpha}$ *with the following properties*:

(i) $\|\chi_k\|^2_{L^2}=c_k^2\gamma_k^2$,
(ii) $\chi_k^{(i)}(0)=\delta_{ik}\cdot\gamma_k$,
(iii) $(\chi_k,\chi_l)_{L^2}=0$ *for all* $k\neq l$,
(iv) $\langle\chi_k,\chi_l\rangle=0$ *for all k, l.*

We denote by $\mathcal{N}$ *the linear subspace of* $\mathscr{S}^{\beta}_{\alpha}$ *generated by* $\{\chi_k\}_{k\in\mathbb{N}_0}$.

The subspace $\mathcal{N}$ is neutral, $\mathcal{N}\subset\mathcal{V}^0$. We also observe that $\mathcal{V}$ is nondegenerate due to the presence of the L^2-part in the indefinite product (1). This property will prevail in the closure of $\mathcal{V}$ we construct in the following. Now, every $f\in\mathscr{S}^{\beta}_{\alpha}$ has, for every finite $N\geqslant 0$, a unique decomposition

$$f=f^{N+}+\sum_{i=0}^{N}f^i\chi_i\quad\text{with}\quad f^i=\frac{f^{(i)}(0)}{\gamma_i},\tag{6}$$

and $f^{N+}\in\mathscr{S}^{\beta}_{\alpha}$ is such that $\int^{(i)}(0)=0$ for $0\leqslant i\leqslant N$. Furthermore, the sum in the decomposition is clearly in $\mathcal{N}$.

Proposition 3.2: The seminorm p given by the limit

$$p(f)^2\overset{\text{def}}{=}\lim_{N\to\infty}\left[\langle f^{N+},f^{N+}\rangle+\sum_{i=0}^{N}\{|\langle f,\chi_i\rangle|^2+|f^i|^2\}\right]\tag{7}$$

exists and defines a majorant topology τ *on* $\mathcal{V}$.

Proof: Taking Lemma B.3 into account, we have to show that (7), if it is well defined, dominates the inner square. Assuming that the limit in question exists, it is easy to show that $p(f)^2$ majorizes the inner square $|\langle f,f\rangle|$ of f. Namely, using (6) we can express $\langle f,f\rangle$ as

$$\langle f,f\rangle=\langle f^{N+},f^{N+}\rangle+\sum_{i=0}^{N}\{f^i\langle f,\chi_i\rangle+\overline{f^i}\langle\chi_i,f\rangle\}$$

using property (iv) of Lemma 3.1, and the fact that $\langle f^{N+},\chi_i\rangle=\langle f,\chi_i\rangle$ which follows from it. Now, in every term in the sum above we have the elementary estimate for complex numbers $|f^i\langle f,\chi_i\rangle+\overline{f^i}\langle\chi_i,f\rangle|\leqslant|\langle f,\chi_i\rangle|^2+|f^i|^2$. If the first term $\langle f^{N+},f^{N+}\rangle$ in (7) has a limit at all, then it tends to $(f^+,f^+)_{L^2}=\|f^+\|^2_{L^2}\geqslant 0$ for a certain $f^+\in L^2$, showing $p(f)^2\geqslant|\langle f,f\rangle|$ in the limit $N\to\infty$. It remains to show that all the limits involved in (7) exist. In order to show finiteness of the first term it suffices to show that the decomposition (6) of f converges in $L^2(\mathbb{R})$ for $N\to\infty$, since it then tends to $\|f^+\|^2_{L^2}$ and is thus necessarily finite as we have just seen. For the sum defining the decomposition, we have by (i) of Lemma 3.1

$$\left\|\sum_{N=0}^{\infty}f^i\chi_i\right\|^2_{L^2}\leqslant\sum_{N=0}^{\infty}\|f^i\chi_i\|^2_{L^2}=\sum_{N=0}^{\infty}|f^{(i)}(0)c_i|^2<\infty,$$

taking (3) and (4) into account, showing that claim. By definition (1) of the inner product, the ith term in the sum in (7) becomes

$$|\langle f,\chi_i\rangle|^2+|f^i|^2=\left|(f,\chi_i)_{L^2}-\sum_{k=0}^{2} c_k^2\overline{f^{(k)}}(0)\chi_i^{(k)}(0)\right|^2+|f^i|^2$$
$$\leqslant|(f,\chi_i)_{L^2}|^2+c_i^4\gamma_i^2|f^{(i)}(0)|^2+\frac{|f^{(i)}(0)|^2}{\gamma_i^2}.$$

For the first term we find, using the Cauchy–Schwartz estimate, by (3) and (5), and of course the assumption of Theorem 2.3:

$$|(f,\chi_i)_{L^2}|^2\leqslant\|f\|_{L^2}^2|c_i^2\gamma_i^2|\leqslant\|f\|_{L^2}^2\frac{C\theta^i}{D^i e^{2i\delta}}.$$

Further using (4), the second term is bounded by

$$c_i^4\gamma_i^2|f^{(i)}(0)|^2\leqslant\frac{C^2C_f^2}{i^{2i(\delta-\beta)}}\left(\frac{\theta(B+\rho)}{e^{2\delta}D}\right)^{2i}.$$

Finally the third term satisfies

$$\frac{|f^{(i)}(0)|^2}{\gamma_i^2}\leqslant\frac{C_f^2}{i^{2i(\delta-\beta)}}(B+\rho)^{2i}.$$

All three terms decay faster than exponentially in i, making the overall sum in (7) convergent in the limit $N\to\infty$. □

Notice that although we chose to see this independently by considering L^2-convergence, the numerical convergence of the $\langle f^{N+},f^{N+}\rangle$-part of the decomposition could have been inferred in the same way as the convergence of the other terms in (7). In fact, one could have inverted the decomposition (6) to yield $f^{N+}=f-\Sigma_{i=0}^{N}f^i\chi_i$ and then see the convergence of $\langle f^{N+},f^{N+}\rangle$ by majorizing it with the same convergent terms as in the previous proof.

It is apparent from the proof of Proposition 3.2 that the decomposition (6) of f converges in the closure $\overline{\mathcal{V}^\tau}$ of $\mathcal{V}$ with respect to τ. In fact, it is easy to see that the increments $p(f^i\chi_i)^2$ decay fast enough to turn the partial sums in the decomposition into a Cauchy sequence. This allows us to write for every $f\in\mathcal{V}$,

$$f=f^+\sum_{i=0}^{\infty}f^i\chi_i\quad\text{with}\quad f^+\in\overline{\mathcal{V}^\tau}. \tag{8}$$

We further see, using the joint continuity of $\langle .,.\rangle$, see Definition B.2, that the indefinite inner product $\langle .,.\rangle$ has a unique extension to $\overline{\mathcal{V}^\tau}$, which we will also denote by $\langle .,.\rangle$. Thus using (8), Eq. (7) extends to a definition of a quadratic normed topology on the τ-complete space $\overline{\mathcal{V}^\tau}$, i.e., a Hilbert majorant topology on that space:

Corollary 3.3: On the closure $\mathcal{K}\overset{\text{def}}{=}\overline{\mathcal{V}^\tau}=(\mathscr{S}_\alpha^\beta)^{-\tau}$ *we define the Hilbert scalar product*

$$(f,g)\overset{\text{def}}{=}\langle f^+,g^+\rangle+\sum_{i=0}^{\infty}\{\langle f,\chi_i\rangle\langle\chi_i,g\rangle+\overline{f^i}g^i\},\quad\forall f,g\in\mathcal{K}. \tag{9}$$

We denote the Hilbert norm on $\mathcal{K}$ *by* $\|.\|\overset{\text{def}}{=}p(.)=(.,.)^{1/2}$. *In particular, we have the identity* $\langle f^+,f^+\rangle=\|f^+\|_{L^2}^2$.

We set

$$\mathcal{P} \overset{\text{def}}{=} \{f \in \mathcal{V} \,|\, f^{(k)}(0) = 0, \quad \forall k \in \mathbb{N}_0\}.$$

Obviously, $\langle .,. \rangle$ is positive definite on $\mathcal{P}$ and equals the L^2-scalar product on that subspace. The decomposition (8) can now be expressed as follows:

Lemma 3.4: Equation (8) *defines a mapping*

$$P : \mathcal{V} \to \overline{\mathcal{V}}^\tau, \quad f \mapsto f^+,$$

with the following properties:

(i) *P is continuous in the topology* τ.
(ii) *P has a continuous extension to* $\mathcal{K}$.
(iii) *P maps* $\mathcal{K}$ *onto* $\overline{\mathcal{P}}^\tau$.
(iv) *P is an orthogonal projection onto* $\overline{\mathcal{P}}^\tau$ *with respect to* $(.,.)$.
(v) *The decomposition*

$$\mathcal{K} = \overline{\mathcal{P}}^\tau \oplus \overline{\mathcal{N}}^\tau$$

is orthogonal with respect to the scalar product (.,.) (denoted by $\oplus$*).*

Proof: To show (i) we estimate

$$\begin{aligned}
\|f^+\|^2 &= \|f^+\|_{L^2}^2 + \sum_{i=0}^{\infty} |\langle f^+, \chi_i \rangle|^2 \\
&= \|f^+\|_{L^2}^2 + \sum_{i=0}^{\infty} |(f^+, \chi_i)_{L^2}|^2 \\
&\leqslant \|f^+\|_{L^2}^2 \left(1 + \sum_{i=0}^{\infty} \|\chi_i\|_{L^2}^2 \right) \\
&\leqslant \|f^+\|_{L^2}^2 \left(1 + \sum_{i=0}^{\infty} c_i^2 \gamma_i^2 \right) \leqslant C \|f^+\|_{L^2}^2 \leqslant C \|f\|^2.
\end{aligned}$$

In the last step we used that we have $\|f\|^2 \geqslant \langle f^+, f^+ \rangle = \|f^+\|_{L^2}^2$ by Corollary 3.3. Assertion (ii) follows from (i). By (i) and (ii) it suffices to show that $f \in \mathcal{V}$ entails $f^+ \in \overline{\mathcal{P}}^\tau$ to show (iii). For that, by the second to last inequality mentioned previously, it suffices to approximate f^+ in the L^2-norm with elements of $\overline{\mathcal{P}}^\tau$. Such an approximation can be easily constructed, e.g., as $f_\varepsilon^+ = (1 - \rho_\varepsilon) f^+$ for $\varepsilon \to 0$, with the cut-off functions ρ_ε of Lemma A.1. That $P : \mathcal{K} \to \overline{\mathcal{P}}^\tau$ is surjective is now clear, since P is the identity on $\overline{\mathcal{P}}^\tau$. For $f^+ \in \mathcal{P}$ and $\chi \in \mathcal{N}$, the scalar product reduces to

$$(f^+, \chi) = \sum_{i=0}^{\infty} \langle f^+, \chi_i \rangle \langle \chi_i, \chi \rangle = 0,$$

since $\langle \chi_i, \chi \rangle = 0$, and because f^+ and χ have decompositions with vanishing $(f^+)^i$ and χ^+, respectively. Continuity of $\langle .,. \rangle$ then implies statement (iv). Assertion (v) follows from (iv) and the fact that the sum in (8) converges to an element of $\overline{\mathcal{N}}^\tau$. □

To construct the metric operator J that connects the indefinite with the Hilbert scalar product on $\mathcal{K}$, we have to decompose this space somewhat further. To that end, we consider the functionals

$$F_i(f) \overset{\text{def}}{=} \langle \chi_i, f_i \rangle, \quad f \in \mathcal{V}$$

on $\mathcal{V}$. These functionals are nonzero since $\mathcal{V}$ is nondegenerate, they vanish on $\mathcal{N}$, and they are clearly bounded with respect to the norm p. In fact, we have $|F_i(f)|/p(f)\leqslant 1$ for $f\in\mathcal{V}$, by (7). That is, the F_i have unique continuations (also denoted by F_i) to $\mathcal{K}$ by the Hahn–Banach theorem, and by continuity these satisfy the same bound $0<\|F_i\|\leqslant 1$.

Lemma 3.5: The uniquely determined vectors $v_i\in\mathcal{K}$ which represent F_i via $F_i(f)=(v_i,f)$ for all $f\in\mathcal{K}$ are actually contained in $\overline{\mathcal{P}^\tau}$.

Proof: That the vectors v_i exist and are unique in $\mathcal{K}$ follows from Riesz' representation theorem applied to the bounded linear functionals F_i on the Hilbert space $\mathcal{K}$. We have to show that they are in $\overline{\mathcal{P}^\tau}$. Choose a sequence $\{v_{in}\}_{n\in\mathbb{N}}$ in $\mathcal{V}$ that approximates v_i, i.e., $\|v_i-v_{in}\|\to 0$ for $n\to\infty$. Using the decomposition (8) for the v_{in} we calculate (adopting Einstein's summation convention for repeated upper and lower indices)

$$\begin{aligned}\|v_i-v_{in}\|^2&=(v_i-(v_{in})^+-(v_{in})^j\chi_j,v_i-(v_{in})^+-(v_{in})^k\chi_k)\\&=\|v_i-(v_{in})^+\|^2-(v_i-(v_{in})^+-(v_{in})^j\chi_j,(v_{in})^k\chi_k)-((v_{in})^j\chi_j,v_i-(v_{in})^+)\\&=\|v_i-(v_{in})^+\|^2-(v_i-v_{in},(v_{in})^j\chi_j)-((v_{in})^j\chi_j,v_i)+((v_{in})^j\chi_j,(v_{in})^+).\end{aligned}$$

The last term on the right-hand side vanishes for all n due to Lemma 3.4(v). The third term is zero since $(v_i,\chi_j)=F_i(\chi_j)=\langle\chi_i,\chi_j\rangle=0$. We use the Cauchy–Schwartz estimate for the scalar product $(.,.)$ and the fact that $\|\chi_i\|=|(\chi_i)^i|=|\chi_i^{(i)}(0)/\gamma_i|=1$ to estimate the second term as follows:

$$|(v_i-v_{in},(v_{in})^j\chi_j)|\leqslant\|v_i-v_{in}\|\sum_{j=0}^{\infty}|(v_{in})^j|\leqslant C\|v_i-v_{in}\|,$$

with some constant $C>0$ independent of n. In fact, since $(v_{in})^j=v_{in}^{(j)}(0)/\gamma_j$, and using (4) and (5) we see that the sum is finite for all n. Since the sequence v_{in} is convergent in the norm p and by definition (7) of this norm, the sum must actually converge and therefore admits a global bound C as above. In conclusion, since v_{in} is τ-convergent to v_i, i.e., $\|v_i-v_{in}\|\to 0$ for $n\to\infty$, we must have $\|v_i-(v_{in})^+\|\to 0$ by necessity, and thus already Pv_{in} is τ-convergent to v_i. This shows the claim. □

The basic properties of the v_i are collected in the next lemma.

Lemma 3.6: The vectors v_i have the following properties:

(i) $\langle\chi_i,v_i\rangle=(v_i,v_i)=1$,
(ii) $(v_i,v_j)=\langle\chi_i,v_j\rangle=0$ for $i\neq j$,
(iii) $\langle v_i,v_i\rangle=0$,
(iv) $\langle v_i,f\rangle=f^i$ *for all* $f\in\mathcal{V}$.

Proof: Statement (i) is clear from the defining property of v_i, except for the last equality that says $\|v_i\|=1$. This will soon turn out to be true. Let $\{v_{in}\}_{n\in\mathbb{N}}\subset\mathcal{P}$ be a sequence converging to v_i in $\mathcal{K}$, which exists by Lemma 3.5. Then with (9), and since $(v_{in})^j=0$ for all j we have

$$\frac{\|v_{in}\|^2}{|\langle\chi_i,v_{in}\rangle|}=\frac{\langle v_{in},v_{in}\rangle}{|\langle\chi_i,v_{in}\rangle|}+1+\frac{\Sigma_{j\neq i}\langle\chi_j,v_{in}\rangle}{|\langle\chi_i,v_{in}\rangle|}.$$

Now $|\langle\chi_i,v_{in}\rangle|=|(v_i,v_{in})|\to\|v_i\|^2$ by (i), so that the left-hand side tends to 1 for $n\to\infty$ (here we assume that the denominators are nonzero which can be achieved by choosing v_{in} suitably). Since the denominators stay bounded, we must necessarily have $|\langle\chi_j,v_{in}\rangle|\to 0$ for $j\neq i$ showing (ii), and also $\langle v_{in},v_{in}\rangle\to 0$ showing (iii) since v_{in} converges to v_i with respect to $\|.\|=p(.)$ and p majorizes the inner square. Incidentally, this also shows

$$\sup_n\frac{|F_i(v_{in})|}{\|v_{in}\|}=\sup_n\frac{|\langle\chi_i,v_{in}\rangle|}{\|v_{in}\|}=1,$$

and this proves the last equality in (i), since the norm of v_i and that of the linear functional F_i coincide by Riesz' theorem. To show (iv), we consider again the decomposition (8) of a vector $f \in \mathcal{V}$ which yields

$$\langle v_{in}, f\rangle = \langle v_{in}, f^+\rangle + f^i\langle v_{in}, \chi_i\rangle + \sum_{j\neq i} f^j\langle v_{in}, \chi_j\rangle.$$

In this expression we find $\langle v_{in}, f^+\rangle \to 0$, since by (iii) v_{in} converges strongly to 0 in $\overline{\mathcal{P}^\tau}$, and due to Lemma 3.4. By arguments similar to that in the proof of Lemma 3.5, the sum stays bounded independently of n, and since every single term in it converges to 0 by (ii), the sum also tends to 0. This leaves us with the second term which converges to $f^i\langle v_i, \chi_i\rangle = f^i$ by (i). This shows (iv).□

The v_i could be constructed concretely as limits of functions which vanish strongly in the L^2-sense, as in Ref. 1. Lemmas 3.5 and 3.6 allow us to avoid such an explicit construction. The vectors v_i are an orthonormal basis of a closed Hilbert subspace of $\mathcal{K}$. This space is isomorphic to the dual space of $\overline{\mathcal{N}^\tau}$ by definition of the functionals F_i and Lemma 3.5, and we mnemonically denote it by the symbol $\overline{\mathcal{N}^{\tau\langle * \rangle}}$.

Lemma 3.7: Denote by $\mathcal{H}$ the closure $\overline{\mathcal{P}^\tau}_+$ of $\mathcal{P}$ with respect to the topology τ_+ induced by the quadratic Hilbert norm $p_+(.)^2 \overset{\text{def}}{=} \langle .,. \rangle$ on $\mathcal{P}$. The space $\mathcal{K}$ admits the decomposition

$$\mathcal{K} = \mathcal{H} \oplus \overline{\mathcal{N}^{\tau\langle * \rangle}} \oplus \overline{\mathcal{N}^\tau},$$

orthogonal with respect to (.,.).

Proof: First, we must show that the decomposition is indeed possible because $\mathcal{H} \subset \overline{\mathcal{V}^\tau}$. To this end, note that the topology τ_+ is stronger than the restriction of τ to $\mathcal{P}$. In fact, if a sequence in $\mathcal{P}$ converges in the norm p_+ then it converges in the L^2-norm by (1), and by the action of the indefinite product on $\mathcal{P}$ it is easy to see that this suffices to ensure convergence in the norm p. Now, taking Lemma 3.4(v) into account, we have to show that the (.,.)-orthogonal decomposition $\overline{\mathcal{P}^\tau} = \mathcal{H} \oplus \overline{\mathcal{N}^{\tau\langle * \rangle}}$ holds. First, observe that the vectors v_i form a τ-complete orthonormal system in $\overline{\mathcal{N}^{\tau\langle * \rangle}}$. Now, for $f^+, g^+ \in \mathcal{P}$ we have

$$(f^+, g^+) = \langle f^+, g^+\rangle + \sum_{i=0}^{\infty} (f^+, v_i)(v_i, g^+),$$

by the definition of v_i and (9). This shows that a sequence $\{f_n^+\}_{n\in\mathbb{N}}$ in $\mathcal{P}$ converges to a limit $f \in \overline{\mathcal{P}^\tau}$ if and only if $p_+(f_n^+ - f) \to 0$ and independently the (.,.)-orthogonal projection of $f_n^+ - f$ onto the closed subspace $\overline{\mathcal{N}^{\tau\langle * \rangle}}$ of $\overline{\mathcal{P}^\tau}$ tends to zero. Denote by $\overline{\mathcal{N}^{\tau\langle \perp \rangle}}$ the orthogonal complement of $\overline{\mathcal{N}^{\tau\langle * \rangle}}$ in $\mathcal{K}$ with respect to (.,.). By the above-given argument, the subset $\mathcal{P} \cap \overline{\mathcal{N}^{\tau\langle \perp \rangle}}$ of $\overline{\mathcal{P}^\tau}$ is dense in $\mathcal{H}$ with respect to the topology τ_+. This shows that the proposed decomposition is indeed (.,.)-orthogonal. In conclusion, a τ-Cauchy sequence in $\mathcal{P}$ can be identified with a pair $(f, \{\lambda_i\}_{i\in\mathbb{N}_0})$ with an $f \in \mathcal{H}$ and $\lambda_i = (v, v_i)$ for some $v \in \overline{\mathcal{N}^{\tau\langle * \rangle}}$. This shows $\overline{\mathcal{P}^\tau} = \mathcal{H} \oplus \overline{\mathcal{N}^{\tau\langle * \rangle}}$. □

It should be noted that by Lemma 3.6 (iii), the vectors v_i indeed converge to zero in the topology τ_+ of $\mathcal{H}$ but are clearly nonzero in $\overline{\mathcal{P}^\tau} \subset \mathcal{K}$. Furthermore, τ_+ is stronger than the L^2-topology although $p_+(f^+) = \|f^+\|_{L^2}$ for $f^+ \in \mathcal{P}$. We will characterize $\mathcal{H}$ as a function space in the following. We have compiled all information needed to exhibit the Krein space structure of $\mathcal{K}$.

Theorem 3.8: *The space $\mathcal{K}$ is a Krein space with countably infinite rank of indefiniteness. Its Hilbert space structure is maximal and given by the metric operator $J: \mathcal{K} \to \mathcal{K}$, satisfying the identity $\langle .,. \rangle = (., J.)$. It holds*

$$Jv_i = \chi_i, \quad J\chi_i = v_i, \quad \text{and } J|_{\mathcal{H}} = \mathbb{I}_{\mathcal{H}},$$

in the decomposition of Lemma 3.7.

Proof: The strategy of the proof will be as follows: The metric operator exists by Proposition B.5, and we have seen in Lemma 3.7 that we can write down its action in the decomposition $\mathcal{K}=\mathcal{H}\oplus\overline{\mathcal{N}^\pi}^{\langle *\rangle}\oplus\overline{\mathcal{N}^\pi}$. We can then explicitly demonstrate that the operator J on $\mathcal{K}$ acts as stated. This special form of J immediately implies that it is a bounded, completely invertible operator on $\mathcal{K}$. Thus by Proposition B.7, $\mathcal{K}$ is a Krein space and since $J^{-1}=J$ is also bounded, its Hilbert space structure $(\mathcal{K}, J)$ is maximal by Lemma B.8. Now, by definition of the v_i we have $\langle f,\chi_i\rangle=(f,J\chi_i)=(f,v_i)$ for all $f\in\mathcal{K}$, showing $J\chi_i=v_i$. On the other hand, by Lemma 3.6(iv) and (9) we have $\langle f,v_i\rangle=(f,Jv_i)=\overline{f^i}=(f,\chi_i)$, showing $Jv_i=\chi_i$. It remains to consider the restriction of J to $\mathcal{H}$. Take $f^\perp, g^\perp\in\mathcal{P}\cap\overline{\mathcal{N}^\pi}^{\langle\perp\rangle}$ (see the proof of Lemma 3.7) and note that $(f^\perp,g^\perp)=\langle f^\perp,g^\perp\rangle$ for those vectors. Since these vectors are dense in $\mathcal{H}$, it follows that the restriction of J to $\mathcal{H}$ is the identity. This shows the claim. □

To conclude the proof of Theorem 2.3, it finally remains to show that $\mathcal{H}$ is the Fourier transform of the space L_0^2 defined in Definition 2.2. Now $\mathcal{F}$ is a topological isomorphism from $\mathscr{S}_\beta^\alpha$ onto $\mathcal{V}=\mathscr{S}_\alpha^\beta$ and for $f\in\mathscr{S}_\beta^\alpha$ we have

$$i^k\hat{f}^{(k)}(0)=\left(i^k\frac{d^k}{d\xi^k}\int_{\mathbb{R}}e^{-ix\xi}f(x)\mathrm{d}x\right)\Bigg|_{\xi=0}=i^k\int_{\mathbb{R}}(-ix)^kf(x)dx=\mu^k(f).$$

By that, the image of $\mathcal{P}$ under $\mathcal{F}^{-1}$ is the subspace of $\mathscr{S}_\beta^\alpha$ of functions f with $\mu^k(f)=0$ for all k. Since $\mathscr{S}_\beta^\alpha$ is dense in L^2 and the Fourier transformation is an L^2-isometry, we can see $\mathcal{H}=\mathcal{F}L_0^2$. Thus Theorem 2.3 is finally proven.

If we test the vectors v_i with states in the ''physical'' subspace $\mathcal{H}$, i.e., the representation space for the Heisenberg-observables, they appear as completely delocalized states. In fact the action of the momentum operator on them is given by Lemma 3.6(iv):

$$\langle pv_i,f\rangle=\langle v_i,pf\rangle=(pf)^i=0\quad\text{for all}\quad f\in\mathcal{H},\quad i\in\mathbb{N}_0,$$

where we denoted the unique extension of the multiplication operator p from $\mathcal{V}$ to $\mathcal{K}$ also by p. This is different from the case of one single negative degree of freedom in Ref. 1, where the single vector v_0 turns out to be completely delocalized on the whole Krein state space.

IV. A CONDITION SUFFICIENT FOR REGULARIZATION

In this section, we want to give a set of conditions on a general indefinite inner product space $\mathcal{V}$, that will be sufficient for the regularization procedure to work. We did not put this generalization in the beginning, and then deduced the special case $\mathcal{V}=\mathscr{S}_\alpha^\beta$ considered previously from it, for two reasons: First and foremost, we wanted to emphasize the case of indefinite inner products generated by singular kernels acting on a test function space, which we think is particularly interesting in view of possible applications in physics. Second, most of the assertions and proofs in Sec. III are already cast abstract enough to be re-used in the proof of the generalized regularization Theorem 4.1 without any modification. Thus, we can stress the essential points that need modification and thereby highlight the principles which put the regularization procedure to work.

Two elements are essential: First, the existence of neutral decomposition elements χ_i that enable us to isolate the positive part of the indefinite product. Second, a certain balance between the growth, respectively, and decay of (a) the inner products of vectors in the space with the neutral elements, and (b) the coefficients of the linear decomposition of a vector with respect to these. These growth conditions constitute the main difference between the case of finite rank of indefiniteness considered in Ref. 4 and the infinite case, where they serve to render the Hilbert majorant topology well defined in the first place.

Let us now formulate our set of conditions. We assume $\mathcal{V}$ to be a complex linear space with an indefinite inner product $\langle .,.\rangle$, which shall be nondegenerate. Assume the following.

(0) There exists an orthogonal system $\{\tilde{\chi}_i\}_{i\in\mathbb{N}_0}$ of mutually linearly independent, neutral vectors in $\mathcal{V}$.

(1) For all $v \in \mathcal{V}$, the unique decomposition for $N \in \mathbb{N}_0$,

$$v = \tilde{v}^{N+} + \sum_{i=0}^{N} \tilde{v}^i \tilde{\chi}_i, \quad \tilde{v}^i \in \mathbb{C}$$

becomes asymptotically positive in the sense that

$$0 \leqslant \lim_{N\to\infty} \langle \tilde{v}^{N+}, \tilde{v}^{N+} \rangle.$$

(2) There exists a sequence of complex numbers $\{\gamma_i\}_{i\in\mathbb{N}_0}$ such that both sequences $\{\gamma_i \langle \tilde{\chi}_i, v\rangle\}$ and $\{\tilde{v}^i/\gamma_i\}$ are in $l^2(\mathbb{N}_0)$.

These conditions enable us to prove an equivalent of Proposition 3.2. In fact, setting $\chi_i \overset{\text{def}}{=} \gamma_i \tilde{\chi}_i$, we obtain the analog of the finite decomposition (6) for a vector $v \in \mathcal{V}$ with coefficients $v^i = \tilde{v}^i/\gamma_i$. We then have to see that the sum (7) with f replaced by v, defining the majorant norm $p(v)^2$, converges. The convergence of the asymptotically positive part $\lim_{N\to\infty}\langle v^{N+}, v^{N+}\rangle$ then follows, as we have already noted after the proof of Proposition 3.2. Now, the ith summand in the definition of $p(v)^2$ becomes

$$|\langle v, \chi_i\rangle|^2 + |v^i|^2 = |\gamma_i \langle v, \tilde{\chi}_i\rangle|^2 + |\tilde{v}^i/\gamma_i|^2,$$

and the sum converges due to condition (2). Thus, we get a majorant Hilbert topology τ on $\mathcal{V}$. A close inspection of the proofs of the various lemmata in Sec. III shows that the only other point which has to be reconsidered is the proof of statement (i) of Lemma 3.4, that the mapping $P: v \mapsto v^+$ is τ-continuous on $\mathcal{K} \overset{\text{def}}{=} \overline{\mathcal{V}}^{\tau}$. There, we have utilized the L^2-norm, but we will see that this can also be shown independently. In fact, we have

$$\|v^+\|^2 = \left(v - \sum_{i=0}^{\infty} v^i \chi_i, v - \sum_{j=0}^{\infty} v^j \chi_j \right) = \|v\|^2 - 2\,\mathrm{Re} \sum_{i=0}^{\infty} v'(\chi_i, v) + \sum_{i,j=0}^{\infty} v^i \overline{v^j} (\chi_i, \chi_j).$$

We use the two consequences $(\chi_i, \chi_j) = \delta_{ij}$ and $(\chi_i, v) = \overline{v^i}$ of Eq. (9) in the third and second term, respectively, to obtain

$$= \|v\|^2 - \sum_{i=0}^{\infty} |v^i|^2 \leqslant \|v\|^2$$

by definition (7) of $\|v\|^2$. Here again, condition (2) ensures the convergence of the sums appearing. From this point, one can proceed word for word as in Sec. III with the definition of the vectors v_i and the demonstration of their properties. We finally obtain a generalization of Theorem 3.8:

Theorem 4.1: *Let $\mathcal{V}$ satisfy (0)–(2). Then $\mathcal{K}$ is a Krein space with rank of indefiniteness $\#\{\chi_i \neq 0\}$. Its Hilbert space structure is maximal, and the metric operator J acts as in Theorem 3.8.*

Note that (0)–(2) and Theorem 4.1 are formulated as to cover the cases of finite as well as of infinite rank of indefiniteness. Namely, in case the rank of indefiniteness is $N < \infty$, one can find at most N neutral, linearly independent vectors, and one has to use them all to obtain a decomposition that, as demanded by (1), becomes positive (in this case not asymptotically). One then chooses $\tilde{\chi}_i = 0$ for $i > N-1$.

We conclude this paper with some comments on the generalized regularization procedure just described. First, the conditions (0)–(2) certainly do not present the utmost general ones possible. In particular, one can perhaps replace the neutral orthogonal system of (0) by a general system of linear independent vectors which lead to an asymptotically positive decomposition. See Ref. 4 Remark A.13, where we describe how to find a maximal neutral orthogonal system in the case of

finite rank of negativity. Furthermore, whether $\langle v^+, v^+ \rangle$ is positive or negative definite is irrelevant, since one can always go over to $-\langle .,. \rangle$ (the so called *antispace* of $\mathcal{V}$). On the other hand, one cannot easily dispense with either of the l^2-conditions in (2), since they represent rather sharply the convergence conditions that enabled us to construct a majorant. Since we made no presuppositions with respect to $\mathcal{V}$ regarding structure and topology, condition (1) is also indispensible.

In our case of main interest in Sec. III, the essence of conditions (0) and (1) are captured in Lemma 3.1 which is proven in Appendix A. A similar construction of neutral decomposition elements will also have to be carried out in any other concrete case, and is thus at the very center of the regularization procedure, in putting flesh to the bones of the abstract conditions (0) and (1). The construction in Appendix A may serve as a blueprint for that at least in the case of test function spaces over $\mathbb{R}^n$ and inner products generated by kernels whose singularities are ''localized'' enough, e.g., concentrated on a compact set. This may justify that we did not delve into a further abstraction of conditions (0) and (1).

Let us consider an instructive special case. Assume the sequence of coefficients $\{\tilde{v}^i\}$ is bounded for all $v \in \mathcal{V}$. If there holds an estimate

$$|\langle \tilde{\chi}_i, v \rangle| \leqslant C(v) i^{-(1+\delta)},$$

with a constant depending on v and for some $\delta > 0$, we can choose

$$\gamma_i = i^{-(1/2+\varepsilon)}$$

for any $0 < \varepsilon < \delta$. Such polynomial growth and decay conditions are obviously much weaker than the conditions that were present in the case $\mathcal{V} = \mathscr{S}^{\beta}_{\alpha}$, see, e.g., our choice of γ's in (5). Thus the range of cases covered by Theorem 4.1 is considerably widened in comparison to Theorem 3.8 and Theorem 2.3.

The question arises naturally, whether we can find uniform properties on $\mathcal{V}$, as opposed to the pointwise ones (1) and (2), that enable regularization. In essence one would look for a simple quantitative measure that tells us when the construction of the majorant is possible. But this is not straightforward. To simplify the discussion, consider the case where $\{\tilde{v}^i\}$ is bounded in $\mathbb{C}$ for all v (these sets can of course not be uniformly bounded). A simple uniform measure that could replace condition (2) can be formulated in terms of the quantities

$$\overline{\beta}_i \overset{\text{def}}{=} \sup_{v \in \mathcal{V}, \tilde{v}^i = 1} |\langle \tilde{\chi}_i, v \rangle|.$$

Notice that at least $\tilde{\chi}_i$ is in the set over which the supremum is taken, and if this is the only element we have $\tilde{\beta}_i = 0$ due to neutrality of that vector. One can then replace (2) by the condition that there shall exist a sequence $\{\gamma_i^{-1}\}$ in $l^2(\mathbb{N}_0)$ such that also $\{\tilde{\beta}_i \gamma_i\}$ is in $l^2(\mathbb{N}_0)$. This uniform growth condition on $\tilde{\beta}_i$ is however by far too restrictive, since it does not even cover the case considered in Theorem 2.3. The basic reason for this is that in most cases the neutral orthogonal system $\{\tilde{\chi}_i\}$ does not exhaust the space $\mathcal{V}$ in the sense that a complete orthogonal system exhausts a Hilbert space. The inner products with these vectors do not contain enough information about the whole space, and especially its positive part, to decide sharply whether $\mathcal{V}$ is regularizable. The problem of finding a good abstract definition of what we would like to call ''regularizable inner product spaces'' remains therefore open.

ACKNOWLEDGMENTS

This research was supported by a research grant from the Deutsche Forschungsgemeinschaft DFG. The author wishes to thank the University of Durban–Westville for its hospitality and South Africa for the weather. Heartfelt thanks go to Erwin Brüning (Durban), Giovanni Morchio, Franco Strocchi (both Pisa), Daniel Lenz, and Matthias Schork (both Frankfurt am Main) for many discussions.

APPENDIX A: CONSTRUCTION OF NEUTRAL DECOMPOSITION ELEMENTS

In this Appendix, we present a simple construction for the neutral decomposing functions of Lemma 3.1. We point out that different and more refined constructions are surely possible, but the one given in the following suffices for our purpose.

We have to show (i)–(iii) since (iv) follows from them. We prove Lemma 3.1 for $\gamma_k=1$, $\forall k$. The general case follows by multiplication of the functions χ_k constructed in the following with the given sequence γ_k. The first thing we need to show is that there are enough functions of compact support in $\mathcal{S}_\alpha^\beta$. For that, we have to consider the spaces $\mathcal{S}_\alpha^{\beta,B}$, which constitute $\mathcal{S}_\alpha^\beta$ as an inductive limit for $B\to\infty$, see Ref. 9, Chap. IV, Sec. 3 for their definition.

Lemma A.1: Let $0\leqslant\alpha\leqslant\infty$ *and* $1<\beta<\infty$. *For* $\varepsilon>0$ *there exists* $B_\varepsilon>0$ *and a function* $\rho_\varepsilon\in\mathcal{S}_\alpha^{\beta,B_\varepsilon}$ *such that*

$$\rho_\varepsilon(x)=\begin{cases}1, & \text{if } |x|<\varepsilon/2\\ 0, & \text{if } |x|>3\varepsilon/2\\ 0\leqslant\rho_\varepsilon(x), & \text{otherwise.}\end{cases}$$

Proof: Under the given conditions, the function ρ_ε can be constructed using the well-known facts about the Gelfand–Shilov spaces, for which we refer to Ref. 9, Chap. IV. The space $\mathcal{S}_\alpha^\beta$ contains the space $\mathcal{S}_0^\beta$ which consists of functions of compact support and is nontrivial for $\beta>1$. Furthermore, for $\phi\in\mathcal{S}_0^\beta$ we have $\phi^2\in\mathcal{S}_0^\beta$. Thus there exists a $B>0$ and a nonzero function ϕ with $\phi(x)\geqslant 0$ in $\mathcal{S}_0^{\beta,B}$, such that supp $\phi\subset[-R,R]$ for some $R>0$. Then

$$\phi_\varepsilon(x)\overset{\text{def}}{=}\frac{\varepsilon}{2R\|\phi\|_{L^1}}\cdot\phi(2Rx/\varepsilon)$$

is an element of $\mathcal{S}_0^{\beta,B_\varepsilon}$ for $B_\varepsilon=2RB/\varepsilon$, see Ref. 9, p. 158. It has L^1-norm 1 and support in $[-\varepsilon/2,\varepsilon/2]$. Since convolution with L^1-functions does not change the regularity, the function $\phi_\varepsilon*\chi_{[-\varepsilon,\varepsilon]}$ is an element of $\mathcal{S}_0^{\beta,B_\varepsilon}$ and therefore *a fortiori* of $\mathcal{S}_\alpha^{\beta,B_\varepsilon}$ with all the desired properties. □

We set

$$\kappa_n(x)\overset{\text{def}}{=}\rho_{1/3}(x-n)/\|\rho_{1/3}\|_{L^2}\ .$$

Since κ_n has support in $[n-1/2,\ n+1/2]$, we have $(\kappa_i,\kappa_j)=0$ for all $i\neq j$. Define a sequence of positive real numbers by

$$\varepsilon_i\overset{\text{def}}{=}\frac{1}{3e}\prod_{k=0}^{i}\min(1,c_k^2). \tag{†}$$

Set

$$\delta_i\overset{\text{def}}{=}\frac{x^i}{i!}\rho_{\varepsilon_i}.$$

Furthermore, for $i\neq j$ define

$$k_{ij}\overset{\text{def}}{=}\text{sign}(i-j)\sqrt{(\delta_j,\delta_i)_{L^2}}.$$

We use the following enumeration for the off-diagonal entries of an infinite matrix (rows and columns counted from 0):

$$\mathbb{N}_0^2\backslash\mathrm{diag}\ni(i,j)\mapsto n(i,j)\overset{\mathrm{def}}{=}\begin{cases}\dfrac{j(j-1)}{2}+i+1 & \text{if } i<j\\ n(j,i), & \text{otherwise.}\end{cases}$$

We use the functions δ_i as building blocks for the desired functions, since they have just the right behavior at 0 to ensure property (ii) of Lemma 3.1. To correct their nonvanishing L^2-overlap with each other we use the corrective

$$K_i\overset{\mathrm{def}}{=}\sum_{j\neq i} k_{ij}\kappa_{n(i,j)}.$$

We must show that this is possible, i.e., that $\|\delta_i+K_i\|_{L^2}^2$ does not exceed c_i^2, in order to satisfy (i). We have

$$\|\delta_i+K_i\|_{L^2}^2=\|\delta_i\|_{L^2}^2+\|K_i\|_{L^2}^2=\sum_{j=0}^{\infty}|(\delta_i,\delta_j)_{L^2}|.$$

The terms in the sum allow for the basic (yet very coarse) estimate

$$|(\delta_i,\delta_j)_{L^2}|\leqslant\frac{2}{i!j!}\left(\frac{3}{2}\min(\varepsilon_i,\varepsilon_j)\right)^{i+j+1}$$

by construction of δ_i. Using (†) we have $\min(\varepsilon_i,\varepsilon_j)\leqslant(i/3\varepsilon)\min(c_i^2,1)$ and therefore we can estimate under the additional assumption $c_i^2\leqslant 1$:

$$\|\delta_i+K_i\|_{L^2}^2\leqslant\sum_{j=0}^{\infty}\frac{2}{i!j!}\left(\frac{c_i^2}{2e}\right)^{i+j+1}\leqslant\frac{2}{i!}\left(\frac{c_i^2}{2e}\right)^{i+1}\sum_{j=0}^{\infty}\frac{c_i^{2j}}{j!}=\frac{2}{i!}\left(\frac{c_i^2}{2e}\right)^{i+1}e^{c_i^2}\leqslant\frac{c_i^2}{i!(2e)^i}\leqslant c_i^2.$$

Now using the function

$$\nu_i=\sqrt{c_i^2-\|\delta_i+K_i\|_{L^2}^2}\,\kappa_{-i}$$

we can set

$$\chi_i\overset{\mathrm{def}}{=}\delta_i+K_i+\nu_i.$$

We are done if we show that χ_i is well defined as a function in $\mathscr{S}_\alpha^\beta$, i.e., that the sum K_i converges in the topology of the namely space. To that end, we have to show convergence in one of the spaces $\mathscr{S}_{\alpha,A}^{\beta,B}$ which constitute the inductive limit $\mathscr{S}_\alpha^\beta=\lim_{\to A,B\to\infty}\mathscr{S}_{\alpha,A}^{\beta,B}$. We show that the increments in the sum K_i, namely $k_{ij}\kappa_{n(i,j)}$, decay fast enough in j to turn the sum into a Cauchy sequence in that topology. In the countably normed space $\mathscr{S}_{\alpha,A}^{\beta,B}$, we therefore have to estimate the increments due to the terms in the sum defining K_i:

$$\|k_{ij}\kappa_{n(i,j)}\|_{\rho,\delta}=\sup_{x_z k.q}\frac{|x^k k_{ij}\kappa_{n(i,j)}|}{(A+\rho)^k(B+\delta)^q k^{k\alpha}q^{q\beta}}\quad\text{with }\rho,\delta>0.$$

We first argue that this quantity can be estimated independently of q. In fact, the functions $\kappa_{n(i,j)}$ are translates of a fixed function in $\mathscr{S}_\alpha^{\beta,B_{1/3}}$, and therefore the supremum over q is smaller than at constant times the supremum over k and x only, if we choose $B=\max(B_{1/3},B_{\varepsilon_i})$:

$$\|k_{ij}\kappa_{n(i,j)}\|_{\rho,\delta} \leqslant C_\kappa \sup_{x,k} \frac{|x^k k_{ij}\kappa_{n(i,j)}|}{(A+\rho)^k k^{k\alpha}}.$$

It suffices to consider this especially for $A \geqslant 1$ and $\alpha = 1$ in which case we have

$$\leqslant C_\kappa \sup_{x,k} \frac{|x^k k_{ij}\kappa_{n(i,j)}|}{k^k}.$$

For j large enough and by definition of $n(i,j)$ we can estimate $|x| \leqslant 2j^2$ on the support of $\kappa_{n(i,j)}$, and with some other constant C'_κ depending only on the function $\kappa_{n(i,j)}$,

$$\leqslant C'_\kappa k_{ij} \sup_k \left(\frac{2j^2}{k}\right)^k.$$

Continuous maximization in k shows

$$\leqslant C'_\kappa k_{ij} e^{cj^2}.$$

Now it is clear from their definition that k_{ij} decay faster than an exponential function of any type in j and thus the claim follows.

APPENDIX B: BASICS OF INDEFINITE INNER PRODUCT SPACES

In this section we recall some facts about indefinite inner product, Krein and Pontryagin spaces needed in the main text. For an extensive discussion of the subject matter we refer the reader to (Refs. 10 and 15). First some notations: Let $\mathcal{V}$ be a vector space equipped with an indefinite inner product $\langle .,. \rangle$ (antilinear in the first, linear in the second argument). The linear span of a subset $\mathcal{A}$ of vectors in $\mathcal{V}$ is denoted by $\langle \mathcal{A} \rangle$. The *linear sum* of subspaces $\mathcal{V}_1,\ldots,\mathcal{V}_n$ of $\mathcal{V}$ is given by $\langle \mathcal{V}_1 \cup \cdots \cup \mathcal{V}_n \rangle$ and denoted by $\mathcal{V}_1 + \cdots + \mathcal{V}_n$. If the spaces $\mathcal{V}_1,\ldots,\mathcal{V}_n$ are linearly independent, their linear sum is termed *direct sum* and denoted by $\mathcal{V}_1 \dot{+} \cdots \dot{+} \mathcal{V}_n$. *Orthogonality* with respect to $\langle .,. \rangle$ is defined, and denoted by the binary relation $\perp$ as usual (but clearly does not have the same strong consequences as in definite inner product spaces). If the $\mathcal{V}_1,\ldots,\mathcal{V}_n$ are mutually orthogonal, their *orthogonal direct sum* is denoted by $\mathcal{V}_1(\dot{+})\cdots(\dot{+})\mathcal{V}_n$, whereas the symbol $\oplus$ is reserved for orthogonal sums with respect to a positive definite inner product, which we will denote with $(.,.)$, following mathematical convention. By *positive definite* we mean as usual $(x,x) \geqslant 0$, $\forall x \neq 0$, and $(x,x) = 0 \Rightarrow x = 0$. A subspace $\mathcal{A}$ of $\mathcal{V}$ is called *positive*, *negative*, or *neutral*, respectively, if one of the possibilities $\langle x,x \rangle > 0$, $\langle x,x \rangle < 0$ or $\langle x,x \rangle = 0$ holds for all $x \in \mathcal{A}$, with $x \neq 0$. One sets

$$\mathcal{V}^{++} \overset{\text{def}}{=} \{x \in \mathcal{V} | \langle x,x \rangle > 0 \text{ or } x = 0\},$$

and calls this subset the *positive part* of $\mathcal{V}$. The *negative* and *neutral* parts $\mathcal{V}^{--}$ and $\mathcal{V}^0$ are defined alike. A subspace $\mathcal{A}$ of $\mathcal{V}$ is called *degenerate*, if its *isotropic part* $\mathcal{A} \cap \mathcal{A}^\perp$ does not only consist of the zero vector. In the main text and the following we will deal merely with *nondegenerate* spaces, i.e., spaces with $\mathcal{V}^\perp = \{0\}$. A nondegenerate inner product space $\mathcal{V}$ is said to be *decomposable* if it admits a *fundamental decomposition*

$$\mathcal{V} = \mathcal{V}^\perp(\dot{+})\mathcal{V}^+(\dot{+})\mathcal{V}^- \quad \text{with } \mathcal{V}^+ \subset \mathcal{V}^{++}, \mathcal{V}^- \subset \mathcal{V}^{--}.$$

For nondegenerate spaces the isotropic part of the decomposition vanishes. The dimension of a maximal negative definite subspace $\mathcal{V}^- \subset \mathcal{V}^{--}$ appearing in a fundamental decomposition of a nondegenerate inner product space is called the *rank of negativity* of $\mathcal{V}$. As proven in Ref. 10,

Corrollaries II.10.4 and IV.7.4, it is a unique positive cardinal denoted by $\varkappa^-(\mathcal{V})$. The *rank of positivity* $\varkappa^+(\mathcal{V})$ is defined in analogy to that. We set $\varkappa \equiv \min(\varkappa^-, \varkappa^+)$ and call this number the *rank of indefiniteness* of $\mathcal{V}$.

Now some less trivial things about the topology of indefinite inner product spaces: A locally convex topology τ on $\mathcal{V}$ defined by a single seminorm p, which is then actually a norm, is called *normed*. If $\mathcal{V}$ is τ-complete, we say that τ is a *Banach topology*. If τ can be defined by a *quadratic norm* $p(x)=(x,x)^{1/2}$, where $(.,.)$ is a positive definite inner product on $\mathcal{V}$, then τ is called a *quadratic normed topology*. Again, if $\mathcal{V}$ is τ-complete, then τ is termed *Hilbert topology*. A normed topology τ_1 is *stronger* than another τ_2, written $\tau_1 \geqslant \tau_2$, if and only if every τ_2-open set is also a τ_1-open set, or equivalently the relation $p_1(x) \geqslant \alpha p_2(x)$ holds for all $x \in \mathcal{V}$, with an $\alpha > 0$. Two norms that define the same topology are called *equivalent*. A locally convex topology τ on $\mathcal{V}$ is called a *partial majorant* of the inner product if $\langle .,. \rangle$ is separately τ-continuous. The *weak topology* on $\mathcal{V}$ is the topology defined by the family of seminorms

$$p_y(x) \overset{\text{def}}{=} |\langle y,x \rangle| \quad \text{for all } x \in \mathcal{V}.$$

Lemma B.1 (Ref. 10, Theorem II.2.1): The weak topology is the weakest partial majorant on $\mathcal{V}$. If a locally convex topology on $\mathcal{V}$ is stronger than the weak topology, then it is a partial majorant.

We will need a stronger concept of topology:

Definition B.2: A locally convex topology τ on $\mathcal{V}$ is called *majorant topology*, if the inner product $\langle .,.. \rangle$ is jointly τ-continuous.

In applications, one can often restrict oneself to majorants defined by a single seminorm which majorizes the inner square, as shown by the following result.

Lemma B.3. (Ref. 10, Lemma IV.1.1. and IV.1.2): It holds:

(i) *To every majorant there exists a weaker majorant defined by a single seminorm.*

(ii) *For a locally convex topology defined by a single seminorm p to be a majorant it is sufficient that p dominates the inner square*:

$$|\langle x,x \rangle| \leqslant \alpha p(x)^2, \quad \alpha > 0, \quad \forall x \in \mathcal{V}.$$

Majorant topologies, and especially majorant Hilbert topologies, have many advantages over partial majorants. Before we describe them, let us see why one would not like to use the weak topology on general indefinite inner product spaces:

Lemma B.4. (Ref. 10, Theorem IV.1.4): The weak topology on the nondegenerate indefinite inner product space $\mathcal{V}$ is a majorant, if and only if $\dim \mathcal{V} < \infty$.

The indefinite inner product on a space equipped with a majorant Hilbert topology admits a simple description by the so-called *metric operator*.

Proposition B.5. (Ref. 10, Theorem IV.5.2): Let $\mathcal{V}$ be an indefinite inner product space with a majorant Hilbert topology τ defined by a norm $\|.\|$. Then there exists a Hermitean linear operator, called metric (or Gram) operator, J on $\mathcal{V}$ such that

$$\langle x,y \rangle = (x,Jy), \quad \forall x,y \in \mathcal{V},$$

where $(.,.)$ is the positive inner product on $\mathcal{V}$ that defines $\|.\|$. Moreover, in this case $\mathcal{V}$ is decomposable and the fundamental decomposition can be chosen so that each of the three components is τ-closed.

The spaces we want to construct in the main text should be complete in a certain sense, which we will now specify.

Definition B.6: If a nondegenerate indefinite inner product space $\mathcal{K}$ admits a decomposition

$$\mathcal{K} = \mathcal{K}^+ (\dot{+}) \mathcal{K}^-, \quad \mathcal{K}^+ \subset \mathcal{K}^{++}, \quad \mathcal{K}^- \subset \mathcal{K}^{--},$$

such that $\mathcal{K}^+,\mathcal{K}^-$ are complete with respect to the restrictions of the weak topology to them (termed *intrinsically complete*), then the space $\mathcal{K}$ is called a *Krein space*.

Krein spaces can easily be characterized:

Proposition B.7. (Ref. 10, Theorem V.1.3): An indefinite inner product space $\mathcal{V}$ is a Krein space if and only if there exists a majorant Hilbert topology τ on $\mathcal{V}$ such that metric operator J is completely invertible.

A Hilbert-space completion $\mathcal{H}$ of an indefinite inner product space $\mathcal{V}$, if it exists together with its metric operator J, is called the *Hilbert space structure* $(\mathcal{H},J)$ associated to $\mathcal{V}$. In applications one would like to find the largest Hilbert space associated to an indefinite inner product space. For that, one considers *minimal* majorant topologies, i.e., topologies τ_* such that no majorant τ is weaker than τ_*. Hilbert space structures given by the completion of $\mathcal{V}$ with respect to a minimal majorant are correspondingly called *maximal*. We find that the Hilbert space structure is maximal, if it leads actually to a Krein space:

Lemma B.8 (Ref. 2, Appendix A.1): A majorant Hilbert topology leads to a maximal Hilbert space structure $(\mathcal{K}, J)$, if and only if J has a bounded inverse. Given a Hilbert space structure one can always construct a maximal one.

The last statement means in effect that every space admitting some majorant Hilbert topology can be completed to a Krein space.

(Received 4 December 2000; accepted for publication 3 October 2001)

The aim of this article is to study certain Lorentz invariant Lagrangians. The first of these Lagrangians could be related to a particle of spin $\frac{1}{2}$ moving in a particular Yang–Mills gauge field. The second Lagrangian is related to the relativistic Newton–Coulomb problem. For each of these Lagrangians, we write the corresponding wave equations and determine the negative energy levels. The article concludes with the construction of a class of Lagrangians associated with pairs of particles, one of which has zero mass. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1420742]

I. INTRODUCTION

The main problem we study in this article is to quantize certain Lorentz invariant Lagrangians; we formally extend the classical two-particle Lagrangians, which have been used in Newtonian gravitation theory and respectively in Pauli's theory of the hydrogen atom.

In the first section, we construct a Lagrangian for a particle moving in a gauge field defined by a Lorentz invariant connection $\mathcal{C}$. The connection $\mathcal{C}$ is defined in a principal bundle $P=\Gamma\to\Sigma$, where Γ is the group of 2×2-complex matrices with positive determinants and Σ is the space of spacelike vectors in Minkowski space. The corresponding Euler–Lagrange equations are similar to Pauli equations, with the differences that they are of order two and refer to a Coulomb field.

We determine the negative energy levels by using representation theory.

The second section is related to the relativistic Kepler–Newton–Coulomb problem, as introduced by L. P. Horwitz (see Ref. 1). We determine the corresponding negative energy levels by using both representation theory as well as the classical theory of second order differential equations of Laplace type.

Representation theory is used in order to determine the eigenvalues of Casimir operators; these values appear in the corresponding radial equations; some of these eigenvalues can also be determined using analysis and imposing specific regularity conditions, as given in Sec. III E.

The final results concerning the energy levels are given in a theorem at the end of Sec. III F.

We had to use many elementary and classical results, which we have written explicitly, in order to dispose of uniform notations for the reader's convenience. Giving proper quotations seems to be a hard task.

We constantly compared the energy spectra obtained in this article to the spectrum obtained by Schrödinger and which is proportional to the sequence $S=(1/n^2)_{n=1,2,3,\ldots}$.

In the two situations we met, certain deviations arose. For instance, in the case of the relativistic Coulomb problem, we obtained a spectrum which is proportional to the sequence $S'=4((2n+1)^{-2})_{n\in\mathbb{N}}=((n+\frac{1}{2})^{-2})_{n\in\mathbb{N}}$.

We assume that we gain the whole of S by introducing the principal series of representations of the group SL(2, $\mathbb{C}$). This can be done by considering some Lorentz invariant Lagrangians associated with two-particle systems, such that one of the two particles lies on the light-cone. These Lagrangians are also linked to two-particle systems, when the particles are separated by a vector of zero length. Though this program is not yet acomplished, the formulas we obtained make our assumption plausible.

II. THE FIRST LAGRANGIAN

A. A principal SU(1, 1)-bundle

We identify each point $x=(x_0,x_1,x_2,x_3)$ in Minkowski space M with a Hermitian matrix by writing

$$x=\begin{pmatrix} x_0+x_3 & x_1-ix_2 \\ x_1+ix_2 & x_0-x_3 \end{pmatrix},$$

and denote the spatial inversion by a hat; more generally, when $\xi=\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ and ψ are 2×2-matrices, we write

$$\hat{\xi}=\begin{pmatrix} d & -b \\ -c & a \end{pmatrix}, \quad |\xi|^2=-\det(\xi), \quad \langle \xi,\psi\rangle=-\frac{1}{2}\mathrm{Tr}(\psi\hat{\xi}).$$

Let Γ be the group of complex 2×2-matrices with real and positive determinant.

The manifold

$$\Sigma=\{x\in M;\ |x|^2=-\det(x)>0\}$$

is diffeomorphic to $\mathbb{R}^2\times S^2$ and there is a transitive action A of Γ on Σ, which is given by the formula

$$A:\Gamma\times\Sigma\to\Sigma, \quad A(g,x)=gxg^*.$$

Let us consider the Pauli matrix $\sigma_3=\left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ and define the map

$$f_3:\Gamma\to\Sigma, \quad f_3(g)=g\sigma_3 g^*.$$

Then

$$f_3^{-1}(\sigma_3)=\mathrm{SU}(1,1), \quad f_3(\Gamma)=\Sigma,$$

and the map f_3 is Γ-equivariant.

The aim of this section is to study the Γ-homogeneous and also principal SU(1, 1)-bundle

$$P=(\Gamma,f_3,\Sigma).$$

For a point $x=(x_0,x_1,x_2,x_3)\in\Sigma$, we denote

$$r=\sqrt{(x_1)^2+(x_2)^2+(x_3)^2}, \quad z=x_1+ix_2,$$

$$R=\sqrt{r^2-(x_0)^2}=\sqrt{-\det(x)}.$$

Each matrix $g=\left(\begin{smallmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{smallmatrix}\right)\in\Gamma$ can be written as a product

$$g=uhv \tag{1}$$

with factors

$$u\in\mathrm{SU}(2), \quad v\in\mathrm{SU}(1,1), \quad h=\mathrm{diag}(h_1,h_2), \quad h_1>0, h_2>0. \tag{2}$$

Let us introduce the notations

$$x=g\sigma_3 g^*, \quad k=h^2\sigma_3=\mathrm{diag}(k_1,k_2).$$

Then $x=uku^*$ and, when we suppose that

$$u=\begin{pmatrix} a & -\overline{b} \\ b & \overline{a} \end{pmatrix},\ \ v=\begin{pmatrix} \alpha & \overline{\beta} \\ \beta & \overline{\alpha} \end{pmatrix},$$

$$|a|^2+|b|^2=1,\ \ |\alpha|^2-|\beta|^2=1,$$

we get

$$2x_0=k_1+k_2,$$

$$2x_3=(k_1-k_2)(|a|^2-|b|^2),$$

$$z=x_1+ix_2=(k_1-k_2)\overline{a}b,$$

$$2r=h_1^2+h_2^2,\ \ R=h_1h_2,$$

$$k_1=x_0+r,\ \ k_2=x_0-r,$$

$$2|a|^2=1+\frac{x_3}{r},\ \ 2|b|^2=1-\frac{x_3}{r},\ \ 2\overline{a}b=\frac{x_1+ix_2}{r}.$$

These relations lead us to the following conclusions:

(1) When the matrix g is given, the matrices h, k are uniquely determined, while the matrices u, v are determined up to a transformation of the form

$$u\mapsto u\ \mathrm{diag}(e^{i\varphi},e^{-i\varphi}),\ \ v\mapsto \mathrm{diag}(e^{-i\varphi},e^{i\varphi})v,\ \ \varphi\in\mathbb{R}.$$

(2) The principal SU(1, 1)-bundle $P=(\Gamma,\ f_3,\Sigma)$ is trivial over each of the sets

$$\Sigma_+=\{x\in\Sigma|x_3>-r\},\ \ \Sigma_-=\{x\in\Sigma|x_3<r\},$$

and we can define the local sections $f_+:\Sigma_+\to\Gamma,\ \ f_-:\Sigma_-\to\Gamma$ by the formulas

$$f_+(x)=u_+(x)h(x),\ \ f_-(x)=u_-(x)h(x), \tag{3}$$

$$u_+(x)=\frac{1}{\sqrt{2r(r+x_3)}}\begin{pmatrix} r+x_3 & -\overline{z} \\ z & r+x_3 \end{pmatrix},$$

$$u_-(x)=\frac{1}{\sqrt{2r(r-x_3)}}\begin{pmatrix} \overline{z} & -r+x_3 \\ r-x_3 & z \end{pmatrix}, \tag{4}$$

$$h(x)=\begin{pmatrix} \sqrt{r+x_0} & 0 \\ 0 & \sqrt{r-x_0} \end{pmatrix}. \tag{5}$$

Then these two local sections are related, over $\Sigma_+\cap\Sigma_-$, by the formula

$$f_+(x)=f_-(x)\ \mathrm{diag}\left(\frac{z}{|z|},\ \frac{\overline{z}}{|z|}\right), \tag{6}$$

showing that the structural group SU(1, 1) of the principal bundle P is reducible to U(1).

B. An invariant Yang–Mills connection

Denote by $V=(E,p,\Sigma)$ the vector bundle with fiber $\mathbb{C}^2$ associated with the principal bundle P. The points of E are equivalence classes

$$[g,\xi]=\{(gv^{-1},v\xi);\ \ v\in \mathrm{SU}(1,1)\},\ \ g\in\Gamma,\ \ \xi\in\mathbb{C}^2. \tag{7}$$

The equation (6) shows that the vector bundle V admits an SU(2)-invariant decomposition into the Whitney sum of two complex line bundles, $V=L_1\oplus L_2$.

By considering the bundle map $f_3:\Gamma\to\Sigma$, we broke the Lorentz symmetry of Minkowski space, since implicitly we distinguish the point $\sigma_3=(0,0,0,1)$; but, considering the bundle P, we gain a richer symmetry, because the group Γ acts transitively on itself by left translations and this action induces a transitive action on Σ.

The Lie algebra sl(2, $\mathbb{C}$) carries an $\mathbb{R}$-bilinear form ω, which is invariant with respect to the linear adjoint representation of SL(2, $\mathbb{C}$) and which is defined by the equation

$$\omega(x,y)=\text{Real part of } \mathrm{Tr}(\hat{x}\ y).$$

When $\omega(x,y)=0$, we say that x is orthogonal to y.

We can use the form ω in order to introduce a Γ-invariant connection $\mathcal{C}$ on the bundle P: the $\mathcal{C}$-horizontal tangent vectors on Γ at a point $g\in\Gamma$ will be the pairs (g,gX) such that $X\in \mathrm{sl}(2,\mathbb{C})\oplus\mathbb{R}\cdot I$ and such that X is orthogonal to all $y\in \mathrm{su}(1,1)$.

The matrices X which are orthogonal to su(1, 1) have the form

$$X=\begin{pmatrix} p+iq & \lambda \\ -\overline{\lambda} & p'+iq \end{pmatrix},\ \ p\in\mathbb{R},\ \ p'\in\mathbb{R},\ \ q\in\mathbb{R},\ \ \lambda\in\mathbb{C}. \tag{8}$$

The equations of the $\mathcal{C}$-horizontal distribution are obtained by writing that the differential matrix $g^{-1}dg$ has the form (8). When we use the decomposition (1), the equations of the $\mathcal{C}$-horizontal distribution take the form

$$d\alpha=-iA\alpha+\overline{B}\beta,\ \ d\beta=B\alpha+iA\beta, \tag{9}$$

where

$$A=-i(\overline{a}da+\overline{b}db),\ \ B=\frac{x_0}{R}(bda-adb). \tag{10}$$

The local sections f_+, f_- defined by formulas (3)–(5) allow us to build the diffeomorphisms

$$\tau_+:\Sigma_+\times \mathrm{SU}(1,1)\to(f_3)^{-1}(\Sigma_+),\ \ \tau_+(x,v)=f_+(x)v, \tag{11}$$

$$\tau_-:\Sigma_-\times \mathrm{SU}(1,1)\to(f_3)^{-1}(\Sigma_-),\ \ \tau_-(x,v)=f_-(x)v. \tag{12}$$

It is convenient to introduce, besides the usual polar coordinates ϑ, φ, a new angle coordinate ψ, so that we have

$$z=r\sin\vartheta\exp(i\varphi),\ \ x_3=r\cos\vartheta,\ \ x_0=r\sin\psi\quad\left(-\frac{\pi}{2}<\psi<\frac{\pi}{2}\right). \tag{13}$$

Then

$$tg\,\psi=\frac{x_0}{R},\ \ tg\,\varphi=\frac{x_2}{x_1},\ \ tg\,\vartheta=\frac{\sqrt{(x_1)^2+(x_2)^2}}{x_3}.$$

The one-forms (10), computed over Σ_+ and Σ_-, become

$$A_+=\frac{x_1dx_2-x_2dx_1}{2r(r+x_3)}=\sin^2\frac{\vartheta}{2}\,d\varphi,$$
$$A_-=-\frac{x_1dx_2-x_2dx_1}{2r(r-x_3)}=-\cos^2\frac{\vartheta}{2}\,d\varphi, \tag{14}$$

$$B_+=-\frac{z^2x_0}{2Rr(r+x_3)}\,d\left(\frac{r+x_3}{z}\right)=-\frac{1}{2}e^{i\varphi}\tan\psi(d\vartheta+i\sin\vartheta d\varphi),$$
$$B_-=-\frac{\overline{z}^2x_0}{2Rr(r-x_3)}\,d\left(\frac{r-x_3}{\overline{z}}\right)=-\frac{1}{2}e^{-i\varphi}\tan\psi(d\vartheta+i\sin\vartheta\,d\varphi). \tag{15}$$

For the reader's convenience, we write down the following formulas, giving the operators of partial derivatives $\partial_\alpha=\partial/\partial_\alpha$:

$$\partial_0=R^{-1}\partial_\psi-tg\psi\,\partial_R,$$

$$\partial_1=R^{-1}\cos\psi\left(-\frac{\sin\varphi}{\sin\vartheta}\partial_\varphi+\cos\varphi\cos\vartheta\,\partial_\vartheta-tg\psi\cos\varphi\sin\vartheta\,\partial_\psi\right)+\frac{\sin\vartheta\cos\varphi}{\cos\psi}\partial_R,$$

$$\partial_2=R^{-1}\cos\psi\left(\frac{\cos\varphi}{\sin\vartheta}\partial_\varphi+\sin\varphi\cos\vartheta\,\partial_\vartheta-tg\psi\sin\varphi\sin\vartheta\,\partial_\psi\right)+\frac{\sin\vartheta\sin\varphi}{\cos\psi}\partial_R,$$

$$\partial_3=-R^{-1}(\cos\psi\sin\vartheta\,\partial_\vartheta+\sin\psi\cos\vartheta\,\partial_\psi)+\frac{\cos\vartheta}{\cos\psi}\partial_R.$$

The connection $\mathcal{C}$ of P induces a connection, also denoted $\mathcal{C}$, on the associated vector bundle V. Since the structural group of V is $SU(1,1)$, V carries an invariant pseudo-Hermitian form H of signature $(1,1)$ and the connection $\mathcal{C}$ is compatible with this structure.

Using the gauge associated with the local section f_+, we can represent a section Φ of V as a pair (Φ^1,Φ^2) of complex valued functions. The covariant derivative D commutes with the action of the group Γ on P and is given by the formula

$$D\Phi=(D\Phi^1,D\Phi^2)=(d\Phi^1+iA\Phi^1-\overline{B}\Phi^2,\,d\Phi^2-B\Phi^1-iA\Phi^2).$$

The group Γ acts on sections $s:\Sigma\to E$ in the bundle V according to the formula $(gs)(x)=g(s(x'))$, where $x'=g^{-1}x(g*)^{-1}$ and

$$g([g_1,\xi])=[gg_1,\xi].$$

This action induces an action α of the Lie algebra of Γ. When we represent the class $[g,\xi]\in E$ through the pair $(g\sigma_3g^*,g\xi)\in\Sigma\times\mathbb{C}^2$, α will associate with the matrices $(i/2)\,\sigma_1,(i/2)\,\sigma_2,(i/2)\,\sigma_3,\frac{1}{2}\sigma_3\in\mathrm{sl}(2,\mathbb{C})$, the following differential operators, acting on maps $\Psi:\Sigma\to\mathbb{C}^2$:

$$d_k=\frac{i}{2}\sigma_k-b_k\sigma_0(k=1,2,3),\quad e_3=\frac{1}{2}\sigma_3+a_3, \tag{16}$$

where

$$b_1=\sin\varphi\,\partial_\vartheta+\cos\varphi\cot\vartheta\,\partial_\varphi,\quad b_2=-\cos\varphi\,\partial_\vartheta+\sin\varphi\cot\vartheta\,\partial_\varphi, \tag{17}$$

$$b_3=-\partial_\varphi,\quad a_3=\cos\vartheta\cos\psi\,\partial_\psi-\sin\vartheta\sin\psi\,\partial_\vartheta. \tag{18}$$

Using the invariant form H of V and the invariant metric of Minkowski space, we get, for any real numbers E_1, C, a Lorentz invariant Lagrangian

$$\mathcal{L}(\Phi)=\int_\Sigma\left(|D\Phi^1|^2-|D\Phi^2|^2+\left(E_1+\frac{C}{R}\right)(|\Phi^1|^2-|\Phi^2|^2)\right)\ dx. \tag{19}$$

C. The Dirac monopole

The bundle P contains an SU(2)-homogeneous principal S^1-subbundle $Q=(\Gamma',q,\Sigma)$ with total space

$$\Gamma'=\{g'=uh|u\in SU(2),\ h=\mathrm{diag}(h_1,h_2),\ h_1>0, h_2>0\},$$

with base-space Σ, projection map $q=f_3|_{\Gamma'}$; the group S^1 acts on Γ' on the right through diagonal matrices diag(exp($i\sigma$),exp($-i\sigma$)).

The connection $\mathcal{C}$ induces a connection $\mathcal{C}'$ on this bundle. The horizontal tangent vectors of Γ' are solutions of the equation

$$d\sigma+iA=0.$$

We easily recognize that the connection $\mathcal{C}'$ represents the vector potential of a Dirac magnetic monopole of magnetic charge 1.

The strength of this magnetic monopole is

$$H=dA=\tfrac{1}{2}\sin\vartheta\ d\vartheta\wedge d\varphi=\frac{1}{2r^3}(x_3\ dx_1\wedge dx_2+x_1\ dx_2\wedge dx_3+x_2\ dx_3\wedge dx_1).$$

As it is well known, reducing the group SL(2,$\mathbb{C}$) to SU(2) is equivalent to fixing the x_0-axis in Minkowski space.

D. The curvature

We now come back to the connection $\mathcal{C}$ and compute the curvature F of $\mathcal{C}$. We have

$$F=d\Lambda-\Lambda\wedge\Lambda,\ \ \Lambda=\begin{pmatrix}-iA & \overline{B}\\ B & iA\end{pmatrix}.$$

More explicitly,

$$F=\begin{pmatrix}-idA+B\wedge\overline{B} & d\overline{B}+2iA\wedge\overline{B}\\ dB-2iA\wedge B & idA-B\wedge\overline{B}\end{pmatrix}.$$

Introducing the differential one-forms

$$f=\frac{\exp(i\varphi)}{\cos\psi}(d\vartheta+i\sin\vartheta\ d\varphi),\ \ j=\frac{d\psi}{\cos\psi},$$

the matrices Λ, F take the forms

$$\Lambda_+=\begin{pmatrix}-i\sin^2\frac{\vartheta}{2}d\varphi & -\frac{1}{2}\sin\psi\ \overline{f}\\ -\frac{1}{2}\sin\psi\ f & i\sin^2\frac{\vartheta}{2}\ d\varphi\end{pmatrix},\quad F_+=\frac{1}{4}\begin{pmatrix}-f\wedge\overline{f} & 2\overline{f}\wedge j\\ 2\,f\wedge j & f\wedge\overline{f}\end{pmatrix}.$$

Using the coordinates R,ϑ,φ,ψ, the metric of Minkowski space, defined as $d\sigma^2=-\det(dx)$ and restricted at Σ, gets the expression

$$d\sigma^2=dR^2+\frac{R^2}{\cos^2\psi}(d\vartheta^2+\sin^2\vartheta\ \ d\varphi^2-d\psi^2). \tag{20}$$

It is now not difficult to compute the Dirac dual $*F$ of the curvature form F and to obtain

$$*F_+=\frac{i}{2}\frac{dR}{R}\wedge\begin{pmatrix} j & -\overline{f} \\ f & -j \end{pmatrix}.$$

It is also not difficult to compute the covariant derivative

$$D(*F_+)=d(*F_+)-[\Lambda,*F_+]=d(*F_+)-\Lambda\wedge *F_+ + *F_+\wedge\Lambda.$$

One verifies the relations

$$df+2i\sin^2\frac{\vartheta}{2}\ \ f\wedge d\varphi+\sin\psi\ \ f\wedge j=0,\ \ dj=0,$$

and obtains the following.

Theorem: The connection $\mathcal{C}$ verifies the Yang–Mills condition

$$D(*F)=0.$$

E. Integrating the Euler–Lagrange equations

In terms of the coordinates R,ϑ,φ,ψ and denoting partial derivatives by indices, the Lagrangian (19) takes the form

$$\begin{aligned}\mathcal{L}(\Phi)=\int_\Sigma\Bigg(&\frac{R^3\sin\vartheta}{\cos^3\psi}(|\Phi^1_R|^2-|\Phi^2_R|^2)-\frac{R\sin\vartheta}{\cos\psi}(|\Phi^1_\psi|^2-|\Phi^2_\psi|^2)+\frac{R\sin\vartheta}{\cos\psi}\Bigg(\left|\Phi^1_\vartheta+\frac{e^{-i\varphi}}{2}\tan\psi\Phi^2\right|^2\\&-\left|\Phi^2_\vartheta+\frac{e^{i\varphi}}{2}\tan\psi\,\Phi^1\right|^2\Bigg)+\frac{R}{\sin\vartheta\cos\psi}\Bigg(\left|\Phi^1_\varphi+i\sin^2\frac{\vartheta}{2}\Phi^1-\frac{i}{2}e^{-i\varphi}\tan\psi\sin\vartheta\,\Phi^2\right|^2\Bigg)\\&-\frac{R}{\sin\vartheta\cos\psi}\Bigg(\left|\Phi^2_\varphi+\frac{i}{2}e^{i\varphi}\tan\psi\sin\vartheta\,\Phi^1-i\sin^2\frac{\vartheta}{2}\Phi^2\right|^2\Bigg)+\left(E_1+\frac{C}{R}\right)\frac{R^3\sin\vartheta}{\cos^3\psi}(|\Phi^1|^2\\&-|\Phi^2|^2)\Bigg)dR\,d\vartheta\,d\varphi\,d\psi.\end{aligned}$$

Looking at the expression to be integrated, we see that there are two corresponding Euler–Lagrange equations for Φ^1 and Φ^2, which can be obtained from one another by interchanging the pairs $(\Phi^1,i),(\Phi^2,-i)$, and there are two other equations, for $\overline{\Phi}^1,\overline{\Phi}^2$, which are obtained from the first ones by complex conjugation.

We can give the Euler–Lagrange equations simple forms by introducing the d'Alembertian

$$\Box=(\partial_0)^2-\sum_{i=1,2,3}(\partial_i)^2. \tag{21}$$

In terms of the coordinates R,ϑ,φ,ψ, one gets

$$\Box=-(\partial_R)^2-\frac{3}{R}\partial_R+\frac{1}{R^2}K, \tag{22}$$

where K is the Casimir operator acting on functions $F:\Sigma\to\mathbb{C}$ and has the expression

$$K=-\cos^2\psi\left((\partial_\vartheta)^2+\cot\vartheta\,\partial_\vartheta+\frac{1}{\sin^2\vartheta}(\partial_\varphi)^2-(\partial_\psi)^2-\tan\psi\,\partial_\psi\right). \tag{23}$$

Note: For the definitions of the Casimir operators used throughout this article, see Secs. II F and III A.

The Euler–Lagrange equations for Φ^1,Φ^2 are written

$$R^2\left(\Box-E_1-\frac{C}{R}\right)\Phi^1=\mathcal{D}_1^+(\Phi^1)+\mathcal{D}_2^+(\Phi^2), \tag{24}$$

$$R^2\left(\Box-E_1-\frac{C}{R}\right)\Phi^2=\mathcal{D}_2^-(\Phi^1)+\mathcal{D}_1^-(\Phi^2), \tag{25}$$

where

$$\mathcal{D}_1^\varepsilon(\Phi)=\varepsilon\frac{i}{2}\frac{\cos^2\psi}{\cos^2(\vartheta/2)}\Phi_\varphi+\frac{1}{4}\left(2-\frac{\cos\vartheta+3}{\cos\vartheta+1}\cos^2\psi\right)\Phi,$$

$$\mathcal{D}_2^\varepsilon(\Phi)=e^{-\varepsilon i\varphi}\sin\psi\cos\psi\left(\Phi_\vartheta-\frac{\varepsilon i}{\sin\vartheta}\Phi_\varphi-\frac{1}{2}tg\frac{\vartheta}{2}\Phi\right).$$

We remark that the two equations (24) and (25) reduce to just one, when we impose the constraint $F^2=\overline{F^1}$.

Suppose we have a particular solution of the form

$$\Phi^1=\rho F^1,\quad \Phi^2=\rho F^2,$$

where ρ is a function of R alone and F^1,F^2 are functions of ϑ,φ and ψ. Then the equations (24), and (25) give

$$\begin{aligned}-\rho^{-1}(R^2\rho_{RR}+3R\rho_R+E_1R^2\rho+CR\rho)&=(F^1)^{-1}((-K+\mathcal{D}_1^+)(F^1)+\mathcal{D}_2^+(F^2))\\&=(F^2)^{-1}(\mathcal{D}_2^-(F^1)+(-K+\mathcal{D}_1^-)(F^2)).\end{aligned}$$

We infer the existence of a constant $\mathbb{K}_0$ such that

$$\rho_{RR}+\frac{3}{R}\rho_R+\left(E_1+\frac{C}{R}-\frac{\mathbb{K}_0}{R^2}\right)\rho=0, \tag{26}$$

$$(-K+\mathcal{D}_1^+)(F^1)+\mathcal{D}_2^+(F^2)=-\mathbb{K}_0F^1, \tag{27}$$

$$\mathcal{D}_2^-(F^1)+(-K+\mathcal{D}_1^-)(F^2)=-\mathbb{K}_0F^2. \tag{28}$$

Considering the map f_+ defined by formula (3), we perform the gauge transformation $F\mapsto G=f_+F$ and ask the new map $G=(G^1,G^2)$ to be **a vector of highest weight**, i.e., we impose the relations

$$d_3G=iMG,\quad (d_1+id_2)G=0,\quad e_3G=NG, \tag{29}$$

where M,N are real numbers and d_1 ,d_2 ,d_3 ,e_3 are the differential matrix operators defined by formulas (16). The equations (29) imply

$$\partial_\varphi G^1=i(M-\tfrac{1}{2})G^1,\quad \partial_\varphi G^2=i(M+\tfrac{1}{2})G^2, \tag{30}$$

$$G^2=-e^{i\varphi}(\partial_\vartheta+i\cot\vartheta\ \ \partial_\varphi)G^1,\ \ (\partial_\vartheta+i\cot\vartheta\ \ \partial_\varphi)G^2=0, \tag{31}$$

$$\cos\vartheta\ \ \cos\psi\ \ G^1_\psi-\sin\vartheta\ \ \sin\psi\ \ G^1_\vartheta=(N-\tfrac{1}{2})G^1, \tag{32}$$

$$\cos\vartheta\ \ \cos\psi\ \ G^2_\psi-\sin\vartheta\ \ \sin\psi\ \ G^2_\vartheta=(N+\tfrac{1}{2})G^2. \tag{33}$$

Denoting $M'=M-\frac{1}{2}$, we find $N=-\frac{1}{2}$ and get the general solution to these equations in the form

$$G^1=C_1\frac{e^{iM'\varphi}(\sin\vartheta)^{M'}(\cos\vartheta-\sin\psi)}{(\cos\psi)^{M'+1}}=C_1\frac{z^{M'}(x_3-x_0)}{R^{M'+1}}, \tag{34}$$

$$G^2=C\frac{e^{i(M'+1)\varphi}(\sin\vartheta)^{(M'+1)}}{(\cos\psi)^{M'+1}}=C\frac{z^{M'+1}}{R^{M'+1}}, \tag{35}$$

where C_1 is a constant. A not very long computation gives

$$\mathbb{K}G=\mathbb{K}_0G, \tag{36}$$

where $\mathbb{K}$ is the Casimir operator (44), defined in the next subsection, and

$$\mathbb{K}_0=M^2+2M+\tfrac{1}{4}=M'^2+3M'+\tfrac{3}{2}. \tag{37}$$

Note that M' must be a positive integer.

Looking at the equations (27), (28), and (36) and having in mind the fact that there exist no Lorentz invariant, non trivial, linear systems of PDEs of the first order, we infer that the equations (27) and (28) transform into the equation (36), when we perform the gauge transformation $G=f_+F$. The gauge map f_+ given by formula (3) can be also written as follows:

$$f_+(x)=R^{1/2}\begin{pmatrix}\cos\dfrac{\vartheta}{2} & -e^{-i\varphi}\sin\dfrac{\vartheta}{2}\\ e^{i\varphi}\sin\dfrac{\vartheta}{2} & \cos\dfrac{\vartheta}{2}\end{pmatrix}\begin{pmatrix}\sqrt{\dfrac{1+\sin\psi}{\cos\psi}} & 0\\ 0 & \sqrt{\dfrac{1-\sin\psi}{\cos\psi}}\end{pmatrix}. \tag{38}$$

Resuming, we can state the following.

Theorem: The equations (34), (35), and (37), joined to $F=(f_+)^{-1}G$, define the solutions to the equations (27) and (28), which are vectors of highest weight with respect to the action of $\mathrm{sl}(2,\mathbb{C})$ on sections in the vector bundle V.

F. Review of classical results

In order to dispose of uniform notations and to be very explicit, we review some classic results. We begin by considering functions

$$F:\mathrm{SL}(2,\mathbb{C})\to\mathbb{C},\ \ g\mapsto F(g,\overline{g}),$$

and introducing the differential operators

$$C_1=-(g^1_jd^j_2+g^2_jd^j_1),\quad C'_1=-(h^1_je^j_2+h^2_je^j_1),$$

$$C_2=-i(g^1_jd^j_2-g^2_jd^j_1),\quad C'_2=i(h^1_je^j_2-h^2_je^j_1),$$

$$C_3=-(g^1_jd^j_1-g^2_jd^j_2),\quad C'_3=-(h^1_je^j_1-h^2_je^j_2),$$

where summation is understood over $j=1,2$ and

$$h_j^i=\overline{g_j^i},\quad d_i^j=\frac{\partial}{\partial g_j^i},\quad e_i^j=\frac{\partial}{\partial \overline{g_j^i}}.$$

Then the following operators are induced by infinitesimal right translations on the group $SL(2,\mathbb{C})$ and generate the Lie algebra $sl(2,\mathbb{C})$:

$$A_k=\frac{1}{2}(C_k+C_k'),\quad B_k=\frac{i}{2}(C_k'-C_k)\quad (k=1,2,3).$$

The Casimir operator K is defined as follows:

$$\begin{aligned}K&=\frac{1}{2}\sum_{k=1}^{3}((C_k)^2+(C_k')^2)\\&=\sum_{k=1}^{3}((A_k)^2-(B_k)^2)\\&=\frac{1}{4}(2g_j^ig_s^kd_k^jd_i^s-g_j^ig_s^rd_i^jd_r^s+2h_j^ih_s^re_r^je_i^s-h_j^ih_s^re_i^je_r^s).\end{aligned}$$

Suppose the function F has the particular form

$$F(g,\overline{g})=\varphi(x),\quad x=g\sigma_3g^*.$$

Then, using the notations

$$\partial_\alpha=\frac{\partial}{\partial x^\alpha},\quad \Box=\partial_0^2-\partial_1^2-\partial_2^2-\partial_3^2,$$

we have

$$K(F)=\left(\sum_{k=1}^{3}(C_k)^2\right)(F)=\left(\sum_{k=1}^{3}(C_k')^2\right)(F),$$

$$((d_1^1d_2^2-d_2^1d_1^2)(F))(g,\overline{g})=\det(\overline{g})\quad(\Box\varphi)(x),\tag{39}$$

$$((e_1^1e_2^2-e_2^1e_1^2)(F))(g,\overline{g})=\det(g)(\Box\varphi)(x),\tag{40}$$

$$K(F)=R^2\Box\varphi+\sum_{\alpha,\beta=0}^{3}x_\alpha x_\beta\ \partial_\alpha\partial_\beta\varphi+3\sum_{\alpha=0}^{3}x_\alpha\ \partial_\alpha\varphi,\tag{41}$$

$$A_i(F)=a_i(\varphi):=(x_0\partial_i+x_i\partial_0)(\varphi),\tag{42}$$

$$B_i(F)=b_i(\varphi):=-(x_j\partial_k-x_k\partial_j)(\varphi),\tag{43}$$

$$(ijk)=(123),(231),(312),$$

$$\left(\sum_{k=1}^{3}A_kB_k\right)(F)=\left(\sum_{k=1}^{3}B_kA_k\right)(F)=0.$$

The Casimir operator of the group $SU(2)$ has the expression

$$K_u=-\sum_{k=1}^{3}(B_k)^2=-r^2\Delta+\sum_{i,j=1}^{3}x_ix_j\partial_i\partial_j+2\sum_{j=1}^{3}x^j\partial_j,$$

where

$$\Delta=(\partial_1)^2+(\partial_2)^2+(\partial_3)^2.$$

When the Casimir operators K,K_u have to act either on maps $\Psi=f_+\Phi:\Sigma\to\mathbb{C}^2$ or on sections of the bundle $P=(\Gamma,f_3,\Sigma)$, their actions are given by the formulas

$$\mathbb{K}=\frac{3}{2}+K+\sum_{k=1}^{3}(a_k+ib_k)\sigma_k, \tag{44}$$

$$\mathbb{K}_u=\frac{3}{4}+K_u+i\sum_{k=1}^{3}b_k\sigma_k. \tag{45}$$

III. THE RELATIVISTIC COULOMB PROBLEM

A. The Lie algebra so(2,3)

There is a spinorial representation of the Lie algebra sl(2,$\mathbb{C}$) on End($\mathbb{C}^2$), which is given by the following endomorphisms:

$$M_{0k}(g)=\frac{1}{2}\sigma_k g\sigma_3,\quad M_{ij}(g)=-\frac{i}{2}\sigma_k g,$$

where $(ijk)=(123),(231),(312)$.

An extension of sl(2,$\mathbb{C}$) is obtained by adding the four endomorphisms:

$$M_{04}(g)=\frac{1}{2}g\sigma_1,\quad M_{k4}(g)=-\frac{i}{2}\sigma_k g\sigma_2.$$

We let $M_{\alpha\beta}=-M_{\beta\alpha}$. Then, omitting to write brackets which vanish, the commutation relations of this extended Lie algebra are

$$[M_{0i}\ ,M_{0j}]=M_{ij},\quad [M_{i4}\ ,M_{j4}]=M_{ij},$$

$$[M_{\alpha i}\ ,M_{i\beta}]=M_{\alpha\beta}.$$

We recognize the structure of the algebra so(2,3). In fact, we produced the fundamental spinorial representation of the algebra so(2,3).

It is not difficult to check that the skew-form $\sigma_0\wedge\sigma_3-i\sigma_1\wedge\sigma_2$ is Lorentz-invariant, showing that so(2,3) is a real form of the simplectic Lie algebra sp(4).

We introduce the notations

$$H_1=M_{03},\quad H_2=M_{12},$$

$$F_+=M_{04}+M_{34},\quad F_-=M_{04}-M_{34},$$

$$G_+=M_{14}+iM_{24},\quad G_-=M_{14}-iM_{24},$$

$$E_{\varepsilon\eta}=[F_\varepsilon\ ,G_\eta]=M_{01}+\varepsilon M_{31}+i\eta(M_{02}-\varepsilon M_{23}),$$

$$\varepsilon,\eta\in\{+,-\}.$$

Suppose we have a linear, finite dimensional, irreducible representation

$$\rho:\mathrm{so}(2,3)\to\mathrm{End}(V).$$

A vector $x_0\in V$, $x_0\neq 0$, is said to be a vector of highest weight if

$$F_+(x_0)=G_+(x_0)=E_{+-}(x_0)=0. \tag{46}$$

Since $E_{++}=[F_+,G_+]$, these conditions also imply

$$E_{++}(x_0)=0,\ (M_{01}+M_{31})(x_0)=0,\ (M_{02}-M_{23})(x_0)=0. \tag{47}$$

The Casimir operator K' of so(2,3) is defined as

$$K'=K+K_1\ , \tag{48}$$

where K is the Casimir operator of sl(2,$\mathbb{C}$), i.e.,

$$K=(M_{01})^2+(M_{02})^2+(M_{03})^2-(M_{12})^2-(M_{23})^2-(M_{31})^2 \tag{49}$$

and where

$$K_1=(M_{14})^2+(M_{24})^2+(M_{34})^2-(M_{04})^2. \tag{50}$$

Direct computations give the following six relations:

$$\begin{aligned}K'&=(H_1)^2-(H_2)^2-\tfrac{1}{2}(F_+F_-+F_-F_+-G_+G_--G_-G_+)\\&\quad-\tfrac{1}{4}(E_{++}E_{--}+E_{--}E_{++}+E_{+-}E_{-+}+E_{-+}E_{+-})\\&=(H_1)^2-(H_2)^2-\tfrac{1}{2}([F_+,F_-]-[G_+,G_-])-F_-F_++G_-G_+\\&\quad-\tfrac{1}{4}([E_{++},E_{--}]+[E_{+-},E_{-+}])-\tfrac{1}{2}(E_{--}E_{++}+E_{-+}E_{+-})\\&=(H_1)^2-(H_2)^2+2H_1+(H_1-iH_2)-\tfrac{1}{2}(E_{--}E_{++}+E_{-+}E_{+-})-(F_-F_+-G_-G_+),\end{aligned}$$

$$[E_{++},E_{--}]=-4(H_1-iH_2),\quad [E_{+-},E_{-+}]=-4(H_1+iH_2),$$

$$[F_+,F_-]=-2H_1,\quad [G_+,G_-]=-2iH_2\ ,$$

which enable us to state the following.

Theorem: (i) Suppose x_0 is a vector of highest weight and that

$$H_1(x_0)=Nx_0,\ H_2(x_0)=iMx_0. \tag{51}$$

Then

$$K'(x_0)=(N^2+M^2+3N+M)x_0. \tag{52}$$

(ii) Due to relations (47), x_0 is a vector of highest weight also with respect to sl(2,$\mathbb{C}$).

(iii) For vectors of highest weight in irreducible representations of sl(2,$\mathbb{C}$), satisfying the relations (46),

$$K(x_0)=(N^2+M^2+2N)x_0\ . \tag{53}$$

(iv) In tensorial representations of so(2,3) or of sl(2,$\mathbb{C}$), M and N are integers, while in spinorial representations, M and N are half integers.

B. The relativistic BLRL vector

We now denote by x^α and $x_\alpha=\eta_{\alpha\beta}x^\beta$ the coordinates of a point x in $\mathbb{R}^4$, where

$$-\eta_{00}=\eta_{11}=\eta_{22}=\eta_{33}=1\ ,\ \ \eta_{\alpha\beta}=0 \qquad \text{for} \quad \alpha\neq\beta.$$

The following differential operators generate the Lie algebra of the Lorentz group:

$$M_{\alpha\beta}=x_\alpha\partial_\beta-x_\beta\partial_\alpha.$$

Following L. P. Horwitz (see Refs. 1–3), we introduce the relativistic BLRL (Bernoulli–Laplace–Runge–Lenz) vector

$$\mathbb{D}=(D_0\ ,D_1\ ,D_2\ ,D_3)$$

with components

$$D_\alpha=2M_{\lambda\alpha}\partial^\lambda+3\partial_\alpha+2kR^{-1}x_\alpha=2\partial^\lambda M_{\lambda\alpha}-3\partial_\alpha+2kR^{-1}x_\alpha=2x_\lambda\partial^\lambda\partial_\alpha-2x_\alpha\partial_\lambda\partial^\lambda+3\partial_\alpha+2kR^{-1}x_\alpha,$$

where k is a real number and

$$R^2=x^\lambda x_\lambda\,,\quad \partial^\lambda=\eta^{\lambda\alpha}\partial_\alpha,\ \ \eta^{\lambda\alpha}=\eta_{\lambda\alpha}.$$

It is not difficult to prove the following.

Proposition: Each component D_α is a Hermitian differential operator which commutes with the Newton–Coulomb Hamiltonian

$$H=-\tfrac{1}{2}\partial^\lambda\partial_\lambda-kR^{-1}.$$

Proposition: The following relations hold:

$$x^\alpha D_\alpha-2kR=-3x^\alpha\ \partial_\alpha+2K,$$

$$D_\alpha\ x^\alpha-2kR=3x^\alpha\ \partial_\alpha+2K+12,$$

$$\{x^\alpha,D_\alpha\}-4kR=4K+12,$$

where $K=-\Sigma_{\alpha<\beta}M^{\alpha\beta}M_{\alpha\beta}$ is the Casimir operator of $\mathrm{sl}(2,\mathbb{C})$.

By direct computations, one derives the relations

$$[M_{\alpha\beta}\ ,M_{\lambda\rho}]=\eta_{\beta\lambda}M_{\alpha\rho}+\eta_{\alpha\rho}M_{\beta\lambda}-\eta_{\beta\rho}M_{\alpha\lambda}-\eta_{\alpha\lambda}M_{\beta\rho},$$

$$[D_\alpha\ ,D_\beta]=-8HM_{\alpha\beta},\quad [M_{\alpha\beta}\ ,D_\lambda]=\eta_{\beta\lambda}D_\alpha-\eta_{\alpha\lambda}D_\beta, \tag{54}$$

$$D^\alpha D_\alpha=2(4K+9)H+4k^2.$$

Let L' be the Lie algebra generated by the operators $M_{\alpha\beta},D_\alpha$ and let us consider a representation space of the Lie algebra L', on which H has a fixed value $E<0$. Then, denoting $D_\alpha=2\sqrt{-2E}\,M_{\alpha4}$, we recognize the commutation relations of the Lie algebra $L'=\mathrm{so}(2,3)$. Taking $\eta_{44}=-1$ and introducing the Casimir operator K' of L',

$$K'=-\sum_{0\leqslant I<J}^{4}M_{IJ}M^{IJ}=K-\frac{D^\alpha D_\alpha}{8E},$$

formula (54), with H replaced by E, gives

$$E=\frac{-2k^2}{4\left(K_0'+\frac{9}{4}\right)}, \tag{55}$$

where K_0' are the eigenvalues of the Casimir operator K', which are given by formula (52).

In order to determine irreducible tensorial representations of L', we try to detect vectors of highest weights, using the equations (47) and (51). More precisely, we look for differentiable functions $f:\Sigma\to\mathbb{C}$ that are solutions of the following system of partial differential equations, characterizing simultaneous (H,M_{12},M_{03}) eigenvectors of highest weights:

$$Hf=Ef,\ \ M_{12}f=iMf,\ \ M_{03}f=Nf, \tag{56}$$

$$(M_{01}+M_{31})f=0,\ \ (M_{02}-M_{23})f=0, \tag{57}$$

$$(D_0+D_3)f=0,\ \ (D_1+iD_2)f=0. \tag{58}$$

The solutions of Eqs. (57) are functions $F(w,R)$ of $w=x^0-x^3$ and R. The equations (56) imply $M=0$ and

$$wF_w=NF,\ \ 2wF_{wR}+RF_{RR}+3F_R+2(k+ER)F=0,$$

and it follows that F has the form $F(w,R)=w^Ng(R)$, where the function g verifies the differential equation

$$Rg''(R)+(2N+3)g'(R)+2(k+ER)g(R)=0.$$

The equations (58) imply $2F_{wR}+3F_R+2kF=0$, and we get $g''=-2Eg$. The general solution of the system (56)–(58) will be, up to a constant factor,

$$f_N(x)=\exp\left(\frac{-2kR}{2N+3}\right)(x^0-x^3)^N$$

with

$$E=\frac{-k^2}{2\left(N+\frac{3}{2}\right)^2}. \tag{59}$$

The relations (52) and (53), giving the eigenvalues of K and K', joined to $M=0$, imply

$$K'(f_N)=N(N+3)f_N,\ \ K(f_N)=N(N+2)f_N.$$

As it is well known, a vector f of highest weight in V is a generator of the representation space V, i.e., $V=L'f$.

The functions $f_{m,N}=(D_1-iD_2)^m(f_N)$ are solutions of the equation $M_{12}f=-imf$. To give an example, we note that

$$f_{1,N}=(D_1-iD_2)(f_N)=-\frac{4nk(x^1-ix^2)}{(2N+3)R}\ f_N.$$

Alternatively, we can treat the eigenvalue problem, in the case of the Hamiltonian $H=-\frac{1}{2}\partial_\lambda\partial^\lambda-kR^{-1}$, by using the reduced symmetry SO(3). Looking for solutions of the system of equations

$$Hf=Ef,\ \ M_{12}f=imf,\quad (M_{23}+iM_{31})f=0,$$

we find

$$f=(x_1+ix_2)^m \;\; r^{-(2m+1)}\psi(R),$$

where ψ is a solution of the following equation:

$$\psi''(R)-\frac{2m-1}{R}\psi'(R)+2\left(E+\frac{k}{R}\right)\psi(R)=0.$$

C. A class of equivalent Lagrangians

The Lagrangian

$$L_1=\frac{m_1}{2}|x'|^2+\frac{m_2}{2}|y'|^2+\frac{C}{R}=\frac{A}{2}|u'|^2+\frac{B}{2}|w'|^2+\frac{C}{R}$$
$$\left(u=x-y,\;\; w=\frac{m_1x+m_2y}{m_1+m_2}\right) \tag{60}$$

is associated with a pair of particles x, y in Minkowski space and is similar to the Lagrangian associated with a two-particle gravitational interaction in Newtonian mechanics. The extremal trajectories obey Kepler's laws (see Ref. 3). The constants A, B are related to the masses m_1, m_2 of the two particles according to the formulas

$$B=(m_1+m_2),\;\; AB=m_1m_2.$$

Consequently, we must have $A>0$, $B>0$, $B\geqslant 4A$.

Let us consider, more generally, Lagrangians of the form

$$L_2=\frac{U}{2}(A|u'|^2+B|w'|^2)+V,$$

where $u=u(s), w=w(s)$ are trajectories in Minkowski space, U,V are functions of $R=|u|$, and A, B are real nonvanishing numbers.

When we introduce the time parameter τ, along each trajectory, such that $ds/d\tau=U$, the Euler–Lagrange equations, for a fixed constant level $L_2-2V=E$, take the form

$$A\frac{d^2u}{d\tau^2}=\left(\frac{d}{dR}(EU+UV)\right)\frac{u}{R},\;\; (Uw')'=0.$$

Besides $E=L_2-2V$, we get two other constants of motion: the vector $P=BUw'$ and the scalar

$$E_{\text{int}}=\frac{A}{2}\left|\frac{du}{d\tau}\right|^2-U(V+E)=U\left(\frac{AU}{2}|u'|^2-V-E\right)=-\frac{|P|^2}{2B}.$$

The extremal trajectories of L_2 obey Kepler's laws, for all energy levels E, when U,V have the form

$$U=\frac{a+bR}{R},\quad V=\frac{c+dR}{a+bR},$$

where a,b,c,d are real numbers and a,bc are not both equal to zero. Under these circumstances, the equations of motion write

$$A\frac{d^2u}{d\tau^2}=-\frac{c+aE}{R^3}u.$$

The constant E_{int} plays the role of internal energy, while $P=BUw'$ is the total momentum vector and $E_{\text{tr}}=-(2B)^{-1}|P|^2$ plays the role of energy of translation. We obtained the equality $E_{\text{int}}=E_{\text{tr}}$.

D. Two-particle relativistic wave equations

The wave equation associated with the Lagrangian L_2 writes

$$\Box_u F-3U^{-1}\frac{dU}{dR}\frac{\partial F}{\partial R}-\frac{2AU(V+E)}{\kappa^2}+\frac{A}{B}\Box_w F=0.$$

In the particular case (60), we get the following wave equation:

$$\Box_u F-\frac{2A}{\kappa^2}\left(E+\frac{C}{R}\right)F+\frac{A}{B}\Box_w F=0.$$

This equation can be given the form

$$\mathcal{H}(F)=E_2F,E_2=E-\frac{\kappa^2}{2B}\Box_w, \tag{61}$$

where $\mathcal{H}$ is the Hamiltonian of the relative motion:

$$\mathcal{H}=\frac{\kappa^2}{2A}\Box_u-\frac{C}{R}. \tag{62}$$

We also introduce the operator of radial derivation

$$X=u^\alpha\partial_\alpha.$$

Making use of formula (41), the wave equation (61) becomes

$$\frac{2AR^2}{\kappa^2}\left(E+\frac{C}{R}-\frac{\kappa^2}{2B}\Box_w\right)F+X^2(F)+2X(F)=KF. \tag{63}$$

Let us suppose that the wave function F is a product of three functions:

$$F(u,w)=f(R)G(u)H(w),$$

where the functions $G(u),H(w)$ satisfy the equations

$$X(G)=0,\quad K(G)=K_0G,\quad \Box_w H=-\frac{\mu^2}{\kappa^2}H, \tag{64}$$

with constant coefficients K_0,μ. Then G is homogeneous of degree 0 and

$$K(fGH)=fK(G)H,\quad R^2\Box G=K_0G.$$

From the wave equation (63) we get the following radial equation:

$$f''(R)+\frac{3}{R}f'(R)+\left(p+\frac{q}{R}-\frac{K_0}{R^2}\right)f(R)=0, \tag{65}$$

where

$$p=\frac{2A}{\kappa^2}\left(E+\frac{\mu^2}{2B}\right),\quad q=\frac{2AC}{\kappa^2}. \tag{66}$$

We assume that E is the energy of the system of two particles, while

$$E_2=E+\frac{\mu^2}{2B}$$

is the energy of the relative motion.

E. The quantization conditions

Using standard methods, we now give some essentially known results concerning the ordinary differential equations of the form

$$f''(x)+\frac{s}{x}f'(x)+\left(p+\frac{q}{x}+\frac{r}{x^2}\right)f(x)=0, \tag{67}$$

where p,q,r,s are real numbers.

We shall solve the equation (67) for $x>0$, under certain regularity conditions and supposing

$$p<0. \tag{68}$$

Problems of this type have been studied since long ago (see Refs. 4 and 5). The regularity conditions generally adopted imply the fact that the solutions f have the form

$$f(x)=\exp(bx)x^a\times\text{polynomial of } x,\quad b<0,$$

and belong to some finite dimensional representation vector spaces of a certain symmetry group.

We shall impose the following regularity conditions:

(i) The function f must be real analytic for all $x>0$.
(ii) f must vanish at infinity.

When we write the solutions of Eq. (67) as follows,

$$f(x)=x^\alpha e^{bx}\vartheta(x),\quad b<0,$$

we get the equation

$$x^2\vartheta''(x)+[2bx^2+(s+2\alpha)x]\vartheta'(x)+[(b^2+p)x^2$$
$$+(q+bs+2\alpha b)x+\alpha(\alpha-1)+r+\alpha s]\vartheta(x)=0.$$

We define h,α,b,l,k such that we have

$$h^2=\frac{(s-1)^2}{4}-r,\quad b^2=-p,\quad \alpha=\frac{1-s}{2}+h,\quad l=2h+1,\quad k=\frac{q}{b}. \tag{69}$$

Then the equation satisfied by ϑ becomes

$$x\vartheta''(x)+(2bx+l)\vartheta'(x)+b(k+l)\vartheta(x)=0. \tag{70}$$

Since we supposed $p<0$, we get two real solutions for b; we choose the negative solution.

Suppose we have a solution f with

$$f(x)=x^{\alpha}e^{bx}\vartheta(x)=x^{\alpha}e^{bx}\sum_{i=-\infty}^{\infty}a_i x^{\beta+i},$$

where $0\leqslant\beta<1$. Then we shall have, for all indices i,

$$(\beta+i+1)(\beta+i+l)a_{i+1}=-2b\left(\beta+i+\frac{k+l}{2}\right)a_i.$$

It follows that the power series $\Sigma_{i=0}^{-\infty}a_i x^i$ is divergent for $x>0$, unless there exists an integer n such that $a_{n-\lambda}=0$ for all $\lambda>0$. Since we look for nontrivial solutions, we shall suppose that $a_n\neq 0$. Then

$$(n+\beta)(n+\beta+l-1)=0.$$

For $i>0$, we introduce the coefficients

$$c_i=\Pi_{j=1}^{i}\left(1+\frac{\beta}{j}\right),\quad a_i'=i!c_i(-2b)^{-i}a_i;$$

since $i!c_i<(i+1)!$, we have $0<c_i<i+1$. We also have

$$f(x)=e^{bx}x^{\alpha+\beta}\vartheta_1(x),\quad \vartheta_1(x)=\sum_{i\geqslant n}(c_i)^{-1}a_i'\frac{(-2bx)^i}{i!},$$

$$(\beta+i+l)a_{i+1}'=\left(\beta+i+\frac{k+l}{2}\right)a_i',$$

$$a_n'\neq 0,$$

and, as long as $\beta+i+l\neq 0$,

$$a_{i+1}'=\left(1+\frac{k-l}{2(\beta+i+l)}\right)a_i'.$$

For i large, all a_i have the same sign and $|a_{i+1}'/a_i'|>2/3$. Then there exist a positive constant C and a natural number N such that, for $i>N$,

$$C|a_i'|>2^i/3^i.$$

Comparing the series $Cx\vartheta(x)$, $\exp(-2bx)$, we get

$$C|a_i'|(-2bx)^i>(-\tfrac{4}{3}bx)^i \text{ for large } i \text{ and } x>0,$$

$$\exp(bx)|x^{1-\beta}\vartheta(x)|>\exp\left(-\frac{bx}{3}\right) \text{ for large positive } x,$$

and we infer that the function f will be bounded at infinity if and only if the number of coefficients $a_i\neq 0$ is finite. Thus there must exist a natural number m such that $a_{m-1}\neq 0$ and $a_i=0$ for $i>m-1$. Then we get

$$\vartheta(x)=x^{\beta}\sum_{i=n}^{m-1}a_i x^i,\quad f(x)=e^{bx}x^{\alpha}\vartheta(x),$$

$$k=2-2m-2\beta-l=1-2(m+\beta+h), \tag{71}$$

$$(\beta+n)(\beta+n+l-1)=0.$$

Note that the number of monomials arising in $\vartheta(x)$ equals $m-n$, so that we must have $m>n$. We also have

$$p=-b^2=-\frac{q^2}{k^2}=-\frac{q^2}{(2\beta+2h+2m-1)^2}. \tag{72}$$

When $q=k=0$, we get

$$h=\frac{1}{2}-m,\quad r=\frac{(1-s)^2}{4}-\left(m-\frac{1}{2}\right)^2.$$

F. The Spectrum

In the radial equation corresponding to the classical Schrödinger equation for the hydrogen atom, one has

$$s=2,\quad r=-l'(l'+1),\quad 2h=-(2l'+1),\quad l'\in\mathbb{N},\quad p=\frac{-q^2}{4(l'+m)^2},$$

where, according to Schrödinger's terminology, $l'+m$ is the principal quantum number, $l'+1$ is the azimuthal quantum number and $m-1$ is the radial quantum number.

The radial equation (26) of the Lagrangian $\mathcal{L}$ in formula (19) has, according to formula (37), $\mathbb{K}_0=M'^2+3M'+\frac{3}{2}$, so that $h^2=(M'+\frac{3}{2})^2+\frac{1}{4}$.

In the case of the equation (65), which is associated with the Lagrangian (60), we get $h^2=K_0+1$, where K_0 is an eigenvalue of the Casimir operator K.

According to formula (53), when F belongs to an irreducible, finite dimensional representation of the group SL(2,$\mathbb{C}$), there exist two positive integers $2M,2N$ such that $K_0+1=M^2+(N+1)^2$.

For a tensorial representation, one has $M=0$, N is an integer and we get $K_0+1=(N+1)^2, h=\pm(N+1), l=\pm 2(N+1)+1$. The relations (71) and $0\leqslant\beta<1$ show that $\beta=0$ and $n(n+l-1)=0$.

Introducing these values in formulas (66), we get the following.

Theorem: Under the regularity conditions (i) and (ii) of Section III E, the negative energy levels E_1,E_2 associated with the Lagrangians (19), respectively with the Hamiltonian (62) with $A>0$, are given by the formulas

$$E_1=\frac{-C^2}{(2\beta_1\pm 2h_1+2m-1)^2},\quad E_2=\frac{-AC^2}{2\kappa^2(m\pm(N+1)-1/2)^2}, \tag{73}$$

where M',m,N are positive integers, $(h_1)^2=(M'^2+\frac{3}{2})^2+\frac{1}{4}$ and β_1 has to be determined by using the equations (69) and (71).

When N is a half integer, E_2 will belong to the Schrödinger spectrum, but the corresponding solution f of the equation (67) will be defined up to sign and will belong to an infinite dimensional representation space of SL(2,$\mathbb{C}$).

Among the unitary, irreducible representations of the group SL(2,$\mathbb{C}$), one distinguishes the principal series of unitary representations (see Ref. 6, Chap. III). For a representation of the principal series, K_0+1 has the form $(N^2-\rho^2)/4$, with $N\in\mathbb{N}$ and $\rho\in\mathbb{R}$. When $\rho=0$, we shall have $h^2=K_0+1=N^2/4$ and, formally, we get

$$E_2=\frac{-AC^2}{2\kappa^2(m\pm N/2-1/2)^2}.$$

This follows:

Proposition: The unitary representations of the principal series with $\rho=0$ give the discrete spectrum obtained by Schrödinger for the atom of hydrogen.

IV. THE NEW LAGRANGIANS

A. Geometric considerations

The representations of the principal series are realized in spaces formed by functions defined on the tangent space of the complex projective line $P^1(\mathbb{C})$.

The complex projective line $P^1(\mathbb{C})$ can be identified, as SL(2,$\mathbb{C}$)-space, with the space Π of straight lines lying on the light-cone

$$\Lambda=\{\xi\in M;|\xi|^2=0\},$$

by identifying each point $[z_1,z_2]\in P^1(\mathbb{C})$ with the vector line generated by the vector

$$\xi=\tfrac{1}{2}(|z_1|^2+|z_2|^2,z_1\overline{z_2}+\overline{z_1}z_2,-i(z_1\overline{z_2}-\overline{z_1}z_2),|z_1|^2-|z_2|^2).$$

The light-cone Λ is the boundary of Σ.

The space Π is a coset space of $\Lambda_0=\Lambda\backslash\{0\}$ and the tangent space $T\Pi$ is a coset space of $T\Lambda_0$. We have

$$T\Lambda_0=\{(\xi,u)\in\Lambda\times M;\xi\neq 0,\langle\xi,u\rangle=0\},$$

$$T\Pi=\{[\xi,u];(\xi,x)\in T\Lambda_0\},$$

where $[\xi,u]=\{(a\xi,au+b\xi);a\in\mathbb{R},a\neq 0,b\in R\}$.

When $(\xi,u)\in T\Lambda_0$ and $|u|^2\neq 0$, we have $|u|^2>0$, i.e., $u\in\Sigma$. Denote

$$T_+\Lambda_0=\{(\xi,u)\in T\Lambda_0;\xi^0>0,|u|^2>0\}$$

and $\pi(\xi,u)=u,\pi_+=\pi|T_+$. When $(\xi,u)\in T_+\Lambda_0$ and $u=\sigma_3=(0,0,0,1)$, we have $\xi^0=\sqrt{(\xi^1)^2+(\xi^2)^2},\xi^3=0$. We then have the following.

Proposition: The triple $(T_+\Lambda_0,\pi_+,\Sigma)$ is a principal $\mathbb{C}^*$-fiber bundle with structure group $\mathbb{C}^*=\{z\in\mathbb{C};z\neq 0\}$.

Suppose that $g\in\Gamma,(\xi,u)=(\sigma_1+\sigma_0,\sigma_3)$ and that $g\xi g^*=\xi,gug^*=u$. Then g has the form $g=\pm\sigma_0+b(\sigma_2+i\sigma_3),b\in\mathbb{R}$ and we can state the following.

Proposition: The space $T_+\Lambda_0$ is isomorphic to Γ/L, where L is the group formed by the matrices $g=\pm\sigma_0+b(\sigma_2+i\sigma_3),b\in\mathbb{R}$.

When $(\xi,u)\in T_+\Lambda_0$ and $\xi^0+\xi^3>0$, the vectors ξ,u can be given, in a unique way, by the expressions

$$\xi=\frac{a}{2}(1+|z|^2,z+\overline{z},-i(z-\overline{z}),1-|z|^2), \tag{74}$$

$$u=\frac{a}{2}(z\overline{Z}+\overline{z}Z,Z+\overline{Z},-i(Z-\overline{Z}),-(z\overline{Z}+\overline{z}Z))+b\xi, \tag{75}$$

where

$$a=\xi^0+\xi^3,\ \ z=\frac{\xi^1+i\xi^2}{\xi^0+\xi^3},\ \ b=\frac{u^0+u^3}{\xi^0+\xi^3},\ \ Z=\frac{u^1+iu^2-(u^0+u^3)z}{\xi^0+\xi^3}.$$

Let $T_0P^1(\mathbb{C})$ be the subspace of nonvanishing tangent vectors of $P^1(\mathbb{C})$. On $T_0P^1(\mathbb{C})$ we can use homogeneous coordinates z_1, z_2, Z_1, Z_2, as well as local coordinates

$$z=\frac{z_2}{z_1},\ \ Z=\dot{z}=\frac{z_1Z_2-z_2Z_1}{(z_1)^2}.$$

Each homographic transformation of $P^1(\mathbb{C})$ prolongs to $T_0P^1(\mathbb{C})$,

$$z\mapsto\frac{az+b}{cz+d},\ \ Z\mapsto\frac{Z}{(cz+d)^2},\ \ ad-bc=1.$$

The group $\mathbb{C}^*$ acts on the fibers of $T_0P^1(\mathbb{C})$ by complex multiplication.

Let $S_{N,\rho}$ be the vector space of smooth functions $F:T_0P^1(\mathbb{C})\to\mathbb{C}$, which satisfy, for all $\lambda\in\mathbb{C},\lambda\neq 0$, the following equation:

$$F(z,\lambda Z)=\left(\frac{\lambda}{|\lambda|}\right)^N|\lambda|^{-1+i\rho}F(z,Z),$$

where N is an integer and ρ is a real number. For F in $S_{N,\rho}$ one has

$$F(z,Z)=f(z)\left(\frac{Z}{|Z|}\right)^{-N}|Z|^{1-i\rho},$$

where

$$f(z)=F\left(\frac{1-z^2}{2},\ \ \frac{1+z^2}{2i},\ \ z\right).$$

Each $S_{N,\rho}$ is a representation space of the group $\mathrm{SL}(2,\mathbb{C})$ and the two-form $|f(z)|^2dz\wedge d\overline{z}$ is an invariant. When we introduce on $S_{N,\rho}$ the norm

$$||F||=\left(\frac{i}{2}\int_{\mathbb{C}}|f(z)|^2dz\wedge d\overline{z}\right)^{1/2},$$

we get by completion the Hilbert space of a unitary representation $R_{N,\rho}$ of the group $\mathrm{SL}(2,\mathbb{C})$.

In Ref. 6 (pp. 130–144) it is proved that each representation $R_{N,\rho}$ is irreducible and that $F\in S_{N,\rho}$ implies $4K(F)=(N^2-\rho^2-4)F$.

B. New invariant Lagrangians

The $\mathrm{SL}(2,\mathbb{C})$-space $T_0P^1(\mathbb{C})$ carries the invariant holomorphic one-form $Z^{-1}dz$.

The space $T_+\Lambda_0$ is defined, as a subset of $M\times M$, by the equations

$$\xi^0=\sqrt{(\xi^1)^2+(\xi^2)^2+(\xi^3)^2},\ \ y^0=\frac{\xi^1y^1+\xi^2y^2+\xi^3y^3}{\xi^0}.$$

Using formulas

$$z=\frac{\xi^1+i\xi^2}{\xi^0+\xi^3},\quad Z=\frac{u^1+iu^2-(u^0+u^3)z}{\xi^0+\xi^3},$$

it is not difficult to prove the following statements:

Proposition: The map $J:(\xi,u)\mapsto(z,Z)$ *defines a principal fibration* $(T_+\Lambda_0,J,T_0P^1(\mathbb{C}))$ *with structure group*

$$L'=\{a\sigma_0+b(\sigma_1-i\sigma_2);\ \ a\neq 0,\ \ b\in\mathbb{R}\}$$

and the map which sends $F\in S_{N,\rho}$ *to* $F^J=F\circ J$ *is an equivariant embedding of* $S_{N,\rho}$ *into the space of functions* $\Phi:T_+\Lambda_0\to\mathbb{C}$.

The space $T_+\Lambda_0$ is a six-dimensional manifold. It is convenient to select six real, independent coordinates on $T_+\Lambda_0$, among or contained in the following variables:

$$R=|u|,\ \ v=u^0+u^3,\ \ \rho=\frac{R}{u^0+u^3},\ \ W=\frac{u^1+iu^2}{u^0+u^3},$$

$$Z=\frac{u^0+u^3}{\xi^0+\xi^3}\ (W-z),\ \ \sigma=|Z|,\ \ H_1=Z^{-1}dz.$$

Note that the following relations hold:

$$u^0=\frac{R}{2\rho}(1-|z|^2+\overline{W}z+W\overline{z}),\ \ u^1=\frac{R}{2\rho}(W+\overline{W}),$$

$$u^2=-\frac{iR}{2\rho}(W-\overline{W}),\ \ u^3=\frac{R}{2\rho}(1+|z|^2-\overline{W}z-W\overline{z}),$$

$$v=ab,\ \ \rho=|z-W|,\ \ \sigma=b\rho,\ \ R=ab\rho,$$

$$H_1=Z^{-1}dz,\ \ \langle d\xi,d\xi\rangle=R^2|H_1|^2=\frac{R^2}{\sigma^2}|dz|^2,$$

$$\langle u,d\xi\rangle=\frac{R^2}{2}(H_1+\overline{H}_1)=\frac{R^2}{2\rho\sigma}[(\overline{W}-\overline{z})dz+(W-z)d\overline{z}],$$

$$\langle du,du\rangle=(dR)^2+\frac{R^2}{\rho^2}[|dW|^2-(d\rho)^2],$$

$$\langle d\xi,du\rangle=\frac{R^2}{2\sigma\rho}\left[((\overline{W}-\overline{z})dz+(W-z)d\overline{z})\ \left(\frac{d\sigma}{\sigma}-\frac{d\rho}{\rho}\right)+dz\ \ d\overline{W}+dW\ \ d\overline{z}\right].$$

We get Lorentz-invariant metrics on $T_+\Lambda_0$ by considering linear combinations of the scalar products

$$A\langle d\xi,d\xi\rangle+B\langle du,du\rangle+C\langle d\xi,du\rangle,\tag{76}$$

with coefficients depending on R.

We look at $\xi\in\Lambda$ as representing a generic electro-magnetic field. A specific electro-magnetic field would be defined by a vector potential $\xi=A(u)$ or, more precisely, by a section $s:\Sigma\to T_+\Lambda_0$, $s(u)=(u,A(u))$.

The manifold $T_+\Lambda_0$ carries the following invariant six-form,

$$du^0 \wedge du^1 \wedge du^2 \wedge du^3 \wedge \frac{dZ \wedge dz}{Z^2} = R^3 dR \wedge dz \wedge d\bar{z} \wedge \frac{d\rho \wedge d\sigma}{2\rho^2\sigma^2} \wedge d\omega.$$

Proposition: The quadratic, differential forms (76) are all degenerate, due to the presence of $\langle d\xi, d\xi \rangle$*; the tangent vectors* $((\xi,u),(\xi',u'))$*, satisfying the equations* $\xi' = C\xi$, $u' = -B\xi$*, are singular.*

The degeneracy of the forms (76) can be removed by introducing a constraint such as $\xi^0 = 1$, which reduces the dimension of the configuration space to five. It is plausible to assume, regarding the formulas above, that Lagrangians of this type produce the whole Schrödinger spectrum.

We finally remark that the Lagrangians which can be built using the invariants indicated above, such as (76), can be linked with two-particle systems $(u, u+\xi)$, for which the difference vector ξ lies on the light-cone.

Fedosov quantization on symplectic ringed spaces

Izu Vaisman[a)]
Department of Mathematics, University of Haifa, Mount Carmel, Haifa 31905, Israel

(Received 19 June 2001; accepted for publication 24 October 2001)

We expose the basics of the Fedosov quantization procedure, placed in the general framework of symplectic ringed spaces. This framework also includes some Poisson manifolds with nonregular Poisson structures, presymplectic manifolds, complex analytic symplectic manifolds, etc. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1427411]

I. INTRODUCTION

On a symplectic manifold (M,ω) *Fedosov quantization* is an embedding of the algebra $C^\infty(M,\mathbf{C})[[h]]$ of formal power series in h, with complex valued differentiable functions on M as coefficients, into the algebra of the cross sections of the *Weyl algebras bundle* $W(TM)$ by means of parallel translation with respect to a *generalized Abelian connection*. This article is an exposition of the basics of Fedosov quantization. The difference between our exposition and that of the original works (Refs. 1 and 2) consists in the fact that we place Fedosov's construction in the general framework of *symplectic ringed spaces*. The generalization is purely formal, and should be seen as folklore, but, it allows for new applications including a class of Poisson manifolds with possibly nonregular Poisson structure, presymplectic manifolds, holomorphic symplectic manifolds, etc. On the other hand, it is important to notice that in the general case one has an obstruction to the existence of a connection. Therefore, Fedosov quantization can be used only on symplectic ringed spaces where this obstruction vanishes.

II. SYMPLECTIC RINGED SPACES

A *Herz–Reinhart Lie algebra*, or *HRL-algebra* (or *Lie pseudo-algebra*[3,4]), L over a pair (K,C), where K is a commutative ring with unit and C is a commutative K-algebra with unit, is a Lie algebra over K which also is a C-module, and is endowed with a mapping $\iota: L\to\mathcal{D}$, the algebra of derivations of C over K, that is both a K-Lie algebra and a C-module homomorphism, with the compatibility condition

$$[X,fY]=f[X,Y]+(\iota(X)f)Y \quad (f\in C;\ X,Y\in L). \tag{2.1}$$

The fundamental example is $K=\mathbf{R}$, $C=C^\infty(M)$, $L=\Gamma TM$, where M is an arbitrary differentiable manifold, and Γ always denotes spaces of cross sections of vector bundles or sheaves.

Now, we define a *Herz–Reinhart–Lie (HRL)-ringed space*, as a topological space M endowed with a sheaf $\mathcal{C}$ of commutative K-algebras with unit and a *sheaf* $\mathcal{L}$ *of HRL-algebras* over $(K,\mathcal{C})$. This latter notion has the obvious definition, namely, for each open subset U of M the space of sections $\Gamma_U(\mathcal{L})$ is a HRL-algebra over $(K,\Gamma_U(\mathcal{C}))$, and the restrictions are homomorphisms of HRL-algebras. The sheaves of HRL-algebras were studied in Ref. 5 under the name of sheaves of *twisted Lie algebras*. A HRL-ringed space whose sheaf $\mathcal{L}$ is a locally free $\mathcal{C}$-module of rank m will be called an HRL-*ringed space of rank* m.

Example 2.1: An m-dimensional differentiable (respectively, complex analytic) manifold M is a HRL-ringed space of rank m, with $K=\mathbf{R}$ (respectively, $K=\mathbf{C}$), $\mathcal{C}=\mathcal{C}^\infty(M)$ [respectively

a)Electronic mail: vaisman@math.haifa.ac.il

$\mathcal{C}^{\mathrm{hol}}(M)]$, the sheaf of germs of differentiable (respectively, holomorphic) functions on M, and $\mathcal{L}$ the sheaf of germs of differentiable (respectively, holomorphic) vector fields on M.

Example 2.2: Let $p:A\to M$ be a differentiable vector bundle of rank m which is a Lie algebroid of anchor $\iota:A\to TM$.[4] Then, if we take $K=\mathbf{R}$, $\mathcal{C}=\mathcal{C}^\infty(M)$, $\mathcal{L}$ the sheaf A of germs of differentiable cross sections of A, and ι induced by the anchor, we again get a HRL-ringed space of rank m.

Example 2.3: Let M be a differentiable manifold endowed with a foliation $\mathcal{F}$ of codimension m, and let $\nu\mathcal{F}$ be the transversal bundle of $\mathcal{F}$. Take $K=\mathbf{R}$, $\mathcal{C}$ the sheaf of germs of differentiable functions on M which are constant along the leaves of $\mathcal{F}$ (*foliated functions*), $\mathcal{L}$ the sheaf of germs of foliated cross sections of $\nu\mathcal{F}$, and $\iota(X)f=\overline{X}f$, where $f\in\mathcal{C}, X\in\mathcal{L}$, and $\overline{X}$ is a germ of foliated vector field on M which projects onto X. The result is a structure of HRL-ringed space of rank m. (We refer to Ref. 6 for the theory of foliated manifolds.)

Because the structure of HRL-ringed space is similar to that of Lie algebroid, the same formulas as in the latter case[7,4] yield a differential calculus for HRL-ringed spaces.

If we refer to the sheaf

$$\Omega^k(M):=Alt_{\mathcal{C}}(\mathcal{L}^k,\mathcal{C}) \tag{2.2}$$

as the sheaf of germs of differential k-forms ($:=$ denotes a definition), there exists an exterior differential $d:\Omega^k(M)\to\Omega^{k+1}(M)$ defined for $\lambda\in\Omega^k(M)$ by

$$\begin{aligned} d\lambda(X_0,\ldots,X_k)=&\sum_{i=0}^{k}(-1)^i\iota(X_i)(\lambda(X_0,\ldots,\hat{X}_i,\ldots,X_k))\\ &+\sum_{i<j=1}^{k}(-1)^{i+j}\lambda([X_i,X_j],X_0,\ldots,\hat{X}_i,\ldots,\hat{X}_j,\ldots,X_k). \end{aligned} \tag{2.3}$$

In (2.3), and in all the similar formulas of this article, the germs always are at the same point of M. The operator d satisfies $d^2=0$, and leads to a usual definition of de Rham cohomology spaces $H^k(\mathcal{L})$. Notice also the existence of the *wedge product* which makes the graded exterior algebra $\{\Omega^k(M)\}_{k\in\mathbf{N}}$ into a differential graded algebra with respect to the exterior differential d.

Furthermore, if the sheaf $\mathcal{M}$ over M is a $\mathcal{C}$-module, we define the spaces of $\mathcal{M}$-valued differential forms by

$$\Omega^k(M,\mathcal{M}):=Alt_{\mathcal{C}}\mathcal{L}^k,\mathcal{M}), \tag{2.4}$$

and a *connection* on $\mathcal{M}$ is a K-linear homomorphism

$$\nabla:\mathcal{M}\to\Omega^1(M,\mathcal{M}), \tag{2.5}$$

which satisfies the condition

$$\nabla(f\xi)=f\nabla\xi+(df)\xi \quad (f\in\mathcal{C},\ \xi\in\mathcal{M}). \tag{2.6}$$

We will also use the notation $\nabla_Y\xi:=(\nabla\xi)(Y)$.

Using a connection, and in analogy with formula (2.3), for all $\lambda\in\Omega^k(M,\mathcal{M})$ one defines

$$\begin{aligned} \nabla\lambda(X_0,\ldots,X_k)=&\sum_{i=0}^{k}(-1)^i\nabla_{X_i}(\lambda(X_0,\ldots,\hat{X}_i,\ldots,X_k))\\ &+\sum_{i<j=1}^{k}(-1)^{i+j}\lambda([X_i,X_j],X_0,\ldots,\hat{X}_i,\ldots,\hat{X}_j,\ldots,X_k)\in\Omega^{k+1}(M,\mathcal{M}). \end{aligned} \tag{2.7}$$

In particular, (2.7) may be used to define the *curvature of the connection* ∇,

$$\Phi=\nabla^2:\mathcal{M}\to\Omega^2(M,\mathcal{M}), \tag{2.8}$$

where

$$\Phi(\xi)(Y,Z)=\nabla_Y\nabla_Z\xi-\nabla_Z\nabla_Y\xi-\nabla_{[Y,Z]}\xi. \tag{2.9}$$

It is easy to check that Φ is a homomorphism over $\mathcal{C}$, and satisfies the *Bianchi identity*

$$\nabla(\Phi(\xi))(Y,Z,U)=\sum_{\mathrm{Cycl}(Y,Z,U)}\Phi(\nabla_Y\xi)(Z,U). \tag{2.10}$$

In (2.9) and (2.10) $Y,Z,U\in\mathcal{L}$, and $\xi\in\mathcal{M}$.

The operators ∇_Y can be extended to any *tensorial sheaf* produced from $\mathcal{M}$ by the usual formulas of differential geometry. In the whole article, tensor and wedge product sheaves are seen as sheaves of $\mathcal{C}$-multilinear morphisms (e.g., Ref. 8). In particular, the curvature Φ can also be seen as a *two-form with values in* $\mathrm{Hom}_{\mathcal{C}}(\mathcal{M},\mathcal{M})$, and, then, the Bianchi identity takes the simple classical form[3,8]

$$\nabla\Phi=0. \tag{2.11}$$

Our interest will be in connections on $\mathcal{L}$, also called *connections on the HRL-ringed space* M. In this case another important invariant is the *torsion*, defined by

$$T(X,Y)=\nabla_XY-\nabla_YX-[X,Y]\quad(X,Y\in\mathcal{L}). \tag{2.12}$$

From (2.1) and (2.6), it follows that $T\in\Omega^2(M,\mathcal{L})$, and a simple computation yields the *torsion Bianchi identity*

$$(\nabla T)(X,Y,Z)=\sum_{\mathrm{Cycl}(X,Y,Z)}\Phi(X)(Y,Z)\quad(X,Y,Z\in\Gamma\mathcal{L}). \tag{2.13}$$

The torsion of a connection on $\mathcal{L}$ yields the following expression of the exterior differential (2.3):

$$\begin{aligned}d\lambda(X_0,\ldots,X_k)=&\sum_{i=0}^{k}(-1)^i(\nabla_{X_i}\lambda)(X_0,\ldots,\hat{X}_i,\ldots,X_k)\\&+\sum_{i<j=1}^{k}(-1)^{i+j}\lambda(T(X_i,X_j),X_0,\ldots,\hat{X}_i,\ldots,\hat{X}_j,\ldots,X_k).\end{aligned} \tag{2.14}$$

This formula suggests considering the operator

$$\nabla\lambda(X_0,\ldots,X_k)=\sum_{i=0}^{k}(-1)^i(\nabla_{X_i}\lambda)(X_0,\ldots,\hat{X}_i,\ldots,X_k)), \tag{2.15}$$

which coincides with $d\lambda$ if the torsion of ∇ is zero.

From (2.6), we see that the difference $D=\nabla^2-\nabla^1$ of two connections on M is a global section of $\mathrm{Hom}_{\mathcal{C}}(\mathcal{L},\Omega^1(M,\mathcal{L}))=\mathrm{Hom}_{\mathcal{C}}(\mathcal{L}\times\mathcal{L},\mathcal{L})$, i.e., a *tensor field*. Using this remark it follows easily that if ∇ is an arbitrary connection, then

$$\nabla^0_XY:=\tfrac{1}{2}(\nabla_XY+\nabla_YX+[X,Y]) \tag{2.16}$$

is a torsionless connection.

If $\mathcal{M}$ is a locally free $\mathcal{C}$-module of finite rank s over a ringed space $(M,\mathcal{C},\mathcal{L})$ of rank m, we may use local bases $(X_i)_{i=1}^m$ of $\mathcal{L}$, and local bases $(\xi_u)_{u=1}^s$ of $\mathcal{M}$, and get the local equations of the connection ∇,

$$\nabla_{X_i}\xi_u=\sum_{v=1}^{s}\Gamma_{iu}^{v}\xi_v, \tag{2.17}$$

where the *connection coefficients* Γ_{iu}^{v} are local sections of $\mathcal{C}$. The local equations (2.17) may be used in exactly the same way as in classical differential geometry, e.g., Ref. 8. For instance, let us take the case $\mathcal{M}=\mathcal{L}$, and look for the local expression of the torsion. For this purpose, we first notice the existence of *structure equations*:

$$[X_i,X_j]=\sum_{k=1}^{m}s_{ij}^{k}X_k \quad (s_{ij}^{k}=-s_{ji}^{k}\in\mathcal{C}).$$

Then, if we put $T(X_i,X_j)=\Sigma_{k=1}^{m}T_{ij}^{k}X_k$, we get

$$T_{ij}^{k}=\Gamma_{ij}^{k}-\Gamma_{ji}^{k}-s_{ij}^{k}.$$

Clearly, in the case of a differentiable manifold M a connection (2.5) on $\mathcal{M}=\mathcal{L}$ is just a linear connection on M. In the case of a complex analytic manifold a connection is the same thing as a holomorphic connection on the manifold, and it exists iff the *Atiyah class* of the manifold vanishes.[9] In the case of the transversal bundle of a foliation, a connection (2.5) on $\mathcal{L}$ is defined by a *projectable connection* of the foliation, and it exists iff the *Atiyah class of the foliation* vanishes.[6] Therefore, not every ringed space has connections. In the case of a Lie algebroid, a connection (2.5) is a *connection of the algebroid*, and any Lie algebroid has connections.

As a matter of fact, the Atiyah class method,[3,5] yields a general result namely, the following theorem.

Theorem 2.1: *For each HRL-ringed space of finite rank* $(M,K,\mathcal{C},\mathcal{L})$, *there exists a well defined sheaf-cohomology class* $a(M)\in H^1(M,Hom_{\mathcal{C}}(\mathcal{L},Hom_{\mathcal{C}}(\mathcal{L},\mathcal{L})))$ *such that existence of a connection on* $\mathcal{L}$ *is equivalent with* $a(M)=0$.

Proof: For any HRL-ringed space $(M,K,\mathcal{C},\mathcal{L})$ there exists a sheaf $\mathcal{J}$, which plays the role of the jet bundle J^1TM of a differentiable manifold M. Namely, $\mathcal{J}$ is the submodule of $\mathcal{L}\oplus\mathrm{Hom}_K(\mathcal{L},\mathcal{L})$ which consists of the pairs $(X,-\mathrm{ad}_X+\varphi)$, where $X\in\mathcal{L},\varphi\in\mathrm{Hom}_{\mathcal{C}}(\mathcal{L},\mathcal{L})$ and $\mathrm{ad}_X:=[X,]$. The fact that $\mathcal{J}$ is a $\mathcal{C}$-module follows from

$$(fX,-f\mathrm{ad}_X+f\varphi)=(fX,-\mathrm{ad}_{fX}+f\varphi-(df)X). \tag{2.18}$$

Now, we notice the existence of the following exact sequence of $\mathcal{C}$-module sheaves

$$0\to\mathcal{F}:=\mathrm{Hom}_{\mathcal{C}}(\mathcal{L},\mathcal{L})\xrightarrow{\epsilon}\mathcal{J}\xrightarrow{p}\mathcal{L}\to 0, \tag{2.19}$$

where $\epsilon(\varphi)=(0,\varphi)$, and $p(X,-\mathrm{ad}_X+\varphi)=X$.

Then, there exists a connection ∇ on $\mathcal{L}$ iff there exists a splitting of (2.19), i.e., a homomorphism $\psi:\mathcal{J}\to\mathcal{F}$ such that $\psi\circ\epsilon=id$. Indeed, if ψ is given, $\nabla X=\psi(X,-\mathrm{ad}_X)$ is a connection. Conversely, if ∇ is a connection, $\psi(X,-\mathrm{ad}_X+\varphi)=\nabla X+\varphi$ is the required homomorphism.

Furthermore, if $\mathcal{L}$ is locally free and of finite rank, the sequence (2.19) behaves as a sequence of finite dimensional vector spaces, and leads to the exact sequence

$$0\to\mathrm{Hom}(\mathcal{L},\mathcal{F})\xrightarrow{p'}\mathrm{Hom}(\mathcal{J},\mathcal{F})\xrightarrow{\epsilon'}\mathrm{Hom}(\mathcal{F},\mathcal{F})\to 0, \tag{2.20}$$

then to the corresponding exact sequence of sheaf-cohomology

$$0\to H^0(M,\mathcal{A})\overset{p^*}{\to}H^0(M,\mathcal{B})\overset{\epsilon^*}{\to}H^0(M,\mathcal{E})\overset{\delta}{\to}H^1(M,\mathcal{A})\to\cdots. \tag{2.21}$$

In (2.20) and (2.21), the morphisms ϵ', ϵ^*, p', p^* are induced by ϵ and p of (2.19), $\mathcal{A}$, $\mathcal{B}$, $\mathcal{E}$ are the second, third and fourth sheaf of the sequence (2.20), respectively, and δ is the connecting morphism.

It follows that the condition for the existence of a connection is that the identity belongs to the image of ϵ^*, and this is equivalent to $\delta(id)=0$. Hence, if we define the *Atiyah class* by $a(M)=\delta(id)\in H^1(M,\mathrm{Hom}(\mathcal{L},\mathcal{F}))$, we precisely have the required result. Q.E.D.

Now, again, let $(M,\mathcal{C},\mathcal{L})$ be a HRL-ringed space. A two-form $\omega\in\Omega^2(M)$ will be called *nondegenerate* if the sheaf homomorphism $\flat_\omega:\mathcal{L}\to\Omega^1(M)$ defined by

$$\flat_\omega(X)(Y)=\omega(X,Y)\quad (X,Y\in\mathcal{L})$$

is an isomorphism. The inverse of this isomorphism will be denoted by $\#_\omega$. A two-form ω which is nondegenerate and *closed*, i.e., $d\omega=0$ is called a *symplectic form*, and, then, $(M,\mathcal{C},\mathcal{L},\omega)$ is called a *symplectic ringed space*.

Example 2.4: The differentiable and holomorphic symplectic manifolds obviously are examples of symplectic ringed spaces.

Example 2.5: Let (M,ω), where M is a $(2n+h)$-dimensional differentiable manifold and ω is a closed two-form of rank $2n$ over M, be a *presymplectic manifold*. It is well known (e.g., Ref. 10) that ker ω is tangent to an h-dimensional foliation $\mathcal{S}$, called the *characteristic foliation*, and that the form ω is projectable with respect to this foliation. By looking at the earlier Example 2.3, we see that the sheaf $\mathcal{L}$ of germs of projectable cross sections of the transversal bundle $\nu\mathcal{S}$ defines a ringed space structure over $M[\mathcal{C}=\mathcal{C}^\infty(M)]$, which is endowed with the symplectic form induced by ω.

Example 2.6: As in Example 2.2, let $A\to M$ be a Lie algebroid of rank $2m$, with the anchor map $\iota:A\to TM$. Then, any nondegenerate cross section $\omega\in\Gamma\wedge^2A^*$, which is closed with respect to the exterior differential d_A (see Refs. 7 and 4), makes the ringed space $(M,\mathcal{C}^\infty(M),\underline{A})$ into a symplectic ringed space. It is also convenient to say that (A,ω) is a *symplectic Lie algebroid*. Following are some concrete examples of symplectic Lie algebroids.

Example 2.7: If $P\in\Gamma\wedge^2TM$ is a regular Poisson structure of M, and if $\mathcal{S}$ is the symplectic foliation of P (e.g., Ref. 11), then $T\mathcal{S}$ with the leafwise two-form provided by the Poisson bracket of P is a symplectic Lie algebroid.

Example 2.8: Let (M,W) be an arbitrary Poisson manifold. Then T^*M is a Lie algebroid of anchor $\iota=\#_W$. A symplectic structure on this algebroid is a nondegenerate bivector field Q on M which is a cocycle in the Poisson–Lichnerowicz cohomology, i.e., $[W,Q]=0$ (e.g., Ref. 11).

Some of the usual symplectic notions straightforwardly transfer to symplectic ringed spaces. For instance, we may define $\Pi\in Alt_{\mathcal{C}}(\Omega^1(M)\times\Omega^1(M),\mathcal{C})$ by

$$\Pi(\sigma_1,\sigma_2)=\langle\sigma_1,\#_\omega\sigma_2\rangle,\quad \sigma_1,\sigma_2\in\Omega^1(M),$$

and also define $\#_\Pi:=\#_\omega$. Furthermore, we may define the *Hamiltonian gradient* X_f of any $f\in\mathcal{C}$ by $X_f=-\#_\Pi df$, and the *Poisson bracket*

$$\{f,g\}:=\omega(X_f,X_g)=\iota(X_f)g=-\iota(X_g)f=\Pi(df,dg). \tag{2.22}$$

The evaluation

$$0=d\omega(X_f,X_g,X_h)=\sum_{\mathrm{Cycl}(f,g,h)}\iota(X_f)\omega(X_g,X_h)-\sum_{\mathrm{Cycl}(f,g,h)}\omega([X_f,X_g],X_h)$$

$$=\sum_{\mathrm{Cycl}(f,g,h)}\{f,\{g,h\}\}-\sum_{\mathrm{Cycl}(f,g,h)}\langle dh,[X_f,X_g]\rangle$$

$$=\sum_{\mathrm{Cycl}(f,g,h)}\{f,\{g,h\}\}-\sum_{\mathrm{Cycl}(f,g,h)}(\iota[X_f,X_g])h$$

$$=\sum_{\mathrm{Cycl}(f,g,h)}\{f,\{g,h\}\}-\sum_{\mathrm{Cycl}(f,g,h)}(\iota(X_f)\iota(X_g)-\iota(X_g)\iota(X_f))h$$

$$=-\sum_{\mathrm{Cycl}(f,g,h)}\{f,\{g,h\}\}$$

shows that the bracket (2.22) satisfies the Jacobi identity. Since the Leibniz rule also obviously holds, we have a structure of *Poisson algebra sheaves* on $\mathcal{C}$. (See, for instance, Ref. 11 for the definition of a Poisson algebra.)

However, not all the classical symplectic properties hold. For instance, the Jacobi identity for the Poisson bracket (2.22) implies

$$X_{\{f,g\}}-[X_f,X_g]\in\ker\iota, \tag{2.23}$$

hence, the result is zero only at the *injectivity points* of ι. Another negative example is obtained if we consider the operation of a *Schouten–Nijenhuis bracket* on a HRL-ringed space (e.g., Ref. 7). Then, the general algebraic computations of Ref. 12 hold, and we have the formula

$$[\Pi,\Pi](df,dg,dh)=2\sum_{\mathrm{Cycl}(f,g,h)}\{\{f,g\},h\}. \tag{2.24}$$

But, since $\{df/f\in\mathcal{C}\}$ may not span $\Omega^1(M)$, generally, we may have $[\Pi,\Pi]\neq 0$.

Let us come back to the symplectic Lie algebroid (A,ω) of Example 2.6. Then, the symplectic objects $\flat_\omega$, Π, X_f, etc. have interpretations in terms of vector bundles: an isomorphism $\flat_\omega:A\to A^*$, a cross section $\Pi\in\Gamma\wedge^2 A$, cross sections $X_f\in\Gamma A$, etc. The Poisson bracket (2.22) becomes a Poisson algebra structure on $C^\infty(M)$, and there exists a corresponding Poisson bivector field $P\in\Gamma\wedge^2 TM$ such that

$$\{f,g\}=\Pi(d_Af,d_Ag)=P(df,dg),\quad [P,P]=0, \tag{2.25}$$

where the final bracket is the usual Schouten–Nijenhuis bracket on M.

For a better understanding of the relation between P and Π, let us consider the transposed homomorphism $\iota':T^*M\to A^*$ of the anchor $\iota:A\to TM$. Then we have

$$d_Af=\iota'(df),\quad \#_P=-\iota\circ\#_\Pi\circ\iota'. \tag{2.26}$$

Notice that the injectivity points of ι are the same as the surjectivity points of ι'. Accordingly, from (2.23) and (2.24), we see that the relations

$$X_{\{f,g\}}=[X_f,X_g],\quad [\Pi,\Pi]_A=0 \tag{2.27}$$

hold at the injectivity points of ι. If the set of injectivity points of ι is dense in M, the equalities (2.27) hold everywhere on M.

The considerations above suggest the following definition: a Poisson structure P on a differentiable manifold M will be called a *quasi-symplectic Poisson structure* if it is induced by a symplectic Lie algebroid, via formula (2.25).

Example 2.7 tells us that every regular Poisson structure is quasi-symplectic. Other quasi-symplectic Poisson structures are provided by Example 2.8. If (M,W) is a Poisson manifold which has a nonsingular Poisson two-cocycle Q (i.e., $Q\in\Gamma\wedge^2TM$, rank $Q=\dim M$, $[W,Q]=0$), the corresponding object Π of (2.25) is a usual two-form on M, and (2.25) defines a quasi-symplectic Poisson structure given by

$$\{f,g\}=\Pi(X_f^W,X_g^W)\quad[f,g\in C^\infty(M)],\tag{2.28}$$

where the arguments are the W-Hamiltonian vector fields of the functions f,g.

For a more concrete situation of this kind, let (M,Π,ϕ) be a *symplectic-Nijenhuis manifold*, with the symplectic form Π and the Nijenhuis tensor ϕ (see, for instance, Ref. 13). Then, M has a Poisson structure W defined by $\#_W=\phi\circ\#_Q$, where Q is the bivector field given by $\#_Q=\flat_\Pi^{-1}$. W is the first structure of the Poisson hierarchy of the symplectic-Nijenhuis manifold M, and it is compatible with the Poisson structure Q of M, i.e., $[W,Q]=0$.[13] Since Q is nondegenerate, we are in the situation described by the previous paragraph, and we get a quasi-symplectic Poisson structure

$$\begin{aligned}\{f,g\}=\Pi(\#_W df,\#_W dg)&=\langle\flat_\Pi\#_W df,\#_W dg\rangle\\&=-\langle\#_W\flat_\Pi\#_W df,dg\rangle=-\langle\phi\#_W df,dg\rangle=-\langle\phi^2\#_Q df,dg\rangle.\end{aligned}$$

Up to the sign, this is the second structure of the Poisson hierarchy of (M,Π,ϕ).[13] Thus, we have proven the following.

Proposition 2.1: *The second Poisson structure of the Poisson hierarchy of a symplectic-Nijenhuis manifold is a quasi-symplectic Poisson structure.*

Of course, the structures of Proposition 2.1 may have singular points.

One of the main ingredients of Fedosov quantization is a symplectic connection. The well known procedure of constructing symplectic connections on symplectic manifolds, as presented for instance, in Ref. 14, holds without modification on a symplectic ringed space.

Namely, if $(M,\mathcal{C},\mathcal{L})$ is a ringed space which possesses a nondegenerate two-form ω (*almost symplectic ringed space*), a connection ∇ on $\mathcal{L}$ (i.e., on M) is said to *preserve* ω if $\nabla_X\omega=0$, $\forall X\in\mathcal{L}$. If there exists a connection ∇^0 on M, the formula

$$\nabla_XY=\nabla^0_XY+\Theta(X,Y)+A(X,Y),\tag{2.29}$$

where

$$\omega(\Theta(X,Y),Z)=\tfrac{1}{2}(\nabla^0\omega)(Y,Z),\quad\omega(A(X,Y),Z)=B(X,Y,Z),\tag{2.30}$$

$\forall X,Y,Z\in\mathcal{L}$, and $\forall B\in\mathrm{Hom}_{\mathcal{C}}(\mathcal{L}\times\mathcal{L}\times\mathcal{L},\mathcal{C})$ which satisfies the condition $B(X,Y,Z)=B(X,Z,Y)$, yields all the connections of M which preserve ω. Θ and A are well defined by (2.30) because ω is nondegenerate.

Furthermore, formula (2.14) shows that a torsionless, ω-preserving connection may exist only if $d\omega=0$. Conversely, if we are in this latter case, and if we assume that ∇^0 has zero torsion [e.g., this ∇^0 is given by applying (2.16) to the original ∇^0], it turns out that ∇ of (2.29), and with

$$B(X,Y,Z)=\tfrac{1}{6}[(\nabla^0_Y\omega)(X,Z)+(\nabla^0_Z\omega)(X,Y)],\tag{2.31}$$

is an ω-preserving, torsionless connection. Indeed, from (2.29), and since $d\omega=\nabla^0\omega$ [in the sense of (2.15)], we deduce that $\omega(T_\nabla(X,Y),Z)=0$ for the chosen value (2.31) of B.

By definition, a connection which preserves the symplectic form ω and has zero torsion is called a *symplectic connection* on the symplectic ringed space $(M,\mathcal{C},\mathcal{L},\omega)$. Above, we saw that if M has an arbitrary connection, it also has symplectic connections, and we wrote down the expression of one symplectic connection ∇, defined by means of (2.31). It follows that all the symplectic connections are given by

$$\tilde{\nabla}_X Y = \nabla_X Y + C(X,Y),$$

where $Q(X,Y,Z) := \omega(C(X,Y),Z)$ is symmetric in all its arguments.

In analogy with Riemannian geometry, one defines the *covariant curvature tensor* of a symplectic connection, namely,

$$S(X_1,X_2,X_3,X_4) = -\omega(X_1,\Phi(X_2)(X_3,X_4)), \tag{2.32}$$

where Φ is given by (2.8). This tensor has the following symmetry properties:

$$\begin{gathered} S(X_1,X_2,X_3,X_4) = -S(X_1,X_2,X_4,X_3), \\ S(X_1,X_2,X_3,X_4) + S(X_1,X_3,X_4,X_2) + S(X_1,X_4,X_2,X_3) = 0, \\ S(X_1,X_2,X_3,X_4) = S(X_2,X_1,X_3,X_4). \end{gathered} \tag{2.33}$$

The first equality is obvious, the second is the *Bianchi identity* (2.13), and the third follows by expressing the derivations via the connection in the identity

$$(\iota(X_3)\iota(X_4) - \iota(X_4)\iota(X_3) - \iota([X_3,X_4]))(\omega(X_1,X_2)) = 0,$$

where $X_1,X_2,X_3,X_4 \in \mathcal{L}$.

Concerning examples of symplectic connections in cases other than symplectic manifolds, we first quote the case of a presymplectic manifold (M,ω). It is easy to see that a symplectic connection on M seen as a symplectic ringed space, as in Example 2.5, may be identified with a connection on M seen as a differentiable manifold, which preserves ω, has torsion tangent to the characteristic foliation of ω, and defines a transversal projectable connection of the same foliation. Details on the construction of these connections can be found in Ref. 15.

Another interesting case is that of a symplectic structure Q on the tangent Lie algebroid T^*M of a Poisson manifold (M,W) (see Example 2.8). In this case, it is natural to start with a connection D on the differentiable manifold M which satisfies the condition $D_X Q = 0$ $(X \in \Gamma TM)$. D exists since (M,Q^{-1}) is an almost symplectic manifold but, generally, D has a nonzero torsion T_D. The connection D yields a connection ∇ on the Lie algebroid T^*M[11,16] by putting

$$\nabla_\alpha \beta = D_{\#_W \alpha}\beta, \quad \alpha,\beta \in \Gamma T^*M. \tag{2.34}$$

A straightforward computation, which uses the Lie bracket of T^*M,[7,11]

$$\{\alpha,\beta\} = L_{\#_W\alpha}\beta - L_{\#_W\beta}\alpha - d(W(\alpha,\beta)),$$

yields the torsion T_∇ by the formula

$$\langle T_\nabla(\alpha,\beta),X\rangle = \alpha(T_D(\#_W\beta,X)) - \beta(T_D(\#_W\alpha,X)) - (D_X W)(\alpha,\beta). \tag{2.35}$$

Therefore, generally, $T_\nabla \neq 0$, and we must apply the general algorithm to get a torsionless symplectic connection on (T^*M,Q). The passage from ∇ of (2.34) to a torsionless connection is given by (2.16), i.e.,

$$\nabla^0_\alpha \beta = \tfrac{1}{2}(\nabla_\alpha\beta + \nabla_\beta\alpha + \{\alpha,\beta\}). \tag{2.36}$$

Furthermore, from (2.34), (2.36), and $d_{T^*M}Q = 0$ we get

$$(\nabla^0_\alpha Q)(\beta,\gamma) = \tfrac{1}{2}Q(\alpha,T_\nabla(\beta,\gamma)). \tag{2.37}$$

Finally, from (2.30), (2.31), and (2.37), we deduce the expression of a symplectic connection

$$\check{\nabla}_\alpha \beta = \nabla^0_\alpha \beta + E(\alpha,\beta), \tag{2.38}$$

where

$$Q(E(\alpha,\beta),\gamma) = \tfrac{1}{4} Q(\alpha, T_\nabla(\beta,\gamma)) + \tfrac{1}{12}[Q(\beta, T_\nabla(\alpha,\gamma)) + Q(\gamma, T_\nabla(\alpha,\beta))]. \tag{2.39}$$

III. FEDOSOV QUANTIZATION

In this section, we describe the Fedosov quantization procedure, following the original works, Refs. 1 and 2, with minor modifications, and emphasizing the ringed space setting. Other expositions of this procedure can be found in Refs. 17–19, etc.

First we recall the construction of the *Weyl algebra* of a complex symplectic vector space $(E, \omega \in \wedge^2 E)$ of dimension $2m$.

We begin with the associative, commutative algebra of formal Laurent series in the parameter h

$$W(E) := \left\{ w = \sum_{k=-\infty}^{\infty} \sum_{i=0}^{\infty} t_{ki} h^k / t_{ki} \in \odot^i E^*, \quad i + 2k \geqslant 0 \right\}, \tag{3.1}$$

where $\odot$ denotes the symmetric tensor product, and it defines the multiplication in $W(E)$.

This algebra will be graded by asking

$$\deg t_{ki} = i, \quad \deg h = 2, \tag{3.2}$$

and we will write the element $w \in W(E)$ which appears in (3.1) as

$$w = \sum_{p=0}^{\infty} \hat{w}_p, \quad \hat{w}_p = \sum_{2k+i=p} t_{ki} h^k. \tag{3.3}$$

In terms of vector spaces, this means

$$W(E) = \prod_{p=0}^{\infty} V_p(E), \quad V_p(E) = \prod_{k=-\infty}^{[p/2]} \odot^{p-2k} E^*. \tag{3.4}$$

Furthermore, consider the *contraction operators*

$$C^p_\omega : (\odot^i E^*) \otimes (\odot^j E^*) \to \odot^{i+j-2p} E^* \tag{3.5}$$

defined by 0 if $p > \min(i,j)$, and by

$$C^p_\omega(\alpha,\beta)(e_1,\ldots,e_{i+j-2p}) = \sum_{\sigma \in S_{i+j-2p}} \sum_{a_1,\ldots,a_p=1}^{m} \frac{1}{(i+j-2p)!} \cdot \alpha(b_{a_1^*},\ldots,b_{a_p^*}, e_{\sigma(1)},\ldots,e_{\sigma(i-p)}) \times \beta(b_{a_1},\ldots,b_{a_p}, e_{\sigma(i-p+1)},\ldots,e_{\sigma(i+j-2p)}) \tag{3.6}$$

if $p \leqslant \min(i,j)$. In (3.6), S is the symmetric group, $e_l \in E$ $(l = 1,\ldots,i+j-2p)$, and (b_a, b_{a*}) $(a^* := a+m)$ is an arbitrary ω-symplectic basis of E.

The contractions extend to series (3.1), and may be used to define the *Moyal product*

$$w \circ w' := \sum_{q=0}^{\infty} \frac{1}{q!} \left(-\frac{ih}{2} \right)^q C^q_\omega(w,w') \quad [w,w' \in W(E)], \tag{3.7}$$

which makes $W(E)$ into a graded [because of (3.2)], associative algebra, called the *Weyl algebra* of (E,ω).

Computations in the Weyl algebra become easy if we consider an arbitrary basis $(u_i)_{i=1}^{2m}$ of E, and represent an element $t \in \odot^q E^*$ by

$$t = t_{i_1,\dots,i_q} y^{j_1} \cdots y^{j_q} = \sum_{|\alpha|=q} \tau_{\alpha_1 \cdots \alpha_{2m}} (y^1)^{\alpha_1} \cdots (y^{2m})^{\alpha_{2m}} = \sum_{|\alpha|=q} \tau_\alpha y^\alpha. \tag{3.8}$$

In (3.8), (y^i) are the coordinates of a generic vector of E with respect to the basis (u_i), and for their indices we use (here and subsequently) the Einstein summation convention. Furthermore, the coefficients t are symmetric, the second equality is obtained by collecting the various factors y^i into a power of y^i, and the third equality is the formal notation of its left hand side, i.e.,

$$\alpha = (\alpha_1,\dots,\alpha_{2m}) \quad (\alpha_i \geqslant 0), \quad y^\alpha = (y^1)^{\alpha_1} \cdots (y^{2r})^{\alpha_{2m}}, \quad |\alpha| = \alpha_1 + \cdots + \alpha_{2m}.$$

With this representation, an element $w \in W(E)$ becomes

$$w(y,h) = \sum_{k=-\infty}^{k=\infty} \sum_{|\alpha|=0}^{\infty} h^k t_{k,\alpha} y^\alpha, \quad |\alpha| + 2k \geqslant 0, \tag{3.9}$$

the usual product of polynomials corresponds to the symmetric tensor product, and the Moyal product is

$$\begin{aligned} w \circ w' &= \sum_{q=0}^{\infty} \frac{1}{q!} \left(-\frac{ih}{2} \right)^q \omega^{i_1 j_1} \cdots \omega^{i_q j_q} \frac{\partial^q w}{\partial y^{i_1} \cdots \partial y^{i_q}} \frac{\partial^q w'}{\partial y^{j_1} \cdots \partial y^{j_q}} \\ &= \exp\left(-\frac{ih}{2} \omega^{ij} \frac{\partial}{\partial z^i} \frac{\partial}{\partial u^j} \right) (w(z,h) w'(s,h)|_{z=s=y}), \end{aligned} \tag{3.10}$$

where $\omega^{ih} \omega_{hk} = \delta^i_k$ and ω_{hk} are the u-components of ω.

It follows easily that the center $Z(W(E))$ is the algebra of formal power series $\mathbf{C}[[h]]$.[1,2]

The next step consists of *enlarging* the Weyl algebra $W(E)$ to the associative algebra

$$\hat{W}(E) := W(E) \otimes (\oplus_{q=0}^{2m} \wedge^q E^*). \tag{3.11}$$

If (u_i) is the basis used in (3.8), and if (ν^i) is its dual cobasis, $\lambda \in \hat{W}(E)$ may be seen as

$$\lambda = \sum_{k=-\infty}^{\infty} \sum_{p=0}^{\infty} \sum_{q=0}^{2m} h^k \lambda_{kpqi_1 \cdots i_p j_1 \cdots j_q} y^{i_1} \cdots y^{i_p} \nu^{j_1} \wedge \cdots \wedge \nu^{j_q}, \quad p + 2k \geqslant 0, \tag{3.12}$$

where the coefficients are symmetric in the indices i, and skew-symmetric in the indices j. The product of $\hat{W}(E)$ is defined by (3.10) with a wedge product of the partial derivatives which appear in that formula.

In $\hat{W}(E)$, the *commutant* is defined as the natural extension of

$$[\lambda, \mu] = \lambda \circ \mu - (-1)^{\tilde{\lambda}\tilde{\mu}} \mu \circ \lambda, \tag{3.13}$$

where tilde denotes the degree of the wedge product factor of an element of $\hat{W}(E)$.

The center $Z(\hat{W}(E))$ is $\mathbf{C}[[h]] \otimes (\oplus_{q=0}^{2m} \wedge^q E^*)$, and one has the *central projections*[1,2] of λ of (3.12):

$$\lambda_0 := \sum_{k=0}^{\infty} \sum_{q=0}^{2m} h^k \lambda_{k0qj_1\cdots j_q} \nu^{j_1} \wedge \cdots \wedge \nu^{j_q} \in Z(\hat{W}(E)), \tag{3.14}$$

$$\lambda_{00} := \sum_{k=0}^{\infty} h^k \lambda_{k00} \in Z(W(E)). \tag{3.15}$$

The following basis-independent operators are essential in the subsequent computations:[1,2]

$$\delta\lambda := \sum_{j=1}^{2m} \nu^j \wedge \frac{\partial \lambda}{\partial y^j}, \quad \delta^*\lambda = \sum_{j=1}^{2m} y^j (i(u_j)\lambda). \tag{3.16}$$

These operators satisfy the properties

$$\delta^2 = 0, \quad \delta^{*2} = 0, \quad \delta(a \circ b) = (\delta a) \circ b + (-1)^{\tilde{a}} a \circ \delta b. \tag{3.17}$$

Furthermore, $\forall \lambda \in \hat{W}(E)$, one can check the *Hodge decomposition* formula

$$\lambda = \delta\delta^{-1}\lambda + \delta^{-1}\delta\lambda + \lambda_{00}, \tag{3.18}$$

where δ^{-1} is defined on the (p,q)-term of (3.12) by

$$\delta^{-1}\lambda := \frac{1}{p+q}\delta^*\lambda. \tag{3.19}$$

We intend to apply the previous algebraic constructions to symplectic ringed spaces. To be able to do so, in what follows we assume that $\mathcal{C}$ is a subsheaf of the sheaf of germs of continuous, complex valued functions on M and that $(M,\mathcal{C},\mathcal{L},\omega)$ is a symplectic ringed space of finite rank. Then $\mathcal{L}$ must be the sheaf of germs of cross sections of a complex symplectic vector bundle over M.[20] This implies that the rank of the space is even, say $2m$, and that $\mathcal{L}$ has local *symplectic bases*, i.e., local bases $(X_i)_{i=1}^{2m}$ such that

$$\omega(X_a, X_b) = 0, \ \ \omega(X_a, X_{b+m}) = \delta_{ab}, \quad \omega(X_{a+m}, X_{b+m}) = 0, \quad a,b = 1,\ldots,r.$$

Then the previous algebraic constructions may be performed on each stalk of $\mathcal{L}$, and using local symplectic bases of germs (X_i). Accordingly, we get *sheaves of Weyl algebras* $\mathcal{W}(\mathcal{L})$, $\hat{\mathcal{W}}(\mathcal{L})$, and the formulas developed earlier in this section hold, with germs instead of algebraic tensors overall. In particular, there is a *central sheaf* $\mathcal{Z}(\mathcal{W}(\mathcal{L})) = \mathcal{C}[[h]]$, which consists of germs of formal power series in h, and a *central sheaf* $\mathcal{Z}(\hat{\mathcal{W}}(\mathcal{L})) = \mathcal{C}[[h]] \otimes (\oplus_{q=0}^{2m} \wedge^q \mathcal{L})$.

In the ringed setting, Fedosov's quantization will be an embedding of $\mathcal{C}[[h]]$ onto the *parallel germs* of $\mathcal{W}(\mathcal{L})$ with respect to a *generalized symplectic connection*. Accordingly, we shall assume that $(M,\mathcal{C},\mathcal{L},\omega)$ has connections [it has a vanishing Atiyah class $a(M)$, as defined in Sec. II], and take a torsionless, symplectic connection ∇ on this space. Then, ∇ extends to a *covariant exterior differential* $\nabla : \hat{\mathcal{W}}(\mathcal{L}) \to \hat{\mathcal{W}}(\mathcal{L})$ defined by[1,2]

$$\nabla(t \otimes \theta) = \sum_{i=1}^{2m} \nu^i \wedge \nabla_{X_i}(t \otimes \theta) \quad (t \in \odot^q \mathcal{L}^*, \theta \in \wedge^s \mathcal{L}^*), \tag{3.20}$$

where (X_i) is a local basis of $\mathcal{L}$ and (ν^i) is the dual cobasis. The definition is invariant by a change of the local basis, and (3.20) reduces to (2.15) if there is no symmetric factor t. Since the connection has zero torsion, in the case of a differential form θ one has $\nabla\theta = d\theta$. Furthermore, since $\nabla\omega = 0$, (3.10) shows that

$$\nabla(\lambda \circ \mu) = (\nabla\lambda) \circ \mu + (-1)^{\tilde{\lambda}} \lambda \circ \nabla\mu, \quad \lambda, \mu \in \hat{\mathcal{W}}(\mathcal{L}). \tag{3.21}$$

The operator (3.20) is what is actually needed in Fedosov quantization, and, subsequently, we will think of this operator when referring to a connection. Fedosov[1,2] writes the operator ∇ in a convenient way as follows. Consider the local equations (2.17) of the connection ∇, and assume that the basis $(\xi_i = X_i)$ used in these equations is symplectic. Then, the symplectic character of the connection is equivalent to

$$\Gamma_{ijk} = \Gamma_{jik} \quad (\Gamma_{ijk} := \omega_{is}\Gamma^s_{jk}). \tag{3.22}$$

Accordingly, $\forall x \in M$, there exists a germ

$$\Gamma := \tfrac{1}{2}\Gamma_{ijk} y^i y^j \nu^k \in (\hat{\mathcal{W}}(\mathcal{L}))_x, \tag{3.23}$$

and *Fedosov's formula* is

$$\nabla\lambda = d\lambda + \frac{i}{h}[\Gamma, \lambda], \tag{3.24}$$

for λ given by (3.12), and with d applied as if h, y would be constants. Formula (3.24) is easily checked for $\lambda = \lambda_i \nu^i$ and $\lambda = \lambda_i y^i$, and it holds in the general case because d and the commutant $[\Gamma, \ ]$ are derivations of $\hat{\mathcal{W}}(\mathcal{L})$. Notice that the germs (3.23) do not define a global section of $\hat{\mathcal{W}}(\mathcal{L})$.

The same method yields the formulas[1,2]

$$\delta\lambda = -\frac{i}{h}[\varpi, \lambda], \quad \varpi := \delta^* \omega = \omega_{ij} y^i \nu^j, \tag{3.25}$$

$$\nabla\delta + \delta\nabla = 0, \tag{3.26}$$

$$\nabla^2\lambda = \frac{i}{h}[S, \lambda], \quad S := -\frac{1}{4} S_{ijkl} y^i y^j \nu^k \wedge \nu^l, \tag{3.27}$$

S_{ijkl} being the components of the covariant curvature tensor of the symplectic connection ∇, which is known to be symmetric in the first two arguments and skew symmetric in the last two arguments [see (3.33)].

Fedosov's formula (3.24) suggests a definition of *generalized symplectic connections*[1,2] as operators

$$\hat{\nabla}\lambda = \nabla\lambda + \frac{i}{h}[\gamma, \lambda], \tag{3.28}$$

where

$$\gamma = \sum_{k=-\infty}^{\infty} \sum_{p=0}^{\infty} h^k \gamma_{ki_1 \cdots i_p j} y^{i_1} \cdots y^{i_p} \nu^j \quad (p + 2k \geqslant 0) \tag{3.29}$$

are germs which define a global section of $\Gamma(\mathcal{W}(\mathcal{L}) \otimes \mathcal{L}^*)$. Then, a straightforward computation yields the *generalized curvature* Φ defined by means of the formulas

$$\hat{\nabla}^2\lambda = \frac{i}{h}[\Phi, \lambda], \quad \Phi = S + \nabla\gamma + \frac{i}{h}\gamma^2, \tag{3.30}$$

and the *Bianchi identity*

$$\hat{\nabla}\Phi=\nabla\Phi+\frac{i}{h}[\gamma,\Phi]=0. \tag{3.31}$$

By definition, if $\hat{\nabla}^2\lambda=0$ for all $\lambda\in\hat{\mathcal{W}}(\mathcal{L})$, $\hat{\nabla}$ is called an *Abelian connection*.

Now, we come to the result which is at the heart of Fedosov quantization.[1,2,17,19]

Theorem 3.1: *Let $(M,\mathcal{C},\mathcal{L},\omega)$ be a symplectic ringed space of finite rank $2m$, with the sheaf $\mathcal{C}$ being a subsheaf of germs of continuous, complex valued functions, and which has connections. Then, there exist generalized, symplectic, Abelian connections $\hat{\nabla}$ on M. Furthermore, for any Abelian connection $\hat{\nabla}$, for any $a\in\mathcal{C}[[h]]$, there exists a unique $\lambda\in\mathcal{W}(\mathcal{L})$ with central projection $\lambda_{00}=a$, such that $\hat{\nabla}\lambda=0$.*

Proof: Consider a generalized connection (3.28), where $\gamma=\varpi+r$ for ϖ given by (3.25), and for an element

$$r=\sum_{p\geqslant 2}^{\infty}\hat{r}_p\in\mathcal{W}(\mathcal{L})\otimes\mathcal{L}^*, \tag{3.32}$$

which satisfies the condition $\delta^{-1}r=0$. The last condition implies that r has the central projection $r_0=0$; therefore, by the Hodge decomposition (3.18) $r=\delta^{-1}\delta r$.

The curvature form of this connection $\hat{\nabla}$ is given by (3.30) and, in view of (3.10), (3.13), (3.25) and $\nabla\omega=0$, it becomes

$$\Phi=S+\nabla r-\delta r+\frac{i}{h}r^2-\omega. \tag{3.33}$$

Since $\omega\in\mathcal{Z}(\hat{\mathcal{W}}(\mathcal{L}))$, the condition

$$\delta r=S+\nabla r+\frac{i}{h}r^2 \tag{3.34}$$

ensures $\hat{\nabla}^2=0$.

We show that (3.34) has a unique solution r with the required properties. Uniqueness will ensure that the germs r define a global cross section of $\mathcal{W}(\mathcal{L})\otimes\mathcal{L}^*$. Indeed, by applying to (3.34) the operator δ^{-1}, we get

$$\delta^{-1}\delta r=r=\delta^{-1}S+\delta^{-1}\nabla r+\frac{i}{h}\delta^{-1}(r^2), \tag{3.35}$$

which is equivalent to the recurrence formula

$$\hat{r}_p=\widehat{(\delta^{-1}S)}_p+\delta^{-1}\nabla\hat{r}_{p-1}+\frac{i}{h}\delta^{-1}\left(\sum_{i=2}^{p-3}\hat{r}_i\circ\hat{r}_{p-1-i}\right). \tag{3.36}$$

Equations (3.32) and (3.36) imply $\hat{r}_2=0$, and, then,

$$\hat{r}_p=(\delta^{-1}\nabla)^{p-3}\delta^{-1}S+\frac{i}{h}\sum_{s=0}^{p-7}\left[(\delta^{-1}\nabla)^s\delta^{-1}\left(\sum_{j=3}^{p-s-2}\hat{r}_j\circ\hat{r}_{p-s-j-1}\right)\right]\quad(p\geqslant 3). \tag{3.37}$$

Now, it remains to establish that the obtained germ r satisfies Eq. (3.34). From (3.35), using the Hodge decomposition (3.18) and the Bianchi identity (3.33), we get

$$\delta r=\delta\delta^{-1}S+\delta\delta^{-1}\nabla r+\frac{i}{h}\delta\delta^{-1}r^2=S+\nabla r+\frac{i}{h}r^2-\delta^{-1}\delta\left(\nabla r+\frac{i}{h}r^2\right). \tag{3.38}$$

Formulas (3.33) and (3.38) give us the curvature

$$\Phi = \delta^{-1}\delta\left(\nabla r + \frac{i}{h}r^2\right) - \omega,$$

and, since

$$\hat{\nabla}\omega \overset{(2.28)}{=} \nabla\omega + \frac{i}{h}[\varpi + r, \omega] = \nabla\omega = d\omega = 0,$$

the Bianchi identity (3.31) yields

$$\hat{\nabla}\delta^{-1}\delta\left(\nabla r + \frac{i}{h}r^2\right) = 0. \tag{3.39}$$

But, if we look at any λ such that $\delta\lambda = 0$ and $\lambda_{00} = 0$, we have $\lambda = \delta\delta^{-1}\lambda$, and we see that

$$\hat{\nabla}\delta^{-1}\lambda \overset{(2.28)}{=} \nabla\delta^{-1}\lambda - \delta\delta^{-1}\lambda + \frac{i}{h}[r, \delta^{-1}\lambda] = 0$$

implies

$$\lambda = \nabla\delta^{-1}\lambda + \frac{i}{h}[r, \delta^{-1}\lambda]. \tag{3.40}$$

This is equivalent to a recurrence relation

$$\hat{\lambda}_p = \nabla\delta^{-1}\hat{\lambda}_{p-1} + \frac{i}{h} \quad (\text{terms in } \hat{\lambda}_i, \quad i \leqslant p-4), \tag{3.41}$$

which yields $\lambda = 0$. Since

$$\lambda = \delta\left(\nabla r + \frac{i}{h}r^2\right)$$

satisfies the required condition, the last term of (3.38) vanishes, and we are done.

Now, we address the second part of the theorem.

From (3.25) and (3.28), we see that $\hat{\nabla}\lambda = 0$ means

$$\delta\lambda = D\lambda, \quad D\lambda = \nabla\lambda + \frac{i}{h}[r, \lambda]. \tag{3.42}$$

Since $\lambda \in \mathcal{W}(\mathcal{L})$, $\delta^{-1}\lambda = 0$, and (3.18) and (3.42) yield

$$\lambda = \lambda_{00} + \delta^{-1}D\lambda = a + \delta^{-1}D\lambda, \tag{3.43}$$

and, with the decomposition $\lambda = \Sigma_{p=0}^{\infty}\hat{\lambda}_p$, we get the recurrence formula

$$\hat{\lambda}_p = (\hat{a})_p + \delta^{-1}\nabla\hat{\lambda}_{p-1} + \frac{i}{h}\delta^{-1}([r, \lambda]_{p-1}), \tag{3.44}$$

which uniquely defines all the terms $\hat{\lambda}_p$.

Particularly, if

$$a=\sum_{k=0}^{\infty} h^k f_k, \tag{3.45}$$

the first eight terms λ_p are given by

$$\hat{\lambda}_p=\sum_{s=0}^{[p/2]} h^s(\delta^{-1}\nabla)^{p-2s} f_s, \quad 0\leqslant p\leqslant 4, \tag{3.46}$$

$$\hat{\lambda}_p=\sum_{s=0}^{[p/2]} h^s(\delta^{-1}\nabla)^{p-2s} f_s+\frac{i}{h}\sum_{s=0}^{p-5}(\delta^{-1}\nabla)^s\delta^{-1}\sum_{j=3}^{p-s-2}[\hat{r}_j,\hat{\lambda}_{p-s-j-1}], \quad 5\leqslant p\leqslant 8. \tag{3.47}$$

The terms $\hat{\lambda}_p$ for larger values of p include commutants with several factors r. If for any $\mu\in\hat{W}(\mathcal{L})$ we denote

$$\overline{\mu}=\sum_{s=0}^{\infty}(\delta^{-1}\nabla)^s\mu, \tag{3.48}$$

and reorder the terms of λ, as determined by (3.46), (3.47), etc., we obtain

$$\lambda=\overline{a}+\frac{i}{h}\delta^{-1}[r,\overline{a}]+\left(\frac{i}{h}\right)^2\delta^{-1}[r,\delta^{-1}[\overline{r,\overline{a}}]]+\cdots. \tag{3.49}$$

Finally, we must check that (3.43) implies $\hat{\nabla}\lambda=0$. First, we notice that (3.43) implies

$$\delta^{-1}\hat{\nabla}\lambda=\delta^{-1}D\lambda-\delta^{-1}\delta\lambda=\lambda-a-\delta^{-1}\delta\lambda=\delta\delta^{-1}\lambda=0. \tag{3.50}$$

This allows us to use the Hodge decomposition (3.18) for $\hat{\nabla}\lambda$, the Abelian character of $\hat{\nabla}$, and (3.43) to get

$$\hat{\nabla}\lambda=\delta^{-1}\delta\hat{\nabla}\lambda=\delta^{-1}(D\hat{\nabla}\lambda-\hat{\nabla}^2\lambda)=\delta^{-1}D\hat{\nabla}\lambda. \tag{3.51}$$

Since the operator $\delta^{-1}D$ raises the degree, (3.51) yields a recurrence relation for the homogeneous terms of $\hat{\nabla}\lambda$, in the sense of the decomposition (3.3), which shows that $\hat{\nabla}\lambda=0$. Q.E.D.

As a consequence of this main theorem we see that there exists an injection

$$l:\mathcal{C}[[h]]\to\mathcal{W}(\mathcal{L}), \tag{3.52}$$

which sends the formal power series $a\in\mathcal{Z}(\mathcal{L})$ to the $\hat{\nabla}$-parallel section λ of $\mathcal{W}(\mathcal{L})$ which has the central projection $\lambda_{00}=a$.

This injection precisely is Fedosov quantization. The reason to see it as a quantization process with links to quantum physics is that the mapping l leads to a deformation of the commutative product fg into a noncommutative product, also known as a *star product*,[21,22] namely,

$$f*g=l^{-1}(l(f)\circ l(g)), \quad f,g\in\mathcal{C}. \tag{3.53}$$

The definition is correct since (3.21) and (3.28) show that $l(f)\circ l(g)$ belongs to the image of l.

In various concrete cases such as the ones in Examples (2.5)–(2.9), the mapping l is defined by corresponding versions of formulas (3.37), (3.46), (3.47), (3.49), etc. In particular, since a Lie algebroid always has connections, our presentation shows that Fedosov quantization works for the regular Poisson manifolds and, also, for the quasi-symplectic Poisson manifolds, even if the latter are nonregular. In other cases, the vanishing Atiyah class condition is required, and it may be very restrictive. For instance, this happens in the case of holomorphic symplectic manifolds.[9]

Note added in proof. In the paper[23] Nest and Tsygan give the classifications of general star products on symplectic Lie algebroids and holomorphic symplectic manifolds based on Fedosov quantization.

Motion of a Yang–Mills particle in a monopole field is proposed and planar orbits are observed. The planar orbits are studied further with some numerical analysis of the equations of motion. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1415088]

I. INTRODUCTION

In the Yang–Mills quantum field theories, such as electroweak and QCD, particles are assigned with some charges like hypercharge and color. In QED (an Abelian gauge theory) the charge is a conserved quantity that is related to the gauge-invariant property of the Lagrangian and expressed by a unique real number. In the non-Abelian theories the charge can no longer be expressed by a unique real number and might be displayed as a vector in the space of the gauge group (space of symmetry).

Wong extracted the classical equations of motion of a particle with a non-Abelian charge in a classical Yang–Mills field. The force on a (non-Abelian) particle in a (non-Abelian) field is the modification of the Lorentz force in the usual electrodynamics. Now the charge is a vector (in the isospace) and therefore may evolve in time. Wong has given the equation of evolution of the charge isovector, while the length of the charge isovector remains constant.

As an application of the Wong equations of motion we consider the 't Hooft or BPS monopoles and launch a Yang–Mills test particle in the field of the monopole. The speed and the total angular momentum of the particle and the field are constants of motion. We explain the equations of motion and enumerate some results. An interesting consequence of this motion is planar orbits. When a test particle is launched in the field of the monopole, while the direction of its charge isovector is normal to its position and velocity vectors, it will move in the plane normal to the charge isovector forever. We have explained the planar motions and the conditions for bounded orbits and their stability, and performed some numerical analysis of the equations of motion.

II. EQUATIONS OF MOTION OF YANG–MILLS PARTICLES IN YANG–MILLS FIELDS

In analogy with an Abelian system (a classical point charged particle interacting with the electromagnetic field), one can see a rich range of phenomena that occurs in non-Abelian systems. Wong proposed a system of equations to describe the classical dynamics of such systems (consisting of colored particles in non-Abelian fields) by generalizing the Lorentz force and Maxwell equations of electrodynamics. The non-Abelian particle is characterized by an isovector $\vec{I}$ (in analogy with the gauge invariant scalar charge q of an electrically charged point particle) which transforms under the adjoint representation of the internal symmetry group of the field—i.e., the gauge group. The following equations have been formulated by Wong:[1]

$$m\ddot{x}_\mu = eF^a_{\mu\nu} I^a \dot{x}^\nu, \tag{2.1}$$

$$\dot{I}^a + e\epsilon^{abc} A^b_\mu I^c \dot{x}^\mu = 0, \tag{2.2}$$

a)Electronic mail: azizi@physics.susc.ac.ir

where $x(\tau)$ is the world line of the particle in space–time, τ is proper time and ''dot'' denotes differentiation with respect to the proper time. The right-hand side of Eq. (2.1) obviously represents a generalization of the Lorentz force in which A^a_μ is a non-Abelian gauge potential and $F^a_{\mu\nu}$ are the gauge field strengths:

$$F^a_{\mu\nu}=\partial_\mu A^a_\nu-\partial_\nu A^a_\mu+e\,\epsilon^{abc}A^b_\mu A^c_\nu. \tag{2.3}$$

In the above equation e is coupling constant. In the limit we are considering a particle is thus described by an internal isovector $\vec{I}$ as well as its space–time coordinates. An immediate consequence of Eq. (2.2) is

$$\frac{d}{d\tau}I^2=0, \quad \text{where } I^2\equiv I^aI^a, \tag{2.4}$$

which shows the isovector I^a performs a precessional motion in isospace, i.e., the vector I^a sweeps the surface of a sphere in isospace such that the radius of this sphere could be understood as norm (absolute value) of charge isovector. Equivalently one can interpret Eq. (2.4) as a conservation law of scalar charge for a non-Abelian point particle.

III. EQUATIONS OF MOTION OF A YANG–MILLS PARTICLE IN A MONOPOLE FIELD

As an interesting problem, one can consider the interaction between a colored particle and a monopole. After discovery of the first monopole in the Yang–Mills–Higgs theories,[2,3] Schechter[4] and later Fehér[5] investigated the classical motion of a colored test particle in an external field given by the BPS monopole.

The ansatz of 't Hooft–Polyakov monopole for a finite-energy nonsingular classic solution can be of the form[2] (see also Ref. 6)

$$A^{a0}(\vec{r})=J(r)\frac{x^a}{er^2}, \tag{3.1}$$

$$A^{ai}(\vec{r})=\epsilon^{aij}\frac{x^j}{er^2}[1-K(r)], \tag{3.2}$$

$$\Phi^a(\vec{r})=\frac{x^a}{er^2}H(r), \tag{3.3}$$

where $J(r)$, $K(r)$, and $H(r)$ are certain functions of the radius r. In the last equation Φ^a is the Higgs field. For the 't Hooft–Polyakov monopoles, replacing the above ansatz with $J(r)=0$ in Eq. (2.3), a direct calculation shows

$$F^a_{0i}=0, \tag{3.4}$$

$$F^a_{ij}=\frac{1}{er^2}\left\{-2\,\epsilon^{aij}(1-K)+\epsilon^{ijk}\frac{x^ax^k}{r^2}(1-K)^2+(\epsilon^{aik}x^jx^k+\epsilon^{akj}x^ix^k)\frac{1}{r^2}(rK'+2(1-K))\right\}, \tag{3.5}$$

where prime indicates d/dr. Using the identity

$$\epsilon^{ijl}x^lx^k+\epsilon^{ilk}x^lx^j+\epsilon^{ljk}x^lx^i=r^2\,\epsilon^{ijk}, \tag{3.6}$$

Eq. (3.5) is simplified to

$$F^a_{ij}=\epsilon^{ijk}\frac{1}{er^2}\left\{\frac{x^ax^k}{r^2}(K^2-rK'-1)+rK'\,\delta^{ak}\right\}. \tag{3.7}$$

For the BPS monopole K and H are supposed to be[7,8]

$$K=\frac{aer}{\sinh(aer)},\quad H=aer\coth(aer)-1, \tag{3.8}$$

where a is magnitude of Higgs field at vacuum.

At large distances, K and K' vanish exponentially; the field has the form of a pure magnetic monopole. Thus an electrically charged particle coupled to vector potential would move exactly as a charged particle in a pure magnetic field.

In a nonrelativistic frame, $\tau=x_0=t$, using Eqs. (3.7), Eqs. (2.1) and (2.2) can be written in vector notation

$$m\dot{\vec{v}}=\frac{K^2-rK'-1}{r^4}(\vec{v}\times\vec{r})(\vec{r}\cdot\vec{I})+\frac{K'}{r}(\vec{v}\times\vec{I}), \tag{3.9}$$

$$\dot{\vec{I}}=\frac{1-K}{r^2}(\vec{r}\times\vec{v})\times\vec{I}. \tag{3.10}$$

Define at each point along the trajectory of the particle an orthogonal set of vectors,

$$\vec{r},\ \ \vec{w}=\vec{r}\times\vec{v},\ \ \vec{z}=\vec{r}\times\vec{w},\quad \text{where}\ \ \vec{v}=\frac{d\vec{r}}{dt}. \tag{3.11}$$

Then without loss of generality, non-Abelian charge I^a may be written as

$$\vec{I}=\alpha\hat{r}+\beta\hat{w}+\gamma\hat{z}, \tag{3.12}$$

where $\hat{r}$, $\hat{w}$ and $\hat{z}$ are unit vectors along the three directions. The coefficients α, β and γ satisfy

$$\alpha^2+\beta^2+\gamma^2=\text{const}, \tag{3.13}$$

which is a direct consequence of Eq. (2.4). Substituting Eq. (3.12) into Eq. (3.10) gives three equations for α, β and γ:

$$\dot{\alpha}=-\gamma|\vec{w}|K/r^2, \tag{3.14}$$

$$\dot{\beta}=\frac{r\gamma}{|\vec{w}|^2}\dot{\vec{v}}\cdot(\vec{r}\times\vec{v}), \tag{3.15}$$

$$\dot{\gamma}=-\frac{r\beta}{|\vec{w}|^2}\dot{\vec{v}}\cdot(\vec{r}\times\vec{v})+\frac{\alpha|\vec{w}|K}{r^2}. \tag{3.16}$$

Next, using the moving frame (3.11) in Eq. (3.9) we obtain the ordinary equation of motion:

$$m\dot{\vec{v}}=\frac{\beta}{r^2}|\vec{w}|K'\,\hat{r}+\frac{\beta}{r^2}(\vec{r}\cdot\vec{v})K'\,\hat{z}-\frac{1}{r^3}[\,\alpha|\vec{w}|(K^2-1)+\gamma r(\vec{r}\cdot\vec{v})K'\,]\hat{w}. \tag{3.17}$$

In addition to the length of the charge isovector, $|\vec{I}|$, the kinetic energy (or the magnitude of velosity $|\vec{v}|$) and the total angular momentum of the particle and the fields,[9]

$$\vec{J}=m(\vec{r}\times\vec{v})+K\vec{I}+\frac{(1-K)(\vec{r}\cdot\vec{I})}{r^2}\vec{r}, \tag{3.18}$$

are constants of motion.

For small distances near the center of the BPS monopole, $K=aer/\sinh(aer)\sim 1$ and $K'\sim 0$. So from Eqs. (3.9) and (3.10), $m\dot{\vec{v}}=0$ and $\dot{\vec{I}}=0$, which show a free motion around the center of the BPS monopole. Schechter has mentioned some properties of motion at large distances in Ref. 4.

Considering a general solution for equations of motion (3.9) and (3.10) is not easy. So, we explain some specific solutions in some detail.

If the particle is launched in a radial direction, while the charge isovector is also initially radial, the particle will move uniformly in the radial direction. This is the only choice for radial motion. This can be simply seen from the equations of motion (3.9) and (3.10), when $\vec{r}\times\vec{v}$ vanishes as the condition for radial motion. So $m\dot{\vec{v}}=(K'/r)(\vec{v}\times\vec{I})$ and $\dot{\vec{I}}=0$. For a radial motion, the acceleration $\dot{\vec{v}}$ must be in the radial direction, while we see $\vec{v}\times\vec{I}$ is normal to the radial direction (as we know $\vec{v}$ is radial). So the only possible case is a constant charge isovector $\vec{I}$ along the radial axis, and therefore a uniform radial motion occurs because $m\dot{\vec{v}}=0$. If the initial velocity points to the origin, the particle passes through the origin.

If the particle is launched in the field (in any direction) while the charge isovector is normal to the both initial particle's radial direction and velocity vector, then the particle will move on a plane normal to the charge isovector and the charge isovector remains constant. Under these circumstances radial motion is not allowed. We will show bounded orbits are allowed in the planar motion sector, while we have not observed bounded motions in the general three-dimensional theory.

In any case other than the two cases mentioned, the particle will move on a spatial curve. At the end of this section a numerical analysis of the general three-dimensional equations is described. In the next section we explain the planar motion of a particle in field of the BPS monopole.

IV. PLANAR ORBITS

A planar motion is identified by a conserved vector normal to the plane of motion. For nonzero values of position and velocity of a nonuniform motion, the plane of motion is normal to $\vec{r}\times\vec{v}$ at each time. Therefore, if in Eq. (3.17) the component of the force in the direction $\vec{r}\times\vec{v}$ vanishes, a planar motion takes place, provided that the equation of evolution for the charge isovector is valid.

A quick look at Eqs. (3.14)–(3.17) shows if we put $\alpha=\gamma=0$ we get

$$\dot{\alpha}=0, \tag{4.1}$$

$$\dot{\beta}=0, \tag{4.2}$$

$$\dot{\gamma}=-\frac{r\beta}{|\vec{w}|^2}\dot{\vec{v}}\cdot(\vec{r}\times\vec{v}), \tag{4.3}$$

$$m\dot{\vec{v}}=\frac{\beta}{r^2}|\vec{w}|K'\,\hat{r}+\frac{\beta}{r^2}(\vec{r}\cdot\vec{v})K'\,\hat{z}, \tag{4.4}$$

where in the last equation there is no component along $\vec{r}\times\vec{v}$ [i.e., $\dot{\vec{v}}\cdot(\vec{r}\times\vec{v})=0$] on the right-hand side, and therefore the condition for a planar motion is obtained. Using Eq. (4.4) the third equation becomes

$$\dot{\gamma}=0. \tag{4.5}$$

The equations (4.1) and (4.5) are consistent with the assumption $\alpha=\gamma=0$, and Eq. (4.2) becomes

$$\beta=\text{const}\neq 0, \tag{4.6}$$

which is required for the nonvanishing charge isovector. So the equations of motion (3.14)–(3.17) transformed to a new set of consistent equations which has only one equation, Eq. (4.4), to be solved. This equation as we said has no component in the direction normal to the position and velocity vectors, and this was the condition for the planar motion we mentioned at the beginning of this subsection. So $\alpha=\gamma=0$ implies planar motion. We will show also that the planar motion condition necessitates $\alpha=\gamma=0$.

To have no term in the direction normal to the plane of motion (as the condition for planar motion), we need to equate the coefficient of $\hat{w}$ in Eq. (3.17) to zero. So, Eq. (3.17) breaks into two separate equations

$$m\dot{\vec{v}}=\frac{\beta}{r^2}|\vec{w}|K'\,\hat{r}+\frac{\beta}{r^2}(\vec{r}\cdot\vec{v})K'\,\hat{z}, \tag{4.7}$$

$$\alpha|\vec{w}|(K^2-1)+\gamma r(\vec{r}\cdot\vec{v})K'=0, \tag{4.8}$$

where the first equation is the same as Eq. (4.4). With this treatment we are imposing an extra constraint on the original equations of motion, and this is not necessarily consistent with the other equations. To show the consistency, we may solve six equations out of seven (six original equations of motion plus one constraint because of the planar motion condition), and examine the validity of the last one with the resulting solution. From Eq. (4.7), $\dot{\vec{v}}$ has no term in the direction $\vec{r}\times\vec{v}$, so from Eq. (3.15), $\dot{\beta}=0$, which gives $\beta=\beta_0=\text{const}$, and equations for α and γ become

$$\dot{\alpha}=-\frac{\gamma|\vec{w}|K}{r^2}, \tag{4.9}$$

$$\dot{\gamma}=\frac{\alpha|\vec{w}|K}{r^2}. \tag{4.10}$$

So, with a solution for Eq. (4.7) we have to show the consistency of Eqs. (4.8)–(4.10) all together. Replacing α from Eq. (4.8) into Eq. (4.10) we obtain

$$\dot{\gamma}=\gamma\frac{KK'}{1-K^2}\dot{r}, \tag{4.11}$$

where we have used $\vec{r}\cdot\vec{v}=r\,\dot{r}$. Equation (4.11) is solvable and the solution is

$$\gamma=\frac{c_1}{\sqrt{1-K^2}}, \tag{4.12}$$

where c_1 is a constant. Using Eqs. (4.8) and (4.12)

$$\alpha=c_1\frac{r^2K'\,\dot{r}}{|\vec{w}|(1-K^2)^{3/2}}. \tag{4.13}$$

From Eqs. (4.9) and (4.10) [or equivalently from Eq. (3.13) and the fact that β is a constant] one may simply find

$$\alpha^2+\gamma^2=c_2^2, \tag{4.14}$$

where $c_2^2=I^2-\beta_0^2$ is another constant. So, finally we have to show the solutions (4.12) and (4.13) for γ and α satisfy Eq. (4.14). As we see, a solution for $\vec{r}$ and $\vec{v}$ (in fact $\vec{v}$ is enough) is needed to replace for appropriate quantities in (4.13).

The equation (4.7) stands alone and may be solved independently from the other equations. Taking the normal direction to the plane of motion as the z-direction in a cylindrical coordinate, one can write down the equations of motion in the polar plane. We can simply replace $\{\hat{r},\hat{w},\hat{z}\}$ by $\{\hat{r},\hat{k},-\hat{\theta}\}$. In the polar plane

$$\vec{v}=\dot{r}\,\hat{r}+r\dot{\theta}\,\hat{\theta}, \tag{4.15}$$

$$\dot{\vec{v}}=(\ddot{r}-r\dot{\theta}^2)\,\hat{r}+(2\dot{r}\dot{\theta}+r\ddot{\theta})\,\hat{\theta}, \tag{4.16}$$

so Eq. (4.7) in the cylindrical coordinates is

$$m[(\ddot{r}-r\dot{\theta}^2)\,\hat{r}+(2\dot{r}\dot{\theta}+r\ddot{\theta})\,\hat{\theta}\,]=\beta\dot{\theta}K'\,\hat{r}-\beta\frac{\dot{r}}{r}K'\,\hat{\theta}. \tag{4.17}$$

A set of two nonlinear differential equations appears,

$$\begin{aligned} m(\ddot{r}-r\dot{\theta}^2)&=\beta\dot{\theta}K',\\ m(2\dot{r}\dot{\theta}+r\ddot{\theta})&=-\beta\frac{\dot{r}}{r}K', \end{aligned} \tag{4.18}$$

which governs the motion of the particle in the polar plane. From the last equation one finds

$$mr^2\dot{\theta}+\beta K\equiv j=\text{const.} \tag{4.19}$$

Obtaining K' from the former equation of Eq. (4.18) and replacing it in the latter one, we find

$$\dot{r}\ddot{r}+r\dot{r}\dot{\theta}^2+r^2\dot{\theta}\ddot{\theta}=0,$$

which produces another constant of motion

$$\dot{r}^2+r^2\dot{\theta}^2\equiv v^2=\text{const.} \tag{4.20}$$

Both of the constants are in agreement with the overall discussion we had earlier about constants of motion.

Now we can replace $\dot{r}$ and $|\vec{w}|=|r^2\dot{\theta}|$ from Eqs. (4.19) and (4.20),

$$|\vec{w}|=|r^2\dot{\theta}|=\left|\frac{j-\beta K}{m}\right|,\quad \dot{r}^2=v^2-\left(\frac{j-\beta K}{mr}\right)^2, \tag{4.21}$$

into Eq. (4.14),

$$\frac{c_1^2}{1-K^2}\left\{1+\frac{r^4(K')^2[v^2-((j-\beta K)/mr)^2]}{((j-\beta K)/m)^2(1-K^2)^2}\right\}=c_2^2, \tag{4.22}$$

to check validity of this constraint that is imposed from the planar motion condition. In the above equation $K=aer/\sinh(aer)$, and c_1, c_2, m, β, v, j, a and e are constants. This means the right-hand side of Eq. (4.22) must be a constant. This can not happen in general. At least numerically, we may show the above function of r is not a constant for many choices of constants. The only clear possibility is for $r=\text{const}$, i.e., for a circular motion. For $r=\text{const}$, $\dot{r}=0$, so from Eq. (4.13) $\alpha=0$ and from Eq. (4.14) [or Eq. (4.12)] $\gamma=\text{const}$, where from Eq. (4.9) this constant must be zero which ceases $c_1=c_2=0$. For the other cases (i.e., not necessarily circular motions),

Eq. (4.22) necessitates $c_1=c_2=0$ and then $\alpha=\gamma=0$. So a planar orbit is possible if and only if the charge isovector has no component in the plane of motion, which means in the planar motion the charge isovector identifies the plane and remains constant.

V. ANALYTIC DESCRIPTION OF PLANAR ORBITS

A Lagrangian for the two-dimensional motion discussed above is offered as

$$L=T-U=\tfrac{1}{2}m\,(\dot{r}^2+r^2\dot{\theta}^2)+\beta\,\dot{\theta}\,K(r). \tag{5.1}$$

The "potential" $U=-\beta\,\dot{\theta}\,K(r)$ shows the force is not central. For a central force, the angular momentum, $l=mr^2\dot{\theta}$, and the total energy of the system, $T+U$, are constants of motion. But in our problem the total angular momentum of the particle and the fields, which was expressed in Eq. (4.19), and the kinetic part of energy alone [Eq. (4.20)] are constants of motion. Using the Euler–Lagrange equations, the equations of motion (4.18) are simply derived from the Lagrangian (5.1).

Replacing $\dot{\theta}$ from Eq. (4.19) into the first equation of Eqs. (4.18),

$$m\ddot{r}=\beta\left(\frac{j-\beta K}{mr^2}\right)K'+mr\left(\frac{j-\beta K}{mr^2}\right)^2=-\frac{m}{2\dot{r}}\frac{d}{dt}\left(\frac{j-\beta K}{mr}\right)^2, \tag{5.2}$$

gives

$$m\ddot{r}=-\frac{dV(r)}{dr}, \tag{5.3}$$

where

$$V(r)=\frac{m}{2}\left(\frac{j-\beta K}{mr}\right)^2. \tag{5.4}$$

The equation (5.3) is a one-dimensional equation of motion. The first integration of Eq. (5.3) gives

$$E=\tfrac{1}{2}m\dot{r}^2+V(r), \tag{5.5}$$

which is indeed equivalent to Eq. (4.20), i.e., $E=mv^2/2$ and $V(r)=mr^2\dot{\theta}^2/2$.

The "effective potential" $V(r)$ is a function of distance r, and through j depends on the initial conditions of the motion. To see how $V(r)$ is, we may simply analyze its derivative with respect to r:

$$V'(r)=\frac{-1}{2\,m\,r^3}(j-\beta K)(j-\beta K+\beta rK'). \tag{5.6}$$

The derivative $V'(r)$ vanishes if one of its two factors vanishes, i.e., $K(r)=j/\beta$ or $K(r)-rK'(r)=j/\beta$. To find the solutions of these equations we may find the points at which the constant function j/β coincides with the functions $K(r)=r/\sinh(r)$ ($a=e=1$) or $K(r)-rK'(r)=r^2\cosh(r)/\sinh^2(r)$. Looking at Fig. 1, for $0<j<j_c$ (say $\beta=1$) there are two solutions for $V'(r)=0$, therefore $V(r)$ has two extrema at r_1 and r_2. The effective potential $V(r)$ is a non-negative function and $V(r)\to 0$ as $r\to\infty$. So the two extrema must be a minimum and a maximum, respectively, i.e., r_1 is the minimum and r_2 is the maximum. For $0<j\leqslant 1$, $V(r)$ is tangent to the r-axis at the minimum point r_1 [because $V(r)$ is also vanishes for $j=\beta K$], and this is the only point that $V(r)$ touches the r-axis. For $1<j<j_c$, $V(r)$ does not coincide with the r-axis. For $j\neq 1$, $V(r)\to\infty$ as $r\to 0$, but for $j=1$ this limit is finite and $V(r)\to 0$ as $r\to 0$ (so $r_1=0$). For

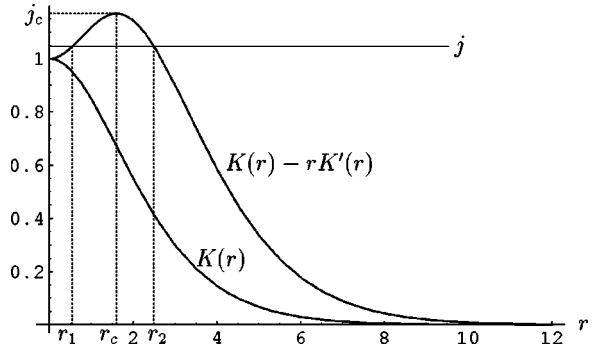

FIG. 1. Solutions of $V'(r)=0$.

$j=j_c$ ($r=r_c$) there is only a saddle point, and for $j\leqslant 0$ and $j>j_c$ there is no extremum and $V(r)$ is monotonically decreasing. Figure 2 shows the possible shapes of $V(r)$.

For a given j we may discuss the orbit of the particle, subject to the initial conditions. The limit value j_c may depend on the other constants of theory such as a, e and β. To see how j_c depends on a and e (instead of setting $a=e=1$ in last steps), we may consider a and e in K as it came in (3.8). Therefore, we have $K=aer/\sinh(aer)$ and $K-rK'=a^2e^2r^2\cosh(aer)/\sinh^2(aer)$. If we plot K and $K-rK'$ in Fig. 1 versus aer, we see r_c is rescaled, but j_c remains unaltered (up to the constant factor β). It is not difficult to find r_c and j_c (with $a=e=\beta=1$):

$$r_c=1.606, \quad j_c=1.169. \tag{5.7}$$

Let see the situation of a motion when j and E (or v) are given. If $0<j<j_c$ but $j\neq 1$, we have the top-left plot in Fig. 2. The altitude and latitude of the extrema from the horizontal and vertical axes are related to the constant j. Figure 3 shows the different possibilities of motion subject to energy E.

If the particle starts its motion with the energy E_4, it will be scattered to infinity and can never come closer to the origin than r_6 (see Fig. 7 in the next subsection). A motion with the energy E_2 will move on a circle of radius r_2 even if it starts its motion from inside or outside of the radius r_2. This motion is unstable, i.e., a small perturbation banishes the particle from the radius r_2. A small perturbation to the left may make a bounded orbit if the perturbed energy is less than E_2, while a small perturbation to the right sends the particle to infinity even if the energy is less than E_2 (see Fig. 8 in the next subsection). A particle with the energy E_3 is bounded and moves between two radii r_3 and r_4 if it starts the motion in between the two radii (see Fig. 7 in the next subsection), but it will be scattered to infinity if starts the motion from $r\geqslant r_5$. A particle with the

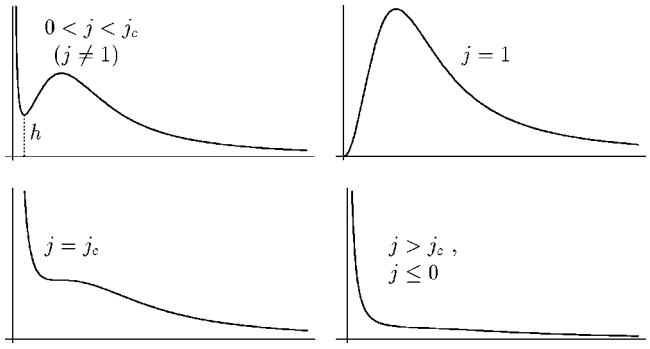

FIG. 2. One dimensional effective potential $V(r)$ (vertical axis) versus radius r (horizontal axis). In the top left plot, the height h is zero for $1<j<j_c$.

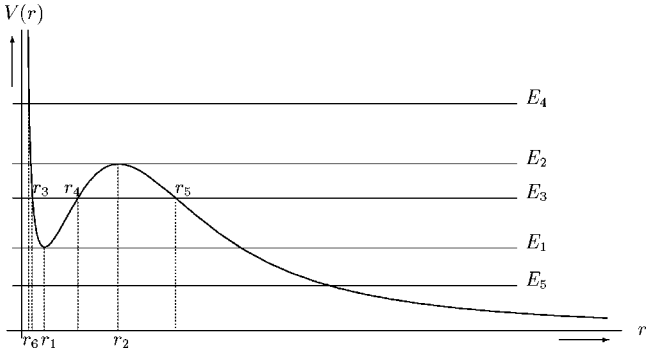

FIG. 3. Different possibilities of motion for $0<j<j_c$ $(j\neq 1)$.

energy E_1 moves on a circle of radius r_1. This is a stable motion (see Fig. 7 in the next subsection). The situation of a particle with the energy E_5 is similar to the particle with the energy E_4. In Fig. 3 r_1 and r_2 are given by r_1 and r_2 in Fig. 1 when j is specified.

For $0<j<1$, $V(r)$ is tangent to the r-axis at r_1, therefore the case with energy E_5 is inappropriate and E_1 lies on the r-axis (so $E_1=0$). A stationary particle (a particle with $E=0$, i.e., $\dot{r}_0=\dot{\theta}_0=0$) settles in this category and remains at r_1 without moving. So a stable circular motion is possible only for $1<j<j_c$.

For $0<j<j_c$, a bounded motion is possible if $E_1\leqslant E\leqslant E_2$. Using Fig. 1, $j=K(r_2)-r_2K'(r_2)=K(r_2)+r_2^2\dot{\theta}_2^2$, which gives $\dot{\theta}_2=-K'(r_2)/r_2$. So $E_2=(\dot{r}_2^2+r_2^2\dot{\theta}_2^2)/2=r_2^2\dot{\theta}_2^2/2=(K'(r_2))^2/2$, where index 2 shows the value of each quantity at r_2. For the minimum value we can do the same. For $1\leqslant j\leqslant j_c$ we have $(K'(r_1))^2/2\leqslant E\leqslant(K'(r_2))^2/2$, and for $0<j\leqslant 1$, $0\leqslant E\leqslant(K'(r_2))^2/2$. For each case radii r_1 and r_2 are determined by j, so with j we can describe the overall properties of the motion. As a problem we may determine the maximum value that E can take for a bounded motion. By equating the derivative of function $(K'(r))^2/2$ to zero, we find $r=1.606$ that is equal to r_c [see Eq. (5.7)] and so the maximum value of $(K'(r))^2/2$ is $E_c=0.0480$. This is not an accident, because in fact the energy E is equal to the potential $V(r)$ at the turning points, so at the turning points $E=V(r)=(j-K)^2/2r^2$. Clearly, the maximum value of E for a bounded motion occurs when $j=j_c$ (see Fig. 1). So if $E>E_c$ we can immediately conclude that the motion is not bounded.

Another point that is worth mentioning isn the following: If the particle is launched into the field from $r>r_m$, (for some r_m) we remain in the category $0<j<1$ for bounded motions. From Fig. 1 one can simply see the maximum distance from the origin for a maximum turning point for the category $1\leqslant j\leqslant j_c$ occurs in $j=1$. Then r_m is the nonzero root of $K(r)-rK'(r)=1$, which gives $r_m=2.676$. Clearly if a particle is launched in the field from $r>r_m$ it will not be bounded if $j\geqslant 1$. So the only possibility for a bounded orbit for this particle is $0<j<1$ (not any motion is necessarily bounded).

Motions with $j\neq 1$ do not pass the origin at all. For the bounded orbits, a particle moves in its path between two circles of radii r_3 and r_4. In the turning points $V(r)=E$, so $\dot{r}=0$. For $0<j<1$, in the radius r_1 [the point which locates between the turning points and minimizes $V(r)$] $V(r)=0$ (see the top-left plot in Fig. 2 with $h=0$), so in this radius $\dot{\theta}=0$ and the orbit must be tangent to a radius at this point (see Fig. 4). In the radius r_1 $(=OP_1=OP_2$ in Fig. 4), $\dot{\theta}=0$, but $\dot{r}\neq 0$ (because $E\neq 0$), so $d\theta/dr=0$. This means at this point the direction of variations of r remains unchanged, while the direction of variations of θ is changed. Therefore, each time that the particle completes a motion between two radii (for example, starting from the upper turning point and returning back to the point after traveling to the lower turning point), it passes two times from the desired point (r_1). So the particle makes an internal loop outside the origin (i.e., the loop does not surround the origin) in each travel. So in a 2π rotation the particle may construct several inner

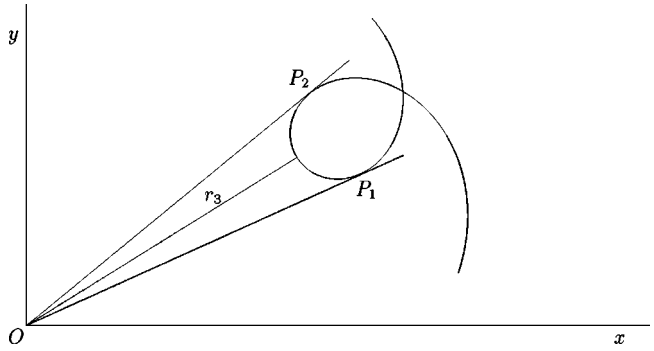

FIG. 4. Internal loops are possible for $0<j<1$.

loops which are lying on the main orbit around the origin. This case does not happen for $1<j<J_c$ because always $V(r)>0$.

This is an important result. For $1<j<J_c$ the particle rotates around the origin once in every 2π rotation (but not necessarily in a closed orbit). This is similar to the Kepler problem in gravitation. This motion definitely can happen only inside the region $r\leqslant r_m$ as we explained earlier. But for $0<j<1$ the situation is different. In a 2π rotation, a particle trajectory may form several loops outside the origin (see Fig. 5). This case may happen anywhere in the plane subject to suitable initial values.

For $j=1$ (the top-right plot in Fig. 2), the situation is the same as $0<j<1$, but here the lower turning point is fixed, $r_3=r_1=0$ (in contrast to the case of $j\neq 1$ where the lower turning point depends on E). In this case, the upper turning point, $r_4\leqslant r_m=2.676$. So in a bounded motion the particle passes the origin periodically. In fact, this case is settled between the two parts of the previously studied case. For $1<j<j_c$ a bounded orbit turns around the origin once in each 2π period, and the particle's orbit comes closer to the origin on a point of its trajectory when j takes a value closer to one (i.e., perihelion becomes shorter). In the limit, for $j=1$ the trajectory crosses the origin, and in each 2π rotation, the particle passes the origin once. When j takes a (positive) value less than 1, the orbit leaves the origin and makes a loop in the opposite side (see Fig. 5).

For $j=1$, $r=0$ is an extremum point of the potential $V(r)$, and $V(r)$ is tangent to the r-axis in $r=0$. So it is important to study any probable ambiguity at the origin. The origin is a turning point, and also the orbit is tangent to a radius at the origin. So it is a question to know about the velocity components at the origin. It is not difficult to show neither $\dot{r}$ nor $\dot{\theta}$ vanishes at $r=0$. One may show

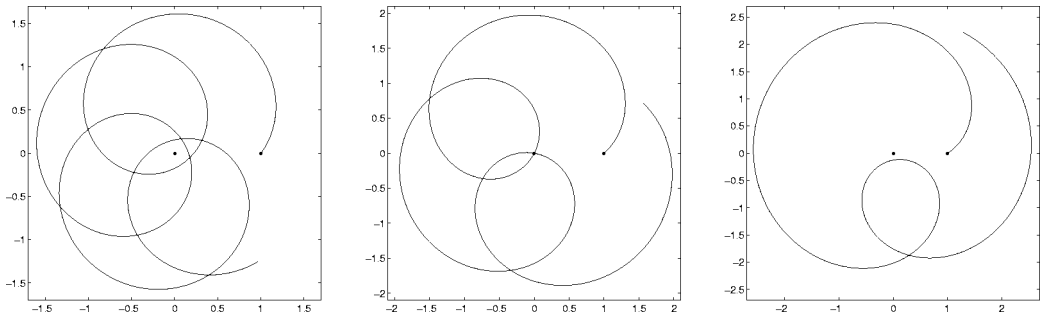

FIG. 5. In the left plot $j>1$, In the middle one $j=1$ and in the right plot $j<1$. In the three cases the particle has started the motion from (0,1) with the same energy, $E=0.025$. The total angular momentum j are 1.03, 1, and 0.97, respectively. The starting point and the origin are marked by black dots.

$$\lim_{r\to 0}\dot{\theta}=\lim_{r\to 0}\left\{\frac{1-K(r)}{r^2}\right\}=\frac{1}{6},$$
$$\lim_{r\to 0}\dot{r}^2=\lim_{r\to 0}\left\{v^2-\left(\frac{1-K(r)}{r}\right)^2\right\}=v^2. \tag{5.8}$$

The above limits may look strange, but still $v^2=\dot{r}^2+r^2\dot{\theta}^2$ is valid.

For $j=j_c$ (bottom-left plot in Fig. 2) a particle with the exact energy E_c has a non-stable circular motion in the saddle point, otherwise the particle is scattered to infinity. For $j\leqslant 0$ and $j>j_c$ the particle is scattered to infinity and there is no chance for bounded orbits.

Finally, if a particle starts its motion from the point (r_0,θ_0) with the velocity $(\dot{r}_0,\dot{\theta}_0)$, we may calculate the two important constants j and E (or equivalently v) and very soon recognize the motion to be bounded or not, and to which of the preceding cases it belongs.

In principle, we have discussed the overall characters and properties of the orbits, but the actual equation of the orbit must be obtained by integrating the differential equations of motion (4.19) and (4.20). Replacing $\dot{\theta}$ from Eq. (4.19) in Eq. (4.20) we get

$$t=\pm\int_{r_0}^{r}\frac{dr}{\sqrt{v^2-((j-\beta K)/mr)^2}}, \tag{5.9}$$

where the motion is supposed to be started from the initial value r_0 at time $t=0$. As it stands Eq. (5.9) gives t as a function of r and the constants of integration E (or v), j and r_0. However, it may be inverted, at least formally, to give r as a function of t and the constants. Once the solution for r is found, the solution for θ follows immediately from Eq. (4.19). At large distances from the center, K and K' vanish and the particle moves in a straight line. Clearly in the areas too close to the center of the monopole, K' vanishes as well (but not K), and a free motion is valid. However, in the other areas K and K' are important and cannot be ignored. Again using $\dot{\theta}$ from Eq. (4.19) and $\dot{r}$ from Eq. (4.20) (after some replacement of $\dot{\theta}$), after some rearrangement of variables an integral equation for the orbit of the particle is found as:

$$\theta-\theta_0=\pm\int_{r_0}^{r}\frac{dr}{r\sqrt{(mvr/(j-\beta K))^2-1}}. \tag{5.10}$$

With the presence of the hyperbolic function in the integral, it seems difficult to solve it by changing the variables. Instead of the above integral equation for the orbit, we may replace dt from Eq. (4.19) into Eq. (5.3) and find a second order differential equation for the orbit. But none of these help us to find analytic solutions for the orbits. So in the next we present some numerical solutions of Eqs. (4.18) and observe the results we found in the previous pages.

VI. NUMERICAL OBSERVATIONS

In this subsection we present some numerical solutions for the set of equations (4.18) for planar motions and Eqs. (3.9) and (3.10) for nonplanar motions. We have used the Runge–Kutta method (of fourth order) for solving first order differential equations. The required programs are written in the ''MATLAB'' programming package. In a planar motion let us suppose a particle of unit mass, $m=1$, and unit charge, $\vec{I}=\beta\hat{k}$, $\beta=+1$, has been launched in the field of a BPS monopole with $a=e=1$, from a point (r_0,θ_0), with an initial velocity $(\dot{r}_0,\dot{\theta}_0)$. The following results are concluded for the different initial values for which we have tested the equations.

The monopole forces the particle to move on a curve in the plane such that if the thumb of the right hand stands in the direction of the charge isovector, then the sense of closing the rest of fingers shows the direction of rotation of particle. In Fig. 6 a particle is launched in four different

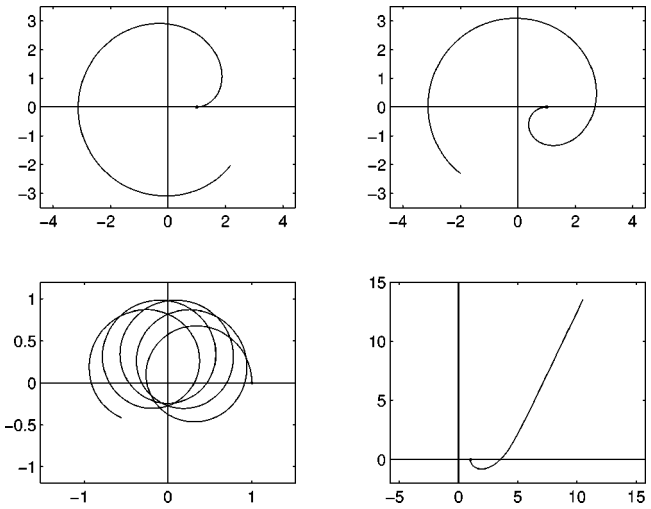

FIG. 6. Particle is launched from point (1,0) (the dark point in the x-axis) with the same speed (0.184) in each case. (The number of significant digits in the velocity is not crucial; it has been chosen for a better illustration of the plots.)

directions (with the same energy), and the particle moves counter-clockwise in each case (the charge isovector is normal to the paper pane and outward). This observation is greatly different from the usual scattering of an electric particle in a Maxwell field. If the behavior of this system was like a usual electrodynamics system, the two bottom plots of Fig. 6 would be the mirror images with respect to the x-axis, while here we see one motion is bounded while the other one is scattered to the infinity. (Note in the last two plots, in spite of the fact that the energy is the same in both cases, j is different so they follow the two different models of $j-E$ graphs we explained in Sec. V.)

This point can be explained analytically when the condition for the planar motion is used in the original equation (3.9). In Eq. (3.9) $\vec{r}\cdot\vec{I}=0$ (for the planar motion), so the equation of motion in a compact form is

$$m\ddot{\vec{r}}=\frac{K'}{r}(\vec{v}\times\vec{I}). \tag{6.1}$$

The term on the right-hand side of Eq. (6.1) is the force that is exerted from the fields onto the particle. The $\vec{I}=\beta\hat{k}$ is a vector normal to the plane of motion and in the upward direction. So the cross-product of $\vec{v}$ and $\vec{I}$ is a vector in the plane of motion and always normal to the velocity vector and in counter-clockwise direction. Therefore, the particle is forced to move counter-clockwise.

Bounded and unbounded orbits are allowed depending on the choice of initial values. Closed bounded orbits may exist for each point in the plane, depending on the initial velocity. There are lots of various orbits: circles, Limaçon-shapes, curves with many loops (loops may surround the center or not), the simple scattered curves and many other complicated curves. A variety of possible orbits are shown in Fig. 7. For closed orbits the initial conditions are specified. For example, in the two top plots of Fig. 7 the initial position of the particle is known [i.e., $(r,\theta)=(1,0)$], the velocities are specified up to some significant digits.

Although the circular motions are closed orbits, in general we can not find a prescription for closed orbits. By numerical methods and trial and error we may find some closed orbits. The top-left plot in Fig. 7 is an example.

Figure 8 shows an unstable motion around the maximum point for $0<j<j_c$. In the top-left plot, the particle is launched from point (1,0) with $(\dot{r}_0,\dot{\theta}_0)=(0.184,0)$, so it will rotate in a radial direction at $r_2=3.163$. This case is calculated only to be compared with the closed top-left plot in

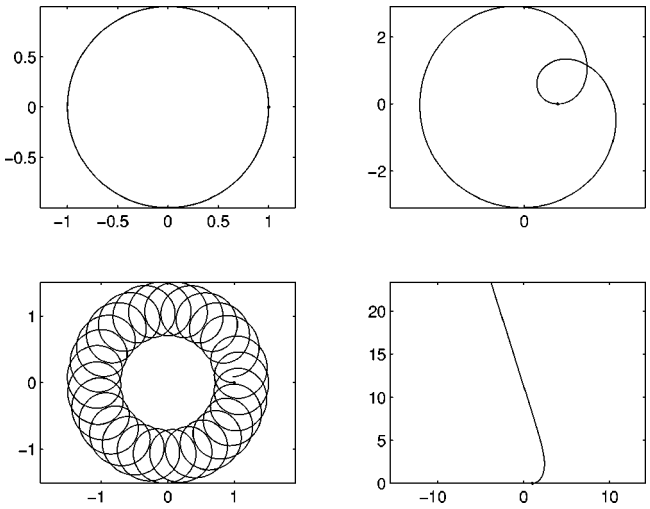

FIG. 7. For each case motion is started from point (1,0) (the dark point), but the initial energy is different for each case. For the circle, initial velocity is 0.266, and for the Limaçon-shape, the initial velocity is $(\dot{r}_0,\dot{\theta}_0)=(0.184,0)$.

Fig. 7. So for any $0<j<j_c$ (i.e., r_0 and $\dot{\theta}_0$ are specified), we can find a value $\dot{r}_0$ and send the particle to rotate on the critical radius r_2. For smaller or bigger energies, the motion will be bounded between two circles, or scattered to infinity, as was explained earlier. The bottom-left and top-right plots show these points. The bottom-right plot is another example of a unstable motion. The particle starts the motion from the same point as the other three, but j and energy are different. We can compare this case with the circular motion in Fig. 7.

VII. NUMERICAL OBSERVATIONS FOR NONPLANAR MOTIONS

Now we explain nonplanar motions which indeed follow the general equations of motion (3.9) and (3.10). Suppose the particle is launched in the field from the point (0,0,10) with an initial velocity $(0,0,-0.1)$ while the charge isovector is initially (0,0,1). As we explained before, the particle moves in the z-direction and passes through the origin in enough time. Now suppose instead of launching the particle in the z-direction, we launch it from the point (0,1,10). So the

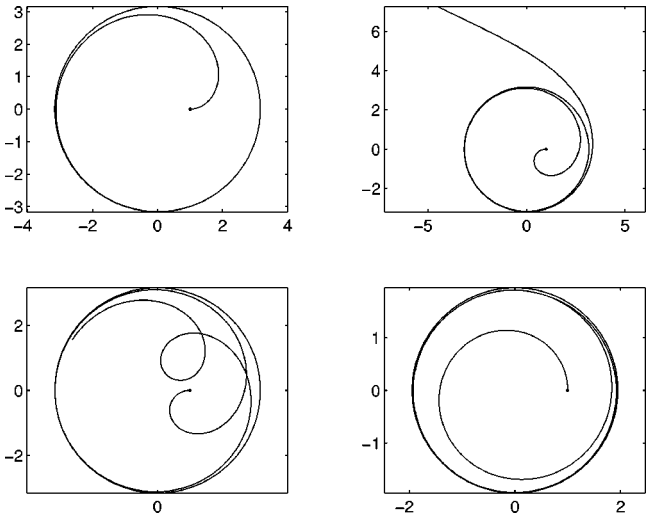

FIG. 8. For each case motion is started from point (1,0) (the dark point). The plots show stability of the orbits around r_2.

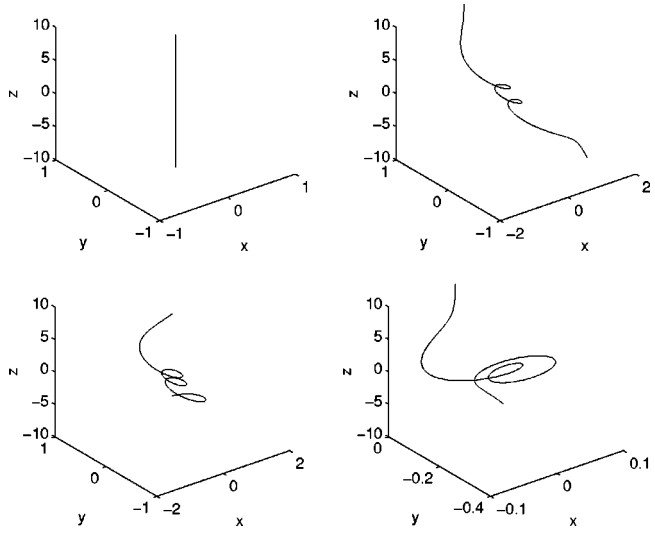

FIG. 9. Spatial orbits.

initial conditions are as before unless an impact parameter is taken into consideration. Of course with these initial conditions the particle moves on a curve which is no longer planar. The top two plots in Fig. 9 show the orbits for the above-mentioned two cases.

Instead of considering an impact parameter in the above case, which leads to a nonplanar motion, any small deviation in the initial velocity in the normal direction to the plane or in the charge isovector in the plane causes nonplanar orbits as well. Examples for these two cases are the bottom plots in Fig. 9. In the right plot the particle is launched from (0,0,10) with the velocity $(0,0.01,-0.1)$ and charge isovector (0,0,1), and in the left plot from (0,0,10) with the velocity $(0,0,-0.1)$ and the charge isovector (0,0.1,1).

By changing the initial values we may collect a wide range of spatial orbits. Organizing these plots to get some useful results is not straightforward, and in addition we need a long time for each computation. As an example, the following observation may lead us to the idea of standard one-dimensional potential we explained on the subject of planar motion. In the continuation of the top two plots in Fig. 9 we can increase the impact parameter. Note that the particle reflects back in the z-direction, when we put (0,2,10) for the location of the particle and the other initial values are unchanged. Now we can decrease the impact parameter and then play with it by adding and subtracting the earlier values to find a plot such that the particle stays around the xy-plane (at least for a while). We may continue this procedure to get a better and better result. In Fig. 10, the left plot is the three-dimensional orbit and the right one shows the time variation of the z component. This plot is resulting from the same initial values as the two top plots in Fig. 9, but with impact parameter 1.953 [i.e., (0,1.953,10) for the initial location]. The particle has a small oscillatory

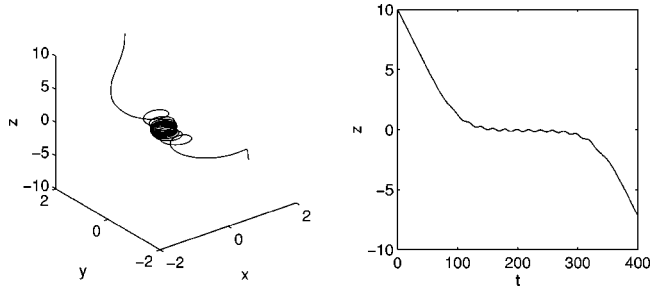

FIG. 10. Nonstable motion.

motion along the z-axis close to the xy-plane for a while. We may increase duration of the delay around the xy-plane for a longer time by changing the value of the impact parameter to a better value.

Based on the observation we explained in the last paragraph, one may compare this situation with the unstable extremum points in the one-dimensional potential model we explained for the planar motions (see Fig. 8), but in a three-dimensional context. So if this is like an unstable extremum, there might exist a stable analog of the one-dimensional potential in the three-dimensional context. If a minimum exists for the general potential model, a stable planar motion would be allowed. This means stability of planar motion might be possible, i.e., if some small normal perturbations disturb the planar motion, the orbit should stay bounded around the plane. In the next topic we analyze this problem in some detail.

It is proper here to say a word about the scattering problem. With the above results from the numerical works, we see the scattering depending on many parameters is not as simple as in the two-dimensional central force problems. We may keep the initial conditions of the problem unchanged but alter the impact parameter. As the impact parameter changes, the plane spanned by the initial and final velocity vectors changes. So it is needed to introduce three scattering angles instead of the one which is used in the usual two-dimensional scattering problems. Even in two-dimensional planar motions the scattering of the particle is not symmetric with respect to the positive and negative values of the impact parameter (see the two bottom plots in Fig. 6). The problem of scattering in three-dimensional motions is a separate problem, so we skip it here.

VIII. STABILITY OF PLANAR MOTIONS

The conditions for planar motion look too strong and therefore the stability of planar motions may be very weak. This means, if a little deviation in the quantities perturbs the planar motion in the normal direction to the plane, the particle will leave the plane and be scattered to infinity. Because the perturbations are generally in three dimensions, we should use the general equations of motion (3.9) and (3.10). So, let us first find the required equations for perturbations in three dimensions.

Suppose small perturbations in $\vec{r}$ and $\vec{I}$ are of the form

$$\vec{r}\to\vec{r}+\vec{\epsilon},\quad \vec{I}\to\vec{I}+\vec{\delta}, \tag{8.1}$$

where $\vec{\epsilon}$ and $\vec{\delta}$ are small quantities. For the other quantities we will have

$$\vec{v}\to\vec{v}+\dot{\vec{\epsilon}},\ \ \dot{\vec{v}}\to\dot{\vec{v}}+\ddot{\vec{\epsilon}},\ \ \dot{\vec{I}}\to\dot{\vec{I}}+\dot{\vec{\delta}},\ \ r\to r+\frac{\vec{\epsilon}\cdot\vec{r}}{r}, \tag{8.2}$$

where in the last one we have kept only the first order approximation. Replacing the unperturbed quantities in equations of motion (3.9) and (3.10) with the perturbed quantities from the right-hand side of the above relations, we find

$$\begin{aligned} m\ddot{\vec{\epsilon}}=&\frac{K^2-rK'-1}{r^4}\{(\vec{v}\times\vec{\epsilon})(\vec{r}\cdot\vec{I})+(\dot{\vec{\epsilon}}\times\vec{r})(\vec{r}\cdot\vec{I})+(\vec{v}\times\vec{r})(\vec{r}\cdot\vec{\delta})+(\vec{v}\times\vec{r})(\vec{\epsilon}\cdot\vec{I})\}\\ &-\frac{4K^2-2rKK'+r^2K''-3rK'-4}{r^3}(\vec{\epsilon}\cdot\vec{r})(\vec{v}\times\vec{r})(\vec{r}\cdot\vec{I})+\frac{K'}{r}\{(\vec{v}\times\vec{\delta})+(\dot{\vec{\epsilon}}\times\vec{I})\}\\ &+\frac{rK''-K'}{r^3}(\vec{\epsilon}\cdot\vec{r})(\vec{v}\times\vec{I}), \end{aligned} \tag{8.3}$$

$$\dot{\vec{\delta}}=\frac{1-K}{r^2}\{(\vec{\epsilon}\times\vec{v})\times\vec{I}+(\vec{r}\times\dot{\vec{\epsilon}})\times\vec{I}+(\vec{r}\times\vec{v})\times\vec{\delta}\}-\frac{2(1-K)+rK'}{r^4}(\vec{\epsilon}\cdot\vec{r})[(\vec{r}\times\vec{v})\times\vec{I}\,], \tag{8.4}$$

where in derivation we have ignored the second order perturbations and used the unperturbed equations (3.9) and (3.10).

Now for the planar motion case, where we have suggested to make a small perturbation in the space, we have

$$m\ddot{\vec{\epsilon}}=\frac{K^2-rK'-1}{r^4}\{(\vec{v}\times\vec{r})(\vec{r}\cdot\vec{\delta})+(\vec{v}\times\vec{r})(\vec{\epsilon}\cdot\vec{I})\}+\frac{K'}{r}\{(\vec{v}\times\vec{\delta})+(\dot{\vec{\epsilon}}\times\vec{I})\}$$
$$+\frac{rK''-K'}{r^3}(\vec{v}\times\vec{I})(\vec{\epsilon}\cdot\vec{r}), \tag{8.5}$$

$$\dot{\vec{\delta}}=\frac{1-K}{r^2}\{(\vec{r}\times\vec{v})\times\vec{\delta}+(\vec{I}\cdot\vec{\epsilon})\,\vec{v}-(\vec{I}\cdot\dot{\vec{\epsilon}})\,\vec{r}\}, \tag{8.6}$$

and we have used $\vec{r}\cdot\vec{I}=\vec{v}\cdot\vec{I}=0$. Only the terms in the second row of Eq. (8.5) can be derived from the planar equation of motion (6.1), and the remaining terms in both equations have appeared by considering the general three-dimensional equations of motion.

Cylindrical coordinates are suitable to write down the equations for each component separately. We may write

$$\vec{\epsilon}=\epsilon_r\hat{r}+\epsilon_\theta\hat{\theta}+\epsilon_z\hat{z},$$
$$\vec{\delta}=\delta_r\hat{r}+\delta_\theta\hat{\theta}+\delta_z\hat{z}. \tag{8.7}$$

So

$$\dot{\vec{\epsilon}}=(\dot{\epsilon}_r-\dot{\theta}\epsilon_\theta)\hat{r}+(\dot{\epsilon}_\theta+\dot{\theta}\epsilon_r)\hat{\theta}+\dot{\epsilon}_z\hat{k},$$
$$\dot{\vec{\delta}}=(\dot{\delta}_r-\dot{\theta}\delta_\theta)\hat{r}+(\dot{\delta}_\theta+\dot{\theta}\delta_r)\hat{\theta}+\dot{\delta}_z\hat{k}, \tag{8.8}$$

and

$$\ddot{\vec{\epsilon}}=(\ddot{\epsilon}_r-\ddot{\theta}\epsilon_\theta-2\dot{\theta}\dot{\epsilon}_\theta-\dot{\theta}^2\epsilon_r)\hat{r}+(\ddot{\epsilon}_\theta+\ddot{\theta}\epsilon_r+2\dot{\theta}\dot{\epsilon}_r-\dot{\theta}^2\epsilon_\theta)\hat{\theta}+\ddot{\epsilon}_z\hat{k}. \tag{8.9}$$

Replacing from Eqs. (8.7)–(8.9) into Eqs. (8.5) and (8.6), and using $\vec{I}=\beta\hat{k}$ ($\beta=$const), $\vec{r}$ and $\vec{v}$ in the polar plane (plane of motion), one may find a complete set of six linear differential equations for six unknown perturbation components:

$$m\ddot{\vec{\epsilon}}=\left\{\beta\frac{K'}{r}\dot{\epsilon}_\theta+\beta K''\dot{\theta}\epsilon_r+K'\dot{\theta}\delta_z\right\}\hat{r}+\left\{-\beta\frac{K'}{r}\dot{\epsilon}_r-\beta\frac{rK''-K'}{r^2}\dot{r}\epsilon_r+\beta\frac{K'}{r}\dot{\theta}\epsilon_\theta-\frac{K'}{r}\dot{r}\delta_z\right\}\hat{\theta}$$
$$+\left\{-\beta\frac{K^2-rK'-1}{r^2}\dot{\theta}\epsilon_z+\frac{1-K^2}{r}\dot{\theta}\delta_r+\frac{K'}{r}\dot{r}\delta_\theta\right\}\hat{k}, \tag{8.10}$$

$$\dot{\vec{\delta}}=\left\{\frac{1-K}{r^2}(-\beta r\dot{\epsilon}_z+\beta\dot{r}\epsilon_z-r^2\dot{\theta}\delta_\theta)\right\}\hat{r}\left\{\frac{1-K}{r}(\beta\dot{\theta}\epsilon_z+r\dot{\theta}\delta_r)\right\}\hat{\theta}, \tag{8.11}$$

where on the left-hand side we may replace $\ddot{\vec{\epsilon}}$ and $\dot{\vec{\delta}}$ from Eqs. (8.9) and (8.8), and write down equations of motion for each component. In the first instance we find $\dot{\delta}_z=0$, so

$$\delta_z=\text{const}. \tag{8.12}$$

Therefore for small perturbations the total component of the charge isovector in the normal direction to the plane of motion, $\beta+\delta_z$, remains constant. For example, if initially the perturbation of the charge isovector takes place in the plane of motion, this perturbation remains in the plane when the perturbation is small.

Let us choose an auxiliary variable $\vec{\sigma}\equiv\dot{\vec{\epsilon}}$

$$\vec{\sigma}=\sigma_r\hat{r}+\sigma_\theta\hat{\theta}+\sigma_z\hat{k},$$
$$\dot{\vec{\sigma}}=(\dot{\sigma}_r-\dot{\theta}\sigma_\theta)\hat{r}+(\dot{\sigma}_\theta+\dot{\theta}\sigma_r)\hat{\theta}+\dot{\sigma}_z\hat{k}. \tag{8.13}$$

Now we can write nine first-order differential equations for the perturbations (let us set $m=1$):

$$\dot{\epsilon}_r=\dot{\theta}\,\epsilon_\theta+\sigma_r,$$

$$\dot{\epsilon}_\theta=-\dot{\theta}\,\epsilon_r+\sigma_\theta,$$

$$\dot{\epsilon}_z=\sigma_z,$$

$$\dot{\sigma}_r=\beta\frac{rK''-k'}{r}\dot{\theta}\,\epsilon_r+\left(\beta\frac{K'}{r}+\dot{\theta}\right)\sigma_\theta+K'\dot{\theta}\,\delta_z,$$

$$\dot{\sigma}_\theta=-\beta\frac{rK''-k'}{r^2}\dot{r}\,\epsilon_r-\left(\beta\frac{K'}{r}+\dot{\theta}\right)\sigma_r+\frac{K'}{r}\dot{r}\,\delta_z, \tag{8.14}$$

$$\dot{\sigma}_z=-\beta\frac{K^2-rK'-1}{r^2}\dot{\theta}\,\epsilon_z+\frac{1-K^2}{r}\dot{\theta}\,\delta_r+\frac{K'}{r}\dot{r}\,\delta_\theta$$

$$\dot{\delta}_r=\beta\frac{1-K}{r^2}\dot{r}\,\epsilon_z-\beta\frac{1-K}{r}\sigma_z+K\dot{\theta}\,\delta_\theta,$$

$$\dot{\delta}_\theta=\beta\frac{1-K}{r}\dot{\theta}\,\epsilon_z-K\dot{\theta}\,\delta_r,$$

$$\dot{\delta}_z=0.$$

Equivalently we may write the above set of equations in matrix form

$$\dot{\vec{S}}=\mathbf{M}\vec{S}, \tag{8.15}$$

where

$$\vec{S}=[\epsilon_r\ \ \epsilon_\theta\ \ \epsilon_z\ \ \sigma_r\ \ \sigma_\theta\ \ \sigma_z\ \ \delta_r\ \ \delta_\theta\ \ \delta_z]^T \tag{8.16}$$

(T stands for the transpose) and

$$\mathbf{M}(\vec{r},\dot{\vec{r}})$$

$$=\begin{bmatrix}
0 & \dot\theta & 0 & 1 & 0 & 0 & 0 & 0 & 0\\
-\dot\theta & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0\\
\dfrac{\beta(rK''-K')\dot\theta}{r} & 0 & 0 & 0 & \dfrac{\beta K'}{r}+\dot\theta & 0 & 0 & 0 & K'\dot\theta\\
-\dfrac{\beta(rK''-K')\dot r}{r^2} & 0 & 0 & -\dfrac{\beta K'}{r}-\dot\theta & 0 & 0 & 0 & 0 & \dfrac{K'\dot r}{r}\\
0 & 0 & \dfrac{\beta(1-K^2+rK')\dot\theta}{r^2} & 0 & 0 & 0 & \dfrac{(1-K^2)\dot\theta}{r} & \dfrac{K'\dot r}{r} & 0\\
0 & 0 & \dfrac{\beta(1-K^2)\dot r}{r^2} & 0 & 0 & -\dfrac{\beta(1-K)}{r} & 0 & K\dot\theta & 0\\
0 & 0 & \dfrac{\beta(1-K)\dot\theta}{r} & 0 & 0 & 0 & -K\dot\theta & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}. \tag{8.17}$$

The matrix **M**, which is a function of the variables $\vec{r}$ and $\dot{\vec{r}}$, is implicitly a function of time t. If **M** was a constant matrix with eigenvalues λ_i and eigenvectors $\vec{R}_i$, the solution of the linear differential equation (8.16) would be $\Sigma_{i=1}^{9} C_i \exp(\lambda_i t)\vec{R}_i$, where C_i are constants. But now the solution cannot be as simple as this, because the eigenvalues of the matrix **M** are functions of time. The only chance for solving the equations in this way is for circular motions when r and $\dot\theta$ are constants and $\dot r$ vanishes. For example, for the circular motion of Fig. (7), $r=1$, $\theta_0=0$, $\dot r=0$, $\dot\theta=0.266$ and $\beta=1$, the eigenvalues of **M** are

$$0.442,\ -0.442,\ 0.509,\ -0.509,\ 0.235i,\ -0.235i,\ 0,\ 0,\ 0.$$

We have used the "MAPLE" programming package to calculate the above values. Using the MAPLE package we can find the eigenvectors as well. Now we need initial values of the perturbation quantities to determine the constants C_i. Suppose in the circular motion, instead of starting the motion at $t=0$ exactly from the point (1,0,0) in the plane of motion, start the motion from (1,0,0.001) and the other initial values of the circular motion do not alter. So we have set a small perturbation only in the z-direction (normal to the plane of motion), i.e., $S(t=0)=[0,0,0.001,0,0,0,0,0,0]^T$. Equating $S(t=0)=\Sigma_{i=1}^{9} C_i\vec{R}_i$, the constants C_i are found. Let us study the result for one of the perturbation's components, e.g., ϵ_z,

$$\epsilon_z = 0.000\,511\, e^{0.509t} + 0.000\,511 e^{-0.509t} - 0.000\,022\,3\, e^{0.235\, i\, t}.$$

Clearly the first exponential term on the right-hand side of the above equation, in spite of its small coefficient, diverges as $t\to\infty$. Therefore, we can judge the circular motion under study is not stable.

An analytic solution of the set of equations (8.14) [or equivalently (8.15)] is not available, so we may examine the equations of perturbation by numerical methods. We can study any solution in the plane, with some small values for perturbation quantities. Suppose a list of data of position and velocity of a planar motion is available. So we may use the data and the set of equations (8.14) and a numerical method such as the Runge–Kutta method (or even simpler methods) for computing the differential equations. It is more convenient to calculate the data of planar motion in a procedure and at the same time compute the perturbation quantities for each set of $(r,\theta,\dot r,\dot\theta)$. We have studied the problem with different choices of the perturbation quantities for different planar solutions, and the results are the same as above. Indeed if the initial perturbation in the charge

isovector is in the z-direction, or the initial perturbation in $\vec{r}$ and $\vec{v}$ is in the plane of motion, the motion will stay planar. The stable and unstable planar motions (for perturbations in the plane) were discussed earlier.

A planar Runge–Lenz vector

S. G. Kamath[a)]
Department of Mathematics, Indian Institute of Technology, Madras 600 036, India

(Received 16 July 2001; accepted for publication 2 October 2001)

Following Dahl's method an exact Runge–Lenz vector **M** with two components M_1 and M_2 is obtained as a constant of motion for a two particle system with charges e_1 and e_2 whose electromagnetic interaction is based on Chern–Simons electrodynamics. The Poisson bracket $\{M_1, M_2\} \neq L_z$ but is modified by the appearance of the product $e_1 e_2$ as central charges. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1420399]

A characteristic feature of the nonrelativistic Kepler problem is that there exists apart from the conservation of energy (E) and the angular momentum vector (**L**) another conserved quantity, namely the Runge–Lenz vector (**A**). A textbook[1] derivation of **A** begins with the equation of motion of a mass m under the central force $\mathbf{F} = f(r)(\mathbf{r}/r)$, namely, $d\mathbf{p}/dt = f(r)(\mathbf{r}/r)$, leading to

$$\frac{d}{dt}(\mathbf{p}\times\mathbf{L}) = -mf(r)r^2\frac{d}{dt}\left(\frac{\mathbf{r}}{r}\right) \tag{1}$$

as $d\mathbf{L}/dt = 0$. With $r^2 f(r) =$ a constant (say-k), thereby implying an inverse square law of force, Eq. (1) immediately yields $\mathbf{A} = \mathbf{p}\times\mathbf{L} - mk(\mathbf{r}/r)$; this is the Runge–Lenz vector. With the definition $\mathbf{K} = (-2mE)^{1/2}\mathbf{A}$, one easily obtains the Poisson bracket relations

$$\{\mathbf{K}, E\} = 0, \{\mathbf{L}, E\} = 0, \{L_i, L_j\} = \epsilon_{ijk}L_k, \{L_i, K_j\} = \epsilon_{ijk}K_k, \{K_i, K_j\} = \epsilon_{ijk}L_k. \tag{2}$$

Thus there exists an internal symmetry associated with the nonrelativistic Kepler problem with the invariance group being isomorphic to the four-dimensional rotation group O_4. Until recently, the presence of this internal symmetry had not been tied to a generally accepted invariance principle. In other words, the phenomenological derivation implied in Eq. (1) begs the question of whether the Runge–Lenz vector has a deeper physical origin. Specifically, the question is if there is a space–time transformation, the invariance of the Lagrangian for the Kepler problem under which directly leads to the conservation of **A**.

An affirmative answer to this question was recently obtained by Dahl[2] by regarding the Kepler problem as the zero-order description of a relativistic two-body problem; or, as emphasized by Dahl,[2] it is absolutely necessary to investigate the relativistic two-body problem in order to discover the connection between the dynamical symmetry of the nonrelativistic Kepler problem and special relativity.

Of special relevance to this paper is the fact[3] that for the Kepler problem the angular momentum vector $\mathbf{L} = \mathbf{r}\times\mathbf{p}$ is conserved so that $\mathbf{r}\cdot\mathbf{L} = 0$. Thus **r** always lies in a plane[4] whose normal is parallel to **L**. Since the motion of the particle is planar because of symmetry considerations it is appropriate to ask the following: Suppose the motion of the particle was de facto planar and not due to symmetry considerations as in the case of motion under a central force, could one still obtain a Runge–Lenz vector that is conserved in this $2+1$ dimensional case? Happily, we derive in this paper, following Dahl's method,[2] a bonafide Runge–Lenz vector [see Eq. (23)] associated with the relativistic Lagrangian with Chern–Simons interactions[5–7] for a two-particle system consisting of masses m_1 and m_2 with charges e_1 and e_2, respectively, given by

a)Electronic mail: kamath@acer.iitm.ernet.in

$$L=-m_1c^2\left(1-\frac{|\dot{\mathbf{x}}_1^2|}{c^2}\right)^{1/2}-m_2c^2\left(1-\frac{|\dot{\mathbf{x}}_2^2|}{c^2}\right)^{1/2}-\frac{e_1e_2}{\pi c}\frac{\mathbf{k}\cdot\mathbf{r}\times\dot{\mathbf{r}}}{|\mathbf{r}|^2} \tag{3}$$

with $\mathbf{r}=\mathbf{x}_1-\mathbf{x}_2$, $\mathbf{x}_1$ (and $\dot{\mathbf{x}}_1$) and $\mathbf{x}_2$ (and $\dot{\mathbf{x}}_2$) being the position (and velocity) vectors of the masses m_1 and m_2 and $\mathbf{k}$ a fictitious unit vector orthogonal to the plane of $\mathbf{x}_1$ and $\mathbf{x}_2$.

It is easy to obtain (3) starting with the electromagnetic potentials $\mathrm{A}^\mu(\mathbf{x},t)$, $\mu=0,1,2$, for Chern–Simons electrodynamics in the radiation gauge with $\boldsymbol{\nabla}\cdot\mathbf{A}=0$, namely,

$$A^0(\mathbf{x},t)=\frac{e}{2\pi c}\frac{(\mathbf{x}-\mathbf{R}(t))\times\dot{\mathbf{R}}(t).\mathbf{k}}{|\mathbf{x}-\mathbf{R}(t)|^2}, \tag{4a}$$

$$\mathbf{A}(\mathbf{x},t)=\frac{e}{2\pi}\frac{(\mathbf{x}-\mathbf{R}(t))\times\mathbf{k}}{|\mathbf{x}-\mathbf{R}(t)|^2}, \tag{4b}$$

the charge e being located at $\mathbf{R}(t)$. Needless to say Eqs. (4a) and (4b) are the $2+1$ dimensional counterparts of the corresponding $3+1$ dimensional $A^\mu(\mathbf{x},t)$ given by Eqs. (26.19) and (26.20) in Fock[8] for example.

Under an infinitesimal Lorentz transformation given by $\delta\mathbf{x}=-\boldsymbol{\nu}t+(\boldsymbol{\nu}.\mathbf{x}/c^2)\dot{\mathbf{x}}$, it is simple to check the change in the Lagrangian L, defined by

$$\begin{aligned}\delta L&=\frac{\partial L}{\partial\mathbf{x}_1}\cdot\delta\mathbf{x}_1+\frac{\partial L}{\partial\mathbf{x}_2}\cdot\delta\mathbf{x}_2+\frac{\partial L}{\partial\dot{\mathbf{x}}_1}\cdot\delta\dot{\mathbf{x}}_1+\frac{\partial L}{\partial\dot{\mathbf{x}}_2}\cdot\delta\dot{\mathbf{x}}_2\\&=\frac{\mathrm{d}}{\mathrm{d}t}\left(-m_1\mathbf{x}_1.\boldsymbol{\nu}\gamma_1-m_2\mathbf{x}_2.\boldsymbol{\nu}\gamma_2+\frac{e_1e_2}{\pi c}\frac{\mathbf{k}.\delta\mathbf{r}\times\mathbf{r}}{|\mathbf{r}|^2}\right),\end{aligned} \tag{5}$$

without the use of the equations of motion for the two masses m_1 and m_2. Here γ_1 and γ_2 are given by

$$\left(1-\frac{|\dot{\mathbf{x}}_1|^2}{c^2}\right)^{1/2}\quad\text{and}\quad\left(1-\frac{|\dot{\mathbf{x}}_2|^2}{c^2}\right)^{1/2},$$

respectively. Since δL works out to a total differential in (5) without the use of the equations of motion, it is clear that the action $S=\int\mathrm{d}t\,L$ is unaffected by the transformation from $\mathbf{x}\rightarrow\mathbf{x}+\delta\mathbf{x}$, thus making the Lagrangian (3) Lorentz invariant.

The constant of motion is now obtained by using the equations of motion for m_1 and m_2 to rewrite the first equality in (5) as

$$\delta L=\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{\mathbf{x}}_1}\cdot\delta\mathbf{x}_1+\frac{\partial L}{\partial\dot{\mathbf{x}}_2}\cdot\delta\mathbf{x}_2\right). \tag{6}$$

From the second equality in (5) and (6) one thus obtains

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{\mathbf{x}}_1}\cdot\delta\mathbf{x}_1+\frac{\partial L}{\partial\dot{\mathbf{x}}_2}\cdot\delta\mathbf{x}_2+m_1\mathbf{x}_1.\boldsymbol{\nu}\gamma_1+m_2\mathbf{x}_2.\boldsymbol{\nu}\gamma_2-\frac{e_1e_2}{\pi c}\frac{\mathbf{k}.\delta\mathbf{r}\times\mathbf{r}}{|\mathbf{r}|^2}\right)=0. \tag{7}$$

With the canonical momenta defined by $\mathbf{p_i}=\partial L/\partial\dot{\mathbf{x}}_i$ it is easy to obtain from (3) $\mathbf{p}_1=m_1\dot{\mathbf{x}}_1\gamma_1^{-1}+\mathbf{g}$ and $\mathbf{p}_2=m_2\dot{\mathbf{x}}_2\gamma_2^{-1}-\mathbf{g}$, where $\pi c|\mathbf{r}|^2\mathbf{g}=e_1e_2(\mathbf{r}\times\mathbf{k})$ and thus rework (7) as $(\mathrm{d}/\mathrm{d}t)(\mathbf{K}.\mathbf{v})=0$ with the constant of motion $\mathbf{K}$ given by

$$\mathbf{K}=-t\mathbf{P}+m_1\mathbf{x}_1\gamma_1^{-1}+m_2\mathbf{x}_2\gamma_2^{-1}, \tag{8}$$

the total momentum $\mathbf{P}$ being defined as $\mathbf{P}=\mathbf{p}_1+\mathbf{p}_2$. Equation (8) is the counterpart of Eq. (20) in Ref. 2; also while the latter is derived from the Darwin Lagrangian[8] for the electromagnetic

N-body problem and is correct in the $1/c^2$ approximation, Eq. (8) is exact. Note that $\mathbf{K}$ depends explicitly on time except in the center-of-momentum system which is the Lorentz frame where $\mathbf{P}=\mathbf{0}$.

For the Lagrangian (3) the Hamiltonian H and the angular momentum vector $\mathbf{L}$ are given by

$$H=m_1c^2\gamma_1^{-1}+m_2c^2\gamma_2^{-1}, \quad \mathbf{L}=\mathbf{x}_1\times\mathbf{p}_1+\mathbf{x}_2\mathbf{x}\mathbf{p}_2 \tag{9a}$$

and in the $\mathbf{P}=0$ frame they work out to

$$H=m_1c^2f_1+m_2c^2f_2, \quad \mathbf{L}=\mathbf{r}\times\mathbf{p}=\mathbf{k}(r_1p_2-r_2p_1)=\mathbf{k}L_z \tag{9b}$$

with p_1 and p_2 being the x and y components of the relative momentum vector $\mathbf{p}$ defined by

$$\mathbf{p}=\frac{m_2\mathbf{p}_1-m_1\mathbf{p}_2}{m_1+m_2}.$$

In deriving the Hamiltonian in (9b) we go through the following steps.

(i) Since $m_1\dot{\mathbf{x}}_1\gamma_1^{-1}=\mathbf{p}_1-\mathbf{g}$, therefore $\gamma_1^{-2}=1+(1/m_1^2c^2)|\mathbf{p}_1-\mathbf{g}|^2$. One can now express $\mathbf{p}_1$ and $\mathbf{p}_2$ in terms of $\mathbf{p}$ and $\mathbf{P}$ via the relations

$$\mathbf{p}_1=\frac{m_1}{m_1+m_2}\mathbf{P}+\mathbf{p}, \quad \mathbf{p}_2=\frac{m_2}{m_1+m_2}\mathbf{P}-\mathbf{p} \tag{10}$$

and find that in the center-of-momentum system with $\mathbf{P}=0$,

$$\gamma_1^{-1}=\left(1+\frac{|\mathbf{B}|^2}{m_1^2c^2}\right)^{1/2} \tag{11a}$$

with $\mathbf{B}=\mathbf{p}-\mathbf{g}$.

(ii) The above-given calculation can be repeated with $m_2\dot{\mathbf{x}}_2\gamma_2^{-1}=\mathbf{p}_2+\mathbf{g}$ to obtain the following result in the case when $\mathbf{P}=0$:

$$\gamma_2^{-1}=\left(1+\frac{|\mathbf{B}|^2}{m_2^2c^2}\right)^{1/2}. \tag{11b}$$

We shall relabel γ_1^{-1} and γ_2^{-1} in Eqs. (11a) and (11b) as f_1 and f_2, respectively, in the following. Using these definitions one can now rework $\mathbf{K}$ in Eq. (8) in the center-of-momentum system with $\mathbf{P}=0$ as

$$\mathbf{K}=(m_1f_1+m_2f_2)\mathbf{R}+\mu(f_1-f_2)\mathbf{r} \tag{12}$$

with the reduced mass μ and the center-of-mass (c.m.) position vector $\mathbf{R}$ defined by

$$\mu=\frac{m_1m_2}{m_1+m_2} \quad \text{and} \quad \mathbf{R}=\frac{m_1\mathbf{x}_1+m_2\mathbf{x}_2}{m_1+m_2}.$$

As emphasized by Dahl[2] the c.m. vector $\mathbf{R}$ should now be eliminated from Eq. (12) to make $\mathbf{K}$ a proper dynamical function and as in Ref. 2 we shall do this with the help of the equation of motion for $\mathbf{R}$ in the $\mathbf{P}=0$ limit, namely,

$$\frac{d\mathbf{R}}{dt}=\left(\frac{\partial H}{\partial\mathbf{P}}\right)_{\mathbf{P}=0}=\left(\frac{\mu}{m_2}\frac{\partial H}{\partial\mathbf{p}_1}+\frac{\mu}{m_1}\frac{\partial H}{\partial\mathbf{p}_2}\right)_{p_1=\mathbf{p},\mathbf{p}_2=-\mathbf{p}}. \tag{13}$$

One should now recast the Hamiltonian H in (9a) in terms of the canonical momenta $\mathbf{p}_1$ and $\mathbf{p}_2$ and it is given by

$$H=m_1c^2g_1+m_2c^2g_2,\quad g_1=\left(1+\frac{|\mathbf{S}_1|^2}{m_1^2c^2}\right)^{1/2},\quad g_2=\left(1+\frac{|\mathbf{S}_2|^2}{m_2^2c^2}\right)^{1/2} \tag{14}$$

with $\mathbf{S}_1=\mathbf{p}_1-\mathbf{g}$ and $\mathbf{S}_2=\mathbf{p}_2+\mathbf{g}$. On calculating the partial derivatives required in Eq. (13) it is easy to get

$$(m_1+m_2)\frac{d\mathbf{R}}{dt}=(\gamma_1-\gamma_2)\mathbf{B}. \tag{15}$$

From the Hamiltonian (9b), the equations of motion are

$$\frac{\partial\mathbf{H}}{\partial\mathbf{p}}=T\mathbf{B}=\dot{\mathbf{r}} \tag{16a}$$

with $T=\gamma_1/m_1+\gamma_2/m_2$, γ_1 and γ_2 being defined by Eqs. (11a) and (11b). Since $\mathbf{B}=\mathbf{p}-\mathbf{g}$ it is clear that

$$\mathbf{k}\times\dot{\mathbf{r}}=T(\mathbf{k}\times\mathbf{p}+h\mathbf{r}), \tag{16b}$$

where $\pi c|\mathbf{r}|^2h=-e_1e_2$. With Eq. (16b) the other equation of motion, namely,

$$\frac{\partial H}{\partial\mathbf{r}}=Th\left(\mathbf{k}\times\mathbf{p}-\mathbf{r}\left(h+2\frac{\mathbf{r}.\mathbf{k}\times\mathbf{p}}{|\mathbf{r}|^2}\right)\right)=-\dot{\mathbf{p}}, \tag{16c}$$

yields

$$\dot{\mathbf{p}}=h\left(\mathbf{k}\times\dot{\mathbf{r}}-2\frac{\mathbf{r}}{|\mathbf{r}|^2}\mathbf{k}\times\dot{\mathbf{r}}.\mathbf{r}\right). \tag{17}$$

Equation (17) easily leads to

$$\frac{d}{dt}(\mathbf{p}+h\mathbf{r}\times\mathbf{k})=\frac{d\mathbf{B}}{dt}=0. \tag{18}$$

Thus $\mathbf{B}$ is a constant in time and so are f_1 and f_2 in Eqs. (11a) and (11b). Returning to Eq. (15) we get

$$\frac{d}{dt}\left(\mathbf{R}+\frac{\gamma_2-\gamma_1}{m_1+m_2}\mathbf{B}\right)=\mathbf{0} \tag{19}$$

on using Eq. (18). Thus the c.m. position vector $\mathbf{R}(t)$ is given by

$$(m_1+m_2)\mathbf{R}(t)=\mathbf{B}(\gamma_1-\gamma_2)t+\mathbf{R}_0, \tag{20}$$

where $\mathbf{R}_0$ is a constant. Equation (20) is the counterpart of Eq. (43) in Ref. 2; however we must emphasize here that Eq. (20) in this paper is exact in that it has been derived using the equations of motion given by (16a) and (16c) without recourse to approximation. In contrast, the solution for $\mathbf{R}(t)$ given by Eq. (43) in Dahl's paper[2] has been obtained in the $1/c^2$ approximation to the equation of motion as given by Eq. (39) therein. On using (20) in (12) one obtains the exact form of the vector $\mathbf{K}$ as

$$\mathbf{K}=\left(\frac{m_1-m_2+m_2f_2\gamma_1-m_1f_1\gamma_2}{m_1+m_2}\right)t\mathbf{B}+\mu(f_1-f_2)\mathbf{r}+\mathbf{R}_0\frac{m_1f_1+m_2f_2}{m_1+m_2}. \tag{21}$$

With the Hamiltonian H in (9b), Eq. (21) can be reworked as

$$\mathbf{K}=\frac{H}{(m_1+m_2)c^2}\mathbf{R}_0+\frac{m_1-m_2}{m_1+m_2}\mathbf{M} \tag{22}$$

with

$$\mathbf{M}=Qt\mathbf{B}+m_1m_2\frac{f_1-f_2}{m_1-m_2}\mathbf{r} \tag{23}$$

and $Q=1+(m_2f_2\gamma_1-m_1f_1\gamma_2)/(m_1-m_2)$. For the Chern–Simons Lagrangian given by Eq. (3) of this paper Eq. (22) is the counterpart of Eq. (46) in Ref. 2; Eq. (23) therefore defines the Runge–Lenz vector **M** of the Lagrangian (3) in the center-of-momentum system.

It is easy to see that the above-noted derivation in (22) and (23) needs a second look for the equal mass $m_1=m_2$ case. Indeed a similar discussion is also in order for the Runge–Lenz vector derived from Eq. (45) in Dahl's paper;[2] note however that the remedy there is quite painless, namely: begin with unequal masses $m_1\neq m_2$ and subsequently derive the correct Lenz vector for the equal mass case, $m_1=m_2=m$, the result being a simple replacement of the factor μ in Eq. (46) there by $m/2$. But a corresponding effort here merits a separate discussion and is therefore relegated to the Appendix.

With M_1 denoting the x component of the two-component vector **M** it is clear that $\partial M_1/\partial t=QB_1$; thus one expects the Poisson bracket $\{M_1,H\}=-QB_1$, since **M** is a constant of motion, with H being given by Eq. (9b). It is easy to check this using the following:

$$\{r_1,f_1\}=\frac{\gamma_1B_1}{m_1^2c^2},\{r_1,f_2\}=\frac{\gamma_2B_1}{m_2^2c^2},\{r_i,p_j\}=\delta_{ij},\{f_1,f_2\}=0,\{\mathbf{B},f_1\}=0=\{\mathbf{B},f_2\}. \tag{24}$$

On replacing r_1 by r_2 in the first pair of Poisson brackets in (24) one should also replace B_1 by B_2.

One can also use Eq. (24) to evaluate the Poisson bracket of **M** with L_z, the latter being given in Eq. (9b). Using $\{B_i,L_z\}=-\varepsilon_{ij}B_j$ it is easy to verify that

$$\{M_i,L_z\}=-\varepsilon_{ij}M_j \tag{25}$$

with $\varepsilon_{12}=-\varepsilon_{21}=1$. We shall now evaluate the $\{M_1,M_2\}$ Poisson bracket; by virtue of Eq. (24) and the fact that $\{B_1,B_2\}=0$ it is easy to obtain the result

$$\{M_1,M_2\}=-\frac{\alpha^2}{c^2}(f_1-f_2)\left(\frac{\gamma_1}{m_1^2}-\frac{\gamma_2}{m_2^2}\right)\left(\frac{e_1e_2}{\pi c}+L_z\right) \tag{26}$$

with $(m_1-m_2)\alpha=m_1m_2$. While Eq. (25) is expected, on account of **M** being a vector, (26) does not match with that given by Eq. (2) for the Runge–Lenz vector **K** and is therefore a novel feature of this paper. The fact that the calculation made here is exact and quite unlike the approximate calculation to order $1/c^2$ of the Runge–Lenz vector by Dahl[2] reinforces our confidence in this assertion.

The extra term $e_1e_2/\pi c$ in Eq. (26) is reminiscent of the observation by Witten and Olive[9,10] long ago that in supersymmetric theories with solitons the usual supersymmetry algebra is modified to include topological quantum numbers as central charges. Interestingly, the last factor on the right-hand side of Eq. (26) can be expressed as $e_1e_2/\pi c+L_z=\mu(\mathbf{r}\times\mathbf{l})_z$, where we define $\mathbf{l}=\dot{\mathbf{x}}_1\gamma_1^{-1}-\dot{\mathbf{x}}_2\gamma_2^{-1}$ with

$$\gamma_1=\left(1-\frac{|\dot{\mathbf{x}}_1|^2}{c^2}\right)^{1/2}$$

and

$$\gamma_2=\left(1-\frac{|\dot{\mathbf{x}}_2|^2}{c^2}\right)^{1/2}.$$

Qualitatively, Eqs. (25) and (26) are important to this paper because we have derived them, besides Eq. (24), as Poisson brackets here. This is not the case with the Poisson bracket relations given by Eq. (4) in Ref. 2; indeed Dahl[2] provides only a qualitative understanding [see Eqs. (56)–(58) in Ref. 2] of the said Poisson bracket and is unable to derive Eq. (4) in the $1/c^2$ order description in his paper. Needless to say, Eq. (26) is the $2+1$ dimensional counterpart of the $3+1$ dimensional Poisson bracket given by Eq. (4) in Ref. 2, namely

$$\{M_i,M_j\}=-\frac{2}{\mu}H\sum_{k=1}^{3}\varepsilon_{ijk}L_k. \tag{27}$$

In conclusion, two distinguishing features characterize the derivation of the Runge–Lenz vector (23) associated with the Chern–Simons Lagrangian (3) in this paper: (a) the calculation here is exact and, (b) as an unexpected bonus the Poisson bracket in (26) contains the product e_1e_2 as a central charge.

I thank Suresh Govindarajan for reminding me of Ref. 9 and G. Date of the Institute of Mathematical Sciences, Chennai and P. K. Panigrahi of the School of Physics, University of Hyderabad, for clarifying discussions.

APPENDIX

When the masses m_1 and m_2 in the Lagrangian (3) are equal the Runge–Lenz vector $\mathbf{M}$ is worked out initially by assuming that $m_1\neq m_2$; taking the limit of Eq. (22) when $m_2\to m_1$ then yields the desired form of $\mathbf{M}$ as explained in the following. Let us assume here that $m_1=m_2+\varepsilon$ where $\varepsilon>0$. For the second term in Eq. (23) of the text one thus has

$$\lim_{\varepsilon\to 0}\frac{1}{\varepsilon}(f_1-f_2)=\lim_{\varepsilon\to 0}\left\{\left(1+\frac{|\mathbf{B}|^2}{c^2(m_2+\varepsilon)^2}\right)^{1/2}-\left(1+\frac{|B|^2}{c^2m_2^2}\right)^{1/2}\right\} \tag{A1}$$

$$=-\frac{|\mathbf{B}|^2}{c^2m_2^3}\gamma_2 \tag{A2}$$

by a Maclaurin expansion of the first term to order ε. Here γ_2 and γ_1 (see the following) are given by Eq. (11) of the text. A similar effort on the first term in Eq. (23) yields

$$\lim_{\varepsilon\to 0}\left(1-\frac{m_1f_1\gamma_2-m_2f_2\gamma_1}{\varepsilon}\right)=2\gamma_2\frac{|\mathbf{B}|^2}{m_2^2c^2}. \tag{A3}$$

Thus when $m_1=m_2=m$, we have instead of Eq. (23) the Runge–Lenz vector

$$\mathbf{M}=\frac{|B|^2\gamma}{mc^2}\left(\frac{2t}{m}\mathbf{B}-\mathbf{r}\right)=\gamma(1-f^2)(m\mathbf{r}-2t\mathbf{B}) \tag{A4}$$

with $f\gamma=1$ and

$$\gamma=\left(1+\frac{|\mathbf{B}|^2}{m^2c^2}\right)^{-1/2}.$$

With the Poisson brackets given by Eq. (24) it is now easy to arrive at the relations $\{M_i,L_z\}=-\epsilon_{ij}M_j$ and

$$\{M_1, M_2\} = -\frac{1}{c^2}\gamma^4(f^4-1)\left(\frac{e_1 e_2}{\pi c}+L_z\right). \tag{A5}$$

Equation (A5) is the equal mass counterpart of Eq. (26) for unequal masses.

(Received 5 July 2001; accepted for publication 2 October 2001)

A geometrical approach to Lagrangian formulation of continuum mechanics in the language of jet-bundles theory is proposed. The resulting environment allows one to deal with a particular class of kinetic constraints, through a suitable implementation of Gauss' principle. A variational formulation of systems subject to such constraints is also outlined. Two explicit examples are given. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1420397]

I. INTRODUCTION

During the last ten years, nonholonomic constraints have drawn the renewed interest of many authors; as a result, a satisfactory mathematical description of nonholonomic mechanics has been recently set up using the tools of fiber-bundles and jet-bundles theory.

So far, the main efforts in this field of research have concerned systems with a finite number of degrees of freedom, providing a large number of devoted papers (see, e.g., Refs. 1–13).

Our aim is to extend the analysis to the continuum case, borrowing the ideas from works proposing a modern geometrical approach to classical mechanics of discrete systems.

To this end, we propose a new geometrical framework for continuum mechanics, based on jet-bundles theory and general enough to suit a description of material continua in Lagrangian formulation.

The resulting mathematical environment provides an advance in the geometrical description of continuum mechanics and it is successfully used to deal with a particular class of nonholonomic systems; despite the fact that the class is presently limited, the opinion of the authors is that the implemented geometrical setup may provide the starting point for a deeper analysis of a more general class of constraints.

The plan of the paper is as follows. Section II starts with a brief review of the basic aspects of mechanics of point particles. Continuous systems are subsequently introduced extending previous ideas along the lines developed by Kijowski.[14] In this connection, both kinematics and unconstrained dynamics are examined; in particular one of the main aspects of the construction is a new geometrical description of interactions involving a suitable extension of the concept of dynamical flow. Eventually, we introduce the class of nonholonomic constraints which will form the object of the subsequent developments; as we shall see, such constraints consist in purely kinetic restrictions imposed separately on each point of the continuum.

In Sec. III we discuss the problem of motion for these constrained systems. In general, the implementation of the equations of motion, in the presence of constraints, requires the assignment of a rule, known as *constitutive characterization*, which allows one to determine the constrained dynamics from the free one. Accordingly, we introduce a constitutive characterization called *iper-ideality*, defined through a suitable revisitation of Gauss' principle of minimal constraint; as we shall see, iper-ideality is equivalent to requiring the ideality of the constraints with respect to any infinitesimal part of the continuum. A comparison with d'Alembert principle, completed with the so-called Chetaev conditions, is worked out. Finally the explicit equations of motion are written.

[b]Electronic mail: bruno@dima.unige.it

Section IV is devoted to the deduction of dynamical equations from a variational principle. Once again, the basic idea is borrowed from the discrete case and consists in restricting the class of deformations with respect to which the stationarity condition of the action functional is imposed.

The paper ends with two explicit examples.

II. THE GEOMETRICAL FRAMEWORK

A. Geometric preliminaries

The proposed geometrical formulation of continuum mechanics relies on an extension of the ideas involved in the geometrization of the equations of motion of discrete systems in the language of jet bundles.

For convenience of the reader, we briefly review the basic topics of the matter focusing our attention on the mechanics of a single point particle. The foundations of the theory and further details may be found in Refs. 1, 2, and 15.

(1) The evolution of a material point P is described in a frame-independent scheme, introducing the so-called *space–time* $\mathcal{V}_4$; in classical mechanics, the latter is a four-dimensional differentiable manifold, fibered over the real line $\Re$ with projection t: $\mathcal{V}_4 \to \Re$ given by the absolute time function; $\mathcal{V}_4$ is usually referred to fibered coordinates t, x^1, x^2, x^3, subject to the transformation laws

$$\overline{t} = t + c, \quad \overline{x}^i = \overline{x}^i(t, x^1, x^2, x^3) \quad i, = 1,...,3. \tag{1}$$

(2) Every evolution of P is described by a corresponding section $\gamma: \Re \to \mathcal{V}_4$; this leads to a natural identification of the velocity space of the material point with the first jet bundle $j_1(\mathcal{V}_4)$, associated with the stated fibration; $j_1(\mathcal{V}_4)$ may be canonically embedded into the tangent bundle $T(\mathcal{V}_4)$, according to the identification

$$j_1(\mathcal{V}_4) \simeq \{X \in T(\mathcal{V}_4) \,|\, \langle X, \mathrm{d}t \rangle = 1\}; \tag{2}$$

every fibered coordinate systems t, x^i on $\mathcal{V}_4$ may be lifted to a corresponding jet-coordinate system $t, x^i, \dot{x}^i$ on $j_1(\mathcal{V}_4)$, with transformation laws

$$\overline{t} = t + c, \quad \overline{x}^i = \overline{x}^i(t, x^1, x^2, x^3), \quad \overline{\dot{x}}^i = \frac{\partial \overline{x}^i}{\partial t} + \frac{\partial \overline{x}^i}{\partial x^j} \dot{x}^j. \tag{3}$$

In jet-coordinates, the identification (2) is made explicit by the relation

$$z = \left(\frac{\partial}{\partial t} + \dot{x}^i(z) \frac{\partial}{\partial x^i} \right)_{\pi(z)} \in j_1(\mathcal{V}_4),$$

$\pi: j_1(\mathcal{V}_4) \to \mathcal{V}_4$ being the natural projection. Moreover, denoting by $V(\mathcal{V}_4)$ and $V(j_1(\mathcal{V}_4))$ the vertical bundles associated with the fibrations $\mathcal{V}_4 \to \Re$ and $j_1(\mathcal{V}_4) \to \mathcal{V}_4$, respectively, the affine character of the fibration $j_1(\mathcal{V}_4) \to \mathcal{V}_4$ provides a canonical isomorphism between the vertical spaces $V_{\pi(z)}(\mathcal{V}_4)$ and $V_z(j_1(\mathcal{V}_4))$ for each $z \in j_1(\mathcal{V}_4)$. The latter, known as the *vertical lift* of vectors, is expressed in coordinates as

$$V = V^i \left(\frac{\partial}{\partial x^i} \right)_{\pi(z)} \to \hat{V} = V^i \left(\frac{\partial}{\partial \dot{x}^i} \right)_z. \tag{4}$$

(3) Similarly, the second jet bundle $j_2(\mathcal{V}_4)$ may be regarded as the acceleration space of P; $j_2(\mathcal{V}_4)$, referred to jet-coordinates $t, x^i, \dot{x}^i, \ddot{x}^i$, is an affine bundle over $j_1(\mathcal{V}_4)$, modeled on the vertical bundle $V(j_1(\mathcal{V}_4))$. Once again, we have a canonical identification between points $w \in j_2(\mathcal{V}_4)$ and vectors on $j_1(\mathcal{V}_4)$, expressed by

$$w=\left(\frac{\partial}{\partial t}+\dot{x}^i(w)\frac{\partial}{\partial x^i}+\ddot{x}^i(w)\frac{\partial}{\partial \dot{x}^i}\right)_{\pi(w)}\in j_2(\mathcal{V}_4), \tag{5}$$

π now denoting the projection $j_2(\mathcal{V}_4)\to j_1(\mathcal{V}_4)$.

(4) In the geometrical approach to dynamics, a central role is played by the sections Z: $j_1(\mathcal{V}_4)\to j_2(\mathcal{V}_4)$. Viewing them as vector fields on $j_1(\mathcal{V}_4)$, they are called *dynamical flows*; in local coordinates every such flow has components

$$Z=\frac{\partial}{\partial t}+\dot{x}^i\frac{\partial}{\partial x^i}+Z^i(t,x^j,\dot{x}^j)\frac{\partial}{\partial \dot{x}^i}. \tag{6}$$

From Eq. (6) it is easily seen that the integral curves of a dynamical flow Z are jet-extensions of sections of $\mathcal{V}_4$, and that the difference between two arbitrary dynamical flows is a vertical vector field on $j_1(\mathcal{V}_4)$.

Referring to Refs. 1 and 2 for more detailed accounts, we now recall that the assignment of a frame of reference $\mathcal{I}$ determines the following.

(a) A representation of the space–time manifold $\mathcal{V}_4$ as a Cartesian product $\mathcal{V}_4=\Re\times E_3$; by the absolute time axiom, each fiber $t=\text{const}$ represents an Euclidean three-space E_3, identified with the physical space of $\mathcal{I}$ at time t. In the following, $\mathbf{x}:\mathcal{V}_4\to E_3$ will indicate the relativization process associated with a generic frame of reference $\mathcal{I}$; the restriction of the push-forward $\mathbf{x}_*$ to $V(\mathcal{V}_4)$ gives rise to an identification of vertical vectors on $\mathcal{V}_4$ with vectors on E_3, based on the relation

$$V\in V(\mathcal{V}_4)\to \mathbf{v}:=\mathbf{x}_*(V)\in T(E_3). \tag{7}$$

Choosing as spatial coordinates x^1,x^2,x^3 on $\mathcal{V}_4$ a set of Euclidean coordinates on E_3 (henceforth such a choice will be systematically done), the correspondence (7) is made explicit by the relation

$$V=V^i\frac{\partial}{\partial x^i}\to \mathbf{v}=V^i\mathbf{e}_{(i)} \tag{8a}$$

with $\mathbf{e}_{(i)}:=\mathbf{x}_*(\partial/\partial x^i)$, $i=1,...,3$, forming an orthonormal basis for $V_3:=T(E_3)$. Using the vertical lift (4), we get a similar identification between vertical vectors on $j_1(\mathcal{V}_4)$ and vectors in V_3, namely

$$\hat{V}=V^i\frac{\partial}{\partial \dot{x}^i}\to \mathbf{v}=V^i\mathbf{e}_{(i)}. \tag{8b}$$

(b) A global section $Z_{\mathcal{I}}: j_1(\mathcal{V}_4)\to j_2(\mathcal{V}_4)$, assigning to each $z\in j_1(\mathcal{V}_4)$ the unique element $Z_{\mathcal{I}}(z)\in j_2(\mathcal{V}_4)$ expressing the instantaneous vanishing of the relative acceleration of the given material point P in the kinetic state z. Given an element $w\in j_2(\mathcal{V}_4)$, Eqs. (5) and (6) show that the difference $\rho_{Z_{\mathcal{I}}}(w):=w-Z_{\mathcal{I}}(\pi(w))=(\ddot{x}^i(w)-Z^i_{\mathcal{I}}(\pi(w)))\partial/\partial\dot{x}^i$ is a vertical vector field on $j_1(\mathcal{V}_4)$; this defines a map $\rho_{Z_{\mathcal{I}}}: j_2(\mathcal{V}_4)\to V(j_1(\mathcal{V}_4))$ yielding a (frame-dependent) identification of the acceleration space of P with $V(j_1(\mathcal{V}_4))$. It is easily seen that, in Cartesian coordinates, the components $Z^i_{\mathcal{I}}$ of $Z_{\mathcal{I}}$ are identically zero.

The correspondence between vertical vectors on $\mathcal{V}_4$ [respectively, on $j_1(\mathcal{V}_4)$] and vectors on E_3 allows one to introduce a fiber metric g on $\mathcal{V}_4$ [on $j_1(\mathcal{V}_4)$]. For this purpose, letting $\hat{g}$ denote the Euclidean metric of E_3, we define

$$g(V,W):=\hat{g}(\mathbf{x}_*(V),\mathbf{x}_*(W))\quad \forall V,W\in V(\mathcal{V}_4)\quad [\forall \hat{V},\hat{W}\in V(j_1(\mathcal{V}_4))] \tag{9}$$

whence, in Cartesian coordinates,

$$g_{ij} := g\left(\frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j}\right) = g\left(\frac{\partial}{\partial \dot{x}^i}, \frac{\partial}{\partial \dot{x}^j}\right) = \hat{g}(\mathbf{e}_{(i)}, \mathbf{e}_{(j)}) = \delta_{ij}. \tag{10}$$

Although the scalar product (9) is defined through the relativization process induced by $\mathcal{I}$, it may be easily verified that it is actually invariant under arbitrary transformations of the frame of reference, thereby representing an intrinsic attribute of the configuration space–time of P.

By means of the fiber metric g, we can invert the correspondences (8) between vectors $\mathbf{v} = v^i \mathbf{e}_{(i)}$ on V_3 and vertical vectors $V = V^i(\partial/\partial x^i)$ on $\mathcal{V}_4$ [or $\hat{V} = V^i(\partial/\partial \dot{x}^i)$ on $j_1(\mathcal{V}_4)$], according to the relation

$$g_{ij} V^j = g\left(V, \frac{\partial}{\partial x^i}\right) = g\left(\hat{V}, \frac{\partial}{\partial \dot{x}^i}\right) := (\mathbf{v}, \mathbf{e}_{(i)}) \tag{11a}$$

equivalent, in Cartesian coordinates, to

$$V^i = v^i. \tag{11b}$$

Collecting all previous results, the geometrical description of the dynamics of a material point P may be formulated as follows.

(i) Through Eq. (11), we first associate with the vector $\mathbf{F}$ on E_3, describing the total force $\mathbf{F} = (F^i/m)\mathbf{e}_{(i)}$ (evaluated in the frame of reference $\mathcal{I}$ and normalized by the inertial mass m of P), the vertical vector field V on $j_1(\mathcal{V}_4)$ given by

$$V := \frac{F^i}{m} \frac{\partial}{\partial \dot{x}^i}. \tag{12}$$

(ii) Then, the dynamical flow

$$Z := Z_{\mathcal{I}} + V \tag{13}$$

provides a frame-independent representation of the dynamics of P, in the sense that the integral curves of Z are the (first jet-extension of) the solutions of the motion of P.

B. Continuous systems: Kinematics

The mathematical description of a continuum is generally based on the introduction of two different spaces: the first one, known as *material space*, takes the physical properties of the continuum into account, while the second one is the space–time $\mathcal{V}_4$, where the evolution of the system is described.

The material space, indicated by $\mathcal{B}$, is regarded as a differentiable manifold of dimension $M \leqslant 3$; we shall denote by $X^1, \ldots, X^M$ a local coordinate system on $\mathcal{B}$, with transformation laws

$$\overline{X}^A = \overline{X}^A(X^1, \ldots, X^M), \quad A = 1, \ldots, M. \tag{14}$$

The physical properties of the continuum will be taken into account by means of a measure of mass μ: $B(\mathcal{B}) \to \Re_+$, which assigns to each Borel set $U \in B(\mathcal{B})$ the total mass $\mu(U)$ contained in it.

From now on, the evolution of the continuum will be described using the so-called "Lagrangian viewpoint," i.e., considering the congruence of world lines of the points of $\mathcal{B}$ in space–time. In this way, we shall be able to extend the ideas outlined in Sec. II A to the continuum case.

The following discussion will be made in a purely mechanical scheme, omitting from our analysis every consideration regarding energetic and thermodynamical aspects. The latter may be taken into account introducing additional spaces for further dependent variables by Cartesian product with $\mathcal{V}_4$, and making use of suitable constitutive relations.

The *configuration* of the continuum at any instant t is described by a map $\varphi_t:\mathcal{B}\rightarrow\Sigma_t\subset\mathcal{V}_4,\Sigma_t$ representing the totality of simultaneous events at time t. Accordingly, the evolution of the system is a map $\varphi:\mathfrak{R}\times\mathcal{B}\rightarrow\mathcal{V}_4$, assigning to each $t\in\mathfrak{R}$ the configuration of the system at that time.

Therefore, we may take as the basic environment for the description of the continuum the Cartesian product $\mathcal{V}_4\times\mathcal{B}$, fibered both on $\mathcal{V}_4$ and $\mathfrak{R}\times\mathcal{B}$, and referred to local fibered coordinates t, x^i,X^A, subject to the transformation laws (1) and (14). In this context, every evolution φ of the continuum may be thought of as a section $\varphi:\mathfrak{R}\times\mathcal{B}\rightarrow\mathcal{V}_4\times\mathcal{B}$, namely

$$\varphi:\begin{cases} t=t \\ X^A=X^A \\ x^i=\varphi^i(t,X^A) \end{cases}. \tag{15}$$

In other words, the Lagrangian formulation of continuum mechanics may be viewed as the study of the sections of the fibered manifold $\mathcal{V}_4\times\mathcal{B}\rightarrow\mathfrak{R}\times\mathcal{B}$.

Special relevance in the following will be held by some geometrical objects induced by the above-mentioned fibration.

To start with, taking Eqs. (1) and (14) into account, it is easily seen that the vertical fiber bundle $V(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, associated with the fibration $\mathcal{V}_4\times\mathcal{B}\rightarrow\mathfrak{R}\times\mathcal{B}$, is canonically identified with the fiber bundle $V(\mathcal{V}_4)\times\mathcal{B}$. In fact, denoting by $\pi_{\mathcal{V}_4}:\mathcal{V}_4\times\mathcal{B}\rightarrow\mathcal{V}_4$ and $\pi_{\mathcal{B}}:\mathcal{V}_4\times\mathcal{B}\rightarrow\mathcal{B}$ the natural projections, the map $\kappa:V(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})\rightarrow V(\mathcal{V}_4)\times\mathcal{B}$ expressed as

$$\kappa:V^i\frac{\partial}{\partial x^i}_{|z}\in V_z(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})\rightarrow\left(V^i\frac{\partial}{\partial x^i}_{|\pi_{\mathcal{V}_4}(z)},\pi_{\mathcal{B}}(z)\right)\in V_{\pi_{\mathcal{V}_4}(z)}(\mathcal{V}_4)\times\mathcal{B}, \tag{16}$$

$\forall z\in\mathcal{V}_4\times\mathcal{B}$, provides the required identification.

Denoting by $V(j_1(\mathcal{V}_4)\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$ the vertical bundle associated with the fibration $j_1(\mathcal{V}_4)\times\mathcal{B}\rightarrow\mathcal{V}_4\times\mathcal{B}$, the same arguments, together with (an obvious extension of) the vertical lift (4), provide a similar identification between $V(j_1(\mathcal{V}_4)\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$ and $V(j_1(\mathcal{V}_4))\times\mathcal{B}$.

Besides, $\mathcal{V}_4\times\mathcal{B}\rightarrow\mathfrak{R}\times\mathcal{B}$ may be endowed with a fiber metric

$$G:=\pi^*_{\mathcal{V}_4}(\mathbf{x}^*(\hat{g})) \tag{17}$$

giving rise to the scalar product $G(V,W)=V^iW^jG(\partial/\partial x^i,\partial/\partial x^j):=G_{ij}V^iW^j\forall V=V^i(\partial/\partial x^i)$, $W=W^i(\partial/\partial x^i)\in V(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$ [the reader may easily verify that the metric (17) is independent of the choice of the frame of reference $\mathcal{I}$, and thus of the induced relativization process $\mathbf{x}$]; once again, using relation (4) as well as the stated identifications, we may lift G to a fiber metric on $j_1(\mathcal{V}_4)\times\mathcal{B}\rightarrow\mathcal{V}_4\times\mathcal{B}$ (still denoted by G), based on the scalar product $G(\hat{V},\hat{W})=G_{ij}V^iW^j\forall\hat{V}=V^i(\partial/\partial\dot{x}^i)$, $\hat{W}=W^i(\partial/\partial\dot{x}^i)\in V(j_1(\mathcal{V}_4)\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$.

In addition to this, the restriction of the map $\mathbf{x}_*\times id_{\mathcal{B}}$ to $V(\mathcal{V}_4)\times\mathcal{B}$ provides the following correspondence:

$$\mathbf{x}_*\times id_{\mathcal{B}}:(V,p)\in V(\mathcal{V}_4)\times\mathcal{B}\rightarrow(\mathbf{v},p)\in V_3\times\mathcal{B} \tag{18}$$

with V and $\mathbf{v}$ related by Eq. (7).

Conversely, taking the identification (16) into account and following the same arguments stated at the end of Sec. II A, the fiber metric (17) allows one to associate with each pair $(\mathbf{v}=v^i\mathbf{e}_{(i)},p)\in V_3\times\mathcal{B}$ a corresponding element $V=V^i(\partial/\partial x^i)\in V_{\pi^{-1}_{\mathcal{B}}(p)}(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$ by means of the relation

$$G_{ij}V^j=G\left(V,\frac{\partial}{\partial x^i}\right):=\hat{g}(\mathbf{v},\mathbf{e}_{(i)}), \tag{19}$$

equivalent, in Cartesian coordinates, to

$$V^i = v^i. \tag{20}$$

Lifting G to a fiber metric on $j_1(\mathcal{V}_4)\times B \to \mathcal{V}_4\times\mathcal{B}$, the previous arguments may be restated taking $V(j_1(\mathcal{V}_4))$ in place of $V(\mathcal{V}_4)$ and $V(j_1(\mathcal{V}_4)\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$ in place of $V(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$. In particular, the correspondence between elements of $V_3\times\mathcal{B}$ and of $V(j_1(\mathcal{V}_4)\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$ is still expressed by equations of the form (19) and (20).

The first jet bundle of $\mathcal{V}_4\times\mathcal{B}\to\mathfrak{R}\times\mathcal{B}$, henceforth denoted by $j_1(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, will be referred to local jet-coordinates t, X^A, x^i, x^i_A, x^i_0 (where $x^i_A = \partial\varphi^i/\partial X^A$, and $x^i_0 = \partial\varphi^i/\partial t$), with transformation laws

$$\overline{t} = t + c, \quad \overline{x^i} = \overline{x^i}(t, x^1, x^2, x^3), \quad \overline{X^A} = \overline{X^A}(X^1,\ldots,X^M) \tag{21a}$$

$$\overline{x^i_0} = \frac{\partial\overline{x^i}}{\partial t} + \frac{\partial\overline{x^i}}{\partial x^j}x^j_0, \quad \overline{x^i_A} = \frac{\partial\overline{x^i}}{\partial x^j}\frac{\partial X^B}{\partial\overline{X^A}}X^j_B. \tag{21b}$$

The comparison of Eq. (21b) with Eq. (3) shows that there exists a natural projection $\tau^1_1: j_1(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B}) \to j_1(\mathcal{V}_4)\times\mathcal{B}$, described in local coordinates as

$$\tau^1_1: (t, x^i, X^A, x^i_0, x^i_A) \to (t, x^i, X^A, \dot{x}^i = x^i_0).$$

More generally, the kth jet-extension of $\mathcal{V}_4\times\mathcal{B}\to\mathfrak{R}\times\mathcal{B}$ will be indicated by $j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$ and referred to local jet-coordinates t, $X^A, x^i, x^i_\alpha, \ldots, x^i_{\alpha_1,\ldots,\alpha_k}$ (from now on, Greek letters run in the set $\{0, 1, 2, 3\}$, with the subindex 0 representing the time derivative).

As before, it is an easy matter to verify that the maps $\tau^k_r: j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B}) \to j_r(\mathcal{V}_4)\times B (\forall r < k)$, defined by

$$\tau^k_r: (t, X^A, x^i, x^i_\alpha, \ldots, x^i_{\alpha_1,\ldots,\alpha_k}) \to (t, x^i, X^A, \dot{x}^i = x^i_0, \ddot{x}^i = x^i_{00}, \ldots)$$

are well-defined projections.

The previous mathematical environments allow one to geometrize the mechanical quantities involved in the description of the evolution of a continuum system $\mathcal{B}$.

Every section $\varphi: \mathfrak{R}\times\mathcal{B}\to\mathcal{V}_4\times\mathcal{B}$, describing the evolution of $\mathcal{B}$ in Lagrangian terms, may be lifted to a section $j_1(\varphi): \mathfrak{R}\times\mathcal{B}\to j_1(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, assigning to each point $(t,p)\in\mathfrak{R}\times\mathcal{B}$ the values of the section and of its tangent plane at (t,p). As a result, the composite map $\tau^1_1\circ j_1(\varphi)$ is a section of the bundle $j_1(\mathcal{V}_4)\times B\to\mathfrak{R}\times\mathcal{B}$, representing the velocity distribution of the points of the continuum. The fibration $j_1(\mathcal{V}_4)\times B\to\mathfrak{R}\times\mathcal{B}$ will therefore be called the *velocity space of the continuum*.

A similar procedure allows one to lift the section $\varphi: \mathfrak{R}\times\mathcal{B}\to\mathcal{V}_4\times\mathcal{B}$ to the second jet bundle $j_2(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, thus generating a section $j_2(\varphi): \mathfrak{R}\times\mathcal{B}\to j_2(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, and then project it into $j_2(\mathcal{V}_4)\times\mathcal{B}$ by means of τ^2_2. The resulting section $\tau^2_2\circ j_2(\varphi): \mathfrak{R}\times\mathcal{B}\to j_2(\mathcal{V}_4)\times\mathcal{B}$ represents the distribution of the accelerations of the points of the continuum. Accordingly, the fibered manifold $j_2(\mathcal{V}_4)\times B\to\mathfrak{R}\times\mathcal{B}$ will be called the *acceleration space of the continuum*.

More generally, the section $\varphi: \mathfrak{R}\times\mathcal{B}\to\mathcal{V}_4\times\mathcal{B}$ may be lifted to any jet-extension $j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, thereby generating a section $j_k(\varphi)$, which, projected into $j_1(\mathcal{V}_4)\times B$ (by means of τ^k_1) or into $j_2(\mathcal{V}_4)\times B$ (by means of τ^k_2), gives rise to corresponding sections

$$\dot{\varphi} := \tau^k_1\circ j_k(\varphi) = \tau^1_1\circ j_1(\varphi): \mathfrak{R}\times\mathcal{B}\to j_1(\mathcal{V}_4)\times\mathcal{B},$$

$$\ddot{\varphi} := \tau^k_2\circ j_k(\sigma) = \tau^2_2\circ j_2(\varphi): \mathfrak{R}\times\mathcal{B}\to j_2(\mathcal{V}_4)\times\mathcal{B}.$$

The situation is summarized into the commutative diagram

$$\begin{array}{ccccc} j_1(\mathcal{V}_4)\times\mathcal{B} & \xleftarrow{\tau_1^k} & j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B}) & \xrightarrow{\tau_2^k} & j_2(\mathcal{V}_4)\times\mathcal{B} \\ \dot{\varphi}\uparrow & & j_k(\varphi)\uparrow & & \ddot{\varphi}\uparrow \\ \mathfrak{R}\times\mathcal{B} & = & \mathfrak{R}\times\mathcal{B} & = & \mathfrak{R}\times\mathcal{B} \end{array} . \tag{22}$$

C. Continuous systems: Dynamics

In this section, it will be shown how interactions may be embodied in the geometrical scheme developed so far.

As is well known, the forces acting on a physical system $\mathcal{B}$ may be classified into:

(i) external forces, due to the interactions of the system with the external world; they are expressed as functions of the motion of the system and possibly of the time variable t;
(ii) internal forces, describing the interactions among the different points of the system and generally represented by more complicated expressions.

The external forces will be modeled introducing the *specific density of external forces* $\mathbf{F}: j_1(\mathcal{V}_4)\times\mathcal{B}\to V_3$, in such a way that, given a section $\varphi:\mathfrak{R}\times\mathcal{B}\to\mathcal{V}_4\times\mathcal{B}$ and a Borel set $U \in B(\mathcal{B})$, the integral

$$\int_U (\mathbf{F}\circ\dot{\varphi})\mu$$

represents the resultant of external forces (evaluated in the frame $\mathcal{I}$) acting on U at time t, in the "kinetic state" $\dot{\varphi}(t,\cdot)$.

Making use of Eqs. (12) and (13), the specific density of external forces $\mathbf{F} = F^i(t,x^i,\dot{x}^i,X^A)\mathbf{e}_{(i)}$ allows one to define a map $Z^{\text{ext}}: j_1(\mathcal{V}_4)\times\mathcal{B}\to j_2(\mathcal{V}_4)\times\mathcal{B}$, fibered on $j_1(\mathcal{V}_4)\times\mathcal{B}$, as expressed by the commutative diagram

$$\begin{array}{ccc} j_1(\mathcal{V}_4)\times\mathcal{B} & \xrightarrow{Z^{\text{ext}}} & j_2(\mathcal{V}_4)\times\mathcal{B} \\ id\downarrow & & \downarrow\pi \\ j_1(\mathcal{V}_4)\times\mathcal{B} & = & j_1(\mathcal{V}_4)\times\mathcal{B} \end{array} , \tag{23}$$

π denoting the natural projection. In local (Cartesian) coordinates, taking Eqs. (12) and (13) into account, Z^{ext} is represented as

$$Z^{\text{ext}}(z,p) = \left(\frac{\partial}{\partial t} + \dot{x}^i(z)\frac{\partial}{\partial x^i} + F^i(z,p)\left.\frac{\partial}{\partial \dot{x}^i}\right|_z, X^A(p) \right). \tag{24}$$

Equation (24) clearly shows that the map Z^{ext} may be thought as a family of dynamical flows, one for each $p\in\mathcal{B}$.

Composing the map (23) with the projection τ_1^k, we may regard external forces as a map (still denoted by) $Z^{\text{ext}}: j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})\to j_2(\mathcal{V}_4)\times\mathcal{B}$, depending at most on first-order time derivatives and not on material ones. We remark that this property is invariant under arbitrary fibered coordinate transformations.

Internal forces are quite different in nature. In fact, the internal forces do not only depend on the kinetic state and (possibly) on time, but also on the *material derivatives* and mixed *time-material* derivatives $x^i_{\alpha_1,\ldots,\alpha_s}$ for s up to an order k, determined by the physical properties of the system; obviously, the time derivative order is limited to the first one, so expressing the condition that forces cannot depend on accelerations. The reader may easily verify that such a condition is actually invariant under arbitrary coordinate transformations in $\mathcal{V}_4\times\mathcal{B}$.

In the present scheme, internal forces may be geometrized introducing the *specific density of internal forces* $\mathbf{f}: j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})\to V_3$; given φ and U as above, the map $\mathbf{f}=f^i(t,X^A,x^i,x^i_\alpha,\ldots,x^i_{\alpha_1,\ldots,\alpha_k})\mathbf{e}_{(i)}$ is such that the integral

$$\int_U (\mathbf{f}\circ j_k(\varphi))\mu$$

yields the resultant of the internal forces acting on U at time t in the configuration $\varphi(t,\cdot)$. In general, $\mathbf{f}$ is deduced as the divergence of a suitable stress tensor associated with the system.

Once again, still taking Eqs. (12) and (13) into account, we may define a map $Z^{\text{int}}: j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})\to j_2(\mathcal{V}_4))\times\mathcal{B}$, fibered over $j_1(\mathcal{V}_4)\times\mathcal{B}$, according to the commutative diagram

$$\begin{array}{ccc} j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B}) & \xrightarrow{\quad Z^{\text{int}}\quad} & j_2(\mathcal{V}_4)\times\mathcal{B} \\ \tau_1^k\downarrow & & \downarrow \\ j_1(\mathcal{V}_4)\times\mathcal{B} & = & j_1(\mathcal{V}_4)\times\mathcal{B} \end{array} \qquad (25)$$

If $z\in j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, the map Z^{int} is expressed locally as

$$Z^{\text{int}}(z)=\left(\frac{\partial}{\partial t}+x^i_0(z)\frac{\partial}{\partial x^i}+f^i(z)\frac{\partial}{\partial \dot{x}^i}\bigg|_{\tau_1^k(z)},X^A(z)\right). \qquad (26)$$

Collecting all previous results, internal and external forces together give rise to a map $Z: j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})\to j_2(\mathcal{V}_4)\times\mathcal{B}$, fibered over $j_1(\mathcal{V}_4)\times\mathcal{B}$; as mentioned previously, Z only depends on the variables $x^i_{\alpha_1,\ldots,\alpha_s}$ $(s\leqslant k)$ in which the time derivative order is limited to the first one. In local (Cartesian) coordinates we have the representation

$$Z(z)=\left(\frac{\partial}{\partial t}+x^i_0(z)\frac{\partial}{\partial x^i}+(F^i+f^i)(z)\frac{\partial}{\partial \dot{x}^i}\bigg|_{\tau_1^{(k)}(z)},X^A(z)\right). \qquad (27)$$

The map (27) will be called the *dynamical map*.

In continuum mechanics, Newton's second law is written for each subset $U\in B(\mathcal{B})$ as follows:

$$\int_U(\varphi_{00}(t,X^A)-(\mathbf{F}+\mathbf{f})(t,X^A,\varphi^i_\alpha,\ldots,\varphi^i_{\alpha_1,\ldots,\alpha_k}))\mu=0. \qquad (28)$$

The arbitrariness in the choice of $U\subset\mathcal{B}$ allows one to regard Eq. (28) as an equation for the integrand. This is the standard procedure used to convert the integral formulation of the equations of continuum mechanics into the differential one. It will be systematically adopted in all subsequent developments.

In order to investigate the geometric interpretation of Eq. (28) we start with the following

Proposition II.1: Let $Q\to M$ and $Q'\to M'$ be fibered manifolds; suppose that $Q\to M$ is an affine bundle and denote by $V\to M$ the corresponding modeling vector bundle. If $f,g: Q'\to Q$ is a pair of fibered morphisms, then the difference $f-g: Q'\to V$ is a bundle morphism, according to the following commutative diagram:

$$\begin{array}{ccc} Q' & \xrightarrow{\quad f-g\quad} & V \\ \downarrow & & \downarrow \\ M' & \longrightarrow & M \end{array} \qquad (29)$$

The proof is totally straightforward and is omitted.

Applying Proposition II.1 to the maps Z and τ_2^k we have that the difference $(Z-\tau_2^k)$ is a bundle morphism such that diagram

$$\begin{array}{ccc} j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B}) & \xrightarrow{Z-\tau_2^k} & V(j_1(\mathcal{V}_4))\times\mathcal{B} \\ \tau_1^k\downarrow & & \downarrow \\ j_1(\mathcal{V}_4)\times\mathcal{B} & = & j_1(\mathcal{V}_4)\times\mathcal{B} \end{array} \tag{30}$$

is commutative. In local (Cartesian) coordinates, if $z\in j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, we have

$$(F-\tau_2^k)(z)=\left((F^i+f^i-x^i_{00})(z)\,\frac{\partial}{\partial\dot{x}^i}\bigg|_{\tau_1^k(z)},X^A(z)\right). \tag{31}$$

As a consequence, the geometric counterpart of Eq. (28) is finding the set of all points belonging to $(Z-\tau_2^k)^{-1}(\{0\}\times\mathcal{B})$; the latter singles out a submanifold of $j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$ which, by definition, may be regarded as the partial differential equation

$$(F^i+f^i)(t,X^A,\varphi^i_\alpha,\ldots,\varphi^i_{\alpha_1,\ldots\alpha_k})-\varphi^i_{00}=0 \tag{32}$$

of order k for the unknown $\varphi:\mathfrak{R}\times\mathcal{B}\to\mathcal{V}_4\times\mathcal{B}$.

Finally, Proposition II.1 implies that the difference Z_1-Z_2 between two different dynamical maps is a map $(Z_1-Z_2):j_k(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})\to V(j_1(\mathcal{V}_4))\times B$, fibered over $j_1(\mathcal{V}_4)\times\mathcal{B}$. This fact will be important in the description of constraints on the continuum.

D. Purely kinetic constraints

As is well known, the presence of constraints acting on a given system $\mathcal{B}$ is expressed, in mathematical terms, by corresponding restrictions imposed on the possible evolutions of $\mathcal{B}$, i.e., on the set of sections $\varphi:\mathcal{B}\times\mathfrak{R}\to\mathcal{V}_4\times\mathcal{B}$.

In the subsequent discussion, we shall concentrate on the study of a particular kind of constraint henceforth referred to as *purely kinetic*, expressed as restrictions of the form

$$g^\sigma(t,x^i,x^i_0)=0,\quad \sigma=1,\ldots,r,\quad r\in\{1,2,3\} \tag{33}$$

simultaneously imposed on *all* particles $p\in\mathcal{B}$.

Equation (33) may be viewed alternatively as the Cartesian representation of a submanifold of $j_1(\mathcal{V}_4\times\mathcal{B},\mathfrak{R}\times\mathcal{B})$, or of a submanifold of $j_1(\mathcal{V}_4)$ (identifying x^i_0 with $\dot{x}^i$).

In the latter case, under the regularity assumption $\operatorname{rank}\|\partial g^\sigma/\partial\dot{x}^i\|=r$, Eq. (33) defines an embedding $i:\mathcal{A}\to j_1(\mathcal{V}_4)$, fibered over $\mathcal{V}_4$, summarized into the commutative diagram

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{i} & j_1(\mathcal{V}_4) \\ \pi\downarrow & & \downarrow\pi, \\ \mathcal{V}_4 & = & \mathcal{V}_4 \end{array} \tag{34}$$

π denoting the natural projection.

The geometry of the *constraints manifold* $\mathcal{A}$ has been thoroughly investigated in the literature (see, e.g., Refs. 1 and 2). For the present purposes, it is sufficient to recall that the push-forward of the embedding i is an injection of the vertical bundle $V(\mathcal{A})$, associated with the fibration $\mathcal{A}\to\mathcal{V}_4$, into the vertical bundle $V(j_1(\mathcal{V}_4))$. For later use, taking the identification (5) into account, we also denote by $\tau(\mathcal{A}):=T(\mathcal{A})\cap j_2(\mathcal{V}_4)$ the intersection between the tangent space on $\mathcal{A}$ and the second-jet space of the fibration $\mathcal{V}_4\to\mathfrak{R}$.

By means of the submanifold $\mathcal{A}$ we may construct—in an obvious way—a second embedding $i:\mathcal{A}\times\mathcal{B}\to j_1(\mathcal{V}_4)\times\mathcal{B}$, fibered over $\mathcal{V}_4\times\mathcal{B}$. Once again, the situation is summarized into the commutative diagram

$$\begin{array}{ccc} \mathcal{A}\times\mathcal{B} & \overset{i}{\to} & j_1(\mathcal{V}_4)\times\mathcal{B} \\ \pi\downarrow & & \downarrow\pi \\ \mathcal{V}_4\times\mathcal{B} & = & \mathcal{V}_4\times\mathcal{B} \end{array} . \tag{35}$$

Let us denote by $V(\mathcal{A}\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$ the vertical bundle associated with the fibration $\mathcal{A}\times\mathcal{B}\to\mathcal{V}_4\times\mathcal{B}$. Then, through (the vertical lift of) Eq. (16), we have the natural identification $V(\mathcal{A}\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})\simeq V(\mathcal{A})\times\mathcal{B}$, systematically used in the following.

Moreover, the push-forward of i is an injection of $V(\mathcal{A})\times\mathcal{B}$ into $V(j_1(\mathcal{V}_4))\times\mathcal{B}$. In view of this, identifying $V(\mathcal{A})\times\mathcal{B}$ with its image $i_*(V(\mathcal{A}))\times\mathcal{B}\subset V(j_1(\mathcal{V}_4))\times\mathcal{B}$, the bundle $V(\mathcal{A})\times\mathcal{B}$ is easily recognized to coincide with the totality of vertical vectors $X^i(\partial/\partial\dot{x}^i)$ satisfying the conditions

$$X^i\frac{\partial g^\sigma}{\partial\dot{x}^i}=0, \quad \forall\sigma=1,...,r. \tag{36}$$

Now, if we identify the submanifold $\mathcal{A}\times\mathcal{B}$ with its image $i(\mathcal{A})\times\mathcal{B}\subset j_1(\mathcal{V}_4)\times\mathcal{B}$, the results stated in Sec. II B allow one to regard $\mathcal{A}\times\mathcal{B}$ itself as the *space of admissible velocities* of $\mathcal{B}$, each point $z\in\mathcal{A}\times\mathcal{B}$ actually representing an admissible kinetic state of a particle of the continuum $\mathcal{B}$. Accordingly, every section $\varphi:\mathcal{B}\times\mathfrak{R}\to\mathcal{V}_4\times\mathcal{B}$ consistent with the constraints (33), i.e., satisfying the requirement

$$g^\sigma(t,\varphi(t,X^A),\dot{\varphi}(t,X^A))=0, \quad \forall(t,X^A)\in\mathfrak{R}\times\mathcal{B},\forall\sigma=1,...,r, \tag{37}$$

will be called *admissible*. Then, the totality of evolutions of $\mathcal{B}$ allowed by the constraints coincides with the class of admissible sections of $\mathcal{V}_4\times\mathcal{B}\to\mathfrak{R}\times\mathcal{B}$. The clear meaning of the requirement (37) is that the image of the first jet-extension of each admissible section under the projection τ_1^k has to be contained in $\mathcal{A}\times\mathcal{B}$.

For later use, we notice that, up to the assignment of initial data $\varphi^i(0,X)$, $\dot{\varphi}^i(0,X)$ s.t. $g^\sigma(0,\varphi(0,X),\dot{\varphi}(0,X))=0\,\forall X\in\mathcal{B}$, Eq. (37) is mathematically equivalent to the "tangency" requirement

$$\frac{\partial g^\sigma}{\partial t}+\frac{\partial g^\sigma}{\partial x^i}\dot{\varphi}^i+\frac{\partial g^\sigma}{\partial\dot{x}^i}\ddot{\varphi}^i=0, \quad \forall(t,X^A)\in\mathfrak{R}\times\mathcal{B};\forall\sigma=1,...,r. \tag{38}$$

III. SOLVING THE DYNAMICS

A. The constitutive characterization of iper-ideality

Within the geometrical framework outlined in Sec. II, the implementation of the equations of motion in the presence of constraints requires the introduction of a rule χ assigning to every free dynamics $\hat{Z}$ a corresponding *effective dynamics* $Z:=\chi(\hat{Z})$ expressing through Eq. (32) the actual evolution of the constrained system.

To start with, let us denote by $j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R})$ the submanifold of $j_k(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R})$ (locally) described by Eq. (33), or, equivalently, the pull-back of $j_k(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R})$ over $\mathcal{A}\times\mathcal{B}$, expressed by the commutative diagram

$$\begin{array}{ccc} j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R}) & \overset{i}{\rightarrow} & j_k(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R}) \\ \downarrow & & \downarrow r_1^k \\ \mathcal{A}\times\mathcal{B} & \overset{i}{\rightarrow} & j_1(\mathcal{V}_4)\times\mathcal{B} \end{array} . \tag{39}$$

From the considerations in Sec. II, taking Eqs. (27), (35), and (38) explicitly into account, it is easily seen that the constrained dynamics Z has to be a differentiable map $Z: j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R}) \rightarrow \tau(\mathcal{A})\times\mathcal{B}$. Within this scheme, it is clear that the required rule χ has to be considered as the *constitutive characterization* of the constraints. Therefore, such a rule χ represents an additional piece of information, related to the physical properties of the devices involved in the implementation of the constraints, which has to be included among the geometrical attributes of the system. In the subsequent discussion we shall characterize a special kind of purely kinetic constraint, defined, as we shall see, by a suitable choice of the rule χ.

First of all, we observe that, due to Proposition II.1, the difference

$$\phi := \chi(\hat{Z}) - \hat{Z} \tag{40}$$

between the effective dynamics and [the restriction to $j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R})$ of] the unconstrained dynamics, defines a differentiable map $\phi: j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R}) \rightarrow V_{\mathcal{A}}(j_1(\mathcal{V}_4))\times\mathcal{B}$, where $V_{\mathcal{A}}(j_1(\mathcal{V}_4))$ denotes the restriction to $\mathcal{A}$ of the vertical bundle $V(j_1(\mathcal{V}_4))$.

In view of the results stated in Sec. II B, the map ϕ has a natural interpretation in terms of *reactive forces*: recalling Eq. (20), the connection between the map ϕ and the distribution $\Phi = \Phi^i e_{(i)}$ of specific density of reactive forces is expressed by

$$\phi^i = \Phi^i. \tag{41}$$

Now, indicating by $\pi_{\tau(\mathcal{A})}$ the projection $\pi_{\tau(\mathcal{A})}: \tau(\mathcal{A})\times\mathcal{B} \rightarrow \mathcal{A}\times\mathcal{B}$, it is easily seen that—independently of the choice of constitutive characterization χ—the reactive force ϕ necessarily satisfies the inequality

$$|\phi_{|z}| = |\chi(\hat{Z})_{|z} - \hat{Z}_{|z}| \geqslant \min\{|Y - \hat{Z}_{|z}|, \quad Y \in \pi_{\tau(\mathcal{A})}^{-1}(\tau_1^k(z))\} \tag{42}$$

for all $z \in j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R})$, the norm $|\cdot|$ being the one induced by the fiber metric G_{ij}. Indeed, by construction, $\chi(\hat{Z})_{|z}$ belongs to $\pi_{\tau(\mathcal{A})}^{-1}(\tau_1^k(z))$.

Borrowing from Ref. 1, we may then state the following

Definition III.1: A set of purely kinetic constraints is said to be iper-ideal if and only if the equality sign identically holds in Eq. (42), i.e., if the corresponding constitutive characterization χ satisfies

$$|\chi(\hat{Z})_{|z} - \hat{Z}_{|z}| = \min\{|Y - \hat{Z}_{|z}|, \quad Y \in \pi_{\tau(\mathcal{A})}^{-1}(\tau_1^k(z))\} \tag{43}$$

for all $z \in j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R})$.

We are now going to see that the constitutive characterization of iper-ideality is essentially equivalent to the requirement that the constraints appear *ideal* with respect to any infinitesimal part of continuum $\mathcal{B}$, ideality being understood in the sense of Gauss' principle of minimal constraint.[1,2]

Indeed, taking the definition of the metric G_{ij} as well as Eq. (41) into account, Eqs. (40) and (43) mean that the motion of any particle of continuum $\mathcal{B}$ is selected among the totality of kinematically admissible evolutions as the one for which the quantity

$$|\phi|^2 = |\Phi|^2 = |\mathbf{a} - \mathbf{F} - \mathbf{f}|^2 \tag{44}$$

attains a minimum at any instant t ($\mathbf{a}$ and $\mathbf{F}+\mathbf{f}$ denote, respectively, the acceleration of the particle and the specific density of active forces). As predicted, this is precisely a restatement of Gauss' principle for any infinitesimal part of $\mathcal{B}$, regarded as the search, within the class of admissible accelerations, for that value $\mathbf{a}$ which minimizes the expression (44) at each instant t.

Once again borrowing from the discrete case[1] and extending the arguments to the present context, Gauss' criterion of minimal constraint may be made equivalent to the principle of virtual work; as we shall see, this is achieved embodying the so-called Chetaev' conditions into the definition of the virtual displacements for any particle of $\mathcal{B}$.

In fact, for each $z \in j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R})$, the image space

$$\rho_z(\hat{Z}) := \{Y-\hat{Z}_{|z} | Y \in \pi^{-1}_{\tau(\mathcal{A})}(\tau_1^k(z))\}$$

is an affine subspace of the vertical space $V_{\tau_1^k(z)}(j_1(\mathcal{V}_4)\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$ $(\simeq V(j_1(\mathcal{V}_4))\times\mathcal{B}_{|\tau_1^k(z)})$, modeled on $V_{\tau_1^k(z)}(\mathcal{A}\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$ $(\simeq V(\mathcal{A})\times\mathcal{B}_{|\tau_1^k(z)})$. For this reason, there exists an element of *minimal norm* in $\rho_z(\hat{Z})$, identified with the unique element $N_z \in \rho_z(\hat{Z})$ *orthogonal* to $V_{\tau_1^k(z)}(\mathcal{A}\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$.

Repeating the reasoning for each $z \in j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R})$, we may define a unique map $\mathcal{P}(\hat{Z}): j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R}) \to \tau(\mathcal{A})\times\mathcal{B}$ such that $\mathcal{P}(\hat{Z})_{|z}-\hat{Z}_{|z}=N_z \forall z$. It is clear that the constitutive characterization (43) is nothing but the ansatz $\chi(\hat{Z}) := \mathcal{P}(\hat{Z})$.

In terms of reactive forces, this implies that the iper-ideality is mathematically equivalent to the orthogonality condition

$$G(\phi_z, X)=0, \quad \forall X \in V_{\tau_1^k(z)}(\mathcal{A}\times\mathcal{B},\mathcal{V}_4\times\mathcal{B}), \forall z \in j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R}). \tag{45}$$

Recalling Eqs. (19), (36), and (41), the scalar product (45) takes the form

$$\Phi_i X^i = 0, \tag{46}$$

Φ_i and X^i denoting, respectively, the (covariant) components of the specific density of reactive force Φ and the components of any vertical vector X satisfying the relations $X^i(\partial g^\sigma/\partial \dot{x}^i)=0$ $\sigma=1,...,r$.

Then, performing the formal substitution $X^i \to \delta\varphi^i$ and defining the virtual displacement $\delta\varphi := (\delta\varphi^1, \delta\varphi^2, \delta\varphi^3)$ for any particle of $\mathcal{B}$, from Eq. (46) we recover the content of the principle of virtual work

$$\Phi \cdot \delta\varphi = 0,$$

for every virtual displacement $\delta\varphi$ obeying the Chetaev conditions $(\partial g^\sigma/\partial \dot{x}^i)\delta\varphi^i=0$ $\sigma=1,...,r$.[1,2,16–18]

B. The equations of motion

In this section we shall examine the construction of the equations of motion for a continuum $\mathcal{B}$ subject to iper-ideal purely kinetic constraints.

First of all, it is worth observing that the identical vanishing of the scalar product $G(\phi,X) = G_{ij}\phi^i X^j = \phi_i X^i = 0$ for all vertical vectors $X = X^i(\partial/\partial\dot{x}^i) \in V(\mathcal{A}\times\mathcal{B},\mathcal{V}_4\times\mathcal{B})$ implies the relations $\phi_i = \lambda_\sigma(\partial g^\sigma/\partial\dot{x}^i)$ or, equivalently, $\phi^i = \lambda_\sigma(\partial g^\sigma/\partial\dot{x}^j)G^{ij}$ for some functions $\lambda_\sigma \in \mathcal{F}(j_k^{\mathcal{A}}(\mathcal{V}_4\times\mathcal{B},\mathcal{B}\times\mathfrak{R}))$, because of the tangency condition $X^i(\partial g^\sigma/\partial\dot{x}^i)=0$ $\sigma=1,...,r$.

This fact, together with Eq. (40), allows one to represent the constrained dynamical map $Z := \chi(\hat{Z})$ in the form

$$Z = \hat{Z} + \lambda_\sigma \frac{\partial g^\sigma}{\partial \dot{x}^i} G^{ij} \frac{\partial}{\partial \dot{x}^j}. \tag{47}$$

In comparison with Eq. (30), Eq. (47) yields the corresponding constrained equations of motion for $\mathcal{B}$, expressed as

$$\ddot{\varphi}^i = F^i + f^i + \lambda_\sigma \frac{\partial g^\sigma}{\partial \dot{x}^j} G^{ij}. \tag{48}$$

The final step is the determination of the multipliers λ_σ. This is easily achieved imposing the "tangency" condition (38), resulting in

$$\frac{\partial g^\gamma}{\partial t} + \frac{\partial g^\gamma}{\partial x^i}\dot{\varphi}^j + (F^i + f^i)\frac{\partial g^\gamma}{\partial \dot{x}^i} + \lambda_\sigma \frac{\partial g^\sigma}{\partial \dot{x}^j} G^{ij} \frac{\partial g^\gamma}{\partial \dot{x}^i} = 0, \quad \gamma = 1,...,r. \tag{49}$$

In view of the regularity assumption $\|\partial g^\sigma/\partial \dot{x}^i\| = r$, ensuring the nonsingularity of the matrix $\Gamma^{\sigma\gamma} := (\partial g^\sigma/\partial \dot{x}^j) G^{ij} (\partial g^\gamma/\partial \dot{x}^i)$, Eq. (49) may be solved uniquely for the λ_σ's, yielding the explicit expressions

$$\lambda_\sigma = \Gamma_{\sigma\gamma}\left[-\left(\frac{\partial g^\gamma}{\partial t} + \frac{\partial g^\gamma}{\partial x^i}\dot{\varphi}^i \right) - (F^i + f^i)\frac{\partial g^\gamma}{\partial \dot{x}^i} \right], \tag{50}$$

$\Gamma_{\sigma\gamma}$ denoting the inverse of the matrix $\Gamma^{\sigma\gamma}$.

Finally, we get the required equations of motion for the system, simply inserting the result (50) into Eq. (48).

IV. VARIATIONAL FORMULATION

The aim of this section is to derive the constrained equations of motion (48), (38) from a suitable variational problem, basing our discussion on the usual variational formulation for general field theories. For simplicity, we focus our attention on first-order variational calculus only. Extensions to higher order cases are essentially straightforward and are left to the reader.

First of all, we consider the totality of local sections $\varphi: \Re \times \mathcal{B} \to \mathcal{V}_4 \times \mathcal{B}$ and denote it by Γ. As is well known, Γ may be endowed with a smooth infinite dimensional manifold structure. Given a section $\varphi \in \Gamma$, we shall call *deformation* of φ a differentiable map $\psi: \Re \times \mathcal{B} \times (-\sigma, \sigma) \to \mathcal{V}_4 \times \mathcal{B} (\sigma \in \Re)$ satisfying the conditions

$$\psi(\cdot, 0) = \varphi(\cdot), \quad \psi_\xi(\cdot) := \psi(\cdot, \xi) \in \Gamma, \quad \forall \xi \in (-\sigma, \sigma). \tag{51}$$

In view of Eq. (51), a deformation of φ defines a curve in Γ, passing through φ for $\xi = 0$. Then, the tangent vector to ψ at φ identifies an element $V \in T_\varphi \Gamma$, defined by the relation

$$V(\cdot) := \frac{d\psi}{d\xi}(\cdot, \xi)_{|\xi = 0}. \tag{52}$$

From Eq. (52) it is easily seen that V has the nature of a vertical vector field along the section φ, namely of a map $V: \Re \times \mathcal{B} \to V_{\varphi(\Re \times \mathcal{B})}(\mathcal{V}_4 \times \mathcal{B}, \Re \times \mathcal{B})$ such that the following diagram

$$\begin{array}{ccc} \Re \times \mathcal{B} & \overset{V}{\rightarrow} & V(\mathcal{V}_4 \times \mathcal{B}, \Re \times \mathcal{B}) \\ \downarrow id & & \downarrow \pi \\ \Re \times \mathcal{B} & \overset{\varphi}{\rightarrow} & \mathcal{V}_4 \times \mathcal{B} \end{array} \tag{53}$$

is commutative, π denoting the canonical projection.

Any map V as in diagram (53) will be called an *infinitesimal deformation* of φ.

Now, let $\mathcal{L}$ be a differentiable $(M+1)$-form on $j_1(\mathcal{V}_4\times\mathcal{B},\Re\times\mathcal{B})$, semibasic with respect to the fibration $j_1(\mathcal{V}_4\times\mathcal{B},\Re\times\mathcal{B})\to\Re\times\mathcal{B}$. In local coordinates, $\mathcal{L}=L(t,X^A,x^i,x^i_\alpha)\times \mathrm{d}t\wedge\mathrm{d}X^1\wedge\cdots\wedge\mathrm{d}X^M$.

For any compact domain $D\subset\Re\times\mathcal{B}$, let us denote by Γ_D the totality of sections $\varphi\in\Gamma$ defined in some open neighborhood $U\subset\Re\times\mathcal{B}$ of D. By means of $\mathcal{L}$, we may then define a real-valued functional I_D on Γ_D, according to the relation

$$I_D(\varphi):=\int_D j_1(\varphi)^*(\mathcal{L}),\quad \forall\varphi\in\Gamma_D. \tag{54}$$

Given a section $\varphi\in\Gamma_D$ and an infinitesimal deformation $V\in T_\varphi\Gamma$, we shall call *first variation* of I_D at φ with respect to V (Gateaux derivative at φ in the direction V) the expression

$$\frac{\delta I_D}{\delta V}(\varphi):=\frac{\mathrm{d}}{\mathrm{d}\xi}\int_D j_1(\psi_\xi)^*(\mathcal{L})_{|_{\xi=0}}, \tag{55}$$

ψ_ξ being any deformation of φ "tangent to V" [i.e., satisfying Eq. (52)].

Following the usual terminology, we shall call the *critical point* of I_D any section $\varphi\in\Gamma_D$ making the functional I_D stationary, i.e., satisfying the condition

$$\frac{\delta I_D}{\delta V}(\varphi)=0$$

for all infinitesimal deformations $V\in T_\varphi\Gamma$.

By definition, the standard variational problem associated with the $(M+1)$-form $\mathcal{L}$—usually called the *Lagrangian*—consists in the search for sections $\varphi\in\Gamma$ which are critical points of all functionals I_D (54) for all compact domains D, with respect to all infinitesimal variations vanishing at the boundary of D, namely such that

$$\frac{\delta I_D}{\delta V}(\varphi)=0,\quad \forall\ \text{compact domain}\ D\subset\Re\times\mathcal{B},\forall V\in T_\varphi\Gamma\ \text{ s.t. }\ V_{|\partial D}=0. \tag{56}$$

For convenience, we introduce the notation $X^0:=t$ and refer the manifolds $\Re\times\mathcal{B}$ and $j_1(\mathcal{V}_4\times\mathcal{B},\Re\times\mathcal{B})$ to local coordinates X^α and X^α, x^i, x^i_α, $\alpha=0,...,M$, respectively. We also denote by $\mathrm{d}S:=\mathrm{d}X^0\wedge\cdots\wedge\mathrm{d}X^M$ the local volume element in $\Re\times\mathcal{B}$.

Taking the condition at the boundary $V_{|\partial D}=0$ explicitly into account, it is a straightforward matter to get the well-known expression[14,19]

$$\frac{\delta I_D}{\delta V}(\varphi)=\int_D\left[\frac{\partial L}{\partial x^i}-\mathrm{d}_\alpha\left(\frac{\partial L}{\partial x^i_\alpha}\right)\right]V^i\circ j_2(\varphi)\mathrm{d}S\ , \tag{57}$$

where the d_α's indicate the formal derivatives $\mathrm{d}_\alpha:\mathcal{F}(j_1(\mathcal{V}_4\times\mathcal{B},\Re\times\mathcal{B}))\to\mathcal{F}(j_2(\mathcal{V}_4\times\mathcal{B},\Re\times\mathcal{B}))$ with respect to any X^α, i.e., $\mathrm{d}_\alpha f=\partial f/\partial X^\alpha+(\partial f/\partial x^i)x^i_\alpha+(\partial f/\partial x^i_\beta)x^i_{\beta\alpha}\forall f=f(X^\alpha,x^i,x^i_\alpha)$.

Because of the arbitrariness in the choice of the compact domains D as well as of the infinitesimal deformations V, it follows from Eq. (57) that a section φ is a solution of the variational problem (56) if and only if it satisfies the well known Euler–Lagrange equations

$$\left[\frac{\partial L}{\partial x^i}-\mathrm{d}_\alpha\left(\frac{\partial L}{\partial x^i_\alpha}\right)\right]\circ j_2(\varphi)=0,\quad i=1,...,3. \tag{58}$$

As mentioned previously, our aim is now to set up a variational formulation for the equations of motion (48), (38) of a continuum system $\mathcal{B}$ subject to purely kinetic constraints.

To this end, let us suppose the existence of a Lagrangian $\mathcal{L}$ which describes the dynamical behavior of the system in the absence of kinetic constraints, by means of the corresponding Euler–Lagrange equations (58).

Borrowing from the arguments developed for the discrete case,[20,21] the idea is not to study the stationarity of functionals (54) with respect to all infinitesimal deformations V vanishing at the boundary, but only with respect to the ones satisfying the Chetaev conditions

$$\frac{\partial g^{\sigma}}{\partial \dot{x}^{i}} V^{i} = 0, \quad \sigma = 1,...,r. \tag{59}$$

We shall call the latter a *constrained* variational problem.

The solutions of (57) and (59) may be obtained by means of the usual Lagrange multipliers' method (see, e.g., Ref. 22), from which we derive the existence of some functions λ_{σ} such that a section φ is a solution of the constrained variational problem if and only if it satisfies the equations

$$\left[\frac{\partial L}{\partial x^{i}} - \mathrm{d}_{\alpha}\left(\frac{\partial L}{\partial x^{i}_{\alpha}}\right)\right] \circ j_2(\varphi) = \lambda_{\sigma} \frac{\partial g^{\sigma}}{\partial \dot{x}^{i}} \circ j_2(\varphi), \quad i = 1,...,3, \tag{60}$$

clearly identical to Eq. (48). The argument is straightforward. The details are left to the reader.

In general, Eq. (60) alone is not sufficient to single out any solution φ. In fact, in addition to (the significant components of) the section φ, we need to determine the multipliers λ_{σ}, too. To restore determinacy, some additional conditions are required.

In this specific case, the significant ansatz is to impose that the solutions φ satisfy the ''tangency'' requirement (38). As already pointed out, this, together with the assignment of consistent initial data, is mathematically equivalent to requiring consistency with the equations of constraints (33), and it is actually sufficient to determine the unknowns λ_{σ}. We underline that these supplementary conditions concern exclusively the solutions, and not their deformations.

We have thus shown that the admissible evolutions of the system $\mathcal{B}$ can be characterized as the solutions $\varphi: \mathfrak{R} \times \mathcal{B} \to \mathcal{V}_4 \times \mathcal{B}$ of a suitable constrained variational problem. An explicit example will be given in Sec. V.

Remark: We notice that the complementary case, consisting in the study of constraints depending on material derivatives only, has been considered in Ref. 23. Although the authors use a geometrical framework quite similar to the one proposed here, they deduce the equations of motion through a variational principle which, in the case of finite dimensional systems subject to nonholonomic constraints, reduces to vakonomic mechanics and thus yields incorrect equations of motion.

For this reason, the approach proposed in Ref. 23 does not seem appropriate to deal with purely kinetic constraints, contrary to the one proposed here based on Gauss' and D'Alembert's principles. Therefore, as mentioned by Marsden and co-workers,[23] it appears that a distinction between time and material partial derivatives is needed.

However, a unified approach would be desirable and, in our opinion, it may be implemented in the framework of infinite-dimensional manifolds. A first step in this direction has been made in Ref. 24.

V. EXAMPLES

A. Rotating continuum

Let us denote by $\{\underline{k}_1, \underline{k}_2, \underline{k}_3\}$ an orthonormal basis in the physical space of a given frame of reference $\mathcal{I}$. We consider a continuum $\mathcal{B}$ subject to a kinetic constraint which keeps it rotating around $\underline{k}_3$ with a constant angular velocity $\underline{\omega} = \omega \underline{k}_3$, so that the tangential velocity $\underline{v}_T(p)$ of each point $p \in \mathcal{B}$ is proportional to the distance from the axis of rotation. The tangential velocity is meant as the component of the velocity of each p which is tangent to the circle centered on $\underline{k}_3$, lying on the plane orthogonal to $\underline{k}_3$ and passing through p at each instant t.

If $\varphi:\Re\times\mathcal{B}\to\mathcal{V}_4$ describes the evolution of the continuum in the frame of reference $\mathcal{I}$, we define:
(1) $\underline{R}=\underline{R}(t,X^A)$ the radius vector, which connects the point $p\in\mathcal{B}$ having coordinates $\{X^1,\ldots,X^M\}$ and the axis of rotation, and lies in the plane orthogonal to $\underline{k}_3$ containing p;
(2) $\hat{R}=(1/\rho)\underline{R}$ where $\rho=\sqrt{\varphi_1^2+\varphi_2^2}$;
(3) $\hat{l}=\underline{k}_3\wedge\hat{R}$.

If $\varphi=\Sigma_{i=1}^3\varphi_i\underline{k}_i$ we have

$$\underline{R}=\varphi_1\underline{k}_1+\varphi_2\underline{k}_2,\quad \hat{l}=\frac{1}{\rho}(-\varphi_2\underline{k}_1+\varphi_1\underline{k}_2).$$

We can describe the constraint by means of

$$\omega|\underline{R}|=|\dot{\varphi}\cdot\hat{l}|. \tag{61}$$

This means that, given a circle centered on $\underline{k}_3$, lying on a plane orthogonal to $\underline{\omega}$, the tangential component of the velocity of each of its points is proportional to the product of the radius of the circle by the magnitude ω of the angular velocity.

Equation (61) may be rephrased as

$$\omega(\varphi_1^2+\varphi_2^2)=|\varphi_1\dot{\varphi}_2-\varphi_2\dot{\varphi}_1|.$$

We thus define the constraints in implicit form by means of the relation

$$g:=|\varphi_1\dot{\varphi}_2-\varphi_2\dot{\varphi}_1|-\omega(\varphi_1^2+\varphi_2^2)=0. \tag{62}$$

Denoting by (F_1,F_2,F_3) the components of the specific density of internal and external forces together and recalling Eqs. (48)–(50) we have

$$\lambda=\frac{1}{\rho^2}[2\omega(\varphi_1\dot{\varphi}_1+\varphi_2\dot{\varphi}_2)-\nu(F_1\varphi_2-F_2\varphi_1)], \tag{63}$$

where

$$\nu=\frac{|\varphi_1\dot{\varphi}_2-\varphi_2\dot{\varphi}_1|}{\varphi_1\dot{\varphi}_2-\varphi_2\dot{\varphi}_1}.$$

The sign of ν is uniquely determined by the choice of initial data. The reader may easily verify that the first term on the right-hand side of (63) is the part of reactive force which annihilates Coriolis force, while the second balances the tangential component of real (internal and external) physical forces.

From all the above-mentioned considerations, we obtain that the equations of motion for the constrained continuum are

$$\begin{cases}\ddot{\varphi}_1=F_1-\dfrac{\varphi_2}{\rho^2}[2\omega\nu(\varphi_1\dot{\varphi}_1+\varphi_2\dot{\varphi}_2)-(F_1\varphi_2-F_2\varphi_1)],\\ \ddot{\varphi}_2=F_2+\dfrac{\varphi_1}{\rho^2}[2\omega\nu(\varphi_1\dot{\varphi}_1+\varphi_2\dot{\varphi}_2)-(F_1\varphi_2-F_2\varphi_1)],\\ \ddot{\varphi}_3=F_3.\end{cases} \tag{64}$$

We finally observe that Eq. (64) represents every continuum subject to the constraint described by Eq. (62); different continua correspond to different choices of the functions F_i.

B. Vibrating string

In a Cartesian frame of reference, let us consider a homogeneous elastic string with fixed ends, moving without friction on a horizontal plane. In addition to this, we require that the string makes transversal vibrations only.

Although both restrictions are positional in nature, we shall deal with them as (integrable) kinetic constraints; actually, the aim is to provide an example in which the iper-ideality condition turns out to be a common physical requirement. Moreover, we shall discuss the problem using the variational formulation.

To this end, denoting by ℓ_0 the rest length of the string, we identify the material space $\mathcal{B}$ of the system with the closed interval $[0,\ell_0]\subset\mathfrak{R}$ and refer it to a coordinate ξ. Moreover, we denote by μ_0 the (constant) density of the string. Finally we indicate by x^1, x^2, x^3 the Cartesian coordinates in the physical space of the given frame chosen in such a way that the horizontal plane coincides with $x^3=0$ and the ends of the string belong to the x^1 axis. Accordingly, the jet-coordinates will be indicated by $t,\xi,x^i,x^i_t,x^i_\xi,x^i_{tt},x^i_{t\xi},x^i_{\xi\xi},\dots$.

In this way, the imposed constraints are, respectively, expressed by

$$g^1 := x^3_t = 0, \quad g^2 := x^1_t = 0. \tag{65}$$

As far as the constraint $g^1=0$ is concerned, the iper-ideality condition is easily recognized to reproduce the requirement of absence of friction.

The implementation of a variational formulation requires the construction of a suitable Lagrangian for the system $\mathcal{B}$. To this purpose, we consider the string as a sequence of material points all connected to the neighbors by springs; in other words, given any pair of points P_1 and P_2 belonging to the string and having distance $\delta\xi$ in the rest configuration, we endow them with a potential energy equal to the one of a spring of rest length $\delta\xi$ and elastic constant $\chi/\delta\xi$, namely

$$\delta U = -\frac{\chi}{2\delta\xi}(\delta s-\delta\xi)^2 = -\frac{\chi}{2}\left(\frac{\delta s}{\delta\xi}-1\right)^2\delta\xi,$$

where δs is the actual length of the piece of string between P_1 and P_2. The constant χ depends on the structural properties of the string; in fact $\chi=ES$, where E is the Young's modulus and S is the (constant) section of the string. Therefore, by an obvious limit process $\delta\xi\to 0$, the total internal potential energy of the system is given by the integral

$$U = -\frac{\chi}{2}\int_0^{\ell_0}\left(\frac{\mathrm{d}s}{\mathrm{d}\xi}-1\right)^2\mathrm{d}\xi.$$

On the other hand, the kinetic energy of the spring is expressed as

$$T = \frac{1}{2}\int_0^{\ell_0}\mu_0\sum_{i=1}^{3}(x^i_t(t,\xi))^2\mathrm{d}\xi.$$

Collecting all the results and taking the weight potential into account, we may define the Lagrangian

$$\mathcal{L} = \left(\frac{\mu_0}{2}\sum_{i=1}^{3}(x^i_t)^2-\frac{\chi}{2}\left(\sqrt{\sum_{i=1}^{3}(x^i_\xi)^2}-1\right)^2-\mu_0 g x^3\right)\mathrm{d}t\wedge\mathrm{d}\xi \tag{66}$$

viewed as a two-form on $j_1(\mathcal{V}_4\times[0,\ell_0],\mathfrak{R}\times[0,\ell_0])$, semibasic with respect to the fibration $j_1(\mathcal{V}_4\times[0,\ell_0],\mathfrak{R}\times[0,\ell_0])\to\mathfrak{R}\times[0,\ell_0]$.

The Euler–Lagrange–Chetaev equations (60) associated with the Lagrangian (66) assume the form

$$\begin{cases} \mu_0\varphi^1_{tt}=\dfrac{\partial}{\partial\xi}\left[\chi\left(\sqrt{\sum_{i=1}^{3}(\varphi^i_\xi)^2}-1\right)\dfrac{\varphi^1_\xi}{\sqrt{\Sigma^3_{i=1}(\varphi^i_\xi)^2}}\right]+\lambda_1, \\ \mu_0\varphi^2_{tt}=\dfrac{\partial}{\partial\xi}\left[\chi\left(\sqrt{\sum_{i=1}^{3}(\varphi^i_3)^2}-1\right)\dfrac{\varphi^2_3}{\sqrt{\Sigma^3_{i=1}(\varphi^i_\xi)^2}}\right], \\ \mu_0\varphi^3_{tt}=\dfrac{\partial}{\partial\xi}\left[\chi\left(\sqrt{\sum_{i=1}^{3}(\varphi^i_\xi)^2}-1\right)\dfrac{\varphi^3_\xi}{\sqrt{\Sigma^3_{i=1}(\varphi^i_\xi)^2}}\right]-\mu_0 g+\lambda_2. \end{cases} \tag{67}$$

Imposing the tangency conditions (38), which in the present case are

$$\varphi^1_{tt}=0, \quad \varphi^3_{tt}=0 \tag{68}$$

directly from Eq. (67) we get the following expressions:

$$\begin{cases} \lambda_1=-\dfrac{\partial}{\partial\xi}\left[\chi\left(\sqrt{\sum_{i=1}^{3}(\varphi^i_\xi)^2}-1\right)\dfrac{\varphi^1_\xi}{\sqrt{\Sigma^3_{i=1}(\varphi^i_\xi)^2}}\right], \\ \lambda_2=\mu_0 g-\dfrac{\partial}{\partial\xi}\left[\chi\left(\sqrt{\sum_{i=1}^{3}(\varphi^i_\xi)^2}-1\right)\dfrac{\varphi^3_\xi}{\sqrt{\Sigma^3_{i=1}(\varphi^i_\xi)^2}}\right] \end{cases}$$

for the multipliers λ. Recalling Eq. (48), the latter provide the explicit description of (the density of) the reactive forces.

Choosing the initial data and the boundary conditions consistent with the constraints, namely

$$\varphi^1(0,\xi)=\frac{\ell}{\ell_0}\xi, \quad \varphi^2(0,\xi)=\psi(\xi), \quad \varphi^3(0,\xi)=0,$$

$$\varphi^1_t(0,\xi)=0, \quad \varphi^2_t(0,\xi)=\dot\psi(\xi), \quad \varphi^3_t(0,\xi)=0,$$

$$\varphi^1(t,0)=0, \quad \varphi^2(t,0)=0, \quad \varphi^3(t,0)=0,$$

$$\varphi^1(t,\ell_0)=\ell, \quad \varphi^2(t,\ell_0)=0, \quad \varphi^3(t,\ell_0)=0,$$

Eq. (68) is solved by

$$\varphi^1(t,\xi)=\frac{\ell}{\ell_0}\xi, \quad \varphi^3(t,\xi)=0. \tag{69}$$

If we replace Eq. (69) in the second equation of (67), we get the partial differential equation

$$\mu_0\varphi^2_{tt}=\frac{\partial}{\partial\xi}\left[\chi\left(\sqrt{\left(\frac{\ell}{\ell_0}\right)^2+(\varphi^2_\xi)^2}-1\right)\frac{\varphi^2_\xi}{\sqrt{\left(\frac{\ell}{\ell_0}\right)^2+(\varphi^2_\xi)^2}}\right], \tag{70}$$

which rules the evolution of φ^2. Under the approximation of small deformations, we may neglect all the quadratic terms in φ^2_ξ in Eq. (70), thus obtaining the well-known D'Alembert equations

$$\varphi^2_{tt}=\frac{\chi}{\mu_0}\left(1-\frac{\ell_0}{\ell}\right)\varphi^2_{\xi\xi}$$

for the linear elastic string.

On a general link between anomalous diffusion and nonextensivity

(Received 4 April 2001; accepted for publication 4 October 2001)

Stochastic processes of systems with composable entropy measures are studied. The processes are described by Fokker–Planck equations which are nonlinear with respect to their probability densities and whose diffusion coefficients are derived from the entropy measures in questions. In nonextensive (extensive) systems anomalous (normal) diffusion is found. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421062]

I. INTRODUCTION

Anomalous diffusion is a phenomenon which can be found in various fields of physics[1–3] ranging from surface diffusion[4] and diffusion through porous media[5] to plasma physics.[6] Anomalous diffusion can be described by non-Fickian linear diffusion equations,[7,8] continuous time random walks,[9–12] fractional Fokker–Planck equations,[13–17] and nonlinear diffusion equations.[5,18–24] The focus of the present article is on nonlinear diffusion equations which have recently been discussed in the context of nonextensive thermostatistics. The interest in such a link between anomalous diffusion and nonextensivity[25] has been fueled by a work of Plastino and Plastino.[26] They derived a nonlinear Fokker–Planck equation (NLFPE) whose stationary solution agrees with the equilibrium distribution obtained by maximizing the nonextensive entropy proposed by Tsallis[27–32] under the constraints of canonical ensembles. Note that in this article nonlinear (or generalized) Fokker–Planck equations are evolution equations for probability densities which are nonlinear with respect to their probability densities as opposed to conventional Fokker–Planck equations which are linear with respect to their probability densities.[33–44] The NLFPE proposed by Plastino and Plastino and modifications of it have been extensively studied in the literature.[45–59] In particular, for the entropy functional

$$S[\mathcal{P}] := B\left[\int_{-\infty}^{\infty} \tilde{S}(\mathcal{P}(x))\mathrm{d}x\right] \tag{1}$$

acting on the probability density $\mathcal{P}(x)$ and involving the outer function $B(z) \in C^{\infty}(\mathbb{R})$ and the entropy kernel $\tilde{S} \in C^{\infty}(0,\infty)$, the NLFPE

$$\frac{\partial}{\partial t}\mathcal{P}(x,t) = -\frac{\partial}{\partial x}\left[M\{\mathcal{P}(x,t)\}\left(h(x)\mathcal{P}(x,t) - \frac{\rho[\mathcal{P}]}{\alpha}\frac{\partial}{\partial x}\hat{L}[\tilde{S}\{\mathcal{P}(x,t)\}]\right)\right] \tag{2}$$

was derived.[51] Here, $\mathcal{P}(x,t)$ describes the time-dependent process probability density, $h(x)$ is the drift, $M\{\cdot\}$ is a function or functional of $\mathcal{P}(x,t)$, the factor $1/\alpha$ with $\alpha > 0$ corresponds to the overall fluctuation strength, the functional $\rho[\cdot]$ is defined by

$$\rho[y] := \left.\frac{\mathrm{d}B(z)}{\mathrm{d}z}\right|_{\int_{-\infty}^{\infty}\tilde{S}(y(x))\mathrm{d}x}, \tag{3}$$

a)Electronic mail: t.frank@fbw.vu.nl

and the differential operator $\hat{L}$ is given by

$$\hat{L}[\chi(y)] := \chi(y) - y\frac{\mathrm{d}\chi(y)}{\mathrm{d}y}. \tag{4}$$

It can be shown that the stationary solution of the NLFPE (2) agrees with the equilibrium distribution derived by maximizing the entropy (1) under the constraints of canonical ensembles.[51] The nonlinear diffusion equation corresponding to the NLFPE (2) can be obtained by putting $M \equiv 1$ and $h(x) \equiv 0$. In this case, we get

$$\frac{\partial}{\partial t}\mathcal{P}(x,t) = \frac{\rho[\mathcal{P}(x,t)]}{\alpha}\frac{\partial^2}{\partial x^2}\hat{L}[\tilde{S}\{\mathcal{P}(x,t)\}]. \tag{5}$$

Note that in contrast to conventional nonlinear diffusion equations[5,18–24] but in line with the Fokker–Planck equation approach, the density function $\mathcal{P}(x,t)$ is normalized to unity [i.e., $\int \mathcal{P}(x,t)\mathrm{d}x = 1$]. In the following, we consider continuous solutions $\mathcal{P}(x,t)$ which are infinitely differentiable on their domains of nonvanishing function values. That is, we assume that (i) $\mathcal{P}(x,t) \geqslant 0$, (ii) $\mathcal{P}(x,\cdot) \in C^0(\mathbb{R})$, and (iii) $\mathcal{P}(x,\cdot) \in C^\infty(\mathrm{supp}\{\mathcal{P}(x,\cdot)\})$ with $\mathrm{supp}\{\mathcal{P}(x,\cdot)\} := \{x : \mathcal{P}(x,\cdot) > 0\}$. Recently, several special cases of Eq. (5) have been examined and explicit solutions have been derived. For the nonextensive entropy proposed by Tsallis anomalous diffusion was found.[46,48,49,53,59] For the extensive Renyi entropy normal diffusion and for the nonextensive Sharma–Mittal entropy anomalous diffusion was found except for the limiting case in which the Sharma-Mittal entropy reduces to the Renyi entropy.[53] For other generalized entropy measures,[30,51,60–65] such a discussion has not been carried out so far. Similarly, until now, a general link between nonextensivity (extensivity) of entropy functionals and anomalous (normal) diffusion which can be applied to all kinds of entropy measures has not been established. In the following, we will derive such a link for composable entropy functionals (Ref. 32, Sec. II.1), that is, for functionals satisfying

$$S[\mathcal{W}] = S[\mathcal{R}_1] + S[\mathcal{R}_2] + N(S[\mathcal{R}_1], S[\mathcal{R}_2]), \tag{6}$$

where the probability densities $\mathcal{R}_1(x)$ and $\mathcal{R}_2(x)$ describe two statistically independent subsystems yielding the joint probability density $\mathcal{W}(x,y) := \mathcal{R}_1(x)\mathcal{R}_2(y)$. Here, $N(u,v) \in C^2(\mathbb{R} \times \mathbb{R})$ denotes an arbitrary function of the entropies $S[\mathcal{R}_1]$ and $S[\mathcal{R}_2]$ of the subsystems. Note that the commutativity of the multiplication [i.e., $\mathcal{R}_1(x)\mathcal{R}_2(y) = \mathcal{R}_1(y)\mathcal{R}_2(x)$] implies the symmetry of N [i.e., $N(u,v) = N(v,u)$]. If N depends on $S[\mathcal{P}]$, we will call the functional S a nonextensive functional. More precisely, S is nonextensive if $\partial N/\partial u|_{u=S[\mathcal{P}(x,t)]} \not\equiv 0$ for $\mathcal{P}(x,t)$ given by Eq. (5). In contrast, if N does not depend on $S[\mathcal{P}]$, we will refer to S as an extensive functional. In particular, for $N = \mathrm{const}$, we can introduced the shifted functional $S' = S + N$, which satisfies the well-known relation of extensive entropies $S'[\mathcal{R}_1\mathcal{R}_2] = S'[\mathcal{R}_1] + S'[\mathcal{R}_2]$ (cf., e.g., Refs. 66–68).

II. NONEXTENSIVITY AND ANOMALOUS DIFFUSION

From Eq. (5) we can derive the evolution equation of the mean $\langle x \rangle$ (which is $\mathrm{d}\langle x \rangle/\mathrm{d}t = 0$) and the second moment $\langle x^2 \rangle$ (which is $\mathrm{d}\langle x^2 \rangle/\mathrm{d}t = 2\,\alpha^{-1}\rho\int \hat{L}\,\mathrm{d}x$). Using Eq. (4), for the variance $\sigma^2 := \langle x^2 \rangle - \langle x \rangle^2$ we then obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\sigma^2(t) = \underbrace{\frac{2}{\alpha}\rho[\mathcal{P}]\int_{-\infty}^{\infty}\left[\tilde{S}(\mathcal{P}(x,t)) - \mathcal{P}(x,t)\left.\frac{\mathrm{d}\tilde{S}(z)}{\mathrm{d}z}\right|_{z=\mathcal{P}(x,t)}\right]\mathrm{d}x}_{\mathcal{Y}[\mathcal{P}]}. \tag{7}$$

Consequently, if the functional $\mathcal{Y}[\mathcal{P}]$ is constant with respect to time we have normal diffusion [i.e., $\sigma^2(t) \propto t$]. Otherwise, we find anomalous diffusion [i.e., $\sigma^2(t) \not\propto t$]. We now derive $\mathcal{Y}$ from

the assumed nonextensivity/extensivity property (6). To this end, let $\mathcal{R}_1(x)$ be defined on the real line and $\mathcal{R}_2(y)$ be defined on the interval $[0,a]$ with $a>0$. Furthermore, let $\mathcal{R}_2(y)$ denote the uniform distribution on $[0,a]$, that is, $\mathcal{R}_2(y)\equiv 1/a$. Then, from Eqs. (1) and (6) it follows

$$B\left[a\int_{-\infty}^{\infty}\tilde{S}\left(\frac{\mathcal{R}_1(x)}{a}\right)\mathrm{d}x\right]=S[\mathcal{R}_1]+B\left[a\tilde{S}\left(\frac{1}{a}\right)\right]+N\left(S[\mathcal{R}_1],B\left[a\tilde{S}\left(\frac{1}{a}\right)\right]\right). \tag{8}$$

Next, we differentiate Eq. (8) with respect to a and put $a=1$. Thus, we obtain

$$\mathcal{Y}[R_1]=C+\left.\frac{\partial N(S[\mathcal{R}_1],v)}{\partial v}\right|_{v=C} \tag{9}$$

with

$$C:=\left(\tilde{S}(1)-\left.\frac{\mathrm{d}\tilde{S}(z)}{\mathrm{d}z}\right|_{z=1}\right)\left.\frac{\mathrm{d}B(z)}{\mathrm{d}z}\right|_{z=\tilde{S}(1)}. \tag{10}$$

Consequently, the variance $\sigma^2(t)$ satisfies the evolution equation

$$\frac{\mathrm{d}}{\mathrm{d}t}\sigma^2(t)=\frac{2C}{\alpha}+\frac{2}{\alpha}\frac{\partial N(S[\mathcal{P}],v)}{\partial v}_{v=C} \tag{11}$$

with $\mathcal{P}(x,t)$ determined by the diffusion equation (5). Since C does not depend on the time variable t, we deal with normal diffusion if the second term on the right hand side of Eq. (11) does not depend on time. Otherwise, we find anomalous diffusion. Therefore, at issue is how $S[\mathcal{P}]$ and $\partial N(S[\mathcal{P}],v)/\partial v|_{v=C}$ evolve as functions of time. From Eq. (5) it follows that $S[\mathcal{P}]$ satisfies the relation

$$\frac{\mathrm{d}}{\mathrm{d}t}S[\mathcal{P}]=\frac{1}{\alpha}(\rho[\mathcal{P}])^2\int_{-\infty}^{\infty}\mathcal{P}(x,t)\left(\frac{\partial}{\partial x}\left.\frac{\mathrm{d}\tilde{S}(z)}{\mathrm{d}z}\right|_{z=\mathcal{P}(x,t)}\right)^2\mathrm{d}x\geqslant 0 \tag{12}$$

[see Ref. 52, Eq. (6) for $M\equiv 1$]. We require now that the entropy functional S is sensitive to unlikely events. More precisely, we require the existence of an interval $(0,l]$ of finite length l (i.e., $l>0$) such that the derivative $\mathrm{d}\tilde{S}(z)/\mathrm{d}z$ maps all elements of $(0,l]$ to nonvanishing function values (i.e., $\exists l:\forall z\in(0,l]:\mathrm{d}\tilde{S}(z)/\mathrm{d}z\neq 0$). We find that for entropies of this kind the expression

$$\frac{\partial}{\partial x}\left.\frac{\mathrm{d}\tilde{S}(z)}{\mathrm{d}z}\right|_{z=\mathcal{P}(x,t)} \tag{13}$$

can have at most a finite number of zeros for $x\in I_k$, where the intervals I_k are defined by $I_k=[x_l^k,x_r^k]$ with $x_l^k<x_r^k$, I_k mutually disjoint, and $0<\mathcal{P}(z,t)\leqslant l$ for all $z\in I_k$. That is, $\partial\mathrm{d}\tilde{S}/\partial x\mathrm{d}z\not\equiv 0$ for $z=\mathcal{P}(x,t)$ and $x\in I_k$. Since we restrict our considerations to continuous probability densities which decay to zero in a smooth fashion (cf. Sec. I), the existence of such intervals is guaranteed. From Eq. (12) we can then read off that

$$\frac{\mathrm{d}}{\mathrm{d}t}S[\mathcal{P}]\geqslant\frac{1}{\alpha}(\rho[\mathcal{P}])^2\sum_k\int_{I_k}\mathcal{P}(x,t)\left(\frac{\partial}{\partial x}\left.\frac{\mathrm{d}\tilde{S}(z)}{\mathrm{d}z}\right|_{z=\mathcal{P}(x,t)}\right)^2\mathrm{d}x>0. \tag{14}$$

In sum, entropies which are sensitive to unlikely events are strictly monotonically increasing functions for the diffusion processes defined by Eq. (5). We are now in the position to examine the evolution of $\partial N(S[\mathcal{P}],v)/\partial v|_{v=C}$. Differentiating this expression with respect to the time variable t yields

$$\left.\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial N(S[\mathcal{P}],v)}{\partial v}\right|_{v=C}=\left.\frac{\partial^2 N(u,v)}{\partial u\,\partial v}\right|_{v=C,u=S[\mathcal{P}]}\frac{\mathrm{d}S[\mathcal{P}]}{\mathrm{d}t}. \tag{15}$$

Using this result and differentiating Eq. (11) with respect to t, we obtain

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}\sigma^2(t)=\frac{2}{\alpha}\underbrace{\frac{\mathrm{d}S[\mathcal{P}]}{\mathrm{d}t}}_{>0}\left.\frac{\partial^2 N(u,v)}{\partial u\,\partial v}\right|_{v=C,u=S[\mathcal{P}]}. \tag{16}$$

Therefore, we have normal diffusion [i.e., $\mathrm{d}^2\sigma^2(t)/\mathrm{d}t^2=0$] if and only if

$$\left.\frac{\partial^2 N(u,v)}{\partial u\,\partial v}\right|_{v=C,u=S[\mathcal{P}]}=0. \tag{17}$$

Since we found in Sec. I that extensivity and nonextensivity, respectively, can be defined by means of the derivative $\partial N(u,v)/\partial u|_{u=S[\mathcal{P}]}$, we can now draw our final conclusions (which are only valid within the NLPFE framework and for composable entropies, of course).

(i) Nonextensive systems with $\partial N(u,v)/\partial v|_{v=C}=0$ and extensive systems show normal diffusion. Normal diffusion only occurs in nonextensive systems with $\partial N(u,v)/\partial v|_{v=C}=0$ and extensive systems.

(ii) Nonextensive systems with $\partial N(u,v)/\partial v|_{v=C}\neq 0$ show anomalous diffusion. Anomalous diffusion only occurs in nonextensive systems satisfying $\partial N(u,v)/\partial v|_{v=C}\neq 0$.

Roughly speaking, nonextensivity implies anomalous diffusion and extensivity implies normal diffusion. But there is an exception to this rule: in nonextensive systems for which the first order partial derivative of $N(u,v)$ with respect to u vanishes for $u=C$ normal diffusion can also occur.

III. CONCLUDING REMARKS

Let us conclude with a few remarks. First, the theory developed here applies to the Renyi entropy,[69,70] the Sharma–Mittal entropy,[71] and the entropy proposed by Tsallis.[27] For the Renyi entropy we find $N\equiv 0$, which implies that the corresponding nonlinear diffusion equation (5) describes normal diffusion. The two other entropies are composable and nonextensive and satisfy

$$S[\mathcal{W}]=S[\mathcal{R}_1]+S[\mathcal{R}_2]+\underbrace{(1-q)S[\mathcal{R}_1]S[\mathcal{R}_2]}_{N(S[\mathcal{R}_1],S[\mathcal{R}_2])}, \tag{18}$$

where $q\neq 1$ measures the degree of nonextensivity.[27,53] Substituting $N(u,v)=(1-q)uv$ into Eq. (16), we obtain

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}\sigma^2(t)=\frac{2(1-q)}{\alpha}\frac{\mathrm{d}S[\mathcal{P}]}{\mathrm{d}t}\neq 0 \quad \text{for } q\neq 1, \tag{19}$$

which illustrates that for these entropies the nonlinear diffusion equation (5) describes anomalous diffusion. Consequently, we reobtain the results previously derived in Refs. 46, 48, 49, 53, and 59. Note that in these studies explicit solutions or scaling arguments have been used, whereas we have exploited the very definition of nonextensive entropies.

Second, for semi-nonextensive systems (i.e., systems for which the energy is an extensive variable whereas the entropy is a nonextensive one) Abe derived explicit expressions for the nonlinearity N [cf. Eq. (6)] of composable entropies.[72] Such systems can exhibit an equilibrium state only for entropy measures satisfying

$$\frac{\partial S[\mathcal{W}=\mathcal{R}_1\mathcal{R}_2]}{\partial S[\mathcal{R}_1]}=\rho[\mathcal{W}]\tilde{g}(S[\mathcal{R}_1])\tilde{h}(S[\mathcal{R}_2])$$

$$\Rightarrow \frac{\partial S[\mathcal{W}=\mathcal{R}_2\mathcal{R}_1]}{\partial S[\mathcal{R}_2]}$$

$$=\rho[\mathcal{W}]\tilde{g}(S[\mathcal{R}_2])\tilde{h}(S[\mathcal{R}_1])$$

$$=\frac{\partial S[\mathcal{W}=\mathcal{R}_1\mathcal{R}_2]}{\partial S[\mathcal{R}_2]}, \tag{20}$$

where $\rho[\cdot]$ is defined by Eq. (3) (and coincides with the function k in Ref. 72) and $\tilde{g}(z)$ and $\tilde{h}(z)$ denote differentiable functions. It can be shown that in the absence of an outer function [i.e., for $\rho\equiv 1$, $B(z)=z$] this decomposition implies

$$S[\mathcal{W}]=S[\mathcal{R}_1]+S[\mathcal{R}_2]+\lambda S[\mathcal{R}_1]S[\mathcal{R}_2], \tag{21}$$

where λ is a separation constant.[72] Obviously, Eq. (21) is a generalization of Eq. (18) (which has been derived for two particular generalized entropies only) and the evolution of the variance can be read off from Eq. (19) by replacing $1-q$ with λ. Consequently, the nonlinear Fokker–Planck approach to stochastic processes employed in the present study predicts the occurrence of anomalous diffusion in semi-nonextensive systems with composable entropies that can be cast into the form (1) with $B(z)=z$. Moreover, Abe suggested to describe the entropy of black holes by a composable measure with $\rho\not\equiv 1$ and $N(u,v)=2\sqrt{uv}$. In this case, Eq. (16) reads

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}\sigma^2(t)=\frac{2}{\alpha\sqrt{C}}\frac{\mathrm{d}}{\mathrm{d}t}\sqrt{S[\mathcal{P}]}, \tag{22}$$

which describes anomalous diffusion provided that S is sensitive to unlikely events (i.e., $\mathrm{d}S>0$, cf. Sec. II). We can easily verify that a simple example of a composable entropy with $N(u,v)=2\sqrt{uv}$ is given by $S:=[S_{\mathrm{BGS}}]^2$, where S_{BGS} denotes the Boltzmann–Gibbs–Shannon entropy $S_{\mathrm{BGS}}[\mathcal{P}]:=-\int\mathcal{P}\ln\mathcal{P}\mathrm{d}x$.[66–68] Then, we obtain $B(z)=z^2$ and (on account of the sensitivity of S_{BGS} to unlikely events) $\mathrm{d}S>0$.

In the absence of an outer function B [i.e., for $B(z)\equiv z$] we usually find $\tilde{S}(1)=0$. The reason for this is that many entropy functionals S are derived from entropies $S_d:=\Sigma_{i=1}^{M}\tilde{S}(p_i)=\Sigma_{i=1}^{M}p_i\tilde{s}(p_i)$ for discrete sets of probabilities p_i. In these cases, by convention, one defines $\tilde{s}(z)$ (information of an event with probability z) in such a way that it vanishes in the case of the certain event with probability one, that is, $\tilde{s}(1)=0\Rightarrow\tilde{S}(1)=1\tilde{s}(1)=0$. For $B(z)\equiv z$ and $\tilde{S}(1)=0$ the constant C reads $C=-\mathrm{d}\tilde{S}(z)/\mathrm{d}z|_{z=1}$. In this special case, the evolution equation of the variance reads

$$\frac{\mathrm{d}}{\mathrm{d}t}\sigma^2(t)=-\frac{2}{\alpha}\frac{\mathrm{d}\tilde{S}(z)}{\mathrm{d}z}\bigg|_{z=1}+\frac{2}{\alpha}\frac{\partial N(S[\mathcal{P}],v)}{\partial v}\bigg|_{v=-\mathrm{d}\tilde{S}(z)/\mathrm{d}z|_{z=1}}. \tag{23}$$

In particular, for the Boltzmann–Gibbs–Shannon entropy $S=S_{\mathrm{BGS}}=-\int\mathcal{P}\ln\mathcal{P}\mathrm{d}x$ we obtain $\mathrm{d}\tilde{S}(z)/\mathrm{d}z=-1-\ln z$ and the well-known relation $\mathrm{d}\sigma^2(t)/\mathrm{d}t=2\alpha^{-1}\Rightarrow\sigma^2(t)=2t/\alpha$.

Finally, the derivation presented in the preceding section does not hold for diffusion processes with infinite variances such as Lévy distributions, cf., e.g., Refs. 3 and 10. In this context, limitations of the approach to anomalous diffusion by means of nonlinear Fokker–Planck equations in combination with the calculation of process variances were illustrated in detail in Refs. 53

and 55. In order to circumvent such problems, one may follow Tsallis and Bukman who introduced the notion of pseudo anomalous diffusion for Lévy distributions and examined the evolution of normalization constants instead of process variances.[59]

ACKNOWLEDGMENTS

My gratitude is to Andreas Daffertshofer for many helpful discussions and to Professor Peter Beek for his support of my studies on generalized Fokker–Planck equations.

Fluctuation operators and spontaneous symmetry breaking

Manfred Requardt[a)]
Institut für Theoretische Physik, Universität Göttingen,
Bunsenstrasse 9, 37073 Göttingen, Germany

(Received 28 June 2001; accepted for publication 15 October 2001)

We develop an alternative approach to this field, which was to a large extent developed by Verbeure *et al*. It is meant to complement their approach, which is largely based on a noncommutative central limit theorem and coordinate space estimates. In contrast to that we deal directly with the limits of l-point truncated correlation functions and show that they typically vanish for $l \geqslant 3$ provided that the respective scaling exponents of the fluctuation observables are appropriately chosen. This direct approach is greatly simplified by the introduction of a smooth version of spatial averaging, which has a much nicer scaling behavior and the systematic development of Fourier space and energy-momentum spectral methods. We both analyze the regime of normal fluctuations, the various regimes of poor clustering and the case of spontaneous symmetry breaking or Goldstone phenomenon. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1424474]

I. INTRODUCTION

In the past decade in a series of papers Verbeure and co-workers developed a beautiful and ingeneous framework to study so-called macroscopic fluctuation phenomena in systems and various regimes of quantum statistical mechanics (see the cited literature). The approach is to a large extent based on a quantum variant of the *central limit theorem* and is mainly performed in real (i.e., configuration) space. Among other things, the general goal is to study the limit behavior of correlation functions of so-called *fluctuation observables*, i.e., appropriately renormalized averages of microscopic observables, averaged over volumes, V, which approach the whole space, $\mathbb{R}^n$, say. Typically, one arrives, depending on the type of clustering of the microscopic l-point functions, at certain simple limit algebras as, e.g., CCR.

We approach the field from a slightly different angle. In a first step we choose another averaging procedure, which avoids sharp volume cut-offs and, *a fortiori*, has a very nice and transparent scaling behavior. This is then exploited in the following analysis which systematically develops so-called Fourier-space and energy-momentum spectral methods of observables and correlation functions. We consider it to be an advantage that the calculations turn out to be relatively transparent and lead in a direct way to the desired results.

We first treat the case of *normal fluctuations* and L^1-clustering. We show that all the truncated l-point functions vanish for $l \geqslant 3$ while they approach a finite, nontrivial limit for $l = 2$. The analysis is done both for the $(k = 0)$-and the $(k \neq 0)$-modes. We emphasize that the calculations for net-momentum different from zero also remain very simple. A variant of the method is then applied to the case of L^2-clustering.

In the second part of the article we embark on the analysis of fluctuations in the presence of *spontaneous symmetry breaking (ssb)*. In a first step we prove some general results in the context of ssb and the *Goldstone phenomenon*. We then address the problem of macroscopic fluctuations within this context. Among other things, we give a general and rigorous proof that the limit fluctuations are always classical for temperature states (a phenomenon already observed by Verbeure *et al.* in various simple models). The article ends with a treatment of extremely poor

a)Electronic mail: requardt@theorie.physik.uni-goettingen.de

clustering, which can be controlled by a new method we develop in the last section. To sum up, we think that in our view the two different frameworks seem to neatly complement each other and should lead to further interesting results if combined.

II. THE SCENARIO OF NORMAL FLUCTUATIONS

The following analysis works for statistical equilibrium states and/or for vacuum states in quantum field theory. To avoid constant mentioning of the respective scenario we are actually working in, we usually treat equilibrium (i.e., KMS) states, to fix the framework. Now, let Ω be the vacuum or equilibrium state (rather its GNS representation; usually we work within a concrete Hilbert space, $\mathcal{H}$). As an abstract state we denote it by ω. Expectations of observables are written as

$$\langle A\rangle = \omega(A) = (\Omega, A\Omega) \tag{1}$$

with A taken from the *local algebra*, $\mathcal{A}_0 \subset \mathcal{A}$, the latter one being the *quasi-local* norm closure of $\mathcal{A}_0$. We assume Ω to be *cyclic* with respect to $\mathcal{A}_0$ or $\mathcal{A}$. That is, we assume

$$\overline{\mathcal{A}_0 \cdot \Omega} = \mathcal{H}. \tag{2}$$

There are certain differences as to the (assumed) locality properties of the dynamics between (non-)relativistic statistical mechanics and relativistic quantum field theory (RQFT). Denoting the time evolution (acting on the algebra of observables) by α_t, we are confronted with the following phenomenon.

Observation 2.1: In RQFT part of the usual framework is the assumption

$$\alpha_t : \mathcal{A}_0 \to \mathcal{A}_0, \tag{3}$$

while in statistical mechanics (due to weaker locality behavior) we have in the generic case only

$$\alpha_t : \mathcal{A} \to \mathcal{A} \tag{4}$$

with $\mathcal{A}_0$ usually not left invariant as the observables will typically develop infinitely extended tails.

Furthermore, we assume once and for all that our system is in a *pure, translation invariant phase*, that is, Ω is extremal translation invariant under the space translations (which can, as in the case of lattice systems, also be a discrete subgroup). There can, of course, exist several coexisting pure phases at the same external parameters as in the regime below a phase transition threshold. These assumptions imply that we can expect certain *cluster properties*, i.e., decay of *correlations* (see e.g., Ref. 1).

A. Definition of ordinary fluctuation operators

We begin by defining the *fluctuation operators* in the *normal* situation as it was done in Ref. 2.

We assume, for the time being, L^1-clustering for the two-point-function, that is,

$$\int |\langle A(x)B\rangle^T| d^n x < \infty \quad A, B \in \mathcal{A} \tag{5}$$

with $A(x)$ the translate of A and

$$\langle AB\rangle^T = \langle AB\rangle - \langle A\rangle \cdot \langle B\rangle. \tag{6}$$

Once and for all we assume, to simplify notation, in our particular context that the occurring observables are normalized to $\langle A\rangle = 0$ unless otherwise stated.

Definition 2.2: We define the normal (finite volume) fluctuation operators as

$$A_V^F := 1/V^{1/2} \cdot \int_V A(x) d^n x =: 1/V^{1/2} \cdot A_V . \tag{7}$$

In a next step one wants to give sense to these objects in the limit $V \to \infty$. From the L^1-condition we, however, infer

$$|(A_V^F \Omega, B\Omega)| \leqslant 1/V^{1/2} \int_{\mathbb{R}^n} |(A(x)\Omega, B\Omega)| d^n x \to 0. \tag{8}$$

Hence, $A_V^F \Omega \to 0$ on a dense set. Furthermore, we have

$$(A_V^F \Omega, A_V^F \Omega) = 1/V \int_V \int_V (A(x)\Omega, A(y)\Omega) dx dy = 1/V \int_V dx \left(\int_{V-x} \langle A^* A(y-x) \rangle d(y-x) \right). \tag{9}$$

This is less than or equal to

$$(1/V) \cdot V \cdot \sup_x \left(\int_{V-x} |(\ldots)| \right) \leqslant \int_{\mathbb{R}^n} |F(y-x)| d^n (y-x) < \infty \tag{10}$$

[for convenience we sometimes denote a general two-point function by $F(x-y)$]. This suffices to prove weak convergence to zero for $A_V^F \Omega$ on the total Hilbert space $\mathcal{H}$.

Remark 2.3: We note that this proves also the well-known normal-fluctuation result $\langle A_V \cdot A_V \rangle \leqslant V$ *in the* L^1*-case. Under certain well-specified conditions the fluctuations can even be weaker than normal. If, e.g.,* Q_V *is the local integral over a conserved quantity, we proved a divergence significantly weaker than* $\sim V$ *(cf. Ref. 3). But, in general, the local fluctuations will diverge in the limit* $V \to \infty$ *in contrast perhaps to ordinary intuition, even if the quantity is globally conserved due to quantum fluctuations (see also the section about spontaneous symmetry breaking).*

A weaker than normal divergence can occur in the following situation. An asymptotic behavior $\sim V$ does only prevail if $\int_V F(u) du \neq 0$ in the limit $V \to \infty$. On the other side such correlation functions tend to oscillate about zero (for physical reasons; there are, e.g., usually preferred relative positions in, say, a quantum liquid). In other words, while

$$\int F(u) du = 0 \tag{11}$$

may seem to be rather ungeneric at first glance, it can nevertheless happen in a specific context. The general situation is analyzed in the above reference; certain examples of better than normal fluctuations were also found by Verbeure *et al.* in, e.g., Ref. 4 (see also Ref. 5).

For the fluctuation operators themselves we have, due to locality, for $A, B \in \mathcal{A}_0$,

$$[A_V, B] \quad \text{independent of} \quad V \quad \text{for} \quad V \supset V_0 \supset V_B \tag{12}$$

for some V_0 which contains the localization region V_B for $B \in \mathcal{A}_0$. We then have

$$\lim_V (A_V^F \cdot C\Omega, B\Omega) = \lim_V ([A_V^F, C]\Omega, B\Omega) + \lim_V (A_V^F \Omega, C^* B\Omega). \tag{13}$$

We have already shown that the second term goes to zero. In the first term the commutator becomes

$$[A_V^F, C] = V^{-1/2} \cdot [A_{V_0}, C], \tag{14}$$

and hence the first term goes also to zero. In case we assume only $A \in \mathcal{A}$, a further L^1-condition for the three-point function is needed to arrive at the same result. As $\mathcal{A}_0\Omega$ is assumed to be dense in $\mathcal{H}$ and $\|A_V^F\| < \infty$ uniformly in V, we have the following.

Proposition 2.4: L^1-clustering implies that

$$A_V^F \to 0 \quad \textit{weakly on } \mathcal{H}, \quad \|A_V^F\Omega\| < \infty \quad \textit{uniformly in } V, \tag{15}$$

but $\|A_V^F\Omega\|$ bounded away from zero in general. That is, A_V^F does not converge strongly to zero and, a fortiori, there is no convergence in norm.

This clearly shows that, in order to have nontrivial limit operators, one has to leave the original Hilbert space of microscopic observables and has to define or construct an entirely new representation living on a different state.

B. A smoothed version of fluctuation operators

Since we employ in the following so-called *Fourier methods* and related calculational tools, it is advantageous to change to a smoother version of fluctuation operators. As everybody knows, sharp volume cut-offs are both a little bit artificial and technically nasty, since they may sometimes lead to nongeneric or spurious effects. In other branches of rigorous statistical mechanics or axiomatic quantum field theory volume integrations have therefore frequently been emulated or implemented in a slightly different way (see, e.g., Ref. 6).

Two choices have basically been in use with the second version having much nicer properties in several respects as we will explain below. Instead of integrating over a sharp volume, V, centered, e.g., around the coordinate origin, one integrates the shifted observable, $A(x)$, over a smooth test function localized basically in V but having smooth tails.

Remark: As V we choose in the following a ball centered at the origin with radius R and let R go to infinity.

Definition 2.5: Two admisssible families of test functions are the following ones: $f_R(x) \geqslant 0$ *smooth with*

$$f_R(x) := \begin{cases} 1 & \text{for } |x| \leqslant R, \\ 0 & \text{for } |x| \geqslant R+h, \end{cases} \tag{16}$$

or

$$f_R(x) := f(|x|/R) \quad \text{with} \quad f(s) = \begin{cases} 1 & \text{for } |x| \leqslant 1, \\ 0 & \text{for } |x| \geqslant 2. \end{cases} \tag{17}$$

Note that the latter choice has much nicer behavior under Fourier transform while working with the Fourier transforms of the former version or, e.g., the indicator function of the volume V is quite cumbersome). On the other hand, the latter version has tails which are also scaled.

Lemma 2.6:

$$\hat{f}_R(k) = \text{const} \cdot R^n \cdot \hat{f}(R \cdot k), \tag{18}$$

where here and in the following ''const'' denotes an (in this context) irrelevant numerical factor which, *a fortiori*, may change in the course of a calculation. With the help of this smearing functions we now define the following.

Definition 2.7 (smooth volume integration): We redefine the fluctuation operators in the following way:

$$A_R^F := R^{-n/2} \cdot \int A(x) \cdot f_R(x) d^n x \tag{19}$$

with f_R, unless otherwise stated, the family given in the second example above (remember $\langle A \rangle := 0$).

III. THE LIMITING CASE FOR NORMAL FLUCTUATIONS

In order to arrive at a rigorous definition of fluctuation operators in a certain limit state we will follow a line of arguments which may complement the treatment of Verbeure *et al.* in several respects. We will study directly the macroscopic limit of the n-point functions with the help of certain *momentum space methods*. As they are perhaps not so common in statistical physics we will give the technical details next.

A. Some generalities

Any n-point (correlation) function of the kind $\langle A_1(x_1)\cdots A_n(x_n)\rangle$ with the $A_i(x_i)$ the translates of the observables A_i (which may also contain an implicit time variable t_i which is, however, kept fixed in the following) is written as $W(x_1,\ldots,x_n)$. With the state Ω being translation invariant we have

$$W(x_1,\ldots,x_n)=W(x_1-x_2,\ldots,x_{n-1}-x_n). \tag{20}$$

To express cluster properties in a clear way, we introduce the so-called *truncated correlation functions* via the following recursion relation:

$$W(x_1,\ldots,x_n)=\sum_{\text{part}}\prod_{P_i} W^T(x_{i_1},\ldots,x_{i_k}), \tag{21}$$

where the sum extends over all partitions of the set $\{1,\ldots,n\}$ into subsets P_i with the elements in each subset ordered as $i_1<i_2\cdots<i_k$. The first elements of the recursion are

$$W(x)=W^T(x)=0 \quad \text{in our case,} \tag{22}$$

$$W^T(x_1,x_2)=W(x_1,x_2)-W(x_1)W(x_2). \tag{23}$$

Observation 3.1: In the truncated correlation functions the vacuum state, ground state or equilibrium state, Ω, has been eliminated in a symmetric way, so that we have, in a sense to be specified,

$$W^T(x_1,\ldots,x_n)\to 0 \quad for \quad \sup|x_i-x_j|\to\infty. \tag{24}$$

In this section we assume the following *cluster property*:

$$W^T(x_1,\ldots,x_n)\in L^1 \ \text{ in the variables } \ \{x_1-x_2,\ldots,x_{n-1}-x_n\}. \tag{25}$$

From the above we see that the original hierarchy of n-point functions can be reconstructed from the new hierarchy of truncated n-point functions, which have more transparent cluster properties. The L^1-condition allows us to Fourier transform the $W^T(x_1,\ldots,x_l)$ and we get from translation invariance:

$$\begin{aligned}
\text{const}\cdot\int \tilde{W}^T(p_1,\ldots,p_l)\cdot e^{-i\Sigma p_i x_i}\prod\, dp_i &= W^T(x_1,\ldots,x_l)\\
&= W^T(x_1-x_2,\ldots,x_{l-1}-x_l)\\
&= \text{const}\int \hat{W}^T(p_1,p_1+p_2,\ldots,p_1+\cdots+p_{l-1})\\
&\quad\cdot\delta(p_1+\cdots+p_l)e^{-i\Sigma p_i x_i}\prod\, dp_i\\
&= \text{const}\int \hat{W}^T(q_1,\ldots,q_{l-1})e^{-i\Sigma_{i=1}^{l-1} q_i y_i}\prod_{i=1}^{l-1} dq_i
\end{aligned} \tag{26}$$

with

$$y_i := x_i - x_{i+1}, \quad q_i = \sum_{j=1}^{i} p_j, \quad i \leqslant (l-1). \tag{27}$$

The functional determinant $\det(\partial q/\partial p)$ is one and we can regard $\hat{W}^T$ either as a function of the q_i's or the p_i's. We hence have the following lemma.

Lemma 3.2: As a Fourier transform of a L^1-function, $\hat{W}^T(p_1,\ldots,p_{l-1}) = \hat{W}^T(q_1,\ldots,q_{l-1})$ is a continuous and bounded function which decreases at infinity in the q-variables.

B. The ($k=0$)-modes

We now study the limit of truncated l-point functions with the entries being fluctuation operators A_R^F, more precisely their Fourier transforms, i.e.,

$$\begin{aligned}\langle A_R^F(1)\cdots A_R^F(l)\rangle^T &= \text{const}\cdot R^{ln/2}\cdot \int \hat{f}(Rp_1)\cdots\hat{f}(-R[p_1+\cdots+p_{l-1}])\cdot \hat{W}^T(p_1,\ldots,p_{l-1})\prod dp_i \\ &= \text{const}\cdot R^{ln/2}\cdot R^{-(l-1)n}\cdot \int \hat{f}(p_1')\cdots\hat{f}(-[p_1'+\cdots+p_{l-1}']) \\ &\quad \cdot \hat{W}^T(p_1'/R,\ldots,p_{l-1}'/R)\prod dp_i' \,. \end{aligned} \tag{28}$$

Here $\hat{W}$ is continuous and bounded and the $\hat{f}$'s are of rapid decrease. Hence we can perform the limit $R\to\infty$ under the integral and get the following theorem.

Theorem 3.3: *The expression $\langle A_R^F(1)\cdots A_R^F(l)\rangle^T$ scales as $\sim R^{(2-l)n/2}$. This implies that for $l>2$ the above limit is zero; for $l=2$ the limit is a finite number bounded away from zero in general. In other words, we have*

$$\lim_{R\to\infty} \langle A_R^F(1)\cdots A_R^F(l)\rangle^T = 0 \quad \text{for } l>2 \tag{29}$$

and

$$\lim_{R\to\infty} \langle A_R^F(1)\cdots A_R^F(l)\rangle = \lim_{R\to\infty} \sum_{\text{part}} \prod_{\{ij\}} \langle A_R^F(i) A_R^F(j)\rangle. \tag{30}$$

The relation between the original microscopic system $(\mathcal{A},\omega)$ and the coarse-grained system of fluctuation operators is a little bit subtle. Note that ω_F, the limit state to be constructed, can no longer be considered as a state or something like that on the original algebra nor can the fluctuation operators be considered as a representation of, say, $\mathcal{A}$. One aspect of the impending problems can perhaps best be seen by realizing that, e.g.,

$$(A\cdot B)_V^F \neq A_V^F \cdot B_V^F, \tag{31}$$

which pertains also in the limit. That is, in a sense to be defined, we have

$$(A\cdot B)^F \neq A^F \cdot B^F, \tag{32}$$

the same holding in general for all the higher products. This is one source of nonuniqueness as there is no invariant discrimination between an observable regarded as a single object to be scaled and as a product of other observables, where now each factor has to be scaled separately. The appropriate point of view has to be a different one [as has also been emphasized by Verbeure *et al.*, cf. e.g., Ref. 2(b), p. 540f and private communication].

The picture remains relatively clear for the intermediate scales, $V<\infty$. We have a start system $(\mathcal{A},\omega)$, labeled by, say, $V=0$. On every scale V we have a new algebra, $\mathcal{A}_V^F$ (actually a subalgebra of $\mathcal{A}$), generated by the observables A_V^F, $A\in\mathcal{A}$ [including arbitrary finite products $(A_1\cdots A_n)_V^F$]. If we prefer to consider this algebra on scale V as a new abstract algebra (i.e., forgetting about the underlying finer algebra $\mathcal{A}$), we get also a new, coarse-grained state via the identification

$$\omega_V^F(\Pi A_V^{F,i}) := \omega(\Pi A_V^{F,i}). \tag{33}$$

(A related philosophy was expounded by Buchholz and Verch in, e.g., Ref. 7 within the context of the algebraic analysis of ultra-violet behavior in quantum field theory.)

The map

$$R_V:\mathcal{A}\to\mathcal{A}_V^F \tag{34}$$

can be viewed as kind of a *renormalization map*, which however, does *not* preserve the algebraic structure (i.e., the algebras are in general not *isomorphic*). Furthermore, one gets a "*new*" dynamics on this algebra by defining

$$\alpha_t^V(A_V^F) := (\alpha_t(A))_V^F. \tag{35}$$

Remark 3.4: In our context α_t is assumed to commute with the space translations or with a corresponding lattice version, that is, we have $\alpha_t(A_V^F)=(\alpha_t A)_V^F$. (Furthermore, it may turn out to be reasonable to scale the time variable on the lhs also.)

On the other hand, in order to construct the limit theory itself, one can proceed in a slightly different direction. The above limits of n-point functions define a consistent hierarchy of new n-point functions which then allow us to define a *new* limit system via the so-called *reconstruction theorem* (for a pendant in quantum field theory, see, e.g., Ref. 8). Put differently, we define limit objects, $\{A_i^F\}$, the so-called fluctuation operators, which live in a new Hilbert space built upon the new state, ω_F, defined by the limits:

$$\omega_F(A_1^F\cdots A_n^F) := \lim_{R\to\infty}\langle A_{1,R}^F\cdots A_{n,R}^F\rangle = \sum_{\text{part}}\prod_{\{ij\}}\omega_F(A_i^F\cdot A_j^F). \tag{36}$$

Note, however, that the so-called *Gelfand-ideal*, I_F, is large, that is, there are many elements of $\mathcal{A}$ which are mapped to zero by this limit with

$$I_F := \{A;\omega_F((A^F)^*\cdot A^F)=0\}. \tag{37}$$

This is, of course, typical for such kinds of *mean-values*, as, e.g., all space-translates of A yield the same limit element. Shifting one of the observables in the above l-point functions by, say, a_i yields an extra factor $e^{ip_ia_i}$ in the Fourier transform which, after the above coordinate tranformation goes over into $e^{ip_i'/R\cdot a_i}$ which goes to one. Summing up, we have the following.

Conclusion 3.5: With the help of Eq. (36) we construct a new limit system, consisting of the algebra of fluctuation operators, $\mathcal{A}_F$, and the limit state ω_F. The well-known GNS construction (see e.g., Ref. 9) allows us to construct the corresponding Hilbert-space representation with

$$\omega_F(A_1^F\cdots A_n^F)=(\Omega_F,A_1^F\cdots A_n^F\Omega_F) \tag{38}$$

(where, by abuse of notation, we do not discriminate between operators and their equivalence classes on the rhs).

As all the n-point functions decay into a product of two-point functions, all the commutators are c-numbers:

$$[A^F,B^F]=\omega_F([A^F,B^F]). \tag{39}$$

The system of fluctuation operators is a quasi-free system (cf. Ref. 10).

Taking now self-adjoint elements one can, as in Ref. 2, represent the new system as a representation of the *CCR* over the real vector space of s.a. operators. Our scalar product, induced by the hierarchy of n-point functions, can be split in the following way:

$$(A^F\Omega_F, B^F\Omega_F) = \mathrm{Re}(\cdots) + i\,\mathrm{Im}(\cdots) =: s_F(A^F,B^F) + (i/2)\sigma_F(A^F,B^F), \tag{40}$$

$$\omega_F([A^F,B^F]) = \sigma_F(A^F,B^F), \tag{41}$$

where σ_F defines a *symplectic form*. The *Weyl-operators*, e^{iA^F} with A^F s.a., fulfill the *CCR* relations

$$\omega_F(e^{iA^F}) = e^{-1/2 s_F(A^F,A^F)}, \tag{42}$$

$$e^{iA^F}\cdot e^{iB^F} = e^{i(A^F+B^F)}\cdot e^{-i/2\sigma_F(A^F,B^F)}. \tag{43}$$

In our context the first equation can, e.g., be verified as follows: Only the $2n$-point functions are different from zero. On the lhs we hence have

$$\omega_F(e^{iA^F}) = \sum\ (-1)^n/(2n)!\cdot\omega_F([A^F]^{2n}). \tag{44}$$

It remains to count the number of partitions of a $2n$-set into two-sets. This number is $(2n)!/2^n\cdot n!$. In (44) we now get for A^F s.a. on the rhs

$$\sum_n\ 1/n!\left(-\frac{1}{2}\cdot\omega_F(A^FA^F)\right)^n = e^{-1/2 s_F(A^FA^F)}. \tag{45}$$

□

The above general cluster result of the limit n-point functions makes the study of the limit time evolution relatively straightforward. In a first step it suffices to study the two-point functions. We define the time evolution in the limit theory by

$$\omega_F(A^F(t')\cdot B^F(t)) := \lim\omega(A_V^F(t')\cdot B_V^F(t)) = \lim\omega(A(t')_V^F\cdot B(t)_V^F). \tag{46}$$

On the limiting GNS–Hilbert space constructed above we now get a bounded *sesquilinear form* $(x,y(t))$ which, by standard results, yields a bounded operator $U^F(t)$ implementing the time evolution. Here we use that the limit n-point functions are products of two-point functions. Furthermore, we infer with the help of the above limit process that

$$(U_t^Fx, U_t^Fy) = \omega_F(\cdots) = \lim\omega(\cdots) = (x,y). \tag{47}$$

In other words, we arrive at the following conclusion.

Theorem 3.6: *The preceding construction yields a strongly continuous unitary time evolution on the limiting GNS–Hilbert space.*

Another point worth mentioning (since it might perhaps be overlooked) is the question of the nontriviality of the commutators

$$[A^F,B^F] = \omega_F([A^F,B^F]). \tag{48}$$

In principle it could happen that all the expectation values on the rhs vanish. In that case the limit algebra would be *Abelian* and the fluctuations *classical*. In a more general context (cf., e.g., Ref. 7) this problem is more complicated. In our situation this question can, however, be answered in a rather straightforward way. We have

$$\lim_V \omega([A_V^F, B_V^F]) = \lim_V \omega([A_V, V^{-1} \cdot B_V]). \tag{49}$$

For $A, B \in \mathcal{A}_0$, i.e., local, the rhs equals

$$\lim_V \omega([A_V, B]). \tag{50}$$

We know candidates which lead to a vanishing of the limit for all $B \in \mathcal{A}_0$. For A chosen s.a. these are the generators of *conserved symmetries*, written

$$Q := \int A(x) d^n x. \tag{51}$$

Usually they are assumed to commute with the time evolution, expressed as $Q(t) = Q$, hence the above limit would also be zero on the full quasi-local algebra. This situation, more specifically the case of *spontaneous symmetry breaking (ssb)* and *Goldstone phenomenon*, will be dealt with in more detail in Sec. V. In any case, as conserved symmetries are usually not so numerous, we may presume that, in the generic case, not all of these commutators will be zero.

For A, B not necessarily strictly local our above more general formalism is useful. With

$$\omega(A(x)B) = F_{AB}(x), \quad \omega(BA(x)) = G_{AB}(x), \tag{52}$$

the vanishing of the commutator would imply

$$\begin{aligned} 0 = [A^F, B^F] &= \lim_R R^n \cdot \int |\hat{f}(Rp)|^2 (\hat{F}_{AB}(p) - \hat{G}_{AB}(p)) d^n p \\ &= \lim_R \int |\hat{f}(p)|^2 (\hat{F}_{AB}(p/R) - \hat{G}_{AB}(p/R)) d^n p \\ &= (\hat{F}_{AB}(0) - \hat{G}_{AB}(0)) \cdot \int |\hat{f}(p)|^2 d^n p. \end{aligned} \tag{53}$$

by the theorem of dominated convergence (note that we are in the L^1-situation). Hence we have the following result.

Proposition 3.7:

$$[A^F, B^F] = 0 \Leftrightarrow \hat{F}_{AB}(0) = \hat{G}_{AB}(0), \tag{54}$$

that is,

$$\int F_{AB}(x) d^n x = \int G_{AB}(x) d^n x \tag{55}$$

or

$$\int (\Omega, [A(x), B]\Omega) d^n x = 0, \tag{56}$$

which is the same result as in the strictly local case.

C. The $(k \neq 0)$-modes

Up to now only the $(k = 0)$-modes of fluctuation operators, i.e., $\lim_V V^{-n/2} \cdot \int_V A(x) d^n x$, have been studied. For various reasons it is useful to have corresponding formulas at hand for fluctua-

tion observables containing a certain net-momentum. This problem was studied by Verbeure *et al.* in, e.g., Ref. 11 and the results were applied in, e.g., Ref. 12 in the analysis of *Goldstone modes*. In the original (real-space) approach the necessary calculations turned out to be quite involved and far from being simple. This is another case in point to demonstrate the merits of our Fourier space scaling methods.

Instead of the original scaling operators, A_V^F or A_R^F, we now study their $k\neq 0$-variants, $A_R^F(k)$. We begin with a technical lemma.

Lemma 3.8:

$$\hat{A}(k) := (2\pi)^{-n/2}\int e^{ikx}A(x)d^nx \tag{57}$$

is an operator-valued distribution. [We use the convention $\hat{f}(k)=(2\pi)^{-n/2}\int e^{-ikx}f(x)d^nx$.]

Remark: For a systematic use and proofs of such energy-momentum techniques in quantum statistical mechanics we refer to, e.g., Ref. 13, where also some more mathematical background is provided.

Integrating now over $e^{iqx}\cdot f_R(x)$, we get the q-mode fluctuation operators:

$$\begin{aligned} A_R^F(q) &:= R^{-n/2}\int A(x)e^{iqx}f_R(x)d^nx \\ &= R^{n/2}\int \hat{A}(k+q)\hat{f}(Rk)d^nk \\ &= R^{n/2}\int \hat{A}(k)\hat{f}(R(k-q))d^nk. \end{aligned} \tag{58}$$

We can now proceed in exactly the same way as above in the case of the zero-mode analysis and calculate the truncated l-point functions $\langle A_R^F(1,q_1)\cdots A_R^F(l,q_l)\rangle^T$ (where the indices 1 to l label different observables). The only thing that changes are the test functions, i.e., $f_R(x)\to e^{iq_kx}\cdot f_R(x)$. We arrive at the conclusion:

Theorem 3.9 (q-mode fluctuation operators): *In the case of L^1-clustering all truncated correlation functions vanish for $l\geqslant 3$ and the l-point functions are again sums of products of two-point functions. The concrete form of the limit-two-point functions is given in formula (62).*

If we calculate the limit-two-point functions explicitly, we get

$$\begin{aligned} \langle A_R^F(q_1)\cdot B_R^F(q_2)\rangle^T &= R^n\int \langle\hat{A}(k_1+q_1)\hat{B}(k_2+q_2)\rangle^T\cdot\delta(k_1+q_1+k_2+q_2)\cdot\hat{f}(Rk_1)\hat{f}(Rk_2)dk_1dk_2 \\ &= R^n\int \langle\hat{A}(k_1+q_1)\hat{B}(-(k_1+q_1))\rangle^T\cdot\hat{f}(Rk_1)\hat{f}(-R(k_1+q_1+q_2))dk_1 \\ &= R^n\int \langle\hat{A}(k)\hat{B}(-k)\rangle^T\cdot\hat{f}(R(k-q_1))\hat{f}(-R(k+q_2))dk. \end{aligned} \tag{59}$$

With $k' := R(k-q_1)$ we arrive at

$$\int \hat{W}^T(k'/R+q_1)\cdot\hat{f}(k')\hat{f}(-k'-R(q_1+q_2))dk'. \tag{60}$$

By assumption $\hat{W}^T$ is in L^1 and $\hat{f}$ is of rapid decrease, so the limit can again be carried out under the integral and we have the following observation.

Observation 3.10: For $q_1+q_2\neq 0$ it holds

$$\lim_R \langle A_R^F(q_1)\cdot B_R^F(q_2)\rangle^T = 0. \tag{61}$$

For $q=q_1=-q_2$ we get on the other side,

$$\lim_R \langle A_R^F(q)\cdot B_R^F(-q)\rangle^T = \hat{W}^T(q)\cdot \int \hat{f}(k)\hat{f}(-k)dk. \tag{62}$$

In other words, the limit tests the spectral momentum of the two-point function.

IV. THE CASE OF L^2-CLUSTERING

Before we embark on an investigation of the situation in the regime where phase transitions, vacuum degeneracy and/or spontaneous symmetry breaking (ssb) prevail, we briefly address the case where the clustering is weaker than L^1 but still L^2, say. Our above Fourier space approach can also easily handle this more singular situation. We hence assume now that the truncated l-point functions cluster only in the L^2-sense in the difference variables.

Now we cannot conclude that the Fourier transform is bounded and continuous, but we know it is again an L^2-function. We repeat the first steps of the above calculation with, however, another *scaling exponent*, α, which we leave open for the moment.

Definition 4.1: In the general case we define fluctuation operators by

$$A_R^F := R^{-\alpha}\cdot \int A(x) f_R(x) d^n x. \tag{63}$$

We get

$$\langle A_R^F(1)\cdots A_R^F(l)\rangle^T = \text{const}\cdot R^{l(n-\alpha)}\cdot \int \hat{f}(Rp_1)\cdots\hat{f}(-Rq_{l-1})\cdot \hat{W}^T(q_1,\ldots,q_{l-1})\prod dq_i, \tag{64}$$

where the $\{p_i\}$ are linear functions of the $\{q_i\}$ as described earlier. We now apply the Cauchy–Schwartz inequality:

$$|lhs| \leqslant \text{const}\cdot R^{l(n-\alpha)}\left[\int (\hat{f}(Rp_1)\cdots\hat{f}(-Rq_{l-1}))^2\prod dq_i\right]^{1/2} \cdot\left[\int (\hat{W}^T(q_1,\ldots,q_{l-1}))^2\prod dq_i\right]^{1/2}. \tag{65}$$

In the first integral on the rhs we make again a variable transformation from q_i to $q_i' := Rq_i$, yielding an overall scaling factor

$$R^{l(n-\alpha)}\cdot R^{-(l-1)n/2}. \tag{66}$$

We again want the limits of the two-point functions to be both finite and nontrivial, i.e., different from zero in general.

Proposition 4.2: To make the rhs of (65) finite in the limit for $l=2$ the maximal α to choose is

$$3n-4\alpha=0, \quad i.e., \quad \alpha=(\tfrac{3}{4})n. \tag{67}$$

For a general l this leads to the scaling exponent $(n-(\frac{1}{2})l\cdot n)/2$, which is negative for $l\geqslant 3$. Hence, all higher truncated l-point functions vanish in the limit.

However, to guarantee that the result is really nontrivial, we have to analyze the situation in more detail as the above estimate is only an inequality. In the case of L^1-clustering $\alpha=n/2$ was appropriate. The largest value which can occur in the L^2-case is the above maximal $\alpha=(\frac{3}{4})n$. If we want to avoid that the two-point functions vanish in the limit we have to choose in the L^2-case

$$(\tfrac{1}{2})n<\alpha\leqslant(\tfrac{3}{4})n \tag{68}$$

depending on the concrete decay of the two-point functions in configuration space. We see that, evidently, the situation is now less canonical as compared to the L^1-case.

Remark: A related situation (on a lattice) was analyzed by Verbeure *et al.* in Ref. 14, where a clustering weaker than L^1 was considered with, however, the additional input that the local algebras, sitting at the points of the lattice, form a finite dimensional *Lie algebra*. In that case, suitable scaling exponents are chosen to render the autocorrelation functions finite and nonvanishing, while, on the other side, the finiteness of the limit three-point functions has to be imposed as an extra assumption. Under this proviso one gets the existence of a limit Lie algebra, but nevertheless results are only partial while perhaps, on the other side, being also more interesting.

We do not want to dwell too much on this point at the moment, as progress seems to be, to a certain extent, model dependent. Furthermore, we develop a different approach in the last section which is able to cope with any kind of poor cluster behavior.

If we want to guarantee the *a priori* existence or vanishing of the truncated three-point functions with the help of our L^2-estimate (65), we have to restrict the chosen α in the following way.

Corollary 4.3: If the appropriate α fulfills $\alpha>(\frac{2}{3})n$, we get a negative scaling exponent for $l\geqslant 3$ as

$$n-(\tfrac{1}{3})ln\leqslant 0 \quad \text{for} \quad l\geqslant 3. \tag{69}$$

For $\alpha=\frac{2}{3}$ the three-point functions are finite.

Remark 4.4: One would get corresponding relations for smaller α but higher correlation functions, beginning from a certain order, $l_0(\alpha)$ say. On the other hand, one cannot guarantee the a priori existence of the l-point functions for $2<l<l_0(\alpha)$ as the general scaling relation reads for $l\geqslant l_0(\alpha)$

$$l(2\alpha-n)>n \quad and \quad \alpha>(1/2)n, \tag{70}$$

α being so chosen that the two-point functions are nontrivial.

V. SPONTANEOUS SYMMETRY BREAKING (SSB) AND THE GOLDSTONE PHENOMENON

A. General remarks

Before we study fluctuation operators in the regime of vacuum-, ground-, equilibrium-state degeneracy, we want to briefly comment, in order to set the stage, on the (rigorous) implementation of *ssb* in the various areas with particular emphasis on (quantum) statistical mechanics, i.e., condensed matter physics. As this topic has, however, been much discussed in the past from various points of view, we do not intend to give an exaustive commentary. We only mention some earlier work being of relevance for our argumentation and sketch the general framework.

We assume that our state, ω or Ω, is (non-)invariant under some automorphism group of $\mathcal{A}_0$ or $\mathcal{A}$. Furthermore, and this is important (while frequently not clearly stated), we assume the time evolution, α_t, to commute with the automorphism group, α_g.

Definition 5.1: α_g is called a symmetry group if

$$\alpha_g\cdot\alpha_t=\alpha_t\cdot\alpha_g. \tag{71}$$

Definition 5.2: If

$$(\Omega,\alpha_g(A)\Omega)=(\Omega,A\Omega) \tag{72}$$

for all $A\in\mathcal{A}$, the symmetry is called conserved and can be implemented by a unitary group of operators in the representation space

$$\alpha_g(A)\to U(g)AU(g^{-1}). \tag{73}$$

On the other side, if

$$(\Omega,\alpha_g(A)\Omega)\neq(\Omega,A\Omega) \tag{74}$$

for some A, A the symmetry-breaking observable, *the symmetry is called* spontaneously broken *since it still commutes with the time evolution (i.e., formally: with the Hamiltonian, modulo* boundary terms *due to* long-range correlations).

In most cases the (continuous) symmetry group derives from a clearly identifiable *generator* (we restrict ourselves, for convenience, to one-parameter groups) which is built from a local operator density, i.e.,

$$U(s)=e^{isQ},\quad Q(t)=\int q(x,t)d^nx,\quad Q(t)=Q(0)\coloneqq Q. \tag{75}$$

Note that there are many technical subtleties lurking behind these operator identities, all of which we cannot mention in the following. [For more details and references see, e.g., Ref. 15. A nice review is Ref. 16, where many of the widely scattered results have been compiled.]

Remark 5.3: In many situations the generator density is the zero-component of a conserved current. Formally, the conservation law encodes the time independence of the global charge, Q. Furthermore, for convenience, we assume the symmetry to commute with the space translations, i.e., $U(x)QU(-x)=Q$. This is, in fact, frequently the case and simplifies certain calculations.

The most crucial consequence is that in case the symmetry is spontaneously broken, some of the above relations do only hold in a formal or algebraic sense. More specifically, we have the following theorem.

Theorem 5.4: *If α_g is spontaneously broken, the global generator Q does only exist in a formal sense as a limit*

$$Q=\lim_V Q_V,\quad Q_V\coloneqq\int_V q(x)d^nx. \tag{76}$$

We have

$$ssb\Leftrightarrow\lim_V(\Omega,[Q_V,A]\Omega)\neq 0 \tag{77}$$

for some $A\in\mathcal{A}$ and Q is in that case only definable as a nasty operator (see below).

In the following we will take (77) as the defining relation of *ssb* (the technical details of the various statements can be found in the literature, mentioned above).

The notion of *ssb* is closely connected with another phenomenon, the so-called *Goldstone-phenomenon*. While there exists a clear picture in, say, *relativistic quantum field theory*, the corresponding picture is a little bit blurred in the nonrelativistic regime. In the relativistic context we have sharp *zero-mass Goldstone modes*, i.e., true particles due to relativistic covariance. On the other hand, in, e.g., condensed matter physics or statistical mechanics, the situation is less generic. In general we no longer have sharp excitation modes; we have rather to expect excitation modes having a *finite lifetime* for momentum different from zero but becoming infinitely sharply peaked for momentum $k\to 0$. The proper view is to analyze these excitation branches in the *full* Fourier space of *energy-momentum* as has, e.g., been done in Ref. 15(d) and earlier in the author's doctoral thesis, the principal object being the spectral-resolution of the two-point correlation functions [in a neighborhood of $(E,k)=(0,0)$]. The *ssb* or Goldstone phenomenon manifests itself in this quantity by a singular contribution in the spectral measure. One should mention at this place the

work of Bros and Buchholz (see, e.g., Ref. 17) about quantum field theory in temperature (i.e., KMS-) states. In this particlar context the residual causality and locality properties of the underlying relativistic theory lead to a, in some respects, more generic behavior as compared to the ordinary nonrelativistic condensed matter regime.

In the nonrelativistic regime it turns out that the concrete structure of the Goldstone mode depends usually on the details of the microscopic interactions (that means both the so-called energy-momentum dispersion law which can be, to give an example, quadratic or linear near $k=0$ in the case of magnons or phonons, say, and the k-dependent width of the branch). This led to the desire to characterize the presence of a Goldstone phenomenon by a simple (if qualitative) property. Sometimes one finds in the literature the saying that the Goldstone phenomenon consists of the vanishing of a *mass-gap* above the ground state. But this statement is in some sense frequently empty. From Ref. 18 we know, e.g., that a *short-ranged Galilei-covariant* theory, with a nonvanishing particle density, cannot have a mass-gap due to *phonon-excitations* which signal the trivial breaking of the Galilei-boosts. Furthermore, in most cases KMS–Hamiltonians have as spectrum the whole real line.

Remark 5.5: Models like the famous BCS-model (having a gap) are no case in point as they are implicitly breaking Galilei-invariance as do all such mean-field-models. This becomes apparent when analyzing the interaction part of the corresponding Hamiltonian. The complete fermion- or boson-liquid is, on the other side, again Galilei-invariant, hence has no mass-gap, but may, of course, still display, e.g., superfluidity.

In the next subsection we will provide a, as we think, more satisfying and completely general characterization of the Goldstone phenomenon which is independent of the details of the model under discussion.

B. Some rigorous results for the symmetry generator in the presence of *ssb*

After the above introductory remarks we want to prove a couple of rigorous results which characterize to some extent the presence of *ssb* in the (non-)relativistic regime. The main observation is that the symmetry generator is no longer defined as a nice operator in the representation (Hilbert or *GNS*-) space when *ssb* is present and that this, at first glance, mathematical result encodes some interesting physics.

Let us work, for simplicity, in the context of *temperature states*. This has the advantage that Ω is separating, i.e.,

$$A\Omega = B\Omega \Rightarrow A = B. \tag{78}$$

The first task is to give $Q := \lim_V Q_V$ a rigorous meaning. The standard procedure (see the above mentioned literature) is to define Q via

$$QA\Omega := \lim_V [Q_V, A]\Omega, \quad Q\Omega := 0, \tag{79}$$

for, e.g., $A \in \mathcal{A}_0$. For V sufficiently large, the commutator on the rhs becomes independent of V, hence there is a chance to get a well-defined Q (at least on a dense set of vectors), as on the lhs we have by *separability*

$$A\Omega = B\Omega \Rightarrow A = B \Rightarrow [Q_V, A-B] = 0. \tag{80}$$

For $A \in \mathcal{A}$ one has to employ cluster properties.

Observation 5.6: We have already seen above that, while such a Q may exist, the corresponding $\|Q_V\Omega\|$ *will nevertheless diverge for* $V \to \mathbb{R}^n$*! This shows that the connection between the global generator and its local approximations is not that simple. The best one can usually expect, even in the case of symmetry conservation, is a weak convergence on a dense set*

$$(B\Omega, QA\Omega) = \lim_V (B\Omega, Q_V\Omega), \tag{81}$$

but, due to the above divergence of $\|Q_V\Omega\|$*, we cannot even have weak convergence on the full Hilbert space. (For more details, see the above cited literature, in particular Ref. 15(c), where the various possibilities in the respective fields have been compared.)*

We see from the above that Q can be defined as a densely defined operator but usually we want to have more. A conserved continuous symmetry is given by a s.a. generator. Let us see under what conditions the above Q is at least *symmetric* provided that the Q_V are symmetric. We assume the symmetry to be conserved, i.e.,

$$\lim_V (\Omega, [Q_V, A]\Omega) = 0 \quad \text{for all} \quad A \in \mathcal{A}. \tag{82}$$

We then have

$$(B\Omega, QA\Omega) = \lim_V (B\Omega, [Q_V, A]\Omega) = \lim_V (([Q_V, B]\Omega, A\Omega) + (Q_v\Omega, B^*A\Omega) - (A^*B\Omega, Q_V\Omega)). \tag{83}$$

Conclusion 5.7: Q *is symmetric if* $\lim_V (A\Omega, Q_V\Omega) = 0$ *for all* $A \in \mathcal{A}_0$*. Under the same proviso it follows*

$$(B\Omega, QA\Omega) = \lim_V (B\Omega, Q_V\Omega). \tag{84}$$

What is the situation if the symmetry is spontaneously broken? For convenience we replace again the sharp volume-integration by our smooth one, i.e.,

$$Q_V \to Q_R := \int q(x) f_R(x) d^n x. \tag{85}$$

We know that there exists a symmetry-breaking observable A s.t.

$$\lim_R (\Omega, [Q_R, A]\Omega) \neq 0 \Rightarrow QA\Omega = \lim_R [Q_R, A]\Omega \neq 0. \tag{86}$$

Due to the assumed translation invariance, i.e.,

$$U(a)QU(-a) = Q \quad \text{or, what is the same,} \quad U(a)q(x)U(-a) = q(x+a), \tag{87}$$

we have

$$(\Omega, QA\Omega) = (\Omega, Q \cdot V^{-1} A_V \Omega) \tag{88}$$

and

$$Q \cdot V^{-1} A_V \Omega = V^{-1} \int_V U(x) d^n x \cdot QA\Omega, \tag{89}$$

where $U(x)$ is the unitary representation of the translations.

Remark: As a result of a discussion with Detlev Buchholz, following a seminar talk about the article, we will give a technically more detailed proof of the above statement in the Appendix at the end of the article. This seems to be advisable since, as we are showing below, the global operator, Q, turns out to be nonclosable, which will make certain limit manipulations more cumbersome.

Lemma 5.8:

$$s-\lim_V V^{-1}\int_V U(x)d^nx=P_\Omega, \tag{90}$$

P_Ω the projector on the (in our case) unique vacuum-,ground-, equilibrium-state.

Proof: The result is well-known (see, e.g., Ref. 1). We give however a very short and slightly different proof using our smooth volume integration. With $V_R:=\int f_R(x)d^nx$, a *spectral resolution* yields

$$V_R^{-1}\cdot\int U(x)f_R(x)d^nx=\text{const}\cdot\left(\int f(x)d^nx\right)^{-1}\cdot\int\hat{f}(Rp)dE_p\,. \tag{91}$$

Applied to a vector ψ we can now employ Lebesgue's theorem of dominated convergence and get

$$\lim_V V^{-1}\int U(x)d^nx\cdot\psi=(\hat{f}(0))^{-1}\cdot\hat{f}(0)P_\Omega\psi=P_\Omega\psi. \tag{92}$$

□

This yields

$$0\neq P_\Omega QA\Omega=\lim_V Q\cdot V^{-1}A_V\Omega. \tag{93}$$

On the other hand,

$$\lim_V\|V^{-1}A_V\Omega\|=\|P_\Omega A\Omega\|=0 \tag{94}$$

by an analogous reasoning [note that we assumed $(\Omega,A\Omega)=0$].

We have now a sequence of vectors, $V^{-1}A_V\Omega$, converging to zero in norm while $Q\cdot V^{-1}A_V\Omega$ converges to $P_\Omega QA\Omega\neq 0$. Summing up what we have shown we arrive at the following conclusion:

Conclusion 5.9 (Goldstone theorem): If we have ssb and a separating vector, Ω (representing the ground or temperature state), Q can still be defined as an operator which is, however, not closable, hence, a fortiori, not symmetric (note that symmetric operators are closable). This abstract result has as a practical consequence the physical property exhibited in the preceding formulas. They express the content of the Goldstone phenomenon in the most general and model-independent way. We infer that Q induces transitions from a singular part of the continuous spectrum, passing through $(E,p)=(0,0)$, to the extremal invariant state Ω. On the other side, a conserved symmetry implies

$$Q\Omega=0,\quad P_\Omega[Q,A]\Omega=0\Rightarrow P_\Omega QA\Omega=0. \tag{95}$$

We show now that the above result really contains the original Goldstone phenomenon. Let us, e.g., assume that we have the above result and, on the other side, a gap in the energy spectrum above the state Ω. We emphasized above that an important ingredient of the notion of *ssb* is the time independence of, say, the above expression. We employ again the spectral resolution of operators with respect to energy-momentum. We hence have

$$0\neq c=P_\Omega Q\int\hat{A}(k,E)e^{-itE}dkdE\Omega \tag{96}$$

with c being independent of t. We choose a real testfunction $g(t)$ with $\int g(t)dt=1$. This yields

$$0\neq c=P_\Omega Q\int A(t)\cdot g(t)dt\Omega=P_\Omega Q\int\hat{A}(E)\hat{g}(E)dE\Omega. \tag{97}$$

If there is a gap above zero, we may choose the support of $\hat{g}$ so that

$$\mathrm{supp}(\hat{g}) \cap \mathrm{supp}(\mathrm{spec}(H)) = 0. \tag{98}$$

Since, by assumption, P_Ω has been extracted in the energy support of A, we get the result $c = 0$, that is, no symmetry breaking. But we can infer more about the nature of the energy-momentum spectrum near (0,0). We see that $P_\Omega QA(g(t))\Omega$ depends only on the value of $\hat{g}(E)$ in $E = 0$, which is one in our case, but not on the shape of g. Inspecting Eq. (93) we can infer the following: The Fourier transform of the rhs contracts around $k = 0$ in the limit $V \to \infty$. On the other side we learned that in the limit both sides have their energy support concentrated in $E = 0$. The lhs shows that the limit vector is parallel to Ω. Whereas we do not want to go into the partly intricate details of the limiting processes of *nonclosable operators* (note that it is, e.g., dangerous to use the adjoint, Q^*, in the reasoning as it is not densely defined), the latter part of the above theorem should now be obvious.

This sharp excitation around $(E,k) = (0,0)$ extends into the full energy-momentum plane in form of a (usually) smeared excitation branch (having a finite k-dependent life-time). For the regime of temperature states the situation was analyzed in some detail in Ref. 15(d) and already in the authors doctoral thesis. We see from the above that a similar situation prevails in the more general case of a separable Ω and, analogously, for ground-state models where Q can be defined in the above way. Even if the above Q is not definable as a nonclosable limit operator we arrive at a similar result by exploiting the limit-expectation values instead of the strong vector- or operator limits, but we do not want to dwell more into the corresponding details in this article which deals with a different topic.

VI. THE CANONICAL (GOLDSTONE) PAIR IN THE PRESENCE OF *ssb*

As far as we can see, the notion of a *canonical Goldstone pair* was introduced by Verbeure *et al.* in Ref. 12. In the following section we want to prove only a few general (model-independent) results, whereas much more could be shown by combining the framework, developed above, with the techniques mentioned in the preceding section.

We remarked above that *ssb* is characterized by the nonvanishing (but time-independence) of the following commutator limit:

$$0 \neq c = \lim_V (\Omega, [Q_V, A(t)]\Omega). \tag{99}$$

To fix the notation: usually a pure phase is characterized by the nonvanishing of a so-called *order parameter* in the presence of *ssb*. This is an observable, B say, with

$$(\Omega, B\Omega) = \begin{cases} c \neq 0 & \text{in the broken phase,} \\ 0 & \text{in the conserved phase (above } T_c\text{, say).} \end{cases} \tag{100}$$

From (99) we see that as order parameter we have to choose

$$B := \lim_V [Q_V, A], \tag{101}$$

while A is the symmetry breaking observable.

Example 6.1: In the Heisenberg ferromagnet with spontaneous magnetization in, say, the z-direction, the order parameter is S_z or $\langle S_z \rangle$. As generator of the broken symmetry one may take ΣS_x and as symmetry breaking observable, e.g., S_y.

We have seen that we can write

$$0 \neq c = \lim_V (\Omega, [Q_V, A]\Omega) = \lim_V (\Omega, [Q_V, V^{-1}A_V]\Omega) = \lim_R (\Omega, [Q_R, V_R^{-1}A_R]\Omega), \tag{102}$$

where

$$Q_R := \int q(x) f_R(x) d^n x, \quad A_R := \int_{S_R} A(x) d^n x \tag{103}$$

with V_R the volume of the sphere, S_R, with radius R.

We can now split the scaling exponent among the two observables (the volume of the unit sphere being absorbed in the constant):

$$0 \neq \text{const} = \lim_R (\Omega, [R^{-\alpha} Q_R, R^{-(n-\alpha)} A_R] \Omega). \tag{104}$$

This form of scaling may yield something reasonable if the scaling exponents can be so adjusted that also

$$(\Omega, R^{-\alpha} Q_R R^{-\alpha} Q \Omega) \text{ and } (\Omega, R^{-(n-\alpha)} A R^{-(n-\alpha)} A \Omega) \tag{105}$$

remain finite in this limit.

In general it does not seem to be easy to get both rigorous and general estimates on the scaling behavior of these quantities. Fortunately, in the case of temperature (KMS) states, such estimates are available. In Refs. 19–21 the following special (*real-space-*) version of the *Bogoliubov inequality* has been proved and employed for the observables Q_R and $V_R^{-1} A_R$:

$$|\langle [Q_R, V_R^{-1} A_R] \rangle|^2 \leqslant \langle V_R^{-1} A_R V_R^{-1} A_R \rangle \cdot \langle [Q_R, [Q_R, H]] \rangle. \tag{106}$$

The delicate term is the double commutator on the rhs. If Q is spontaneously broken, boundary terms will survive in the commutator of Q_R and the Hamiltonian, H, when taking the limit $R \to \infty$, while in a formal sense they commute. The double commutator saves us two powers of R, so to say. That is we arrive after some cumbersome manipulations at

$$\langle [Q_R, [Q_R, H]] \rangle \sim R^{(n-2)} \text{ for } R \to \infty, \tag{107}$$

hence

$$\langle V_R^{-1} A_R V_R^{-1} A_R \rangle \gtrsim R^{(2-n)} \text{ for } R \to \infty \tag{108}$$

as the limit on the lhs is a constant different from zero in the case of ssb.

Theorem 6.2: *For temperature states we have for the symmetry-breaking observable*

$$\langle A_R A_R \rangle \gtrsim R^{(n+2)}. \tag{109}$$

That is, compared with the ordinary, normal scaling behavior ($\sim R^n$), *the divergence is worse. From this one infers the following decay of the two-point correlation function itself:*

$$|\langle A(x) A \rangle| \gtrsim R^{(n-2)}. \tag{110}$$

Putting all the pieces together we now have to make the following identification:

$$n - \alpha \geqslant (n+2)/2 \Rightarrow \alpha \leqslant (n-2)/2 \tag{111}$$

in order that the limit commutator is nontrivial, i.e., nonclassical. On the other hand, the divergence behavior of $\langle Q_R Q_R \rangle$ can frequently be inferred either from covariance properties [as in relativistic quantum field theory; see, e.g., Ref. 6(c)] or from an analysis of the spectral behavior in concrete (nonrelativistic) models. Summing up we have the following.

Conclusion 6.3 (canonical pair): For a covariant four-current in relativistic quantum field theory the two-point function in Fourier space contains a prefactor $\sim p^2$ *which yields (after some*

calculations) an $\alpha=\frac{1}{2}$ (for space dimension, $n=3$). On the other side, if we do not have such nice covariance properties, the divergence of $\langle Q_R Q_R\rangle$ is generically much worse than $\sim R$ (in three dimensions). This holds, in particular, for the above temperature states. It follows that for temperature states we cannot find a critical exponent α so that both the autocorrelations remain finite in the limit and the commutator nontrivial. That is, for temperature states the limit fluctuations are classical (an observation already made by Verbeure et al. for special models, see, e.g., Ref. 12).

The situation seems to be less generic for ground state models, i.e., the temperature-zero case. For one, we do not automatically have an *a priori* estimate as in the above conclusion, from which we can infer that it is the autocorrelation of A_R which is ill-behaved. For another, in temperature states, as was shown in, e.g., Ref. 15(d) by the author, the spectral weight has to become infinite along the Goldstone excitation branch in a specific way (which is governed by the dispersion law of the Goldstone mode) for energy-momentum approaching zero. This sort of singularity is mainly responsible for the poor decay of the respective autocorrelation function. This phenomenon may be absent in the case of ground states as has also been shown for certain Bose-gas models in Ref. 12, where some of these questions have been dealt with in greater detail. Note in particular that a variety of aspects may depend on the precise shape of the Goldstone mode near energy-momentum equal to (0,0) as was shown in the above mentioned paper of the author or in the unpublished doctoral thesis.

On the other side, there has been some interesting work of Pitaevskii and Stringari (see, e.g., Ref. 22), who showed that variants of the *uncertainty principle* may lead to nontrivial results in certain cases for ground state systems if one can exploit and control certain additional *sum rules*.

Remark 6.4: Note that the ordinary uncertainty principle (for, e.g., Hermitian operators and ignoring possible domain questions) reads

$$\tfrac{1}{4}\cdot|\langle[A,B]\rangle|^2\leqslant\langle AA\rangle\cdot\langle BB\rangle. \tag{112}$$

One sees that instead of the double commutator of the local symmetry generator and the Hamiltonian now a term like $\langle Q_R Q_R\rangle$ occurs. While we have an *a priori* estimate of the large-R behavior of the double commutator, the behavior of $\langle Q_R Q_R\rangle$ is probably less generic (in particular in the ground state situation) and we need some extra information of the kind mentioned above.

VII. THE CASE OF ssb OR VERY POOR DECAY OF CORRELATIONS

In the preceding sections we studied the case of L^1- or L^2-clustering. In this last section we want to briefly show how we can proceed in the case of extremely poor clustering. We want, however, for the sake of brevity and in order to better illustrate the method, to concentrate on the simpler case of a uniformly poor decay of all the correlation functions we are discussing. This is of course not always the case but the scheme can be easily generalized (we discuss this topic in more detail in Ref. 23, where we treat this question in the context of the renormalization group analysis).

We hence assume that the truncated l-point functions cluster weaker than L^2 or L^1, say, in the difference variables, $y_i:=x_{i+1}-x_i$ (see Sec. III A). The following reasoning works both in the case of non-L^1 or non-L^2 clustering. In the latter case one would again use the *Cauchy–Schwarz inequality* (as in Sec. III B). To illustrate the method we choose the non-L^1 procedure.

So let us assume

$$W^T(y_1,\ldots,y_{l-1})\notin L^1. \tag{113}$$

For each l we assume the existence of a weight factor with a suitable exponent, $\alpha_l\in\mathbb{R}$:

$$P_l(y):=\left(1+\sum y_i^2\right)^{\alpha_l/2}, \tag{114}$$

so that

$$F(y) := P_l(y)^{-1} \cdot W^T(y) \in L^1 \quad \text{for} \quad \alpha_l > \alpha_l^{\inf}. \tag{115}$$

On the other side, we define the fluctuation operators with the exponent γ, which will be adjusted later:

$$A_R^F := R^{-\gamma} \cdot A_R \,. \tag{116}$$

It follows

$$W^T(y) = P_l(y) \cdot F(y) \tag{117}$$

with $F(y)$ an (in general, l-dependent) L^1-function.

For the limit correlation functions we then get

$$\langle A_R^F(1) \cdots A_R^F(l) \rangle^T = R^{ln} \cdot R^{-l\gamma} \cdot \int \hat{F}(q) \cdot \hat{P}_l(q) [\hat{f}(Rp_1) \cdots \hat{f}(-Rq_{l-1})] \prod \, dq_i \tag{118}$$

(cf. Sec. III A).

Remark 7.1: We write the Fourier transform of $P_l(y)$ formally as

$$\hat{P}_l(q) = \left(1 + \sum \, D_{q_i}^2 \right)^{\alpha_l/2} \tag{119}$$

(with D_{q_i} the partial derivatives). For noninteger $\alpha_l/2$ this is a pseudo-differential operator. At the moment, for the sake of brevity, we do not want to say more about the corresponding mathematical framework (see Ref. 23 for a complete discussion). What we in fact only need are the scaling properties of the expression. If one wants to be careful, one may equally well take the explicit expression for the Fourier transform of the above polynomial in the y-coordinates applied to the product of the f_R's and exploit its scaling properties.

In any case, we get (with this proviso) and the usual variable transformation $p_i' := Rp_i$:

$$\langle A_R^F(1) \cdots A_R^F(l) \rangle^T = R^{ln - l\gamma - (l-1)n + \alpha_l} \cdot \int \hat{F}(q'/R) \cdot \left(R^{-2} + \sum \, D_{q_i'}^2 \right)^{\alpha_l/2}$$

$$\times [\hat{f}(p_1') \cdots \hat{f}(-q_{l-1}')] \prod \, dq_i' \,. \tag{120}$$

Again only the explicit scaling prefactor matters in the limit $R \to \infty$. [Note that for nonminimal α_l we may have $\hat{F}(0) = 0$. Technical intricacies like this one will be discussed at length in Ref. 23.] To get a finite result for *all* correlation functions we have to adjust the scaling parameter, γ, so that the exponents vanish or are negative. We choose α_2 for $l = 2$ so that the limit two-point function is finite and nonvanishing, that is,

$$n - 2\gamma + \alpha_2 = 0 \to \gamma = (n + \alpha_2)/2. \tag{121}$$

Inserting this γ in the general expression for $l \geqslant 3$, we conclude that the scaling prefactor is finite in the limit provided that

$$\alpha_l \leqslant l\gamma - n = ((l-1)n + l\alpha_2)/2 \tag{122}$$

with γ fixed by the two-point function. For $\alpha_l < l\gamma - n$ we can even conclude that all(!) higher limit correlation functions vanish and that the resulting theory is (quasi-)free. The latter would, for example, be the case if

$$\alpha_l \leqslant (l-1) \cdot \alpha_2 \tag{123}$$

holds, since we then have (with $\alpha_2<n$)

$$\alpha_l \leqslant (l-1)\cdot\alpha_2 < (l-\tfrac{1}{2})\alpha_2 = (2l-1)\cdot\alpha_2/2 < ((l-1)n+l\alpha_2)/2, \tag{124}$$

but nothing can be concluded in general for, say, $\alpha_l = l\cdot\alpha_2$.

We see that it is of tantamount importance to better understand the assymptotic behavior of truncated l-point functions and, in particular, the rate of decay as a function of l. We address this topic in more detail in Ref. 23.

APPENDIX: NONCLOSABLE SYMMETRY GENERATORS

The rigorous implementation of the formula

$$U(a)q(x)U(-a) = q(x+a) \tag{A1}$$

is

$$\begin{aligned} U(a)Q_R U(-a) &= U(a)\int q(x) f_R(x) d^n x U(-a) \\ &= \int q(x+a) f_R(x) d^n x \\ &= \int q(y) f_R(y-a) d^n y =: Q_R(a). \end{aligned} \tag{A2}$$

The first question is: how does the global Q behave under translations? To answer this question we have to take recourse to the definition of the global Q as a limit of local operations. We have

$$U(a)QA\Omega = U(a)\lim_R [Q_R, A]\Omega = \lim_R [Q_R(a), A(a)]\Omega \tag{A3}$$

since it holds

$$\lim_n U(a)\psi_n = U(a)\lim_n \psi_n \tag{A4}$$

as $U(a)$ is bounded. If A is local, we have for sufficiently large R (and hence, in the limit)

$$\lim_R [(Q_R(a) - Q_R(0)), A(a)] = 0. \tag{A5}$$

We hence arive at

$$U(a)QA\Omega = \lim_R [Q_R, A(a)]\Omega = QA(a)\Omega = QU(a)A\Omega. \tag{A6}$$

Lemma 7.2: On the dense set $\mathcal{A}_0\Omega$, Q commutes with the translations.

In a next step we have to analyze the action of Q on integrals or averages like $\int_V U(x)AU(-x)d^n x\Omega$. More specifically, we want to show that Q commutes, so to speak, with the operation of *integration*. We have

$$Q\cdot\int_V A(x)d^n x\Omega := \lim_R \left[Q_R, \int_V A(x) d^n x \right]\Omega. \tag{A7}$$

We approximate the integral by a sum, that is

$$\int_V A(x)d^n x\psi := \lim_i \sum_i d^n x_i \cdot A(x_i)\psi, \tag{A8}$$

and get (as the Q_R are assumed to be nice, that is, closed operators)

$$\left[Q_R, \int_V A(x)d^n x\right]\Omega = \lim_i \left[Q_R, \sum_i d^n x_i \cdot A(x_i)\right]\Omega = \lim_i \sum_i d^n x_i \cdot U(x_i)[Q_R(-x_i), A]\Omega. \tag{A9}$$

We again choose R so large that

$$[Q_R(-x), A] = [Q_R, A] \quad \text{for all } x \in V, \tag{A10}$$

which leads to

$$\left[Q_R, \int_V A(x)d^n x\right]\Omega = \lim_i \sum_i d^n x_i \cdot U(x_i)[Q_R, A]\Omega = \int_V U(x)d^n x \cdot [Q_R, A]\Omega. \tag{A11}$$

Taking now the limit $R \to \infty$, we get obtain the following lemma.

Lemma 7.3:

$$Q\int_V A(x)d^n x\Omega = \int_V U(x)d^n x \cdot QA\Omega. \tag{A12}$$

This shows, that our manipulations can be justified.

(Received 15 November 2000; accepted for publication 20 September 2001)

After the separation of the center-of-mass motion, a new privileged class of canonical Darboux bases is proposed for the nonrelativistic N-body problem by exploiting a geometrical and group theoretical approach to the definition of *body frame* for deformable bodies. This basis is adapted to the rotation group SO(3), whose canonical realization is associated with a symmetry Hamiltonian *left action*. The analysis of the SO(3) coadjoint orbits contained in the N-body phase space implies the existence of a *spin frame* for the N-body system. Then, the existence of appropriate nonsymmetry Hamiltonian *right actions* for nonrigid systems leads to the construction of an N-dependent discrete number of *dynamical body frames* for the N-body system, hence to the associated notions of *dynamical* and *measurable* orientation and shape variables, angular velocity, rotational and vibrational configurations. For $N=3$ the dynamical body frame turns out to be unique and our approach reproduces the *xxzz gauge* of the gauge theory associated with the *orientation-shape* SO(3) principal bundle approach of Littlejohn and Reinsch. For $N\geqslant 4$ our description is different, since the dynamical body frames turn out to be *momentum dependent*. The resulting Darboux bases for $N\geqslant 4$ are connected to the coupling of the *spins* of particle clusters rather than the coupling of the *centers of mass* (based on Jacobi relative normal coordinates). One of the advantages of the spin coupling is that, unlike the center-of-mass coupling, it admits a relativistic generalization. © *2002 American Institute of Physics.*

I. INTRODUCTION

In this paper we deal with the construction of a specialized system of coordinates for the nonrelativistic N-body problem which could be instrumental to nuclear, atomic and molecular physics, as well as to celestial mechanics. In particular, we shall exploit the technique of the canonical realizations of Lie symmetry groups[1–5] within the framework of the nonrelativistic version of the *rest-frame Wigner covariant instant form* of dynamics[6,7] to the effect of obtaining coordinates adapted (locally in general) to the SO(3) group. In most of the paper we consider only free particles, since the mutual interactions are irrelevant to the definition of the kinematics.

Isolated systems of N particles possess $3N$ degrees of freedom in configuration space and $6N$

in phase space. The Abelian nature of the overall translational invariance, with its associated three commuting Noether constants of motion, allows for the decoupling and, therefore, for the elimination of either three configurational variables or three pairs of canonical variables, respectively (separation of the center-of-mass motion). In this way one is left with either $3N$-3 relative coordinates $\vec{\rho}_a$ or $6N$-6 relative phase space variables $\vec{\rho}_a$, $\vec{\pi}_a$, $a=1,...,N-1$ and the center-of-mass angular momentum or spin is $\vec{S}=\Sigma_{a=1}^{N-1}\vec{\rho}_a\times\vec{\pi}_a$. In the nonrelativistic theory most of the calculations employ the sets of $3N-3$ *Jacobi normal relative coordinates* $\vec{s}_a$ which diagonalize the quadratic form associated with the relative kinetic energy (the spin becomes $\vec{S}=\Sigma_{a=1}^{N-1}\vec{s}_a\times\vec{\pi}_{sa}$, with $\vec{\pi}_{sa}$ momenta conjugated to the $\vec{s}_a$'s). Each set of relative Jacobi normal coordinates $\vec{s}_a$, $a=1,...,N-1$, is associated with a *different clustering* of the N particles, corresponding to the centers of mass of the various subclusters. In special relativity Jacobi normal coordinates do not exist, as it will be shown in Ref. 8, and a different strategy must be used.

On the other hand, the non-Abelian nature of the overall rotational invariance entails the impossibility of an analogous intrinsic separation of *rotational* (or *orientational*) configurational variables from others which could be called *shape* or *vibrational*. As a matter of fact, this is one of the main concerns of molecular physics and of advanced mechanics of deformable bodies. Recently, a new approach inspired by the geometrical techniques of fiber bundles has been proposed in these fields of research: a self-contained and comprehensive exposition of this viewpoint and a rich bibliography can be found in Ref. 9.

In the theory of deformable bodies one loses any intrinsic notion of *body frame*, which is a fundamental tool for the description of rigid bodies and their associated Euler equations. *A priori*, for a given configuration of a nonrelativistic continuous body, and in particular for an N-body system, any barycentric orthogonal frame could be named *body frame* of the system with its associated notion of *vibrations*.

This state of affairs suggested[9] replacing the kinematically accessible region of the nonsingular configurations[10] in the $(3N\text{-}3)$-dimensional relative configuration space by a SO(3) principal fiber bundle over a $(3N\text{-}6)$-dimensional base manifold, called *shape* space. The SO(3) fiber on each shape configuration carries the *orientational* variables (e.g., the usual Euler angles) referred to the chosen *body frame*. A local cross section of the principal fiber bundle selects just one orientation of a generic N-body configuration in each fiber [SO(3) orbit] and this is equivalent to a *gauge convention*, namely to a possible definition of a *body frame* (*reference orientation*), to be adopted after a preliminary choice of the *shape* variables. It turns out that this principal bundle is trivial only for $N=3$, so that in this case global cross sections exist, and in particular the identity cross section may be identified with the *space frame*. Any global cross section is a copy of the 3-body shape space and its coordinatization gives a description of the *internal vibrational* motions associated with the chosen gauge convention for the reference orientation. For $N\geqslant 4$, however, global cross sections do not exist[11] and the definition of the reference orientation (*body frame*) can be given only locally. This means that the shape space cannot be identified with a $(3N\text{-}6)$-dimensional submanifold of the $(3N\text{-}3)$-dimensional relative configuration space. The *gauge convention* about the reference orientation and the consequent individuation of the internal *vibrational degrees of freedom* requires the choice of a connection Γ on the SO(3) principal bundle (i.e., a concept of *horizontality*) and this leads in turn to the introduction of a SO(3) gauge potential on the base manifold. In this way a natural gauge invariant concept of *purely rotational* N-body configurations exists (*vertical* velocity vector field, i.e., null shape velocities). Of course a gauge fixing is needed in order to select a particular Γ-horizontal cross section and the correlated gauge potential on the shape space. Obviously, physical quantities like the rotational or vibrational kinetic energies and, in general, any observable feature of the system must be gauge invariant. Note instead that both the space frame and the body frame components of the angular velocity are gauge quantities in the *orientation-shape bundle* approach and their definition depends upon the gauge convention. See Ref. 9 for a review of the gauge fixings used in molecular physics literature and, in particular, for the virtues of a special connection C corresponding to the shape configurations with vanishing center-of-mass angular momentum $\vec{S}$. The C-horizontal cross sections are

orthogonal to the fibers with respect to the Riemannian metric dictated by the kinetic energy.

This *orientation-shape* approach replaces the usual Euler kinematics of rigid bodies and entails in general a coupling between the internal *shape* variables and some of the *orientational* degrees of freedom. In Ref. 9 it is interestingly shown that the nontriviality of the SO(3) principal bundle, when extended to continuous deformable bodies, is at the heart of the explanation of problems like the *falling cat* and the *diver*. A characteristic role of SO(3) gauge potentials in this case is to *generate rotations by changing the shape*.

In Ref. 9 the Hamiltonian formulation of this framework is also given, but no explicit procedure for the construction of a canonical Darboux basis for the orientational and shape variables is worked out. See Refs. 9, 12 for the existing sets of shape variables for $N=3,4$ and for the determination of their physical domain.

Independent of this SO(3) principal bundle framework and having in mind the relativistic N-body problem where only Hamiltonian methods are available, we have been induced to search for a *constructive procedure* for building canonical Darboux bases in the $(6N\text{-}6)$-dimensional relative phase space, suited to the non-Abelian canonical reduction of the overall rotational symmetry. Our procedure surfaced from the following independent pieces of information.

(A) In recent years a systematic study of relativistic kinematics of the N-body problem, in the framework of the *rest-frame Wigner covariant instant form of dynamics* has been developed in Ref. 13 and then applied to the isolated system composed by N scalar charged particles plus the electromagnetic field.[14,15]

These papers contain the construction of a special class of canonical transformations, of the Shanmugadhasan type.[16,6] Such transformations are simultaneously adapted to the following: (i) the Dirac first class constraints appearing in the Hamiltonian formulation of relativistic models; (ii) the timelike Poincaré orbits associated with most of their configurations. In the Darboux bases one of the final canonical variables is the square root of the Poincaré invariant P^2 (P_μ is the conserved time-like four-momentum of the isolated system). Subsequently, by using the constructive theory of the canonical realizations of Lie groups[1–5] a new family of canonical transformations was introduced in Ref. 17. This latter leads to the definition of the so-called *canonical spin bases*, in which also the Pauli–Lubanski Poincaré invariant $W^2=-P^2\vec{S}_T^2$ for time-like Poincaré orbits[18] becomes one of the final canonical variables. The construction of the spin bases exploits the clustering of spins rather than the Jacobi clustering of centers of mass.

In spite of its genesis in a relativistic context, the technique used in the determination of the spin bases, related to a *typical form*[1] of the canonical realizations of the $E(3)$ group, can be easily adapted to the nonrelativistic case, where W^2 is replaced by the invariant $\vec{S}^2$ of the extended Galilei group.

(B) These results provide the starting point for the construction of a canonical Darboux basis adapted to the non-Abelian SO(3) symmetry. The three non-Abelian Noether constants of motion $\vec{S}$ are arranged in these canonical Darboux bases as an array containing the canonical pair S^3, $\beta=\tan^{-1}(S^2/S^1)$ and the unpaired variable $S=|\vec{S}|$[19] [*scheme A* of the canonical realization of SO(3)[2]]. The angle canonically conjugated to S, say α, is an *orientational* variable, which, being coupled to the internal *shape* degrees of freedom, cannot be a constant of motion. Being conjugate to a constant of the motion, it is an *ignorable* variable in the Hamiltonian formalism, so that its equation of motion can be solved by quadratures after the solution of the other equations. In conclusion, in this non-Abelian case one has only two (instead of three as in the Abelian case) commuting constants of motion, namely S and S^3 (like in quantum mechanics).

This is also the outcome of the momentum map canonical reduction[20–22] by means of adapted coordinates. Let us stress that α, S^3, β are a local coordinatization of any coadjoint orbit of SO(3) contained in the N-body phase space. Each coadjoint orbit is a 3-dimensional embedded submanifold and is endowed with a Poisson structure whose neutral element is α. This latter is also the essential coordinate for the definition of the *flag* of spinors (see Refs. 23 and 2, Sec. V). On the other hand, the spinor flag is nothing else than a unit vector $\hat{R}$ orthogonal to $\vec{S}$,[24] which is going to be a fundamental tool in what follows.

By fixing nonzero values of the variables S^3, $\beta=\tan^{-1}(S^2/S^1)$ through second class constraints, one can define a $(6N\text{-}8)$-dimensional reduced phase space. However, the canonical reduction cannot be furthered by eliminating S, since α is not a constant of motion.

(C) The group-theoretical treatment of rigid bodies[21] (see Chap. IV, Sec. 10 of Ref. 21) is based on the existence of the realization of the (free and transitive) *left* and *right* Hamiltonian actions of the SO(3) rotation group on either the tangent or cotangent bundle over their configuration space. Given a *laboratory or space frame* $\hat{f}_r$, the generators of the *left* Hamiltonian action[25] are the non-Abelian constants of motion S^1, S^2, S^3, $[\{S^r,S^s\}=\epsilon^{rsu}S^u]$, viz., the spin components in the *space frame*. In the approach of Ref. 9 the SO(3) principal bundle is built starting from the *relative configuration space* and, upon the choice of a body-frame convention, a gauge-dependent SO(3) *right* action is introduced.

Correspondingly, taking into account the *relative phase space* of any isolated system, one may investigate whether one or more SO(3) *right* Hamiltonian actions could be implemented besides the global canonical realization of the SO(3) *left* Hamiltonian action, which is a symmetry action. In other words, one may look for solutions $\check{S}^r$, $r=1,2,3$ [with $\Sigma_r(\check{S}^r)^2=\Sigma_r(S^r)^2=S^2$], of the partial differential equations $\{S^r,\check{S}^s\}=0$, $\{\check{S}^r,\check{S}^s\}=-\epsilon^{rsu}\check{S}^u$ and then build corresponding *left* invariant Hamiltonian vector fields. Alternatively, one may look for the existence of a pair $\check{S}^3$, $\gamma=\tan^{-1}(\check{S}^2/\check{S}^1)$, of canonical variables satisfying $\{\gamma,\check{S}^3\}=-1$, $\{\gamma,S^r\}=\{\check{S}^3,S^r\}=0$ and also $\{\gamma,\alpha\}=\{\check{S}^3,\alpha\}=0$. Local theorems given in Refs. 1, 2 guarantee that this is always possible provided $N\geqslant 3$. See Chap. IV of Ref. 21 for what is known in general about the actions of Lie groups on symplectic manifolds. Clearly, the functions $\check{S}^r$ do not generate symmetry actions, because they are not constants of the motion.

The inputs coming from (A), (B), (C) together with the technique of the spin bases introduced in Ref. 17 suggest the following strategy for the geometrical and group-theoretical identification of a privileged class of canonical Darboux bases for the N-body problem.

(1) Every such basis must be a *scheme B* (i.e., a canonical completion of *scheme A*)[1,2] for the canonical realization of the rotation group SO(3), viz., it must contain its invariant S and the canonical pair S^3, $\beta=\tan^{-1}(S^2/S^1)$. Therefore, all the remaining variables in the canonical basis except α are SO(3) scalars.

(2) As said above, the existence of the angle α satisfying $\{\alpha,S\}=1$ and $\{\alpha,S^3\}=\{\alpha,\beta\}=0$ leads to the geometrical identification of a unit vector $\hat{R}$ orthogonal to $\vec{S}$ and, therefore, of a orthonormal frame $\hat{S}$, $\hat{R}$, $\hat{S}\times\hat{R}$ (the notation $\hat{}$ means unit vector), which will be called *spin frame*.

(3) The study of the equations $\hat{R}^2=1$ and $\{\vec{S}\cdot\hat{R},\hat{R}^i\}=0$ entails the symplectic result $\{\hat{R}^i,\hat{R}^j\}=0$. As a byproduct we get a canonical realization of an $E(3)$ group with generators $\vec{S}$, $\hat{R}$ $[\{\hat{R}^i,\hat{R}^j\}=0, \{\hat{R}^i,S^j\}=\epsilon^{ijk}\hat{R}^k]$ and fixed values of its invariants $\hat{R}^2=1$, $\vec{S}\cdot\hat{R}=0$ (nonirreducible type 3 realization according to Ref. 17).

(4) In order to implement a SO(3) *Hamiltonian right action* in analogy with the rigid body theory,[21] we must construct an orthonormal triad or *body frame* $\hat{N}$, $\hat{\chi}$, $\hat{N}\times\hat{\chi}$. The decomposition,

$$\vec{S}=\check{S}^1\hat{\chi}+\check{S}^2\hat{N}\times\hat{\chi}+\check{S}^3\hat{N}\overset{\text{def}}{=}\check{S}^r\hat{e}_r, \tag{1.1}$$

identifies the SO(3) scalar generators $\check{S}^r$ of the right action provided they satisfy $\{\check{S}^r,\check{S}^s\}=-\epsilon^{rsu}\check{S}^u$. This latter condition together with the obvious requirement that $\hat{N}$, $\hat{\chi}$, $\hat{N}\times\hat{\chi}$ be SO(3) vectors $[\{\hat{N}^r,S^s\}=\epsilon^{rsu}\hat{N}^u$, $\{\hat{\chi}^r,S^s\}=\epsilon^{rsu}\hat{\chi}^u$, $\{\hat{N}\times\hat{\chi}^r,S^s\}=\epsilon^{rsu}\hat{N}\times\hat{\chi}^u]$ entails the equations[26]

$$\{\hat{N}^r,\hat{N}^s\}=\{\hat{N}^r,\hat{\chi}^s\}=\{\hat{\chi}^r,\hat{\chi}^s\}=0. \tag{1.2}$$

To each solution of these equations is associated a couple of canonical realizations of the $E(3)$ group (type 2, nonirreducible): one with generators $\vec{S}$, $\vec{N}$ and nonfixed invariants $\check{S}^3=\vec{S}\cdot\hat{N}$ and $|\vec{N}|$; another with generators $\vec{S}$, $\vec{\chi}$ and nonfixed invariants $\check{S}^1=\vec{S}\cdot\hat{\chi}$ and $|\vec{\chi}|$. These latter contain the relevant information for constructing the angle α and the new canonical pair $\check{S}^3$, $\gamma=\tan^{-1}(\check{S}^2/\check{S}^1)$ of SO(3) scalars. Since $\{\alpha,\check{S}^3\}=\{\alpha,\gamma\}=0$ must hold, it follows that the vector $\vec{N}$ necessarily belongs to the $\vec{S}-\hat{R}$ plane. The three canonical pairs S, α, S^3, β, $\check{S}^3$, γ will describe the *orientational* variables of our Darboux basis, while $|\vec{N}|$ and $|\vec{\chi}|$ will belong to the *shape* variables. Alternatively, an anholonomic basis can be constructed by replacing the above six variables by $\check{S}^r$ (or S^r) and three uniquely determined Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$.

Let us consider the case $N=3$ as a first example. It turns out that a solution of Eqs. (1.2) corresponding to a *body frame* (determined only by the 3-body system configuration, as in the *rigid body* case) is completely individuated once two orthonormal vectors $\vec{N}$ and $\vec{\chi}$, functions of the relative coordinates and independent of the momenta, are found such that $\vec{N}$ lies in the $\vec{S}-\hat{R}$ plane.[27] We do not know whether in the case $N=3$ other solutions of Eqs. (1.2) exist leading to momentum-dependent body frames. Anyway, our constructive method necessarily leads to momentum-dependent solutions of Eqs. (1.2) for $N\geqslant 4$ and therefore to momentum-dependent or *dynamical body frames*.

We can conclude that in the N-body problem there are *hidden structures allowing the identification of special dynamical body frames which, being independent of gauge conditions, are endowed with a physical meaning*.

The following particular results can be proven.

(i) For $N=2$, a single $E(3)$ group can be defined: it allows the construction of an orthonormal *spin frame* $\hat{S}$, $\hat{R}$, $\hat{R}\times\hat{S}$ in terms of the measurable relative coordinates and momenta of the particles.

(ii) For $N=3$, $\vec{S}=\vec{S}_1+\vec{S}_2$, a pair of $E(3)$ groups emerge associated with $\vec{S}_1$ and $\vec{S}_2$, respectively. In this case, besides the orthonormal *spin frame*, an orthonormal *dynamical body frame* $\hat{N}$, $\hat{\chi}$, $\hat{N}\times\hat{\chi}$ can be defined such that $\check{S}^1=\vec{S}\cdot\hat{\chi}$, $\check{S}^2=\vec{S}\cdot\hat{N}\times\hat{\chi}$, $\check{S}^3=\vec{S}\cdot\hat{N}$ are the canonical generators of a SO(3) Hamiltonian *right* action. The nonconservation of $\check{S}^r$ entails that *the dynamical body frame evolves in a way dictated by the equations of motion*, just as it happens in the rigid body case.

It can be shown that for $N=3$ this definition of a *dynamical body frame* can be reinterpreted as a special global cross section (*xxzz gauge*, where *x* stays for $\hat{\chi}$ and *z* for $\hat{N}$; this outcome is independent from the particular choice made for $\vec{N}$ and $\vec{\chi}$) of the trivial SO(3) principal bundle of Ref. 9, namely a privileged choice of body frame. Actually, the three canonical pairs of orientational variables S^3, $\beta=\tan^{-1}(S^2/S^1)$; S, α; $\check{S}^3$, $\gamma=\tan^{-1}(\check{S}^2/\check{S}^1)$, can be replaced by the anholonomic basis of three Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ and by $\check{S}^1$, $\check{S}^2$, $\check{S}^3$ as it is done in Ref. 9. In our construction, however, the Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ are determined as the *unique set* of *dynamical orientation variables*. Then, the remaining canonical pairs q^μ, p_μ, $\mu=1,2,3$, of this spin-adapted Darboux basis describe the *dynamical shape* phase space.

While the above *dynamical body frame* can be identified with the global cross section corresponding to the *xxzz gauge*, all other global cross sections cannot be interpreted as *dynamical body frames* (or *dynamical right* actions), because the SO(3) principal bundle of Ref. 9 is built starting from the relative configuration space and, therefore, it is a *static*, velocity-independent, construction. As a matter of fact, after the choice of the shape configuration variables q^μ and of a space frame in which the relative variables have components ρ^r_a, the approach of Ref. 9 begins with the definition of the body-frame components $\check{\rho}^r_a(q^\mu)$ of the relative coordinates, in the form $\rho^r_a=R^{rs}(\theta^\alpha)\check{\rho}^s_a(q^\mu)$,[28] and then extends it in a *velocity-independent* way to the relative velocities $\dot{\rho}^r_a \overset{\text{def}}{=} R^{rs}(\theta^\alpha)\check{v}^s_a$. In

our construction we get instead $\rho_a^r = R^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}_a^s(q^\mu)$ in the *xxzz gauge*, so that in the present case ($N=3$) all *dynamical* variables of our construction coincide with the *static* variables in the *xxzz gauge*. On the other hand, in the relative phase space, the construction of the *evolving dynamical body frame* is based on nonpoint canonical transformations.

(iii) For $N=4$, where $\vec{S}=\vec{S}_1+\vec{S}_2+\vec{S}_3$, it is possible to construct *three* sets of *spin frames* and *dynamical body frames* corresponding to the hierarchy of clusterings $((ab)c)$ [i.e., ((12)3), ((23)1), ((31)2)] of the relative spins $\vec{S}_a$.[29] The associated three canonical Darboux bases share the three variables S^3, β, S (viz., $\vec{S}$), while both the remaining three orientational variables and the shape variables depend on the spin clustering. This entails the existence of three different SO(3) *right* actions with nonconserved canonical generators $\check{S}^r_{(A)}$, $A=1,2,3$. Therefore, one can define three anholonomic bases $\tilde{\alpha}_{(A)}$, $\tilde{\beta}_{(A)}$, $\tilde{\gamma}_{(A)}$, $\check{S}^r_{(A)}$ and associated shape variables $q^\mu_{(A)}$, $p_{(A)\mu}$, $\mu=1,...,6$, connected by canonical transformations leaving S^r fixed. These anholonomic bases and the associated *evolving dynamical body frames*, however, have no relations with the $N=4$ *static* nontrivial SO(3) principal bundle of Ref. 9, which admits only local cross sections. As a matter of fact, one gets $\rho_a^r = R^{rs}(\tilde{\alpha}_{(A)},\tilde{\beta}_{(A)},\tilde{\gamma}_{(A)})\check{\rho}_{(A)a}(q^\mu_{(A)},p_{(A)\mu},\check{S}^r_{(A)})$ instead of $\rho_a^r = R^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}_a^s(q^\mu)$.

These results imply that, for $N=4$, the 18-dimensional relative phase space admits three operationally well defined *dynamical body frames*, and associated *right* actions, and its coordinates are naturally split in three different ways into 6 dynamical rotational variables and 12 generalized dynamical shape variables. As a consequence, we get three possible definitions of *dynamical vibrations*. Each set of 12 generalized dynamical canonical shape variables is obviously defined modulo canonical transformations so that it should even be possible to find local canonical bases corresponding to the local cross sections of the $N=4$ *static* nontrivial SO(3) principal bundle of Ref. 9.

Our results can be extended to arbitrary N, with $\vec{S}=\Sigma_{a=1}^{N-1}\vec{S}_a$. There are as many independent ways (say K) of spin clustering as in quantum mechanics. For instance for $N=5$, $K=15$: 12 spin clusterings correspond to the pattern $(((ab)c)d)$ and 3 to the pattern $((ab)(cd))$ $[a,b,c,d=1,...,4]$. For $N=6$, $K=105$: 60 spin clusterings correspond to the pattern $((((ab)c)d)e)$, 15 to the pattern $((ab)(cd)e)$ and 30 to the pattern $(((ab)c)(de))$ $[a,b,c,d,e=1,...,5]$. Each spin clustering is associated to (a) a related *spin frame*; (b) a related *dynamical body frame*; (c) a related Darboux spin canonical basis with orientational variables S^3, β, S, $\alpha_{(A)}$, $\check{S}^3_{(A)}$, $\gamma_{(A)}=\tan^{-1}(\check{S}^2_{(A)}/\check{S}^1_{(A)})$, $A=1,...,K$ [their anholonomic counterparts are $\tilde{\alpha}_{(A)}$, $\tilde{\beta}_{(A)}$, $\tilde{\gamma}_{(A)}$, $\check{S}^r_{(A)}$ with uniquely determined orientation angles] and shape variables $q^\mu_{(A)}$, $p_{\mu(A)}$, $\mu=1,...,3N-6$. Furthermore, for $N\geq 4$ we find the following relation between spin and angular velocity: $\check{S}^r = \mathcal{I}^{rs}(q^\mu_{(A)})\check{\omega}^s_{(A)} + f^\mu(q^\nu_{(A)})p_{(A)\mu}$.

Let us conclude this Introduction with some remarks.

The $\vec{S}=0$, *C-horizontal*, cross section of the *static* SO(3) principal bundle corresponds to N-body configurations that cannot be included in the previous Hamiltonian construction based on the canonical realizations of SO(3): these configurations (which include the singular ones) have to be analyzed independently since they are related to the exceptional orbit of SO(3), whose little group is the whole group.

While physical observables have to be obviously independent of the gauge-dependent *static body frames*, they do depend on the *dynamical body frame*, whose axes are operationally defined in terms of the relative coordinates and momenta of the particles. In particular, a *dynamical* definition of *vibration*, which replaces the $\vec{S}=0$ *C-horizontal* cross section of the *static* approach,[30] is based on the requirement that the components of the *angular velocity* vanish. Actually, the angular velocities with respect to the dynamical body frames become now *measurable quantities*, in agreement with the phenomenology of extended deformable bodies.

In this connection, let us recall that the main efforts done in developing canonical transformations for the N-body problem took place in the context of celestial mechanics. As a conse-

quence, these transformations are necessarily adapted to the Newtonian gravitational potential. This latter, together with the harmonic potential, corresponds to the only interactions having extra dynamical symmetries besides the rotational one. The particularity of the final canonical transformations which have been worked out in that mechanical context is that of containing the Hamiltonian as one among the final momenta. This is in particular true for the $N=2$ body problem (Delauny variables) and for the $N=3$ body problem (Jacobi's methos of *the elimination of the nodes*). On the other hand, it is well-known that, for generic nonintegrable interactions, putting the Hamiltonian in the canonical bases is quite useless, since it does not bring to *isolating integrals* of the motion having the capability of reducing the dimensions of phase space. We stress again here that our construction rests only on the left and right actions of the SO(3) group and is therefore completely independent of the interactions (e.g., the treatment of spinning stars in astrophysics).

It is an open problem whether the use of more general body frames for $N=3$ and $N\geqslant 4$ obtained by using the freedom of making arbitrary configurations dependent rotations[27] may be used to simplify the free Hamiltonian and/or some type of interaction.

It is hoped that our results may be instrumental for nuclear, atomic and molecular physics, since a description based on spin clustering rather than on the standard Jacobi center-of-mass clusterings was lacking until now.

Let us observe that the extension of the *dynamical body frames* to continuous deformable bodies (see Ref. 31 for an initial study of the relativistic configurations of a Klein–Gordon field from this point of view) is a lacking piece of kinematical information and will be studied elsewhere.

The fact that we use nonpoint canonical transformations will make the quantization more difficult than in the orientation-shape bundle approach, where a separation of rotations from vibrations in the Schrödinger equation is reviewed in Ref. 9. The quantizations of the original canonical relative variables and of the canonical spin bases will give equivalent quantum theories only if the nonpoint canonical transformations are unitarily implementable. These problems are completely unexplored.

In a future paper[8] we shall study the relativistic N-body problem, where the definition and separation of the center-of-mass motion are known to be a complicated issue. Moreover the schematization with rigid bodies does not exist in special relativity: the only relativistic concept of rigidity are Born's rigid motions.[32] This problem has found a solution within the Wigner-covariant rest-frame instant form of dynamics.[13] It will be shown that concepts like reduced masses, Jacobi normal relative coordinates and tensor of inertia do not exist at the relativistic level. Yet, in the framework of the rest-frame instant form, both the orientation-shape SO(3) principal bundle approach and the canonical spin bases can be defined just as in the nonrelativistic case.

In Sec. II the rest-frame description of N free particles is introduced.

In Sec. III the *canonical spin bases*, the *spin frame* and the *dynamical body frames* are introduced and the cases $N=2$, $N=3$ and $N\geqslant 4$ are analyzed separately.

In Appendix A detailed calculations are given for the case $N=3$.

In Appendix B some notions on Euler angles are reviewed.

In Appendix C the construction of the *canonical spin bases* is given for the $N=4$ case.

See the preliminary version[33] of this paper for a more complete review of the SO(3) principal bundle approach (see also Refs. 34–37), many more technical details on the new canonical transformations and some examples of interaction potentials.

II. THE NONRELATIVISTIC REST-FRAME DESCRIPTION

In this section we give a summary of the description of N nonrelativistic free particles in the rest frame.

Given the coordinates $\vec{\eta}_i(t)$, $i=1,...,N$, of N particles of mass m_i, the standard Lagrangian is $L=\Sigma_{i=1}^{N}(m_i/2)\dot{\vec{\eta}}_i^2$. By introducing the center-of-mass coordinates $\vec{q}_{\rm nr}$ and a set of relative variables, the Lagrangian can be rewritten as $L=(m/2)\dot{\vec{q}}_{\rm nr}+$ (quadratic form in the relative veloci-

ties), $m=\Sigma_{i=1}^{N} m_i$. The canonical momenta are $\vec{p}_i = m_i \dot{\vec{\eta}}_i$, while the total momentum conjugated to $\vec{q}_{\rm nr}$ is $\vec{P}=\Sigma_{i=1}^{N}\vec{p}_i$. The Hamiltonian is $H=\Sigma_{i=1}^{N}(\vec{p}_i^{\,2}/2m_i)=\vec{P}^2/2m+$ (quadratic form in the relative momenta).

The rest-frame description (equivalent to the decoupling of the center of mass) is obtained by imposing the vanishing of the conserved total momentum $\vec{P}=\Sigma_{i=1}^{N}\vec{p}_i=0$. It can be obtained as the nonrelativistic $c\to\infty$ limit of the relativistic rest-frame instant form of Ref. 8. Equivalently we can start from the Lagrangian

$$L_D(t)=\sum_{i=1}^{N}\frac{m_i}{2}[\dot{\vec{\eta}}_i(t)+\vec{\lambda}(t)]^2, \quad S_D=\int dt\, L_D(t) \tag{2.1}$$

in which the Lagrange multipliers $\vec{\lambda}(t)$ are considered as configurational variables.

The canonical momenta are

$$\vec{\kappa}_i(t)=\frac{\partial L_D(t)}{\partial \dot{\vec{\eta}}_i(t)}=m_i[\dot{\vec{\eta}}_i(t)+\vec{\lambda}(t)],$$
$$\vec{\pi}_\lambda(t)=\frac{\partial L_D(t)}{\partial \dot{\vec{\lambda}}(t)}=0. \tag{2.2}$$

Therefore, $\vec{\pi}_\lambda(t)\approx 0$ is a primary constraint. The canonical and Dirac Hamiltonians are [the variables $\vec{\mu}(t)$ being the Dirac multipliers in front of the primary constraints $\vec{\pi}_\lambda(t)\approx 0$]

$$H_c=\vec{\pi}_\lambda\cdot\dot{\vec{\lambda}}+\sum_{i=1}^{N}\vec{\kappa}_i\cdot\dot{\vec{\eta}}_i-L_D=\sum_{i=1}^{N}\frac{\vec{\kappa}_i^{\,2}}{2m_i}-\vec{\lambda}\cdot\vec{\kappa}_+, \quad \vec{\kappa}_+=\sum_{i=1}^{N}\vec{\kappa}_i,$$
$$H_D=\sum_{i=1}^{N}\frac{\vec{\kappa}_i^{\,2}}{2m_i}-\vec{\lambda}\cdot\vec{\kappa}_+ +\vec{\mu}\cdot\vec{\pi}_\lambda. \tag{2.3}$$

The time constancy of the primary constraints implies the following secondary constraint:

$$\dot{\vec{\pi}}_\lambda(t)\stackrel{\circ}{=}\{\vec{\pi}_\lambda(t),H_D\}=\vec{\kappa}_+\approx 0, \tag{2.4}$$

which is the nonrelativistic rest-frame condition.

There are two first class constraints $\vec{\pi}_\lambda\approx 0$, $\vec{\kappa}_+\approx 0$: $\vec{\lambda}(t)$ and a center-of-mass variable are gauge variables. The Hamilton and Euler–Lagrange equations are ($\stackrel{\circ}{=}$ means evaluated on the trajectories which minimize the action principle)

$$\dot{\vec{\eta}}_i(t)\stackrel{\circ}{=}\{\vec{\eta}_i(t),H_D\}=\frac{\vec{\kappa}_i(t)}{m_i}-\vec{\lambda}(t), \quad \dot{\vec{\lambda}}(t)\stackrel{\circ}{=}\vec{\mu}(t),$$
$$\dot{\vec{\kappa}}_i(t)\stackrel{\circ}{=}0, \quad \dot{\vec{\pi}}_\lambda(t)\stackrel{\circ}{=}\vec{\kappa}_+\approx 0, \tag{2.5}$$
$$m_i(\ddot{\vec{\eta}}_i+\dot{\vec{\lambda}})(t)\stackrel{\circ}{=}0.$$

This is the nonrelativistic limit of the relativistic rest-frame instant form of dynamics: Minkowski spacetime is replaced by Galilei spacetime and the Wigner hyperplanes are replaced by the inertial observers seeing the isolated system as instantaneously at rest in the $t=\text{const}$ hyperplanes. Defining the nonrelativistic center of mass,

$$\vec{q}_{\rm nr}=\sum_{i=1}^{N}\frac{m_i}{m}\,\vec{\eta}_i\,, \tag{2.6}$$

with $m=\Sigma_{i=1}^{N}m_i$, the gauge fixing $\vec{q}_{\rm nr}\approx 0$ implies $\vec{\lambda}(\tau)\approx 0$ and the decoupling of the center of mass, see Eq. (2.9).

In analogy with the relativistic case of Ref. 13, let us introduce the following family of nonrelativistic point canonical transformations:

$$\begin{array}{|c|}\hline \vec{\eta}_i \\ \hline \vec{\kappa}_i \\ \hline \end{array} \qquad \longrightarrow \qquad \begin{array}{|c|c|}\hline \vec{q}_{nr} & \vec{\rho}_a \\ \hline \vec{\kappa}_+ & \vec{\pi}_a \\ \hline \end{array} \tag{2.7}$$

defined by

$$\vec{\eta}_i=\vec{q}_{\rm nr}+\frac{1}{\sqrt{N}}\sum_{a=1}^{N-1}\Gamma_{ai}\vec{\rho}_a\,,$$

$$\vec{\kappa}_i=\frac{m_i}{m}\,\vec{\kappa}_+ +\sqrt{N}\sum_{a=1}^{N-1}\gamma_{ai}\vec{\pi}_a\,,$$

$$\vec{q}_{\rm nr}=\sum_{i=1}^{N}\frac{m_i}{m}\,\vec{\eta}_i\,,$$

$$\vec{\kappa}_+=\sum_{i=1}^{N}\vec{\kappa}_i\,,$$

$$\vec{\rho}_a=\sqrt{N}\sum_{i=1}^{N}\gamma_{ai}\vec{\eta}_i\,,$$

$$\vec{\pi}_a=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\Gamma_{ai}\vec{\kappa}_i\,, \tag{2.8}$$

$$\vec{S}=\sum_{a=1}^{N-1}\vec{\rho}_a\times\vec{\pi}_a\,,$$

$$\Gamma_{ai}=\gamma_{ai}-\sum_{k=1}^{N}\frac{m_k}{m}\gamma_{ak}\,,\quad \gamma_{ai}=\Gamma_{ai}-\frac{1}{N}\sum_{k=1}^{N}\Gamma_{ak}\,,$$

$$\sum_{i=1}^{N}\gamma_{ai}=0,\quad \sum_{i=1}^{N}\frac{m_i}{m}\Gamma_{ai}=0,$$

$$\sum_{i=1}^{N}\gamma_{ai}\gamma_{bi}=\delta_{ab}\,,\quad \sum_{i=1}^{N}\gamma_{ai}\Gamma_{bi}=\delta_{ab}\,,$$

$$\sum_{a=1}^{N-1} \gamma_{ai}\gamma_{aj} = \delta_{ij} - \frac{1}{N}, \quad \sum_{a=1}^{N-1} \gamma_{ai}\Gamma_{aj} = \delta_{ij} - \frac{m_i}{m}.$$

Here, the γ_{ai}'s (and the Γ_{ai}'s) are numerical parameters depending on $\frac{1}{2}(N-1)(N-2)$ free parameters.[13,38]

Then, by using the equations of motion $m[\dot{\vec{q}}_{\rm nr}(t) + \vec{\lambda}(t)] \stackrel{\circ}{=} 0$, we get the Lagrangian $L_{\rm rel}$ and the Hamiltonian $H_{\rm rel}$ describing the relative motions after the separation of the center-of-mass motion,

$$L_D(t) = \sum_{i=1}^{N} \frac{m_i}{2}\left[\dot{\vec{q}}_{\rm nr}(t) + \vec{\lambda}(t) + \frac{1}{\sqrt{N}}\sum_{a=1}^{N-1} \Gamma_{ai}\dot{\vec{\rho}}_a(t)\right]^2$$

$$\stackrel{\circ}{=} L_{\rm rel}(t) = \frac{1}{2}\sum_{a,b}^{1\cdot N-1} k_{ab}[m_i, \Gamma_{ai}]\dot{\vec{\rho}}_a(t)\cdot\dot{\vec{\rho}}_b(t),$$

$$k_{ab}[m_i, \Gamma_{ci}] = k_{ba}[m_i, \Gamma_{ci}] = \frac{1}{N}\sum_{i=1}^{N} m_i\Gamma_{ai}\Gamma_{bi},$$

$$k^{-1}_{ab}[m_i, \Gamma_{ci}] = N\sum_{i=1}^{N} \frac{\gamma_{ai}\gamma_{bi}}{m_i},$$

$$\Downarrow$$

$$\vec{\pi}_a(t) = \sum_{b=1}^{N-1} k_{ab}[m_i, \Gamma_{ci}]\dot{\vec{\rho}}_b(t),$$

$$\Rightarrow H_{\rm rel} = \frac{1}{2}\sum_{ab}^{1\ldots N-1} k^{-1}_{ab}[m_i, \Gamma_{ai}]\vec{\pi}_a(t)\cdot\vec{\pi}_b(t). \tag{2.9}$$

The same result can be obtained by adding the gauge fixings $\vec{q}_{\rm nr} \approx 0$ which imply $\vec{\lambda}(t) = 0$, and by going to Dirac brackets with respect to the second class constraints $\vec{\kappa}_+ \approx 0$, $\vec{q}_{\rm nr} \approx 0$. The $(6N\text{-}6)$-dimensional reduced phase space is now spanned by $\vec{\rho}_a$, $\vec{\pi}_a$ and from Eq. (2.8) we have $\vec{S} \equiv \Sigma_{a=1}^{N-1}\vec{\rho}_a \times \vec{\pi}_a$.

At the nonrelativistic level[9,39] the next problem for each N is to diagonalize the matrix $k_{ab}[m_i, \Gamma_{ai}]$. The off-diagonal terms of the matrix $k_{ab}[m_i, \Gamma_{ai}]$ are called *mass polarization terms*, while its eigenvalues are the *reduced masses* (see for instance Ref. 40).

III. CANONICAL SPIN BASES

Following the preliminary work of Ref. 17, we look for a set of nonpoint canonical transformations from the relative canonical variables $\vec{\rho}_a = \sqrt{N}\Sigma_{i=1}^{N}\gamma_{ai}\vec{\eta}_i$, $\vec{\pi}_a = (1/\sqrt{N})\,\Sigma_{i=1}^{N}\Gamma_{ai}\vec{\kappa}_i$ of Eq. (2.8) to a canonical basis adapted to the SO(3) subgroup[1,2] of the extended Galilei group and containing one of its invariants, namely the modulus of the spin. Jacobi coordinates will not be used.

A. 2-body systems

The relative variables are $\vec{\rho} = \vec{\rho}$, $\vec{\pi}$ and the Hamiltonian is $H_{\rm rel} = \vec{\pi}^2/2\mu$, where $\mu = m_1 m_2/(m_1 + m_2)$ is the reduced mass. The spin is $\vec{S} = \vec{\rho} \times \vec{\pi}$ $[S = \sqrt{\vec{S}^2}]$.

Let us define the following decomposition:

$$\vec{\rho}=\rho\hat{R},\quad \rho=\sqrt{\vec{\rho}^2},\quad \hat{R}=\frac{\vec{\rho}}{\rho}=\hat{\rho},\quad \hat{R}^2=1,$$

$$\vec{\pi}=\tilde{\pi}\hat{R}-\frac{S}{\rho}\hat{R}\times\hat{S}=\tilde{\pi}\hat{\rho}-\frac{S}{\rho}\hat{\rho}\times\hat{S}, \tag{3.1}$$

$$\tilde{\pi}=\vec{\pi}\cdot\hat{R}=\vec{\pi}\cdot\hat{\rho},\quad \hat{S}=\frac{\vec{S}}{S},\quad \hat{S}\cdot\hat{R}=0.$$

Therefore, besides the standard *space or laboratory frame* with unit vectors $\hat{f}_r$, we can build a *spin frame*, whose basis unit vectors $\hat{S}$, $\hat{R}$, $\hat{S}\times\hat{R}$ are identified by the 2-body system itself. Since $\{S^i,S^j\}=\epsilon^{ijk}S^k$, $\{\hat{R}^i,\hat{R}^j\}=0$, $\{\hat{R}^i,S^j\}=\epsilon^{ijk}\hat{R}^k$, $\vec{S}$ and $\hat{R}$ are the generators of an $E(3)$ group containing SO(3) as a subgroup. The $E(3)$ invariants turn out to have the fixed values $\hat{R}^2=1$ and $\vec{S}\cdot\hat{R}=0$.

As shown in Ref. 17, it is instrumental to consider the following nonpoint canonical transformation adapted to the SO(3) group valid when $\vec{S}\neq 0$ (the invariant $S=|\vec{S}|$ becomes one of the new canonical variables),

$$\begin{array}{|c|}\hline \vec{\rho}\\ \hline \vec{\pi}\\ \hline\end{array}\quad\longrightarrow\quad \begin{array}{|cc|c|}\hline \alpha & \beta & \rho\\ \hline S & S^3 & \tilde{\pi}\\ \hline\end{array}\ , \tag{3.2}$$

where

$$\alpha=\tan^{-1}\frac{1}{S}\left(\vec{\rho}\cdot\vec{\pi}-\frac{(\rho)^2}{\rho^3}\pi^3\right),$$

$$\beta=\tan^{-1}\frac{S^2}{S^1},\quad \sin\beta=\frac{S^2}{\sqrt{(S)^2-(S^3)^2}},\quad \cos\beta=\frac{S^1}{\sqrt{(S)^2-(S^3)^2}}. \tag{3.3}$$

The two pairs of canonical variables α, S, β, S^3 form the irreducible kernel of the *scheme A* of a (nonirreducible, type 3; see Ref. 17) canonical realization of the group $E(3)$ generated by $\vec{S}$, $\hat{R}$, with fixed values of the invariants $\hat{R}^2=1$, $\hat{R}\cdot\vec{S}=0$, just as the variables S^3, β and S form the *scheme A* of the SO(3) group with invariant S.

Geometrically we have the following:

(i) The angle α is the angle between the plane determined by $\vec{S}$ and $\hat{f}_3$ and the plane determined by $\vec{S}$ and $\hat{R}$.

(ii) The angle β is the angle between the plane $\vec{S}-\hat{f}_3$ and the plane $\hat{f}_3-\hat{f}_1$.

We have

$$\begin{aligned} S^1&=\sqrt{(S)^2-(S^3)^2}\cos\beta,\\ S^2&=\sqrt{(S)^2-(S^3)^2}\sin\beta,\end{aligned} \tag{3.4}$$

$$\hat{R}^1=\hat{\rho}^1=\sin\beta\sin\alpha-\frac{S^3}{S}\cos\beta\cos\alpha,$$

$$\hat{R}^2=\hat{\rho}^2=-\cos\beta\sin\alpha-\frac{S^3}{S}\sin\beta\cos\alpha,$$

$$\hat{R}^3=\hat{\rho}^3=\frac{1}{S}\sqrt{(S)^2-(S^3)^2}\cos\alpha,$$

$$(\hat{S}\times\hat{R})^1=\hat{S}^2\hat{R}^3-\hat{S}^3\hat{R}^2=\sin\beta\cos\alpha+\frac{S^3}{S}\cos\beta\sin\alpha,$$

$$(\hat{S}\times\hat{R})^2=\hat{S}^3\hat{R}^1-\hat{S}^1\hat{R}^3=-\cos\beta\cos\alpha+\frac{S^3}{S}\sin\beta\sin\alpha,$$

$$(\hat{S}\times\hat{R})^3=-\hat{S}^1\hat{R}^2-\hat{S}^2\hat{R}^1=\frac{1}{S}\sqrt{(S)^2-(S^3)^2}\sin\alpha,$$

$$\hat{S}\times\hat{R}(\alpha)=\frac{\partial\hat{R}(\alpha)}{\partial\alpha}=\hat{R}\left(\alpha+\frac{\pi}{2}\right),$$

$$\Rightarrow\alpha=-\tan^{-1}\frac{(\hat{S}\times\hat{R})^3}{[\hat{S}\times(\hat{S}\times\hat{R})]^3}. \tag{3.5}$$

From the last line of this equation we see that the angle α can be expressed in terms of $\hat{S}$ and $\hat{R}$. Given the Hamiltonian description of any isolated system (a deformable body) in its rest frame with conserved spin $\vec{S}(q,p)$ (q,p denote a canonical basis for the system), a solution $\alpha(q,p)$ of the equations $\{\alpha(q,p),S(q,p)\}=1$, $\{\alpha(q,p),\beta(q,p)\}=\{\alpha(q,p),S^3(q,p)\}=0$, allows us to construct the unit vector $\hat{R}$ associated with the isolated system and then to build the spin frame and the $E(3)$ group.

Let us remark that *the Delaunay Hamilton–Jacobi transformation for the 2-body problem with the Newton potential*, used in celestial mechanics (see for instance Sec. 2.5 of Ref. 41), is *different* from Eq. (3.2). In fact, even if it contains S^3, β, S, it has (i) an angle α' differing from α for the choice of the origin; (ii) the Hamiltonian and a conjugate variable replacing ρ, $\tilde{\pi}$.

The following inverse canonical transformation holds true:

$$\vec{\rho}=\rho\hat{R}(\alpha,\beta,S,S^3),$$

$$\vec{\pi}=\tilde{\pi}\hat{R}(\alpha,\beta,S,S^3)+\frac{S}{\rho}\hat{S}(\beta,S,S^3)\times\hat{R}(\alpha,\beta,S,S^3),$$

$$\Rightarrow\vec{\pi}^2=\tilde{\pi}^2+\frac{S^2}{\rho^2}. \tag{3.6}$$

In this degenerate case, the *dynamical* shape variables ρ, $\tilde{\pi}$ coincide with the *static* ones and describe the vibration of the dipole.

The rest-frame Hamiltonian for the relative motion becomes ($\check{I}$ is the barycentric tensor of inertia of the dipole)

$$H_{\rm rel}=\frac{1}{2}\left[\check{I}^{-1}S^2+\frac{\tilde{\pi}^2}{\mu}\right],\quad \check{I}=\mu\rho^2,\quad \mu=\frac{m_1m_2}{m_1+m_2}, \tag{3.7}$$

while the body frame angular velocity is

$$\check{\omega}=\frac{\partial H_{\rm rel}}{\partial\check{S}}=\frac{\check{S}}{\check{I}}. \tag{3.8}$$

When $\vec{S}\neq 0$, Eq. (3.2) explicitly shows that a non-Abelian symmetry group like SO(3) does not allow a canonical reduction like in the Abelian case of translations. In this latter case we can eliminate the three Abelian constants of motion $\vec{\kappa}_+\approx 0$ and gauge fix the three conjugate variables $\vec{q}_{\rm nr}\approx 0$. In the non-Abelian case we could surely fix S^3, β by imposing second class constraints $S^3-a\approx 0$, $\beta-b\approx 0$, and eliminate this pair of canonical variables by going to Dirac brackets. However, since α is not a constant of motion [see later on Eq. (3.7); we get instead $(d/dt)(S-s)\overset{\circ}{=}0$], we can only add by hand the first class constraint $S-s\approx 0$ $(s\neq 0)$. It is only after the solution of the equations of motion, that we could also complete the reduction by adding $\alpha-\alpha_{\rm solution}\approx 0$ as a gauge-fixing. Let us remark that, since S is a constant of the motion, the angle α is an *ignorable* variable, which does not occur in the Hamiltonian.

In the absence of interactions the solution for α can be easily worked out (in any case it can be obtained by quadratures after the solution of the other equations of motion). The Hamilton equations, equivalent to $\ddot{\vec{\rho}}\overset{\circ}{=}0$, are $\dot{\rho}\overset{\circ}{=}\tilde{\pi}/\mu$, $\dot{\tilde{\pi}}\overset{\circ}{=}(S)^2/\mu\rho^3$, $\dot{S}\overset{\circ}{=}0$, $\dot{\alpha}\overset{\circ}{=}S/\mu\rho^2$. The solution $\vec{\rho}\overset{\circ}{=}\vec{b}t+\vec{a}$ ($\vec{a}$, $\vec{b}$ constant vectors) implies $\rho\overset{\circ}{=}|\vec{b}t+\vec{a}|$, $\hat{R}\overset{\circ}{=}(\vec{b}t+\vec{a})/|\vec{b}t+\vec{a}|$, $\tilde{\pi}\overset{\circ}{=}2\mu\vec{b}\cdot(\vec{b}t+\vec{a})/|\vec{b}t+\vec{a}|$, $S\overset{\circ}{=}\mu\sqrt{2}|\vec{a}\times\vec{b}|$, $\alpha\overset{\circ}{=}\arccos(\hat{R}^3S/\sqrt{(S)^2-(S^3)^2})$.

In the 2-body case the condition $\vec{S}\approx 0$, imposed as three first class constraints, is equivalent to $\vec{\rho}-k\vec{\pi}\approx 0$ and selects only the solution $\vec{\rho}(t)\overset{\circ}{=}\vec{A}e^{Bt}$ (k, $\vec{A}$ and B are constants).

B. 3-body systems

In the case $N=3$ the range of the indices is $i=1,2,3$, $a=1,2$. The spin is $\vec{S}=\Sigma_{a=1}^2\vec{\rho}_a\times\vec{\pi}_a=\Sigma_{a=1}^2\vec{S}_a$ after the canonical transformation (2.7) and the relative motions are governed by the Hamiltonian (2.9) for $N=3$.

Again, we shall assume $\vec{S}\neq 0$, because the exceptional SO(3) orbit $S=0$ has to be studied separately. This is done by adding $S\approx 0$ as a first class constraint and studying the following two disjoint strata with a different number of first class constraints separately: (a) $\vec{S}\approx 0$, but $\vec{S}_1=-\vec{S}_2\neq 0$; (b) $\vec{S}_a\approx 0$, $a=1,2$ (in this case we have $\vec{\rho}_a-k_a\vec{\pi}_a\approx 0$).[42]

For each value of $a=1,2$, we consider the nonpoint canonical transformation (3.2),

$$\begin{array}{|c|}\hline \vec{\rho}_a \\ \hline \vec{\pi}_a \\ \hline \end{array} \quad \longrightarrow \quad \begin{array}{|cc|c|}\hline \alpha_a & \beta_a & \rho_a \\ \hline S_a & S_a^3 & \tilde{\pi}_a \\ \hline \end{array} \tag{3.9}$$

where

$$\alpha_a=\tan^{-1}\frac{1}{S_a}\left(\vec{\rho}_a\cdot\vec{\pi}_a-\frac{(\rho_a)^2}{\rho_a^3}\pi_a^3\right),$$

$$\beta_a=\tan^{-1}\frac{S_a^2}{S_a^1},\quad \sin\beta_a=\frac{S_a^2}{\sqrt{(S_a)^2-(S_a^3)^2}},\quad \cos\beta_a=\frac{S_a^1}{\sqrt{(S_a)^2-(S_a^3)^2}}. \tag{3.10}$$

$$\vec{\rho}_a=\rho_a\hat{R}_a,\quad \rho_a=\sqrt{\vec{\rho}_a^2},\quad \hat{R}_a=\frac{\vec{\rho}_a}{\rho_a}=\hat{\rho}_a,\quad \hat{R}_a^2=1, \tag{3.11}$$

$$\vec{\pi}_a=\tilde{\pi}_a\hat{R}_a+\frac{S_a}{\rho_a}\hat{S}_a\times\hat{R}_a,\quad \tilde{\pi}_a=\vec{\pi}_a\cdot\hat{R}_a.$$

$$\vec{\rho}_a=\rho_a\hat{\rho}_a(\alpha_a,\beta_a,S_a,S_a^3)=\rho_a\hat{R}_a(\alpha_a,\beta_a,S_a,S_a^3),$$

$$\vec{\pi}_a=\tilde{\pi}_a\hat{\rho}_a(\alpha_a,\beta_a,S_a,S_a^3)+\frac{S_a}{\rho_a}\hat{S}_a(\beta_a,S_a,S_a^3)\times\hat{\rho}_a(\alpha_a,\beta_a,S_a,S_a^3)$$

$$=\tilde{\pi}_a\hat{R}_a(\alpha_a,\beta_a,S_a,S_a^3)+\frac{S_a}{\rho_a}\hat{S}_a(\beta_a,S_a,S_a^3)\times\hat{R}_a(\alpha_a,\beta_a,S_a,S_a^3). \tag{3.12}$$

We have now *two* unit vectors $\hat{R}_a$ and *two* $E(3)$ realizations generated by $\vec{S}_a$, $\hat{R}_a$, respectively, and fixed invariants $\hat{R}_a^2=1$, $\vec{S}_a\cdot\hat{R}_a=0$ (nonirreducible, type 2; see Ref. 17).

Then, the *simplest choice*, within the existing arbitrariness,[27] for the orthonormal vectors $\vec{N}$ and $\vec{\chi}$ functions only of the relative coordinates is (it is the canonical transformation of Ref. 17 with the interchange $\vec{\rho}_a\leftrightarrow\vec{\pi}_a$)

$$\vec{N}=\frac{1}{2}(\hat{R}_1+\hat{R}_2)=\frac{1}{2}(\hat{\rho}_1+\hat{\rho}_2),\quad \hat{N}=\frac{\vec{N}}{|\vec{N}|},\quad |\vec{N}|=\sqrt{\frac{1+\hat{\rho}_1\cdot\hat{\rho}_2}{2}},$$

$$\vec{\chi}=\frac{1}{2}(\hat{R}_1-\hat{R}_2)=\frac{1}{2}(\hat{\rho}_1-\hat{\rho}_2),\quad \hat{\chi}=\frac{\vec{\chi}}{|\vec{\chi}|},\quad |\vec{\chi}|=\sqrt{\frac{1-\hat{\rho}_1\cdot\hat{\rho}_2}{2}}=\sqrt{1-\vec{N}^2},$$

$$\vec{N}\times\vec{\chi}=-\frac{1}{2}\hat{\rho}_1\times\hat{\rho}_2,\quad |\vec{N}\times\vec{\chi}|=|\vec{N}||\vec{\chi}|=\frac{1}{2}\sqrt{1-(\hat{\rho}_1\cdot\hat{\rho}_2)^2}, \tag{3.13}$$

$$\vec{N}\cdot\vec{\chi}=0,\quad \{N^r,N^s\}=\{\chi^r,\chi^s\}=\{N^r,\chi^s\}=0,$$

$$\hat{R}_1=\hat{\rho}_1=\vec{N}+\vec{\chi},\quad \hat{R}_2=\hat{\rho}_2=\vec{N}-\vec{\chi},\quad \hat{R}_1\cdot\hat{R}_2=\hat{\rho}_1\cdot\hat{\rho}_2=\vec{N}^2-\vec{\chi}^2.$$

Likewise, we have for the spins

$$\vec{S}=\vec{S}_1+\vec{S}_2,$$

$$\vec{W}=\vec{S}_1-\vec{S}_2,$$

$$\vec{S}_1=\tfrac{1}{2}(\vec{S}+\vec{W}),\quad \vec{S}_2=\tfrac{1}{2}(\vec{S}-\vec{W}), \tag{3.14}$$

$$\{W^r,W^s\}=\epsilon^{rsu}S^u.$$

We therefore succeeded in constructing an orthonormal triad (the *dynamical body frame*) and two $E(3)$ realizations (nonirreducible, type 3; see Ref. 17): one with generators $\vec{S}$, $\vec{N}$ and nonfixed invariants $|\vec{N}|$ and $\vec{S}\cdot\hat{N}$, the other with generators $\vec{S}$ and $\vec{\chi}$ and nonfixed invariants $|\vec{\chi}|$ and $\vec{S}\cdot\hat{\chi}$. As said in the Introduction, Eq. (1.1), this is equivalent to the determination of the nonconserved generators $\check{S}^r$ of a Hamiltonian *right action* of SO(3): $\check{S}^1=\vec{S}\cdot\hat{\chi}=\vec{S}\cdot\hat{e}_1$, $\check{S}^2=\vec{S}\cdot\hat{N}\times\hat{\chi}=\vec{S}\cdot\hat{e}_2$, $\check{S}^3=\vec{S}\cdot\hat{N}=\vec{S}\cdot\hat{e}_3$.

The realization of the $E(3)$ group with generators $\vec{S}$, $\vec{N}$ and nonfixed invariants $\vec{N}^2$, $\vec{S}\cdot\vec{N}$ leads to the final canonical transformation introduced in Ref. 17

$$\begin{array}{|c|}\hline \vec{\rho}_a \\ \hline \vec{\pi}_a \\ \hline \end{array}\quad\longrightarrow\quad \begin{array}{|cc|cc|c|}\hline \alpha_1 & \beta_1 & \alpha_2 & \beta_2 & \rho_a \\ \hline S_1 & S_1^3 & S_2 & S_2^3 & \tilde{\pi}_a \\ \hline \end{array}\quad\longrightarrow\quad \begin{array}{|ccc|c|c|}\hline \alpha & \beta & \gamma & |\vec{N}| & \rho_a \\ \hline S=\check{S} & S^3 & \check{S}^3=\vec{S}\cdot\hat{N} & \xi & \tilde{\pi}_a \\ \hline \end{array} \tag{3.15}$$

where

$$|\vec{N}|=\sqrt{\frac{1+\hat{\rho}_1\cdot\hat{\rho}_2}{2}},$$

$$\check{S}^3=\vec{S}\cdot\hat{N}=\frac{1}{\sqrt{2}}\sum_{a=1}^{2}\vec{\rho}_a\times\vec{\pi}_a\cdot\frac{\hat{\rho}_1+\hat{\rho}_2}{\sqrt{1+\hat{\rho}_1\cdot\hat{\rho}_2}}\equiv S\cos\psi,$$

$$\cos\psi=\hat{S}\cdot\hat{N}=\frac{\check{S}^3}{S},\quad \sin\psi=\frac{1}{S}\sqrt{(S)^2-(\check{S}^3)^2},$$

$$S=\check{S}=\left|\sum_{a=1}^{2}\vec{\rho}_a\times\vec{\pi}_a\right|,$$

$$S^3=\sum_{a=1}^{2}(\vec{\rho}_a\times\vec{\pi}_a)^3,$$

$$\alpha=-\tan^{-1}\frac{(\hat{S}\times\hat{N})^3}{[\hat{S}\times(\hat{S}\times\hat{N})]^3}=-\tan^{-1}\frac{[\hat{S}\times(\hat{\rho}_1+\hat{\rho}_2)]^3}{[\hat{S}\times(\hat{S}\times[\hat{\rho}_1+\hat{\rho}_2])]^3},\tag{3.16}$$

$$\beta=\tan^{-1}\frac{S^2}{S^1},$$

$$\gamma=\tan^{-1}\frac{\vec{S}\cdot(\hat{N}\times\hat{\chi})}{\vec{S}\cdot\hat{\chi}}=\tan^{-1}\frac{\check{S}^2}{\check{S}^1},$$

$$\Rightarrow\sin\gamma=\frac{\check{S}^2}{\sqrt{(\check{S})^2-(\check{S}^3)^2}},\quad \cos\gamma=\frac{\check{S}^1}{\sqrt{(\check{S})^2-(\check{S}^3)^2}},$$

$$\xi=\frac{\vec{W}\cdot(\hat{N}\times\hat{\chi})}{|\vec{\chi}|}=\frac{\vec{W}\cdot(\hat{N}\times\hat{\chi})}{\sqrt{1-\vec{N}^2}}=\frac{\sqrt{2}\Sigma_{a=1}^{2}(-)^{a+1}\vec{\rho}_a\times\vec{\pi}_a\cdot(\hat{\rho}_2\times\hat{\rho}_1)}{[1-\hat{\rho}_1\cdot\hat{\rho}_2]\sqrt{1+\hat{\rho}_1\cdot\hat{\rho}_2}}.$$

For $N=3$ the *dynamical shape variables*, functions of the relative coordinates $\vec{\rho}_a$ only, are $|\vec{N}|$ and ρ_a, while the conjugate shape momenta are ξ, $\tilde{\pi}_a$.

Let us remark that *this transformation is different from the canonical transformation* of Ref. 43 introduced for the method of *elimination of the nodes*. Since S is a constant of motion, the conjugate variable α is *ignorable* and does not occur in the Hamiltonian. We recover the result that the effective order of the 3-body equations of motion is 8, before using the conservation of the energy.

The final array (3.15) is nothing other than a *scheme* B^1 of a realization of the $E(3)$ group with generators $\vec{S}$, $\vec{N}$ (nonirreducible type 3). In particular, the two canonical pairs S^3, β, S, α, constitute the irreducible kernel of the $E(3)$ *scheme A*, whose invariants are $\check{S}^3$, $|\vec{N}|$; γ and ξ are the so-called *supplementary variables* conjugated to the invariants; finally, the two pairs ρ_a, $\tilde{\pi}_a$

are so-called *inessential variables*. Let us remark that S^3, β, S, α, γ, ξ, are a local coordinatization of every $E(3)$ coadjoint orbit with $\check{S}^3=\text{const}$, $|\vec{N}|=\text{const}$ and fixed values of the inessential variables, present in the 3-body phase space.

We can now reconstruct $\vec{S}$ and define a *new* unit vector $\hat{R}$ orthogonal to $\vec{S}$ by adopting the prescription of Eq. (3.5).

The vectors $\hat{S}$, $\hat{R}$, $\hat{S}\times\hat{R}$ build up the *spin frame* for $N=3$. The angle α conjugate to S is explicitly given by

$$\alpha=-\tan^{-1}\frac{(\hat{S}\times\hat{N})^3}{[\hat{S}\times(\hat{S}\times\hat{N})]^3}=-\tan^{-1}\frac{(\hat{S}\times\hat{R})^3}{[\hat{S}\times(\hat{S}\times\hat{R})]^3}. \tag{3.17}$$

The two expressions of α given here are consistent with the fact that $\hat{S}$, $\hat{R}$ and $\hat{N}$ are coplanar, so that $\hat{R}$ and $\hat{N}$ differ only by a term in $\hat{S}$.

As a consequence of this definition of $\hat{R}$, we get the following expressions for the *dynamical body frame* $\hat{N}$, $\hat{\chi}$, $\hat{N}\times\hat{\chi}$ in terms of the final canonical variables,

$$\hat{N}=\cos\psi\hat{S}+\sin\psi\hat{R}=\frac{\check{S}^3}{S}\hat{S}+\frac{1}{S}\sqrt{(S)^2-(\check{S}^3)^2}\hat{R}=\hat{N}[S,\alpha;S^3,\beta;\check{S}^3,\gamma],$$

$$\hat{\chi}=\sin\psi\cos\gamma\hat{S}-\cos\psi\cos\gamma\hat{R}+\sin\gamma\hat{S}\times\hat{R}=\frac{\check{S}^1}{S}\hat{S}-\frac{\check{S}^3}{S}\frac{\check{S}^1\hat{R}+\check{S}^2\hat{S}\times\hat{R}}{\sqrt{(S)^2-(\check{S}^3)^2}}=\hat{\chi}[S,\alpha;S^3,\beta;\check{S}^3,\gamma],$$

$$\begin{aligned}\hat{N}\times\hat{\chi}&=\sin\psi\sin\gamma\hat{S}-\cos\psi\sin\gamma\hat{R}-\cos\gamma\hat{S}\times\hat{R}\\&=\frac{\check{S}^2}{S}\hat{S}-\frac{\check{S}^3}{S}\frac{\check{S}^1\hat{R}-\check{S}^2\hat{S}\times\hat{R}}{\sqrt{(S)^2-(\check{S}^3)^2}}=(\hat{N}\times\hat{\chi})[S,\alpha;S^3,\beta;\check{S}^3,\gamma],\end{aligned}$$

$$\Downarrow \tag{3.18}$$

$$\hat{S}=\sin\psi\cos\gamma\hat{\chi}+\sin\psi\sin\gamma\hat{N}\times\hat{\chi}+\cos\psi\hat{N}\overset{\text{def}}{=}\frac{1}{S}[\check{S}^1\hat{\chi}+\check{S}^2\hat{N}\times\hat{\chi}+\check{S}^3\hat{N}],$$

$$\hat{R}=-\cos\psi\cos\gamma\hat{\chi}-\cos\psi\sin\gamma\hat{N}\times\hat{\chi}+\sin\psi\hat{N},$$

$$\hat{R}\times\hat{S}=-\sin\gamma\hat{\chi}+\cos\gamma\hat{N}\times\hat{\chi}.$$

While ψ is the angle between $\hat{S}$ and $\hat{N}$, γ is the angle between the plane $\hat{N}-\hat{\chi}$ and the plane $\hat{S}-\hat{N}$. As in the case $N=2$, α is the angle between the plane $\hat{S}-\hat{f}_3$ and the plane $\hat{S}-\hat{R}$, while β is the angle between the plane $\hat{S}-\hat{f}_3$ and the plane $\hat{f}_3-\hat{f}_1$. See Fig. 1.

Owing to the results of Appendix A, which allow us to re-express $S_a=|\vec{S}_a|$, S^3_a, $\beta_a=\tan^{-1}(S^2_a/S^1_a)$ in terms of the final variables and owing to Eqs. (3.13), (3.17) which allow us to get $\alpha_a=-\tan^{-1}[(\hat{S}_a\times\hat{R}_a)^3/(\hat{S}_a\times(\hat{S}_a\times\hat{R}_a))^3]$, we can reconstruct the inverse canonical transformation.

The existence of the *spin frame* and of the *dynamical body frame* allows to define two decompositions of the relative variables, which make explicit the inverse canonical transformation. For the relative coordinates we get from Eqs. (3.13) and (A3),

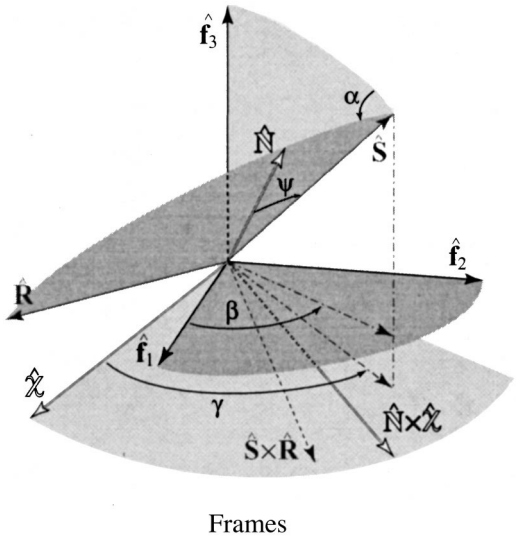

FIG. 1. *Space* frame ($\hat{f}_r$), *spin* frame ($\hat{S}$, $\hat{R}$, $\hat{S}\times\hat{R}$) and *dynamical body* frame ($\hat{N}$, $\hat{\chi}$, $\hat{N}\times\hat{\chi}$) for $N\geqslant 3$ particles. ψ—angle between $\hat{N}$ and $\hat{S}$; α—angle between the planes $\hat{S}-\hat{f}_3$ and $\hat{S}-\hat{R}$; β—angle between $\hat{f}_1$ and the projection of $\hat{S}$ onto the plane $\hat{f}_1-\hat{f}_2$; γ—angle between $\hat{\chi}$ and the projection of $\hat{S}$ onto the plane $\hat{\chi}-\hat{N}\times\hat{\chi}$.

$$
\begin{aligned}
\vec{\rho}_a &= \rho_a \hat{R}_a \\
&= \rho_a[\vec{N}+(-)^{a+1}\vec{\chi}] \\
&= \rho_a[|\vec{N}|\hat{N}+(-)^{a+1}\sqrt{1-\vec{N}^2}\hat{\chi}] \\
&= [\vec{\rho}_a\cdot\hat{S}]\hat{S}+[\vec{\rho}_a\cdot\hat{R}]\hat{R}+[\vec{\rho}_a\cdot\hat{S}\times\hat{R}]\hat{S}\times\hat{R} \\
&= \vec{\rho}_a[S,\alpha;S^3,\beta;\check{S}^3,\gamma;\rho_a,|\vec{N}|]. \qquad (3.19)
\end{aligned}
$$

The analogous formulas for the relative momenta are [see Eq. (A3) for the expression of the body frame components of $\vec{\pi}_a$]

$$
\begin{aligned}
\vec{\pi}_a &= \tilde{\pi}_a\hat{R}_a+\frac{S_a}{\rho_a}\hat{S}_a\times\hat{R}_a \\
&= \tilde{\pi}_a\hat{\rho}_a+\frac{S_a}{\rho_a}\hat{S}_a\times\hat{\rho}_a \\
&= [\vec{\pi}_a\cdot\hat{N}]\hat{N}+[\vec{\pi}_a\cdot\hat{\chi}]\hat{\chi}+[\vec{\pi}_a\cdot\hat{N}\times\hat{\chi}]\hat{N}\times\hat{\chi} \\
&= [\vec{\pi}_a\cdot\hat{S}]\hat{S}+[\vec{\pi}_a\cdot\hat{R}]\hat{R}+[\vec{\pi}_a\cdot\hat{S}\times\hat{R}]\hat{S}\times\hat{R} \\
&= \vec{\pi}_a[S,\alpha;S^3,\beta;\check{S}^3,\gamma;|\vec{N}|,\xi;\rho_a,\tilde{\pi}_a]. \qquad (3.20)
\end{aligned}
$$

Finally, the results of Appendix B allow us to perform a sequence of a canonical transformation to Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ with their conjugate momenta, followed by a transition to the anholonomic basis used in the orientation-shape bundle approach,[9]

$$
\begin{array}{|c c c|} \hline \alpha & \beta & \gamma \\ S=\check{S} & S^3 & \check{S}^3 \\ \hline \end{array}
\quad\longrightarrow\quad
\begin{array}{|c c c|} \hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} \\ p_{\tilde{\alpha}} & p_{\tilde{\beta}} & p_{\tilde{\gamma}} \\ \hline \end{array}
\quad\xrightarrow{non\ can.}\quad
\begin{array}{|c c c|} \hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} \\ \check{S}^1 & \check{S}^2 & \check{S}^3 \\ \hline \end{array}
$$

$$S=\check{S}=\sqrt{(\check{S}^1)^2+(\check{S}^2)^2+(\check{S}^3)^2},$$

$$S^3=-\sin\tilde{\beta}\cos\tilde{\gamma}\check{S}^1+\sin\tilde{\beta}\sin\tilde{\gamma}\check{S}^2+\cos\tilde{\beta}\check{S}^3,$$

$$\alpha=\arctan\frac{p_{\tilde{\beta}}\tan\tilde{\beta}}{\check{S}-\dfrac{p_{\tilde{\alpha}}p_{\tilde{\gamma}}}{\check{S}\cos\tilde{\beta}}},\tag{3.21}$$

$$\gamma=\frac{\pi}{2}-\tilde{\gamma}-\arctan\frac{\cot\tilde{\beta}p_{\tilde{\gamma}}-\dfrac{p_{\tilde{\alpha}}}{\sin\tilde{\beta}}}{p_{\tilde{\beta}}},$$

$$\beta=\tilde{\alpha}+\arctan\frac{\cot\tilde{\beta}p_{\tilde{\alpha}}-\dfrac{p_{\tilde{\gamma}}}{\sin\tilde{\beta}}}{p_{\tilde{\beta}}}-\frac{\pi}{2}.$$

Here $p_{\tilde{\alpha}}$, $p_{\tilde{\beta}}$, $p_{\tilde{\gamma}}$ are the functions of $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$, $\check{S}^r$ given in Eqs. (B3). The equations (B3), (3.21), (3.13) and $\check{S}^2=\vec{S}\cdot\hat{N}\times\hat{\chi}$ lead to the determination of the *dynamical orientation variables* $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ in terms of $\vec{\rho}_a$, $\vec{\pi}_a$. Let us stress that, while in the orientation-shape bundle approach the orientation variables θ^α are gauge variables, the Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ are *uniquely determined* in terms of the original configurations and momenta.

In conclusion, the complete transition to the anholonomic basis used in the *static* theory of the orientation-shape bundle is (another possible anholonomic basis is $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$, S^r)

α	β	γ	$\lvert\vec{N}\rvert$	ρ_a
$S=\check{S}$	S^3	$\check{S}^3$	ξ	$\tilde{\pi}_a$

$\xrightarrow{non\ can.}$

$\tilde{\alpha}$	$\tilde{\beta}$	$\tilde{\gamma}$	$\lvert\vec{N}\rvert$	ρ_a
$\check{S}^1$	$\check{S}^2$	$\check{S}^3$	ξ	$\tilde{\pi}_a$

(3.22)

In order to further the comparison with the orientation-shape bundle approach, let us note the following relation between the space and body components of the relative coordinates. Eqs. (3.20), (3.22), (3.18) and (B2) imply

$$\rho^r_a=\mathcal{R}^r{}_s(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}^s_a(q),$$

with

$$\check{\rho}^1_a(q)=(-)^{a+1}\rho_a\sqrt{1-\vec{N}^2},\quad \check{\rho}^2_a(q)=0,\quad \check{\rho}^3_a(q)=\rho_a|\vec{N}|,$$

and

$$S^r=\mathcal{R}^r{}_s(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{S}^s,\tag{3.23}$$

so that the final visualization of our sequence of transformations is

$\vec{\rho}_a$
$\vec{\pi}_a$

$\xrightarrow{non\ can.}$

$\tilde{\alpha}$	$\tilde{\beta}$	$\tilde{\gamma}$	$q^\mu(\vec{\rho}_a)$
$\check{S}^1$	$\check{S}^2$	$\check{S}^3$	$p_\mu(\vec{\rho}_a,\vec{\pi}_a)$

(3.24)

Note furthermore that we get $\check{\rho}_a^2=\vec{\rho}_a\cdot\hat{N}\times\hat{\chi}=0$ by construction and this entails that using our *dynamical body frame* is equivalent to a convention (*xxzz gauge*) about the body frame of the type of *xxz* and similar gauges quoted in Ref. 9.

Finally, we can give the expression of the Hamiltonian for relative motions in terms of the anholonomic Darboux basis of Eqs. (3.21). By using Eq. (A3) we get

$$
\begin{aligned}
H_{\rm rel}=&\frac{1}{2\vec{N}^2}\left[\frac{1}{2}\left(\frac{k^{-1}{}_{11}}{\rho_1^2}+\frac{k^{-1}{}_{22}}{\rho_2^2}\right)+\frac{k^{-1}{}_{12}}{\rho_1\rho_2}\right](\check{S}^1)^2+\frac{1}{2}\left[\frac{1}{2}\left(\frac{k^{-1}{}_{11}}{\rho_1^2}+\frac{k^{-1}{}_{22}}{\rho_2^2}\right)+\frac{k^{-1}{}_{12}(2\vec{N}^2-1)}{\rho_1\rho_2}\right](\check{S}^2)^2\\
&+\frac{1}{2(1-\vec{N}^2)}\left[\frac{1}{2}\left(\frac{k^{-1}{}_{11}}{\rho_1^2}+\frac{k^{-1}{}_{22}}{\rho_2^2}\right)-\frac{k^{-1}{}_{12}}{\rho_1\rho_2}\right](\check{S}^3)^2+\sqrt{1-\vec{N}^2}\left[\frac{\xi}{2}\left(\frac{k^{-1}{}_{11}}{\rho_1^2}-\frac{k^{-1}{}_{22}}{\rho_2^2}\right)\right.\\
&\left.+2k^{-1}{}_{12}|\vec{N}|\sqrt{1-\vec{N}^2}\left(\frac{\tilde{\pi}_1}{\rho_2}-\frac{\tilde{\pi}_2}{\rho_1}\right)\right]\check{S}^2-\frac{1}{2|\vec{N}|\sqrt{1-\vec{N}^2}}\left(\frac{k^{-1}{}_{11}}{\rho_1^2}-\frac{k^{-1}{}_{22}}{\rho_2^2}\right)\check{S}^1\check{S}^3+k^{-1}{}_{11}\\
&\times\left[\tilde{\pi}_1^2+\frac{\xi^2(1-\vec{N}^2)}{4\rho_1^2}\right]+k^{-1}{}_{22}\left[\tilde{\pi}_2^2+\frac{\xi^2(1-\vec{N}^2)}{4\rho_2^2}\right]+2k^{-1}{}_{12}\left[(2\vec{N}^2-1)\tilde{\pi}_1\tilde{\pi}_2-|\vec{N}|(1-\vec{N}^2)\right.\\
&\left.\times\xi\left(\frac{\tilde{\pi}_1}{\rho_2}+\frac{\tilde{\pi}_2}{\rho_1}\right)+\frac{\xi^2(1-\vec{N}^2)(2\vec{N}^2-1)}{4\rho_1\rho_2}\right]\overset{\rm def}{=}\frac{1}{2}[\check{S}^r(\check{\mathcal{I}}^{-1})^{rs}\check{S}^s+\tilde{g}^{\mu\nu}(p_\mu-\vec{S}\cdot\vec{\mathcal{A}}_\mu)(p_\nu-\check{\vec{S}}\cdot\check{\vec{\mathcal{A}}}_\nu)],
\end{aligned}
\tag{3.25}
$$

where $q^\mu=(\rho_1,\rho_2,|\vec{N}|)$, $p_\mu=(\tilde{\pi}_1,\tilde{\pi}_2,\xi)$ are the dynamical shape variables. By reason of comparison, in the last line we have presented the Hamiltonian in the form of the static SO(3) principal bundle approach. In Appendix E of Ref. 33 there is the determination of the quantities $\check{\mathcal{A}}_\mu^r(q)$ [the SO(3) gauge potential], $\tilde{g}^{\mu\nu}(q)$ (the inverse metric), $\check{\mathcal{I}}^{-1rs}(q)$ (the tensor of inertia) appearing in the *xxzz gauge*. Recall that the special *xxzz gauge* potentials $\check{\mathcal{A}}_\mu^r(q)$ are measurable quantities in our approach. The same holds for the angular velocity in the evolving dynamical body frame.

By evaluating $p_\mu|_{\dot{q}=0}$, we can recover the rotational kinetic energy (the centrifugal potential) $H_{\rm rel}^{\rm (rot)}=\frac{1}{2}\check{S}^r(\check{\mathcal{I}}^{-1})^{rs}\check{S}^s$ of the *xxzz gauge*. In our approach the measurable *vibrational* kinetic energy $H_{\rm rel}^{\rm (vib)}$ for $\vec{S}\neq 0$ nonsingular $N=3$ configurations can be obtained by restricting $\check{S}^r$ in $H_{\rm rel}$ to the value $\check{S}^r|_{\check{\omega}^s=0}$ [see Eq. (3.32) and Appendix E of Ref. 33], upon the requirement that the dynamical angular velocity vanishes in the *xxzz gauge*. Let us remark that we get $H_{\rm rel}\neq H_{\rm rel}^{\rm (rot)}+H_{\rm rel}^{\rm (vib)}$, differently from the static orientation-shape bundle result associated with the C-connection. In order to get the theory with the Jacobi normal coordinates one has to perform our sequence of canonical transformations after having diagonalized k_{ab}.

The Hamiltonian in the basis (3.15) can be obtained with the following replacements $\check{S}^1=\sqrt{(S)^2-(\check{S}^3)^2}\cos\gamma$ and $\check{S}^2=\sqrt{(S)^2-(\check{S}^3)^2}\sin\gamma$.

C. *N*-body systems

Let us now consider the general case with $N\geqslant 4$ without introducing Jacobi normal coordinates. Instead of coupling the centers of mass of particle clusters as it is done with Jacobi coordinates (*center-of-mass clusters*), the *canonical spin bases* will be obtained by coupling the spins of the 2-body subsystems (*relative particles*) $\vec{\rho}_a$, $\vec{\pi}_a$, $a=1,...,N-1$, defined in Eqs. (2.7), in all possible ways (*spin clusters* from the addition of angular momenta). Let us stress that we can build a *spin basis* with a pattern of *spin clusters* completely unrelated to a possible pre-existing *center-of-mass clustering*.

Let us consider the case $N=4$ as a prototype of the general construction. We have now three relative variables $\vec{\rho}_1$, $\vec{\rho}_2$, $\vec{\rho}_3$ and related momenta $\vec{\pi}_1$, $\vec{\pi}_2$, $\vec{\pi}_3$. In the following formulas we use the convention that the subscripts a, b, c mean any permutation of 1,2,3.

By using the explicit construction given in Appendix C, we define the following sequence of canonical transformations (we assume $S\neq 0$; $S_A\neq 0$, $A=a,b,c$) corresponding to the *spin clustering* pattern $abc\mapsto(ab)c\mapsto((ab)c)$ [build first the spin cluster (ab), then the spin cluster $((ab)c)$]:

$$
\begin{array}{|cccc|}\hline \vec{\rho}_a & \vec{\rho}_b & \vec{\rho}_c & \\ \vec{\pi}_a & \vec{\pi}_b & \vec{\pi}_c & \\ \hline \end{array} \longrightarrow
$$

$$
\longrightarrow \begin{array}{|cc|cc|cc|ccc|}\hline \alpha_a & \beta_a & \alpha_b & \beta_b & \alpha_c & \beta_c & \rho_a & \rho_b & \rho_c \\ S_a & S_a^3 & S_b & S_b^3 & S_c & S_c^3 & \tilde{\pi}_a & \tilde{\pi}_b & \tilde{\pi}_c \\ \hline \end{array} \longrightarrow
$$

$$
\xrightarrow{(ab)c} \begin{array}{|cc|c|cc|ccc|}\hline \alpha_{(ab)} & \beta_{(ab)} & \gamma_{(ab)} & \alpha_c & \beta_c & |\vec{N}_{(ab)}| & \rho_a & \rho_b & \rho_c \\ S_{(ab)} & S^3_{(ab)} & \check{S}^3_{(ab)}=\vec{S}_{(ab)}\cdot\hat{N}_{(ab)} & S_c & S_c^3 & \xi_{(ab)} & \tilde{\pi}_a & \tilde{\pi}_b & \tilde{\pi}_c \\ \hline \end{array} \longrightarrow
$$

$$
\longrightarrow \begin{array}{|cc|c|c|cc|ccc|}\hline \alpha_{((ab)c)} & \beta_{((ab)c)} & \gamma_{((ab)c)} & |\vec{N}_{((ab)c)}| & \gamma_{(ab)} & |\vec{N}_{(ab)}| & \rho_a & \rho_b & \rho_c \\ S=\check{S} & S^3 & \check{S}^3=\vec{S}\cdot\hat{N}_{((ab)c)} & \xi_{((ab)c)} & \vec{S}_{(ab)}\cdot\hat{N}_{(ab)} & \xi_{(ab)} & \tilde{\pi}_a & \tilde{\pi}_b & \tilde{\pi}_c \\ \hline \end{array} \longrightarrow
$$

$$
\xrightarrow{non\ can.} \begin{array}{|ccc|c|c|cc|ccc|}\hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} & |\vec{N}_{((ab)c)}| & \gamma_{(ab)} & |\vec{N}_{(ab)}| & \rho_a & \rho_b & \rho_c \\ \check{S}^1 & \check{S}^2 & \check{S}^3 & \xi_{((ab)c)} & \Omega_{(ab)}=\vec{S}_{(ab)}\cdot\hat{N}_{(ab)} & \xi_{(ab)} & \tilde{\pi}_a & \tilde{\pi}_b & \tilde{\pi}_c \\ \hline \end{array} \tag{3.26}
$$

The first nonpoint canonical transformation is based on the existence of the three unit vectors $\hat{R}_A$, $A=a,b,c$, and of three $E(3)$ realizations with generators $\vec{S}_A$, $\hat{R}_A$ and fixed values ($\hat{R}_A^2=1$, $\vec{S}_A\cdot\hat{R}_A=0$) of the invariants. Use Eqs. (3.10), (3.11) and (3.12).

In the next canonical transformation the spins of the *relative particles a* and *b* are coupled to form the spin cluster (ab), leaving the *relative particle c* as a spectator. We use Eq. (3.13) to define $\vec{N}_{(ab)}=\frac{1}{2}(\hat{R}_a+\hat{R}_b)$, $\vec{\chi}_{(ab)}=\frac{1}{2}(\hat{R}_a-\hat{R}_b)$, $\vec{S}_{(ab)}=\vec{S}_a+\vec{S}_b$, $\vec{W}_{(ab)}=\vec{S}_a-\vec{S}_b$. We get $\vec{N}_{(ab)}\cdot\vec{\chi}_{(ab)}=0$, $\{N^r_{(ab)},N^s_{(ab)}\}=\{N^r_{(ab)},\chi^s_{(ab)}\}=\{\chi^r_{(ab)},\chi^s_{(ab)}\}=0$ and a new $E(3)$ realization generated by $\vec{S}_{(ab)}$ and $\vec{N}_{(ab)}$, with nonfixed invariants $|\vec{N}_{(ab)}|$, $\vec{S}_{(ab)}\cdot\hat{N}_{(ab)}\overset{\text{def}}{=}\Omega_{(ab)}$. From Eqs. (3.20) it follows that

$$
\begin{aligned}
\vec{\rho}_a&=\rho_a[|\vec{N}_{(ab)}|\hat{N}_{(ab)}+\sqrt{1-\vec{N}^2_{(ab)}}\hat{\chi}_{(ab)}],\\
\vec{\rho}_b&=\rho_b[|\vec{N}_{(ab)}|\hat{N}_{(ab)}-\sqrt{1-\vec{N}^2_{(ab)}}\hat{\chi}_{(ab)}],\\
\vec{\rho}_c&=\rho_c\hat{R}_c\,.
\end{aligned}
\tag{3.27}
$$

Equation (3.16) defines $\alpha_{(ab)}$ and $\beta_{(ab)}$, so that Eq. (3.5) defines a unit vector $\hat{R}_{(ab)}$ with $\vec{S}_{(ab)}\cdot\hat{R}_{(ab)}=0$, $\{\hat{R}^r_{(ab)},\hat{R}^s_{(ab)}\}=0$. This unit vector identifies the *spin cluster* (ab) in the same way as the unit vectors $\hat{R}_A=\hat{\vec{\rho}}_A$ identify the *relative particles A*.

The next step is the coupling of the *spin cluster* (ab) with unit vector $\hat{R}_{(ab)}$ [described by the canonical variables $\alpha_{(ab)}$, $S_{(ab)}$, $\beta_{(ab)}$ $S^3_{(ab)}$] with the *relative particle c* with unit vector $\hat{R}_c$ and described by α_c, S_c, β_c, S_c^3: this builds the *spin cluster* $((ab)c)$.

Again, Eq. (3.13) allows us to define $\vec{N}_{((ab)c)}=\frac{1}{2}(\hat{R}_{(ab)}+\hat{R}_c)$, $\vec{\chi}_{((ab)c)}=\frac{1}{2}(\hat{R}_{(ab)}-\hat{R}_c)$, $\vec{S}=\vec{S}_{((ab)c)}=\vec{S}_{(ab)}+\vec{S}_c$, $\vec{W}_{((ab)c)}=\vec{S}_{(ab)}-\vec{S}_c$. Since we have $\vec{N}_{((ab)c)}\cdot\vec{\chi}_{((ab)c)}=0$ and $\{N^r_{((ab)c)},N^s_{((ab)c)}\}=\{N^r_{((ab)c)},\chi^s_{((ab)c)}\}=\{\chi^r_{((ab)c)},\chi^s_{((ab)c)}\}=0$ due to $\{\hat{R}^r_{(ab)},\hat{R}^s_c\}=0$, a new $E(3)$ realization generated by $\vec{S}$ and $\vec{N}_{((ab)c)}$ with nonfixed invariants $|\vec{N}_{((ab)c)}|$, $\vec{S}\cdot\hat{N}_{((ab)c)}=\check{S}^3$ emerges. Equation (3.16) defines $\alpha_{((ab)c)}$ and $\beta_{((ab)c)}$, so that Eq. (3.5) allows us to identify a final unit vector $\hat{R}_{((ab)c)}$ with $\vec{S}\cdot\hat{R}_{((ab)c)}=0$ and $\{\hat{R}^r_{((ab)c)},\hat{R}^s_{((ab)c)}\}=0$.

In conclusion, when $S\neq 0$, we find both a *spin frame* $\hat{S}$, $\hat{R}_{((ab)c)}$, $\hat{R}_{((ab)c)}\times\hat{S}$ and a *dynamical body frame* $\hat{\chi}_{((ab)c)}$, $\hat{N}_{((ab)c)}\times\hat{\chi}_{((ab)c)}$, $\hat{N}_{((ab)c)}$, like in the 3-body case. There is an *important difference*, however: the orthonormal vectors $\vec{N}_{((ab)c)}$ and $\vec{\chi}_{((ab)c)}$ depend on the momenta of the

relative particles a and b through $\hat{R}_{(ab)}$, so that our results do not share any relation with the $N=4$ nontrivial SO(3) principal bundle of the orientation-shape bundle approach.

The final 6 *dynamical shape variables* are $q^{\mu}=\{|\vec{N}_{((ab)c)}|,\gamma_{(ab)},|\vec{N}_{(ab)}|,\rho_a,\rho_b,\rho_c\}$. While the last four depend only on the original relative coordinates $\vec{\rho}_A$, $A=a,b,c$, the first two depend also on the original momenta $\vec{\pi}_A$: therefore they are *generalized shape variables*. By using Appendix B, we obtain

$$\rho_A^r=\mathcal{R}^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}_A^s(q^{\mu},p_{\mu},\check{S}^r),\quad A=a,b,c. \tag{3.28}$$

This means that for $N=4$ the dynamical body frame components $\check{\rho}_A^r$ depend also on the dynamical shape momenta and on the dynamical body frame components of the spin. It is clear that this result stands completely outside the orientation-shape bundle approach.

As shown in Appendix F of Ref. 33, starting from the Hamiltonian $H_{\mathrm{rel}((ab)c)}$ expressed in the final variables, we can define a rotational Hamiltonian $H^{(\mathrm{rot})}_{\mathrm{rel}((ab)c)}$ and a vibrational Hamiltonian $H^{(\mathrm{vib})}_{\mathrm{rel}((ab)c)}$ (vanishing of the physical dynamical angular velocity $\check{\omega}^r_{((ab)c)}=0$), but $H_{\mathrm{rel}((ab)c)}$ fails to be the sum of these two Hamiltonians showing once again the nonseparability of rotations and vibrations. Let us stress that in the rotational Hamiltonian we find an *inertia-like tensor* depending only on the dynamical shape variables. A similar result, however, does not hold for the spin-angular velocity relation.

The price to be paid for the existence of 3 global *dynamical body frames* for $N=4$ is a more complicated form of the Hamiltonian kinetic energy. On the other hand, *dynamical vibrations* and *dynamical angular velocity* are measurable quantities in each dynamical body frame.

For $N=5$ we can repeat the previous construction either with the sequence of spin clusterings $abcd\mapsto(ab)cd\mapsto((ab)c)d)\mapsto(((ab)c)d)$ or with the sequence $abcd\mapsto(ab)(cd)\mapsto((ab)\times(cd))$ (a, b, c, d any permutation of 1,2,3,4) as stated in the Introduction. Each *spin cluster* $(\cdots)$ will be identified by the unit vector $\hat{R}_{(\cdots)}$, the axis of the *spin frame* of the cluster. All the final *dynamical body frames* built with this construction will have their axes depending on both the original configurations and momenta.

This construction is trivially generalized to any N: we have only to classify all the possible *spin clustering patterns*.

Therefore, for $N\geq 4$ our sequence of canonical and noncanonical transformations leads to the following result, to be compared with Eq. (3.22) of the 3-body case,

$$\begin{array}{|c|}\hline \vec{\rho}_A \\ \hline \vec{\pi}_A \\ \hline \end{array} \quad \overset{non\ can.}{\longrightarrow} \quad \begin{array}{|ccc|c|}\hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} & q^{\mu}(\vec{\rho}_A,\vec{\pi}_A) \\ \hline \check{S}^1 & \check{S}^2 & \check{S}^3 & p_{\mu}(\vec{\rho}_A,\vec{\pi}_A) \\ \hline \end{array} \tag{3.29}$$

This state of affairs suggests that for $N\geq 4$ and with $S\neq 0$, $S_A\neq 0$, $A=a,b,c$, namely when the standard $(3N\text{-}3)$-dimensional orientation-shape bundle is not trivial, the original $(6N\text{-}6)$-dimensional relative phase space admits the definition of as many *dynamical body frames* as spin canonical bases, which are globally defined (apart isolated coordinate singularities) for the nonsingular N-body configurations with $\vec{S}\neq 0$ (and with nonzero spin for each spin subcluster).

These *dynamical body frames* do not correspond to local cross sections of the static nontrivial orientation-shape SO(3) principal bundle and the spin canonical bases do not coincide with the canonical bases associated with the static theory.

ACKNOWLEDGMENTS

We are warmly indebted to our friend Michele Vallisneri for his irreplaceable help in drawing our *frames*.

APPENDIX A: SOME FORMULAS FOR THE CASE $N=3$

In this appendix we justify Eq. (3.19). To find the expression of $\vec{\pi}_a\cdot\hat{N}$, $\vec{\pi}_a\cdot\hat{\chi}$, $\vec{\pi}_a\cdot\hat{N}\times\hat{\chi}$ let us consider the following quantities:

$$\vec{S}_1=\vec{\rho}_1\times\vec{\pi}_1=\rho_1[\vec{N}\times\vec{\pi}_1+\vec{\chi}\times\vec{\pi}_1],$$

$$\vec{S}_2=\vec{\rho}_2\times\vec{\pi}_2=\rho_2[\vec{N}\times\vec{\pi}_2-\vec{\chi}\times\vec{\pi}_2],$$

$$\vec{S}=\vec{S}_1+\vec{S}_2=\vec{N}\times[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]+\vec{\chi}\times[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2],$$

$$\vec{W}=\vec{S}_1-\vec{S}_2=\vec{N}\times[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]+\vec{\chi}\times[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2],$$

$$\vec{S}\cdot\vec{N}=|\vec{N}|\check{S}^3=|\vec{N}||\vec{\chi}|[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]\cdot\hat{N}\times\hat{\chi}=|\vec{N}||\vec{\chi}|b_3,$$

$$\vec{S}\cdot\vec{\chi}=|\vec{\chi}|\check{S}^1=-|\vec{N}||\vec{\chi}|[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]\cdot\hat{N}\times\hat{\chi}=-|\vec{N}||\vec{\chi}|a_3,$$

$$\vec{S}\cdot\vec{N}\times\vec{\chi}=|\vec{N}\times\vec{\chi}|\check{S}^2=\vec{N}^2|\vec{\chi}|[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]\cdot\hat{\chi}-\vec{\chi}^2|\vec{N}|[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]\cdot\hat{N}=\vec{N}^2|\vec{\chi}|a_2-\vec{\chi}^2|\vec{N}|b_1,$$

$$\vec{W}\cdot\vec{N}=-\vec{S}\cdot\vec{\chi},\tag{A1}$$

$$\vec{W}\cdot\vec{\chi}=-\vec{S}\cdot\vec{N},$$

$$\vec{W}\cdot\vec{N}\times\vec{\chi}=\vec{N}^2|\vec{\chi}|[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]\cdot\hat{\chi}-\vec{\chi}^2|\vec{N}|[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]\cdot\hat{N}=\vec{N}^2|\vec{\chi}|b_2-\vec{\chi}^2|\vec{N}|a_1,$$

$$\rho_1\tilde{\pi}_1=\vec{\rho}_1\cdot\vec{\pi}_1=\rho_1[\vec{\pi}_1\cdot\vec{N}+\vec{\pi}_1\cdot\vec{\chi}],$$

$$\rho_2\tilde{\pi}_2=\vec{\rho}_2\cdot\vec{\pi}_2=\rho_2[\vec{\pi}_2\cdot\vec{N}-\vec{\pi}_2\cdot\vec{\chi}],$$

$$\rho_1\tilde{\pi}_1+\rho_2\tilde{\pi}_2=\vec{\rho}_1\cdot\vec{\pi}_1+\vec{\rho}_2\cdot\vec{\pi}_2=[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]\cdot\vec{N}+[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]\cdot\vec{\chi}=|\vec{N}|a_1+|\vec{\chi}|b_2,$$

$$\rho_1\tilde{\pi}_1-\rho_2\tilde{\pi}_2=\vec{\rho}_1\cdot\vec{\pi}_1-\vec{\rho}_2\cdot\vec{\pi}_2=[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]\cdot\vec{N}+[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]\cdot\vec{\chi}=|\vec{N}|b_1+|\vec{\chi}|a_2,$$

where

$$a_1=[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]\cdot\hat{N},$$

$$a_2=[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]\cdot\hat{\chi},$$

$$a_3=[\rho_1\vec{\pi}_1+\rho_2\vec{\pi}_2]\cdot\hat{N}\times\hat{\chi},$$

$$b_1=[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]\cdot\hat{N},\tag{A2}$$

$$b_2=[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]\cdot\hat{\chi},$$

$$b_3=[\rho_1\vec{\pi}_1-\rho_2\vec{\pi}_2]\cdot\hat{N}\times\hat{\chi}.$$

Since $\vec{S}\cdot\hat{N}=\check{S}^3$, $\vec{S}\cdot\hat{\chi}=\sin\psi\cos\gamma=\check{S}^1$, $\vec{S}\cdot\hat{N}\times\hat{\chi}=\sin\psi\sin\gamma=\check{S}^2$, $\vec{W}\cdot\hat{N}\times\hat{\chi}=\xi\sqrt{1-\vec{N}^2}$, from Eq. (A1) we get $\vec{\pi}_a$ in terms of the final canonical variables:

$$\vec{\pi}_1\cdot\hat{N}=\frac{a_1+b_1}{2\rho_1}=\tilde{\pi}_1|\vec{N}|-\frac{\sqrt{1-\vec{N}^2}}{2\rho_1}[\check{S}^2+\xi\sqrt{1-\vec{N}^2}],$$

$$\vec{\pi}_2\cdot\hat{N}=\frac{a_1-b_1}{2\rho_2}=\tilde{\pi}_2|\vec{N}|+\frac{\sqrt{1-\vec{N}^2}}{2\rho_2}[\check{S}^2-\xi\sqrt{1-\vec{N}^2}],$$

$$\vec{\pi}_1\cdot\hat{\chi}=\frac{a_2+b_2}{2\rho_1}=\tilde{\pi}_1\sqrt{1-\vec{N}^2}+\frac{|\vec{N}|}{2\rho_1}[\check{S}^2+\xi\sqrt{1-\vec{N}^2}],$$

$$\vec{\pi}_2\cdot\hat{\chi}=\frac{a_2-b_2}{2\rho_2}=-\tilde{\pi}_2\sqrt{1-\vec{N}^2}+\frac{|\vec{N}|}{2\rho_2}[\check{S}^2-\xi\sqrt{1-\vec{N}^2}], \tag{A3}$$

$$\vec{\pi}_1\cdot\hat{N}\times\hat{\chi}=\frac{a_3+b_3}{2\rho_1}=\frac{1}{2\rho_1}\left[-\frac{\check{S}^1}{|\vec{N}|}+\frac{\check{S}^3}{\sqrt{1-\vec{N}}^2}\right],$$

$$\vec{\pi}_2\cdot\hat{N}\times\hat{\chi}=\frac{a_3-b_3}{2\rho_2}=-\frac{1}{2\rho_2}\left[\frac{\check{S}^1}{|\vec{N}|}+\frac{\check{S}^3}{\sqrt{1-\vec{N}^2}}\right].$$

With these results we can obtain the expression of the spin quantities $\vec{W}$, $\vec{S}_a$ in terms of the final variables [see Eq. (C6) of Ref. 33].

APPENDIX B: EULER ANGLES

Let us denote by $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ the Euler angles chosen as orientation variables θ^α.

Let $\hat{f}_1=\hat{\imath}$, $\hat{f}_2=\hat{\jmath}$, $\hat{f}_3=\hat{k}$ be the unit 3-vectors along the axes of the space frame and $\hat{e}_1=\hat{\chi}$, $\hat{e}_2=\hat{N}\times\hat{\chi}$, $\hat{e}_3=\hat{N}$, the unit 3-vectors along the axes of a *body frame*. Then we have

$$\vec{S}=S^r\hat{f}_r=R^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{S}^s\hat{f}_r=\check{S}^s\hat{e}_s,$$
$$\hat{e}_s=(R^T)^{sr}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\hat{f}_r=\mathcal{R}_s{}^r(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\hat{f}_r. \tag{B1}$$

There are two main conventions for the definition of the Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$.

(A) The *y-convention* [see Refs. 44 (Appendix B) and 45]:

(i) perform a first rotation of an angle $\tilde{\alpha}$ around $\hat{f}_3$ [$\hat{f}_1\mapsto\hat{e}'_1=\cos\tilde{\alpha}\hat{f}_1+\sin\tilde{\alpha}\hat{f}_2$, $\hat{f}_2\mapsto\hat{e}'_2=-\sin\tilde{\alpha}\hat{f}_1+\cos\tilde{\alpha}\hat{f}_2$, $\hat{f}_3\mapsto\hat{e}'_3=\hat{f}_3$];

(ii) perform a second rotation of an angle $\tilde{\beta}$ around $\hat{e}'_2$ [$\hat{e}'_1\mapsto\hat{e}''_1=\cos\tilde{\beta}\hat{e}'_1-\sin\tilde{\beta}\hat{e}'_3$, $\hat{e}'_2\mapsto\hat{e}''_2=\hat{e}'_2$, $\hat{e}'_3\mapsto\hat{e}''_3=\sin\tilde{\beta}\hat{e}'_1+\cos\tilde{\beta}\hat{e}'_3$];

(iii) perform a third rotation of an angle $\tilde{\gamma}$ around $\hat{e}''_3$ [$\hat{e}''_1\mapsto\hat{e}_1=\cos\tilde{\gamma}\hat{e}''_1+\sin\tilde{\gamma}\hat{e}''_2$, $\hat{e}''_2\mapsto\hat{e}_2=-\sin\tilde{\gamma}\hat{e}''_1+\cos\tilde{\gamma}\hat{e}''_2$]. In this way we get

$$\begin{pmatrix}\hat{\chi}\\ \hat{N}\times\hat{\chi}\\ \hat{N}\end{pmatrix}\equiv\begin{pmatrix}\hat{e}_1\\ \hat{e}_2\\ \hat{e}_3\end{pmatrix}=\mathcal{R}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\begin{pmatrix}\hat{f}_1\\ \hat{f}_2\\ \hat{f}_3\end{pmatrix},$$

$$\mathcal{R}_r{}^s(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})$$
$$= R^{Trs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})$$
$$= \begin{pmatrix} \cos\tilde{\gamma}\cos\tilde{\beta}\cos\tilde{\alpha}-\sin\tilde{\gamma}\sin\tilde{\alpha} & \cos\tilde{\gamma}\cos\tilde{\beta}\sin\tilde{\alpha}+\sin\tilde{\gamma}\cos\tilde{\alpha} & -\cos\tilde{\gamma}\sin\tilde{\beta} \\ -(\sin\tilde{\gamma}\cos\tilde{\beta}\cos\tilde{\alpha}+\cos\tilde{\gamma}\sin\tilde{\alpha} & -\sin\tilde{\gamma}\cos\tilde{\beta}\sin\tilde{\alpha}+\cos\tilde{\gamma}\cos\tilde{\alpha} & \sin\tilde{\gamma}\sin\tilde{\beta} \\ \sin\tilde{\beta}\cos\tilde{\alpha} & \sin\tilde{\beta}\sin\tilde{\alpha} & \cos\tilde{\beta} \end{pmatrix},$$

with

$$\tan\tilde{\alpha}=\frac{\hat{N}^2}{\hat{N}^1},\quad \cos\tilde{\beta}=\hat{N}^3,\quad \tan\tilde{\gamma}=-\frac{\hat{\chi}^3}{(\hat{N}\times\hat{\chi})^3}. \tag{B2}$$

Since $\hat{N}$ and $\hat{\chi}$ are functions of $\vec{\rho}_a$ only, see Eq. (3.13), we get $\{\tilde{\alpha},\tilde{\beta}\}=\{\tilde{\beta},\tilde{\gamma}\}=\{\tilde{\gamma},\tilde{\alpha}\}=0$.

(B) The *x-convention* (see Refs. 46, 44 (in the text) and 2): the Euler angles θ, φ and ψ are: (i) $\theta=\tilde{\beta}$; (ii) $\cos\varphi=-\sin\tilde{\alpha}$, $\sin\varphi=\cos\tilde{\alpha}$; (iii) $\cos\psi=\sin\tilde{\gamma}$, $\sin\psi=-\cos\tilde{\gamma}$.

We use the *y-convention*. Following Ref. 2, let us introduce the canonical momenta $p_{\tilde{\alpha}}$, $p_{\tilde{\beta}}$, $p_{\tilde{\gamma}}$ conjugated to $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$: $\{\tilde{\alpha},p_{\tilde{\alpha}}\}=\{\tilde{\beta},p_{\tilde{\beta}}\}=\{\tilde{\gamma},p_{\tilde{\gamma}}\}=1$ (note that this Darboux chart does not exist globally). Then, the results of Ref. 2 imply

$$\begin{aligned}
S^1&=-\sin\tilde{\alpha}p_{\tilde{\beta}}+\frac{\cos\tilde{\alpha}}{\sin\tilde{\beta}}p_{\tilde{\gamma}}-\cos\tilde{\alpha}\cot\tilde{\beta}p_{\tilde{\alpha}},\\
S^2&=\cos\tilde{\alpha}p_{\tilde{\beta}}+\frac{\sin\tilde{\alpha}}{\sin\tilde{\beta}}p_{\tilde{\gamma}}-\sin\tilde{\alpha}\cot\tilde{\beta}p_{\tilde{\alpha}},\\
S^3&=p_{\tilde{\alpha}},\\
\check{S}^1&=\sin\tilde{\gamma}p_{\tilde{\beta}}-\frac{\cos\tilde{\gamma}}{\sin\tilde{\beta}}p_{\tilde{\alpha}}+\cos\tilde{\gamma}\cot\tilde{\beta}p_{\tilde{\gamma}},\\
\check{S}^2&=\cos\tilde{\gamma}p_{\tilde{\beta}}+\frac{\sin\tilde{\gamma}}{\sin\tilde{\beta}}p_{\tilde{\alpha}}-\sin\tilde{\gamma}\cot\tilde{\beta}p_{\tilde{\gamma}},\\
\check{S}^3&=p_{\tilde{\gamma}},\\
&\Downarrow\\
p_{\tilde{\alpha}}&=S^3=-\sin\tilde{\beta}\cos\tilde{\gamma}\check{S}^1+\sin\tilde{\beta}\sin\tilde{\gamma}\check{S}^2+\cos\tilde{\beta}\check{S}^3,\\
p_{\tilde{\beta}}&=-\sin\tilde{\alpha}S^1+\cos\tilde{\alpha}S^2=\sin\tilde{\gamma}\check{S}^1-\cos\tilde{\gamma}\check{S}^2,\\
p_{\tilde{\gamma}}&=\check{S}^3=\cos\tilde{\alpha}\sin\tilde{\beta}S^1+\sin\tilde{\alpha}\sin\tilde{\beta}S^2+\cos\tilde{\beta}S^3.
\end{aligned} \tag{B3}$$

APPENDIX C: 4-BODY CASE

Let us give the main steps of the construction of the spin basis in the case $N=4$. From Eqs. (3.27) we have

$$\vec{\rho}_a=\rho_a[|\vec{N}_{(ab)}|\hat{N}_{(ab)}+\sqrt{1-\vec{N}^2_{(ab)}}\hat{\chi}_{(ab)}],$$

$$\vec{\rho}_b=\rho_b[|\vec{N}_{(ab)}|\hat{N}_{(ab)}-\sqrt{1-\vec{N}^2_{(ab)}}\hat{\chi}_{(ab)}], \tag{C1}$$

$$\vec{\rho}_c=\rho_c\hat{R}_c\,.$$

The definitions given after Eqs. (3.27) and Appendix B imply

$$\vec{N}\overset{\text{def}}{=}\vec{N}_{((ab)c)}=\frac{1}{2}(\hat{R}_{(ab)}+\hat{R}_c),$$

$$\vec{\chi}\overset{\text{def}}{=}\vec{\chi}_{((ab)c)}=\frac{1}{2}(\hat{R}_{(ab)}-\hat{R}_c),$$

$$\vec{N}\times\vec{\chi}=-\frac{1}{2}\hat{R}_{(ab)}\times\hat{R}_c\,, \tag{C2}$$

$$\Downarrow$$

$$\vec{\rho}_c=\rho_c[|\vec{N}|\hat{N}-\sqrt{1-\vec{N}^2}\hat{\chi}],$$

$$\Rightarrow\rho^r_c=\mathcal{R}^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}^s_c(|\vec{N}|,\rho_c).$$

Let us remember that the dynamical shape variables of Eq. (3.26) are $q^\mu=\{|\vec{N}|,\gamma_{(ab)},|\vec{N}_{(ab)}|,\ \rho_a,\ \rho_b,\ \rho_c\}$. Then, from Eqs. (3.16) and (3.18), for the subsystem (ab) we get

$$\hat{R}_{(ab)}=\vec{N}+\vec{\chi},\quad \vec{S}_{(ab)}\cdot\hat{R}_{(ab)}=0,$$

$$\vec{S}_{(ab)}\overset{\text{def}}{=}\vec{S}_a+\vec{S}_b=S_{(ab)}(\sin\psi_{(ab)}[\cos\gamma_{(ab)}\,\hat{\chi}_{(ab)}+\sin\gamma_{(ab)}\hat{N}_{(ab)}\times\hat{\chi}_{(ab)}]=\cos\psi_{(ab)}\hat{N}_{(ab)}),$$

$$\hat{\chi}_{(ab)}=\tfrac{1}{2}(\hat{R}_a-\hat{R}_b)=\cos\gamma_{(ab)}(\sin\psi_{(ab)}\hat{S}_{(ab)}-\cos\psi_{(ab)}\hat{R}_{(ab)})-\sin\gamma_{(ab)}\hat{R}_{(ab)}\times\hat{S}_{(ab)}\,,$$

$$\hat{N}_{(ab)}=\cos\psi_{(ab)}\hat{S}_{(ab)}+\sin\psi_{(ab)}\hat{R}_{(ab)}\,, \tag{C3}$$

$$\hat{N}_{(ab)}\times\hat{\chi}_{(ab)}=\sin\gamma_{(ab)}(\sin\psi_{(ab)}\hat{S}_{(ab)}-\cos\psi_{(ab)}\hat{R}_{(ab)})+\cos\gamma_{(ab)}\hat{R}_{(ab)}\times\hat{S}_{(ab)}\,,$$

$$\cos\psi_{(ab)}=\frac{\Omega_{(ab)}}{S_{(ab)}},\quad \sin\psi_{(ab)}=\sqrt{1-\left(\frac{\Omega_{(ab)}}{S_{(ab)}}\right)^2},\quad \Omega_{(ab)}=\vec{S}_{(ab)}\cdot\hat{N}_{(ab)}\,.$$

We have, moreover,

$$\vec{S}_c=\tfrac{1}{2}(\vec{S}-\vec{W}_{((ab)c)}),$$

$$\vec{W}_{((ab)c)}\cdot\vec{N}=-\vec{S}\cdot\vec{\chi},\quad \vec{W}_{((ab)c)}\cdot\vec{\chi}=-\vec{S}\cdot\vec{N},$$

$$\check{W}^1=-\frac{|\vec{N}|\check{S}^3}{\sqrt{1-\vec{N}^2}},\quad \check{W}^2=\xi\sqrt{1-\vec{N}^2},$$

$$\check{W}^3 = -\frac{\sqrt{1-\vec{N}^2}}{|\vec{N}|}\cos\gamma\sqrt{(S)^2-(\check{S}^3)^2},$$

$$\gamma_{((ab)c)} = \tan^{-1}\frac{\vec{S}\cdot(\hat{N}\times\hat{\chi})}{\vec{S}\cdot\hat{\chi}} = \tan^{-1}\frac{\check{S}^2}{\check{S}^1},$$

$$\xi_{((ab)c)} = \frac{\vec{W}_{((ab)c)}\cdot(\hat{N}\times\hat{\chi})}{\sqrt{1-\vec{N}^2}},$$

$$\begin{aligned}\vec{S}_{(ab)} &= \tfrac{1}{2}(\vec{S}+\vec{W})_{((ab)c)}\\ &= \check{S}^1_{(ab)}\hat{\chi}+\check{S}^2_{(ab)}\hat{N}\times\hat{\chi}+\check{S}^3_{(ab)}\hat{N}\\ &= \tfrac{1}{2}(\check{S}^1+\check{W}^1_{((ab)c)})\hat{\chi}+\tfrac{1}{2}(\check{S}^2+\check{W}^2_{((ab)c)})\hat{N}\times\hat{\chi}+\tfrac{1}{2}(\check{S}^3+\check{W}^3_{((ab)c)})\hat{N},\end{aligned}$$

$$\begin{aligned}&\vec{S}=\vec{S}_a+\vec{S}_b+\vec{S}_c=\vec{S}_{(ab)}+\vec{S}_c\overset{\text{def}}{=}\vec{S}_{((ab)c)}=\check{S}^1\hat{\chi}+\check{S}^3\hat{N}+\check{S}^2\hat{N}\times\hat{\chi},\\ &\check{S}^1_{(ab)}=\frac{1}{2}\left(\check{S}^1-\frac{|\vec{N}|}{\sqrt{1-\vec{N}^2}}\check{S}^3\right),\\ &\check{S}^2_{(ab)}=\tfrac{1}{2}(\check{S}^2+\xi_{((ab)c)}\sqrt{1-\vec{N}^2}),\\ &\check{S}^3_{(ab)}=\frac{1}{2}\left(\check{S}^3-\frac{\sqrt{1-\vec{N}^2}}{|\vec{N}|}\check{S}^1\right),\end{aligned}\tag{C4}$$

$$\check{S}^1=\cos\gamma_{((ab)c)}\sqrt{(S)^2-(\check{S}^3)^2},\quad \check{S}^2=\sin\gamma_{((ab)c)}\sqrt{(S)^2-(\check{S}^3)^2},$$

$$S_{(ab)}=\sqrt{(\check{S}^1_{(ab)})^2+(\check{S}^2_{(ab)})^2+(\check{S}^3_{(ab)})^2}=\frac{1}{2}\sqrt{(\check{S}^2+\xi_{((ab)c)}\sqrt{1-\vec{N}^2})^2+\left(\frac{\check{S}^1}{|\vec{N}|}-\frac{\check{S}^3}{\sqrt{1-\vec{N}^2}}\right)^2},$$

$$\hat{S}_{(ab)}=\frac{1}{2S_{(ab)}}\left[(\check{S}^2+\xi_{((ab)c)}\sqrt{1-\vec{N}^2})\hat{N}\times\hat{\chi}+\left(\check{S}^1-\frac{|\vec{N}|}{\sqrt{1-\vec{N}^2}}\check{S}^3\right)\hat{\chi}+\left(\check{S}^3-\frac{\sqrt{1-\vec{N}^2}}{|\vec{N}|}\check{S}^1\right)\hat{N}\right],$$

$$\hat{R}_{(ab)}=|\vec{N}|\hat{N}+\sqrt{1-\vec{N}^2}\hat{\chi},$$

$$\begin{aligned}\hat{R}_{(ab)}\times\hat{S}_{(ab)}=\frac{1}{2S_{(ab)}}\Bigg[&(\check{S}^2+\xi_{((ab)c)}\sqrt{1-\vec{N}^2})(\sqrt{1-\vec{N}^2}\hat{N}-|\vec{N}|\hat{\chi})\\ &+\left(|\vec{N}|\left(\check{S}^1-\frac{|\vec{N}|}{\sqrt{1-\vec{N}^2}}\check{S}^3\right)-\sqrt{1-\vec{N}^2}\left(\check{S}^3-\frac{\sqrt{1-\vec{N}^2}}{|\vec{N}|}\check{S}^1\right)\right)\hat{N}\times\hat{\chi}\Bigg].\end{aligned}$$

The final result is $[\check{S}^1=1/S\sqrt{(S)^2-(S^3)^2}\cos\beta_{((ab)c)},\ \check{S}^2=1/S\sqrt{(S)^2-(S^3)^2}\sin\beta_{((ab)c)}]$

$$\hat{N}_{(ab)}=\cos\psi_{(ab)}\hat{S}_{(ab)}+\sin\psi_{(ab)}\hat{R}_{(ab)}$$
$$=\left[\frac{\Omega_{(ab)}\left(\check{S}^3-\frac{\sqrt{1-\vec{N}^2}}{|\vec{N}|}\check{S}^1\right)}{2(S_{(ab)})^2}+|\vec{N}|\sqrt{1-\left(\frac{\Omega_{(ab)}}{S_{(ab)}}\right)^2}\right]\hat{N}+\left[\frac{\Omega_{(ab)}\left(\check{S}^1-\frac{|\vec{N}|}{\sqrt{1-\vec{N}^2}}\check{S}^3\right)}{2(S_{(ab)})^2}\right.$$
$$\left.+\sqrt{1-\vec{N}^2}\sqrt{1-\left(\frac{\Omega_{(ab)}}{S_{(ab)}}\right)^2}\right]\hat{\chi}+\frac{\Omega_{(ab)}(\check{S}^2+\xi_{((ab)c)}\sqrt{1-\vec{N}^2}}{2(S_{(ab)})^2}\hat{N}\times\hat{\chi},$$

$$\hat{\chi}_{(ab)}=\cos\gamma_{(ab)}(\sin\psi_{(ab)}\hat{S}_{(ab)}-\cos\psi_{(ab)}\hat{R}_{(ab)})-\sin\gamma_{(ab)}\hat{R}_{(ab)}\times\hat{S}_{(ab)}$$
$$=\left(\cos\gamma_{(ab)}\left[\sqrt{1-\left(\frac{\Omega_{(ab)}}{S_{(ab)}}\right)^2}\frac{\left(\check{S}^3-\frac{\sqrt{1-\vec{N}^2}}{|\vec{N}|}\check{S}^1\right)}{2S_{(ab)}}-|\vec{N}|\frac{\Omega_{(ab)}}{S_{(ab)}}\right]\right.$$
$$\left.-\frac{\sqrt{1-\vec{N}^2}\sin\gamma_{(ab)}}{2S_{(ab)}}(\check{S}^2+\xi_{((ab)c)}\sqrt{1-\vec{N}^2})\right)\hat{N}$$
$$+\left(\cos\gamma_{(ab)}\left[\sqrt{1-\left(\frac{\Omega_{(ab)}}{S_{(ab)}}\right)^2}\frac{\left(\check{S}^1-\frac{|\vec{N}|}{\sqrt{1-\vec{N}^2}}\check{S}^3\right)}{2S_{(ab)}}-\sqrt{1-\vec{N}^2}\frac{\Omega_{(ab)}}{S_{(ab)}}\right]\right.$$
$$\left.+\frac{|\vec{N}|\sin\gamma_{(ab)}}{2S_{(ab)}}(\check{S}^2+\xi_{((ab)c)}\sqrt{1-\vec{N}^2})\right)\hat{\chi}+(\cos\gamma_{(ab)}\sqrt{1-\left(\frac{\Omega_{(ab)}}{S_{(ab)}}\right)^2}$$
$$\times\left(\frac{\check{S}^2+\xi_{((ab)c)}\sqrt{1-\vec{N}^2}}{2S_{(ab)}}\right)-\frac{\sin\gamma_{(ab)}}{2S_{(ab)}}\left[|\vec{N}|\left(\check{S}^1-\frac{|\vec{N}|}{\sqrt{1-\vec{N}^2}}\check{S}^3\right)\right.$$
$$\left.-\sqrt{1-\vec{N}^2}\left(\check{S}^3-\frac{\sqrt{1-\vec{N}^2}}{|\vec{N}|}\check{S}^1\right)\right]\hat{N}\times\hat{\chi}. \tag{C5}$$

Then, Eqs. (C1) and (C2) imply

$$\rho_a^r=\mathcal{R}^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}_a^s[|\vec{N}|,\gamma_{(ab)},|\vec{N}_{(ab)}|,\rho_a;\xi,\Omega_{(ab)};\check{S}^r],$$
$$\rho_b^r=\mathcal{R}^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}_b^s[|\vec{N}|,\gamma_{(ab)},|\vec{N}_{(ab)}|,\rho_a;\xi,\Omega_{(ab)};\check{S}^r], \tag{C6}$$
$$\rho_c^r=\mathcal{R}^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}_c^s[|\vec{N}|,\rho_c].$$

This means that $\check{\rho}^r_{a\text{ or }b}$ depend not only on the dynamical shape variables $q^\mu=\{|\vec{N}|=|\vec{N}_{((ab)c)}|,\gamma_{(ab)},|\vec{N}_{(ab)}|,\rho_a,\rho_b,\rho_c\}$ but also on some of the conjugate shape momenta $p_\mu=\{\xi_{((ab)c)},\Omega_{(ab)}=\vec{S}_{(ab)}\cdot\hat{N}_{(ab)},\xi_{(ab)},\tilde{\pi}_a,\tilde{\pi}_b,\tilde{\pi}_c\}$ and the dynamical body frame components $\check{S}^r$ of the spin.

By using Eq. (A3), for the canonical momenta we get [$|\vec{N}|=|\vec{N}_{((ab)c)}|$, $S_{(ab)}$ given by Eq. (C4)]

$$\vec{\pi}_a = \left[\tilde{\pi}_a |\vec{N}_{(ab)}| - \frac{\sqrt{1-\vec{N}^2_{(ab)}}}{2\rho_a} \left(\sqrt{(S_{(ab)})^2 - (\Omega_{(ab)})^2} \sin\gamma_{(ab)} + \xi_{(ab)} \sqrt{1-\vec{N}^2_{(ab)}} \right) \right] \hat{N}_{(ab)}$$
$$+ \left[\tilde{\pi}_a \sqrt{1-\vec{N}^2_{(ab)}} + \frac{|\vec{N}_{(ab)}|}{2\rho_a} \left(\sqrt{(S_{(ab)})^2 - (\Omega_{(ab)})^2} \sin\gamma_{(ab)} + \xi_{(ab)} \sqrt{1-\vec{N}^2_{(ab)}} \right) \right] \hat{\chi}_{(ab)}$$
$$- \frac{1}{2\rho_a} \left((\sqrt{S_{(ab)}})^2 - (\Omega_{(ab)})^2 \right) \frac{\cos\gamma_{(ab)}}{|\vec{N}_{(ab)}|} - \frac{\Omega_{(ab)}}{\sqrt{1-\vec{N}^2_{(ab)}}} \hat{N}_{(ab)} \times \hat{\chi}_{(ab)},$$

$$\vec{\pi}_b = \left[\tilde{\pi}_b |\vec{N}_{(ab)}| + \frac{\sqrt{1-\vec{N}^2_{(ab)}}}{2\rho_b} \left(\sqrt{(S_{(ab)})^2 - (\Omega_{(ab)})^2} \sin\gamma_{(ab)} - \xi_{(ab)} \sqrt{1-\vec{N}^2_{(ab)}} \right) \right] \hat{N}_{(ab)}$$
$$- \left[\tilde{\pi}_b \sqrt{1-\vec{N}^2_{(ab)}} - \frac{|\vec{N}_{(ab)}|}{2\rho_b} \left(\sqrt{(S_{(ab)})^2 - (\Omega_{(ab)})^2} \sin\gamma_{(ab)} - \xi_{(ab)} \sqrt{1-\vec{N}^2_{(ab)}} \right) \right] \hat{\chi}_{(ab)}$$
$$- \frac{1}{2\rho_b} \left(\sqrt{(S_{(ab)})^2 - (\Omega_{(ab)})^2} \frac{\cos\gamma_{(ab)}}{|\vec{N}_{(ab)}|} + \frac{\Omega_{(ab)}}{\sqrt{1-\vec{N}^2_{(ab)}}} \right) \hat{N}_{(ab)} \times \hat{\chi}_{(ab)},$$

$$\vec{\pi}_c = \left[\tilde{\pi}_c |\vec{N}| + \frac{\sqrt{1-\vec{N}^2}}{2\rho_c} \left(\check{S}^2 - \xi_{((ab)c)} \sqrt{1-\vec{N}^2} \right) \right] \hat{N} - \left[\tilde{\pi}_c \sqrt{1-\vec{N}^2} - \frac{|\vec{N}|}{2\rho_c} \left(\check{S}^2 - \xi_{((ab)c)} \sqrt{1-\vec{N}^2} \right) \right] \hat{\chi}$$
$$- \frac{1}{2\rho_c} \left(\frac{\check{S}^1}{|\vec{N}|} + \frac{\check{S}^3}{\sqrt{1-\vec{N}}^2} \right) \hat{N} \times \hat{\chi}, \tag{C7}$$

$$\vec{\pi}^2_a = \tilde{\pi}^2_a + \frac{1}{4\rho^2_a} \left[\xi^2_{(ab)} (1-\vec{N}^2_{(ab)}) + \left(\sin^2\gamma_{(ab)} + \frac{\cos^2\gamma_{(ab)}}{\vec{N}^2_{(ab)}} \right) \left((S_{(ab)})^2 - (\Omega_{(ab)})^2 \right) + \frac{(\Omega_{(ab)})^2}{1-\vec{N}^2_{(ab)}} \right.$$
$$\left. + 2\sqrt{(S_{(ab)})^2 - (\Omega_{(ab)})^2} \left(\xi_{(ab)} \sqrt{1-\vec{N}^2_{(ab)}} \sin\gamma_{(ab)} - \frac{\Omega_{(ab)} \cos\gamma_{(ab)}}{|\vec{N}_{(ab)}| \sqrt{1-\vec{N}^2_{(ab)}}} \right) \right],$$

$$\vec{\pi}^2_b = \tilde{\pi}^2_b + \frac{1}{4\rho^2_b} \left[\xi^2_{(ab)} (1-\vec{N}^2_{(ab)}) + \left(\sin^2\gamma_{(ab)} + \frac{\cos^2\gamma_{(ab)}}{\vec{N}^2_{(ab)}} \right) \left((S_{(ab)})^2 - (\Omega_{(ab)})^2 \right) + \frac{(\Omega_{(ab)})^2}{1-\vec{N}^2_{(ab)}} \right.$$
$$\left. - 2\sqrt{(S_{(ab)})^2 - (\Omega_{(ab)})^2} \left(\xi_{(ab)} \sqrt{1-\vec{N}^2_{(ab)}} \sin\gamma_{(ab)} - \frac{\Omega_{(ab)} \cos\gamma_{(ab)}}{|\vec{N}_{(ab)}| \sqrt{1-\vec{N}^2_{(ab)}}} \right) \right],$$

$$\vec{\pi}^2_c = \tilde{\pi}^2_c + \frac{1}{4\rho^2_c} \left[\xi^2_{((ab)c)} (1-\vec{N}^2) + (\check{S}^2)^2 + \frac{(\check{S}^1)^2}{\vec{N}^2} + \frac{(\check{S}^3)^2}{1-\vec{N}^2} \right.$$
$$\left. - 2 \left(\xi_{((ab)c)} \sqrt{1-\vec{N}^2} \check{S}^2 - \frac{\check{S}^1 \check{S}^3}{|\vec{N}| \sqrt{1-\vec{N}^2}} \right) \right].$$

To evaluate $\vec{\pi}_c$ one defines an auxiliary variable $\vec{\pi}_{(ab)}$ such that $\vec{S}_{(ab)}=\hat{R}_{(ab)}\times\vec{\pi}_{(ab)}$ (its component along $\hat{R}_{(ab)}$ is arbitrary; remember that $\hat{R}_{(ab)}\cdot\vec{S}_{(ab)}=0$). Then we use the equations $\vec{S}=\vec{S}_{(ab)}+\vec{S}_c$ and $\vec{W}=\vec{S}_{(ab)}-\vec{S}_c$ (with $\vec{S}_c=\vec{\rho}_c\times\vec{\pi}_c$) to extract the form of $\vec{\pi}_c$ like in the 3-body case [Eq. (A3)].

The resulting Hamiltonian is not a polynomial of second order in the dynamical body frame components of the spin, unlike that of the static orientation-shape bundle approach. Yet, the rotational part of the Hamiltonian, determined by putting the dynamical shape velocities equal to zero ($\dot{q}^\mu=0$), can be shown to have the standard form of the rigid body case (see Appendix F of Ref. 33), with a nonstandard *dynamical inertia-like tensor* depending only on the shape variables.

[10] See Refs. 9, 12 for a discussion of the singular (colinear and N-body collision) configurations. Applying the SO(3) operations to any given configuration of the $3N$-3 relative variables (a point in the relative configuration space) gives rise to 3 possibilities only: (i) for *generic configurations* the orbit containing all the rotated copies of the configuration is a 3-dimensional manifold [diffeomorphic to the group manifold of SO(3)]; (ii) for *collinear configurations* the orbit is diffeomorphic to the 2-sphere S^2; (iii) for the *N-body collision configuration* (in which all the particles coincide at a single point in space) the orbit is a point.
[11] This is due to the topological complexity of the shape space generated by the singular configurations (Ref. 12), which are dispersed among the generic configurations for $N\geqslant 4$.

B. Wolf (Springer-Verlag, Berlin, 1980).
[25] We follow the convention of Ref. 9; note that this action is usually denoted as a *right* action in mathematical texts. The S^r's are the Hamiltonians, associated with the momentum map from the symplectic manifold to $so(3)^*$ [the dual of the Lie algebra $so(3)$], which allow the implementation of the symplectic action through Hamiltonian vector fields.
[26] With $\check{S}^r=\vec{S}\cdot\hat{e}_r$, the conditions $\{\check{S}^r,\check{S}^s\}=-\epsilon^{rsu}\check{S}^u$ imply the equations $\vec{S}\cdot\hat{e}_r\times\hat{e}_s+S^iS^j\{\hat{e}^i_r,\hat{e}^j_s\}=\epsilon_{rsu}S^k\hat{e}^u_k$, hence the quoted result.
[27] Let us remark that any pair of orthonormal vectors $\vec{N}$, $\vec{\chi}$ function only of the relative coordinates can be used to build a body frame. This freedom is connected to the possibility of redefining a body frame by using a configuration-dependent arbitrary rotation, which leaves $\vec{N}$ in the $\vec{S}$–$\hat{R}$ plane.
[28] R is a rotation matrix, θ^α are arbitrary gauge orientational parameters and $\check{\rho}^r_a(q^\mu)$ is assumed to depend on the shape variables only and not on their conjugate momenta.

[29] In a way analoguous to the angular momentum composition in quantum mechanics, note that this spin clustering is independent of the center-of-mass clustering associated with the Jacobi coordinates: the existence of these two unrelated clusterings might prove to be a useful and flexible tool in molecular physics.
[30] Being connected to the Riemannian metric of the nonrelativistic Lagrangian, this concept does not survive the transition to special relativity anyway.

[42] Let us remark that with the canonical basis (3.9) the degenerate case defined by imposing the constraints $\vec{S}\approx 0$ with $\vec{S}_1\approx -\vec{S}_2\neq 0$ implies the three extra first class constraints $S_1-S_2\approx 0$, $S_1^3+S_2^3\approx 0$, $\beta_1-\beta_2\approx 0$: therefore we get three arbitrary conjugate gauge variables $1/2\,(\alpha_1-\alpha_2)$,$1/2\,(\beta_1+\beta_2)$,$1/2\,(S_1^3+S_2^3)\neq 0$. Besides these three pairs of conjugate variables, a canonical basis adapted to $\vec{S}\approx 0$ (with $\vec{S}_1\approx -\vec{S}_2\neq 0$) also contains the physical variables $\overline{\alpha}=\alpha_1+\alpha_2$, $\overline{S}=1/2\,(S_1+S_2)$, ρ_a, $\tilde{\pi}_a$, and the Hamiltonian becomes $H_D=1/2\,\Sigma_{a,b}^{1,2}k_{ab}^{-1}\vec{\pi}_a\cdot\vec{\pi}_b|_{\vec{S}=0}+\lambda_1(t)(S_1-S_2)+\lambda_2(t)(S_1^3+S_2^3)+\lambda_3(t)(\beta_1-\beta_2)$ (the λ's are Dirac multipliers).

We construct the classical r-matrix structure for the Lax formulation of BC_N Ruijsenaars–Schneider systems proposed in Commun. Math. Phys., **115**, 127 (1988). The r-matrix structure takes a quadratic form similar to the A_N Ruijsenaars–Schneider Poisson bracket behavior, although the dynamical dependence is more complicated. Commuting Hamiltonians stemming from the BC_N Ruijsenaars–Schneider Lax matrix are shown to be linear combinations of particular Koornwinder–van Diejen ''external fields'' Ruijsenaars–Schneider models, for specific values of the exponential one-body couplings. Uniqueness of such commuting Hamiltonians is established once the first of them and the general analytic structure are given. © *2002 American Institute of Physics.*

I. INTRODUCTION

The integrable relativistic extensions of Calogero–Moser N-body integrable systems were originally introduced by Ruijsenaars and Schneider[1] (classical case) and Ruijsenaars[2] (quantum case) for an underlying Lie algebra structure A_N. They have been the subject of numerous investigations in these last years. Their exact connection to field-theoretical integrable systems, initially described in Ref. 1, was clarified in Ref. 3; their dynamical classical r-matrix structure, first tackled in Refs. 4, 5 was finally established in Ref. 6 and characterized as a quadratic structure, à la Sklyanin,[7,8] stemming from the dynamical linear r-matrix structure of Calogero-Moser systems.[9] This in turn is connected to the realization of such systems[10] as ''Hamiltonian reduction,'' in a more general sense, see Ref. 11, of dynamical systems living on a Heisenberg double,[11–13] where the quadratic r-matrix structure is natural.[11] More complete descriptions may be found in Ref. 14.

Using a $\mathbb{Z}_2$-folding of the original A_{2N} or A_{2N+1} algebra lead[15] to a consistent construction of classical integrable Hamiltonians and Lax formulation for resp. BC_N and C_N Ruijsenaars trigonometric systems. Classical elliptic-interaction BC_N and C_N models were subsequently introduced in Ref. 16. More recently the Lax matrices, obtained by the aforementioned folding procedure for Lie algebra structures BC_N, C_N, and D_N, were explicited in a series of papers.[17,18] Their classical r-matrix structure remained unknown.

Several one-body extensions of the Ruijsenaars–Schneider systems were also considered. First of all, quantum integrable trigonometric one-body-potential (or ''external field extensions''), and rational limits thereof, were constructed in Ref. 19. The quantum integrability proof, and construction of the quantum Hamiltonians themselves, rested upon polynomial-algebraic arguments pioneered by Koornwinder[20] and interestingly indicating a connection to BC_N-type algebras. In this case, both classical Lax formulation and classical r-matrix construction are lacking. Conjectural quantum elliptic Hamiltonians were introduced in Ref. 16. The BC_N and C_N elliptic classical potentials obtained by the folding procedure, were identified with classical limits of a specific realization (albeit with a smaller number of free parameters) of this conjecture. Explicit construction of quantum elliptic van Diejen-type Hamiltonians was then achieved in Ref. 21 using

corner-transfer-matrix methods. It pointed again to a BC_N structure underlying at least some particular Koornwinder–van Diejen potentials. The corner-transfer-matrix method used in Ref. 21 however does not relate clearly to the previous procedures, using as it does two types of Lax operators.

This series of results begs several questions and we wish to address here two points which remained unclarified.

First of all we construct the classical r-matrix for the folded Lax matrices of trigonometric BC_N systems. (We expect that the C_N and D_N case, and the elliptic potentials, may be treated by similar techniques although the elliptic case may endow more complicated algebraic manipulations.) This problem may seem academic, since in any case commutation of the Hamiltonians follows from the construction itself.[15] However it actually sheds light on the delicate question of interplay between the folding procedure $A_{2N} \to BC_N$ and the initial ''quadratization'' of Poisson structure entailed by the change of base symplectic manifold for the ''Hamiltonian'' reduction from T^*g (cotangent bundle Lie group) to $D\,g_H$ (Heisenberg double of Lie group). Similar difficulties occur when considering the quantum deformation of BC- or D-type algebras, compared with deformation of A_N algebras (this fact was pointed out to us by Arnaudon). Indeed it will eventually turn out that the classical r-matrix for hyperbolic Ruijsenaars–Schneider BC_N models may be recast under a quadratic form, similar to the A_N case, but contrary to what occurred in the Calogero–Moser models[22] the structure (after folding) exhibits now a dependence in both sets of conjugated dynamical variables, and the quadratic r-matrix is thus not directly related to the linear dynamical r-matrix structure for BC_N Calogero–Moser models.

The second problem which we consider here deals with the connection between the initial trigonometric classical Koornwinder–van Diejen Hamiltonians and the ''canonical'' Poisson commuting Hamiltonians generated by the traces of powers of the Lax matrix for BC_N systems. The previous results hint at some nice dovetailing between the two approaches (folding and algebraic-polynomial arguments) at least in some particular cases. Indeed the two sets of Hamiltonians exhibit a striking similarity of structure. It will be shown that the Koornwinder–van Diejen Hamiltonians, with a certain choice of one-body potential are in fact combinations of the ''canonical ones.'' More importantly this property of ''uniqueness up to linear transformations'' is shown to be true for any set of Poisson-commuting Hamiltonians once the functional structure (to be explicited hereafter) is given.

II. THE CLASSICAL r-MATRIX STRUCTURE

A. The BC_N Ruijsenaars–Schneider models and notations

The canonical variables are a set of rapidities $\{\theta_i, i=1,\cdots,N\}$ and conjugate positions q_i such that $\{\theta_i, q_j\}=\delta_{ij}$. The Hamiltonian reads

$$H=\sum_{\substack{j=1\\ \varepsilon=\pm 1}}^{N} e^{-\varepsilon\,\beta\,\theta_j} f_j + \mathcal{U}, \tag{1}$$

where

$$f_j=\left[f(q_j)\, f(2\,q_j) \prod_{\substack{k=1,\\ k\neq=j}}^{N} f(q_j-q_k)\, f(q_j+q_k) \right]^{1/2} \quad \text{and} \quad \mathcal{U}=\prod_{k=1}^{N} f(q_k).$$

Function f may take different forms, namely,

$$f(q)=1-\frac{g^2}{q^2}\,(\text{rational}),$$

$$f(q)=1-\frac{\sinh^2\gamma}{\sinh^2\dfrac{\nu q}{2}}\,(\text{hyperbolic}),$$

$$f(q)=1-\frac{\sin^2\gamma}{\sin^2\dfrac{\nu q}{2}}\,(\text{trigonometric}).$$

The most general elliptic case where

$$f(q)=(\lambda+\nu\mathcal{P}(q)),\quad \mathcal{P}=\text{Weierstrass function}$$

will not yet be considered here.

The trigonometric and hyperbolic cases define the same model at least locally up to a redefinition of the parameters (the global structure of trigonometric versus hyperbolic models is however quite different, owing to topological properties, as can be seen for instance in Ref. 23). The rational case is obtained by an easy limit procedure from one of these models. We shall therefore consider in the following only the hyperbolic version.

Let us note that one can also write $f(q)=v(q)\,v(-q)$, with

$$v(q)=\frac{\sinh\left(\dfrac{\nu q}{2}+\gamma\right)}{\sinh\dfrac{\nu q}{2}}$$

or even as a rational function of an exponential variable,

$$v(q)=\lambda^{-1/2}\frac{z-\lambda}{z-1}\quad\text{with}\quad z=e^{\nu q}\quad\text{and}\quad \lambda=e^{-2\gamma}.$$

This rational formulation will be useful to establish some functional identities à la Liouville.[11]

B. The BC_N Lax operator

The Lax formulation of BC_N Ruijsenaars–Schneider system may be obtained as a folding of the A_{2N} case.[15] The reduction works as follows: labeling the $2N+1$ rapidities $\{\theta_i, i=-N\cdots N\}$ and conjugate positions $\{q_i, i=-N\cdots N\}$, one sets $\theta_i=\varepsilon_i\theta_{|i|}$ and $q_i=\varepsilon_i q_{|i|}$ with

$$\varepsilon_i=\begin{cases}+1 & \text{for } 1\leqslant i\leqslant N\\ 0 & \text{for } i=0\\ -1 & \text{for } -1\geqslant i\geqslant -N\end{cases}.$$

The Lax matrix for the A_{2N} cases is

$$\mathcal{L}=\sum_{i,j=-N}^{N}\mathcal{L}_{ij}\,e_{ij}$$

$$\mathcal{L}_{ij}(q_1,\ldots,q_N,q_0,q_{-1},\ldots,q_{-N},\theta_j)=c(q_i-q_j)\,e^{-\beta\theta_j}\prod_{\substack{k=-N,\\ k\neq j}}^{N}f^{1/2}(q_j-q_k),\qquad(2)$$

where $\{e_{ij}\}$ is the standard basis for $(2N+1)\times(2N+1)$ matrices; f was given in the previous subsection and

$$c(q)=\frac{\sinh\gamma}{\sinh\left(\dfrac{\nu q}{2}+\gamma\right)}=(1-\lambda)\,\frac{z^{1/2}}{z-\lambda}.$$

The Lax matrix for the BC_N Ruijsenaars–Schneider systems then reads[17]

$$L=\sum_{i,j=-N}^{N} L_{ij}\,e_{ij} \quad \text{with} \quad L_{ij}=\mathcal{L}_{ij}(q_1,\ldots,q_N,0,-q_1,\ldots,-q_N,\varepsilon_j\,\theta_{|j|}). \tag{3}$$

It can be rewritten, $L_{ij}=c(q_i-q_j)\,e^{-\beta\,\varepsilon_j\,\theta_{|j|}}\,f_j$, extending the definition of f_j given in (1) to $j\in\{-N\cdots N\}$. Note that with this extension of f_j one has $f_0=\mathcal{U}$ and $f_j=f_{-j}$.

It has been shown that the Lax operator (2) satisfies the quadratic fundamental Poisson bracket,[6]

$$\{\overset{\otimes}{\mathcal{L}},\mathcal{L}\}=\mathcal{L}\otimes\mathcal{L}a_1-a_2\mathcal{L}\otimes\mathcal{L}+\mathcal{L}_2\,s_1\,\mathcal{L}_1-\mathcal{L}_1\,s_2\,\mathcal{L}_2, \tag{4}$$

where $\mathcal{L}_1=\mathcal{L}\otimes 1$, $\mathcal{L}_2=1\otimes\mathcal{L}$ and the quadratic structure coefficients read

$$a_1=a+w, \quad s_1=s-w,$$

$$a_2=a+s-s^{\pi}-w, \quad s_2=s^{\pi}+w.$$

For any matrix M, the matrix M^{π} is defined by

$$\text{if } M\equiv\sum_{ijkl=-N}^{N} M_{ijkl}\,e_{ij}\otimes e_{kl}, \text{ then } M^{\pi}=\sum_{ijkl=-N}^{N} M_{ijkl}\,e_{kl}\otimes e_{ij}.$$

Matrices a,s,w take the form,

$$a=\alpha\sum_{\substack{j,k=-N\\k\neq j}}^{N}\coth\frac{\nu}{2}(q_k-q_j)\,e_{jk}\otimes e_{kj}, \tag{5}$$

$$s=-\alpha\sum_{\substack{j,k=-N\\k\neq j}}^{N}\frac{1}{\sinh\dfrac{\nu}{2}(q_k-q_j)}\,e_{jk}\otimes e_{kk},$$

$$w=\alpha\sum_{\substack{j,k=-N\\k\neq j}}^{N}\coth\frac{\nu}{2}(q_k-q_j)\,e_{kk}\otimes e_{jj},$$

where $\alpha\equiv\beta\,(\nu/2)$.

It must be recalled here that the most general structure of Poisson bracket for a Lax operator of a Liouville-integrable system is a linear one,[24]

$$\{\overset{\otimes}{L},L\}=[r,L_1]-[r^{\pi},L_2]. \tag{6}$$

The quadratic form (4) corresponds to the case where the r-matrix itself assumes a linear dependency in L of type,

$$r=b\,L_2+L_2\,c, \tag{7}$$

with b and c arbitrary matrices determining the quadratic coefficients a_1,a_2,s_1,s_2,

$$a_1=c^{\pi}-c,\ \ a_2=b^{\pi}-b,\ \ s_1=c+b^{\pi},\ \text{ and }\ s_2=s_1^{\pi}.$$

In the next subsection, we will show that the BC_N Ruijsenaars–Schneider Lax operator (3) also satisfies a quadratic fundamental Poisson bracket (4) albeit with a fundamental difference with respect to (5) regarding the dependence on the dynamical variables. We will give explicitly the generalizations of the matrices $a_1, a_2, s_1,$ and $s_2,$ hereafter denoted "quadratic r-matrices" for obvious semantic reasons.

C. Computation of the classical *r*-matrix

Let us calculate the Poisson brackets of the Lax matrix (3),

$$\{L_{ij},L_{kl}\}=\beta\, L_{ij}L_{kl}\left(\varepsilon_l\frac{\partial \ln L_{ij}}{\partial q_{|l|}}-\varepsilon_j\frac{\partial \ln L_{kl}}{\partial q_{|j|}}\right)$$

and express it in terms of the Lax matrix (2),

$$\varepsilon_l\frac{\partial \ln L_{ij}}{\partial q_{|l|}}=\left(\frac{\partial \ln \mathcal{L}_{ij}}{\partial q_l}-\frac{\partial \ln \mathcal{L}_{ij}}{\partial q_{-l}}\right).$$

We thus get

$$\{L_{ij},L_{kl}\}=\{\mathcal{L}_{ij},\mathcal{L}_{kl}\}+\beta\, L_{ij}L_{kl}\left(\frac{\partial \ln \mathcal{L}_{kl}}{\partial q_{-j}}-\frac{\partial \ln \mathcal{L}_{ij}}{\partial q_{-l}}\right).$$

The Poisson bracket of the first term on the right-hand side keeps the same form (4) where one should fold the dynamical variables ($\theta_i=\varepsilon_i\,\theta_{|i|}$ and $q_i=\varepsilon_i\,q_{|i|}$). We thus only need to concentrate on the remaining term, introducing the four-index object,

$$U_{ijkl}\equiv\frac{2}{\nu}\left(\frac{\partial \ln \mathcal{L}_{kl}}{\partial q_{-j}}-\frac{\partial \ln \mathcal{L}_{ij}}{\partial q_{-l}}\right).$$

Straightforward calculations yield

$$U_{ijkl}=\delta_{j,-l}\,u_j+(\delta_{i,-l}-\delta_{j,-l})\,t_{ij}-(\delta_{j,-k}-\delta_{j,-l})\,t_{kl},$$

where

$$t_{ij}=-\frac{2}{\nu}(\ln c)'(q_i-q_j)=\coth\left(\frac{\nu}{2}(q_i-q_j)+\gamma\right)=\frac{z_i+\lambda\, z_j}{z_i-\lambda\, z_j},$$

$$u_j=\frac{2}{\nu}\sum_{\substack{k=-N,\\ k\neq j}}^{N}(\ln f)'(q_k-q_j)$$

$$=\sum_{\substack{k=-N,\\ k\neq j}}^{N}2\coth\frac{\nu}{2}(q_j-q_k)+\coth\left(\frac{\nu}{2}(q_k-q_j)+\gamma\right)$$

$$-\coth\left(\frac{\nu}{2}(q_j-q_k)+\gamma\right)$$

$$= \sum_{\substack{k=-N,\\ k\neq j}}^{N} 2\,\frac{z_j+z_k}{z_j-z_k} + \frac{z_k+\lambda\, z_j}{z_k-\lambda\, z_j} - \frac{z_j+\lambda\, z_k}{z_j-\lambda\, z_k}$$

$$= \sum_{\substack{k=-N,\\ k\neq j}}^{N} 2\, a_{jk} + t_{kj} - t_{jk},$$

with

$$a_{jk} = \coth\frac{\nu}{2}(q_j-q_k) = \frac{z_j+z_k}{z_j-z_k} \quad \text{for } j\neq k.$$

Note the following properties of these objects on the folded space:

$$t_{-j-i} = t_{ij}, \quad a_{-j-i} = a_{ij}, \quad \text{and} \quad u_{-i} = -u_i.$$

In the expression of U_{ijkl}, the terms in $\delta_{j,-l}$ are not on the same footing as the others since they are separately antisymmetric under the exchange of the two spaces (operation π) whereas the remaining terms verify this property only altogether.

We thus first take care of the $\delta_{j,-l}$ terms, introducing the matrix ρ,

$$\rho = \alpha \sum_{k,l=-N}^{N} L_{kl}\left(\frac{1}{2}u_l - t_{kl}\right) e_{-l-l}\otimes e_{kl},$$

realizing them as a linear r-matrix form (6),

$$([\rho, L_1] - [\rho^{\pi}, L_2])_{ijkl} = \alpha\, L_{ij}L_{kl}\,(\delta_{j,-l}(u_j - t_{ij} + t_{kl}) + \delta_{i,-l}(\tfrac{1}{2}u_l - t_{kl}) - \delta_{j,-k}(\tfrac{1}{2}u_j - t_{ij}))$$

$$= \alpha\, L_{ij}L_{kl}\,(U_{ijkl} - \tilde{U}_{ijkl}),$$

$$\text{with } \tilde{U}_{ijkl} = \delta_{i,-l}(t_{ij} + t_{kl} - \tfrac{1}{2}u_l) - \delta_{j,-k}(t_{ij} + t_{kl} - \tfrac{1}{2}u_j).$$

We may furthermore bring it back to our sought general quadratic form by setting $\rho = \tau L_2$ [i.e., taking $b=\tau$ and $c=0$ in (7)], since the matrix L is invertible,

$$\tau = \rho\, L_2^{-1} = \alpha \sum_{i,k,l=-N}^{N} L_{k-i}\, L_{-il}^{-1}\left(\frac{1}{2}u_{-i} - t_{k-i}\right) e_{ii}\otimes e_{kl}. \tag{8}$$

One should immediately note, from the explicit form of L (3), that this matrix τ actually does not depend on the rapidities θ_i's. We are therefore still in the ''canonical'' quadratic structure (à la Suris) of type (4) with dynamical quadratic r-matrices depending only on one set of canonical variables (the q_i's).

We will now show that there exists a matrix σ, such that $\sigma^{\pi} = \sigma$ and

$$\alpha\, L_{ij}L_{kl}\,\tilde{U}_{ijkl} = [L_2\,\sigma\, L_1 - L_1\,\sigma^{\pi}\, L_2]_{ijkl}.$$

This corresponds to setting $c=\sigma$ and $b=0$ in (7) and thus actually formally completes the quadratic r-matrix structure (4).

In order to ensure self-consistency of the dependence in the indices, we assume the following tensorial structure:

$$\sigma = \sum_{m,n=-N}^{N} \sigma_{mn}\, e_{mn}\otimes e_{-n-m}, \quad \text{satisfying} \quad \sigma^{\pi} = \sigma, \ \text{i.e.,} \ \sigma_{-n-m} = \sigma_{mn},$$

yielding

$$[L_2\,\sigma\,L_1-L_1\,\sigma^{\pi}\,L_2]_{ijkl}=\delta_{i,-l}\sum_{n=-N}^{N}\sigma_{in}\,L_{k-n}\,L_{nj}-\delta_{j,-k}\sum_{n=-N}^{N}\sigma_{kn}\,L_{i-n}\,L_{nl}\,.$$

The set of equations to be solved then reads

$$\delta_{i,-l}\left(\sum_{n=-N}^{N}\sigma_{in}\frac{L_{k-n}\,L_{nj}}{L_{ij}L_{kl}}-\alpha\left(t_{ij}+t_{kl}-\frac{1}{2}u_l\right)\right)$$
$$=\delta_{j,-k}\left(\sum_{n=-N}^{N}\sigma_{kn}\frac{L_{i-n}\,L_{nl}}{L_{ij}L_{kl}}-\alpha\left(t_{ij}+t_{kl}-\frac{1}{2}u_j\right)\right),$$

or, equivalently,

$$\sum_{n=-N}^{N}\sigma_{in}\frac{L_{k-n}\,L_{nj}}{L_{ij}L_{k-i}}-\alpha\left(t_{ij}+t_{k-i}+\frac{1}{2}u_i\right)=\delta_{j,-k}\,s_{ik},\quad\text{with}\quad s_{ik}=s_{ki}\,.$$

Direct calculations yield

$$\frac{L_{k-n}\,L_{nj}}{L_{ij}L_{k-i}}=\frac{e^{\beta\,\theta_n}f_n}{e^{\beta\,\theta_i}f_i}\left((1-\delta_{j,-k})\frac{t_{nj}-t_{n-k}}{t_{ij}-t_{i-k}}+\delta_{j,-k}\frac{t_{nj}^2-1}{t_{ij}^2-1}\right),$$

and equations become

$$\sum_{n=-N}^{N}\tilde{\sigma}_{in}\,(t_{nj}-t_{n-k})=\alpha\left(t_{ij}^2-t_{i-k}^2+\frac{1}{2}u_i\,t_{ij}-\frac{1}{2}u_i\,t_{i-k}\right)\sum_{n=-N}^{N}\tilde{\sigma}_{in}\frac{t_{nj}^2-1}{t_{ij}^2-1}-\alpha\left(2\,t_{ij}+\frac{1}{2}u_i\right)$$
$$=s_{i-j},\quad\text{with}\quad\tilde{\sigma}_{in}=\frac{e^{\beta\,\theta_n}f_n}{e^{\beta\,\theta_i}f_i}\sigma_{in}\,.$$

Let us recall here that the only additional contraints on matrices $\tilde{\sigma}$ and s read

$$\begin{cases}\tilde{\sigma}_{-j-i}=\dfrac{f_i^2}{f_j^2}\tilde{\sigma}_{ij}\\ s_{ij}=s_{ji}\,.\end{cases}\tag{9}$$

According to the previous equations, the matrix s is determinated given the matrix $\tilde{\sigma}$, and $\tilde{\sigma}$ is obtained, up to a one-dimensional degree of freedom v_i, by

$$\sum_{n=-N}^{N}\tilde{\sigma}_{in}\,t_{nj}=\alpha\,(t_{ij}^2+\tfrac{1}{2}u_i\,t_{ij}+v_i),\tag{10}$$

since t is invertible.

Remains to verify that one can find v_i's, such that the compatibility relations (9) be satisfied, namely,

$$\sum_{m=-N}^{N}t_{im}\,f_m^2\,t_{mj}(t_{mj}-t_{im}+u_m)=\sum_{m=-N}^{N}f_m^2\,(v_{-m}\,t_{mj}-v_m\,t_{im}),\tag{11}$$

$$(v_i+1)\sum_{n,m=-N}^{N}(t_{-jm}^2-1)\,(t^{-1})_{mn}=(v_{-j}+1)\sum_{n,m=-N}^{N}(t_{im}^2-1)\,(t^{-1})_{mn}\,.\tag{12}$$

Equation (12) directly yields $v_i=-1+\eta\,\Sigma_{n,m=-N}^{N}(t_{im}^2-1)\,(t^{-1})_{mn}$, with η an arbitrary constant.

In order to solve (11) we shall first compute its left-hand side.

We do so by twofold evaluation of the following contour integral in the complex plane around infinity,

$$I_{ij}=\frac{1}{2\pi i}\oint_{C_\infty}\frac{dz}{z}\,\frac{z_i+\lambda z}{z_i-\lambda z}\,\frac{z+\lambda z_j}{z-\lambda z_j}\prod_{k=-N}^{N}\frac{z-\lambda z_k}{z-z_k}\,\frac{z_k-\lambda z}{\lambda(z_k-z)}.$$

Contour C_∞ is oriented counterclockwise and loops around infinity. Residue at infinity gives $I_{ij}=-1$.

Whereas I_{ij} also equals the sum of residues at poles of the meromorph integrand in the whole complex plane, that is, a single pole at $z=0$ with residue -1 and a set of double poles at $z=z_m$. We thus obtain

$$\sum_{m=-N}^{N}\left[\frac{z_i+\lambda z}{z_i-\lambda z}\,\frac{z+\lambda z_j}{z-\lambda z_j}\,\frac{(z-\lambda z_m)\,(z_m-\lambda z)}{-\lambda z}\prod_{\substack{k=-N,\\ k\neq m}}^{N}\frac{z-\lambda z_k}{z-z_k}\,\frac{z_k-\lambda z}{\lambda(z_k-z)}\right]'(z=z_m)=0.$$

Noticing that

$$\begin{aligned}u_m&=\frac{2}{\nu}\sum_{\substack{k=-N,\\ k\neq m}}^{N}(\ln f)'(q_k-q_m)\\&=-\frac{2}{\nu}\frac{\partial}{\partial q_m}\ln\prod_{\substack{k=-N,\\ k\neq m}}^{N}f(q_k-q_m)\\&=-2\,z_m\frac{\partial}{\partial z_m}\ln\prod_{\substack{k=-N,\\ k\neq m}}^{N}\frac{z_m-\lambda z_k}{z_m-z_k}\,\frac{z_k-\lambda z_m}{\lambda(z_k-z_m)}\\&=-2\,z_m\left[\ln\prod_{\substack{k=-N,\\ k\neq m}}^{N}\frac{z-\lambda z_k}{z-z_k}\,\frac{z_k-\lambda z}{\lambda(z_k-z)}\right]'(z=z_m)\end{aligned}$$

and also

$$z_m\left[\ln\left(\frac{z_i+\lambda z}{z_i-\lambda z}\,\frac{z+\lambda z_j}{z-\lambda z_j}\right)\right]'(z=z_m)=\frac{1}{2}\left((t_{im}-t_{mj})-\left(\frac{1}{t_{im}}-\frac{1}{t_{mj}}\right)\right),$$

we obtain

$$\sum_{m=-N}^{N}t_{im}\,f_m^2\,t_{mj}\left[t_{mj}-t_{im}+u_m+\left(\frac{1}{t_{im}}-\frac{1}{t_{mj}}\right)\right]=0,$$

or equivalently,

$$\sum_{m=-N}^{N}t_{im}\,f_m^2\,t_{mj}(t_{mj}-t_{im}+u_m)=\sum_{m=-N}^{N}f_m^2\,(t_{im}-t_{mj}).$$

This derivation of Liouville-type functional identities stems from similar derivations to be found in Ref. 10.

Equation (11) now reads

$$\sum_{m=-N}^{N}t_{im}\,f_m^2\,(v_m+1)=\sum_{m=-N}^{N}(v_{-m}+1)\,f_m^2\,t_{mj}=\sum_{m=-N}^{N}t_{-jm}\,f_m^2\,(v_m+1),$$

and can be solved straightforwardly, $v_i=-1+\xi\,(1/f_i^2)\,\Sigma_{m=-N}^{N}(t^{-1})_{im}$, with ξ any constant.

We thereby prove the consistency of (9) and (10), since $v_i=-1$ is an obvious solution (with $\eta=\xi=0$).

In addition, performing calculations of the same type of contour integrals, one gets

$$\sum_{n,m=-N}^{N}(t_{im}^2-1)\,(t^{-1})_{mn}=-\frac{4\lambda}{(\lambda-1)^2}\frac{1}{f_i^2}\sum_{m=-N}^{N}(t^{-1})_{im}\propto\frac{1}{D_i^+},$$

with

$$D_i^+=\prod_{\substack{k=-N,\\ k\neq i}}^{N}\frac{z_i-\lambda\,z_k}{z_i-z_k}.$$

The two forms which the v_i's should satisfy, are actually identical, $v_i=-1+(\zeta/D_i^+)$, ζ being an arbitrary constant.

We fix this remaining gauge, setting $\zeta=(1-\lambda^{2N+1})/(1-\lambda)$, in order to obtain the simplest form for $\tilde{\sigma}$ from relation (10),

$$\tilde{\sigma}_{ij}=\alpha\frac{D_j^+}{D_i^+}(\delta_{i,j}\,s_i-(1-\delta_{i,j})\,a_{ij}),\quad\text{where}\quad s_i=\frac{1+\lambda}{1-\lambda}+\sum_{m=-N}^{N}\frac{1}{2}(t_{mi}+t_{im}).$$

We finally give the expression of the matrix σ,

$$\sigma=\alpha\sum_{i,j=-N}^{N}\frac{\mathcal{A}_j}{\mathcal{A}_i}(\delta_{i,j}\,s_i-(1-\delta_{i,j})\,a_{ij})\,e_{ij}\otimes e_{-j-i},\quad\text{with}\quad\mathcal{A}_i=\sqrt{\frac{D_i^+}{D_{-i}^+}}e^{-\beta\,\theta_i}.\tag{13}$$

The r-matrix structure is now completely defined by a quadratic Poisson bracket of type (4) where the quadratic r-matrices a_1, a_2, s_1, and s_2 are changed into

$$\begin{aligned}
a_1&\to\tilde{a}_1=a_1,\\
s_1&\to\tilde{s}_1=s_1+\sigma+\tau^{\pi},\\
s_2&\to\tilde{s}_2=\tilde{s}_1^{\pi}=s_2+\sigma^{\pi}+\tau=s_2+\sigma+\tau,\\
a_2&\to\tilde{a}_2=\tilde{a}_1+\tilde{s}_1-\tilde{s}_2=a_2+\tau^{\pi}-\tau,
\end{aligned}\tag{14}$$

and matrices σ and τ are, respectively, defined by Eqs. (13) and (8).

D. Comments

One should notice that this quadratic r-matrix structure is now fully dynamical, depending both on the positions q_i's and rapidities θ_i's. Moreover, its conjugating factor $\mathcal{A}_i$, which bears this double dependance, is deeply connected to the structure of the matrix L under folding,

$$L_{ij}^{-1}=\frac{\mathcal{A}_j}{\mathcal{A}_i}L_{-i-j}.$$

We have here an interesting first example of a ''doubly dynamical'' r-matrix dependence, stemming from the interplay between the folding procedure leading from A_{2N} to BC_N, and the quadratic structure of Ruijsenaars–Schneider-type models. This seems to open new perspectives, first of all on the classification of such doubly dynamical r-matrices. The only other example known to us at this time is the classical linear r-matrix structure for the Lax formulation of the A_N elliptic Calogero–Moser model in the absence of the spectral parameter.[25] Proof of its double dynamical

dependence is given in Ref. 26 although the explicit form is yet conjectural.[27] Curiously however, it occurs in relation with an A_N model with no folding and may therefore be of a different nature.

Interpretation of doubly dynamical objects in the frame of quantum group theory is yet lacking. ''Simply'' dynamical r-matrices are known to be connected to the theory of Drinfel'd-twisted quantum groups, specifically of the type of Felder's Dynamical Quantum Groups[28] (see, for instance, Refs. 29, 30). Whether doubly dynamical objects have such connections is a new problem and we have no further comments to make on this point. A very recent result[31] may however give indications on how to twist quantum groups by non-Abelian twisted cocycles (here the twist would occur ''along'' a Heisenberg algebra).

III. THE CANONICAL HAMILTONIANS

A. Preliminaries

We first describe the Poisson-commuting Hamiltonians[15] generated by traces of powers of the BC_N Lax matrix (3). Subsequent comparison with Koornwinder–van Diejen Hamiltonians is made easier by using as an algebraic basis the coefficients of the characteristic polynomial of the Lax operator. They read for any integer $l \in \{1 \cdots N\}$,

$$\mathcal{H}_l = \sum_{\substack{\mathcal{J} \subset \{-N \cdots N\} \\ |\mathcal{J}| = l}} m_{\mathcal{J}}(L),$$

with $m_{\mathcal{J}}(L)$ the principal minor of L with lines and columns indexed by $\mathcal{J}$.

Taking into account the form of L and properties of Cauchy matrices,

$$m_{\mathcal{J}}(L) = e^{-\beta\theta_{\mathcal{J}}} \prod_{\substack{j \in \mathcal{J} \\ k \notin \mathcal{J}}} f^{1/2}(q_j - q_k), \quad \text{where} \quad \theta_{\mathcal{J}} = \sum_{j \in \mathcal{J}} \theta_j .$$

Because of the folding, we now rearrange these terms so as to sort them with respect to linearly independent exponentials of rapidities. We thus decompose $\mathcal{J} = \varepsilon J \cup S$, separating indices of $\mathcal{J}$ such that their opposite does not belong to $\mathcal{J}$ (set $\varepsilon J = \{\varepsilon_j |j| / j \in \mathcal{J} \wedge -j \notin \mathcal{J}\}$ and $J = \{|j| / j \in \varepsilon J\} \subset \{1 \cdots N\}$) and the complementary parts, symmetric under folding S,

$$\mathcal{H}_l = \sum_{\substack{J \subset \{1 \cdots N\},\ |J| \leqslant l \\ \varepsilon_j = \pm 1,\ j \in J}} \mathcal{U}_{J^c, l-|J|}\, e^{-\beta\theta_{\varepsilon J}} \prod_{\substack{j \in \varepsilon J \\ k \notin \varepsilon J}} f^{1/2}(q_j - q_k), \tag{15}$$

with

$$\mathcal{U}_{K,p} = \sum_{\substack{S \subset \mathcal{A}_K = K \cup -K \cup \{0\} \\ S = -S,\ |S| = p}} \prod_{\substack{s \in S \\ k \in \mathcal{A}_K \setminus S}} f^{1/2}(q_s - q_k) = \sum_{\substack{S \subset \mathcal{A}_K \\ S = -S,\ |S| = p}} \prod_{\substack{s \in S \\ k \in \mathcal{A}_K \setminus S}} v(q_s - q_k). \tag{16}$$

We now recall the Koornwinder–van Diejen Hamiltonians[16] in the classical case,

$$H_l = \sum_{\substack{J \subset \{1 \cdots N\},\ |J| \leqslant l \\ \varepsilon_j = \pm 1,\ j \in J}} U_{J^c, l-|J|}\, e^{-\beta\theta_{\varepsilon J}}\, V^{1/2}_{\varepsilon J; J^c}\, V^{1/2}_{-\varepsilon J; J^c}, \tag{17}$$

where, after some rearrangements,

$$V_{\varepsilon J; K} = \prod_{j \in \varepsilon J} \frac{w(q_j)}{v(2\, q_j)\, v(q_j)} \prod_{\substack{j \in \varepsilon J \\ k \in \mathcal{A}_K \cup -\varepsilon J}} v(q_j - q_k)$$

and

$$U_{K,p}=(-1)^p \sum_{\substack{\varepsilon I\subset \mathcal{A}_K \\ |I|=p}} \prod_{i\in \varepsilon I} \frac{w(q_i)}{v(2q_i)\,v(q_i)} \prod_{\substack{i,i'\in \varepsilon I \\ i<i'}} \frac{v(-q_i-q_{i'})}{v(q_i+q_{i'})} \prod_{\substack{i\in \varepsilon I \\ k\in \mathcal{A}_K\setminus \varepsilon I}} v(q_i-q_k).$$

The potentials w are particular functions and may be interpreted as an interaction with some external field.

Direct computation yields

$$V_{\varepsilon J;J^c}V_{-\varepsilon J;J^c}=\prod_{j\in \varepsilon J} \frac{w(q_j)}{v(2q_j)\,v(q_j)} \frac{w(-q_j)}{v(-2q_j)\,v(-q_j)} \prod_{\substack{j\in \varepsilon J \\ k\notin \varepsilon J}} f(q_j-q_k).$$

Setting $w(q_j)=v(2q_j)\,v(q_j)$, which is an admissible choice according to Ref. 16, H_l (17) takes actually the same form as $\mathcal{H}_l$ (15), up to the crucial change of $\mathcal{U}_{K,p}$ into $U_{K,p}$. $U_{K,p}$ takes a simpler form, for this choice of one-body potential w,

$$U_{K,p}=(-1)^p \sum_{\substack{\varepsilon I\subset \mathcal{A}_K \\ |I|=p}} \prod_{\substack{i,i'\in \varepsilon I \\ i<i'}} \frac{v(-q_i-q_{i'})}{v(q_i+q_{i'})} \prod_{\substack{i\in \varepsilon I \\ k\in \mathcal{A}_K\setminus \varepsilon I}} v(q_i-q_k), \tag{18}$$

nevertheless *it is generally not equal to* $\mathcal{U}_{K,p}$ (the notation used in Ref. 17 is in this respect misleading).

They are actually only equal for $p=0$, where trivially, $U_{K,0}=1=\mathcal{U}_{K,0}$. For instance when $p=1$, one gets

$$U_{K,1}=-\sum_{i\in \mathcal{A}_K\setminus\{0\}} \prod_{\substack{k\in \mathcal{A}_K \\ k\neq i}} v(q_i-q_k) \quad \text{and} \quad \mathcal{U}_{K,1}=\prod_{\substack{k\in \mathcal{A}_K \\ k\neq 0}} v(q_k).$$

We compute a suitable contour integral on the same lines as in the previous section to obtain the Liouville-type functional identity,

$$\sum_{i\in \mathcal{A}_K} \prod_{\substack{k\in \mathcal{A}_K \\ k\neq i}} v(q_i-q_k)=\frac{\sinh \gamma(2|K|+1)}{\sinh \gamma},$$

and thus show that

$$U_{K,1}=\mathcal{U}_{K,1}-\frac{\sinh \gamma(2|K|+1)}{\sinh \gamma}.$$

It will now be shown that these two relations, for $p=0$ and $p=1$, between the $U_{K,p}$'s and $\mathcal{U}_{K,1}$'s are actually sufficient to establish that the two sets of Hamiltonians define the same family of commuting dynamical flows, namely one set of Hamiltonians is a triangular linear combination of the other set.

A more general result will in fact be proved in the following subsection.

B. Uniqueness theorem

Theorem 1: *Let q_i and θ_i, $i\in\mathbb{N}$, be a set of conjugated variables such that $\{\theta_i,q_j\}=\delta_{ij}$. Let I and K be arbitrary finite sets of indices included in $\mathbb{N}$. Assume the existence of a set of complex functions $u_{K,p}$ depending upon the set of indices K and a natural integer p, and of another set of complex functions $v_{\varepsilon J,I}$ depending upon the sets of indices J and I $(J\subset I)$ and a $|J|$-uple of signs $\varepsilon=(\varepsilon_j, j\in J)$, such that:*

(a) $u_{K,p}$ and $v_{\varepsilon J,I}$ be independent of the rapidities θ_is;

(b) $u_{K,0}=1$, $v_{\varnothing,I}=1$, *and* $v_{\varepsilon\{j\},I}\neq 0$;
(c) $S^I=\{h_l^I=\sum_{\substack{J\subset I,\,|J|\leqslant l\\ \varepsilon_j=\pm 1,\,j\in J}} u_{J^c,l-|J|}\, e^{-\beta\theta_{\varepsilon J}}\, v_{\varepsilon J,I},\ l\in\{1\cdots|I|\}\}$ *be a family of Poisson-commuting functions* $(\theta_{\varepsilon J}=\sum_{j\in J}\varepsilon_j\theta_j)$.

If there exists a second set of complex functions $\tilde{u}_{K,p}$ *obeying the first two conditions; such that* $\tilde{S}^I=\{\tilde{h}_l^I=\sum_{\substack{J\subset I,\,|J|\leqslant l\\ \varepsilon_j=\pm 1,\,j\in J}} \tilde{u}_{J^c,l-|J|}\, e^{-\beta\theta_{\varepsilon J}}\, v_{\varepsilon J,I},\ l\in\{1\cdots|I|\}\}$ *be a new family of Poisson-commuting functions; and* $\tilde{u}_{K,1}=u_{K,1}+c_1(|K|)$, *then there exist coefficients* $c_r(m)$, $(r,m)\in\mathbb{N}^2$, *independent of all dynamical variables, connecting the two families of Hamiltonians as*

$$\tilde{h}_l^I=\sum_{s=0}^{l} c_{l-s}(|I|-s)\, h_s^I, \quad \text{with} \quad \forall m\in\mathbb{N}, c_0(m)=1.$$

Proof: The strategy of the proof relies upon a recursive procedure on p, showing that

$$\tilde{u}_{K,p}=\sum_{r=0}^{p} c_{p-r}(|K|-r)\, u_{K,r}, \quad \forall K\subset\mathbb{N} \text{ finite and such that } |K|\geqslant p. \tag{19}$$

Let l_0 be a strictly positive integer; the recursion hypothesis hereafter denoted r.h., states that (19) is valid for any $p\leqslant l_0$.

The assumptions in the theorem immediately imply the validity of r.h. for $l_0=1$, which can be directly rewritten as

$$\tilde{h}_1^I=h_1^I+c_1(|I|). \tag{20}$$

Let us assume r.h. up to l_0 and establish it for l_0+1. We have

$$\tilde{h}_{l_0+1}^I=\tilde{u}_{I,l_0+1}+\sum_{\substack{J\subset I,1\leqslant|J|\leqslant l_0+1\\ \varepsilon_j=\pm 1,j\in J}} \tilde{u}_{J^c,l_0+1-|J|}\, e^{-\beta\theta_{\varepsilon J}}\, v_{\varepsilon J,I}.$$

Since $l_0+1-|J|\leqslant l_0$ in the previous summation, we apply r.h. to get

$$\tilde{h}_{l_0+1}^I=\tilde{u}_{I,l_0+1}+\sum_{s=1}^{l_0+1} c_{l_0+1-s}(|I|-s)\sum_{\substack{J\subset I,1\leqslant|J|\leqslant s\\ \varepsilon_j=\pm 1,j\in J}} u_{J^c,s-|J|}\, e^{-\beta\theta_{\varepsilon J}}\, v_{\varepsilon J,I}$$

$$=\tilde{u}_{I,l_0+1}-\sum_{s=1}^{l_0+1} c_{l_0+1-s}(|I|-s)\, u_{I,s}+\sum_{s=1}^{l_0+1} c_{l_0+1-s}(|I|-s)\, h_s^I. \tag{21}$$

We now use the Poisson-commutation property of $\tilde{S}^I$ as

$$\{\tilde{h}_{l_0+1}^I,\tilde{h}_1^I\}=0.$$

Combining (20), (21) and the Poisson-commutation property of S^I yields

$$0=\left\{\tilde{u}_{I,l_0+1}-\sum_{s=1}^{l_0+1} c_{l_0+1-s}(|I|-s)\,u_{I,s},h_1^I\right\}$$

$$=\sum_{j\in I,\varepsilon=\pm 1}\beta\,\varepsilon\,e^{-\beta\,\varepsilon\,\theta_j}v_{\varepsilon\{j\},I}\frac{\partial}{\partial q_j}$$

$$\times\left(\tilde{u}_{I,l_0+1}-\sum_{s=1}^{l_0+1} c_{l_0+1-s}(|I|-s)\,u_{I,s}\right).$$

By functional independence of $\Sigma_{\varepsilon=\pm 1}\varepsilon\,e^{-\beta\,\varepsilon\,\theta_j}v_{\varepsilon\{j\},I}$, it follows that the function obtained as $\tilde{u}_{I,l_0+1}-\Sigma_{s=1}^{l_0+1}c_{l_0+1-s}(|I|-s)\,u_{I,s}$ *does not depend on any dynamical variable*. Hence it defines the coefficient $c_{l_0+1}(|I|)$, thereby proving the r.h. to order l_0+1. Finally, relation (19) immediately implies the result of the theorem. □

C. Comments

An immediate consequence of this theorem is the existence of linear triangular relations between the BC_N Ruijsenaars–Schneider Hamiltonians and the classical Koornwinder–van Diejen Hamiltonians when $w(q_j)=v(2\,q_j)\,v(q_j)$. Such relations were indicated in Ref. 32 for the lowest and highest-order Hamiltonians.

The explicit coefficient have to be computed order by order since at this time no general recursion formula is available. As an example we have worked out the first two functions,

$$U_{K,1}=\mathcal{U}_{K,1}+c_1(|K|)\quad\text{and}\quad U_{K,2}=\mathcal{U}_{K,2}+c_1(|K|-1)\,\mathcal{U}_{K,1}+c_2(|K|)$$

with

$$c_1(|K|)=-\frac{\sinh\gamma(2\,|K|+1)}{\sinh\gamma},$$

$$c_2(|K|)=\frac{1}{2}\left(\frac{\sinh\gamma(2\,|K|-1)}{\sinh\gamma}\,\frac{\sinh\gamma(2\,|K|+1)}{\sinh\gamma}-\frac{\sinh 4\,\gamma\,|K|}{\sinh 2\,\gamma}-2\right).$$

No obvious pattern appears yet. As a consequence, an algebraic interpretation of the Koornwinder–van Diejen Hamiltonians in connection with the canonical Hamiltonians is still lacking.

More generally, the theorem implies that a hierarchy of Poisson-commuting Hamiltonians with the generic form given is uniquely determinated by the giving of the family of v-functions and the first Hamiltonian, or equivalently the first ''potential term'' $u_{K,1}$. In the Koornwinder–van Diejen case, this first Hamiltonian is given in Ref. 20.

We wish to end this section with a conjecture on the classical Koornwinder–van Diejen Hamiltonians with a general one-body potential chosen as in Ref. 19 [this time dropping the restriction to $w(q_j)=v(2\,q_j)\,v(q_j)$]. They have not yet been constructed by a Lax formalism. We expect that the suitable Lax matrix for this hierarchy may be obtained by multiplying the BC_N Lax matrix (3) by a $2\,N+1$ diagonal matrix: $L_W=LD_W$, with $D_{W_{ii}}=\mathcal{W}(q_i)\,\mathcal{W}(-q_i)$. This one-body potential function $\mathcal{W}$ has to be determinated by integrability conditions. In addition, we conjecture that, after some canonical transformation on the dynamical variables, the Hamiltonians $\mathcal{H}_W^l$ generated by $\mathrm{tr}(L_W^l)$ will take the same form as the Koornwinder–van Diejen Hamiltonians (17) up to the change of $U_{K,p}$ into some $\mathcal{U}_{W_{K,p}}$. The theorem will then apply, thereby yielding the full connection between BC_N-type Ruijsenaars–Schneider potentials and the classical Koornwinder–van Diejen Hamiltonians.

The global finite structure of generic envelope loci for Hamilton–Jacobi equations

Franco Cardin[a)]
Dipartimento di Matematica Pura ed Applicata, Università degli Studi di Padova, via Belzoni, 7-35131 Padova, Italy

(Received 1 August 2001; accepted for publication 10 October 2001)

We discuss in some detail the existence of global generating functions describing Lagrangian submanifolds connected with evolution problems for Hamilton–Jacobi (H–J) equations. First, we produce a physical application of a result by Viterbo: for generic (in a suitable sense) Hamiltonian functions and initial data, the envelopes, i.e., the wave front sets, related to Hamilton–Jacobi problems are globally finitely generated. Furthermore, we show how to compute global space–time generating functions with finite parameters for geometric solutions of a H–J equation of the evolution kind. © *2002 American Institute of Physics.*

I. INTRODUCTION: THE HAMILTON–JACOBI PROBLEM

Dynamical mechanical systems, even infinite-dimensional evolution systems, like the wave propagation problems of Continuum Mechanics or Optics, are often governed by a Hamilton–Jacobi equation, for some Hamiltonian function $H:\mathbb{R}\times T^*Q\to\mathbb{R}$. Here, we take as standard scenario T^*Q, the symplectic manifold of dynamics, and in what follows $Q=\mathbb{R}^n$ is the ''space,'' while $\mathcal{Q}=\mathbb{R}^{n+1}$ is the ''space–time.''

We are interested in a Cauchy Problem, which, in the so-called *classical* formulation, reads as

$$\frac{\partial S}{\partial t}(q,t)+H\left(t,q,\frac{\partial S}{\partial q}(q,t)\right)=0,$$

(Classical Cauchy Problem)

$$S(q,t)\big|_{t=0}=\sigma(q).$$

It is well known that it is not possible to find classical *global* solutions for the above (CCP): this is mainly due to the nonlinearity of the problem. From the physical point of view, the main objects of interest related to the solutions are often precisely these obstructions, sometimes called *caustics*.

In order to overcome the difficulties connected to the obstructions to existence of global solutions, we can begin from a simple observation in the classical case, that is when a global classical solution exists. Let

$$S:\mathbb{R}^n\times\mathbb{R}\to\mathbb{R},\quad (q,t)\mapsto S(q,t),$$

be a classical solution of the above problem, and, transforming it to the so-called ''homogeneous version,'' set

$$\mathcal{Q}:=\mathbb{R}^n\times\mathbb{R},\quad x:=(q,t),\quad (x,\xi):=(q,t;p,\tau),$$

$$\mathcal{H}:T^*\mathcal{Q}\to\mathbb{R},\quad \mathcal{H}(x,\xi):=\tau+H(t,q,p).$$

a)Electronic mail: cardin@math.unipd.it

Then the differential of $S:\mathcal{Q}\to\mathbb{R}$ is a 1-form $dS:\mathcal{Q}\to T^*\mathcal{Q}$, and setting

$$\mathrm{im}(dS):=\left\{(x,\xi):\xi=\frac{\partial S}{\partial x}(x),x\in\mathcal{Q}\right\}\subset T^*\mathcal{Q},$$

the H–J equation reads as

$$\mathrm{im}(dS)\subset\mathcal{H}^{-1}(0).$$

As is usual, we introduce the Liouville 1-form $\theta_{\mathcal{Q}}=\xi\,dx$ on $T^*\mathcal{Q}$, so that $d\theta_{\mathcal{Q}}$ is the standard symplectic 2-form on $T^*\mathcal{Q}$.

We note that

$$(1)\quad \dim\ \mathrm{im}(dS)=\dim\mathcal{Q},$$

$$(2)\quad d\theta_{\mathcal{Q}}\big|_{\mathrm{im}(dS)}=(d\xi\wedge dx)\big|_{\mathrm{im}(dS)}=\frac{\partial^2 S}{\partial x\,\partial x}dx\wedge dx\equiv 0,$$

It is a well known fact in symplectic geometry—see, e.g., Arnold and Novikov (1990)—that the two properties (1) and (2) characterize the *Lagrangian submanifolds* of $T^*\mathcal{Q}$. Furthermore, $\Lambda=\mathrm{im}(dS)$ is *transverse* to the fibers of $\mathcal{Q}$ (since it has a graph structure).

We recognize here a way to overcome the difficulty in finding a global solution: instead of a function $S(x)$, we are now searching for a *Lagrangian submanifold* Λ (i.e., such that $\dim\Lambda=\dim\mathcal{Q}$, and $d\theta_{\mathcal{Q}}\big|_{\Lambda}=0$) satisfying what can be considered the ''new'' geometric version of the H–J equation:

$$\Lambda\subset\mathcal{H}^{-1}(0).$$

A crucial theorem in symplectic geometry, due mainly to Maslov (1965) and Hörmander (1971), characterizes the Lagrangian submanifolds locally: let Λ be a Lagrangian submanifold of $T^*\mathcal{Q}$; then for each point $\lambda\in\Lambda$ there exists a description of Λ by means of a local *generating function*, $U(\subset\mathcal{Q})\times\mathbb{R}^k\ni(x,u)\mapsto S(x,u)\in\mathbb{R}$, such that (locally)

$$\Lambda=\left\{(x,y):\xi=\frac{\partial S}{\partial x}(x,u),\quad 0=\frac{\partial S}{\partial u}(x,u),\quad \text{for some } u\in\mathbb{R}^k\right\},$$

where S can be assumed to satisfy the rank condition:

$$\mathrm{rk}\left(\frac{\partial^2 S}{\partial x\,\partial u}\ \frac{\partial^2 S}{\partial u\,\partial u}\right)\Bigg|_{\partial S/\partial u=0}=\max=k.$$

Whenever, locally at λ, we can describe Λ without introducing auxiliary parameters u—in other words, if Λ is the image of dS, so that $k=0$—then λ is a point of transverse intersection of Λ with the fiber $T^*\mathcal{Q}\to\mathcal{Q}$. The following questions arise naturally:

(1) How to obtain Λ satisfying the H-J equation $\Lambda\subset\mathcal{H}^{-1}(0)$?
(2) Given a Lagrangian submanifold Λ, is it possible to find a *global* generating function $S(x,u)$ for it?

The answer to question (1) is formally easy: by a standard procedure of the gluing of characteristics of the Hamiltonian field X_H (which we suppose to be complete) we obtain the geometric object Λ:

$$\Lambda=\bigcup_{t\in I\subset\mathbb{R}}\Phi^t_{X_H}(\mathrm{im}(d\sigma))\quad \Phi^t_{X_H}:\text{flow of } X_H.$$

Hence, by Maslov–Hörmander, we can construct the local generating functions; see also Benenti and Tulczyjew (1979).

Question (2) is crucial, especially whenever we want to generate *true* solutions (in the sense of ''functions,'' not submanifolds) to H–J equations.

In fact, if we know a *global* generating function of the Lagrangian submanifold solution of some H–J problem, then we have the following.

(a) We can try to generate the *viscosity* solution (Crandall–Evans–Lions) by some suitable inf/sup procedure on the auxiliary parameters u. These techniques were first introduced by Hopf (1965); also, an existence and uniqueness theorem exists in this context; see Bardi and Capuzzo-Dolcetta (1997) and Cardin (1993);
(b) sometimes, with due care, we can generate the Chaperon–Sikorav–Viterbo solution by a Morse (Lusternik–Schnirelman) procedure; see, e.g., Dubrovin, Fomenko and Novikov (1990). Rather surprisingly, this last solution sometimes differs from the viscosity solution for the same problem; see Viterbo (1990), Viterbo (1996), Capitanio (1999).

Very important developments on the links between viscosity and geometric solutions of the H–J equation, mainly on the classification and stability of the singularities, have been performed by Izumiya and Kossioris; among many interesting papers, see, e.g., Izumiya and Kossioris (1997).

Here, one might naturally suspect that global generating functions $S(x,u)$ of geometric solutions for a H–J equation exist *only* for Hamiltonian functions that are *integrable* on the fiber zero ($\mathcal{H}=0$). This idea arises from the following fact: if there exists a *complete integral*, $W(x^i,a^A)$, $i=1,...,n+1$, $A=1,...,n$, then the H–J general problem with initial data σ on a submanifold Σ of co-dimension one into $\mathcal{Q}$,

$$\mathcal{H}\left(x,\frac{\partial S}{\partial x}(x)\right)=0, \quad \text{or} \quad \Lambda\subset\mathcal{H}^{-1}(0);$$

$$S|_{\Sigma}=\sigma, \quad \text{or} \quad S(\tilde{x}^i(\chi^A))=\sigma(\chi^A),$$

admits—see Cardin (1989)—the following *global* generating function describing the Lagrangian submanifold solution Λ:

$$S(x^i;\chi^A,a^B):=W(x^i,a^B)-W(\tilde{x}^i(\chi^A),a^B)+\varphi(\chi^A).$$

For example, if $\mathcal{H}(x,\xi)=\tau+H(p)$, then a complete integral is $W(x,a)=W(t,q,a)=-tH(a)+q\cdot a$, and the above formula works. It is remarkable that just by means of this formula Bardi and Evans (1984) found that the inf-sup procedure generates precisely the viscosity solution. Nevertheless, in the sequel, we will see that the above belief is false, more precisely, it is too pessimistic.

In order to exploit this point, we start from a very remarkable fact, more or less well known: *every* Lagrangian submanifold $\Lambda\subset\mathcal{H}^{-1}(0)\subset T^*\mathcal{Q}$, where $\mathcal{H}(x,\xi)=\tau+H(q,p,t)$ (i.e., of the evolution kind), admits a *formal* global generating function. This function is precisely the Action Functional of the related Calculus of Variations, and the auxiliary parameters belong to an *infinite*-dimensional space, the space of curves. We remind the reader that, if locally the q-components of the characteristics related to H do not cross each other, then, locally, a suitable interpretation of $A=\int_{t_0}^{t_1}L\,dt$ gives us Hamilton's Principal Function, which is a well known local complete integral. As we will soon see, in order to obtain a global generating function from the Action Functional we will *relax* the above restriction on the intersection of the q-characteristics.

Some remarks follow.

- Surely, the first powerful use of this idea was done by Feynman; see, e.g., Feynman and Hibbs (1965), where, roughly speaking, he generalized the *phase* functions—generating functions with a finite number of auxiliary parameters—of stationary phase theory for high frequency integrals, using the aforementioned Action Functionals.
- It is notable that Berry and Upstill, in a well known survey on global Optics—see p. 265 of Berry and Upstill (1980)—gave some pioneering ideas about the possibility of reducing to a finite number of auxiliary parameters.
- The search for global generating functions has a long story. A first theorem by Lees (1979) defined the obstructions in a cohomological and *k*-theoretical framework, but Giroux (1988) found a gap in that proof. Besides Giroux, Chaperon (1984), Laudenbach (1987) and Sikorav (1987) proved similar theorems, but only for *compact* parallelizable manifolds $\mathcal{Q}$.
- Here, we will consider some ideas of Viterbo (1990), more precisely we will give the details of his reduction procedure in the *noncompact* case: $Q=\mathbb{R}^n$, see also Aebischer *et al.* (1994). Some of the mathematical techniques were introduced by Amann, Conley, and Zehnder, see Amann and Zehnder (1980), Conley and Zehnder (1984), in connection with the search for periodic solutions of Hamiltonian systems.

First, we recall that a *Hamiltonian isotopy* is a canonical transformation, obtained via the flow of a Hamiltonian vector field X_H, generated by a Hamiltonian function H, possibly depending on the real evolution parameter $s\in[0,T]$.

Theorem 1: *Let $\Lambda\subset T^*\mathbb{R}^n$ be a Lagrangian submanifold connected by a Hamiltonian isotopy, generated by H, to the zero-section of $T^*\mathbb{R}^n$. If the second derivatives of H are globally uniformly bounded, then Λ admits a global generating function with a finite number of auxiliary parameters.*

Remark: The generating function coming from Theorem 1 generally does not satisfy the above rank condition of the Maslov–Hörmander theorem; really, that condition assures that the locus,

$$\left\{(q,p):p=\frac{\partial S}{\partial q}(q,u),\quad 0=\frac{\partial S}{\partial u}(q,u)\right\},$$

is a *smooth* Lagrangian manifold: we do not impose this fact, since it is a hypothesis of Theorem 1.

A constructive and physically meaningful consequence of Theorem 1 concerning envelopes—wave front sets—will be presented in Sec. III. Furthermore, in Sec. IV we built the global space–time generating functions with finite parameters of the Lagrangian submanifolds solving Cauchy problems for generic H–J equations of the evolution type.

II. A PROOF OF THEOREM 1

Let us consider the set of curves

$$\Gamma:=\{\gamma(\cdot)=(q(\cdot),p(\cdot))\in H^{1,2}([0,T],\mathbb{R}^{2n}):p(0)=0\}.$$

By the Rellich–Kondrachov theorem (or by the Sobolev imbedding theorem),

$$H^{1,2}((0,T),\mathbb{R}^{2n})\hookrightarrow\mathcal{C}^0([0,T],\mathbb{R}^{2n}),$$

compactly, so in the above definition it is understood that the elements of Γ are the natural continuous extension of the curves of $H^{1,2}((0,T),\mathbb{R}^{2n})$: more explicitly the continuous curves in $T^*\mathbb{R}^n$, $t\mapsto\gamma(t)$, arriving to the zero-section, such that $\dot\gamma=d\gamma/dt\in L^2:=L^2((0,T),\mathbb{R}^{2n})$. The following is self-evident.

Lemma 1 (linear structure of Γ): The set Γ has a natural structure of linear space, and then $T_\gamma\Gamma=\Gamma$, for all $\gamma\in\Gamma$.

An equivalent way to describe the curves of Γ is to assign the q-projection of the end point, $q(T)\in\mathbb{R}^n$, and the velocity $\dot{\gamma}$, for each $s\in[0,T]$, of the curve γ by means of a function $\phi\in L^2$.

Lemma 2 (the bijection g): For all $\phi\in L^2$ *set* $\phi=(\phi_q,\phi_p)$. The map g,

$$g:\mathbb{R}^n\times L^2\to\Gamma,\quad (q(T),\phi)\mapsto g(q(T),\phi)(s):=\left(q(T)-\int_s^T\phi_q(r)dr,\int_0^s\phi_p(r)dr\right),$$

is a bijection.

Proof: Let $\gamma(\cdot)=(q(\cdot),p(\cdot))\in\Gamma$, since $(\dot{q}(s),\dot{p}(s))\in L^2$, then $\gamma(s)=g(q(T),(\dot{q}(s),\dot{p}(s)))$. This proves that g is surjective.

Now, let $q(T)$, $\overline{q}(T)\in\mathbb{R}^n$ ϕ, $\overline{\phi}\in L^2$, such that $g(q(T),\phi)=g(\overline{q}(T),\overline{\phi})$; in other words,

$$\left(q(T)-\int_s^T\phi_q(r)dr,\int_0^s\phi_p(r)dr\right)=\left(\overline{q}(T)-\int_s^T\overline{\phi}_q(r)dr,\int_0^s\overline{\phi}_p(r)dr\right).$$

Thus, for all $s\in[0,T]$ one has

$$\overline{q}(T)-q(T)-\int_s^T(\overline{\phi}_q(r)-\phi_q(r))dr=0,\quad \int_0^s(\overline{\phi}_p(r)-\phi_p(r))dr=0^*,$$

hence

$$\overline{q}(T)=q(T),\quad \overline{\phi}_q=\phi_q,\quad \overline{\phi}_p=\phi_p.$$

This shows that g is injective.

Let $\{\Phi^s\}_{s\in[0,T]}$ be a Hamiltonian isotopy of $T^*\mathbb{R}^n$, where $H=H(s,q,p)$, $s\in[0,T]$, is the Hamiltonian generating it:

$$\Phi^s=\Phi_{X_H}^{s,0},\quad \Phi_{X_H}^{0,0}=\mathrm{id}_{\mathbb{R}^{2n}}.$$

We remind that the flow Φ^s transforms Lagrangian manifolds into Lagrangian manifolds: $\Lambda_s=\Phi^s(\Lambda_0)$. Our hypothesis is

$$\Lambda=\Lambda_T=\Phi^T(\Lambda_0),$$

where $\Lambda_0=\{(q,p)\in T^*\mathbb{R}^n:q\in\mathbb{R}^n,p=0\}$ is the *zero-section* of $T^*\mathbb{R}^n=\mathbb{R}^{2n}$. Set

$$\mathbb{E}=\begin{pmatrix}\mathbb{O}&-\mathbb{I}\\ \mathbb{I}&\mathbb{O}\end{pmatrix},\quad \gamma=\begin{pmatrix}p\\ q\end{pmatrix},\quad \dot{\gamma}=\begin{pmatrix}\dot{p}\\ \dot{q}\end{pmatrix},\quad \nabla H=\begin{pmatrix}\dfrac{\partial H}{\partial p}\\ \dfrac{\partial H}{\partial q}\end{pmatrix},$$

the Hamilton's equations related to $X_H=\mathbb{E}\nabla H$,

$$\dot{p}=-\frac{\partial H}{\partial q},\quad \dot{q}=\frac{\partial H}{\partial q},$$

can be written in the form $\dot{\gamma}-\mathbb{E}\nabla H=0$, or, equivalently,

$$\mathbb{E}\dot{\gamma}+\nabla H=0.$$

The map,

$$A:\Gamma\to\mathbb{R},\quad \gamma\mapsto A|\gamma|:=\int_0^T[p(s)\cdot\dot q(s)-H(s,q(s),p(s))]ds,$$

is the Action Functional of the Hamilton–Helmholtz variational principle related to the Hamiltonian H.

Lemma 3 (Hamilton–Helmholtz): A curve $\gamma\in\Gamma$ solves the Hamilton's equations if and only if

$$(\delta\text{:Gâteaux derivative})\quad \delta A[\gamma]\delta\gamma=0,\quad \forall\,\delta\gamma\in\Gamma\ \ \textit{such that}\ \ \delta q(T)=0.$$

Proof: By a direct computation: $\forall\,\delta\gamma\in T_\gamma\Gamma=\Gamma$,

$$\begin{aligned}
\delta A|\gamma|\delta\gamma&=\frac{dA}{d\lambda}(\gamma+\lambda\,\delta\gamma)|_{\lambda=0}\\
&=\frac{DA}{D\gamma}\delta\gamma\\
&=\int_0^T\left(\delta p\cdot\dot q+p\cdot\delta\dot q-\frac{\partial H}{\partial q}\cdot\delta q-\frac{\partial H}{\partial p}\cdot\delta p\right)ds\\
&=\int_0^T\left(\dot q-\frac{\partial H}{\partial p}\right)\cdot\delta p\ \ ds-\int_0^T\frac{\partial H}{\partial q}\cdot\delta q\ \ ds+\int_0^T p\cdot\delta\dot q\ \ ds\\
&=\int_0^T\left(\dot q-\frac{\partial H}{\partial p}\right)\cdot\delta p\ \ ds-\int_0^T\frac{\partial H}{\partial q}\cdot\delta q\ \ ds+p\cdot\delta q\Big|_0^T-\int_0^T\dot p\cdot\delta q\ \ ds\\
&=\int_0^T\left(\dot q-\frac{\partial H}{\partial p}\right)\cdot\delta p\ \ ds-\int_0^T\left(\dot p+\frac{\partial H}{\partial q}\right)\cdot\delta q\ \ ds+p(T)\cdot\delta q(T)\\
&=-\int_0^T(\mathbb{E}\dot\gamma+\nabla H)\cdot\delta\gamma\ \ ds+p(T)\cdot\delta q(T).
\end{aligned}$$

□

Lemma 4 below allows us to regard the Action functional A as a generating function of Λ_T with infinite parameters (in L^2).

Lemma 4 (∞-parameters generating function): The map,

$$W:=A\circ g:\mathbb{R}^n\times L^2\to\mathbb{R},\quad (q(T),\phi)\mapsto W(q(T),\phi):=A\circ g(q(T),\phi)=A[g(q(T),\phi)],$$

generates Λ_T, that is,

$$\Lambda_T=\left\{(q(T),p(T)):\ \ q(T)\in\mathbb{R}^n,\quad p(T)=\frac{\partial W}{\partial q(T)}(q(T),\phi),\quad \frac{DW}{D\phi}(q(T),\phi)=0\right\}.$$

Proof: Let us write explicitly W:

$$W(q(T),\phi)=\int_0^T\left[\phi_q(s)\int_0^s\phi_p(r)dr-H\left(s,q(T)-\int_s^T\phi_q(r)dr,\int_0^s\phi_p(r)dr\right)\right]ds;$$

then, by writing $DW/D\phi$ the Gateaux derivative on infinite-dimensional spaces,

$$\frac{DW}{D\phi}\delta\phi=\int_0^T\Bigg[\delta\phi_q(s)\int_0^s\phi_p(r)dr+\phi_q(s)\int_0^s\delta\phi_q(r)dr-\frac{\partial H}{\partial q}\Bigg(-\int_s^T\delta\phi_q(r)dr\Bigg)$$
$$-\frac{\partial H}{\partial p}\int_0^s\delta\phi_p(r)dr\Bigg]ds.$$

Let us rewrite the first term. Preliminarily, one has

$$\frac{d}{ds}\Bigg(\int_0^s\phi_p(r)dr\int_T^s\delta\phi_q(r)dr\Bigg)=\phi_p(s)\int_T^s\delta\phi_q(r)dr+\delta\phi_q(s)\int_0^s\phi_p(r)dr;$$

by integrating from $s=0$ to $s=T$ one obtains

$$0=\Bigg(\int_0^s\phi_p(r)dr\int_T^s\delta\phi_q(r)dr\Bigg)\Bigg|_0^T=\int_0^T\Bigg(\delta\phi_q(s)\int_0^s\phi_p(r)dr-\phi_p(s)\int_s^T\delta\phi_q(r)dr\Bigg)ds,$$

and hence

$$\int_0^T\delta\phi_q(s)\int_0^s\phi_p(r)dr\ \ ds=\int_0^T\phi_p(s)\int_s^T\delta\phi_q(r)dr\ \ ds.$$

Using this result to rewrite the expression of $DW/D\phi$ we obtain

$$\frac{DW}{D\phi}\delta\phi=\int_0^T\Bigg[\phi_p(s)\int_s^T\delta\phi_q(r)dr+\phi_q(s)\int_0^s\delta\phi_p(r)dr-\frac{\partial H}{\partial q}\Bigg(-\int_s^T\delta\phi_q(r)dr\Bigg)$$
$$-\frac{\partial H}{\partial p}\int_0^s\delta\phi_p(r)dr\Bigg]ds$$
$$=\int_0^T\Bigg[-\Bigg(\phi_p(s)+\frac{\partial H}{\partial q}\Bigg)\Bigg(-\int_s^T\delta\phi_q(r)dr\Bigg)-\Bigg(-\phi_q(s)+\frac{\partial H}{\partial p}\Bigg)\int_0^s\delta\phi_p(r)dr\Bigg]ds$$
$$=-\int_0^T(\mathbb{E}\dot\gamma+\nabla H)\delta\gamma\ \ ds,$$

where $\delta\gamma=(-\int_s^T\delta\phi_q(r)dr,\int_0^s\delta\phi_p(r)dr)\in\Gamma$. Hence, one obtains that

$$\frac{\partial W}{\partial q(T)}\Bigg|_{DW/D\phi=0}=\int_0^T\Bigg(-\frac{\partial H}{\partial q}\Bigg)ds=\int_0^T\dot p(s)ds=p(T).$$

Fourier Expansions and Fixed Point: For every $\phi\in L^2$ let us consider the Fourier expansion,

$$\phi(s)=\sum_{k\in\mathbb{Z}}\phi_k e^{i(2\pi k/T)s}.$$

For each fixed $N\in\mathbb{N}$ let us consider the projection maps on the basis $\{e^{i(2\pi k/T)s}\}_{k\in\mathbb{Z}}$ of L^2,

$$\mathbb{P}_N\phi(s):=\sum_{|k|\leqslant N}\phi_k e^{i(2\pi k/T)s},\quad \mathbb{Q}_N\phi(s):=\sum_{|k|>N}\phi_k e^{i(2\pi k/T)s}.$$

Clearly,

$$\mathbb{P}_N L^2\oplus\mathbb{Q}_N L^2=L^2,$$

and for $\phi \in L^2$ we will write $u := \mathbb{P}_N \phi$ and $v := \mathbb{Q}_N \phi$.

Remark: The idea to prove the existence of a generating function with finitely many parameters is to show that the "infinite" tail $\mathbb{Q}_N \dot{\gamma}$ of $\dot{\gamma}$, for γ a curve in Γ solving Hamilton's equations, can be dropped out from the expression of the Action functional; in other words, γ is completely determined by a suitable choice of its "finite" part $\mathbb{P}_N \dot{\gamma}$, for suitable (large) $N \in \mathbb{N}$.

Lemma 5 (Lipschitz): For fixed $q(T) \in \mathbb{R}^n$ and $u \in \mathbb{P}_N L^2$, the map,

$$\mathbb{Q}_N L^2 \to (\Gamma, \|\cdot\|_{L^2}), \quad v \mapsto g(q(T), u+v),$$

is Lipschitz with

$$\mathrm{Lip}(g) \leqslant \frac{T}{2\pi N}(1+\sqrt{2N}).$$

Proof: In some more details, the above map is

$$v \mapsto \left(q(T) - \int_s^T (u_q + v_q)(r)dr, \int_0^s (u_p + v_p)(r)dr \right).$$

For each v_1, $v_2 \in \mathbb{Q}_N L^2$, let us consider the Fourier expansion:

$$v := v_2 - v_1 = \sum_{|k|>N} v_k e^{i(2\pi k/T)s}, \quad v_k = (q_k, p_k).$$

We compute $g(q(T), u+v_2) - g(q(T), u+v_1)$:

$$\begin{aligned}
g(v_2) - g(v_1) &= \left(-\int_s^T (v_{q2} - v_{q1})(r)dr, \int_0^s (v_{p2} - v_{p1})(r)dr \right) \\
&= \left(-\int_s^T \sum_{|k|>N} q_k e^{i(2\pi k/T)r} dr, \int_0^s \sum_{|k|>N} p_k e^{i(2\pi k/T)r} dr \right) \\
&= T\left(\sum_{|k|>N} \frac{q_k e^{i(2\pi k/T)r}}{i2\pi k}\bigg|_T^s, \quad \sum_{|k|>N} \frac{p_k e^{(2\pi k/T)r}}{i2\pi k}\bigg|_0^s \right) \\
&= T\left(\sum_{|k|>N} \frac{(q_k, p_k)}{i2\pi k} e^{i(2\pi k/T)s} - \sum_{|k|>N} \frac{(q_k, q_k)}{i2\pi k} \right) \\
&= T\left(\sum_{|k|>N} \frac{v_k}{i2\pi k} e^{i(2\pi k/T)s} - \sum_{|k|>N} \frac{v_k}{i2\pi k} \right).
\end{aligned}$$

Hence the estimate of $\|g(q(T), u+v_2) - g(q(T), u+v_1)\|_{L^2}$ follows:

$$\begin{aligned}
\|g(v_2) - g(v_1)\|_{L^2} &\leqslant T\left(\left\| \sum_{|k|>N} \frac{v_k}{i2\pi k} e^{i(2\pi k/T)t} \right\|_{L^2} + \left\| \sum_{|k|>N} \frac{v_k}{i2\pi k} \right\|_{L^2} \right) \\
&\leqslant T\left(\frac{1}{2\pi N}\|v\|_{L^2} + \|\langle v, \mathbb{Q}_N \,\mathrm{iD}_{[0,T]} \rangle_{L^2}\|_{L^2} \right) \\
&\leqslant T\left(\frac{1}{2\pi N}\|v\|_{L^2} + \|v\|_{L^2} \|\mathbb{Q}_N \,\mathrm{id}_{[0,T]}\|_{L^2} \right) \\
&\leqslant T\left(\frac{1}{2\pi N}\|v\|_{L^2} + \frac{1}{2\pi}\sqrt{\frac{2}{N}}\|v\|_{L^2} \right)
\end{aligned}$$

$$\leqslant \frac{T}{2\pi N}(1+\sqrt{2N})\|v\|_{L^2}.$$

Lemma 6 (contraction map): Suppose that

$$\sup_{y\in\mathbb{R}^{2n}s\in[0,T]}|\nabla^2_{yy}H| = C < +\infty \quad (y := (q,p)).$$

For N large enough: $TC/2\pi N(1+\sqrt{2N})<1$, for every fixed $q(T)\in\mathbb{R}^n$ and $u\in\mathbb{P}_N L^2([0,T|;\mathbb{R}^{2n})$ the map:

$$\mathbb{Q}_N L^2([0,T];\mathbb{R}^{2n})\to\mathbb{Q}_N L^2([0,T];\mathbb{R}^{2n}),$$

$$v\to\mathbb{Q}_N\mathbb{E}\nabla H(g(q(T),u+v)),$$

is a contraction map.

Proof:

$$\begin{aligned}&\|\mathbb{Q}_N\mathbb{E}\nabla H(g(q(T),u+v_2))-\mathbb{Q}_N\mathbb{E}\nabla H(g(q(T),u+v_1))\|_{L^2}\\ &\leqslant \sup_{y\in\mathbb{R}^{2n}s\in[0,T]}|\nabla^2_{yy}H|\|g(q(T),u+v_2)-g(q(T),u+v_1)\|_{L^2}\\ &\leqslant \frac{TC}{2\pi N}(1+\sqrt{2N})\|v_2-v_1\|_{L^2}.\end{aligned}$$

□

By the Banach–Caccioppoli theorem there exists one and only one fixed point $f(q(T),u)$ for the above contraction map. By standard arguments one can easily see that this fixed point depends smoothly on $q(T)$ and u. In the formula, $f(q(T),u)$ is such that

$$f(q(T),u)=\mathbb{Q}_N\mathbb{E}\nabla H(g(q(T),u+f(q(T),u))).$$

It is crucial to observe that, if we solve the *finite* (say, algebraic) equation for u,

$$u=\mathbb{P}_N\mathbb{E}\nabla H(g(q(T),u+f(q(T),u))),$$

and we sum the last two formulas, then the resulting equation,

$$\dot\gamma=\mathbb{E}\nabla H(\gamma),$$

implies that the curve $\gamma=g(q(T),u+f(q(T),u))$ *solves* the Hamilton canonical differential equations, and it is starting from the zero section (so that $\gamma\in\Gamma$). Furthermore, we point out that $\dim(\mathbb{P}_N L^2([0,T];\mathbb{R}^{2n}))=2n(2N+1):=k(n,N)$.

To conclude the proof of Theorem 1 we need to show the following.

Lemma 7 (the finite-parameters generating function): The following function:

$$S:\mathbb{R}^n\times\mathbb{R}^{k(n,N)}\to\mathbb{R},$$

$$(q(T),u)\to S(q(T),u):=A\circ g(q(T),u+f(q(T),u))=W(q(T),u+f(q(T),u)),$$

is a global generating function for $\Lambda=\Phi^T(\Lambda_0)$.

Proof: We write

$$\frac{\partial S}{\partial u}(q(T),u)=\frac{DW}{D\phi}\left(\frac{D\phi}{Du}+\frac{D\phi}{Dv}\frac{Df}{Du}\right)$$

(note that $D\phi/Du$ and $D\phi/Dv$ are the projectors $\mathbb{P}_N$ and $\mathbb{Q}_N$, respectively),

$$\frac{\partial S}{\partial u}(q(T),u) = -\int_0^T [\mathbb{P}_N(\mathbb{E}\dot\gamma + \nabla H(\gamma))]\big|_{\gamma = g(q(T),u+f(q(T),u))} ds$$
$$-\int_0^T [\mathbb{Q}_N(\mathbb{E}\dot\gamma + \nabla H(\gamma))]\big|_{\gamma = g(q(T),u+f(q(T),u))} \frac{Df}{Du} ds.$$

By the very construction of $f(q(T),u)$ the second integral vanishes, so

$$\frac{\partial S}{\partial u}(q(T),u) = -\int_0^T [\mathbb{P}_N(\mathbb{E}\dot\gamma + \nabla H(\gamma))]\big|_{\gamma = g(q(T),u+f(q(T),u))} ds,$$

so that

$$\frac{\partial S}{\partial u}(q(T),u) = 0 \quad \text{is equivalent to} \quad [\mathbb{P}_N(\mathbb{E}\dot\gamma + \nabla H(\gamma))]\big|_{\gamma = g(q(T),u+f(q(T),u))} = 0.$$

On the other hand,

$$\frac{\partial S}{\partial q(T)} = \frac{\partial W}{\partial q(T)} + \frac{DW}{D\phi}\frac{D\phi}{Dv}\frac{Df}{Dq(T)},$$

$$\frac{\partial S}{\partial q(T)} = \frac{\partial W}{\partial q(T)} - \int_0^T [\mathbb{Q}_N(\mathbb{E}\dot\gamma + \nabla H(\gamma))]\big|_{\gamma = g(q(T),u+f(u(T),u))} \frac{Df}{Dq(T)} ds;$$

hence

$$\frac{\partial S}{\partial q(T)}(q(T),u) = \frac{\partial W}{\partial q(T)}(q(T),\phi)\big|_{\phi = u+f(q(T),u)}.$$

Now it is easy to conclude that the pair $(q(T),\phi) \in \mathbb{R}^n \times L^2$ satisfies

$$p(T) = \frac{\partial W}{\partial q(T)}(q(T),\phi),$$

$$0 = \frac{DW}{D\phi}(q(T),\phi),$$

if and only if the pair $(q(T),u) \in \mathbb{R}^n \times \mathbb{R}^{k(n,N)}$, where

$$\phi = u + f(q(T),u), \quad \text{so that } u = \mathbb{P}_N\phi,$$

satisfies

$$p(T) = \frac{\partial S}{\partial q(T)}(q(T),u),$$

$$0 = \frac{\partial S}{\partial u}(q(T),u).$$

III. THE GLOBAL FINITE ENVELOPE STRUCTURE OF THE PHASE FRONT SETS

Let us recall the general evolution problem, $q \in \mathbb{R}^n$,

$$\frac{\partial S}{\partial t}(t,q)+H\left(t,q,\frac{\partial S}{\partial q}(t,q)\right)=0,$$

$$S(t,q)|_{t=0}=\sigma(q),$$

where, e.g., we may suppose the initial data $\sigma(q)$ to be a suitable regularization of a Heaviside function defined around a one-co-dimensional surface $\Sigma \subset \mathbb{R}^n$ (a smooth Riemann problem), as could be a model to propagation phenomena starting from (some neighborhood of) Σ. The canonical transformation $(q,p) \to (\tilde{q},\tilde{p})$ generated by the function

$$F(q,\tilde{q})=\tilde{p}\cdot q+\sigma(q),$$

is given by

$$p=\frac{\partial F}{\partial q}(q,\tilde{p}):\ \ p=\tilde{p}+\frac{\partial \sigma}{\partial q}(q),$$

$$\tilde{q}=\frac{\partial F}{\partial \tilde{p}}(q,\tilde{p}):\ \ \tilde{q}=q.$$

The transformed Hamiltonian function of $H(q,p,t)$ is

$$K(\tilde{q},\tilde{p},t)=H\left(\tilde{q},\tilde{p}+\frac{\partial \sigma}{\partial q}(\tilde{q}),t\right),$$

so that the characteristics of X_K starting at $t=0$ from the zero-section $\{(\tilde{q},0)\}$ of T^*Q correspond to the characteristics of X_H starting from the initial Lagrangian submanifold $\Lambda_0 = \{(q,\partial\sigma/\partial q(q))\}$. Let us now consider the Action Functional of the Hamilton–Helmholtz variational principle related to the Hamiltonian function K,

$$A[\gamma] := \int_0^T [\tilde{p}(s)\cdot \dot{\tilde{q}}(s)-K(\tilde{q}(s),\tilde{p}(s),s)]ds,$$

defined for $\gamma \in \Gamma = \{(\tilde{q}(\cdot),\tilde{p}(\cdot)) \in H^{1,2}([0,T],\mathbb{R}^{2n}):\tilde{p}(0)=0\}$. We have seen above that A is a global generating function for $\hat{\Lambda}_T = \{(\tilde{q}(T),\tilde{p}(T))\}$ with infinite parameters. If the condition

$$\sup_{y\in\mathbb{R}^{2n},t\in[0,T]}|\nabla^2_{yy}K(y,t)|<+\infty \quad (y=(\tilde{q},\tilde{p})\in\mathbb{R}^{2n})$$

holds, then Theorem 1 allows us to describe the generalized Envelope at the time $t=T$, i.e. Λ_T, by a global generating function $\tilde{S}(\tilde{q},u_1,\ldots,u_N)$ with *finite* parameters $N<+\infty$. Finally, by turning from $(\tilde{q},\tilde{p})$ to the original setting (q,p), the Lagrangian submanifold is now generated by (check the structure of the canonical transformation above)

$$S(q,u)=\sigma(q)+\tilde{S}(q,u).$$

Note that the above condition on $\nabla^2_{yy}K$ involves both H and σ.

IV. THE GLOBAL GENERATING FUNCTION FOR THE SPACE–TIME SOLUTION

Now we consider the set of curves (as above),

$$\Gamma := \{\gamma(\cdot)=(q(\cdot),p(\cdot)) \in H^{1,2}([0,T],\mathbb{R}^{2n}):p(0)=0\},$$

the *new* functional,

$$\hat{A}:[0,T]\times\Gamma\to\mathbb{R},\quad (t,\gamma(\cdot))\mapsto\hat{A}[t,\gamma(\cdot)]:=\int_0^t[p(r)\cdot\dot{q}(r)-H(r,q(r),p(r))]dr,$$

and the *new* bijection:

$$\hat{g}:[0,T]\times\mathbb{R}^n\times L^2([0,T],\mathbb{R}^{2n})\to[0,T]\times\Gamma,$$

$$(t,q,\phi)\mapsto\hat{g}(t,q,\phi)=(t,\gamma(\cdot)),\quad \gamma(s)=(q(s),p(s)):=\left(q-\int_s^t\phi_q(r)dr,\int_0^S\phi_p(r)dr\right).$$

The second value of the map $\hat{g}(t,q,\phi)$ is the curve $\gamma(\cdot)=(q(\cdot),p(\cdot))$ which is (*i*) starting from $p(0)=0$, such that (*ii*) $\dot{\gamma}(\cdot)=\phi(\cdot)$, and (*iii*) $q(t)=q$.

Consider the infinite-parameters function:

$$\hat{W}:=\hat{A}\circ\hat{g}:[0,T]\times\mathbb{R}^n\times L^2\to\mathbb{R},$$

$$(t,q,\phi)\mapsto\hat{W}(t,q,\phi):=\hat{A}\circ\hat{g}(t,q,\phi).$$

We will prove that $\hat{W}$ generates $\hat{\Lambda}:=\cup_{t\in[0,T]}\Lambda_t$, the Lagrangian submanifold of $T^*([0,T]\times\mathbb{R}^n)$; i.e., that

$$\hat{\Lambda}=\left\{(t,q;\tau,p):t\in[0,T],\ q\in\mathbb{R}^n,\ \tau=\frac{\partial\hat{W}}{\partial t}(t,q,\phi),\ p=\frac{\partial\hat{W}}{\partial q}(t,q,\phi),\quad \frac{D\hat{W}}{D\phi}(t,q,\phi)=0\right\},$$

is the geometric solution of the Hamilton–Jacobi problem,

$$\frac{\partial S}{\partial t}+H\left(t,q,\frac{\partial S}{\partial q}\right)=0,\quad S(0,q)=0.$$

In order to prove this, we write explicitly $\hat{W}$:

$$\hat{W}(t,q,\phi)=\int_0^t\left[\int_0^s\phi_p(r)dr\cdot\phi_q(s)-H\left(s,q-\int_s^t\phi_q(r)dr,\int_0^s\phi_p(r)dr\right)\right]ds;$$

then, for $D\hat{W}/D\phi=0$, we compute $\partial\hat{W}/\partial q$:

$$\frac{\partial\hat{W}}{\partial q}=-\int_0^t\frac{\partial H}{\partial q}ds=\int_0^t\dot{p}(s)ds=p(t).$$

Finally, we compute, $\partial\hat{W}/\partial t$:

$$\frac{\partial \hat{W}}{\partial t}(t,q,\phi)=p(t)\cdot\dot{q}(t)-H\left(t,q,\frac{\partial \hat{W}}{\partial q}\right)+\int_0^t \frac{\partial H}{\partial q}\left(s,q-\int_s^t \phi_q(r)dr,\int_0^s \phi_p(r)dr\right)\phi_q(t)ds$$

$$=p(t)\cdot\dot{q}(t)-H\left(t,q,\frac{\partial \hat{W}}{\partial q}\right)+\int_0^t \frac{\partial H}{\partial q}ds\dot{q}(t)$$

$$=\frac{\partial \hat{W}}{\partial q}\dot{q}-H-\frac{\partial}{\partial q}\left(\int_0^t [p\cdot\dot{q}-H]d\tau\right)\dot{q}(t)$$

$$=-H\left(t,q,\frac{\partial \hat{W}}{\partial q}\right).$$

Therefore, $\hat{W}(t,q,\phi)$ is a global generating function, with infinite parameters ϕ, for the geometric solution $\hat{\Lambda}$ within $T^*([0,T]\times\mathbb{R}^n)$.

Now, with minor changes, the reduction machinery used in the preceding sections still works for $\hat{W}$, and, by means of the trick of Sec. III, we obtain global generating functions for general initial problems (for nontrivial σ). In some more detail, for fixed $N\in\mathbb{N}$, $(t,q)\in[0,T]\times\mathbb{R}^n$, and $u(\cdot)\in\mathbb{P}_N L^2([0,T];\mathbb{R}^{2n})$, the map,

$$\mathbb{Q}_N L^2\to(\Gamma,\|\cdot\|_{L^2}),$$

$$v(\cdot)\mapsto\hat{g}(t,q,u(\cdot)+v(\cdot)),$$

is Lipschitz with constant

$$\frac{T}{2\pi N}(1+\sqrt{2N}),$$

and the theory goes in the same way above, so, lastly, we can determine a global generating function with finite parameters $S(t,q,u)$ for $\hat{\Lambda}$, which is solving, for all $(t,q)\in[0,T]\times\mathbb{R}^n$ and for some $u\in\mathbb{R}^k$,

$$\frac{\partial S}{\partial t}(t,q,u)+H\left(t,q,\frac{\partial S}{\partial q}(t,q,u)\right)=0,\quad S(0,q,u)=0,\quad \frac{\partial S}{\partial u}(t,q,u)=0.$$

Now, for more general initial data $\sigma\neq 0$, we may argue in a strictly similar way as done in Sec. III.

More precisely, consider coordinates $\hat{t},\hat{q},\hat{p}$ and let now $S(\hat{t},\hat{q},u)$ be a generating $\hat{\Lambda}$, geometrical solution of H–J starting, at $\hat{t}=0$, from the zero-section $(\hat{p}\equiv 0)$ for the Hamiltonian $K(\hat{t},\hat{q},\hat{p}):=H(\hat{t},\hat{q},\hat{p}+(\partial\sigma/\partial q)(\hat{q}))$ where $\nabla^2 K$ are bounded; moreover, let us consider the canonical transformation $\Psi:(t,q;\tau,p)\mapsto(\hat{t},\hat{q};\hat{\tau},\hat{p})$ generated by the function

$$G(t,q,\hat{\tau},\hat{p})=\hat{\tau}t+\hat{p}\cdot q+\sigma(q),$$

$$\tau=\frac{\partial G}{\partial t}:\quad \tau=\hat{\tau},$$

$$p=\frac{\partial G}{\partial q}:\quad p=\hat{p}+\frac{\partial\sigma}{\partial q}(q),$$

$$\hat{t}=\frac{\partial G}{\partial\hat{\tau}}:\quad \hat{t}=t,$$

$$\hat{q}=\frac{\partial G}{\partial \hat{p}}: \quad \hat{q}=q.$$

If we let $\hat{S}(\hat{t},\hat{q},u)$ be the finite global generating function of $\hat{\Lambda}$, it is an easy matter to see that the Lagrangian submanifold,

$$\Lambda=\Psi^{-1}(\hat{\Lambda}),$$

is the geometrical solution of the $H-J$ equation $\tau+H=0$, starting, at $t=0$, from $\mathrm{im}(d\sigma)$, and we note that a global generating function for it is given by

$$S(t,q,u)=\hat{S}(t,q,u)+\sigma(q).$$

(Received 11 April 2001; accepted for publication 10 October 2001)

Two Harmonic Oscillators (isotropic and nonisotropic 2:1) are studied on the two-dimensional sphere S^2 and the hyperbolic plane H^2. Both systems are integrable and super-integrable with constants of motion quadratic in the momenta. These properties are shown to derive from a complex factorization for the constants of motion, which holds for arbitrary values of the curvature κ, and the dynamics of the Euclidean harmonic 1:1 and 2:1 oscillators is directly recovered for $\kappa=0$. The harmonic oscillators on either the standard unit sphere (radius $R=1$) or the unit Lobachewski plane (''radius'' $R=1$) appear as the particular values of the κ-dependent potentials for the values $\kappa=1$ and $\kappa=-1$. Finally a particular potential is proposed for representing the general spherical (hyperbolic) $n:1$ anisotropic harmonic oscillator on a two-dimensional manifold of constant curvature. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1423402]

I. INTRODUCTION

Dynamics on a nonflat configuration space Q remains as a very partially studied subject, even in the simplest two-dimensional constant curvature cases where Q is either the sphere S^2 or the hyperbolic (Lobachewski) plane H^2 (see Refs. 1, 2, 3 for the case of spherical central potentials). In fact, there exist some noncentral but rather simple problems, e.g., the nonisotropic harmonic oscillators, still awaiting to be studied in manifolds of nonzero curvature.

It is well known that integrable systems, in the classical sense of Arnold–Liouville, must have as many independent constants of motion in involution as degrees of freedom. On the other hand, a system is called super-integrable if it is integrable and, in addition, possesses more independent first integrals than degrees of freedom. It is known that these additional first integrals give rise to a higher degree of regularity in the phase space (e.g., the existence of periodic orbits) since the trajectories are restricted to submanifolds with less than n dimensions. In particular, if a system with n degrees of freedom possesses $2n-1$ independent first integrals, then it is called maximally super-integrable. The Kepler problem, the harmonic oscillator and the Calogero–Moser system are some cases of this very particular class of systems (for other super-integrable systems see Refs. 4–15 and references therein).

In a recent paper[16] the existence of super-integrable systems on the two-dimensional sphere S^2 and on the hyperbolic plane H^2 was analyzed. The study was focused on the quadratic super-integrability, that is, on the existence of systems that, besides the energy, admit two further independent constants of motion quadratic in the velocities (quadratic super-integrability is related with super-separability in the sense of Ref. 14). Some of the spherical (hyperbolic) potentials obtained by this approach were already known, but some others were apparently new. Particularly

a)Electronic mail: mfran@posta.unizar.es
b)Electronic mail: santander@fta.uva.es

interesting was the existence of a potential that seems to represent the spherical (hyperbolic) version of the Euclidean nonisotropic 2:1 oscillator $4x^2+y^2$ or x^2+4y^2 (for other Euclidean nonisotropic oscillators the additional constant of motion is not quadratic, but higher order in momenta). We recall that the spherical version of the central oscillator was studied by Higgs in Ref. 2 and is known as the Higgs oscillator.

The main objective of this article is to develop a deeper analysis of these two spherical (hyperbolic) oscillators: the central Higgs oscillator and noncentral 2:1 oscillator. We will show, as a basic point, that these two systems are endowed with the same fundamental properties as the standard Euclidean one. This means that those properties to be considered as fundamental (e.g., the existence of constants of motion, super-integrability, complex factorization) are preserved under non-Euclidean deformations. Conversely, the Euclidean Oscillator can be considered as a very particular case (the flat limit) of the general ''curved'' Harmonic Oscillator. We will carry out this approach by considering the curvature as a parameter.

The article is organized as follows: In Sec. II we discuss the fundamental properties of the Euclidean Harmonic Oscillator related with the existence of super-integrability. We are interested in obtaining non-Euclidean deformations of these Euclidean properties. Section III is devoted to the geometry of the Riemannian two-dimensional (2-D) manifolds of constant curvature. We first discuss some properties of the curvilinear systems of coordinates and then we introduce a formalism with the curvature κ as a parameter (this formalism was already used in Ref. 16). This is made so that the Euclidean geometry is directly recovered for $\kappa=0$.

In Secs. IV and V we study the integrability and the super-integrability of both oscillators (isotropic central oscillator and non-isotroipc 2:1 oscillator) in the the sphere S^2 and in the hyperbolic plane H^2 with curvature κ (these two sections have been written in such a way that can be read independently). First, in Sec. IV, the study is presented in ''geodesic polar'' coordinates, and then, in Sec. V, we will obtain the results by using ''geodesic parallel'' coordinates. The dynamics in the Euclidean plane (studied in Sec. II) appears as a very particular case. The harmonic oscillators on either the standard unit sphere (radius $R=1$) or the unit Lobachewski plane (''radius'' $R=1$) correspond to the values $\kappa=1$ and $\kappa=-1$. Finally, in Sec. VI we provide a discussion and an outlook to the results obtained.

II. SUPER-INTEGRABILITY OF THE EUCLIDEAN HARMONIC OSCILLATOR

The two-dimensional harmonic oscillator,

$$L_{\mathrm{HO}}=(\tfrac{1}{2})(v_x^2+v_y^2)-(\tfrac{1}{2})(\omega_1^2x^2+\omega_2^2y^2),$$

is a trivially integrable system, since it is a direct sum of one-degree of freedom systems and, therefore, it has the two one-degree of freedom energies, $I_1=E_x$ and $I_2=E_y$, as involutive integrals. If the oscillator is isotropic then it has the angular momentum as an additional integral of motion. If the oscillator is nonisotroipc then the angular momentum is not preserved but in the very particular case in which the quotient of the two frequencies is rational the system has a third additional nonlinear integral.

In geometric terms the phase space is foliated by tori and every integral curve is a curve with constant slope on a torus. The slope of the curve is determined by the ratio ω_2/ω_1. Thus, if this ratio is irrational the corresponding curve will be dense on the torus.[17,18] If this ratio is rational then the orbit becomes closed and the motion will be periodic.

The super-integrability of the rational case, $\omega_1=n_1\omega_0$, $\omega_2=n_2\omega_0$, with integers n_1,n_2, can be approached by using a complex formalism.[18,19] The following proposition states the existence of the additional constant of motion and give a method for obtaining it explicitly.

Proposition 1: Let J_1, J_2, be the following two functions:

$$J_1=v_x+\mathrm{i}n_1\omega_0x, \quad J_2=v_y+\mathrm{i}n_2\omega_0y.$$

Then the complex function J_{12} defined as

$$J_{12}=J_1^{n_2}(J_2^*)^{n_1}$$

is a constant of motion.

Proof: The time-evolution of the functions J_1, J_2, is given by

$$\frac{d}{dt}J_1=-\mathrm{i}\,n_1\omega_0 J_1 \quad \frac{d}{dt}J_2=-\mathrm{i}\,n_2\omega_0 J_2.$$

Hence we have

$$\frac{d}{dt}J_{12}=n_2J_1^{(n_2-1)}(J_2^*)^{n_1}\dot{J}_1+n_1J_1^{n_2}(J_2^*)^{(n_1-1)}\dot{J}_2^*=J_1^{n_2}(J_2^*)^{n_1}(\mathrm{i}\,\omega_0)(n_2n_1-n_1n_2)=0. \quad (1)$$

Therefore J_{12} is a constant of motion. Notice that J_{12}, which can be considered as coupling the two degrees of freedom, depends on the relation between ω_2 and ω_1. As stated above, J_{12} is well defined as a constant of motion only if the quotient ω_2/ω_1 is rational.

Since J_{12} is a complex function it determines two different real first integrals,

$$I_3=\mathrm{Im}(J_{12}), \quad I_4=\mathrm{Re}(J_{12}),$$

which are polynomials in the velocities (momenta) of degree n_1+n_2-1 and n_1+n_2, respectively. Only one of these two functions must be considered as fundamental, because I_1,I_2,I_3,I_4 are functionally dependent (I_3 is independent of I_1 and I_2, but I_4 is a dependent function of I_1, I_2 and I_3).

Next we give the expressions of I_3 and I_4 for the first two rational cases.

(i) Isotropic case $\omega_1=\omega_2=\omega_0$:

$$I_4=\mathrm{Re}(J_{12})=v_xv_y+\omega_0^2xy, \quad I_3=\mathrm{Im}(J_{12})=\omega_0(xv_y-yv_x); \quad (2)$$

$\mathrm{Im}(J_{12})$ is just the angular momentum, and $\mathrm{Re}(J_{12})$ is the nondiagonal component of the Fradkin tensor.[20]

(ii) The nonisotroipc case with $\omega_1=2\omega_0$, $\omega_2=\omega_0$:

$$\begin{aligned} I_4&=\mathrm{Re}(J_{12})=v_xv_y^2+\omega_0^2(4xv_y-yv_x)y,\\ I_3&=\mathrm{Im}(J_{12})=(xv_y-yv_x)v_y-\omega_0^2xy^2. \end{aligned} \quad (3)$$

Summarizing: Proposition 1 states two properties: (i) super-integrability of the rational case, and (ii) complex factorization of the additional constant of motion, that can be considered as the two fundamental features characterizing the two-dimensional harmonic oscillator. In fact, they can even be considered as defining properties. That is, any dynamical system defined in a non-Euclidean space must satisfy the appropriate non-Euclidean versions of points (i) and (ii) to be in fact considered as an (non-Euclidean) Harmonic Oscillator.

III. GEOMETRY AND DYNAMICS ON THE SPHERE S^2 AND THE HYPERBOLIC PLANE H^2

A two-dimensional manifold M can be described by using different coordinate systems. If we consider it as an imbedded submanifold of $\mathbb{R}^3$, then the points of M can be characterized by the

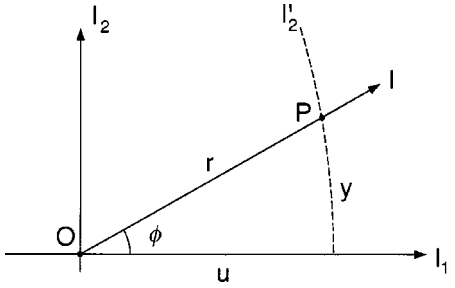

FIG. 1. Polar (r,ϕ) and parallel (u,y) coordinates based on the oriented geodesic l_1 and reference point O. All these coordinates are lengths or angles measured in the intrinsic metric of the space of constant curvature. The figure follows the pattern of a stereographic projection of the sphere from the South Pole, with O at the North Pole, but the geometrical meaning of these coordinates holds for any value of the curvature.

three external coordinates (x,y,z) plus an additional constraint. Nevertheless, in differential geometric terms, a more appropriate approach is to develop the study by using two-dimensional systems of coordinates adapted to M.

On any general two-dimensional Riemannian space (not neccesarily of constant curvature) there are two distinguished types of local coordinate systems: ''geodesic parallel'' and ''geodesic polar'' coordinates. They reduce to the familiar Cartesian and polar coordinates on the Euclidean plane (see Refs. 16 and 21) and both are based on an origin point O and an oriented geodesic l_1 through O (Fig. 1).

For any point P in some suitable neigboorhood of O, there is a unique geodesic l joining O and P. The (geodesic) polar coordinates (r,ϕ) of P, relative to the origin O and the positive geodesic ray of l_1, are the (positive) distance r between O and P measured along l, and the angle ϕ between l and the positive ray l_1, measured around O. These coordinates are defined in a neigborhood of O not extending beyond the cut locus of O; polar coordinates are singular at O, and ϕ is discontinuous on the positive ray of l_1.

Now, consider the geodesic l_2' through P and orthogonal to l_1 and let P_1 be the intersection point of l_2' and l_1 nearest to P. The (geodesic) parallel coordinates (u,y) of P, relative to the origin O and base geodesic l_1, are defined as the distance u between O and P_1, measured along l_1, and the distance y, between P_1 and P, measured along l_2'. Again these coordinates will be regular and without singularities in some suitable strip centered in l_1. If instead of l_1 another line is taken as the base, we obtain another system of geodesic parallel coordinates. Figure 2 also display the particular case with base l_2, orthogonal to l_1 through O; these second sets of parallel coordinates will be denoted (v,x).

These systems are suitable for most general purposes, because the coordinates (r,ϕ), (u,y) and (v,x) have a *direct* geometric significance, as distances and angles measured in the intrinsic metric of the surface. Closed expressions are usually only possible for spaces of *constant curva-*

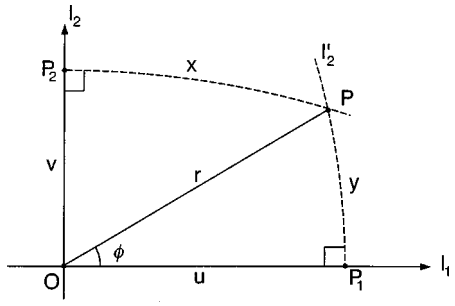

FIG. 2. The three coordinate systems (r,ϕ), (u,y) and (v,x) of a point P. Relationships among these coordinates are discussed in the text for any curvature value κ.

ture. In the constant *positive* curvature case, i.e., the sphere, the geodesics are great circles, and relations among distances and angles are the subject of spherical geometry. Polar coordinates on the sphere are singular at the origin (pole) O and also at its antipodal point (the cut locus of O). Parallel coordinates are singular in the two poles of the base geodesic. While in the Euclidean plane a line orthogonal to both l_1 and l_2 do not exist (nor does it exist in the hyperbolic plane), there is such a line l_3 for the sphere (the polar of the point O); so we have here a third set of parallel coordinates. These three sets are based on three geodesics mutually orthogonal by pairs and the third system with base l_3 is essentially equivalent to the polar coordinates whose center is the pole of l_3.

The notation has been chosen to emphasize the similarities with the Euclidean case. For a point P, r is the distance measured in either S^2 or H^2 (with curvature κ) from P to the origin point O, and ϕ determines the orientation of the line OP through O. On the other side, x, y are the geodesic distances from P to the two "coordinate axes" l_1, l_2; there are other two quantities, u, v which are distances, measured along l_1, l_2, between O and the orthogonal projections of P on l_1, l_2. In the Euclidean case, we have the identities $x=u, y=v$, but once we deal with nonzero curvature these equalities are no longer true; recall that y is the distance from P to the "x" coordinate axis, but *u is not* the distance from P to the "y" coordinate axis. Both polar (r,ϕ) and the two systems of parallel coordinates (u,y) and (v,x) are always *orthogonal*; however, the coordinate system (x,y) made up of the distances to the two coordinate axes is orthogonal in the Euclidean plane, but *not* in S^2 nor in H^2.

For a sphere of radius R the "geographic" coordinates (θ,ϕ) (where θ is the latitude and ϕ the longitude) are closely related to both polar and parallel type coordinate systems: $(R(\pi/2-\theta),\phi)$ are *polar* coordinates with an origin in the North pole, while $(R\phi, R\theta)$ are *parallel* coordinates with the equator as the base line. This equivalence does not exist in the Euclidean and hyperbolic case, where polar and parallel coordinates are very different, so there are reasons to keep their consideration separate, even for the sphere, in the context in which we are working. The fundamental properties of the harmonic oscillator on manifolds of constant curvature will be more clearly seen this way.

The metric of the sphere of curvature $\kappa = 1/R^2$ is given in parallel and polar coordinates by

$$ds^2 = \cos^2(y/R)\,du^2 + dy^2, \quad ds^2 = dr^2 + R^2 \sin^2(r/R)\,d\phi^2,$$

reducing to du^2+dy^2 and $dr^2+r^2\,d\phi^2$ when $R\to\infty$. It is possible to write these expressions in a form which holds simultaneously for the sphere, the Euclidean plane and the hyperbolic plane, by introducing the following "tagged" trigonometric functions:[22]

$$\mathrm{C}_\kappa(x) = \begin{cases} \cos\sqrt{\kappa}\,x, & \text{if } \kappa>0, \\ 1, & \text{if } \kappa=0, \\ \cosh\sqrt{-\kappa}\,x, & \text{if } \kappa<0, \end{cases} \qquad \mathrm{S}_\kappa(x) = \begin{cases} \dfrac{1}{\sqrt{\kappa}}\sin\sqrt{\kappa}\,x, & \text{if } \kappa>0, \\ x, & \text{if } \kappa=0, \\ \dfrac{1}{\sqrt{-\kappa}}\sinh\sqrt{-\kappa}\,x, & \text{if } \kappa<0, \end{cases}$$

and

$$\mathrm{T}_\kappa(x) = \frac{\mathrm{S}_\kappa(x)}{\mathrm{C}_\kappa(x)}.$$

When $\kappa=1$ the three "tagged" functions are the ordinary trigonometrical functions, i.e., $\mathrm{S}_1(x)=\sin x$, $\mathrm{C}_1(x)=\cos x$, $\mathrm{T}_1(x)=\tan x$. For $\kappa=0$ one gets the "parabolic" sine $\mathrm{S}_0(x)=x$, cosine $\mathrm{C}_0(x)=1$, and tangent $\mathrm{T}_0(x)=x$. For $\kappa=-1$, these functions are the hyperbolic cosine, sine, and tangent. Therefore, in the flat case $\kappa=0$ all $\mathrm{C}_\kappa(x)$ are replaced by 1, while all $\mathrm{S}_\kappa(x)$, $\mathrm{T}_\kappa(x)$ are

replaced by its variable x; this suggests that in the curved case, $C_\kappa(x)$ should be looked at as a kind of ''curved'' deformation of the function 1, while both $S_\kappa(x)$ and $T_\kappa(x)$ are two kinds of deformations of the linear function x.

The idea is to obtain relations between the different coordinates (u,y), (v,x), (r,ϕ), in a way that holds regardless of the value of κ. In the cases $\kappa>0$ or $\kappa<0$ they reduce to formulas of spherical or hyperbolic trigonometry, while for $\kappa=0$ they are well-known Euclidean relations.

In any rectangular triangle, as P_1PO in Fig. 1, the three sides r,u,y, and the angle ϕ at O are related by the following equations:

$$S_\kappa(y)=S_\kappa(r)\sin\phi, \quad C_\kappa(r)=C_\kappa(u)C_\kappa(y),$$

$$T_\kappa(u)=T_\kappa(r)\cos\phi, \quad T_\kappa(y)=S_\kappa(u)\tan\phi,$$

and similar equations for the triangle P_2PO (sides r,v,x, angle $\pi/2-\phi$ at O):

$$S_\kappa(x)=S_\kappa(r)\cos\phi, \quad C_\kappa(r)=C_\kappa(v)C_\kappa(x),$$

$$T_\kappa(v)=T_\kappa(r)\sin\phi, \quad T_\kappa(x)\tan\phi=S_\kappa(v).$$

Starting from these equations we get many relations with a rather symmetrical appearance in the pairs x,y and u,v. The change from *polar* to *parallel* coordinates, in any constant curvature plane, can be read from these equations.

The harmonic oscillator potential will be closely related with the particular function $T_\kappa^2(r)$ that can be presented, in terms of (y,u) or (x,v), in several alternative ways:

$$T_\kappa^2(r)=T_\kappa^2(u)+\frac{T_\kappa^2(y)}{C_\kappa^2(u)}=\frac{T_\kappa^2(u)}{C_\kappa^2(y)}+T_\kappa^2(y)=T_\kappa^2(v)+\frac{T_\kappa^2(x)}{C_\kappa^2(v)}=\frac{T_\kappa^2(v)}{C_\kappa^2(x)}+T_\kappa^2(x). \tag{4}$$

These expressions can be considered as different κ-deformed versions of the Pythagorean theorem. In fact for the $\kappa=0$ Euclidean plane we have $u=x$, $v=y$, and they reduce to $r^2=x^2+y^2$.

IV. THE 1:1 AND 2:1 HARMONIC OSCILLATORS ON A 2-D SPACE OF CONSTANT CURVATURE I: POLAR COORDINATES

In the Euclidean plane, central potentials are better discussed in polar coordinates. This is also true for $\kappa\neq0$. Nevertheless we know that nonisotroipc Euclidean oscillators are better presented in Cartesian coordinates. As we deal with both types when the configuration space is assumed to be a space of constant curvature κ, our idea is to develop both approaches. In this section the study is presented in geodesic polar coordinates, and in the next section we will make use of parallel coordinates (we begin with polar coordinated because it is the usual way of presenting the Higgs oscillator). In any case the properties we are looking for are intrinsic properties of the harmonic oscillator considered as a dynamical system, that is, as a vector field defined on the tangent bundle of a particular manifold (sphere S^2 or hyperbolic plane H^2). So all the issues we are interested in, such as integrability, super-integrability, or complex factorization, will prove to be reached by both approaches. Nevertheless we will find some differences between both approaches; this will be important with a view to facilitate further generalizations to other $n:1$ oscillators.

The differential element of distance on a manifold Q of constant curvature (S^2 if $\kappa>0$, the Euclidean plane if $\kappa=0$, or H^2 if $\kappa<0$) becomes, when written in ''geodesic polar'' coordinates:

$$ds^2=dr^2+S_\kappa^2(r)\,d\phi^2.$$

Thus a general standard Lagrangian has the following form:

$$L(\kappa)=(\tfrac{1}{2})(v_r^2+S_\kappa^2(r)v_\phi^2)-U(r,\phi,\kappa),$$

in such a way that for $\kappa=0$ we recover the standard Euclidean system,

$$\lim_{\kappa\to 0} L(\kappa)=(\tfrac{1}{2})(v_r^2+r^2v_\phi^2)-V(r,\phi),\quad V(r,\phi)=U(r,\phi,0).$$

The systems we are concerned with are systems endowed with quadratic integrals of motion depending on the curvature κ as a parameter, but we will first recall, as a previous step, the properties of the linear constants, which arise from exact Noether symmetries. An exact Noether symmetry is a complete vector field Y defined on the configuration space Q such that its natural lift Y^t to phase space TQ is an exact symmetry of the Lagrangian, that is, $Y^t(L)=0$. Then, if we denote by θ_L the Cartan one-form,

$$\theta_{\mathrm{L}}=\left(\frac{\partial L}{\partial v_r}\right)dr+\left(\frac{\partial L}{\partial v_\phi}\right)d\phi,$$

the function I defined as $I=i(Y^t)\theta_L$ is a constant of motion. The important point is that if L is a natural Lagrangians of mechanical type (Riemannian metric minus a potential) then the constant I is linear function in the velocities, and the vector field Y must necessarily be symmetry of the kinetic term (isometry of the metric) and symmetry of the potential.

In this particular spherical (hyperbolic) case the kinetic term is endowed with the following three symmetries:

$$Y_{P_1}(\kappa)=(\cos\phi)\frac{\partial}{\partial r}-\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\sin\phi\right)\frac{\partial}{\partial\phi},$$

$$Y_{P_2}(\kappa)=(\sin\phi)\frac{\partial}{\partial r}+\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\cos\phi\right)\frac{\partial}{\partial\phi},$$

$$Y_J(\kappa)=\frac{\partial}{\partial\phi}.$$

These three vector fields generate a Lie algebra,

$$[Y_{P_1},Y_{P_2}]=-\kappa Y_J,\quad [Y_{P_1},Y_J]=-Y_{P_2},\quad [Y_{P_2},Y_J]=Y_{P_1},$$

isomorphic to the Lie algebra of isometries of the spherical (Euclidean, hyperbolic) space; only if $\kappa=0$ (Euclidean plane) Y_{P_1} and Y_{P_2} conmute.

Constants of motion linear in the velocities only appear for some specific potentials. In particular, we have three cases.

(i) If the potential U is of the form $U=U(z(r,\phi))$, $z(r,\phi)=\mathrm{S}_\kappa(r)\sin\phi$, then

$$P_1(\kappa)=i(Y^t_{P_1}(\kappa))\theta_L=(\cos\phi)v_r-(\mathrm{C}_\kappa(r)\mathrm{S}_\kappa(r)\sin\phi)v_\phi$$

is a constant of motion.

(ii) If the potential U is of the form $U=U(z'(r,\phi))$, $z'(r,\phi)=\mathrm{S}_\kappa(r)\cos\phi$, then

$$P_2(\kappa)=i(Y^t_{P_2}(\kappa))\theta_L=(\sin\phi)v_r+(\mathrm{C}_\kappa(r)\mathrm{S}_\kappa(r)\cos\phi)v_\phi$$

is a constant of motion.

(iii) If the potential U depends only on r, i.e., $U=U(r)$; then

$$J(\kappa)=i(Y^t_J(\kappa))\theta_L=\mathrm{S}^2_\kappa(r)v_\phi$$

is a constant of motion.

Notice that, in geometric terms, the two functions z and z' are in fact the "tagged" sines $z=S_k(y)$ and $z'=S_k(x)$. Concerning (iii) it represents the Kepler area law which in this form holds for any κ.

The most general linear constant of motion turns out to be a linear combination of $P_1(\kappa)$, $P_2(\kappa)$, $J(\kappa)$, with constant coefficients:

$$I_{11}=a_1P_1(\kappa)+a_2P_2(\kappa)+cJ(\kappa).$$

Suppose now that L has a constant of the motion $I=I(r,\phi,v_r,v_\phi)$ which is quadratic in the velocities

$$I=I_{22}+I_{20}(r,\phi,\kappa),\quad I_{22}=av_r^2+2bv_rv_\phi+cv_\phi^2,$$

where a, b, and c, are functions of r and ϕ (κ-dependent). Then the three functions a, b, and c must take the form

$$a=a_0\cos^2\phi+c_0\sin^2\phi+b_0\sin\phi\cos\phi,$$

$$b=(\tfrac{1}{2})\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)[(c_0-a_0)\sin 2\phi+b_0\cos 2\phi]+(\tfrac{1}{2})\mathrm{S}_\kappa^2(r)(-a_1\cos\phi+c_1\sin\phi),$$

$$c=\mathrm{S}_\kappa^2(r)\mathrm{C}_\kappa^2(r)(a_0\sin^2\phi+c_0\cos^2\phi-b_0\sin\phi\cos\phi)+\mathrm{S}_\kappa^3(r)\mathrm{C}_\kappa(r)(c_1\cos\phi+a_1\sin\phi)+a_2\mathrm{S}_\kappa^4(r)\ ,$$

where a_0, b_0, c_0; a_1, c_1; a_2 are real parameters. The most general form for I_{22} turns out to be a linear combination of binary products of linear constants:

$$I_{22}(\kappa)=a_0P_1^2(\kappa)+b_0P_1(\kappa)P_2(\kappa)+c_0P_2^2(\kappa)+a_1P_2(\kappa)J(\kappa)+c_1P_1(\kappa)J(\kappa)+a_2J^2(\kappa)\ .$$

In the flat $\kappa=0$ limit, we have $\mathrm{S}_\kappa(r)\to r$ and $\mathrm{C}_\kappa(r)\to 1$, so all these equations coincide with the ones obtained for $Q=E^2$. In the more general κ-dependent approach, the case where the configuration space is Euclidean can be considered, not as a limit case, but simply as the particular case $\kappa=0$. Generically r appears through $\mathrm{S}_\kappa(r)$, and there are also some factors which in the curved case appear through a tagged cosine of r, $\mathrm{C}_\kappa(r)$, which in the Euclidean case degenerates to $\mathrm{C}_0(r)\equiv 1$ and which therefore becomes invisible; of course these terms turn visible once we deal with the case of nonzero curvature κ. We also notice that the dependence on the curvature κ is only present in the radial part of the functions. The angular functions (e.g., $\cos\phi$,$\sin\phi$) are κ-independent.

A. Isotropic oscillator

Let us consider the following spherical (Euclidean, hyperbolic) Lagrangian with curvature κ,

$$L=(\tfrac{1}{2})(v_r^2+\mathrm{S}_\kappa^2(r)v_\phi^2)-(\tfrac{1}{2})\omega_0^2\,U_{11}(r,\phi,\kappa),\quad U_{11}=\mathrm{T}_\kappa^2(r),$$

so that the standard oscillator potential on the unit sphere (Higgs oscillator), on the Euclidean plane, or on the unit Lobachewski plane, arise as the following three particular cases:

$$U_{11}(1)=\tan^2 r,\quad V_{11}=U_{11}(0)=r^2,\quad U_{11}(-1)=\tanh^2 r.$$

The Euclidean oscillator V_{11} (parabolic potential without singularities) appears in this formalism as making a separation between two different situations (see Fig. 3). The spherical potential is

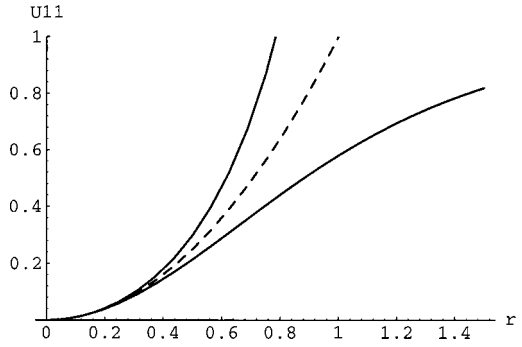

FIG. 3. Plot of U_{11} as a function of r, for $\kappa=-1$ (lower curve), $\kappa=0$ (dashed line) and $\kappa=1$ (upper curve).

represented by a well with singularities on the border (impenetrable walls at the equatorial circle $r=\pi/2\sqrt{\kappa}$ if the potential center is at the poles), and the hyperbolic potential by a well with finite depth since $U_{11}\to 1/|\kappa|$ when $r\to\infty$.

The dynamics is given by the following κ-dependent vector field:

$$X_{11}=v_r\frac{\partial}{\partial r}+v_\phi\frac{\partial}{\partial\phi}+f_r\frac{\partial}{\partial v_r}+f_\phi\frac{\partial}{\partial v_\phi},$$

$$f_r=(\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r))v_\phi^2-\omega_0^2\left(\frac{\mathrm{S}_\kappa(r)}{\mathrm{C}_\kappa^3(r)}\right),$$

$$f_\phi=-2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)v_r v_\phi.$$

This is an integrable system endowed with two fundamental quadratic integrals of motion:

$$I_1(\kappa)=P_1^2(\kappa)+\omega_0^2(\mathrm{T}_\kappa(r)\cos\phi)^2,\quad I_2(\kappa)=P_2^2(\kappa)+\omega_0^2(\mathrm{T}_\kappa(r)\sin\phi)^2.$$

These constants are sum of two squares (as in the Euclidean plane) so they can be interpreted as the modulus of appropriate complex functions. Notice also that they can be considered as the κ-deformed versions of the two Euclidean one-degree of freedom energies; nevertheless, for $\kappa\neq 0$, the sum $I_1(\kappa)+I_2(\kappa)$ does not represent the total energy.

We begin our analysis by considering the time-derivative of the the two κ-dependent functions $P_1(\kappa)$ and $P_2(\kappa)$. They are given by

$$\frac{d}{dt}P_1(\kappa)=-\omega_0^2\left(\frac{\mathrm{S}_\kappa(r)}{\mathrm{C}_\kappa^3(r)}\right)\cos\phi,\quad \frac{d}{dt}P_2(\kappa)=-\omega_0^2\left(\frac{\mathrm{S}_\kappa(r)}{\mathrm{C}_\kappa^3(r)}\right)\sin\phi\ .$$

In a similar way, the time-derivative of the two velocity-independent functions $\mathrm{T}_\kappa(r)\cos\phi$, $\mathrm{T}_\kappa(r)\sin\phi$, is given by

$$\frac{d}{dt}(\mathrm{T}_\kappa(r)\cos\phi)=\frac{P_1(\kappa)}{\mathrm{C}_\kappa^2(r)},\quad \frac{d}{dt}(\mathrm{T}_\kappa(r)\sin\phi)=\frac{P_2(\kappa)}{\mathrm{C}_\kappa^2(r)}.$$

The following proposition states the super-integrability of the system and proves the existence of a complex factorization.

Proposition 2: Let K_1, K_2, *be the following two functions*:

$$K_1 = P_1(\kappa) + \mathrm{i}\omega_0(\mathrm{T}_\kappa(r)\cos\phi), \quad K_2 = P_2(\kappa) + \mathrm{i}\omega_0(\mathrm{T}_\kappa(r)\sin\phi).$$

Then (i) The modulus of K_1 *and* K_2 *are constants of motion and coincide with* $I_1(\kappa), I_2(\kappa)$:

$$|K_1|^2 = I_1(\kappa), \quad |K_2|^2 = I_2(\kappa).$$

(ii) The complex function K_{12} *defined as*

$$K_{12} = K_1 K_2^*$$

is also a constant of motion.

Proof: (i) follows directly from the definition of K_1 and K_2. For proving (ii) we analyze the time-evolution of K_1 and K_2. We have

$$\frac{d}{dt}K_1 = \frac{d}{dt}P_1(\kappa) + \mathrm{i}\,\omega_0\frac{d}{dt}(\mathrm{T}_\kappa(r)\cos\phi) = -\omega_0^2\left(\frac{\mathrm{S}_\kappa(r)}{\mathrm{C}_\kappa^3(r)}\right)\cos\phi + \mathrm{i}\,\omega_0\frac{P_1(\kappa)}{\mathrm{C}_\kappa^2(r)} = \left(\frac{\mathrm{i}\omega_0}{\mathrm{C}_\kappa^2(r)}\right)K_1,$$

and a similar calculus leads to

$$\frac{d}{dt}K_2 = \left(\frac{\mathrm{i}\omega_0}{\mathrm{C}_\kappa^2(r)}\right)K_2.$$

Thus we obtain

$$\frac{d}{dt}(K_1 K_2^*) = 0,$$

which states the function K_{12} as an additional constant of motion. It can be decomposed into real and imaginary parts as follows:

$$K_{12} = I_4(\kappa) + \mathrm{i}I_3(\kappa),$$

where $I_4(\kappa)$, $I_3(\kappa)$ are real constants of motion, respectively, quadratic and linear in the velocities, and given by

$$I_4(\kappa) = P_1(\kappa)P_2(\kappa) + \omega_0^2(\mathrm{T}_\kappa^2(r)\cos\phi\sin\phi), \quad I_3(\kappa) = \omega_0 J(\kappa).$$

These are the general κ-dependent versions of the flat space constants denoted I_4, I_3. A direct calculation shows that

$$I_1(\kappa) + I_2(\kappa) + \kappa(J(\kappa))^2 = (\tfrac{1}{2})[v_r^2 + \mathrm{S}_\kappa^2(r)v_\phi^2 + \omega_0^2 U_{11}(r,\phi,\kappa)],$$

which means that in any space of nonzero constant curvature κ the total energy can be written as a sum of *three* summands, one of which carries the spherical (Euclidean, hyperbolic) angular momentum with the curvature κ as a coefficient and vanishes into the limit $\kappa \to 0$.

Summarizing: the isotropic harmonic oscillator is super-integrable for any value of the curvature κ (positive, zero or negative) and an additional constant of motion K_{12} can be obtained by complex factorization. The fundamental integral of motion $I_3(\kappa)$ represents the spherical or hyperbolic version of the angular momentum (because the potential U_{11} is central independently of

the value of the curvature). Concerning $I_4(\kappa)$, it represents the κ-dependent spherical or hyperbolic versions of the so–called Fradkin constant.[20]. Next, we give the expressions of these two constants for three particular cases.

(i) Higgs oscillator in the unit sphere (radius $R=1$). In this case we have

$$P_1=(\cos\phi)v_r-(\cos r\ \sin r\sin\phi)\,v_\phi,$$
$$P_2=(\sin\phi)v_r+(\cos r\ \sin r\cos\phi)v_\phi,$$
$$J=\sin^2 r\,v_\phi,$$

and then I_4, I_3, are given by

$$I_4=P_1P_2+\omega_0^2(\tan^2 r\cos\phi\sin\phi),\quad I_3=\omega_0 J.$$

(ii) Isotropic oscillator in the unit Lobachewski plane (''radius'' $R=1$). In this case we have

$$P_1=(\cos\phi)v_r-(\cosh r\sinh r\sin\phi)v_\phi,$$
$$P_1=(\sin\phi)v_r+(\cosh r\sinh r\cos\phi)v_\phi,$$
$$J=\sinh^2 rv_\phi,$$

and then I_4, I_3, are given by

$$I_4=P_1P_2+\omega_0^2(\tanh^2 r\cos\phi\sin\phi),\quad I_3=\omega_0 J.$$

(iii) The expressions for $\kappa=0$ become the usual formulas for the standard isotropic oscillator.

B. Nonisotropic 2:1 oscillator

As mentioned in the Introduction, systems on the two-dimensional sphere (Euclidean, hyperbolic plane) with the first integrals quadratic in the velocities were studied in Ref. 16. Several different potentials were obtained as solutions of a system of two coupled differential equations depending on the parameter κ. One of the potentials obtained in this approach was

$$U_{21}(r,\phi,\kappa)=\frac{1}{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2}\left[4\left(\frac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2}\right)^2+(\mathrm{S}_\kappa(r)\sin\phi)^2\right],$$

which satisfies

$$\lim_{\kappa\to 0}U_{21}=4r^2\cos^2\phi+r^2\sin^2\phi$$

and was interpreted as representing the potential of the spherical (hyperbolic) version of the 2:1 harmonic oscillator.

So, let us now study the following spherical (hyperbolic) Lagrangian with curvature κ:

$$L=(\tfrac{1}{2})(v_r^2+\mathrm{S}_\kappa^2(r)v_\phi^2)-(\tfrac{1}{2})\omega_0^2U_{21}(r,\phi,\kappa).$$

The dynamics is given by the following vector field:

$$X_{21}=v_r\frac{\partial}{\partial r}+v_\phi\frac{\partial}{\partial\phi}+f_r\frac{\partial}{\partial v_r}+f_\phi\frac{\partial}{\partial v_\phi},$$

where the κ-dependent forces f_r and f_ϕ are given by

$$f_r = \mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r)v_\phi^2 - (\omega_0^2 \mathrm{S}_\kappa(r)\mathrm{C}_\kappa(r))\left[\frac{\mathrm{C}_\kappa^2(r)(4\cos^2\phi+\sin^2\phi)+\kappa \mathrm{S}_\kappa(r)(3+\cos^2\phi)\cos^2\phi}{(\mathrm{C}_\kappa^2(r)-\kappa \mathrm{S}_\kappa^2(r)\cos^2\phi)^3}\right],$$

$$f_\phi = -2\left(\frac{\mathrm{C}_\kappa(r)}{\mathrm{S}_\kappa(r)}\right)v_r v_\phi + (\omega_0^2 \sin\phi\cos\phi)\left[\frac{3\mathrm{C}_\kappa^2(r)+\kappa \mathrm{S}_\kappa^2(r)\cos^2\phi}{(\mathrm{C}_\kappa^2(r)-\kappa \mathrm{S}_\kappa^2(r)\cos^2\phi)^3}\right].$$

It was proved in Ref. 16 that this system possesses the following two quadratic integrals of motion:

$$\begin{aligned} I_1(\kappa) &= P_1^2(\kappa) + 4\omega_0^2\left(\frac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2}\right)^2, \\ I_2(\kappa) &= P_2^2(\kappa) + \kappa J^2(\kappa) + \omega_0^2[1+\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2]\left(\frac{\mathrm{T}_\kappa(r)\sin\phi}{1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2}\right)^2. \end{aligned} \tag{5}$$

For further convenience, it will be useful to write the constant I_2 as

$$I_2(\kappa) = P_2^2(\kappa) + \kappa J^2(\kappa) + \omega_0^2 F(r,\phi,\kappa)(\mathrm{T}_\kappa(r)\sin\phi)^2,$$

where we have denoted by $F(r,\phi,\kappa)$ the following function:

$$F(r,\phi,\kappa) = \frac{1+\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2}{(1-\kappa \mathrm{T}_\kappa^2(r)\cos^2\phi)^2}.$$

Notice that if we denote by $I_0(\kappa)$ the trivial constant of motion (energy),

$$I_0(\kappa) = (\tfrac{1}{2})(v_r^2 + \mathrm{S}_\kappa^2(r)v_\phi^2) + (\tfrac{1}{2})\omega_0^2 U_{21}(r,\phi,\kappa);$$

then

$$2I_0(\kappa) = I_1(\kappa) + I_2(\kappa).$$

Let us now denote by K_1 the following complex function:

$$K_1 = P_1(\kappa) + (2\mathrm{i}\omega_0)\left(\frac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa(\mathrm{T}_\kappa(r)\cos\phi)^2}\right).$$

By using

$$\frac{d}{dt}P_1(\kappa) = -\left(\frac{4\omega_0^2}{\mathrm{C}_\kappa^2(r)}\right)F(r,\phi,\kappa)\left[\frac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa\,\mathrm{T}_\kappa^2(r)\sin^2\phi}\right],$$

$$\frac{d}{dt}\left(\frac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa \mathrm{T}_\kappa^2(r)\sin^2\phi}\right) = \left(\frac{1}{\mathrm{C}_\kappa^2(r)}\right)F(r,\phi,\kappa)\,P_1(\kappa),$$

we get the time-evolution of the function K_1 given by

$$\frac{d}{dt}K_1 = \left(\frac{2\mathrm{i}\omega_0}{\mathrm{C}_\kappa^2(r)}\right)F(r,\phi,\kappa)\,K_1.$$

It seems that the following step must be the analysis of the time evolution of $P_2(\kappa)$ (as we have done for the case of the central Higgs oscillator). Nevertheless instead of considering $P_2(\kappa)$ by

itself, we will consider two other related functions obtained by addition (subtraction) of a new term related with the spherical (hyperbolic) version of the angular momentum:

$$\frac{d}{dt}[P_2(\kappa)+\sqrt{\kappa}\,J(\kappa)]=-\left(\frac{\omega_0}{\mathrm{C}_\kappa(r)}\right)^2\left(\frac{1}{1+\sqrt{\kappa}\,\mathrm{T}_\kappa(r)\cos\phi}\right)^2\left[\frac{\mathrm{T}_\kappa(r)\sin\phi}{1+\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi}\right],$$

$$\frac{d}{dt}[P_2(\kappa)-\sqrt{\kappa}J(\kappa)]=-\left(\frac{\omega_0}{\mathrm{C}_\kappa(r)}\right)^2\left(\frac{1}{1-\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi}\right)^2\left[\frac{\mathrm{T}_\kappa(r)\sin\phi}{1-\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi}\right].$$

On the other hand, the time-derivative of the two velocity-independent functions,

$$\left[\frac{\mathrm{T}_\kappa(r)\sin\phi}{1+\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi}\right],\quad\left[\frac{\mathrm{T}_\kappa(r)\sin\phi}{1-\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi}\right],$$

is given by

$$\frac{d}{dt}\left[\frac{\mathrm{T}_\kappa(r)\sin\phi}{1+\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi}\right]=\left(\frac{1}{\mathrm{C}_\kappa^2(r)}\right)\left(\frac{1}{1+\sqrt{\kappa}\,\mathrm{T}_\kappa(r)\cos\phi}\right)^2[P_2(\kappa)+\sqrt{\kappa}\,J(\kappa)],$$

$$\frac{d}{dt}\left[\frac{\mathrm{T}_\kappa(r)\sin\phi}{1-\sqrt{\kappa}\,\mathrm{T}_\kappa(r)\cos\phi}\right]=\left(\frac{1}{\mathrm{C}_\kappa^2(r)}\right)\left(\frac{1}{1-\sqrt{\kappa}\,\mathrm{T}_\kappa(r)\cos\phi}\right)^2[P_2(\kappa)-\sqrt{\kappa}\,J(\kappa)].$$

These relations to us suggests to define not one, but two functions, similar to K_2:

$$K_2^+=P_2(\kappa)+\sqrt{\kappa}J(\kappa)+\mathrm{i}\omega_0\left(\frac{\mathrm{T}_\kappa(r)\sin\phi}{1+\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi}\right),$$

$$K_2^-=P_2(\kappa)-\sqrt{\kappa}J(\kappa)+\mathrm{i}\,\omega_0\left(\frac{\mathrm{T}_\kappa(r)\sin\phi}{1-\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi}\right),$$

whose time derivatives are given by

$$\frac{d}{dt}K_2^+=\left(\frac{\mathrm{i}\omega_0}{\mathrm{C}_\kappa^2(r)}\right)\left[\frac{1}{(1+\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi)^2}\right]K_2^+,$$

$$\frac{d}{dt}K_2^-=\left(\frac{\mathrm{i}\omega_0}{\mathrm{C}_\kappa^2(r)}\right)\left[\frac{1}{(1-\sqrt{\kappa}\mathrm{T}_\kappa(r)\cos\phi)^2}\right]K_2^-.$$

Then we have the following proposition.

Proposition 3: Let the complex functions K_1, K_2^+, K_2^- be defined as above. Then the complex function K_{122} defined as

$$K_{122}=K_1\,K_2^{+*}\,K_2^{-*}$$

is a constant of motion.

Proof: We have already obtained the time derivatives of everyone of the three functions K_1, K_2^+, K_2^-. Because of this, the time evolution of K_{122} is given by

$$\frac{d}{dt}K_{122}=\dot{K}_x K_2^+ * K_2^- * + K_1 \dot{K}_y^+ * K_2^- * + K_1 K_2^+ * \dot{K}_2^- *$$

$$=\left(\frac{\mathrm{i}\,\omega_0}{\mathrm{C}_\kappa^2(r)}\right)\left[2F(r,\phi,\kappa)-\frac{1}{(1+\sqrt{\kappa}\,\mathrm{T}_\kappa(r)\cos\phi)^2}-\frac{1}{(1-\sqrt{\kappa}\,\mathrm{T}_\kappa(r)\cos\phi)^2}\right]K_{122}\,.$$

But the function F is such that the term in square brackets vanishes identically, and we arrive at

$$\frac{d}{dt}K_{122}=0.$$

Thus we have shown that complex function $K_{122}=I_4(\kappa)+\mathrm{i}\,I_3(\kappa)$ as well as the two associated real functions, $I_4(\kappa)$ and $I_3(\kappa)$, are all of them constants of motion. After some computations (we omit the details) we have obtained

$$I_4(\kappa)=[P_2^2(\kappa)-\kappa J^2(\kappa)]\,P_1(\kappa)+\omega_0^2 I_{41}(\kappa),$$

$$I_3(\kappa)=P_2(\kappa)\,J(\kappa)-\omega_0^2 I_{30}(\kappa),$$

with

$$I_{41}(\kappa)=\left(\frac{\mathrm{T}_\kappa(r)\sin\phi)}{(1-\kappa\,\mathrm{T}_\kappa^2(r)\cos^2\phi)^2}\right)[I_{41}^a(\kappa)+\kappa\,I_{41}^b(\kappa)],$$

$$I_{41}^a(\kappa)=4P_2(\kappa)\mathrm{T}_\kappa(r)\cos\phi-P_1(\kappa)\mathrm{T}_\kappa(r)\sin\phi,$$

$$I_{41}^b(\kappa)=(\mathrm{T}_\kappa^2(r)\cos^2\phi)(4J(\kappa)+P_1(\kappa)\mathrm{T}_\kappa(r)\sin\phi),$$

$$I_{30}(\kappa)=\frac{\mathrm{T}_\kappa^3(r)\cos\phi\sin^2\phi}{(1-\kappa\,\mathrm{T}_\kappa^2(r)\cos^2\phi)^2}.$$

We close this section observing that, although these κ-dependent polar coordinates (r,ϕ) prove to be convenient for the central U_{11} case, the results of this noncentral subsection [actually, even the function $U_{21}(r,\phi)$ itself] suggest the convenience of a new study in a new and more appropriate system of coordinates.

V. THE 1:1 AND 2:1 HARMONIC OSCILLATORS ON A 2-D SPACE OF CONSTANT CURVATURE II: PARALLEL COORDINATES

The dynamics of a system defined in a two-dimensional space with constant curvaure κ can also be studied by using the ''geodesic parallel'' system of coordinates introduced in Sec. II. In this case the differential element of distance is

$$ds^2=\mathrm{C}_\kappa^2(y)du^2+dy^2,$$

so a standard Lagrangian (kinetic term minus potential function) has the following form:

$$L(\kappa)=(\tfrac{1}{2})(\mathrm{C}_\kappa^2(y)v_u^2+v_y^2)-U(u,y,\kappa),$$

in such a way that the Euclidean system is just given by the particular value of $L(\kappa)$ in $\kappa=0$,

$$\lim_{\kappa\to 0} L(\kappa)=(\tfrac{1}{2})\,(v_x^2+v_y^2)-V(x,y),\quad V(x,y)=U(x,y,0)\,.$$

The kinetic term remains invariant under the action of the three κ-dependent vector fields Y_{P_1}, Y_{P_2}, $Y_J(\kappa)$, whose expressions in parallel coordinates are

$$Y_{P_1}(\kappa)=\frac{\partial}{\partial u},\quad Y_{P_2}(\kappa)=\kappa\,\mathrm{S}_\kappa(u)\mathrm{T}_\kappa(y)\,\frac{\partial}{\partial u}+\mathrm{C}_\kappa(u)\,\frac{\partial}{\partial y},$$

$$Y_J(\kappa)=\mathrm{C}_\kappa(u)\mathrm{T}_\kappa(y)\,\frac{\partial}{\partial u}-\mathrm{S}_\kappa(u)\,\frac{\partial}{\partial y}.$$

Moreover, the potentials U_1, U_2, U_J, now characterized by the following dependence:

$$U_1=U(y),\quad U_2=U(\mathrm{S}_\kappa(u)\mathrm{C}_k(y)),\quad \text{and}\quad U_J=U\left(\frac{\mathrm{T}^2_\kappa(u)}{\mathrm{C}^2_\kappa(y)}+\mathrm{T}^2_\kappa(y)\right)$$

(remark that these expressions embody the same dependence as derived in the previous section) are endowed with $Y_{P_1}(\kappa)$, $Y_{P_2}(\kappa)$, $Y_J(\kappa)$, as exact Noether symmetries. The associated linear constants of motion are given by

$$\begin{gathered}P_1(\kappa)=\mathrm{C}^2_\kappa(y)\,v_u,\quad P_2(\kappa)=\kappa\,\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y)\,v_u+\mathrm{C}_\kappa(u)\,v_y,\\ J(\kappa)=\mathrm{C}_\kappa(u)\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y)\,v_u-\mathrm{S}_\kappa(u)\,v_y,\end{gathered}\tag{6}$$

and hence the more general form for a linear constant of motion I_{11}, is as a linear combination of these three functions, $I_{11}=a_1P_1(\kappa)+a_2P_2(\kappa)+cJ(\kappa)$.

The constants of motion which are quadratic in the velocities arise from generalized Noether symmetries (hidden symmetries) of $L(\kappa)$, and they have the following expression:

$$I=I_{22}+I_{20}(u,y,\kappa),$$

with the term I_{22} again given by a linear combination of quadratic pairings,

$$I_{22}(\kappa)=a_0P_1^2(\kappa)+b_0P_1(\kappa)P_2(\kappa)+c_0P_2^2(\kappa)+a_1P_2(\kappa)J(\kappa)+c_1P_1(\kappa)J(\kappa)+a_2J^2(\kappa).$$

In contrast to the formalism in polar coordinates (r,ϕ), the κ-dependence is now present in both coordinates, u and y, because both are lengths.

A. Isotropic oscillator

The Lagrangian of isotropic spherical (Euclidean, hyperbolic) oscillator with curvature κ is

$$L=\left(\frac{1}{2}\right)(\mathrm{C}^2_\kappa(y)v_u^2+v_y^2)-\left(\frac{1}{2}\right)\omega_0^2\,U_{11}(u,y,\kappa),\quad U_{11}=\frac{\mathrm{T}^2_\kappa(u)}{\mathrm{C}^2_\kappa(y)}+\mathrm{T}^2_\kappa(y).$$

This potential is indeed the same discussed with polar coordinates as $\mathrm{T}^2_\kappa(r)$ [see (4)]. In Sec. III we pointed out that the fuction $\mathrm{T}^2_\kappa(r)$ admits several alternative expressions in terms of the coordinates (u,y) which can be considered as curvature versions of the Pythagorean theorem. Because of this, the potential $U_{11}=U_{11}(u,y,\kappa)$ can also be written as

$$U_{11}=\mathrm{T}_\kappa^2(u)+\frac{\mathrm{T}_\kappa^2(y)}{\mathrm{C}_\kappa^2(u)}.$$

The dynamics is given by the following κ-dependent vector field:

$$X_{11}=v_u\frac{\partial}{\partial u}+v_y\frac{\partial}{\partial y}+f_u\frac{\partial}{\partial v_u}+f_y\frac{\partial}{\partial v_y},$$

$$f_u=2\,\kappa\,\mathrm{T}_\kappa(y)\,v_u v_y-\omega_0^2\left(\frac{\mathrm{S}_\kappa(u)}{\mathrm{C}_\kappa^3(u)\,\mathrm{C}_\kappa^4(y)}\right),$$

$$f_y=-\,\kappa\,\mathrm{C}_\kappa(y)\,\mathrm{S}_\kappa(y)\,v_u^2-\omega_0^2\left(\frac{\mathrm{S}_\kappa(y)}{\mathrm{C}_\kappa^2(u)\,\mathrm{C}_\kappa^3(y)}\right).$$

The following two κ-dependent functions remain constant along the trajectories of X_{11}:

$$I_1(\kappa)=P_1^2(\kappa)+\omega_0^2\,\mathrm{T}_\kappa^2(u),\quad I_2(\kappa)=P_2^2(\kappa)+\omega_0^2\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(u)}\right)^2. \tag{7}$$

They are integrals of motion quadratic in the velocities (momenta in the Hamiltonian formalism) which correspond to the κ-deformed versions of the two Euclidean one-degree of freedom energies.

The following proposition states the super-integrability of the system and proves the existence of a complex factorization.

Proposition 4: Let K_1, K_2, be the following two functions:

$$K_1=P_1(\kappa)+\mathrm{i}\,\omega_0\,\mathrm{T}_\kappa(u),\quad K_2=P_2(\kappa)+\mathrm{i}\,\omega_0\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(u)}\right).$$

Then the complex function K_{12} defined as

$$K_{12}=K_1K_2^*$$

is a constant of motion.

Proof: The time-evolution of the functions K_1, K_2 is given by

$$\frac{d}{dt}K_1\equiv X_{11}(K_1)=X_{11}[\mathrm{C}_\kappa^2(y)\,v_u]+\mathrm{i}\,\omega_0\,X_{11}[\mathrm{T}_\kappa(u)]=\left(\frac{\mathrm{i}\,\omega_0}{\mathrm{C}_\kappa^2(u)\mathrm{C}_\kappa^2(y)}\right)K_1,$$

$$\frac{d}{dt}K_2\equiv X_{11}(K_2)=X_{11}[P_2(\kappa)]+\mathrm{i}\,\omega_0\,X_{11}\left[\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(u)}\right]=\left(\frac{\mathrm{i}\,\omega_0}{\mathrm{C}_\kappa^2(u)\mathrm{C}_\kappa^2(y)}\right)K_2.$$

Hence we have

$$\frac{d}{dt}K_{12}=X_{11}(K_1)K_2^*+K_1\,X_{11}(K_2^*)=0,$$

which states the function K_{12} as an additional constant of motion. The associated real integrals of motion I_4, I_3 are

$$I_4=\mathrm{Re}(K_1 K_2^*)=P_1(\kappa)P_2(\kappa)+\omega_0^2\,\mathrm{T}_\kappa(u)\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(u)}\right),$$

$$I_3=\mathrm{Im}(K_1 K_2^*)=\omega_0\,P_2(\kappa)\mathrm{T}_\kappa(u)-\omega_0\,P_1(\kappa)\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(u)}\right)=\omega_0\,J(\kappa).$$

We close with two properties. First, the relation between the modulus of the functions K_1, K_2, and the two fundamental constants of motion is the same that of the Euclidean plane,

$$|K_1|^2=I_1(\kappa),\quad |K_2|^2=I_2(\kappa).$$

Second, the three constants of motion $I_1(\kappa),I_2(\kappa),I_3(\kappa)$ are functionally independent, and the total energy is related to them as

$$(\tfrac{1}{2})(\mathrm{C}_\kappa^2(y)v_u^2+v_y^2)+(\tfrac{1}{2})\omega_0^2\,U_{11}(u,y,\kappa)=(\tfrac{1}{2})(I_1(\kappa)+I_2(\kappa)+\kappa\,J^2(\kappa)),$$

because of

$$P_1^2(\kappa)+P_2^2(\kappa)+\kappa\,J^2(\kappa)=\mathrm{C}_\kappa^2(y)v_u^2+v_y^2.$$

B. Nonisotropic 2:1 oscillator

In parallel coordinates the Lagrangian of the spherical (hyperbolic) 2:1 harmonic oscillator with curvature κ is

$$L=(\tfrac{1}{2})(\mathrm{C}_\kappa^2(y)v_u^2+v_y^2)-(\tfrac{1}{2})\omega_0^2\,U_{21}(u,y,\kappa),$$

$$U_{21}=\frac{\mathrm{T}_\kappa^2(2\,u)}{\mathrm{C}_\kappa^2(y)}+\mathrm{T}_\kappa^2(y)=\mathrm{T}_\kappa^2(2\,u)+\frac{\mathrm{T}_\kappa^2(y)}{\mathrm{C}_\kappa^2(2\,u)}.$$

Therefore, the dynamics is represented by the following κ-dependent vector field:

$$X_{21}=v_u\frac{\partial}{\partial u}+v_y\frac{\partial}{\partial y}+f_u\frac{\partial}{\partial v_u}+f_y\frac{\partial}{\partial v_y},$$

$$f_u=2\,\kappa\,\mathrm{T}_\kappa(y)v_u v_y-2\,\omega_0^2\left(\frac{\mathrm{S}_\kappa(2\,u)}{\mathrm{C}_\kappa^3(2\,u)\mathrm{C}_\kappa^4(y)}\right),$$

$$f_y=-\kappa\,\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y)\,v_u^2-\omega_0^2\left(\frac{\mathrm{S}_\kappa(y)}{\mathrm{C}_\kappa^2(2\,u)\mathrm{C}_\kappa^3(y)}\right).$$

This system possesses two integrals of motion quadratic in the velocities:

$$I_1(\kappa)=P_1(\kappa)^2+4\,\omega_0^2\left(\frac{\mathrm{T}_\kappa(u)}{1-\kappa\,\mathrm{T}_\kappa^2(u)}\right)^2,$$

$$I_2(\kappa)=P_2^2(\kappa)+\kappa\,J^2(\kappa)+\omega_0^2\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2\,u)}\right)^2=[v_y^2+\kappa\,\mathrm{C}_\kappa^2(y)\mathrm{S}_\kappa^2(y)v_u^2]+\omega_0^2\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2\,u)}\right)^2.$$

In the two-dimensional sphere S^2 (hyperbolic plane) with curvature κ, the expression for the tangent of the double-angle is $\mathrm{T}_\kappa(2\,\alpha)=2\,\mathrm{T}_\kappa(\alpha)/(1-\kappa\,\mathrm{T}_\kappa^2(\alpha))$; thus the function $I_1(\kappa)$ can also be rewritten as follows:

$$I_1(\kappa)=P_1(\kappa)^2+\omega_0^2\,\mathrm{T}_\kappa^2(2\,u).$$

The dynamics is κ-dependent and so are the two integrals of motion. Hence the following two equations:

$$X_{21}(I_1(\kappa))=0,\quad X_{21}(I_2(\kappa))=0,$$

remain true for any value (positive, negative or null) of the curvature κ. Moreover, if we denote by $I_0(\kappa)$ the trivial constant of motion:

$$I_0(\kappa)=(\tfrac{1}{2})(\mathrm{C}_\kappa^2(y)v_u^2+v_y^2)+(\tfrac{1}{2})\omega_0^2\,U_{21}(u,y,\kappa),$$

then we have

$$2I_0(\kappa)=I_1(\kappa)+I_2(\kappa).$$

So the total energy $I_0(\kappa)$ splits as a sum of two terms, $I_1(\kappa)$ and $I_2(\kappa)$, as was the case in the Euclidean plane. Nevertheless, for $\kappa\neq 0$ the second integral contains an additional term proportional to the angular momentum. For the zero curvature limit, this additional term vanishes, and we obtain the correct Euclidean expressions,

$$\lim_{\kappa\to 0} I_1(\kappa)=v_x^2+4\omega_0^2x^2,\qquad \lim_{\kappa\to 0} I_2(\kappa)=v_y^2+\omega_0^2y^2.$$

Let us denote by K_1, K_2^+, K_2^-, the following three complex functions:

$$K_1=P_1(\kappa)+\mathrm{i}\,\omega_0\,\mathrm{T}_\kappa(2\,u),$$

$$K_2^+=[P_2(\kappa)+\sqrt{\kappa}\,J(\kappa)]+\mathrm{i}\,\omega_0(\mathrm{C}_\kappa(u)+\sqrt{\kappa}\,\mathrm{S}_\kappa(u))\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2\,u)}\right),$$

$$K_2^-=[P_2(\kappa)-\sqrt{\kappa}\,J(\kappa)]+\mathrm{i}\,\omega_0(\mathrm{C}_\kappa(u)-\sqrt{\kappa}\,\mathrm{S}_\kappa(u))\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2\,u)}\right).$$

The first function can be considered as a ''curved'' version of the Euclidean function J_1 (see the notation of Sec. II), and K_2^+, K_2^-, two different κ-dependent deformations of the Euclidean function J_2.

Proposition 5: Let the complex functions K_1, K_2^+, K_2^-, be defined as above. Then

(i) *The modulus of K_1 is a constant of motion and coincides with $I_1(\kappa)$; the sums of the modulus of K_2^+ and K_2^- is a constant of motion and coincides with $I_2(\kappa)$.*

(ii) *The complex function K_{122}, defined as*

$$K_{122}=K_1\,K_2^{+*}\,K_2^{-*},$$

is a constant of motion.

Proof: (i) The modulus of the first function K_1 is the constant value of the first integral of motion,

$$|K_1|^2 = P_1^2(\kappa) + \omega_0^2[\mathrm{T}_\kappa(2u)]^2 = I_1(\kappa),$$

and the sum of the modulus of K_2^+ and K_2^- coincides with $2I_2(\kappa)$:

$$|K_2^+|^2 + |K_2^-|^2 = 2\left(P_2^2(\kappa) + \kappa J^2(\kappa) + \omega_0^2 \left[\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2u)} \right]^2 \right) = 2I_2(\kappa).$$

(ii) The time evolution of the first function K_1 is given by

$$\frac{d}{dt} K_1 \equiv X_{21}(K_1) = \frac{d}{dt}(\mathrm{C}_\kappa^2(y) v_u) + (\mathrm{i}\omega_0) \frac{d}{dt} \mathrm{T}_\kappa(2u) = \left[\frac{2\mathrm{i}\omega_0}{\mathrm{C}_\kappa^2(2u)\mathrm{C}_\kappa^2(y)} \right] K_1,$$

and a similar calculus leads to

$$\frac{d}{dt} K_2^+ \equiv X_{21}(K_2^+) = \mathrm{i}\omega_0 \left[\frac{\mathrm{C}_\kappa(u) + \sqrt{\kappa}\,\mathrm{S}_\kappa(u)}{\mathrm{C}_\kappa(2u)\mathrm{C}_\kappa(y)} \right]^2 K_2^+,$$

$$\frac{d}{dt} K_2^- \equiv X_{21}(K_2^-) = \mathrm{i}\omega_0 \left[\frac{\mathrm{C}_\kappa(u) - \sqrt{\kappa}\,\mathrm{S}_\kappa(u)}{\mathrm{C}_\kappa(2u)\mathrm{C}_\kappa(y)} \right]^2 K_2^-.$$

The important point is that we get the following expression for the time evolution of the function product $K_{22} = K_2^+ K_2^-$:

$$\begin{aligned} \frac{d}{dt}(K_2^+ K_2^-) &= X_{21}(K_2^+) K_2^- + K_2^+ X_{21}(K_2^-) \\ &= \left[\frac{\mathrm{i}\omega_0}{\mathrm{C}_\kappa^2(2u)\mathrm{C}_\kappa^2(y)} \right] [(\mathrm{C}_\kappa(u) + \sqrt{\kappa}\,\mathrm{S}_\kappa(u))^2 + (\mathrm{C}_\kappa(u) - \sqrt{\kappa}\,\mathrm{S}_\kappa(u))^2](K_2^+ K_2^-) \\ &= \left[\frac{2\mathrm{i}\omega_0}{\mathrm{C}_\kappa^2(2u)\mathrm{C}_\kappa^2(y)} \right] (K_2^+ K_2^-). \end{aligned}$$

Thus we arrive at the property

$$\frac{d}{dt} K_{122} = X_{21}(K_1)(K_2^{+*} K_2^{-*}) + K_1 X_{21}(K_2^{+*} K_2^{-*}) = 0$$

and the function K_{122} is an integral of motion. As it is complex, we obtain two real κ-dependent constants, $I_3(\kappa)$ and $I_4(\kappa)$, defined in the usual form

$$K_{122} = I_4(\kappa) + \mathrm{i} I_3(\kappa).$$

After some simplification the expressions for these two constants become

$$I_3(\kappa) = J(\kappa) P_2(\kappa) + \omega_0^2 \left(\frac{\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(u)}{\mathrm{C}_\kappa^2(2u)} \right) \mathrm{T}_\kappa^2(y),$$

$$I_4(\kappa) = [P_2^2(\kappa) - \kappa J^2(\kappa)] P_1(\kappa) + \omega_0^2 [2\,\mathrm{T}_\kappa(2u)\, v_y - \mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y)\, v_u] \left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2u)} \right).$$

We close this section with the following observations.

(i) Although K_2^+ and K_2^- are two different κ-dependent functions, $K_2^+ \neq K_2^-$, they have the same function J_2 as the Euclidean limit. We have

$$\lim_{\kappa\to 0} K_1 = v_x + \mathrm{i}\,\omega_0\,(2x), \quad \lim_{\kappa\to 0} K_2^+ = \lim_{\kappa\to 0} K_2^- = v_y + \mathrm{i}\,\omega_0\, y.$$

The coefficient $n_1=2$ in the Euclidean function J_1 (see the notation of Sec. II) is now present, not as a global multiplicative factor on the imaginary part of K_1, but as a coefficient inside the argument of the tangent function.

(ii) The Euclidean function J_2 is κ-deformed in two different ways, K_2^+ and K_2^-, in such a way that the Euclidean square factor J_2^2 becomes the product $K_2^+ K_2^-$.

(iii) The transition of U_{11} to U_{21} is very simple: just the change $\mathrm{T}_\kappa(u)$ by $\mathrm{T}_\kappa(2\,u)$ in the potential expressed in parallel coordinates.

VI. FINAL COMMENTS AND OUTLOOK

We have started with a discussion of the curvilinear systems of coordinates on 2-D spaces of constant curvature and then we have studied the two oscillators with quadratic super-integrability. We have proved that they can be considered as κ-deformations of the Euclidean oscillator or, alternatively, that the classic and well-known Euclidean oscillator appears just as a very particular case of a much more general ''curved'' system. Concerning our approach, two important points are, first, that the results have been obtained for a general value of the curvature κ, in such a way that they cover simultaneously the case of a Euclidean plane ($\kappa=0$), the 2-sphere ($\kappa>0$) and the hyperbolic plane ($\kappa<0$); and, second, that all the computations have been carried out in both ''geodesic polar'' and ''geodesic parallel'' coordinates. The ''geodesic parallel'' coordinates may seem rather unusual, but they have proved to be the more appropriate ones for the study of the nonisotropic case.

The results obtained in Sec. V suggest that the appropriate potential $U_{n1}(u,y,\kappa)$ for representing the general nonisotropic $n{:}1$ oscillator, with an n integer, on a 2-D manifold of constant curvature κ, is given by

$$U_{n1} = \frac{\mathrm{T}_\kappa^2(n\,u)}{\mathrm{C}_\kappa^2(y)} + \mathrm{T}_\kappa^2(y) = \mathrm{T}_\kappa^2(n\,u) + \frac{\mathrm{T}_\kappa^2(y)}{\mathrm{C}_\kappa^2(n\,u)}.$$

This potential satisfies the appropriate Euclidean limit,

$$\lim_{\kappa\to 0} U_{n1}(\kappa) = (nx)^2 + y^2,$$

and is integrable for arbitrary values of the integer n. The two fundamental integrals of motion are both quadratic in the velocities

$$I_1(\kappa) = P_1^2(\kappa) + \omega_0^2\,[\mathrm{T}_\kappa(n\,u)]^2,$$

$$I_2(\kappa) = [P_2^2(\kappa) + \kappa\, J^2(\kappa)] + \omega_0^2 \left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(n\,u)}\right)^2,$$

and can be considered as κ-deformations of the two quadratic Euclidean energies:

$$\lim_{\kappa\to 0} I_1(\kappa) = v_x^2 + \omega_0^2\,(nx)^2, \quad \lim_{\kappa\to 0} I_2(\kappa) = v_y^2 + \omega_0^2\, y^2.$$

It seems natural to conjecture that U_{n1} (for any integer value of n) is super-integrable as well, and that the corresponding additional (nonquadratic) integral can also be obtained through a complex constant similar to the one obtained for the $2{:}1$ case in Sec. V. A more difficult problem seems to be the obtaining of the spherical (hyperbolic) version of the rational $n_1{:}n_2$ oscillator, since a direct

generalization will lead to problems with the domain and range of the potential (in this general case, the spherical system looks more complicated than the hyperbolic one). We think that these are open questions that must be investigated.

I. INTRODUCTION

Recently, various properties of the solutions for lattice dynamical systems have been studied by many authors; see Refs. 1–5 and the references therein. Lattice systems arise in many applications, for example, in chemical reaction theory, image processing and pattern recognition, material science, and biology. They possess their own form, but in some cases they arise as spatial discretizations of partial differential equations.

In this paper, by introducing a new weight norm that is equivalent to the usual norm in the phase space, we shall consider the existence and approximation of the global attractor for the second-order damped lattice dynamical system:

$$\ddot{u}_i-\gamma(\dot{u}_{i-1}-2\dot{u}_i+\dot{u}_{i+1})+h(\dot{u}_i)-(u_{i-1}-2u_i+u_{i+1})+\lambda u_i+f(u_i)=g_i,\quad i\in Z, \tag{1}$$

where $\gamma\geqslant 0$ and $\lambda>0$ are constants, g_i is given, and f, $h\in C^1(R,R)$ satisfy some monotonic conditions. Equation (1) can be regarded as a model of damped coupled nonlinear oscillators (see Ref. 1, pp. 442–451) and a model of a discrete analog of the following continuous strongly damped semilinear wave equation in R:

$$u_{tt}-\gamma u_{xxt}+h(u_t)-u_{xx}+\lambda u+f(u)=g, \tag{2}$$

which arises in wave phenomena of various areas with a strong damping in mathematical physics. The global attractor and its dimension to Eq. (2) in bounded domain have been widely studied; see Refs. 6–9 and the references therein. It is important to have some rigorous study on the dynamics of system (1). Here we shall study the asymptotic behavior for system (1) when the initial date belongs to the space l^2.

This paper is organized as follows. In the second section, we show the existence and uniqueness of solutions for system (1). In Sec. III, we prove the existence of an absorbing set of (1) (that is, the uniform boundedness of solutions). In Sec. IV, we prove the asymptotic compactness for the semigroup associated with (1) and the existence of the global attractor. In Sec. V, we consider the finite-dimensional approximations to the global attractor.

II. EXISTENCE AND UNIQUENESS OF SOLUTIONS

In this section, we present the existence and uniqueness of solutions for system (1). We consider the system

$$\ddot{u}_i-\gamma(\dot{u}_{i-1}-2\dot{u}_i+\dot{u}_{i+1})+h(\dot{u}_i)-(u_{i-1}-2u_i+u_{i+1})+\lambda u_i+f(u_i)=g_i,\quad i\in Z, \tag{3}$$

a)Electronic mail: zhoushengfan@263.net

with the initial conditions

$$u_i(0)=u_{i,0}, \quad \dot{u}_i(0)=u_{1i,0}, \quad i\in Z, \tag{4}$$

where $\gamma\geqslant 0$, $\lambda>0$, $g=(g_i)_{i\in Z}$, and f, $h\in C^1(R,R)$.

We make the following assumptions on f, h:

$$f(s)s\geqslant \nu G(s)\geqslant 0, \quad \forall s\in R, \tag{5}$$

$$h(0)=0, \quad 0<\alpha\leqslant h'(s)\leqslant \beta<+\infty, \quad \forall s\in R; \tag{6}$$

here ν, α, β are positive constants and $G(s)=\int_0^s f(t)dt$, $s\in R$. Obviously, $f(s)=\Sigma_{j=0}^m a_j s^{2j+1}$, with $a_j>0$, $j=0,1,...,m$, satisfies (5).

We also assume that α, β, γ, λ satisfy

$$0\leqslant \gamma\leqslant \frac{\beta^2+4\lambda}{\alpha\lambda}. \tag{7}$$

For our purpose, we introduce some spaces and operators. Let $l^2=\{u=(u_i)_{i\in Z}|\Sigma_{i\in Z}|u_i|^2<\infty\}$. Define the linear operators B, $\overline{B}$, A from l^2 to l^2 as follows. For any $u=(u_i)_{i\in Z}\in l^2$,

$$(Bu)_i=u_{i+1}-u_i, \quad (\overline{B}u)_i=u_{i-1}-u_i, \quad (Au)_i=-(u_{i-1}-2u_i+u_{i+1}), \quad \forall i\in Z.$$

Then we have

$$A=\overline{B}B=B\overline{B}.$$

For any two elements of l^2, $u=(u_i)_{i\in Z}$, $v=(v_i)_{i\in Z}\in l^2$, define bilinear forms as

$$(u,v)=\sum_{i\in Z} u_i v_i, \quad \|u\|^2=(u,u)=\sum_{i\in Z}|u_i|^2;$$

$$(u,v)_\lambda=\rho(Bu,Bv)+\lambda(u,v), \tag{8}$$

$$\|u\|_\lambda^2=(u,u)_\lambda=\rho\|Bu\|^2+\lambda\|u\|^2=\sum_{i\in Z}(\rho|u_{i+1}-u_i|^2+\lambda|u_i|^2),$$

where ρ is chosen as

$$\rho=1-\frac{\alpha\lambda}{\beta^2+4\lambda}\gamma\geqslant 0.$$

It is easy to check that above two bilinear forms $(\cdot,\cdot)$ and $(\cdot,\cdot)_\lambda$ in (8) are both the inner products; moreover, the norms $\|\cdot\|$ and $\|\cdot\|_\lambda$ are equivalent to each other because

$$\lambda\|u\|^2\leqslant\|u\|_\lambda^2=\sum_{i\in Z}(\rho|u_{i+1}-u_i|^2+\lambda|u_i|^2)\leqslant(4\rho+\lambda)\|u\|^2.$$

Denote by l^2, l_λ^2 the spaces with the inner products and norms in (8), respectively,

$$l^2=(l^2,(\cdot,\cdot),\|\cdot\|), \quad l_\lambda^2=(l^2,(\cdot,\cdot)_\lambda,\|\cdot\|_\lambda);$$

then l^2 and l_λ^2 are Hilbert spaces.

Let $E=l_\lambda^2\times l^2$, endowed with the inner product and norm as, for $\varphi_j=(u^{(j)},v^{(j)})=((u_i^{(j)}),(v_i^{(j)}))_{i\in Z}\in E$, $j=1,2$,

$$(\varphi_1,\varphi_2)_E=(u^{(1)},u^{(2)})_\lambda+(v^{(1)},v^{(2)})=\sum_i\ [\rho(Bu^{(1)})_i(Bu^{(2)})_i+\lambda u_i^{(1)}u_i^{(2)}+v_i^{(1)}v_i^{(2)}],$$

$$\|\varphi\|_E^2=(\varphi,\varphi)_E,\quad \forall\varphi\in l_\lambda^2\times l^2. \tag{9}$$

Now we consider the existence and uniqueness of solutions of system (3)–(4). With the above notations, Eq. (3) can be written as

$$\ddot{u}+\gamma A\dot{u}+h(\dot{u})+Au+\lambda u+f(u)=g,\quad t>0, \tag{10}$$

and the initial data (4) are

$$u(0)=(u_{i,0})_{i\in Z}=u_0,\quad \dot{u}(0)=(u_{1i,0})_{i\in Z}=u_{10}, \tag{11}$$

where

$$u=(u_i)_{i\in Z},\quad h(\dot{u})=(h(\dot{u}_i))_{i\in Z},\quad f(u)=(f(u_i))_{i\in Z},\quad g=(g_i)_{i\in Z}.$$

It is convenient to reduce (10) to an evolution equation of the first order in time. Let $v=\dot{u}+\varepsilon u$, where ε is chosen as

$$\varepsilon=\frac{\alpha\lambda}{\beta^2+4\lambda}>0; \tag{12}$$

then system (10)–(11) is equivalent to the following initial value problem in Hilbert space E:

$$\dot{\varphi}+C(\varphi)=F(\varphi),\quad \varphi(0)=(u_0,v_0)^T=(u_0,u_{10}+\varepsilon u_0)^T, \tag{13}$$

where

$$\varphi=(u,v)^T,\quad v=\dot{u}+\varepsilon u,\quad F(\varphi)=(0,-f(u)+g)^T,$$

$$C(\varphi)=\begin{pmatrix}\varepsilon u-v\\ Au+\lambda u-\gamma\varepsilon Au+\varepsilon^2u+\gamma Av-\varepsilon v\end{pmatrix}+\begin{pmatrix}0\\ h(v-\varepsilon u)\end{pmatrix}. \tag{14}$$

Let us show that the function $F(\varphi)-C(\varphi)$ is locally Lipschitz continuous from E to E. By condition (5), $f(0)=0$, and for any $u=(u_i)_{i\in z}\in l^2$,

$$\|f(u)\|^2=\sum_{i\in Z}|f(u_i)|^2=\sum_{i\in Z}|f'(\theta_iu_i)|^2|u_i|^2,$$

where $\theta_i\in(0,1)$. By $|\theta_iu_i|\leqslant|u_i|\leqslant\|u\|$,

$$\|f(u)\|\leqslant\|u\|\max_{s\in[0,\|u\|]}|f'(s)|; \tag{15}$$

thus, from $f\in C^1$, it follows that $f(u)\in l^2$, i.e., f maps l^2 into l^2, hence, F maps E into itself.

By (6),

$$\|h(v-\varepsilon u)\|^2=\sum_{i\in Z}|h'(\tilde{\theta}_i(v_i-\varepsilon u_i))|^2|v_i-\varepsilon u_i|^2\leqslant 2\beta^2(\|v\|^2+\varepsilon^2\|u\|^2); \tag{16}$$

thus, if $\varphi=(u,v)\in E$, then $h(v-\varepsilon u)\in l^2$, i.e., $H(\varphi)=(0,h(v-\varepsilon u))^T$ maps E into E.

Let B be a bounded set in E, $\varphi_j=(u^{(j)},v^{(j)})=((u_i^{(j)}),(v_i^{(j)}))_{i\in Z}\in B$, $j=1,2$, similar to (15), there exists $L(B)$ depending on B such that

$$\|F(\varphi_1)-F(\varphi_2)\|_E^2=\|f(u^{(1)})-f(u^{(2)})\|^2$$

$$=\sum_{i\in z}|f'(u_i^{(1)}+\theta_i(u_i^{(2)}-u_i^{(1)})|^2|u_i^{(1)}-u_i^{(2)}|^2)$$

$$\leqslant\left(\max_{s\in[0,\|u^{(1)}\|+\|u^{(2)}\|]}|f'(s)|\right)\cdot\|u^{(1)}-u^{(2)}\|^2\leqslant L(B)\|\varphi_1-\varphi_2\|_E^2,$$

and similar to (16),

$$\|H(\varphi_1)-H(\varphi_2)\|_E^2=\|h(v^{(1)}-\varepsilon u^{(1)})-h(v^{(2)}-\varepsilon u^{(2)})\|^2$$

$$=\sum_{i\in z}|h'(\xi_i)|^2|(v_i^{(1)}-v_i^{(1)})-\varepsilon(u_i^{(1)}-u_i^{(2)})|^2$$

$$\leqslant 2\beta^2(\|v^{(1)}-v^{(1)}\|^2+\varepsilon^2\|u^{(1)}-u^{(2)}\|^2)$$

$$\leqslant 2\beta^2(1+\varepsilon^2/\lambda)\|\varphi_1-\varphi_2\|_E^2,$$

which imply that $F(\varphi)-C(\varphi)$ is locally Lipschitz from E to E. By the standard theory of ordinary differential equations, we obtain the existence and uniqueness of local solution φ for problem (13).

Lemma 2.1: If $g=(g_i)_{i\in Z}\in l^2$ and f, h satisfy (5), (6), then for any initial data $\varphi(0)=(u_0,v_0)^T\in E$, there exists a unique local solution $\varphi(t)=(u(t),v(t))^T$ of (13) such that $\varphi\in C^1((0,T_0),E)$ for some $T_0>0$. If $T_0<+\infty$, then $\lim_{t\to T_0}\|\varphi(t)\|_E=+\infty$.

In fact, it is shown from Lemma 3.2 below that the local solution $\varphi(t)$ of (13) exists globally, that is, $\varphi\in C^1(R_+,E)$, which implies that maps

$$S(t):\varphi(0)=(u_0,v_0)\in E\to\varphi(t)=S(t)\varphi(0)=(u(t),v(t))\in E,\quad t\geqslant 0, \tag{17}$$

generates a continuous semigroup $\{S(t)\}_{t\geqslant 0}$ on E, where $v(t)=\dot{u}(t)+\varepsilon u(t)$.

Remark: It is easy to see that the solutions of problem (13) are backward unique in time t, i.e., the solution $\varphi(t)\in C^1(R,E)$.

III. ABSORBING SET

In this section, we consider the uniform boundedness of solutions of system (13). First, we present a positivity of the nonlinear operator C.

Lemma 3.1: For any $\varphi=(u,v)^T\in E$,

$$(C(\varphi),\varphi)_E\geqslant\sigma\|\varphi\|_E^2+\frac{\alpha}{2}\|v\|^2, \tag{18}$$

where

$$\sigma=\frac{\alpha\lambda}{\sqrt{\beta^2+4\lambda}(\beta+\sqrt{\beta^2+4\lambda})}. \tag{19}$$

Proof: It is easy to check that

$$(Bu,v)=(u,\overline{B}v)\quad\text{and}\quad(Au,v)=(Bu,Bv),\quad\forall u,v\in l^2. \tag{20}$$

By the definition of $(\cdot,\cdot)_E$ in (9), (14), and (20),

$$(C(\varphi),\varphi)_E=\varepsilon[\rho\|Bu\|^2+\lambda\|u\|^2]+\varepsilon^2(u,v)+\gamma(Av,v)+(h(v-\varepsilon u),v)-\varepsilon(v,v),$$

and by (6),

$$\varepsilon^2(u,v)+(h(v-\varepsilon u),v)=\varepsilon^2\sum_{i\in Z}u_iv_i+\sum_{i\in Z}h'(\tau_i(v_i-\varepsilon u_i))(v_i-\varepsilon u_i)v_i$$
$$\geqslant\alpha\|v\|^2-\varepsilon(\beta-\varepsilon)\|u\|\cdot\|v\|;$$

then

$$(C(\varphi),\varphi)_E-\sigma\|\varphi\|_E^2-\frac{\alpha}{2}\|v\|^2\geqslant(\varepsilon-\sigma)[\rho\|Bu\|^2+\lambda\|u\|^2]+\gamma\|Bv\|^2$$
$$+\left(\frac{\alpha}{2}-\varepsilon-\sigma\right)\|v\|^2-\beta\varepsilon\|u\|\cdot\|v\|$$
$$\geqslant(\varepsilon-\sigma)[\rho\|Bu\|^2+\lambda\|u\|^2]+\left(\frac{\alpha}{2}-\varepsilon-\sigma\right)\|v\|^2-\frac{\beta\varepsilon}{\sqrt{\lambda}}[\rho\|Bu\|^2$$
$$+\lambda\|u\|^2]^{1/2}\|v\|,$$

and a simple computation from (12), (19) shows

$$4(\varepsilon-\sigma)\left(\frac{\alpha}{2}-\varepsilon-\sigma\right)=\frac{\beta^2\varepsilon^2}{\lambda}.$$

Thus, the proof is completed.

Now we consider the boundedness of solutions $\varphi(t)$ of (13).

Lemma 3.2: If (5)–(7) hold and $g\in l^2$, then there exists a bounded ball $O=O_E(0,r_0)$, centered at 0 with radius r_0, such that for every bounded set B of E, there exists $T(B)\geqslant 0$ such that

$$S(t)B\subset O,\quad \forall t\geqslant T(B), \tag{21}$$

where $r_0^2=(2/\alpha\mu)\|g\|^2$. Therefore, there exists a constant $T_0\geqslant 0$ depending on O such that

$$S(t)O\subset O,\quad \forall t\geqslant T_0. \tag{22}$$

Proof: Assume that (5)–(7) hold and $g\in l^2$. Let $\varphi(t)=(u(t),v(t))^T\in E$ be a solution of (13), where $v(t)=\dot{u}(t)+\varepsilon u(t)$. Taking the inner product $(\cdot,\cdot)_E$ of (13) with $\varphi(t)$, we have

$$\frac{1}{2}\frac{d}{dt}\|\varphi\|_E^2+(C(\varphi),\varphi)_E+(f(u),\dot{u})+\varepsilon(f(u),u)=(g,v). \tag{23}$$

By (18),

$$(C(\varphi),\varphi)_E\geqslant\sigma\|\varphi\|_E^2+\frac{\alpha}{2}\|v\|^2. \tag{24}$$

By (5),

$$(f(u),\dot{u})=\sum_{i\in Z}f(u_i)\dot{u}_i=\frac{d}{dt}\left(\sum_{i\in Z}G(u_i)\right), \tag{25}$$

$$(f(u),u)=\sum_{i\in Z}f(u_i)u_i\geqslant\nu\sum_{i\in Z}G(u_i), \tag{26}$$

and

$$(g,v)\leqslant\frac{1}{2\alpha}\|g\|^2+\frac{\alpha}{2}\|v\|^2. \tag{27}$$

By putting (24)–(27) into (23), we find

$$\frac{d}{dt}\left[\|\varphi\|_E^2+2\sum_{i\in Z}G(u_i)\right]+\mu\left[\|\varphi\|_E^2+2\sum_{i\in Z}G(u_i)\right]\leqslant\frac{1}{\alpha}\|g\|^2, \tag{28}$$

where $\mu=\min\{2\sigma,\nu\varepsilon\}$. Since

$$G(u_i)\geqslant 0,\quad \|\varphi\|_E^2+2\sum_{i\in Z}G(u_i)\geqslant 0,$$

by Gronwall's inequality,

$$\|\varphi\|_E^2+2\sum_{i\in Z}G(u_i)\leqslant\left[\|\varphi(0)\|_E^2+2\sum_{i\in Z}G(u_{i0})\right]e^{-\mu t}+\frac{1}{\alpha\mu}\|g\|^2(1-e^{-\mu t}). \tag{29}$$

By (5),

$$\sum_{i\in Z}G(u_{i0})\leqslant\frac{1}{\nu}\sum_{i\in Z}f(u_{i0})_{ui0}\leqslant\frac{1}{\nu}\max_{s\in[0,\|u(0)\|]}|f'(s)|\cdot\|u(0)\|^2. \tag{30}$$

By (29) and (28),

$$\|\varphi\|_E^2\leqslant\left[\|\varphi(0)\|_E^2+\frac{2}{\nu}\max_{s\in[0,\|u(0)\|]}|f'(s)|\cdot\|u(0)\|^2\right]e^{-\mu t}+\frac{1}{\alpha\mu}\|g\|^2(1-e^{-\mu t}) \tag{31}$$

and

$$\limsup_{t\to\infty}\|\varphi\|_E^2\leqslant\frac{1}{\alpha\mu}\|g\|^2. \tag{32}$$

Inequality (31) [or (32)] implies that the semigroup $\{S(t)\}_{t\geqslant 0}$ possesses a bounded absorbing set in E. The proof is completed.

From (31), for any initial data $\varphi(0)=(u_0,v_0)^T\in E$, then the solution $\varphi(t)=(u(t),v(t))^T$ is bounded for all $t\in[0,+\infty)$, that is, the solution $\varphi(t)$ exists globally on $[0,+\infty)$, maps $\{S(t)_{t\geqslant 0}\}$ defined by (17) form a semigroup on E.

IV. GLOBAL ATTRACTOR

In this section, we prove the existence of a global attractor for the semigroup $\{S(t)_{t\geqslant 0}\}$ associated with (13) on E. For this purpose, we need to prove the asymptotic compactness of $\{S(t)_{t\geqslant 0}\}$.

Lemma 4.1: If (5)–(7) hold, $g\in l^2$ and $\varphi(0)=(u_0,v_0)\in O$, then $\forall\,\eta>0$, there exist $T(\eta)$ and $K(\eta)$ such that the solution $\varphi(t)=(\varphi_i)_{i\in Z}=((u_i(t)),(v_i(t)))_{i\in Z}\in E$ of problem (13), $v(t)=\dot{u}(t)+\varepsilon u(t)$, satisfies

$$\sum_{|i|\geqslant K(\eta)}\|\varphi_i(t)\|_E^2=\sum_{|i|\geqslant K(\eta)}[\rho|(Bu(t))_i|^2+\lambda|u_i(t)|^2+|v_i(t)|^2]\leqslant\eta,\quad\forall t\geqslant T(\eta), \tag{33}$$

where $(Bu(t))_i=u_{i+1}(t)-u_i(t)$.

Proof: Choosing a smooth function $\theta\in C^1(R^+,R)$ satisfies

$$\theta(s)=0,\quad 0\leqslant s\leqslant 1,$$

$$0\leqslant\theta(s)\leqslant 1,\quad 1\leqslant s\leqslant 2, \tag{34}$$

$$\theta(s)=1, \quad s\geqslant 2;$$

then there exists a constant C_0 such that $|\theta'(s)|\leqslant C_0$ for $s\in R^+$.

Let $\varphi(t)=(u(t),v(t))=(\varphi_i)_{i\in Z}=((u_i(t)),(v_i(t)))_{i\in Z}$ be a solution of (13), where $v(t)=\dot{u}(t)+\varepsilon u(t)$, $\varphi_i=(u_i,v_i)$, ε is as in (12).

Let k be a fixed integer. Set $w_i=\theta(|i|/k)u_i$, $z_i=\theta(|i|/k)v_i$, $y=(w,z)=((w_i),(z_i))_{i\in Z}$. Taking the inner product $(\cdot,\cdot)_E$ of (13) with y, we have

$$(\dot{\varphi},y)_E+(C(\varphi),y)_E=(F(\varphi),y)_E. \tag{35}$$

It is possible to check that

$$(\dot{\varphi},y)_E=\frac{1}{2}\frac{d}{dt}\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)\|\varphi_i\|_E^2, \tag{36}$$

where

$$\|\varphi_i\|_E^2=\rho|(Bu)_i|^2+\lambda|u_i|^2+|v_i|^2=\rho|u_{i+1}-u_i|^2+\lambda|u_i|^2+|v_i|^2, \tag{37}$$

and

$$\begin{aligned}(C(\varphi),y)_E=&\varepsilon\rho(Bu,Bw)-\rho(Bv,Bw)+\lambda\varepsilon(u,w)-\lambda(v,w)+(Bu,Bz)+\lambda(u,z)+\varepsilon^2(u,z)\\&-\varepsilon\gamma(Bu,Bz)-\varepsilon(v,z)+(h(v-\varepsilon u),z),\end{aligned} \tag{38}$$

$$\begin{aligned}(Bu,Bw)(t)&=\sum_{i\in Z}\left\{\left[\theta\left(\frac{|i+1|}{k}\right)-\theta\left(\frac{|i|}{k}\right)\right](u_{i+1}-u_i)u_{i+1}+\theta\left(\frac{|i|}{k}\right)(u_{i+1}-u_i)^2\right\}\\&\geqslant-\frac{4C_0r_0^2}{k}+\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)(u_{i+1}-u_i)^2, \quad \forall t\geqslant T_0,\end{aligned}$$

$$(Bv,Bw)=\sum_{i\in Z}\left[\theta\left(\frac{|i+1|}{k}\right)(v_{i+1}-v_i)u_{i+1}-\theta\left(\frac{|i|}{k}\right)(v_{i+1}-v_i)u_i\right],$$

$$(Bu,Bz)=\sum_{i\in Z}\left[\theta\left(\frac{|i+1|}{k}\right)(u_{i+1}-u_i)v_{i+1}-\theta\left(\frac{|i|}{k}\right)(u_{i+1}-u_i)v_i\right],$$

$$\begin{aligned}(1-\varepsilon\gamma)(Bu,Bz)-\rho(Bv,Bw)&=\rho\sum_{i\in Z}\left(\theta\left(\frac{i+1}{k}\right)-\theta\left(\frac{|i|}{k}\right)\right)(u_{i+1}v_i-u_iv_{i+1})\\&\geqslant-\rho\sum_{i\in Z}\frac{|\theta'(\tau_i)|}{k}|u_{i+1}v_i-u_iv_{i+1}|\\&\geqslant-\frac{4\rho C_0r_0^2}{k}, \quad \forall t\geqslant T_0,\end{aligned}$$

$$(u,w)=\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)u_i^2, \quad (v,w)=\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)u_iv_i=(u,z), \quad (v,z)=\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)v_i^2,$$

$$\varepsilon^2(u,z)+(h(v-\varepsilon u),z)\geqslant\alpha\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)u_i^2-\varepsilon(\beta-\varepsilon)\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)u_iv_i.$$

By (38) and the proof of (18),

$$(C(\varphi),y)\geqslant -\frac{8\rho C_0 r_0^2}{k}+\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)\left[\sigma\|\varphi_i\|_E^2+\frac{\alpha}{2}|v_i|^2\right],\quad \forall t\geqslant T_0. \tag{39}$$

And

$$(F(\varphi),y)_E=-(f(u),z)+(g,z),$$

$$\begin{aligned}(f(u),z)&=\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)f(u_i)\dot{u}_i+\varepsilon\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)f(u_i)u_i\\&\geqslant\frac{d}{dt}\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)G(u_i)+\varepsilon\nu\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)G(u_i),\end{aligned} \tag{40}$$

$$\begin{aligned}(g,z)=\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)g_iv_i&=\sum_{|i|\geqslant k}\theta\left(\frac{|i|}{k}\right)g_iv_i\leqslant\frac{\alpha}{2}\sum_{|i|\geqslant k}\theta^2\left(\frac{|i|}{k}\right)v_i^2+\frac{1}{2\alpha}\sum_{|i|\geqslant k}g_i^2\\&\leqslant\frac{\alpha}{2}\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)v_i^2+\frac{1}{2\alpha}\sum_{|i|\geqslant k}g_i^2.\end{aligned} \tag{41}$$

Putting inequalities (36), (39)–(41) into (35), we obtain

$$\frac{d}{dt}\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)[\|\varphi_i\|_E^2+2G(u_i)]+\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)[2\sigma\|\varphi_i\|_E^2+2\varepsilon\nu G(u_i)]\leqslant\frac{8\rho C_0r_0^2}{k}+\frac{1}{\alpha}\sum_{|i|\geqslant k}g_i^2.$$

Since $g\in l^2$, then $\forall\,\eta>0$, there exists $K(\eta)$ such that

$$\frac{8\rho C_0r_0^2}{k}+\frac{1}{\alpha}\sum_{|i|\geqslant k}g_i^2\leqslant\eta,\quad \forall k\geqslant K(\eta),$$

i.e., for $t\geqslant T_0, k\geqslant K(\eta)$,

$$\frac{d}{dt}\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)[\|\varphi_i\|_E^2+2G(u_i)]+\mu\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)[\|\varphi_i\|_E^2+2G(u_i)]\leqslant\eta,$$

where $\mu=\min\{2\sigma,\varepsilon\nu\}$. So, by Gronwall's inequality,

$$\begin{aligned}\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)[\|\varphi_i\|_E^2+2G(u_i)]&\leqslant e^{-\mu(t-T_0)}\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)[\|\varphi_i(T_0)\|_E^2+2G(u_i(T_0))]+\frac{\eta}{\mu}\\&\leqslant e^{-\mu(t-T_0)}r_0^2\left(1+\frac{2}{\nu}M_0\right)+\frac{\eta}{\mu},\quad \forall t\geqslant T_0,\end{aligned}$$

where $M_0=\max_{s\in[0,r_0/\nu]}|f'(s)|$. Taking

$$T(\eta)=\max\left\{T_0,T_0+\frac{1}{\mu}\ln\frac{\mu}{\eta}\left(1+\frac{2}{\nu}M_0\right)r_0^2\right\},$$

then for $t\geqslant T(\eta)$ and $k\geqslant K(\eta)$, we have

$$\sum_{|i|\geqslant 2k}\|\varphi_i\|_E^2\leqslant\sum_{i\in Z}\theta\left(\frac{|i|}{k}\right)\|\varphi_i\|_E^2\leqslant\frac{2\eta}{\mu}, \tag{42}$$

which implies Lemma 4.1. The proof is completed.

Lemma 4.2: If (5)–(7) hold and $g \in l^2$, then the semigroup $\{S(t)\}_{t\geqslant 0}$ is asymptotically compact in E, that is, if $\{\varphi_n\}$ is bounded in E and $t_n \to +\infty$, then $\{S(t_n)\varphi_n\}$ is precompact in E.

Proof: Since $\{\varphi_n\} \subset E = l^2_\lambda \times l^2$ is bounded, assume that $\|\varphi_n\|_E \leqslant r$ for some positive constant r, $n = 1,2,\ldots$. By Lemma 3.2, there exists T_r such that

$$S(t)\{\varphi_n\} \subset O, \quad \forall t \geqslant T_r, \tag{43}$$

where O is the absorbing set in Lemma 2.3. By $t_n \to +\infty$, there exists $N_1(r)$ such that $t_n \geqslant T_r$ if $n \geqslant N_1(r)$, thus,

$$S(t_n)\{\varphi_n\} \subset O, \quad \forall n \geqslant N_1(r). \tag{44}$$

Since E is a Hilbert space and by (44), there exists $\varphi_0 \in E$ and a subsequence of $\{S(t_n)\varphi_n\}$ (denoted still by $\{S(t_n)\varphi_n\}$), such that

$$S(t_n)\varphi_n \to \varphi_0, \quad \text{weakly in } E. \tag{45}$$

In fact, the convergence here is a strong one, i.e., $\forall \eta > 0$, there exists $N(\eta)$ such that

$$\|S(t_n)\varphi_n - \varphi_0\|_E \leqslant \eta, \quad \forall n \geqslant N(\eta).$$

For $\eta > 0$, by Lemma 4.1 and (43), there exist $K_1(\eta), T(\eta)$ such that

$$\sum_{|i|\geqslant K_1(\eta)} \|(S(t)(S(T_r))\varphi_n)_i\|^2_E \leqslant \frac{\eta^2}{8}, \quad t \geqslant T(\eta).$$

By $t_n \to +\infty$, there exists $N_2(r,\eta)$ such that $t_n \geqslant T_r + T(\eta)$ if $n \geqslant N_2(r,\eta)$; hence,

$$\sum_{|i|\geqslant K_1(\eta)} \|(S(t_n)\varphi_n)_i\|^2_E = \sum_{|i|\geqslant K_1(\eta)} \|(S(t_n - T_r)S(T_r)\varphi_n)_i\|^2_E \leqslant \frac{\eta^2}{8}. \tag{46}$$

Again, since $\varphi_0 \in E$, there exists $K_2(\eta)$ such that

$$\sum_{|i|\geqslant K_2(\eta)} \|(\varphi_0)_i\|^2_E \leqslant \frac{\eta^2}{8}. \tag{47}$$

Let $K(\eta) = \max\{K_1(\eta), K_2(\eta)\}$, by (45),

$$((S(t_n)\varphi_n)_i)_{|i|\leqslant K(\eta)} \to ((\varphi_0)_i)_{|i|\leqslant K(\eta)}, \quad \text{strongly in} \quad R^{2K(\eta)+1}_\lambda \times R^{2K(\eta)+1}, \quad \text{as} \quad n \to +\infty,$$

that is, there exists $N_3(\eta)$ such that

$$\sum_{|i|\leqslant K(\eta)} \|(S(t_n)\varphi_n)_i - (\varphi_0)_i\|^2_E \leqslant \frac{\eta^2}{2}, \forall n \geqslant N_3(\eta). \tag{48}$$

Setting $N(\eta) = \max\{N_1(r), N_2(r,\eta), N_3(\eta)\}$, from (46)–(48), then for $n \geqslant N(\eta)$,

$$\begin{aligned}\|S(t_n)\varphi_n - \varphi_0\|^2_E &= \sum_{|i|\leqslant K(\eta)} \|(S(t_n)\varphi_n)_i - (\varphi_0)_i\|^2_E + \sum_{|i|> K(\eta)} \|(S(t_n)\varphi_n)_i - (\varphi_0)_i\|^2_E \\ &\leqslant \frac{\eta^2}{2} + 2\sum_{|i|> K(\eta)} (\|(S(t_n)\varphi_n)_i\|^2_E - \|(\varphi_0)_i\|^2_E) \leqslant \eta^2.\end{aligned}$$

The proof is completed.

As a direct consequence of Lemma 3.2, Lemma 4.2 and Theorem I.1.1 in Ref. 10, we obtain the existence of a global attractor for semigroup $\{S(t)\}_{t\geqslant 0}$.

Theorem 4.1: If (5)–(7) hold and $g \in l^2$, then the semigroup $\{S(t)\}_{t\geqslant 0}$ associated with (13) possesses a global attractor ß in E.

Remark: Since the solutions of problem (13) are backward unique in time, the invariance of the global attractor ß means

$$S(t)ß = ß, \quad \text{for } t \in R. \tag{49}$$

V. APPROXIMATION OF ATTRACTOR

In this section, we present the approximation to the global attractor ß by the global attractors of finite-dimensional ordinary differential systems.

Let $n \in Z_+$ be a positive integer, we consider the $(2n+1)$-dimensional ordinary differential equations:

$$\begin{gathered}\ddot{w}_i - \gamma(\dot{w}_{i-1} - 2\dot{w}_i + \dot{w}_{i+1}) + h(\dot{w}_i) = (w_{i-1} - 2w_i + w_{i+1}) - \lambda w_i - f(w_i) + g_i, \\ i = -n, \quad -n+1, \quad \ldots, \quad n-1, \quad n, \quad w_{-n} = w_{n+1}, \quad w_n = w_{-n+1},\end{gathered} \tag{50}$$

with the initial values

$$w_i(0) = w_{i0}, \quad \dot{w}_i(0) = z_{i0} \in R, \quad i = -n, -n+1, \ldots, n-1, n. \tag{51}$$

Then equations (50)–(51) can be written as

$$\begin{gathered}\ddot{w} + \gamma\tilde{A}\dot{w} + h(\dot{w}) = -\tilde{A}w - \lambda w - \tilde{f}(w) + \tilde{g}, \\ w(0) = (w_{i0})_{|i|\leqslant n}, \quad \dot{w}(0) = (z_{i0})_{|i|\leqslant n} \in R^{2n+1},\end{gathered} \tag{52}$$

where $w = (w_i)_{|i|\leqslant n}$, $h(\dot{w}) = (h(\dot{w}_i))_{|i|\leqslant n}$, $\tilde{f}(w) = (f(w_i))_{|i|\leqslant n}$, $\tilde{g} = (g_i)_{|i|\leqslant n}$,

$$\tilde{A} = \begin{pmatrix} 2 & -1 & 0 & 0 & 0 & \cdots & 0 & 0 & -1 \\ -1 & 2 & -1 & 0 & 0 & \cdots & 0 & 0 & 0 \\ 0 & -1 & 2 & -1 & 0 & \cdots & 0 & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \ddots & \cdot & \cdot & \cdot \\ 0 & 0 & 0 & 0 & 0 & \cdots & -1 & 2 & -1 \\ -1 & 0 & 0 & 0 & 0 & \cdots & 0 & -1 & 2 \end{pmatrix}_{(2n+1)\times(2n+1)}.$$

Let us introduce some Hilbert spaces and operators similar to Sec. II.
Let

$$B = \begin{pmatrix} -1 & 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & -1 & 1 & 0 & \cdots & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \ddots & \cdot & \cdot \\ 0 & 0 & 0 & 0 & \cdots & -1 & 1 \\ 1 & 0 & 0 & 0 & \cdots & 0 & -1 \end{pmatrix}_{(2n+1)\times(2n+1)};$$

then

$$\tilde{A} = \tilde{B}\tilde{B}^T = \tilde{B}^T\tilde{B}.$$

For any $w = (w_i)_{|i|\leqslant n}$, $z = (z_i)_{|i|\leqslant n} \in R^{2n+1}$, define

$$(w,z)=\sum_{|i|\leqslant n} w_i z_i, \|w\|^2=\sum_{|i|\leqslant n} |w_i|^2,$$

$$(w,z)_\lambda=\rho(\tilde{B}w,\tilde{B}z)+\lambda(w,z),$$

$$\|w\|_\lambda^2=\rho\|\tilde{B}w\|^2+\lambda\|w\|^2=\sum_{|i|\leqslant n}(\rho|w_{i+1}-w_i|^2+\lambda|w_i|^2),$$

where ρ is as in Sec. II. Let $R_\lambda^{2n+1}=(R^{2n+1},\|\cdot\|_\lambda)$, $\tilde{E}=R_\lambda^{2n+1}\times R^{2n+1}$, endowed with the inner product and norm as follows: for $W_j=(w^{(j)},z^{(j)})=((w_i^{(j)}),(z_i^{(j)}))_{|i|\leqslant n}\in\tilde{E}$, $j=1,2$,

$$(W_1,W_2)_{\tilde{E}}=(w^{(1)},w^{(2)})_\lambda+(z^{(1)},z^{(2)})=\sum_i [\rho(\tilde{B}w^{(1)})_i(\tilde{B}w^{(2)})_i+\lambda w_i^{(1)}w_i^{(2)}+z_i^{(1)}z_i^{(2)}],$$

$$\|W_1\|_E^2=(W_1,W_1)_{\tilde{E}};$$

then $\tilde{E}$ is a Hilbert space.

Let $z=\dot{w}+\varepsilon w$, where ε is as in (12); then problem (52) is equivalent to the following first-order system in Hilbert space $\tilde{E}$:

$$\dot{Y}+\tilde{C}(Y)=\tilde{F}(Y),\quad Y(0)=(w(0),z(0)+\varepsilon w(0))^T\in\tilde{E}, \tag{53}$$

where $Y=(w,z)$,

$$\tilde{F}(Y)=\begin{pmatrix}0\\ -\tilde{f}(w)+\tilde{g}\end{pmatrix},$$

$$\tilde{C}(Y)=\begin{pmatrix}\varepsilon w-z\\ \tilde{A}w+\lambda w+\varepsilon^2 w-\varepsilon\gamma\tilde{A}w+\gamma\tilde{A}z-\varepsilon z+h(z-\varepsilon w)\end{pmatrix}.$$

Obviously, the problem (53) is well posed in $\tilde{E}$, that is, for any $Y(0)\in\tilde{E}$, there exists a unique solution $Y\in C([0,+\infty),\tilde{E})\cap C^1((0,+\infty),\tilde{E})$, and maps of solutions $S_n(t):Y(0)\to Y(t)=S_n(t)Y(0)\in\tilde{E}$ generate a continuous semigroup $\{S_n(t)\}_{t\geqslant 0}$ on $\tilde{E}$.

Similar to Lemma 3.2 and Theorem 4.1, we have the following lemma.

Lemma 5.1: If (5)–(7) hold and $g\in l^2$, then there exists a bounded ball $\tilde{O}=\tilde{O}_{\tilde{E}}(0,r_0)$, centered at 0 with radius r_0, such that $\tilde{O}$ is an absorbing set of $\{S_n(t)\}_{t\geqslant 0}$, where r_0 is the same constant in Lemma 3.2, which is independent of n. The semigroup $\{S_n(t)\}_{t\geqslant 0}$ possesses a global attractor $ß_n\subset\tilde{O}\subset\tilde{E}$.

It is easy to see that

$$S_n(t)ß_n=ß_n,\quad \text{for}\quad \text{all}\ \ t\in R.$$

To prove $ß_n$ being an approximation to ß, in the following, we extend the element $w=(w_i)_{|i|\leqslant n}\in R^{2n+1}$ to an element of l^2 such that $w_i=0$ for $|i|>n$ (we still denote it by w).

Lemma 5.2: If (5)–(7) hold, $g\in l^2$, and $\varphi_n(0)\in ß_n$, then there exists a subsequence $\{\varphi_{n_k}(0)\}$ of $\{\varphi_n(0)\}$ and $\varphi_0\in ß$ such that $\varphi_{n_k}(0)$ converges to φ_0 in E.

Proof: Let $\varphi_n(t)=S_n(t)\varphi_n(0)=(u_n(t),v_n(t))\in\tilde{E}=R_\lambda^{2n+1}\times R^{2n+1}$ be a solution of problem (53). Since $\varphi_n(0)\in ß_n$, $\varphi_n(t)\in ß_n\subset\tilde{O}$ for all $t\in R$, thus, for any $t\in R$, $n=1,2,...$,

$$\|\varphi_n(t)\|_{\tilde{E}}=\|\varphi_n(t)\|_E=(\rho\|Bu_n\|^2+\lambda\|u_n\|^2+\|v_n\|^2)^{1/2}\leqslant r_0. \tag{54}$$

By (53),

$$\|\dot{\varphi}_n(t)\|_E \leqslant \|\tilde{C}(\varphi_n(t))\|_E + \|\tilde{F}(\varphi(t))\|_E . \tag{55}$$

Here

$$\|\tilde{C}\varphi_n(t)\|_E^2 \leqslant 8\{\varepsilon^2\rho\|Bu_n\|^2 + \rho\|Bv_n\|^2 + (\lambda\varepsilon^2 + \lambda^2 + \varepsilon^4 + 2\beta^2\varepsilon^2)\|u_n\|^2$$
$$+ (\lambda + \varepsilon^2 + 2\beta^2)\|v_n\|^2 + (1-\varepsilon\gamma)^2\|\tilde{A}u_n\|^2 + \gamma^2\|\tilde{A}v_n\|^2\},$$

and

$$\|Bv_n\|^2 \leqslant 4\|v_n\|^2, \quad \|\tilde{A}u_n\|^2 \leqslant 16\|u_n\|^2, \quad \|\tilde{A}v_n\|^2 \leqslant 16\|v_n\|^2;$$

thus, by (54), there exists $C_1(r_0)$ and $C_2(r_0,\|g\|)$ such that

$$\|\tilde{C}\varphi_n(t)\|_E^2 \leqslant C_1(r_0), \quad \|\tilde{F}(\varphi(t))\|_E \leqslant C_2(r_0,\|g\|), \quad \forall t \in R, \quad n = 1,2,\ldots . \tag{56}$$

So, by (55) and (56),

$$\|\dot{\varphi}_n(t)\|_E \leqslant C_3(r_0,\|g\|), \quad \forall t \in R, \quad n = 1,2,\ldots . \tag{57}$$

Let J_k ($k=1, 2,\ldots$) be a sequence of compact intervals of R such that $J_k \subset J_{k+1}$ and $\cup_k J_k = R$. Taking $s, t \in J_k$, we have

$$\|\varphi_n(t) - \varphi_n(s)\|_E < 2C_3(r_0,\|g\|)|t-s|,$$

which implies the equicontinuity of $\{\varphi_n(t)\}_{n=1}^{\infty}$ in $C(J_k,E)$. By (54), $\{\varphi_n(t)\}_{n=1}^{\infty}$ is uniformly bounded in E for fixed t, hence there exists a subsequence of $\{\varphi_n(t)\}_{n=1}^{\infty}$ (still denoted by $\{\varphi_n(t)\}_{n=1}^{\infty}$) and $\tilde{\varphi}_t \in E$, such that

$$\varphi_n(t) \to \tilde{\varphi}_t, \quad \text{weakly in } E, \quad \text{as } n \to +\infty. \tag{58}$$

Similar to the proof of Lemma 4.2, we show that the weak convergence in (58) is a strong one, that is, $\forall t \in J_k$, $\{\varphi_n(t)\}_{n=1}^{\infty}$ is precompact in E. By Ascoli's theorem, there exists a subsequence $\{\varphi_{n_1}(t)\}$ of $\{\varphi_n(t)\}$ and $\varphi_t \in C(J_1,E)$ such that $\varphi_{n_1}(t)$ converges to φ_t in $C(J_1,E)$. Again, by Ascoli's theorem and induction, there exists a subsequence of $\{\varphi_{n_{k+1}}(t)\}$ of $\{\varphi_{n_k}(t)\}$ such that $\varphi_{n_{k+1}}(t)$ converges to φ_t in $C(J_{k+1},E)$. Taking a diagonal subsequence in the usual way, there exists a subsequence $\{\varphi_{n_k}(t)\}$ of $\{\varphi_n(t)\}$ and $\varphi(t) \in C(R,E)$ such that

$$\varphi_n(t) \to \varphi(t), \quad \text{in } C(J,E), \quad \text{as } n \to +\infty, \quad \text{for any compact set } J \subset R. \tag{59}$$

By (54), for $\varphi(t) = (u(t),v(t)) = (u_i(t),v_i(t))_{i\in Z} \in E$, $v(t) = \dot{u}(t) + \varepsilon u(t)$,

$$\|\varphi(t)\|_E = (\rho\|Bu\|^2 + \lambda\|u\|^2 + \|v\|^2)^{1/2} \leqslant C_4(r_0), \quad \forall t \in R. \tag{60}$$

Now we will prove $\varphi(t) \in$ ß, the global attractor for semigroup $\{S(t)_{t\geqslant 0}\}$ associated with problem (13). We denote $\{\varphi_{n_k}(t)\}$ by $\{\varphi_n(t)\}$, from (57),

$$\dot{\varphi}_n(t) \to \dot{\varphi}(t), \quad \text{weak star in } L^{\infty}(R,E), \quad \text{as } n \to +\infty. \tag{61}$$

Let $i \in Z$ and $n \geqslant |i|$. Since $\varphi_n(t) = (u_{n,i}(t),v_{n,i}(t))_{|i|\leqslant n} \in \tilde{E}$ is the solution of problem (53), for every $t \in R$,

$$\ddot{u}_{n,i} - \gamma(\dot{u}_{n,i-1} - 2\dot{u}_{n,i} + \dot{u}_{n,i+1}) + h(\dot{u}_{n,i}) = (u_{n,i-1} - 2u_{n,i} + u_{n,i+1}) - \lambda u_{n,i} - f(u_{n,i}) + g_i ; \tag{62}$$

then $\forall \delta \in C_0^\infty(J)$; we have

$$\int_J [\ddot{u}_{n,i} - \gamma(\dot{u}_{n,i-1} - 2\dot{u}_{n,i} + \dot{u}_{n,i+1})]\delta(t)dt + \int_J h(\dot{u}_{n,i})\delta(t)dt$$
$$= \int_J [(u_{n,i-1} - 2u_{n,i} + u_{n,i+1}) - \lambda u_{n,i+1} + g_i]\delta(t)dt + \int_J f(u_{n,i})\delta(t)dt,$$

where

$$\left| \int_J f(u_{n,i})\delta(t)dt - \int_J f(u_i)\delta(t)dt \right|$$
$$\leqslant \int_J |f(u_{n,i}) - f(u_i)\| \delta(t)|dt|$$
$$\leqslant \sup_{t\in J}|f'(u_{n,i} + \vartheta_i(u_i - u_{n,i}))| \sup_{t\in J}|u_i - u_{n,i}| \int_J |\delta(t)|dt \to 0 \quad (n\to\infty),$$

and

$$\left| \int_J h(\dot{u}_{n,i})\delta(t)dt \right| - \int_J h(\dot{u}_i)\delta(t)dt$$
$$\leqslant \int_J |h(\dot{u}_{n,i}) - h(\dot{u}_i)\| \delta(t)|dt|$$
$$\leqslant \sup_{t\in J}|h'(\dot{u}_{n,i} + \tilde{\vartheta}_i(\dot{u}_i - \dot{u}_{n,i}))| \sup_{t\in J}|\dot{u}_i(t) - \dot{u}_{n,i}(t)| \int_J |\delta(t)|dt$$
$$\leqslant \beta \sup_{t\in J}|\dot{u}_i(t) - \dot{u}_{n,i}(t)| \int_J |\delta(t)|dt \to 0 \quad (n\to\infty),$$

because by (59), $\sup_{t\in J}|u_i - u_{n,i}| \to 0$, $\sup_{t\in J}|\dot{u}_i(t) - \dot{u}_{n,i}(t)| \to 0$ as $n\to\infty$ and by (54), (60),

$$|u_{n,i} + \vartheta(u_i - u_{n,i})| \leqslant \|u(t)\| + \|u_n(t)\| \leqslant C_5(r_0, \|g\|), \quad \forall t \in R.$$

Therefore, we have

$$\ddot{u}_i - \gamma(\dot{u}_{i-1} - 2\dot{u}_i + \dot{u}_{i+1}) + h(\dot{u}_i) = (u_{i-1} - 2u_i + u_{i+1}) - \lambda u_i - f(u_i) + g_i, \quad t \in J. \tag{63}$$

Since J is arbitrary, (63) holds for all $t \in R$, which means $\varphi(t) = (u(t), v(t))$ is a solution of (13). By (60), $\varphi(t)$ is bounded for $t \in R$, so, $\varphi(t) \in ß$, hence, $\varphi_n(0) \to \varphi(0) \in ß$. The proof is completed.

As a direct consequence of Lemma 5.2, we obtain the upper semicontinuity of ß.

Theorem 4.1: If (5)–(7) hold and $g \in l^2$, then $\lim_{n\to+\infty} d_E(ß_n, ß) = 0$, where $d_E(ß_n, ß) = \sup_{a\in ß_n} \inf_{b\in ß} \|a - b\|_E$.

Remark: For the mapping $S_0(t): (u_0, u_{10})^T \to (u(t), \dot{u}(t))^T \in l^2 \times l^2$ associated with problem (3)–(4) in the space $l^2 \times l^2$ with the usual inner product and norm, since $S_0(t) = R_{-\varepsilon} S(t) R_\varepsilon$, $R_\varepsilon = \left(\begin{smallmatrix} 1 & 0 \\ \varepsilon & 1 \end{smallmatrix}\right)$ is an isomorphism on $l^2 \times l^2$ and $\{S(t)\}_{t\geqslant 0}$ possesses a global attractor ß in E, the global attractor of $\{S_0(t)\}_{t\geqslant 0}$ in E is $R_{-\varepsilon} ß$, which implies that $\{S_0(t)\}_{t\geqslant 0}$ possesses a global attractor in $l^2 \times l^2$ because $l^2 \times l^2$ and E have the same elements and their norms are equivalent.

A direct method for establishing integrable couplings is proposed in this paper. As an example illustration, integrable couplings of TD hierarchy are obtained by constructing a suitable transformation of Lax pairs and a new Lie algebra. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1398061]

I. INTRODUCTION

Integrable couplings are a quite new interesting aspect in the field of soliton theory. It originates from an investigation on soliton equations. Mathematically, the problem of integrable couplings may be defined in the following way.

For a given integrable system of evolution equations

$$u_t = K(u), \tag{1}$$

the following system:

$$\begin{cases} u_t = K(u) \\ v_t = S(u,v) \end{cases}, \tag{2}$$

is called integrable coupling of (1), if (2) is also integrable and $S(u,v)$ includes u or its x-derivatives explicitly.

Two methods for discovering integrable couplings were proposed in Refs. 1–3:

(1) the original system and its linearized system

$$\begin{cases} u_t = K(u) \\ u_t = K'(u)[v] \end{cases}, \tag{3}$$

(2) the perturbation approach.

The above two methods have the common characteristics: Starting from the original equation (1) yields the integrable coupling of only one equation. In this paper, we proceed first to consider an isospectral problem, then a suitable loop algebra $\tilde{G}$ is constructed. The results obtained are integrable couplings of a family of evolution equations. As an example illustration, we try to establish the integrable couplings of TD hierarchy. However, it is not easy to obtain directly the integrable coupling. Thus a transformation of Lax pairs is made first. The second section is the TD hierarchy obtained by the Lax transformation. In the third section, integrable couplings of TD hierarchy are presented. Finally some remarks are made in Sec. IV.

Consider the isospectral problem

$$\varphi_x = U_1(u,\lambda)\varphi, \lambda_t = 0, u = (q,r)^T, \varphi = (\varphi_1, \varphi_2)^T, \tag{4}$$

where $U_1 = U_1(u,\lambda)$ is a matrix of order 2, T means transposition of the matrix.

Solving the adjoint representation of Eq. (4)

$$V_x = [U_1, V] \equiv U_1 V - V U_1, V = \begin{pmatrix} a & b \\ c & -a \end{pmatrix}, \tag{5}$$

yields recursion relations on a_i, b_i, c_i, $i \geqslant 1$, where

$$a=\sum_{i\geqslant 0} a_i\lambda^{-i}, b=\sum_{i\geqslant 0} b_i\lambda^{-i}, c=\sum_{i\geqslant 0} c_i\lambda^{-i}.$$

The Lax pair is obtained by using Tu-model[4]

$$\varphi_x=U_1\varphi, \varphi_{t_n}=V_1^{(n)}\varphi. \tag{6}$$

The compatibility of (6) leads to the zero-curvature equation

$$U_{1t}-V_{1x}^{(n)}+[U_1, V_1^{(n)}]=0. \tag{7}$$

By the use of the trace identity,[4] the generalized Hamiltonian hierarchy in the Liouville sense is obtained

$$u_{t_n}=\begin{pmatrix} q \\ r \end{pmatrix}_{t_n}=J\frac{\delta H_n}{\delta u}=JL\frac{\delta H_{n-1}}{\delta u}, \tag{8}$$

where J, L are a Hamiltonian operator and a recursion operator, respectively, $\delta/\delta u$ denotes variational derivative.

Consider the isospectral problem

$$\varphi_x=U(u,\lambda)\varphi, U=U_1(u,\lambda)+e(u,\lambda), \tag{9}$$

the matrix U is homogeneous rank, the second-order matrix $e(u,\lambda)$ meets that

$$[e,V]=0, [e,V_1^{(n)}]=0. \tag{10}$$

Let $f_n=f_n(u,\lambda)$ have the same order with U and meet the following:

$$[U_1,f_n]=0, [e,f_n]=0, e_{t_n}=f_{nx}. \tag{11}$$

Put $V^{(n)}=V_1^{(n)}+f_n$, we have

$$U_{t_n}-V_x^{(n)}+[U,V^{(n)}]=U_{1t_n}-V_{1x}^{(n)}+[U_1,V_1^{(n)}]=0, \tag{12}$$

that is, the compatibility of the new Lax pairs

$$\varphi_x=U\varphi, \varphi_{t_n}=V^{(n)}\varphi, \tag{13}$$

leads to (8) as well. In fact, $e=e(u,\lambda)$ and $f_n=f_n(u,\lambda)$ are chosen easily which satisfy (10) and (11). For example, we may take the forms $e=g(u,\lambda)E_2$, $f_n=h_n(u,\lambda)E_2$, where E_2 denotes second-order unit matrix. When reducing the zero-curvature equation derived from (9) to the Hamiltonian hierarchy, we have that[4]

$$\left\langle V,\frac{\partial U}{\partial\lambda}\right\rangle=\left\langle V,\frac{\partial U_1}{\partial\lambda}\right\rangle, \left\langle V,\frac{\partial U}{\partial u}\right\rangle=\left\langle V,\frac{\partial U_1}{\partial u}\right\rangle. \tag{14}$$

Thus the same trace identities are obtained

$$\frac{\delta}{\delta u}\left\langle V,\frac{\partial U}{\partial\lambda}\right\rangle=\left(\lambda^{-\gamma}\frac{\partial}{\partial\lambda}\lambda^{\gamma}\right)\left\langle V,\frac{\partial U}{\partial u}\right\rangle, \frac{\delta}{\delta u}\left\langle V,\frac{\partial U_1}{\partial\lambda}\right\rangle=\left(\lambda^{-\gamma}\frac{\partial}{\partial\lambda}\lambda^{\gamma}\right)\left\langle V,\frac{\partial U_1}{\partial u}\right\rangle. \tag{15}$$

Therefore, (4) and (9) lead to the same Hamiltonian system. But the Lax pair (6) is different from (13).

II. TD HIERARCHY

Taking the loop algebra $\tilde{A}_1$ with the basis $h_1=\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)$, $h_2=\left(\begin{smallmatrix}0&0\\0&1\end{smallmatrix}\right)$, $e=\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)$, $f=\left(\begin{smallmatrix}0&0\\1&0\end{smallmatrix}\right)$ for which we have that

$$[h_1,e]=-[h_2,e]=e,[h_1,f]=-[h_2,f]=-f,[e,f]=h_1-h_2\equiv h,h_i(n)=\lambda^n h_i,$$

$$e(n)=\lambda^n e,f(n)=\lambda^n f,\deg h_i(n)=\deg e(n)=\deg f(n)=n,i=1,2.$$

Consider the spectral problem of TD equation[5]

$$\begin{gathered}\varphi_x=U_1\varphi,U_1=U_1(u,\lambda)=\begin{pmatrix}-\lambda+r & q\\ q & \lambda\end{pmatrix}=-h(1)+rh_1(0)+q(e(0)+f(0)),\\ \varphi=(\varphi_1,\varphi_2)^T,u=(q,r)^T.\end{gathered}\tag{16}$$

Solving the adjoint equation

$$V_x=[U_1,V],\tag{17}$$

yields that

$$\begin{cases}a_{nx}=q(c_n-b_n),b_{n+1}=\frac{1}{2}(rb_n-2qa_n-b_{nx})\\ c_{nx}=2c_{n+1}+2qa_n-rc_n,a_0=-1,b_0=c_0=0,a_1=0,b_1=c_1=q\,.\\ a_2=\frac{1}{2}q^2,b_2=\frac{1}{2}(qr-q_x),c_2=\frac{1}{2}(qr+q_x)\end{cases}\tag{18}$$

Let

$$\varphi_x=U_1\varphi,\varphi_{t_n}=V_1^{(n)}\varphi,V_1^{(n)}=\begin{pmatrix}\sum_{i=0}^{n}a_i\lambda^{n-i}+q^{-1}(b_{n+1}+c_{n+1}) & \sum_{i=0}^{n}b_i\lambda^{n-i}\\ \sum_{i=0}^{n}c_i\lambda^{n-i} & -\sum_{i=0}^{n}a_i\lambda^{n-i}\end{pmatrix}.\tag{19}$$

Then the compatibility of the Lax pairs (19) leads to the well-known TD hierarchy as follows:

$$u_{t_n}=\begin{pmatrix}q\\ r\end{pmatrix}_{t_n}=J\frac{\delta H_n}{\delta u}=J\begin{pmatrix}b_{n+1}+c_{n+1}\\ a_{n+1}\end{pmatrix}=JL^{n-1}\begin{pmatrix}b_2+c_2\\ a_2\end{pmatrix},\tag{20}$$

where $J=\left(\begin{smallmatrix}0&\partial q^{-1}\\ q^{-1}\partial&0\end{smallmatrix}\right)$ is a Hamiltonian operator, $L=\frac{1}{2}\left(\begin{smallmatrix}r&\partial q^{-1}\partial-4q\\ \partial^{-1}q\partial&\partial^{-1}r\partial\end{smallmatrix}\right)$, $\partial\equiv\partial/\partial x$, $\partial^{-1}\partial=\partial\partial^{-1}=1$. Put $e=-r/2\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$, $f_n=-1/2q\,(b_{n+1}+c_{n+1})\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$, it is easy to verify that e and f_n meet (10) and (11).

Taking loop algebra $\overline{A_1}$ with the basis

$$h(n)=\begin{pmatrix}\lambda^n&0\\0&-\lambda^n\end{pmatrix},\quad e(n)=\begin{pmatrix}0&\lambda^n\\0&0\end{pmatrix},\quad f(n)=\begin{pmatrix}0&0\\\lambda^n&0\end{pmatrix},$$

$$[h(m),f(n)]=-2\,f(m+n),[h(m),e(n)]=2e(m+n),[e(m),f(n)]=h(m+n),$$

then the compatibility of the following Lax pair

$$\varphi_x = U\varphi = (U_1 + e)\varphi = \begin{pmatrix} -\lambda + \frac{r}{2} & q \\ q & \lambda - \frac{r}{2} \end{pmatrix} \begin{pmatrix} \varphi_1 \\ \varphi_2 \end{pmatrix} = \left(-h(1) + \frac{r}{2}h(0) + q(e(0) + f(0)) \right) \varphi,$$

$$\varphi_{t_n} = V^{(n)}\varphi = (V_1^{(n)} + f_n)\varphi,$$

$$V^{(n)} = \begin{pmatrix} \sum_{i=0}^{n} a_i \lambda^{n-i} + \frac{1}{2q}(b_{n+1} + c_{n+1}) & \sum_{i=0}^{n} b_i \lambda^{n-i} \\ \sum_{i=0}^{n} c_i \lambda^{n-i} & -\sum_{i=0}^{n} a_i \lambda^{n-i} - \frac{1}{2q}(b_{n+1} + c_{n+1}) \end{pmatrix}, \tag{21}$$

also gives rise to the TD hierarchy (20) and eq. $V_x = [U, V]$ is equivalent to (18).

III. INTEGRABLE COUPLINGS OF TD HIERARCHY

To obtain integrable couplings of TD hierarchy, we will establish a suitable loop algebra $\tilde{G}$. Let G be a linear space with basis $\{e_1, e_2, e_3, e_4, e_5\}$, we define the commutative relations as follows:

$$\begin{cases} [e_1, e_2] = 2e_2, [e_1, e_3] = -2e_3, [e_1, e_4] = e_4 \\ [e_1, e_5] = -e_5, [e_2, e_3] = e_1, [e_2, e_4] = 0 \\ [e_2, e_5] = e_4, [e_3, e_4] = e_5, [e_3, e_5] = 0 \\ [e_4, e_5] = 0 \end{cases}. \tag{22}$$

Set $a = \Sigma_{i=0}^{5} a_i e_i$, $b = \Sigma_{i=0}^{5} b_i e_i$, $c = \Sigma_{i=0}^{5} c_i e_i$, where a_i, b_i, c_i are all arbitrary constants or functions, then we have

$$[a, [b, c]] + [b, [c, a]] + [c, [a, b]] = 0, \tag{23}$$

that is, Jacobi identity holds. Thus G is a Lie algebra. If we let

$$\begin{cases} e_i(n) = e_i \lambda^n, i = 1,2,3,4,5 \\ [e_i(m), e_j(n)] = [e_i, e_j]\lambda^{m+n}, 1 \leqslant i, j \leqslant 5, \\ \deg e_i(n) = n, i = 1,2,3,4,5 \end{cases} \tag{24}$$

then the loop algebra $\tilde{G}$ is constructed. Set the subalgebras $\tilde{G}_1$, $\tilde{G}_2$ to have bases $\{e_1(n), e_2(n), e_3(n)\}, \{e_4(n), e_5(n)\}$, respectively. Of course, $\tilde{G}_1$ and $\tilde{G}_2$ meet the relations as follows:

$$\tilde{G}_1 \text{ is isomorphic to } \overline{A_1}, [\tilde{G}_1, \tilde{G}_2] \subset \tilde{G}_2. \tag{25}$$

Taking the form of linear spectral problem

$$\begin{cases} \Psi_x = [U, \Psi], \lambda_t = 0 \\ \Psi_t = [V, \Psi] \end{cases}, \tag{26}$$

where $\Psi = \Sigma_{i=1}^{5} \Psi_i e_i, \Psi_i$ is an arbitrary function, $U = U(u, \lambda) \in \tilde{G}, V = V(u, \lambda) \in \tilde{G}$, and $u = (u_1, u_2, \ldots, u_p)^T$ is a function vector. λ is a spectral parameter. The compatibility of (26) leads to that

$$\Psi_{xt}=[U_t,\Psi]+[U,\Psi_t]=[U_t,\Psi]+[U,[V,\Psi]]=\Psi_{tx}=[V_x,\Psi]+[V,\Psi_x]$$

$$=[V_x,\Psi]+[V,[U,\Psi]],$$

$$[U_t,\Psi]+[U,[V,\Psi]]-[V_x,\Psi]-[V,[U,\Psi]]=0. \tag{27}$$

By using Jacobi identity (23) and (27) may reduce to that

$$[U_t,\Psi]-[V_x,\Psi]+[[U,V],\Psi]=0. \tag{28}$$

Since Ψ is arbitrary, (28) reduces to the zero-curvature equation

$$U_t-V_x+[U,V]=0. \tag{29}$$

In particular, we take the isospectral problem

$$\Psi_x=[U,\Psi],\lambda_t=0,$$

$$U=-e_1(1)+u_1(e_2(0)+e_3(0))+\frac{u_2}{2}e_1(0)+u_3e_4(0)+u_4e_5(0), \tag{30}$$

$$V=\sum_{m=0}^{\infty}(a_me_1(-m)+b_me_2(-m)+c_me_3(-m)+d_me_4(-m)+f_me_5(-m)).$$

Solving the adjoint representation equation

$$V_x=[U,V], \tag{31}$$

yields that

$$\begin{gathered}a_{mx}=u_1(c_m-b_m),b_{mx}=-2b_{m+1}-2u_1a_m+u_2b_m,c_{mx}=2c_{m+1}+2u_1a_m-u_2c_m,\\ d_{m+1}=u_1f_m+\frac{u_2}{2}d_m-u_3a_m-u_4b_m-d_{mx},\\ f_{mx}=f_{m+1}+u_1d_m-\frac{u_2}{2}f_m-u_3c_m+u_4a_m,\\ a_0=-1,b_0=c_0=d_0=f_0=0,a_1=0,b_1=c_1=u_1,d_1=u_3,f_1=-u_4.\end{gathered} \tag{32}$$

Set

$$\begin{cases}V_{1+}^{(n)}=\\ \displaystyle\sum_{m=0}^{n}(a_me_1(n-m)+b_me_2(n-m)+c_me_3(n-m)+d_me_4(n-m)+f_me_5(n-m)).\\ V_{1-}^{(n)}=\lambda^nV-V_{1+}^{(n)}\end{cases}$$

Then we have

$$-V_{1+x}^{(n)}+[U,V_{1+}^{(n)}]=V_{1-x}^{(n)}-[U,V_{1-}^{(n)}]. \tag{33}$$

Note that the terms in the left-hand side of (33) are of degree $\geqslant 0$, while the terms of the right-hand side are of degree $\leqslant 0$. Thus by using Tu-model, we have

$$-V_{1+x}^{(n)}+[U,V_{1+}^{(n)}]=2b_{n+1}e_2(0)-2c_{n+1}e_3(0)+d_{n+1}e_4(0)-f_{n+1}e_5(0).$$

In terms of (21), taking $V^{(n)}=V_{1+}^{(n)}+1/2u_1(b_{n+1}+c_{n+1})e_1(0)$, we have

$$-V_x^{(n)}+[u,V^{(n)}]=(b_{n+1}-c_{n+1})(e_2(0)+e_3(0))-\left(\frac{1}{2u_1}(b_{n+1}+c_{n+1})\right)_x e_1(0)$$
$$+\left(d_{n+1}-\frac{u_3}{2u_1}(b_{n+1}+c_{n+1})\right)e_4(0)+\left(\frac{u_4}{2u_1}(b_{n+1}+c_{n+1})-f_{n+1}\right)e_5(0).$$

The zero-curvature equation (29) determines the system

$$u_t=\begin{pmatrix}u_1\\u_2\\u_3\\u_4\end{pmatrix}_t=\begin{pmatrix}c_{n+1}-b_{n+1}\\\left(\frac{1}{u_1}(b_{n+1}+c_{n+1})\right)_x\\-d_{n+1}+\frac{u_3}{2u_1}(b_{n+1}+c_{n+1})\\f_{n+1}-\frac{u_4}{2u_1}(b_{n+1}+c_{n+1})\end{pmatrix}=\begin{pmatrix}\frac{1}{u_1}a_{n+1,x}\\\left(\frac{1}{u_1}(b_{n+1}+c_{n+1})\right)_x\\-d_{n+1}+\frac{u_3}{2u_1}(b_{n+1}+c_{n+1})\\f_{n+1}-\frac{u_4}{2u_1}(b_{n+1}+c_{n+1})\end{pmatrix}$$
$$=\begin{pmatrix}0&u_1^{-1}\partial&0&0\\\partial u_1^{-1}&0&0&0\\\frac{u_3}{2u_1}&0&-1&0\\-\frac{u_4}{2u_1}&0&0&-1\end{pmatrix}\begin{pmatrix}b_{n+1}+c_{n+1}\\a_{n+1}\\d_{n+1}\\f_{n+1}\end{pmatrix}=J\begin{pmatrix}b_{n+1}+c_{n+1}\\a_{n+1}\\d_{n+1}\\f_{n+1}\end{pmatrix}. \tag{34}$$

From (32), we have

$$\begin{pmatrix}b_{n+1}+c_{n+1}\\a_{n+1}\\d_{n+1}\\f_{n+1}\end{pmatrix}=\frac{1}{2}\begin{pmatrix}u_2&\partial u_1^{-1}\partial-4u_1&0&0\\\partial^{-1}u_1\partial&\partial^{-1}u_2\partial&0&0\\-u_4&u_4u_1^{-1}\partial-2u_3&u_2-2\partial&2u_1\\u_3&u_3u_1^{-1}\partial-2u_4&-2u_1&u_2+2\partial\end{pmatrix}\begin{pmatrix}b_n+c_n\\a_n\\d_n\\f_n\end{pmatrix}$$
$$=L\begin{pmatrix}b_n+c_n\\a_n\\d_n\\f_n\end{pmatrix}. \tag{35}$$

In terms of (35), the hierarchy (34) reduces to the following:

$$u_t=\begin{pmatrix}u_1\\u_2\\u_3\\u_4\end{pmatrix}_t=JL^n\begin{pmatrix}b_1+c_1\\a_1\\d_1\\f_1\end{pmatrix}. \tag{36}$$

The hierarchy (36) is derived from the zero-curvature equation (29), therefore, it is integrable. Comparison J and L in (36) with those in (20), we see that (36) is integrable coupling of the TD hierarchy (20).

IV. CONCLUDING REMARKS

This paper proposed a new method—called a direct method to find integrable couplings of evolution equations, which developed the existed method for seeking for integrable couplings in Refs. 1–3. However, one open problem remains. The integrable couplings obtained by the direct method are integrable in the Lax sense. Can we generalize the well-known trace identity into the loop algebra $\tilde{A}_2$ so that the integrable couplings which are obtained by our method are integrable in the Liouville sense? Can we use the similar method to discover the integrable couplings of BPT hierarchy? These are problems to tackle in future.

(Received 5 September 2000; accepted for publication 17 September 2001)

A prescription for computing the propagator for D-dimensional higher-derivative gravity theories, based on the Barnes–Rivers operators, is presented. A systematic study of the tree-level unitarity of these theories is developed and the agreement of their linearized versions with Newton's law is investigated by computing the corresponding effective nonrelativistic potential. Three-dimensional quadratic gravity with a gravitational Chern–Simons term is also analyzed. A discussion on the issue of light bending within the framework of both D-dimensional quadratic gravity and three-dimensional quadratic gravity with a Chern–Simons term is provided as well. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1415743]

I. INTRODUCTION

Undoubtedly, Einstein's field theory accounts very well for all known macroscopic gravitational phenomena. However, as a quantum theory it is less satisfactory: it has an S matrix which, despite being finite at the one-loop level,[1] diverges at the two-loop order.[2] This is not surprising, since one of the most difficult field theories when it comes to quantization is certainly the theory of the space–time structure itself. It is not known what the correct quantum theory of gravitation is.

Now, as is well known, the four-dimensional space–time is the most problematic place for a quantum field theory to live. Indeed, quantum field theories are notorious for being ill defined in four-dimensional space–time but can often be handled in space–times of a different dimensionality. Dimensional regularization is a common example of such a procedure: results that are divergent in four dimensions are convergent for $D>4$. The divergences of the four-dimensional theory are removed by considering our space–time as a limit $D\to 4$ of higher-dimensional space–times.[3] On the other side of the dimensionality spectrum, there are field theories in space–times with $2\leqslant D<4$. In some cases, such quantum models are exactly soluble and provide a valuable insight into the clockwork of quantum field theory.

In this vein, here we study—at the tree level—various higher-derivative gravity theories. First, we shall consider gravitational theories which will be called, for short, D-dimensional higher-derivative gravity theories. These theories share some basic points with general relativity:

(i) General covariance and
(ii) the action is extremized under variation of the metric.

On the other hand, they differ from general relativity in the following respects:

(i) The field equations for the metric are of fourth order.

[a]Electronic mail: accioly@ift.unesp.br

(ii) Space–time is allowed to have any number of dimensions, which is a condition absolutely necessary in the context of string theory.

Quadratic gravity in four dimensions is the most typical example of such a theory.[4–6] At this point it is reasonable to pose the question: What is the use of probing into these theories? Before answering this question, let us comment, in passing, on some results recently obtained concerning quadratic gravity in four dimensions. In a series of papers on the photon propagation around a massive body in quadratic theories of gravitation it was shown that, unlike Einstein's gravity, quadratic gravity produces dispersive photon propagation.[7–9] To be more specific, quadratic gravity produces energy-dependent photon scattering. An interesting consequence of this fact is that gravity's rainbows and higher-derivative gravity can coexist without conflict.[9] In this sense quadratic gravity is closer to quantum electrodynamics than any currently known gravitational theory. In fact, dispersive photon propagation is a trivial phenomenon in the context of QED. Based on the fact that the rainbow effect which is present in quadratic gravity is undetectable, nowadays it is possible to find a new constraint on the value of the contribution of the quadratic part. This is a very important result given the scarcity of observational constraints on gravitational theories. In addition, it was also found that the gravitational deflection predicted by quadratic gravity is always smaller than that predicted by Einstein's theory.[7–9] It is worth mentioning that the R^2 sector of the theory of gravitation with higher derivatives does not contribute anything to the gravitational deflection.[10,11] After this little digression we return to the question raised previously. Our motivation for studying D-dimensional higher-derivative gravity theories is to try to answer, among other things, the following questions:

(i) Which is the lowest dimension in which these theories make sense?
(ii) Are these D-dimensional theories unitary at the tree level?
(iii) Is the massless excitation a dynamical degree of freedom in any dimension?
(iv) Does D-dimensional linearized quadratic gravity agree with Newton's theory in the limiting case of motion at low velocity in a weak gravitational field?
(v) Is the gravitational deflection within the context of the theories mentioned above greater or smaller than that related to the corresponding Einstein's theory?

Second, we shall analyze three-dimensional quadratic gravity with a gravitational Chern–Simons term. Now the action is extremized *à la* Palatini (independently varied connection). In other words, the propagation of the metric and affine structures of space–time are independent. Our goal here is, first of all, to find out how the nature of the field excitations is affected by the addition of a gravitational Chern–Simons term to the Lagrangian concerning three-dimensional quadratic gravity. Second, we shall study the tree-level unitarity of the above theory, the nonrelativistic limit of its linearized version and light bending within the framework of the same.

The plan of this work is as follows. In Sec. II we find the appropriate Lagrangian for computing the propagator concerning D-dimensional quadratic gravity. In Sec. III we present an algorithm for computing the propagator for D-dimensional higher-derivative gravity theories based on the Barnes–Rivers operators.[12–16] Using this prescription we get the propagator for D-dimensional quadratic gravity in an unconventional gauge. From this result we obtain in a straightforward way the propagator in a series of interesting gauges which for $D=4$ reduce to well known results which are broadly used in the literature.[17] In Sec. IV we study in a systematic way the tree-level unitarity of D-dimensional higher-derivative gravity theories. It is shown that for $D>2$ quadratic gravity is nonunitary at the tree level. On the other hand, we get that D-dimensional $R+R^2$ gravity is unitary at the tree level for $D>2$. Section V is devoted to the study of the effective nonrelativistic potential for D-dimensional quadratic gravity. An expression for computing this potential is obtained for $D>2$ and from that we get, in particular, the potential for three-dimensional linearized quadratic gravity. Unlike the Newtonian potential, this potential is well behaved: it is finite at the origin and zero at infinity. In Sec. VI we analyze the gravitational deflection in the framework of D-dimensional quadratic gravity. Section VII deals with three-

dimensional quadratic gravity with a gravitational Chern–Simons term. Finally, a summary of the main results is presented in Sec. VIII.

In our notation the signature is $(+-\cdots-)$. The curvature tensor is defined by $R^{\alpha}_{\beta\gamma\delta}=-\partial_{\delta}\Gamma^{\alpha}_{\beta\gamma}+\cdots$, the Ricci tensor by $R_{\mu\nu}=R^{\alpha}_{\mu\nu\alpha}$, and the curvature scalar by $R=g^{\mu\nu}R_{\mu\nu}$, where $g_{\mu\nu}$ is the metric tensor. Natural units are used throughout.

II. FINDING THE APPROPRIATE LAGRANGIAN FOR COMPUTING THE PROPAGATOR CONCERNING *D*-DIMENSIONAL QUADRATIC GRAVITY

The action for quadratic gravity in $D>1$ dimensions is given by

$$I=\int d^{D}x\sqrt{(-1)^{D-1}g}\left[\frac{2R}{\kappa^{2}}+\frac{\alpha}{2}R^{2}+\frac{\beta}{2}R^{2}_{\mu\nu}+\frac{\gamma}{2}R^{2}_{\mu\nu\rho\sigma}+\frac{\delta}{2}\Box R\right], \tag{1}$$

where κ^{2} is a suitable constant with dimension L^{D-2} which in four dimensions is equal to $32\pi G$, with G being Newton's constant, and α, β, γ and δ are constants with dimension L^{4-D}. The $\Box R$ term in this action is manifestly a total covariant divergence and can be ignored. For $D=1$ the space is flat and all the tensors $R_{\mu\nu\alpha\beta}$, $R_{\mu\nu}$, R identically vanish. Of course, there can be no dynamics in a space which does not possess both a spacelike and a timelike dimension. The lowest dimension in which the quadratic theory makes sense is thus $D=2$.

Proposition 1: We can drop out the $R^{2}_{\mu\nu\rho\sigma}$ term of the linearized Lagrangian related to gravity with higher derivatives in dimensions higher than second.

Proof: Let $\mathcal{L}^{1}(\mathcal{L}^{2})$ be the Lagrangian corresponding to the gravity theory without (with) the $R^{2}_{\mu\nu\rho\sigma}$ term, namely,

$$\mathcal{L}^{1}\equiv\sqrt{(-1)^{D-1}g}\left[\frac{2R}{\kappa^{2}}+\frac{\alpha}{2}R^{2}+\frac{\beta}{2}R^{2}_{\mu\nu}\right], \tag{2}$$

$$\mathcal{L}^{2}\equiv\sqrt{(-1)^{D-1}g}\left[\frac{2R}{\kappa^{2}}+\frac{\alpha}{2}R^{2}+\frac{\beta}{2}R^{2}_{\mu\nu}+\frac{\gamma}{2}R^{2}_{\mu\nu\rho\sigma}\right]. \tag{3}$$

Decomposing the metric, $g_{\mu\nu}$, as

$$g_{\mu\nu}=\eta_{\mu\nu}+\kappa h_{\mu\nu}, \tag{4}$$

where $\eta_{\mu\nu}$ is the Minkowski metric, and inserting (4) into (2) and (3) yields

$$\mathcal{L}^{1}_{lin.}=\frac{b}{4}[\Box h_{\mu\nu}\Box h^{\mu\nu}-(A^{\mu}_{,\mu})^{2}-F^{2}_{\mu\nu}+(1+4c)(A^{,\alpha}_{\alpha}-\Box\phi)^{2}]-\frac{1}{2}[h^{\mu\nu}\Box h_{\mu\nu}+A^{2}_{\nu}+(A_{\nu}-\phi_{,\nu})^{2}], \tag{5}$$

$$\mathcal{L}^{2}_{lin.}=\left(\frac{b}{4}+d\right)\left[\Box h_{\mu\nu}\Box h^{\mu\nu}-(A^{\mu}_{,\mu})^{2}-F^{2}_{\mu\nu}+\frac{(b/4)\,(1+4c)}{b/4+d}(A^{,\alpha}_{\alpha}-\Box\phi)^{2}\right]-\frac{1}{2}[h^{\mu\nu}\Box h_{\mu\nu}+A^{2}_{\nu}+(A_{\nu}-\phi_{,\nu})^{2}],$$

where $A^{\mu}\equiv h^{\mu\nu}_{,\nu}$, $\phi\equiv h$, $F_{\mu\nu}=A_{\mu,\nu}-A_{\nu,\mu}$, $b\equiv\beta\kappa^{2}/2$, $c\equiv\alpha/\beta$, and $d\equiv\gamma\kappa^{2}/2$. Indices are lowered (raised) using $\eta_{\mu\nu}(\eta^{\mu\nu})$. □

It is worth mentioning that we could have arrived at the conclusion that the $R^{2}_{\mu\nu\rho\sigma}$ term need never be considered in calculating the propagator by simply noting that the linearized Gauss–Bonet invariant is a total derivative in any space–time dimension, the restriction to $D=4$ coming in only when we take the full nonlinear structure into account.

Thus, we come to the conclusion that the appropriate Lagrangian for computing the propagator concerning quadratic gravity in $D>2$ dimensions is

$$\overline{\mathcal{L}}=\sqrt{(-1)^{D-1}g}\left[\frac{2R}{\kappa^2}+\frac{\alpha}{2}R^2+\frac{\beta}{2}R_{\mu\nu}^2\right]. \tag{6}$$

Proposition 2: In two dimensions

$$\frac{\alpha}{2}R^2+\frac{\beta}{2}R_{\mu\nu}^2+\frac{\gamma}{2}R_{\mu\nu\rho\sigma}^2=\left(\frac{\alpha}{2}+\frac{\beta}{4}+\frac{\gamma}{2}\right)R^2.$$

Proof: In two dimensions both the Riemann tensor and the Ricci tensor can be expressed in terms of the curvature scalar. Indeed,[18]

$$R_{\mu\nu\rho\sigma}=\tfrac{1}{2}R(g_{\mu\sigma}g_{\nu\rho}-g_{\mu\rho}g_{\nu\sigma}),$$

and

$$R_{\mu\nu}=\tfrac{1}{2}Rg_{\mu\nu}.$$

Therefore,

$$\frac{\alpha}{2}R^2+\frac{\beta}{2}R_{\mu\nu}^2+\frac{\gamma}{2}R_{\mu\nu\rho\sigma}^2=\frac{\alpha}{2}R^2+\frac{\beta}{2}\frac{R^2}{2}+\frac{\gamma}{2}R^2=\left(\frac{\alpha}{2}+\frac{\beta}{4}+\frac{\gamma}{2}\right)R^2.$$

□

Obviously, for $D=2$ the suitable Lagrangian for calculating the propagator related to quadratic gravity is $\overline{\mathcal{L}}=\sqrt{-g}[2R/\kappa^2+(\alpha/2)R^2]$. Nonetheless, we will not discuss this theory here. From now on we shall assume that $D>2$.

III. FINDING THE PROPAGATOR FOR *D*-DIMENSIONAL HIGHER-DERIVATIVE GRAVITY THEORIES

We begin by describing a prescription for computing the propagator for gravity theories with higher derivatives in $D>2$ dimensions. The algorithm is used afterward to get the propagator for D-dimensional quadratic gravity in an unconventional gauge. From this result we obtain the propagator in a series of gauges which in the $D=4$ case reduce to well known gauges that are widely used in the literature.[17]

A. The prescription

Let $\overline{\mathcal{L}}$ be the Lagrangian for any metric theory of gravity with higher derivatives. To compute the graviton propagator we need the bilinear part of this Lagrangian. The latter is obtained by decomposing the metric, $g_{\mu\nu}$, as in (4), and inserting (4) into $\overline{\mathcal{L}}$. Let $\mathcal{L}_g$ be the resulting Lagrangian. In the specific case of gauge-invariant theories, we add to $\mathcal{L}_g$ a gauge-fixing Lagrangian $\mathcal{L}_{gf}$. Accordingly, $\mathcal{L}=\mathcal{L}_g+\mathcal{L}_{gf}$ can be written as

$$\mathcal{L}=\tfrac{1}{2}h^{\mu\nu}\mathcal{O}_{\mu\nu,\rho\sigma}h^{\rho\sigma}. \tag{7}$$

In performing these calculations it is extremely convenient to work in terms of the Barnes–Rivers operators[12–16] in the space of symmetric rank-two tensors. The complete set of D-dimensional operators is given by

$$P^1_{\mu\nu,\rho\sigma}=\tfrac{1}{2}(\theta_{\mu\rho}\omega_{\nu\sigma}+\theta_{\mu\sigma}\omega_{\nu\rho}+\theta_{\nu\rho}\omega_{\mu\sigma}+\theta_{\nu\sigma}\omega_{\mu\rho}),$$

$$P^2_{\mu\nu,\rho\sigma}=\frac{1}{2}(\theta_{\mu\rho}\theta_{\nu\sigma}+\theta_{\mu\sigma}\theta_{\nu\rho})-\frac{1}{D-1}\theta_{\mu\nu}\theta_{\rho\sigma},$$

$$P^0_{\mu\nu,\rho\sigma}=\frac{1}{D-1}\,\theta_{\mu\nu}\theta_{\rho\sigma},$$

$$\overline{P}^0_{\mu\nu,\rho\sigma}=\omega_{\mu\nu}\omega_{\rho\sigma},$$

$$\bar{\bar{P}}^0_{\mu\nu,\rho\sigma}=\theta_{\mu\nu}\omega_{\rho\sigma}+\omega_{\mu\nu}\theta_{\rho\sigma},$$

where $\theta_{\mu\nu}$ and $\omega_{\mu\nu}$ are the usual transverse and longitudinal vector projection operators

$$\theta_{\mu\nu}=\eta_{\mu\nu}-\frac{k_\mu k_\nu}{k^2},\quad \omega_{\mu\nu}=\frac{k_\mu k_\nu}{k^2},$$

which satisfy the relations

$$\theta_{\mu\rho}\theta^\rho_\nu=\theta_{\mu\nu},\quad \omega_{\mu\rho}\omega^\rho_\nu=\omega_{\mu\nu},\quad \theta_{\mu\rho}\omega^\rho_\nu=0.$$

Here k_μ is the momentum of the graviton exchanged and $k^2\equiv k_\mu k^\mu$.

The set of operators $\{P^1,P^2,P^0,\overline{P}^0\}$ is a complete set of projection operators for symmetric rank-two tensors, i.e., they are idempotent, mutually orthogonal and satisfy the completness relation

$$[P^1+P^2+P^0+\overline{P}^0]_{\mu\nu,\rho\sigma}=\tfrac{1}{2}(\eta_{\mu\rho}\eta_{\nu\sigma}+\eta_{\mu\sigma}\eta_{\nu\rho})\equiv I_{\mu\nu,\rho\sigma}.$$

In the rest frame of a massive tensor field, the family of operators $\{P^1,P^2,P^0,\overline{P}^0\}$ project out the spin-1, spin-2, and two spin-0 parts of the field. The operator $\bar{\bar{P}}^0$, in turn, is nothing but the sum of two spin-0 transfer operators, namely,

$$\bar{\bar{P}}^0_{\mu\nu,\rho\sigma}\equiv[P^{\theta\omega}+P^{\omega\theta}]_{\mu\nu,\rho\sigma},$$

where $P^{\theta\omega}_{\mu\nu,\rho\sigma}\equiv\theta_{\mu\nu}\omega_{\rho\sigma}$ and $P^{\omega\theta}_{\mu\nu,\rho\sigma}\equiv\omega_{\mu\nu}\theta_{\rho\sigma}$. Its multiplicative table is given by

$$\bar{\bar{P}}^0P^1=P^1\bar{\bar{P}}^0=\bar{\bar{P}}^0P^2=P^2\bar{\bar{P}}^0=O,$$

$$(\bar{\bar{P}}^0)^2=(D-1)(P^0+\overline{P}^0),$$

$$P^0\bar{\bar{P}}^0=\bar{\bar{P}}^0\overline{P}^0=P^{\theta\omega},$$

$$\overline{P}^0\bar{\bar{P}}^0=\bar{\bar{P}}^0P^0=P^{\omega\theta},$$

where O is the null operator.

The expansion of the operator $\mathcal{O}$ in the basis $\{P^1,P^2,P^0,\overline{P}^0,\bar{\bar{P}}^0\}$ is trivially obtained using the following tensorial identities:

$$\tfrac{1}{2}(\eta_{\mu\rho}\eta_{\nu\sigma}+\eta_{\mu\sigma}\eta_{\nu\rho})=[P^1+P^2+P^0+\overline{P}^0]_{\mu\nu,\rho\sigma},$$

$$\eta_{\mu\nu}\eta_{\rho\sigma}=[(D-1)P^0+\overline{P}^0+\bar{\bar{P}}^0]_{\mu\nu,\rho\sigma},$$

$$\frac{1}{k^2}(\eta_{\mu\rho}k_\nu k_\sigma+\eta_{\mu\sigma}k_\nu k_\rho+\eta_{\nu\rho}k_\mu k_\sigma+\eta_{\nu\sigma}k_\mu k_\rho)=[2P^1+4\overline{P}^0]_{\mu\nu,\rho\sigma},\tag{8}$$

$$\frac{1}{k^2}(\eta_{\mu\nu}k_\rho k_\sigma+\eta_{\rho\sigma}k_\mu k_\nu)=[\bar{\bar{P}}^0+2\overline{P}^0]_{\mu\nu,\rho\sigma},$$

$$\frac{1}{k^4}(k_\mu k_\nu k_\rho k_\sigma)=\overline{P}^0_{\mu\nu,\rho\sigma}.$$

The identities,

$$P^2_{\mu\nu,\rho\sigma}=\frac{1}{2}(\eta_{\mu\rho}\eta_{\nu\sigma}+\eta_{\mu\sigma}\eta_{\nu\rho})-\frac{1}{D-1}\eta_{\mu\nu}\eta_{\rho\sigma}-\left[P^1+\frac{D-2}{D-1}\overline{P}^0-\frac{1}{D-1}\bar{\bar{P}}^0\right]_{\mu\nu,\rho\sigma},$$
$$P^0_{\mu\nu,\rho\sigma}=\frac{1}{D-1}\eta_{\mu\nu}\eta_{\rho\sigma}-\frac{1}{D-1}[\overline{P}^0+\bar{\bar{P}}^0]_{\mu\nu,\rho\sigma}, \tag{9}$$

in turn, greatly facilitate the task of casting the propagator in a form wherein the terms proportional to the graviton momentum are omitted, which in practice widely simplifies computations involving conserved currents.

We will not display the demonstrations of (8) and (9) since they follow straightforwardly from the very definition of the operators $P^1,\ldots,\bar{\bar{P}}^0$.

We are now ready to find the propagator, $\mathcal{O}^{-1}$. To accomplish this we have to invert the operator $\mathcal{O}$. Expanding the latter in the basis $\{P^1,P^2,P^0,\overline{P}^0,\bar{\bar{P}}^0\}$ with the help of the identities (8), we get

$$\mathcal{O}=x_1P^1+x_2P^2+x_0P^0+\overline{x}_0\overline{P}^0+\bar{\bar{x}}_0\bar{\bar{P}}^0.$$

Assume then that $\mathcal{O}^{-1}=y_1P^1+y_2P^2+y_0P^0+\overline{y}_0\overline{P}^0+\bar{\bar{y}}_0\bar{\bar{P}}^0$, where $y_1,y_2,\ldots,\bar{\bar{y}}_0$ are parameters to be determined. Since $\mathcal{O}\mathcal{O}^{-1}=I$, we promptly obtain the following set of simultaneous equations:

$$\begin{aligned}
x_1y_1&=1,\\
x_2y_2&=1,\\
x_0y_0+(D-1)\bar{\bar{x}}_0\bar{\bar{y}}_0&=1,\\
\overline{x}_0\overline{y}_0+(D-1)\bar{\bar{x}}_0\bar{\bar{y}}_0&=1,\\
\bar{\bar{x}}_0y_0+\overline{x}_0\bar{\bar{y}}_0&=0,\\
\bar{\bar{x}}_0\overline{y}_0+x_0\bar{\bar{y}}_0&=0.
\end{aligned} \tag{10}$$

Before going on we need a lemma.

Lemma: If $x_1\neq0$, $x_2\neq0$, *and* $[x_0\overline{x}_0-(D-1)\bar{\bar{x}}_0]\neq0$, *then (10) has one and only one solution.*

Proof: Row reducing the argumented matrix of the system (10) to echelon form yields

$$\begin{bmatrix}
x_1 & 0 & 0 & 0 & 0 & 1\\
0 & x_2 & 0 & 0 & 0 & 1\\
0 & 0 & x_0 & 0 & (D-1)\bar{\bar{x}}_0 & 1\\
0 & 0 & \bar{\bar{x}}_0 & 0 & \overline{x}_0 & 0\\
0 & 0 & 0 & \overline{x}_0 & (D-1)\bar{\bar{x}}_0 & 1\\
0 & 0 & 0 & \bar{\bar{x}}_0 & x_0 & 0
\end{bmatrix}\sim\begin{bmatrix}
x_1 & 0 & 0 & 0 & 0 & 1\\
0 & x_2 & 0 & 0 & 0 & 1\\
0 & 0 & x_0 & 0 & (D-1)\bar{\bar{x}}_0 & 1\\
0 & 0 & 0 & \overline{x}_0 & (D-1)\bar{\bar{x}}_0 & 1\\
0 & 0 & 0 & 0 & [x_0\overline{x}_0-(D-1)\bar{\bar{x}}_0^2] & -\bar{\bar{x}}_0\\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}.$$

□

Therefore, the propagator is given by

$$\mathcal{O}^{-1}=\frac{1}{x_1}P^1+\frac{1}{x_2}P^2+\frac{1}{x_0\overline{x}_0-(D-1)\bar{\bar{x}}_0^2}[\overline{x}_0P^0+x_0\overline{P}^0-\bar{\bar{x}}_0\bar{\bar{P}}^0]. \tag{11}$$

In summary, the prescription for computing the propagator consists of the following procedures.

(1) Linearize the original Lagrangian using (4).
(2) Add to the previous result a suitable gauge-fixing Lagrangian. Obviously, we only do this in the case of gauge-invariant theories.
(3) Cast the resulting Lagrangian into the bilinear form $\mathcal{L}=\frac{1}{2}h^{\mu\nu}\mathcal{O}_{\mu\nu,\rho\sigma}h^{\rho\sigma}$.
(4) Find the coefficients $x_1,x_2,\ldots,\bar{\bar{x}}_0$ by expanding the operator $\mathcal{O}$ in the basis $\{P^1,P^2,P^0,\overline{P}^0,\bar{\bar{P}}^0\}$ with the help of the identities (8).
(5) Insert these coefficients in (11).

B. Propagator for *D*-dimensional quadratic gravity in an unconventional gauge

Let us then find the propagator by means of the prescription developed in Sec. III A. Of course, the linearization of (6) leads to (5). So, $\mathcal{L}_g\equiv\mathcal{L}^{1}_{lin.}$. Lagrangian (5) is invariant under the infinitesimal coordinate transformation $x^\mu\rightarrow x^\mu+\kappa\xi^\mu(x)$, where $\xi^\mu(x)$ is an infinitesimal vector field. It must be infinitesimal to avoid inconsistency with (4). Under this transformation we have from (4)

$$h_{\mu\nu}(x)\rightarrow h_{\mu\nu}(x)-\xi_{\mu,\nu}-\xi_{\nu,\mu}. \tag{12}$$

The presence of the local gauge symmetry (12) requires the addition of a gauge-fixing term, $\mathcal{L}_{gf}$, to Lagrangian (5). It is common practice to choose a linear combination of A_μ and $\phi_{,\mu}$ as gauge functions. However, looking at (5) we clearly see the presence not only of this linear combination but also of its curl ($F_{\mu\nu}$) and its divergence ($A^\mu_{,\mu}-\Box\phi$). Hence, we choose the following unconventional gauge-fixing Lagrangian,

$$\mathcal{L}_{gf}=\lambda_1(A_\nu-\lambda\phi_{,\nu})^2+\frac{b}{4}[\lambda_2(A^\mu_{,\mu}-\lambda\Box\phi)^2+\lambda_3F^2_{\mu\nu}],$$

where λ, λ_1, λ_2, and λ_3 are suitable gauge parameters. Casting the Lagrangian, $\mathcal{L}=\mathcal{L}_g+\mathcal{L}_{gf}$, into the bilinear form $\mathcal{L}=\frac{1}{2}h^{\mu\nu}\mathcal{O}_{\mu\nu,\rho\sigma}h^{\rho\sigma}$, and expanding the operator $\mathcal{O}$ in the basis $\{P^1,P^2,\ldots,\bar{\bar{P}}^0\}$ with the help of (8), we obtain

$$\mathcal{O}=x_1P^1+x_2P^2+x_0P^0+\overline{x}_0\overline{P}^0+\bar{\bar{x}}_0\bar{\bar{P}}^0,$$

whereupon

$$x_1\equiv\frac{b}{2}\left(\lambda_3k^4+\frac{2\lambda_1k^2}{b}\right),$$

$$x_2\equiv\frac{b}{2}\left(k^4+\frac{2k^2}{b}\right),$$

$$x_0\equiv\frac{b}{2}\left[Dk^4-\frac{2(D-2)k^2}{b}+4(D-1)k^4c+(D-1)k^4\lambda_2\lambda^2+\frac{4(D-1)k^2\lambda_1\lambda^2}{b}\right],$$

$$\overline{x}_0\equiv\frac{b}{2}\left(k^4\lambda_2-2k^4\lambda\lambda_2+\frac{4k^2\lambda_1}{b}-\frac{8k^2\lambda\lambda_1}{b}+k^4\lambda_2\lambda^2+\frac{4k^2\lambda_1\lambda^2}{b}\right),$$

$$\bar{\bar{x}}_0\equiv\frac{b}{2}\left(\frac{4k^2\lambda_1\lambda^2}{b}+k^4\lambda_2\lambda^2-k^4\lambda\lambda_2-\frac{4k^2\lambda\lambda_1}{b}\right).$$

The propagator in momentum space is given by (11). From this result we can find the propagator in a series of interesting gauges, by judiciously choosing the parameters λ, λ_1, λ_2, and λ_3. We list below the most important covariant gauges that result from such choices.

(1) *Julve–Tonin gauge* ($\lambda=0$)*:*[19]

$$\mathcal{L}_{gf}=\lambda_1 A_\nu^2+\frac{b}{4}[\lambda_2(A^\mu_{,\mu})^2+\lambda_3 F^2_{\mu\nu}].$$

Propagator:

$$\mathcal{O}^{-1}=\frac{m_1^2}{k^2(m_1^2\lambda_1-\lambda_3k^2)}P^1+\frac{m_1^2}{k^2(m_1^2-k^2)}P^2+\frac{m_0^2}{2k^2[k^2-[(D-2)/2]\,m_0^2]}P^0 + \frac{m_1^2}{(2m_1^2\lambda_1-\lambda_2k^2)k^2}\overline{P}^0, \tag{13}$$

where

$$m_0^2\equiv\frac{2}{D\beta\kappa^2/4+(D-1)\kappa^2\alpha},\quad m_1^2\equiv-\frac{4}{\beta\kappa^2}.$$

Absence of tachyons requires $\beta<0$ and $(D-1)\alpha+\beta D/4>0$. Note that the choice $\lambda=0$ gives a propagator that only contains the spin-projection operators, i.e., P^1, P^2, P^0, $\overline{P}^0$, and it gives also a propagator all parts of which behave like k^{-4}.

(2) *de Donder gauge* ($\lambda_2=\lambda_3=0,\lambda=\frac{1}{2}$)*:*

$$\mathcal{L}_{gf}=\lambda_1(A_\nu-\tfrac{1}{2}\partial_\nu\phi)^2.$$

Propagator:

$$\mathcal{O}^{-1}=\frac{1}{\lambda_1k^2}P^1+\frac{m_1^2}{k^2(m_1^2-k^2)}P^2+\frac{m_0^2}{2k^2[k^2-[(D-2)/2]\,m_0^2]}P^0 +\left[\frac{2}{\lambda_1k^2}+\frac{(D-1)m_0^2}{2k^2[k^2-[(D-2)/2]\,m_0^2]}\right]\overline{P}^0+\frac{m_0^2}{2k^2[k^2-[(D-2)/2]\,m_0^2]}\bar{\bar{P}}^0.$$

(3) *Feynman gauge* ($\lambda_2=\lambda_3=0,\lambda_1=1,\lambda=\frac{1}{2}$):

$$\mathcal{L}_{gf}=(A_\nu-\tfrac{1}{2}\partial_\nu\phi)^2.$$

Propagator:

$$\mathcal{O}^{-1}=\frac{1}{k^2}P^1+\frac{m_1^2}{k^2(m_1^2-k^2)}P^2+\frac{m_0^2}{2k^2[k^2-[(D-2)/2]\,m_0^2]}P^0 +\left[\frac{2}{k^2}+\frac{(D-1)m_0^2}{2k^2[k^2-[(D-2)/2]\,m_0^2]}\right]\overline{P}^0+\frac{m_0^2}{2k^2[k^2-[(D-2)/2]\,m_0^2]}\bar{\bar{P}}^0.$$

IV. A SYSTEMATIC STUDY OF TREE-LEVEL UNITARITY

Now we present a method for analyzing the unitarity at the tree level of D-dimensional higher-derivative gravity theories.

In order to verify whether ghosts and tachyons are absent in a given theory of gravity with higher derivatives we require that the corresponding propagator has only first poles at k^2-M^2

$=0$ with real masses M (no tachyons) and with positive residues (no ghosts).[20–22] Therefore, to probe the tree-level unitarity of D-dimensional higher-derivative gravity theories we couple the propagator to external conserved currents, $T^{\mu\nu}$, compatible with the symmetries of the theory, and afterward we examine the current-current amplitude at the poles. The transition amplitude in momentum space, in turn, can be cast in the form

$$\mathcal{A}=\mathsf{g}^2 T^{\mu\nu}\mathcal{O}^{-1}_{\mu\nu,\rho\sigma}T^{\rho\sigma}, \tag{14}$$

where g is the effective coupling constant of the theory. Note that only the spin-projectors P^2 and P^0 will give a non-null contribution to the current-current amplitude since $k_\mu T^{\mu\nu}=0$.

Let us then expand the sources in a suitable basis. The set of independent vectors in momentum space,

$$k^\mu\equiv(k^0,\mathbf{k}),\quad \tilde{k}^\mu\equiv(k^0,-\mathbf{k}),\quad \varepsilon_i^\mu\equiv(0,\vec{\epsilon}_i),\quad i=1,\ldots,D-2,$$

where $\vec{\epsilon}_1,\ldots,\vec{\epsilon}_{D-2}$ are mutually orthogonal unit vectors which are also orthogonal to $\mathbf{k}$, serves our purpose. Accordingly, the symmetric current tensor $T^{\mu\nu}(k)$ can be written as

$$T^{\mu\nu}=ak^\mu k^\nu+b\tilde{k}^\mu\tilde{k}^\nu+c^{ij}\varepsilon_i^{(\mu}\varepsilon_j^{\nu)}+dk^{(\mu}\tilde{k}^{\nu)}+e^i k^{(\mu}\varepsilon_i^{\nu)}+f^i\tilde{k}^{(\mu}\varepsilon_i^{\nu)}. \tag{15}$$

The current conservation, $k_\mu T^{\mu\nu}=0$, gives the following constraints for the coefficients a, b, d, e^i and f^i

$$ak^2+(k_0^2+\mathbf{k}^2)\frac{d}{2}=0, \tag{16}$$

$$b(k_0^2+\mathbf{k}^2)+d\frac{k^2}{2}=0, \tag{17}$$

$$e^i k^2+f^i(k_0^2+\mathbf{k}^2)=0. \tag{18}$$

If we saturate the indices of $T^{\mu\nu}$ with momenta k_μ, we obtain the equation $k_\mu k_\nu T^{\mu\nu}=0$, which yields a consistency relation for the coefficients a, b, and d:

$$ak^4+b(k_0^2+\mathbf{k}^2)^2+dk^2(k_0^2+\mathbf{k}^2)=0. \tag{19}$$

Now, all we have to do is to compute the residue of $\mathcal{A}$ at each first pole of the propagator and verify whether its sign is positive.

Proposition 3: Higher-derivative gravity is nonunitary at the tree level in $D>2$ dimensions. If $m_0^2>0$ $[D\beta/4+(D-1)\alpha>0]$ and $m_1^2>0(-\beta>0)$, the theory is nontachyonic and has one normal massless spin-2 particle, one massive spin-2 ghost and one normal massive spin-0 particle. The massless excitation is not a dynamical degree of freedom in $D=3$.

Proof: From (14) and (13) we promptly obtain

$$\begin{aligned}\mathcal{A}&=\mathsf{g}^2 T^{\mu\nu}\left\{\frac{m_1^2}{k^2(m_1^2-k^2)}P^2+\frac{m_0^2}{2k^2[k^2-(D-2)m_0^2/2]}P^0\right\}T^{\rho\sigma}\\&=\mathsf{g}^2\left\{\frac{T_{\mu\nu}T^{\mu\nu}-T^2/(D-2)}{k^2}-\frac{T_{\mu\nu}T^{\mu\nu}-T^2/(D-1)}{k^2-m_1^2}\right.\\&\quad\left.+\frac{T^2}{(D-1)(D-2)[k^2-(D-2)m_0^2/2]}\right\},\end{aligned} \tag{20}$$

where $T=\eta_{\mu\nu}T^{\mu\nu}$. Thus, we have two poles for the spin-2 sector, i.e., $k^2=0$, $k^2=m_1^2$, and one pole for the spin-0 sector, namely, $k^2=(D-2)m_0^2/2$. Let us then find the sign of the residue at these poles. We assume that D-dimensional quadratic gravity has no tachyons, which implies $m_0^2>0$ and $m_1^2>0$.

• *Pole* $k^2=0$. From (16)–(18) and (20), we get that the residue of $\mathcal{A}$ at the pole $k^2=0$ is

$$\text{Res}\,\mathcal{A}|_{k^2=0}=\mathrm{g}^2\left[(c^{ij})^2-\frac{(c^{ii})^2}{D-2}\right]_{k^2=0}.$$

Therefore, the massless excitation is not a dynamical degree of freedom in three dimensions. For $D>3$ the result above tells us that $\text{Res}\,\mathcal{A}|_{k^2=0}>0$.

• *Pole* $k^2=(D-2)m_0^2/2$. In this case

$$\text{Res}\,\mathcal{A}|_{k^2=(D-2)m_0^2/2}=\left[\frac{\mathrm{g}^2T^2}{(D-1)(D-2)}\right]_{k^2=(D-2)m_0^2/2},$$

which implies that the residue of the current-current amplitude at the pole $k^2=(D-2)m_0^2/2$ is always positive for $D>2$. Thence, the scalar massive particle is a physical one.

• *Pole* $k^2=m_1^2$. The residue of the transition amplitude at the pole $k^2=m_1^2$ is given by

$$\begin{aligned}\text{Res}\,\mathcal{A}|_{k^2=m_1^2}&=-\mathrm{g}^2\Bigg\{ab(k_0^2+\mathbf{k}^2)^2+b^2k^4+bdk^2(k_0^2+\mathbf{k}^2)+(c^{ij})^2-\frac{1}{2}(k_0^2+\mathbf{k}^2)e^if^i-\frac{k^2}{2}(f^i)^2\\&\quad-\frac{1}{D-1}[ak^2+bk^2-c^{ii}+d(k_0^2+\mathbf{k}^2)]^2\Bigg\}_{k^2=m_1^2},\\&=-\mathrm{g}^2\Bigg\{[(a-b)k^2]^2+(c^{ij})^2+\frac{k^2}{2}[(e^i)^2-(f^i)^2]-\frac{1}{D-1}[(b-a)k^2-c^{ii}]^2\Bigg\}_{k^2=m_1^2},\end{aligned}$$

where use has been made of (16)–(19). This expression can also be written as

$$\begin{aligned}\text{Res}\,\mathcal{A}|_{k^2=m_1^2}=-\mathrm{g}^2\Bigg\{&\frac{D-2}{D-1}[(a-b)k^2]^2+\left[(c^{ij})^2-\frac{(c^{ii})^2}{D-1}\right]+\frac{k^2}{2}[(e^i)^2-(f^i)^2]\\&-\frac{2}{D-1}(a-b)k^2c^{ii}\Bigg\}_{k^2=m_1^2}.\end{aligned}$$

Now, assuming as usual that $T\geqslant 0$, we get that $c^{ii}\leqslant 0$, which implies that $\text{Res}\,\mathcal{A}|_{k^2=m_1^2}<0$ for $D>2$. So, we have a nontachyonic massive spin-2 ghost in the propagator of higher-derivative gravity. In conclusion we way say that D-dimensional higher-derivative gravity is nonunitary at the tree level. □

Corollary 1: D-dimensional $R+R^2$ gravity is unitary at the tree level for $D>2$. In three dimensions the massless excitation is not a dynamical degree of freedom.

Proof: Clear. □

V. EFFECTIVE NONRELATIVISTIC POTENTIAL

In principle any relativistic theory of gravitation ought to agree with Newton's theory in the limiting case of motion at low velocity in a weak gravitational field. Accordingly it is worthwhile to probe whether D-dimensional linearized quadratic gravity leads to the right nonrelativistic law for gravitational interactions. To do this we compute the effective nonrelativistic potential for the interaction of two identical massive bosons of zero spin via a graviton exchange. The expression for the potential is

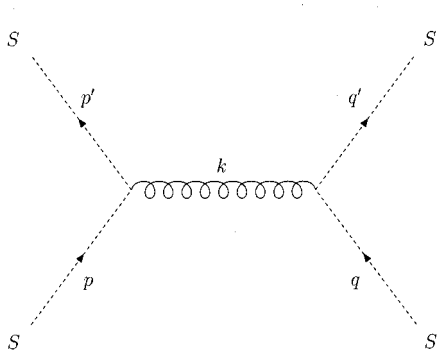

FIG. 1. One-graviton-exchange contribution to the scattering of two identical spinless massive bosons. S denotes a scalar particle with mass m.

$$U(r)=\frac{1}{4m^2}\,\frac{1}{(2\pi)^{D-1}}\int d^{D-1}\mathbf{k}\mathcal{M}_{N.R.}e^{-i\mathbf{k}\cdot\mathbf{r}}, \tag{21}$$

whereupon $\mathcal{M}_{N.R.}$ is the nonrelativistic limit of the Feynman amplitude for the process $S+S\rightarrow S+S$, where S stands for a spinless boson of mass m. The corresponding Feynman diagram is shown in Fig. 1.

The Lagrangian for the interaction of gravity with a free, massive scalar field $\tilde{\phi}$ is

$$\mathcal{L}_{int}=-\frac{\kappa h^{\mu\nu}}{2}\left[\partial_\mu\tilde{\phi}\partial_\nu\tilde{\phi}-\frac{1}{2}\,\eta_{\mu\nu}(\partial_\alpha\tilde{\phi}\partial^\alpha\tilde{\phi}-m^2\tilde{\phi}^2)\right].$$

From the previous expression the Feynman rule for the elementary vertex may readily be deduced. It is shown in Fig. 2. The invariant amplitude for the process shown in Fig. 1 is

$$\begin{aligned}\mathcal{M}=&\frac{m_1^2}{k^2(m_1^2-k^2)}\,\frac{\kappa^2}{2}\Bigg\{(p.q)(p'.q')+(p.q')(p'.q)+(p.p')(m^2-q.q')+(q.q')(m^2-p.p')\\&+\frac{D}{2}(m^2-p.p')(m^2-q.q')-\frac{1}{2(D-1)}[Dm^2-(D-2)p.p'][Dm^2-(D-2)q.q']\Bigg\}\\&+\frac{m_0^2}{k^2(k^2-[(D-2)/2]\,m_0^2)}\,\frac{\kappa^2}{8(D-1)}[Dm^2-(D-2)p.p'][Dm^2-(D-2)q.q'].\end{aligned}$$

In the nonrelativistic limit this expression reduces to

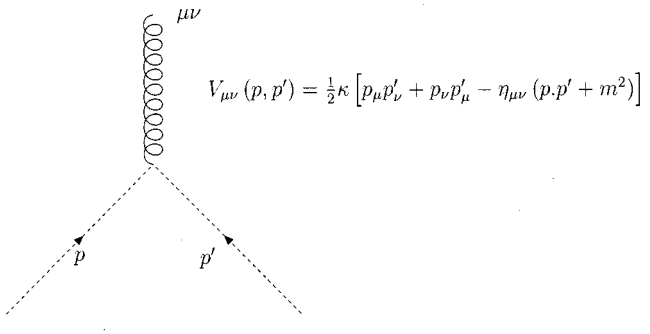

FIG. 2. The relevant Feynman rule for boson-boson interaction.

$$\mathcal{M}_{N.R.}=-\frac{D-2}{D-1}\frac{\kappa^2 m^4 m_1^2}{\mathbf{k}^2(\mathbf{k}^2+m_1^2)}+\frac{\kappa^2 m^4 m_0^2}{2(D-1)\mathbf{k}^2(\mathbf{k}^2+[(D-2)/2]\,m_0^2)}. \tag{22}$$

Substituting (22) into (21) we obtain[23]

$$U(r)=I_1+I_2,$$

where

$$I_1\equiv-\frac{\kappa^2 m^2 m_1^2}{4(2\pi)^{D-1}}\frac{D-2}{D-1}\int_0^\infty\int_0^\pi\cdots\int_0^\pi\int_0^\pi\int_0^{2\pi}\left[\frac{e^{-i\mathbf{k}.\mathbf{r}}}{\mathbf{k}^2(\mathbf{k}^2+m_1^2)}|\mathbf{k}|^{D-2}d|\mathbf{k}|\sin^{D-3}\right.$$
$$\left.\times\,\theta_{D-2}d\theta_{D-2}\cdots\sin^2\theta_3 d\theta_3\sin\theta_2\,d\theta_2 d\theta_1\right], \tag{23}$$

$$I_2\equiv\frac{\kappa^2 m^2 m_0^2}{8(2\pi)^{D-1}}\frac{1}{D-1}\int_0^\infty\int_0^\pi\cdots\int_0^\pi\int_0^\pi\int_0^{2\pi}\left[\frac{e^{-i\mathbf{k}.\mathbf{r}}}{\mathbf{k}^2(\mathbf{k}^2+[(D-2)/2]\,m_0^2)}|\mathbf{k}|^{D-2}d|\mathbf{k}|\sin^{D-3}\right.$$
$$\left.\times\,\theta_{D-2}d\theta_{D-2}\cdots\sin^2\theta_3 d\theta_3\sin\theta_2 d\theta_2 d\theta_1\right]. \tag{24}$$

Hence, the problem of computing the effective nonrelativistic potential was reduced to quadratures. We give in the following two examples to illustrate the efficacy of the method: linearized quadratic gravity in three and four dimensions, respectively.

• *Three-dimensional linearized quadratic gravity*. For $D=3$ the expressions (23) and (24) tell us that

$$U(r)=\frac{\kappa^2 m^2}{8(2\pi)^2}\int_0^\infty\left(\int_0^{2\pi}e^{-i|\mathbf{k}|r\cos\theta}d\theta\right)\left(\frac{1}{\mathbf{k}^2+m_1^2}-\frac{1}{\mathbf{k}^2+m_0^2/2}\right)|\mathbf{k}|d|\mathbf{k}|$$
$$=\frac{\kappa^2 m^2}{16\pi}\int_0^\infty\left(\frac{1}{\mathbf{k}^2+m_1^2}-\frac{1}{\mathbf{k}^2+m_0^2/2}\right)J_0(|\mathbf{k}|r)|\mathbf{k}|d|\mathbf{k}|,$$

where J_0 is the Bessel function of the first kind of order zero. Now, from a mathematical point of view, $\int_0^\infty[xJ_0(ax)/(x^2+b^2)]\,dx$ only makes sense if[24] $a>0$, $\mathrm{Re}\,b>0$. Accordingly, we assume that $m_0^2>0(\frac{3}{4}\beta+2\alpha>0)$ and $m_1^2>0(-\beta>0)$, which is nothing but the condition for absence of tachyons (both positive and negative energy) in the dynamical field. Performing the integration yields

$$U(r)=2\overline{G}m^2[K_0(m_1 r)-K_0(m_0 r/\sqrt{2})],$$

where K_0 is the modified Bessel function of the order of zero and $\overline{G}\equiv\kappa^2/32\pi$.

Therefore, the potential is given by

$$V(r)=2\overline{G}m[K_0(m_1 r)-K_0(m_0 r/\sqrt{2})].$$

Note that $V(r)$ behaves as $2\overline{G}m\ln(m_0/m_1\sqrt{2})$ at the origin and as $2\overline{G}m[\sqrt{\pi/2m_1 r}e^{-m_1 r}-\sqrt{\pi/m_0 r\sqrt{2}}e^{-m_0 r/\sqrt{2}}]$ asymptotically.[25]

Three comments are in order here:

(i) Unlike the Newtonian potential, $V_N=2Gm\ln r_0/r$, which has a logarithmic singularity at the origin and is unbounded at infinity, the potential concerning three-dimensional linearized quadratic gravity is extremely well behaved: it is finite at the origin and zero at the infinity.

(ii) $V(r)\to 0$ as m_0 and $m_1\to\infty$, confirming in this way the well known fact that the standard correspondence of three-dimensional linearized Einstein's theory with Newton's theory breaks down.[26]

(iii) Recently it was shown that the solution of the linearized field equations concerning three-dimensional linearized quadratic gravity, having as source a static point like mass m, is given by[27]

$$h_{00}=\frac{\kappa m}{8\pi}[K_0(m_1 r)-K_0(m_0 r/\sqrt{2})],$$

$$h_{11}=h_{22}=\frac{\kappa m}{8\pi}[2\ln r+K_0(m_1 r)+K_0(m_0 r/\sqrt{2})].$$

Since $V=\kappa h_{00}/2$, we see that this independent computation of the potential leads to the same result as that obtained via the effective nonrelativistic potential. The former is, in a sense, a major test of our semiclassical computation.

• *Four-dimensional linearized quadratic gravity*. The effective nonrelativistic potential is computed in this case as follows:

$$U(r)=\frac{\kappa^2 m^2}{6(2\pi)^2}\int_0^\infty\left(\int_0^\pi e^{-i|\mathbf{k}|r\cos\theta}\sin\theta d\theta\right)\left[-\frac{3}{4}\frac{1}{\mathbf{k}^2}+\frac{1}{\mathbf{k}^2+m_1^2}-\frac{1}{4(\mathbf{k}^2+m_0^2)}\right]\mathbf{k}^2 d|\mathbf{k}|$$

$$=\frac{\kappa^2 m^2}{6(2\pi)^2}\frac{1}{r}\mathrm{Im}\left[\int_{-\infty}^{+\infty}e^{ix}\left(-\frac{3}{4x}+\frac{x}{x^2+m_1^2r^2}-\frac{1}{4}\frac{x}{x^2+m_0^2r^2}\right)dx\right]. \tag{25}$$

Now, the condition for the existence of integrals like $\int_{-\infty}^{+\infty}[(x\sin x)/(x^2+a^2)]dx$ $(a\neq 0)$ is that $a>0$. In this case they can be easily evaluated by the method of contour integration. Therefore, assuming that $3\alpha+\beta>0$ and $-\beta>0$, which corresponds to the absence of tachyons in the dynamical field, we promptly obtain from (25)

$$U(r)=Gm^2\left[-\frac{1}{r}+\frac{4}{3}e^{-m_1 r}-\frac{1}{3}e^{-m_0 r}\right].$$

So, the potential for linearized higher-derivative gravity is given by the expression[4,7]

$$V(r)=Gm\left[-\frac{1}{r}+\frac{4}{3}\frac{e^{-m_1 r}}{r}-\frac{1}{3}\frac{e^{-m_0 r}}{r}\right],$$

which agrees asymptotically with Newton's law. At the origin it tends to the finite value $Gm((m_0-4m_1)/3)$.

From the computation of $V(r)$ for linearized quadratic gravity in three and four dimensions we learned that the existence of the potential is related to the absence of tachyons in the dynamical field. Consequently, we may conjecture that this is so in any dimension $D>2$. This issue will be treated elsewhere.

VI. GRAVITATIONAL DEFLECTION

Using the mathematical apparatus developed in the last sections we consider now the issue of light bending within the framework of D-dimensional quadratic gravity. Accordingly, let us con-

sider the interaction between a fixed source and a light ray. The associated energy-momentum tensors will be designated respectively as $T^{\mu\nu}$ and $F^{\mu\nu}$. The current-current amplitude for this process is given by

$$\mathcal{A}=\mathsf{g}^2 T_{\mu\nu}\mathcal{O}^{-1}_{\mu\nu,\rho\sigma}F^{\rho\sigma}.$$

But, on mass shell, $k_\mu T^{\mu\nu}=0$ and $k_\mu F^{\mu\nu}=0$, implying that only P^2 and P^0 will give a non-null contribution to the current-current amplitude. Therefore,

$$\mathcal{A}=\mathsf{g}^2 T^{\mu\nu}F^{\rho\sigma}\left[\frac{m_1^2}{k^2(m_1^2-k^2)}P^2+\frac{m_0^2}{2k^2[k^2-[(D-2)/2]m_0^2]}P^0\right]_{\mu\nu,\rho\sigma}.$$

Now, taking (9) into account and recalling that the energy-momentum tensor for light (electromagnetic radiation) is traceless, while $T^{\mu\nu}=\eta^{\mu 0}\eta^{\nu 0}T^{00}$ for a static source, we promptly obtain

$$\mathcal{A}=\mathsf{g}^2 T^{00}F^{00}\left[\frac{1}{k^2}-\frac{1}{k^2-m_1^2}\right].$$

Since $\mathsf{g}^2T^{00}F^{00}/k^2$ is precisely the current-current amplitude for the interaction between a fixed source and a light ray in the context of D-dimensional linearized general relativity, we come to the conclusion that the gravitational deflection predicted by D-dimensional linearized quadratic gravity is always smaller than that predicted by D-dimensional linearized Einstein's theory.

Let us then discuss in more detail the result above in the particular case $D=3$. Proposition 3 tell us that the massless excitation is not a dynamical degree of freedom in three dimensions. Consequently, only $-\mathsf{g}^2T^{00}F^{00}/(k^2-m_1^2)$ will contribute to light deflection. Thus, we come to the surprising result that in the framework of three-dimensional linearized quadratic gravity a light ray is deflected upward instead of downward as its four-dimensional counterpart. This is, perhaps, a property peculiar to quadratic gravity in $D=3$. It is worth mentioning that a classical computation of the gravitational deflection[27] assures us of the correctness of our result which is based on a semiclassical approach.

VII. THREE-DIMENSIONAL QUADRATIC GRAVITY WITH A GRAVITATIONAL CHERN–SIMONS TERM

To conclude we consider quadratic gravity with a gravitational Chern–Simons term. The topological Chern–Simons Lagrangian is given by

$$\mathcal{L}_{C.S.}=\frac{1}{2\mu}\varepsilon^{\mu\nu\lambda}\left(R^{\alpha}_{\beta\mu\nu}\Gamma^{\beta}_{\alpha\lambda}-\frac{2}{3}\Gamma^{\alpha}_{\beta\mu}\Gamma^{\beta}_{\gamma\nu}\Gamma^{\gamma}_{\alpha\lambda}\right)=\frac{\varepsilon^{\lambda\mu\nu}}{\mu}\Gamma^{\rho}_{\sigma\lambda}\left(\partial_\mu\Gamma^{\sigma}_{\rho\nu}+\frac{2}{3}\Gamma^{\sigma}_{\omega\mu}\Gamma^{\omega}_{\nu\rho}\right), \tag{26}$$

where μ is a dimensionless parameter. Linearizing (26), we obtain

$$\mathcal{L}_{C.S.lin.}=\frac{1}{2}\frac{1}{M}h^{\mu\nu}\mathcal{P}_{\mu\nu,\rho\sigma}h^{\rho\sigma}, \tag{27}$$

where[28]

$$\mathcal{P}_{\mu\nu,\rho\sigma}\equiv\frac{\Box\partial^\lambda}{4}[\varepsilon_{\mu\lambda\rho}\theta_{\nu\sigma}+\varepsilon_{\mu\lambda\sigma}\theta_{\nu\rho}+\varepsilon_{\nu\lambda\rho}\theta_{\mu\sigma}+\varepsilon_{\nu\lambda\sigma}\theta_{\mu\rho}], \tag{28}$$

and $M\equiv\mu/\kappa^2$. In order to have a complete basis for the operator space of the field equations concerning higher-derivative gravity theories in three dimensions with a Chern–Simons term, we

TABLE I. Multiplication table for the three-dimensional operators P^1, P^2, P^0, $\overline{P}^0$, $\bar{\bar{P}}^0$, and P.

	P^1	P^2	P^0	$\overline{P}^0$	$\bar{\bar{P}}^0$	P
P^1	P^1	O	O	O	O	O
P^2	O	P^2	O	O	O	P
P^0	O	O	P^0	O	$P^{\theta\omega}$	O
$\overline{P}^0$	O	O	O	$\overline{P}^0$	$P^{\omega\theta}$	O
$\bar{\bar{P}}^0$	O	O	$P^{\omega\theta}$	$P^{\theta\omega}$	$2(P^0+\overline{P}^0)$	O
P	O	P	O	O	O	$-k^6P^2$

include in the collection of three-dimensional operators $\{P^1,P^2,P^0,\overline{P}^0,\bar{\bar{P}}^0\}$ (see Sec. III A) the operator P (28). The multiplication table for these operators is displayed in Table I.

We are now ready to compute the propagator. Expanding both operators $\mathcal{O}$ and $\mathcal{O}^{-1}$ in the basis $\{P^1,P^2,P^0,\overline{P}^0,\bar{\bar{P}}^0\}$, we obtain

$$\mathcal{O}=x_1P^1+x_2P^2+x_0P^0+\overline{x}_0\overline{P}^0+\bar{\bar{x}}_0\bar{\bar{P}}^0+pP,$$

$$\mathcal{O}^{-1}=y_1P^1+y_2P^2+y_0P^0+\overline{y}_0\overline{P}^0+\bar{\bar{y}}_0\bar{\bar{P}}^0+qP.$$

With the help of Table I and taking into account that $\mathcal{O}\mathcal{O}^{-1}=I$, we find that $y_1=1/x_1$, $y_2=x_2/(x_2^2-p^2k^6)$, $y_0=\overline{x}_0/(x_0\overline{x}_0-2\bar{\bar{x}}_0^2)$, $\overline{y}_0=x_0/(x_0\overline{x}_0-2\bar{\bar{x}}_0^2)$, $\bar{\bar{y}}_0=-\bar{\bar{x}}_0(x_0\overline{x}_0-2\bar{\bar{x}}_0^2)$, and $q=-p/(x_2^2-p^2k^6)$, while the propagator is given by

$$\mathcal{O}^{-1}=\frac{1}{x_1}P^1+\frac{x_2}{x_2^2-p^2k^6}P^2+\frac{\overline{x}_0}{x_0\overline{x}_0-2\bar{\bar{x}}_0^2}P^0+\frac{x_0}{x_0\overline{x}_0-2\bar{\bar{x}}_0^2}\overline{P}^0-\frac{\bar{\bar{x}}_0}{x_0\overline{x}_0-2\bar{\bar{x}}_0^2}\bar{\bar{P}}^0-\frac{p}{x_2^2-p^2k^6}P. \tag{29}$$

Accordingly, let us then find the propagator for quadratic gravity with a Chern–Simons term. This theory is defined by the Lagrangian

$$\overline{\mathcal{L}}=-\frac{2R\sqrt{g}}{\kappa^2}+\frac{\varepsilon^{\mu\nu\lambda}}{\mu}\Gamma^{\rho}_{\sigma\lambda}\left(\partial_\mu\Gamma^{\sigma}_{\rho\nu}+\frac{2}{3}\Gamma^{\sigma}_{\omega\mu}\Gamma^{\omega}_{\nu\rho}\right)+\left(\frac{\alpha}{2}R^2+\frac{\beta}{2}R^2_{\mu\nu}\right)\sqrt{g}.$$

In the Julve–Tonin gauge the operator $\mathcal{O}$ has the form

$$\mathcal{O}=-k^2\left(\lambda_1+\lambda_3\frac{b}{2}k^2\right)P^1+k^2\left(k^2\frac{b}{2}-1\right)P^2+\left[k^2+bk^4\left(\frac{3}{2}+4c\right)\right]P^0$$
$$-k^2\left(\frac{b}{2}\lambda_2k^2+2\lambda_1\right)\overline{P}^0+\frac{P}{M},$$

and the propagator is given by

$$\mathcal{O}^{-1}=\frac{-2}{k^2[2\lambda_1+b\lambda_3k^2]}P^1+\left[-\frac{1}{k^2}+\frac{1}{1+(bM_2^2/2)}\frac{1}{k^2-M_2^2}+\frac{1}{1+(bM_1^2/2)}\frac{1}{k^2-M_1^2}\right]P^2$$
$$+\left[\frac{1}{k^2}-\frac{1}{k^2-m^2}\right]P^0-\frac{1}{k^2[2\lambda_1+\lambda_2(b/2)k^2]}\overline{P}^0$$
$$-\left[\frac{4}{b^2M(M_1^2-M_2^2)}\left(\frac{1}{k^2-M_1^2}-\frac{1}{k^2-M_2^2}\right)\frac{1}{k^4}\right]P, \tag{30}$$

where

$$M_1^2 \equiv \left(\frac{2}{b^2M^2}\right)[1+bM^2+\sqrt{1+2bM^2}],$$

$$M_2^2 \equiv \left(\frac{2}{b^2M^2}\right)[1+bM^2-\sqrt{1+2bM^2}],$$

$$m^2 \equiv \frac{-1}{b\left(\frac{3}{2}+4c\right)}.$$

If we do not want tachyons in the dynamical field, we may choose, for instance, $b>0$ and $(\frac{3}{2}+4c)<0$. In this case the theory is causal at the tree level. In this vein we assume from now on m^2, M_1^2, M_2^2, and $M^2>0$.

We discuss in the following tree-level unitarity, nonrelativistic limit and gravitational deflection for quadratic-Chern-Simons gravity in $D=3$.

A. Tree-level unitarity

From (14) and (30) we obtain at once

$$\mathcal{A}=\mathrm{g}^2\left[\frac{2}{b^2}\frac{bM_2^2-2}{(M_2^2-M_1^2)M_2^2}\frac{T_{\mu\nu}T^{\mu\nu}-\frac{1}{2}T^2}{k^2-M_2^2}+\frac{2}{b^2}\frac{2-bM_1^2}{(M_2^2-M_1^2)M_1^2}\frac{T_{\mu\nu}T^{\mu\nu}-\frac{1}{2}T^2}{k^2-M_1^2}-\frac{\frac{1}{2}T^2}{k^2-m^2}\right.$$
$$\left.+\frac{4}{b^2M_1^2M_2^2}\frac{T^2-T_{\mu\nu}T^{\mu\nu}}{k^2}\right]. \tag{31}$$

Therefore, if $b>0$ and $(\frac{3}{2}+4c)<0$, (20) tells us that $\mathrm{Res}\,\mathcal{A}|_{k^2=M_1^2}>0$, $\mathrm{Res}\,\mathcal{A}|_{k^2=M_2^2}>0$, $\mathrm{Res}\,\mathcal{A}|_{k^2=m^2}<0$, and $\mathrm{Res}\,\mathcal{A}|_{k^2=0}=0$.

Proposition 4: Quadratic gravity with a gravitational Chern–Simons term is nonunitary at the tree level. If $b>0$ and $(\frac{3}{2}+4c)<0$, the theory in nontachyonic and has one normal massless spin-2 particle, one normal spin-2 particle of mass M_2, one normal spin-2 particle of mass M_1 and one spin-0 ghost of mass m. The massless excitation is not a dynamical degree of freedom.

Corollary 2: $R+R^2$ gravity with a Chern–Simons term is nonunitary at the tree level. If $\alpha<0$, the theory is nontachyonic and has one physical massless spin-2 particle, one physical particle of spin-2 and mass M and one spin-0 ghost of mass $m\equiv\sqrt{-1/2\alpha\kappa^2}$. The massless excitation is not a dynamical degree of freedom.

Proof: Clear. □

Therefore, we come to the conclusion that neither quadratic gravity with a Chern–Simons term nor $R+R^2$ gravity with a Chern–Simons term is unitary at the tree level.

A detailed comparison between three-dimensional quadratic gravity with quadratic gravity with a Chern–Simons term clearly shows that the harmless massive scalar mode of the former becomes a troublesome massive spin-0 ghost within the context of the latter, while the massive spin-2 ghost related to three-dimensional quadratic gravity is now replaced by two massive physical particles both of spin-2. On the other hand, if we make a comparison between three-dimensional $R+R^2$ gravity with $R+R^2$ gravity with a Chern–Simons term, we come to the conclusion that the gravitational Chern–Simons term is responsible for breaking down the unitarity of the former.

B. Nonrelativistic limit

In this case the invariant amplitude for the process $S+S\rightarrow S+S$, where S denotes a spinless boson of mass $\tilde{m}$, as well as for its nonrelativistic limit, are given respectively by

$$\mathcal{M}=\kappa^2\Bigg[-\frac{1}{2k^2}+\frac{1}{bM_2^2+2}\,\frac{1}{k^2-M_2^2}+\frac{1}{b^2M_1^2+2}\,\frac{1}{k^2-M_1^2}\Bigg]\times\Bigg[(p\cdot q)(p'\cdot q')+(p\cdot q')(p'\cdot q)$$
$$+p\cdot p'(\tilde{m}^2-q\cdot q')+(\tilde{m}^2-p\cdot p')q\cdot q'+\frac{3}{2}(\tilde{m}^2-q\cdot q')(\tilde{m}^2-p\cdot p')-\frac{1}{4}(3\tilde{m}^2-p\cdot p')$$
$$\times(3\tilde{m}^2-q\cdot q')\Bigg]+\frac{\kappa^2}{8}\Bigg\{(3\tilde{m}^2-p\cdot p')(3\tilde{m}^2-q\cdot q')\Bigg[\frac{1}{k^2}-\frac{1}{k^2-m^2}\Bigg]\Bigg\}$$

and

$$\mathcal{M}_{N.R.}=\kappa^2\tilde{m}^4\Bigg[\frac{1}{2}\,\frac{1}{\mathbf{k}^2+m^2}-\frac{1}{2+bM_2^2}\,\frac{1}{\mathbf{k}^2+M_2^2}-\frac{1}{2+bM_1^2}\,\frac{1}{\mathbf{k}^2+M_1^2}\Bigg]. \tag{32}$$

Inserting (32) into (21) and performing the integration yields

$$U(r)=2\tilde{m}^2\overline{G}\Bigg[K_0(rm)-\frac{1}{1+(bM_1^2/2)}K_0(rM_1)-\frac{1}{1+(bM_2^2/2)}K_0(rM_2)\Bigg].$$

As a result, the potential is given by the expression

$$V(r)=2\tilde{m}\overline{G}\Bigg[K_0(rm)-\frac{1}{1+(bM_1^2/2)}K_0(rM_1)-\frac{1}{1+(bM_2^2/2)}K_0(rM_2)\Bigg].$$

Note that $V(r)$ behaves as $2\tilde{m}\overline{G}\,\ln M_1^{1+(bM_1^2/2)}M_2^{1+(bM_2^2/2)}/m$ at the origin and as

$$2\tilde{m}\overline{G}\Bigg[\sqrt{\frac{\pi}{2mr}}e^{-rm}-\frac{1}{1+(bM_1^2/2)}\sqrt{\frac{\pi}{2M_1r}}e^{-M_1r}-\frac{1}{1+(bM_2^2/2)}\sqrt{\frac{\pi}{2M_2r}}e^{-M_2r}\Bigg]$$

asymptotically. Two comments are in order here:

(i) Unlike the Newtonian potential $V_N=2\overline{G}\tilde{m}\ln r_0/r_1$ which has a logarithmic singularity at the origin and is unbounded at infinity, the potential concerning linearized quadratic Chern–Simons gravity in $(2+1)D$ is extremely well behaved: it is finite at the origin and zero at infinity.

(ii) $V(r)\rightarrow 0$ as α and $\beta\rightarrow 0$, confirming in this way the fact that the standard correspondence of three-dimensional linearized Einstein–Chern–Simons gravity with Newton's theory breaks down.[29,30]

C. Light deflection

The current-current amplitude for the interaction of a light ray with a fixed source is given by

$$\mathcal{A}=\mathsf{g}^2T^{\mu\nu}F^{\rho\sigma}\Bigg[\Bigg(-\frac{1}{k^2}+\frac{1}{1+(bM_2^2/2)}\,\frac{1}{k^2-M_2^2}+\frac{1}{1+(bM_1^2/2)}\,\frac{1}{k^2-M_1^2}\Bigg)P^2$$
$$+\Bigg(\frac{1}{k^2}-\frac{1}{k^2-m^2}\Bigg)P^0\Bigg]_{\mu\nu,\rho\sigma}.$$

Taking (9) into account we can rewrite the expression above as

$$\mathcal{A}=\mathcal{A}_0+\mathcal{A}_1,$$

where

$$\mathcal{A}_0\equiv-\frac{\mathrm{g}^2T_{00}F_{00}}{k^2},$$

$$\mathcal{A}_1\equiv\mathrm{g}^2T_{00}F_{00}\left(\frac{1}{1+(bM_2^2/2)}\,\frac{1}{k^2-M_2^2}+\frac{1}{1+(bM_1^2/2)}\,\frac{1}{k^2-M_1^2}\right).$$

Of course, only $\mathcal{A}_1$ will contribute to light deflection since the massless excitation is not a degree of freedom. Hence, the light ray will be deflected downward as usual.

VIII. SUMMARY AND DISCUSSION

We proposed a prescription for finding the propagator concerning higher-derivative gravity theory in D dimensions based on the Barnes–Rivers operators. Using this algorithm, we computed the propagator for the latter in an unconventional gauge and, by a suitable choice of the gauge parameters, we reobtained the propagator in a series of gauges which are used in day-to-day physics.

A systematic study of the tree-level unitarity of D-dimensional higher-derivative gravity theory was presented afterward. It was shown that it is nonunitary at the tree level: the term quadratic in the Ricci tensor is the Achille's heel of the theory. This term is responsible for the presence of a massive spin-2 particle of negative residue, i.e., a ghost, in the bare propagator. Nevertheless, this may be a hasty conclusion. Indeed, as pointed out by Antoniadis and Tomboulis,[15] this excitation is unstable in four dimensions. Perhaps it would be unstable as well in any dimension. Therefore, D-dimensional quadratic gravity cannot yet be rejected as a viable possibility.

On the other hand, D-dimensional $R+R^2$ gravity is unitary at the tree level. We call attention to the fact that our discussion was confined to a particular style of variational principle. Perhaps there are richer unitary combinations in higher dimensions with the connection varied independently. If this is the case, that would be worth knowing. This matter will be the object of a future investigation.

The problem of computing the effective nonrelativistic potential for D-dimensional quadratic gravity was then reduced to quadratures. It seems that the existence of this potential in any dimension is related to the absence of tachyons (both positive and negative energy) in the dynamical field. It was also shown that, unlike three-dimensional linearized gravity which has no Newtonian limit, three-dimensional linearized quadratic gravity has a potential that, despite being rather different from the corresponding Newtonian one, is extremely well behaved.

It was shown afterward that the gravitational deflection is always smaller than that predicted by the corresponding Einstein's theory. This conclusion is totally independent of the value of D. For $D=3$ we arrive at the astonishing result that a light ray would be deflected upward instead of downward as its four-dimensional counterpart. It can be shown, in addition, that in $D=3$ a gravitational force is exerted on a slowly moving test particle.[31] This force greatly resembles that of a straight $U(1)$-gauge cosmic string in the framework of linearized quadratic gravity in four dimensions[32] and it is absent in three-dimensional general relativity.

Finally, we discussed three-dimensional quadratic gravity augmented by a Chern–Simons term. It was shown that neither the latter nor three-dimensional $R+R^2$ gravity with a Chern–Simons term are unitary at the tree level. On the other hand, as it was shown previously, light deflection has the ''wrong sign'' within the context of three-dimensional quadratic gravity. The addition of a topological massive term to the latter ''repairs'' the aforementioned sign. Is worth mentioning that ''antigravity'' is possible in the context of three-dimensional quadratic Chern–Simons gravity.[33]

To conclude we raise two interesting questions:

(i) Is it possible that gravity's rainbows and quadratic gravity theories can coexist without conflict in any dimension?

(ii) Is the photon propagation dispersive in the framework of three-dimensional quadratic gravity with a Chern–Simons term such as in four-dimensional quadratic gravity? These issues will be discussed elsewhere.

We study the set of invariants CZ [E. Zakhary and J. Carminati, J. Math. Phys. **42**, 1474 (2001)] for the class of space–times whose Ricci tensors do not possess a null eigenvector. We show that all cases are completely backsolvable in terms of sets of invariants from CZ. We provide algebraically complete sets for each canonically different space–time. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1418427]

I. INTRODUCTION

In a previous paper[1] we introduced a new set of polynomial Riemann invariants CZ, satisfying the minimum degree property, which was claimed to be ''determining.'' (The various new definitions which are used here were introduced in the previous article.[1] In particular, we shall use the term ''complete'' to mean ''algebraically complete'' when referring to sets of invariants.) The main purpose of this article and a sequel will be to rigorously establish this fact. This will be achieved with the use of a ''backsolving'' technique. Moreover, we will explicitly give algebraically complete sets of invariants for each canonically different space–time. Essential to our approach is the notion of ''maximally backsolvable,'' which is the ability to backsolve, with a given set of invariants, for all of the theoretically possible, ''independent,'' Riemann curvature information, i.e., we call a set of invariants ''maximal'' if it contains all of the theoretically possible (not necessarily all) curvature information from the Riemann tensor, once all of the possible remaining tetrad freedom, which can act on the curvature components, is completely used up. It follows that such a maximal set must be determining and vice versa. Also, we need to further distinguish when a maximal set contains *all* of the information in the Riemann tensor and when it does not. We call a set of invariants ''curvature complete'' if it contains *all* of the independent information that is in the Riemann tensor and complete backsolving is then achievable. Clearly, curvature complete implies maximal but not vice versa.

Regarding explicitly giving algebraically complete sets of invariants for each canonically different space–time, we will show that this is always possible by choosing certain subsets of CZ. We will, in general, not give explicit solutions of the independent curvature components in terms of our invariants as in many cases this is not possible since the resulting polynomial expressions are very large and of high degree. As was shown previously,[1] for some Segre and Weyl types not all of the information that is in the Riemann tensor is in its second order polynomial invariants. Hence, complete backsolving is not always possible for these cases but maximal backsolving should always, at least in principle, be achievable with an algebraically complete set of invariants. Note, obviously, that ''completely backsolvable'' implies ''maximally backsolvable'' but not vice versa.

a)Electronic mail: jcarm@deakin.edu.au

Our backsolving procedure is carried out, in almost all cases, in the Ricci canonical frames corresponding to the different Segre types (and general Petrov type). We note that the backsolving for the Ricci (or Weyl) components only in terms of the pure Ricci (or pure Weyl) invariants, in their respective canonical frames, has been previously done by Carminati and McLenaghan[2] and Zakhary.[3]

Regarding our method of proof, after having established that a set of invariants is maximal or determining by backsolving and if necessary using the index theorem, we then check that we have retained the minimum possible number of invariants [i.e., that it cannot be further reduced (in number[4] of invariants) and still achieve the same "measure" [5] of backsolving]. It follows that once this is done, we have established that the set is algebraically complete. In cases where complete backsolving has been achieved (i.e., we have curvature complete sets), which is for all of class A (see below), the "minimal number" property is established by simply observing that the number[4] of invariants is the same as the number[4] of unknown functions in the curvature components (after all of the possible remaining tetrad freedom, which can act on the curvature components, is completely used up).

Since the backsolving method yields, in general, nonunique solutions, this could lead to significantly different space–times and/or Petrov types. A full investigation of this issue is planned for the future. However, our main concern in this article and a future paper (as was in Ref. 1) is centered on how much algebraically independent information that is in the Riemann tensor is present in its polynomial invariants and the backsolving technique introduced is achieving this.

Any Segre type falls into one of two classes: class A, in which the Ricci tensor does not possess a null eigenvector, and class B, in which the Ricci tensor possesses a null eigenvector. As we shall show in this article and a future paper, all space–times in class A are always completely backsolvable (CB), while space–times in class B are completely backsolvable except for special cases (excluding the trivial Segre type [(1,111)]). These exceptional cases will be designated as "not (generally) completely backsolvable" (NCB).[6] We will also show, in a future paper, that there is a geometric link between the NCB space–times in class B and the alignment of the eigenvectors of the Ricci tensor with the repeated principal null directions (PNDs) of the Weyl tensor. In this article, we will consider only those Segre types in class A.

Recall, the CZ set consists of the following invariants:[1]

$$
\begin{aligned}
R &:= g^{ab}g^{cd}R_{acdb},\\
w_1 &:= \tfrac{1}{6}\Psi_{ABCD}\Psi^{ABCD},\\
w_2 &:= \tfrac{1}{6}\Psi_{ABCD}\Psi^{CD}{}_{EF}\Psi^{EFAB},\\
r_1 &:= \tfrac{1}{3}\Phi_{AB\dot{A}\dot{B}}\Phi^{AB\dot{A}\dot{B}},\\
r_2 &:= \tfrac{1}{6}\Phi_{AB\dot{A}\dot{B}}E^{AB\dot{A}\dot{B}},\\
r_3 &:= \tfrac{1}{12}E_{AB\dot{A}\dot{B}}E^{AB\dot{A}\dot{B}},\\
m_1 &:= \Psi_{ABCD}\Phi^{CD}{}_{\dot{C}\dot{D}}\Phi^{AB\dot{C}\dot{D}},\\
m_2 &:= \Psi_{(AB}{}^{EF}\Psi_{CD)EF}\Phi^{AB}{}_{\dot{C}\dot{D}}\Phi^{CD\dot{C}\dot{D}},\\
m_3 &:= \Psi_{ABCD}\Phi^{AE\dot{A}\dot{B}}\Phi^{B}{}_{E\dot{A}\dot{C}}\Phi^{CF\dot{C}\dot{D}}\Phi^{D}{}_{F\dot{D}\dot{B}},\\
m_4 &:= \Psi^{AB}{}_{CD}\Phi^{CD}{}_{\dot{A}\dot{B}}\overline{\Psi}^{\dot{A}\dot{B}}{}_{\dot{C}\dot{D}}\Phi_{AB}{}^{\dot{C}\dot{D}},\\
m_5 &:= \Psi_{(AB}{}^{CD}\Psi_{EF)CD}\overline{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}\Phi^{AB\dot{C}\dot{D}}\Phi^{EF\dot{A}\dot{B}},\\
m_6 &:= \Psi^{AB}{}_{CD}\Psi^{CD}{}_{EF}\Phi^{EF}{}_{\dot{A}\dot{B}}\overline{\Psi}^{\dot{A}\dot{B}}{}_{\dot{C}\dot{D}}\overline{\Psi}^{\dot{C}\dot{D}}{}_{\dot{E}\dot{F}}\Phi_{AB}{}^{\dot{E}\dot{F}},
\end{aligned}
\tag{1}
$$

For future reference, we give, in Table I the relations between the various sets. Further, we give other tables (Tables II and III)[7–9] which summarize the syzygies for the different Petrov and Segre types of the Weyl and Ricci tensors, respectively.

II. RICCI CANONICAL FRAMES

In this section we will set up the canonical frames for the different Segre types using Hall's approach.[10] Our analysis is somewhat more detailed than Hall's in that we give more explicit descriptions of the canonical forms together with the remaining tetrad freedom for each case. Briefly, a local real null tetrad $\{l^a,n^a,x^a,y^a\}$, with l^a and n^a being null vectors and x^a and y^a being spacelike vectors, is introduced on the space–time manifold M. The only nonvanishing inner products are $l^a n_a=1$ and $x^a x_a=y^a y_a=-1$. In this case the completeness relation takes the form

$$g_{ab}=l_a n_b+n_a l_b-x_a x_b-y_a y_b. \tag{3}$$

We note that the Newman–Penrose (NP) complex null tetrad $\{l^a,n^a,m^a,\overline{m}^a\}$ is related to the above tetrad via the relation $m^a=(1/\sqrt{2})(x^a+iy^a)$.

The covariant Ricci tensor with components R_{ab} can be written as

$$\begin{aligned} R_{ab}=&2R^1 l_{(a}n_{b)}+R^2 l_a l_b+R^3 n_a n_b+2R^4 l_{(a}x_{b)}+2R^5 l_{(a}y_{b)}+2R^6 n_{(a}x_{b)}\\ &+2R^7 n_{(a}y_{b)}+2R^8 x_{(a}y_{b)}+R^9 x_a x_b+R^{10} y_a y_b. \end{aligned} \tag{4}$$

TABLE II. The Weyl syzygies.

{4}	[(3,1)], [(2,11)], [(1,111)]	$r_1=r_2=r_3=0$

The mixed Ricci tensor with components $R^a{}_b$ can be represented as a linear transformation $\mathbf{R}: T_p(M)\to T_p(M)$ with matrix $R^a{}_b$.

The classification of the Ricci tensor **R** depends on the following general results due to Churchill:[11]

(i) There always exists a two-dimensional subspace of $T_p(M)$ which is an invariant two-space of **R**.
(ii) If **V** is an invariant two-space of **R**, then so is the two-space orthogonal to **V**.
(iii) **R** has two distinct spacelike eigenvectors.
(iv) **R** has a null invariant two-space ⇔**R** has a null eigenvector.

It follows that the canonical forms of the Ricci tensor naturally split into two different classes (as previously stated): class A, the Ricci tensor has no null eigenvectors, and class B, the Ricci tensor has a null eigenvector. Below, we summarize the results of our investigation for class A.

For later use, we present the transformations of the null tetrad, Weyl and Ricci components, in the following compact form:

$$X'=\Pi X\overline{\Pi}^T,\quad \Psi'=\Xi\Psi\Xi^T,\quad \Phi'=\Xi\Phi\overline{\Xi}^T,$$

where

$$X=\begin{bmatrix}\mathbf{l} & \mathbf{m}\\ \overline{\mathbf{m}} & \mathbf{n}\end{bmatrix},\quad \Pi=\begin{bmatrix}A & B\\ C & D\end{bmatrix},\quad \Psi=\begin{bmatrix}\Psi_0 & \Psi_1 & \Psi_2\\ \Psi_1 & \Psi_2 & \Psi_3\\ \Psi_2 & \Psi_3 & \Psi_4\end{bmatrix},$$

$$\Phi=\begin{bmatrix}\Phi_{00} & \Phi_{01} & \Phi_{02}\\ \Phi_{10} & \Phi_{11} & \Phi_{12}\\ \Phi_{20} & \Phi_{21} & \Phi_{22}\end{bmatrix},\quad \Xi=\begin{bmatrix}A^2 & 2AB & B^2\\ AC & AD+BC & BD\\ C^2 & 2CD & D^2\end{bmatrix},$$

and $AD-BC=1$.

A. Class A: The Ricci tensor has no null eigenvectors

1. PP type I, Segre type [1,111]:

Canonical form of R_{ab}*:*

$$R_{ab}=2\rho_1 l_{(a}n_{b)}+\rho_2(l_al_b+n_an_b)-\rho_3x_ax_b-\rho_4y_ay_b,$$

with

$$\rho_2 \neq 0,\ \rho_2 \neq \rho_4,\ \rho_1 \pm \rho_2 \neq \rho_3,\ \rho_1 \pm \rho_2 \neq \rho_4.$$

Inner products:

$$R_{ab}l^b = \rho_1 l_a + \rho_2 n_a,\ R_{ab}n^b = \rho_2 l_a + \rho_1 n_a,\ R_{ab}x^b = \rho_3 x_a,\ R_{ab}y^b = \rho_4 y_a.$$

Eigenvectors: $l^a + n^a,\ l^a - n^a,\ x^a,\ y^a$.
Eigenvalues: $\rho_1 + \rho_2,\ \rho_1 - \rho_2,\ \rho_3,\ \rho_4$.
Canonical form of Ricci components Φ_{ab}*:*

$$\Phi_{00} = \Phi_{22} = -\tfrac{1}{2}\rho_2 \neq 0,$$

$$\Phi_{11} = \tfrac{1}{8}(\rho_3 + \rho_4 - 2\rho_1),$$

$$\Phi_{02} = \Phi_{20} = \tfrac{1}{4}(\rho_3 - \rho_4) \neq 0,$$

$$\Phi_{01} = \Phi_{12} = 0,$$

with

$$4\Phi_{11}^2 \neq (\Phi_{00} \pm \Phi_{02})^2.$$

Remaining tetrad freedom: None.

2. PP type I, Segre type [$Z\bar{Z}$,11]:

Canonical form of R_{ab}*:*

$$R_{ab} = 2\rho_1 l_{(a}n_{b)} + \rho_2(l_a l_b - n_a n_b) - \rho_3 x_a x_b - \rho_4 y_a y_b,$$

with

$$\rho_2 \neq 0,\ \rho_3 \neq \rho_4.$$

Inner Products:

$$R_{ab}l^b = \rho_1 l_a - \rho_2 n_a,\ R_{ab}n^b = \rho_2 l_a + \rho_1 n_a,\ R_{ab}x^b = \rho_3 x_a,\ R_{ab}y^b = \rho_4 y_a.$$

Eigenvectors: $l^a + in^a,\ l^a - in^a,\ x^a,\ y^a$.
Eigenvalues: $\rho_1 + i\rho_2,\ \rho_1 - i\rho_2,\ \rho_3,\ \rho_4$.

Canonical form of Ricci components Φ_{ab}*:*

$$\Phi_{00} = -\Phi_{22} = \tfrac{1}{2}\rho_2 \neq 0,$$

$$\Phi_{11} = \tfrac{1}{8}(\rho_3 + \rho_4 - 2\rho_1),$$

$$\Phi_{02} = \Phi_{20} = \tfrac{1}{4}(\rho_3 - \rho_4) \neq 0,$$

$$\Phi_{01} = \Phi_{12} = 0.$$

Remaining tetrad freedom: None.

3. PP type D, Segre type [1,1(11)]:

Canonical form of R_{ab}*:*

$$R_{ab} = 2\rho_1 l_{(a}n_{b)} + \rho_2(l_a l_b + n_a n_b) - \rho_3 x_a x_b - \rho_3 y_a y_b,$$

with

$$\rho_2 \neq 0,\ \rho_1 \pm \rho_2 \neq \rho_3 .$$

Inner products:

$$R_{ab}l^b = \rho_1 l_a + \rho_2 n_a ,\ R_{ab}n^b = \rho_2 l_a + \rho_1 n_a ,\ R_{ab}x^b = \rho_3 x_a ,\ R_{ab}y^b = \rho_3 y_a .$$

Eigenvectors: $l^a + n^a,\ l^a - n^a,\ x^a,\ y^a$.
Eigenvalues: $\rho_1 + \rho_2,\ \rho_1 - \rho_2,\ \rho_3,\ \rho_3$.

Canonical form of Ricci components Φ_{ab}*:*

$$\Phi_{00} = \Phi_{22} = -\tfrac{1}{2}\rho_2 \neq 0, \quad \Phi_{11} = \tfrac{1}{4}(\rho_3 - \rho_1), \quad \Phi_{01} = \Phi_{02} = \Phi_{12} = 0,$$

with

$$4\Phi_{11}^2 \neq \Phi_{00}^2 .$$

Remaining tetrad freedom: Spatial rotations: $D = \overline{A},\ A\overline{A} = 1,\ B = C = 0$.

4. PP type D, Segre type [$Z\overline{Z}$,(11)]

Canonical form of R_{ab}*:*

$$R_{ab} = 2\rho_1 l_{(a}n_{b)} + \rho_2(l_a l_b - n_a n_b) - \rho_3 x_a x_b - \rho_3 y_a y_b ,$$

with

$$\rho_2 \neq 0.$$

Inner Products:

$$R_{ab}l^b = \rho_1 l_a - \rho_2 n_a ,\ R_{ab}n^b = \rho_2 l_a + \rho_1 n_a ,\ R_{ab}x^b = \rho_3 x_a ,\ R_{ab}y^b = \rho_3 y_a .$$

Eigenvectors: $l^a + in^a,\ l^a - in^a,\ x^a,\ y^a$.
Eigenvalues: $\rho_1 + i\rho_2,\ \rho_1 - i\rho_2,\ \rho_3,\ \rho_3$.

Canonical form of Ricci components Φ_{ab}*:*

$$\Phi_{00} = -\Phi_{22} = \tfrac{1}{2}\rho_2 \neq 0, \quad \Phi_{11} = \tfrac{1}{4}(\rho_3 - \rho_1), \quad \Phi_{01} = \Phi_{02} = \Phi_{12} = 0.$$

Remaining tetrad freedom: Spatial rotations: $D = \overline{A},\ A\overline{A} = 1,\ B = C = 0$.

5. PP Type O, Segre Type [1,(111)]:

Canonical form of R_{ab}*:*

$$R_{ab} = 2\rho_1 l_{(a}n_{b)} + \rho_2(l_a l_b + n_a n_b) - (\rho_1 - \rho_2)(x_a x_b + y_a y_b),$$

with

$$\rho_2 \neq 0.$$

Inner products:

$$R_{ab}l^b = \rho_1 l_a + \rho_2 n_a ,\ R_{ab}n^b = \rho_2 l_a + \rho_1 n_a ,\ R_{ab}x^b = (\rho_1 - \rho_2)x_a ,$$

$$R_{ab}y^b = (\rho_1 - \rho_2)y_a .$$

Eigenvectors: $l^a+n^a,\ l^a-n^a,\ x^a,\ y^a$.
Eigenvalues: $\rho_1+\rho_2,\ \rho_1-\rho_2,\ \rho_1-\rho_2,\ \rho_1-\rho_2$.

Canonical form of Ricci components Φ_{ab}*:*

$$\Phi_{00}=2\Phi_{11}=\Phi_{22}=-\tfrac{1}{2}\rho_2\neq 0,$$

$$\Phi_{01}=\Phi_{02}=\Phi_{12}=0.$$

Remaining tetrad freedom: 3-d spatial rotations SO(3): $D=\overline{A},\ C=-\overline{B},\ A\overline{A}+B\overline{B}=1$.

At this point, we would like to compare our canonical forms with those as given by MacIntosh *et al.*[12] and Joly and MacCallum.[7] Specifically, apart from changes due to $\mathbf{l}\leftrightarrow\mathbf{n}$ interchange, our work differs from theirs in that Φ_{11} could be zero for Segre types [1,111], [$Z\overline{Z}$,11], [1,1(11)] and [$Z\overline{Z}$,(11)] (and also [2,11] and [(1,1)11]), whereas they report that Φ_{11} is necessarily nonzero for these types.

III. COMPLETE BACKSOLVING

In this section, we will prove that the CZ set is determined for class A by explicitly showing that complete backsolving is always possible for each Segre type, for certain selected subsets chosen from CZ. These subsets are all algebraically complete since they are all curvature complete and a simple count[4] shows that they are, in each case, the smallest possible sets. Most of the computations were done with the algebraic computing system Maple.

A. Segre type [1,111]

In this case, the algebraically complete set of invariants is $\{R,w_1,w_2,r_1,r_2,r_3,m_1,m_2,m_3\}$ and we will now show that complete backsolving is always possible, at least in principle. We begin with the backsolving for the Ricci components Φ_{ab}. In our canonical frame, the Ricci invariants are

$$r_1=\tfrac{2}{3}(\Phi_{00}^2+\Phi_{02}^2+2\Phi_{11}^2),$$

$$r_2=2\Phi_{11}(\Phi_{00}^2-\Phi_{02}^2),$$

$$r_3=\tfrac{1}{3}(\Phi_{00}^4-2\Phi_{00}^2\Phi_{02}^2+8\Phi_{00}^2\Phi_{11}^2+8\Phi_{02}^2\Phi_{11}^2+\Phi_{02}^4).$$

Since the Jacobian which is given by $\frac{64}{9}J$, where

$$J=\Phi_{00}\Phi_{02}(\Phi_{00}+\Phi_{02}+2\Phi_{11})(\Phi_{00}+\Phi_{02}-2\Phi_{11})(\Phi_{00}-\Phi_{02}+2\Phi_{11})(\Phi_{00}-\Phi_{02}-2\Phi_{11})$$

is always nonzero, it follows that the Ricci invariants $r_1,\ r_2,\ r_3$ are always backsolvable for Φ_{ab}.

To facilitate the backsolving of the Weyl components Ψ_a, we make the following substitutions:

$$\Psi_0=x+y,\ \ \Psi_1=u+v,\ \ \Psi_3=u-v,\ \ \Psi_4=x-y.$$

The Weyl and mixed invariants then take the form

$$w_1=\tfrac{1}{3}(x^2-y^2-4u^2+4v^2+3\Psi_2^2),$$

$$w_2=2\Psi_2u^2-2\Psi_2v^2-\Psi_2^3-2u^2x+4yuv-2v^2x+\Psi_2x^2-\Psi_2y^2,$$

$$m_1=2(\Phi_{00}^2-4\Phi_{11}^2+\Phi_{02}^2)\Psi_2+4\Phi_{00}\Phi_{02}x,$$

$$m_2 = -2\Psi_2^2\Phi_{02}^2 + 8\Psi_2^2\Phi_{11}^2 - 2\Psi_2^2\Phi_{00}^2 + \tfrac{16}{3}\Phi_{11}^2 v^2 - \tfrac{4}{3}\Phi_{02}^2 v^2 - \tfrac{4}{3}\Phi_{00}^2 v^2 - \tfrac{16}{3}\Phi_{11}^2 u^2 + \tfrac{4}{3}\Phi_{02}^2 u^2 + \tfrac{4}{3}\Phi_{00}^2 u^2 - 8\Phi_{00} v^2 \Phi_{02} - 8\Phi_{00} u^2 \Phi_{02} - \tfrac{8}{3}\Phi_{11}^2 x^2 + \tfrac{8}{3}\Phi_{11}^2 y^2 + \tfrac{2}{3}\Phi_{02}^2 x^2 - \tfrac{2}{3}\Phi_{02}^2 y^2 + \tfrac{2}{3}\Phi_{00}^2 x^2 - \tfrac{2}{3}\Phi_{00}^2 y^2 + 8\Psi_2 \Phi_{00}\Phi_{02} x,$$

$$m_3 = 2(4\Phi_{00}^2\Phi_{11}^2 + 2\Phi_{00}^2\Phi_{02}^2 + 4\Phi_{02}^2\Phi_{11}^2 - \Phi_{00}^4 - \Phi_{02}^4)\Psi_2 - 16\Phi_{00}\Phi_{02}\Phi_{11}^2 x.$$

We begin by noting that the system $\{m_1, m_3\}$ which contains only the Weyl variables x and Ψ_2 has Jacobian equal to $-8J$ which is nonzero. Hence, we may regard x and Ψ_2 as (locally) implicit functions of m_1 and m_3 and Φ_{ab} (which in turn are determined by the Ricci invariants). Next, we solve w_1 for u^2 and use this equation to eliminate u from m_2. We can always solve this resulting equation for v^2, since its coefficient is nonzero. Finally, after solving w_2 for $4yuv$ and squaring, we substitute the solutions for u^2 and v^2 into this expression to obtain a polynomial equation of degree 6 in y with the coefficients being polynomials in x, Ψ_2, Φ_{ab}, and invariants. This polynomial can always be solved for y, since the coefficient of y^6 is $J/(\Phi_{00}\Phi_{02}) \neq 0$.

B. Segre type [$Z\bar{Z}$,11]

For this Segre type, the complete set of invariants is the same as that for [1,111], and the backsolving follows virtually the same procedure, providing the following substitutions: $\Psi_0 = x + y$, $\Psi_1 = u + v$, $\Psi_3 = i(v - u)$, $\Psi_4 = y - x$ are used instead of the previous ones.

C. Segre type [1,1(11)]

For this Segre type, the Ricci canonical frame is determined up to a spatial rotation. At the appropriate stage, we will use this remaining tetrad freedom to simplify the Weyl components. We will show that in all subcases complete backsolving can be achieved.

We begin with the backsolving for the Ricci components Φ_{ab}. In our canonical frame, the independent Ricci invariants are

$$r_1 = \tfrac{2}{3}(\Phi_{00}^2 + 2\Phi_{11}^2),$$

$$r_2 = 2\Phi_{00}^2\Phi_{11}.$$

Since the Jacobian $J = \frac{8}{3}\Phi_{00}(\Phi_{00} - 2\Phi_{11})(\Phi_{00} + 2\Phi_{11}) \neq 0$, it follows that the Ricci invariants r_1, r_2 are always backsolvable for Φ_{ab}.

Case 1: $\Psi_0 \neq 0$: In this case, we may use the tetrad freedom to make Ψ_0 real. Further, we shall need to treat the cases where $\Psi_3 = 0$ separately.

Case 1A: $\Psi_3 \neq 0$: We now show that the complete set is $\{R, w_1, w_2, r_1, r_2, m_1, m_2, m_4\}$. We begin by expressing the invariants in this frame.

$$w_1 = \tfrac{1}{3}(\Psi_0\Psi_4 - 4\Psi_1\Psi_3 + 3\Psi_2^2),$$

$$w_2 = 2\Psi_1\Psi_2\Psi_3 - \Psi_2^3 - \Psi_0\Psi_3^2 - \Psi_1^2\Psi_4 + \Psi_0\Psi_2\Psi_4,$$

$$m_1 = 2\Psi_2(\Phi_{00}^2 - 4\Phi_{11}^2),$$

$$m_2 = \tfrac{2}{3}(\Phi_{00}^2\Psi_0\Psi_4 + 2\Phi_{00}^2\Psi_1\Psi_3 + 12\Phi_{11}^2\Psi_2^2 - 4\Phi_{11}^2\Psi_0\Psi_4 - 3\Phi_{00}^2\Psi_2^2 - 8\Phi_{11}^2\Psi_1\Psi_3),$$

$$m_4 = \Phi_{00}^2\Psi_4\bar{\Psi}_4 + 16\Phi_{11}^2\Psi_2\bar{\Psi}_2 + \Phi_{00}^2\Psi_0^2 + 8\Phi_{00}\Phi_{11}\Psi_3\bar{\Psi}_3 + 2\Phi_{00}^2\Psi_2\bar{\Psi}_2 + 8\Phi_{00}\Phi_{11}\Psi_1\bar{\Psi}_1.$$

m_1 can always be solved for Ψ_2 since $\Phi_{00}^2 - 4\Phi_{11}^2 \neq 0$. We can always solve w_1 and m_2 to get $\Psi_1 = C_1/\Psi_3$ and $\Psi_4 = C_4/\Psi_0$, where C_1, C_4 are given by Φ_{ab}, Ψ_2 and invariants. Substituting these expressions into w_2 we get the quadratic polynomial equation

$$\psi^2+(w_2-2C_1\Psi_2-C_4\Psi_2+\Psi_2^3)\psi+C_1^2C_4=0$$

where $\psi=\Psi_0\Psi_3^2$. This can always be solved for ψ in terms of Φ_{ab}, Ψ_2 and invariants. Substituting $\Psi_3=(\psi/\Psi_0)^{1/2}$ into m_4, we get a quartic polynomial equation in Ψ_0, which can always be solved for Ψ_0 since the coefficient of Ψ_0^4 is $\Phi_{00}^2(\psi\bar{\psi})^{1/2}\neq 0$.

Case 1B(i): $\Psi_3=0$ & $\Psi_4\neq 0$: In this case, the complete set is $\{R,w_1,w_2,r_1,r_2,m_1,m_4\}$. This is established as follows. The non-Ricci invariants, when expressed in this frame, take the form

$$w_1=\tfrac{1}{3}(\Psi_0\Psi_4+3\Psi_2^2),$$

$$w_2=\Psi_0\Psi_2\Psi_4-\Psi_2^3-\Psi_1^2\Psi_4,$$

$$m_1=2\Psi_2(\Phi_{00}^2-4\Phi_{11}^2),$$

$$m_4=\Phi_{00}^2\Psi_4\bar{\Psi}_4+16\Phi_{11}^2\Psi_2\bar{\Psi}_2+\Phi_{00}^2\Psi_0^2+2\Phi_{00}^2\Psi_2\bar{\Psi}_2+8\Phi_{00}\Phi_{11}\Psi_1\bar{\Psi}_1.$$

Again, m_1 can always be solved for Ψ_2 since $\Phi_{00}^2-4\Phi_{11}^2\neq 0$. We can always solve w_1 and w_2 to get

$$\Psi_1^2=\Psi_0(3\Psi_2w_1-4\Psi_2^3-w_2)/[3(w_1-\Psi_2^2)] \quad \text{and} \quad \Psi_4=3(w_1-\Psi_2^2)/\Psi_0\neq 0.$$

After solving the invariant m_4 for $\Psi_1\bar{\Psi}_1$ and squaring, we substitute the expressions for Ψ_1^2, $\bar{\Psi}_1$ and Ψ_4 to get a polynomial equation of degree 8 in Ψ_0 with coefficients being polynomials in Φ_{ab}, Ψ_2 and invariants. The leading term of this polynomial is $3\Phi_{00}^4(\Psi_2^2-w_1)\Psi_0^8$. Since $\Psi_4\neq 0$, the coefficient of Ψ_0^8 is nonzero and consequently the polynomial algebraically determines Ψ_0 for suitably restricted values of the invariants.

Case 1B(ii): $\Psi_3=\Psi_4=0$: In this case, the complete set is $\{R,w_1,r_1,r_2,m_4,m_5\}$. To prove this, we consider the non-Ricci invariants, which in this frame become

$$w_1=\Psi_2^2,$$

$$m_4=16\Phi_{11}^2\Psi_2\bar{\Psi}_2+\Phi_{00}^2\Psi_0^2+2\Phi_{00}^2\Psi_2\bar{\Psi}_2+8\Phi_{00}\Phi_{11}\Psi_1\bar{\Psi}_1,$$

$$m_5=2\Phi_{00}^2\Psi_0^2\Psi_2-2\Phi_{00}^2\Psi_2^2\bar{\Psi}_2-8\Phi_{00}\Phi_{11}\Psi_1\bar{\Psi}_1\Psi_2-2\Phi_{00}^2\Psi_0\Psi_1^2-16\Phi_{11}^2\Psi_2^2\bar{\Psi}_2.$$

w_1 can always be solved for Ψ_2. We eliminate Ψ_1 and $\bar{\Psi}_1$ from m_4 and m_5 to obtain a polynomial in Ψ_0 in the following manner. First, we eliminate the product $\Psi_1\bar{\Psi}_1$ from m_4 and m_5 and solve for Ψ_1^2. Then, we solve m_4 for $\Psi_1\bar{\Psi}_1$, square this result and substitute in the previous expression for Ψ_1^2. The resulting condition is a polynomial (bi-cubic) of degree 6 in Ψ_0.

$$\begin{aligned}\Psi_0^6\Phi_{00}^6+2\Phi_{00}^4(2\Psi_2\Phi_{00}^2\bar{\Psi}_2-m_4-56\Psi_2\Phi_{11}^2\bar{\Psi}_2)\Psi_0^4+\Phi_{00}^2(4\bar{\Psi}_2^2\Psi_2^2\Phi_{00}^4\\ -4\Phi_{00}^2\bar{\Psi}_2\Psi_2m_4+64\Phi_{00}^2\bar{\Psi}_2^2\Psi_2^2\Phi_{11}^2+256\Psi_2^2\Phi_{11}^4\bar{\Psi}_2^2+m_4^2+48\Phi_{11}^2\Psi_2\bar{m}_5\\ +64\Psi_2\Phi_{11}^2\bar{\Psi}_2m_4+48\Phi_{11}^2m_5\bar{\Psi}_2)\Psi_0^2-16\Phi_{11}^2(\Psi_2m_4+m_5)(m_4\bar{\Psi}_2+\bar{m}_5)=0.\end{aligned}$$

Since the last term in the polynomial condition is negative definite, it has a positive solution for Ψ_0^2. Thus Ψ_0 is (implicitly) determined in terms of the invariants and, therefore, we conclude that all of the Ricci and Weyl components are now determined (implicitly and nonuniquely) in terms of the invariants.

Case 2: $\Psi_0=0$ *and* $\Psi_1\neq 0$: In this case, we may use the tetrad freedom to make Ψ_1 real.

Case 2A: $\Phi_{11}\neq 0$ *or* $\Psi_4\neq 0$: In this case, the complete set is $\{R,w_1,w_2,r_1,r_2,m_1,m_4\}$. To show this, we begin by expressing the invariants in this frame:

$$w_1=\tfrac{1}{3}(3\Psi_2^2-4\Psi_1\Psi_3),$$

$$w_2=2\Psi_1\Psi_2\Psi_3-\Psi_2^3-\Psi_1^2\Psi_4,$$

$$m_1=2\Psi_2(\Phi_{00}^2-4\Phi_{11}^2),$$

$$m_4=\Phi_{00}^2\Psi_4\overline{\Psi}_4+16\Phi_{11}^2\Psi_2\overline{\Psi}_2+8\Phi_{00}\Phi_{11}\Psi_3\overline{\Psi}_3+2\Phi_{00}^2\Psi_2\overline{\Psi}_2+8\Phi_{00}\Phi_{11}\Psi_1^2.$$

m_1 can always be solved for Ψ_2 since $\Phi_{00}^2-4\Phi_{11}^2\neq 0$. Using the invariants w_1, w_2 and m_1 we obtain

$$\Psi_2=m_1/[2(\Phi_{00}^2-4\Phi_{11}^2)],\quad \Psi_3=A_3/\Psi_1,\quad \Psi_4=A_4/\Psi_1^2$$

where $A_3=3(\Psi_2^2-w_1)/4$ and $A_4=(\Psi_2^3-3\Psi_2w_1-2w_2)/2$.

Substituting these expressions into m_4 we get the bi-cubic polynomial equation

$$8\Phi_{00}\Phi_{11}\Psi_1^6-[m_4-2(\Phi_{00}^2-8\Phi_{11}^2)\Psi_2\overline{\Psi}_2]\Psi_1^4+8\Phi_{00}\Phi_{11}A_3\overline{A}_3\Psi_1^2+\Phi_{00}^2A_4\overline{A}_4=0.$$

For suitably restricted values of the invariants, this polynomial equation can be solved for Ψ_1.

Case 2B: $\Phi_{11}=\Psi_4=0$: The complete set is $\{R,w_1,w_2,r_1,m_6\}$. As before, we show this by first expressing the invariants in this frame:

$$w_1=\tfrac{1}{3}(3\Psi_2^2-4\Psi_1\Psi_3),$$

$$w_2=2\Psi_1\Psi_2\Psi_3-\Psi_2^3,$$

$$m_6=2\Phi_{00}^2(4\Psi_1^2\Psi_3\overline{\Psi}_3-2\Psi_1\Psi_3\overline{\Psi}_2^2+2\Psi_1^4-2\Psi_1\Psi_2^2\overline{\Psi}_3+\Psi_2^2\overline{\Psi}_2^2+2\Psi_3^2\overline{\Psi}_3^2).$$

Eliminating the product $\Psi_1\Psi_3$ between w_1 and w_2 yields the equation $\Psi_2^3-3w_1\Psi_2-2w_2=0$, which always determines Ψ_2 in terms of w_1 and w_2. Next, we solve w_1 for Ψ_3 to obtain $\Psi_3=3(\Psi_2^2-w_1)/(4\Psi_1)$. Substituting these results into the expression for m_6 yields the following polynomial condition which is quadratic in Ψ_1^4:

$$256\Psi_1^8\Phi_{00}^2-32(2m_6-9\overline{w}_1w_1\Phi_{00}^2-\Psi_2^2\Phi_{00}^2\overline{\Psi}_2^2+3\overline{w}_1\Psi_2^2\Phi_{00}^2+3\overline{\Psi}_2^2w_1\Phi_{00}^2)\Psi_1^4$$
$$+81\Phi_{00}^2(w_1-\Psi_2^2)^2(\overline{w}_1-\overline{\Psi}_2^2)^2=0.$$

For suitably restricted values of the invariants, this polynomial equation can be solved for Ψ_1.

Case 3: $\Psi_0=\Psi_1=0$, *and* $\Psi_3\neq 0$: In this case, we may use the tetrad freedom to make Ψ_3 real.

Case 3A: $\Phi_{11}\neq 0$ *or* $\Psi_4\neq 0$: We will now show that the complete set is $\{R,w_1,r_1,r_2,m_4,m_5\}$. We begin by expressing the invariants in this frame:

$$w_1=\Psi_2^2,$$

$$m_4=16\Phi_{11}^2\Psi_2\overline{\Psi}_2+\Phi_{00}^2\Psi_4\overline{\Psi}_4+2\Phi_{00}^2\Psi_2\overline{\Psi}_2+8\Phi_{00}\Phi_{11}\Psi_3^2,$$

$$m_5=2\Phi_{00}^2\Psi_4\overline{\Psi}_4\Psi_2-2\Phi_{00}^2\Psi_2^2\overline{\Psi}_2-8\Phi_{00}\Phi_{11}\Psi_2\Psi_3^2-2\Phi_{00}^2\overline{\Psi}_4\Psi_3^2-16\Phi_{11}^2\Psi_2^2\overline{\Psi}_2.$$

w_1 determines Ψ_2. Combining m_4 and m_5 we obtain the following rational expression for $\overline{\Psi}_4$:

$$\overline{\Psi}_4=(2\Psi_2 m_4-24\Psi_3^2\Psi_2\Phi_{00}\Phi_{11}-m_5-6\Psi_2^2\overline{\Psi}_2\Phi_{00}^2-48\Psi_2^2\overline{\Psi}_2\Phi_{11}^2)/(2\Phi_{00}^2\Psi_3^2).$$

Substituting this equation and its complex conjugate into the expression for m_4 we obtain the bi-cubic

$$\begin{aligned}&32\Psi_3^6\Phi_{11}\Phi_{00}^3+4\Phi_{00}^2(2\Psi_2\Phi_{00}^2\overline{\Psi}_2-m_4+160\Psi_2\Phi_{11}^2\overline{\Psi}_2)\Psi_3^4+24\Phi_{00}\Phi_{11}(12\Psi_2^2\Phi_{00}^2\overline{\Psi}_2^2\\&+96\Psi_2^2\Phi_{11}^2\overline{\Psi}_2^2-4\overline{\Psi}_2\Psi_2 m_4+\overline{m}_5\Psi_2+\overline{\Psi}_2 m_5)\Psi_3^2+(48\overline{\Psi}_2^2\Psi_2\Phi_{11}^2-2\overline{\Psi}_2 m_4\\&+6\overline{\Psi}_2^2\Psi_2\Phi_{00}^2+\overline{m}_5)(6\Psi_2^2\overline{\Psi}_2\Phi_{00}^2-2\Psi_2 m_4+m_5+48\Psi_2^2\overline{\Psi}_2\Phi_{11}^2)=0,\end{aligned}$$

which determines Ψ_3.

Case 3B: $\Phi_{11}=\Psi_4=0$: The complete set is $\{R,w_1,r_1,m_6\}$ since the invariants in this frame are

$$w_1=\Psi_2^2,$$

$$m_6=2\Phi_{00}^2(\Psi_2^2\overline{\Psi}_2^2+2\Psi_3^4),$$

which always determine Ψ_2 and Ψ_3.

Case 4: $\Psi_0=\Psi_1=\Psi_3=0$: In this case, if $\Psi_4\neq 0$, we may use the tetrad freedom to make Ψ_4 real. The invariants in this frame are

$$w_1=\Psi_2^2,$$

$$m_4=16\Phi_{11}^2\Psi_2\overline{\Psi}_2+\Phi_{00}^2\Psi_4^2+2\Phi_{00}^2\Psi_2\overline{\Psi}_2,$$

which always determine Ψ_2 and Ψ_4. Hence the complete set is $\{R,w_1,r_1,r_2,m_4\}$. Note that if $\Psi_4=0$, then w_1 determines Ψ_2 (and m_4 is dependent).

D. Segre type [$z\bar{z}$,(11)]

The backsolving analysis for this Segre type is virtually identical to that for Segre type [1,1(11)] except for minor sign differences.

E. Segre type [1,(111)]

For this Segre type, it is easier to use the Weyl canonical frame. The Ricci components for this Segre type, in general, are[3] $\Phi_{00}=\pm 2\alpha^2$, $\Phi_{01}=\pm 2\alpha\beta$, $\Phi_{02}=\pm 2\beta^2$, $\Phi_{11}=\pm(\alpha\gamma+\beta\overline{\beta})$, $\Phi_{12}=\pm 2\beta\gamma$, and $\Phi_{22}=\pm 2\gamma^2$ (with same sign all through) where α and γ are real, β is complex and $0\leqslant\beta\overline{\beta}<\alpha\gamma$. The only independent Ricci invariant is $r_1=4(\alpha\gamma-\beta\overline{\beta})^2$, therefore, $\gamma=(2\beta\overline{\beta}+\sqrt{r_1})/(2\alpha)$. Note that, in this case, α cannot equal zero.

1. Segre type [1,(111)], Petrov type I:

For this Petrov type $w_2^2\neq w_1^3$. In our Weyl canonical frame, the only nonzero Weyl components are Ψ_2 and $\Psi_0=\Psi_4$ where $\Psi_0^2\neq 9\Psi_2^2$. The Weyl invariants in this frame are $w_1=\frac{1}{3}(\Psi_0^2+3\Psi_2^2)$ and $w_2=\Psi_2(\Psi_0^2-\Psi_2^2)$. The Jacobian of this system of equations is $\frac{2}{3}\Psi_0(\Psi_0^2-9\Psi_2^2)\neq 0$ and, hence, it is backsolvable for Ψ_0 and Ψ_2.

We will now show that the complete set is $\{R,w_1,w_2,r_1,m_4,m_5\}$. The mixed invariants in this frame are

$$\begin{aligned}m_4=4(&\Psi_0\overline{\beta}^4\overline{\Psi}_0+6\Psi_0\alpha^2\beta^2\overline{\Psi}_2+6\Psi_2\alpha^2\overline{\beta}^2\overline{\Psi}_0+\Psi_0\beta^4\overline{\Psi}_0+6\Psi_2\overline{\Psi}_2\alpha^2\gamma^2+\Psi_0\overline{\Psi}_0\gamma^4\\&+6\Psi_2\beta^2\overline{\Psi}_2\overline{\beta}^2+6\Psi_2\beta^2\overline{\Psi}_0\gamma^2+24\Psi_2\alpha\beta\overline{\Psi}_2\overline{\beta}\gamma+6\Psi_0\overline{\beta}^2\overline{\Psi}_2\gamma^2+\Psi_0\alpha^4\overline{\Psi}_0),\end{aligned}$$

$$m_5 = 8(4\overline{\Psi}_2\alpha\gamma\beta\overline{\beta} + \overline{\Psi}_2\overline{\beta}^2\beta^2 + \overline{\Psi}_2\alpha^2\gamma^2 + \overline{\Psi}_0\beta^2\gamma^2 + \overline{\Psi}_0\alpha^2\overline{\beta}^2)\Psi_0^2 + 8\Psi_2(6\alpha^2\beta^2\overline{\Psi}_2 + \overline{\Psi}_0\gamma^4 + \overline{\Psi}_0\beta^4 + \overline{\Psi}_0\overline{\beta}^4 + 6\overline{\beta}^2\overline{\Psi}_2\gamma^2 + \overline{\Psi}_0\alpha^4)\Psi_0 - 24\Psi_2^2(4\overline{\Psi}_2\alpha\gamma\beta\overline{\beta} + \overline{\Psi}_2\overline{\beta}^2\beta^2 + \overline{\Psi}_2\alpha^2\gamma^2 + \overline{\Psi}_0\beta^2\gamma^2 + \overline{\Psi}_0\alpha^2\overline{\beta}^2).$$

After eliminating γ using the Ricci invariant r_1, and some simple recombining, these equations reduce to

$$16(\overline{q}^4\Psi_0 + \Psi_0 + 6\overline{q}^2\Psi_2)(6q^2\overline{\Psi}_2 + q^4\overline{\Psi}_0 + \overline{\Psi}_0)\alpha^8 + 32\overline{q}\sqrt{\overline{r_1}}q(3\Psi_2 + \overline{q}^2\Psi_0)(\overline{\Psi}_0q^2 + 3\overline{\Psi}_2)\alpha^6 + (24r_1\overline{q}^2q^2\overline{\Psi}_0\Psi_0 + 24r_1\Psi_0\overline{q}^2\overline{\Psi}_2 - 4u_4 + 24r_1\Psi_2q^2\overline{\Psi}_0)\alpha^4 + 8\Psi_0\overline{\Psi}_0r_1^{3/2}q\alpha^2\overline{q} + \Psi_0\overline{\Psi}_0r_1^2 = 0, \tag{5}$$

$$8\overline{q}^2(6q^2\overline{\Psi}_2 + \overline{\Psi}_0q^4 + \overline{\Psi}_0)\alpha^4 + 8\overline{q}\sqrt{\overline{r_1}}q(\overline{\Psi}_0q^2 + 3\overline{\Psi}_2)\alpha^2 + 2r_1\overline{\Psi}_0q^2 + u_5 = 0, \tag{6}$$

where the nonzero term $(3\Psi_2 - \Psi_0)(3\Psi_2 + \Psi_0)$ has been cancelled from Eq. (6) and where $q = \beta/\alpha$ and u_4 and u_5 are defined by

$$u_4 = m_4 - 6r_1\overline{\Psi}_2\Psi_2,$$

$$m_5 = u_5(3\Psi_2 - \Psi_0)(3\Psi_2 + \Psi_0) + 2\Psi_2m_4 - 18r_1\overline{\Psi}_2\Psi_2^2 + 2r_1\overline{\Psi}_2\Psi_0^2.$$

Solving Eq. (6) for q^4 and substituting it into Eq. (5) yields

$$16\overline{q}\sqrt{\overline{r_1}}\Psi_0q(\overline{q}-1)(\overline{q}+1)(\overline{q}^2+1)(\overline{\Psi}_0q^2 + 3\overline{\Psi}_2)\alpha^6 + (24\overline{\Psi}_2\overline{q}^4\Psi_0r_1 + 20\overline{q}^4\Psi_0r_1\overline{\Psi}_0q^2 - 12\Psi_2\overline{q}^2u_5 - 4\Psi_0r_1\overline{\Psi}_0q^2 - 2\overline{q}^4\Psi_0u_5 - 4u_4\overline{q}^2 - 2\Psi_0u_5)\alpha^4 - 8\Psi_0\overline{\Psi}_0r_1^{3/2}q\alpha^2\overline{q}^3 + \Psi_0\overline{\Psi}_0r_1^2\overline{q}^2 = 0. \tag{7}$$

Finally, making one more variables change $\{f = q^2, h = q\overline{q}\alpha^2\}$ Eqs. (6) and (7) become

$$(48f\overline{\Psi}_2 + 8\overline{\Psi}_0f^2 + 8\overline{\Psi}_0)h^2 + 8\sqrt{r_1}f(\overline{\Psi}_0f + 3\overline{\Psi}_2)h + f(2\overline{\Psi}_0r_1f + u_5) = 0 \tag{8}$$

and

$$16\sqrt{r_1}\Psi_0(\overline{f}-1)(\overline{f}+1)(\overline{\Psi}_0f + 3\overline{\Psi}_2)h^3 + (-4u_4\overline{f} - 2\Psi_0u_5 + 24r_1\Psi_0\overline{f}^2\overline{\Psi}_2 + 20\Psi_0r_1\overline{\Psi}_0f\overline{f}^2 - 12\Psi_2\overline{f}u_5 - 4\Psi_0r_1\overline{\Psi}_0f - 2\Psi_0u_5\overline{f}^2)h^2 + 8\Psi_0\overline{\Psi}_0r_1^{3/2}h\overline{f}^2f + \Psi_0\overline{\Psi}_0r_1^2\overline{f}^2f = 0. \tag{9}$$

Next we compute the resultant of Eqs. (8) and (9) with respect to f to obtain the consistency condition

$$-1024r_1\Psi_0^2(\overline{f}-1)^2(\overline{f}+1)^2(3\overline{\Psi}_2 - \overline{\Psi}_0)(3\overline{\Psi}_2 + \overline{\Psi}_0)h^6 - 512\Psi_0^2r_1^{3/2}(\overline{f}-1)(\overline{f}+1)(5\overline{f}^2-1) \times (3\overline{\Psi}_2 - \overline{\Psi}_0)(3\overline{\Psi}_2 + \overline{\Psi}_0)h^5 + (384r_1\Psi_0\overline{f}^3\overline{\Psi}_2u_4 + 64u_4{}^2\overline{f}^2 + 16128\overline{\Psi}_2^2\Psi_0^2r_1{}^2\overline{f}^2 + 32\Psi_0^2u_5{}^2\overline{f}^2 + 16\Psi_0^2u_5{}^2 + 384\overline{\Psi}_2\Psi_0r_1u_4\overline{f} - 192\overline{\Psi}_2\Psi_0^2r_1u_5 + 384\Psi_2\overline{f}^2u_5u_4 + 64\overline{\Psi}_0^2\Psi_0^2r_1{}^2 + 64\Psi_0u_5\overline{f}^3u_4 + 16\Psi_0^2u_5{}^2\overline{f}^4 + 192\Psi_2\overline{f}^3u_5{}^2\Psi_0 + 192\Psi_2\overline{f}u_5{}^2\Psi_0 + 1152r_1\Psi_0\overline{f}^3\overline{\Psi}_2\Psi_2u_5 - 23040r_1{}^2\Psi_0^2\overline{f}^4\overline{\Psi}_2^2 + 1152r_1\Psi_0^2\overline{f}^2\overline{\Psi}_2u_5 - 192r_1\Psi_0^2\overline{f}^4\overline{\Psi}_2u_5 + 1152\overline{\Psi}_2\Psi_0r_1\Psi_2\overline{f}u_5$$

$$+576\Psi_2^2\overline{f}^2u_5{}^2+2624\overline{\Psi}_0^2\Psi_0^2r_1{}^2\overline{f}^4-1664\overline{\Psi}_0^2\Psi_0^2r_1{}^2\overline{f}^2+64u_4\overline{f}\Psi_0u_5)h^4$$

$$-32\overline{f}\sqrt{r_1}(-18r_1\Psi_2u_5\Psi_0\overline{\Psi}2-6r_1u_4\Psi_0\overline{\Psi}_2-u_4\Psi_0u_5-44r_1{}^2\overline{f}^3\overline{\Psi}_0^2\Psi_0^2-\overline{f}^3\Psi_0^2u_5{}^2$$

$$-6\overline{f}u_5{}^2\Psi_2-2\overline{f}u_5u_4-u_5{}^2\Psi_0)=0. \tag{10}$$

Finally, we take the resultant with respect to $\overline{f}$ of Eq. (10) with the complex conjugate of Eq. (8) to obtain, after some nonzero common factors have been cancelled,

$$4\,294\,967\,296r_1^2(\Psi_0-3\Psi_2)^2(\Psi_0+3\Psi_2)^2(3\overline{\Psi}_2-\overline{\Psi}_0)^2(3\overline{\Psi}_2+\overline{\Psi}_0)^2h^{16}$$

$$+193\,273\,528\,320r_1{}^{5/2}(\Psi_0^2\overline{\Psi}_2^2-9\Psi_2^2\overline{\Psi}_2^2+\Psi_2^2\overline{\Psi}_0^2)(-2\Psi_0^2\overline{\Psi}_0^2+9\Psi_0^2\overline{\Psi}_2^2$$

$$-81\Psi_2^2\overline{\Psi}_2^2+9\Psi_2^2\overline{\Psi}_0^2)h^{15}-134\,217\,728r_1(\Psi_0-3\Psi_2)(\Psi_0+3\Psi_2)(3\overline{\Psi}_2-\overline{\Psi}_0)(3\overline{\Psi}_2+\overline{\Psi}_0)$$

$$\times(-3276\overline{\Psi}_2^2r_1^2\Psi4^2+29\,160\overline{\Psi}_2^2r_1^2\Psi_2^2+216\overline{\Psi}_2^2\Psi_2\overline{u}_5r_1-24\overline{\Psi}_2\Psi_0^2r_1u_5+216\overline{\Psi}_2r_1u_5\Psi_2^2$$

$$+36\overline{\Psi}_2r_1\Psi_2u_4+364\overline{\Psi}_0^2\Psi_0^2r_1^2-3276r_1^2\Psi_2^2\overline{\Psi}_0^2-24\Psi_2\overline{\Psi}_0^2\overline{u}_5r_1-u_4^2)h^{14}+\cdots=0.$$

This is a polynomial of degree 16 in h. The leading term is

$$4\,294\,967\,296r_1^2(\Psi_0-3\Psi_2)^2(\Psi_0+3\Psi_2)^2(3\overline{\Psi}_2-\overline{\Psi}_0)^2(3\overline{\Psi}_2+\overline{\Psi}_0)^2h^{16},$$

which is always nonzero. Hence, with suitable restrictions on the values of the invariants, this polynomial can, in principle, determine h. Once h is determined, the remaining variables α,β and γ are determined and complete backsolving has been achieved.

2. Segre type [1,(111)], Petrov type II:

For this Petrov type $w_2^2=w_1^3$ and $\Psi_2^2=w_1$. In our Weyl canonical frame, the only nonzero Weyl components are Ψ_2 and $\Psi_4=1$. In this case, the complete set is $\{R,w_1,r_1,m_4,m_5\}$. To show this we consider the mixed invariants, which in this frame become

$$m_4=2(2\alpha^4+12\Psi_2\alpha^2\overline{\beta}^2+12\overline{\Psi}_2\alpha^2\beta^2+72\beta^2\overline{\beta}^2\Psi_2\overline{\Psi}_2+36\sqrt{r_1}\beta\overline{\beta}\Psi_2\overline{\Psi}_2+3r_1\Psi_2\overline{\Psi}_2),$$

$$m_5=2(4\Psi_2\alpha^4-12\Psi_2^2\alpha^2\overline{\beta}^2+24\Psi_2\overline{\Psi}_2\alpha^2\beta^2-72\beta^2\overline{\beta}^2\Psi_2^2\overline{\Psi}_2-36\sqrt{r_1}\beta\overline{\beta}\Psi_2^2\overline{\Psi}_2-3r_1\Psi_2^2\overline{\Psi}_2).$$

Eliminating $\overline{\beta}$ from m_4 and m_5 yields

$$\alpha^2+6\Psi_2\beta^2=0$$

or

$$12\Psi_2\alpha^4+\Psi_2\overline{\Psi}_2\alpha^2\beta^2-\Psi_2 m_4-m_5=0$$

or both.

Eliminating $\overline{\beta}$ from m_4 and $\overline{m}_5$ and substituting the resulting expression for β into these two equations yields, respectively,

$$144r_1\Psi_2\overline{\Psi}_2\alpha^4=m_4^2+12r_1\Psi_2\overline{m}_5+36r_1\Psi_2^2\overline{\Psi}_2^2$$

or

$$186\,624r_1\Psi_2\overline{\Psi}_2\alpha^{12}+\cdots=0,$$

which is a polynomial of degree 12 in α. Separately, each of these polynomials can determine α and hence β; then r_1 determines γ.

3. Segre type [1,(111)], Petrov type III:

For this Petrov type $w_1=w_2=0$. In our Weyl canonical frame, the only nonzero Weyl component is $\Psi_3=1$.

The complete set is $\{R,r_1,m_4,m_5\}$. The mixed invariants in this frame take the form

$$m_4=64\alpha^2\beta\overline{\beta}+8\sqrt{r_1}\alpha^2,$$

$$m_5=32\alpha^3\beta.$$

Eliminating β and $\overline{\beta}$ from m_4, m_5 and $\overline{m}_5$ we get

$$128\sqrt{r_1}\alpha^6-16m_4\alpha^4+m_5\overline{m}_5=0,$$

which can be solved for α. Then β and γ are determined by m_5 and r_1, respectively, and complete backsolving has been achieved.

4. Segre type [1,(111)], Petrov type D:

For this Petrov type $w_1=\Psi_2^2$ which determines Ψ_2. In our Weyl canonical frame, the only nonzero Weyl component is Ψ_2. We will use the remaining tetrad freedom to simplify the Ricci components.

Case 1: $\beta\neq0$: In this case, we can make $\beta=1/\alpha$ (real). We will show that the complete set is $\{R,w_1,r_1,m_4\}$. Note that $m_5^2=w_1m_4^2$. Substituting $\gamma=(2\beta\overline{\beta}+\sqrt{r_1})/(2\alpha)$ and $\beta=1/\alpha$ into the mixed invariant m_4 we get $m_4=6\Psi_2\overline{\Psi}_2(\alpha^4r_1+12\alpha^2\sqrt{r_1}+24)/\alpha^4$. This determines α and hence, β and then γ.

Case 2: $\gamma\neq0$ *and* $\beta=0$: In this case, we can make $\alpha=1$, and hence, $\gamma=\frac{1}{2}\sqrt{r_1}$. The complete set is $\{R,w_1,r_1\}$. Note that $m_5^2=w_1m_4^2=36w_1^2\overline{w}_1r_1^2$.

5. Segre type [1,(111)], Petrov type N:

For this Petrov type $w_1=w_2=0$. In our Weyl canonical frame, the only nonzero Weyl component is $\Psi_4=1$. We can use the remaining tetrad freedom to make $\beta=0$ (since $\alpha\neq0$).

In this case, $m_4=4\alpha^4$, $m_5=0$ and $\gamma=\sqrt{r_1}/(2\alpha)$. Hence, the complete set is $\{R,r_1,m_4\}$ and complete backsolving is always possible.

TABLE IV. The complete sets for the different Segre types with no null eigenvector.

PP type	Segre type	Conditions (in Ricci canonical frame)	Complete sets (and subsets thereof)
I	[1,111] [$Z\bar{Z}$,11]		$\{R,w_1,w_2,r_1,r_2,r_3,m_1,m_2,m_3\}$
D	[1,1(11)] [$Z\bar{Z}$,(11)]	$\Psi_0=\Psi_4=\Phi_{11}=0$ $\{\Psi_0=\Psi_1=0$ and $(\Psi_4\neq 0$ or $\Phi_{11}\neq 0)\}$ or $\{\Psi_3=\Psi_4=0$ and $(\Psi_0\neq 0$ or $\Phi_{11}\neq 0)\}$ Otherwise	$\{R,w_1,w_2,r_1,m_6\}$ $\{R,w_1,r_1,r_2,m_4,m_5\}$ $\{R,w_1,w_2,r_1,r_2,m_1,m_2,m_4\}$
O	[1,(111)]		$\{R,w_1,w_2,r_1,m_4,m_5\}$

6. Segre type [1,(111)], Petrov type O

For this Petrov type $w_1=w_2=0$ and $\Psi_i=0$. We can use the tetrad freedom to make $\alpha=\gamma$ and $\beta=0$, i.e., the Ricci canonical frame as well. In this case, $m_4=m_5=0$ and $\alpha^2=\frac{1}{4}r_1$. Hence, the complete set is $\{R,r_1\}$.

IV. SUMMARY OF RESULTS

In Table IV, we give the complete sets of invariants for the different Segre types (with ''essential'' special cases) whose Ricci tensors do not have a null eigenvector. The ''essential'' special cases in this table, although expressed in the Ricci canonical frame, are linked to invariant geometric properties. If $\Psi_0=\Psi_4=0$, then it follows that the two PNDs of the Weyl tensor lie in the two-plane spanned (real or complex) by the two eigenvectors, which lie in the timelike blade $\{l^a,n^a\}$, of the Ricci tensor. If $\Psi_0=\Psi_1=0$, then the Weyl tensor is algebraically special and the repeated PND lies in the two-plane spanned (real or complex) by the two eigenvectors, which lie in the timelike blade $\{l^a,n^a\}$, of the Ricci tensor. Similarly for $\Psi_3=\Psi_4=0$. Finally, if $\Phi_{11}=0$, then the sum of the eigenvalues of the eigenvectors in the timelike blade $\{l^a,n^a\}$ equals twice the eigenvalue of either eigenvector in the spacelike blade $\{x^a,y^a\}$.

V. CONCLUSION

In this second article on the problem of algebraic completeness for the invariants of the Riemann tensor, we have exhaustively analyzed all canonically different space–times in which the Ricci tensor does not have a null eigenvector. In each case, we have given algebraically complete sets. It follows from this work, at least for these cases (class A), that the set CZ is determining, as previously claimed.[1] In a sequel paper, we will present a complete analysis of all Segre types which correspond to the cases when the Ricci tensor has a null eigenvector (class B). Interestingly, we will then show that complete backsolving is, in general,[13] not always possible when there is an alignment between an eigenvector of the Ricci tensor with the repeated principal null directions of the Weyl tensor (excluding [(1,111)]). As previously mentioned, we suspect that some space–times within such classes will, in general, prove to be more difficult to distinguish as inequivalent. As a final point, there still remains to fully clarify the geometric meaning of the invariants, principally the mixed ones. This will be the main focus of future work in this area.

(Received 17 January 2001; accepted for publication 4 October 2001)

A nonsingular static and spherically symmetric space–time endowed with nonminimally coupled scalar field described by the action $S=\int d^4x\,(\sqrt{-g}/2)(R-g^{\alpha\beta}\phi_{,\alpha}\phi_{,\beta}-\xi R\,\phi^2)$ is presented for the case in which the coupling parameter $\xi>1/6$. This solitonlike space–time is obtained using the technique of conformal transformation that associates solutions produced by ordinary scalar fields in general relativity with those with nonminimally coupled scalar fields. The dynamical stability of the solution is examined through the Galerkin method. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421060]

I. INTRODUCTION

Nonminimally coupled scalar fields are characterized by the following action integral,

$$S=\int d^4x\,\frac{\sqrt{-g}}{2}(R-g^{\alpha\beta}\,\phi_{,\alpha}\,\phi_{,\beta}-\xi R\,\phi^2), \tag{1.1}$$

where we are adopting $8\pi G=c=1$ and ξ is the coupling constant between the scalar field and the gravitational field. This constant is a free parameter, since particle theory and quantum field calculations are not able to provide a definitive value. Nonminimally coupled scalar fields have been taken into consideration in the inflationary cosmological scenario,[1] with black holes and the No-Hair theorem,[2] and recently connected with gravitational collapse.[3] Some authors in the realm of inflationary scenario have investigating possible constraints on ξ based in the recent observational results from the cosmic microwave background.[4] There are two exceptional cases given by $\xi=0$ and that corresponds to minimal coupling and $\xi=\frac{1}{6}$ for the conformal coupling.

We report here an interesting result concerning the existence of a soliton solution with nonminimally coupled scalar field. In classical field theories a soliton configuration is characterized by a finite distribution of matter confined to a finite region of space for all time, without singularity, and, in general is associated to the existence of conserved Noether currents in the theories. However, there are soliton solutions without an explicit conserved Noether current.[5] The interest on such solitonic configurations relies on the problem of dark matter in cosmology, because the visible and baryonic matter can account for only a small fraction of the total mass of the Universe. Then, a possible solution of this problem is to consider that the dark matter is nonbaryonic in the form of soliton configuration such as scalar soliton stars, oscillating soliton stars, boson stars, Q-balls[6] and nontopological solitons that can arise in a second-order phase transition in the early universe.[7]

The plan of this work is as follows. In Sec. II we present the solution obtained by the technique of conformal transformation together with the discussion of its basic properties. Section

III deals with the problem of stability of the soliton under small radial perturbations, in which the we have used the Galerkin method. Finally, Sec. IV is devoted to our conclusions.

II. THE CONFORMAL TRANSFORMATION AND THE SOLITONLIKE SOLUTION

The starting point is to consider static and spherically symmetric space–times endowed with a nonminimally coupled scalar field. For the sake of simplicity, we make use of the conformal transformation technique that allows us to transform the action (1.1) in the Einstein frame. This is done if the metric on the Einstein frame, $\tilde{g}_{\mu\nu}$, is related to the metric of the physical frame $g_{\mu\nu}$ by

$$\tilde{g}_{\mu\nu}=\Omega^2 g_{\mu\nu}, \tag{2.1}$$

where $\Omega^2=1-\xi\phi^2$. Also, we introduce the scalar field Φ such that

$$\Phi=\int \frac{\sqrt{1-\xi(1-6\xi)\phi^2}}{1-\xi\phi^2}d\phi. \tag{2.2}$$

Introducing (2.1) and (2.2) into the action (1.1), we obtain

$$S=\int d^4x\frac{\sqrt{-\tilde{g}}}{2}(\tilde{R}-\tilde{g}^{\alpha\beta}\Phi_{,\alpha}\Phi_{,\beta}), \tag{2.3}$$

where Φ is the minimally coupled scalar field in the Einstein frame. Therefore, once a given solution is known in the Einstein frame, it is possible to determine the solution in the physical frame from relations (2.1) and (2.2). Also, it is worthwhile mentioning that the conformal transformation does not modify the symmetries present in the space–time. There is a vast literature about applications of conformal transformations that is not restricted to nonminimally coupled scalar fields, but it can be also used for general scalar-tensor theories and for nonlinear theories of gravity.[8]

To generate static and spherically symmetric space–times with nonminimally coupled scalar fields, we consider the most general asymptotically flat solution for static and spherically symmetric space–time found by Janis *et al.*[9] and also by Wyman:[10]

$$d\tilde{s}^2=-w^{2\alpha}dt^2+w^{-2\alpha}dr^2+r^2w^{2(1-\alpha)}(d\vartheta^2+\sin^2\vartheta\,d\varphi^2), \tag{2.4}$$

$$\Phi=\pm\sqrt{2(1-\alpha^2)}\ln w, \tag{2.5}$$

where $w=\sqrt{1-2M/r}$, M is a positive quantity, and the parameter α is restricted to $0\leqslant\alpha<1$, since the mass measured by an observer at infinity (the Bondi mass), αM, must be positive. The case $\alpha=1$ corresponds to the Schwarzshild space–time. The above solution has a naked singularity at $r=2M$ if $2M<r<\infty$, or at $r=0$ if $-\infty<r<0$, which is in accordance with the No-Hair theorem concerning the absence of a black hole with scalar charge. Bekenstein[11] was the first to present the method of conformal transformation applied to the case $\xi=\frac{1}{6}$, and generate all classes of static and spherically symmetric solutions for conformally coupled scalar fields. The main result was a solution representing a black hole with a nontrivial scalar field, which in principle threatened the No-Hair theorem. However, later it was shown[12] that the Bekenstein solution is actually unstable under small radial perturbations. In order to complete the analysis connected with this issue, Bekenstein and Saa[2] have proved that there is no black hole configurations with general nonminimally coupled scalar fields. Then, the question is: why would we be interested in searching for any new solution for static and spherically symmetric space–times with nonminimally scalar fields, if, except for the Bekenstein black hole, all remaining solutions have naked singularities? If this information is true, then our analysis would not make sense, but we are going to show that there exist a class of solitonlike configurations generated by nonminimally coupled scalar fields.

Let us consider the case $\xi>\frac{1}{6}$. Integrating Eq. (2.2), the resulting relation between Φ and ϕ is

$$\Phi = -\sqrt{\frac{6\,\xi-1}{\xi}}\sinh^{-1}\sqrt{\xi\,(6\,\xi-1)}\,\phi + \sqrt{\frac{3}{2}}\ln\left|\frac{\sqrt{6}\,\xi\,\phi+\sqrt{1-\xi\,(1-6\,\xi)\,\phi^2}}{\sqrt{6}\,\xi\,\phi-\sqrt{1-\xi\,(1-6\,\xi)\,\phi^2}}\right|. \tag{2.6}$$

From above, it is not possible to derive an expression $\phi=\phi(r)$ after substituting Eq. (2.5) into Eq. (2.6), except for the conformally coupled case $\xi=\frac{1}{6}$. This difficulty is overcome if we consider ϕ as the new ''radial'' coordinate, so that $r=r(\phi)$, and consequently $w=w(\phi)$. Therefore, the line element in the physical frame can be written as

$$d\,s^2 = -\frac{w^{2\,\alpha}}{(1-\xi\,\phi^2)}\,d\,t^2 + \frac{w^{-2\,\alpha}}{(1-\xi\,\phi^2)}\left(\frac{d\,r}{d\,\phi}\right)^2 d\,\phi^2 + \Sigma(\phi)^2\,(d\,\vartheta^2+\sin^2\vartheta\,d\,\varphi^2), \tag{2.7}$$

where $\Sigma(\phi)$ is the proper radius of the two-spheres given by

$$\Sigma(\phi)^2 = \frac{r^2\,(\phi)\,w^{2\,(1-\alpha)}}{1-\xi\,\phi^2}, \tag{2.8}$$

with $r(\phi)=2\,M/[1-w^2\,(\phi)]$. The function for $w(\phi)$ is determined after substituting Eq. (2.5) into Eq. (2.6). For sake of completeness, we have

$$w(\phi) = \left(\pm\frac{\sqrt{6}\,\xi\,\phi+\sqrt{1+\xi\,(6\,\xi-1)\,\phi^2}}{-\sqrt{6}\,\xi\,\phi+\sqrt{1+\xi\,(6\,\xi-1)\,\phi^2}}\right)^{\gamma}\exp\left(-2\,\gamma\,\sqrt{\frac{6\,\xi-1}{6\,\xi}}\sinh^{-1}(\sqrt{\xi\,(6\,\xi-1)}\,\phi)\right), \tag{2.9}$$

where $\gamma=\pm\sqrt{3}/2\,\sqrt{1-\alpha^2}$. The solutions can be divided into types $A(B)$ according the sign $+(-)$ taken on the rhs of the above equation. Indeed, both types of solution A and B are equivalent due the symmetry of the Eqs. (2.7)–(2.9) under the change $\phi\to-\phi$ and $\gamma\to-\gamma$. For our proposal, we shall consider type A solutions only. Another very important quantity is the local mass function m defined by

$$1-\frac{2\,m}{\Sigma} = g^{\mu\nu}\Sigma_{,\mu}\Sigma_{,\nu} = \Omega^2\,w^{2\,\alpha}\left(\frac{d\,r}{d\,\phi}\right)^{-2}\left(\frac{d\,\Sigma}{d\,\phi}\right)^2, \tag{2.10}$$

with m being interpreted as the effective gravitational mass inside the sphere of radius Σ.

At this point a complete analysis is obtained after accomplishing the following items: (a) behavior of the proper area Σ^2 taking into account that $|\gamma|\geqslant\sqrt{3}/2$ (this corresponds to $0\leqslant\alpha<1$); (b) behavior of the mass function; (c) determination of singularities and regular event horizons; and (d) behavior of radial null rays. As already mentioned, it was shown in previous works that regular event horizons are present only for $\xi=\frac{1}{6}$ and $\gamma=1$ (or $\alpha=\frac{1}{2}$) corresponding to the Bekenstein black hole.

In order to study the behavior of the proper area $\Sigma(\phi)^2$, the scalar field is restricted to assume values inside the interval $|\phi|<1/\sqrt{\xi}$, necessary for the positiveness of the conformal factor $\Omega^2=1-\xi\,\phi^2$. Thus, for all $|\gamma|\geqslant\sqrt{3}/2$, except $|\gamma|=1$, the proper area varies from $\Sigma^2\,(|\phi|=1/\sqrt{\xi})=0$ to $\Sigma^2\,(|\phi|=0)=\infty$ for $|\gamma|>1$, or is infinity in both extremes, namely, $\Sigma^2\,(|\phi|=1/\sqrt{\xi})=\infty$ and $\Sigma^2\,(|\phi|=0)=\infty$, if $\sqrt{3}/2\leqslant|\gamma|\leqslant1$. In both cases, the space–time is asymptotically flat and has a naked singularity at $|\phi|=1/\sqrt{\xi}$, since invariants like R, $R_{\mu\nu}R^{\mu\nu}$ diverge in this region. Considering now the case $\gamma=1$ (type A solution), the scalar field varies in the following intervals: $\phi_*\leqslant\phi\leqslant0$ and $0\leqslant\phi\leqslant1/\sqrt{\xi}$, where $\phi_*<-1/\sqrt{\xi}$ is a solution of $w(\phi_*)^2=1$ (Ref. 13) distinct from $\phi=0$. Both domains of ϕ correspond to different solutions, and we are interested in the solution of the first interval ($\phi_*\leqslant\phi\leqslant0$). The proper area Σ^2 becomes unbounded at $\phi=0$ or $\phi=\phi_*$, having a minimum value distinct from zero for $\phi\in[\phi_*,0]$ as shown in Fig. 1. If one inspects the behavior of the conformal factor $\Omega^2=1-\xi\,\phi^2$, it is immediate to conclude that for $\phi=-1/\sqrt{\xi}$, Ω^2 vanishes, and inside the interval $\phi_*\leqslant\phi\leqslant-1/\sqrt{\xi}$, Ω^2 becomes negative, but the metric remains finite and keeps its signature.[14] This fact can be confirmed analytically after substituting

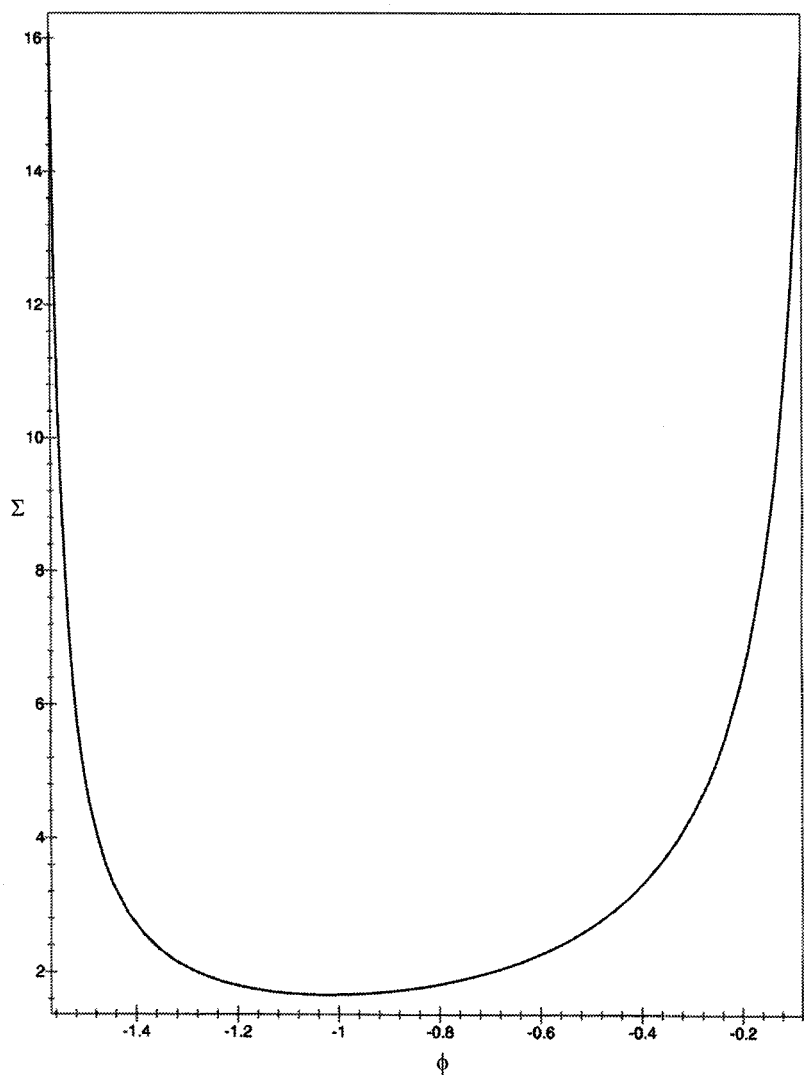

FIG. 1. Plot of the proper radius Σ given by Eq. (2.8), where we have assumed $\xi=1.0$ and $M=1.0$. In this case $\phi_* \approx -1.596\,441\,702\,3$ that characterizes the asymptotically flat region together with $\phi=0$. Here the minimum of the proper radius occurs for $\phi\approx -1.020\,491$.

$\alpha=\frac{1}{2}$ (or $\gamma=1$) into Eq. (2.8), for instance, where for $\phi=-1/\sqrt{\xi}$ both $w(\phi)$ and the conformal factor $\Omega^2=1-\xi\,\phi^2$ vanish, but the quantity $w(\phi)/(1-\xi\,\phi^2)$ remains finite and positive; also for $\phi_*<\phi<-1/\sqrt{\xi}$, both terms of are negative, rendering, again, a positive quantity. The same result is valid for all metric coefficients. We have studied the behavior of the invariants like R, $R_{\mu\nu}R^{\mu\nu}$, $R_{\mu\nu\tau\beta}R^{\mu\nu\tau\beta}$ and $W_{\mu\nu\tau\beta}W^{\mu\nu\tau\beta}$, where $W_{\mu\nu\tau\beta}$ is the Weyl tensor, and the result is depicted in Fig. 2. As we can see, such invariants reach to a finite maximum value at the minimum of the proper area Σ^2 and tend to zero as the proper area approaches to infinity, either for $\phi\to 0$ and $\phi\to\phi_*$. A better understanding of the structure of the space–time is obtained analyzing the behavior of radial light rays, which is done properly using the coordinates (t,Σ). After a straightforward calculation, it follows

$$\frac{d\,\Sigma}{d\,t}=\pm\,\frac{1}{2\,\sqrt{w\,(1-\xi\,\phi^2)}}\left(\frac{1+3\,w^2}{2}-\frac{3\,\xi\,(1-w^2)\,|\phi|}{\sqrt{6}\,\sqrt{1-\xi\,(1-6\,\xi)\,\phi^2}}\right), \tag{2.11}$$

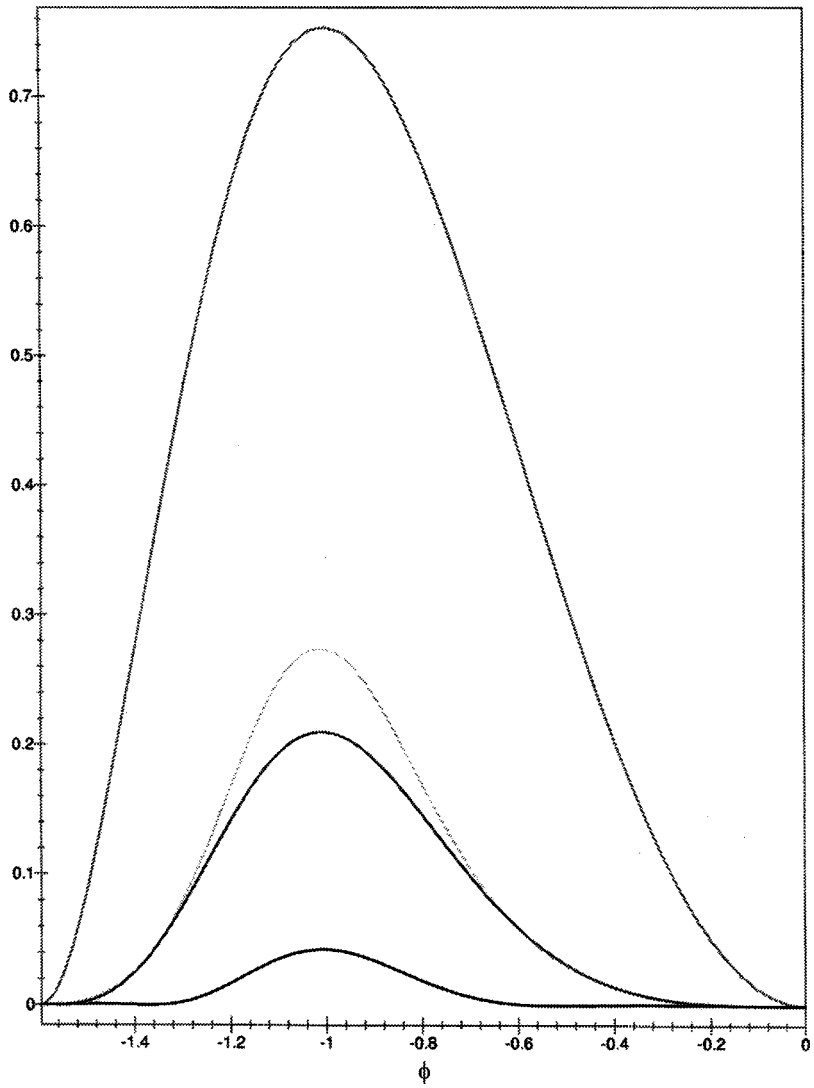

FIG. 2. Invariants R, $R_{\mu\nu}R^{\mu\nu}$, $R_{\mu\nu\tau\beta}R^{\mu\nu\tau\beta}$ and $W_{\mu\nu\tau\beta}W^{\mu\nu\tau\beta}$ versus the scalar field ϕ are plotted for $\xi=1.0$ and $M=1.0$. The maximum value of them occurs at the minimum of the proper radius and tends to zero for either $\phi\to\phi_*$ and $\phi\to 0$.

where the signal $+(-)$ denotes outgoing (ingoing) radial light rays. In Fig. 3, the plot of the above equation is shown, making clear that an initially, say, ingoing ray ($d\Sigma/dt<0$) becomes an outgoing ray ($d\Sigma/dt>0$) after bouncing at the minimum of the proper area where $d\Sigma/dt=0$. An interesting effect appears when the above expression is evaluated in both asymptotic limits, that is, for $\phi=0$ we have $|d\Sigma/dt|=1$, and for $\phi=\phi_*$, it follows $|d\Sigma/dt|=1/\sqrt{\xi\phi_*^2-1}$, such that this ratio is always less than 1 (indeed, we have shown numerically that this is true for all $\xi>\frac{1}{6}$). Therefore, in the asymptotic region characterized by $\phi=\phi_*$, the radial null ray behaves as if it propagates in a medium with an effective "index of refraction" $n=\sqrt{\xi\phi_*^2-1}$. In the limit $\xi\gg\frac{1}{6}$ the velocity of light approaches to 1 (here with the units adopted $c=1$), whereas for ξ tending to $\frac{1}{6}$ the velocity decreases, and in the exact limit $\xi=\frac{1}{6}$ corresponding to the Bekenstein black hole, the velocity vanishes. This means that the light rays are frozen in the event horizon of the black hole in which the proper radius has a finite value and $\phi_*=-\infty$. The last quantity to be

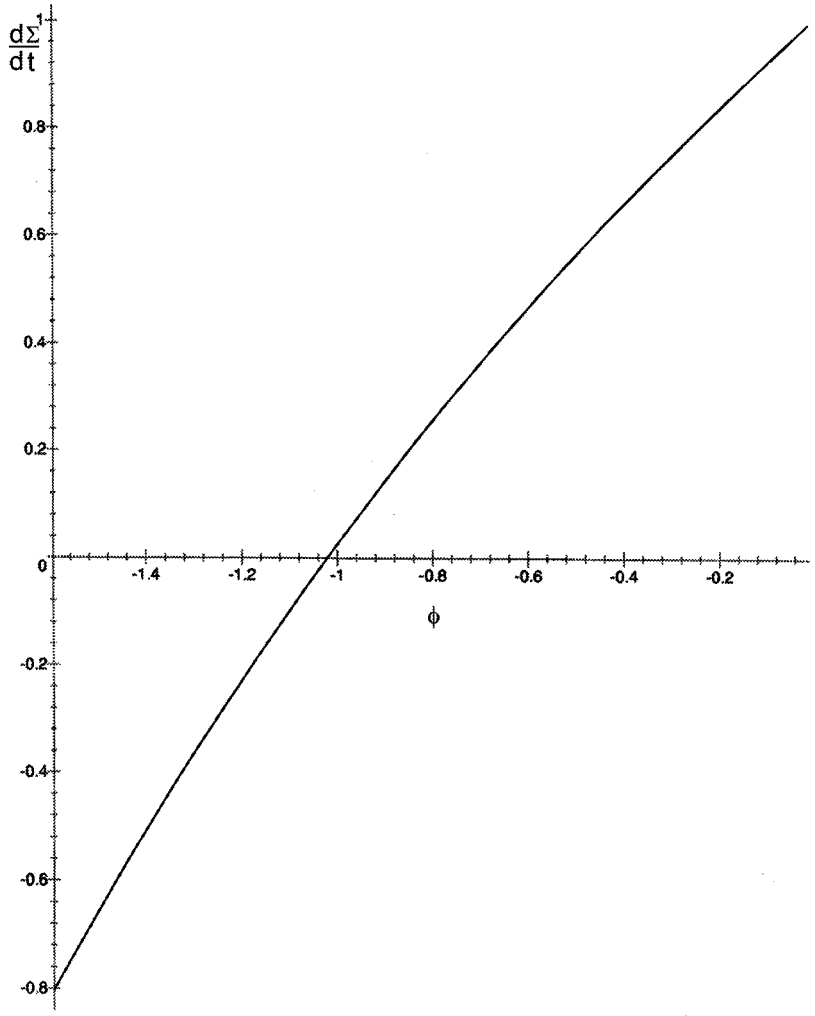

FIG. 3. Behavior of $d\,\Sigma/d\,t$ for radial light rays. The bounce take place at $\Sigma_{\min}$, where $d\,\Sigma/d\,t=0$ for $\phi \approx -1.020\,491$, with the choice $\xi=1.0$. In the asymptotic limit $\phi\to\phi_{*}\approx -1.596\,441\,702\,3$, $d\,\Sigma/d\,t\to 0.814\,53$.

studied is the local mass function defined in Eq. (2.10), whose behavior is sketched in Fig. 4 for $\gamma=1$ and $\xi>\frac{1}{6}$. According to it, the mass function is positive everywhere and has maximum finite value at the minimum of the proper area.

III. STABILITY ANALYSIS AND THE GALERKIN METHOD

We will proceed with the discussion of the stability of the soliton under radial perturbations. For this we first consider the following general spherically symmetric line element

$$ds^2=-e^{\nu(t,\rho)}dt^2+e^{\lambda(t,\rho)}d\rho^2+e^{\beta(t,\rho)}(d\theta^2+\sin^2\theta\,d\varphi^2), \tag{3.1}$$

where ρ is a suitable radial coordinate whose relations with the coordinate r and the scalar field of the background solution, ϕ_0, will be given later. From now on the subscript ''0'' denotes the quantities related to the static background solution described in the last section. The metric functions and the scalar field are perturbations around the background configuration written as

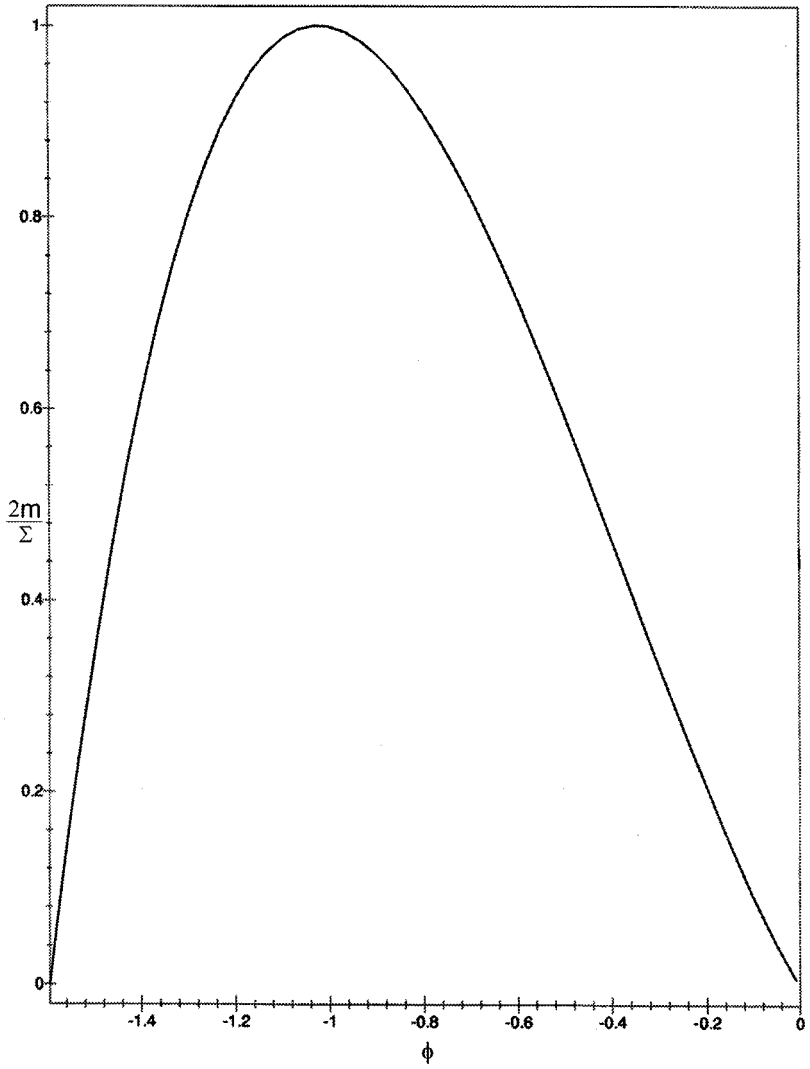

FIG. 4. Behavior of the mass function for $\xi=1.0$ and $M=1.0$, showing that it is positive everywhere.

$$\nu=\nu_0(\rho)+\delta\nu(t,\rho),\quad \lambda=\lambda_0(\rho)+\delta\nu(t,\rho),$$
$$\beta=\beta_0(\rho)+\delta\beta(t,\rho),\quad \phi=\phi_0(\rho)+\delta\phi(\rho,t). \tag{3.2}$$

The set of equations for $\delta\nu$, $\delta\lambda$, $\delta\beta$ and $\delta\phi$ is obtained after substituting the previous ansatz into the field equations and collecting only linear terms in the perturbations. It is possible to decouple the equation for $\delta\phi$ from the other perturbed functions, and afterwards to express $\delta\nu$, $\delta\lambda$ and $\delta\beta$ in terms of $\delta\phi$. Then, the stability/instability is actually determined by the behavior of $\delta\phi$. In order to perform the mentioned decoupling, we impose the following coordinate condition,[12]

$$\delta\nu+2\,\delta\beta=\delta\lambda, \tag{3.3}$$

together with $\nu_0+2\beta_0=\lambda_0$, that is, the same condition is valid for the background metric.

We begin with the equation of motion of the scalar field generated by the action (1.1)

$$g^{\alpha\mu}\phi_{,\alpha;\mu}+h(\phi)g^{\alpha\beta}\phi_\alpha\phi_\mu=0, \tag{3.4}$$

where

$$h(\phi)=\frac{1}{\Delta}\frac{d\Delta}{d\phi}=-\frac{\xi(1-6\xi)\phi}{1-\xi(1-6\xi)\phi^2},$$

with $\Delta=\sqrt{1-\xi(1-6\xi)\phi^2}$, were introduced as a matter of convenience. Note that if $\xi=0$ or $\xi=\frac{1}{6}$, $\Delta=1$ and $h(\phi)=0$. Considering in the above equation the background scalar field together with the coordinate condition $\nu_0+2\beta_0=\lambda_0$, it can be shown that $d\phi_0/d\rho=\text{const}/\Delta_0$. Then, in the special cases $\xi=0,\frac{1}{6}$ the radial coordinate ρ is proportional do the scalar field ϕ_0. Taking the line element (3.1), the ansatz (3.2) and the condition (3.3), the following linearized equation for $\delta\phi$ is derived:

$$e^{\lambda_0-\nu_0}(\ddot{\delta\phi})-(\delta\phi)''-2h(\phi_0)\phi_0'(\delta\phi)'-\left(\frac{dh}{d\phi}\right)_0\phi_0^2\delta\phi=0, \tag{3.5}$$

where prime and dot denote derivative with respect to ρ and t, respectively. The next step is to introduce the function $\psi(\rho,t)$ by

$$\delta\phi=\frac{\psi e^{-\beta_0/2}}{\Delta_0}, \tag{3.6}$$

such that Eq. (3.5) becomes

$$\frac{\partial^2\psi}{\partial x^2}+V(x)\psi=\frac{\partial^2\psi}{\partial t^2}, \tag{3.7}$$

where $V(x)=\frac{1}{2}e^{-2\beta_0}(\frac{1}{2}\beta_0'^2-\beta_0'')$ and x is a new variable related to ρ by $dx/d\rho=e^{\beta_0}$. Also, $dx/d\phi_0=e^{\beta_0}\Delta_0$, which provides a useful relation between ϕ_0 and x, since the background solution is given in function of ϕ_0. In Fig. 5 the potential is plotted as a function of ϕ_0. As expected $V(x(\phi_0))$ is a well behaved function, its maximum value occurs for the minimum of $\Sigma(\phi_0)$, and it vanishes at $\phi_0=\phi_*,0$ which characterizes the asymptotic flat regions. It can be shown that the these asymptotic regions correspond to $x=+\infty,-\infty$, respectively. To Eq. (3.7) suitable boundary conditions must be specified in order to determine the dynamical stability of the soliton. We choose

$$\psi\to 0 \quad \text{for} \quad \phi_0\to 0,\phi_*. \tag{3.8}$$

In the sequence we use the Galerkin method[15] to study the dynamical stability of the background solution. This method is known in applications involving the derivation of finite-dimensional dynamical systems from approximations of infinite-dimensional systems, where one of the most celebrated systems of this form is the one obtained by Lorenz.[16] To begin with we express ψ as a finite sum of time-dependent modal coefficients multiplied by elements of a suitable basis as

$$\psi=\sum_{j=1}^{N}a_j(t)b_j(\phi_0), \tag{3.9}$$

where $b_j(\phi_0)=\sqrt{2/L}\sin j\pi(\phi_0-\phi_*)/L$, $L=|\phi_*|$ are the basis functions that satisfies the boundary conditions (3.8) and are orthonormal, or $(b_j,b_k)=\int_{\phi_*}^{0}b_j(\phi_0)b_k(\phi_0)d\phi_0=\delta_{jk}$. Substituting Eq. (3.9) into Eq. (3.7) and taking the inner product with each basis function, say, $b_k(\phi_0)$, $k=1,2,...,N$, the ϕ_0 dependence will be removed by the spatial integration and we will be left with a set of N coupled ordinary differential equations for the coefficients $a_j(t)$. Then, after direct calculation,

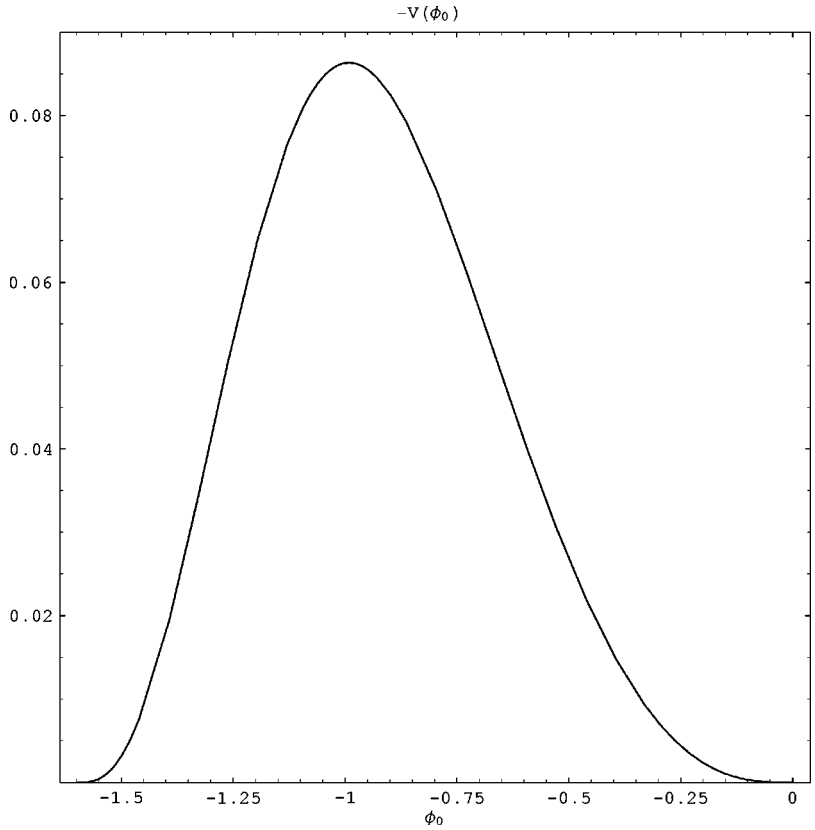

FIG. 5. Potential $V(\phi_0)$ for $\xi=1.0$ and $M=1.0$.

$$\sum_{j=1}^{N} a_j(t)\left[\frac{1}{2}\int_{\phi_*}^{0}\left(\frac{d\phi_0}{dx}\right)^2\left(\frac{d^2b_j}{d\phi_0^2}b_k-\frac{db_j}{d\phi_0}\frac{db_k}{d\phi_0}\right)d\phi_0+(Vb_j,b_k)\right]=\ddot{a}_k(t). \tag{3.10}$$

The first term on the lhs was obtained by integration by parts after taking into account the relation between x and ϕ_0, whereas the rhs is a consequence of the orthogonality condition. Note that the potential is expressed as a function of ϕ_0, or $V(\phi_0)=\frac{1}{2}e^{-2\beta_0}(\frac{1}{2}\beta'^2-\beta'')$ with $e^{\beta_0(\phi_0)}=\Sigma^2(\phi_0)$ given by Eq. (2.8).

The evaluation of the integrals on the lhs of Eq. (3.10) is performed using the background solution of Fig. 1 in which $\xi=1.0$, $M=1.0$ and $\phi_*\approx-1.596\,441\,702\,3$. Choosing the truncation of order five ($N=5$), the set of coupled ordinary differential equations is

$$\begin{aligned}\ddot{a}_1(t)=&-0.091\,674\,171\,681\,681\,25a_1(t)-0.036\,715\,247\,928\,300\,85a_2(t)\\&+0.152\,808\,191\,765\,106\,3a_3(t)+0.073\,750\,165\,035\,988\,63a_4(t)\\&-0.028\,833\,005\,465\,299\,63a_5(t),\end{aligned}$$

$$\begin{aligned}\ddot{a}_2(t)=&-0.021\,125\,139\,415\,259\,99a_1(t)-0.182\,175\,598\,496\,4850a_2(t)\\&-0.040\,747\,263\,640\,001\,60a_3(t)+0.277\,739\,497\,569\,803\,4a_4(t)\\&+0.113\,557\,063\,854\,599\,9a_5(t),\end{aligned}$$

$$\ddot{a}_3(t) = 0.057\,469\,035\,104\,788\,86 a_1(t) - 0.031\,992\,557\,900\,804\,12 a_2(t) - 0.360\,250\,782\,811\,640\,0 a_3(t) - 0.071\,039\,065\,011\,462\,57 a_4(t) + 0.446\,499\,972\,214\,607\,3 a_5(t), \tag{3.11}$$

$$\ddot{a}_4(t) = 0.022\,063\,739\,688\,377\,25 a_1(t) + 0.145\,486\,338\,858\,8478 a_2(t) - 0.056\,014\,320\,562\,388\,30 a_3(t) - 0.611\,788\,072\,949\,546\,4 a_4(t) - 0.109\,873\,233\,512\,505\,2 a_5(t),$$

$$\ddot{a}_5(t) = -0.007\,321\,852\,906\,258\,496 a_1(t) + 0.049\,500\,537\,610\,535\,84 a_2(t) + 0.274\,359\,783\,320\,026\,4 a_3(t) - 0.089\,803\,091\,260\,416\,16 a_4(t) - 0.935\,094\,586\,190\,751\,3 a_5(t),$$

where we have retained only those terms in the sum containing modal coefficients with indices 1 to 5. It is not difficult to show that the solution for each mode has the form of $e^{\kappa t}$, where κ is found to be

$$\pm 1.060\,072\,109\,542\,642 i, \quad \pm 0.835\,466\,769\,461\,132\,2 i, \quad \pm 0.466\,451\,337\,306\,448\,5 i, \quad \pm 0.182\,644\,756\,929\,545\,0 i, \quad \pm 0.329\,073\,934\,727\,850\,6 i. \tag{3.12}$$

For higher-order truncations, the number of equations for the modal coefficients increases, and we have verified that κ is always pure imaginary numbers. This result indicates that all modes oscillate about the background solution, implying the stability of the solution under small radial perturbations.

IV. CONCLUSIONS

We have discussed a static solitonlike solution generated by nonminimally coupled scalar field. The solution was obtained using the technique of conformal transformation that relates the actions integrals (1) and (4). In addition, we have examined the problem of dynamical stability under small radial perturbations, in which the Galerkin method was applied successfully. This method allowed us to reduce Eq. (3.7) to a set of five coupled linear differential equations for the temporal evolution of the perturbations provided that we have restricted ourselves to a truncation of order five in the decomposition (3.9). The system has shown to be identical to a set of coupled harmonic oscillators whose characteristics frequencies are given by (3.12), therefore indicating the stability of the soliton under radial perturbations. As a matter of fact, the effect of higher-order truncations is to increase the number of equations, but not change the nature of the system as a set of coupled harmonic oscillators. As a final remark, we point out the possibility of using the Galerkin method to study semi-analytically the behavior of nonlinear perturbations of either the soliton presented here or any other static configuration, as for instance, a boson star. In this case the resulting finite set of ordinary differential equations is no longer linear and a wealthy behavior is expected.

(Received 9 June 2001; accepted for publication 25 October 2001)

We address the question of the existence and construction of nontrivial, regular solutions of the Einstein–conformally invariant massless scalar field equations, i.e., solutions (g,Φ) satisfying $(1-\alpha\Phi^2)R_{\mu\nu}=\alpha(4\nabla_\mu\Phi\nabla_\nu\Phi-2\Phi\nabla_\mu\nabla_\nu\Phi-g_{\mu\nu}\nabla^\sigma\Phi\nabla_\sigma\Phi)$, $\nabla^\mu\nabla_\mu\Phi=0$, and additionally geometry and the scalar field are regular across the degeneracy region defined as the zeros of $(1-\alpha\Phi^2)$. Under the assumptions (1) the solution (g,Φ) is minimally of class C^3 and admits a hypersurface orthogonal, timelike Killing vector field ξ, and (2) relative to the three spacelike hypersurfaces perpendicular to the Killing field, the degeneracy region constitute regular two-surfaces, and the induced positive definite three metric possesses a degenerate Ricci, we show that the conformal system admits nontrivial, regular across the degeneracy region solutions and we demonstrate that any such solution necessarily admits an additional local $G(3)$ group of isometries possessing two-dimensional orbits of constant Gaussian curvature coinciding with the $\Phi=$cons-equipotential two surfaces. Those solutions exhibit similar properties as the Levi–Civita–Ehlers–Kundt class of static solutions of Einstein's vacuum equations. We investigate this coincidence and in particular we probe the origin of the additional local $G(3)$ group of isometries exhibited by both classes of solutions. From the partial differential equations point of view, both systems, i.e., conformal system as well as the vacuum system, degenerate or become singular, the conformal system along solutions subject to $\alpha\Phi^2=1$ within the static region, the vacuum along solutions subject to $V=(-\xi\cdot\xi)^{1/2}\to 0^+$. We demonstrate that as a consequence of the singular nature of the dynamical equations, among all solutions possessing degenerate Ricci in the open vicinity of $\alpha\Phi^2=1$, respectively, $V\to 0^+$, the only regular across degeneracy region solutions are those characterized by a vanishing York–Cotton tensor and, furthermore, such solutions necessarily admit an additional local $G(3)$ group of isometries possessing two-dimensional orbits of constant Gaussian curvature.

I. INTRODUCTION

It is well known that the n-dimensional conformally invariant generalization of the flat Laplace or massless Klein–Gordon equation is provided by[1]

$$g^{AB}\nabla_A\nabla_B\Phi-\frac{(n-2)}{4(n-1)}R\Phi=0. \tag{1a}$$

If Φ is a solution of this equation and Ω is any smooth positive function, then $\bar{\Phi}=\Omega^{1-n/2}\Phi$ also

a)Electronic mail: zannias@ginette.ifm.umich.mx

satisfies (1a) provided all geometrical quantities are formed using the conformal metric $\bar{g}_{AB} = \Omega^2 g_{AB}$. Augmenting the conformally invariant action functional $S[g,\Phi]$ by the Einstein–Hilbert term and specializing to $n=4$ space–time dimensions, a theory involving a massless scalar field Φ conformally coupled to the background scalar curvature R is generated. The combined action functional is given by

$$S[g,\Phi] = \int \left(\frac{1}{16\pi G} R - \frac{1}{12}\Phi^2 R + \frac{1}{2}\nabla^\mu \Phi \nabla_\mu \Phi \right) \sqrt{-g}\, d^4x. \tag{1b}$$

and yields, after some rearrangement, the following coupled system:

$$(1-\alpha\Phi^2) R_{\mu\nu} = \alpha(4\nabla_\mu \Phi \nabla_\nu \Phi - 2\Phi \nabla_\mu \nabla_\nu \Phi - g_{\mu\nu} \nabla^\sigma \Phi \nabla_\sigma \Phi), \tag{1c}$$

$$\nabla^\mu \nabla_\mu \Phi = 0, \tag{1d}$$

where in the above $\alpha = k/6 = 8\pi G/6$ stands for an ''effective'' coupling constant and all indices involved are four-dimensional. Thus the concept of the conformally invariant scalar wave equation (1a) leads to a system which is no longer conformally invariant and, moreover, (1c) and (1d) exhibit features that are absent whenever Φ is minimally coupled to gravity. The presence of the second derivatives on the right-hand side of (1c), as well as the presence of the $(1-\alpha\Phi^2)$ factor on its left-hand side, are two notable features.

Bekenstein,[2,3] by cleverly exploiting conformal techniques, was able to generate solutions of the conformal equations starting from solutions of the minimally coupled equations. Additional solutions and properties of solutions can be found in Refs. 4–9. The black hole sector of the theory has been explored in Refs. 10–12, and in summary the theory admits no other classes of static black holes besides the familiar Schwartzschild class, Refs. 10 and 12 The stationary black hole sector has not been exploited in all details, but the circular sector contains only the Kerr family.[11] Solutions of cosmological interest have been presented in Refs. 2 and 13. Noakes, in Ref. 14, has shown that (1c) and (1d) admit a well-posed initial value formulation, a property that is an asset for the theory. Despite all this activity, still the peculiar structure of Eqs. (1c) and (1d) raises a number of questions begging for an answer. If (g,Φ) is a solution (1c) and (1d), then its Ricci tensor fails in general to be semi positive definite i.e., if l is an arbitrary smooth timelike or null vector field, then $R_{\mu\nu} l^\mu l^\nu$ can have any sign. As consequence one cannot easily infer geodesic incompleteness, formation of trapped surface, or, for a black hole space–time, a well-behaved domain of outer communication.[1,15] In short, the analysis of the global structure of space–times (M, g, Φ) with (g,Φ) a solution of (1c) and (1d) is not a trivial issue. The present article primarily is focused on exploring consequences of the intriguing $(1-\alpha\Phi^2)$ factor multiplying the left-hand side of (1c). If (g,Φ) is a solution of (1c) and (1d) so that $(1-\alpha\Phi^2)$ is vanishing but only locally, then (1c) shows that regularity of the simplest scalar invariant $R^{\mu\nu}R_{\mu\nu}$ across zeros of $(1-\alpha\Phi^2)$ requires a special relationship between Φ its first and second derivatives. But what is the precise nature of such interrelationship guaranteeing regularity of (g,Φ) across zeros of $(1-\alpha\Phi^2)$?

If such solutions (g,Φ) exist (and in fact exist), then from the partial differential equation's point of view the system (1c) and (1d) degenerates or becomes singular, in the sense that its highest-order derivatives are nullified on the set of points where $1-\alpha\Phi^2=0$. This latter set will be referred to hereafter as the degeneracy region associated with the particular solution (g,Φ). Accordingly, an answer to the above-posed questions calls for an understanding of the regularity properties of solutions of (1c) and (1d) in the local vicinity of the degeneracy region. Such inquiry is also relevant in another respect that partially motivated the present work. As is well known, Müller zum Hagen,[16] some time ago, has shown that all static, minimally C^3 solutions of Einstein's vacuum equations are real analytic tensor fields within the static region. This analyticity property follows from the fact that sufficiently regular vacuum metrics, whenever expressed relative to a local harmonic chart, satisfy a second-order manifestly elliptic system of equations. Standard result of the so-called elliptic regularity theory then implies real analyticity for the

space–time metric. As it is shown in Ref. 17, Müller zum Hagen theorem extends to suitably smooth static solutions of the nonvacuum Einstein's equations provided the latter equations do not degenerate anywhere within the static region. In that regard static solutions of the Einstein–Klein–Gordon, electrovacuum, or Dilaton gravity of class C^3, or more generally of class $C^{2+\mu}$, $0<\mu<1$, exhibit the same analyticity property as their vacuum counterparts:[17] both geometry and matter fields are analytic within the static region of the space–time manifold. However, an extension of this analyticity property to solutions along which the dynamical equations degenerate runs into obstacles and, in fact, establishing their analyticity (if it holds) is by no means a trivial problem. The conformal system (1c) and (1d) is perhaps the simplest set of equations exhibiting such behavior. It degenerates on static solutions (g,Φ) subject to the vanishing of $(1-\alpha\Phi^2)$ within the static domain. Thus an understanding of the behavior of solutions of (1c) and (1d) across degeneracies would be helpful in formulating a suitable extension of Müller zum Hagen theorem encompassing also solutions along which the relevant equations degenerate.

For orientation purposes, it is worth mentioning here that degenerate set of equations are encountered in other context as well. For instance, the ''conformal vacuum Einstein equations'' written in the ''unphysical manifold,'' degenerate on any solution which is asymptotically flat at future $\mathcal{J}^+$, past $\mathcal{J}^-$ or spacelike infinity i^0.[18] Also the conformally rescaled vacuum Einstein equations degenerate on static, asymptotically Euclidean solutions in the vicinity of the point at infinity.[19–21] Moreover, degeneracies in the Einstein equations may also occur away from the asymptotic regions. On numerous occasions the field equations written relative to a local coordinate chart exhibit such degeneracies.[22] Analysis of the above-mentioned systems reveals that solutions along which a given set of equations degenerates may be smooth across degeneracies. Friedrich, in Ref. 18, has shown that the ''conformal vacuum Einstein equations'' admit analytic solutions across degeneracies while the work of Beig and Simon, and also of Kundu,[21] shows that sufficiently smooth asymptotically flat, static, or stationary solutions of Einstein vacuum equation with nonzero ADM mass are analytic in a vicinity of the point at infinity. The results of Refs. 18 and 21 have been established via a ''desingularization'' procedure, i.e., via a process by which solutions along which the original equations become singular are shown to satisfy an effective set of regular equations. An analysis, then, of the latter system establishes the existence of smooth solutions across the degeneracy region. In brief, therefore, an analysis of solutions of a degenerate system of equations possesses the challenge of constructing an effective set of regular equations where one regains the full strength of the highest-order derivatives. However, and depending upon the structure of the original set, the effective equivalent set is not obvious and often requires considerable labor in constructing it.

The present article is focused on an analysis and properties of solutions (g,Φ) along which the conformal equations (1c) and (1d) degenerate. As far as we are aware, the only knowledge regarding the behavior of solutions of (1c) and (1d) near degeneracies is provided by the work of Ref. 6. In this work static, spherically symmetric, and asymptotically flat solutions of the conformal system have been analyzed and those results are very illuminating within the present context. The conformal system admits the following classes of static, asymptotically flat, and spherically symmetric solutions:[6]

$$ds^2=-\left(1-\frac{r_0}{r}\right)^2dt^2+\left(1-\frac{r_0}{r}\right)^{-2}dr^2+r^2(d\theta^2+\sin^2\theta\,d\varphi^2), \tag{2a}$$

$$\Phi=-\alpha^{-1/2}\frac{r_0}{r-r_0},\quad r_0>0, \tag{2b}$$

$$ds^2=-K^2(r)dt^2+Q^2(r)[dr^2+r^2(d\theta^2+\sin^2\theta d\varphi^2)], \tag{2c}$$

$$K(r)=\frac{1}{2}(R^{(\eta-1)(\eta+3)/4\eta}+R^{(\eta+1)(\eta-3)/4\eta}),\quad Q(r)=\frac{(r-r_0)^2}{2r^2}(R^{(3-\eta)/2\eta}+R^{(3+\eta)/2\eta}),$$

$$\Phi(r)=\alpha^{-1/2}\frac{1-R}{1+R},\quad R(r)=\left(\frac{r+r_0}{r-r_0}\right)^{4\eta/(\eta^2+3)},\quad \eta>0. \tag{2d}$$

However, the curvature of the above metrics exhibits diverse behavior. The curvature of (2a) and (2b) is perfectly smooth across the zeros of the $1-\alpha\Phi^2$, occurring at $r=2r_0$ clearly within the static region. In fact, (2a) and (2b) are the only regular, asymptotically flat, spherical and analytic metric within the static region.[6] On the other hand, the curvature of (2c) and (2d), away from the value $\eta=1$, exhibits different behavior. Even though the factor $1-\alpha\Phi^2$ admits roots (again at $r=2r_0$), the curvature diverges as those roots are approached. The paradigm of (2a)–(2d) suggests that (1c) and (1d) admit solutions where the geometry and the field Φ are perfectly regular over zeros of $(1-\alpha\Phi^2)$, but also solutions where the zeros of $(1-\alpha\Phi^2)$ are accompanied by a singular geometry. Moreover, the ''majority'' of static, spherically symmetric, and asymptotically flat solutions of (1c) and (1d) are singular ''across degeneracies,'' one parameter family of singular solutions versus isolated regular ones. Notice, however, that a third class, involving all those static, with or without spherical symmetry, solutions where the factor $(1-\alpha\Phi^2)$ is nowhere vanishing within the static region is not *a priori* excluded. This class can be handled rather ''straightforwardly'' and according two theorems established by Bekenstein[23] can be put, via a conformal transformation, into a correspondence with solutions of the Einstein–Klein–Gordon massless minimally coupled to gravity equations or even static vacuum solutions of Einstein equations.

The discussion so far and, in particular, the existence of the regular class (2a) and (2b) shows that (1c) and (1d) admit at least one class of regular solution across degeneracies. Naturally then we ask: Do (1c) and (1d) admit other classes of solutions exhibiting the same regularity properties as the class (2a) and (2b)? If so, how one can construct them explicitly? In principle, the construction question can be addressed by taking advantage of the fact that the initial value formulation of the theory is well posed[14] or casting (1c) and (1d) into a system of elliptic equations, once considerations are restricted to static solutions. Unfortunately, however, there are a number of technical difficulties that have to be surpassed first. Solutions of the initial value constraints or choice of boundary data for the elliptic system have to be first addressed and those steps are by no means trivial tasks.

In the present article we shall adopt a method that bypasses the above-mentioned difficulties and it is tailored towards to the construction of degenerate solutions of (1c) and (1d). We shall, however, restrict our considerations to the question of the existence and regularity properties of degenerate solutions (g,Φ) of (1c) and (1d) admitting a hypersurface orthogonal timelike Killing vector field. Since, moreover, very little is known about the connection between the regularity properties of degenerate solutions and the structure of zeros of the $(1-\alpha\Phi^2)$ factor, we shall also invoke some assumptions regarding the structure of the latter ''zero set.'' The hypersurface orthogonal property of the Killing field allows us to project (1c) and (1d) along the local spacelike hypersurfaces perpendicular to the Killing field, thus casting (1c) and (1d) into an equivalent system involving a positive definite metric, the redshift factor, and the scalar field as the field variables. Since the projected equations involve a positive definite metric, the eigenstructure of the associated Ricci tensor is rather simple. We exploit this property and, in fact, the present article is focused exclusively on the investigation of the structure of static solutions of (1c) and (1d) admitting a degenerate three Ricci tensor.[24] Degeneracy on Ricci implies that any static solutions of (1c) and (1d) satisfy a set of nontrivial integrability conditions. Those integrability conditions have been analyzed in detail for the particular case that the redshift factor and the scalar field are functionally related. This functional relation reduces considerably the complexity of the field equations and associated integrability conditions. The latter enable us to write an effective set of regular equations satisfied by any solution of (1c) and (1d) along which the conformal equations degenerate. The study of this effective system allowed us to infer the local existence of solutions

of (1c) and (1d) regular across degenerate regions. Moreover, we have been able to integrate the effective equations and thus provide explicit solutions of (1c) and (1d) regular across the degeneracy regions. Their construction is discussed in detail in Sec. III. Since, as it will become clear further below, all static solutions of (1c) and (1d) admitting a degenerate Ricci and regular across the degeneracy region necessarily admit a local $G(3)$ group of isometries with two-dimensional orbits of constant Gaussian curvature, we devote some effort to understanding the origin of those additional local isometries. As a part of this effort in Sec. IV we turn our attention to Einstein vacuo equations. This vacuum set, written relative to a specific coordinate gauge, also degenerates on any static solution approaching the regions where the magnitude of the Killing field vanishes. We then compare the properties of degenerate classes of solutions of the two systems, and the results of this section make contact with the Levi–Civita–Ehlers–Kundt class of static solutions of the vacuum Einstein equations.[25,26] This contact furnishes further insights into the structure of solutions of the conformal system and those insights are discussed in Sec. IV as well as in the concluding part of the article. As a byproduct, using the integration techniques developed in the present work an *ab initio* construction of the Levi–Civita–Ehlers–Kundt class of vacuum degenerate solutions is also presented.

II. ON STATIC, REGULAR SOLUTIONS OF THE CONFORMAL EQUATIONS

We start by considering a space–time manifold (M,g,Φ) with M a C^k, for some integer k, $k\geqslant 4$, connected, orientable, and paracompact manifold and (g,Φ) a solution of (1c) and (1d) admitting a timelike, hypersurface orthogonal, Killing vector field ξ. We restrict considerations to "classical solutions," i.e., solutions of class C^m, $m\geqslant 3$, so that the field equations and Bianchi identities are pointwise well defined and, in this section, we disregard any (g,Φ) subject to an everywhere constant scalar field Φ. Exploiting the timelike and hypersurface orthogonal property of ξ, a standard construction[1] yields a set of local coordinates, referred to hereafter as Killing coordinates, so that the space–time metric takes the form

$$ds^2=g_{\mu\nu}dx^\mu dx^\nu=-V^2dt^2+\gamma_{ab}dx^a dx^b. \tag{3a}$$

Relative to such coordinates a solution (g,Φ) of (1c) and (1d) satisfies

$$(1-\Phi^2)(R_{ab}-V^{-1}D_aD_bV)=(4D_a\Phi D_b\Phi-2\Phi D_aD_b\Phi-\gamma_{ab}D^c\Phi D_c\Phi), \tag{3b}$$

$$(1-\Phi^2)D^aD_aV=VD^a\Phi D_a\Phi+2\Phi D^a\Phi D_aV, \tag{3c}$$

$$VD^aD_a\Phi=-D^a\Phi D_aV, \tag{3d}$$

where above and hereafter the effective coupling constant α has been absorbed in the field Φ. For part of this article, it is convenient to work with (U,Λ_{ab}) where $V=e^U$, $\gamma_{ab}=V^{-2}\Lambda_{ab}$ instead of (V,γ_{ab}). Performing the local conformal transformation $\gamma_{ab}=V^{-2}\Lambda_{ab}$, the above equations lead into the following equivalent system:

$$(1-\Phi^2)(\overline{R}_{ab}-2\overline{D}_aU\overline{D}_bU)=4\overline{D}_a\Phi\overline{D}_b\Phi-2\Phi\overline{D}_a\overline{D}_b\Phi-2\Phi\overline{D}_a\Phi\overline{D}_bU-2\Phi\overline{D}_aU\overline{D}_b\Phi$$
$$-2\Lambda_{ab}\overline{D}^c\Phi\overline{D}_c\Phi, \tag{4a}$$

$$(1-\Phi)^2\overline{D}^a\overline{D}_aU=\overline{D}^a\Phi\overline{D}_a\Phi+2\Phi\overline{D}^a\Phi\overline{D}_aU, \tag{4b}$$

$$\overline{D}^a\overline{D}_a\Phi=0, \tag{4c}$$

where $(\overline{R}_{ab},\overline{D})$ stand for the Ricci tensor and covariant derivative computed using the positive definite metric Λ.

We are interested in analyzing solutions (Λ,U,Φ) subject to the vanishing of the $1-\Phi^2$ factor within the static region. However, at this point, we know nothing about the structure of the

''zero set,'' i.e., the set defined by $\{x \in M | 1-\Phi^2=0\}$, except that it is a closed subset of M.[27] Its precise nature requires the advance knowledge of the solution itself and the existence of solutions characterized by a topologically complicated zero set cannot be *a priori* excluded. We break this circular state by first imposing conditions on $\{x \in M | 1-\Phi^2=0\}$ and subsequently investigate whether (4a)–(4c) admits solutions compatible with such conditions. As we have also indicated in the Introduction, we shall also functionally relate U and the scalar field Φ and more precisely we shall inquire whether the set (4a)–(4c) admits solutions satisfying

(a) the equipotential ''surfaces'' of U and Φ coincide and
(b) with reference to the local (x^1,x^2,x^3) coordinates covering the $t=$const spacelike hypersurfaces, the (local) level surface $\{(x^1,x^2,x^3)|1-\Phi^2(x^1,x^2,x^3)=0\}$ is not a critical one, i.e., $\overline{D}_a\Phi|_{\Phi^2=1} \neq 0$.

Condition (a) implies that $U=U(\Phi)$ and this relation eliminates the field U from (4a)–(4c), yielding a slightly simpler system to work with. Even though the condition $U=U(\Phi)$ is restrictive, nevertheless it sheds considerable light on the nature of degenerate solutions of (4a)–(4c). In the conclusion section, a few comments regarding the existence of solutions of (4a)–(4c) away from this assumption will be made. Condition (b) ensures that each connected component of the local level surface $\{(x^1,x^2,x^3)|1-\Phi^2(x^1,x^2,x^3)=0\}$ is a regular two-surface. The fact that $\overline{D}_a\Phi|_{\Phi^2=1} \neq 0$ coupled with the differentiability assumptions on Φ implies that an open vicinity of any $\Phi^2=1$ equipotential surface is characterized by the absence of critical points and this property will be used heavily in the upcoming sections. In the alternative possibility, i.e., if (b) is not imposed, then the local level surface $\{(x^1,x^2,x^3)|1-\Phi^2(x^1,x^2,x^3)=0\}$ may admit critical points.[28] The analysis and properties of solutions of (4a)–(4c) near critical points is a rather delicate and difficult issue. Ultimately a complete understanding of the behavior of degenerate solutions of (4a)–(4c) [or of (1c) and (1d)] has to address that possibility. In the present article we gloss it over on the grounds that an understanding of solutions of (4a)–(4c) near critical points would require altogether different techniques than those employed in the present work. We do, however, hope to present such an analysis in the near future. For this section and unless otherwise explicitly stated, all solutions of (3b)–(3d), or equivalently of (4a)–(4c), will be assumed to obey conditions (a) and (b) defined above.

We begin by first utilizing the relation $U=U(\Phi)$ combined with (4b) and (4c). After some algebra, Eqs. (4b) and (4c) imply

$$U(\Phi)=-\frac{1}{2}\left[\ln(1-\Phi^2)+C_1\ln\left(\frac{1-\Phi}{1+\Phi}\right)\right]+C_2, \tag{5a}$$

where (C_1,C_2) are arbitrary integration constants. Substituting this expression into (4a) and tracing, we arrive at

$$(1-\Phi^2)^2\overline{R}=2(C_1^2-1)\overline{D}^a\Phi\overline{D}_a\Phi, \tag{5b}$$

which, combined with condition (b), implies that scalar curvature $\overline{R}$ is regular on any $\Phi^2=1$ equipotential surface provided $C_1^2=1$. Accordingly, regularity of the geometry on $\Phi^2=1$ implies via (5b) that $\overline{R}$ must be vanishing in an open vicinity of any $\Phi^2=1$ equipotential surface. Choosing for the moment $C_1=1$, relation (5a) leads to

$$U(\Phi)=-\ln(1-\Phi)+C_2, \tag{6a}$$

which is manifestly regular on and near any equipotential surface labeled by $\Phi=-1$, but it fails to be so on equipotential surfaces labeled by $\Phi=1$. The choice $C_1=-1$ leads to

$$U(\Phi)=-\ln(1+\Phi)+C_2, \tag{6b}$$

which now exhibits the ''reverse'' behavior, namely it is regular in the vicinity of $\Phi=1$ but singular on the $\Phi=-1$ ones. Since, however, a singular $U(\Phi)$ implies singular space–time geometry, it follows that all solutions of (1c) and (1d) are singular, if they satisfy conditions (a) and (b) and at the same time both types of equipotential surfaces labeled by $\Phi=1$ and $\Phi=-1$ coexist within the static region covered by the local Killing coordinates. Notice that since $\xi\cdot\xi=-e^{2U}$, the above-mentioned singularities are timelike in character. Thus we restrict considerations hereafter to the construction of solutions admitting only one type of equipotential surface taken without loss of generality to be described by $\Phi=1$. Substituting (6b) in (4a)–(4c) combined with $\overline{R}=0$ leads to

$$(1-\Phi^2)\overline{R}_{ab}=6\overline{D}_a\Phi\overline{D}_b\Phi-2\Phi\overline{D}_a\overline{D}_b\Phi-2\Lambda_{ab}\overline{D}^c\Phi\overline{D}_c\Phi, \tag{7a}$$

$$\overline{D}^a\overline{D}_a\Phi=0. \tag{7b}$$

Solutions (Λ,Φ) of this system are characterized by $R=0$ and, if Φ takes the value $\Phi=1$ somewhere within the local $t=$const spacelike hypersurface, then necessarily (7a) and (7b) degenerate on such solutions. Furthermore, every regular solution (g,Φ) satisfies an important property: its York–Cotton tensor R_{abc} (Ref. 29) satisfies

$$\Phi(1-\Phi^2)\overline{R}_{abc}=4\overline{D}_b\Phi\overline{R}_{ca}-4\overline{D}_c\Phi\overline{R}_{ab}-2\overline{D}^d\Phi\overline{R}_{dc}\Lambda_{ba}+2\overline{D}^d\Phi\overline{R}_{db}\Lambda_{ca}, \tag{8a}$$

where we recall that $\overline{R}_{abc}$ is defined by $\overline{R}_{abc}=\overline{D}_b\overline{R}_{ca}-\overline{D}_c\overline{R}_{ba}+\frac{1}{4}(\Lambda_{ab}\overline{D}_c\overline{R}-\Lambda_{ac}\overline{D}_b\overline{R})$. The derivation of (8a) proceeds via differentiation of (7a), antisymmetrization, use of the Ricci identity $\overline{D}_a\overline{D}_b\overline{D}_c\Phi-\overline{D}_b\overline{D}_a\overline{D}_c\Phi=\overline{R}_{abcd}\overline{D}^d\Phi$, and the fact that at three dimensions the Riemann tensor is determined entirely by the Ricci curvature, i.e.,

$$\overline{R}_{abcd}=\Lambda_{ac}\overline{R}_{db}-\Lambda_{bc}\overline{R}_{da}+\Lambda_{bd}\overline{R}_{ca}-\Lambda_{ad}\overline{R}_{cb}+\tfrac{1}{2}(\Lambda_{ad}\Lambda_{cb}-\Lambda_{ac}\Lambda_{db})\overline{R}. \tag{8b}$$

Relation (8a) is satisfied by all regular solutions of (7a) and (7b), and this property is of fundamental importance. As it has been derived here, it holds for every regular solution (Λ,Φ) of (7a) and (7b), but in the sequel we shall use it as a consistency-integrability condition in the following sense: Let $(\overline{\Lambda},\overline{\Phi})$ be a smooth configuration consisting of a three Riemannian metric $\overline{\Lambda}$ and a scalar function $\overline{\Phi}$. In order that this configuration satisfies (7a) and (7b), it is necessary that the Ricci tensor of $\overline{\Lambda}$ and the gradient of $\overline{\Phi}$ satisfy (8a). However, (8a) constrains the Ricci curvature of $\overline{\Lambda}$ and this constraint sheds considerable light onto the nature of potential solutions of (7a) and (7b). Moreover, (8a) must hold true across the $\Phi=1$ equipotential surfaces, provided regular across $\Phi=1$ solution exists. Validity of (8a) across degeneracies demands a fine balance between the Ricci and the gradient of $\overline{\Phi}$. In particular, whenever (8a) is applied to metrics possessing a degenerate Ricci, it imposes strong constraints on the behavior of the Ricci eigenvalues and, in turn, those constraints will help us to identify the classes of regular metrics across the $\Phi=1$ equipotential surface from those that are singular.

With those comments in mind, we first inquire whether in a local vicinity of the $\Phi=1$ equipotential surface, the system (7a) and (7b) admits solutions (Λ,Φ) characterized by a degenerate Ricci tensor. More precisely, we look for solutions (Λ,Φ) so that in an open vicinity of $\Phi=1$ their Ricci is given by

$$\overline{R}_{ab}=\overline{\lambda}(3\hat{\Phi}_a\hat{\Phi}_b-\Lambda_{ab}), \tag{9a}$$

where $\hat{\Phi}=\hat{\Phi}^a\partial/\partial x^a=[\overline{D}^a\Phi/(\overline{D}^a\Phi\overline{D}_a\Phi)^{1/2}]\partial/\partial x^a$ and $\overline{\lambda}$ is a scalar field, a measure of the Ricci eigenvalues. It is implicitly assumed in (9a) that $\overline{\lambda}$ is not identically vanishing and is at least of

class C^1. The special case of an identically vanishing $\overline{\lambda}$ will be discussed at the end of this section while the most general case of a degenerate Ricci will be addressed in Sec. VI. Combining (9a) with Eq. (7a) one finds

$$\overline{D}_a\overline{D}_b\Phi \equiv \lambda_\Phi(3\hat{\Phi}_a\hat{\Phi}_b - \Lambda_{ab}), \tag{9b}$$

where hereafter λ_Φ is defined by

$$\lambda_\Phi := \frac{2\Phi^a\Phi_a - (1-\Phi^2)\overline{\lambda}}{2\Phi}. \tag{9c}$$

Thus $\overline{D}_a\overline{D}_b\Phi$ viewed as a real symmetric matrix admits $D_a\Phi$ also as its distinct eigendirection with corresponding eigenvalue determined by $\overline{\lambda}$ and the gradient of Φ. Notice that had we assumed that a solution (Λ, Φ) existed so that in the open vicinity of $\Phi=1$ the real symmetric matrix $\overline{D}_a\overline{D}_b\Phi$ is given by (9b), then (7a) and (7b) would imply Ricci degeneracy over the same region and thus there is no loss in generality by assuming degeneracy in the Ricci.

With regard to the system (9a)–(9c) one notices the following: If $(\Lambda,\Phi,\overline{\lambda})$ is any regular solution of (9a)–(9c) so that $\Phi=1$ is a regular two-surface, then this (Λ,Φ) necessarily satisfies (7a) and (7b) and, moreover, (7a) and (7b) degenerates on such solutions. Indeed, substituting the right-hand sides of (9a) and (9b) into the left- and right-hand sides of (7a) and (7b), respectively, yields an equality, provided (9c) holds. But if (9c) holds, then multiplying (9a) by $(1-\Phi^2)$ and using (9c) we obtain

$$\begin{aligned}(1-\Phi)\overline{R}_{ab} &= (1-\Phi^2)\overline{\lambda}(3\hat{\Phi}_a\hat{\Phi}_b - \Lambda_{ab}) \\ &= (1-\Phi^2)\frac{2(\Phi^c\Phi_c - \Phi\lambda_\Phi)}{1-\Phi^2}(3\hat{\Phi}_a\hat{\Phi}_b - \Lambda_{ab}) \\ &= 6\overline{D}_a\Phi\overline{D}_b\Phi - 2\Phi\overline{D}_a\overline{D}_b\Phi - 2\Lambda_{ab}\overline{D}^c\Phi\overline{D}_c\Phi.\end{aligned} \tag{9d}$$

where the above string of equalities holds away from $\Phi=1$, but by continuity arguments they are also valid across $\Phi=1$. Thus particular solutions of the manifestly regular system (9a) and (9b), subject to $\Phi=1$ locally, also satisfy the system (7a) and (7b) and, moreover, the latter system degenerates on such solutions. Accordingly the system (9a)–(9c) offers the means of constructing degenerate solutions of (7a) and (7b) and, in fact, one could construct all degenerate solutions of (7a) and (7b) subject of course to the satisfaction of (9a). Indeed, if (7a) and (7b) admits a regular solution (Λ, Φ) so that its Ricci tensor is given by (9a), then (Λ,Φ) satisfy (9a) and (9b) for a λ_Φ determined by (9c). Regularity of the geometry on and around $\Phi=1$ implies $\overline{R}^{ab}\overline{R}_{ab}=6\overline{\lambda}^2$ and that $\overline{\lambda}$ is necessarily bounded. But for such $\overline{\lambda}$ Eq. (7a) implies that $\overline{D}_a\overline{D}_b\Phi$ is also degenerate with a corresponding eigenvalue λ_Φ related to $\overline{\lambda}$ via (9c) from which it follows that (Λ,Φ) satisfy (9a)–(9c).

In view of those remarks, we now turn our attention to the local properties of solutions (Λ,Φ) satisfying (9a)–(9c). At first, if $(\Lambda,\Phi,\overline{\lambda})$ is any such solution, then the Ricci identity applied to $\overline{D}_a\Phi$ in view of (9b) and (8b) implies

$$\begin{aligned}&(3\hat{\Phi}_b\hat{\Phi}_c - \Lambda_{bc})\overline{D}_a\lambda_\Phi - (3\hat{\Phi}_a\hat{\Phi}_c - \Lambda_{ac})\overline{D}_b\lambda_\Phi + 3\lambda_\Phi(\hat{\Phi}_b\overline{D}_a\hat{\Phi}_c - \hat{\Phi}_a\overline{D}_b\hat{\Phi}_c) \\ &\quad = \overline{\lambda}(\Phi^d\Phi_d)^{1/2}(\hat{\Phi}_b\Lambda_{ac} - \hat{\Phi}_a\Lambda_{bc}),\end{aligned} \tag{10a}$$

where, in arriving at the above results, use of the following easily verifiable relation obtained from (9b) has been made:

$$\overline{D}_a\hat{\Phi}_b=\lambda_\Phi\frac{\hat{\Phi}_a\hat{\Phi}_b-\Lambda_{ab}}{(\Phi^c\Phi_c)^{1/2}}. \tag{10b}$$

Substituting (9a) in (8a) it follows that the right-hand side of the latter is identically zero and thus necessarily Λ is locally conformally flat. Consistency would require $\overline{D}_a\overline{R}_{cb}-\overline{D}_c\overline{R}_{ab}=0$ and this relation demands that the ''eigenvalue'' $\overline{\lambda}$, Φ_a, and Λ_{ab} ought to satisfy

$$\overline{R}_{abc}\equiv(3\hat{\Phi}_c\hat{\Phi}_a-\Lambda_{ca})\overline{D}_b\overline{\lambda}-(3\hat{\Phi}_b\hat{\Phi}_a-\Lambda_{ba})\overline{D}_c\overline{\lambda}+3\overline{\lambda}(\hat{\Phi}_c\overline{D}_b\hat{\Phi}_a-\hat{\Phi}_b\overline{D}_c\hat{\Phi}_a)=0. \tag{10c}$$

Relations (10a) and (10c) constitute a set of tensorial consistency relations required to be satisfied by λ_Φ, $\overline{\lambda}$, $\overline{D}_a\Phi$ as well as Λ_{ab}. Indeed, starting from (10c) and after contracting it with $\hat{\Phi}^b$ we find

$$\overline{R}_{abc}\hat{\Phi}^a\equiv 2(\hat{\Phi}_c\overline{D}_b\overline{\lambda}-\hat{\Phi}_b\overline{D}_c\overline{\lambda})=0. \tag{11a}$$

Utilizing this relation back in R_{abc} we obtain

$$\overline{R}_{abc}\equiv\Lambda_{ba}\overline{D}_c\overline{\lambda}-\Lambda_{ca}\overline{D}_b\overline{\lambda}+3\overline{\lambda}(\hat{\Phi}_c\overline{D}_b\hat{\Phi}_a-\hat{\Phi}_b\overline{D}_c\hat{\Phi}_a)=0. \tag{11b}$$

Forming now $\overline{R}_{abc}\Lambda^{ab}$ it yields

$$\overline{R}_{abc}\Lambda^{ab}\equiv 2\overline{D}_c\overline{\lambda}+3\overline{\lambda}\hat{\Phi}_c\overline{D}^b\hat{\Phi}_b=0, \tag{11c}$$

while, on the other hand, contracting (11b) with $\hat{\Phi}^c$ we get

$$\overline{R}_{abc}\hat{\Phi}^c\equiv\Lambda_{ba}\hat{\Phi}^c\overline{D}_c\overline{\lambda}-\hat{\Phi}_a\overline{D}_b\overline{\lambda}+3\overline{\lambda}\overline{D}_b\hat{\Phi}_a=0, \tag{11d}$$

where in arriving at the above equation use of the fact that $\hat{\Phi}^a$ is a unit geodesic field has been made a conclusion that follows directly from (10b). Although in this and the next section we shall not make use of (11b), nevertheless it is an important relation and its significance will become clear in Sec. VI. Contacting (11c) with any arbitrary smooth vector field Y perpendicular to $\hat{\Phi}^c$ yields

$$\overline{R}_{abc}\Lambda^{ab}Y^c\equiv 2Y^c\overline{D}_c\overline{\lambda}=0, \tag{12a}$$

a relation implying that the gradient of $\overline{\lambda}$ is parallel to Φ^a. On the other hand, forming $\overline{R}_{abc}\Lambda^{ab}\Phi^c$ and rearrangement yields

$$\frac{4\Phi^c\overline{D}_c\overline{\lambda}}{3\overline{\lambda}}-\frac{\Phi^a\overline{D}_a(\Phi^c\Phi_c)}{\Phi^c\Phi_c}=0, \tag{12b}$$

from which we infer

$$\Phi^c\overline{D}_c\left[\log\left(\frac{\overline{\lambda}}{(\Phi^c\Phi_c)^{3/4}}\right)\right]=0. \tag{12c}$$

However, this relation yields

$$\overline{\lambda}=A^2(\Phi^c\Phi_c)^{3/4}, \tag{12d}$$

and A^2 a nonvanishing function constant along the integral curves of $\Phi^c\partial/\partial x^c$. Substituting (12d) back into (9a) and applying the contracted Bianchi identity on $\overline{R}_{ab}$ we eventually conclude with the help of (12a) that A is constant. Thus the satisfaction of the integrability conditions (10c) leads to the ''specification'' of $\overline{\lambda}$ [and thus also of λ_Φ via (9c)]. Let us now turn our attention to condition (10a). As it stands, it involves $\overline{\lambda}$ and λ_Φ, but eliminating λ_Φ using (9c) and straightfor-

ward but long algebra shows that (10a) reduces to (9a). Accordingly, satisfaction of (10a) and (9c) implies satisfaction of (9a). Notice, however, if condition (9c) is not *a priori* imposed, then (10a) yields the following differential constraint relating $\overline{\lambda}$ and λ_Φ:

$$2\Phi^a \overline{D}_a \lambda_\Phi - 6\lambda_\Phi^2 = 2\overline{\lambda}(\Phi^c \Phi_c). \tag{13}$$

This constraint implies that not every solution of (9a) and (9b) is necessarily a solution of (7a) and (7b), but rather, and as we have discussed above, only those solutions of (9a) and (9b) subject additionally to satisfaction of (9c) are solutions of (7a) and (7b). Of course (9c) satisfies (13) as it can easily verified.

Thus the analysis of the integrability conditions (10a) and (10c) leads us to the following problem: Construct all (Λ,Φ) satisfying in the vicinity of the $\Phi=1$ equipotential surface the following equations:

$$\overline{R}_{ab} = A^2(\Phi^c \Phi_c)^{3/4}(3\hat{\Phi}_a \hat{\Phi}_b - \Lambda_{ab}), \tag{14a}$$

$$\overline{D}_a \overline{D}_b \Phi = \frac{1}{2\Phi}(\Phi^c \Phi_c - (1-\Phi^2)A^2(\Phi^c \Phi_c)^{3/4})(3\hat{\Phi}_a \hat{\Phi}_b - \Lambda_{ab}). \tag{14b}$$

Accordingly, the problem of the existence and properties of degenerate solutions of (7a) and (7b) is now shifted in constructing solutions of the above regular effective system of equations characterized by the property that the level surface (or surfaces) defined by $\Phi=1$ are regular two-surfaces. Here the relatively ''simple'' structure of the effective system (14a) and (14b) is mainly due to the special choice of Ricci shown in (9a). In latter sections we shall move away from metrics obeying (9a) but still characterized by a degenerate Ricci. Again we shall construct an effective system of equations but the latter system would be much more complex in comparison to (14a) and (14b). For the moment we turn our attention to the integration of the system (14a) and (14b).

III. THE LOCAL BEHAVIOR OF GEOMETRY AND FIELD NEAR $\Phi=1$

The construction of all Riemannian metrics and fields satisfying (14a) and (14b) is not a trivial task since this system is a set of partial differential equations and at this point no spatial symmetries have been imposed (and, in fact, will not be imposed). Nevertheless, we shall be able to integrate it thanks to the insights furnished by the integrability conditions exploited in the previous section. At first (14b), or equivalently (10b) coupled with the regular nature of the $\Phi=1$ surface, implies that the components of the extrinsic curvature of the family of two-surfaces $\Phi=c$, $c \in (1-\epsilon,1+\epsilon)$, are proportional to their intrinsic two-metric $\gamma^{(2)}$ and that is an important insight. In order to take advantage of it, we shall cast Eqs. (14a) and (14b) into an equivalent first-order system describing the ''evolution'' of the intrinsic metric $\gamma^{(2)}$ and components of the extrinsic curvature K across the equipotential surfaces. Such a procedure is best performed by employing Israel's coordinates[30] adapted to the present situation. Such coordinates are well defined once considerations are constricted to solutions obeying condition (b) of Sec. II. Under that assumption, the equipotential surface $\Phi=1$ is a regular two-space and this coupled with the minimally C^3 assumption on Φ, it follows that $\overline{D}_a\Phi$ is nonvanishing in a local vicinity of $\Phi=1$ equipotential surface. Accordingly, the vector field $n=n^a\partial/\partial x^a=\hat{\Phi}^a\partial/\partial x^a$ ''normal'' to $\Phi=c$, $c\in(1-\epsilon,1+\epsilon)$ is nonsingular for some $\epsilon>0$. Let now (θ^1,θ^2) be arbitrary local coordinates on the $\Phi=1$ surface. Israel's coordinates are constructed by first extending (θ^1,θ^2) of the $\Phi=1$ surface by Lie dragging, them along the integral curves of the ''normal'' field, i.e., $n^a\partial\theta^i/\partial x^a=0$, $i=1,2$. We augment (θ^1,θ^2) by taking as a third coordinate the value of the scalar field Φ viewed as parametrizing the family of the equipotential surfaces. The set (Φ,θ^1,θ^2) provides a local coordinazation of an open vicinity of the $\Phi=1$ surface and, relative to such coordinates, the metric can be written in the form

$$ds^2=\frac{d\Phi^2}{\Phi^a\Phi_a}+\gamma^{(2)}_{ij}d\theta^i d\theta^j=\frac{d\Phi^2}{S^2(\Phi,\theta^1,\theta^2)}+\gamma_{ij}(\Phi,\theta^1,\theta^2)d\theta^i d\theta^j, \tag{15a}$$

where hereafter γ_{ij} stands for the intrinsic metric of the $\Phi=\text{const}$ two-surfaces. Relative to those coordinates, the components of the extrinsic curvature or second fundamental form K_{ij} are given by[1]

$$K_{ij}=\frac{1}{2}L_n\gamma_{ij}=\frac{1}{2}(\Phi^a\Phi_a)^{1/2}\frac{\partial\gamma_{ij}}{\partial\Phi}=\frac{1}{2}S\frac{\partial\gamma_{ij}}{\partial\Phi}. \tag{15b}$$

Projecting Eq. (14a) along the normal and perpendicular directions to the $\Phi=\text{const}$ two-surfaces, we lead into

$$-R^{(2)}-K^{ij}K_{ij}+K^2=4A^2S^{3/2}, \tag{16a}$$

$$D_iK-D_jK^j{}_i=0, \tag{16b}$$

$$-S\frac{\partial K_{ij}}{\partial\Phi}+2K_{il}K^l{}_j-KK_{ij}+\frac{1}{2}R^{(2)}\gamma_{ij}+\frac{1}{S}D_iD_jS-\frac{2}{S^2}D_iSD_jS=-A^2S^{3/2}\gamma_{ij}, \tag{16c}$$

$$\frac{1}{2}S\frac{\partial\gamma_{ij}}{\partial\Phi}=K_{ij}, \tag{16d}$$

$$\frac{\partial S}{\partial\Phi}+K=0, \tag{16e}$$

where in the above $R^{(2)}$ is the scalar curvature of the $\Phi=c$, $c\in(1-\epsilon,1+\epsilon)$ two-surfaces. Equations (16a)–(16e) constitute a complete set of equations describing the ''evolution'' of (γ_{ij},K_{ij}) along the family of $\Phi=c$, $c\in(1-\epsilon,1+\epsilon)$ surfaces. Equations (16a) and (16b) are the ''Hamiltonian'' and ''momentum'' constraint, respectively, while Eqs. (16d) and (16c) are the ''evolution'' equation for (γ_{ij},K_{ij}). Equation (16e) stands for the $(2+1)$ content of $\overline{D}^a\overline{D}_a\Phi=0$.

Our task is now shifted to the integration of the system (16a)–(16e). We shall first satisfy the ''Hamiltonian'' and ''momentum'' constraints and then move into the evolution equations. To start with we recall that Eq. (10b) or equivalently (14b) implies that $\overline{D}_a\hat{\Phi}_b=-\lambda_\Phi\gamma_{ab}/S$ and, in view of the fact that $\hat{\Phi}=[1/(\Phi^a\Phi_a)^{1/2}]d\Phi=n_\Phi d\Phi$ is the field of the unit normals of the $\Phi=c$, $c\in(1-\epsilon,1+\epsilon)$, it follows that relative to the (Φ,θ^1,θ^2) coordinates, the components of K_{ij} are also given by

$$K_{ij}=\overline{D}_i\hat{\Phi}_j=-\frac{\lambda_\Phi\gamma_{ij}}{S}=-\frac{1}{2}\frac{\partial S}{\partial\Phi}\gamma_{ij}, \tag{17a}$$

where in passing to the second equality use of (10b) has been made which, via the relation $(\partial/\partial\Phi)\equiv(\Phi^a/\Phi^b\Phi_b)(\partial/\partial x^a)$, leads to the following string of useful equalities:

$$\lambda_\Phi=\frac{1}{2}\hat{\Phi}^a\hat{\Phi}^b\overline{D}_a\overline{D}_b\Phi=\frac{\Phi^a\Phi^b}{2S^2}\overline{D}_a\overline{D}_b\Phi=\frac{1}{4}\Phi^aD_a(\log S^2)=\frac{1}{4}\frac{\partial S^2}{\partial\Phi}=\frac{1}{2}S\frac{\partial S}{\partial\Phi}. \tag{17b}$$

Substituting the right-hand side of (17a) in the ''momentum constraint'' (16b) it follows that $S(\Phi,\theta^1,\theta^2)$ satisfies

$$\frac{\partial^2S}{\partial\theta^i\partial\Phi}=0. \tag{18a}$$

This equation can be satisfied by any S of the form $S(\Phi,\theta^1,\theta^2)=f(\Phi)+g(\theta^1)+h(\theta^2)$. However, using the fact that $S=(\Phi^a\Phi_a)^{1/2}=(\overline{\lambda}/A^2)^{2/3}$ and appealing to the content of (12a) by identifying Y with $(\partial/\partial\theta^1),(\partial/\partial\theta^2)$, respectively, it follows immediately that

$$\frac{\partial S}{\partial\theta^1}=\frac{\partial S}{\partial\theta^2}=0, \tag{18b}$$

and thus $S=S(\Phi)$ alone, a conclusion of extreme importance. Taking now the trace part of the evolution equation (16c) combined with the ''Hamiltonian constraint'' we lead into

$$-S\frac{d^2S}{d\Phi^2}+\frac{1}{2}\left(\frac{dS}{d\Phi}\right)^2+2A^2S^{3/2}=0, \tag{18c}$$

$$R^{(2)}=K^2+S\frac{\partial K}{\partial\Phi}-2A^2S^{3/2}, \tag{18d}$$

but now (18d) coupled with the fact that A^2 is a constant implies that $R^{(2)}$ is a function only of Φ and thus the Gaussian curvature $G=\frac{1}{2}R^{(2)}$ of any $\Phi=\text{const}$ surface is constant in the sense $R^{(2)}=R^{(2)}(\Phi)$ and this is a second important conclusion. On the other hand, the integration of (18c) yields

$$S(\Phi)=\left(\frac{A^2}{2}\Phi^2+C_1\Phi+C_2\right)^2, \tag{18e}$$

where C_1 and C_2 are arbitrary integration constants. The components of the intrinsic metric γ_{ij} are computed by taking into account that, on the one hand, $K_{ij}=-\frac{1}{2}(\partial S/\partial\Phi)\gamma_{ij}$ while on the other hand from (15b), $K_{ij}=1/2S\partial\gamma_{ij}/\partial\Phi$. It follows from those two equations that $\partial(\gamma_{ij}S)/\partial\Phi=0$, implying further the following expression for the components of the two-metric:

$$\gamma_{ij}=\frac{B}{S(\Phi)}\hat{\gamma}_{ij}, \tag{18f}$$

where B is an arbitrary nonvanishing integration constant and we have taken $\hat{\gamma}_{ij}$ to be a two-Riemannian metric of constant Gaussian curvature $G=(\pm1,0)$. Since two-dimensional spaces of constant Gaussian curvature are locally isometric to a two-Euclidean plane, two-sphere, and the Lobachevsky plane, respectively,[31] there exist local canonical coordinates $(\hat{x}^1,\hat{x}^1)$ such that $\hat{\gamma}_{ij}$ on any $\Phi=\text{const}$ surface can be written in the standard form:

$$ds^2_{(2)}=(d\hat{x}^1)^2+\Sigma^2(\hat{x}^1)(d\hat{x}^2)^2, \tag{18g}$$

with $(\Sigma^2(\hat{x})=\sin^2(\hat{x}),\sinh^2(\hat{x}),1)$ for the case that G equals to $(1,-1,0)$ respectively. With the help of (18f) and the form of $S(\Phi)$ shown in (18e), it follows that the trace-free part of the evolution equations (16c) is identically satisfied. On the other hand, (16e) by virtue of the first and last equalities in (17a) is identically satisfied while requiring equality between the last two expressions requires that (18e) has to satisfy

$$\frac{1}{2}\frac{\partial S}{\partial\Phi}=\frac{\lambda_\Phi}{S}=\frac{2S-(1-\Phi^2)A^2S^{1/2}}{2\Phi}, \tag{18h}$$

and this yields an identity provided $C_2=A^2/2$. Thus eventually $S(\Phi)$ reduces to

$$S(\Phi)=\left(\frac{A^2}{2}\Phi^2+C\Phi+\frac{A^2}{2}\right)^2. \tag{18i}$$

From (18f) it follows that the scalar curvature $R^{(2)}$ of any $\Phi=\text{const}$ surface is given by $R^{(2)}=\pm 2S(\Phi)/B$ and zero, respectively, while use of (18i) in Eq. (18d) gives $R^{(2)}=2S(\Phi)\times(C^2;A^4)$. Consistency of those two expressions fixes a relation between the free parameters $C^2;A^4$ and B. The relation $B=(C^2-A^4)^{-1}>0$ leads to a three-metric relative to which the family of $\Phi=c,\ c\in(1-\epsilon,1+\epsilon)$, equipotential surfaces possess positive Gaussian curvature, while the relations $B=(A^4-C^2)^{-1}>0$, $C^2=A^4$, furnishes metrics where the $\Phi=c,\ c\in(1-\epsilon,1+\epsilon)$, surfaces posses negative and zero curvature, respectively. In summary, therefore, all three metrics Λ satisfying (14a) are given by

$$ds^2=\frac{d\Phi^2}{S(\Phi)^2}+\frac{B}{S(\Phi)}[(dx^1)^2+\Sigma^2(x^1)(dx^2)^2],\quad \Phi\in(1-c,1+c),\ \ c>0, \tag{19a}$$

with $S(\Phi)$ given by (18i) and the constant B is paired to the specific form of $\Sigma(x)$ according to

$$(B=(C^2-A^4)^{-1}>0,\quad \Sigma(x)=\sin x);$$

$$(B=(A^4-C^2)^{-1}>0,\quad \Sigma(x)=\sinh x);\quad (B=1,\ C^2=A^4,\Sigma(x)=1). \tag{19b}$$

As an overall check, the scalar curvature of (19a) for all choices implied by (19b) is identically zero, while a computation of Ricci and $\overline{D}_a\overline{D}_b\Phi$ returns us back (14a) and (14b) as it should be. Notice hereafter we shall disregard the metrics with plane orbits obtained by taking $C=-A^2$ in (19b). Such solutions satisfy $\lim_{\Phi\to 1}\overline{D}^a\Phi\overline{D}_a\Phi=0$, and although they are interesting, their analysis will get us away from the main focus of this article.

The metrics defined by (18g) admit a three-parameters group of isometries acting on any $\Phi=\text{const}$ two-surfaces and if, $\xi_{(i)}$, $i=1,2,3$, stand for the corresponding Killing vectors, they satisfy the following algebra:

$$[\xi_i,\xi_j]=\varepsilon_{ijk}\xi_k,\quad G=1,$$

$$[\xi_1,\xi_2]=\xi_3,\quad [\xi_2,\xi_3]=\xi_1,\quad [\xi_3,\xi_1]=\xi_2,\quad G=-1,$$

$$[\xi_1,\xi_2]=\xi_3,\quad [\xi_2,\xi_3]=\xi_1,\quad [\xi_3,\xi_1]=0,\quad G=0.$$

Because of (18f) and (18i), it is clear that the above Killing vectors generate a local three-parameter Lie group of isometries $G(3)$ for the full three-metric (19a). Thus we arrive at the conclusion that all solutions of (14a) and (14b) necessarily admit a local $G(3)$ group of isometries possessing two-dimensional orbits of constant Gaussian curvature identified with the equipotential $\Phi=c,\ c\in(1-\epsilon,1+\epsilon)$, two-surfaces.[32]

The corresponding space–time metrics can be easily constructed. In fact, it is convenient to express them relative to the same spatial coordinate chart (Φ,θ^1,θ^2) augmented with the Killing parameter taken as the timelike coordinate.[32] Relative to such coordinates they take the following form:

$$ds^2=-\frac{dt^2}{(1+\Phi)^2}+\frac{(1+\Phi)^2}{S(\Phi)}\left(\frac{d\Phi^2}{S(\Phi)}+Bds^2_{(2)}\right),\quad \Phi\in(1-c,1+c),\ \ c>0, \tag{20}$$

where $S(\Phi)$ and $ds^2_{(2)}$ are given by (18i) and (18g), respectively. It can be verified that Φ is a harmonic coordinate relative to the above space–time metric, i.e., $\nabla^a\nabla_a\Phi=0$ and the above metrics combined with (6b) satisfy (4a)–(4c).

Before we analyze their properties, let us for the moment consider the special case where the scalar $\overline{\lambda}$ defined in (9a) is assumed to be identically vanishing in the open vicinity of $\Phi=1$. In that event Eq. (9c) fixes λ_Φ to

$$\lambda_\Phi = \frac{\Phi^a \Phi_a}{\Phi},$$

and thus the conformal system leads (7a) and (7b) to the following effective set of equations:

$$R_{ab} = 0, \tag{21a}$$

$$\overline{D}_a \overline{D}_b \Phi = \frac{\Phi^c \Phi_c}{\Phi}(3\hat{\Phi}_a \hat{\Phi}_b - \Lambda_{ab}). \tag{21b}$$

This system can be integrated by applying the same technique used for (14a) and (14b). Because of (21a) the constraint (10c) is trivially satisfied while a substitution of the value of λ_Φ in (10a) yields also an identity. The $2+1$ splitting of (21a) yields a set of equations obtained directly from (16a)–(16e) by setting $A=0$, while from (21b) one obtains

$$\overline{D}_a \hat{\Phi}_b = \frac{\Phi^c \Phi_c}{\Phi} \frac{(\hat{\Phi}_a \hat{\Phi}_b - \Lambda_{ab})}{(\Phi_c \Phi^c)^{1/2}} = \frac{(\Phi^c \Phi_c)^{1/2}}{\Phi}(\hat{\Phi}_a \hat{\Phi}_b - \Lambda_{ab}).$$

Following identical steps as that carried out in the integration of (14a) and (14b), one now gets in the place of (18c) and (18d)

$$-S\frac{d^2 S}{d\Phi^2} + \frac{1}{2}\left(\frac{dS}{d\Phi}\right)^2 = 0, \tag{22a}$$

$$R^{(2)} = K^2 + S\frac{\partial K}{\partial \Phi}. \tag{22b}$$

Equation (22a) implies

$$S(\Phi) = (C^2 \Phi + C_1)^2, \tag{23a}$$

and the analog of (18h) for the present system requires the above $S(\Phi)$ ought to satisfy

$$\frac{1}{2}\frac{\partial S}{\partial \Phi} = \frac{\lambda_\Phi}{S} = \frac{\Phi^a \Phi_a}{S\Phi} = \frac{S}{\Phi}, \tag{23b}$$

which is the case, provided $C_1 = 0$. However, now $S(\Phi)$ reduces to $S(\Phi) = C^4 \Phi^2$, where we have to rename the integration constant, and in turn (22b) implies

$$R^{(2)} = 2C^4 S(\Phi).$$

Thus for every solution of (21a) and (21b) the $\Phi = c$, $c \in (1-c, 1+c)$, two-spaces are spaces of positive Gaussian curvature. Notice that $C=0$ implies $\overline{D}_a \Phi = 0$, a case excluded by choice. For $S(\Phi) = C^4 \Phi^2$, Eq. (15a) implies that the solution may be written in the form

$$ds^2 = \frac{d\Phi^2}{C^8 \Phi^4} + \frac{1}{C^8 \Phi^2}(d\theta^2 + \sin^2\theta d\phi^2), \tag{24a}$$

yielding the following space–time metric:

$$ds^2 = -\frac{dt}{(1+\Phi)^2} + \frac{(1+\Phi)^2}{C^8 \Phi^4} d\Phi^2 + \frac{(1+\Phi)^2}{C^8 \Phi^2}(d\theta^2 + \sin^2\theta d\phi^2). \tag{24b}$$

Introducing a new coordinate r via $r^2 = (1/C^8)[(1+\Phi)^2/\Phi^2]$, then (24b) can be written in the form

$$ds^2=-\left(1-\frac{r_0}{r}\right)^2 dt^2+\left(1-\frac{r_o}{r}\right)^{-2} dr^2+r^2(d\theta^2+\sin^2\theta d\phi^2),$$

$$\Phi=\frac{r_o}{r-r_o}, \quad r_0=\pm\frac{1}{C^4}, \tag{24c}$$

but this is the solution (2a) and (2b) discussed earlier on, originally discovered by Bekenstein[2,3] and also by Bocharova *et al.* (Ref. 4), rederived in Ref. 6 and analyzed further in Ref. 12. We may add parenthetically that the metrics (2c) and (2d) discussed earlier on, cannot be reached via the techniques of this section. Such metrics satisfy $\bar{R}\neq 0$ (in fact $\bar{R}$ diverges as $\Phi=1$) and thus via Eqs. (5) and (6) are automatically excluded from the present considerations.

Finally, for completeness, let us also examine an intermediate case, i.e., the case where the scalar $\bar{\lambda}$ in (9a) is a nonzero constant. In that event the contracting Bianchi identity applied to (9a) implies $\bar{D}^a\bar{R}_{ab}=6\bar{\lambda}\lambda_\Phi(\bar{D}^a\Phi\bar{D}_a\Phi)^{-1/2}\hat{\Phi}_b$ and thus necessarily $\bar{\lambda}\lambda_\Phi=0$. The case $\bar{\lambda}=0$ has been examined above, while the case $\lambda_\Phi=0$ and $\bar{\lambda}\neq 0$ implies via (9b) that $\bar{D}_a\bar{D}_b\Phi=0$. The contracted Ricci identity applied to $\bar{D}_a\Phi$ yields $\bar{D}^a\bar{D}_a\bar{D}_b\Phi=\bar{R}_{ab}\bar{D}^a\Phi+\bar{D}_b(\bar{D}^a\bar{D}_a\Phi)$, from which we obtain $\bar{R}_{ab}\bar{D}^b\Phi=0$, requiring in turn $\bar{\lambda}=0$. Notice that imposing simultaneously $\bar{\lambda}=0$ and $\lambda_\Phi=0$, then (9c) requires $\bar{D}^a\Phi\bar{D}_a\Phi=0$, i.e., $\bar{D}_a\Phi$ vanishes in the local vicinity of $\Phi=1$ and thus $\Phi=$const. This case, however, has been excluded by choice and one expects all solutions to be vacuum solutions.

In summary we have constructed four classes of nontrivial solutions of the conformal system obeying conditions (a) and (b) and satisfying $1-\Phi^2=0$ within the region covered by the Killing chart. In Sec. V we shall establish their regular nature in the vicinity of the degeneracy, i.e., along and across the $\Phi^2=1$ two-surface. Those solutions are highly symmetric, admitting a local $G(3)$ group of isometries possessing two-dimensional orbits of constant Gaussian curvature, and this striking property needs further elaboration. What is the origin of those local isometries? Is there something special in the structure of (7a) and (7b) that dictates this high degree of symmetry on its solutions, or they are artifacts of the special form of the Ricci employed in (9a)? Do solutions of other degenerate system of equations exhibit such property? In the upcoming sections we shall attempt to provide some insights in the above interrelated questions. We shall do so by comparing properties of solutions of (7a) and (7b) to solutions of a distinct degenerate system of equations. This latter degenerate system of equations is provided by the Einstein' vacuum equations. The two systems exhibit structural similarities and, due to the fact that static solutions of Einstein vacuum equation have been studied for a longer period of time, this comparison offers complementary insights.

IV. STATIC, VACUUM, DEGENERATE SOLUTIONS

In accordance with the above plan, in this section, we shall briefly recall a few aspects of Einstein vacuum equations that will be useful in the sequel. We consider a space–time manifold (M,g), with M a C^k, for some integer k, $k\geqslant 4$, connected, orientable, and paracompact manifold and g a minimally C^3 solution of Einsteins vacuum equations admitting a timelike, hypersurface orthogonal, Killing vector field ξ. Utilizing the timelike and hypersurface orthogonal property of ξ, local Killing coordinates can be employed so that the metric can be written in the form (3a). Relative to such coordinates, Eqs. (3b)–(3d) with $\Phi=0$ yield the effective Einstein vacuum equations

$$VR_{ab}=D_aD_bV, \tag{25a}$$

$$D^aD_aV=0, \tag{25b}$$

where $V^2=-\xi^\mu\xi_\mu$, and γ stands for a positive definite metric, on each $t=$const local coordinate slice. For our purpose, we shall view the above equations as defined on a smooth, orientable,

connected, and paracompact three-dimensional manifold Σ. A triplet then (Σ,γ,V), with (γ,V) satisfying (25a) and (25b), V a positive function on Σ and γ a Riemannian metric, gives rise to four-dimensional Ricci flat solutions of Einstein's vacuum equations. As is well known, (25a) and (25b) does not admit nonflat solutions on any closed manifold Σ. Moreover, a classical theorem due to Lichnerowicz[33] asserts that if (Σ,γ) is complete and $V\to 1$ at infinity, then necessarily $V=1$ everywhere and Σ is the standard R^3 with the flat metric or quotients of R^3 by discrete isometry groups (for a recent derivation of Lichnerowicz theorem under weaker conditions, see the work in Ref. 34). Thus nontrivial solutions (γ,V) of (25a) and (25b) require Σ to be on open manifold possessing nontrivial metric boundary $\dot{\Sigma}$ defined by $\dot{\Sigma}=\bar{\Sigma}-\Sigma$ where $\bar{\Sigma}$ is the Cauchy completion of Σ. Solution (Σ,γ,V), which cannot be extended into a larger domain Σ' consistent with $V>0$, possesses a metric boundary $\dot{\Sigma}$ that may contain nonempty components where $V=0$. Following the terminology in Ref. 34 we designate hereafter this part of $\dot{\Sigma}$ by S and refer to it as the "horizon" associated with the particular solution (Σ,γ,V). If nonempty, it may contain several disconnected components and some of them may even be noncompact. For our purpose we shall be interested in examining solutions (Σ,γ,V) that possess a nonempty S and moreover, (γ,V) extends smoothly up to and including S. In particular, we shall look for solutions subject to the condition that all geometrical scalars are bounded as the "horizon" S is approached and hereafter such solutions, if they exist, will be referred to as a regular in the "open vicinity" of $V=0$. Such solutions will obey $D_aV\neq 0$ on S (Ref. 35) and thus a local vicinity of S can be "foliated" by a sequence of $V=c$, $c\in(0,c)$, $c>0$ equipotential surfaces much the same way as the $\Phi=c$, $c\in(1-\epsilon,1+\epsilon)$, $\epsilon>0$ equipotential surfaces foliate the local vicinity of $\Phi=1$. Moreover, if such solutions exist then by considering any sequence of points in Σ with a limit point on S, the system (25a) and (25b) degenerates on any (γ,V) as the "horizon" S is approached. However, such behavior is also exhibited by the conformal Eqs. (7a) and (7b) as well. If (Λ,Φ) is any solution of (7a) and (7b) satisfying $\Phi>1$, then by considering any sequence of points in the vicinity of $\Phi=c$, $c\in(1,1+\epsilon)$, $\epsilon>0$, and having a limit point on $\Phi=1$, then (7a) and (7b) degenerates along such sequence [although such solutions can be extended as solutions of (7a) and (7b) to a larger domain]. From this viewpoint, the (regular) "horizon" S plays an identical role as the (regular) $\Phi=1$ equipotential surface played in the analysis of regular solutions of the conformal system. Besides this degeneracy aspect, both (25a) and (25b), respectively, (7a) and (7b) contain the second derivatives of the V, respectively, Φ, and as we shall shortly see that is of crucial importance. A minor difference between the two is due to the fact that the right-hand side of (7a) contains additionally the gradient of Φ. Below we shall access the significance of that gradient, but it ought to be stressed that as far as the structure of the equations is concerned, this gradient is insignificant. The crucial structural similarities between the two systems lies in the factors V, respectively $(1-\Phi^2)$ multiplying the highest-order derivatives in the field equations as well as the presence of the second derivatives of V, respectively, Φ, on their right-hand sides. Those two properties are responsible for many common properties shared by corresponding solutions of the two systems.

In the previous section we have seen that solutions of the conformal system possessing a degenerate Ricci and regular in the open vicinity of $\Phi=1$ equipotential surface necessarily possesses an additional local $G(3)$ group of isometries. Due to the similarities between the conformal and vacuo system discussed above it is natural to inquire first whether the vacuo system (25a) and (25b) admits degenerate solutions (γ,V) smooth up to and including the horizon and second, whether such solutions, if they exist, exhibit similar properties to those of the conformal system. Thus we shall look for solutions (γ,V) of (25a) and (25b) subject to the condition that the Ricci tensor of γ is given by [compare to (9a)]

$$R_{ab}=\lambda(3\hat{V}_a\hat{V}_b-\gamma_{ab}), \tag{26a}$$

where $\hat{V}^a\equiv V^a/(V^bV_b)^{1/2}$ and λ is minimally a C^1 function of the local coordinates. Such a Ricci implies via (25a)

$$D_aD_bV=V\lambda(3\hat{V}_a\hat{V}_b-\gamma_{ab})=\lambda_V(3\hat{V}_a\hat{V}_b-\gamma_{ab}). \tag{26b}$$

Moreover, it is rather easy to show that any solution (γ,V) of (25a) and (25b) possesses a York–Cotton tensor R_{abc} satisfying

$$VR_{abc}=2R_{ba}V_c-2R_{ca}V_b+\gamma_{ba}R_{cd}V^d-\gamma_{ca}R_{bd}V^d, \tag{27}$$

a relation which is the analog of Eq. (8a) for the conformal system. Substituting the right-hand side of (26a) in (27) it follows immediately that $R_{abc}=0$. By arguments similar to the conformal case it follows that the analogs to Eqs. (10a) and (10c) are for the present case given by

$$\begin{aligned}&(3\hat{V}_b\hat{V}_c-\gamma_{bc})D_a\lambda_V-(3\hat{V}_a\hat{V}_c-\gamma_{ac})D_b\lambda_V+3\lambda_V(\hat{V}_bD_a\hat{V}_c-\hat{V}_aD_b\hat{V}_c)\\&\quad=\lambda(V_aV^a)^{1/2}[\gamma_{ac}\hat{V}_b-\gamma_{bc}\hat{V}_a],\end{aligned} \tag{28a}$$

$$R_{abc}\equiv(3\hat{V}_c\hat{V}_a-\gamma_{ca})D_b\lambda-(3\hat{V}_b\hat{V}_a-\gamma_{ba})D_c\lambda+3\lambda(\hat{V}_cD_b\hat{V}_a-\hat{V}_bD_c\hat{V}_a)=0. \tag{28b}$$

As long as $\lambda_V=\lambda V$ it follows that satisfaction of (28b) implies satisfaction of (28a) and similar arguments as those used in the previous section leads us into a set of equations analogous to (11a)–(11d) with the sole exception that $\hat{\Phi}_a$ is replaced by $\hat{V}_a$. Thus contracting (28b) with $\gamma^{ac}V^b$ it follows again that

$$V^aD_a[\log(\lambda(V^bV_b)^{-3/4})]=0, \tag{29a}$$

implying $\lambda=A^2(V^bV_b)^{3/4}$. Imposing further the contracted Bianchi identity to (26a), it implies eventually that A^2 is a constant. Thus we lead into the following set of effective equations describing in the open vicinity of $V=0$, vacuo solutions possessing a degenerate Ricci:

$$R_{ab}=A^2(V^bV_b)^{3/4}(3\hat{V}_a\hat{V}_b-\gamma_{ab}), \tag{30a}$$

$$D_aD_bV=A^2V(V^bV_b)^{3/4}(3\hat{V}_a\hat{V}_b-\gamma_{ab}),\quad V\in(0,\epsilon),\quad \epsilon>0. \tag{30b}$$

Obviously this system is identical in structure to that of (14a) and (14b). As a consequence the integration of (30a) and (30b) proceeds in parallel to the method employed for (14a) and (14b) and thus we shall be rather sketchy. The fact that a vicinity of $V=0$ is characterized by the absence of critical points of V allows us to introduce again Israel coordinates.[30] In fact Israel in the original 1967 paper introduced those coordinates precisely to analyze solutions of (25a) and (25b) without, of course, imposing conditions (26a). Thus we shall write locally the metric in the form (15a) with the sole exception that $\Phi^a\Phi_a$ is replaced by V^aV_a. Projecting (30a) and (30b) along the $V=$const two-surface we lead into the system analogous to (16a) where (V,D_aV) replaces $(\Phi,\overline{D}_a\Phi)$ and in (15a) it is now understood that $S(V,\theta^1,\theta^2)$. Applying the same steps that lead us into (18c) and (18d), one now gets

$$S(V)=\left(\frac{A^2}{2}V^2+C_1V+C_2\right)^2.$$

However, since the components of the extrinsic curvature of the $V=$const surfaces are different than the $\Phi=$const surfaces, indeed are given by $K_{ij}=-A^2VS^{1/2}\gamma_{ij}$ [compare to (17a)], it follows now that (18h) rewritten for the present case requires that $C_1=0$, implying that

$$S(V)=\left(\frac{A^2}{2}V^2+C\right)^2. \tag{30c}$$

Completing the integration procedure of (30a) and (30b) we are led to the following three classes of vacuum metric, the analogs of (19a) and (19b) for the conformal case:

$$ds^2=\frac{dV^2}{S(V)^2}+\frac{1}{BS(V)}[(dx^1)^2+\Sigma^2(x^1)(dx^2)^2], \tag{31a}$$

$$B=-2A^2C, \quad C<0, \quad \Sigma(x)=\sin x;$$

$$B=2A^2C, \quad C>0, \quad \Sigma(x)=\sinh x; \quad B=1, \quad C=0, \quad \Sigma(x)=1. \tag{31b}$$

However, it is clear that those solutions exhibit identical symmetry properties as those of the conformal system (7a) and (7b). Indeed, they admit a local $G(3)$ group of isometries possessing two-dimensional orbits of constant Gaussian curvature coinciding with the $V=c$, $c\in(0,\epsilon)$ equipotential surfaces. The corresponding algebra of the infinitesimal generators is identical to the corresponding algebra obeyed by the conformal solutions. Before we continue it is worthwhile to consider the associated space–time metrics. Using (31a), it follows that corresponding space–time metrics are given by

$$ds^2=-V^2dt^2+\frac{dV^2}{S(V)^2}+\frac{1}{BS(V)}[dx^{1^2}+\Sigma^2(x^1)dx^{2^2}], \quad V\in(0,c), \quad c>0, \tag{31c}$$

which are the analogs of (20). Due to the relatively simple form of $S(V)$ the above metrics can be reexpressed in a different coordinate gauge. In fact, setting $S(V)=1/Br^2$ where r is an arbitrary coordinate we lead into

$$ds^2=-\left(1-\frac{2M}{r}\right)dt^2+\left(1-\frac{2M}{r}\right)^{-1}dr^2+r^2(dx^2+\sin^2 x dy^2),$$

$$2M<r<\infty, \quad \text{if } M>0 \quad \text{and} \quad 0<r<\infty, \quad \text{if } M<0, \tag{32a}$$

$$ds^2=-\left(\frac{2M}{r}-1\right)dt^2+\left(\frac{2M}{r}-1\right)^{-1}dr^2+r^2(dx^2+\sinh^2 x dy^2), \quad 0<r<2M, \tag{32b}$$

$$ds^2=-\frac{1}{r}dt^2+rdr^2+r^2(dx^2+dy^2), \quad 0<r<\infty, \tag{32c}$$

where we have defined $M=1/(2C)^{3/2}A$. For the case of (32c) the ranges of each of the (x,y) coordinates is the entire real line, while for the classes (32a) and (32b) the corresponding (x,y) ranges are the familiar ones associated with metrics of constant nonzero Gaussian curvature. The metrics (32a)–(32c) have been derived long ago by Levi–Civita[25] and much later by Ehlers and Kundt[26] with an entirely different motive and point of view than the one pursued here. Here they have been derived as the static solutions of (25a) and (25b) possessing a degenerate Ricci given by (26a) and, as we shall verify in the next sections, possessing regular ''horizon'' S. In the classification scheme of Ref. 26 they belong to the class A and we have chosen to present brief derivation here since, and as far as we are aware, their construction has not been discussed in the current literature.[36] The structure and properties of the above solutions will be compared with the class of solutions of the conformal system constructed in the previous section and this is the subject of the next section.

V. REGULARITY PROPERTIES OF THE DEGENERATE SOLUTIONS

We now briefly turn our attention to the regularity properties of the metrics constructed in the last two sections. At first, for all classes of solutions, the geometry is regular as the degenerate points of the corresponding equations are approached. Indeed from (19a) and (19b) or (32a) and (32b) one gets

$$\overline{R}^{ab}\overline{R}_{ab}=6\overline{\lambda}^2,$$

where $\overline{\lambda}$ equals $A^2S^{3/2}(\Phi)$, respectively, $A^2S^{3/2}(V)$, for the conformal respectively vacuum case, and thus their regular nature as $\Phi=1$, respectively, $V\to 0^+$, is manifest. Examining the Kretchman scalar $K=R^{\mu\nu\sigma\tau}R_{\mu\nu\sigma\tau}$ and $\hat{G}=C^{\mu\nu\sigma\tau}C_{\mu\nu\sigma\tau}$ for the corresponding four metrics (20) one obtains the following expressions:[37]

$$K=\frac{F(\Phi)}{(1+\Phi)^8},\quad \hat{G}=\frac{3(C-A^2)^2(A^2\Phi^2+2C\Phi+A^2)^6}{4(1+\Phi)^8},\quad G=1, \tag{33a}$$

$$K=\frac{F(\Phi)}{(1+\Phi)^8},\quad \hat{G}=\frac{3(C-A^2)^2(A^2\Phi^2+2C\Phi+A^2)^6}{4(1+\Phi)^8},\quad G=-1, \tag{33b}$$

$$K=\frac{3A^{16}(1+\Phi)^8}{32},\quad \hat{G}=0,\quad G=0, \tag{33c}$$

where the function $F(\Phi)$ is defined by

$$F(\Phi)=\tfrac{1}{32}[3A^4\Phi^4+4A^2(4A^2-C)\Phi^3+2(15A^4-8A^2C+2C^2)\Phi^2+4A^2(4A^2-C)\Phi$$
$$+3(9A^4-16A^2C+8C^2)](A^2\Phi^2+2C\Phi+A^2)^6 \tag{33d}$$

and satisfies $F(-1)=56(A^2-C)^8$ and $F(1)=8(23A^4-18A^2C+7C^2)(A^2+C)^6$. The corresponding invariants for the vacuum metrics (31b) and (31c) are given by

$$K=\hat{G}=\tfrac{3}{4}A^4(A^2V^2+2C)^6,\quad G=1, \tag{33e}$$

$$K=\hat{G}=\tfrac{3}{4}A^4(A^2V^2-2C)^6,\quad G=-1, \tag{33f}$$

$$K=\hat{G}=\tfrac{3}{4}A^{16}V^{12},\quad G=0. \tag{33g}$$

Expressions (33a)–(33c) imply that the space–time metrics (20) are regular across the $\Phi=1$ timelike hypersurface, while (33e)–(33g) imply regularity of the geometry as the $V=0$ null hypersurface is approached [disregarding here the case of $M<0$ in (32a)].

As it is clear from their derivations, the metrics (19a) and (19b) and thus also the space–time metrics (20) are local solutions valid within the space–time region covered by the local Killing chart. However, we may extend them maximally and consistently with the existence of the timelike Killing field, by enlarging the Φ-coordinate range, i.e., assuming $\Phi\in(-1,\infty)$ and similarly $V\in(0,\infty)$ [or possibly $V\in(0,1)$]. Let us first consider extension of (20). Disregarding the innocuous coordinate singularities associated with the local (x^1,x^2), coordinates, then for all $t\in(-\epsilon,\epsilon)$ and $\Phi\in(-1,\infty)$ the extended metrics (20) satisfy the conformal equations (1c) and (1d). The three spaces $\Phi=c$, $c\in(-1,\infty)$, are timelike hypersurfaces and, for the special case where the equipotential surfaces $\Phi=\text{const}$, $t=\text{const}$ are assumed to be complete, simply connected Riemannian two-spaces, and thus identified as either the two-sphere, hyperbolic two-space, or the Euclidean plane, respectively, then any $\Phi=c$, $c\in(-1,\infty)$, timelike hypersurface is topologically $(-\epsilon,\epsilon)\times K$ with K either a two-sphere, the hyperbolic two-space or the Euclidean two-space, respectively.[38] However, the so-extended solutions exhibit curvature singularities. In-

deed an examination of (33a) and (33b) shows that the space–time curvature grows unbounded as $\Phi \to -1$ and thus no further extension of the space–time is possible across the $\Phi=-1$ ''timelike hypersurface.'' Exception to that rule constitutes the metrics with plane orbits. For such metrics K, $\hat{G}$ are given by (33c), and thus both of them have smooth limit as $\Phi \to -1^{+}$. This two-''plane'' is at infinite proper distance away from any point on any $t=$const spacelike hypersurface and, moreover, an analysis of the ''outgoing'' timelike, resp. null geodesics, shows that it is located at the ''space–time boundary.'' An infinite amount of proper time, resp. affine parameter, along outgoing causal geodesics is required in order to be reached. In addition to the above-discussed timelike singularities, the extended metrics (20) also exhibit unbounded growth as $\Phi \to \infty$. However, the structure of this singularity is not immediately obvious. In order to get some insights into its structure, let us first introduce advanced Eddington–Finkelstein coordinates[1,15] associated with the line element (20). In such (u,Φ,x^1,x^2) coordinate systems, with $du=dt+[(1+\Phi)^2/S(\Phi)]d\Phi$, (20) takes the form

$$ds^2=-\frac{du^2}{(1+\Phi)^2}+2\frac{2}{S(\Phi)}du d\Phi+\frac{B(1+\Phi)^2}{S(\Phi)}ds^2_{(2)}.$$

An analysis of the geometry using this coordinates is rather tedious. However, since we are only interested in analyzing the structure of the geometry as $\Phi \to \infty$, it is sufficient to examine the behavior of the geometry for large values of Φ. In such limits the leading behavior of the above line element takes the following form:

$$ds^2=-\frac{du^2}{\Phi^2}+2\frac{du d\Phi}{\Phi^4}+\frac{1}{\Phi^2}ds^2_{(2)},$$

where hereafter and for notational simplicity we have set all constants to unit values. Defining further a new coordinate x via $x=-1/\Phi$, $x\in(-\epsilon,0)$, $\epsilon>0$, it follows that the above line element takes the form

$$ds^2=-x^2du^2+2x^2dudx+x^2ds^2_{(2)}=-y^{2/3}du^2+2dudy+y^{2/3}ds^2_{(2)}, \tag{33h}$$

where in passing to the second equality we have defined the coordinate y via $dy=x^2dx$. However, in the above form, the limit $\Phi \to \infty$ corresponds to $y \to 0^{-}$. An analysis of the curvature for $y \in (-\epsilon',0)$ shows that $K=R^{\mu\nu\sigma\tau}R_{\mu\nu\sigma\tau}\equiv 4/27[(27y^{4/3}-6y^{2/3}+2)/y^{8/3}]$ and thus all null geodesic generators of each $u=$const null hypersurface terminate after a finite amount of affine parameter in a curvature singularity. Moreover, the set $y \to 0^{-}$ corresponds to a ''null hypersurface'' and thus the structure of $\Phi \to \infty$ singularity for all extended metrics (20) corresponds to a ''null singularity.''

Let us now briefly discuss the regularity properties of the vacuum metrics (32a)–(32c). At first (33e)–(33g) shows no pathologies in the geometry takes place as the ''$V=0$'' null hypersurface is approached, and the ''bad behavior'' of the metric across ''$V=0$'' is simply a coordinate singularity. The metric (32a) (for $M>0$) as well as (32b) can be analytically extended across the corresponding Killing horizons and their analytical extensions are discussed in the work of Ehlers and Kundt.[26] No analytical extension is required for the case of the metric (32c) since the $V \to 0^{+}$ null hypersurface occurs at the boundary of the space–time, a situation similar to that encountered in the analysis of the metrics (20) possessing plane orbits at the limit $\Phi \to -1$. On the other hand, if the magnitude of the timelike Killing vector is left unrenormalized, then (33) shows that all classes of vacuum metrics becomes singular as the $V \to \infty$ timelike hypersurface is approached and this property is in accord with the behavior of the metrics (20) at the limit of $\Phi \to \infty$ with the exception that the later singularities are null whereas the former are timelike. Imposing asymptotic flatness on (32a)–(32c), one gets the well-known results.

A high degree of subtlety is, however, exhibited by the metric (24c). At first and by construction, (24) is a solution of (1c) and (1d) within the static region, i.e., for all $r>r_0$. An examination

of the scalar invariants K and C shows that both of them are regular for all $r>r_0$. Moreover, the metric can be extended so that it is manifestly regular at $r=r_0$. Indeed, for an analysis along the same lines as those that lead us into (33h) one gets

$$ds^2=-x^2du^2+2dudx+(1-x)^2ds^2_{(2)},\quad x\in(-\epsilon,0),$$

as the $\Phi\to\infty$ limit of the line element (20). However, now $K=R^{\mu\nu\sigma\tau}R_{\mu\nu\sigma\tau}=8(3x^2+1)/(1-x)^2$ from which now it follows that the $x=0$ null hypersurface is regular one, an expectable fact since (20) is isometric to the metric of the extreme Reisner–Nordstrom manifold. Thus the geometry can be extended through the Killing horizon and details of this extension are for instance, discussed in Ref. 15. However, due to the fact that the scalar field Φ diverges as the Killing horizon is approached, the solution (24c) cannot be extended across the Killing horizon as a solution of the conformal equations (7a) and (7b). The reason for this failure as well as its implications are discussed in detail in Ref. 12.

VI. DEGENERATE SINGULAR SOLUTIONS

In the last three sections we have analyzed solutions of the conformal system (7a) and (7b) as well as of the vacuum system (25a) and (25b) possessing a degenerate Ricci tensor given by (9a), resp. (26a). However, as we indicated in Sec. II, the Ricci of (9a), resp. (26a), is rather special in the sense that its unique principal direction is normal to $\Phi=\text{const}$, resp. $V=\text{const}$, equipotential surfaces. Thus it is of considerable interest to investigate whether (7a) and (7b), resp. (25a) and (25b), admit other regular solutions across degeneracies subject to the condition that the unique principal direction of the Ricci is no longer normal to the above-mentioned two spaces. Accordingly, in this section we shall examine whether (7a) and (7b), resp. (25a) and (25b), admit solutions possessing a degenerate Ricci such that in the vicinity of $\Phi=1$, respectively, $V\to0^+$, the distinct Ricci eigenvector X is no longer parallel to $\overline{D}_a\Phi$, resp. D_aV. More precisely, we assume a Ricci given by

$$\overline{R}_{ab}=\overline{\lambda}(3X_aX_b-\Lambda_{ab}),\tag{34a}$$

and shall focus our attention primarily on the conformal system (7a) and (7b). As we shall see, the treatment of the vacuum system follows identical steps.

Combining (34a) with Eqs. (7a) and (7b), it follows that the scalar field Φ satisfies

$$2\Phi\overline{D}_a\overline{D}_b\Phi=2(3\Phi_a\Phi_b-\Lambda_{ab}\Phi^c\Phi_c)-\overline{\lambda}(1-\Phi^2)(3X_aX_b-\Lambda_{ab}),\tag{34b}$$

and thus the real symmetric matrix $\overline{D}_a\overline{D}_b\Phi$ longer exhibits identical eigenstructure as the corresponding Ricci. Substituting further (34a) in (8a) and straightforward algebra yield

$$\begin{aligned}\Phi(1-\Phi^2)[&(3X_cX_a-\Lambda_{ca})\overline{D}_b\overline{\lambda}-(3X_bX_a-\Lambda_{ba})\overline{D}_c\overline{\lambda}\\&+3\overline{\lambda}(X_c\overline{D}_bX_a+X_a\overline{D}_bX_c-X_b\overline{D}_cX_a-X_a\overline{D}_cX_b)]\\&=6\overline{\lambda}[2X_a(X_c\Phi_b-\Phi_cX_b)-\Lambda_{ca}(\Phi_b-X^d\Phi_dX_b)+\Lambda_{ab}(\Phi_c-X^d\Phi_dX_c)].\end{aligned}\tag{34c}$$

We write this equation hereafter in the form $\Phi(1-\Phi^2)\overline{R}_{abc}=\overline{S}_{abc}$, where $\overline{S}_{abc}$ stands for the right-hand side of (34c). It is clear that $\Phi(1-\Phi^2)\overline{R}_{abc}=\overline{S}_{abc}$ is the generalization of the constraint $\overline{R}_{abc}=0$ encountered in the previous sections. However, the structure of the new constraint shows that if (7a) and (7b) admit a solution (Λ,Φ) subject to (34a), then Λ is no longer locally conformally flat and thus we are dealing with a more ''complex geometry.'' Moreover, since (34c) is ''singular'' as the $\Phi=1$ two-surface is approached, it is expected that if (7a) and (7b) admit solutions characterized by a Ricci given by (34a), then their properties would be different than the

properties of their counterparts constructed in the previous sections. On the other hand, differentiating once more (34b) and appealing to the Ricci commutation relation, we obtain the following condition, which is the analog of (10a):

$$
\begin{aligned}
&2\Phi(\overline{D}_c\overline{D}_a\overline{D}_b\Phi-\overline{D}_a\overline{D}_c\overline{D}_b\Phi)+2\Phi_c\overline{D}_a\overline{D}_b\Phi-2\Phi_a\overline{D}_c\overline{D}_b\Phi\\
&\quad=6(\Phi_a\overline{D}_c\overline{D}_b\Phi-\Phi_c\overline{D}_a\overline{D}_b\Phi)-2\Phi^d(\Lambda_{ab}\overline{D}_c\overline{D}_d\Phi-\Lambda_{cb}\overline{D}_a\overline{D}_d\Phi)-3\overline{\lambda}(1-\Phi^2)\\
&\qquad\times(X_a\overline{D}_cX_b-X_c\overline{D}_aX_b+X_b\overline{D}_cX_a-X_b\overline{D}_aX_c)+(3X_bX_c-\Lambda_{bc})[(1-\Phi^2)\overline{D}_a\overline{\lambda}-2\Phi\overline{\lambda}\Phi_a]\\
&\qquad-(3X_bX_a-\Lambda_{ba})[(1-\Phi^2)\overline{D}_c\overline{\lambda}-2\Phi\overline{\lambda}\Phi_c].
\end{aligned}
$$

Substituting (34b) in the above and after lengthy algebra it yields Eqs. (34c). Thus it is sufficient to examine the content of the integrability condition (34c). Forming $\Phi(1-\Phi^2)\overline{R}_{abc}X^a=\overline{S}_{abc}X^a$ it yields

$$
\Phi(1-\Phi^2)[2X_c\overline{D}_b\overline{\lambda}-2X_b\overline{D}_c\overline{\lambda}+3\overline{\lambda D}_bX_c-3\overline{\lambda D}_cX_b]=6\overline{\lambda}[X_c\Phi_b-\Phi_cX_b], \tag{35a}
$$

while the combination $\Phi(1-\Phi^2)\overline{R}_{abc}X^aX^c=\overline{S}_{abc}X^aX^c$ yields

$$
\Phi(1-\Phi^2)[2\overline{D}_b\overline{\lambda}-2X_bX^c\overline{D}_c\overline{\lambda}-3\overline{\lambda}X^c\overline{D}_cX_b]=6\overline{\lambda}[\Phi_b-X^c\Phi_cX_b]. \tag{35b}
$$

Combining the contents of $\Phi(1-\Phi^2)\overline{R}_{abc}X^aX^c=\overline{S}_{abc}X^aX^c$, and $\Phi(1-\Phi^2)\overline{R}_{abc}X^a=\overline{S}_{abc}X^a$ with $\Phi(1-\Phi^2)\overline{R}_{abc}=\overline{S}_{abc}$, it yields $\Phi(1-\Phi^2)\hat{R}_{abc}=0$ where hereafter $\hat{R}_{abc}$ is defined by

$$
\begin{aligned}
\hat{R}_{abc}\equiv&(X_cX_a-\Lambda_{ca})\overline{D}_b\overline{\lambda}-(X_bX_a-\Lambda_{ba})\overline{D}_c\overline{\lambda}+3\overline{\lambda}(X_a\overline{D}_bX_c-X_a\overline{D}_cX_b-X_c\overline{D}_bX_a+X_b\overline{D}_cX_a)\\
&+2X^d\overline{D}_d\overline{\lambda}\Lambda_{ca}X_b-2X^d\overline{D}_d\overline{\lambda}\Lambda_{ab}X_c+3\overline{\lambda}\Lambda_{ca}X^d\overline{D}_dX_b-3\overline{\lambda}\Lambda_{ba}X^d\overline{D}_dX_c=0.
\end{aligned} \tag{35c}
$$

However, $\Phi(1-\Phi^2)\hat{R}_{abc}=0$ and continuity arguments show that $\hat{R}_{abc}=0$ in the open vicinity of $\Phi=1$. Forming $\hat{R}_{abc}X^c$ it follows that

$$
\hat{R}_{abc}X^c\equiv(\Lambda_{ba}-X_bX_a)X^c\overline{D}_c\overline{\lambda}-3\overline{\lambda}X_bX^c\overline{D}_cX_a+3\overline{\lambda D}_bX_a=0, \tag{35d}
$$

while a contraction of above with Λ_{ab} implies

$$
\hat{R}_{abc}X^c\Lambda^{ab}\equiv2X^a\overline{D}_a\overline{\lambda}+3\overline{\lambda D}_aX^a=0. \tag{35e}
$$

Considering now $\hat{R}_{abc}\Lambda^{ab}=0$ and taking into account the above equation results in

$$
\hat{R}_{abc}\Lambda^{ab}\equiv\overline{D}_c\overline{\lambda}-3\overline{\lambda}X^d\overline{D}_dX_c-X_cX^d\overline{D}_d\overline{\lambda}=0. \tag{35f}
$$

The content of this equation combined with $\hat{R}_{abc}X^c=0$ yields

$$
\hat{R}_{abc}X^c\equiv\Lambda_{ba}X^c\overline{D}_c\overline{\lambda}-X_b\overline{D}_a\overline{\lambda}+3\overline{\lambda D}_bX_a=0. \tag{36a}
$$

This is an important equation and we shall make use of it later on. For the moment we shall combine $\Phi(1-\Phi^2)\overline{R}_{abc}=\overline{S}_{abc}$ with the content of $\hat{R}_{abc}=0$. Indeed $\Phi(1-\Phi^2)\overline{R}_{abc}X^aX^b=\overline{S}_{abc}X^aX^b$ combined with the content of $\hat{R}_{abc}\Lambda^{ab}=0$ yields

$$
\Phi(1-\Phi^2)[\overline{D}_a\overline{\lambda}-X_aX^b\overline{D}_b\overline{\lambda}]=6\overline{\lambda}[\Phi_a-X^b\Phi_bX_a]. \tag{36b}
$$

Contracting the above equation with any arbitrary smooth vector field Y^a perpendicular to X^a yields

$$
\Phi(1-\Phi^2)Y^a\overline{D}_a\overline{\lambda}=6\overline{\lambda}Y^a\overline{D}_a\Phi,
$$

which in turn implies

$$Y^a\overline{D}_a\left[\log\left(\frac{\overline{\lambda}^{1/3}(1-\Phi^2)}{\Phi^2}\right)\right]=0,$$

and thus eventually we conclude

$$\overline{\lambda}^{1/3}=\frac{G^2(x)\Phi^2}{(1-\Phi^2)}, \tag{36c}$$

where in the above $G^2(x)$ stands for a nonvanishing function constant along the integral curves of the vector field X and in the above x stands for a set of comoving ''coordinates'' enumerating the integral curves of X. However, now (36c) implies that $\overline{R}_{ab}\overline{R}^{ab}$ is given by

$$\overline{R}^{ab}\overline{R}_{ab}=6\overline{\lambda}^2=\frac{6G^{12}(x)\Phi^{12}}{(1-\Phi^2)^6},$$

which shows that if a solution (Λ,Φ) of (7a) and (7b) exist so that the Ricci tensor of Λ is given by (34a), then the geometry is necessarily singular as $\Phi^2\to 1$. The only way that such a singularity can be avoided is to assume that $G(x)\equiv 0$, but this possibility implies that $\overline{R}_{ab}=0$ in the vicinity of $\Phi=1$ and such a Ricci returns as to the system (21a) and (21b) analyzed in Sec. III. Thus (7a) and (7b) does not admit regular solutions across $\Phi=1$ possessing a Ricci given by (34a). Interestingly and in concordance to the results of Secs. II and IV, an identical conclusion holds true for the vacuo system (25a) and (25b) as well. In fact, starting from (25a) and (25b) and looking for solutions (γ,V) subject to (34a), then the analog of (34c) takes the form $VR_{abc}=S_{abc}$, where, in this particular case, S_{abc} is given by

$$S_{abc}=3\lambda[2X_a(X_bV_c-X_cV_b)+\gamma_{ba}(X^dV_dX_c-V_c)-\gamma_{ca}(X^dV_dX_b-V_b)]. \tag{37a}$$

Repetition of the steps that leads into (35c) shows that $\hat{R}_{abc}=0$, where the three tensor $\hat{R}_{abc}$ has precisely the same form as that shown in Eq. (35c). It follows then that the corresponding eigenvalue λ satisfies

$$\lambda^{1/3}=\frac{G^2(x)}{V}, \tag{37b}$$

which is the analog of (36c). Accordingly vacuum solutions (γ,V) subject to (34a) become singular as $V\to 0^+$.

The above conclusions regarding the behavior of solutions of (7a) and (7b) characterized by a Ricci given by (34a) were reached via an analysis of the integrability conditions alone and thus it is not clear whether such solutions really exist. If they exist, and are defined in an open neighborhood of $\Phi=1$, respectively in $V\in(0,c)$, then they must become singular across $\Phi=1$, resp. $V\to 0^+$. It would therefore be of an independent interest to devote some effort to analyze the existence question. Moreover, if we will be able to construct them explicitly, them we shall be able to study the local isometry groups (if any), and thus compare their symmetry properties to those exhibited by solutions of (14a) and (14b), resp. (26a) and (26b). We shall show below that such solutions indeed exist and shall present their explicit construction. Since, however, the integration procedure is rather lengthy, we shall report below our findings and the reader is referred to the Appendix for details of the intermediate computations leading to their constructions.

Our effective system of equations consists of (34a) and (34b) augmented by the integrability condition (34c). By arguments along the lines that lead us to the equivalence of (7a) and (7b) to that of (14a) and (14b) via (9a)–(9c), here as well it is easily inferred that any solution (Λ,Φ) of (7a) and (7b) subject to (34a) necessarily satisfies (34b) and (34c) and conversely solutions of

(34a) and (34b) satisfying additionally (34c) are also solutions of (7a) and (7b). Of course here our considerations are restricted to the local vicinity of $\Phi=c,\ c\in(1,1+\epsilon)$ [or $\Phi=c,\ c\in(1-\epsilon,1)$]. One of the most important insights furnished by the integrability condition (34c) is the content of (36a). It implies the existence of a local coordinate system (x,y,z) covering the open vicinity of $\Phi=c,\ c\in(1,1+\epsilon)$, and such that the metric Λ can be written in the following form:

$$ds^2=\bar{\lambda}^{-2/3}\left(\frac{dx^2}{a^2(x)}+\frac{dy^2}{b^2(y)}+b^2(y)dz^2\right). \tag{38}$$

Relative to such coordinates the eigenvector X is parallel to $\partial/\partial x$, while (y,z) are local coordinates on the family of the two-surfaces perpendicular to $\partial/\partial x$ (see the Appendix). With the help of the above insight the integration of the field equations (34a) and (34b) remarkably can be accomplished and, after a long and tedious intermediate algebra, leads us to the solutions described by

$$\bar{\lambda}^{2/3}=(x+y)^2,$$

$$a^2(x)=2x^3+\frac{2k^3+mk-n}{k^2}x^2+mx+n>0, \tag{39a}$$

$$b^2(y)=2y^3-\frac{2k^3+mk-n}{k^2}y^2+my-n>0, \tag{39b}$$

$$\Phi(x,y)=\left(\frac{2k(x+y)(x+k)}{2k(x+k)y-2k^2x-km+2n}\right)^{1/2}, \tag{39c}$$

where in the above (k,m,n) are integration constants chosen so that for a given range of the (x,y) coordinates, the metric coefficients ought to be consistent with the positive definite character of the metric. Furthermore, for such choices of (k,m,n), an analysis of $\Phi(x,y)$ given by (39c) or more conveniently using (A30), shows that the intersection of any $x=c,\ c<\infty$, local two-coordinate surface with $\Phi=1$ appears as $\lim y\to\infty$. Moreover, (38), (39a), and (39b) show that the proper distance of any point $y=y_0$ lying on any $x=c,\ c<\infty$, is at finite proper distance away from the limiting value $\lim y\to\infty$ and at $\lim y\to\infty$ the scalar invariant $R^{ab}R_{ab}$ diverges. Thus and in accord with (36c), indeed the geometry is singular as points subject to $\Phi(x,y)=1$ are approached. Away from such singular regions, (38) and (39a)–(39c) show that the metric admits a local group of isometrics generated by $\partial/\partial z$, a situation that is in sharp contrast to the previously constructed solutions. Even though still symmetric, one parameter local group of isometrics, not as symmetric as the corresponding solutions of (7a) and (7b) possessing a Ricci given by (9a). We shall return to that point below, after the construction of the corresponding vacuum solutions. For the vacuo case the corresponding equations are

$$R_{ab}=\lambda(3X_aX_b-\Lambda_{ab}), \tag{40a}$$

$$D_aD_bV=V\lambda(3X_aX_b-\Lambda_{ab}). \tag{40b}$$

We are again looking for solution valid in the local vicinity of the ''horizon,'' and relative to the same coordinate gauge shown in (38) the above system admits the following solutions (see also the Appendix for details):

$$\lambda^{2/3}=(x+y)^2,$$
$$a^2(x)=2x^3+mx+n>0,\quad b^2(y)=2y^3+my-n>0, \tag{41a}$$

$$V(x,y)=\frac{c_1a(x)}{x+y}, \tag{41b}$$

where again in the above (m,n,c_1) are integration constants subject to $c_1>0$. The set of points lying on the horizon correspond to the limit of $y\to\infty$ for all x finite. Like the corresponding solution of the conformal system, (41a) and (41b) also admit a local group of isometrics generated by $\partial/\partial z$.

The space–time metric associated with (39a)–(39c), (41a), and (41b) can be easily inferred. Indeed for the conformal system it is given by

$$ds^2=-\frac{dt^2}{(1+\Phi)^2}+\frac{(1+\Phi)^2}{(x+y)^2}\left(\frac{dx^2}{a^2(x)}+\frac{dy^2}{b^2(y)}+b^2(y)dz^2\right), \tag{42a}$$

$$\Phi(x,y)=\left(\frac{2k(x+y)(x+k)}{2k(x+k)y-2k^2x-km+2n}\right)^{1/2}, \tag{42b}$$

while for the vacuum case it is given by

$$ds^2=\frac{1}{(x+y)^2}\left(-a^2(x)dt^2+\frac{dx^2}{a^2(x)}+\frac{dy^2}{b^2(y)}+b^2(y)dz^2\right). \tag{43}$$

It can be verified directly that (42a) and (42b), resp. (43), satisfy the covariant equations (1c) and (1d), resp. $G_{\mu\nu}=0$, while their counterparts (39a)–(39c), resp. (41a) and (41b), satisfy (7a) and (7b), resp. (25a) and (25b), of course away from the degeneracies. The vacuum solution (43) belongs to the C-class of metrics in the classification scheme proposed by Ehlers and Kundt.[26] Judging from the corresponding comments in Ref. 26, it appears that originally this solution was derived by Levi–Civita.[25] Maintaining the same nomenclature as that adopted in Ref. 26 we shall refer to (42a) and (42b) as the corresponding C-class of solutions for the conformal system. To the best of our knowledge, the solutions (42a) and (42b) are new and, due to their complexity, we shall refrain from discussing here their global structure and particularly the structure of the singularity occurring as $\Phi\to 1$. This analysis will be presented elsewhere. With the above explicit form of the C-class of solutions, it appears that the metrics possessing a degenerate Ricci and satisfying (7a) and (7b) is now complete and those solutions, except (24c), are in correlation with the corresponding degenerate solutions of the vacuo system (25a) and (25b).

It is worthwhile at this point to return to the important issue of the origin of the additional local isometrics present in all constructed degenerate solutions of (7a) and (7b), resp. (25a) and (25b). Actually there are two intertwined issues involved here; first, the issue of the origin of the local isometrics and, second the regularity of the solutions across degeneracies. The analysis of the previous sections shows that a degenerate Ricci is not by itself solely responsible for the origin of the local isometrics, but, rather, it is Ricci degeneracy combined with the fundamental constraints (8a), resp. (27). Whenever a particular solution possesses a (degenerate) Ricci so that the right-hand-sides of (8a), resp. (27), are identically zero, and this occurs only when $\overline{D}_a\Phi$ resp. D_aV, are parallel to the Ricci principal distinct eigendirection, as it can be easily inferred from the right-hand sides of (8a), resp. (27), then the corresponding Ricci eigenvalue has a gradient parallel to its distinct eigendirections [see Eq. (12a)]. This fact combined with the Hamiltonian constraint shows that the two surfaces perpendicular to the Ricci eigendirection lack any distinct direction and thus are maximally symmetric [see Eqs. (18b) and (18d)]. The existence then of the local $G(3)$ admitting orbits of constant Gaussian curvature follows naturally. However away from this case, whenever a solution is characterized by a three-metric, which even though it possesses a degenerate Ricci it is not by itself conformally flat, then the Ricci eigenvalue exhibits a gradient that possesses a nonvanishing component tangential to the family of the two-surfaces perpendicular to the distinct Ricci eigendirection [see Eq. (36b)]. As a consequence this family of two-surfaces, their existence guaranteed by relations like (36a), is no longer a space of constant Gaussian curvature [see Eqs. (A26)]. As a consequence the solution cannot have a $G(3)$ possessing orbits of constant Gaussian curvature. However, as it is clear from (42) and (43), Ricci degeneracy guarantees only the existence of an additional local $G(1)$.

As far as the regularity of the geometry across the degeneracy region is concerned, it should be stressed that this issue involves the full system i.e., (7a) and (7b), resp. (25a) and (25b). In the previous sections we have worked with an effective regular set of equations, augmented by a set of singular integrability conditions i.e., Eqs. (8a) and (27). Whenever a particular solution possesses as a degenerate Ricci so that the right-hand sides of (8a) and (27) are vanishing then this solution satisfies a system of effective equations, namely (10c), (14a), and (14b), resp. (26a), and (26b), and (28b), which has no traces of the singular nature of the original singular equations i.e., (7a), (7b), (25a), and (25b). Accordingly, any regular solution of the effective equations is necessarily regular over the degeneracy regions as well, since the latter region is not registered as anything peculiar in the structure of the effective equations [in that regard, recall the arguments before and above Eq. (9d)]. The fact that all regular solutions of the effective equations (10c), (14a), and (14b), resp. (26a), (26b), and (28b) exhibit high symmetry is to be interpreted as due to the special nonsingular structure of the effective system. Once, however, a particular solution possesses a degenerate Ricci so that the right-hand sides of (8a) and (27) are no longer vanishing, the situation is different. In such events the corresponding effective system is no longer regular since it also contains the integrability conditions (8a), resp. (27), which themselves are singular along solutions subject to $\Phi=1$, resp. $V\rightarrow 0^{+}$. Equations (36c) and (37b) then describe the consequences.

This summary makes clear the importance of the York–Cotton tensor. Its special role in controlling the symmetries and regularity properties of any solution of (7a), and (7b), resp. (25a), and (25b) is due to the special singular structure of (7a) and (7b), resp. (25a) and (25b) since as we have shown earlier, all solutions of those equations necessarily satisfy (8a), resp. (27). We may recall that such a property of the York–Cotton tensor is encountered in other situations as well. In Robinson's derivations of the uniqueness of the Schwartzschild black hole,[39] the vanishing of R_{abc} on the asymptotically Euclidean three-manifold Σ possessing a regular S was one of the key elements in the proof. The existence of the SO(3) symmetry then followed as the consequence of the vanishing of the York–Cotton tensor combined with the asymptotically Euclidean character of the geometry of Σ.

VII. DISCUSSION

In this work we have analyzed some consequences of the $(1-\Phi^2)$ factor multiplying the left-hand side of Eq. (1c) and, as it is clear, its presence adds a special flavor to the dynamics of the conformal system. In accord with the results of Refs. 18 and 21, the mere fact that the conformal system degenerates on specific classes of solutions, it does not follow that such solutions are singular over degeneracies. The regular solutions constructed in the previous sections offer another concrete example. It also clear from the analysis presented here that an understanding of the properties of solutions across degeneracies is a subtle and involved issue. The solutions constructed in this work although on the one hand offer insights to the dynamics of the conformal system, on the other hand call for more work. Although we have been able to construct and analyze classes of regular solutions across degeneracies, they were derived under the assumption that such solutions possess a degenerate Ricci and, moreover, the zeros of the $1-\Phi^2$ factor possess a ''nice'' structure. Naturally they lead us to ask: Do there exist other regular across degeneracies solution characterized by a nondegenerate Ricci? If yes, are they always accompanied by additional local isometries? And what is the role of the York–Cotton tensor if any? We do not have an answer to those questions, but we may add that the fundamental constraint (8a), holding for every solution of (7a) and (7b), imposes constraints on the two distinct Ricci eigenvalues. A preliminary analysis of the constraints indicates that it is conceivable that the conformal system may admit regular solutions across the degeneracy region possessing a non degenerate Ricci. Unfortunately, however, progress towards settling that issue is obstructed by the complicated nature of the integrability conditions that is a set of coupled tensorial differential constraints. As far as the presence of additional local isometries as a requirement of regularity across degeneracies, we may note that a contraction of (8a) by itself yields

$$\overline{R}^{abc}\overline{R}_{abc}=\frac{A^{abc}A_{abc}}{1-\Phi^2},$$

where A_{abc} is an expression involving gradients of the Ricci eigenvalues and corresponding eigenvectors. Thus any solution (Λ,Φ) would be singular as $\Phi^2\to 1$, unless some special arrangement is operating at the level of the York–Cotton tensor and the Ricci curvature. On the other hand, the comparison of the singular conformal equations to vacuum Einstein equations describing static solutions offers support to the contention that regularity of the solution across the singularities of the equations may be accompanied by additional isometries. Some time ago Israel[40] and much later Geroch and Hartle[41] analyzed the so-called distorted class of black hole solutions of Einstein vacuum equations. Such solutions possess a regular event horizon, distorted by the presence of some axisymmetric distribution of matter. It can be easily seen that the distorted class of black holes can be put into a correspondence with local solutions of (25a) and (25b) possessing a regular ''horizon'' *S*. Xanthopoulos *et al.*[42,43] showed that the distorted classes of black holes are necessary for type *D* on the event horizon. Moreover, those solutions, within the present formalism, do not possess a degenerate Ricci, but of course are axisymmetric and thus provided examples of regular solutions as the degenerate region is approached possessing a local $G(1)$ and whose Ricci is not degenerate in the local vicinity of the ''horizon'' *S*. The question of whether there exist local static black hole solutions possessing a regular horizon and without any additional symmetry is for the moment an open question. Some progress towards resolving that question is discussed in Ref. 44.

On an entirely different aspect, the results of the present work can be extended into different directions. An obvious natural extension concerns the question of the existence of static, regular across degeneracies solutions of (1c) and (1d) without imposing the functional relationship $U(\Phi)$ nor the condition (b) introduced in Sec. II. As far as the first question is concerned, some progress has been made in Ref. 45. It was shown there that (1c) and (1d) indeed admit regular across degeneracies solutions and those solutions as well as their properties and construction will be discussed elsewhere. Moreover, the method discussed in the present article can be applied to analyze the structure of solutions of other singular systems of equations, particularly equations associated with theories involving scalar fields arbitrarily coupled to the background curvature. One such system is provided by the theory involving Einstein gravity and a scalar field Φ nonconformally coupled to the background curvature. For such theories the factor $(1-\alpha\Phi^2)$ is replaced by $(1-k\xi\Phi^2)$ and the dynamical equations have similar structure as those of the conformal system. It would be therefore illuminating to extend the present analysis to such theories and compare the behavior of their solutions to the corresponding solutions presented here.

Finally, in closing we may add that scalar fields and relativistic gravity mix rather well. Primarily due to their simplicity, scalar fields often are employed to get insights into the complex dynamics of Einstein field equations. Soliton-like solutions[46] as well as models of strongly gravitating sources involving matter and scalar fields arbitrarily coupled to gravity with or without Higgs-type potentials have been studied in detail in the current literature.[47] Even though still direct observational evidence supporting the existence of long range scalar fields is lacking, current cosmological observations are interpreted as favoring an accelerating universe, and the possibility that scalars fields may provide a natural explanation is currently under active investigation.[48] Therefore, theories involving scalar fields besides their pure mathematical importance may turn out to be of physical importance as well. Observations will tell.

APPENDIX: C-CLASS METRICS FOR THE CONFORMAL SYSTEM

In this appendix we shall present some intermediate computations leading to the construction of the singular metrics discussed in Sec. VI. Our problem is the integration of the system (34a) and (34b) and as we have indicated earlier on, an extremely important insight is offered by the following relation, natural consequence of the integrability condition (8a) [see in particular, Eqs. (11d) and (36a)]:

$$\Lambda_{ab}X^c\overline{D}_c\overline{\lambda}-X_a\overline{D}_b\overline{\lambda}+3\overline{\lambda}\overline{D}_aX_b=0. \tag{A1}$$

The significance of this relation has been pointed out in the influential report of Ehlers and Kundt in Ref. 26 and that remark helped us enormously. An initial attempt, centered on adopting the integration technique of Sec. III to the system (34a) and (34b), lead us into a complex set of unyielding coupled differential equations. It was only after we became aware of Ref. 26 that we were able to integrate (34a) and (34b).

In order to see the implications of (A1), let us first consider a conformal transformation generated by an arbitrary conformal factor Ω^2, i.e., define $g_{ab}=\Omega^2\Lambda_{ab}$. Standard formula using the behavior of the connection under conformal transformation[1] shows that the following identity holds true:

$$D_a(\Omega X_b)=\Omega\overline{D}_aX_b-X_a\overline{D}_b\Omega+\Lambda_{ab}X^c\overline{D}_c\Omega, \tag{A2}$$

where in the above the covariant derivative operator D_a is formed using the g metric. However, a comparison of (A2) with (A1) implies that by choosing $\Omega=\overline{\lambda}^{1/3}$ as the conformal factor, then

$$D_a(\overline{\lambda}^{1/3}X_b)=0, \tag{A3}$$

implying that $g_{ab}=\overline{\lambda}^{1/3}\Lambda_{ab}$ admits $\overline{\lambda}^{1/3}X_a$, a parallel vector field. However, the existence of such a field imposes strong constraints on g_{ab} (and thus also on Λ_{ab} and $\overline{\lambda}$). A theorem in Ref. 29 (see also Ref. 26) assures that in the region admitting parallel fields exist local coordinates (x,y,z) so that x is parallel to $\partial/\partial x$ and g admits the following representation:

$$ds^2=g_{ab}dx^adx^b=dx^2+ds^2_{(2)},$$

from which we also conclude that

$$ds^2=\Lambda_{ab}dx^adx^b=\overline{\lambda}^{-2/3}g_{ab}dx^adx^b=\overline{\lambda}^{-2/3}(dx^2+ds^2_{(2)}), \tag{A4}$$

where $ds^2_{(2)}=\hat{\gamma}_{ij}(y,z)dx^idx^j$. Thus, relative to the coordinate (x,y,z) predicted by the existence of the parallel field $\overline{\lambda}^{1/3}X_a$, the coordinate dependence of the metric Λ has been constrained considerably. We write (A4) in the following form,

$$ds^2=\frac{dx^2}{S^2(x,y,z)}+\frac{1}{S^2(x,y,z)}\hat{\gamma}_{ij}(y,z)dx^idx^j=\frac{dx^2}{S^2}+\gamma_{ij}dx^idx^j, \tag{A5}$$

and project first Eq. (34a) along and perpendicular to $x=$const local coordinate surfaces, thus getting

$$-R^{(2)}-K^{ij}K_{ij}+K^2=4S^3, \tag{A6}$$

$$D_iK-D_jK^j{}_i=0, \tag{A7}$$

$$-S\frac{\partial K_{ij}}{\partial x}+2K_{il}K^l{}_j-KK_{ij}+\frac{1}{2}R^{(2)}\gamma_{ij}+\frac{1}{S}D_iD_jS-\frac{2}{S^2}D_iSD_jS=-S^3\gamma_{ij}, \tag{A8}$$

$$\frac{1}{2}S\frac{\partial\gamma_{ij}}{\partial x}=K_{ij}, \tag{A9}$$

where the extrinsic curvature of the $x=\text{const}$ two-surfaces is given by

$$K_{ij}=\frac{1}{2}L_n\gamma_{ij}=\frac{1}{2}S\frac{\partial}{\partial x}\frac{\hat{\gamma}_{ij}}{S^2}=-\frac{\hat{\gamma}_{ij}}{S^2}\frac{\partial S}{\partial x}=-\frac{\partial S}{\partial x}\gamma_{ij}. \tag{A10}$$

Substituting this K_{ij} into the Hamiltonian, momentum constraint and evolution equations, we get

$$R^{(2)}+4S^3-2\left(\frac{\partial S}{\partial x}\right)^2=0, \tag{A11}$$

$$\frac{\partial^2 S}{\partial x\partial x^i}=0, \tag{A12}$$

$$\left[S\frac{\partial^2 S}{\partial x^2}-\left(\frac{\partial S}{\partial x}\right)^2-S^3\right]\gamma_{ij}+\frac{1}{S}D_iD_jS-\frac{2}{S^2}D_iSD_jS=0. \tag{A13}$$

But Eq. (A12) implies that one may write

$$S(x,y,z)=f(x)+g(y)+h(z), \tag{A14}$$

where $(f(x),g(y),h(z))$ are arbitrary functions that ought to be specified. Taking the trace of (A13) leads into

$$2\left[S\frac{\partial^2 S}{\partial x^2}-\left(\frac{\partial S}{\partial x}\right)^2-S^3\right]+\frac{1}{S}D^iD_iS-\frac{2}{S^2}D^iSD_iS=0. \tag{A15}$$

It is convenient from this point onward to work with the metric $\hat{\gamma}_{ij}(y,z)$, and relative to this metric the Hamiltonian and the trace of the evolution equation read

$$S^2\hat{R}^{(2)}+2S\hat{D}^i\hat{D}_iS-2\hat{D}^iS\hat{D}_iS+4S^3-2\left(\frac{\partial S}{\partial x}\right)^2=0, \tag{A16}$$

$$2\left[S\frac{\partial^2 S}{\partial x^2}-\left(\frac{\partial S}{\partial x}\right)^2-S^3\right]+S\hat{D}^i\hat{D}_iS-2\hat{D}^iS\hat{D}_iS=0, \tag{A17}$$

where in the above $\hat{R}^{(2)}$ and all geometrical tensors are formed using $\hat{\gamma}_{ij}=\hat{\gamma}_{ij}(y,z)$. Due to the fact that local coordinates (x,y,z) involve a considerable amount of gauge freedom, we exploit this freedom and define a new set $(\overline{x},\overline{y},\overline{z})$ by

$$\overline{x}=f(x),\qquad \overline{y}=g(y),\qquad \overline{z}=h(z).$$

Relative to such coordinates, the scalar function S takes the form $S=\overline{x}+\overline{y}+\overline{z}$ and the metric (A5) transforms into

$$ds^2=\frac{1}{S^2}\left(\frac{d\overline{x}^2}{a^2(\overline{x})}+\hat{\gamma}_{ij}(\overline{y},\overline{z})d\overline{x}^i d\overline{x}^j\right). \tag{A18}$$

Expressing the derivatives of S in terms of $(\overline{x},\overline{y},\overline{z})$ via

$$\frac{\partial S}{\partial x}=\frac{\partial S}{\partial\overline{x}}\frac{\partial\overline{x}}{\partial x}=\frac{\partial\overline{x}}{\partial x}\equiv a(\overline{x}),\quad \frac{\partial^2 S}{\partial x^2}=a\frac{da}{d\overline{x}}=\frac{1}{2}\frac{da^2}{d\overline{x}},$$

then Eqs. (A16) and (A17) take the form

$$S^2\hat{R}^{(2)}+2S\hat{D}^i\hat{D}_iS-2\hat{D}^iS\hat{D}_iS+4S^3-2a^2=0, \tag{A19}$$

$$S\hat{D}^i\hat{D}_iS-2\hat{D}^iS\hat{D}_iS+S\frac{da^2}{d\bar{x}}-2a^2-2S^3=0. \tag{A20}$$

Differentiating now (A20) with respect to $\bar{x}$ we obtain

$$\hat{D}^i\hat{D}_iS+S\frac{d^2a^2}{d\bar{x}^2}-\frac{da^2}{d\bar{x}}-6S^2=0, \tag{A21}$$

and an additional differentiation of (A21) yields

$$S\left[\frac{d^3a^2}{d\bar{x}^3}-12\right]=0, \tag{A22}$$

from which we get

$$a^2(\bar{x})=2\bar{x}^3+\frac{l}{2}\bar{x}^2+m\bar{x}+n, \tag{A23}$$

where l, m, n are arbitrary integration constants. Substituting this equation back in (A21) we obtain

$$\hat{D}^i\hat{D}_iS=6(\bar{y}+\bar{z})^2-l(\bar{y}+\bar{z})+m, \tag{A24}$$

while substituting (A23) and (A24) back into (A20) we get

$$\hat{D}^iS\hat{D}_iS=2(\bar{y}+\bar{z})^3-\frac{l}{2}(\bar{y}+\bar{z})^2+m(\bar{y}+\bar{z})-n, \tag{A25}$$

and upon substituting (A23)–(A25) back into (A19) we get

$$\hat{R}=-12(\bar{y}+\bar{z})+l. \tag{A26}$$

Since Eqs. (A24)–(A26) involves only the coordinates $\bar{y}$ and $\bar{z}$ via the combination $\bar{y}+\bar{z}$, we take advantage of it and define new coordinates (y,z) via

$$y=\bar{y}+\bar{z}, \qquad z=z(\bar{y},\bar{z})$$

with $z=z(\bar{y},\bar{z})$ arbitrary for the moment function of its arguments. Using the arbitrariness in the choice of z, we demand

$$\hat{\gamma}^{yz}=(\hat{\gamma}^{\bar{y}\bar{y}}+\hat{\gamma}^{\bar{y}\bar{z}})\frac{\partial z}{\partial\bar{y}}+(\hat{\gamma}^{\bar{y}\bar{z}}+\hat{\gamma}^{\bar{z}\bar{z}})\frac{\partial z}{\partial\bar{z}}=0.$$

The above equation is a first-order linear partial differential equation and locally always admits solutions. In terms of the new coordinates (y,z), S takes the simpler form: $S=x+y$ and, for such S, (A25) fixes $\hat{\gamma}^{yy}$ to the form

$$\hat{\gamma}^{yy}=y^3-\frac{l}{2}y^2+my-n \tag{A27}$$

with the help of which Eq. (A24) implies

$$\frac{\partial\sqrt{\hat{\gamma}}}{\partial y}=0.$$

Since the two-metric is diagonal, we also get $\hat{\gamma}_{yy}=c^2\hat{\gamma}_{zz}^{-1}$ where c^2 is an arbitrary constant that is absorbed here after the z coordinate. Thus eventually we lead

$$ds^2=\frac{1}{S^2}\left(\frac{dx^2}{a^2(x)}+\frac{dy^2}{b^2(y)}+b^2(y)dz^2\right) \tag{A28}$$

with

$$a^2(x)=2x^3+\frac{l}{2}x^2+mx+n,\quad b^2(y)=2y^3-\frac{l}{2}y^2+my-n. \tag{A29}$$

Computing the scalar curvature $\hat{R}^{(2)}$ of the $x=$const using the metric $\hat{\gamma}_{ij}$, we find that $\hat{R}=-12y+l$, showing that (A26) is identically satisfied. Moreover, returning back to the trace-free part of the evolution equations (A13), using (A28) and (A29) and the form of S, we find that it is identically satisfied.

Up to this point we have constructed all metrics satisfying $\overline{R}_{ab}=\overline{\lambda}(3X_aX_b-\Lambda_{ab})$ subject to $(\overline{\lambda},X)$ satisfying (A1). In order, however, to complete the solution of (34a) and (34b) we must also specify Φ for the conformal case (or V for the vacuum case). Let us first consider the conformal case. Starting from the equation $\overline{D}^a\overline{D}_a\Phi=0$ and utilizing Eq. (36c) it follows via $\overline{\lambda}^{-1/3}=S=x+y$ that

$$\Phi(x,y)=\left(\frac{x+y}{x+y+G^2(x)}\right)^{1/2},\quad G^2(x)>0. \tag{A30}$$

Demanding that this Φ satisfy $\overline{D}_a\overline{D}^a\Phi=0$ and, after algebra, using (A28) and (A29) we obtain the following consistency relations for $G(x)$:

$$\begin{aligned}&H_1(x)y^3+[(3x+G^2)H_1(x)+\tfrac{1}{2}H_2(x)]y^2+x[(3x+2G^2)H_1(x)+H_2(x)]y\\&\quad+x^2[(x+G^2)H_1(x)+\tfrac{1}{2}H_2(x)]=0,\end{aligned} \tag{A31}$$

where $H_1(x)$ and $H_2(x)$ are defined by

$$H_1(x)=(4x^2+lx^2+2mx+2n)\frac{d^2G^2}{dx^2}+(6x^2+lx+m)\frac{dG^2}{dx}-(6G^2+12x+l)G^2, \tag{A32}$$

$$H_2(x)=2\left(2x^2+\frac{l}{2}x^2+mx+n\right)\left(2+\frac{dG^2}{dx}\right)\frac{dG^2}{dx}-[4G^4+(12x+l)G^2+2(6x^2+lx+m)]G^2. \tag{A33}$$

Since, however, (A31) must be satisfied identically, it follows that necessarily $H_1(x)=H_2(x)=0$. Due the fact that $H_1(x)=0$ can be viewed as a differential equation for $G^2(x)$, and $H_1(x)=0$ possesses analytic coefficients, we look for polynomial solutions $G(x)$. It takes a rather long and tedious algebra to show that the following function $G^2(x)$ satisfies (A32) and (A33),

$$G^2(x)=-\frac{2k(x+k)^2-2k^3+mk-2n}{2k(x+k)}, \tag{A34}$$

provided the integration constants appearing in (A29) are adjusted so that $a^2(x)$ and $b^2(y)$ have the form

$$a^2(x)=2x^3+\frac{2k^3+mk-n}{k^2}x^2+mx+n>0, \tag{A35}$$

$$b^2(y)=2y^3-\frac{2k^3+mk-n}{k^2}y^2+my-n>0. \tag{A36}$$

Using (A34), then the corresponding expression for the scalar field Φ takes the form

$$\Phi(x,y)=\left(\frac{2k(x+y)(x+k)}{2k(x+k)y-2k^2x-km+2n}\right)^{1/2}. \tag{A37}$$

Up to this point we have satisfied only the trace-free part of Eq. (34b). In order to complete the solution we must also satisfy the other components of Eq. (34b). Setting

$$K_{ab}=2\Phi\overline{D}_a\overline{D}_b\Phi-2(3\Phi_a\Phi_b-\Lambda_{ab}\Phi^d\Phi_d)+\overline{\lambda}(1-\Phi^2)(3X_aX_b-\Lambda_{ab}) \tag{A38}$$

and substituting in (A34)–(A37), then after a long and tedious algebra we find that K_{ab} is diagonal and, in fact, as long as $H_1(x)=H_2(x)=0$, then necessarily $K_{ab}=0$. Thus the set of functions (A35)–(A37) describes the general solution of (7a) and (7b) subject to Ricci given by (34a) and of course satisfaction of the integrability conditions (34c).

Let us now briefly discuss the integration of the vacuum system (40a) and (40b). As it is clear from the above integration procedure, we only need to verify Eq. (40b) for the metric (A28) and (A29). From Eq. (37b) we have $V=G^2(x)/(x+y)$ and, demanding $D^aD_aV=0$, we obtain the following ordinary equations for $G^2(x)$:

$$G_1(x)y^2+G_2(x)y+x(G_2(x)+xG_1(x)-2lx)=0, \tag{A39}$$

where $G_1(x)$ and $G_2(x)$ are defined by

$$G_1(x)=a^2\frac{d^2G^2}{dx^2}+\frac{1}{2}\frac{da^2}{dx}\frac{dG^2}{dx}-\left(6x+\frac{5}{2}l\right)G^2, \tag{A40}$$

$$G_2(x)=2xa^2\frac{d^2G^2}{dx^2}+\left(x\frac{da^2}{dx}-3a^2\right)\frac{dG^2}{dx}-\left(\frac{1}{2}\frac{da^2}{dx}-lx-2m\right)G^2. \tag{A41}$$

Again (A39) must be satisfy identically, and thus necessarily $G_1(x)=0$, $G_2(x)=0$, and additionally $l=0$. Forming a linear combination of $G_1(x)=G_2(x)=0$, namely, $G_2(x)-2xG_1(x)=0$, we obtain

$$a^2\frac{dG^2}{dx}+\frac{1}{2}\frac{da^2}{dx}G^2-2(6x^2+m)G^2=0.$$

Since, on the other hand, $a^2(x)=2x^3+mx+n$, it follows that the above equation can be written in the form

$$\frac{1}{G^2}\frac{dG^2}{dx}-\frac{1}{2a^2}\frac{da^2}{dx}=0,$$

which in turn implies

$$\frac{d}{dx}\left[\log\left(\frac{G^2}{a}\right)\right]=0$$

from which we infer that $G^2(x)=c_1^2 a(x)$. Substituting the above equation in (A40) and (A41) we find that they are identically satisfied. Finally, the vacuum metric is given by (A28) combined with $a^2(x)$ and $b^2(y)$ given by (A29) with $l=0$ while $V(x,y)$ given by

$$V(x,y)=\frac{c_1^2 a(x)}{x+y}.$$

That set of functions constitutes the general solution of (40a) and (40b).

[18] On a given space–time (M, g) the Einstein vacuum equations $R_{\mu\nu}(g)=0$ expressed in terms of $\tilde{g}_{\mu\nu}=\Omega^2 g_{\mu\nu}$ imply the ''conformal vacuum Einstein equations:'' $\tilde{R}_{\mu\nu}(\tilde{g})=3\Omega^{-2}\tilde{g}_{\mu\nu}\tilde{\nabla}^\sigma\Omega\tilde{\nabla}_\sigma\Omega-\Omega^{-1}(2\tilde{\nabla}_\mu\tilde{\nabla}_\nu\Omega+\tilde{g}_{\mu\nu}\tilde{\nabla}^\sigma\tilde{\nabla}_\sigma\Omega)$. A standard analysis (see, for example, Refs. 1 and 15), shows that vacuum asymptotically flat at $\mathcal{J}^\pm$ solutions satisfy $\tilde{\nabla}_\mu\tilde{\nabla}_\nu\Omega\big|_{\mathcal{J}^\pm}=0$. Viewing the ''conformal vacuum Einstein equations'' as determining the fields $(\tilde{g},\Omega)$ on the ''unphysical'' manifold $(\tilde{M},\tilde{g})$, then the above system degenerates whenever $\Omega=0$, i.e., on the null conformal infinity. An analysis of this singular set of equations has been performed by Friedrich in H. Friedrich, Proc. R. Soc. London, Ser. A **381**, 361 (1982); The author introduces an equivalent set of equations that avoids this degeneracy and the latter system is well defined at the conformal infinity. We may parenthetically add that the singular conformal vacuo equations exhibit similar structure as the conformal equations (1c) and (1d). In fact, after multiplication with Ω^2 this yields $\Omega^2\tilde{R}_{\mu\nu}(\tilde{g})=3\tilde{g}_{\mu\nu}\tilde{\nabla}^\sigma\Omega\tilde{\nabla}_\sigma\Omega-\Omega(2\tilde{\nabla}_\mu\tilde{\nabla}_\nu\Omega+\tilde{g}_{\mu\nu}\tilde{\nabla}^\sigma\tilde{\nabla}_\sigma\Omega)$, and thus the similarities with (1c) and (1d) are manifest. In the present work emphasis is placed on the construction of solutions defined on the physical space–time while the conformal vacuum Einstein equations are mainly employed in the analysis of solutions in the vicinity of the conformal infinity.
[19] The behavior of static or stationary vacuum asymptotically Euclidean solutions of Einstein equations has been the subject of many investigations. Within Geroch's (Ref. 20) coordinates-free description of asymptotic flatness at spatial infinity, a conformally rescaled positive metric $\tilde{g}=\Omega^2 g$ defined on an unphysical three manifold $(\tilde{M},\tilde{g})$ satisfies a formally degenerate system of equations in the neighborhood of the so-called point at infinity Λ attached to M so that $\tilde{M}=M\cup\{\Lambda\}$ is diffeomorphic to an open ball of R^3. The analysis of $\tilde{g}$ near Λ has been performed in Ref. 21 where the analyticity of $\tilde{g}$ is also established.

[21] R. Beig and W. Simon, Commun. Math. Phys. **78**, 75 (1980); P. Kundu, J. Math. Phys. **22**, 2006 (1981).
[22] A rather interesting case of such degeneracy is encountered in the analysis of static, spherically symmetric solutions of Einstein non Abelian–Yang–Mills theory analyzed in detail in P. Breitenlohner, P. Forgacs, and D. Maison, Commun. Math. Phys. **163**, 141 (1994). In particular, the content of Proposition 1 in this reference is very suggestive. It shows that a given set of singular ordinary differential equations under suitable conditions upon its coefficients admits local analytic solutions in the vicinity of the degeneracy.
[23] Those theorems, established in Ref. 2 and so far highly unexplored, offer considerable insights into the structure of the space of solutions of the conformal system. Briefly, their content has as follows: relative to the coordinate gauge of (3a), if $V=e^U$, $\gamma_{ab}=V^{-2}\Lambda_{ab}$ is a static vacuum solution of Einstein equations, then for any $\gamma=(1-3\beta^2)^{1/2}$, $\beta\in[-3^{-1/2},3^{-1/2}]$, the following configurations (Φ,g), $\Phi=\alpha^{-1/2}(1\mp e^{2\beta U})(1\pm e^{-2\beta U})$, $g=\frac{1}{4}(e^{\beta U}\pm e^{-\beta U})(-e^{2\gamma U}dt^2+e^{2\gamma U}\Lambda_{ab}dx^a dx^b)$, satisfy the conformal equations (4a)–(4c). However, since $1-\alpha\Phi^2=\pm 4e^{2\beta U}/(1\pm e^{2\beta U})^2$ it follows that $1-\alpha\Phi^2$ is nonwhere vanishing within the entire static region, and, unfortunately, this theorem cannot employed, at least in a straightforward manner, to address our problem. The second theorem states that if $(\bar{\Phi},\bar{\Lambda}_{ab})$ is a solution of the Einstein–massless minimal coupled equations, then $\Phi=\tanh\bar{\Phi}$, $\Omega=(1-\Phi^2)$, and $\bar{\Lambda}_{ab}=\Omega^2\Lambda_{ab}$ is a

static solution of the conformal equations (4a)–(4c). Again regularity of Ω requires $1-\Phi^2\neq 0$ and thus similar comments apply to the content of the this theorem as well.

[24] Unfortunately the term ''degenerate'' will appear in various places in the text with different meanings. It has been used in the title, and there and elsewhere in the text degenerate solutions refers to solutions which in the first place are defined in the vicinity of degeneracy and, moreover, in the same region satisfy the relevant equations. The term degenerate equations has been explained in the text while the term degenerate Ricci refers to a Ricci where at least two of its eigenvalues coincide at a point or in an open vicinity of a given point.

[26] J. Ehlers and W. Kundt in *Relativity, Introduction to Current Research*, edited by L. Witten (Academic, New York, 1962).

[27] A theorem proven in Müller zum Hagen, D. C. Robinson, and H. J. Seifert, Gen. Relativ. Gravit. **4**, 53 (1973) asserts that on general grounds, the zeros of any nonidentically zero, analytic function in three variables consist of a finite union of analytical submanifolds of R^3 of dimensions zero (the case of an isolated zero), one, or two. Even though Φ satisfies an elliptic equation, unfortunately at this point we cannot infer local analyticity of Φ across degeneracies since nothing is known about the differentiability properties of the metric in an open vicinity of the zeros of $1-\Phi^2$. Thus the conclusion of the above-mentioned theorem is not of any help within the present context.

[28] In such an event the level surface of Φ is in general many-sheeted and a proof of this property can be found, for instance, in the appendix of Israel-1967 paper (Ref. 30). Additional discussion can also be found in P. Kellogg, *Potential Theory* (Dover, New York, 1931).

[29] For the definition as well as properties of this tensor see for instance, L. P. Eisenhard, *Riemannian Geometry* (Princeton University Press, Princeton, NJ, 1949).

[30] W. Israel, Phys. Rev. D **164**, 1776 (1967).

[31] This is a standard result and a proof can be found, for instance, in M. Spivak, *Introduction to Differential Geometry*, Vol. II (Publish or Perish, Houston, TX, 1979); J. A. Wolf, *Spaces of Constant Curvature* (McGraw-Hill, New York, 1967).

[32] It should be noted though that during this integration procedure the range of the Φ-coordinate nonwhere enters in a crucial manner, except that one implicitly assumes that the level surface of $\Phi=c$ admits no critical points. It is that property that allows us to consider the solutions as valid in a Φ-range given by $(1-\epsilon,1+\epsilon)$, $\epsilon>0$. In fact, since by construction $S(\Phi)|_{\Phi=1}\neq 0$, one may introduce a new coordinate r defined via $d\Phi/dr=c/S(\Phi)$, and obeying $\Phi(r=1)=1$. This ordinary equation admits a local solution and thus it is clear that $\Phi(r)$ satisfies $1-\Phi(r)=0$. We have avoided introducing this parametrization since the resulting $\Phi(r)$ is a rather complex expression involving in general transcendental functions.

[34] M. T. Anderson, gr-qc/0001018; Ann. Henri Poincare **1**, 995 (2000).

[35] This property of S, rather than being assumed, can also deduced from different considerations. Viewing Σ as an embedded spacelike hypersurface, the set S then is defined as the intersection of Σ with a Killing horizon. Topological properties of this intersection depend crucially on the structure of the Killing horizon and have been addressed in the literature. A concise account of the situation can be found in the work of Chruściel nicely summarized in the propositions (3.2) and (3.3) in P. T. Chruściel, Class. Quantum Grav. **16**, 661 (1999).

[36] We are not aware of any work in the literature where the construction of those metrics is derived *ab initio*. A comment in Ref. 26 indicates that in P. Jordan, J. Ehlers, and W. Kundt, Akad. Wiss. Lit. Mainz Abh. Math. Naturwiss. Kl. **1960**, 2 (1960) a derivation of the vacuum degenerate metrics is presented. Unfortunately, however, we had no access to that reference and thus we cannot offer any comment regarding the way those metrics have been constructed. The brief construction of the vacuum metrics presented in this work follows naturally from the integration procedure elaborated in Sec. II and the Appendix.

[37] All computations involving the construction of the scalar invariants reported in the present article have been done using the algebraic manipulation package GRtensorII developed by P. Musgrave, D. Pollney, and K. Lake, GRTensorII (Queen's University, Kingston, Ontario, 1994).

[38] Note that, in general, we cannot infer that the timelike Killing vector field possesses complete orbits. The issue is by no means trivial and it requires separate treatment. The passage from the local considerations, i.e., existence of the Killing field, to global considerations, i.e., completeness of its orbits, is a rather subtle issue and it is discussed at length in P. T. Chruściel, Class. Quantum Grav. **10**, 2091 (1993).

A rigidity theorem for nonvacuum initial data

Gábor Etesi[a)]
Yukawa Institute for Theoretical Physics, Kyoto University, 606-8502 Kyoto, Japan

(Received 26 January 2001; accepted for publication 8 October 2001)

In this note we prove a theorem on nonvacuum initial data for general relativity. The result presents a ''rigidity phenomenon'' for the extrinsic curvature, caused by the nonpositive scalar curvature. More precisely, we claim that in the case of an asymptotically flat nonvacuum initial data if the spatial metric has everywhere nonpositive scalar curvature, then the extrinsic curvature cannot be compactly supported. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421422]

I. INTRODUCTION

According to our experiences there are many different gravitational configurations in our physical world. Therefore, if general relativity is a correct theory of gravitational phenomena (at least at low energies), then it is important to know whether or not these various patterns can be modeled in general relativity, i.e., Einstein equations provide enough solutions for describing many different gravitational fields. Unfortunately or fortunately, Einstein equations form an extraordinarily difficult system of nonlinear partial differential equations for the four dimensional Lorentzian metric mainly because of the rich self-interactions of the gravitational field; hence in general it is a hard job to write down explicit solutions in this theory. Therefore, all methods which prove at least the existence of solutions are very important. From this viewpoint, the Cauchy problem or initial value formulation of general relativity is maybe the most powerful method to generate plenty of solutions.

As it is well known, the initial value formulation gives rise to a correspondence between globally hyperbolic space–times and gravitational initial data. Maybe we can say without an exaggeration that the class of globally hyperbolic space–times is the most important class of space–times from the physical point of view. Consequently, the initial data formulation provides not only many but also physically relevant solutions. The constraint equations between initial data are in the focal point of the initial data formulation. The question is whether or not these constraint equations are easier to solve than the original Einstein equation itself, making the method effective. Of course, the answer is typically yes.

This motivates the serious efforts made in order to understand the structure and provide solutions of constraint equations. Far from being complete we just mention the early works of Lichnerowicz (1944), Bruhat (1962), Choquet-Bruhat and Geroch (1969), Choquet-Bruhat and York (1980), Fisher and Marsden (1979), and Christodoulou and Klainerman (1993). These papers mainly deal with the analytical properties of the solutions. Witt proved the existence of solutions on a general three-manifold (Witt, 1986). More recently, in a sequence of papers Isenberg, Moncrief, Choquet-Bruhat, and York proved the existence of solutions under milder and milder assumptions (cf., e.g., Isenberg, 1995; Choquet-Bruhat *et al.*, 1992; Isenberg and Moncrief, 1996, moreover Choquet-Bruhat *et al.*, 2000).

The constraint equations involve the scalar curvature of the metric on the underlying Cauchy surface which is a three dimensional smooth manifold. Various properties of the solutions depend crucially on the scalar curvature, especially on its sign. But we know that in the problem of describing the sign of the scalar curvature, especially on a compact manifold, one encounters the topology of the space. Parallel to the investigations of solutions of the constraint equations by

[a)]Electronic mail: etesi@yukawa.kyoto-u.ac.jp

physicists and mathematicians, mathematicians proved remarkable results on the properties of the scalar curvature of Riemannian manifolds. By an early general result of Kazdan and Warner (1975) we know that for compact manifolds of dimension greater than two there is no constraint on the scalar curvature *if there is at least one point where it is negative*. This shows that it is easy to construct manifolds with negative scalar curvature. If we wish to construct manifolds with non-negative scalar curvature, however, we have to face various obstacles coming from the topology of the manifold. We just mention two basic examples. By results of Lichnerowicz and Hitchin, on spin manifolds it is often impossible to construct metrics of positive scalar curvature because of a subtle topological invariant, the so-called $\hat{A}$-genus (Hitchin, 1974; Lichnerowicz, 1963). Moreover, in three dimensions, the size of the fundamental group provides another obstruction for positive scalar curvature by results of Gromow and Lawson (1983) and Schoen–Yau (1984). An excellent survey on this branch of differential geometry is Besse (1987).

These observations make it not surprising that the topology of the Cauchy surface has a strong influence on the properties of initial data on it. The goal of this article is to understand this link a bit better. Our motivation is a paper by Witt (1986) who studied the problem of existence of initial data on general three-manifolds and examined certain characteristics of these initial data. In Sec. III we prove a theorem which states that on open Riemannian manifolds with everywhere nonpositive scalar curvature the extrinsic curvature field of nonvacuum initial data cannot be compactly supported, i.e., it has a ''tail'' at infinity although this tail may have sufficiently fast fall-off to make such an initial data still asymptotically flat. The proof of this theorem is elementary and is based on the following idea.

By using the initial data set (M,g,k) and the assumption that $\operatorname{supp} k$ is compact, we construct another ''universal'' initial data set $(M,g,\varphi g)$ where $\varphi: M \to \mathbb{R}$ is a compactly supported at least once continuously differentiable (or C^1-) function on M (with a little more effort this function could be smoothened but we do not need this). However, this leads us to a contradiction if the scalar curvature of g is nonpositive everywhere. In other words, we deform the original initial data set into a standard one whose properties are easier to understand.

II. BACKGROUND MATERIAL

First let us introduce some notations. Let W be a smooth manifold. We will call a tensor field T of type (m,n) over W if it is a smooth section of the bundle

$$T^{(m,n)}W := \underbrace{TW \otimes \ldots \otimes TW}_{m} \otimes \underbrace{T^*W \otimes \ldots \otimes T^*W}_{n}.$$

Remember that an *initial data set for general relativity* is a triple (M,g,k), where M is a (not necessarily compact) connected, oriented, smooth three-manifold, $g=(g_{ij})$ is a smooth, complete Riemannian metric on M, i.e., a nondegenerate smooth symmetric tensor field of type (0,2) on M while $k=(k_{ij})$ is a smooth, symmetric tensor field on M also of (0,2)-type. These fields must satisfy the following constraint equations (Hawking and Ellis, 1973; Wald, 1984):

$$\begin{aligned} s_g - |k|_g^2 + \mathrm{tr}^2 k &= 16\pi\rho, \\ \operatorname{div}(k - (\mathrm{tr}k)g) &= 8\pi J, \\ \rho \geqslant |J|_g &\geqslant 0. \end{aligned} \tag{1}$$

Here s_g is the scalar curvature of the metric g and $|\cdot|_g$ denotes various norms given by the induced scalar product on $T^{(m,n)}M$, e.g., $|k|_g^2 = \langle k,k\rangle = k_{ij}k^{ij}$. The operator $\mathrm{tr}: T^{(m,n)}M \to T^{(m-1,n-1)}M$ is the trace with respect to the metric, e.g., $\mathrm{tr}k = k^i_i$. For the sake of simplicity in the second equation we also denote by g and k the (1,1)-tensors with respect to the metric g [i.e., $g=(g^i_j)$, $k=(k^i_j)$ in the second equation]. The linear differential operator $\operatorname{div}: C^\infty(T^{(m,n)}M) \to C^\infty(T^{(m-1,n)}M)$ is the covariant divergence, defined by

$$\mathrm{div}T:=\mathrm{tr}(\nabla T),$$

where T is a tensor field of (m,n)-type and ∇ is the Levi–Civitá covariant derivative of the metric g. The smooth function $\rho:M\to\mathbb{R}$ is the energy-density, and the smooth covector field $J\in C^\infty(T^*M)$ with $|J|_g^2=\langle J,J\rangle=J_iJ^i$ is interpreted as the momentum-density of matter.

Supposing the energy- and momentum-densities correspond to classical nondissipative matter sources or vacuum ($J=0$, $\rho=0$), the coupled Einstein equations can be used to evolve the initial data set (M,g,k) into a (globally hyperbolic) smooth space–time (N,h) where $N\cong M\times\mathbb{R}$ and M is a Cauchy surface in N. Furthermore, $h|_M=g$ and k is the second fundamental form or extrinsic curvature of M in (N,h) (Hawking and Ellis, 1973; Wald, 1984)

Also remember that the open oriented three-manifold M has an *end* $E\subset M$ if there is a compact set $C\subset M$ such that $M\backslash C=E$ and $E\cong S_g\times(\mathbb{R}^+\backslash\{0\})$ where S_g is a compact, oriented surface of genus g and $\mathbb{R}^+=[0,\infty)$. An initial value data set (M,g,k) is called *asymptotically flat along E if M has an end* $E\cong S^2\times(\mathbb{R}^+\backslash\{0\})$ and the following asymptotical fall-off conditions hold for the complete metric g and the field k (r parametrizes $\mathbb{R}^+$ in E):

$$(g|_E)_{ij}=\delta_{ij}+O(1/r),\quad (k|_E)_{ij}=O(1/r^2),$$

$$\partial_l(g|_E)_{ij}=O(1/r^2),\quad \partial_l(k|_E)_{ij}=O(1/r^3),$$

$$\partial_l\partial_k(g|_E)_{ij}=O(1/r^3).$$

Notice that the definition of a manifold with an end does not exclude the possibility that M still has a boundary, different from the end E (strictly speaking, E is not a boundary). But the boundary points are added to M because $C=M\backslash E$ is compact according to our assumption. Consequently geodesic completeness of g requires that this extra boundary must be empty, in other words M is diffeomorphic to the punctured manifold $\tilde{M}\backslash\{y\}$ where $\tilde{M}$ is a connected, compact, oriented three-manifold without boundary.

Finally, the *support* of a tensor field $T\in C^\infty(T^{(m,n)}W)$ is the closed set

$$\mathrm{supp}T:=\overline{\{x\in W|T(x)\neq 0\}}.$$

After this background material, we are in a position to prove our theorem. The motivation is the following.

III. THE THEOREM

It was proved by Witt (1986) that every three-manifold with an end admits a nonvacuum, asymptotically flat initial data set. For a typical three-manifold, the resulting Cauchy developed space–time does not admit maximal slices, however; i.e., there are no maximal spacelike submanifolds whose extrinsic curvature is identically zero. One may raise the question: to what extent are these slices not maximal? In other words, what are the conditions on a Riemannian manifold (M,g) for its extrinsic curvature in the Cauchy development to be compactly supported at least? We will answer this question in our theorem.

Theorem (rigidity for nonvacuum initial data): *Let (M,g) be a connected, oriented, complete Riemannian three-manifold with an end $E\cong S^2\times(\mathbb{R}^+\backslash\{0\})$. Suppose the scalar curvature s_g of g is nonpositive everywhere and there is a nonvacuum initial data set (M,g,k) on it which is asymptotically flat along the end E. Then* $\mathrm{supp}\,k$ *is noncompact.*

Proof: Since the scalar curvature is nonpositive, the set $\mathrm{supp}\,s_g$ consists of the closure of those points where s_g is negative. Then the first and third (in)equalities of (1) show that $\mathrm{supp}\,s_g\subseteq\mathrm{supp}\,k$; therefore, if the scalar curvature is negative everywhere, the statement is trivially true, consequently we may assume that $\mathrm{supp}\,s_g\subset M$. In the same fashion, since (M,g,k) is a nonvacuum data set, there is a point $x_0\in M$ such that $\rho(x_0)\neq 0$. This yields $\mathrm{supp}\,\rho\neq\emptyset$. Being the scalar curvature nonpositive, via the first and third (in)equalities of (1) again we have $k(x_0)\neq 0$,

i.e., $\operatorname{supp}\rho\subseteq\operatorname{supp}k$. Therefore, if the energy density is supported everywhere, the theorem is again trivially valid, consequently we may assume $\operatorname{supp}\rho\subset M$. Consider a subset $C\subset M$ such that $\operatorname{supp}s_g\subset C$ and $\operatorname{supp}\rho\subset C$ and suppose the decomposition $M=C\cup E$ is valid where E denotes the end of M. Consequently, by the structure of M we may assume that C is compact. This shows that there is a constant

$$0<a:=\sup_{x\in C}(-|k(x)|_g^2+\operatorname{tr}^2k(x))<\infty.$$

Consider a triple $(M,g,\varphi g)$ where $\varphi:M\to\mathbb{R}$ is a C^1-function. This triple is a weak initial data set if it obeys the constraint equations (here by "weak" we mean that the initial data set in question is not smooth, only C^k for some $k\in\mathbb{N}$):

$$s_g+6\varphi^2=16\pi\rho,$$

$$-2\operatorname{div}(\varphi g)=-2\operatorname{tr}(\nabla(\varphi g))=-2\operatorname{tr}(\mathrm{d}\varphi\otimes g)=8\pi J,$$

$$\rho\geqslant|J|_g\geqslant 0.$$

In the second equation we have used the fact that $\nabla g=0$. These (in)equalities can be combined into a first order partial differential inequality for the unknown function φ:

$$\tfrac{1}{4}(s_g+6\varphi^2)\geqslant|\mathrm{d}\varphi|_g, \tag{2}$$

taking into account that $|\operatorname{tr}(\mathrm{d}\varphi\otimes g)|_g=|\mathrm{d}\varphi|_g$. *Assume $\varnothing\neq\operatorname{supp}k\subset M$ is compact, i.e., the theorem is not true.* In this case we construct a compactly supported function φ out of the original data (M,g,k) such that $(M,g,\varphi g)$ is a weak initial data set. We achieve this in three steps.

(*i*) *Construction of φ in the compact interior of M.* Let us identify the end $E\subset M$ with $S^2\times(\mathbb{R}^+\setminus\{0\})$. By assumption $\operatorname{supp}k$ is compact in M, consequently there is an $R_1\in\mathbb{R}^+$ satisfying $S^2\times(R_1,\infty)\not\subset\operatorname{supp}k$. Note that this is possible only if $s_g|_{S^2\times(R_1,\infty)}=0$. We can take the choice $C:=M\setminus(S^2\times(R_1,\infty))$ for the compact set used in the definition of the constant a. We construct the function φ in C as follows:

$$\varphi(x):=-\sqrt{a},\quad x\in C.$$

In other words φ is a constant negative function on M except the infinite tube $S^2\times(R_1,\infty)$. Note that with this function (2) is trivially satisfied in C because (M,g,k) is an initial data set on C.

(*ii*) *Construction of φ along an annulus in E.* Consider an inner point $x_0\in C\subset M$ where $\rho(x_0)>0$ and $k(x_0)\neq 0$. There is an open (geodesic) ball $B_\varepsilon(x_0)\subset M$ of radius $\varepsilon>0$ such that $\rho|_{B_\varepsilon(x_0)}>0$ and $k|_{B_\varepsilon(x_0)}\neq 0$. Consider the annulus $U_\varepsilon:=\overline{B_\varepsilon(x_0)\setminus B_{\varepsilon/2}(x_0)}\cong S^2\times[\varepsilon/2,\varepsilon]$. Take another constant $R_1<R_2<\infty$ and the diffeomorphism

$$\beta:U_\varepsilon\to S^2\times[R_1,R_2],\quad x_t=(p,t)\mapsto\left(p,R_1+\frac{2t-\varepsilon}{\varepsilon}(R_2-R_1)\right)=(p,r),$$

where $p\in S^2$ and the point $x_t\in U_\varepsilon$ is identified with $(p,t)\in S^2\times[\varepsilon/2,\varepsilon]$. Here $S^2\times[R_1,R_2]$ is also an annulus in the tube E. By assumption g is asymptotically flat, i.e., the function $\sqrt{g^{11}}\geqslant 0$ is bounded, consequently there is a constant

$$0<b:=\sup_{x\in M}\sqrt{g^{11}(x)}<\infty$$

(here $x^1=r$). Choose a smooth function $\psi:[R_1,R_2]\to\mathbb{R}^-$. Viewing it as a function on $S^2\times[R_1,R_2]$ (i.e., a function depending only on r), one obtains the estimate

$$b|\psi'| \geqslant |\sqrt{g^{11}}\psi'| = |\mathrm{d}\psi|_g , \tag{3}$$

where prime denotes differentiation with respect to r. Now we define ψ as follows:

$$\psi(\beta(x_t)) := \begin{cases} -\sqrt{a}, & \text{if } t = \dfrac{\varepsilon}{2} \\ \text{arbitrary but the derivative of } \psi \text{ is small}, & \text{if } t \in \left(\dfrac{\varepsilon}{2}, \varepsilon\right), \\ 0, & \text{if } t = \varepsilon . \end{cases}$$

In this definition the smallness of ψ' means the following. Consider a differentiable curve $\gamma : [\varepsilon/2, \varepsilon] \to U_\varepsilon$ given by

$$t \mapsto x_t := (\Theta_{\varepsilon/2} + A \sin(R_2 - R_1)t,\ \phi_{\varepsilon/2} + A \sin(R_2 - R_1)t, t).$$

This is a high-speed curve because it oscillates rapidly inside $B_\varepsilon(x_0)$. More precisely, for its speed $|\dot{\gamma}(t)|_g \sim R_2 - R_1$ is valid (dot denotes differentiation with respect to t). We can take a choice for the point x_0 and the amplitude A, and initial phases $\Theta_{\varepsilon/2}$ and $\phi_{\varepsilon/2}$ of the curve γ such that

$$\mathrm{d}\left(\sqrt{-|k(x_t)|_g^2 + \mathrm{tr}^2 k(x_t)}\right)(\dot{\gamma}(t)) \sim -(R_2 - R_1) < 0$$

holds for each $t \in [\varepsilon/2, \varepsilon]$. Then we suppose

$$0 \leqslant \psi'(\beta(x_t)) \leqslant \min\left(-\frac{\varepsilon}{4(R_2 - R_1)} \mathrm{d}\left(\sqrt{-|k(x_t)|_g^2 + \mathrm{tr}^2 k(x_t)}\right)(\dot{\gamma}(t)), \frac{16\pi}{b}\rho(x_t) \right). \tag{4}$$

It is also clear that such a function exists if R_2 is suitably large: let ψ be an arbitrarily smooth, negative-valued function $\psi : S^2 \times [R_1, R_2] \to \mathbb{R}^-$ with initial value $\psi(p, R_1) = \psi(\beta(x_{\varepsilon/2})) = -\sqrt{a}$. Suppose there is an interval $[R, R+T] \subset [R_1, R_2]$ such that ψ' obeys (4), but there is a constant $c > 0$ with $\psi'(p,r) \geqslant c$ if $r \in [R, R+T]$. This constant can be chosen to be independent of $R_2 - R_1$. In this case we can estimate for large R_1 and R_2 as follows:

$$\psi(p, R_2) \geqslant -\sqrt{a} + \frac{1}{2}\int_{R_1}^{R_2} \psi'(p,r)\mathrm{d}r \geqslant -\sqrt{a} + \frac{1}{2}\int_{R}^{R+T} \psi'(p,r)\mathrm{d}r \geqslant -\sqrt{a} + \frac{c}{2}T.$$

In other words, if T, that is, $R_2 - R_1$, is sufficiently large, we can achieve that $\psi(p, R_2) = 0$. We choose φ on $S^2 \times [R_1, R_2]$ to be the ψ just constructed.

It is not difficult to check that φ obeys (2) in $S^2 \times [R_1, R_2]$. Indeed, by the definition of the constant a we have

$$\varphi(p, R_1) = \varphi(\beta(x_{\varepsilon/2})) = -\sqrt{a} \leqslant -\sqrt{-|k(x_{\varepsilon/2})|_g^2 + \mathrm{tr}^2 k(x_{\varepsilon/2})}.$$

Taking suitable large R_1 and R_2, exploiting the decay of the metric g and using (4) this implies that for each $t \in [\varepsilon/2, \varepsilon]$ we have

$$\begin{aligned} \varphi(\beta(x_t)) = \varphi(p,r) &= -\sqrt{a} + \int_{R_1}^{r} \mathrm{d}\varphi(p,\varrho)(\beta'(x_\tau))\mathrm{d}\varrho \\ &= -\sqrt{a} + \int_{R_1}^{r} \varphi'(p,\varrho)\Big(g_{11}(p,\varrho) + A\frac{\varepsilon}{2}(g_{12}(p,\varrho) + g_{13})(p,\varrho) \\ &\quad \times \cos\frac{\varepsilon}{2}(\varrho + R_2)\Big)\mathrm{d}\varrho \end{aligned}$$

$$\leqslant -\sqrt{a}+2\int_{R_1}^{r}\varphi'(p,\varrho)\,\mathrm{d}\varrho$$

$$=-\sqrt{a}+\frac{4(R_2-R_1)}{\varepsilon}\int_{\varepsilon/2}^{t}\varphi'(\beta(x_\tau))\,\mathrm{d}\tau$$

$$\leqslant -\sqrt{-|k(x_{\varepsilon/2})|_g^2+\mathrm{tr}^2k(x_{\varepsilon/2})}-\int_{\varepsilon/2}^{t}\mathrm{d}\big(\sqrt{-|k(x_\tau)|_g^2+\mathrm{tr}^2k(x_\tau)}\big)(\dot\gamma(\tau))\,\mathrm{d}\tau$$

$$=-\sqrt{-|k(x_t)|_g^2+\mathrm{tr}^2k(x_t)}.$$

Consequently,

$$\varphi^2(\beta(x_t))\geqslant -|k(x_t)|_g^2+\mathrm{tr}^2k(x_t).$$

Therefore, since $s_g(\beta(x_t))=0$ and $0\geqslant s_g(x_t)$, we can write

$$\tfrac{1}{4}(s_g(\beta(x_t))+6\varphi^2(\beta(x_t)))=\tfrac{3}{2}\varphi^2(\beta(x_t))\geqslant s_g(x_t)-|k(x_t)|_g^2+\mathrm{tr}^2k(x_t)=16\pi\rho(x_t).$$

Moreover, also by (4), we have for the same $x_t\in U_\varepsilon$ that $16\pi\rho(x_t)\geqslant b\varphi'(\beta(x_t))$. This gives rise to our key inequality

$$\tfrac{3}{2}\varphi^2(\beta(x_t))\geqslant b\varphi'(\beta(x_t)),\tag{5}$$

showing via (3) that (2) is again satisfied in the annulus $S^2\times[R_1,R_2]$.

(iii) Construction of φ along the remaining part of the infinitely long tube in M. Finally, define

$$\varphi(x):=0\quad\text{if } x\in S^2\times[R_2,\infty).$$

Again, (2) is trivially valid.

Consider the function $\varphi:M\to\mathbb{R}^-$ defined through (i)–(iii). This is a continuous negative function on M and is compactly supported: it is equal to zero for all $r\geqslant R_2$ and equal to the constant $-\sqrt{a}$ if $r\leqslant R_1$. Its derivative is also compactly supported in $S^2\times[R_1,R_2]$ and is positive. Moreover, φ can be adjusted to be C^1 on M (note that φ is smooth except at the junction points): it is clearly C^1 at $r=R_2$ by (5). However, by exploiting the freedom in the construction of φ in the inner points of the annulus, we can deform it to be C^1 at $r=R_1$ as well [i.e., we may assume that $\varphi'(p,r)\to 0$ as $r\to R_1$]. In this way we have constructed a weak C^1 initial data set $(M,g,\varphi g)$ (with a little effort we could smooth this data but we do not need this).

The compactly supported φ depends nontrivially only on r with $(p,r)=\beta(x_t)\in S^2\times[R_1,R_2]$ and satisfies the ordinary differential inequality (5). Now we demonstrate that it is impossible. Dividing by φ'^2 and taking reciprocies in (5) we get

$$\left(\frac{\varphi'}{\varphi}\right)^2\leqslant\frac{3\varphi'}{2b},$$

which is nothing but

$$-\sqrt{\frac{3\varphi'}{2b}}\leqslant\frac{\varphi'}{\varphi}\leqslant\sqrt{\frac{3\varphi'}{2b}}.$$

By integrating the left inequality from R_1 to $r<R_2$ we arrive at the following estimate:

$$\log\sqrt{a}-\sqrt{\frac{3}{2b}}\int_{R_1}^{R_2}\sqrt{\varphi'(p,\varrho)}\,\mathrm{d}\varrho\leqslant\log(-\varphi(p,r)).$$

At this point we have used the inequality

$$0<\int_{R_1}^{r}\sqrt{\varphi'(p,\varrho)}\,\mathrm{d}\varrho\leqslant\int_{R_1}^{R_2}\sqrt{\varphi'(p,\varrho)}\,\mathrm{d}\varrho<\infty$$

for the non-negative function φ'. This shows that the logarithm of φ is bounded from below. However, being φ compactly supported, $\log(-\varphi(p,r))$ is unbounded, as r approaches R_2. Consequently the last but one inequality shows a contradiction yielding our original assumption, that $\operatorname{supp} k$ is compact, was wrong. We finished the proof. ◇

Remarks. (1) We would like to summarize here how the original initial data (M,g,k) was used in the construction because apparently its behavior has been taken into account only in a particular small ball $B_\varepsilon(x_0)$. But, in fact, the construction is sensitive for the global characteristics of the original initial data. In step (i) we considered (M,g,k) in the whole interior C by exploiting the existence of the constant a which is in some sense the maximum of k in the whole compact C. This enabled us to ''pump up'' the original initial data in C into a standard one which corresponds to the extremal point(s) of the original extrinsic curvature in some sense. Concerning part (iii), we have seen in the beginning of the proof that the only interesting possibility for our would-be initial data with compactly supported extrinsic curvature was the case where both the scalar curvature and energy-density were compactly supported. Consequently all fields in the initial data vanish along the tube for very large r yielding the hypothetical initial data did not carry ''information'' along an infinitely long part of the end E. This is in accordance with the fact that our adjusted universal initial data $(M,g,\varphi g)$ was also trivial on this portion. Finally, part (ii), which is the descending regime, is nothing but a magnification of the behavior of (M,g,k) in a small ball where matter is present via the diffeomorphism β. Indeed this small ball is responsible for the details of the fall-off of φ (we could have used equally well any other ball), however, the fact that this function can vanish within a finite distance is again guaranteed by the global properties of the original would-be initial data set: namely the only interesting case was when all fields were compactly supported.

(2) Note that even if $\operatorname{supp} k$ is noncompact the nonvacuum data (M,g,k) may be asymptotically flat, as it is shown by Witt (1986) who constructs nonvacuum, asymptotically flat initial data for every three-manifold with an end. But the above theorem is sharp in the following sense. If we allow for a Riemannian manifold (M,g) to have positive scalar curvature in a suitable region in M, it is possible to construct nonvacuum asymptotically flat initial data with compactly supported second fundamental form. An example is the Tolman–Bondi solution. This is because in this case the key inequality (5) can be written in the form

$$\tfrac{1}{4}(s_g+6\varphi^2)\geqslant b\varphi'$$

with $s_g>0$ in the positive scalar curvature regime and it may have compactly supported solutions. But if s_g is still negative somewhere, then k is nonzero in that point; consequently, the initial surface is not a maximal slice in this case.

(3) Notice that the above considerations do not remain valid for *vacuum initial data*. For example, the Schwarzschild space–time has initial data with nonpositive scalar curvature (namely it is identically zero) but the extrinsic curvature of the initial surface is compactly supported (namely identically zero, i.e., the initial surface is a maximal slice). We conjecture that the analog of the above theorem for vacuum initial data is the following: if (M,g) is an asymptotically flat three-manifold with *some*where negative scalar curvature, then any vacuum initial data set (M,g,k) cannot be asymptotically flat (i.e., the extrinsic curvature cannot decay at the required rate). But in this moment we are unable to prove this.

IV. CONCLUDING REMARKS

In the previous section we have studied gravitational initial data from a general point of view. We have found that in the case of nonpositive scalar curvature, the behavior of the extrinsic curvature becomes very ''rigid:'' for open manifolds, the fall-off of the extrinsic curvature cannot be arbitrary.

The negativity of the scalar curvature becomes important by an early general result of Kazdan and Warner (1975):

Theorem (Kazdan–Warner): *Let W be a compact manifold with* $\dim W \geqslant 3$, *and $f: W \to \mathbb{R}$ be a smooth function on it such that there is a point $x \in W$ obeying $f(x) < 0$. Then there is a smooth Riemannian metric h on W such that $s_h = f$,* i.e., *whose scalar curvature is the prescribed function f.* ◇

The theorem demonstrates that a compact manifold of sufficiently large dimension always can be endowed with a metric with somewhere negative scalar curvature. This shows, taking into account the constraint equations, that it is relatively easy to construct initial data with somewhere non-zero extrinsic curvature.

The classical results of Gromow and Lawson (1983) and Schoen and Yau (Schoen, 1984), however, show that closed three-manifolds whose prime decomposition contains a $K(\pi,1)$ factor (this implies such manifolds have infinite fundamental groups) do not carry any metric with positive scalar curvature. Consequently, initial data with positive scalar curvature must be rare at least in the compact case.

If the compact $\tilde{M}$ does not have positive scalar curvature, the punctured, open manifold $M = \tilde{M} \backslash \{y\}$ of this type, which is nothing but a manifold with an end, does not have a metric with non-negative scalar curvature, too. Consequently, these punctured manifolds do not admit nonvacuum, asymptotically flat initial data with identically zero extrinsic curvature. Furthermore, if the scalar curvature is everywhere nonpositive, then this extrinsic curvature has noncompact support, as we have seen.

These results are quite surprising because all the fields in question are defined in the class of smooth functions, so one would expect that initial data can be altered *locally* in a nontrivial way. In other words, we have reduced the local degrees of freedom of the gravitational field in some sense.

In this paper we use a general version of Fermat's principle for light rays in general relativity and a curve shortening method to write the Morse relations for light rays joining an event with a smooth timelike curve in a Lorentzian manifold with boundary. The Morse relations are obtained under the most general assumptions and one can apply them to have a mathematical description of the *gravitational lens effect* in a very general context. Moreover, Morse relations can be used to check if existing models are corrected. © *2002 American Institute of Physics.*

I. INTRODUCTION

Fermat's principle in classical optics states that the trajectory of a light ray from a source A to a target B is such that it is a minimizer, or better, a stationary curve for the travel time among all the paths joining points A and B.

This variational principle can be extended in the context of general relativity where the trajectory of a light ray under the action of the gravitational field in vacuum is given by a null geodesic in the Lorentzian manifold modeling the space–time generated by a gravitational mass distribution.

A formulation of Fermat's principle is given once the following data are determined:

(1) a set of *trial curves* joining the light source and the observer;
(2) a *functional* that associates to each trial curve a real number, which has to be related to a measurement of the *time* passed from the instant at which the photon departed from the light source to the instant at which the photon arrives to the observer.

A mathematical proof of Fermat's principle consists in proving that the trajectory of a light ray is *characterized* as a stationary point of the time functional in the set of trial curves.

The geodesics in a semi-Riemannian manifold are characterized as solutions of differential equations, and the *local* theory of the light rays can be developed in terms of systems of differential equations in $\mathbb{R}^n$. However, the variational approach has the advantage of providing techniques for proving *global* existence results, and also for producing several kinds of estimates on the number of solutions, given in terms of the topology of the space of trial curves. To this aim in this paper we prove the *Morse relations* for light rays, which will be presented in detail in Sec. II. We now proceed to a general discussion of the mathematical problem, its physical applications, and a presentation of the results that will be proven in this paper.

We fix a Lorentzian manifold $(\mathcal{M},g)$ that is the mathematical model of our relativistic space–time, and we assume that $\mathcal{M}$ is endowed with a time orientation given by the choice of a continuous timelike vector field W on $\mathcal{M}$. Such assumption is indeed very mild; namely, given

[a)]Electronic mail: giannoni@campus.unicam.it
[b)]Electronic mail: masiello@pascal.dm.uniba.it
[c)]Electronic mail: piccione@ime.usp.br

any Lorentzian manifold, there always exists a twofold covering $\tilde{\mathcal{M}}$ of $\mathcal{M}$ that admits a time orientation (cf. Ref. 1), and clearly there is a two-to-one correspondence between the geodesics in $\tilde{\mathcal{M}}$ and those on $\mathcal{M}$. If we want to study the light rays emitted by some source at a given time in the past, represented by an event p of $\mathcal{M}$, and reaching an observer sometimes during its life, whose worldline is given by a timelike curve γ in $\mathcal{M}$, then we need to determine all the lightlike future pointing geodesics joining p and γ in $\mathcal{M}$. We are assuming here that both the source and the receivers are *pointlike*, i.e., they have dimensions which are neglectible with respect to their distance; a variational principle for light rays between a spatially extended source and a spatially extended receiver may be found in Ref. 2.

In analogy with the principle in classical optics, the set of trial curves is chosen to be the set of all possible future pointing trajectories joining the source with the observer, and that are run at the speed of light. This amounts to saying that a trial curve is a curve whose tangent vector is everywhere in the light cone, and it belongs to the same half light cone as the vector field W.

The choice of the *regularity* to impose on the trial curves and, most of all, the choice of the functional to be extremized are rather delicate questions, which have deep consequences for the mathematical theory to be developed.

The first relativistic formulation of the principle, valid in the case of a *static* space–time, is due to Weyl (see Ref. 3); the validity of the general relativistic Fermat's principle was successively extended to the case of *stationary* space–times by Levi-Civita (see Ref. 4). For *conformally stationary* space–times an alternative formulation of the principle is given in Ref. 5.

The first attempt to extend Fermat's principle beyond the (conformally) stationary case is due to Uhlenbeck (see Ref. 6), who considered a Lorentzian manifold diffeomorphic to a space–time splitting $\mathcal{M}_0\times\mathbb{R}$ and a time-dependent metric which is diagonal with respect to this product. The variational principle proven in Ref. 6 employs the time functional given by the projection onto the second factor calculated at the final point of each trial curve. Such functional does not depend on the parametrization of the trial curve as, for instance, the *length* functional for curves in a Riemannian manifold, and this lack of *rigidity* makes it a difficult task to obtain results of the existence and multiplicity of critical points. For this reason, in order to prove the classical Morse relations the author employs an action functional whose Lagrangian function depends quadratically on the velocities. This kind of functional has a strict relationship with the *energy* functional for Riemannian geodesics, obtained by *removing the square root* inside the integral that defines the length. The same variational principle was used in Ref. 7 to obtain Morse relations for light rays on orthogonal splitting Lorentzian manifolds, using an infinite dimensional setting and covering some gaps that occur in Ref. 6. Such a variational principle was extended in Ref. 8 to *stably causal* Lorentzian manifolds having a smooth time function and applied in Refs. 9 and 10 to obtain multiplicity results and Morse relations for light rays joining an event p with a timelike curve γ in the presence of a smooth convex boundary.

A very general version of the principle, valid in all space–times, was given recently by Kovner (see Ref. 11), who introduced the so called *arrival time* functional with respect to the observer γ, defined on the space of *piecewise smooth* lightlike curves joining p and γ. Such functional is given by fixing any (future pointing) parametrization of γ, and assigning to each trial curve the value of the parameter of γ at the arrival point. Any two future pointing parametrizations of γ differ by an order preserving diffeomorphism between two intervals of the real line; it is an easy observation that the stationary points of the arrival time functional do not indeed depend on the choice of the parametrization of γ.

A rigorous mathematical proof of the Kovner's claim was given in Ref. 12. However, the proof in Ref. 12 needs the assumption that the critical points have nonzero derivative everywhere.

An alternative variational principle on the space of lightlike curves z with a suitable prescribed parametrization and satisfying $\dot{z}(s)\neq 0$ for all s, can be found in Ref. 13. However, using this approach it is not possible to obtain Morse relations, as will be clear from the discussion presented in Appendix B.

In Ref. 10 the reader will find a more detailed presentation of the different versions of the

relativistic Fermat principle and some examples and applications to the multiple image effect (the so called "gravitational lens effect").

In Ref. 14 published in 1979, Walsh, Carlswell, and Weymann discussed the possibility that the double quasar $0957+561$ would be a good candidate for a gravitational lens effect. Such a name refers to the phenomena occurring when a multiple image of some stellar object is observed. The multiple image effects are due to the deflection of the light in the presence of a gravitational field. We refer, e.g., to Refs. 15 and 16 for a detailed physical description of the gravitational lens effect and many physical examples. In Refs. 17 and 18 it is shown how one can use the Morse relations to check if a model is corrected or not. The version of the relativistic Fermat principle introduced by Kovner also allows one to treat nonstationary situations such as a gravitational wave sweeping over a gravitational lensing situation. More details can be found in Ref. 19.

Some natural questions arise in the study of the gravitational lensing effect; for instance, an attempt is made to understand under which circumstances a multiple imaging of a distant source can occur, and, in this case, how many images of the source can be seen. In mathematical terms, these questions can be answered by giving conditions on the topology and the metric of the space–time that guarantee a multiplicity of lightlike geodesics between p and γ lying inside an open set Λ, which represent the region of the universe in which to localize the description for any gravitational lens. As already mentioned, a technique for investigating these issues is provided by the Morse theory, which is a well-established mathematical theory that relates the critical points of a smooth functional with the topology of the underlying space.

The main purpose of this paper is to develop an infinite dimensional Morse theory under *minimal* assumptions on the global structure of the space–time and on the timelike curve γ. This, in particular, allows us to extend the results in Refs. 5, 6, 7, and 10 concerning Morse relations. Most of all, we want to push the results beyond the compactness assumption of *global hyperbolicity* made in Refs. 6 and 7; we also generalize the results of Ref. 10 in the following directions:

(1) we do not assume the *stable causality* of the Lorentzian manifold $(\mathcal{M},g)$, which will only be assumed to be time orientable;
(2) we do not assume any regularity for the boundary $\partial\Lambda$ of the region Λ;
(3) we do not assume that γ is embedded as a *closed* subset of $\Lambda\subseteq\mathcal{M}$.

Observe in particular that the second generalization above allows one to also extend the results to light rays moving on a region of the universe exterior to a static blackhole (see Ref. 20). For the functional framework, we will employ Kovner's arrival time functional, denoted by τ; observe that the definition of τ does not require the existence of a *global time function* on Λ, which was a crucial assumption in Refs. 7 and 10.

For a correct physical interpretation of our results, all the relevant information about the light rays joining p and γ must be encoded in the open subset Λ. For this reason, if $\Lambda\neq\mathcal{M}$, we assume the following *convexity* property of Λ:

$$\begin{aligned}&\textit{every lightlike geodesic starting from any event in } \Lambda\\ &\textit{and moving outside } \overline{\Lambda} \textit{ does not come back in } \Lambda.\end{aligned}\tag{$*$}$$

Note that assumption $(*)$ is not strictly necessary to develop our theory. As a matter of fact, we will use a more general assumption: the light convexity of the boundary of Λ (cf. (3) in Sec. III). Observe also that in the Minkowski space–time a set $\Lambda_0\times\mathbb{R}$ satisfies condition $(*)$ precisely when Λ_0 is convex. Other simple examples of space–times satisfying $(*)$ are the regions outside the event horizon of the Schwarzschild and Reissner–Nordström space–times (see Ref. 21).

Our Morse relations are given for future pointing lightlike geodesics; we remark here that there is also a time-reversed version of Fermat's principle. Namely, p can be interpreted as a pointlike receiver at a particular instant of time and γ as the worldline of a pointlike light source, in which case one is interested in determining the past pointing light rays from p to γ. Clearly, the results proven in the paper are still valid in the past pointing case. From a mathematical point of

view, the case of past pointing light rays is completely analogous, and will not be treated explicitly in this paper.

In Sec. II we will give a formal statement of our results, and we will present arguments to show that our assumptions cannot be weakened to obtain a Morse theory.

The reader is referred to classical books such as those noted in Refs. 1, 20, and 22 for the main notions and properties in Lorentzian geometry.

Finally, we remark that alternative approaches to the study of the Morse theory for light rays are available in Refs. 23–25; the author applies the Morse theory in a time independent *quasi-Newtonian* setting.

II. STATEMENT OF THE RESULTS AND SOME DISCUSSION ABOUT THE ASSUMPTIONS

Let $(\mathcal{M},g)$ be a smooth Lorentz manifold, Λ an open connected subset of $\mathcal{M}$, $p\in\Lambda$, $\gamma:]\alpha,\beta[\to\Lambda$ a smooth timelike curve such that $p\notin\gamma(]\alpha,\beta[)$. Here and in the rest of the paper we will often set $\langle\cdot,\cdot\rangle\equiv g(z)[\cdot,\cdot]$.

We assume that $(\mathcal{M},g)$ is time orientable. This means that there exists a smooth vector field W on $\mathcal{M}$ such that $\langle W(z),W(z)\rangle<0$ for any $z\in\mathcal{M}$. With respect to the orientation W we assume that

(1) *γ is future pointing,*

namely

$$\langle\dot\gamma(s),W(\gamma(s))\rangle<0\,\forall s\in]\alpha,\beta[.$$

Since we want to study future pointing light rays joining p and γ in Λ, we shall only consider past and future relative to Λ. More precisely given two points q_1 and q_2 in Λ, we say that q_2 is in the future of q_1 [in symbols $q_2\in J^+(q_1,\Lambda)$] if there exists a piecewise smooth curve $y:[0,1]\to\Lambda$ such that $\langle\dot y,\dot y\rangle\leqslant 0$ (i.e., y is a causal curve), $\langle\dot y,W(y)\rangle<0$ (i.e., y is future pointing), $y(0)=q_1, y(1)=q_2$. In general if $A\subset\Lambda$ the future of A (in Λ) is the set

$$J^+(A,\Lambda)=\bigcup_{a\in A}J^+(a,\Lambda),$$

while the past of A (in Λ) is the set

$$J^-(A,\Lambda)=\{q\in\Lambda: A\cap J^+(q,\Lambda)=\varnothing\}.$$

To have future pointing lightlike curves joining p and γ in Λ, clearly we need the following assumptions:

(2) *there exists $q_+\in\gamma(]\alpha,\beta[)\cap J^+(p,\Lambda)$.*

Moreover a light-convexity assumption on the closure $\overline{\Lambda}$ of the open subset Λ is needed:

(3) *$\overline{\Lambda}$ is light convex, i.e., all the lightlike geodesics in $\Lambda\cup\partial\Lambda$ with endpoints in Λ are enterely contained in Λ.*

Here $\partial\Lambda$ is the topological boundary of Λ. Finally, to be able to define the arrival time functional we need

(4) $\gamma:]\alpha,\beta[\mapsto\Lambda$ *is injective.*

By (4), on the space of the curves joining p and γ on the interval $[0,1]$, the arrival time functional is well defined

$$\tau(z)=\gamma^{-1}(z(1)). \tag{2.1}$$

The following assumptions says that τ is bounded from below on the set of the future pointing lightlike curves joining p and γ.

(5) *There exists $q_-\in\gamma(]\alpha,\beta[)\setminus J^+(p,\Lambda)$.*

Since we do not require that $\partial\Lambda$ is smooth we are not able to use the same penalizing argument as in Refs. 9 and 10 to overcome the difficulties due to the presence of the boundary. To

develop a Morse theory for the arrival time functional we should need a flow which is strictly decreasing far from the critical points. Since the boundary is not smooth a convenient approach is a shortening method.

Assumption (3) is necessary because we need a flow that it is invariant with respect to the lightlike curves with image in Λ. Note that to develop a Morse theory the presence of the boundary is a difficulty to bypass because we want to treat with ''free'' critical points lying in $\overline{\Lambda}$. Note also that, even if the boundary would be smooth, a shortening method seems technically more simple that the penalized techniques used in Refs. 7, 9, and 10. Moreover, since τ is invariant by reparametrizations, as well as the space of future pointing lightlike curves joining p and γ, a shortening approach also seems to be a good help to overcome this kind of difficulty.

To use the shortening method we need an assumption assuring the existence of minimizers in Λ between events and timelike curves. For this reason we also need the following assumption (6) *there exists a smooth timelike vector field W in $\mathcal{M}$ having the following properties:* (a) *γ is an integral curve of W* (*namely $\dot{\gamma}=W(\gamma)$ for any $s\in]\alpha,\beta[$*), (b) *for any $q\in J^+(p,\Lambda)\cup J^-(\gamma(]\alpha,\beta[),\Lambda)$ if γ_q is the maximal integral curve of W such that $\gamma_q(0)=q$, there is $\overline{q}\in[\mathrm{Im}\,\gamma_q\cap\Lambda]\backslash J^+(p,\Lambda)$.*

Here Im γ_q denotes the image of the curve γ_q. Note that assumption (6) is certainly satisfied if Λ is invariant with respect to the flow of W.

Morse theory gives an algebraic relation (in terms of formal series) between the critical points of a suitable functional (in our case the arrival time functional) and the topology of the space where the functional is defined. At this point there are two options: to introduce a Sobolev space of lightlike curves or to use broken lightlike geodesics as space of trial curves.

To state Morse relations we prefer here to use the second choice since it does not require the use of any auxiliary (Riemann) structure. Nevertheless in Sec. III we shall give an infinite dimensional formulation of the Fermat principle using Sobolev spaces. Indeed, even if we use a shortening procedure it is more convenient than an infinite dimensional approach to study the arrival time functional close to its critical points. This is due to the fact that here it is hard to try to reduce (as, e.g., in Refs. 6 and 7) the study of the functional τ on a space of curves joining two fixed points.

For this reason we are not able to adapt to our case the Milnor finite dimensional approximation scheme (cf. Ref. 26) close to critical points.

Now set

$$\begin{aligned}\mathcal{B}^+_{p,\gamma}(\Lambda)&\\ &=\{z:[0,1]\to\Lambda : z \textit{ is a } C^2 \textit{ piecewice curve such that } z(0)\\ &=p, z(1)\in\gamma(]\alpha,\beta[) \textit{ and, on any interval } [a,b]\subset]\alpha,\beta[\\ &\textit{where } z \textit{ is of class } C^2,\ z \textit{ is a constant or a future pointing light-like geodesic}\}.\end{aligned} \tag{2.2}$$

We point out that a curve $z\in\mathcal{B}^+_{p,\gamma}(\Lambda)$ may be constant on some interval $[a,b]\subset[0,1]$ (and therefore $z_{|[a,b]}$ is not a lightlike geodesic). Nevertheless the topological structure of the problem is carried on by the space $\mathcal{B}^+_{p,\gamma}(\Lambda)$, instead of the space $\hat{\mathcal{B}}^+_{p,\gamma}(\Lambda)$ of the broken lightlike geodesics (without subintervals where z is constant). A simple example in Appendix B shows that Morse relations cannot be written using $\hat{\mathcal{B}}^+_{p,\gamma}(\Lambda)$.

In Sec. V we shall prove the homotopy equivalence between $\mathcal{B}^+_{p,\gamma}(\Lambda)$ (endowed with the uniform topology) and the Sobolev spaces of future pointing, lightlike, $H^{1,r}$-curves joining p and γ ($r\in[1,+\infty]$).

Using the space $\mathcal{B}^+_{p,\gamma}(\Lambda)$ we can state our last assumptions. In Sec. III we shall prove that it is equivalent to the one formulated in Refs. 9 and 10.

For any $c\in]\alpha,\beta[$ [cf. (4)] we denote by τ^c the c-sublevel of the functional τ in $\mathcal{B}^+_{p,\gamma}(\Lambda)$:

$$\tau^c=\{z\in\mathcal{B}^+_{p,\gamma}(\Lambda):\tau(z)\leqslant c\}. \tag{2.3}$$

Definition 2.1: Fix $c>\alpha$. We say that $\mathcal{B}^+_{p,\gamma}(\Lambda)$ is c-precompact if any sequence $\{z_n:n\in\mathbb{N}\}\subset\tau^c$ has a subsequence uniformly convergent in $\overline{\Lambda}$, up to reparametrizations. We say that τ is pseudocoercive in $\mathcal{B}^+_{p,\gamma}(\Lambda)$, if $\mathcal{B}^+_{p,\gamma}(\Lambda)$ is c-precompact for any $c\in]\alpha,\beta[$.

Note that by assumption (5) there exists $\hat{s}>\alpha$ such that τ^c is the empty set for any $c\in]\alpha,\hat{s}]$.)

Whenever $\Lambda=\mathcal{M}$ pseudocoercivity coincides with the global hyperbolicity of the set of the events in the future of p, (cf. Ref. 9).

Before stating our main result, we recall some definitions.

Definition 2.2: Let $(\mathcal{M},\langle\cdot,\cdot\rangle)$ be a Lorentzian manifold, and $z:[0,1]\to\mathcal{M}$ be a geodesic. A smooth vector field ζ along z is called a Jacobi field if it satisfies

$$D_s^2\zeta+R(\zeta,\dot{z})\dot{z}=0, \tag{2.4}$$

where R is the curvature tensor of the metric $\langle\cdot,\cdot\rangle$ (cf. Ref. 22). *A point $z(s)$, $s\in]0,1]$ is said to be conjugate to $z(0)$ along z if there exists a nonvanishing Jacobi field ζ along $z_{|[0,s]}$ such that*

$$\zeta(0)=\zeta(s)=0. \tag{2.5}$$

The multiplicity of the conjugate point $z(s)$ is the maximal number of linearly independent Jacobi fields satisfying (2.5).

By (2.4) the set of the Jacobi fields is a vector space of dimension $2\dim\mathcal{M}$. Hence the multiplicity of a conjugate point is finite and, by (2.5), is at most $\dim\mathcal{M}$ [actually it is at most $\dim\mathcal{M}-1$ because $\zeta(s)=s\dot{z}(s)$ is a Jacobi field which is zero only at $s=0$].

Definition 2.3: The index $\mu(z)$ is the number of conjugate points $z(s)$, $s\in]0,1[$ to $z(0)$, counted with their multiplicity.

It is well known that the index of a lightlike geodesic is finite (see Ref. 22).

Definition 2.4: Let p be a point and γ a timelike curve on a Lorentzian manifold $(\mathcal{M},g)$. Then p and γ are said to be nonconjugate by lightlike geodesics if for any lightlike geodesic $z:[0,1]\to\mathcal{M}$ joining p and γ, $z(1)$ is nonconjugate to p along z.

It is well known that such a condition is true except for a residual set of pairs (p,γ). For some results whenever p and γ are conjugate see Ref. 27.

Let X be a topological space and $\mathbb{K}$ a field. For any $l\in\mathbb{N}$ let $H_l(X;\mathbb{K})$ be the lth homology group of X with coefficients in $\mathbb{K}$. Since $\mathbb{K}$ is a field, then $H_l(X;\mathbb{K})$ is a vector space whose dimension $\beta_l(X;\mathbb{K})$ (eventually $+\infty$) is called the lth *Betti number of X* (with coefficients in $\mathbb{K}$). The *Poincaré polynomial* $\mathcal{P}(X;\mathbb{K})$ is defined as the following formal series:

$$\mathcal{P}(X;\mathbb{K})(\kappa)=\sum_{l\in\mathbb{N}}\beta_l(X;\mathbb{K})\kappa^l.$$

Let $\mathcal{G}^+_{p,\gamma}(\Lambda)$ be the set of the future pointing lightlike geodesics joining p and γ and having image contained in Λ. The main result of this paper is the following theorem.

Theorem 2.5: *Let Λ, p, γ satisfy* (1)–(6). *Assume that the following assumptions hold true:*

(L_1) *p and γ are nonconjugate*;

(L_2) *τ is pseudocoercive on $\mathcal{B}^+_{p,\gamma}(\Lambda)$*;

then for any field $\mathbb{K}$ there exists a formal series $S(\kappa)$ with coefficients in $\mathbb{N}\cup\{+\infty\}$, such that

$$\sum_{z\in\mathcal{G}^+_{p,\gamma}(\Lambda)}\kappa^{\mu(z)}=\mathcal{P}(\mathcal{B}^+_{p,\gamma}(\Lambda);\mathbb{K})(\kappa)+(1+\kappa)S(\kappa). \tag{2.6}$$

The same result holds for the lightlike geodesics joining p and γ in the past of p, under an obvious modification of the assumptions.

Remark 2.6: Observe that the Betti numbers $\beta_l(X;\mathbb{K})$ [and the coefficient of the formal series $S(\kappa)$ in (2.6)] depend in a substantial way on the choice of the field $\mathbb{K}$. On the other hand, the left-hand side of the equality (2.6) does not depend on $\mathbb{K}$, hence one can obtain more information on $\mathcal{G}^+_{p,\gamma}(\Lambda)$ by letting the coefficient field $\mathbb{K}$ be arbitrary in (2.6). For example, a result of Serre, where the choice of $\mathbb{K}$ is essential (cf. Ref. 28), is used to prove part (b) of Theorem 2.11.

Remark 2.7: Note that assumption (L_2) cannot be removed. Indeed, let $(\mathcal{M}_0,\langle\cdot,\cdot\rangle_0)$ be a Riemannian manifold such that there exist two points p_1, $p_2\in\mathcal{M}_0$ which are not joined by any geodesic for the metric $\langle\cdot,\cdot\rangle_0$. Consider the (static) Lorentzian manifold $(\mathcal{M},\langle\cdot,\cdot\rangle)$, where $\mathcal{M}=\mathcal{M}_0\times\mathbb{R}$ and $\langle\cdot,\cdot\rangle$ is given by

$$\langle\zeta,\zeta\rangle=\langle\xi,\xi\rangle_0-\theta^2,$$

for any $z=(x,t)\in\mathcal{M}_0\times\mathbb{R}$ and $\zeta=(\xi,\theta)\in T_z\mathcal{M}$. Let $\Lambda=\mathcal{M}$. Consider the point $p=(p_1,0)$ and the timelike curve $\gamma(s)=(p_2,s)$. Clearly assumptions (1)–(6) are satisfied, but not (L_2). Theorem 2.5 does not hold for p and γ, since there are no lightlike geodesics joining p and γ, while $\mathcal{P}(\mathcal{B}^+_{p,\gamma}(\Lambda),\mathbb{K})(\kappa)\neq=0$ for any field $\mathbb{K}$.

Remark 2.8: Let c_l be the number of the future pointing lightlike geodesics joining p and γ having index q. Then (2.6) can be written in the following way:

$$\sum_{l=0}^{\infty} c_l\kappa^l=\sum_{l=0}^{\infty}\beta_l(\mathcal{B})^+_{p,\gamma}(\Lambda;\mathbb{K})\kappa^l+(1+\kappa)S(\kappa). \tag{2.7}$$

From (2.7) we deduce that a certain number of future pointing light rays joining p and γ are obtained according to the topology of $\mathcal{B}^+_{p,\gamma}(\Lambda)$. In particular, setting $\kappa=1$ in (2.7), we have the following estimate on the number $\mathrm{card}(\mathcal{G}^+_{p,\gamma}(\Lambda))$ of the light rays joining p and γ:

$$\mathrm{card}(\mathcal{G}^+_{p,\gamma}(\Lambda))=\sum_{l=0}^{\infty}\beta_l(\mathcal{B}^+_{p,\gamma}(\Lambda);\mathbb{K})+2S(1). \tag{2.8}$$

Since $S(1)$ is non-negative we also get the classical Morse inequalities

$$c_l\geqslant\beta_l(\mathcal{B}^+_{p,\gamma}(\Lambda);\mathbb{K}),\quad \forall l\in\mathbf{N}. \tag{2.9}$$

An example of the influence of the topology of $\mathcal{B}^+_{p,\gamma}(\Lambda)$ on the number of future pointing, lightlike geodesics between p and γ is given by the next theorem.

Theorem 2.9: *Under the assumptions of* Theorem 1.5 *we have the following.*

(a) *If* $\mathcal{B}^+_{p,\gamma}(\Lambda)$ *is contractible the number* $\mathrm{card}\,\mathcal{G}^+_{p,\gamma}(\Lambda)$ *is infinite or odd.*
(b) *If* $\mathcal{B}^+_{p,\gamma}(\Lambda)$ *is not contractible, there exist at least two future pointing light rays joining p and* γ. (We recall that a topological space is said to be *contractible* if it is homotopically equivalent to a point.)

Actually, the topology of $\mathcal{B}^+_{p,\gamma}(\Lambda)$ is in general not known for arbitrary Lorentzian manifold. More information can be obtained if its topology can be related to the topology of the manifold Λ. Let $\Omega(\Lambda)$ be the *based loop space* of all the continuous curves $z:[0,1]\to\Lambda$ such that $z(0)=z(1)=\overline{z}$. Since Λ is connected, $\Omega(\Lambda)$ does not depend on $\overline{z}$. We equip $\Omega(\Lambda)$ with the *uniform topology*. Since the Poincaré polynomial is a homotopical invariant, we have the following result as an immediate consequence of Theorem 2.5.

Theorem 2.10: *Besides the assumptions of Theorem 2.5, assume also:*
(L_3) $\mathcal{B}^+_{p,\gamma}(\Lambda)$ *has the same homotopy type of the based loop space* $\Omega(\Lambda)$.
Then for any field $\mathcal{K}$ *there exists a formal series* $S(\kappa)$ *with coefficients in* $\mathbb{N}\cup\{+\infty\}$, *such that*

$$\sum_{z\in\mathcal{G}^+_{p,\gamma}(\Lambda)} r^{\mu(z)}=\mathcal{P}(\Omega(\Lambda),\mathbb{K})(\kappa)+(1+\kappa)S(\kappa). \tag{2.10}$$

In Appendix A we give a general condition assuring that (L_3) is satisfied. Thanks to the results proved in Sec. 5 and Appendix A we see that assumption (L_3) is certainly satisfied if $(\Lambda,\langle\cdot,\cdot\rangle)$ is conformally stationary and this is the case, with a good approximation, of the accepted cases of multiple quasars (see, e.g., Ref. 16).

Theorem 2.11: *Under the assumptions of Theorem 2.10 we have:*

(a) If Λ is contractible, then the number of the future pointing lightlike geodesics joining p with γ and with image in Λ is infinite or odd.
(b) If Λ is noncontractible, then the number of the future pointing lightlike geodesics joining p with γ and with image in Λ is infinite.

Conditions assuring the finiteness of the images can be found in Ref. 29. To write Morse relations for light rays using the arrival time functional τ it does not seem that the pseudocoercivity assumption can be weakened. Indeed it is necessary to have that the sublevels τ^c of the arrival time functional are complete with respect to a suitable metric and the Palais–Smale sequences are precompact (with respect to such a metric). Note that the sequences in Definition 2.1 are allowed to reach $\partial\Lambda$. The light convexity of $\overline{\Lambda}$ will guarantee the existence of minimizers with image entirely included in Λ.

Morse relations are proved regarding lightlike geodesics as critical points of the functional τ. They are written using the geometric index μ instead of the Morse index thanks to Theorem 5.13. Its proof is based on a different approach to the index theorem for lightlike geodesics, with respect to the one of Ref. 22, where the index theorem is proved on a quotient space of the admissible variations. For the proof of Theorem 5.13 we have to choose a suitable manifold where the critical points of τ are lightlike geodesics.

III. MINIMIZERS FOR THE ARRIVAL TIME ON SOBOLEV CURVE SPACES

We begin the section by introducing the Sobolev spaces $H^{1,r}([0,1],\Lambda)$ with $r\in[1,+\infty]$. This can be rapidly done in the following way.

Let W be the smooth timelike vector field on $\mathcal{M}$ whose existence is assumed in (1). The manifold $\mathcal{M}$ can be equipped by a natural Riemannian structure setting

$$\langle\zeta,\zeta\rangle_R=\langle\zeta,\zeta\rangle-\frac{2\langle W(z),\zeta\rangle^2}{\langle W(z),W(z)\rangle.} \tag{3.1}$$

The Riemannian metric (3.1) can be used to introduce a Riemann distance on Λ that we shall denote by d_R. Such a distance allows us to introduce the space of the absolutely continuous curves between $[0,1]$ and Λ (denoted by $AC([0,1],\Lambda)$). Finally for any $r\in[1,+\infty[$ we set

$$H^{1,r}([0,1],\Lambda)=\left\{z\in AC([0,1],\Lambda):\int_0^1(\langle\dot z,\dot z\rangle_R)^{r/2}\,\mathrm{ds}<+\infty\right\}$$

while

$$H^{1,\infty}([0,1],\Lambda)=\{z\in AC([0,1],\Lambda):\sup\{\langle\dot z(s),\dot z(s)\rangle_R:s\in[0,1]\}<+\infty\}.$$

Using local coordinates and the Palais definition of the Sobolev manifold (cf. Ref. 30) we see that the above defined spaces do not depend on the choice of W. Moreover we set

$$\Omega^{1,r}_{p,\gamma}(\Lambda)=\{z\in H^{1,r}([0,1],\Lambda):z(0)=p,z(1)\in\gamma(]\alpha,\beta[)\}. \tag{3.2}$$

For any absolutely continuous curve z we can extend the classical definition of causal curve saying that z is a causal curve if $\langle\dot z(s),\dot z(s)\rangle\leqslant 0$ almost everywhere (a.e.). Moreover we say that a causal curve is future pointing if

$$\langle \dot{z}(s), W(z(s))\rangle < 0 \quad \textit{for almost every } s \textit{ such that } \dot{z}(s) \neq 0.$$

It is possible to prove that the above-presented notions are equivalent to the ones given in Ref. 20 for continuous curves, whenever we deal with absolutely continuous curves. This can be done using Proposition 3.2.

To develop a Morse theory for light rays the following spaces will be also used:

$$\mathcal{L}^{+,r}_{p,\gamma}(\Lambda) = \{z \in \Omega^{1,r}_{p,\gamma}([0,1],\Lambda) : \langle \dot{z}, \dot{z}\rangle = 0 \text{ a.e. and } z \text{ is future pointing}\}. \tag{3.3}$$

More in general for any event p_* and any future pointing, injective, timelike curve $\gamma_* :]\alpha_*, \beta_*[\to \Lambda$ we shall use the following notation:

$$\mathcal{L}^{+,r}_{p_*,\gamma_*}([a,b],\Lambda) = \{z \in H^{1,r}([a,b],\Lambda):$$

$$\langle \dot{z}, \dot{z}\rangle = 0 \text{ a.e., } z \textit{ is future pointing, } z(a) = p_* \text{ and } z(b) \in \gamma_*(]\alpha_*, \beta_*[\}.$$

We shall denote by the same symbol τ the functional defined by $\gamma_*^{-1}(z(b))$ on the space $\mathcal{L}^{+,r}_{p_*,\gamma_*}([a,b],\Lambda)$.

Remark 3.1: Note that the above-mentioned spaces are not smooth manifold: a tangent space is not well defined on the curves z such that $\dot{z}(s) = 0$ on a subset of $[0,1]$ having positive Lebesgue measure.

For this reason if we want to deal with smooth manifolds we need to use an approximation of $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ by suitable smooth manifolds and to study *a priori* estimates for the limit process (cf. Refs. 9 and 10). In this paper we shall work directly on $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ showing first that assumptions (1)–(6) and pseudocoercivity allow one to find smooth minimizers in Λ which are lightlike geodesics.

This is a further motivation to choose a shortening procedure for the arrival time functional, since it permits one to bypass the nonsmoothness of the spaces defined by (3.3). It will be possible to write Morse relations using the Poincaré polynomial of $\mathcal{B}^{+}_{p,\gamma}(\Lambda)$ because we shall prove in Sec. IV that it is homotopically equivalent to $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$.

The next result is a local version of the relativistic Fermat principle and it is the first step for the shortening procedure.

Proposition 3.2: Let $q \in \mathcal{M}$. Then there exists $\rho(q) > 0$ having the following property. For any γ_* timelike injective curve and integral curve of Y such that:

(1) $0 < \mathrm{d}_R(q, \mathrm{Im}\ \gamma_*) \leqslant \rho(q)$,
(2) $\mathrm{Im}\ \gamma_* \cap J^+(q,\mathcal{M}) \neq \varnothing$,
(3) $\mathrm{Im}\ \gamma_* \setminus J^+(q,\mathcal{M}) \neq \varnothing$,

there exists a unique future pointing lightlike geodesic joining q and γ_* and minimizing the arrival time on $\mathcal{L}^{+,r}_{q,\gamma_*}(\mathcal{M})$.

The proof can be, e.g., obtained as a limit process of timelike problems using the results of Ref. 31. Anyway here we shall give a variational proof working directly in the lightlike case. The proof is quite different from the classical geometrical one (cf. Ref. 20). The following remarks will be used for the proof of Proposition 3.2 and other results in the present paper.

Remark 3.3: For any $z \in \Lambda$ there exists a neighborhood $\mathcal{U}_z$ of z and a coordinate system $\varphi = (x_1, \ldots, x_{N-1}, t)$ $(N = \dim \Lambda)$ on $\mathcal{U}_z$ such that $W = \partial/\partial t$ and $\mathcal{U}_z = \Sigma \times]a,b[$ where Σ is a spacelike hypersurface parametrized by $x_1, \ldots, x_{N-1}$.

Moreover, in the coordinates $x = (x_1, \ldots, x_{N-1})$ and $t \in]a,b[$ the metric g is given by

$$g(x,t)[(\xi,\theta),(\xi,\theta)] = \langle \alpha(x,t)\xi, \xi\rangle_0 + 2\langle \delta(x,t)), \xi\rangle_0 \theta - \beta(x,t)\theta^2,$$

where $(\xi,\theta)\in T_{(x,(a+b)/2)}\Sigma\times\mathbb{R}$, $\langle\cdot,\cdot\rangle_0$ is the restriction of g to Σ, α is a smooth, symmetric positive definite operator, δ is a smooth vector field on Σ, and β is a smooth positive real function. Note that $\langle\cdot,\cdot\rangle_0$ is a Riemannian metric on Σ.

Indeed it is sufficient to choose $\Sigma=\{(x,t):t=(a+b)/2\}$, $\alpha(x,t)$, $\delta(x,t)$, and $\beta(x,t)$ such that

$$\langle\alpha(x,t)\xi_1,\xi_2\rangle_0=g(x,t)[\xi_1,\xi_2]\quad\text{for any}\quad\xi_1,\xi_2\in T_{(x,(a+b)/2)}\Sigma,$$

$$\delta(x,t)=[G_0(x,t)]^{-1}(\overline{\delta}(x,t)),\quad\overline{\delta}(x,t)=\sum_{i=1}^{N-1}g_{iN}(x,t)\frac{\partial}{\partial x_i},$$

$$G_0(x,t)=(g_{i,j})_{i,j=1,\ldots,N-1},$$

and $\beta(x,t)=-g(x,t)[W,W]$.

Remark 2.4: We will assume henceforth that W is *renormalized* in such a way that

$$\langle W(z),W(z)\rangle=-1\quad\text{for any}\quad z\in\mathcal{M}.$$

In particular, $\langle\dot\gamma,\dot\gamma\rangle\equiv-1$, and so the parameter of γ can be interpreted as proper time.

Therefore, in the coordinate systems $(x_1,\ldots,x_{N-1},t)$ with $\partial/\partial t=W$ (cf. Remark 3.3), $z=(x,t)\in\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ if and only if

$$\dot t=\langle\delta,\dot x\rangle_0+\sqrt{\langle\delta,\dot x\rangle_0^2+\langle\alpha\dot x,\dot x\rangle_0}\tag{3.4}$$

because

$$\beta(x,t)=-\langle W(z),W(z)\rangle\equiv1.$$

Moreover, in such a coordinate system, any integral curve of W can be written as

$$s\mapsto(\overline{x},s),$$

for some $\overline{x}\in\Sigma$.

In order to prove Proposition 2.2, the following preliminary results are needed.

Lemma 2.5: Under the assumptions of Proposition 3.2, if $\rho(q)$ is sufficiently small, there exists a minimizer of τ on $\mathcal{L}^{+,1}_{q,\gamma_*}(\mathcal{M})$ having $H^{1,\infty}$ regularity.

Proof: By Remarks 3.3–3.4 and the assumptions of Proposition 3.2, if $\rho(q)$ is sufficiently small, we can consider a sufficiently small neighborhood $\mathcal{U}$ of q such that $\mathcal{U}=V\times I$, where V is an open neighborhood contained in Σ, $I=]-\lambda_0,\lambda_0[$, $q=(q_0,0)\in V\times I$, the curve $\gamma_*(t)=(q_*,t)$ is defined in $]-\lambda_0,\lambda_0[$ and $\mathrm{d_R}(q_0,q_*)\to0$ whenever $\mathrm{d_R}(q,\mathrm{Im}\,\gamma_*)\to0$. If $z\in\mathcal{L}^+_{p,\gamma}$ and takes its values in $\mathcal{U}$, then $z(s)=(x(s),t(s))$, $x(0)=q_0$, $x(1)=q_*$, and $t(s)$ satisfies the Cauchy problem

$$\begin{cases}\dot t=\langle\delta(x,t),\dot x\rangle_0+\sqrt{\langle\alpha(x,t)\dot x,\dot x\rangle_0+\langle\delta(x,t),\dot x\rangle_0^2},\\ t(0)=0.\end{cases}\tag{3.5}$$

Moreover

$$\tau(z)=t_x(1)=\int_0^1\langle\delta(x,t_x),\dot x\rangle_0\,\mathrm{d}s+\int_0^1\sqrt{\langle\alpha(x,t_x)\dot x,\dot x\rangle_0+\langle\delta(x,t_x),\dot x\rangle_0^2}\,\mathrm{d}s,$$

where t_x is the solution of the above-mentioned Cauchy problem above. Using a minimal Riemannian geodesic between q_0 and q_* in V shows that

$$\inf_{\mathcal{L}^{+}_{q,\gamma_*}} \tau \to 0 \quad \text{as} \quad \mathrm{d}_R(q,\gamma_*) \to 0.$$

We show now the existence of a minimizer for τ.

Consider a minimizing sequence (z_m) for τ and set $z_m=(x_m,t_m)$. The coercivity of α shows that the Riemann length of x_m is bounded. Then by (3.5) we deduce that $\dot{t}_m$ is bounded in L^1. Then we can reparametrize z_m proportionally to arclength obtaining a curve $y_m \in \mathcal{L}^{+,1}_{q,\gamma_*}(\Lambda)$ such that $y_m(\theta)=z_m(\sigma)$ where

$$\theta=\frac{\int_a^\sigma \langle -\dot{z}_m, W(z_m)\rangle \mathrm{d}s}{\int_a^b \langle -\dot{z}_m, W(z_m)\rangle \mathrm{d}s}.$$

Since

$$\int_a^b |\dot{z}_m| \mathrm{d}s$$

is uniformly bounded, there exists a positive constant M independent of $m \in \mathbb{N}$ such that

$$\left| \int_a^b \langle \dot{z}_m, W(z_m)\rangle \mathrm{d}s \right| \leq M.$$

Then it is not difficult to see that $\dot{y}_m$ is uniformly bounded.

So we have a sequence of curves $z_m=(x_m,t_m)$ such that, up to a reparametrization (and replacing y_m with z_m),

$$(x_m,t_m) \text{ uniformly converges to a curve } z=(x,t);$$

$$\text{the sequence } (\dot{x}_m) \text{ is bounded in } L^\infty;$$

$$\text{the sequence } (\dot{x}_m) \text{ weakly converges to } \dot{x} \text{ in } L^2.$$

In particular the sequence $(\dot{x}_m)$ weakly converges to $\dot{x}$ in L^1 and then by well-known properties of the weak convergence (see, e.g., Ref. 32),

$$\int_0^1 \sqrt{\langle \alpha(x,t)\dot{x},\dot{x}\rangle_0 + \langle \delta(x,t)\dot{x},\dot{x}\rangle_0^2}\, \mathrm{d}s \leq \liminf_{m\to\infty} \int_0^1 \sqrt{\langle \alpha(x,t)\dot{x}_m,\dot{x}_m\rangle_0 + \langle \delta(x,t)\dot{x}_m,\dot{x}_m\rangle_0^2}\, \mathrm{d}s.$$

Moreover, we clearly have

$$\left| \int_a^b \left(\sqrt{\langle \alpha(x,t)\dot{x}_m,\dot{x}_m\rangle_0 + \langle \delta(x,t),\dot{x}_m\rangle_0^2} - \sqrt{\langle \alpha(x_m,t_m)\dot{x}_m,\dot{x}_m\rangle_0 + \langle \delta(x_m,t_m),\dot{x}_m\rangle_0^2} \right) \mathrm{d}s \right|$$

$$\leq \int_a^b \left(\left| \langle (\alpha(x_m,t_m)-\alpha(x,t))\dot{x}_m,\dot{x}_m\rangle_0 \right| + \left| \langle \delta(x_m,t_m)+\delta(x,t),\dot{x}_m\rangle_0 \langle \delta(x_m,t_m) - \delta(x,t),\dot{x}_m\rangle_0 \right| \right)^{1/2} \mathrm{d}s \mapsto 0 \quad \text{as} \quad m \to +\infty.$$

Finally, by the uniform convergence of (x_m,t_m) to (x,t),

$$\int_a^b \langle \delta(x_m,t_m),\dot{x}_m\rangle_0 \to \int_a^b \langle \delta(x,t),\dot{x}\rangle_0.$$

It follows that for any $s_1<s_2$,

$$\liminf_{m\to\infty}(t_m(s_2)-t_m(s_1))=\liminf_{m\to\infty}\Bigg(\int_{s_1}^{s_2}\langle\delta(x_m,t_m),\dot{x}_m\rangle_0\,\mathrm{d}s + \int_{s_1}^{s_2}\sqrt{\langle\alpha(x_m,t_m)\dot{x}_m,\dot{x}_m\rangle_0+\langle\delta(x_m,t_m),\dot{x}_m\rangle_0^2}\,\mathrm{d}s\Bigg)$$
$$\geqslant\Bigg(\int_{s_1}^{s_2}\langle\delta(x,t),\dot{x}\rangle_0\,\mathrm{d}s+\int_{s_1}^{s_2}\sqrt{\langle\alpha(x,t)\dot{x},\dot{x}\rangle_0+\langle\delta(x,t),\dot{x}\rangle_0^2}\,\mathrm{d}s\Bigg).$$

So we have obtained:

$$\begin{cases}\dot{t}\geqslant\langle\delta(x,t),\dot{x}\rangle_0+\sqrt{\langle\alpha(x,t)\dot{x},\dot{x}\rangle_0+\langle\delta(x,t),\dot{x}\rangle_0^2},\\ t(0)=0.\end{cases}$$

Let t_x be the solution of the above-assigned Cauchy problem relative to the curve x. Comparison theorems for ordinary differential equations show that $t_x\leqslant t$. Hence, (x,t_x) is a minimizer for τ.

Finally, our (reparametrized) minimizing sequence z_m satisfies:

$$\begin{cases}\langle\dot{z}_m,W(z_m)\rangle \text{ is bounded and}\\ \dot{z}_m \text{ is weakly convergent to } \dot{z} \text{ in } L^2.\end{cases}$$

Therefore $\langle\dot{z},W(z)\rangle$ is bounded and the minimizer z is therefore in $H^{1,\infty}$. □

Lemma 3.6: Assume $q\notin\gamma_*([\alpha,\beta[)$. Let z be a minimizer of τ on $\mathcal{L}^{+,1}_{q,\gamma_*}(\mathcal{M})$ such that $z\in H^{1,\infty}([0,1],\mathcal{M})$. Then there exists a curve $y\in\mathcal{L}^{+,\infty}_{q,\gamma_*}$ such that y minimizes τ and

$$\inf\{\|\dot{y}(s)\|_{\mathrm{R}}:s\in[0,1]\backslash N\}>0, \tag{3.6}$$

where N is a subset of $[0,1]$ having zero Lebesgue measure.

Moreover,

$$y([0,1])=z([0,1]).$$

Proof: Choose $y(\theta)=z(\sigma)$ where

$$\theta=\frac{\int_0^\sigma\langle-\dot{z},W(z)\rangle\mathrm{d}s}{\int_0^1\langle-\dot{z},W(z)\rangle\mathrm{d}s}.$$

It is easy to see that $y\in\mathcal{L}^{+,\infty}_{q,\gamma_*}(\Lambda)$, $y([0,1])=z([0,1])$ and

$$\langle\dot{y}(\theta),W(\theta)\rangle=\int_0^1\langle-\dot{z},W(z)\rangle\mathrm{d}s \text{ a.e.} \tag{3.7}$$

Since $\int_0^1\langle-\dot{z},W(z)\rangle\mathrm{d}s\neq0$ we deduce immediately (3.6). □

Lemma 3.7: Let z be a curve in $\mathcal{L}^{+,\infty}_{p,\gamma}$ satisfying (3.6). Then there exists a neighborhood $\mathcal{V}$ of z in $H^{1,\infty}([0,1],\Lambda)$ such that $\mathcal{V}\cap\mathcal{L}^{+,\infty}_{p,\gamma}$ is a C^1-manifold and for any $z\in\mathcal{V}$ its tangent space is given by

$$T_z(\mathcal{L}^{+,\infty}_{p,\gamma})=\{\zeta\in H^{1,\infty}([0,1],T\Lambda):\zeta(s)\in T_{z(s)}\Lambda \text{ for any } s,$$
$$\zeta(0)=0,\zeta(1)\|\dot{\gamma}(\tau(z)),\langle D_s\zeta,\dot{z}\rangle=0 \text{ a.e.}\}.$$

Here $T\Lambda$ denotes the tangent bundle of Λ and D_s the covariant derivative along z.

Proof: Consider the map $\psi:\Omega^{1,\infty}_{p,\gamma}(\Lambda)\to L^\infty([0,1],\mathbb{R})$ such that

$$\psi(z)=\sqrt{2}\langle \dot{z},W(z)\rangle+\sqrt{\langle \dot{z},\dot{z}\rangle+2\langle \dot{z},W(z)\rangle^2}=\sqrt{2}\langle \dot{z},W(z)\rangle+\sqrt{\langle \dot{z},\dot{z}\rangle_R}.$$

Note that $\psi^{-1}(0)=\mathcal{L}^{+,\infty}_{p,\gamma}$. The set $\Omega^{1,\infty}_{p,\gamma}(\Lambda)$ is a manifold and, for any $z\in\Omega^{1,\infty}_{p,\gamma}$, its tangent space is

$$T_z\Omega^{1,\infty}_{p,\gamma}=\{\zeta\in H^{1,\infty}([0,1],T\Lambda):\zeta(s)\in T_{z(s)}\Lambda \text{ for any } s\in[0,1],$$

$$\zeta(0)=0,\quad \zeta(1)\|\dot{\gamma}(\tau(z))\}.$$

By the above-mentioned formula we immediately deduce that ψ is of class C^1 in a neighborhood of z. We claim that, $\forall z\in\mathcal{V}\cap\mathcal{L}^{+,\infty}_{p,\gamma}$, the differential $d\psi(z)[\,\cdot\,]$ is surjective.

Indeed let U_z be the parallel transport of $\dot{\gamma}(\tau(z))$ along z, i.e., the solution of the Cauchy problem

$$\begin{cases} D_{\dot{z}}U_z=0,\\ U_z(1)=\dot{\gamma}(\tau(z)).\end{cases}$$

Then for any $\varphi\in L^\infty([0,1],\mathbb{R})$ it is easy to show the existence of $\lambda\in H^{1,\infty}([0,1],\mathbb{R})$ such that $\lambda(0)=0$,

$$d\psi(z)[\lambda U_z]=\varphi,$$

and the kernel of $d\psi(z)$ splits. Then $V\cap\psi^{-1}(0)$ is a manifold whose tangent space at z is the kernel of $d\psi(z)$ in $T_z\Omega^{1,\infty}_{p,\gamma}$. □

Remark 3.8: The functional τ is differentiable on $\Omega^{1,\infty}_{p,\gamma}$. Since τ is defined by setting $\gamma(\tau(z))=z(1)$, its differential satisfies

$$\dot{\gamma}(\tau(z))d\tau(z)[\zeta]=\zeta(1)$$

and therefore

$$d\tau(z)[\zeta]=0,$$

if and only if

$$\zeta(1)=0 \text{ for any } \zeta\in T_z(\mathcal{L}^{+,\infty}_{p,\gamma}).$$

Now let V be a smooth vector field along z such that $V(0)=V(1)=0$ and U_z the parallel transport of $\gamma(\tau(z))$ along z. If z satisfies (3.6) put

$$\lambda(s)=\int_0^s\left\langle D_rV,\frac{\dot{z}}{\langle U_z,\dot{z}\rangle}\right\rangle dr.$$

Then $V-\lambda U_z\in T_z(\mathcal{L}^{+,\infty}_{p,\gamma})$ and if z is a critical point of τ on $\mathcal{L}^{+,\infty}_{p,\gamma}$ it is

$$\tau(z)[V-\lambda U_z]=0 \text{ for any } V$$

and therefore

$$0=\lambda(1)=\int_0^1\left\langle D_sV,\frac{\dot{z}}{\langle U_z,\dot{z}\rangle}\right\rangle ds \text{ for any } V.$$

Conversely if z satisfies the above-mentioned condition, $\zeta(1)=0$ for any V, hence z is a critical point of τ.

The following theorem is the relativistic Fermat principle proved in $H^{1,\infty}$ (see also Ref. 12).

Theorem 3.9 (Fermat principle): *Let $z \in \mathcal{L}^{+,\infty}_{p,\gamma}$ such that (3.6) is satisfied. Then, z is a critical point of τ if and only if it is a reparametrization of a C^2-geodesic in $\mathcal{L}^{+,\infty}_{p,\gamma}$.*

Proof: If z is a critical point of τ [satisfying (3.6)] it is

$$\int_0^1 \left\langle D_r V, \frac{\dot{z}}{\langle U_z, \dot{z}\rangle} \right\rangle \mathrm{d}r = 0$$

for any V along z such that $V(0)=V(1)=0$. If y is a reparametrization of z such that $\langle U_w, \dot{w}\rangle$ is constant we deduce $\int_0^1 \langle D_r V, \dot{y}\rangle = 0$ for any V and therefore y is a smooth geodesic.

Conversely if z is a reparametrization of a C^2-geodesic, it is $D_s(\mu' \dot{z}) = 0$ for some $\mu \in H^{1,\infty}([0,1],\mathbb{R})$. Then $\langle U_z, \mu' \dot{z}\rangle$ is constant, so

$$\int_0^1 \left\langle D_r V, \frac{\dot{z}}{\langle U_z, \dot{z}\rangle} \right\rangle \mathrm{d}r = 0$$

for any V such that $V(0)=V(1)=0$. Then, by Remark 3.8 we deduce that z is a critical point of τ. □

We are finally ready to prove Proposition 3.2.

Proof of Proposition 2.2: By Lemmas 3.5 and 3.6 and Theorem 3.9 there exists a future pointing lightlike geodesic w joining q and γ_*, minimizing τ on $\mathcal{L}^{+,r}_{q,*}$. The uniqueness of w is a consequence of the local invertibility of the exponential map (cf. Ref. 1).

Remark 3.10: Fix $z \in \mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ and $[a_1,a_2] \subset [0,1]$. Let γ_2 be the integral curve of W such that $\gamma_2(0) = z(a_2)$. Since it is future pointing, a simple contradiction argument shows that, whenever $\mathrm{d}_R(z(a_1), z(a_2)) \to 0$, the infimum of τ on $\mathcal{L}^{+,r}_{z(a_1),\gamma_2}([a_1,a_2],\Lambda)$ tends to 0, and if $z(a_1) = z(a_2)$ the infimum is 0.

Remark 3.11: Since τ and $\mathcal{L}^{+,r}_{q,\gamma_*}(\Lambda)$ are invariant by reparametrizations, it is clear that there are nonsmooth minimizers. Note that, among the minimizers there are also curves having null derivatives in subsets of $[0,1]$ with positive Lebesgue measure.

Now we shall prove the equivalence between Definition 2.1 and the corresponding definition given in Refs. 9 and 10 [where the pseudocoercivity of τ is given in $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$].

Lemma 3.12: Let $z \in \mathcal{L}^{+,1}_{p,\gamma}(\Lambda)$. Then there exists z_n in $\mathcal{B}^{+}_{p,\gamma}(\Lambda)$ such that $z_n \to z$ uniformly.

Proof: We can apply Proposition 3.2 to obtain the existence of a minimizer in the space $\mathcal{L}^{+,1}_{z(a_1),\gamma_2}([a_1,a_2],\Lambda)$ where γ_2 is the integral curve of w such that $\gamma_2(0) = z_2$. Since z is fixed, if $a_2 - a_1$ is sufficiently small, $\int_{a_1}^{a_2} \sqrt{\langle \dot{z}, \dot{z}\rangle_R}\, \mathrm{d}s$ is small and also the length [with respect to the Riemann structure (3.1)] of the geodesic minimizing τ is small. Then, choosing a suitable partition of the interval $[0,1]$ allows one to construct a broken geodesic $\hat{z}$ such that the distance between z and $\hat{z}$ with respect to the $H^{1,1}$-norm is arbitrarily small. Therefore, the uniform distance can be made as small as we want and we are done. □

By Lemma 3.12 it follows immediately

Proposition 3.13: For any $r \in [1,+\infty]$, τ is pseudocoercive on $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ if and only if it is pseudocoercive on $\mathcal{B}^{+}_{p,\gamma}(\Lambda)$.

For any $z \in H^{1,1}([0,1],\Lambda)$ denote by $\ell(z)$ its length induced by the Riemann structure (3.1).

Lemma 3.14: Assume τ is pseudocoercive on $\mathcal{B}^{+}_{p,\gamma}(\Lambda)$. Then, for any $c \in]\alpha,\beta[$ there exists $D(c) > 0$ such that

$$\tau(z) \leqslant c \Rightarrow \ell(z) \leqslant D(c) \quad \text{for any} \quad z \in \mathcal{L}^{+,r}_{p,\gamma}(\Lambda).$$

Proof: Assume by contradiction the existence of a sequence z_n in $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ such that $\tau(z_n) \leqslant c \in]\alpha,\beta[$ and $\ell(z_n) \to +\infty$. Since τ and ℓ are invariant by reparametrizations, by the pseudocoercivity of τ (and Proposition 3.13) we can assume that z_n has a subsequence (that we

shall continue to denote by z_n) uniformly convergent to a continuous curve $z:[0,1]\to\overline{\Lambda}$. Since $z([0,1])$ is compact, it can be covered by a finite number of open neighborhoods U_i in $\mathcal{M}$ such that, on any U_i, the metric g has the form

$$ds^2=\langle\alpha(x,t)\xi,\xi\rangle_0+2\langle\delta(x,t),\xi\rangle_0\theta-\theta^2$$

(cf. Remarks 3.3 and 3.4). If $]a_n^i,b_n^i[$ is an interval such that $z_n(s)\in U_i$ for any $s\in]a_n^i,b_n^i[$ and $z_n=(x_n,t_n)$ we have

$$t_n(b_n^i)-t_n(a_n^i)=\int_{a_n^i}^{b_n^i}\dot{t}_n\,ds=\int_{a_n^i}^{b_n^i}(\langle\delta,\dot{x}_n\rangle_0+\sqrt{\langle\delta,\dot{x}_n\rangle_0^2+\langle\alpha\dot{x}_n,\dot{x}_n\rangle_0})ds.$$

Since any $\overline{U_i}$ is compact and the number of U_i is finite we deduce that $\int_{a_n^i}^{b_n^i}\sqrt{\langle\dot{x}_n,\dot{x}_n\rangle_0}\,ds$ (and consequently $\int_{a_n^i}^{b_n^i}|\dot{t}_n|ds$) is bounded independently by n and i. Finally, since any z_n is included in

$$\bigcup_i U_i$$

and $\dot{z}_n=(\dot{x}_n,\dot{t}_n)$ on any U_i, we deduce that $\int_{a_n^i}^{b_n^i}\|\dot{z}_n\|_R\,ds$ is bounded independently by n and i. Then $\ell(z_n)$ is bounded getting a contradiction. □

Lemma 3.14 will be used, together with the following proposition, to construct the shortening flow for τ.

Proposition 3.15: Let W, Λ, and $\gamma:]\alpha,\beta[\to\Lambda$ satisfy (1)–(6) of Sec. II. Assume that τ is pseudocoercive on $\mathcal{B}^+_{p,\gamma}(\Lambda)$ and fix $c\in]\alpha,\beta[$.

Then there exists $\rho_*(c)>0$ satisfying the following property. Let $z\in\tau^c\cap\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$, $[a,b]\subset[0,1]$, $z_1,z_2\in z([0,1])$ with $z_1=z(a),z_2=z(b)$, and $d_R(z_1,z_2)\leqslant\rho_*(c)$. Let $\gamma_i:]\alpha_i^-,\beta_i^+[\to\Lambda(i=1,2)$ be the maximal integral curve (in Λ) of

$$\begin{cases}\dot{\eta}=W(\eta),\\ \eta(0)=z_i,\quad i=1,2.\end{cases}\tag{3.8}$$

Moreover, for any $\hat{z}_1\in\gamma(]\alpha_1^-,0])$ with $d_R(\hat{z}_1,z_1)\leqslant\rho_*(c)$ there exists a unique future pointing lightlike geodesic Γ such that $\Gamma(a)=\hat{z}_1$, $\Gamma(b)$ is in the image of γ_2, $\Gamma(s)\in\Lambda$ for any $s\in[a,b]$, and

$$\tau(\Gamma)=\inf\{\tau(y):y\in\mathcal{L}^{+,r}_{\hat{z}_1,\gamma_2}([a,b],\Lambda)\}.\tag{3.9}$$

Proof: By pseudocoercivity it is immediate to check the existence of K, compact subset of $\overline{\Lambda}$, such that

$$z\in\tau^c\Rightarrow z([0,1])\subset K.\tag{3.10}$$

Now take a finite family $U_1,\ldots,U_m$ of open subsets of $\mathcal{M}$ covering K and such that any U_i is compact and U_i satisfies the properties of Remarks 3.3 and 3.4. By Proposition 3.2 and Remark 3.10 if $\rho_*(c)$ is sufficiently small there exists a minimizer w in $\mathcal{L}^{+,r}_{\hat{z}_1,\gamma_2}([a,b],U_i)$ for some $i=1,\ldots,m$. [Note that, by assumption (6), $w(b)\in\Lambda$]. Since

$$\bigcup_{i=1}^m\overline{U_i}$$

is compact, by the local invertibility of the exponential map [and the minimality of $\tau(w)$] we see that, if $\rho_*(c)$ is sufficiently small, the minimizing geodesic is unique. Then we have just to prove that the minimizer is included in Λ. If $z_1=z_2$ this is obvious. Then suppose that $z_1\neq z_2$. If $\rho_*(c)$ is sufficiently small and $\mathrm{d}_R(z_1,z_2)\leqslant\rho_*(c)$, $z_1,z_2\in U_i\cap\Lambda$ (for some i). Then, using Proposition 3.2 and choosing $\rho_*(c)$ sufficiently small, we can construct two continuous maps $\theta_1,\theta_2:[0,1]\to U_i\cap\Lambda$ having the following properties:

(1) for any $\lambda\in[0,1]$, $\theta_2(\lambda)$ is in the future of $\theta_1(\lambda)$,
(2) $\theta_1(0)=\hat{z}_1\theta_2(0)=z_2$,
(3) $\theta_1(\lambda)\neq\theta_2(\lambda)$ for any $\lambda\neq 1$,
(4) $\theta_1(1)=\theta_2(1)$,
(5) for any $\lambda\in[0,1]$ there exists a unique minimizer of τ on $\mathcal{L}_{\theta_1(\lambda),\gamma_2(\lambda)}([a,b],U_i)$ where $\gamma_2(\lambda)$ is the maximal integral curve of W such that $\gamma_2(\lambda)(0)=\theta_2(\lambda)$.

Now set

$$A=\{\lambda\in[0,1]:\ \textit{the lightlike or constant geodesic minimizing } \tau \textit{ on } \mathcal{L}_{\theta_1(\lambda),\gamma_2(\lambda)}([a,b],U_i) \textit{ does not intersect } \partial\Lambda\}.$$

Since $\theta_1(1)=\theta_2(1)\in\Lambda,1\in A$. Take

$$\lambda_0\equiv\inf A\geqslant 0.$$

By the definition of λ_0, there exists $\lambda_n\to\lambda_0^+$ and a sequence w_n of lightlike geodesic minimizing τ on $\mathcal{L}^{+,r}_{\theta_1(\lambda_n),\gamma_2(\lambda_n)}([a,b],U_i)$ such that $w_n([0,1])\subset\Lambda$. Unless to consider a subsequence, by (3.4) we obtain the existence of a lightlike geodesic w such that

$$w_n\to w \text{ with respect to the } C^2-\text{norm},$$

$$w(a)=\theta_1(\lambda_0),\quad w(b)\in\gamma_2^{-1}(\lambda_0)\quad(\gamma_2\subset\Lambda),$$

$$w([a,b])\subset\overline{\Lambda}.$$

If $w([a,b])\subset\Lambda$, then $\lambda_0=0$ and we are done. If $w([a,b])\cap\partial\Lambda\neq\varnothing$, since $\theta_1(\lambda_0)\neq\theta_2(\lambda_0)$ are in Λ we get a contradiction with the light-convexity of $\overline{\Lambda}$. □

IV. HOMOTOPICAL EQUIVALENCE BETWEEN $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ AND $\mathcal{B}^{+}_{p,\gamma}(\Lambda)$

In this section [under assumptions (1)–(6)] we shall introduce a shortening flow and we shall use it to prove that $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ and $\mathcal{B}^{+}_{p,\gamma}(\Lambda)$ are homotopically equivalent for any $r\in[1,+\infty]$. This flow will also be used to get the deformation of the sublevels of τ for the Morse theory, whenever we are far from lightlike geodesics.

Indeed far from lightlike geodesics, τ will be strictly decreasing with a speed uniformly far from zero. In other words τ will verify the Palais–Smale compactness condition along the flow.

To construct the shortening flow we shall use the same ideas as in Ref. 26 adapting them to our case. Note that here we cannot use the finite dimensional approach near critical curves (used in Ref. 26 for Riemannian geodesics) because we are not working with fixed end points. So the shortening approach will be used only far from geodesics.

The shortening procedure can be introduced in the following way. Fix $c>\inf\{\tau(z),z\in\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)\}$. Consider $D(c)$ as in Lemma 3.14, $\rho_*(c)$ as in Proposition 3.15, and take $N=N(c)$ such that

$$\frac{D(c)}{N}<\rho_*(c).$$

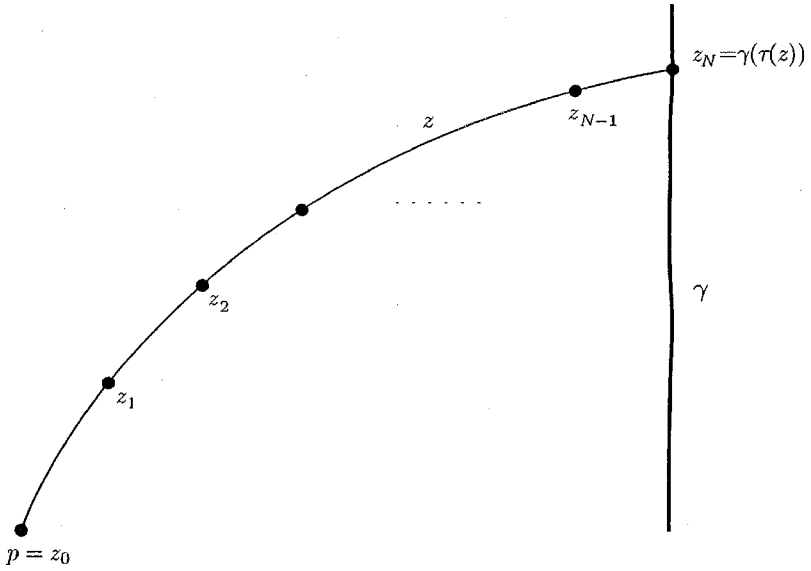

FIG. 1.

Choose a partition $\{0=s_0<s_1,\ldots,s_{N-1}<s_N=1\}$ of $[0,1]$ such that for any $i\in\{1,\ldots,N\}$,

$$s_i-s_{i-1}=\frac{1}{N}.$$

For any $z\in\tau^c\cap\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$, choose $N+1$ points $z_0,z_1,\ldots,z_N$ on $z([0,1])$ such that $z(0)=p$, $z_N=z(1)$, and $\mathrm{d}_R(z_i,z_{i-1})=l(z)/N$, for any $i\in\{1,\ldots,N\}$, where $l(z)$ denotes the length of z with respect to the Riemannian structure (3.1) (see Fig. 1).

Denote by γ_i $(i=1,\ldots,N)$ the maximal integral curve of W such that $\gamma_i(0)=z_i$ (see Fig. 2). Observe that $\gamma_N(s)=\gamma(s+\tau(z))$ for all s.

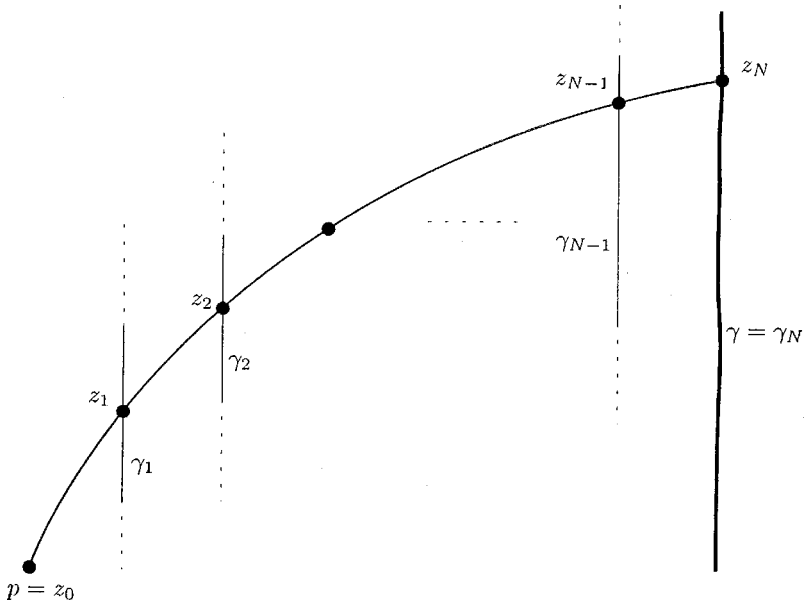

FIG. 2.

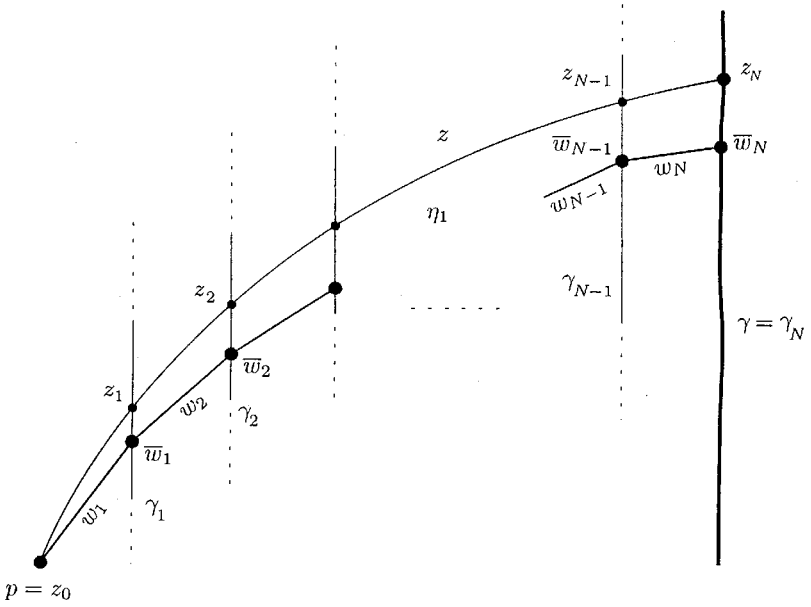

FIG. 3.

Let w_1 be the lightlike geodesic minimizing τ on $\mathcal{L}^{+,r}_{p,\gamma_1}([s_0,s_1],\Lambda)$ (recall that $z_0=p$ and $s_0=0$), w_2 the lightlike geodesic minimizing τ on $\mathcal{L}^{+,r}_{w_1(s_1),\gamma_2}([s_1,s_2],\Lambda)$, and so on (see Fig. 3). In Figs. 3–5, the points $w_i(s_i)$ are denoted by $\overline{w_i}$.

Note that the number N can be chosen big enough in order that $\mathrm{d}_R(w_i(s_i),z_{i+1})\leqslant\rho_*(c)$, for any $i=1,\ldots,N-1$ and for any $z\in\tau^c$.

Remark 4.1: Let $K=K(c)$ be a compact subset of $\overline{\Lambda}$ as in (3.10). By compactness, $K(c)$ can be covered by a finite family (U_j) satisfying Remark 3.3. Moreover, N can be chosen so large that $z([s_{i-1},s_i])$ and the minimizer of τ on $\mathcal{L}^{+,r}_{w_{i-1}(s_{i-1}),\gamma_i}([s_{i-1},s_i],\Lambda)$ are contained in some U_j.

The Lorentzian metric on U_j is described as

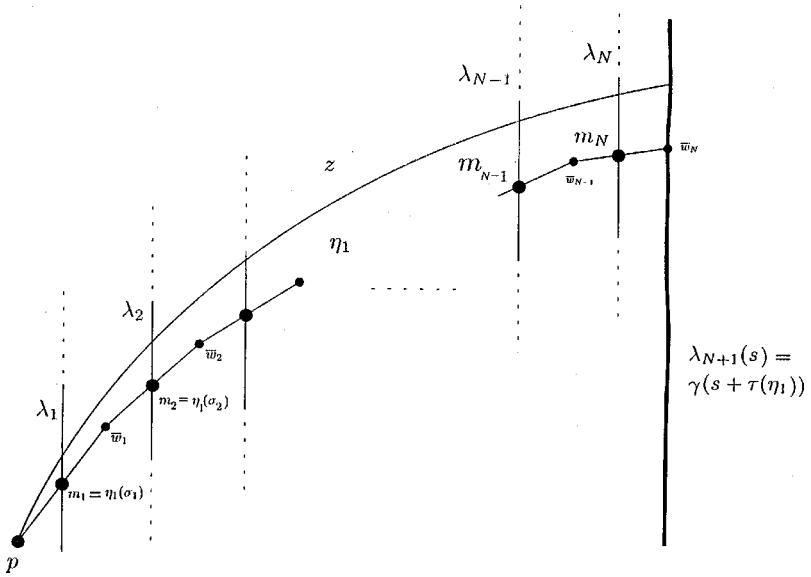

FIG. 4.

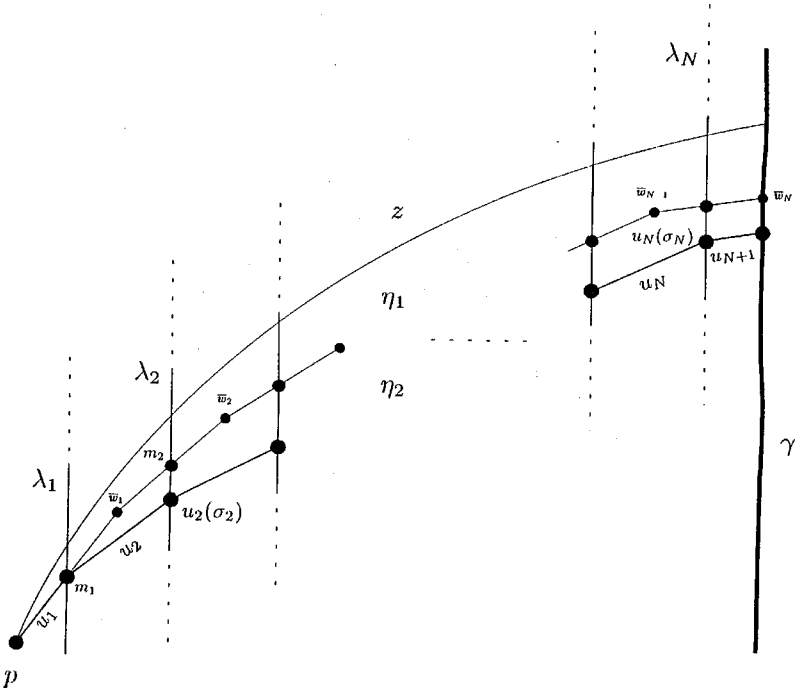

FIG. 5.

$$\langle \zeta, \zeta \rangle = \langle \alpha_j(x,t)\xi, \xi \rangle_0 + 2\langle \delta_j(x,t), \xi \rangle_0 \theta - \theta^2 \tag{4.1}$$

(cf. Remark 3.3), where $\alpha_j(x,t)$ is a positive linear operator, $\delta_j(x,t)$ is smooth vector field, $z = (x,t) \in U_j$, and $\zeta = (\xi, \theta) \in T_z\mathcal{M}$.

With the above notation, for any future pointing curve z with image contained in some U_j, the condition $\langle \dot{z}, \dot{z} \rangle = 0$ holds if and only if

$$\dot{t} = \langle \delta_j(x,t), \dot{x} \rangle_0 + \sqrt{\langle \alpha_j(x,t), \dot{x}, \dot{x} \rangle_0 + \langle \delta_j(x,t), \dot{x} \rangle_0^2}. \tag{4.2}$$

Moreover, any γ_i is an integral curve of W, so, in U_j, it has the form $s \mapsto (x_j, t_j + s)$, if $z_j = (x_j, t_j)$.

Note that $\mathcal{L}^{+,r}_{p,\gamma_1}([s_0, s_1], \Lambda)$ is nonempty, since it contains the restriction $z_{|[s_0,s_1]}$. Now, using elementary comparison theorems for ordinary differential equations and the metric (4.1) on U_j allow one to deduce also that any space $\mathcal{L}^{+,r}_{w_{i-1}(s_{i-1}),\gamma_i,\epsilon}([s_{i-1}, s_i], \Lambda)$ is nonempty for any $i \in \{2, \ldots, N\}$.

Note also that, if η_1 is the curve defined by setting $\eta_1([s_{i-1}, s_i]) = w_i$, then $\tau(\eta_1) \leqslant \tau(z) \leqslant c$ (always by comparison theorems in O.D.E.). In particular $\eta_1([0,1])$ is contained in $K(c)$.

Remark 4.2: A second curve η_2 will be constructed in the following way starting from η_1. On any minimizer w_i $(i = 1, \ldots, N)$ consider the point m_i such that $\mathrm{d}(w_i(s_{i-1}), m_i) = \mathrm{d}(m_i, w(s_i))$.

For $i = 1, \ldots, N$, we denote by λ_i the maximal integral curve of W such that $\lambda_i(0) = m_i$; moreover, we set $\lambda_{N+1}(s) = \gamma(s + \tau(\eta_1))$ (see Fig. 4).

Consider now the following subdivision of the interval $[0,1]$. Let $\sigma_0 = 0$, $\sigma_1 = 1/2N$, $\sigma_j = (2j-1)/2N$ for $j = 2, \ldots, N$, and $\sigma_{N+1} = 1$.

Denote by u_1 the minimizer of τ on $\mathcal{L}^{+,r}_{p,\lambda_1}([\sigma_0, \sigma_1], \Lambda)$, by u_2 the minimizer of τ on $\mathcal{L}^{+,r}_{u_1(\sigma_1),\lambda_2}([\sigma_1, \sigma_2], \Lambda)$ and so, inductively, we denote by u_j the minimizer of τ in $\mathcal{L}_{u_{j-1}(\sigma_{j-1}),\lambda_j,\epsilon}([\sigma_{j-1}, \sigma_j], \Lambda)$, $j = 2, \ldots, N+1$.

Finally, (see Fig. 5) we denote by η_2 the curve such that

$$\eta_2|_{[\sigma_{j-1},\sigma_j]} = u_j .$$

Using again comparison theorems in ordinary differential equations one proves that $\tau(\eta_2) \leqslant \tau(\eta_1)$.

The continuous flow $\eta(\sigma,z)$ can be constructed as follows. Fix $\sigma \in [0,1]$ and consider for instance the interval $[s_0,s_1]$. We choose $\eta(\sigma,z)_{|[s_0,s_1]}$ as follows. Set $p=(x_0,0)$ and $\gamma_1(s) = (x_1,t_1+s)$ (in some neighborhood U_j as in Remark 4.1). Since $z(s)=(x(s),t(s))$, the curve $x(s)$ joins x_0 with x_1.

Let $y(\sigma)$ be the minimizer of the functional

$$y \mapsto \int_{s_0}^{\sigma s_1} \langle \delta_i(y,t_y),\dot{y}\rangle_0 \, \mathrm{ds} + \int_{s_0}^{\sigma s_1} \sqrt{\langle \alpha_i(y,t_y),\dot{y},\dot{y}\rangle_0 + \langle \delta_i(y,t_y),\dot{y}\rangle_0^2} \, \mathrm{ds}$$

with boundary conditions $y(0)=x_0$ and $y(\sigma s_1)=x(\sigma s_1)$, where t_y is the solution of (4.2) with $t_y(0)=0$ in the interval $[0,\sigma s_1]$.

Denote by $\hat{y}(\sigma)$ the extension of $y(\sigma)$ to $[s_0,s_1]$ taking $\hat{y}(s)=x(s)$ for $s \in [\sigma s_1,s_1]$. Finally, denote by $\hat{t}_y$ the corresponding solution of (4.2) in the interval $[s_0,s_1]$. The curve $(\hat{y}(\sigma),\hat{t}_y(\sigma))$ will be $\eta(\sigma,z)$ in the interval $[s_0,s_1]$. In the same way we can construct $\eta(\sigma,z)$ on the other intervals $[s_{i-1},s_i]$. Note that, by construction, $\eta(1,z)=\eta_1$. Similarly, we can extend the flow η to a map defined on $[0,2]\times\tau^c$ in such a way that $\eta(2,z)=\eta_2$.

Now, we iterate the above-mentioned shortening argument, replacing the original curve z with the curve η_2. Successively we apply the above-mentioned construction, starting from η_2. By induction we obtain a flow $\eta(\sigma,z)$, defined on $\mathbb{R}^+\times\tau^c$.

Since $\tau(\eta(\sigma,z)) \leqslant \tau(z)$ for any σ and for any z, using η we immediately deduce

Lemma 4.3: Fix $r \in [1,+\infty]$. For any $c \in]\alpha,\beta[$, $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)\cap\tau^c$ is homotopically equivalent to $\mathcal{B}^+_{p,\gamma}\cap\tau^c$.

Moreover choosing a suitable continuous map $\rho_*(c)$ $(c \in]\alpha,\beta[)$ and arguing as in Sec. 9 of Ref. 7 we can also obtain the following result.

Proposition 4.4: $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ is homotopically equivalent to $\mathcal{B}^+_{p,\gamma}(\Lambda)$.

Suppose that $\tau(\eta_1)=\tau(\eta_2)$ and consider the situation is a single interval $[\sigma_j,\sigma_{j+1}]$. Since $\tau(\eta_1)=\tau(\eta_2)$ simple comparison theorems in O.D.E. show that η_1 is a minimizer on the interval $[\sigma_j,\sigma_{j+1}]$. Suppose that it consists of two (nonconstant) lightlike geodesics. If it is not a lightlike geodesic, by the above-given construction it has a discontinuity at $s_{j+1}=(\sigma_{j+1}+\sigma_j)/2$. Denote by U_{η_1} the parallel transport of $\dot{\gamma}(\tau(\eta_1))$ along the curve η_1. Since η_1 is a minimizer satisfying (3.6), by Lemma 3.7 and Remark 3.8 it is

$$\int_{\sigma_j}^{\sigma_{j+1}} \frac{\langle D_s V,\, \dot{\eta}_1\rangle}{\langle U_{\eta_1},\dot{\eta}_1\rangle} \mathrm{ds} = 0$$

for any C^∞-vector field along η_1 such that $V(0)=0, V(1)=0$. In particular $\dot{\eta}_1/\langle U_{\eta_1},\dot{\eta}_1\rangle$ is a C^1 curve. Therefore $\dot{\eta}_1(s^-_{j+1})=\dot{\eta}_1(s^+_{j+1})$, so η_1 is the image of a future pointing lightlike geodesic in the interval $[\sigma_j,\sigma_{j+1}]$.

Then, whenever we are far from lightlike geodesics and there are not intervals where η_1 is a constant, $\tau(\eta_2)<\tau(\eta_1)$. If η_1 possesses some interval where it is a constant it is possible to construct a ''localized'' flow where τ is strictly decreasing ignoring such intervals and using the above-given construction of the flow in a small neighborhood of η_1.

Finally compactness arguments similar to the ones used for the shortening method for Riemannian geodesics (cf. Ref. 26) allow one to obtain the analogous of the classical deformation results (see, e.g. Refs. 33 and 34) for the functional τ on $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$.

Since, to obtain Morse relations, we shall work with respect to the $H^{1,2}$ structure, we give the statements of the deformation results only for $r=2$.

Proposition 4.5: Let c be a regular value for τ on $\mathcal{L}^{+,2}_{p,\gamma}$ [namely $\tau^{-1}(\{c\})$ *does not contain geodesics*].

Then, there exists a positive number $\delta=\delta(c)$ and a continuous map $H\in C^0([0,1]\times\tau^{c+\delta},\tau^{c+\delta})$, such that:

(a) $H(0,z)=z$, *for every* $z\in\tau^{c+\delta}$,
(b) $H(1,\tau^{c+\delta})\subseteq\tau^{c-\delta}$,
(c) $H(\sigma,z)\in\tau^{c-\delta}$
for any $\sigma\in[0,1]$ *and* $z\in\tau^{c-\delta}$;

Proposition 4.6: Let K_c be the set of lightlike geodesics on $\tau^{-1}(\{c\})\cap\mathcal{L}^{+,2}_{p,\gamma}$. Then for any open neighborhood U of K_c, there exists a positive number $\delta=\delta(U,c)$ and a homotopy $H\in C^0([0,1]\times\tau^{c+\delta},\tau^{c+\delta})$, such that

(a) $H(0,z)=z$, *for any* $z\in\tau^{c+\delta}$,
(b) $H(1,\tau^{c+\delta}\backslash U)\subset\tau^{c-\delta}$,
(c) $H(\sigma,z)\in\tau^{c-\delta}$, *for every* $\sigma\in[0,1]$ *and* $z\in\tau^{c-\delta}$.

Remark 4.7: There are two main differences between the shortening method described previously and the classical shortening method for Riemannian geodesics. In our case, we locally minimize a functional which is is not given in an integral form. Second, we minimize the functional in the space of curves joining a point with a curve, and not two fixed points.

Remark 4.8: The flows used in Propositions 4.5 and 4.6 are just what we need for a Ljusternik–Schnirelmann theory. Then, without using the nondegeneracy assumption of Theorem 2.5 we can obtain the existence of at last $\mathrm{cat}(\mathcal{B}^+_{p,\gamma}(\Lambda))$ future pointing lightlike geodesic in $\mathcal{B}^+_{p,\gamma}(\Lambda)$. (Here cat X denotes the minimal number of contractible subsets of X covering it). Moreover if $\mathrm{cat}(\mathcal{B}^+_{p,\gamma}(\Lambda))=+\infty$ there is a sequence z_n of future pointing lightlike geodesics in $\mathcal{B}^+_{p,\gamma}(\Lambda)$ such that $\tau(z_n)\to\beta$.

V. ON THE BEHAVIOR OF τ NEAR LIGHTLIKE GEODESICS

To develop a Morse theory we shall use the space $\mathcal{L}^{+,2}_{p,\gamma}(\Lambda)$ [that contains $\mathcal{B}^{+,2}_{p_1\gamma}(\Lambda)$], because $H^{1,2}([0,1],\Lambda)$ is an Hilbert manifold (endowed with its natural metric). Since $\mathcal{L}^{+,2}_{p,\gamma}(\Lambda)$ is invariant by reparametrization as well as τ, it will be useful to consider equivalence classes of curves or, better, to single out one parametrization. This will be done on an open neighborhood $\mathcal{N}_w$ of $w([0,1])$ for any lightlike geodesic w.

Toward this goal consider the parallel vector field U_w along w of $\dot\gamma(\tau(w))$ (which is a timelike vector). Since γ is an integral curve of W, by Remark 4.4 it is $\langle U_w,U_w\rangle\equiv-1$. Now, by the pseudocoercivity of τ it follows that w does not have self-intersection, so its image is a submanifold and U_w can be extended to a smooth vector field Y on Λ such that

$$\langle Y(z),Y(z)\rangle=-1 \quad \text{for any } z\in\Lambda, \tag{5.1}$$

$$D_{\dot w(s)}Y(w(s))=0 \quad \text{for any } s\in[0,1] \tag{5.2}$$

(cf. Ref. 35). Using the vector field Y we define the following space:

$$\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)=\left\{z\in\mathcal{L}^{+,2}_{p,\gamma}(\Lambda):\langle Y(z),\dot z\rangle=\int_0^1\langle Y(z),\dot z\rangle\mathrm{d}s \ \text{ a.e.}\right\}. \tag{5.3}$$

Note that by (5.2), the geodesic w is in $\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ and

$$\int_0^1\langle Y(w),\dot w\rangle\mathrm{d}s<0..$$

The space $\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ will be used to study Morse theory near the critical point w for the functional τ. The first step in this direction is to prove that $\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ is a C^1-manifold.

Remark 5.1: It is well known that the space $\Omega^{+,2}_{p,\gamma}(\Lambda)$ defined by (3.2) is a C^∞-manifold and its tangent space at any z is given by

$$T_z\Omega^{+,2}_{p,\gamma}(\Lambda)=\{\zeta\in H^{1,2}([0,1],\mathcal{T}\Lambda):$$

$$\zeta(s)\in T_{z(s)}\Lambda \text{ for any } s,\zeta(0)=0,\zeta(1)) \text{ is parallel to } \dot\gamma(\tau(z))\}$$

where $\mathcal{T}\Lambda$ denotes the tangent bundle of Λ.

Remark 5.2: Consider the map

$$\phi:\Omega^{+,2}_{p,\gamma}(\Lambda)\to\left\{h\in L^2([0,1],\mathbb{R}):\int_0^1 h\,\mathrm{d}s=0\right\}$$

defined as

$$\phi(z)=\langle Y(z),\dot z\rangle-\int_0^1\langle Y(z),\dot z\rangle\mathrm{d}s. \tag{5.4}$$

It is a standard computation to prove that ϕ is of class C^∞ and its differential satisfies:

$$\mathrm{d}\phi(z)[\zeta]=\langle Y,D_s\zeta\rangle+\langle D_\zeta Y,\dot z\rangle-\int_0^1(\langle Y,D_s\zeta\rangle+\langle D_\zeta Y,\dot z\rangle)\mathrm{d}s, \tag{5.5}$$

where D is the Levi-Civita connection relative to the Lorentzian structure g.

Proposition 5.3: The space

$$\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)=\left\{z\in\Omega^{+,2}_{p,\gamma}(\Lambda):\langle Y(z),\dot z\rangle=\int_0^1\langle Y(z),\dot z\rangle\mathrm{d}s<0\right\} \tag{5.6}$$

is a manifold whose tangent space is given by

$$T_z\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)=\left\{\zeta\in T_z\Omega^{+,2}_{p,\gamma}(\Lambda):\langle Y,D_s\zeta\rangle+\langle D_\zeta Y,\dot z\rangle=\int_0^1(\langle Y,D_s\zeta\rangle+\langle D_\zeta Y,\dot z\rangle)\mathrm{d}s\right\}. \tag{5.7}$$

Proof: Consider the map ϕ defined by (5.4). By (5.5) and the implicit function theorem it is sufficient to prove that for any $h\in L^2([0,1],\mathbb{R})$ such that $\int_0^1 h\,\mathrm{d}s=0$ there exists $\zeta\in T_z\Omega^{+,2}_{p,\gamma}(\Lambda)$ such that

$$\langle Y,D_s\zeta\rangle+\langle D_\zeta Y,\dot z\rangle=h. \tag{5.8}$$

Choose $\zeta=\mu Y$ with $\mu(0)=0$. Then ζ satisfies (5.8) if and only if μ satisfies the Cauchy problem

$$\begin{cases}-\dot\mu+\mu\langle D_Y Y,\dot z\rangle=h,\\ \mu(0)=0,\end{cases}$$

because, by (5.1), $\langle Y,Y\rangle\equiv-1$. Such a problem has a (unique) solution in $H^{1,2}([0,1],\mathbb{R})$ and we are done. □

Remark 5.4: For any $z\in\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)$, $\|\dot z\|_R$ is uniformly far from 0. [Here $\|\cdot\|_R$ is the norm induced by the Riemann structure (3.1)]. Indeed if $z\in\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)$ it is

$$0<-\int_0^1\langle Y(z),\dot z\rangle\mathrm{d}s=-\langle Y(z),\dot z\rangle\leqslant|\langle Y(z),\dot z\rangle_R|\leqslant\|Y(z)\|_R\|\dot z\|_R.$$

Lemma 5.5: Let $\psi:\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)\to L^2([0,1],\mathbb{R})$ *defined as*

$$\psi(z)=\sqrt{2}\langle \dot z, W(z)\rangle+\sqrt{\langle \dot z,\dot z\rangle_R}. \tag{5.9}$$

Then ψ *is of class* C^1 *and, for any* $\zeta\in\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)$,

$$\begin{aligned}\mathrm{d}\psi(z)[\zeta]=&\sqrt{2}(\langle D_s\zeta, W(z)\rangle+\langle D_\zeta W,\dot z\rangle)\\&+\frac{1}{\sqrt{\langle \dot z,\dot z\rangle_R}}(\langle D_s\zeta,\dot z\rangle+2\langle \dot z, W(z)\rangle(\langle D_s\zeta, W(z)\rangle+\langle D_\zeta W,\dot z\rangle)).\end{aligned} \tag{5.10}$$

Note that, by Remark 5.4, since $\zeta\in H^{1,2}$ it is $\mathrm{d}\psi(z)[\zeta]\in L^2$.

Proof: Standard computations show that the differential of the map

$$\psi_1(z)=\sqrt{2}\langle \dot z, W(z)\rangle$$

along the direction ζ is given by

$$\mathrm{d}\psi_1(z)[\zeta]=\sqrt{2}(\langle D_s\zeta, W(z)\rangle+\langle D_\zeta W,\dot z\rangle).$$

To evaluate the differential of the map

$$\psi_2(z)=\sqrt{\langle \dot z,\dot z\rangle_R}$$

(at an instant s_0) we can assume that [in a neighborhood of $z(s_0)$] we are in $\mathbb{R}^n$ and

$$\langle \zeta,\zeta\rangle_R=\langle L(z)[\zeta],\zeta\rangle_E,$$

where $\langle\cdot,\cdot\rangle_E$ is the Euclidean scalar product of $\mathbb{R}^n$ and $L(z)$ is a smooth positive definite linear operator. Using such a position the vector fields in the tangent space at any curve z (on a suitable interval $[s_0-\delta,s_0+\delta]$) will be $H^{1,2}$-vector fields (defined on $[s_0-\delta,s_0+\delta]$) with values in $\mathbb{R}^n$.

Suppose that ζ is of class C^1. Then, by Remark 5.4, $\dot z+\lambda\dot\zeta$ is uniformly far from 0 for any λ sufficiently small, and

$$\mathrm{d}\psi_2(z)[\zeta]=\lim_{\lambda\to0}\frac{1}{\lambda}(\sqrt{\langle L(z+\lambda\zeta)[\dot z+\lambda\dot\zeta],\dot z+\lambda\dot\zeta\rangle_E}-\sqrt{\langle L(z)[\dot z],\dot z\rangle_E}).$$

Therefore there exists $\theta=\theta(\lambda,s)\in[0,1]$ such that

$$\mathrm{d}\psi_2(z)[\zeta]=\lim_{\lambda\to0}\frac{\langle \mathrm{d}L(z+\lambda\theta\zeta)[\zeta][\dot z+\lambda\dot\zeta],\dot z+\lambda\dot\zeta\rangle_E+2\langle L(z+\lambda\theta\zeta)[\dot\zeta],\dot z+\lambda\theta\dot\zeta\rangle_E}{2\sqrt{\langle L(z+\lambda\theta\zeta)[\dot z+\lambda\theta\dot\zeta],\dot z+\lambda\theta\dot\zeta\rangle_E}},$$

where the limit is done with respect to the L^2-norm.

Then, by the Lebesgue convergence theorem we obtain

$$\mathrm{d}\psi_2(z)[\zeta]=\frac{\langle \mathrm{d}L(z)[\zeta][\dot z],\dot z\rangle_E+2\langle L(z)[\dot\zeta],\dot z\rangle_E}{2\sqrt{\langle L(z)[\dot z],\dot z\rangle_E}},$$

which is a map in $L^2([s_0-\delta,s_0+\delta])$ by Remark 5.4.

Since

$$\langle L(z)[\dot z],\dot z]\rangle_E=\langle \dot z,\dot z\rangle_R=\langle \dot z,\dot z\rangle+2\langle W(z),\dot z\rangle^2$$

and

$$\langle \mathrm{d}L(z)[\zeta][\dot{z}],\dot{z}\rangle_E + 2\langle L(z)[\dot{\zeta}],\dot{z}\rangle_E = \mathrm{d}(\langle L(z)[\dot{z}],\dot{z}\rangle_E)[\zeta],$$

we obtain

$$\mathrm{d}\psi_2(z)[\zeta] = \frac{1}{\sqrt{\langle \dot{z},\dot{z}\rangle_R}}(\langle D_s\zeta,\dot{z}\rangle + 2\langle \dot{z},W(z)\rangle(\langle D_s\zeta,W(z)\rangle + \langle D_\zeta W,\dot{z}\rangle)). \tag{5.11}$$

Now consider $\zeta \in H^{1,2}([s_0-\delta,s_0+\delta],\mathbb{R}^n)$ and ζ_1 of class C^1. Then (in local coordinates) for any λ sufficiently small with respect to $\|\dot{\zeta}_1\|_{L^\infty}$, there exist $C_1, C_2 > 0$ such that

$$\begin{aligned}
&\left|\frac{\psi_2(z+\lambda\zeta_1)-\psi_2(z+\lambda\zeta)}{\lambda}\right| \\
&= \frac{1}{\lambda}\left|\frac{\langle L(z+\lambda\zeta_1)[\dot{z}+\lambda\dot{\zeta}_1],\dot{z}+\lambda\dot{\zeta}_1\rangle_E - \langle L(z+\lambda\zeta)[\dot{z}+\lambda\dot{\zeta}],\dot{z}+\lambda\dot{\zeta}\rangle_E}{\sqrt{\langle L(z+\lambda\zeta_1)[\dot{z}+\lambda\dot{\zeta}_1],\dot{z}+\lambda\dot{\zeta}_1\rangle_E} + \sqrt{\langle L(z+\lambda\zeta)[\dot{z}+\lambda\dot{\zeta}],\dot{z}+\lambda\dot{\zeta}\rangle_E}}\right| \\
&\leqslant \frac{C_1\|\zeta-\zeta_1\|_{L^\infty}\langle \dot{z}+\lambda\dot{\zeta}_1,\dot{z}+\lambda\dot{\zeta}_1\rangle_E}{\sqrt{\langle L(z+\lambda\zeta_1)[\dot{z}+\lambda\dot{\zeta}_1],\dot{z}+\lambda\dot{\zeta}_1\rangle_E}} \\
&\quad + \frac{C_2|\dot{z}+\lambda\dot{\zeta}_1+\dot{z}+\lambda\dot{\zeta}|_E|\zeta_1-\zeta|_E}{\sqrt{\langle L(z+\lambda\zeta_1)[\dot{z}+\lambda\dot{\zeta}_1],\dot{z}+\lambda\dot{\zeta}_1\rangle_E} + \sqrt{\langle L(z+\lambda\zeta)[\dot{z}+\lambda\dot{\zeta}],\dot{z}+\lambda\dot{\zeta}\rangle_E}},
\end{aligned}$$

where $|\cdot|_E$ is the Euclidean norm in $\mathbb{R}^n$. Then there exists $C>0$ such that

$$\left|\frac{\psi_2(z+\lambda\zeta_1)-\psi_2(z+\lambda\zeta)}{\lambda}\right| \leqslant C(\|\zeta_1-\zeta\|_{L^\infty}|\dot{z}+\lambda\dot{\zeta}_1|_E + |\dot{\zeta}_1-\dot{\zeta}|_E).$$

Therefore, since $\dot{z}$ is in L^2, $\|\dot{\zeta}_1\|_{L^2}$ is bounded (according to the L^2-norm of ζ) and $\zeta(0)=\zeta_1(0)$ we deduce the existence of a constant C_0 such that for any $\lambda \leqslant 1$,

$$\frac{1}{\lambda}\|\psi_2(z+\lambda\zeta_1)-\psi_2(z+\lambda\zeta)\|_{L^2} \leqslant C_0\|\zeta_1-\zeta\|_{H^{1,2}}. \tag{5.12}$$

Now, by the Lebesgue convergence theorem and Remark 5.4 it is not difficult to see that the linear operator $\mathrm{d}\psi_2(z)$ is continuous as linear map from $T_z\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)$ to $L^2([0,1],\mathbb{R})$. Then for any $\epsilon > 0$ there exists $\vartheta \in]0,\epsilon[$ such that

$$\|\zeta_1-\zeta\|_{H^{1,2}} \leqslant \vartheta \Rightarrow \|\mathrm{d}\psi_2(z)[\zeta]-\mathrm{d}\psi_2(z)[\zeta_1]\|_{L^2} < \epsilon. \tag{5.13}$$

Moreover always fixing ζ_1 such that $\|\zeta_1-\zeta\|_{H^{1,2}} \leqslant \vartheta$, for any $\lambda \leqslant 1$ we have

$$\frac{1}{\lambda}\|\psi_2(z+\lambda\zeta_1)-\psi_2(z+\lambda\zeta)\|_{L^2} \leqslant C_0\vartheta \leqslant C_0\epsilon. \tag{5.14}$$

Finally

$$\begin{aligned}
\frac{\psi_2(z+\lambda\zeta)-\psi_2(z)}{\lambda} - \mathrm{d}\psi_2(z)[\zeta] &= \frac{\psi_2(z+\lambda\zeta_1)-\psi_2(z)}{\lambda} - \mathrm{d}\psi_2(z)[\zeta_1] + \frac{\psi_2(z+\lambda\zeta)-\psi_2(z+\lambda\zeta_1)}{\lambda} \\
&\quad + \mathrm{d}\psi_2(z)[\zeta_1] - \mathrm{d}\psi_2(z)[\zeta].
\end{aligned}$$

Since ψ_2 is differentiable at z along the direction ζ_1, for any λ sufficiently small it is

$$\left\| \frac{\psi_2(z+\lambda\zeta_1)-\psi_2(z)}{\lambda} - d\psi_2(z)[\zeta_1] \right\|_{L^2} \leqslant \epsilon,$$

so, combining (5.13) and (5.14) gives the existence of $\hat{\lambda}$ such that $|\lambda| \leqslant \hat{\lambda}$ implies

$$\left\| \frac{\psi_2(z+\lambda\zeta)-\psi_2(z)}{\lambda} - d\psi_2(z)[\zeta] \right\|_{L^2} \leqslant \epsilon + C_0\epsilon + \epsilon,$$

proving that (5.11) is satisfied for any $\zeta \in H^{1,2}$.

The continuity of $d\psi_2(\cdot)$ (which is a consequence of Remark 5.4 and the Lebesgue Theorem) says that ψ_2 is of class C^1 in $\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)$ and its differential is given by (5.11). □

Remark 5.6: If $z \in \mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ then $\dot{z} \neq 0$ almost everywhere and it is lightlike. Since $\langle Y(z), \dot{z} \rangle$ is negative and Y is timelike, there exists a positive constant ν_z such that

$$-\langle Y(z), \dot{z} \rangle \geqslant \nu_z \|Y(z)\|_R \|\dot{z}\|_R .$$

Moreover $\langle Y(z), \dot{z} \rangle$ is constant, therefore $\|\dot{z}\|_R$ is uniformly bounded.

Now we can finally prove that $\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ is a manifold in a neighborhood of w.

Proposition 5.7: There exists an open neighborhood $\mathcal{O}_w$ of the geodesic w in $\Omega^{+,2}_{p,\gamma}(\Lambda)$ such that $\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda) \cap \mathcal{O}_w$ is a manifold of class C^1 and, for any $z \in \mathcal{Q}^{+,2}_{p,\gamma}(\Lambda) \cap \mathcal{O}_w$,

$$T_z(\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda) \cap \mathcal{O}_w) = \Big\{ \zeta \in \Omega^{+,2}_{p,\gamma}(\Lambda) : \langle D_s\zeta, \dot{z} \rangle = 0 \ \text{ a.e., and}$$

$$\langle Y, D_s\zeta \rangle + \langle D_\zeta Y, \dot{z} \rangle = \int_0^1 (\langle Y, D_s\zeta \rangle + \langle D_\zeta Y, \dot{z} \rangle) ds \ \text{a.e.,} \Big\}. \tag{5.15}$$

Proof: Let $\psi : \mathcal{P}^{+,2}_{p,\gamma}(\Lambda) \to L^2([0,1]\mathbb{R})$ be the C^1-map given by (5.9). By (5.10) its differential at any point $z \in \mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ is

$$d\psi(z)[\zeta] = \frac{\langle D_s\zeta, \dot{z} \rangle}{\sqrt{\langle \dot{z}, \dot{z} \rangle_R}}.$$

Since our result is of local nature (in a neighborhood of the geodesic w), by (5.7) it suffices to show that, for any $h \in L^2([0,1]\mathbb{R})$, there exists $\zeta \in T_z\Omega^{+,2}_{p,\gamma}(\Lambda)$ such that

$$\begin{cases} \langle Y(w), D_s\zeta \rangle + \langle D_\zeta Y(w), \dot{w} \rangle = \displaystyle\int_0^1 (\langle Y, D_s\zeta \rangle + \langle D_\zeta Y(w), \dot{w} \rangle) ds, \\ \dfrac{\langle D_s\zeta, \dot{w} \rangle}{\sqrt{\langle \dot{w}, \dot{w} \rangle_R}} = h . \end{cases}$$

Choose $\zeta(s) = \mu(s) Y(w(s)) + \lambda(s)\dot{w}(s)$. Since $\langle Y, Y \rangle \equiv -1$, denoting by c_w the real constant $\langle Y, \dot{w} \rangle$, it will be sufficient to verify the existence of two real functions μ and λ such that $\mu(0) = 0$, $\lambda(0) = \lambda(1) = 0$ and

$$\begin{cases} \mu' + \mu\langle D_Y Y, \dot{w} \rangle + \lambda' c_w \quad \text{is constant,} \\ \mu' c_w = h\sqrt{\langle \dot{w}, \dot{w} \rangle_R}, \end{cases}$$

and this can be done choosing

$$\mu(s)=\frac{1}{c_w}\int_0^s h\sqrt{\langle \dot w,\dot w\rangle_R}\,\mathrm{d}r,$$

and

$$c_w\lambda'=c+\frac{1}{c_w}h\sqrt{\langle \dot w,\dot w\rangle_R}-\frac{\langle D_YY,\dot w\rangle}{c_w}\int_0^s h\sqrt{\langle \dot w,\dot w\rangle_R}\,\mathrm{d}r,$$

where (integrating both terms of the above mentioned equality) the constant c can be chosen so that $\lambda(1)=\lambda(0)=0$. □

Remark 5.8: To describe the tangent space $T_z(\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)\cap\mathcal{O}_w)$ we can operate in the following way. Take $\zeta\in T_z\mathcal{P}^{+,2}_{p,\gamma}(\Lambda)$ and choose $\mu\in H^{1,2}([0,1],\mathbb{R})$ such that $\mu(0)=0$ and

$$\langle D_{\dot z}[\zeta-\mu Y],\dot z\rangle=0,$$

namely, μ has to satisfy

$$\begin{cases}\langle D_{\dot z}\zeta,\dot z\rangle-\mu' c_z-\mu\langle D_{\dot z}Y,\dot z\rangle=0,\\ \mu(0)=0,\end{cases}$$

where $c_z\equiv\langle Y,\dot z\rangle$ is a negative constant. Then μ is given by

$$\mu(s)=\int_0^s\frac{\langle D_{\dot z}\zeta,\dot z\rangle}{c_z}\exp\left(-\int_r^s\frac{\langle D_{\dot z}Y,\dot z\rangle}{c_z}\mathrm{d}\sigma\right)\mathrm{d}r, \tag{5.16}$$

and by (5.16):

$$\mathrm{d}\tau(z)[\zeta-\mu Y]=-\langle\dot\gamma(\tau(z),\zeta(1)\rangle+\langle\dot\gamma(\tau(z)),Y(z(1)\rangle\mu(1)$$

where

$$\mu(1)=\int_0^1\frac{\langle D_{\dot z}\zeta,\dot z\rangle}{c_z}\exp\left(-\int_r^1\frac{\langle D_{\dot z}Y,\dot z\rangle}{c_z}\mathrm{d}\sigma\right)\mathrm{d}r.$$

Then, using Remark 5.4 and the same technique of the proof of Lemma 5.5 allows one to deduce that τ is of class C^2 on $\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)\cap\mathcal{O}_w$.

In Sec. III we proved the existence (for any timelike curve sufficiently closed to a fixed event) of minimizing lightlike geodesics for the functional τ. Now we need a sort of converse of the above-mentioned principle.

Proposition 5.9: Any future pointing lightlike geodesic w is a critical point of τ on $\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)\cap\mathcal{O}_w$.

Proof: Take $V\in T_w\Omega^{+,2}_{p,\gamma}(\Lambda)$ such that $V(0)=V(1)=0$ and $\mu\in H^{1,2}([0,1],\mathbb{R})$ such that $\mu(0)=0$ and

$$\langle D_{\dot w}[V-\mu Y],\dot w\rangle=0. \tag{5.17}$$

By (5.16), Proposition 5.7, and Remark 5.8 it will be sufficient to prove that

$$0=\mathrm{d}\tau(w)[V-\mu Y]=\mu(1)\langle Y(w(1)),\dot\gamma(\tau(w))\rangle. \tag{5.18}$$

Now by (5.17)

$$\mu(1)=\int_0^1\frac{\langle D_{\dot w}V,\dot w\rangle}{\langle Y,\dot w\rangle}\mathrm{d}s$$

because $D_{\dot w}\dot w=0$. Then $\mu(1)=0$ for any V because $\langle Y,\dot w\rangle$ is constant ($\neq 0$) and w is a geodesic. □

Remark 5.10: The above-mentioned proof also shows that, for any $\zeta\in T_w(\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)\cap\mathcal{O}_w)$, since w is a geodesic it is $\zeta(1)=0$.

Remark 5.11: Let w be a future pointing lightlike geodesic. The same computations as in Ref. 13 allow one to prove that, for any $\zeta\in T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$, the Hessian of τ along the direction ζ is given by

$$H^\tau(w)[\zeta,\zeta]=\frac{-1}{\langle\dot\gamma(\tau(w)),\dot w(1)\rangle}\int_0^1(\langle D_s\zeta,D_s\zeta\rangle-\langle R(\zeta,\dot w)\dot w,\zeta\rangle)\mathrm{d}s. \tag{5.19}$$

Now we equip $T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ with the Hilbert structure

$$\langle\zeta_1,\zeta_2\rangle=\int_0^1\langle D^Y_s\zeta_1,D^Y_s\zeta_2\rangle_Y\,\mathrm{d}s, \tag{5.20}$$

where $\langle\zeta,\zeta\rangle_Y=\langle\zeta,\zeta\rangle-2\langle Y(w),\zeta\rangle^2$ [which is equivalent to (3.1)] and D^Y_s is the covariant derivative with respect to $\langle\zeta,\zeta\rangle_Y$.

Proposition 5.12: The linear map associated with the quadratic form (5.19) on $T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ is a compact perturbation of the identity with respect to the Hilbert structure (5.20).

Proof: It is

$$\langle D_s\zeta,D_s\zeta\rangle=\langle D_s\zeta,D_s\zeta\rangle+2\langle D_s\zeta,Y(w)\rangle^2-2\langle D_s\zeta,Y(w)\rangle^2=\langle D_s\zeta,D_s\zeta\rangle_Y-2\langle D_s\zeta,Y(w)\rangle^2. \tag{5.21}$$

Now there exists a bilinear map Γ defined on the vector fields on Λ such that

$$D_s\zeta=D^Y_s\zeta+\Gamma(w)[\zeta,\zeta].$$

Moreover, by (5.15)

$$\langle D_s\zeta,Y(w)\rangle=-\langle D_\zeta Y,\dot w\rangle+\int_0^1(\langle D_s\zeta,Y(w)\rangle+\langle D_\zeta Y,\dot w\rangle)\mathrm{d}s \tag{5.22}$$

while, by Remark 5.10,

$$\int_0^1\langle D_s\zeta,Y(w)\rangle=-\int_0^1\langle\zeta,D_sY\rangle. \tag{5.23}$$

Since $H^{1,2}$ is compactly embedded in L^∞, combining (5.21), (5.22) and (5.23) gives the proof. □

Now denote by $m(w,\tau)$ the maximal dimension of a subspace of $T_w(\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)\cap\mathcal{O}_w)$ where the restriction of $H^\tau(w)[\cdot,\cdot]$ is negative definite. It is called the Morse index of the quadratic form $H^\tau(w)[\cdot,\cdot]$. The following index theorem holds:

Theorem 5.13: *Let w be a geodesic in $\mathcal{Q}^{+,2}_{\nu,\gamma}(\Lambda)$. Then*

$$m(w,\tau)=\mu(w).$$

To prove Theorem 5.13 some preliminary results are needed.

Lemma 5.14: Let ζ be a Jacobi field along w such that $\zeta(0)=0,\zeta(1)=0$. Then $\zeta\in T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$.

Proof: Let ζ be a Jacobi field along w with $\zeta(0)=0$ and $\zeta(1)=0$. It is immediately checked that $\langle\dot w,D_s\zeta\rangle\equiv 0$. Therefore we just have to prove that the function

$$\varphi(s)=\langle D_s\zeta,Y(w)\rangle+\langle\zeta,D_\zeta Y\rangle$$

is constant. Since $D_sY\equiv 0$ and w is a geodesic

$$\varphi'(s)=\langle D_s^2\zeta,Y(w)\rangle+\langle\zeta,D_sD_\zeta Y\rangle.$$

Now, since ζ is a Jacobi field and

$$D_sD_\zeta Y=D_\zeta D_sY+R(\dot w,\zeta)Y$$

(cf. Ref. 22), it is

$$\begin{aligned}\varphi'(s)&=-\langle R(\zeta,\dot w)\dot w,Y(w)\rangle+\langle D_\zeta D_sY+R(\dot w,\zeta)Y,\dot w\rangle\\&=-\langle R(\zeta,\dot w)\dot w,Y(w)\rangle+\langle R(\dot w,\zeta)Y,\dot w\rangle=0\end{aligned}$$

because of the symmetry properties of the curvature tensor R (cf. Ref. 22). □

An integration by parts shows immediately that the following Lemma holds.

Lemma 5.15: If ζ is a Jacobi field along w such that $\zeta(0)=0$ and $\zeta(1)=0$, then

$$H^\tau(w)[\zeta,\zeta_1]=0\quad\text{for any}\quad\zeta_1\in T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda).\tag{5.24}$$

Lemma 5.16: Let $\zeta\in T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ such that (5.24) *is satisfied. Then ζ is a C^2-Jacobi field along w such that $\zeta(0)=0$ and $\zeta(1)=0$.*

Proof: If $\zeta\in T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$, $\zeta(0)=0$ and by Remark 5.10, $\zeta(1)=0$ because w is a geodesic. Then, assuming that (5.24) holds, we have to verify that ζ is of class C^2 and it satisfies (2.4).

Let V be a C^∞-vector field along w such that $V(0)=0$, $V(1)=0$. Set $c_w=\langle Y(w),\dot w\rangle$ (which is a nonzero constant) and choose

$$\mu(s)=\int_0^s\frac{1}{c_w}\langle D_sV,\dot w\rangle.$$

Now let λ be the unique real map such that

$$\langle D_sV,Y(w)\rangle+\langle\dot w,D_VY\rangle-\mu'\langle Y(w),Y(w)\rangle-\mu\langle\dot w,D_YY\rangle-\lambda' c_w=\text{const},$$

$$\lambda(0)=\lambda(1)=0.$$

A straightforward computation shows that $\zeta_1=V-\mu Y(w)-\lambda\dot w\in T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$. Therefore by (5.24) we have

$$\int_0^1(\langle D_s\zeta,D_sV-\mu'Y(w)-\lambda'\dot w\rangle-\langle R(\zeta,\dot w)\dot w,V-\mu Y(w)-\lambda\dot w\rangle)\,\mathrm{d}s=0$$

for any C_0^∞-vector field V along w. Now $\langle D_s\zeta,\dot w\rangle\equiv0$ and $\langle R(\zeta,\dot w)\dot w,\dot w\rangle\equiv0$. This allows us to deduce immediately that ζ is of class C^2. So, to obtain (2.4), it suffices to prove that, for any V,

$$\int_0^1(-\mu'\langle D_s\zeta,Y(w)\rangle+\mu\langle R(\zeta,\dot w)\dot w,Y(w)\rangle)\,\mathrm{d}s=0,\tag{5.25}$$

which is equivalent to

$$\int_0^1(-\langle D_sV,\dot w\rangle\langle D_s\zeta,Y(w)\rangle+\langle V,\dot w\rangle\langle R(\zeta,\dot w)\dot w,Y(w)\rangle)\,\mathrm{d}s=0.$$

Then an integration by parts shows that (5.25) is equivalent to

$$\frac{\mathrm{d}}{\mathrm{d}s}(\langle D_s\zeta,Y(w)\rangle\dot w)+\langle R(\zeta,\dot w)\dot w,Y(w)\rangle)=0.$$

Now, w is a geodesic while, by (5.15),

$$\langle D_s\zeta, Y(w)\rangle = \int_0^1 (\langle D_s\zeta, Y(w)\rangle + \langle D_\zeta Y, \dot w\rangle)\mathrm{d}s - \langle D_\zeta Y, \dot w\rangle,$$

therefore (5.25) is equivalent to

$$-\frac{\mathrm{d}}{\mathrm{d}s}(\langle D_\zeta Y, \dot w\rangle) + \langle R(\zeta, \dot w)\dot w, Y(w)\rangle = 0.$$

But

$$D_s D_\zeta Y = D_\zeta D_s Y + R(\dot w, \zeta)Y,$$

w is a geodesic and $D_s Y \equiv 0$, therefore (5.25) follows by the symmetry properties of R. □

Proof of Theorem 5.13: We prove a generalization of the Morse index theorem for Riemannian geodesics (see, e.g., Refs. 21 and 26) to lightlike geodesics. For any $\sigma \in]0,1]$ set

$$T_\sigma = \{\zeta \in H^{1,2}([0,\sigma]), \mathcal{T}\Lambda) : \zeta(s) \in T_{w(s)} \text{ for any } s \in]0,\sigma],$$

$$\zeta(0) = 0, \quad \zeta(\sigma) = 0,$$

$$\langle Y, D_s\zeta\rangle + \langle D_\zeta Y, \dot w\rangle \equiv c_\zeta \text{ a.e. in } [0,\sigma],$$

$$\langle D_s\zeta, \dot w\rangle = 0 \text{ a.e. in } [0,\sigma]\}.$$

Note that $T_1 = T_w\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$. Set, for any $\zeta \in T_\sigma$,

$$H_\sigma[\zeta,\zeta] = \int_0^\sigma (\langle D_s\zeta, D_s\zeta\rangle - \langle R(\zeta, \dot w)\dot w, \zeta\rangle)\mathrm{d}s.$$

Note that

$$H^\tau(w)[\cdot,\cdot] = \frac{-1}{\langle \dot\gamma(\tau(w)), \dot w(1)\rangle} H_1([\cdot,\cdot],$$

while $-\langle \dot\gamma(\tau(w)), \dot w(1)\rangle > 0$ because

$$\dot\gamma(\tau(w)) = Y(\gamma(\tau(w))) = Y(w(1))$$

and $\langle Y(w(s)), \dot w(s)\rangle$ is constant.

Therefore, denoting by $i(H_1)$ the Morse index of the quadratic form H_1 we have to prove that

$$i(H_1) = \mu(w). \tag{5.26}$$

On T_σ we define the Hilbert structure

$$\langle \zeta, \zeta\rangle_\sigma = \int_0^\sigma \langle D^Y_r\zeta, D^Y_r\zeta\rangle_Y \mathrm{d}r. \tag{5.27}$$

Denote by L_σ the linear operator in T_σ such that

$$\langle L_\sigma\zeta_1, \zeta_2\rangle_\sigma = H_\sigma([\zeta_1, \zeta_2]). \tag{5.28}$$

By Proposition 5.12 we see that

$$L_\sigma = I_\sigma - K_\sigma,$$

where I_σ is the identity on T_σ and $K_\sigma : T_\sigma \to T_\sigma$ is a compact operator. We shall denote by w_σ the geodesic $w_{|[0,\sigma]}$. It is well known that T_σ has the following orthogonal decomposition consisting of eigenspaces of L_σ,

$$T_\sigma = H_\sigma^+ \oplus H_\sigma^0 \oplus H_\sigma^-,$$

where (5.28) is positive definite on H_σ^+, definite negative on H_σ^-, and $H_\sigma^0 = \mathrm{Ker}\, L_\sigma$.

For any $\sigma \in]0,1]$ let $\lambda_1(\sigma) \geqslant \cdots \geqslant \lambda_k(\sigma)$ be the eigenvalues of the compact operator K_σ. Any eigenvalues are here repeated according to its (finite) multiplicity. By Lemmas 5.15–5.16 $w(\sigma)$ is conjugate to $w(0)$ with multiplicity equal to m if and only if there exists $k \in \mathbb{N}$ such that

$$\lambda_k(\sigma) < 1, \quad \lambda_{k+1}(\sigma), \ldots, \lambda_{k+m}(\sigma) = 1, \quad \text{and} \quad \lambda_{k+m+1}(\sigma) > 1.$$

Since K_σ is compact the eigenvalues of K_σ are characterized by the well-known Poincaré formula:

$$\lambda_k(\sigma) = \max_{\dim V = k} \Big[\min_{\zeta \in V, |\zeta|_\sigma = 1} (\langle K_\sigma \zeta, \zeta \rangle_\sigma) \Big], \tag{5.29}$$

which holds whenever the eigenvalues are positive. (Here $|\cdot|_\sigma = \langle \cdot, \cdot \rangle_\sigma^{1/2}$). Since we are interested in studying the behavior of $\lambda_k(\sigma)$ when its value is close to 1, we shall assume that all the $\lambda_k(\sigma)$'s are positive. The general case can be treated by small changes.

Using (5.29) it is not difficult to prove that any λ_k is a continuous function of σ. Moreover using (5.21)–(5.23) it is easy to show that there exists $\sigma_0 > 0$ such that, for any $\sigma \in]0,\sigma_0]$, H_σ is positive definite on T_σ. Then it will be sufficient to show that

$$\text{any } \lambda_k \text{ is strictly increasing.} \tag{5.30}$$

Fix $k \in \mathbb{N}$ and $0 \leqslant \sigma_1 < \sigma_2 \leqslant 1$. By (5.29) there exists a subspace V of T_{σ_1} having dimension k such that

$$\lambda_k(\sigma_1) = \min_{\zeta \in V, |\zeta|_{\sigma_1} = 1} (\langle K_{\sigma_1} \zeta, \zeta \rangle_{\sigma_1}). \tag{5.31}$$

For any $\zeta \in V$ set $c_\zeta \equiv \langle D_s \zeta, Y(w) \rangle + \langle \dot{w}, D_\zeta Y \rangle$ and $c_w \equiv \langle \dot{w}, Y(w) \rangle$. Take the vector field

$$A_\zeta = \zeta + \lambda \dot{w}$$

where $\lambda' = -c_\zeta / c_w$ and $\lambda(\sigma_1) = 0$. Since $\zeta \in T_{\sigma_1}$, w is a lightlike geodesic and $D_s Y \equiv 0$ it is

$$\langle D_s A_\zeta, \dot{w} \rangle \equiv 0, \tag{5.32}$$

$$\langle D_s A_\zeta, Y(w) \rangle + \langle \dot{w}, D_{A_\zeta} Y \rangle \equiv 0, \tag{5.33}$$

and

$$A_\zeta(\sigma_1) = 0, A_\zeta(0) = \lambda(0) \dot{w}(0). \tag{5.34}$$

Now denote by $\hat{A}_\zeta$ the extension to $[0,\sigma_2]$ of A_σ obtained by setting $\hat{A}_\zeta = 0$ on $[\sigma_1, \sigma_2]$. Note that, for any $\zeta \in V$,

$$\langle K_{\sigma_2} \hat{A}_\zeta, \hat{A}_\zeta \rangle_{\sigma_2} = \langle K_{\sigma_1} \zeta, \zeta \rangle_{\sigma_1}.$$

Now set

$$B_\zeta = \hat{A}_\zeta + \mu \dot{w},$$

where μ satisfies

$$\mu' = \text{const}, \quad \mu(0) = -\lambda(0), \quad \mu(\sigma_2) = 0. \tag{5.35}$$

Since $\hat{A}_\zeta$ satisfies (5.32)–(5.34) (with A_ζ replaced by $\hat{A}_\zeta$), thanks to (5.35) we deduce that $B_\zeta \in T_{\sigma_2}$. Note that the map

$$B_\cdot : V \to T_{\sigma_2}$$

is a linear and injective. Then the space

$$V_* = \{B_\zeta : \zeta \in V\}$$

is a subspace of T_{σ_2} having dimension k. Moreover, by our construction,

$$\langle K_{\sigma_2} B_\zeta, B_\zeta \rangle_{\sigma_2} = \langle K_{\sigma_1} \zeta, \zeta \rangle_{\sigma_1} \text{for any} \zeta \in V.$$

Then, by (5.29) and (5.31)

$$\lambda_k(\sigma_1) = \min_{\zeta \in V, |\zeta|_{\sigma_1} = 1} ((\langle K_{\sigma_1} \zeta, \zeta \rangle_{\sigma_1}) = \min_{\zeta \in V_*, |\zeta|_{\sigma_2} = 1} (\langle K_{\sigma_2} \zeta, \zeta \rangle_{\sigma_2}) \leqslant \lambda_k(\sigma_2). \tag{5.36}$$

To conclude the proof assume by contradiction that

$$\lambda \equiv \lambda_k(\sigma_1) = \lambda_k(\sigma_2). \tag{5.37}$$

By the spectral properties of K_{σ_2}, T_{σ_2} admits the orthogonal decomposition

$$T_{\sigma_2} = H^- \oplus H^0 \oplus H^+,$$

such that $\lambda I_{\sigma_2} - K_{\sigma_2}$ is negative definite on H^-, positive definite on H^+, and $H^0 = \text{Ker}(\lambda I_{\sigma_2} - K_{\sigma_2})$.

We claim that

$$V_* \cap (H^0 \oplus H^+) = \{0\}. \tag{5.38}$$

Indeed if $\zeta = \zeta_0 + \zeta_+ \in V_* \cap (H^0 \oplus H^+)$, where $\zeta_0 \in H^0$ and $\zeta_+ \in H^+$, if $\zeta_+ \neq = 0$ and $|\zeta|_{\sigma_2} = 1$ it is

$$\langle K_{\sigma_2} \zeta_0, \zeta_0 \rangle_{\sigma_2} + \langle K_{\sigma_2} \zeta_+, \zeta_+ \rangle_{\sigma_2} = \lambda \langle \zeta_0, \zeta_0 \rangle_{\sigma_2} + \langle K_{\sigma_2} \zeta_+, \zeta_+ \rangle_{\sigma_2} < \lambda \langle \zeta_0, \zeta_0 \rangle_{\sigma_2} + \lambda \langle \zeta_+, \zeta_+ \rangle_{\sigma_2} = \lambda$$

in contradiction with (5.36) and (5.37) because $\zeta \in V_*$. Then $\zeta_+ = 0$ and

$$\zeta = \zeta_0 \in \text{Ker}(\lambda I_{\sigma_2} - K_{\sigma_2}).$$

Then the same proof of Lemma 5.16 allows one to deduce that ζ is of class C^2. Since $\mu \dot{w}$ is of class C^2 then $\hat{A}_\zeta$ is of class C^2, and by the construction of $\hat{A}_\zeta$ we deduce that

$$D_s(A_\zeta)(\sigma_1) = 0.$$

Since ζ is a Jacobi field in $[0, \sigma_1]$, w is a geodesic and λ' is constant, $A_\zeta = \zeta + \lambda \dot{w}$ satisfies (2.4) with initial condition $A_\zeta(\sigma_1) = 0$ and $D_s(A_\zeta)(\sigma_1) = 0$. Then by the uniqueness of the Cauchy

problem it is $A_\zeta \equiv 0$. Since $\zeta(0)=0$, then $\lambda(0)=0$ and therefore $\lambda \equiv 0$. This implies that $\mu \equiv 0$ and $B_\sigma \equiv 0$ proving (5.38). Then the orthogonal projection of V_* on H^- has dimension n and

$$\lambda_k(\sigma_1)=\lambda < \min_{\zeta \in V_*, |\zeta|_{\sigma_2}=1} \langle K_{\sigma_2}\zeta,\zeta\rangle_{\sigma_2} \leqslant \lambda_k(\sigma_2)$$

proving (5.30) and concluding the proof of Theorem 5.13. □

VI. PROOF OF THEOREMS 2.5, 2.9, AND 2.11

Now we are finally ready to prove Theorem 2.5.

Proof of Theorem 2.5: Whenever we are far from the geodesics in $\mathcal{L}^{+,2}_{p,\gamma}(\Lambda)$, we can use the shortening flow at Sec IV to obtain a flow where τ is strictly decreasing.

Near any geodesic we can construct an homotopy equivalence between $\mathcal{L}^{+,2}_{p,\gamma}(\Lambda)$ and $\mathcal{Q}^{+,2}_{p,\gamma}(\Lambda)$ simply by a convex combination between the identity in $H^{1,2}([0,1],\mathbb{R})$ and the parametrization described by the condition

$$\langle \dot z, Y(z)\rangle = \int_0^1 \langle \dot z, Y(z)\rangle ds \quad \text{a.e.}$$

Then we can use the shortening flow for τ far from geodesics and, thanks to Proposition 5.7, Remark 5.8, and Proposition 5.9, we can use the classical Morse theory (see, e.g., Refs. 33 and 34) to describe the topology nearby a geodesic. In this way we obtain

$$\sum_{w \in \mathcal{G}_{p,\gamma}(\Lambda)} \lambda^{m(w,\tau)} = \mathcal{P}(\mathcal{L}^{+,2}_{p,\gamma}(\Lambda))(\kappa) + (1+\kappa)S(\kappa),$$

where S is a formal series with coefficients in $\mathbb{N}\cup\{+\infty\}$.

Since $\mathcal{B}^+_{p,\gamma}(\Lambda)$ is homotopically equivalent to $\mathcal{L}^{+,2}_{p,\gamma}(\Lambda)$ (cf. Proposition 4.4), applying Theorem 5.13 gives the proof of (2.6). □

Proof of Theorem 2.9: Assume that $\mathcal{B}^+_{p,\gamma}(\Lambda)$ is contractible. Then the Poincaré polynomial of $\mathcal{B}^+_{p,\gamma}(\Lambda)$ with respect to any field $\mathbb{K}$ is given by

$$\mathcal{P}(\mathcal{B}^+_{p,\gamma}(\Lambda),\mathbb{K})(\kappa)=1.$$

Let $\mathcal{G}^+_{p,\gamma}(\Lambda)$ be the set of future pointing lightlike geodesics joining p with γ. Formula (2.6) gives

$$\operatorname{card}\mathcal{G}^+_{p,\gamma}(\Lambda)=1+2S(1).$$

Then $\operatorname{card}\mathcal{G}^+_{p,\gamma}(\Lambda)$ is odd or infinite, according to whether $S(1)$ is finite or infinite. If $\mathcal{B}^+_{p,\gamma}(\Lambda)$ is not contractible, $\operatorname{cat}\mathcal{B}^+_{p,\gamma}(\Lambda)\geqslant 2$ so the conclusion follows by Remark 4.8. □

Proof of Theorem 2.11: If Λ is contractible, then $\Omega(\Lambda)$ is contractible. Then by assumption (L_3), $\mathcal{B}^+_{p,\gamma}(\Lambda)$ is contractible and the proof follows from the first part of Theorem 2.9. If Λ is not contractible by (L_3) and a result of Serre,[28] for a suitable field $\mathbb{K}$ the Poincaré polynomial $\mathcal{P}(\mathcal{B}^+_{p,\gamma}(\Lambda),\mathbb{K})$ has infinitely many coefficients different from zero and the conclusion follows from formula (2.6). □

APPENDIX A: ON THE TOPOLOGY OF $\mathcal{B}^+_{p,\gamma}(\Lambda)$

Under light-convexity and pseudocoercivity of τ we have seen in Sec. IV that $\mathcal{B}^+_{p,\gamma}(\Lambda)$ is homotopically equivalent to $\mathcal{L}^{+,r}_{p,\gamma}(\Lambda)$ (for any $r\in[1,+\infty]$).

In this Appendix we shall give a general condition assuring that $\mathcal{L}^{+,1}_{p,\gamma}(\Lambda)$ is homeomorphic to $\Omega^{1,1}_{p,\gamma}(\Lambda)$. Then, using a standard technique one sees that $\Omega^{1,1}_{p,\gamma}(\Lambda)$ is homotopically equivalent to the based loop space of Λ.

Proposition A1: Suppose that there exists a smooth hypersurface Λ_0 in Λ and a smooth timelike vector field Y in Λ such that

(1) *Y is complete in Λ.*
(2) *$\Lambda=\{\eta(\sigma,y): y\in\Lambda_0, \sigma\in\mathbb{R}, \dot\eta=Y(\eta), \eta(0)=y\}$.*
(3) *For any integral curve η of Y there exists a unique $s\in\mathbb{R}$ such that $\eta(s)\in\Lambda_0$.*
(4) *$\gamma:\mathbb{R}\to\Lambda$ is an integral curve of Y with $\gamma(0)\in\Lambda_0$.*
(5) *$p\in\Lambda_0$ and $p\neq\gamma(0)$.*
(6) *The Cauchy problem*

$$\begin{cases} \sigma' = \dfrac{-1}{\langle Y,Y\rangle}\left(\langle Y,\eta_y[\dot y]\rangle + \dfrac{1}{2}\sqrt{\langle Y,\eta_y[\dot y]\rangle^2 - \langle Y,Y\rangle\langle \eta_y[\dot y],\eta_y[\dot y]\rangle}\right), \\ \sigma(0)=0 \end{cases} \tag{A1}$$

can be solved in the interval $[0,1]$ for any $y\in H^{1,1}([0,1],\Lambda)$ such that $y(0)=p$ and $y(1)=\gamma(0)$.

Then $\mathcal{L}^{+,1}_{p,\gamma}(\Lambda)$ *is homeomorphic to* $\Omega^{1,1}_{p,\gamma}(\Lambda)$.

[Here $Y=Y(\eta(\sigma,y))$ and η_y denotes the derivative of η with respect to the second variable].

Proof: Take $z(s)=\eta(\sigma(s),y(s))$. Suppose $y\in H^{1,1}([0,1],\Lambda)$, $y(0)=p$ and $y(1)=\gamma(0)$. If σ satisfies (6) a straightforward computation shows that the curve $z(s)$ is in $\mathcal{L}^{+,1}_{p,\gamma}(\Lambda)$. Conversely $z\in\mathcal{L}^{+,1}_{p,\gamma}(\Lambda)$ can be projected on Λ_0 using the integral curve of Y [cf. assumption (3)]. Since (A.1) has a unique solution we are done. □

APPENDIX B: MORSE RELATIONS ON THE SPACE OF THE PIECEWISE LIGHTLIKE GEODESICS

In this Appendix we show by a simple example that we cannot write Morse relations using the topology of the piecewise (non-null) lightlike geodesics (endowed with the topology of the uniform convergence). This space, as in Sec. II, will be denoted by $\hat{\mathcal{B}}^{+}_{p,\gamma}(\Lambda)$.

On the space $\mathbb{R}^2\times\mathbb{R}$ we consider the flat Minkowski metric

$$ds^2 = dx_1^2 + dx_2^2 - dt^2.$$

Take $p=(y_0,0)$ and $\gamma(s)=(y_1,s)$. It is immediate to verify that $\hat{\mathcal{B}}^{+}_{p,\gamma}(\Lambda)$ is homeomorphic to the space $\mathcal{C}_{y_0,y_1}$ of the piecewise nonzero geodesics in $\mathbb{R}^2$ (with respect to the Euclidean metric) joining y_0 with y_1 endowed with the uniform topology. Considering the positions on the unit circle assumed by the unit speed of any broken geodesic it is not difficult to show that $\mathcal{C}_{y_0,y_1}$ has infinitely many connect components. Then, if Morse relations hold, one should obtain the existence of infinitely many geodesics joining p and γ and this is clearly false.

Analogously one sees that in the $(2+1)$-dimensional Minkowski space–time the infinite dimensional space where the relativistic Fermat principle is proved has infinitely many connect components. Then also in this case it is not possible to write the Morse relations.

Scaling behavior in the Einstein–Yang–Mills monopoles and dyons

Yutaka Hosotani[a)]

(Received 20 July 2001; accepted for publication 9 October 2001)

Scaling behavior in the moduli space of monopole and dyon solutions in the Einstein–Yang–Mills theory in the asymptotically anti-de Sitter space is derived. The mass of monopoles and dyons scales with respect to their magnetic and electric charges, independent of the values of the cosmological constant and gauge coupling constant. The stable monopole and dyon solutions are approximated by solutions in the fixed anti-de Sitter spacetime. Unstable solutions can be viewed as the Bartnik–McKinnon solutions dressed with monopole and dyon solutions in the fixed anti-de Sitter space. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421637]

I. INTRODUCTION

It has been shown that there exist a continuum of stable and unstable monopole and dyon solutions in the Einstein–Yang–Mills theory in the asymptotically anti-de Sitter (AdS) space.[1,2] They generalize a discrete family of unstable particlelike solutions in the asymptotically Minkowski or de Sitter space.[3] Similarly, black hole solutions exist with discrete values of magnetic charges in the asymptotically flat or de Sitter space,[4,5] and with continuous values of non-Abelian electric and magnetic charges in the asymptotically AdS space.[6,2,7,8]

Monopole and dyon solutions are characterized by their mass and non-Abelian magnetic/electric charges. The spectrum defines the moduli space of the solutions, which varies with the cosmological constant (Λ) and the gauge and gravitational coupling constants (e and G). The spectrum consists of infinitely many discrete points for $\Lambda \geqslant 0$, whereas it has a finite number of continuous branches for $\Lambda < 0$. When the parameter $\Lambda < 0$ approaches zero, an already-existing branch of monopole and dyon solutions collapses to a single point in the moduli space. At the same time new branches of solutions emerge. A fractal structure in the moduli space has been observed.[2,9]

In this paper we derive a scaling law for the mass spectrum of the solutions with respect to their magnetic and electric charges (Q_M and Q_E), the cosmological constant $\Lambda(<0)$, and the ratio of the gravitational constant to the gauge coupling constant $v \equiv 4\pi G/e^2$. Some of the results in Ref. 2 indicate that the mass of monopoles and dyons is expressed in terms of a universal function $f(Q_M, Q_E)$. We shall show that this follows from the factorization property of the solutions and that $f(Q_M, Q_E)$ is determined by the monopole and dyon solutions in the fixed AdS background metric.

AdS spacetime has many special properties. In some models it accommodates the holographic principle; the information on the boundary of the space determines physics in the bulk.[10] We shall see a trace of this property in the classical Einstein–Yang–Mills theory. The existence of stable monopole and dyon solutions in the asymptotically AdS space seems tightly connected to boundary data on non-Abelian charges, though a more thorough investigation is necessary.

II. MONOPOLES AND DYONS

There exist static, spherically symmetric monopole and dyon solutions in the Einstein–Yang–Mills theory. The action of the system is

a)Electronic mail: hosotani@phys.sci.osaka-u.ac.jp

$$S=\int d^4x\sqrt{-g}\left[\frac{1}{16\pi G}(R-2\Lambda)-\frac{1}{4}F^{a\mu\nu}F^{a}{}_{\mu\nu}\right]. \tag{1}$$

The Einstein and Yang–Mills equations are given by

$$\begin{aligned} &R^{\mu\nu}-\tfrac{1}{2}g^{\mu\nu}(R-2\Lambda)=8\pi GT^{\mu\nu},\\ &F^{\mu\nu}{}_{;\mu}+e[A_\mu,F^{\mu\nu}]=0. \end{aligned} \tag{2}$$

The metric of spacetime is given by

$$\begin{aligned} &ds^2=-\frac{H}{p^2}dt^2+\frac{dr^2}{H}+r^2(d\theta^2+\sin^2\theta\, d\phi^2),\\ &H=1-\frac{2m}{r}-\frac{\Lambda}{3}r^2, \end{aligned} \tag{3}$$

where H, p, and m depend on r only. $m(r)/G$ represents a total mass contained inside r in the $c=1$ unit. (Numerical values below are given in the $c=\hbar=G=1$ unit.) The $SU(2)$ Yang–Mills fields take

$$A^{(0)}=\frac{\tau^j}{2e}\left\{u(r)\frac{x_j}{r}dt-\epsilon_{jkl}\frac{1-w(r)}{r^2}x_k\,dx_l\right\}, \tag{4}$$

in the Cartesian coordinates ($x_1^2+x_2^2+x_3^2=r^2$). The gauge coupling constant is denoted as e. With these ansatz (3) and (4) the Einstein and Yang–Mills equations (2) reduce to

$$\left(\frac{H}{p}w'\right)'=-\frac{p}{H}u^2w-\frac{w}{p}\frac{(1-w^2)}{r^2}, \tag{5}$$

$$(r^2pu')'=\frac{2p}{H}w^2u, \tag{6}$$

$$m'=v\left[H(w')^2+\frac{(1-w^2)^2}{2r^2}+\frac{1}{2}r^2p^2(u')^2+\frac{u^2w^2p^2}{H}\right], \tag{7}$$

$$p'=-\frac{2v}{r}p\left[(w')^2+\frac{u^2w^2p^2}{H^2}\right], \tag{8}$$

with the boundary conditions $u=m=0$ and $w=p=1$ at the origin. The set of the equations contains two parameters: the cosmological constant Λ and the ratio of the gravitational constant to the gauge coupling constant $v=4\pi G/e^2$.

There are soliton-type solutions with finite masses. There are infinitely many conserved, gauge-covariant charges. In the spherically symmetric case the nonvanishing charges of importance are[1,2]

$$\begin{pmatrix}Q_E\\ Q_M\end{pmatrix}=\frac{e}{4\pi}\int dS_k\sqrt{-g}\,\mathrm{Tr}\begin{pmatrix}F^{k0}\\ \tilde{F}^{k0}\end{pmatrix}\frac{x^j\tau^j}{r}=\begin{pmatrix}-u_1p_\infty\\ 1-w_\infty^2\end{pmatrix}, \tag{9}$$

where u_1, p_∞, and w_∞ are defined by the asymptotic expansion $u\sim u_\infty+(u_1/r)+\ldots$, etc. Each solution is specified by its mass (multiplied by G), $M=m(\infty)$, non-Abelian electric and magnetic charges, Q_E and Q_M, and the number, n, of the nodes of $w(r)$. For $\Lambda\geqslant 0$ the spectrum of the solutions is discrete, $u(r)=0$ ($Q_E=0$), $n=1,2,3,\ldots$, and all solutions are unstable. For $\Lambda<0$ the

spectrum is completely different. It is continuous. For each $n(=0,1,2,...)$ there are a family of solutions with continuous values of Q_E and Q_M.[1,2] In particular, the nodeless solutions ($n=0$) are stable. In the moduli space of the solutions, M of a particular point (solution) is a function of Λ, v, n, Q_E, and Q_M. M, Λ, and v have dimensions of (length), (length)$^{-2}$, and (length)^2, respectively, whereas n, Q_E, and Q_M are dimensionless. We show that M is expressed in terms of a universal function of Q_E and Q_M up to an overall factor.

III. SOLUTIONS IN THE FIXED AdS BACKGROUND METRIC

To understand why stable solutions exist only in the asymptotically AdS space ($\Lambda<0$), we consider soliton solutions in the fixed AdS background metric, setting $p=1$ and $H=1-\Lambda r^2/3$ in Eqs. (5) and (6) and on the rhs of Eq. (7). Introduce $x=(|\Lambda|/3)^{1/2}r$ and $\hat{u}=(3/|\Lambda|)^{1/2}u$. Then Eqs. (5), (6), and (7) become

$$\frac{d}{dx}\left\{(1+x^2)\frac{dw}{dx}\right\}=-\frac{w(1-w^2)}{x^2}-\frac{\hat{u}^2 w}{1+x^2},$$
$$\frac{d}{dx}\left\{x^2\frac{d\hat{u}}{dx}\right\}=\frac{2w^2\hat{u}}{1+x^2}, \tag{10}$$

and

$$\frac{dm}{dx}=v\sqrt{\frac{|\Lambda|}{3}}\left\{(1+x^2)\left(\frac{dw}{dx}\right)^2+\frac{(1-w^2)^2}{2x^2}+\frac{x^2}{2}\left(\frac{d\hat{u}}{dx}\right)^2+\frac{\hat{u}^2w^2}{1+x^2}\right\}. \tag{11}$$

The equations for $\hat{u}(x)$ and $w(x)$ do not involve either v or Λ. The charges of the solutions are

$$Q_M=1-w_\infty^2, \quad Q_E=x^2\left.\frac{d\hat{u}}{dx}\right|_{x=\infty}. \tag{12}$$

Hence a family of the solutions in the fixed AdS background metric satisfy

$$w(r;\Lambda,w_\infty,Q_E)^{\mathrm{AdS}}=\tilde{w}^{\mathrm{AdS}}(x;w_\infty,Q_E),$$
$$u(r;\Lambda,w_\infty;Q_E)^{\mathrm{AdS}}=\sqrt{\frac{|\Lambda|}{3}}\tilde{u}^{\mathrm{AdS}}(x;w_\infty,Q_E). \tag{13}$$

Here $\{\tilde{w}^{\mathrm{AdS}}(r),\tilde{u}^{\mathrm{AdS}}(r)\}$ represents a solution for $\Lambda=-3$. Further dm/dx is expressed in terms of $\hat{u}$ and w with an overall factor $v(|\Lambda|/3)^{1/2}$, which implies that

$$m(r;\Lambda,v,w_\infty,Q_E)^{\mathrm{AdS}}=v\sqrt{\frac{|\Lambda|}{3}}\tilde{m}^{\mathrm{AdS}}(x;w_\infty,Q_E),$$
$$M^{\mathrm{AdS}}=m^{\mathrm{AdS}}|_{r=\infty}=v\sqrt{|\Lambda|}f(Q_M,Q_E), \tag{14}$$

where $\tilde{m}^{\mathrm{AdS}}(r)$ is the mass function for $v=1$ and $\Lambda=-3$. $f(Q_M,Q_E)$ defines a universal scaling function, as we shall see below. Note that f is a double-valued function of Q_M as $Q_M=1-w_\infty^2$.

The size of the solutions also scales. One definition of the size, l, of a solution is given in terms of $m(r)$ by $m(l)=0.5\cdot m(\infty)$, where we have arbitrarily taken a size factor 0.5. It immediately follows that

$$l^{\mathrm{AdS}}=\frac{1}{\sqrt{|\Lambda|}}h(Q_M,Q_E). \tag{15}$$

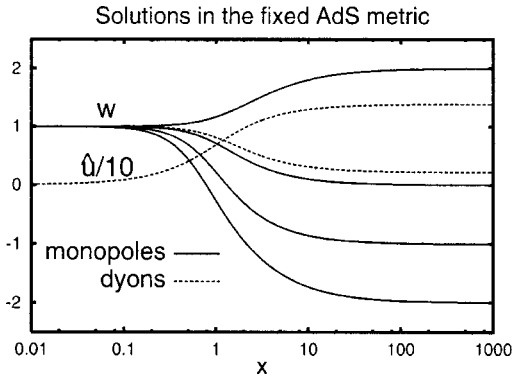

FIG. 1. $w(x)$ and $\hat{u}(x)$ of typical monopole and dyon solutions in the fixed AdS metric. The particular dyon solution displayed in the figure has $(Q_M, Q_E) = (0.954, 0.527)$.

Typical solutions are depicted in Fig. 1. Both $w(x)$ and $\hat{u}(x)$ monotonically decrease or increase. The solutions have, at most, one node in $w(r)$. Most of the energy of each solution is localized in $x < 10$.

There is a special solution,[11]

$$\hat{u} = 0, \quad w = \frac{1}{\sqrt{1+x^2}}, \tag{16}$$

for which $Q_E = 0$, $Q_M = 1$, and $M = (\sqrt{3}\pi/8)v|\Lambda|^{1/2}$. $Q_M = 1$ corresponds to the same quantized magnetic charge as for the 't Hooft and Polyakov monopole.

Further, $w^{\mathrm{AdS}} \sim 1$ and $m^{\mathrm{AdS}} \sim 0$ for $x < 0.1$. It is also numerically confirmed that

$$\mathrm{Max}_r \frac{2m^{\mathrm{AdS}}}{r} \cdot \frac{1}{1-(\Lambda r^2/3)} \sim \begin{cases} 0.03(v|\Lambda|)^{1/2} M^{1/2} |\Lambda|^{1/4}, & \text{for } w_\infty > 1, \\ 0.1 M |\Lambda|^{1/2}, & \text{for } w_\infty < 1, \end{cases} \tag{17}$$

for monopole solutions. As far as $v|\Lambda|$ and $M|\Lambda|^{1/2}$ are small enough, corrections to the metric may be ignored, and the solution in the fixed AdS background metric gives a good approximation to a solution in the EYM theory. [$p(r) \sim 1$ for those solutions.]

IV. FACTORIZATION

Let us turn to the EYM solutions in the $\Lambda = 0$ case. Set $u = 0$. Expressed in terms of $y = r/\sqrt{v}$, $H = 1 - (2\overline{m}/y)$, and $\overline{m} = m/\sqrt{v}$, Eqs. (5), (7), and (8) contain no parameter;

$$\begin{aligned} \frac{d}{dy}\left(\frac{H}{p}\frac{dw}{dy}\right) &= -\frac{w}{p}\frac{(1-w^2)}{y^2}, \\ \frac{d\overline{m}}{dy} &= \frac{(1-w^2)^2}{2y^2} + H\left(\frac{dw}{dy}\right)^2, \\ \frac{dp}{dy} &= -\frac{2p}{y}\left(\frac{dw}{dy}\right)^2. \end{aligned} \tag{18}$$

Solutions $\{w, p, \overline{m}\}$ are functions of y only. In each solution $w(r)$ crosses the axis n times ($n = 1,2,...$), and approaches $(-1)^n$ asymptotically. A physical mass is given by M/G, or $\overline{m}(\infty)\sqrt{v}/G = \overline{m}(\infty) M_{\mathrm{Pl}}/\sqrt{\alpha}$ where $\alpha = e^2/4\pi$ and $G = M_{\mathrm{Pl}}^{-2}$. The mass of the nth Bartnik–McKinnon solution is

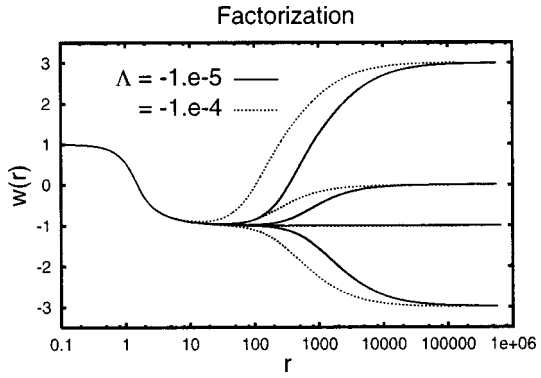

FIG. 2. Factorization property of the EYM monopole solutions. $\Lambda=-10^{-4}$ and -10^{-5} with $v=1$.

$$(\text{mass})_n^{\Lambda=0}(v)=\frac{M_{\text{Pl}}}{\sqrt{\alpha}}e_n \quad (n=1,2,...). \tag{19}$$

$e_n=M_n^{\Lambda=0}|_{v=1}$ is numerically given by $(e_1,e_2,\ldots)=(0.8286,0.9713,...)$. For $n\gg 1$, $e_n\sim 1-1.081e^{-\pi n/\sqrt{3}}$.[12] $w_n^{\Lambda=0}(r)$, $p_n^{\Lambda=0}(r)$, and $m_n^{\Lambda=0}(r)$ of the nth solution reach their asymptotic values at $r\sim a_n\sqrt{v}$, where $a_n\sim 10^n$.[5] The size of the Bartnik–McKinnon solutions is characterized by $l_n^{\Lambda=0}\sim a_n\sqrt{v}$.

Monopole and dyon solutions in $\Lambda<0$ are labeled by $(n,v,\Lambda,w_\infty,Q_E)$. The index n runs over 0, 1, 2,.... We would like to show that for $l_n^{\Lambda=0}\sqrt{|\Lambda|}\ll 1$, the Einstein–Yang–Mills monopole solutions are well approximated by

$$\begin{aligned} w_n&=w_n^{\Lambda=0}(r;v)w^{\text{AdS}}(r;\Lambda,(-1)^n w_\infty,Q_E),\\ u_n&=u^{\text{AdS}}(r;\Lambda,(-1)^n w_\infty,Q_E)/p_n^{A=0}(\infty;v),\\ p_n&=p_n^{\Lambda=0}(r;v),\\ m_n&=m_n^{\Lambda=0}(r;v)+m^{\text{AdS}}(r;\Lambda(-1)^n w_\infty;Q_E,v), \end{aligned} \tag{20}$$

where it has been understood that $w_0^{\Lambda=0}(r;v)=p_0^{\Lambda=0}(r;v)=1$ and $m_0^{\Lambda=0}(r;v)=0$. First, the solution in the fixed AdS metric approximately solves the EYM equations for $n=0$, as remarked above.

Secondly, for $n\geqslant 1$ we consider two regions; [I] $r<0.1(3/|\Lambda|)^{1/2}$ and [II] $r>a_n\sqrt{v}$. The two regions overlap with each other if $|\Lambda|v<0.03a_n^{-2}$. In the region I, $w^{\text{AdS}}\sim 1$, $m^{\text{AdS}}\sim 0$, and $-\Lambda r^2/3\ll 1$ so that the solution is well approximated by that in the $\Lambda=0$ case, provided u^2 is sufficiently small. In the region II, $w_n^{\Lambda=0}\sim(-1)^n$, $p_n^{\Lambda=0}\sim p_n^{\Lambda=0}|_{r=\infty}$, and $m_n^{\Lambda=0}\sim\sqrt{v}e_n$. In Eqs. (5)–(8) the value of constant p is irrelevant with pu substituted by u. H is approximated by $H=1-\Lambda r^2/3$ as $m_n^{\Lambda=0}/r<1/a_n\ll 1$. Hence the solutions are given by those in the fixed AdS background metric with w at $r=\infty$ given by $(-1)^n w_\infty$. The solutions in the asymptotically AdS space are obtained by dressing solutions in the fixed-AdS background metric to the Bartnik–McKinnon solutions in the asymptotically flat space, as expressed in (20).

The factorization property of the solutions, (20), is confirmed by numerical evaluation of the solutions. In Fig. 2, $w(r)$ of the monopole solutions at $\Lambda=-10^{-4}$, -10^{-5}, and $v=1$ with various $w_\infty=3$, 0, -1, -3 are depicted. For $r<10$ these solutions are well approximated by the first Bartnik–McKinnon solution at $\Lambda=0$. For larger r the solutions are essentially given by $-w^{\text{AdS}}(x;\Lambda=-1,-w_\infty)$.

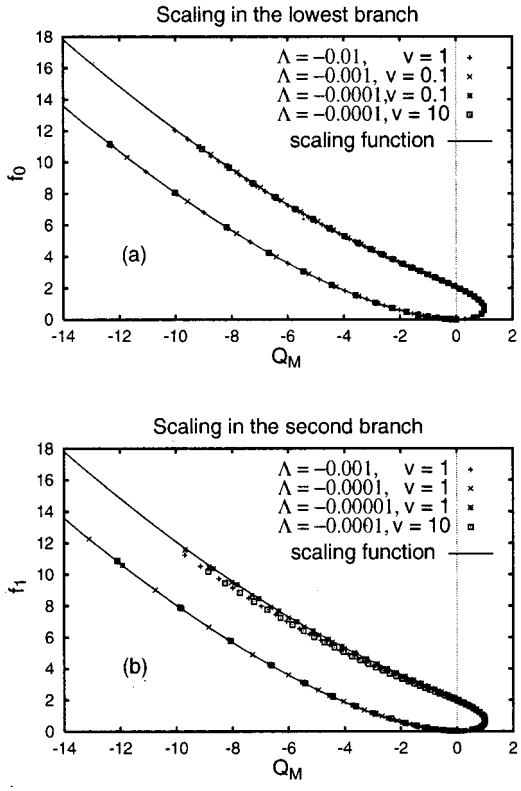

FIG. 3. Scaling (a) for $f_0 \equiv M_0(v,\Lambda,w_\infty,0)/(v|\Lambda|^{1/2})$, and (b) for $f_1 \equiv (M_1(v,\Lambda,w_\infty,0) - v^{1/2}e_1)/(v|\Lambda|^{1/2})$. The scaling function $f(Q_M,0)$ is also depicted.

V. SCALING

A scaling law follows from the factorization property. From (14) and (20),

$$\frac{M_n(v,\Lambda,w_\infty,Q_E) - \sqrt{v}\,e_n}{v\sqrt{|\Lambda|}} = f(Q_M,Q_E), \tag{21}$$

the rhs of which is independent of Λ and v, and also of n. The scaling law is valid for $|\Lambda|v < 0.03a_n^{-2}$ and small $|Q_E|$.

In Fig. 3 numerical data of monopole solutions for the lowest $(n=0)$ and second $(n=1)$ branches is depicted. It is seen that all data for $v|\Lambda| < 0.01$ falls on the universal function $f(Q_M,0)$ for $n=0$, and for $v|\Lambda| < 0.0001$ for $n=1$. It follows from (21) that the mass is given by

$$(\text{mass})_n(v,\Lambda,w_\infty,Q_E) = \frac{e_n}{\sqrt{a}} M_{\text{Pl}} + \frac{\sqrt{|\Lambda|}}{\alpha} f(Q_M,Q_E). \tag{22}$$

In the lowest branch the magnitude of the mass is determined by $\sqrt{|\Lambda|}/\alpha$, whereas in the higher branches it is given by $M_{\text{Pl}}/\sqrt{\alpha}$.

The size of a monopole or dyon is essentially the same as that of the solution in the fixed AdS background metric, as the dressed fields cover the inside Bartnik–McKinnon core. $h(Q_M,0)$ in (15) is depicted in Fig. 4.

As $\Lambda(<0)$ approaches 0, the branch in the $Q_M - M$ plane collapses to a flat line $M = \sqrt{v}\,e_n$. The size of the solution grows as $|\Lambda|^{-1/2}$ so that Bartnik–McKinnon solutions with higher n can be accommodated inside the AdS solutions, allowing more solutions in higher branches. This explains the phenomenon observed in Ref. 2. In the $\Lambda = 0$ limit only solutions with $Q_M = 0$ survive.

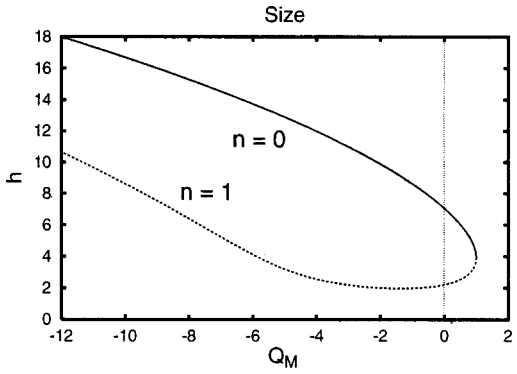

FIG. 4. Scaling function, $h(Q_M,0)$, for the size in (9). The portion with $n=0$ or $n=1$ corresponds to solutions with no node or one node in $w^{\mathrm{AdS}}(x)$, respectively.

VI. SUMMARY

In this paper we have examined monopole-dyon solutions in the Einstein–Yang–Mills theory in the asymptotically AdS space. The monopole and dyon solutions in the lowest branch $(n=0)$ are essentially the solutions in the fixed AdS background metric. The solutions in the higher branches $(n>0)$ are obtained by dressing monopole and dyon solutions in the fixed AdS background metric around the Bartnik–McKinnon solutions in the asymptotically flat space. As all Bartnik–McKinnon solutions are unstable, the monopole and dyon solutions in the higher branches are unstable, whereas the nodeless solutions are stable against small perturbations.

Because of the factorization property of the solutions there arises a scaling law in the mass of the solutions when regarded as a function of e, G, Λ, Q_M, and Q_E. Up to an overall factor it scales to a universal function $f(Q_M,Q_E)$ determined by the solutions in the fixed AdS metric. The factorization/dressing mechanism is expected to apply for black hole solutions as well.

In quantum theory Q_M and Q_E are expected to be quantized. Solutions with minimal $|Q_M|$ or $|Q_E|$ must be absolutely stable. The stable solutions discussed in the present paper are, in nature, nontopological solitons. They exist only with gravitational force. In this sense they may be called gravitational solitons.[13]

(Received 6 July 2001; accepted for publication 24 September 2001)

Formulas for the expansion of arbitrary invariant group functions in terms of the characters for the Sp($2N$), SO($2N+1$), and SO($2N$) groups are derived using a combinatorial method. The method is similar to one used by Balantekin to expand group functions over the characters of the U(N) group. All three expansions have been checked for all N by using them to calculate the known expansions of the generating function of the homogeneous symmetric functions. An expansion of the exponential of the traces of group elements, appearing in the finite-volume gauge field partition functions, is worked out for the orthogonal and symplectic groups. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1418014]

I. INTRODUCTION

The expansion of invariant functions of a group into its characters (traces of the representation matrices)[1] is very useful in a number of physical situations. In U(N) lattice gauge theories and in the lattice expansion of the nonlinear U(N)×U(N) sigma model calculation of certain U(N) group integrals are needed.[2–6] If the integrands can be expanded in terms of the U(N) characters, then such integrals can easily be calculated.[3,7,8] Similar U(N) integrals also arise in the statistical theory of nuclear reactions.[9] In 1980 Itzykson and Zuber calculated a particular unitary group integral[10] which turned out to be a special case of a more general formula by Harish-Chandra.[11] The Itzykson–Zuber integral and its generalizations[12–15] are also easily dealt with using character expansions.[1]

The character expansion of an invariant function of group elements is given by

$$f(\det U, TrU, \ldots) = \sum_r a_r \chi_r(U), \tag{1.1}$$

where $\chi_r(U)$ is the character of the representation r. Since group characters form an orthogonal set[16] the coefficients can be obtained by explicitly integrating the product of this function with the characters over the group manifold:

$$a_r = \int dU \chi_r^*(U) f(\det U, TrU, \ldots). \tag{1.2}$$

(Note that a_0 is the integral of the function itself over the group manifold). It is rather difficult to obtain complicated character expansions by explicit integration. In 1984 Balantekin[8] developed a combinatorial method that enabled one to solve for the coefficients in some expansions over the

c)Electronic mail: pcassak@nucth.physics.wisc.edu

U(N) group characters that was quite simple in comparison to performing group integrals. Needing a more general version, the result was recently extended in its range of applicability.[1]

In a parallel development it was shown that the spectral density of the Dirac operator for a gauge theory near its zero eigenvalues should only depend on the symmetries in question.[17–19] Although the original work[17–19] used a Gaussian random matrix model, the results from the random matrix theory can be proven to be universal.[20–24] This implies that the spectral density of the Dirac operator near the origin can be extracted from random matrix theories which provide a description of common aspects of various quantum phenomena (for a review see Ref. 25). Hence to study the low-energy limit of, for example, quantum chromodynamics (QCD), one needs to choose a random matrix theory with the global symmetries of the QCD partition function. The partition functions calculated from the effective field theory and random matrix theory agree.[17,26,27] These random matrix theories are characterized by the Dyson index β which is the number of independent variables per matrix element.[19,28] For fermions in the fundamental representation $\beta=1$ for $N_c=2$ and $\beta=2$ for $N_c\geqslant 2$ where N_c is the number of colors. For fermions in the adjoint representation and $N_c\geqslant 2$ we have $\beta=4$. For $\beta=2$ the low-energy (finite-volume) QCD partition function is the same as the one-link integral of two-dimensional lattice QCD[5,29] and is calculated using the U(N) character expansion[1] and other methods.[30,14,31] For $\beta=4$ the zero momentum Goldstone modes belong to the coset space $\mathrm{SU}(N_f)/\mathrm{SO}(N_f)$[30,15] where N_f is the number of fermion flavors. Hence the finite-volume partition function is a group integral where the argument is the exponential of an SO(N_f) group element. Similarly in the $\beta=1$ case the coset space of the Goldstone modes is $\mathrm{SU}(2N_f)/\mathrm{Sp}(2N_f)$.[30,15] Massive partition functions of random matrix ensembles with $\beta=1$ and 4 were considered in Refs. 24 and 32. To calculate these partition functions it is very useful to have expressions for character expansions over the orthogonal and symplectic groups. Explicit expressions for these partition functions, for example, may help in finding solutions of Virasoro constraints which were found so far only for the $\beta=2$ case. (For the application of Virasoro constraints on the effective finite volume partition function, see, for example, Refs. 33–35).

The present work is an extension of Balantekin's method of finding the expansion coefficients for expansions over the characters for the symplectic group Sp($2N$), the odd dimensional special orthogonal group SO($2N+1$), and the even dimensional special orthogonal group SO($2N$). Some background material will be treated in Sec. II, including general information about the characters of the groups in question. The procedures for developing the expansions for the different groups are similar, so Sec. III will treat the general idea. The specific expressions will be derived in Sec. IV for Sp($2N$), in Sec. V for SO($2N+1$), and in Sec. VI for SO($2N$). Finally, some examples of expansions will be given for each of the groups in Sec. VII.

For quick reference, the expansions and the most general expressions for their coefficients for Sp($2N$), SO($2N+1$), and SO($2N$) are found in Eqs. (4.10) and (4.11), (5.8) and (5.9), and (6.10) and (6.12), respectively.

II. BACKGROUND AND FORMULAS FOR CHARACTERS

In order to calculate expressions for the character expansions, we will need expressions for the characters. These characters have been furnished by Weyl.[36] For reference, the Weyl formulas for the U(N), Sp($2N$), SO($2N+1,\mathfrak{R}$), and SO($2N,\mathfrak{R}$) group characters are reprinted below. [We have included the formula for the U(N) group characters for completeness even though we will not need them in the present work.]

In the following, $\det[\mathcal{A}_{ij}]$ refers to the determinant of the $N\times N$ matrix $\mathcal{A}$ whose entry in the ith row and jth column is $\mathcal{A}_{ij}$. Furthermore, we will denote a matrix in the unitary group as U, the symplectic group as P, and the orthogonal group as R, and the eigenvalues of any of these matrices are labeled by t_i. For the U(N) case, there are N eigenvalues that are all phases. For the Sp($2N$) and SO($2N$) cases, there are $2N$ eigenvalues, but they come in pairs of a phase and its reciprocal. Thus, a complete list of eigenvalues would be $t_1,t_2,\ldots,t_N,t_1^{-1},t_2^{-1},\ldots,t_N^{-1}$. For the SO($2N+1$) case, it is the same as the even dimensional cases with an additional eigenvalue of

$t=1$. The determinants given below, then, are determinants of $N\times N$ matrices which contain functions of only the individual eigenvalues, not their reciprocals. Finally, the character is a function of the representation, which is labeled by a partition $(n_1,n_2,\ldots,n_N)$ where the nonnegative integers n_i satisfy $n_1\geqslant n_2\geqslant\cdots\geqslant n_N$. Each representation corresponds to a permissible Young tableau.

The expressions for the simple characters of the U(N), Sp($2N$), and SO($2N+1$) groups are

$$\chi_{(n_1,n_2,\ldots,n_N)}(U)=\frac{\det[t_i^{n_j+N-j}]}{\det[t_i^{N-j}]}, \tag{2.1}$$

$$\chi_{(n_1,n_2,\ldots,n_N)}(P)=\frac{\det[t_i^{n_j+N-j+1}-t_i^{-(n_j+N-j+1)}]}{\det[t_i^{N+1-j}-t_i^{-(N+1-j)}]}, \tag{2.2}$$

and

$$\chi_{(n_1,n_2,\ldots,n_N)}(R)=\frac{\det[t_i^{n_j+N-j+1/2}-t_i^{-(n_j+N-j+1/2)}]}{\det[t_i^{N+1/2-j}-t_i^{-(N+1/2-j)}]}, \tag{2.3}$$

respectively.

The SO($2N$) case requires more attention. We define

$$\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R)=\frac{\det[t_i^{n_j+N-j}+t_i^{-(n_j+N-j)}-\delta_{jN}\delta_{n_N0}]}{\det[t_i^{N-j}+t_i^{-(N-j)}-\delta_{jN}]} \tag{2.4}$$

and

$$\mathcal{S}_{(n_1,n_2,\ldots,n_N)}(R)=\frac{\det[t_i^{n_j+N-j}-t_i^{-(n_j+N-j)}]}{\det[t_i^{N-j}+t_i^{-(N-j)}-\delta_{jN}]}. \tag{2.5}$$

(The notation in the previous two equations is nonstandard, but they give the proper elements as stated in Ref. 16 in a more modern and manipulable form.) $\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R)$ alone is the simple character of SO($2N$) if and only if $n_N=0$. If $n_N\neq 0$, then $\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R)$ is a double character. For this case, the simple characters are given by $\frac{1}{2}(\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R)\pm\mathcal{S}_{(n_1,n_2,\ldots,n_N)}(R))$. In the present work, only the expression for $\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R)$ given in Eq. (2.4) will be needed. This statement will be justified in Sec. VI where SO($2N$) is treated.

One last property of these expressions that will be useful for checking the reliability of the expansions derived in this article is the value of the characters for representations corresponding to Young tableaux of one row ($n_1=n$, all others are 0) and one column ($n_n=1$ for all n up to some value, all others are 0). The characters for representations with one row, labeled (n), and one column, labeled (1^n), are

$$\chi_{(n)}(U)=h_n(t_i),\quad \chi_{(1^n)}(U)=a_n(t_i), \tag{2.6}$$

$$\chi_{(n)}(P)=h_n(t_i,t_i^{-1}),\quad \chi_{(1^n)}(P)=a_n(t_i,t_i^{-1})-a_{n-2}(t_i,t_i^{-1}), \tag{2.7}$$

$$\chi_{(n)}(R)=h_n(t_i,t_i^{-1},1)-h_{n-2}(t_i,t_i^{-1},1),\quad \chi_{(1^n)}(R)=a_n(t_i,t_i^{-1},1), \tag{2.8}$$

$$\mathcal{C}_{(n)}(R)=h_n(t_i,t_i^{-1})-h_{n-2}(t_i,t_i^{-1}),\quad \mathcal{C}_{(1^n)}(R)=a_n(t_i,t_i^{-1}), \tag{2.9}$$

for the U(N), Sp($2N$), SO($2N+1$), and SO($2N$) groups, respectively. The functions $h_n(t_i)$ are the homogeneous symmetric functions of order n, and the functions $a_n(t_i)$ are the elementary symmetric functions of order n. Further discussion is given in Ref. 1.

III. GENERAL PROPERTIES OF THE DERIVATION

We are now ready to derive the form for the expansions of group functions over the characters of the various groups mentioned in the previous section. As with any expansion, the crux of this issue is being able to determine and calculate the coefficients in the expansion. The goal of the next four sections will be to find these coefficients.

The derivation is very similar to the one used by Balantekin[1] in finding the coefficients of the expansion over the unitary group characters. As the expressions for the group characters for $\mathrm{Sp}(2N)$, $\mathrm{SO}(2N+1)$, and $\mathrm{SO}(2N)$ are all similar, the derivations for all three will proceed in much the same manner. To make the general method more transparent, the common aspects of the derivation will be presented in this section without mention of the specific groups. The following three sections will be devoted to using the result of this section to derive expressions for the coefficients in the expansions over the characters in each group.

We begin by noting that each of the expressions for the characters given by Eqs. (2.2)–(2.4) are all ratios of determinants, so that we can write

$$\chi_{(n_1,n_2,\ldots,n_N)}(M)=\frac{\mathcal{N}}{\mathcal{D}}, \tag{3.1}$$

where M is a matrix element of the group in question and $\mathcal{N}$ and $\mathcal{D}$ refer to numerator and denominator. For any of these groups, the denominator $\mathcal{D}$ can be expressed generally as

$$\mathcal{D}=\det[t_i^{N-j+q}\pm t_i^{-(N-j+q)}-\delta_{q0}\delta_{jN}], \tag{3.2}$$

where q can take on the value 1 for the $\mathrm{Sp}(2N)$ group, $\frac{1}{2}$ for the $\mathrm{SO}(2N+1)$ group, and 0 for the $\mathrm{SO}(2N)$ group. In this form, we choose the appropriate value of q and the proper sign of the $\pm$ sign to specify which group we are discussing. Namely, we see that the minus sign will be used for $\mathrm{Sp}(2N)$ and $\mathrm{SO}(2N+1)$ whereas the plus sign will be used for $\mathrm{SO}(2N)$.

In following the derivation of the $\mathrm{U}(N)$ expansion given in Ref. 1, we define a ''generating function,'' $G(x,t)$, to be some function of a variable t and any necessary parameters x. Later, we will take t to be an eigenvalue of a group matrix. For now, we expand the generating function in a power series in the variable t around $t=0$. Thus,

$$G(x,t)=\sum_{n=-\infty}^{\infty}A_n(x)t^n. \tag{3.3}$$

We assume that the series expansion converges for $|t|=1$. However, there are no other restrictions on the coefficients, so that some of the $A_n(x)$ can be zero. For instance, if the expansion is a Taylor series, then $A_n\equiv 0$ for all $n<0$.

Now, we define a function $\mathcal{F}$ by

$$\mathcal{F}=\mathcal{D}\prod_{i=1}^{N}G(x,t_i)G(x,t_i^{-1}), \tag{3.4}$$

where $\mathcal{D}$ is given in Eq. (3.2). By using the definition of $G(x,t)$ from Eq. (3.3), $\mathcal{F}$ can be written as (suppressing the x dependence of A_n)

$$\mathcal{F}=\mathcal{D}\left[\sum_{n=-\infty}^{\infty}A_nt_1^n\right]\left[\sum_{n=-\infty}^{\infty}A_nt_1^{-n}\right]\left[\sum_{n=-\infty}^{\infty}A_nt_2^n\right]\left[\sum_{n=-\infty}^{\infty}A_nt_2^{-n}\right]\cdots\left[\sum_{n=-\infty}^{\infty}A_nt_N^n\right]\left[\sum_{n=-\infty}^{\infty}A_nt_N^{-n}\right], \tag{3.5}$$

or, by combining the product of sums over the same variable, it can be written as

$$\mathcal{F}=\mathcal{D}\left[\sum_{n=-\infty}^{\infty}\sum_{p=-\infty}^{\infty}A_nA_pt_1^{n-p}\right]\left[\sum_{n=-\infty}^{\infty}\sum_{p=-\infty}^{\infty}A_nA_pt_2^{n-p}\right]\cdots\left[\sum_{n=-\infty}^{\infty}\sum_{p=-\infty}^{\infty}A_nA_pt_N^{n-p}\right]. \quad (3.6)$$

To proceed, we use the expression for $\mathcal{D}$ in Eq. (3.2). This determinant can be laboriously expanded as an alternating sum of products of the elements [see Eq. (A3)]. Upon doing so, we can combine the factors of the variable t_i in the determinant with the factor in Eq. (3.6) of the same variable. However, before naively doing so, we notice that there is a symmetry in the exponents in the determinant. We also notice that the double summations of the t_i's are unaffected by interchange of the dummy indices n and p. So the symmetry of the exponents will be preserved if we use $n-p$ in the product of the first term, $p-n$ in the product of the second term, and split the delta term in half using $n-p$ in the first one and $p-n$ in the second one. Upon doing so, we find that the new expression is again a determinant. Rewriting this as a determinant, we obtain

$$\mathcal{F}=\det\left[\sum_{n=-\infty}^{\infty}\sum_{p=-\infty}^{\infty}A_nA_p\left(t_i^{N-j+q+n-p}\pm t_i^{-(N-j+q+n-p)}-\frac{1}{2}\delta_{q0}\delta_{jN}(t_i^{n-p}+t_i^{p-n})\right)\right]. \quad (3.7)$$

Now, we change variables, defining a new integer $r=N-j+n-p$. This gives

$$\mathcal{F}=\det\left[\sum_{p=-\infty}^{\infty}\sum_{r=-\infty}^{\infty}A_{r-N+j+p}A_p\left(t_i^{r+q}\pm t_i^{-(r+q)}-\frac{1}{2}\delta_{q0}\delta_{jN}(t_i^{r-N+j}+t_i^{N-j-r})\right)\right]. \quad (3.8)$$

The order of the summation for r and p is interchangeable. Also, the delta term chooses only $N=j$. Thus,

$$\mathcal{F}=\det\left[\sum_{r=-\infty}^{\infty}\sum_{p=-\infty}^{\infty}A_{r-N+j+p}A_p\left(t_i^{r+q}\pm t_i^{-(r+q)}-\frac{1}{2}\delta_{q0}\delta_{jN}(t_i^{r}+t_i^{-r})\right)\right]. \quad (3.9)$$

We notice that all of the dependence on the dummy variable p can be isolated by defining

$$c_{r,j}=\sum_{p=-\infty}^{\infty}A_{r-N+j+p}A_p\,. \quad (3.10)$$

Also, by combining the delta term with the other term [again remembering that it is only present for the SO($2N$) case in which $q=0$ and we use the $+$ sign], we can write our expression for $\mathcal{F}$ as

$$\mathcal{F}=\det\left[\sum_{r=-\infty}^{\infty}c_{r,j}(t_i^{r+q}\pm t_i^{-(r+q)})\left(1-\frac{1}{2}\delta_{q0}\delta_{jN}\right)\right]. \quad (3.11)$$

We have come to the point in the derivation where it will be necessary to specialize Eq. (3.11) for the three different types of groups by making appropriate choices for q and the $\pm$ sign. This will be taken up in the next three sections.

IV. THE EXPANSION OVER SP(2*N*) CHARACTERS

We begin with the Sp($2N$) case, as it is the simplest one. The starting point will be Eq. (3.11). For the Sp($2N$) case, $q=1$ and we choose the minus sign. Thus, we have

$$\mathcal{F}=\det\left[\sum_{r=-\infty}^{\infty}c_{r,j}(t_i^{r+1}-t_i^{-(r+1)})\right], \quad (4.1)$$

where $c_{r,j}$ is defined in Eq. (3.10). Before proceeding, it is beneficial to change dummy indices again by letting $r+1\rightarrow r$. This gives us

$$\mathcal{F}=\det\left[\sum_{r=-\infty}^{\infty} c'_{r,j}(t_i^r-t_i^{-r})\right], \tag{4.2}$$

where

$$c'_{r,j}=\sum_{p=-\infty}^{\infty} A_{r-N+j-1+p}A_p\,. \tag{4.3}$$

This sum over r from $-\infty$ to ∞ can be broken up into positive r, negative r, and $r=0$. The $r=0$ term vanishes because $t_i^0-t_i^0=0$. Then, changing the negative values to positive by replacing r with $-r$ and collecting terms, we get

$$\mathcal{F}=\det\left[\sum_{r=0}^{\infty} d_{r,j}(t_i^r-t_i^{-r})\right], \tag{4.4}$$

where

$$d_{r,j}=c'_{r,j}-c'_{-r,j}\,. \tag{4.5}$$

Equation (4.4) is very similar to an expression that is treated in Theorem 1.2.1 from Ref. 37. We will need a slightly more general form of this theorem, which we present in the Appendix. Using the result, Eq. (A8), we get

$$\mathcal{F}=\sum_{r_1>r_2>\cdots>r_N\geqslant 0}^{\infty} \det[d_{r_j,i}]\det[t_i^{r_j}-t_i^{-r_j}]. \tag{4.6}$$

Now, if, in the summation, $r_N=0$, then both determinants vanish, so we can restrict $r_N\geqslant 1$. Let us define

$$r_j=n_j+N-j+1. \tag{4.7}$$

Then, $r_j>r_{j+1}$ implies that $n_j\geqslant n_{j+1}$. Furthermore, since $r_N\geqslant 1$, then $n_N\geqslant 0$. Thus, we can write the summation as

$$\mathcal{F}=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty} \det[d_{n_j+N-j+1,i}]\det[t_i^{n_j+N-j+1}-t_i^{-(n_j+N-j+1)}]. \tag{4.8}$$

In the above expression, the second determinant is seen to be exactly the numerator in the Weyl formula for the characters of the symplectic group given in Eq. (2.2). We even have the appropriate restrictions on the values of the n_i that are necessary to make the equation valid. Thus, we can write the above expression as

$$\mathcal{F}=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty} \det[d_{n_j+N-j+1,i}]\mathcal{N}. \tag{4.9}$$

Now we recall our definition of $\mathcal{F}$ from Eq. (3.4). If we divide both sides by the denominator $\mathcal{D}$ and recall that our expression for the character of the Sp($2N$) group is $\chi_{(n_1,n_2,\ldots,n_N)}(P)=\mathcal{N}/\mathcal{D}$, then we obtain

$$\prod_{i=1}^{N} G(x,t_i)G(x,t_i^{-1})=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty} \det[d_{n_j+N-j+1,i}]\chi_{(n_1,n_2,\ldots,n_N)}(P). \tag{4.10}$$

This is our desired character expansion over the Sp($2N$) group! It is a sum over all irreducible representations of the symplectic group. Expressions for the coefficients are obtained using Eqs. (4.5) and (4.3). The result is

$$d_{n_j+N-j+1,i}=\sum_{p=-\infty}^{\infty} A_p(A_{n_j+i-j+p}-A_{-n_j-2N-2+i+j+p}). \tag{4.11}$$

In the special case in which the expansion of the generating function $G(x,t)$ is a Taylor series expansion with $A_p\equiv 0$ for all $p<0$, this simplifies slightly to

$$d_{n_j+N-j+1,i}=\sum_{p=0}^{\infty} A_p(A_{p+|n_j+i-j|}-A_{p+n_j+2N+2-i-j}). \tag{4.12}$$

We defer examples of the usage of this expansion until Sec. VII.

V. THE EXPANSION OVER SO($2N+1$) CHARACTERS

Once again, we start from Eq. (3.11). For SO($2N+1$), we have $q=\frac{1}{2}$ and we choose the minus sign. Then, we have

$$\mathcal{F}=\det\left[\sum_{r=-\infty}^{\infty} c_{r,j}(t_i^{r+1/2}-t_i^{-(r+1/2)})\right] \tag{5.1}$$

and $c_{r,j}$ is defined in Eq. (3.10).

This sum over r from $-\infty$ to ∞ can be broken up into ranges of $r\geqslant 0$ and $r<0$, which gives

$$\mathcal{F}=\det\left[\sum_{r=0}^{\infty} c_{r,j}(t_i^{r+1/2}-t_i^{-(r+1/2)})+\sum_{r=-\infty}^{-1} c_{r,j}(t_i^{r+1/2}-t_i^{-(r+1/2)})\right]. \tag{5.2}$$

Changing variables in the second summation using $r\to -(r+1)$ and collecting terms, we get

$$\mathcal{F}=\det\left[\sum_{r=0}^{\infty} d_{r,j}(t_i^{r+1/2}-t_i^{-(r+1/2)})\right], \tag{5.3}$$

where

$$d_{r,j}=c_{r,j}-c_{-r-1,j}\,. \tag{5.4}$$

Once again, we refer to Eq. (A8) in the Appendix to simplify Eq. (5.3) and we write

$$\mathcal{F}=\sum_{r_1>r_2>\cdots>r_N\geqslant 0}^{\infty} \det[d_{r_j,i}]\det[t_i^{r_j+1/2}-t_i^{-(r_j+1/2)}]. \tag{5.5}$$

If we define

$$r_j=n_j+N-j, \tag{5.6}$$

then the summation becomes

$$\mathcal{F}=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty} \det[d_{n_j+N-j,i}]\det[t_i^{n_j+N-j+1/2}-t_i^{-(n_j+N-j+1/2)}]. \tag{5.7}$$

The second determinant is simply the numerator of the Weyl formula for SO($2N+1$) as given in Eqs. (2.3), so using the definition of $\mathcal{F}$ from Eq. (3.4) and dividing by $\mathcal{D}$ gives

$$\prod_{i=1}^{N} G(x,t_i)G(x,t_i^{-1}) = \sum_{n_1 \geqslant n_2 \geqslant \cdots \geqslant n_N \geqslant 0}^{\infty} \det[d_{n_j+N-j,i}]\chi_{(n_1,n_2,\ldots,n_N)}(R). \tag{5.8}$$

This is the expansion for the SO($2N+1$) group, again a sum over all irreducible representations. Note, however, that this expression does not include the spinor representations of SO($2N+1$). The expression for the coefficient is found using Eqs. (5.4) and (3.10) with the result given by

$$d_{n_j+N-j,i} = \sum_{p=-\infty}^{\infty} A_p(A_{n_j+i-j+p} - A_{-n_j-2N-1+i+j+p}). \tag{5.9}$$

In the special case of a Taylor series with $A_p \equiv 0$ for all $p<0$, this simplifies to

$$d_{n_j+N-j,i} = \sum_{p=0}^{\infty} A_p(A_{p+|n_j+i-j|} - A_{p+n_j+2N+1-i-j}). \tag{5.10}$$

We conclude this section with a reminder that care must be taken in the usage of the above formulas for SO($2N+1$). One must remember that the number 1 is always an additional eigenvalue of the matrix R. Thus, in forming group functions, one must manually include a factor of $G(x,1)$ on both sides of the equation in order to have a function on the left hand side that treats all eigenvalues equally. This tricky point will be illustrated by example in Sec. VII, after we treat the SO($2N$) case in the next section.

VI. THE EXPANSION OVER SO(2*N*) CHARACTERS

One more time, we start from Eq. (3.11). Recall that for SO($2N$), we have $q=0$ and we use the + sign. Thus, we have

$$\mathcal{F} = \det\left[\sum_{r=-\infty}^{\infty} c_{r,j}(t_i^r + t_i^{-r})\left(1 - \frac{1}{2}\delta_{jN}\right)\right], \tag{6.1}$$

where $c_{r,j}$ is defined in Eq. (3.10). The delta function term serves to divide each entry in the last column by a factor of 2. When taking the determinant, a factor of 2 comes out and divides the equation. Thus,

$$\mathcal{F} = \frac{1}{2}\det\left[\sum_{r=-\infty}^{\infty} c_{r,j}(t_i^r + t_i^{-r})\right]. \tag{6.2}$$

This sum over r from $-\infty$ to ∞ can be broken up into positive r, negative r, and $r=0$. Then changing the negative values to positive by replacing r with $-r$ and collecting terms, we get

$$\mathcal{F} = \frac{1}{2}\det\left[\sum_{r=0}^{\infty} d_{r,j}\left(1 - \frac{1}{2}\delta_{r0}\right)(t_i^r + t_i^{-r})\right], \tag{6.3}$$

where

$$d_{r,j} = c_{r,j} + c_{-r,j} \tag{6.4}$$

and the δ_{r0} is inserted to ensure the correct coefficient for $r=0$. Once again, we can use Eq. (A8) from the Appendix to simplify Eq. (6.3) which gives

$$\mathcal{F} = \frac{1}{2}\sum_{r_1 > r_2 > \cdots > r_N \geqslant 0}^{\infty} \det[d_{r_j,i}]\det\left[(t_i^{r_j} + t_i^{-r_j})\left(1 - \frac{1}{2}\delta_{r_j 0}\right)\right]. \tag{6.5}$$

Let us define

$$r_j = n_j + N - j. \tag{6.6}$$

Then the summation becomes

$$\mathcal{F} = \frac{1}{2} \sum_{n_1 \geqslant n_2 \geqslant \cdots \geqslant n_N \geqslant 0}^{\infty} \det[d_{n_j+N-j,i}] \det\left[(t_i^{n_j+N-j} + t_i^{-(n_j+N-j)}) \left(1 - \frac{1}{2} \delta_{n_j+N-j,0} \right) \right]. \tag{6.7}$$

Focusing on the second determinant on the right hand side, we can multiply the two binomials to give

$$\det\left[t_i^{n_j+N-j} + t_i^{-(n_j+N-j)} - \frac{1}{2} \delta_{n_j+N-j,0} (t_i^{n_j+N-j} + t_i^{-(n_j+N-j)}) \right]. \tag{6.8}$$

Now, the delta function is only nonzero when $n_j + N - j = 0$, which can only occur for $j = N$ and $n_N = 0$ because n_j is non-negative. In this event, the exponents vanish and the sum in parentheses becomes 2, which cancels the $\frac{1}{2}$. Thus, we can write Eq. (6.7) as

$$\mathcal{F} = \frac{1}{2} \sum_{n_1 \geqslant n_2 \geqslant \cdots \geqslant n_N \geqslant 0}^{\infty} \det[d_{n_j+N-j,i}] \det[t_i^{n_j+N-j} + t_i^{-(n_j+N-j)} - \delta_{jN} \delta_{n_N 0}]. \tag{6.9}$$

We see that the second determinant is precisely the appropriate numerator in the Weyl formula for the quantity $\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R)$ given in Eq. (2.4). By recalling the definition of $\mathcal{F}$ from Eq. (3.4) and dividing by $\mathcal{D}$, we get

$$\prod_{i=1}^{N} G(x,t_i) G(x,t_i^{-1}) = \sum_{n_1 \geqslant n_2 \geqslant \cdots \geqslant n_N \geqslant 0}^{\infty} \frac{1}{2} \det[d_{n_j+N-j,i}] \mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R), \tag{6.10}$$

This is the character expansion for SO($2N$). As with the SO($2N+1$) case, the expansion does not include the spinor representations. Note that the above expansion is not an expansion over the simple characters of the SO($2N$) group because the $\mathcal{C}$'s are double characters if $n_N > 0$ as discussed in Sec. II. If one desires an expansion over the simple characters, one can write

$$\mathcal{C} = \tfrac{1}{2}(\mathcal{C} + \mathcal{S}) + \tfrac{1}{2}(\mathcal{C} - \mathcal{S}), \tag{6.11}$$

which puts the two simple characters on the right hand side, as explained earlier. At the present time, we find it simpler to apply the formula in the state that it is in. The expression for the coefficient is found using Eqs. (6.4) and (3.10) and is found to be

$$d_{n_j+N-j,i} = \sum_{p=-\infty}^{\infty} A_p (A_{n_j+i-j+p} + A_{-n_j-2N+i+j+p}). \tag{6.12}$$

In the special case of a Taylor series with $A_p = 0$ for all $p < 0$, this simplifies to

$$d_{n_j+N-j,i} = \sum_{p=0}^{\infty} A_p (A_{p+|n_j+i-j|} + A_{p+n_j+2N-i-j}). \tag{6.13}$$

The derivations of the expansions are complete. We now turn to some examples.

VII. EXAMPLES OF CHARACTER EXPANSIONS

In this section, we give some examples of expansions of group functions over the characters of the Sp($2N$), SO($2N+1$), and SO($2N$) groups. In Sec. VII A, we will present the expansion of

the generating function of the homogeneous symmetric functions. This can be used as a check of the formulas derived in the present article, as the expansions are known. In Sec. VII B, we present the expansion for the function $\exp(xTrM)$, where M is some matrix element of one of the three groups we treat.

A. Homogeneous symmetric functions

Consider the generating function of the homogeneous symmetric functions, namely

$$G(x,t)=\frac{1}{1-xt}=\sum_{n=0}^{\infty} x^n t^n. \tag{7.1}$$

Thus, we have $A_n(x)=x^n$ for $n\geqslant 0$ and $A_n(x)=0$ otherwise. Consider the $\mathrm{Sp}(2N)$ expansion. Note that

$$\prod_{i=1}^{N} G(x,t_i)G(x,t_i^{-1})=\frac{1}{\det[I-xP]}, \tag{7.2}$$

where I is the $2N\times 2N$ identity matrix. The expansion is given by Eq. (4.10). Since the series expansion of the generating function in Eq. (7.1) does not contain negative powers of t, the coefficients are given by Eq. (4.12). Thus, the coefficients are given by

$$\det[d_{n_j+N-j+1,i}]=\det\left[\sum_{p=0}^{\infty} x^p(x^{p+|n_j+i-j|}-x^{p+n_j+2N+2-i-j})\right], \tag{7.3}$$

which after simplifying becomes

$$\det[d_{n_j+N-j+1,i}]=\det\left[\frac{x^{|n_j+i-j|}-x^{n_j+2N+2-i-j}}{1-x^2}\right]. \tag{7.4}$$

We simplify by noticing that if $n_2\geqslant 1$, then the first column of the determinant is a multiple of the second column, thereby making the determinant vanish. Thus, n_2 must be zero in order to have a nonvanishing coefficient. Now, since $n_2\geqslant n_3$ and so on, we see that the only surviving terms in the expansion are those for which $n_2=n_3=\cdots=n_N=0$. This corresponds to one row Young tableaux, labeled (n) earlier. The above determinant then becomes

$$\det[d_{n_j+N-j+1,i}]=\det\left[\frac{x^{|n_1\delta_{1j}+i-j|}-x^{n_1\delta_{1j}+2N+2-i-j}}{1-x^2}\right]. \tag{7.5}$$

This, in turn, can be written as

$$\det[d_{n_j+N-j+1,i}]=\frac{x^{n_1}}{(1-x^2)^N}\det[x^{|i-j|}-x^{2N+2-i-j}]. \tag{7.6}$$

By an induction argument on the dimension of the determinant on the right hand side, one can prove that

$$\det[x^{|i-j|}-x^{2N+2-i-j}]=(1-x^2)^N \tag{7.7}$$

and thus

$$\det[d_{n_j+N-j+1,i}]=x^{n_1}, \tag{7.8}$$

where we recall that all n's other than n_1 are 0. Then, the character expansion is Eq. (4.10) with the coefficients found above is

$$\frac{1}{\det[I-xP]}=\prod_{i=1}^{N}\left(\frac{1}{1-xt_i}\right)\left(\frac{1}{1-xt_i^{-1}}\right)=\sum_{n_1=0}^{\infty}x^{n_1}\chi_{(n_1)}(P). \tag{7.9}$$

If we use Eq. (2.7), which relates the character of one row Young tableaux to the homogeneous symmetric functions, we have

$$\frac{1}{\det[I-xP]}=\prod_{i=1}^{N}\left(\frac{1}{1-xt_i}\right)\left(\frac{1}{1-xt_i^{-1}}\right)=\sum_{n=0}^{\infty}x^{n}h_n(t_i,t_i^{-1}). \tag{7.10}$$

However, this is exactly the defining equation for the homogeneous symmetric functions. Thus, we see that the expansion derived for Sp($2N$) agrees with the known expansion.

To perform the same expansion over the SO($2N+1$) group, one must use caution. As alluded to earlier, we must manually include the eigenvalue 1. Mathematically, we have

$$\frac{1}{\det[I-xR]}=G(x,1)\prod_{i=1}^{N}G(x,t_i)G(x,t_i^{-1}), \tag{7.11}$$

where $G(x,t)$ is still given by Eq. (7.1) and I is the $(2N+1)\times(2N+1)$ identity matrix. Then, we have the expansion from Eq. (5.8) and we scale both sides by $G(x,1)=(1-x)^{-1}$ to get

$$G(x,1)\prod_{i=1}^{N}G(x,t_i)G(x,t_i^{-1})=\frac{1}{1-x}\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty}\det[d_{n_j+N-j,i}]\chi_{(n_1,n_2,\ldots,n_N)}(R). \tag{7.12}$$

The coefficient is given by Eq. (5.10)

$$\det[d_{n_j+N-j,i}]=\det\left[\sum_{p=0}^{\infty}x^{p}(x^{p+|n_j+i-j|}-x^{p+n_j+2N+1-i-j})\right], \tag{7.13}$$

or, after simplifying,

$$\det[d_{n_j+N-j,i}]=\det\left[\frac{x^{|n_j+i-j|}-x^{n_j+2N+1-i-j}}{1-x^2}\right]. \tag{7.14}$$

Once again it can be shown that if $n_2\geqslant 1$, the first two columns are multiples and the coefficient vanishes. It can also be shown using the result of the similar expression for the Sp($2N$) expansion that if $n_1=n$ and all other $n_i=0$, then

$$\det[d_{n_j+N-j,i}]=\frac{x^n}{1+x} \tag{7.15}$$

so that

$$\frac{1}{\det[I-xR]}=\frac{1}{(1-x)}\prod_{i=1}^{N}\frac{1}{(1-xt_i)}\frac{1}{(1-xt_i^{-1})}=\sum_{n=0}^{\infty}\frac{x^n}{1-x^2}\chi_{(n)}(R). \tag{7.16}$$

Finally, using the value of the single row characters for the SO($2N+1$) group from Eq. (2.8), one can show that

$$\frac{1}{\det[I-xR]}=\frac{1}{(1-x)}\prod_{i=1}^{N}\frac{1}{(1-xt_i)}\frac{1}{(1-xt_i^{-1})}=\sum_{n=0}^{\infty}x^{n}h_n(t_i,t_i^{-1},1), \tag{7.17}$$

which again agrees with the definition of the homogeneous symmetric functions.

We continue on with the same expansion for the SO($2N$) group. Using the same generating function and using the character expansion from Eq. (6.10), we have

$$\frac{1}{\det[I-xR]}=\prod_{i=1}^{N}\frac{1}{(1-xt_i)}\frac{1}{(1-xt_i^{-1})}=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty}\frac{1}{2}\det[d_{n_j+N-j,i}]\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R). \tag{7.18}$$

Note the appearance of the factor of $\frac{1}{2}$ in this expression. The coefficient is given by Eq. (6.13) to be

$$\det[d_{n_j+N-j,i}]=\det\left[\sum_{p=0}^{\infty}x^p(x^{p+|n_j+i-j|}+x^{p+n_j+2N-i-j})\right], \tag{7.19}$$

or, after simplification,

$$\det[d_{n_j+N-j,i}]=\det\left[\frac{x^{|n_j+i-j|}+x^{n_j+2N-i-j}}{1-x^2}\right]. \tag{7.20}$$

Once again, the first two columns are multiples if $n_2\geqslant 1$, so the only surviving coefficients are the ones corresponding to $n_1=n$, all others are zero. Again, the determinant can be evaluated with the help of the result from the Sp($2N$) case, and the result is

$$\det[d_{n_j+N-j,i}]=\frac{2x^n}{1-x^2}. \tag{7.21}$$

We note that the 2 cancels with the $\frac{1}{2}$ built into the SO($2N$) expansion and the remaining expression is exactly the same as the SO($2N+1$) expression. Thus, we see that the expansions derived in the present work indeed give the correct expansion. In all three of these examples, we have tacitly assumed that N is at least 2, but one can check that the expansions are correct for the $N=1$ cases as well.

We could also consider the generating function for the alternating symmetric functions, $G(x,t)=1-xt$, and calculate the expansions as another check for reliability. One can check that the expansions derived from the present work in fact give the known expansions. This task will not be undertaken in the present work.

B. Expansion of exp(*x Tr* M)

Now that we have confidence in the character expansions derived here, we can start considering more interesting examples. Of course, any generating function can be chosen as long as it can be expanded in a power series. For our example, we will choose the exponential function because it is expected that this technique will prove useful in performing group integrals that arise in low-energy effective QCD partition functions and the integrals are of exponential functions.

We begin by defining the generating function

$$G(x,t)=e^{xt}=\sum_{n=0}^{\infty}\frac{x^n}{n!}t^n \tag{7.22}$$

so that $A_n(x)=x^n/n!$ for $n\geqslant 0$ and zero otherwise. Let us first consider Sp($2N$). We have

$$\prod_{i=1}^{N}G(x,t_i)G(x,t_i^{-1})=e^{x(t_1+t_2+\cdots+t_N+t_1^{-1}+t_2^{-1}+\cdots+t_N^{-1})}=\exp(xTrP). \tag{7.23}$$

Our character expansion is given by Eq. (4.10) as

$$\exp(xTrP)=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty}\det[d_{n_j+N-j+1,i}]\chi_{(n_1,n_2,\ldots,n_N)}(P), \tag{7.24}$$

where the coefficients are given directly by Eq. (4.12) as

$$\det[d_{n_j+N-j+1,i}]=\det\left[\sum_{p=0}^{\infty}\frac{x^p}{p!}\left(\frac{x^{p+|n_j+i-j|}}{(p+|n_j+i+j|)!}-\frac{x^{p+n_j+2N+2-i-j}}{(p+n_j+2N+2-i-j)!}\right)\right]. \tag{7.25}$$

This can be recognized as a modified Bessel function, which has the expansion

$$I_\lambda(x)=\sum_{p=0}^{\infty}\frac{1}{p!(p+\lambda)!}\left(\frac{x}{2}\right)^{2p+\lambda}. \tag{7.26}$$

Note also that $I_\lambda(x)=I_{-\lambda}(x)$ for any x. Thus, we can rewrite the coefficient as (dropping the absolute value sign)

$$\det[d_{n_j+N-j+1,i}]=\det[I_{n_j+i-j}(2x)-I_{n_j+2N+2-i-j}(2x)] \tag{7.27}$$

so that, finally,

$$\exp(xTrP)=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty}\det[I_{n_j+i-j}(2x)-I_{n_j+2N+2-i-j}(2x)]\chi_{(n_1,n_2,\ldots,n_N)}(P). \tag{7.28}$$

We proceed with the same expansion for the SO($2N+1$) group. Using the same generating function, Eq. (5.8) gives us the expansion as

$$\prod_{i=1}^{N}\exp(xt_i)\exp(xt_i^{-1})=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty}\det[d_{n_j+N-j,i}]\chi_{(n_1,n_2,\ldots,n_N)}(R), \tag{7.29}$$

where Eq. (5.10) gives

$$\det[d_{n_j+N-j,i}]=\det\left[\sum_{p=0}^{\infty}\frac{x^p}{p!}\left(\frac{x^{p+|n_j+i-j|}}{(p+|n_j+i-j|)!}-\frac{x^{p+n_j+2N+1-i-j}}{(p+n_j+2N+1-i-j)!}\right)\right], \tag{7.30}$$

or, using the definition of the modified Bessel function,

$$\det[d_{n_j+N-j,i}]=\det[I_{n_j+i-j}(2x)-I_{n_j+2N+1-i-j}(2x)]. \tag{7.31}$$

Thus, our expression is

$$\prod_{i=1}^{N}\exp(xt_i)\exp(xt_i^{-1})=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty}\det[I_{n_j+i-j}(2x)-I_{n_j+2N+1-i-j}(2x)]\chi_{(n_1,n_2,\ldots,n_N)}(R). \tag{7.32}$$

Now, the left hand side is not yet $\exp(xTrR)$. We need to include the eigenvalue 1. Thus we multiply both sides by e^x and we get

$$\exp(xTrR)=\exp(x)\prod_{i=1}^{N}\exp(xt_i)\exp(xt_i^{-1})$$

$$=e^{x}\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty}\det[I_{n_j+i-j}(2x)-I_{n_j+2N+1-i-j}(2x)]\chi_{(n_1,n_2,\ldots,n_N)}(R), \tag{7.33}$$

which is the desired expansion. We emphasize the appearance of the e^x on the right hand side of the expression. This extra term is unique to the SO($2N+1$) group.

As our final example, we develop the same expansion for the SO($2N$) group. As before, we write the expansion from Eq. (6.10) as

$$\exp(xTrR)=\prod_{i=1}^{N}\exp(xt_i)\exp(xt_i^{-1})=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N>0}^{\infty}\frac{1}{2}\det[d_{n_j+N-j,i}]\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R). \tag{7.34}$$

The coefficients are given by Eq. (6.13) as

$$\det[d_{n_j+N-j,i}]=\det\left[\sum_{p=0}^{\infty}\frac{x^p}{p!}\left(\frac{x^{p+|n_j+i-j|}}{(p+|n_j+i-j|)!}+\frac{x^{p+n_j+2N-i-j}}{(p+n_j+2N-i-j)!}\right)\right]. \tag{7.35}$$

Again using the modified Bessel equation expansion, we get

$$\det[d_{n_j+N-j,i}]=\det[I_{n_j+i-j}(2x)+I_{n_j+2N-i-j}(2x)]. \tag{7.36}$$

Thus, the desired expansion is

$$\exp(xTrR)=\sum_{n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0}^{\infty}\frac{1}{2}\det[I_{n_j+i-j}(2x)+I_{n_j+2N-i-j}(2x)]\mathcal{C}_{(n_1,n_2,\ldots,n_N)}(R). \tag{7.37}$$

Once again, we emphasize the factor of $\frac{1}{2}$ in this expression. This is unique to the SO($2N$) expansion.

VIII. CONCLUSIONS

The present article, along with Refs. 1 and 8 completes the program of finding character expansions for all classical Lie groups. We expect these formulas to be useful in a wide range of applications. We already described some of these applications in the Introduction.

One should emphasize that the success in understanding the relationship between the random matrix theories and the low-lying eigenvalues of the QCD Dirac operator suggests investigating other aspects of QCD in a statistical framework (for a recent review see Ref. 38). More recently a similarity between disordered systems in condensed matter physics and QCD, namely the existence of a universal energy scale known as Thouless energy, was suggested.[39–41] This problem can be treated using the supersymmetry approach.[42,25,43] In the supersymmetry approach to this problem one needs to calculate integrals over supergroups.[44,45] One should note that integration over unitary supergroups was already considered in Refs. 13 and 45–47. Invariant integration over an Osp($N/2M$) manifold was also previously discussed in Refs. 48 and 49. An approach based on Gelfand–Tzetlin coordinates was developed and a recursion formula for both ordinary and supergroup integrals was found.[50–53] Character expansions for supergroups may be useful to understand the nature and extent of this approach. The characters of supergroups are given by formulas similar to the Weyl formulas except that complete symmetric functions are replaced by the graded homogeneous symmetric functions or alternately traces by supertraces.[54–57] Since our character

expansion formulas are basically combinatorial in nature they are applicable to the supergroups as well by the appropriate substitution of traces with supertraces. Thus one can obtain character expansions of the orthosymplectic supergroup Osp($N/2M$) from our formulas for SO(N)[54] and of the supergroup P(N) from our formulas for Sp($2N$).[55]

APPENDIX: A THEOREM ON DETERMINANTS

Here we take up the issue of slightly generalizing a theorem on determinants that can be found in Hua's book.[37] His Theorem 1.2.1 states that

$$\det\left[\sum_{r=0}^{\infty} d_{r,j}t_i^r\right]=\sum_{r_1>r_2>\ldots>r_N\geqslant 0}^{\infty} \det[d_{r_j,i}]\det[t_i^{r_j}]. \tag{A1}$$

We would like to prove the following more general statement, which we state as a theorem.

Theorem 1: *Let $f_r(t)$ be an arbitrary function of the variable t with dependence on the index r. Then the following equality holds*:

$$\det\left[\sum_{r=0}^{\infty} d_{r,j}f_r(t_i)\right]=\sum_{r_1>r_2>\ldots>r_N\geqslant 0}^{\infty} \det[d_{r_j,i}]\det[f_{r_j}(t_i)]. \tag{A2}$$

To prove the theorem, we recall the expansion of determinants of $N\times N$ matrices, namely,

$$\det[\mathcal{A}_{i,j}]=\sum_{m_1=1}^{N}\sum_{m_2=1}^{N}\cdots\sum_{m_N=1}^{N}\epsilon_{m_1m_2\cdots m_N}\mathcal{A}_{1,m_1}\mathcal{A}_{2,m_2}\cdots\mathcal{A}_{N,m_N}, \tag{A3}$$

where the tensor $\epsilon_{m_1m_2\cdots m_N}$ is completely antisymmetric. Then, the left hand side of Eq. (A2) becomes

$$\begin{aligned}\det\left[\sum_{r=0}^{\infty} d_{r,j}f_r(t_i)\right]=&\sum_{m_1=1}^{N}\sum_{m_2=1}^{N}\cdots\sum_{m_N=1}^{N}\epsilon_{m_1m_2\cdots m_N}\left[\sum_{r_1=0}^{\infty} d_{r_1,m_1}f_{r_1}(t_1)\right]\\&\times\left[\sum_{r_2=0}^{\infty} d_{r_2,m_2}f_{r_2}(t_2)\right]\cdots\left[\sum_{r_N=0}^{\infty} d_{r_N,m_N}f_{r_N}(t_N)\right].\end{aligned} \tag{A4}$$

Isolating the dependence on the m_i's, we get

$$\begin{aligned}\det\left[\sum_{r=0}^{\infty} d_{r,j}f_r(t_i)\right]=&\sum_{r_1=0}^{\infty}\sum_{r_2=0}^{\infty}\cdots\sum_{r_N=0}^{\infty} f_{r_1}(t_1)f_{r_2}(t_2)\cdots f_{r_N}(t_N)\\&\times\left[\sum_{m_1=1}^{N}\sum_{m_2=1}^{N}\cdots\sum_{m_N=1}^{N}\epsilon_{m_1m_2\cdots m_N}d_{r_1,m_1}d_{r_2,m_2}\cdots d_{r_N,m_N}\right].\end{aligned} \tag{A5}$$

We recognize the term on the right hand side in the large brackets as a determinant, so

$$\det\left[\sum_{r=0}^{\infty} d_{r,j} f_r(t_i)\right] = \sum_{r_1=0}^{\infty}\sum_{r_2=0}^{\infty}\cdots\sum_{r_N=0}^{\infty} f_{r_1}(t_1) f_{r_2}(t_2)\cdots f_{r_N}(t_N)\det[d_{r_i,j}]. \tag{A6}$$

Now, if any of the r_i are equal, then the determinant on the right hand side will vanish because two rows would be identical. Thus, the sum can be restricted to distinct values of the r_i's. Next, since the r_i's are all different, we would like to order them in descending order so that $r_i > r_{i+1}$. In doing so, we would like to not change the form of the determinant on the right hand side. So, for any switch of labels, we permute the rows to leave the form unchanged. This brings in a factor of $+1$ or -1, depending on how many permutations are needed. We can express this simply by using the Nth rank alternating tensor as

$$\det\left[\sum_{r=0}^{\infty} d_{r,j} f_r(t_i)\right] = \sum_{r_1>r_2>\cdots>r_N\geqslant 0}^{\infty} \det[d_{r_i,j}] \sum_{m_1=1}^{N}\sum_{m_2=1}^{N}\cdots\sum_{m_N=1}^{N} \epsilon_{m_1 m_2\cdots m_N} f_{r_{m_1}}(t_1) f_{r_{m_2}}(t_2)\cdots f_{r_{m_N}}(t_N). \tag{A7}$$

Here we note that the term involving m_i sums is a determinant. Thus, taking the transpose of the determinant of the d's, we conclude

$$\det\left[\sum_{r=0}^{\infty} d_{r,j} f_r(t_i)\right] = \sum_{r_1>r_2>\cdots>r_N\geqslant 0}^{\infty} \det[d_{r_j,i}]\det[f_{r_j}(t_i)], \tag{A8}$$

which proves the theorem.

Algebro-geometric solution of the 2+1 dimensional Burgers equation with a discrete variable

Cewen Cao,[a] Xianguo Geng, and Hongye Wang
Department of Mathematics, Zhengzhou University, Zhengzhou, Henan 450052, People's Republic of China

(Received 11 October 2000; accepted for publication 13 September 2001)

The quasiperiodic solution of the 2+1 dimensional Burgers equation with a discrete variable is obtained through three steps: (a) decomposition into a symplectic map plus two finite-dimensional Hamiltonian systems; (b) straightening out of both the discrete and the continuous flows in the Jacobian variety; (c) inversion into the original variables. Inner relation with the modified Kadomtsev–Petviashvili equation is presented. The explicit theta function solutions for these two 2+1 integrable models are given. © *2002 American Institute of Physics.*

I. INTRODUCTION

The most attractive point in the celebrated Liouville–Arnold theory is the straightening out of various flows on the invariant torus, which reveals the basic structure of the Liouville integrability.[1] There were a series of brilliant examples in the development of classical mechanics, such as the two-body problem of Newton, the geodesic flow on the ellipsoid of Jacobi, the harmonic oscillator constrained on the sphere of C. Neumann, and the integrable tops of Euler, Lagrange, and Kovalevski. They have a common feature: the motions are all quasiperiodic. The ingenious mathematical skill in solving these problems is essentially reduced in finding the angular variables and proving the uniform way of their evolution. Hence, in the window of angular coordinates, the motion is linear locally, and quasiperiodic globally.

The discovery of the N-soliton solution to the Korteweg–de Vries equation (KdV) in 1967 is a prominent event in mathematical physics. As for the quasiperiodic solutions, after a series of independent works by Novikov,[2] Matveev,[3] Lax,[4,5] and Marchenko,[6] the final expression,

$$u(x,t) = -2\partial_x^2 \ln \theta(\Omega_1 x + \Omega_2 t + K) + C, \tag{1.1}$$

was found by Its and Matveev in 1975.[7,8] This is tremendous progress along the direction initiated by the pioneer studies in classic mechanics. Since the solution is closely related to the finite-band spectrum of the associated differential operator, it is also called the finite-band solution. The angular argument $\phi = \Omega_1 x + \Omega_2 t + K$ suggests the straightening out of x- and t-flows:

$$\frac{\mathrm{d}\phi}{\mathrm{d}x} = \Omega_1, \quad \frac{\mathrm{d}\phi}{\mathrm{d}t} = \Omega_2. \tag{1.2}$$

Further exciting results appeared later, including the finite-band solution of the 1+1 dimensional discrete Toda equation,[9–14] that of the Kadomtsev–Petviashvili (KP) equation and others, which could be found in the wonderful work of Belokolos, *et al.*[15] The straightening out of the discrete flow

$$\phi(n+1) - \phi(n) = \Omega_S, \quad (\mathrm{mod}\, T) \tag{1.3}$$

[a]Electronic mail: CWCao@public2.zz.ha.cn

was first proved by Toda through the spectral analysis of the discrete Toda eigenvalue problem.[11–13] As for the KP equation, we have the beautiful formula in Ref. 15:

$$w(x,y,t)=2\partial_x^2 \ln \theta(\Omega_1 x+\Omega_2 y+\Omega_3 t+D)+w_0, \tag{1.4}$$

which suggests the straightening out of the x-, y-, and t-flows in the framework of the angular variable $\phi=\Omega_1 x+\Omega_2 y+\Omega_3 t+D$:

$$\frac{d\phi}{dx}=\Omega_1, \quad \frac{d\phi}{dy}=\Omega_2, \quad \frac{d\phi}{dt}=\Omega_3. \tag{1.5}$$

However, the number of positive results remain very limited for the $(2+1)$-dimensional case since it is very hard to find the angular variable. Based on the observation and analysis of the Lax representation of soliton models, we have developed an approach to get finite-band solutions of spatially multidimensional integrable models. The well-known formula (1.4) for the KP equation is again derived through different means.[16] We also succeeded in getting an algebro-geometric solution of the special $(2+1)$-dimensional Toda lattice model.[17]

Our method is divided into three steps:

(a) decomposition;
(b) straightening out;
(c) inversion.

First the well-known Lax representation is used to decompose the higher dimensional integrable system into lower dimensional ones. A clear formalism of the decomposition is obtained through the so-called nonlinearization technique.[16–28] Second, the resulting finite-dimensional integrable system (the nonlinearized eigenvalue problem) serves as a base to construct the associated algebraic curve and the Abel–Jacobi coordinates, through which the flows are straightened out and the linear superposition yields the solution of the $(2+1)$-dimensional integrable models, expressed in the Abel–Jacobi coordinates. Third, an inverse procedure is indispensable in transforming the explicit solution in the original coordinates, which manifests abundant diversity in different examples. The main tool in our theory is the algebraic curve associated with the Lax matrix.

In the present paper we are going to investigate the $2+1$ dimensional Burgers equation with a discrete variable

$$B_y=2BB_x+\tfrac{1}{2}B_{xx}+\Delta^{-1}B_{xx}, \tag{1.6}$$

where Δ is the onward difference operator with regard to the discrete variable: $\Delta f(n)=f(n+1)-f(n)$, which is closely related to the first two members of the Kac–van Moerbeke (KvM) lattice hierarchy:

$$\frac{da(n)}{dx}=X_0=a(n)[a^2(n+1)-a^2(n-1)], \tag{1.7}$$

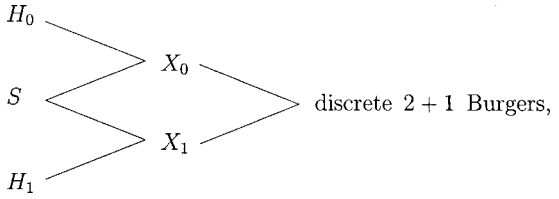
$$\begin{aligned}\frac{da(n)}{dy}=X_1=a(n)[&a^2(n+2)a^2(n+1)+a^4(n+1)+a^2(n+1)a^2(n)-a^2(n)a^2(n-1)\\&-a^4(n-1)-a^2(n-1)a^2(n-2)].\end{aligned} \tag{1.8}$$

The Kac–van Moerbeke equation (1.7) and its variants are sometimes called the Langmuir lattice, the Volterra system or the discrete Korteweg–de Vries equation, which have attracted wide attention.[9,14,29–38] A thorough investigation is made by Bulla *et al.*, for the algebro-geometric solutions of the KvM hierarchy.[39]

Let $a(n,x,y)$ be a compatible solution of Eqs. (1.7) and (1.8). Then $B(n,x,y)=a^2(n,x,y)$ solves Eq. (1.1), which is verified by direct calculations. The KvM hierarchy is the isospectral class of the discrete eigenvalue problem

$$E\chi=U\chi, \quad U=\frac{1}{a}\begin{pmatrix} 0 & a^2 \\ -1 & \lambda \end{pmatrix}, \tag{1.9}$$

where E is the shift operator: $Ef(n)=f(n+1)$. The nonlinearization of N copies of Eq. (1.9) with $\lambda=\alpha_1,\alpha_2,\ldots,\alpha_N$ yields an integrable symplectic map $\mathcal{S}$ in the symplectic space $(\mathbb{R}^{2N},\mathrm{d}p\wedge\mathrm{d}q)$ with N functionally independent integrals $H_0,H_1,\ldots,H_{N-1}$, involutive with each other (see Sec. II). Let $(p(n,\tau_k),q(n,\tau_k))$ be the compatible solution of the H_k-flow and the discrete flow generated by $\mathcal{S}$. Then the nonlinearized map $f_{\mathcal{S}}$ maps (p,q) exactly into a solution of the KvM flow X_k (see Sec. III). Thus we have the decomposition diagram:



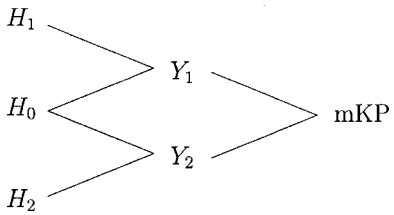
(1.10)

which is the basis of computing the algebro-geometric solution of Eq. (1.6).

The discrete 2+1 Burgers model (1.6) has an inner relation with the modified Kadomtsev–Petviashvili (mKP) equation:

$$v_t=\tfrac{1}{16}(v_{xx}-2v^3)_x+\tfrac{3}{4}\partial_x^{-1}v_{yy}-\tfrac{3}{4}v_x\partial_x^{-1}v_y, \tag{1.11}$$

which is a continuous 2+1 dimensional integrable model, and whose decomposition leads to the same Hamiltonian functions $\{H_k\}$ as noted previously (see Sec. IV):



(1.12)

In other words, the algebro-geometric solution of the discrete 2+1 model (1.6) is built up with the "bricks" H_0,H_1, and $\mathcal{S}$, while that of the continuous 2+1 model (1.11) is made up of the bricks H_0,H_1, and H_2.

The meaning of straightening out of the flows is that the velocities of the Abel–Jacobi coordinates along the H_k flow and the discrete $\mathcal{S}$ flow are constants:

$$\frac{\mathrm{d}\phi}{\mathrm{d}\tau_k}=\Omega_k, \quad \frac{\mathrm{d}\psi}{\mathrm{d}\tau_k}=-\Omega_k, \quad k=0,1,2,\ldots, \tag{1.13}$$

$$\begin{aligned} \phi(2m+1)-\phi(2m-1)=\psi(2m+1)-\psi(2m-1)\equiv\Omega_{\mathcal{S}} \pmod T, \\ \phi(2m+2)-\phi(2m)=\psi(2m+2)-\psi(2m)\equiv\Omega_{\mathcal{S}} \pmod T. \end{aligned} \tag{1.14}$$

Let $\omega=(\omega_1,\ldots,\omega_g)$ be the standard holomorphic differential of the associated elliptic curve Γ. It is interested to see that the continuous speed Ω_k is the kth coefficient in the asymptotic expansion of ω, while the discrete speed $\Omega_{\mathcal{S}}$ is the integral of ω from ∞_1 and ∞_2 (see Secs. IV and V).

The discrete evolution (1.14) is a little more complicated than (1.3) in the Toda case. We have given another proof of Eq. (1.3) through the nonlinearization approach,[17] which makes it possible to treat other types of examples, including the present one.

Thus through the ''window'' of the Abel–Jacobi coordinate we have a clear evolution picture of various flows; the special algebro-geometric solutions of higher dimensional integrable models could be essentially reduced as a linear superposition. The same pictures are observed in the KP and the 2+1 Toda cases. The final explicit solutions, expressed resorting to the theta function, are obtained through the Abel–Riemann–Jacobi inversion.[16,17,40,41]

II. THE KAC–van MOERBEKE HIERARCHY

The Kac–van Moerbeke hierarchy is the isospectral class of the discrete eigenvalue problem

$$E\begin{pmatrix} p_j \\ q_j \end{pmatrix} = U(a,\alpha_j)\begin{pmatrix} p_j \\ q_j \end{pmatrix}, \tag{2.1}$$

$$U(a,\lambda) = \frac{1}{a}\begin{pmatrix} 0 & a^2 \\ -1 & \lambda \end{pmatrix}, \tag{2.2}$$

where E is the shift operator: $Ef(n)=f(n+1)$. Denote $E^-f(n)=f(n-1)$, $\Delta=E-1$, and

$$\sigma_1=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \sigma_2=\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \sigma_3=\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

Proposition 2.1. (Fundamental identity): Let $\sigma(a,\lambda)$ be a linear map defined by

$$V=\sigma(a,\lambda)[G]=\{(a^2E-E^-a^2-\lambda^2)G\}\sigma_1+(2\lambda E^-a^2G)\sigma_2+(-2\lambda G)\sigma_3. \tag{2.3}$$

Then the discrete commutative relation

$$(EV)U-UV=U_*\{(K-\lambda^2J)G\} \tag{2.4}$$

holds for any function G, where

$$K=a(E+1)(a^2E-E^-a^2), \quad J=a\Delta, \tag{2.5}$$

$$U_*(a)\delta a=\left.\frac{\mathrm{d}}{\mathrm{d}\epsilon}\right|_{\epsilon=0} U(a+\epsilon\delta a)=\frac{1}{a^2}\begin{pmatrix} 0 & a^2 \\ 1 & -\lambda \end{pmatrix}\delta a. \tag{2.6}$$

Corollary 2.2: $(K-\lambda^2J)G=0$ implies $\det\sigma[G]=$constant, independent of n.
Proof: By (2.4), $V=\sigma[G]$ satisfies $V_{n+1}=UV_nU^{-1}$. Thus $\det V_{n+1}=\det V_n$.
The Lenard gradients $\{g_k\}$ are universal polynomials of a:

$$\begin{gathered} g_{-1}(n)=1, \quad g_0(n)=a^2(n)+a^2(n-1), \\ g_1(n)=a^2(n+1)a^2(n)+[a^2(n)+a^2(n-1)]^2+a^2(n-1)a^2(n-2), \text{ etc.}, \end{gathered} \tag{2.7}$$

satisfying the recursive formula:

$$Jg_{-1}=0, \quad Kg_{j-1}=Jg_j, \tag{2.8}$$

which means $(K-\lambda^2J)g_\lambda=0$ for the generating function:

$$g_\lambda=\sum_{j=0}^{\infty} g_{j-1}\lambda^{-2j}. \tag{2.9}$$

By Corollary 2.2, $\det \sigma[g_\lambda]=$constant. Since the Lenard gradients are universal polynomials of a, this constant can be determined by considering the class of a with rapidly decaying condition as $n\to\infty$. This yields

$$\det \sigma[g_\lambda]=-\lambda^4. \tag{2.10}$$

The discrete Kac–van Moerbeke equations are defined as ($m=0,1,2,\ldots$):

$$\frac{da}{d\tau_m}=X_m=Jg_m. \tag{2.11}$$

The first two are Eqs. (1.7) and (1.8) with $x=\tau_0$ and $y=\tau_1$.

III. THE INTEGRABLE SYMPLECTIC MAP

Consider N copies of Eq. (2.1) with distinct eigenvalues $\alpha_1,\ldots,\alpha_N$, and write them in the vector form:

$$\begin{aligned} p(n+1)&=a(n)q(n),\\ a(n)q(n+1)&=Aq(n)-p(n), \end{aligned} \tag{3.1}$$

where $p=(p_1,\ldots,p_N)^T$, $q=(q_1,\ldots,q_N)^T$, and $A=\mathrm{diag}(\alpha_1,\ldots,\alpha_N)$. Denote the usual inner product of two N-dimensional vectors ξ, η by $\langle\xi,\eta\rangle$. According to the principle of nonlinearization,[18] consider the Bargmann condition

$$g_0=\sum_{j=1}^{N}\alpha_j q_j^2, \tag{3.2}$$

i.e.,

$$a^2(n)+a^2(n-1)=\langle Aq(n),q(n)\rangle. \tag{3.3}$$

Lemma 3.1: The sufficient condition for Eq. (3.2) is

$$a=\sqrt{\langle Aq,q\rangle-\langle p,q\rangle}\equiv f_{\mathcal{S}}(p,q). \tag{3.4}$$

Proof: By (3.1) we have

$$\begin{aligned} a^2(n)&=\langle Aq(n),q(n)\rangle-\langle p(n),q(n)\rangle=\langle a(n)q(n+1),q(n)\rangle=\langle p(n+1),q(n+1)\rangle,\\ a^2(n-1)&=\langle p(n),q(n)\rangle. \end{aligned} \tag{3.5}$$

Hence we obtain Eq. (3.3).

We take Eq. (3.4) as the starting point and call it the Bargmann constraint, which implies the Bargmann condition (3.2). Equations (3.4) and (3.2) are not equivalent as in the case of the Toda lattice.[17] Nevertheless, it is enough for our purpose. Substituting Eq. (3.4) into Eq. (3.1), we obtain a symplectic map:

$$\begin{aligned} E\begin{pmatrix}p\\q\end{pmatrix}&=\begin{pmatrix}aq\\ a^{-1}(Aq-p)\end{pmatrix}\equiv\mathcal{S}\begin{pmatrix}p\\q\end{pmatrix},\\ a&=\sqrt{\langle Aq,q\rangle-\langle p,q\rangle}, \end{aligned} \tag{3.6}$$

with

$$\mathrm{d}p(n+1)\wedge\mathrm{d}q(n+1)=\mathrm{d}p(n)\wedge\mathrm{d}q(n).$$

Lemma 3.2: For the solution $(p_j,q_j),\alpha_j$ of the spectral problem (2.1), we have

$$(K-\alpha_j^2 J)q_j^2=0, \tag{3.7}$$

$$\sigma(a,\lambda)q_j^2=[-(\lambda^2-\alpha_j^2)q_j^2-2\alpha_j p_j q_j]\sigma_1+(2\lambda p_j^2)\sigma_2+(-2\lambda q_j^2)\sigma_3. \tag{3.8}$$

Proof: By direct calculations.

Lemma 3.3: Under the Bargmann constraint (3.4), the equation $(K-\lambda^2 J)G_\lambda=0$ has a solution

$$G_\lambda=g_{-1}+\sum_{j=1}^{N}\frac{\alpha_j q_j^2}{\lambda^2-\alpha_j^2}=1+Q_\zeta(Aq,q), \tag{3.9}$$

where $\zeta=\lambda^2$ and

$$Q_\zeta(\xi,\eta)=\sum_{j=1}^{N}\frac{\xi_j\eta_j}{\lambda^2-\alpha_j^2}.$$

Proof: Using Eqs. (3.7) and (3.2), we calculate

$$(K-\lambda^2 J)G_\lambda=Jg_0+\sum_{j=1}^{N}\frac{\alpha_j(\alpha_j^2-\lambda^2)q_j^2}{\lambda^2-\alpha_j^2}=J\left(g_0-\sum_{j=1}^{N}\alpha_j q_j^2\right)=0.$$

We define the Lax matrix of the Kac–van Moerbeke hierarchy as

$$V_\lambda=\sigma(f_{\mathcal{S}}(p,q),\lambda)[G_\lambda], \tag{3.10}$$

which satisfies the stationary zero-curvature equation (discrete version):

$$(EV_\lambda)U-UV_\lambda=0. \tag{3.11}$$

By corollary 2.2, its determinant gives rise to the generating function of the conserved integrals of the symplectic map $\mathcal{S}$:

$$F_\lambda=\det V_\lambda. \tag{3.12}$$

The expression of V_λ and F_λ is obtained from Eq. (3.8):

$$\frac{1}{\lambda}V_\lambda=\begin{pmatrix}-\lambda & 2\langle p,q\rangle\\ -2 & \lambda\end{pmatrix}-2\begin{pmatrix}\lambda Q_\zeta(p,q) & -Q_\zeta(Ap,p)\\ Q_\zeta(Aq,q) & -\lambda Q_\zeta(p,q)\end{pmatrix}, \tag{3.13}$$

$$\frac{1}{\lambda^2}F_\lambda=-\lambda^2-4Q_\zeta(A^2p,q)+4Q_\zeta(Ap,p)+4\langle p,q\rangle Q_\zeta(Aq,q)+4\{Q_\zeta(Ap,p)Q_\zeta(Aq,q)$$

$$-\lambda^2Q_\zeta^2(p,q)\}=-\lambda^2+\sum_{m=0}^{\infty}\lambda^{-2m-2}F_m. \tag{3.14}$$

Hence we have the integrals of the map $\mathcal{S}$ $(m=1,2,\ldots)$:

$$\begin{aligned}\tfrac{1}{4}F_0&=-\langle A^2p,q\rangle+\langle Ap,p\rangle+\langle p,q\rangle\langle Aq,q\rangle-\langle p,q\rangle^2,\\ \frac{1}{4}F_m&=-\langle A^{2m+2}p,q\rangle+\langle A^{2m+1}p,p\rangle+\langle p,q\rangle\langle A^{2m+1}q,q\rangle\\ &\quad+\sum_{k+j=m-1}\langle A^{2j+1}p,p\rangle\langle A^{2k+1}q,q\rangle-\sum_{k+j=m}\langle A^{2j}p,q\rangle\langle A^{2k}p,q\rangle.\end{aligned}\tag{3.15}$$

The proof of the involutivity of $\{F_m\}$ is based on the generating function method. Consider F_λ as a Hamiltonian function in the symplectic space $(\mathbb{R}^{2N},\mathrm{d}p\wedge\mathrm{d}q)$ and denote the flow variable by t_λ. Then the canonical equation is expressed as

$$\frac{\mathrm{d}}{\mathrm{d}t_\lambda}\begin{pmatrix}p_k\\ q_k\end{pmatrix}=\begin{pmatrix}-\partial F_\lambda/\partial q_k\\ \partial F_\lambda/\partial p_k\end{pmatrix}=W(\lambda,\alpha_k)\begin{pmatrix}p_k\\ q_k\end{pmatrix},\tag{3.16}$$

$$W(\lambda,\mu)=-\frac{4\lambda\mu}{\lambda^2-\mu^2}V_\lambda+2\lambda\left(-\frac{2}{\lambda+\mu}V_\lambda^{11}+V_\lambda^{21}\right)\sigma_1.\tag{3.17}$$

Proposition 3.4:

$$\frac{\mathrm{d}}{\mathrm{d}t_\lambda}V_\mu=[W(\lambda,\mu),V_\mu],\quad\forall\lambda,\mu\in\mathbb{C},\tag{3.18}$$

$$(F_\mu,F_\lambda)=0,\quad\forall\lambda,\mu\in\mathbb{C},\tag{3.19}$$

$$(F_j,F_k)=0,\quad\forall j,k=0,1,2,\ldots.\tag{3.20}$$

Proof: A direct calculation yields (3.18), which implies the invariance of $F_\mu=\det V_\mu$ along the t_λ-flow. By definition, the Poisson bracket is essentially a derivative along the phase flow, thus we have:

$$0=\frac{\mathrm{d}F_\mu}{\mathrm{d}t_\lambda}=(F_\mu,F_\lambda).$$

The expansion of (3.19) according to the negative powers of λ,μ gives rise to (3.20).

IV. DECOMPOSITION OF THE INTEGRABLE MODELS

In order to decompose the KvM equations and further the 2+1 discrete Burgers equation, one should establish the inner relation between the Hamiltonian vector field $I\nabla F_m$ and the KvM vector field X_m. It turns out that the derivative map $\mathrm{d}f_{\mathcal{S}}$ does map $I\nabla F_m$ into X_m, but with an annoying remainder. F_m should be adjusted into some H_m so that $\mathrm{d}f_{\mathcal{S}}$ maps $I\nabla H_m$ exactly into X_m. Fortunately, just as in the case of KP and Toda, the square root of F_λ yields the desired generating function H_λ of $\{H_m\}$ [see Eq. (4.8)]. Later (in Sec. VI) we shall see that H_λ is essentially the eigenvalue of the Lax matrix V_λ, acting on the invariant solution space of the linear equation $E\chi=U\chi$ under the commutative condition (3.11).

We start from the Bargmann condition (3.2), which becomes ($k=0,1,2,\ldots$)

$$\sum_{j=1}^{N}\alpha_j^{2k+1}q_j^2(n)=g_k+c_2g_{k-2}+\cdots+c_kg_0+c_{k+1}g_{-1},\tag{4.1}$$

after being exerted k times by the operator $J^{-1}K$. An extra term cg_{-1} appears each time, since the linear space $\ker J$ is one dimensional with the generator g_{-1}. The coefficient c_m is a constant of

motion. It is surprising that c_{m+2} is the desired H_m up to a factor 2 [see Eq. (4.10)]. Two kinds of linear combinations of Eq. (4.1) give the following two important relations.

Proposition 4.1: The solution $(p(n),q(n))^T=\mathcal{S}^n(p_0,q_0)$ of the discrete flow generated by the symplectic map $\mathcal{S}$ is mapped by f_S into a solution of the stationary KvM equation:

$$X_N+c_{N1}X_{N-1}+\cdots+c_{NN}X_0=0. \tag{4.2}$$

Proof: Define a polynomial

$$\alpha(\lambda^2)=\prod_{j=1}^{N}(\lambda^2-\alpha_j^2)=\lambda^{2N}+\alpha_{N1}\lambda^{2N-2}+\cdots+\alpha_{NN}. \tag{4.3}$$

Let $\lambda=\alpha_j$. A linear combination of Eq. (4.1) with the coefficients $\alpha_{NN},\cdots,\alpha_{N1},1$ yields

$$0=\sum_{j=1}^{N}\alpha(\alpha_j^2)\alpha_j q_j^2=g_N+c_{N1}g_{N-1}+\cdots+c_{NN}g_0+c_{N,N+1}g_{-1},$$

which becomes Eq. (4.2) after being acted with J.

Proposition 4.2: Under the Bargmann constraint (3.4), G_λ and g_λ have a direct relation:

$$G_\lambda=c_\lambda g_\lambda, \tag{4.4}$$

where c_λ is the generating function of the coefficients $\{c_k\}$ in Eq. (4.1),

$$c_\lambda=1+\sum_{k=2}^{\infty}c_k\lambda^{-2k}. \tag{4.5}$$

Proof: Multiplied by λ^{-k-1} and summed with respect to k from 0 to ∞, the linear combination of Eq. (4.1) becomes Eq. (4.4).

As a corollary we have the following expressions for the Lax matrix V_λ and the generation function F_λ of the conserved integrals:

$$V_\lambda=c_\lambda\sigma_\lambda[g_\lambda], \tag{4.6}$$

$$F_\lambda=-c_\lambda^2\lambda^4, \tag{4.7}$$

where Eq. (2.10) is used. Introduce H_λ by $c_\lambda=1+2H_\lambda$. Then

$$(1+2H_\lambda)^2=-\frac{1}{\lambda^4}F_\lambda, \tag{4.8}$$

from which the coefficients $\{H_m\}$ of the expansion

$$H_\lambda=\sum_{m=0}^{\infty}\frac{H_m}{\lambda^{2m+4}} \tag{4.9}$$

are determined uniquely ($c_{k+2}=2H_k$),

$$\begin{aligned}&H_0=-\tfrac{1}{4}F_0,\quad H_1=-\tfrac{1}{4}F_1,\\ &H_m=-\tfrac{1}{4}F_m-\sum_{\substack{i+j=m-2\\ i,\,j\geqslant 0}}H_iH_j,\quad m=2,3,4,\ldots.\end{aligned} \tag{4.10}$$

Specifically,

$$H_0=\langle A^2p,q\rangle-\langle Ap,p\rangle-\langle p,q\rangle\langle Aq,q\rangle+\langle p,q\rangle^2. \tag{4.11}$$

We shall see later (in Sec. VIII) that the integral H_0 is the starting point to link up the discrete 2+1 model (1.6) and the continuous 2+1 model (1.11).

Denote the variables of the H_λ- and H_m-flows by τ_λ and τ_m, respectively. Resorting to Eqs. (3.1) and (3.16), we have the evolution equation of $a=f_{\mathcal{S}}(p,q)$ alone these flows:

$$\frac{\mathrm{d}a}{\mathrm{d}t_\lambda}=-4\lambda^4JG_\lambda, \tag{4.12}$$

$$\frac{\mathrm{d}a}{\mathrm{d}\tau_\lambda}=\frac{1}{\lambda^2}Jg_\lambda, \tag{4.13}$$

in virtue of

$$\frac{\mathrm{d}}{\mathrm{d}\tau_\lambda}=\frac{-1}{4\lambda^4c_\lambda}\frac{\mathrm{d}}{\mathrm{d}t_\lambda}, \tag{4.14}$$

which is a corollary of Eq. (4.8). Comparing the coefficients in the asymptotic expansions of both sides of Eq. (4.13), we get

$$\frac{\mathrm{d}a}{\mathrm{d}\tau_m}=Jg_m=X_m. \tag{4.15}$$

Theorem 4.3: Let $(p(n,\tau_m),q(n,\tau_m)^T$ be a compatible solution of the discrete flow (3.6) ($\mathcal{S}$-flow for short) and the H_m-flow:

$$\frac{\mathrm{d}}{\mathrm{d}\tau_m}\begin{pmatrix}p\\q\end{pmatrix}=I\nabla H_m=\begin{pmatrix}-\partial H_m/\partial p\\ \partial H_m/\partial q\end{pmatrix}. \tag{4.16}$$

Then $a(n,\tau_m)=f_{\mathcal{S}}(p(n,\tau_m),q(n,\tau_m))$ solves the mth KvM equation (4.15).

Theorem 4.4: Let $(p(n,x,y),q(n,x,y)^T$ be a compatible solution of the $\mathcal{S}$-flow, H_0-flow, and H_1-flow with $x=\tau_0,y=\tau_1$. Then

$$B(n,x,y)=\langle Aq(n,x,y),q(n,x,y)\rangle-\langle p(n,x,y),q(n,x,y)\rangle \tag{4.17}$$

is a solution of the discrete 2+1 dimensional Burgers equation (1.6).

Proposition 4.5:

$$\mathrm{d}f_{\mathcal{S}}(p,q):\quad I\nabla H_m\to X_m. \tag{4.18}$$

Proof:

$$X_m=\frac{\mathrm{d}a}{\mathrm{d}\tau_m}=\mathrm{d}f_{\mathcal{S}}(p,q)\left[\frac{\mathrm{d}}{\mathrm{d}\tau_m}\begin{pmatrix}p\\q\end{pmatrix}\right]=\mathrm{d}f_{\mathcal{S}}[I\nabla H_m].$$

Decomposition diagram: discrete $\mathcal{S}$ flow / continuous H_m flow → KvM flow X_m. (4.19)

V. STRAIGHTENING OUT OF THE CONTINUOUS H_k-FLOW

In later analysis, especially in the construction of the algebraic curve Γ, it is indispensable to consider the analytic dependence upon $\zeta=\lambda^2$, rather than λ. Note that $F_\lambda,\lambda^{-1}V_\lambda^{12},\lambda^{-1}V_\lambda^{21}$ are rational functions of $\zeta=\lambda^2$ with simple poles at $\zeta=\alpha_j^2$, which are factorized as:

$$F_\lambda = -V_\lambda^{12}V_\lambda^{21} - (V_\lambda^{11})^2 = \frac{-\zeta\beta(\zeta)}{\alpha(\zeta)} = \frac{-R(\zeta)}{\alpha^2(\zeta)}, \tag{5.1}$$

$$V_\lambda^{12} = 2\lambda[\langle p,q\rangle + Q_\zeta(Ap,p)] = 2\lambda\langle p,q\rangle\frac{m(\zeta)}{\alpha(\zeta)}, \tag{5.2}$$

$$V_\lambda^{21} = -2\lambda[1 + Q_\zeta(Aq,q)] = -2\lambda\frac{n(\zeta)}{\alpha(\zeta)}, \tag{5.3}$$

where

$$\alpha(\zeta) = \prod_{j=1}^{N}(\zeta - \alpha_j^2), \quad \beta(\zeta) = \prod_{j=1}^{N+1}(\zeta - \beta_j^2),$$

$$R(\zeta) = \zeta\alpha(\zeta)\beta(\zeta) = \zeta\prod_{j=1}^{2N+1}(\zeta - \zeta_j), \tag{5.4}$$

$$m(\zeta) = \prod_{j=1}^{N}(\zeta - \gamma_j), \quad n(\zeta) = \prod_{j=1}^{N}(\zeta - \varepsilon_j).$$

with $\zeta_j = \alpha_j^2, j = 1,\ldots,N; \zeta_{N+j} = \beta_j^2, j = 1,\ldots,N+1$. $\{\gamma_j\}$ and $\{\varepsilon_j\}$ are called elliptic coordinates.

Note: $m(\zeta)$ and $n(\zeta)$ are polynomials of ζ, while m and n are indices. The shortage of letters causes the abuse of symbols. There will be no confusion since $m(\zeta)$ and $n(\zeta)$ are used temporarily and do not appear in the final results of this section.

Proposition 5.1:

$$\frac{\langle Ap,p\rangle}{\langle p,q\rangle} = \sum_{j=1}^{N}(\alpha_j^2 - \gamma_j), \quad \langle Aq,q\rangle = \sum_{j=1}^{N}(\alpha_j^2 - \epsilon_j), \tag{5.5}$$

$$\partial_x \ln a(n-1) = \sum_{j=1}^{N}(\gamma_j(n) - \epsilon_j(n)). \tag{5.6}$$

Proof: The first asymptotic terms of Eqs. (5.2) and (5.3) give rise to Eq. (5.5). By Eq. (4.11), the canonical system of the H_0-flow is

$$\begin{aligned} p_x &= (-A^2 + \langle Aq,q\rangle - 2\langle p,q\rangle)p + 2\langle p,q\rangle Aq, \\ q_x &= (A^2 - \langle Aq,q\rangle + 2\langle p,q\rangle)q - 2Ap. \end{aligned} \tag{5.7}$$

Thus

$$\langle p,q\rangle_x = 2\langle p,q\rangle\langle Aq,q\rangle - 2\langle Ap,p\rangle,$$

$$\partial_x \ln a^2(n-1) = \partial_x \ln\langle p,q\rangle = 2\langle Aq,q\rangle - 2\frac{\langle Ap,p\rangle}{\langle p,q\rangle} = 2\sum_{j=1}^{N}(\gamma_j - \epsilon_j).$$

The calculation of the evolution of the elliptic coordinates along the F_λ-flow is based on the components of the Lax equation (3.18):

$$\frac{\mathrm{d}}{\mathrm{d}t_\lambda} V_\mu^{12} = -2W_{\lambda\mu}^{12}V_\mu^{11} + 2W_{\lambda\mu}^{11}V_\mu^{12},$$

$$\frac{\mathrm{d}}{\mathrm{d}t_\lambda} V_\mu^{21} = 2W_{\lambda\mu}^{21}V_\mu^{11} - 2W_{\lambda\mu}^{11}V_\mu^{21},$$

and (5.1) with $\zeta=\gamma_k$ and ε_k, respectively:

$$V_\lambda^{11}|_{\zeta=\gamma_k} = \frac{[R(\gamma_k)]^{1/2}}{\alpha(\gamma_k)}, \quad V_\lambda^{11}|_{\zeta=\epsilon_k} = \frac{[R(\epsilon_k)]^{1/2}}{\alpha(\epsilon_k)}.$$

Differentiate Eqs. (5.2) and (5.3) with respect to t_λ, and let $\zeta=\gamma_k$ and ϵ_k, respectively. Then we have

$$\begin{aligned}\frac{1}{2\sqrt{R(\gamma_k)}}\frac{\mathrm{d}\gamma_k}{\mathrm{d}t_\lambda} &= -\frac{4\zeta m(\zeta)}{\alpha(\zeta)(\zeta-\gamma_k)m'(\gamma_k)},\\ \frac{1}{2\sqrt{R(\epsilon_k)}}\frac{d\epsilon_k}{\mathrm{d}t_\lambda} &= \frac{4\zeta n(\zeta)}{\alpha(\zeta)(\zeta-\epsilon_k)n'(\epsilon_k)}.\end{aligned} \tag{5.8}$$

Resorting to the interpolation formula, we have ($j=1,2,\ldots,N$)

$$\begin{aligned}\sum_{k=1}^{N}\frac{\gamma_k^{N-j}}{2\sqrt{R(\gamma_k)}}\frac{\mathrm{d}\gamma_k}{\mathrm{d}t_\lambda} &= -\frac{4\zeta^{N-j+1}}{\alpha(\zeta)},\\ \sum_{k=1}^{N}\frac{\epsilon_k^{N-j}}{2\sqrt{R(\varepsilon_k)}}\frac{\mathrm{d}\epsilon_k}{\mathrm{d}t_\lambda} &= \frac{4\zeta^{N-j+1}}{\alpha(\zeta)}.\end{aligned} \tag{5.9}$$

These formulas lead naturally to the consideration of the elliptic curve Γ given by the affine equation, $\xi^2 - R(\zeta) = 0$. The genus is $g=N$ since $\deg R = 2N+2$. Denote $P(\zeta) = (\zeta, \xi = \sqrt{R(\zeta)})$. The usual holomorphic differentials on Γ:

$$\tilde{\omega}_j = \frac{\zeta^{g-j}\,\mathrm{d}\zeta}{2\sqrt{R(\zeta)}}, \quad j=1,\ldots,g \tag{5.10}$$

imply the introduction of the quasi-Abel–Jacobi coordinates:

$$\tilde{\phi}_j = \sum_{P\in D_1}\int_{P_0}^{P}\tilde{\omega}_j, \quad \tilde{\psi}_j = \sum_{P\in D_2}\int_{P_0}^{P}\tilde{\omega}_j, \tag{5.11}$$

with fixed point $P_0\in\Gamma$ and the divisors: $D_1 = \Sigma_1^g P(\gamma_k)$, $D_2 = \Sigma_1^g P(\epsilon_k)$, which make Eq. (5.9) very simple:

$$\frac{\mathrm{d}\tilde{\phi}_j}{\mathrm{d}t_\lambda}=-\frac{4\zeta^{g-j+1}}{\alpha(\zeta)},\quad \frac{\mathrm{d}\tilde{\psi}_j}{\mathrm{d}t_\lambda}=\frac{4\zeta^{g-j+1}}{\alpha(\zeta)}. \tag{5.12}$$

Hence

$$\frac{\mathrm{d}\tilde{\phi}_j}{\mathrm{d}\tau_\lambda}=\frac{\zeta^{g-j}}{\sqrt{R(\zeta)}},\quad \frac{\mathrm{d}\tilde{\psi}_j}{\mathrm{d}\tau_\lambda}=-\frac{\zeta^{g-j}}{\sqrt{R(\zeta)}} \tag{5.13}$$

by (4.14), (4.8), and (5.1).

The Abel–Jacobi coordinates are obtained through some normalization. Let $a_1,b_1,\ldots,a_g,b_g$ be the canonical basis of the homology group of cycles on Γ, and $C=(A_{jk})_{g\times g}^{-1}$, where A_{jk} is equal to the integral of $\tilde{\omega}_j$ along the path a_k. Then we have the normalized holomorphic differential $\omega=C\tilde{\omega}$ with the following properties:

$$\int_{a_k}\omega_j=\delta_{jk},\quad \int_{b_k}\omega_j=B_{jk}, \tag{5.14}$$

where the matrix $B=(B_{jk})$ is symmetric and has positively definite imaginary part and is used to construct the Riemann theta function of Γ.[16,17,40,41] The Abel map is defined as

$$\mathcal{A}(P)=\int_{P_0}^{P}\omega$$

and is extended linearly to the whole divisor group of Γ, $\mathcal{A}$: $\mathrm{Div}(\Gamma)\to\mathcal{J}(\Gamma)=\mathbb{C}^g/\mathcal{T}$, where the lattice $\mathcal{T}$ is spanned by the periodic vectors $\{\delta_k,B_k\}$ with components given by Eq. (5.14). The Abel–Jacobi coordinates are defined as

$$\phi=\mathcal{A}(D_1)=C\tilde{\phi},\quad \psi=\mathcal{A}(D_2)=C\tilde{\psi}. \tag{5.15}$$

Theorem 5.2 (Straightening out of the continuous flow): The H_k-flow is straightened out by the Abel–Jacobi coordinates:

$$\frac{\mathrm{d}\phi}{\mathrm{d}\tau_k}=\Omega_k,\quad \frac{\mathrm{d}\psi}{\mathrm{d}\tau_k}=-\Omega_k, \tag{5.16}$$

where the angular speed Ω_k is determined as the coefficient in the asymptotic expansion of the normalized holomorphic differential ω at infinities $\infty_s(s=1,2)$ with $z=\zeta^{-1}$:

$$\omega=\frac{1}{2}(-1)^{s-1}\sum_{k=0}^{\infty}\Omega_k z^k\,\mathrm{d}z. \tag{5.17}$$

The proof is completed with the help of the following lemmas, which also give the algorithm to calculate Ω_k.

Lemma 5.3: Let $S_k=\zeta_1^k+\cdots+\zeta_{2g+1}^k$. Then the coefficients in

$$\frac{\zeta^{g+1}}{\sqrt{R(\zeta)}}=\sum_{k=0}^{\infty}\Lambda_k\zeta^{-k} \tag{5.18}$$

are determined by the recursive formula

$$\Lambda_0=1,\quad \Lambda_1=\tfrac{1}{2}S_1,$$
$$\Lambda_k=\frac{1}{2k}\left(S_k+\sum_{\substack{i+j=k\\ i,j\geqslant 1}} S_i\Lambda_j\right). \tag{5.19}$$

Lemma 5.4: Let $C_1,\ldots,C_g$ be the column vectors of C. Then the coefficients in

$$\frac{\zeta^{g+1}}{\sqrt{R(\zeta)}}(C_1\zeta^{-1}+\cdots+C_g\zeta^{-g})=\sum_{k=0}^{\infty}\Omega_k\zeta^{-k-1} \tag{5.20}$$

are written as

$$\Omega_k=\Lambda_kC_1+\Lambda_{k-1}C_2+\cdots+\Lambda_1C_k \tag{5.21}$$

with supplementary defined $\Lambda_{-s}=0$, $s=1,2,\ldots$. Specifically:

$$\Omega_0=C_1,\quad \Omega_1=\Lambda_1C_1+C_2,\quad \Omega_2=\Lambda_2C_1+\Lambda_1C_2+C_3. \tag{5.22}$$

Proof of theorem 5.2:

$$\frac{\mathrm{d}\phi}{\mathrm{d}\tau_\lambda}=C\frac{\mathrm{d}\tilde{\phi}}{\mathrm{d}\tau_\lambda}=\left(C_1\frac{\mathrm{d}\tilde{\phi}_1}{\mathrm{d}\tau_\lambda}+\cdots+C_g\frac{\mathrm{d}\tilde{\phi}_g}{\mathrm{d}\tau_\lambda}\right)=(C_1\zeta^{-1}+\cdots+C_g\zeta^{-g})\frac{\zeta^g}{\sqrt{R(\zeta)}}=\sum_{k=0}^{\infty}\Omega_k\zeta^{-k-2},$$

$$\frac{\mathrm{d}\phi}{\mathrm{d}\tau_\lambda}=(\phi,H_\lambda)=\sum_{k=0}^{\infty}(\phi,H_k)\zeta^{-k-2}.$$

Hence $(\phi,H_k)=\Omega_k$. The second equation of (5.16) is obtained similarly. Note that for the same ζ there are two corresponding points $P(\zeta)=(\zeta,\sqrt{R(\zeta)})$ and $P^-(\zeta)=(\zeta,-\sqrt{R(\zeta)})$ on the upper and lower sheets of Γ, respectively. Thus in the local coordinate $z=\zeta^{-1}$ near the infinities $\infty_s(s=1,2)$, we have

$$\omega=C\tilde{\omega}=C_1\tilde{\omega}_1+\cdots+C_g\tilde{\omega}_g=(C_1\zeta^{-1}+\cdots+C_g\zeta^{-g})\frac{\zeta^g\,\mathrm{d}\zeta}{2[R(\zeta)]^{1/2}}$$

$$=\frac{1}{2}(-1)^s\sum_{k=0}^{\infty}\Omega_k\zeta^{-k-2}\,\mathrm{d}\zeta=\frac{1}{2}(-1)^{s-1}\sum_{k=0}^{\infty}\Omega_kz^k\,\mathrm{d}z.$$

Note: It is in this section (and only in this section) that a_k and B_k are used to designate the cycle and periodic vector, respectively. In other sections, they have different meaning. There is some abuse of letters, but no confusion.

VI. STRAIGHTENING OUT OF THE DISCRETE FLOW $\mathcal{S}^n$

In the present section p and q are designated as scalars, not N dimensional vectors. It would not cause any confusion since no p,q are contained in the final results of this section. Consider the discrete eigenvalue problem

$$\chi(n+1)=U_n\chi(n),\quad U_n=\frac{1}{a(n)}\begin{pmatrix}0 & a^2(n)\\ -1 & \lambda\end{pmatrix}. \tag{6.1}$$

with $\chi(n)=(p(n),q(n))^T$. The fundamental solution matrix

$$M(n)=(\chi^{(1)}(n),\chi^{(2)}(n))=\begin{pmatrix} p^{(1)}(n) & p^{(2)}(n) \\ q^{(1)}(n) & q^{(2)}(n) \end{pmatrix}, \quad M(0)=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

has an explicit expression:

$$M(n+1)=U_nU_{n-1}\cdots U_0. \tag{6.2}$$

Denote $a_k=a(k)$ for short. By mathematical induction, we have

$$M(1)=\frac{1}{a_0}\begin{pmatrix} 0 & a_0^2 \\ -1 & \lambda \end{pmatrix}, \quad M(2)=\frac{1}{a_0a_1}\begin{pmatrix} -a_1^2 & a_1^2\lambda \\ -\lambda & \lambda^2-a_0^2 \end{pmatrix},$$

$$M(3)=\frac{1}{a_0a_1a_2}\begin{pmatrix} -a_2^2\lambda & a_2^2\lambda^2-a_0^2a_2^2 \\ -\lambda^2+a_1^2 & \lambda^3-(a_0^2+a_1^2)\lambda \end{pmatrix},$$

$$M(4)=\frac{1}{a_0a_1a_2a_3}\begin{pmatrix} -a_3^2\lambda^2+a_1^2a_3^2 & a_3^2\lambda^3-(a_0^2+a_1^2)a_3^2\lambda \\ -\lambda^3+(a_1^2+a_2^2)\lambda & \lambda^4-(a_0^2+a_1^2+a_2^2)\lambda^2+a_0^2a_2^2 \end{pmatrix},$$

$$p^{(1)}(n)=\frac{-a(n-1)}{a(0)\cdots a(n-2)}\left\{\lambda^{n-2}-\left[\sum_{j=1}^{n-3}a^2(j)\right]\lambda^{n-4}+\cdots\right\}, \tag{6.3}$$

$$p^{(2)}(n)=\frac{a(n-1)}{a(0)\cdots a(n-2)}\left\{\lambda^{n-1}-\left[\sum_{j=0}^{n-3}a^2(j)\right]\lambda^{n-3}+\cdots\right\},$$

$$q^{(1)}(n)=\frac{-1}{a(0)\cdots a(n-1)}\left\{\lambda^{n-1}-\left[\sum_{j=1}^{n-2}a^2(j)\right]\lambda^{n-3}+\cdots\right\},$$

$$q^{(2)}(n)=\frac{1}{a(0)\cdots a(n-1)}\left\{\lambda^{n}-\left[\sum_{j=0}^{n-2}a^2(j)\right]\lambda^{n-2}+\cdots\right\}.$$

Lemma 6.1: The following functions are polynomials of $\zeta=\lambda^2$ with degrees as tabled:

$\lambda^{-1}p^{(1)}(2k-1)$	$k-2$	$p^{(1)}(2k)$	$k-1$
$p^{(2)}(2k-1)$	$k-1$	$\lambda^{-1}p^{(2)}(2k)$	$k-1$
$q^{(1)}(2k-1)$	$k-1$	$\lambda^{-1}q^{(1)}(2k)$	$k-1$
$\lambda^{-1}q^{(2)}(2k-1)$	$k-1$	$q^{(2)}(2k)$	k

The discrete commutative equation (3.11) satisfied by the Lax matrix V_λ is the key to straightening out the discrete flow generated by the symplectic map $\mathcal{S}$. It implies that the solution space of the linear equation (6.1): $E\chi=U\chi$ is invariant under the action of V_λ. Let ρ and χ be the eigenvalue and eigenfunction, respectively, of the linear operator V_λ in the solution space. Then they satisfy:

$$E\chi=U\chi, \quad V_\lambda\chi=\rho\chi. \tag{6.4}$$

Evidently $\det|\rho-V_\lambda|=\rho^2+F_\lambda=0$, which yields the algebraic curve Γ used in Sec. V. There are two eigenvalues $\rho^\pm=\pm\rho$, whereby Eqs. (5.1), (4.7), and (4.8):

$$\rho=\lambda^2(1+2H_\lambda)=\frac{[R(\zeta)]^{1/2}}{\alpha(\zeta)}. \tag{6.5}$$

Proposition 6.2: The eigenvalue ρ of the Lax matrix V_λ is the generating function of the conserved integrals $\{H_m\}$ of the symplectic map $\mathcal{S}$.

The eigenfunction of the Lax matrix V_λ is called the Baker function after some kind of normalization. It could be taken as

$$\chi^{\pm}(n)=c^{\pm}\chi^{(1)}(n)+\chi^{(2)}(n), \tag{6.6}$$

where

$$c^{\pm}=\frac{V_\lambda^{11}(0)\pm\rho}{V_\lambda^{21}(0)}=\frac{-V_\lambda^{12}(0)}{V_\lambda^{11}(0)\mp\rho}. \tag{6.7}$$

The proof is based on the equation

$$0=(V_\lambda(n)\mp\rho)\chi^{\pm}(n)=(V_\lambda(n)\mp\rho)M(n)\begin{pmatrix} c^{\pm} \\ 1 \end{pmatrix},$$

which yields Eq. (6.7) after letting $n=0$. There is a wonderful relation between the elliptic coordinates and the Baker function.

Proposition 6.3 (formula of Dubrovin–Novikov type): Let $q^{\pm}(n,\lambda)$ be the second component of the Baker function $\chi^{\pm}(n,\lambda)$. Then

$$q^{+}(n,\lambda)q^{-}(n,\lambda)=\frac{V_\lambda^{21}(n)}{V_\lambda^{21}(0)}=\prod_{j=1}^{N}\frac{\lambda^2-\epsilon_j(n)}{\lambda^2-\epsilon_j(0)}. \tag{6.8}$$

Proof: Resorting to Eqs. (3.11) and (6.2), we have

$$V_\lambda(n)M(n)=M(n)V_\lambda(0), \tag{6.9}$$

which serves as the main tool in the direct calculation to derive Eq. (6.8).

Proposition 6.4: For $\lambda\to\infty$,

$$q^{+}(n,\lambda)=\frac{\lambda^n}{a(0)\cdots a(n-1)}[1+O(\lambda^{-2})], \tag{6.10}$$

$$q^{-}(n,\lambda)=a(0)\cdots a(n-1)\lambda^{-n}[1+O(\lambda^{-2})]. \tag{6.11}$$

Proof: By Eqs. (3.13), (6.5), and (5.3), we have

$$V_\lambda^{11}=-\lambda^2-2\lambda^2Q_\zeta(p,q)=-\lambda^2-2\langle p,q\rangle+O(\lambda^{-2}), \tag{6.12}$$

$$\rho=\lambda^2+2\lambda^2H_\lambda=\lambda^2+O(\lambda^{-2}),\quad V_\lambda^{21}(0)=-2\lambda+O(\lambda^{-1}). \tag{6.13}$$

Substituting into Eq. (6.7), we get

$$c^{+}=\langle p,q\rangle\lambda^{-1}+O(\lambda^{-3}),\quad c^{-}=\lambda+O(\lambda^{-1}). \tag{6.14}$$

Put this and Eq. (6.3) into $q^{+}=c^{+}q^{(1)}+q^{(2)}$, and we have Eq. (6.10). The estimation Eq. (6.11) for q^{-} is obtained from Eq. (6.10) and $q^{+}q^{-}=1+O(\lambda^{-2})$, which is a corollary of the Dubrovin–Novikov formula (6.8).

According to Eqs. (5.2), (5.3), (6.12), and (6.3), λc^{+} and λc^{-} are analytic functions of ζ, which can be regarded as the values of the single-valued function $[\lambda c](P)$ on the upper and lower sheets of Γ. Furthermore, resorting to Lemma 6.1 and the following expressions:

$$q^{\pm}(2k,\lambda)=(\lambda c^{\pm})\left\{\frac{1}{\lambda}q^{(1)}(2k,\lambda)\right\}+q^{(2)}(2k,\lambda),$$

$$\lambda q^{\pm}(2k-1,\lambda)=(\lambda c^{\pm})q^{(1)}(2k-1,\lambda)+\zeta\left\{\frac{1}{\lambda}q^{(2)}(2k-1,\lambda)\right\},$$

we have two meromorphic functions on Γ: $q(2k,P)$ and $[\lambda q](2k-1,P)$.

In the local coordinates $z=\zeta^{-1},\hat{\xi}=\zeta^{-N-1}\xi$, the equation of Γ near infinity is written as

$$\hat{\xi}^2-R_*(z)=0,\quad R_*=\prod_{j=1}^{2N+1}(1-\zeta_j z). \tag{6.15}$$

There are two infinities $\infty_s=(z=0,\hat{\xi}=(-1)^s)$, $s=1,2$, located on the upper ($s=2$) and lower ($s=1$) sheets, respectively. By Proposition 6.4, the principal asymptotic terms of $q(2k,P)$ near ∞_2 and ∞_1 are

$$\frac{z^{-k}}{a(0)\cdots a(2k-1)},\quad a(0)\cdots a(2k-1)z^k,$$

respectively, while those of $[\lambda q](2k-1,P)$ are

$$\frac{z^{-k}}{a(0)\cdots a(2k-2)},\quad a(0)\cdots a(2k-2)z^{k-1},$$

respectively. Based on the Dubrovin-Novikov formula (6.8) and through an elementary analysis, we have

Proposition 6.5: The Baker function $q(2k,P)$ has

(i) g simple poles at $\epsilon_1(0),\ldots,\epsilon_g(0)$ and a pole of kth order at ∞_2;

(ii) g simple zeros at $\epsilon_1(2k),\ldots,\epsilon_g(2k)$ and a zero of the kth order at ∞_1. The Baker function $[\lambda q](2k-1,P)$ has

(i) g simple poles at $\epsilon_1(0),\ldots,\epsilon_g(0)$ and a pole of kth order at ∞_2;

(ii) $g+1$ simple zeros at $0,\epsilon_1(2k-1),\ldots,\epsilon_g(2k-1)$ and a zero of the $(k-1)$th order at ∞_1.

Note: In the above-given expressions, we use ϵ_j, instead of $(\epsilon_j,\sqrt{R(\epsilon_j)})$, for short.

Theorem 6.6 (Straightening out of the discrete flow):

$$\psi(2k)-\psi(0)\equiv k\Omega_{\mathcal{S}}\pmod{\mathcal{T}}, \tag{6.16}$$

$$\psi(2k-1)-\psi(0)\equiv k\Omega_{\mathcal{S}}-\eta_1\pmod{\mathcal{T}}, \tag{6.17}$$

or

$$\psi(n)-\psi(0)\equiv\frac{n}{2}\Omega_{\mathcal{S}}+\frac{(-1)^n-1}{4}(\eta_1+\eta_2),\pmod{\mathcal{T}}, \tag{6.18}$$

where $\mathcal{T}$ is the lattice spanned by the periodic vectors and

$$\Omega_{\mathcal{S}}=\int_{\infty_1}^{\infty_2}\omega,\quad \eta_s=\int_{\infty_s}^{P_0}\omega,\quad (s=1,2), \tag{6.19}$$

with $P_0=(0,\sqrt{R(0)})$.

Proof: For $n=2k$, consider the meromorphic differential on Γ:

$$\omega_{\mathcal{S}}(2k)=\left\{\frac{\mathrm{d}}{\mathrm{d}\zeta}\ln q(2k,P)\right\}\mathrm{d}\zeta \tag{6.20}$$

with the residue $-1,1$ at $\epsilon_j(0),\epsilon_j(2k)$, respectively, and the residue $-k,k$ at ∞_2,∞_1, respectively. Expand Eq. (6.20) as a linear combination[13,40]

$$\omega_{\mathcal{S}}(2k)=\Omega+k\omega[\infty_1,\infty_2]+\sum_{j=1}^{g}\omega[\epsilon_j(2k),\epsilon_j(0)]+\sum_{j=1}^{g}e_j\omega_j, \tag{6.21}$$

where ω_j is the normalized Abel differential of the first kind given by Eq. (5.14), Ω is the Abel differential of the second kind, and $\omega(P,Q)$ is the Abel differential of the third kind with the residue $1,-1$ at P,Q, respectively, and the properties

$$\int_{a_j}\omega(P,Q)=0,\quad \int_{b_j}\omega(P,Q)=2\pi\sqrt{-1}\int_{Q}^{P}\omega_j.$$

Integrating (6.21) along a_i and b_i, we have

$$\sum_{j=1}^{g}\int_{\epsilon_j(0)}^{\epsilon_j(2k)}\omega=k\int_{\infty_1}^{\infty_2}\omega+\sum_{j=1}^{g}(n_jB_j+m_j\delta_j),$$

for some integers n_j,m_j. This completes the proof of Eq. (6.16).

For $n=2k-1$, consider the meromorphic differential

$$\begin{aligned}\omega_{\mathcal{S}}(2k-1)&=\left\{\frac{\mathrm{d}}{\mathrm{d}\zeta}\ln[\lambda q](2k-1,P)\right\}\mathrm{d}\zeta=\Omega+(k-1)\omega[\infty_1,\infty_2]+\omega[0,\infty_2]\\&\quad+\sum_{j=1}^{g}\omega[\epsilon_j(2k-1),\epsilon_j(0)]+\sum_{j=1}^{g}e_j\omega_j.\end{aligned} \tag{6.22}$$

Similar treatments lead to the proof of Eq. (6.17).

In order to investigate the evolution of anther Abel–Jacobi coordinate ϕ along the discrete flow generated by the symplectic map $\mathcal{S}$, consider the Baker function with the following normalization:

$$\begin{aligned}p^{\pm}(n,\lambda)&=p^{(1)}(n,\lambda)+d^{\pm}p^{(2)}(n,\lambda),\\d^{\pm}&=(c^{\pm})^{-1}=-\frac{V_\lambda^{11}(0)\mp\rho}{V_\lambda^{12}(0)}.\end{aligned} \tag{6.23}$$

In a similar way, we have:

Proposition 6.7:

$$p^{+}(n,\lambda)p^{-}(n,\lambda)=\frac{V_\lambda^{12}(n)}{V_\lambda^{12}(0)}=\prod_{j=1}^{g}\frac{\zeta-\gamma_j(n)}{\zeta-\gamma_j(0)}, \tag{6.24}$$

$$\begin{aligned}p^{+}(n,\lambda)&=\frac{a(n-1)\lambda^n}{\langle p,q\rangle a(0)\cdots a(n-2)}[1+O(\lambda^{-2})],\\p^{-}(n,\lambda)&=\frac{\langle p,q\rangle a(0)\cdots a(n-2)\lambda^{-n}}{a(n-1)}[1+O(\lambda^{-2})].\end{aligned} \tag{6.25}$$

The functions $p(2k,P)$ and $[\lambda p](2k-1,P)$ are defined similarly, by which we construct the meromorphic differentials

$$\omega_{\mathcal{S}}(2k)=\left\{\frac{\mathrm{d}}{\mathrm{d}\zeta}\ln p(2k,P)\right\}\mathrm{d}\zeta, \tag{6.26}$$

$$\omega_{\mathcal{S}}(2k-1)=\left\{\frac{\mathrm{d}}{\mathrm{d}\zeta}\ln[\lambda p](2k-1,P)\right\}\mathrm{d}\zeta. \tag{6.27}$$

$\omega_{\mathcal{S}}(2k)$ has the residue $k,-k,1,-1$, at $\infty_1,\infty_2,\gamma_j(2k),\gamma_j(0)$, respectively, while $\omega_{\mathcal{S}}(2k-1)$ has the residue $k-1,-k,1,1,-1$, at $\infty_1,\infty_2,0,\gamma_j(2k-1),\gamma_j(0)$, respectively. Having these preparations, finally we obtain:

Theorem 6.8 (Straightening out of the discrete flow):

$$\phi(2k)-\phi(0)\equiv k\Omega_{\mathcal{S}},\quad (\mathrm{mod}\,\mathcal{T}), \tag{6.28}$$

$$\phi(2k-1)-\phi(0)\equiv k\Omega_{\mathcal{S}}-\eta_1,\quad (\mathrm{mod}\,\mathcal{T}), \tag{6.29}$$

or

$$\phi(n)-\phi(0)\equiv\frac{n}{2}\Omega_{\mathcal{S}}+\frac{(-1)^n-1}{4}(\eta_1+\eta_2),\quad (\mathrm{mod}\,\mathcal{T}). \tag{6.30}$$

Now we have a clear evolution picture of the continuous H_m-flows and discrete $\mathcal{S}$-flow in the ''window'' of the Abel–Jacobi coordinates: (i) they are straightened out and have uniform velocities; (ii) they commute each other. Therefore, the compatible solution of various flow is obtained simply through a linear superposition. Specifically, for the KvM equation (2.11) with the label m we have

$$\begin{aligned}\phi(n,\tau_m)&=\frac{n}{2}\Omega_{\mathcal{S}}+\tau_m\Omega_m+\frac{(-1)^n-1}{4}(\eta_1+\eta_2)+\phi_0,\\ \psi(n,\tau_m)&=\frac{n}{2}\Omega_{\mathcal{S}}-\tau_m\Omega_m+\frac{(-1)^n-1}{4}(\eta_1+\eta_2)+\psi_0,\end{aligned} \tag{6.31}$$

based on the decomposition diagram (4.19). Moreover, for the 2+1 Burgers equation (1.6) with a discrete variable, we have

$$\begin{aligned}\phi(n,x,y)&=\frac{n}{2}\Omega_{\mathcal{S}}+x\Omega_0+y\Omega_1+\frac{(-1)^n-1}{4}(\eta_1+\eta_2)+\phi_0,\\ \psi(n,x,y)&=\frac{n}{2}\Omega_{\mathcal{S}}-x\Omega_m-y\Omega_1+\frac{(-1)^n-1}{4}(\eta_1+\eta_2)+\psi_0,\end{aligned} \tag{6.32}$$

based on the decomposition diagram (1.10).

VII. INVERSION. ALGEBRO-GEOMETRIC SOLUTION

Equation (6.32) gives the explicit solution of the 2+1 Burgers equation (1.6) with a discrete variable in the Abel–Jacobi coordinates (ϕ,ψ). In order to get the solution in the original coordinate B, the following steps should be completed:

$$(\phi,\psi)\to(\gamma_j,\epsilon_j)\to a\to B. \tag{7.1}$$

We have $B=a^2$ and

$$\partial_x \ln a(n)=\sum_{j=1}^{g}\left[\gamma_j(n+1)-\epsilon_j(n+1)\right] \tag{7.2}$$

by Eq. (5.6). To express $\Sigma\gamma_j$ and $\Sigma\epsilon_j$ by means of (ϕ,ψ), we use the Riemann theorem,[40,41] which asserts that there exist constant vectors K_1 and K_2 (the Riemann constants) such that $\theta(\mathcal{A}(P(\zeta))-\phi-K_1)$ has exactly g zeros: $\gamma_1,\ldots,\gamma_g$; and $\theta(\mathcal{A}(P(\zeta))-\psi-K_2)$ has exactly g zeros: $\epsilon_1,\ldots,\epsilon_g$ as well. Resorting to the asymptotic expansion (5.17) and through a standard treatment,[16,17] we obtain:

$$\sum_{j=1}^{g}\gamma_j=I_1(\Gamma)-\sum_{s=1}^{2}\operatorname*{Res}_{\infty_s}\zeta d\ln\theta(\mathcal{A}(P(\zeta))-\phi-K_1)=I_1(\Gamma)+\frac{1}{2}\sum_{j=1}^{g}\Omega_0^j\partial_j\ln\frac{\theta(\phi+K_1+\eta_1)}{\theta(\phi+K_1+\eta_2)}, \tag{7.3}$$

$$\sum_{j=1}^{g}\epsilon_j=I_1(\Gamma)-\sum_{s=1}^{2}\operatorname*{Res}_{\infty_s}\zeta d\ln\theta(\mathcal{A}(P(\zeta))-\psi-K_2)=I_1(\Gamma)-\frac{1}{2}\sum_{j=1}^{g}\Omega_0^j\partial_j\ln\frac{\theta(-\psi-K_2-\eta_1)}{\theta(-\psi-K_2-\eta_2)}, \tag{7.4}$$

where ∂_j denotes the differentiation with regard to the jth argument of the theta function and

$$I_k(\Gamma)=\sum_{j=1}^{g}\int_{a_j}\zeta^k\omega_j. \tag{7.5}$$

After these preparations, we transform the solution (6.32) into the original coordinate B through direct calculations.

Theorem 7.1: The $2+1$ dimensional Burgers equation with a discrete argument (1.6) has the quasiperiodic solution:

$$\begin{aligned}
&B(2k-1,x,y)\\
&=\frac{\theta[x\Omega_0+y\Omega_1+(k+1)\Omega_S+\phi_0+K_1+\eta_2]\theta[x\Omega_0+y\Omega_1-(k+1)\Omega_S-\psi_0-K_2-\eta_2]}{\theta[x\Omega_0+y\Omega_1+k\Omega_S+\phi_0+K_1+\eta_2]\theta[x\Omega_0+y\Omega_1-k\Omega_S-\psi_0-K_2-\eta_2]}\\
&\quad\cdot\frac{\theta[y\Omega_1+k\Omega_S+\phi_0+K_1+\eta_2]\theta[y\Omega_1-k\Omega_S-\psi_0-K_2-\eta_2]}{\theta[y\Omega_1+(k+1)\Omega_S+\phi_0+K_1+\eta_2]\theta[y\Omega_1-(k+1)\Omega_S-\psi_0-K_2-\eta_2]}B(2k-1,0,y),
\end{aligned} \tag{7.6}$$

$$\begin{aligned}
B(2k,x,y)&=\frac{\theta[x\Omega_0+y\Omega_1+(k+1)\Omega_S+\phi_0+K_1]\theta[x\Omega_0+y\Omega_1-(k+1)\Omega_S-\psi_0-K_2]}{\theta[x\Omega_0+y\Omega_1+k\Omega_S+\phi_0+K_1]\theta[x\Omega_0+y\Omega_1-k\Omega_S-\psi_0-K_2]}\\
&\quad\cdot\frac{\theta[y\Omega_1+k\Omega_S+\phi_0+K_1]\theta[y\Omega_1-k\Omega_S-\psi_0-K_2]}{\theta[y\Omega_1+(k+1)\Omega_S+\phi_0+K_1]\theta[y\Omega_1-(k+1)\Omega_S-\psi_0-K_2]}B(2k,0,y),
\end{aligned}$$

VIII. THE MODIFIED KADOMTSEV–PETVIASHVILI EQUATION

The canonical equations (5.7) of the Hamiltonian H_0 defined by Eq. (4.11) is put in the linear form

$$\begin{pmatrix}p_j\\q_j\end{pmatrix}_x=\hat{U}(u,v,\alpha_j)\begin{pmatrix}p_j\\q_j\end{pmatrix},\quad \hat{U}(u,v,\lambda)=\begin{pmatrix}-\lambda^2+u & -\lambda v\\ -2\lambda & \lambda^2-u\end{pmatrix} \tag{8.1}$$

with the nonlinearization condition (the Bargmann constraint):

$$\begin{pmatrix}u\\v\end{pmatrix}=\begin{pmatrix}\langle Aq,q\rangle-2\langle p,q\rangle\\ -2\langle p,q\rangle\end{pmatrix}\equiv f_C(p,q). \tag{8.2}$$

In a standard way, Eq. (8.1) leads to the 2+1 dimensional mKP equation (1.11) and its algebro-geometric solution, just as in the above-presented example of the 2+1 Burgers equation and in the previous examples of the KP equation[16,17] and the special 2+1 Toda equation.[17] The general structure and steps are basically the same, though with different features in various continuous and discrete models. We list the main steps and results without proof as follows.

Proposition 8.1 (The fundamental identity): Let $G=(G_1,G_2)^T$ be an arbitrary smooth function of x ($\partial=\partial/\partial_x$), and $\hat{\sigma}$ be a linear operator defined as

$$\hat{V}=\hat{\sigma}(u,v,\lambda)[G]=\{(\tfrac{1}{2}\partial+u-\lambda^2)G_2\}\sigma_1+\{\lambda(\tfrac{1}{2}\partial G_1-vG_2)\}\sigma_2+(-2\lambda G_2)\sigma_3. \tag{8.3}$$

Then

$$\hat{V}_x-[\hat{U},\hat{V}]=\hat{U}_*\{(\hat{K}-\lambda^2\hat{J})G\}, \tag{8.4}$$

where

$$\hat{K}=\begin{pmatrix} 0 & \frac{1}{2}\partial^2+\partial u \\ -\frac{1}{2}\partial^2+u\partial & v\partial+\partial v \end{pmatrix}, \quad \hat{J}=\begin{pmatrix} \partial & \partial \\ \partial & 0 \end{pmatrix}, \tag{8.5}$$

$$\hat{U}_*\begin{pmatrix} \delta u \\ \delta v \end{pmatrix}=\begin{pmatrix} \delta u & -\lambda\delta v \\ 0 & -\delta u \end{pmatrix}. \tag{8.6}$$

The Lenard gradients are defined recursively by $\hat{J}\hat{g}_m=\hat{K}\hat{g}_{m-1}$, with

$$\hat{g}_{-2}=\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \hat{g}_{-1}=\begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad \hat{g}_0=\begin{pmatrix} v \\ u-v \end{pmatrix},$$

$$\hat{g}_1=\begin{pmatrix} -\frac{1}{2}v_x+2uv-\frac{3}{2}v^2 \\ \frac{1}{2}u_x+u^2-3uv+\frac{3}{2}v^2 \end{pmatrix}, \tag{8.7}$$

$$\hat{g}_2=\begin{pmatrix} \frac{1}{4}v_{xx}+\frac{3}{2}vv_x-\frac{3}{2}uv_x+3u^2v-6uv^2+\frac{5}{2}v^3 \\ \frac{1}{4}u_{xx}-\frac{1}{4}v_{xx}+\frac{3}{2}uu_x-\frac{3}{2}u_xv+u^3-6u^2v+\frac{15}{2}uv^2-\frac{5}{2}v^3 \end{pmatrix}, \quad \text{etc.}$$

with

$$\det\hat{\sigma}_\lambda[\hat{g}_\lambda]=-\lambda^4, \quad \hat{g}_\lambda=\hat{g}_{-1}+\sum_{k=0}^{\infty}\hat{g}_k\lambda^{-k-1}. \tag{8.8}$$

The associated soliton vector field is defined as $Y_j=J\hat{g}_j$ with

$$Y_0=\begin{pmatrix} u_x \\ v_x \end{pmatrix}, \quad Y_1=\begin{pmatrix} \partial(\frac{1}{2}u_x-\frac{1}{2}v_x+u^2-uv) \\ \partial(-\frac{1}{2}v_x+2uv-\frac{3}{2}v^2) \end{pmatrix},$$

$$Y_2=\begin{pmatrix} \partial(\frac{1}{4}u_{xx}+\frac{3}{2}(uu_x-u_xv-uv_x+vv_x)+u^3-3u^2v+\frac{3}{2}uv^2) \\ \partial(\frac{1}{4}v_{xx}+\frac{3}{2}(vv_x-uv_x)+3u^2v-6uv^2+\frac{5}{2}v^3) \end{pmatrix}. \tag{8.9}$$

Proposition 8.2: Let $(u(x,y,t),v(x,y,t))$ be the compatible solution of

$$\begin{pmatrix} u \\ v \end{pmatrix}_y = Y_1, \quad \begin{pmatrix} u \\ v \end{pmatrix}_t = Y_2. \tag{8.10}$$

Then $v(x,y,t)$ satisfies the $2+1$ dimensional mKP equation (1.11).

Let $(p_j, q_j)^T$ be the solution of Eq. (8.1). Then

$$\hat{\nabla}\alpha_j = \begin{pmatrix} \delta\alpha_j/\delta u \\ \delta\alpha_j/\delta v \end{pmatrix} = \begin{pmatrix} -2p_jq_j \\ \alpha_j q_j^2 \end{pmatrix}. \tag{8.11}$$

It is easy to see that Eq. (8.2) is equivalent with

$$\hat{g}_0 = \sum_{j=1}^{N} \hat{\nabla}\alpha_j. \tag{8.12}$$

The Lenard eigenvalue problem $(K-\alpha_j^2 J)G=0$ has the solution $\hat{\nabla}\alpha_j$, which is used to construct the solution of $(K-\lambda^2 J)G=0$ with general eigenparameter $\lambda^2=\zeta$;

$$\hat{G}_\lambda = \hat{g}_{-1} + \sum_{j=1}^{N} \frac{\hat{\nabla}\alpha_j}{\lambda^2-\alpha_j^2} = \begin{pmatrix} -2Q_\zeta(p,q) \\ 1+Q_\zeta(Aq,q) \end{pmatrix}, \tag{8.13}$$

under the Bargmann condition (8.2) or (8.12). By the fundamental identity (8.4), the commutator equation $\partial\hat{V}-[\hat{U},\hat{V}]=0$ has a solution

$$\hat{V}_\lambda = \hat{\sigma}[\hat{G}_\lambda] = \begin{pmatrix} -\lambda^2[1+2Q_\zeta(p,q)] & 2\lambda[\langle p,q\rangle + Q_\zeta(Ap,p)] \\ -2\lambda[1+2Q_\zeta(Aq,q)] & \lambda^2[1+2Q_\zeta(p,q)] \end{pmatrix}, \tag{8.14}$$

which coincides with the Lax matrix (3.13) of the KvM hierarchy: $\hat{V}_\lambda = V_\lambda$. Hence in the context of the soliton hierarchy $\{Y_m\}$, we again obtain the integrals $\{F_m\}$, generated as the coefficients of the asymptotic expansion of $F_\lambda = \det V_\lambda$. Again we have the integrals $\{H_m\}$ by Eqs. (4.7), (4.8), and (4.10). The present formalism enables us to establish the direct relation between $\{H_m\}$ and $\{Y_m\}$.

Proposition 8.3: (i) f_C defined by the Bargmann condition (8.2) maps the solution $(p(x),q(x))^T$ of the H_0-flow (5.7), or equivalently (8.1)+(8.2), into a solution of the stationary soliton equation

$$Y_N + \hat{c}_{N1}Y_{N-1} + \cdots + \hat{c}_{NN}Y_0 = 0. \tag{8.15}$$

(ii) Let $(p(x,\tau_m),q(x,\tau_m))^T$ be the compatible solution of the H_0- and the H_m-flows. Then $(u(x,\tau_m),v(x,\tau_m))^T = f_C(p,q)$ satisfies both Eq. (8.15) and

$$\frac{\mathrm{d}}{\mathrm{d}\tau_m}\begin{pmatrix} u \\ v \end{pmatrix} = Y_m. \tag{8.16}$$

Besides,

$$\mathrm{d}f_C(I\nabla H_m) = Y_m. \tag{8.17}$$

(iii) Let $(p(x,y,t),q(x,y,t))^T$ be the compatible solution of the H_0-, H_1-, and H_2-flow with the flow variables $x=\tau_0, y=\tau_1$, and $t=\tau_2$, respectively. Then

$$v(x,y,t) = -2\langle p(x,y,t), q(x,y,t)\rangle \tag{8.18}$$

is a solution of the mKP equation (1.11).

Graphically, for the decomposition of the mKP equation, we have diagram (1.12), and for the Y_m-flow, we have the diagram:

$$\begin{matrix} H_0 \\ H_m \end{matrix} \searrow \quad Y_m \tag{8.19}$$

Since there is no more discrete flow $\mathcal{S}$, which is a little more complicated since it splits into two series according to n even or odd, we have a rather simple evolution picture:

$$\begin{gathered} \left.\begin{matrix} \text{Bargmann} & \text{flow} \\ \text{stationary} & \text{flow} \end{matrix}\right\} \phi=\phi_0+x\Omega_0, \quad \psi=\psi_0-x\Omega_0, \\ H_m\text{-flow:} \quad \phi=\phi_0+\tau_m\Omega_m, \quad \psi=\psi_0-\tau_m\Omega_m, \\ Y_m\text{-flow:} \quad \phi=\phi_0+x\Omega_0+\tau_m\Omega_m, \quad \psi=\psi_0-x\Omega_0-\tau_m\Omega_m, \\ \text{mKP-flow:} \quad \phi=\phi_0+x\Omega_0+y\Omega_1+t\Omega_2, \quad \psi=\psi_0-x\Omega_0-y\Omega_1-t\Omega_2. \end{gathered} \tag{8.20}$$

The feature of linear superposition is clear. By Eqs. (5.5), (5.7), (8.3), and (8.4) we have

$$\partial_x \ln v=\frac{v_x}{v}=\frac{\langle p,q\rangle_x}{\langle p,q\rangle}=2\sum_{j=1}^{g}(\gamma_j-\epsilon_j)=\partial_x \ln\frac{\theta(\phi+K_1+\eta_1)\theta(-\psi-K_2-\eta_1)}{\theta(\phi+K_1+\eta_2)\theta(-\psi-K_2-\eta_2)}, \tag{8.21}$$

so long as ϕ and ψ contain the terms $x\Omega_0$ and $-x\Omega_0$, respectively. Thus we get:

Theorem 8.4: The modified Kadomtsev–Petviashvili equation (1.11) has the algebro-geometric solution:

$$\begin{aligned} v(x,y,t)=&\frac{\theta(x\Omega_0+y\Omega_1+t\Omega_2+\phi_0+K_1+\eta_1)\theta(x\Omega_0+y\Omega_1+t\Omega_2-\psi_0-K_2-\eta_1)}{\theta(x\Omega_0+y\Omega_1+t\Omega_2+\phi_0+K_1+\eta_2)\theta(x\Omega_0+y\Omega_1+t\Omega_2-\psi_0-K_2-\eta_2)} \\ &\cdot\frac{\theta(y\Omega_1+t\Omega_2+\phi_0+K_1+\eta_2)\theta(y\Omega_1+t\Omega_2-\psi_0-K_2-\eta_2)}{\theta(y\Omega_1+t\Omega_2+\phi_0+K_1+\eta_1)\theta(y\Omega_1+t\Omega_2-\psi_0-K_2-\eta_1)}v(0,y,t). \end{aligned} \tag{8.22}$$

(Received 12 December 2000; accepted for publication 9 October 2001)

We present a new approach for constructing covariant symplectic structures for geometrical theories, based on the concept of adjoint operators. Such geometric structures emerge by direct exterior derivation of underlying symplectic potentials. Differences and similarities with other approaches and future applications are discussed. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421636]

I. INTRODUCTION

Usually quantum field theories are studied by means of Feynman path integrals or by means of canonical quantization. Path integral quantization has the virtue to preserve all relevant symmetries, including Poincaré invariance; however, the resultant theory has not (unlike the canonical formalism) necessarily the standard interpretation in terms of quantum mechanical states and operators. On the other hand, the canonical formalism is considered to be the antithesis of a manifestly covariant treatment.

However, more recently, the essence of the canonical formulation has been developed independently by Witten *et al.*[1,2] and Suckerman[3] in such a way that manifestly preserves Poincaré invariance as well as other relevant symmetries. Such a formulation is based on a covariant description of Poisson brackets in terms of a symplectic structure defined on the manifold representing the phase space of classical solutions; thus, quantization is carried out as the replacement of Poisson brackets with commutators, and the resultant quantum theory will be of the conventional type. Specifically, the Witten *et al.* approach requires the construction, *a priori*, of a bilinear product on variations of classical solutions. Subsequently, one needs to verify that such a bilinear form corresponds to a nondegenerate closed two-form on the phase space. Moreover, the bilinear form must be a covariantly conserved current in its spacetime dependence, as required for obtaining a symplectic structure manifestly covariant. More specifically, in such a description, the classical phase space is defined as *the space of solutions of the classical equations of motion*: such a definition is manifestly covariant. The construction of a covariantly conserved two-form J^μ on such phase space yields a symplectic structure ω, defined as $\omega \equiv \int_\Sigma J^\mu \, d\Sigma_\mu$ (Σ being an initial value hypersurface), independent of the choice of Σ and, in particular, Poincaré invariant. Additionally, in terms of the symplectic structure ω, the fact that Poisson brackets satisfy the Jacoby identity, is equivalent that ω to be a closed two-form on the phase space, which holds if J^μ itself is closed. With these properties, J^μ is known as *the symplectic current*. Such a quantization scheme has been applied, for example, for the analysis of two-dimensional gravity (Ref. 4 and references therein), and for the investigation of the Wess–Zumino–Witten model on a circle.[5]

Although in the present article we shall obtain essentially the same geometric structures described above, the main novelty is that such structures emerge in a direct and natural way using the concept of adjoint operators. Particularly, the concept of self-adjoint operators shows that, in the cases considered here, there exist, in general, covariantly conserved currents, which correspond on the phase space, to zero-, one-, and, two-forms. Such differential forms are not independent, but that the two-form turns out to be the exterior derivative of the corresponding one-

[a)]Electronic mail: rcartas@sirio.ifuap.buap.mx
[b)]Permanent address.

form, and correspond, thus, to an *exact* two-form (and automatically to a closed two-form, as required for the symplectic structure). In this manner, the present approach allows us to find, unlike the Witten–Zuckerman procedure, fundamental one-forms playing the role of *symplectic potentials* for the theory.

In the next section, we shall discuss the key concept of adjoint operators, and its consequences on the existence of covariantly conserved currents. The interpretation of the terms involved in such a definition as wedge products on the phase space is also discussed. In Sec. III only the non-Abelian gauge theories and pure general relativity are considered with the purpose of clarifying our basic ideas and to have a direct comparison with previously known results, particularly with those given in Ref. 2. In Sec. IV, we shall finish with some concluding remarks on our results and possible extensions of the present approach.

Concepts and definitions on differential forms, wedge products, exterior derivative, etc., come entirely from Ref. 2.

II. ADJOINT OPERATORS AND CONSERVED CURRENTS

The general relationship between adjoint operators and covariantly conserved currents has been already given in previous works (Ref. 6 and references cited therein), however, we shall discuss it in this section for completeness.

If $\mathcal{P}$ is a linear partial differential operator that takes matrix-valued tensor fields into themselves, then, the adjoint operator of $\mathcal{P}$, is that operator $\mathcal{P}^\dagger$, such that

$$\mathrm{Tr}\{f^{\rho\sigma\cdots}[\mathcal{P}(g_{\mu\nu\cdots})]_{\rho\sigma\cdots}-[\mathcal{P}^\dagger(f^{\rho\sigma\cdots})]^{\mu\nu\cdots}g_{\mu\nu\cdots}\}=\nabla_\mu J^\mu, \tag{1}$$

where Tr denotes the trace and J^μ is some vector field. From this definition, if $\mathcal{Q}$ and $\mathcal{R}$ are any two linear operators, one easily finds the following properties:

$$(\mathcal{QR})^\dagger=\mathcal{R}^\dagger\mathcal{Q}^\dagger, \quad (\mathcal{Q}+\mathcal{R})^\dagger=\mathcal{Q}^\dagger+\mathcal{R}^\dagger,$$

and in the case of a function F,

$$F^\dagger=F,$$

which will be used implicitly below.

From Eq. (1) we can see that this definition automatically guarantees that, if the field f is a solution of the linear system $\mathcal{P}(f)=0$, and g a solution of the adjoint system $\mathcal{P}^\dagger(g)=0$, then we obtain the continuity law $\nabla_\mu J^\mu=0$, which establishes that J^μ is a covariantly conserved current depending on the fields f and g. This fact means that for any homogeneous equation system, one can always construct a conserved current, taking into account the adjoint system. This general result contains the self-adjoint case ($\mathcal{P}^\dagger=\mathcal{P}$) as a particular one, for which f and g correspond to two independent solutions (in fact, the cases treated in the present article are self-adjoint). Although this result has been established assuming only tensor fields and the presence of a single equation, such a result can be extended in a direct way to equations involving spinor fields, matrix fields, and the presence of more than one field.[6,7]

Our main task in this work is to apply this very general result for the analysis of the symplectic forms on the phase space of the theories under consideration. Hence, it is important to clarify, in the first instance, what the fields f, g, J^μ and the differential operators $\mathcal{P}$, $\mathcal{P}^\dagger$, and ∇_μ will mean on the phase space at the level of Eq. (1). First, such operators will depend only on the background fields, and will correspond thus to zero-forms. Second, although in our previous works we have identified the fields f and g with solutions of the equations governing the first-order variations $[\mathcal{P}(f)=0=\mathcal{P}(g)]$, in the present work we shall see that it is possible to find simultaneously that $\mathcal{P}(G)=0$, where G is some background field. Thus, since the background fields and the first-order variations correspond, on the phase space, to zero-forms and one-forms, respectively,[2] the left-hand side of Eq. (1) must be understood as a wedge product, $\mathrm{Tr}\{f\wedge\mathcal{P}(g)$

$-\mathcal{P}^{\dagger}(f)\wedge g\}=\nabla_{\mu}J^{\mu}$, on such phase space, and something similar for the field J^{μ} in its dependence on the fields f and g. This subject will be clarified in the examples below.

III. GEOMETRICAL THEORIES AND THEIR SYMPLECTIC STRUCTURES

In this section we shall see that the problem of finding the symplectic structures (and in some cases the symplectic potentials), is reduced to identify some fields satisfying some homogeneous linear equations.

A. Yang–Mills theory

Let us consider first the Yang–Mills equations:

$$\partial\!\!\!/^{\mu}F_{\mu\nu}=0, \tag{2}$$

where $F_{\mu\nu}=\partial\!\!\!/_{\mu}A_{\nu}-\partial\!\!\!/_{\nu}A_{\mu}$ is the Yang–Mills curvature, A_{μ} the background gauge connection, and $\partial\!\!\!/_{\mu}\equiv\partial_{\mu}+[A_{\mu},\ \ ]$, the gauge covariant derivative.

From Eq. (2), the variations of the background fields are governed by the equations

$$\partial\!\!\!/^{\mu}\delta F_{\mu\nu}+[\delta A^{\mu},F_{\mu\nu}]=[\delta^{\alpha}_{\nu}\partial\!\!\!/^{\mu}\partial\!\!\!/_{\mu}-\partial\!\!\!/^{\alpha}\partial\!\!\!/_{\nu}]\delta A_{\alpha}+[\delta A_{\alpha},F^{\alpha}{}_{\nu}]\equiv[\mathcal{P}(\delta A_{\alpha})]_{\nu}=0, \tag{3}$$

where $\delta F_{\mu\nu}=\partial\!\!\!/_{\mu}\delta A_{\nu}-\partial\!\!\!/_{\nu}\delta A_{\mu}$, is the variation of the curvature, δA_{μ} the variation of the gauge connection, and the operator $\mathcal{P}$ is a homogeneous linear operator depending only on the background fields. Up to here, the usual equations for the Yang–Mills fields and their variations.

Now the idea is to apply our present approach for obtaining all on the symplectic structure for the theory, directly from the basic equations (2) and (3). For this purpose, let B_{μ} and C_{μ} be any two matrix-valued fields (which will be identified below as a pair of gauge connection variations in one case, and as the background gauge connection and its variation in the particular case of Abelian fields), and using the explicit form of the operator $\mathcal{P}$ in Eq. (3), we have that

$$\begin{aligned}B^{\nu}\wedge[\mathcal{P}(C_{\alpha})]_{\nu}-[\mathcal{P}(B^{\nu})]^{\alpha}\wedge C_{\alpha}=\partial\!\!\!/_{\mu}[B^{\nu}\wedge(\partial\!\!\!/^{\mu}C_{\nu}-\partial\!\!\!/_{\nu}C^{\mu})+(\partial\!\!\!/^{\nu}B^{\mu}-\partial\!\!\!/^{\mu}B^{\nu})\wedge C_{\nu}]\\ +[F_{\mu\nu},B^{\mu}\wedge C^{\nu}],\end{aligned} \tag{4}$$

where

$$B^{\nu}\wedge[C_{\alpha},F^{\alpha}{}_{\nu}]-[B_{\alpha},F^{\alpha}{}_{\nu}]\wedge C^{\nu}=[F_{\mu\nu},B^{\mu}\wedge C^{\nu}], \tag{5}$$

and identities of the form $B^{\nu}\wedge\partial\!\!\!/^{\alpha}\partial\!\!\!/_{\nu}C_{\alpha}\equiv\partial\!\!\!/_{\mu}(B^{\nu}\partial\!\!\!/_{\nu}C^{\mu}-\partial\!\!\!/^{\nu}B^{\mu}\wedge C_{\nu})+\partial\!\!\!/_{\nu}\partial\!\!\!/^{\alpha}B^{\nu}\wedge C_{\alpha}$ have been used. Taking the trace of Eq. (4), we obtain

$$\mathrm{Tr}[B^{\nu}\wedge[\mathcal{P}(C_{\alpha})]_{\nu}-[\mathcal{P}(B^{\nu})]^{\alpha}\wedge C_{\alpha}]=\partial_{\mu}\,\mathrm{Tr}[B_{\nu}\wedge\partial\!\!\!/^{[\mu}C^{\nu]}-\partial\!\!\!/^{[\mu}B^{\nu]}\wedge C_{\nu}], \tag{6}$$

which has the form of Eq. (1) with $\mathcal{P}=\mathcal{P}^{\dagger}$. Thus, we can obtain the continuity equation:

$$\partial_{\mu}J^{\mu}=0,\quad J^{\mu}\equiv\mathrm{Tr}[B_{\nu}\wedge\partial\!\!\!/^{[\mu}C^{\nu]}-\partial\!\!\!/^{[\mu}B^{\nu]}\wedge C_{\nu}], \tag{7}$$

provided that

$$[\mathcal{P}(C_{\alpha})]_{\nu}=0\quad\text{and}\quad[\mathcal{P}(B^{\nu})]^{\alpha}=0. \tag{8}$$

As we shall see, the whole physical information about the covariant symplectic structure of the Yang–Mills theory is contained in Eq. (7), it remains only to identify the fields B_{μ} and C_{μ} satisfying Eqs. (8). In according to Eq. (3), the obvious case is to choose such fields as a pair of variations, say $B_{\mu}=\delta A^{1}_{\mu}$, and $C_{\mu}=\delta A^{2}_{\mu}$ (they have not to correspond necessarily to the same variation). In this manner, J^{μ} in Eq. (7) corresponds, in this case, to the following (nondegenerate) two-form on the phase space:

$$J_\mu = \mathrm{Tr}[\,\delta A_1^\nu \wedge \delta F^2_{\mu\nu} - \delta F^1_{\mu\nu} \wedge \delta A_2^\nu] = \tfrac{1}{2}\delta\,\mathrm{Tr}[A_1^\nu\,\delta F^2_{\mu\nu} - F^2_{\mu\nu}\,\delta A_1^\nu - F^1_{\mu\nu}\,\delta A_2^\nu + A_2^\nu\,\delta F^1_{\mu\nu}] \equiv \delta\theta_\mu, \tag{9}$$

where $F^i_{\mu\nu} = \partial_\mu A^i_\nu - \partial_\nu A^i_\mu$, $\delta F^i_{\mu\nu} = \partial_\mu \delta A^i_\nu - \partial_\nu \delta A^i_\mu$ $(i=1,2)$, and we have used the Leibniz rule for the exterior derivative δ, and the fact that $\delta^2 = 0$. In particular, if $\delta A^1_\mu = \delta A_\mu = \delta A^2_\mu$, from Eq. (9) $J_\mu = 2\,\mathrm{Tr}(\delta A^\nu \wedge \delta F_{\mu\nu})$, which is essentially the Crncović–Witten current.[2] Furthermore, we have defined the one-form θ_μ as

$$\theta_\mu \equiv \tfrac{1}{2}\mathrm{Tr}[A_1^\nu\,\delta F^2_{\mu\nu} - F^2_{\mu\nu}\,\delta A_1^\nu - F^1_{\mu\nu}\,\delta A_2^\nu + A_2^\nu\,\delta F^1_{\mu\nu}], \tag{10}$$

in this manner, θ_μ is the *symplectic potential* for the theory. Note that, according to Eq. (9), the symplectic potential is defined up to the exterior derivative of any matrix-valued field λ_μ: $J_\mu = \delta(\theta_\mu + \delta\lambda_\mu)$.

In the particular case of Abelian fields, from Eqs. (2) and (3) we have that $[\mathcal{P}(A_\alpha)]_\nu = 0$, where A_α is the background gauge connection. In this manner, we can identify $B_\nu = \delta A^1_\nu$ and $C_\nu = A^2_\nu$ (a variation and a background gauge connection, respectively), and then the symplectic potential θ_μ given in Eq. (10) is [like the corresponding symplectic current in Eq. (9)] covariantly conserved. Moreover, we can identify for Abelian fields $B_\nu = A^1_\nu$, and $C_\nu = A^2_\nu$ (a pair of background fields) in Eq. (8); thus, from Eq. (7) $J_\mu = A_1^\nu F^2_{\mu\nu} - A_2^\nu F^1_{\mu\nu}$, which is a covariantly conserved zero-form on the phase space (a conserved current for the exact theory).

Since J_μ in Eq. (9) is an *exact* two-form (it comes from the variations of the symplectic potential θ_μ), corresponds automatically to a closed two-form ($\delta J^\mu = \delta^2\theta^\mu = 0$), as required for the symplectic structure. Unlike the Crncović–Witten approach, we do not need to verify the covariant conservation of our symplectic current, such a property is guaranteed for Eqs. (7) and (8). Therefore, $\omega = \int_\Sigma J^\mu\, d\Sigma_\mu$ is the symplectic structure with the wanted properties for the Yang–Mills theory.[2] Moreover, since the present symplectic structure is essentially the Crncović–Witten result, it has the same invariance properties under gauge transformations.[2] Specifically, as shown in Ref. 2, under gauge transformations of the gauge connection $A_\mu \to A_\mu + \partial_\mu\varepsilon + [A_\mu, \varepsilon]$, δA^i_μ and $\delta F^i_{\mu\nu}$ transform homogeneously, and then J^μ and ω are gauge invariant. Furthermore, following Ref. 2, one can verify easily that ω has vanishing components in the gauge directions in field space [see Eq. (30) in such a reference], which allows us to construct the symplectic structure on the corresponding gauge-invariant space (reduced phase space).

The above results are obtained displaying explicitly the variation of the gauge connection δA_α in Eq. (3). However, it is not the only way for obtaining such results. One can consider Eq. (3) in its original form $\partial^\mu \delta F_{\mu\nu} + [\delta A^\mu, F_{\mu\nu}] = 0$, and the relation $\delta F_{\mu\nu} = \partial_\mu \delta A_\nu - \partial_\nu \delta A_\mu$, as a system of equations governing the field variations $\delta F_{\mu\nu}$, and δA_μ, considering them as independent field variables:

$$\begin{bmatrix} \partial^\mu & -[F^\alpha{}_\nu, \quad] \\ 1 & (\delta^\alpha_\mu \partial_\nu - \delta^\alpha_\nu \partial_\mu) \end{bmatrix} \begin{bmatrix} \delta F_{\mu\nu} \\ \delta A_\alpha \end{bmatrix} = 0,$$

and using again the definition (1) with $\mathcal{P}$ now being the matrix operator in the preceding equation, one obtains essentially the same results.

B. General relativity

The variations of the vacuum Einstein equations $R_{\mu\nu} = 0$ are

$$\nabla_\alpha \delta\Gamma^\alpha_{\mu\nu} - \nabla_\mu \delta\Gamma^\alpha_{\nu\alpha} = 0, \tag{11}$$

where ∇_α is the covariant derivative compatible with the background metric $g_{\mu\nu}$, and $\delta\Gamma^\alpha_{\mu\nu} = \frac{1}{2}g^{\alpha\beta}(\nabla_\mu \delta g_{\nu\beta} + \nabla_\nu \delta g_{\mu\beta} - \nabla_\beta \delta g_{\mu\nu})$, the variation of the metric connection.[2] Displaying explicitly the metric variations $\delta g_{\mu\nu}$, Eqs. (11) take the form

$$[g^{\alpha}_{\nu}\nabla^{\beta}\nabla_{\mu}+g^{\alpha}_{\mu}\nabla^{\beta}\nabla_{\nu}-g^{\alpha}_{\mu}g^{\beta}_{\nu}\nabla^{\rho}\nabla_{\rho}-g^{\alpha\beta}\nabla_{\mu}\nabla_{\nu}+g_{\mu\nu}(g^{\alpha\beta}\nabla^{\rho}\nabla_{\rho}-\nabla^{\beta}\nabla^{\alpha})]\delta g_{\alpha\beta}=0, \quad (12)$$

which can be written in a compact form as

$$[\mathcal{E}(\delta g_{\alpha\beta})]_{\mu\nu}=0, \quad (13)$$

where $\mathcal{E}$ is the linear operator (depending only on the background fields) appearing in Eq. (12). With the same idea of the above case, let $A_{\mu\nu}$, and $B_{\mu\nu}$ be any two 2-index (symmetric) tensor fields (in the first case these fields will be identified as a pair of metric variations for constructing the symplectic current, and as the background metric and a metric variation in the second case for obtaining the corresponding symplectic potential), and using the explicit form of the operator $\mathcal{E}$, we have that

$$B^{\mu\nu}\wedge[\mathcal{E}(A_{\alpha\beta})]_{\mu\nu}-[\mathcal{E}(B^{\mu\nu})]_{\alpha\beta}\wedge A^{\alpha\beta}=\nabla_{\mu}S^{\mu\alpha\beta\lambda\rho\gamma}(B_{\alpha\beta}\wedge\nabla_{\lambda}A_{\rho\gamma}-\nabla_{\lambda}B_{\rho\gamma}\wedge A_{\alpha\beta}), \quad (14)$$

where

$$S^{\mu\alpha\beta\lambda\rho\gamma}=g^{\mu(\rho}g^{\gamma)(\alpha}g^{\beta)\lambda}-\tfrac{1}{2}g^{\mu\lambda}g^{\alpha(\rho}g^{\gamma)\beta}-\tfrac{1}{2}g^{\mu(\alpha}g^{\beta)\lambda}g^{\rho\gamma}-\tfrac{1}{2}g^{\alpha\beta}g^{\mu(\rho}g^{\lambda)\lambda}+\tfrac{1}{2}g^{\alpha\beta}g^{\mu\lambda}g^{\rho\gamma}. \quad (15)$$

Like the Yang–Mills case, Eq. (14) has the form of Eq. (1) with $\mathcal{E}=\mathcal{E}^{\dagger}$. Then, we obtain the local continuity equation:

$$\nabla_{\mu}J^{\mu}=0, \quad J^{\mu}\equiv S^{\mu\alpha\beta\lambda\rho\gamma}(B_{\alpha\beta}\wedge\nabla_{\lambda}A_{\rho\gamma}-\nabla_{\lambda}B_{\rho\gamma}\wedge A_{\alpha\beta}), \quad (16)$$

provided that

$$[\mathcal{E}(A_{\alpha\beta})]_{\mu\nu}=0 \quad \text{and} \quad [\mathcal{E}(B^{\mu\nu})]_{\alpha\beta}=0. \quad (17)$$

In according to Eq. (13), an obvious identification for the fields $A_{\mu\nu}$, and $B_{\mu\nu}$ satisfying Eqs. (17) is

$$A_{\alpha\beta}=\delta g^{1}_{\alpha\beta} \quad \text{and} \quad B_{\mu\nu}=\delta g^{2}_{\mu\nu}, \quad (18)$$

we mean, a pair of variations. In this manner, from Eq. (16),

$$J^{\mu}=S^{\mu\alpha\beta\lambda\rho\gamma}(\delta g^{2}_{\alpha\beta}\wedge\nabla_{\lambda}\delta g^{1}_{\rho\gamma}-\nabla_{\lambda}\delta g^{2}_{\rho\gamma}\wedge\delta g^{1}_{\alpha\beta}), \quad (19)$$

corresponds to a covariantly conserved two-form on the phase space. The last expression can be rewritten, using Eq. (15), in terms of the variations of the metric connection:

$$J^{\mu}=(\delta\Gamma^{\mu}_{\alpha\beta})_1\wedge[\delta g_2^{\alpha\beta}+\tfrac{1}{2}g^{\alpha\beta}(\delta\ln g)_2]-(\delta\Gamma^{\nu}_{\alpha\nu})_1\wedge[\delta g_2^{\mu\alpha}+\tfrac{1}{2}g^{\mu\alpha}(\delta\ln g)_2]-(1\leftrightarrow 2), \quad (20)$$

where $(\delta\Gamma^{\mu}_{\alpha\beta})_1=\frac{1}{2}g^{\mu\rho}[\nabla_{\alpha}\delta g^{1}_{\beta\rho}+\nabla_{\beta}\delta g^{1}_{\alpha\rho}-\nabla_{\rho}\delta g^{1}_{\alpha\beta}]$, $(\delta\ln g)_2=g^{\mu\nu}\delta g^{2}_{\mu\nu}=-g_{\mu\nu}\delta g_2^{\mu\nu}$, and $(1\leftrightarrow 2)$ means a term similar to the first one, just interchanging the subscripts 1 and 2, such as Eq. (19). If we set $\delta g^{1}_{\mu\nu}=\delta g^{2}_{\mu\nu}=\delta g_{\mu\nu}$, J^{μ} in Eq. (20) reduces exactly to the Crncović–Witten current [see Eq. (34) of Ref. 2].

However, the choice (18) for the fields $A_{\alpha\beta}$, and $B_{\mu\nu}$, is not the unique one for satisfying Eqs. (17). We can keep $A_{\alpha\beta}=\delta g^{1}_{\alpha\beta}$, but to identify $B_{\mu\nu}$ as the background metric $g_{\mu\nu}$, since $\nabla_{\lambda}g_{\mu\nu}=0$, and the explicit form of $\mathcal{E}$ in Eq. (12), we have that

$$[\mathcal{E}(g_{\mu\nu})]_{\alpha\beta}=0. \quad (21)$$

Therefore, from Eq. (16), we have that the one-form

$$\theta^{\mu} \equiv S^{\mu\alpha\beta\lambda\rho\gamma} g_{\alpha\beta} \nabla_{\lambda} \delta g^{1}_{\rho\gamma}, \tag{22}$$

is also a covariantly conserved current on the phase space. θ^{μ} can also be rewritten in terms of the variations of the metric connection:

$$\theta^{\mu} = g^{\mu\alpha} (\delta\Gamma^{\nu}_{\alpha\nu})_1 - g^{\alpha\beta} (\delta\Gamma^{\mu}_{\alpha\beta})_1 . \tag{23}$$

Moreover, the conserved currents J^{μ} and θ^{μ} given in Eqs. (19)–(20) and (22)–(23), respectively, are not independent. Considering that $\delta\sqrt{g} = \frac{1}{2}\sqrt{g}\,\delta \ln g$, from Eq. (23), we have that

$$\begin{aligned} \delta(\sqrt{g}\,\theta^{\mu}) = {} & \sqrt{g}[\,\delta g^{\mu\alpha}_{2} \wedge (\delta\Gamma^{\nu}_{\alpha\nu})_1 - \delta g^{\alpha\beta}_{2} \wedge (\delta\Gamma^{\mu}_{\alpha\beta})_1] \\ & - \tfrac{1}{2}\sqrt{g}[g^{\mu\alpha} (\delta\Gamma^{\nu}_{\alpha\nu})_1 - g^{\alpha\beta} (\delta\Gamma^{\mu}_{\alpha\beta})_1] \wedge (\delta \ln g)_2 , \end{aligned} \tag{24}$$

where we have considered also that $\delta^2 = 0$, the Leibniz rule for the exterior derivative, and a variation of the background metric appearing in Eq. (23), in general, different from $\delta g^{1}_{\mu\nu}$, and denoted conveniently by $\delta g^{2}_{\mu\nu}$. Making a direct comparison, the right-hand side of Eq. (24) corresponds, by a factor of $\sqrt{g}$, to the first term on the right-hand side of Eq. (20). With an interchange of the superscripts 1 and 2 in Eq. (24) (which corresponds to identify $A_{\alpha\beta}$ with the background metric and $B_{\mu\nu}$ with the metric variation), we obtain essentially the second term on the right-hand side of Eq. (20). In this manner, we can rewrite

$$\theta^{\mu} = S^{\mu\alpha\beta\lambda\rho\gamma} (g^{2}_{\alpha\beta} \nabla_{\lambda} \delta g^{1}_{\rho\gamma} + g^{1}_{\alpha\beta} \nabla_{\lambda} \delta g^{2}_{\rho\gamma}), \tag{25}$$

and then

$$\delta(\sqrt{g}\,\theta^{\mu}) = \sqrt{g} J^{\mu}, \tag{26}$$

which means that $\sqrt{g} J^{\mu}$ is an *exact* two-form, and $\sqrt{g}\,\theta^{\mu}$ is then the *symplectic potential* for the theory (which is defined up to the exterior derivative of any vector field). Since $\nabla_{\lambda} g_{\mu\nu} = 0$ and $g = g(g_{\mu\nu})$, $\sqrt{g}\,\theta^{\mu}$ and $\sqrt{g} J^{\mu}$ are, like θ^{μ} and J^{μ}, also covariantly conserved.

In the Crncović–Witten approach, one needs to show that $\nabla_{\mu} J^{\mu} = 0$; in the present approach J^{μ} comes directly from the continuity equation (16). Moreover, from Eq. (26), $\sqrt{g} J^{\mu}$ is an exact two-form, and automatically a closed two-form, as required for the symplectic structure $\omega = \int_{\Sigma} \sqrt{g} J^{\mu} d\Sigma_{\mu}$, which has the wanted properties. Since ω is essentially that given in Ref. 2, it has the same invariance properties under gauge transformations described in such a reference.

If we choose $A_{\mu\nu} = g^{1}_{\mu\nu}$, and $B_{\alpha\beta} = g^{2}_{\alpha\beta}$ (a pair of background solutions), both satisfying Eq. (21), then from the local equation (16), we have that $J^{\mu} = 0$, which means that there no exist a (local) conserved current for the exact theory different to the trivial one.

Finally, if we consider Eq. (11) and the relation between $\delta\Gamma$ and $\delta g_{\mu\nu}$ as a system for these field variations (considering them as independent), one obtains essentially the same results.

IV. CONCLUDING REMARKS

As we have seen, the present approach based on the concept of (self-)adjoint operators leads, in a rigorous way, to local continuity laws for the theory under study. Such continuity equations disclose the existence of different conserved currents, in particular those associated with a covariant description of the corresponding symplectic structure.

The symplectic structures described in Refs. 1–3, are always related to a pair of solutions of the equations governing the variations of classical solutions. In the present scheme, the self-adjoint case corresponds, as we have seen in the examples, to that case. Nevertheless, as discussed in Sec. II, there exists a more general case, which establishes the possibility of constructing a (nondegenerate) two-form related to a solution of the equations governing the variations, and a solution of the corresponding adjoint system. No such possibility was previously known in the literature. However, such a two-form is not necessarily closed, remaining to study under what conditions this

two-form represents a symplectic structure. In fact, there are several cases in physics involving operators that are not self-adjoint, where the present approach will be useful: usual free massless fields equations of spin greater that one on a curved spacetime, equations for first-order variations coming from string-inspired actions, etc. Works along these lines are in progress and will be the subject of forthcoming communications.

On the other hand, the Zuckerman formalism, unlike the present one, requires an explicit extension for covering fermionic fields.[3] Even though in the present article we have limited our discussion to bosonic field theories, the adjoint operator formalism allows us to treat bosonic and fermionic fields (and the simultaneous presence of both) on the same footing, since the fundamental definition (1), which is our starting point, extends for spinor fields.[7] In this case, we are particularly interested in superstring theory, and works along these lines are also in progress.

Finally, the connection between adjoint operators and conserved currents used in the present article, has been also used in Ref. 6, although for a different purpose: for obtaining conserved quantities from non-Hermitian systems. In this manner, a scheme based on adjoint operators has different ramifications of wide interest in physics, whose applications also will be the aim of future investigations.

APPENDIX: NO "PUZZLE" FOR THE SYMPLECTIC CURRENT

In the Crncović–Witten approach,[2] unlike the present scheme, there is not a procedure for obtaining the explicit form for the symplectic structure (or for the symplectic potential). In fact, it may be very difficult to guess such an explicit form for more general and complicated cases. However, without invoking the concept of adjoint operators used in the present scheme, one may be able to obtain the explicit form of the potential symplectic, starting directly from the basic equations for the variations. For example, in the general relativity case, the equation (11) for the variations can be rewritten in the form

$$\nabla_\alpha(\delta\Gamma^\alpha_{\mu\nu}-\delta^\alpha_\mu\delta\Gamma^\lambda_{\nu\lambda})=0, \tag{A1}$$

which implies that the tensor field $T^\alpha_{\mu\nu}\equiv\delta\Gamma^\alpha_{\mu\nu}-\delta^\alpha_\mu\delta\Gamma^\lambda_{\nu\lambda}$ is a covariantly conserved one-form on the phase space. Since $\nabla_\lambda g_{\mu\nu}=0$, and $g=g(g_{\mu\nu})$, the one-form $T^\alpha\equiv\sqrt{g}g^{\mu\nu}T^\alpha_{\mu\nu}$ is also covariantly conserved: $\nabla_\alpha T^\alpha=0$. Using Eq. (23), it is very easy to find that $g^{\mu\nu}T^\alpha_{\mu\nu}=\theta^\alpha$, thus $T^\alpha=\sqrt{g}\,\theta^\alpha$. In this manner, T^α coming from Eq. (A1), is the symplectic potential, whose variations generate automatically a closed two-form. However, regardless of adjoint operators, one must verify the covariant conservation of such a two-form in order to obtain a covariant description.

(Received 21 August 2001; accepted for publication 22 October 2001)

It is shown how solutions to the Tzitzéica equation can be used to construct a family of (pseudo) hyper-complex metrics in four dimensions. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1426687]

I. INTRODUCTION

A striking *universal* feature of integrable systems is that the same integrable equations often arise from many unrelated sources. The Tzitzéica equation[1]

$$\omega_{xy}=e^{\omega}-e^{-2\omega} \tag{1}$$

is a good example. It first arose in a study of surfaces in $\mathbb{R}^3$ for which the ratio of the negative Gaussian curvature to the fourth power of a distance from a tangent plane to some fixed point is a constant. Tzitzéica has shown that if x and y are coordinates on such a surface in which the second fundamental form is off-diagonal, then there exists a real function $\omega(x,y)$ such that the Peterson–Codazzi equations reduce to (1). Moreover, he has demonstrated[2] that (1) is a consistency condition for an otherwise overdetermined system of partial differential equations (PDEs) for $\psi_i(x,y)$, $i=1,2,3$:

$$\begin{aligned}\partial_x\begin{pmatrix}\psi_1\\ \psi_2\\ \psi_3\end{pmatrix}&=\begin{pmatrix}-\omega_x & 0 & \lambda\\ 1 & \omega_x & 0\\ 0 & 1 & 0\end{pmatrix}\begin{pmatrix}\psi_1\\ \psi_2\\ \psi_3\end{pmatrix},\\ \partial_y\begin{pmatrix}\psi_1\\ \psi_2\\ \psi_3\end{pmatrix}&=\begin{pmatrix}0 & e^{-2\omega} & 0\\ 0 & 0 & e^{\omega}\\ \lambda^{-1}e^{\omega} & 0 & 0\end{pmatrix}\begin{pmatrix}\psi_1\\ \psi_2\\ \psi_3\end{pmatrix}.\end{aligned} \tag{2}$$

[Strictly speaking the linear system given by Tzitzéica consisted of three second order PDEs for one function. These three equations can be recovered from (2) if one eliminates ψ_1 and ψ_2 by cross-differentiating.] The above linear system is in modern terminology known as a ''Lax pair with a spectral parameter.'' It underlines the complete integrability of the Tzitzéica equation.[3]

Equation (1) reappeared in the context of soliton solutions,[4] gas dynamics[5] as well as geometry of affine spheres.[6] In this article I shall reveal yet another occurrence of (1), and show how its solutions can be used to generate explicit pseudo-hyper-complex structures in four dimensions. This will be done by regarding (2) as a reduced Lax pair for SL(3,$\mathbb{R}$) anti-self-dual Yang–Mills (ASDYM) equations, embedding SL(3,$\mathbb{R}$) in Diff($\mathbb{RP}^2$), and reinterpreting the Lax pair in terms of vector fields on $\mathcal{M}=\mathbb{R}^2\times\mathbb{RP}^2$. Four independent vector fields in this Lax pair will provide a null frame for a pseudo-hyper-complex conformal structure on $\mathcal{M}$.

In the next section the Lax formulation of the pseudo-hyper-complex condition in four dimensions will be given following Refs. 7 and 8. In Sec. III the connection with the ASDYM will be established, and the explicit embedding of **sl**(3,$\mathbb{R}$) in **diff**($\mathbb{RP}^2$) will be given. The resulting

a)Electronic mail: dunajski@maths.ox.ac.uk

pseudo-hyper-complex structure will be constructed in Sec. IV. All considerations in this section will be local. Finally, Sec. V contains the twistor interpretation of the construction.

II. PSEUDO HYPER-COMPLEX STRUCTURES

A smooth real $4n$-dimensional manifold $\mathcal{M}$ equipped with three real endomorphisms $I,S,T:T\mathcal{M}\to T\mathcal{M}$ of the tangent bundle satisfying the algebra of pseudo-quaternions

$$-I^2=S^2=T^2=1, \quad IST=1,$$

is called pseudo-hyper-complex iff the almost complex structure

$$\mathcal{J}_\lambda=aI+bS+cT \tag{3}$$

is integrable for any point of the hyperboloid $a^2-b^2-c^2=1$. [We identify two sheets of this hyperboloid with two unit discs D_- and D_+, and use λ as a projective coordinate on a Riemann sphere $\mathbb{CP}^1=D_-+D_++S^1$. The coordinate λ plays a role of a complex spectral parameter in the Lax pair (4).] This integrability is equivalent to a vanishing of its Nijenhuis tensor

$$N(X_1,X_2):=(\mathcal{J}_\lambda)^2[X_1,X_2]-\mathcal{J}_\lambda[\mathcal{J}_\lambda X_1,X_2]-\mathcal{J}_\lambda[X_1,\mathcal{J}_\lambda X_2]+[\mathcal{J}_\lambda X_1,\mathcal{J}_\lambda X_2]$$

for arbitrary vectors X_1 and X_2. A convenient matrix representation of the canonical pseudo-hyper-complex structure on $\mathbb{R}^4$ is given by

$$I=\begin{pmatrix} 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\\ -1 & 0 & 0 & 0\\ 0 & -1 & 0 & 0\end{pmatrix}, \quad S=\begin{pmatrix} 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\\ 1 & 0 & 0 & 0\\ 0 & 1 & 0 & 0\end{pmatrix}, \quad T=\begin{pmatrix} 1 & 0 & 0 & 0\\ 0 & 1 & 0 & 0\\ 0 & 0 & -1 & 0\\ 0 & 0 & 0 & -1\end{pmatrix}.$$

In the general case the components of I,S,T depend smoothly on coordinates on $\mathcal{M}$. The endomorphism I endows $\mathcal{M}$ with the structure of a two-dimensional complex manifold, and S and T determine a pair of transverse null foliations. Let g be a metric of signature $(2n,2n)$ on $\mathcal{M}$. If $(\mathcal{M},\mathcal{J}_\lambda)$ is pseudo-hyper-complex and

$$g(TX_1,TX_2)=g(SX_1,SX_2)=-g(IX_1,IX_2)=-g(X_1,X_2)$$

for all vectors X_1,X_2, then the triple $(\mathcal{M},\mathcal{J}_\lambda,g)$ is called a pseudo-hyper-Hermitian structure.

From now on we shall restrict ourselves to oriented four manifolds, where the notions of pseudo-hyper-complex and pseudo-hyper-Hermitian structures coincide. To see it choose any vector $X\in T\mathcal{M}$, and define a conformal structure $[g]$ of signature $(++--)$, by choosing a conformal frame of vector fields (X,IX,SX,TX). Any $g\in[g]$ is then pseudo-hyper-Hermitian. We shall use the following characterization of the pseudo-hyper-Hermiticity condition:

Proposition 1:[7] *Let (X,Y,U,V) be four independent real vector fields on a four-dimensional real manifold $\mathcal{M}$, and let*

$$L_0=X-\lambda V, \quad L_1=U-\lambda Y, \quad \textit{where } \lambda\in\mathbb{CP}^1. \tag{4}$$

If

$$[L_0,L_1]=0 \tag{5}$$

for every λ, then (X,Y,U,V) is a null tetrad for a pseudo-hyper-Hermitian contravariant metric

$$g=X\otimes Y+Y\otimes X-U\otimes V-V\otimes U$$

on $\mathcal{M}$. Every pseudo-hyper-Hermitian metric arises in this way.

For a future reference we write Eq. (4) in full:

$$[X,U]=0, \quad [Y,V]=0, \quad [X,Y]-[U,V]=0. \tag{6}$$

Given the null tetrad (X,Y,U,V) we define the pseudo hyper-complex structure by

$$\begin{gathered} I(X)=-V, \quad I(U)=-Y, \quad I(Y)=U, \quad I(V)=X, \\ S(X)=V, \quad S(U)=Y, \quad S(Y)=U, \quad S(V)=X, \\ T(X)=X, \quad T(U)=U, \quad T(Y)=-Y, \quad T(V)=-V. \end{gathered} \tag{7}$$

Proposition 1 asserts that integrability of I, S, T is guaranteed by (6). Let $\nu\in\Lambda^4(T^*\mathcal{M})$ be the volume form on $\mathcal{M}$. The covariant metric is conveniently expressed in a dual frame

$$\begin{gathered} e_X=\nu(\ldots,Y,U,V), \quad e_Y=\nu(X,\ldots,U,V), \\ e_U=\nu(X,Y,\ldots,V), \quad e_V=\nu(X,Y,U,\ldots), \end{gathered}$$

and is given by

$$g=e_X\otimes e_Y+e_Y\otimes e_X-e_U\otimes e_V-e_V\otimes e_U.$$

The result of Boyer[9] originally formulated for hyper-complex manifolds still applies (with some sign alterations) in the $(++--)$ signature: a four-manifold is pseudo-hyper-complex iff there exists a basis $(\Omega_1,\Omega_2,\Omega_3)$ of the space of self-dual two forms Λ^2_+, and a one-form $\mathcal{A}$ (called a Lee form) such that

$$\mathrm{d}\Omega_i=\mathcal{A}\wedge\Omega_i. \tag{8}$$

If we change a representative of a pseudo-conformal structure according to $g\to e^f g$, then

$$\Omega_i\to e^f\Omega_i, \quad \mathcal{A}\to\mathcal{A}+\mathrm{d}f.$$

Therefore, if $\mathcal{A}$ is exact, then g is conformally pseudo-hyper-Kähler (Ricci-flat).

III. FROM THE TZITZÉICA EQUATION TO ASDYM

The idea of looking at integrable systems as reductions of the anti-self-dual Yang-Mills (ASDYM) equations goes back to Ward.[10] In this section the list of possible reductions will be enlarged by showing that (1) arises from the SL(3,$\mathbb{R}$) ASDYM with two commuting translational symmetries. In Sec. III A the connection matrices will be reinterpreted as vector fields on the projective plane.

Consider the flat metric of signature (2,2) on $\mathbb{R}^4$, which in double null coordinates $x^a=(x,y,u,v)$ takes a form

$$\mathrm{d}x\mathrm{d}y-\mathrm{d}u\mathrm{d}v,$$
