[22] For infinite systems, this is more generally applicable than the Heisenberg picture. The essential point here is that the Heisenberg picture of the dynamics of infinite systems corresponds to automorphisms of their algebras of observables, which exist only for particular models, e.g., those of lattice systems with finite range interactions. For details, see Ref. 20 and articles cited therein.

[24] A folium is a norm-closed, convex set of states that is stable under the local modifications $\omega \rightarrow \omega_A(.) = \omega(A^\star(.)A)/\omega(A^\star A)$, for all elements A of $\mathfrak{A}$. It is thus a subset, possibly a proper one, of the *mathematical* state space, given by the positive, normalized, continuous linear functionals on $\mathfrak{A}$.
[25] The local normality condition signifies that the restriction of a state to a local algebra $\mathfrak{A}_\Lambda$ corresponds to a density matrix in $\mathcal{H}_\Lambda$, and ensures that the state cannot harbor an infinite number of particles in a bounded spatial region.
[26] A linear transformation ϕ of $\mathfrak{A}$ is completely positive if $\phi \otimes I$ is a positive transformation of $\mathfrak{A} \otimes M_n$, where M_n is the algebra of $n \times n$ matrices. It is a stronger property than positivity because of quantum interference, and is naturally required in the present physical context. See Refs. 26 and 27.

(Received 19 June 2001; accepted for publication 8 November 2001)

In this paper we study the large N_c limit of $SO(N_c)$ gauge theory coupled to a real scalar field following ideas of Rajeev [Int. J. Mod. Phys. A **9**, 5583 (1994)]. We will see that the phase space of this resulting classical theory is $Sp_1(\mathcal{H})/U(\mathcal{H}_+)$ which is the analog of the Siegel disk in infinite dimensions. The linearized equations of motion give us a version of the well-known 't Hooft equation of two dimensional quantum chromodynamics. © *2002 American Institute of Physics.*

I. INTRODUCTION

Gauge theories are the fundamental theories that describe nature: Quantum chromodynamics (QCD) is the gauge theory of hadrons, and it is believed that one can compute the masses and excitations of all these hadrons from QCD. As yet there is no satisfactory understanding of these bound states. All the hadrons are color singlets, in fact we never see the underlying quarks as asymptotic states. That means QCD should be a confining theory and there should be an independent formulation of it which is expressed completely in terms of these color invariant states.

In Ref. 1, Rajeev has constructed such a theory of mesons in two dimensions in the limit N_c, the number of colors in $SU(N_c)$, goes to infinity. The idea that QCD should simplify while keeping all its essential features in this limit goes back to 't Hooft[2,3] and that this limit should be a kind of classical mechanics to Migdal and Witten. Even this large-N_c theory is quite complicated and 't Hooft looked at a two-dimensional model to understand the meson spectrum in this limit and obtained his bound state equation.[3] It is not so clear how to treat the baryons in the large-N_c limit. Witten suggested that baryons could also be understood (as solitonic excitations) in his classic papers (Refs. 4 and 5). A much more ambitious program was presented by Lee and Rajeev[6] for the large-N_c limit of more complicated gauge theories.

In this paper we study the large N_c limit of $SO(N_c)$ gauge theory coupled to a real scalar field. This theory is not physical, but it is a good model to test some of the ideas about gauge theories. We will apply the methods developed by Rajeev to this toy model. We recommend the lectures of Rajeev for a more detailed exposition of the underlying ideas.[7] Rajeev in his work[1] has shown that the phase space of the two-dimensional QCD is an infinite dimensional Grassmannian, well known from the theory of integrable systems and loop groups.[8] Scalar QCD was worked out using the same methods in Ref. 9, where it was shown that the phase space of the theory is an infinite dimensional disk. Originally scalar two-dimensional QCD was worked out by Shei and Tsao in Ref. 10 following 't Hooft, and later by Tomaras using Hamiltonian methods in Ref. 11. These works obtained the analog of the 't Hooft equation for this case. A natural extension of these would be to look at combined (fermionic) QCD and scalar QCD. This is done in a paper of Aoki,[12] where it is shown that the various types of mesons are possible and they all obey 't Hooft equations. At about the same time, following a path integral approach and bilocal fields, coupled fermions and bosons as well as some other models in two dimensions were worked out in a

[a)]Electronic mail: turgutte@boun.edu.tr

beautiful article by Cavicchi.[13] Recently, Konechny and O.T.T. have extended the methods of Ref. 1 to the above-mentioned case and showed that the underlying large-N_c phase space is a certain kind of super-Grassmannian. The linearized equations agree with the ones found in Ref. 12. The correct equations are nonlinear, and there is a baryon number operator which corresponds to the supertrace of the basic variable.[14]

The real scalar field is an interesting testing ground. There are some ideas in the literature which suggest that gauge theories in two dimensions all behave in a very similar way.[15] In this work we show that the phase space of the resulting classical theory is $Sp_1(\mathcal{H})/U(\mathcal{H}_+)$, which is the analog of the Siegel disk in infinite dimensions. The linearized equations of motion give us a version of the well-known 't Hooft equation of two-dimensional QCD, and this new one is the same equation found in Ref. 10 apart from some numerical factors. That means that we have the same spectral behavior for the mesons of the theory. Since most of the details are very similar to the ones in Rajeev's lectures[7] and various aspects of the geometry of the phase space were given in a few other places[16–18] our treatment will be brief.

II. THE SCALAR $SO(N_c)$ MODEL IN THE LIGHT CONE

Since the basic philosophy was explained in Ref. 1 we will state our conventions and write down the Lagrangian of the theory. We will use the light cone coordinates $x^+=(1/\sqrt{2})\,(t+x)$, $x^-=(1/\sqrt{2})\,(t-x)$ and choose $A_-=0$ gauge,

$$S=\int \mathrm{d}x^+\,\mathrm{d}x^-\left[\frac{1}{2}\,\mathrm{Tr}\,F_{+-}F^{+-}+\frac{1}{2}\,\phi^\alpha(-2\partial_-)\partial_+\phi_\alpha\right.$$
$$\left.+\frac{g}{2}(\partial_-\phi^\alpha A_{+\alpha}^{\ \ \beta}\phi_\beta-\phi^\alpha A_{+\alpha}^{\ \ \beta}\partial_-\phi_\beta)-\frac{m^2}{2}\,\phi^\alpha\phi_\alpha\right]. \tag{1}$$

Here we have $SO(N_c)$ gauge theory for which the matter fields are in the fundamental representation and Tr denotes an invariant inner product in the Lie algebra. The Lie algebra condition implies that $A_+^T=-A_+$. To compute the variations we need the independent degress of freedom, we can expand $A_+=A_+^a T^a$, where T^a are the generators of $SO(N_c)$ Lie algebra. We can choose them such that $\mathrm{Tr}\,T^aT^b=-1/2\,\delta^{ab}$. When we use the light cone approach in $1+1$ dimensions, the gauge fields do not carry dynamical degrees of freedom. We first eliminate the gauge fields and then write the resulting action. Let us find the equation of motion for the gauge field once we rewrite the action,

$$S=\int \mathrm{d}x^+\,\mathrm{d}x^-\left[\frac{1}{2}\,\phi^\alpha(-2\partial_-)\partial_+\phi_\alpha+\frac{g}{2}A_+^a(\partial_-\phi^\alpha T^{a\beta}_{\ \ \alpha}\phi_\beta-\phi^\alpha T^{a\beta}_{\ \ \alpha}\partial_-\phi_\beta)\right.$$
$$\left.+\frac{1}{2}(\partial_-A_+^a)^2-\frac{m^2}{2}\,\phi^\alpha\phi_\alpha\right]. \tag{2}$$

If we define the current $J^a=1/2\,(\phi^\alpha T^{a\beta}_{\ \ \alpha}\partial_-\phi_\beta-\partial_-\phi^\alpha T^{a\beta}_{\ \ \alpha}\phi_\beta)$, we get

$$-\partial_-^2A_+^a=gJ^a, \tag{3}$$

which can be solved formally (an actual solution can be found if we specify some boundary conditions) and by substituting this into our Lagrangian again,

$$S=\int \mathrm{d}x^+\,\mathrm{d}x^-\left(\frac{1}{2}\,\phi^\alpha(-2\partial_-)\partial_+\phi_\alpha+\left[\frac{g^2}{2}J^a\frac{1}{\partial_-^2}J^a+\frac{m^2}{2}\,\phi^\alpha\phi_\alpha\right]\right). \tag{4}$$

Written in this form we immediately see that[1,19] we have the following symplectic form:

$$\omega^{-1}(x^-,y^-)=\langle x^-|(-2\partial_-)^{-1}|y^-\rangle=-\tfrac{1}{4}\,\mathrm{sgn}(x^--y^-) \tag{5}$$

and the Hamiltonian,

$$H=\int \mathrm{d}x^{-}\left[-\frac{g^2}{2}J^a\frac{1}{\partial_{-}^2}J^a+\frac{m^2}{2}\phi^{\alpha}\phi_{\alpha}\right]. \tag{6}$$

The same boundary conditions as the one used to find the symplectic form gives us the more explicit expression,

$$H=\frac{m^2}{2}\int \mathrm{d}x^{-}\ \phi^{\alpha}(x^{-})\phi_{\alpha}(x^{-})-\frac{g^2}{4}\int \mathrm{d}x^{-}\,\mathrm{d}y^{-}J^a(x^{-})|x^{-}-y^{-}|J^a(y^{-}). \tag{7}$$

We note that one needs the properties of the group and its represention to compute the interaction term. This can be achieved due to the identity $\Sigma_a(T^a)_{\alpha\beta}(T^a)_{\lambda\gamma}=-1/2(\delta_{\alpha\gamma}\delta_{\lambda\beta}-\delta_{\alpha\lambda}\delta_{\beta\gamma})$.

It is now possible to compute the equations of motion for the classical variable $\phi(x^{-};x^{+})$ using

$$\frac{\partial\phi}{\partial x^{+}}=\{\phi,H\}. \tag{8}$$

It is a useful exercise to find the equations of motion even for the free field theory (see the beautiful lectures by Heinzl[19]). Another important exercise is to check that the theory is Poincaré invariant written in this new way, by finding the generators.

We will follow Ref. 1 (or Ref. 7) and rewrite the theory in terms of the color invariant bilinears of the field variable ϕ after canonical quantization. In the large N_c limit these will be the only dynamical variables, and the theory has a completely classical formulation in terms of these bilinears. We will see that the remaining global $SO(N_c)$ symmetry we have imposes a constraint for these variables and that means the phase space of the theory is a curved manifold in infinite dimensions.

Canonical quantization is standard, since the theory is super-renormalizable the result is the same as free field theory and the choice of vacuum is exactly the same. The equal ''time'' commutator is given by

$$[\hat{\phi}_{\alpha}(x^{-},x^{+}),\hat{\phi}_{\beta}(y^{-},x^{+})]=-\frac{i}{4}\delta_{\alpha\beta}\,\mathrm{sgn}(x^{-}-y^{-}). \tag{9}$$

This means that it is simpler to introduce creation and annihilation operators, satisfying

$$[a_{\alpha}(p),a_{\beta}(q)]=2\pi\delta(p+q)\delta_{\alpha\beta}\,\mathrm{sgn}(p), \tag{10}$$

such that

$$\hat{\phi}_{\alpha}(x^{-})=\int\frac{\mathrm{d}p}{2\pi}\frac{a_{\alpha}(p)}{\sqrt{2|p|}}e^{-ipx^{-}}. \tag{11}$$

For quantum theory we introduce the Fock vacuum $|0\rangle$:

$$a_{\alpha}(p)|0\rangle=0 \quad \text{when } 0\leqslant p. \tag{12}$$

To get well-defined expressions for various operators—such as the Hamiltonian—we need a normal ordering prescription:

$$:a_{\alpha}(p)a_{\beta}(q):=\begin{cases}a_{\beta}(q)a_{\alpha}(p) & \text{if } q<0,\quad p>0\\ a_{\alpha}(p)a_{\beta}(q) & \text{otherwise.}\end{cases} \tag{13}$$

We note that it is also possible to think about the creation and annihilation operators via a Fourier expansion,

$$\hat{\phi}_\alpha(x^-)=\int_0^\infty \frac{dp}{2\pi\sqrt{2|p|}}(a_\alpha(p)e^{-ipx^-}+a_\alpha^\dagger(p)e^{ipx^-}), \tag{14}$$

manifesting the real valuedness of the field $\hat{\phi}_\alpha^\dagger=\hat{\phi}_\alpha$. This automatically implies that $a_\alpha^\dagger(p)=a_\alpha(-p)$ for $p>0$. In Sec. III we will see that this is a more appropriate way to think about quantization, yet from a calculational point of view the other is better. One notes that this is consistent with the commutation relations of a_α's. (See Refs. 19 and 20 for more details about the light-cone vacuum structure of the real scalar field.)

The normal ordering can be written in terms of the ordinary products of the operators and a vacuum subtraction,

$$:a_\alpha(p)a_\beta(q):=a_\alpha(p)a_\beta(q)-\tfrac{1}{2}(\mathrm{sgn}(p)+1)2\pi\delta(p+q)\delta_{\alpha\beta}. \tag{15}$$

We will make use of this relation quite frequently in Sec. III.

III. ALGEBRA OF COLOR INVARIANT OPERATORS

In this section we will discuss the class of operators we will use to reformulate the gauge theory in the large-N_c limit. Since we have fixed the gauge as $A_-=0$ we are not allowed to make any more space-dependent gauge transformations. (The equations of motion at the quantum level imply that the ''time''-dependent transformations cannot be made arbitrarily but given by the evolution of the scalar field. We do not need to look at these in any case since in the Hamiltonian formalism observables at a fixed ''time'' slice are enough.) Yet there is still a global $SO(N_c)$ symmetry which is left over. To emphasize the contraction we write down the color invariant bilinears with one index up, the other index down,

$$N(x^-,y^-)=\frac{1}{N_c}:\hat{\phi}^\alpha(x^-)\hat{\phi}_\alpha(y^-):. \tag{16}$$

The set of these equal time bilinears constitute the set of all possible color invariant operators for this theory. One may equally look at the Fourier transform of these operators, so the basic bilinears in this case become

$$\hat{T}(p,q)=\frac{2}{N_c}\sum_\alpha :a_\alpha(p)a_\alpha(q):. \tag{17}$$

As we will see in Sec. IV conceptually it is more natural to use the variables

$$\hat{K}(p,q)=-\frac{2}{N_c}\mathrm{sgn}(p)\sum_\alpha :a_\alpha^\dagger(p)a_\alpha(q):, \tag{18}$$

but for calculations it is easier to keep the above-given variables. The basic idea of the large-N_c theory is to write everything in terms of these color invariant bilinears. In the limit N_c becomes large only the color invariant operators survive and furthermore the expectation values of color invariant operators split as a product up to $1/N_c$ corrections. This implies that the set of color invariant operators becomes classical; all color invariant operators should be representable as classical observables. The resulting theory, restricted to the space of color invariant states, therefore becomes a classical theory.[1,7,21] To define this classical theory we compute the commutator of two such color invariant operators and then take the appropriate large-N_c limit. The result will be

postulated as a classical Poisson bracket of these classical variables. We will see later on that this Poisson bracket actually comes from a symplectic form on a very natural infinite dimensional homogeneous symplectic manifold.[17]

When we compute the commutator of such bilinears we get

$$[\hat{T}(p,q),\hat{T}(s,t)]=\frac{2}{N_c}(\mathrm{sgn}(p)\,\delta[p+s]\hat{T}(q,t)+\mathrm{sgn}(q)\,\delta[q+s]\hat{T}(p,t)$$
$$+\mathrm{sgn}(p)\,\delta[p+t]\hat{T}(s,q)+\mathrm{sgn}(q)\,\delta[q+t]\hat{T}(s,p)$$
$$+(\mathrm{sgn}(p)+\mathrm{sgn}(q))(\,\delta[p+s]\delta[q+t]+\delta[p+t]\delta[s+q])),$$

where we defined $\delta[p+q]=2\pi\delta(p+q)$ for convenience.

If we take the limit $N_c\to\infty$ we assume that there are corresponding classical observables and the commutators go to Poisson brackets of these observables. We still denote them by the same letter except we drop the caret on the top. Applying the rule $-(i/\hbar)[A,B]\mapsto\{A,B\}$, as $\hbar=N_c^{-1}\to 0$, we get

$$\{T(p,q),T(s,t)\}=-2i(\mathrm{sgn}(p)\,\delta[p+s]T(q,t)+\mathrm{sgn}(q)\,\delta[q+s]T(p,t)$$
$$+\mathrm{sgn}(p)\,\delta[p+t]T(s,q)+\mathrm{sgn}(q)\,\delta[q+t]T(s,p)$$
$$+(\mathrm{sgn}(p)+\mathrm{sgn}(q))(\,\delta[p+s]\delta[q+t]+\delta[p+t]\delta[s+q])).$$

(There is really no way to determine the correct quantization parameter in this approach. We can only find this when we quantize the theory back again. The most natural method to employ is geometric quantization, due to the natural geometry of the phase space. We will come back to these issues in a separate publication.) We will postulate these to be the basic Poisson brackets of our dynamical variables. It is a good exercise to compute the equations of motion for the free field in this language and write down the solution.

These variables acting on the color invariant sector are not completely independent, there is a constraint coming from the global color invariance. Recall that the global $SO(N_c)$ is generated by the operators acting on the Fock space,

$$\hat{Q}_{\alpha\beta}=\int_0^\infty\frac{\mathrm{d}p}{2\pi}a_\alpha^\dagger(p)a_\beta(p)-\int_0^\infty\frac{\mathrm{d}p}{2\pi}a_\beta^\dagger(p)a_\alpha(p). \tag{19}$$

These operators satisfy $\hat{Q}_{\alpha\beta}|0\rangle=0$ and

$$[\hat{Q}_{\alpha\beta},\hat{Q}_{\lambda\gamma}]=\hat{Q}_{\lambda\alpha}\delta_{\beta\gamma}+\hat{Q}_{\beta\lambda}\delta_{\alpha\gamma}+\hat{Q}_{\gamma\beta}\delta_{\lambda\alpha}+\hat{Q}_{\lambda\alpha}\delta_{\gamma\beta}. \tag{20}$$

One can see that $\hat{Q}_{\alpha\beta}=-\hat{Q}_{\beta\alpha}$. Recall the related set of bilinear variables,

$$\hat{K}(p,q)=-\frac{2}{N_c}\mathrm{sgn}(p):a_\alpha^\dagger(p)a_\alpha(q):, \tag{21}$$

a careful computation shows that when we restrict these variables to the color invariant sector of the Fock space in the large-N_c limit we get

$$\int_{-\infty}^{\infty}K(p,s)K(s,q)[\mathrm{ds}]-\mathrm{sgn}(p)K(p,q)-K(p,q)\mathrm{sgn}(q)=0. \tag{22}$$

This operator equation is now interpreted as an equation for the kernel of an integral operator acting on the one-particle Hilbert space. We can write the same constraint in a more succint manner as

$$(K+\epsilon)^2=I, \tag{23}$$

where $\epsilon(p,q)=-\mathrm{sgn}(p)\delta[p-q]$ and we interpret this as an operator equation again. We will talk about the meaning of this equation from a more geometric point of view in Sec. IV. The important assumption is that when we let $N_c\mapsto\infty$, the above-mentioned constraint translated into a constraint for the classical variables K. So the dynamical variables K satisfy this constraint, which implies a constraint for $T(p,q)$ trivially.

We rewrite the Hamiltonian by redefining the coupling constant as $g^2N_c\mapsto g^2$ and dividing the Hamiltonian by an overall factor of N_c. Thus the Hamiltonian becomes, after mass renormalization,

$$H_0=\frac{1}{8}\left(m_R^2-\frac{g^2}{2\pi}\right)\mathcal{P}\int\frac{[\mathrm{d}p]}{|p|}T(-p,p), \tag{24}$$

where the renormalized mass is given by $m^2=m_R^2+(g^2/4\pi)\ln(\Lambda_U/\Lambda_I)$, Λ_U, Λ_I referring to the ultraviolet and infrared cutoffs, respectively, we also used the shorthand $[\mathrm{d}p]=\mathrm{d}p/2\pi$, and $\mathcal{P}$ denotes the principal value prescription. This is not a simple computation but the essential steps are given in Ref. 7, and the interaction part

$$H_I=\frac{g^2}{64}\mathcal{FP}\int\frac{[\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t]}{\sqrt{|pqst|}}\delta[p+q+s+t]\frac{sq-st+pt-pq}{(p+s)^2}T(p,q)T(s,t), \tag{25}$$

where $\mathcal{FP}$ denotes the finite part, as explained in Ref. 7. For simplicity of notation from now on we will drop the symbols, $\mathcal{P}$ and $\mathcal{FP}$, but the calculations should be performed keeping these in mind. At this point we have the complete formulation of our theory—one can compute the equations of motion using the above-mentioned form of the Hamiltonian and the Poisson brackets of the variables $T(u,v)$. At this stage we will not be able to give an analysis of these nonlinear equations and instead confine ourselves to the linear approximation.

For the linear approximation we follow Ref. 7 and we will write the above-mentioned constraint in terms of the T variables and ignore the second-order term in T. This will be our linearized constraint,

$$[1-\mathrm{sgn}(u)\mathrm{sgn}(v)]T(u,v)=0. \tag{26}$$

In the following we will keep all the equations of motion to this approximation and search for a bound state solution.

We can compute the equations of motion in the linear approximation: this means we look at $T(u,v)$ for $u,v>0$ or $u,v<0$, the other cases imply $T(u,v)=0$ from the constraint equation. Let us look at the $u,v<0$ case and define $P=-(u+v)$ and $x=-u/P$. This means $u=-Px$, $v=-P(1-x)$ and $0<x<1$. If we actually compute the equations of motion $\partial_+T(u,v;x^+)=\{T(u,v;x^+),H\}$, and make an ansatz, $T(u,v)=e^{iP_+x^+}\zeta(x)$, we get

$$\mu^2\zeta(x)=\left(m_R^2-\frac{g^2}{2\pi}\right)\left[\frac{1}{x}+\frac{1}{1-x}\right]\zeta(x)-\frac{g^2}{8\pi}\int_0^1\left[\frac{y(1-x)+x(1-y)+y(1-y)+x(1-x)}{(x-y)^2}\right.$$
$$\left.+\frac{xy+(1-x)(1-y)+y(1-y)+x(1-x)}{(y-(1-x))^2}\right]\frac{\zeta(y)\mathrm{d}y}{\sqrt{x(1-x)y(1-y)}},$$

where $\mu^2=2P_+P$ is the invariant mass of this excitation. We should solve this eigenvalue equation to find the allowed values of μ^2 and the function ζ. This will determine the spectrum of the theory. One notes that the equation is symmetric under $x\mapsto1-x$ and $y\mapsto1-y$, that means we may choose $\zeta(x)=\zeta(1-x)$. This simplifies our equation to

$$\mu^2\zeta(x)=\left(m_R^2-\frac{g^2}{2\pi}\right)\left[\frac{1}{x}+\frac{1}{1-x}\right]\zeta(x)-\frac{g^2}{4\pi}\int_0^1\frac{(x+y)(2-x-y)}{(x-y)^2}\frac{\zeta(y)\mathrm{d}y}{\sqrt{x(1-x)y(1-y)}}. \quad (27)$$

The above-given form is in fact identical to the bound state equation found in Ref. 10 and later on by Tomaras using Hamiltonian methods apart from the numerical factors (this approach is closer to the one in Ref. 1). It is known that this theory has only discrete states, that is we only have bound state solutions and no scattering states.

We may search for the baryons in this theory [from a more standard point of view, we do not have any $U(1)$ symmetry in the classical action; this suggests that there should not be baryon number conservation and no baryons—we will see that the baryon number is indeed not conserved for the gauge theory].

Note that there is no antibaryon. Let us write down a typical baryonic operator,

$$B(p_1,p_2,\ldots,p_{N_c})=\frac{1}{Z}\epsilon_{\alpha_1\alpha_2\ldots\alpha_{N_c}}a^\dagger_{\alpha_1}(p_1)a^\dagger_{\alpha_2}(p_2)\cdots\ a^\dagger_{\alpha_{N_c}}(p_{N_c}), \quad (28)$$

where Z is an appropriate normalization factor. When we take the large-N_c limit these operators become infinite strings which are not representable in a simple way. But we can still detect them if they are present in a physical state. We write a one-baryon state as $B(p_1,p_2,\ldots,p_{N_c})|0\rangle$, and define the baryon operator,

$$\hat{B}=\frac{1}{N_c}\int_0^\infty[\mathrm{d}p]{:}a^\dagger_\alpha(p)a_\alpha(p){:}. \quad (29)$$

In general we have the action of the baryon operator on many baryon states,

$$\frac{1}{N_c}\int_0^\infty[\mathrm{d}p]{:}a^\dagger_\alpha(p)a_\alpha(p){:}B(p_1,p_2,\ldots,p_{N_c})B(q_1,q_2,\ldots,q_{N_c})\ldots B(s_1,s_2,\ldots,s_{N_c})|0\rangle$$
$$=(\textbf{number of baryons})B(p_1,p_2,\ldots,p_{N_c})B(q_1,q_2,\ldots,q_{N_c})\ \cdots B(s_1,s_2,\ldots,s_{N_c})|0\rangle.$$

We may have mesonic parts in general, but in this picture they seem to be of smaller order. Note that this operator will survive the large-N_c limit and can be represented as the half trace of the variable $T(p,q)$ evaluated only for the positive momenta. A natural question is if the baryon number operator is conserved under the evolution of our system—it does not follow from a simple symmetry principle—a direct method is to see if this operator Poisson commutes with a quadratic Hamiltonian. Let us write down a general quadratic Hamiltonian as

$$H=\int[\mathrm{d}p]h(p)T(-p,p)+\int[\mathrm{d}p\ \mathrm{d}q\ \mathrm{d}s\ \mathrm{d}t]G(p,q;s,t)T(p,q)T(s,t). \quad (30)$$

The Poincaré invariance will impose certain restrictions on the choice of functions h, G. There are a few obvious symmetries coming from the properties of the variable T, the considerations of Sec. IV show all the symmetries required on $G(p,q;s,t)$. If we now compute

$$\left\{H,\int_{-\infty}^{\infty}T(-u,u)[\mathrm{d}u]\right\}=2i\int[\mathrm{sgn}(p)+\mathrm{sgn}(q)]G(p,q;s,t)T(p,q)T(s,t)[\mathrm{d}p\ \mathrm{d}q\ \mathrm{d}s\ \mathrm{d}t], \quad (31)$$

the use of the symmetries in general will not give zero: this means that the baryon number is not conserved in general! In our case the computation gives a nonzero result, thus in the conventional sense *we do not have baryons*, yet we may have nonzero values of the trace implying possible baryonic states. We will see more comments on this from the geometry in Sec. IV.

IV. GEOMETRY OF THE PHASE SPACE

In this section we present a somewhat more rigorous approach and provide an interpretation of the underlying phase space of the theory. To do this let us discuss quantization again, for this we closely follow the ideas in the article by Bowick and Rajeev[17] and for a more detailed presentation we refer to the beautiful article by Gracia-Bondia and Varilly.[16] There is also a nice group theoretic presentation in Ref. 22.

When we look at a real scalar field in two dimensions in the light cone formalism, we may formally quantize the system by declaring the existence of operators corresponding to the fields and we replace the Poisson bracket relations of these fields by commutators with an additional factor of i. Of course we assume that there is an underlying *complex* Hilbert space on which these operators act! In this formal process we do not see where the complex structure comes from. In fact there is a natural complex structure: let us assume that the free Hamiltonian is formally written as a quadratic form in the fields, $H_0=\int 1/2\,\phi_\alpha Q_{\alpha\beta}\phi_\beta$, and we have a symplectic structure, ω, $\int 1/2\,\phi_\alpha \omega_{\alpha\beta}\partial_+\phi_\beta$. This symplectic structure defines a skew form on the space of solutions to the classical field equations. The natural operator to introduce is $\tilde{\omega}=\omega^{-1}Q$, this is a real antisymmetric operator(matrix) of type (1,1), and comes from the equations of motion. We use its polar decomposition, $\tilde{\omega}=JS$, where $J^TJ=1$ and $S^T=S$ with $S>0$. Now using the antisymmetry of $\tilde{\omega}$ we see that $J^2=-1$. This defines a complex structure which we can use to complexify our real Hilbert space. If we apply this to our case, the metric coming from the free Hamiltonian, $H_0=(m^2/2)\int dx^-\,\phi_\alpha(x^-)\phi_\alpha(x^-)$, becomes $Q_{\alpha\beta}(x^-,y^-)=m^2\delta(x^--y^-)\,\delta_{\alpha\beta}$, and the symplectic form (see Sec. III) $\omega_{\alpha\beta}(x^-,y^-)=\langle x^-|-2\partial_-|y^-\rangle\,\delta_{\alpha\beta}$. If we write down the polar decomposition, we have

$$J_{\alpha\beta}(x^-,y^-)=\langle x^-|-(\partial_-^T\partial_-)^{1/2}\partial_-^{-1}|y^-\rangle\,\delta_{\alpha\beta}=\langle x^-|-(-\partial_-^2)^{1/2}\partial_-^{-1}|y^-\rangle\,\delta_{\alpha\beta}. \tag{32}$$

Written in this form this is a real operator acting on the L_2 space of initial data on the light cone. We can extend this operator to a complex Hilbert space and it is then possible to diagonalize the above-mentioned J in this complexified space. So we think of a complex L_2 space, $V^{\mathbf{C}}=V\otimes\mathbf{C}=W\oplus\overline{W}$, where W is isomorphic to $\overline{W}$, in the infinite dimensional case they are both separable. The decomposition we use corresponds to the eigenspaces of J. If we write J as a block diagonal on such a decomposition we get

$$J=\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}.$$

We know from our experience in physics that this is the form we use. If we decompose the fields into Fourier modes at the initial data surface $x^+=0$,

$$\phi_\alpha(x^-)=\int_0^\infty \frac{[dp]}{\sqrt{2p}}(\overline{z_\alpha}(p)e^{-ipx^-}+z_\alpha(p)e^{ipx^-}) \tag{33}$$

and act upon it by J, we see that we get

$$(J\phi_\alpha)(x^-)=\int_0^\infty \frac{[dp]}{\sqrt{2p}}(-i\overline{z_\alpha}(p)e^{-ipx^-}+iz_\alpha(p)e^{ipx^-}). \tag{34}$$

So we see that the decomposition of the field into its positive and negative frequency modes is the same as using the eigenvalue decomposition of the underlying complex structure. (We note that this decomposition is relativistically invariant, and the division by momentum variable $\sqrt{2p}$ is for convenience.) Now we can also see that the inverse of our skew form transforms under such a change of basis as $R^{-1}\omega^{-1}(R^{-1})^T$, where we represent the Fourier transform as R. Here T refers to the ordinary transpose. Thus we evaluate

$$\int \mathrm{d}x^- \,\mathrm{d}y^- \, e^{iqx^-}\sqrt{2|q|}\left(\frac{-1}{2\partial_-}\right)e^{ipy^-}\sqrt{2|p|} = i\,\mathrm{sgn}(p)\,\delta[p+q], \tag{35}$$

which shows that the symplectic form transforms to the standard form now defined on a complex Hilbert space.

The correct quantization in the infinite dimensional case requires this complex structure, the formal quantization rule,

$$[\hat{\phi}_\alpha(x^-),\hat{\phi}_\beta(y^-)] = -\frac{i}{4}\,\delta_{\alpha\beta}\,\mathrm{sgn}(x^- - y^-), \tag{36}$$

clearly requires a complex space, we assume the real field is a self-adjoint operator, $\hat{\phi}(x^-) = \hat{\phi}(x^-)$. In fact we really think of this system in terms of creation and annihilation operators acting on a complex Hilbert space. This is best done by going into a Fourier decomposition and introducing the creation and annihilation operators corresponding to positive and negative frequency components. Such a decomposition is necessary to make the commutation relations meaningful, a glance at them shows that $[a_\alpha(p),a_\beta(q)] = \mathrm{sgn}(p)\delta[p+q]$ is consistent with the creation and annihilation operator interpretation if we define $a_\alpha(p)$ to be the annihilation and $a_\alpha(-p)$ to be the creation operators for $p>0$. Now we see that what determines this is precisely the complex structure, $J=-i\,\mathrm{sgn}(p)$. This form of the complex structure reveals another important aspect of this problem: there is no dependence on the mass. *If the bare mass changes due to the interactions, this does not change the quasifree representation of our commutation relations that were chosen at the start using the free part only*. The frequencies obviously change but that does not affect the representation. To make the Hamiltonian and various other operators of physical interest well-defined in this Fock space we must introduce a normal ordering prescription.

If we compute the commutator of two normal ordered bilinears of the field operators, that provides a realization of the real symplectic Lie algebra in its standard form. When we switch to the Fourier modes, and use the corresponding creation and annihilation operators we use the embedding of the real symplectic Lie algebra into the complex symplectic Lie algebra. In fact our operators $K(p,q)$, in the large-N_c limit, correspond to the Lie algebra generators with respect to this embedding. We will discuss this in the following. If we define our symplectic form as a matrix $\omega = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, and the complex structure as $J = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, we can diagonalize our complex structure in a complex Hilbert space by $R = (1/\sqrt{2})\left(\begin{smallmatrix} i & -i \\ 1 & 1 \end{smallmatrix}\right)$, then $R^{-1}JR = \left(\begin{smallmatrix} -i & 0 \\ 0 & i \end{smallmatrix}\right)$, whereas $R^T\omega R = i\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$. In such an embedding the real symlectic group defined by ω becomes

$$\begin{pmatrix} a & b \\ \overline{b} & \overline{a} \end{pmatrix}, \tag{37}$$

and naturally still preserves the transformed form of ω, but that is the same as the complex symplectic group, since ω as a matrix preserves its form. A general complex symplectic matrix $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, satisfies,

$$a^T c = c^T a, \quad b^T d = d^T b, \quad a^T d - c^T b = 1. \tag{38}$$

In our example we see that the Fourier transform does this transformation: it brings J into diagonal form and ω to the standard form.

The real Lie algebra can be written as

$$1 + i\begin{pmatrix} F & G \\ -\overline{G} & -\overline{F} \end{pmatrix}, \tag{39}$$

where $F^\dagger = F$ and $G^T = G$. In fact one can check that the large-N_c limit operators $K(p,q)$ obey these conditions. Furthermore there will be convergence conditions coming from the super-

renormalizability of our theory. This corresponds to the fact that we require normal ordered bilinears to create finite norm states when they act on any other state constructed from the vacuum by the action of creation operators—of course strictly speaking we should think about smeared out operators but we will ignore this technical part for this work. We can simply say that the off-diagonal components of these operators, that is b parts, should be Hilbert–Schmidt operators. In the same way we demand the same for the Lie algebra elements. (In higher dimensional theories this requirement is not satisfied and one needs a much more sophisticated not completely understood approach. One possibility was proposed by Mickelsson and Rajeev.[23,24])

In this language the constraint should be written as $(iK+i\epsilon)^2=-1$, and $i\epsilon=J$, i.e., it is the diagonal form of the complex structure we were to begin with. There is the skew form which has a matrix form in this basis $\omega=\left(\begin{smallmatrix}0 & 1\\ -1 & 0\end{smallmatrix}\right)$, which defines the symplectic group on $W\oplus\overline{W}$. We will see that the constraint actually defines a homogeneous manifold of the underlying real symplectic group. If we introduce a variable $\Phi=K+\epsilon$, the constraint becomes

$$\Phi^2=1. \tag{40}$$

One can also verify the following condition:

$$\Phi^T=\omega^{-1}\Phi\omega. \tag{41}$$

This is nothing but the Lie algebra condition. In this basis there is no difference as matrices between ω and ω^{-1} but we should remember that they transform differently. Furthermore the convergence condition becomes,

$$[\epsilon,\Phi]\in\text{Hilbert}-\text{Schmidt}. \tag{42}$$

As we will see in the following part these conditions correspond to the infinite dimensional version of the Siegel disk.

We now define a homogeneous manifold which will be denoted by D_1^R. It is essentially a real version of the disk which corresponds to the pseudounitary group. Let us define a Hilbert space $\mathcal{H}_+$, which refers to the positive frequency modes of the theory. We can also say that these are the functions which have only positive modes in their Fourier decomposition. We introduce a set of operators $Z:\mathcal{H}_+\to\mathcal{H}_-$, where $\mathcal{H}_-$ is $\overline{\mathcal{H}_+}$ in the above-given language. (If we use the full complex Hilbert space, $\mathcal{H}=\mathcal{H}_+\oplus\mathcal{H}_-$.) We impose $Z^T=Z$. We have a complex conjugation σ, this intertwines between $\mathcal{H}_+$ and $\mathcal{H}_-$, we define $Z^T=\sigma Z^\dagger\sigma$, note that $Z^\dagger:\mathcal{H}_-\to\mathcal{H}_+$, thus $Z^T:\mathcal{H}_+\to\mathcal{H}_-$. Furthermore $\overline{Z}=\sigma Z\sigma:\mathcal{H}_+\to\mathcal{H}_-$. There is an extra condition on Z: $1-Z^\dagger Z>0$. We also need a convergence condition which comes from the infinite dimensionality of the theory: $Z\in\mathcal{I}_2$, where $\mathcal{I}_2$ denotes the Hilbert–Schmidt ideal.[7,24,25]

We introduce a real restricted symplectic group, Sp_1 embedded into the above-mentioned complex symplectic group, which we precisely define in the following:

$$Sp_1^c(\mathcal{H})=\{g:\mathcal{H}\to\mathcal{H}|g^{-1}\text{ exits},\ \ g^T\omega g=\omega\ \text{ and }\ [\epsilon,g]\in\mathcal{I}_2\}. \tag{43}$$

Here we are using ordinary matrix transpose to be able to write explicit matrix elements. We can see that this is a group and we call it the restricted complex symplectic group, and its subgroup of the form

$$\begin{pmatrix} a & b\\ \overline{b} & \overline{a}\end{pmatrix},\ \text{where } b\in\mathcal{I}_2 \tag{44}$$

corresponds to the restricted real symplectic group $Sp_1(\mathcal{H})$. J itself is a real symplectic matrix and we are using a basis for the complexified Hilbert space in which J becomes diagonal.

The real symplectic group has an action on the space of operators Z, given by

$$g\circ Z=(aZ+b)(\overline{b}Z+\overline{a})^{-1}. \tag{45}$$

We can check that the action obeys the usual rule $g_1\circ(g_2\circ Z)=(g_1g_2)\circ Z$. To prove that the action preserves all the conditions we look at the orbit of $Z=0$, which is obviously in this set D_1^R. We see that the resulting element $b\overline{a}^{-1}$ satisfies all the properties, hence the orbit remains inside the disk. (We should of course see that the inverse of $\overline{a}$ exists, but that is easy using the properties of the group.) Let us assume that a Z is given, we claim that any such element lies in the orbit of $Z=0$. To show this we explicitly construct a group element which does this:

$$g(Z)=\begin{pmatrix} (1-\overline{Z}Z)^{-1/2} & Z(1-\overline{Z}Z)^{-1/2} \\ \overline{Z}(1-Z\overline{Z})^{-1/2} & (1-\overline{Z}Z)^{-1/2} \end{pmatrix}. \tag{46}$$

Note that everything here is well-defined. We leave it to the reader to check that $g(Z)$ is an element of the real group. This shows that the disk is actually a homogeneous space: take any element Z, pull it back to $Z=0$ by $g^{-1}(Z)$ and to reach any element $\tilde{Z}$ use the group element corresponding to this for the orbit of $Z=0$, $g(\tilde{Z})$ and use the compatibility condition, $\tilde{Z}=(g(\tilde{Z})g^{-1}(Z))\circ Z$. It is clear that the action then remains inside the disk.

We see that the disk is actually a complex homogeneous space, the stability subgroup corresponding to $Z=0$ is given by

$$U(\mathcal{H}_+)=\begin{pmatrix} a & 0 \\ 0 & \overline{a} \end{pmatrix}. \tag{47}$$

If we use symplectic condition we get $a^\dagger a=aa^\dagger=1$, which means a is an element of the unitary group of $\mathcal{H}_+$. This means we have

$$D_1^R=\frac{Sp_1(\mathcal{H})}{U(\mathcal{H}_+)}. \tag{48}$$

We will in fact see that the above-mentioned space is a complex homogeneous symplectic manifold, but before this it is useful to introduce a variable $\Phi(Z)$:

$$\Phi(Z)=-1+2\begin{pmatrix} (1-Z\overline{Z})^{-1} & -(1-Z\overline{Z})^{-1}Z \\ \overline{Z}(1-Z\overline{Z})^{-1} & -\overline{Z}(1-Z\overline{Z})^{-1}Z \end{pmatrix}. \tag{49}$$

Using the defining properties of Z we can check that

$$\Phi(Z)^2=1, \quad \Phi(Z)^T=\omega^{-1}\Phi(Z)\omega, \quad [\epsilon,\Phi(Z)]\in\mathcal{I}_2, \tag{50}$$

where we used the explicit standard matrix form of ω. Note that these are the same conditions on our physical variable Φ. We claim that all such $\Phi(Z)$ lie on the orbit of $\epsilon=\Phi(Z=0)$. This is easy to see using

$$\Phi(Z)=-g(Z)\epsilon\omega^{-1}g(Z)^T\omega, \tag{51}$$

which also verifies the above-mentioned conditions once more. One can see using the above-mentioned identification that the action of the group on Z becomes quite simple in terms of Φ,

$$g\circ Z\mapsto g\Phi g^{-1}. \tag{52}$$

We can check that this action preserves all the conditions on Φ.

The manifold we have found is actually symplectic. We may define a natural two form,

$$\Omega = \frac{i}{4} \mathrm{Tr}\, \Phi\, d\Phi \wedge d\Phi. \tag{53}$$

This formal expression should be understood as follows. We look at vector fields at a point Φ, any such thing can be expressed in terms of the Lie algebra elements, $V_u(\Phi) = [u, \Phi]$, where u is an element of the Lie algebra. then the two form becomes.

$$\Omega(V_u, V_v) = \frac{i}{8} \mathrm{Tr}\, \Phi[[u,\Phi],[v,\Phi]] = \frac{i}{8} \mathrm{Tr}\, \epsilon[[\epsilon, g^{-1}ug],[\epsilon, g^{-1}vg]]. \tag{54}$$

The above-mentioned form shows that the trace is well-defined due to the Hilbert–Schmidt conditions.[1,7,9] From this point of view it is easy to see that the above-mentioned form is homogeneous, and it is closed (see Refs. 1 and 7). Nondegeneracy can be proved at $\Phi = \epsilon$ and using homogeneity this is true over the manifold. If we look at the symplectic form at ϵ by using the Z coordinates, we get

$$\Omega|_{\epsilon} = 2i\, \mathrm{Tr}\, d\bar{Z} \wedge dZ. \tag{55}$$

A short computation reveals that when we write $g^{-1}ug = i\left(\begin{smallmatrix} F_1 & G_1 \\ -\bar{G}_1 & -\bar{F}_1 \end{smallmatrix}\right)$ and the same for v, $g^{-1}vg = i\left(\begin{smallmatrix} F_2 & G_2 \\ -\bar{G}_2 & -\bar{F}_2 \end{smallmatrix}\right)$ we get

$$\Omega(V_u, V_v) = -\frac{i}{2} \mathrm{Tr}(G_1 \bar{G}_2 - G_2 \bar{G}_1) = -i\, \Im\mathrm{m}\, \mathrm{Tr}\, G_1 \bar{G}_2. \tag{56}$$

In fact the previous Poisson brackets come from this sympectic form, as can be checked. We will leave the details to the reader. We note an important point about Φ. The reader can verify that

$$\Phi - \epsilon = \begin{pmatrix} 2Z(1-\bar{Z}Z)^{-1}\bar{Z} & -(1-Z\bar{Z})^{-1}Z \\ 2\bar{Z}(1-Z\bar{Z})^{-1} & -2\bar{Z}(1-Z\bar{Z})Z \end{pmatrix} \in \begin{pmatrix} \mathcal{I}_1 & \mathcal{I}_2 \\ \mathcal{I}_2 & \mathcal{I}_1 \end{pmatrix}, \tag{57}$$

where $\mathcal{I}_1$ denotes the ideal of trace class operators, hence a conditional trace for the variable $\Phi - \epsilon$ exists. We may therefore find moment maps which generate the underlying symmetry of the theory. We write down the answer but do not spend much time on it since we will not make use of these maps: $F_u = -1/2 \mathrm{Tr}_{\epsilon}\, u(\Phi - \epsilon)$, here $\mathrm{Tr}_{\epsilon} A = 1/2 \mathrm{Tr}(A + \epsilon A \epsilon)$. These provide a Poisson realization of the Lie algebra.

There could be baryonic states in the finite N_c theory given by

$$\frac{1}{Z} \epsilon_{\alpha_1 \alpha_2 \cdots \alpha_{N_c}} a^{\dagger}_{\alpha_1}(p_1) a^{\dagger}_{\alpha_2}(p_2) \cdots a^{\dagger}_{\alpha_{N_c}}(p_{N_c}) |0\rangle, \tag{58}$$

where all the momenta are positive (see Sec. III). We can measure this baryonic content by the half-trace of the operator K. We iterate again that *this is not a conserved quantity*, hence there is no baryon in the usual sense or a baryon number. The full trace gives zero since there is no antibaryon. Let us see this by looking at the operator Φ. If we evaluate the trace $\mathrm{Tr}_{\epsilon}(\Phi - \epsilon) = 2(\mathrm{Tr}\, bb^{\dagger} - \mathrm{Tr}\, \bar{b}\bar{b}^{T})$, where we used the appropriate group element $g = \left(\begin{smallmatrix} a & b \\ \bar{b} & \bar{a} \end{smallmatrix}\right)$ to write Φ. One can see that $\mathrm{Tr}\, \bar{b}\bar{b}^{T} = \overline{\mathrm{Tr}\, bb^{\dagger}} = \mathrm{Tr} bb^{\dagger}$ since $bb^{\dagger}$ is poisitive Hermitian. This shows that the trace is zero. In fact physically the correct one to take is half of this trace as we have seen in Sec. III, so we define

$$B = \frac{1}{2} \mathrm{Tr}\left[\left(\frac{1+\epsilon}{2} \right) (\Phi - \epsilon) \right]. \tag{59}$$

We see that this is a positive number, which in the large-N_c limit corresponds to the some type of baryonic content. The authors are unable to find a reason for this to be an integer, unlike the case discussed by Rajeev in Ref. 1, where the trace is related to the Fredholm index of the operators, and thus is automatically an integer. Not only is the baryonic content noninteger, it is always nonzero. That is, when there are mesons there are also baryonic states. The limit we use seems to suggest that the baryon content and mesonic states start to mix up, since the above-mentioned trace is zero only for the vacuum ϵ. Another perspective on baryons is to think of the solitonic excitations of the gauge theory, and in our case a nonzero trace perhaps implies these type of excitations. The reader may then question the validity of the linear approximation, since we claim that the baryon number is always nonzero. In the linear approximation the above-mentioned trace should be taken as zero, since it corresponds to a quadratic.

ACKNOWLEDGMENTS

Apart from the geometry of the phase space, this paper constitutes E.T.'s masters thesis. The authors would like to thank Bogazici Physics Department for all the support they have provided. Many ideas in this paper evolved through O.T.T.'s discussions with S. G. Rajeev. O.T.T. would like to thank S. G. Rajeev for being a constant source of inspiration. Discussions with M. Arik, Ö. F. (Received 2 July 2001; accepted for publication 14 December 2001)

We show the emergence of Clifford algebras of nonsymmetric bilinear forms as cotangent algebras of Kaluza–Klein (KK) spaces pertaining to teleparallel space–times. These spaces are canonically determined by the horizontal differential invariants of Finsler bundles of the type, $B'(M)\rightarrow S(M)$, where $B'(M)$ is the set of all the tangent frames to a differentiable manifold M, and where $S(M)$ is the sphere bundle. If M is space–time itself, M^4, the ''geometric phase space,'' $S(M^4)$, has dimension seven. This reformulation of the horizontal invariants as pertaining to a KK space removes the mismatch between the dimensionality of the tangent frames to M^4 and the dimensionality of $S(M^4)$. In the KK space, a symmetric tangent metric induces a cotangent metric which is not symmetric in general. An interior covariant derivative in the sense of Kaehler is defined. It involves the antisymmetric part of the cotangent metric, which thus enters electrodynamics and the Dirac equation. © *2002 American Institute of Physics.*

I. INTRODUCTION

In this paper, we follow Fauser and Ablamowicz in using the term quantum Clifford algebra (QCA) to refer to the Clifford algebra of a bilinear, not necessarily symmetric, metric.[1] The main interest of these algebras is their applicability to problems in quantum field theory, particle physics, and condensed matter physics. Some of the applications that have been suggested are fermion creation and annihilation,[2] regularization,[3] vertex ordering,[4] generating functionals,[5] and composite and multiparticle theory.[1] Also, the relation of QCAs to q-deformations of Clifford algebras[6] allows one to claim for QCA applications such as collective excitations, already claimed for q-deformations of Clifford algebras.[7] The impending issue is: where do these Clifford algebras of nonsymmetric form come from? In this paper, we show that they emerge naturally in the Kaluza–Klein (KK) context intimated in the abstract. But, first, we shall explain the title of the paper.

A more precise, though cumbersome, version of the title could have been as follows: *Quantum Clifford algebra from the differential invariants that are already present in (and are usually but incorrectly thought to be exclusive of) the traditional sector of classical differential geometry*. We use the term ''classical'' to refer to geometry in the tangent bundle, rather than Yang–Mills geometry. The term ''traditional sector'' is used to refer to the part of classical differential geometry that studies connections, metric relations, their interplay, etc. The term ''nontraditional sector'' is used to refer to Kähler's exterior–interior calculus and concomitant theory of Dirac equations.[8] The basic equations of structure of the traditional sector concern clearly the differentials of deeply geometric objects. In the case of the Kähler theory, on the other hand, the equation which plays the central role, the Kähler equation, is

a)Electronic mail: vargas@att.net

$$\partial u = a \vee u, \tag{1}$$

where ∂ represents the sum of the exterior and interior covariant derivatives, "a" is a given tensor-valued differential form (TVDF), and "u" is the unknown TVDF. Dirac's original equation is a most simple particular case of Eq. (1). It corresponds to a being given by the scalar-valued differential form $m + eA$, up to universal constants (m is mass, e is charge, and A is electromagnetic potential). The motivation to view the theory of Eq. (1) as an extension of classical differential geometry is enhanced by the possibility of using a geometric object to play the role of a,[9,10] especially since the unknown TVDF u does not make part of the differential invariants which make a and define ∂.

It is legitimate to ask why even bother about classical differential geometry in connection with QCAs, given the success of Yang–Mills theory. The reason is that "the key feature of Yang–Mills theory is that it deals with connections on auxiliary bundles, not directly tied to the geometry of the base manifold." [11] In mathematics, a bundle is auxiliary because we make it to be so as a matter of definition in the context of some geometry, say Riemannian geometry. In physics, on the other hand, the Riemannicity of space–time might in principle be just the geometrically identified part of a deeper classical-geometric reality of the world. For instance, a Riemannian structure can be reconfigured on the Finsler bundle without loss of information but with increased structural richness. A bundle may be auxiliary simply because of our inability to identify it as pertaining to a more sophisticated bundle directly tied to the base manifold, like a Finsler bundle. Weyl geometry was considered—and still is considered—as the first of the Yang–Mills theories, ahead of the times. And yet, Weyl geometry is directly related to the geometry of base manifolds endowed with metric-compatible affine connections of the particular type that Cartan called metric connections (whose fibers contain the rotations, as in Riemannian geometry, plus the dilatations or similarity transformations).[12] For Cartan's related discussions of Weyl's spaces see Refs. 13–15. One thus has to leave open the possibility that some Yang–Mills theories may eventually become part of classical differential geometry of some more general type.

The contents of the paper is organized as follows. In Sec. II, we refer to the evolution of some modern mathematics that are relevant for this work, like the emergence of the concept of quantum Clifford algebra and recent developments in both the exterior–interior calculus of Kähler and in Finsler geometry. It is precisely in the context of these developments that, in Sec. III, nonsymmetric cotangent algebras emerge from symmetric tangent algebras, both pertaining to a Kaluza–Klein (KK) structure that is canonical of Finslerian teleparallelism. However, the same structure arises if one confronts the issue of making the metric, $ds^2 = g_{\mu\nu} dx^\mu \otimes dx^\nu$, fit the mold of Clifford algebras. In Sec. IV, we relate this KK space to standard geometric structures, for the purpose of deriving in Sec. V the expression for the interior covariant derivative in the KK space. In Sec. VI, we discuss issues that should follow this work.

II. RECENT DEVELOPMENTS IN CLIFFORD ALGEBRA AND THE EXTERIOR–INTERIOR CALCULUS

Clifford algebras of nonsymmetric metrics were first considered in implicit form by Chevalley[16] and explicitly by Helmstetter,[17] Crumeyrolle,[18] and Lounesto.[19] Independently of these developments, Oziewicz also suggested new directions in Clifford algebras (algebras of multivectors and algebras of nonsymmetric metrics) and pointed out applications of these algebras to quantum field theory.[2] The physical impact of nonsymmetric metrics was not yet suggested, however. These two lines of development started to come together first in a paper by Ablamowicz and Lounesto,[20] but especially when applications of nonsymmetric metrics to quantum field theory were shown.[1,3–5]

At an even earlier time, Kähler's incorporation of Clifford algebras in the Cartan calculus resulted in a powerful, general theory of harmonic functions and Dirac equations.[8] Kähler's scheme is so clean and general that, in principle, it can be used to extend the concepts of interior derivatives and Laplacian operators to new realms of classical differential geometry, like Finsler geometry, provided that the new spaces have the appropriate algebraic structure. In the case of

Finsler geometry, for example, this requires that it be viewed from the enhanced algebraic perspective that frame bundles and affine connections bring to differential geometry, rather than from the purely metric perspective, as was the case with Riemannian geometry before the Levi-Civita connection.[21] Unfortunately the metric perspective is still dominant in Finsler geometry, which is indeed viewed, more often than not, as the geometry of spaces in which the length of curves is defined. In the alternative perspective, it is the geometry of purely affine (and of metric-compatible affine) connections in bundles where the total space is the same set of vector bases (respectively, orthonormal frames or Euclidean bases) tangent to a differentiable manifold M, but refibrated over the tangent bundle or, better yet, the bundle of directions, $S(M)$.[22]

In Sec. I, we suggested the possibility that the classical geometric reality of the space may be richer than it presently appears to be. It is then worth emphasizing that (a) the Levi-Civita affine connection is two years younger than general relativity itself and (b) although this connection uses the much older Cristoffel symbols, the two should not be identified at the conceptual level. For the enormous significance of this connection as a conceptual breakthrough, see Cartan.[23–25] Eventually, general relativity incorporated the Levi-Civita affine connection, but it might as well have incorporated any other metric compatible affine connection. All such theories share the same metric relations. No experiment has been proposed or performed that would test the affine connection of space–time, as an issue separate from the testing of the metric relations. By virtue of the fact that teleparallel connections—and only they—define an equality of vectors from different tangent spaces to a differentiable manifold, teleparallelism (TP) enhances geometric structure beyond the enhancement already achieved by the use of affine connections and bundles.

The status of the mathematical subjects that we have touched upon is as follows. The Kähler calculus has limitations[9,10] (for minimal background on the Kähler calculus, we refer readers to the appendix of our paper on the adaptation of this calculus to TP[26]). The important issue of the interior derivative remains unresolved in Finsler geometry. We have shown how the problems in these two areas are solved at the same time in a KK type of context corresponding to a teleparallel Finsler structure.[9,10,27] This paper constitutes a new step in the understanding of this KK structure, the arena where the QCA emerges. It can, however, be viewed in a way which does not explicitly resort to those developments. First, reformulate space–time geometry in a Hamilton framework (meaning that we have additional independent coordinates), as opposed to an Euler framework, since this is what our view of a particular sector of Finsler geometry amounts to. Instead of $u^i = \mathrm{d}x^i/\mathrm{d}t$, we now have $\mathrm{d}x^i - u^i\,\mathrm{d}t = 0$. These two sets of equations are equivalent only on curves. Second, further reformulate this Hamiltonian theory in five dimensions so as to include the distance element $\mathrm{d}s$ as an additional differential one-form, which presently it is not.

III. CANONICAL QUANTUM CLIFFORD ALGEBRA

In order to motivate the ''logical necessity,'' or at least the ''naturalness'' of quantum Clifford algebras, we provide a brief introduction to the ''Hamiltonian view'' of the base space for affine and Euclidean (i.e., metric compatible affine) connections. In other words, the affine Finsler bundle and Euclidean Finsler bundle (which we call the metric Finsler bundle, even if we do not include the dilations) provide an alternative arena for the treatment of metric-compatible connections on Lorentzian metrics of the usual pre-Finslerian type. On differentiable manifolds M with no metric yet assumed, denote one of the coordinates as x^0, and let $\mathbf{e}_0$ be its dual basis vector. The $\mathrm{d}x^i/\mathrm{d}x^0$ on curves generates velocity coordinates of the ''phase-space–time manifold'' $S(M)$. Via an isomorphism, one refibrates over $S(M)$, with coordinates (x^0, x^i, u^i), the set of all tangent bases to M. This refibration constitutes a bundle $B(M) \to S(M)$ which we call the affine-Finsler bundle.[22] In the isomorphism, the basis vectors named $\mathbf{e}_0$ play the role of a preferred direction.

Assume that we now put on M a pseudo-Riemannian metric of Lorentzian signature. This restricts the bundle of bases to the bundle of frames, or metric-Finsler bundle, $B'(M) \to S(M)$. If $\mathbf{e}_0$ is timelike, the group on the fibers is $O(3)$. But the group is $O(2,1)$ if $\mathbf{e}_0$ is spacelike. This second choice artificially creates a special role for a spatial direction, rather than assigning the role of the preferred direction that is used in the aforementioned isomorphism to the canonically distinguished time direction. Hence, the Lorentzian signature is distinguished or canonical for the

Finsler bundle, since it is the only one which has a direction to match the preferred direction of the Finslerian structure. The Finsler bundle of space–time with canonical choice of direction is very useful to do geometry of manifolds where the distance on curves is post-Riemannian or Finslerian. Doing Finsler geometry on this bundle complies with Cartan's view of geometry as pertaining to the tangent bundles rather than to the base manifold proper. But this is by no means the only use of this bundle, and it is not the one in which we are interested. When the usual affine connections are formulated on the Finsler bundle, the new formulation is to the old formulation of these connections what the Hamiltonian formalism is to the Euler/Lagrange formalism. Furthermore, Finsler bundles have the advantage of accepting more general connections than the usual bundles.

As in the usual bundles, ω^μ determines the translation part, $\mathrm{d}\mathbf{P}=\omega^\mu\mathbf{e}_\mu$, of the affine connection. When a metric is given, the ω^μ are implicit in the canonical form of the metric, since $\mathrm{d}s^2=(\omega^0)^2-\Sigma_i(\omega^i)^2$. On sections of Finsler bundles, we need to specify, in addition, a number $n-1$ of differential one-forms, ω_0^i, which are linear combinations of $\mathrm{d}x^0,\mathrm{d}x^i$, and $\mathrm{d}u^i$. They determine the derivative of the four-velocity vector through $\mathrm{d}\mathbf{u}=\mathrm{d}\mathbf{e}_0=\omega_0^i\mathbf{e}_i$. The identification of $\mathbf{u}$ with $\mathbf{e}_0$ is due to the fact that, in the refibration, the bases and frames become adapted to $S(M)$: all those at the point of coordinates (t,x^i,u^i) have the common velocity of components u^i and are related just by the $O(3)$ rotations. Correspondingly, the subset $(\omega_0^{\cdot i})$ of the set $(\omega_\mu^{\cdot\nu})$ has left the fibers to sit on the new (larger) base space, for both the affine-Finsler and metric-Finsler connections. The metric determines the dot product $\mathrm{d}x^\mu\cdot\mathrm{d}x^\nu=g^{\mu\nu}$. Equivalently, it determines what are the ω^μ such that $\omega^\mu\cdot\omega^\nu=\delta^{\mu\nu}$. But there is no satisfactory definition of the other dot products, $\omega^\mu\cdot\omega_0^{\cdot i}$ and $\omega_0^j\cdot\omega_0^{\cdot i}$, of the horizontal invariant forms ω^μ and $\omega_0^{\cdot i}$ of the metric-Finsler bundles.

Consider now the direct sum $M^4\oplus M^1$ of a teleparallel space–time M^4, endowed with a metric-compatible connection, and a space M^1 whose mission is to represent space–time curves when lifted to M^4. As in traditional KK, one is limited on the allowed transformations on this space by virtue of its nature as a direct sum. We endow $M^4\oplus M^1$ with connection equations:

$$\mathrm{d}\wp=\mathrm{d}\mathbf{P}+\mathrm{d}\tau\,\mathbf{e}_4,\quad \mathrm{d}\mathbf{e}_A=\omega_A^{\cdot B}\mathbf{e}_B, \tag{2}$$

where $A,B,\ldots=0,1,\ldots,4$ and where $\mathbf{e}_4$ is viewed as a tangent vector on M^1 of square minus one.[27] The $\{\mathbf{e}_\mu\}$ will be chosen to be orthonormal though not necessarily constant. Thus, with g_{AB} defined as $\mathbf{e}_A\cdot\mathbf{e}_B$, the entries $g_{\mu\nu}$ are the $\eta_{\mu\nu}$. The basis $\{\mathbf{e}_A\}$ is not a canonical basis, i.e., not a (pseudo)-orthonormal basis, of the tangent Clifford algebra defined by this dot product since the products $\mathbf{e}_4\cdot\mathbf{e}_\mu=g_{4\mu}=\mathbf{e}_\mu\cdot\mathbf{e}_4$, which evolve into components of the four-velocity on the pullbacks to (curves of) space–time, are assumed to be different from zero. We postulated

$$\omega^A\cdot\omega^B=0\quad for\ \ A\neq B \tag{3}$$

and saw the double dot product of $\mathrm{d}\wp$ with itself become

$$\mathrm{d}\wp(\cdot,\cdot)\mathrm{d}\wp=\omega^A\cdot\omega^B\mathbf{e}_A\cdot\mathbf{e}_B=\omega^0\cdot\omega^0-\omega^1\cdot\omega^1-\ldots-\mathrm{d}\tau\cdot\mathrm{d}\tau. \tag{4}$$

We further postulated $\mathrm{d}\wp(\cdot,\cdot)\mathrm{d}\wp=0$, which yielded the *natural lifting condition*:

$$\mathrm{d}\tau\cdot\mathrm{d}\tau=\mathrm{d}s\cdot\mathrm{d}s, \tag{5}$$

where

$$\mathrm{d}s\cdot\mathrm{d}s\equiv\omega^0\cdot\omega^0-\omega^1\cdot\omega^1-\omega^2\cdot\omega^2-\omega^3\cdot\omega^3. \tag{6}$$

Equations (5) and (6) justify referring to $\mathrm{d}\tau$ and $\mathbf{e}_4$, respectively, as the differential of proper time and as the five-vector whose "differential" plays the role of the acceleration one-form, even if $\mathbf{e}_4$ has projection on but is not contained in space–time (i.e., it is not a linear combination of only the $\mathbf{e}_\mu$'s). We shall now relax the conditions (3) and still obtain Eqs. (4)–(6).

We introduce the symbols "$\dot\wedge$" and "$\cdot$" to refer to the antisymmetric and symmetric parts,

$$a\dot{\wedge}b=\tfrac{1}{2}(a\vee b-b\vee a),\quad a\cdot b=\tfrac{1}{2}(a\vee b+b\vee a),\tag{7}$$

of the Clifford product "$\vee$" of two vectors, a and b, from some vector space. We obviously have $a\vee b=a\dot{\wedge}b+a\cdot b$. It is well known that the usual Clifford algebras are specified when the symmetric products $\gamma^{\mu}\cdot\gamma^{\nu}$ are given, where the (γ^{μ}) constitute a basis of the vector space (or the module) to which the a and b belong. The Clifford algebra can be tangent or cotangent, depending on whether a and b are both tangent vectors or both differential one-forms. As explained elsewhere,[9] our differential r-forms are functions of r-surfaces and not antisymmetric r-linear functions of vectors. Let us illustrate this for one-forms, like the ω^{μ}. These are functions of curves and their exterior derivative in the sense of Kähler is the usual exterior derivative. On the other hand, an element ϕ^{μ} of a field of bases (ϕ^{μ}) of the space of linear functions of vectors, $\phi^{\mu}(\mathbf{e}_{\nu})=\boldsymbol{\delta}^{\mu}_{\nu}$, can be replaced with $\mathbf{e}^{\mu}$ defined by $\mathbf{e}^{\mu}\cdot\mathbf{e}_{\nu}=\boldsymbol{\delta}^{\mu}_{\nu}$. The exterior derivative of $\mathbf{e}^{\mu}$ in the sense of Kähler is the connection-dependent derivative $\mathrm{d}\mathbf{e}^{\mu}=-\omega^{\mu}_{\nu}\mathbf{e}^{\nu}$. Hence the tangent algebra (of the ϕ^{μ} and $\mathbf{e}_{\nu}$) and cotangent algebras (of the ω^{μ}) are intertwined but not identifiable with each other. We assume that the tangent metric is symmetric. The tangent algebra is then defined by $\mathbf{e}_{\mu}\cdot\mathbf{e}_{\nu}+\mathbf{e}_{\nu}\cdot\mathbf{e}_{\mu}=2g_{\mu\nu}$. Equivalently, it is defined by $\mathbf{e}_{\mu}\vee\mathbf{e}_{\nu}+\mathbf{e}_{\nu}\vee\mathbf{e}_{\mu}=2g_{\mu\nu}$ with $g_{\mu\nu}=g_{\nu\mu}$. The symbol $\dot{\wedge}$ is in this case the symbol $\wedge$ of standard Clifford algebra. No other symbols for products are needed in the symmetric case.

Since we have to deal with two algebras at the same time, we need to introduce symbols for pairs of products. Given a pair of symbols for products within parentheseis, the first symbol will refer to the cotangent algebra and the second one to the tangent algebra. As an example, $\alpha\mathbf{a}(\dot{\wedge},\cdot)\beta\mathbf{b}=(\alpha\dot{\wedge}\beta)(\mathbf{a}\cdot\mathbf{b})$. If A and B are vector-valued one-forms, we have

$$A(\vee,\vee)B=A(\dot{\wedge},\dot{\wedge})B+A(\dot{\wedge},\cdot)B+A(\cdot,\dot{\wedge})B+A(\cdot,\cdot)B.\tag{8}$$

When A equals B, mixed products, like $A(\dot{\wedge},\cdot)A$ and $A(\cdot,\dot{\wedge})A$, cancel out. We thus have $\mathrm{d}\varphi(\vee,\vee)\mathrm{d}\varphi=\mathrm{d}\varphi(\wedge,\wedge)\mathrm{d}\varphi$ if $\mathrm{d}\varphi(\cdot,\cdot)\mathrm{d}\varphi=0$.

The key point now is that we let the cotangent algebra emerge as it may, not necessarily with a symmetric inner product even if the inner product of the tangent algebra is. We use closed circle ($\bullet$) to refer to nonsymmetric inner products. Let the center dot ($\cdot$) and the open circle ($\circ$) denote the symmetric and antisymmetric parts of the inner product "$\bullet$" of two differential scalar-valued differential one-forms, i.e., $a\bullet b=a\circ b+a\cdot b$. Since the first equation of (7) is the definition of the $\dot{\wedge}$ product, $a\dot{\wedge}b$ contains the antisymmetric part $a\circ b$ of $a\bullet b$. In other words, $a\dot{\wedge}b$ has bivector and scalar parts, namely $a\wedge b$ and $a\circ b$, respectively,

$$a\dot{\wedge}b=a\wedge b+a\circ b,\tag{9}$$

where the grading is with respect to the undotted product. The definition of $\wedge$ is such that $a\wedge b$ is the suface integrand formed with the one-forms a and b in the given order. We thus have

$$a\vee b=a\wedge b+a\circ b+a\cdot b=a\wedge b+a\bullet b.\tag{10}$$

In the same way as the usual Clifford algebra is specified when a symmetric quadratic form is given, the quantum Clifford algebra is specified when both the $a\circ b$ and $a\cdot b$ products are given

$$\omega^{A}\circ\omega^{B}=A^{AB},\quad \omega^{A}\cdot\omega^{B}=Q^{AB},\tag{11}$$

$$\omega^{A}\bullet\omega^{B}=A^{AB}+Q^{AB}.\tag{12}$$

Hence, a nonsymmetric cotangent algebra is specified by A^{AB} and Q^{AB}. We let A^{AB} be an arbitrary antisymmetric matrix whose entries are numbers or real valued functions. We define the

$\omega^A \cdot \omega^B$, equivalently the Q^{AB}, so that we precisely obtain Eq. (6). In terms of a basis of differential forms, Eq. (6) reads $\mathrm{d}\tau \cdot \mathrm{d}\tau = g_{\mu\nu} \mathrm{d}x^\mu \cdot \mathrm{d}x^\nu$ and means nothing other than $\mathrm{d}\tau\,\mathrm{d}\tau = g_{\mu\nu}\mathrm{d}x^\mu\,\mathrm{d}x^\nu$, usually written as $\mathrm{d}s^2 = g_{\mu\nu}\mathrm{d}x^\mu\,\mathrm{d}x^\nu$.

We still need to verify that Eq. (5) is satisfied. This is indeed the case,

$$0 = \mathrm{d}\wp(\cdot,\cdot)\mathrm{d}\wp = Q^{AB} g_{AB} = \omega^\mu \cdot \omega^\nu - \mathrm{d}\tau.\mathrm{d}\tau + 2Q^{\mu 4} g_{\mu 4}, \tag{13}$$

if we require that

$$Q^{\mu 4} g_{\mu 4} = 0. \tag{14}$$

In matrix form, the symmetric part, $\omega^\mu \cdot \omega^\nu$, of the cotangent inner product, $\omega^\mu \bullet \omega^\nu$, is

$$Q^{AB} = \omega^A \cdot \omega^B = \begin{bmatrix} \omega^0 \cdot \omega^0 & 0 & 0 & 0 & Q^0 \\ 0 & \omega^1 \cdot \omega^1 & 0 & 0 & Q^1 \\ 0 & 0 & \omega^2 \cdot \omega^2 & 0 & Q^2 \\ 0 & 0 & 0 & \omega^3 \cdot \omega^3 & Q^3 \\ Q^0 & Q^1 & Q^2 & Q^3 & \mathrm{d}\tau.\mathrm{d}\tau \end{bmatrix}. \tag{15}$$

The matrix Q^{AB} is not to be confused with the matrix g^{AB} inverse to g_{AB}. The conditions (15) are far more general than the conditions (3). There is no restriction on the quantities A^{AB} other than antisymmetry. Hence, the specification of the intertwined tangent and cotangent algebras requires the specification of $g_{\mu\nu}$, $g_{\mu 4}(=g_{4\mu})$, A^{AB} and a Q^μ that satisfies Eq. (14). The $g_{\mu 4}$ will now be interpreted.

IV. RELATION BETWEEN THE KALUZA–KLEIN AND STANDARD GEOMETRIC FORMULATIONS

In this section, we relate the KK formulation to the standard formulation of classical differential geometry by first identifying flat space–time itself in the first of these formulations. In Ref. 27, we produced a KK connection for teleparallel Finsler spaces. We simply assumed metric compatibility and that

$$\omega_\rho^{\cdot\sigma} = 0 \tag{16}$$

and obtained

$$\omega_{4\rho} = \mathrm{d}g_{4\rho}, \tag{17}$$

and

$$\omega_4^{\cdot\rho} = \eta_\rho(\omega_{4\rho} - g_{4\rho}\omega_4^{\cdot 4}), \quad \omega_4^{\cdot 4} = G^{-1}\eta_\rho g_{4\rho}\mathrm{d}g_{4\rho} = \omega_4^{\cdot\rho} g_{4\rho}, \quad \omega_\rho^{\cdot 4} = 0, \tag{18}$$

where η_ρ is $(+1,-1,-1,-1)$ and where

$$G \equiv 1 + (g_{40})^2 - (g_{41})^2 - (g_{42})^2 - (g_{43})^2. \tag{19}$$

We return momentarily to the Finsler bundle. One imposes six conditions among the seven horizontal forms of $S(M^4)$ to obtain curves. Three of these conditions constitute, for instance, the statement that $\mathrm{d}\mathbf{e}_4 = \mathbf{0}$, or, as another important option, the statement of stationary length. Three additional conditions are the "Cartan conditions," $\mathrm{d}x^i - u^i\,\mathrm{d}t = 0$. These six forms together determine the curves of interest in the seven-dimensional $S(M^4)$ space. All differential one-forms become proportional to just one, say $\mathrm{d}t$. In the five-dimensional KK space, we need to impose only four conditions. For example, the statement $\mathrm{d}\mathbf{u} = 0$ achieves this. Although this amounts to the five equations

$$\omega_4^{\cdot A}=0, \tag{20}$$

these equations are not independent since

$$\omega_4^{\cdot 4}=\omega_4^{\cdot \mu}g_{4\mu}. \tag{21}$$

Equation (20) thus provides four independent conditions to determine curves in the KK space.

The condition $\omega_\mu^{\cdot \nu}=0$ (constant frame fields in TP) together with metric compatibility yielded the full set of $\omega_A^{\cdot B}$. These equations then allowed us in turn to reduce the torsion to the form:

$$\Omega'^{\mu}=\mathrm{d}\omega^{\mu}-\mathrm{d}\tau\wedge\omega_4^{\cdot \mu}, \tag{22}$$

$$\Omega'^{4}=-\mathrm{d}\tau\wedge\omega_4^{\cdot 4}. \tag{23}$$

The conditions $\omega_4^{\cdot \mu}=0$ and $\omega_4^{\cdot 4}=0$ that determine the autoparallels are the same conditions that project Ω'^{μ} and Ω'^{4} down to space–time. This opens the door for the interpretation that $\omega_4^{\cdot \mu}$ embodies inertial forces, since they do not affect the space–time structure. In this case, $\omega_4^{\cdot 4}$ also does, by virtue of Eq. (21). Only when the "additional structure" generated by $\omega_4^{\cdot \mu}$ is zero, all the forces are noninertial.[28]

We proceed to unearth in the KK formalism the standard equations of the autoparallels of space–time. For this, we do not assume constant frame fields, where $\omega_\mu^{\cdot \nu}=0$, even if we assume TP. The reason is that, in these fields, we have

$$\mathrm{d}\mathbf{u}=\mathrm{d}(u^{\mu}\mathbf{e}_{\mu})=\mathrm{d}u^{\mu}\mathbf{e}_{\mu}+u^{\mu}\omega_{\mu}^{\cdot \nu}\mathbf{e}_{\nu}=\mathrm{d}u^{\mu}\mathbf{e}_{\mu}. \tag{24}$$

The statement $\mathrm{d}\mathbf{u}=0$ would amount to assuming constant u^{μ}. In the relativistic analog that $\mathbf{u}$ were the four-velocity, this would represent motion under gravitational forces being referred to free-falling comoving reference frames. The problem of finding the equations of the motion has metamorphosed into the problem of finding the relation of the free falling frames to the bases attached to matter (say, the coordinate basis fields). We readily have

$$\mathrm{d}g_{4\rho}=\mathrm{d}(\mathbf{e}_4\cdot\mathbf{e}_{\rho})=\mathrm{d}\mathbf{e}_4\cdot\mathbf{e}_{\rho}+\mathbf{e}_4\cdot\omega_{\rho}^{\cdot \nu}\mathbf{e}_{\nu}-\omega_{\rho}^{\cdot 4}. \tag{25}$$

By virtue of the assumption $\mathrm{d}\mathbf{e}_4=\mathbf{0}$ for the equations of the motion, we further get

$$\mathrm{d}g_{4\rho}=g_{4\nu}\omega_{\rho}^{\cdot \nu}-\omega_{\rho}^{\cdot 4}. \tag{26}$$

With orthonormal frames, we have: $\omega_{\rho}^{\cdot \nu}=\eta_{\nu}\omega_{\rho\nu}=-\eta_{\nu}\omega_{\nu\rho}=-\omega_{\cdot\rho}^{\nu}$. Hence:

$$\mathrm{d}g_{4\rho}+\omega_{\cdot\rho}^{\nu}g_{4\nu}=-\omega_{\rho}^{\cdot 4}. \tag{27}$$

The equations of the autoparallels are present here if the pull-back of $g_{4\rho}$ to space–time curves is interpreted as constituting the components of the four-velocity on those curves, consistently with a previous related discussion.[27] The interpretation of $\omega_{\rho}^{\cdot 4}$ will be dealt with in a paper in preparation. Notice that this equation is not affected by the antisymmetric part of the dot product in the cotangent Clifford algebra. We shall now see the impact of this antisymmetric part on the physics through the interior derivative.

V. IMPACT OF THE QCA ON THE INTERIOR DERIVATIVE

The combined exterior–interior derivative, ∂, of the Kähler calculus is given by

$$\partial\alpha=\omega^{\mu}\vee\mathrm{d}_{\mu}\alpha=\omega^{\mu}\dot{\wedge}\mathrm{d}_{\mu}\alpha+\omega^{\mu}\cdot\mathrm{d}_{\mu}\alpha=\omega^{\mu}\wedge\mathrm{d}_{\mu}\alpha+\omega^{\mu}\bullet\mathrm{d}_{\mu}\alpha \tag{28}$$

where the symbols for the products are as defined in Sec. III and where $\mathrm{d}_\mu\alpha$ is what Kähler denotes as the covariant derivative of α. So far, the relation between the two exterior products may be viewed from the equivalent definitions

$$\omega^\mu \dot{\wedge} \mathrm{d}_\mu\alpha = \omega^\mu \wedge \mathrm{d}_\mu\alpha + \omega^\mu \bigcirc \mathrm{d}_\mu\alpha \tag{29}$$

and

$$\omega^\mu \wedge \mathrm{d}_\mu\alpha = \omega^\mu \dot{\wedge} \mathrm{d}_\mu\alpha - \omega^\mu \bigcirc \mathrm{d}_\mu\alpha. \tag{30}$$

We identify the gradation of "$\wedge$" with the one defined by Stokes theorem. The choice of A^{BC} together with Eq. (9) (viewed as a definition) then fix the $\dot{\wedge}$ product. Kähler's interior derivative must then be taken to be the complement, $\omega^\mu \bullet \mathrm{d}_\mu\alpha$, of the exterior derivative, $\omega^\mu \wedge \mathrm{d}_\mu\alpha$, that enters Stokes' theorem (Kähler conceived the covariant derivative so that $\omega^\mu \wedge \mathrm{d}_\mu\alpha$ coincides with the exterior derivative when α is scalar-valued, and with the exterior covariant derivative when it is a TVDF). The interior derivative so defined has both symmetric and antisymmetric contributions from the "$\bullet$" product.

It is clear that electrodynamics and quantum mechanics will depend on the nonsymmetric part of the metric in this new scenario, since the interior derivative enters both of these theories in an essential way. The relevance of the interior derivative in the case of gravitation, precisely the most geometric of all these theories in the present paradigm, depends on what we assume to be the connection of space–time and the role that this connection is postulated to play in the theory. Indeed, the affine curvature is the exterior covariant derivative $\mathrm{d}(\omega_\mu^{\cdot\nu}\mathbf{e}_\nu)$ of $\omega_\mu^{\cdot\nu}\mathbf{e}_\nu$, i.e.,

$$\mathrm{d}(\omega_\mu^{\cdot\nu}\mathbf{e}_\nu) = (\mathrm{d}\omega_\mu^{\cdot\nu} - \omega_\mu^{\cdot\lambda} \wedge \omega_\lambda^{\cdot\nu})\mathbf{e}_\nu. \tag{31}$$

Einstein's field equations involve only the Einstein tensor and thus fail to involve the full curvature in the field equations. Hence they fail to involve the full exterior derivative of $\omega_\mu^{\cdot\nu}\mathbf{e}_\nu$. The interior derivative is not even mentioned in general relativity. Denoting this derivative with the symbol δ, we have

$$\delta(\omega_\mu^{\cdot\nu}\mathbf{e}_\nu) = \omega^\rho \bullet R_{\mu\cdot\rho\sigma}^{\cdot\nu}\omega^\sigma\mathbf{e}_\nu, \tag{32}$$

which is not zero for general connection. It is, however, zero for teleparallel connections since $R_{\mu\cdot\rho\sigma}^{\cdot\nu}$ itself is then zero. The conclusion is that the cotangent Clifford algebra (QCA) does not impact the gravitational sector of the physical theory canonically determined by TP. It fails to impact general relativity for a completely different reason, namely that this theory does not involve the Kähler derivative of the connection.

We proceed to consider interior derivatives. In order to avoid the clutter produced by connection terms, we shall assume space–time TP, so that we can use frame fields where $\omega_\mu^{\cdot\nu} = 0$. Whether we assume TP or not, we can still neglect the connection terms in the computations and restore them in the final results through replacement of the partial derivatives with covariant derivatives. A connection-dependent result, however, is that $\omega_\mu^{\cdot\nu} = 0$ (TP) implies $\omega_\mu^{\cdot A} = 0$, at least when all the $g_{4\mu}$ are different from zero.[27]

We shall limit ourselves to space–time differential forms on practical grounds, although there may well be deep reasons not to consider differential forms with a term proportional to $\mathrm{d}\tau$ for most purposes. This is reminiscent of the limited form of the transformations allowed in the traditional KK theory. In order to deal with bases ω^μ, we extend the meaning of the comma when used as a subscript. The $f_{,\mu}$ means the coefficients defined by the equation $\mathrm{d}f = f_{,\mu}\omega^\mu$. The $f_{,\mu}$ become the partial derivatives when ω^μ is $\mathrm{d}x^\mu$ itself.

Let α be the one-form $a_\mu\omega^\mu$. We then have:

$$\mathrm{d}(a_\mu\omega^\mu) = \mathrm{I} + \mathrm{II} + \mathrm{III}, \tag{33}$$

where

$$\mathrm{I}=a_{\nu,\mu}\omega^{\mu}\wedge\omega^{\nu}, \tag{34}$$

$$\mathrm{II}=a_{\nu}\Omega^{\nu}, \tag{35}$$

$$\mathrm{III}=a_{\nu}\omega^{C}\wedge\omega_{C}^{\nu}=a_{\nu}\omega^{4}\wedge\omega_{4}^{\nu}. \tag{36}$$

The interior derivative, δ_{I}, resulting from the I term is

$$\delta_{\mathrm{I}}=a_{\nu,\mu}\omega^{\mu}\bullet\omega^{\nu}=a_{\nu,\mu}A^{\mu\nu}+\sum_{\nu}a_{\nu,\nu}\omega^{\nu}\cdot\omega^{\nu}. \tag{37}$$

For the II term, we use that the torsion in KK space is

$$\mathbf{\Omega}'=\mathrm{d}(\mathrm{d}\wp)=\mathrm{d}(\mathrm{d}\mathbf{P}+\mathrm{d}\tau\mathbf{e}_4)=\Omega-\mathrm{d}\tau\wedge\mathrm{d}\mathbf{e}_4. \tag{38}$$

Hence, we have $\Omega'^{\mu}=\Omega^{\mu}-\mathrm{d}\tau\wedge\omega_4^{\mu}$ and $\Omega'^{4}=-\mathrm{d}\tau\wedge\omega_4^{4}$. It follows that

$$\mathrm{II}=a_{\nu}\Omega'^{\nu}=a_{\nu}\Omega^{\nu}-a_{\nu}\,\mathrm{d}\tau\wedge\omega_4^{\nu}. \tag{39}$$

For the above-stated reasons, we drop the term III, or simply compute mod ω_4^{ν}. We thus have

$$\delta_{\mathrm{II}}=a_{\nu}R^{\nu}_{\mu\lambda}\omega^{\mu}\bullet\omega^{\lambda}=a_{\nu}R^{\nu}_{\mu\lambda}A^{\mu\lambda}. \tag{40}$$

The symmetric part of the product has dropped out because $R^{\nu}_{\mu\lambda}=-R^{\nu}_{\lambda\mu}$. The third term disappears mod ω_4^{ν}. Collecting terms, we get

$$\delta(a_{\mu}\omega^{\mu})=\sum_{\nu}a_{\nu,\nu}\omega^{\nu}\cdot\omega^{\nu}+a_{\nu,\mu}A^{\mu\nu}+a_{\nu}R^{\nu}_{\mu\lambda}A^{\mu\lambda}. \tag{41}$$

Consider now a two-form, $\beta=b_{\lambda\rho}\omega^{\lambda}\wedge\omega^{\rho}$, and assume the same simplifying assumptions. We have

$$\mathrm{d}\beta=\mathrm{d}(b_{\lambda\rho}\omega^{\lambda}\wedge\omega^{\rho})=b_{\lambda\rho,\mu}\omega^{\mu}\wedge\omega^{\lambda}\wedge\omega^{\rho}+b_{\sigma\rho}\mathrm{d}\omega^{\sigma}\wedge\omega^{\rho}-b_{\rho\sigma}\omega^{\rho}\wedge\mathrm{d}\omega^{\sigma}. \tag{42}$$

The first term on the right of this equation contributes to the interior derivative $\delta\beta$ with

$$\delta_{\mathrm{I}}=b_{\lambda\rho,\mu}\omega^{\mu}\bullet(\omega^{\lambda}\wedge\omega^{\rho})=b_{\lambda\rho,\mu}\omega^{\mu}\bullet(\omega^{\lambda}\dot{\wedge}\omega^{\rho}-\omega^{\lambda}\bigcirc\omega^{\rho}). \tag{43}$$

We proceed to compute this "$\bullet$" product. For any clifform B, we have

$$\omega^{\mu}\bullet B=\omega^{\mu}\vee B-\omega^{\mu}\wedge B=\omega^{\mu}\dot{\wedge}B+\omega^{\mu}\cdot B-\omega^{\mu}\wedge B. \tag{44}$$

Hence, for $B=\omega^{\lambda}\wedge\omega^{\rho}$, we get

$$\begin{aligned}\omega^{\mu}\bullet(\omega^{\lambda}\wedge\omega^{\rho})&=\omega^{\mu}\bullet(\omega^{\lambda}\dot{\wedge}\omega^{\rho}-\omega^{\lambda}\bigcirc\omega^{\rho})\\&=\omega^{\mu}\dot{\wedge}(\omega^{\lambda}\dot{\wedge}\omega^{\rho}-\omega^{\lambda}\bigcirc\omega^{\rho})+\omega^{\mu}\cdot(\omega^{\lambda}\dot{\wedge}\omega^{\rho}-\omega^{\lambda}\bigcirc\omega^{\rho})-\omega^{\mu}\wedge\omega^{\lambda}\wedge\omega^{\rho}.\end{aligned} \tag{45}$$

Of the five terms that arise from Eq. (45), the first and fifth together yield $\omega^{\mu}A^{\lambda\rho}+\omega^{\lambda}A^{\rho\mu}+\omega^{\rho}A^{\mu\lambda}$. The second term is $-\omega^{\mu}A^{\lambda\rho}$. The third term is $(\omega^{\mu}\cdot\omega^{\lambda})\omega^{\rho}-(\omega^{\mu}\cdot\omega^{\rho})\omega^{\lambda}$. The fourth term is zero, since $\omega^{\lambda}\bigcirc\omega^{\rho}(=A^{\lambda\rho})$ is scalar-valued. All this together yields

$$\omega^{\mu}\bullet(\omega^{\lambda}\wedge\omega^{\rho})=\omega^{\lambda}A^{\rho\mu}+\omega^{\rho}A^{\mu\lambda}+(\omega^{\mu}\cdot\omega^{\lambda})\omega^{\rho}-(\omega^{\mu}\cdot\omega^{\rho})\omega^{\lambda}. \tag{46}$$

Combining the first term with the fourth one and the second with the third, we get

$$\omega^{\mu}\bullet(\omega^{\lambda}\wedge\omega^{\rho})=\omega^{\rho}(\omega^{\mu}\bullet\omega^{\lambda})-\omega^{\lambda}(\omega^{\mu}\bullet\omega^{\rho}). \tag{47}$$

Either Eq. (46) or (47) is to be substituted in Eq. (43).

The second term of Eq. (42) yields, with $\omega_{\mu}^{\cdot\nu}=0$, that $b_{\sigma\rho}\mathrm{d}\omega^{\sigma}\wedge\omega^{\rho}$ equals $b_{\sigma\rho}\Omega^{\sigma}\wedge\omega^{\rho}$. We shall denote as δ_{IV} the contribution to the interior derivative of this term. We readily get

$$\delta_{\mathrm{IV}}=b_{\sigma\rho}R^{\sigma}_{\mu\lambda}\omega^{\mu}\bullet(\omega^{\lambda}\wedge\omega^{\rho}). \tag{48}$$

Finally, the last term on the right-hand side of Eq. (42) can be written as $-b_{\rho\sigma}\mathrm{d}\omega^{\sigma}\wedge\omega^{\rho}$, which equals the second term. The sought $\delta\beta$ then is $\delta_{\mathrm{I}}+2\,\delta_{\mathrm{IV}}$. Using first Eqs. (43) and (48), and then Eq. (46), we obtain

$$\begin{aligned}\delta\beta=\delta(b_{\lambda\rho}\omega^{\lambda}\wedge\omega^{\rho})&=[b_{\lambda\rho,\mu}+2b_{\sigma\rho}R^{\sigma}_{\mu\lambda}]\omega^{\mu}\bullet(\omega^{\lambda}\wedge\omega^{\rho})\\&=b_{\lambda\rho,\mu}(\omega^{\lambda}A^{\rho\mu}+\omega^{\rho}A^{\mu\lambda})+b_{\lambda\rho,\mu}[(\omega^{\mu}\cdot\omega^{\lambda})\omega^{\rho}-(\omega^{\mu}\cdot\omega^{\rho})\omega^{\lambda}]\\&\quad+2b_{\sigma\rho}R^{\sigma}_{\mu\lambda}(\omega^{\lambda}A^{\rho\mu}+\omega^{\rho}A^{\mu\lambda})+2b_{\sigma\rho}R^{\sigma}_{\mu\lambda}[(\omega^{\mu}\cdot\omega^{\lambda})\omega^{\rho}-(\omega^{\mu}\cdot\omega^{\rho})\omega^{\lambda}].\end{aligned} \tag{49}$$

Hence, we finally get

$$\delta\beta=2(b_{\mu\rho,\mu}-b_{\sigma\mu}R^{\sigma}_{\mu\rho})(\omega^{\mu}\cdot\omega^{\mu})\omega^{\rho}+2b_{\lambda\rho,\mu}A^{\rho\mu}\omega^{\lambda}+2(b_{\sigma\rho}R^{\sigma}_{\mu\lambda}-b_{\sigma\lambda}R^{\sigma}_{\mu\rho})A^{\rho\mu}\omega^{\lambda}. \tag{50}$$

The factors $b_{\lambda\rho,\mu}$ go into $b_{\lambda\rho;\mu}$ when the connection is taken into account. The factor of 2 (actually $r!$ if we were dealing with an r-form) disappears when we introduce r-forms with the standard coefficient of $(1/r!)$.

It is now clear what the interior derivative, $\delta\mathbf{T}$, of a vector-valued two-form $\mathbf{T}=(1/2)T^{\pi}_{\lambda\rho}\omega^{\lambda}\wedge\omega^{\rho}\mathbf{e}_{\pi}$ is

$$\delta\mathbf{T}=[(T^{\pi}_{\mu\rho,\mu}-T^{\pi}_{\sigma\mu}R^{\sigma}_{\mu\lambda})(\omega^{\mu}\cdot\omega^{\mu})\omega^{\rho}+T^{\pi}_{\lambda\rho,\mu}A^{\rho\mu}\omega^{\lambda}+(T^{\pi}_{\sigma\rho}R^{\sigma}_{\mu\lambda}-T^{\pi}_{\sigma\lambda}R^{\sigma}_{\mu\rho})A^{\rho\mu}\omega^{\lambda}]\mathbf{e}_{\pi}. \tag{51}$$

The most interesting result happens when the vector-valued two-form is the torsion itself, which, for present purposes, we shall restrict to the space–time type, $\mathbf{\Omega}=(1/2)R^{\pi}_{\lambda\rho}\omega^{\lambda}\wedge\omega^{\rho}\mathbf{e}_{\pi}$. We then have

$$\delta\mathbf{\Omega}=[(R^{\pi}_{\mu\rho,\mu}-R^{\pi}_{\sigma\mu}R^{\sigma}_{.\mu\lambda})(\omega^{\mu}\cdot\omega^{\mu})\omega^{\rho}+R^{\pi}_{\lambda\rho,\mu}A^{\rho\mu}\omega^{\lambda}+(R^{\pi}_{\sigma\rho}R^{\sigma}_{\mu\lambda}-R^{\pi}_{\sigma\lambda}R^{\sigma}_{\mu\rho})A^{\rho\mu}\omega^{\lambda}]\mathbf{e}_{\pi}. \tag{52}$$

In this case, $A^{\rho\mu}$ multiplies linear terms on the torsion's partial derivatives, and quadratic but not linear terms on the torsion itself. This seems to indicate that the effects of $A^{\rho\mu}$ will be the larger in absolute terms the greater the torsion is (the terms $R^{\pi}_{\lambda\rho,\mu}A^{\rho\mu}\omega^{\lambda}$, however, make qualitative arguments nontrivial).

VI. CONCLUDING REMARKS

The issue of the interior derivative is one which typically resists treatment in post-Riemannian contexts, especially when Finsler metrics are involved. In contrast, Finslerian TP on Riemannian metrics yields one such derivative in a canonical way. A better understanding of terms proportional to $\omega^{\mu}\cdot\omega^{\mu}$ and $(\omega^{\mu}\cdot\omega^{\mu})\omega^{\rho}$ is to be sought. It is probably safe to assume, however, that $\omega^{\mu}\cdot\omega^{\mu}$ and $(\omega^{\mu}\cdot\omega^{\mu})\omega^{\rho}$ have to be seen as members of a basis. The coefficients of these basis elements on the left- and right-hand sides of equations would have to be matched. On the right-hand sides, they would arise in the process of obtaining Hodge duals of the three-forms j and $\mathbf{j}$ that constitute the current, in equations such as $\mathrm{d}F=*j$ and $\mathrm{d}\mathbf{\Omega}=*\mathbf{j}$. The process of obtaining this dual should give rise to terms of this type in a natural way, but this is a topic which certainly deserves closer scrutiny.

A second area of research to follow the present work has to do with the possibility of using the equations of structure of the traditional and nontraditional sectors of Finslerian TP as the field equations of the physics.[10] In this regard recall that, in a Finslerian torsion,

$$\Omega^0 = R^0_{\mu\nu}\omega^\mu \wedge \omega^\nu + S^0_{\mu j}\omega^\mu \wedge \omega_0^{\cdot j}, \tag{53}$$

$$\Omega^i = R^i_{\mu\nu}\omega^\mu \wedge \omega^\nu + S^i_{\mu j}\omega^\mu \wedge \omega_0^{\cdot j}. \tag{54}$$

The coefficients $R^0_{\mu\nu}$, $R^i_{\mu\nu}$, and $S^0_{\mu j}$ can tentatively be interpreted as the components of the electromagnetic, strong, and weak fields.[28] One must then associate $S^i_{\mu j}$ with some weak/strong complex. The interpretation of $R^i_{\mu\nu}$ as the weak interaction is already present in Pandres,[29,30] though his context is not Finslerian. One would, therefore, expect that boosts would mix the $R^0_{\mu\nu}$ and $R^i_{\mu\nu}$ components, which does not make sense. The way in which this problem is avoided in the non-Finslerian context is by using tetrads, use which comes accompanied by a separate treatment of the superscript and the subscripts in the tetrads. One further stipulates *ab initio* that the Lorentz transformations (or at least the boosts) only affect the subscripts in the tetrads, equivalently in the components of the torsion. The Finslerian context provides a natural interpretation of this, since the boosts are no longer transformations in the fibers of the Finsler bundles, but rather ''translations'' in the seven-dimensional ''phase-space–time'' manifold $S(M^4)$.

The differential invariants that determine the teleparallel Finslerian classical differential geometry are the same ones as those that determine the KK space. One thus has to assume that the degrees of freedom contained in the S components of the torsion have moved to other places in the KK structure. We thus tentatively associate the A^{BC} entries with $S^0_{\mu j}$ and, therefore, with the strong interaction. It then appears that the Q^μ would have to be associated with the other S quantities, namely with the $S^i_{\mu j}$ interaction, if the basic equations of the physics happen to be a manifestation of a teleparallel Finsler structure of space–time. The association of Q^μ with the weak/strong complex represented by $S^i_{\mu j}$ is suggested by Eq. (13), expressing the orthogonality of the velocity and Q^μ (recall that, from a Finslerian perspective, ''weak'' appears to be associated with orthogonality to the four-velocity[28]). Of course, it would seem that there are too few degrees of freedom in the Q^μ, as compared with the three indices in $S^i_{\mu j}$. This is not, however, the case, for the following reason. The $\omega_i^{\cdot j}$ represents a rotation of both the moving frame (MF) and the reference frame (RF) in standard differential geometry viewed as a theory of moving frames, since the motion of the MF is referred to itself and the MF and RF coincide. In our KK treatment, the boosts of the MF are represented by $d\mathbf{u}$, and the boosts and rotations of the RF are represented by $d\mathbf{e}_\mu$. The rotations of the MF have been removed *ab initio* from our KK construction. This was possible because a standard teleparallel structure is determined once the ω^μ's are given in a constant frame field, and a Finslerian teleparallel structure is determined once the $(\omega^\mu,\ \omega^i_0)$ are given on a constant section $(\omega^i_j = 0)$ of the metric-Finsler bundle. Thus the active rotations must be introduced by hand (say like a direct product) in the KK formalism, which is consistent with, but is not in principle about, MFs. It is in the context of such process that the relation to $S^i_{\mu j}$ of Q^μ (together with the differential invariants of the attached rotations) have to be viewed. The correspondence between the differential invariants in the teleparallel Finsler structure, on the one hand, and in its associated KK structure, on the other hand, thus emerges as an interesting subject for further research.

We conclude with the statement of our main finding, namely that the canonical geometry of Finslerian TP and its ramifications provides a solution to the issue of the interior derivative which is deeply connected with the cutting edge subject of Clifford algebras of nonsymmetric metrics.

On separable Pauli equations

Alexander Zhalij[a)]
Institute of Mathematics of the Academy of Sciences of Ukraine, Tereshchenkivska Street 3, 01601 Kyiv-4, Ukraine

(Received 2 October 2001; accepted for publication 30 November 2001)

We classify $(1+3)$-dimensional Pauli equations for a spin-$\frac{1}{2}$ particle interacting with the electro-magnetic field, that are solvable by the method of separation of variables. As a result, we obtain the 11 classes of vector-potentials of the electro-magnetic field $A(t,\vec{x})=(A_0(t,\vec{x}),\vec{A}(t,\vec{x}))$ providing separability of the corresponding Pauli equations. It is established, in particular, that the necessary condition for the Pauli equation to be separable into second-order matrix ordinary differential equations is its equivalence to the system of two uncoupled Schrödinger equations. In addition, the magnetic field has to be independent of spatial variables. We prove that coordinate systems and the vector-potentials of the electro-magnetic field providing the separability of the corresponding Pauli equations coincide with those for the Schrödinger equations. Furthermore, an efficient algorithm for constructing all coordinate systems providing the separability of Pauli equation with a fixed vector-potential of the electro-magnetic field is developed. Finally, we describe all vector-potentials $A(t,\vec{x})$ that (a) provide the separability of Pauli equation, (b) satisfy vacuum Maxwell equations without currents, and (c) describe non-zero magnetic field. [DOI: 10.1063/1.1436563]

I. INTRODUCTION

A quantum mechanical system consisting of a spin-$\frac{1}{2}$ charged particle, moving with momentum $\vec{p}$ in a time-dependent electro-magnetic field with the four-component vector-potential $(A_0,\vec{A})$, is described in a nonrelativistic approximation by the Pauli equation (see, e.g., Ref. 1)

$$(p_0-eA_0(t,\vec{x})-(\vec{p}-e\vec{A}(t,\vec{x}))^2+e\vec{\sigma}\vec{H})\psi(t,\vec{x})=0. \tag{1}$$

Here $\psi(t,\vec{x})$ is the two-component wave function in three space dimensions $\vec{x}=(x_1,x_2,x_3)$, $\vec{H}=\mathrm{rot}\vec{A}$ is the magnetic field, and $\vec{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$ is a vector consisting of three Pauli matrices

$$\sigma_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}. \tag{2}$$

Hereafter we use the notations

$$p_0=i\frac{\partial}{\partial t},\quad \vec{p}=-i\vec{\nabla},\quad a=1,2,3, \tag{3}$$

and summation over the repeated Latin indices from 1 to 3 is implied.

As the Pauli equation has variable coefficients, we cannot apply the standard Fourier transformation. The only regular way for solving (1) is the classical method of separation of variables in curvilinear coordinate systems. In this respect, a natural question arises, which equations of the form (1) are separable, namely, which potentials A_0, $\vec{A}$ allow for separability of the Pauli equation

a)Electronic mail: zhaliy@imath.kiev.ua

in some curvilinear coordinate system? One of the principal objectives of the present article is to provide an efficient algorithm for answering these kinds of questions for systems of partial differential equations. It is essentially based on the results of Ref. 2, where the problem of separation of variables in the Schrödinger equation has been analyzed in detail. As the Pauli equation (1) differs from the Schrödinger equation by the term $e\vec{\sigma}\vec{H}$ only, it is natural to attempt modifying the technique employed in Ref. 2 in order to make it applicable to system of partial differential equations (PDEs) (1).

Integrable Hamiltonian systems with velocity-dependent potentials have been studied for the case $n=2$, i.e., in a Euclidean plane by Winternitz with co-authors.[3,4] Recently Benenti with co-authors[5] studied the problem of separation of variables in the stationary Hamilton–Jacobi equation with vector-potential from a geometrical point of view.

The problem of separation of variables for linear systems of first-order partial differential equations such as the Dirac equation has been repeatedly addressed by Shapovalov and Bagrov with co-authors[6,7] and by Kalnins and Miller with co-authors.[8–10] They developed a symmetry approach to the separation of variables in the Dirac equation where separability is characterized by the existence of a complete set of first-order matrix symmetry operators.

Symmetry and supersymmetry properties of the Pauli equations are studied in Ref. 11–13. Let us also mention Ref. 14, where physical aspects of the problem of separation of variables in some $(1+3)$-dimensional Pauli equations with time-dependent potentials are studied, and Ref. 7, where some classes of exact solutions of the Pauli equation are presented.

With all the variety of approaches to separation of variables in PDEs one can notice the three generic principles, namely,

(a) representation of a solution to be found in a separated (factorized) form via several functions of one variable,
(b) requirement that the above mentioned functions of one variable should satisfy some ordinary differential equations, and
(c) dependence of so found solution on several arbitrary (continuous or discrete) parameters, called spectral parameters or separation constants.

By a proper formalizing of the above features we have formulated in Ref. 2 an algorithm for variable separation in the Schrödinger equation with vector-potential. Below we generalize this algorithm for the case of system of PDEs (1).

To have a right to talk about description of *all* potentials and *all* coordinate systems enabling us to separate the Pauli equation, one needs to provide a rigorous definition of separation of variables. The definition we intend to use is based on ideas contained in the paper by Koornwinder.[15]

Let us introduce a new coordinate system t, $\omega_a=\omega_a(t,\vec{x})$, $a=1,2,3$, where ω_a are real-valued functions, functionally independent with respect to the spatial variables x_1, x_2, x_3, i.e.,

$$\det\left\|\frac{\partial\omega_a}{\partial x_b}\right\|_{a,b=1}^{3}\neq 0. \tag{4}$$

For a solution to be found we adopt the following separation ansatz:

$$\psi(t,\vec{x})=Q(t,\vec{x})\varphi_0(t)\prod_{a=1}^{3}\varphi_a(\omega_a(t,\vec{x}),\vec{\lambda})\chi, \tag{5}$$

where Q, φ_μ, $(\mu=0,1,2,3)$ are nonsingular 2×2-matrix functions of the indicated variables and χ is an arbitrary two-component constant column. What is more, the condition of commutativity of the matrices φ_μ is imposed, namely,

$$[\varphi_\mu,\varphi_\nu]=\varphi_\mu\varphi_\nu-\varphi_\nu\varphi_\mu=0,\quad \mu,\nu=0,1,2,3. \tag{6}$$

Note that the restriction (6) is an extra requirement, which narrows the class of separable Pauli equations. However, without this condition an efficient handling of the ansätze of the form (6) seems to be impossible. At least, in all papers devoted to variable separation in a systems of PDEs the condition of commutativity is imposed (explicitly or implicitly).

Definition 1: We say that the Pauli equation (1) admits separation of variables in a coordinate system t, $\omega_a=\omega_a(t,\vec{x})$, $a=1,2,3$, *if there are nonsingular* 2×2 *-matrix function* $Q(t,\vec{x})$ *and four matrix ordinary differential equations*

$$\begin{aligned} i\dot{\varphi}_0 &= -(P_{00}(t)+P_{0b}(t)\lambda_b)\varphi_0, \\ \ddot{\varphi}_a &= (P_{a0}(\omega_a)+P_{ab}(\omega_a)\lambda_b)\varphi_a, \quad a=1,2,3, \end{aligned} \tag{7}$$

jointly depending in an analytic way on three independent complex parameters λ_1, λ_2, λ_3 *(separation constants), such that, for each triplet* $(\lambda_1, \lambda_2, \lambda_3)$ *and for each set of solutions* $\varphi_0(t)$, $\varphi_1(\omega_1)$, $\varphi_2(\omega_2)$, $\varphi_3(\omega_3)$ *of (7), function (5) under condition (6) is a solution of (1).*

In the above formulas $P_{\mu\nu}$, μ, $\nu=0,1,2,3$, are some complex 2×2-matrix functions of the indicated variables.

Definition 2: Three complex parameters λ_1, λ_2, λ_3 *in (7) are called independent if the equality*

$$\operatorname{rank}\|P_{\mu a}\|_{\mu=0}^{3}{}_{a=1}^{3}=6 \tag{8}$$

holds, whenever $\varphi_0(t)\varphi_1(\omega_1)\varphi_2(\omega_2)\varphi_3(\omega_3)\neq 0$.

Condition (8) secures essential dependence of a solution with separated variables on the separation constants $\vec{\lambda}$.

Note that putting $Q=I$, $\omega_a=x_a$, $a=1,2,3$, in (6) yields the standard separation of variables in the Cartesian coordinate system. Next, choosing the spherical coordinates as ω_1, ω_2, ω_3 we arrive at the variable separation in the spherical coordinate system and so on. The principal task is describing all possible forms of the functions Q, ω_a, $a=1,2,3$, that provide separability of the Pauli equation in the sense of the definition given above. Solution of this problem, in its turn, requires describing the functions $A_0,\ldots,A_3$ that enable variable separation in the Pauli equation in the corresponding coordinate system. More precisely, we will need to solve the two mutually connected principal problems:

(i) to describe *all* cases of coefficients, for which the corresponding Pauli equation (1) is separable (in the sense of Definition 1) in at least one coordinate system, and
(ii) to construct *all* coordinate systems that allow for separation of variables (in the sense of Definition 1) in the Pauli equation (1) with some fixed vector-potential $(A_0,\vec{A})$.

Note, that formulas (5)–(8) form the input data of the method. We can change these conditions and thereby modify the definition of separation of variables. For instance, we can change the order of the reduced equations (7) or the number of essential parameters λ_a (a more detailed analysis of this problem for the Schrödinger equation can be found in Ref. 16). So, our claim of obtaining the *complete description* of vector-potentials and coordinate systems providing separation of variables in (1) makes sense only within the framework of Definition 1. If one uses a more general definition, it might be possible to construct new coordinate systems and vector-potentials providing separability of Eq. (1). But all solutions of the Pauli equation with separated variables known to us fit into the above suggested scheme.

Transformations

$$\lambda_a\to\lambda_a'=\Lambda_a(\lambda_1,\lambda_2,\lambda_3), \quad a=1,2,3, \tag{9}$$

under condition

$$\det\left\|\frac{\partial\Lambda_a}{\partial\lambda_b}\right\|_{a,b=1}^{3}\neq 0, \tag{10}$$

preserve the form of relations (5)–(8). So we can regard the corresponding spectral parameters $\vec{\lambda}$ and $\vec{\lambda}'$ as *equivalent* ones. Within the framework of this equivalence relation we can choose $\vec{\lambda}$ in such a way that all matrices $P_{\mu\nu}$, μ, $\nu=0,1,2,3$, in reduced Eqs. (7) are Hermitian ones and parameters λ_1, λ_2, λ_3 are real numbers.

Next, we introduce an equivalence relation on the set of all vector-potentials $A_0(t,\vec{x})$, $\vec{A}(t,\vec{x})$ providing separability of Eq. (1), on the sets of solutions with separated variables and corresponding coordinate systems.

Definition 3: We say that two vector-potentials $A(t,\vec{x})$ and $A'(t,\vec{x})$ are equivalent if they are transformed one into another by the gauge transformation

$$\vec{A}\to\vec{A}'=\vec{A}+\vec{\nabla}f,\quad A_0\to A_0'=A_0-\frac{\partial f}{\partial t}, \tag{11}$$

where $f=f(t,\vec{x})$ is an arbitrary smooth function.

For the Pauli equations to be invariant with respect to the above transformation, the wave function $\psi(t,\vec{x})$ is to be transformed according to the rule

$$\psi\to\psi'=\psi\exp(ief). \tag{12}$$

Indeed, if the transformations (11) and (12) in the Pauli equation (1) are performed one after another, we obtain the initial equation, provided we replace the functions $\vec{A}$, A_0, ψ with $\vec{A}'$, A_0', ψ'.

Note that the system of PDEs (1) admits a wider equivalence group from the point of view of the standard theory of partial differential equations (Shapovalov and Sukhomlin, Ref. 17). However this group cannot be regarded as an equivalence group within the context of quantum mechanics, since allowed transformations of the wave function must preserve the probability density $\psi^*\psi$. And it is straightforward to check the the wider Shapovalov and Sukhomlin equivalence group breaks this rule, because it, generally speaking, does not preserve $\psi^*\psi$. By this very reason, we restrict our considerations to the gauge transformations only.

Definition 4: Two solutions of the Pauli equation with separated variables are called equivalent if they can be transformed one into another by group transformations from the Lie transformation group admitted by Pauli equation (1). Moreover, solutions of the Pauli equation with separated variables having equivalent [in the sense of equivalence relation (9) and (10)] spectral parameters $\vec{\lambda}$ are equivalent.

Definition 5: Two coordinate systems t, ω_1, ω_2, ω_3 and t', ω_1', ω_2', ω_3' are called equivalent if they give equivalent solutions with separated variables. In particular, two coordinate systems are equivalent if the corresponding ansätze (5) are transformed one into another by reversible transformations of the form

$$t\to t'=f_0(t),\quad \omega_a\to\omega_a'=f_a(\omega_a),\quad a=1,2,3, \tag{13}$$

$$Q\to Q'=Ql_0(t)l_1(\omega_1)l_2(\omega_2)l_3(\omega_3), \tag{14}$$

where $f_0,\ldots,f_3$ are some smooth functions and $l_0,\ldots,l_3$ are some smooth 2×2-matrix functions of the indicated variables.

Indeed, transformations (13) and (14) preserve the form of ansätze (5). So, after completing the procedure of separation of variables in these coordinate systems we obtain the same solutions with separated variables.

These equivalence relations reflect the freedom in choice of the functions Q, ω_1, ω_2, ω_3 and separation constants λ_1, λ_2, λ_3 preserving the form of the conditions (5)–(8). They split the set

of all possible vector-potentials, providing separability of Eq. (1), and sets of solutions with separated variables and corresponding coordinate systems into equivalence classes. In a sequel, when presenting the corresponding lists we will give only one representative for each equivalence class.

II. CLASSIFICATION OF SEPARABLE PAULI EQUATIONS (1)

In this section we obtain an exhaustive classification of the Pauli equations solvable within the framework of the approach described in the Introduction. Furthermore, we describe curvilinear coordinate systems enabling separation of variables in (1).

Using the equalities (7) and (6) we get

$$[P_{\mu 0}+P_{\mu a}\lambda_a, P_{\nu 0}+P_{\nu a}\lambda_a]=0.$$

Splitting the expression with respect to λ_a yields

$$[P_{\mu\alpha}, P_{\nu\beta}]+[P_{\mu\beta}, P_{\nu\alpha}]=0, \tag{15}$$

where $\mu,\nu,\alpha,\beta=0,1,2,3$ and henceforth summation over repeated Greek indices is not used. Choosing $\alpha=\beta$ we have

$$[P_{\mu\alpha}, P_{\nu\alpha}]=0.$$

Taking into account this equality and the fact that any Hermitian (2×2)-matrix can be represented as a linear combination of the unit and Pauli matrices (2), we get the following form of $P_{\mu\alpha}$:

$$P_{\mu\alpha}=F_{\mu\alpha}(\omega_\mu)I+G_{\mu\alpha}(\omega_\mu)\vec{s}_\alpha\vec{\sigma}, \tag{16}$$

where $F_{\mu\alpha}$, $G_{\mu\alpha}$ are some smooth scalar functions of the indicated variables, $\omega_0=t$ and $\vec{s}_\alpha$ is a constant three-component vector. Substitution of expression (16) into (15) yields

$$(G_{\mu\alpha}G_{\nu\beta}-G_{\mu\beta}G_{\nu\alpha})[\vec{s}_\alpha\vec{\sigma}, \vec{s}_\beta\vec{\sigma}]=0.$$

From this equality we conclude that there are two distinct cases: either $\vec{s}_\alpha\sim\vec{s}_\beta$ or $G_{\mu\alpha}\sim G_{\mu\beta}$. In view of this fact we get the two possible forms for the Eqs. (7):

$$\begin{aligned} i\dot{\varphi}_0&=-(F_{00}(t)+F_{0b}(t)\lambda_b+(G_{00}(t)+G_{0b}(t)\lambda_b)\vec{s}\vec{\sigma})\varphi_0,\\ \ddot{\varphi}_a&=(F_{a0}(\omega_a)+F_{ab}(\omega_a)\lambda_b+(G_{a0}(\omega_a)+G_{ab}(\omega_a)\lambda_b)\vec{s}\vec{\sigma})\varphi_a, \end{aligned} \tag{17}$$

and

$$\begin{aligned} i\dot{\varphi}_0&=-(F_{00}(t)+F_{0b}(t)\lambda_b+G_0(t)(\vec{s}_0+\vec{s}_b\lambda_b)\vec{\sigma})\varphi_0,\\ \ddot{\varphi}_a&=(F_{a0}(\omega_a)+F_{ab}(\omega_a)\lambda_b+G_a(\omega_a)(\vec{s}_0+\vec{s}_b\lambda_b)\vec{\sigma})\varphi_a, \end{aligned} \tag{18}$$

with $a=1,2,3$.

Definition 1 is quite algorithmic in the sense that it contains a regular algorithm of variable separation in Pauli equation (1). Formulas (5), (17), and (18) form the input data of the method. The principal steps of the procedure of variable separation in Pauli equation (1) are as follows.

(1) We insert the ansatz (5) into the Pauli equation and express the derivatives $\dot{\varphi}_0$, $\ddot{\varphi}_1$, $\ddot{\varphi}_2$, $\ddot{\varphi}_3$ in terms of functions φ_0, φ_1, φ_2, φ_3, using Eqs. (17) and (18).
(2) We regard φ_0, φ_1, φ_2, φ_3, λ_1, λ_2, λ_3 as new independent variables $y_1,\ldots,y_7$. As the functions Q, ω_1, ω_2, ω_3, A_0, A_1, A_2, A_3 are independent on the variables $y_1,\ldots,y_7$, we can demand that the obtained equality is transformed into identity under arbitrary $y_1,\ldots,y_7$. In other words, we should split the equality with respect to these variables under condition of

commutativity (6). After splitting we get an overdetermined system of nonlinear partial differential equations for unknown functions Q, ω_1, ω_2, ω_3, A_0, A_1, A_2, A_3.

(3) After solving the above system we get an exhaustive description of vector-potentials $A(t,\vec{x})$ providing separability of the Pauli equation and corresponding coordinate systems.

Having performed the first two steps of the above algorithm we obtain the system of nonlinear matrix PDEs:

$$(i) \quad \frac{\partial \omega_b}{\partial x_a}\frac{\partial \omega_c}{\partial x_a}=0, \quad b\neq c, \quad b,c=1,2,3.$$

$$(ii) \quad \sum_{a=1}^{3} F_{ab}(\omega_a)\frac{\partial \omega_a}{\partial x_c}\frac{\partial \omega_a}{\partial x_c}=F_{0b}(t), \quad b=1,2,3.$$

(*iiia*) For the case of reduced equations given by (17),

$$\sum_{a=1}^{3} G_{a\mu}(\omega_a)\frac{\partial \omega_a}{\partial x_c}\frac{\partial \omega_a}{\partial x_c}=G_{0\mu}(t), \quad \mu=0,1,2,3.$$

(*iiib*) For the case of reduced equations given by (18),

$$\sum_{a=1}^{3} G_{a}(\omega_a)\frac{\partial \omega_a}{\partial x_c}\frac{\partial \omega_a}{\partial x_c}=G_{0}(t).$$

$$(iv) \quad 2\left(\frac{\partial Q}{\partial x_b}-ieQA_b\right)\frac{\partial \omega_a}{\partial x_b}+Q\left(i\frac{\partial \omega_a}{\partial t}+\Delta\omega_a\right)=0, \quad a=1,2,3.$$

$$(v) \quad Q\sum_{a=1}^{3} F_{a0}(\omega_a)\frac{\partial \omega_a}{\partial x_b}\frac{\partial \omega_a}{\partial x_b}+i\frac{\partial Q}{\partial t}+\Delta Q-2ieA_b\frac{\partial Q}{\partial x_b}$$
$$+\left(-F_{00}(t)-ie\frac{\partial A_b}{\partial x_b}-eA_0-e^2A_bA_b+e\vec{\sigma}\vec{H}\right)Q=0.$$

Thus the problem of variable separation in the Pauli equation reduces to integrating a system of nonlinear PDEs for eight unknown functions A_0, A_1, A_2, A_3, Q, ω_1, ω_2, ω_3 of four variables $t,\vec{x}$. What is more, some coefficients are arbitrary matrix functions which should be determined in the process of integrating of the system of PDEs (i)–(v). We succeeded in constructing the general solution of the latter which yields, in particular, all possible vector-potentials $A(t,\vec{x})=(A_0(t,\vec{x}),\ldots,A_3(t,\vec{x}))$ such that Pauli equation (1) is solvable by the method of separation of variables.

In view of (8) we can always choose from each set of the equations (ii), $(iiia)$, and (ii), $(iiib)$ three such equations that the matrix of coefficients of $\omega_{ax_c}\omega_{ax_c}$ $(a=1,2,3)$ is nonsingular. It is called the Stäckel matrix.[18] The system consisting of these three equations and of the equations (i) was integrated in Ref. 2. Its general solution $\vec{\omega}=\vec{\omega}(t,\vec{x})$ is given implicitly within the equivalence relation (13) by the following formulas:

$$\vec{x}=\mathcal{O}(t)\mathcal{L}(t)(\vec{z}(\vec{\omega})+\vec{v}(t)). \tag{19}$$

Here $\mathcal{O}(t)$ is a time-dependent 3×3 orthogonal matrix with Euler angles $\alpha(t)$, $\beta(t)$, $\gamma(t)$:

$$\mathcal{O}(t)=\begin{pmatrix} \cos\alpha\cos\beta-\sin\alpha\sin\beta\cos\gamma & -\cos\alpha\sin\beta-\sin\alpha\cos\beta\cos\gamma & \sin\alpha\sin\gamma \\ \sin\alpha\cos\beta+\cos\alpha\sin\beta\cos\gamma & -\sin\alpha\sin\beta+\cos\alpha\cos\beta\cos\gamma & -\cos\alpha\sin\gamma \\ \sin\beta\sin\gamma & \cos\beta\sin\gamma & \cos\gamma \end{pmatrix}; \tag{20}$$

$\vec{v}(t)$ stands for the vector-column whose entries $v_1(t)$, $v_2(t)$, $v_3(t)$ are arbitrary smooth functions of t; $\vec{z}=\vec{z}(\vec{\omega})$ is given by one of the eleven formulas

(1) Cartesian coordinate system,

$$z_1=\omega_1,\quad z_2=\omega_2,\quad z_3=\omega_3,$$

$$\omega_1,\omega_2,\omega_3\in\mathbf{R}.$$

(2) Cylindrical coordinate system,

$$z_1=e^{\omega_1}\cos\omega_2,\quad z_2=e^{\omega_1}\sin\omega_2,\quad z_3=\omega_3,$$

$$0\leqslant\omega_2<2\pi,\quad \omega_1,\omega_3\in\mathbf{R}.$$

(3) Parabolic cylindrical coordinate system,

$$z_1=(\omega_1^2-\omega_2^2)/2,\quad z_2=\omega_1\omega_2,\quad z_3=\omega_3,$$

$$\omega_1>0,\quad \omega_2,\omega_3\in\mathbf{R}.$$

(4) Elliptic cylindrical coordinate system,

$$z_1=a\cosh\omega_1\cos\omega_2,\quad z_2=a\sinh\omega_1\sin\omega_2,\quad z_3=\omega_3,$$

$$\omega_1>0,\quad -\pi<\omega_2\leqslant\pi,\quad \omega_3\in\mathbf{R},\quad a>0.$$

(5) Spherical coordinate system,

$$z_1=\omega_1^{-1}\operatorname{sech}\omega_2\cos\omega_3,$$

$$z_2=\omega_1^{-1}\operatorname{sech}\omega_2\sin\omega_3,$$

$$z_3=\omega_1^{-1}\tanh\omega_2,$$

$$\omega_1>0,\quad \omega_2\in\mathbf{R},\quad 0\leqslant\omega_3<2\pi.$$

(6) Prolate spheroidal coordinate system,

$$z_1=a\operatorname{csch}\omega_1\operatorname{sech}\omega_2\cos\omega_3,\quad a>0,$$

$$z_2=a\operatorname{csch}\omega_1\operatorname{sech}\omega_2\sin\omega_3,$$

$$z_3=a\coth\omega_1\tanh\omega_2,$$

$$\omega_1>0,\quad \omega_2\in\mathbf{R},\quad 0\leqslant\omega_3<2\pi. \tag{21}$$

(7) Oblate spheroidal coordinate system,

$$z_1=a\csc\omega_1\operatorname{sech}\omega_2\cos\omega_3,\quad a>0,$$

$$z_2=a\csc\omega_1\operatorname{sech}\omega_2\sin\omega_3,$$

$$z_3 = a \cot \omega_1 \tanh \omega_2,$$

$$0 < \omega_1 < \pi/2, \quad \omega_2 \in \mathbf{R}, \quad 0 \leqslant \omega_3 < 2\pi.$$

(8) Parabolic coordinate system,

$$z_1 = e^{\omega_1 + \omega_2} \cos \omega_3, \quad z_2 = e^{\omega_1 + \omega_2} \sin \omega_3,$$

$$z_3 = (e^{2\omega_1} - e^{2\omega_2})/2,$$

$$\omega_1, \omega_2 \in \mathbf{R}, \quad 0 \leqslant \omega_3 \leqslant 2\pi.$$

(9) Paraboloidal coordinate system,

$$z_1 = 2a \cosh \omega_1 \cos \omega_2 \sinh \omega_3, \quad a > 0,$$

$$z_2 = 2a \sinh \omega_1 \sin \omega_2 \cosh \omega_3,$$

$$z_3 = a(\cosh 2\omega_1 + \cos 2\omega_2 - \cosh 2\omega_3)/2,$$

$$\omega_1, \omega_3 \in \mathbf{R}, \quad 0 \leqslant \omega_2 < \pi.$$

(10) Ellipsoidal coordinate system,

$$z_1 = a \frac{1}{\mathrm{sn}(\omega_1, k)} \mathrm{dn}(\omega_2, k') \, \mathrm{sn}(\omega_3, k), \quad a > 0,$$

$$z_2 = a \frac{\mathrm{dn}(\omega_1, k)}{\mathrm{sn}(\omega_1, k)} \mathrm{cn}(\omega_2, k') \mathrm{cn}(\omega_3, k),$$

$$z_3 = a \frac{\mathrm{cn}(\omega_1, k)}{\mathrm{sn}(\omega_1, k)} \mathrm{sn}(\omega_2, k') \, \mathrm{dn}(\omega_3, k),$$

$$0 < \omega_1 < K, \quad -K' \leqslant \omega_2 \leqslant K', \quad 0 \leqslant \omega_3 \leqslant 4K.$$

(11) Conical coordinate system,

$$z_1 = \omega_1^{-1} \mathrm{dn}(\omega_2, k') \, \mathrm{sn}(\omega_3, k),$$

$$z_2 = \omega_1^{-1} \mathrm{cn}(\omega_2, k') \, \mathrm{cn}(\omega_3, k),$$

$$z_3 = \omega_1^{-1} \mathrm{sn}(\omega_2, k') \, \mathrm{dn}(\omega_3, k),$$

$$\omega_1 > 0, \quad -K' \leqslant \omega_2 \leqslant K', \quad 0 \leqslant \omega_3 \leqslant 4K;$$

and $\mathcal{L}(t)$ is a 3×3 diagonal matrix

$$\mathcal{L}(t) = \begin{pmatrix} l_1(t) & 0 & 0 \\ 0 & l_2(t) & 0 \\ 0 & 0 & l_3(t) \end{pmatrix}, \tag{22}$$

where $l_1(t), l_2(t), l_3(t)$ are arbitrary nonzero smooth functions that satisfy the following conditions:

(i) $l_1(t) = l_2(t)$ for the partially split coordinate systems [cases 2–4 from (21)],

(ii) $l_1(t)=l_2(t)=l_3(t)$ for nonsplit coordinate systems [cases 5-11 from (21)].

Here we use the usual notations for the trigonometric, hyperbolic and Jacobi elliptic functions, number $k\,(0<k<1)$ being the modulus of the latter and $k'=(1-k^2)^{1/2}$.

From a geometric point of view the right-hand side of formula (19) is a result of application to vector $\vec{z}(\vec{\omega})$ of the following time-dependent transformations performed one after another:

(1) translations $\vec{z}\to\vec{z}'=\vec{z}+\vec{v}(t)$,
(2) dilatations $\vec{z}\to\vec{z}'=\mathcal{L}(t)\vec{z}$,
(3) three-dimensional rotations $\vec{z}\to\vec{z}'=\mathcal{O}(t)\vec{z}$ with Euler angles $\alpha(t),\ \beta(t),\ \gamma(t)$.

Together with the rotations the following vector $\vec{\Omega}(t)=(\Omega_1,\Omega_2,\Omega_3)$ is considered (Ref. 19, Sec. 35),

$$\begin{aligned}\Omega_1(t)&=\dot{\gamma}(t)\cos\alpha(t)+\dot{\beta}(t)\sin\alpha(t)\sin\gamma(t),\\ \Omega_2(t)&=\dot{\gamma}(t)\sin\alpha(t)-\dot{\beta}(t)\cos\alpha(t)\sin\gamma(t),\\ \Omega_3(t)&=\dot{\alpha}(t)+\dot{\beta}(t)\cos\gamma(t),\end{aligned}\tag{23}$$

that is directed along momentary axis of rotation and called *angular velocity vector*.

Note that we have chosen the coordinate systems $\omega_1,\ \omega_2,\ \omega_3$ by means of the equivalence relation (13) in such a way that the relations

$$\Delta\omega_a=0,\quad a=1,2,3,\tag{24}$$

hold for all the cases 1–11 in (21).

After integration of system $(i)-(iii)$ it is not difficult to integrate the remaining (iv) and (v) from the system under study, since they can be regarded as algebraic equations for the functions $A_a(t,\vec{x}),(a=1,2,3)$ and $A_0(t,\vec{x})$, correspondingly.

Multiplying (iv) from the right by Q^{-1} we obtain for each component of matrices $(\partial Q/\partial x_b)\,Q^{-1}$, $b=1,2,3$, the systems of three linear algebraic equations. The determinants of the systems do not vanish according to (4). So they have the unique solution

$$\frac{\partial Q}{\partial x_b}Q^{-1}=f_b(t,\vec{x})I,\quad b=1,2,3,\tag{25}$$

where $f_b(t,\vec{x})$ are scalar smooth functions and I is unit 2×2-matrix. From the compatibility conditions

$$\frac{\partial f_a}{\partial x_b}=\frac{\partial f_b}{\partial x_a},\quad a,b=1,2,3,$$

of the above system of PDEs we obtain that there exists such function $g(t,\vec{x})$ that the equalities $f_a=\partial g/\partial x_a$, $a=1,2,3$, hold. So (25) takes the form

$$\frac{\partial Q}{\partial x_b}=\frac{\partial g}{\partial x_b}Q,\quad b=1,2,3.$$

The general solution of this system of matrix PDEs is

$$Q=\mathcal{U}(t)\exp g(t,\vec{x}),\tag{26}$$

where $\mathcal{U}(t)$ is arbitrary 2×2-matrix function of t.

Let us represent the complex-valued function $g(t,\vec{x})$ in (26) as $g=S_1+iS$, where S_1, S are real-valued functions. Now, if we take into account that the components of the vector potential $A(t,\vec{x})$ and functions ω_1, ω_2, ω_3 are real-valued functions, then after inserting (26) into (iv) with the use of (24) we can split the obtained equations into real and imaginary parts:

$$\frac{\partial S_1}{\partial x_b}\frac{\partial \omega_a}{\partial x_b}=0, \quad a=1,2,3; \tag{27}$$

$$2\left(\frac{\partial S}{\partial x_b}-eA_b\right)\frac{\partial \omega_a}{\partial x_b}+\frac{\partial \omega_a}{\partial t}=0, \quad a=1,2,3. \tag{28}$$

Taking into account the equality (4), we obtain from (27) the equalities $\partial S_1/\partial x_b=0$, $b=1,2,3$. It gives that $S_1=S_1(t)$.

Let us denote $e\vec{\mathcal{A}}=e\vec{A}-\vec{\nabla}S$. Then the system (28) takes the form of three linear algebraic equations for functions $\mathcal{A}_1$, $\mathcal{A}_2$, $\mathcal{A}_3$:

$$\frac{\partial \omega_a}{\partial t}=2e\frac{\partial \omega_a}{\partial x_b}\mathcal{A}_b, \quad a=1,2,3.$$

The determinant of this system does not vanish due to (4). Consequently, it has a unique solution. Making in this solution the hodographic transformation

$$t=t, \quad x_a=u_a(t,\omega_1,\omega_2,\omega_3), \quad a=1,2,3, \tag{29}$$

we get the following expressions for $\mathcal{A}_1$, $\mathcal{A}_2$, $\mathcal{A}_3$:

$$\vec{\mathcal{A}}=-\frac{1}{2e}\frac{\partial \vec{u}(t,\vec{\omega})}{\partial t}.$$

After substitution into this formula expression for $\vec{u}(t,\vec{\omega})$ (19), we return to variables t,x_1,x_2,x_3 and thus obtain the following system:

$$2(-e\vec{A}(t,\vec{x})+\vec{\nabla}S)=\mathcal{M}(t)\vec{x}+\mathcal{O}(t)\mathcal{L}(t)\dot{\vec{v}}. \tag{30}$$

Here we use the designation

$$\mathcal{M}(t)=\dot{\mathcal{O}}(t)\mathcal{O}^{-1}(t)+\mathcal{O}(t)\dot{\mathcal{L}}(t)\mathcal{L}^{-1}(t)\mathcal{O}^{-1}(t), \tag{31}$$

where $\mathcal{O}(t)$, $\mathcal{L}(t)$ are variable 3×3 matrices defined by formulas (20) and (22), correspondingly, $\vec{v}=(v_1(t),v_2(t),v_3(t))^T$. Note that $\dot{\mathcal{O}}\mathcal{O}^{-1}$ is antisymmetric and $\mathcal{O}\dot{\mathcal{L}}\mathcal{L}^{-1}\mathcal{O}^{-1}$ is the symmetric part of matrix $\mathcal{M}$.

The direct calculation shows that (v) and (30) are invariant under gauge transformations (11). Thus the function S is transformed by the rule

$$S\to S'=S+ef, \tag{32}$$

which follows from (12). In other words, if the transformations (11) and (32) in (v) and (30) are performed one after another, we obtain the initial equations where functions $\vec{A}$, A_0, S should be replaced with functions $\vec{A}'$, A_0', S'. So, if the Pauli equation (1) with potential $\vec{A}$, A_0 admits separation of variables in some coordinate system, then the Pauli equation with potential $\vec{A}'$, A_0' admits separation of variables in the same coordinate system [the multiplier Q (26) is changed only]. Therefore, it is worthwhile to fix some gauge and to work only with representatives of the equivalence classes of potentials $A(t,\vec{x})$ [in the sense of equivalence relation (11)].

We choose the gauge in a way that the equality

$$2\vec{\nabla}S=\mathcal{O}(t)\dot{\mathcal{L}}(t)\mathcal{L}^{-1}(t)\mathcal{O}^{-1}(t)\vec{x}+\mathcal{O}(t)\mathcal{L}(t)\dot{\vec{v}} \tag{33}$$

holds. After integration of this system of PDEs we obtain the expression for S

$$S=\frac{1}{4}\sum_{a=1}^{3}\left(\frac{\dot{l}_a}{l_a}x'^2_a+2l_a\dot{v}_a x'_a\right), \tag{34}$$

where we use the notations

$$\vec{x}'=\mathcal{O}^{-1}\vec{x}. \tag{35}$$

Next, we obtain from Eq. (30) the explicit form for spacelike components of vector-potential of electromagnetic field

$$\vec{A}(t,\vec{x})=-\frac{1}{2e}\dot{\mathcal{O}}\mathcal{O}^{-1}\vec{x}, \tag{36}$$

where the explicit form of matrix $\dot{\mathcal{O}}\mathcal{O}^{-1}$ is given by the formula

$$\dot{\mathcal{O}}\mathcal{O}^{-1}=\begin{pmatrix} 0 & -(\dot{\alpha}+\dot{\beta}\cos\gamma) & \dot{\gamma}\sin\alpha-\dot{\beta}\cos\alpha\sin\gamma \\ \dot{\alpha}+\dot{\beta}\cos\gamma & 0 & -(\dot{\gamma}\cos\alpha+\dot{\beta}\sin\alpha\sin\gamma) \\ -(\dot{\gamma}\sin\alpha-\dot{\beta}\cos\alpha\sin\gamma) & \dot{\gamma}\cos\alpha+\dot{\beta}\sin\alpha\sin\gamma & 0 \end{pmatrix}, \tag{37}$$

where α,β,γ are arbitrary functions of t.

Thus formula (36) means that the spacelike components of electromagnetic field $A(t,\vec{x})$ are linear with respect of spatial variables. So the magnetic field $\vec{H}=\mathrm{rot}\vec{A}$ should be homogeneous, i.e., independent of spatial variables $\vec{x}$. From formulas (36) and (37) we can obtain its explicit form

$$\begin{aligned} eH_1&=-\dot{\gamma}(t)\cos\alpha(t)-\dot{\beta}(t)\sin\alpha(t)\sin\gamma(t), \\ eH_2&=-\dot{\gamma}(t)\sin\alpha(t)+\dot{\beta}(t)\cos\alpha(t)\sin\gamma(t), \\ eH_3&=-\dot{\alpha}(t)-\dot{\beta}(t)\cos\gamma(t). \end{aligned} \tag{38}$$

Now the spacelike components of the electromagnetic field take the final form

$$\vec{A}(t,\vec{x})=\frac{1}{2}\begin{pmatrix} 0 & -H_3(t) & H_2(t) \\ H_3(t) & 0 & -H_1(t) \\ -H_2(t) & H_1(t) & 0 \end{pmatrix}\vec{x}=\frac{1}{2}\vec{H}(t)\times\vec{x}, \tag{39}$$

where symbol $\times$ denotes cross product.

Within the equivalence relation (14) we can always choose the function $\mathcal{U}(t)$ to be a solution of matrix ODE

$$i\dot{\mathcal{U}}=(-e\vec{\sigma}\vec{H}(t))\mathcal{U} \tag{40}$$

with the initial conditions $\mathcal{U}(0)=I$. Due to the theorem of existence and the uniqueness of the solution of the Cauchy problem for the system of ODEs there is unique solution $\mathcal{U}(t)$ of system (40) for each fixed configuration of magnetic field $\vec{H}(t)$. Moreover, matrix $\mathcal{U}(t)$ is a unitary one. Indeed, taking into account (40), we have the equality

$$\frac{d}{dt}(\mathcal{U}^*\mathcal{U})=\mathcal{U}^*(ie\vec{\sigma}\vec{H})\mathcal{U}+\mathcal{U}^*(-ie\vec{\sigma}\vec{H})\mathcal{U}=0,$$

i.e., $\mathcal{U}^*\mathcal{U}=\text{const}$. The initial conditions give $\mathcal{U}^*\mathcal{U}=I$.

Thus we can consider the following change of variables in the Pauli equation (1),

$$\psi=\mathcal{U}(t)\tilde{\psi}. \tag{41}$$

Due to the unitarity of the matrix $\mathcal{U}$ the quantity $\psi^*\psi$, which is regarded in quantum mechanics as the probability density, is not changed. So the change of variables (41) is the correct one. As a result, the term $e\vec{\sigma}\vec{H}$ in Pauli equation (1) vanishes, and we obtained a system of two Schrödinger equations for the function $\tilde{\psi}$.

Thus we proved the following assertion.

Lemma 1: A necessary condition for the Pauli equation (1) to be separable (in the sense of Definition 1) is that it has to be equivalent [in the sense of equivalence relation (41)] to a system of two uncoupled Schrödinger equations.

Let us substitute the equality (26) into (v), taking into account Eq. (40) and $S_1=S_1(t)$. Splitting the equation obtained into real and imaginary parts (note that all functions F_{00}, F_{a0}, $a=1,2,3$, are real-valued ones), we obtain the equalities

$$\sum_{a=1}^{3} F_{a0}(\omega_a)\frac{\partial\omega_a}{\partial x_b}\frac{\partial\omega_a}{\partial x_b}-\frac{\partial S}{\partial t}-\frac{\partial S}{\partial x_b}\frac{\partial S}{\partial x_b}+2eA_b\frac{\partial S}{\partial x_b}-F_{00}(t)-eA_0-e^2A_bA_b=0, \tag{42}$$

$$\dot{S}_1+\Delta S-e\frac{\partial A_b}{\partial x_b}=0. \tag{43}$$

Inserting into Eq. (42) expressions for S (34) and A_1, A_2, A_3 (39), we obtain the explicit form of A_0:

$$eA_0(t,\vec{x})=\sum_{a=1}^{3} F_{a0}(\omega_a)\frac{\partial\omega_a}{\partial x_b}\frac{\partial\omega_a}{\partial x_b}-F_{00}(t)-e^2A_bA_b-\frac{1}{4}P. \tag{44}$$

Here A_bA_b follows from (39) and (37):

$$4A_bA_b=(H_2x_3-H_3x_2)^2+(H_3x_1-H_1x_3)^2+(H_2x_1-H_1x_2)^2, \tag{45}$$

where H_1, H_2, H_3 are components of magnetic field (38); function P has the form

$$P=\sum_{a=1}^{3}\left(\frac{\ddot{l}_a}{l_a}x'^2_a+2(l_a\ddot{v}_a+2\dot{l}_a\dot{v}_a)x'_a+l_a^2\dot{v}_a^2\right), \tag{46}$$

where x'_1, x'_2, x'_3 are given by formula (35) and $l_a=l_a(t)$, $v_a=v_a(t)$, $a=1,2,3$, are arbitrary smooth functions, which define new coordinate system (19).

Let us emphasize that the expression for A_0 includes arbitrary functions $F_{10}(\omega_1)$, $F_{20}(\omega_2)$, $F_{30}(\omega_3)$, $F_{00}(t)$, where functions $\omega_a=\omega_a(t,\vec{x})$, $a=1,2,3$, belong to one of 11 classes, whose representatives are given implicitly by the formulas (19)–(22).

Below we give explicit forms of the eikonals $R_a^{-2}=(\partial\omega_a/\partial x_b)(\partial\omega_a/\partial x_b)$ for each class of ω_a (see also Ref. 2):

$$(1)\quad R_i^{-2}=h_i^{-2},\quad i=1,2,3;$$

$$(2)\quad R_1^{-2}=R_2^{-2}=h_1^{-2}e^{-2\omega_1},\quad R_3^{-2}=h_3^{-2};$$

$$(3)\quad R_1^{-2}=R_2^{-2}=h_1^{-2}(\omega_1^2+\omega_2^2)^{-1},\quad R_3^{-2}=h_3^{-2};$$

$$(4)\quad R_1^{-2}=R_2^{-2}=h_1^{-2}a^{-2}(\cosh^2\omega_1-\cos^2\omega_2)^{-1},\quad R_3^{-2}=h_3^{-2};$$

$$(5)\quad R_1^{-2}=h_1^{-2}\omega_1^4,\quad R_2^{-2}=R_3^{-2}=h_1^{-2}\omega_1^2\cosh^2\omega_2;$$

$$(6)\quad R_1^{-2}=h_1^{-2}a^{-2}\sinh^2\omega_1(\sinh^{-2}\omega_1+\cosh^{-2}\omega_2)^{-1},$$

$$R_2^{-2}=h_1^{-2}a^{-2}\cosh^2\omega_2(\sinh^{-2}\omega_1+\cosh^{-2}\omega_2)^{-1},$$

$$R_3^{-2}=h_1^{-2}a^{-2}\sinh^2\omega_1\cosh^2\omega_2; \tag{47}$$

$$(7)\quad R_1^{-2}=h_1^{-2}a^{-2}\sin^2\omega_1(\sin^{-2}\omega_1-\cosh^{-2}\omega_2)^{-1},$$

$$R_2^{-2}=h_1^{-2}a^{-2}\cosh^2\omega_2(\sin^{-2}\omega_1-\cosh^{-2}\omega_2)^{-1},$$

$$R_3^{-2}=h_1^{-2}a^{-2}\sin^2\omega_1\cosh^2\omega_2;$$

$$(8)\quad R_1^{-2}=h_1^{-2}e^{-2\omega_1}(e^{2\omega_1}+e^{2\omega_2})^{-1},$$

$$R_2^{-2}=h_1^{-2}e^{-2\omega_2}(e^{2\omega_1}+e^{2\omega_2})^{-1},\quad R_3^{-2}=h_1^{-2}e^{-2(\omega_1+\omega_2)};$$

$$(9)\quad R_1^{-2}=h_1^{-2}a^{-2}(\cosh 2\omega_1-\cos 2\omega_2)^{-1}(\cosh 2\omega_1+\cosh 2\omega_3)^{-1},$$

$$R_2^{-2}=h_1^{-2}a^{-2}(\cosh 2\omega_1-\cos 2\omega_2)^{-1}(\cos 2\omega_2+\cosh 2\omega_3)^{-1},$$

$$R_3^{-2}=h_1^{-2}a^{-2}(\cosh 2\omega_1+\cosh 2\omega_3)^{-1}(\cos 2\omega_2+\cosh 2\omega_3)^{-1};$$

$$(10)\quad R_1^{-2}=h_1^{-2}a^{-2}\left(\frac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)}-k'^2\mathrm{cn}^2(\omega_2,k')\right)^{-1}\left(\frac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)}+k^2\mathrm{cn}^2(\omega_3,k)\right)^{-1},$$

$$R_2^{-2}=h_1^{-2}a^{-2}\left(\frac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)}-k'^2\mathrm{cn}^2(\omega_2,k')\right)^{-1}(k'^2\mathrm{cn}^2(\omega_2,k')+k^2\mathrm{cn}^2(\omega_3,k))^{-1},$$

$$R_3^{-2}=h_1^{-2}a^{-2}\left(\frac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)}+k^2\mathrm{cn}^2(\omega_3,k)\right)^{-1}(k'^2\mathrm{cn}^2(\omega_2,k')+k^2\mathrm{cn}^2(\omega_3,k))^{-1};$$

$$(11)\quad R_1^{-2}=h_1^{-2}\omega_1^4,\quad R_2^{-2}=R_3^{-2}=h_1^{-2}\omega_1^2(k'^2\mathrm{cn}^2(\omega_2,k')+k^2\mathrm{cn}^2(\omega_3,k))^{-1}.$$

At last, let us find the multiplier Q. Substituting the formulas (34) and (39) into Eq. (43) gives

$$\dot{S}_1=-\frac{1}{2}\sum_{a=1}^{3}\frac{\dot{l}_a}{l_a},$$

where it follows that

$$S_1=-\frac{1}{2}\sum_{a=1}^{3}\ln l_a. \tag{48}$$

Taking into account expression for S (34), we obtain from formula (26) the explicit form of Q

$$Q=\mathcal{U}(t)\frac{1}{\sqrt{l_1l_2l_3}}\exp\sum_{a=1}^{3}\frac{i}{4}\left(\frac{\dot{l}_a}{l_a}x'^2_a+2l_a\dot{v}_ax'_a\right), \tag{49}$$

where $\mathcal{U}(t)$ is given by Eq. (40), and x'_1,x'_2,x'_3 are given by formula (35).

Thus we have proved the main result of the article:

Theorem 1: *Pauli equation (1) admits separation of variables (in the sense of Definition 1) if and only if it is gauge equivalent to Pauli equation where*

(*i*) *the magnetic field* $\vec{H}=\mathrm{rot}\ \vec{A}$ *is independent of the spatial variables,*
(*ii*) *the spacelike components* A_1, A_2, A_3 *of the vector-potential of the electromagnetic field are given by* (*39*)*, and*
(*iii*) *the timelike component* A_0 *is given by formulas (44)–(47).*

Comparing the components of magnetic field (38) with components of angular velocity vector (23) of rotation of coordinate system (19), we obtain the equality $e\vec{H}=-\vec{\omega}$. So, we prove the following assertion:

Corollary 1: Let Pauli equation (1) admit separation of variables in some nonstationary coordinate system t, $\omega_a=\omega_a(t,\vec{x})$, $a=1,2,3$, *where functions* $\omega_1(t,\vec{x})$, $\omega_2(t,\vec{x})$, $\omega_3(t,\vec{x})$ *are given implicitly by formulas* (*19*)–(*22*). *Then angular velocity vector* (*23*) *of rotation of this coordinate system equals* $-e\vec{H}$, *where* $\vec{H}=\mathrm{rot}\ \vec{A}$ *is magnetic field.*

It follows from the corollary that a necessary condition for the Pauli equation (1) with nonzero magnetic field $\vec{H}$ to be separable (in the sense of our Definition 1) is that the angular velocity vector (23) of rotation of the separation coordinate system (19)–(22) has to be nonzero.

Summing up we conclude that coordinate systems and vector-potentials of the electromagnetic field $A(t,\vec{x})=(A_0(t,\vec{x}),\vec{A}(t,\vec{x}))$ providing separability of the corresponding Pauli equations coincide with those for the Schrödinger equations. Namely, we prove that the magnetic field $\vec{H}=\mathrm{rot}\ \vec{A}$ has to be independent of the spatial variables. Next, we have 11 classes of potentials $A_0(t,\vec{x})$, corresponding to 11 classes of coordinate systems $t,\omega_a=\omega_a(t,\vec{x})$, $a=1,2,3$, where the functions $\omega_1(t,\vec{x}),\omega_2(t,\vec{x}),\omega_3(t,\vec{x})$ are given implicitly by formulas (19)–(22). Pauli equation (1) for each class of the functions $A_0(t,\vec{x}),\vec{A}(t,\vec{x})$ defined by (39), (44) and (47) under arbitrary $F_{00}(t),F_{a0}(\omega_a)$ and fixed arbitrary functions $\alpha(t)$, $\beta(t)$, $\gamma(t)$, $v_a(t)$, $l_a(t)$, $a=1,2,3$, separates in exactly one coordinate system.

The solutions with separated variables are of the form (5), where Q is given by (49). The separation equations read as (17) or (18), where the functions $F_{\mu0}$, $\mu=0,1,2,3$, are arbitrary smooth functions defining the form of the timelike component of the vector-potential $A(t,\vec{x})$ [see (44)]. The explicit forms of other coefficients $F_{\mu a}$, $G_{\mu\nu}$, G_μ of reduced equations can be obtained by splitting relations (*ii*) and (*iii*) with respect to independent variables ω_1, ω_2, ω_3, t for each class of the functions $\vec{z}=\vec{z}(\vec{\omega})$ given in (21). Let us denote

$$S=\begin{pmatrix} T_1 & T_2 & T_3\\ S_{11} & S_{12} & S_{13}\\ S_{21} & S_{22} & S_{23}\\ S_{31} & S_{32} & S_{33}\end{pmatrix}, \tag{50}$$

where the functions $S_{ab}(\omega_a)$ $(a,b=1,2,3)$ are given below as entries of 3×3 Stäckel matrices, whose structure is determined by the choice of the functions $\vec{z}=\vec{z}(\vec{\omega})$:

$$\mathcal{F}_1=\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix},\quad \mathcal{F}_2=\begin{pmatrix}e^{2\omega_1}&-1&0\\0&1&0\\0&0&1\end{pmatrix},\quad \mathcal{F}_3=\begin{pmatrix}\omega_1^2&-1&0\\\omega_2^2&1&0\\0&0&1\end{pmatrix},$$

$$\mathcal{F}_4=\begin{pmatrix} a^2\cosh^2\omega_1 & 1 & 0\\ -a^2\cos^2\omega_2 & -1 & 0\\ 0 & 0 & 1\end{pmatrix},\quad \mathcal{F}_5=\begin{pmatrix} \omega_1^{-4} & -\omega_1^{-2} & 0\\ 0 & \cosh^{-2}\omega_2 & -1\\ 0 & 0 & 1\end{pmatrix},$$

$$\mathcal{F}_6=\begin{pmatrix} a^2\sinh^{-4}\omega_1 & -\sinh^{-2}\omega_1 & -1\\ a^2\cosh^{-4}\omega_2 & \cosh^{-2}\omega_2 & -1\\ 0 & 0 & 1\end{pmatrix},\quad \mathcal{F}_7=\begin{pmatrix} a^2\sin^{-4}\omega_1 & -\sin^{-2}\omega_1 & 1\\ -a^2\cosh^{-4}\omega_2 & \cosh^{-2}\omega_2 & -1\\ 0 & 0 & 1\end{pmatrix},\tag{51}$$

$$\mathcal{F}_8=\begin{pmatrix} e^{4\omega_1} & -e^{2\omega_1} & -1\\ e^{4\omega_2} & e^{2\omega_2} & -1\\ 0 & 0 & 1\end{pmatrix},\quad \mathcal{F}_9=\begin{pmatrix} a^2\cosh^2 2\omega_1 & -a\cosh 2\omega_1 & -1\\ -a^2\cos^2 2\omega_2 & a\cos 2\omega_2 & 1\\ a^2\cosh^2 2\omega_3 & a\cosh 2\omega_3 & -1\end{pmatrix},$$

$$\mathcal{F}_{10}=\begin{pmatrix} a^2\dfrac{\mathrm{dn}^4(\omega_1,k)}{\mathrm{sn}^4(\omega_1,k)} & -\dfrac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)} & 1\\ -a^2k'^4\,\mathrm{cn}^4(\omega_2,k') & k'^2\,\mathrm{cn}^2(\omega_2,k') & -1\\ a^2k^4\,\mathrm{cn}^4(\omega_3,k) & k^2\,\mathrm{cn}^2(\omega_3,k) & 1\end{pmatrix},$$

$$\mathcal{F}_{11}=\begin{pmatrix} \omega_1^{-4} & -\omega_1^{-2} & 0\\ 0 & k'^2\mathrm{cn}^2(\omega_2,k') & -1\\ 0 & k^2\mathrm{cn}^2(\omega_3,k) & 1\end{pmatrix}.$$

The functions $T_1(t)$, $T_2(t)$, $T_3(t)$ are expressed in terms of the functions $h_1(t)$, $h_2(t)$, $h_3(t)$:

$$\begin{aligned}&(1)\quad T_i=h_i^{-2},\quad i=1,2,3;\\ &(2)\text{-}(4)\quad T_1=h_1^{-2},\quad T_2=0,\quad T_3=h_3^{-2};\\ &(5)\text{-}(11)\quad T_1=h_1^{-2},\quad T_2=T_3=0.\end{aligned}\tag{52}$$

Let K and M be 3×3 constant matrices. Now, if the reduced equations are given by (17), then

$$F=\|F_{\mu a}\|_{\mu=0}^{3}\ {}_{a=1}^{3},\quad G=\|G_{\mu a}\|_{\mu=0}^{3}\ {}_{a=1}^{3}$$

are block (6×8)-matrices, where $F_{\mu a}$ and $G_{\mu a}$ are 2×2-matrices that are equal to products of the corresponding entries of the matrices SK and SM by the unit (in the case of the matrix F) or $\vec{s}\vec{\sigma}$ (in the case of the matrix G) matrices. Accordingly, Eq. (8) takes the form

$$\mathrm{rank}\,(F+G)=6.\tag{53}$$

If rank $K=3$, then we can always rearrange $\lambda_1,\lambda_2,\lambda_3$ with the use of the equivalence relation (9) in order to get $K=I$. Analogously, without loss of generality we may put $M=I$, provided rank $M=3$ and $\vec{s}^2\neq 0$.

If rank $M=0$, then the column $\|G_{\mu 0}\|_{\mu=0}^{3}$ has necessarily the form $S\vec{g}$, where $\vec{g}$ is a constant three-component column. If rank $M\neq 0$, then we can always kill this column by a proper rearranging of $\lambda_1,\lambda_2,\lambda_3$ with the use of the equivalence relation (9).

Next, if the reduced equations are given by (18), then the matrix F is defined in the same way as in the previous case. Furthermore,

$$G=\|G_\mu\vec{s}_a\vec{\sigma}\|_{\mu=0}^{3}\ {}_{a=1}^{3}$$

is a block (6×8)-matrix, where G_μ are the three-component columns $S\vec{g}_\mu$ ($\vec{g}_\mu$ is a constant three-component column). In addition, in this case identity (53) holds, so that we can put $K=I$, when rank $K=3$. If $\vec{s}_a$, $(1=1,2,3)$ are three linear independent vectors, then we can always put $\vec{s}_0=0$.

We will finish this section with the following remark. It follows from Theorem 1 that a choice of magnetic fields $\vec{H}$ allowing for variable separation in the corresponding Pauli equation is very restricted. Namely, the magnetic field should be independent of spatial variables x_1, x_2, x_3 in order to provide the separability of Pauli equation (1) into three second-order matrix ordinary differential equations of the form (7). However, if we allow for separation equations to be of a lower order, then additional possibilities for variable separation in the Pauli equation arise. As an example, we give the vector potential

$$A(t,\vec{x})=(A_0(\sqrt{x_1^2+x_2^2}),\ 0,\ 0,\ A_3(\sqrt{x_1^2+x_2^2})),$$

where A_0, A_3 are arbitrary smooth functions. The Pauli equation (1) with this vector-potential separates in the cylindrical coordinate system

$$t,\quad \omega_1=\ln(\sqrt{x_1^2+x_2^2}),\quad \omega_2=\arctan(x_1/x_2),\quad \omega_3=x_3$$

into two first-order and one second-order matrix ordinary differential equations. The corresponding magnetic field $\vec{H}=\mathrm{rot}\,\vec{A}$ is evidently x-dependent. In this respect, let us also mention the recent paper by Benenti with co-authors,[5] where the problem of separation of variables in the stationary Hamilton–Jacobi equation with vector-potential has been studied. They have presented a number of vector-potentials, for which the Hamilton–Jacobi equation is separable, and the corresponding magnetic fields are inhomogeneous ones. These potentials allow for separation of variables in the stationary Schrödinger and Pauli equations with vector-potentials as well (see, e.g., Ref. 15 concerning the relationship between the separation of variables in the Schrödinger and Hamilton–Jacobi equations). These facts imply an importance of application of our approach to classify the nonstationary Pauli equations of the form (1), which admit separation of variables into first- and second-order matrix ordinary differential equations. We remind that here we give the classification results for the case, when all the reduced equations are second-order ones. We intend to address this problem in one of our future publications.

III. ALGORITHM OF SEPARATION OF VARIABLES IN THE PAULI EQUATION WITH FIXED POTENTIAL

Theorem 1 gives the solution of the problem of classification of the Pauli equations (1) with variable coefficients that are separable (in the sense of Definition 1) at least in one coordinate system.

Let us consider the problem of classification of coordinate systems that allow for separation of variables (in the sense of Definition 1) in the Pauli equation (1) with fixed vector-potential A_0, $\vec{A}$.

Let some fixed vector-potential $\vec{A}(t,\vec{x})$, $A_0(t,\vec{x})$ be given. The scheme of finding all coordinate systems providing separation of variables is as follows:

(1) With help of gauge transformations (11) we reduce the spacelike components of vector-potential $\vec{A}(t,\vec{x})$ to the form (39). If it is impossible, then Pauli equation (1) with this vector-potential is not solvable by the method of separation of variables in the framework of our approach.

(2) We solve the system of ODE (38) for given magnetic field $\vec{H}(t)$ and obtain the explicit form of functions $\alpha(t)$, $\beta(t)$, $\gamma(t)$.

(3) For each of 11 classes of coordinate systems t, $\omega_a=\omega_a(t,\vec{x})$, $a=1,2,3$, which are given by formulas (19)–(22), taking into account restrictions obtained on the first step of the algorithm, we find the explicit form of

(a) the timelike component A_0 of the vector-potential in terms of $\vec{\omega}$;
(b) function P, substituting in (46) the expression for $\vec{x}'$ in terms of $\vec{\omega}$ [see formulas (35) and (19)]:

$$\vec{x}' = \mathcal{L}(t)(\vec{z}(\vec{\omega}) + \vec{v}(t)); \tag{54}$$

(c) quantity $e^2 A_b A_b$ by the formula

$$4e^2 A_b A_b = (n_2 x_3' - n_3 x_2')^2 + (n_3 x_1' - n_1 x_3')^2 + (n_2 x_1' - n_1 x_2')^2,$$

where x_1', x_2', x_3' are given by the formula (54), and functions n_1, n_2, n_3 are as follows

$$\begin{aligned} n_1 &= \dot{\gamma}(t)\cos\beta(t) + \dot{\alpha}(t)\sin\beta(t)\sin\gamma(t), \\ n_2 &= -\dot{\gamma}(t)\sin\beta(t) + \dot{\alpha}(t)\cos\beta(t)\sin\gamma(t), \\ n_3 &= \dot{\beta}(t) + \dot{\alpha}(t)\cos\gamma(t); \end{aligned} \tag{55}$$

(d) eikonals $(\partial\omega_a/\partial x_b)(\partial\omega_a/\partial x_b) = R_a^{-2}$, $a = 1,2,3$, which are determined from the list (47) for given class of coordinates.

(4) We substitute the equalities obtained into Eq. (44) and obtain 11 equations for each of 11 classes of coordinate systems t, ω_1, ω_2, ω_3. For each of these equalities we find all possible functions $F_{a0}(\omega_a)$, $a = 1,2,3$, $F_{00}(t)$ that reduce it to the identity by the independent variables t, ω_1, ω_2, ω_3 (i.e., we split this equality with respect to these variables). It gives, in its turn, the explicit form of the functions $v_a(t)$, $l_a(t)$, $a = 1,2,3$, and additional restriction on $\alpha(t)$, $\beta(t)$, $\gamma(t)$, giving the form of the coordinate system in question. All obtained coordinates for which the functions $F_{a0}(\omega_a)$, $a = 1,2,3$, $F_{00}(t)$ exist are only coordinate systems providing separability of Pauli equations in the sense of Definition 1.

Example: As illustration of this algorithm consider the problem of separation of variables in Pauli equation (1) for a particle interacting with a constant magnetic field. Without loss of generality we can always choose it as directed along axes OZ: $e\vec{H} = (0,0,c)^T$, where c is a nonzero real constant. The vector-potential of electro-magnetic field has the form

$$2e\vec{A} = \begin{pmatrix} 0 & -c & 0 \\ c & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \vec{x}, \quad eA_0 = \frac{q}{|\vec{x}|} - \frac{c^2}{12}(x_1^2 + x_2^2 - 2x_3^2), \tag{56}$$

where q is a nonzero real constant and $|\vec{x}| = \sqrt{x_1^2 + x_2^2 + x_3^2}$.

A direct check shows this vector-potential satisfies the vacuum Maxwell equations without currents,

$$\begin{aligned} \Box A_0 - \frac{\partial}{\partial t}\left(\frac{\partial A_0}{\partial t} + \operatorname{div}\vec{A}\right) &= 0, \\ \Box \vec{A} + \overrightarrow{\operatorname{grad}}\left(\frac{\partial A_0}{\partial t} + \operatorname{div}\vec{A}\right) &= \vec{0}, \end{aligned} \tag{57}$$

where $\Box = \partial^2/\partial t^2 - \Delta$ is d'Alembert operator. Therefore, it is a natural generalization of the standard Coulomb potential, which is obtained from (56) under $c \to 0$.

Proposition 1: The set of inequivalent coordinate systems providing separability of the Pauli equation (1) with vector potential of electromagnetic field (56) is exhausted by the following ones:

$$\vec{x} = \mathcal{O}(t)\vec{z}, \tag{58}$$

where $\mathcal{O}$ is a time-dependent 3×3 orthogonal matrix (20), *with Euler angles*

$$\alpha(t)=-ct, \quad \beta=\text{const}, \quad \gamma=\text{const}, \tag{59}$$

and $\vec{z}$ is one of the following coordinate systems:

(*1*) *spherical [formula 5 from list (21)]*,
(*2*) *prolate spheroidal II [formula 6 from (21), where one should replace z_3 with $z_3=a(\coth\omega_1\tanh\omega_2\pm 1)$]*,
(*3*) *conical [formula 11 from (21)]*.

Proof: The spacelike component $\vec{A}(t,\vec{x})$ of the given vector-potential (56) is already reduced to form (39).

The system of ODE (38) for given magnetic field takes the form

$$\dot\gamma\ \cos\alpha+\dot\beta\ \sin\alpha\sin\gamma=0, \quad \dot\gamma\ \sin\alpha-\dot\beta\ \cos\alpha\sin\gamma=0, \quad \dot\alpha+\dot\beta\ \cos\gamma=-c.$$

This implies the equivalent system

$$\dot\gamma=0, \quad \dot\beta\ \sin\gamma=0, \quad \dot\alpha+\dot\beta\ \cos\gamma=-c.$$

Its general solution up to translation by t is given by formulas (59) [solution $\alpha\pm\beta=-ct$ for case $\sin\gamma=0$ is included into (59) as a particular case after denoting $\alpha\pm\beta\to\alpha$].

The steps 3 and 4 of the above algorithm will be illustrated by the case of spherical coordinate system 5 from (21) (for other coordinate systems this procedure is an analogous one). For this case the equality (44) in terms ω_1, ω_2, ω_3 takes the form

$$\begin{aligned} &l^{-2}(F_{10}(\omega_1)\omega_1^4+(F_{20}(\omega_2)+F_{30}(\omega_3))\omega_1^2\cosh^2\omega_2)-F_{00}(t)\\ &\quad=\frac{q}{|\vec{x}'|}+\left(\frac{c^2}{6}+\frac{1}{4}\frac{\ddot l}{l}\right)|\vec{x}'|^2+\sum_{a=1}^{3}(2(l\ddot v_a+2\dot l\dot v_a)x_a'+l^2\dot v_a^2), \end{aligned} \tag{60}$$

where $l=l_1=l_2=l_3$, $l\neq 0$ (because of the spherical coordinate system is a nonsplit one), and

$$x_1'=l(\omega_1^{-1}\,\mathrm{sech}\,\omega_2\cos\omega_3+v_1(t)),$$

$$x_2'=l(\omega_1^{-1}\,\mathrm{sech}\,\omega_2\sin\omega_3+v_2(t)),$$

$$x_3'=l(\omega_1^{-1}\tanh\omega_2+v_3(t)).$$

Next we perform on both parts of equality (60) the following step by step operations:

(1) multiplying by ω_1,
(2) differentiation with respect to ω_1,
(3) division by ω_1^2,
(4) differentiation with respect to ω_1,
(5) differentiation with respect to ω_2,
(6) multiplying by $l\omega_1^7|\vec{x}'|^7$,
(7) twice multiplying by ω_1.

As result we get

$$\begin{aligned} &-24q\,\mathrm{sech}^3\omega_2(v_1^2+v_2^2+v_3^2)(v_1\cos\omega_3+v_2\sin\omega_3+v_3\sinh\omega_2)\\ &\quad\times(-v_3+(v_1\cos\omega_3+v_2\sin\omega_3)\sinh\omega_2)=0. \end{aligned}$$

The equality obtained is transformed into an identity with respect to independent variables ω_1, ω_2, ω_3 if and only if the condition $v_1=v_2=v_3=0$ holds. Now the equality (60) takes the form

$$l^{-2}(F_{10}(\omega_1)\omega_1^4+(F_{20}(\omega_2)+F_{30}(\omega_3))\omega_1^2\cosh^2\omega_2)-F_{00}(t)=\frac{q}{l}\omega_1+\left(\frac{c^2}{6}+\frac{1}{4}\frac{\ddot{l}}{l}\right)\frac{l^2}{\omega_1^2}. \quad (61)$$

Performing on both parts of equality (61) the following step by step operations,

(1) differentiation with respect to ω_1,
(2) multiplying by l^2,
(3) differentiation with respect to t,
(4) multiplying by ω_1^3,
(5) differentiation with respect to ω_1,

we get the equality $3q\dot{l}\omega_1^2=0$. This implies $l=\text{const}$ and with the help of dilatations we can put without loss of generality $l=1$. Thus the coordinate system takes the form (58).

The equation (61) yields

$$F_{10}(\omega_1)\omega_1^4+(F_{20}(\omega_2)+F_{30}(\omega_3))\omega_1^2\cosh^2\omega_2-F_{00}(t)=q\omega_1+\frac{c^2}{6}\omega_1^{-2}.$$

We can split the equation obtained by the independent variables ω_1, ω_2, ω_3. As a result we get

$$F_{10}=q\omega_1^{-3}+\frac{c^2}{6}\omega_1^{-6}+k_1\omega_1^{-4}-k_2\omega_1^{-2},$$

$$F_{20}=k_2\,\mathrm{sech}^2\omega_2-k_3, \quad F_{30}=k_3, \quad F_{00}=k_1.$$

The theorem is proved. □

IV. SEPARATION OF VARIABLES IN THE PAULI–MAXWELL SYSTEM

The expressions (39) and (44)–(47) give the most general form of the vector-potential of the electromagnetic field, providing separability of the corresponding Pauli equations. But, because of generality of the results, these expressions are too cumbersome, and their physical interpretation is somewhat difficult. Therefore it would be interesting to know the form of these potentials under certain physical restrictions. The most natural restriction is that the vector-potential satisfies the vacuum Maxwell equations without currents (57).

In this section we describe all explicit forms of the vector-potentials $A(t,\vec{x})$ that

(a) provide separability of Pauli equation,
(b) satisfy vacuum Maxwell equations without currents (57), and
(c) describe the nonzero magnetic field.

Furthermore, we construct inequivalent coordinate systems enabling us to separate variables in the corresponding Pauli equation.

The similar problem with more strong restrictions was analyzed in Ref. 20 for a two-dimensional Schrödinger equation with vector-potential. Note that an analogous problem for the Dirac equation for an electron was analyzed in Ref. 21.

Taking into account the form of $\vec{A}$ (39), the Maxwell equations (57) take the form

$$\Delta A_0=0, \quad (62)$$

and

$$\frac{\partial^2 A_0}{\partial t\partial x_1}=-\ddot{l}_3x_2+\ddot{l}_2x_3,\quad \frac{\partial^2 A_0}{\partial t\partial x_2}=\ddot{l}_3x_1-\ddot{l}_1x_1,\quad \frac{\partial^2 A_0}{\partial t\partial x_3}=-\ddot{l}_2x_1+\ddot{l}_1x_2.$$

From the compatibility conditions of the above system of PDEs we get

$$\begin{gathered}\ddot{l}_1=\ddot{l}_2=\ddot{l}_2=0,\\ \frac{\partial^2 A_0}{\partial t\partial x_a}=0,\quad a=1,2,3.\end{gathered}\tag{63}$$

Inserting expression for potential $A_0(t,\vec{x})$ (44) into (62) with subsequent change of independent variables (19) yields (we use the relations $\Delta\omega_i=0$, $\omega_{ix_a}\omega_{jx_a}=0$, $i\neq j$, $i,j=1,2,3$)

$$\sum_{j=1}^{3}\frac{\partial^2}{\partial\omega_j^2}\left(\sum_{i=1}^{3}F_{i0}(\omega_i)R_i^{-2}\right)R_j^{-2}=\frac{1}{2}\sum_{i=1}^{3}\frac{\ddot{l}_i}{l_i}+e^2(H_1^2+H_2^2+H_3^2),\tag{64}$$

where the eikonals

$$R_i^{-2}=\frac{\partial\omega_i}{\partial x_a}\frac{\partial\omega_i}{\partial x_a},\quad i=1,2,3,\tag{65}$$

are given in the list (47).

Thus we get 11 functional relations $\mathcal{P}_1,\ldots,\mathcal{P}_{11}$ for each class of coordinate system (19), whose form is determined by the form of 1 of the 11 expressions $z_1(\omega_1,\omega_2,\omega_3)$, $z_2(\omega_1,\omega_2,\omega_3)$, $z_3(\omega_1,\omega_2,\omega_3)$ from the list (21). As t, ω_1, ω_2, ω_3 are functionally independent, we can split the above relations with respect to the variables t, ω_1, ω_2, ω_3, thus getting ordinary differential equations for the functions $F_{i0}(\omega_i),l_i(t)$, $i=1,2,3$. After solving them the formula (44) yields the expressions for A_0 in terms of variables t, ω_1, ω_2, ω_3. Returning to variables t, x_1, x_2, x_3 [with the aid of (19)], we should split the expression obtained for $A_0(t,\vec{x})$ with respect to t. Indeed, the general solution of the second equation from the system (63) is

$$A_0(t,\vec{x})=f_1(\vec{x})+f_2(t).$$

At the expense of the gauge invariance of the Pauli equation we may choose $f_2(t)=0$. Thus the potential A_0 should be a function of $\vec{x}$ only. This condition restricts the choice of A_0, thus giving ordinary differential equations for the functions $l_i(t)$, $v_i(t)$, $i=1,2,3$. Solving them we obtain the explicit forms of the function $F_{00}(t)$ and coordinate systems (19). After simplifying these coordinate systems with the aid of equivalence transformations we get a full description of the vector-potentials $A(t,\vec{x})$ and coordinate systems, giving the solution of the problem under study.

Omitting the details of the calculations (they are very cumbersome) we present below the results. Note, when presenting lists of the vector-potentials $A(t,\vec{x})$ and coordinate systems we use invariance of the system of the Pauli and Maxwell equations with respect to the groups of rotations by spatial variables x_1, x_2, x_3 and translations by all variables t, x_1, x_2, x_3 (see, e.g., Ref. 22).

A. Case of nonstationary magnetic field

$$e\vec{H}=(0,0,At+B),$$

$$eA_0=-\frac{k}{2}(x_1^2+x_2^2-2x_3^2)+a_1x_1+a_2x_2+a_3x_3,$$

where A, B, k, a_1, a_2, a_3 are arbitrary real constants.

The coordinate system is

$$\vec{x}=\mathcal{L}\mathcal{O}(\vec{z}+\vec{v}).$$

Here $\mathcal{O}$ is a time-dependent 3×3 orthogonal matrix $\mathcal{O}(\alpha,\beta,\gamma)$, where

$$\alpha=-\tfrac{1}{2}At^2-Bt,\quad \beta=0,\quad \gamma=0;$$

$\vec{z}$ is a cartesian, cylindrical or elliptic cylindrical coordinate system [formulas 1, 2, and 4 from (21)]; $\mathcal{L}$ is the 3×3 diagonal matrix

$$\mathcal{L}=\begin{pmatrix} l(t) & 0 & 0\\ 0 & l(t) & 0\\ 0 & 0 & l_3(t)\end{pmatrix},$$

and $\vec{v}(t)$ is vector-column $\vec{v}(t)=(v_1,v_2,v_3)^T$ where functions $l(t)$, $l_3(t)$, $v_1(t)$, $v_2(t)$, $v_3(t)$ are solutions of the following system of ordinary differential equations:

$$2\frac{c}{l^4}-\frac{1}{2}\frac{\ddot{l}}{l}+k=\frac{1}{2}(At+B)^2,\quad \frac{c_3}{l_3^4}-\frac{1}{4}\frac{\ddot{l}_3}{l_3}=k,$$

$$l\ddot{v}_1+2\dot{l}\dot{v}_1+4c\frac{v_1}{l^3}-2c_{11}\frac{1}{l}=-2(a_1\cos\alpha+a_2\sin\alpha),$$

$$l\ddot{v}_2+2\dot{l}\dot{v}_2+4c\frac{v_2}{l^3}-2c_{12}\frac{1}{l}=-2(-a_1\sin\alpha+a_2\cos\alpha),$$

$$l_3\ddot{v}_3+2\dot{l}_3\dot{v}_3+4c_3\frac{v_3}{l_3^3}-2c_{13}\frac{1}{l_3}=-2a_3.$$

Here c, c_3, c_{11}, c_{12}, c_{13} are arbitrary real constants.

B. Cases of stationary magnetic field

1. Case 1

Here

$$e\vec{H}=(0,0,k),\quad k=\text{const}\neq0;$$

$$eA_0=-\frac{k^2}{12}(x_1^2+x_2^2-2x_3^2)+a_1x_1+a_2x_2+a_3x_3,$$

where $\vec{a}=(a_1,a_2,a_3)$ is constant vector.

The coordinate system is

$$\vec{x}=l\mathcal{O}(\vec{z}+\vec{v}).$$

Here $\mathcal{O}$ is a time-dependent 3×3 orthogonal matrix $\mathcal{O}(\alpha,\beta,\gamma)$, where $\alpha=-kt$, $\beta=\text{const}$, $\gamma=\text{const}$; $\vec{z}$ is one of coordinate system, given by formulas 1–11 from (21); function $l(t)$ is solution of the equation

$$k^2+\frac{3}{2}\frac{\ddot{l}}{l}=\frac{c}{l^4}$$

given by one of the formulas

$$c=\mp 1, \quad l^2=\sqrt{C_1^2\pm\frac{1}{k^2}}\sin\left(2\sqrt{\frac{2}{3}}kt\right)+C_1,$$

for coordinate system $\vec{z}$ given by the formulas 1, 2, 4, 5, 6, 7, 10, and 11 from the list (21) and

$$c=0, \quad l=C_1\sin\left(\sqrt{\frac{2}{3}}kt\right)$$

for coordinate system $\vec{z}$ given by the formulas 1–11 from the list (21). Here C_1 is an arbitrary real constant. Vector $\vec{v}$ is a solution of the following system of ordinary differential equations:

$$3l\ddot{\vec{v}}+6\dot{l}\dot{\vec{v}}+\frac{2c}{l^3}\vec{v}=-6\mathcal{O}^{-1}\vec{a}.$$

2. Case 2

Here

$$e\vec{H}=(0,0,k), \quad k=\text{const}\neq 0;$$

$$eA_0=\frac{a}{\sqrt{x_1^2+x_2^2+x_3^2}}-\frac{k^2}{12}(x_1^2+x_2^2-2x_3^2), \quad a=\text{const}\neq 0.$$

The coordinate system is

$$\vec{x}=\mathcal{O}\vec{z}.$$

Here $\mathcal{O}$ is a time-dependent 3×3 orthogonal matrix $\mathcal{O}(\alpha,\beta,\gamma)$, where $\alpha=-kt$, $\beta=\text{const}$, $\gamma=\text{const}$; and $\vec{z}$ is one of the following coordinate systems:

(1) spherical [formula 5 from (21)],
(2) prolate spheroidal II [formula 6 from (21), where one should replace z_3 with $z_3=a(\coth\omega_1\tanh\omega_2\pm 1)$], and
(3) conical [formula 11 from (21)].

3. Case 3

Here

$$e\vec{H}=(0,0,k), \quad k=\text{const}\neq 0;$$

$$eA_0=-\frac{k^2}{12}(x_1^2+x_2^2-2x_3^2)+\frac{a_1}{r}+a_2\frac{x_3}{r^3}+\frac{a_3}{r^2}\left(\frac{x_3}{2r}\ln\frac{r+x_3}{r-x_3}-1\right),$$

where $r=\sqrt{x_1^2+x_2^2+x_3^2}$ and a_1, a_2, a_3 are real constant numbers.

The coordinate system is

$$\vec{x}=l\mathcal{O}\vec{z}.$$

Here $\mathcal{O}$ is a time-dependent 3×3 orthogonal matrix $\mathcal{O}(\alpha,\beta,\gamma)$, where $\alpha=-kt$, $\beta=\gamma=0$; $\vec{z}$ is the spherical coordinate system, given by formula 5 from (21); and function $l(t)$ is given by

$$l^2=\sqrt{C_1^2\pm\frac{1}{k^2}}\sin\left(2\sqrt{\frac{2}{3}}kt\right)+C_1, \quad \text{or} \quad l=C_1\sin\left(\sqrt{\frac{2}{3}}kt\right)$$

under condition $a_1=0$ and $l=1$ under condition $a_1\neq 0$. Here C_1 is an arbitrary real constant.

4. Case 4

Here

$$e\vec{H}=(0,0,k),\quad k=\text{const}\neq 0;$$

$$eA_0=-\frac{k^2}{12}(x_1^2+x_2^2-2x_3^2)+\frac{a_1}{r^+}+\frac{a_2}{r^-}+a_3\left(\frac{1}{r^+}\operatorname{arctanh}\frac{x_3^+}{r^+}-\frac{1}{r^-}\operatorname{arctanh}\frac{x_3^-}{r^-}\right),$$

where $x_3^{\pm}=x_3\pm a$ and $r^{\pm}=\sqrt{x_1^2+x_2^2+(x_3\pm a)^2}$, and a, a_1, a_2, a_3 are arbitrary real constants. The coordinate system is

$$\vec{x}=\mathcal{O}\vec{z}.$$

Here $\mathcal{O}$ is a time-dependent 3×3 orthogonal matrix $\mathcal{O}(\alpha,\beta,\gamma)$, where $\alpha=-kt$, $\beta=\gamma=0$, and $\vec{z}$ is a prolate spheroidal coordinate system, given by formula 6 from (21).

5. Case 5

Here

$$e\vec{H}=(0,0,k),\quad k=\text{const}\neq 0;$$

$$eA_0=-\frac{k^2}{12}(x_1^2+x_2^2-2x_3^2)+2a_1a\frac{f_1}{f}+2a_2\frac{x_3}{ff_1}-2a_3\left(a\frac{f_1}{f}\operatorname{arccot}f_1-\frac{x_3}{ff_1}\operatorname{arctanh}\frac{x_3}{af_1}\right),$$

where

$$f=\sqrt{(a^2-r^2)^2+4a^2x_3^2},\quad f_1=\sqrt{\frac{-a^2+r^2+f}{2a^2}},\quad r=\sqrt{x_1^2+x_2^2+x_3^2},$$

and a, a_1, a_2, a_3 are arbitrary real constants. The coordinate system is

$$\vec{x}=\mathcal{O}\vec{z}.$$

Here $\mathcal{O}$ is a time-dependent 3×3 orthogonal matrix $\mathcal{O}(\alpha,\beta,\gamma)$, where $\alpha=-kt$, $\beta=\gamma=0$, and $\vec{z}$ is an oblate spheroidal coordinate system, given by formula 7 from (21).

Note that expression for A_0 can be rewritten in the form

$$eA_0=-\frac{k^2}{12}(x_1^2+x_2^2-2x_3^2)+\frac{a_1+ia_2}{\tilde{r}^+}+\frac{a_1-ia_2}{\tilde{r}^-}+ia_3\left(\frac{1}{\tilde{r}^+}\operatorname{arctanh}\frac{\tilde{x}_3^+}{\tilde{r}^+}-\frac{1}{\tilde{r}^-}\operatorname{arctanch}\frac{\tilde{x}_3^-}{\tilde{r}^-}\right),$$

where $\tilde{x}_3^{\pm}=x_3\pm ia$ and $\tilde{r}^{\pm}=\sqrt{x_1^2+x_2^2+(x_3\pm ia)^2}$.

6. Case 6

Here

$$e\vec{H}=(0,0,k),\quad k=\text{const}\neq 0;$$

$$eA_0=-\frac{k^2}{6}(x_1^2+x_2^2-2x_3^2)+\frac{a_1}{r}+a_2x_3+\frac{a_3}{r}\ln\frac{r+x_3}{r-x_3},$$

where $r=\sqrt{x_1^2+x_2^2+x_3^2}$ and a_1, a_2, a_3 are arbitrary real constants.

The coordinate system is

$$\vec{x}=\mathcal{O}\vec{z}.$$

Here $\mathcal{O}$ is a time-dependent 3×3 orthogonal matrix $\mathcal{O}(\alpha,\beta,\gamma)$, where $\alpha=-kt$ and $\beta=\gamma=0$, and $\vec{z}$ is a parabolic coordinate system, given by formula 8 from (21).

7. Case 7

Here

$$e\vec{H}=(0,0,k),\quad k=\text{const}\neq 0;$$

$$eA_0=-\frac{q}{2}(x_1^2+x_2^2-2x_3^2)+a\ln(x_1+x_2)+a_3x_3,$$

where k, a, a_3 are arbitrary real constants.

The coordinate system is

$$x_1=e^{\omega_1}\cos(\omega_1-kt),\quad x_2=e^{\omega_1}\sin(\omega_1-kt),\quad x_3=l_3\omega_3+v_3,$$

where l_3, v_3 are solutions of the system of ordinary differential equations

$$\frac{c_3}{l_3^4}-\frac{1}{4}\frac{\ddot{l}_3}{l_3}=q,\quad l_3\ddot{v}_3+2\dot{l}_3\dot{v}_3+4c_3\frac{v_3}{l_3^3}-2c_{13}\frac{1}{l_3}=-2a_3.$$

Note that some of the potentials obtained have the clear physical meaning. For instance, cases 2 and 3 under condition $k=a_2=a_3=0$ give the standard Coulomb potential. Case 4 under condition $k=a_3=0$ gives the potential for a well-known two-center Kepler problem, i.e., the problem of finding wave functions of electrons moving in the field of two fixed Coulomb centers with charges a_1, a_2 and intercenter distance $2a$ (the model of ionized hydrogen molecule). Coulson and Joseph[23] showed that the corresponding Schrödinger equation admits separation of variables in the prolate coordinate system only. We obtained this potential as a particular case of the more general potential.

V. CONCLUDING REMARKS

Theorem 1 provides the complete solution of the problem of classification of the Pauli equations (1), which are solvable within the framework of the method of separation of variables in the sense of our Definition 1. According to these theorems the coordinate systems and the vector-potentials of the electromagnetic field $A(t,\vec{x})=(A_0(t,\vec{x}),\vec{A}(t,\vec{x}))$ providing separability of the corresponding Pauli equations coincide with those for the Schrödinger equations with vector-potential. So the results obtained in the article are valid for the Schrödinger equation as well.

It is well known that the possibility of variable separation in a system of PDEs is closely connected to its symmetry properties.[9,10] Namely, solutions with separated variables are common eigenfunctions of three matrix mutually commuting symmetry operators of the equation under study. For all the cases of variable separation in Pauli equation (1) such matrix second-order operators can be constructed in the explicit form, by analogy to what has been done in Ref. 24 for the $(1+2)$-dimensional Schrödinger equation. They are expressed in terms of the matrix coefficients of the separation equations (17) and (18).

A promising development of the research is classification and study of superintegrable (admitting sufficiently many higher symmetries) cases of Pauli equation. Notice that the notions of separability and superintegrability are closely related. By now, superintegrable physical systems can be regarded as one of the most intensively developed and significant fields of mathematical physics. The problem of classifying superintegrable stationary Schrödinger equations with scalar

potential has been solved by Winternitz with co-workers[25] and Evans[26] for space dimensions $n=2$ and $n=3$ (see also Ref. 4). They have found all potentials that allow for separability of the corresponding Schrödinger equation in more than one coordinate system. We intend to modify and generalize this approach to $(1+3)$-dimensional Pauli equation (1). A study of the problem is in progress now and will be reported in our future publications.

(Received 9 July 2001; accepted for publication 14 November 2001)

We consider an arbitrary translationally invariant chain model with nearest neighbors interaction and satisfying periodic boundary condition. The approach developed here allows a thermodynamic description of the chain model directly in terms of grand potential per site. This thermodynamic function is derived from an auxiliary function constructed only from open connected subchains. In order to exemplify its application and how this approach works we consider the Heisenberg XXZ model. We obtain the coefficients of the high temperature expansion of the free energy per site of the model up to third order. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1432484]

I. INTRODUCTION

Chain models, such as the spin-$\frac{1}{2}$ Heisenberg models XYZ and XXZ[1,2] and their extensions,[3,4] the one-dimensional Hubbard model,[5] etc., have attracted intense interest due to their property of integrability. We also have other models like the one-dimensional d-p model[6] and its generalizations,[7,8] employed to simulate a Cu–O linear chain with strong Coulomb repulsion. These models are also relevant because they may explain high temperature superconductivity.

The solution of the XXZ model[9] and the one-dimensional Hubbard model[5] at $T=0$ are examples of the success of the Bethe ansatz. In 1972 Takahashi and Suzuki[10] obtained the exact thermodynamics of the XXZ model. More recently the same results were reobtained by Kuniba *et al.*[11] using the quantum transfer matrix approach. The exact thermodynamics of the one-dimensional Hubbard model was also derived by this same method.[12–14] In all those models the thermodynamic functions are solutions of integral coupled equations, and it is possible to obtain their behavior in the very high temperature limit. However, it is not an easy task to derive a systematic temperature expansion for the thermodynamic functions in such temperature range.

The high temperature limit of any model can be obtained by a standard expansion in terms of the inverse of temperature β,[15] $\beta=1/kT$, where k is the Boltzmann constant and T is the absolute temperature. Sometimes, perturbation theory can be applied to obtain the coefficients of the β-expansion method; this approach is also called the high temperature expansion and it has been applied to the t-J model[16] and to the Hubbard model.[17–19] In all standard high temperature expansions we always need to calculate the weight of each graph in the grand canonical partition function as well as to determine all graphs that contribute at a given β-order term.

Recently, we applied the basic properties of the Grassmann generators to calculate analytically the coefficients of the β-expansion of the grand canonical partition function $\mathcal{Z}(\beta,\mu)$ of self-interacting fermionic fields in any dimension.[20] We applied it to the one-dimensional Hubbard model.[21,22] We have two drawbacks in our method: a large number of graphs must be calculated, as well as counting the number of times each graph contributes to each β-term in the expansion of $\mathcal{Z}(\beta,\mu)$.

In this article restrict ourselves to the study of translationally invariant chain models with first neighbor interactions and subject to periodic boundary condition. Instead of calculating the grand canonical partition function, we derive a β-expansion for the grand potential per site, that is, an intensive quantity. The coefficient of order β^n is exactly obtained for arbitrary values of n. The proposed approach is not restricted to self-interacting fermionic models.

In Sec. II, we expand the grand canonical partition function as a Taylor series around $\beta=0$. In fact, the idea behind this method was previously developed, up to order β^5, in Ref. 20 for fermions only. Here we generalize the expansion for fermionic and bosonic fields to arbitrary orders of β^n. In performing this expansion we write $\mathcal{Z}(\beta,\mu)$ as a sum of traces whose coefficients are known. We obtain the expansion of the grand potential per site, and verify that it is an intensive quantity. In this calculation we do not use the traditional method of quantum transfer matrix. As an illustrative example of the method developed here, in Sec. III we apply it to spin-$\frac{1}{2}$ Heisenberg XXZ model. We calculate the β-expansion of the Helmholtz free energy of the model up to order β^3. Taking $\Delta=h=0$ we recover the β-expansion of this thermodynamic function of the free fermion model[23] whereas when $t=0$ we recover the limiting Ising model.[24] In Sec. IV we draw our main conclusions. In Appendix A we explain our graphic representation of the normalized traces; in Appendix B we extend our results for $\langle \mathbb{K}^n \rangle$ with arbitrary n; in Appendix C we write the grand potential per site in terms of an auxiliary function $\varphi(\lambda)$ that is constructed only from open connected subchains; and finally in Appendix D we write the function $K_{1,m}^{(n)}$ as sums of normalized traces for n up to 4.

II. GRAND CANONICAL PARTITION FUNCTION FOR A CHAIN MODEL

Let us consider a one-dimensional regular lattice (a periodic chain) with N sites, so that the Hilbert space of the chain model is simply $\mathcal{H}^{(N)}=\otimes^N\mathcal{H}$, $\mathcal{H}$ being the irreducible representation at one site, including all its degrees to freedom. The dimension of this Hilbert space is $\dim\mathcal{H}^{(N)}=\mathrm{tr}_N(\mathbb{1})$. The notation tr_N means the trace over all N sites and their internal degrees of freedom, such as spin.

The grand canonical partition function of a quantum system in the chain with N sites is given by

$$\mathcal{Z}_N(\beta,\mu)=\mathrm{tr}_N(\mathrm{e}^{-\beta\mathbb{K}}), \tag{1}$$

where $\mathbb{K}=\mathbb{H}-\mu\mathbb{N}$, with μ being the chemical potential and $\mathbb{N}$ being an operator that acts on $\mathcal{H}^{(N)}$ and that commutes with the Hamiltonian of the system. The expansion of $\mathcal{Z}_N(\beta,\mu)$ around $\beta=0$ is

$$\mathcal{Z}_N(\beta,\mu)=\mathrm{tr}_N(\mathbb{1})+\sum_{n=1}^{\infty}(-\beta)^n\frac{\mathrm{tr}_N(\mathbb{K}^n)}{n!}. \tag{2}$$

Let $\mathbf{A}$ be any operator that acts on $\mathcal{H}^{(M)}$ where $M\leqslant N$. We define $\langle\mathbf{A}\rangle\equiv\mathrm{tr}_M(\mathbf{A})/\mathrm{tr}_M(\mathbf{1})$, for any dimension of $\mathcal{H}^{(M)}$. From now on, we call $\langle\mathbf{A}\rangle$ the *normalized trace* of operator $\mathbf{A}$. The dimension of the subspace $\mathcal{H}^{(M)}$ is determined by the operator $\mathbf{A}$.

Using the definition of normalized trace, Eq. (2) becomes

$$\mathcal{Z}_N(\beta,\mu)=\mathrm{tr}_N(\mathbb{1})\left\{1+\sum_{n=1}^{\infty}(-\beta)^n\frac{\langle\mathbb{K}^n\rangle}{n!}\right\}. \tag{3}$$

Along this section we consider a general Hamiltonian $\mathbb{H}$ subject to two constraints: the interaction is only between first neighbors and the Hamiltonian $\mathbb{H}$ is invariant under translation along the chain. The most general operator $\mathbb{K}$ satisfying both conditions is

$$\mathbb{K}=\sum_{i=1}^{N}\tilde{\mathbf{K}}_{i,i+1}, \tag{4}$$

where $\tilde{\mathbf{K}}_{i,i+1}\in\mathcal{H}^{(N)}$. Each operator $\tilde{\mathbf{K}}_{i,i+1}$ is defined as

$$\tilde{\mathbf{K}}_{1,2}=\mathbf{K}_{1,2}\otimes\mathbf{1}_3\otimes\cdots\otimes\mathbf{1}_N$$

$$\tilde{\mathbf{K}}_{2,3}=\mathbf{1}_1\otimes\mathbf{K}_{2,3}\otimes\mathbf{1}_4\otimes\cdots\otimes\mathbf{1}_N$$

$$\vdots$$

$$\tilde{\mathbf{K}}_{i,i+1}=\mathbf{1}_1\otimes\cdots\otimes\mathbf{1}_{i-1}\otimes\mathbf{K}_{i,i+1}\otimes\mathbf{1}_{i+2}\otimes\cdots\otimes\mathbf{1}_N \tag{5}$$

and $\mathbf{K}_{i,i+1}\in\mathcal{H}_i\otimes\mathcal{H}_{i+1}$. We use the notation $\mathbf{1}_i\in\mathcal{H}_i$ for the identity matrix on the irreducible subspace of the ith particle.

Our aim is to get the coefficients $\langle\mathbb{K}^n\rangle$, on the rhs of Eq. (3), in terms of the normalized traces of products of operators $\mathbf{K}_{i,i+1}$. Let us calculate explicitly the first three coefficients ($n=1$, $n=2$, and $n=3$) of the expansion (3). They will help us to construct the coefficient $\langle\mathbb{K}^n\rangle$ for arbitrary n. We begin with $n=1$.

Since the operator $\mathbf{K}_{i,i+1}$ acts only on the sites i and $i+1$, we have

$$\mathrm{tr}_N(\tilde{\mathbf{K}}_{i,i+1})=\mathrm{tr}_2(\mathbf{K}_{i,i+1})(\mathrm{tr}_1(\mathbf{1}))^{N-2}. \tag{6}$$

We stress out that the traces of the rhs of Eq. (6) are calculated on the subspace $\mathcal{H}^{(1)}$ and $\mathcal{H}^{(2)}$ whereas the trace on the lhs is calculated on the complete space $\mathcal{H}^{(N)}$. Dividing both sides of Eq. (6) by $\mathrm{tr}_N(\mathbb{1})$,

$$\frac{\mathrm{tr}_N(\tilde{\mathbf{K}}_{i,i+1})}{\mathrm{tr}_N(\mathbb{1})}=\frac{\mathrm{tr}_2(\mathbf{K}_{i,i+1})}{\mathrm{tr}_2(\mathbf{1}\otimes\mathbf{1})}=\langle\mathbf{K}_{i,i+1}\rangle. \tag{7}$$

Due to the property of the Hamiltonian being translationally invariant we have $\langle\tilde{\mathbf{K}}_{i,i+1}\rangle=\langle\mathbf{K}_{i,i+1}\rangle=\langle\mathbf{K}_{1,2}\rangle$. Taking into account the periodic boundary condition ($\mathbf{K}_{N,N+1}=\mathbf{K}_{N,1}$), we have that $\langle\mathbb{K}\rangle$ is equal to

$$\langle\mathbb{K}\rangle=\sum_{i=1}^{N}\langle\mathbf{K}_{i,i+1}\rangle=N\langle\mathbf{K}_{1,2}\rangle. \tag{8}$$

For $n=2$ on the rhs of expansion (3) we have to calculate the normalized traces of $\langle\mathbb{K}^2\rangle$. From the definition of operator $\mathbb{K}$ [see Eq. (4)], we have

$$\langle\mathbb{K}^2\rangle=\sum_{i,j=1}^{N}\langle\mathbf{K}_{i,i+1}\mathbf{K}_{j,j+1}\rangle. \tag{9}$$

In the normalized trace $\langle\mathbf{K}_{i,i+1}\mathbf{K}_{j,j+1}\rangle$ we have three different cases (in Appendix A we explain our graphic representation):

(i) $i=j$:

$$\langle\mathbf{K}^2_{i,i+1}\rangle=\langle\mathbf{K}^2_{1,2}\rangle \quad\longrightarrow\quad \cdots\bullet\cdots\bullet\!\!=\!\!\bullet\cdots\bullet\cdots \qquad i-1 \quad i \quad i+1 \quad i+2 \tag{10a}$$

This equality comes from the invariance under translation and the periodic boundary condition satisfied by the model. In the double sum (9) we have N terms of this type.

(*ii*) $i = j \pm 1$:

- $i = j+1:\quad \langle \mathbf{K}_{i,i+1}\mathbf{K}_{i+1,i+2}\rangle \longrightarrow$ 
(10b)

- $i = j-1:\quad \langle \mathbf{K}_{i+1,i+2}\mathbf{K}_{i,i+1}\rangle \longrightarrow$ 
(10c)

In the double sum on the rhs of Eq. (9) we have N terms of the type of one of these two previous configurations. Using the cyclic property of traces and translation invariance, we get that the normalized traces (10b) and (10c) are equal. Therefore, we can write $\langle \mathbf{K}_{i,i+1}\mathbf{K}_{i-1,i}\rangle = \langle \mathbf{K}_{i,i+1}\mathbf{K}_{i+1,i+2}\rangle$.

(*iii*) $i \neq j$ and $i \neq j \pm 1$:

$\langle \mathbf{K}_{i,i+1}\mathbf{K}_{j,j+1}\rangle \longrightarrow$ 
(10d)

The normalized trace (10d) can be written as $\langle \mathbf{K}_{i,i+1}\rangle\langle \mathbf{K}_{j,j+1}\rangle = \langle \mathbf{K}_{1,2}\rangle^2$. The number of terms in the double sum in Eq. (9) that satisfies configuration (10d) is equal to $N(N-3)$.

The terms that contribute to $\langle \mathbb{K}^2\rangle$, with respective of number of configurations (weight) in the sum on the rhs of Eq. (9) are

$$\langle \mathbb{K}^2\rangle = N\langle \mathbf{K}_{1,2}^2\rangle + 2N\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\rangle + N(N-3)\langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\rangle. \tag{11}$$

The last term on the rhs of (11) can be written as a product of normalized traces with $n=1$.

The term $\langle \mathbb{K}^3\rangle$ has a richer structure of traces than the two previous ones. Its explicit study will help us to generalize the results for arbitrary n. The expansion of normalized traces in $\langle \mathbb{K}^3\rangle$ is

$$\langle \mathbb{K}^3\rangle = \sum_{i,j,k=1}^{N} \langle \mathbf{K}_{i,i+1}\mathbf{K}_{j,j+1}\mathbf{K}_{k,k+1}\rangle. \tag{12}$$

Similarly to $\langle \mathbb{K}\rangle$ and $\langle \mathbb{K}^2\rangle$, we determine the types of configurations we have in the sum on the rhs of Eq. (12) and their respective weights. For $\langle \mathbb{K}^3\rangle$ we have

$$\begin{aligned}\langle \mathbb{K}^3\rangle = {} & N\langle \mathbf{K}_{1,2}^3\rangle + 3N\left\{\frac{\langle \mathbf{K}_{1,2}^2\mathbf{K}_{2,3}\rangle}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}^2\rangle}{2!}\right\} + 3N\{\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{3,4}\rangle + \langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{2,3}\rangle\} \\ & + 3N(N-3)\left\{\frac{\langle \mathbf{K}_{1,2}^2\mathbf{K}_{3,4}\rangle}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}^2\rangle}{2!}\right\} + 3N(N-4)\{\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{4,5}\rangle + \langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{4,5}\rangle\} \\ & + N(N-4)(N-5)\langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{5,6}\rangle. \end{aligned} \tag{13}$$

From the expressions (8), (11) and (13) we have that each type of normalized trace (in the expression of $\langle \mathbb{K}^3\rangle$ we collect them inside of braces) corresponds to all normalized traces that we

can write for that set of operators. For example, the term: $3\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{3,4}\rangle + 3\langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{2,3}\rangle$ includes all normalized traces that we can write for the set of operators $\{\mathbf{K}_{1,2},\mathbf{K}_{2,3},\mathbf{K}_{3,4}\}$. The factors 3 come from the fact that some of them are equals by the cyclic property of the trace.

To make ours simpler and generalize our results for arbitrary n, we define the *g-trace*:

$$\langle \mathbf{K}^{n_1}_{i_1,i_1+1}\mathbf{K}^{n_2}_{i_2,i_2+1}\cdots\mathbf{K}^{n_m}_{i_m,i_m+1}\rangle_{\mathrm{g}} \equiv \frac{n_1!\cdots\ n_m!}{n!}\sum_{\mathcal{P}}\ \langle \mathcal{P}(\mathbf{K}^{n_1}_{i_1,i_1+1},\mathbf{K}^{n_2}_{i_2,i_2+1},\ldots,\mathbf{K}^{n_m}_{i_m,i_m+1})\rangle, \tag{14}$$

where $\Sigma_{i=1}^{m} n_i = n$ with $n_i \neq 0$ and the indices i_k, $k=1,...,m$ are distinct among themselves. By definition, $\langle \mathcal{P}(\mathbf{K}^{n_1}_{i_1,i_1+1},\mathbf{K}^{n_2}_{i_2,i_2+1},\ldots,\mathbf{K}^{n_m}_{i_m,i_m+1})\rangle$ represents all distinct permutations that we can write the n operators $\{\mathbf{K}_{i_1,i_1+1},\mathbf{K}_{i_2,i_2+1},\ldots,\mathbf{K}_{i_m,i_m+1}\}$. In the particular case when the operators $\{\mathbf{K}_{i_1,i_1+1},\mathbf{K}_{i_2,i_2+1},\ldots,\mathbf{K}_{i_m,i_m+1}\}$ commute among themselves, $\langle \mathbf{K}^{n_1}_{i_1,i_1+1}\mathbf{K}^{n_2}_{i_2,i_2+1}\cdots \mathbf{K}^{n_m}_{i_m,i_m+1}\rangle_g$ reduces to the normalized trace $\langle \mathbf{K}^{n_1}_{i_1,i_1+1}\mathbf{K}^{n_2}_{i_2,i_2+1}\cdots\ \mathbf{K}^{n_m}_{i_m,i_m+1}\rangle$.

The normalized traces $\langle \mathbb{K}\rangle$, $\langle \mathbb{K}^2\rangle$ and $\langle \mathbb{K}^3\rangle$ written in terms of the g-traces become

$$\langle \mathbb{K}\rangle = N\langle \mathbf{K}_{1,2}\rangle_{\mathrm{g}}, \tag{15a}$$

$$\frac{\langle \mathbb{K}^2\rangle}{2!} = N\frac{\langle \mathbf{K}^2_{1,2}\rangle_{\mathrm{g}}}{2!} + N\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\rangle_{\mathrm{g}} + \frac{N(N-3)}{2!}\langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\rangle_{\mathrm{g}}, \tag{15b}$$

and

$$\begin{aligned}\frac{\langle \mathbb{K}^3\rangle}{3!} = {} & N\frac{\langle \mathbf{K}^3_{1,2}\rangle_{\mathrm{g}}}{3!} + N\left\{\frac{\langle \mathbf{K}^2_{1,2}\mathbf{K}_{2,3}\rangle_{\mathrm{g}}}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}^2_{2,3}\rangle_{\mathrm{g}}}{2!}\right\} + N\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{3,4}\rangle_{\mathrm{g}} + \frac{N(N-3)}{2!}\left\{\frac{\langle \mathbf{K}^2_{1,2}\mathbf{K}_{3,4}\rangle_{\mathrm{g}}}{2!}\right. \\ & \left. + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}^2_{3,4}\rangle_{\mathrm{g}}}{2!}\right\} + \frac{N(N-4)}{2!}\{\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{4,5}\rangle_{\mathrm{g}} + \langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{4,5}\rangle_{\mathrm{g}}\} \\ & + \frac{N(N-4)(N-5)}{3!}\langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{5,6}\rangle_{\mathrm{g}}.\end{aligned} \tag{15c}$$

Some of the g-traces at order n can be written as the product of the normalized traces of lower order. The latter are already calculated, which means that we have a smaller number of new normalized traces to be calculated at order n. To distinguish the normalized traces that appear for the first time at order n from the others we use the notation $\mathrm{K}^{(n)}_{r,m}$, where n is the power ($\langle \mathbb{K}^n\rangle$) of the term in expansion (3) to which the g-traces contribute, r is the number of products of the traces that the original trace can be broken and m is the number of distinct $\mathbf{K}_{i,i+1}$ operators that appear in the g-trace. The terms $\mathrm{K}^{(n)}_{r,m}$ with $r=1$ are the g-traces that appear in the expansion for the first time at order β^n.

We begin by defining $\mathrm{K}^{(n)}_{1,m}$ as

$$\mathrm{K}^{(n)}_{1,1} = \frac{\langle \mathbf{K}^n_{1,2}\rangle_{\mathrm{g}}}{n!}, \tag{16a}$$

$$\mathrm{K}^{(n)}_{1,2} = \sum_{\{n_i\}}^{n}{}'' \ \frac{\langle \mathbf{K}^{n_1}_{1,2}\mathbf{K}^{n_2}_{2,3}\rangle_{\mathrm{g}}}{n_1!\quad n_2!}, \tag{16b}$$

$$\vdots$$

$$\mathrm{K}^{(n)}_{1,m} = \sum_{\{n_i\}}^{n}{}'' \ \frac{\langle \mathbf{K}^{n_1}_{1,2}\mathbf{K}^{n_2}_{2,3}\cdots\ \mathbf{K}^{n_m}_{m,m+1}\rangle_{\mathrm{g}}}{n_1!n_2!\cdots\ n_m!}. \tag{16c}$$

From now on we use the notation $\Sigma''_{\{n_i\}}$ to mean the restriction $\Sigma_{i=1}^{n} n_i = n$ and $n_i \neq 0$ for $i = 1,2,...,m$. The index m satisfies the condition: $1 \leqslant m \leqslant \min(n,N)$. In Eq. (16c) we are assuming $m \leqslant n$. However, if $m > n$, we define $\mathrm{K}_{1,m}^{(n)} = 0$.

Since in the definition of the g-traces are included all possible permutations of the n operators, we have

$$\mathrm{K}_{1,m}^{(n)} = \sum_{\{n_i\}}^{n}{}'' \left\langle \prod_{i=1}^{m} \frac{\mathbf{K}_{i,i+1}^{n_i}}{n_i!} \right\rangle_{\mathrm{g}} . \tag{17}$$

For $r = 2$, the natural definition is

$$\mathrm{K}_{2,2}^{(n)} = \sum_{\{n_i\}}^{n}{}'' \frac{\langle \mathbf{K}_{1,2}^{n_1} \mathbf{K}_{3,4}^{n_2} \rangle_{\mathrm{g}}}{n_1! \quad n_2!} = \sum_{\{n_i\}}^{n}{}'' \frac{\langle \mathbf{K}_{1,2}^{n_1} \rangle_{\mathrm{g}}}{n_1!} \frac{\langle \mathbf{K}_{3,4}^{n_2} \rangle_{\mathrm{g}}}{n_2!} = \sum_{\{n_i\}}^{n}{}'' \mathrm{K}_{1,1}^{(n_1)} \mathrm{K}_{1,1}^{(n_2)} , \tag{18a}$$

$$\mathrm{K}_{2,3}^{(n)} = \sum_{\{n_i\}}^{n}{}'' \left(\frac{\langle \mathbf{K}_{1,2}^{n_1} \mathbf{K}_{2,3}^{n_2} \mathbf{K}_{4,5}^{n_3} \rangle_{\mathrm{g}}}{n_1! n_2! n_3!} + \frac{\langle \mathbf{K}_{1,2}^{n_1} \mathbf{K}_{3,4}^{n_2} \mathbf{K}_{4,5}^{n_3} \rangle_{\mathrm{g}}}{n_1! n_2! n_3!} \right) = \sum_{\{n_i\}}^{n}{}'' (\mathrm{K}_{1,1}^{(n_1)} \mathrm{K}_{1,2}^{(n_2)} + \mathrm{K}_{1,2}^{(n_1)} \mathrm{K}_{1,1}^{(n_2)}), \tag{18b}$$

where we took into account the invariance of the model under translations and the fact that

$$[\mathbf{K}_{i,i+1}, \mathbf{K}_{j,j+1}] = \begin{cases} \mathbf{0}, & \text{when } i \neq j \pm 1, \\ \neq \mathbf{0}, & \text{when } i = j \pm 1. \end{cases} \tag{19}$$

To obtain the second equality on the rhs of Eq. (18b) we rearrange the indices in the double sum. We see that these g-traces can always be written as the product of g-traces of lower order which give us

$$\mathrm{K}_{2,m}^{(n)} = \sum_{\{n_i\}}^{n}{}'' \sum_{l=1}^{m-1} \mathrm{K}_{1,l}^{(n_1)} \mathrm{K}_{1,m-l}^{(n_2)} = \sum_{\{n_i\}}^{n}{}'' \sum_{\{m_j\}}^{m}{}'' \mathrm{K}_{1,m_1}^{(n_1)} \mathrm{K}_{1,m_2}^{(n_2)} . \tag{20}$$

The indices n_i satisfy the condition $n_1 + n_2 = n$ while $m_1 + m_2 = m$ and $2 \leqslant m \leqslant \min(n,N)$. We are assuming $m \leqslant n$, otherwise $\mathrm{K}_{2,m}^{(n)} = 0$. For $\mathrm{K}_{3,3}^{(n)}$ and $\mathrm{K}_{3,4}^{(n)}$ we have

$$\mathrm{K}_{3,3}^{(n)} = \sum_{\{n_i\}}^{n}{}'' \mathrm{K}_{1,1}^{(n_1)} \mathrm{K}_{1,1}^{(n_2)} \mathrm{K}_{1,1}^{(n_3)} , \tag{21a}$$

$$\mathrm{K}_{3,4}^{(n)} = \sum_{\{n_i\}}^{n}{}'' (\mathrm{K}_{1,1}^{(n_1)} \mathrm{K}_{1,1}^{(n_2)} \mathrm{K}_{1,2}^{(n_3)} + \mathrm{K}_{1,1}^{(n_1)} \mathrm{K}_{1,2}^{(n_2)} \mathrm{K}_{1,1}^{(n_3)} + \mathrm{K}_{1,2}^{(n_1)} \mathrm{K}_{1,1}^{(n_2)} \mathrm{K}_{1,1}^{(n_3)}). \tag{21b}$$

It follows for arbitrary m, where $3 \leqslant m \leqslant \min(n,N)$,

$$\mathrm{K}_{3,m}^{(n)} = \sum_{\{n_i\}}^{n}{}'' \sum_{\{m_i\}}^{m}{}'' \mathrm{K}_{1,m_1}^{(n_1)} \mathrm{K}_{1,m_2}^{(n_2)} \mathrm{K}_{1,m_3}^{(n_3)} , \tag{22}$$

and $\mathrm{K}_{3,m}^{(n)} = 0$ for $m > n$.

We generalize our definition of $\mathrm{K}_{r,m}^{(n)}$

$$\mathrm{K}_{r,m}^{(n)} \equiv \sum_{\{n_i\}}^{n}{}'' \sum_{\{m_i\}}^{m}{}'' \prod_{j=1}^{r} \mathrm{K}_{1,m_j}^{(n_j)} , \tag{23}$$

where $\{n_i\}\equiv\{n_1,n_2,\ldots,n_r\}$ and $\{m_i\}\equiv\{m_1,m_2,\ldots,m_r\}$. Equation (23) is valid for $r>1$ and it makes possible to write $\mathrm{K}_{r,m}^{(n)}$ as products of $\mathrm{K}_{1,m}^{(n)}$ [see Eq. (16c)]. The indices r and m satisfy the conditions $1\leqslant r\leqslant\min(n,N)$ and $r\leqslant m\leqslant\min(n,N)$. We are assuming $n\geqslant r$ and m, otherwise $\mathrm{K}_{r,m}^{(n)}=0$.

In terms of $\mathrm{K}_{r,m}^{(n)}$, the normalized traces $\langle\mathbb{K}\rangle$, $\langle\mathbb{K}^2\rangle$ and $\langle\mathbb{K}^3\rangle$ are simply

$$\langle\mathbb{K}\rangle=N\mathrm{K}_{1,1}^{(1)}, \tag{24a}$$

$$\frac{\langle\mathbb{K}^2\rangle}{2!}=N\mathrm{K}_{1,1}^{(2)}+N\mathrm{K}_{1,2}^{(2)}+\frac{N(N-3)}{2!}\mathrm{K}_{2,2}^{(2)}, \tag{24b}$$

$$\frac{\langle\mathbb{K}^3\rangle}{3!}=N\mathrm{K}_{1,1}^{(3)}+N\mathrm{K}_{1,2}^{(3)}+N\mathrm{K}_{1,3}^{(3)}+\frac{N(N-3)}{2!}\mathrm{K}_{2,2}^{(3)}+\frac{N(N-4)}{2!}\mathrm{K}_{2,3}^{(3)}+\frac{N(N-4)(N-5)}{3!}\mathrm{K}_{3,3}^{(3)}. \tag{24c}$$

In Appendix B we write $\langle\mathbb{K}^4\rangle$ in terms of $\mathrm{K}_{r,m}^{(4)}$ and the coefficients of $\mathrm{K}_{1,m}^{(n)}$, $\mathrm{K}_{2,m}^{(n)}$ and $\mathrm{K}_{3,m}^{(n)}$ for $n=1,2$ and 3 are rewritten in terms of binomial coefficients. In this appendix we also extend the previous results for arbitrary n.

For arbitrary n, Eq. (B8) gives the expression of $\langle\mathbb{K}^n\rangle$, that is,

$$\frac{\langle\mathbb{K}^n\rangle}{n!}=\sum_{r=1}^{[n,N]}\sum_{m=r}^{[n,N]}\frac{N}{r}\binom{N-m-1}{r-1}\mathrm{K}_{r,m}^{(n)}. \tag{25}$$

The notation $[n,N]$ means the $\min(n,N)$. Differently from our previous work,[20–22] in Eq. (25) we already have the weight of each set of subchain $\mathrm{K}_{r,m}^{(n)}$ in $\langle\mathbb{K}^n\rangle$. The coefficient that multiplies $\mathrm{K}_{r,m}^{(n)}$ in Eq. (25) is independent of the particular Hamiltonian under consideration.

For $n<N$ the trace will be calculated on a maximum subspace given by $\mathcal{H}^{(n+1)}$, whereas for $n\geqslant N$ due to the periodic boundary condition the operators act on the whole Hilbert space $\mathcal{H}^{(N)}$, therefore we can say that the operators act more than one period in the periodic chain.

Rewriting the coefficient of $\mathrm{K}_{r,m}^{(n)}$ in Eq. (25) in a more convenient way,

$$\frac{\langle\mathbb{K}^n\rangle}{n!}=\sum_{r=1}^{[n,N]}\sum_{m=r}^{[n,N]}\sum_{k=1}^{r}(-1)^{r+k}\frac{k}{r}\binom{m+r-k-1}{r-k}\binom{N}{k}\mathrm{K}_{r,m}^{(n)}\equiv\sum_{k=1}^{[n,N]}\binom{N}{k}\mathfrak{K}_{k,n} \tag{26}$$

with

$$\mathfrak{K}_{k,n}\equiv\sum_{r=k}^{[n,N]}\sum_{m=r}^{[n,N]}(-1)^{r+k}\frac{k}{r}\binom{m+r-k-1}{r-k}\mathrm{K}_{r,m}^{(n)}. \tag{27}$$

From Eq. (27) we have that the biggest possible value of k is $\min(n,N)$ while there is no restriction on n. The function $\mathfrak{K}_{k,n}$ has the property,

$$\mathfrak{K}_{k,n}=\sum_{\{n_i\}}^{n}{}''\prod_{i=1}^{k}\mathfrak{K}_{1,n_i}, \tag{28}$$

where $\{n_i\}\equiv\{n_1,n_2,\ldots,n_k\}$. Replacing Eq. (26) in Eq. (3) we get

$$\mathcal{Z}_N(\beta,\mu)=\mathrm{tr}_N(\mathbb{1})\left\{1+\sum_{k=1}^{N}\binom{N}{k}\sum_{n=k}^{\infty}(-\beta)^n\mathfrak{K}_{k,n}\right\}. \tag{29}$$

From property (28) and recombining the summations conveniently, Eq. (29) is finally written for any value of N as

$$\mathcal{Z}_N(\beta,\mu)=\left\{\mathrm{tr}_1(\mathbf{1})\left(1+\sum_{n=1}^{\infty}(-\beta)^n\mathfrak{K}_{1,n}\right)\right\}^N. \tag{30}$$

The grand potential per site $\mathcal{W}(\beta,\mu)$ is

$$\mathcal{W}_N(\beta,\mu)=-\frac{1}{N\beta}\ln\mathcal{Z}_N(\beta,\mu)=-\frac{1}{\beta}\ln\left(\mathrm{tr}_1(\mathbf{1})\left(1+\sum_{n=1}^{\infty}(-\beta)^n\mathfrak{K}_{1,n}\right)\right). \tag{31}$$

This expansion can be used to obtain analytical results of chain models in the high temperature limit.

We can be misled by the notation $\mathfrak{K}_{1,n}$ in Eq. (31) since in it are included not only connected subchains but also disconnected ones. For finite N, Eq. (31) is the simplest form of the grand potential per site since in this case n can be bigger than N which means to go around the chain more than once.

A. The thermodynamic limit

Our main interest is to get the thermodynamical behavior of physical quantities that characterize physical systems. Those are attained only in the thermodynamic limit ($N\to\infty$). We first take the thermodynamic limit and after make the expansion (2), so that we never goes along the chain more than once when we calculate the normalized traces. In this thermodynamic limit the rhs of Eq. (30) is equal to the highest eigenvalue obtained from the associated quantum transfer matrix[24] to the quantum system of interest. From Eq. (31), the grand potential per site $\mathcal{W}(\beta,\mu)$ in this limit is

$$\mathcal{W}(\beta,\mu)=-\lim_{N\to\infty}\frac{1}{N\beta}\ln\mathcal{Z}_N(\beta,\mu)=-\frac{1}{\beta}\ln\left(\mathrm{tr}_1(\mathbf{1})\left(1+\sum_{n=1}^{\infty}(-\beta)^n\mathfrak{K}_{1,n}\right)\right). \tag{32}$$

Equations (31) and (32) look alike. Their difference relies on the fact that in Eq. (32) the biggest subchain that contributes to $\mathfrak{K}_{1,n}$ has at most the length of the chain. Equation (32) confirms that the grand potential is an intensive quantity.

Certainly our aim is to be able to calculate the smallest possible number of open subchains to obtain the grand potential per site. But the definition of $\mathfrak{K}_{1,n}$ [see Eq. (27)] includes connected as well disconnected subchains. In Eq. (32) we have the following sum to calculate:

$$\xi\equiv\sum_{n=1}^{\infty}(-\beta)^n\mathfrak{K}_{1,n}. \tag{33}$$

Let us define

$$\Gamma_m\equiv\sum_{n=m}^{\infty}(-\beta)^n\mathrm{K}_{1,m}^{(n)} \tag{34}$$

as a summation of powers series of β. The expression of $\mathrm{K}_{1,m}^{(n)}$ is given by Eq. (16c). We point out that only connected open subchains contribute to the functions Γ_m. We define the function $\varphi(\lambda)$ in terms of the functions Γ_m as follows:

$$\varphi(\lambda)=\sum_{m=1}^{\infty}\frac{\Gamma_m}{\lambda^m}, \tag{35}$$

where λ is a parameter. In Appendix C we show that the

$$\xi=\sum_{n=0}^{\infty}\frac{\mathrm{d}^n}{\mathrm{d}\lambda^n}\left(\frac{\varphi(\lambda)^{n+1}}{(n+1)!}\right)\Bigg|_{\lambda=1}. \tag{36}$$

From Eqs. (27) and (32) we have that the connected and disconnected open subchains contribute to the grand potential per site. In the thermodynamic limit we have from Eqs. (34)–(36) that all these subchains can be derived only from a sum of connected open subchains (for details see Appendix C). We finally write the grand potential per site simply as

$$\mathcal{W}(\beta,\mu)=-\frac{1}{\beta}\{\ln(\mathrm{tr}_1(\mathbf{1}))+\ln(1+\xi)\}. \tag{37}$$

Due to the fact that ξ can be derived from the function $\varphi(\lambda)$, one has the consequence that a much smaller number of terms has to be calculated at each β-order in the β-expansion of $\mathcal{W}(\beta,\mu)$. The weight of each g-trace in Eq. (37) is already included in the definition of ξ.

III. THE HEISENBERG XXZ MODEL

Let us consider the Hamiltonian of the well known anisotropic one-dimensional Heisenberg XXZ model with spin-$\frac{1}{2}$,[1,2]

$$\mathbb{H}=\frac{1}{2}\sum_{j=1}^{N}(\sigma_j^x\sigma_{j+1}^x+\sigma_j^y\sigma_{j+1}^y+\Delta\sigma_j^z\sigma_{j+1}^z-2h\sigma_j^z), \tag{38}$$

where h is the external magnetic field and $(\sigma_j^x,\sigma_j^y,\sigma_j^z)$ are the Pauli matrices at the jth site on a periodic chain with N space sites and Δ is called the anisotropy parameter. For $\Delta>0$ ($\Delta<0$) we have a repulsive (attractive) interaction core. The case $\Delta=1$ ($\Delta=-1$) corresponds to the isotropic antiferromangetic (ferromagnetic) Heisenberg model with fully polarized ground state.

Through the Jordan–Wigner transformation,[25] the Hamiltonian (38) is mapped on a spinless fermionic model, whose Hamiltonian is

$$\mathbb{H}=\sum_{j=1}^{N}(t(\mathbf{a}_j^{\dagger}\mathbf{a}_{j+1}+\mathbf{a}_{j+1}^{\dagger}+\mathbf{a}_j)+V\mathbf{n}_j\mathbf{n}_{j+1}+E\mathbf{n}_j)+N\left(h+\frac{\Delta}{2}\right), \tag{39}$$

with $V=2\Delta$, $E=-2h-2\Delta$, where $\mathbf{n}_i=\mathbf{a}_i^{\dagger}\mathbf{a}_i$ and $\mathbf{a}_i^{\dagger}(\mathbf{a}_i)$ is the fermionic creation(annihilation) operator at site j. The operators $\mathbf{a}_i^{\dagger}$ and $\mathbf{a}_i$ satisfy the usual anticommutation relations of the fermionic fields. The hopping constant t is included in Hamiltonian (39) only to help us count the powers of the terms that contribute to a given order β^n in the β-expansion of the Helmholtz free energy per site. Throughout our calculations, we take $t=1$. The term $N(h+\Delta/2)$ leads to a shift in the energy of the ground state of the model.

A. High temperature expansion

In this section we calculate the β-expansion of the Helmholtz free energy per site of the XXZ model, whose Hamiltonian is given by Eq. (39), up to order β^3.

In order to apply the method derived in Sec. II, we write Hamiltonian (38) as $\mathbb{H}=\Sigma_{i=1}^{N}\mathbf{H}_{i,i+1}$, where

$$\mathbf{H}_{i,i+1}\equiv\mathbf{E}_{i,i+1}+\mathbf{T}_{i,i+1}^{+}+\mathbf{T}_{i,i+1}^{-}+\mathbf{V}_{i,i+1}, \tag{40}$$

and each term on the rhs of Eq. (40) is defined as $\mathbf{E}_{i,i+1}\equiv\frac{1}{2}E(\mathbf{n}_i+\mathbf{n}_{i+1})$, $\mathbf{T}_{i,i+1}^{-}\equiv t\mathbf{a}_i^{\dagger}\mathbf{a}_{i+1}$, $\mathbf{T}_{i,i+1}^{+}\equiv t\mathbf{a}_{i+1}^{\dagger}\mathbf{a}_i$ and $\mathbf{V}_{i,i+1}\equiv V\mathbf{n}_i\mathbf{n}_{i+1}$.

Our aim is to obtain the Helmholtz free energy per site of the XXZ model in the thermodynamic limit. For doing that we need the auxiliary function $\varphi(\lambda)$ [see Eq. (35)] of the XXZ model. This function is calculated from the functions Γ_m that are written in terms of $\mathrm{K}_{1,m}^{(n)}$ [see Eq. (34)].

Since we intend to calculate the β-expansion of the Helmholtz free energy per site of the XXZ model up to order β^3, we need to obtain the analytical expressions of $\Gamma_1,\ldots,\Gamma_4$, namely,

$$\Gamma_1=-\beta \mathrm{K}_{1,1}^{(1)}+\beta^2\mathrm{K}_{1,1}^{(2)}-\beta^3\mathrm{K}_{1,1}^{(3)}+\beta^4\mathrm{K}_{1,1}^{(4)}+\mathcal{O}(\beta^5), \tag{41a}$$

$$\Gamma_2=\beta^2\mathrm{K}_{1,2}^{(2)}-\beta^3\mathrm{K}_{1,2}^{(3)}+\beta^4\mathrm{K}_{1,2}^{(4)}+\mathcal{O}(\beta^5), \tag{41b}$$

$$\Gamma_3=-\beta^3\mathrm{K}_{1,3}^{(3)}+\beta^4\mathrm{K}_{1,3}^{(4)}+\mathcal{O}(\beta^5), \tag{41c}$$

$$\Gamma_4=\beta^4\mathrm{K}_{1,4}^{(4)}+\mathcal{O}(\beta^5). \tag{41d}$$

In Appendix D the functions $\mathrm{K}_{1,m}^{(n)}$ in Eqs. (41) are written as sums of normalized traces.

In particular, for Hamiltonian (39) the hopping terms ($\mathbf{T}_{i,i+1}^{+}$ and $\mathbf{T}_{i,i+1}^{-}$) in the normalized traces only contribute to those functions $\mathrm{K}_{1,m}^{(n)}$ where we have $\mathbf{H}_{i,i+1}^{l}$ with $l>1$. Since we are calculating traces, the number of $\mathbf{T}_{i,i+1}^{+}$'s in a given normalized trace has to be equal to the number of terms $\mathbf{T}_{i,i+1}^{-}$'s in it. Otherwise, the normalized trace is null.

Calculating explicitly the normalized traces that contribute to $\mathrm{K}_{1,m}^{(n)}$ (see Appendix D) for the XXZ model, we obtain the following.

(*i*) $m=1$:

$$\mathrm{K}_{1,1}^{(1)}=\frac{E}{2}+\frac{V}{4}, \tag{42a}$$

$$\mathrm{K}_{1,1}^{(2)}=\frac{t^2}{4}+\frac{3E^2}{16}+\frac{EV}{4}+\frac{V^2}{8}, \tag{42b}$$

$$\mathrm{K}_{1,1}^{(3)}=\frac{5E^3}{96}+\frac{V^3}{24}+\frac{Et^2}{8}+\frac{VE^2}{8}+\frac{EV^2}{8}, \tag{42c}$$

$$\mathrm{K}_{1,1}^{(4)}=\frac{t^4}{48}+\frac{E^2t^2}{32}+\frac{3E^4}{256}+\frac{VE^3}{24}+\frac{E^2V^2}{16}+\frac{EV^3}{24}+\frac{V^4}{96}. \tag{42d}$$

(*ii*) $m=2$:

$$\mathrm{K}_{1,2}^{(2)}=\frac{5E^2}{16}+\frac{3EV}{8}+\frac{V^2}{8}, \tag{43a}$$

$$\mathrm{K}_{1,2}^{(3)}=\frac{E^3}{4}+\frac{V^3}{8}+\frac{Et^2}{4}+\frac{17VE^2}{32}+\frac{7EV^2}{16}+\frac{Vt^2}{8}, \tag{43b}$$

$$\mathrm{K}_{1,2}^{(4)}=\frac{t^4}{24}+\frac{5E^2t^2}{24}+\frac{95E^4}{768}+\frac{25VE^3}{64}+\frac{33E^2V^2}{64}+\frac{5EV^3}{16}+\frac{7V^4}{96}+\frac{t^2V^2}{24}+\frac{EVt^2}{6}. \tag{43c}$$

(*iii*) $m=3$:

$$\mathrm{K}_{1,3}^{(3)}=\frac{3E^3}{16}+\frac{V^3}{16}+\frac{23VE^2}{64}+\frac{EV^2}{4}, \tag{44a}$$

$$\mathrm{K}_{1,3}^{(4)}=\frac{41E^2t^2}{192}+\frac{59E^4}{256}+\frac{85VE^3}{128}+\frac{101E^2V^2}{128}+\frac{7EV^3}{16}+\frac{7t^2V^2}{96}+\frac{23EVt^2}{96}+\frac{3V^4}{32}. \tag{44b}$$

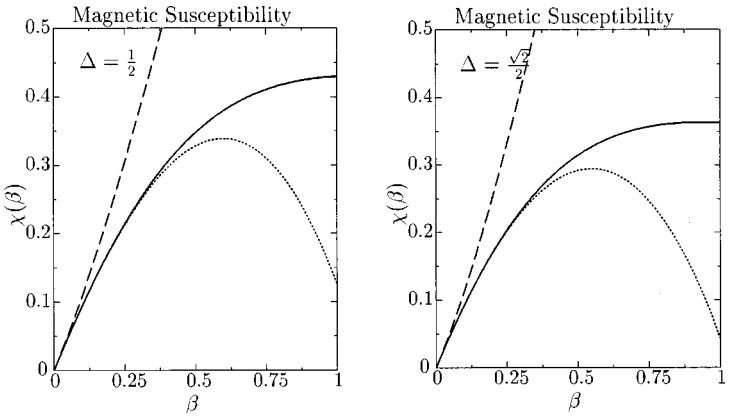

FIG. 1. The pointed line corresponds the β-expansion (46), the dashed line represents the β-expansion obtained by Destri and de Vega (Ref. 27) and the solid line corresponds to the numerical solution of the NLIE in Ref. 23 and 27.

(iv) $m=4$:

$$\mathrm{K}_{1,4}^{(4)}=\frac{29E^4}{256}+\frac{19VE^3}{64}+\frac{5E^2V^2}{16}+\frac{5EV^3}{32}+\frac{V^4}{32}. \tag{45}$$

Substituting those expressions in Eqs. (41) (taking $t=1$) and those in Eq. (35) we obtain the auxiliary function $\varphi(\lambda)$ for the XXZ model. Using the algebraic language MAPLE 5.1 we calculate the Helmholtz free energy per site of the model up to order β^3, that is,

$$\mathcal{W}(\beta)=\frac{\ln(2)}{\beta}+\mathcal{W}_I(\beta)+\mathcal{W}_F(\beta)-\frac{\Delta}{8}\beta^2+\frac{1}{4}\left(h^2+\frac{\Delta^2}{6}\right)\beta^3+\mathcal{O}(\beta^4), \tag{46}$$

where $\mathcal{W}_I(\beta)$ is the Helmholtz free energy per site of the Ising model[24,26] up to order β^3, that is,

$$\mathcal{W}_I(\beta)=-\frac{\ln(2)}{\beta}-\left(\frac{h^2}{2}+\frac{\Delta^2}{8}\right)\beta+\frac{h^2\Delta}{2}\beta^2+\left(\frac{h^4}{12}-\frac{h^2\Delta^2}{4}+\frac{\Delta^4}{192}\right)\beta^3+\mathcal{O}(\beta^4) \tag{47}$$

and $\mathcal{W}_F(\beta)$ is the Helmholtz free energy per site of the free fermion model[23,26] up to same β-order,

$$\mathcal{W}_F(\beta)=-\frac{\ln(2)}{\beta}-\frac{t^2}{4}\beta-\frac{t^4}{32}\beta^3+\mathcal{O}(\beta^4). \tag{48}$$

We rewrite the Helmholtz free energy per site [Eq. (46)] using the constants of Hamiltonian in Ref. 27. Comparing our results with Eq. (6.5) of this reference, we conclude (i) both results agree up to order β; (ii) our coefficient at order β^2 is $-J^3\cos(\gamma)+J\cos(\gamma)h^2$, which means that we have two misprints in Eq. (6.5) of Ref. 27, that is, the sign of $-J^3\cos(\gamma)\beta^2$ and a missing power of J multiplying h^2 [the two terms that contribute to order β^2 in Eq. (6.5) have different dimensions]; (iii) and it is missing the term $-J^2\cos^2(\gamma)h^2\beta^3$ in Eq. (6.5) of Ref. 27 (we point out that without this term we do not recover the limiting case of Ising model[24,26] ($t=0$) from XXZ model). Morever, the other terms at order β^3 in Eq. (6.5) have the following misprints: $-\frac{1}{4}J^4\beta^3$ should be $\frac{1}{2}J^4\beta^3$ and the term $-\frac{1}{6}J^4\cos^2(\gamma)\beta^3$ should be $\frac{2}{3}J^4\cos^2(\gamma)\beta^3$. With the previous corrections we get the Helmholtz free energy per site of the Ising model and the free fermion model as limiting cases of the XXZ model.

In Ref. 27 Destri and de Vega obtained the Helmholtz free energy per site of the XXZ model as a nonlinear integral equation (NLIE), as similarly obtained by Klümper.[23] Once our disagreement with the result of Ref. 27 is proportional h^2 at order β^3, we calculate the β-expansion of the magnetic susceptibility $\chi(\beta)$ $[\chi(\beta)=-\partial^2\mathcal{W}(\beta)/\partial h^2]$, obtained from Eq. (46). In Fig. 1 we plot the curve of the magnetic susceptibility derived from NLIE in Refs. 23 and 27, the β-expansion of

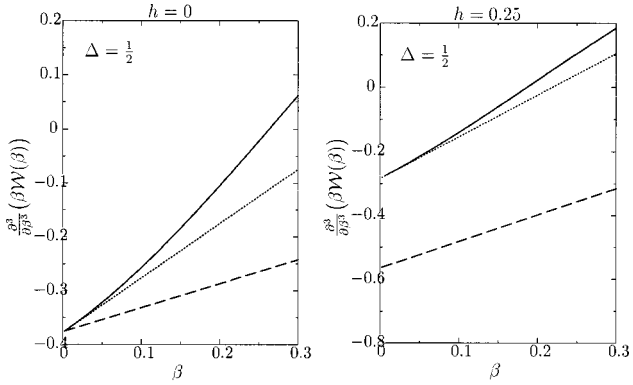

FIG. 2. We plot the function $(\partial^3/\partial\beta^3)(\beta\mathcal{W}(\beta))$ vs β. The pointed line (a straight line) corresponds to the results obtained from (46), the dashed line the β-expansion obtained by Destri and de Vega (Ref. 27) and the solid line the numerical solution of the NLIE (Refs. 23 and 27).

$\chi(\beta)$ derived in Ref. 27 and our own β-expansion of $\chi(\beta)$. From Fig. 1 we see that our result with $\Delta=\frac{1}{2}$ and $\Delta=\sqrt{2}/2$ coincides with the one derived from the NLIE in Refs. 23 and 27 for β up to 0.3, while the β-expansion of Destri and de Vega does not.

As a final check of our β-expansion (46) we plot in Fig. 2 the third partial derivative with respect to β of the function $\beta\mathcal{W}(\beta)$. We compare the numerical solution for this function obtained from the NLIE,[23,27] in the same reference, and our results derived from Eq. (46). In the region $\beta\approx 0$, the function $(\partial^3/\partial\beta^3)(\beta\mathcal{W}(\beta))$ is a straight line. From Fig. 2 we see that the result derived from Eq. (46) is identical to the one from the NLIE for β up to 0.1. For $h\neq 0$ in Fig. 2 we get that the function $(\partial^3/\partial\beta^3)(\beta\mathcal{W}(\beta))$ derived from the β-expansion in Ref. 27 does not even touch the exact curve.

We conclude that even though the NLIE derived in Refs. 23 and 27 gives the exact thermodynamics of the XXZ model with spin-$\frac{1}{2}$ the β-expansion obtained in Ref. 27 is not correct.

IV. CONCLUSIONS

There are several interesting one-dimensional models with translational invariance, with interactions between first neighbors only, satisfying periodic boundary conditions. They are generically called chain models, some of which have the property of integrability and to which the Bethe ansatz has been applied to solve them exactly at $T=0$ and at finite T. Their thermodynamical properties are obtained through coupled integral equations which demand numerical analysis to be solved (as examples see Refs. 10–14).

In this article we present a new analytical method to get the β-expansion coefficients of the grand potential per site, for translationally invariant chain models with nearest-neighbors interactions. Differently from our previous works[20–22] we calculate directly the β-expansion of the grand potential per site $\mathcal{W}(\beta,\mu)$. The weight of each subchain in $\mathcal{W}(\beta,\mu)$ is obtained, and we show explicitly that the grand potential per site is an intensive quantity. In the thermodynamic limit $(N\to\infty)$ we show that $\mathcal{W}(\beta,\mu)$ can be derived from an auxiliary function $\varphi(\lambda)$ that is written only in terms of open connected subchains. The present approach gives a β-expansion of $\mathcal{W}(\beta,\mu)$, whose coefficient of order β^n can be obtained exactly for arbitrary value of n. The existence of this auxiliary function allows us to get higher order terms in the β-expansion of $\mathcal{W}(\beta,\mu)$ than we were able to before, in Refs. 20–22. The coefficient of order β^n is analytically obtained, and it is exact. The number of terms (traces) to be calculated when deriving each coefficient in the β-expansion of $\mathcal{W}(\beta,\mu)$ is much smaller than before.

The present method applies to chains in both real space and momentum space, and the result given by Eq. (37) is valid for both classic and quantum models (bosonic and/or fermionic fields).

As an illustrative application of the method, we consider the spin-$\frac{1}{2}$ Heisenberg XXZ chain model and derive its Helmholtz free energy per site up to order β^3. The exact thermodynamics of the XXZ model is derived in Refs. 23 and 27. Our results in the high temperature region fully agree with the numerical solution of the NLIE derived in those references in this interval of temperature. Our β-expansion (46) recovers the Helmholtz free energy per site in two limiting cases: the Ising model ($t=0$) and the free fermion model ($\Delta=h=0$). We compare our high temperature expansion of the $\mathcal{W}(\beta)$ Eq. (46) of the XXZ model with the one derived by Destri and de Vega.[27] We show that Eq. (6.5) of this last reference has misprints and it is missing a term at order β^3.

As a final word we want to point out that the present approach can be well applied to models that do not have the property of integrability. Besides, once we have closed expressions for the coefficients of the β-expansion of $\mathcal{W}(\beta)$, the method can be implemented through a procedure in an algebraic language to get high β-order terms of the high temperature expansion of $\mathcal{W}(\beta)$ for the model under interest. We hope to report in the future progress in this direction.

APPENDIX A: GRAPHIC REPRESENTATION OF NORMALIZED TRACES

We have a better visualization of the normalized traces that contribute to $\langle \mathbb{K}^n \rangle$ through a graphic representation. In the graph, the operator $\mathbf{K}_{i,i+1}$ is represented by a straight line that links the sites i and $i+1$. In the case where we have a product of operators $\mathbf{K}_{i,i+1}$, for each operator a line is drawn at a different step of the ladder. It is important in the normalized trace the order in which the operators $\mathbf{K}_{i,i+1}$ appear in the string. We take this order into account in our graph representation of the normalized traces. To exemplify how to take into account the order of the operators in the string, we consider the following examples:

$\langle \mathbf{K}_{i,i+1} \rangle \longrightarrow$ 
(A1)

$\langle \mathbf{K}_{i,i+1}\mathbf{K}_{i+1,i+2} \rangle \longrightarrow$ 
(A2)

$\langle \mathbf{K}_{i,i+1}\mathbf{K}_{i-1,i}\mathbf{K}_{i+1,i+2} \rangle \longrightarrow$ 
(A3)

$\langle \mathbf{K}_{i,i+1}\mathbf{K}_{i+1,i+2}\mathbf{K}_{i-1,i} \rangle \longrightarrow$ 
(A4)

The graphs (A1)–(A4) are *connected* graphs, which means that the normalized trace cannot be written as a product of normalized traces of smaller number of operators $\mathbf{K}_{i,i+1}$.

APPENDIX B: CALCULATION OF $\langle \mathbb{K}^n \rangle$

In this appendix we give the explicit definition of $K^{(4)}_{r,m}$ in terms of which we write $\langle \mathbb{K}^4 \rangle$. The expression of $\langle \mathbb{K}^4 \rangle$ plus Eqs. (24) will allow us to write down $\langle \mathbb{K}^n \rangle$ for arbitrary n.

We define $K^{(4)}_{1,m}$ as

$$K^{(4)}_{1,1} = \frac{\langle \mathbf{K}^4_{1,2} \rangle_g}{4!}, \tag{B1a}$$

$$K^{(4)}_{1,2} = \frac{\langle \mathbf{K}^3_{1,2}\mathbf{K}_{2,3} \rangle_g}{3!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}^3_{2,3} \rangle_g}{3!} + \frac{\langle \mathbf{K}^2_{1,2}\mathbf{K}^2_{2,3} \rangle_g}{2!2!}, \tag{B1b}$$

$$K^{(4)}_{1,3} = \frac{\langle \mathbf{K}^2_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{3,4} \rangle_g}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}^2_{2,3}\mathbf{K}_{3,4} \rangle_g}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}^2_{3,4} \rangle_g}{2!}, \tag{B1c}$$

$$K^{(4)}_{1,4} = \langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{3,4}\mathbf{K}_{4,5} \rangle_g. \tag{B1d}$$

The other traces can be written as products of traces of lower order and they are

$$K^{(4)}_{2,2} = \frac{\langle \mathbf{K}^3_{1,2}\mathbf{K}_{3,4} \rangle_g}{3!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}^3_{3,4} \rangle_g}{3!} + \frac{\langle \mathbf{K}^2_{1,2}\mathbf{K}^2_{3,4} \rangle_g}{2!2!}, \tag{B2a}$$

$$\begin{aligned} K^{(4)}_{2,3} = {} & \frac{\langle \mathbf{K}^2_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{4,5} \rangle_g}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}^2_{2,3}\mathbf{K}_{4,5} \rangle_g}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}^2_{4,5} \rangle_g}{2!} \\ & + \frac{\langle \mathbf{K}^2_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{4,5} \rangle_g}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}^2_{3,4}\mathbf{K}_{4,5} \rangle_g}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}^2_{4,5} \rangle_g}{2!}, \end{aligned} \tag{B2b}$$

$$K^{(4)}_{2,4} = \langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{3,4}\mathbf{K}_{5,6} \rangle_g + \langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{4,5}\mathbf{K}_{5,6} \rangle_g + \langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{4,5}\mathbf{K}_{5,6} \rangle_g, \tag{B2c}$$

$$K^{(4)}_{3,3} = \frac{\langle \mathbf{K}^2_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{5,6} \rangle_g}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}^2_{3,4}\mathbf{K}_{5,6} \rangle_g}{2!} + \frac{\langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}^2_{5,6} \rangle_g}{2!}, \tag{B2d}$$

$$K^{(4)}_{3,4} = \langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{4,5}\mathbf{K}_{6,7} \rangle_g + \langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{4,5}\mathbf{K}_{6,7} \rangle_g + \langle \mathbf{K}_{1,2}\mathbf{K}_{2,3}\mathbf{K}_{4,5}\mathbf{K}_{6,7} \rangle_g, \tag{B2e}$$

$$K^{(4)}_{4,4} = \langle \mathbf{K}_{1,2}\mathbf{K}_{3,4}\mathbf{K}_{5,6}\mathbf{K}_{7,8} \rangle_g. \tag{B2 f}$$

From those definitions, the normalized trace $\langle \mathbb{K}^4 \rangle$ is written as

$$\begin{aligned} \frac{\langle \mathbb{K}^4 \rangle}{4!} = {} & N K^{(4)}_{1,1} + N K^{(4)}_{1,2} + N K^{(4)}_{1,3} + N K^{(4)}_{1,4} + \frac{N(N-3)}{2!} K^{(4)}_{2,2} + \frac{N(N-4)}{2!} K^{(4)}_{2,3} + \frac{N(N-5)}{2!} K^{(4)}_{2,4} \\ & + \frac{N(N-4)(N-5)}{3!} K^{(4)}_{3,3} + \frac{N(N-5)(N-6)}{3!} K^{(4)}_{3,4} + \frac{N(N-5)(N-6)(N-7)}{4!} K^{(4)}_{4,4}. \end{aligned} \tag{B3}$$

We use the following notations to write the coefficients of Eqs. (24) and (B3):

$$C^N_{1,1} = N,$$

$$C^N_{1,2} = N, \quad C^N_{2,2} = \frac{N(N-3)}{2!}, \tag{B4}$$

$$C_{1,3}^N = N,\quad C_{2,3}^N = \frac{N(N-4)}{2!},\quad C_{3,3}^N = \frac{N(N-4)(N-5)}{3!},$$

$$C_{1,4}^N = N,\quad C_{2,4}^N = \frac{N(N-5)}{2!},\quad C_{3,4}^N = \frac{N(N-5)(N-6)}{3!},\quad C_{4,4}^N = \frac{N(N-5)(N-6)(N-7)}{4!}.$$

Replacing the definitions given by Eqs. (B4) in Eqs. (24) and (B3), we obtain a compact way of writing the normalized traces:

$$\langle \mathbb{K} \rangle = C_{1,1}^N K_{1,1}^{(1)}, \tag{B5a}$$

$$\frac{\langle \mathbb{K}^2 \rangle}{2!} = C_{1,1}^N K_{1,1}^{(2)} + C_{1,2}^N K_{1,2}^{(2)} + C_{2,2}^N K_{2,2}^{(2)}, \tag{B5b}$$

$$\frac{\langle \mathbb{K}^3 \rangle}{3!} = C_{1,1}^N K_{1,1}^{(3)} + C_{1,2}^N K_{1,2}^{(3)} + C_{1,3}^N K_{1,3}^{(3)} + C_{2,2}^N K_{2,2}^{(3)} + C_{2,3}^N K_{2,3}^{(3)} + C_{3,3}^N K_{3,3}^{(3)}, \tag{B5c}$$

$$\begin{aligned}\frac{\langle \mathbb{K}^4 \rangle}{4!} &= C_{1,1}^N K_{1,1}^{(4)} + C_{1,2}^N K_{1,2}^{(4)} + C_{1,3}^N K_{1,3}^{(4)} + C_{1,4}^N K_{1,4}^{(4)} + C_{2,2}^N K_{2,2}^{(4)} + C_{2,3}^N K_{2,3}^{(4)} \\ &\quad + C_{2,4}^N K_{2,4}^{(4)} + C_{3,3}^N K_{3,3}^{(4)} + C_{3,4}^N K_{3,4}^{(4)} + C_{4,4}^N K_{4,4}^{(4)}.\end{aligned} \tag{B5d}$$

From Eqs. (B4) we see that the coefficient that multiplies $K_{r,m}^{(n)}$ is independent of n and it is equal to

$$C_{1,m}^N = N, \quad 1 \leqslant m, \tag{B6a}$$

$$C_{2,m}^N = \frac{N(N-m-1)}{2!}, \quad 2 \leqslant m, \tag{B6b}$$

$$C_{3,m}^N = \frac{N(N-m-1)(N-m-2)}{3!}, \quad 3 \leqslant m, \tag{B6c}$$

$$C_{4,m}^N = \frac{N(N-m-1)(N-m-2)(N-m-3)}{4!}, \quad 4 \leqslant m. \tag{B6d}$$

Afterwards, for any $r \leqslant m \leqslant \min(n,N)$, we obtain a general relation from Eqs. (B6) given by

$$C_{r,m}^N = \frac{N}{r}\binom{N-m-1}{r-1} = \frac{1}{r}\sum_{k=1}^{r} (-1)^{r+k} k \binom{m+r-k-1}{r-k}\binom{N}{k}, \tag{B7}$$

such that

$$\frac{\langle \mathbb{K}^n \rangle}{n!} = \sum_{r=1}^{[n,N]} \sum_{m=r}^{[n,N]} \frac{N}{r}\binom{N-m-1}{r-1} K_{r,m}^{(n)}. \tag{B8}$$

We are using the notation $[n,N] = \min(n,N)$.

APPENDIX C: RELATION BETWEEN THE AUXILIARY FUNCTION $\varphi(\lambda)$ AND ξ

In Eq. (34) we define the function Γ_m,

$$\Gamma_m \equiv \sum_{n=m}^{\infty} (-\beta)^n \mathrm{K}_{1,m}^{(n)}, \tag{C1}$$

and the auxiliary function $\varphi(\lambda)$,

$$\varphi(\lambda) \equiv \sum_{m=1}^{\infty} \frac{\Gamma_m}{\lambda^m}. \tag{C2}$$

In this appendix we show that the grand potential per site, in the thermodynamic limit, can be obtained from derivatives of powers of the function $\varphi(\lambda)$.

To calculate the grand potential per site [see Eq. (32)] we need to perform the sum

$$\sum_{n=0}^{\infty} (-\beta)^n \mathfrak{K}_{1,n} \equiv \xi. \tag{C3}$$

Substituting the expression of $\mathfrak{K}_{1,n}$ [Eq. (27) with $k=1$] in ξ and taking into account that in $\mathrm{K}_{1,m}^{(n)}$ we have to have $n>m$, Eq. (C3) becomes

$$\xi = \sum_{n=1}^{\infty} \sum_{m=1}^{n} (-\beta)^n \mathrm{K}_{1,m}^{(n)} - \frac{1}{2} \sum_{n=2}^{\infty} \sum_{m=2}^{n} (-\beta)^n \binom{m}{1} \mathrm{K}_{2,m}^{(n)} + \frac{1}{3} \sum_{n=3}^{\infty} \sum_{m=3}^{n} (-\beta)^n \binom{m+1}{2} \mathrm{K}_{3,m}^{(n)} + \ldots \tag{C4}$$

$$\equiv \sum_{r=1}^{\infty} \varphi_r, \tag{C5}$$

where φ_r is such that

$$\varphi_r \equiv \frac{(-1)^{r+1}}{r} \sum_{n=r}^{\infty} \sum_{m=r}^{n} (-\beta)^n \binom{m+r-2}{r-1} \mathrm{K}_{r,m}^{(n)}. \tag{C6}$$

We drop the upper limit $[n,N]$ condition in the sum over m [see Eq. (27)] because now we are taking first the thermodynamic limit ($N \to \infty$), which means that we always have $n<N$.

Applying the equality

$$\sum_{n=r}^{\infty} \sum_{m=r}^{n} \cdots = \sum_{m=r}^{\infty} \sum_{n=r}^{\infty} \cdots \tag{C7}$$

on Eq. (C6), we obtain

$$\varphi_r = \frac{(-1)^{r+1}}{r} \sum_{m=r}^{\infty} \binom{m+r-2}{r-1} \sum_{n=r}^{\infty} (-\beta)^n \mathrm{K}_{r,m}^{(n)}. \tag{C8}$$

From Eqs. (C1) and (C2) we have

$$\varphi(\lambda) = \sum_{m=1}^{\infty} \frac{1}{\lambda^m} \sum_{n=1}^{\infty} (-\beta)^n \mathrm{K}_{1,m}^{(n)}. \tag{C9}$$

Our next step is to take powers of the function $\varphi(\lambda)$. We begin with $\varphi(\lambda)^2$:

$$\varphi(\lambda)^2=\sum_{m_1,m_2=1}^{\infty}\frac{1}{\lambda^{m_1+m_2}}\sum_{n_1,n_2=1}^{\infty}(-\beta)^{n_1+n_2}\mathrm{K}_{1,m_1}^{(n_1)}\mathrm{K}_{1,m_2}^{(n_2)}$$

$$=\sum_{m=2}^{\infty}\frac{1}{\lambda^m}\sum_{n=2}^{\infty}(-\beta)^n\sum_{\{n_i\}}^{n}{}''\sum_{\{m_i\}}^{m}{}''\mathrm{K}_{1,m_1}^{(n_1)}\mathrm{K}_{1,m_2}^{(n_2)}$$

$$=\sum_{m=2}^{\infty}\frac{1}{\lambda^m}\sum_{n=2}^{\infty}(-\beta)^n\mathrm{K}_{2,m}^{(n)}. \tag{C10}$$

For arbitrary r we obtain

$$\varphi(\lambda)^r=\sum_{m=r}^{\infty}\frac{1}{\lambda^m}\sum_{n=r}^{\infty}(-\beta)^n\mathrm{K}_{r,m}^{(n)} \tag{C11}$$

and we note that

$$\varphi(\lambda)\big|_{\lambda=1}=\varphi_1, \tag{C12a}$$

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}\left(\frac{\varphi(\lambda)^2}{2!}\right)\bigg|_{\lambda=1}=\varphi_2, \tag{C12b}$$

$$\vdots$$

$$\frac{\mathrm{d}^{r-1}}{\mathrm{d}\lambda^{r-1}}\left(\frac{\varphi(\lambda)^r}{r!}\right)\bigg|_{\lambda=1}=\varphi_r. \tag{C12c}$$

Finally we have

$$\xi=\sum_{r=1}^{\infty}\varphi_r=\sum_{r=1}^{\infty}\frac{\mathrm{d}^{r-1}}{\mathrm{d}\lambda^{r-1}}\left(\frac{\varphi(\lambda)^r}{r!}\right)\bigg|_{\lambda=1}, \tag{C13}$$

which shows that the sum (C3) can be obtained from a function that contains only open connected subchains.

APPENDIX D: USEFUL RELATIONS BETWEEN $\mathrm{K}_{1,m}^{(n)}$ AND THE NORMALIZED TRACES

In Sec. III we calculate the β-expansion of the Helmholtz free energy per site of the XXZ model up to order β^3. In order to do so, we need to write the functions $\mathrm{K}_{1,m}^{(n)}$ [see Eq. (16c)] in terms of the normalized traces instead of the g-traces.

For any quantum system driven by a Hamiltonian with interactions between first neighbors only, invariant under translations along the chain, and null chemical potential, we have the following.

(*i*) $m=1$:

$$\mathrm{K}_{1,1}^{(1)}=\langle\mathbf{H}_{1,2}\rangle, \tag{D1a}$$

$$\mathrm{K}_{1,1}^{(2)}=\frac{1}{2!}\langle\mathbf{H}_{1,2}^2\rangle, \tag{D1b}$$

$$\mathrm{K}_{1,1}^{(3)}=\frac{1}{3!}\langle\mathbf{H}_{1,2}^3\rangle, \tag{D1c}$$

$$K_{1,1}^{(4)}=\frac{1}{4!}\langle \mathbf{H}_{1,2}^4\rangle. \tag{D1d}$$

(*ii*) $m=2$:

$$K_{1,2}^{(2)}=\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}\rangle, \tag{D2a}$$

$$K_{1,2}^{(3)}=\frac{1}{2!}[\langle \mathbf{H}_{1,2}^2\mathbf{H}_{2,3}\rangle+\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}^2\rangle], \tag{D2b}$$

$$K_{1,2}^{(4)}=\frac{1}{3!}\left[\langle \mathbf{H}_{1,2}^3\mathbf{H}_{2,3}\rangle+\frac{1}{2!}(2\langle \mathbf{H}_{1,2}^2\mathbf{H}_{2,3}^2\rangle+\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}\mathbf{H}_{1,2}\mathbf{H}_{2,3}\rangle)+\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}^3\rangle\right]. \tag{D2c}$$

(*iii*) $m=3$:

$$K_{1,3}^{(3)}=\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}\mathbf{H}_{3,4}\rangle, \tag{D3a}$$

$$K_{1,2}^{(4)}=\frac{1}{2}\left[\langle \mathbf{H}_{1,2}^2\mathbf{H}_{2,3}\mathbf{H}_{3,4}\rangle+\frac{2}{3}\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}^2\mathbf{H}_{3,4}\rangle+\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}\mathbf{H}_{3,4}^2\rangle+\frac{1}{3}\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}\mathbf{H}_{3,4}\mathbf{H}_{2,3}\rangle\right]. \tag{D3b}$$

(*iv*) $m=4$:

$$K_{1,4}^{(4)}=\langle \mathbf{H}_{1,2}\mathbf{H}_{2,3}\mathbf{H}_{3,4}\mathbf{H}_{4,5}\rangle. \tag{D4}$$

A bi-Hamiltonian formulation for triangular systems by perturbations

Wen-Xiu Ma[a)]
Department of Mathematics, City University of Hong Kong, Kowloon, Hong Kong, China

(Received 15 January 2001; accepted for publication 15 November 2001)

A bi-Hamiltonian formulation is proposed for triangular systems resulting from perturbations around solutions, from which infinitely many symmetries and conserved functionals of triangular systems can be explicitly constructed, provided that one operator of the Hamiltonian pair is invertible. Through our formulation, four examples of triangular systems are exhibited, which also show that bi-Hamiltonian systems in both lower dimensions and higher dimensions are many and varied. Two of four examples give local $2+1$ dimensional bi-Hamiltonian systems and illustrate that multiscale perturbations can lead to higher-dimensional bi-Hamiltonian systems. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1432775]

I. INTRODUCTION

The bi-Hamiltonian formulation is a great success in the Hamiltonian theory of differential equations.[1] It has attracted the attention of a wide audience within both the mathematical community and the physical community due to its importance in producing symmetries and conserved functionals, and has already become one of active research directions in the field of soliton theory and integrable systems.

In this paper, we are concerned with the bi-Hamiltonian formulation of triangular systems resulting from various perturbations around solutions, specific systems of which were furnished in Refs. 2–4. Such triangular systems provide candidates of integrable couplings for given integrable systems.[5,6] A general triangular system reads as

$$\begin{cases} u_t = K(u) = K(u,\ldots,u^{(k)}), \\ v_t = S(u,v) = S(u,v,\ldots,u^{(l)},v^{(l)}), \end{cases} \tag{1.1}$$

where $u=u(t,x)$, $v=v(t,x)$, and $u^{(n)}$ and $v^{(n)}$ are derivatives with respect to the spatial variable x. Such a concrete example by a first-order perturbation is given by

$$\begin{cases} u_t = K(u), \\ v_t = K'(u)[v], \end{cases} \tag{1.2}$$

where $K'(u)[v]$ denotes the Gateaux derivative of $K(u)$ at a direction v, i.e.,

$$K'(u)[v] = \frac{\partial}{\partial \varepsilon}\bigg|_{\varepsilon=0} K(u+\varepsilon v).$$

A mathematical structure called the perturbation bundle has been established in Ref. 5 to study its integrable properties. Note that the second component of the above-mentioned system is just the linearized system of the original system $u_t=K(u)$, and thus the symmetry problem leads to a triangular system together with the original system, which also shows the importance of studying triangular systems (see Ref. 6 for more discussion). Other similar examples of specific triangular

[a)]Also at Department of Mathematics, University of South Florida, Tampa, Florida 33620-5700. Electronic mail: mawx@cityu.edu.hk

systems were presented by means of perturbations in Refs. 2–4. However, there is no discussion on the bi-Hamiltonian formulation of general triangular systems by perturbations, even the specific systems mentioned previously.

With a view to exposing integrability, we would like to answer whether there exists any bi-Hamiltonian formulation for triangular systems resulting from various perturbations around solutions. It will be shown that a bi-Hamiltonian formulation of the resulting triangular systems can be inherited from an original bi-Hamiltonian system. The general formulation allows us to present various examples of bi-Hamiltonian systems, in both $1+1$ and $2+1$ dimensions.

The paper is organized as follows. In Sec. II, we shall choose perturbed systems of given bi-Hamiltonian systems as starting systems and introduce our triangular systems by using perturbations around solutions of starting systems, which contain many special triangular systems in Refs. 2–4. Then in Sec. III, a bi-Hamiltonian formulation for the resulting triangular systems will be proposed, based on the bi-Hamiltonian formulation of starting systems. In Sec. IV, we will go on to exhibit four examples of triangular systems through the general bi-Hamiltonian formulation, which also show that bi-Hamiltonian systems in both $1+1$ and $2+1$ dimensions are many and varied. Two of four examples give local $2+1$ dimensional bi-Hamiltonian systems and illustrate that multiscale perturbations can lead to higher-dimensional bi-Hamiltonian systems. Finally in Sec. V, some concluding remarks will be given.

II. TRIANGULAR SYSTEMS BY PERTURBATIONS

A. Bi-Hamiltonian systems

Assume that we have a bi-Hamiltonian system

$$u_t = K(u) = J\frac{\delta \tilde{H}_1}{\delta u} = M\frac{\delta \tilde{H}_0}{\delta u}, \quad \tilde{H}_0 = \int H_0\,\mathrm{d}x, \quad \tilde{H}_1 = \int H_1\,\mathrm{d}x, \tag{2.1}$$

where J and M constitute a Hamiltonian pair (see Refs. 7–9 for more information), t is a single variable but x can be a single or vector variable. If one operator of the Hamiltonian pair is invertible, we can have infinitely many symmetries $\{K_n\}_{n=0}^{\infty}$ and conserved functionals $\{\tilde{H}_n\}_{n=0}^{\infty}$, which can be explicitly computed through

$$\begin{cases} K_n = \Phi^{n-1}K(u) = (MJ^{-1})^{n-1}K(u), \quad n \geqslant 1, \\ \tilde{H} = \int H_n\,\mathrm{d}x, \quad H_n = \int_0^1 \langle u, (J^{-1}\Phi^{n-1}K)(\lambda u)\rangle \mathrm{d}\lambda, \quad n \geqslant 0, \end{cases} \tag{2.2}$$

where $\langle \cdot, \cdot \rangle$ denotes the standard inner product of the corresponding Euclidean space. Moreover, they are related through the bi-Hamiltonian formulation[10]

$$K_n = J\frac{\delta \tilde{H}_n}{\delta u} = M\frac{\delta \tilde{H}_{n-1}}{\delta u}, \quad n \geqslant 1. \tag{2.3}$$

Fuchssteiner and Fokas[11] discovered an important fact that when J and M constitute a Hamiltonian pair and J is invertible, the operator $\Phi = MJ^{-1}$ is hereditary,[12] i.e.,

$$\Phi'[\Phi X]Y - \Phi\Phi'[X]Y = \Phi'[\Phi Y]X - \Phi\Phi'[Y]X$$

holds for any vector fields X and Y, where $\Phi'[X]$ denotes the Gateaux derivative

$$\Phi'[X] = \frac{\partial}{\partial \epsilon}\bigg|_{\varepsilon=0} \Phi(u + \varepsilon X).$$

This condition is actually equivalent to an invariance of Lie derivative of Φ (see, e.g., Refs. 13 and 14). It is the hereditariness of Φ that gives rise to an explanation why soliton systems come in hierarchies.

B. Perturbed systems

Let us now choose a perturbed system with a perturbation parameter ε:

$$u_t = K^{\mathrm{per}}(u) := \sum_{j=0}^{m} \alpha_j \varepsilon^j K_{i_j}(u) = J\frac{\delta \tilde{H}_1^{\mathrm{per}}}{\delta u} = M\frac{\delta \tilde{H}_0^{\mathrm{per}}}{\delta u}, \tag{2.4}$$

where $m \geqslant 0$, the α_j are arbitrary constants, the i_j are arbitrary natural numbers [which means to take arbitrary vector fields $K_{i_j}(u)$ from $\{K_n\}_{n=1}^{\infty}$], and two Hamiltonian functionals read

$$\tilde{H}_0^{\mathrm{per}} = \int H_0^{\mathrm{per}}\,\mathrm{d}x, \quad H_0^{\mathrm{per}} = \sum_{j=0}^{m} \alpha_j \varepsilon^j H_{i_j}, \quad \tilde{H}_1^{\mathrm{per}} = \int H_1^{\mathrm{per}}\,\mathrm{d}x, \quad H_1^{\mathrm{per}} = \sum_{j=0}^{m} \alpha_j \varepsilon^j H_{i_j+1}. \tag{2.5}$$

This system (2.4) is called a starting system, which is nothing but a generalized system of the original bi-Hamiltonian system (2.1). Following the general scheme shown in (2.2), we have infinitely many symmetries and conserved functionals

$$\begin{cases} K_n^{\mathrm{per}} := \Phi^{n-1} K^{\mathrm{per}} = \sum_{j=0}^{m} \alpha_j \varepsilon^j K_{i_j+n-1}(u), \quad n \geqslant 1, \\ \tilde{H}_n^{\mathrm{per}} := \int H_n^{\mathrm{per}}\,\mathrm{d}x, \quad H_n^{\mathrm{per}} = \sum_{j=0}^{m} \alpha_j \varepsilon^j H_{i_j+n}(u), \quad n \geqslant 0, \end{cases} \tag{2.6}$$

for the starting system (2.4), since we can directly check that

$$K_n^{\mathrm{per}} = J\frac{\delta \tilde{H}_n^{\mathrm{per}}}{\delta u} = M\frac{\delta \tilde{H}_{n-1}^{\mathrm{per}}}{\delta u}, \quad n \geqslant 1.$$

C. Triangular systems

For any integers $N \geqslant 0$ and $r \geqslant 0$, take a perturbation series:

$$\hat{u}_N = \sum_{i=0}^{N} \varepsilon^i \eta_i, \quad \eta_i = \eta_i(y_0, y_1, y_2, \ldots, y_r, t), \tag{2.7}$$

where $y_i = \varepsilon^i x$, $0 \leqslant i \leqslant N$, are all slow variables. Now we make a perturbation around solutions of the starting system (2.4) and observe the Nth order perturbation system

$$\hat{u}_{Nt} = K^{\mathrm{per}}(\hat{u}_N) + \mathrm{o}(\varepsilon^N),$$

where u, η_i, $0 \leqslant i \leqslant N$ are supposed to be column vectors of the same dimension. By the Taylor expansion, this leads to an equivalent and bigger system

$$\eta_{it} = \frac{1}{i!}\frac{\partial^i}{\partial \varepsilon^i} K^{\mathrm{per}}(\hat{u}_N)\bigg|_{\varepsilon=0} = \sum_{j=0}^{\min(m,i)} \frac{\alpha_j}{(i-j)!}\frac{\partial^{i-j}}{\partial \varepsilon^{i-j}} K_{i_j}(\hat{u}_N)\bigg|_{\varepsilon=0}, \quad 0 \leqslant i \leqslant N. \tag{2.8}$$

For brevity, we rewrite it as a concise form

$$\hat{\eta}_{Nt} = (\mathrm{per}_N K^{\mathrm{per}})(\hat{\eta}_N) = ((\mathrm{per}_N K^{\mathrm{per}})_0^T, \ldots, (\mathrm{per}_N K^{\mathrm{per}})_N^T)^T, \quad \hat{\eta}_N = (\eta_0^T, \ldots, \eta_N^T)^T, \tag{2.9}$$

where T denotes the matrix transpose. Noting that

$$\hat{u}_N=\hat{u}_i+\varepsilon^{i+1}\sum_{j=0}^{N-i-1}\varepsilon^j\eta_{j+i+1},\quad \hat{u}_i=\sum_{j=0}^{i}\varepsilon^j\eta_j,\quad 0\leqslant i\leqslant N-1,$$

an application of the Taylor expansion tells us that

$$(\mathrm{per}_N K^{\mathrm{per}})_i=\frac{1}{i!}\frac{\partial^i}{\partial\varepsilon^i}K^{\mathrm{per}}(\hat{u}_N)\bigg|_{\varepsilon=0}=\frac{1}{i!}\frac{\partial^i}{\partial\varepsilon^i}K^{\mathrm{per}}(\hat{u}_i)\bigg|_{\varepsilon=0},\quad 0\leqslant i\leqslant N-1,$$

and thus the perturbation system (2.8) is triangular, i.e., the $(i+1)$th component $\eta_{it}=(\mathrm{per}_N K^{\mathrm{per}})_i$ just involves the first $i+1$ dependent variables $\eta_0,\ldots,\eta_i$ but no the other dependent variables $\eta_{i+1},\ldots,\eta_N$.

In our formulation, the superscript ''per'' denotes the perturbed objects such as the perturbed tensor fields and the perturbed functionals as in (2.4) and (2.5), but the prefix ''per_N'' means the perturbation resulting from the Nth order perturbation (2.7) of the dependent variable u. The small parameter ε is involved in both the starting system (2.4) and the perturbation series (2.7), but there is no relation among three integers m, N, and r that we need to take in the starting system (2.4) and the perturbation series (2.7). This demonstrates diversity to formulate our triangular systems. If we take a special choice of $\alpha_0=1$ and $K_{i_0}=K$ in our construction, the triangular system (2.8) becomes a coupling system of $u_t=K(u)$, because its first component is $\eta_{0t}=K(\eta_0)$. This paves a way for constructing integrable couplings of given integrable systems.[4,6] If a starting system is particularly chosen as

$$u_t=K^{\mathrm{per}}(u)=K(u)+\alpha\varepsilon K(u),\quad \alpha=\mathrm{const},\tag{2.10}$$

the following specific triangular system

$$\begin{cases}\eta_{0t}=K(\eta_0),\\ \eta_{1t}=K'(\eta_0)[\eta_1]+\alpha K(\eta_0),\end{cases}\tag{2.11}$$

will be engendered upon making a first-order perturbation. This system looks simple, but it generalizes the triangular system (1.2) resulting from the symmetry problem. The main objective of this paper is to propose a bi-Hamiltonian formulation for the triangular systems determined by (2.8), which contain two specific interesting triangular systems (1.2) and (2.11).

III. BI-HAMILTONIAN FORMULATION

For now on, we focus on the establishment of a bi-Hamiltonian formulation for the triangular systems determined by (2.8). We would actually like to show that a bi-Hamiltonian formulation of the resulting triangular systems can be inherited from an original bi-Hamiltonian system (2.1).

To the end, let us first introduce a new Hamiltonian pair:

$$(\mathrm{per}_N J)(\hat{\eta}_N)\equiv\hat{J}_N(\hat{\eta}_N),\quad (\mathrm{per}_N M)(\hat{\eta}_N)\equiv\hat{M}_N(\hat{\eta}_N),\tag{3.1}$$

which are defined as follows:

$$
\begin{aligned}
(\mathrm{per}_N P)(\hat{\eta}_N) \equiv \hat{P}_N(\hat{\eta}_N) &= [(\hat{P}_N(\hat{\eta}_N))_{ij}]_{(N+1)\times(N+1)} \\
&= \left[\frac{1}{(i+j-N)!} \quad \frac{\partial^{i+j-N} P(\hat{u}_N)}{\partial \varepsilon^{i+j-N}}\bigg|_{\varepsilon=0} \right]_{(N+1)\times(N+1)} \\
&= \begin{bmatrix} 0 & \cdots & 0 & P(\eta_0) \\ \vdots & \iddots & \vdots & \frac{1}{1!}\frac{\partial P(\hat{u}_N)}{\partial \varepsilon}\big|_{\varepsilon=0} \\ 0 & \vdots & \vdots & \vdots \\ P(\eta_0) & \frac{1}{1!}\frac{\partial P(\hat{u}_N)}{\partial \varepsilon}\big|_{\varepsilon=0} & \cdots & \frac{1}{N!}\frac{\partial^N P(\hat{u}_N)}{\partial \varepsilon^N}\big|_{\varepsilon=0} \end{bmatrix}, \quad P = J, M;
\end{aligned} \tag{3.2}
$$

and a new hereditary recursion operator defined by

$$
\begin{aligned}
(\mathrm{per}_N \Phi)(\hat{\eta}_N) \equiv \hat{\Phi}_N(\hat{\eta}_N) &= [(\hat{\Phi}_N(\hat{\eta}_N))_{ij}]_{(N+1)\times(N+1)} \\
&= \left[\frac{1}{(i-j)!} \frac{\partial^{i-j} \Phi(\hat{u}_N)}{\partial \varepsilon^{i-j}}\bigg|_{\varepsilon=0} \right]_{(N+1)\times(N+1)} \\
&= \begin{bmatrix} \Phi(\eta_0) & 0 & \cdots & 0 \\ \frac{1}{1!}\frac{\partial \Phi(\hat{u}_N)}{\partial \varepsilon}\big|_{\varepsilon=0} & \Phi(\eta_0) & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ \frac{1}{N!}\frac{\partial \Phi(\hat{u}_N)}{\partial \varepsilon}\big|_{\varepsilon=0} & \cdots & \frac{1}{1!}\frac{\partial \Phi(\hat{u}_N)}{\partial \varepsilon}\big|_{\varepsilon=0} & \Phi(\eta_0) \end{bmatrix},
\end{aligned} \tag{3.3}
$$

where $i,j=0,1,\ldots,N$, and $\hat{u}_N$ is defined by (2.7). These operators will be used to establish our new bi-Hamiltonian formulation for the triangular systems by (2.8). The structures of these operators originate from those proposed for single Hamiltonian formulations in Ref. 4. The only difference is the scale of perturbations. In our previous work,[4] single-scale perturbations were considered, but in this paper, multiscale perturbations will need to be considered. Like single-scale perturbations, multiscale perturbations also guarantee that two operators defined by (3.2) constitute a Hamiltonian pair and the operator defined by (3.3) is hereditary. The proofs are direct and very similar to those in the case of single-scale perturbations,[4] although they are rather laborious and much harder (see Ref. 6 for a detailed proof). Obviously, however, new operators still satisfy the following coupled condition:

$$
\hat{\Phi}_N = \hat{M}_N (\hat{J}_N)^{-1}, \quad \hat{J}_N \hat{\Psi}_N = \hat{\Phi}_N \hat{J}_N, \quad \hat{\Psi}_N = (\hat{\Phi}_N)^{\dagger}, \tag{3.4}
$$

where the superscript † means to take the adjoint operation. The existence of the inverse operator $(\hat{J}_N)^{-1}$ is guaranteed by the existence of J^{-1}, following the definition of $\hat{J}_N^{-1}$ as in (3.1) and (3.2). The coupled condition (3.4) ensures[1] that conserved functionals recursively determined by $\hat{\Phi}_N$ commute with each other under two Poisson brackets generated by $\hat{J}_N$ and $\hat{M}_N$.

For the triangular system defined by (2.8), new Hamiltonian functionals can be chosen as

$$
(\mathrm{per}_N \tilde{H}_0^{\mathrm{per}})(\hat{\eta}_N) := \frac{1}{N!} \frac{\partial^N}{\partial \varepsilon^N} \tilde{H}_0^{\mathrm{per}}(\hat{u}_N)\bigg|_{\varepsilon=0} = \sum_{j=0}^{\min(m,N)} \frac{\alpha_j}{(N-j)!} \frac{\partial^{N-j}}{\partial \varepsilon^{N-j}} \tilde{H}_{i_j}(\hat{u}_N)\bigg|_{\varepsilon=0}, \tag{3.5}
$$

$$(\mathrm{per}_N\tilde{H}_1^{\mathrm{per}})(\hat{\eta}_N) := \frac{1}{N!}\frac{\partial^N}{\partial\varepsilon^N}\tilde{H}_1^{\mathrm{per}}(\hat{u}_N)\Big|_{\varepsilon=0} = \sum_{j=0}^{\min(m,N)} \frac{\alpha_j}{(N-j)!}\frac{\partial^{N-j}}{\partial\varepsilon^{N-j}}\tilde{H}_{i_j+1}(\hat{u}_N)\Big|_{\varepsilon=0}, \quad (3.6)$$

where $\tilde{H}_0^{\mathrm{per}}$ and $\tilde{H}_1^{\mathrm{per}}$ are defined by (2.5), and $\hat{u}_N$ is defined by (2.7). They will offer the required Hamiltonian functionals in our bi-Hamiltonian formulation of the triangular system (2.8). The above-mentioned crucial form of the Hamiltonian functionals are motivated by a study of the perturbation system of the KdV equation.[16]

Now a direct computation can show that the triangular system (2.8) has the following bi-Hamiltonian formulation:

$$\hat{\eta}_{Nt} = \hat{J}_N\frac{\delta(\mathrm{per}_N\tilde{H}_1^{\mathrm{per}})}{\delta\hat{\eta}_N} = \hat{M}_N\frac{\delta(\mathrm{per}_N\tilde{H}_0^{\mathrm{per}})}{\delta\hat{\eta}_N}, \quad \hat{\eta}_N = (\eta_0^T, \eta_1^T, \ldots, \eta_N^T)^T. \quad (3.7)$$

Here a Hamiltonian pair of $\hat{J}_N$ and $\hat{M}_N$ is defined by (3.1) and (3.2), and two Hamiltonian functionals $\mathrm{per}_N\tilde{H}_0^{\mathrm{per}}$ and $\mathrm{per}_N\tilde{H}_1^{\mathrm{per}}$ are defined by (3.5) and (3.6). The bi-Hamiltonian formulation (3.7) is what we intend to establish for the triangular system (2.8). It follows that the triangular system (2.8) is a good example of integrable systems.

In fact, let us first introduce

$$\begin{cases} \mathrm{per}_N K_n^{\mathrm{per}} := \left((K_n^{\mathrm{per}}(\hat{u}_N))^T\Big|_{\varepsilon=0}, \frac{1}{1!}\frac{\partial}{\partial\varepsilon}(K_n^{\mathrm{per}}(\hat{u}_N))^T\Big|_{\varepsilon=0}, \ldots, \frac{1}{N!}\frac{\partial^N}{\partial\varepsilon^N}(K_n^{\mathrm{per}}(\hat{u}_N))^T\Big|_{\varepsilon=0}\right)^T, \quad n\geqslant 1, \\ \mathrm{per}_N\tilde{H}_n^{\mathrm{per}} := \frac{1}{N!}\frac{\partial^N}{\partial\varepsilon^N}\tilde{H}_n^{\mathrm{per}}(\hat{u}_N)\Big|_{\varepsilon=0}, \quad n\geqslant 0, \end{cases} \quad (3.8)$$

where K_n^{per} and $\tilde{H}_n^{\mathrm{per}}$ are defined by (2.6), and $\hat{u}_N$ is defined by (2.7). Then it can directly be verified that

$$\begin{cases} \mathrm{per}_N K_n^{\mathrm{per}} = (\hat{\Phi}_N)^{n-1}(\mathrm{per}_N K^{\mathrm{per}}), \quad n\geqslant 1, \\ \mathrm{per}_N\tilde{H}_n^{\mathrm{per}} = \sum_{j=0}^{\min(m,N)} \frac{\alpha_j}{(N-j)!}\frac{\partial^{N-j}}{\partial\varepsilon^{N-j}}\tilde{H}_{i_j+n}(\hat{u}_N)\Big|_{\varepsilon=0}, \quad n\geqslant 0, \end{cases}$$

and further

$$\mathrm{per}_N K_n^{\mathrm{per}} = \hat{J}_N\frac{\delta(\mathrm{per}_N\tilde{H}_n^{\mathrm{per}})}{\delta\hat{\eta}_N} = \hat{M}_N\frac{\delta(\mathrm{per}_N\tilde{H}_{n-1}^{\mathrm{per}})}{\delta\hat{\eta}_N}, \quad n\geqslant 1.$$

Therefore, it follows from the bi-Hamiltonian formulation (3.7) that $\mathrm{per}_N K_n^{\mathrm{per}}$, $n\geqslant 1$, and $\mathrm{per}_N(\tilde{H}_n^{\mathrm{per}}), n\geqslant 0$, defined by (3.8), are symmetries and conserved functionals of the triangular system (2.8), respectively. This implies that the triangular system (2.8) is integrable if we start from a bi-Hamiltonian system (2.1).

Summing up, the above-given manipulation shows how to inherit the bi-Hamiltonian formulation and to compute symmetries and conserved functionals for the triangular system (2.8) while taking perturbations for the starting system (2.4). In Sec. IV, we perform applications of the above-given formulation to four concrete examples, in which new bi-Hamiltonian systems in both $1+1$ dimensions and $2+1$ dimensions will be formulated.

IV. ILLUSTRATIVE EXAMPLES

Let us consider the KdV equation

$$u_t = K(u) = u_{xxx} + 6uu_x. \tag{4.1}$$

It is well known that it has a local bi-Hamiltonian formulation[1,10]

$$u_t = K(u) = J\frac{\delta \tilde{H}_1}{\delta u} = M\frac{\delta \tilde{H}_0}{\delta u}, \tag{4.2}$$

where the Hamiltonian pair and the Hamiltonian functionals are given by

$$J = \partial_x, \quad M = \partial_x^3 + 4u\partial_x + 2u_x, \quad \tilde{H}_0 = \int \frac{1}{2}u^2\,dx, \quad \tilde{H}_1 = \int \left(\frac{1}{2}uu_{xx} + u^3\right) dx. \tag{4.3}$$

Therefore, it has infinitely many symmetries and conserved functionals

$$K_n = \Phi^n u_x, \quad \tilde{H}_n = \int H_n\,dx, \quad H_n = \int_0^1 u(\Psi^n u)(\lambda u)\,d\lambda, \quad n \geqslant 0, \tag{4.4}$$

where the hereditary recursion operator Φ and its adjoint operator Ψ read as

$$\Phi(u) = MJ^{-1} = \partial_x^2 + 4u + 2u_x\partial_x^{-1}, \quad \Psi = \Phi^\dagger = \partial_x^2 + 4u - 2\partial_x^{-1}u_x, \tag{4.5}$$

where $\partial^{-1}\partial = \partial\partial^{-1} = 1$. For example, we can obtain

$$\begin{cases} K_2(u) = u_{5x} + 10uu_{xxx} + 20u_xu_{xx} + 30u^2u_x, \\ H_2(u) = \dfrac{1}{2}uu_{4x} + \dfrac{10}{3}u^2u_{xx} + \dfrac{5}{3}uu_x^2 + \dfrac{5}{2}u^4. \end{cases} \tag{4.6}$$

Note that in (4.4) we added $K_0 = u_x$ to the Abelian symmetry algebra $\{K_n\}_{n=1}^{\infty}$ as defined in (2.2).

If we choose the original KdV equation as a starting equation, taking single-scale perturbations leads to the standard perturbation KdV systems,[15] which were proved to be bi-Hamiltonian.[16] In what follows, we will formulate other examples of integrable couplings for the KdV equation, by choosing proper perturbed equations as starting equations and taking biscale perturbations in Sec. IV B. All examples also show that bi-Hamiltonian systems in both $1+1$ and $2+1$ dimensions are many and varied.

A. The case of single-scale perturbations

We take a special perturbed equation

$$u_t = K^{\mathrm{per}}(u) = K_1(u) + \varepsilon K_1(u) = J\frac{\delta \tilde{H}_1^{\mathrm{per}}}{\delta u} = M\frac{\delta \tilde{H}_0^{\mathrm{per}}}{\delta u} \tag{4.7}$$

with two Hamiltonian functionals

$$\tilde{H}_0^{\mathrm{per}} = \tilde{H}_0 + \varepsilon\tilde{H}_0, \quad \tilde{H}_1^{\mathrm{per}} = \tilde{H}_1 + \varepsilon\tilde{H}_1 \tag{4.8}$$

as a starting equation. Here $K_1 = K, J, M, \tilde{H}_0, \tilde{H}_1$ are given by (4.3), (4.4), and (4.5). The first-order perturbation

$$\hat{u}_1 = \eta_0 + \varepsilon\,\eta_1$$

yields the following triangular system:

$$\begin{cases} \eta_{0t}=K_1(\eta_0)=\eta_{0xxx}+6\,\eta_0\eta_{0x}, \\ \eta_{1t}=K_1'(\eta_0)[\eta_1]+K_1(\eta_1)=\eta_{1xxx}+6(\eta_0\eta_1)_x+\eta_{0xxx}+6\,\eta_0\eta_{0x}. \end{cases} \tag{4.9}$$

According to our scheme of construction in Sec. III, its Hamiltonian pair and corresponding hereditary recursion operator are

$$\hat{J}_1=\begin{bmatrix} 0 & \partial_x \\ \partial_x & 0 \end{bmatrix}, \quad \hat{M}_1=\begin{bmatrix} 0 & M_0 \\ M_0 & M_1 \end{bmatrix}, \quad \hat{\Phi}_1=\begin{bmatrix} \Phi_0 & 0 \\ \Phi_1 & \Phi_0 \end{bmatrix}, \tag{4.10}$$

with the entries of $\hat{M}_1$ and $\hat{\Phi}_1$ being defined by

$$M_i=\delta_{i0}\partial_x^3+4\,\eta_0\partial_x+2\,\eta_{0x}, \quad \Phi_i=\delta_{i0}\partial_x^2+4\,\eta_i+2\,\eta_{ix}\partial_x^{-1}, \quad i=0,1, \tag{4.11}$$

where δ_{0i} is the Kronecker symbol. The triangular system (4.9) has a local bi-Hamiltonian formulation:

$$\hat{\eta}_{1t}=\hat{J}_1\frac{\delta(\mathrm{per}_1\tilde{H}_1^{\mathrm{per}})}{\delta\hat{\eta}_1}=\hat{M}_1\frac{\delta(\mathrm{per}_1\tilde{H}_0^{\mathrm{per}})}{\delta\hat{\eta}_1}, \quad \hat{\eta}_1=(\eta_0,\eta_1)^T, \tag{4.12}$$

with two Hamiltonian functionals

$$\begin{cases} \mathrm{per}_1\tilde{H}_0^{\mathrm{per}}=(\mathrm{per}_1\tilde{H}_0^{\mathrm{per}})(\hat{\eta}_1)=\dfrac{\partial\tilde{H}_0(\hat{u}_1)}{\partial\varepsilon}\Big|_{\varepsilon=0}+\tilde{H}_0(\eta_0) \\ \qquad\qquad =\displaystyle\int\left(\eta_0\eta_1+\frac{1}{2}\eta_0^2\right)\mathrm{d}x, \\ \mathrm{per}_1\tilde{H}_1^{\mathrm{per}}=(\mathrm{per}_1\tilde{H}_1^{\mathrm{per}})(\hat{\eta}_1)=\dfrac{\partial\tilde{H}_1(\hat{u}_1)}{\partial\varepsilon}\Big|_{\varepsilon=0}+\tilde{H}_1(\eta_0) \\ \qquad\qquad =\displaystyle\int\left(\frac{1}{2}\eta_{0xx}\eta_1+\frac{1}{2}\eta_0\eta_{1xx}+3\,\eta_0^2\eta_1+\frac{1}{2}\eta_0\eta_{0xx}+\eta_0^3\right)\mathrm{d}x. \end{cases} \tag{4.13}$$

Noting that in this example, we have

$$K_n^{\mathrm{per}}=K_n+\varepsilon K_n, \quad \tilde{H}_n^{\mathrm{per}}=\tilde{H}_n+\varepsilon\tilde{H}_n, \quad n\geqslant 0,$$

infinitely many symmetries and conserved functionals of the triangular system (4.9) are computed as follows:

$$\begin{cases} \mathrm{per}_1(K_n^{\mathrm{per}})=\begin{bmatrix} K_n(\eta_0) \\ \dfrac{\partial K_n(\hat{u}_1)}{\partial\varepsilon}\Big|_{\varepsilon=0}+K_n(\eta_0) \end{bmatrix}, \quad n\geqslant 0, \\ \mathrm{per}_1(\tilde{H}_n^{\mathrm{per}})=\dfrac{\partial\tilde{H}_n(\hat{u}_1)}{\partial\varepsilon}\Big|_{\varepsilon=0}+\tilde{H}_n(\eta_0), \quad n\geqslant 0. \end{cases} \tag{4.14}$$

Second, we take another special perturbed equation

$$u_t=K^{\mathrm{per}}(u)=K_1(u)+\varepsilon K_2(u), \tag{4.15}$$

as a starting equation, which can be written as a bi-Hamiltonian system

$$u_t = K^{\mathrm{per}}(u) = J\frac{\delta \tilde{H}_1^{\mathrm{per}}}{\delta u} = M\frac{\delta \tilde{H}_0^{\mathrm{per}}}{\delta u}, \quad \tilde{H}_0^{\mathrm{per}} = \tilde{H}_0 + \varepsilon \tilde{H}_1, \quad \tilde{H}_1^{\mathrm{per}} = \tilde{H}_1 + \varepsilon \tilde{H}_2. \tag{4.16}$$

Here $K_1 = K$, J, M, $\tilde{H}_0$, $\tilde{H}_1$, $\tilde{H}_2$, K_2, are determined by (4.1), (4.3), and (4.6). The second-order perturbation yields the following triangular system:

$$\begin{cases} \eta_{0t} = \eta_{0xxx} + 6\eta_0\eta_{0x}, \\ \eta_{1t} = \eta_{1xxx} + 6(\eta_0\eta_1)_x + K_2(\eta_0), \\ \eta_{2t} = \eta_{2xxx} + 6(\eta_0\eta_2)_x + 6\eta_1\eta_{1x} + \left.\dfrac{\partial K_2(\hat{u}_2)}{\partial \varepsilon}\right|_{\varepsilon=0}, \end{cases} \tag{4.17}$$

where

$$\begin{aligned} \left.\frac{\partial K_2(\hat{u}_2)}{\partial \varepsilon}\right|_{\varepsilon=0} &= \eta_{1,5x} + 10\eta_1\eta_{0xxx} + 10\eta_0\eta_{1xxx} + 20\eta_{1x}\eta_{0xx} \\ &\quad + 20\eta_{0x}\eta_{1xx} + 60\eta_0\eta_{0x}\eta_1 + 30\eta_0^2\eta_{1x}. \end{aligned} \tag{4.18}$$

The corresponding Hamiltonian pair and hereditary recursion operator are

$$\hat{J}_2 = \begin{bmatrix} 0 & 0 & \partial_x \\ 0 & \partial_x & 0 \\ \partial_x & 0 & 0 \end{bmatrix}, \quad \hat{M}_2 = \begin{bmatrix} 0 & 0 & M_0 \\ 0 & M_0 & M_1 \\ M_0 & M_1 & M_2 \end{bmatrix}, \quad \hat{\Phi}_2 = \begin{bmatrix} \Phi_0 & 0 & 0 \\ \Phi_1 & \Phi_0 & 0 \\ \Phi_2 & \Phi_1 & \Phi_0 \end{bmatrix}, \tag{4.19}$$

where the entries of $\hat{M}_2$ and $\hat{\Phi}_2$ are given by

$$M_i = \delta_{i0}\partial_x^3 + 4\eta_0\partial_x + 2\eta_{0x}, \quad \Phi_i = \delta_{i0}\partial_x^2 + 4\eta_i + 2\eta_{ix}\partial_x^{-1}, \quad 0 \leqslant i \leqslant 2. \tag{4.20}$$

Through our scheme of construction in Sec. III, the triangular system (4.17) has a local bi-Hamiltonian formulation

$$\hat{\eta}_{2t} = \hat{J}_2\frac{\delta(\mathrm{per}_2\tilde{H}_1^{\mathrm{per}})}{\delta\hat{\eta}_2} = \hat{M}_2\frac{\delta(\mathrm{per}_2\tilde{H}_0^{\mathrm{per}})}{\delta\hat{\eta}_2}, \quad \hat{\eta}_2 = (\eta_0, \eta_1, \eta_2)^T, \tag{4.21}$$

with two Hamiltonian functionals

$$\begin{cases} \mathrm{per}_2\tilde{H}_0^{\mathrm{per}} = (\mathrm{per}_2\tilde{H}_0^{\mathrm{per}})(\hat{\eta}_2) = \dfrac{1}{2}\left.\dfrac{\partial^2\tilde{H}_0(\hat{u}_2)}{\partial\varepsilon^2}\right|_{\varepsilon=0} + \left.\dfrac{\partial\tilde{H}_1(\hat{u}_2)}{\partial\varepsilon}\right|_{\varepsilon=0} \\ \qquad = \displaystyle\int\left(\frac{1}{2}\eta_1^2 + \eta_0\eta_2 + \frac{1}{2}\eta_{0xx}\eta_1 + \frac{1}{2}\eta_0\eta_{1xx} + 3\eta_0^2\eta_1\right)\mathrm{d}x, \\ \mathrm{per}_2\tilde{H}_1^{\mathrm{per}} = (\mathrm{per}_2\tilde{H}_1^{\mathrm{per}})(\hat{\eta}_2) = \dfrac{1}{2}\left.\dfrac{\partial^2\tilde{H}_1(\hat{u}_2)}{\partial\varepsilon^2}\right|_{\varepsilon=0} + \left.\dfrac{\partial\tilde{H}_2(\hat{u}_2)}{\partial\varepsilon}\right|_{\varepsilon=0} \\ \qquad = \displaystyle\int\left(\frac{1}{2}\eta_{0xx}\eta_2 + \frac{1}{2}\eta_1\eta_{1xx} + \frac{1}{2}\eta_0\eta_{2xx} + 3\eta_0\eta_1^2 + 3\eta_0^2\eta_2\right)\mathrm{d}x \\ \qquad\quad + \left.\dfrac{\partial\tilde{H}_2(\hat{u}_2)}{\partial\varepsilon}\right|_{\varepsilon=0}, \end{cases} \tag{4.22}$$

where

$$\left.\frac{\partial \tilde{H}_2(\hat{u}_2)}{\partial \varepsilon}\right|_{\varepsilon=0} = \int \left(\frac{1}{2}\eta_{0,4x}\eta_1 + \frac{1}{2}\eta_0\eta_{1,4x} + \frac{5}{3}\eta_{0x}^2\eta_1 + \frac{10}{3}\eta_0\eta_{0x}\eta_{1x} + \frac{20}{3}\eta_0\eta_{0xx}\eta_1 + \frac{10}{3}\eta_0^2\eta_{1x} + 10\eta_0^3\eta_1 \right) \mathrm{d}x. \tag{4.23}$$

Its infinitely many symmetries and conserved functionals read as

$$\begin{cases} \mathrm{per}_2(K_n^{\mathrm{per}}) = \begin{bmatrix} K_n(\eta_0) \\ \left.\dfrac{\partial K_n(\hat{u}_2)}{\partial \varepsilon}\right|_{\varepsilon=0} + K_{n+1}(\eta_0) \\ \left.\dfrac{1}{2}\dfrac{\partial^2 K_n(\hat{u}_2)}{\partial \varepsilon^2}\right|_{\varepsilon=0} + \left.\dfrac{\partial K_{n+1}(\hat{u}_2)}{\partial \varepsilon}\right|_{\varepsilon=0} \end{bmatrix}, \quad n \geqslant 0, \\ \mathrm{per}_2\tilde{H}_n^{\mathrm{per}} = \left.\dfrac{1}{2}\dfrac{\partial^2 \tilde{H}_n(\hat{u}_2)}{\partial \varepsilon^2}\right|_{\varepsilon=0} + \left.\dfrac{\partial \tilde{H}_{n+1}(\hat{u}_2)}{\partial \varepsilon}\right|_{\varepsilon=0}, \quad n \geqslant 0, \end{cases} \tag{4.24}$$

by using $K_n^{\mathrm{per}} = K_n + \varepsilon K_{n+1}$ and $\tilde{H}_n^{\mathrm{per}} = \tilde{H}_n + \varepsilon \tilde{H}_{n+1}$ in this example.

B. The case of biscale perturbations

We would like to exhibit two examples in the case of biscale perturbations and show that multiscale perturbations can lead to bi-Hamiltonian systems in higher spatial dimensions. A concrete example in $2+1$ dimensions for the KdV equation is the following triangular system:

$$\begin{cases} \eta_{0t_1} = \eta_{0xxx} + 6\eta_0\eta_{0x}, \\ \eta_{1t_1} = \eta_{1xxx} + 3\eta_{0xxy} + 6(\eta_0\eta_1)_x + 6\eta_0\eta_{0y}, \end{cases} \tag{4.25}$$

resulting from the KdV equation (4.1) by a first-order biscale perturbation

$$\hat{u}_1 = \eta_0(t,x,y) + \varepsilon\eta_1(t,x,y), \quad y = \varepsilon x. \tag{4.26}$$

This system was furnished in Ref. 16, and based on our scheme of construction in Sec. III, it has the following local bi-Hamiltonian formulation:

$$\hat{\eta}_{1t} = \hat{J}_1 \frac{\delta(\mathrm{per}_1\tilde{H}_1)}{\delta\hat{\eta}_1} = \hat{M}_1 \frac{\delta(\mathrm{per}_1\tilde{H}_0)}{\delta\hat{\eta}_1}, \quad \hat{\eta}_1 = (\eta_0, \eta_1)^T, \tag{4.27}$$

where the Hamiltonian pair reads as

$$\hat{J}_1 = \begin{bmatrix} 0 & \partial_x \\ \partial_x & \partial_y \end{bmatrix}, \quad \hat{M}_1 = \begin{bmatrix} 0 & \partial_x^3 + 2\eta_{0x} + 4\eta_0\partial_x \\ \partial_x^3 + 2\eta_{0x} + 4\eta_0\partial_x & Q \end{bmatrix}, \tag{4.28}$$

with Q being defined by

$$Q = \left.\frac{\partial}{\partial\varepsilon}M(\hat{u}_1)\right|_{\varepsilon=0} = 3\partial_x^2\partial_y + 2\eta_{1x} + 2\eta_{0y} + 4\eta_1\partial_x + 4\eta_0\partial_y, \tag{4.29}$$

and the Hamiltonian functionals are

$$\begin{cases} \mathrm{per}_1 \tilde{H}_0 = \dfrac{\partial}{\partial \varepsilon} \tilde{H}_0(\hat{u}_1)\Big|_{\varepsilon=0} = \int \int \eta_0 \eta_1 \, \mathrm{d}x \, \mathrm{d}y, \\ \mathrm{per}_1 \tilde{H}_1 = \dfrac{\partial}{\partial \varepsilon} \tilde{H}_1(\hat{u}_1)\Big|_{\varepsilon=0} = \int \int \left(\dfrac{1}{2} \eta_0 \eta_{1xx} + \eta_0 \eta_{0xy} + \dfrac{1}{2} \eta_1 \eta_{0xx} + 3 \eta_0^3 \eta_1 \right) \mathrm{d}x \, \mathrm{d}y. \end{cases} \tag{4.30}$$

Moreover, the above-given Hamiltonian pair yields a hereditary recursion operator in $2+1$ dimensions

$$\hat{\Phi}_1 = \begin{bmatrix} \partial_x^2 + 2\eta_{0x}\partial_x^{-1} + 4\eta_0 & 0 \\ 2\partial_x\partial_y - 2\eta_{0x}\partial_x^{-2}\partial_y + 2(\eta_{1x} + \eta_{0y})\partial_x^{-1} + 4\eta_1 & \partial_x^2 + 2\eta_{0x}\partial_x^{-1} + 4\eta_0 \end{bmatrix}, \tag{4.31}$$

for the triangular system (4.25).

The second example is the following:

$$\begin{cases} \eta_{0t_1} = K_1(\eta_0) = \eta_{0xxx} + 6\eta_0\eta_{0x}, \\ \eta_{1t_1} = \dfrac{\partial K_1(\hat{u}_2)}{\partial \varepsilon}\Big|_{\varepsilon=0} + K_1(\eta_0) \\ \quad = \eta_{1xxx} + 3\eta_{0xxy} + 6(\eta_0\eta_1)_x + 6\eta_0\eta_{0y} + \eta_{0xxx} + 6\eta_0\eta_{0x}, \\ \eta_{2t_1} = \dfrac{1}{2!}\dfrac{\partial^2 K_1(\hat{u}_2)}{\partial \varepsilon^2}\Big|_{\varepsilon=0} + \dfrac{\partial K_1(\hat{u}_2)}{\partial \varepsilon}\Big|_{\varepsilon=0} \\ \quad = \eta_{2xxx} + 3\eta_{1xxy} + 3\eta_{0xyy} + 6(\eta_0\eta_2)_x + 6\eta_1\eta_{1x} + 6(\eta_0\eta_1)_y \\ \qquad + \eta_{1xxx} + 3\eta_{0xxy} + 6(\eta_0\eta_1)_x + 6\eta_0\eta_{0y}, \end{cases} \tag{4.32}$$

which can be generated from a perturbed KdV equation (4.7) under the second-order biscale perturbation

$$\hat{u}_2 = \eta(t,x,y) + \varepsilon\eta_1(t,x,y) + \varepsilon\eta_2(t,x,y), \quad y = \varepsilon x. \tag{4.33}$$

According to our scheme of construction in Sec. III, the corresponding Hamiltonian pair and recursion operator read as

$$\hat{J}_2 = \begin{bmatrix} 0 & 0 & \partial_x \\ 0 & \partial_x & \partial_y \\ \partial_x & \partial_y & 0 \end{bmatrix}, \quad \hat{M}_2 = \begin{bmatrix} 0 & 0 & M_0 \\ 0 & M_0 & M_1 \\ M_0 & M_1 & M_2 \end{bmatrix}, \quad \hat{\Phi}_2 = \begin{bmatrix} \Phi_0 & 0 & 0 \\ \Phi_1 & \Phi_0 & 0 \\ \Phi_2 & \Phi_1 & \Phi_0 \end{bmatrix}, \tag{4.34}$$

where the entries of $\hat{M}_2$ are defined by

$$\begin{cases} M_0 = M(\hat{u}_2)|_{\varepsilon=0} = \partial_x^3 + 2\eta_{0x} + 4\eta_0\partial_x, \\ M_1 = \dfrac{1}{1!}\dfrac{\partial M(\hat{u}_2)}{\partial \varepsilon}\Big|_{\varepsilon=0} = 3\partial_x^2\partial_y + 2\eta_{1x} + 2\eta_{0y} + 4\eta_1\partial_x + 4\eta_0\partial_y, \\ M_2 = \dfrac{1}{2!}\dfrac{\partial^2 M(\hat{u}_2)}{\partial \varepsilon^2}\Big|_{\varepsilon=0} = 3\partial_x\partial_y^2 + 2\eta_{2x} + 2\eta_{1y} + 4\eta_2\partial_x + 4\eta_1\partial_y, \end{cases} \tag{4.35}$$

and the entries of $\hat{\Phi}_2$ by

$$\begin{cases} \Phi_0=\Phi(\hat{u}_2)|_{\varepsilon=0}=\partial_x^2+2\,\eta_{0x}\partial_x^{-1}+4\,\eta_0, \\ \Phi_1=\dfrac{1}{1!}\dfrac{\partial\Phi(\hat{u}_2)}{\partial\varepsilon}\bigg|_{\varepsilon=0}=2\,\partial_x\partial_y+2(\eta_{1x}+\eta_{0y})\partial_x^{-1}-2\,\eta_{0x}\partial_x^{-2}\partial_y+4\,\eta_1, \\ \Phi_2=\dfrac{1}{2!}\dfrac{\partial^2\Phi(\hat{u}_2)}{\partial\varepsilon^2}\bigg|_{\varepsilon=0}=\partial_y^2+2(\eta_{2x}+\eta_{1y})\partial_x^{-1}-2(\eta_{1x}+\eta_{0y})\partial_x^{-2}\partial_y+2\,\eta_{0x}\partial_x^{-3}\partial_y^2+4\,\eta_2. \end{cases} \tag{4.36}$$

The $2+1$ triangular system (4.32) has a local bi-Hamiltonian formulation

$$\hat{\eta}_{2t}=\hat{J}_2\frac{\delta(\mathrm{per}_2\widetilde{H}_1)}{\delta\hat{\eta}_2}=\hat{M}_2\frac{\delta(\mathrm{per}_2\widetilde{H}_0)}{\delta\hat{\eta}_2}, \quad \hat{\eta}_2=(\eta_0,\eta_1,\eta_2)^T, \tag{4.37}$$

with a Hamiltonian pair $\hat{J}_2$ and $\hat{M}_2$ being defined by (4.34), and two Hamiltonian functionals by

$$\begin{cases} \mathrm{per}_2\widetilde{H}_0^{\mathrm{per}}=\dfrac{1}{2!}\dfrac{\partial^2\widetilde{H}_0^{\mathrm{per}}}{\partial\varepsilon^2}\bigg|_{\varepsilon=0}=\dfrac{1}{2!}\dfrac{\partial^2\widetilde{H}_0}{\partial\varepsilon^2}\bigg|_{\varepsilon=0}+\dfrac{\partial\widetilde{H}_0}{\partial\varepsilon}\bigg|_{\varepsilon=0}=\int\int\left(\frac{1}{2}\eta_0\eta_2+\frac{1}{4}\eta_1^2+\eta_0\eta_1\right)\mathrm{d}x\,\mathrm{d}y, \\ \mathrm{per}_2\widetilde{H}_1^{\mathrm{per}}=\dfrac{1}{2!}\dfrac{\partial^2\widetilde{H}_1^{\mathrm{per}}}{\partial\varepsilon^2}\bigg|_{\varepsilon=0}=\dfrac{1}{2!}\dfrac{\partial^2\widetilde{H}_1}{\partial\varepsilon^2}\bigg|_{\varepsilon=0}+\dfrac{\partial\widetilde{H}_1}{\partial\varepsilon}\bigg|_{\varepsilon=0} \\ \qquad=\int\int\left[\frac{1}{4}(\eta_0\eta_{2xx}+\eta_1\eta_{1xx}+\eta_2\eta_{0xx}+2\,\eta_0\eta_{1xx}+2\,\eta_1\eta_{0xx})\right. \\ \qquad\left.+\frac{1}{2}(\eta_0\eta_{1xy}+\eta_1\eta_{0xy}+2\,\eta_0\eta_{0xy})+\frac{1}{4}\eta_0\eta_{0yy}+3(\eta_0\eta_1^2+\eta_0^2\eta_1+\eta_0^2\eta_2)\right]\mathrm{d}x\,\mathrm{d}y. \end{cases} \tag{4.38}$$

Both $2+1$ dimensional triangular systems above have infinitely many symmetries and conserved functionals due to the existence of hereditary recursion operators, and thus they are also integrable in the sense of the existence of the Abelian symmetry algebra.[17] Note that under the biscale perturbation

$$\hat{u}_N=\sum_{i=0}^{N}\varepsilon^i\eta_i(t,x,y), \quad y=\varepsilon x,$$

we have, for example,

$$\partial_x\to\partial_x+\varepsilon\partial_y, \quad \hat{u}_{Nx}\to\sum_{i=0}^{N}\varepsilon^i(\eta_{ix}+\varepsilon\eta_{iy}), \quad \hat{u}_{Nxx}\to\sum_{i=0}^{N}\varepsilon^i(\eta_{ixx}+2\varepsilon\eta_{ixy}+\varepsilon^2\eta_{iyy}).$$

These equalities have been used in the above-mentioned deduction of bi-Hamiltonian systems in $2+1$ dimensions.

V. CONCLUDING REMARKS

We have proposed a bi-Hamiltonian formulation (3.7) for the triangular systems (2.8) resulting from perturbations around solutions of the perturbed systems. The symmetry problem can lead to a special case (1.2) of our triangular systems (2.8), which is generated by the first-order perturbation. However, the perturbation system (1.2) is a little more general than the symmetry problem itself. It is because the second component system of the perturbation system (1.2) needs to hold only for a solution of the original system $u_t=K(u)$, but the same system in the symmetry problem needs to hold for all solutions of $u_t=K(u)$. The resulting formulation gives a way to construct various integrable couplings in both lower dimensions and higher dimensions for bi-

Hamiltonian systems, all of which at least possess infinitely many commuting symmetries and conserved functionals. Four illustrative examples were given for the KdV equation, which contain two $2+1$ dimensional local bi-Hamiltonian systems (4.27) and (4.37).

The triangular system (4.25) was first introduced in Ref. 16, whose Painlevé property and zero curvature representation were discussed by Sakovich.[18] General triangular systems resulting from multiscale perturbations also can possess rich structures of zero curvature representations. If multiscale perturbations are taken into account, the involved spectral parameters, denoted by μ_i, $0 \leqslant i \leqslant N$, may vary with respect to the spatial variables,[18,6] although they need to satisfy some conditions, for example,

$$\mu_{0x}=0, \quad \mu_{ix}+\mu_{i-1,y}=0, \quad 1 \leqslant i \leqslant N,$$

in the case of biscale perturbations

$$\hat{u}_N=\sum_{i=0}^{N} \varepsilon^i \eta_i(x,y,t)=\sum_{i=0}^{N} \varepsilon^i \eta_i(x,\varepsilon x,t).$$

More interestingly, our $2+1$ dimensional bi-Hamiltonian systems (4.27) and (4.37) are local and possess hereditary recursion operators, and thus they enjoy a different feature from known scalar integrable equations in $2+1$ dimensions. To our best knowledge, (4.27) and (4.37) are the first two examples of local $2+1$ dimensional bi-Hamiltonian systems with hereditary recursion operators. They also can provide useful information for classifying integrable systems in $2+1$ dimensions by the symmetry approach.[19]

We remark that our general bi-Hamiltonian formulation in Sec. III can be used to establish bi-Hamiltonian formulations for a hierarchy of coupled KdV systems introduced in Ref. 20, although it does not work for the other two hierarchies of coupled KdV systems furnished in Refs. 21, 22 and 23. Moreover, our triangular systems, especially (2.11), starting from the KdV equation, provide examples of bi-Hamiltonian systems among the integrable coupled KdV systems described by Gürses and Karasu,[24] and general triangular systems can provide new bi-Hamiltonian systems of other types, e.g., bi-Hamiltonian systems of coupled fifth KdV equations and coupled modified KdV equations. Nonlinearization resulting from symmetry constraints also can be manipulated for linking our triangular systems to finite-dimensional integrable Hamiltonian systems.[25]

We finally point out that our general scheme requires a bi-Hamiltonian structure of the starting system. Nevertheless, we can still make the perturbation to get triangular systems from non-Hamiltonian systems such as the KP hierarchy, and study integrable properties for the resulting triangular systems.

(Received 20 September 2001; accepted for publication 4 December 2001)

We present a new and effective method of determining separable coordinate systems for natural Hamiltonians with two degrees of freedom in flat Riemannian space. The method is based on intrinsic properties of the associated Killing tensors and their invariants under the group of rigid motions $E(2)$. Applications to the Hamiltonian systems derived by the late V. A. Yatsun from $O(4)$-symmetric Yang–Mills theories are presented. In addition, an equivalence between separability of two-dimensional Hamiltonian systems and the existence of Pfaffian quasi-bi-Hamiltonian representations is specified. © *2002 American Institute of Physics.*

I. INTRODUCTION

The aim of this paper is twofold. First, we present a comprehensive and tractable method of classifying orthogonally separable Hamiltonian systems with two degrees of freedom in terms of intrinsic properties of the associated Killing tensors. This leads to a direct algorithm for determining the transformation to separable coordinates which in practice is *completely algebraic*, and hence can be easily implemented in a symbolic computer algebra system. Our second goal is to use the above-mentioned algorithm to solve explicitly the two integrable Hamiltonian systems derived by the late Yatsun[1–5] from $O(4)$-symmetric Yang–Mills theories. Notably, to the best of our knowledge, these two integrable cases (referred throughout this paper as YIC1 and YIC2, respectively) have not been integrated before by quadratures in the most general case.

We consider a general Hamiltonian system defined by a Hamiltonian (total energy) function in the following general form:

$$H(\mathbf{q},\mathbf{p})=\tfrac{1}{2}g^{ij}(\mathbf{q})p_ip_j+V(\mathbf{q}),\quad i,j=1,2, \tag{1}$$

where g^{ij} denote the components of the contravariant metric tensor $\mathbf{g}$ on a pseudo-Riemannian two-dimensional base manifold $\hat{M}$, V is a scalar potential field on $\hat{M}$, and $\mathbf{q}=(q^1,q^2)$ denote local (position) coordinates, while $\mathbf{p}=(p_1,p_2)$ are the corresponding conjugate (momenta) coordinates. This means that the corresponding Hamiltonian vector field $\mathbf{X_H}$ is determined by the equation

$$\mathbf{X_H}=[\mathbf{P_0},H], \tag{2}$$

where $\mathbf{P_0}=\Sigma_{i=1}^{n}\,\partial/\partial q^i\wedge\partial/\partial p_i$ is the standard canonical Poisson bi-vector. Here in the following, unless otherwise indicated, $[\,,\,]$ denotes the Schouten bracket,[6] which generalizes the usual Lie

bracket of vector fields. In terms of the components X_H^i of the Hamiltonian vector field $\mathbf{X_H}$, formula (2) means that $X_H^i = P_0^{ij}(\partial H/\partial x^j)$, where $\mathbf{x}=(x^1,\ldots,x^4)$ are local coordinates on the cotangent bundle $T\hat{M}$.

The problem of solving the Hamiltonian system defined by (1) by the method of separation of variables can be traced back to Bertrand,[7] who considered the situation when a Hamiltonian system admits an additional integral of motion, yet the external forces acting on the system are unknown. This problem was later resurrected in the study of Hamiltonian systems with two degrees of freedom admitting an additional integral of motion. The fundamental result, commonly known as the *Bertrand–Darboux theorem* (see Ref. 8 and the relevant references therein), is the following: If a Hamiltonian system defined by (1) admits an additional first integral quadratic in the momenta which is functionally independent of H, then there exists a system of coordinates (u,v) with respect to which the Hamiltonian (1) takes the *Liouville form* (see the following). The latter result immediately entails separability of the Hamiltonian system defined by (1) in the framework of the Hamilton–Jacobi theory. This method is still widely used. We note, however, that its main drawback is in having to solve every time a second-order partial differential equation (PDE) for a given V of (1) by the method of characteristics (first used by Darboux in this context[8]), thus transforming V to the form (10) in separable coordinates (u,v). This fact indicates that this analytical technique is not tensorial.

Another approach to this problem was initiated by Eisenhart[9] for the n-dimensional geodesic case and recently generalized by Benenti (Ref. 10, see also references therein) for a general Hamiltonian system with n degrees of freedom defined by a Hamiltonian with potential. As before, the problem of finding a solution to the system of ordinary differential equations corresponding to a general Hamiltonian vector field (2) defined by (1) can be related via Jacobi's theorem to the problem of finding an orthogonally separable complete integral W of the corresponding Hamilton–Jacobi equation

$$\tfrac{1}{2} g^{ij}(\mathbf{q})\partial_i W \partial_j W + V(\mathbf{q}) = E, \tag{3}$$

under the standard separation ansatz:

$$W(\mathbf{q};\mathbf{c}) = W_1(q^1;\mathbf{c}) + W_2(q^2;\mathbf{c}), \tag{4}$$

where $\mathbf{c}=(c_1,c_2)$ is an integration constant. This is possible iff H admits a second first integral F quadratic in momenta:

$$F = K^{ij}(\mathbf{q})p_i p_j + U(\mathbf{q}), \quad i,j=1,2. \tag{5}$$

Here the emphasis is on the quantity $\mathbf{K}$ of (5) rather than the potential V of (1) as is the case in the Bertrand–Darboux theorem. Recall that $\mathbf{K}$ is a symmetric *tensor* with pointwise simple and real eigenvalues satisfying the *Killing tensor equation*:

$$[\mathbf{g},\mathbf{K}] = 0, \tag{6}$$

which in component form may be written as

$$[\mathbf{g},\mathbf{K}]^{ijk} = g^{(ij}{}_{,l}K^{k)l} - K^{(ij}{}_{,l}g^{k)l} = 0. \tag{7}$$

A solution $\mathbf{K}$ of (6) is called a *Killing tensor*. The quantity U in (5) is defined by

$$\mathrm{d}U = \hat{\mathbf{K}}\,\mathrm{d}V, \tag{8}$$

where the (1,1) tensor $\hat{\mathbf{K}}$ is defined by $\hat{\mathbf{K}} := \mathbf{Kg}$, or in terms of its components $\hat{K}_i{}^j := K_{il}g^{lj}$. We note that the integrability condition for (8) gives rise to the *compatibility condition*:

$$\mathrm{d}(\hat{\mathbf{K}}\,\mathrm{d}V) = 0. \tag{9}$$

The Hamiltonian system defined by (1) is Liouville-integrable in this case. Furthermore, it is worth noting that the involutiveness of H and F, namely

$$0=\{H,F\}=P_0^{ij}\frac{\partial H}{\partial x^i}\frac{\partial F}{\partial x^j},$$

is equivalent to (6) and (8). In what follows we use intrinsic properties of the associated Killing tensor $\mathbf{K}$ to recover canonical separable coordinates (u,v) leading to integration by quadratures of the system (1). More specifically, we classify the four separable cases in the Euclidean plane, known to be Cartesian, polar, parabolic, and elliptic-hyperbolic coordinates, according to various combinations afforded by the eigenvalues λ_1 and λ_2 of $\mathbf{K}$. We also classify the Killing tensors corresponding to the four separable cases in terms of their invariants under the group of rigid motions $E(2)$ of the Euclidean plane. Our classification scheme is equivalent to that given by Benenti and Rastelli,[11] who based their treatment on a classification of the singular points of the Killing tensors represented in terms of sums of symmetrized products of the Killing tensors of the Euclidean plane. Our approach allows us to recognize immediately the Liouville-integrable Hamiltonian systems YIC1 and YIC2 as separable in parabolic and translated elliptic-hyperbolic systems of coordinates, respectively. The existence of the canonical coordinates (u,v) in either case leads to the conclusion that both YIC1 and YIC2 are Pfaffian quasi-bi-Hamiltonian (QBH) systems. These are the subjects of the considerations that follow.

II. GEOMETRICAL BACKGROUND

The underlying structure of an orthogonally separable Hamiltonian system with two degrees of freedom (1) defined on a pseudo-Riemannian space is such that in the separable coordinates (u,v) the Hamiltonian function (1) takes on the *Liouville form*:[12]

$$H=(A(u)+B(v))^{-1}[\tfrac{1}{2}(\epsilon_1 p_u^2+\epsilon_2 p_v^2)+C(u)+D(v)], \tag{10}$$

while the second first integral (5) quadratic in momenta enjoys the following representation:

$$F=\frac{\epsilon_1 B(v)p_u^2-\epsilon_2 A(u)p_v^2+2(B(v)C(u)-A(u)D(v))}{A(u)+B(v)}, \tag{11}$$

where $A(u),C(u)$ and $B(v),D(v)$ are arbitrary smooth functions of u and v respectively, and $(\epsilon_1)^2=(\epsilon_2)^2=1$. Liouville[12] showed that the Hamiltonian systems defined by (10) are separable, while Morera[13] established the converse via an ingenious use of local coordinates. More precisely, if a Hamiltonian system defined by (1) admits additive separation of variables, it enjoys the Liouville form (10)–(11) in the canonical separable coordinates (u,v). Alternatively, this equivalence can be established by employing the coordinate-free moving frames method,[14–17] which also leads to additional interpretations of this remarkable fact, namely, the Killing tensor of (5) in this case has real and distinct eigenvalues and the system defined by (1) admits a certain quasi-bi-Hamiltonian (QBH) representation.[18] Formulas (10) and (11) describe separable Hamiltonian systems with two degrees of freedom defined in pseudo-Riemannian manifolds of arbitrary curvature. We note that the metric defined by (10) is the metric of the Liouville surface:

$$ds^2=(A(u)+B(v))(\epsilon_1\,du^2+\epsilon_2\,dv^2). \tag{12}$$

Similarly, the general covariant Killing tensor corresponding to (11) reads

$$K_{ij}^{(L)}=(A(u)+B(v))\,\mathrm{diag}(\epsilon_1 B(v),-\epsilon_2 A(u)). \tag{13}$$

Hence, $B(v)$ and $-A(u)$ are the eigenvalues of the linear operator $\hat{\mathbf{K}}=\mathbf{K}^{(\mathbf{L})}\mathbf{g}^{-1}$. It can be shown by integrating the Killing tensor equations (6) in the moving frame of normalized eigenvectors of $\mathbf{K}$ that the general solution has the form

$$\mathbf{K}=l\mathbf{g}+m\mathbf{K}^{(\mathrm{L})}, \tag{14}$$

where l and m are arbitrary constants. In order to classify the separable coordinate systems for Hamiltonian systems of the type (10) on Liouville surfaces of given curvature one has to impose conditions on the corresponding Riemann curvature tensor R_{ijkl}. Important cases are the spaces of constant curvature for which

$$R_{ijkl}=\kappa g_{i[k}g_{|j|l]}, \tag{15}$$

where κ is constant (see Ref. 19 for more details). The cases $\kappa=0$ and $\kappa\neq 0$ have to be distinguished in addition to the two possible signatures of the pseudo-Riemannian metric. In each case the separable coordinate systems may be determined based on the eigenvalues of $\mathbf{K}$ which are invariants. For more details on this method see Refs. 16 and 18 where the Riemannian and Lorentzian cases have been studied, respectively.

In the present paper we focus attention on the locally flat Riemannian case $\kappa=0$. It is well known that for this case (the Euclidean plane) there exist four separable coordinate systems, namely Cartesian, polar, parabolic, and elliptic-hyperbolic coordinates. The corresponding metrics, coordinate transformations, and associated Killing tensors for each case are listed in the following:

$$\text{Cartesian:}\quad \begin{cases} \mathrm{d}s^2=\mathrm{d}u^2+\mathrm{d}v^2, \\ x=u,\quad y=v, \\ K^{(C)}_{ij}=\mathrm{diag}(1,0), \end{cases} \tag{16}$$

$$\text{Polar:}\quad \begin{cases} \mathrm{d}s^2=\mathrm{d}u^2+u^2\,\mathrm{d}v^2, \\ x=u\cos v,\quad y=u\sin v, \\ K^{(P)}_{ij}=\mathrm{diag}(0,u^4), \end{cases} \tag{17}$$

$$\text{Parabolic:}\quad \begin{cases} \mathrm{d}s^2=(u^2+v^2)(\mathrm{d}u^2+\mathrm{d}v^2), \\ x=\frac{1}{2}(u^2-v^2),\quad y=uv, \\ K^{(\mathrm{PB})}_{ij}=(u^2+v^2)\,\mathrm{diag}(v^2,-u^2), \end{cases} \tag{18}$$

$$\text{Elliptic-Hyperbolic:}\quad \begin{cases} \mathrm{d}s^2=k^2(\cosh^2 u-\cos^2 v)(\mathrm{d}u^2+\mathrm{d}v^2), \\ x=k\cosh u\cos v,\quad y=k\sinh u\sin v, \\ K^{(\mathrm{EH})}_{ij}=k^4(\cosh^2 u-\cos^2 v)\,\mathrm{diag}(\cos^2 v,\cosh^2 u). \end{cases} \tag{19}$$

In (19) the parameter k is assumed positive and is interpretable as half the distance between the foci of the elliptic-hyperbolic coordinate system.

We observe that the metric (17) for polar coordinates is not in Liouville form. However, it can be written in this form by an appropriate coordinate transformation. We further observe that in all the above-mentioned cases except for polar coordinates we can immediately read off the functions $A(u)$ and $B(v)$ appearing in (12) and thus determine the form of the Hamiltonian (10) for which a complete integral of the corresponding Hamilton–Jacobi equation (3) can be obtained by quadratures from the ansatz (4). However, in most physical applications, a given Hamiltonian system (1) is defined in terms of *Cartesian* (usually, position-momenta) coordinates and hence has the form

$$H=\tfrac{1}{2}(p_1^2+p_2^2)+V(q^1,q^2). \tag{20}$$

The following questions are then crucial:

(1) Is the system separable in one of the above-mentioned coordinate systems?
(2) If yes, how does one determine the coordinate transformation to separable coordinates?

An answer to question (1) may be obtained from Benenti's theorem.[10] One first derives the general solution of the Killing tensor equation (7) in Cartesian coordinates obtaining

$$K_{ij}=\begin{pmatrix} A+2\alpha q^2+\gamma(q^2)^2 & C-\alpha q^1-\beta q^2-\gamma q^1 q^2 \\ C-\alpha q^1-\beta q^2-\gamma q^1 q^2 & B+2\beta q^1+\gamma(q^1)^2 \end{pmatrix}, \tag{21}$$

where A, B, C, α, β, γ are arbitrary parameters. These six constants obviously represent the *maximum* dimension of the space of linearly independent Killing tensors in our Riemannian space that can also be computed by employing the Takeuchi–Thompson formula:[20,21]

$$\dim K^p(M,\mathbf{g})=\frac{1}{n}\begin{pmatrix} n+p \\ p+1 \end{pmatrix}\begin{pmatrix} n+p-1 \\ p \end{pmatrix}, \quad p\geqslant 0$$

for the dimension of the space of $(p,0)$ Killing tensors defined in a pseudo-Riemannian manifold $(\hat{M},\mathbf{g})$ of constant curvature. One next imposes the compatibility condition (9), which may restrict the values of the parameters in (21). Finally, one determines whether the eigenvalues of the resulting K_{ij} are distinct. If they are, the system is orthogonally separable. The answer to question (2) is more difficult, due to the fact that Cartesian coordinates are not unique being defined only up to a translation and a rotation. One of the main objectives of this paper is to provide a theoretical framework in which question (2) may be answered based on a set of invariants of the Killing tensor (21) under the group of rigid motions $E(2)$ of the Euclidean plane. We further describe an algorithm for determining the transformation to separable coordinates which is straightforward and easy to apply.

III. SEPARABLE KILLING TENSORS IN CARTESIAN COORDINATES

We begin our study of orthogonal separability in terms of the associated Killing tensors by observing that the canonical Killing tensors corresponding to the four separable metrics (16)–(19) can be easily transformed to *canonical Cartesian coordinates* (x,y), i.e., the Cartesian coordinates centered at the origin and properly aligned with the four separable systems of coordinates defined by (16)–(19). Note that the *given Cartesian coordinates* (q^1,q^2) may differ, namely when they are related to the canonical Cartesian coordinates through a combination of translations and rotations. Indeed, using the standard coordinate transformations from canonical Cartesian coordinates to the separable coordinates, and the appropriate tensor transformation law we easily obtain the components of the four corresponding "separable" Killing tensors $\mathbf{K}^{(\mathbf{C})}$, $\mathbf{K}^{(\mathbf{P})}$, $\mathbf{K}^{(\mathbf{PB})}$, and $\mathbf{K}^{(\mathbf{EH})}$ with respect to canonical Cartesian coordinates (x,y), namely:

$$\begin{aligned} K^{(C)}_{ij} &:= \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad \text{Cartesian}, \\ K^{(P)}_{ij} &:= \begin{pmatrix} y^2 & -xy \\ -xy & x^2 \end{pmatrix}, \quad \text{Polar}, \\ K^{(\mathrm{PB})}_{ij} &:= \begin{pmatrix} 0 & y \\ y & -2x \end{pmatrix}, \quad \text{Parabolic}, \\ K^{(\mathrm{EH})}_{ij} &:= \begin{pmatrix} k^2+y^2 & -xy \\ -xy & x^2 \end{pmatrix}, \quad \text{Elliptic-hyperbolic}. \end{aligned} \tag{22}$$

It is easy to see that the polar case is a limiting case $(k=0)$ of the elliptic-hyperbolic case, since $\lim_{k\to 0}\mathbf{K}^{(\mathbf{EH})}=\mathbf{K}^{(\mathbf{P})}$.

Cartesian coordinates are determined only up to the transformations that preserve the metric $\mathbf{g}$, namely the isometry group which consists of translations $t_{\mathbf{a}}$, rotations ρ_θ, and reflections of the

Euclidean plane. We consider only the translations and rotations since it can be shown that reflections play no role in the invariant classification scheme to be presented. Thus, the given Cartesian coordinates (q^1,q^2) of the physical situations are related to the canonical Cartesian coordinates (x,y) via the formula:

$$\begin{pmatrix} q^1 \\ q^2 \end{pmatrix} = t_{\mathbf{a}}\rho_\theta \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} a \\ b \end{pmatrix} \tag{23}$$

for some fixed parameters θ, $\mathbf{a}=(a,b)$. The above-mentioned transformation induces the following transformation laws for the parameters appearing in (21):

$$\begin{aligned} \overline{\gamma} &= \gamma, \\ \overline{\alpha} &= \alpha\cos\theta + \beta\sin\theta - \gamma b, \\ \overline{\beta} &= \beta\cos\theta - \alpha\sin\theta - \gamma a, \\ \overline{A} &= A\cos^2\theta - 2C\cos\theta\sin\theta + B\sin^2\theta - 2b\alpha\cos\theta - 2b\beta\sin\theta + \gamma b^2, \\ \overline{B} &= A\sin^2\theta + 2C\cos\theta\sin\theta + B\cos^2\theta - 2a\beta\cos\theta + 2a\alpha\sin\theta + \gamma a^2, \\ \overline{C} &= (A-B)\sin\theta\cos\theta + C(\cos^2\theta - \sin^2\theta) + (a\alpha + b\beta)\cos\theta + (a\beta - b\alpha)\sin\theta - \gamma ab, \end{aligned} \tag{24}$$

where the quantities with a bar refer to the components of the Killing tensor in the (q^1,q^2) coordinates system. It follows that the components of the four separable Killing tensors relative to (q^1,q^2) coordinates are:

$$\begin{aligned} \widetilde{K}_{ij}^{(C)} &:= \begin{pmatrix} \cos^2\theta & \cos\theta\sin\theta \\ \cos\theta\sin\theta & \sin^2\theta \end{pmatrix}, \\ \widetilde{K}_{ij}^{(P)} &:= \begin{pmatrix} (q^2-b)^2 & -(q^1-a)(q^2-b) \\ -(q^1-a)(q^2-b) & (q^1-a)^2 \end{pmatrix}, \\ \widetilde{K}_{ij}^{(\mathrm{PB})} &:= \begin{pmatrix} 2\sin\theta(b-q^2) & (q^2-b)\cos\theta + (q^1-a)\sin\theta \\ (q^2-b)\cos\theta + (q^1-a)\sin\theta & 2\cos\theta(a-q^1) \end{pmatrix}, \\ \widetilde{K}_{ij}^{(\mathrm{EH})} &:= \begin{pmatrix} k^2\cos^2\theta + (q^2-b)^2 & k^2\cos\theta\sin\theta - (q^1-a)(q^2-b) \\ k^2\cos\theta\sin\theta - (q^1-a)(q^2-b) & k^2\sin^2\theta + (q^1-a)^2 \end{pmatrix}. \end{aligned} \tag{25}$$

Suppose $\mathbf{K}^{(\Lambda)}$ (for some $\Lambda = C$, P, PB, or EH) is a compatible Killing tensor whose components with respect to given Cartesian coordinates are of the form $\widetilde{K}_{ij}^{(\Lambda)}$ for fixed parameters k, θ, $\mathbf{a}$. Then the transformation to separable coordinates (u,v) can be realized as

$$\begin{pmatrix} q^1 \\ q^2 \end{pmatrix} = (t_{\mathbf{a}}\rho_\theta \circ T_\Lambda) \begin{pmatrix} u \\ v \end{pmatrix}, \tag{26}$$

where $(x,y)=T_\Lambda(u,v)$ is one of the standard coordinate transformations associated with Λ-coordinates listed in (16)–(19).

Now if every compatible Killing tensor $\mathbf{K}$ had components relative to (q^1,q^2) coordinates in the form $\widetilde{K}_{ij}^{(\Lambda)}$, or a multiple thereof, then we could intrinsically characterize the separable cases using the natural invariants of $\mathbf{K}$. Indeed, the signs of the determinants along with their eigenvalues could be used in a classification scheme as follows:

Cartesian: $\det \mathbf{K}^{(\mathbf{C})} = 0$ and both eigenvalues constant,

$$\text{Polar:} \quad \det \mathbf{K}^{(\mathbf{P})}=0 \quad \text{and one nonconstant eigenvalue,}$$

$$\text{Parabolic:} \quad \det \mathbf{K}^{(\mathbf{PB})}<0, \tag{27}$$

$$\text{Elliptic-hyperbolic:} \quad \det \mathbf{K}^{(\mathbf{EH})}>0.$$

However, if $\mathbf{K}$ is a compatible Killing tensor with components $\tilde{K}_{ij}^{(\Lambda)}$ relative to (q^1,q^2) coordinates, then $l\mathbf{g}+m\mathbf{K}$, where l and $m\neq 0$ are arbitrary constants, is also a compatible Killing tensor whose components are not of the assumed form. Indeed, addition of the metric changes the eigenvalues and the determinant. Hence, a more precise classification is needed.

IV. GROUP INVARIANTS OF KILLING TENSORS

To classify the separable coordinate systems based on their associated Killing tensors, we study invariants of Killing tensors under the three-parameter group of rigid motions $E(2)$. Since the components of a Killing tensor take the form (21) with respect to *any* Cartesian coordinates, the action of $E(2)$ on the space $\mathcal{K}$ of Killing tensors can be represented by the induced change in the six parameters $\sigma=(A,B,C,\alpha,\beta,\gamma)$ given by (24). We will search for real-valued functions of σ that are invariants of $E(2)$.

As a compatible Killing tensor, $\mathbf{g}$ only indicates that the Hamiltonian H is a first integral. Thus, the subspace $G=\{l\mathbf{g}\,|\,l\in\mathbb{R}\}$ generated by the metric is trivial, since it does not give any information concerning the separable coordinates. Hence, if $\mathbf{K}$ is a compatible Killing tensor, then both $\mathbf{K}$ and $\mathbf{K}+l\mathbf{g}$, $\forall l\in\mathbb{R}$, should determine the same separable coordinate systems. These considerations motivate us to focus on the action of $E(2)$ on the quotient space $Q:=\mathcal{K}/G$, in which $\mathbf{K}$ and $\mathbf{K}+l\mathbf{g}$, $\forall l\in\mathbb{R}$ are considered to be the same element. There is a natural bijection between Q and the parameter space $\mathbb{R}^5$ defined by

$$Q\simeq\left\{\begin{pmatrix}(A-B)+2\alpha y+\gamma y^2 & C-\alpha x-\beta y-\gamma xy\\ C-\alpha x-\beta y-\gamma xy & 2\beta x+\gamma x^2\end{pmatrix}\right\}\simeq\{(A-B,C,\alpha,\beta,\gamma)\}\simeq\mathbb{R}^5.$$

Essentially, in this framework we will be searching for invariants of $\mathbf{K}$ with respect to $E(2)$ which are also invariant under ''metric additions.''

The group $E(2)$ is a Lie group whose Lie algebra $\mathfrak{e}(2)$ is the space of Killing vectors. The algebra $\mathfrak{e}(2)$ is generated by the three basis vectors

$$\mathbf{X}=\frac{\partial}{\partial x},\quad \mathbf{Y}=\frac{\partial}{\partial y},\quad \mathbf{R}=y\frac{\partial}{\partial x}-x\frac{\partial}{\partial y},$$

satisfying the commutator relations $[\mathbf{X},\mathbf{Y}]=0$, $[\mathbf{X},\mathbf{R}]=-\mathbf{Y}$, $[\mathbf{Y},\mathbf{R}]=\mathbf{X}$.

Take any vector $\mathbf{v}\in\mathfrak{e}(2)$. Exponentiation of $\mathbf{v}$ gives a connected one-parameter subgroup $T_{\mathbf{v}}=\{\exp(\epsilon\mathbf{v})|\forall\epsilon\in\mathbb{R}\}$ of $E(2)$. The set of transformations $T_{\mathbf{v}}$ induces a family of one-parameter curves in M. Denote the maximal parametrized curve passing through $\sigma\in M$ by $\Psi(\exp(\epsilon\mathbf{v}),\sigma)$, where Ψ is the flow generated by $\mathbf{v}$ in Q.

Definition 4.1: Let $\mathbf{K}$ *be a Killing tensor, whose components with respect to Cartesian coordinates* (x,y) are

$$K_{ij}=\begin{pmatrix}A+2\alpha y+\gamma y^2 & C-\alpha x-\beta y-\gamma xy\\ C-\alpha x-\beta y-\gamma xy & B+2\beta x+\gamma x^2\end{pmatrix}.$$

Then an $E(2)$-invariant *of* $\mathbf{K}$ *is a real-valued function* $F:\mathbb{R}^6\to\mathbb{R}$ *of* $\sigma=(A,B,C,\alpha,\beta,\gamma)$ *such that*

(1) $F(\Psi(m,\sigma))=F(\sigma)$, $\forall m\in E(2)$,
(2) $F(\sigma+l\hat{g})=F(\sigma)$, $\forall l\in\mathbb{R}$, *where* $\hat{g}=(1,1,0,0,0,0)$.

Letting $E(2)$ act on the quotient space Q, we can use standard techniques from the Lie group theory of differential equations to construct the $E(2)$-invariants. In the proof of the following proposition, the notations are consistent with those used in Ref. 22.

Proposition 4.1: Let

$$\Delta=(\alpha^2-\beta^2+\gamma(B-A))^2+4(\gamma C+\alpha\beta)^2. \tag{28}$$

Then every smooth $E(2)$-invariant of $\mathbf{K}$ *is of the form* $F(\Delta,\gamma)$, *where* $F:\mathbb{R}^2\to\mathbb{R}$ *is an arbitrary smooth function.*

Proof: The corresponding infinitesimal action of the Lie algebra $\mathfrak{e}(2)$ on M is given by

$$\psi(\mathbf{v})\Big|_{\sigma}=\frac{\mathrm{d}}{\mathrm{d}\epsilon}\Psi(\exp(\epsilon\mathbf{v}),\sigma)\Big|_{\epsilon=0}$$

for any $\mathbf{v}\in\mathfrak{e}(2)$, $\sigma\in M$. Equivalently, we can write

$$\psi(\mathbf{v})=\pi(\mathcal{L}_{\mathbf{v}}(\mathbf{K})), \tag{29}$$

where $\mathcal{L}_{\mathbf{v}}(\mathbf{K})$ is the Lie derivative of $\mathbf{K}$ with respect to $\mathbf{v}$ and $\pi:\mathcal{K}\to\mathbb{R}^5$ is the projection map defined by

$$\pi\begin{pmatrix} A_0+2\alpha_0 y+\gamma_0 y^2 & C_0-\alpha_0 x-\beta_0 y-\gamma_0 xy \\ C_0-\alpha_0 x-\beta_0 y-\gamma_0 xy & B_0+2\beta_0 x+\gamma_0 x^2 \end{pmatrix}$$
$$=(A_0-B_0)\frac{\partial}{\partial(A-B)}+C_0\frac{\partial}{\partial C}+\alpha_0\frac{\partial}{\partial\alpha}+\beta_0\frac{\partial}{\partial\beta}+\gamma_0\frac{\partial}{\partial\gamma}.$$

Note that π is a linear surjection and $\pi(\mathbf{K^{(1)}})=\pi(\mathbf{K^{(2)}})$ iff $\mathbf{K^{(1)}}=\mathbf{K^{(2)}}+l\mathbf{g}$ for any $l\in\mathbb{R}$. Equation (29) follows from a straightforward application of the definitions of ψ, $\mathcal{L}$, and π.

The corresponding infinitesimal generators in Q are

$$\mathbf{V_1}=\pi(\mathcal{L}_X(K))=-2\beta\frac{\partial}{\partial(A-B)}-\alpha\frac{\partial}{\partial C}+\gamma\frac{\partial}{\partial\beta},$$

$$\mathbf{V_2}=\pi(\mathcal{L}_Y(K))=2\alpha\frac{\partial}{\partial(A-B)}-\beta\frac{\partial}{\partial C}+\gamma\frac{\partial}{\partial\alpha},$$

$$\mathbf{V_3}=\pi(\mathcal{L}_R(K))=-4C\frac{\partial}{\partial(A-B)}+(A-B)\frac{\partial}{\partial C}+\beta\frac{\partial}{\partial\alpha}-\alpha\frac{\partial}{\partial\beta}.$$

Note that $\mathbf{V_1}$, $\mathbf{V_2}$, $\mathbf{V_3}$ satisfy the commutator relations

$$[\mathbf{V_1},\mathbf{V_2}]=0,\quad [\mathbf{V_1},\mathbf{V_3}]=-\mathbf{V_2},\quad [\mathbf{V_2},\mathbf{V_3}]=\mathbf{V_1}.$$

Hence, ψ is a Lie algebra homomorphism from $\mathfrak{e}(2)$ to the Lie algebra of vector fields generated by $\{\mathbf{V_1},\mathbf{V_2},\mathbf{V_3}\}$ on Q.

It is well known that invariance of an object under an entire Lie group is equivalent to infinitesimal invariance under the infinitesimal generators of the corresponding Lie algebra. The image in Q of the Lie algebra $\mathfrak{e}(2)$ has basis $\{\mathbf{V_1},\mathbf{V_2},\mathbf{V_3}\}$. Hence, $F:Q\to\mathbb{R}$ is a smooth $E(2)$-invariant iff $\mathbf{V_i}(F)\equiv 0$ for $i=1,2,3$. This is a system of three homogeneous linear partial differential equations in five variables. Solving this system by the method of characteristics yields the solution $F(\Delta,\gamma)$. □

As a consequence of Proposition IV, we obtain two essential $E(2)$-invariants, Δ and γ. Let

$$\operatorname{sgn}|x| = \begin{cases} 1 & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases},$$

and impose the following equivalence relation on $\mathcal{K}$:

$$\mathbf{K}^{(1)} \sim \mathbf{K}^{(2)} \Leftrightarrow \begin{cases} \operatorname{sgn}|\Delta_{\mathbf{K}^{(1)}}| = \operatorname{sgn}|\Delta_{\mathbf{K}^{(2)}}| \\ \operatorname{sgn}|\gamma_{\mathbf{K}^{(1)}}| = \operatorname{sgn}|\gamma_{\mathbf{K}^{(2)}}|. \end{cases}$$

Note that $\sim$ partitions $\mathcal{K} \setminus G$ into four equivalence classes corresponding to whether Δ and γ are zero or nonzero. Take the components of the ''separable'' Killing tensors with respect to canonical Cartesian coordinates listed in (22), and designate them to be representative elements from their respective equivalence classes. Evaluating the $E(2)$-invariants Δ and γ on each produces the following classification scheme:

$$\begin{gathered} \gamma = 0, \quad \Delta = 0: \quad \text{Cartesian}, \\ \gamma = 0, \quad \Delta \neq 0: \quad \text{Parabolic}, \\ \gamma \neq 0, \quad \Delta = 0: \quad \text{Polar}, \\ \gamma \neq 0, \quad \Delta \neq 0: \quad \text{Elliptic-hyperbolic}. \end{gathered} \tag{30}$$

Now recall that the general solution of the Killing tensor equation is given by the *tensor* equation (14). This implies that if $\mathbf{K}$ is linearly independent of $\mathbf{g}$, we have in (q^1, q^2) coordinates,

$$K_{ij} = l g_{ij} + m \tilde{K}_{ij}^{(\Lambda)} \tag{31}$$

for some $l, m \in \mathbb{R}, m \neq 0$, some unique $\Lambda = C$, P, PB, or EH, and where $\tilde{K}_{ij}^{(\Lambda)}$ depends on the parameters θ, a, b, k as in (25). By comparing the components on both sides (31) and using the $E(2)$-invariant classification, we can express θ, a, b, k as functions of the constants A, B, C, α, β, γ for any particular Killing tensor. We illustrate this method for the elliptic-hyperbolic case in the following.

Take a particular Killing tensor $\mathbf{K}$ whose components with respect to Cartesian coordinates (q^1, q^2) are of the form (21) and suppose that $\gamma \neq 0$, $\Delta \neq 0$. $\mathbf{K}$ is of elliptic-hyperbolic type, and so comparing the components on both sides of (31), we obtain

$$A + 2\alpha q^2 + \gamma (q^2)^2 = l + m(k^2 \cos^2 \theta + (q^2 - b)^2), \tag{32}$$

$$C - \alpha q^1 - \beta q^2 - \gamma q^1 q^2 = m(k^2 \cos\theta \sin\theta - (q^1 - a)(q^2 - b)), \tag{33}$$

$$B + 2\beta q^1 + \gamma (q^1)^2 = l + m(k^2 \sin^2 \theta + (q^1 - a)^2). \tag{34}$$

The coefficients of the terms quadratic and linear in q^1, q^2 yield $m = \gamma$, and $a = -\beta/\gamma$, $b = -\alpha/\gamma$, respectively. Simplifying, we now have

$$A - \frac{\alpha^2}{\gamma} - l = \gamma k^2 \cos^2 \theta, \tag{35}$$

$$C + \frac{\alpha\beta}{\gamma} = \gamma k^2 \cos\theta \sin\theta, \tag{36}$$

$$B - \frac{\beta^2}{\gamma} - l = \gamma k^2 \sin^2 \theta, \tag{37}$$

Note that the product of the left-hand sides of (35) and (37) equals the square of the left-hand side of (36). Solving this for l yields

$$l_{\pm}=\frac{1}{2\gamma}(\gamma(A+B)-\alpha^2-\beta^2\pm\sqrt{\Delta}). \tag{38}$$

Adding (35) and (36) and solving for k^2 yields

$$k^2=\frac{\gamma(A+B)-\alpha^2-\beta^2}{\gamma^2}-\frac{2l}{\gamma}=\mp\frac{\sqrt{\Delta}}{\gamma^2}\neq 0, \tag{39}$$

which forces $l=l_{-}$.

Let $\sigma:=\alpha^2-\beta^2+\gamma(B-A)$. To find the rotation angle θ, we have to consider various cases. If $\gamma C+\alpha\beta\neq 0$, then dividing (37) by (36) gives

$$\tan\theta=\frac{\gamma(B+l)-\beta^2}{\gamma C+\alpha\beta}=\frac{\sigma+\Delta}{2(\gamma C+\alpha\beta)}.$$

If $\gamma C+\alpha\beta=0$, then by (36) we have $\sin\theta\cos\theta=0$, since $\gamma\neq 0$. By (35) and (37), this implies that either $\gamma(A-l)-\alpha^2=0$ (if $\cos\theta=0$) or $\gamma(B-l)-\beta^2=0$ (if $\sin\theta=0$). Using (38), (39), and the fact that $l=l_{-}$, we obtain

$$\begin{aligned}&\sigma=+k^2\gamma^2, \quad \text{if}\cos\theta=0, \text{ or}\\ &\sigma=-k^2\gamma^2, \quad \text{if}\sin\theta=0.\end{aligned}$$

Thus if $\sigma>0$, then $\tan\theta=\pm\infty$, and if $\sigma<0$, then $\tan\theta=0$. Clearly, θ is only unique mod π. In a similar fashion, expressions for θ, a, b in terms of the constants $A, B, C, \alpha, \beta, \gamma$ can be found for the Cartesian, polar, and parabolic cases.

The *singular points* of each coordinate system can also be described in this framework. It follows from Benenti[10] that they are characterized as the points where the eigenvalues of the Killing tensor K_{ij} are equal. The conditions for equal roots for the characteristic equation are

$$K_{11}=K_{22}, \quad K_{12}=0, \tag{40}$$

which in view of (21) give rise to

$$\begin{aligned}&A+2\alpha q^2+\gamma(q^2)^2=B+2\beta q^1+\gamma(q^1)^2,\\ &\gamma q^1q^2+\alpha q^1+\beta q^2=C.\end{aligned} \tag{41}$$

We consider the solution of the above-mentioned system for each equivalence class of Killing tensors in $\mathcal{K}\backslash G$:

(1) *Cartesian* ($\gamma=0,\Delta=0$): In this case, $\alpha=\beta=0$, and (41) is equivalent to $A=B$, $C=0$, which is true only for elements in G. Hence, there are no solutions in this case.

(2) *Parabolic* ($\gamma=0,\Delta\neq 0$). One solution:

$$(q^1,q^2)=\left(\frac{\beta(A-B)+2\alpha C}{2(\alpha^2+\beta^2)},\frac{\alpha(B-A)+2\beta C}{2(\alpha^2+\beta^2)}\right).$$

(3) *Polar* ($\gamma\neq 0,\Delta=0$). One solution:

$$(q^1,q^2)=\left(\frac{-\beta}{\gamma},\frac{-\alpha}{\gamma}\right).$$

(4) *Elliptic-hyperbolic* ($\gamma\neq 0,\Delta\neq 0$). Two solutions:

TABLE I. Formulas for transformation to separable coordinates. Transformation to separable coordinates:

$$\begin{pmatrix} q^1 \\ q^2 \end{pmatrix} = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} T_\Lambda \begin{pmatrix} u \\ v \end{pmatrix} + \begin{pmatrix} a \\ b \end{pmatrix}.$$

Standard coordinate transformations: $T_C: x=u,\ y=v$, $T_P: x=u\cos v,\ y=u\sin v$, $T_{\mathrm{PB}}: x=\frac{1}{2}(u^2-v^2),\ y=uv$, $T_{\mathrm{EH}}: x=k\cosh u\cos v,\ y=k\sinh u\sin v$.

Coordinate type	γ	Δ	a	b	$\tan(\theta)$	k^2	Singular points
Cartesian	0	0	Arbitrary	Arbitrary	$\begin{cases} 0 \quad \text{if } C=0, \\ \dfrac{B-A+\sqrt{(B-A)^2+4C^2}}{2C} \quad \text{if } C\neq 0. \end{cases}$ (θ unique mod $\dfrac{\pi}{2}$)	0/0	Two at ∞
Parabolic	0	$\neq 0$	$\dfrac{\beta(A-B)+2\alpha C}{2(\alpha^2+\beta^2)}$	$\dfrac{\alpha(B-A)+2\beta C}{2(\alpha^2+\beta^2)}$	$\begin{cases} \pm\infty \quad \text{if } \beta=0, \\ \dfrac{\alpha}{\beta} \quad \text{if } \beta\neq 0. \end{cases}$ (θ unique mod π)	∞	One at **a**, One at ∞
Polar	$\neq 0$	0	$-\dfrac{\beta}{\gamma}$	$-\dfrac{\alpha}{\gamma}$	Arbitrary. Define $\sigma=\alpha^2-\beta^2+\gamma(B-A)$.	0	Two coincide at **a**
Elliptic-hyperbolic	$\neq 0$	$\neq 0$	$-\dfrac{\beta}{\gamma}$	$-\dfrac{\alpha}{\gamma}$	$\begin{cases} 0 \quad \text{if } \gamma C+\alpha\beta=0,\ \sigma<0, \\ \pm\infty \quad \text{if } \gamma C+\alpha\beta=0,\ \sigma>0, \\ \dfrac{\sigma+\sqrt{\Delta}}{2(\gamma C+\alpha\beta)} \quad \text{if } \gamma C+\alpha\beta\neq 0. \end{cases}$ (θ unique mod π)	$\dfrac{\sqrt{\Delta}}{\gamma^2}$	Two distinct

$$(q^1,q^2)=\left(\frac{-\beta}{\gamma}+\frac{1}{\gamma}\left(\frac{\sqrt{\Delta}-\sigma}{2}\right)^{1/2},\frac{-\alpha}{\gamma}+\frac{1}{\gamma}\left(\frac{\sqrt{\Delta}+\sigma}{2}\right)^{1/2}\right),$$

$$(q^1,q^2)=\left(\frac{-\beta}{\gamma}-\frac{1}{\gamma}\left(\frac{\sqrt{\Delta}-\sigma}{2}\right)^{1/2},\frac{-\alpha}{\gamma}-\frac{1}{\gamma}\left(\frac{\sqrt{\Delta}+\sigma}{2}\right)^{1/2}\right).$$

In the elliptic-hyperbolic system, there are two singular points corresponding to the foci with k being half the distance between them, as mentioned earlier. The polar system is a limiting case of the elliptic-hyperbolic system when the foci coincide, so here $k^2=\lim_{\Delta\to 0}\sqrt{\Delta}/\gamma^2=0$ and there is one singular point at the center of the polar system. The parabolic system is also a limiting case of the elliptic-hyperbolic system in the sense that there is one finite singular point and one singular point which has been ''pushed'' to infinity, so $k^2=\lim_{\gamma\to 0}\sqrt{\Delta}/\gamma^2=\infty$. Finally, in the Cartesian system, both singular points from the elliptic-hyperbolic system have been ''pushed'' to infinity. Hence, no (finite) singular points exist. The above classification of the singular points is equivalent to that given by Benenti and Rastelli.[11] Our results are summarized in Table I.

V. MAIN ALGORITHM

The above-presented considerations lead to the following systematic and computationally efficient method of determining separable coordinates for the natural Hamiltonian (20):

(1) Using a generic Killing tensor $\mathbf{K}$ of the form (21) in terms of the given Cartesian coordinates (q^1,q^2), impose the compatibility condition (9) to obtain the equivalent conditions on the parameters A, B, C, α, β, γ.

(2) Decompose the general solution obtained in step (1) as follows:

$$\mathbf{K}=l_0\mathbf{g}+l_1\mathbf{K}^{(1)}+\cdots+l_n\mathbf{K}^{(n)}, \tag{42}$$

where l_i, $i=0,1,\ldots,n$ are arbitrary constants and $\{\mathbf{g},\mathbf{K}^{(1)},\ldots,\mathbf{K}^{(n)}\}$ is a pointwise linearly independent set of Killing tensors. Since $\dim\mathcal{K}=6$, then $n\leqslant 5$. If $n=0$, then H is not orthogonally separable. If $n\geqslant 2$, then H is superseparable.

(3) Each $\mathbf{K}^{(i)}$ will characterize separation in some coordinate system. For each $\mathbf{K}^{(i)}$, evaluate the $E(2)$-invariants γ and Δ. Then use Table I to determine: (1) the separable coordinate system type, and (2) the essential parameters θ, a, b, k. The transformation to separable coordinates can be carried out by using Eq. (26).

A main feature of this algorithm is that once an additional Killing tensor is known, the task of finding separable coordinates reduces to simply looking up the appropriate parameters in Table I. *No additional computations are necessary*. Computationally, the most difficult part of the algorithm is finding the general solution of the compatibility condition (9) in step (1). However, using the generic form (21) of $\mathbf{K}$ with respect to Cartesian coordinates, this computation only amounts to solving a system of linear equations in six variables. This method should be contrasted with that which implements the Bertrand–Darboux theorem in which a second-order PDE must be solved by the method of characteristics. Our algorithm is *completely algebraic*, and hence is well suited for implementation in a symbolic computer algebra system. We have implemented such a program in the MAPLE system and it has been used successfully to analyze the Hamiltonian systems discussed in this paper.

As a brief illustration, we discuss the implications of this algorithm on the two known separable cases of the Hénon–Heiles system (see Ref. 23, and references therein) which is defined by the Hamiltonian

$$H_{\mathrm{HH}}=\frac{1}{2}(p_1^2+p_2^2+c(q^1)^2+d(q^2)^2)+aq^1(q^2)^2-\frac{b}{3}(q^1)^3 \tag{43}$$

for some constants a, b, c, and d. Imposing the compatibility condition (9) with a generic Killing tensor (21) and the above-given potential, we can identify all integrable cases which correspond to an additional first integral quadratic in momenta. In particular, the only nontrivial (i.e., $ab\neq 0$) systems we recover are the first and second known integrable cases. We list these in the following, along with the corresponding compatible Killing tensors, and the transformation to separable coordinates obtained by using Table I:

(1) $b=-a$, $c=d$:

$$K_{ij}=l_0 g_{ij}+l_1\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},$$

$$q^1=\frac{1}{\sqrt{2}}(u-v),\quad q^2=\frac{1}{\sqrt{2}}(u+v).$$

(2) $b=-6a$, c, d arbitrary:

$$K_{ij}=l_0 g_{ij}+l_1\begin{pmatrix}\dfrac{4d-c}{2a} & -\beta q^2\\ -\beta q^2 & 2\beta q^1\end{pmatrix},$$

$$q^1=\frac{4d-c}{4a}+\frac{1}{2}(u^2-v^2),\quad q^2=uv.$$

The third known integrable case $b=-16a$, $d=16c$ is not recovered by this method. This indicates that the corresponding system does not have an additional first integral quadratic in momenta, and hence is not orthogonally separable.

In step (2) of the algorithm, we remarked that if $n\geqslant 2$, then H is superseparable. An example of such a system is the two-dimensional Calogero–Moser system defined by the Hamiltonian

$$H_{\mathrm{CM}}=\frac{1}{2}(p_1^2+p_2^2)+\frac{1}{(q^1-q^2)^2}. \tag{44}$$

Solving the compatibility condition yields the following general compatible Killing tensor:

$$K_{ij}=l_0 g_{ij}+l_1\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}+l_2\begin{pmatrix}(q^2)^2 & -q^1q^2\\ -q^1q^2 & (q^1)^2\end{pmatrix}+l_3\begin{pmatrix}2q^2 & -q^1-q^2\\ -q^1-q^2 & 2q^1\end{pmatrix}, \tag{45}$$

from which we conclude that the system is separable in the following coordinate systems:

(1) Cartesian: $q^1=(1/\sqrt{2})\,(u-v)$, $q^2=(1/\sqrt{2})\,(u+v)$,
(2) Polar: $q^1=u\cos v$, $q^2=u\sin v$,
(3) Parabolic: $q^1=(1/2\sqrt{2})\,(u^2-2uv-v^2)$, $q^2=(1/2\sqrt{2})\,(u^2+2uv-v^2)$,

thus recovering known results. Again, in contrast with previous methods, the algorithm that we have presented is *exhaustive* in the sense that a given system is separable in some system of coordinates iff the associated Killing tensor is a particular solution of the compatibility condition. The general form of the compatible Killing tensor gives us essentially all the information about the separation properties of a given system. We remark that the algorithm can be used in the reverse direction as a method for determining the general forms of the superseparable potentials in the Euclidean plane. In order to classify such potentials, we specify two (or more) Killing tensors linearly independent from the metric, construct the general Killing tensor (42), and then proceed to solve the compatibility condition (9) for the potential V. For example, if we wish to find the potential V which is separable in both polar and parabolic coordinates, let

$$K_{ij}=l_0 g_{ij}+l_1\begin{pmatrix}y^2 & -xy\\ -xy & x^2\end{pmatrix}+l_2\begin{pmatrix}0 & y\\ y & -2x\end{pmatrix}, \tag{46}$$

where l_0, l_1, l_2 are arbitrary parameters. Solving the compatibility condition recovers the known potential

$$V=\frac{1}{\sqrt{x^2+y^2}}\left(c_0+\frac{c_1 x}{y^2}\right)+\frac{c_2}{y^2}, \tag{47}$$

where c_0, c_1, c_2 are arbitrary constants of integration. Note that for any $k\in\mathbb{R}$, if we let $l_0=k^2$, $l_1=1$, $l_2=k$ in (46), we obtain the Killing tensor

$$K_{ij}=\begin{pmatrix}k^2+y^2 & -(x-k)y\\ -(x-k)y & (x-k)^2\end{pmatrix}, \tag{48}$$

which indicates separation in *translated* elliptic-hyperbolic coordinates, with the origin of the polar and parabolic systems located at one of the *foci* of the elliptic-hyperbolic system of coordinates. Hence, the potential (46) which is superseparable in polar and parabolic coordinates is necessarily also separable in these specific coordinates. This is the *only* translated and rotated elliptic-hyperbolic coordinate system for which V is also separable in polar and parabolic coordinates. Although this method is a systematic way of determining superseparable potentials, it is computationally intensive. Solving the compatibility condition for the potential V given $\mathbf{K}$ amounts to solving the associated PDEs satisfied by V. Using this method, we have recovered the known set of superseparable potentials (see Ref. 24, and the relevant references therein).

In Sec. VI, and the remainder of this paper, we will illustrate this algorithm in more detail for the two integrable systems YIC1 and YIC2 derived by Yatsun.[1–5]

VI. SEPARABLE COORDINATES EXHIBITED

Recall that the Yang–Mills theories provide a reasonable model for the unification of electromagnetic and weak forces. Naturally, many aspects of the theory have become active areas of research developed from algebraic, differential geometric, dynamical, etc., points of view. In particular, many integrable models (see, for instance, Ref. 25) have been derived from self-dual Yang–Mills equations by symmetry reductions.

In a series of papers[1–5] Yatsun investigated two SU(2) gauge theories defined in $\mathbb{R}^4$ over the bundle $P(\mathbb{R}^4,\mathrm{SU}(2))$ from this viewpoint.

A. Yatsun's integrable case 1 (YIC1)

The first SU(2) Yang–Mills theory considered has a Lagrangian density of the form

$$\mathcal{L}_1=\frac{1}{4g^2}F^a_{\mu\nu}F^a_{\mu\nu}+\frac{1}{2}\mathcal{D}_\mu\phi_i\mathcal{D}_\mu\phi_i+\frac{1}{4}\lambda(\phi_i\phi_i)^2, \tag{49}$$

for $\phi_i, i=1,\ldots,4$ in vector representations, where under SU(2) gauge transformations $h=u_4+iu_a\sigma_a\phi_i$ transforms into $\tilde{\phi}_i=u_4\phi_i+\overline{\eta}_{aij}u_a\phi_j$ and $\mathcal{D}_\mu\phi_i=\partial_\mu\phi_i-\frac{1}{2}\overline{\eta}_{aij}A^a_\mu\phi_j$, $\overline{\eta}_{aij}=\epsilon_{aij4}+\delta_{i4}\delta_{aj}-\delta_{j4}\delta_{ai}$ is the anti-self-dual 't Hooft tensor. (For the symmetry properties of the Yang–Mills Lagrangians see Fatibene *et al.*[26]). To solve the problem of finding the fields A_μ and ϕ_ν satisfying the equations of motion of the model (49), namely

$$\begin{gathered}\tilde{D}_\mu F^a_{\mu\nu}+\tfrac{1}{2}g^2\overline{\eta}_{a\rho\tau}\phi_\rho\mathcal{D}_\nu\phi_\tau=0,\\ \mathcal{D}_\mu\mathcal{D}_\mu\phi_\mu+\lambda\phi^2\phi_\nu=0,\end{gathered} \tag{50}$$

where $\tilde{D}_\mu F^a_{\mu\nu}=\partial_\mu F^a_{\mu\nu}+\epsilon_{abc}A^b_\mu F^c_{\mu\nu}$, and $\phi^2=\phi_\nu\phi_\nu$ for which the integral of action is bounded, the author employs the $O(4)$-symmetry reduction

$$A^a_\mu=2\psi(x)\overline{\eta}_{a\mu\nu}\frac{x_\nu}{x^2},\quad \phi_\nu=\varphi(x)\frac{x_\nu}{x}, \tag{51}$$

where $x=(x_\nu x_\nu)^{1/2}$. These equations transform the equations of the motion (50) into the following system of second-order ordinary differential equations (ODEs):

$$\begin{gathered}\psi''+\frac{1}{x}\psi'-\frac{4}{x^2}\psi(1-\psi)(1-2\psi)-\frac{g^2}{4}\varphi^2(1-\psi)=0,\\ \varphi''+\frac{3}{x}\varphi'-\frac{3}{x^2}\varphi(1-\psi)^2+\lambda\varphi^3=0.\end{gathered} \tag{52}$$

By the coordinate transformation

$$t=\ln x,\quad q_1=\psi+1,\quad q_2=\left(\frac{g^2}{12}\right)^{1/2}x\varphi,\quad p_i=\frac{\mathrm{d}q_i}{\mathrm{d}t}, \tag{53}$$

where $i=1,2$, Eq. (52) is reduced to the canonical Hamilton equations defined by the Hamiltonian

$$H_1=\tfrac{1}{2}(p_1^2+p_2^2)+V_1, \tag{54}$$

where

$$V_1=-2\left((q^1)^4+\frac{3}{4}(q^1)^2(q^2)^2+\frac{3}{2}\frac{\lambda}{g^2}(q^2)^4\right)+12\left((q^1)^3+\frac{1}{2}q^1(q^2)^2\right)$$
$$-26\left((q^1)^2+\frac{1}{4}(q^2)^2\right)+24q^1. \tag{55}$$

It is shown next that for $g^2=24\lambda$ the Hamiltonian system is completely integrable having the following additional integral of motion independent of H_1:

$$F_1=p_1p_2q_2-p_2^2q^1-(q^2)^2\{(q^1)^3+\tfrac{1}{2}q^1(q^2)^2-6((q^1)^2+\tfrac{1}{4}(q^2)^2)+13q^1-12\}. \tag{56}$$

Note that (56) is quadratic in momenta, hence the system is orthogonally separable. At this point the author uses the technique developed in Ref. 27 which utilizes the Hamilton–Jacobi equation of (55) to find a *particular* solution of (52) by first finding a particular solution to the Hamilton–Jacobi equation in order to reduce the system of second-order ODEs to a system of first-order ODEs in $\psi(x)$ and $\varphi(x)$ that can be solved explicitly. We are able to show that the Hamiltonian system defined by (55) can be solved in full generality by making use of the Hamilton–Jacobi method of separation of variables under the separation ansatz (4) as described previously. Indeed, we observe that any Killing tensor compatible with V_1 [i.e., $\mathrm{d}(\mathbf{K}\,\mathrm{d}V_1)=0$] is of the form $\mathbf{K}=l_0\mathbf{g}+l_1\mathbf{K^{(1)}}$, l_0, l_1 arbitrary parameters, where

$$K_{ij}^{(1)}=\begin{pmatrix}0 & -q^2\\ -q^2 & 2q^1\end{pmatrix}. \tag{57}$$

Comparing $K_{ij}^{(1)}$ with (21), we see that $A=B=C=\alpha=\gamma=0$, $\beta=1$. Table I indicates that the separable coordinates are of parabolic type with $\theta=a=b=0$. Hence, we use the standard transformation to parabolic coordinates:

$$\begin{aligned}q^1&=\tfrac{1}{2}(u^2-v^2),\\ q^2&=uv.\end{aligned} \tag{58}$$

Transforming the momenta and potential accordingly, we obtain the following form of the Hamiltonian H_1 in parabolic coordinates:

$$H_1=\frac{\frac{1}{2}(p_u^2+p_v^2)+h_+(u^2)+h_-(v^2)}{u^2+v^2}, \tag{59}$$

where $p_u=\partial W/\partial u$, $p_v=\partial W/\partial v$, and

$$h_\pm(\eta)=\frac{-\eta^5}{8}+\frac{3\eta^4}{2}-\frac{13\eta^3}{2}\pm 12\eta^2. \tag{60}$$

The Hamiltonian H_1 is separable in u,v coordinates. Setting $H_1=E$, E an arbitrary constant, and seeking a separable solution $W=W_1(u)+W_2(v)-Et$, the Hamilton–Jacobi equation becomes

$$\left(\frac{\mathrm{d}W_1}{\mathrm{d}u}\right)^2+2h_+(u^2)-2Eu^2=-\left(\frac{\mathrm{d}W_2}{\mathrm{d}v}\right)^2-2h_-(v^2)+2Ev^2=\sigma, \tag{61}$$

where σ is the separation constant. Consequently, the separated equations yield the solution up to quadrature:

$$W_1(u)=\int \sqrt{2Eu^2+\sigma-2h_+(u^2)}\,\mathrm{d}u, \tag{62}$$

$$W_2(v)=\int \sqrt{2Ev^2-\sigma-2h_-(v^2)}\,\mathrm{d}v. \tag{63}$$

Next, solving

$$\beta_1=\frac{\partial W}{\partial \sigma}, \quad t-t_0=\frac{\partial W}{\partial E}, \tag{64}$$

where $W(u,v)=W_1(u)+W_2(v)$, one can obtain the general solution to the dynamical system in closed form.

B. Yatsun's integrable case 2 (YIC2)

A similar approach is used to treat the Yang–Mills theory with the Lagrangian density

$$\mathcal{L}_2=\frac{1}{4g^2}F^a_{\mu\nu}F^a_{\mu\nu}+\frac{1}{2}D_\mu\phi^a_i D_\mu\phi^a_i+\frac{1}{4}\lambda[\phi_i,\phi_j]^a[\phi_i,\phi_j]^a, \tag{65}$$

where the real scalar fields $\phi_i, i=1,\ldots,4$ are given in adjoint representation and $D_\mu\phi^a_i=\partial_\mu\phi^a_i+[A_\mu,\phi_i]^a$, thus leading to the Hamiltonian system defined by

$$H_2=\tfrac{1}{2}(p_1^2+p_2^2)+V_2, \tag{66}$$

where

$$V_2=-2\left((q^1)^4+2(q^1)^2(q^2)^2+\frac{2\lambda}{g^2}(q^2)^4\right)+4((q^1)^3+q^1(q^2)^2)-2((q^1)^2+(q^2)^2). \tag{67}$$

It is shown that the Hamiltonian system is completely integrable if $g^2=2\lambda$ enjoying the following additional first integral independent from (66):

$$\begin{aligned}F_2=&((q^2)^2+\tfrac{3}{4})p_1^2-(2q^1-1)q^2p_1p_2+(q^1-1)q^1p_2^2-3(q^1)^4\\&-2(q^1)^2(q^2)^2+(q^2)^4+6(q^1)^3+2(q^1)(q^2)^2-3(q^1)^2.\end{aligned} \tag{68}$$

As in the previous case the integral F_2 is quadratic in momenta, thus confirming orthogonal separability of (66). More specifically, any Killing tensor compatible with V_2 is of the form $\mathbf{K}=l_0\mathbf{g}+l_1\mathbf{K^{(1)}}$, l_0, l_1 arbitrary parameters, where

$$K^{(1)}_{ij}=\begin{pmatrix}\frac{3}{4}+(q^2)^2 & \frac{1}{2}1\,q^2-q^1q^2\\ \frac{1}{2}q^2-q^1q^2 & -q^1+(q^1)^2\end{pmatrix}. \tag{69}$$

Comparing $K^{(1)}_{ij}$ with (21), we see that $A=\frac{3}{4}$, $B=C=\alpha=0$, $\beta=-\frac{1}{2}$, $\gamma=1$. Table I indicates that the separable coordinates are of elliptic-hyperbolic type with $\theta=b=0$, $a=\frac{1}{2}$, $k=1$. We use *translated* elliptic-hyperbolic coordinates:

$$\begin{aligned}q^1&=\tfrac{1}{2}+\cosh(u)\cos(v),\\ q^2&=\sinh(u)\sin(v).\end{aligned} \tag{70}$$

Transforming the momenta and potential accordingly, we obtain the following form of the Hamiltonian H_2 in parabolic coordinates

$$H_2=\frac{\frac{1}{2}(p_u^2+p_v^2)+g(\cos^2(v))-g(\cosh^2(u))}{\cosh^2(u)-\cos^2(v)}, \tag{71}$$

where $p_u=\partial W/\partial u$, $p_v=\partial W/\partial v$, and

$$g(\eta)=2\eta^3-3\eta^2+\tfrac{9}{8}\eta. \tag{72}$$

The Hamiltonian H_2 is separable in u, v coordinates. Setting $H_2=E$, E an arbitrary constant, and seeking a separable solution $W=W_1(u)+W_2(v)-Et$, the Hamilton–Jacobi equation becomes

$$\left(\frac{\mathrm{d}W_1}{\mathrm{d}u}\right)^2-2g(\cosh^2(u))-2E\cosh^2(u)=-\left(\frac{\mathrm{d}W_2}{\mathrm{d}v}\right)^2-2g(\cos^2(v))+2E\cos^2(v)=\sigma, \tag{73}$$

where σ is the separation constant. Consequently, the separated equations yield the solution up to quadrature:

$$W_1(u)=\int \sqrt{2E\cosh^2(u)+\sigma+2g(\cosh^2(u))}\,\mathrm{d}u, \tag{74}$$

$$W_2(v)=\int \sqrt{-2E\cos^2(v)-\sigma-2g(\cos^2(v))}\,\mathrm{d}v. \tag{75}$$

Finding the complete solution $W(u,v)=W_1(u)+W_2(v)$ leads to the general solution of the dynamical system in closed form [see (64)].

VII. QUASI-BI-HAMILTONIAN REPRESENTATIONS

It is instructive to comment on yet another important property of the completely integrable Hamiltonian systems defined by (55) and (66), respectively, considered in Sec. VI. Recall that a Hamiltonian system is said to be quasi-bi-Hamiltonian (QBH) if its vector field X_{H_1,H_2} enjoys the following representations:

$$\mathbf{X_{H_1,H_2}}=[\mathbf{P_1},H_1]=\frac{1}{\rho}[\mathbf{P_2},H_2], \tag{76}$$

where $\mathbf{P_1}$ and $\mathbf{P_2}$ are compatible Poisson bi-vectors (i.e., $[\mathbf{P_1},\mathbf{P_2}]=0$), H_1, H_2 are the corresponding Hamiltonians, and ρ is some function. If $\rho=-\Pi_{i=1}^{n}\lambda_i$, where λ_i, $i=1,\ldots,n$ are eigenvalues of the operator $\mathbf{A}=\mathbf{P_2}\mathbf{P_1}^{-1}$, assuming $\mathbf{A}$ is of minimal degeneracy (i.e., it has exactly n distinct eigenvalues) having real eigenvalues and $\mathbf{P_1}$ is invertible, the QBH system (76) is called *Pfaffian*. For the case of a Hamiltonian system with two degrees of freedom defined by (1) we will show that this property is equivalent to the Hamilton–Jacobi separability.

Theorem 7.1: *The following statements are equivalent:*

(a) *The pseudo-Riemannian manifold* $(\hat{M},\mathbf{g})$ *defined by (1) admits a valence two Killing tensor* $\mathbf{K}$ *with real and distinct eigenvalues satisfying* $\mathrm{d}(\hat{\mathbf{K}}\mathrm{d}V)=0$, *where the* (1,1) *tensor* $\hat{\mathbf{K}}$ *is given by* $\hat{\mathbf{K}}=\mathbf{Kg}$.

(b) *The Hamiltonian system defined by (1) in the pseudo-Riemannian manifold* $(\hat{M},\mathbf{g})$ *can be integrated by separation of variables within the framework of the Hamilton–Jacobi theorem.*

(c) *A Hamiltonian system defined by (1) admits a Pfaffian QBH representation (76), where* $\mathbf{P_1}$ *is canonical and* $\mathbf{A}=\mathbf{P_2}\mathbf{P_1}^{-1}$ *is of minimal degeneracy with real and distinct eigenvalues.*

Proof: We note that a version of this theorem was announced in Ref. 18. The equivalence (a) $\Leftrightarrow$ (b) is simply a restatement of Benenti's theorem.[10] To prove the validity of the implication (b)

$\Rightarrow$ (c), we use the fact that a completely integrable Hamiltonian system defined by (1) that can be integrated by separation of variables admits the Liouville form (10)–(11) in the canonical separable coordinates (u,v)[13] [although it may also be separable in other coordinates related to (u,v)]. Then direct substitution of the functions $H_1=H$, $H_2=F/2$, where H and F are defined by (10) and (11), respectively, $\rho=-A(u)B(v)$ and the Poisson bi-vectors defined by

$$\mathbf{P_1}=\frac{\partial}{\partial u}\wedge\frac{\partial}{\partial p_u}+\frac{\partial}{\partial v}\wedge\frac{\partial}{\partial p_v},$$
$$\mathbf{P_2}=-A(u)\frac{\partial}{\partial u}\wedge\frac{\partial}{\partial p_u}+B(v)\frac{\partial}{\partial v}\wedge\frac{\partial}{\partial p_v}, \tag{77}$$

into the representation formula (76) confirms the claim. We note that the functions $A(u)$ and $B(v)$ are the eigenvalues of both the linear operator $\mathbf{A}=\mathbf{P_2}\mathbf{P_1}^{-1}$ ($\mathbf{A}$ has doubly degenerate eigenvalues) and Killing tensor $\hat{\mathbf{K}}=\mathbf{Kg}$. Next, (c) $\Rightarrow$ (b) can be easily obtained by making use of the principal result of Ref. 28, namely that there is a canonical transformation to the Darboux–Nijenhuis coordinates with respect to which the Poisson bi-vectors P_1 and P_2 are given by (77) (see also Ref. 29). Moreover, the system admits the Gantmakher form in these coordinates. Indeed, it is easy to verify that in our notations the Hamiltonian (1) takes the following form, corresponding to (77):

$$H_1=H=\frac{C_1(u,p_1)+C_2(v,p_2)}{A(u)+B(v)}, \tag{78}$$

where C_1 and C_2 are arbitrary functions, and thus is separable with respect to the coordinates (u,v). □

Remark 7.1: Taking into account that under the assumption of the theorem the linear operators $\hat{\mathbf{K}}$ and $\mathbf{A}$ share the same eigenvalues [$A(u)$ and $B(v)$ in the canonical separable coordinates (u,v)], we conclude that it is possible to classify alternatively the separable cases in terms of the eigenvalues of $\mathbf{A}$ using the Pfaffian QBH representation (76).

The following corollary describes separation of variables with respect to Cartesian coordinates.

Corollary 7.1: A Hamiltonian system defined by (1) is separable in Catesian coordinates iff it admits the Pfaffian QBH representation (76) with the (1,1) *tensor* $\mathbf{A}$: $=\mathbf{P_2}\mathbf{P_1}^{-1}$ *having constant and distinct eigenvalues*.

Separation of variables of two-dimensional Hamiltonian systems and the existence of Pfaffian QBH representations are thus intimately related. In conclusion we observe that the Liouville-integrable Hamiltonian systems investigated in Sec. VI, that is YIC1 and YIC2, are Pfaffian QBH systems, for example, in the canonical separable coordinate systems.

VIII. CONCLUDING REMARKS

In this paper we have developed an algebraic method of determining separable coordinates in the Euclidean plane based on group invariants of Killing tensors. The main advantage of our approach is that once an additional first integral quadratic in momenta is known, no additional nontrivial computations need to be performed. In a forthcoming paper, we will describe a similar algorithm for investigating orthogonal separability in the Minkowski plane based on an analogous set of group invariants. This framework also provides another starting point for investigating orthogonal separability in three-dimensional pseudo-Riemannian manifolds of constant curvature in a systematic and efficient manner. Work in this direction is under way.

We have also demonstrated that separation of variables in Hamiltonian systems with two degrees of freedom is intimately related to the existence of the Pfaffian QBH representations for the Hamiltonian systems in question. As a matter of fact the separable cases can also be classified by considering the eigenvalues of the linear operator $\mathbf{A}=\mathbf{P_2}\mathbf{P_1}^{-1}$ associated with the QBH repre-

sentation. The results presented in the last part of the paper may also lead to generalizations involving Hamiltonian systems defined in three-dimensional pseudo-Rimemannian manifolds.

Multi-Lagrangians for integrable systems

Y. Nutku and M. V. Pavlov
Feza Gürsey Institute, P.O. Box 6, Çengelköy, Istanbul 81220, Turkey

(Received 15 May 2001; accepted for publication 25 October 2001)

We propose a general scheme to construct multiple Lagrangians for completely integrable nonlinear evolution equations that admit multi-Hamiltonian structure. The recursion operator plays a fundamental role in this construction. We use a conserved quantity higher/lower than the Hamiltonian in the potential part of the new Lagrangian and determine the corresponding kinetic terms by generating the appropriate momentum map. This leads to some remarkable new developments. We show that nonlinear evolutionary systems that admit N-fold first order local Hamiltonian structure can be cast into variational form with $2N-1$ Lagrangians which will be local functionals of Clebsch potentials. This number increases to $3N-2$ when the Miura transformation is invertible. Furthermore we construct a new Lagrangian for polytropic gas dynamics in $1+1$ dimensions which is a *free, local* functional of the physical field variables, namely density and velocity, thus dispensing with the necessity of introducing Clebsch potentials entirely. This is a consequence of bi-Hamiltonian structure with a compatible pair of first and third order Hamiltonian operators derived from Sheftel's recursion operator. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1427765]

I. INTRODUCTION

In this paper we shall point out a general technique for the construction of inequivalent solutions to the inverse problem in the calculus of variations. We shall show that completely integrable partial differential equations in $1+1$ dimensions that admit multi-Hamiltonian structure can be cast into variational form with multiple Lagrangians. It is remarkable that all these new Lagrangians can be obtained directly from our present knowledge of complete integrability of the evolutionary system without doing any new calculations.

One of the important properties we expect from a completely integrable system is multi-Hamiltonian structure. A vector evolutionary system can then be cast into Hamiltonian form in more than one way

$$u^i_{t_{\aleph+\alpha-1}}=\{u^i,H_\alpha\}_\aleph=J^{ik}_\aleph\delta_k H_\alpha \quad i=1,2,\ldots,n \quad \aleph=1,2,\ldots N. \quad \alpha=-1,0,1,\ldots,\infty, \quad (1)$$

where the variational derivative is denoted by $\delta_k\equiv\delta/\delta u^k$ and J is a matrix of differential operators satisfying the properties of a Poisson tensor, namely skew-symmetry and Jacobi identity. For integrable systems there exists more than one such Hamiltonian operator and Hamiltonian function as the respective Hebrew and Greek indices indicate. Then, by the theorem of Magri[1] completely integrable systems admit infinitely many conserved Hamiltonian functions which are in involution with respect to Poisson brackets defined by compatible Hamiltonian operators.

The essential element in the multi-Hamiltonian approach to integrability is the construction of the Hamiltonian operators themselves. Fortunately this is a rich subject[2] that can be put to good use. We shall be interested in the consequences of multi-Hamiltonian structure on the Lagrangian formulation of completely integrable evolutionary equations. We shall work in the opposite direc-

tion to the traditional approach of deriving Hamiltonian structure from a Lagrangian. The crucial fact that we shall exploit is the relationship between Hamiltonian operators and Dirac brackets[3] for degenerate Lagrangian systems which was first pointed out by Macfarlane.[4] In the case of completely integrable systems we have much more information on Hamiltonian structure than Lagrangian and it became clear only recently[5–7] how we can construct multiple Lagrangians for systems that admit multi-Hamiltonian structure. We shall now present the general and most simple technique for generating these new Lagrangians.

II. MULTI-LAGRANGIANS

Evolutionary systems (1) cannot be cast into variational form with a local expression for the Lagrangian using the velocity fields u^i alone but require the introduction of Clebsch potentials. In $1+1$-dimensions the general expression for Clebsch potentials is given by

$$u^i=\phi^i_x \tag{2}$$

and in this paper we shall only consider Lagrangians that are local functionals of these potentials. In the time-honored way we shall split the Lagrangian density for Eqs. (1) into two

$$\mathcal{L}=\mathcal{T}-\mathcal{V}. \tag{3}$$

that consist of the kinetic and potential pieces, respectively. For the first Lagrangian density, an enumeration which will become clear presently, the kinetic term is always given by

$$\mathcal{T}_1=g_{ik}\phi^i_t\phi^k_x, \tag{4}$$

where g_{ik} are constants with $\det g_{ik}\neq 0$ and

$$\mathcal{V}_1=2\mathcal{H}_1 \tag{5}$$

is the Hamiltonian density. We note that the Hamiltonian function that appears in (1) is the space integral of the density. We shall number the conserved Hamiltonians by reserving the subscript 1 to the ''usual'' Hamiltonian function but of course there exists conserved quantities such as Casimirs and the momentum which are of lower order. In fact, for complete integrability, an n-component vector evolutionary system (1) must admit n infinite series of conserved Hamiltonians. We shall denote their densities by

$$\mathcal{H}_{\alpha[i]}, \quad i=1,2,...,n, \quad \alpha=-1,...,\infty \tag{6}$$

and recall that each series starts with a Casimir

$$\mathcal{H}_{-1[i]}=g_{ik}u^k \tag{7}$$

which will carry the label minus one. One of these series is distinguished in that it contains the ''usual'' Hamiltonian function which is the one that appears in Eqs. (1). For the two-component systems that we shall discuss in this paper these are the Eulerian and Lagrangian series. We note also that the two series may coincide up to a relabelling dictated by the recursion operator. This is in fact the case for the $\gamma=2$ case of gas dynamics and in most examples of completely integrable dispersive equations except the Boussinesq equation.

The potential part of the Lagrangian does not depend on the velocities and from Eq. (4) it follows that the Hessian

$$\det\left|\frac{\partial^2\mathcal{L}_1}{\partial\phi^i_t\partial\phi^k_t}\right|=0$$

vanishes identically. We have therefore a degenerate Lagrangian system and in order to cast it into Hamiltonian form we must use Dirac's theory of constraints,[3] or the covariant Witten–Zuckerman theory[8,9] of symplectic structure. In particular, the first Hamiltonian operator obtained from the first Lagrangian is given by

$$J_1^{ik}=g^{ik}D, \quad D\equiv\frac{d}{dx}, \tag{8}$$

where g^{ik} is the inverse of the coefficients in the kinetic part of the first Lagrangian (4) which is nondegenerate.

The construction of multiple Lagrangians relies on the use of the Lenard recursion relation which is implicit in Eqs. (1) that in the Greek and Hebrew indices we have a symmetric matrix

$$J^{ik}_{[\aleph}\delta_{|k|}H_{\alpha]}=0 \tag{9}$$

where square brackets denote complete skew-symmetrization and bars enclose indices which are excluded in this process. Provided we can invert these Hamiltonian operators, we can construct recursion operators

$$R^{\aleph_1\ \ i}_{\aleph_2\ \ k}=J^{im}_{\aleph_2}(J^{mk}_{\aleph_1})^{-1} \tag{10}$$

that map gradients of conserved Hamiltonians into each other (9).

For the construction of Lagrangians we start with the crucial observation that the first Lagrangian is of the form

$$\mathcal{L}_1=\mathcal{H}_{-1[i]}\phi_t^i-2\mathcal{H}_1, \tag{11}$$

which is manifest from (4). The original fields that enter into the evolutionary system (1) are Casimirs which is evident from the subscript minus one. The second Lagrangian will be of the same general structure as (11) if we further suppose that Eqs. (1) can be written in bi-Hamiltonian form. Thus there will exist H_2 which is the next conserved Hamiltonian function in the hierarchy and the momentum H_0 which comes after Casimirs. The higher Lagrangian should simply be

$$\mathcal{L}_2=\mathcal{H}_{0[i]}\phi_t^i-2\mathcal{H}_2,$$

but there is an important refinement that we need to insert here. It is not the conserved density but rather the momentum map that enters into the kinetic part of the Lagrangian. The two differ only by total derivatives which is irrelevant in the context of conservation laws and therefore generally skipped over. However, these divergence terms are of crucial interest as the momentum map in the theory of symplectic structure. We shall show that given αth local Hamiltonian structure, the full new Lagrangian is simply given by

$$\mathcal{L}_\alpha=\{\mathcal{H}_{\alpha-2[i]}+(\mathcal{G}_{\alpha-2[i]})_x\}\phi_t^i-2\mathcal{H}_\alpha, \tag{12}$$

where $\mathcal{G}_{\alpha[i]}$ is a functional of the potentials. The coefficient of ϕ_t^i above is the momentum map and this is the only calculation necessary to find the new Lagrangian.

The fact that it is the momentum map rather than the conserved density that plays an important role in the Lagrangian can be seen at the level of the first Lagrangian. Now the Casimirs play the role of the momentum map and they are used to construct the next higher conserved quantity according to the construction of the canonical energy-momentum tensor

$$\mathcal{H}_0=\frac{\partial\mathcal{L}_1}{\partial\phi_t^i}\phi_x^i=\mathcal{H}_{-1[i]}u^i=\frac{1}{2}g^{ik}\mathcal{H}_{-1[i]}\mathcal{H}_{-1[k]},$$

which is the momentum. This classical result for Lagrangians linear in the velocity can be generalized at each level we have a higher Lagrangian. We have

$$2\mathcal{H}_{\alpha-1}=g^{ik}[\mathcal{H}_{\alpha-2[i]}+(\mathcal{G}_{\alpha-2[i]})_x]\mathcal{H}_{-1[k]} \tag{13}$$

ending at the level where a local Lagrangian is no longer possible. In fact the validity of this equation is directly related to the existence of the Lagrangian. If a check of (13) fails for some α, then there exists no local Lagrangian at αth level.

Now we come to an important reservation that our new Lagrangians will necessarily carry. The Euler equations that follow from the variation of the action with the second Lagrangian will be

$$R_2^{1\ i}{}_k[u_t^k-J_1^{km}\delta_m H_1]=0, \tag{14}$$

so that the first variation of the second action will certainly be an extremum for the original equations of motion (1) but the Euler equations (14) require something weaker, namely linear combinations of functionals in the kernel of the recursion operator can be added to the right-hand side of the equations of motion and the new action will still be an extremum.

From this construction it is manifest that for every Hamiltonian function in the infinite hierarchy of conserved Hamiltonians that we have for completely integrable systems, there exists a degenerate Lagrangian (12) that yields the equations of motion as its Euler equation up to functionals in the kernel of the recursion operator. The number of Lagrangians that can be constructed in this way is therefore infinite in number. Given bi-Hamiltonian structure we have two local Hamiltonian operators but the Lenard recursion operator (10) is nonlocal. However, the special form of the first Hamiltonian operator (8) leads to a local expression for the second Lagrangian in terms of Clebsch potentials. But it is clear that the repeated application of the recursion operator will require the introduction of nonlocal terms in higher Lagrangians. Strictly speaking, this is not a problem because the original Lagrangian is itself nonlocal in terms of the velocity fields u^i which are the original variables. We swept this problem under the rug by introducing Clebsch potentials. Higher Lagrangians for evolutionary equations (1) can be written in local form by introducing potentials for the Clebsch potentials themselves. If, however, the equations of motion admit N local Hamiltonian operators, then our construction guarantees the existence of N Lagrangians which are local functionals of the Clebsch potentials. Thus we have the following theorems.

Theorem 1: *A completely integrable system that admits N-fold local first order Hamiltonian structure can be given N different variational formulations with degenerate Lagrangians that are local functionals of the Clebsch potentials.*

By a convenient abuse of language we claim that we have a Lagrangian for an equation that involves fields when the Lagrangian is in fact only a functional of the Clebsch potentials for these fields. Then we have the audacity to put in by hand the expression for the fields in terms of potentials after the variation. This can be at best only a shorthand for the real variational principle where we must impose the relationship between the fields and their potentials through Lagrange multipliers.

So far we have been guilty of this abuse ourselves. But now we must say that the first Lagrangian is actually

$$\mathcal{L}_1^{\text{full}}=\mathcal{L}_1(\phi^i,\phi_x^i,\phi_{xx}^i,\ldots)+\lambda_i(u^i-\phi_x^i) \tag{15}$$

so that upon variation with respect to all the variables ϕ^i, u^i, λ_i we get (2), $\lambda_i=0$ and arrive at the equations of motion (1) expressed in terms of the original fields u^i without fudging.

Now this obvious observation may seem correct but naive, however, we shall now find that it dramatically increases the number of new Lagrangians we can construct for integrable systems.

For every evolutionary equation that admits, say for simplicity, bi-Hamiltonian structure there exists a differential substitution

$$u^i = M^i(r^k, r^k_x, \ldots) \tag{16}$$

that brings the second Hamiltonian operator to the canonical form (8) of Darboux. This differential substitution is a Miura transformation. Strictly speaking the theorem of Darboux remains unproved in field theory where the number of degrees of freedom is infinite but we shall assume it. Miura transformation works in a direction opposite to the usual action of the recursion operator. It leads to Hamiltonian equations

$$r^i_t = \{r^i, H_0\}_1 = g^{ik} D \delta_{r^k} H_0|_{u^m = M^m(r^n)}, \tag{17}$$

where H_0 is the momentum for Eqs. (1) expressed through (16). These are modified equations, different from the original equations, but the two sets are related by

$$u^i_t - J^{ik}_2 \delta_{u^k} H_0(u) = \mathcal{O}^i_j(r^l)[r^j_t - J^{jk}_1 \delta_{r^k} H_0|_{u^m = M^m(r^n)}] \tag{18}$$

up to functions in the kernel of some matrix differential operator $\mathcal{O}^i_j$.

A comparison of Eqs. (14) and Miura's relation (18) shows us that using the differential substitution of Miura we can obtain new Lagrangians for nonlinear evolution equations that admit multi-Hamiltonian structure in the opposite direction to our earlier construction. Transforming to the variables r^i and using new Clebsch potentials

$$r^i = \psi^i_x \tag{19}$$

we can write the classical Lagrangian for the modified system (17)

$$\mathcal{L}^{\text{modified}}_1 = g_{ik} \psi^i_x \psi^k_t - 2\mathcal{H}_0|_{u^m = M^m(\psi_x, \psi_{xx}, \ldots)}, \tag{20}$$

where the labeling of $\mathcal{H}_0$ refers to its expression in the original variables u^i but these need to be substituted for in terms of r^i according to (16) and expressed through the potentials (19). We note that the Casimirs $r^i = \psi^i_x$ for the modified system are absent in the polynomial $\mathcal{H}_\alpha(u)$ hierarchy. We would expect naively that the Euler equations resulting from the first variation of the action with the Lagrangian (20) would result in the modified equations (17). This would indeed be the case if we were to impose the constraint between the fields r^i and their potentials ψ^i as in (15) but now using (19). However, by imposing the constraint through Miura's differential substitution

$$\mathcal{L}^{\text{full}}_0 = \mathcal{L}^{\text{modified}}_1(\psi^i_x, \psi^i_{xx}, \ldots) + \lambda_i[u^i - M^i(\psi^i_x, \psi^i_{xx}, \ldots)] \tag{21}$$

we obtain a new Lagrangian for the original equation (1) in the original variables u^i. We shall use this construction to derive new Lagrangians, in particular for KdV in Sec. III. It is evident that this construction can be extended when there exists multi-Hamiltonian structure but, as we shall find in the example of KdV, sometimes it is possible to arrive at local Lagrangians using nonlocal Hamiltonian operators as well. We conclude with the following.

Theorem 2: *The first Lagrangian of every modified equation obtained through a Miura transformation will serve as a new zeroth Lagrangian for the original equations of motion provided the constraint between the fields and their potentials is imposed through a Miura-type differential substitution. For N-fold Hamiltonian structure there exists* $N-1$ *such new Lagrangians.*

Miura transformation is in general not invertible because it is a differential substitution. But there exist interesting examples where it reduces to a point transformation which is invertible. In that case we can construct $N-1$ further Lagrangians.

We conclude that for an evolutionary system that admits N-fold first order Hamiltonian structure, the number of different variational principles where the first variation will be an extremum by virtue of the original equations of motion is $2N-1$ and in the case Miura transformation is invertible $3N-2$. We illustrate this situation for the case of bi-Hamiltonian structure in Tables I

TABLE I. The hierarchy of local Hamiltonian structures and Lagrangians which are local functionals of Clebsch potentials for evolutionary system $u_t=J_1\delta H_1=J_2\delta H_0$ where J_1 is in the canonical Darboux form.

Equations of motion	$u_t=J_2\delta H_0$	$u_t=J_1\delta H_1$	$J_2J_1^{-1}u_t=-\delta_\phi H_2$
Local Hamiltonian op.	J_2	J_1	no
Local Lagrangian	no	$\mathcal{L}_1$	$\mathcal{L}_2$
Modified equations	$r_t=\tilde{J}_2\delta H_0$	$r_t=\tilde{J}_1\delta H_1$	
Local Hamiltonian op.	$\tilde{J}_2=J_1$	$\tilde{J}_1$	
Local Lagrangian	$\mathcal{L}_0$	no	

and II. The general situation is much more complicated than what these tables would lead us to expect. Starting with tri-Hamiltonian structure the individual entries in each one of these tables will need to be a table by itself because there are inequivalent Hamiltonian operators that yield the same equations of motion with the same Hamiltonian function. We shall discuss this interesting situation in a future publication on the Chaplygin–Born–Infeld equation.

III. KDV

KdV stands as the symbol of completely integrable systems. We think we know it, but it turns out to be so rich that there is still new information to be learned about it. We recall that KdV

$$u_t+6uu_x-u_{xxx}=0 \tag{22}$$

admits the Kruskal sequence of conserved Hamiltonian densities

$$\mathcal{H}_{-1}^{\mathrm{KdV}}=u, \tag{23}$$

$$\mathcal{H}_{0}^{\mathrm{KdV}}=\tfrac{1}{2}u^2, \tag{24}$$

$$\mathcal{H}_{1}^{\mathrm{KdV}}=u^3+\tfrac{1}{2}u_x^2, \tag{25}$$

$$\mathcal{H}_{2}^{\mathrm{KdV}}=\tfrac{5}{2}u^4+5uu_x^2+\tfrac{1}{2}u_{xx}^2, \tag{26}$$

$$\cdots$$

which are in involution with respect to Poisson brackets defined by two Hamiltonian operators

$$J_1=D, \qquad J_2=-D^3+2uD+2Du, \tag{27}$$

that form a Poisson pencil. By introducing the potential

$$u=\phi_x. \tag{28}$$

KdV can be cast into variational form with two Lagrangians

$$\mathcal{L}_1^{\mathrm{KdV}}=\mathcal{H}_{-1}^{\mathrm{KdV}}\phi_t-2\mathcal{H}_1^{\mathrm{KdV}}, \tag{29}$$

TABLE II. When the Miura transformation is invertible we need to include an additional column to the left of Table I.

Equations of motion		$u_t=J_2\delta H_0$	$\cdots$
Local Hamiltonian op.		J_2	$\cdots$
Local Lagrangian		no	$\cdots$
Modified equations	$\tilde{J}_1\tilde{J}_2^{-1}r_t=-\delta_\psi H_{-1}$	$r_t=\tilde{J}_2\delta H_0$	$\cdots$
Local Hamiltonian op.	no	$\tilde{J}_2=J_1$	$\cdots$
Local Lagrangian	$\mathcal{L}_{-1}$	$\mathcal{L}_0$	$\cdots$

$$\mathcal{L}_2^{\mathrm{KdV}}=(\mathcal{H}_0^{\mathrm{KdV}}+\phi_{xxx})\phi_t-2\mathcal{H}_2^{\mathrm{KdV}}, \tag{30}$$

which consist of the classical Lagrangian and the second Lagrangian,[5] respectively. Note that there is a misprint in the potential term of the second Lagrangian reported in Ref. 6 but the results that follow are correct. Here we observe that both (29) and (30) are examples of our general expression (12) for higher Lagrangians.

The second application of Lenard's recursion operator to J_1 results in a third Hamiltonian operator which is nonlocal so we cannot continue to generate higher Lagrangians. But we can use Theorem 2 to generate new lower Lagrangians for KdV. For this purpose we note that in both Lagrangians (29) and (30) we should have added the constraint $\lambda(u-\phi_x)$ and written the full Lagrangian. But following the convenient abuse of language we did not do so because it was manifest. It is, however, necessary to write the full Lagrangian in the case of lower Lagrangians.

According to our general construction of lower Lagrangians we first recall the original Miura transformation

$$u=r^2+r_x \tag{31}$$

that brings J_2 to the canonical form of J_1 in the variable r. The equation of motion for r is mKdV which is different from (22) but under the substitution (31) we have Miura's result

$$u_t+6uu_x-u_{xxx}=(D+2r)(r_t+6r^2r_x-r_{xxx})=0, \tag{32}$$

so that, on shell, if mKdV is satisfied then so is KdV. Now we can introduce the Clebsch potential for the modified field variable

$$r=\psi_x \tag{33}$$

and write the first Lagrangian for mKdV

$$\mathcal{L}_1^{\mathrm{mKdV}}=\psi_x\psi_t+\mathcal{H}_0^{\mathrm{KdV}}|_{u=\psi_x^2+\psi_{xx}} \tag{34}$$

in a straightforward manner. But now enforcing the constraint in the full Lagrangian through the Miura transformation

$$\mathcal{L}_0^{\mathrm{KdV\ full}}=\mathcal{L}_1^{\mathrm{mKdV}}+\lambda(u-\psi_x^2-\psi_{xx}) \tag{35}$$

we shall arrive at a new Lagrangian for KdV because the Euler equation that comes from the first variation of this action will be satisfied by virtue of (32). Unlike (30) which is a higher Lagrangian, (35) is a lower Lagrangian in the sense of the action of the recursion operator on the equations of motion.

And the saga of KdV continues. We consider the third Hamiltonian operator for KdV

$$J_3=R^2J_1 \tag{36}$$

which is nonlocal but the relationship between differential substitutions and Hamiltonian structures of KdV (Ref. 24) enables us to construct another new local Lagrangian for KdV. For this purpose we recall that the differential substitution

$$r=\alpha q+\frac{\varepsilon}{q}+\frac{q_x}{2q}, \tag{37}$$

which transforms mKdV into twice modified KdV

$$q_t=\left(q_{xx}-\frac{3q_x^2}{2q}+\frac{6\varepsilon^2}{q}-2\alpha^2q^3\right)_x \tag{38}$$

is a Miura transformation for (36). This can best be seen by the expression

$$J_3=\tfrac{1}{2}(q^2D+Dq^2)-q_xD^{-1}q_x \tag{39}$$

for the third nonlocal Hamiltonian operator for KdV in terms of the twice modified variable q. We recall that J_3 is fifth order in u. We have the Miura relation

$$r_t+6r^2r_x-r_{xxx}=\left(\alpha-\frac{\varepsilon}{q^2}-\frac{q_x}{2q^2}+\frac{1}{q}D\right)\left[q_t-\left(q_{xx}-\frac{3q_x^2}{2q}+\frac{6\varepsilon^2}{q}-2\alpha^2q^3\right)_x\right]=0 \tag{40}$$

between modified and twice modified KdV's. Introducing the potential for the twice modified variable $q=\chi_x$ we have

$$u=\Phi(\chi_x,\chi_{xx},\chi_{xxx})\equiv\frac{\chi_{xxx}}{\chi_x}-\frac{\chi_{xx}^2}{\chi_x^2}+2\alpha\chi_{xx}+\alpha^2\chi_x^2+2\alpha\varepsilon+\frac{\varepsilon^2}{\chi_x^2} \tag{41}$$

in terms of the original field u. The first Lagrangian for twice modified KdV is simply

$$\mathcal{L}_1^{\mathrm{m}_2\mathrm{KdV}}=\chi_x\chi_t+\mathcal{H}_{-1}^{\mathrm{KdV}}|_{u=\Phi(\chi_x,\chi_{xx},\chi_{xxx})} \tag{42}$$

and therefore the second lower Lagrangian for KdV is given by

$$\mathcal{L}_{-1}^{\mathrm{KdV\ full}}=\mathcal{L}_1^{\mathrm{m}_2\mathrm{KdV}}+\lambda[u-\Phi(\chi_x,\chi_{xx},\chi_{xxx})] \tag{43}$$

which provides another illustration of (21). This process can be continued.

We note that an alternative to the Clebsch potential for KdV is the Schwartzian which was pointed out by Schiff.[10] We shall postpone consideration of Schwartzian potentials to future work.

IV. POLYTROPIC GAS DYNAMICS

The simplest examples for applying our construction of multi-Lagrangians consist of quasi-linear second order hyperbolic equations that Dubrovin and Novikov[11] have called equations of hydrodynamic type. The distinguished example in this set consists of the Eulerian equations of polytropic gas dynamics in $1+1$ dimensions,

$$\rho_t+u\rho_x+\rho u_x=0,\quad u_t+uu_x+\rho^{\gamma-2}\rho_x=0, \tag{44}$$

and in particular for $\gamma=-1$ we have the case of Chaplygin gas, or Born–Infeld equation that was recently shown to have a string theory antecedent.[12] This system can be cast into quadri-Hamiltonian form.[13] For the Chaplygin–Born–Infeld case the complete Hamiltonian structure can be found in Ref. 14 and its symmetries were given in Ref. 15. In the following we shall use the labeling $u^1=\rho$ and $u^2=u$.

First we have three local Hamiltonian structures of first order[16]

$$J_1=\begin{pmatrix}0 & D\\ D & 0\end{pmatrix}=\sigma^1D, \tag{45}$$

$$J_2=\begin{pmatrix}\rho D+D\rho & (\gamma-2)Du+uD\\ Du+(\gamma-2)uD & \rho^{\gamma-2}D+D\rho^{\gamma-2}\end{pmatrix}, \tag{46}$$

$$J_3=\begin{pmatrix} u\rho D+Du\rho & D\left[\frac{1}{2}(\gamma-2)u^2+\frac{1}{\gamma-1}\rho^{\gamma-1}\right]+\left[\frac{1}{2}u^2+\frac{1}{\gamma-1}\rho^{\gamma-1}\right]D \\ D\left[\frac{1}{2}u^2+\frac{1}{\gamma-1}\rho^{\gamma-1}\right]+\left[\frac{1}{2}(\gamma-2)u^2+\frac{1}{\gamma-1}\rho^{\gamma-1}\right]D & u\rho^{\gamma-2}D+Du\rho^{\gamma-2} \end{pmatrix}, \tag{47}$$

which form a Poisson pencil $\mathcal{J}=J_1+c_1J_2+c_2J_3$ with c_1,c_2 constants, i.e., these Hamiltonian operators are compatible. In Eq. (45) σ^1 is the Pauli matrix and this is the canonical Darboux form of first order Hamiltonian operators. The equations of polytropic gas dynamics admit two infinite hierarchies of conserved Hamiltonians which are in involution with respect to Poisson brackets defined by all three of these Hamiltonian operators. In the first set, which is called Eulerian,[13] the Hamiltonian densities are given by

$$\mathcal{H}^E_{-1}=\rho, \tag{48}$$

$$\mathcal{H}^E_0=u\rho, \tag{49}$$

$$\mathcal{H}^E_1=\frac{1}{2}u^2\rho+\frac{1}{\gamma(\gamma-1)}\rho^{\gamma}, \tag{50}$$

$$\mathcal{H}^E_2=\frac{1}{6}u^3\rho+\frac{1}{\gamma(\gamma-1)}u\rho^{\gamma}, \tag{51}$$

$$\mathcal{H}^E_3=\frac{1}{24}u^4\rho+\frac{1}{2\gamma(\gamma-1)}u^2\rho^{\gamma}+\frac{1}{2\gamma(\gamma-1)^2(2\gamma-1)}\rho^{2\gamma-1}, \tag{52}$$

$$\cdots,$$

where (49) is the momentum, (50) is the familiar Hamiltonian function, the Casimir is in (48) and the rest consist of higher Hamiltonians. Therefore, the Euler series is the distinguished one in the terminology of Sec. II. The second series

$$\mathcal{H}^L_{-1}=u, \tag{53}$$

$$\mathcal{H}^L_0=\frac{1}{2}(\gamma-2)u^2+\frac{1}{\gamma-1}\rho^{\gamma-1}, \tag{54}$$

$$\mathcal{H}^L_1=\frac{1}{6}(\gamma-2)u^3+\frac{1}{\gamma-1}u\rho^{\gamma-1}, \tag{55}$$

$$\mathcal{H}^L_2=\frac{1}{24}(\gamma-2)u^4+\frac{1}{4(\gamma-1)}u^2\rho^{\gamma-1}+\frac{1}{2(\gamma-1)^2(2\gamma-3)}\rho^{2(\gamma-1)}, \tag{56}$$

$$\cdots$$

is the Lagrangian series which starts with the Casimir (53). Note that for $\gamma=2$ this series is no longer polynomial as logarithms will enter and the same remark holds for integer and half-integer values of γ in both series.

Finally, we note that the recursion operator $R_2^1=J_2J_1^{-1}$ can be used to write infinitely many Hamiltonian operators by letting it to act n times on J_1. However, in general none of these operators will be local. In particular we note that

$$R_3^1=J_3(J_1)^{-1}\neq(R_2^1)^2, \quad J_3\neq J_2J_1^{-1}J_2, \tag{57}$$

except in the case of shallow water waves where $\gamma=2$ which admits extension to integrable dispersive equations.

Next, there is a third order Hamiltonian operator[17] which was obtained from Sheftel's remarkable recursion operator[18]

$$J_4=DU_x^{-1}DU_x^{-1}\sigma^1D, \tag{58}$$

where

$$U=\begin{pmatrix} u & \rho \\ \dfrac{1}{\gamma-2}\rho^{\gamma-2} & u \end{pmatrix} \tag{59}$$

which is only compatible with J_0. Higher conserved Hamiltonians start with the density[18,19]

$$\hat{\mathcal{H}}_{-1}^{SV(E)}=\frac{\rho_x}{u_x^2-\rho^{\gamma-3}\rho_x^2} \tag{60}$$

and its flux,

$$\mathcal{F}_{-1}^{SV(L)}=-\frac{u_x}{u_x^2-\rho^{\gamma-3}\rho_x^2}, \tag{61}$$

which is the first in an infinite hierarchy of non-polynomial conservation laws for gas dynamics that depend on space derivatives.

We will be interested in the Lagrangian formulation of the equations of polytropic gas dynamics (44) that correspond to all these Hamiltonian structures. Introducing the Clebsch potentials[20]

$$u=\varphi_x, \quad \rho=\psi_x \tag{62}$$

we have the first Lagrangian representation for this system

$$\mathcal{L}_1^\gamma=\mathcal{H}_{-1}^L\psi_t+\mathcal{H}_{-1}^E\varphi_t-2\mathcal{H}_1^E(\varphi_x,\psi_x) \tag{63}$$

but using the recursion operators $J_2J_1^{-1}$ and $J_3J_1^{-1}$ we find two further Lagrangians

$$\mathcal{L}_2^\gamma=\mathcal{H}_0^L\psi_t+\mathcal{H}_0^E\varphi_t-2\mathcal{H}_2^E(\varphi_x,\psi_x), \tag{64}$$

$$\mathcal{L}_3^\gamma=\mathcal{H}_1^L\psi_t+\mathcal{H}_1^E\varphi_t-2\mathcal{H}_3^E(\varphi_x,\psi_x), \tag{65}$$

which are local functionals of the Clebsch potentials. The Lagrangian obtained through the action of the recursion operator $J_4J_1^{-1}$ is the most interesting one. Because J_4 is a third order operator, the fourth Lagrangian

$$\mathcal{L}_4^\gamma=\mathcal{H}_{-1}^{SV(E)}u_t+\mathcal{F}_{-1}^{SV(L)}\rho_t-2\mathcal{H}_{-1}^E(\varphi_x,\psi_x), \tag{66}$$

$$\mathcal{L}_4^\gamma=\frac{\rho_xu_t-u_x\rho_t}{u_x^2-\rho^{\gamma-3}\rho_x^2}-2\rho \tag{67}$$

is *free*, i.e., it does not contain any Lagrange multipliers, and furthermore it is *local in the original fields*, namely the density and velocity. This is the first time it has been possible to write down such a Lagrangian for polytropic gas dynamics. It was made possible only because of bi-Hamiltonian structure with a pair of first and third order Hamiltonian operators. Here we find another remarkable situation in that the number of Lagrangians that we can construct by repeated application of Sheftel's recursion operator $J_4 J_1^{-1}$ is *infinite* in number. All of these Lagrangians will be *free* and *local* in the original field variables ρ and u.

Now we come to lower Lagrangians that will arise from Miura transformations. The Miura transformations that bring the Hamiltonian operators (46) and (47) to the Darboux form of (45) are point transformations for equations of hydrodynamic type. Dubrovin and Novikov had pointed out that first order Hamiltonian operators for equations of hydrodynamic type are given by

$$J^{ik}=g^{ik}D-g^{im}\Gamma^k_{mn}u^n_x \tag{68}$$

where g_{ik} are the components of a Riemannian metric which is flat by virtue of the Jacobi identities. The Miura transformation provides manifestly flat coordinates for this metric. For example from (46) we find the flat metric

$$ds_2^2=\frac{2}{4\rho^{\gamma-1}-(\gamma-1)^2u^2}[\rho^{\gamma-2}\,d\rho^2-(\gamma-1)u\,d\rho\,du+\rho\,du^2] \tag{69}$$

and it can be verified that the Miura transformation

$$\rho=rp, \qquad u=\frac{1}{\gamma-1}(r^{\gamma-1}+p^{\gamma-1}) \tag{70}$$

brings it into the manifestly flat form $2\,dr\,dp$. In these variables we find the first modified equations of gas dynamics

$$\begin{aligned} &r_t+\frac{\gamma}{\gamma-1}(r^{\gamma-1}+p^{\gamma-1})r_x+\gamma rp^{\gamma-2}p_x=0,\\ &p_t+\gamma pr^{\gamma-2}r_x+\frac{\gamma}{\gamma-1}(r^{\gamma-1}+p^{\gamma-1})p_x=0, \end{aligned} \tag{71}$$

and linear combinations of these equations with variable coefficients give Eqs. (44) of gas dynamics. Introducing the potentials

$$r=\chi_x, \quad p=v_x, \tag{72}$$

we have the Lagrangian

$$\mathcal{L}_0^{\gamma\text{full}}=\chi_x v_t+v_x\chi_t-2\mathcal{H}_0^E+\lambda\left(u-\frac{\chi_x^{\gamma-1}+v_x^{\gamma-1}}{\gamma-1}\right)+\sigma(\rho-\chi_x v_x), \tag{73}$$

where $\mathcal{H}_0^E$ is the momentum (49) expressed in terms of the potentials χ and v. Transforming to the first modified variables r, p we get $\tilde{J}_1$, $\tilde{J}_2=J_1$ and $\tilde{J}_3$ defining the tri-Hamiltonian structure of Eqs. (71). Now there is a new lower Lagrangian that we can construct from the recursion operator $\tilde{J}_1\tilde{J}_2^{-1}$. We find

$$\tilde{J}_1=\begin{pmatrix} (1-\gamma)[rp^{\gamma-2}\Delta D+Dp^{\gamma-2}\Delta] & [(\gamma-2)r^{\gamma-1}+p^{\gamma-1}]\Delta D \\ [r^{\gamma-1}+(\gamma-2)p^{\gamma-1}]\Delta D & +D[r^{\gamma-1}+(\gamma-2)p^{\gamma-1}]\Delta \\ +D[(\gamma-2)r^{\gamma-1}+p^{\gamma-1}]\Delta & (1-\gamma)[pr^{\gamma-2}\Delta D+Dpr^{\gamma-2}\Delta] \end{pmatrix}, \tag{74}$$

$$\Delta \equiv \frac{1}{(\gamma-1)(r^{\gamma-1}-p^{\gamma-1})^2},$$

where the labeling of the variables is in the order r and p. The new Lagrangian is given by

$$\mathcal{L}_{-1}^{\gamma\text{full}} = \frac{\chi_x v_t - v_x \chi_t}{\chi_x^{\gamma-1} - v_x^{\gamma-1}} - \mathcal{H}_{-1}^{E} + \lambda\left(u - \frac{\chi_x^{\gamma-1} + v_x^{\gamma-1}}{\gamma-1}\right) + \sigma(\rho - \chi_x v_x), \tag{75}$$

where the momenta do not belong to the polynomial series of conserved Hamiltonians. However, we can identify the lower momenta from this Lagrangian

$$\mathcal{H}_{-2}^{\gamma\pm} = \xi_{\pm}^{(3-\gamma)/(\gamma-1)}(\xi_+\xi_-)^{-1/2}, \quad \xi^2 + (\gamma-1)u\xi + \rho^{\gamma-1} = 0$$

where $\pm$ refers to Eulerian and Lagrangian series as well as the roots of the quadratic equation.

We now turn to the third Hamiltonian structure (47) defined by the flat metric

$$ds_3^2 = -\frac{8(\gamma-1)^2}{[(\gamma-1)^2u^2 - 4\rho^{\gamma-1}]^2}\left\{u\rho^{\gamma-2}\,d\rho^2 - \frac{1}{2(\gamma-1)}[(\gamma-1)^2u^2 + 4\rho^{\gamma-1}]d\rho\,du + u\rho\,du^2\right\}$$
$$= 2\,dq\,dw, \tag{76}$$

and the coordinate transformation that brings it to the manifestly flat form is given by

$$q = [(\gamma-1)^2u^2 - 4\rho^{\gamma-1}]^{[(\gamma-3)/2(1-\gamma)]}, \tag{77}$$

$$w = \int^z \frac{1}{\sqrt{1+\xi^2}}\,\xi^{(\gamma-3)/(1-\gamma)}\,d\xi, \tag{78}$$

$$z = \sinh\left\{\frac{1}{2}\ln\frac{(\gamma-1)u + 2\rho^{(\gamma-1)/2}}{(\gamma-1)u - 2\rho^{(\gamma-1)/2}}\right\},$$

where, in general, the last integral cannot be done in closed form. For some specific values of γ the integral (78) is elementary as in the notable case of Chaplygin–Born–Infeld. But this paper is devoted to the general case of polytropic gas dynamics and we shall not consider inverting (77), (78) to obtain u, ρ as functions of q and w. We shall only remark that after this inversion we can obtain two more new Lagrangians.

The Lagrangians (63), (64), and (65) for polytropic gas dynamics are examples illustrating the general expression (12) for higher Lagrangians. For equations of hydrodynamic type there is no dispersion and hence $\mathcal{G}$ vanishes identically. We have given only two (73), (75) of the four lower Lagrangians because the integral (78) must be carried out before we arrive at the second modified equations of gas dynamics which will lead to two further new Lagrangians. Certainly the Lagrangian (67) which is derived from bi-Hamiltonian structure with a compatible pair of first and third order operators according to (12) is the most remarkable one because this is the first time it has been possible to write an unconstrained Lagrangian for polytropic gas dynamics that is local in the original field variables, namely the density and velocity. Furthermore it is only the first element in an infinite series of such Lagrangians.

V. KAUP–BOUSSINESQ SYSTEM

Gas dynamics with $\gamma=2$ governs the behavior of long waves in shallow water. From the point of view of complete integrability it is a remarkable case, because in this case we find several completely integrable dispersive generalizations of Eqs. (44). Most prominent among them is the well-known Kaup–Boussinesq system[21]

$$u_t=\left(\frac{u^2}{2}+p\right)_x, \quad \rho_t=(u\rho+\varepsilon^2 u_{xx})_x, \tag{79}$$

which admits tri-Hamiltonian structure. The first Hamiltonian structure is given by the Hamiltonian operator (45) and

$$J_2^{KBq}=\begin{pmatrix} D & \frac{1}{2}Du \\ \frac{1}{2}uD & \frac{1}{2}(\rho D+D\rho)+\varepsilon^2 D^3 \end{pmatrix}, \tag{80}$$

where D^{-1} denotes the principal value integral, is the second Hamiltonian operator for the Kaup–Boussinesq system. In the limit $\varepsilon\to 0$ this Hamiltonian operator reduces to (46) with $\gamma=2$. The recursion operator is given by

$$R_2^{1\,KBq}=\begin{pmatrix} \frac{1}{2}u+\frac{1}{2}u_x D^{-1} & 1 \\ \varepsilon^2 D^2+\rho+\frac{1}{2}\rho_x D^{-1} & \frac{1}{2}u \end{pmatrix} \tag{81}$$

and there is a third local Hamiltonian operator obtained by the action of the recursion operator $J_2^{KBq}=(R_2^{1KBq})^2 J_0$ as in the $\gamma=2$ case of gas dynamics.

The conserved Hamiltonians in the Eulerian and Lagrangian series are

$$\mathcal{H}_{-1}^{KBq}=\rho, \tag{82}$$

$$\mathcal{H}_{0}^{KBq}=u\rho, \tag{83}$$

$$\mathcal{H}_{1}^{KBq}=\tfrac{1}{2}(\rho u^2+\rho^2+\varepsilon^2 u u_{xx}), \tag{84}$$

$$\mathcal{H}_{2}^{KBq}=\tfrac{1}{2}[\rho u^3+3\rho^2 u-\varepsilon^2(4u_x\rho_x+3uu_x^2)], \tag{85}$$

$$H_{3}^{KBq}=\tfrac{1}{4}u^4\rho+\tfrac{3}{2}u^2\rho^2+\tfrac{1}{2}\rho^3+\varepsilon^4 u_{xx}^2-\varepsilon^2(\tfrac{5}{2}\rho u_x^2+4uu_x\rho_x+\rho_x^2+\tfrac{3}{2}u^2u_x^2), \tag{86}$$

$$\cdots,$$

and the degeneracy in the $\gamma=2$ case of gas dynamics is repeated in its dispersive generalization. In particular, the Lagrangian and Eulerian series coincide apart from a relabeling

$$\begin{gathered} \mathcal{H}_{-2}^{KBq(E)}=u=\mathcal{H}_{-1}^{KBq(L)}, \\ \mathcal{H}_{-1}^{KBq(E)}=\rho=\mathcal{H}_{0}^{KBq(L)}, \\ \cdots, \\ \mathcal{H}_{-2+n}^{KBq(E)}=\mathcal{H}_{-1+n}^{KBq(L)}, \end{gathered} \tag{87}$$

that is dictated by the recursion operator.

With the aid of the Clebsch potentials

$$u=\varphi_x, \qquad \rho=\psi_x, \tag{88}$$

we obtain

$$\mathcal{L}_1^{KBq}=\mathcal{H}_{-1}^{KBq}\varphi_t+\mathcal{H}_{-2}^{KBq}\psi_t-2\mathcal{H}_1^{KBq}(\varphi_x,\psi_x,\varphi_{xx},\psi_{xx},\ldots) \tag{89}$$

for the first Lagrangian. Using the technique we have presented in Sec. II we shall now construct higher Lagrangians. These three local Hamiltonian structures enable us to construct two new Lagrangians

$$\mathcal{L}_2^{KBq}=(\mathcal{H}_0^{KBq}+\varepsilon^2\varphi_{xxx})\varphi_t+\mathcal{H}_{-1}^{KBq}\psi_t-2\mathcal{H}_2^{KBq}(\varphi_t,\psi_x,\varphi_{xx},\psi_{xx},\ldots) \tag{90}$$

and

$$\mathcal{L}_3^{KBq}=[\mathcal{H}_1^{KBq}+\varepsilon^2(2\psi_{xxx}+\varphi_{xx}^2+\varphi_x\varphi_{xxx})]\varphi_t+(\mathcal{H}_0^{KBq}+\varepsilon^2\varphi_{xxx})\psi_t-2\mathcal{H}_3^{KBq}(\varphi_x,\psi_x,\ldots) \tag{91}$$

for the Kaup–Boussinesq system. The determination of $\mathcal{G}_{\beta;[i]}$ is according to Eq. (12) with $\beta=2,3$ and $[2]=[1]-1$ because of the relabeling difference (87) between the Lagrangian and Eulerian series. Note that the momentum map which is the coefficient of ϕ_t in (90) is exactly the same as the momentum in front of ψ_t in (91). The reason for this goes back to the degeneration of the Eulerian and Lagrangian series into one and the fact that it is the momentum map that is the important element in the general construction (12). In the dispersionless limit the Lagrangians (89), (90), (91) reduce to the gas dynamics Lagrangians (63), (64), and (65) with $\gamma=2$.

VI. KAUP–BROER SYSTEM

There is another completely integrable dispersive version of the $\gamma=2$ case of gas dynamics which is the Kaup–Broer system.[21,22] The triangular invertible differential substitution

$$\rho=\eta+\varepsilon u_x \tag{92}$$

transforms the Kaup–Boussinesq system (79) into the Kaup–Broer system

$$u_t=uu_x+\eta_x+\varepsilon u_{xx},\qquad \eta_t=(\eta u)_x-\varepsilon\eta_{xx}, \tag{93}$$

which also has three local Hamiltonian structures.[23] For the Kaup-Broer system the conserved Hamiltonians in the Eulerian series are given by

$$\mathcal{H}_0^{KBr}=u\eta, \tag{94}$$

$$\mathcal{H}_1^{KBr}=\tfrac{1}{2}[u^2\eta+\eta^2-2\varepsilon\eta u_x], \tag{95}$$

$$\mathcal{H}_2^{KBr}=\tfrac{1}{2}[u^3\eta+3u\eta^2+6\varepsilon\eta uu_x-4\varepsilon^2u_x\eta_x], \tag{96}$$

$$\mathcal{H}_3^{KBr}=\tfrac{1}{4}u^4\eta+\tfrac{3}{2}u^2\eta^2+\tfrac{1}{2}\eta^3+\varepsilon(\tfrac{3}{2}\eta^2u_x-u^3\eta_x)+\varepsilon^2(2u^2\eta_{xx}-\eta u_x^2-\eta_x^2)-2\varepsilon^2\eta_xu_{xx}, \tag{97}$$

which can be obtained from (83)–(85) through the substitution (92). The first Hamiltonian operator for the Kaup–Broer system is given by (45) and the second Hamiltonian operator

$$J_1^{KBr}=\begin{pmatrix} D & \tfrac{1}{2}Du+\varepsilon D^2 \\ \tfrac{1}{2}uD-\varepsilon D^2 & \tfrac{1}{2}(\eta D+D\eta) \end{pmatrix} \tag{98}$$

can be obtained from (80) of the Kaup–Boussinesq system using the substitution (92).

For Kaup–Broer system we introduce the potentials

$$\eta=w_x,\qquad \psi=w+\varepsilon\varphi_x, \tag{99}$$

and arrive at the first Lagrangian

$$\mathcal{L}_1^{KBr}=\mathcal{H}_{-1}^{KBq}\varphi_L+\mathcal{H}_{-2}^{KBr}w_t-2\mathcal{H}_1^{KBr}(w_x,\varphi_x,w_{xx},\varphi_{xx},\ldots), \tag{100}$$

but now we can derive two further Lagrangians using the recursion operator obtained from the Hamiltonian operators (98) and (45). Following our procedure of Sec. II we find the second Lagrangian

$$\mathcal{L}_2^{KBr}=(\mathcal{H}_0^{KBr}-2\varepsilon w_{xx})\varphi_t+\mathcal{H}_{-1}^{KBr}w_t-2\mathcal{H}_2^{KBr}(w_x,\varphi_x,w_{xx},\varphi_{xx},\ldots) \tag{101}$$

which is the same as the Lagrangian of Kaup–Boussinesq system (91) subject to the differential substitution (92). Similarly we find

$$\mathcal{L}_3^{KBr}=(\mathcal{H}_1^{KBr}+2\varepsilon^2 w_{xxx})\varphi_t+(\mathcal{H}_0^{KBr}+\varepsilon\varphi_x\varphi_{xx}+\varepsilon^2\varphi_{xxx})w_t-2\mathcal{H}_3^{KBr}(\varphi_x,w_x,\ldots) \tag{102}$$

for the third Lagrangian for the Kaup–Broer equations (93). As in the case of Kaup–Boussinesq, these Lagrangians reduce to $\gamma=2$ gas dynamics Lagrangians in the dispersionless limit. In the Kaup–Broer Lagrangians we find another example of the general formula (12) for Lagrangians.

VII. NONLINEAR SHRÖDINGER EQUATION

We shall consider the nonlinear Shrödinger equation in the two-component real version

$$v_t=\left[\frac{v^2}{2}+\eta+\varepsilon^2\left(\frac{\eta_{xx}}{\eta}-\frac{\eta_x^2}{2\eta^2}\right)\right]_x,\qquad \eta_t=(\eta v)_x, \tag{103}$$

which is a reaction–diffusion system. Again this reduces to the $\gamma=2$ case of gas dynamics in the dispersionless limit. This version of NLS can be obtained by another triangular differential substitution

$$u=v+\varepsilon\,\eta_x/\eta \tag{104}$$

from the Kaup–Broer system.

NLS has the same first local Hamiltonian structure (45) as in the case of Kaup–Boussinesq or Kaup–Broer systems. Once again the second Hamiltonian operator for NLS can be found by the transformation (104) from the second Hamiltonian operator (98) of the Kaup–Broer system. Thus for the two-component real version of NLS the second Hamiltonian operator is given by

$$J_2^{\mathrm{NLS}}=\begin{pmatrix} D+\varepsilon^2\begin{Bmatrix}\eta^{-1}D^3+D^3\eta^{-1}\\ -\frac{1}{2}[(\eta^{-1})_{xx}D+D(\eta^{-1})_{xx}]\end{Bmatrix} & \frac{1}{2}Dv \\ \frac{1}{2}vD & \frac{1}{2}(\eta D+D\eta)\end{pmatrix} \tag{105}$$

and the conserved Hamiltonians are

$$\mathcal{H}_{-2}^{\mathrm{NLS}}=v, \tag{106}$$

$$\mathcal{H}_{-1}^{\mathrm{NLS}}=\eta, \tag{107}$$

$$\mathcal{H}_0^{\mathrm{NLS}}=v\,\eta, \tag{108}$$

$$\mathcal{H}_1^{\mathrm{NLS}}=\frac{1}{2}\left(\eta v^2+\eta^2-\varepsilon^2\frac{\eta_x^2}{\eta}\right), \tag{109}$$

$$\mathcal{H}_2^{\mathrm{NLS}}=\frac{1}{2}\left[\eta v^2+3v\,\eta^2+\varepsilon^2\left(v_x\eta_x-3\frac{v\,\eta_x^2}{\eta}\right)\right], \tag{110}$$

$$\mathcal{H}_3^{\mathrm{NLS}}=\frac{3}{4}\eta^2v^2+\frac{1}{4}\eta^3+\frac{1}{8}v^4\eta+\varepsilon^4\left(\frac{\eta_{xx}^2}{2\eta}-\frac{5\eta_x^4}{24\eta^3}\right)+\varepsilon^2\left(v^2\eta_{xx}-\frac{5}{4}\eta_x^2-\frac{3}{4}\frac{\eta_x^2}{\eta}v^2-\frac{1}{2}v_x^2\eta\right), \tag{111}$$

$$\cdots$$

which forms an infinite sequence combining both Eulerian and Lagrangian series according to (87).

In order to construct the Lagrangians for NLS we introduce the potentials

$$v=z_x, \quad z=\varphi-\varepsilon\ln w_x, \tag{112}$$

together with the definition (99) and the first Lagrangian

$$\mathcal{L}_1^{\mathrm{NLS}}=\mathcal{H}_{-1}^{\mathrm{NLS}}z_t+\mathcal{H}_{-2}^{\mathrm{NLS}}w_t-2\mathcal{H}_1^{\mathrm{NLS}}(w_x,z_x,\ldots) \tag{113}$$

is the classical result. Once again we shall use the techniques of Sec. II to construct higher Lagrangians with the recursion operator obtained from (105) and (45). We obtain two higher Lagrangians for NLS,

$$\mathcal{L}_2^{\mathrm{NLS}}=\mathcal{H}_0^{\mathrm{NLS}}z_t+\left[\mathcal{H}_{-1}^{\mathrm{NLS}}+\varepsilon^2\left(\frac{w_{xxx}}{w_x}-\frac{w_{xx}^2}{w_x^2}\right)\right]w_t-2\mathcal{H}_2^{\mathrm{NLS}}(w_x,z_x,\ldots) \tag{114}$$

and

$$\mathcal{L}_3^{\mathrm{NLS}}=\left\{\mathcal{H}_0^{\mathrm{NLS}}+\varepsilon^2\left[z_{xxx}+\left(\frac{z_xw_{xx}}{w_x}\right)_x\right]\right\}w_t+(\mathcal{H}_1^{\mathrm{NLS}}+2\varepsilon^2w_{xxx})z_t-2\mathcal{H}_3^{\mathrm{NLS}}(z_x,w_x,\ldots), \tag{115}$$

that are local functionals of the potentials. Here again, in the dispersionless limit we find the $\gamma=2$ gas dynamics Lagrangians. The remarkable strength of the general expression (12) for new Lagrangians is manifest.

VIII. BOUSSINESQ EQUATION

In order to discuss the bi-Hamiltonian structure and the Lagrangians for the Boussinesq equation in a unified framework we first turn to its dispersionless limit. For polytropic gas dynamics we had

$$\rho_t=(\rho u)_x, \quad u_t=\left(\frac{u^2}{2}+\frac{\rho^{\gamma-1}}{\gamma-1}\right)_x \tag{116}$$

with its first nontrivial commuting flow

$$\rho_y=u_x, \quad u_y=\left(\frac{\rho^{\gamma-2}}{\gamma-2}\right)_x, \tag{117}$$

both of which reduce to a second order quasi-linear wave equation.[13] If we express Boussinesq equation in the form

$$\rho_{yy}-(\tfrac{1}{2}\rho^2-\varepsilon^2\rho_{xx})_{xx}=0 \tag{118}$$

or

$$\rho_y = u_x, \quad u_y = \left(\frac{\rho^2}{2} - \varepsilon^2 \rho_{xx} \right)_x \tag{119}$$

as a first order evolutionary system and compare its dispersionless limit to polytropic gas dynamics, we find that it corresponds to the commuting flow for $\gamma = 4$. The completely integrable dispersive equation

$$\rho_t = [\rho u - 2\varepsilon^2 u_{xx}]_x, \quad u_t = \left[\frac{u^2}{2} + \frac{1}{3}\rho^3 - \frac{3}{2}\varepsilon^2 (2\rho\rho_{xx} + \rho_x^2) + 2\varepsilon^4 \rho_{xxxx} \right]_x \tag{120}$$

is the commuting flow to the Boussinesq equation.

This system admits bi-Hamiltonian structure[25] with the Hamiltonian operators (45) and

$$J_2^B = \begin{pmatrix} \rho D + D\rho - 8\varepsilon^2 D^3 & 3uD + 2u_x \\ 3Du - 2u_x & 8(\rho^2 D + D\rho^2) + 8\varepsilon^4 D^5 - \varepsilon^2 [5(\rho D^3 + D^3 \rho) - 3(\rho_{xx} D + D\rho_{xx})] \end{pmatrix} \tag{121}$$

which are compatible. The conserved Hamiltonian densities for the Boussinesq system are given by

$$\mathcal{H}_{-1}^E = \rho, \tag{122}$$

$$\mathcal{H}_0^E = \rho u, \tag{123}$$

$$\mathcal{H}_1^E = \tfrac{1}{4}[2\rho u^2 + \tfrac{1}{3}\rho^4 + \varepsilon^2 (6\rho\rho_x^2 + 4u_x^2) + 4\varepsilon^4 \rho_{xx}^2], \tag{124}$$

$$\begin{aligned} \mathcal{H}_2^E = \tfrac{1}{28}[& \tfrac{14}{3}\rho u^3 + \tfrac{7}{3}\rho^4 u + 14\varepsilon^2 (2uu_x^2 + 4\rho^2 \rho_x u_x + 3u\rho\rho_x^2) \\ & + 28\varepsilon^4 (u\rho_{xx}^2 + \rho_x^2 u_{xx} + 4\rho_{xx} u_{xx}) + 64\varepsilon^6 \rho_{xxx} u_{xxx}] \end{aligned} \tag{125}$$

in the Eulerian sequence and we also have

$$\mathcal{H}_{-1}^L = u, \tag{126}$$

$$\mathcal{H}_0^L = u^2 + \tfrac{1}{3}\rho^3 + \varepsilon^2 \rho_x^2, \tag{127}$$

$$\mathcal{H}_1^L = \tfrac{1}{3}u^3 + \tfrac{1}{3}\rho^3 u - \varepsilon^2 u(4\rho\rho_{xx} + 3\rho_x^2) + \tfrac{16}{5}\varepsilon^4 u_{xx}\rho_{xx}, \tag{128}$$

$$\begin{aligned} \mathcal{H}_2^L = & \tfrac{2}{3}u^4 + \tfrac{4}{3}\rho^3 u^2 + \tfrac{4}{45}\rho^6 + \varepsilon^2 (\tfrac{28}{3}\rho^3 \rho_x^2 + 4u^2 \rho_x^2 + 32\rho u \rho_x u_x + 8\rho^2 u_x^2) + \varepsilon^4 (\tfrac{136}{5}\rho^2 \rho_{xx}^2 - \tfrac{248}{5}\rho_x^4 \\ & + \tfrac{128}{5} u u_{xx} \rho_{xx} + \tfrac{16}{5} u_x^2 \rho_{xx} + \tfrac{96}{5}\rho u_{xx}^2) + \varepsilon^6 (32\rho\rho_{xxx}^2 - \tfrac{592}{15}\rho_{xx}^3 + \tfrac{64}{5} u_{xxx}^2) + \tfrac{64}{5}\varepsilon^8 \rho_{xxxx}^2 \end{aligned} \tag{129}$$

in the Lagrangian sequence. The Hamiltonian function of Boussinesq system with the first order Hamiltonian operator in Darboux form (45) is $\frac{1}{2}H_0^L$. We note that the system (119) for the Boussinesq equation differs from all dispersive integrable examples we encountered earlier in that its familiar Hamiltonian function (128) is in the Lagrangian sequence. This is because Boussinesq equation belongs to the family of commuting flows of the regular gas dynamics hierarchy. The first commuting higher flow for the Boussinesq system (120) has the Hamiltonian function (124) in the Eulerian series.

By introducing potentials

$$u = \varphi_x, \quad \rho = \psi_x \tag{130}$$

we can obtain two local Lagrangian densities for the Boussinesq system. First we have the classical Lagrangians

$$\mathcal{L}_1^{B(L)} = \mathcal{H}_{-1}^{L\ \gamma=4}\psi_y + \mathcal{H}_{-1}^{E\ \gamma=4}\varphi_y - \mathcal{H}_0^{L\ \gamma=4}, \tag{131}$$

$$\mathcal{L}_1^{B(E)} = \mathcal{H}_{-1}^{L\ \gamma=4}\psi_t + \mathcal{H}_{-1}^{L\ \gamma=4}\varphi_t - 2\mathcal{H}_1^{E\ \gamma=4} \tag{132}$$

for Boussinesq system and its first nontrivial commuting flow (120). The second Lagrangians are given by

$$\mathcal{L}_2^{B(L)} = (\mathcal{H}_0^{E\ \gamma=4} - 4\varepsilon^2\varphi_{xxx})\varphi_y + [\mathcal{H}_0^{L\ \gamma=4} - 5\varepsilon^2(\psi_x\psi_{xx})_x + 4\varepsilon^4\psi_{xxxxx}]\psi_y - \mathcal{H}_1^{L\ \gamma=4}, \tag{133}$$

$$\mathcal{L}_2^{B(E)} = (\mathcal{H}_0^{E\ \gamma=4} - 4\varepsilon^2\varphi_{xxx})\varphi_t + [\mathcal{H}_0^{L\ \gamma=4} - 5\varepsilon^2(\psi_x\psi_{xx})_x + 4\varepsilon^4\psi_{xxxxx}]\psi_t - 2\mathcal{H}_2^{E\ \gamma=4}, \tag{134}$$

according to the general construction of Lagrangians in (12). Here we see also that the Lagrangian for the commuting flow is obtained by flipping the Hamiltonian functions between the Lagrangian and Eulerian series while keeping the momenta fixed. In Sec. IV we had constructed Lagrangians for gas dynamics using the Hamiltonians from the Eulerian series in the potential part of the Lagrangian. The general formula (12) can readily be used to construct Lagrangians for the commuting flow (119) by this simple flip in the potential.

IX. CONCLUSION

This is the first time it has been possible to write an unconstrained Lagrangian for polytropic gas dynamics that is local in the original field variables, namely the density and velocity. Earlier variational principles enforced the continuity equation through Lagrange multipliers.[26,27] It is a result of the general expression (12) that serves to identify immediately multi-Lagrangians for completely integrable systems. What is even more remarkable is that this is only the first element in an infinite series of such local Lagrangians for polytropic gas dynamics.

It is worth emphasizing again that the scheme we have presented in Sec. II is a universal one for the construction of multi-Lagrangians appropriate to evolutionary systems. The expressions (12) and (21) for Lagrangians of completely integrable systems has general validity. We note that (12) with $\alpha=1$ is true even in the case of nonintegrable equations, provided the equations are presented in the form of conservation laws and the system admits one further conserved quantity, namely the Hamiltonian. We have discussed in detail the higher Lagrangians for the completely integrable nonlinear evolution equations of polytropic gas dynamics, Kaup–Boussinesq, Kaup–Broer, NLS, and Boussinesq equations all of which bear out the universal applicability of (12) in the construction of higher Lagrangians. We have also presented the lower Lagrangians (21) fully for KdV and partially for gas dynamics owing to the difficulty of writing the second modified variables in closed form.

The invariance group of these multi-Lagrangians and their Noether currents should prove to be of interest in discovering new hidden symmetries of fluid mechanics. We did not discuss this important issue here. Recently Jackiw and co-workers[28] have used hidden symmetries in the classical Lagrangian for fluid mechanics to construct very interesting field theory models of fluid mechanics. Multi-Lagrangians may prove to be of interest in this connection also.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 3 MARCH 2002

Perturbation theory for nearly integrable multicomponent nonlinear PDEs

V. S. Shchesnovich[a)]
Department of Mathematics and Applied Mathematics, University of Cape Town, Private Bag 7701 Rondebosch, South Africa

(Received 27 April 2001; accepted for publication 12 December 2001)

The Riemann–Hilbert problem associated with the integrable PDE is used as a nonlinear transformation of the nearly integrable PDE to the spectral space. The temporal evolution of the spectral data is derived with account for arbitrary perturbations and is given in the form of exact equations, which generate the sequence of approximate ordinary differential equations in successive orders with respect to the perturbation. For vector nearly integrable PDEs, embracing the vector nonlinear Schrödinger and complex modified Korteweg–de Vries equations, the main result is formulated in a theorem. For a single vector soliton the evolution equations for the soliton parameters and first-order radiation are given in explicit form. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1448135]

I. INTRODUCTION

Multicomponent (or coupled) nonlinear PDEs have been a subject of considerable interest for many years (see, for instance, Ref. 1, and references therein). Recent revival of interest in multicomponent PDEs is due to new discoveries and technological advances in nonlinear optics and physics of condensed matter. An important example is the incoherent spatial optical solitons, or self-trapped spatially incoherent light beams, recently experimentally observed in nonlinear media,[2] which are described by the multicomponent nonlinear Schrödinger (NLS) equations.[3] Another example of possible application of the coupled NLS equations is the creation and dynamics of solitary waves in the multispecies Bose–Einstein condensates.[4] Similar models of coupled nonlinear PDEs appear in the wavelength division multiplexing, i.e., copropagation of pulses in an optical fiber on beams with different wavelengthes[5–7] and in other important applications.[8,9]

Some of the multicomponent models are integrable. Integrable multicomponent PDEs have another specific feature, which makes them important for applications as zero-approximation models for analytical description of the real phenomena. It has been known for quite some time that dimensional reductions of matrix generalizations of the integrable PDEs, such as the NLS and Korteweg–de Vries (KdV) equations, can produce a variety of new integrable equations.[10] For instance, some of the coupled NLS equations are integrable reductions of the general matrix NLS equation. The N-dimensional matrix NLS equation is the simplest integrable PDE associated with the $(N+1)$-dimensional Zakharov–Shabat spectral problem.[11–13] Recently a variety of integrable coupled higher-order NLS equations was discovered,[14–16] which are important in view of applications to the soliton propagation of subpicosecond pulses in optical fiber.[17–19] Some of these integrable PDEs arise as dimensional reductions of the matrix complex modified KdV (cmKdV) equation, which is also associated with the Zakharov–Shabat spectral problem.

In most cases, the multicomponent PDE is not integrable. However, frequently the terms destroying integrability contain small parameters and the nonintegrable equation can be considered as a perturbation of the integrable one. In this case, a perturbation theory is required for analytical description of the effect of small perturbations. For instance, one is especially interested

a)On leave from the Division for Optical Problems in Information Technologies, National Academy of Sciences of Belarus, Zhodinskaya St. 1/2, 220141 Minsk-41, Belarus; electronic mail: valery@maths.uct.ac.za

in the dynamics of solitons in nearly integrable PDEs. Soliton solutions to multicomponent equations have many parameters, and their evolution may exhibit a variety of new interesting regimes. Therefore, it is necessary to have at hand a perturbation theory for multicomponent nearly integrable equations. Such perturbation theory is developed in the present paper.

Perturbation theory for nearly integrable PDEs has a long history.[20–45] There are two basic approaches in the perturbation theory based on the inverse scattering transform (IST) method. The first one originated in works of Kaup[20] and Karpman and Maslov,[21] where the perturbation theory was developed for nearly integrable PDEs associated in the integrable limit with the 2×2 matrix Zakharov–Shabat spectral problem. A quite different approach originated from other works (Refs. 22–26). It was found that an integro-differential operator, generating the whole hierarchy of integrable PDEs related to a given spectral problem, called the recursion operator, has a complete set of eigenfunctions, which can be used for the perturbation expansion. Several other methods, not related to the IST, were applied for description of the perturbed soliton dynamics. For instance, a method based on the Green functions was developed in Ref. 29. The IST-independent perturbation theories for solitons are usually referred to as the direct perturbation theories (see, e.g., Ref. 40, and references therein). However, notwithstanding the long history of the perturbation theory, with rare exceptions, only the 2×2 matrix spectral problems were considered. It was noted that construction of the perturbation theory for higher-dimensional matrix spectral problems along the standard approach becomes technically more involved.

To overcome technical difficulties of the standard approach when dealing with multicomponent PDEs, the method based on the Riemann–Hilbert (RH) problem was proposed in Ref. 41, where the perturbation theory was developed for the Zakharov–Shabat spectral problem of an arbitrary matrix dimension. The RH problem was used before for construction of the perturbation theory for the Landau–Lifschitz equation,[30] the NLS, and Maxwell–Bloch equations,[34] which are integrable by the 2×2 matrix spectral problem. The approach of Ref. 41 was applied to the Manakov system[42] (i.e., the two-component NLS equation), modified NLS equation,[43] and massive Thirring model.[44] These examples demonstrate that the perturbation theory based on the RH problem always works. Recently, the RH problem was applied to nearly integrable equations on the half line, arising from the singular dispersion relations.[45] In Refs. 41–45 the perturbation-induced evolution equations for the spectral data were derived with the help of some matrix functional [in the following, the evolution functional $\Pi(x,t,k)$]. It is important to emphasize that the form of the evolution functional is invariant under the gauge transformations of the considered PDE.[43] Thus, once constructed, the evolution functional is valid not only for the whole hierarchy of PDEs associated with a given spectral problem, but also for their images under the gauge transformations. Writing the dispersion law, generating the spectral problem, in an abstract form $\Lambda(k)$ (see Sec. II for details) we discover that the form of the evolution functional remains invariant under the change of the *spectral problem* as well. This invariance trivially extends to the general initial-boundary value problems. For instance, for the half-line, where one would expect a difference, we have found that the evolution functional has similar form.[45] Therefore, it seems that the approach based on the evolution functional is universal for construction of the perturbation theories for nearly integrable PDEs. It is also technically simple. Derivation of the perturbation-induced evolution equations for the spectral data using the evolution functional reduces to calculation of integrals.

This paper is a further development of Ref. 41. The previous results are substantially advanced. In particular, the evolution equations for the spectral data are considerably simplified with the help of some identities found for the evolution functional. We start Sec. II with a brief discussion of the multicomponent integrable PDEs associated with the Zakharov–Shabat spectral problem. We consider two examples, the matrix NLS and cmKdV equations, however, our approach is valid for many other multicomponent PDEs. We have not made an attempt to give a complete exposition of the properties of integrable equations. We need only the Lax representation. Hence a way of deriving the Lax pair for an integrable PDE from the dispersion relation of its linearization is briefly indicated. For completeness of the exposition, a detailed derivation of the RH problem is given in Sec. III. Solution of the RH problem for multicomponent equations

involves some technicalities, which are discussed and detailed derivations are provided in the appendices. We derive evolution equations for the spectral data with account for perturbations in Sec. IV. There, for an important special case of the vector nearly integrable PDEs the main result of this paper is formulated in a theorem. In Sec. V the equations of the first-order perturbation theory for a single vector soliton are given in explicit form.

II. PRELIMINARIES: INTEGRABLE MULTICOMPONENT NONLINEAR PDEs

Here we briefly discuss integrable PDEs with emphasis on the multicomponent equations whose reductions are important for applications. In particular, we consider the matrix nonlinear Schrödinger and complex modified Korteweg–de Vries equations. We do not try to review this subject, for general considerations the reader can consult, for instance, Refs. 1, 10–13, 46–53 and the references therein. The purpose of this section is to recall some of the basic notions in the IST method. Though the approach in the following can be applied to any nonlinear PDE solvable by the RH problem, we restrict the consideration to the integrable equations associated with the N-dimensional Zakharov–Shabat spectral problem (1).

Consider the integrable PDEs which arise as the compatibility condition for the following $N\times N$ matrix linear system (Lax pair):

$$\partial_x\Phi = ik[A,\Phi] + iQ(x,t)\Phi \equiv \Phi\Lambda(k) + U(x,t,k)\Phi, \tag{1}$$

$$\partial_t\Phi = i\omega(k)\Phi A + V(x,t,k)\Phi \equiv \Phi\Omega(k) + V(x,t,k)\Phi, \tag{2}$$

with

$$A = \begin{pmatrix} I_n & 0 \\ 0 & -I_{N-n} \end{pmatrix}, \quad Q = \begin{pmatrix} 0 & \mathbf{q} \\ \overline{\mathbf{q}} & 0 \end{pmatrix},$$

$$\mathbf{q} = \begin{pmatrix} q_{11} & q_{12} & \cdots & q_{1,N-n} \\ q_{21} & q_{22} & \cdots & q_{2,N-n} \\ \vdots & \vdots & & \vdots \\ q_{n1} & q_{n2} & \cdots & q_{n,N-n} \end{pmatrix}, \quad \overline{\mathbf{q}} = \begin{pmatrix} \overline{q}_{11} & \overline{q}_{21} & \cdots & \overline{q}_{n1} \\ \overline{q}_{12} & \overline{q}_{22} & \cdots & \overline{q}_{n2} \\ \vdots & \vdots & & \vdots \\ \overline{q}_{1,N-n} & \overline{q}_{2n} & \cdots & \overline{q}_{n,N-n} \end{pmatrix},$$

where $\Lambda(k) = -ikA$ and $\Omega = i\omega(k)A$ are the dispersion laws, Q is called the potential. Here the overline does not mean complex conjugation by default, e.g., in general, the functions q_{ij} and $\overline{q}_{ij}$ are not considered as complex conjugate to each other. When the overline does denote complex conjugation in the following text, each time it will be specially indicated. This special case corresponds to the Hermitian potential Q, $Q^\dagger = Q$ or $\mathbf{q}^\dagger = \overline{\mathbf{q}}$, and it will be referred to as the involution. The temporal evolution equation (2) is specified by choice of the dispersion relation $\omega(k)$ in the following manner. For simplicity, let the dispersion relation be polynomial $\omega(k) = \sum_{p=1}^{M} w_p k^p$, then

$$V(k) = -\mathcal{P}\{\Phi\Omega\Phi^{-1}\} \equiv -\Omega(k) + \sum_{p=0}^{M-1} V_p k^p. \tag{3}$$

Here the matrix function $\Phi(k)$ is expanded into the asymptotic series:

$$\Phi(k) = I + k^{-1}\Phi^{(1)} + k^{-2}\Phi^{(2)} + \cdots, \quad k\to\infty,$$

and the operator $\mathcal{P}$ takes the polynomial in k part of $\Phi\Omega\Phi^{-1}$ on the asymptotics. For example, the Zakharov–Shabat spectral problem (1) is derived in this way,

$$U = -\mathcal{P}\{\Phi\Lambda\Phi^{-1}\} = ikA + i[\Phi^{(1)},A],$$

with the obvious relation

$$Q=[\Phi^{(1)},A]. \tag{4}$$

Hence, the Lax pair satisfies the property $\mathrm{Tr}\,U=-\mathrm{Tr}\,\Lambda$ and $\mathrm{Tr}\,V=-\mathrm{Tr}\,\Omega$.

The integrable nonlinear PDE related to the Lax pair (1)–(2) is given by the compatibility condition (in our case, polynomial in k)

$$i\partial_t Q-\partial_x V+[ikA+iQ,V]=0 \tag{5}$$

via setting $k=0$, while the positive powers of k supply the expressions of the coefficients V_p in (3) as functions of the potential Q and its x-derivatives, $V_p=V_p(Q,Q_x,Q_{xx},\dots)$. For instance, choosing $\omega(k)=2k^2$ we obtain the well-known matrix nonlinear Schrödinger equation. Indeed, in this case

$$V=-2ik^2A-2ikQ-AQ_x+iAQ^2$$

and Eq. (5) becomes

$$iAQ_t+Q_{xx}+2Q^3=0. \tag{6}$$

For a complete classification of the matrix integrable NLS equations with various reductions to Hermitian symmetric spaces consult Ref. 10. A particular important case of Eq. (6) is the vector NLS equation, a generalization of the two-component vector NLS, which was shown to be integrable by Manakov.[12] The vector NLS equation corresponds to the Hermitian potential and the reduction $n=N-1$ (see the expression for A.) In this case we have

$$Q=\begin{pmatrix} 0 & \dots & 0 & q_1 \\ \vdots & & \vdots & \vdots \\ 0 & \dots & 0 & q_n \\ \overline{q_1} & \dots & \overline{q_n} & 0 \end{pmatrix} \tag{7}$$

and matrix equation (6) becomes the vector NLS equation:

$$i\partial_t q_l+\partial_x^2 q_l+2\left(\sum_{j=1}^{n}|q_j|^2\right)q_l=0, \quad l=1,\dots,n. \tag{8}$$

Let us consider another important example of multicomponent nonlinear integrable equations. It is given by setting $\omega(k)=4k^3$. After simple computation we get

$$V=-4ik^3A+4ik^2Q+2ikA(iQ_x+Q^2)-iQ_{xx}+[Q,Q_x]-2iQ^3,$$

which produces the matrix cmKdV equation

$$Q_t+Q_{xxx}+3(Q^2Q_x+Q_xQ^2)=0. \tag{9}$$

Combining together the two considered dispersion laws, i.e., letting $\omega(k)=4i\epsilon k^3+2i\beta k^2$, one can obtain

$$iQ_t+\beta A(Q_{xx}+2Q^3)+i\epsilon Q_{xxx}+3i\epsilon(Q^2Q_x+Q_xQ^2)=0,$$

a special case of the (generally, nonintegrable) matrix higher-order NLS equation

$$iE_z+A(\alpha_1E_{\tau\tau}+\alpha_2E^3)+i\{\alpha_3E_{\tau\tau\tau}+\alpha_4(E^3)_\tau+\alpha_5(E^2)_\tau E\}=0. \tag{10}$$

Our examples are just illustrative. There are many other integrable matrix PDEs which we do not mention here. However, the perturbation theory developed in Sec. IV applies to such PDEs also.

III. RIEMANN–HILBERT PROBLEM FOR MULTICOMPONENT PDEs

In this section we derive the RH problem for the multicomponent integrable PDEs and discuss its solution (for more details consult Refs. 46, 54–57). We are interested in the initial-value problem for nonlinear PDEs on the whole real line with the asymptotically vanishing conditions (Cauchy problem) $q_{ij}\to 0$ as $|x|\to\infty$. The vanishing asymptotics allows us to concentrate entirely on the spectral equation (1) in derivation of the RH problem, while t dependence enters parametrically in our approach (for the RH problem for initial-boundary value problems consult Ref. 47). In the following we omit the explicit t dependence for simplicity of the presentation. To begin with, let us summarize the properties of the spectral problem (1). Define the following $N\times N$ matrix projectors:

$$H_1=\mathrm{diag}(I_n,0),\quad H_2=\mathrm{diag}(0,I_{N-n}). \tag{11}$$

Then $A=H_1-H_2$ and any matrix can be decomposed into the sum of two matrices, commuting and anticommuting with A:

$$\Phi=\Phi^{(c)}+\Phi^{(a)},\quad \Phi^{(c)}=H_1\Phi H_1+H_2\Phi H_2,\quad \Phi^{(a)}=H_1\Phi H_2+H_2\Phi H_1, \tag{12}$$

where $[A,\Phi^{(c)}]=0$ and $\{A,\Phi^{(a)}\}=0$. We will use the block-index notations for the decomposition of matrix Φ with respect to the projectors H_1 and H_2:

$$\Phi=\begin{pmatrix}\Phi_{\mathrm{I,I}} & \Phi_{\mathrm{I,II}}\\ \Phi_{\mathrm{II,I}} & \Phi_{\mathrm{II,II}}\end{pmatrix}.$$

The RH problem is a one-to-one mapping (nonlinear Fourier transform) between the set of smooth (e.g., belonging to the Schwartz space) potentials $Q(x)$ and some set of the spectral data. To identify the RH problem one must construct two solutions, one, $\Phi_+(x,k)$, to the spectral equation (1) and the other, $\Phi_-^{-1}(x,k)$, to the adjoint equation [the second function is inverse of some matrix function satisfying (1), hence the "-1" in its definition], holomorphic with respect to the spectral parameter k in some complementary domains covering the whole complex k-plane. Such solutions can be built from the columns and rows of the Jost solutions $J_\pm$, i.e., solutions defined by the asymptotic conditions: $J_\pm(x,k)\to I$ as $x\to\pm\infty$.

As $\mathrm{Tr}\,Q=0$, letting $x\to\pm\infty$ we conclude that $\det J_\pm=1$. Hence, the columns of either of the two Jost solutions give a linear basis in the space of solutions of the spectral equation. The inverse matrices $J_\pm^{-1}$ satisfy the adjoint spectral equation:

$$\partial_x\tilde{\Phi}=ik[A,\tilde{\Phi}]-i\tilde{\Phi}Q. \tag{13}$$

Each column of $J_\pm(x,k)$ and, respectively, row of $J_\pm^{-1}(x,k)$ is holomorphic and bounded in either upper ($\mathrm{Im}\,k\geqslant 0$) or lower ($\mathrm{Im}\,k\leqslant 0$) half of the complex k-plane. Indeed, this can be easily seen from the Volterra integral equations for the Jost matrices written for the two blocks of columns:

$$J_\pm(x,k)H_1=H_1+i\int_{\pm\infty}^{x}\mathrm{d}\xi\, e^{-2ik(x-\xi)H_2}Q(\xi)J_\pm(\xi,k)H_1,$$

$$J_\pm(x,k)H_2=H_2+i\int_{\pm\infty}^{x}\mathrm{d}\xi\, e^{2ik(x-\xi)H_1}Q(\xi)J_\pm(\xi,k)H_2.$$

The columns of $J_+(k)H_1$ and $J_-(k)H_2$ are holomorphic and bounded in the upper half of the complex plane, while columns of $J_+(k)H_2$ and $J_-(k)H_1$ have the same property in the lower half plane. Similarly, the rows of $J_\pm^{-1}$ satisfy integral equations

$$H_1J_\pm^{-1}(x,k)=H_1-i\int_{\pm\infty}^{x}\mathrm{d}\xi\, H_1J_\pm^{-1}(\xi,k)Q(\xi)e^{2ik(x-\xi)H_2},$$

$$H_2J_\pm^{-1}(x,k)=H_2-i\int_{\pm\infty}^{x}\mathrm{d}\xi\, H_2J_\pm^{-1}(\xi,k)Q(\xi)e^{-2ik(x-\xi)H_1},$$

from which we immediately conclude that $H_1J_+^{-1}(k)$ and $H_2J_-^{-1}(k)$ are holomorphic and bounded in the upper half plane, while $H_2J_+^{-1}(k)$ and $H_1J_-^{-1}(k)$ have the same properties in the lower half plane.

On the real line, the Jost solutions are transformed into each other by the scattering matrix $S(k)$,

$$J_-(x,k)=J_+(x,k)e^{ikxA}S(k)e^{-ikxA}. \tag{14}$$

For the Hermitian potential, $Q^\dagger=Q$, the matrix Jost solutions satisfy the involution (here the overline means complex conjugation)

$$J_\pm^\dagger(x,k)=J_\pm^{-1}(x,\overline{k}), \tag{15}$$

where the spectral parameter takes complex values in the upper or lower half plane depending on the considered column of the Jost matrix. In this case, the scattering matrix also satisfies the involution

$$S^\dagger(k)=S^{-1}(k),\quad k\in\mathrm{Re}. \tag{16}$$

The holomorphic matrix functions $\Phi_+(k)$ and $\Phi_-^{-1}(k)$, satisfying Eqs. (1) and (13), respectively, are given in terms of columns and rows of the Jost solutions:

$$\Phi_+=J_+H_1+J_-H_2,\quad \Phi_-^{-1}=H_1J_+^{-1}+H_2J_-^{-1}. \tag{17}$$

The above-defined matrix functions are holomorphic and bounded in the upper and lower half planes, respectively. They have the following asymptotics:

$$\Phi_\pm(x,k)\to I,\quad k\to\infty, \tag{18}$$

which follow from the Volterra integral equations for the Jost solutions. For the involution (15) the matrices $\Phi_+(k)$ and $\Phi_-^{-1}(k)$ are related via

$$\Phi_+^\dagger(k)=\Phi_-^{-1}(\overline{k}). \tag{19}$$

These matrices can be conveniently expressed in terms of only one Jost solution and elements of the scattering matrix $S(k)$. Indeed,

$$\Phi_+=J_+e^{ikxA}(H_1+SH_2)e^{-ikxA}\equiv J_-e^{ikxA}(H_2+S^{-1}H_1)e^{-ikxA},$$

$$\Phi_-^{-1}=e^{ikxA}(H_1+H_2S^{-1})e^{-ikxA}J_+^{-1}\equiv e^{ikxA}(H_2+H_1S)e^{-ikxA}J_-^{-1}.$$

Denote $S_+=H_1+SH_2$, $S_-=H_2+S^{-1}H_1$. These matrices provide a factorization of the scattering matrix: $S_+=SS_-$. Similarly, $\overline{S_+}=H_1+H_2S^{-1}$ and $\overline{S_-}=H_2+H_1S$, which also factorize the scattering matrix: $\overline{S_+}S=\overline{S_-}$. Then

$$\Phi_+ = J_+ e^{ikxA} S_+ e^{-ikxA} \equiv J_- e^{ikxA} S_- e^{-ikxA}, \tag{20a}$$

$$\Phi_-^{-1} = e^{ikxA} \overline{S}_+ e^{-ikxA} J_+^{-1} \equiv e^{ikxA} \overline{S}_- e^{-ikxA} J_-^{-1}. \tag{20b}$$

The factorization matrices have the block-triangular structure. For instance, S_+ and $\overline{S}_+$ are upper and lower block-triangular, respectively:

$$S_+ = \begin{pmatrix} I_n & \mathbf{b} \\ 0 & \mathbf{a} \end{pmatrix}, \quad \overline{S}_+ = \begin{pmatrix} I_n & 0 \\ \overline{\mathbf{b}} & \overline{\mathbf{a}} \end{pmatrix}, \tag{21}$$

where $\mathbf{b} = S_{\mathrm{I,II}}$, $\mathbf{a} = S_{\mathrm{II,II}}$, $\overline{\mathbf{b}} = (S^{-1})_{\mathrm{II,I}}$, and $\overline{\mathbf{a}} = (S^{-1})_{\mathrm{II,II}}$. The following identity follows from these definitions:

$$\overline{\mathbf{b}}\mathbf{b} + \overline{\mathbf{a}}\mathbf{a} = I_{N-n}, \quad k \in \mathrm{Re}. \tag{22}$$

For the involution (19) the factorizations satisfy

$$S_\pm^\dagger(k) = \overline{S}_\pm(k), \quad k \in \mathrm{Re}.$$

Hence, $\overline{\mathbf{b}} = \mathbf{b}^\dagger$ and $\overline{\mathbf{a}} = \mathbf{a}^\dagger$ in the case of involution.

Considering the product $\Phi_-^{-1}\Phi_+$ we obtain the problem of analytic factorization of a matrix $G(k)$ given on the real line, i.e., the matrix RH problem:

$$\Phi_-^{-1}(x,k)\Phi_+(x,k) = e^{ikxA} G(k) e^{-ikxA}, \quad k \in \mathrm{Re} \tag{23}$$

and $\Phi_\pm(x,k) \to I$ for $k \to \infty$. Here the matrix $G = \overline{S}_+ S_+ \equiv \overline{S}_- S_-$ reads

$$G = \begin{pmatrix} I_n & \mathbf{b} \\ \overline{\mathbf{b}} & I_{N-n} \end{pmatrix}. \tag{24}$$

As was mentioned, the RH problem is a nonlinear mapping between the potential $Q(x)$ and the set of the spectral data, which are necessary for unique identification of the solution to (23). For instance, given a potential, one can obtain the spectral data by solving the spectral equation and its adjoint for $\Phi_+(x,k)$ and $\Phi_-^{-1}(x,k)$. Conversely, by asymptotic expansion of $\Phi_\pm(x,k)$ as $k \to \infty$ one recovers the potential. The asymptotic expansion of $\Phi_\pm(x,k)$ can be derived via integration by parts (in the blocks with $e^{\pm 2ikx}$) in the Volterra integral equations for $J_\pm$ and $J_\pm^{-1}$. It reads

$$\Phi_\pm(x,k) = I - \left(AQ(x) + i\int_{-\infty}^{x} \mathrm{d}\xi\, Q^2(\xi) H_2 + i\int_{x}^{\infty} \mathrm{d}\xi\, Q^2(\xi) H_1 \right) \frac{1}{2k} + \mathcal{O}\left(\frac{1}{k^2}\right).$$

Hence, we obtain [cf. with (4)]

$$Q(x) = \lim_{k\to\infty} k[\Phi_+(x,k), A] = \lim_{k\to\infty} k[A, \Phi_-^{-1}(x,k)]. \tag{25}$$

Solution of the RH problem: Normalization. Let us discuss the way of solution of the RH problem. The coordinate dependence is not important for this purpose and is omitted in the following. In general, the determinants $\det \Phi_+(k)$ and $\det \Phi_-^{-1}(k)$ have zeros and the RH problem is said to be nonregular or with zeros. Note that the determinants do not depend on x as readily seen from Eqs. (1) and (13). We consider only the RH problem with zero index, i.e.,

$$\int_{-\infty}^{\infty} \mathrm{d}\ln\{\det G(k)\}=0,$$

assuming that $G(k)$ is nondegenerate. Since $\Phi_{\pm}\to I$ as $k\to\infty$, the index is equal to the difference between the number of zeros in the upper and lower half planes. Let $k_1,\ldots,k_M$ and $\overline{k_1},\ldots,\overline{k_M}$ be zeros (where some may be equal) of $\det\Phi_+(k)$ and $\det\Phi_-^{-1}(k)$, respectively. Two conditions are imposed on the zeros. First, the geometric multiplicity of a zero must be equal to its order (which we will refer to as the algebraic multiplicity). Here the geometric multiplicity of k_j is defined as the dimension d_j of the null space of $\Phi_+(k_j)$, i.e., $d_j=N-\mathrm{rank}\Phi_+(k_j)$. Trivially, the two multiplicities are equal to 1 in the case of simple zeros. In the case of involution zeros of the RH problem come in complex conjugate pairs [due to formula (19)], with coinciding algebraic (and geometric) multiplicities within each pair. (Due to the involution the index is equal to zero, in this case $\det G(k)$ is real and definite.) Second, as we are mainly interested in the Hermitian potentials Q, i.e., in the case of the involution, we will consider only paired zeros k_j and $\overline{k_j}$, $j=1,\ldots,s\leqslant M$, whose algebraic multiplicities are equal, however without assuming them to be complex conjugate to each other. The algebraic multiplicity ν_j of k_j always satisfies the following inequality (see Appendix A):

$$\nu_j\geqslant N-\mathrm{rank}\Phi_+(k_j)=d_j,$$

while $\mathrm{rank}\Phi_+\geqslant\max(n,N-n)$ by construction of Φ_+ (17). For instance, if $n=N-1$, there can be not more than one vector in the null space of $\Phi_+(k)$, i.e., $d_j=1$ for all $j=1,\ldots,s$. Hence, for this reduction, zeros of $\det\Phi_+(k)$ must be simple to satisfy the equal multiplicity condition. Similar for zeros of $\Phi_-^{-1}(k)$. (More detailed consideration of the multiplicities of zeros is placed in Appendix A.)

Let $\det\Phi_+(k)$ and $\det\Phi_-^{-1}(k)$ have zeros $k_1,\ldots,k_s$ and $\overline{k_1},\ldots,\overline{k_s}$, respectively, with the (algebraic and geometric) multiplicities $\nu_1,\ldots,\nu_s$. Exactly ν_j independent vector-columns $|p_l^{(j)}\rangle$ (vector-rows $\langle\overline{p}_l^{(j)}|$), where $l=1,\ldots,\nu_j$, correspond to each zero k_j (respectively, $\overline{k_j}$), such that

$$\Phi_+(k_j)|p_l^{(j)}\rangle=0,\quad \langle\overline{p}_l^{(j)}|\Phi_-^{-1}(\overline{k_j})=0. \tag{26}$$

To specify a unique solution to the RH problem, additionally to the continuous datum $G(k)$, the set of the discrete data $\{k_j,|p_l^{(j)}\rangle,\overline{k_j},\langle\overline{p}_l^{(j)}|,l=1,\ldots,\nu_j,j=1,\ldots,s\}$ must be given. This becomes evident from the fact that the RH problem with zeros (i.e., nonregular) can be regularized, i.e., reduced to a modified RH problem without zeros by factoring them out with some rational matrix $\Gamma(k)$:

$$\Phi_+(k)=\phi_+(k)\Gamma(k),\quad \Phi_-^{-1}(k)=\Gamma^{-1}(k)\phi_-^{-1}(k). \tag{27}$$

The regularized RH problem reads

$$\phi_-^{-1}(k)\phi_+(k)=\Gamma(k)e^{ikxA}G(k)e^{-ikxA}\Gamma^{-1}(k),\quad k\in\mathrm{Re} \tag{28}$$

and $\phi_{\pm}(k)\to I$ as $k\to\infty$.

The rational matrix functions $\Gamma(k)$ and $\Gamma^{-1}(k)$—for details see Appendix B,

$$\Gamma=I-\sum_{j,l;i,m}\frac{|p_m^{(i)}\rangle(D^{-1})_{im,jl}\langle\overline{p}_l^{(j)}|}{k-\overline{k_j}},\quad \Gamma^{-1}=I+\sum_{j,l;i,m}\frac{|p_l^{(j)}\rangle(D^{-1})_{jl,im}\langle\overline{p}_m^{(i)}|}{k-k_j}, \tag{29}$$

where

$$D_{im,jl}=\frac{\langle \overline{p}_m^{(i)}|p_l^{(j)}\rangle}{k_j-\overline{k_i}},$$

have the same zeros as $\Phi_+(k)$ and $\Phi_-^{-1}(k)$, respectively, and the same null spaces:

$$\Gamma(k_j)|p_l^{(j)}\rangle=0, \quad \langle \overline{p}_l^{(j)}|\Gamma^{-1}(\overline{k_j})=0, \quad l=1,\ldots,\nu_j, \quad j=1,\ldots,s.$$

Moreover,

$$\det\Gamma=\Pi_{j=1}^{s}\left(\frac{k-k_j}{k-\overline{k_j}}\right)^{\nu_j}.$$

Precisely these properties allow us to factor out zeros of $\Phi_+(x,k)$ and $\Phi_-^{-1}(x,k)$.

It is important to emphasize that there is a freedom in choice of the basis vectors spanning the null spaces. Indeed, it is easy to verify that the regularization matrix Γ is invariant under the transformations:

$$|p_l^{(j)}\rangle\to\sum_{m=1}^{\nu_j}|p_m^{(j)}\rangle M_{ml}^{(j)}, \quad \langle \overline{p}_l^{(j)}|\to\sum_{m=1}^{\nu_j}\overline{M}_{lm}^{(j)}\langle \overline{p}_m^{(j)}|, \tag{30}$$

where $M^{(j)}$ and $\overline{M}^{(j)}$ are arbitrary nondegenerate $\nu_j\times\nu_j$-matrices. For the involution, due to Eq. (19) we can choose $\langle \overline{p}_l^{(j)}|=|p_l^{(j)}\rangle^\dagger$. This evidently leads to

$$\Gamma^\dagger(k)=\Gamma^{-1}(\overline{k}). \tag{31}$$

The (x,t)-dependence of the RH data can be found in the following way. The t-dependence of the continuous datum (which does not depend on x) can be derived from Eqs. (23) and (2). We obtain

$$\partial_t G=[G,\Omega]. \tag{32}$$

This equation can be cast in a more explicit form:

$$\partial_t\mathbf{b}=-2i\omega(k)\mathbf{b}, \quad \partial_t\overline{\mathbf{b}}=2i\omega(k)\overline{\mathbf{b}}. \tag{33}$$

Recalling that $\operatorname{Tr}Q=0$ and $\operatorname{Tr}V=-\operatorname{Tr}\Omega$, one can verify that the determinants of $\Phi_\pm$ do not depend on the coordinates. Therefore, the zeros are coordinate independent as well:

$$\partial_x k_j=\partial_t k_j=0, \quad \partial_x\overline{k_j}=\partial_t\overline{k_j}=0, \quad j=1,\ldots,s. \tag{34}$$

Now, let us derive the coordinate dependence of the vector-parameters. Differentiating Eq. (26) we obtain

$$\Phi_+(k_j)(\partial_x|p_l^{(j)}\rangle-ik_jA|p_l^{(j)}\rangle)=0, \quad \Phi_+(k_j)(\partial_t|p_l^{(j)}\rangle+\Omega(k_j)|p_l^{(j)}\rangle)=0.$$

Therefore

$$\partial_x|p_l^{(j)}\rangle=ik_jA|p_l^{(j)}\rangle+\sum_{m=1}^{\nu_j}F_{lm}^{(j)}|p_m^{(j)}\rangle, \quad \partial_t|p_l^{(j)}\rangle=-\Omega(k_j)|p_l^{(j)}\rangle+\sum_{m=1}^{\nu_j}K_{lm}^{(j)}|p_m^{(j)}\rangle,$$

where F and K are some matrices. Using a suitable invariance transformation of the type (30) one can put $F=K=0$ without loss of generality. Hence we have

$$\partial_x|p_l^{(j)}\rangle = ik_jA|p_l^{(j)}\rangle, \quad \partial_t|p_l^{(j)}\rangle = -\Omega(k_j)|p_l^{(j)}\rangle. \tag{35}$$

Similarly,

$$\partial_x\langle\overline{p}_l^{(j)}| = -\langle\overline{p}_l^{(j)}|i\overline{k}_jA, \quad \partial_t\langle\overline{p}_l^{(j)}| = \langle\overline{p}_l^{(j)}|\Omega(\overline{k}_j). \tag{36}$$

Some comments are needed on the reconstruction of the potential Q. First of all, the soliton part of the potential is given by the rational matrix function $\Gamma(k)$ (29). The pure soliton potentials are also called reflectionless; they solve the simplest RH problem with $G=I$, i.e., with zero reflection coefficients: $\mathbf{b}(k)=\overline{\mathbf{b}}(k)=0$. The discrete RH data have the following meaning. Zeros provide the amplitudes and velocities of the solitons, while the null vectors give their initial position, polarization, and phase parameters. Second, the radiation part of the potential is given by the solution to the regularized RH problem (28). The continuous RH data $\mathbf{b}(k)$ and $\overline{\mathbf{b}}(k)$ represent the nonlinear spectral densities of radiation. The regular RH problem is equivalent to some matrix integral equation of the Fredholm type (for instance, consult Ref. 46). Though the solution cannot be given in explicit form, its properties can be explored by the standard technique of the theory of Fredholm integral equations.

For the following, it is convenient to introduce x-independent null vectors $|P_l^{(j)}\rangle$ and $\langle\overline{P}_l^{(j)}|$ setting

$$|p_l^{(j)}\rangle = e^{ik_jxA}|P_l^{(j)}\rangle, \quad \langle\overline{p}_l^{(j)}| = \langle\overline{P}_l^{(j)}|e^{-i\overline{k}_jxA}. \tag{37}$$

Then, we have an x-independent set of the RH data, which we will call the spectral data: $\{\mathbf{b}(k),\overline{\mathbf{b}}(k),k_j,|P_l^{(j)}\rangle,\overline{k}_j,\langle\overline{P}_l^{(j)}|, l=1,\ldots,\nu_j, j=1,\ldots,s\}$.

As the illustrative example, consider one-soliton solution. It is given by $\Gamma(k)$ having only one pole, say $k_1=i\eta+\xi$. In this case,

$$Q=(k_1-\overline{k}_1)[A,P_r], \quad P_r=\sum_{l,m=1}^{\nu_1}|p_l\rangle(\Delta^{-1})_{lm}\langle\overline{p}_m|,$$

with $\Delta_{lm}=\langle\overline{p}_l|p_m\rangle$. Here $\langle\overline{p}_l|\Phi_-^{-1}(\overline{k}_1)=0$ and $\Phi_+(k_1)|p_l\rangle=0$. In the particular case of $n=N-1$ and the Hermitian potential we get the vector soliton solution, for which

$$P_r=\frac{|p\rangle\langle p|}{\langle p|p\rangle}, \quad |p\rangle=\exp\{ik_1xA\}|P\rangle.$$

Define complex parameters $C_l=P_l/P_N$. The t-dependence of C_l then follows from Eq. (35). It can be accounted for in a convenient way by introducing real t-dependent parameters $\overline{x}$, and δ_l, $l=1,\ldots,n$, the soliton position and phases of its components. Let $C_l=\theta_le^{2(\eta-i\xi)\overline{x}}$, where $\theta_l=s_le^{i\delta_l}$. The amplitudes s_l, satisfying

$$\sum_{l=1}^{n}s_l^2=1, \tag{38}$$

describe polarization of the multicomponent soliton. Integrating Eq. (35) we obtain

$$\overline{x}=\overline{x}_0+\frac{\mathrm{Im}\{\omega(i\eta+\xi)\}t}{\eta}, \quad \delta_l=\delta_{l0}+\frac{2}{\eta}\mathrm{Im}\{(\xi-i\eta)\omega(i\eta+\xi)\}t. \tag{39}$$

The vector soliton then takes the form

$$q_l=2i\eta\theta_le^{i(\xi/\eta)z}\,\mathrm{sech}\,z \tag{40}$$

with $z=2\eta(x-\overline{x})$. For instance, for the vector NLS equation $\omega(k)=2k^2$ and we arrive at the n-component generalization of the well-known vector soliton solution for the two-component NLS equation.[12]

IV. PERTURBATION-INDUCED EVOLUTION OF THE SPECTRAL DATA

A perturbation of the integrable PDE, following from the Lax representation (1)–(2), can be written in the form

$$iQ_t - V_x + [ikA + iQ, V] = R, \tag{41}$$

where R (which is k-independent in case of the Zakharov–Shabat spectral problem) represents the terms destroying integrablity. The perturbation matrix R, similar to the potential Q, satisfies $[A,R]=0$. For the Hermitian potential $Q^\dagger = Q$ we also get $R^\dagger = -R$.

In the following we derive evolution equations for the spectral data with account for arbitrary perturbation. For simplicity of the presentation we will frequently omit the explicit dependence on x and t. To distinguish between the ''integrable'' and ''perturbation'' contributions to the evolution let us assign the variational derivatives to the latter. For instance, the perturbation-induced evolution in Eq. (41) reads

$$i\frac{\delta Q}{\delta t} = R,$$

or, explicitly

$$i\frac{\delta \mathbf{q}}{\delta t} = \mathbf{r} \quad \text{and} \quad i\frac{\delta \overline{\mathbf{q}}}{\delta t} = -\overline{\mathbf{r}},$$

where $\mathbf{r} = R_{\mathrm{I,II}}$ and $\overline{\mathbf{r}} = -R_{\mathrm{II,I}}$. For Hermitian Q, $\overline{\mathbf{r}} = \mathbf{r}^\dagger$.

We start with derivation of evolution equations for Φ_+ and Φ_-^{-1}, the solution to the RH problem (23). In other terms, we are going to derive the generalized Lax pair [see Eqs. (52) and (53)] for the *perturbed* nonlinear PDE (41). Differentiation of Eq. (1) with respect to t gives

$$\partial_x\left(\frac{\delta\Phi}{\delta t}\right) = ik\left[A, \frac{\delta\Phi}{\delta t}\right] + iQ\frac{\delta\Phi}{\delta t} + R\Phi,$$

and consequently

$$\partial_x\left(\Phi^{-1}\frac{\delta\Phi}{\delta t}\right) = ik\left[A, \Phi^{-1}\frac{\delta\Phi}{\delta t}\right] + \Phi^{-1}R\Phi.$$

Let us integrate the above-given formula for $\Phi = J_\pm$. We get

$$\frac{\delta J_\pm}{\delta t}(x,k) = J_\pm(x,k)e^{ikxA}\left(\int_{\pm\infty}^{x} \mathrm{d}\xi\, e^{-ik\xi A} J_\pm^{-1}(\xi,k) R(\xi) J_\pm(\xi,k) e^{ik\xi A}\right) e^{-ikxA}.$$

Here we have used that $\delta J_\pm \to 0$ as $x \to \pm\infty$. Let us employ the relation between $J_\pm$ and Φ_+ to rewrite this formula in a more convenient form. Using (20a) we get

$$\frac{\delta J_\pm}{\delta t}(x,k) = J_\pm(x,k)e^{ikxA}S_\pm(k)\Upsilon(\pm\infty, x; k)S_\pm^{-1}(k)e^{-ikxA}. \tag{42}$$

In much the same way, using (20b), we derive

$$\frac{\delta J_{\pm}^{-1}}{\delta t}(x,k) = -e^{ikxA}\overline{S_{\pm}^{-1}}(k)\overline{\Upsilon}(\pm\infty,x;k)\overline{S_{\pm}}(k)e^{-ikxA}J_{\pm}^{-1}(x,k). \tag{43}$$

Here we have introduced the notations:

$$\Upsilon(\pm\infty,x;k) = \int_{\pm\infty}^{x} \mathrm{d}\xi\, e^{-ik\xi A}\Phi_{+}^{-1}R\Phi_{+}e^{ik\xi A}, \tag{44}$$

$$\overline{\Upsilon}(\pm\infty,x;k) = \int_{\pm\infty}^{x} \mathrm{d}\xi\, e^{-ik\xi A}\Phi_{-}^{-1}R\Phi_{-}e^{ik\xi A}. \tag{45}$$

These matrix functionals will enter every formula describing perturbation-induced evolution of the spectral data. For the involution, due to formula (19) these matrix functionals satisfy

$$\Upsilon^{\dagger}(\pm\infty,x;k) = -\overline{\Upsilon}(\pm\infty,x,\overline{k}). \tag{46}$$

Using Eqs. (42), (43), and the definition of the scattering matrix S (14) we get

$$\frac{\delta S}{\delta t} = e^{-ikxA}\frac{\delta}{\delta t}(J_{+}^{-1}J_{-})e^{ikxA} = -\overline{S_{+}^{-1}}\overline{\Upsilon}(\infty,x)\overline{S_{+}}S + SS_{-}\Upsilon(-\infty,x)S_{-}^{-1}$$

$$= S_{+}\Upsilon(-\infty,x)S_{-}^{-1} + \overline{S_{+}^{-1}}\overline{\Upsilon}(x,\infty)\overline{S_{-}}.$$

Setting $x\to\pm\infty$ in this formula produces two simple equivalent formulas:

$$\frac{\delta S(k)}{\delta t} = S_{+}(k)\Upsilon(-\infty,\infty;k)S_{-}^{-1}(k) \equiv \overline{S_{+}^{-1}}(k)\overline{\Upsilon}(-\infty,\infty;k)\overline{S_{-}}(k). \tag{47}$$

Now we can easily obtain the perturbation-induced evolution of the solution to the RH problem. Taking into account the definitions of $S_{\pm}$ and $\overline{S_{\pm}}$ and (20) we write:

$$\frac{\delta\Phi_{+}}{\delta t} = \frac{\delta J_{+}}{\delta t}e^{ikxA}S_{+}e^{-ikxA} + J_{+}e^{ikxA}\frac{\delta}{\delta t}(H_1 + SH_2)e^{-ikxA}$$

$$= \Phi_{+}e^{ikxA}(-\Upsilon(x,\infty) + \Upsilon(-\infty,\infty)H_2)e^{-ikxA}$$

$$= \Phi_{+}e^{ikxA}\Pi e^{-ikxA}, \tag{48a}$$

$$\frac{\delta\Phi_{-}^{-1}}{\delta t} = e^{ikxA}\overline{S}_{+}e^{-ikxA}\frac{\delta J_{+}^{-1}}{\delta t} + e^{ikxA}\frac{\delta}{\delta t}(H_1 + H_2S^{-1})J_{+}^{-1}e^{-ikxA}$$

$$= e^{ikxA}(\overline{\Upsilon}(x,\infty) - H_2\overline{\Upsilon}(-\infty,\infty))\Phi_{-}^{-1}e^{-ikxA}$$

$$= -e^{ikxA}\overline{\Pi}\Phi_{-}^{-1}e^{-ikxA}. \tag{48b}$$

The right-hand sides of the above formulas contain the evolution functionals,

$$\Pi(x,k) = -\Upsilon(x,\infty;k)H_1 + \Upsilon(-\infty,x;k)H_2, \tag{49}$$

$$\overline{\Pi}(x,k) = H_1\overline{\Upsilon}(x,\infty;k) - H_2\overline{\Upsilon}(-\infty,x;k), \tag{50}$$

which account for the perturbation-induced evolution of the solution to the RH problem. As follows from formula (46), for the case of the involution the evolution functionals satisfy

$$\Pi^{\dagger}(k) = -\overline{\Pi}(\overline{k}). \tag{51}$$

From the definitions (49), (50) and also (44), (45) it is easy to see that the matrices $e^{ikxA}\Pi(k)e^{-ikxA}$ and $e^{ikxA}\overline{\Pi}(k)e^{-ikxA}$ are meromorphic and bounded in the upper and lower half planes of the k-plane, respectively. They have simple poles, respectively, at zeros of $\det\Phi_+(k)$ and $\det\Phi_-^{-1}(k)$.

Let us write down the generalized Lax representation for the perturbed PDE (41) in terms of $\Phi_+(x,k)$:

$$\partial_x\Phi_+ = ik[A,\Phi_+] + iQ\Phi_+, \tag{52}$$

$$\partial_t\Phi_+ = \Phi_+\Omega + V\Phi_+ + \Phi_+ e^{ikxA}\Pi e^{-ikxA}. \tag{53}$$

It is easy to check by direct calculation that the compatibility condition for the above-given linear system is equivalent to the perturbed equation (41) (indeed, $\partial_x\Pi = e^{-ikxA}\Phi_+^{-1}R\Phi_+e^{ikxA}$).

Now, let us derive the perturbation-induced evolution of the spectral data. From (48) we immediately obtain

$$\frac{\delta G}{\delta t} = \frac{\delta}{\delta t}(e^{-ikxA}\Phi_-^{-1}\Phi_+e^{ikxA}) = G\Pi - \overline{\Pi}G.$$

Hence, the complete evolution of the continuous datum reads

$$\partial_t G = [G,\Omega] + G\Pi - \overline{\Pi}G, \tag{54}$$

where we have taken into account the integrable evolution given by (32). It is important to notice that the left-hand side of (54) does not depend on x. Therefore, we can put $x\to\pm\infty$ in this equation to simplify it. Equation (54) can be rewritten in a more explicit form. Using the definition (24), formulas (49) and (50) we get two equivalent evolution equations for $\mathbf{b}$ corresponding to the two limits $x\to\pm\infty$:

$$\partial_t\mathbf{b} = -2i\omega(k)\mathbf{b} + \mathbf{b}H_2\Upsilon(-\infty,\infty;k)H_2 + H_1\Upsilon(-\infty,\infty;k)H_2, \tag{55a}$$

$$\partial_t\mathbf{b} = -2i\omega(k)\mathbf{b} - H_1\overline{\Upsilon}(-\infty,\infty;k)H_1\mathbf{b} - H_1\overline{\Upsilon}(-\infty,\infty;k)H_2. \tag{55b}$$

Similarly,

$$\partial_t\overline{\mathbf{b}} = 2i\omega(k)\overline{\mathbf{b}} + \overline{\mathbf{b}}H_1\Upsilon(-\infty,\infty;k)H_1 + H_2\Upsilon(-\infty,\infty;k)H_1, \tag{56a}$$

$$\partial_t\overline{\mathbf{b}} = 2i\omega(k)\overline{\mathbf{b}} - H_2\overline{\Upsilon}(-\infty,\infty;k)H_2\overline{\mathbf{b}} - H_2\overline{\Upsilon}(-\infty,\infty;k)H_1. \tag{56b}$$

Evolution of zeros k_j and $\overline{k_j}$ of $\det\Phi_+(k)$ and $\det\Phi_-^{-1}(k)$, respectively, is derived by differentiation of the determinants. In the integrable limit zeros do not depend on t. Then, for instance,

$$\frac{dk_j}{dt} = -\left.\frac{\partial_t\det\Phi_+(k)}{\partial_k\det\Phi_+(k)}\right|_{k=k_j} = -\left.\frac{\mathrm{Tr}\{\Pi(k)\}\det\Phi_+(k)}{\partial_k\det\Phi_+(k)}\right|_{k=k_j}.$$

To calculate the right-hand side in this formula recall that the evolution functional Π has simple pole at $k=k_j$ and that $\det\Phi_+(k)$ can be written as

$$\det\Phi_+(k) = \det\phi_+(k)\det\Gamma(k) = \det\phi_+(k)\prod_{i=1}^{s}\left(\frac{k-k_i}{k-\overline{k_i}}\right)^{\nu_i},$$

where $\det\phi_+(k)\neq 0$. Simple calculations give

$$\frac{\mathrm{d}k_j}{\mathrm{d}t} = -\frac{\mathrm{Tr}\{\mathrm{Res}\,\Pi(k_j)\}}{\nu_j}.$$

Here "Res" denotes the residue of $\Pi(k)$ at $k=k_j$. Noticing that the left-hand side does not depend on x, we simplify the above-mentioned equation setting $x\to\pm\infty$:

$$\frac{\mathrm{d}k_j}{\mathrm{d}t} = -\frac{\mathrm{Tr}\{\mathrm{Res}\,\Upsilon(-\infty,\infty;k_j)H_2\}}{\nu_j} \equiv \frac{\mathrm{Tr}\{\mathrm{Res}\,\Upsilon(-\infty,\infty;k_j)H_1\}}{\nu_j}. \tag{57}$$

Similarly, using $\det\Phi_-^{-1}$, we get

$$\frac{\mathrm{d}\overline{k_j}}{\mathrm{d}t} = -\frac{\mathrm{Tr}\{\mathrm{Res}\,\overline{\Upsilon}(-\infty,\infty;\overline{k_j})H_2\}}{\nu_j} \equiv \frac{\mathrm{Tr}\{\mathrm{Res}\,\overline{\Upsilon}(-\infty,\infty;\overline{k_j})H_1\}}{\nu_j}. \tag{58}$$

In derivation of the perturbation-induced evolution of the null vectors we will use the following remarkable identities [written for the x-independent null vectors; see (37)]:

$$\mathrm{Res}\,\Pi(k_j)|P_l^{(j)}\rangle = -\frac{\delta k_j}{\delta t}|P_l^{(j)}\rangle, \quad \langle\overline{P}_l^{(j)}|\mathrm{Res}\,\overline{\Pi}(\overline{k_j}) = \langle\overline{P}_l^{(j)}|\frac{\delta\overline{k_j}}{\delta t}, \tag{59}$$

as well as other two identities:

$$\Phi_+(k_j)e^{ik_jxA}\mathrm{Res}\,\Pi(k_j)=0, \quad \mathrm{Res}\overline{\Pi}(\overline{k_j})e^{-i\overline{k}_jxA}\Phi_-^{-1}(\overline{k_j})=0, \tag{60}$$

which follow from (48). To verify the identities (59) one can proceed as follows. Introduce functions $F_j^{(+)}(k)=(k-k_j)\Phi_+^{-1}(k)$ and $F_j^{(-)}(k)=(k-\overline{k_j})\Phi_-(k)$. The regularization matrices $\Gamma^{-1}(k)$ and $\Gamma(k)$ have simple poles at $k=k_j$ and $k=\overline{k_j}$, respectively. Hence the introduced matrix functions are holomorphic in some neighborhoods of these points. Now compute the product

$$\left\{F_j^{(+)}(k)\frac{\delta\Phi_+(k)}{\delta t}|p_l^{(j)}\rangle\right\}_{k=k_j} = \{(k-k_j)e^{ikxA}\Pi(k)e^{-ikxA}|p_l^{(j)}\rangle\}_{k=k_j}$$
$$= e^{ik_jxA}\mathrm{Res}\,\Pi(k_j)e^{-ik_jxA}|p_l^{(j)}\rangle.$$

On the other hand,

$$\left\{F_j^{(+)}(k)\frac{\delta\Phi_+(k)}{\delta t}\right\}_{k=k_j} = \left\{\frac{\delta}{\delta t}(k-k_j)I\right\}_{k=k_j} - \left\{\frac{\delta F_j^{(+)}(k)}{\delta t}\Phi_+(k)\right\}_{k=k_j}$$
$$= -\frac{\delta k_j}{\delta t}I - \frac{\delta F_j^{(+)}(k_j)}{\delta t}\Phi_+(k_j).$$

Multiplication by $|p_l^{(j)}\rangle$ of the latter formula and comparison with the former leads to the first identity in (59). The second one can be checked in a similar way.

Now let us derive evolution equations for the x-independent null vectors defined in (37). To this goal we simply differentiate Eq. (26),

$$\frac{\delta}{\delta t}(\Phi_+(k_j)e^{ik_jxA}|P_l^{(j)}\rangle) = \{\Phi_+(k)e^{ikxA}\Pi(k)|P_l^{(j)}\rangle\}_{k=k_j} + \frac{\delta k_j}{\delta t}\frac{\partial\Phi_+(k_j)}{\partial k}e^{ik_jxA}|P_l^{(j)}\rangle$$
$$+ \frac{\delta k_j}{\delta t}\Phi_+(k_j)ixAe^{ik_jxA}|P_l^{(j)}\rangle + \Phi_+(k_j)e^{ik_jxA}\frac{\delta|P_l^{(j)}\rangle}{\delta t} = 0.$$

Denote $\Pi_r(k_j)$ the value of the regular part of $\Pi(k)$ at $k=k_j$,

$$\Pi_r(k_j)=\left\{\Pi(k)-\frac{\mathrm{Res}\,\Pi(k_j)}{k-k_j}\right\}_{k=k_j}. \tag{61}$$

Then, using (59) and (60) to cancel out secular terms, we arrive at

$$\Phi_+(k_j)e^{ik_jxA}\left\{\frac{\delta|P_l^{(j)}\rangle}{\delta t}+\Pi_r(k_j)|P_l^{(j)}\rangle\right\}=0.$$

Using the same arguments as in Sec. III for derivation of the integrable evolution we get, adding the latter,

$$\frac{\mathrm{d}|P_l^{(j)}\rangle}{\mathrm{d}t}=-\Omega(k_j)|P_l^{(j)}\rangle-\Pi_r(k_j)|P_l^{(j)}\rangle. \tag{62}$$

Similarly,

$$\frac{\mathrm{d}\langle\overline{P}_l^{(j)}|}{\mathrm{d}t}=\langle\overline{P}_l^{(j)}|\Omega(\overline{k}_j)+\langle\overline{P}_l^{(j)}|\overline{\Pi}_r(\overline{k}_j), \tag{63}$$

where

$$\overline{\Pi}_r(\overline{k}_j)=\left\{\overline{\Pi}(k)-\frac{\mathrm{Res}\,\overline{\Pi}(k_j)}{k-\overline{k}_j}\right\}_{k=\overline{k}_j}. \tag{64}$$

In the case of the involution equation (63) is Hermitian conjugate to (62). Note that the left-hand sides of Eqs. (62) and (63) do not depend on x. Hence we can send $x\to\pm\infty$ to considerably simplify these equations. Consider, for instance, (62). Letting $x\to\infty$ and introducing the notations

$$|P_l^{(j)}\rangle=H_1|P_l^{(j)}\rangle+H_2|P_l^{(j)}\rangle\equiv|P_l^{(j)},1\rangle+|P_l^{(j)},2\rangle$$

and $\Upsilon^{(1)}=H_1\Upsilon H_2$, $\Upsilon^{(2)}=H_2\Upsilon H_2$ we get the following system;

$$\frac{\mathrm{d}|P_l^{(j)},1\rangle}{\mathrm{d}t}=-i\omega(k_j)|P_l^{(j)},1\rangle-\Upsilon_r^{(1)}(-\infty,\infty;k_j)|P_l^{(j)},2\rangle, \tag{65a}$$

$$\frac{\mathrm{d}|P_l^{(j)},2\rangle}{\mathrm{d}t}=\{i\omega(k_j)-\Upsilon_r^{(2)}(-\infty,\infty;k_j)\}|P_l^{(j)},2\rangle. \tag{65b}$$

Here $\Upsilon_r(k_j)$ is the value of the regular part of the matrix $\Upsilon(k)$ at $k=k_j$:

$$\Upsilon_r(k_j)=\left\{\Upsilon(k)-\frac{\mathrm{Res}\,\Upsilon(k_j)}{k-k_j}\right\}_{k=k_j}. \tag{66}$$

When dealing with vector PDEs, i.e., for $n=N-1$, one can define the polarization-phase parameters of vector solitons as quotients of components of the null vectors (note that the zeros are simple in this particular case). Let $C_l^{(j)}=P_l^{(j)}/P_N^{(j)}$, $l=1,\ldots,n=N-1$, where $|P^{(j)}\rangle=(P_1^{(j)},\ldots,P_N^{(j)})^T$. Then from (65) we obtain

$$\frac{\mathrm{d}C_l^{(j)}}{\mathrm{d}t}=\{-2i\omega(k_j)+\Upsilon_{rNN}(-\infty,\infty;k_j)\}C_l^{(j)}-\Upsilon_{rlN}(-\infty,\infty;k_j),\quad l=1,...,n.$$

This particular case ($n=N-1$) contains the vector NLS (8) and the complex modified KdV (9) equations as examples. In view of the considerable importance of such vector nonlinear PDEs, we formulate the result of this section in the following theorem.

Theorem: *Let*

$$iQ_t+V_0(Q,Q_x,Q_{xx},\ldots)=\epsilon R(x,t,Q,Q_x,Q_{xx},\ldots) \tag{67}$$

be a perturbed nonlinear PDE associated with the $N\times N$ matrix Zakharov–Shabat spectral problem,

$$\partial_x\Phi=ik[A,\Phi]+iQ(x,t)\Phi, \quad A=\mathrm{diag}(I_n,-1), \tag{68}$$

where ($n=N-1$)

$$Q=\begin{pmatrix}0 & \mathbf{q}\\ \mathbf{q}^\dagger & 0\end{pmatrix}, \quad R=\begin{pmatrix}0 & \mathbf{r}\\ -\mathbf{r}^\dagger & 0\end{pmatrix}, \quad \mathbf{q}=(q_1,q_2,\ldots,q_n)^T, \quad \mathbf{r}=(r_1,r_2,\ldots,r_n)^T.$$

Here the matrix function V_0 represents the limiting integrable evolution given by the dispersion relation $\Omega(k)=i\omega(k)A$, while R contains the terms destroying integrability (ϵ is a small parameter). Then the perturbed evolution is equivalent to the following evolution of the spectral data:

$$\frac{dk_j}{dt}=-\epsilon\,\mathrm{Res}\,\Upsilon_{NN}(t,k_j), \tag{69}$$

$$\frac{dC_l^{(j)}}{dt}=\{-2i\omega(k_j)+\epsilon\Upsilon_{rNN}(t,k_j)\}C_l^{(j)}-\epsilon\Upsilon_{rlN}(t,k_j), \quad l=1,\ldots,n, \tag{70}$$

$$\frac{\partial b_l(k)}{\partial t}=\{-2i\omega(k)+\epsilon\Upsilon_{NN}(t,k)\}b_l(k)+\epsilon\Upsilon_{lN}(t,k), \quad l=1,\ldots,n. \tag{71}$$

Here

$$\Upsilon(t,k)=\int_{-\infty}^{\infty}dx e^{-ikxA}\Phi_+^{-1}(x,t,k)R(x,t)\Phi_+(x,t,k)e^{ikxA}, \tag{72}$$

$$\Upsilon_r(t,k_j)=\left\{\Upsilon(t,k)-\frac{\mathrm{Res}\,\Upsilon(t,k_j)}{k-k_j}\right\}_{k=k_j}.$$

The matrix function $\Phi_+(x,t,k)$ solves the spectral problem (68) and the RH problem

$$\Phi_+^\dagger(x,t,k)\Phi_+(x,t,k)=e^{ikxA}G(k,t)e^{-ikxA}, \quad k\in\mathrm{Re},$$

$$\Phi_+(k)\to I, \quad k\to\infty$$

of analytic factorization of matrix $G(k,t)$,

$$G(k,t)=\begin{pmatrix}I_n & \mathbf{b}(k,t)\\ \mathbf{b}^\dagger(k,t) & 1\end{pmatrix}, \quad \mathbf{b}=(b_1,b_2,\ldots,b_n)^T.$$

The Riemann–Hilbert problem has (simple) zeros $k_j(t)$, $j=1,\ldots,s$, given by $a(k_j,t)=\det\Phi_+(x,t,k_j)=0$. The vector-columns $|C^{(j)}(t)\rangle=(C_1^{(j)}(t),C_2^{(j)}(t),\ldots,C_n^{(j)}(t),1)$ are the null vectors of the matrices $\Phi_+(x,t,k_j)e^{ik_jxA}$:

$$\Phi_+(x,t,k_j)e^{ik_jxA}|C^{(j)}(t)\rangle=0, \quad j=1,\ldots,s.$$

The initial spectral data are obtained via solution of the spectral equation (68) and represent the spectral characterization of the potential $Q(x,0)$. *For real* k, *the spectral densities of radiation* $b_l(k,t)$ *and the function* $a(k,t)$ *satisfy the following identity*

$$\overline{a}a = 1 - \sum_{l=1}^{n} \overline{b}_l b_l .$$

The potential $\mathbf{q}(x,t)$ *is reconstructed by the formula*

$$q_l(x,t) = 2 \lim_{k\to\infty} k(\Phi_+)_{l,N}(x,t,k), \quad l = 1,...,n.$$

Some comments are necessary on the use of Eqs. (69)–(71) for the spectral data. These equations are *exact*, i.e., they account for the perturbation exactly. As a consequence, for the nonintegrable PDE (67), these equations are nonclosed ODEs. Equations (69)–(71) are nonclosed because they explicitly contain the matrix $\Phi_+(x,t,k)$, solution of the RH problem. Therefore, Eqs. (69)–(71) serve as the generating equations for the perturbation expansion: expanding the spectral data into the asymptotic power series in ϵ, one obtains the sequence of closed approximate ODEs for the spectral data. In this way, one does not need to solve the RH problem—the computations are algebraic. In Sec V, we consider a single multicomponent soliton as an example.

V. MULTICOMPONENT SOLITON UNDER PERTURBATIONS

In this section we apply the theorem for construction of the perturbation theory for a single multicomponent soliton. This can be done without specifying the dispersion relation $\omega(k)$ determining the evolution of the spectral data in the unperturbed PDE. Hence our results apply to all nearly integrable vector PDEs associated with the Zakharov–Shabat spectral problem. In the following, we derive equations describing the evolution of the soliton parameters and give formulas for the first-order radiation. For a single vector soliton given by formula (40), i.e., $q_l = 2i\eta\theta_l e^{i(\xi/\eta)z}\operatorname{sech} z$, where $z = 2\eta(x - \overline{x})$, the regularization matrix Γ has the form

$$\Gamma = I - \frac{i\eta}{(k-\overline{k}_1)\cosh z} \begin{pmatrix} e^{-z}|\theta\rangle\langle\theta| & e^{i(\xi/\eta)z}|\theta \\ \langle\theta|e^{-i(\xi/\eta)z} & e^{z} \end{pmatrix}. \tag{73}$$

Here $k_1 = \xi + i\eta$ and we have used the vector notations $|\theta\rangle = (\theta_1,\ldots,\theta_n)^T$ and $\langle\theta| = (\overline{\theta}_1,\ldots,\overline{\theta}_n)$. To simplify some of the calculations introduce the following basis (in the n-dimensional subspace):

$$|\theta^{(1)}\rangle = |\theta\rangle, \quad |\theta^{(2)}\rangle, \quad \ldots, \quad |\theta^{(n)}\rangle; \quad \langle\theta^{(l)}|\theta^{(m)}\rangle = \delta_{lm}.$$

The explicit form of the vectors $|\theta^{(l)}\rangle$ for $l = 2,...,n$ will not be needed at all. Also we will use the basis

$$|e_1\rangle = (1,0,...,0)^T, \quad |e_2\rangle = (0,1,0,...,0)^T, \quad \ldots, \quad |e_n\rangle = (0,...,0,1)^T.$$

With the help of the unitary transformation matrix Ξ, defined as

$$\Xi = \begin{pmatrix} B & 0 \\ 0 & 1 \end{pmatrix}, \quad B = \sum_{l=1}^{n} |e_l\rangle\langle\theta^{(l)}|, \tag{74}$$

the regularization matrix Γ can be considerably simplified:

$$\tilde{\Gamma} = \Xi\Gamma\Xi^{-1} = I - \frac{i\eta}{(k-\overline{k}_1)\cosh z} \begin{pmatrix} e^{-z}|e_1\rangle\langle e_1| & e^{i(\xi/\eta)z}|e_1 \\ \langle e_1|e^{-i(\xi/\eta)z} & e^{z} \end{pmatrix}. \tag{75}$$

Note the evident property $\tilde{\Gamma}^{-1}=\tilde{\Gamma}^{\dagger}$.

The transformation matrix Ξ depends on t due to the perturbation-induced time dependence of the θ-parameters, but does not depend on x. This simple fact allows us to use the transformation with Ξ inside the integrals defining Υ (72). Taking into account that $\Phi_{+}=\Gamma$ for the pure soliton solution of the unperturbed PDE, in the first order we get

$$\tilde{\Upsilon}=\Xi\Upsilon\Xi^{-1}=\int_{-\infty}^{\infty}\mathrm{d}x\, e^{-ikxA}\tilde{\Gamma}^{-1}\tilde{R}\tilde{\Gamma}e^{ikxA}.$$

Here we have defined

$$\tilde{R}=\Xi R\Xi^{-1}=\begin{pmatrix}0 & B|r\rangle\\ -\langle r|B^{\dagger} & 0\end{pmatrix}, \tag{76}$$

where, for convenience of the following presentation, we have changed the notation for the perturbation: $|r\rangle=\mathbf{r}=(r_1,\ldots,r_n)^T$.

In fact, we will need only one diagonal element

$$\Upsilon_{NN}=(\Xi^{-1}\tilde{\Upsilon}\Xi)_{NN}=\int_{-\infty}^{\infty}\mathrm{d}x(\tilde{\Gamma}^{\dagger}\tilde{R}\tilde{\Gamma})_{NN}$$

and the following nondiagonal matrix elements:

$$\Upsilon_{lN}=(\Xi^{-1}\tilde{\Upsilon}\Xi)_{lN}=\sum_{m=1}^{n}B^{-1}_{lm}\tilde{\Upsilon}_{mN}=\theta_l\tilde{\Upsilon}_{1N}+\sum_{m=2}^{n}B^{-1}_{lm}\tilde{\Upsilon}_{mN}=\theta_l\tilde{\Upsilon}_{1N}+F_l,$$

where $l=1,\ldots,n$. The second term simplifies as follows:

$$\begin{aligned}F_l&=\int_{-\infty}^{\infty}\mathrm{d}x\, e^{-2ikx}\sum_{m=2}^{n}B^{-1}_{lm}\tilde{R}_{mN}\tilde{\Gamma}_{NN}\\&=\int_{-\infty}^{\infty}\mathrm{d}x\, e^{-2ikx}\tilde{\Gamma}_{NN}\sum_{m=2}^{n}\langle e_l|B^{-1}|e_m\rangle\langle e_m|B|r\rangle\\&=\int_{-\infty}^{\infty}\mathrm{d}x\, e^{-2ikx}\tilde{\Gamma}_{NN}(r_l-\theta_l\langle\theta|r\rangle).\end{aligned} \tag{77}$$

After simple calculations we get

$$\Upsilon_{NN}=\frac{i}{4}\int_{-\infty}^{\infty}\mathrm{d}z\,\mathrm{sech}^2 z\left(\frac{e^{-z}}{k-k_1}+\frac{e^{z}}{k-\overline{k_1}}\right)(r_0(z)+\overline{r_0}(-z)), \tag{78}$$

$$\begin{aligned}\Upsilon_{lN}=&\frac{\theta_l}{8\eta}\int_{-\infty}^{\infty}\mathrm{d}z\,\mathrm{sech}^2 z\,\frac{\exp\{-2ikx+i(\xi/\eta)z\}}{(k-k_1)(k-\overline{k_1})}\\&\times\{-4\eta^2\overline{r_0}(-z)+[e^{-2z}(k-\overline{k_1})+e^{2z}(k-k_1)]^2 r_0(z)\}+F_l.\end{aligned} \tag{79}$$

Here we have used the notation

$$r_0=e^{-i(\xi/\eta)z}\tilde{R}_{1N}=e^{-i(\xi/\eta)z}\langle\theta|r\rangle=e^{-i(\xi/\eta)z}\sum_{l=1}^{n}\overline{\theta_l}r_l. \tag{80}$$

A. Evolution of the soliton parameters

Let us first derive evolution equations for the soliton parameters η, ξ, $\overline{x}$, and θ_l, $l=1,\ldots,n$. Using the identity $-2ik_1x+i(\xi/\eta)z=z+2\eta\overline{x}-2i\xi\overline{x}$ and the definition $C_l=\theta_l e^{2(\eta-i\xi)\overline{x}}$ from Sec. III, we obtain

$$\mathrm{Res}\,\Upsilon_{NN}(k_1)=\frac{i}{4}\int_{-\infty}^{\infty}\mathrm{d}z\, e^{-z}\mathrm{sech}^2\, z(r_0(z)+\overline{r_0}(-z)), \tag{81}$$

$$\Upsilon_{rNN}(k_1)=\frac{1}{8\eta}\int_{-\infty}^{\infty}\mathrm{d}z\, e^{z}\mathrm{sech}^2\, z(r_0(z)+\overline{r_0}(-z)), \tag{82}$$

$$\Upsilon_{rlN}(k_1)=C_l\{-2i\overline{x}\,\mathrm{Res}\{\Upsilon_{NN}(k_1)\}+\Upsilon_{rNN}(k_1)+J_0\}+f_l, \tag{83}$$

where

$$J_0=\frac{1}{4\eta}\int_{-\infty}^{\infty}\mathrm{d}z\,\mathrm{sech}^2\, z(\cosh z+ze^{-z})(r_0(z)-\overline{r_0}(-z))$$

and

$$f_l=F_l(k_1)=\frac{e^{2(\eta-i\xi)\overline{x}}}{4\eta}\int_{-\infty}^{\infty}\mathrm{d}z\,\mathrm{sech}\, z(e^{-i(\xi/\eta)z}r_l-\theta_l r_0).$$

Let us first consider the more involved derivation of equations for $\overline{x}$ and θ_l. From Eqs. (70), (82), and (83) we get

$$\frac{\mathrm{d}C_l}{\mathrm{d}t}=(-2i\omega(k_1)+2\epsilon i\overline{x}\,\mathrm{Res}\,\Upsilon_{NN}(k_1)-\epsilon J_0)C_l-\epsilon f_l, \tag{84}$$

from which it follows that

$$\frac{\mathrm{d}|C_l|^2}{\mathrm{d}t}=[4\,\mathrm{Im}\{\omega(k_1)\}-4\epsilon\overline{x}\,\mathrm{Im}\{\mathrm{Res}\,\Upsilon_{NN}(k_1)\}-2\epsilon\,\mathrm{Re}\{J_0\}]|C_l|^2-2\epsilon\,\mathrm{Re}\{f_l\overline{C_l}\}.$$

Recalling that $\Sigma_{l=1}^{n}|\theta_l|^2=1$ we obtain

$$\frac{\mathrm{d}\overline{x}}{\mathrm{d}t}=\frac{e^{-4\eta\overline{x}}}{4\eta}\sum_{l=1}^{n}\frac{\mathrm{d}|C_l|^2}{\mathrm{d}t}-\frac{\overline{x}}{\eta}\frac{\mathrm{d}\eta}{\mathrm{d}t},$$

$$\frac{\mathrm{d}\theta_l}{\mathrm{d}t}=\theta_l\left(C_l^{-1}\frac{\mathrm{d}C_l}{\mathrm{d}t}-2\frac{\mathrm{d}(\eta\overline{x})}{\mathrm{d}t}+2i\frac{\mathrm{d}(\xi\overline{x})}{\mathrm{d}t}\right).$$

The rest calculations are straightforward substitutions and using the identity $\Sigma_{l=1}^{n}f_l\overline{C_l}=0$, which follows from the definitions of C_l, r_0, and f_l. After simple calculations one gets a system of equations for the soliton parameters:

$$\frac{\mathrm{d}\eta}{\mathrm{d}t}=-\frac{\epsilon}{2}\int_{-\infty}^{\infty}\mathrm{d}z\,\mathrm{sech}\, z\,\mathrm{Re}\{r_0\}, \tag{85}$$

$$\frac{\mathrm{d}\xi}{\mathrm{d}t}=-\frac{\epsilon}{2}\int_{-\infty}^{\infty}\mathrm{d}z\,\mathrm{sech}\, z\tanh z\,\mathrm{Im}\{r_0\}, \tag{86}$$

$$\frac{d\overline{x}}{dt}=\frac{\mathrm{Im}\{\omega(k_1)\}}{\eta}-\frac{\epsilon}{4\eta^2}\int_{-\infty}^{\infty}dz\, z\,\mathrm{sech}\, z\,\mathrm{Re}\{r_0\}, \tag{87}$$

$$\frac{d\theta_l}{dt}=i\theta_l\left\{\frac{2\,\mathrm{Im}\{\overline{k_1}\omega(k_1)\}}{\eta}-\frac{\epsilon}{2\eta^2}\int_{-\infty}^{\infty}dz\,\mathrm{sech}\, z[\xi z\,\mathrm{Re}\{r_0\}+\eta(1-z\tanh z)\mathrm{Im}\{r_0\}]\right\}$$
$$+\frac{\epsilon}{4\eta}\int_{-\infty}^{\infty}dz\,\mathrm{sech}\, z(\theta_l r_0-e^{-i(\xi/\eta)z}r_l). \tag{88}$$

These equations can be compared with the adiabatic equations derived by Karpman[21] for the single scalar soliton. First, it is convenient to introduce the average phase $\overline{\delta}$ of the soliton by setting

$$\overline{\delta}=\sum_{l=1}^{n}|\theta_l|^2\delta_l.$$

The evolution equation for the average phase then follows from Eq. (88):

$$\frac{d\overline{\delta}}{dt}=\frac{2\,\mathrm{Im}\{\overline{k_1}\omega(k_1)\}}{\eta}-\frac{\epsilon}{2\eta^2}\int_{-\infty}^{\infty}dz\,\mathrm{sech}\, z[\xi z\,\mathrm{Re}\{r_0\}+\eta(1-z\tanh z)\mathrm{Im}\{r_0\}]. \tag{89}$$

Remarkably, the slow evolution of the soliton amplitude η, phase gradient ξ, position $\overline{x}$, and average phase $\overline{\delta}$ is given by equations similar to those derived for the single scalar soliton. The only trace of the vector nature of the soliton in Eqs. (85)–(87) and (89) is that the ''scalar'' perturbation r_0 obtains by averaging the original vector perturbation as follows:

$$r_0=e^{-i(\xi/\eta)z}\sum_{l=1}^{n}\overline{\theta_l}r_l.$$

The equation for $\theta_l=s_l e^{i\delta_l}$ can be cast in the form of two separate equations, one for the polarization parameters s_l and the other for the phases δ_l. We get

$$\frac{ds_l}{dt}=\frac{\epsilon}{4\eta}\int_{-\infty}^{\infty}dz\,\mathrm{sech}\, z\,\mathrm{Re}\{s_l r_0-e^{-i(\xi/\eta)z-i\delta_l}r_l\}, \tag{90}$$

$$\frac{d\delta_l}{dt}=\frac{2\,\mathrm{Im}\{\overline{k_1}\omega(k_1)\}}{\eta}-\frac{\epsilon}{2\eta^2}\int_{-\infty}^{\infty}dz\,\mathrm{sech}\, z[\xi z\,\mathrm{Re}\{r_0\}+\eta(1-z\tanh z)\mathrm{Im}\{r_0\}]$$
$$+\frac{\epsilon}{4\eta}\int_{-\infty}^{\infty}dz\,\mathrm{sech}\, z\,\mathrm{Im}\{r_0-s_l^{-1}e^{-i(\xi/\eta)z-i\delta_l}r_l\}. \tag{91}$$

Note that the equation for δ_l contains s_l in the denominator as a reflection of the fact that the phase is not defined for the components which are not excited.

B. First-order radiation

Now let us consider the evolution of the spectral densities $b_l(k)$ of radiation. Taking into account radiation in the first-order approximation amounts to solving the linearized regular Riemann–Hilbert problem (or the jump problem),

$$\phi_+(k)-\phi_-(k)=\Gamma(k)\begin{pmatrix}0 & e^{2ikx}|b(k)\rangle\\ \langle b(k)|e^{-2ikx} & 0\end{pmatrix}\Gamma^{-1}(k),$$

where we have used the notation $|b\rangle=\mathbf{b}=(b_1,\ldots,b_n)^T$. Solution of the above-mentioned jump problem is obtained by integration and using the normalization condition $\phi_{\pm}(k)\to I$ as $k\to\infty$. We obtain

$$\phi(k)=I+\frac{1}{2i\pi}\int_{-\infty}^{\infty}\frac{d\not{\ell}}{\not{\ell}-k}\Gamma(\not{\ell})\begin{pmatrix}0 & e^{2i\not{\ell}x}|b(\not{\ell})\rangle\\ \langle b(\not{\ell})|e^{-2i\not{\ell}x} & 0\end{pmatrix}\Gamma^{-1}(\not{\ell}).$$

The contribution from radiation to the solution follows from the formula (4),

$$q_l^{(\mathrm{rad})}=-2\lim_{k\to\infty}k\phi_{lN}(k)=\frac{1}{i\pi}\int_{-\infty}^{\infty}dk\left\{\Gamma(k)\begin{pmatrix}0 & e^{2ikx}|b(k)\rangle\\ \langle b(k)|e^{-2ikx} & 0\end{pmatrix}\Gamma^{-1}(k)\right\}_{lN}.$$

As in derivation of the equations for the soliton parameters it is convenient to use the transformation with the matrix Ξ. Using this transformation and formula (75) one can easily simplify the formula for radiation contribution. We get $q_l^{(\mathrm{rad})}=q_l^{(\|)}+q_l^{(\perp)}$, where the "parallel" and "perpendicular" parts of radiation are defined as follows:

$$q_l^{(\|)}=\frac{\eta\theta_l e^{i(\xi/\eta)z}}{i\pi}\int_{-\infty}^{\infty}\frac{d\lambda}{\lambda^2+1}\{(\lambda+i\tanh z)^2e^{i\lambda z}\langle\theta|g(\lambda)\rangle+\mathrm{sech}^2 z e^{-i\lambda z}\langle g(\lambda)|\theta\rangle\},\quad(92a)$$

$$q_l^{(\perp)}=\frac{\eta e^{i(\xi/\eta)z}}{i\pi}\int_{-\infty}^{\infty}\frac{d\lambda}{\lambda-i}e^{i\lambda z}(\lambda+i\tanh z)(g_l(\lambda)-\theta_l\langle\theta|g(\lambda)\rangle).\quad(92b)$$

Here, for convenience, we have introduced the modified spectral parameter by setting $k=\eta\lambda+\xi$ and the modified spectral densities of radiation:

$$g_l(\lambda)=e^{2i(\eta\lambda+\xi)\overline{x}}\overline{b}_l(\eta\lambda+\xi).\quad(93)$$

The separation of radiation into parallel and perpendicular parts is due the following facts. While the perpendicular part $q_l^{(\perp)}$ satisfies the orthogonality property

$$\sum_{l=1}^{n}\overline{\theta}_l q_l^{(\perp)}=0,\quad(94)$$

the parallel part of the radiation is given by the same formula as the radiation of the scalar soliton (multiplied by θ_l), but for the averaged spectral density $\langle\theta|g(\lambda)\rangle$.

Consider the evolution equation (71) for the spectral densities of radiation. In the first-order approximation the term with Υ_{NN} can be neglected. When deriving evolution equations for the modified spectral densities in the first-order approximation one must take into account only the fast (or "integrable") evolution of the soliton parameters involved in the definition of $g(\lambda)$. In particular, the modified spectral parameter λ is t-independent. The only parameter which has the fast t-dependence in (93) is $\overline{x}$. By differentiation of (93) and using (71) and (87) we obtain

$$\frac{\partial g_l(\lambda)}{\partial t}=i\Omega_r(\lambda)g_l(\lambda)+\epsilon\theta_l\Upsilon^{(\|)}(\lambda)+\epsilon\Upsilon_l^{(\perp)}(\lambda),\quad(95)$$

where

$$\Omega_r(\lambda)=2[\lambda\,\mathrm{Im}\{\omega(k_1)\}+\mathrm{Re}\{\omega(k_1)\}-\omega(\eta\lambda+\xi)].\quad(96)$$

The last two terms in Eq. (95) come from Υ_{lN} (79) [the second one is the contribution of F_l (77)]. They read

$$\Upsilon^{(\|)}(\lambda)=\frac{1}{2\,\eta(\lambda^2+1)}\int_{-\infty}^{\infty}\mathrm{d}z\,e^{-i\lambda z}[(\lambda-i\tanh z)^2 r_0-\mathrm{sech}^2\,z\,\overline{r_0}], \tag{97}$$

$$\Upsilon_l^{(\perp)}(\lambda)=\frac{1}{2\,\eta(\lambda+i)}\int_{-\infty}^{\infty}\mathrm{d}z\,e^{-i\lambda z}(\lambda-i\tanh z)(e^{-i(\xi/\eta)z}r_l-\theta_l r_0). \tag{98}$$

Due to the definition of r_0 (80), the perpendicular component satisfies the identity

$$\sum_{l=1}^{n}\overline{\theta_l}\Upsilon_l^{(\perp)}=0. \tag{99}$$

Integrating the equation for $g_l(\lambda)$ with $g_l(\lambda,t=0)=0$ and using the result in (92) we arrive at the first-order correction to initially pure soliton solution. In this case we obtain

$$q_l^{(\|)}=\epsilon\frac{\eta\theta_l e^{i(\xi/\eta)z}}{i\pi}\int_{-\infty}^{\infty}\frac{\mathrm{d}\lambda}{\lambda^2+1}\{(\lambda+i\tanh z)^2 e^{i\lambda z+i\Omega_r(\lambda)t}\gamma^{(\|)}(\lambda)+\mathrm{sech}^2\,z\,e^{-i\lambda z-i\Omega_r(\lambda)t}\overline{\gamma}^{(\|)}(\lambda)\}, \tag{100a}$$

$$q_l^{(\perp)}=\epsilon\frac{\eta e^{i(\xi/\eta)z}}{i\pi}\int_{-\infty}^{\infty}\frac{\mathrm{d}\lambda}{\lambda-i}(\lambda+i\tanh z)e^{i\lambda z+i\Omega_r(\lambda)t}\gamma_l^{(\perp)}(\lambda), \tag{100b}$$

where

$$\gamma^{(\|)}=\frac{1}{2\,\eta(\lambda^2+1)}\int_{-\infty}^{\infty}\mathrm{d}z\,e^{-i\lambda z}[(\lambda-i\tanh z)^2\hat{r}_0^{(+)}-\mathrm{sech}^2\,z\,\hat{r}_0^{(-)}],$$

$$\gamma_l^{(\perp)}=\frac{1}{2\,\eta(\lambda+i)}\int_{-\infty}^{\infty}\mathrm{d}z\,e^{-i\lambda z}(\lambda-i\tanh z)(e^{-i(\xi/\eta)z}\hat{r}_l-\theta_l\hat{r}_0^{(+)}),$$

with

$$\hat{r}_0^{(+)}(z,t,\lambda)=\int_0^t\mathrm{d}\tau\,e^{-i\Omega_r(\lambda)\tau}r_0(z,\tau),\quad \hat{r}_0^{(-)}(z,t,\lambda)=\int_0^t\mathrm{d}\tau\,e^{-i\Omega_r(\lambda)\tau}\overline{r_0}(z,\tau),$$

$$\hat{r}_l(z,t,\lambda)=\int_0^t\mathrm{d}\tau\,e^{-i\Omega_r(\lambda)\tau}r_l(z,\tau).$$

VI. CONCLUSIONS

In construction of the perturbation theory our main idea is to use the Riemann–Hilbert problem associated with the integrable PDE for the nonlinear transformation of the *perturbed* PDE to the spectral space. The evolution equations for the spectral data follow from the evolution functional, an additional object one needs to introduce into the IST theory to account for perturbations. For a single vector soliton, the equations describing evolution of the soliton parameters and first-order radiation are given in explicit form. The method is not restricted to the first order only. For instance, the second-order equations can also be derived. The perturbation theory can be applied for description of dynamics of the spatial optical solitons, soliton pulses in the multispecies Bose–Einstein condensates, soliton propagation in optical fiber with account of the arbitrary polarization of light pulses, and for many other applications of the multicomponent soliton equations.

In this paper we have restricted the consideration to the Zakharov–Shabat spectral problem. However, the approach of this paper was successfully applied to other spectral problems as

well.[41–45] There, the evolution functional was derived and the evolution equations for the spectral data were obtained. The overall result of this and the previous works on the perturbation theory based on the Riemann–Hilbert problem is that this approach *always works*. The explicit form of the evolution functional was the same for all considered spectral problems and, moreover, it undergoes only insignificant changes in the transition from the Cauchy problem to an initial-boundary value problem.[45]

APPENDIX A: SOME COMMENTS ON MULTIPLICITY OF ZEROS

Here we explore in more detail the algebraic and geometric multiplicities of zeros of $\det \Phi_+(k)$ and $\det \Phi_-^{-1}(k)$. For instance, consider the determinant

$$\det \Phi_+ = J_{+1} \wedge \cdots \wedge J_{+n} \wedge J_{-n+1} \wedge \cdots \wedge J_{-N}. \tag{A1}$$

None of the columns $J_{\pm l}(x,k)$ is equal to zero [otherwise, due to uniqueness of solution to Eq. (1) we would have $J_{\pm l}=0$ for all x]. Moreover, the minors in the wedge products of columns of J_+ and J_- satisfy linear homogeneous equations, which follow from (1), Sec. III,

$$\partial_x J_{+1} \wedge \cdots \wedge J_{+n} = \left\{ ik \left(\hat{A}^{(n)} - \frac{n(n+1)}{2} \hat{I}^{(n)} \right) + i\hat{Q}^{(n)} \right\} J_{+1} \wedge \cdots \wedge J_{+n},$$

$$\partial_x J_{-n+1} \wedge \cdots \wedge J_{-N} = \left\{ ik \left(\hat{A}^{(N-n)} - \frac{(N-n)(N-n+1)}{2} \hat{I}^{(N-n)} \right) + i\hat{Q}^{(N-n)} \right\} \times J_{-n+1} \wedge \cdots \wedge J_{-N}.$$

Here $\hat{M}^{(j)}$ denotes a supermatrix, whose action on the wedge products of vector-columns is defined by the rule

$$\hat{M}^{(j)} \Psi_1 \wedge \cdots \wedge \Psi_j = \sum_{p=1}^{j} \Psi_1 \wedge \cdots \wedge M\Psi_p \wedge \cdots \wedge \Psi_j.$$

Therefore, rank $J_{+1} \wedge \cdots \wedge J_{+n} = \operatorname{rank} e_1 \wedge \cdots \wedge e_n = n$, and rank $J_{-n+1} \wedge \cdots \wedge J_{-N} = \operatorname{rank} e_{n+1} \wedge \cdots \wedge e_{N-n} = N-n$. Hence, the only possibility for $\det \Phi_+(k)=0$ is the linear dependence of the columns in J_+H_1 and J_-H_2, e.g., at least one of the columns of J_-H_2 is given as a linear combination of the columns of J_+H_1.

Let ν_j and d_j be the algebraic and geometric multiplicities of the jth zero k_j, i.e.,

$$\det \Phi_+(k) = (k-k_j)^{\nu_j} \psi(k), \quad \psi(k_j) \neq 0, \quad d_j = N - \operatorname{rank} \Phi_+(k_j).$$

Writing down the Taylor expansion of $\Phi_+(k)$ about $k=k_j$ we immediately conclude that

$$\operatorname{rank} \Phi_+(k_j) \geqslant N - \nu_j. \tag{A2}$$

Therefore, in general, the algebraic multiplicity is greater than the geometric one; trivially, they coincide for simple zeros. Representation (A1) gives

$$\operatorname{rank} \Phi_+(k_j) \geqslant \max(n, N-n).$$

Hence the geometric multiplicity satisfies

$$d_j \leqslant N - \max(n, N-n). \tag{A3}$$

We consider only zeros whose algebraic multiplicity is equal to the geometric one. In particular, if $n=N-1$, there can be only one vector in the null space of Φ_+, i.e., $d_j=1$. Hence, in this case, zeros of $\det\Phi_+(k)$ must be simple to satisfy the equal multiplicity condition. This condition requires that the only case of a multiple zero, $\det\Phi_+(k_j)=0$, of order ν_j is that there are precisely ν_j columns of $J_-(k_j)H_2$ and $J_+(x,k)H_1$ which are linear combinations of the columns of $J_+(k_j)H_1$ and $J_-(k_j)H_2$, respectively.

The equal multiplicity condition can be guaranteed by the following constraint [imposed for some (x,t)]

$$\operatorname{rank}\left(\Phi_+, \frac{\partial\Phi_+}{\partial k}\right)=N. \tag{A4}$$

Indeed, for algebraic multiplicity ν_j, by the Taylor expansion, (A4) gives $\operatorname{rank}\Phi_+(k_j)=N-\nu_j$. Conversely, if $\operatorname{rank}\Phi_+(k_j)=N-\nu_j$, for algebraic multiplicity ν_j, then there are at least ν_j columns in $\partial\Phi_+(k_j)/\partial k$ independent from the columns of $\Phi_+(k_j)$. Hence (A4) also holds. Similar results are valid for multiplicities of zeros $\overline{k_j}$, $j=1,\ldots,s$, of $\det\Phi_-^{-1}(k)$.

APPENDIX B: PROPERTIES OF THE REGULARIZATION MATRIX

Here we derive the regularization matrix $\Gamma(k)$ and prove its properties (in the main, we follow Refs. 13 and 58). Dependence on the coordinates x and t is not important for this purpose and omitted. Consider one pair of zeros, say, k_s and $\overline{k_s}$ of $\det\Phi_+(k)$ and $\det\Phi_-^{-1}(k)$, respectively. Let the vectors $|p_l^{(s)}\rangle$ and $\langle\overline{p}_l^{(s)}|$, $l=1,\ldots,\nu_s$, satisfying

$$\Phi_+(k_s)|p_l^{(s)}\rangle=0, \quad \langle\overline{p}_l^{(s)}|\Phi_-^{-1}(\overline{k_s})=0, \tag{B1}$$

span the respective null spaces. Construct the following rational matrix functions

$$\chi_s(k)=I-\frac{k_s-\overline{k_s}}{k-\overline{k_s}}P_s, \quad \overline{\chi_s}(k)=I+\frac{k_s-\overline{k_s}}{k-k_s}P_s,$$

where

$$P_s=\sum_{l,m=1}^{\nu_s}|p_l^{(s)}\rangle(M^{-1})_{lm}\langle\overline{p}_m^{(s)}|, \quad M_{lm}=\langle\overline{p}_l^{(s)}|p_m^{(s)}\rangle$$

and P_s is a projector: $P_s^2=P_s$, $\operatorname{rank}P_s=\nu_s$. It is easy to verify that $\overline{\chi_s}(k)$ is inverse to $\chi_s(k)$: $\chi_s(k)\overline{\chi_s}(k)=I$.

The determinant of $\chi_s(k)$ is easily computed in some appropriate basis, where the projector is represented by a diagonal matrix with ν_s ones and $N-\nu_s$ zeros on the diagonal. We get

$$\det\chi_s(k)=\left(\frac{k-k_s}{k-\overline{k_s}}\right)^{\nu_s}.$$

Hence, with such rational matrices we can factor out the sth pair of zeros. Indeed, consider the products $\Phi_+(k)\chi_s^{-1}(k)$ and $\chi_s(k)\Phi_-^{-1}(k)$. These matrix functions are holomorphic in the upper and lower half planes, respectively [the poles are removable due to the identities (B1)]. On the other hand, the determinants are nonzero for $k=k_s$ and $k=\overline{k_s}$, respectively; thus one pair of zeros is factored out. By introducing a sequence of such matrices,

$$\chi_j(k)=I-\frac{k_j-\overline{k_j}}{k-\overline{k_j}}P_j, \quad \overline{\chi_j}(k)=I+\frac{k_j-\overline{k_j}}{k-k_j}P_j, \quad j=1,\ldots,s, \tag{B2}$$

where $\overline{\chi_j}(k)=\chi_j^{-1}(k)$, we factor out all zeros using the regularization matrix Γ and its inverse, where

$$\Gamma(k)=\chi_1(k)\chi_2(k)\cdots\chi_s(k). \tag{B3}$$

The projector P_j is given by

$$P_j=\sum_{l,m=1}^{s}|e_l^{(j)}\rangle(M^{-1})_{lm}\langle\overline{e}_m^{(j)}|,\quad M_{lm}=\langle\overline{e}_l^{(j)}|e_m^{(j)}\rangle.$$

Here the vectors $|e_l^{(j)}\rangle$ and $\langle\overline{e}_l^{(j)}|$ are related to the basis vectors of the null spaces of $\Phi_+(k_j)$ and $\Phi_-^{-1}(\overline{k_j})$ by triangular equations (if scanned starting from s down to 1):

$$|p_l^{(j)}\rangle=\chi_s^{-1}(k_j)\cdot\chi_{s-1}^{-1}(k_j)\cdots\chi_{j+1}^{-1}(k_j)|e_l^{(j)}\rangle, \tag{B4}$$

$$\langle\overline{e}_l^{(j)}|\chi_{j+1}(\overline{k_j})\cdot\chi_{j+2}(\overline{k_j})\cdots\chi_s(\overline{k_j})=\langle\overline{p}_l^{(j)}|. \tag{B5}$$

Due to $P_j^2=P_j$, these vectors satisfy the identities:

$$\chi_j(k_j)|e_l^{(j)}\rangle=0,\quad\langle\overline{e}_l^{(j)}|\chi_j^{-1}(k_j)=0,\quad l=1,\ldots,\nu_j. \tag{B6}$$

The regularization matrix $\Gamma(k)$ can be made parametrized entirely by the vectors from the null spaces. Indeed, let us decompose $\Gamma(k)$ and the inverse matrix into the partial fractions:

$$\Gamma(k)=I-\sum_{j=1}^{s}\frac{\overline{B}_j}{k-\overline{k}_j},\quad\Gamma^{-1}(k)=I+\sum_{j=1}^{s}\frac{B_j}{k-k_j}, \tag{B7}$$

where due to (B4) and (B5) we have

$$B_j=\sum_{l=1}^{\nu_j}|p_l^{(j)}\rangle\langle v_l^{(j)}|,\quad\overline{B}_j=\sum_{l=1}^{\nu_j}|\overline{v}_l^{(j)}\rangle\langle\overline{p}_l^{(j)}|. \tag{B8}$$

From (B7) and the identity $\Gamma\Gamma^{-1}=\Gamma^{-1}\Gamma=I$ it follows that

$$\Gamma(k_j)|p_l^{(j)}\rangle=0,\quad\langle\overline{p}_l^{(j)}|\Gamma^{-1}(\overline{k_j})=0,\quad l=1,\ldots,\nu_j,\quad j=1,\ldots,s. \tag{B9}$$

These are the equations defining the unknown vectors $|\overline{v}_l^{(j)}\rangle$ and $\langle v_l^{(j)}|$. Indeed, rewriting (B9) we have

$$|p_l^{(j)}\rangle=\sum_{i=1}^{s}\frac{1}{k_j-\overline{k}_i}\sum_{m=1}^{\nu_i}|\overline{v}_m^{(i)}\rangle\langle\overline{p}_m^{(i)}|p_l^{(j)}\rangle,\quad\langle\overline{p}_l^{(j)}|=-\sum_{i=1}^{s}\frac{1}{\overline{k}_j-k_i}\sum_{m=1}^{\nu_i}\langle\overline{p}_l^{(j)}|p_m^{(i)}\rangle\langle v_m^{(i)}|.$$

Inversion of these formulas gives

$$|\overline{v}_l^{(j)}\rangle=\sum_{i=1}^{s}\sum_{m=1}^{\nu_i}|p_m^{(i)}\rangle(D^{-1})_{im,jl},\quad\langle v_l^{(j)}|=\sum_{i=1}^{s}\sum_{m=1}^{\nu_i}(D^{-1})_{jl,im}\langle\overline{p}_m^{(i)}|. \tag{B10}$$

Here the matrix D is defined by

$$D_{im,jl}=\frac{\langle\overline{p}_m^{(i)}|p_l{}^{(j)}\rangle}{k_j-\overline{k}_i}.$$

Substitution of (B10) into (B7) produces the needed formula (29).

Euclidean Friedman–Robertson–Walker cosmology in Brans–Dicke-like theories of gravity

Bertrand Chauvineau[a)]
UMRILGA, Département Fresnel, Observatoire de la Côte d'Azur, Avenue Copernic, 06130 Grasse, France

(Received 6 September 2001; accepted for publication 12 December 2001)

An explicit and tractable form of the complete solution of Brans–Dicke Euclidean Friedman–Robertson–Walker cosmology, in the matter dominated area, is proposed. In this derivation, the (generally imposed) constraint on the Brans–Dicke parameter $\omega > -3/2$ is relaxed. An isolated power-law solution is exhibited, which turns out to describe an accelerated expansion of the universe, without recourse to any cosmological constant or quintessence matter. It appears that this solution can be generalized for all Brans–Dicke-like theories of gravity. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1447589]

I. INTRODUCTION

In the standard cosmological model, the universe is modeled as being isotropic and homogeneous. The metric of such a space–time can always be written in the Friedman–Robertson–Walker form

$$ds^2 = -dt^2 + a(t)^2\left[\frac{dr^2}{1-kr^2} + r^2(d\theta^2 + \sin^2\theta\, d\varphi^2)\right], \tag{1}$$

where $a(t)$ (>0) is the universe scale factor. k $(=+1,0,-1$ for a closed, a flat and an open universe, respectively) describes the geometrical properties of spatial sections. The scale factor is determined inserting the metric (1) in the field equation of the considered theory, in which the matter content is described by a perfect fluid stress tensor, $T_{\alpha\beta} = (\rho + p)u_\alpha u_\beta + p g_{\alpha\beta}$, where the density and pressure fields are related by the state equation $p(\rho)$. For cosmological applications, two extreme cases are generally considered: the so-called matter dominated area, described by $p = 0$, and the so-called radiative area, described by $p = \rho/3$. The cosmological model derived from the general relativity theory (GRT) can be completely integrated, in the matter area, whatever the geometry, leading to the well-known Friedman models.

As soon as Brans and Dicke obtained the equations of their scalar-tensor theory of gravity (BDT, for Brans–Dicke theory), they have reconsidered the standard cosmological model.[1] They have considered the matter dominated area only. The geometrical properties of the space–time are described by the metric (1) and by a time-dependent scalar field $\Phi(t)$. The BDT equations, when written for the metric (1) and the scalar field $\Phi(t)$, are

$$\left(\frac{\dot a}{a} + \frac{\dot\Phi}{2\Phi}\right)^2 + \frac{k}{a^2} = \frac{2\omega+3}{12}\left(\frac{\dot\Phi}{\Phi}\right)^2 + \frac{4K}{3\Phi a^3}, \tag{2}$$

$$\frac{d}{dt}(\dot\Phi a^3) = \frac{4K}{2\omega+3}. \tag{3}$$

The upper point represents the time derivative. K is a (positive) constant, corresponding to $2\pi\rho a^3$ in Brans–Dicke (and standard) notations, where ρ is the mass density (ρa^3 being conserved in the

a)Electronic mail: chauvineau@obs-azur.fr

pressureless case). In the Euclidean case, they have derived an exact solution, where the scale factor and scalar field are power laws of time.[1] The time exponent of the scale factor converges to the GRT value (2/3), when $\omega\to\infty$, while the scalar field, and then the related "effective gravitational constant" (Ref. 1), reduces to a true constant.

Recently, Park and Sin[2] have investigated the Euclidean problem, with a barotropic equation of state $p=(\gamma-1)\rho$, where γ is a constant. They find the solution under a parametric integral form, from which they derive the main properties (singularities, asymptotic forms,...) of the solutions. More recently, Quiros, Bonal, and Cardenas[3] have reinvestigated this problem. As in Park and Sin, the solution is found under a (non easily tractable) parametric integral form. However, these authors point out some divergences between their results and those of Park and Sin, for $-3/2<\omega<-4/3$. Holden and Wands[4] have derived, from a phase-plane analysis, the qualitative properties of the solutions for the elliptic and hyperbolic problems. All these papers are restricted (in the four-dimensional case we are interested in) to the case $\omega>-3/2$.

In this paper, we concentrate on the sole matter dominated case ($p=0$), described by Eqs. (2) and (3). We obtain the complete solution, $a(t)$ and $\Phi(t)$, without the constraint $\omega>-3/2$ (but with the restriction $\omega\neq 3/2$, the scalar Brans–Dicke equation being not defined for $\omega=-3/2$). A power law solution, different from the one considered by Brans and Dicke, is exhibited, in the case $\omega<-3/2$, which describes an accelerated expanding universe. This solution turns out to have its counterpart in the framework of all Brans–Dicke-like theories of gravity.

II. THE GENERAL SOLUTION OF THE EUCLIDEAN CASE IN BRANS–DICKE THEORY

Let us consider the Euclidean case ($k=0$). Equation (2) reduces to

$$\left(\frac{\dot a}{a}+\frac{\dot\Phi}{2\Phi}\right)^2=\frac{3+2\omega}{12}\left(\frac{\dot\Phi}{\Phi}\right)^2+\frac{4K}{3\Phi a^3}, \tag{4}$$

while Eq. (3) can be integrated as

$$\dot\Phi a^3=\frac{4K}{3+2\omega}t. \tag{5}$$

Let us remark that, setting the integration constant to zero in Eq. (5), a choice of the origin of time has been made implicitly. As a consequence, looking for solutions under the form $a\propto t^q$ (and $\Phi\propto t^r$), as made by Brans and Dicke for their exact solution, has the consequence of selecting only solutions with singularity at the so defined origin of time.

Multiplying Eq. (4) by $9\Phi^2a^6$, and using Eq. (5), it turns out that

$$\left[\frac{\mathrm{d}}{\mathrm{d}t}\left(\Phi a^3+\frac{Kt^2}{3+2\omega}\right)\right]^2=12K\left(\Phi a^3+\frac{Kt^2}{3+2\omega}\right). \tag{6}$$

Using the new variable $Z=\Phi a^3+Kt^2/(3+2\omega)$, this equation is rewritten as

$$\left[\frac{\mathrm{d}Z}{\mathrm{d}t}\right]^2=12KZ. \tag{7}$$

This equation shows that one has necessarily $Z\geqslant 0$. Let us rewrite this equation under the form

$$\frac{\mathrm{d}Z}{\mathrm{d}t}=\epsilon.2\sqrt{3K}\sqrt{Z}, \tag{8}$$

where $\epsilon=\pm 1$. Since the choice $\epsilon=-1$ corresponds to a mere reversal of time, let us consider the case $\epsilon=+1$ only.

Equation (8) admits the trivial solution $Z=0$, which leads to an isolated family of solutions

$$\Phi = Pt^{-4}, \tag{9}$$

$$a = At^2, \tag{10}$$

where A and P are two constants related by $A^3P = -K/(3+2\omega)$.

If now $Z>0$, Eq. (8) integrates into

$$\Phi a^3 + \frac{Kt^2}{3+2\omega} = \left(\sqrt{3K}t + A\sqrt{\frac{K}{|3+2\omega|}} \right)^2, \tag{11}$$

where A is an integration constant. Combining this equation with Eq. (5), one obtains

$$\frac{\dot{\Phi}}{\Phi} = \frac{4t}{(3+2\omega)\left(\sqrt{3}t + \dfrac{A}{\sqrt{|3+2\omega|}} \right)^2 - t^2}. \tag{12}$$

Now, two cases have to be distinguished, according to the sign of $3+2\omega$.

If $3+2\omega>0$, Eq. (12) leads to

$$\Phi = P|t-t_1|^{-2/(\sqrt{3(3+2\omega)}+1)}|t-t_2|^{2/(\sqrt{3(3+2\omega)}-1)} \tag{13}$$

and Eq. (5) gives

$$a^3 = s\frac{2K}{P}\frac{4+3\omega}{3+2\omega}|t-t_1|^{(\sqrt{3(3+2\omega)}+3)/(\sqrt{3(3+2\omega)}+1)}|t-t_2|^{(\sqrt{3(3+2\omega)}-3)/(\sqrt{3(3+2\omega)}-1)}, \tag{14}$$

where s is the sign of $(t-t_1)(t-t_2)$. t_1 and t_2 are given by

$$t_1 = \frac{-A}{\sqrt{3(3+2\omega)}+1} \tag{15}$$

and

$$t_2 = \frac{-A}{\sqrt{3(3+2\omega)}-1}. \tag{16}$$

This solution corresponds to the case $\gamma=1$ (the pressureless case) given, for instance, in Ref. 4.

Let us remark that this solution is well-defined for all positive value of $3+2\omega$, apart from $\omega=-4/3$, for which t_2 is not defined. This case can be obtained directly from the integration of Eq. (12). This leads to

$$\Phi = P\left|1+\frac{2t}{A}\right|^{-1}\exp\left(\frac{2t}{A}\right) \tag{17}$$

and Eq. (5) gives

$$a^3 = s\frac{3KA^2}{P}\left(1+\frac{2t}{A}\right)^2\exp\left(-\frac{2t}{A}\right), \tag{18}$$

where s is the sign of $1+2t/A$.

If $3+2\omega<0$, Eq. (12) leads to, up to a mere change of time origin,

$$\Phi = P\left\{1+\left(\frac{t}{\tau}\right)^2\right\}^{-1/|4+3\omega|} \exp\left\{2\,\frac{\sqrt{3|3+2\omega|}}{|4+3\omega|}\arctan\left(\frac{t}{\tau}\right)\right\} \tag{19}$$

while a^3, derived from Eq. (5), writes

$$a^3 = \frac{2K}{P}\,\frac{|4+3\omega|}{|3+2\omega|}\,\tau^2\left\{1+\left(\frac{t}{\tau}\right)^2\right\}^{3|1+\omega|/|4+3\omega|} \times \exp\left\{-2\,\frac{\sqrt{3|3+2\omega|}}{|4+3\omega|}\arctan\left(\frac{t}{\tau}\right)\right\}. \tag{20}$$

In these expressions, one has written

$$\tau = \frac{A}{2|4+3\omega|}. \tag{21}$$

Remark that solutions (13), (14); (17), (18); and (19), (20), when time reflected, correspond to the same solutions (respectively), with the integration constant A changed for $-A$, in such a way that both cases $\epsilon = \pm 1$ are described by the solutions (13), (14); (17), (18) and (19), (20).

III. DETAILED PROPERTIES OF THE SOLUTION AND DISCUSSION

Since Φ determines the effective gravitational constant (Ref. 1), which is positive, we will consider, in all the present discussion, only solutions such that $P>0$. The peculiar properties of these solutions are highlighted in this section.

Consider first the case $\omega > -3/2$. If the integration constant A is chosen to be zero, the Brans–Dicke power law solution is recovered.

If $A \neq 0$, two peculiar dates t_1 and t_2 $(\neq 0)$ enter the solution. As pointed out in Sec. II, changing the sign of A is the same as considering the time-reflected solution. Let us then consider the case $A>0$ only. Since $q_1 = (\sqrt{1+2\omega/3}+1)/(3\sqrt{1+2\omega/3}+1) > 0$, t_1 is a date of singularity, while t_2 is a date of singularity if and only if $q_2 = (\sqrt{1+2\omega/3}-1)/(3\sqrt{1+2\omega/3}-1) > 0$, i.e., if and only if $\omega \notin [-4/3, 0]$. The condition $a>0$ shows that $s=+1$ (respectively -1) in the case $\omega > -4/3$ (respectively $< -4/3$).

If $\omega > -4/3$, one then has $t_2 < t_1 < 0$, and the time t is necessarily outside the time interval $[t_2, t_1]$. The solution exhibits two disconnected branches. Let us point out that, in both branches, a varies as $|t|^{q_1+q_2}$ at $\pm\infty$, where $q_1+q_2 = 2(1+\omega)/(4+3\omega)$. Studying the variations of (14), one finds the following.

(1) If $\omega > 0$, a decreases in the first branch from $+\infty$ at $t=-\infty$ to zero at $t=t_2$, and increases in the second branch from zero at $t=t_1$ to $+\infty$ at $t=+\infty$. $\ddot{a}$, the second time derivative of the scale factor, remains negative in both branches.

(2) If $\omega = 0$, one has $q_2 = 0$. The solution takes the form $a \propto |t-t_1|^{1/2}$. Let us point out that it is defined outside the interval $[t_2, t_1]$ $(=[-A/2, -A/4])$ only. a decreases in the first branch from $+\infty$ at $t=-\infty$ to a finite nonzero value at $t=t_2$, and increases in the second branch from zero at $t=t_1$ to $+\infty$ at $t=+\infty$. $\ddot{a}$ remains negative in both branches.

(3) If $-1 < \omega < 0$, a decrease in the first branch from $+\infty$ at $t=-\infty$, reaches a strictly positive minimum value at a date $t_{\min}$, and increases to $+\infty$ at $t=t_2$. In the second branch, a increases from zero at $t=t_1$ to $+\infty$ at $t=+\infty$. In the first branch, $\ddot{a} < 0$ until a date t_{infl} $(< t_{\min})$, and is positive between t_{infl} and t_2. $\ddot{a}$ remains negative in the second branch.

(4) If $\omega = -1$, one has $q_1+q_2 = 0$. The solution takes the form $a \propto |(t-t_1)/(t-t_2)|^{1/\sqrt{3}}$. It reaches asymptotically a constant value when $t \to \pm\infty$.

(5) If $-4/3 < \omega < -1$, a increases in the first branch from 0 at $t=-\infty$ to $+\infty$ at $t=t_2$. In the second branch, a increases from zero at $t=t_1$ to a maximum value at a date $t_{\max}$, and decreases to zero at $t=+\infty$. $\ddot{a}$ is positive in all the first branch, is negative in the second branch between t_1 and a date t_{infl} $(> t_{\max})$, and is positive between t_{infl} and $+\infty$.

If $\omega = -4/3$, the solution is given by (17) and (18). This solution exhibits a singularity at the time $t_1 = -A/2$. Since $a>0$, one has $s=+1$, and then $t/A > -1/2$. The case $A>0$, being under consideration, one finds the following.

(6) If $\omega=-4/3$, the solution has one branch. a increases from zero at $t_1=-A/2$ to $+\infty$ at $t=+\infty$. $\ddot{a}<0$ from t_1 to a date t_{infl}, and is positive after.

If $\omega<-4/3$, $t_1<0<t_2$, and the condition $a>0$ leads to $s=-1$. The time t is then inside the time interval $[t_1,t_2]$, and one has the following.

(7) If $-3/2<\omega<-4/3$, a increases from zero at $t=t_1$, reaches a maximum value at a date $t_{\max}$, and decreases to zero at $t=t_2$. It is remarkable that the singularity at $t=t_1$ is such that $\dot{a}=\infty$, while the singularity at $t=t_2$ is such that $\dot{a}=0$. $\ddot{a}<0$ from t_1 to a date t_{infl} ($>t_{\max}$), and is positive after.

Consider now the case $\omega<-3/2$. In this case, the solution $a(t)$ is defined for all real value of the time, and turns out to be singularity-free. It reaches a minimum value at a time $t_{\min}$. Here again, if the integration constant A is chosen to be (asymptotically) zero, the Brans–Dicke power law solution is recovered. If, besides, $\omega=-2$, one finds $a\sim t$ and $\Phi\sim 1/t$, the linear solution (in t for the scale factor) to which reduces the linear solution exhibited by Banerjee and Pavon, in the Euclidean case.[5]

Here again, since changing the sign of A is the same as considering the time-reflected solution, we consider the case $A>0$. From Eq. (20), one finds the following two cases.

(8) If $-2\leqslant\omega<-3/2$, a decreases from $+\infty$ at $t=-\infty$, reaches a minimum value at $t_{\min}$, and increases to $+\infty$ at $t=+\infty$. $\ddot{a}$ remains positive for all time.

(9) If $\omega<-2$, a decreases from $+\infty$ at $t=-\infty$, reaches a minimum value at $t_{\min}$, and increases to $+\infty$ at $t=+\infty$. $\ddot{a}$ is positive in an interval $[t_{\text{infl1}},t_{\text{infl2}}]$ containing $t_{\min}$, and is negative outside.

The time-reflected cases $(1')-\ldots.(9')$ of the nine previous cases (in the same order) correspond to the same cases, but with negative values of A.

One has to add the isolated solution (9) and (10) to these cases. For this solution, the relation $PA^3=-K/(3+2\omega)$ shows that $\omega<-3/2$ (from $a>0$, A is necessarily >0 for this solution). One then adds the tenth case.

(10) If $\omega<-3/2$, $a\propto t^2$, and $\ddot{a}$ is positive for all time.

Let us insist on the, at first sight, very strange comportment of the solution (2) near the date t_2: the first branch of the solution ends suddenly at t_2, encountering neither a singularity nor a divergence. This can be checked directly inserting the solution (13) and (14), with $\omega=0$, in the field equations (4) and (5). A careful inspection of the transition from the solution (1) to the solution (3) shows, indeed, that it is a reasonable comportment, since the first branches of (1) and (3) become closer and closer to the curve $a\propto|t-t_1|^{1/2}$, but remain outside $[t_2,t_1]$, when $\omega\to 0^+$ or 0^-. The second branch of the time reversed $(2')$ of (2) begins then suddenly at the date $-t_2$ ($>-t_1$), which is neither the date of a singularity nor of an infinite value for the scale factor $a(t)$.

It could seem disturbing that the solution (6) possesses one branch only. In fact, this is the logical continuity of the case (5), since $\lim_{\omega\to-4/3^+}(t_2)=-\infty$.

Let us remark that the solution (7) does not fill the conclusion derived by Quiros, Bonal and Cardenas for the same values of ω. In this case, these authors have concluded that the problem [as well in the pressureless case as in the barotropic perfect fluid case $p=(\gamma-1)\rho$] is singularity-free in the Jordan frame (the frame considered in the current paper), which, from the present approach made directly in this frame, seems not to be correct, at least in the pressureless case.

It is worth pointing out that the solutions (3), $(3')$, (5), $(5')$, (6), $(7')$, (8), $(8')$, (9), $(9')$, and (10) exhibit phases of accelerated expansion without any recourse to quintessence matter (or to cosmological constant). This possibility, which has already been pointed out[5] for some peculiar power law exact solutions, is enforced here, since it appears to be the case for a wide class of solutions.

Besides, let us mention that, when $\omega\gg 1$, both the exponents q_1 and q_2 are close to 1/3, with the consequence that near the singularity (i.e., at dates such that $|t-t_k|\ll t_1-t_2$), one has $a\propto|t-t_k|^{1/3}$ ($\gg|t-t_k|^{2/3}$). The scale factor varies then as the power 1/3 of time, a comportment drastically different from that of the Friedman solution of GRT (power 2/3 of time). Since $\lim_{\omega\to\infty}(t_1-t_2)=0$, this comportment disappears as soon as the limit is reached.

It can easily be checked that both solutions (13) and (14) and (19) and (20) develop in power series of $1/\omega$, and then converge through the analog GRT solution, i.e., $\Phi = P$ (i.e., a constant) and $a \propto t^{2/3}$, when $|\omega| \to \infty$. However, let us point out the pathological comportment of the isolated solution (9), (10) in this limit process. Indeed, the limit of this solution is highly unphysical (whilst the solution itself, i.e., for a finite ω, is physical), since $\lim_{|\omega|\to\infty}(PA^3) = 0$, which means that either $a \to 0$ (no universe) and/or $\Phi \to 0$ (infinitely strong effective gravitational constant).

IV. A SOLUTION FOR ALL BRANS–DICKE-LIKE THEORIES OF GRAVITY

Let us now consider the previous problem in the framework of general scalar-tensor theories (STT) of gravity, where the Brans–Dicke parameter ω is replaced by an arbitrary function $\omega(\Phi)$ (each such function defining a peculiar STT). For a general presentation of these theories, see for instance Ref. 6. Modulo this change, Eq. (4) remains unchanged, while Eq. (3) is replaced by

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\sqrt{|2\omega(\Phi)+3|}\frac{\mathrm{d}\Phi}{\mathrm{d}t}a^3 \right) = \sigma \frac{4K}{\sqrt{|2\omega(\Phi)+3|}}, \tag{22}$$

where σ is the sign of $2\omega(\Phi)+3$. Let us define a new time variable τ by

$$\mathrm{d}t = \mathrm{d}\tau \sqrt{|2\omega(\Phi)+3|} \tag{23}$$

and let us write X^* for $\mathrm{d}X/\mathrm{d}\tau$. Equation (22) can be integrated, and gives

$$a^3\Phi^* = \sigma 4K\tau, \tag{24}$$

while Eq. (4) can be rewritten as

$$\left[\frac{\mathrm{d}}{\mathrm{d}t}(\Phi a^3 + \sigma K\tau^2) \right]^2 = 12K(\Phi a^3 + \sigma K\tau^2), \tag{25}$$

which generalizes Eq. (6). As in the Brans–Dicke case, this equation admits a trivial solution, which verifies $\Phi a^3 + \sigma K\tau^2 = 0$. Since the case $\Phi > 0$ only is considered, one has necessarily $\sigma = -1$, and then $3 + 2\omega(\Phi) < 0$. This leads to the solution under the parametric form

$$\Phi = P\tau^{-4}, \tag{26}$$

$$a = A\tau^2, \tag{27}$$

and

$$t = \int \mathrm{d}\tau \sqrt{-3 - 2\omega\left(\frac{P}{\tau^4}\right)}, \tag{28}$$

where A and P are related by $A^3P = K$. This solution extends the isolated solution (9) and (10) of the Brans–Dicke problem to the general case of STT.

As in the Brans–Dicke case, this solution leads to an accelerated expansion for a large class of STT. For instance, considering gravity theories characterized by $3 + 2\omega(\Phi) \sim \Phi^\lambda$, where λ is a constant, an accelerated expansion is recovered for $-1/2 < \lambda < +1/2$, which includes, of course, the Brans–Dicke case $\lambda = 0$.

(Received 29 May 2001; accepted for publication 17 December 2001)

This work is devoted to a mathematical analysis of the distributional Schwarzschild geometry. The Schwarzschild solution is extended to include the singularity; the energy momentum tensor becomes a δ-distribution supported at $r=0$. Using generalized distributional geometry in the sense of Colombeau's (special) construction the nonlinearities are treated in a mathematically rigorous way. Moreover, generalized function techniques are used as a tool to give a unified discussion of various approaches taken in the literature so far; in particular we comment on geometrical issues. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1448684]

I. INTRODUCTION

Since the formulation of the first singularity theorems it is generally conceded that singular space–times are of fundamental importance in general relativity. Geometrically, a singularity is defined via the notion of (geodesic) incompleteness, a viewpoint which fits in the singularity theorems of Hawking and Penrose (see, e.g., Ref. 1, Chap. 8), forcing us to regard a singularity as some kind of singular boundary point of space–time. Recently, as an alternative, it has been suggested to describe (mild) singularities as internal points, where the field equations are satisfied in a weak (probably distributional) sense (cf. Ref. 2). General relativity as a physical theory is governed by particular physical equations; the focus of interest is the breakdown of physics which need not coincide with the breakdown of geometry.

In the context of conical space–times algebras of generalized functions[3,4] have been used to overcome the problem of simultaneously dealing with singular (i.e., distributional) metrics and the nonlinearities of general relativity.[5–7] These techniques allow one to assign to the cone metric a singular energy momentum tensor supported on a submanifold of codimension two, which, by a result of Geroch and Traschen,[8] is not possible within classical (i.e., linear) distribution theory.

The main focus of this work is a (nonlinear) distributional description of the Schwarzschild space–time. Although the nature of the Schwarzschild singularity is much ''worse'' than the quasiregular conical singularity, there are several distributional treatments in the literature (cf. Ref. 9–13), mainly motivated by the following considerations: the physical interpretation of the Schwarzschild metric is clear as long as we consider it merely as an exterior (vacuum) solution of an extended (sufficiently large) massive spherically symmetric body. Together with the interior solution it describes the entire space–time. The concept of point particles—well understood in the context of linear field theories—suggests a mathematical idealization of the underlying physics: one would like to view the Schwarzschild solution as defined on the entire space–time and regard it as generated by a point mass located at the origin and acting as the gravitational source. This of course amounts to the question of whether one can reasonably ascribe distributional curvature quantities to the Schwarzschild singularity at the origin.

b)Electronic mail: roland.steinbauer@univie.ac.at

The emphasis of the present work lies on mathematical rigor. We derive the ''physically expected'' result for the distributional energy momentum tensor of the Schwarzschild geometry, i.e., $T_0^0 = 8\pi m \delta^{(3)}(\vec{x})$, in a conceptually satisfactory way. Additionally, we set up a unified language to comment on the respective merits of some of the approaches taken so far. In particular, we discuss questions of differentiable structure as well as smoothness and degeneracy problems of the regularized metrics, and present possible refinements and workarounds. These aims are accomplished using the framework of nonlinear generalized functions (Colombeau algebras)[3,4] and, in particular, the geometric approach taken in Refs. 14 and 15.

The paper is organized in the following way: in Sec. II we discuss the conceptual as well as the mathematical prerequisites. In particular we comment on geometrical matters (differentiable structure, coordinate invariance) and recall the basic facts of nonlinear distributional geometry in the context of algebras of generalized functions. Moreover, we derive sensible regularizations of the singular functions to be used throughout the paper. Section III is devoted to a first approach to the problem; a detailed discussion follows in Sec. IV: we comment on problems and obstacles associated with the direct approach. Finally, in Sec. V, we present a new conceptually satisfactory method to derive the main result. Overly technical calculations are shifted to various appendices. In Sec. VI we investigate the horizon and describe its distributional curvature. Using nonlinear distributional geometry and generalized functions it seems possible to show that the horizon singularity is only a coordinate singularity *without leaving Schwarzschild coordinates*.

II. PREREQUISITES

To begin with, let us have a look at the conceptually much simpler problem of point charges in Maxwell's theory and consider the Coulomb solution $1/r$ of an extended spherically symmetric body. In an idealized picture the charged body is reduced to a point charge, and this way of looking at the problem has proven to be very fruitful, mainly due to the following two reasons: first, the function $1/r \in \mathcal{C}^2(\mathbb{R}^3\backslash\{0\})$, since also in $L^1_{\mathrm{loc}}(\mathbb{R}^3)$, naturally gives rise to a distribution on $\mathbb{R}^3$. Reinserting this distributional potential into the field equation we obtain $\Delta(1/r) = -4\pi\delta$, which has the clear physical interpretation as the charge density of a point charge. Second, also in accordance with physical intuition, the situation may be interpreted in terms of the following sensible regularization scenario: consider a regularization of the ''singular'' potential by any sequence of (say smooth) functions converging weakly to $1/r$. Then, by virtue of linearity of the field equation, distribution theory guarantees that the corresponding sequence of charge densities will converge weakly to $-4\pi\delta$, i.e., the density of the point charge.

The general relativistic case is much more involved. Consider the Schwarzschild metric inside the horizon: extending the space–time to $r=0$ we are confronted with several distinct problems. First—according to the standard picture of general relativity—no manifold structure is given at the singularity $r=0$, since the field equations are meaningless there within the smooth category. In addition, the differentiable structure of the extended manifold cannot be uniquely determined from the differentiable structure of the original space–time. This problem is dealt with in the relevant literature by fixing some differentiable structure by hand, most often the one induced by Cartesians associated with Schwarzschild coordinates.

In analogy to the Maxwell case, we want to regard the metric as a distribution on the whole extended space–time. Now, the second conceptual problem is due to the inherently nonlinear nature of general relativity: no distributional meaning can be given to the field equations, since it is not possible to calculate the curvature from a distributional metric. In the literature, this obstacle is circumvented by using various—more or less—*ad hoc* regularization approaches in order to calculate a regularized Ricci tensor within the smooth category. Eventually, its distributional limit is computed and—via the field equations—a distributional energy momentum tensor is obtained. This tensor may then be interpreted as distributional source of the Schwarzschild geometry.[9–13] However, using ad-hoc regularizations we are confronted with the problem of regularization independence of the results which may not be suitably addressed within this setting.

In this work, while arguing from a related point of view, we are going to use a different

apparatus to deal with the nonlinearities of general relativity: the theory of algebras of generalized functions gives us the additional flexibility and power of a rigorous mathematical framework in which distributions may undergo nonlinear operations. In particular, following the procedure of Ref. 5, we will first model the distributionally extended Schwarzschild metric by a generalized metric obtained by a suitable (and general) regularization procedure. Then, after entering the generalized framework (cf. Ref. 15) we may calculate all the relevant curvature quantities from the generalized metric and subject it to the field equations. Note that within the generalized setting the field equations possess a well-defined meaning. Finally, we may descend to the distributional level for the purpose of interpretation using the concept of association (see the following).

Note that, in general, a regularization procedure depends on the coordinate system it is performed in (for a diffeomorphism invariant notion of regularization using paths of mollifiers see Refs. 16 and 17). However, since we had to fix the differentiable structure beforehand this is no further restriction. Actually, geometric considerations play an important role: as shown in the following, a brute force regularization attempt does not lead to a sensible description of the problem at hand. Indeed, we shall see that a satisfactory treatment of the distributional Schwarzschild space–time has to use the Kerr–Schild form of the Schwarzschild metric (which fixes both the differentiable structure and the coordinates); moreover, it must be retained during the whole regularization process. Note that this is in accordance with physical intuition since in the Kerr–Schild form the radial coordinate retains its spatial character near the singularity which of course is not the case in Schwarzschild coordinates.

In Secs. II A and II B we are going to introduce some mathematical prerequisites. First, we are going to briefly recall generalized tensor analysis and generalized curvature (in Colombeau's so-called special setting). For all further details we refer the reader to Refs. 14 and 15. Second, we explicitly calculate the regularization of the relevant components of the metric tensor to be used throughout the paper.

A. Nonlinear distributional geometry

The basic idea of Colombeau's theory of generalized functions[3,4] is regularization by sequences (nets) of smooth functions and the use of asymptotic estimates in terms of a regularization parameter ϵ. Let $(u_\varepsilon)_{\varepsilon\in(0,1]}$ with $u_\varepsilon\in\mathcal{C}^\infty(M)$ for all ε (M a separable, smooth orientable Hausdorff manifold of dimension n). The algebra of generalized functions on M is defined as the quotient $\mathcal{G}(M):=\mathcal{E}_M(M)/\mathcal{N}(M)$ of the space $\mathcal{E}_M(M)$ of sequences of moderate growth modulo the space $\mathcal{N}(M)$ of negligible sequences. More precisely the notions of moderateness, respectively, negligibility are defined by the following asymptotic estimates [$\mathfrak{X}(M)$ denoting the space of smooth vector fields on M]:

$$\mathcal{E}_M(M):=\{(u_\varepsilon)_\varepsilon:\forall K\subset\subset M,\ \forall k\in\mathbb{N}_0\exists N\in\mathbb{N}\forall \xi_1,\dots,\xi_k\in\mathfrak{X}(M):\sup_{p\in K}|L_{\xi_1}\cdots\ L_{\xi_k}u_\varepsilon(p)|$$
$$=O(\varepsilon^{-N})\},$$
$$\mathcal{N}(M):=\{(u_\varepsilon)_\varepsilon:\forall K\subset\subset M,\ \forall k,q\in\mathbb{N}_0\forall \xi_1,\dots,\xi_k\in\mathfrak{X}(M):\sup_{p\in K}|L_{\xi_1}\cdots\ L_{\xi_k}u_\varepsilon(p)|=O(\varepsilon^q))\}.$$

Elements of $\mathcal{G}(M)$ are denoted by $u=\mathrm{cl}[(u_\varepsilon)_\varepsilon]=(u_\varepsilon)_\varepsilon+\mathcal{N}(M)$. With componentwise operations $\mathcal{G}(M)$ is a fine sheaf of differential algebras with respect to the Lie derivative defined by $L_\xi u:=\mathrm{cl}[(L_\xi u_\varepsilon)_\varepsilon]$. The spaces of moderate, respectively, negligible sequences and hence the algebra itself may be characterized locally, i.e., $u\in\mathcal{G}(M)$ iff $u\circ\psi_\alpha\in\mathcal{G}(\psi_\alpha(V_\alpha))$ for all charts (V_α,ψ_α), where on the open set $\psi_\alpha(V_\alpha)\subset\mathbb{R}^n$ in the respective estimates Lie derivatives are replaced by partial derivatives. Smooth functions are embedded into $\mathcal{G}$ simply by the "constant" embedding σ, i.e., $\sigma(f):=\mathrm{cl}[(f)_\varepsilon]$, hence $\mathcal{C}^\infty(M)$ is a faithful subalgebra of $\mathcal{G}(M)$. On open sets of $\mathbb{R}^n$ compactly supported distributions are embedded into $\mathcal{G}$ via convolution with a mollifier $\rho\in\mathcal{S}(\mathbb{R}^n)$ with unit integral satisfying $\int\rho(x)x^\alpha dx=0$ for all $|\alpha|\geqslant 1$; more precisely setting $\rho_\varepsilon(x)=(1/\varepsilon^n)\rho(x/\varepsilon)$ we have $\iota(w):=\mathrm{cl}[(w*\rho_\varepsilon)_\varepsilon]$. In case $\mathrm{supp}(w)$ is not compact one uses a

sheaf-theoretical construction. However, in the special case of the functions to be treated in the context of the Schwarzschild metric this will not be necessary (see the following). From the explicit formula it is clear that (on open subsets of Euclidean space) embedding commutes with partial differentiation. On a general manifold, however, there is no canonical embedding of $\mathcal{D}'$ available; a suitable replacement (cf. Ref. 14) is provided by physically motivated modeling and the use of the notion of association (see the following). Inserting $p \in M$ into $u \in \mathcal{G}(M)$ yields a well-defined element of the ring of constants (also called generalized numbers) $\mathcal{K}$ (corresponding to $\mathbb{K}=\mathbb{R}$, respectively, $\mathbb{C}$), defined as the set of moderate nets of numbers $((r_\varepsilon)_\varepsilon \in \mathbb{K}^{(0,1]}$ with $|r_\varepsilon| = O(\varepsilon^{-N})$ for some N) modulo negligible nets ($|r_\varepsilon| = O(\varepsilon^m)$ for each m). Finally, generalized functions on M are characterized by their generalized point values, i.e., by their values on points in $\tilde{M}_c$, the space of equivalence classes of compactly supported nets $(p_\varepsilon)_\varepsilon \in M^{(0,1]}$ with respect to the relation $p_\varepsilon \sim p'_\varepsilon :\Leftrightarrow d_h(p_\varepsilon, p'_\varepsilon) = O(\varepsilon^m)$ for all m, where d_h denotes the distance on M induced by any Riemannian metric.

The $\mathcal{G}(M)$-module of generalized sections in vector bundles—especially the space of generalized tensor fields $\mathcal{G}^r_s(M)$—is defined along the same lines using analogous asymptotic estimates with respect to the norm induced by any Riemannian metric on the respective fibers. However, it is more convenient to use the following algebraic description of generalized tensor fields:

$$\mathcal{G}^r_s(M) \cong \mathcal{G}(M) \otimes \mathcal{T}^r_s(M), \tag{1}$$

where $\mathcal{T}^r_s(M)$ denotes the space of smooth tensor fields and the tensor product is taken over the module $\mathcal{C}^\infty(M)$. Hence generalized tensor fields are just given by classical ones with generalized coefficient functions. Many concepts of classical tensor analysis carry over to the generalized setting,[14] in particular Lie derivatives with respect to both classical and generalized vector fields, Lie brackets, exterior algebra, etc. Moreover, generalized tensor fields may also be viewed as $\mathcal{G}(M)$-multilinear maps taking generalized vector and covector fields to generalized functions, i.e., as $\mathcal{G}(M)$-modules we have

$$\mathcal{G}^r_s(M) \cong L_{\mathcal{G}(M)}(\mathcal{G}^0_1(M)^r, \mathcal{G}^1_0(M)^s; \mathcal{G}(M)).$$

In particular a generalized metric is defined to be a symmetric, generalized (0,2)-tensor field $g_{ab} = \mathrm{cl}[(g_{ab\,\varepsilon})_\varepsilon]$ (with its index independent of ε and) whose determinant $\det(g_{ab})$ is invertible in $\mathcal{G}(M)$. The latter condition is equivalent to the following notion called strictly nonzero on compact sets: for any representative $\det(g_{ab\,\varepsilon})_\varepsilon$ of $\det(g_{ab})$ we have $\forall K \subset\subset M \exists m \in \mathbb{N}: \inf_{p \in K} |\det(g_{ab\,\varepsilon})| \geqslant \varepsilon^m$ for all ε small enough. This notion captures the intuitive idea of a generalized metric to be a sequence of classical metrics approaching a singular limit in the following sense: g_{ab} is a generalized metric iff (on every relatively compact open subset V of M) there exists a representative $(g_{ab\,\varepsilon})_\varepsilon$ of g_{ab} such that for fixed ε (small enough) $g_{ab\,\varepsilon}$ (respectively, $g_{ab\,\varepsilon}|_V$) is a classical pseudo-Riemannian metric and $\det(g_{ab})$ is invertible in the algebra of generalized functions. A generalized metric induces a $\mathcal{G}(M)$-linear isomorphism from $\mathcal{G}^1_0(M)$ to $\mathcal{G}^0_1(M)$ and the inverse metric $g^{ab} := \mathrm{cl}[(g^{-1}_{ab\,\varepsilon})_\varepsilon]$ is a well-defined element of $\mathcal{G}^2_0(M)$ [i.e., independent of the representative $(g_{ab\,\varepsilon})_\varepsilon$]. Also the generalized Levi-Civita connection as well as the generalized Riemann, Ricci, and Einstein tensor of a generalized metric are defined simply by the usual coordinate formulas on the level of representatives.

Finally, the above-introduced setting displays maximal consistency (in the light of Schwartz's impossibilty result[18]) with respect to smooth, respectively, distributional geometry most conveniently formalized in terms of the notion of association. A generalized function $u \in \mathcal{G}(M)$ is called associated to zero, $u \approx 0$, if one (hence any) representative $(u_\varepsilon)_\varepsilon$ converges to zero weakly. (In a sloppy fashion we shall often write $u_\varepsilon \approx 0$.) The equivalence relation $u \approx v :\Leftrightarrow u - v \approx 0$ gives rise to a linear quotient of $\mathcal{G}$ that extends distributional equality. Moreover we call a distribution $w \in \mathcal{D}'(M)$ the distributional shadow or macroscopic aspect of u and write $u \approx w$ if for all compactly supported n-forms ν and one (hence any) representative $(u_\varepsilon)_\varepsilon$,

$$\lim_{\varepsilon\to 0}\int_M u_\varepsilon \nu = \langle w,\nu\rangle,$$

where $\langle,\rangle$ denotes the distributional action. By (1) the concept of association extends to generalized tensor fields in a natural way.

B. Regularizations of the singular functions occurring in the Schwarzschild metric

The two most important singular functions we will work with throughout this paper (namely the singular components of the Schwarzschild metric) are $1/r$ and $1/(r-c)$ ($r=\|\vec{x}\|$; c a positive constant). Since $1/r\in L^1_{\mathrm{loc}}(\mathbb{R}^3)$, it gives rise to the regular distribution $1/r\in\mathcal{D}'(\mathbb{R}^3)$. By convolution with a mollifier ρ (adapted to the symmetry of the space–time, thus chosen radially symmetric) we embed it into the Colombeau algebra $\mathcal{G}(\mathbb{R}^3)$,

$$\frac{1}{r}\overset{\iota}{\to}\iota\left(\frac{1}{r}\right)=\left(\frac{1}{r}*\rho_\varepsilon\right)=:\left(\frac{1}{r}\right)_\varepsilon. \tag{2}$$

Using radial symmetry of the convoluted function and inserting $\rho_\varepsilon(r)=(1/\varepsilon^3)\,\rho(r/\varepsilon)$ we obtain

$$\left(\frac{1}{r}\right)_\varepsilon=\frac{4\pi}{r}\int_0^{r/\varepsilon}\mathrm{d}t\,t^2\,\rho(t)+\frac{4\pi}{\varepsilon}\int_{r/\varepsilon}^{\infty}\mathrm{d}t\,t\rho(t). \tag{3}$$

It is easy to confirm that $(1/r)_\varepsilon=\sigma(1/r)_\varepsilon=(1/r)$ on $\mathbb{R}^3\backslash\{0\}$, and at the origin we have $(1/r)_\varepsilon|_{r=0}=(4\pi/\varepsilon)\int_0^\infty dt\,t\rho(t)$.

In contrast to $1/r$, the function $1/(r-c)$ is not in $L^1_{\mathrm{loc}}(\mathbb{R}^3)$. A canonical regularization (in the sense of Gelfand–Shilov[19]) is the principal value $vp(1/(r-c))\in\mathcal{D}'(\mathbb{R}^3)$ which can be embedded into $\mathcal{G}(\mathbb{R}^3)$,

$$\frac{1}{r-c}\to vp\left(\frac{1}{r-c}\right)\in\mathcal{D}'(\mathbb{R}^3)\overset{\iota}{\to}\iota\left(vp\left(\frac{1}{r-c}\right)\right)=:\left(vp\left(\frac{1}{r-c}\right)\right)_\varepsilon. \tag{4}$$

Making use of $vp(1/(r-c))=(\partial/\partial r)\log|r-c|$ we obtain

$$\begin{aligned}\iota\left(vp\left(\frac{1}{r-c}\right)\right)(x)=&\left(1+r\frac{\partial}{\partial r}\right)\int \mathrm{d}^3y\,\frac{1}{|x-y|}\log|\,|x-y|-c|\,\rho_\varepsilon(y)\\&-\frac{\partial}{\partial x^i}\int \mathrm{d}^3y\,y^i\frac{1}{|x-y|}\log|\,|x-y|-c|\,\rho_\varepsilon(y)\end{aligned}$$

and finally for $v\geqslant c$,

$$\begin{aligned}\iota\left(vp\left(\frac{1}{r-c}\right)\right)(x)=&\frac{4\pi}{r-c}\int_0^{r-c}\mathrm{d}s\,\rho_\varepsilon(s)s^2+\frac{4\pi}{r}\int_{r-c}^{\infty}\mathrm{d}s\,\rho_\varepsilon(s)s^2\\&+\frac{4\pi}{r-c}\frac{c}{r}\int_0^{r-c}\mathrm{d}s\,\rho_\varepsilon(s)s^2\sum_{l=1}^{\infty}\frac{1}{2l+1}\left(\frac{s}{r-c}\right)^{2l}\\&+\frac{4\pi}{r-c}\frac{c}{r}\int_{r-c}^{\infty}\mathrm{d}s\,\rho_\varepsilon(s)(r-c)^2\sum_{l=0}^{\infty}\frac{1}{2l+1}\left(\frac{r-c}{s}\right)^{2l}.\end{aligned} \tag{5}$$

For $0<r\leqslant c$ the roles of r and c are interchanged and we obtain $vp(1/(r-c))_\varepsilon|_{r=0}=-1/c+O(\varepsilon)$.

III. A FIRST APPROACH TO THE PROBLEM

In this section we present a first approach to the "Schwarzschild point mass problem," thereby essentially following earlier treatments in the literature (Refs. 9, 11–13). However, we are going to use the language of nonlinear distributional geometry introduced previously in order to obtain a unified view, which will enable us to carry out a detailed analysis of the previous approaches in Sec. IV.

In the usual Schwarzschild coordinates $(t,r>0,\theta,\phi)$ the metric takes the form

$$\mathrm{d}s^2=h(r)\mathrm{d}t^2-h(r)^{-1}\mathrm{d}r^2+r^2\,\mathrm{d}\Omega^2 \quad \text{with} \quad h(r)=-1+\frac{2m}{r}. \tag{6}$$

Following the above-presented discussion we consider the singular metric coefficient $h(r)$ as an element of $L^1_{\mathrm{loc}}(\mathbb{R}^3)\subseteq\mathcal{D}'(\mathbb{R}^3)$ and embed it into $\mathcal{G}(\mathbb{R}^3)$ by convolution with a mollifier. Note that, accordingly, we have fixed the differentiable structure of the manifold: the Cartesian coordinates associated with the spherical Schwarzschild coordinates in (6) are extended through the origin. We have

$$h(r)=-1+\frac{2m}{r}\overset{\iota}{\to}\iota(h(r))=h_\varepsilon(r)=-1+2m\left(\frac{1}{r}\right)_\varepsilon\in\mathcal{G}(\mathbb{R}^3), \tag{7}$$

where $(1/r)_\varepsilon$ is given by (3). Inserting (7) into (6) we obtain a generalized object modeling the singular Schwarzschild metric, i.e.,

$$\mathrm{d}s^2_\epsilon=h_\epsilon(r)\mathrm{d}t^2-h_\epsilon(r)^{-1}\mathrm{d}r^2+r^2\,\mathrm{d}\Omega^2. \tag{8}$$

The generalized Ricci tensor may now be calculated componentwise using the classical formulas

$$(R^0_{\ 0})_\varepsilon=(R^1_{\ 1})_\varepsilon=\frac{1}{2}\left(h''_\varepsilon+\frac{2}{r}h'_\varepsilon\right)=\frac{1}{2}\Delta h_\varepsilon, \tag{9}$$

$$(R^2_{\ 2})_\varepsilon=(R^3_{\ 3})_\varepsilon=\frac{h'_\varepsilon}{r}+\frac{1+h_\varepsilon}{r^2}. \tag{10}$$

Due to the linear structure of $R^0_{\ 0}$ it is evident that it is associated to a constant times the δ-distribution, i.e.,

$$(R^0_{\ 0})_\varepsilon=\frac{1}{2}\Delta h_\varepsilon=m\Delta\left(\frac{1}{r}\right)_\varepsilon\to-4\pi m\,\delta\quad(\varepsilon\to0). \tag{11}$$

Investigating the weak limit of the angular components of the Ricci tensor [using the abbreviation $\tilde{\Phi}(r)=\int\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi\Phi(\vec{x})$] we get (cf. Appendix A)

$$\begin{aligned}\int(R^2_{\ 2})_\varepsilon\Phi\,\mathrm{d}^3x&=\int(rh'_\varepsilon+1+h_\varepsilon)\tilde{\Phi}(r)\mathrm{d}r\\&\overset{(3)}{=}8\pi m\int\frac{1}{\varepsilon}\left[\int_{r/\varepsilon}^{\infty}t\rho(t)\mathrm{d}t\right]\tilde{\Phi}(r)\mathrm{d}r\\&=8\pi m\int\mathrm{d}x\,\tilde{\Phi}(\varepsilon x)\int_x^\infty t\rho(t)\mathrm{d}t\\&\to32\pi^2m\,\Phi(0)\int_0^\infty\mathrm{d}x\int_x^\infty t\rho(t)\mathrm{d}t\overset{(A3)}{=}8\pi m\langle\delta|\Phi\rangle\quad(\varepsilon\to0).\end{aligned}$$

Hence, the Ricci tensor and the curvature scalar R are of δ-type, i.e.,

$$R^0_0=R^1_1\approx -4\pi m\ \delta, \quad R^2_2=R^3_3\approx 8\pi m\ \delta, \quad R\approx \pi m\ \delta. \tag{12}$$

Equation (12) is obviously given in spherical coordinates. Strictly speaking this is not sensible, because the basis fields $\{\partial/\partial r, \partial/\partial\phi, \partial/\partial\theta\}$ are not globally defined. Representing distributions concentrated at the origin requires a basis regular at the origin. Transforming the results for $(R^i_j)_\varepsilon$ [i.e., (9) and (10)] into Cartesian coordinates associated with the spherical ones (i.e., $\{r,\theta,\phi\}\leftrightarrow\{x^i\}$) we obtain, e.g., for the Einstein tensor

$$G^i{}_j\approx -8\pi m\ \delta\ \delta^i_0\delta^0_j. \tag{13}$$

Note that the use of the particular regularization (7) is not essential here. We could have replaced (7) by any other smooth *ad hoc* regularization of $h(r)$, as has been done, e.g., in Ref. 11, by setting $h_\varepsilon(r)=-1+2m/(\sqrt{r^2+\varepsilon^2})$. Indeed, we can show that the results (12) hold for all regularizations, i.e., for all sequences of the form $h_\varepsilon(r)=-1+2ms_\varepsilon(r)\to h(r)$ (i.e., $\forall\ s_\varepsilon$ smooth, $s_\varepsilon\to 1/r$ in $\mathcal{D}'$). For the (0,0)- and (1,1)-components of the Ricci tensor the result follows from the special form of (9). For the angular components [cf. (10)] we write

$$2m\int_0^\infty r^2\left(\frac{s'_\varepsilon(r)}{r}+\frac{s_\varepsilon(r)}{r^2}\right)\tilde{\Phi}(r)\,\mathrm{d}r=-2m\int_0^\infty \mathrm{d}r\, r^2 s_\varepsilon\frac{1}{r}\tilde{\Phi}'(r)\to 8\pi m\Phi(0), \tag{14}$$

where in the last step we used the fact that $(1/r)\,\tilde{\Phi}'\in\mathcal{D}(\mathbb{R})$.

IV. COMMENTS AND PROBLEMS

In order to be able to calculate the curvature from the metric we must keep the regularization $h_\varepsilon(r)$ smooth on the entire space–time. This fact—although somewhat hidden because we worked with spherical coordinates—is essential from the conceptual point of view. In fact, choosing a regularization $h_\varepsilon(r)$ which is smooth only on $\mathbb{R}^3\backslash\{0\}$ is not sufficient to derive the result as is explicitly shown by the following counterexample. Set $h_\varepsilon=-1+2ms_\varepsilon$ and $s_\varepsilon=(1/r)\,o_\varepsilon$ (with $o_\varepsilon\to 1$ weakly) consisting of regular distributions, so that $s_\varepsilon\in L^1_{\mathrm{loc}}(\mathbb{R}^3)$ with $s_\varepsilon\to 1/r\in\mathcal{D}'(\mathbb{R}^3)$. Moreover, we may require $o_\varepsilon(r)$ to be smooth on $\mathbb{R}^3\backslash\{0\}$. Summing over (9) and (10) we get $R_\varepsilon=2m((1/r)\,o''_\varepsilon+(2/r^2)\,o'_\varepsilon)$. Choosing $o_\varepsilon(r)=(1+c\,[r^\varepsilon-1])$ we obtain for R_ε different weak limits as the constant c varies, i.e.,

$$R_\varepsilon\to 8\pi mc\ \delta. \tag{15}$$

For $o_\varepsilon=r^{-\varepsilon}$ the situation is even worse. Although $o_\varepsilon\in L^1_{\mathrm{loc}}\ \forall\ \varepsilon$ and $o_\varepsilon\to 1\in\mathcal{D}'$ as $\varepsilon\to 0$, R_ε does not converge weakly, so that we obtain no distributional result whatsoever.

Nonetheless, similar nonsmooth regularizations have been considered in the literature. In these cases the desired result (12) can only be produced by means of a clever choice of explicit formulas; in particular, $o_\varepsilon=r^\varepsilon$ in Ref. 13 and $o_\varepsilon(r)=\Theta(r-\varepsilon)$ in Ref. 12. The authors of Ref. 9 have shown that the result (12) may be reproduced as long as $o_\varepsilon|_{r=0}=0$. However, the conceptual problem remains untouched: $R_\varepsilon[h_\varepsilon]$ can only be derived for smooth regularizations h_ε; distributions cannot be used as an input for nonlinear operations.

Prior to a more detailed investigation of the choice of regularization, we briefly comment on two more attempts in the literature. In Ref. 12 a regularization of the metric using thin shell solutions is investigated. The limit ($\varepsilon\to 0$) corresponds to a shrinking of the shell. However, the shells can only be placed outside the horizon (of a black hole with identical mass). This implies that a shrinking of the shell must be coupled to a decrease in mass: m converges to zero in the limiting process, so the obtained results should either be considered trivial ($R\sim m\delta|_{m=0}=0$) or be rejected completely.

In Ref. 11 the authors claim to have found different results for the curvature quantities by regularizing the Schwarzschild metric in a different coordinate system. They study the interrelations of regularizations and coordinate transformations for this particular problem. However, some details are not overly convincing. If we choose a new radial coordinate $\tilde{r}$ such that $r=\Lambda\tilde{r}+a$ with $a=2m$, then $\tilde{r}=0$ does not describe the Schwarzschild singularity. Instead, $\tilde{r}=0$ corresponds to the coordinate singularity at the horizon $r=2m$, but shrunk to one point. Obviously, we should not compare the outcome of these considerations with our former results.

We now begin with an in-depth analysis of certain aspects of the regularization procedure commencing with the issue of componentwise regularization and invertibility of the regularized metric. According to (1) in Sec. II, regularizing a tensor such as the Schwarzschild metric (6) comes up to regularizing each distribution-valued component separately. Following this rule we obtain a regularized metric slightly different from (8), namely

$$\mathrm{d}s^2_\varepsilon = h_\varepsilon(r)\mathrm{d}t^2-(h^{-1})_\varepsilon(r)\mathrm{d}r^2+r^2\,\mathrm{d}\Omega^2. \tag{16}$$

Since $\mathrm{cl}[h_\varepsilon]\mathrm{cl}[(h^{-1})_\varepsilon]\neq 1\in\mathcal{G}$, the determinant of the regularized metric (16) is no longer identically one. (This, in fact, does not come as a surprise; cf. Schwartz's impossibility result.[18]) However, the product *is* preserved in the sense of association, i.e., $h_\varepsilon(h^{-1})_\varepsilon\approx 1$. Analogous issues arise from the inverse metric: embedding also g^{-1} componentwise into $\mathcal{G}$ we obtain regularized objects, g_ε and $(g^{-1})_\varepsilon$, which are only inverse to each other in the sense of association. Taking a different viewpoint, however, it is comparatively easy to avoid these issues: on the classical level the Schwarzschild geometry is uniquely determined by the set of variables $\{g_{tt},g_{rr},g_{\theta\theta},g_{\varphi\varphi}\}$, or, e.g., equivalently by $\{g_{tt},g_{\theta\theta},g_{\varphi\varphi},\det g\}$. Embedding the second set of variables into $\mathcal{G}$ leads directly to the regularization (8) used previously; no invertibility problems arise at all since $\det g_\varepsilon$ is forced to equal one.

Finally we return to discussing the problem of smoothness of the regularized metric from a different, more geometrical point of view. We regard this problem to be so essential that in Sec. V we propose an approach entirely different form the one taken so far.

In fact, the regularizations used so far (as all the other regularizations in the relevant literature) do *not* provide a *smooth* regularized metric tensor. This fact is hidden again by the use of spherical coordinates. In Cartesian coordinates pertaining to (r,θ,ϕ)—which we used to fix the differentiable structure of the extended manifold at $r=0$—however, it can be explicitly seen from the form of the metric

$$\mathrm{d}s^2 = h(r)\mathrm{d}t^2+\mathrm{d}\vec{x}^2-(1+h(r)^{-1})\frac{x_ix_j}{r^2}\mathrm{d}x^i\,\mathrm{d}x^j. \tag{17}$$

In order to obtain a smooth regularization it is not sufficient to merely regularize $h(r)$. In fact, we must embed the singular coefficient $(1+h(r)^{-1})(x_ix_j/r^2)$ as a whole into $\mathcal{G}$. Apart from technical difficulties this approach should provide a smooth regularized metric $\mathrm{d}s_\varepsilon$. However, we have reached an impasse: the regularized metric will not be invertible at some distinct value r_0 of the radial coordinate, where $r_0\to 0(\varepsilon\to 0)$. This will be shown in the remainder of this section.

As shown in Appendix B, the regularization of (17) takes the form

$$\mathrm{d}s^2_\varepsilon = h_\varepsilon(r)\mathrm{d}t^2+(1-a_\varepsilon(r))\mathrm{d}r^2+(1-b_\varepsilon(r))r^2\,\mathrm{d}\Omega^2, \tag{18}$$

with $a_\varepsilon(0)\to\frac{1}{3}(\varepsilon\to 0)$. This implies that the rr-component of the regularized metric (18) is positive at $r=0$ (at least for small ε), because $(g_{rr})_\varepsilon(0)=(1-a_\varepsilon(0))\to\frac{2}{3}$ $(\varepsilon\to 0)$. On the other hand, $(1-a_\varepsilon)$ approximates $-h^{-1}$, i.e., $(g_{rr})_\varepsilon(r\neq 0)\to -r/(2m-r)<0$ $(\varepsilon\to 0)$. So we conclude that at some value r_0 of r the smooth function $(g_{rr})_\varepsilon(r)$ must have a zero at least for small ε. (Interestingly enough, this is not the case for negative masses since $-r/(2m-r)$ is positive then). In other words, this means that the regularization of the metric (17) degenerates at some radius r_0. Evidently, $r_0\to 0$ as $\varepsilon\to 0$.

Note that the occurrence of this radius of degeneracy is neither due to the fact that we choose the particular regularization (18), nor is it possible to avoid it by giving up spherical symmetry. To see this in some more detail consider the spatial part of (17) [set $\tilde{h}(r) := h^{-1}(r)$] and consider a certain class of regularizations

$$ds_\varepsilon^2 = d\vec{x}^2 - (1+\tilde{h}_\varepsilon(r))\frac{x_i x_j}{r^2}dx^i\,dx^j, \tag{19}$$

where $\tilde{h}_\varepsilon(r)$ denotes an arbitrary regularization of $\tilde{h}(r)$. However, for ds_ε^2 to become smooth, we must require that $\tilde{h}_\varepsilon(r)$ be $-1+O(r^2)$ for $(r\to 0)$. Now, an arbitrary regularization of ds^2 not necessarily respecting spherical symmetry is obtained by adding zero-sequences to (19),

$$ds_\varepsilon^2 = d\vec{x}^2 - (1+\tilde{h}_\varepsilon(r))\frac{x_i x_j}{r^2}dx^i dx^j + (a_{ij})_\varepsilon(\vec{x})\,dx^i\,dx^j. \tag{20}$$

For special cases of $(a_{ij})_\varepsilon$ it is easy to show that (20) is degenerate. Choose, e.g., $(a_{ij})_\varepsilon$ such that only $(a_{12})_\varepsilon =: b_\varepsilon(\vec{x})$ is nonvanishing. The determinant of (20) at $\vec{x}=(0,0,r)$ is equal to $-\tilde{h}_\varepsilon(r)\times(1-b_\varepsilon(\vec{x})^2)$. As $-\tilde{h}_\varepsilon(0)=1$ and $-\tilde{h}_\varepsilon(r)<0$ for small ε and finite r, there exists a radius r_ε (with $r_\varepsilon\to 0$ for $\varepsilon\to 0$), such that $\det(g_\varepsilon)=0$. Again, we observe degeneracy.

V. THE KERR–SCHILD APPROACH

To begin with let us summarize what we have done so far: we considered regularizations of the Schwarzschild metric (using the language of algebras of generalized functions) to calculate the (distributional) curvature at the singularity. The regularizations used were essentially based on Cartesian coordinates associated with the spherical Schwarzschild coordinates. However, it turned out that all these regularizations were either nonsmooth or not invertible. *Smoothness and invertibility mutually exclude each other* in this context. Hence, we are going to take another more geometrical viewpoint in this section. The main idea—following Refs. 20 and 10—is to use the Kerr–Schild form of the Schwarzschild metric. Retaining this preferred structure also during the whole regularization process will enable us to derive the physically desired result in a rigorous manner.

A metric belongs to the so-called Kerr-Schild class[21] if it can be written as

$$g_{ij} = \eta_{ij} + f k_i k_j \quad \text{with} \quad k^i k_i = 0. \tag{21}$$

Here, the null vector field $k \in \mathfrak{X}$ is normalized $(k^0=1)$ and f is a smooth function. Exploiting the Kerr–Schild form, some curvature quantities take a particularly simple form, e.g.,

$$R = \partial_a \partial_b (f k^a k^b). \tag{22}$$

The Schwarzschild metric is a member of the Kerr–Schild class. In fact, transformation to Eddington–Finkelstein coordinates $(\bar{t} = t + 2m\log|2m-r|)$ yields

$$ds^2 = -d\bar{t}^2 + dr^2 + r^2\,d\Omega^2 + \frac{2m}{r}(d\bar{t}-dr)^2. \tag{23}$$

Evidently, (23) is of Kerr–Schild form, $g_{ij} = \eta_{ij} + f k_i k_j$, with

$$k = \frac{\partial}{\partial \bar{t}} + \frac{\partial}{\partial r}, \quad f = \frac{2m}{r}. \tag{24}$$

Analogous to Sec. III, we regard f and k as distributions on $\mathbb{R}^4$. By this we again implicitly fix the differentiable structure: the coordinates $(\overline{t},x^i)$ are extended through the origin.

We now proceed by regularizing *both* f and k. Indeed, this is necessary due to the fact that not only the profile function f is singular, but also the null vector field k is nonsmooth. Recall that, on account of the nonlinearities in $R[g]$, (22) can only be derived for smooth functions; it is inaccessible for distributional input. [Note the analogy of this situation with the one encountered in (8).] Hence, f and k are chosen to be the fundamental variables characterizing the metric (compare with the remarks in Sec. IV). Regularizing the function f as in Sec. III gives

$$f(r)=\frac{2m}{r}\overset{\iota}{\to}\iota(f(r))=f_\varepsilon(r)=2m\left(\frac{1}{r}\right)_\varepsilon. \tag{25}$$

The regularization of k_i is carried out in detail in Appendix C, yielding

$$k_i(r)=\frac{x_i}{r}\overset{\iota}{\to}\iota\left(\frac{x_i}{r}\right)=k_{i\varepsilon}=\left(\frac{x_i}{r}\right)_\varepsilon=x_iF_\varepsilon(r)\quad(i=1,\ldots,3), \tag{26}$$

where F_ε is given by (C3). Note that, for the moment, $k_0=1$ is embedded trivially into $\mathcal{G}$. Collecting the results of (25) and (26) we get the regularized metric

$$\mathrm{d}s^2_\varepsilon=(-1+f_\varepsilon)\mathrm{d}t^2-2rf_\varepsilon F_\varepsilon\,\mathrm{d}t\,\mathrm{d}r+(1+\tilde{f}_\varepsilon)\mathrm{d}r^2+r^2\,\mathrm{d}\Omega^2, \tag{27}$$

where, for simplicity, $\overline{t}$ has been replaced by t again, and $\tilde{f}_\varepsilon$ abbreviates $r^2f_\varepsilon F^2_\varepsilon$. Unfortunately, (27) is no longer of Kerr–Schild form. This can be shown indirectly: assuming that (27) is Kerr–Schild, i.e., assuming that $\mathrm{d}s^2_\varepsilon=-\mathrm{d}t'^2+\mathrm{d}r^2+r^2\,\mathrm{d}\Omega^2+f'_\varepsilon(\mathrm{d}t'-\mathrm{d}r)^2$ can be achieved by a transformation $t\to t'(t,r)$, it follows that $f'_\varepsilon=\tilde{f}_\varepsilon/(1-f_\varepsilon+\tilde{f}_\varepsilon)$ and $(dt/dt')^2=1/(1-f_\varepsilon+\tilde{f}_\varepsilon)$. As a consequence, the denominator $1-f_\varepsilon+\tilde{f}_\varepsilon$ must be a strictly positive function. In fact, in the sense of association, it is equal to one. However, at the origin $r=0$, we obtain $1-f_\varepsilon+\tilde{f}_\varepsilon=1-8\pi m\,1/\varepsilon\int_0^\infty t\rho(t)\mathrm{d}t$, which is negative for small ε as long as $\int_0^\infty t\rho(t)\mathrm{d}t>0$, a contradiction.

The fact that the embedding (27) is no longer of Kerr–Schild form bears a strong relation to the fact that smooth regularizations degenerate at a certain value of r (see Sec. IV): the determinant of (27) contains the factor $1-f_\varepsilon+\tilde{f}_\varepsilon$, which was shown to possess a zero.

Additionally, in analogy to the statements made at the end of Sec. IV, we note that the loss of the Kerr–Schild form does not stem from choosing to regularize the singular coefficient functions via convolution. On the contrary, it may be shown that any regularization of the metric displays this behavior as long as only the spatial components of k are taken into account.

We will now take the announced geometrical viewpoint: we consider regularizations retaining the Kerr–Schild decomposition. This requires, in particular, that the regularized vector k_ε is still null. Thus, we consider the regularization

$$k^i_\varepsilon=rF_\varepsilon k^i\quad(i=0,\ldots,3). \tag{28}$$

While the spatial components of (28) coincide with (26), k^0_ε is only associated to $1(k^0_\varepsilon=rF_\varepsilon\approx 1)$. As required, k_ε satisfies the condition $k^i_\varepsilon k_{\varepsilon i}=0$. Note that, in order to obtain (28), the functions f, $k^i(i=1,\ldots,3)$ and $k\cdot k$ are chosen as fundamental variables determining the geometric structure of the spacetime.

Using (25) and (28) the regularized metric takes the form

$$g_{ij\varepsilon}=\eta_{ij}+f_\varepsilon k_{\varepsilon i}k_{\varepsilon j}=\eta_{ij}+(r^2F^2_\varepsilon f_\varepsilon)k_ik_j=\eta_{ij}+\tilde{f}_\varepsilon k_ik_j. \tag{29}$$

Obviously, (29) is of Kerr–Schild form. Finally we have arrived at a regularization of the Schwarzschild metric which is *both smooth and invertible* (the inverse being $\eta^{ij}-\tilde{f}_\varepsilon k^i k^j$). This allows us to fully exploit the Kerr–Schild form, i.e., to use (22), to obtain

$$R_\varepsilon=\partial_a\partial_b(\tilde{f}_\varepsilon k^a k^b)=\frac{4}{r}\tilde{f}'_\varepsilon+\tilde{f}''_\varepsilon+\frac{2}{r^2}\tilde{f}_\varepsilon\,. \tag{30}$$

To complete our program we calculate the weak limit of R_ε. The technically involved calculations are deferred to Appendix D. Finally we derive

$$(R_\varepsilon)_\varepsilon\approx 8\pi m\,\delta. \tag{31}$$

The Ricci tensor can be treated in complete analogy to obtain the Einstein tensor

$$(G^a_{b\varepsilon})_\varepsilon\approx -8\pi m\,\delta\delta^a_0\delta^0_b\,. \tag{32}$$

VI. THE HORIZON

In this section we leave the neighborhood of the singularity at the origin and turn to the singularity at the horizon. The question we are aiming at is the following: using distributional geometry (thus without leaving Schwarzschild coordinates), is it possible to show that the horizon singularity of the Schwarzschild metric is merely a coordinate singularity? In order to investigate this issue we calculate the distributional curvature at the horizon (in Schwarzschild coordinates).

Examining the Schwarzschild metric (6) in a neighborhood of the horizon, we see that, whereas $h(r)$ is smooth, $h^{-1}(r)$ is not even L^1_{loc} (note that the origin is now always excluded from our considerations; the space we are working on is $\mathbb{R}^3\backslash\{0\}$). Thus, regularizing the Schwarzschild metric amounts to embedding h^{-1} into $\mathcal{G}$ [as done in (5)].

$$\mathrm{d}s^2_\varepsilon=h(r)\mathrm{d}t^2-(h^{-1})_\varepsilon(r)\mathrm{d}r^2+r^2\,\mathrm{d}\Omega^2 \tag{33}$$

with

$$h(r)=-1+\frac{2m}{r},\quad (h^{-1})_\varepsilon(r)=-1-2m\left[vp\left(\frac{1}{r-2m}\right)\right]_\varepsilon. \tag{34}$$

Obviously, (33) is degenerate at $r=2m$, because $h(r)$ is zero at the horizon. However, this does not come as a surprise. Both $h(r)$ and $h^{-1}(r)$ are positive outside of the black hole and negative in the interior. As a consequence *any* (smooth) regularization of $h(r)$ (or h^{-1}) must pass through zero somewhere and, additionally, this zero must converge to $r=2m$ as the regularization parameter goes to zero (note the analogy to the situation in Sec. IV).

Due to the degeneracy of (33), the Levi-Cività connection is not available. Consider, therefore, the following connection $\Gamma^l_{kj}\in\mathcal{G}$:

$$\Gamma^l_{kj}=\tfrac{1}{2}[\iota(g^{-1})]^{lm}[\iota(g)_{mk,j}+\iota(g)_{mj,k}-\iota(g)_{kj,m}]. \tag{35}$$

Clearly, Γ coincides with the Levi-Cività connection on $\mathbb{R}^3\backslash\{r=2m,r=0\}$, as $\iota(g)=g$ and $\iota(g^{-1})=g^{-1}$ there.

Unfortunately, Γ does not respect the regularized metric $\iota(g)$ (33), i.e., $\iota(g)_{ij;k}\neq 0$, e.g., $\iota(g)_{00;1}=(1-h(h^{-1})_\varepsilon)h'$. However, compatibility with the metric $\iota(g)$ is *a priori* ruled out by the following statement: there exists no connection whatsoever under which $\iota(g)$ would be a parallel tensor. To show this, just look at (L^i_{jk} denoting a not necessarily torsion-free connection) $\iota(g)_{00;1}=\iota(g)_{00,1}-2L^0_{10}\iota(g)_{00}$. At the horizon $\iota(g)_{00}=0$, so that $\iota(g)_{00;1}|_{r=2m}=h'(2m)=-(1/2)m\neq 0$. In the sense of association, however, the connection (35) is in fact metric compatible: $\iota(g)_{ij;k}\approx 0$.

We now investigate the curvature pertaining to the connection (35), picking out $R_{00\varepsilon}$ as a characteristic example. The result of the calculations displays the following structure:

$$R_{00\varepsilon}(r)=vp'_\varepsilon\left(-\frac{m^2}{r^2}+4\frac{m^3}{r^3}-4\frac{m^4}{r^4}\right)+vp_\varepsilon\left(2\frac{m^3}{r^4}-4\frac{m^4}{r^5}\right)+\left(-\frac{m^2}{r^4}-2\frac{m^3}{r^5}\right) \tag{36}$$

$$=vp'_\varepsilon(r)\sum_{l=2}^{\infty}c_l x^l+vp_\varepsilon(r)\sum_{l=1}^{\infty}d_l x^l-\frac{1}{8m^2}-\frac{1}{16m^2}\sum_{l=1}^{\infty}e_l x^l. \tag{37}$$

Here, the abbreviations $vp_\varepsilon=[vp(1/(r-2m))]_\varepsilon$ and $x=(r-2m)/2m$ are used; c_l, d_l, and e_l are constants. Equation (37) holds for $|x|<1$; the infinite sums converge in this case.

If the horizon is excluded, $R_{00\varepsilon}=0(\mathrm{mod}\,\mathcal{N})$, because (35) coincides with the Schwarzschild Levi-Cività connection there. In the neighborhood of $r=2m$ we aim at comparing $R_{00\varepsilon}(r)$ with a Colombeau object of the type $f((r-2m)/\varepsilon)$ (f a Schwartz function). To this end we choose a fundamental sequence $r_\varepsilon=2m+\varepsilon^q a_0$ converging to $r=2m$ and examine $R_{00\varepsilon}(r_\varepsilon)$ [use (37) together with (5)].

$q>1$: $R_{00\varepsilon}(r_\varepsilon)=\mathrm{const}+o(\varepsilon^{q-1})$.

$q<1$: Using (5) we find that $vp_\varepsilon(r_\varepsilon)=1/(r_\varepsilon-2m)$ and $vp'_\varepsilon(r_\varepsilon)=-1/(r_\varepsilon-2m)^2$ (in the sense of generalized numbers). Inserting these results into Eq. (36), we obtain $R_{00\varepsilon}(r_\varepsilon)=0$.

$q=1$: $R_{00\varepsilon}(r_\varepsilon)=\mathrm{const}+o(1)$.

Thus, $R_{00\varepsilon}(r_\varepsilon)$ has the same asymptotic behavior as a sequence of the type $f((r_\varepsilon-2m)/\varepsilon)$ (as $\varepsilon\to 0$). As a consequence, the weak limit of $R_{00\varepsilon}(r)$ can be calculated easily, simply by evaluating $\int \mathrm{d}r\, r^2\tilde{\Phi}(r)f((r-2m)/\varepsilon)$. Evidently, this expression vanishes as $\epsilon\to 0$. Since analogous results hold for the other components of the Ricci tensor, we are finally able to state

$$R_{ij\varepsilon}\approx 0. \tag{38}$$

In other words: viewed as a distribution, $R_{ij}=0$ on $\mathbb{R}^3\backslash\{0\}$, i.e., including the horizon. If we were courageous enough we could take this as a proof that the metric singularity at the horizon is only a coordinate singularity.

We conclude this section with a remark on the connection (35). Due to the degeneracy of any regularization of the metric [e.g., (33)] no canonical (Levi-Cività) connection could be defined. The choice of connection (35) bears a strong relation to the regularized metric; however, there seems no way of telling if this choice is canonical in some sense and thus preferred to other choices. Despite this open question, at least it is clear that the connection (35) is a regularization of the Schwarzschild *connection*. Indeed, we could change our viewpoint: we consider the Schwarzschild connection (forgetting where it came from, i.e., forgetting about the metric), regularize its distribution-valued components, and calculate the distributional curvature from it. Proceeding in this manner, we obtain the result (38), i.e., the space–time is weakly Ricci-flat (the origin was excluded from our considerations).

APPENDIX A: MOLLIFIER INTEGRALS

Throughout this paper we work invariably with radially symmetric mollifiers $\rho(r)$ (cf. Sec. II). Most importantly, we have the properties

$$\int_0^\infty \mathrm{d}t\, t^2\rho(t)=\frac{1}{4\pi},\quad \int_0^\infty \mathrm{d}t\, t^{2k}\rho(t)=0\quad (k>1). \tag{A1}$$

We investigate multiple integrals involving the mollifier $\rho(r)$ and powers of r:

$$\int_x^\infty \mathrm{d}t\, t^n\int_t^\infty s\rho(s)\mathrm{d}s=-\frac{x^{n+1}}{n+1}\int_x^\infty t\rho(t)\mathrm{d}t+\frac{1}{n+1}\int_x^\infty \mathrm{d}t\, t^{n+2}\rho(t). \tag{A2}$$

(A2) holds for $(n,k\neq -1)$, it is proven by simply performing integration by parts. One of the most interesting cases resulting from (A2) is $n=0$ and $x\to 0$:

$$\int_0^\infty \mathrm{d}t\int_t^\infty s\rho(s)\mathrm{d}s=\frac{1}{4\pi}. \tag{A3}$$

APPENDIX B: EMBEDDING OF THE CARTESIAN COMPONENTS

Referring to Sec. IV we investigate

$$\iota\left(\frac{1+h(r)^{-1}}{r^2}x_ix_j\right)\mathrm{d}x^i\,\mathrm{d}x^j=\left(2m\int f(\|\vec{z}\|)z_iz_j\rho_\varepsilon(\|\vec{z}+\vec{x}\|)\mathrm{d}^3z\right)\mathrm{d}x^i\,\mathrm{d}x^j, \tag{B1}$$

where $f(q)=1/(2m-q)(1/q^2)$. In order to simplify (B1) we show the following relation:

$$\iota\left(\frac{1+h(r)^{-1}}{r^2}x_ix_j\right)=x_ix_jc_\varepsilon(\vec{x})\quad \text{for } i\neq j\quad (c_\varepsilon \text{ smooth}). \tag{B2}$$

Proof: Since both $f(\|\vec{z}\|)$ and ρ_ε are even functions in z_i, we observe that

$$\iota\left(\frac{1+h(r)^{-1}}{r^2}x_ix_j\right)\Big|_{x_i=0}=2m\int f(\|\vec{z}\|)z_iz_j\rho_\varepsilon(\ldots,z_i,\ldots)\mathrm{d}^3z=0. \tag{B3}$$

We can conclude that

$$\iota\left(\frac{1+h(r)^{-1}}{r^2}x_ix_j\right)=x_ic'_\varepsilon(\vec{x})\quad (c'_\varepsilon \text{ smooth}). \tag{B4}$$

Also,

$$\iota\left(\frac{1+h(r)^{-1}}{r^2}x_ix_j\right)\Big|_{x_j=0}=0,$$

from which follows that $c'_\varepsilon(\vec{x})=x_jc_\varepsilon(\vec{x})$, yielding (B2). Note, however, that the smooth function $c_\varepsilon(\vec{x})$ in (B2) is not equal to $\iota((1+h(r)^{-1})/r^2)$. ■

In the case $i=j$, Eq. (B2) is no longer valid. We are able to calculate the $ii-$component in the limiting case $\varepsilon\to 0$, i.e.,

$$\iota\left(\frac{1+h(r)^{-1}}{r^2}x_i^2\right)\Big|_{\vec{x}=0}=2m\int f(\|\vec{z}\|)z_i^2\rho_\varepsilon(\|\vec{z}\|)\mathrm{d}^3z\to\frac{1}{3}\quad (\varepsilon\to 0). \tag{B5}$$

Proof: Clearly, $2m\int f(\|\vec{z}\|)z_i^2\rho_\varepsilon(\|\vec{z}\|)\mathrm{d}^3z$ is independent of the choice of the index i, so that we may substitute it by $(2m/3)\int f(\|\vec{z}\|)\|\vec{z}\|^2\rho_\varepsilon(\|\vec{z}\|)\mathrm{d}^3z$. Obviously, this converges to $\frac{1}{3}$ as ε goes to zero. ■

The regularized metric (B1) is radially symmetric, $R^*g_\varepsilon=g_\varepsilon$ (R a rotation), as long as radially symmetric mollifiers are used. Thus, it must be of the form of a general radially symmetric metric $\mathrm{d}s^2=a(r)\mathrm{d}r^2+r^2b(r)\ \mathrm{d}\Omega^2$, hence

$$\iota\left(\frac{1+h(r)^{-1}}{r^2}x_ix_j\right)\mathrm{d}x^i\,\mathrm{d}x^j=(a_\varepsilon-b_\varepsilon)(r)\frac{x_i}{r}\frac{x_j}{r}\mathrm{d}x^i\,\mathrm{d}x^j+b_\varepsilon(r)\mathrm{d}\vec{x}^2. \tag{B6}$$

For the general radially symmetric metric (B6) to be smooth $(a_\varepsilon-b_\varepsilon)(r)=O(r^2)$ is required. We observe consistency with (B2) and conclude

$$a_\varepsilon(r)=b_\varepsilon(r)+c_\varepsilon r^2. \tag{B7}$$

At the origin $r=0$ only the second term $b(r)\mathrm{d}\vec{x}^2$ remains relevant, since

$$(a-b)(r)\frac{x_i}{r}\frac{x_j}{r}\bigg|_{r=0}=c_\varepsilon x_ix_j|_{r=0}=0.$$

Turning Eq. (B5) to good account we obtain

$$b_\varepsilon(0)\to\tfrac{1}{3}\quad(\varepsilon\to0),\quad a_\varepsilon(0)\to\tfrac{1}{3}\quad(\varepsilon\to0). \tag{B8}$$

Combining (17) with (B6), we finally obtain

$$\mathrm{d}s_\varepsilon^2=h_\varepsilon(r)\mathrm{d}t^2+(1-a_\varepsilon(r))\mathrm{d}r^2+(1-b_\varepsilon(r))r^2\,\mathrm{d}\Omega^2. \tag{B9}$$

APPENDIX C: EMBEDDING OF k^i

We explicitly embed the radially outward pointing unit vector field $k_i=(x_i/r)$ $(i=1,\ldots,3)$ into the Colombeau algebra, i.e.,

$$\iota\left(\frac{x_i}{r}\right)=\int\mathrm{d}^3x'\frac{x_i-x_i'}{\|\vec{x}-\vec{x}'\|}\rho_\varepsilon(\|\vec{x}'\|)=-\int\mathrm{d}^3z\frac{z_i}{\|\vec{z}\|}\rho_\varepsilon(\|\vec{x}+\vec{z}\|). \tag{C1}$$

Equation (C1) is of an analogous form to (B1). We may conclude that $\iota(x_i/r)$ is a radially symmetric vector field. Moreover, despite $\iota(x_i/r)\neq x_i\iota(1/r)$, we must still have [repeating (B2)ff.]

$$\iota\left(\frac{x_i}{r}\right)=x_iF_\varepsilon(\vec{x})\quad(i=1,\ldots,3). \tag{C2}$$

Here, $F_\varepsilon(\vec{x})$ is a smooth function and moreover, because this function must be radially symmetric, $F_\varepsilon(\vec{x})=F_\varepsilon(r)$.

This fact makes it possible to calculate $\iota(x_i/r)$ explicitly. Take $x=(0,0,r)$ and investigate $\iota(x_3/r)=x_3F_\varepsilon(r)=rF_\varepsilon(r)$:

$$
\begin{aligned}
rF_\varepsilon(r) &= \int \frac{x_3 - x_3'}{\|\vec{x}-\vec{x}'\|}\rho_\varepsilon(r')\,\mathrm{d}^3x' \\
&= 2\pi \int r'^2\,\mathrm{d}r'\,\rho_\varepsilon(r') \int_{-1}^{1} \mathrm{d}(\cos\theta')\,\frac{r - r'\cos\theta'}{\sqrt{r^2+r'^2-2rr'\cos\theta'}} \\
&= r\left(\frac{1}{r}\right)_\varepsilon - 2\pi \int r'^2\,\mathrm{d}r'\,\rho_\varepsilon\left(\frac{1}{r}(|r-r'|+(r+r'))+\frac{1}{3}\frac{1}{r^2}\frac{1}{r'}(|r-r'|^3-(r+r')^3)\right) \\
&= r\left(\frac{4\pi}{r}\int_0^r \mathrm{d}s\, s^2\rho_\varepsilon(s) + \frac{8\pi}{3}\int_r^\infty \mathrm{d}s\, s\rho_\varepsilon(s) - \frac{4\pi}{3}\frac{1}{r^3}\int_0^r \mathrm{d}s\, s^4\rho_\varepsilon(s)\right).
\end{aligned} \tag{C3}
$$

Clearly, $F_\varepsilon(r) = 1/r$ on $\mathbb{R}^3\backslash\{0\}$ and, moreover, $F_\varepsilon(r) \approx 1/r$ on the whole space. We can write the latter also in the form $rF_\varepsilon(r) \approx 1$.

APPENDIX D: WEAK LIMITS FOR THE KERR–SCHILD CASE

We investigate the distributional limit of (30). Inserting for $\tilde{f}_\varepsilon$, (30) becomes

$$
\begin{aligned}
R_\varepsilon = \frac{128\pi^3 m}{3}\Bigg(& 16[1]_\varepsilon^3 + \frac{4}{r^7}[2]_\varepsilon[4]_\varepsilon^2 + \frac{2}{r^6}[1]_\varepsilon[4]_\varepsilon^2 - \frac{4}{r^5}[4]_\varepsilon[2]_\varepsilon^2 + \frac{32}{r}[2]_\varepsilon[1]_\varepsilon^2 + \frac{14}{r^2}[1]_\varepsilon[2]_\varepsilon^2 \\
& - 3\rho_\varepsilon[2]_\varepsilon^2 - 4r\rho_\varepsilon[1]_\varepsilon[2]_\varepsilon - \frac{4r^2}{3}\rho_\varepsilon[1]_\varepsilon^2 - \frac{1}{3r^4}\rho_\varepsilon[4]_\varepsilon^2 + 2\frac{1}{r^2}\rho_\varepsilon[2]_\varepsilon[4]_\varepsilon + \frac{4}{3r}\rho_\varepsilon[1]_\varepsilon[4]_\varepsilon\Bigg),
\end{aligned} \tag{D1}
$$

where $[1]_\varepsilon := \int_r^\infty \mathrm{d}s\, s\rho_\varepsilon(s)$, $[2]_\varepsilon := \int_0^r \mathrm{d}s\, s^2\rho_\varepsilon(s)$, $[4]_\varepsilon := \int_0^r \mathrm{d}s\, s^4\rho_\varepsilon(s)$.

In order to compute the weak limit of (D1), expressions of the form (D2) and (D3) have to be investigated [note that the negative powers of r are compensated by the integrals so that both (D2) and (D3) are well-defined as $r \to 0$],

$$
r^{-4+2j+3i}\,\rho_\varepsilon(r)\,[1]_\varepsilon^i\,[2]_\varepsilon^j\,[4]_\varepsilon^k \quad (i+j+k=2), \tag{D2}
$$

$$
r^{-9+2j+3i}\,[1]_\varepsilon^i\,[2]_\varepsilon^j\,[4]_\varepsilon^k \quad (i+j+k=3). \tag{D3}
$$

Terms of the forms (D2) and (D3) possess related distributional limits:

$$
\begin{aligned}
(r^{-9+2j+3i}[1]_\varepsilon^i[2]_\varepsilon^j[4]_\varepsilon^k)_\varepsilon \approx & + \frac{i}{2j+3i-6}(r^{-7+2j+3i}\rho_\varepsilon(r)[1]_\varepsilon^{i-1}[2]_\varepsilon^j[4]_\varepsilon^k)_\varepsilon \\
& - \frac{j}{2j+3i-6}(r^{-6+2j+3i}\rho_\varepsilon(r)[1]_\varepsilon^i[2]_\varepsilon^{j-1}[4]_\varepsilon^k)_\varepsilon \\
& - \frac{k}{2j+3i-6}(r^{-4+2j+3i}\rho_\varepsilon(r)[1]_\varepsilon^i[2]_\varepsilon^j[4]_\varepsilon^{k-1})_\varepsilon .
\end{aligned}
$$

In order to show this, consider the distributional action on a test function $\Phi(\vec{x})$, i.e., $\int_0^\infty \mathrm{d}r\tilde{\Phi}(r)r^{-7+2j+3i}[1]_\varepsilon^i[2]_\varepsilon^j[4]_\varepsilon^k$. Here, we have introduced $\tilde{\Phi}(r) := \int \sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi\ \Phi(\vec{x})$. Integrating by parts and using $\tilde{\Phi}'(0) = 0$, the claim is established.

Taking $(j=2; k=1)$ as an example, we obtain the following weak limit:

$$\int \mathrm{d}r\tilde{\Phi}(r)\frac{1}{r^3}[2]_\varepsilon^2[4]_\varepsilon \overset{\varepsilon\to 0}{\to} \tilde{\Phi}(0)\int \mathrm{d}x\,\rho(x)[2][4]+\frac{1}{2}\tilde{\Phi}(0)\int \mathrm{d}x\,x^2\rho(x)[2]^2$$
$$\overset{(A1)}{=} \tilde{\Phi}(0)\int \mathrm{d}x\,\rho(x)[2][4]+\frac{1}{6}\frac{1}{64\pi^3}\tilde{\Phi}(0).$$

Here,

$$[1]:=\int_x^\infty \mathrm{d}t\,t\rho(t),\quad [2]:=\int_0^x \mathrm{d}t\,t^2\rho(t),\quad [4]:=\int_0^x \mathrm{d}t\,t^4\rho(t).$$

Eventually, we obtain the result (31) for the distributional limit of (D1).

Adding twist to anisotropic fluids

J. P. Krisch and E. N. Glass[a)]
Department of Physics, University of Michigan, Ann Arbor, Michigan 48109

(Received 18 November 2001; accepted for publication 17 December 2001)

We present a solution generating technique for anisotropic fluids which preserves specific Killing symmetries. Anisotropic matter distributions that can be used with the one parameter Ehlers–Geroch transform are discussed. Example space–times that support the appropriate anisotropic stress-energy are found and the transformation applied. The $3+1$ black string solution is one of the space–times with the appropriate matter distribution. Use of the transform with a black string seed is discussed. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1448683]

I. INTRODUCTION

Physically relevant solution generating techniques were developed in the 1960s and 1970s. Ehlers,[1] Harrison,[2] and Geroch[3,4] showed that a projective transform on the norm and twist (λ,ω), of a Killing vector will generate a Killing vector with norm and twist (λ',ω'). Starting with a vacuum space–time and a twist-free Killing vector, their method adds twist. For example, their method applied to the vacuum Schwarzschild metric generates a NUT metric. The generating method can be applied to any vacuum space–time with a Killing vector and has been generalized to the Einstein–Maxwell spaces[5] and to some matter space–times.[6] The extension to matter metrics is restrictive; Stephani[7] has shown that the only two equations of state that can be treated within this formalism are

$$\rho = P, \qquad \rho + 3P = 0. \tag{1}$$

Raca and Zsigrai[8] have also considered solution generating on fluids with this equation of state. The result clearly applies to fluids with isotropic stress. A close examination of the method used to generate the allowed matter distributions shows that it can be generalized to fluids with anisotropic stresses.

There has been increasing interest in general relativistic systems with anisotropic stress. Herrera and Santos[9] have reviewed some of the possible causes and the related general relativistic solutions. Anisotropic fluid spheres have been a useful model for discussing anisotropy since the early work of Bowers and Liang[10] on anisotropic fluid spheres. More recently Corchero[11] has discussed a post-Newtonian approximation to anisotropic fluid spheres. Das *et al.*[12] and Das and Kloster[13] have investigated the spherically symmetric collapse of anisotropic fluid objects into a black hole. Hernandez, Lunez, and Percoco[14] have treated anisotropy and nonlocal equations of state in radiating spheres. Conformally flat anisotropic spheres were examined by Herrera *et al.*[15] Glass and Krisch[16] have discussed diffusion induced anisotropies in a Vaidya atmosphere. Following up the recent interest in dimensional effects, Harko and Mak[17] discussed charged anisotropic fluid spheres in D-dimensions. Anisotropy in cosmological solutions has also been studied by McManus and Coley,[18] vandenHoogen and Coley,[19] Giovannini,[20] and Rainsford.[21] Relative motion as a source of anisotropy in multifluid systems was suggested long ago by Jeans.[22]

[a)]Permanent address: Physics Department, University of Windsor, Ontario N9B 3P4, Canada; electronic mail: englass@umich.edu

Letelier[23] has shown that two perfect fluids in relative motion can be described as a system with anisotropic pressures and has given the standard two-fluid stress energy form.

Physically, anisotropy is finding increasing application in systems at the density extremes of very compact objects and very diffuse mass clusters. This increasing interest in fluid solutions with anisotropic pressures suggests it would be of interest to extend the solution generating technique to space–times that have anisotropic fluid content. While it is relatively simple to create anisotropic fluid solutions by changing the functional dependence of metric potentials, the generating technique here will preserve specific Killing symmetries while obtaining new anisotropic solutions.

In Sec. II, we briefly review the formalism that leads to the isotropic pressure restrictions on the standard solution generating technique. The extension to anisotropic stresses follows directly from this. Isotropic seed space–times are discussed in Sec. III. Some examples of space–times containing the allowed anisotropies are in Sec. IV. Killing symmetries for the possible anisotropic spaces are covered in Sec. V, and Sec. VI has a discussion of the effect of the Geroch transformation on the fluid description in these spaces.

II. FORMALISM

A. The Killing description

Let (M,g_{ab}) be a solution of the Einstein field equations with energy density ρ and isotropic pressure P. Assume that g_{ab} has a Killing vector ξ^a with norm λ and twist ω^a where

$$\begin{aligned} \lambda &:= \xi^a \xi_a , \\ \omega^a &:= \epsilon^{abcd} \xi_b \nabla_c \xi_d . \end{aligned} \tag{2}$$

The induced metric on the three-dimensional space of vectors orthogonal to the Killing vector is

$$h_{ab} = g_{ab} - \xi_a \xi_b / \lambda . \tag{3}$$

The vacuum field equations can be written in terms of λ, ω and γ_{ab},

$$\begin{aligned} \gamma_{ab} &= |\lambda| h_{ab} , \\ \omega_a &= D_a \omega , \end{aligned} \tag{4}$$

where γ_{ab} is conformally related to h_{ab},[3] ω is the scalar potential associated with the Killing twist, and D_a is the covariant derivative for metric γ_{ab}.

B. Vacuum space–times

Consider the action written in the conformal three-space of γ_{ab},

$$I = \int d^3x \sqrt{\gamma} \left[\mathcal{R} - \frac{1}{2\lambda^2} (D_a \lambda D^a \lambda + D_a \omega D^a \omega) \right]. \tag{5}$$

A projective transform of the complex potential $\tau = \omega + i\lambda$ can be written

$$\tau' = \frac{\tau \cos(\delta) + \sin(\delta)}{\cos(\delta) - \tau \sin(\delta)}, \tag{6}$$

where δ is a transformation parameter. The action is invariant under this transformation, so we have added twist to the Killing vector with γ_{ab} unchanged and can generate the new $3+1$ space–time, g'_{ab}, from the formalism. The development of the transformation method is described in Refs. 3 and 4. We briefly review the transformation method for twist-free Killing vectors.

C. Generating the new space–time from a twist-free seed

The generation method as described by Geroch[3,4] for vacuum will be the same in the matter space–times. Starting with metric g_{ab}, define forms α_a, β_a, and η_a based on a seed Killing vector, ξ_a, with norm λ and transformation parameter δ,

$$\beta_a = \xi_a(\lambda - \lambda^{-1}), \tag{7a}$$

$$2\alpha_{[b,a]} = \varepsilon_{abcd}\nabla^c \xi^d, \tag{7b}$$

$$\eta_a = \lambda^{-1}\xi_a + \alpha_a \sin(2\delta). \tag{7c}$$

The new metric is then given by

$$g'_{ab} = F(g_{ab} - \lambda^{-1}\xi_a\xi_b) + (\lambda/F)\,\eta_a\eta_b \tag{8}$$

with

$$F = \cos^2(\delta) + \lambda^2 \sin^2(\delta). \tag{9}$$

The norm of the Killing vector becomes

$$\lambda' = \lambda/F. \tag{10}$$

The scalar twist potential that has been added to the Killing vector is

$$\omega' = \frac{\sin(\delta)\cos(\delta)(1-\lambda^2)}{F}. \tag{11}$$

These are the equations that will generate the new space–time from static seed metrics.

III. ISOTROPIC MATTER DESCRIPTIONS

A. Isotropic model 1

To find the isotropic matter space–times that can be used with this method, consider the action[24]

$$I = \int \mathrm{d}^3x\sqrt{\gamma}\left[\mathcal{R} - \frac{D_a\lambda D^a\lambda}{2\lambda^2} + \Psi\right] \tag{12}$$

with Ψ a specified function. Stephani[7] has shown that the Ricci tensor in four dimensions is

$$R_{ab} = -\Psi|\lambda|(g_{ab} - \xi_a\xi_b/\lambda) \tag{13}$$

and clearly the action will be invariant under the projective transform on τ. In the isotropic case, this Ricci tensor is associated with a perfect fluid for ξ^a timelike. The fluid has an equation of state $\rho + 3P = 0$, with $8\pi\rho = 3\Psi\lambda/2$.

B. Isotropic model 2

A second action that one can consider is[24]

$$I = \int \mathrm{d}^3x\sqrt{\gamma}\left[\mathcal{R} - \frac{D_a\lambda D^a\lambda}{2\lambda^2} - s_a s^a\right] \tag{14}$$

with

$$s_a \xi^a = 0. \tag{15}$$

The four-dimensional Ricci tensor for this action is

$$R_{ab} = s_a s_b \tag{16}$$

which, in the isotropic case, describes a perfect fluid if the Killing vector is spacelike. The fluid has density and pressure

$$\begin{aligned} 8\pi\rho &= -s^a s_a/2, \\ P &= \rho. \end{aligned} \tag{17}$$

Solution generating with both of these isotropic forms has been examined by Garfinkle, Glass, and Krisch.[25]

IV. ANISOTROPIC MATTER DESCRIPTION

The form of the Ricci tensor will be the same for fluids with nonisotropic stress. The stress-energy content can be written as

$$(1/8\pi) T_{ab} = \rho u_a u_b + p_1 e_a^{(1)} e_b^{(1)} + p_2 e_a^{(2)} e_b^{(2)} + p_3 e_a^{(3)} e_b^{(3)}, \tag{18}$$

where $(u^a, e_a^{(i)}, i = 1,2,3)$ is a convenient orthogonal tetrad. The associated Ricci tensor is

$$R_{ab} = T_{ab} - (T/2) g_{ab}, \tag{19}$$

$$(1/8\pi) R_{ab} = \rho u_a u_b + p_1 e_a^{(1)} e_b^{(1)} + p_2 e_a^{(2)} e_b^{(2)} + p_3 e_a^{(3)} e_b^{(3)} + \left(\frac{\rho - p_\Sigma}{2} \right) g_{ab}, \tag{20}$$

where $p_\Sigma = p_1 + p_2 + p_3$.

A. Anisotropic model 1

Consider Ricci tensor $R_{ab} = -\Psi |\lambda| (g_{ab} - \xi_a \xi_b / \lambda)$. There are two Killing vector possibilities: $\xi_a = \lambda u_a$ and $\xi_a = \lambda e_a^{(1)}$, where we have chosen $e_a^{(1)}$ for convenience. The timelike Killing vector will generate isotropic stress. Consider the spacelike vector $\xi_a = \lambda e_a^{(1)}$. We have

$$-(1/8\pi)\Psi|\lambda|(g_{ab} - e_a^{(1)} e_b^{(1)}) = \rho u_a u_b + p_1 e_a^{(1)} e_b^{(1)} + p_2 e_a^{(2)} e_b^{(2)} + p_3 e_a^{(3)} e_b^{(3)} + \left(\frac{\rho - p_\Sigma}{2} \right) g_{ab}. \tag{21}$$

Multiplying by $e_a^{(1)}$ we have

$$p_1 + \rho = p_2 + p_3. \tag{22}$$

Contracting with u_a we find

$$(1/8\pi) 2\Psi |\lambda| = \rho + p_\Sigma. \tag{23}$$

The other spatial contractions give

$$\begin{aligned} -(1/8\pi) 2\Psi |\lambda| &= p_2 - p_1 - p_3 + \rho, \\ -(1/8\pi) 2\Psi |\lambda| &= p_3 - p_1 - p_2 + \rho. \end{aligned} \tag{24}$$

Comparing, we must have $p_2 = p_3$, and

$$-(1/8\pi)2\Psi|\lambda| = -p_1 + \rho. \tag{25}$$

Combining, we find an anisotropic fluid with density and stress

$$\begin{aligned} 8\pi\rho &= -\Psi\lambda/2, \\ 8\pi p_1 &= 3\Psi\lambda/2, \\ p_2 &= p_3 = -\rho. \end{aligned} \tag{26}$$

B. Anisotropic model 2

Consider Ricci tensor $R_{ab} = s_a s_b$. This Ricci tensor model requires that the vector s^a be orthogonal to the Killing vector. Again there are two choices for the Killing vector, and in this model it is the timelike Killing vector that generates the anisotropic stress energy. Consider $\xi_a = \lambda u_a$. Since s_a is orthogonal to the Killing vector, s_a is spacelike. Choose function Φ and $s_a = \Phi e_a^{(1)}$,

$$\frac{s_a s_b}{8\pi} = \frac{\Phi^2 e_a^{(1)} e_b^{(1)}}{8\pi} = \rho u_a u_b + p_1 e_a^{(1)} e_b^{(1)} + p_2 e_a^{(2)} e_b^{(2)} + p_3 e_a^{(3)} e_b^{(3)} + \left(\frac{\rho - p_\Sigma}{2}\right) g_{ab}. \tag{27}$$

Following the same method used in the previous section, we obtain

$$\begin{aligned} 8\pi\rho &= 8\pi p_1 = \Phi^2/2, \\ 8\pi p_2 &= 8\pi p_3 = -\Phi^2/2. \end{aligned} \tag{28}$$

The indices can be relabeled to describe s_a lying along $e_a^{(2)}$ or $e_a^{(3)}$.

V. SPACE–TIMES FOR THE ANISOTROPIC MATTER DISTRIBUTIONS

In Sec. IV we examined two anisotropic models. One has a timelike Killing vector and one a spacelike Killing vector. We now find examples of space–times that could contain the anisotropic matter distribution.

A. Timelike Killing vector

For density and pressures $\rho = p_1 = -p_2 = -p_3$ consider the metric with function $\chi(z)$:

$$ds^2 = -e^{2n\chi}\,dt^2 + dz^2 + e^{2\chi}(dr^2 + r^2\,d\varphi^2). \tag{29}$$

The field equations are

$$\begin{aligned} 8\pi\rho &= -2\chi_{,zz} - 3\chi_{,z}^2, \\ 8\pi p_z &= \chi_{,z}^2(2n+1), \\ 8\pi p_k &= (n+1)\chi_{,zz} + \chi_{,z}^2(n^2+n+1) \end{aligned} \tag{30}$$

with p_k labeling both p_r and p_φ. Enforcing the stress relations, one finds the solution

$$e^{(n+2)\chi} = az + b$$

with fluid $\rho = p_z = -p_k$

$$8\pi\rho = \frac{(2n+1)a^2}{(n+2)^2(az+b)^2} \tag{31}$$

and metric

$$ds^2 = -(az+b)^{2n/(n+2)}dt^2 + dz^2 + (az+b)^{2/(n+2)}(dr^2 + r^2\, d\varphi^2). \tag{32}$$

For $n=1$, this space–time is conformally flat.

B. Spacelike Killing vector

A simple space–time whose fluid content has the necessary anisotropic structure is the conformally flat space–time with metric

$$ds^2 = e^{2az}(-dt^2 + dr^2 + r^2\, d\varphi^2 + dz^2). \tag{33}$$

The fluid parameters are easily shown to be

$$\begin{aligned} 8\pi\rho &= -a^2 e^{-2az}, \\ 8\pi p_z &= 3a^2 e^{-2az}, \\ 8\pi p_k &= a^2 e^{-2az}, \end{aligned} \tag{34}$$

where p_k are the radial and φ-stresses. The negative density does not readily lend itself to a physical description. An interesting space–time that also has the appropriate anisotropic stress relations is the simple lift of the $2+1$ BTZ black hole space–time[26] describing an infinite black string:[27,28]

$$ds^2 = -(-m+\Lambda_3 r^2)dt^2 + \frac{dr^2}{-m+\Lambda_3 r^2} + r^2\, d\varphi^2 + dz^2. \tag{35}$$

In $2+1$ there is a stress energy

$$T_{ii} = \Lambda_3 g_{ii}$$

with Λ_3 the $2+1$ cosmological constant. When the z coordinate is added the fluid content is

$$\begin{aligned} 8\pi\rho &= -\Lambda_3, \\ 8\pi p_r &= 8\pi p_\varphi = \Lambda_3, \\ 8\pi p_z &= 3\Lambda_3, \end{aligned} \tag{36}$$

which has the required anisotropic stress-energy structure. The relation between the $2+1$ BTZ solution and the $3+1$ black string has been studied by Lemos and Zanchin.[29] The negative density in this case can be physically motivated from the cosmological constant. It will be of interest to apply the Geroch transform to this $3+1$ BTZ lift and then project back down to $2+1$ to examine the effects on the cosmological fluid.

VI. APPLYING THE GEROCH TRANSFORMATION

In this section we will use the Geroch formalism described by Eqs. (7)–(10) to add twist to the Killing vectors of our example space–times. The new space–time will be generated and the effect of the transformation on the fluid parameters examined.

A. Timelike Killing vector

The space–time with a timelike Killing vector that we found had metric

$$ds^2 = -(az+b)^{2n/(n+2)}dt^2 + dz^2 + (az+b)^{2/(n+2)}(dr^2 + r^2\, d\varphi^2).$$

The Geroch transform process can be applied to this space–time adding twist to the timelike Killing vector and vorticity to the fluid. From Eqs. (7) to (9) we have

$$\xi_a^{(t)}\xi^a_{(t)}=\lambda=-(az+b)^{2n/(n+2)}, \tag{37}$$

$$F=\cos^2(\delta)+\lambda^2\sin^2(\delta), \tag{38}$$

$$\alpha_{\varphi,r}-\alpha_{r,\varphi}=-\frac{2nar}{n+2}\eta_{tr\varphi z}, \tag{39}$$

$$\alpha_\varphi=-\frac{nar^2}{n+2}+\alpha_0, \tag{40}$$

where $\eta_{tr\varphi z}=1$. The new metric is

$$ds^2=-\frac{(az+b)^{2n/(n+2)}}{F}[dt+\sin(2\delta)\alpha_\varphi\, d\varphi]^2+F\,dz^2+F(az+b)^{2/(n+2)}(dr^2+r^2\,d\varphi^2). \tag{41}$$

The fluid parameters in this space–times are the original parameters scaled by F:

$$\begin{aligned}\rho'&=\rho/F,\\ p_i'&=p_i/F.\end{aligned} \tag{42}$$

The fluid has acquired vorticity along the z axis

$$\omega^{(z)}=\frac{2na\sin(2\delta)}{(n+2)F^2}(az+b)^{(n-2)/(n+2)}. \tag{43}$$

The projective transform on the Killing parameters that generates the new space–time has two fixed points. For the case where the initial space is twist free, the fixed points of the projective transform are $\lambda=\pm1$. For this example, $F=1$ at the fixed points, and the fluid parameters are the same in both the seed and transformed space–times.

B. Spacelike Killing vector

In this example, we wish to add twist to a spacelike Killing vector. We will consider the lift of the BTZ metric as the seed spacetime. The seed metric is

$$ds^2=-(-m+\Lambda_3 r^2)dt^2+\frac{dr^2}{-m+\Lambda_3 r^2}+r^2\,d\varphi^2+dz^2. \tag{44}$$

There are two Killing vector choices: $\xi_a^{(\varphi)}$ or $\xi_a^{(z)}$. We will work with the φ-Killing vector and assume that the metric remains independent of the z-coordinate. From Eq. (7) we have

$$\xi_a^{(\varphi)}\xi^a_{(\varphi)}=\lambda=r^2, \tag{45}$$

$$\alpha_{t,z}-\alpha_{z,t}=2\,\eta_{tzr\varphi}(-m+\Lambda_3 r^2). \tag{46}$$

Calculating α_a and η_a we have

$$\alpha_z=2(m-\Lambda_3 r^2)t+\alpha_0, \tag{47}$$

$$\eta_a=\xi_a^{(\varphi)}/\lambda+\sin(2\delta)\alpha_a, \tag{48}$$

with $F=\cos^2(\delta)+r^4\sin^2(\delta)$. The new $3+1$ metric is

$$ds^2=F\left[-(-m+\Lambda_3 r^2)dt^2+\frac{dr^2}{-m+\Lambda_3 r^2}+dz^2\right]+\frac{r^2}{F}[d\varphi+\alpha_z\sin(2\delta)dz]^2. \tag{49}$$

This black string solution is an anisotropic member of the cylindrical black hole solution family discussed by Lemos.[30]

Using $\delta=\pi/2$, it is easy to see the effect of the transform on the fluid parameters. For this value, the new $3+1$ space–time becomes

$$ds^2=r^4\left[-(-m+\Lambda_3 r^2)dt^2+\frac{dr^2}{-m+\Lambda_3 r^2}+dz^2\right]+\frac{1}{r^2}d\varphi^2 \tag{50}$$

with a fluid content

$$\begin{aligned} 8\pi\rho&=-\Lambda_3/r^4,\\ 8\pi p_r&=\Lambda_3/r^4,\\ 8\pi p_\varphi&=9\Lambda_3/r^4,\\ 8\pi p_z&=3\Lambda_3/r^4. \end{aligned} \tag{51}$$

The new general space–time can be projected back into $2+1$ with the result

$$\begin{aligned} h_{ab}&=g_{ab}-\xi_a^{(z)}\xi_b^{(z)}/\lambda_z,\\ h_{ab}dx^a\,dx^b&=F\left[-(-m+\Lambda_3 r^2)dt^2+\frac{dr^2}{-m+\Lambda_3 r^2}\right]+\frac{r^2}{F}d\varphi^2, \end{aligned} \tag{52}$$

which can be written as

$$\begin{aligned} h_{ab}dx^a\,dx^b=&-(-m+\Lambda_3 r^2)dt^2+\frac{dr^2}{-m+\Lambda_3 r^2}+r^2d\varphi^2+(r^4-1)\\ &\times\sin^2(\delta)\left[-(-m+\Lambda_3 r^2)dt^2+\frac{dr^2}{-m+\Lambda_3 r^2}+\frac{r^2}{1+(r^4-1)\sin^2(\delta)}d\varphi^2\right]. \end{aligned} \tag{53}$$

For $\delta=0$ the original $2+1$ BTZ space–time is recovered. It is also recovered at the $r^2=1$ fixed point. The fluid content of the $2+1$ space–time is

$$\begin{aligned} 8\pi\rho&=\frac{-\Lambda_3}{F}+\frac{2r^2\sin^2(\delta)}{F^3}\{mF+(-m+\Lambda_3 r^2)[7\cos^2(\delta)-r^4\sin^2(\delta)]\},\\ 8\pi p_r&=\frac{\Lambda_3}{F}-\frac{2r^2\sin^2(\delta)}{F^3}\{mF+2r^4\sin^2(\delta)(-m+\Lambda_3 r^2)\},\\ 8\pi p_\varphi&=\frac{\Lambda_3}{F}+\frac{2r^2\sin^2(\delta)}{F^3}\{2mF+(-m+\Lambda_3 r^2)[5\cos^2(\delta)+r^4\sin^2(\delta)]\}. \end{aligned} \tag{54}$$

The original BTZ solution described a black hole of mass m surrounded by a cosmological fluid with parameters $8\pi\rho=-\Lambda_3$, $8\pi p_r=8\pi p_\varphi=\Lambda_3$. From Eq. (54) it is clear that the cosmological fluid is still present but scaled by F, and that in addition a new fluid has been added. For $\delta=\pi/2$, for example, the fluid parameters are

$$8\pi\rho=(4m-3r^2\Lambda_3)/r^6,$$
$$8\pi p_r=(2m-3r^2\Lambda_3)/r^6, \tag{55}$$
$$8\pi p_\varphi=(2m+3r^2\Lambda_3)/r^6.$$

At infinity, the new solution describes an empty vacuum in contrast to the cosmological vacuum found in the BTZ asymptotic limit. The original BTZ solution had constant negative curvature making it locally isometric to AdS while the new space–time has a nonconstant Ricci scalar

$$R=-\frac{6\Lambda_3}{F}+(-m+\Lambda_3 r^2)\frac{8r^2\sin^2(\delta)\cos^2(\delta)}{F^3}. \tag{56}$$

VII. DISCUSSION

We have shown that the simple one parameter Ehlers–Geroch transform can be applied to space–times with anisotropic matter content for two different stress-energy situations. The formalism broadens the way in which anisotropy can be introduced and studied with relation to the Killing symmetry of the space–time. The formalism was applied to the simple lift of the BTZ solution and when the new $3+1$ solution was projected back to $2+1$, a different static $2+1$ solution was obtained. It describes a $2+1$ black hole with a horizon at the same position as the original BTZ horizon but with an additional fluid atmosphere. The asymptotic structure of the two solutions is very different. This result suggests that it would be useful to develop the formalism in dimensions higher than $3+1$, and use the projection technique to generate and study the resulting anisotropic $3+1$ solutions. Another generalization which could prove interesting is to broaden the fixed point structure of the projective transform. The fixed points described by Eq. (6) are $\lambda=\pm1$, as discussed previously. When using the Ehlers–Geroch method with a spacelike Killing vector, generalizing the projective transform by placing the fixed points at $\lambda=L^2$ offers a better chance of interpreting the fixed points and would broaden the applicability of the method.

In summary, the solution generating method developed here preserves specific Killing symmetries while creating new anisotropic solutions. These solutions may be useful for investigating relativistic behavior at the density extremes.

(Received 17 June 2001; accepted for publication 4 January 2002)

Some areas of modern theoretical physics such as modern cosmology contain different manifolds which must be glued together along a common boundary. These boundaries can be spacelike, timelike, or lightlike hypersurfaces. This paper shows how this gluing for different hypersurfaces is possible. Two different approaches are considered and the extent to which these approaches are equivalent are discussed. In particular, we will construct a distributional approach for dynamics of lightlike hypersurfaces in general relativity. Since Einstein's equations are nonlinear PDEs, for discontinuous metrics such as signature changing metrics, product of distributions are unavoidable. To glue two different manifolds which admit signature change, we consider this problem in the context of Colombeau's new theory of generalized functions. Some examples are given for clarification. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1452758]

I. INTRODUCTION

In the inflationary scenario of cosmology, when two phases coexist, the wall separating them can be treated as an infinitely thin bubble or shell, whose history is a timelike surface layer.[1] Analogously, in sudden global phase transition, the transition region can sometimes be considered as an infinitely thin spacelike surface layer.[2,3] Lightlike thin shells arise, for example, when sufficiently large bubbles in a sea of false vacuum are rapidly accelerated toward the speed of light by the imbalance of normal pressures. So the dynamics of bubbles and surface layers in general relativity has been studied extensively in the last two decades.[4–7] There are two different approaches to study these hypersurfaces: the Darmois–Israel (DI)[8–10] and Mansouri–Khorrami (MKh) distributional approach.[11,12]

In the DI approach, the formalism now commonly in use expresses the surface properties in terms of the jump of the extrinsic curvature across the shell wall. In this approach, the properties are obtained directly as functions of the shell's intrinsic coordinates. The intrinsic geometry of the layer must be continuous at the hypersurface, i.e., the intrinsic metric of the hypersurface must be the same determined from either side, and the discontinuity across the hypersurface of its extrinsic curvature (second fundamental form) is related via the Einstein field equations to the stress-energy associated with the surface layer.

This approach must be modified for the case of null hypersurfaces. The extrinsic curvature tensor of a spacelike or timelike hypersurface measures the change in the normal vector to the hypersurface as that vector is transported along the hypersurface. But the normal vector to a null hypersurface is also tangential to it, and the definition of Gaussian normal coordinates cannot be based on a null hypersurface. Since the normal to the null hypersurface declines into tangency with hypersurface, the normal prescription breaks down, because the normal extrinsic curvature is disabled as a carrier of transverse geometrical information. The degeneration of the induced metric

a)Electronic mail: knozari@umcc.ac.ir

to the hypersurface is the other complication and definition of the normal distance to the null shell is not simple as the case of timelike or spacelike shells.

On the other hand, the distributional approach of MKh considers the whole space–time, including the singular hypersurface, with a unified metric without bothering about the junction conditions along the hypersurface. These conditions are shown to be automatically fulfilled as part of the field equations. In this approach one chooses special coordinates which are continuous along the singular hypersurface to avoid nonlinear operations of distributions.

The aim of this paper is to compare different approaches to gluing space–time manifolds. To do this we first give an overview of the DI approach for both nonlightlike and lightlike hypersurfaces. Since Mansouri and Khorrami in Ref. 12 constructed their distributional approach for the case of nonlightlike hypersurfaces, here we will show that this approach is applicable for the case of null hypersurfaces also and there is no need for considerable change in their formalism. For examining this claim, we consider the well-known example of spherical lightlike shells in this framework and compare the results with the DI approach. It is shown that two formalism gives the same results and so our distributional approach for the case of a null shell is correct. Since equations of general relativity are nonlinear PDEs, for steplike metrics such as signature changing metrics, nonlinear operations on distributions are unavoidable. Here, using Colombeau algebra, which allows for nonlinear operations of distributions,[13–16] we generalize the MKh method to the special case of signature changing cosmological models. In each case, for clarification, some examples are given.

Notations and Conventions: We use the signature $(-\ +\ +\ +)$, and follow the curvature conventions of Misner, Thorne, and Wheeler.[17] However, our sign convention for extrinsic curvature is that of Israel.[8] The Greek indices run from 0 to 3 and Latin indices i, j, and k from 1 to 3. A semicolon indicates covariant derivatives with respect to either the four-metric of the whole space–time or the three-metric of the layer. $\nabla^{\pm}$ denotes the covariant derivative with respect to either of the metrics of partial manifolds $M^{\pm}$ which are to be glued together. The square brackets, $[F]$, are used to indicate the jump of any quantity F at the layer, and the terms proportional to the δ-function in equations are denoted by $\breve{F}$.

The organization of the paper is as follows: Section II first considers spacelike and timelike hypersurfaces in the DI approach. As we have stated, lightlike hypersurfaces must be studied more carefully and therefore Sec. II B is devoted to this subject. Section III considers dynamics of hypersurfaces in the MKh distributional approach in a unified formalism. Section IV gives an example which shows both the possibility of application of the MKh approach to the case of lightlike hypersurfaces and comparison of its results with respect to the DI method. Section V considers discontinuous metrics, which leads to nonlinear operations on distributions. To perform such operations, we use Colombeau theory of new generalized functions. As an example, we consider signature changing manifolds with steplike metrics and, as a special case, junction conditions for de Sitter space–time in this framework are derived.

II. DARMOIS–ISRAEL FORMALISM

A. Spacelike and timelike hypersurfaces

Assume two space–time manifolds M^+ and M^- with spacelike or timelike boundaries Σ^+ and Σ^-. We want to glue these two space–time manifolds together. Coordinates on the two space–time manifolds are defined independently as x_+^μ and x_-^μ, and the metrics denoted by $g^+_{\alpha\beta}(x_+^\mu)$ and $g^-_{\alpha\beta}(x_-^\mu)$. The induced metrics on the boundaries are called $g^+_{ij}(\xi_+^k)$ and $g^-_{ij}(\xi_-^k)$, where $\xi_\pm^k$ are intrinsic coordinates on $\Sigma^\pm$, respectively. Now to paste the manifolds together, we demand that the boundaries be isometric having the same coordinates, $\xi_-^k=\xi_+^k=\xi^k$. The identification $\Sigma_-=\Sigma_+=:\Sigma$ gives us the single glued manifold $M=M_+\cup M_-$. This condition, which is the minimum requirement for gluing two manifolds together formulated as

$$[g_{ij}]=0, \tag{1}$$

gives, together with the continuity of second fundamental form on Σ,

$$[K_{ij}]=0, \tag{2}$$

the Darmois conditions. Both conditions should be satisfied if Σ is just a boundary surface. But in the case of a thin shell we do not expect the second condition to be satisfied since the matter content of the shell should lead to a jump in the extrinsic curvature K_{ij}. On Σ we define a three-bein

$$e_i=\frac{\partial}{\partial\xi^i} \tag{3}$$

having the component

$$e_i^\mu=\frac{\partial x^\mu}{\partial\xi^i}. \tag{4}$$

The induced metric on Σ is given by the scalar product

$$g_{ij}=e_i\cdot e_j=g_{\mu\nu}e_i^\mu e_j^\nu. \tag{5}$$

Let the parametric equation of the Σ be

$$\Phi(x^\mu(\xi^i))=0 \tag{6}$$

having the unit normal four-vector n^μ given by

$$n_\mu=\alpha^{-1}\partial_\mu\Phi, \tag{7}$$

where

$$\alpha=\pm\sqrt{\left|g^{\mu\nu}\frac{\partial\Phi}{\partial x^\mu}\frac{\partial\Phi}{\partial x^\nu}\right|}. \tag{8}$$

Therefore

$$n_\mu e_i^\mu=0 \tag{9}$$

and

$$n_\mu n^\mu=\epsilon, \tag{10}$$

where

$$\epsilon\equiv\mathrm{sign}(\alpha)=\frac{|\alpha|}{\alpha} \tag{11}$$

and in our case, since Σ is spacelike or timelike, ϵ becomes by definition equal to -1 or $+1$, respectively. The extrinsic curvature of Σ is defined as

$$K_{ij}^\pm=e_i^\mu e_j^\nu\nabla_\mu^\pm n_\nu=K_{ji}^\pm. \tag{12}$$

Now we have all the prerequisites to write Einstein's equations for hypersurface Σ in the Darmois–Israel approach. These are ten equations which will be written in components normal and tangent to the hypersurface. The first and second contracted Gauss–Kodazzi equations are

$$G_{\mu\nu}n^{\mu}n^{\nu}=\tfrac{1}{2}(K^2-K_{ij}K^{ij}-\epsilon^{3}R), \tag{13}$$

$$G_{\mu\nu}e_i^{\mu}n^{\nu}=K_{ij}^{j}-K_{,i}, \tag{14}$$

where $K=K_{ij}K^{ij}$ and ${}^3R$ is the Ricci scalar of the three metric, g_{ij}. Now to discover the effect of the energy–momentum tensor S_{ij} of Σ on space–time geometry, we perform a "pill-box" integration of Einstein's equation across Σ:

$$S_{\mu\nu}=\lim_{\sigma\to 0}\int_{-\sigma}^{\sigma}\left(T_{\mu\nu}-g_{\mu\nu}\frac{\Lambda}{\kappa}\right)dn=\frac{1}{\kappa}\lim_{\sigma\to 0}\int_{-\sigma}^{\sigma}G_{\mu\nu}\,dn, \tag{15}$$

where n is the proper distance through Σ in the direction of the normal n^{μ}. $S_{\mu\nu}$ is the associated four-tensor of energy–momentum of the shell. According to Eqs. (13) and (14), there is no moment associated with the surface layer, flows out of Σ. Therefore $S_{\mu\nu}$ vanishes off the Σ,

$$S_{\mu\nu}n^{\nu}=0. \tag{16}$$

The energy–momentum four- and three-tensors of Σ are related as

$$S^{\mu\nu}=e_i^{\mu}e_j^{\nu}S^{ij}. \tag{17}$$

Similarly we can associate to the three-tensor K_{ij} defined on Σ, the corresponding four-dimensional tensor:

$$K^{\mu\nu}=K^{ij}e_i^{\mu}e_j^{\nu}, \tag{18}$$

satisfying

$$K^{\mu\nu}n_{\nu}=0. \tag{19}$$

The remaining components of Einstein's equations lead to the following nonvanishing result:

$$\lim_{\sigma\to 0}\int_{-\sigma}^{\sigma}G_{\mu\nu}e_i^{\mu}e_j^{\nu}\,\mathrm{d}N=\epsilon([K_{ij}]-g_{ij}[K])=\kappa S_{ij}. \tag{20}$$

This distributional equivalent of Einstein's equation is called the Lanczos equation, which partly determines the dynamics of the thin shell. The other dynamical equations come from the defining equation of the matter contents of the shell.

B. Lightlike hypersurfaces

Now assume two space–time manifolds M^{+} and M^{-} with lightlike boundaries Σ^{+} and Σ^{-}. We want to glue these two manifolds together. In this case, K_{ij} must be defined carefully, since normal prescription breaks down. For this end we proceed as follows. We want to define a coordinate system in the vicinity of a null hypersurface of discontinuity, tied to the geometry of that hypersurface and analogous to Gaussian normal coordinates. Suppose Σ denotes the intended null hypersurface of discontinuity. A well-known theorem says that the null generators of Σ must be geodesics, i.e., if a congruence of curves is both null and hypersurface-orthogonal, then it is also geodesic.[18] Each generator possesses an affine parameter, η, unique up to change of origin on each generator and changes of scale uniform on each generator. Since Σ is a three-dimensional hypersurface, the null generators are labeled by two parameters. These two parameters, x^a where $a=2$, 3 are constant on any given generator, and the affine parameter η along the generators, provide a reasonably natural coordinate system for Σ. The coordinates η and x^a:$a=2$, 3, the coordinate basis vectors $\partial/\partial\eta$ and $\partial/\partial x^a$, and the metric components g_{ij}, on the hypersurface Σ, are components of the intrinsic geometry of Σ. To calculate the curvature associated with any

δ-function surface layers on Σ for the rest of the junction conditions, it is necessary to extend the coordinate system off Σ. One way to do this, in the spirit of Gaussian normal coordinates, is as follows. At each point of Σ, the tangent vectors $\partial/\partial\eta$ and $\partial/\partial x^a$ define a unique null direction off Σ on both sides, i.e., on each side of Σ there exists a unique null vector $\mathbf{N}$ satisfying $\mathbf{N}\cdot(\partial/\partial\eta) = -1$ and $\mathbf{N}\cdot(\partial/\partial x^a) = 0$. At each point of Σ a null geodesic tangent to this direction extends off Σ. Defining these geodesics to be loci of constant η and x^a and using an affine parameter N on each geodesics (with $N=0$ on Σ) as fourth coordinate establishes the desired coordinate system in some neighborhood of Σ. The direction of the vector $\mathbf{N}$ plays the same role here as the normal direction for timelike or spacelike hypersurfaces of discontinuity. Note that for null hypersurface Σ, the normal direction is that of $\partial/\partial\eta$, which is also tangent to Σ. Now, the parametric equation for Σ is

$$\Phi(x^\mu(\xi^i)) = 0, \tag{21}$$

where $\xi^i = (x^a, \eta)$ with $a = 2, 3$. The normal four-vector to Σ is given by

$$n_\mu = \alpha^{-1}\partial_\mu\Phi, \tag{22}$$

where $n_\mu n^\mu = 0$, since Σ is null hypersurface. Here we use the normalization condition,

$$N^\mu n_\mu = -1. \tag{23}$$

We now introduce a slight generalization of the concept of extrinsic curvature by defining

$$K_{ij} = -N_\mu \frac{\delta e_i^\mu}{\delta\xi^j} = K_{ji}, \tag{24}$$

where $\delta/\delta\xi^j$ shows the absolute derivatives and $e_i^\mu = \partial x^\mu/\partial x^i$, where $x^i = (\eta, x^a)$. K_{ij} so defined is called the transverse extrinsic curvature. K_{ij} is not independent of the choice of transversal vector. Now we have all the prerequisites to write Einstein's equations for null hypersurfaces in the Darmois–Israel approach. To do this we define

$$\gamma_{ij} = 2[K_{ij}], \tag{25}$$

which is well defined and free of arbitrariness in the transversal $\mathbf{N}$. γ_{ij} is the projection onto Σ of the $\gamma_{\mu\nu}$, which is defined as

$$\gamma_{\mu\nu} = N^\alpha[\partial_\alpha g_{\mu\nu}], \tag{26}$$

i.e.,

$$\gamma_{ij} = \gamma_{\mu\nu} e^\mu_{(i)} e^\nu_{(j)}. \tag{27}$$

The four vectors $(\mathbf{N}, \mathbf{e_{(i)}})$ form an oblique basis with respect to which the normal vector $\mathbf{n}$ can be decomposed as

$$\mathbf{n} = -\boldsymbol{\epsilon}\mathbf{N} + \mathbf{l}^i\mathbf{e}_i, \tag{28}$$

where l^i are smooth functions and $\boldsymbol{\epsilon} = \mathbf{n}\cdot\mathbf{n} = \mathbf{0}$. This decomposition gives

$$g_{ij}l^j = \boldsymbol{\epsilon}N_i = 0, \tag{29}$$

which shows that the induced metric is degenerate and its inverse cannot be defined. To raising the indices i, j we see that a symmetric matrix g_*^{ij} exists such that

$$g_*^{ik}g_{jk} = \delta^i_j + l^i N_j. \tag{30}$$

In particular g_*^{ij} could be chosen as the contravariant two-metric g^{ab} in convected coordinates ($l^i=\delta_1^i$) with the choice $\mathbf{N}\cdot\mathbf{e_i}=\mathbf{0}$.[9,10] In this case $g_{ij}g_*^{ij}=2$, $g_{ij}l^j=0$ and $\gamma_{ij}l^il^j=0$ and we find for dynamics of the null hypersurface Σ:

$$\kappa S^{ij}=-\tfrac{1}{2}(g_*^{ik}l^jl^l+l^il^kg_*^{jl}-l^il^jg_*^{kl})\gamma_{kl}, \tag{31}$$

which implies that $S^{ij}n_j=0$ where S^{ij} is the singular part of $T^{\mu\nu}$ in the distributional sense.

III. DISTRIBUTIONAL APPROACH

In this section we give a unified distributional approach to glue two different manifolds with boundaries which can be spacelike, timelike, or lightlike hypersurfaces. We assume the metric to be continuous at the hypersurface Σ,

$$[g^{\mu\nu}]=0. \tag{32}$$

Write the metric in the following form:

$$g_{\mu\nu}=g_{\mu\nu}^{+}\Theta(\Phi(x))+g_{\mu\nu}^{-}\Theta(-\Phi(x)), \tag{33}$$

where Θ is the Heaviside step function and

$$g_{\mu\nu}^{+}|_{\Phi(x)=0}=g_{\mu\nu}^{-}|_{\Phi(x)=0}. \tag{34}$$

This condition guarantees the smoothness of the metric on the hypersurface. Should this not be the case we try a coordinate transformation $x=x(x')$ having a jump in the first derivative:

$$\frac{\partial x^\mu}{\partial x'^\rho}=\alpha_\rho^{+\mu}\Theta(\Phi(x))+\alpha_\rho^{-\mu}\Theta(-\Phi(x)). \tag{35}$$

The condition for the new metric to be continuous comes out to be

$$\alpha_\rho^{+\mu}\alpha_\sigma^{+\nu}g_{\mu\nu}^{+}|_{\Phi(x)=0}=\alpha_\rho^{-\mu}\alpha_\sigma^{-\nu}g_{\mu\nu}^{-}|_{\Phi(x)=0}. \tag{36}$$

We assume from now on that the metric is smooth everywhere, C^0 at the hypersurface, and C^∞ on both sides of it. Although the metric is continuous on Σ, its derivatives, and so the corresponding connection coefficients, are discontinuous. The connection coefficients can be written as

$$\Gamma_{\mu\nu}^{\rho}=\tfrac{1}{2}g^{\rho\sigma}(g_{\mu\sigma,\nu}+g_{\nu\sigma,\mu}-g_{\mu\nu,\sigma})=\Theta(\Phi(x))\Gamma_{\mu\nu}^{+\rho}+\Theta(-\Phi(x))\Gamma_{\mu\nu}^{-\rho}, \tag{37}$$

where $\Gamma_{\mu\nu}^{\pm\rho}$ are the ordinary connection coefficients on $M^{\pm}$. The above connection has jump discontinuity on Σ. To write the field equation for the hypersurface Σ, we define the energy–momentum tensor of the hypersurface as

$$\breve{T}_{\mu\nu}=CS_{\mu\nu}\delta(\Phi(x)), \tag{38}$$

where C is a constant which can be calculated as follows. We integrate (38) in the direction normal (transverse in the lightlike case) to the hypersurface Σ,

$$\int \breve{T}_{\mu\nu}\,\mathrm{d}\zeta=CS_{\mu\nu}\int \delta(\Phi(x))\mathrm{d}\zeta=CS_{\mu\nu}\left|\frac{\mathrm{d}\zeta}{\mathrm{d}\Phi}\right|, \tag{39}$$

where ζ is a distance in the direction of n^μ or N^μ for nonlightlike or lightlike Σ, respectively. Now by means of (15), we obtain

$$C=\left|\frac{d\Phi}{d\zeta}\right|=|\zeta^{\mu}\partial_{\mu}\Phi|=|\alpha|, \tag{40}$$

where ζ^{μ} is n^{μ} or N^{μ} for nonlightlike or lightlike Σ, respectively. Therefore (38) can be written as

$$\check{T}_{\mu\nu}=CS_{\mu\nu}\delta(\Phi(x))=S_{\mu\nu}|\zeta^{\rho}\partial_{\rho}\Phi|\,\delta(\Phi(x))=|\alpha|S_{\mu\nu}\delta(\Phi(x)). \tag{41}$$

In order to write field equations, there is no need to change the ordinary concept of covariant derivative. The covariant derivative of the tensor

$$T^{(\rho)}=\Theta(\Phi)T^{+(\rho)}+\Theta(-\Phi)T^{-(\rho)}, \tag{42}$$

where (ρ) stands for any number of indices, is calculated to be

$$T^{(\rho)}_{;\nu}=\nabla_{\nu}T^{(\rho)}+[T^{(\rho)}](\partial_{\nu}\Phi)\,\delta(\Phi). \tag{43}$$

Now to writing Einstein's field equation for hypersurface, Σ, we expect the curvature and Einstein tensor to be proportional to δ. This means that in calculating the connection coefficients and the components of the Ricci tensor we consider only terms proportional to δ. Since

$$R_{\mu\nu}=\Gamma^{\rho}_{\mu\rho,\nu}-\Gamma^{\rho}_{\mu\nu,\rho}+\Gamma^{\sigma}_{\mu\rho}\Gamma^{\rho}_{\sigma\nu}-\Gamma^{\sigma}_{\mu\nu}\Gamma^{\rho}_{\rho\sigma}, \tag{44}$$

the term proportional to δ is

$$\check{R}_{\mu\nu}=\check{\Gamma}^{\rho}_{\mu\rho,\nu}-\check{\Gamma}^{\rho}_{\mu\nu,\rho}. \tag{45}$$

Now,

$$\Gamma^{\rho}_{\mu\rho}=\frac{1}{2g}g_{,\mu}, \tag{46}$$

where g is the determinant of the metric $g_{\mu\nu}$. The δ distribution can only occur in the second derivatives of the metric. Therefore,

$$\check{\Gamma}^{\rho}_{\mu\rho,\nu}=\frac{1}{2g}\check{g}_{,\mu\nu}. \tag{47}$$

For the second term in (45) we have

$$\check{\Gamma}^{\rho}_{\mu\nu,\rho}=\tfrac{1}{2}g^{\rho\sigma}(\check{g}_{\sigma\mu,\nu\rho}+\check{g}_{\sigma\nu,\mu\rho}-\check{g}_{\mu\nu,\sigma\rho}). \tag{48}$$

Having the metric in the form (33), we obtain

$$\check{g}_{\alpha\beta,\mu\nu}=[g_{\alpha\beta,\mu}](\partial_{\nu}\Phi)\,\delta(\Phi(x)) \tag{49}$$

and

$$\check{g}_{,\mu\nu}=[g_{,\mu}](\partial_{\nu}\Phi)\,\delta(\Phi(x)). \tag{50}$$

Therefore we obtain for terms in the Ricci tensor proportional to δ,

$$\begin{aligned}\check{R}_{\mu\nu}&=\left(\frac{1}{2g}[g_{,\mu}]\partial_{\nu}\Phi-g^{\rho\sigma}([g_{\sigma\mu,\nu}]+[g_{\sigma\nu,\mu}]-[g_{\mu\nu,\sigma}])\partial_{\rho}\Phi\right)\delta(\Phi)\\&=\left(\frac{1}{2g}[g_{,\mu}]\partial_{\nu}\Phi-[\Gamma^{\rho}_{\nu\mu}]\partial_{\rho}\Phi\right)\delta(\Phi(x)).\end{aligned} \tag{51}$$

Now we can write Einstein's field equation for the hypersurface Σ as

$$\check{G}_{\mu\nu}=\kappa\check{T}_{\mu\nu}. \tag{52}$$

Defining

$$Q_{\mu\nu}=(\alpha^{-1})\left(\frac{1}{2g}[g_{,\mu}]\delta^{\rho}_{\nu}-[\Gamma^{\rho}_{\mu\nu}]\right)\partial_{\rho}\Phi=\left(\frac{1}{2g}[g_{,\mu}]\delta^{\rho}_{\nu}-[\Gamma^{\rho}_{\mu\nu}]\right)n_{\rho}, \tag{53}$$

we obtain, using Eqs. (41) and (51) for the energy–momentum tensor, the field equations in the four-dimensional form

$$Q_{\mu\nu}-\tfrac{1}{2}g_{\mu\nu}Q=\epsilon\kappa S_{\mu\nu}, \tag{54}$$

where $Q=Q_{\mu\nu}g^{\mu\nu}$ and $\epsilon=|\alpha|/\alpha$. $Q_{\mu\nu}$ is a tensor with support on Σ and this equation describes the dynamics of Σ. Multiplying (53) with n^{μ} we obtain

$$S_{\mu\nu}n^{\nu}=0, \tag{55}$$

which tells us that the components corresponding to $S_{\mu\nu}n^{\mu}n^{\nu}$ and $S_{\mu\nu}n^{\mu}e^{\nu}_{i}$ in the nonlightlike case and $S_{\mu\nu}N^{\mu}n^{\nu}$ and $S_{\mu\nu}n^{\mu}e^{\nu}_{i}$ in the lightlike case identically vanishes. To obtain the proper three-dimensional components we have

$$Q_{ij}=Q_{\mu\nu}e^{\mu}_{i}e^{\nu}_{j}=-[\Gamma^{\rho}_{\mu\nu}]n_{\rho}e^{\mu}_{i}e^{\nu}_{j}=[K_{ij}]. \tag{56}$$

The three-dimensional analoge of (54) is therefore

$$Q_{ij}=\epsilon\kappa(S_{ij}-\tfrac{1}{2}g_{ij}S), \tag{57}$$

where $S=S_{ij}S^{ij}$ and this is equivalent to Lanczos equation (20), (31).

IV. EXAMPLE: SPHERICAL LIGHTLIKE SHELLS

The equivalence of the DI and MKh methods for spacelike and timelike thin shells in general relativity has been shown in Ref. 12. In Sec. III it was shown that the MKh method is applicable for the case of the null shell with few changes. Now to examine our claim, we consider the familiar example of lightlike shells with spherical symmetry. This example has been studied extensively in the DI approach,[9] but we want to consider it in our distributional method. Expressed in terms of Eddington retarded or advanced time u, the metric of a general spherisymmetric geometry is

$$ds^2=-e^{\psi}du(fe^{\psi}du+2\xi\,dr)+r^2\,d\Omega^2, \tag{58}$$

where ψ and f are functions of u and r. The sign factor ξ is $+1$ if r increases toward the future along a ray $u=$constant, i.e., if the light cone $u=$constant is expanding; if it contracts then $\xi=-1$. It is useful to introduce a local mass function $m(u,r)$ defined as $f=1-2m/r$. We consider the case where the geometry on both sides of the lightlike shell is static, i.e., $\psi=0$ and $f=f(r)$ in (58). The Einstein field equations then take the form

$$\begin{aligned} T_{rr}&=0,\\ T^{r}_{u}&=0,\\ \frac{\partial m}{\partial r}&=-4\pi r^2T^{u}_{u}. \end{aligned} \tag{59}$$

We consider a thin shell whose history Σ, a light cone $u=$constant, splits space–time into past and future domains M_- and M_+. The four metric has the form (58) in both M_- and M_+, but with different functions f_- and f_+. We want to glue two space–times M_- and M_+ along the hypersurface Σ defined as $\Phi(x)=u=$const, using the distributional approach. The normal vector to the hypersurface Σ has the component

$$n_\mu=\partial_\mu\Phi=(1,0,0,0). \tag{60}$$

Now using (53) we find

$$Q_{uu}=\frac{1}{2}\left[\frac{\mathrm{d}f}{\mathrm{d}r}\right] \tag{61}$$

and other component of $Q_{\mu\nu}$ are vanishing. The inverse four-metric nonvanishing components are

$$\begin{gathered} g^{ur}=g^{ru}=-1, \\ g^{rr}f, \\ g^{\theta\theta}=\frac{1}{r^2}, \\ g^{\phi\phi}=\frac{1}{r^2\sin^2\theta}. \end{gathered} \tag{62}$$

Therefore it is easy to show that $Q=0$. Now from (54) we find

$$Q_{uu}-\tfrac{1}{2}g_{uu}Q=8\pi S_{uu}, \tag{63}$$

which leads to

$$\frac{1}{2}\left[\frac{\mathrm{d}f}{\mathrm{d}r}\right]=8\pi S_{uu} \tag{64}$$

or in terms of m,

$$[m]=8\pi r^2 S_{uu}. \tag{65}$$

This equation tell us how we can embed Σ in four-dimensional space–time and is the same as Eq. (51) of Ref. 9.

V. DISCONTINUOUS METRICS

In this section we consider the general case of discontinuous metrics. Since Einstein's field equations are nonlinear, with these types of metrics, product of distributions are unavoidable. Classical theory of distributions (the so-called Schwartz–Sobolov theory of distributions) do not allow nonlinear operations on distributions, thus we consider the problem in the context of Colombeau's new theory of generalized functions. We consider the case of signature changing manifolds as an interesting problem in modern cosmology. It is important to note that the MKh distributional approach assumes the continuity of the metric at the hypersurface. Since in the Colombeau algebra, step function and other classically sharp functions become smooth and continuous, it is possible to continue to use the MKh method for classically discontinuous (in the sense of Schwartz–Sobolov) metrics.

A. New generalized functions

Suppose $\Phi \in D(\mathbb{R}^n)$ with $D(\mathbb{R}^n)$ the space of smooth (i.e., C^∞) C-valued test functions on $\mathbb{R}^n$. For $f:\mathbb{R}^n \to C$, not necessarily continuous, we define the smoothing process for f as one of the convolutions

$$\tilde{f}(x) := \int f(y)\Phi(y-x)d^n y, \tag{66}$$

or

$$\tilde{f}_\epsilon(x) := \int f(y)\,\frac{1}{\epsilon^n}\,\Phi\left(\frac{y-x}{\epsilon}\right)d^n y. \tag{67}$$

This smoothing procedure is valid for distributions too. Take the distribution R, then by smoothing of R we mean one of the two convolutions (66) or (67) with f replaced by R. Now we can perform the product Rf of the distribution R with the discontinuous function f through the action of the product on a test function Ψ as follows:

$$(Rf,\psi) = \lim_{\epsilon \to 0} \int \tilde{R}_\epsilon(x)\tilde{f}_\epsilon(x)\Psi(x)d^n x. \tag{68}$$

The multiplication so defined does not coincide with the ordinary multiplication even for continuous functions. To resolve this difficulty consider one-parameter families (f_ϵ) of C^∞ functions used to construct the algebra

$$\mathcal{E}_{\mathcal{M}}(\mathbb{R}^n) = \{(f_\epsilon) | f_\epsilon \in C^\infty(\mathbb{R}^n) \forall K \subset \mathbb{R}^n \text{ compact},$$

$$\forall \alpha \in \mathbb{N}^n \exists N \in \mathbb{N}, \quad \exists \eta > 0, \quad \exists > 0$$

$$\text{such that } \sup_{x \in K} |D^\alpha f_\epsilon(x)| \leqslant c\epsilon^{-N} \forall 0 < \epsilon < \eta\}, \tag{69}$$

where

$$D^\alpha = \frac{\partial^{|\alpha|}}{(\partial x^1)^{\alpha_1} \cdots (\partial x^n)^{\alpha_n}}, \tag{70}$$

and

$$|\alpha| = \alpha_1 + \alpha_2 + \cdots + \alpha_n .$$

Accordingly, C^∞-functions are embedded into $\mathcal{E}_{\mathcal{M}}(\mathbb{R}^n)$ as constant sequences. Now, we have to identify different embeddings of C^∞ functions. Take a suitable ideal $\mathcal{N}(\mathbb{R}^n)$ defined as

$$\mathcal{N}(\mathbb{R}^n) = \{(f_\epsilon) | (f_\epsilon) \in \mathcal{E}_{\mathcal{M}}(\mathbb{R}^n) \forall K \subset \mathbb{R}^n \text{ compact},$$

$$\forall \alpha \in \mathbb{N}^n, \quad \forall N \in \mathbb{N} \exists \eta > 0, \quad \exists c > 0,$$

$$\text{such that } \sup_{x \in K} |D^\alpha f_\epsilon(x)| \leqslant c \in {}^N \forall 0 < \epsilon < \eta\}, \tag{71}$$

containing negligible functions such as

$$f(x) - \int d^n y\,\frac{1}{\epsilon^n}\,\varphi\left(\frac{y-x}{\epsilon}\right) f(y). \tag{72}$$

Now, the Colombeau algebra $\mathcal{G}(\mathbb{R}^n)$ is defined as

$$\mathcal{G}(\mathbb{R}^n)=\frac{\mathcal{E}_{\mathcal{M}}(\mathbb{R}^n)}{\mathcal{N}(\mathbb{R}^n)}. \tag{73}$$

A Colombeau generalized function is thus a moderate family $(f_\epsilon(x))$ of C^∞ functions modulo negligible families. Two Colombeau objects (f_ϵ) and (g_ϵ) are said to be associated [written as $(g_\epsilon)\approx(f_\epsilon)$] if

$$\lim_{\epsilon\to 0}\int d^n x(f_\epsilon(x)-g_\epsilon(x))\varphi(x)=0,$$
$$\forall\varphi\in D(\mathbb{R}^n). \tag{74}$$

For example, if $\varphi(x)=\varphi(-x)$ then $\delta\theta\approx\frac{1}{2}\delta$, where δ is Dirac delta function and θ is Heaviside step function. Moreover, we have in this algebra $\theta^n\approx\theta$ and not $\theta^n=\theta$.

B. Signature changing manifolds

In distributional formalism of gluing manifolds, the whole space–time, including the singular hypersurface, is treated with a unified metric without bothering about the junction conditions along the hypersurface. These conditions are shown to be automatically fulfilled as part of the field equations.[12] In this approach one chooses special coordinates which are continuous along the singular hypersurface to avoid nonlinear operations of distributions. Here, using Colombeau algebra, which allows for nonlinear operations of distributions, we generalize our distributional method to the special case of signature changing cosmological models.

Consider as a simple model universe a space–time with the following FRW metric containing a steplike lapse function

$$\mathrm{d}s^2=-f(t)\mathrm{d}t^2+a^2(t)\left(\frac{\mathrm{d}r^2}{1-kr^2}+r^2\,\mathrm{d}\theta^2+r^2\sin^2\theta\,\mathrm{d}\rho^2\right), \tag{75}$$

where

$$f(t)=\theta(t)-\theta(-t) \tag{76}$$

and

$$a^2(t)=a_+^2(t)\,\theta(t)+a_-^2(t)\,\theta(-t). \tag{77}$$

We assume $[a]=a_+-a_-=0$ to achieve continuity of the metric on the surface of signature change. Note that we have assumed for simplicity $k_+=k_-=k$. This metric describes a signature changing space–time with the singular surface $t=0$. It describes a Riemannian space for $t<0$ and a Lorentzian space–time for $t>0$. In Colombeau's point of view, $f(t)$ has a microscopic structure around $t=0$ with a jump equal to ϵ as shown in Fig. 1. Since we are going to construct a signature changing model, we choose

$$\theta(t)|_{t=0}=\tau \quad \text{with} \quad \tau>\tfrac{1}{2}. \tag{78}$$

Since $\theta(-t)=1-\theta(t)$, we have $\theta(-t)=1-\tau$ and

$$f(t)|_{t=0}=2\tau-1. \tag{79}$$

This value gives us the correct change of sign in going from $t<0$ to $t>0$. This "regularization" of $f(t)$ at $t=0$ allows us to use operations such as $f(t)^{-1}$, $f^2(t)$, and $|f(t)|^{-1}$.

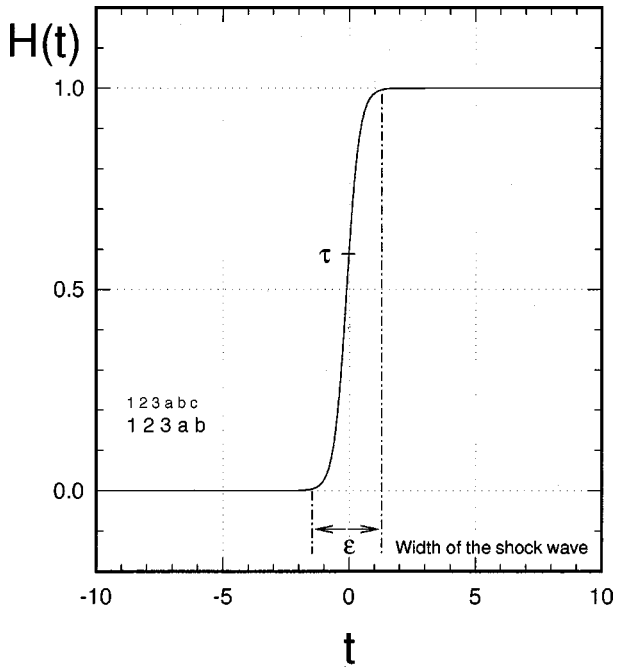

FIG. 1. The profile of Heaviside step function as it is used in Colombeau's theory.

In what follows we consider $f(t)$ to be the regularized function $\tilde{f}_\epsilon$, defined according to Colombeau's algebra. Now, we are prepared to calculate the dynamics of the signature changing hypersurface in the line of distributional procedure.[19] First we calculate the relevant components of the Einstein tensor for the metric (75):

$$G_{tt}=-\frac{-3kf^3f^3}{f^2a^2}-\frac{3f^2(\dot{a}^2)}{f^2a^4}, \tag{80}$$

$$G_{rr}=\frac{1}{1-kr^2}\left(\frac{2a\ddot{a}f}{f^2}-\frac{a\dot{a}\dot{f}}{f^2}+\frac{f(a\dot{a})^2}{a^2f^2}+\frac{kf^2}{f^2}\right), \tag{81}$$

$$G_{\theta\theta}=r^2\left(\frac{2a\ddot{a}f}{f^2}-\frac{a\dot{a}\dot{f}}{f^2}+\frac{f(a\dot{a})^2}{a^2f^2}+\frac{kf^2}{f^2}\right), \tag{82}$$

$$G_{\varphi\varphi}=r^2\sin^2\theta\left(\frac{2a\ddot{a}f}{f^2}-\frac{a\dot{a}\dot{f}}{f^2}+\frac{f(a\dot{a})^2}{a^2f^2}+\frac{kf^2}{f^2}\right). \tag{83}$$

According to standard calculus of distributions, we have

$$\dot{f}(t)=\dot{\theta}(t)-\dot{\theta}(-t)=\delta(t)+\delta(-t)=2\,\delta(t), \tag{84}$$

taking into account $\delta(-t)=\delta(t)$. Now, using Colombeau algebra we can write

$$\theta(t)\,\delta(t)\approx\tfrac{1}{2}\delta(t). \tag{85}$$

Therefore we may write

$$f(t)\,\delta(t)=\theta(t)\,\delta(t)-\theta(-t)\,\delta(t)\approx\tfrac{1}{2}\delta(t)-\tfrac{1}{2}\delta(t)\approx 0. \tag{86}$$

In evaluating (80)–(83) we should take care of the following property of association. Having

$$AB \approx AC,$$

we are not allowed to conclude

$$B \approx C.$$

Since the time derivative of any discontinuous function F is given by

$$\dot{F} = \dot{F}_+ \theta(t) + \dot{F}_- \theta(-t) + [F]\delta(t), \tag{87}$$

using relations (80)–(83) we obtain for the singular parts of these equations:

$$\hat{G}^t_t \approx 0, \tag{88}$$

$$\hat{G}^r_r \approx \left(\frac{f[\dot{a}]}{f^2 a} - \frac{[\dot{a}]}{f^2 a} \right) \delta(t), \tag{89}$$

$$\hat{G}^\theta_\theta \approx \left(\frac{f[\dot{a}]}{f^2 a} - \frac{[\dot{a}]}{f^2 a} \right) \delta(t), \tag{90}$$

$$\hat{G}^\varphi_\varphi \approx \left(\frac{f[\dot{a}]}{f^2 a} - \frac{[\dot{a}]}{f^2 a} \right) \delta(t), \tag{91}$$

where multiplication of the distribution $\delta(t)$ with the generalized functions $1/f^2$ and f/f^2 is defined as in (68).

This is a rigorous calculation which shows definitely that there are nonvanishing terms on the left-hand side of the field equations related to the signature change surface. Now we have to look at the energy–momentum tensor on the right-hand side of the field equations, its possible interpretation, and consequences for the dynamics of the signature change surface.

The complete energy–momentum tensor of space–time (with any kind of matter content) can be written as

$$T_{\mu\nu} = \theta(t) T^+_{\mu\nu} + \theta(-t) T^-_{\mu\nu} + C S_{\mu\nu} \delta(t), \tag{92}$$

where $T^\pm_{\mu\nu}$ are energy–momentum tensors corresponding to Lorentzian and Euclidean regions, respectively, and C is a constant which can be obtained by a little algebra to find

$$C = \left| \frac{\mathrm{d}\Phi}{\mathrm{d}n} \right| = |n^\mu \partial_\mu \Phi| = \frac{1}{|f(t)|}, \tag{93}$$

where $\Phi = t = 0$ defines the singular surface Σ, the vector n_μ is normal to the surface Φ, and n measures the distance along it. The distributional part of the Einstein equations read as follows:

$$\hat{G}_{\mu\nu} = \kappa \hat{T}_{\mu\nu} \tag{94}$$

using Eqs. (88)–(91), (93), (94) we obtain

$$0 \approx \frac{\kappa}{|f(t)|} S^t_t \delta(t), \tag{95}$$

$$\hat{G}^r_r \approx \left(\frac{f[\dot{a}]}{f^2 a} - \frac{[\dot{a}]}{f^2 a} \right) \delta(t) \approx \frac{\kappa}{|f(t)|} S^r_r \delta(t), \tag{96}$$

$$\hat{G}^{\theta}_{\theta}\approx\left(\frac{f[\dot{a}]}{f^2a}-\frac{[\dot{a}]}{f^2a}\right)\delta(t)\approx\frac{\kappa}{|f(t)|}S^{\theta}_{\theta}\delta(t), \tag{97}$$

$$\hat{G}^{\varphi}_{\varphi}\approx\left(\frac{f[\dot{a}]}{f^2a}-\frac{[\dot{a}]}{f^2a}\right)\delta(t)\approx\frac{\kappa}{|f(t)|}S^{\varphi}_{\varphi}\delta(t). \tag{98}$$

Now using Eq. (68), we must define the multiplication of δ-distribution with the discontinuous functions $1/|f|$ and $1/f^2$. To this end we consider them as Colombeau's regularized functions:

$$\tilde{G}_{1\epsilon}(t):=\delta_{\epsilon}(t)\left(\frac{1}{|f(t)|}\right)_{\epsilon}, \tag{99}$$

and

$$\hat{G}_{2\epsilon}(t):=\delta_{\epsilon}(t)\left(\frac{1}{f^2(t)}\right)_{\epsilon}. \tag{100}$$

Now according to (68), these two multiplications are defined as follows:

$$\left(\delta(t)\frac{1}{|f(t)|},\Psi\right):=\lim_{\epsilon\to 0}\int\tilde{G}_{1\epsilon}(t)\Psi(t)\mathrm{d}t, \tag{101}$$

and

$$\left(\delta(t)\frac{1}{f^2(t)},\Psi\right):=\lim_{\epsilon\to 0}\int\tilde{G}_{2\epsilon}(t)\Psi(t)\mathrm{d}t, \tag{102}$$

for any test function, Ψ. Now we argue that $\tilde{G}_{1\epsilon}$ and $\tilde{G}_{2\epsilon}$ are associated in Colombeau's sense, i.e.,

$$\lim_{\epsilon\to 0}\int(\tilde{G}_{1\epsilon}(t)-\tilde{G}_{2\epsilon}(t))\Psi(t)\mathrm{d}t=0. \tag{103}$$

This is correct for any test function Ψ because, although $\tilde{G}_{1\epsilon}$ and $\tilde{G}_{2\epsilon}$ are divergent at a common point, the difference in their ''microscopic structure'' at that point tends to zero for $\epsilon\to 0$. Therefore, we obtain from (95) to (98) the final form of the energy–momentum tensor of the singular surface, or the dynamics of Σ:

$$S^{t}_{t}\approx 0, \tag{104}$$

$$\kappa S^{r}_{r}\approx\left(\frac{f[\dot{a}]}{a}-\frac{[\dot{a}]}{a}\right), \tag{105}$$

$$\kappa S^{\theta}_{\theta}\approx\left(\frac{f[\dot{a}]}{a}-\frac{[\dot{a}]}{a}\right), \tag{106}$$

$$\kappa S^{\varphi}_{\varphi}\approx\left(\frac{f[\dot{a}]}{a}-\frac{[\dot{a}]}{a}\right). \tag{107}$$

Therefore the ''energy–momentum'' tensor of the singular hypersurface is

$$\kappa S_{\mu}^{\nu} = \mathrm{diag}\left(0, \frac{f[\dot{a}]}{a} - \frac{[\dot{a}]}{a}, \frac{f[\dot{a}]}{a} - \frac{[\dot{a}]}{a}, \frac{f[\dot{a}]}{a} - \frac{[\dot{a}]}{a}\right)$$
$$= \mathrm{diag}(0, 2[H_0](\tau - 1), 2[H_0](\tau - 1), 2[H_0](\tau - 1)), \tag{108}$$

where we have used (79). In this equation all quantities are to be taken at $t=0$, and H_0 is defined as

$$H_0 = \frac{\dot{a}}{a}\Big|_{t=0}, \tag{109}$$

which is the familiar Hubble constant at the signature change surface. This is our nontrivial and nonexpected result. One may question the validity of Coloumbeau algebra,[20] although it sounds physically well motivated and based on good physical intuition.[16,21,22] The above-given result is telling us that within this algebra it is not reasonable to assume that the energy–momentum tensor at the singular hypersurface of signature change is vanishing, as is usually assumed in the literature. If we assume that $[\dot{a}]=0$ (as is usually assumed in the literature) then Eq. (108) will give $S_{\mu}^{\nu}=0$, but this is not necessary in general. Therefore the condition $[\dot{a}]=0$ is not compulsory on the singular surface.

We have seen that the requirement of signature change leads to a very specific and nonvanishing form for the $S_{\mu\nu}$. Since the nonvanishing terms of $S_{\mu\nu}$ are related to the extrinsic curvature of the signature change surface, they tell us how it is embedded in the space–time. Therefore one should not be bothered about its matter interpretation. This form of the energy–momentum tensor of the singular hypersurface we have obtained set limits to the possible space–times emerging after signature change. As an example, we will consider in Sec. V C the possibility of the emergence of de Sitter space–time after signature change.

C. Junction conditions for de Sitter space–time

According to the Hartle–Hawking proposal,[23–25] the universe after signature change should be a de Sitter universe (inflationary phase). Let us assume that the space–time after signature change is a de Sitter one. Consider now the following de Sitter metric with appropriate lapse function $f(t)$ in order to contain signature change at $t=0$. The $t=$const sections of this metric are surfaces of constant curvature $k=1$:[26]

$$\mathrm{d}s^2 = -f(t)\mathrm{d}t^2 + a^2(t)(\mathrm{d}\chi^2 + \sin^2\chi(\mathrm{d}\,\theta^2 + \sin^2\theta\,\mathrm{d}\theta^2)) \tag{110}$$

where $f(t)$ is defined as in (77) and

$$a^2(t) = \alpha_+^2 \cosh^2(\alpha_+^{-1}t)\,\theta(t) + \alpha_-^2 \cos^2(\alpha_-^{-1}t)\,\theta(-t). \tag{111}$$

Since $[a]=0$ we will have $\alpha_+ = \alpha_- := R$. Now, the Euclidean sector can be interpreted as a S^4 with S^3 sections defined by $t=$const. The boundary of the Euclidean sector, defined by $t=0$, is an S^3 having the radius $R=\alpha_-=H_0^{-1}$ which is the maximum value of $\alpha_-\cos(\alpha_-^{-1}t)$. In the Lorentzian sector the cosmological constant is given by $\Lambda = 3\alpha_+^{-2} = 3H_0^2$.[26] The $t=$const surfaces are S^3 with radius $\alpha_+\cosh(\alpha_+^{-1}t)$ having the minimum value $R=\alpha_+=H_0^{-1}$.[23] Therefore, the following relation between the cosmological constant and the radius of the boundary is obtained:

$$\Lambda = \frac{3}{R^2}. \tag{112}$$

Following the same procedure as for the metric (75) and again using Colombeau's algebra, or simply using (108), we find for the elements of energy–momentum tensor of the hypersurface

$$\kappa S_{\mu}^{\nu} = \mathrm{diag}(0, \Pi, \Pi, \Pi), \tag{113}$$

where Π is defined as

$$\Pi=\left(\frac{2}{R}\tanh(R^{-1}t)-\frac{2}{R}\tan(R^{-1}t)\right)|_{(t=0)}(\tau-1)=0. \tag{114}$$

We therefore conclude that given the de Sitter metric in the form of (110) the energy–momentum tensor of the hypersurface of signature change defined by $t=0$ vanishes. This is a familiar result the previous authors usually assume from the beginning but we obtain it as a special case depending on the form of the metric of space–time.

It may be useful to look at the Darmois–Israel approach. There we have the following relation between the energy–momentum tensor of the singular hypersurface and the jump of the extrinsic curvature:

$$\kappa S_i^j=[K_i^j]-h_i^j[K], \tag{115}$$

where h_i^j is the three-metric of the singular hypersurface. The extrinsic curvature is defined as

$$K_{ij}=e_i^\mu e_j^\nu \nabla_\mu n_\nu, \tag{116}$$

where e_i, the mutually normal unit four-vectors in signature changing surface Φ, are defined as

$$e_i^\mu=\frac{\partial x^\mu}{\partial \xi^i}, \quad i=1,2,3. \tag{117}$$

ξ^i are coordinates adopted to the signature changing surface Σ and ∇_μ denotes the covariant derivative with respect to the four-geometry. We then find for the nonvanishing components of extrinsic curvature in Lorentzian sector [with $f(t)=+1$]

$$K_i^{+i}=-\frac{1}{\alpha_+}\tanh(\alpha_+^{-1}t), \quad i=1,2,3. \tag{118}$$

The corresponding components in the Euclidean sector are [with $f(t)=-1$]

$$K_i^{-i}=\frac{1}{\alpha_-}\tan(\alpha_-^{-1}t), \quad i=1,2,3. \tag{119}$$

Now we obtain for the jump of the extrinsic curvature on the signature change surface

$$[K_i^i]=(K_i^{+i}-K_i^{-i})|_{t=0}=\left(-\frac{1}{R}\tanh(R^{-1}t)-\frac{1}{R}\tan(R^{-1}t)\right)|_{t=0}=0, \quad i=1,2,3. \tag{120}$$

Within the Darmois–Israel approach to signature change it is used to assume that the energy–momentum tensor of the singular hypersurface vanishes. Therefore, given the above-mentioned result, the junction condition (115) is satisfied and it is concluded that the matching is possible. In contrast to this within the distributional approach, using Coloumbeau algebra, we obtain in general a nonvanishing expression for the energy–momentum tensor $S_{\mu\nu}$ and no explicit junction condition. The Einstein equations written for the whole manifold imply the junction conditions. Only in the special case of the metric (110) does the matching at $t=0$ lead to $S_{\mu\nu}=0$. One could require a matching along other sections corresponding to a nonmaximum radius of the Euclidean sector or a nonminimum radius of the Lorenzian sector. In this case the energy–momentum tensor of the singular surface may not be vanishing anymore, and has to be checked in each case.

VI. CONCLUSIONS

There are two different approaches for gluing manifolds in general relativity: the Darmois–Israel and distributional approaches. In this paper we have shown how these approaches can be used to find dynamics of hypersurfaces in general relativity and modern cosmology. We have discussed the extent to which these approaches are equivalent and it has been shown that lightlike hypersurfaces can be treated in the framework of distributional approach and there is a unified formalism for treating all kinds of hypersurfaces. Also it has been shown that theory of new generalized functions combined with distributional approach is a reasonable framework for treating signature changing manifolds. It is important to note that one of our main results is nonvanishing jump of extrinsic curvature in general signature changing hypersurfaces. This potentially contains interesting results about the nature of space–times emerging after signature change and theory of cosmological perturbations in signature changing space–times.[26] The other main result is the possibility of treating null hypersurfaces in the framework of distributional approach.

Boost–rotation symmetric vacuum space–times with spinning sources which correspond to gravitational field of uniformly accelerated spinning ''particles'' are studied. Regularity conditions and asymptotic properties are analyzed. News functions are derived by transforming the general spinning boost–rotation symmetric vacuum metric to Bondi–Sachs coordinates. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1433941]

I. INTRODUCTION AND SUMMARY

Boost–rotation symmetric space–times correspond to gravitational field of uniformly accelerated ''particles.'' Usually conical singularities, which provide the ''source'' of the acceleration, are also present on the axis of the axial symmetry.

Boost–rotation symmetric space–times have two Killing vectors (the axial ξ and the boost η Killing vectors) and it has been proven that they are the only axially symmetric space–times with an additional symmetry that are radiative and admit global null infinity.[1] This result was generalized for spinning sources, i.e., for nonhypersurface orthogonal Killing vectors, in Ref. 2. Moreover boost–rotation symmetric space–times are the only radiative asymptotically flat space–times known in an analytical form which represent moving sources. While there are several known boost–rotation symmetric solutions with nonrotating sources (see Refs. 3 and 4, and references therein), there is only one known exact solution with spinning sources—the spinning C-metric[5–8] corresponding to two uniformly accelerated Kerr black holes.

Thanks to the rotation of sources there appear torsion singularities besides conical singularities on the axis of the axial symmetry and consequently there can be regions with closed timelike curves (see Ref. 9, Refs. 6, 8 and 10 for examples, and Ref. 10 for references).

The structure of a boost–rotation symmetric space–time with hypersurface orthogonal Killing vectors was studied in Ref. 11 and the general form of its news function was found in Refs. 12, and 13. Recently, news functions for spinning boost–rotation symmetric Petrov-type D space–times were computed in late time approximation in Ref. 14.

The present paper, where some results by Bičák and Bičák and Schmidt from Refs. 11–13 are generalized, is organized as follows. In Sec. II spinning boost–rotation symmetric (brs) vacuum space–times in coordinates adapted to the boost and rotation symmetries and null coordinates are examined, e.g., regularity of the space–time on the roof and on the axis and asymptotic flatness at null infinity are studied. In Sec. III the spinning brs metric is transformed from the coordinates adapted to the boost and rotation symmetries to the Bondi–Sachs coordinates,[15–17] suitable for examining radiation, to find the news functions of spinning brs space–times.

II. SPINNING BOOST–ROTATION SYMMETRIC SPACE–TIMES: REGULARITY CONDITIONS, ASYMPTOTIC BEHAVIOR

The general form of a spinning brs metric in coordinates adapted to the boost and rotation symmetries $\{t,\rho,z,\varphi\}$ is[6]

[a]Electronic mail: pravdova@math.cas.cz
[b]Electronic mail: pravda@math.cas.cz

$$ds^2=-e^{\lambda}\,d\rho^2-\rho^2e^{-\mu}\,d\varphi^2+2ae^{\mu}(z\,dt-t\,dz)d\varphi+a^2e^{\mu}(z^2-t^2)d\varphi^2$$
$$-\frac{1}{z^2-t^2}[(e^{\lambda}z^2-e^{\mu}t^2)dz^2-2zt(e^{\lambda}-e^{\mu})dz\,dt-(e^{\mu}z^2-e^{\lambda}t^2)dt^2], \tag{1}$$

where μ, λ, and a are functions of

$$A=\rho^2, \quad B=z^2-t^2.$$

It has two Killing vectors

$$\xi=\frac{\partial}{\partial\varphi}, \quad \eta=t\frac{\partial}{\partial z}+z\frac{\partial}{\partial t} \tag{2}$$

with norms

$$\xi^{\alpha}\xi_{\alpha}=g_{\varphi\varphi}=-\rho^2e^{-\mu}+a^2(z^2-t^2)e^{\mu}=-Ae^{-\mu}+a^2Be^{\mu},$$

$$\eta^{\alpha}\eta_{\alpha}=g_{tt}z^2+g_{zz}t^2+2g_{zt}zt=Be^{\mu}.$$

As in the nonspinning case,[11] two null hyperplanes $B=0$, i.e., $z=\pm t$, will be called the "roof," the points with $A=0$ the "axis," the region of the space–time with $B<0$ "above the roof," and finally the region with $B>0$ "below the roof." Notice that the behavior of the boost and axial Killing vectors (2) is more complicated in the spinning case. Below the roof $(B>0)$, the boost Killing vector η is mostly timelike as in the nonspinning case but in the vicinity of spinning sources there may also occur ergoregions where it is spacelike. Due to the presence of spinning strings there may be also regions in their neighborhood with closed timelike curves where the axial Killing vector ξ is timelike. In order to determine if there exist both timelike and spacelike Killing vectors everywhere below the roof $(B>0)$, we study a general linear combination of the boost and the axial Killing vectors with constant coefficients $X=c_1\xi+c_2\eta$. Its norm may be both positive and negative if the product of eigenvalues of the quadratic form $({c_1}^2g_{\phi\phi}+\cdots)$ given by the norm is negative, i.e., if $-\rho^2B<0$, which is satisfied everywhere below the roof, where the space–time is thus stationary and may be transformed to the stationary Weyl metric (A1) (see, e.g., Ref. 6). However, above the roof $(B<0)$, the product is everywhere positive $-\rho^2B>0$ and thus there does not exist a timelike Killing vector and the space–time is nonstationary there. (It is easier to perform these calculations in coordinates $\{\gamma,\rho,\beta,\varphi\}$ and $\{b,\rho,\chi,\varphi\}$, given in Appendix A, for regions below and above the roof, respectively.)

Vacuum Einstein's equations for the spinning brs metric (1) are

$$A\mu_{,AA}+B\mu_{,BB}+\mu_{,A}+\mu_{,B}=-\frac{B}{A}e^{2\mu}(Aa_{,A}{}^2+Ba_{,B}{}^2), \tag{3}$$

$$0=AB(e^{2\mu}a_{,A})_{,A}+(B^2e^{2\mu}a_{,B})_{,B}, \tag{4}$$

$$(A+B)\lambda_{,A}=(A-B)\mu_{,A}-2B\mu_{,B}-B(B\mu_{,B}{}^2-A\mu_{,A}{}^2)+2AB\mu_{,A}\mu_{,B}$$
$$+\frac{B^2}{A}e^{2\mu}(Ba_{,B}{}^2-Aa_{,A}{}^2-2Aa_{,A}a_{,B}), \tag{5}$$

$$(A+B)\lambda_{,B}=(A-B)\mu_{,B}+2A\mu_{,A}+A(B\mu_{,B}{}^2-A\mu_{,A}{}^2)+2AB\mu_{,A}\mu_{,B}$$
$$-Be^{2\mu}(Ba_{,B}{}^2-Aa_{,A}{}^2+2Ba_{,A}a_{,B}). \tag{6}$$

Notice that Eqs. (3) and (4) are integrability conditions for Eqs. (5) and (6).

First let us investigate the regularity of the roof and the axis. From Eq. (5) it follows that on the roof (i.e., for $B=0$)

$$\lambda_{,A}(A,0)=\mu_{,A}(A,0) \quad \rightarrow \quad \lambda(A,0)-\mu(A,0)=K_1=\text{const.}$$

The roof is regular [i.e., g_{zz}, g_{tt}, and g_{tz} in (1) are nonsingular on the roof] if for $B=0$

$$\lambda(A,0)=\mu(A,0), \quad \text{i.e.,} \quad K_1=0. \tag{7}$$

From Eqs. (3), (5), and (6) on the axis ($A=0$) we get

$$a_{,B}(0,B)=0 \quad \rightarrow \quad a=\tilde{a}_0+\tilde{a}_1(B)A+\mathcal{O}(A^2), \quad \tilde{a}_0=\text{const},$$

$$\lambda_{,B}(0,B)+\mu_{,B}(0,B)=0 \quad \rightarrow \quad \lambda(0,B)+\mu(0,B)=K_2=\text{const.}$$

The axis regularity condition

$$\lim_{\rho_0\to 0}\frac{1}{2\pi}\frac{\int_0^{2\pi}\sqrt{g_{\varphi\varphi}|_{\rho_0}}\mathrm{d}\varphi}{\int_0^{\rho_0}\sqrt{g_{\rho\rho}}\mathrm{d}\rho}=1$$

[or equivalently g_{xx}, g_{yy} are nonsingular and $g_{xy}=0$ there, see (A5)] is satisfied if

$$a(0,B)=0 \quad \rightarrow \quad a=\tilde{a}_1(B)A+\mathcal{O}(A^2), \quad \text{i.e.,} \quad \tilde{a}_0=0, \tag{8}$$

$$\lambda(0,B)+\mu(0,B)=0, \quad \text{i.e.,} \quad K_2=0. \tag{9}$$

If $K_2\neq 0$ there is a conical singularity along the axis and if $\tilde{a}_0\neq 0$ a torsion singularity is present there. The regularity condition of the roof (7) is the same as for nonspinning brs space–times,[11] however, a new condition (8) arises for the regularity of the axis except for (9) which also appears in the nonspinning case.[11]

Now let us turn our attention to asymptotic behavior of spinning brs space–times at null infinity. For this purpose we transform (1) to null coordinates in two steps: first transforming it to coordinates $\{b,\rho,\chi,\varphi\}$ by (3.10) in Ref. 11

$$b=\sqrt{-B}=\sqrt{t^2-z^2}, \quad \tanh\chi=\pm\frac{z}{t}$$

we obtain the metric

$$\mathrm{d}s^2=e^{\lambda}(\mathrm{d}b^2-\mathrm{d}\rho^2)-\rho^2e^{-\mu}\,\mathrm{d}\varphi^2-b^2e^{\mu}(\mathrm{d}\chi+a\,\mathrm{d}\varphi)^2. \tag{10}$$

Finally transforming (10) to coordinates $\{\bar{u},\bar{v},\chi,\varphi\}$ by (3.15) in Ref. 11

$$\bar{u}=b-\rho, \quad \bar{v}=b+\rho$$

we obtain

$$\mathrm{d}s^2=e^{\lambda}\,\mathrm{d}\bar{u}\,\mathrm{d}\bar{v}-\frac{(\bar{v}-\bar{u})^2}{4}e^{-\mu}\,\mathrm{d}\varphi^2-\frac{(\bar{v}+\bar{u})^2}{4}e^{\mu}(\mathrm{d}\chi+a\,\mathrm{d}\varphi)^2. \tag{11}$$

Vacuum Einstein's equations for (11) read

$$
\begin{aligned}
&\mu_{,\bar{u}\bar{v}}+\frac{1}{\bar{v}^2-\bar{u}^2}(\bar{v}\mu_{,\bar{u}}-\bar{u}\mu_{,\bar{v}})=\left(\frac{\bar{v}+\bar{u}}{\bar{v}-\bar{u}}\right)^2 e^{2\mu}a_{,\bar{u}}a_{,\bar{v}},\\
&0=a_{,\bar{u}\bar{v}}+a_{,\bar{u}}\left(\mu_{,\bar{v}}+\frac{\bar{v}-2\bar{u}}{\bar{v}^2-\bar{u}^2}\right)+a_{,\bar{v}}\left(\mu_{,\bar{u}}+\frac{2\bar{v}-\bar{u}}{\bar{v}^2-\bar{u}^2}\right),\\
&-\bar{u}\lambda_{,\bar{u}}=\bar{v}\mu_{,\bar{u}}+\frac{\bar{v}^2-\bar{u}^2}{4}\mu_{,\bar{u}}^2+\frac{(\bar{v}+\bar{u})^3}{\bar{v}-\bar{u}}\frac{e^{2\mu}}{4}a_{,\bar{u}}^2,\\
&-\bar{v}\lambda_{,\bar{v}}=\bar{u}\mu_{,\bar{v}}-\frac{\bar{v}^2-\bar{u}^2}{4}\mu_{,\bar{v}}^2-\frac{(\bar{v}+\bar{u})^3}{\bar{v}-\bar{u}}\frac{e^{2\mu}}{4}a_{,\bar{v}}^2.
\end{aligned}
\tag{12}
$$

Assuming the metric functions μ, λ, and a to have expansions in $\bar{v}^{-1}$ for $\bar{v}\to\infty$ ($\mu(\bar{u},\bar{v})=\mu_0(\bar{u})+\mu_1(\bar{u})/\bar{v}+\cdots$) and solving Eqs. (12) at null infinity, i.e., for the limit $\bar{v}\to\infty$ and $\bar{u}$, χ, φ constant, we get

$$
\mu=\mu_0+\frac{\mu_1(\bar{u})}{\bar{v}}+\mathcal{O}(\bar{v}^{-2}),\quad \lambda=\lambda_0(\bar{u})+\frac{\lambda_1(\bar{u})}{\bar{v}}+\mathcal{O}(\bar{v}^{-2}),\quad a=a_0+\frac{a_1(\bar{u})}{\bar{v}}+\mathcal{O}(\bar{v}^{-2}),
\tag{13}
$$

where a_0 and μ_0 are constants and $\lambda_0(\bar{u})$ satisfies

$$
\lambda_{0,\bar{u}}=-\frac{1}{4\bar{u}}(4\mu_{1,\bar{u}}+\mu_{1,\bar{u}}^2+e^{2\mu_0}a_{1,\bar{u}}^2).
$$

The metric (11) with the metric functions (13) is asymptotically Minkowskian at null infinity as in the limit $\bar{v}\to\infty$ and $\bar{u}$, χ, φ constant, it can be transformed to the Minkowski metric using the transformations (3.23) and (3.24) in Ref. 11

$$
\bar{u}'=e^{(1/2)\mu_0}\int e^{\lambda_0(\bar{u})}\,\mathrm{d}\bar{u},\quad \bar{v}'=e^{-(1/2)\mu_0}\bar{v},\quad \chi'=e^{\mu_0}\chi
$$

and

$$
\chi''=\chi'+a_0e^{\mu_0}\varphi.
$$

III. THE BONDI–SACHS COORDINATES AND NEWS FUNCTIONS FOR SPINNING brs SPACE–TIMES

In this section we transform the spinning brs metric (1) into the Bondi–Sachs coordinates $\{u,r,\theta,\phi\}$, in which the metric that does not depend on ϕ because of the axial symmetry, has the form[15–17]

$$
\mathrm{d}s^2=g_{uu}\,\mathrm{d}u^2+2g_{ur}\,\mathrm{d}u\,\mathrm{d}r+2g_{u\theta}\,\mathrm{d}u\,\mathrm{d}\theta+2g_{u\phi}\,\mathrm{d}u\,\mathrm{d}\phi+g_{\theta\theta}\,\mathrm{d}\theta^2+g_{\phi\phi}\,\mathrm{d}\phi^2+2g_{\theta\phi}\,\mathrm{d}\theta\,\mathrm{d}\phi
\tag{14}
$$

with the following expansion for $r\to\infty$ and u, θ, and ϕ constant:

$$g_{uu}=1-\frac{2M}{r}+\mathcal{O}(r^{-2}),$$

$$g_{ur}=1-\frac{c^2+d^2}{2r^2}+\mathcal{O}(r^{-4}),$$

$$g_{u\theta}=-(c_{,\theta}+2c\cot\theta)+\mathcal{O}(r^{-1}),$$

$$g_{u\phi}=-(d_{,\theta}+2d\cot\theta)\sin\theta+\mathcal{O}(r^{-1}), \tag{15}$$

$$g_{\theta\theta}=-r^2-2cr-2(c^2+d^2)+\mathcal{O}(r^{-1}),$$

$$g_{\theta\phi}=-2dr\sin\theta+\mathcal{O}(r^0),$$

$$g_{\phi\phi}=-r^2\sin^2\theta+2cr\sin^2\theta-2(c^2+d^2)\sin^2\theta+\mathcal{O}(r^{-1}),$$

where c, d, and M are functions of u and θ. As a consequence of Einstein's equations, time dependence of the mass aspect M is determined by the news functions $c_{,u}$ and $d_{,u}$ (Refs. 16 and 17),

$$M_{,u}=-(c_{,u}{}^2+d_{,u}{}^2)+\tfrac{1}{2}(c_{,\theta\theta}+3c_{,\theta}\cot\theta-2c)_{,u}.$$

If there is nonvanishing news function, gravitational radiation is present and the total Bondi mass at future null infinity is decreasing.

In order to find the transformation of spinning brs space–times from the coordinates $\{t,\rho,z,\varphi\}$ with the metric (1) into the Bondi–Sachs coordinates $\{u,r,\theta,\phi\}$ with the metric (14) and its expansions (15) we follow Ref. 12 and we first transform the metric (1) to flat-space spherical coordinates $\{R,\Theta,\varphi\}$ and a flat-space retarded time U using the relations

$$t=U+R,\quad \rho=R\sin\Theta,\quad z=R\cos\Theta. \tag{16}$$

We assume the metric functions to have the expansions in powers R^{-1},

$$\lambda(U,\Theta)=\lambda_0(U,\Theta)+\frac{\lambda_1(U,\Theta)}{R}+\mathcal{O}(R^{-2}),$$

$$\mu(U,\Theta)=\mu_0+\frac{\mu_1(U,\Theta)}{R}+\mathcal{O}(R^{-2}), \tag{17}$$

$$a(U,\Theta)=a_0+\frac{a_1(U,\Theta)}{R}+\mathcal{O}(R^{-2}),$$

where μ_0 and a_0 are constants and thus

$$e^{\lambda}=\beta(U,\Theta)\left(1+\frac{\lambda_1(U,\Theta)}{R}+\mathcal{O}(R^{-2})\right),\quad e^{\mu}=\alpha\left(1+\frac{\mu_1(U,\Theta)}{R}+\mathcal{O}(R^{-2})\right) \tag{18}$$

with

$$\beta(U,\Theta)=e^{\lambda_0(U,\Theta)},\quad \alpha=e^{\mu_0}. \tag{19}$$

Now we transform the metric further to the Bondi–Sachs coordinates by an asymptotic transformation

$$
\begin{aligned}
U &= \overset{0}{\pi}(u,\theta) + \frac{\overset{1}{\pi}(u,\theta)}{r} + \frac{\overset{2}{\pi}(u,\theta)}{r^2} + \mathcal{O}(r^{-3}),\\
R &= q(u,\theta)r + \overset{0}{\sigma}(u,\theta) + \frac{\overset{1}{\sigma}(u,\theta)}{r} + \mathcal{O}(r^{-2}),\\
\Theta &= \overset{0}{\tau}(u,\theta) + \frac{\overset{1}{\tau}(u,\theta)}{r} + \frac{\overset{2}{\tau}(u,\theta)}{r^2} + \mathcal{O}(r^{-3}),\\
\varphi &= \phi + \overset{0}{f}(u,\theta) + \frac{\overset{1}{f}(u,\theta)}{r} + \frac{\overset{2}{f}(u,\theta)}{r^2} + \mathcal{O}(r^{-3}).
\end{aligned}
\tag{20}
$$

Comparing the resulting metric expansions with the expansions (15) we obtain differential equations for coefficients entering the asymptotic transformation (20). Since these equations are lengthy we present only their solutions in Appendix B. Their integrability condition [obtained comparing (B4) and (B5)] turns out to be the same as in the nonspinning case[12]

$$
\beta,_{\overset{0}{\pi}}\overset{0}{\pi} + \beta,_{\overset{0}{\tau}}\tan\overset{0}{\tau} = 0, \quad \text{or equivalently} \quad \lambda_{0,U}U + \lambda_{0,\Theta}\tan\Theta = 0,
$$

where the relations $\beta,_u = \beta,_{\overset{0}{\pi}}\overset{0}{\pi},_u$ and $\beta,_\theta = \beta,_{\overset{0}{\tau}}\overset{0}{\tau},_\theta + \beta,_{\overset{0}{\pi}}\overset{0}{\pi},_\theta$ have been used. Solving Eqs. (B1), (B2), (B3), and (B6) one may infer the first-order coefficients in the expansions (20),

$$
\overset{0}{\tau} = 2\arctan[e^{-\nu}(\tan\tfrac{1}{2}\theta)^K], \tag{21}
$$

$$
q = \frac{1}{\sqrt{K}}\sin\frac{1}{2}\theta\cos\frac{1}{2}\theta\left[e^{\nu}\left(\cot\frac{1}{2}\theta\right)^K + e^{-\nu}\left(\tan\frac{1}{2}\theta\right)^K\right], \tag{22}
$$

$$
\overset{0}{f} = \frac{a_0\alpha}{K}\ln\left(\frac{\sin\overset{0}{\tau}}{1+\cos\overset{0}{\tau}}\right), \tag{23}
$$

$$
\overset{0}{\pi},_u = \frac{1}{\beta q}, \tag{24}
$$

where $K \equiv (1+a_0^2\alpha^2)/\alpha$ and ν is an arbitrary constant. The axis (which is the same in both coordinates, i.e., $\Theta = 0$, $\pi \to \theta = 0$, π) is singular for $K \neq 1$ as q goes to 0 for $K<1$ and to ∞ for $K>1$ there. Since the coordinate system $\{t,\rho,z,\varphi\}$ can be chosen in such a way that $a_0 = 0$, we present here news functions for $a_0 = 0$ and the case $a_0 \neq 0$ is given in Appendix B. From Eqs. (B7) and (B8) we obtain the news functions

$$
c,_u = \frac{1}{2}\mu_1,_u - \frac{q,_\theta{}^2}{2q^2} - \frac{q,_\theta\cot\overset{0}{\tau}}{q^2\sqrt{\alpha}} + \frac{1}{2q^2\beta\sin^2\overset{0}{\tau}} - \frac{1}{2} - \frac{\cot^2\overset{0}{\tau}}{2q^2\alpha}, \tag{25}
$$

$$d_{,u} = -\tfrac{1}{2}\alpha a_{1,u}. \tag{26}$$

Having the news functions of the system one can then compute the Bondi mass (see Ref. 2).

For a special case $K=\alpha=1$, i.e., for a regular axis, we get from (21), (22), and (23)

$$\overset{0}{\tau} = 2\arctan(e^{-\nu}\tan\tfrac{1}{2}\theta), \quad q=\cosh\nu+\cos\theta\sinh\nu, \quad \overset{0}{f}=0. \tag{27}$$

Coordinate systems with different ν are connected by Lorentz transformations along the axis belonging to the Bondi–Metzner–Sachs group and thus as in Ref. 12 we may without loss of generality put $\nu=1$ which implies $q=1$ and $\overset{0}{\tau}=\theta$. Then the coefficient $\overset{0}{\tau}$ can be computed from the relation

$$\int e^{\lambda_0(\overset{0}{\pi},\theta)}\,\mathrm{d}\overset{0}{\pi} = u+\omega(\theta) \tag{28}$$

obtained from Eq. (24). The function $\omega(\theta)$ in (28) represents a supertranslation also belonging to the Bondi–Metzner–Sachs group and thus it may be again put equal to zero without loss of generality. Finally the news functions (25) and (26) read

$$c_{,u} = -\frac{1}{2\sin^2\theta}+\frac{1}{2\beta\sin^2\theta}+\frac{1}{2}\mu_{1,u} = \frac{1}{2\beta\sin^2\theta}(1-\beta+\mu_{1,u}\beta\sin^2\theta), \tag{29}$$

$$d_{,u} = -\tfrac{1}{2}a_{1,u}. \tag{30}$$

For $a_1=0$ (29) and (30) reduce to news functions as given in Refs. 12 and 13 for the nonrotating case.

ACKNOWLEDGMENTS

The authors are grateful to Professor J. Bičák for many inspiring discussions on boost–rotation symmetric space–times. They also thank University of Texas, Austin, for hospitality. V.P. was supported by Grant No. GACR-202/00/P030 and A.P. by Grant No. GACR-202/00/P031. The work was also partially supported by the National Science Foundation under the Grant No. NSF-Czech Rep. INT-9724783.

APPENDIX A: COORDINATE SYSTEMS ADAPTED TO THE BOOST AND ROTATION SYMMETRIES

In the nonradiative stationary region below the roof, a spinning brs metric can be transformed to the stationary Weyl coordinates $\{\overline{t},\overline{\rho},\overline{z},\overline{\varphi}\}$ with the Killing vectors $\xi=\partial_{\overline{\varphi}}$, $\eta=\partial_{\overline{t}}$, and the metric

$$\mathrm{d}s^2 = -e^{-2U}[e^{2\nu}(\mathrm{d}\overline{\rho}^2+\mathrm{d}\overline{z}^2)+\overline{\rho}^2\,\mathrm{d}\overline{\varphi}^2]+e^{2U}(\mathrm{d}\overline{t}+a\,\mathrm{d}\overline{\varphi})^2. \tag{A1}$$

Vacuum Einstein's equations have the form[18]

$$
\begin{aligned}
&U,_{\overline{\rho}\overline{\rho}}+U,_{\overline{z}\overline{z}}+\frac{U,_{\overline{\rho}}}{\overline{\rho}}=-\frac{e^{4U}}{2\overline{\rho}^2}(a,_{\overline{\rho}}^{\ 2}+a,_{\overline{z}}^{\ 2}),\\
&0=\left(e^{4U}\frac{a,_{\overline{\rho}}}{\overline{\rho}}\right),_{\overline{\rho}}+\left(e^{4U}\frac{a,_{\overline{z}}}{\overline{\rho}}\right),_{\overline{z}},\\
&\frac{\nu,_{\overline{\rho}}}{\overline{\rho}}=U,_{\overline{\rho}}^{\ 2}-U,_{\overline{z}}^{\ 2}-\frac{e^{4U}}{4\overline{\rho}^2}(a,_{\overline{\rho}}^{\ 2}-a,_{\overline{z}}^{\ 2}),\\
&\frac{\nu,_{\overline{z}}}{\overline{\rho}}=2U,_{\overline{\rho}}U,_{\overline{z}}-\frac{e^{4U}}{2\overline{\rho}^2}a,_{\overline{\rho}}a,_{\overline{z}}.
\end{aligned}
\tag{A2}
$$

Another appropriate coordinate system in the stationary region below the roof is $\{\gamma,\rho,\beta,\varphi\}$ with Killing vectors $\xi=\partial_\varphi$, $\eta=\partial_\gamma$ and the metric

$$
ds^2=-e^{\lambda}(d\rho^2+d\beta^2)-\rho^2e^{-\mu}\,d\varphi^2+\beta^2e^{\mu}(d\gamma+a\,d\varphi)^2, \tag{A3}
$$

connected with the stationary Weyl coordinates by [see (5.4) and (5.6) in Ref. 11]

$$
\overline{t}=\gamma,\quad \overline{\rho}=\rho\beta,\quad \overline{z}-\overline{z}_0=\frac{\beta^2-\rho^2}{2},\quad \overline{\varphi}=\varphi,\quad \overline{z}_0=\text{const},\quad e^{2U}=\beta^2e^{\mu},\quad e^{2\nu}=\frac{\beta^2}{\rho^2+\beta^2}e^{\mu+\lambda}.
$$

Vacuum Einstein's equations read

$$
\begin{aligned}
&\mu,_{\rho\rho}+\mu,_{\beta\beta}+\frac{\mu,_{\rho}}{\rho}+\frac{\mu,_{\beta}}{\beta}=-\frac{\beta^2}{\rho^2}e^{2\mu}(a,_{\rho}^{\ 2}+a,_{\beta}^{\ 2}),\\
&0=\left(\frac{\beta^3}{\rho}e^{2\mu}a,_{\rho}\right),_{\rho}+\left(\frac{\beta^3}{\rho}e^{2\mu}a,_{\beta}\right),_{\beta},\\
&(\rho^2+\beta^2)\lambda,_{\rho}=(\rho^2-\beta^2)\mu,_{\rho}-2\rho\beta\mu,_{\beta}-\tfrac{1}{2}\rho\beta^2(\mu,_{\beta}^{\ 2}-\mu,_{\rho}^{\ 2})+\rho^2\beta\mu,_{\rho}\mu,_{\beta}\\
&\qquad+\frac{\beta^4}{2\rho}e^{2\mu}\left(a,_{\beta}^{\ 2}-a,_{\rho}^{\ 2}-2\frac{\rho}{\beta}a,_{\rho}a,_{\beta}\right),\\
&(\rho^2+\beta^2)\lambda,_{\beta}=(\rho^2-\beta^2)\mu,_{\beta}+2\rho\beta\mu,_{\rho}+\tfrac{1}{2}\rho^2\beta(\mu,_{\beta}^{\ 2}-\mu,_{\rho}^{\ 2})+\rho\beta^2\mu,_{\rho}\mu,_{\beta}\\
&\qquad-\frac{1}{2}\beta^3e^{2\mu}\left(a,_{\beta}^{\ 2}-a,_{\rho}^{\ 2}+2\frac{\beta}{\rho}a,_{\rho}a,_{\beta}\right).
\end{aligned}
\tag{A4}
$$

The stationary region of a brs space–time, under the roof, is composed of two identical regions ($z>0$, $z>|t|$ and $z<0$, $z<-|t|$) and each of them can be transformed to coordinates $\{\overline{t},\overline{\rho},\overline{z},\overline{\varphi}\}$ or $\{\gamma,\rho,\beta,\varphi\}$.

By further transformation (3.5) in Ref. 11 to coordinates $\{t,\rho,z,\varphi\}$

$$
\tanh\gamma=\pm\frac{t}{z},\quad \beta=\sqrt{z^2-t^2},\quad B\equiv\beta^2,\quad A\equiv\rho^2,
$$

we arrive at the metric (1) where a nonstationary region above the roof (again composed of two identical regions) appears as in the nonspinning case.[11]

For examining regularity of the axis it is convenient to transform (1) to coordinates $\{t,x,y,z\}$, where $x=\rho\cos\varphi$, $y=\rho\sin\varphi$:

$$
\begin{aligned}
ds^2=&-\frac{1}{x^2+y^2}\Big[(e^{\lambda}x^2+e^{-\mu}y^2)dx^2+(e^{\lambda}y^2+e^{-\mu}x^2)dy^2+2xy(e^{\lambda}-e^{-\mu})dx\,dy\\
&-\frac{z^2-t^2}{x^2+y^2}a^2e^{\mu}(-y\,dx+x\,dy)^2-2ae^{\mu}(-yz\,dx\,dt+yt\,dx\,dz+xz\,dy\,dt-xt\,dy\,dz)\\
&-\frac{1}{z^2-t^2}[(e^{\lambda}z^2-e^{\mu}t^2)dz^2-2zt(e^{\lambda}-e^{\mu})dz\,dt-(e^{\mu}z^2-e^{\lambda}t^2)dt^2].
\end{aligned}
\tag{A5}
$$

Let us finally write down vacuum Einstein's equations for the metric (10) with the Killing vectors $\xi=\partial_{\varphi}$, $\eta=\partial_{\chi}$

$$
\begin{aligned}
&\mu_{,\rho\rho}-\mu_{,bb}+\frac{\mu_{,\rho}}{\rho}-\frac{\mu_{,b}}{b}=\frac{b^2}{\rho^2}e^{2\mu}({a_{,\rho}}^2-{a_{,b}}^2),\\
&0=\left(\frac{b^3}{\rho}e^{2\mu}a_{,\rho}\right)_{,\rho}-\left(\frac{b^3}{\rho}e^{2\mu}a_{,b}\right)_{,b},\\
&(\rho^2-b^2)\lambda_{,\rho}=(\rho^2+b^2)\mu_{,\rho}-2\rho b\mu_{,b}-\tfrac{1}{2}\rho b^2({\mu_{,b}}^2+{\mu_{,\rho}}^2)+\rho^2b\mu_{,\rho}\mu_{,b}\\
&\qquad+\frac{b^4}{2\rho}e^{2\mu}\left(-{a_{,b}}^2-{a_{,\rho}}^2+2\frac{\rho}{b}a_{,\rho}a_{,b}\right),\\
&(\rho^2-b^2)\lambda_{,b}=-(\rho^2+b^2)\mu_{,b}+2\rho b\mu_{,\rho}-\tfrac{1}{2}\rho^2b({\mu_{,b}}^2+{\mu_{,\rho}}^2)+\rho b^2\mu_{,\rho}\mu_{,b}\\
&\qquad+\frac{b^3}{2}e^{2\mu}\left(-{a_{,b}}^2-{a_{,\rho}}^2+2\frac{b}{\rho}a_{,\rho}a_{,b}\right).
\end{aligned}
\tag{A6}
$$

The coordinates $\{b,\rho,\chi,\varphi\}$ for the nonstationary region above the roof are analogical to coordinates $\{\gamma,\rho,\beta,\varphi\}$ (A3) in the stationary region below the roof.

As for (3)–(6), in each set of Einstein's equations (A2), (A4), and (A6), the first two are integrability conditions for the other two.

APPENDIX B: TRANSFORMATION OF THE SPINNING brs METRIC TO THE BONDI–SACHS COORDINATES

The spinning brs metric (1) with expansions (17)–(19) being transformed to the Bondi–Sachs coordinates with the metric (14) using transformations (16), (20) and compared with (15) leads to lengthy equations for coefficients of the asymptotic transformation (20) and metric functions from (15). We present here only their solutions:

$$
\begin{aligned}
&(g_{u\phi},r^2)=0 \quad \to \overset{0}{f}{}_{,u}=\overset{0}{\tau}{}_{,u}\frac{a_0\alpha}{K\sin\tau},\\
&(g_{uu},r^2)=0 \quad \to \overset{0}{\tau}{}_{,u}=0=\overset{0}{f}{}_{,u},\\
&(g_{uu},r^1)=0 \quad \to q_{,u}=0,\\
&(g_{\theta\phi},r^2)=0 \quad \to \overset{0}{f}{}_{,\theta}=\overset{0}{\tau}{}_{,\theta}\frac{a_0\alpha}{K\sin\tau},
\end{aligned}
\tag{B1}
$$

$$(g_{\theta\theta},r^2)=-1 \quad \to \overset{0}{\tau}{}_{,\theta}=\pm\frac{\sqrt{K}}{q} \quad \text{(we use the sign +)}, \tag{B2}$$

$$(g_{ur},r^0)=1 \quad \to \overset{0}{\pi}{}_{,u}=\frac{1}{\beta q}, \tag{B3}$$

$$(g_{r\phi},r^0)=0 \quad \to \overset{1}{f}=\frac{a_0\alpha}{q\sin^2\overset{0}{\tau}}\frac{\overset{1}{\tau}q\sin\overset{0}{\tau}+\overset{0}{\pi}\cos\overset{0}{\tau}}{K},$$

$$(g_{r\theta},r^0)=0 \quad \to \overset{1}{\tau}=-\frac{1}{\overset{0}{\tau}{}_{,\theta}q\sin\overset{0}{\tau}}[\overset{0}{\pi}{}_{,\theta}\beta K\sin\overset{0}{\tau}+\overset{0}{\pi}\overset{0}{\tau}{}_{,\theta}\cos\overset{0}{\tau}(1-\beta K)], \tag{B4}$$

$$(g_{r\phi},r^0)=0 \quad \to \overset{1}{f}=\frac{a_0\alpha\beta}{\overset{0}{q}\tau_{,\theta}\sin^2\overset{0}{\tau}}(\overset{0}{\pi}\overset{0}{\tau}{}_{,\theta}\cos\overset{0}{\tau}-\overset{0}{\pi}{}_{,\theta}\sin\overset{0}{\tau}),$$

$$(g_{u\theta},r^1)=0 \quad \to \overset{1}{\tau}{}_{,u}=\frac{1}{\overset{0}{\beta}q^3\overset{0}{\tau}{}_{,\theta}\sin\overset{0}{\tau}}[q_{,\theta}\beta K\sin\overset{0}{\tau}+\overset{0}{\tau}{}_{,\theta}q\cos\overset{0}{\tau}(-1+\beta K)], \tag{B5}$$

$$\begin{aligned}(g_{\theta\theta}g_{\phi\phi},r^3)=0 \quad \to \overset{0}{\sigma}=&\frac{1}{\overset{0}{2}\tau_{,\theta}^3\sin^2\overset{0}{\tau}}\{\overset{0}{\tau}{}_{,\theta}^3(1-2\sin^2\overset{0}{\tau})\overset{0}{\pi}(1-\beta K)+K\sin\overset{0}{\tau}[\beta\overset{0}{\pi}{}_{,\theta}(\overset{0}{\tau}{}_{,\theta}^2\cos\overset{0}{\tau}\\&-\overset{0}{\tau}{}_{,\theta\theta}\sin\overset{0}{\tau})+\overset{0}{\tau}{}_{,\theta}(\beta_{,\theta}(\overset{0}{\pi}{}_{,\theta}\sin\overset{0}{\tau}-\overset{0}{\pi}\overset{0}{\tau}{}_{,\theta}\cos\overset{0}{\tau})+\beta\overset{0}{\pi}{}_{,\theta\theta}\sin\overset{0}{\tau})]\},\end{aligned}$$

$$(g_{\phi\phi},r^2)=-\sin^2\theta \quad \to \sin\overset{0}{\tau}=\pm\frac{\sin\theta}{q\sqrt{K}}, \tag{B6}$$

$$\begin{aligned}&(g_{\phi\phi},r^1)=2c\sin^2\theta\\&\to c=-\frac{1}{2q\sin^2\overset{0}{\tau}(1+a_0^2\alpha^2)}[2\sin\overset{0}{\tau}(1+a_0^2\alpha^2)(\overset{0}{\sigma}\sin\overset{0}{\tau}+\overset{1}{\tau}q\cos\overset{0}{\tau})\\&\quad+\mu_1 q\sin^2\overset{0}{\tau}(-1+a_0^2\alpha^2)+2a_0\alpha^2(a_0\overset{0}{\pi}+a_1 q\sin^2\overset{0}{\tau})]\\&\to c_{,u}=-\frac{a_0\alpha}{K}a_{1,u}+\frac{1-a_0^2\alpha^2}{2(1+a_0^2\alpha^2)}\mu_{1,u}-\frac{q_{,\theta}^2}{2q^2}-\frac{q_{,\theta}\cot\overset{0}{\tau}\sqrt{K}}{q^2}\\&\quad+\frac{1-a_0^2\alpha^2}{2q^2\beta\sin^2\overset{0}{\tau}(1+a_0^2\alpha^2)}-\frac{1}{2}-\frac{K\cot^2\overset{0}{\tau}}{2q^2},\end{aligned} \tag{B7}$$

$$(g_{\theta\phi},r^1)=-2d\sin\theta \quad \rightarrow d=-\frac{1}{2qK\sin^2{}^0\tau}[(1-a_0^2\alpha^2)qa_1\sin^2{}^0\tau+2qa_0\mu_1\sin^2{}^0\tau+2a_0{}^0\pi]$$

$$\rightarrow d_{,u}=-\frac{a_0}{q^2K\beta\sin^2{}^0\tau}-\frac{a_0}{K}\mu_{1,u}-\frac{1-a_0^2\alpha^2}{2K}a_{1,u}. \tag{B8}$$

Equations $(g_{uu},r^0)=1$, $(g_{u\theta},r^2)=0$, $(g_{u\phi},r^1)=0$, $(g_{rr},r^{-1})=0$, $(g_{r\theta},r^1)=0$, $(g_{r\phi},r^1)=0$, and $(g_{\theta\theta},r^1)=-2c$ are satisfied identically.

The multiple sum formulas for 12*j* coefficients of SU(2) and $u_q(2)$

Sigitas Ališauskas
Institute of Theoretical Physics and Astronomy, A. Goštauto 12, Vilnius 2600, Lithuania

(Received 22 September 2000; accepted for publication 29 November 2001)

The expressions for $12j$ coefficients of the both kinds (without and with braiding) of the SU(2) group and the quantum algebra $u_q(2)$ are considered. Using Dougall's summation formula of the very well-poised hypergeometric ${}_5F_4(1)$ series and its q-generalization, several fourfold sum formulas [with each sum related to the balanced ${}_5F_4(1)$ or ${}_5\phi_4$ series] for the q-$12j$ coefficients of the second kind (without braiding) are derived. Applying q-generalizations of rearrangement formulas of the very well-poised hypergeometric ${}_6F_5(-1)$ series [which correspond to a new expression for the Clebsch–Gordan coefficients of SU(2) and $u_q(2)$], the new expressions with five sums [of the ${}_4F_3(1)$ and ${}_3F_2(1)$ or ${}_4\phi_3$ and ${}_3\phi_2$ type] are derived for the q-$12j$ coefficients of the first kind (with braiding) instead of the usual expansions in terms of q-$6j$ coefficients. Stretched and doubly stretched q-$12j$ coefficients [as triple, double, or single sums, related to composed or separate hypergeometric ${}_4F_3(1)$ and ${}_5F_4(1)$ or ${}_4\phi_3$ and ${}_5\phi_4$ series and, particularly, to q-$9j$ or q-$6j$ coefficients] are considered. © *2002 American Institute of Physics.*

I. INTRODUCTION AND PRELIMINARIES

The $3nj$ coefficients arise as the recoupling coefficients of several irreducible representations (irreps) of the SU(2) group and play the important role in the quantum mechanical angular momentum theory[1,2] and the Wigner–Racah irreducible tensor calculus, for construction of the complicated matrix elements of the coupled irreducible tensor operators. After the $6j$ (Racah) and $9j$ (Wigner) coefficients (with single and triple sums in expressions, respectively), the $12j$ coefficients of both kinds[1,2] also have many applications as the recoupling coefficients of the five irreps of the SU(2) group.

There are two known types of expressions for $9j$ coefficients: the usual expansion[1,2] of $9j$ coefficients in terms of $6j$ coefficients [including four sums, three in $6j$ coefficients and the last one weighted with factor $(2j+1)$] and the more compact formula, derived originally by Ališauskas and Jucys.[3] Different new expressions (of the second type, i.e., as a triple sum series) for the $9j$ coefficients of the SU(2) group and the quantum algebra $u_q(2)$ were derived recently,[4] generalizing the second Rosengren[5,6] approach to the $9j$ coefficients of the $\mathfrak{su}(1,1)$ algebra, when their expansion in terms of $6j$ coefficients was rearranged using Dougall's summation formula[7] of the very well-poised ${}_4F_3(-1)$ series.

For the quantum algebra $u_q(2)$, the expansion of the q-$9j$ coefficients in terms of q-$6j$ coefficients (Nomura[8–10] and Smirnov *et al.*[11]) was also extended to q-$3nj$ coefficients (particularly, those of the second and the first kinds) by Nomura,[9,10] who discussed their role in frames of the Yang–Baxter relations. The corresponding summation formula of the twisted q-factorial series (generalizing Dougall's summation formula and resembling the very well-poised basic hypergeometric ${}_5\phi_4$ series), depending on three parameters and used in our previous paper,[4] was derived by Ališauskas,[12] when the twisted very well-poised q-factorial series, resembling the basic hypergeometric ${}_7\phi_6$ series (depending on five parameters) appear in a new approach[13] to the Clebsch–Gordan (CG) coefficients of $u_q(2)$. In the $u_q(3)$ context, Ališauskas[12] also used the summation formula of the q-factorial series depending on four parameters which correspond to Dougall's summation formula of the very well-poised hypergeometric ${}_5F_4(1)$ or basic hypergeometric ${}_6\phi_5$ series.[7,14]

The main purpose of the present article is to rearrange expressions for the q-12j and the usual 12j coefficients of both kinds into more convenient forms, with minimal number of sums, or at least without the cumbersome factorial sums weighted with factors $[2j+1]$ or $(2j+1)$, which appear from the compositions of the q-6j or usual 6j coefficients expanded in different forms. We also consider the stretched and doubly stretched 12j and q-12j coefficients, representative for the new types of the higher single and multiple (ordinary and basic) hypergeometric series.

Further in this section, the appropriate expressions for the 6j coefficients of SU(2) and $u_q(2)$ are discussed, which allow one to generalize Rosengren's[6,4] approach. Section II is devoted to rearrangement of the usual expansion formula (in terms of 6j and q-6j coefficients) of 12j and q-12j coefficients of the second kind[1,2,10] (i.e., without braiding[9]) into the fourfold sums, using Dougall's summation formula[7,14] of the very well-poised ${}_5F_4(1)$ and ${}_6\phi_5$ series, depending on four parameters (see Appendix A, where usable Saalschützian and Minton's summation formulas are also presented). Also, specific stretched and doubly stretched 12j and q-12j coefficients of the second kind are studied. As a rule, we present explicitly only those doubly stretched q-12j coefficients, which cannot be derived simply by inserting some fixed values of summation parameters.

In Sec. III, expressions of 12j and q-12j coefficients of the first kind[1,2] (with braiding[10]) in terms of q-6j coefficients are rearranged using the transformation formula[12] of the very well-poised ${}_6F_5(-1)$ series or q-factorial sums (depending on five parameters and weighted with factors $(2j+1)$ or $[2j+1]$), resembling the very well-poised basic hypergeometric ${}_7\phi_6$ series and related to a new expression for the Clebsch–Gordan coefficients of SU(2) and $u_q(2)$ (see Appendix B). Diversity of the stretched and doubly stretched 12j and q-12j coefficients of the first kind are also considered, including the explicit doubly stretched q-12j coefficients, which are proportional to some q-9j and q-6j coefficients.

Here and in what follows $[x]$ and $[x]!$ are, respectively, q-numbers and q-factorials,

$$[x]=(q^x-q^{-x})/(q-q^{-1}),\quad [x]!=[x][x-1]\cdots[2][1],\quad [1]!=[0]!=1, \tag{1.1}$$

which are invariant under substitution $q\to q^{-1}$ and turn into usual integers x and factorials $x!$ for $q=1$.

Only those expressions (see Sec. II of Ref. 4) for the 6j (Racah) coefficients[2,15–17] of SU(2) and $u_q(2)$ are appropriate for our purpose, that include asymmetric triangle coefficients,

$$\nabla[abc]=\left(\frac{[a+b-c]![a-b+c]![a+b+c+1]!}{[b+c-a]!}\right)^{1/2}, \tag{1.2}$$

before the q-factorial sum. They are given by

$$\begin{Bmatrix} a & b & e \\ d & c & f \end{Bmatrix}_q=\frac{\nabla[acf]\nabla[dbf]}{\nabla[abe]\nabla[dce]}\sum_z \frac{(-1)^{a+b+c+d+z}[c+f-a+z]!}{[z]![a+c-f-z]![b+d-f-z]!}$$
$$\times\frac{[b+f-d+z]![a+d+e-f-z]!}{[e+f-a-d+z]![2f+z+1]!} \tag{1.3a}$$

$$=\frac{\nabla[eab]\nabla[fbd]}{\nabla[ecd]\nabla[fac]}\sum_z \frac{(-1)^{b+c+e+f+z}[2b-z]!}{[z]![b+e-a-z]![b+f-d-z]!}$$
$$\times\frac{[b+e+f-c-z]![b+c+e+f-z+1]!}{[a+b+e-z+1]![b+d+f-z+1]!}, \tag{1.3b}$$

where each parameter $b,c,e,$ or [after some shift of summation parameter, see (2.1b) of Ref. 4] f appears only twice in the factorial arguments under the summation sign in (1.3a), as well as each parameter $a,c,d,$ or [after inversion of summation parameter, see (2.2b) of Ref. 4] b under the summation sign in (1.3b). Hence, the very well-poised series may appear only when the j-type

summation parameters (weighted with factors $[2j+1]$) accept the corresponding position in expansions in terms of q-6j coefficients. Otherwise, the most symmetric (Racah) and the remaining expressions for 6j and q-6j coefficients[1,2,15,16] (which include only usual symmetric triangle coefficients $\Delta[abc]$ in the numerator and denominator before the summation sign, with each parameter appearing four times in the factorial arguments under the summation sign) for this purpose are useless.

It should also be noted that only the expressions presented above (1.3a) and (1.3b) are correlated with the Racah polynomials as introduced by Askey and Wilson,[18,19] (see Ref. 14). In contrast, the most symmetric and the remaining expressions for 6j and q-6j coefficients turn into the Racah polynomials only after some Whipple[20] (Bailey[21]) or Sears[22] transform[14] of the balanced hypergeometric ${}_4F_3(1)$ or ${}_4\phi_3$ series are used.

II. EXPRESSIONS FOR 12j COEFFICIENTS OF THE SECOND KIND OF SU(2) AND $U_q(2)$

A. Generic properties

The 3nj coefficients of the second kind[1,23] ($n\geqslant 4$), whose graphs are planar [hence without braiding,[9,10] in contrast with the 3nj coefficients of the first kind ($n\geqslant 3$), whose graphs are possible only on the Möbius strip] usually are expanded[1,2] in terms of factorized n different 6j coefficients,

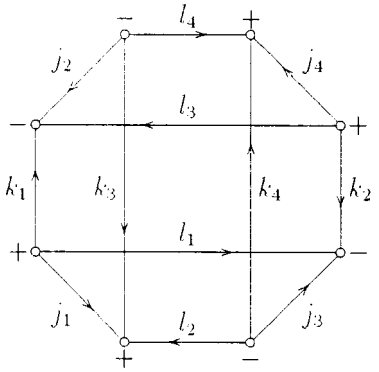
$$\begin{bmatrix} j_1 & & j_2 & & \cdots & & j_n & \\ & l_1 & & l_2 & & \cdots & & l_n \\ k_1 & & k_2 & & \cdots & & k_n & \end{bmatrix} = \sum_x (2x+1)(-1)^{R_n+nx} \begin{Bmatrix} j_1 & k_1 & x \\ k_2 & j_2 & l_1 \end{Bmatrix} \times \begin{Bmatrix} j_2 & k_2 & x \\ k_3 & j_3 & l_2 \end{Bmatrix} \cdots \begin{Bmatrix} j_{n-1} & k_{n-1} & x \\ k_n & j_n & l_{n-1} \end{Bmatrix} \begin{Bmatrix} j_n & k_n & x \\ k_1 & j_1 & l_n \end{Bmatrix}, \tag{2.1}$$

where

$$R_n = \sum_{i=1}^{n} (j_i + k_i + l_i),$$

and the triangular conditions are satisfied by the triplets of the nearest neighbors as l_i, j_i, j_{i+1}, or l_i, k_i, k_{i+1} ($i=1,2,\ldots,n-1$), or l_n, j_n, j_1, or l_i, k_n, k_1, respectively.

The 12j coefficients of the second kind, which may be extracted from the recoupling coefficients of the five irreps without braiding,[9] hence, with the cubic graph[1]



(2.2)

were introduced by Elliott and Flowers[24] and redefined by Vanagas and Čiplys.[25] These $12j$ coefficients and their q-generalizations satisfy 24 symmetries,[1,2,25] generated by the following substitutions:

$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \end{bmatrix}_q = (-1)^{j_1-j_2-j_3+j_4+k_1-k_2-k_3+k_4} \begin{bmatrix} j_1 & & k_1 & & j_2 & & k_3 & \\ & l_1 & & l_3 & & l_4 & & l_2 \\ j_3 & & k_2 & & j_4 & & k_4 & \end{bmatrix}_q \tag{2.3a}$$

$$= \begin{bmatrix} j_4 & j_3 & j_2 & j_1 \\ l_4 & l_3 & l_2 & l_1 \\ k_4 & k_3 & k_2 & k_1 \end{bmatrix}_q = \begin{bmatrix} l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \\ j_1 & j_2 & j_3 & j_4 \end{bmatrix}_q \tag{2.3b}$$

$$= \begin{bmatrix} k_4 & k_2 & k_3 & k_1 \\ l_4 & l_2 & l_3 & l_1 \\ j_4 & j_2 & j_3 & j_1 \end{bmatrix}_q = \begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_2 & l_1 & l_4 & l_3 \\ k_3 & k_4 & k_1 & k_2 \end{bmatrix}_q . \tag{2.3c}$$

Eight triangular conditions may be visualized[2] by means of the extended array

$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \end{bmatrix}$$
$$\begin{matrix} & j_2 & j_3 & \\ & l_2 & l_3 & \end{matrix}$$

and are satisfied by the triplets of parameters in the first and fourth columns, as well as by the skew triplets descending from some parameter of the first or fourth column, e.g., by l_1, k_2, j_3, or by j_4, l_3, k_2.

We restrict ourselves to the following rearrangements of the q-$6j$ coefficients in expressions[1,2,10] for the q-$12j$ coefficients of the second kind:

$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \end{bmatrix}_q = (-1)^{l_1-l_2-l_3+l_4} \sum_x [2x+1] \begin{Bmatrix} k_1 & j_1 & l_1 \\ j_3 & k_2 & x \end{Bmatrix}_q \times \begin{Bmatrix} k_3 & k_4 & x \\ j_3 & j_1 & l_2 \end{Bmatrix}_q \begin{Bmatrix} k_3 & j_2 & l_4 \\ j_4 & k_4 & x \end{Bmatrix}_q \begin{Bmatrix} k_1 & k_2 & x \\ j_4 & j_2 & l_3 \end{Bmatrix}_q \tag{2.4a}$$

$$= (-1)^{l_1-l_2-l_3+l_4} \sum_x [2x+1] \begin{Bmatrix} k_1 & j_1 & l_1 \\ j_3 & k_2 & x \end{Bmatrix}_q \times \begin{Bmatrix} j_3 & x & j_1 \\ k_3 & l_2 & k_4 \end{Bmatrix}_q \begin{Bmatrix} k_3 & k_4 & x \\ j_4 & j_2 & l_4 \end{Bmatrix}_q \begin{Bmatrix} k_1 & x & k_2 \\ j_4 & l_3 & j_2 \end{Bmatrix}_q \tag{2.4b}$$

$$=(-1)^{l_1-l_2-l_3+l_4}\sum_x [2x+1])\begin{Bmatrix} k_1 & j_1 & l_1 \\ j_3 & k_2 & x \end{Bmatrix}_q$$
$$\times\begin{Bmatrix} k_3 & k_4 & x \\ j_3 & j_1 & l_2 \end{Bmatrix}_q\begin{Bmatrix} j_4 & x & j_2 \\ k_3 & l_4 & k_4 \end{Bmatrix}_q\begin{Bmatrix} k_1 & x & k_2 \\ j_4 & l_3 & j_2 \end{Bmatrix}_q \tag{2.4c}$$

$$=(-1)^{l_1-l_2-l_3+l_4}\sum_x [2x+1]\begin{Bmatrix} j_3 & x & j_1 \\ k_1 & l_1 & k_2 \end{Bmatrix}_q$$
$$\times\begin{Bmatrix} k_3 & x & k_4 \\ j_3 & l_2 & j_1 \end{Bmatrix}_q\begin{Bmatrix} j_4 & x & j_2 \\ k_3 & l_4 & k_4 \end{Bmatrix}_q\begin{Bmatrix} l_3 & j_2 & k_1 \\ x & k_2 & j_4 \end{Bmatrix}_q^{(\prime)}. \tag{2.4d}$$

This allows us to cancel the differently distributed asymmetric triangle coefficients depending on the summation parameter x, when all the q-6j coefficients are expressed by means of (1.3a), with exception of the last (primed) q-6j coefficient in (2.4d), in which case (1.3b) should be used. In particular, using expression (1.3a) with shifted summation parameter [see (2.1b) of Ref. 4] for the q-6j coefficients with summation parameter x in the right lower position, then Eq. (1.3a) with inverted summation parameter for the q-6j coefficients with x in the middle column, followed by Eq. (1.3a) in the remaining cases [with exception of the last one in (2.4d)], the summation intervals are ensured, and we may use the summation formula (A1a) for expansion (2.4a) and formula (A1b) (see Ref. 12) for expansions (2.4b)–(2.4d). Again (cf. the rearrangement[4] of expressions for q-6j coefficients) the formal summation intervals may exceed the interval determined by triangular conditions, and we need to consider each case separately. For example, when $\min(j_2+j_4,k_3+k_4)<x\leqslant\min(j_1+j_3,k_1+k_2)$, or $\max(j_1-j_3,k_2-k_1)>x\geqslant\max(|j_2-j_4|,|k_3-k_4|,j_3-j_1,k_1-k_2)$, the definite sum of the type (1.3a) (from two depending on the parameters in the left-hand side of the corresponding inequality) in expansion of (2.4b) turns into 0, in accordance with the q-version[14] of Karlsson's summation formula[26] as presented by Eq. (2.13) of Ref. 4.

B. General expressions with fourfold sums

By carrying out the steps outlined above, we derive four different expressions for the q-12j coefficients of the second kind:

$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \end{bmatrix}_q$$
$$=(-1)^{l_2-l_3+k_1-k_3-j_3+j_4}\frac{\nabla[k_3j_1l_2]\nabla[j_3k_4l_2]\nabla[k_1j_2l_3]\nabla[j_4k_2l_3]}{\nabla[k_1j_1l_1]\nabla[j_3k_2l_1]\nabla[k_3j_2l_4]\nabla[j_4k_4l_4]}$$
$$\times\sum_{z_1,z_2,z_3,z_4}\frac{(-1)^{z_1+z_2+z_3+z_4}[k_2+j_3-l_1+z_1]![k_1+j_1-l_1+z_1]!}{[z_1]![z_2]![z_3]![z_4]![l_1+k_2-j_3-z_1]![j_1+l_1-k_1-z_1]!}$$
$$\times\frac{[2l_1-z_1]![j_1+l_2-k_3+z_2]![l_2-j_3+k_4+z_2]!}{[j_1-l_2+k_3-z_2]![j_3+k_4-l_2-z_2]![2l_2+z_2+1]!}$$
$$\times\frac{[j_4+k_4-l_4+z_3]![j_2+k_3-l_4+z_3]![2l_4-z_3]!}{[k_4+l_4-j_4-z_3]![j_2-k_3+l_4-z_3]![k_1+j_2-l_3-z_4]![2l_3+z_4+1]!}$$
$$\times\frac{[j_2+l_3-k_1+z_4]![k_2+l_3-j_4+z_4]!}{[k_2-l_3+j_4-z_4]![k_1+k_3+j_3+j_4-l_1-l_4+z_1+z_3+1]!}$$

$$\times\frac{[k_1+k_3+j_3+j_4-l_2-l_3-z_2-z_4]!}{[k_1+l_2-l_1-k_3+z_1+z_2]![l_3-l_1+j_3-j_4+z_1+z_4]!}$$

$$\times\frac{[l_2+l_3-l_1-l_4+z_1+z_2+z_3+z_4]!}{[l_2-l_4-j_3+j_4+z_2+z_3]![k_3-k_1+l_3-l_4+z_3+z_4]!} \tag{2.5a}$$

$$=(-1)^{j_1-j_3-k_1+k_2-l_1-l_2-l_3+l_4}\frac{\nabla[j_3k_4l_2]\nabla[k_3j_2l_4]\nabla[k_1j_2l_3]\nabla[j_4k_4l_4]}{\nabla[k_1j_1l_1]\nabla[j_3k_2l_1]\nabla[k_3j_1l_2]\nabla[j_4k_2l_3]}$$

$$\times\sum_{z_1,z_2,z_3,z_4}\frac{(-1)^{z_2+z_3+z_4}[k_2+j_3-l_1+z_1]![k_1+j_1-l_1+z_1]!}{[z_1]![z_2]![z_3]![z_4]![l_1+k_2-j_3-z_1]![j_1+l_1-k_1-z_1]!}$$

$$\times\frac{[2l_1-z_1]![2l_2-z_2]![j_1-l_2+k_3+z_2]!}{[l_2+j_3-k_4-z_2]![j_1+l_2-k_3-z_2]![l_2+j_3+k_4-z_2+1]!}$$

$$\times\frac{[j_2-k_3+l_4+z_3]![k_4+l_4-j_4+z_3]!}{[j_4+k_4-l_4-z_3]![j_2+k_3-l_4-z_3]![2l_4+z_3+1]![k_1-j_2+l_3-z_4]!}$$

$$\times\frac{[2l_3-z_4]![k_2-l_3+j_4+z_4]!}{[k_2+l_3-j_4-z_4]![k_1+j_2+l_3-z_4+1]![k_1+k_3-l_1-l_2+z_1+z_2]!}$$

$$\times\frac{[j_3+j_4+l_2-l_4-z_2-z_3]![k_1+k_3+l_3-l_4-z_3-z_4]!}{[k_1-k_3+j_3-j_4-l_1+l_4+z_1+z_3]![j_3+j_4-l_1-l_3+z_1+z_4]!}$$

$$\times\frac{[j_3-j_4+k_1-k_3+l_2+l_3-z_2-z_4]!}{[l_1+l_2+l_3-l_4-z_1-z_2-z_3-z_4]!} \tag{2.5b}$$

$$=(-1)^{k_1-k_2+l_1-l_2+l_3+l_4-j_2+j_4}\frac{\nabla[k_3j_1l_2]\nabla[j_3k_4l_2]\nabla[j_4k_4l_4]\nabla[k_1j_2l_3]}{\nabla[k_1j_1l_1]\nabla[j_3k_2l_1]\nabla[k_3j_2l_4]\nabla[j_4k_2l_3]}$$

$$\times\sum_{z_1,z_2,z_3,z_4}\frac{(-1)^{z_2+z_3+z_4}[j_3+k_2-l_1+z_1]![j_1+k_1-l_1+z_1]!}{[z_1]![z_2]![z_3]![z_4]![l_1+k_2-j_3-z_1]![j_1-k_1+l_1-z_1]!}$$

$$\times\frac{[2l_1-z_1]![j_1+l_2-k_3+z_2]![l_2-j_3+k_4+z_2]!}{[j_1-l_2+k_3-z_2]![j_3+k_4-l_2-z_2]![2l_2+z_2+1]![j_4-k_4+l_4-z_3]!}$$

$$\times\frac{[2l_4-z_3]![j_2-l_4+k_3+z_3]!}{[j_2-k_3+l_4-z_3]![j_4+k_4+l_4-z_3+1]![k_1-j_2+l_3-z_4]!}$$

$$\times\frac{[2l_3-z_4]![k_2-l_3+j_4+z_4]!}{[k_2+l_3-j_4-z_4]![k_1+j_2+l_3-z_4+1]![k_1-k_3-l_1+l_2+z_1+z_2]!}$$

$$\times\frac{[j_3+j_4-l_2+l_4-z_2-z_3]![j_3-j_4+k_1+k_3-l_2+l_3-z_2-z_4]!}{[j_3-j_4+k_1+k_3-l_1-l_4+z_1+z_3]![j_3+j_4-l_1-l_3+z_1+z_4]!}$$

$$\times\frac{[k_1-k_3+l_3+l_4-z_3-z_4]!}{[l_1-l_2+l_3+l_4-z_1-z_2-z_3-z_4]!} \tag{2.5c}$$

$$=(-1)^{k_3+k_4-l_1+l_2+l_3-l_4-j_1-j_3}\frac{\nabla[j_3k_2l_1]\nabla[k_3j_1l_2]\nabla[j_4k_4l_4]\nabla[k_1j_2l_3]}{\nabla[k_1j_1l_1]\nabla[j_3k_4l_2]\nabla[k_3j_2l_4]\nabla[j_4k_2l_3]}$$

$$\times\sum_{z_1,z_2,z_3,z_4}\frac{(-1)^{z_1+z_2+z_3}[2l_1-z_1]![j_1+k_1-l_1+z_1]!}{[z_1]![l_1-k_2+j_3-z_1]![j_1-k_1+l_1-z_1]![l_1+k_2+j_3-z_1+1]!}$$

$$\times\frac{[2l_2-z_2]![k_4+j_3-l_2+z_2]!}{[z_2]![k_3+l_2-j_1-z_2]![l_2-j_3+k_4-z_2]![j_1+l_2+k_3-z_2+1]!}$$

$$\times\frac{[2l_4-z_3]![j_2+k_3-l_4+z_3]!}{[z_3]![z_4]![j_4+l_4-k_4-z_3]![j_2-k_3+l_4-z_3]![j_4+k_4+l_4-z_3+1]!}$$
$$\times\frac{[2j_2-z_4]![j_2+j_4+k_1-k_2-z_4]![j_2+j_4+k_1+k_2-z_4+1]!}{[k_1+j_2-l_3-z_4]![k_1+j_2+l_3-z_4+1]![j_2+k_3-l_4+z_3-z_4]!}$$
$$\times\frac{[l_1+l_2-k_1+k_3-z_1-z_2]![j_3+j_4-k_3-k_1+l_1+l_4-z_1-z_3]!}{[j_2-j_3+j_4+k_1-l_1+z_1-z_4]![j_2+j_3+j_4-k_3-l_2+z_2-z_4]!}$$
$$\times\frac{[l_2+l_4-j_3+j_4-z_2-z_3]!}{[l_1+l_2+l_4-k_1-j_2-z_1-z_2-z_3+z_4]!}. \tag{2.5d}$$

The numerator–denominator distribution of factorials, depending on the summation parameters z_1,z_2,z_3,z_4, is different in each expression (2.5a)–(2.5d). No single formula exhibites the full symmetry (2.3b)–(2.3c) of the q-12j-symbol, but (2.5a) is invariant with respect to the transition from the main notation to the left array of (2.3c), as well as under transposition

$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \end{bmatrix}_q = \begin{bmatrix} k_2 & k_4 & k_1 & k_3 \\ l_1 & l_3 & l_2 & l_4 \\ j_3 & j_1 & j_4 & j_2 \end{bmatrix}_q, \tag{2.6}$$

which, in turn, is a composition of symmetry relations (2.3b)–(2.3c). Expression (2.5b) is invariant with respect to the same symmetry (2.6), but (2.5c) and (2.5d) do not satisfy any symmetry relations. Since all the sums in these expressions correspond to the balanced hypergeometric functions, the q-phases are also trivial.[9]

All the terms in the first sum of (2.5b) and (2.5c) are of the same sign, as well as in the last sum of (2.5d). Each separate sum corresponds in these expressions to the finite balanced basic hypergeometric series ${}_5F_4[q,1]$ as defined by Eq. (3.2) of Ref. 4, which also appeared in the elementary overlap coefficients of the definite biorthogonal coupled states[12] of $u_q(3)$ and SU(3). The summation intervals are mainly restricted by eight [in (2.5a)–(2.5c)], or seven [in (2.5d)] triangle linear combinations of parameters, respectively. In addition to the correspondence of numerator and denominator factorials, determined by Eq. (A1a) or (A1b), definite correlation between the factorials under summation signs reveals itself in four quintuplets of factorials of each expression (2.5a)–(2.5d), depending on the couples of adjacent summation parameters (z_i and z_{i+1}, where $i=1,2,3$, or z_1 and z_4), although their expansion using the Chu–Vandermonde formulas (cf. Sec. IV of Ref. 4) is not helpful for further rearrangement of the generic expressions.

C. Stretched cases of the q-12j coefficients of the second kind

Let us consider the stretched cases of q-12j coefficients. For definite stretched triangles some summation parameters in (2.5a)–(2.5d) are either fixed (31 times), or expressions are partially summable (in the 11 cases) by means of Minton's summation formulas (A3a) or (A3b) (see Ref. 14). One of three remaining sums turns into the balanced basic hypergeometric series ${}_4F_3[q,1]$, the rearrangement[14] of which enables us to transform a ${}_5F_4[q,1]$ type series into a ${}_4F_3[q,1]$ type series, with only the last one remaining of the ${}_5F_4[q,1]$ type. Particularly, for $j_1+l_1=k_1$ with $z_1=0$, the sum over z_2 in expression (2.5a) corresponds to a q-6j coefficient, which may be reexpressed in such a form (using Regge symmetry and change of the summation parameter) that the sum over z_3 also corresponds to a q-6j coefficient. Hence, we obtain

$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_4 \\ j_1+l_1 & k_2 & k_3 & k_4 \end{bmatrix}_q$$
$$= \frac{(-1)^{j_1+l_2-k_3}\nabla[k_1 j_2 l_3]\nabla[j_4 k_2 l_3]}{\nabla[j_1 l_2 k_3]\nabla[k_4 j_3 l_2]\nabla[k_3 j_2 l_4]\nabla[j_4 k_4 l_4]\nabla[l_1 k_2 j_3]}\left(\frac{[2l_1]![2j_1]!}{[2k_1+1]!}\right)^{1/2}$$
$$\times \sum_{z_1,z_3,z_4} \frac{(-1)^{z_1+z_3}[l_2-j_3+k_4+z_1]![j_1+j_3+k_3-k_4-z_1]!}{[z_1]![z_3]![z_4]![l_2+j_3-k_4-z_1]![j_3-j_4-l_1+l_3+z_4-z_1]!}$$
$$\times \frac{[2j_3-z_1]![j_4+k_4-l_4+z_3]![j_2+k_3-l_4+z_3]![2l_4-z_3]!}{[j_2-k_3+l_4-z_3]![k_3+j_1+j_3+j_4-l_4-z_1+z_3+1]!}$$
$$\times \frac{[j_2+l_3-k_1+z_4]![k_2+l_3-j_4+z_4]!}{[k_4+l_1-l_3+l_4-j_3+z_1-z_3-z_4]![k_3-k_1+l_3-l_4+z_3+z_4]!}$$
$$\times \frac{[k_1+k_3+k_4+j_4-l_3-z_4+1]!}{[k_1+j_2-l_3-z_4]![k_2-l_3+j_4-z_4]![2l_3+z_4+1]!}, \tag{2.7}$$

which is the composition of two balanced ${}_4F_3[q,1]$ series and the third balanced ${}_5F_4[q,1]$ series.

After the summation over z_3 of the balanced ${}_3F_2[q,1]$ series is carried out [see Eqs. (A2a) and (A2b)] in this doubly stretched case of q-12j coefficient with $k_1=j_1+l_1$ and $l_3=k_1+j_2$ [i.e., for adjacent consecutive stretched triangles in graph (2.2)], we recognize some q-6j coefficients, which may also be obtained using the symmetries (2.3b)–(2.3c) and the defining relations (2.4a)–(2.4d) of the q-12j coefficients. In this way, we derive the following relation:

$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & k_1+j_2 & l_4 \\ j_1+l_1 & k_2 & k_3 & k_4 \end{bmatrix}_q = \frac{(-1)^{j_1+l_2-k_3+j_4+k_4+l_4}\nabla[l_3 j_4 k_2]\nabla[j_1+j_2,l_2,l_4]}{\nabla[j_1 l_2 k_3]\nabla[j_2 k_3 l_4]\nabla[l_1 k_2 j_3]\nabla[j_1+j_2,j_3,j_4]}$$
$$\times \left(\frac{[2l_1]![2j_1]![2j_2]!}{[2k_1+1][2l_3+1]!}\right)^{1/2} \begin{Bmatrix} j_1+j_2 & l_4 & l_2 \\ k_4 & j_3 & j_4 \end{Bmatrix}. \tag{2.8}$$

In the doubly stretched case of the q-12j coefficient for $j_1=k_1-l_1=l_2-k_3$ [i.e., when the adjacent stretched triangles in graph (2.2) are diverging], we obtain from Eq. (2.5a) or (2.5c), and from Eq. (2.5b) with fixed $z_1=z_2=0$, two different double sum expressions, each depending on ten parameters and corresponding to the q-generalizations of the Kampé de Fériet[27] function $F_{1:3}^{1:4}$, as defined by Eq. (4.6) of Ref. 4. Each separate sum corresponds to the balanced basic hypergeometric ${}_5F_4[q,1]$ series. Again, we may identify the couples of quintuplets of factorials under summation signs in the numerator and denominator, each depending on the summation parameters z_3 and z_4.

Otherwise, in the case of the merging adjacent stretched triangles (e.g., for $k_1=j_1+l_1=j_2+l_3$), the straightforwardly derived expressions include the triple sums; in particular all three sums in (2.8) correspond to the balanced basic hypergeometric ${}_4F_3[q,1]$ series. The ${}_4F_3[q,1]$ type sum over z_4 may be rearranged in analogy with expressions for the q-6j coefficients[2,16] into another form (cf. Ref. 14) in a such way that the sum over z_3 turns into summable balanced basic hypergeometric ${}_3F_2[q,1]$ series. Hence, we obtain the doubly stretched q-12j coefficient in terms of the double sum,

$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & k_1-j_2 & l_4 \\ j_1+l_1 & k_2 & k_3 & k_4 \end{bmatrix}_q$$

$$= \frac{(-1)^{j_1+l_2-k_3}([2l_1]![2j_1]![2j_2]![2l_3]!)^{1/2}\nabla[k_4l_4j_4]}{\nabla[l_3k_2j_4]\nabla[j_1l_2k_3]\nabla[k_4j_3l_2]\nabla[j_2k_3l_4]\nabla[l_1k_2j_3]}$$

$$\times\sum_{z,u}\frac{[l_2-j_3+k_4+z]![l_1+k_2-j_3+z]![j_1+j_3+k_3-k_4-z]!}{[z]![l_2+j_3-k_4-z]![k_2-l_1+j_3-z]![k_3+k_4-j_1-j_3+z]!}$$

$$\times\frac{[2j_3-z]!(-1)^{z+u}[j_4-k_4+l_4+u]![j_4+l_3-k_2+u]!}{[u]![k_4-j_4+l_4-u]![k_3-k_4-j_2+j_4+u]![2j_4+u+1]!}$$

$$\times\frac{[k_3+k_4+j_2-j_4-u]![k_2+l_3+j_4+u+1]!}{[j_1+j_2+j_3-j_4-z-u]![l_1+l_3-j_3+j_4+z+u+1]!}, \tag{2.9}$$

which again depends on ten parameters and corresponds to the q-generalization of the Kampé de Fériet[27] function $F^{1:4}_{1:3}$, with each separate sum corresponding to the balanced basic hypergeometric ${}_5F_4[q,1]$ series. Perhaps this expression is related to the above mentioned special case of (2.5a) with fixed $z_1=z_2=0$ and the adjacent diverging stretched triangles of q-12j coefficient with respect to some composition of the usual and "mirror reflection" ($j\to -j-1$) symmetries.[2]

In the doubly stretched case of the q-12j coefficient with $k_1=j_1+l_1$ and $j_4=k_4+l_4$ [i.e., for antipode stretched triangles of graph (2.2)], we derive from Eq. (2.7), with fixed $z_3=0$ and $z_4=l_1-l_3-j_3+j_4+z_1$, an expression with a single sum, which corresponds to the balanced basic hypergeometric ${}_6F_5[q,1]$ series and depends on ten parameters:

$$\begin{bmatrix} j_1 & j_2 & j_3 & l_4+k_4 \\ l_1 & l_2 & l_3 & l_4 \\ j_1+l_1 & k_2 & k_3 & k_4 \end{bmatrix}_q = \frac{(-1)^{j_1+l_2-k_3}\nabla[k_1j_2l_3]\nabla[j_4k_2l_3]}{\nabla[j_1l_2k_3]\nabla[k_4j_3l_2]\nabla[l_4k_3j_2]\nabla[l_1k_2j_3]}$$

$$\times\left(\frac{[2l_1]![2j_1]![2l_4]![2k_4]!}{[2k_1+1]![2j_4+1]!}\right)^{1/2}$$

$$\times\sum_{z_1}\frac{(-1)^{z_1}[l_2-j_3+k_4+z_1]![j_4-j_3+j_2-j_1+z_1]!}{[z_1]![l_2+j_3-k_4-z_1]![j_1+j_2+j_3-j_4-z_1]!}$$

$$\times\frac{[l_1+k_2-j_3+z_1]![2j_3-z_1]!}{[k_2+j_3-l_1-z_1]![k_3+k_4-j_1-j_3+z_1]!}$$

$$\times\frac{[j_1+j_3+k_3-k_4-z_1]!}{[l_1-l_3-j_3+j_4+z_1]![l_1+l_3-j_3+j_4+z_1+1]!}. \tag{2.10}$$

In the doubly stretched case with $k_1=j_1+l_1$ and $k_4=j_4+l_4$ (again for antipode stretched triangles) from (2.5c), after the summation over z_2 of the balanced ${}_3F_2[q,1]$ series (see Appendix A), we obtain

$$\left[\begin{array}{cccc} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_4 \\ j_1+l_1 & k_2 & k_3 & j_4+l_4 \end{array}\right]_q = \frac{(-1)^{l_1-l_2-k_2+k_4}\nabla[k_1j_2l_3]\nabla[k_4j_3l_2]}{\nabla[j_1l_2k_3]\nabla[l_4k_3j_2]\nabla[j_4l_3k_2]\nabla[l_1k_2j_3]}$$

$$\times\left(\frac{[2l_1]![2j_1]![2l_4]![2j_4]!}{[2k_1+1]![2k_4+1]!}\right)^{1/2}$$

$$\times\sum_{z_4}\frac{(-1)^{z_4}[j_2+l_3-k_1+z_4]![k_1+k_2-j_2+j_4-z_4]!}{[z_4]![k_1-j_2+l_3-z_4]![k_2+j_2-k_1-j_4+z_4]!}$$

$$\times\frac{[l_4-k_3+j_2+z_4]![j_3-j_4+j_2-j_1+z_4]!}{[j_1-j_2+j_3+j_4-z_4]![l_4-l_2-j_1+j_2+z_4]!}$$

$$\times\frac{[j_2+k_3+l_4+z_4+1]!}{[2j_2+z_4+1]![l_2+l_4-j_1+j_2+z_4+1]!}. \tag{2.11}$$

Again the summation corresponds to the balanced ${}_6F_5[q,1]$ series and depends on ten parameters. Both expressions (2.10) and (2.11) satisfy some Regge type symmetry relations.

Consider also the doubly stretched cases of q-12j coefficients, the case of the remote stretched triangles of graph (2.2) with touching angular momenta forming four-cycles (quadrangles). There are four possible different distributions of the total (maximal) angular momenta of the stretched triangles: both these momenta may be in the same four-cycle, either (a) adjacent, (b) antiparallel, (c) the first angular momentum may be inside and the second one outside of the four-cycle, or (d) both these momenta may be outside of the four-cycle. For q-12j coefficients of the ''adjacent'' (a) type, e.g., with $k_1=j_1+l_1$ and $l_3=k_2+j_4$, we derive from Eq. (2.7) the relation

$$\left[\begin{array}{cccc} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & k_2+j_4 & l_4 \\ j_1+l_1 & k_2 & k_3 & k_4 \end{array}\right]_q = \frac{(-1)^{j_1+l_2-k_3}\nabla[l_3j_2k_1]}{\nabla[j_1l_2k_3]\nabla[k_4j_3l_2]\nabla[k_3j_2l_4]\nabla[j_4k_4l_4]\nabla[l_1k_2j_3]}$$

$$\times\left(\frac{[2l_1]![2j_1]![2k_2]![2j_4]!}{[2k_1+1]![2l_3+1]!}\right)^{1/2}$$

$$\times\sum_{z_1,z_3}\frac{(-1)^{z_1+z_3}[l_2-j_3+k_4+z_1]![j_1+j_3+k_3-k_4-z_1]!}{[z_1]![l_2+j_3-k_4-z_1]![j_3+k_2-l_1-z_1]!}$$

$$\times\frac{[2j_3-z_1]![2l_4-z_3]![j_4+k_4-l_4+z_3]!}{[z_3]![j_2-k_3+l_4-z_3]![k_4+l_1-l_3+l_4-j_3+z_1-z_3]!}$$

$$\times\frac{[j_2+k_3-l_4+z_3]!}{[k_3-k_1+l_3-l_4+z_3]![k_3+j_1+j_3+j_4-l_4-z_1+z_3+1]!}. \tag{2.12}$$

The double sum depends on nine (from ten free) parameters and corresponds to the q-generalization of the Kampé de Fériet[27] function $F^{1:3}_{1:2}$, again defined by Eq. (4.6) of Ref. 4 with $b_1+b_1'=c_1$, and each separate sum corresponding to the balanced ${}_4F_3[q,1]$ or ${}_4\phi_3$ series. Different (i.e., not equivalent) expressions of the (a) type appear also for $k_3=j_1+l_2$ and $j_2=k_1$

$+l_3$ from Eq. (2.5b) and for $j_3=l_1+k_2$ and $k_4=j_4+l_4$ from Eq. (2.5c). Furthermore, the doubly stretched q-12j coefficients of the "antiparallel" (b) type, with $k_1=j_1+l_1$ and $k_3=j_2+l_4$, expressions (2.5a), (2.5c), and (2.5d) (with fixed parameters z_1 and z_3) also turn into (mutually different) double sums again depending on nine (from ten free) parameters and related to the $F_{1:2}^{1:3}$ type functions. This is also the case for expression (2.5b) (with fixed $z_1=z_3=0$) for the doubly stretched q-12j coefficients of the "inside–outside" (c) type, with $k_1=j_1+l_1$ and $l_4=j_2+k_3$ [or, expression (2.5c) with $l_2=j_1+k_3$ and $j_2=k_1+l_3$]. Finally, expression (2.5a) with fixed $z_2=z_4=0$ and $l_2=j_1+k_3$ and $l_3=k_1+j_2$ again turns into the double sums depending on nine (from ten free) parameters and related to the $F_{1:2}^{1:3}$ type function for the doubly stretched q-12j coefficients with the both total angular momenta of the "outside" (d) type. These eight independent expressions should be related to (2.12) by means of some compositions of the usual and "mirror reflection" ($j\rightarrow -j-1$) symmetries.[2] Otherwise, many special versions of (2.5a)–(2.5d) with fixed $z_i=z_{i+1}=0$ ($i=1,2,3$) or $z_1=z_4=0$ give expressions for the doubly stretched q-12j coefficients with remote stretched triangles in terms of the double sums, related to compositions of the balanced ${}_4F_3[q,1]$ and ${}_5F_4[q,1]$ series.

Equation (2.5b) also turns into a single term for $l_1+l_2+l_3-l_4=0$ (when the all summation parameters z_i are fixed),

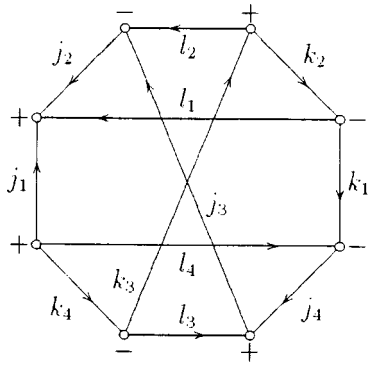
$$\begin{bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_1+l_2+l_3 \\ k_1 & k_2 & k_3 & k_4 \end{bmatrix}_q = \frac{(-1)^{j_1-j_3-k_1+k_2}[2l_1]![2l_2]![2l_3]!\nabla[l_4k_3j_2]\nabla[l_4j_4k_4]}{[2l_4+1]!\nabla[l_1j_1k_1]\nabla[l_1k_2j_3]\nabla[l_2j_1k_3]\nabla[l_2j_3k_4]\nabla[l_3j_2k_1]\nabla[l_3k_2j_4]}. \tag{2.13}$$

For this special q-12j coefficient [as well as in (2.5c) for $l_1-l_2+l_3+l_4=0$ and in (2.5d) for $l_1+l_2-l_3+l_4=0$], four linearly dependent angular momenta appear as disconnected in certain positions on a Hamilton line of graph (2.2). Actually, the single term expression of this virtually stretched case appears in accordance with symmetries (2.3b)–(2.3c) from expansion (2.4a) with $j_1+j_2-j_3+j_4=0$ and fixed $x=j_3-j_1=j_2+j_4$.

III. EXPRESSIONS FOR 12j COEFFICIENTS OF THE FIRST KIND

A. Generic properties

Next, we consider the rearrangement of expressions for the q-12j coefficients of the first kind[1,2,28,29] whose graphs are not planar:



(3.1)

(include some braiding[10]). These coefficients satisfy 16 symmetries, generated by the following substitutions:

$$\begin{Bmatrix} j_1 & j_2 & j_3 & j_4 \\ & l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \end{Bmatrix}_q = \begin{Bmatrix} j_2 & j_3 & j_4 & k_1 \\ & l_2 & l_3 & l_4 & l_1 \\ k_2 & k_3 & k_4 & j_1 \end{Bmatrix}_q \tag{3.2a}$$

$$= \begin{Bmatrix} k_1 & j_4 & j_3 & j_2 \\ & l_4 & l_3 & l_2 & l_1 \\ j_1 & k_4 & k_3 & k_2 \end{Bmatrix}_q . \tag{3.2b}$$

There expression[1,2,10] in terms of the factorized four differently rearranged q-6j coefficients is

$$\begin{Bmatrix} j_1 & j_2 & j_3 & j_4 \\ & l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \end{Bmatrix}_q$$

$$= \sum_x (2x+1)(-1)^{R_4-x} q^{x(x+1)+Z_{j_1j_2j_3j_4}+Z_{k_1k_2k_3k_4}} \times \begin{Bmatrix} j_1 & j_2 & l_1 \\ k_2 & k_1 & x \end{Bmatrix}_q \begin{Bmatrix} j_3 & k_3 & x \\ k_2 & j_2 & l_2 \end{Bmatrix}_q \begin{Bmatrix} j_3 & j_4 & l_3 \\ k_4 & k_3 & x \end{Bmatrix}_q \begin{Bmatrix} k_1 & j_1 & x \\ k_4 & j_4 & l_4 \end{Bmatrix}_q \tag{3.3a}$$

$$= \sum_x (2x+1)(-1)^{R_4-x} q^{x(x+1)+Z_{j_1j_2j_3j_4}+Z_{k_1k_2k_3k_4}} \times \begin{Bmatrix} j_1 & j_2 & l_1 \\ k_2 & k_1 & x \end{Bmatrix}_q \begin{Bmatrix} k_2 & x & j_2 \\ j_3 & l_2 & k_3 \end{Bmatrix}_q \begin{Bmatrix} j_3 & k_3 & x \\ k_4 & j_4 & l_3 \end{Bmatrix}_q \begin{Bmatrix} k_1 & x & j_1 \\ k_4 & l_4 & j_4 \end{Bmatrix}_q , \tag{3.3b}$$

where

$$Z_{abcd} = -a(a+1)-b(b+1)-c(c+1)-d(d+1),$$

and the triangular conditions are to be satisfied by all the triplets of the nearest neighbors such as l_i, j_i, j_{i+1}, or l_i, k_i, k_{i+1} $(i=1,2,3)$, or l_4, j_1, k_4, or l_4, k_1, j_4, respectively.

Again, after using expression (1.3a) with shifted summation parameter [see Eq. (2.1b) of Ref. 4] for the q-6j coefficients with summation parameter x in the right lower position, Eq. (1.3a) with inverted summation parameter for q-6j coefficients with x in the middle column, and (1.3a) directly in the remaining cases, the differently distributed asymmetric triangle coefficients (depending on the summation parameter x) cancel in the numerators or denominators of the q-6j coefficients in expansions (3.3a) and (3.3b), with the exception of the factors

$$\frac{\nabla[j_1k_1x]}{\nabla[k_1j_1x]} = \frac{[j_1-k_1+x]!}{[k_1-j_1+x]!}.$$

Then, the sums over x correspond to the q-generalization of the very well-poised classical hypergeometric ${}_6F_5(-1)$ series (resembling the basic hypergeometric ${}_7\phi_6$ series) and may be rearranged into the ${}_3\phi_2$ or ${}_3F_2[q,x]$ type series using the following two formulas:

$$\sum_j \frac{(-1)^{p_2+j+1}q^{j(j+1)}[2j+1][j-p_1-1]![j-p_2-1]![j-p_3-1]!}{[p_1+j+1]![p_2+j+1]![p_3+j+1]![p_4-j]![p_4+j+1]![p_5-j]![p_5+j+1]!}$$

$$=\frac{q^{-(p_4+1)(p_5+1)-p_2(p_4+p_5+1)}[-p_1-p_3-2]!}{[p_1+p_4+1]![p_2+p_5+1]![p_3+p_4+1]!}$$

$$\times\sum_u \frac{(-1)^u q^{u(p_2+p_5+1)}[p_4-p_3-1-u]![p_4-p_1-1-u]!}{[u]![-p_1-p_3-2-u]![p_2+p_4+1-u]![p_4+p_5+1-u]!} \tag{3.4a}$$

with parameters

$$p_1=k_1-j_1-1,\quad p_4=j_1+k_2-l_1+z_1,\quad p_5=j_3+k_4-l_3+z_3,$$

$$p_2=l_2-k_2-j_3+z_2-1,\quad p_3=l_4-k_1-k_4+z_4-1;$$

$$\sum_j \frac{q^{j(j+1)}[2j+1][j-p_1-1]![j-p_2-1]![j-p_3-1]![j-p_5-1]!}{[p_1+j+1]![p_2+j+1]![p_3+j+1]![p_4-j]![p_4+j+1]![p_5+j+1]!}$$

$$=q^{-(p_4+1)(p_5+1)-p_2(p_4+p_5+1)}\frac{[-p_1-p_3-2]![-p_2-p_5-2]!}{[p_1+p_4+1]![p_3+p_4+1]!}$$

$$\times\sum_u \frac{(-1)^u q^{u(p_2+p_5+1)}[p_4-p_3-1-u]![p_4-p_1-1-u]!}{[u]![p_4+p_5+1-u]![p_2+p_4+1-u]![-p_1-p_3-2-u]!} \tag{3.4b}$$

with parameters

$$p_1=k_1-j_1-1,\quad p_2=j_3-k_3-z_2-1,\quad p_3=j_1-k_1-z_4-1,$$

$$p_4=j_1+k_2-l_1+z_1,\quad p_5=l_3-j_3-k_4+z_3-1.$$

Equation (3.4a) may be derived by comparing alternative expressions for the Clebsch–Gordan coefficients of $u_q(2)$ (see Appendix B) and corresponds to Eq. (5.5) [or (5.6), when $q=1$] of Ref. 12, with the right-hand side of (5.5) replaced by the less symmetric (Bandzaitis–Jucys) expression[2,17,30] for the Clebsch–Gordan coefficients of SU(2) and $u_q(2)$, instead of the most symmetric (Van der Waerden) expression[1,2,8,17,31,32] (cf. also Refs. 13 and 33). Relation (3.4b) is derived from (3.4a) using the analytical continuation technique. Summation formulas (A1) and (A2) of Ref. 4 (each depending on three parameters) may be obtained after canceling some factorials in the numerators and denominators of (3.4a) and (3.4b), respectively, for $p_3=-p_1-2$.

B. General expressions with five sums

Substituting the summation parameter u, which appeared after using (3.4a) and (3.4b) in (3.3a) and (3.3b), by $u+z_1$, we obtain the following expressions for the q-12j coefficients of the first kind:

$$
\begin{Bmatrix} j_1 & j_2 & j_3 & j_4 \\ l_1 & l_2 & l_3 & l_4 \\ k_1 & k_2 & k_3 & k_4 \end{Bmatrix}_q
$$

$$
\begin{aligned}
&=(-1)^{k_1+k_2-k_3-j_2+j_3+j_4-l_4}\,\frac{\nabla[j_3j_2l_2]\nabla[k_2k_3l_2]\nabla[k_1j_4l_4]\nabla[k_4j_1l_4]}{\nabla[j_1j_2l_1]\nabla[k_2k_1l_1]\nabla[j_3j_4l_3]\nabla[k_4k_3l_3]}\\
&\quad\times q^{-(j_1+k_2-l_1+1)(k_4-l_3+l_2-k_2)-(l_2-k_2-j_3-1)(j_3+k_4-l_3)+Z_{j_1j_2j_3j_4}+Z_{k_1k_2k_3k_4}}\\
&\quad\times\sum_{z_1,z_2,z_3,z_4,u}\frac{(-1)^{z_3+z_4+u}[j_1+j_2-l_1+z_1]![2l_1-z_1]!}{[z_1]![z_2]![z_3]![z_4]![k_1-k_2+l_1-z_1]![l_1-j_1+j_2-z_1]!}\\
&\quad\times\frac{q^{-z_2(j_1+j_3+k_2+k_4-l_1-l_3+z_3+1)}[l_2+j_2-j_3+z_2]![l_2+k_3-k_2+z_2]!}{[j_2+j_3-l_2-z_2]![k_2+k_3-l_2-z_2]![2l_2+z_2+1]![2l_4+z_4+1]!}\\
&\quad\times\frac{[k_3+k_4-l_3+z_3]![j_3+j_4-l_3+z_3]![2l_3-z_3]!}{[k_3+l_3-k_4-z_3]![l_3-j_3+j_4-z_3]![k_1+j_4-l_4-z_4]!}\\
&\quad\times\frac{q^{z_3(l_1-l_2-j_1+j_3)}[j_4+l_4-k_1+z_4]![j_1+l_4-k_4+z_4]!}{[l_2-l_3-k_2+k_4+z_2+z_3]![j_1-k_1+k_2-k_4-l_1+l_4+z_1+z_4]!}\\
&\quad\times\frac{q^{u(k_4-k_2-l_3+l_2+z_2+z_3)}[j_1+k_1+k_2+k_4-l_1-l_4-z_4-u]!}{[u+z_1]![j_1+k_4-l_4-z_1-z_4-u]![j_1-j_3-l_1+l_2+z_2-u]!}\\
&\quad\times\frac{[2j_1-k_1+k_2-l_1-u]!}{[j_1+j_3+k_2+k_4-l_1-l_3+z_3-u+1]!}
\end{aligned}
\tag{3.5a}
$$

$$
\begin{aligned}
&=(-1)^{j_1+j_3+j_4+k_2-k_3-k_4+l_2-l_3+l_4}\frac{\nabla[j_3j_4l_3]\nabla[k_4k_3l_3]\nabla[k_2k_3l_2]\nabla[k_1j_4l_4]}{\nabla[j_1j_2l_1]\nabla[k_2k_1l_1]\nabla[j_3j_2l_2]\nabla[k_4j_1l_4]}\\
&\quad\times q^{(j_1+k_2-l_1+1)(l_2+k_2-l_3+k_4+1)-(l_2+k_2-j_3+1)(j_3+k_4-l_3+1)+Z_{j_1j_2j_3j_4}+Z_{k_1k_2k_3k_4}}\\
&\quad\times\sum_{z_1,z_2,z_3,z_4,u}\frac{(-1)^{z_2+z_3+z_4+u}[j_1+j_2-l_1+z_1]![2l_1-z_1]!}{[z_1]![z_2]![z_3]![k_1-k_2+l_1-z_1]![l_1-j_1+j_2-z_1]!}\\
&\quad\times\frac{q^{-z_2(j_1-j_3+k_2-k_4-l_1+l_3+z_3)}[j_2+j_3-l_2+z_2]![2l_2-z_2]!}{[l_2+k_2-k_3-z_2]![j_2-j_3+l_2-z_2]![l_2+k_2+k_3-z_2+1]!}\\
&\quad\times\frac{q^{-z_3(j_1+j_3-l_1-l_2)}[k_3-k_4+l_3+z_3]![j_4-j_3+l_3+z_3]!}{[k_3+k_4-l_3-z_3]![j_3+j_4-l_3-z_3]![2l_3+z_3+1]!}\\
&\quad\times\frac{[2l_4-z_4]![j_1+k_4-l_4+z_4]![k_2+k_4+l_2-l_3-z_2-z_3]!}{[z_4]![k_1+l_4-j_4-z_4]![j_1-k_1+k_2+k_4-l_1-l_4+z_1+z_4]!}\\
&\quad\times\frac{q^{-u(k_2+k_4+l_2-l_3-z_2-z_3+1)}[2j_1-k_1+k_2-l_1-u]!}{[k_1+l_4+j_4-z_4+1]![u+z_1]![j_1-k_4+l_4-z_1-z_4-u]!}\\
&\quad\times\frac{[j_1+k_1+k_2-k_4-l_1+l_4-z_4-u]!}{[j_1+j_3-l_1-l_2+z_2-u]![j_1-j_3+k_2-k_4-l_1+l_3+z_3-u]!}.
\end{aligned}
\tag{3.5b}
$$

Each of expressions (3.5a) and (3.5b) includes five summations, with four separate sums (over z_1,z_2,z_3, and z_4) corresponding to the finite (balanced in the first and last cases) basic hypergeometric series ${}_4\phi_3$ or ${}_4F_3[\cdots;q,1]$ [as defined by Eq. (3.2) of Ref. 4], and the fifth sum (over $u+z_1$) corresponding to the finite hypergeometric series ${}_3\phi_2$ or ${}_3F_2(1)$, related in the case of (3.5a) to the Clebsch–Gordan coefficients of $u_q(2)$ or SU(2). However, it is impossible to rearrange all

five sums together into standard basic hypergeometric series ${}_{p+1}\phi_p$. Some correlation between the factorials under the summation signs reveals itself in two quintuplets of factorials of each expression (3.5a) and (3.5b), depending on the couples of summation parameters z_2, z_3 and z_1, z_4. Definite correspondences may be observed in Eqs. (3.5a) and (3.5b) between the q-phase structure and three particular factorial arguments, depending on the couples of summation parameters z_2, z_3, and u, respectively [as well as in q-9j coefficients, presented by Eqs. (3.1a)–(3.1e) of Ref. 4, between the q-phases and three factorial arguments, depending on the couples of summation parameters z_1, z_2, and z_3]. The summation intervals in (3.5a) and (3.5b) are mainly restricted by eight triangle linear combinations of parameters, respectively, but in the stretched cases only (3.5a) for $k_4 = l_4 - j_1$ and (3.5b) for $k_4 = l_4 + j_1$ (with $z_4 = u + z_1 = 0$ in the both cases) turn into the triple sums.

C. Stretched cases of the *q*-12*j* coefficients of the first kind

When the total (maximal) angular momentum in a stretched triangle of the q-12j coefficient of the first kind corresponds to a crossbar of the Möbius strip (3.1) [in the middle row of standard array (3.2a), e.g., for $l_4 = k_4 + j_1$], we obtain the following expression:

$$
\begin{Bmatrix} j_1 & j_2 & j_3 & j_4 \\ & l_1 \quad l_2 \quad l_3 & & k_4 + j_1 \\ k_1 & k_2 & k_3 & k_4 \end{Bmatrix}_q
$$

$$
= (-1)^{k_1 + k_2 - k_3 - j_2 + j_3 + j_4 - l_4}
$$

$$
\times \frac{\nabla[j_3 j_2 l_2]\nabla[k_2 k_3 l_2]\nabla[l_4 j_4 k_1]}{\nabla[j_1 j_2 l_1]\nabla[k_2 k_1 l_1]\nabla[j_3 j_4 l_3]\nabla[k_4 k_3 l_3]} \left(\frac{[2k_4]![2j_1]!}{[2l_4+1]!} \right)^{1/2}
$$

$$
\times q^{-(j_1 + k_2 - l_1 + 1)(k_4 - k_2 + l_2 - l_3) - (l_2 - k_2 - j_3 - 1)(j_3 + k_4 - l_3) + Z_{j_1 j_2 j_3 j_4} + Z_{k_1 k_2 k_3 k_4}}
$$

$$
\times \sum_{z_1, z_2, z_3} \frac{(-1)^{z_1 + z_3}[j_1 + j_2 - l_1 + z_1]![k_1 + k_2 - l_1 + z_1]![2l_1 - z_1]!}{[z_1]![z_2]![z_3]![k_1 - k_2 + l_1 - z_1]![l_1 - j_1 + j_2 - z_1]!}
$$

$$
\times \frac{[l_2 + j_2 - j_3 + z_2]![l_2 + k_3 - k_2 + z_2]!}{[j_2 + j_3 - l_2 - z_2]![k_2 + k_3 - l_2 - z_2]![2l_2 + z_2 + 1]!}
$$

$$
\times \frac{[k_3 + k_4 - l_3 + z_3]![j_3 + j_4 - l_3 + z_3]![2l_3 - z_3]!}{[k_3 + l_3 - k_4 - z_3]![l_3 - j_3 + j_4 - z_3]![j_1 - j_3 - l_1 + l_2 + z_1 + z_2]!}
$$

$$
\times \frac{q^{z_3(l_1 - l_2 - j_1 + j_3) - z_2(j_3 + k_2 - l_1 - l_3 + l_4 + z_3 + 1) - z_1(l_2 - l_3 - k_2 + k_4 + z_2 + z_3)}}{[l_2 - l_3 - k_2 + k_4 + z_2 + z_3]![j_3 + k_2 - l_1 - l_3 + l_4 + z_1 + z_3 + 1]!}. \tag{3.6}
$$

This special case of (3.5a) with three separate sums corresponds to the finite basic hypergeometric series ${}_4F_3[\cdots; q, x]$. Expression (3.6) does not simplify noticeably for two adjacent merging stretched triangles (with $l_4 = k_4 + j_1 = k_1 + j_4$) in the same q-6j coefficient of expansion (3.3a), but one of the sums turns into a ${}_3F_2[\cdots; q, x]$ series for two adjacent diverging stretched triangles (e.g., with $j_1 = l_4 - k_4 = l_1 - j_2$, or with $j_1 = l_4 - k_4 = j_2 - j_1$). The Chu–Vandermonde summation formula [see (B1c) of Ref. 4] may be used in Eq. (3.6) for $j_1 = 0$, $l_1 = j_2$, $k_4 = l_4$ and for $k_4 = 0$, $l_4 = j_1$, $k_3 = l_3$. In these cases, the couples of the q-6j coefficients appear in accordance with Eq. (33.21) of Ref. 2, as well as the consequences of expansions (3.3a)–(3.3b) for fixed x.

When the total angular momentum in a stretched triangle of the q-12j coefficient of the first kind is located along the Möbius strip (3.1) (e.g., for $k_4 = l_4 + j_1$), we obtain from (3.5b), after change of summation parameter $z_2 \to l_2 + k_2 - k_3 - z_2$ the following expression:

$$\left\{\begin{array}{ccccc} j_1 & & j_2 & & j_3 & & j_4 & \\ & l_1 & & l_2 & & l_3 & & l_4 \\ k_1 & & k_2 & & k_3 & & l_4+j_1 & \end{array}\right\}_q$$

$$=\frac{(-1)^{j_3+j_4-l_3+l_2+k_2-k_3}\nabla[j_3j_4l_3]\nabla[k_4k_3l_3]\nabla[k_2k_3l_2]}{\nabla[j_1j_2l_1]\nabla[k_2k_1l_1]\nabla[j_3j_2l_2]\nabla[l_4k_1j_4]}\left(\frac{[2j_1]![2l_4]!}{[2k_4+1]!}\right)^{1/2}$$

$$\times q^{(j_1+k_2-l_1+1)(k_2+k_4+l_2-l_3+1)-(l_2+k_2-j_3+1)(j_3-l_3+k_4+1)+Z_{j_1j_2j_3j_4}+Z_{k_1k_2k_3k_4}}$$

$$\times\sum_{z_1,z_2,z_3}\frac{[j_1+j_2-l_1+z_1]![k_1+k_2-l_1+z_1]![2l_1-z_1]!}{[z_1]![z_2]![z_3]![k_1-k_2+l_1-z_1]![l_1-j_1+j_2-z_1]!}$$

$$\times\frac{(-1)^{z_1+z_2+z_3}[j_2+j_3-l_2+z_2]![2l_2-z_2]!}{[l_2+k_2-k_3-z_2]![j_2-j_3+l_2-z_2]![l_2+k_2+k_3-z_2+1]!}$$

$$\times\frac{q^{z_1(k_2+k_4+l_2-l_3-z_2-z_3+1)}[k_3-k_4+l_3+z_3]![j_4-j_3+l_3+z_3]!}{[k_3+k_4-l_3-z_3]![j_3+j_4-l_3-z_3]![2l_3+z_3+1]!}$$

$$\times\frac{q^{-z_2(k_2-j_3-l_1+l_3-l_4+z_3)-z_3(j_1+j_3-l_1-l_2)}[k_2+k_4+l_2-l_3-z_2-z_3]!}{[j_1+j_3-l_1-l_2+z_1+z_2]![k_2-j_3-l_1+l_3-l_4+z_1+z_3]!}. \tag{3.7}$$

Expression (3.7) does not simplify for two couples of adjacent diverging stretched triangles [with $l_4=k_4-j_1=k_1-j_4$, or with $l_4=k_4-j_1=j_4-k_1$, respectively, again in the same q-6j coefficient of expansion (3.3b)], but for $l_4=0$, $k_4=j_1$, $j_4=k_1$ (after substitution $q\to q^{-1}$) it corresponds to the general expression (3.1a) of Ref. 4 for the q-9j coefficients,

$$([2j_1+1][2k_1+1])^{-1/2}\left\{\begin{array}{ccc} j_1 & l_1 & j_2 \\ k_3 & k_2 & l_2 \\ l_3 & k_1 & j_3 \end{array}\right\}_q$$

[cf. Eq. (33.20) of Ref. 2]. The triple sums in (3.6) and (3.7) resemble expressions for the q-9j coefficients and definite correspondences may be observed between the q-phases and three factorial arguments, depending on the couples of summation parameters z_1,z_2, and z_3, respectively. Expansion of the present couples of the factorial quintuplets (depending on parameters z_1,z_2 and z_2,z_3, respectively), using the Chu–Vandermonde summation formulas enables one to perform the summation over z_2 and thus obtain expressions for the stretched q-12j coefficients of the first kind as fourfold sums, related to compositions of ${}_3F_2[\cdots;q,x]$ series.

Again, one of the sums in (3.7) turns into a ${}_3F_2[\cdots;q,x]$ series for two adjacent diverging stretched triangles in two adjacent q-6j coefficients of expansion (3.3a) (e.g., with $j_1=k_4-l_4=l_1-j_2$, or with $j_1=k_4-l_4=j_2-l_1$), as well as for two adjacent merging stretched triangles (e.g., with $k_4=l_4+j_1=k_3+l_3$). The possible rearrangement of the ${}_3F_2[\cdots;q,x]$ series is not helpful for reducing the remaining ${}_4F_3[\cdots;q,x]$ series.

The doubly stretched q-12j coefficients of the first kind with the adjacent consecutive stretched triangles may be expressed for $k_4=l_4+j_1$ and $j_1=l_1+j_2$ or $l_3=k_3+k_4$ by means of (3.7), as well as for $l_4=k_4+j_1$ and $j_1=l_1+j_2$ or $k_4=k_3+l_3$ by means of (3.6), as the double sums, related to the stretched q-9j coefficients, respectively, of the type (3.1a) or (3.1b) of Ref. 4 (with some "reflected" parameters in the last cases). In this way we derive, for $k_4=l_4+j_1$ and $j_1=l_1+j_2$ [comparing (3.7) with Eq. (3.1a) of Ref. 4], the following relation:

$$\begin{Bmatrix} l_1+j_2 & j_2 & j_3 & j_4 \\ & l_1 \quad & l_2 \quad & l_3 \quad & l_4 \\ k_1 & k_2 & k_3 & l_4+j_1 \end{Bmatrix}_q$$

$$=(-1)^{j_3+j_4-l_3+l_2+k_2-k_3}q^{Z_{j_1j_2j_3j_4}+Z_{k_1k_2k_3k_4}-Z_{l_2,l_3,l_1+l_4}}\frac{\nabla[l_1+l_4,j_4,k_2]}{\nabla[l_1k_1k_2]\nabla[l_4k_1j_4]}$$

$$\times\left(\frac{[2l_1]![2l_4]!}{[2l_1+2l_4]![2j_1+1]}\right)^{1/2}\begin{Bmatrix} k_4 & k_3 & l_3 \\ j_2 & l_2 & j_3 \\ l_1+l_4 & k_2 & j_4 \end{Bmatrix}_{q^{-1}}. \tag{3.8}$$

Similarly, for $k_4=l_4+j_1$ and $l_3=k_3+k_4$ we obtain

$$\begin{Bmatrix} j_1 & j_2 & j_3 & j_4 \\ & l_1 \quad & l_2 \quad & k_3+k_4 & l_4 \\ k_1 & k_2 & k_3 & l_4+j_1 \end{Bmatrix}_q$$

$$=q^{Z_{j_1j_2j_3j_4}+Z_{k_1k_2k_3k_4}-Z_{l_2,j_1+k_3,l_1}}\frac{(-1)^{j_3+j_4-l_4-l_2-k_2-j_2+l_1}\nabla[l_3j_3j_4]}{\nabla[l_4k_1j_4]\nabla[j_1+k_3,j_3,k_1]}$$

$$\times\left(\frac{[2l_4]![2j_1+2k_3+1]!}{[2l_3+1]![2k_4+1]}\right)^{1/2}\begin{Bmatrix} j_1 & k_3 & j_1+k_3 \\ j_2 & l_2 & j_3 \\ l_1 & k_2 & k_1 \end{Bmatrix}_{q^{-1}}. \tag{3.9}$$

We remark that the doubly stretched q-12j coefficients of the first kind for $l_4=k_4+j_1$ and $l_2=j_2+j_3$ or $l_2=k_2+k_3$ as obtained from (3.6), as well as for $k_4=l_4+j_1$ and $j_3=l_2+j_2$ or $k_3=l_2+k_2$ as obtained from (3.7), turn into double sums equivalent to compositions of ${}_4F_3[\cdots;q,x]$ and ${}_3F_2[\cdots;q,x]$ series. However, although the ${}_3F_2[\cdots;q,x]$ series may be rearranged into other forms, these double sums are not equivalent to any composition of two generic ${}_3F_2[\cdots;q,x]$ series and, moreover, they are not related to any q-9j coefficient. Minton's summation formula (A3a) (see Ref. 14) may be helpful in the analogical position of the stretched triangles in (3.6) for $l_4=k_4+j_1$ and $j_2=l_2+j_3$ or $k_3=k_2+l_2$, as well as in (3.7) for $k_4=l_4+j_1$ and $l_2=k_2+k_3$. Otherwise, the ${}_3F_2[\cdots;q,x]$ series appearing in the triple sums, which remain in Eq. (3.6) for $j_3=j_2+l_2$ or $k_2=l_2+k_3$, and in Eq. (3.7) for $j_2=l_2+j_3$ or $k_2=l_2+k_3$, may be rearranged, but it is more reasonable in such a case to use the different expansions of the type (3.3a)–(3.3b) with inserted stretched q-6j coefficients and adapted [e.g., expansion (3.3b) for $l_4=k_4+j_1$ and $j_3=j_2+l_2$ or expansion (3.3a) for $k_4=l_4+j_1$ and $j_2=l_2+j_3$, with transposed the middle and the right columns of the third q-6j coefficients in the both cases] for summation by means of (A2) or (A3) of Ref. 4.

Furthermore, expression (3.6) turns into double sums equivalent to compositions of two ${}_4F_3[\cdots;q,x]$ series for the remote stretched triangles of graph (3.1) $l_4=k_4+j_1$ and $j_3=l_3+j_4$ or $k_2=k_1+l_1$ (when two couples of the touching angular momenta form the four-cycles, or quadrangles), as well as expression (3.7) for $k_4=l_4+j_1$ and $l_3=j_3+j_4$ or $k_2=k_1+l_1$. Again, Minton's summation formula (A3a) may be used in (3.7) for $j_4=j_3+l_3$ and the ${}_3F_2[\cdots;q,x]$ series may be rearranged in the triple sums, which remain in Eq. (3.6) for $l_1=k_1+k_2$ or $l_3=j_3+j_4$ and in Eq. (3.7) for $j_3=l_3+j_4$ or $k_1=k_2+l_1$. Expansion (3.3a) with inserted stretched q-6j coefficients may be used for summation by means of (A1) of Ref. 4 for $l_4=k_4+j_1$ and $l_1=k_1+k_2$, as well as expansion (3.3b) for summation by means of (A2) of Ref. 4 for $k_4=l_4+j_1$ and $k_1=k_2+l_1$, after in the both cases the middle and the right columns of the second q-6j coefficients are transposed.

In general, the triply stretched cases of the q-12j coefficients of the first kind may always be expressed in terms of the double sums, applying some "mirror reflection" ($j\to -j-1$) operations

to the above mentioned expressions, or using the above mentioned rearrangements. In particular, the double sums (compositions of two ${}_3F_2[\cdots;q,x]$ series) related to the most generic Kampé de Fériet[27] functions of the type $F_{1:1}^{0:3}$ (with nine independent parameters) appear instead of (3.7) in the triply stretched cases with $k_4=l_4+j_1=k_3+l_3$ and $j_3=j_2+l_2$, or with $j_1=k_4-l_4=j_2-j_1$ and $k_3=k_2+l_2$.

Let us return to the generic expressions (3.5a) and (3.5b). In both formulas, for $j_2=0$, $l_1=j_1$, $l_2=j_3$, the summation parameters z_1,z_2 and u are fixed, the two remaining separate sums (over z_3,z_4) correspond to the balanced ${}_4F_3[q,1]$ series, and the couples of the q-$6j$ coefficients appear straightforwardly, in accordance with the expansion (3.3a)–(3.3b) for fixed x. Furthermore, in both (3.5a) and (3.5b), the parameters z_1,z_2 and u are also fixed for $j_1+j_2+k_1-k_2=0$, i.e., for the adjacent consecutive stretched triangles $k_2=k_1+l_1=k_1+j_1+j_2$ with the intermediate angular momentum corresponding to a crossbar of the Möbius strip (3.1). Two remaining separate sums (over z_3,z_4) correspond to the balanced (Saalschützian) ${}_4F_3[q,1]$ [related to q-$6j$ coefficient of the type (1.3a)] and summable [see Eq. (A2a)] ${}_3F_2[q,1]$ series. In this way, we derived the following relation:

$$\begin{Bmatrix} j_1 & & j_2 & & j_3 & & j_4 & \\ & j_1+j_2 & & l_2 & & l_3 & & l_4 \\ k_1 & & k_1+l_1 & & k_3 & & k_4 & \end{Bmatrix}_q$$
$$=(-1)^{k_1+j_3-l_3-l_4+2k_3}\frac{q^{2j_1k_1+Z_{j_2j_3j_4}+Z_{k_2k_3k_4}}\nabla[k_2k_3l_2]\nabla[k_1+j_1,j_4,k_4]}{\nabla[j_1k_4l_4]\nabla[j_2l_2j_3]\nabla[k_1j_4l_4]\nabla[k_1+j_1,j_3,k_3]}$$
$$\times\left(\frac{[2j_2]![2j_1]![2k_1]!}{[2k_2+1]![2l_1+1]!}\right)^{1/2}\begin{Bmatrix} j_3 & j_4 & l_3 \\ k_4 & k_3 & k_1+j_1 \end{Bmatrix}_q. \tag{3.10}$$

For 4 mutual positions of the couples of the stretched triangles in the graph of the q-$12j$ coefficient of the first kind, there are 22 different orientations of the total (maximal) angular momenta. In seven cases, the expressions include triple sums, twice they are proportional to the stretched q-$9j$ coefficients, and once to the q-$6j$ coefficient. In the remaining 12 cases, double sums may be obtained. Otherwise, for three mutual positions of the stretched triangles in the q-$12j$ coefficient of the second kind, only nine different orientations of the total angular momenta are possible, and in six cases double sums appear, and in three cases the expressions are single sums (only once proportional to the q-$6j$ coefficient).

Finally, the summation parameters z_1,z_3 and u in (3.5b) are fixed for $j_1-j_3+k_1+k_3=0$, as well as for $x=j_3-k_3=j_1+k_1$ in expansion (3.3a), in which cases four linearly dependent angular momenta appear (disconnected) on the Hamilton line of graph (3.1). In this case, two remaining separate sums (over z_2,z_4) are summable Saalschützian series ${}_3F_2[q,1]$ [see Eqs. (A2a) and (A2b)], and the following expression may be derived:

$$\begin{Bmatrix} j_1 & & j_2 & & j_1+k_1+k_3 & & j_4 & \\ & l_1 & & l_2 & & l_3 & & l_4 \\ k_1 & & k_2 & & k_3 & & k_4 & \end{Bmatrix}_q$$
$$=(-1)^{j_2+j_4-l_1-k_1-j_1-l_4}$$
$$\times\frac{q^{2j_1k_1+Z_{j_2j_3j_4}+Z_{k_2k_3k_4}}[2j_1]![2k_1]![2k_3]!\nabla[j_3j_4l_3]\nabla[j_3j_2l_2]}{[2j_3+1]!\nabla[j_1j_2l_1]\nabla[k_1k_2l_1]\nabla[j_1k_4l_4]\nabla[k_1j_4l_4]\nabla[k_3k_2l_2]\nabla[k_3k_4l_3]}. \tag{3.11}$$

As for (2.13), the virtually stretched triangles are seen only in the q-$6j$ coefficients, which appear in expansion of the q-$12j$ coefficient of the first kind with extreme parameters.

IV. CONCLUDING REMARKS

Using Dougall's summation formula[7] of the very well-poised ${}_5F_4(1)$ series and the transformation formula[12] of the very well-poised ${}_6F_5(-1)$ series, we eliminated the factorial sums weighted with factor $(2j+1)$ and the very well-poised series in the traditional expressions of the $12j$ coefficients of SU(2) in terms of $6j$ coefficients, as well as in the expressions of the q-$12j$ coefficients of $u_q(2)$ weighted with factor $[2j+1]$. Although the obtained generic expressions for the q-$12j$ coefficients of the first kind include fivefold sums and the generic expressions for the q-$12j$ coefficients of the second kind contain fourfold sums, the stretched and doubly stretched q-$12j$ coefficients of both become considerably simpler and present some new versions of triple, double, or single basic hypergeometric series, but more unusual and complicated than appear in the manuals of the angular momentum theory (cf. Ref. 34). The single term expressions for the q-$12j$ coefficients of the both kinds also embrace the virtually stretched cases with four extreme linearly dependent disconnected angular momentum parameters appearing on the Hamilton lines of graphs (2.2) or (3.1).

The symmetry properties and variety of expressions for the $12j$ and q-$12j$ coefficients of the both kinds may inspire new possibilities of rearrangement of the classical and basic hypergeometric series. Expressions for $3nj$ coefficients of SU(2) (with $n>4$) in terms of $6j$ coefficients also may be rearranged using, e.g., Watson's transformation formula of the very well-poised ${}_7F_6(1)$ series [see Eq. (2.5.1) of Ref. 14 or Eq. (6.10) of Ref. 35]. One may also use Eq. (5.3) of Ref. 12 for rearrangement of the very well-poised ${}_8F_7(-1)$ series, or Eqs. (A5) of Ref. 36 for rearrangement of the very well-poised ${}_9F_8(1)$ series. The number of sums in two last cases increases with elimination of the sums dependent on $(2j+1)$.

APPENDIX A: DOUGALL'S, SAALSCHÜTZIAN, AND MINTON'S SUMMATION FORMULAS

In Appendix A of Ref. 4, we presented three summation formulas of the twisted very well-poised q-factorial series as generalizations of Dougall's summation formula (2.3.4.8) of Ref. 7 of the ${}_4F_3(-1)$ series, depending on three parameters. We present here two summation formulas of the very well-poised q-factorial series, depending on four parameters:[12]

$$\sum_j \frac{[2j+1][j-p_1-1]![j-p_2-1]!}{[p_1+j+1]![p_2+j+1]![p_3-j]![p_3+j+1]![p_4-j]![p_4+j+1]!}$$
$$= \frac{[-p_1-p_2-2]![p_1+p_2+p_3+p_4+2]!}{[p_1+p_4+1]![p_2+p_4+1]![p_3+p_4+1]![p_2+p_3+1]![p_1+p_3+1]!}; \tag{A1a}$$

$$\sum_j \frac{(-1)^{p_4-j}[2j+1][j-p_1-1]![j-p_2-1]![j-p_3-1]!}{[p_1+j+1]![p_2+j+1]![p_3+j+1]![p_4-j]![p_4+j+1]!}$$
$$= \frac{[-p_1-p_2-2]![-p_2-p_3-2]![-p_1-p_3-2]!}{[p_1+p_4+1]![p_2+p_4+1]![p_3+p_4+1]![-p_1-p_2-p_3-p_4-3]!}. \tag{A1b}$$

[Cf. Dougall's summation theorem of special very well-poised hypergeometric series ${}_5F_4(1)$ as (2.3.4.5) of Ref. 7 and special very well-poised basic hypergeometric series ${}_6\phi_5$ as (2.4.2) of Ref. 14. Note that the very well-poised basic hypergeometric series ${}_{2k}\phi_{2k-1}$ cannot be expressed in terms of ${}_{2k}F_{2k-1}[\cdots;q,x]$ series.[4,13]]

Under condition $c+d=a+b+e$, we may use also the summation formulas of the balanced (Saalschützian) ${}_3F_2[q,1]$ series [cf. Eq. (2.3.1.4) of Ref. 7 and Eqs. (1.7.1) and (1.7.2) of Ref. 14]:

$$\sum_s \frac{(-1)^s[c+s]![d-s]!}{[s]![a-s]![b-s]![e+s+1]!} = \frac{[c]![d-a]![d-b]![c+d+1]!}{[a]![b]![a+e+1]![b+e+1]![e-c]!} \tag{A2a}$$

for $e-c\geqslant 0$ and

$$\sum_s \frac{(-1)^s[c-s]![d-s]!}{[s]![a-s]![b-s]![e-s+1]!}=\frac{[c-a]![c-b]![d-a]![d-b]!}{[a]![b]![e-c]![e-d]![e+1]!} \tag{A2b}$$

for $e-c\geqslant 0$ and $e-d\geqslant 0$.

It is sometimes useful to implement the q-version of Minton's summation formula[37] or its inverse [cf. Eq. (1.9.6) of Ref. 14]:

$$\sum_s \frac{(-1)^s q^{s(n-\Sigma_{i=1}^r m_i)}}{[s]![n-s]![S+s]}\prod_{j=1}^m (b_j+s|q)_{m_j}=\frac{q^{S(\Sigma_{i=1}^r m_i-n)}}{(S|q)_{n+1}}\prod_{j=1}^m (b_j-S|q)_{m_j}, \tag{A3a}$$

if $S+s\neq 0$ for $s=0,1,\ldots,n$, and $n\geqslant\Sigma_{i=1}^r m_i$;

$$\sum_s \frac{(-1)^s q^{s(a+b-c-m)}[c-s]!}{[s]![a-s]![b-s]![S-s+1]}\prod_{j=1}^m [A_j-s]$$

$$=(-1)^{a+b-c-m}q^{(S+1)(a+b-c-m)}\frac{[S-a]![S-b]!}{[S-c]![S+1]!}\prod_{j=1}^m [S-A_j+1], \tag{A3b}$$

which is valid if $S-s+1\neq 0$ for $s=0,1,\ldots,\min(a,b)$ and $a+b-c-m\geqslant 0$. Note that the analytical continuation of the summation formulas (A3a) and (A3b) of the alternating series to related series with the fixed sign of all terms is impossible.

APPENDIX B: CLEBSCH–GORDAN COEFFICIENTS OF SU(2) AND $u_q(2)$ AND TWISTED VERY WELL-POISED SERIES

The very well-poised ${}_6F_5(-1)$ and ${}_7F_6(1)$ series appear in context of the Clebsch–Gordan and $6j$ coefficients of SU(2) as presented in Ref. 33 (see also Ref. 2), as well as their q-analogs in the CG (cf. Ref. 13, where the dual Hahn q-polynomials are considered) and $6j$ coefficients (cf. Ref. 35) of $u_q(2)$.

We deduce here a new expression for the Clebsch–Gordan coefficients of SU(2) and $u_q(2)$ directly from the recoupling relation:

$$\begin{bmatrix}(j_2+m_2)/2 & (j_2-m_2)/2 & j_2\\ (j_2+m_2)/2 & (m_2-j_2)/2 & m_2\end{bmatrix}_q\begin{bmatrix}j_1 & j_2 & j\\ m_1 & m_2 & m\end{bmatrix}_q$$

$$=\sum_x (-1)^{j_1+j_2+j}([2x+1][2j_2+1])^{1/2}\begin{Bmatrix}(j_2+m_2)/2 & (j_2-m_2)/2 & j_2\\ j & j_1 & x\end{Bmatrix}_q$$

$$\times\begin{bmatrix}j_1 & (j_2+m_2)/2 & x\\ m_1 & (j_2+m_2)/2 & m'\end{bmatrix}_q\begin{bmatrix}x & (j_2-m_2)/2 & j\\ m' & (m_2-j_2)/2 & m\end{bmatrix}_q, \tag{B1}$$

where $m'=m_1+\frac{1}{2}(j_2+m_2)=m+\frac{1}{2}(j_2-m_2)$. Inserting the stretched $6j$ and extreme CG coefficients expressed without sums, we obtain the following expression,

$$\begin{bmatrix}j_1 & j_2 & j\\ m_1 & m_2 & m\end{bmatrix}_q=\nabla[j_2j_1j]\left(\frac{[2j+1][j_2+m_2]![j_2-m_2]![j_1-m_1]![j-m]!}{[j_1+m_1]![j+m]!}\right)^{1/2}$$

$$\times q^{\{j_2(j_2+1)-j_1(j_1+1)-j(j+1)\}/2-m_1j_2-(j_2+m_2)(j_2+m_2+2)/4}$$

$$\times\sum_x \frac{(-1)^{j_1+(j_2+m_2)/2-x}q^{x(x+1)}[2x+1][x+m']!}{\nabla^2[\frac{1}{2}(j_2+m_2),j_1,x]\nabla^2[\frac{1}{2}(j_2-m_2),j,x][x-m']!}, \tag{B2}$$

where the right-hand side is related to the left-hand side of Eq. (3.4a) with parameters

$$p_1=\tfrac{1}{2}(j_2-m_2)-j-1,\quad p_2=-m'-1,\quad p_3=\tfrac{1}{2}(j_2+m_2)-j_1-1,$$

$$p_4=\tfrac{1}{2}(j_2-m_2)+j,\quad p_5=\tfrac{1}{2}(j_2+m_2)+j_1.$$

Expression (B2) is invariant under 12 relations of the Regge symmetry, corresponding to the permutations in the sets p_1,p_2,p_3 or p_4,p_5. After expressing the CG coefficient of $u_q(2)$ by means of Eq. (5.17) of Ref. 30 [which after some cyclic permutation, is equivalent to Eq. (65) of Chapter 3 of Ref. 17 or, for $q=1$, related to Eq. (13.1c) of Ref. 2], and using the symmetry relation (4.13) of Ref. 15 (which allows one to interchange the parameters j_2,m_2 and $j,-m$ in the CG coefficients, cf. Ref. 17), we derive our Eq. (3.4a) straightforwardly. The remaining very well-poised series with different numerator and denominator distributions of q-factorial arguments [e.g., the nonalternating left-hand side of (3.4b) or the nonalternating right-hand side of Eq. (5.3) of Ref. 12 with $p_3=-p_2-2$, and their other analytical continuations] are not related to the Clebsch–Gordan coefficients of $u_q(2)$, although sometimes they may be related to the CG coefficients of $u_q(1,1)$.

Modified braid equations for $SO_q(3)$ and noncommutative spaces

A. Chakrabarti[a)]
Centre de Physique Théorique, Laboratoire Propre du CNRS UPR A.0014, Ecole Polytechnique, 91128 Palaiseau Cedex, France

(Received 14 March 2001; accepted for publication 4 September 2001)

General solutions of the $\hat{R}TT$ equation with a maximal number of free parameters in the specrtal decomposition of vector $SO_q(3)$ $\hat{R}$ matrices are implemented to construct modified braid equations (MBE). These matrices conserve the given, standard, group relations of the nine elements of T, but are not constrained to satisfy the standard braid equation (BE). Apart from q and a normalization factor our $\hat{R}$ contains two free parameters, instead of only one such parameter for deformed unitary algebras studied in a previous paper [Math. QA/0009178] where the nonzero right hand side of the MBE had a linear term proportional to $(\hat{R}_{(12)} - \hat{R}_{(23)})$. In the present case the rhs is, in general, nonlinear. Several particular solutions are given (Sec. II) and the general structure is analyzed (Appendix A). Our formulation of the problem in terms of projectors yields also two new solutions of standard (nonmodified) braid equation (Sec. II) which are further discussed (Appendix B). The noncommutative three-spaces obtained by implementing such generalized $\hat{R}$ matrices are studied (Sec. III). The role of coboundary $\hat{R}$ matrices (not satisfying the standard BE) is explored. The MBE and Baxterization are presented as complementary facets of the same basic construction, namely, the general solution of $\hat{R}TT$ equation (Sec. IV). A new solution is presented in this context. As a simple but remarkable particular case a nontrivial solution of BE is obtained (Appendix B) for $q=1$. This solution has no free parameter and is not obtainable by twisting the identity matrix. In the concluding remarks (Sec. V), among other points, generalization of our results to $SO_q(N)$ is discussed. [DOI: 10.1063/1.1413225]

I. INTRODUCTION

In a previous paper[1] a particular class of inhomogeneous, modified, braid equations (MBE) was shown to correspond to general solutions of $\hat{R}TT$ relations. Fundamental 2×2 T matrices and the corresponding 4×4 $\hat{R}(=PR)$ matrices for $GL_{p,q}(2)$, $GL_{g,h}(2)$ and $GL_{q,h}(1/1)$ were used as examples. The inputs were the known group relations of the elements (a,b,c,d) for each of the above cases. Then the most general solution (without imposing the Yang–Baxter (YB) equation for R or, equivalently, the braid equation for $\hat{R}$) was sought, for each case, of the relation

$$\hat{R}T_1T_2 = T_1T_2\hat{R}, \tag{1}$$

where

$$T_1 = T\otimes I_2, \quad T_2 = I_2\otimes T.$$

a)Electronic mail: chakra@cpht.polytechnique.fr

The only constraint on $\hat{R}$ was the conservation of the given group relations for (a,b,c,d). In each case $\hat{R}$ was found to depend, apart from the two parameters $((p,q),(g,h),(q,h))$, linearly on a third one (K) such that, for a suitable normalization, one obtains

$$\hat{R}_{(12)}\hat{R}_{(23)}\hat{R}_{(12)}-\hat{R}_{(23)}\hat{R}_{(12)}\hat{R}_{(23)}=\left(\frac{K}{K_1}-1\right)\left(\frac{K}{K_2}-1\right)(\hat{R}_{(23)}-\hat{R}_{(12)}). \tag{2}$$

This is the MBE with

$$(K_1,K_2)=(1,p/q),\quad (1,1),\quad (1,1/q), \tag{3}$$

respectively, for the above-mentioned cases.

It was pointed out in Ref. 1 that (2) reexpressed in terms of R provides a particular, interesting class of modified quantum YB equations (MQYBE) of Gerstenhaber, Giaquinto, and Schack (see Ref. 2 and sources cited therein).

The special features of (2) as indicated in Ref. 1, are as follows.

(1) The explicit stucture on the right carries interesting information. After obtaining the general solution of (1) and the MBE it corresponds to, one obtains the unmodified, standard braid or YB matrices as byproducts. One just sets $K=K_1$ or $K=K_2$, the two solutions being related through

$$\hat{R}(K_2)=\hat{R}(K_1)^{-1}. \tag{4}$$

(2) Setting, as explained in Ref. 1,

$$K=2K_1K_2(K_1+K_2)^{-1}, \tag{5}$$

one obtains

$$(\hat{R}(K))^2=I. \tag{6}$$

Hence the construction of ''triangular'' (or ''unitary'' or ''coboundary'') R matrices is again reduced to the choice of a particular value of K in the general solution. This aspect will be studied further later in this work.

(3) It was pointed out in Ref. 1 that MBE and Baxterization are complementary facets of the same basic construction, namely, the general solution of (1). This links MBE to integrable models. This aspect will be taken up in Sec. IV with new examples.

(4) The parameter K plays an interesting role in noncommutative spaces obtained by implementing the general $\hat{R}(K)$. The detailed discussion in Ref. 1 of this aspect will be generalized to higher dimensions in Sec. III.

A. Spectral decomposition and generalization to higher dimensions

Our construction can be generalized to higher dimensional cases most conveniently by introducing arbitrary constant coefficients in the spectral decomposition of R matrices for *vector representations*. The standard solutions (not ''modified'' in our sense) are well-known.[3,4] Instead of wading through larger and larger numbers of group relations $[n^2(n^2-1)/2$ for n^2 elements of $T]$ one starts with the following results for vector representations.

For $\mathrm{GL}_q(N)$ one has, in terms of the projectors $P^{(\pm)}$,

$$\hat{R}=qP^{(+)}-q^{-1}P^{(-)}, \tag{7}$$

where

$$P^{(+)}P^{(-)}=0,\quad (P^{(\pm)})^2=P^{(\pm)},\quad P^{(+)}+P^{(-)}=I. \tag{8}$$

Here $\hat{R}$ satisfies the braid equation and

$$(\hat{R}-qI)(\hat{R}+q^{-1}I)=0. \tag{9}$$

One has also

$$P^{(+)}=\frac{(\hat{R}+q^{-1}I)}{(q+q^{-1})}, \quad P^{(-)}=-\frac{(\hat{R}-qI)}{(q+q^{-1})}. \tag{10}$$

If one sets, *with the same projectors*,

$$\hat{R}(u,v)=uP^{(+)}+vP^{(-)}, \tag{11}$$

where (u,v) are nonzero, unequal but otherwise arbitrary parameters, one obtains

$$(\hat{R}(u,v)-uI)(\hat{R}(u,v)-vI)=0, \tag{12}$$

$$P^{(+)}=\frac{(\hat{R}(u,v)-vI)}{(u-v)}, \quad P^{(-)}=\frac{(\hat{R}(u,v)-uI)}{(v-u)}. \tag{13}$$

Of the two parameters (u,v) one can be fixed by choosing a suitable normalization, leading effectively to one independent, arbitrary parameter. Apart from differences in notations, our construction of $\hat{R}(K)$ in Ref. 1 (see Sec. 3.2 in Ref. 1), namely,

$$\hat{R}(K)=(1-(K/K_1+K/K_2))P_1+P_2, \tag{14}$$

corresponds directly to (11). This and certain other aspects of our previous formalism *can be directly generalized* to $\mathrm{GL}_q(N)$, though the noncommutative spaces will now be of N dimensions.

For $\mathrm{SO}_q(N)$ [and for $\mathrm{Sp}_q(N)$ which we do not consider here] there is a major change. One has now *three* projectors in the spectral decomposition of $\hat{R}$ matrices for vector representations. The consequences for MBE will be seen to be important.

For $\hat{R}$ satisfying the braid equation one obtains[3,4]

$$(\hat{R}-qI)(\hat{R}+q^{-1}I)(\hat{R}-q^{1-N}I)=0 \tag{15}$$

and

$$\hat{R}=qP^{(+)}-q^{-1}P^{(-)}+q^{1-N}P^{(0)}, \tag{16}$$

where [with (i,j) denoting a pair from $(+,-,0)$]

$$P^{(i)}P^{(j)}=P^{(i)}\delta_{ij}, \quad P^{(+)}+P^{(-)}+P^{(0)}=I. \tag{17}$$

Generalizing as before, we introduce [with nonzero and unequal (u,v,w) and the projectors being the *same* as before, independent of (u,v,w)]

$$\hat{R}(u,v,w)=uP^{(+)}+vP^{(-)}+wP^{(0)}. \tag{18}$$

Now [denoting $\hat{R}(u,v,w)$ as $\hat{R}$],

$$(\hat{R}-uI)(\hat{R}-vI)(\hat{R}-wI)=0 \tag{19}$$

and

$$P^{(+)}=\frac{(\hat{R}-vI)(\hat{R}-wI)}{(u-v)(u-w)},$$

$$P^{(-)}=\frac{(\hat{R}-uI)(\hat{R}-wI)}{(v-u)(v-w)}, \tag{20}$$

$$P^{(0)}=\frac{(\hat{R}-uI)(\hat{R}-vI)}{(w-u)(w-v)}.$$

Here, fixing the normalization, *two* independent parameters are left.

In the next section we will study the MBE corresponding to (18). We will set $N=3$. This will permit us to display explicitly matrices of managaeble size. *The essential new features will, however, be present already for* $N=3$.

Let us now note how the number of coboundary (or unitary) solutions for vector representations changes with the number of projectors.

For $\mathrm{GL}_q(N)$ it is seen from (8) and (11) that

$$(\hat{R}(u,v))^2=u^2P^{(+)}+v^2P^{(-)}=P^{(+)}+P^{(-)} \tag{21}$$

for

$$u^2=v^2=1.$$

Hence, apart from an overall $(\pm)$ sign, the only nontrivial solution is

$$\hat{R}_c=P^{(+)}-P^{(-)}=I-2P^{(-)}=-(I-2P^{(+)}), \quad \hat{R}_c^2=I. \tag{22}$$

For $\mathrm{SO}_q(n)$, from (17) and (18) apart from an overall sign one obtains analogously *three* solutions

$$\hat{R}_c=(I-2P^{(+)}), \quad (I-2P^{(-)}), \quad (I-2P^{(0)}). \tag{23}$$

Each satisfies

$$\hat{R}_c^2=I$$

and the product of any two gives the third one with a change of sign. Thus, for example,

$$(I-2P^{(+)})(I-2P^{(-)})=-(I-2P^{(0)}). \tag{24}$$

If the coefficient (-2) in (23) is replaced by an arbitrary number, $\hat{R}$ still satifies as is easily seen a *quadratic* equation, not the cubic (19).

If complex solutions are considered for real q but with complex coefficients in (18), one obtains the unitarity relation when (u,v,w) are phases in (18). Thus (with real deltas)

$$\hat{R}=e^{i\delta_1}P^{(+)}+e^{i\delta_2}P^{(-)}+e^{i\delta_3}P^{(0)} \tag{25}$$

gives, since the projectors are symmetric for the orhogonal case,

$$\hat{R}^\dagger\hat{R}=I.$$

In (18), (u,v,w) were postulated to be unequal. This permits one to express *all the three* projectors in terms of $\hat{R}$ as in (20). But this is not obligatory. As noted in (23) other cases (with

$u=v=-w=1$ and so on) can indeed be of special interest. For (23) in each case one has *two* mutually orthogonal combinations. Selecting the second case, for example, one obtains

$$P^{(-)}=-\tfrac{1}{2}(\hat{R}_c-I), \quad P^{(+)}+P^{(0)}=\tfrac{1}{2}(\hat{R}_c+I). \tag{26}$$

We conclude with a fully explicit statement of our approach. If one has

$$\hat{R}T_1T_2=T_1T_2\hat{R},$$

then any function $f(\hat{R})$ of $\hat{R}$ satisfies

$$f(\hat{R})T_1T_2=T_1T_2f(\hat{R}). \tag{27}$$

To start with let us suppose (for definiteness, such a starting point not being essential) that $\hat{R}$ satifies BE.

For $\mathrm{GL}_q(N)$, $\hat{R}$ satisfies a quadratic constraint (9). Hence any power series in $\hat{R}$ can be reduced to a linear function in $\hat{R}$. Hence, apart from an overall normalization factor, the most general solution of (27), for a given set of group relations, becomes effectively (14) as studied in Ref. 1. [It is easy to see from (7) and (10) that even fractional powers of $\hat{R}$ can be obtained as a linear funtion of $\hat{R}$ but, in general, with complex coefficients. Having noted this, we will usually implicitly consider real coefficients. An analogous situation will hold for the orthogonal case considered later. Complex coefficients, such as in (25), will not be introduced explicitly. Except when roots of unity are involved, complexification of our formalism is, however, straightforward.]

For $\mathrm{SO}_q(N)$, $\hat{R}$ satisfies a cubic constraint (15). Hence the general solution, using analogous arguments, is seen effectively to be, with constant coefficients c_i,

$$f(\hat{R})=c_1(\hat{R})^2+c_2\hat{R}+c_3I. \tag{28}$$

Using the spectral decomposition (16) along with (17),

$$\begin{aligned} f(\hat{R})=c_1(q^2P^{(+)}+q^{-2}P^{(-)}+q^{2(1-N)}P(0))+c_2(qP^{(+)}-q^{-1}P^{(-)} \\ +q^{(1-N)}P(0))+c_3(P^{(+)}+P^{(-)}+P^{(0)}). \end{aligned}$$

Hence, collecting together the coefficients one obtains the form

$$f(\hat{R})=uP^{(+)}+vP^{(-)}+wP^{(0)}. \tag{29}$$

This is the motivation for (18). The starting point is the most general solution, for a given set of group relations, as given by (29). The right hand side of the MBE will be a *consequence* (see Appendix A). In this larger space one then looks for points with particularly attractive properties (for example, those corresponding to $\hat{R}_c$) and, more generally, explores the consequences of the free parameters in (29) such as in related noncommutative geometries (Sec. III).

II. MBE FOR $\mathrm{SO}_q(3)$

We fix the normalization by choosing the top left element (row 1, col. 1) to be unity. In order to simplify the explicit form of $\hat{R}$ we denote the remaining parameters in (18) as follows:

$$\begin{aligned} \hat{R}&=P^{(+)}+(1+a(1+q^2))P^{(-)}+(1+b(1+q+q^2))P^{(0)} \\ &=I+a(1+q^2)P^{(-)}+b(1+q+q^2)P^{(0)}. \end{aligned} \tag{30}$$

The projectors are given explicitly at the end of Appendix A. The 9×9 symmetric $\hat{R}$ is now

$$\hat{R}(a,b;q)$$

$$= \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & (1+a) & 0 & -aq & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & (1+aq+b) & 0 & (b+a(q-1))\sqrt{q} & 0 & (b-a)q & 0 & 0 \\ 0 & -aq & 0 & (1+aq^2) & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & (b+a(q-1))\sqrt{q} & 0 & (1+a(q-1)^2+bq) & 0 & (bq-a(q-1))\sqrt{q} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & (1+a) & 0 & -aq & 0 \\ 0 & 0 & (b-a)q & 0 & (bq-a(q-1))\sqrt{q} & 0 & (1+aq+bq^2) & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -aq & 0 & (1+aq^2) & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{31}$$

This $\hat{R}(a,b;q)$ satisfies the braid equation for

$$\text{case 1:} \quad a=-q^{-2}, \quad b=-q^{-2}+q^{-3}, \qquad \text{case 2:} \quad a=-1, \quad b=-1+q, \tag{32}$$

the two sets giving mutually inverse matrices.

For this $\hat{R}$ [the parameters (a,b) being implicit and I being the 3×3 unit matrix] we define

$$\hat{R}_{12}=\hat{R}\otimes I, \quad \hat{R}_{23}=I\otimes\hat{R}. \tag{33}$$

The general structure of the MBE is presented in Appendix A. We present here three cases obtained for particular constraints on (a,b). One has

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12}-\hat{R}_{23}\hat{R}_{12}\hat{R}_{23}=l_1(\hat{R}_{12}-\hat{R}_{23})+l_2(\hat{R}_{12}{}^2-\hat{R}_{23}{}^2), \tag{34}$$

where for case 1, $a=0$ and arbitrary b,

$$l_2=0, \quad l_1=(1+b(1+q+q^2)+b^2q^2); \tag{35}$$

and for case 2, $b=(1-q)a$,

$$l_2=(1+a), \quad l_1=(3+2(2+q^2)a+(1+2q^2)a^2); \tag{36}$$

Setting $a=-1$ one obtains case 2 of (32) with

$$l_1=0, \quad l_2=0.$$

For case 3, $b=(1-q^{-1})a$,

$$l_2=(1+q^2a), \quad l_1=(3+2(1+2q^2)a+q^2(2+q^2)a^2). \tag{37}$$

Setting $a=-q^{-2}$ one obtains case 1 of (32) with

$$l_1=0, \quad l_2=0.$$

Let us note the following features:

The right hand side of (34) is linear only for $a=0$ (case 1). This is evidently not included in the standard cases (32). *Yet the braid equation is satisfied* for

$$a=0, \quad (b^2q^2+b(1+q+q^2)+1)=0,$$

hence (when $q\neq 0$) for

$$b=-\frac{1}{2q^2}(1+q+q^2)\pm\frac{1}{2q^2}((1+3q+q^2)(1-q+q^2))^{1/2}. \tag{38}$$

This gives real b for $q>0$. (See Appendix B for further discussion.)

To complete the picture, we note that the braid matrix becomes for

$$q=0,\quad a=0,\quad b=-1,$$
$$\hat{R}(0,-1;0)=\mathrm{diag}(1,1,0,1,1,1,1,1,1). \tag{39}$$

When a and b are independent and arbitrary even the quadratic terms of the rhs of (34) do not suffice (Appendix A).

III. NONCOMMUTATIVE THREE-SPACE FROM $\hat{R}(a,b;q)$:

When $\hat{R}$ satisfies the braid equation [for (32)] the quantum vector space is discussed in Refs. 3–5. [See, in particular, Sec. (9.3.2) of Refs. 4 and Ex. (4.1.22) of Ref. 5. Our results below are to be compared to these treatments.] We will treat the more general case with parameters (a,b). The explicit form of the rhs of the MBE (Sec. II) is not directly relevant here. We treat (a,b) as free parameters to start with. With a slight change of notation (with respect to Sec. I) we set in (30)

$$v=a(1+q^2),\quad w=b(1+q+q^2),$$

giving

$$\hat{R}=I+vP^{(-)}+wP^{(0)}=P^{+}+(1+v)P^{(-)}+(1+w)P^{(0)}. \tag{40}$$

The coordinates are denoted (x_-,x_0,x_+). Let $(x\otimes x)$ (without "tilde" for simplicity) denote the nine-component *column* obtained from the tensor product. Let (ξ_-,ξ_0,ξ_+) denote the differentials (dx_-,dx_0,dx_+). Let the columns for the other tensor products be denoted, in evident notations, as $(\xi\otimes\xi)$, $(x\otimes\xi)$, $(\xi\otimes x)$.

As in Ref. 1 we will adopt prescriptions that give commutators of (x_i,x_j) and of (ξ_i,ξ_j) independent of (v,w) while those of (x_i,ξ_j) do depend on them.

Let

$$(\hat{R}-I)(\hat{R}-(1+w)I)(x\otimes x)=0$$

or

$$P^{(-)}(x\otimes x)=0. \tag{41}$$

This agrees with Refs. 3–5. Now set

$$(x\otimes\xi)=M(\xi\otimes x). \tag{42}$$

Exterior derivation gives

$$(\xi\otimes\xi)=-M(\xi\otimes\xi) \tag{43}$$

or

$$(M+I)(\xi\otimes\xi)=0.$$

Now exterior derivation of (41) along with (42) gives the typical constraint

$$(\hat{R}-I)(\hat{R}-(1+w)I)(M+I)=0. \tag{44}$$

Hence one can choose (k being an arbitrary constant parameter)

$$(M+I)=k(\hat{R}-(1+v)I)=k(-vP^{(+)}+(w-v)P^{(0)}). \tag{45}$$

From (43) and (45), due to the orthogonality of the projectors, one obtains (in agreement with Refs. 4 and 5)

$$P^{(+)}(\xi\otimes\xi)=0, \quad P^{(0)}(\xi\otimes\xi)=0. \tag{46}$$

From (41) and (46) one obtains (as in the standard treatments cited earlier)

$$\begin{gathered} x_-x_0=qx_0x_-, \quad x_0x_+=qx_+x_0, \\ x_+x_--x_-x_+=hx_0^2, \end{gathered} \tag{47}$$

with

$$h\equiv\left(\sqrt{q}-\frac{1}{\sqrt{q}}\right)$$

and

$$\begin{gathered} \xi_-^2=0, \quad \xi_+^2=0, \quad \xi_-\xi_++\xi_+\xi_-=0, \\ q\xi_-\xi_0+\xi_0\xi_-=0, \quad q\xi_0\xi_++\xi_+\xi_0=0, \\ \xi_0^2=h\xi_-\xi_+. \end{gathered} \tag{48}$$

Now we come to the part specific to our formalism. We define

$$\begin{gathered} \Phi_-=(\xi_-x_0-q\xi_0x_-), \quad \Phi_+=(\xi_0x_+-q\xi_+x_0), \\ \Phi_0=(\xi_-x_++\sqrt{q}\xi_0x_0+q\xi_+x_-), \quad \Phi_0'=(\xi_-x_++h\xi_0x_0-\xi_+x_-). \end{gathered} \tag{49}$$

Then, implementing the definition of M in terms of $\hat{R}(a,b)$ and the explicit form of the latter one obtains from (42), denoting

$$k_1=-(kv+1)=-(ka(q^2+1)+1),$$

the module structure

$$\begin{gathered} x_-\xi_-=k_1\xi_-x_-, \quad x_-\xi_0=k_1\xi_-x_0+ka\Phi_-, \\ x_-\xi_+=k_1\xi_-x_++kaq\Phi_0'+kb\Phi_0, \quad x_0\xi_-=k_1\xi_0x_--kaq\Phi_-, \\ x_0\xi_0=k_1\xi_0x_0+ka(q-1)\sqrt{q}\Phi_0'+kb\sqrt{q}\Phi_0, \\ x_0\xi_+=k_1\xi_0x_++ka\Phi_+, \quad x_+\xi_-=k_1\xi_+x_--kaq\Phi_0'+kbq\Phi_0, \\ x_+\xi_0=k_1\xi_+x_0-kaq\Phi_+, \quad x_+\xi_+=k_1\xi_+x_+. \end{gathered} \tag{50}$$

One can verify that one obtains the relations given in Ex. 4.1.22 of Ref. 5 (p. 133) on setting

$$k=q^2, \quad a=-q^{-2}, \quad b=-q^{-2}+q^{-3}. \tag{51}$$

For

$$k=1, \quad a=-2(1+q^2)^{-1}, \quad b=0 \tag{52}$$

one obtains the case (26) of $\hat{R}_{(c)}$ (with $\hat{R}_{(c)}{}^2=I$) where

$$P^{(-)}=\tfrac{1}{2}(\hat{R}_{(c)}-1), \quad (M+I)=2(P^{(+)}+P^{(0)}). \tag{53}$$

Hence (47) and (48) are conserved along with a particularly simple form of (50). Here one moves out of the restricted space of solutions of BE (or YBE) to implement the particular simplicity of $\hat{R}_{(c)}$. (See the relevant remarks in Sec. V.)

IV. MBE AND BAXTERIZATION

In Ref. 1 we briefly pointed out that MBE and Baxterization are two complementary aspects of the same basic construction: the general solution of $\hat{R}TT$ equation for a given set of group relations of the elements of T. For the cases considered in Ref. 1 [generalizable to $\mathrm{GL}_q(N)$] the correspondence is relatively simple. In (2) the same, single parameter K appears in each member on the left leading to the nonzero rhs (thus modifying the BE) as shown in (2). In a complementary approach, one can vary K in different members on the left in a prescribed fashion (indicated in Ref. 1) so that the rhs remains zero. This is Baxterization. The *same* parameter that leads to MBE thus leads also to integrable systems in a complementary fashion.

One can make a parallel study for $\mathrm{SO}_q(3)$ [generalizable to $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$]. But the presence of three projectors and hence (apart from a normalization factor) of two arbitrary parameters leads to a more complex situation. Even restricted cases give the MBE of (34) with quadratic terms on the right, the general structure being given in Appendix A. Let us now look at the complementary situation, namely, Baxterization.

In Sec. 3.9 of Ref. 6 solutions of

$$\hat{R}_{(12)}(x)\hat{R}_{(23)}(xy)\hat{R}_{(12)}(y)=\hat{R}_{(23)}(y)\hat{R}_{(12)}(xy)\hat{R}_{(23)}(x) \tag{54}$$

are given. In our notations and conventions they can be expressed as

$$\hat{R}(x)=I+v(x)P^{(-)}+w(x)P^{(0)}, \tag{55}$$

where

$$v(x)=-1+\frac{f(x)}{f(x^{-1})}, \quad w(x)=-1+\frac{g(x)}{g(x^{-1})},$$

$$f(x)=(xq-x^{-1}q^{-1})$$

and

$$g(x)=(xq^3+x^{-1})$$

or

$$g(x)=(x^{-1}-qx)(xq-x^{-1}q^{-1}).$$

Here we consider $\mathrm{SO}_q(N)$ for $N=3$. But $f(x)$ is independent of N and N appears in $g(x)$ in a simple! fashion.[6] Above $v(x)$ is assumed to be nonzero. We present a distinct class of solutions which is a Baxterization of the new class of *BE* given by our (38). For

$$\hat{R}(x)=I+w(x)P^{(0)} \tag{56}$$

using (A.15) one finds from (54) the single constraint

$$w(xy)=\frac{w(x)+w(y)+w(x)w(y)}{1-k^2w(x)w(y)}, \tag{57}$$

where

$$k^2=(1+q+q^{-1})^{-2}=(1+[2])^{-2}.$$

For $N>3$, $[2]$ is replaced by $[N-1]$. The solutions are

$$\begin{aligned} w(x)&=-1+\frac{g(x)}{g(x^{-1})}\\ g(x)&=-(x-x^{-1})\pm\sqrt{1-4k^2}(x+x^{-1}). \end{aligned} \tag{58}$$

For real q,

$$(1-4k^2)=\frac{((q^{1/2}+q^{-1/2})^2+1)((q^{1/2}-q^{-1/2})^2+1)}{(1+q+q^{-1})^2}$$

is positive and the square root real. Note that for any $(v(x),w(x))$

$$(\hat{R}(x))^{-1}=I-\frac{v(x)}{1+v(x)}P^{(-)}-\frac{w(x)}{1+w(x)}P^{(0)} \tag{59}$$

provided that the denominators are nonzero. Considering the inverse of both sides of (54) one finds that if $(v(x),w(x))$ are to be general solutions one must have

$$-\frac{v(x)}{1+v(x)}=v(x'),\quad -\frac{w(x)}{1+w(x)}=w(x'), \tag{60}$$

where x' is some suitable function of x. The forms following (55), independently of the explicit expressions for (f,g) assure that

$$x'=x^{-1}$$

and

$$\hat{R}(x)\hat{R}(x^{-1})=I. \tag{61}$$

The same is valid for (58). In (55), respectively, for

$$x\gg 1,\quad x\ll 1$$

one obtains the limits

$$v=-(1+q^{\epsilon 2}),\quad w=-(1-q^{\epsilon 3})$$

(where $\epsilon=\pm 1$) the braid values noted in (A.9), (A.10). Let us finally note that setting

$$\epsilon\sqrt{1-4k^2}=\tanh!ta,\quad x=\exp(\theta)$$

one obtains from (58) the elegant Baxterization

$$w(x)=-1+\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}. \tag{62}$$

For $q=1$ with

$$\text{than}\,\eta=\epsilon\frac{5}{\sqrt{3}}$$

one obtains Baxterization of the case studied in Appendix B.

V. REMARKS

We conclude by noting the following points.

(1) After the introductory remarks (Sec. I) on the spectral decomposition of $\hat{R}$ for vector representations of $GL_q(N)$, $SO_q(N)$ and $Sp_q(N)$, from Sec. II onwards we restricted our study to $SO_q(3)$. But a substantial part of our results are evidently generalizable to $SO_q(N)$ with $N>3$. The crucial feature is the number of projectors in the spectral decomposition. The MBE for $GL_q(2)$ with two projectors and that for $SO_q(3)$ with three exhibit major differences, made explicit here. But in $SO_q(N)$ the number of projectors does not vary with N. Still, a careful study of the case of $SO_q(4)$ and comparison of the results with those for $SO_q(3)$ would be of real interest. This is beyond the scope of this article.

(2) In Ref. 1 we started with the criterion of using the most general solution $\hat{R}$ of the $\hat{R}TT$ relations for a given set of group relations of the elements of T. This, being implemented in the standard trilinear structure of the braid equation, modified the right hand side, making it nonzero but *linear* in the R's as shown in (2). *No a priori postulate was made concerning the rhs of the equation*. The explicit form was a *consequence* of the free parameter K in $\hat{R}$. It was then noted in Ref. 1 that the MBE thus obtained [Eq. (2) of this article] coincided with that introduced in Ref. 2 (and sources cited there). Now this is seen to be a *coincidence* valid for the cases studied in Ref. 1 [generalizable to $GL_q(N)$]. All those cases involved two projectors (the sum being I). As soon as this number increases [such as already for $SO_q(3)$], the rhs has a more complex structure. Our starting point (the general solution of $\hat{R}TT$) is exactly the same here. But only in the very particular case (35) one has a linear structure on the right.

(3) In Sec. III we present all the relations involving the coordinates and the differentials. But much remains to be done to better understand the noncommutative space thus obtained. The properties of the Φ's introduced in (49) deserve study. To render the geometry more transparent one should construct the ''frame basis'' in terms of operators commuting with the algebra. (See Refs. 5 and 7 and sources cited there.) Thus equipped, one can study possible attractive consequences concerning the metric of implementing $\hat{R}_c$ as in (53). We hope to explore these aspects elsewhere.

(4) After Ref. 1 we emphasize here again the complementary nature of MBE and Baxterization. We provide a simple new example of the latter in (57). Let us repeat another point made in Ref. 1. The standard braid equation can be made to correspond to the third Reidemeister move in knot theory. Hence (54) can be viewed as a parametrization of this move. It would be worth exploring in the context of knot theory whether this provides access to a richer class of invariants.

(5) Here we have studied coboundary $\hat{R}$ martices in vector representations in terms of projectors. An approach using Drinfeld's transformation can be found in Ref. 8.

(6) Finally, let us recapitulate the remarkable properties of the solution provided by (38). It satifies the $\hat{R}TT$ equation for the standard group relations of $SO_q(3)$. It satisfies the standard braid equation [(34) with zero rhs]. It continues (as shown in Appendix B) to be nontrivial even for $q=1$. It can be relatively simply Baxterized as shown at the end of Sec. IV. This sets the stage for a full study of the corresponding integrable model. This also suggests a search of analogous new solutions, more generally, for $SO_q(N)$ and $Sp_q(N)$ and also for higher dimensional representations of $SO_q(3)$. We hope to explore such possibilities elsewhere.

ACKNOWLEDGMENTS

The author discussed many aspects of this article with M. A. Sokolov, who also provided, using a program, the explicit expressions of the coefficients in the solutions in Sec. II. It is a pleasure to thank him. The author also thanks John Madore for instructive discussions concerning the noncommutative geometric aspects.

APPENDIX A: GENERAL STRUCTURE OF MBE

In the notation of (30) or (40),

$$\hat{R}=I+vP^{(-)}+wP^{(0)}. \tag{A1}$$

For elucidating the sructure of the consequent MBE we start with a number of definitions and auxiliary relations.

We define

$$X_1=P^{(-)}_{(12)},\quad X_2=P^{(-)}_{(23)},\quad Y_1=P^{(0)}_{(12)},\quad Y_2=P^{(0)}_{(23)}. \tag{A2}$$

The orthonormal properties of the projectors imply [for $i=(1,2)$]

$$X_i^2=X_i,\quad Y_i^2=Y_i,\quad X_iY_i=Y_iX_i=0. \tag{A3}$$

We also define

$$S_1=X_1-X_2,\quad S_2=Y_1-Y_2, \tag{A4}$$

$$S_3=(X_1X_2Y_1+X_1Y_2X_1+Y_1X_2X_1)-(X_2X_1Y_2+X_2Y_1X_2+Y_2X_1X_2), \tag{A5}$$

$$S_4=(Y_1Y_2X_1+Y_1X_2Y_1+X_1Y_2Y_1)-(Y_2Y_1X_2+Y_2X_1Y_2+X_2Y_1Y_2), \tag{A6}$$

$$S_5=(X_1X_2X_1-X_2X_1X_2),\quad S_6=(Y_1Y_2Y_1-Y_2Y_1Y_2). \tag{A7}$$

Using these definitions and the properties (A3) one obtains quite generally,

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12}-\hat{R}_{23}\hat{R}_{12}\hat{R}_{23}=(v+v^2)S_1+(w+w^2)S_2+v^2wS_3+vw^2S_4+v^3S_5+w^3S_6. \tag{A8}$$

The S's depend on q *only*. The dependence on (v,w) is explicitly displayed in the coefficients of (A8).

Now we exploit systematically the constraints on the S's provided by the known solutions, namely, (32) and (34)–(37).

The rhs of (A8) must vanish for the braid solutions (32), namely, for

$$v=-(1+q^{-2}),\quad w=-(1-q^{-3}), \tag{A9}$$

and also for

$$v=-(1+q^2),\quad w=-(1-q^3). \tag{A10}$$

Implementing these (for $q\neq 1$) we choose to express (S_3,S_4) as

$$S_3=\frac{q^2}{(q^2+1)(q^2+q+1)}S_1-\frac{q^2}{(q^2+1)^2}S_2-\frac{(q^2+1)}{(q^2+q+1)}S_5-\frac{(q^3-1)^2}{q(q^2+1)^2}S_6, \tag{A11}$$

$$S_4=\frac{q^3}{(q^3-1)^2}S_1+\frac{q^2}{(q^2+1)(q^2+q+1)}S_2-q\frac{(q^2+1)^2}{(q^3-1)^2}S_5+\frac{(q^3-1)(q-1)}{q(q^2+1)}S_6. \tag{A12}$$

Now note that implementing (A3) one can express the rhs of (34) as

$$l_1(\hat{R}_{12}-\hat{R}_{23})+l_2(\hat{R}_{12}{}^2-\hat{R}_{23}{}^2)=(l_1v+l_2(2v+v^2))S_1+(l_1w+l_2(2w+w^2))S_2. \quad \text{(A13)}$$

Combining this result with (case 1) or (35) one obtains (since $v=0$, $l_2=0$)

$$l_1wS_2=\left((w+w^2)+\frac{q^2w^3}{(q^2+q+1)^2}\right)S_2=(w+w^2)S_2+w^3S_6. \quad \text{(A14)}$$

Hence

$$S_6=q^2(q^2+q+1)^{-2}S_2. \quad \text{(A15)}$$

From (A11), (A12) and (A15) one obtains

$$S_3=\frac{q^2}{(q^2+1)(q^2+q+1)}S_1-\frac{q(q^2-q+1)}{(q^2+1)^2}S_2-\frac{(q^2+1)}{(q^2+q+1)}S_5, \quad \text{(A16)}$$

$$S_4=\frac{q^3}{(q^3-1)^2}S_1+\frac{q(q^2-q+1)}{(q^2+1)(q^2+q+1)}S_2-q\frac{(q^2+1)^2}{(q^3-1)^2}S_5. \quad \text{(A17)}$$

Combining all the preceding results one finally obtains

$$\begin{aligned}&\hat{R}_{12}\hat{R}_{23}\hat{R}_{12}-\hat{R}_{23}\hat{R}_{12}\hat{R}_{23}\\&\quad=c_1S_1+c_2S_2+c_5S_5\\&\quad=c_1(P^{(-)}_{(12)}-P^{(-)}_{(23)})+c_2(P^{(0)}_{(12)}-P^{(0)}_{(23)})+c_5(P^{(-)}_{(12)}P^{(-)}_{(23)}P^{(-)}_{(12)}-P^{(-)}_{(23)}P^{(-)}_{(12)}P^{(-)}_{(23)}).\end{aligned} \quad \text{(A18)}$$

Here

$$\begin{aligned}c_1&=v+v^2+\frac{v^2wq^2}{(q^2+1)(q^2+q+1)}+vw^2\frac{q^3}{(q^3-1)^2},\\c_2&=w+w^2+\frac{w^2vq(q^2-q+1)}{(q^2+1)(q^2+q+1)}-wv^2\frac{q(q^2-q+1)}{(q^2+1)^2}+\frac{w^3q^2}{(q^2+q+1)^2},\\c_5&=\frac{v}{(q^3-1)^2}((q^3-1)v+(q^2+1)w)((q^3-1)v-q(q^2+1)w).\end{aligned} \quad \text{(A19)}$$

As checks one verifies that $c_1=c_2=c_5=0$ for (A9) and (A10). Moreover, $c_5=0$ for

$$(q^2+1)w=-(q^3-1)v$$

and

$$q(q^2+1)w=(q^3-1)v.$$

Thus one gets back, respectively, case 2 of (36) and case 3 of (37).

The form (A18) makes the dependence on (v,w) entirely explicit, the c's being given by (A19) and the S's depending only on q. This is particularly suitable for our purpose. The P's can be reexpressed in terms of $\hat{R}(v,w)$ using (20). But only for $c_5=0$ [cases 1–3 of (35)–(37), respectively] one obtains a relatively simple form as in (34). For S_5 there is no crucial simplification as for S_6 in (A15). Setting $w=0$ in (A18) one gets no new simplification but an identity.

Throughout this article the projectors $P^{(-)}$ and $P^{(0)}$ have served as the essential building blocks. They can be easily extracted comparing (30) and (31). But for completeness and convenience they are presented below explicitly.

$$(q^2+1)P^{(-)}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & -q & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & q & 0 & (q-1)\sqrt{q} & 0 & -q & 0 & 0 \\ 0 & -q & 0 & q^2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & (q-1)\sqrt{q} & 0 & (q-1)^2 & 0 & -(q-1)\sqrt{q} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & -q & 0 \\ 0 & 0 & -q & 0 & -(q-1)\sqrt{q} & 0 & q & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -q & 0 & q^2 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{A20}$$

$$(q^2+q+1)P^{(0)}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & \sqrt{q} & 0 & q & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \sqrt{q} & 0 & q & 0 & q\sqrt{q} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & q & 0 & q\sqrt{q} & 0 & q^2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{A21}$$

APPENDIX B: NONTRIVIAL BE FOR $q=1$

We pointed out in Sec. II that for $a=0$ and b satisfying (38) one obtains two solutions of BE (not modified, with vanishing rhs). Setting

$$q=1$$

in (38) one obtains

$$b^2+3b+1=0$$

or

$$b=\tfrac{1}{2}(-3\pm\sqrt{5})\equiv -e^{\mp m}. \tag{B1}$$

[It is amusing to note the relation of b, or rather that of $-(b+1)$ with the famous Golden Mean i.e., $\frac{1}{2}(\sqrt{5}-1)$.]

Now one obtains

$$\hat{R}(\mp m)=I-3e^{\mp m}\hat{P}^{(0)}, \tag{B2}$$

where the projector $\hat{P}^{(0)}$ is obtained from $P^{(0)}$ by setting $q=1$. Thus

$$3\hat{P}^{(0)}=\begin{pmatrix} 0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0\\ 0&0&1&0&1&0&1&0&0\\ 0&0&0&0&0&0&0&0&0\\ 0&0&1&0&1&0&1&0&0\\ 0&0&0&0&0&0&0&0&0\\ 0&0&1&0&1&0&1&0&0\\ 0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0 \end{pmatrix}.$$

From (B2) one easily obtains the nontrivial Hecke condition

$$(\hat{R}(\mp m)-I)(\hat{R}(\mp m)+(3e^{\mp m}-1)I)=0. \tag{B3}$$

Thus $\hat{R}(\mp m)$ are *not* coboundary matrices. They cannot be obtained by twisting I since

$$(\hat{R}(\mp m))^2\neq I.$$

For

$$q=1, \quad b=0, \quad a=-1 \tag{B4}$$

again [from (30), (36), and (37)] one obtains $\hat{R}$ satifying BE given by

$$\hat{R}=I-2\hat{P}^{(-)}, \tag{B5}$$

where $\hat{P}^{(-)}$ is obtained from $P^{(-)}$ setting $q=1$ in (A20).

But now, in contrast to (B3), one has

$$\hat{R}^2=I.$$

The $R(\mp m)$ satisfying YB (Yang–Baxter equation) can be obtained from (B2) as

$$R(\mp m)=P\hat{R}(\mp m)=P-3e^{\mp m}\hat{P}^{(0)}, \tag{B6}$$

where the matrix P [permuting the rows (2,4), (3,7), (6,8)] leaves $\hat{P}^{(0)}$ invariant.

In Hieterinta's classification[9] of 4×4 R matrices appear examples without free parameters. Such a case has been studied[10] in the context of ''exotic bialgebras.'' Here we have obtained 9×9 examples of such matrices.

(Received 16 February 2001; accepted for publication 14 August 2001)

In this work we establish a relationship between Cartan's geometric approach to third-order ordinary differential equations and the three-dimensional null surface formulation. We then generalize both constructions to allow for caustics and singularities that necessarily arise in these formalisms. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1408282]

I. INTRODUCTION

During the first half of the twentieth century, while trying to understand the group of transformations of differential equations, Cartan laid down the foundations of modern differential geometry and established a link between analysis and geometry. One particular example that will be discussed in this work shows Cartan's approach to the classification of solutions of ordinary differential equations (ODEs).[1–3] Consider the two-dimensional (2D) space E^2 with local coordinates (x,y) and the following third-order ODE,

$$y'''=F(x,y,y',y''), \tag{1}$$

with ''prime'' denoting the derivative with respect to the independent variable.

If one performs a coordinate transformation on E^2 one gets another ODE that is trivially related to Eq. (1). Cartan thus considered the issue of how to classify solutions of third-order ODEs into equivalence classes, with two solutions belonging to the same class if the corresponding ODEs were related by a coordinate transformation on E^2. It is clear that one can spend many hours before finding the appropriate coordinate transformation that will turn one ODE into the other. Cartan showed that with the general solution of a given third-order ODE, like that shown previously, one can explicitly construct a connection one form on a four-dimensional (4D) space E^4 with local coordinates (x,y,y',y'') (the details are presented in Sec. II). Furthermore, Cartan showed that two third-order ODEs are equivalent if their corresponding solutions yield the same geometric structure on E^4. Cartan also showed that when F satisfies a given partial differential equation (PDE) on E^4, symbolically written as $M[F]=0$, then the connection is torsion free and a unique conformal structure can be given on the solution space [three-dimensional (3D) parameter space] of the starting ODE.

It is worth mentioning that the same equation $M[F]=0$ arises in the three-dimensional version of the so-called null surface formulation (NSF) of general relativity (GR).[4] As we will see in the following, this is not mere coincidence since we will show that the 3D version of NSF is almost contained in one of Cartan's works.[1] Finding the correspondence between these two constructions was one of the motivations for writing this work.

In the NSF the main variable is a function $u=Z(\phi)$, with $\phi\in S^1$, subject to a third-order ordinary differential equation of the form

$$u'''=\Lambda(\phi,u,u',u''), \tag{2}$$

[a]Electronic mail: forni@fis.uncor.edu

where the function Λ is restricted to satisfy the "metricity condition" $M[\Lambda]=0$. The general solution of (2) is given by $u=Z(x^a,\phi)$, with the constants of integration x^a taken as coordinates of the 3D solution manifold E^3. From this solution a space–time metric for E^3 can be constructed such that the level surfaces of Z are null foliations of E^3 for each fixed value of ϕ. Furthermore, the covector $l_a \equiv \partial_a Z$ spans, for fixed values of x^a, the circle of null directions and thus the parameter $\phi \in S^1$. Except for the relabeling of functions and the topology of the starting space E^2, both formulations share many geometric features, with Cartan emphasizing the role of the connection one-form and the NSF the explicit construction of a metric on the solution space of (2).

But a key point arises by noting that, by assumption, both formulations are local constructions in the 2D manifold. It follows from this fact that the solutions to (1) are families of smooth curves and (as we will see in the following) that the level sets $Z(x^a,\phi)=\text{const}$ are smooth null surfaces of the induced metric in the 3D solution space. However, we know that characteristic surfaces develop caustics and singularities as a result of the "focusing" properties of null geodesic congruences established in GR singularity theorems.[5] Moreover, the solutions to (1) that yield these null surfaces with caustics cannot be smooth curves on E^2, so they must develop self-intersections and singular points.

A second motivation for this work is thus to consider the nondiffeomorphic generalization of these geometric constructions in order to account for the folds and nondifferentiable edges of curves on E^2 that yield null congruences with caustics. The first step is to introduce the curves on E^2 according to Arnold's theory of Lagrangian manifolds as[6]

$$u=G(p)-pG'(p), \tag{3}$$

$$\phi=-G'(p); \tag{4}$$

[$G(p)$ is called the generating function]. Although G may be smooth, the curve $(u(p),\phi(p))$ might have self-intersections and singular points if $\phi(p)$ is not injective. The question is how to find the proper G such that (3) and (4) define a null surface by setting u and ϕ constant. As we will show in this work, curves with singular points in E^2 will induce null surfaces with caustics in E^3. Conversely, we will also show that if the null surfaces have conjugate points then the corresponding families of curves on E^2 have singularities.

In this reformulation, Eq. (2) for Z is changed to an equation for G, of the same type,

$$\frac{\mathrm{d}^3 G}{\mathrm{d}p^3}=\tilde{\Lambda}(p,G,G',G'') \tag{5}$$

and the metricity condition $M[\Lambda]=0$, which becomes singular at a caustic point, yields an entirely well-behaved equation $\tilde{M}[\tilde{\Lambda}]=0$ whose solutions are the "appropriate" right-hand side of (5). As we will see in an example, among the solutions of (5) we obtain generating functions of caustics as listed in Ref. 6. This result encounters an immediate application inside the $2+1$ NSF and also in the full theory because, to be in complete agreement with the standard GR formulation, it always remained as an open problem to write the metricity conditions of NSF in a form that explicitly shows the existence of the singular solutions.[7]

The work is organized as follows: In Sec. II we first give an account of Cartan's geometric construction obtained in Ref. 1 starting from the third-order equation (2). This review is presented in modern language since the original reference was written before modern differential geometry was invented and it is very difficult to follow. (It is worth mentioning that one "variation" on Cartan's work has appeared in the literature[8] but it is different from the original construction.) We then give a brief review of the NSF in 3D and show that this formalism is a particular case of Cartan's construction. In Sec. III we proceed to generalize the local analysis of Sec. II and write the regularized metricity condition $\tilde{M}[\tilde{\Lambda}]=0$. We also find a relation between curves with caustics on E^2 and null surfaces with conjugate points on E^3. A simple example shows how to generate

germs of caustics for the solutions to (5). We conclude this work with some comments on the possibility of attaching a similar geometric structure to the original construction of the NSF in four dimensions.

II. GEOMETRIC APPROACHES TO A THIRD-ORDER ODE

In this section we present two geometric constructions that arise from a third-order ordinary differential equation

$$u'''=\Lambda(\phi,u,u',u''), \tag{6}$$

where (ϕ,u) are coordinates on the cylinder $S^1\times\mathbf{R}$. As we will see in the following, it turns out that one of these constructions is almost contained as a particular case of the other.

A. Cartan's construction

We first present Cartan's approach,[1,3] achieved by interpreting the integral curves $u(\phi,x^a)$ as points $x^a(a=1,2,3)$ of the three-dimensional solution space E^3, attaching to it a Lorenztian metric g_{ab} and giving the structure of a one-dimensional fiber bundle over E^3, with $\phi\in[0,2\pi)$ as the coordinate of the fiber. On the base space we attach a ''null frame'' satisfying

$$\mathbf{e}_1\cdot\mathbf{e}_1=\mathbf{e}_1\cdot\mathbf{e}_2=\mathbf{e}_3\cdot\mathbf{e}_3=\mathbf{e}_2\cdot\mathbf{e}_3=0,\quad \mathbf{e}_2\cdot\mathbf{e}_2+\mathbf{e}_1\cdot\mathbf{e}_3=0, \tag{7}$$

where $\mathbf{e}_i\cdot\mathbf{e}_j=g_{ab}\,\mathbf{e}_i{}^a\mathbf{e}_j{}^b=g_{ij}$. In terms of the dual basis $\sigma_a{}^i$ of the null frame, the metric can be written as

$$g_{ab}=g_{ij}\,\sigma_a{}^i\sigma_b{}^i=\sigma_a{}^2\otimes\sigma_b{}^2-2\sigma_a{}^{(1}\otimes\sigma_b{}^{3)},$$

where we have chosen $g_{13}=-1$. Note that for fixed values of ϕ, the three functions

$$(\theta^0,\theta^1,\theta^2)\equiv(u,\omega,r)\equiv(u,u',u''), \tag{8}$$

can be taken as coordinates on the base space of the bundle. Thus, each point of the bundle is locally described by (ϕ,u,ω,r).

Equation (6) yields the associated pfaffian system[9] on the bundle which, written in terms of these coordinates, reads

$$\begin{aligned}\sigma^1&=\mathrm{d}u-\omega\,\mathrm{d}\phi,\\ \sigma^2&=\mathrm{d}\omega-r\,\mathrm{d}\phi,\\ \sigma^3&=\lambda(\mathrm{d}r-\Lambda\,\mathrm{d}\phi-\alpha\,\sigma^1-\beta\,\sigma^2),\end{aligned} \tag{9}$$

where α, β, and λ are functions to be determined. The bundle of null directions is constructed by selecting σ^i as the soldering forms and the $\sigma_a{}^i$ as the projections of (9) to the base space. Note that the solution of (6) will give null surfaces $S\in E^3$ by setting $u(\phi,x^a)=\text{const}$, $\phi=\text{const}$. The bundle constructed in this way will be denoted by $\mathcal{N}(E^3,g)$.

To characterize the geometric structure defined from (6), Cartan introduces a connection and a covariant exterior derivative as

$$D\mathbf{e}_i=\omega_i{}^j\mathbf{e}_j,$$

where D is the covariant exterior derivative with respect to this connection (see Refs. 10–12) and $\omega_i{}^j$ are the connection one-forms. Furthermore, Cartan demands that the connection will be compatible with the metric in the sense that a null frame remains null under parallel transport, i.e.,

$$Dg_{ij}=2\overline{\omega}\,g_{ij},$$

where $\overline{\omega}$ is a one-form on the bundle. Therefore,

$$\omega_{ij}+\omega_{ji}=-2g_{ij}\,\overline{\omega},$$

where $\omega_{ij}=\omega_i{}^k g_{kj}$.

It follows from the above that

$$\omega_{11}=\omega_{33}=0, \quad \omega_{13}+\omega_{31}=-2\overline{\omega},$$

$$\omega_{12}=-\omega_{21}, \quad \omega_{23}=-\omega_{32}, \omega_{22}=\overline{\omega}.$$

Thus, the connection is determined by four arbitrary one-forms, namely

$$\omega_{12}, \omega_{23}, \omega_{31}, \quad \overline{\omega}.$$

Note that σ^i, ω_{23} are linearly independent forms in $\mathcal{N}(E^3, g)$. This assertion can be understood from the geometrical meaning that these forms have.

(1) $\sigma^1=\omega_{23}=0$ is the differential system for null 2 surfaces, since on this surface $D\ \mathbf{e}_3=\omega_{13}\ \mathbf{e}_3$ and $D\ \mathbf{e}_2=-\omega_{22}\ \mathbf{e}_2+\omega_{12}\ \mathbf{e}_3$.
(2) $\sigma^1=\sigma^2=\omega_{23}=0$ is the differential system for null geodesic, since on this curve $D\ \mathbf{e}_3=\omega_{13}\ \mathbf{e}_3$.
(3) $\sigma^1=\sigma^2=\sigma^3=0$ is the differential system for a point of E^3.

Note also that the vanishing of σ^1 and ω_{23} is equivalent to imposing $u=\text{const}$, $\phi=\text{const}$. Thus, ω_{23} can be chosen to be of the form $\omega_{23}=\mu(\mathrm{d}\phi+\gamma\sigma^1)$ with γ and μ being *a priori* arbitrary.

The idea is to write the nontrivial connection one-forms in terms of the basis σ^i, ω_{23} and then to impose certain conditions on the torsion and curvature of the connection to uniquely determine the functions α, β, γ, λ, and μ.

Using Cartan's structure equations,

$$\Theta^i=\mathrm{d}\sigma^i+\omega^i{}_j\wedge\sigma^j, \tag{10}$$

$$\Omega^i{}_j=\mathrm{d}\omega^i{}_j+\omega^i{}_k\wedge\omega^k{}_j, \tag{11}$$

and imposing

$$\Theta^1=\Theta^2=0, \quad \Theta^3=A\ \sigma^1\wedge\omega_{23} \tag{12}$$

on the torsion two-forms, we find that

$$\lambda=\mu=1,$$

$$\alpha=\tfrac{1}{3}\partial_r\Lambda,$$

$$\beta=\alpha^2-\frac{1}{2}\frac{\mathrm{d}\alpha}{\mathrm{d}\phi}+\frac{1}{2}\partial_\omega\Lambda,$$

where

$$\frac{\mathrm{d}F}{\mathrm{d}\phi}(u,\omega,r,\phi)=\partial_\phi F+\omega\ \partial_u F+r\ \partial_\omega F+\Lambda\,\partial_r F \tag{13}$$

for any function $F(u,\omega,r,\phi)$. Equation (12) has the following geometrical meaning: Given a point in E^3 and two vectors, we construct a geodesic parallelogram from that point (see Ref. 13); then in order to come back to the same point, we only need a translation in the null direction $\mathbf{e}_3$. If the parallelogram is on the null surface (when $\sigma^1=0$ and $\omega_{23}=0$), no translation is needed.

Furthermore, if we require

$$\Omega_{23}=B\sigma^1\wedge\sigma^2+C\sigma^1\wedge\sigma^3, \tag{14}$$

we find that

$$\gamma=\tfrac{1}{2}\partial_r\alpha.$$

The geometrical meaning of (14) is that the above-mentioned curvature two-form should vanish when $\mathbf{e}_3$ is parallely transported around a parallelogram with one of its sides being the null geodesic generated by $\mathbf{e}_3$.[1]

Summarizing, conditions (12) and (14) suffice to uniquely determine the non trivial components of the connection one-form. They are given by

$$\begin{aligned}
\omega_{23}&=\mathrm{d}\phi+\gamma\sigma^1,\\
\overline{\omega}&=-\alpha\,\mathrm{d}\phi+\left(2\frac{\mathrm{d}\gamma}{\mathrm{d}\phi}-\partial_\omega\alpha\right)\sigma^1-2\gamma\sigma^2,\\
\omega_{31}&=\alpha\,\mathrm{d}\phi+\left(\frac{\mathrm{d}\gamma}{\mathrm{d}\phi}+\alpha\gamma\right)\sigma^1+\gamma\sigma^2,\\
\omega_{12}&=-\beta\,\mathrm{d}\phi+(\partial_u\alpha-\partial_\omega\beta+3\beta\gamma-\alpha\partial_r\beta)\sigma^1+\left(2\frac{\mathrm{d}\gamma}{\mathrm{d}\phi}-\partial_\omega\alpha\right)\sigma^2-\gamma\sigma^3.
\end{aligned} \tag{15}$$

Using the equations in (15) one determines the remaining coefficients for the torsion and curvature in terms of Λ. In particular, the only nontrivial coefficient of the torsion is given by

$$A=\frac{1}{6}\frac{\mathrm{d}^2\partial_r\Lambda}{\mathrm{d}\phi^2}-\frac{1}{3}\partial_r\Lambda\frac{\mathrm{d}\partial_r\Lambda}{\mathrm{d}\phi}-\frac{1}{2}\frac{\mathrm{d}\partial_\omega\Lambda}{\mathrm{d}\phi}+\frac{2}{27}(\partial_r\Lambda)^3+\frac{1}{3}\partial_\omega\Lambda\partial_r\Lambda+\partial_u\Lambda.$$

A connection compatible with a Lorenztian metric constructed in this way was called by Cartan a normal metric connection. The main result of Cartan can be stated as follows:

Theorem 2.1: *To each third-order ordinary differential equation [up to diffeomorphism in (ϕ,u)] one can associate a null bundle with a unique normal metric connection and vice versa, i.e., to each bundle of null directions with normal metric connection one can associate a third-order ordinary differential equation up to diffeomorphism.*

One special class of Cartan's connection is particularly interesting to us. If we impose $A=0$, the connection is torsion free and Monge's equation

$$g_{ab}Y^aY^b=0$$

is constant along the fiber, since

$$\frac{\mathrm{d}g_{ab}}{\mathrm{d}\phi}=-\frac{2}{3}\partial_r\Lambda g_{ab}+2A\sigma_a{}^1\otimes\sigma_b{}^1. \tag{16}$$

Thus, the condition $A=0$ defines a unique conformal structure on the solution space of (6). Moreover, $A=0$ is also the condition that the third-order ODE must satisfy so that the contact of two neighboring integral curves can be given by a Monge's equation of the second order between the parameters of those curves.[14]

Note that even in the case that the connection is torsion free, the metric so obtained depends on ϕ, i.e., we have a monoparametric family of conformally related metrics.

B. NSF's construction

We now turn our attention to the NSF formulation, in which we have a function $u=Z(\phi)$ satisfying a third-order ODE

$$u'''=\Lambda(\phi,u,u',u''), \tag{17}$$

with $\phi\in S^1$ and Λ a smooth generic function. The solutions to this equation are of the form $u=Z(x^a;\phi)$, with $x^a(a=1,2,3)$ representing three constants of integration which define the 3D manifold of solutions E^3 (equivalent to R^3).

Note that the function $Z(x^a;\phi)$ plays a double role, namely:

(1) For each fixed x^a in E^3, $u=Z(x^a;\phi)$ yields a curve C_x on E^2 with coordinates (u,ϕ); these curves will be called cuts.
(2) Fixing (u,ϕ) in E^2, the relation $u=Z(x^a;\phi)$ now defines a surface $S_{(u,\phi)}$ living in E^3.

It is important to realize that the analysis is merely done at a local level, so that the curve C_x is certainly the graph of a function in E^2 and $S_{(u,\phi)}$ turns out to be a smooth surface in E^3.

The key assumption of NSF comes when we require that, for any value of u and ϕ, $S_{(u,\phi)}$ be indeed a null surface of some space–time metric $g_{ab}(x^a)$ to be attached to E^3. This condition implies that for fixed values of x^a and arbitrary values of ϕ the gradient of Z satisfies

$$g^{ab}(x^a)\nabla_a Z(x^a;\phi)\nabla_b Z(x^a;\phi)=0. \tag{18}$$

Note that as the families of foliations intersect at a single but arbitrary point x^a, the enveloping surface forms the light cone of the point x^a. Thus, the parameter ϕ spans the circle of null directions.

The idea now is to consider (18) as an algebraic equation from which the five components of the conformal metric can be determined in terms of $\nabla_a Z(x^a,\phi)$. Given an arbitrary function Z, the problem has no solution since we have an infinite number of algebraic equations (one for each value of ϕ) for five unknowns. Therefore, we must impose conditions on $Z(x^a,\phi)$ so that a solution exists. The solution and conditions are obtained by repeatedly operating $\mathrm{d}/\mathrm{d}\phi$ on (18). They are best expressed when written in the canonical coordinate system (u,ω,r) given in Eq. (8). The final expression for the metric components reads

$$g^{ij}=\Omega^2\begin{pmatrix} 0 & 0 & 1 \\ 0 & -1 & -\frac{1}{3}\partial_r\Lambda \\ 1 & -\frac{1}{3}\partial_r\Lambda & -\frac{1}{3}\partial(\partial_r\Lambda)+\frac{1}{9}(\partial_r\Lambda)^2+\partial_\omega\Lambda \end{pmatrix}, \tag{19}$$

where the conformal factor must satisfy the differential equation (see Ref. 4 for details)

$$\frac{\mathrm{d}}{\mathrm{d}\phi}\Omega=\frac{1}{3}\partial_r\Lambda\,\Omega,$$

so that the metric is independent of ϕ. Note that the above-mentioned equation is invariant under $\Omega(x,\phi)\to\Omega'(x,\phi)=f(x)\Omega(x,\phi)$ for an arbitrary $f(x)$. This freedom is a consequence of the conformal invariance of the formulation.

The metricity condition is given by

$$M[\Lambda]\equiv 2\left(\frac{\mathrm{d}(\partial_r\Lambda)}{\mathrm{d}\phi}-\partial_\omega\Lambda-\frac{2}{9}(\partial_r\Lambda)^2\right)\partial_r\Lambda-\frac{\mathrm{d}^2(\partial_r\Lambda)}{\mathrm{d}\phi^2}+3\frac{\mathrm{d}(\partial_\omega\Lambda)}{\mathrm{d}\phi}-6\partial_u\Lambda=0,$$

and constraints the available Λ's that must enter in the differential equation (17), for only if $M[\Lambda]=0$ holds, one is able to construct from the solutions $Z(x^a;\phi)$ to the ODE a metric according to (19) such that the level surfaces $S_{(u,\phi)}$ of Z are its characteristic surfaces. Note that this condition is the one deduced by Cartan imposing the connection in the three-dimensional manifold E^3 to be torsion free $(A=0)$.

Summarizing, one solves $M[\Lambda]=0$, which is a partial differential equation in the variables (u,ω,r,ϕ) and, denoting by $\Lambda_0(u,\omega,r,\phi)$ its solution and using the coordinates definitions (8), Eq. (17) becomes

$$Z'''=\Lambda_0(\phi,Z,Z',Z''), \tag{20}$$

which is the ODE whose solutions $Z(x^a;\phi)$ allow for the construction of a metric g_{ab} on E^3 such that the level surfaces of Z are its null hypersurfaces.

Remark 2.1: It is clear from the above that the NSF construction is the special case of Cartan's geometric structure with vanishing torsion.

III. SINGULARITIES IN TERMS OF SMOOTH MANIFOLDS

By assumption, both Cartan's and the NSF are local constructions in the 2D manifold. It follows from this that the cuts $C_x\subset E^2$ are families of smooth curves and (as we will see in the following) that the level sets $Z=u_0$ are smooth null surfaces of the induced metric in the 3D solution space.

It also follows from the above-mentioned assumption that these formalisms are not capable of including the caustics that null surfaces necessarily possess.[6,15,16] Moreover, one might foresee that the families of cuts that yield these null surfaces with caustics will also fail to be smooth, developing self-intersections and singular points. Thus, in this section, we are faced with the problem of generalizing the geometric constructions presented in Sec. II to include the description of singularities of both, cuts and null hypersurfaces.

Our starting assumption is that the cuts develop caustics in the 2D space. Technically this means that cuts are projections onto E^2 of a (smooth) Legendrian submanifold and the caustics arise where the projection map fails to be one to one. In a similar way as in Ref. 17, we use a generating function to describe a cut in the neighborhood of a caustic. Using this function we will be able to see how Λ diverges at a caustic point. Since the original equation and the metricity condition become useless around that point, we will obtain a regularized metricity condition to select the class of generating functions which yield conformal metrics on the solution space. We will also show that caustics come inseparably paired in the Cartan and NSF constructions, in the sense that the existence of caustics in the cut implies the same singular behavior in the null surfaces of the manifold E^3 (and vice versa). Section III C presents an example of a generating function in a Minkowskian space–time.

A. The generating function

The regular solutions of (17) can be used to define smooth curves on the so-called projective cotangent space of E^2 with local coordinates (u,ϕ,π), where π is the momentum canonically conjugated to ϕ. The curves are given by

$$u=Z(x^a;p),$$

$$\phi=p,$$

$$\pi = \frac{dZ}{dp},$$

with x^a parameters to be interpreted as coordinates in the solution space. These smooth curves are called Legendrian submanifolds and the projection of these submanifolds onto the space (u,ϕ) gives the local description of the cuts of E^2. The above-mentioned equations describe the Legendrian submanifolds in the diffeomorphic region since the coordinate ϕ is used as a parameter to describe these curves.

In order to describe the cuts in regions containing caustic points, we introduce a generating function of the form $G=G(x^a;p)$. In this case the Legendrian submanifold is given locally as

$$\begin{aligned} u &= G - pG', \\ \phi &= -G', \\ \pi &= p, \end{aligned} \tag{21}$$

where G' denotes the derivative of G with respect to p holding x^a fixed. The equations of (21) locally describe smooth curves on the projective cotangent space of E^2. Note that the projection of these curves onto the space (u,ϕ) is not necessarily a diffeomorphism, since ϕ fails to be injective in p when G'' vanishes. Therefore, this description includes caustic points in a natural way. It is easy to see that Λ diverges at the caustic points. For this we analyze the behavior of the coordinates (u,ω,r,ϕ) and the function Λ as we approach a caustic in E^2. These variables, expressed in terms of G and p, become

$$\begin{aligned} u &= G - pG', \\ \omega &= \frac{\mathrm{d}u}{\mathrm{d}\phi} = p, \\ r &= \frac{\mathrm{d}\omega}{\mathrm{d}\phi} = -(G'')^{-1}, \end{aligned} \tag{22}$$

and since $\Lambda = \mathrm{d}^3u/\mathrm{d}^3\phi$ we obtain

$$\Lambda = \frac{-G'''}{(G'')^3}.$$

Since at a caustic point $G''=0$, we see from Eq. (22) that both u and ω are bounded while r and Λ diverge at that point. One might argue that G could be such that G''' also vanishes at a caustic point in such a way that Λ remains finite. However, smoothness requires G to be expandable as a polynomial around a caustic point. Thus G''' is always a polynomial of lower degree than G'' and the previous argument does not apply. It follows from these considerations that (a) the third-order ODE (17) will not be defined around caustic points and (b) the coordinate system, metric construction, and metricity condition will not be regular on the 3D solution space.

We look then for a regular third-order ODE where the right-hand side of this equation satisfies a regularized metricity condition. For this we introduce a new set of coordinates (G,G',G'',p). In terms of these coordinates we have

$$G''' = \tilde{\Lambda}(G,G',G'',p) = -(G'')^3\Lambda(G-pG',p,-(G'')^{-1},-G')$$

and the metricity condition $\tilde{M}[\tilde{\Lambda}]=0$ becomes

$$\tilde{M}[\tilde{\Lambda}]=G''\left(2(\tilde{\Lambda}_p+G'\tilde{\Lambda}_G)\tilde{\Lambda}_{G''}-3\tilde{\Lambda}\frac{\mathrm{d}}{\mathrm{d}p}\tilde{\Lambda}_{G''}-5\frac{\mathrm{d}\tilde{\Lambda}}{\mathrm{d}p}\tilde{\Lambda}_{G''}+2\tilde{\Lambda}(\tilde{\Lambda}_{G''})^2\right)$$
$$+G''\left(3\frac{\mathrm{d}^2\tilde{\Lambda}}{\mathrm{d}p^2}-3\frac{\mathrm{d}}{\mathrm{d}p}(\tilde{\Lambda}_p+G'\tilde{\Lambda}_G)\right)+(G'')^2\left(2\tilde{\Lambda}_{G''}\frac{\mathrm{d}}{\mathrm{d}p}\tilde{\Lambda}_{G''}-6\tilde{\Lambda}_G\right)$$
$$-(G'')^2\left(\frac{4}{9}(\tilde{\Lambda}_{G''})^3+\frac{\mathrm{d}^2}{\mathrm{d}p^2}\tilde{\Lambda}_{G''}\right)+3\tilde{\Lambda}\left((\tilde{\Lambda}_p+G'\tilde{\Lambda}_G)+\tilde{\Lambda}\tilde{\Lambda}_{G''}-\frac{\mathrm{d}\tilde{\Lambda}}{\mathrm{d}p}\right)$$
$$=0, \tag{23}$$

where $\mathrm{d}F/\mathrm{d}p=F_p+G'\ F_G+G''\ F_{G'}+\tilde{\Lambda}\ F_{G''}$ for any function $F(G,G',G'',p)$. Note that Eq. (23) is regular in a neighborhood of the caustic $(G''=0)$.

Finally, to obtain null surfaces and study them near a caustic, we proceed in a similar way as we did in the diffeormophic region, i.e., we first solve $\tilde{M}[\tilde{\Lambda}]=0$. Denoting by $\tilde{\Lambda}_0$ a particular solution to this equation we then generate solutions of the ordinary differential equation

$$G'''=\tilde{\Lambda}_0(G,G',G'',p), \tag{24}$$

and construct families of curves with caustics on E^2.

Remark 3.1: Note that in the (G,p) space the solutions to (24) will generate smooth curves. To construct the families of curves with caustics one must use G as the generating function of the contact transformation (21) and the null surfaces are given by the conditions $u=\text{const}$, $\phi=\text{const}$.

Remark 3.2: Note that the contact transformation (21) induces a coordinate transformation (22) which preserves the metric tensor defined on E^3. Thus, Cartan's theorem 2.1 is immediately generalized to include coordinate and contact transformations on E^2.

B. Caustics on null surfaces and cuts

In this section, we prove that the existence of caustic points in the cuts yields the existence of caustic points in the null surfaces of E^3 and vice versa. As it is known (Ref. 5), the divergence of a congruence of null geodesics $\rho=-\nabla_a l^a$ $(l^a=g^{ab}\nabla_a Z)$ becomes infinite at a caustic. Therefore, to prove our assertions, we will derive a relation between ρ of a congruence contained in the null surface and the scalar $Z''(x^a,\phi)$ constructed from the general solution $u=Z(x^a,\phi)$ to (17).

Let l^a be the tangent vector to a geodesic with affine parameter τ, then

$$l^a=\frac{\mathrm{d}x^a}{\mathrm{d}\tau}=g^{ab}\theta^0{}_b=\Omega^2\theta_2{}^a, \tag{25}$$

where $\theta^i{}_b$ and $\theta_j{}^a$ are the form basis and its corresponding dual vector basis associated with the canonical coordinate system (8).

To this tangent vector we associate a triad $\{l^a,m^a,n^a\}$ parallely propagated along the geodesic satisfying

$$m^a m_a=1,\quad n^a n_a=0,\quad l^a m_a=0,\quad l^a n_a=-1,\quad n^a m_a=0.$$

In this frame the metric tensor and the divergence become

$$g_{ab}=m_a m_b-2n_{(a}l_{b)},\quad \rho=m^a m^b\nabla_a l_b,$$

respectively. Since $\theta_1{}^a$ and $\theta_2{}^a$ are coordinate vectors they satisfy

$$\theta_2{}^a\nabla_a\theta_1{}^b=\theta_1{}^a\nabla_a\theta_2{}^b. \tag{26}$$

Expresing the geodesic deviation vector ${\theta_1}^a$ in terms of the triad

$$ {\theta_1}^a = \xi m^a + \alpha l^a, \tag{27} $$

in (26) gives

$$ l^a \nabla_a \xi = \xi m^a m^b \nabla_a l_b = \xi \rho $$

or equivalently

$$ \rho = \xi^{-1} \frac{\mathrm{d}\xi}{\mathrm{d}\tau}. \tag{28} $$

On the other hand we can easily derive a differential equation for the divergence by considering the geodesic deviation equation as follows:

$$ m_c l^a \nabla_a ({\theta_1}^b \nabla_b l^c) = m_c {\theta_1}^a \nabla_a (l^b \nabla_b l^c) + \xi {R_{abd}}^c l^a m^b l^d m_c . $$

Since l^a is a tangent vector of a null geodesic and the triad is parallely propagated along it, using (27) we obtain

$$ m_c l^a \nabla_a (\xi m^b \nabla_b l^c) = \frac{\mathrm{d}\xi}{\mathrm{d}\tau} \rho + \xi \frac{\mathrm{d}\rho}{\mathrm{d}\tau} = \xi \Phi, $$

with $\Phi = {R_{abd}}^c l^a m^b l^d m_c$. Finally, from (28), we see that ρ must satisfy the differential equation

$$ \frac{\mathrm{d}\rho}{\mathrm{d}\tau} + \rho^2 = \Phi. \tag{29} $$

To prove our claims we start with the general solution $u = Z(x^a, \phi)$ to (17), and we assume that the cut $u = Z(x_0^a, \phi)$ has a caustic at $\phi = \phi_0$. As we have seen in Sec. III A, this is equivalent to saying that the function $Z''(x_0^a, \phi)$ diverges at ϕ_0. To show that there is a caustic in the null surface defined by $Z(x^a, \phi_0) = Z(x_0^a, \phi_0) = u_0$, we must prove that $\lim_{r \to \infty} \rho = \infty$, with $r = Z''(x^a, \phi_0)$.

From (25) it follows that

$$ \frac{\mathrm{d}}{\mathrm{d}\tau} = \Omega^2 \frac{\partial}{\partial r} = -\Omega^2 s^2 \frac{\partial}{\partial s}, $$

with the coordinate $s = r^{-1}$. As $\mathrm{d}/\mathrm{d}\tau$ and $\partial/\partial s$ are regular operators near $s = 0$, the factor $\Omega^2 s^2$ must be a nonzero smooth function of s. Hence $\Omega = \mathcal{O}(s^{-1})$, meaning that the conformal factor Ω diverges when we approach a caustic in the cut.

Finally, noting that $g_{11} = g_{ab} {\theta_1}^a {\theta_1}^b$, we express ξ in terms of the conformal factor in the following manner

$$ g_{11} = \Omega^{-2} = g_{ab} (\xi m^a + \alpha l^a)(\xi m^b + \alpha l^b) = \xi^2, $$

therefore

$$ \rho = \frac{\mathrm{d}}{\mathrm{d}\tau} \ln \Omega = -\Omega^2 s^2 \frac{\partial}{\partial s} \ln \Omega, $$

which yields

$$ \rho = \mathcal{O}(s^{-1}). $$

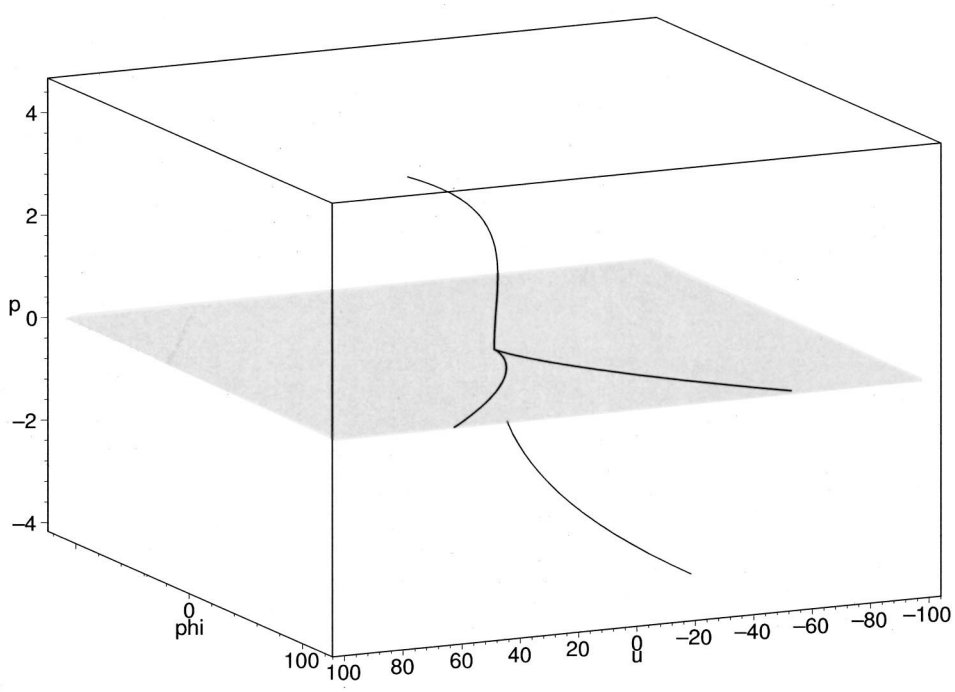

FIG. 1. Legendre submanifold and the corresponding cut for $X^1=X^2=X^3=0$.

We conclude that when s goes to zero (in a singular point of the cut) ρ diverges, i.e., we approach a caustic of the null surface.

It remains now to prove that a caustic in the null surface leads to the same singular behavior in the cut. Suppose that the null surface is defined by $u_0=Z(x^a,\phi_0)$, then near a caustic point x_0^a in the surface the solution of the differential equation (29) in the flat case yields

$$\rho=\frac{1}{\tau-\tau_0},$$

where the singular point x_0^a corresponds to $\tau=\tau_0$. By means of (28) we find $\xi=\Omega^{-1}=\tau-\tau_0$, thus the conformal factor Ω diverges when we approach a caustic in the null surface and since $d\tau=\Omega^{-2}dr$, r diverges (for τ is the affine parameter of the curve and so $d\tau$ is bounded) at x_0^a.

On the other hand, we know that $u=Z(x_0^a,\phi)$ is a solution of (17), then at the singular point x_0^a the function $r=Z''(x_0^a,\phi_0)$ diverges. Thus, the cut $u=Z(x_0^a,\phi)$ also has a caustic point at $\phi=\phi_0$.

Remark 3.3: Note that the spaces E^2 and E^3, used to describe the cuts and null surfaces respectively, are not related in any way. The only tool that was used to prove the above results relating the cuts with null surfaces is the starting ODE (17). This is in contrast with similar results obtained in three and four dimensions where the reciprocity theorem for null congruences and the assumption that E^2 is a hypersurface of E^3 is explicitly used in the proof (Ref. 4).

C. An example: Caustics in flat space

An arbitrary constant function is clearly a solution of the metricity condition $\tilde{M}[\tilde{\Lambda}]=0$, which yields a polynomial of third degree in p for G. Therefore we choose $\tilde{\Lambda}=-1$ and (24) yields

$$G(p,x^a)=-\frac{p^3}{3}+\frac{1}{2}X^1p^2+X^2p+X^3.$$

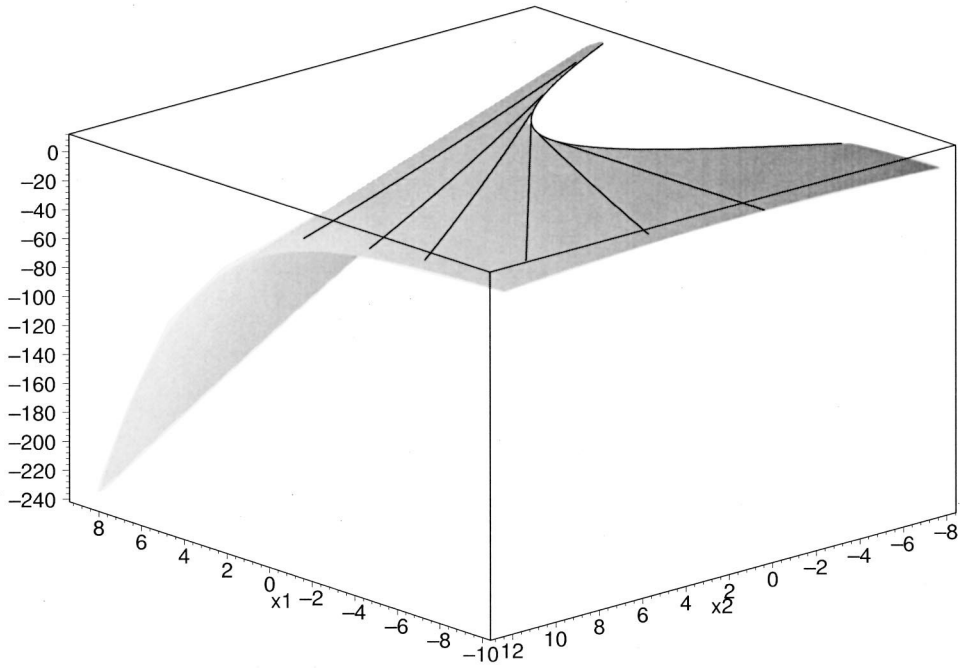

FIG. 2. Null surface for $(u,\phi)=(0,0)$.

With this generating function the Legendre submanifold is given parametrically by

$$u=\tfrac{2}{3}p^3-\tfrac{1}{2}X^1p^2+X^2, \tag{30}$$

$$\phi=p^2-X^1p-X^2, \tag{31}$$

$$p=p. \tag{32}$$

The projection of this submanifold onto E^2, $(u,\phi,p)\rightarrow(u,\phi)$, is the cut and possesses a cusp-like caustic when $p=X^1/2$ (see Fig. 1).

Since ϕ is not an injective function of p, there are two values of p for each ϕ, namely

$$p(\phi)=\tfrac{1}{2}X^1\pm\tfrac{1}{2}\sqrt{(X^1)^2+4\phi+4X^2}. \tag{33}$$

Inserting this expression into Eq. (30) we obtain the corresponding space–time coordinates

$$u=\tfrac{1}{12}((X^1)^2+4\phi+4X^2)^{3/2}+\tfrac{1}{12}(X^1)^3+\tfrac{1}{2}X^1\,\phi+\tfrac{1}{2}X^1\,X^2+X^3,$$

$$\omega=\tfrac{1}{2}X^1+\tfrac{1}{2}\sqrt{(X^1)^2+4\,\phi+4\,X^2}, \tag{34}$$

$$r=\frac{1}{\sqrt{(X^1)^2+4\,\phi+4\,X^2}}.$$

It is clear from (33) that $\sqrt{(X^1)^2+4\phi+4X^2}$ becomes null in the caustic, hence r diverges while u and ω remain bounded at this point.

Figure 2 shows a null surface and null geodesics on it for $(u,\phi)=(0,0)$, which end tangent to the caustic curve. The above-mentioned generating function gives $\Lambda=-r^3$, which yields a flat metric for the conformal factor $\Omega=r$.

IV. CONCLUSIONS

We have shown in this work how the 3D NSF can be recast in terms of a well-known mathematical frame, like Cartan's geometrical theory of differential equations. In this manner, the metricity condition of NSF becomes a simple geometric imposition within Cartan's framework, namely the vanishing of the torsion of the connection in the space E^4.

Moreover, both constructions have been extended from their local scopes to the nondifferentiable regions, in order to account for the singular behavior that null surfaces necessarily possess. As result of this extension,

(1) generalized version of the metricity condition was obtained, whose solutions yield null foliations of a $2+1$ dimensional manifold with caustics and other singularities that the local construction of NSF by definition is not capable of describing.
(2) the singularities of cuts and null surfaces were shown to be closely related in the sense that the singular behavior in one of them induces a similar behavior in the other.

At this point, one can think of applying the same ideas of this work to the original 4D version of NSF.[7,18] This would imply a change from ordinary differential equations over partial ones, since the variable Z now depends on two coordinates (α,β) on S^2 and is subject to the following system of PDEs:

$$Z_{\alpha\alpha}=\Lambda(\alpha,\beta,Z,Z_\alpha,Z_\beta,Z_{\alpha\beta}), \tag{35}$$

$$Z_{\beta\beta}=\Gamma(\alpha,\beta,Z,Z_\alpha,Z_\beta,Z_{\alpha\beta}), \tag{36}$$

where Z_α, Z_β are the partial derivatives of Z with respect to the coordinates. Since the above-given system of equations is integrable, its solution space can be parametrized by four constants x^a, which locally define the 4D solution space M. Thus, one would be able in principle to construct an S^2 bundle over M and attach a similar set of geometric structures that have been presented in this paper.

If this program can be done, the NSF could be described within a well-established context of differential equations; one would be able to give a geometrical interpretation to the metricity conditions (possibly in terms of requirements analogous to the vanishing of the torsion).

A recently proposed technique to solve a class of second order functional difference equations arising in electromagnetic diffraction theory is further investigated by applying it to a case of intermediate complexity. The proposed approach is conceptually simple and relies on first obtaining well-defined branched solutions to a pair of associated first order difference equations. The construction of these branched expressions leads to an equation system whose solution requires relationships akin to Riemann's bilinear relations for differentials of the first and third kinds; their derivation necessitates the application of Cauchy's theorem on Riemann surfaces of, in this particular instance, genera one and three. Branch-free solutions of the second order difference equation are then obtained by taking appropriate linear combinations of the branched solutions of the first order equations. Analysis and computation demonstrate that the resulting expressions have the desired analytical properties and recover known solutions in the appropriate limit. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1445287]

I. INTRODUCTION

The Sommerfeld–Maliuzhinets technique[1,2] remains today the most general approach to solve electromagnetic scattering problems involving wedge-shaped structures with faces characterized by impedance boundary conditions[3] under plane wave illumination. Within its framework solutions are sought by expressing components of the total electric and magnetic fields in terms of unknown plane wave angular spectra, defined here in the complex α plane, which, besides being meromorphic, must satisfy a number of analyticity requirements. In particular, since poles of the spectral functions give rise to plane wave contributions, the spectra are required to be analytic—save for a pole necessary to reproduce the illuminating incident field—in a strip of the complex plane corresponding to the angular opening of the wedge. Additionally, besides the boundary conditions characterizing the surfaces of the wedge, obtaining a unique solution of the wave equation also requires knowledge of the behavior of the fields at the tip of the wedge and enforcement of the resulting edge condition[4] specifies the asymptotic behavior[2,3] of the spectral functions for large imaginary values of α. The imposition of the boundary conditions on the spectral representation of the fields together with a theorem put forward by Maliuzhinets[5] leads to a pair of first order difference equations for the spectra and their periods are related to the open angle of the wedge. The problem is thus reduced to obtaining spectra that satisfy both the difference equations as well as the analyticity requirements outlined above.

In the special case of normal incidence, where the illuminating plane wave is incident perpendicularly to the edge of the structure, the technique leads to uncoupled first order difference equations whose coefficients are rational trigonometric functions and solutions subject to the required constraints are readily obtained in terms of Maliuzhinets functions.[1] At skew (non-normal) incidence, the equation pair is generally coupled and solutions are obtainable for a few particular wedge/angle combinations for which uncoupled first order equations for linear combi-

nations of the spectra can be found. Recent examples of this include the polarization independent wedge studied by Bernard[6] and the right-angled anisotropic impedance wedge with one perfectly conducting face examined by Manara and Nepa.[7] In general the equation pair cannot be uncoupled and we are faced with solving a second order functional difference equation whose coefficients are rational functions of trigonometric polynomials. Its solutions are linear combinations of the desired spectral functions, a consequence of the decoupling procedure, and must therefore satisfy analyticity requirements analogous to those of the spectral functions. A pair of associated first order difference equations can be obtained from the second order one, but these, as we shall see below, typically involve branched functions and Maliuzhinets's technique does not apply.

There have been few attempts published in the literature to solve second order difference equations due to the complicated nature of the problem. A successful example is provided by Gaudin[8] who considers the second order difference equation that arises in the study of the quantum mechanical problem of two electrons interacting with a localized magnetic moment. The particular equation studied is of a high order of complexity and the ensuing analysis is prohibitively complicated. In electromagnetic theory, the second order functional difference equation of form

$$t(\alpha+3\pi)-2\left\{1-2\frac{\cos^2\eta-\cos^2\theta}{\cos^2\alpha-\cos^2\theta}\right\}t(\alpha+\pi)+t(\alpha-\pi)=0 \tag{1}$$

was recently solved by Senior and Legault.[9] It is a generalization of the one considered by Demetrescu *et al.*[10] in their study of the penetrable composite right-angled wedge consisting of abutted resistive and perfectly conducting semi-infinite half-planes. In this particular instance, the parameters η and θ are both related to the resistivity of the wedge. As noted above, the function $t(\alpha)$ represents a combination of the unknown spectral functions and it therefore satisfies requirements related to those imposed on the spectral functions. Accordingly, the solutions $t(\alpha)$ obtained in Ref. 9 are (i) meromorphic, (ii) free of poles and zeros in the strip of analyticity $\mathcal{S}_{2\pi}=\{\alpha:|\mathrm{Re}\,\alpha|\leqslant\pi\}$ (the inclusion of zeros here is a consequence of reciprocal symmetry between solution pairs in certain limits), and, in accordance with the edge condition, (iii) $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$. Two linearly independent solutions satisfying the above analyticity requirements were constructed by successively eliminating the undesired singularities in the strip $\mathcal{S}_{2\pi}$. The conceptual simplicity of the technique hinges on recognizing that expressions recovered during the course of the analysis are of the same nature as those occurring in Riemann's bilinear relations for differentials of the first and third kinds.[11,12] In contrast, the solution based on a Fourier transform approach proposed in Ref. 10 fails to satisfy requirement (i) above since it is free of branch points only in the strip of analyticity $\mathcal{S}_{2\pi}$ as opposed to the entire α plane.

Equation (1) may be qualified as being of moderate complexity due to the relatively low number of singularities (poles and branch points) which must be eliminated to successfully complete the analysis. In comparison, geometries of contemporary interest such as the right-angled wedge characterized by isotropic impedance boundary conditions on both faces or the anisotropic impedance half-plane (see Ref. 13 for an approximate solution) lead to substantially more complicated equations. To gain insight into the applicability of the technique in such cases and also provide some details on the procedure, as opposed to focusing on a particular physical problem, we examine here a case of intermediate complexity by considering an equation of the same form as (1) but with the period doubled to 4π, viz.

$$t(\alpha+5\pi)-2\left\{1-2\frac{\cos^2\eta-\cos^2\theta}{\cos^2\alpha-\cos^2\theta}\right\}t(\alpha+\pi)+t(\alpha-3\pi)=0, \tag{2}$$

and, consistent with the requirement for (1), a solution is sought which is (i) meromorphic, (ii) free of poles and zeros in the strip of analyticity $\mathcal{S}_{4\pi}=\{\alpha:|\mathrm{Re}\,\alpha|\leqslant 2\pi\}$, and (iii) $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$. The increase in complexity arises from the doubling of the strip of analyticity as this effectively doubles the number of singularities, both poles and branch points, that must be con-

sidered in the course of the analysis. Consequently, whereas the solution for (1) required analysis on a Riemann surface corresponding to a torus (handlebody of genus one), in the case of (2) it will be seen that we are required to work on Riemann surfaces whose corresponding handlebodies are of genera one and three.

In what follows, Sec. II gives the solution procedure for the branched first order equations associated with (2) and provides the derivation of a system of four equations in four unknowns to be satisfied in order for their solutions to be well-defined. The unknowns consist of two multiplicative constants associated with elliptic integrals of the first kind with periods 2π and 4π, and the location of the logarithmic singularities associated with two elliptic integrals of the third kind also of periods 2π and 4π. Section III shows how to solve for the quantities associated with the 2π periodic elliptic integrals. The analysis, which is carried out on a torus, is of the same nature as that required in Ref. 9 but it is examined here in greater detail. Section IV gives the solution for the quantities associated with the elliptic integrals of period 4π and it is now required to carry out the analysis on a Riemann surface which is the topological equivalent of a handlebody of genus three. The branched solutions to the first order equations are used in Sec. V to construct branch-free solutions to the second order equation. A fully analytic solution that satisfies all of the prescribed requirements is provided. The only shortcoming of the solution is that it vanishes in a certain limit and, in an effort to address this shortcoming, an alternative approach that relies on numerically locating zeros is also examined.

II. FIRST ORDER EQUATIONS AND SOLUTIONS

Since there is no available technique to directly attack the type of second order difference equation with which we are concerned, it must first be recast as an associated pair of more easily handled first order difference equations. Unfortunately the latter generally involve branch points; the price paid for this reduction in order is that the established solution technique for first order equations by Maliuzhinets[1] fails to apply. However, solutions to the first order difference equations can, in principle at least, be obtained by applying a logarithmic derivative and this is the approach taken here. This yields a solution expressed in terms of an initially ill-defined path integral and multiplicative terms of period 4π, corresponding to the period of the difference equation, must be added to rectify this. This ultimately leads to the derivation of a system of four equations in four unknowns which can be partially decoupled into two systems in two unknowns, one involving 2π periodic quantities and the other 4π periodic ones.

A. Reduction to first order equations

The second order functional difference equation (2) can be rewritten in terms of first order difference equations quite straightforwardly by exploiting the periodicity of the functional coefficient. To see this consider the second order difference equation

$$t(\alpha+5\pi)+p(\alpha)t(\alpha+\pi)+\frac{1}{p(\alpha)}\{t(\alpha+\pi)+p(\alpha)t(\alpha-3\pi)\}=0 \tag{3}$$

whose solutions $t(\alpha)$, provided $p(\alpha)$ is 4π periodic, must also explicitly satisfy first order difference equations. Enforcing equality between (3) and (2) then yields the equation pair

$$\frac{t(\alpha+2\pi)}{t(\alpha-2\pi)}=g(\alpha,+u(\alpha))=\frac{u(\alpha)-u(\theta)}{u(\alpha)+u(\theta)}, \tag{4}$$

$$\frac{t(\alpha+2\pi)}{t(\alpha-2\pi)}=g(\alpha,-u(\alpha))=\frac{u(\alpha)+u(\theta)}{u(\alpha)-u(\theta)}, \tag{5}$$

where

$$u(\alpha)=\sqrt{\cos^2\alpha-\cos^2\eta}. \tag{6}$$

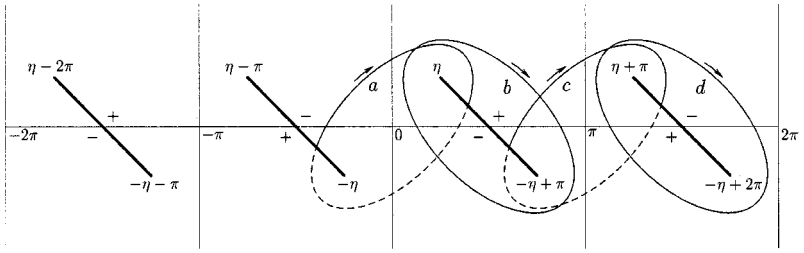

FIG. 1. The strip of analyticity $\mathcal{S}_{4\pi}=\{\alpha:|\mathrm{Re}\,\alpha|\leqslant 2\pi\}$. The thick lines indicate the branch cuts of $u(\alpha)$, the positive and negative signs indicate relative changes in sign of $u(\alpha)$ across the different cuts. The clockwise cycles a, b, c and d used to define the cyclic periods are as indicated. Note that the cycles a and c cross from the upper Riemann sheet (solid line) to the lower Riemann sheet (dashed line) whereas b and d are confined to the upper sheet.

Alternatively, one could also proceed by factoring the associated second order difference operator in (2) into a pair of first order difference operators and recover the same result as above. The first order equations obtained are generally branched owing to the presence of the root $u(\alpha)$ which has branch points at $\alpha=\pm\eta,\pm(\eta-\pi),\pm(\eta+\pi),\pm(-\eta+2\pi)$ in the strip of analyticity $\mathcal{S}_{4\pi}$ and is made well defined in the complex α plane by introducing the cuts shown in Fig. 1. These are such that $u(\alpha)$ has the same symmetry as $\cos\alpha$ so that

$$u(\alpha)=u(-\alpha)=-u(\alpha\pm\pi). \tag{7}$$

Note that the function $t(\alpha)$ is used here to generally denote solutions of the second order equation and each of the first order equations above identifies one such solution. If $t(\alpha)=w(\alpha,u(\alpha))$ is a solution of (4), then $t(\alpha)=w(\alpha,-u(\alpha))$ is a solution of (5), and this follows from the symmetry of the right-hand sides of (4) and (5) with respect to the sign (the branch) of $u(\alpha)$. It is therefore sufficient to consider $w(\alpha,u)$—writing $w(\alpha,u)$ instead of $w(\alpha,u(\alpha))$ for convenience—and, since $g(-\alpha,u)=g(\alpha,u)$, we can construct $w(\alpha,u)$ such that

$$w(-\alpha,u)=\frac{1}{w(\alpha,u)}=w(\alpha,-u). \tag{8}$$

In terms of the solutions of the first order difference equations, solutions to (2) are

$$t(\alpha)=C_1(\alpha)w(\alpha,u)+C_2(\alpha)w(\alpha,-u), \tag{9}$$

where $C_{1,2}(\alpha)$ are 4π periodic functions. This generally conflicts with the requirement for a branch-free solution but there are particular cases of (9) that overcome this difficulty and the simplest two such linearly independent expressions free of branch points are

$$t(\alpha)=w(\alpha,u)+w(\alpha,-u), \quad \text{and} \quad t(\alpha)=\frac{1}{u(\alpha)}\{w(\alpha,u)-w(\alpha,-u)\}. \tag{10}$$

While the branch-free property of these two symmetric forms can be ascertained rigorously by means of Taylor expansions in the neighborhood of branch points of $u(\alpha)$, it can also be appreciated from the fact that both are invariant under a change of the branch of $u(\alpha)$. This crucial feature makes the constructs (10) the fundamental building blocks from which branch-free solutions to the second order difference equation can be assembled once branched solutions of the associated first order equations have been obtained. As we shall soon see, the presence of branch points makes this task quite challenging and the brunt of the subsequent analysis focuses on deriving solutions to the first order equations.

B. Special cases of interest

It is worthwhile to first consider the special cases $\eta=0$ and $\eta=\pi/2$ as the branch points then vanish and known solutions, which are useful when characterizing the behavior of the general solution obtained below, can be obtained in terms of Maliuzhinets functions. The first one when $\eta=\pi/2$ proves to be especially interesting since the branch cuts of $u(\alpha)$, as illustrated in Fig. 1 and chosen so that (7) holds, vanish as $\eta\to\pi/2$. In this instance (4) becomes

$$\frac{w(\alpha+2\pi,u)}{w(\alpha-2\pi,u)}=\frac{\cos\alpha-\cos\theta}{\cos\alpha+\cos\theta},$$

and, despite the fact that the right-hand side is now meromorphic, the dependence of $w(\alpha,u)$ on $u(\alpha)$ is maintained to distinguish it from $w(\alpha,-u)$, the solution to Eq. (5) in the same limit. A solution free of poles and zeros in $\mathcal{S}_{4\pi}$ and $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$ follows directly from Maliuzhinets.[1] It may be written as

$$\begin{aligned} w(\alpha,u)&=\Psi_1(\alpha)\\ &=\frac{\psi_\pi(\alpha+\pi/2-\theta)}{\psi_\pi(\alpha-\pi/2+\theta)}\\ &=\exp\int_0^\alpha\frac{-(\alpha'/2\pi)\cos\theta\sin\alpha'+\gamma_1+\gamma_2\cos(\alpha'/2)+\gamma_3\cos\alpha'+\gamma_4\cos(3\alpha'/2)}{\cos^2\alpha'-\cos^2\theta}d\alpha', \end{aligned} \tag{11}$$

where

$$\begin{aligned} \gamma_1&=-\tfrac{1}{4}\sin\theta\cos\theta,\\ \gamma_2&=\frac{1}{4}\left(-\cos\frac{\theta}{2}+\sin\frac{\theta}{2}\right)+\frac{1}{2}\cos\frac{\theta}{2}\left(\cos\frac{\theta}{2}+\sin\frac{\theta}{2}\right),\\ \gamma_3&=\left(\frac{\theta}{2\pi}-\frac{1}{4}\right)\sin\theta,\\ \gamma_4&=\frac{1}{4}\left(-\cos\frac{\theta}{2}+\sin\frac{\theta}{2}\right), \end{aligned} \tag{12}$$

and $\psi_\pi(\alpha)$ is the Maliuzhinets function.[1] Since $\Psi_1(-\alpha)=1/\Psi_1(\alpha)$, consistent with (8), two linearly independent solutions of (2) are

$$t_1(\alpha)=\Psi_1(\alpha),\quad t_2(\alpha)=\Psi_1(-\alpha),$$

and these are both $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$. The other case of interest where the branch points also vanish is $\eta=0$ and in that instance two linearly independent solutions, also $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$, are provided by

$$t_1(\alpha)=\Psi_2(\alpha)=\cos\frac{\alpha}{4}\,\frac{\psi_\pi^2(\pi/2-\theta)}{\psi_\pi(\alpha+\pi/2-\theta)\psi_\pi(\alpha-\pi/2+\theta)},\quad t_2(\alpha)=\frac{1}{t_1(\alpha)}, \tag{13}$$

and we must now contend with poles or zeros at $\alpha=\pm2\pi$.

C. General case

We now proceed to solve (4) in the general case where $\eta \neq 0$, $\pi/2$ and Maliuzhinets's technique does not apply. The solutions sought should preferably reduce to one or both of the known limiting functions when η goes to the appropriate limit and, consistent with the limiting cases, they must also be $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha| \to \infty$ for all η. As we shall see, while the solution $\Psi_1(\alpha)$ [and $1/\Psi_1(\alpha)$] are easily recovered as $\eta \to \pi/2$, the recovery of $\Psi_2(\alpha)$ [and $1/\Psi_2(\alpha)$] as $\eta \to 0$ proves to be much more difficult. Taking the logarithmic derivative of (4), we obtain

$$\frac{d}{d\alpha}\ln w(\alpha+2\pi,u)-\frac{d}{d\alpha}\ln w(\alpha-2\pi,u)=\frac{d}{d\alpha}\ln g(\alpha,u)=-\frac{u(\theta)}{u(\alpha)}\frac{2\sin\alpha\cos\alpha}{\cos^2\alpha-\cos^2\theta}, \quad (14)$$

and if $v_0(\alpha,u)=d/d\alpha \ln w(\alpha,u)$, then

$$v_0(\alpha+2\pi,u)-v_0(\alpha-2\pi,u)=-\frac{u(\theta)}{u(\alpha)}\frac{2\sin\alpha\cos\alpha}{\cos^2\alpha-\cos^2\theta}$$

and a solution to (4) can tentatively be written as

$$w(\alpha,u)=\exp\int_{\alpha_0}^{\alpha} v_0(\alpha',u)\,d\alpha', \quad (15)$$

with

$$v_0(\alpha,u)=-\frac{\alpha}{2\pi}\frac{u(\theta)}{u(\alpha)}\frac{\sin\alpha\cos\alpha}{\cos^2\alpha-\cos^2\theta}.$$

The form proposed in (15) is, however, ill-defined owing to the presence of the polar and the cyclic periods (we borrow here the terminology used in Ref. 11 when characterizing differentials of the third kind) due to, respectively, the poles and the branch points of $v_0(\alpha,u)$. In order to obtain a single-valued integral expression, we must consider instead

$$w(\alpha,u)=\exp\int_{\alpha_0}^{\alpha}\{v_0(\alpha',u)+v_\Sigma(\alpha',u)\}\,d\alpha', \quad (16)$$

where the added term $v_\Sigma(\alpha,u)$ represents a sum of 4π periodic terms, of even parity like $v_0(\alpha,u)$, specifically selected to remove the offending periods. Not all classes of 4π periodic functions are acceptable: it turns out that $v_\Sigma(\alpha,u)$ must fulfill certain order requirements in order for $\exp\int v_\Sigma(\alpha)d\alpha$ to be a 4π periodic function and a simple analysis shows that, for the case at hand, it is sufficient to consider expressions such that $v_\Sigma(\alpha,u)\to 0$ as $|\mathrm{Im}\,\alpha|\to\infty$. It will be shown below that $v_\Sigma(\alpha,u)$ will consist of five terms: $v_1(\alpha,u)$ to eliminate the polar periods and $v^1_{2\pi}(\alpha,u)$, $v^3_{2\pi}(\alpha,u)$, $v^1_{4\pi}(\alpha,u)$, $v^3_{4\pi}(\alpha,u)$ to eliminate the cyclic periods.

It is worthwhile to discuss the nature of the lower limit α_0 at this juncture as its selection may appear at first glance to be somewhat arbitrary. This is not the case as consideration of the symmetric forms in (10) together with the requirement for continuity reveals that the lower limit α_0 must be a branch point in $\mathcal{S}_{4\pi}$ so that $\alpha_0 \in \{\pm\eta, \pm(\eta-\pi), \pm(\eta+\pi), \pm(2\pi-\eta)\}$. Furthermore, once $v_\Sigma(\alpha,u)$ has been properly defined, the solution is independent of the choice of the particular branch point and this will become more obvious when we consider the elimination of the cyclic periods. We first examine the elimination of the polar periods.

1. Elimination of polar periods

The presence of poles will generally make a path integral such as the one in (16) multivalued. A pole of residue Res will give rise to a polar period equal to $2\pi i\,\mathrm{Res}$ and, depending on the orientation of the integration path and its winding number around the pole, the contribution to the integral will be $2\pi i\mathbb{Z}\mathrm{Res}$. In the case of (15), polar periods arise at the poles of $v_0(\alpha,u)$ at α

$=\pm\theta$, $\pm(\theta-\pi)$, $\pm(\theta+\pi)$, $\pm(2\pi-\theta)$. Elimination of these poles serves two purposes as it not only eliminates their associated polar periods but goes toward fulfilling the requirement for a solution that is pole-free in $\mathcal{S}_{4\pi}$. We eliminate them by introducing the 4π periodic

$$v_1(\alpha,u)=\frac{u(\theta)}{u(\alpha)}\frac{\cos(\alpha)}{\cos(\theta)}\frac{\gamma_1+\gamma_2\cos(\alpha/2)+\gamma_3\cos\alpha+\gamma_4\cos(3\alpha/2)}{\cos^2\alpha-\cos^2\theta},$$

which is even, vanishes as $|\mathrm{Im}\,\alpha|\to\infty$, and has poles coinciding with those of $v_0(\alpha,u)$. The constants γ_n are chosen to eliminate the residues and straightforward algebra yields the coefficients in (12). It then follows from (11) that

$$v_0(\alpha,u)+v_1(\alpha,u)=\frac{u(\theta)}{u(\alpha)}\frac{\cos\alpha}{\cos\theta}\frac{d}{d\alpha}\ln\Psi_1(\alpha),$$

which correctly reduces to $d/d\alpha\ln\Psi_1(\alpha)$ when $\eta=\pi/2$. We therefore recognize that, in the simpler case where the right-hand side of (14) is meromorphic so that (15) is free of cyclic periods, the known solutions expressed in terms of Maliuzhinets can be recovered by following the above procedure of pole elimination. We also note in passing that poles with integer residue $\mathbb{Z}$ do not compromise path independence. Indeed, their capture leads to an additive $2\pi i\mathbb{Z}$ contribution in the exponent of (16) which has no effect on the final value of $w(\alpha,u)$.

2. Elimination of cyclic periods

In a fashion similar to polar periods, a cyclic period arises from the nonzero contribution incurred when integrating along a loop encircling a branch cut in $\mathcal{S}_{4\pi}$, thereby making the path integral multivalued. For example, such a period is obtained when integrating v_0+v_1 along the cycle b, shown in Fig. 1, which encircles the branch cut joining the branch points η and $-\eta+\pi$. As in the case of the polar periods, it is strictly speaking not required for the cyclic periods to vanish identically to avoid jeopardizing single-valuedness since periods equal to $2\pi i\mathbb{Z}$ do not change the value of (16). However, as $\eta\to\pi/2$ the branch points of $1/u(\alpha)$ in $v_{0,1}$ coalesce into poles at $\pm\pi/2$ and $\pm3\pi/2$ and their associated cyclic periods then become polar periods. Consequently, the cyclic periods associated with the cycles b and d in Fig. 1 must be annulled, as opposed to setting them equal to some nonzero integer multiple of $2\pi i$, to eliminate poles that would otherwise arise as $\eta\to\pi/2$. We observe that this requirement is equivalent to annulling the integral of v_0+v_Σ along the cuts between η and $\pi-\eta$ as well as $\pi+\eta$ and $2\pi-\eta$. There is also a similar requirement, which is not obvious when solely considering integration on either of the Riemann sheets, on the cyclic periods associated with the cycles a and c which loop from one Riemann sheet to the other. Its necessity is revealed by examining either of the symmetric forms in (10) together with the requirement for continuity. In short, the above implies, taking advantage of the even parity, the need to annul the cyclic periods of $v_0(\alpha,u)+v_\Sigma(\alpha,u)$ on the clockwise cycles a, b, c and d shown in Fig. 1. Alternatively, this can be thought of as requiring that all branch point to branch point integrals vanish in $\mathcal{S}_{4\pi}$ and, under this condition, the lower limit α_0 can be arbitrarily chosen among any of the branch points located within the strip. This also ensures that the resulting expressions will remain free of poles despite coalescing branch points in the limits $\eta\to0$ and $\eta\to\pi/2$.

Four degrees of freedom are required to annul the cyclic periods of v_0+v_1 on the cycles a, b, c and d. We introduce the following four even 4π periodic terms which, like $v_0(\alpha,u)$ and $v_1(\alpha,u)$, vanish as $|\mathrm{Im}\,\alpha|\to\infty$:

$$v^1_{2\pi}(\alpha,u)=\frac{1}{u(\alpha)},\quad v^3_{2\pi}(\alpha,u)=\frac{u(\zeta_{2\pi})}{u(\alpha)}\frac{\cos\alpha}{\cos\zeta_{2\pi}}\frac{\sin\zeta_{2\pi}}{\cos\alpha-\cos\zeta_{2\pi}},\tag{17}$$

and

$$v^1_{4\pi}(\alpha,u)=\frac{\cos(\alpha/2)}{u(\alpha)},\quad v^3_{4\pi}(\alpha,u)=\frac{u(\zeta_{4\pi})}{u(\alpha)}\frac{\cos\alpha}{\cos\zeta_{4\pi}}\frac{\frac{1}{2}\sin(\zeta_{4\pi}/2)}{\cos(\alpha/2)-\cos(\zeta_{4\pi}/2)}. \tag{18}$$

These all give rise to elliptic integrals with the first pair being 2π periodic and the second 4π periodic. The subscript identifies the periodicity of the term while the superscript identifies the type of elliptic integral to which it gives rise. Hence $v^1_{2\pi}(\alpha,u)$ is 2π periodic and gives rise to an elliptic integral of the first kind while $v^3_{2\pi}(\alpha,u)$, also 2π periodic, gives rise to an elliptic integral of the third kind with logarithmic singularities within $\mathcal{S}_{4\pi}$ at $\pm\zeta_{2\pi},\pm(\zeta_{2\pi}+2\pi)$. Likewise, $v^3_{4\pi}(\alpha,u)$ is 4π periodic and gives rise to an elliptic integral of the third kind with logarithmic singularities at $\pm\zeta_{4\pi}$. The use of expressions associated with integrals of the third kind (with poles having nonvanishing residues) results from the impossibility of introducing the required number of degrees of freedom without violating the order requirement. It must be emphasized that the poles of both $v^3_{2\pi}(\alpha,u)$ and $v^3_{4\pi}(\alpha,u)$ have residues ±1 and their polar periods therefore do not disrupt the single-valuedness of the path integral. Their elimination from the strip of analyticity is the objective of the last step in the construction of the solution and this is carried out in Sec. V. For future reference we define the cyclic periods

$$\begin{aligned}A^{1,3}_{2\pi,4\pi}&=\int_a v^{1,3}_{2\pi,4\pi}(\alpha,u)d\alpha,\quad B^{1,3}_{2\pi,4\pi}=\int_b v^{1,3}_{2\pi,4\pi}(\alpha,u)d\alpha,\\ C^{1,3}_{2\pi,4\pi}&=\int_c v^{1,3}_{2\pi,4\pi}(\alpha,u)d\alpha,\quad D^{1,3}_{2\pi,4\pi}=\int_d v^{1,3}_{2\pi,4\pi}(\alpha,u)d\alpha,\end{aligned} \tag{19}$$

and use similar definitions for $v_{0,1}(\alpha,u)$ [i.e., $A_0=\int_a v_0(\alpha,u)d\alpha$]. Inspection of (17) and (18) reveals that the periods associated with the integrals of the third kind are functions of the poles $\zeta_{2\pi}$ and $\zeta_{4\pi}$, providing two of the four degrees of freedoms required to annul the periods of $v_0(\alpha,u)+v_\Sigma(\alpha,u)$. In contrast, the periods associated with the integrals of the first kind are constant and two multiplicative constants, $\kappa_{2\pi}$ and $\kappa_{4\pi}$, must be introduced to produce the two additional degrees of freedom. The solution to (4) then takes the form

$$\begin{aligned}w(\alpha,u)=\exp\int_{\alpha_0}^{\alpha}\{&v_0(\alpha',u)+v_1(\alpha',u)+\kappa_{2\pi}v^1_{2\pi}(\alpha',u)+\sigma_{2\pi}v^3_{2\pi}(\alpha',u)\\&+\kappa_{4\pi}v^1_{4\pi}(\alpha',u)+\sigma_{4\pi}v^3_{4\pi}(\alpha',u)\}d\alpha',\end{aligned} \tag{20}$$

where the four unknowns to be determined are $\kappa_{2\pi}$, $\zeta_{2\pi}$ and $\kappa_{4\pi}$, $\zeta_{4\pi}$. The quantities $\sigma_{2\pi}=\pm1$ and $\sigma_{4\pi}=\pm1$ have been introduced to avoid loss of generality in the definition of the terms associated with the integrals of the third kind. They account for the eventuality where the sign of the logarithmic residues of $v^3_{2\pi}(\alpha,u)$ or $v^3_{4\pi}(\alpha,u)$ must be changed, thereby swapping poles and zeros of $w(\alpha,u)$ between the two Riemann sheets. Their proper definition will be determined in the course of the analysis and, to reduce clutter, they will be omitted in what follows pending their reintroduction when appropriate.

An equation system consisting of four equations in the four unknowns is obtained by enforcing vanishing cyclic periods on the cycles a, b, c and d. Doing so for the cycle d, for example, leads to

$$\int_{\eta+\pi^-}^{-\eta+2\pi^-}(v_0+v_1+\kappa_{2\pi}v^1_{2\pi}+v^3_{2\pi}+\kappa_{4\pi}v^1_{4\pi}+v^3_{4\pi})d\alpha=0 \tag{21}$$

with the superscript negative sign in the limits indicating the corresponding side of the branch cut (see Fig. 1) along which to integrate. Upon use of (19) this becomes

$$D_0+D_1+\kappa_{2\pi}D^1_{2\pi}+D^3_{2\pi}+\kappa_{4\pi}D^1_{4\pi}+D^3_{4\pi}=0,$$

which is further simplified by exploiting the symmetries $D^1_{2\pi}=-B^1_{2\pi}$, $D^3_{2\pi}=-B^3_{2\pi}$ and $D^1_{4\pi}=B^1_{4\pi}$. Introducing the notation $D_{0+1}=D_0+D_1$, we finally obtain

$$D_{0+1}-\kappa_{2\pi}B^1_{2\pi}-B^3_{2\pi}+\kappa_{4\pi}B^1_{4\pi}+D^3_{4\pi}=0,$$

a relationship equivalent to (21). Repeating the same process for the a, b and c cycles yields

$$A_{0+1}+\kappa_{2\pi}A^1_{2\pi}+A^3_{2\pi}+\kappa_{4\pi}A^1_{4\pi}+A^3_{4\pi}=0, \tag{22a}$$

$$B_{0+1}+\kappa_{2\pi}B^1_{2\pi}+B^3_{2\pi}+\kappa_{4\pi}B^1_{4\pi}+B^3_{4\pi}=0, \tag{22b}$$

$$C_{0+1}-\kappa_{2\pi}A^1_{2\pi}-A^3_{2\pi}+C^3_{4\pi}=0, \tag{22c}$$

$$D_{0+1}-\kappa_{2\pi}B^1_{2\pi}-B^3_{2\pi}+\kappa_{4\pi}B^1_{4\pi}+D^3_{4\pi}=0, \tag{22d}$$

with the explicit unknowns $\kappa_{2\pi}$ and $\kappa_{4\pi}$ and the unknowns $\zeta_{2\pi}$ and $\zeta_{4\pi}$ implied by the presence of cyclic periods associated with the integrals of the third kind. Note that $C^1_{4\pi}$ vanishes since $v^1_{4\pi}(\alpha,u)$, which is odd symmetric with respect to π [see (18)], does not contribute when integrated on cycle c (see Fig. 1). This seemingly intractable system can be fully solved analytically. The quantities associated with the 4π periodic elliptic integrals can be decoupled by adding Eq. (22a) to (22c) and (22b) to (22d) to obtain

$$\kappa_{4\pi}A^1_{4\pi}+A^3_{4\pi}+C^3_{4\pi}=-(A_{0+1}+C_{0+1}), \tag{23a}$$

$$2\kappa_{4\pi}B^1_{4\pi}+B^3_{4\pi}+D^3_{4\pi}=-(B_{0+1}+D_{0+1}), \tag{23b}$$

and the elimination of $\kappa_{4\pi}$ produces

$$A^1_{4\pi}(B^3_{4\pi}+D^3_{4\pi})-2B^1_{4\pi}(A^3_{4\pi}+C^3_{4\pi})=-A^1_{4\pi}(B_{0+1}+D_{0+1})+2B^1_{4\pi}(A_{0+1}+C_{0+1}) \tag{24}$$

in which the only (implicit) unknown $\zeta_{4\pi}$ determines the periods $A^3_{4\pi}$, $B^3_{4\pi}$, $C^3_{4\pi}$ and $D^3_{4\pi}$. Despite appearances, the above equation can be inverted to obtain $\zeta_{4\pi}$ and the technique for doing so is described in Sec. IV. Once $\zeta_{4\pi}$ has been obtained, the value of $\kappa_{4\pi}$ immediately follows either from Eq. (23a) or (23b). One can then proceed to solve for $\zeta_{2\pi}$ by subtracting Eq. (22c) from (22a) and (22d) from (22b) to obtain, respectively,

$$2\kappa_{2\pi}A^1_{2\pi}+2A^3_{2\pi}=-\kappa_{4\pi}A^1_{4\pi}-A^3_{4\pi}+C^3_{4\pi}-A_{0+1}+C_{0+1}, \tag{25a}$$

$$2\kappa_{2\pi}B^1_{2\pi}+2B^3_{2\pi}=-B^3_{4\pi}+D^3_{4\pi}-B_{0+1}+D_{0+1}, \tag{25b}$$

and the elimination of $\kappa_{2\pi}$ gives

$$\begin{aligned}A^1_{2\pi}B^3_{2\pi}-B^1_{2\pi}A^3_{2\pi}=\tfrac{1}{2}\{&A^1_{2\pi}(-B^3_{4\pi}+D^3_{4\pi}-B_{0+1}+D_{0+1})\\&-B^1_{2\pi}(-\kappa_{4\pi}A^1_{4\pi}-A^3_{4\pi}+C^3_{4\pi}-A_{0+1}+C_{0+1})\},\end{aligned} \tag{26}$$

where the only unknown is now $\zeta_{2\pi}$, the value of which determines the periods $A^3_{2\pi}$ and $B^3_{2\pi}$. This equation is of the same form as the one obtained in Ref. 9 and the solution follows the same approach. To set the stage for the comparatively more complicated inversion required for $\zeta_{4\pi}$, we first reexamine the analysis required for $\zeta_{2\pi}$ in more detail.

III. DETERMINATION OF $\zeta_{2\pi}$ AND $\kappa_{2\pi}$

The key to inverting for $\zeta_{2\pi}$ in (26) lies in the application of Cauchy's theorem on the Riemann surface delimited by the contour $\mathcal{C}_1$ shown in Fig. 2. Indeed, by judiciously choosing the integrand it is possible to obtain an alternative expression for the left-hand side of (26) in which

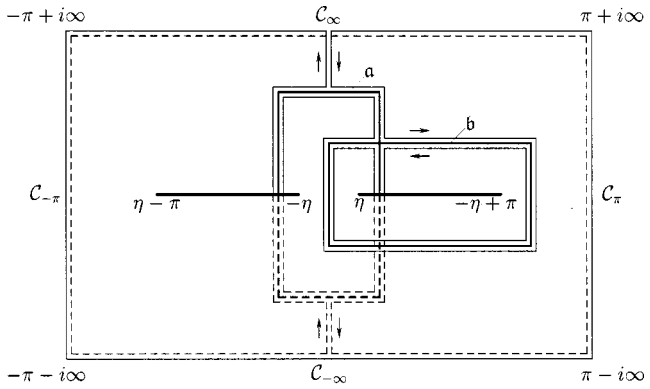

FIG. 2. The contour $\mathcal{C}_1=\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}\cup\mathcal{C}_{\pm\pi}\cup\mathcal{C}_{\pm\infty}$ on the upper (solid line) and lower (dashed line) sheets of the Riemann surface. The thicker inner lines are the dissections $\mathfrak{a}$ and $\mathfrak{b}$ introduced to make the Riemann surface simply connected. The path $\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}$ denotes the portion of the contour enclosing the dissecting cycles $\mathfrak{a}$ and $\mathfrak{b}$.

the unknown $\zeta_{2\pi}$ appears more explicitly as the argument of an elliptic integral of the first kind, paving the way for its inversion by means of the Jacobian elliptic sine function. This follows from recognizing that the relationship between cyclic periods on the left-hand side of (26) is of the same form as the expressions found in Riemann's bilinear relationships for differentials of the first and third kinds;[11,12] these equate expressions involving cyclic periods such as the one on the left-hand side of (26) to sums of residues. To achieve this, we seek to evaluate

$$\int_{\mathcal{C}_1} V^1_{2\pi}(\alpha,u)\,dV^3_{2\pi}(\alpha,u)=2\pi i\sum \text{ Res}, \tag{27}$$

where the elliptic integral $V^1_{2\pi}(\alpha,u)$ of the first kind and $V^3_{2\pi}(\alpha,u)$ of the third kind are defined as

$$V^n_{2\pi}(\alpha,u)=\int_{(\eta,0)}^{(\alpha,u)} v^n_{2\pi}(\alpha',u)\,d\alpha', \quad n\in\{1,3\}.$$

The path of integration $\mathcal{C}_1$, shown in Fig. 2, delimits a strip of width 2π centered at the origin of both Riemann sheets and encloses the dissections and branch cuts contained therein. For 2π periodic functions the enclosed surface is topologically equivalent to a torus (a handlebody of genus 1) as shown in Fig. 3. The canonical dissections $\mathfrak{a}$ and $\mathfrak{b}$ are introduced to make the surface

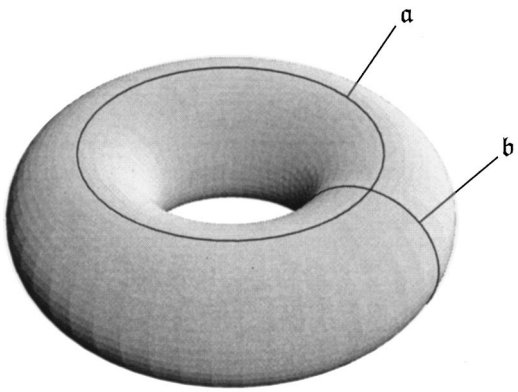

FIG. 3. The torus, handlebody of genus 1, is topologically equivalent to the Riemann surface in Fig. 2. It has been made simply connected by introducing the dissections $\mathfrak{a}$ and $\mathfrak{b}$.

simply connected, a key requirement in order for Cauchy's theorem to apply, and this is more easily appreciated on the dissected torus in Fig. 3. Examination of the integral in (27) shows that only $\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}$, the portion of the path enclosing the branch cuts and dissections, provides a contribution. The rest of the integral vanishes either by symmetry, as for the parts along $\mathrm{Re}\,\alpha=\pm\pi$ on $\mathcal{C}_{\pm\pi}$, or identically, as in the case where $|\mathrm{Im}\,\alpha|=\pm\infty$ on $\mathcal{C}_{\pm\infty}$. Evaluation of the integral along $\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}$ produces[11,12]

$$\int_{\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}} V^1_{2\pi}(\alpha,u)\,dV^3_{2\pi}(\alpha,u)=\mathfrak{A}^1_{2\pi}\mathfrak{B}^3_{2\pi}-\mathfrak{B}^1_{2\pi}\mathfrak{A}^3_{2\pi},$$

where, extending our notation, capitalized letters denote cyclic periods on cycles identified by the correspond lower case letters so that, for example, $\mathfrak{A}^1_{2\pi}=\int_{\mathfrak{a}} v^1_{2\pi}\,d\alpha$. The cycles defined by the dissections $\mathfrak{a}$ and $\mathfrak{b}$ in Fig. 2 are the same as the cycles a and b shown in Fig. 1 so that $\mathfrak{A}^n_{2\pi}=A^n_{2\pi}$ and $\mathfrak{B}^n_{2\pi}=B^n_{2\pi}$. We therefore obtain, in light of (26), the remarkable result

$$\int_{\mathcal{C}_1} V^1_{2\pi}(\alpha,u)\,dV^3_{2\pi}(\alpha,u)=\mathfrak{A}^1_{2\pi}\mathfrak{B}^3_{2\pi}-\mathfrak{B}^1_{2\pi}\mathfrak{A}^3_{2\pi}=A^1_{2\pi}B^3_{2\pi}-B^1_{2\pi}A^3_{2\pi}, \tag{28}$$

which, by virtue of (27), can be expressed as a sum of residues. On the Riemann surface, the residues of the integrand in (27) are given by

$$-\frac{u(\zeta_{2\pi})}{u(\alpha)}\frac{\cos\alpha}{\cos\zeta_{2\pi}}\frac{\sin\zeta_{2\pi}}{\sin\alpha}\int_{(\eta,0)}^{(\alpha,u)} v^1_{2\pi}(\alpha')\,d\alpha'\Bigg|_{\alpha=(\pm\zeta_{2\pi},\pm u)}$$

$$=\begin{cases}\mp\displaystyle\int_{(\eta,0)}^{(\alpha,u)} v^1_{2\pi}(\alpha')\,d\alpha', & \alpha=(\zeta_{2\pi},\pm u),\\ \pm\displaystyle\int_{(\eta,0)}^{(\alpha,u)} v^1_{2\pi}(\alpha')\,d\alpha', & \alpha=(-\zeta_{2\pi},\pm u),\end{cases}$$

and these, after carrying out the integration on the dissected Riemann surface, can be expressed in terms of the elliptic integral $V^1_{2\pi}(\alpha)$ defined on the upper Riemann sheet. Being mindful of the dissections and exploiting the numerous symmetries involved, we obtain

$$\sum \mathrm{Res}=-A^1_{2\pi}\pm 2B^1_{2\pi}-4V^1_{2\pi}(\zeta_{2\pi}),\quad V^1_{2\pi}(\zeta_{2\pi})\in\left\{-\tau'\frac{A^1_{2\pi}}{4}\pm\tau\frac{B^1_{2\pi}}{2}:0\leqslant\tau',\tau\leqslant 1\right\}. \tag{29}$$

It would of course be impossible to obtain a unique expression for the above if the Riemann surface had not previously been made simply connected. Substitution of (28) and (29) in (27) yields

$$V^1_{2\pi}(\zeta_{2\pi})=-\frac{A^1_{2\pi}}{4}\pm\frac{B^1_{2\pi}}{2}-\frac{\sigma_{2\pi}}{8\pi i}(A^1_{2\pi}B^3_{2\pi}-B^1_{2\pi}A^3_{2\pi})=-\frac{A^1_{2\pi}}{4}\pm\frac{B^1_{2\pi}}{2}+\sigma_{2\pi}i\Lambda_{2\pi}, \tag{30}$$

where the only unknown is $\zeta_{2\pi}$ and we have reintroduced $\sigma_{2\pi}$ from Eq. (20). The quantity $\Lambda_{2\pi}$ is, from (26), defined as

$$\Lambda_{2\pi}=\frac{1}{16\pi}\{A^1_{2\pi}(-B^3_{4\pi}+D^3_{4\pi}-B_{0+1}+D_{0+1})-B^1_{2\pi}(-\kappa_{4\pi}A^1_{4\pi}-A^3_{4\pi}+C^3_{4\pi}-A_{0+1}+C_{0+1})\}. \tag{31}$$

This is a known quantity provided equation system (23) has been solved, a procedure carried out in the next section.

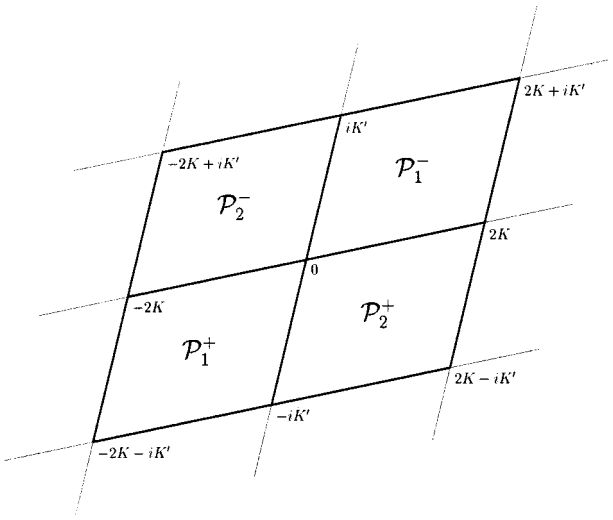

FIG. 4. The regions $\mathcal{P}_1^{\pm}$ and $\mathcal{P}_2^{\pm}$ in terms of the complete integrals of the first kind K and K' with $k=\cos\eta$. The parallelograms $\mathcal{P}$ indicate the various ranges in which $\Lambda_{2\pi}$ must lie when carrying out the inversion for $\zeta_{2\pi}$ with Eq. (34).

A closed-form expression for $\zeta_{2\pi}$ can be found by using the Jacobian elliptic sine function sn to invert the elliptic integral of the first kind in (30). Legendre's standard form for the integral is

$$F(x,k)=\int_0^x \frac{dt}{\sqrt{(1-t^2)(1-k^2t^2)}},$$

where k is the modulus of the integral and the elliptic sine function is such that

$$\mathrm{sn}[F(x,k),k]=x$$

with x located in the fundamental period parallelogram of dimensions $4K$ and $2iK'$ centered at the origin of the complex plane. The periods K and K' are the standard quantities defined, respectively, by the complete elliptic integrals of the first kind with modulus k and complementary modulus k'. The transformation $x=\cos\alpha/\cos\eta$ then shows that

$$V_{2\pi}^1(\alpha)=\int_\eta^\alpha \frac{d\alpha'}{\sqrt{\cos^2\alpha'-\cos^2\eta}}=i\left\{F\left(\frac{\cos\alpha}{\cos\eta},\cos\eta\right)+i\frac{B_{2\pi}^1}{4}\right\} \tag{32}$$

and we note the following useful relationships:

$$k=\cos\eta,\quad A_{2\pi}^1=4K',\quad B_{2\pi}^1=4iK. \tag{33}$$

Finally, taking into account the definition of $\Sigma\mathrm{Res}$ in terms of the range of $V_{2\pi}^1(\zeta_{2\pi})$ given in (29) and inserting (32) in (30), we obtain after some algebraic manipulations

$$\zeta_{2\pi}=\begin{cases}\arccos[k\,\mathrm{sn}(iK'+3K+\sigma_{2\pi}\Lambda_{2\pi},k)], & \Lambda_{2\pi}\in\mathcal{P}_1^{\sigma_{2\pi}},\\ \arccos[k\,\mathrm{sn}(iK'-K+\sigma_{2\pi}\Lambda_{2\pi},k)], & \Lambda_{2\pi}\in\mathcal{P}_2^{\sigma_{2\pi}},\end{cases} \tag{34}$$

which is an explicit expression for $\zeta_{2\pi}$. The correct expression to use in (34) as well as the correct definition for $\sigma_{2\pi}=\pm1$ follow from locating $\Lambda_{2\pi}$ in the appropriate $\mathcal{P}$ parallelogram in Fig. 4. For instance, if $\Lambda_{2\pi}\in\mathcal{P}_2^-$, then $\sigma_{2\pi}=-1$ and $\zeta_{2\pi}=\arccos[k\,\mathrm{sn}(iK'-K-\Lambda_{2\pi},k)]$. The multiplicative constant $\kappa_{2\pi}$ follows immediately from (25a) or (25b). The period parallelograms in Fig. 4 were obtained by using (30) and (29) to specify the range of $\Lambda_{2\pi}$ in terms of that of $V_{2\pi}^1(\zeta_{2\pi})$. For

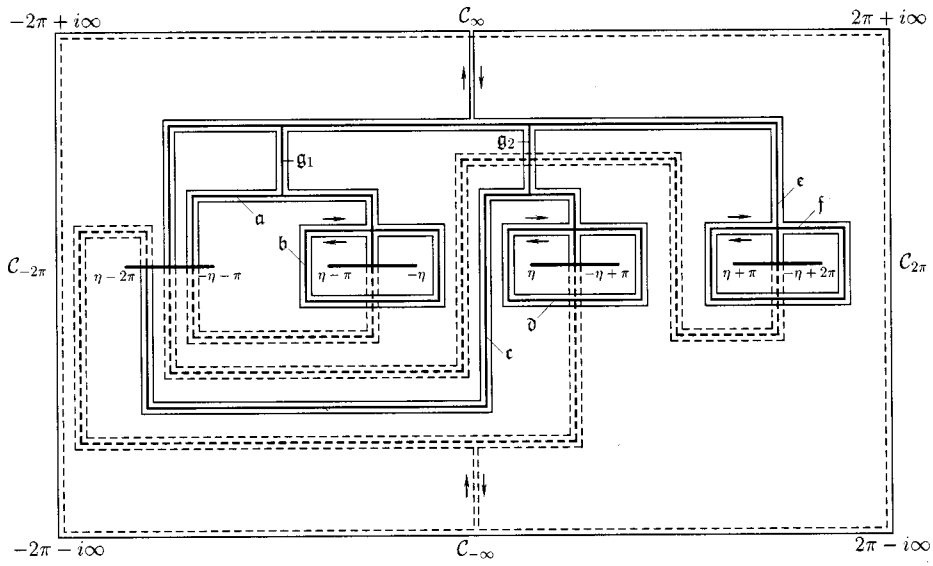

FIG. 5. The contour $\mathcal{C}_2=\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}\cup\mathcal{C}_{\mathfrak{c}\cup\mathfrak{d}}\cup\mathcal{C}_{\mathfrak{e}\cup\mathfrak{f}}\cup\mathcal{C}_{\mathfrak{g}_{1,2}}\cup\mathcal{C}_{\pm 2\pi}\cup\mathcal{C}_{\pm\infty}$ on the upper (solid line) and lower (dashed line) Riemann sheets. The thicker inner lines are the dissections $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$, $\mathfrak{d}$, $\mathfrak{e}$, $\mathfrak{f}$ and $\mathfrak{g}_{1,2}$ introduced to make the Riemann surface simply connected. The path $\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}$ denotes, for example, the portion of the contour enclosing the dissecting cycles $\mathfrak{a}$ and $\mathfrak{b}$.

example, if we consider the case of $+2B^1_{2\pi}$, then it follows that $\sigma_{2\pi}\Lambda_{2\pi}\in[-2K,0]\times[-iK',0]$ and, since $\sigma_{2\pi}=\pm 1$, this corresponds to the requirement that $\Lambda_{2\pi}$ lies in either of the parallelograms $\mathcal{P}_1^{\sigma_{2\pi}}$ shown in Fig. 4. One proceeds similarly for the case where we have $-2B^1_{2\pi}$ to obtain the $\mathcal{P}_2^{\sigma_{2\pi}}$ parallelograms in the figure. Taking into account the periodicity of the elliptic sine function, (34) becomes

$$\zeta_{2\pi}=\arccos[k\mathrm{sn}(iK'+3K+\sigma_{2\pi}\Lambda_{2\pi},k)],\quad \Lambda_{2\pi}\in\mathcal{P}_1^{\sigma_{2\pi}}\cup\mathcal{P}_2^{\sigma_{2\pi}},\tag{35}$$

where $\Lambda_{2\pi}$ is given in (31) and the standard periods K and iK' (as well as the parameter k) are given in (33).

IV. DETERMINATION OF $\zeta_{4\pi}$ AND $\kappa_{4\pi}$

A similar procedure to the one given in the previous section is required to successfully invert for $\zeta_{4\pi}$ in (24). However, the cyclic periods appearing on the left-hand side of (24) are now related to 4π periodic expressions and the application of Cauchy's theorem must now be carried out on the Riemann surface delimited by the contour $\mathcal{C}_2$ of width 4π shown in Fig. 5. Proceeding as in Sec. III we consider

$$\int_{\mathcal{C}_2} V^1_{4\pi}(\alpha,u)\,dV^3_{4\pi}(\alpha,u)=2\pi i\sum\ \mathrm{Res},\tag{36}$$

with the elliptic integrals defined as in the previous section but using the 4π periodic terms $v^{1,3}_{4\pi}(\alpha,u)$. For 4π periodic functions, the enclosed surface is now the topological equivalent of a handlebody of genus three (a sphere with three handles) as shown in Fig. 6 and it can be appreciated that making it simply connected involves a larger number of dissections than the torus of the previous section. To make it so, three pairs of canonical dissections $\mathfrak{a},\mathfrak{b}$; $\mathfrak{c},\mathfrak{d}$ and $\mathfrak{e},\mathfrak{f}$ are required as well as the two auxiliary dissections $\mathfrak{g}_1$ and $\mathfrak{g}_2$. They are shown in both Figs. 5 and 6; the simple connectedness is once again better appreciated by examining the handlebody representation of the Riemann surface. To keep the analysis relatively straightforward it is beneficial to draw the dissections such that only members of dissection pairs, $\mathfrak{a}$ and $\mathfrak{b}$, for example, intersect. This,

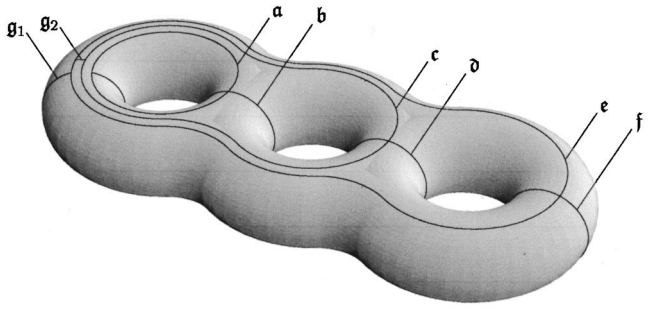

FIG. 6. Handlebody of genus 3, the topological equivalent of the Riemann surface in Fig. 5. It has been made simply connected by introducing the dissections $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$, $\mathfrak{d}$, $\mathfrak{e}$, $\mathfrak{f}$ and $\mathfrak{g}_{1,2}$.

while simplifying the evaluation of the path integral around the dissections, entails the rather intricate set of dissections shown in Fig. 5. Carrying out the integration it is seen that only $\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}\cup\mathcal{C}_{\mathfrak{c}\cup\mathfrak{d}}\cup\mathcal{C}_{\mathfrak{e}\cup\mathfrak{f}}$, the portion of the path enclosing the dissection pairs, contributes. The rest of the integral vanishes either by symmetry, as for the parts along $\mathrm{Re}\,\alpha=\pm 2\pi$ on $\mathcal{C}_{\pm 2\pi}$, or identically, as in the case where $|\mathrm{Im}\,\alpha|=\pm\infty$ on $\mathcal{C}_{\pm\infty}$. The contributions from the path enclosing the three dissection pairs, following our previous work, are

$$\int_{\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}} V^1_{4\pi}(\alpha,u)\,dV^3_{4\pi}(\alpha,u)=\mathfrak{A}^1_{4\pi}\mathfrak{B}^3_{4\pi}-\mathfrak{B}^1_{4\pi}\mathfrak{A}^3_{4\pi}, \tag{37}$$

$$\int_{\mathcal{C}_{\mathfrak{c}\cup\mathfrak{d}}} V^1_{4\pi}(\alpha,u)\,dV^3_{4\pi}(\alpha,u)=\mathfrak{C}^1_{4\pi}\mathfrak{D}^3_{4\pi}-\mathfrak{D}^1_{4\pi}\mathfrak{C}^3_{4\pi}, \tag{38}$$

$$\int_{\mathcal{C}_{\mathfrak{e}\cup\mathfrak{f}}} V^1_{4\pi}(\alpha,u)\,dV^3_{4\pi}(\alpha,u)=\mathfrak{E}^1_{4\pi}\mathfrak{F}^3_{4\pi}-\mathfrak{F}^1_{4\pi}\mathfrak{E}^3_{4\pi}. \tag{39}$$

Comparing the canonical cycles defined by the dissections with those defined in Fig. 1, together with symmetry, it is possible to rewrite the above canonical periods in terms of the cyclic periods defined in (19). The cyclic periods are defined on intervals between adjacent branch points and extending these definitions to the negative real axis, by means of the even parity of the expressions, the contributions from the branch point to branch point integrals in $\mathcal{S}_{4\pi}$ can then be identified as shown in Fig. 7(a). The canonical cycles $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$, $\mathfrak{d}$, $\mathfrak{e}$ and $\mathfrak{f}$ from Fig. 5 are then partitioned into branch point to branch point contributions, as shown in Figs. 7(b)–7(d). By comparing with Fig. 7(a), they are easily expressed in terms of the cyclic periods and it can thus be shown that

$$\mathfrak{A}=C,\quad \mathfrak{B}=-B,$$

$$\mathfrak{C}=A+B+C+D,\quad \mathfrak{D}=B,$$

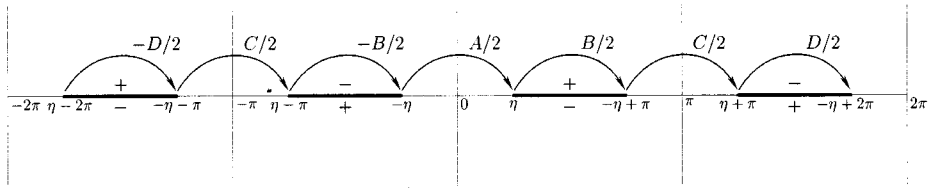
$$\mathfrak{E}=A+B+2C,\quad \mathfrak{F}=D.$$

This yields the following equalities for the right-hand sides of the above equations:

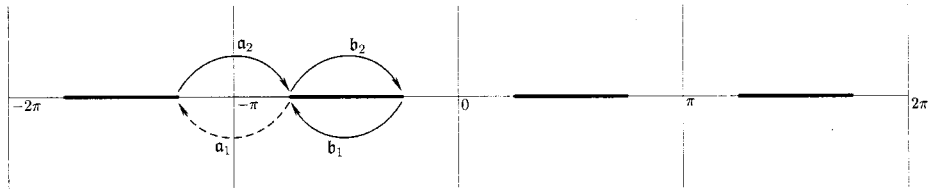
$$\mathfrak{A}^1_{4\pi}\mathfrak{B}^3_{4\pi}-\mathfrak{B}^1_{4\pi}\mathfrak{A}^3_{4\pi}=B^1_{4\pi}C^3_{4\pi}-C^1_{4\pi}B^3_{2\pi},$$

$$\mathfrak{C}^1_{4\pi}\mathfrak{D}^3_{4\pi}-\mathfrak{C}^1_{4\pi}\mathfrak{D}^3_{4\pi}=A^1_{4\pi}B^3_{4\pi}-B^1_{4\pi}A^3_{4\pi}+C^1_{4\pi}B^3_{4\pi}-B^1_{4\pi}C^3_{4\pi}+D^1_{4\pi}B^3_{4\pi}-B^1_{4\pi}D^3_{4\pi},$$

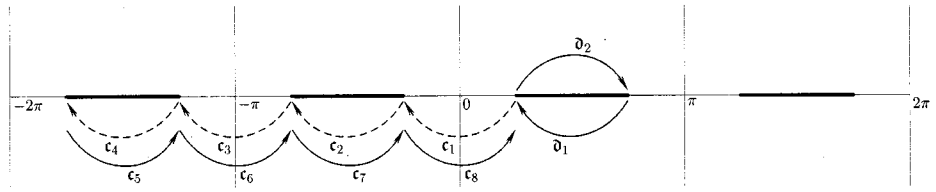
$$\mathfrak{E}^1_{4\pi}\mathfrak{F}^3_{4\pi}-\mathfrak{E}^1_{4\pi}\mathfrak{F}^3_{4\pi}=A^1_{4\pi}D^3_{4\pi}-D^1_{4\pi}A^3_{4\pi}+B^1_{4\pi}D^3_{4\pi}-D^1_{4\pi}B^3_{4\pi}+2(C^1_{4\pi}D^3_{4\pi}-D^1_{4\pi}C^3_{4\pi}).$$



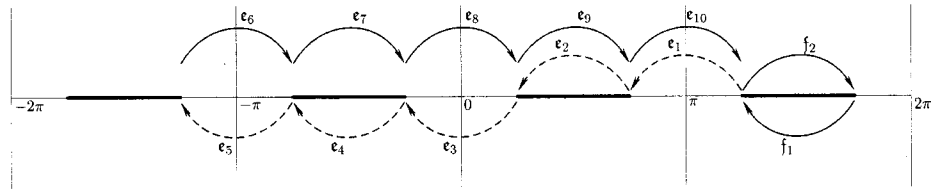
(a) Basic cyclic periods



(b) Canonical cycles $\mathfrak{a}$ and $\mathfrak{b}$



(c) Canonical cycles $\mathfrak{c}$ and $\mathfrak{d}$



(d) Canonical cycles $\mathfrak{e}$ and $\mathfrak{f}$

FIG. 7. Figures used to express the canonical periods in Fig. 5 in terms of the basic cyclic periods in Fig. 1 (e.g., $\mathfrak{A}$ in terms of A, B, C, D). The canonical cycles on the (solid lines) upper and (dashed lines) lower sheets in (b), (c) and (d) are written as chains of branch point to branch point segments—$\mathfrak{e}$ into a sequence of $\mathfrak{e}_n$, for example—which are easily expressed in terms of the basic cyclic periods given in (a).

Summing up these contributions,

$$\begin{aligned}\int_{\mathcal{C}_2} V^1_{4\pi}(\alpha,u)\,dV^3_{4\pi}(\alpha,u) &= \left(\int_{\mathcal{C}_{\mathfrak{a}\cup\mathfrak{b}}} + \int_{\mathcal{C}_{\mathfrak{c}\cup\mathfrak{d}}} + \int_{\mathcal{C}_{\mathfrak{e}\cup\mathfrak{f}}}\right) V^1_{4\pi}(\alpha,u)\,dV^3_{4\pi}(\alpha,u)\\ &= A^1_{4\pi}B^3_{4\pi} - B^1_{4\pi}A^3_{4\pi} + A^1_{4\pi}D^3_{4\pi} - D^1_{4\pi}A^3_{4\pi} + 2(C^1_{4\pi}D^3_{4\pi} - D^1_{4\pi}C^3_{4\pi})\\ &= A^1_{4\pi}(B^3_{4\pi} + D^3_{4\pi}) - 2B^1_{4\pi}(A^3_{4\pi} + C^3_{4\pi}),\end{aligned} \tag{40}$$

where on the last line we have made use of $D^1_{4\pi} = B^1_{4\pi}$ and $C^1_{4\pi} = 0$. This is remarkable in that it reproduces the left-hand side of (24) and can be expressed in terms of residues in accordance with (36). The integrand in (36) has residues

$$-\frac{u(\zeta_{4\pi})}{u(\alpha)}\frac{\cos\alpha}{\cos\zeta_{4\pi}}\frac{\sin(\zeta_{4\pi}/2)}{\sin(\alpha/2)}\int_{(\eta,0)}^{(\alpha,u)} v_{4\pi}^{1}(\alpha')\,d\alpha'\Bigg|_{\alpha=(\pm\zeta_{4\pi},\pm u)}$$

$$=\begin{cases} \mp\displaystyle\int_{(\eta,0)}^{(\alpha,u)} v_{4\pi}^{1}(\alpha')\,d\alpha', & \alpha=(\zeta_{4\pi},\pm u),\\ \pm\displaystyle\int_{(\eta,0)}^{(\alpha,u)} v_{4\pi}^{1}(\alpha')\,d\alpha', & \alpha=(-\zeta_{4\pi},\pm u),\end{cases}$$

which are expressed in terms of $V_{4\pi}^{1}(\zeta_{4\pi})$ and $V_{4\pi}^{1}(2\pi-\zeta_{4\pi})$—both taken on the top Riemann sheet—after carrying out the path integrals on the dissected Riemann surface. Taking advantage of the numerous symmetries and avoiding the crossing of any dissection leads to

$$\sum \text{Res}=\begin{cases} -A_{4\pi}^{1}\pm 4B_{4\pi}^{1}-4V_{4\pi}^{1}(\zeta_{4\pi}), & V_{4\pi}^{1}(\zeta_{4\pi})\in\left\{-\tau'\dfrac{A_{4\pi}^{1}}{4}\pm\tau\dfrac{B_{4\pi}^{1}}{2}:0\leqslant\tau',\tau\leqslant 1\right\},\\ -A_{4\pi}^{1}-4V_{4\pi}^{1}(2\pi-\zeta_{4\pi}), & V_{4\pi}^{1}(2\pi-\zeta_{4\pi})\in\left\{-\tau'\dfrac{A_{4\pi}^{1}}{4}\pm\tau\dfrac{B_{4\pi}^{1}}{2}:0\leqslant\tau',\tau\leqslant 1\right\}.\end{cases} \tag{41}$$

In the short analysis that follows, we restrict for now our attention to the first case given above with the $+4B_{4\pi}^{1}$ term for the sake of brevity. Using (40) and (41) in (36) then produces

$$\begin{aligned} V_{4\pi}^{1}(\zeta_{4\pi}) &= -\frac{A_{4\pi}^{1}}{4}+B_{4\pi}^{1}-\frac{\sigma_{4\pi}}{8\pi i}\{A_{4\pi}^{1}(B_{4\pi}^{3}+D_{4\pi}^{3})-2B_{4\pi}^{1}(A_{4\pi}^{3}+C_{4\pi}^{3})\}\\ &= -\frac{A_{4\pi}^{1}}{4}+B_{4\pi}^{1}+\frac{\sigma_{4\pi}}{\cos(\eta/2)}\Lambda_{4\pi}, \end{aligned} \tag{42}$$

where the only unknown is $\zeta_{4\pi}$ and the sign $\sigma_{4\pi}$ from Eq. (20) has been reintroduced. The $\cos\eta/2$ term is used for future convenience and, in agreement with (24), we have

$$\Lambda_{4\pi}=\frac{\cos(\eta/2)}{8\pi i}\{A_{4\pi}^{1}(B_{0+1}+D_{0+1})-2B_{4\pi}^{1}(A_{0+1}+C_{0+1})\}. \tag{43}$$

In order to use the Jacobian elliptic sine function sn to invert the elliptic integral of the first kind, we recast $V_{4\pi}^{1}(\alpha)$ in terms of Legendre's standard form. The transformation $x=(\sin\alpha/2)/(\sin\eta/2)$, together with the alternative expression to (6),

$$u(\alpha)=2\sqrt{\left(\cos^2\frac{\alpha}{2}-\cos^2\frac{\eta}{2}\right)\left(\cos^2\frac{\alpha}{2}-\sin^2\frac{\eta}{2}\right)},$$

enables us to write

$$V_{4\pi}^{1}(\alpha)=\int_{\eta}^{\alpha}\frac{\cos(\alpha'/2)}{u(\alpha')}d\alpha'=\frac{1}{\cos(\eta/2)}\left\{F\left(\frac{\sin(\alpha/2)}{\sin(\eta/2)},\tan\frac{\eta}{2}\right)-\frac{\cos(\eta/2)}{4}A_{4\pi}^{1}\right\}, \tag{44}$$

and we have the following relationships for the parameter k and the cyclic periods:

$$k=\tan\frac{\eta}{2},\quad A_{4\pi}^{1}=\frac{4K}{\cos(\eta/2)},\quad B_{4\pi}^{1}=\frac{2iK'}{\cos(\eta/2)}. \tag{45}$$

Inserting (44) in (42), solving for $\zeta_{4\pi}$ then produces, after some algebraic manipulations,

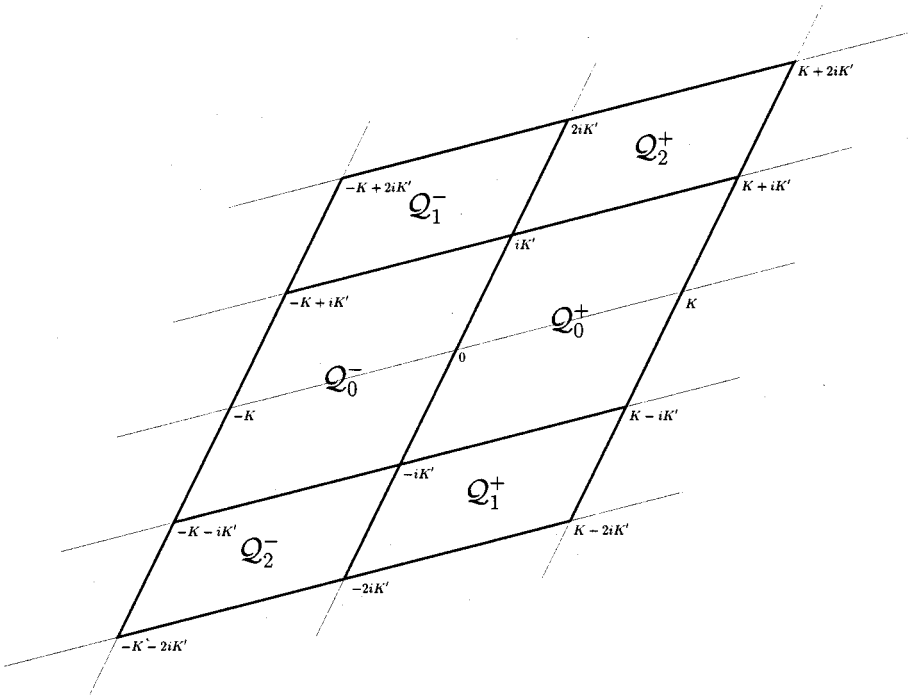


FIG. 8. The regions $\mathcal{Q}_0^{\pm}$, $\mathcal{Q}_1^{\pm}$ and $\mathcal{Q}_2^{\pm}$ in terms of the complete integrals of the first kind K and K' with $k=\tan\eta/2$. The parallelograms $\mathcal{Q}$ indicate the various ranges in which $\Lambda_{4\pi}$ must lie when carrying out the inversion for $\zeta_{4\pi}$ with Eq. (46).

$$\zeta_{4\pi}=2\arcsin\left[\sin\frac{\eta}{2}\,\mathrm{sn}(2iK'+\sigma_{4\pi}\Lambda_{4\pi},k)\right].$$

It follows from (42) and (41) that this holds if $\sigma_{4\pi}\Lambda_{4\pi}$ lies in the period parallelogram $[0,K]\times[-iK',-2iK']$. As $\sigma_{4\pi}=\pm1$, the acceptable range for $\Lambda_{4\pi}$ is therefore $\pm[0,K]\times\pm[-iK',-2iK']$ with the plus sign corresponding to $\sigma_{4\pi}=1$. These regions are identified in Fig. 8 by the period parallelograms $\mathcal{Q}_1^{\sigma_{4\pi}}$. Repeating this process for the other cases in (41), it can be shown that

$$\zeta_{4\pi}=\begin{cases}2\pi-2\arcsin\left[\sin\dfrac{\eta}{2}\,\mathrm{sn}(\sigma_{4\pi}\Lambda_{4\pi},k)\right], & \Lambda_{4\pi}\in\mathcal{Q}_0^{\sigma_{4\pi}},\\ 2\arcsin\left[\sin\dfrac{\eta}{2}\,\mathrm{sn}(2iK'+\sigma_{4\pi}\Lambda_{4\pi},k)\right], & \Lambda_{4\pi}\in\mathcal{Q}_1^{\sigma_{4\pi}},\\ 2\arcsin\left[\sin\dfrac{\eta}{2}\,\mathrm{sn}(-2iK'+\sigma_{4\pi}\Lambda_{4\pi},k)\right], & \Lambda_{4\pi}\in\mathcal{Q}_2^{\sigma_{4\pi}},\end{cases}\tag{46}$$

which is an explicit expression for $\zeta_{4\pi}$. The proper expression and the sign of $\sigma_{4\pi}=\pm1$ are selected by using Fig. 8 in order to determine in which period parallelogram $\mathcal{Q}$ lies the quantity $\Lambda_{4\pi}$. The multiplicative constant $\kappa_{4\pi}$ immediately follows from (23a) or (23b). Note that (46) can be simplified by exploiting the periodicity of the sn function to obtain

$$\zeta_{4\pi}=\begin{cases}2\pi-2\arcsin\left[\sin\dfrac{\eta}{2}\,\mathrm{sn}(\sigma_{4\pi}\Lambda_{4\pi},k)\right], & \Lambda_{4\pi}\in\mathcal{Q}_0^{\sigma_{4\pi}},\\ 2\arcsin\left[\sin\dfrac{\eta}{2}\,\mathrm{sn}(\sigma_{4\pi}\Lambda_{4\pi},k)\right], & \Lambda_{4\pi}\in\mathcal{Q}_1^{\sigma_{4\pi}}\cup\mathcal{Q}_2^{\sigma_{4\pi}},\end{cases}\tag{47}$$

where $\Lambda_{4\pi}$ is given in (43) and k, iK' are given in (45).

V. BRANCH-FREE SOLUTIONS

The determination of the unknowns $\zeta_{2\pi,4\pi}$ and $\kappa_{2\pi,4\pi}$ completes the definition of the solution to the first order difference equations $w(\alpha,u)$ as given in (20). It still has branch points and is therefore multivalued owing to the arbitrariness of the branch of $u(\alpha)$ but its integrand is now such that the path integral is single-valued on either of the Riemann sheets. Meromorphic solutions to the second order difference equation can now be obtained through the use of expressions (10). We recall, however, that solutions free of poles and zeros in the strip $\mathcal{S}_{4\pi}$ are required and therefore seek to use specific linear combinations of (10) to finalize the construction of the solutions. Knowledge of the poles and zeros of $w(\alpha,u)$ is required to successfully complete this endeavor and, since they arise solely due to $v^3_{2\pi}(\alpha,u)$ and $v^3_{4\pi}(\alpha,u)$, it is straightforward to show that in $\mathcal{S}_{4\pi}$

$$w(\alpha,\pm u)\sim\left\{\frac{\alpha+\zeta_{2\pi}}{\alpha-\zeta_{2\pi}}\,\frac{\alpha+(\zeta_{2\pi}-2\pi)}{\alpha-(\zeta_{2\pi}-2\pi)}\,\frac{\alpha+\zeta_{4\pi}}{\alpha-\zeta_{4\pi}}\right\}^{\pm 1}, \tag{48}$$

where $\sigma_{2\pi}=\sigma_{4\pi}=1$ is assumed for simplicity. With this information in hand, the poles of any linear combinations involving (10) are easily determined. Zeros are by nature more elusive and we rely on knowledge of the limiting functions in order to determine their number as well as general location. The cancellation of the poles and zeros is also complicated by the order requirement on the solutions which must be $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$.

We first present an entirely analytic approach from which two independent solutions are obtained. They satisfy the analyticity requirements, recover the known solutions $\Psi_1(\alpha)$ and $1/\Psi_1(\alpha)$ when $\eta\to\pi/2$, and their only shortcoming is that they vanish as $\eta\to 0$, though knowledge of (13) circumvents this difficulty. In an effort to obtain expressions that also recover the known solution $\Psi_2(\alpha)$ when $\eta\to 0$, a number of approaches relying on numerically locating zeros were explored but, despite producing more desirable behaviors, they fail as $\eta\to 0$ due to inadmissible poles that arise in the strip of analyticity in that limit. An example of such an approach is provided here which nearly succeeds in recovering both limiting functions $\Psi_1(\alpha)$ and $\Psi_2(\alpha)$.

In the following, we use the primed functions $t'_n(\alpha)$ to denote intermediate branch-free solutions of the second order difference equation (2) which still have undesired poles and zeros in the strip $\mathcal{S}_{4\pi}$ whereas the unprimed functions $t_n(\alpha)$ denote the appropriate branch-free and pole/zero-free solutions.

A. Analytical solution

We proceed by constructing two meromorphic solutions of (2), $t'_1(\alpha)$ and $t'_2(\alpha)$, sharing a common pole at $\zeta_{4\pi}$ but having distinct unknown zeros α_1 and α_2, and then use a linear combination to obtain an expression with a known pole/zero pair. Proceeding in a manner similar to the technique presented in Ref. 9, we write

$$t'_1(\alpha)=\frac{T_{2\pi}(\alpha)}{2}\left\{\left(1+\frac{f_1(\alpha)}{u(\alpha)}\right)w(\alpha,u)+\left(1-\frac{f_1(\alpha)}{u(\alpha)}\right)w(\alpha,-u)\right\}, \tag{49}$$

a linear combination of the branch-free forms (10). The functions $f_1(\alpha)$ and $T_{2\pi}(\alpha)$ are 4π periodic; $f_1(\alpha)$ is a trigonometric polynomial used to introduce zeros at appropriate locations in the α plane while the external multiplicative function $T_{2\pi}(\alpha)$ is a rational trigonometric function used to annul poles and zeros. We observe that the introduction of double zeros coincident with the poles of either $w(\alpha,u)$ or $w(\alpha,-u)$ produces, by (48), a simple zero in the term in curly braces above. Thus, if we require

$$1-\frac{f_1(\alpha)}{u(\alpha)}\sim(\alpha+\zeta_{2\pi})^2(\alpha+(\zeta_{2\pi}-2\pi))^2(\alpha+\zeta_{4\pi}), \tag{50}$$

then the second term in braces in (49) has simple zeros coinciding with those of $w(\alpha,u)$ at $\alpha=-\zeta_{2\pi},2\pi-\zeta_{2\pi}$ and is finite at $\alpha=-\zeta_{4\pi}$. This implies

$$\left(1+\frac{f_1(\alpha)}{u(\alpha)}\right)w(\alpha,u)+\left(1-\frac{f_1(\alpha)}{u(\alpha)}\right)w(\alpha,-u)\sim\frac{\alpha+\zeta_{2\pi}}{\alpha-\zeta_{2\pi}}\frac{\alpha+(\zeta_{2\pi}-2\pi)}{\alpha-(\zeta_{2\pi}-2\pi)}\frac{\alpha-\alpha_1}{\alpha-\zeta_{4\pi}},$$

where α_1 is the unknown location of a zero in the $\mathcal{S}_{4\pi}$ strip. While the exact location of α_1 is not easily determined, its general location is known when η is in the neighborhood of $\pi/2$. Indeed, as $\eta\to\pi/2$ we have $f_1(\alpha)/u(\alpha)\to 1$ and

$$\frac{1}{2}\left\{\left(1+\frac{f_1(\alpha)}{u(\alpha)}\right)w(\alpha,u)+\left(1-\frac{f_1(\alpha)}{u(\alpha)}\right)w(\alpha,-u)\right\}\overset{\eta\to\pi/2}{\to}w(\alpha,u),$$

and we conclude, see (48), that when η is in the neighborhood of $\pi/2$, α_1 is in the neighborhood of $-\zeta_{4\pi}$. Choosing $T_{2\pi}(\alpha)$ to eliminate the poles and zeros associated with $\zeta_{2\pi}$ gives

$$T_{2\pi}(\alpha)=\frac{\tan(\zeta_{2\pi}/2)-\tan(\alpha/2)}{\tan(\zeta_{2\pi}/2)+\tan(\alpha/2)}$$

so that

$$t_1'(\alpha)\sim\frac{\alpha-\alpha_1}{\alpha-\zeta_{4\pi}}.$$

The 4π periodic $f_1(\alpha)$ is obtained by letting

$$f_1(\alpha)=\nu_1+\nu_2\cos\alpha+\nu_3\sin\alpha+\nu_4\cos\frac{\alpha}{2}+\nu_5\sin\frac{\alpha}{2}$$

and enforcement of (50) produces

$$\nu_1=\frac{1}{1-\cos(\zeta_{2\pi}-\zeta_{4\pi})}\left\{u(\zeta_{2\pi})-\frac{1}{u(\zeta_{4\pi})}(\sin^2\eta\cos\zeta_{2\pi}\cos\zeta_{4\pi}-\cos^2\eta\sin\zeta_{2\pi}\sin\zeta_{4\pi})\right\},$$

$$\nu_2=\cos\zeta_{2\pi}\left(-\nu_1+\frac{\sin^2\eta}{u(\zeta_{2\pi})}\right),$$

$$\nu_3=\sin\zeta_{2\pi}\left(\nu_1+\frac{\cos^2\eta}{u(\zeta_{2\pi})}\right),$$

with $\nu_4=\nu_5=0$. We note that, in agreement with the analyticity requirements, the function $T_{2\pi}(\alpha)$ and the ratio $f_1(\alpha)/u(\alpha)$ are $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$. A related meromorphic solution to the second order difference equation sharing the same pole but having a different zero is

$$t_2'(\alpha)=\frac{T_{2\pi}(\alpha)}{2}\left\{\left(1-\frac{f_2(\alpha)}{u(\alpha)}\right)w(\alpha,u)+\left(1+\frac{f_2(\alpha)}{u(\alpha)}\right)w(\alpha,-u)\right\},\tag{51}$$

where $f_2(\alpha)$ is now chosen, following the same kind of procedure as for $f_1(\alpha)$, such that

$$1-\frac{f_2(\alpha)}{u(\alpha)}\sim(\alpha-\zeta_{2\pi})^2(\alpha-(\zeta_{2\pi}-2\pi))^2,$$

$$1+\frac{f_2(\alpha)}{u(\alpha)}\sim(\alpha+\zeta_{4\pi}),$$

and hence

$$t_2'(\alpha)\sim\frac{\alpha-\alpha_2}{\alpha-\zeta_{4\pi}}.$$

By the same reasoning as above, the zero α_2 is also in the neighborhood of $\alpha=-\zeta_{4\pi}$ when η is in the neighborhood of $\pi/2$. The meromorphic solutions $t_1'(\alpha)$ and $t_2'(\alpha)$ then share the same pole and a linear combination can now be used to introduce a zero at $\alpha=-\zeta_{4\pi}$ such that

$$t_1'(\alpha)+\xi t_2'(\alpha)\sim\frac{\alpha+\zeta_{4\pi}}{\alpha-\zeta_{4\pi}} \tag{52}$$

and this requires

$$\xi=-\frac{t_1'(-\zeta_{4\pi})}{t_2'(-\zeta_{4\pi})}=-T_{2\pi}^2(-\zeta_{4\pi})\frac{\sin\zeta_{4\pi}\cos\zeta_{4\pi}-u(\zeta_{4\pi})(\nu_2\sin\zeta_{4\pi}+\nu_3\cos\zeta_{4\pi})}{\sin\zeta_{4\pi}\cos\zeta_{4\pi}+u(\zeta_{4\pi})(\nu_2\sin\zeta_{4\pi}+\nu_3\cos\zeta_{4\pi})}.$$

An acceptable solution of the second order difference equation (2), free of poles and zeros in $\mathcal{S}_{4\pi}$ and $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$, is then

$$t_1(\alpha)=\frac{\tan(\zeta_{4\pi}/4)-\tan(\alpha/4)}{\tan(\zeta_{4\pi}/4)+\tan(\alpha/4)}\{t_1'(\alpha)+\xi t_2'(\alpha)\}, \tag{53}$$

and

$$t_1(\alpha)\overset{\eta\to\pi/2}{\to}\Psi_1(\alpha),\quad t_1(\alpha)\overset{\eta\to0}{\to}0.$$

The first limit stems from the fact that, as $\eta\to\pi/2$, $1-f_1(\alpha)/u(\alpha)\to0$, $\xi\to0$ and, since in that limit $\kappa_{2\pi,4\pi}\to0$,

$$w(\alpha,u)\overset{\eta\to\pi/2}{\to}\frac{\tan(\zeta_{2\pi}/2)+\tan(\alpha/2)}{\tan(\zeta_{2\pi}/2)-\tan(\alpha/2)}\frac{\tan(\zeta_{4\pi}/4)+\tan(\alpha/4)}{\tan(\zeta_{4\pi}/4)-\tan(\alpha/4)}\Psi_1(\alpha),$$

where we are still assuming that $\sigma_{2\pi}=\sigma_{4\pi}=1$. For the second limit, it is can be shown that $t_1'\to t_2'$ and $\xi\to-1$ as $\eta\to0$, and $t_1(\alpha)$ therefore vanishes in that limit. Following the same prescription as above, a second independent solution $t_2(\alpha)$ can be derived by seeking instead a common pole at $-\zeta_{4\pi}$ and it can easily be shown that

$$t_2(\alpha)=t_1(-\alpha), \tag{54}$$

but we now have, using the same arguments as above,

$$t_2(\alpha)\overset{\eta\to\pi/2}{\to}\frac{1}{\Psi_1(\alpha)},\quad t_2(\alpha)\overset{\eta\to0}{\to}0.$$

The pair of solutions $t_1(\alpha)$ and $t_2(\alpha)$ satisfy the prescribed analyticity requirements listed in Sec. I and recover the known solutions $\Psi_1(\alpha)$ and $1/\Psi_1(\alpha)$ as $\eta\to\pi/2$. However, both vanish as $\eta\to0$ and they therefore fall short of the preferred behavior obtained in Ref. 9 where the solutions are seen to vary smoothly as a function of η between the two known limiting functions when $\eta=\pi/2$ and $\eta=0$. Although undesirable, this is not a serious shortcoming since a pair of linearly independent solutions are known when $\eta=0$ and are given in (13). This vanishing of $t_{1,2}(\alpha)$ when $\eta\to0$ can be attributed to the use of linear combinations [see (52)] in order to create known zeros, a procedure which was not required in Ref. 9. Experience suggests that a purely multiplicative

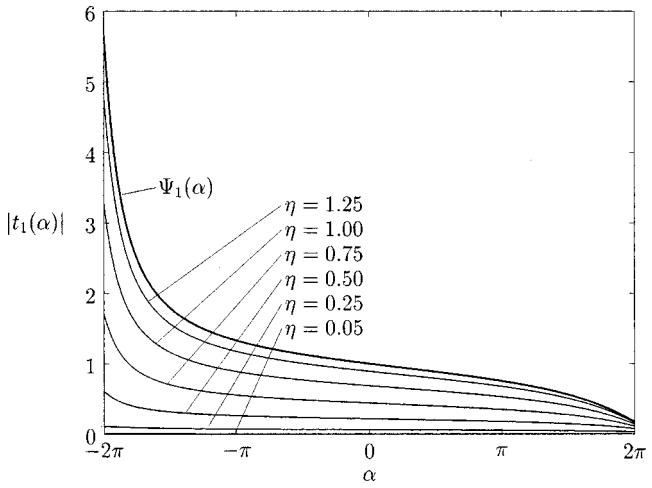

FIG. 9. Magnitude of the branch-free solution $t_1(\alpha)$ given in (53) when $\theta=0.25(1+i)$ for various values of η. The thicker line corresponds to the known limiting function $\Psi_1(\alpha)$, per (11), for $\eta=\pi/2$. The case for $\eta=1.57$ is indistinguishable from $\Psi_1(\alpha)$.

method for eliminating the poles and zeros would likely reproduce the desired behavior, but this so far remains elusive. The continuation of $t_1(\alpha)$ and $t_2(\alpha)$ outside the strip $|\mathrm{Re}\,\alpha|\leqslant 2\pi$ is provided by the first order difference equations (4) and (5), and the results confirm the fact that the solutions are free of branch points everywhere. Indeed, the expressions so obtained are linear combinations of the branch-free forms (10). The technique has been implemented and sample curves for $|t_1(\alpha)|$ are provided in Fig. 9 for various values of η when $\theta=0.25(1+i)$. We observe that $t_1(\alpha)\rightarrow\Psi_1(\alpha)$ as $\eta\rightarrow\pi/2$, and $t_1(\alpha)\rightarrow 0$ as $\eta\rightarrow 0$.

We close this section by summarizing the procedure for computing the solutions $t_1(\alpha)$ and $t_2(\alpha)$. The fundamental building block is $w(\alpha,u)$, given in (20), the solution to the first order equation (4) and its computation requires the quantities $\kappa_{2\pi,4\pi}$, $\zeta_{2\pi,4\pi}$ and $\sigma_{2\pi,4\pi}$. The preliminary step in obtaining those quantities is to first compute the cyclic periods (19) using numerical integration. The quantities $\zeta_{2\pi}$ and $\sigma_{2\pi}$ then follow from (35) and $\kappa_{2\pi}$ from (25). The quantities $\zeta_{4\pi}$, $\sigma_{4\pi}$ and $\kappa_{4\pi}$ are likewise obtained from (47) and (23). The function $w(\alpha,u)$ can then be computed by carrying out numerically the path integral in (20); the functions $t_1'(\alpha)$, $t_2'(\alpha)$ and $t_1(\alpha)$, $t_2(\alpha)$ then respectively follow from (49), (51) and (53), (54).

B. Numerical solution

By foregoing an entirely analytical approach, it is possible to construct solutions that, unlike $t_{1,2}(\alpha)$, do not vanish as $\eta\rightarrow 0$ but we must however resort to the numerical identification of zeros, a somewhat unattractive prospect. The main motivation behind this approach is to proceed with the pole/zero cancellation in a multiplicative fashion and avoid the use of linear combinations of the type (52). Interestingly, it is possible to reproduce in this manner the more desirable behavior obtained in Ref. 9 where Eq. (1) is solved. Therein, the solutions obtained are observed to smoothly vary between two known limiting functions corresponding to, in the case at hand, $\Psi_1(\alpha)$ as $\eta\rightarrow\pi/2$ and $\Psi_2(\alpha)$ as $\eta\rightarrow 0$. This can be achieved here but at the price of having to numerically locate four zeros though, as discussed below, a pole that arises at $\eta\rightarrow 0$ proves to be problematic. Turning once again to the by now familiar form, we write

$$t_3'(\alpha)=\frac{T_{4\pi}(\alpha)}{2}\left\{\left(1+\frac{f_3(\alpha)}{u(\alpha)}\right)w(\alpha,u)+\left(1-\frac{f_3(\alpha)}{u(\alpha)}\right)w(\alpha,-u)\right\}, \tag{55}$$

and examination of the behavior of the solution in Ref. 9 now suggests using

$$f_3(\alpha)=\frac{\cos\zeta_{4\pi}\sin^2\eta\cos\alpha+\sin\zeta_{4\pi}\cos^2\eta\sin\alpha}{u(\zeta_{4\pi})},$$

so that

$$1-\frac{f_3(\alpha)}{u(\alpha)}\sim(\alpha+\zeta_{4\pi})^2(\alpha+(\zeta_{4\pi}-2\pi))^2.$$

The term in braces in (55) is then such that

$$\{\}\sim\frac{\alpha+\zeta_{4_\pi}}{\alpha-\zeta_{4_\pi}}\frac{(\alpha-\alpha_1)(\alpha-\alpha_2)(\alpha-\alpha_3)(\alpha-\alpha_3)}{(\alpha+\zeta_{2\pi})(\alpha-\zeta_{2\pi})(\alpha+(\zeta_{2\pi}-2\pi))(\alpha+(\zeta_{2\pi}+2\pi))}$$

and the pole and zero associated with $\zeta_{4\pi}$ are eliminated by choosing

$$T_{4\pi}(\alpha)=\frac{\tan(\zeta_{4\pi}/4)-\tan(\alpha/4)}{\tan(\zeta_{4\pi}/4)+\tan(\alpha/4)}.$$

In the limit as $\eta\to\pi/2$ we have

$$t_3'(\alpha)\sim\frac{\alpha+\zeta_{2\pi}}{a-\zeta_{2\pi}}\frac{\alpha+(\zeta_{2\pi}-2\pi)}{\alpha-(\zeta_{2\pi}-2\pi)},$$

which implies that, when η is in the neighborhood of $\pi/2$, the poles at $\alpha=-\zeta_{2\pi}$ and $\alpha=-\zeta_{2\pi}+2\pi$ will each have a closely located pair of zeros α_n. Once the location of these zeros has been obtained numerically by evaluating $t_3'(\alpha)$ in (55), the desired solution may be written as

$$t_3(\alpha)=\frac{\cos\alpha-\cos\zeta_{2\pi}}{1-\cos\zeta_{2\pi}}\left(\prod_{n=1}^{4}\frac{\sin(\alpha_n/4)}{\sin\frac{1}{4}(\alpha_n-\alpha)}\right)t_3'(\alpha) \tag{56}$$

so that $t_3(\alpha)$ is free of poles and zeros in $\mathcal{S}_{4\pi}$. It is easily shown that

$$t_3(\alpha)\overset{\eta\to\pi/2}{\to}\Psi_1(\alpha),$$

and since $f_3(\alpha)/u(\alpha)\to\pm1$ as $\eta\to0$, albeit in a branched fashion, it can also be shown (numerically) that

$$t_3(\alpha)\overset{\eta\to0}{\to}\Psi_2(\alpha).$$

Figure 10 provides sample curves for $|t_3(\alpha)|$ for various values of η when $\theta=0.25(1+i)$. The behavior obtained is reminiscent of the one in Ref. 9 since the solution now varies smoothly between the two limiting functions $\Psi_{1,2}(\alpha)$ as a function of η. Once again, a second solution is provided by $t_3(-\alpha)$ and this recovers $1/\Psi_1(\alpha)$ as $\eta\to\pi/2$ and $\Psi_2(\alpha)$ as $\eta\to0$. Despite this, the approach is, however, flawed since one of the numerical zeros strays slightly outside $\mathcal{S}_{4\pi}$ when $\eta\simeq0.001$. This leads to failure of the solution in that limit since the corresponding zero canceling term in (56) gives rise to a pole within the strip of analyticity. It is unclear at this time if this is due to numerical inaccuracies or a fundamental limitation of the approach. It does, however, suggest that the construction procedure based on branch-free combinations of the function $w(\alpha,u)$ has the potential to recover solutions that vary smoothly between the two known limiting functions provided a proper method can be devised for constructing the branch-free solutions.

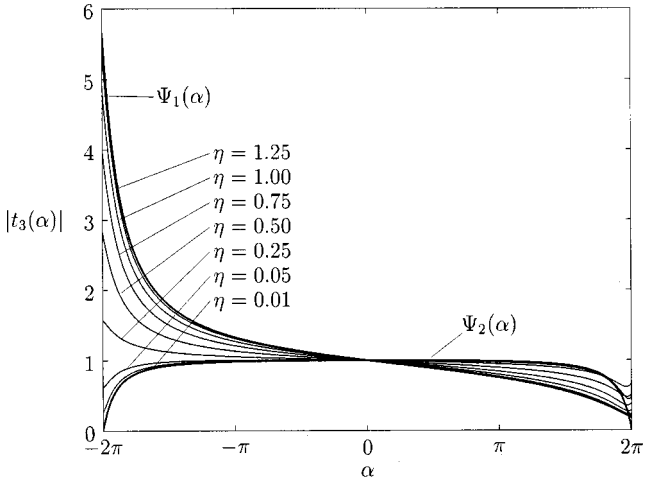

FIG. 10. Magnitude of the branch-free solution $t_3(\alpha)$ given in (56) when $\theta=0.25(1+i)$ for various values of η. The thicker lines corresponds to the known limiting function $\Psi_1(\alpha)$, per (11), for $\eta=\pi/2$ and $\Psi_2(\alpha)$, per (13), for $\eta=0$.

VI. CONCLUSION

A recently proposed solution technique for a class of second order functional difference equations was applied to a case of intermediate complexity in order to assess its potential use for solving certain electromagnetic scattering problems. The essence of this conceptually simple approach lies in the construction of branched solutions to first order difference equations and this is achieved by systematically eliminating singular contributions to produce single-valued expressions. This requirement leads to an equation system whose analytical solution is made possible by obtaining, through the application of Cauchy's theorem on Riemann surfaces, specialized versions of relationships arising in the bilinear relations of Riemann. While the portion of the analysis carried out on a Riemann surface of genus one has the same order of complexity as the one found in Ref. 9, we were also now required to carry out a similar but more intricate analysis on a Riemann surface of genus three in order to obtain well-defined branched solutions to the related first order equations. The final solutions, expressed in terms of branch-free linear combinations of the branched solutions to the first order equations, have all the desired analyticity properties and also recover the known solution $\Psi_1(\alpha)$ as $\eta\rightarrow\pi/2$. The fully analytical approach presented satisfies all of the solution requirements and the fact that it vanishes as $\eta\rightarrow 0$ is not a critical shortcoming since known exact solutions are available in that particular limit. The other variation provided, which requires the numerical identification of zeros in the complex α plane, represents an attempt at resolving this shortcoming and, although it fails when $\eta\sim 0$, it otherwise recovers a solution which varies smoothly between the two known limiting functions $\Psi_1(\alpha)$ and $\Psi_2(\alpha)$. This is encouraging since it suggests that the proposed approach has the potential to produce a solution that smoothly recovers the two known limiting functions provided a proper method for constructing branch-free solutions can be found.

The results obtained demonstrate the promise of the proposed technique but there are still a large number of interesting issues to be addressed. Indeed, while the procedure for constructing branch-free solutions is fairly well understood, the construction of such meromorphic solutions free of poles and zeros in particular regions of the complex α plane, the strip $\mathcal{S}_{4\pi}$ in this instance, remains challenging. Consequently, a fully analytical solution displaying the more desirable behavior obtained for the numerical approach, where the solutions recovers $\Psi_1(\alpha)$ and $\Psi_2(\alpha)$ in the appropriate limits, is still sought. The success of this endeavor is apparently dependent on gaining more insight into the behavior of the zeros of the meromorphic functions constructed. Additionally, a better understanding of the dependency of the quantities $\Lambda_{2\pi,4\pi}$ on the problem parameters η and θ is required. Ideally, this would take the form of specific requirements on, for instance, the

impedances characterizing the structure and would provide a range over which the procedure for determining the values $\zeta_{2\pi,4\pi}$ can be carried out. Indeed, it is not inconceivable that under certain circumstances $\Lambda_{2\pi,4\pi}$ might lie outside the $\mathcal{P}$ and $\mathcal{Q}$ parallelograms, leading to a failure of the technique. Another highly interesting item is the application of the approach when solutions of different orders (i.e., not $\mathcal{O}(1)$ as $|\mathrm{Im}\,\alpha|\to\infty$) are required since in such cases the integrand of $w(\alpha,u)$ is required not to vanish as $|\mathrm{Im}\,\alpha|\to\infty$. It is, however, apparent that, unless beneficial symmetries can be found in cases of higher complexity, a sufficiently large number of singularities in the strip of analyticity, while not precluding a solution in principle, may well make such an approach impractical. Despite this and some of the currently unresolved issues mentioned above, the technique proposed in Ref. 9, as demonstrated herein, can be applied relatively straightforwardly to cases of intermediate complexity. Current efforts focus on its application to cases of higher complexity such as the diffraction from an anisotropic impedance half-plane illuminated at skew incidence.

(Received 6 June 2001; accepted for publication 26 November 2001)

In this paper we provide a complete classification of the Darboux invariants, of the irreducible Darboux polynomials, of the rational first integrals and of the algebraic integrability for the classical Lorenz system $\dot{x}=s(y-x)$, $\dot{y}=rx-y-xz$, $\dot{z}=-bz+xy$. In the proofs, we use the weight homogeneous polynomials and the method of characteristic curves for solving linear partial differential equations. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1435078]

I. INTRODUCTION AND DEFINITIONS

The Lorenz system:

$$\begin{aligned}\dot{x}&=s(y-x)=P(x,y,z),\\ \dot{y}&=rx-y-xz=Q(x,y,z),\\ \dot{z}&=-bz+xy=R(x,y,z),\end{aligned}\tag{1}$$

is a famous dynamical model (see, e.g., Lorenz, 1963), where x, y, and z are real variables; and s, r, and b are real parameters. This system has been thoroughly investigated as a dynamical system (see, e.g., Sparrow, 1982). From the point of view of integrability it was also intensively studied using different integrability theories (see, e.g., Cairó and Hua, 1993; Giacomini, Repetto, and Zandron, 1991; Goriely, 1996; Gupta, 1993; Kús, 1983; Schwarz, 1985; Segur, 1982; Steeb, 1982; and Strelcyn and Wojciechowski, 1988).

The problem involving the algebraic integrability and the Darboux polynomials is classical and difficult. It mainly received contributions from Darboux (1878), and Poincaré (1981, 1987). The former gave a link between algebraic geometry and the search of first integrals, and showed how to construct the first integrals of a planar polynomial vector field having sufficient number of invariant algebraic curves. The latter was mainly interested in rational first integrals and noticed the difficulty for obtaining an algorithm to compute Darboux polynomials. For three-dimensional systems, Labrunie (1996) and Moulin Ollagnier (1997) characterized all polynomial first integrals of the (a,b,c) Lotka–Volterra system. Moulin Ollagnier (1999) studied its homogeneous rational first integrals. Giacomini, Repetto, and Zandron (1991) investigated the integrals of motion for three-dimensional non-Hamiltonian dynamical systems. Llibre and Zhang (2000) characterized all the invariant algebraic surfaces, the polynomial first integrals, the rational first integrals, the invariants, and the algebraic integrability for the Rikitake system.

For the Lorenz system only six independent Darboux invariants had been found:

[a)]Electronic mail: jllibre@mat.uab.es
[b)]Electronic mail: m_x_zhang@263.net

Darboux invariant	Parameters
$(x^2-2sz)e^{2st}$	$b=2s$
$(-rx^2+\frac{1}{3}y^2+\frac{2}{3}xy+x^2z-\frac{3}{4}x^4)e^{4t/3}$	$b=0,\ s=\frac{1}{3}$
$(y^2+z^2)e^{2t}$	$b=1,\ r=0$
$(4(1-r)z+rx^2+y^2-2xy+x^2z-\frac{1}{4}x^4)e^{4t}$	$b=4,\ s=1$
$(-rx^2+y^2+z^2)e^{2t}$	$b=1,\ s=1$
$\left(\frac{1}{s}(2s-1)^2x^2+sy^2-(4s-2)xy+x^2z-\frac{1}{4s}x^4\right)e^{4st}$	$b=6s-2,\ r=2s-1.$

The first three invariants were found by Segur (1982) using the Painlevé method (see also Steeb, 1982; Tabor and Weiss, 1981). The last three invariants were found by Kús (1983) using the method of Carlemann embedding. Furthermore, it is easy to prove that the function $H=(y^2+z^2)/(x^2-z)^2$ is a rational first integral under the conditions $b=1$, $s=1/2$, and $r=0$.

Using these invariants, Giacomini and Neukirch (1997) constructed families of two-dimensional surfaces transverse to the flow of the Lorenz system, in which everyone separates the phase space $\mathbb{R}^3$ and hence can be used to describe the location of the global attractor of the flow.

In this paper, by using the weight homogeneous polynomials and the method of characteristics, we obtain the classification of all the irreducible invariant algebraic surfaces, of the invariants, of the rational first integrals and of the algebraic integrability for the Lorenz system. Before presenting our main results, we first recall some definitions.

A real polynomial $f(x,y,z)$ is called a *Darboux polynomial* for the Lorenz system if

$$\frac{\partial f}{\partial x}P+\frac{\partial f}{\partial y}Q+\frac{\partial f}{\partial z}R=kf \tag{2}$$

for some real polynomial $k(x,y,z)$, which is called a *cofactor* of f. It is easy to prove that the degree of k is less than or equal to 1. Therefore, we can assume that the cofactor is of the form

$$k(x,y,z)=k_1x+k_2y+k_3z+c. \tag{3}$$

If $f(x,y,z)$ is a Darboux polynomial of the Lorenz system, then the algebraic surface $f=0$ in $\mathbb{R}^3$ is called an *invariant algebraic surface*. The name is due to the fact that if a solution of (1) has a point on the invariant algebraic surface, then the whole solution is contained in it.

We say that a nonconstant real function $H(x,y,z,t):\mathbb{R}^3\times\mathbb{R}\to\mathbb{R}$, is an *invariant* of the Lorenz system, if it is constant on all solution curves $(x(t),y(t),z(t))$ of the Lorenz system, i.e., $H(x(t),y(t),z(t),t)\equiv$constant for all values of t for which the solution $(x(t),y(t),z(t))$ is defined on $\mathbb{R}^3$. Obviously, if H is differentiable on $\mathbb{R}^3\times\mathbb{R}$, then H is an invariant of the Lorenz system if and only if along every solution of the Lorenz system we have

$$\frac{\partial H}{\partial t}+\frac{\partial H}{\partial x}P+\frac{\partial H}{\partial y}Q+\frac{\partial H}{\partial z}R\equiv 0. \tag{4}$$

If the invariant H is independent on the time, then it is called a *first integral*. If the first integral H is a polynomial (respectively, a rational function), then it is called a *polynomial first integral* (respectively, a *rational first integral*). If the invariant H is of the form $f(x,y,z)\exp(\sigma t)$ with f a polynomial in x,y and z, and σ a real constant, then H is called a *Darboux invariant*. We remark that a Darboux invariant is also called an *integral of motion* by some physicists. Moreover, it is easy to prove that $H=f(x,y,z)\exp(\sigma t)$ is a Darboux invariant if and only if f is a Darboux polynomial with the cofactor $-\sigma$. If H is a Darboux invariant, then σ is called an *exponent* of H.

Let $\mathcal{S}$ be the set of all Darboux polynomials (or Darboux invariants) for the Lorenz system. If $\mathcal{J}$ is a minimum subset of $\mathcal{S}$ such that every element of $\mathcal{S}$ is obtained by doing finitely many product of the elements of $\mathcal{J}$ and the addition of finitely many these new elements having the same cofactor (or having the same exponent), then we say that every element of $\mathcal{J}$ is a *generator* of $\mathcal{S}$.

Two first integrals $H_1(x,y,z)$ and $H_2(x,y,z)$ are said to be *independent*, if their gradients are linearly independent vectors for all points $(x,y,z)\in\mathbb{R}^3$ except perhaps for a set of zero Lebesgue measure. If the Lorenz system has two independent first integrals, then we say that it is *completely integrable*. We note that in this case the orbits of the Lorenz system are contained in the curves $\{H_1(x,y,z)=h_1\}\cap\{H_2(x,y,z)=h_2\}$ when h_1 and h_2 vary in $\mathbb{R}$.

An *algebraic function* $H(x,y,z)=C$ is a solution of the algebraic equation

$$f_0+f_1C+f_2C^2+\cdots+f_{n-1}C^{n-1}+C^n=0,$$

where $f_i(x,y,z)$ are rational functions, and n is the smallest positive integer for which such a relation holds. Obviously, any rational function is algebraic. The Lorenz system is said to be *algebraically integrable* if it has two independent algebraic first integrals.

This paper is organized as follows. In Sec. II, we state our main results and recall some tools we will need later on. In Sec. III, we prove Theorem 1. The proof of Corollary 2 is given in Sec. IV.

II. STATEMENT OF THE MAIN RESULTS AND SOME PRELIMINARY TOOLS

Our main results are the following.

Theorem 1: *When $s\neq 0$, a set of generators for the set of all Darboux polynomials of the Lorenz system consists of the following six ones:*

Darboux polynomial	Cofactor	Parameters
x^2-2sz	$-2s$	$b=2s$
$x^4-\frac{4}{3}x^2z-\frac{4}{9}y^2-\frac{8}{9}xy+\frac{4}{3}rx^2$	$-\frac{4}{3}$	$b=0,\ s=\frac{1}{3}$
y^2+z^2	-2	$b=1,\ r=0$
$x^4-4x^2z-4y^2+8xy-4rx^2-16(1-r)z$	-4	$b=4,\ s=1$
$y^2+z^2-rx^2$	-2	$b=1,\ s=1$
$x^4-4sx^2z-4s^2y^2+4s(4s-2)xy-(4s-2)^2x^2$	$-4s$	$b=6s-2,\ r=2s-1$

Corollary 2: For the Lorenz system, if $s\neq 0$ then the following statements hold:

(a) The cofactor corresponding to every Darboux polynomial of the Lorenz system is a constant.

(b) The generators of Darboux invariants for the Lorenz system are the known six ones of the previous list.

(c) The Lorenz system has no polynomial first integrals.

(d) The Lorenz system has a rational first integral if and only if $b=1$, $s=1/2$, and $r=0$. The rational first integrals are of the form

$$\frac{\displaystyle\sum_{i+2j=K} a_{ij}(x^2-z)^i(y^2+z^2)^j}{\displaystyle\sum_{i_1+2j_1=K} b_{i_1j_1}(x^2-z)^{i_1}(y^2+z^2)^{j_1}},$$

where $a_{ij},b_{i_1j_1}\in\mathbb{R}$ and $i,j,i_1,j_1,K\in\mathbb{N}$.

(e) The Lorenz system is not algebraically integrable.

We remark that when $s=0$, the Lorenz system has the first integral $H(x,y,z)=x$, and then on each plane $x=$constant the system becomes linear.

In the proof of Theorem 1 we will use the following notions and tools.

A polynomial $g(\mathbf{x})$ with $\mathbf{x}\in\mathbb{R}^n$ is said to be *weight homogeneous* if there exist $\mathbf{s}=(s_1,\ldots,s_n)\in\mathbb{N}^n$ and $m\in\mathbb{N}$ such that for all $\alpha\in\mathbb{R}\backslash\{0\}$,

$$g(\alpha^{\mathbf{s}}\mathbf{x})=g(\alpha^{s_1}x_1,\alpha^{s_2}x_2,\ldots,\alpha^{s_n}x_n)=\alpha^m g(\mathbf{x}),$$

where $\mathbb{R}$ denotes the set of real numbers, and $\mathbb{N}$ the set of positive integers. We shall refer $\mathbf{s}$ to the *weight* of g, m the *weight degree*, and $\mathbf{x}\to\alpha^{\mathbf{s}}\mathbf{x}$ the weight change of the variables.

Now we recall the method of characteristic curves for solving linear partial differential equations [for instance, see Bleecker and Csordas (1992), Chap. 2].

Consider the following first-order linear partial differential equation:

$$a(x,y,z)A_x+b(x,y,z)A_y+c(x,y,z)A_z+d(x,y,z)A=f(x,y,z), \tag{5}$$

where $A=A(x,y,z)$, a, b, c, d, and f are C^1 maps.

A curve $(x(t),y(t),z(t))$ in the xyz space is a *characteristic curve* for the partial differential equation (5), if at each point (x_0,y_0,z_0) on the curve, the vector $(a(x_0,y_0,z_0)$, $b(x_0,y_0,z_0),c(x_0,y_0,z_0))$ is tangent to the curve. So, a characteristic curve is a solution of the system

$$\frac{\mathrm{d}x}{\mathrm{d}t}=a(x(t),y(t),z(t)),\quad \frac{\mathrm{d}y}{\mathrm{d}t}=b(x(t),y(t),z(t)),\quad \frac{\mathrm{d}z}{\mathrm{d}t}=c(x(t),y(t),z(t)).$$

In practice, for convenience we treat z as the independent variable instead of t, then the above system is reduced to the system [assuming $c(x,y,z)\neq 0$]

$$\frac{\mathrm{d}x}{\mathrm{d}z}=\frac{a(x,y,z)}{c(x,y,z)},\quad \frac{\mathrm{d}y}{\mathrm{d}z}=\frac{b(x,y,z)}{c(x,y,z)}. \tag{6}$$

This ordinary differential equation is known as the *characteristic equation* of (5).

Suppose that (6) has a solution in the implicit form $g(x,y,z)=c_1$, $h(x,y,z)=c_2$, where c_1 and c_2 are arbitrary constants. We consider the change of the variables

$$u=g(x,y,z),\quad v=h(x,y,z),\quad w=z, \tag{7}$$

and write its inverse transformation as $x=p(u,v,w)$, $y=q(u,v,w)$, and $z=r(u,v,w)$ (of course, sometimes the explicit inverse transformation cannot be obtained, or it is not well defined). Then the linear partial differential equation (5) becomes the following ordinary differential equation in w (for fixed u and v):

$$\overline{c}(u,v,w)\overline{A}_w+\overline{d}(u,v,w)\overline{A}=\overline{f}(u,v,w), \tag{8}$$

where $\overline{c}$, $\overline{d}$, $\overline{A}$, and $\overline{f}$ are c, d, A, and f, are written in terms of u, v, and w.

If $\overline{A}=\overline{A}(u,v,w)$ is a solution of (8), then by transformation (7) we get that

$$A(x,y,z)=\overline{A}(g(x,y,z),h(x,y,z),z)$$

is a solution of the linear partial differential equation (5). Moreover, the general solution of (8) is also the general solution of (5) when, using (7), we write u, v, and w in function of x, y, and z.

III. PROOF OF THEOREM I

In order that readers can follow our proof easily, and use our method to other systems, we state the global strategy of the proof for a general system. Consider the polynomial system

$$\dot{\mathbf{x}}=\mathbf{g}(\mathbf{x}),\quad \mathbf{x}\in\mathbb{R}^n. \tag{9}$$

Step 1. We select a suitable weight change of the variables, denoted by $\mathbf{X}=\alpha^{\mathbf{s}}\mathbf{x}$ $=(\alpha^{s_1}x_1,\ldots,\alpha^{s_n}x_n)$, and rescale the time by $T=\alpha^{-s_0}t$, where $s_i\in\mathbb{N}$ for $i=0,1,\ldots,n$, such that system (9) is transformed to

$$\mathbf{X}' = \sum_{j=0}^{r} \alpha^j \mathbf{g}_{m-j}(\mathbf{X}), \quad r \leqslant m, \tag{10}$$

where the prime denotes the derivative with respect to T, $\mathbf{g}_{m-j}$ is a polynomial vector, such that every component is a weight homogeneous polynomial. Obviously, system (10) with $\alpha=0$ is invariant by the selected transformation.

Step 2. Suppose that $f(\mathbf{x})$ is a Darboux polynomial of (9) with a cofactor $k(\mathbf{x})$. Set

$$F(\mathbf{X}) = \alpha^l f(\alpha^{-\mathbf{s}}\mathbf{X}) = \sum_{i=0}^{p} \alpha^i F_i(\mathbf{X}),$$

$$K(\mathbf{X}) = \alpha^h k(\alpha^{-\mathbf{s}}\mathbf{X}) = \sum_{j=0}^{q} \alpha^j K_j(\mathbf{X}),$$

where $\alpha^{-\mathbf{s}}\mathbf{X} = (\alpha^{-s_1}X_1, \ldots, \alpha^{-s_n}X_n)$, $p,q \in \mathbb{N}$, l and h are the highest weight degrees of the weight homogeneous components for f and k, respectively, and F_i and K_j are weight homogeneous polynomials. Then $F(\mathbf{X})$ is a Darboux polynomial of system (10) with the cofactor $\alpha^{s_0-h}K(\mathbf{X})$. From

$$\left\langle \sum_{j=0}^{r} \alpha^j \mathbf{g}_{m-j}, \frac{\partial F}{\partial \mathbf{X}} \right\rangle = \alpha^{s_0-h} K F, \tag{11}$$

and by equating the terms with α^j in (11), i.e., the weight homogeneous components with the same weight degree, we get

$$L[F_i] = G_i(F_i) + H_i(F_0, \ldots, F_{i-1}), \tag{12}$$

with $i=0,1,\ldots,\max\{r+p, s_0-h+q+p\}$, where G_i is a linear function in F_i, H_i is known by induction, and L a linear partial differential operator of the form

$$L = \left\langle \mathbf{g}_m, \frac{\partial}{\partial \mathbf{X}} \right\rangle.$$

Step 3. Solving (12) we obtain the weight homogeneous polynomial solution F_i. The main tool is the method of characteristic curves for solving linear partial differential equations.

First we transfer Eq. (12) with $i=0$ to an ordinary differential equation. By solving the ordinary differential equation we get a general solution F_0^* of (12) with $i=0$. Generally, F_0^* is not a weight homogeneous polynomial with the given degree. So we must let the components with nonweight homogeneous polynomials of the given degree be equal to zero. Then we get F_0 and the corresponding conditions.

Second, introducing F_0 into (12) with $i=1$ and working in a similar way to solve F_0, we can obtain F_1 and some conditions which must be satisfied. Then introducing F_0 and F_1 into (12) with $i=2$, we obtain F_2. According to this process we obtain all the weight homogeneous polynomial solutions F_i for (12) and the conditions on the coefficients of system (12).

Step 4. From $f(\mathbf{x}) = F(\mathbf{X})|_{\alpha=1} = \Sigma_{i=1}^{p} F_i$, we get all the Darboux polynomials for system (9).

We remark that there is a double aim using the weight change of the variables. First, the general solution of the characteristic equations for $L[F_i] = G_i + H_i$ is easy to obtain, because the reduction process from the linear partial differential equation to the ordinary differential equations becomes simpler. Second, the computation for solving F_i becomes easier.

Proof of Theorem 1: We make the change of the variables

$$x = \alpha^{-1}X, \quad y = \alpha^{-2}Y, \quad z = \alpha^{-2}Z, \quad t = \alpha T, \tag{13}$$

then the Lorenz system (1) becomes

$$X' = s(Y - \alpha X),$$

$$Y' = -XZ - \alpha Y + r\alpha^2 X, \tag{14}$$

$$Z' = XY - b\alpha Z,$$

where the prime denotes the derivative with respect to T. We note that this transformation is almost equivalent to the one introduced by Robbins (1979), but the aim for introducing the changes is different. In Robbins (1979), by rescaling the variables the author changes the Lorenz model with a high valued parameter R to a system with a small parameter ϵ. Then, he uses the first integrals of the new system for $\epsilon = 0$ to construct a solution in power series of ϵ for the new system. In this way the author investigated the behavior of the orbits for the Lorenz model. In our change of the variables, we introduce the auxiliary parameter α and the weight homogeneous polynomials in order that the computations for searching the Darboux polynomials becomes easier.

Suppose that $f(x,y,z)$ is a Darboux polynomial of the Lorenz system (1) with a cofactor $k(x,y,z)$. Using transformation (13), and setting $F(X,Y,Z) = \alpha^l f(\alpha^{-1}X, \alpha^{-2}Y, \alpha^{-2}Z)$, and $K(X,Y,Z) = \alpha^2 k(\alpha^{-1}X, \alpha^{-2}Y, \alpha^{-2}Z)$, where l is the highest weight degree in the weight homogeneous components of f in x, y, and z with weight (1,2,2).

We claim that F is a Darboux polynomial of system (14) with the cofactor $\alpha^{-1}K$. Indeed, along the flow of system (14) we have

$$\frac{\mathrm{d}F}{\mathrm{d}T} = \frac{\partial F}{\partial X}\frac{\mathrm{d}X}{\mathrm{d}T} + \frac{\partial F}{\partial Y}\frac{\mathrm{d}Y}{\mathrm{d}T} + \frac{\partial F}{\partial Z}\frac{\mathrm{d}Z}{\mathrm{d}T} = \alpha^{l+1}\left(\frac{\partial f}{\partial x}\frac{\mathrm{d}x}{\mathrm{d}t} + \frac{\partial f}{\partial y}\frac{\mathrm{d}y}{\mathrm{d}t} + \frac{\partial f}{\partial z}\frac{\mathrm{d}z}{\mathrm{d}t}\right) = \alpha^{l+1}\frac{\mathrm{d}f}{\mathrm{d}t} = \alpha^{l+1}kf = \alpha^{-1}KF.$$

Assume that $F = F_0 + \alpha F_1 + \alpha^2 F_2 + \cdots + \alpha^m F_m$, where F_i is a weight homogeneous polynomial in X, Y, and Z with the weight degree $l-i$ for $i = 0,1,\ldots,m$, and $l \geqslant m$. Obviously, $f = F|_{\alpha=1}$. From the definition of a Darboux polynomial, we have

$$s(y - \alpha x)\sum_{i=0}^{m} \alpha^i \frac{\partial F_i}{\partial x} + (-xz - \alpha y + r\alpha^2 x)\sum_{i=0}^{m} \alpha^i \frac{\partial F_i}{\partial y} + (xy - b\alpha z)\sum_{i=0}^{m} \alpha^i \frac{\partial F_i}{\partial z}$$

$$= (k_1 x + k_2 \alpha^{-1} y + k_3 \alpha^{-1} z + c\alpha)\sum_{i=0}^{m} \alpha^i F_i,$$

where we still use x,y and z instead of X, Y, and Z. Equating the terms with α^{-1} we can prove that $k_2 = k_3 = 0$. Equating the terms with α^i for $i = 0,1,\ldots,m+2$, we get

$$L[F_0] = k_1 x F_0,$$

$$L[F_1] = k_1 x F_1 + cF_0 + sx\frac{\partial F_0}{\partial x} + y\frac{\partial F_0}{\partial y} + bz\frac{\partial F_0}{\partial z}, \tag{15}$$

$$L[F_j] = k_1 x F_j + cF_{j-1} + sx\frac{\partial F_{j-1}}{\partial x} + y\frac{\partial F_{j-1}}{\partial y} + bz\frac{\partial F_{j-1}}{\partial z} - rx\frac{\partial F_{j-2}}{\partial y}$$

for $j = 2, 3,\ldots,m+2$, where $F_j = 0$ for $j > m$ and L is the linear partial differential operator of the form

$$L = sy\frac{\partial}{\partial x} - xz\frac{\partial}{\partial y} + xy\frac{\partial}{\partial z}.$$

The characteristic equations associated with the first linear partial differential equation of system (15) are

$$\frac{dx}{dz}=\frac{sy}{xy},\quad \frac{dy}{dz}=-\frac{xz}{xy}.$$

This system of equations has the general solution

$$x^2-2sz=d_1,\quad y^2+z^2=d_2,$$

where d_1 and d_2 are constants of integration.

According with the method of characteristics, we make the change of the variables

$$u=x^2-2sz,\quad v=y^2+z^2,\quad w=z. \tag{16}$$

Its inverse transformation is

$$x=\pm\sqrt{u+2sw},\quad y=\pm\sqrt{v-w^2},\quad z=w. \tag{17}$$

In the following, for simplicity we only consider the case $x=\sqrt{u+2sw}$, $y=\sqrt{v-w^2}$, and $z=w$. Under changes (16) and (17), the first equation of (15) becomes the following ordinary differential equation (for fixed u,v):

$$\sqrt{v-w^2}\frac{d\overline{F_0}}{dw}=k_1\overline{F_0},$$

where $\overline{F_0}$ is F_0, written in u, v, and w. In what follows, we always use $\overline{\theta}$ to denote a function $\theta(x,y,z)$ written in terms of u, v, and w. The above equation has the general solution

$$\overline{F_0}=\overline{G_0}(u,v)\exp\left(k_1\arcsin\frac{w}{\sqrt{v}}\right),$$

where $\overline{G_0}$ is an arbitrary smooth function in u and v. So,

$$F_0(x,y,z)=\overline{F_0}(u,v,w)=\overline{G_0}(x^2-2sz,y^2+z^2)\exp\left(k_1\arcsin\frac{z}{\sqrt{x^2+y^2}}\right).$$

In order that F_0 be a weight homogeneous polynomial, we must have $k_1=0$ and $\overline{G_0}$ a polynomial in u and v. Consequently, the cofactor of every Darboux polynomial for the Lorenz system is a constant. Since u and v are weight homogeneous polynomials in x, y, and z of weight degrees 2 and 4, respectively, F_0 should be weight degree either $l=4n$, or $l=4n-2$ for some convenient $n\in\mathbb{N}$. So, F_0 has the form $\Sigma_{i=0}^{n}a_iu^{2i}v^{n-i}$, or $\Sigma_{i=1}^{n}a_iu^{2i-1}v^{n-i}$. Therefore, we have

$$F_0=\sum_{i=0}^{n}a_i(x^2-2sz)^{2i}(y^2+z^2)^{n-i}, \tag{18}$$

with the weight degree $4n$, or

$$F_0=\sum_{i=1}^{n}a_i(x^2-2sz)^{2i-1}(y^2+z^2)^{n-i}, \tag{19}$$

with the weight degree $4n-2$.

Accordingly, with these two different cases, we divide the proof into two subsections.

A. F_0 has the form (19)

Substituting F_0 into the second equation of (15) and doing some computations, we obtain that

$$L[F_1]=\sum_{i=1}^{n}[c+2(2i-1)s+2(n-i)]a_i(x^2-2sz)^{2i-1}(y^2+z^2)^{n-i}$$
$$+\sum_{i=1}^{n}(4s^2-2sb)(2i-1)a_i(x^2-2sz)^{2i-2}(y^2+z^2)^{n-i}z$$
$$+\sum_{i=1}^{n}2(n-i)(b-1)a_i(x^2-2sz)^{2i-1}(y^2+z^2)^{n-i-1}z^2.$$

Using transformations (16) and (17) and working in a similar way to solve $\overline{F}_0$, we get the following ordinary differential equation (for fixed u and v):

$$\sqrt{u+2sw}\,\sqrt{v-w^2}\frac{d\overline{F}_1}{dw}=\sum_{i=1}^{n}[c+2(2i-1)s+2(n-i)]a_iu^{2i-1}v^{n-i}$$
$$+\sum_{i=1}^{n}(4s^2-2sb)(2i-1)a_iu^{2i-2}v^{n-i}w$$
$$+\sum_{i=1}^{n}2(n-i)(b-1)a_iu^{2i-1}v^{n-i-1}w^2.$$

Integrating this equation with respect to w and using formula (A1) from Appendix A, we get

$$\overline{F}_1=\sum_{i=1}^{n}\frac{1}{s}[c+2(2i-1)s+2(n-i)]a_iu^{2i-1}v^{n-i-1}\sqrt{u+2sw}\,\sqrt{v-w^2}$$
$$+\sum_{i=0}^{n}\left\{(4s^2-2sb)(2i+1)a_{i+1}+\frac{1}{s}[c+2(2i-1)s+2(n-i)]a_i\right\}$$
$$\cdot u^{2i}v^{n-i-1}\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\sum_{i=1}^{n}[3c+6(2i-1)s+(2b+4)$$
$$\times(n-i)]a_iu^{2i-1}v^{n-i-1}\int\frac{w^2\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G}_1(u,v),$$

where $\overline{G}_1(u,v)$ is an arbitrary smooth function in u and v.

Since $G_1(x,y,z)=\overline{G}_1(u,v)=\overline{G}_1(x^2-2sz,y^2+z^2)$, in order that F_1 be a weight homogeneous polynomial of weight degree $4n-3$, from (A2) and (A3) we have $\overline{G}_1(u,v)=0$, and

$$(4s^2-2sb)(2i+1)a_{i+1}+\frac{1}{s}[c+2(2i-1)s+2(n-i)]a_i=0,\quad i=0,1,\ldots,n$$
$$[3c+6(2i-1)s+(n-i)(2b+4)]a_i=0,\quad i=1,2,\ldots,n \tag{20}$$

where $a_0=a_{n+1}=0$. We claim that conditions (20) are equivalent to one of the following conditions:

(i) $b=1$, $s=1/2$, $c=-(2n-1)$ and there exists an $i_0\in\{1,\ldots,n-1\}$ such that $a_{i_0}\neq 0$,
(ii) $b=2s$, $c=-2(2n-1)s$, and $F_0=a_n(x^2-2sz)^{2n-1}$,

(iii) $b\neq 2s$ and $F_0=0$.

Indeed, we first assume that $b=2s$. Then, conditions (20) can be reduced to

$$(b-1)(n-i)a_i=0,\quad [c+2(2i-1)s+2(n-i)]a_i=0,\quad i=1,\ldots,n.$$

If there exists an $i_0\in\{1,\ldots,n-1\}$ such that $a_{i_0}\neq 0$, then $b=1$. So, we have $s=1/2$ and $c=-(2n-1)$. If $a_i=0$ for $i=1,\ldots,n-1$, then $a_n\neq 0$ (otherwise, $F_0=0$). Thus, we have $c=-2(2n-1)s$. Next, we assume that $b\neq 2s$. Then, by induction, from the first equation of (20) we get that $a_i=0$ for $i=1,\ldots,n$. This proves the claim.

Case (i): $b=1$, $s=1/2$, $c=-(2n-1)$ and there exists an $i_0\in\{1,\ldots,n-1\}$ such that $a_{i_0}\neq 0$. Then $F_1=0$. From (15) with $j=2$ we get

$$L[F_2]=-\sum_{i=1}^{n} 2r(n-i)a_i xy(x^2-2sz)^{2i-1}(y^2+z^2)^{n-1-i}.$$

Using transformations (16) and (17), we get the following ordinary differential equation:

$$\frac{d\overline{F}_2}{dw}=-\sum_{i=1}^{n-1} 2r(n-i)a_i u^{2i-1}v^{n-1-i}.$$

Integrating this equation with respect to w, we have

$$\overline{F}_2=-\sum_{i=1}^{n-1} 2r(n-i)a_i u^{2i-1}v^{n-1-i}w+\overline{G}_2(u,v),$$

where $\overline{G}_2(u,v)$ is an arbitrary smooth function. In order that $F_2(x,y,z)=\overline{F}_2(u,v,w)$ be a weight homogeneous polynomial of weight degree $4n-4$, it must have the form

$$F_2=-\sum_{i=1}^{n-1} 2r(n-i)a_i(x^2-2sz)^{2i-1}(y^2+z^2)^{n-1-i}z+\sum_{i=0}^{n-1} a_i^{(2)}(x^2-2sz)^{2i}(y^2+z^2)^{n-1-i},$$

where $a_i^{(2)}$ are real constants for $i=0,1,\ldots,n-1$.

Substituting F_1 and F_2 into (15) with $j=3$ and working in a similar way to solve F_1 and F_2, we can obtain that

$$\begin{aligned}F_3(x,y,z)&=\overline{F}_3(u,v,w)\\&=-\sum_{i=0}^{n-1} a_i^{(2)}u^{2i}v^{n-1-i}\int\frac{dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}\\&\quad+\sum_{i=1}^{n-1} 2r(n-i)a_i u^{2i-1}v^{n-1-i}\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G}_3(u,v).\end{aligned}$$

Since F_3 is a weight homogeneous polynomial of weight degree $4n-5$, we get that $\overline{G}_3=0$, and

$$a_i^{(2)}=0\quad\text{for } i=0,1,\ldots,n-1;\quad r(n-i)a_i=0\quad\text{for } i=1,2,\ldots,n-1.$$

This means that $r=0$ (because there exists an $i_0\in\{1,\ldots,n-1\}$ such that $a_{i_0}\neq 0$). Furthermore, we have $F_2=F_3=0$. By recursive calculations, we can prove that $F_i=0$ for $i=4,\ldots,m$. Hence, the Darboux polynomial is

$$\sum_{i=1}^{n} a_i(x^2-z)^{2i-1}(y^2+z^2)^{n-i}.$$

Its generators are x^2-z and y^2+z^2, which are two Darboux polynomials of the Lorenz system.

Case (ii): $b=2s$, $c=-2(2n-1)s$, and $F_0=(x^2-2sz)^{2n-1}$. Here, we set $a_n=1$, because $a_n\neq 0$ otherwise $F_0=0$ and consequently $F=0$. So, $F_1=0$. From (15) with $j=2$, we can easily prove that

$$F_2=\sum_{i=0}^{n-1} a_i^{(2)}(x^2-2sz)^{2i}(y^2+z^2)^{n-1-i},$$

where $a_i^{(2)}$ are real constants for $i=0,1,\ldots,n-1$.

Working in a similar way to solve F_1 and F_3 as in case (i), we get from (15) with $j=3$ that

$$\begin{aligned}F_3(x,y,z)&=\overline{F}_3(u,v,w)\\&=\sum_{i=0}^{n-1}[-2(2n-1)s+4si+2(n-1-i)]\\&\quad\times a_i^{(2)}u^{2i}v^{n-1-i}\int\frac{dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\sum_{i=0}^{n-1}(n-1-i)(4s-2)\\&\quad\times a_i^{(2)}u^{2i}v^{n-2-i}\int\frac{w^2\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G}_3(u,v).\end{aligned}$$

Since F_3 is a weight homogeneous polynomial of weight degree $4n-5$, we should have $\overline{G}_3=0$ and

$$[-(2n-1)s+2si+(n-1-i)]a_i^{(2)}=0,\quad (n-1-i)(4s-2)a_i^{(2)}=0,\quad i=0,1,\ldots,n-1.$$

This implies that $F_3=0$. The above-mentioned conditions are equivalent to $a_i^{(2)}=0$ for $i=0,1,\ldots,n-1$, that is, $F_2=0$. By recursive calculations, we can prove that $F_i=0$ for $i=4,\ldots,m$. Hence, the Darboux polynomial is $(x^2-2sz)^{2n-1}$ with the cofactor $-2(2n-1)s$.

Case (iii): $b\neq 2s$ and $F_0=0$. Obviously, the Lorenz system has no Darboux polynomials of the given form.

B. F_0 has the form (18)

Substituting F_0 into the second equation in (15), we get that

$$\begin{aligned}L[F_1]=&\sum_{i=0}^{n}[c+4si+2(n-i)]a_i(x^2-2sz)^{2i}(y^2+z^2)^{n-i}\\&+\sum_{i=0}^{n}4s(2s-b)ia_iz(x^2-2sz)^{2i-1}(y^2+z^2)^{n-i}\\&+\sum_{i=0}^{n}2(b-1)(n-i)a_iz^2(x^2-2sz)^{2i}(y^2+z^2)^{n-i-1}.\end{aligned}$$

Working in a similar way as in Sec. III A we obtain that

$$\overline{F_1}=\sum_{i=0}^{n}\frac{1}{s}[c+4si+2(n-i)]a_i u^{2i}v^{n-i-1}\sqrt{u+2sw}\,\sqrt{v-w^2}$$
$$+\sum_{i=0}^{n-1}\left\{\frac{1}{s}[c+4si+2(n-i)]a_i+4s(2s-b)(i+1)a_{i+1}\right\}$$
$$\cdot u^{2i+1}v^{n-i-1}\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\frac{1}{s}(c+4sn)a_n u^{2n+1}v^{-1}$$
$$+\sum_{i=0}^{n-1}[3c+12si+2(b+2)(n-i)]a_i u^{2i}v^{n-i-1}\int\frac{w^2\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G_1}(u,v).$$

In order that $F_1(x,y,z)=\overline{F_1}(u,v,w)$ be a weight homogeneous polynomial of weight degree $4n-1$, we should have $\overline{G_1}(u,v)=0$ and

$$(c+4sn)a_n=0,$$
$$(c+4si+2(n-i))a_i+4s^2(2s-b)(i+1)a_{i+1}=0, \tag{21}$$
$$(3c+12si+2(b+2)(n-i))a_i=0,$$

with $i=0,1,\ldots,n-1$. We claim that conditions (21) are equivalent to one of the following conditions:

(i) $b=2s$, $c=-4sn$, $a_n\neq 0$, and $a_i=0$ for $i=0,1,\ldots,n-1$,
(ii) $b=1$, $s=1/2$, $c=-2n$, and $a_i\neq 0$ for some $i\in\{0,1,\ldots,n-1\}$,
(iii) $b=1$, $c=-2n$, $s\neq 1/2$, $a_0\neq 0$, and $a_i=0$ for $i=1,2,\ldots,n$,
(iv) $b=6s-2$, $c=-4sn$, $s\neq 1/2$, $a_{n-i}=(-4s^2)^i\binom{n}{i}a_n$, and $a_n\neq 0$.

Indeed, we first assume that $b=2s$. Then conditions (21) are reduced to

$$(c+4sn)a_n=0,\quad (c+4si+2(n-i))a_i=0,\quad (3c+12si+4(s+1)(n-i))a_i=0,$$

with $i=0,1,\ldots,n-1$. If $a_i=0$ for $i=0,1,\ldots,n-1$, then $a_n\neq 0$. Otherwise, $F_0=0$. So, $c=-4sn$. This is condition (i). If there exists an $i_0\in\{0,1,\ldots,n-1\}$ such that $a_{i_0}\neq 0$, then we have $c+4si_0+2(n-i_0)=0$ and $3c+12si_0+4(s+1)(n-i_0)=0$. This means that $s=1/2$ and $c=-2n$. Hence, we get condition (ii).

Now we assume that $b\neq 2s$. From the second equality of (21), we get that $a_0\neq 0$. Otherwise, $a_i=0$ for $i=0,1\ldots,n$. Hence, from the third equality of (21) we have

$$3c+2(b+2s)n=0. \tag{22}$$

If $c+2n=0$, then $b=1$ and $c=-2n$. Since $b\neq 2s$, we have $s\neq 1/2$. So, from the first and third equalities of (21) we get that $a_i=0$ for $i=1,\ldots,n$. This is condition (iii). If $c+2n\neq 0$, since $a_0\neq 0$, we obtain from the second equality of (21) that $a_1\neq 0$. So, we have $3c+12s+2(b+2)(n-1)=0$, by the third equality of (21). From equality (22) we have $b=6s-2$ and $c=-4sn$. So, $s\neq 1/2$. Moreover, from the second equality of (21) we get that $a_{n-i}=(-4s^2)^i\binom{n}{i}a_n$. This proves the claim.

In what follows we study the four cases.

Case (i): $b=2s$, $c=-4sn$, $a_n\neq 0$, and $a_i=0$ for $i=0,1,\ldots,n-1$. Then we have $F_0=a_n(x^2-2sz)^{2n}$ and $F_1=0$. Substituting F_0 and F_1 into (15) with $j=2$, we get that $L[F_2]=0$. It is easy to prove that

$$F_2=\sum_{i=1}^{n} a_i^{(2)}(x^2-2sz)^{2i-1}(y^2+z^2)^{n-i},$$

where $a_i^{(2)}$ for $i=1,2,\ldots,n$, are real constants.

From (15) with $j=3$ and doing some computations as in Sec. III A we obtain that

$$\begin{aligned}\overline{F}_3=&\sum_{i=1}^{n}\frac{1}{s}[-4sn+2s(2i-1)+2(n-i)]a_i^{(2)}u^{2i-1}v^{n-i-1}\sqrt{u+2sw}\,\sqrt{v-w^2}\\&+\sum_{i=1}^{n}\frac{1}{s}[-4sn+2s(2i-1)+2(n-i)]a_i^{(2)}u^{2i}v^{n-i-1}\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}\\&+\sum_{i=1}^{n}[-12sn+6s(2i-1)+6(n-i)+(4s-2)(n-i)]\\&\cdot a_i^{(2)}u^{2i-1}v^{n-i-1}\int\frac{w^2dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G}_3(u,v),\end{aligned}$$

where $\overline{G}_3$ is an arbitrary smooth function in u and v. In order that $F_3(x,y,z)=\overline{F}_3(u,v,w)$ be a weight homogeneous polynomial of weight degree $4n-3$, we would have $\overline{G}_3=0$ and

$$[-4sn+2s(2i-1)+2(n-i)]a_i^{(2)}=0,\quad (4s-2)(n-i)a_i^{(2)}=0,\quad i=1,2,\ldots,n.$$

This implies that $F_3=0$. The above conditions are equivalent to $a_i^{(2)}=0$ for $i=1,2,\ldots,n$. This means that $F_2=0$.

By induction we can prove that $F_i=0$ for $i=4,\ldots,m$. Therefore, the Darboux polynomial is $F=F_0=a_n(x^2-2sz)^{2n}$ with the cofactor $-4sn$. The corresponding irreducible Darboux polynomial is $f=x^2-2sz$ with the cofactor $-2s$.

Case (ii): $b=1$, $s=1/2$, and $c=-2n$. Then $F_1=0$. From (15) with $j=2$, we can prove that the weight homogeneous polynomial F_2 with the weight degree $4n-2$ has the form

$$F_2=-\sum_{i=0}^{n-1}2r(n-i)a_i(x^2-z)^{2i}(y^2+z^2)^{n-i-1}z+\sum_{i=1}^{n}a_i^{(2)}(x^2-z)^{2i-1}(y^2+z^2)^{n-i}.$$

Similarly, from (15) with $j=3$ we get

$$\begin{aligned}\overline{F}_3=&\sum_{i=0}^{n-1}2r(n-i)a_iu^{2i}v^{n-i-1}\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}\\&-\sum_{i=1}^{n}a_i^{(2)}u^{2i-1}v^{n-i}\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G}_3(u,v).\end{aligned}$$

In order that $F_3(x,y,z)=\overline{F}_3(u,v,w)$ be a weight homogeneous polynomial of weight degree $4n-3$, we should have $\overline{G}_3(u,v)=0$, $r(n-i)a_i=0$ for $i=0,1,\ldots,n-1$ and $a_i^{(2)}=0$ for $i=1,\ldots,n$. This means that $r=0$, $F_2=0$, and $F_3=0$.

By induction, we obtain that the Darboux polynomial is

$$F=F_0=\sum_{i=0}^{n}a_i(x^2-z)^{2i}(y^2+z^2)^{n-i},$$

with the cofactor $-2n$. The corresponding generators are two Darboux polynomials $f_1=x^2-z$ with the cofactor -1 and $f_2=y^2+z^2$ with the cofactor -2.

Case (iii): $b=1$, $c=-2n$, $s\neq 1/2$, and $F_0=a_0(y^2+z^2)^n$. Since $F_1=0$, solving (15) with $j=2$ we get

$$F_2=-2rna_0(y^2+z^2)^{n-1}z+\sum_{i=1}^{n} a_i^{(2)}(x^2-2sz)^{2i-1}(y^2+z^2)^{n-i}.$$

Substituting F_1 and F_2 into (15) with $j=3$ we can prove that

$$\overline{F_3}=2rna_0v^{n-1}\int \frac{w\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\sum_{i=1}^{n}[2i(2s-1)-2s]a_i^{(2)}u^{2i-1}v^{n-i}\int \frac{\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}$$
$$+\sum_{i=1}^{n}(4s^2-2s)(2i-1)a_i^{(2)}u^{2i-2}v^{n-i}\int \frac{w\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G}_3(u,v).$$

In order that $F_3(x,y,z)=\overline{F_3}(u,v,w)$ be a weight homogeneous polynomial of weight degree $4n-3$ in x,y, and z, we should have $\overline{G_3}(u,v)=0$ and

$$[2i(2s-1)-2s]a_i^{(2)}=0,\quad i=1,2,\ldots,n,$$

$$2rna_0+(4s^2-2s)a_1^{(2)}=0,\quad (4s^2-2s)(2i-1)a_i^{(2)}=0,\quad i=2,\ldots,n.$$

This means that $F_3=0$. These last conditions are equivalent to

(1) $r=0$ and $a_i^{(2)}=0$ for $i=1,2,\ldots,n$, i.e., $F_2=0$.
(2) $r\neq 0$, $s=1$, $a_1^{(2)}=-rna_0\neq 0$ and $a_i^{(2)}=0$ for $i=2,\cdots,n$.

Subcase (1): $r=0$ and $F_2=0$. By induction, we can prove that $F_i=0$ for $i=4,\ldots,m$. Hence, the Darboux polynomial is $f=a_0(y^2+z^2)^n$ with the cofactor $-2n$. The irreducible Darboux polynomial is y^2+z^2 with the cofactor -2.

Subcase (2): $r\neq 0$ and $s=1$. Then we have

$$\begin{aligned}F_2&=-2rna_0(y^2+z^2)^{n-1}z-rna_0(x^2-2z)(y^2+z^2)^{n-1}\\&=-rna_0(y^2+z^2)^{n-1}x^2\\&=a_0\binom{n}{1}(y^2+z^2)^{n-1}(-rx^2).\end{aligned}$$

Substituting F_2 and F_3 into (15) with $j=4$, we get that

$$F_4=2r^2n(n-1)a_0(x^2-z)(y^2+z^2)^{n-2}z+\sum_{i=0}^{n-1} a_i^{(4)}(x^2-2z)^{2i}(y^2+z^2)^{n-i-1},$$

where $a_i^{(4)}$ for $i=0,1,\ldots,n-1$, are arbitrary real constants.

From (15) with $j=5$ we obtain that

$$\overline{F_5}=\left[\sum_{i=0}^{n-1}4ia_i^{(4)}u^{2i-1}v^{n-i-1}-2r^2n(n-1)a_0uv^{n-2}\right]\int \frac{w\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}$$
$$+\sum_{i=0}^{n-1}2(i-1)a_i^{(4)}u^{2i}v^{n-i-1}\int \frac{\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G}_5(u,v),$$

where $\overline{G}_5(u,v)$ is an arbitrary smooth function. In order that $F_5(x,y,z)=\overline{F}_5(u,v,w)$ be a weight homogeneous polynomial with the weight degree $4n-5$ in x,y, and z, we must have $\overline{G}_5(u,v)=0$ and

$$(i-1)a_i^{(4)}=0, \quad i=0,1,\ldots,n-1,$$

$$\sum_{i=0}^{n-1} 4ia_i^{(4)}u^{2i-1}v^{n-i-1}-2r^2n(n-1)a_0uv^{n-2}=0.$$

This reduces to

$$a_1^4=\frac{n(n-1)}{2}r^2a_0, \quad a_i^{(4)}=0, \quad j=0,2,\ldots,n-1.$$

Therefore, we have

$$F_4=\binom{n}{2}a_0(y^2+z^2)^{n-2}(-rx^2)^2, \quad F_5=0.$$

By recursive calculations, we can prove that

$$F_{2i}=\binom{n}{i}a_0(y^2+z^2)^{n-i}(-rx^2)^i, \quad F_{2i+1}=0, \quad i\geqslant 5, \quad 2i\leqslant m.$$

Hence, the Darboux polynomial of the Lorenz system is

$$f=\sum_{i=0}^{n}\binom{n}{i}a_0(y^2+z^2)^{n-i}(-rx^2)^i=a_0(y^2+z^2-rx^2)^n$$

with the cofactor $-2n$. Moreover, the irreducible Darboux polynomial is $y^2+z^2-rx^2$ with the cofactor -2.

Case (iv): $b=6s-2$, $c=-4sn$, and $s\neq 1/2$. Since $a_{n-i}=(-4s^2)^i\binom{n}{i}a_n$ for $i=1,2,\ldots,n$ and $a_n\neq 0$, without loss of generality, we set $a_n=1$, then we have

$$F_0=[(x^2-2sz)^2-4s^2(y^2+z^2)]^n.$$

Moreover, we have

$$\begin{aligned}
F_1&=\sum_{i=0}^{n-1}\frac{1}{s}[-4sn+4si+2(n-i)]a_i(x^2-2sz)^{2i}(y^2+z^2)^{n-i-1}xy\\
&=-\frac{4s-2}{s}\sum_{j=1}^{n}j(-4s^2)^j\binom{n}{j}(x^2-2sz)^{2(n-j)}(y^2+z^2)^{j-1}xy\\
&=4s(4s-2)\sum_{j=0}^{n-1}(-4s^2)^jn\binom{n-1}{j}(x^2-2sz)^{2(n-1-j)}(y^2+z^2)^jxy\\
&=\binom{n}{1}[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-1}4s(4s-2)xy.
\end{aligned}$$

Substituting F_0 and F_1 into the second equation of (15), we get that

$$F_2=[(4s-2)(4s-12s^2)+8rs^2]n[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-1}z$$
$$+16s^3(4s-2)^2n(n-1)(y^2+z^2)[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-2}z-8s^2(4s-2)^2n(n-1)$$
$$\times x^2[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-2}z^2+\sum_{i=1}^{n} a_i^{(2)}(x^2-2sz)^{2i-1}(y^2+z^2)^{n-i},$$

where $a_i^{(2)}$ are real constants for $i=1,2,\ldots,n$.

From (15) with $j=3$ and working in a similar way to solve F_1, we can prove that

$$\overline{F}_3=-\sum_{i=1}^{n}[(4s-2)(n-i)+2s]a_i^{(2)}u^{2i-1}v^{n-i}\int\frac{dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$-\sum_{i=1}^{n}2s(4s-2)(2i-1)a_i^{(2)}u^{2i-2}v^{n-i}\int\frac{w\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$+\sum_{i=1}^{n}3(4s-2)(n-i)a_i^{(2)}u^{2i-1}v^{n-1-i}\int\frac{w^2\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$-4s(4s-2)rnu(u^2-4s^2v)^{n-1}\int\frac{dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$+32s^3(4s-2)rn(n-1)uv(u^2-4s^2v)^{n-2}\int\frac{dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$+16s[(s-1)(2s-1)(1-3s)-s^2r]n(u^2-4s^2v)^{n-1}\int\frac{w\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$+16s^3[(4s-2)^2(1-5s)+6s(4s-2)r]n(n-1)v\cdot(u^2-4s^2v)^{n-2}\int\frac{w\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$+64s^5(4s-2)^3n(n-1)(n-2)v^2(u^2-4s^2v)^{n-3}\int\frac{w\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$+16s^2[(4s-2)^2-4s(4s-2)r]n(n-1)u\cdot(u^2-4s^2v)^{n-2}\int\frac{w^2\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$-96s^4(4s-2)^3n(n-1)(n-2)uv(u^2-4s^2v)^{n-3}\int\frac{w^2\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}$$
$$+16s^3(4s-2)n(n-1)[2(4s-2)^2(n-2)+5(3s-1)(4s-2)-10sr](u^2-4s^2v)^{n-2}$$
$$\times\int\frac{w^3\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}-128s^5(4s-2)^3n(n-1)(n-2)v(u^2-4s^2v)^{n-3}$$
$$\times\int\frac{w^3\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}+160s^4(4s-2)^3n(n-1)(n-2)u(u^2-4s^2v))^{n-3}$$
$$\times\int\frac{w^4\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}+192s^5(4s-2)^3n(n-1)(n-2)(u^2-4s^2v)^{n-3}$$
$$\times\int\frac{w^5\,dw}{\sqrt{u+2sw}\sqrt{v-w^2}}+\overline{G}_3(u,v).$$

Using formulas (A4)–(A6), $\overline{F}_3$ can be simplified to

$$\begin{aligned}\overline{F}_3=&\left\{8s(4s-2)[-2(4s-2)r(u+2sw)+(6s-2)(4sr-2s(4s-2))w]\binom{n}{2}\cdot(u^2-4s^2v)^{n-2}\right.\\&\left.+64s^3(4s-2)^3\binom{n}{3}(u+2sw)(v-w^2)(u^2-4s^2v)^{n-3}\right\}\cdot\sqrt{u+2sw}\sqrt{v-w^2}+16s(3s-1)\\&\times(s-1)[r-(2s-1)]n\binom{n-1}{i}(-4s^2)^{n-i-i}\cdot u^{2i}v^{n-1-i}\int\frac{w\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}\\&-6s\sum_{i=1}^{n}\left\{a_i^{(2)}+2(4s-2)n\left[r\binom{n-1}{i-1}+(4s-2)(n-1)\cdot\binom{n-2}{i-1}\right](-4s^2)^{n-i}\right\}u^{2i-1}v^{n-1-i}\\&\times\int\frac{w^2dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\overline{G}_3(u,v).\end{aligned}$$

For details, see Appendix B.

Since $F_3(x,y,z)=\overline{F}_3(u,v,w)$ is a weight homogeneous polynomial with weight degree $4n-3$ in x,y and z, we should have $\overline{G}_3(u,v)=0$ and

$$(3s-1)(s-1)[r-(2s-1)]=0,$$

$$a_i^{(2)}=-2(4s-2)n\left[r\binom{n-1}{i-1}+(4s-2)(n-1)\binom{n-2}{i-1}\right](-4s^2)^{n-i},$$

for $i=1,2,\ldots,n$. Furthermore, we have

$$\begin{aligned}F_2=&[(4s-2)(4s-12s^2)+8rs^2]n[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-1}z+16s^3(4s-2)^2n(n-1)(y^2\\&+z^2)[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-2}z-8s^2(4s-2)^2n(n-1)x^2[(x^2-2sz)^2-4s^2(y^2\\&+z^2)]^{n-2}z^2-2(4s-2)rn(x^2-2sz)[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-1}+8s^2(4s-2)^2n(n-1)\\&\times(x^2-2sz)(y^2+z^2)[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-2}\\=&\binom{n}{2}[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-2}[4s(4s-2)xy]^2+\binom{n}{1}[(x^2-2sz)^2\\&-4s^2(y^2+z^2)]^{n-1}\cdot\{-2(4s-2)rx^2+[(4s-2)(4s-12s^2)+4s(6s-2)r]z\},\end{aligned}$$

$$\begin{aligned}F_3=&\binom{n}{3}[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-3}[4s(4s-2)xy]^3\\&+\binom{n}{2}[(x^2-2sz)^2-4s^2(y^2+z^2)]^{n-2}2[4s(4s-2)xy]\\&\cdot\{-2(4s-2)rx^2+[(4s-2)(4s-12s^2)+4s(6s-2)r]z\}.\end{aligned}$$

If $s=1/3$, then $b=0$, $c=-4n/3$. It is known that the polynomial

$$f_2=x^4-\tfrac{4}{3}x^2z-\tfrac{4}{9}y^2-\tfrac{8}{9}xy+\tfrac{4}{3}rx^2,$$

is a Darboux polynomial with the cofactor $-4/3$. It is easy to prove that F_0, F_1, F_2, and F_3 are the terms of

$$(x^4-\tfrac{4}{3}x^2z-\tfrac{4}{9}y^2-\tfrac{8}{9}xy+\tfrac{4}{3}rx^2)^n=[(x^2-\tfrac{2}{3}z)^2-\tfrac{4}{9}(y^2+z^2)-\tfrac{8}{9}xy+\tfrac{4}{3}rx^2]^n,$$

with weight degrees $4n$, $4n-1$, $4n-2$ and $4n-3$ associated with the weight $\mathbf{s}=(1,2,2)$, respectively. This last function, denoted by f^*, is also a Darboux polynomial with the cofactor $-4n/3$. We claim that $f=F|_{\alpha=1}$ is equal to f^*. Indeed, if not, then $f-f^*$ $(\neq 0)$ is a Darboux polynomial of the Lorenz system with the cofactor $-4n/3$, and the highest weight degree less than $4n-3$ in the weight homogeneous components of $f-f^*$. It is in contradiction with the fact that under the condition $b\neq 2s$, the highest weight degree of the weight homogeneous components of a Darboux polynomial for the Lorenz system is $4h$ for some positive integer h, and that the Darboux polynomial has the cofactor $-4hs$. This proves the claim. Therefore, the irreducible Darboux polynomial is the known one, i.e., f_2.

If $s=1$, then $b=4$ and $c=-4n$. Working in a similar way as in the proof of the previous paragraph, we get that the Darboux polynomial is

$$(x^4-4x^2z-4y^2+8xy-4x^2-16(1-r)z)^n,$$

with the cofactor $-4n$.

If $r=2s-1$, since $c=-4sn$ and $b=6s-2$ with $s\neq 1/2$, we can prove that the Darboux polynomial is

$$(x^4-4sx^2z-4s^2y^2+4s(4s-2)xy-4(2s-1)^2x^2)^n,$$

with the cofactor $-4sn$. This completes the proof of the theorem. ■

IV. THE PROOF OF COROLLARY 2

Proof of statement (a): It is made inside the proof of Theorem 1. ■

Proof of statement (b): The proof of this statement follows from the following result, whose proof is easy.

Lemma 3: Let $\mathbf{X}$ *be an n-dimensional polynomial vector field. Then* $f\in\mathbb{R}[\mathbf{x}]$ *with* $\mathbf{x}\in\mathbb{R}^n$ *is a Darboux polynomial of* $\mathbf{X}$ *with a constant cofactor* k *if and only if the function* $H(\mathbf{x},t)=f(\mathbf{x})e^{-kt}$ *is an invariant.* ■

Proof of statement (c): Since every polynomial first integral is a Darboux polynomial with the cofactor $k=0$, statement (c) follows from Theorem 1 and its proof. ■

Proof of statement (d): In order to prove this statement, we need the following results.

Lemma 4: Let $\mathbf{X}$ *be a polynomial vector field in* $\mathbb{R}^n$. *Then the following statements hold.*

(1) Assume that f_i *for* $i=1,\ldots,m$, *is the Darboux polynomial of* $\mathbf{X}$ *with a cofactor* k_i. *If there exist* $\lambda_i\in\mathbb{R}$ *not all equal to zero such that* $\Sigma_{i=1}^m\lambda_i k_i\equiv 0$, *then* $H=\Pi_{i=1}^m f_i^{k_i}$ *is a first integral of the field* $\mathbf{X}$.

(2) Assume that $f(\mathbf{x})$ *is a polynomial function. Let* $f=f_1^{n_1}\ldots f_m^{n_m}$ *be the factorization of* f *in irreducible factors over* $\mathbb{R}[\mathbf{x}]$. *Then* f *is a Darboux polynomial with a cofactor* k_f *of* $\mathbf{X}$ *if and only if each* f_i *is a Darboux polynomial with a cofactor* k_{f_i} *for* $i=1,\ldots,m$. *Moreover,* $k_f=n_1k_{f_1}+\cdots+n_mk_{f_m}$.

The first statement was proved by Darboux (1878). We call such a first integral a *Darboux first integral*. The second statement was proved in Christopher and Llibre (2000).

From Theorem 1 it is easy to check that the values of the parameters in the Lorenz system in order to have two different generators for the Darboux polynomials are $s=1/2$, $b=1$, and $r=0$. Then, the generators of the Darboux polynomials are x^2-z with the cofactor -1, and y^2+z^2 with the cofactor -2. From statement (1) of Lemma 4, it follows easily that $(x^2-z)^2/((y^2+z^2)$ is a rational first integral. Moreover, from statement (2) of Lemma 4 we obtain that any Darboux polynomial has the form

$$\sum_{i+2j=K} a_{ij}(x^2-z)^i(y^2+z^2)^j,$$

with the cofactor $-K$, where $i,j,K\in\mathbb{N}$. This proves statement (d) using again Lemma (1). ■

Proof of statement (e): We first recall the following result.

Lemma 5: A vector field $\mathbf{X}$ *in* $\mathbb{R}^n$ *has* l $(1\leqslant l<n)$ *independent algebraic first integrals if and only if it has* l *independent rational first integrals.*

It was obtained by Bruns in 1887 [for a proof, see Forsyth (1900) or Goriely (1996)]. This lemma means that the vector field $\mathbf{X}$ is algebraically integrable if and only if it has $n-1$ independent rational first integrals. Therefore, from statement (d) and taking into account that any two rational first integrals given in (d) are dependent we obtain that statement (e) holds. ■

This completes the proof of the corollary.

APPENDIX A: SOME ELLIPTIC INTEGRALS

The following formulas are used in the proof of Theorem 1:

$$\int \frac{\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}} = \frac{1}{sv}\sqrt{u+2sw}\,\sqrt{v-w^2} + \frac{u}{sv}\int \frac{w\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}} + \frac{3}{v}\int \frac{w^2\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}. \tag{A1}$$

The following two integrating formulas are obtained by using the change $w=\sqrt{v}\sin\theta$ for $\theta\in[-\pi/2,\pi/2)$ and formulas 2.571.2 and 2.571.3 of Gradshteyn and Ryzhik (1980).

$$\int \frac{w\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}$$

$$= \int \frac{\sqrt{v}\sin\theta}{\sqrt{u+2s\sqrt{v}\sin\theta}}\mathrm{d}\theta$$

$$= \begin{cases} \dfrac{u}{s\sqrt{u+2s\sqrt{v}}}W(\delta,\gamma) - \dfrac{\sqrt{u+2s\sqrt{v}}}{s}E(\delta,\gamma), & \text{for } u>2s\sqrt{v}>0, \quad -\dfrac{\pi}{2}\leqslant\theta<\dfrac{\pi}{2}, \\ \sqrt{v}\sqrt{\dfrac{1}{s\sqrt{v}}}\left[W\left(\beta,\dfrac{1}{\gamma}\right)-2E\left(\beta,\dfrac{1}{\gamma}\right)\right], & \text{for } 0<|u|<2s\sqrt{v}, \quad -\arcsin\dfrac{u}{2s\sqrt{v}}<\theta<\dfrac{\pi}{2}, \end{cases} \tag{A2}$$

$$\int \frac{w^2\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}$$

$$=v\int \frac{\sin^2\theta}{\sqrt{u+2s\sqrt{v}\sin\theta}}\mathrm{d}\theta$$

$$=\begin{cases} \dfrac{u\sqrt{u+2s\sqrt{v}}}{3s^2}E(\delta,\gamma)-\dfrac{u^2+2s^2v}{3s^2\sqrt{u+2s\sqrt{v}}}W(\delta,\gamma)-\dfrac{1}{3s}\sqrt{v-w^2}\sqrt{u+2sw}, \\ \qquad \text{for } u>2s\sqrt{v}>0, \quad -\dfrac{\pi}{2}\leqslant\theta<\dfrac{\pi}{2}, \\ \sqrt{\dfrac{1}{s\sqrt{v}}}\left[\dfrac{2u\sqrt{v}}{3s}E\left(\beta,\dfrac{1}{\gamma}\right)-\dfrac{\sqrt{v}(u+s\sqrt{v})}{3s}W\left(\beta,\dfrac{1}{\gamma}\right)\right]-\dfrac{1}{3s}\sqrt{v-w^2}\,\sqrt{u+2sw}, \\ \qquad \text{for } 0<|u|<2s\sqrt{v}, \quad -\arcsin\dfrac{u}{2s\sqrt{v}}<\theta<\dfrac{\pi}{2}, \end{cases} \tag{A3}$$

where

$$\beta=\arcsin\sqrt{\frac{2s\sqrt{v}(1-\sin\theta)}{u+2s\sqrt{v}}}=\arcsin\sqrt{\frac{2s(\sqrt{v}-w)}{u+2s\sqrt{v}}},$$

$$\gamma=\sqrt{\frac{4s\sqrt{v}}{u+2s\sqrt{v}}}, \quad \delta=\arcsin\sqrt{\frac{1-\sin\theta}{2}}=\arcsin\sqrt{\frac{\sqrt{v}-w}{2\sqrt{v}}},$$

and

$$W(\phi,k)=\int_0^{\phi}\frac{\mathrm{d}\zeta}{\sqrt{1-k^2\sin^2\zeta}}=\int_0^{\sin\phi}\frac{dx}{\sqrt{(1-x^2)(1-k^2x^2)}},$$

$$E(\phi,k)=\int_0^{\phi}\sqrt{1-k^2\sin^2\zeta}\,\mathrm{d}\zeta=\int_0^{\sin\phi}\frac{\sqrt{1-k^2x^2}}{\sqrt{1-x^2}}\mathrm{d}x,$$

are elliptic integrals of the first and second kind in the Legendre normal form [see, for instance, formulas 8.111.2 and 8.111.3 of Gradshteyn and Ryzhik (1980)]:

$$\int \frac{w^3\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}=\left(\frac{u}{5s^2}-\frac{w}{5s}\right)\sqrt{u+2sw}\,\sqrt{v-w^2}+\left(\frac{u^2}{5s^2}+\frac{3}{5}v\right)\int\frac{w\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}$$
$$+\frac{u}{5s}\int\frac{w^2\,\mathrm{d}w}{\sqrt{u+2sw}\,\sqrt{v-w^2}}, \tag{A4}$$

$$\int \frac{w^4\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}=\left(-\frac{3u^2}{35s^3}+\frac{3uw}{35s^2}-\frac{w^2}{7s}\right)\sqrt{u+2sw}\,\sqrt{v-w^2}+\left(\frac{uv}{35s}-\frac{3u^3}{35s^3}\right)\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\left(\frac{5}{7}v-\frac{3u^2}{35s^2}\right)\int\frac{w^2\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}},\tag{A5}$$

$$\int \frac{w^5\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}=\left(\frac{7uv}{45s^2}-\frac{7vw}{45s}+\frac{4u^3}{105s^4}-\frac{4u^2w}{105s^3}+\frac{4uw^2}{63s^2}-\frac{w^3}{9s}\right)\sqrt{u+2sw}\,\sqrt{v-w^2}+\left(\frac{u^2v}{7s^2}+\frac{21}{45}v^2+\frac{4u^4}{105s^4}\right)\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}+\left(\frac{6uv}{35s}+\frac{4u^3}{105s^3}\right)\int\frac{w^2\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}}.\tag{A6}$$

APPENDIX B: THE COEFFICIENTS C_1, C_2, AND C_3

In this appendix we compute the coefficients, denoted by C_1, C_2, and C_3, of

$$\sqrt{u+2sw}\,\sqrt{v-w^2}\int\frac{w\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}},\quad \int\frac{w^2\,dw}{\sqrt{u+2sw}\,\sqrt{v-w^2}},$$

in the expression of $\overline{F_3}$ for case (iv) of Sec. III B.

From the formulas of Appendix A and the expression of $\overline{F_3}$, we have

$$\begin{aligned}C_3=&-\sum_{i=1}^{n}3[(4s-2)(n-i)+2s]a_i^{(2)}u^{2i-1}v^{n-1-i}+\sum_{i=1}^{n}3(4s-2)(n-i)a_i^{(2)}u^{2i-1}v^{n-1-i}\\&-12s(4s-2)rnuv^{-1}(u^2-4s^2v)^{n-1}+96s^3(4s-2)rn(n-1)u(u^2-4s^2v)^{n-2}\\&+16s^2[(4s-2)^2-4s(4s-2)r]n(n-1)u(u^2-4s^2v)^{n-2}-96s^4(4s-2)^3\\&\times n(n-1)(n-2)uv(u^2-4s^2v)^{n-3}+\frac{16}{5}s^2(4s-2)n(n-1)[2(4s-2)^2(n-2)+5(3s-1)\\&\times(4s-2)-10sr]u(u^2-4s^2v)^{n-2}-\frac{128}{5}s^4(4s-2)^3n(n-1)(n-2)uv(u^2-4s^2v)^{n-3}\\&+160s^4(4s-2)^3n(n-1)(n-2)u\left(\frac{5}{7}v-\frac{3u^2}{35s^2}\right)(u^2-4s^2v)^{n-3}\\&+192s^5(4s-2)^3n(n-1)(n-2)\left(\frac{6uv}{35s}+\frac{4u^3}{105s^3}\right)(u^2-4s^2v)^{n-3}\\=&-\sum_{i=1}^{n}6sa_i^{(2)}u^{2i-1}v^{n-1-i}-12s(4s-2)rnuv^{-1}(u^2-4s^2v)^{n-1}\\&+48s^3(4s-2)^2n(n-1)u(u^2-4s^2v)^{n-2}\end{aligned}$$

$$
\begin{aligned}

(Received 5 June 2001; accepted for publication 4 December 2001)

As an alternative to Chevalley generators, we introduce Jacobson generators for the quantum superalgebra $U_q[sl(n+1|m)]$. The expressions of all Cartan–Weyl elements of $U_q[sl(n+1|m)]$ in terms of these Jacobson generators become very simple. We determine and prove certain triple relations between the Jacobson generators, necessary for a complete set of supercommutation relations between the Cartan–Weyl elements. Fock representations are defined, and a substantial part of this paper is devoted to the computation of the action of Jacobson generators on basis vectors of these Fock spaces. It is also determined when these Fock representations are unitary. Finally, Dyson and Holstein–Primakoff realizations are given, not only for the Jacobson generators, but for all Cartan–Weyl elements of $U_q[sl(n+1|m)]$. © *2002 American Institute of Physics.*

I. INTRODUCTION

The quantization of simple Lie algebras[1,2] or Lie superalgebras[3–7] as quasitriangular Hopf (super)algebras has been carried out more than a decade ago. Since then, these structures have received much attention both in the mathematical and physical literature. In a physical context, one is mostly dealing with representations or realizations of these quantized algebras. This is in fact the main topic of the present paper: Certain special representations (Fock representations) and related realizations (Dyson and Holstein–Primakoff) of the quantum superalgebra $U_q[sl(n+1|m)]$ are presented.

The Lie superalgebra $sl(n+1|m)$ is one of the basic classical simple Lie superalgebras in Kac's classification.[8] It can be considered as the superanalogue of the special linear Lie algebra $sl(n+1)$. The quantum superalgebra $U_q[sl(n+1|m)]$ is a Hopf superalgebra deformation of the associative superalgebra $U[sl(n+1|m)]$, the universal enveloping superalgebra of $sl(n+1|m)$. At this point, it is already worth observing that the more familiar case of $sl(n+1)$ and $U_q[sl(n+1)]$ just follows by putting $m=0$. The readers who are interested in this case only can still use all formulas presented in this paper, simply taking m equal to 0.

For a definition of the quantum superalgebra $U_q[sl(n+1|m)]$, we refer to Refs. 3–7. Usually, $U_q[sl(n+1|m)]$ is defined by its Chevalley generators (often denoted by e_i, f_i, and h_i, with

$i=1,\ldots,n+m$), subject to the Cartan–Kac relations and the Serre relations.[5–7] Besides these defining relations, also the other Hopf superalgebra maps (comultiplication, co-unit, and antipode) are part of the definition. In this paper, however, we do not use these other Hopf superalgebra maps; so we shall concentrate on $U_q[sl(n+1|m)]$ as an associative superalgebra.

The definition in terms of Chevalley generators has the advantage that the comultiplication, co-unit and antipode are easy to give. Furthermore, certain representations can be constructed explicitly (e.g., for the essentially typical representations a Gelfand–Zetlin basis exist for which the action of the Chevalley generators is known[9]). Having certain physical applications in mind, however, it is sometimes more useful to work with a different set of generators for $U_q[sl(n+1|m)]$.

The different set of generators for $U_q[sl(n+1|m)]$ given here are the Jacobson generators (denoted by a_i^+, a_i^- and H_i, with $i=1,\ldots,n+m$). For the case of $sl(n+1)$, such generators were originally introduced by Jacobson.[10,11] The use of Jacobson generators has a number of advantages.

First of all, in certain applications it is necessary to have a complete basis of $U_q[sl(n+1|m)]$ (following from the Poincaré–Birkhoff–Witt theorem). Such a basis is given in terms of the Cartan–Weyl elements. Although it is possible to express all Cartan–Weyl elements in terms of the Chevalley generators, such expressions soon become rather unmanageable. In terms of the Jacobson generators, the description of all Cartan–Weyl elements is very easy.

Secondly, the Jacobson generators allow for the construction of a class of irreducible $U_q[sl(n+1|m)]$ modules W_p, $p\in\mathbb{C}$, called Fock representations. The Fock representations corresponding to different p are inequivalent. For p a positive integer they provide an explicit construction (basis and transformation of the basis under the action of the generators) of (deformations of) atypical representations of $U_q[sl(n+1|m)]$. This is an interesting mathematical result, since even in the nondeformed case all atypical representations of $sl(n+1|m)$ were not explicitly constructed so far (e.g., even a dimension formula is unknown).

A disadvantage of the Jacobson generators compared to the Chevalley generators is that the explicit expressions for the other Hopf (super)algebra maps (comultiplication, co-unit and antipode) become very lengthy and complicated.

The results of the present paper provide a mathematical background for further studies of noncanonical quantum statistics initiated in Ref. 12 (see also Refs. 11 and 13 for further references). The approach is based on the concept of creation and annihilation operators (CAO's) of a simple Lie (super)algebra $\mathcal{A}$ and its Fock representations.[14] The CAO's of $\mathcal{A}$ provide a description of $\mathcal{A}$ in terms of generators and relations, which are different from the Chevalley generators. In this terminology any n pairs of para-Fermi operators[15] are CAO's of so$(2n+1)$[16] and any n pairs of para-Bose operators[15] are CAO's of the orthosymplectic Lie superalgebra osp$(1|2n)$.[17] The CAO's of $sl(n+1)$[12] and of $sl(1|n)$[14] lead to new quantum statistics. Generalizing the results of Jacobson on Lie triple systems,[10] Okubo has reformulated all above statistics in terms of Lie supertriple systems.[18] In this setting the CAO's of the Lie (super)algebras mentioned above are generators of the related (super)triple systems. This is another reason to call them Jacobson generators (JG's). The link between the JG's and the simple Lie superalgebras provides a natural background for their q-deformations (we refer to Ref. 19 for more discussion in this respect).

The representations of (quantum) superalgebras have certainly wider applications. These algebras (and in particular $U_q[gl(n+1|m)]$[20]) play a role for finding new solutions of the quantum Yang–Baxter equations and for the construction of solvable models. As examples we mention the supersymmetric solvable $t-J$ models of correlated electrons[21] and their quantum analogue.[22] Some other potential physical applications are mentioned in the last section.

In Sec. II we define the Jacobson generators of $U_q[sl(n+1|m)]$, as a special subset of the Cartan-Weyl elements. The description of all Cartan–Weyl elements in terms of the Jacobson generators becomes very simple (Theorem 1). However, in order to apply these results (e.g., in representations) one must have a list of all (super)commutation relations between these Cartan–Weyl elements; in terms of Jacobson generators, this means one has to determine certain triple relations. These are also given in Theorem 1, together with their proof.

In Sec. III we define Fock representations for $U_q[sl(n+1|m)]$, related to the earlier defined Jacobson generators. The main part of this section is devoted to the proof of Theorem 2, describing the action of the Jacobson generators on a basis of the Fock representation. This proof is rather technical and lengthy, and has been divided in a number of lemmas. The essential result is that these Fock representations are labeled by a number p; when p is a nonnegative integer, the Fock representation is finite-dimensional.

The Fock representations determined in Sec. III are further analyzed in Sec. IV. In particular, following conditions required in a physical context, it is determined when these Fock representations are unitary (or unitarizable, or Hermitian), see Theorem 6. In that case, an orthonormal basis of the Fock space is given, together with the action of the Jacobson generators on these basis elements.

Inspired by the Fock representations, we can give new expressions for the Dyson and Holstein–Primakoff realizations of $U_q[sl(n+1|m)]$ (Sec. V). In Ref. 23, the Dyson and Holstein–Primakoff realizations for the Chevalley generators of $U_q[gl(n|m)]$ was already given. Here, we give Dyson and Holstein–Primakoff realizations for the Jacobson generators of $U_q[sl(n+1|m)]$ (Theorems 7 and 8); from these, the corresponding realization for all Cartan–Weyl elements are deduced. All these realizations are in terms of n pairs of Bose and m pairs of Fermi creation and annihilation operators. The Holstein–Primakoff realization becomes particularly simple when expressed in terms of q-deformed Bose and Fermi creation and annihilation operators.

Unless otherwise stated, we consider in this paper $U_q[sl(n+1|m)]$ as a module over the algebra $\mathbb{C}[[h]]$ (with $q=e^h$) of formal power series over an indeterminate h. It is important to note, however, that all considerations remain true if one replaces h by a complex number such that $q=e^h$ is not a root of unity. In fact, most of our results hold also for q being a root of 1, including the unitary Fock representations and the Dyson and Holstein–Primakoff realizations.

Throughout the paper we use the notation: JGs for Jacobson generators; $\mathbb{Z}$ (resp. $\mathbb{Z}_+$) for the set of all integers (resp. of all nonnegative integers); $\mathbb{Z}_2=\{\overline{0},\overline{1}\}$ for the ring of all integers modulo 2; $\mathbb{C}$ for all complex numbers. Furthermore

$$[x]=\frac{q^x-q^{-x}}{q-q^{-1}}, \quad \text{when} \quad x\in\mathbb{C}, \tag{1.1}$$

$$[r;s]=\{r,r+1,r+2,\ldots,s-1,s\}, \quad \text{for} \quad r\leqslant s\in\mathbb{Z}; \tag{1.2}$$

$$\theta_i=\begin{cases}\overline{0} & \text{if} \quad i\in[0;n]\\ \overline{1} & \text{if} \quad i\in[n+1;n+m]\end{cases}; \quad \theta_{ij}=\theta_i+\theta_j; \tag{1.3}$$

$$[a,b]=ab-ba, \quad \{a,b\}=ab+ba, \quad [\![a,b]\!]=ab-(-1)^{\deg(a)\deg(b)}ba; \tag{1.4}$$

$$[a,b]_x=ab-xba, \quad \{a,b\}_x=ab+xba, \quad [\![a,b]\!]_x=ab-(-1)^{\deg(a)\deg(b)}xba, \tag{1.5}$$

where $\deg(a)\in\mathbb{Z}_2$ refers to the degree (or grading) of a when a is a homogeneous element of a superalgebra.

II. JACOBSON GENERATORS OF $U_q[sl(n+1|m)]$

Although the quantization (q-deformation) of simple Lie algebras and basic Lie superalgebras is usually carried out in terms of their Chevalley generators, there exist alternative descriptions in terms of so-called deformed creation and annihilation operators for the q-deformation of $\mathrm{osp}(1|2n)$,[24] $\mathrm{so}(2n+1)$,[25] $\mathrm{osp}(2n+1|m)$,[19] $sl(n+1)$,[26] and $sl(n+1|m)$.[27] These alternative generators have the advantage that in some natural interpretation they have a direct physical significance; furthermore, they allow the definition and construction of a mathematically interesting and physically important class of irreducible representations, the Fock representations.

The Hopf superalgebra $U_q[sl(n+1|m)]$ is defined in the sense of Drinfeld,[1] as a topologically free $\mathbb{C}[[h]]$ module. As a superalgebra, $U_q[sl(n+1|m)]$ is usually defined by means of its Chevalley generators, subject to the Cartan–Kac relations and the Serre relations.[5–7] Unlike the Lie algebra case, there is an ''extra Serre relation'' involving the generator associated with an odd simple root.[5–7,28] This property was investigated further by Yamane.[29,30] Indeed, for the basic classical Lie superalgebras there exist many nonisomorphic simple root systems;[8] one of these, having only one odd simple root, is known as the distinguished simple root system.[8] The classical description of $U_q[sl(n+1|m)]$ is in terms of relations and generators associated with this distinguished simple root system. Yamane[29,30] studied Hopf superalgebras in terms of relations and generators associated with other simple root systems. Apparently, this gives rise to more involved extra Serre relations. Moreover, the structure of the Hopf superalgebra seems to depend on the choice of simple root system.[29,30] In this paper, $U_q[sl(n+1|m)]$ stands for the usual Hopf superalgebra associated with the distinguished simple root system. But we shall be dealing with an alternative set of generators (and relations) for $U_q[sl(n+1|m)]$.

In this Sec. we shall recall the definition of deformed creation and annihilation operators of $U_q[sl(n+1|m)]$, and refer to them as Jacobson generators (JGs) since they are closely related to generators in the sense of a Lie supertriple system[18] (and for Lie triple systems, such generators were originally introduced by Jacobson[10,11]). The definition of JGs can be best presented in the framework of a set of Cartan–Weyl elements of $U_q[sl(n+1|m)]$. Furthermore, in order to construct the Fock representations explicitly, it is necessary to have a complete list of so-called triple relations between the JGs. Such relations can be deduced from the supercommutation relations between all Cartan–Weyl elements. So we begin this section by recalling some properties of Cartan–Weyl elements of $U_q[gl(n+1|m)]$, deduced in Ref. 31, which are then easily restricted to the case of $U_q[sl(n+1|m)]$.

Although a set of generators, such as the Chevalley generators, is sufficient for the definition of $U_q[gl(n+1|m]$ as an associative algebra, it is not sufficient for describing a basis of $U_q[gl(n+1|m]$. For this purpose, the construction of a set of Cartan–Weyl elements is necessary. For $U_q[gl(n+1|m]$, a set of Cartan–Weyl elements is given by elements e_{ij}, with $i,j \in [0;n+m]$; for an explicit expression of these elements e_{ij} in terms of the standard Chevalley generators, see Ref. 31. Finding a set of Cartan–Weyl elements, and their (super)commutation relations, is necessary for the construction of a Poincaré–Birkhoff–Witt basis of $U_q[gl(n+1|m]$. The elements e_{ij} are the q-analogues of the defining basis of $gl(n+1|m)$; their grading is given by $\deg(e_{ij})=\theta_{ij}$. We shall refer to e_{ij} as a positive root vector (resp. negative root vector) if $i<j$ (resp. $i>j$). For the formulation of the Poincaré–Birkhoff–Witt theorem, it is necessary to fix a total order for the set of elements e_{ij}. Among the positive root vectors, this order is given by

$$e_{ij}<e_{kl}, \text{ if } i<k \text{ or } i=k, \text{ and } j<l, \tag{2.1}$$

for the negative root vectors e_{ij} one takes the same rule (2.1), and total order is fixed by choosing

$$\text{positive root vectors} < \text{negative root vectors} < e_{ii}.$$

The order among the elements e_{ii} is of no real importance since they commute. A complete set of relations between the Cartan–Weyl elements e_{ij} is given by (2.2)–(2.7) [see Eqs. (3.10)–(3.15) of Ref. 31]

$$[e_{ii},e_{jj}]=0, \tag{2.2}$$

$$[e_{ii},e_{jk}]=(\delta_{ij}-\delta_{ik})e_{jk}, \tag{2.3}$$

$$(e_{ij})^2=0 \text{ if } \theta_{ij}=1, \tag{2.4}$$

for two positive root vectors $e_{ij}<e_{kl}$:

$$[\![e_{ij},e_{kl}]\!]_{q^{(-1)^{\theta_j}\delta_{jl}-(-1)^{\theta_j}\delta_{jk}+(-1)^{\theta_i}\delta_{ik}}}=\delta_{jk}e_{il}+(q-q^{-1})(-1)^{\theta_k}\theta(l>j>k>i)e_{kj}e_{il}, \tag{2.5}$$

for two negative root vectors $e_{ij}>e_{kl}$

$$[\![e_{ij},e_{kl}]\!]_{q^{-(-1)^{\theta_j}\delta_{jl}+(-1)^{\theta_j}\delta_{jk}-(-1)^{\theta_i}\delta_{ik}}}=\delta_{jk}e_{il}-(q-q^{-1})(-1)^{\theta_k}\theta(i>k>j>l)e_{kj}e_{il}, \quad (2.6)$$

and finally for a positive root vector e_{ij} and a negative root vector e_{kl}

$$\begin{aligned}[\![e_{ij},e_{kl}]\!]=&\frac{\delta_{il}\delta_{jk}}{q-q^{-1}}(q^{e_{ii}-(-1)^{\theta_{ij}}e_{jj}}-q^{-e_{ii}+(-1)^{\theta_{ij}}e_{jj}})+((q-q^{-1})\theta(j>k>i>l)(-1)^{\theta_k}e_{kj}e_{il}\\&-\delta_{il}\theta(j>k)(-1)^{\theta_{kl}}e_{kj}+\delta_{jk}\theta(i>l)e_{il})q^{(-1)^{\theta_k}e_{kk}-(-1)^{\theta_i}e_{ii}}+q^{(-1)^{\theta_l}e_{ll}-(-1)^{\theta_j}e_{jj}}\\&\times(-(q-q^{-1})\theta(k>j>l>i)(-1)^{\theta_j}e_{il}e_{kj}-\delta_{il}\theta(k>j)(-1)^{\theta_{ij}}e_{kj}+\delta_{jk}\theta(l>i)e_{il}). \quad (2.7)\end{aligned}$$

Herein,

$$\theta(i_1>i_2>\cdots>i_r)=\begin{cases}1, & \text{if } i_1>i_2>\cdots>i_r,\\ 0, & \text{otherwise.}\end{cases} \quad (2.8)$$

The difference between $U_q[sl(n+1|m)]$ and $U_q[gl(n+1|m)]$ lies in the elements of the Cartan subalgebra. For $U_q[gl(n+1|m)]$ the Cartan subalgebra is generated by e_{ii} ($i\in[0;n+m]$). For $U_q[sl(n+1|m)]$ the Cartan subalgebra is generated by the elements H_i, with

$$H_i=e_{00}-(-1)^{\theta_i}e_{ii}, \quad i\in[1;n+m]. \quad (2.9)$$

Sometimes, it will be useful to work with the elements L_i and $\overline{L_i}$, where

$$L_i=q^{H_i}, \quad \overline{L_i}=q^{-H_i}, \quad i\in[1;n+m]. \quad (2.10)$$

The Cartan–Weyl elements of $U_q[sl(n+1|m)]$ are now given by $\{H_i;i\in[1;n+m]\}\cup\{e_{ij};i\neq j\in[0;n+m]\}$. The complete set of supercommutation relations between these Cartan–Weyl elements is given by

$$[H_i,H_j]=0, \quad (2.11)$$

$$[H_i,e_{jk}]=(\delta_{0j}-\delta_{0k}-(-1)^{\theta_i}(\delta_{ij}-\delta_{ik}))e_{jk}, \quad (2.12)$$

(2.4)–(2.6) and finally the relation between a positive root vector e_{ij} and a negative root vector e_{kl}:

$$\begin{aligned}[\![e_{ij},e_{kl}]\!]=&\frac{\delta_{il}\delta_{jk}}{q-q^{-1}}(L_j^{(-1)^{\theta_i}}\overline{L_i}^{(-1)^{\theta_i}}-\overline{L_j}^{(-1)^{\theta_i}}L_i^{(-1)^{\theta_i}})+((q-q^{-1})\theta(j>k>i>l)(-1)^{\theta_k}e_{kj}e_{il}\\&-\delta_{il}\theta(j>k)(-1)^{\theta_{kl}}e_{kj}+\delta_{jk}\theta(i>l)e_{il})L_i\overline{L_k}+L_j\overline{L_l}(-(q-q^{-1})\theta(k>j>l>i)\\&\times(-1)^{\theta_j}e_{il}e_{kj}-\delta_{il}\theta(k>j)(-1)^{\theta_{ij}}e_{kj}+\delta_{jk}\theta(l>i)e_{il}). \quad (2.13)\end{aligned}$$

The Jacobson generators of $U_q[sl(n+1|m)]$ are now defined as the Cartan elements H_i ($i\in[1;n+m]$) together with the elements

$$a_i^-=e_{0i}, \quad a_i^+=e_{i0}, \quad i\in[1;n+m]. \quad (2.14)$$

From (2.13) it is easy to deduce that

$$[\![a_i^-,a_j^+]\!]=-(-1)^{\theta_i}L_ie_{ji}, \quad (i<j); \quad [\![a_i^-,a_j^+]\!]=-(-1)^{\theta_j}e_{ji}\overline{L_j}, \quad (i>j). \quad (2.15)$$

However, these relations are not complete in order to reshuffle all Cartan–Weyl elements in an arbitrary expression in the right order. For this purpose, we have the following result:

Theorem 1: *A set of Cartan–Weyl elements of* $U_q[sl(n+1|m)]$ *is given by* H_i, $a_i^{\pm}$, $[\![a_i^+,a_j^-]\!]$ $(i\neq j\in[1;n+m])$. *A complete set of supercommutation relations between these elements is given by*

$$[H_i,H_j]=0;\quad [H_i,a_j^{\pm}]=\mp(1+(-1)^{\theta_i}\delta_{ij})a_j^{\pm}, \tag{2.16}$$

$$[\![a_i^-,a_i^+]\!]=\frac{L_i-\overline{L_i}}{q-q^{-1}}, \tag{2.17}$$

$$[\![a_i^{\eta},a_j^{\eta}]\!]_q=0\quad (i<j);\quad (a_i^{\pm})^2=0\quad (i\in[n+1;n+m]), \tag{2.18}$$

$$\begin{aligned}[\![[\![a_i^{\eta},a_j^{-\eta}]\!],a_k^{\eta}]\!]_{q^{\xi(1+(-1)^{\theta_i}\delta_{ik})}}&=\eta^{\theta_j}\delta_{jk}L_k^{-\xi\eta}a_i^{\eta}+(-1)^{\theta_k}\epsilon(j,k,i)(q-\overline{q})[\![a_k^{\eta},a_j^{-\eta}]\!]a_i^{\eta}\\&=\eta^{\theta_j}\delta_{jk}L_k^{-\xi\eta}a_i^{\eta}+(-1)^{\theta_k\theta_j}\epsilon(j,k,i)q^{\xi}(q-\overline{q})a_i^{\eta}[\![a_k^{\eta},a_j^{-\eta}]\!],\end{aligned} \tag{2.19}$$

where $(j-i)\xi>0$, ξ, $\eta=\pm$

$$and\quad \epsilon(j,k,i)=\begin{cases}1, & \text{if } j>k>i;\\ -1, & \text{if } j<k<i;\\ 0, & \textit{otherwise},\end{cases}$$

and we have used the notation $\overline{q}=q^{-1}$.

Proof: The first part of the statement is obvious. Relation (2.16) follows from (2.11) and (2.12); (2.17) follows from (2.13) with $l=i<j=k$; the first relation in (2.18) follows from (2.5) with $i=k<j<l$ and from (2.6) with $l=j<k<i$, whereas the second relation in (2.18) comes from (2.4). Finally, it remains to prove (2.19). There are four similar cases to consider, according to $\eta=\pm$ and $\xi=\pm$. For $\eta=-$ and $\xi=+$, we use the first relation in (2.15) and find

$$\begin{aligned}[\![[\![a_i^-,a_j^+]\!],a_k^-]\!]_{q^{1+(-1)^{\theta_i}\delta_{ik}}}&=-(-1)^{\theta_i}[\![L_ie_{ji},a_k^-]\!]_{q^{1+(-1)^{\theta_i}\delta_{ik}}}=-(-1)^{\theta_i}L_i[\![e_{ji},a_k^-]\!]\\&=-(-1)^{\theta_i}L_i[\![e_{ji},e_{0k}]\!]=(-1)^{\theta_i+\theta_{ij}\theta_k}L_i[\![e_{0k},e_{ji}]\!].\end{aligned}$$

Herein, we have used the last equation of (2.16) to change the order of L_i and a_k^-. For the last supercommutator, we use (2.13)

$$[\![[\![a_i^-,a_j^+]\!],a_k^-]\!]_{q^{1+(-1)^{\theta_i}\delta_{ik}}}=(-1)^{\theta_i+\theta_{ij}\theta_k}L_iL_k\overline{L_i}(-(q-\overline{q})\,\theta(j>k>i)(-1)^{\theta_k}e_{0i}e_{jk}+\delta_{kj}e_{0i}).$$

Using trivial properties of the θ_i-symbols, the second term in the right-hand side (rhs) of this expression becomes $(-1)^{\theta_j}\delta_{jk}L_ka_i^-$; for the first term we use similar properties and replace according to (2.15) e_{jk} by $-(-1)^{\theta_k}\overline{L_k}[\![a_k^-,a_j^+]\!]$, so there comes

$$(-1)^{\theta_k}q(q-\overline{q})\,\theta(j>k>i)a_i^-[\![a_k^-,a_j^+]\!].$$

This coincides with the second expression in (2.19). Exchanging indices i and k, and using the relation just obtained, one shows that also the first expression in (2.19) is valid.

For the remaining choices of η and ξ, the proof is similar. □

Finally, we wish to remark that in order to construct $U_q[sl(n+1|m)]$ by means of the JGs subject to a set of relations, not all relations of Theorem 1 are needed. Such a minimal set of relations was determined in Ref. 27.

III. FOCK REPRESENTATIONS

In this section we shall construct so-called Fock representations of $U_q[sl(n+1|m)]$. The representations considered here are diagonal with respect to the Cartan elements H_i. So it will be convenient to fix q (or h) as a complex number in this and in the following section.

The Fock representations, or modules, can be defined by means of an induced module construction. First observe that $G=U_q[sl(n+1|m)]$, with Cartan–Weyl elements H_i, $a_i^{\pm}$ and $[\![a_i^+,a_j^-]\!]$ $(i\neq j\in[1;n+m])$, has a subalgebra $H=U_q[gl(n|m)]$ with Cartan–Weyl elements H_i and $[\![a_i^+,a_j^-]\!]$ $(i\neq j\in[1;n+m])$. A trivial one-dimensional H module is defined as follows:

$$[\![a_i^-,a_j^+]\!]|0\rangle=0, \quad (i\neq j\in[1;n+m]), \tag{3.1}$$

$$H_i|0\rangle=p|0\rangle, \tag{3.2}$$

where p is any complex number. Let P be the (associative) subalgebra of $G=U_q[sl(n+1|m)]$ generated by the elements of H and $\{a_i^-;i\in[1;n+m]\}$. The one-dimensional module $\mathbb{C}|0\rangle$ can be extended to a one-dimensional module of P by requiring

$$a_i^-|0\rangle=0, \quad i\in[1;n+m]. \tag{3.3}$$

Now the G module $\overline{W}_p$ is defined as

$$\overline{W}_p=\mathrm{Ind}_P^G\ \mathbb{C}|0\rangle.$$

By construction, this means that $\overline{W}_p$ is freely generated by the generators a_i^+ $(i\in[1;n+m])$ acting on $|0\rangle$. In other words, a basis for $\overline{W}_p$ is given by

$$|p;r_1,r_2,\ldots,r_{n+m}\rangle\equiv(a_1^+)^{r_1}(a_2^+)^{r_2}\cdots(a_n^+)^{r_n}(a_{n+1}^+)^{r_{n+1}}(a_{n+2}^+)^{r_{n+2}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle, \tag{3.4}$$

where

$$r_i\in\mathbb{Z}_+ \ \text{ for } \ i\in[1;n] \ \text{ and } \ r_i\in\{0,1\} \ \text{ for } \ i\in[n+1;n+m].$$

So $\overline{W}_p$ is an infinite-dimensional G module. The main part of this section is devoted to the computation of the action of the JGs on the basis vectors (3.4) of $\overline{W}_p$. This, of course, completely determines the action of $U_q[sl(n+1|m)]$ on $\overline{W}_p$.

Theorem 2: *The transformation of the basis (3.4) of $\overline{W}_p$ under the action of the JGs reads:*

$$H_i|p;r_1,r_2,\ldots,r_{n+m}\rangle=\left(p-(-1)^{\theta_i}r_i-\sum_{j=1}^{n+m}r_j\right)|p;r_1,r_2,\ldots,r_{n+m}\rangle, \tag{3.5}$$

$$a_i^-|p;r_1,r_2,\ldots,r_{n+m}\rangle=(-1)^{\theta_1r_1+\theta_2r_2+\cdots+\theta_{i-1}r_{i-1}}q^{r_1+\cdots+r_{i-1}}[r_i]\left[p-\sum_{j=1}^{n+m}r_j+1\right]$$
$$\times|p;r_1,r_2,\ldots,r_{i-1},r_i-1,r_{i+1},\ldots,r_{n+m}\rangle, \tag{3.6}$$

$$a_i^+|p;r_1,r_2,\ldots,r_{n+m}\rangle=(-1)^{\theta_1r_1+\theta_2r_2+\cdots+\theta_{i-1}r_{i-1}}\overline{q}^{r_1+\cdots+r_{i-1}}(1-\theta_ir_i)|p;r_1,r_2,\ldots,r_{i-1},r_i$$
$$+1,r_{i+1},\ldots,r_{n+m}\rangle, \tag{3.7}$$

where $i\in[1;n+m]$.

Proof: Equation (3.5) is an immediate consequence of $[H_i,a_j^+]=-(1+(-1)^{\theta_i}\delta_{ij})a_j^+$, which is one of the last relations in (2.16). Also the action of a_i^+ on the basis vectors is easy: (3.7) follows directly from (2.18). The hard work lies in the proof of (3.6). For this purpose, we shall use a number of technical lemmas.

Lemma 3: The following relations hold:

(i) $$[\![A,B_1B_2\cdots B_{i-1}B_iB_{i+1}\cdots B_j]\!]_{q^{b_1+b_2+\ldots+b_j}}$$
$$=\sum_{i=1}^{j} q^{b_1+b_2+\cdots+b_{i-1}}(-1)^{\alpha(\beta_1+\cdots+\beta_{i-1})}B_1B_2\cdots B_{i-1}[\![A,B_i]\!]_{q^{b_i}}B_{i+1}\cdots B_j,$$

$$\text{where}\quad \alpha=\deg(A)\quad \text{and}\quad \beta_i=\deg(B_i), \tag{3.8}$$

(ii) $$[\![a_i^-,(a_j^+)^r]\!]=\begin{cases}\dfrac{\overline{q}^{2r}-1}{\overline{q}^2-1}(a_j^+)^{r-1}[\![a_i^-,a_j^+]\!] & \text{when}\quad i<j\\ \dfrac{q^{2r}-1}{q^2-1}(a_j^+)^{r-1}[\![a_i^-,a_j^+]\!] & \text{when}\quad i>j\end{cases}, \tag{3.9}$$

(iii) $$[\![a_i^-,(a_i^+)^r]\!]=\frac{(a_i^+)^{r-1}}{q-\overline{q}}\left(\frac{\overline{q}^{2r}-1}{\overline{q}^2-1}L_i-\frac{q^{2r}-1}{q^2-1}\overline{L}_i\right), \tag{3.10}$$

(iv) $$[\![[\![a_i^-,a_j^+]\!],(a_i^+)^r]\!]_{q^r}=-(-1)^{\theta_j}\frac{\overline{q}^{2r}-1}{\overline{q}^2-1}\overline{L}_ia_j^+(a_i^+)^{r-1},\quad i>j, \tag{3.11}$$

(v) $$[\![[\![a_i^-,a_j^+]\!],(a_k^+)^r]\!]_{q^r}=(-1)^{\theta_j}(q^{2r}-1)a_j^+(a_k^+)^{r-1}[\![a_i^-,a_k^+]\!],\quad i>k>j. \tag{3.12}$$

Proof: Equation (3.8) follows by direct calculation. We need to prove Eq. (3.9) only when $r>1$, i.e., only when $\theta_j=\overline{0}$. Then one writes, using (3.8)

$$[\![a_i^-,(a_j^+)^r]\!]=[\![a_i^-,(a_j^+)^{r-1}a_j^+]\!]=[\![a_i^-,(a_j^+)^{r-1}]\!]a_j^++(a_j^+)^{r-1}[\![a_i^-,a_j^+]\!].$$

Now the result follows using induction on r and using the triple relation (2.19) with $k=j$ and $\eta=-$. The proof of (3.10) is similar, using (3.8), induction on r, and (2.17). Also the proof of (3.11) goes along the same line: First one writes $(a_i^+)^r$ as $a_i^+(a_i^+)^{r-1}$ (for $r>1$); using (3.8) this yields two terms: On the first term one applies (2.19), and on the second term one applies (3.11) by induction; then the result follows. The proof of (3.12) is essentially the same. □

Lemma 4: For $i>1$ the following relation holds:

$$\begin{aligned}&[\![a_i^-,a_1^+]\!](a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle\\ &\quad=-(-1)^{\theta_1+\theta_2r_2+\theta_3r_3+\cdots+\theta_{i-1}r_{i-1}}q^{2r_2+\cdots+2r_{i-1}+r_i+\cdots+r_{n+m}-p}[r_i]\\ &\qquad\times a_1^+(a_2^+)^{r_2}\cdots(a_{i-1}^+)^{r_{i-1}}(a_i^+)^{r_i-1}(a_{i+1}^+)^{r_{i+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle.\end{aligned} \tag{3.13}$$

Proof: Consider first $i=2$. Using (3.8), one finds

$$\begin{aligned}[\![a_2^-,a_1^+]\!](a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle&=[\![[\![a_2^-,a_1^+]\!],(a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]_{q^{r_2+\cdots+r_{n+m}}}|0\rangle\\ &=[\![[\![a_2^-,a_1^+]\!],(a_2^+)^{r_2}]\!]_{q^{r_2}}(a_3^+)^{r_3}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle\\ &\quad+(-1)^{(\theta_1+\theta_2)r_2\theta_2}q^{r_2}(a_2^+)^{r_2}\\ &\quad\times[\![[\![a_2^-,a_1^+]\!],(a_3^+)^{r_3}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]_{q^{r_3+\cdots+r_{n+m}}}|0\rangle.\end{aligned} \tag{3.14}$$

From (3.8) and (2.19) it follows that the second term in the rhs of (3.14) is zero. For the first term, apply (3.11) and use the action of $\overline{L_2}$ as given by (3.5) and (2.10). Then the result follows.

Next we shall use induction on i to prove (3.13) in general. So suppose (3.13) holds for all $j=2,3,\ldots,i-1$, i.e.,

$$\begin{aligned}&[\![a_j^-,a_1^+]\!](a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle\\&\quad=-(-1)^{\theta_1+\theta_2 r_2+\theta_3 r_3+\cdots+\theta_{j-1}r_{j-1}}q^{2r_2+\cdots+2r_{j-1}+r_j+\cdots+r_{n+m}-p}[r_j]\\&\quad\times a_1^+(a_2^+)^{r_2}\cdots(a_{j-1}^+)^{r_{j-1}}(a_j^+)^{r_j-1}(a_{j+1}^+)^{r_{j+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle.\end{aligned}\tag{3.15}$$

Making a shift of indices in (3.15) (thereby putting the last r_k-values equal to zero), leads to the following equivalent equation:

$$\begin{aligned}&[\![a_i^-,a_j^+]\!](a_{j+1}^+)^{r_{j+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle\\&\quad=-(-1)^{\theta_j+\theta_{j+1}r_{j+1}+\theta_{j+2}r_{j+2}+\cdots+\theta_{i-1}r_{i-1}}q^{2r_{j+1}+\cdots+2r_{i-1}+r_i+\cdots+r_{n+m}-p}[r_i]\\&\quad\times a_j^+(a_{j+1}^+)^{r_{j+1}}\cdots(a_{i-1}^+)^{r_{i-1}}(a_i^+)^{r_i-1}(a_{i+1}^+)^{r_{i+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle,\quad(j<i).\end{aligned}\tag{3.16}$$

Now consider the left-hand side (lhs) of (3.13) and apply (3.8)

$$\begin{aligned}[\![a_i^-,a_1^+]\!](a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle&=[\![[\![a_i^-,a_1^+]\!],(a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]_{q^{r_2+\cdots+r_{n+m}}}|0\rangle\\&=\sum_{k=2}^{n+m}q^{r_2+\cdots+r_{k-1}}(-1)^{(\theta_i+\theta_1)(\theta_2 r_2+\theta_3 r_3+\cdots+\theta_{k-1}r_{k-1})}\\&\quad\times(a_2^+)^{r_2}\cdots(a_{k-1}^+)^{r_{k-1}}[\![[\![a_i^-,a_1^+]\!],(a_k^+)^{r_k}]\!]_{q^{r_k}}\\&\quad\times(a_{k+1}^+)^{r_{k+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle.\end{aligned}\tag{3.17}$$

In this last sum, all terms with $k>i$ are easily seen to vanish. For the terms with $k<i$, we apply (3.12), and for the term with $k=i$, we apply (3.11). Then there comes

$$\begin{aligned}&\sum_{k=2}^{i-1}(-1)^{\theta_1+\theta_2 r_2+\theta_3 r_3+\cdots+\theta_{k-1}r_{k-1}}(q^{2r_k}-1)a_1^+(a_2^+)^{r_2}\cdots(a_{k-1}^+)^{r_{k-1}}(a_k^+)^{r_k-1}[\![a_i^-,a_k^+]\!]\\&\quad\times(a_{k+1}^+)^{r_{k+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle-(-1)^{\theta_1+\theta_2 r_2+\theta_3 r_3+\cdots+\theta_{i-1}r_{i-1}}q^{-p+\Sigma_{l=i}^{n+m}r_l}[r_i]\\&\quad\times a_1^+(a_2^+)^{r_2}\cdots(a_{i-1}^+)^{r_{i-1}}(a_i^+)^{r_i-1}(a_{i+1}^+)^{r_{i+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle.\end{aligned}\tag{3.18}$$

For the terms in (3.18) with $k<i$, we can apply (3.16). Then it is a matter of appropriately summing all contributions, which leads finally to the rhs of (3.13). □

Proof of Theorem 2: There remains to prove Eq. (3.6). First, assume that $i=1$ in (3.6); then we have according to (3.8)

$$\begin{aligned}a_1^-|p;r_1,r_2,\ldots,\ldots,r_{n+m}\rangle&=[\![a_1^-,(a_1^+)^{r_1}(a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]|0\rangle\\&=[\![a_1^-,(a_1^+)^{r_1}]\!](a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle\\&\quad+\sum_{j=2}^{n+m}(-1)^{\theta_1(\theta_1 r_1+\theta_2 r_2+\cdots+\theta_{j-1}r_{j-1})}\\&\quad\times(a_1^+)^{r_1}\cdots(a_{j-1}^+)^{r_{j-1}}[\![a_1^-,(a_j^+)^{r_j}]\!](a_{j+1}^+)^{r_{j+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle.\end{aligned}\tag{3.19}$$

The terms with $j \geqslant 2$ in the rhs of (3.19) are found to be zero using (3.9) and (2.19). So only the first term in the rhs of (3.19) gives a contribution; using (3.10) this is

$$[r_1]\left[p-\sum_{j=1}^{n+m} r_j+1\right]|p;r_1-1,r_2,\ldots,r_{n+m}\rangle,$$

so the case $i=1$ is proved. Now we use again induction on i. So the following equation holds for $j<i$:

$$a_j^-(a_1^+)^{r_1}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle=(-1)^{\theta_1 r_1+\theta_2 r_2+\cdots+\theta_{j-1}r_{j-1}}q^{r_1+\cdots+r_{j-1}}[r_j] \times\left[p-\sum_{l=1}^{n+m} r_l+1\right]|p;r_1,r_2,\ldots,r_{j-1},r_j-1,r_{j+1},\ldots,r_{n+m}\rangle. \tag{3.20}$$

In this equation, put $r_{n+m}=0$ and raise all indices by 1. Then the following (equivalent) equation holds:

$$a_i^-(a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle=(-1)^{\theta_2 r_2+\theta_3 r_3+\cdots+\theta_{i-1}r_{i-1}}q^{r_2+\cdots+r_{i-1}}[r_i] \times\left[p-\sum_{l=2}^{n+m} r_l+1\right] \times(a_2^+)^{r_2}\cdots(a_{i-1}^+)^{r_{i-1}}(a_i^+)^{r_i-1}(a_{i+1}^+)^{r_{i+1}}\cdots(a_{n+m}^+)^{r_{n+m}}|0\rangle. \tag{3.21}$$

Now consider

$$\begin{aligned} a_i^-|p;r_1,r_2,\ldots,r_{n+m}\rangle&=[\![a_i^-,(a_1^+)^{r_1}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]|0\rangle\\ &=[\![a_i^-,(a_1^+)^{r_1}]\!](a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]|0\rangle\\ &\quad+(-1)^{\theta_i\theta_1 r_1}(a_1^+)^{r_1}[\![a_i^-,(a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]|0\rangle\\ &=\frac{q^{2r_1-1}}{q^2-1}(a_1^+)^{r_1-1}[\![a_i^-,a_1^+]\!](a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]|0\rangle\\ &\quad+(-1)^{\theta_i\theta_1 r_1}(a_1^+)^{r_1}[\![a_i^-,(a_2^+)^{r_2}\cdots(a_{n+m}^+)^{r_{n+m}}]\!]|0\rangle. \end{aligned} \tag{3.22}$$

This was obtained by applying (3.9) on the first term. The rhs of (3.22) can now be determined as follows: For the first term we use (3.13), and for the second term, we use (3.21) in which both sides have been multiplied (on the left) by $(a_1^+)^{r_1}$. Adding both contributions leads to the desired result. □

The action of the elements H_i and $a_i^{\pm}$ $(i\in[1;n+m])$ on the basis vectors of $\overline{W}_p$, determined in Theorem 2, clearly imply that $\overline{W}_p$ has an invariant submodule when p is a nonnegative integer. From now on we shall assume that $p\in\mathbb{Z}_+$. Then we have

Corollary 5: The $U_q[sl(n+1|m)]$ module $\overline{W}_p$ has an invariant submodule V_p with basis vectors

$$|p;r_1,r_2,\ldots,r_{n+m}\rangle,\ \textit{with}\ \sum_{i=1}^{n+m} r_i>p.$$

The quotient module $W_p=\overline{W}_p/V_p$ is an irreducible representation for $U_q[sl(n+1|m)]$. The basis vectors of W_p are given by (*the representatives of*)

$$|p;r_1,r_2,\ldots,r_{n+m}\rangle, \ \ with \ \sum_{i=1}^{n+m} r_i \leqslant p. \tag{3.23}$$

These finite-dimensional irreducible $U_q[sl(n+1|m)]$ modules W_p are referred to as the Fock modules or Fock representations of $U_q[sl(n+1|m)]$. Also in the Fock modules, the action of the elements H_i and $a_i^{\pm}$ $(i\in[1;n+m])$ on the basis vectors (3.23) is essentially given by the equations of Theorem 2.

One can verify that the irreducible Fock representations W_p are so-called atypical representations of $U_q[sl(n+1|m)]$. Atypicality is usually defined for highest weight representations of simple Lie superalgebras,[32] but it can be extended to highest weight representations of the corresponding Hopf superalgebras.[33] In the standard basis, the Dynkin labels of W_p (or of its highest weight) are given by $(p,0,\ldots,0)$. This means that in general the representation W_p is multiply atypical.[32,34] More precisely, if $n\geqslant m$, then W_p is m-fold atypical; if $n<m$, then W_p is $(n+1)$-fold atypical for $p<m-n$ and n-fold atypical for $p\geqslant m-n$. Observe that in this way we have obtained the action of a set of generators of $U_q[sl(n+1|m)]$ on a class of atypical irreducible representations, i.e., the Fock modules. In general, an explicit basis for atypical representations is not known, not even in the case of $sl(n+1|m)$. For typical representations of $U_q[sl(n+1|m)]$, it is easier to construct a basis. For a subclass of these, the so-called essentially typical representations, a (Gelfand–Zetlin) basis has been constructed together with the action of the Chevalley generators.[9]

IV. UNITARY FOCK REPRESENTATIONS

In this section we select a class of Fock modules important for physical applications. These are the ones for which the standard Fock metric is positive definite, and for which the representatives of $a_i^{\pm}$ and H_i $(i\in[1;n+m])$ satisfy the Hermiticity conditions

$$(a_i^+)^\dagger = a_i^-, \quad (a_i^-)^\dagger = a_i^+, \quad (H_i)^\dagger = H_i. \tag{4.1}$$

In quantum mechanics, including its generalization to the noncommutative case (see, for instance Refs. 35 and 36), (4.1) follows from the relations $a_k^{\pm}=\text{const}(x_k\mp ip_k)$ and the requirement that the position operators x_k and the momentum operators p_k should be self-adjoint operators. By definition, representations for which (4.1) holds are said to be unitary (with respect to the antiinvolution in $U_q[sl(n+1|m)]$ defined by (4.1), and the Fock space scalar product).

For the Fock representation W_p, we can define a Hermitian form $(,)$ by requiring

$$(|0\rangle, |0\rangle) = \langle 0|0\rangle = 1, \tag{4.2}$$

and by postulating that the Hermiticity conditions (4.1) should be satisfied, i.e.,

$$(a_i^{\pm}v,w) = (v,a_i^{\mp}w), \quad \forall v,w\in W_p. \tag{4.3}$$

It is now easy to determine that any two vectors $|p;r_1,r_2,\ldots,r_{n+m}\rangle$ and $|p;r_1',r_2',\ldots,r_{n+m}'\rangle$ with $(r_1,r_2,\ldots,r_{n+m})\neq(r_1',r_2',\ldots,r_{n+m}')$ are orthogonal. Furthermore, one can compute

$$(|p;r_1,r_2,\ldots,r_{n+m}\rangle,|p;r_1,r_2,\ldots,r_{n+m}\rangle) = \frac{[p]!}{[p-R]!}\prod_{i=1}^{n+m}[r_i]! = \frac{[p]!}{[p-R]!}\prod_{i=1}^{n}[r_i]!, \tag{4.4}$$

where $R=r_1+r_2+\cdots+r_{n+m}$. Clearly, it holds for $R=0$; then use induction on R together with (3.6) and (3.7).

Assume now that $1\leqslant i<j\leqslant n+m$. According to (4.4) we have

$$(a_i^+a_j^+|0\rangle, a_i^+a_j^+|0\rangle) = [p][p-1]. \tag{4.5}$$

From (2.18) we have $a_i^+ a_j^+ = (-1)^{\theta_i\theta_j} q a_j^+ a_i^+ = (-1)^{\theta_i} q a_j^+ a_i^+$ [since $(-1)^{\theta_i\theta_j} = (-1)^{\theta_i}$ for $i < j$]; thus we find

$$(a_j^+ a_i^+|0\rangle, a_i^+ a_j^+|0\rangle) = ((-1)^{\theta_i}\overline{q} a_i^+ a_j^+|0\rangle, a_i^+ a_j^+|0\rangle) = (-1)^{\theta_i}\overline{q}^*[p][p-1], \tag{4.6}$$

where $\overline{q}^*$ is the complex conjugate of $\overline{q} = q^{-1}$. On the other hand, using (3.6),

$$\begin{aligned}(a_j^+ a_i^+|0\rangle, a_i^+ a_j^+|0\rangle) &= (a_i^+|0\rangle, a_j^-|p;0,\ldots,0,1_i,0,\ldots,0,1_j,0,\ldots,0\rangle)\\ &= (a_i^+|0\rangle, (-1)^{\theta_i} q[p-1]|p;0,\ldots,0,1_i,0,\ldots,0\rangle)\\ &= (-1)^{\theta_i} q[p-1](a_i^+|0\rangle, a_i^+|0\rangle) = (-1)^{\theta_i} q[p][p-1].\end{aligned} \tag{4.7}$$

Herein, 1_i stands for a number 1 at the position i. When $p \geqslant 2$, the comparison of (4.6) and (4.7) yields $|q|^2 = 1$. Hence a necessary condition for the Fock space to be unitary is that q must be a phase, i.e.,

$$q = e^{i\phi}, \quad (-\pi < \phi < \pi). \tag{4.8}$$

Let us now further investigate when the Fock module is unitary, i.e., when the Hermitian form (,) is an inner product. This means that for every $(r_1,\ldots,r_{n+m})$ with $0 \leqslant R \leqslant p$, the value in (4.4) should be positive. In particular, this implies that all the numbers

$$[p],\ [p-1],\ [p-2],\ldots,[2],\ [1],$$

should be positive. However, since $q = e^{i\phi}$ is a phase, we have

$$[k] = \frac{q^k - q^{-k}}{q - q^{-1}} = \frac{\sin(k\phi)}{\sin(\phi)}.$$

So we are left with the following question: let $p > 1$, find the values of ϕ $(-\pi < \phi < \pi)$ where all of the following functions:

$$\frac{\sin(2\phi)}{\sin(\phi)}, \frac{\sin(3\phi)}{\sin(\phi)}, \ldots, \frac{\sin(p\phi)}{\sin(\phi)},$$

are positive. For each of these functions $\sin(k\phi)/\sin(\phi)$, the zeros and hence the signs are easy to determine. So the common domain where all of these functions are positive is given by

$$\frac{-\pi}{p} < \phi < \frac{\pi}{p}.$$

Thus we have

Theorem 6: *The irreducible Fock module W_p $(p \geqslant 2)$ is unitary if and only if q is a phase, i.e., $q = e^{i\phi}$, with $-\pi/p < \phi < \pi/p$.*

Observe that whether q is a root of unity or not does not have any effect on the irreducibility or unitarity of the Fock module W_p, as long as the conditions of Theorem 6 are satisfied. Indeed, suppose that $q = e^{i\phi}$ is a root of unity with ϕ a rational multiple of π and $-\pi/p < \phi < \pi/p$. Then the smallest integer N for which $q^N = -1$ is greater than p. As a consequence, the rhs in (4.4) is never zero. This implies that there are no singular vectors among the weight vectors $|p;r_1,\ldots,r_{n+m}\rangle$, and thus irreducibility holds.

Under the conditions of Theorem 6, we can define an orthonormal basis of W_p

$$|p;r_1,r_2,\ldots,r_{n+m}) = \sqrt{\frac{[p-\Sigma_{l=1}^{n+m} r_l]!}{[p]![r_1]!\ldots[r_{n+m}]!}}\,|p;r_1,r_2,\ldots,r_{n+m}\rangle, \tag{4.9}$$

where $0 \leqslant \Sigma_{i=1}^{n+m} r_i \leqslant p$. In the new basis (4.9) the transformation formulas (3.5)–(3.7) read ($i \in [1;n+m]$)

$$H_i|p;r_1,r_2,\ldots,r_{n+m}) = \left(p-(-1)^{\theta_i} r_i - \sum_{j=1}^{n+m} r_j \right) |p;r_1,r_2,\ldots,r_{n+m}), \tag{4.10}$$

$$a_i^-|p;r_1,\ldots,r_{n+m}) = (-1)^{\theta_1 r_1+\cdots+\theta_{i-1}r_{i-1}} \times q^{r_1+\cdots+r_{i-1}} \sqrt{[r_i]\left[p-\sum_{l=1}^{n+m} r_l+1 \right]}\ |p;r_1,\ldots r_{i-1},r_i-1,r_{i+1},\ldots,r_{n+m}), \tag{4.11}$$

$$a_i^+|p;r_1,\ldots,r_{n+m}) = (-1)^{\theta_1 r_1+\cdots+\theta_{i-1}r_{i-1}} \overline{q}^{r_1+\cdots+r_{i-1}}(1-\theta_i r_i) \times \sqrt{[r_i+1]\left[p-\sum_{l=1}^{n+m} r_l \right]}\ |p;r_1,\ldots r_{i-1},r_i+1,r_{i+1},\ldots,r_{n+m}). \tag{4.12}$$

From (2.15) it is now easy to determine the action of the remaining Cartan–Weyl generators e_{ji} on the basis elements of W_p

$$e_{ji}|p;r_1,\ldots,r_{n+m}) = (-1)^{\theta_i(r_i+1)+\theta_{i+1}r_{i+1}+\cdots+\theta_{j-1}r_{j-1}} \overline{q}^{r_{i+1}+\cdots+r_{j-1}-2\theta_i(1-r_i)}(1-\theta_j r_j) \times \sqrt{[r_i][r_j+1]}\ |p;r_1,\ldots r_{i-1},r_i-1,r_{i+1},\ldots,r_{j-1},r_j+1,r_{j+1},\ldots,r_{n+m}), \quad (i<j), \tag{4.13}$$

$$e_{ji}|p;r_1,\ldots,r_{n+m}) = (-1)^{\theta_j r_j+\cdots+\theta_{i-1}r_{i-1}} q^{2\theta_j r_j+r_{j+1}+\cdots+r_{i-1}}(1-\theta_j r_j) \times \sqrt{[r_i][r_j+1]}\ |p;r_1,\ldots r_{j-1},r_j+1,r_{j+1},\ldots,r_{i-1},r_i-1,r_{i+1},\ldots,r_{n+m}), \quad (i>j). \tag{4.14}$$

In particular, it is possible to extend W_p to a $U_q[gl(n+1|m)]$ module, the actions being given by (4.11)–(4.14) and

$$e_{00}|p;r_1,\ldots,r_{n+m}) = \left(p-\sum_{l=1}^{n+m} r_l \right) |p;r_1,\ldots,r_{n+m}), \tag{4.15}$$

$$e_{ii}|p;r_1,\ldots,r_{n+m}) = r_i|p;r_1,\ldots,r_{n+m}), \quad i \in [1;n+m]. \tag{4.16}$$

V. DYSON AND HOLSTEIN–PRIMAKOFF REALIZATIONS OF $U_q[sl(n+1|m)]$

Consider $(n+m)$ $\mathbb{Z}_2$-graded indeterminates $c_i^{\pm}$ ($i \in [1;n+m]$) with

$$\deg(c_i^{\pm}) = \theta_i. \tag{5.1}$$

Denote by $W(n|m)$ the free $\mathbb{C}[[h]]$ module (completed in the h-adic topology) generated by the elements $c_i^{\pm}$ subject to the relations

$$[\![c_i^-, c_j^+]\!] = \delta_{ij}, \quad [\![c_i^+, c_j^+]\!] = [\![c_i^-, c_j^-]\!] = 0. \tag{5.2}$$

As usual, let

$$N_i = c_i^+ c_i^- , \quad N = \sum_{j=1}^{n+m} N_j . \tag{5.3}$$

The algebra $W(n|m)$ of n pairs of Bose and m pairs of Fermi CAO's has a natural action in the Fock space $\mathcal{F}(n|m)$, defined as follows. Let $\mathcal{F}(n|m)$ be the free $W(n|m)$ module generated by a vector $|0\rangle$ subject to the relations

$$c_i^- |0\rangle = 0, \text{ for all } i \in [1;n+m].$$

Then it follows easily that a basis of $\mathcal{F}(n|m)$ is given by

$$(c_1^+)^{l_1}(c_2^+)^{l_2}\cdots(c_{n+m}^+)^{l_{n+m}}|0\rangle \equiv |l_1, l_2, \ldots, l_{n+m}\rangle, \tag{5.4}$$

where

$$l_i \in \mathbb{Z}_+ \text{ for } i \in [1;n] \text{ and } l_i \in \{0,1\} \text{ for } i \in [n+1;n+m].$$

The Dyson[37] and Holstein–Primakoff[38] realizations of $U_q[sl(n+1|m)]$ are two different algebra homomorphisms of $U_q[sl(n+1|m)]$ into $W(n|m)$.[23] Since $W(n|m)$ has the natural Fock representation $\mathcal{F}(n|m)$, these realizations will provide representations of $U_q[sl(n+1|m)]$ in $\mathcal{F}(n|m)$.

Theorem 7 (Dyson realization): *Let p be any complex number. The linear map $\rho: U_q[sl(n+1|m)] \to W(n|m)$, defined on the Jacobson generators by*

$$\rho(H_i) = p - (-1)^{\theta_i} c_i^+ c_i^- - \sum_{j=1}^{n+m} c_j^+ c_j^- = p - (-1)^{\theta_i} N_i - N,$$

$$\rho(a_i^-) = q^{N_1+\cdots+N_{i-1}} \frac{[N_i+1]}{N_i+1} [p-N] c_i^- , \tag{5.5}$$

$$\rho(a_i^+) = \overline{q}^{N_1+\cdots+N_{i-1}} c_i^+ ,$$

is a (associative algebra) homomorphism of $U_q[sl(n+1|m)]$ into $W(n|m)$.

The inspiration of this mapping comes from Theorem 2. The actual proof of Theorem 7 is straightforward but tedious: one has to verify that all relations in Theorem 1 are satisfied under the substitution of H_i and $a_i^\pm$ by $\rho(H_i)$ and $\rho(a_i^\pm)$. These computations are lengthy and based upon easy relations such as

$$f(N_i) c_j^\pm = c_j^\pm f(N_i \pm \delta_{ij}), \quad i,j \in [1;n+m]; \quad q^{N_i} = 1 - N_i + qN_i \text{ for } i > n,$$

or simple q-identities such as $[x+1][y] - [x][y+1] = [y-x]$.

The Dyson realization of the JGs of $U_q[sl(n+1|m)]$ leads to an explicit realization of all Cartan–Weyl elements of $U_q[sl(n+1|m)]$ in terms of the Bose and Fermi CAO's. Indeed, using (2.15) and (5.5) one obtains

$$\rho(e_{ji}) = q^{2\theta_j(N_j-1)+N_{j+1}+N_{j+2}+\cdots+N_{i-1}} \frac{[N_i+1]}{N_i+1} c_j^+ c_i^- , \quad (j<i) \tag{5.6}$$

$$\rho(e_{ji}) = \overline{q}^{2\theta_i N_i + N_{i+1}+N_{i+2}+\cdots+N_{j-1}} \frac{[N_i+1]}{N_i+1} c_j^+ c_i^- , \quad (j>i). \tag{5.7}$$

In (5.6), the convention is that the summation (in the power of q) is 0 when $j = i-1$ [and similarly for (5.7)]. Since $\mathcal{F}(n|m)$ is a $W(n|m)$ module, the Dyson realization provides a representation of

$U_q[sl(n+1|m)]$ into $\mathcal{F}(n|m)$. It is easy to see that the action of every $\rho(H_i)$ and $\rho(a_i^{\pm})$ upon $|l_1,\ldots,l_{n+m}\rangle$ is the same as the action of H_i and $a_i^{\pm}$ in the representation on $\overline{W}_p$ given by Theorem 2, under the identification

$$|l_1,\ldots,l_{n+m}\rangle \equiv |p;l_1,\ldots,l_{n+m}\rangle.$$

Therefore, it follows that the representation ρ of $U_q[sl(n+1|m)]$ into $\mathcal{F}(n|m)$ (under the Dyson realization) is irreducible when $p \notin \mathbb{Z}_+$. When $p \in \mathbb{Z}_+$, the representation ρ is indecomposable. The subspace $\mathcal{F}_1(n|m)$, spanned on the vectors

$$|l_1,\ldots,l_{n+m}\rangle \quad \text{with} \quad l_1+\cdots+l_{n+m}>p$$

is clearly invariant under the action of $U_q[sl(n+1|m)]$. We denote the (finite dimensional) quotient module by $\mathcal{F}_0(n|m)=\mathcal{F}(n|m)/\mathcal{F}_1(n|m)$, and (by abuse of notation) its vectors are denoted by

$$|l_1,\ldots,l_{n+m}\rangle \quad \text{with} \quad l_1+\cdots+l_{n+m}\leqslant p.$$

For h an indeterminate ($q=e^h$), the representation of $U_q[sl(n+1|m)]$ into $\mathcal{F}_0(n|m)$ is irreducible. It is obvious how to identify $\mathcal{F}_0(n|m)$ with W_p.

In order to turn $\mathcal{F}_0(n|m)$ into a unitary $U_q[sl(n+1|m)]$ module, we introduce the Holstein–Primakoff realization.

Theorem 8 (Holstein–Primakoff realization): *Let $p \in \mathbb{C}$. The linear map $\varrho: U_q[sl(n+1|m)] \to W(n|m)$, defined on the Jacobson generators by*

$$\varrho(H_i)=p-(-1)^{\theta_i}c_i^+c_i^- - \sum_{j=1}^{n+m} c_j^+c_j^- = p-(-1)^{\theta_i}N_i - N,$$

$$\varrho(a_i^-)=q^{N_1+\cdots+N_{i-1}}\sqrt{\frac{[N_i+1]}{N_i+1}[p-N]}\,c_i^-, \tag{5.8}$$

$$\varrho(a_i^+)=\overline{q}^{N_1+\cdots+N_{i-1}}\sqrt{\frac{[N_i]}{N_i}[p-N+1]}\,c_i^+,$$

is a homomorphism of $U_q[sl(n+1|m)]$ into $W(n|m)$.

Let us now also consider the special case that p is a positive integer. Just as in the previous case, the subspace $\mathcal{F}_1(n|m)$ is invariant for the action of $U_q[sl(n+1|m)]$ under ϱ when $p \in \mathbb{Z}_+$. It is clearly invariant under the action of $U_q[sl(n+1|m)]$. Let us consider the following basis of the (finite dimensional) quotient module $\mathcal{F}_0(n|m)$:

$$\frac{(c_1^+)^{l_1}(c_2^+)^{l_2}\cdots(c_{n+m}^+)^{l_{n+m}}}{\sqrt{l_1!l_2!\cdots l_{n+m}!}}|0\rangle \equiv |l_1,l_2,\ldots,l_{n+m}), \quad l_1+\cdots+l_{n+m}\leqslant p. \tag{5.9}$$

It is easy to verify that the action of every $\varrho(H_i)$ and $\varrho(a_i^{\pm})$ upon $|l_1,\ldots,l_{n+m})$ is the same as the action of H_i and $a_i^{\pm}$ in the representation on W_p given by (4.11)-(4.12), under the identification

$$|l_1,\ldots,l_{n+m}) \equiv |p;l_1,\ldots,l_{n+m}).$$

Therefore, it follows that the representation ϱ of $U_q[sl(n+1|m)]$ into $\mathcal{F}_0(n|m)$ (under the Holstein–Primakoff realization with $p \in \mathbb{Z}_+$) is an irreducible unitary module when

$$q=e^{i\phi} \quad \text{with} \quad -\frac{\pi}{p}<\phi<\frac{\pi}{p}.$$

From (2.15) and (5.8), one obtains the Holstein–Primakoff realization of the remaining Cartan–Weyl elements of $U_q[sl(n+1|m)]$

$$\varrho(e_{ji})=q^{2\theta_j(N_j-1)+N_{j+1}+N_{j+2}+\cdots+N_{i-1}}\sqrt{\frac{[N_j][N_i+1]}{N_j(N_i+1)}}c_j^+c_i^-,\quad (j<i),$$

$$\varrho(e_{ji})=\overline{q}^{2\theta_iN_i+N_{i+1}+N_{i+2}+\cdots+N_{j-1}}\sqrt{\frac{[N_j][N_i+1]}{N_j(N_i+1)}}c_j^+c_i^-,\quad (j>i). \tag{5.10}$$

Observe that there is an alternative description of the Holstein–Primakoff realization, in terms of deformed Bose[39–42] and Fermi[43] CAO's $\tilde{c}_i^{\pm}$ defined as

$$\tilde{c}_i^-=\sqrt{\frac{[N_i+1]}{N_i+1}}c_i^-,\quad \tilde{c}_i^+=\sqrt{\frac{[N_i]}{N_i}}c_i^+,\quad \tilde{N}_i=N_i,\quad i\in[1;n+m]. \tag{5.11}$$

These elements of $W(n|m)$ satisfy the relations

$$[\![\tilde{c}_i^-,\tilde{c}_j^+]\!]_{q^{\delta_{ij}}}=\delta_{ij}\overline{q}^{(-1)^{\theta_i}\tilde{N}_i},\quad [\tilde{N}_i,\tilde{c}_j^{\pm}]=\pm\delta_{ij}\tilde{c}_j^{\pm},\quad [\![\tilde{c}_i^{\pm},\tilde{c}_j^{\pm}]\!]=[\tilde{N}_i,\tilde{N}_j]=0. \tag{5.12}$$

The Holstein–Primakoff realization can be rewritten in terms of these deformed Bose and Fermi operators $\tilde{c}_i^{\pm}$. We give it here for all Cartan–Weyl elements

$$\begin{aligned}
\varrho(H_i)&=p-(-1)^{\theta_i}\tilde{N}_i-\tilde{N},\\
\varrho(a_i^-)&=q^{\tilde{N}_1+\cdots+\tilde{N}_{i-1}}\sqrt{[p-\tilde{N}]}\tilde{c}_i^-,\\
\varrho(a_i^+)&=\overline{q}^{\tilde{N}_1+\cdots+\tilde{N}_{i-1}}\sqrt{[p-\tilde{N}+1]}\tilde{c}_i^+,\\
\varrho(e_{ji})&=q^{2\theta_j(\tilde{N}_j-1)+\tilde{N}_{j+1}+\tilde{N}_{j+2}+\cdots+\tilde{N}_{i-1}}\tilde{c}_j^+\tilde{c}_i^-,\quad (j<i),\\
\varrho(e_{ji})&=\overline{q}^{2\theta_i\tilde{N}_i+\tilde{N}_{i+1}+\tilde{N}_{i+2}+\cdots+\tilde{N}_{j-1}}\tilde{c}_j^+\tilde{c}_i^-,\quad (j>i).
\end{aligned} \tag{5.13}$$

Furthermore, this is easy to extend to a Holstein–Primakoff realization of $U_q[gl(n+1|m)]$ by

$$\varrho(e_{00})=p-\tilde{N},\quad \varrho(e_{ii})=\tilde{N}_i. \tag{5.14}$$

The Holstein–Primakoff realization has given us a realization in terms of oscillators [in (5.8) and (5.10)] or q-oscillators [in (5.13)]. Observe that this oscillator realization is different from the one given by Floreanini *et al.*:[43] In Ref. 43 only the Chevalley generators are realized in terms of oscillators or q-oscillators. Furthermore all generators are bilinear expressions in the oscillators, whereas here the JGs are linear expressions in the oscillators.

VI. CONCLUSIONS

We have constructed a class of representations of the quantum superalgebra $U_q[sl(n+1|m)]$, which was also extended to $U_q[gl(n+1|m)]$. Our approach is entirely along the lines of Fock representations of parastatistics of order p, for which the defining relations are given by (3.1)–(3.3). The analogy with parastatistics goes further: Within the Fock representations, the JGs $a_i^{\pm}$ can be interpreted as operators creating or annihilating (quasi)particles, or excitations of a new kind of quantum statistics.

In order to be more concrete consider a Hamiltonian $H=\Sigma_{i=1}^{n+m}\ \varepsilon_ie_{ii}$. Then, see (4.16),

$$H|p;r_1,\ldots,r_{n+m})=\sum_{i=1}^{n+m}\varepsilon_ir_i|p;r_1,\ldots,r_{n+m}).$$

Therefore the vector $|p;r_1,\ldots,r_{n+m})$ can be interpreted as a state consisting of r_1 particles with energy ε_1, r_2 particles with energy ε_2, and so on, r_{n+m} particles with energy ε_{n+m}. Moreover,

according to (4.11) and (4.12) any operator a_i^+ (resp. a_i^-) creates (resp. annihilates) a particle on the orbital i. Since $r_i \in \mathbb{Z}_+$ for $i \in [1;n]$ and $r_i \in \{0,1\}$ for $i \in [n+1;m]$ the particles on the first n orbitals behave like bosons, and the particles on the next orbitals like fermions. This is, however, not quite the case if $p<n+m$, since $\Sigma_{i=1}^{n+m} r_i \leqslant p$. In other words the system cannot accommodate more than p particles. Therefore, the statistics falls in the group of exclusion statistics in the broad sense:[44] The number of particles to be accommodated on a certain orbital depends on the number of particles already accommodated in the system. What are the properties of the underlying statistics is a question still to be answered.

Another property worthy of study is to analyze what happens if $p \to \infty$ and $q \to 1$. Having in mind the results from Ref. 11 we expect that in this limit the operators $A(p,q)_i^{\pm} = a_i^{\pm}/\sqrt{p}$ become genuine Bose CAO's for $i \in [1;n]$ and genuine Fermi CAO's for $i \in [n+1;n+m]$. If so, then for large p and values of q close to 1 the operators $A(p,q)_i^{\pm}$ describe small deviations from the canonical quantum statistics. Moreover these CAO's are defined in a state space with positive definite scalar product. Among the various noncanonical statistics (Gentile intermediate statistics,[45] parastatistics,[15] infinite statistics,[46] parons,[47] quons[48]) only the quons have the same property. Therefore, parallel to quons the $A(p,q)_i^{\pm}$ operators may appear as another candidate to describe eventual small violations of canonical quantum statistics (see Ref. 47 where also experiments for detecting small violations of statistics are discussed).

We believe also (having in mind again the results in Ref. 11) that the CAO's of $U_q[sl(n+1|m)]$ and their Fock representations will be natural "building blocks" for any multicomponent $t-J$ supersymmetric lattice model. To this end we note that at each site i the Hubbard operators X^{0k} and X^{k0},[49] (we suppress the site index) are nothing but nondeformed Jacobson generators a_k^- and a_k^+, respectively. Then the representations with $p=1$ satisfy the hard-core condition forbidding configurations with two or more particles to be accommodated simultaneously on each lattice site.

Some of the results related to this quantum statistics were already published in an earlier paper.[50] Let us underline the new contributions in the present paper. Theorem 1 (Sec. II) was already stated without proof in Ref. 50, since it is the main ingredient to describe the quantum statistics; here we have given its relevant background and a complete proof. Sections III and IV contain our key results; all of them are original. We have constructed a class of representations of $U_q[sl(n+1|m)]$ labeled by an arbitrary number p. When p is a positive integer, this representation is indecomposable and the corresponding quotient module is finite dimensional. The derivation of the action of the JGs on basis elements of these representations is highly nontrivial. In Sec. IV we have selected the unitary representations, with respect to the (in physics) natural Hermiticity condition (4.1) considered as an anti-involution, and the requirement that the usual Fock space metric should be positive definite. It is interesting to note that the selected representations remain irreducible when q is a root of unity.

The Dyson and Holstein–Primakoff realizations of $U_q[sl(n+1|m)]$ were given in an earlier paper by one of us,[23] but only for the Chevalley generators. Here, in Sec. V, we give the realization for all Cartan–Weyl elements of $U_q[sl(n+1|m)]$. Such realizations are relevant since also in the classical case ($q=1$) the realization of all Cartan–Weyl generators (Bargmann–Schwinger realizations, ladder representations) are of physical importance. Observe that it is far from trivial to deduce the realization for all Cartan–Weyl elements from those of the realization for the Chevalley generators. This would be rather hard because the expressions of all Cartan–Weyl elements in terms of the Chevalley generators are very involved and difficult to manage, see e.g., Ref. 31. In the present case, the problem was overcome because we were able to give the Dyson and Holstein–Primakoff realizations of the Jacobson generators of $U_q[sl(n+1|m)]$. Since the expressions of the remaining Cartan–Weyl elements in terms of the Jacobson generators is simple, the Dyson and Holstein–Primakoff realizations of all Cartan–Weyl elements followed without too much trouble.

Analytic Coulomb matrix elements in the lowest Landau level in disk geometry

E. V. Tsiper[a)]
Department of Chemistry, Princeton University, Princeton, New Jersey 08544

(Received 19 May 2001; accepted for publication 6 December 2001)

Using Darling's theorem on products of generalized hypergeometric series, an analytic expression is obtained for the Coulomb matrix elements in the lowest Landau level in the representation of angular momentum. The result is important in the studies of fractional quantum Hall effect (FQHE) in disk geometry. Matrix elements are expressed as simple finite sums of positive terms, eliminating the need to approximate these quantities with slowly convergent series. As a by-product, an analytic representation for certain integrals of products of Laguerre polynomials is obtained. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1446244]

I. INTRODUCTION

The following integrals,

$$M^l_{mn}=(m+l,n|r_{12}^{-1}|m,n+l)=\int\int d^2r_1 d^2r_2 \psi^*_{m+l}(\mathbf{r}_1)\psi^*_n(\mathbf{r}_2)\frac{1}{|\mathbf{r}_1-\mathbf{r}_2|}\psi_m(\mathbf{r}_1)\psi_{n+l}(\mathbf{r}_2), \quad (1)$$

represent the Coulomb interaction matrix elements in the lowest Landau level. These are the basic quantities for studies of correlated two-dimensional systems in quantizing magnetic fields.[1–7] The single-particle wave functions in the angular momentum representation are given by

$$\psi_m(\mathbf{r})=(2\pi 2^m m!)^{-1/2} r^m e^{im\phi-r^2/4}, \quad (2)$$

where r and ϕ are polar coordinates in the plane, and the magnetic length $\sqrt{\hbar c/eH}$ is taken as a unit of length. The axial gauge for the vector potential $\mathbf{A}=\frac{1}{2}[\mathbf{H},\mathbf{r}]$ is chosen.

Full Coulomb interaction has been shown to play a crucial role in edge effects in fractional quantum Hall systems, not captured by Laughlin's wave function.[1,2] The results of Refs. 1 and 2 would have been difficult to obtain without an analytic formula for M^l_{mn}, the derivation of which is the subject of this work. Use of well-known expressions by Girvin and Jach[3] is prohibitive at moderately large m and n because of large cancellations. The problem was addressed in Ref. 8, where slowly convergent series to approximate M^l_{mn} have been derived.

Here we present analytic formulas for M^l_{mn} that contain simple finite sums of positive terms, which can be easily evaluated for any m, n, and l. Moreover, the symmetry with respect to interchanging m and n is explicitly preserved.

II. FORMULA FOR MATRIX ELEMENTS

We start with the result, which reads

$$M^l_{mn}=\sqrt{\frac{(m+l)!(n+l)!}{m!n!}}\frac{\Gamma(l+m+n+\frac{3}{2})}{\pi 2^{l+m+n+2}}[A^l_{mn}B^l_{nm}+B^l_{mn}A^l_{nm}], \quad (3)$$

where

a)Electronic mail: etsiper@princeton.edu

$$A^l_{mn}=\sum_{i=0}^{m}\binom{m}{i}\frac{\Gamma(\frac{1}{2}+i)\Gamma(\frac{1}{2}+l+i)}{(l+i)!\Gamma(\frac{3}{2}+l+n+i)}, \tag{4a}$$

and

$$B^l_{mn}=\sum_{i=0}^{m}\binom{m}{i}\frac{\Gamma(\frac{1}{2}+i)\Gamma(\frac{1}{2}+l+i)}{(l+i)!\Gamma(\frac{3}{2}+l+n+i)}(\tfrac{1}{2}+l+2i). \tag{4b}$$

The rest of the article presents the derivation of Eqs. (3) and (4). First, we substitute

$$\frac{1}{|\mathbf{r}_1-\mathbf{r}_2|}=\int\frac{d^2q}{2\pi q}\exp[i\mathbf{q}(\mathbf{r}_1-\mathbf{r}_2)] \tag{5}$$

into Eq. (1). The two separate integrals over $\mathbf{r}_1$ and $\mathbf{r}_2$ can be evaluated in terms of Laguerre polynomials $L^l_m(q^2/2)$.[9] Substituting $q^2/2=x$ we obtain

$$M^l_{mn}=\sqrt{\frac{m!n!}{2(m+l)!(n+l)!}}\int dx x^{l-1/2}e^{-2x}L^l_m(x)L^l_n(x). \tag{6}$$

The above integral can be expressed[10] using generalized hypergeometric function[11,12]

$$M^l_{mn}=\sqrt{\frac{(l+m)!}{2\pi m!n!(l+n)!}}\frac{\Gamma(n+\frac{1}{2})\Gamma(l+\frac{1}{2})}{l!}F\left(\left.\begin{matrix}1/2, & l+\frac{1}{2}, & l+m+1\\ & -n+\frac{1}{2}, & l+1\end{matrix}\right|z\right) \tag{7}$$

in the limit $z\to-1$, approached from the right. The function F is defined as

$$F\left(\left.\begin{matrix}a, & b, & c\\ & d, & e\end{matrix}\right|z\right)=\sum_{i=0}^{\infty}\frac{z^i(a)_i(b)_i(c)_i}{i!(d)_i(e)_i}, \tag{8}$$

where $(z)_i=z(z+1)\cdots(z+i-1)=\Gamma(z+i)/\Gamma(z)$. Taking the limit avoids problems at $z=-1$, which is at the radius of convergence of the power series (8). For $|z|<1$ the right-hand side of Eq. (7) gives a more general integral of $x^{l-1/2}e^{(z-1)x}L^l_m(-zx)L^l_n(x)$, which is analytic in z.

When one of the upper parameters is a negative integer, the series (8) terminate yielding a finite sum. At $z=-1$ we have

$$F\left(\left.\begin{matrix}-k, & b, & c\\ & d, & e\end{matrix}\right|-1\right)=\sum_{i=0}^{k}\binom{k}{i}\frac{(b)_i(c)_i}{(d)_i(e)_i}. \tag{9}$$

Since none of the upper parameters of F in Eq. (7) are negative integers, the series is infinite. However, it appears possible to transform Eq. (7) in such a way that the result contains only terminating hypergeometric series. Using Darling's theorem on products,[13] the infinite series (7) are brought into a sum of products of generalized hypergeometric series that each have at least one negative integer upper argument, therefore, representing a finite sum. Darling's theorem for the function F reads

$$(1-z)^{a+b+c-d-e}F\left(\begin{matrix}a, & b, & c\\ & d, & e\end{matrix}\middle| z\right)$$
$$=\frac{e-1}{e-d}F\left(\begin{matrix}d-a, & d-b, & d-c\\ & d, & d+1-e\end{matrix}\middle| z\right)F\left(\begin{matrix}e-a, & e-b, & e-c\\ & e-1, & e+1-d\end{matrix}\middle| z\right)$$
$$+\frac{d-1}{d-e}F\left(\begin{matrix}e-a, & e-b, & e-c\\ & e, & e+1-d\end{matrix}\middle| z\right)F\left(\begin{matrix}d-a, & d-b, & d-c\\ & d-1, & d+1-e\end{matrix}\middle| z\right). \quad (10)$$

Using Eq. (10) and setting $z=-1$ in the end we obtain

$$M^l_{mn}=\sqrt{\frac{(l+m)!}{\pi m!n!(l+n)!}}\frac{\Gamma(n+\frac{1}{2})\Gamma(l+\frac{1}{2})}{2^{l+m+n+1}(l+n+\frac{1}{2})l!}$$
$$\times\left\{(n+\tfrac{1}{2})F\left(\begin{matrix}-m, & \frac{1}{2}, & l+\frac{1}{2}\\ & l+1, & l+n+\frac{3}{2}\end{matrix}\middle| -1\right)F\left(\begin{matrix}-n, & -n-l, & -n-l-m-\frac{1}{2}\\ & -n-\frac{1}{2}, & -n-l+\frac{1}{2}\end{matrix}\middle| -1\right)\right.$$
$$\left.+lF\left(\begin{matrix}-m, & \frac{1}{2}, & l+\frac{1}{2}\\ & l, & l+n+\frac{3}{2}\end{matrix}\middle| -1\right)F\left(\begin{matrix}-n, & -n-l, & -n-l-m-\frac{1}{2}\\ & -n+\frac{1}{2}, & -n-l+\frac{1}{2}\end{matrix}\middle| -1\right)\right\}. \quad (11)$$

Further, we prove the following hypergeometric identity, valid for any positive integer k:

$$F\left(\begin{matrix}-k, & -k-a, & -k-b\\ & -k-c, & -k-d\end{matrix}\middle| -1\right)=\frac{(1+a)_k(1+b)_k}{(1+c)_k(1+d)_k}F\left(\begin{matrix}-k, & 1+c, & 1+d\\ & 1+a, & 1+b\end{matrix}\middle| -1\right). \quad (12)$$

The proof is obtained by reversing the order of summation in the (finite) sum, $i\to k-i$, using the symmetry of the binomial coefficients with respect to this substitution, and noticing that $(-k-a)_{k-i}=(-1)^{k-i}(1+a)_k/(1+a)_i$. Using identity (12) to transform the second hypergeometric function in each of the two terms in Eq. (11), we get

$$M^l_{mn}=\sqrt{\frac{(l+m)!(l+n)!}{m!n!}}\frac{\Gamma(l+m+n+\frac{3}{2})}{\pi 2^{l+m+n+1}(l+n+\frac{1}{2})}$$
$$\times\left\{\sum_{i=0}^{m}\binom{m}{i}\frac{\Gamma(\frac{1}{2}+i)\Gamma(\frac{1}{2}+l+i)}{(l+i-1)!\Gamma(\frac{3}{2}+l+n+i)}\sum_{j=0}^{n}\binom{n}{j}\frac{\Gamma(\frac{1}{2}+j)\Gamma(\frac{1}{2}+l+j)}{(l+j)!\Gamma(\frac{3}{2}+l+m+j)}\right.$$
$$\left.+\sum_{i=0}^{m}\binom{m}{i}\frac{\Gamma(\frac{1}{2}+i)\Gamma(\frac{1}{2}+l+i)}{(l+i)!\Gamma(\frac{3}{2}+l+n+i)}\sum_{j=0}^{n}\binom{n}{j}\frac{\Gamma(\frac{3}{2}+j)\Gamma(\frac{1}{2}+l+j)}{(l+j)!\Gamma(\frac{3}{2}+l+m+j)}\right\}. \quad (13)$$

The two terms in Eq. (13) can be brought together, restoring the symmetry with respect to m and n:

$$M^l_{mn}=\sqrt{\frac{(l+m)!(l+n)!}{m!n!}}\frac{\Gamma(l+m+n+\frac{3}{2})}{\pi 2^{l+m+n+1}(l+n+\frac{1}{2})}\sum_{i=0}^{m}\sum_{j=0}^{n}(l+i+j+\tfrac{1}{2})$$
$$\times\binom{m}{i}\frac{\Gamma(\frac{1}{2}+i)\Gamma(\frac{1}{2}+l+i)}{(l+i)!\Gamma(\frac{3}{2}+l+n+i)}\binom{n}{j}\frac{\Gamma(\frac{1}{2}+j)\Gamma(\frac{1}{2}+l+j)}{(l+j)!\Gamma(\frac{3}{2}+l+m+j)}. \quad (14)$$

Finally, regrouping the terms to split the double sum back into a product of single sums while preserving the $m \leftrightarrow n$ symmetry we arrive at Eqs. (3) and (4).

We note that Eqs. (3) and (4) also represent a useful analytic representation for the integrals of products of Laguerre polynomials (6).

Braided oscillators

A. Yildiz
Feza Gürsey Institute, P.O. Box 6, 81220, Çengelköy, Istanbul, Turkey

(Received 29 June 2001; accepted for publication 29 November 2001)

A generalized oscillator algebra is proposed and the braided Hopf algebra structure for this generalized oscillator is investigated. Using the solutions for the braided Hopf algebra structure, two types of braided Fibonacci oscillators are introduced. This leads to two types of braided Biedenharn–Macfarlane oscillators as special cases of the Fibonacci oscillators. We also find the braided Hopf algebra solutions for the three dimensional braided space. One of these, as a special case, gives the Hopf algebra given in the literature. © *2002 American Institute of Physics.*

I. INTRODUCTION

The harmonic oscillator has a wide variety of applications from quantum optics to the realizations of the angular momentum algebra and hence the deformations of the oscillator algebra play an important role in q-deformed theories. The realization of the q-deformed angular momentum algebra by Biedenharn–Macfarlane oscillators[1] and the realization of the Hermitian braided matrices by a pair of q-oscillators[2] are some of the examples. The two parameter deformations and some of their applications can be found in Ref. 3. Braided group theory (a self-contained review can be found in Ref. 4) deforms the notion of tensor product (called braided tensor product) and hence deforms the independence of the objects. Although braided groups arise in the formulation of quantum group covariant structures, the idea of braiding can be used without any reference to quantum groups to generalize the statistics.[5]

The permutation map π (π:$A\otimes B\rightarrow B\otimes A$) in the tensor product algebra of boson algebras

$$(a\otimes b)(c\otimes d)=a\,\pi(b\otimes c)d=ac\otimes bd$$

is replaced by a generalized map called braiding ψ (ψ:$A\otimes B\rightarrow B\otimes A$) such that

$$(a\otimes b)(c\otimes d)=a\,\psi(b\otimes c)d.$$

This generalization leads to the generalization of the Hopf algebra called braided Hopf algebra[6] whose axioms in algebraic (not diagrammatic) form read as

$$m\circ(id\otimes m)=m\circ(m\otimes id),$$

$$m\circ(id\otimes\eta)=m\circ(\eta\otimes id)=id,$$

$$(id\otimes\Delta)\circ\Delta=(\Delta\otimes id)\circ\Delta,$$

$$(\epsilon\otimes id)\circ\Delta=(id\otimes\epsilon)\circ\Delta=id,$$

$$m\circ(id\otimes S)\circ\Delta=m\circ(S\otimes id)\circ\Delta=\eta\circ\epsilon,$$

$$\psi\circ(m\otimes id)=(id\otimes m)\circ(\psi\otimes id)\circ(id\otimes\psi),$$

$$\psi\circ(id\otimes m)=(m\otimes id)\circ(id\otimes\psi)\circ(\psi\otimes id), \tag{1}$$

$$(id\otimes\Delta)\circ\psi=(\psi\otimes id)\circ(id\otimes\psi)\circ(\Delta\otimes id),$$

$$(\Delta\otimes id)\circ\psi=(id\otimes\psi)(\psi\otimes id)\circ(id\otimes\Delta),$$

$$\Delta\circ m=(m\otimes m)(id\otimes\psi\otimes id)\circ(\Delta\otimes\Delta),$$

$$S\circ m=m\circ\psi\circ(S\otimes S),$$

$$\Delta\circ S=(S\otimes S)\circ\psi\circ\Delta,$$

$$\epsilon\circ m=\epsilon\otimes\epsilon,$$

$$(\psi\otimes id)\circ(id\otimes\psi)\circ(\psi\otimes id)=(id\otimes\psi)\circ(\psi\otimes id)\circ(id\otimes\psi),$$

where $m:A\otimes A\to A$ is the multiplication map, $\Delta:A\to A\otimes A$ is the comultiplication map, $\eta:K\to A$ is the unit map, $\epsilon:A\to K$ is the counit map, $S:A\to A$ is the antipode map and $\psi:A\otimes A\to A\otimes A$ is the braiding map. The consistency of the relations (1) requires that

$$\Delta(1_A)=1_A\otimes 1_A,\quad \psi(1_A\otimes a)=a\otimes 1_A,\quad \psi(a\otimes 1_A)=1_A\otimes a\quad \forall a\in A, \tag{2}$$

where 1_A is the identity of the algebra A. From now on we will drop the subscript and write 1 for the identity of the algebra. All these maps are linear. Note that in the limit $\psi\to\pi$ the braided Hopf algebra axioms reduce to the ordinary Hopf algebra axioms. The braided Hopf algebra axioms[7] reduce to the axioms given above when the counit map (ϵ) is an algebra homomorphism. The $*$-structure for a braided algebra B is different[8] from the nonbraided one such that

$$\Delta\circ *=\pi\circ(*\otimes *)\circ\Delta,$$

$$S\circ *=*\circ S, \tag{3}$$

$$(a\otimes b)^*=b^*\otimes a^*,\quad \forall a,b\in B.$$

II. GENERALIZED OSCILLATOR

We propose a generalized oscillator algebra generated by a, a^*, q^N and 1 satisfying

$$aq^N=qq^Na,$$

$$q^Na^*=qa^*q^N, \tag{4}$$

$$aa^*-Q_1a^*a=Q_2q^{2N}+Q_3q^N+Q_4,$$

where q,Q_1,Q_2,Q_3,Q_4 are real constants whose values determine the type of the oscillator. For example, if Q_1 is a free parameter, then the $Q_2=1$, $Q_3=Q_4=0$ case and the $Q_3=1$, $Q_2=Q_4=0$ case define two different Fibonacci oscillators. For the $*$-structure we impose $(q^N)^*=q^N$, $(a^*)^*=a$. The actions of the generators on the Hilbert space are given by

$$a|n\rangle=a_n|n-1\rangle,$$

$$a^*|n\rangle=a^*_{n+1}|n+1\rangle, \tag{5}$$

$$q^N|n\rangle=q^n|n\rangle.$$

Using the fact that for a given algebra the Hopf algebra structure is not unique, we write the general forms of the coproducts

$$\Delta(q^N)=A_1q^N\otimes q^N+A_2a\otimes a^*+A_3a^*\otimes a+A_4 1\otimes q^N+A_5q^N\otimes 1+A_6 1\otimes 1,$$
$$\Delta(a)=B_1q^N\otimes a+B_2a\otimes q^N+B_3 1\otimes a+B_4a\otimes 1, \tag{6}$$
$$\Delta(a^*)=B_1a^*\otimes q^N+B_2q^N\otimes a^*+B_3a^*\otimes 1+B_4 1\otimes a^*,$$

the counits

$$\epsilon(q^N)=e_1,\quad \epsilon(a)=\epsilon(a^*)=e_2, \tag{7}$$

the antipodes

$$S(q^N)=k_1q^N+k_2a+k_3a^*+k_4,$$
$$S(a)=m_1q^N+m_2a+m_3a^*+m_4, \tag{8}$$
$$S(a^*)=m_1q^N+m_2a^*+m_3a+m_4,$$

and the braidings

$$\psi(q^N\otimes q^N)=g_1q^N\otimes q^N+g_2a\otimes a^*+g_3a^*\otimes a+g_4 1\otimes q^N+g_5q^N+g_6 1\otimes 1,$$
$$\psi(q^N\otimes a)=d_1a\otimes q^N+d_2q^N\otimes a+d_3 1\otimes a+d_4a\otimes 1,$$
$$\psi(a^*\otimes q^N)=d_1q^N\otimes a^*+d_2a^*\otimes q^N+d_3a^*\otimes 1+d_4 1\otimes a^*,$$
$$\psi(q^N\otimes a^*)=f_1a^*\otimes q^N+f_2q^N\otimes a^*+f_3 1\otimes a^*+f_4a^*\otimes 1,$$
$$\psi(a\otimes q^N)=f_1q^N\otimes a+f_2a\otimes q^N+f_3a\otimes 1+f_4 1\otimes a, \tag{9}$$
$$\psi(a\otimes a)=z_1a\otimes a,$$
$$\psi(a^*\otimes a^*)=z_1a^*\otimes a^*,$$
$$\psi(a\otimes a^*)=b_1q^N\otimes q^N+b_2a\otimes a^*+b_3a^*\otimes a+b_4 1\otimes q^N+b_5q^N\otimes 1+b_6 1\otimes 1,$$
$$\psi(a^*\otimes a)=c_1q^N\otimes q^N+c_2a\otimes a^*+c_3a^*\otimes a+c_4 1\otimes q^N+c_5q^N\otimes 1+c_6 1\otimes 1,$$

where symbols with a subscript are the constants to be determined.

III. BRAIDED HOPF ALGEBRA STRUCTURE OF THE GENERALIZED OSCILLATOR

To find the general braided Hopf algebra structure for the oscillator algebra given by (4) we substitute these general forms into the braided Hopf algebra axioms (1) and find the solutions using the computer programming Maple V. The constants which are the same for all solutions read as

$$Q_4=A_1=A_6=B_1=B_2=0,\quad A_4=A_5=B_3=B_4=1, \tag{10}$$
$$k_2=k_3=k_4=m_1=m_3=m_4=e_1=e_2=0,\quad m_2=-1, \tag{11}$$
$$b_4=b_5=b_6=c_4=c_5=c_6=g_4=g_5=g_6=d_3=d_4=f_3=f_4=0. \tag{12}$$

The solutions for the other parameters are given in the tables. The constants given by (10)–(12) show that the antipodes and the counits of all generators and the coproducts of raising/lowering

$A_2=A_3=0$ for all solutions

operators are uniquely determined. We also found that for a free deformation parameter Q_1 at most one of the other deformation parameters, namely Q_2 or Q_3, is nonzero. For $Q_2\neq 0$, we have

$$aa^*-Q_1a^*a=Q_2q^{2N}. \tag{13}$$

Without loss of generality we can take $Q_2=1$ or by rescaling a and a^* the oscillator relation (13) can be reduced to

$$aa^*-Q_1a^*a=q^{2N}. \tag{14}$$

We found that there are only six possible braided Hopf algebra solutions for this two-parameter oscillator which are given in Table I. Defining the free deformation parameter $Q_1\equiv p^{-2}$ the algebra (14) can be rewritten as

$$aa^*-p^{-2}a^*a=q^{2N}, \tag{15}$$

which is the more familiar form of the q, p oscillator algebra (Fibonacci oscillator) which we call the first-type Fibonacci oscillator. Using the actions (5) the eigenvalue of the operator a^*a on the state $|n\rangle$ is found to be

$$a_n^* a_n = \frac{p^{-2n} - q^{2n}}{p^{-2} - q^2}. \tag{16}$$

Substituting $Q_1 = q^{-2}$ into (14) we obtain the Biedenharn–Macfarlane oscillator algebra which we call the first-type Biedenharn–Macfarlane oscillator defined by

$$aa^* - q^{-2}a^*a = q^{2N}. \tag{17}$$

The eigenvalue of the operator a^*a on the state $|n\rangle$ is found to be

$$a_n^* a_n = \frac{q^{2n} - q^{-2n}}{q^2 - q^{-2}}. \tag{18}$$

There are only six braided Hopf algebra solutions for the first-type Biedenharn–Macfarlane oscillator (17) which can be obtained by substituting $Q_1 = q^{-2}$ into the solutions given in Table I. Similarly, for $Q_3 \neq 0$ the oscillator relation

$$aa^* - Q_1 a^*a = Q_3 q^N \tag{19}$$

can again be reduced to

$$aa^* - Q_1 a^*a = q^N, \tag{20}$$

which we call the second-type Fibonacci oscillator. Setting the free deformation $Q_1 \equiv p^{-1}$ the eigenvalue of the operator a^*a on the state $|n\rangle$ is found to be

$$a_n^* a_n = \frac{p^{-n} - q^n}{p^{-1} - q}. \tag{21}$$

The second-type Fibonacci oscillator (20) has only two braided Hopf algebra solutions which are given in Table II. The second-type Biedenharn–Macfarlane oscillator can be obtained simply by substituting $Q_1 = q^{-1}$ into (20) and the same substitution into Table II gives braided Hopf algebra solutions.

A wide variety of one-parameter oscillators can be obtained by assigning $Q_1 = f(q)$ in the algebras (14) and (20). The braided Hopf algebra solutions for these oscillators can be obtained by substituting $Q_1 = f(q)$ into the Tables I and II. However, there are extra solutions for some values Q_1 which are given in Table III.

The braided Hopf algebra structure of the quantum space (called braided space) defined by

$$x_i x_j = q x_j x_i, \quad i > j, \tag{22}$$

determines the structure of the braided integration, derivation and Fourier transform defined on that space.[9] For $Q_1 = q$, $Q_2 = 0$, $Q_3 = 0$, $Q_4 = 0$ the algebra (4) reduces to the three dimensional quantum space with the identifications

$$x_1 \equiv a^*, \quad x_2 \equiv q^N, \quad x_3 \equiv a. \tag{23}$$

The braided Hopf algebra solutions for the three dimensional braided space are given in Table IV. Setting the free parameter $g_1 = q^2$ in the sol5 of Table IV gives the braided Hopf algebra given in Ref. 10 and references therein) as a special case.

IV. CONCLUSION

The braidings imply the relations between independent copies of algebras. For example, the implication of the braiding $\psi(a\otimes a)$ can be found by using the identifications $a_1\equiv a\otimes 1$ and $a_2\equiv 1\otimes a$ such that

$$a_2a_1=(1\otimes a)(a\otimes 1)=\psi(a\otimes a)=za\otimes a=za_1a_2.$$

Thus the braiding relations imply a two-body system of oscillators which can be extended to n-body oscillators using the n-fold braided tensor product as done by Baskerville and Majid in the context of the braided version of the q-Heisenberg algebra.[11] The Fock space representations of the n-fold braided tensor product of oscillators can also be found. This requires the braidings of the generators of the algebra with the states. All these constructions depend on the braiding relations of the generators of the algebra. Since each solution for the braiding gives a different system of oscillators, the solutions we found may provide a general framework for the interacting oscillators and hence for the statistical mechanical quantities calculated by using these oscillators.

Because of the connection between symmetry and statistics it is interesting to investigate the underlying symmetry transformations of the braided oscillators which gives rise to the braiding relations given in the tables. It may also be interesting to find the unbraiding transformations[12] or the decoupling of the braided oscillators. The generalization of supersymmetry to fractional supersymmetry requires the deformation parameter to be a root of unity[13] and this case deserves to be discussed on a seperate study.

The braided Hopf algebra solutions we present for the oscillators and for the three dimensional braided space may provide a general frame on which other structures can be defined.

(Received 21 February 2001; accepted for publication 27 November 2001)

A relativistic kinematics for the *N*-body problem which solves all the problems raised until now on this topic is constructed by exploting the Wigner-covariant *rest-frame instant form of dynamics* in the context of *parametrized Minkowski theories*. The Wigner hyperplanes, orthogonal to the total timelike four-momentum of any *N*-body configuration, define the intrinsic rest frame and realize the separation of the center-of-mass motion. The point chosen as origin in each Wigner hyperplane can be made to coincide with the covariant noncanonical Fokker–Pryce *center of inertia*. As is well known, the latter is distinct from the *canonical* pseudo-four-vector describing the decoupled motion of the center of mass (which possess the same Euclidean covariance as the quantum Newton–Wigner three-position operator) and from the noncanonical pseudo-four-vector known as Møller's *center of energy*. Our approach leads to the splitting of the notion of center of mass into an *external* one, defined in terms of an external Poincaré group realization, and an *internal* one defined in terms of an internal unfaithful realization of the group inside the Wigner hyperplane. Because of the first class constraints defining the rest frame (vanishing of the *internal* three-momentum), the latter three *internal* concepts of center of mass weakly *coincide*. The resulting unique *internal* center of mass is thereby a gauge variable which, by a suitable gauge fixing, can be localized at the origin of the Wigner hyperplane. An adapted canonical basis of relative variables is constructed by means of the classical counterpart of the Gartenhaus–Schwartz transformation. The invariant mass of the *N*-body configuration is the Hamiltonian for the relative motions. Within this general framework, the rotational kinematics can be developed in terms of the same *dynamical body frames, orientation-shape* variables, *spin frame*, and *canonical spin bases* already introduced in the case of the nonrelativistic *N*-body problem.
[DOI: 10.1063/1.1435424]

I. INTRODUCTION

The separation of the *absolute translational motion* of the center of mass from the relative motions for the nonrelativistic *N*-body problem can be easily carried out due to the Abelian character of the translation symmetry group. This character implies that the associated Noether constants of motion (the conserved total three-momentum) are in involution, so that the center-

[a)]Electronic mail: alba@fi.infn.it
[b)]Electronic mail: lusanna@fi.infn.it
[c)]Electronic mail: pauri@pr.infn.it

of-mass degrees of freedom decouple. Moreover, the fact that the nonrelativistic kinetic energy of the relative motions is a quadratic form in the relative velocities allows for the introduction of special sets of relative coordinates, the *Jacobi normal relative coordinates*, that diagonalize the quadratic form and correspond to different patterns of clustering of the centers of mass of the particles. Each set of Jacobi coordinates arrange the N particles into a *hierarchy of clusters*, in which each cluster of two or more particles has a mass given by an eigenvalue (*reduced mass*) of the quadratic form; the Jacobi normal coordinates join the centers of mass of cluster pairs.

On the other hand, the non-Abelian nature of the rotational symmetry, whose associated Noether constants of motion (the conserved total angular momentum) are not in involution, prevents the possibility of a global separation of *absolute rotations* from the relative motions, so that there is no global definition of *absolute vibrations*. This has the consequence that an *isolated* deformable body can undergo rotations by changing its own shape (as shown by the *falling cat* and the *diver*). It was just to deal with these problems that the theory of the *orientation-shape* $SO(3)$ *principal bundle*[1] has been developed in the context of molecular physics, emphasizing the *gauge* nature of a *static* (i.e., velocity-independent) definition of *body frame* for a deformable body. Both the laboratory and body frame angular velocities as well as the orientational variables of the static body frame thereby become *unobservable gauge* variables. This approach is associated with a set of point canonical transformations, which allow one to define the body frame components of relative motions in a velocity-independent way.

In a previous paper[2] we showed that a more general class of nonpoint canonical transformations exists for $N \geqslant 3$, which allows one to identify a family of *canonical spin bases* connected to the patterns of the possible *clusterings of the spins* associated with relative motions (namely the components of the center-of-mass angular momenta). The definition of these *spin bases* is independent of the use of Jacobi normal relative coordinates, just as the patterns of spin clustering are independent of the patterns of center-of-mass Jacobi clustering.

Two basic frames associated with each spin basis exist: the *spin frame* and the *dynamical body frame*. Their construction is guaranteed by the fact that, besides the existence of a Hamiltonian symmetry *left* action of $SO(3)$[3] on the relative phase space, it is possible to define as many Hamiltonian non-symmetry *right* actions of SO(3) as the possible patterns of spin clustering. While the generators of the left action are the components of the center-of-mass angular momentum (Noether constants of motion), the generators of the right actions are not constants of motion. For $N=3$ the unique canonical *spin basis* coincides with a special class of global cross sections of the trivial orientation-shape SO(3) principal bundle. On the other hand, for $N \geqslant 4$ the existing *spin bases* and *dynamical body frames* turn out to be unrelated to the local cross sections of the *static* nontrivial orientation-shape SO(3) principal bundle, and *evolve* in a dynamical way dictated by the equations of motion. Both the orientation variables and the angular velocities become *measurable* quantities in each canonical spin basis.

For each N, we get a finite number of physically well-defined separations between *rotational* and *vibrational* degrees of freedom. The unique *body frame* of rigid bodies is replaced here by a discrete number of *evolving dynamical body frames* and of *spin canonical bases*. Both of them are grounded on patterns of spin couplings which are the direct analogues of the coupling of quantum angular momenta. Let us note that these results might be useful in nonrelativistic nuclear and molecular physics.

Besides translations and rotations, every isolated nonrelativistic system admits the internal energy, the total mass, and the (time-dependent) Galilei boosts (which amounts essentially to the inertial motion of the center of mass) as constants of the motion. All together, there are 11 constants of motion (the total mass being a central charge) which generate a realization of the kinematical extended Galilei algebra.[4,5]

We want to see what happens when we replace Galilean space–time with Minkowski space–time. More precisely, to see what can be said in this case about the separation of the center of mass from the relative motions and about the rotations, already for the simple model-system of N free scalar positive-energy particles.

First of all we have to describe a relativistic scalar particle. Among the various possibilities

(see Ref. 6 for a review of the various options) we will choose the manifestly Lorentz covariant approach based on Dirac's first class constraints[7]

$$p_i^2 - \epsilon m_i^2 \approx 0. \tag{1.1}$$

The associated Lagrangian description is based on the four-vector positions $x_i^\mu(\tau)$ and the action $S = \int d\tau(-\epsilon \Sigma_i m_i \sqrt{\epsilon \dot{x}_i^2(\tau)})$, where τ is a Lorentz scalar *mathematical* time parameter, i.e., an affine parameter for the particle timelike worldlines. Then Lorentz covariance implies singular Lagrangians and the associated Dirac's theory of constraints for the Hamiltonian description. The individual time variables $x_i^0(\tau)$ are the *gauge variables* associated with the mass-shell constraints, which have the two topologically disjoint solutions $p_i^0 \approx \pm \sqrt{m_i^2 + \vec{p}_i^2}$. As discussed in Refs. 8 and 9 this implies that:

(i) a combination of the time variables may be identified to the clock of one arbitrary observer labeling the evolution of the isolated system;
(ii) the $N-1$ relative times are related to the observer's freedom of looking at the N particles either at the same time or with any prescribed relative delay.

These two gauge arbitrariness describe the *generalized inertial effects* arising from the conventions adopted to quantify the temporal evolution of the particles.

Introducing interactions in this picture without destroying the first class nature of the constraints[10] is a well-known difficult problem. It originated, in the two-particle case, the DrozVincent–Komar–Todorov model.[11] On the other hand, *its extension to N particles has never been given in closed form.*

When the particle is charged and interacts with a dynamical electromagnetic field a *problem of covariance* reappears. The standard description is based on the action

$$S = -\epsilon m \int d\tau \sqrt{\epsilon \dot{x}^2(\tau)} - e \int d\tau \int d^4 z\, \delta^4(z - x(\tau)) \dot{x}^\mu(\tau) A_\mu(z) - \frac{1}{4} \int d^4 z F^{\mu\nu}(z) F_{\mu\nu}(z). \tag{1.2}$$

By evaluating the canonical momenta of the isolated system, *charged particle plus electromagnetic field*, we find two primary constraints:

$$\chi(\tau) = (p - eA(x(\tau)))^2 - \epsilon m^2 \approx 0, \quad \pi^0(z^0, \vec{z}) \approx 0. \tag{1.3}$$

It is immediately seen that, since there is no concept of *equal time*, it is impossible to evaluate the Poisson bracket of these constraints. Also, due to the same reason, the Dirac Hamiltonian which would be $H_D = H_c + \lambda(\tau)\chi(\tau) + \int d^3 z \lambda^0(z^0, \vec{z}) \pi^0(z^0, \vec{z})$ with H_c the canonical Hamiltonian and with $\lambda(\tau)$, $\lambda^0(z^0, \vec{z})$ Dirac's multipliers, does not make sense. This problem is present even at the level of the Euler–Lagrange equations: how to formulate a *Cauchy problem* for a system of coupled equations some of which are ordinary differential equations in the affine parameter τ along the particle worldline, while the others are partial differential equations depending on Minkowski coordinates z^μ? Since the problem is due to the lack of a covariant concept of *equal time* between field and particle variables, a new formulation of the problem is needed. In Ref. 9, after a discussion of the many time formalism, a solution of the problem was found within a context suited to incorporate the gravitational field. The starting point is an arbitrary $3+1$ splitting of Minkowski space–time with spacelike hypersurfaces, which is equivalent to a congruence of timelike accelerated observers. This is essentially Dirac's reformulation[12] of classical field theory (suitably extended to particles) on arbitrary spacelike hypersurfaces (*equal time* or simultaneity Cauchy surfaces). Note incidentally that it is also the classical basis of the Tomonaga–Schwinger formulation of quantum field theory. Given any isolated system (containing any combination of particles, strings, and fields) one is lead to a reformulation of it as a *parametrized Minkowski theory*,[9] with the extra bonus that the theory is already prepared for the coupling to gravity in its ADM formulation. The price to be paid is that the functions $z^\mu(\tau, \vec{\sigma})$ describing the embedding of

the spacelike hypersurface in Minkowski space–time become *additional configuration variables* of the action principle. Since the action is invariant under separate τ-reparametrizations and space-diffeomorphisms, first class constraints appear to ensure the independence of the description from the choice of the $3+1$ splitting. The embedding configuration variables $z^\mu(\tau,\vec{\sigma})$ are the *gauge* variables associated with this kind of general covariance and describe all the possible *inertial effects* compatible with special relativity.

Let us come back to the discussion of the free case within the parametrized Minkowski theory approach. Since the intersection of a timelike worldline with a spacelike hypersurface corresponding to a value τ of the time parameter is identified by three numbers $\vec{\sigma}=\vec{\eta}(\tau)$ and *not by four*, each particle must have a well-defined sign of the energy. Therefore, we cannot describe the two topologically disjoint branches of the mass hyperboloid simultaneously as in the standard manifestly Lorentz-covariant approach. Then, there are no more mass-shell constraints. Each particle with a definite sign of the energy is described by the canonical coordinates $\vec{\eta}_i(\tau)$, $\vec{\kappa}_i(\tau)$ with the derived four-position of the particles given by $x_i^\mu(\tau)=z^\mu(\tau,\vec{\eta}_i(\tau))$. The derived four-momenta $p_i^\mu(\tau)$ are $\vec{\kappa}_i$-dependent solutions of $p_i^2-\epsilon m_i^2=0$ with the given sign of the energy.

Because of the independence from the $3+1$ splitting of Minkowski space–time in parametrized theories, the foliation can be restricted to spacelike hyperplanes. In particular, for each configuration of the isolated system with timelike four-momentum, the leaves are best chosen as the hyperplanes orthogonal to the conserved total four-momentum (*Wigner hyperplanes*). Note that this special foliation is intrinsically determined by the configuration of the isolated system alone. This leads to the definition of the *Wigner-covariant rest-frame instant form of dynamics*,[9] for every isolated system whose configurations have well-defined and finite Poincaré generators with timelike total four-momentum.[13,14]

Such formulation allows one to clarify the roles of the various relativistic centers of mass. This is a long-standing problem which arose just after the foundation of special relativity in the first decade of the last century. In the next 90 years it became clear that the problem of the relativistic center of mass is highly nontrivial: no definition can enjoy all the properties of the ordinary nonrelativistic center of mass. See Refs. 15–20 for a partial bibliography of all the existing attempts and Ref. 21 for reviews.

Let us now summarize some relevant points of the rest-frame instant form on Wigner hyperplanes (see Appendix A). Only four first class constraints survive in this case so that the original configurational variables $z^\mu(\tau,\vec{\sigma})$, $\vec{\eta}_i(\tau)$ and their conjugate momenta $\rho_\mu(\tau,\vec{\sigma})$, $\vec{\kappa}_i(\tau)$ are reduced to the following.

(i) A decoupled point $\tilde{x}_s^\mu(\tau)$, p_s^μ (the only remnant of the spacelike hypersurface) with a positive mass $\epsilon_s=\sqrt{\epsilon p_s^2}$ determined by the first class constraint $\epsilon_s-M_{\rm sys}\approx 0$ ($M_{\rm sys}$ is the invariant mass of the isolated system). Its rest-frame Lorentz scalar time $T_s=(\tilde{x}_s\cdot p_s)/\epsilon_s$ is put equal to the mathematical time by the gauge fixing $T_s-\tau\approx 0$ for the previous constraint. Here, $\tilde{x}_s^\mu(\tau)$ is a *noncovariant canonical variable for the four-center of mass*. After the elimination of T_s and ϵ_s with the previous pair of second class constraints, we are left with a decoupled free point (*point particle clock*) of mass $M_{\rm sys}$ and canonical three-coordinates $\vec{z}_s=\epsilon_s(\vec{\tilde{x}}_s-(\vec{p}_s/p_s^0)\tilde{x}^0)$, $\vec{k}_s=\vec{p}_s/\epsilon_s$. The position $\vec{q}_s=\vec{z}_s/\epsilon_s$ is the classical analog of the Newton–Wigner three-position operator[16] and shares the reduced covariance under the Euclidean subgroup of the Poincaré group. The unit timelike four-vector $u^\mu(p_s)=p_s^\mu/\epsilon_s$ is orthogonal to the Wigner hyperplanes and describes their orientation in the chosen inertial frame. Note that the noncovariant canonical $\tilde{x}_s^\mu(\tau)$ should not be confused with the four-vector $x_s^\mu(\tau)=z^\mu(\tau,\vec{\sigma}=0)$ identifying the origin of the three-coordinates $\vec{\sigma}$ inside the Wigner hyperplanes. The worldline $x_s^\mu(\tau)$ is arbitrary since it depends on $x_s^\mu(0)$, while its four-velocity $\dot{x}_s^\mu(\tau)$ depends on the Dirac multipliers associated with the four first class constraints (see the following). This worldline may be considered as an arbitrary *centroid* for the isolated system.

(ii) The particle canonical variables $\vec{\eta}_i(\tau)$, $\vec{\kappa}_i(\tau)$ *inside* the Wigner hyperplanes. They are restricted by the three first class constraints (the *rest-frame conditions*) $\vec{\kappa}_+=\Sigma_{i=1}^N\vec{\kappa}_i\approx 0$. They are Wigner spin-one three-vectors, like the coordinates $\vec{\sigma}$.

Let us stress that *our approach leads to a doubling of the usual concepts.*

(1) The concepts defined according to the *external* viewpoint of an arbitrary inertial Lorentz observer, describing the Wigner hyperplanes as leaves of a foliation of Minkowski space–time and determined by the timelike configurations of the isolated system. A Lorentz transformation rotates the Wigner hyperplanes and induces a Wigner rotation of the three-vectors inside each Wigner hyperplane. Each such hyperplane inherits an induced *internal Euclidean structure* while the *external* realization of the Poincaré group induces an *internal* unfaithful Euclidean action (the internal translations are generated by the first class constraints $\vec{\kappa}_+ \approx 0$, so that they are eliminable gauge variables).

As stated previously, an arbitrary worldline, the *centroid* $x_s^\mu(\tau)$, is chosen as origin of the *internal* three-coordinates on the Wigner hyperplanes; its velocity $\dot{x}_s^\mu(\tau)$ is determined only after the introduction of four gauge fixings for the four first class constraints (one of them is $T_s - \tau \approx 0$).

Then, three *external* concepts of four-center of mass can be defined (each having an *internal* three-location inside the Wigner hyperplanes) starting from the kinematics of the Wigner hyperplanes and from known concepts of three-centers of mass.[15]

(a) The *external* noncovariant canonical *four-center of mass* $\tilde{x}_s^\mu$ (with three-location $\vec{\tilde{\sigma}}$), extension of the *canonical three-position vector* $\vec{q}_s$ (also named *center of spin*[19]). $\vec{q}_s$ is the classical analog of the Newton–Wigner position operator[16] (Foldy–Wouthuysen mean position operator[22] for Dirac equation). $\tilde{x}_s^\mu$ is not a four-vector ($\vec{q}_s$ does not satisfy the *world line condition*[15]), but it is canonical: $\{\tilde{x}_s^\mu, \tilde{x}_s^\nu\} = 0$.

(b) The *external* noncovariant and noncanonical Møller *four-center of energy* R_s^μ (with three-location $\vec{\sigma}_R$), extension of the Møller three-center of mass $\vec{R}_s$,[17] which corresponds to the standard nonrelativistic definition of center of mass of a system of particles with masses replaced by energies. $\vec{R}_s$ does not satisfy the world line condition, so that R_s^μ is not a four-vector and moreover it satisfies $\{R_s^\mu, R_s^\nu\} \neq 0$.

(c) The *external* noncanonical but covariant Fokker–Pryce *four-center of inertia* Y_s^μ (with three-location $\vec{\sigma}_Y$), extension of the Fokker–Pryce three-center of inertia.[18,19] Y_s^μ is a four-vector by construction: it is the Lorentz transform of the rest-frame pseudo-worldline $R_s^{(\mathrm{rest})\,\mu}$ of the Møller center of energy to an arbitrary frame. It holds $\{Y_s^\mu, Y_s^\nu\} \neq 0$.

Note that while the Fokker–Pryce Y_s^μ is the only four-vector by construction, only $\tilde{x}_s^\mu(\tau)$ can be an adapted coordinate in a Hamiltonian treatment with Dirac constraints,

(2) The concepts defined according to the *internal* viewpoint associated with the Wigner hyperplanes, corresponding to an unfaithful *internal* realization of the Poincaré algebra: the *internal* three-momentum $\vec{\kappa}_+$ vanishes due to the rest-frame conditions. The *internal* energy and angular momentum are given by the invariant mass M_{sys} and by the spin [angular momentum with respect to $\tilde{x}_s^\mu(\tau)$] of the isolated system, respectively.

In analogy with the external viewpoint, we can define three *internal* three-centers of mass: the *internal* canonical three-center of mass $\vec{q}_+$, the *internal* Møller three-center of energy $\vec{R}_+$, and the *internal* Fokker–Pryce three-center of inertia $\vec{y}_+$. However, due to the rest-frame conditions, they *coincide* ($\vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+$) and become essentially a unique *gauge* variable conjugate to $\vec{\kappa}_+$. As a natural gauge fixing for the rest-frame conditions $\vec{\kappa}_+ \approx 0$, we can add the vanishing of the *internal* Lorentz boosts: this is equivalent to locating the internal canonical three-center of mass $\vec{q}_+$ in $\vec{\sigma} = 0$, i.e., in the external centroid $x_s^\mu(\tau) = z^\mu(\tau, \vec{0})$ origin of the internal three-coordinates in each Wigner hyperplane. With these gauge fixings and with $T_s - \tau \approx 0$, the world-line $x_s^\mu(\tau)$ of the centroid becomes uniquely determined except for the arbitrariness in the choice of $x_s^\mu(0)$ [$u^\mu(p_s) = p_s^\mu / \epsilon_s$,]

$$x_s^\mu(\tau) = x_s^\mu(0) + u^\mu(p_s) T_s, \tag{1.4}$$

and coincides with the *external* covariant noncanonical Fokker–Pryce four-center of inertia, $x_s^\mu(\tau) = x_s^\mu(0) + Y_s^\mu$.

This doubling of concepts *replaces* the separation of the nonrelativistic three-center of mass due to the Abelian translation symmetry. The nonrelativistic conserved three-momentum is replaced by the *external* $\vec{p}_s = \epsilon_s \vec{k}_s$, while the *internal* three-momentum vanishes, $\vec{\kappa}_+ \approx 0$, as a definition of the rest frame.

In the final gauge we have $\epsilon_s \equiv M_{\rm sys}$, $T_s \equiv \tau$, and the canonical basis $\vec{z}_s$, $\vec{k}_s$, $\vec{\eta}_i$, $\vec{\kappa}_i$ restricted by the three pairs of second class constraints $\vec{\kappa}_+ = \Sigma_{i=1}^N \vec{\kappa}_i \approx 0$, $\vec{q}_+ \approx 0$. Therefore the N particles are described by $6N$ canonical variables like in the nonrelativistic case: 6 $(\vec{z}_s, \vec{k}_s)$ for the external decoupled center of mass and $6(N-1)$ for the relative motions. We still need a canonical transformation $\vec{\eta}_i$, $\vec{\kappa}_i \mapsto \vec{q}_+ [\approx 0]$, $\vec{\kappa}_+ [\approx 0]$, $\vec{\rho}_a$, $\vec{\pi}_a$ $(a = 1,...,N-1)$ in order to identify a set of relative canonical variables. The final $6N$-dimensional canonical basis is $\vec{z}_s$, $\vec{k}_s$, $\vec{\rho}_a$, $\vec{\pi}_a$. In order to get this result we exploit a *highly nonlinear* canonical transformation obtained from the Gartenhaus–Schwartz singular transformation.[23]

In the end, we obtain the Hamiltonian for relative motions as *a sum of N square roots*, each one containing a squared mass and a quadratic form in the relative momenta. Such Hamiltonian goes over its nonrelativistic counterpart in the limit $c \to \infty$. This result has the following implications.

(a) If one tries to make the inverse Legendre transformation to find the associated Lagrangian, it turns out that, due to the presence of square roots, the Lagrangian is a hyperelliptic function of $\dot{\vec{\rho}}_a$ already in the free case. A closed form exists only for $N=2$, $m_1 = m_2 = m$: $L = -\epsilon m \sqrt{4 - \dot{\vec{\rho}}^2}$. This exceptional case already shows that the existence of the limiting velocity c *forbids the traditional linear relation between the spin and the angular velocity*. Moreover, determining the allowed range of the relative velocities is a difficult task (for $N=2$, $m_1 = m_2 = m$, we get $|\dot{\vec{\rho}}| \leq 2c$).

(b) The N quadratic forms in the relative momenta which appear in the relative Hamiltonian *cannot* be diagonalized simultaneously. In any case, the Hamiltonian is a sum of square roots, so that concepts like *reduced masses*, *Jacobi normal relative coordinates*, and *tensor of inertia* cannot be extended to special relativity. This entails that the orientation-shape SO(3) principal bundle of Ref. 1 we would like to exploit can be defined only by using unspecified relative coordinates. Therefore:

(c) The best way of studying rotational kinematics is based on the *canonical spin bases* of Ref. 2 with their *spin frames* and *dynamical body frames*. The important point is that *such frames can be constructed in the same way as in the nonrelativistic case starting from the canonical basis* $\vec{\rho}_a$, $\vec{\pi}_a$.

Finally, once this program has been fulfilled in the free case, the introduction of mutual action-at-a-distance interactions among the particles can be done without extra complications.

The paper is organized as follows. In Sec. II we review the rest-frame instant form on the Wigner hyperplane of N positive energy free scalar particles. In Sec. III we discuss the *internal* realization of the Poincaré algebra and define the *internal center-of-mass* concepts. In Sec. IV we discuss the *external* realization of the Poincaré algebra and define the *external center-of-mass* concepts. In Sec. V we construct the relative canonical variables associated with the canonical *internal* center of mass. In Sec. VI we analyze the relativistic rotational kinematics of relative motions inside the Wigner hyperplane using the Hamiltonian methods for the construction of the spin bases introduced in Ref. 2. Some final comments on open problems are given in Sec. IV.

Appendix A contains a review of parametrized Minkowski theories. The results of Sec. V are extended to spinning particles in Appendix B.

Glossary of symbols: $z^\mu(\tau, \vec{\sigma}) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\, \sigma^r$—embedding of a Wigner hyperplane in M^4 $(u^\mu(p_s) = p_s^\mu / \sqrt{\epsilon\, p_s^2})$; $x_s^\mu(\tau)$—arbitrary four-vector (centroid), chosen as origin of the *internal* three-coordinates $\vec{\sigma}$; $x_i^\mu(\tau) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\, \eta_i^r(\tau)$—world line of particle i, with *internal* three-position $\vec{\eta}_i(\tau)$ and three-momentum $\vec{\kappa}_i(\tau)$; $\tilde{x}_s^\mu(\tau) = (\tilde{x}_s^0; \vec{q}_s + \tilde{x}_s^0 \vec{p}_s / p_s^0) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\, \tilde{\sigma}^r$—*external* canonical noncovariant four- and three-center of mass; $R_s^\mu(\tau) = (\tilde{x}_s^0; \vec{R}_s) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\, \sigma_R^r$—*external* noncanonical noncovariant Møller four- and three-

center of energy; $Y^\mu_s(\tau)=(\tilde{x}^0_s;\vec{Y}_s)=x^\mu_s(\tau)+\epsilon^\mu_r(u(p_s))\,\sigma^r_Y$—*external* noncanonical covariant Fokker–Pryce four- and three-center of inertia; $T_s=u(p_s))\cdot x_s=u(p_s)\cdot\tilde{x}_s=u(p_s)\cdot Y_s=u(p_s)\cdot R_s$—rest frame time; $\vec{\kappa}_+=\Sigma_i\,\vec{\kappa}_i\approx 0$—rest frame conditions; $\vec{q}_+$, $\vec{R}_+$, $\vec{y}_+$—*internal* canonical three-center of mass, Møller three-center of energy, Fokker–Pryce three-center of inertia; $\vec{q}_+\approx\vec{R}_+\approx\vec{y}_+$ due to $\vec{\kappa}_+\approx 0$; and $\vec{q}_+\approx 0$ implies $x^\mu_s(\tau)=x^\mu_s(0)+Y^\mu_s(\tau)$.

II. THE REST-FRAME INSTANT FORM OF *N* FREE SCALAR RELATIVISTIC PARTICLES

Let us consider a system of N free scalar positive-energy particles in the framework of parametrized Minkowski theory (see Appendix A).

The configuration variables are a three-vector $\vec{\eta}_i(\tau)$ for each particle $[x^\mu_i(\tau)=z^\mu(\tau,\vec{\eta}_i(\tau))]$.[9,24] The sign of the energy must be chosen for each particle, because there is no mass-shell constraint (like $\epsilon p_i^2-m_i^2\approx 0$) at our disposal (there are only three degrees of freedom for particle, determined by the intersection of a timelike trajectory and of the spacelike hypersurface Σ_τ). For each choice of the sign of the energy of the N particles, we describe only one of the 2^N branches of the mass spectrum of the manifestly covariant approach based on the coordinates $x^\mu_i(\tau)$, $p^\mu_i(\tau)$, $i=1,...,N$, and on the constraints $\epsilon p_i^2-m_i^2\approx 0$ (in the free case). In this way, we get a description of relativistic particles with a given sign of the energy with consistent couplings to fields.[25–27]

The system of N free scalar and positive energy particles is described by the action[9,24,26]

$$S=\int \mathrm{d}\tau\,\mathrm{d}^3\sigma\,\mathcal{L}(\tau,\vec{\sigma})=\int \mathrm{d}\tau\,L(\tau),$$

$$\mathcal{L}(\tau,\vec{\sigma})=-\sum_{i=1}^N\,\delta^3(\vec{\sigma}-\vec{\eta}_i(\tau))m_i\sqrt{g_{\tau\tau}(\tau,\vec{\sigma})+2g_{\tau\check{r}}(\tau,\vec{\sigma})\,\dot{\eta}^{\check{r}}_i(\tau)+g_{\check{r}\check{s}}(\tau,\vec{\sigma})\,\dot{\eta}^{\check{r}}_i(\tau)\,\dot{\eta}^{\check{s}}_i(\tau)},$$

$$L(\tau)=-\sum_{i=1}^N\,m_i\sqrt{g_{\tau\tau}(\tau,\vec{\eta}_i(\tau))+2g_{\tau\check{r}}(\tau,\vec{\eta}_i(\tau))\,\dot{\eta}^{\check{r}}_i(\tau)+g_{\check{r}\check{s}}(\tau,\vec{\eta}_i(\tau))\,\dot{\eta}^{\check{r}}_i(\tau)\,\dot{\eta}^{\check{s}}_i(\tau)},\tag{2.1}$$

where the configuration variables are $z^\mu(\tau,\vec{\sigma})$ and $\vec{\eta}_i(\tau)$, $i=1,...,N$. The action is invariant under separate τ- and $\vec{\sigma}$-reparametrizations.

The canonical momenta are

$$\rho_\mu(\tau,\vec{\sigma})=-\frac{\partial\mathcal{L}(\tau,\vec{\sigma})}{\partial z^\mu_\tau(\tau,\vec{\sigma})}=\sum_{i=1}^N\,\delta^3(\vec{\sigma}-\vec{\eta}_i(\tau))m_i$$
$$\times\frac{z_{\tau\mu}(\tau,\vec{\sigma})+z_{\check{r}\mu}(\tau,\vec{\sigma})\,\dot{\eta}^{\check{r}}_i(\tau)}{\sqrt{g_{\tau\tau}(\tau,\vec{\sigma})+2g_{\tau\check{r}}(\tau,\vec{\sigma})\,\dot{\eta}^{\check{r}}_i(\tau)+g_{\check{r}\check{s}}(\tau,\vec{\sigma})\,\dot{\eta}^{\check{r}}_i(\tau)\,\dot{\eta}^{\check{s}}_i(\tau)}}$$
$$=[(\rho_\nu l^\nu)l_\mu+(\rho_\nu z^\nu_{\check{r}})\gamma^{\check{r}\check{s}}z_{\check{s}\mu}](\tau,\vec{\sigma}),$$

$$\kappa_{i\check{r}}(\tau)=-\frac{\partial L(\tau)}{\partial\dot{\eta}^{\check{r}}_i(\tau)}=m_i\frac{g_{\tau\check{r}}(\tau,\vec{\eta}_i(\tau))+g_{\check{r}\check{s}}(\tau,\vec{\eta}_i(\tau))\,\dot{\eta}^{\check{s}}_i(\tau)}{\sqrt{g_{\tau\tau}(\tau,\vec{\eta}_i(\tau))+2g_{\tau\check{r}}(\tau,\vec{\eta}_i(\tau))\,\dot{\eta}^{\check{r}}_i(\tau)+g_{\check{r}\check{s}}(\tau,\vec{\eta}_i(\tau))\,\dot{\eta}^{\check{r}}_i(\tau)\,\dot{\eta}^{\check{s}}_i(\tau)}},$$

$$\{z^\mu(\tau,\vec{\sigma}),\rho_\nu(\tau,\vec{\sigma}')\}=-\eta^\mu_\nu\delta^3(\vec{\sigma}-\vec{\sigma}'),\tag{2.2}$$

$$\{\eta^{\check{r}}_i(\tau),\kappa_{j\check{s}}(\tau)\}=-\delta_{ij}\delta^{\check{r}}_{\check{s}}.$$

The canonical Hamiltonian H_c is zero, the Dirac Hamiltonian is given by Eq. (A9) [there are no other system-dependent primary constraints] and Eq. (A8) becomes

$$\mathcal{H}_\mu(\tau,\vec{\sigma})=\rho_\mu(\tau,\vec{\sigma})-l_\mu(\tau,\vec{\sigma})\sum_{i=1}^{N}\delta^3(\vec{\sigma}-\vec{\eta}_i(\tau))\sqrt{m_i^2-\gamma^{\check{r}\check{s}}(\tau,\vec{\sigma})\kappa_{i\check{r}}(\tau)\kappa_{i\check{s}}(\tau)}$$

$$-z_{\check{r}\mu}(\tau,\vec{\sigma})\gamma^{\check{r}\check{s}}(\tau,\vec{\sigma})\sum_{i=1}^{N}\delta^3(\vec{\sigma}-\vec{\eta}_i(\tau))\kappa_{i\check{s}}\approx 0. \tag{2.3}$$

The conserved Poincaré generators are

$$p_s^\mu=\int \mathrm{d}^3\sigma\rho^\mu(\tau,\vec{\sigma}),$$

$$J_s^{\mu\nu}=\int \mathrm{d}^3\sigma[z^\mu(\tau,\vec{\sigma})\rho^\nu(\tau,\vec{\sigma})-z^\nu(\tau,\vec{\sigma})\rho^\mu(\tau,\vec{\sigma})]. \tag{2.4}$$

After the restriction to spacelike hyperplanes, the Dirac Hamiltonian is reduced to Eq. (A13) with the surviving ten constraints given by

$$\tilde{\mathcal{H}}^\mu(\tau)=\int \mathrm{d}^3\sigma\mathcal{H}^\mu(\tau,\vec{\sigma})=p_s^\mu-l^\mu\sum_{i=1}^{N}\sqrt{m_i^2+\vec{\kappa}_i^2(\tau)}+b_{\check{r}}^\mu(\tau)\sum_{i=1}^{N}\kappa_{i\check{r}}(\tau)\approx 0,$$

$$\tilde{\mathcal{H}}^{\mu\nu}(\tau)=b_{\check{r}}^\mu(\tau)\int \mathrm{d}^3\sigma\sigma^{\check{r}}\mathcal{H}^\nu(\tau,\vec{\sigma})-b_{\check{r}}^\nu(\tau)\int \mathrm{d}^3\sigma\sigma^{\check{r}}\mathcal{H}^\mu(\tau,\vec{\sigma})=S_s^{\mu\nu}(\tau)-[b_{\check{r}}^\mu(\tau)b_\tau^\nu$$

$$-b_{\check{r}}^\nu(\tau)b_\tau^\mu]\sum_{i=1}^{N}\eta_i^{\check{r}}(\tau)\sqrt{m_i^2+\vec{\kappa}_i^2(\tau)}-[b_{\check{r}}^\mu(\tau)b_{\check{s}}^\nu(\tau)-b_{\check{r}}^\nu(\tau)b_{\check{s}}^\mu(\tau)]\sum_{i=1}^{N}\eta_i^{\check{r}}(\tau)\kappa_i^{\check{s}}(\tau)\approx 0. \tag{2.5}$$

Here $S_s^{\mu\nu}$ is the spin part of the Lorentz generators

$$J_s^{\mu\nu}=x_s^\mu p_s^\nu-x_s^\nu p_s^\mu+S_s^{\mu\nu},$$

$$S_s^{\mu\nu}=b_{\check{r}}^\mu(\tau)\int \mathrm{d}^3\sigma\ \sigma^{\check{r}}\rho^\nu(\tau,\vec{\sigma})-b_{\check{r}}^\nu(\tau)\int \mathrm{d}^3\sigma\ \sigma^{\check{r}}\rho^\mu(\tau,\vec{\sigma}). \tag{2.6}$$

On the Wigner hyperplane, we obtain the following constraints and Dirac Hamiltonian:[9,26]

$$\tilde{\mathcal{H}}^\mu(\tau)=p_s^\mu-u^\mu(p_s)\sum_{i=1}^{N}\sqrt{m_i^2+\vec{\kappa}_i^2}+\epsilon_r^\mu(u(p_s))\sum_{i=1}^{N}\kappa_{ir}$$

$$=u^\mu(p_s)\left[\epsilon_s-\sum_{i=1}^{N}\sqrt{m_i^2+\vec{\kappa}_i^2}\right]+\epsilon_r^\mu(u(p_s))\sum_{i=1}^{N}\kappa_{ir}\approx 0,$$

or

$$\epsilon_s-M_{\mathrm{sys}}\approx 0,\quad M_{\mathrm{sys}}=\sum_{i=1}^{N}\sqrt{m_i^2+\vec{\kappa}_i^2},$$

$$\vec{p}_{\mathrm{sys}}=\vec{\kappa}_+=\sum_{i=1}^{N}\vec{\kappa}_i\approx 0,$$

$$H_D=\lambda^\mu(\tau)\tilde{\mathcal{H}}_\mu(\tau)=\lambda(\tau)[\epsilon_s-M_{\rm sys}]-\vec{\lambda}(\tau)\sum_{i=1}^N \vec{\kappa}_i,$$

$$\lambda(\tau)\approx-\dot{x}_{s\mu}(\tau)u^\mu(p_s),$$

$$\lambda_r(\tau)\approx-\dot{x}_{s\mu}(\tau)\epsilon^\mu_r(u(p_s)),\quad \dot{\tilde{x}}^\mu_s(\tau)=-\lambda(\tau)u^\mu(p_s),$$

$$\dot{x}^\mu_s(\tau)\approx-\tilde{\lambda}^\mu(\tau)=-\lambda(\tau)u^\mu(p_s)+\epsilon^\mu_r(u(p_s))\lambda_r(\tau). \tag{2.7}$$

While the Dirac multiplier $\lambda(\tau)$ is determined by the gauge fixing $T_s-\tau\approx0$, the three Dirac's multipliers $\vec{\lambda}(\tau)$ describe the *classical zitterbewegung* of the centroid $x^\mu_s(\tau)$ which is the origin of the three-coordinates on the Wigner hyperplane: each gauge-fixing $\vec{\chi}(\tau)\approx0$ to the three first class constraints $\vec{\kappa}_+\approx0$ (defining the *internal rest-frame*) gives a different determination of the multipliers $\vec{\lambda}(\tau)$ and therefore identifies a different world-line $x^{(\vec{\chi})\mu}_s(\tau)$ for the covariant non-canonical centroid.

The embedding describing Wigner hyperplanes is $z^\mu(\tau,\vec{\sigma})=x^\mu_s(\tau)+\epsilon^\mu_r(u(p_s))\sigma^r$, with the $\epsilon^\mu_r(u(p_s))$ defined in Eqs. (A24).

The various spin tensors and vectors are[9]

$$J^{\mu\nu}_s=x^\mu_s p^\nu_s-x^\nu_s p^\mu_s+S^{\mu\nu}_s=\tilde{x}^\mu_s p^\nu_s-\tilde{x}^\nu_s p^\mu_s+\tilde{S}^{\mu\nu}_s,$$

$$\begin{aligned}S^{\mu\nu}_s&=[u^\mu(p_s)\epsilon^\nu(u(p_s))-u^\nu(p_s)\epsilon^\mu(u(p_s))]\overline{S}^{\tau r}_s+\epsilon^\mu(u(p_s))\epsilon^\nu(u(p_s))\overline{S}^{rs}_s\\&\equiv[\epsilon^\mu_r(u(p_s))u^\nu(p_s)-\epsilon^\nu(u(p_s))u^\mu(p_s)]\sum_{i=1}^N \eta^r_i\sqrt{m^2_ic^2+\vec{\kappa}^2_i}\\&\quad+[\epsilon^\mu_r(u(p_s))\epsilon^\nu_s(u(p_s))-\epsilon^\nu_r(u(p_s))\epsilon^\mu_r(u(p_s))]\sum_{i=1}^N \eta^r_i\kappa^s_i,\end{aligned}$$

$$\overline{S}^{AB}_s=\epsilon^A_\mu(u(p_s))\epsilon^B_\nu(u(p_s))S^{\mu\nu}_s, \tag{2.8}$$

$$\overline{S}^{rs}_s\equiv\sum_{i=1}^N(\eta^r_i\kappa^s_i-\eta^s_i\kappa^r_i),\quad \overline{S}^{\tau r}_s\equiv-\sum_{i=1}^N\eta^r_i\sqrt{m^2_ic^2+\vec{\kappa}^2_i},$$

$$\tilde{S}^{\mu\nu}_s=S^{\mu\nu}_s+\frac{1}{\sqrt{\epsilon p^2_s}(p^0_s+\sqrt{\epsilon p^2_s})}[p_{s\beta}(S^{\beta\mu}_s p^\nu_s-S^{\beta\nu}_s p^\mu_s)+\sqrt{p^2_s}(S^{0\mu}_s p^\nu_s-S^{0\nu}_s p^\mu_s)],$$

$$\tilde{S}^{ij}_s=\delta^{ir}\delta^{js}\overline{S}^{rs}_s,\quad \tilde{S}^{0i}_s=-\frac{\delta^{ir}\overline{S}^{rs}_s p^s_s}{p^0_s+\sqrt{\epsilon p^2_s}},$$

$$\vec{\tilde{S}}\equiv\vec{\tilde{S}}=\sum_{i+1}^N\vec{\eta}_i\times\vec{\kappa}_i\approx\sum_{i=1}^N\vec{\eta}_i\times\vec{\kappa}_i-\vec{\eta}_+\times\vec{\kappa}_+=\sum_{a=1}^{N-1}\vec{\rho}_a\times\vec{\pi}_a.$$

Note that while $L^{\mu\nu}_s=x^\mu_s p^\nu_s-x^\nu_s p^\mu_s$ and $S^{\mu\nu}_s$ are not constants of the motion due to the *classical zitterbewegung*, both $\tilde{L}^{\mu\nu}_s=\tilde{x}^\mu_s p^\nu_s-\tilde{x}^\nu_s p^\mu_s$ and $\tilde{S}^{\mu\nu}_s$ are conserved.

The only remaining canonical variables describing the Wigner hyperplane in the final Dirac brackets are the noncovariant canonical coordinates $\tilde{x}^\mu_s(\tau)$ and p^μ_s. The point with coordinates $\tilde{x}^\mu_s(\tau)$ is the decoupled canonical *external four-center of mass*, playing the role of a kinematical

external four-center of mass and of a decoupled observer with his parametrized clock (*point particle clock*). Its velocity $\dot{\tilde{x}}^\mu_s(\tau)$ is parallel to p^μ_s, so that it has no *classical zitterbewegung*. The connection between the centroid $x^\mu_s(\tau)$ and $\tilde{x}^\mu_s(\tau)$ is given in Eq. (4.1).

After the separation of the relativistic canonical noncovariant *external* four-center of mass $\tilde{x}^\mu_s(\tau)$, on the Wigner hyperplane the N particles are described by the $6N$ Wigner spin-one-three-vectors $\vec{\eta}_i(\tau)$, $\vec{\kappa}_i(\tau)$ restricted by the rest-frame condition $\vec{\kappa}_+ = \Sigma_{i=1}^N \vec{\kappa}_i \approx 0$.

The canonical variables $\tilde{x}^\mu_s$, p^μ_s for the *external* four-center of mass may be replaced by the canonical pairs[28]

$$T_s = \frac{p_s \cdot \tilde{x}_s}{\epsilon_s} = \frac{p_s \cdot x_s}{\epsilon_s}, \quad \epsilon_s = \pm\sqrt{\epsilon p_s^2},$$
$$\vec{z}_s = \epsilon_s \left(\vec{\tilde{x}}_s - \frac{\vec{p}_s}{p^0_s} \tilde{x}^0_s \right), \quad \vec{k}_s = \frac{\vec{p}_s}{\epsilon_s}, \tag{2.9}$$

with the inverse transformation

$$\tilde{x}^0_s = \sqrt{1+\vec{k}_s^2} \left(T_s + \frac{\vec{k}_s \cdot \vec{z}_s}{\epsilon_s} \right), \quad p^0_s = \epsilon_s \sqrt{1+\vec{k}_s^2},$$
$$\vec{\tilde{x}}_s = \frac{\vec{z}_s}{\epsilon_s} + \left(T_s + \frac{\vec{k}_s \cdot \vec{z}_s}{\epsilon_s} \right) \vec{k}_s, \quad \vec{p}_s = \epsilon_s \vec{k}_s . \tag{2.10}$$

This nonpoint canonical transformation in the rest-frame instant form can be summarized as $[\epsilon_s - M_{\rm sys} \approx 0,\ \vec{\kappa}_+ = \Sigma_{i=1}^N \vec{\kappa}_i \approx 0]$

$$\left| \begin{array}{c|c|c} \tilde{x}^\mu_s & \vec{\eta}_i \\ \hline p^\mu_s & \vec{\kappa}_i \end{array} \right| \longrightarrow \left| \begin{array}{c|c|c} \epsilon_s & \vec{z}_s & \vec{\eta}_i \\ \hline T_s & \vec{k}_s & \vec{\kappa}_i \end{array} \right| \quad . \tag{2.11}$$

The invariant mass $M_{\rm sys}$ of the system, which is also its *internal* energy, replaces the nonrelativistic Hamiltonian $H_{\rm rel}$ for the relative degrees of freedom, after the addition of the gauge-fixing $T_s - \tau \approx 0$.[29] This recalls the frozen Hamilton–Jacobi theory, in which the time evolution can be reintroduced by using the energy generator of the Poincaré group as Hamiltonian (see Refs. 30 for a different derivation of this result).

After the gauge fixings $T_s - \tau \approx 0$, the final Hamiltonian and the embedding of the Wigner hyperplane into Minkowski space–time become

$$H_D = M_{\rm sys} - \vec{\lambda}(\tau) \cdot \vec{\kappa}_+ ,$$
$$z^\mu(\tau, \vec{\sigma}) = x^\mu_s(\tau) + \epsilon^\mu_r(u(p_s))\sigma^r = x^\mu_s(0) + u^\mu(p_s)\tau + \epsilon^\mu_r(u(p_s))\sigma^r,$$

with

$$\dot{x}^\mu_s(\tau) = \frac{\overset{\circ}{\mathrm{d}} x^\mu_s(\tau)}{\mathrm{d}\tau} + \{x^\mu_s(\tau), H_D\} = u^\mu(p_s) + \epsilon^\mu_r(u(p_s))\lambda_r(\tau), \tag{2.12}$$

where $x^\mu_s(0)$ is an arbitrary point and $\epsilon^\mu_r(u(p_s)) = L^\mu{}_r(p_s, \mathring{p}_s)$. This equation visualizes the role of the Dirac multipliers as sources of the *classical zitterbewegung* and consequently the *gauge nature* of the latter. Let us remark that the constant $x^\mu_s(0)$ [and $\tilde{x}^\mu_s(0)$] is arbitrary, reflecting the arbitrariness in the absolute location of the origin of the *internal* coordinates on each hyperplane in Minkowski space–time.

The particles' world lines in Minkowski space–time and the associated momenta are then

$$\begin{aligned} &{}^{\mu}_{i}(\tau)=z^{\mu}(\tau,\vec{\eta}_i(\tau))=x^{\mu}_{s}(\tau)+\epsilon^{\mu}_{r}(u(p_s))\,\eta^{r}_{i}(\tau),\\ &p^{\mu}_{i}(\tau)=\sqrt{m^2_i+\vec{\kappa}^2_i(\tau)}\,u^{\mu}(p_s)+\epsilon^{\mu}_{r}(u(p_s))\,\kappa_{ir}(\tau)\Rightarrow \epsilon p^2_i=m^2_i\,. \end{aligned} \tag{2.13}$$

Inside the Wigner hyperplane three degrees of freedom of the isolated system, describing an *internal* center-of-mass three-variable $\vec{\sigma}_{\rm com}$ conjugate to $\vec{\kappa}_+$ (when the $\vec{\sigma}_{\rm com}$ are canonical variables they are denoted $\vec{q}_+$), are *gauge* variables. The natural gauge fixing in order to eliminate the three first class constraints $\vec{\kappa}_+\approx 0$ is $\vec{\chi}=\vec{q}_+\approx 0$, which implies $\lambda_r(\tau)=0$: in this way the *internal* three-center of mass gets located in the centroid $x^{\mu}_s(\tau)=z^{\mu}(\tau,\vec{\sigma}=0)$ of the Wigner hyperplane. The determination of $\vec{q}_+$ for the N particle system will be carried through by the group theoretical methods of Ref. 31 in the next section.[32–34]

It turns out that the Wigner hyperplane is the natural setting for the study of the Dixon multipoles of extended relativistic systems[35] (Dixon's multipoles for the N-body problem are studied in Ref. 36) and the definition of their canonical relative variables with respect to the center of mass. Note, incidentally, that the Euclidean metric structure of the Wigner hyperplane offers a natural solution to the problem of boost for lattice gauge theories and explicitly realizes the Machian view of dynamics according to which only relative motions are relevant.

The *external* rest-frame instant form realization of the Poincaré generators[37] with nonfixed invariants $\epsilon p^2_s=\epsilon^2_s\approx M^2_{\rm sys}$ and $W^2=-\epsilon p^2_s\vec{\bar{S}}^2_s\approx -\epsilon M^2_{\rm sys}\vec{\bar{S}}^2$, is obtained from Eq. (2.8):

$$\begin{aligned} &p^{\mu}_s\,,\quad J^{\mu\nu}_s=\tilde{x}^{\mu}_s p^{\nu}_s-\tilde{x}^{\nu}_s p^{\mu}_s+\tilde{S}^{\mu\nu}_s\,,\\ &p^0_s=\sqrt{\epsilon^2_s+\vec{p}^2_s}=\epsilon_s\sqrt{1+\vec{k}^2_s}\approx\sqrt{M^2_{\rm sys}+\vec{p}^2_s}=M_{\rm sys}\sqrt{1+\vec{k}^2_s},\\ &\vec{p}_s=\epsilon_s\vec{k}_s\approx M_{\rm sys}\vec{k}_s\,,\\ &J^{ij}_s=\tilde{x}^i_s p^j_s-\tilde{x}^j_s p^i_s+\delta^{ir}\delta^{js}\sum_{i=1}^{N}\,(\eta^r_i\kappa^s_i-\eta^s_i\kappa^r_i)=z^i_s k^j_s-z^j_s k^i_s+\delta^{ir}\delta^{js}\epsilon^{rsu}\bar{S}^u_s\,, \end{aligned} \tag{2.14}$$

$$\begin{aligned} K^i_s=J^{0i}_s=\tilde{x}^0_s p^i_s-\tilde{x}^i_s\sqrt{\epsilon^2_s+\vec{p}^2_s}-\frac{1}{\epsilon_s+\sqrt{\epsilon^2_s+\vec{p}^2_s}}\,\delta^{ir}p^s_s\sum_{i=1}^{N}\,(\eta^r_i\kappa^s_i-\eta^s_i\kappa^r_i)=-\sqrt{1+\vec{k}^2_s}\,z^i_s-\frac{\delta^{ir}k^s_s\epsilon^{rsu}\bar{S}^u_s}{1+\sqrt{1+\vec{k}^2_s}}\\ \approx\tilde{x}^0_s p^i_s-\tilde{x}^i_s\sqrt{M^2_{\rm sys}+\vec{p}^2_s}-\frac{\delta^{ir}p^s_s\epsilon^{rsu}\bar{S}^u_s}{M_{\rm sys}+\sqrt{M^2_{\rm sys}+\vec{p}^2_s}}\,. \end{aligned}$$

On the other hand, the *internal* realization of the Poincaré algebra is built inside the Wigner hyperplane by using the expression of $\bar{S}^{AB}_s$ given by Eq. (2.8)

$$\begin{aligned} &M_{\rm sys}=H_M=\sum_{i=1}^{N}\,\sqrt{m^2_i+\vec{\kappa}^2_i},\\ &\vec{\kappa}_+=\sum_{i=1}^{N}\,\vec{\kappa}_i(\approx 0),\\ &\vec{J}=\sum_{i=1}^{N}\,\vec{\eta}_i\times\vec{\kappa}_i\,,\quad J^r=\bar{S}^r=\frac{1}{2}\,\epsilon^{ruv}\bar{S}^{uv}\equiv\bar{S}^r_s\,,\\ &\vec{K}=-\sum_{i=1}^{N}\,\sqrt{m^2_i+\vec{\kappa}^2_i}\,\vec{\eta}_i\,,\quad K^r=J^{0r}=\bar{S}^{\tau r}_s\,, \end{aligned}$$

$$\Pi = M_{\rm sys}^2 - \vec{\kappa}_+^2 \approx M_{\rm sys}^2 > 0, \quad W^2 = -\epsilon (M_{\rm sys}^2 - \vec{\kappa}_+^2)\vec{S}_s^2 \approx -\epsilon M_{\rm sys}^2 \vec{S}_s^2 . \tag{2.15}$$

The meaning of the constraints $\epsilon_s - M_{\rm sys} \approx 0$, $\vec{\kappa}_+ \approx 0$ is the following.

(i) The constraint $\epsilon_s - M_{\rm sys} \approx 0$ is the bridge connecting the *external* and *internal* realizations. The external spin coincides with the internal angular momentum due to Eq. (A16).

(ii) The constraints $\vec{\kappa}_+ \approx 0$, together with $\vec{K} \approx 0$, leads to an unfaithful *internal* realization in which the only non-null generators are the conserved energy and the spin of the isolated system. As we shall see in the next section, $\vec{K} \approx 0$ is implied by the natural gauge fixing $\vec{q}_+ \approx 0$: this makes the internal realization even more unfaithful.

For isolated systems the constraint manifold[38] is a stratified manifold with each stratum corresponding to a type of Poincaré orbit. The main stratum (dense in the constraint manifold) corresponds to all configurations of the isolated system belonging to timelike Poincaré orbits with $\epsilon p_s^2 \approx \epsilon M_{\rm sys}^2 > 0$. As said in Ref. 39, this implies that the center-of-mass coordinates have been adapted to the co-adjoint orbits of the Poincaré group. But, since the second Poincaré invariant (the Pauli–Lubanski invariant $\vec{W}_s^2 = -p_s^2 \vec{S}_s^2$) does not appear among the canonical variables, this canonical basis is not adapted, as yet, to a typical form of canonical action of the Poincaré group[31] on the phase space of the isolated system. As shown in Ref. 39, it possible to construct a canonical basis including both Poincaré invariants in such a way that all of the coordinates are adapted to the co-adjoint action of the group and the new relative variables are thereby adapted to the SO(3) group.

Let us now make here a first simplified attempt to construct the relative variables: the complete solution is in Sec. V. In Ref. 9 a naive *internal* center-of-mass variable $\vec{\eta}_+ = 1/N \sum_{i=1}^N \vec{\eta}_i$ has been introduced together with the definition of relative variables $\vec{\rho}_a$, $\vec{\pi}_a$ based on the following point canonical transformation:

$$\begin{array}{|c|} \hline \vec{\eta}_i \\ \hline \vec{\kappa}_i \\ \hline \end{array} \longrightarrow \begin{array}{|c|c|} \hline \vec{\eta}_+ & \vec{\rho}_a \\ \hline \vec{\kappa}_+ & \vec{\pi}_a \\ \hline \end{array} \quad , \qquad a = 1,\ldots, N-1$$

$$\vec{\eta}_i = \vec{\eta}_+ + \frac{1}{\sqrt{N}} \sum_{a=1}^{N-1} \gamma_{ai} \vec{\rho}_a , \quad \vec{\kappa}_i = \frac{1}{N} \vec{\kappa}_+ + \sqrt{N} \sum_{a=1}^{N-1} \gamma_{ai} \vec{\pi}_a ,$$

$$\vec{\eta}_+ = \frac{1}{N} \sum_{i=1}^{N} \vec{\eta}_i , \quad \vec{\kappa}_+ = \sum_{i=1}^{N} \vec{\kappa}_i \approx 0,$$

$$\vec{\rho}_a = \sqrt{N} \sum_{i=1}^{N} \gamma_{ai} \vec{\eta}_i , \quad \vec{\pi}_a = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \gamma_{ai} \vec{\kappa}_i ,$$

$$\{\eta_i^r, \kappa_j^s\} = \delta_{ij} \delta^{rs}, \quad \{\eta_+^r, \kappa_+^s\} = \delta^{rs}, \quad \{\rho_a^r, \pi_b^s\} = \delta_{ab} \delta^{rs},$$

$$\sum_{i=1}^{N} \gamma_{ai} = 0, \quad \sum_{a=1}^{N-1} \gamma_{ai} \gamma_{aj} = \delta_{ij} - \frac{1}{N}, \quad \sum_{i=1}^{N} \gamma_{ai} \gamma_{bi} = \delta_{ab} . \tag{2.16}$$

This is a family of canonical transformations depending on $\frac{1}{2}(N-1)(N-2)$ free parameters (the independent parameters in the γ_{ai} of Ref. 6).

In the gauge

$$T_s - \tau \approx 0, \tag{2.17}$$

[which entails $0\approx\dot{T}_s-1=\dot{x}_s\cdot u(p_s)-1=-\lambda(\tau)-1$; after going to Dirac brackets we get $T_s\equiv\tau$ and $\epsilon_s\equiv\pm M_{\rm sys}$], the Hamiltonian and the rest-frame constraints become

$$H_D=M_{\rm sys}-\vec{\lambda}(\tau)\cdot\vec{\kappa}_+,\quad \vec{\kappa}_+\approx 0, \tag{2.18}$$

with the invariant mass given by

$$M_{\rm sys}=H_M=\sum_{i=1}^{N}\sqrt{m_i^2+\vec{\kappa}_i^2}=\sum_{i=1}^{N}\sqrt{m_i^2+\left[\frac{1}{N}\vec{\kappa}_+ +\sqrt{N}\sum_{a=1}^{N-1}\gamma_{ai}\vec{\pi}_a\right]^2}$$
$$\approx\sum_{i=1}^{N}\sqrt{m_i^2+N\sum_{a,b}^{1..N-1}\gamma_{ai}\gamma_{bi}\vec{\pi}_a\cdot\vec{\pi}_b}. \tag{2.19}$$

The centroid, origin of the three-coordinates, results

$$x_s^\mu(T_s)=x_s^\mu(0)+u^\mu(p_s)T_s+\epsilon_r^\mu(u(p_s))\int_0^{T_s}d\tau\,\lambda_r(\tau). \tag{2.20}$$

It can be checked that, if we add the gauge fixings $\vec{\eta}_+\approx 0$ and use Hamilton's equations, their time constancy does not imply $\vec{\lambda}(\tau)=0$. *Therefore* $\vec{\sigma}_{\rm sys}=\vec{\eta}_+$ *is not the searched natural gauge fixing* $\vec{q}_+\approx 0$ *for the separation of the center-of-mass motion.*

In Sec. III we construct the natural canonical *internal* three-center-of-mass variable $\vec{q}_+$ (replacing the naive $\vec{\eta}_+$): its vanishing implies $\vec{\lambda}(\tau)=0$. It will be seen that, unlike in the nonrelativistic theory, $\vec{q}_+$ is not a linear combination of the $\vec{\eta}_i$'s with coefficients depending on the masses, but is connected to the Møller *internal* three-center of energy, with the masses replaced by the particle energies.

III. THE *INTERNAL* RELATIVISTIC CENTER-OF-MASS VARIABLES ON THE WIGNER HYPERPLANE

As we have seen, in the relativistic case of N free scalar particles with positive energy, the Hamiltonian kinetic energy is not a quadratic form in the momenta and the Lagrangian form is unknown. The first problem is to separate the global translations: this is the old problem of the definition of a relativistic center of mass. As already said, the rest-frame instant form of dynamics allows one to clarify the problem by splitting the concept of relativistic center of mass into an *external* one (a pseudo-four-vector) and an *internal* one (a Wigner spin-one-three-vector).

The determination of the *internal* three-center of mass can be achieved using the group theoretical methods of Ref. 31 (see also Ref. 15). Given a canonical realization of the ten Poincaré generators, only three three-position variables are definable in terms of them alone, namely:

(i) a canonical *internal* center of mass (or *center of spin*) $\vec{q}_+$; it is the classical analog[19,20] of the Newton–Wigner position operator;[16]
(ii) a noncanonical *internal* Møller *center of energy* $\vec{R}_+$;[17]
(iii) a noncanonical *internal* Fokker–Pryce *center of inertia* $\vec{y}_+$.[18,19]

We shall see that on Wigner hyperplanes, due to $\vec{\kappa}_+\approx 0$, all of them coincide: $\vec{q}_+\approx\vec{R}_+\approx\vec{y}_+$.

Following Ref. 31 we shall determine $\vec{R}_+$, $\vec{q}_+$, $\vec{y}_+$ starting from the *internal* realization (2.15) of the Poincaré algebra. We get the following Wigner spin-one three-vectors:

(i) The *internal* Møller three-center of energy and the associated spin vector

$$\vec{R}_+ = -\frac{1}{M_{\rm sys}}\vec{K} = \frac{\Sigma_{i=1}^N \sqrt{m_i^2+\vec{\kappa}_i^2}\,\vec{\eta}_i}{\Sigma_{k=1}^N \sqrt{m_k^2+\vec{\kappa}_k^2}},$$

$$\vec{S}_R = \vec{J} - \vec{R}_+ \times \vec{\kappa}_+ ,$$

$$\{R_+^r, \kappa_+^s\} = \delta^{rs}, \quad \{R_+^r, M_{\rm sys}\} = \frac{\kappa_+^r}{M_{\rm sys}}, \quad \{R_+^r, R_+^s\} = -\frac{1}{M_{\rm sys}^2}\epsilon^{rsu} S_R^u , \tag{3.1}$$

$$\{S_R^r, S_R^s\} = \epsilon^{rsu}\left(S_R^u - \frac{1}{M_{\rm sys}^2}\vec{S}_R\cdot\vec{\kappa}_+\,\kappa_+^u \right), \quad \{S_R^r, M_{\rm sys}\} = 0.$$

Note that the gauge fixing $\vec{R}_+ \approx 0$ gives

$$\vec{R}_+ \approx 0 \Rightarrow \mathring{\vec{R}}_+ = \{\vec{R}_+, H_D\} = \frac{\vec{\kappa}_+}{\Sigma_{k=1}^N \sqrt{m_k^2+\vec{\kappa}_k^2}} - \vec{\lambda}(\tau)\frac{\Sigma_{i=1}^N \sqrt{m_i^2+\vec{\kappa}_i^2}}{\Sigma_{k=1}^N \sqrt{m_k^2+\vec{\kappa}_k^2}} \approx -\vec{\lambda}(\tau) \approx 0. \tag{3.2}$$

Furthermore, the *internal* boost generator of Eq. (2.15) may be rewritten as $\vec{K} = -M_{\rm sys}\vec{R}_+$, so that $\vec{R}_+ \approx 0$ implies $\vec{K} \approx 0$.

(ii) The canonical *internal* three-center of mass[41] and the associated spin vector

$$\vec{q}_+ = \vec{R}_+ - \frac{\vec{J}\times\vec{\Omega}}{\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}(M_{\rm sys}+\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2})} = -\frac{\vec{K}}{\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}} + \frac{\vec{J}\times\vec{\kappa}_+}{\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}(M_{\rm sys}+\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2})}$$

$$+ \frac{\vec{K}\cdot\vec{\kappa}_+\,\vec{\kappa}_+}{M_{\rm sys}\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}(M_{\rm sys}+\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2})} \approx \vec{R}_+ \quad \text{for} \quad \vec{\kappa}_+ \approx 0, \quad \{\vec{q}_+, M_{\rm sys}\} = \frac{\vec{\kappa}_+}{M_{\rm sys}},$$

$$\vec{S}_q = \vec{J} - \vec{q}_+\times\vec{\kappa}_+ = \frac{M_{\rm sys}\vec{J}}{\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}} + \frac{\vec{K}\times\vec{\kappa}_+}{\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}} - \frac{\vec{J}\cdot\vec{\kappa}_+\,\vec{\kappa}_+}{\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}(M_{\rm sys}+\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2})} \approx \vec{\vec{S}} = \vec{J},$$

$$\{\vec{S}_q, \vec{\kappa}_+\} = \{\vec{S}_q, \vec{q}_+\} = 0, \quad \{S_q^r, S_q^s\} = \epsilon^{rsu} S_q^u . \tag{3.3}$$

Let us recall that the *scheme A* for the *internal* realization of the Poincaré group[31] contains the canonical pairs $\vec{\kappa}_+$, $\vec{q}_+$, S_q^3, $\mathrm{arctg}\,(S_q^2/S_q^1)$, and the two Casimirs invariants $|\vec{S}_q| = \sqrt{-W^2/M_{\rm sys}^2}$, $M_{\rm sys} = \Sigma_{i=1}^N \sqrt{m_i^2+\vec{\kappa}_i^2}$ [see Eq. (3.4)].

(iii) The *internal* noncanonical Fokker–Pryce center of inertia $\vec{y}_+$,

$$\vec{y}_+ = \vec{q}_+ + \frac{\vec{S}_q\times\vec{\kappa}_+}{\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}(M_{\rm sys}+\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2})} = \vec{R}_+ + \frac{\vec{S}_q\times\vec{\kappa}_+}{M_{\rm sys}\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}},$$

$$\vec{q}_+ = \vec{R}_+ + \frac{\vec{S}_q\times\vec{\kappa}_+}{M_{\rm sys}(M_{\rm sys}+\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2})} = \frac{M_{\rm sys}\vec{R}_+ + \sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}\,\vec{y}_+}{M_{\rm sys}+\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}},$$

$$\{y_+^r, y_+^s\} = \frac{1}{M_{\rm sys}\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}}\epsilon^{rsu}\left[S_q^u + \frac{\vec{S}_q\cdot\vec{\kappa}_+\kappa_+^u}{\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2}(M_{\rm sys}+\sqrt{M_{\rm sys}^2-\vec{\kappa}_+^2})}\right], \tag{3.4}$$

$$\vec{\kappa}_+ \approx 0 \Rightarrow \vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+ .$$

We see that the gauge fixings $\vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+ \approx 0$ imply $\vec{\lambda}(\tau) \approx 0$ and force the three *internal* collective variables to coincide with the centroid, origin of the three-coordinates, which now becomes

$$x_s^{(\vec{q}_+)\mu}(T_s) = x_s^\mu(0) + u^\mu(p_s) T_s \,. \tag{3.5}$$

It can also be shown that the *centroid* $x_s^\mu(\tau)$ coincides with the *Dixon center of mass* of an extended object[42] as well as with the *Pirani*[43] and the *Tulczyjew*[44] *centroids* (the Dixon multipoles for the *N*-body problem on the Wigner hyperplane are studied in Ref. 36).

We are left with the construction of a canonical transformation bringing from the basis $\vec{\eta}_i$, $\vec{\kappa}_i$, to a new canonical basis $\vec{q}_+$, $\vec{\kappa}_+ (\approx 0)$, $\vec{\rho}_{q,a}$, $\vec{\pi}_{q,a}$, in which $\vec{S}_q = \Sigma_{a=1}^{N-1} \vec{\rho}_{q,a} \times \vec{\pi}_{q,a}$:

$$\begin{array}{|c|}\hline \vec{\eta}_i \\ \hline \vec{\kappa}_i \\ \hline \end{array} \longrightarrow \begin{array}{|c|c|}\hline \vec{q}_+ & \vec{\rho}_{qa} \\ \hline \vec{\kappa}_+ & \vec{\pi}_{qa} \\ \hline \end{array} \quad . \tag{3.6}$$

Let us stress that this cannot be a point transformation, because of the momentum dependence of the relativistic internal center of mass $\vec{q}_+$, realizing the effective separation of the center of mass from the relative motions in the kinetic energy.

The canonical transformation (3.6) will be constructed in Sec. V by using the method of Gartenhaus–Schwartz[23] as delineated in Ref. 45 (see Refs. 31, 45, and 23 for the $N=2$ case).

In Ref. 46 there is the nonrelativistic limit of the rest-frame Lagrangian. This allows to define the rest-frame nonrelativistic Hamiltonian. These quantities have been used in Ref. 2 [see Eq. (2.1) of Ref. 2] to describe the relative motions in the nonrelativistic rest frame. Note that in the nonrelativistic limit $\vec{q}_+$ tends to the nonrelativistic center of mass

$$\vec{q}_{\rm nr} = \frac{\Sigma_{i=1}^N m_i \vec{\eta}_i}{\Sigma_{i=1}^N m_i} .$$

In conclusion, the nonrelativistic Abelian translation symmetry generating the nonrelativistic Noether constants $\vec{P} = \text{const}$ is split at the relativistic level into the two following symmetries: (i) the *external* Abelian translation symmetry whose Noether constants of motion are $\vec{p}_s = \epsilon_s \vec{k}_s \approx M_{\rm sys} \vec{k}_s = \text{const}$ (its conjugate variable being the *external* three-center of mass $\vec{z}_s$); (ii) the *internal* Abelian gauge symmetry generating the three first class constraints $\vec{\kappa}_+ \approx 0$ (rest-frame conditions) inside the Wigner hyperplane (the conjugate *gauge* variable being the *internal* three-center of mass $\vec{q}_+ \approx \vec{R}_+ \approx \vec{y}_+$). Of course, its nonrelativistic counterpart is the nonrelativistic rest-frame condition $\vec{P} \approx 0$.

IV. THE *EXTERNAL* CENTER-OF-MASS VARIABLES ON THE WIGNER HYPERPLANE

We turn now to the localization of the *external* center-of-mass variables on the Wigner hyperplane. Recall first of all[9] that the *external* canonical noncovariant point of coordinates

$$\tilde{x}_s^\mu(\tau) = (\tilde{x}_s^0(\tau); \vec{\tilde{x}}_s(\tau)) = z^\mu(\tau, \vec{\tilde{\sigma}}) = x_s^\mu(\tau) - \frac{1}{\epsilon_s (p_s^0 + \epsilon_s)} \left[p_{s\nu} S_s^{\nu\mu} + \epsilon_s \left(S_s^{0\mu} - S_s^{0\nu} \frac{p_{s\nu} p_s^\mu}{\epsilon_s^2} \right) \right], \tag{4.1}$$

lies on the Wigner hyperplane $z^\mu(\tau, \vec{\sigma}) = x_s^\mu(\tau) + \epsilon_r^\mu(u(p_s))\sigma^r$ at some three-position $\tilde{\sigma}^r$, just like the centroid, origin of the three-coordinates, $x_s^\mu(\tau) = z^\mu(\tau, \vec{0})$, because $p_s \cdot \tilde{x}_s = p_s \cdot x_s$, see Ref. 9.

As in Eqs. (3.1), (3.3), and (3.4) one can build[31] three *external* three-variables, the canonical $\vec{q}_s$, the Møller $\vec{R}_s$, and the Fokker–Pryce $\vec{Y}_s$ by using the rest-frame realization of the Poincaré algebra given in Eq. (2.14),

$$\vec{R}_s = -\frac{1}{p_s^0}\vec{K}_s = \left(\vec{\tilde{x}}_s - \frac{\vec{p}_s}{p_s^0}\tilde{x}_s^0\right) - \frac{\vec{\bar{S}}_s \times \vec{p}_s}{p_s^0(p_s^0+\epsilon_s)},$$

$$\vec{q}_s = \vec{\tilde{x}}_s - \frac{\vec{p}_s}{p_s^0}\tilde{x}_s^0 = \frac{\vec{z}_s}{\epsilon_s} = \vec{R}_s + \frac{\vec{\bar{S}}_s \times \vec{p}_s}{p_s^0(p_s^0+\epsilon_s)} = \frac{p_s^0 \vec{R}_s + \epsilon_s \vec{Y}_s}{p_s^0+\epsilon_s},$$

$$\vec{Y}_s = \vec{q}_s + \frac{\vec{\bar{S}}_s \times \vec{p}_s}{\epsilon_s(p_s^0+\epsilon_s)} = \vec{R}_s + \frac{\vec{\bar{S}}_s \times \vec{p}_s}{p_s^0 \epsilon_s},$$

$$\{R_s^r, R_s^s\} = -\frac{1}{(p_s^0)^2}\epsilon^{rsu}\Omega_s^u, \quad \vec{\Omega}_s = \vec{J}_s - \vec{R}_s \times \vec{p}_s, \tag{4.2}$$

$$\{q_s^r, q_s^s\} = 0, \quad \{Y_s^r, Y_s^s\} = \frac{1}{\epsilon_s p_s^0}\epsilon^{rsu}\left[\bar{S}_s^u + \frac{\vec{\bar{S}}_s \cdot \vec{p}_s\, p_s^u}{\epsilon_s(p_s^0+\epsilon_s)}\right],$$

$$\vec{p}_s \cdot \vec{q}_s = \vec{p}_s \cdot \vec{R}_s = \vec{p}_s \cdot \vec{Y}_s = \vec{k}_s \cdot \vec{z}_s,$$

$$\vec{p}_s = 0 \Rightarrow \vec{q}_s = \vec{Y}_s = \vec{R}_s.$$

All of these have the same velocity and coincide in the Lorentz rest frame where $\mathring{p}_s^\mu = \epsilon_s(1;\vec{0})$.

We can now construct the following *external* four-vectors on the Wigner hyperplane:

(i) the *external* canonical noncovariant four-center of mass $\tilde{x}_s^\mu$;
(ii) the *external* noncanonical and noncovariant Møller four-center of energy R_s^μ;
(iii) the *external* covariant noncanonical Fokker–Pryce four-center of inertia Y_s^μ. It will be shown that the gauge fixings $\vec{q}_+ \approx 0$ force them to coincide with the centroid x_s^μ.

In Ref. 31, within a one-time framework without constraints and at a fixed time, it is shown that the three-vector $\vec{Y}_s$ (but not $\vec{q}_s$ and $\vec{R}_s$) satisfies the world-line condition $\{K_s^r, Y_s^s\} = (1/c^2)\, Y_s^r \{Y_s^s, p_s^0\}$ and is therefore the space part of a four-vector Y_s^μ. On the other hand, within the enlarged canonical approach including time variables, it is not clear which are the time components to be added to $\vec{q}_s$, $\vec{R}_s$, $\vec{Y}_s$, in order to rebuild four-dimensional quantities $\tilde{x}_s^\mu$, R_s^μ, Y_s^μ, in an arbitrary Lorentz frame Γ having the origin of the Wigner hyperplane coincident with the centroid four-vector $x_s^\mu = (x_s^0; \vec{x}_s)$. From Eq. (2.10), we obtain the following expressions of the noncovariant (frame-dependent) canonical four-center of mass and its conjugate momentum:

$$\tilde{x}_s^\mu(\tau) = (\tilde{x}_s^0(\tau); \vec{\tilde{x}}_s(\tau)) = x_s^\mu - \frac{1}{\epsilon_s(p_s^0+\epsilon_s)}\left[p_{s\nu} S_s^{\nu\mu} + \epsilon_s\left(S_s^{0\mu} - S_s^{0\nu}\frac{p_{s\nu}p_s^\mu}{\epsilon_s^2}\right)\right], \quad p_s^\mu,$$

$$\tilde{x}_s^0 = \sqrt{1+\vec{k}_s^2}\left(T_s + \frac{\vec{k}_s \cdot \vec{z}_s}{\epsilon_s}\right) = \sqrt{1+\vec{k}_s^2}(T_s + \vec{k}_s \cdot \vec{q}_s) \neq x_s^0, \quad p_s^0 = \epsilon_s\sqrt{1+\vec{k}_s^2}, \tag{4.3}$$

$$\vec{\tilde{x}}_s = \frac{\vec{z}_s}{\epsilon_s} + \left(T_s + \frac{\vec{k}_s \cdot \vec{z}_s}{\epsilon_s}\right)\vec{k}_s = \vec{q}_s + (T_s + \vec{k}_s \cdot \vec{q}_s)\vec{k}_s, \quad \vec{p}_s = \epsilon_s \vec{k}_s.$$

Each Wigner hyperplane intersects the world line of the arbitrary centroid four-vector $x_s^\mu(\tau) = z^\mu(\tau, \vec{0})$ in $\vec{\sigma} = 0$, the pseudo-world-line of $\tilde{x}_s^\mu(\tau) = z^\mu(\tau, \vec{\tilde{\sigma}})$ in some $\vec{\tilde{\sigma}}$ and the world line of the Fokker–Pryce four-vector $Y_s^\mu(\tau) = z^\mu(\tau, \vec{\sigma}_Y)$ in some $\vec{\sigma}_Y$; one also has $R_s^\mu = z^\mu(\tau, \vec{\sigma}_R)$. Since we have $T_s = u(p_s) \cdot x_s = u(p_s) \cdot \tilde{x}_s \equiv \tau$ on the Wigner hyperplane labeled by τ, we will also require

Y_s^μ, R_s^μ to have time components such that $u(p_s)\cdot Y_s = u(p_s)\cdot R_s = T_s \equiv \tau$. It is reasonable therefore to assume that, consistently with Eqs. (4.2) and (4.3), $\tilde{x}_s^\mu$, Y_s^μ, and R_s^μ satisfy the following equations:

$$\tilde{x}_s^\mu = (\tilde{x}_s^0;\vec{\tilde{x}}_s) = \left(\tilde{x}_s^0;\vec{q}_s + \frac{\vec{p}_s}{p_s^0}\tilde{x}_s^0\right) = \left(\tilde{x}_s^0;\frac{\vec{z}_s}{\epsilon_s} + \left(T_s + \frac{\vec{k}_s\cdot\vec{z}_s}{\epsilon_s}\right)\vec{k}_s\right) = x_s^\mu + \epsilon_u^\mu(u(p_s))\tilde{\sigma}^u,$$

$$Y_s^\mu = (\tilde{x}_s^0;\vec{Y}_s) = \left(\tilde{x}_s^0;\frac{1}{\epsilon_s}\left[\vec{z}_s + \frac{\vec{\overline{S}}_s\times\vec{p}_s}{\epsilon_s[1+u^0(p_s)]}\right] + \left(T_s + \frac{\vec{k}_s\cdot\vec{z}_s}{\epsilon_s}\right)\vec{k}_s\right)$$

$$= \tilde{x}_s^\mu + \eta_r^\mu\frac{(\vec{\overline{S}}_s\times\vec{p}_s)^r}{\epsilon_s[1+u^0(p_s)]} = x_s^\mu + \epsilon_u^\mu(u(p_s))\sigma_Y^u,$$

$$R_s^\mu = (\tilde{x}_s^0;\vec{R}_s) = \left(\tilde{x}_s^0;\quad \frac{1}{\epsilon_s}\left[\vec{z}_s - \frac{\vec{\overline{S}}_s\times\vec{p}_s}{\epsilon_s u^0(p_s)[1+u^0(p_s)]}\right] + \left(T_s + \frac{\vec{k}_s\cdot\vec{z}_s}{\epsilon_s}\right)\vec{k}_s\right)$$

$$= \tilde{x}_s^\mu - \eta_r^\mu\frac{(\vec{\overline{S}}_s\times\vec{p}_s)^r}{\epsilon_s u^0(p_s)[1+u^0(p_s)]} = x_s^\mu + \epsilon_u^\mu(u(p_s))\sigma_R^u,$$

$$T_s = u(p_s)\cdot x_s = u(p_s)\cdot\tilde{x}_s = u(p_s)\cdot Y_s = u(p_s)\cdot R_s,$$

$$\tilde{\sigma}^r = \epsilon_{r\mu}(u(p_s))[x_s^\mu - \tilde{x}_s^\mu] = \frac{\epsilon_{r\mu}(u(p_s))[u_\nu(p_s)S_s^{\nu\mu} + S_s^{0\mu}]}{[1+u^0(p_s)]} = -\overline{S}_s^{\tau r} + \frac{\overline{S}_s^{rs}p_s^s}{\epsilon_s[1+u^0(p_s)]} \tag{4.4}$$

$$= \epsilon_s R_+^r + \frac{\overline{S}_s^{rs}u^s(p_s)}{1+u^0(p_s)} \overset{\vec{q}_+\approx 0}{\approx} \epsilon_s q_+^r + \frac{\overline{S}_s^{rs}u^s(p_s)}{1+u^0(p_s)} \approx \frac{\overline{S}_s^{rs}u^s(p_s)}{1+u^0(p_s)},$$

$$\sigma_Y^r = \epsilon_{r\mu}(u(p_s))[x_s^\mu - Y_s^\mu] = \tilde{\sigma}^r - \epsilon_{ru}(u(p_s))\frac{(\vec{\overline{S}}_s\times\vec{p}_s)^u}{\epsilon_s[1+u^0(p_s)]} = \tilde{\sigma}^r + \frac{\overline{S}_s^{rs}u^s(p_s)}{1+u^0(p_s)}$$

$$= \epsilon_s R_+^r \approx \epsilon_s q_+^r \overset{\vec{q}_+\approx 0}{\approx} 0,$$

$$\Rightarrow x_s^{(\vec{q}_+)\mu}(\tau) = x_s^\mu(0) + Y_s^\mu, \quad when \quad \vec{q}_+ \approx 0,$$

$$\sigma_R^r = \epsilon_{r\mu}(u(p_s))[x_s^\mu - R_s^\mu] = \tilde{\sigma}^r + \epsilon_{ru}(u(p_s))\frac{(\vec{\overline{S}}_s\times\vec{p}_s)^u}{\epsilon_s u^0(p_s)[1+u^0(p_s)]} = \tilde{\sigma}^r - \frac{\overline{S}_s^{rs}u^s(p_s)}{u^0(p_s)[1+u^0(p_s)]}$$

$$= \epsilon_s R_+^r + \frac{[1-u^0(p_s)]\overline{S}_s^{rs}u^s(p_s)}{u^0(p_s)[1+u^0(p_s)]} \overset{\vec{q}_+\approx 0}{\approx} \frac{[1-u^0(p_s)]\overline{S}_s^{rs}u^s(p_s)}{u^0(p_s)[1+u^0(p_s)]}.$$

It is seen that *the external Fokker–Pryce noncanonical center of inertia coincides with the centroid* $x_s^{(\vec{q}_+)\mu}(\tau)$ *carrying the internal three-center of mass.* Let us recall that the centroid $x_s^\mu(\tau)$ corresponds to the *unique* special-relativistic center-of-mass-like world line of Ref. 47.

In each Lorentz frame one has different pseudo-world-lines describing R_s^μ and $\tilde{x}_s^\mu$: the canonical four-center of mass $\tilde{x}_s^\mu$ lies in between Y_s^μ and R_s^μ in every (nonrest)-frame. In an arbitrary Lorentz frame, the pseudo-world-lines associated with $\tilde{x}_s^\mu$ and R_s^μ fill a world tube[17] around the world line Y_s^μ of the covariant noncanonical Fokker–Pryce four-center of inertia Y_s^μ. The *invariant radius* of the tube is $\rho = \sqrt{-\epsilon W^2}/p^2 = |\vec{S}|/\sqrt{\epsilon p^2}$ where ($W^2 = -\epsilon p^2\vec{S}^2$ is the Pauli–Lubanski invariant when $\epsilon p^2 > 0$). This classical intrinsic radius delimits the noncovariance effects (the pseudo-world lines) of the canonical four-center of mass $\tilde{x}_s^\mu$. See Ref. 38 for a discussion of the

properties of the *Møller radius*. At the quantum level ρ becomes the Compton wavelength of the isolated system times its spin eigenvalue $\sqrt{s(s+1)}$, $\rho \mapsto \hat{\rho} = \sqrt{s(s+1)}\hbar/M = \sqrt{s(s+1)}\lambda_M$ with $M = \sqrt{\epsilon p^2}$ the invariant mass and $\lambda_M = \hbar/M$ its Compton wavelength. The criticism to classical relativistic physics argued from quantum pair production concerns testing of distances where, due to the Lorentz signature of space–time, intrinsic classical covariance problems emerge: the canonical four-center of mass $\tilde{x}^\mu_s$ adapted to the first class constraints of the system cannot be localized in a frame-independent way.

Finally, recall[9] that ρ is likewise a remnant of the energy conditions of general relativity in flat Minkowski space–time: since the Møller noncanonical, noncovariant four-center of energy R^μ has noncovariance properties localized inside the same world tube with radius ρ,[17] it turns out that for an extended relativistic system with a material radius smaller than its intrinsic radius ρ one has: (i) its peripheral rotation velocity can exceed the velocity of light; (ii) its classical energy density cannot be positive definite everywhere in every frame.

V. GETTING THE INTERNAL RELATIVE VARIABLES FROM A GARTENHAUS–SCHWARTZ TRANSFORMATION

Given $\vec{\eta}_i$, $\vec{\kappa}_i$, we must find the canonical basis $\vec{q}_+$, $\vec{\kappa}_+$, $\vec{\rho}_{qa}$, $\vec{\pi}_{qa}$ of Eq. (3.6).

We shall exploit the classical analog of the Gartenhaus–Schwartz singular transformation[23] following the scheme used in Ref. 45 in order to find the center-of-mass subspace of phase space defined by $\vec{\kappa}_+ = 0$ (see Ref. 48)

$$U(\alpha) = e^{\alpha\{.,\vec{q}_+ \cdot \vec{\kappa}_+\}},$$

$$\vec{q}_+ \cdot \vec{\kappa}_+ = -\frac{|\vec{\kappa}_+|}{\sum_{k=1}^N \sqrt{m_k^2 + \vec{\kappa}_k^2}} \vec{n}_+ \cdot \vec{K}, \quad \vec{n}_+ = \frac{\vec{\kappa}_+}{|\vec{\kappa}_+|}, \quad \vec{K} = -\sum_{i=1}^N \sqrt{m_i^2 + \vec{\kappa}_i^2}\, \vec{\eta}_i,$$

$$\vec{\kappa}_+(\alpha) = U(\alpha)\vec{\kappa}_+ = e^{-\alpha}\vec{\kappa}_+ \to_{\alpha\to\infty} 0, \tag{5.1}$$

$$\vec{q}_+(\alpha) = U(\alpha)\vec{q}_+ = e^{\alpha}\vec{q}_+ \to_{\alpha\to\infty} \infty, \quad U(-\alpha)\vec{q}_+ = e^{-\alpha}\vec{q}_+ \to_{\alpha\to\infty} 0,$$

$$\Rightarrow \vec{\kappa}_+(\alpha) \cdot \vec{q}_+(\alpha) = \vec{\kappa}_+ \cdot \vec{q}_+, \quad \vec{n}_+(\alpha) = \vec{n}_+.$$

Therefore, $\lim_{\alpha\to\infty} U(\alpha)$ can only be applied to the set of functions on phase space which have vanishing Poisson bracket with $\vec{\kappa}_+$, namely to

$$\vec{\kappa}_i \left[\text{or } \vec{\pi}_a = \frac{1}{\sqrt{N}} \sum_{i=1}^N \gamma_{ai} \vec{\kappa}_i \right] \text{ and to } \vec{\rho}_a = \sqrt{N} \sum_{i=1}^N \gamma_{ai} \vec{\eta}_i$$

of Eq. (2.16). Such a canonical transformation does not identify a good internal center of mass but nevertheless provides a canonical set of relative variables suitable for the application of the Gartenhaus–Schwartz transformation.

Since, for finite α, $U(\alpha)$ is a canonical transformation, the Poisson brackets are preserved even in the limit $\alpha\to\infty$:$[\{f(\alpha), g(\alpha)\} = U(\alpha)\{f,g\}]$.

Let $f = f(\vec{\eta}_i, \vec{\kappa}_i)$ have zero Poisson bracket with $\vec{\kappa}_+$, $\{f, \vec{\kappa}_+\} = 0$, and let be $f(\alpha) = U(\alpha)f$. Then, it follows

$$\{\vec{\kappa}_+, f(\alpha)\} = e^{\alpha}\{\vec{\kappa}_+(\alpha), f(\alpha)\} = e^{\alpha}(U(\alpha)\{\vec{\kappa}_+, f\}) = 0. \tag{5.2}$$

Since the Jacobi identity $\{\vec{\kappa}_+, \{\vec{q}_+, f\}\} + \{f, \{\vec{\kappa}_+, \vec{q}_+\}\} + \{\vec{q}_+, \{f, \vec{\kappa}_+\}\} \equiv 0$ implies $\{\vec{\kappa}_+, \{\vec{q}_+, f\}\} \equiv 0$ [namely also $\{\vec{q}_+, f\}$ has zero Poisson bracket with $\vec{\kappa}_+$ if $\{f, \vec{\kappa}_+\} = 0$, so that $U(\alpha)\{\vec{q}_+, f\}$ has a well-defined limit for $\alpha\to\infty$] one also has

$$\{\vec{q}_+, f(\alpha)\} = e^{-\alpha}\{\vec{q}_+(\alpha), f(\alpha)\} = e^{-\alpha}(U(\alpha)\{\vec{q}_+, f\}) \to_{\alpha\to\infty} 0. \tag{5.3}$$

Moreover it holds

$$\frac{\mathrm{d}f(\alpha)}{\mathrm{d}\alpha}=\{f(\alpha),\vec{\kappa}_+\cdot\vec{q}_+\}=\{f(\alpha),\vec{\kappa}_+(\alpha)\cdot\vec{q}_+(\alpha)\}. \tag{5.4}$$

Therefore, the relative variables $\vec{\pi}_a=(1/\sqrt{N})\,\Sigma_{i=1}^N\gamma_{ai}\vec{\kappa}_i$ and $\vec{\rho}_a=\sqrt{N}\,\Sigma_{i=1}^N\,\gamma_{ai}\vec{\eta}_i$, which commute with $\vec{\kappa}_+$ [see Eq. (2.16)], satisfy

$$\begin{aligned}\vec{\pi}_a(\alpha)&=U(\alpha)\vec{\pi}_a\to_{\alpha\to\infty}\vec{\pi}_a(\infty)\overset{\text{def}}{=}\vec{\pi}_{qa},\\ \vec{\rho}_a(\alpha)&=U(\alpha)\vec{\rho}_a\to_{\alpha\to\infty}\vec{\rho}_a(\infty)\overset{\text{def}}{=}\vec{\rho}_{qa},\end{aligned} \tag{5.5}$$

where $\vec{\rho}_{qa}$, $\vec{\pi}_{qa}$, is a pair of canonical vectors having zero Poisson bracket with $\vec{q}_+$, $\vec{\kappa}_+$. The searched canonical transformation (3.6) is thereby obtained.

First evaluate $\vec{\pi}_{qa}$ following the scheme of Ref. 45. From Eq. (5.4) we get

$$\frac{\mathrm{d}\vec{\kappa}_i(\alpha)}{\mathrm{d}\alpha}=\{\vec{\kappa}_i(\alpha),\vec{\kappa}_+(\alpha)\cdot\vec{q}_+(\alpha)\}=-\frac{\vec{\kappa}_+(\alpha)}{H_M(\alpha)}H_i(\alpha), \tag{5.6}$$

with the notations

$$M_{\text{sys}}=\sum_{i=1}^N H_i,\quad H_M(\alpha)=\sum_{i=1}^N H_i(\alpha)\to_{\alpha\to\infty}H_M(\infty)\overset{\text{def}}{=}H_{(\text{rel})},$$

$$H_i=\sqrt{m_i^2+\vec{\kappa}_i^2},\quad H_i(\alpha)=\sqrt{m_i^2+\vec{\kappa}_i^2(\alpha)}\to_{\alpha\to\infty}H_i(\infty)\overset{\text{def}}{=}H_{(\text{rel})i}, \tag{5.7}$$

$$\Pi=M_{\text{sys}}^2-\vec{\kappa}_+^2\approx M_{\text{sys}}^2.$$

From $m_i^2=H_i^2(\alpha)-\vec{\kappa}_i^2(\alpha)$, it follows

$$\frac{\mathrm{d}H_i(\alpha)}{\mathrm{d}\alpha}H_i(\alpha)=\frac{\mathrm{d}\vec{\kappa}_i(\alpha)}{\mathrm{d}\alpha}\cdot\vec{\kappa}_i(\alpha),$$

$$\Rightarrow\frac{\mathrm{d}H_i(\alpha)}{\mathrm{d}\alpha}=-\vec{\kappa}_i(\alpha)\cdot\frac{\vec{\kappa}_i(\alpha)}{H_M(\alpha)},$$

$$\Rightarrow\frac{\mathrm{d}H_M(\alpha)}{\mathrm{d}\alpha}=\sum_{i=1}^N\frac{\mathrm{d}H_i(\alpha)}{\mathrm{d}\alpha}=-\frac{\vec{\kappa}_+^2(\alpha)}{H_M(\alpha)},$$

$$\Rightarrow\Pi=H_M^2-\vec{\kappa}_+^2=H_M^2(\alpha)-\vec{\kappa}_+^2(\alpha)\to_{\alpha\to\infty}M_{\text{sys}}^2(\infty)=H_{(\text{rel})}^2,$$

$$or\quad\frac{\mathrm{d}\Pi}{\mathrm{d}\alpha}=0. \tag{5.8}$$

Let us now introduce $\theta(\alpha)$ such that $[\mathrm{ch}^2\,\theta(\alpha)-\mathrm{sh}^2\,\theta(\alpha)=1$ also for $\alpha\to\infty]$

$$\text{sh}\,\theta(\alpha)=\frac{|\vec{\kappa}_+|H_M(\alpha)-|\vec{\kappa}_+(\alpha)|M_{\rm sys}}{\Pi}\to_{\alpha\to\infty}\frac{|\vec{\kappa}_+|}{\sqrt{\Pi}},$$

$$\text{ch}\,\theta(\alpha)=\frac{M_{\rm sys}H_M(\alpha)-|\vec{\kappa}_+||\vec{\kappa}_+(\alpha)|}{\Pi}\to_{\alpha\to\infty}\frac{M_{\rm sys}}{\sqrt{\Pi}},\tag{5.9}$$

$$\theta(\alpha)=\tanh^{-1}\frac{|\vec{\kappa}_+|}{M_{\rm sys}}-\tanh^{-1}\frac{|\vec{\kappa}_+(\alpha)|}{H_M(\alpha)}\to_{\alpha\to 0}0,\quad\to_{\alpha\to\infty}\tanh^{-1}\frac{|\vec{\kappa}_+|}{M_{\rm sys}}.$$

Since we have

$$\frac{d\theta(\alpha)}{d\alpha}=\frac{|\vec{\kappa}_+(\alpha)|}{H_M(\alpha)},\quad\frac{d\vec{n}_+(\alpha)}{d\alpha}=0\Rightarrow\vec{n}_+(\alpha)=\vec{n}_+,\tag{5.10}$$

we obtain the coupled equations

$$\frac{d\vec{\kappa}_i(\alpha)}{d\theta}=-H_i(\alpha)\vec{n}_+,\quad\frac{dH_i(\alpha)}{d\theta}=-\vec{\kappa}_i(\alpha)\cdot\vec{n}_+,\tag{5.11}$$

whose integration gives

$$\begin{aligned}\vec{\kappa}_i(\alpha)&=\vec{\kappa}_i+([\text{ch}\,\theta(\alpha)-1]\vec{n}_+\cdot\vec{\kappa}_i-\text{sh}\,\theta(\alpha)H_i)\vec{n}_+\to_{\alpha\to\infty}\vec{\kappa}_i(\infty)\\&=\vec{\kappa}_i+\left[\left(\frac{M_{\rm sys}}{\sqrt{\Pi}}-1\right)\vec{n}_+\cdot\vec{\kappa}_i-\frac{|\vec{\kappa}_+|}{\sqrt{\Pi}}H_i\right]\vec{n}_+\approx\vec{\kappa}_i,\end{aligned}$$

$$\begin{aligned}H_i(\alpha)&=\sqrt{m_i^2+\vec{\kappa}_i^2(\alpha)}=\text{ch}\,\theta(\alpha)H_i-\text{sh}\,\theta(\alpha)\vec{n}_+\cdot\vec{\kappa}_i\to_{\alpha\to\infty}H_i(\infty)\\&=\sqrt{m_i^2+\vec{\kappa}_i^2(\infty)}=\frac{1}{\sqrt{\Pi}}(M_{\rm sys}H_i-\vec{\kappa}_+\cdot\vec{\kappa}_i)\approx H_i,\end{aligned}$$

$$\begin{aligned}\Rightarrow H_i&=\sqrt{m_i^2+\vec{\kappa}_i^2}=H_i(\alpha)\text{ch}\,\theta(\alpha)+\vec{n}_+\cdot\vec{\kappa}_i(\alpha)\text{sh}\,\theta(\alpha)\\&=\frac{1}{\sqrt{\Pi}}[H_i(\infty)\,M_{\rm sys}+\vec{n}_+\cdot\vec{\kappa}_i(\infty)|\vec{\kappa}_+|\approx H_i(\infty),\end{aligned}$$

$$\text{with}\quad\sum_{i=1}^{N}H_i(\infty)=H_M(\infty)=\sqrt{\Pi}\overset{\text{def}}{=}H_{(\text{rel})},$$

$$\vec{\kappa}_i=\vec{\kappa}_i(\alpha)+[\text{ch}\,\theta(\alpha)-1]\vec{n}_+\cdot\vec{\kappa}_i(\alpha)\vec{n}_++\text{sh}\,\theta(\alpha)H_i(\alpha).\tag{5.12}$$

Therefore, we get

$$\vec{\pi}_a(\alpha)=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\gamma_{ai}\vec{\kappa}_i(\alpha),$$

$$\vec{\pi}_{qa}\overset{\text{def}}{=}\vec{\pi}_a(\infty)=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\vec{\kappa}_i(\infty)=\vec{\pi}_a+\frac{\vec{n}_+}{\sqrt{\Pi}}[(M_{\text{sys}}-\sqrt{\Pi})\vec{n}_+\cdot\vec{\pi}_a-|\vec{\kappa}_+|H_a]$$

$$=\vec{\pi}_a-\frac{\vec{\kappa}_+}{\sqrt{M_{\text{sys}}^2-\vec{\kappa}_+^2}}\left[H_a-\frac{M_{\text{sys}}-\sqrt{M_{\text{sys}}^2-\vec{\kappa}_+^2}}{\vec{\kappa}_+^2}\vec{\kappa}_+\cdot\vec{\pi}_a\right]\approx\vec{\pi}_a,$$

$$H_a=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\gamma_{ai}H_i,$$

$$\vec{\kappa}_i(\infty)=\sqrt{N}\sum_{a=1}^{N-1}\gamma_{ai}\vec{\pi}_{qa},$$

$$H_{(\text{rel})i}=H_i(\infty)=\sqrt{m_i^2+N\sum_{ab}^{1..N-1}\gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}},$$

$$M_{\text{sys}}=\sum_{i=1}^{N}H_i=\sqrt{\Pi+\vec{\kappa}_+^2}\approx H_{(\text{rel})}=H_M(\infty)=\sqrt{\Pi}=\sum_{i=1}^{N}H_i(\infty)$$

$$=\sum_{i=1}^{N}\sqrt{m_i^2+N\sum_{ab}^{1..N-1}\gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}}. \tag{5.13}$$

Let us turn to $\vec{\rho}_{qa}$. Let us remark first of all that the following two quantities are invariant under the canonical transformation $U(\alpha)$:

$$\begin{aligned}I_i^{(1)}&=M_{\text{sys}}H_i-\vec{\kappa}_+\cdot\vec{\kappa}_i=H_M(\alpha)\,H_i(\alpha)-\vec{\kappa}_+(\alpha)\cdot\vec{\kappa}_i(\alpha),\quad\Rightarrow\frac{\mathrm{d}I_i^{(1)}}{\mathrm{d}\alpha}=0,\\ I^{(2)}&=\frac{\vec{\kappa}_+\cdot\vec{K}}{M_{\text{sys}}}=-\sum_{i=1}^{N}|\vec{\kappa}_+|\left(\vec{n}_+\cdot\frac{\vec{\eta}_iH_i}{M_{\text{sys}}}\right)=\frac{\vec{\kappa}_+(\alpha)\cdot\vec{K}(\alpha)}{H_M(\alpha)},\quad\Rightarrow\frac{\mathrm{d}I^{(2)}}{\mathrm{d}\alpha}=0,\end{aligned} \tag{5.14}$$

and that we have

$$\frac{1}{H_M(\alpha)|\vec{\kappa}_+(\alpha)|}=\frac{\mathrm{d}J^{(1)}(\alpha)}{\mathrm{d}\alpha},\quad\text{with}\quad J^{(1)}(\alpha)=\frac{\operatorname{sh}\theta(\alpha)}{|\vec{\kappa}_+(\alpha)||\vec{\kappa}_+|},$$

$$\frac{\vec{\kappa}_i(\alpha)}{H_i^2(\alpha)}=\frac{\mathrm{d}\vec{J}_i^{(2)}(\alpha)}{\mathrm{d}\theta(\alpha)}$$

with

$$\vec{J}_i^{(2)}(\alpha)=\frac{\vec{\kappa}_i(\alpha)\operatorname{sh}\theta(\alpha)}{H_iH_i(\alpha)}+(\operatorname{ch}\theta(\alpha)-1)\frac{\vec{n}_+}{H_i}. \tag{5.15}$$

Since we also have

$$n^r_+ \frac{\partial}{\partial \kappa^r_i} n^s_+ = \frac{n^r_+}{|\vec{\kappa}_+|}(\delta^{rs} - n^r_+ n^s_+) = 0, \tag{5.16}$$

we get preliminarly, for $\vec{n}_+ \cdot \vec{\eta}_i(\alpha)$,

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}\alpha}\vec{n}_+ \cdot \vec{\eta}_i(\alpha) &= \{\vec{n}_+ \cdot \vec{\eta}_i(\alpha), \vec{\kappa}_+(\alpha)\cdot\vec{q}_+(\alpha)\} \\ &= -n^r_+ \frac{\partial}{\partial \kappa^r_i(\alpha)} \frac{\vec{n}_+ \cdot \vec{K}(\alpha)|\vec{\kappa}_+(\alpha)|}{H_M(\alpha)} \\ &= -n^r_+ n^s_+ \frac{\partial}{\partial \kappa^r_i(\alpha)} \frac{|\vec{\kappa}_+(\alpha)| K^s(\alpha)}{H_M(\alpha)}.\end{aligned} \tag{5.17}$$

Then, since

$$n^r_+ \frac{\partial}{\partial \kappa^r_i(\alpha)} \frac{|\vec{\kappa}_+(\alpha)|}{H_M(\alpha)} = \frac{I^{(1)}_i}{H^2_M(\alpha) H_i(\alpha)}, \quad \frac{\partial}{\partial \kappa^r_i(\alpha)} K^s(\alpha) = -\frac{\kappa^r_i(\alpha)\eta^s_i(\alpha)}{H_i(\alpha)}, \tag{5.18}$$

we get

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}\alpha}\vec{n}_+ \cdot \vec{\eta}_i(\alpha) &= -\frac{I^{(2)} I^{(1)}_i}{H_M(\alpha) H_i(\alpha) |\vec{\kappa}_+(\alpha)|} + \frac{\vec{n}_+ \cdot \vec{\eta}_i(\alpha) \vec{n}_+ \cdot \vec{\kappa}_i(\alpha)}{H_i(\alpha)} \frac{|\vec{\kappa}_+(\alpha)|}{H_M(\alpha)} \\ &= -\frac{\vec{n}_+ \cdot \vec{\eta}_i(\alpha)}{H_i(\alpha)} \frac{\mathrm{d}H_i(\alpha)}{\mathrm{d}\alpha} - \frac{I^{(1)}_i I^{(2)}}{H_i(\alpha)} \frac{\mathrm{d}J^{(1)}(\alpha)}{\mathrm{d}\alpha}.\end{aligned} \tag{5.19}$$

These equations have the solution

$$\vec{n}_+ \cdot \vec{\eta}_i(\alpha) = \frac{H_i}{H_i(\alpha)} \vec{n}_+ \cdot \vec{\eta}_i - \frac{I^{(1)}_i I^{(2)}}{H_i(\alpha)} \frac{\mathrm{sh}\,\theta(\alpha)}{|\vec{\kappa}_+(\alpha)||\vec{\kappa}_+|} = \frac{H_i}{H_i(\alpha)} \vec{n}_+ \cdot \vec{\eta}_i - \frac{I^{(2)}}{|\vec{\kappa}_+|}\left(e^{\alpha} - \frac{H_i}{H_i(\alpha)}\right). \tag{5.20}$$

For $\vec{\eta}_i(\alpha)$ we have

$$\begin{aligned}\frac{\mathrm{d}\eta^r_i(\alpha)}{\mathrm{d}\alpha} &= \{\eta^r_i(\alpha), \vec{\kappa}_+(\alpha)\cdot\vec{q}_+(\alpha)\} = -n^s_+ \frac{\partial}{\partial \kappa^r_i(\alpha)} \frac{|\vec{\kappa}_+(\alpha)| K^s(\alpha)}{H_M(\alpha)} = \vec{n}_+ \cdot \vec{\eta}_i(\alpha) \frac{|\vec{\kappa}_+(\alpha)| \kappa^r_i(\alpha)}{H_i(\alpha) H_M(\alpha)} \\ &+ \frac{\sum_{j=1}^N H_j(\alpha) \vec{n}_+ \cdot \vec{\eta}_j(\alpha)}{H_M(\alpha)} \left[\frac{|\vec{\kappa}_+(\alpha)| \kappa^r_i(\alpha)}{H_i(\alpha) H_M(\alpha)} - n^r_+\right].\end{aligned} \tag{5.21}$$

By putting Eq. (5.20) in Eq. (5.21) we get the equations determining $\vec{\eta}_i(\alpha)$.

Instead of integrating these equations, let us study the equations for $\vec{\rho}_a(\alpha) = \sqrt{N}\sum_{i=1}^N \gamma_{ai}\vec{\eta}_i(\alpha)$, since for interactions depending on $\vec{\eta}_i - \vec{\eta}_j$ we have $\vec{\eta}_i(\alpha) - \vec{\eta}_j(\alpha) = (1/\sqrt{N})\sum_{a=1}^{N-1}(\gamma_{ai} - \gamma_{aj})\vec{\rho}_a(\alpha)$. Equations (5.21) and (5.20) imply

$$\frac{\mathrm{d}\vec{\rho}_a(\alpha)}{\mathrm{d}\alpha} = -\sum_{i,j=1}^N \sum_{b=1}^{N-1} \vec{n}_+ \cdot \vec{\rho}_b \frac{H_i H_j}{M_{\mathrm{sys}}} \gamma_{aj}(\gamma_{bi} - \gamma_{bj}) \frac{\vec{\kappa}_j(\alpha)|\vec{\kappa}_+(\alpha)|}{H^2_j(\alpha) H_M(\alpha)},$$

$$\Downarrow$$

$$\frac{\mathrm{d}\vec{\rho}_a(\alpha)}{\mathrm{d}\theta(\alpha)} = -\sum_{i,j=1}^N \sum_{b=1}^{N-1} \vec{n}_+ \cdot \vec{\rho}_b \frac{H_i H_j}{M_{\mathrm{sys}}} \gamma_{aj}(\gamma_{bi} - \gamma_{bj}) \frac{\mathrm{d}\vec{J}^{(2)}_j(\alpha)}{\mathrm{d}\theta(\alpha)}, \tag{5.22}$$

whose solution is

$$\vec{\rho}_a(\alpha)=\vec{\rho}_a-\sum_{i,j=1}^{N}\sum_{b=1}^{N-1}\vec{n}_+\cdot\vec{\rho}_b\frac{H_iH_j}{M_{\rm sys}}\gamma_{aj}(\gamma_{bi}-\gamma_{bj})\vec{J}_j^{(2)}(\alpha). \tag{5.23}$$

For $\alpha\to\infty$ we get

$$\begin{aligned}\vec{\rho}_{qa}\overset{\rm def}{=}\vec{\rho}_a(\infty)&=\vec{\rho}_a-\sum_{i,j=1}^{N}\sum_{b=1}^{N-1}\gamma_{aj}(\gamma_{bi}-\gamma_{bj})\frac{H_i}{M_{\rm sys}}\left[\frac{|\vec{\kappa}_+|\vec{\kappa}_j(\infty)}{H_j(\infty)\sqrt{\Pi}}+\left(\frac{M_{\rm sys}}{\sqrt{\Pi}}-1\right)\vec{n}_+\right]\vec{n}_+\cdot\vec{\rho}_b\\&=\vec{\rho}_a-\sum_{i,j=1}^{N}\sum_{b=1}^{N-1}\gamma_{aj}(\gamma_{bi}-\gamma_{bj})\frac{H_i}{M_{\rm sys}}\frac{\vec{\kappa}_j(\infty)}{H_j(\infty)\sqrt{\Pi}}\vec{\kappa}_+\cdot\vec{\rho}_b\approx\vec{\rho}_a\,.\end{aligned} \tag{5.24}$$

One can check that for $N=2$ and $\gamma_1=-\gamma_2=1/\sqrt{2}$ the results of Ref. 45 are reobtained.

Let us now consider the spin vector $\vec{S}_q=\vec{\tilde{S}}_s-\vec{q}_+\times\vec{\kappa}_+=[\vec{\eta}_+-\vec{q}_+]\times\vec{\kappa}_++\Sigma_{a=1}^{N-1}\vec{\rho}_a\times\vec{\pi}_a$. For arbitrary α we have $\vec{S}_q(\alpha)=\Sigma_{a=1}^{N-1}\vec{\rho}_a(\alpha)\times\vec{\pi}_a(\alpha)+[\vec{\eta}_+(\alpha)-\vec{q}_+(\alpha)]\times\vec{\kappa}_+(\alpha)$ and, since $\vec{q}_+(\alpha)\cdot\vec{\kappa}_+(\alpha)$ is a scalar, $\{\vec{S}_q(\alpha),\vec{q}_+(\alpha)\cdot\vec{\kappa}_+(\alpha)\}=0$. Since $\lim_{\alpha\to\infty}\vec{\kappa}_+(\alpha)=0$, we get

$$\vec{S}_q(\alpha)\to_{\alpha\to\infty}\vec{S}_q=\sum_{a=1}^{N-1}\vec{\rho}_{qa}\times\vec{\pi}_{qa}\,, \tag{5.25}$$

if we can show that $\vec{\eta}_+(\alpha)-\vec{q}_+(\alpha)\to_{\alpha\to\infty}$ *finite value*. Now, since the boost generator may be written as

$$\begin{aligned}\vec{K}(\alpha)&=-\sum_{i=1}^{N}\vec{\eta}_i(\alpha)H_i(\alpha)=-\vec{\eta}_+(\alpha)H_M(\alpha)+\sum_{a=1}^{N-1}\vec{\rho}_a(\alpha)H_a(\alpha),\\H_a(\alpha)&=\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\gamma_{ai}H_i(\alpha),\end{aligned} \tag{5.26}$$

we get

$$\begin{aligned}\vec{\eta}_+(\alpha)-\vec{q}_+(\alpha)&=\frac{\Sigma_{a=1}^{N}\vec{\rho}_a(\alpha)H_a(\alpha)}{H_M(\alpha)}+\frac{\vec{\kappa}_+(\alpha)\times(\Sigma_{a=1}^{N-1}\vec{\rho}_a(\alpha)\times\vec{\pi}_a(\alpha))}{\sqrt{\Pi}(\sqrt{\Pi}+M_{\rm sys})}\\&\quad+\frac{\vec{\kappa}_+(\alpha)\times(\vec{\kappa}_+(\alpha)\times\Sigma_{a=1}^{N-1}\vec{\rho}_a(\alpha)H_a(\alpha))}{H_M(\alpha)\sqrt{\Pi}(\sqrt{\Pi}+M_{\rm sys})}\to_{\alpha\to\infty}\frac{1}{\sqrt{\Pi}}\sum_{a=1}^{N}\vec{\rho}_a(\infty)H_a(\infty)\\&=\frac{1}{\sqrt{\Pi}}\sum_{a=1}^{N-1}\vec{\rho}_{qa}\frac{1}{\sqrt{N}}\sum_{i=1}^{N}\gamma_{ai}\sqrt{m_i^2+N\sum_{ab}^{1,\ldots,N-1}\gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}},\end{aligned}$$

$$\Downarrow$$

$$\begin{aligned}\vec{q}_+=\vec{\eta}_+-\frac{1}{\sqrt{N}}\frac{\Sigma_{a=1}^{N-1}\vec{\rho}_a}{\sqrt{(\Sigma_{i=1}^{N}\sqrt{m_i^2+\vec{\kappa}_i^2})^2-\vec{\kappa}_+^2}}\sum_{i=1}^{N}\gamma_{ai}\sqrt{m_i^2+\vec{\kappa}_i^2}+(\text{terms}\to_{\alpha\to\infty}0,i.e.,\\\approx 0\ \text{ due to }\ \vec{\kappa}_+\approx 0),\end{aligned} \tag{5.27}$$

to be compared with Eq. (2.14).

In this way, although it is not known how to get the inverse transformation, we have successfully achieved the searched canonical transformation (3.6)

$$\boxed{\begin{array}{c}\vec{\eta}_i\\ \vec{\kappa}_i\end{array}} \longrightarrow \boxed{\begin{array}{c|c}\vec{q}_+ & \vec{\rho}_{qa}\\ \vec{\kappa}_+ & \vec{\pi}_{qa}\end{array}} \quad . \tag{5.28}$$

Adding the gauge fixings $\vec{q}_+ \approx 0$ for $\vec{\kappa}_+ \approx 0$ and going to Dirac brackets, we finally obtain

$$\vec{\rho}_{qa} \equiv \vec{\rho}_a\,, \quad \vec{\pi}_{qa} \equiv \vec{\pi}_a\,, \quad \vec{S}_q = \sum_{a=1}^{N-1} \vec{\rho}_{qa} \times \vec{\pi}_{qa} \stackrel{\text{def}}{=} \sum_{a=1}^{N-1} \vec{\rho}_a \times \vec{\pi}_a\,,$$

$$H_{(\text{rel})} = H_M(\infty) = \sum_{i=1}^{N} \sqrt{m_i^2 + N \sum_{ab}^{1,\ldots,N-1} \gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}} \equiv \sqrt{\Pi} \equiv M_{\text{sys}}\,. \tag{5.29}$$

$H_{(\text{rel})}$ replaces the nonrelativistic one $H_{\text{rel,nr}} = \frac{1}{2}\Sigma_{a,b=1}^{N-1} k_{ab}^{-1}[m_i, \gamma_{ai}]\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}$ of Eq. (2.9) of Ref. 2 for $c \to \infty$.

See Appendix B for the case of spinning particles.

VI. RELATIVISTIC ROTATIONAL KINEMATICS

Each square root in the Hamiltonian equation (5.29) for the relative motions in the rest frame instant form contains a $(N-1)\times(N-1)$ matrix $K_{(i)ab}^{-1} = N\gamma_{ai}\gamma_{bi} = K_{(i)ba}^{-1}$.[49] The existence of relativistic normal Jacobi coordinates would require the simultaneous diagonalization of these N matrices. This is impossible, however, because

$$[K_{(i)}^{-1}, K_{(j)}^{-1}]_{ab} = G_{(ij)ab} = -G_{(ij)ba} = -G_{(ji)ab} = -N[\gamma_{ai}\gamma_{bj} - \gamma_{aj}\gamma_{bi}]. \tag{6.1}$$

There are $\frac{1}{2}N(N-1)$ matrices G_{ij}, each one with $\frac{1}{2}(N-1)(N-2)$ independent elements. While the conditions $G_{(ij)ab} = 0$ are $\frac{1}{4}N(N-1)^2(N-2)$, the free parameters at our disposal in the γ_{ai} are only $\frac{1}{2}(N-1)(N-2)$. For $N=3$, there are three conditions and only one parameter; for $N=4$, eighteen conditions and three parameters.

In conclusion, it is impossible to diagonalize the N quadratic forms under the square roots simultaneously: *there are no relativistic normal Jacobi coordinates, and no definition of reduced masses and inertia tensor is allowed.*

In order to find the analog of $L_{rel,nr} = \frac{1}{2}\Sigma_{a,b=1}^{N-1} k_{ab}[m_i, \gamma_{ai}]\dot{\vec{\rho}}_a\cdot\dot{\vec{\rho}}_b$ [Eq. (2.9) of Ref. 2], we should perform an inverse Legendre transformation. The first half of Hamilton equations gives

$$\dot{\rho}_{qa}^r \stackrel{\circ}{=} \{\rho_{qa}^r, H_{(\text{rel})}\} = \sum_{i=1}^{N} \frac{N\gamma_{ai}\Sigma_{b=1}^{N-1}\gamma_{bi}\pi_{qb}^r}{\sqrt{m_i^2 + N\Sigma_{ab}^{1..N-1}\gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}}},$$

$$\Downarrow$$

$$\dot{\vec{\rho}}_{qa}\cdot\dot{\vec{\rho}}_{qb} = \sum_{i,j}^{1,\ldots,N} \frac{N\gamma_{ai}\Sigma_{e=1}^{N-1}\gamma_{ei}\vec{\pi}_{qe}}{\sqrt{m_i^2 + N\Sigma_{a_1b_1}^{1..N-1}\gamma_{a_1i}\gamma_{b_1i}\vec{\pi}_{qa_1}\cdot\vec{\pi}_{qb_1}}} \cdot \frac{N\gamma_{bj}\Sigma_{f=1}^{N-1}\gamma_{fj}\vec{\pi}_{qf}}{\sqrt{m_j^2 + N\Sigma_{a_2b_2}^{1..N-1}\gamma_{a_2j}\gamma_{b_2j}\vec{\pi}_{qa_2}\cdot\vec{\pi}_{qb_2}}}. \tag{6.2}$$

However, in order to get $\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}$ in terms of $\dot{\vec{\rho}}_{qa}\cdot\dot{\vec{\rho}}_{qb}$ we should solve higher order algebraic equations. As already pointed out, this implies that $L_{\text{rel}}(\vec{\rho}_{qa}, \dot{\vec{\rho}}_{qa}) = \Sigma_{a=1}^{N-1}\vec{\pi}_{qa}\cdot\dot{\vec{\rho}}_{qa} - H$ is a hyperelliptic function already in the free case. This in turn means that, unlike the nonrelativistic case, it

is not even possible to define either an Euclidean or a Riemannian metric on the space of velocities from the kinetic energy (see Ref. 2). A Lagrangian dynamics cannot be made explicit as in the nonrelativistic case. The form of the canonical momenta

$$\pi^r_{qa}=\frac{\partial L_{\rm rel}}{\partial \dot\rho^r_{qa}}=\sum_{b=1}^{N-1} f_{ab}(\dot{\vec\rho}_{qc}\cdot\dot{\vec\rho}_{qd})\dot\rho^r_{qb}, \tag{6.3}$$

can only be given in implicit form. Also the restrictions upon the relative velocities $\dot{\vec\rho}_{qa}(\tau)$ resulting from the existence of the limiting light velocity c cannot be evaluated.

We could tentatively try to follow the nonrelativistic pattern of the *static* orientation-shape bundle approach (see Ref. 2). We would get[50]

$$\rho^r_{qa}=R^{rs}(\theta^\alpha)\check\rho^s_{qa}(q),$$

$$\dot\rho^r_{qa}\overset{\rm def}{=}R^{rs}(\theta^\alpha)\check v^s_{qa},\quad \vec v_{qa}=\vec\omega\times\vec\rho_{qa}+\frac{\partial\vec\rho_{qa}}{\partial q^\mu}\dot q^\mu,$$

$$\dot\rho^r_{qa}\overset{\circ}{=}\{\rho^r_{qa},H_{\rm rel}\},$$

$$\pi^r_{qa}=\sum_{b=1}^{N-1} f_{ab}(\dot{\vec\rho}_{qc}\cdot\dot{\vec\rho}_{qd})\dot\rho^r_{qb}=R^{rs}(\theta^\alpha)\check\pi^s_{qa},\quad \check\pi^r_{qa}=\sum_{b=1}^{N-1} f_{ab}(\check{\vec v}_{qc}\cdot\check{\vec v}_{qd})\check v^r_{qb},$$

$$S^r_q=R^{rs}(\theta^\alpha)\check S^s_q=\sum_{a=1}^{N-1}[\vec\rho_{qa}\times\vec\pi_{qa}]^r,$$

$$\vec S_q=\sum_{ab}^{1,\dots,N-1} f_{ab}\left[\left(\vec\omega\times\vec\rho_{qc}+\frac{\partial\vec\rho_{qc}}{\partial q^\mu}\dot q^\mu\right)\cdot\left(\vec\omega\times\vec\rho_{qd}+\frac{\partial\vec\rho_{qd}}{\partial q^\mu}\dot q^\mu\right)\right]\vec\rho_{qa}\times\left(\vec\omega\times\vec\rho_{qb}+\frac{\partial\vec\rho_{qb}}{\partial q^\mu}\dot q^\mu\right), \tag{6.4}$$

$$\check S^r_q=\sum_{ab}^{1,\dots,N-1} f_{ab}[\check I^{uv}_{(cd)}(q)(\check\omega^u+\check A^u_{(cd)\mu}(q)\dot q^\mu)(\check\omega^v+\check A^v_{(cd)\nu}(q)\dot q^\nu)]\check I^{rs}_{(ab)}(q)(\check\omega^s+\check A^s_{(ab)\mu}(q)\dot q^\mu),$$

$$\check{\mathcal I}^{rs}(\check{\vec\omega},q,m)=\sum_{ab}^{1,\dots,N-1} f_{ab}(\vec v_{qc}\cdot\vec v_{qd})\check I^{rs}_{(ab)}(q),$$

$$\check I^{rs}_{(ab)}(q)=\vec\rho_{qa}\cdot\vec\rho_{qb}\delta^{rs}-\frac{1}{2}(\check\rho^r_{qa}\check\rho^s_b+\check\rho^r_{qb}\check\rho^s_{qa}),$$

$$\check a^u_{(ab)\mu}(q)=\frac{1}{2}\left[\vec\rho_{qa}\times\frac{\partial\vec\rho_{qb}}{\partial q^\mu}+\vec\rho_{qb}\times\frac{\partial\vec\rho_{qa}}{\partial q^\mu}\right]^u\overset{\rm def}{=}\check I^{uv}_{(ab)}(q)\check A^v_{(ab)\mu}(q).$$

It is seen, however, that *there is no more a linear relation* between the body frame spin and angular velocity. By expanding $f_{ab}(x)$ in a power series around $x=0$, we see that $\check S^r_q$ is an infinite series containing all the powers of the body frame angular velocity. The lowest term is $\check S^r_{q(0)}=\Sigma^{N-1}_{a,b} f_{ab}(0)\check I^{rs}_{(ab)}(q)(\check\omega^s+\check A^s_{(ab)\mu}(q)\dot q^\mu)$ with $f_{ab}(0)$ playing the role of the nonrelativistic k_{ab}.

Therefore, the tensor of inertia loses a clear identification: only *its building blocks* $\check I^{rs}_{(ab)}$, which appear at the nonrelativistic level, survive within the relativistic construction.

The relative Lagrangian can be worked out in the special case of $N=2$ with equal masses $m_1=m_2=m$. It results in

$$L_{\rm rel}(\vec{\rho},\dot{\vec{\rho}}) = -m\sqrt{4-\dot{\vec{\rho}}^2}. \tag{6.5}$$

so that the relative velocity is bounded by $|\dot{\vec{\rho}}| \leq 2$.

Let us write $\vec{\rho} = \rho\hat{\rho}$ with $\rho = |\vec{\rho}|$ and $\hat{\rho} = \vec{\rho}/|\vec{\rho}|$. With a single relative variable the three Euler angles θ^α are redundant: there are only two independent angles, identifying the position of the unit three-vector $\hat{\rho}$ on S^2. We shall use the parametrization (Euler angles $\theta^1 = \phi,\ \theta^2 = \theta,\ \theta^3 = 0$)

$$\hat{\rho}^r = R^{rs}(\theta,\phi)\,\hat{\rho}_0^s = (R_z(\theta)R_y(\phi))^{rs}\,\hat{\rho}_0^s, \quad \hat{\rho}_0 = (0,0,1). \tag{6.6}$$

By continuing the attempt to follow the *static* orientation-shape bundle approach, we get the following body frame velocity and angular velocity (ρ is the only shape variable for $N=2$):

$$\begin{aligned} &\check{v}^r = R^{T\,rs}\dot{\rho}^s = \rho(R^T\dot{R})^{rs}\hat{\rho}_0^s + \dot{\rho}\hat{\rho}_0^r = \rho\epsilon^{ru3}\check{\omega}^u + \dot{\rho}\hat{\rho}_0^r = \rho(\vec{\omega}\times\hat{\rho}_0)^r + \dot{\rho}\hat{\rho}_0^r, \\ &\vec{\omega} = (\tfrac{1}{2}\epsilon^{urs}(R^T\dot{R})^{rs}) = (\check{\omega}^1 = -\sin\theta\dot{\phi}, \check{\omega}^2 = \dot{\theta}, 0), \\ &\vec{v}^2 = \check{I}(\rho)\vec{\omega}^2 + \dot{\rho}^2, \quad \check{I}(\rho) = \rho^2. \end{aligned} \tag{6.7}$$

The nonrelativistic inertia tensor of the dipole $\check{I}_{\rm nr} = \mu\rho^2$ ($\mu = m_1m_2/m_1+m_2$ is the reduced mass) is replaced by $\check{I} = \check{I}_{\rm nr}/\mu = \rho^2$. The Lagrangian in anholonomic variables becomes

$$\tilde{L}(\vec{\omega},\rho,\dot{\rho}) = -m\sqrt{4-\check{I}(\rho)\vec{\omega}^2-\dot{\rho}^2}. \tag{6.8}$$

It is clear that the bound $|\dot{\vec{\rho}}| \leq 2$ puts upper limitations upon the kinetic energy of both the rotational and vibrational motions.

The canonical momenta are

$$\begin{aligned} \vec{S} &= \frac{\partial\tilde{L}}{\partial\vec{\omega}} = \frac{m\check{I}(\rho)\vec{\omega}}{\sqrt{4-\check{I}(\rho)\vec{\omega}^2-\dot{\rho}^2}}, \\ \pi &= \frac{\partial\tilde{L}}{\partial\dot{\rho}} = \frac{m\dot{\rho}}{\sqrt{4-\check{I}(\rho)\vec{\omega}^2-\dot{\rho}^2}}. \end{aligned} \tag{6.9}$$

When $|\dot{\vec{\rho}}|$ varies between 0 and 2 the momenta vary between 0 and ∞, so that in phase space there is no bound from the limiting light velocity. This shows once more that in special relativity it is convenient to work in the Hamiltonian framework avoiding relative and angular velocities.

Since we have

$$\sqrt{4-\check{I}(\rho)\vec{\omega}^2-\dot{\rho}^2} = \frac{2m}{\sqrt{m^2+\check{I}^{-1}(\rho)\vec{S}^2+\pi^2}},$$

the inversion formulas become

$$\begin{aligned} \vec{\omega} &= \frac{\vec{S}}{m\check{I}(\rho)}\sqrt{4-\check{I}(\rho)\vec{\omega}^2-\dot{\rho}^2} = \frac{2\check{I}^{-1}(\rho)\vec{S}}{\sqrt{m^2+\check{I}^{-1}(\rho)\vec{S}^2+\pi^2}}, \\ \dot{\rho} &= \frac{\pi}{m}\sqrt{4-\check{I}(\rho)\vec{\omega}^2-\dot{\rho}^2} = \frac{2\pi}{\sqrt{m^2+\check{I}^{-1}(\rho)\vec{S}^2+\pi^2}}. \end{aligned} \tag{6.10}$$

On the other hand, the Hamiltonian results

$$\tilde{H}=\pi\dot{\rho}+\vec{S}\cdot\vec{\omega}-\tilde{L}=2\sqrt{m^2+\check{I}^{-1}(\rho)\vec{S}^2+\pi^2}. \tag{6.11}$$

It is seen that the special case we are discussing leads to a point-canonical transformation followed by a transformation to an anholonomic basis, as in the nonrelativistic treatment

$$\begin{array}{|c|}\hline \vec{\rho} \\ \hline \vec{\pi}_q \\ \hline \end{array} \longrightarrow \begin{array}{|ccc|}\hline \theta & \phi & \rho \\ \hline \pi_\theta & \pi_\phi & \pi \\ \hline \end{array} \overset{non\ can.}{\longrightarrow} \begin{array}{|ccc|}\hline \theta & \phi & \rho \\ \hline \check{S}^1 & \check{S}^2 & \pi \\ \hline \end{array} ,$$

$$\rho^r=\rho R^{rs}(\theta,\phi)\hat{\rho}_0^s=\rho(\sin\theta\cos\phi,\sin\theta\sin\phi,\cos\theta),$$

$$\pi_q^r=R^{rs}(\theta,\phi)\,\check{\pi}_q^s=R^{rs}(\theta,\phi)\,\frac{m\check{v}^s}{\sqrt{4-\vec{v}^2}}$$

$$=R^{rs}(\theta,\phi)\,\frac{m[\rho\vec{\omega}\times\hat{\rho}_o+\dot{\rho}\hat{\rho}_o]^s}{\sqrt{4-\check{I}(\rho)\vec{\omega}^2-\dot{\rho}^2}}=R^{rs}(\theta,\phi)[\rho\check{I}^{-1}(\rho)\vec{S}\times\hat{\rho}_o+\pi\hat{\rho}_o]^s. \tag{6.12}$$

In conclusion, because of the lack of a workable Lagrangian approach, we are forced to try to define everything at the Hamiltonian level. Correspondingly, in order to get an extension for arbitrary N, abandoning the *static* orientation-shape bundle approach, we shall exploit the *canonical spin bases* technique utilized in the nonrelativistic case of Ref. 2. We will have to guess in some way a set of nonpoint canonical transformations getting from the canonical variables $\vec{\rho}_{qa}$, $\vec{\pi}_{qa}$ to a basis in which the results of the special case $N=2$ and equal masses can be explicitly generalized.

The nonrelativistic non-Abelian rotational symmetry generating the Noether constants of motion $\vec{S}=$constant will be replaced by the *internal* non-Abelian rotational symmetry generating the constants of motion $\vec{S}_q$ inside the Wigner hyperplane, with the rest-frame conditions $\vec{\kappa}_+\approx 0$.

VII. CANONICAL SPIN BASES

Because of the group-theoretical nature of our technique, the relativistic construction of the *canonical spin bases* with the associated *spin frame* and *evolving dynamical body frames*, starting from the relative canonical variables $\vec{\rho}_{qa}$, $\vec{\pi}_{qa}$, $a=1,..,N-1$, is identical to that proposed in Ref. 2 for the nonrelativistic case. More precisely, this occurs since the total conserved rest-frame spin maintains its nonrelativistic form $\vec{S}_q=\Sigma_{a=1}^{N-1}\vec{\rho}_{qa}\times\vec{\pi}_{qa}=\Sigma_{a=1}^{N-1}\vec{S}_{qa}$ and the construction is essentially based on the *spin clusterings* built from the individual $\vec{S}_{qa}$. Only the Hamiltonian for relative motions turns out to be different.

We shall report here the main results for $N=2$, $N=3$, and $N\geqslant 4$ by referring to Ref. 2 for the relevant calculations.

A. Two-body systems

Consider the initial transformation for the case $N=2$, $i=1,2$,

$$\begin{array}{|c|}\hline \vec{\eta}_i \\ \hline \vec{\kappa}_i \\ \hline \end{array} \longrightarrow \begin{array}{|cc|}\hline \vec{q}_+ & \vec{\rho}_q \\ \hline \vec{\kappa}_+ & \vec{\pi}_q \\ \hline \end{array} . \tag{7.1}$$

After the elimination of the internal center-of-mass degrees of freedom by means of the gauge fixings $\vec{q}_+\approx 0$, the rest-frame dynamics of the relative motions is ruled by the Hamiltonian

$$H_{(\mathrm{rel})}=\sqrt{m_1^2+\vec{\pi}_q^2}+\sqrt{m_2^2+\vec{\pi}_q^2}\equiv M_{\mathrm{sys}}. \tag{7.2}$$

The spin is $\vec{S}_q=\vec{\rho}_q\times\vec{\pi}_q$ $[S_q=\sqrt{\vec{S}_q^2}]$. Define the following decomposition (the notation $\hat{R}$ for the unit vector $\hat{\rho}_q$ is used for comparison with Ref. 39)

$$\vec{\rho}_q=\rho_q\hat{R},\quad \rho_q=\sqrt{\vec{\rho}_q^2},\quad \hat{R}=\frac{\vec{\rho}_q}{\rho_q}=\hat{\rho}_q,\quad \hat{R}^2=1, \tag{7.3}$$

$$\vec{\pi}_q=\tilde{\pi}_q\hat{R}-\frac{S_q}{\rho_q}\hat{R}\times\hat{S}_q=\tilde{\pi}_q\hat{\rho}_q-\frac{S_q}{\rho_q}\hat{\rho}_q\times\hat{S}_q,\quad \tilde{\pi}_q=\vec{\pi}_q\cdot\hat{R}=\vec{\pi}_q\cdot\hat{\rho}_q,\quad \hat{S}_q=\frac{\vec{S}_q}{S_q},\quad \hat{S}_q\cdot\hat{R}=0.$$

The *spin frame* of R^3 is defined by $\hat{S}_q$, $\hat{R}$, $\hat{R}\times\hat{S}_q$ with $\{S_q^i,S_q^j\}=\epsilon^{ijk}S_q^k$, $\{\hat{R}^i,\hat{R}^j\}=0$, $\{\hat{R}^i,S_q^j\}=\epsilon^{ijk}\hat{R}^k$. The vectors $\vec{S}_q$ and $\hat{R}$ are the generators of an E(3) group containing SO(3) as a subgroup.

Consider the canonical transformation adapted to the *spin*

$$\left[\begin{array}{c}\vec{\rho}_q\\ \vec{\pi}_q\end{array}\right]\quad\longrightarrow\quad\left[\begin{array}{cc|c}\alpha & \beta & \rho_q\\ S_q & S_q^3 & \tilde{\pi}_q\end{array}\right]\quad, \tag{7.4}$$

where

$$\alpha=\mathrm{tg}^{-1}\frac{1}{S_q}\left(\vec{\rho}_q\cdot\vec{\pi}_q-\frac{(\rho_q)^2}{\rho_q^3}\pi_q^3\right),\quad \beta=\mathrm{tg}^{-1}\frac{S_q^2}{S_q^1}. \tag{7.5}$$

It holds

$$S_q^1=\sqrt{(S_q)^2-(S_q^3)^2}\cos\beta,\quad S_q^2=\sqrt{(S_q)^2-(S_q^3)^2}\sin\beta,\quad S_q^3, \tag{7.6}$$

$$\hat{R}^1=\hat{\rho}_q^1=\sin\theta\cos\varphi=\sin\beta\sin\alpha-\frac{S_q^3}{S_q}\cos\beta\cos\alpha,$$

$$\hat{R}^2=\hat{\rho}_q^2=\sin\theta\sin\varphi=-\cos\beta\sin\alpha-\frac{S_q^3}{S_q}\sin\beta\cos\alpha,$$

$$\hat{R}^3=\hat{\rho}_q^3=\cos\theta=\frac{1}{S_q}\sqrt{(S_q)^2-(S_q^3)^2}\cos\alpha,$$

$$(\hat{S}_q\times\hat{R})^1=\hat{S}_q^2\hat{R}^3-\hat{S}_q^3\hat{R}^2=\sin\beta\cos\alpha+\frac{S_q^3}{S_q}\cos\beta\sin\alpha,$$

$$(\hat{S}_q\times\hat{R})^2=\hat{S}_q^3\hat{R}^1-\hat{S}_q^1\hat{R}^3=-\cos\beta\cos\alpha+\frac{S_q^3}{S_q}\sin\beta\sin\alpha, \tag{7.7}$$

$$(\hat{S}_q\times\hat{R})^3=-\hat{S}_q^1\hat{R}^2-\hat{S}_q^2\hat{R}^1=\frac{1}{S_q}\sqrt{(S_q)^2-(S_q^3)^2}\sin\alpha,$$

with the inverse canonical transformation

$$\vec{\rho}_q=\rho_q\hat{R}(\alpha,\beta,S_q,S_q^3),$$

$$\vec{\pi}_q=\tilde{\pi}_q\hat{R}(\alpha,\beta,S_q,S_q^3)-\frac{S_q}{\rho_q}\hat{R}(\alpha,\beta,S_q,S_q^3)\times\hat{S}_q(\beta,S_q,S_q^3),$$

$$\Rightarrow\vec{\pi}_q^2=\tilde{\pi}_q^2+\frac{S_q^2}{\rho_q^2},\quad \hat{S}_q\times\hat{R}(\alpha)=\frac{\partial\hat{R}(\alpha)}{\partial\alpha}=\hat{R}\left(\alpha+\frac{\pi}{2}\right),$$

$$\Rightarrow\alpha=-\operatorname{tg}^{-1}\frac{(\hat{S}_q\times\hat{R})^3}{[\hat{S}_q\times(\hat{S}_q\times\hat{R})]^3}. \tag{7.8}$$

From the last line of this equation it is seen that the angle α can be expressed in terms of $\hat{S}_q$ and $\hat{R}$.

The conjugate variables ρ_q, $\tilde{\pi}_q$ will be called *dynamical shape variables*: they describe the vibration of the dipole.

The rest-frame Hamiltonian for the relative motion becomes

$$H_{(\mathrm{rel})}=H_M(\infty)=\sqrt{m_1^2+\vec{\pi}_q^2}+\sqrt{m_2^2+\vec{\pi}_q^2}=\sqrt{m_1^2+\frac{1}{\breve{I}}(S_q)^2+\tilde{\pi}_q^2}+\sqrt{m_2^2+\frac{1}{\breve{I}}(S_q)^2+\tilde{\pi}_q^2},$$

$$\Rightarrow\breve{\omega}\overset{\circ}{=}\frac{\partial H_{(\mathrm{rel})}}{\partial S_q}=\frac{S_q}{\breve{I}}\left(\frac{1}{\sqrt{m_1^2+\frac{1}{\breve{I}}(S_q)^2+\tilde{\pi}_q^2}}+\frac{1}{\sqrt{m_2^2+\frac{1}{\breve{I}}(S_q)^2+\tilde{\pi}_q^2}}\right),$$

$$\dot{\rho}_q\overset{\circ}{=}\frac{\partial H_{(\mathrm{rel})}}{\partial\tilde{\pi}_q}=\tilde{\pi}_q\left(\frac{1}{\sqrt{m_1^2+\frac{1}{\breve{I}}(S_q)^2+\tilde{\pi}_q^2}}+\frac{1}{\sqrt{m_2^2+\frac{1}{\breve{I}}(S_q)^2+\tilde{\pi}_q^2}}\right),$$

$$\tilde{\pi}_q\big|_{\dot{\rho}_q=0}=0,$$

$$H_{(\mathrm{rel})}^{(S)}=H_{(\mathrm{rel})}\big|_{\dot{\rho}_q=0}=\sqrt{m_1^2+\frac{1}{\breve{I}}(S_q)^2}+\sqrt{m_2^2+\frac{1}{\breve{I}}(S_q)^2}, \tag{7.9}$$

$$H_{(\mathrm{rel})}^{(S=0)}=H_{(\mathrm{rel})}\big|_{S_q=0}=\sqrt{m_1^2+\tilde{\pi}_q^2}+\sqrt{m_2^2+\tilde{\pi}_q^2},$$

where $\breve{I}=\rho_q^2=\breve{I}_{\mathrm{nr}}/\mu$ is the nonrelativistic baricentric inertia tensor $\breve{I}_{\mathrm{nr}}$ of the dipole divided by the reduced mass $\mu=m_1m_2/(m_1+m_2)$. The quantities $H_{(\mathrm{rel})}^{(S)}$ and $H_{(\mathrm{rel})}^{(S=0)}$ are the purely rotational and purely vibrational Hamiltonians, respectively.

For equal masses, by making the identifications $\pi=\tilde{\pi}_q$, $\rho=\rho_q$, and $\hat{R}^r=R^{rs}(\theta,\phi)\hat{\rho}_0^s$, we get formally the same results of the previous section but in a different canonical basis. Only after a nonpoint transformation α, S_q, β, $S_q^3\mapsto\theta$, π_θ, ϕ, π_ϕ [i.e. from Eqs. (7.7) to (7.4)], Eq. (7.11) becomes Eq. (6.12).

B. Three-body systems

For $N=3$ the range of the indices is $i=1,2,3$, $a=1,2$. The spin is $\vec{S}_q=\Sigma_{a=1}^{2}\vec{\rho}_{qa}\times\vec{\pi}_{qa}=\Sigma_{a=1}^{2}\vec{S}_{qa}$ after the canonical transformation which separates the internal center of mass

$$\boxed{\begin{array}{|c|}\hline \vec{\eta}_i \\ \hline \vec{\kappa}_i \\ \hline \end{array}} \longrightarrow \boxed{\begin{array}{|c|c|}\hline \vec{q}_+ & \vec{\rho}_{qa} \\ \hline \vec{\kappa}_+ & \vec{\pi}_{qa} \\ \hline \end{array}} \quad . \tag{7.10}$$

Upon the gauge fixings $\vec{q}_+\approx 0$, the relative motions in the rest-frame instant form are ruled by the Hamiltonian

$$H_{(\mathrm{rel})}=H_M(\infty)=\sum_{i=1}^{3}\sqrt{m_i^2+3\sum_{a,b=1}^{2}\gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}}\equiv M_{\mathrm{sys}}. \tag{7.11}$$

We shall assume $\vec{S}_q\neq 0$, because the exceptional SO(3) orbit $S_q=0$ has to be studied separately.[2]

For each value of $a=1,\ 2$ consider the canonical transformation (7.7)

$$\boxed{\begin{array}{|c|}\hline \vec{\rho}_{qa} \\ \hline \vec{\pi}_{qa} \\ \hline \end{array}} \longrightarrow \boxed{\begin{array}{|c|c|c|}\hline \alpha_a & \beta_a & \rho_{qa} \\ \hline S_{qa} & S_{qa}^3 & \tilde{\pi}_{qa} \\ \hline \end{array}} \quad , \tag{7.12}$$

where

$$\alpha_a=\mathrm{tg}^{-1}\frac{1}{S_{qa}}\left(\vec{\rho}_{qa}\cdot\vec{\pi}_{qa}-\frac{(\rho_{qa})^2}{\rho_{qa}^3}\pi_{qa}^3\right),$$

$$\beta_a=\mathrm{tg}^{-1}\frac{S_{qa}^2}{S_{qa}^1},\quad \sin\beta_a=\frac{S_{qa}^2}{\sqrt{(S_{qa})^2-(S_{qa}^3)^2}},\quad \cos\beta_a=\frac{S_{qa}^1}{\sqrt{(S_{qa})^2-(S_{qa}^3)^2}}, \tag{7.13}$$

$$\vec{\rho}_{qa}=\rho_{qa}\hat{R}_a,\quad \rho_{qa}=\sqrt{\vec{\rho}_{qa}^2},\quad \hat{R}_a=\frac{\vec{\rho}_{qa}}{\rho_{qa}}=\hat{\rho}_{qa},\quad \hat{R}_a^2=1,$$

$$\vec{\pi}_{qa}=\tilde{\pi}_{qa}\hat{R}_a-\frac{S_{qa}}{\rho_{qa}}\hat{R}_a\times\hat{S}_{qa},\quad \tilde{\pi}_{qa}=\vec{\pi}_{qa}\cdot\hat{R}_a. \tag{7.14}$$

We now have *two* unit vectors $\hat{R}_a$ and *two* E(3) realizations generated by $\vec{S}_{qa}$, $\hat{R}_a$, respectively, with fixed invariants $\hat{R}_a^2=1$, $\vec{S}_{qa}\cdot\hat{R}_a=0$ (*nonirreducible, type 2*[39]).

Now, we want to implement a SO(3) *Hamiltonian right action* in analogy with the rigid body theory. To this aim, we must construct an orthonormal triad or *body frame* $\hat{N}$, $\hat{\chi}$, $\hat{N}\times\hat{\chi}$. The decomposition $\vec{S}=\check{S}^1\hat{\chi}+\check{S}^2\hat{N}\times\hat{\chi}+\check{S}^3\hat{N}\equiv\check{S}^r\hat{e}_r$, identifies the SO(3) scalar generators $\check{S}^r$ of the right action provided they satisfy $\{\check{S}^r,\check{S}^s\}=-\epsilon^{rsu}\check{S}^u$. This latter condition together with the obvious requirement that $\hat{N}$, $\hat{\chi}$, $\hat{N}\times\hat{\chi}$ be SO(3) vectors $[\{\hat{N}^r,S^s\}=\epsilon^{rsu}\hat{N}^u,\ \{\hat{\chi}^r,S^s\}=\epsilon^{rsu}\hat{\chi}^u,\ \{\hat{N}\times\hat{\chi}^r,S^s\}=\epsilon^{rsu}\hat{N}\times\hat{\chi}^u]$ entails the equations $\{\hat{N}^r,\hat{N}^s\}=\{\hat{N}^r,\hat{\chi}^s\}=\{\hat{\chi}^r,\hat{\chi}^s\}=0$.

To each solution of these equations is associated a couple of canonical realizations of the E(3) group (*nonirreducible, type 2*): one with generators $\vec{S}$, $\vec{N}$ and nonfixed invariants $\check{S}^3=\vec{S}\cdot\hat{N}$ and $|\vec{N}|$; another with generators $\vec{S}$, $\vec{\chi}$ and nonfixed invariants $\check{S}^1=\vec{S}\cdot\hat{\chi}$ and $|\vec{\chi}|$. These realizations contain the relevant information for constructing the angle α and the new canonical pair $\check{S}^3$, $\gamma=\mathrm{tg}^{-1}\check{S}^2/\check{S}^1$ of SO(3) scalars. Since $\{\alpha,\check{S}^3\}=\{\alpha,\gamma\}=0$ must hold, it follows that the vector $\vec{N}$ necessarily belongs to the $\vec{S}-\hat{R}$ plane. The three canonical pairs S, α, S^3, β, $\check{S}^3$, γ will describe

the *orientational* variables of our Darboux basis, while $|\vec{N}|$ and $|\vec{\chi}|$ will belong to the *shape* variables. Alternatively, an anholonomic basis can be constructed by replacing the above-mentioned six variables by $\check{S}^r$ and three uniquely determined Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$.

In the $N=3$ case it turns out that a solution of the previous equation exists corresponding to a *body frame* determined by the three-body system configuration only, as in the *rigid body* case. This solution is completely identified once two orthonormal vectors $\vec{N}$ and $\vec{\chi}$, functions of the relative coordinates and independent of the momenta, are found such that $\vec{N}$ lies in the $\vec{S}-\hat{R}$ plane.[51]

The *simplest choice* for the orthonormal vectors $\vec{N}$ and $\vec{\chi}$, functions of the coordinates alone, is

$$\vec{N}=\frac{1}{2}(\hat{R}_1+\hat{R}_2)=\frac{1}{2}(\hat{\rho}_{q1}+\hat{\rho}_{q2}),\quad \hat{N}=\frac{\vec{N}}{|\vec{N}|},\quad |\vec{N}|=\sqrt{\frac{1+\hat{\rho}_{q1}\cdot\hat{\rho}_{q2}}{2}},$$

$$\vec{\chi}=\frac{1}{2}(\hat{R}_1-\hat{R}_2)=\frac{1}{2}(\hat{\rho}_{q1}-\hat{\rho}_{q2}),\quad \hat{\chi}=\frac{\vec{\chi}}{|\vec{\chi}|},\quad |\vec{\chi}|=\sqrt{\frac{1-\hat{\rho}_{q1}\cdot\hat{\rho}_{q2}}{2}}=\sqrt{1-\vec{N}^2},$$

$$\vec{N}\times\vec{\chi}=-\frac{1}{2}\hat{\rho}_{q1}\times\hat{\rho}_{q2},\quad |\vec{N}\times\vec{\chi}|=|\vec{N}||\vec{\chi}|=\frac{1}{2}\sqrt{1-(\hat{\rho}_{q1}\cdot\hat{\rho}_{q2})^2}, \tag{7.15}$$

$$\vec{N}\cdot\vec{\chi}=0,\quad \{N^r,N^s\}=\{\chi^r,\chi^s\}=\{N^r,\chi^s\}=0,$$

$$\hat{R}_1=\hat{\rho}_{q1}=\vec{N}+\vec{\chi},\quad \hat{R}_2=\hat{\rho}_{q2}=\vec{N}-\vec{\chi},\quad \hat{R}_1\cdot\hat{R}_2=\hat{\rho}_{q1}\cdot\hat{\rho}_{q2}=\vec{N}^2-\vec{\chi}^2.$$

Likewise, we have for the spins

$$\vec{S}_q=\vec{S}_{q1}+\vec{S}_{q2},\quad \vec{W}_q=\vec{S}_{q1}-\vec{S}_{q2},\quad \{W_q^r,W_q^s\}=\epsilon^{rsu}S_q^u,$$
$$\vec{S}_{q1}=\tfrac{1}{2}(\vec{S}_q+\vec{W}_q),\quad \vec{S}_{q2}=\tfrac{1}{2}(\vec{S}_q-\vec{W}_q). \tag{7.16}$$

In this way, we succeeded in constructing an orthonormal triad (the *dynamical body frame*) and two E(3) realizations: one with generators $\vec{S}_q$, $\vec{N}$ and nonfixed invariants $|\vec{N}|$ and $\vec{S}\cdot\hat{N}$, the other with generators $\vec{S}_q$ and $\vec{\chi}$ and nonfixed invariants $|\vec{\chi}|$ and $\vec{S}_q\cdot\hat{\chi}$. As said in Ref. 2 this is equivalent to the determination of the nonconserved generators $\check{S}_q^r$ of a Hamiltonian *right action* of SO(3): $\check{S}_q^1=\vec{S}_q\cdot\hat{\chi}=\vec{S}_q\cdot\hat{e}_1$, $\check{S}_q^2=\vec{S}_q\cdot\hat{N}\times\hat{\chi}=\vec{S}_q\cdot\hat{e}_2$, $\check{S}_q^3=\vec{S}_q\cdot\hat{N}=\vec{S}_q\cdot\hat{e}_3$.

The realization of the E(3) group with generators $\vec{S}_q$, $\vec{N}$ and nonfixed invariants $\mathcal{I}_1=\vec{N}^2$, $\mathcal{I}_2=\vec{S}_q\cdot\vec{N}$ leads to the final canonical transformation

$$\left|\begin{array}{c}\vec{\rho}_{qa}\\ \vec{\pi}_{qa}\end{array}\right| \longrightarrow \left|\begin{array}{cccc|c}\alpha_1 & \beta_1 & \alpha_2 & \beta_2 & \rho_{qa}\\ S_{q1} & S_{q1}^3 & S_{q2} & S_{q2}^3 & \tilde{\pi}_{qa}\end{array}\right| \longrightarrow \left|\begin{array}{ccc|c|c}\alpha & \beta & \gamma & |\vec{N}| & \rho_{qa}\\ S_q=\check{S}_q & S_q^3 & \check{S}_q^3=\vec{S}_q\cdot\hat{N} & \xi & \tilde{\pi}_{qa}\end{array}\right|, \tag{7.17}$$

where

$$|\vec{N}| = \sqrt{\frac{1+\hat{\rho}_{q1}\cdot\hat{\rho}_{q2}}{2}},$$

$$\check{S}^3_q = \vec{S}_q\cdot\hat{N} = \frac{1}{\sqrt{2}}\sum_{a=1}^{2}\vec{\rho}_{qa}\times\vec{\pi}_{qa}\cdot\frac{\hat{\rho}_{q1}+\hat{\rho}_{q2}}{\sqrt{1+\hat{\rho}_{q1}\cdot\hat{\rho}_{q2}}} \equiv S_q\cos\psi,$$

$$\cos\psi = \hat{S}_q\cdot\hat{N} = \frac{\check{S}^3_q}{S_q}, \quad \sin\psi = \frac{1}{S_q}\sqrt{(S_q)^2-(\check{S}^3_q)^2},$$

$$S_q = \check{S}_q = \left|\sum_{a=1}^{2}\vec{\rho}_{qa}\times\vec{\pi}_{qa}\right|, \quad S^3_q = \sum_{a=1}^{2}(\vec{\rho}_{qa}\times\vec{\pi}_{qa})^3,$$

$$\alpha = -\mathrm{tg}^{-1}\frac{(\hat{S}_q\times\hat{N})^3}{[\hat{S}_q\times(\hat{S}_q\times\hat{N})]^3} = -\mathrm{tg}^{-1}\frac{[\hat{S}_q\times(\hat{\rho}_{q1}+\hat{\rho}_{q2})]^3}{[\hat{S}_q\times(\hat{S}_q\times[\hat{\rho}_{q1}+\hat{\rho}_{q2}])]^3},$$

$$\beta = \mathrm{tg}^{-1}\frac{S^2_q}{S^1_q},$$

$$\gamma = \mathrm{tg}^{-1}\frac{\vec{S}_q\cdot(\hat{N}\times\hat{\chi})}{\vec{S}_q\cdot\hat{\chi}} = \mathrm{tg}^{-1}\frac{\check{S}^2_q}{\check{S}^1_q},$$

$$\xi = \frac{\vec{W}_q\cdot(\hat{N}\times\hat{\chi})}{|\vec{\chi}|} = \frac{\sqrt{2}\Sigma^2_{a=1}(-)^{a+1}\vec{\rho}_{qa}\times\vec{\pi}_{qa}\cdot(\hat{\rho}_{q2}\times\hat{\rho}_{q1})}{[1-\hat{\rho}_{q1}\cdot\hat{\rho}_{q2}]\sqrt{1+\hat{\rho}_{q1}\cdot\hat{\rho}_{q2}}}. \tag{7.18}$$

For $N=3$ the *dynamical shape variables*, functions of the relative coordinates alone $\vec{\rho}_{qa}$, are $|\vec{N}|$, $\hat{\rho}_{qa}$, while the conjugate shape momenta are ξ, $\tilde{\pi}_{qa}$.

The final array (7.17) is nothing else than a *scheme* B[40] of a realization of an E(3) group with generators $\vec{S}_q$, $\vec{N}$ (*nonirreducible, type 3*). In particular, the two canonical pairs S^3_q, β, S_q, α, constitute the irreducible kernel of the E(3) *scheme A*, whose invariants are $\check{S}^3_q$, $|\vec{N}|$; γ and ξ are the so-called *supplementary variables* conjugated to the invariants; finally, the two pairs ρ_{qa}, $\tilde{\pi}_{qa}$ are so-called *inessential variables*. Let us remark that S^3_q, β, S_q, α, γ, ξ, are a local coordinatization of every E(3) coadjoint orbit with $\check{S}^3_q=$const, $|\vec{N}|=$const and fixed values of the inessential variables, present in the three-body phase space.

By using Eqs. (7.6), (7.7) and adopting the prescription of Eq. (7.10), we can reconstruct $\vec{S}_q$ and define a *new* unit vector $\hat{R}$ orthogonal to $\vec{S}_q$ and satisfying $\{\hat{R}^r,\hat{R}^s\}=0$.

The vectors $\hat{S}_q$, $\hat{R}$, $\hat{S}_q\times\hat{R}$ build up the *spin frame* for $N=3$. The angle α conjugate to S_q is explicitly given by[52]

$$\alpha = -\mathrm{tg}^{-1}\frac{(\hat{S}_q\times\hat{N})^3}{[\hat{S}_q\times(\hat{S}_q\times\hat{N})]^3} = -\mathrm{tg}^{-1}\frac{(\hat{S}_q\times\hat{R})^3}{[\hat{S}_q\times(\hat{S}_q\times\hat{R})]^3}. \tag{7.19}$$

As a consequence of this definition of $\hat{R}$, we get the following expressions for the *dynamical body frame* $\hat{N}$, $\hat{\chi}$, $\hat{N}\times\hat{\chi}$ in terms of the final canonical variables (see Ref. 2 for the explicit expressions and a geometric visualization)

$$\hat{N} = \cos\psi \hat{S}_q + \sin\psi \hat{R} = \hat{N}[S_q, \alpha; S^3_q, \beta; \check{S}^3_q, \gamma],$$

$$\hat{\chi} = \sin\psi \cos\gamma \hat{S}_q - \cos\psi \cos\gamma \hat{R} + \sin\gamma \hat{S}_q \times \hat{R} = \hat{\chi}[S_q, \alpha; S^3_q, \beta; \check{S}^3_q, \gamma],$$

$$\hat{N} \times \hat{\chi} = \sin\psi \sin\gamma \hat{S}_q - \cos\psi \sin\gamma \hat{R} - \cos\gamma \hat{S}_q \times \hat{R} = (\hat{N} \times \hat{\chi})[S_q, \alpha; S^3_q, \beta; \check{S}^3_q, \gamma],$$

$$\Downarrow$$

$$\hat{S}_q = \sin\psi \cos\gamma \hat{\chi} + \sin\psi \sin\gamma \hat{N} \times \hat{\chi} + \cos\psi \hat{N} \stackrel{\text{def}}{=} \frac{1}{S_q}[\check{S}^1_q \hat{\chi} + \check{S}^2_q \hat{N} \times \hat{\chi} + \check{S}^3_q \hat{N}],$$

$$\hat{R} = -\cos\psi \cos\gamma \hat{\chi} - \cos\psi \sin\gamma \hat{N} \times \hat{\chi} + \sin\psi \hat{N},$$

$$\hat{R} \times \hat{S}_q = -\sin\gamma \hat{\chi} + \cos\gamma \hat{N} \times \hat{\chi}. \tag{7.20}$$

While ψ is the angle between $\hat{S}_q$ and $\hat{N}$, γ is the angle between the plane $\hat{N}-\hat{\chi}$ and the plane $\hat{S}_q - \hat{N}$. As in the case $N=2$, α is the angle between the plane $\hat{S}_q - \hat{f}_3$ and the plane $\hat{S}_q - \hat{R}$, while β is the angle between the plane $\hat{S}_q - \hat{f}_3$ and the plane $\hat{f}_3 - \hat{f}_1$.

Owing to the results of Appendix C of Ref. 2, which allow one to reexpress

$$S_{qa} = |\vec{S}_{qa}|, \quad S^3_{qa}, \quad \beta_a = \mathrm{tg}^{-1}\frac{S^2_{qa}}{S^1_{qa}}, \quad \text{and} \quad \alpha_a = -\mathrm{tg}^{-1}\frac{(\hat{S}_{qa} \times \hat{R}_a)^3}{(\hat{S}_{qa} \times (\hat{S}_{qa} \times \hat{R}_a))^3}$$

in terms of the final variables, we can reconstruct the inverse canonical transformation.

The existence of the *spin frame* and of the *dynamical body frame* allows one to define two decompositions of the relative variables, which make the inverse canonical transformation explicit. For the relative coordinates, from Eq. (7.15) and Appendix C of I, we obtain

$$\begin{aligned}
\vec{\rho}_{qa} &= \rho_{qa}\hat{R}_a = \rho_{qa}[\vec{N} + (-)^{a+1}\vec{\chi}] = \rho_{qa}[|\vec{N}|\hat{N} + (-)^{a+1}\sqrt{1-\vec{N}^2}\hat{\chi}] \\
&= [\vec{\rho}_{qa} \cdot \hat{S}_q]\hat{S}_q + [\vec{\rho}_{qa} \cdot \hat{R}]\hat{R} + [\vec{\rho}_{qa} \cdot \hat{S}_q \times \hat{R}]\hat{S}_q \times \hat{R} \\
&= \frac{\rho_{qa}}{S_q}\Bigg[(|\vec{N}|\check{S}^3_q + (-)^{a+1}\sqrt{1-\vec{N}^2}\,\check{S}^1_q)\hat{S}_q + \Bigg(|\vec{N}|\sqrt{(S_q)^2 - (\check{S}^3_q)^2} \\
&\quad - (-)^{a+1}\sqrt{1-\vec{N}^2}\frac{\check{S}^1_q \check{S}^3_q}{\sqrt{(S_q)^2 - (\check{S}^3_q)^2}} \Bigg)\hat{R} \\
&\quad - (-)^{a+1}\sqrt{1-\vec{N}^2}\,\frac{\check{S}^2_q}{\sqrt{(S_q)^2 - (\check{S}^3_q)^2}}\hat{S}_q \times \hat{R} \Bigg] \\
&= \vec{\rho}_{qa}[S_q, \alpha; S^3_q, \beta; \check{S}^3_q, \gamma; \rho_{qa}, |\vec{N}|].
\end{aligned} \tag{7.21}$$

The results of Appendix C of Ref. 2 give the analogous formulas for the relative momenta.

As shown in Ref. 2, it is possible to perform a sequence of a canonical transformation to Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ with their conjugate momenta, followed by a transition to the anholonomic basis used in the orientation-shape bundle approach[1]

$$\boxed{\begin{array}{|ccc|}\hline \alpha & \beta & \gamma \\ S_q = \check{S}_q & S_q^3 & \check{S}_q^3 \\ \hline\end{array}} \longrightarrow \boxed{\begin{array}{|ccc|}\hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} \\ p_{\tilde{\alpha}} & p_{\tilde{\beta}} & p_{\tilde{\gamma}} \\ \hline\end{array}} \overset{non\ can.}{\longrightarrow} \boxed{\begin{array}{|ccc|}\hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} \\ \check{S}_q^1 & \check{S}_q^2 & \check{S}_q^3 \\ \hline\end{array}} ,$$

$$S_q = \check{S}_q = \sqrt{(\check{S}_q^1)^2 + (\check{S}_q^2)^2 + (\check{S}_q^3)^2},$$

$$S_q^3 = -\sin\tilde{\beta}\cos\tilde{\gamma}\check{S}_q^1 + \sin\tilde{\beta}\sin\tilde{\gamma}\check{S}_q^2 + \cos\tilde{\beta}\check{S}_q^3,$$

$$\alpha = \mathrm{arctg}\frac{p_{\tilde{\beta}} tg\,\tilde{\beta}}{\check{S}_q - \dfrac{p_{\tilde{\alpha}} p_{\tilde{\gamma}}}{\check{S}_q \cos\tilde{\beta}}}, \quad \beta = \tilde{\alpha} + \mathrm{arctg}\frac{\mathrm{ctg}\,\tilde{\beta} p_{\tilde{\alpha}} - \dfrac{p_{\tilde{\gamma}}}{\sin\tilde{\beta}}}{p_{\tilde{\beta}}} - \frac{\pi}{2},$$

$$\gamma = \frac{\pi}{2} - \tilde{\gamma} - \mathrm{arctg}\frac{\mathrm{ctg}\,\tilde{\beta} p_{\tilde{\gamma}} - \dfrac{p_{\tilde{\alpha}}}{\sin\tilde{\beta}}}{p_{\tilde{\beta}}},$$

(7.22)

with the *dynamical orientation variables* $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ determined in terms of $\vec{\rho}_{qa}$, $\vec{\pi}_{qa}$. Let us stress that, while in the orientation-shape bundle approach the orientation variables θ^α are gauge variables, the Euler angles $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ we are using here are *uniquely determined* in terms of the original variables.

In conclusion, the complete transition to the anholonomic basis used in the *static* theory of the orientation-shape bundle is

$$\boxed{\begin{array}{|ccc|c|c|}\hline \alpha & \beta & \gamma & |\vec{N}| & \rho_{qa} \\ S_q = \check{S}_q & S_q^3 & \check{S}_q^3 & \xi & \tilde{\pi}_{qa} \\ \hline\end{array}} \overset{non\ can.}{\longrightarrow} \boxed{\begin{array}{|ccc|c|c|}\hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} & |\vec{N}| & \rho_{qa} \\ \check{S}_q^1 & \check{S}_q^2 & \check{S}_q^3 & \xi & \tilde{\pi}_{qa} \\ \hline\end{array}} ,$$

(7.23)

with the three pairs of conjugate canonical dynamical shape variables: ρ_{qa}, $\tilde{\pi}_{qa}$, $|\vec{N}|$, ξ and with

$$\rho_{qa}^r = \mathcal{R}^r{}_s(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{\rho}_{qa}^s(q),$$

with

$$\check{\rho}_{qa}^1(q) = (-)^{a+1}\rho_{qa}\sqrt{1-\vec{N}^2}, \quad \check{\rho}_{qa}^2(q) = 0, \quad \check{\rho}_{qa}^3(q) = \rho_{qa}|\vec{N}|,$$
$$S_q^r = \mathcal{R}^r{}_s(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\check{S}_q^s.$$

(7.24)

The final visualization of our sequence of transformations is

$$\boxed{\begin{array}{|c|}\hline \vec{\rho}_{qa} \\ \vec{\pi}_{qa} \\ \hline\end{array}} \overset{non\ can.}{\longrightarrow} \boxed{\begin{array}{|ccc|c|}\hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} & q^\mu(\vec{\rho}_{qa}) \\ \check{S}_q^1 & \check{S}_q^2 & \check{S}_q^3 & p_\mu(\vec{\rho}_{qa},\vec{\pi}_{qa}) \\ \hline\end{array}} .$$

(7.25)

Note incidentally that we have $\check{\rho}_{qa}^2 = \vec{\rho}_{qa}\cdot\hat{N}\times\hat{\chi} = 0$ by construction, and this entails that using our *dynamical body frame* is equivalent to a convention (*xxzz gauge*) about the body frame of the type of *xxz* and similar gauges quoted in Ref. 1.

The kinematical calculations of Appendix E of Ref. 46 allow one to obtain the following expression of the Hamiltonian for the relative motions in terms of the anholonomic Darboux basis (7.22):

$$H_{(\mathrm{rel})} \equiv M_{\mathrm{sys}} = H_M(\infty) = \sum_{i=1}^{3} \sqrt{m_i^2 + 3 \sum_{a,b=1}^{2} \gamma_{ai}\gamma_{bi}\vec{\pi}_{qa}\cdot\vec{\pi}_{qb}} = \sum_{i=1}^{3} \Bigg(m_i^2 + \frac{3}{\vec{N}^2}\Bigg[\frac{(\gamma_{1i})^2}{2\rho_{q1}^2} + \frac{(\gamma_{2i})^2}{2\rho_{q2}^2}$$
$$+ \frac{\gamma_{1i}\gamma_{2i}}{\rho_{q1}\rho_{q2}}\Bigg](\check{S}_q^1)^2 + 3\Bigg[\frac{(\gamma_{1i})^2}{2\rho_{q1}^2} + \frac{(\gamma_{2i})^2}{2\rho_{q2}^2} + \frac{\gamma_{1i}\gamma_{2i}(2\vec{N}^2-1)}{\rho_{q1}\rho_{q2}}\Bigg](\check{S}_q^2)^2 + \frac{3}{1-\vec{N}^2}\Bigg[\frac{(\gamma_{1i})^2}{2\rho_{q1}^2} + \frac{(\gamma_{2i})^2}{2\rho_{q2}^2}$$
$$- \frac{\gamma_{1i}\gamma_{2i}}{\rho_{q1}\rho_{q2}}\Bigg](\check{S}_q^3)^2 + 3\sqrt{1-\vec{N}^2}\Bigg[\xi\Bigg(\frac{(\gamma_{1i})^2}{2\rho_{q1}^2} - \frac{(\gamma_{2i})^2}{2\rho_{q2}^2}\Bigg) + 4\gamma_{1i}\gamma_{2i}|\vec{N}|\sqrt{1-\vec{N}^2}\Bigg(\frac{\tilde{\pi}_{q1}}{\rho_{q2}} - \frac{\tilde{\pi}_{q2}}{\rho_{q1}}\Bigg)\Bigg]\check{S}_q^2$$
$$- \frac{3}{|\vec{N}|\sqrt{1-\vec{N}^2}}\Bigg(\frac{(\gamma_{1i})^2}{\rho_{q1}^2} - \frac{(\gamma_{2i})^2}{\rho_{q2}^2}\Bigg)\check{S}_q^1\check{S}_q^3 + 6(\gamma_{1i})^2\Bigg[\tilde{\pi}_{q1}^2 + \frac{\xi^2(1-\vec{N}^2)}{4\rho_{q1}^2}\Bigg] + 6(\gamma_{2i})^2\Bigg[\tilde{\pi}_{q2}^2$$
$$+ \frac{\xi^2(1-\vec{N}^2)}{4\rho_{q2}^2}\Bigg] + 12\gamma_{1i}\gamma_{2i}\Bigg[(2\vec{N}^2-1)\tilde{\pi}_{q1}\tilde{\pi}_{q2} - |\vec{N}|(1-\vec{N}^2)\xi\Bigg(\frac{\tilde{\pi}_{q1}}{\rho_{q2}} + \frac{\tilde{\pi}_{q2}}{\rho_{q1}}\Bigg)$$
$$+ \frac{\xi^2(1-\vec{N}^2)(2\vec{N}^2-1)}{4\rho_{q1}\rho_{q2}}\Bigg]\Bigg)^{1/2} = \sum_{i=1}^{3} H_{(\mathrm{rel})i}, \tag{7.26}$$

where $q^\mu = (\rho_{q1}, \rho_{q2}, |\vec{N}|)$, $p_\mu = (\tilde{\pi}_{q1}, \tilde{\pi}_{q2}, \xi)$ are the dynamical shape variables.

In Ref. 46, this Hamiltonian is put in a form reminiscent of the nonrelativistic orientation-shape bundle approach. It is also shown how to recover the nonrelativistic Hamiltonian (with its splitting in rotational and vibrational parts) and the tensor of inertia in the nonrelativistic limit. We could also define rotational and vibrational relativistic Hamiltonians, but the total Hamiltonian would not result to be their sum.

C. *N*-body systems

Finally, we shall discuss the general case with $N \geqslant 4$. Unlike the method of the Jacobi coordinates, based on coupling the *center-of-mass clusters*, our method of the *canonical spin bases* is based on coupling the spins of the two-body subsystems (*relative particles*) $\vec{\rho}_{qa}$, $\vec{\pi}_{qa}$, $a = 1,..,N-1$, defined in Eq. (3.6), in all possible ways (*spin clusters* from the addition of angular momenta). Let us stress that we can build a *spin basis* with a pattern of *spin clusters* which is completely unrelated to a possible pre-existing *center-of-mass clustering.*

Consider the case $N=4$ as a prototype of the general construction. We have now three relative variables $\vec{\rho}_{q1}$, $\vec{\rho}_{q2}$, $\vec{\rho}_{q3}$ and related momenta $\vec{\pi}_{q1}$, $\vec{\pi}_{q2}$, $\vec{\pi}_{q3}$. In the following formulas we use the convention that the subscripts a, b, c mean any permutation of 1,2,3.

As in Ref. 2, we define a sequence of canonical transformations corresponding to the *spin clustering* pattern $abc \mapsto (ab)c \mapsto ((ab)c)$: first build the spin cluster (ab), then the spin cluster $((ab)c)$, (assume $S_q \neq = 0$; $S_{qA} \neq = 0$, $A = a, b, c$):

$$
\begin{array}{l}
\boxed{\begin{array}{|ccc|}\hline \vec{\rho}_{qa} & \vec{\rho}_{qb} & \vec{\rho}_{qc} \\ \vec{\pi}_{qa} & \vec{\pi}_{qb} & \vec{\pi}_{qc} \\ \hline\end{array}} \longrightarrow \\
\longrightarrow \boxed{\begin{array}{|cc|cc|cc|ccc|}\hline \alpha_a & \beta_a & \alpha_b & \beta_b & \alpha_c & \beta_c & \rho_{qa} & \rho_{qb} & \rho_{qc} \\ S_{qa} & S^3_{qa} & S_{qb} & S^3_{qb} & S_{qc} & S^3_{qc} & \tilde{\pi}_{qa} & \tilde{\pi}_{qb} & \tilde{\pi}_{qc} \\ \hline\end{array}} \longrightarrow \\
\xrightarrow{(ab)c} \boxed{\begin{array}{|ccc|cc|ccc|}\hline \alpha_{(ab)} & \beta_{(ab)} & \gamma_{(ab)} & \alpha_c & \beta_c & |\vec{N}_{(ab)}| & \rho_{qa} & \rho_{qb} & \rho_{qc} \\ S_{q(ab)} & S^3_{q(ab)} & \check{S}^3_{q(ab)} = \vec{S}_{q(ab)} \cdot \hat{N}_{(ab)} & S_{qc} & S^3_{qc} & \xi_{(ab)} & \tilde{\pi}_{qa} & \tilde{\pi}_{qb} & \tilde{\pi}_{qc} \\ \hline\end{array}} \longrightarrow \\
\longrightarrow \boxed{\begin{array}{|ccc|ccc|ccc|}\hline \alpha_{((ab)c)} & \beta_{((ab)c)} & \gamma_{((ab)c)} & |\vec{N}_{((ab)c)}| & \gamma_{(ab)} & |\vec{N}_{(ab)}| & \rho_{qa} & \rho_{qb} & \rho_{qc} \\ S_q = \check{S}_q & S^3_q & \check{S}^3_q = \vec{S}_q \cdot \hat{N}_{((ab)c)} & \xi_{((ab)c)} & \vec{S}_{q(ab)} \cdot \hat{N}_{(ab)} & \xi_{(ab)} & \tilde{\pi}_{qa} & \tilde{\pi}_{qb} & \tilde{\pi}_{qc} \\ \hline\end{array}} \longrightarrow \\
\xrightarrow{non\,can.} \boxed{\begin{array}{|ccc|ccc|ccc|}\hline \tilde{\alpha} & \tilde{\beta} & \tilde{\gamma} & |\vec{N}_{((ab)c)}| & \gamma_{(ab)} & |\vec{N}_{(ab)}| & \rho_{qa} & \rho_{qb} & \rho_{qc} \\ \check{S}^1_q & \check{S}^2_q & \check{S}^3_q & \xi_{((ab)c)} & \Omega_{(ab)} = \vec{S}_{q(ab)} \cdot \hat{N}_{(ab)} & \xi_{(ab)} & \tilde{\pi}_{qa} & \tilde{\pi}_{qb} & \tilde{\pi}_{qc} \\ \hline\end{array}}
\end{array}
\tag{7.27}
$$

See Appendix F of Ref. 2 for the explicit construction of the canonical transformations.

The first nonpoint canonical transformation is based on the existence of the three unit vectors $\hat{R}_A$, $A=a,\ b,\ c$, and of three E(3) groups with fixed values ($\hat{R}^2_A=1$, $\vec{S}_A\cdot\hat{R}_A=0$) of their invariants. Use Eqs. (7.13) and (7.14).

In the next canonical transformation the spins of the *relative particles a* and *b* are coupled to form the spin cluster (ab), leaving the *relative particle c* as a spectator. As said in Ref. 2 the cluster (ab) has a unit vector $\hat{R}_{(ab)}$ with $\vec{S}_{(ab)}\cdot\hat{R}_{(ab)}=0$, $\{\hat{R}^r_{(ab)},\hat{R}^s_{(ab)}\}=0$. This unit vector identifies the *spin cluster* (ab) in the same way as the unit vectors $\hat{R}_A=\hat{\vec{\rho}}_{qA}$ identify the *relative particles A*.

The next step is the coupling of the *spin cluster* (ab) with unit vector $\hat{R}_{(ab)}$ with the *relative particle c* with unit vector $\hat{R}_c$ and described by α_c, S_{qc}, β_c, S^3_{qc}: this builds the *spin cluster* $((ab)c)$. As shown in Ref. 2 it is possible to define the vectors $\vec{N}_{((ab)c)}$, $\vec{\chi}_{((ab)c)}$, $\vec{S}_q=\vec{S}_{q((ab)c)}$ $=\vec{S}_{q(ab)}+\vec{S}_{qc}$, $\vec{W}_{q((ab)c)}=\vec{S}_{q(ab)}-\vec{S}_{qc}$. Since $\vec{N}_{((ab)c)}\cdot\vec{\chi}_{((ab)c)}=0$ and $\{N^r_{((ab)c)},N^s_{((ab)c)}\}$ $=\{N^r_{((ab)c)},\chi^s_{((ab)c)}\}=\{\chi^r_{((ab)c)},\chi^s_{((ab)c)}\}=0$ because of $\{\hat{R}^r_{(ab)},\hat{R}^s_c\}=0$, a new E(3) group generated by $\vec{S}_q$ and $\vec{N}_{((ab)c)}$ with nonfixed invariants $|\vec{N}_{((ab)c)}|$, $\vec{S}_q\cdot\vec{N}_{((ab)c)}=\check{S}^3_q|\vec{N}_{((ab)c)}|$ emerges. Again it is possible to define $\alpha_{((ab)c)}$ and $\beta_{((ab)c)}$, and then to identify a final unit vector $\hat{R}_{((ab)c)}$ with $\vec{S}_q\cdot\hat{R}_{((ab)c)}=0$ and $\{\hat{R}^r_{((ab)c)},\hat{R}^s_{((ab)c)}\}=0$.

In conclusion, when $S_q\neq 0$, we construct both a *dynamical body frame* $\hat{\chi}_{((ab)c)}$, $\hat{N}_{((ab)c)}$ $\times\hat{\chi}_{((ab)c)}$, $\hat{N}_{((ab)c)}$, and a *spin frame* $\hat{S}_q$, $\hat{R}_{((ab)c)}$, $\hat{R}_{((ab)c)}\times\hat{S}_q$ as in the three-body case. There is an *important difference*, however: *the orthonormal vectors* $\vec{N}_{((ab)c)}$ and $\vec{\chi}_{((ab)c)}$ *depend on the momenta of the relative particles a and b through* $\hat{R}_{(ab)}$, *so that our results do not share any relation with the* $N=4$ *nontrivial SO(3) principal bundle of the orientation-shape bundle approach.*

The final six *dynamical shape variables* are $q^\mu=\{|\vec{N}_{((ab)c)}|,\gamma_{(ab)},|\vec{N}_{(ab)}|,\rho_{qa},\rho_{qb},\rho_{qc}\}$. While the last four depend only on the original relative coordinates $\vec{\rho}_{qA}$, $A=a,\ b,\ c$, the first two also depend on the original momenta $\vec{\pi}_{qA}$: therefore they are *generalized shape variables*. It follows

$$
\rho^r_{qA}=\mathcal{R}^{rs}(\tilde{\alpha},\tilde{\beta},\tilde{\gamma})\,\check{\rho}^s_{qA}(q^\mu,p_\mu,\check{S}^r_q),\quad A=a,b,c. \tag{7.28}
$$

It is seen that for $N=4$ the dynamical body frame components $\check{\rho}^r_{qA}$ also depend on the dynamical shape momenta and on the dynamical body frame components of the spin. It is clear that this result stands completely outside the orientation-shape bundle approach.

The price to be paid for the existence of three global *dynamical body frames* for $N=4$ is a more complicated form of the Hamiltonian kinetic energy. On the other hand, *dynamical vibrations* and *dynamical angular velocity* are measurable quantities in each dynamical body frame.

For $N=5$ we can repeat the previous construction with either the sequence of spin clusterings $abcd \mapsto (ab)cd \mapsto ((ab)c)d) \mapsto (((ab)c)d)$ or with the sequence $abcd \mapsto (ab)(cd) \mapsto ((ab) \times (cd))$ $[a,b,c,d$ any permutation of 1,2,3,4]. Each *spin cluster* $(\ldots)$ is identified by the unit vector $\hat{R}_{(\ldots)}$, axis of the *spin frame* of the cluster. All the final *dynamical body frames* built with this construction have their axes depending on both the original configurations and momenta.

This construction is trivially generalized to any N: we have only to classify all the possible *spin clustering patterns*.

In conclusion, for $N \geq 4$ our sequence of canonical and noncanonical transformations leads to the following result [compare with Eq. (7.22) of the three-body case]:

$$\boxed{\begin{array}{c}\vec{\rho}_{qA} \\ \vec{\pi}_{qA}\end{array}} \xrightarrow{non\ can.} \boxed{\begin{array}{c|c}\tilde{\alpha}\ \ \tilde{\beta}\ \ \tilde{\gamma} & q^{\mu}(\vec{\rho}_{qA}, \vec{\pi}_{qA}) \\ \tilde{S}_q^1\ \tilde{S}_q^2\ \tilde{S}_q^3 & p_{\mu}(\vec{\rho}_{qA}, \vec{\pi}_{qA})\end{array}} \quad . \tag{7.29}$$

This state of affairs tells us that for $N \geq 4$ and with $S_q \neq 0$, $S_{qA} \neq 0$, $A=a,\ b,\ c$, viz. when the standard $(3N\text{-}3)$-dimensional orientation-shape bundle is not trivial, the original $(6N\text{-}6)$-dimensional relative phase space admits the definition of as many *dynamical body frames* as spin canonical bases,[53] which are globally defined (apart isolated coordinate singularities) for the nonsingular N-body configurations with $\vec{S}_q \neq 0$ (and with nonzero spin for each spin subcluster). Such *dynamical body frames* do not correspond to local cross sections of the static nontrivial orientation-shape SO(3) principal bundle and the spin canonical bases do not coincide with the canonical bases associated with the static theory.

VIII. THE CASE OF INTERACTING PARTICLES

As shown in Ref. 26 and its bibliography, the action-at-a-distance interactions inside the Wigner hyperplane may be introduced either under the square roots (scalar and vector potentials) or outside (scalar potential like the Coulomb one) appearing in the free Hamiltonian (2.19).

In the rest-frame instant form the most general Hamiltonian with action-at-a-distance interactions is

$$H = \sum_{i=1}^{N} \sqrt{m_i^2 + U_i + [\vec{k}_i - \vec{V}_i]^2} + V, \tag{8.1}$$

where $U = U(\vec{\kappa}_k, \vec{\eta}_h - \vec{\eta}_k)$, $\vec{V}_i = \vec{V}_i(\vec{k}_{j\neq i}, \vec{\eta}_i - \vec{\eta}_{j\neq i})$, $V = V_o(|\vec{\eta}_i - \vec{\eta}_j|) + V'(\vec{k}_i, \vec{\eta}_i - \vec{\eta}_j)$.

The rest frame Hamiltonian for the relative motion becomes

$$H_{(\mathrm{rel})} = \sum_{i=1}^{N} \sqrt{m_i^2 + \tilde{U}_i + \left[\sqrt{n}\sum_{a=1}^{N-1} \gamma_{ai}\vec{\pi}_{qa} - \tilde{\vec{V}}_i\right]^2} + \tilde{V}, \tag{8.2}$$

where

$$\begin{aligned}
\tilde{U}_i &= U\left(\sqrt{n}\sum_{a=1}^{N-1} \gamma_{ak}\vec{\pi}_{qa}, \frac{1}{\sqrt{N}}\sum_{a=1}^{N-1}(\gamma_{ah} - \gamma_{ak})\vec{\rho}_{qa}\right), \\
\tilde{\vec{V}}_i &= \vec{V}_i\left(\sqrt{n}\sum_{a=1}^{N-1} \gamma_{aj\neq i}\vec{\pi}_{qa}, \frac{1}{\sqrt{N}}\sum_{a=1}^{N-1}(\gamma_{ai} - \gamma_{aj\neq i})\vec{\rho}_{qa}\right), \\
\tilde{V} &= V_o\left(\left|\frac{1}{\sqrt{N}}\sum_{a=1}^{N-1}(\gamma_{ai} - \gamma_{aj})\vec{\rho}_{qa}\right|\right) + V'\left(\sqrt{n}\sum_{a=1}^{N-1} \gamma_{ai}\vec{\pi}_{qa}, \frac{1}{\sqrt{N}}\sum_{a=1}^{N-1}(\gamma_{ai} - \gamma_{aj})\vec{\rho}_{qa}\right).
\end{aligned} \tag{8.3}$$

The price to be paid for the existence of three global *dynamical body frames* for $N=4$ is:

(i) a more complicated form of the Hamiltonian kinetic energy (it allows, however, for a definition of measurable *dynamical vibrations* and *dynamical angular velocity* in each dynamical body frame);

(ii) the fact that a potential $V(\vec{\eta}_{ij}\cdot\vec{\eta}_{hk})$ with $\vec{\eta}_{ij}=\vec{\eta}_i-\vec{\eta}_j$ becomes shape-momenta dependent, since

$$V(\vec{\eta}_{ij}\cdot\vec{\eta}_{hk})=V\left[\frac{1}{N}\sum_{a,b}^{1,..,N-1}(\Gamma_{ai}-\Gamma_{aj})(\Gamma_{bh}-\Gamma_{bk})\vec{\rho}_{qa}\cdot\vec{\rho}_{qb}\right]. \tag{8.4}$$

For $N=4$, in the pattern $((ab)c)$, it follows

$$V=\tilde{V}_{((ab)c)}[\rho_{qa},\rho_{qb},\rho_{qc},|\vec{N}_{((ab)c)}|,\gamma_{(ab)},|\vec{N}_{(ab)}|;\xi_{((ab)c)},\Omega_{(ab)};\check{S}^r_q]. \tag{8.5}$$

For more general potentials $V(\vec{\eta}_{ij}\cdot\vec{\eta}_{hk},\vec{\kappa}_i\cdot\vec{\eta}_{hk},\vec{\kappa}_i\cdot\vec{\kappa}_j)$, such as that appearing in the nonrelativistic limit of the relativistic Darwin potential of Ref. 26, more complicated expressions emerge.

IX. CONCLUSIONS

In this paper we have explored the relativistic kinematics of a system of N scalar positive-energy particles. In the framework of the rest-frame instant form of dynamics it is possible to find the relativistic extension of the Abelian translational and non-Abelian rotational symmetries whose associated Noether constants of motion are fundamental for the study of isolated systems. In the relativistic case the rest-frame description on the Wigner hyperplanes allows one to clarify all the problems by virtue of a doubling of all the concepts: they can be either *external* (namely observed by an arbitrary inertial Lorentz frame) or *internal* (namely observed by an inertial observer at rest inside the Wigner hyperplane). Correspondingly, two realizations of the Poincaré algebra are naturally defined.

After a clarification of the possible *external* and *internal* definitions of relativistic center of mass, we have shown that it is possible to define a family of canonical transformations leading to the construction of relative canonical variables. The rest-frame Hamiltonian can be expressed in terms of these variables. It turns out that, due to the presence of multiple square roots in the Hamiltonian, the nonrelativistic concepts of *Jacobi normal relative coordinates*, *reduced masses*, and *barycentric tensor of inertia* cannot be extended to the relativistic formulation.

On the other hand, the rest-frame description (Wigner hyperplanes) allows one to exploit the nonrelativistic formalism developed in Ref. 2 for the analysis of the rotational kinematics, being independent of Jacobi coordinates. It is possible, therefore, to extend the concepts of *canonical spin bases*, *spin frames*, and *dynamical body frames* to the relativistic level. It follows again that, because of the non-Abelian nature of rotations, a global separation of rotations from vibrations is *not* possible.

In a future paper[36] we will conclude the discussion of relativistic kinematics by defining Dixon's multipoles[35] for the relativistic N-body problem in the rest-frame instant form of dynamics. It will be shown that concepts like the *tensor of inertia* can be recovered by using the quadrupole moment.

The final task should be the extension of all these results to relativistic extended (*continua*) isolated systems.

APPENDIX A: PARAMETRIZED MINKOWSKI THEORIES

We review here the main features of *parametrized Minkowski theories* and of the canonical reduction of gauge systems, following Refs. 9, 26, and 38, where a complete treatment for N scalar charged positive energy particles plus the electromagnetic field is given.

The starting point is Dirac's[12] reformulation of classical field theory on spacelike hypersurfaces foliating Minkowski space–time M^4. The foliation is defined by an embedding $R\times\Sigma \to M^4$, $(\tau,\vec{\sigma})\mapsto z^\mu(\tau,\vec{\sigma})$, with Σ an abstract three-surface diffeomorphic to R^3.

Let $\{\Sigma_\tau\}$ be the resulting one-parameter family of spacelike hypersurfaces. We use the notations $\sigma^{\check{A}}=(\sigma^\tau=\tau;\vec{\sigma}=\{\sigma^{\check{r}}\})$[54] and $\partial_{\check{A}}=\partial/\partial\sigma^{\check{A}}$. Define the cotetrads

$$z^\mu_{\check{A}}(\tau,\vec{\sigma})=\partial_{\check{A}}z^\mu(\tau,\vec{\sigma}),\quad \partial_{\check{B}}z^\mu_{\check{A}}-\partial_{\check{A}}z^\mu_{\check{B}}=0, \tag{A1}$$

so that the metric on Σ_τ is

$$\begin{aligned} &g_{\check{A}\check{B}}(\tau,\vec{\sigma})=z^\mu_{\check{A}}(\tau,\vec{\sigma})\,\eta_{\mu\nu}z^\nu_{\check{B}}(\tau,\vec{\sigma}),\quad \epsilon g_{\tau\tau}(\tau,\vec{\sigma})>0,\\ &g(\tau,\vec{\sigma})=-\det\|\,g_{\check{A}\check{B}}(\tau,\vec{\sigma})\,\|=(\det\|\,z^\mu_{\check{A}}(\tau,\vec{\sigma})\,\|)^2,\\ &\gamma(\tau,\vec{\sigma})=-\det\|g_{\check{r}\check{s}}(\tau,\vec{\sigma})\|=\det\|{}^3g_{\check{r}\check{s}}(\tau,\vec{\sigma})\|, \end{aligned} \tag{A2}$$

where $g_{\check{r}\check{s}}=-\epsilon\,{}^3g_{\check{r}\check{s}}$, with ${}^3g_{\check{r}\check{s}}$ having positive signature $(+++)$.

If $\gamma^{\check{r}\check{s}}(\tau,\vec{\sigma})=-\epsilon^3g^{\check{r}\check{s}}$ is the inverse of the three-metric $g_{\check{r}\check{s}}(\tau,\vec{\sigma})$ $[\gamma^{\check{r}\check{u}}(\tau,\vec{\sigma})g_{\check{u}\check{s}}(\tau,\vec{\sigma})=\delta^{\check{r}}_{\check{s}}]$, the inverse $g^{\check{A}\check{B}}(\tau,\vec{\sigma})$ of $g_{\check{A}\check{B}}(\tau,\vec{\sigma})$ $[g^{\check{A}\check{C}}(\tau,\vec{\sigma})g_{\check{C}\check{b}}(\tau,\vec{\sigma})=\delta^{\check{A}}_{\check{B}}]$ is given by

$$\begin{aligned} &g^{\tau\tau}(\tau,\vec{\sigma})=\frac{\gamma(\tau,\vec{\sigma})}{g(\tau,\vec{\sigma})},\\ &g^{\tau\check{r}}(\tau,\vec{\sigma})=-\left[\frac{\gamma}{g}g_{\tau\check{u}}\gamma^{\check{u}\check{r}}\right](\tau,\vec{\sigma})=\epsilon\left[\frac{\gamma}{g}g_{\tau\check{u}}\,{}^3g^{\check{u}\check{r}}\right](\tau,\vec{\sigma}),\\ &g^{\check{r}\check{s}}(\tau,\vec{\sigma})=\gamma^{\check{r}\check{s}}(\tau,\vec{\sigma})+\left[\frac{\gamma}{g}g_{\tau\check{u}}g_{\tau\check{v}}\gamma^{\check{u}\check{r}}\gamma^{\check{v}\check{s}}\right](\tau,\vec{\sigma})=-\epsilon\,{}^3g^{\check{r}\check{s}}(\tau,\vec{\sigma})+\left[\frac{\gamma}{g}g_{\tau\check{u}}g_{\tau\check{v}}\,{}^3g^{\check{u}\check{r}}\,{}^3g^{\check{v}\check{s}}\right](\tau,\vec{\sigma}), \end{aligned} \tag{A3}$$

so that $1=g^{\tau\check{C}}(\tau,\vec{\sigma})g_{\check{C}\tau}(\tau,\vec{\sigma})$ is equivalent to

$$\frac{g(\tau,\vec{\sigma})}{\gamma(\tau,\vec{\sigma})}=g_{\tau\tau}(\tau,\vec{\sigma})-\gamma^{\check{r}\check{s}}(\tau,\vec{\sigma})g_{\tau\check{r}}(\tau,\vec{\sigma})g_{\tau\check{s}}(\tau,\vec{\sigma}). \tag{A4}$$

We have

$$z^\mu_\tau(\tau,\vec{\sigma})=\left(\sqrt{\frac{g}{\gamma}}l^\mu+g_{\tau\check{r}}\gamma^{\check{r}\check{s}}z^\mu_{\check{s}}\right)(\tau,\vec{\sigma}), \tag{A5}$$

and

$$\eta^{\mu\nu}=z^\mu_{\check{A}}(\tau,\vec{\sigma})g^{\check{A}\check{B}}(\tau,\vec{\sigma})z^\nu_{\check{B}}(\tau,\vec{\sigma})=(l^\mu l^\nu+z^\mu_{\check{r}}\gamma^{\check{r}\check{s}}z^\nu_{\check{s}})(\tau,\vec{\sigma}), \tag{A6}$$

where

$$l^\mu(\tau,\vec{\sigma})=\left(\frac{1}{\sqrt{\gamma}}\epsilon^\mu{}_{\alpha\beta\gamma}z^\alpha_{\check{1}}z^\beta_{\check{2}}z^\gamma_{\check{3}}\right)(\tau,\vec{\sigma}),\quad l^2(\tau,\vec{\sigma})=1,\quad l_\mu(\tau,\vec{\sigma})z^\mu_{\check{r}}(\tau,\vec{\sigma})=0, \tag{A7}$$

is the unit (future pointing) normal to Σ_τ at $z^\mu(\tau,\vec{\sigma})$.

The price to be paid for carrying out this approach is the necessity of *adding* the embeddings $z^\mu(\tau,\vec{\sigma})$ identifying the points of the spacelike hypersurface Σ_τ as new configuration variables, as a matter of fact the only ones carrying Lorentz indices. A scalar parameter τ labels the leaves of

the foliation and $\vec{\sigma}$ are curvilinear coordinates on Σ_τ. It is then possible to redefine the fields on Σ_τ so that they *know* the whole hypersurface Σ_τ of τ-simultaneity. For a Klein–Gordon field $\phi(x)$, this new field is $\tilde{\phi}(\tau,\vec{\sigma})=\phi(z(\tau,\vec{\sigma}))$: it contains the nonlocal information about the embedding and the associated notion of *equal time*. This is a parametrized field theory with a covariant $3+1$ splitting of flat space–time which is set in a form already suited for the transition to general relativity in its ADM canonical formulation.

The Lagrangian of a isolated system can be rewritten in the form required by the coupling to an external gravitational field, the $3+1$ splitting of Minkowski space–time can be introduced and all the fields of the system can replaced by new fields on Σ_τ, which are Lorentz scalars, carrying only surface indices. Instead of considering the four-metric as describing a gravitational field, one replaces the four-metric by the induced metric $g_{\check{A}\check{B}}[z]=z^\mu_{\check{A}}\eta_{\mu\nu}z^\nu_{\check{B}}$ on Σ_τ (a functional of z^μ), and considers the embedding coordinates $z^\mu(\tau,\vec{\sigma})$ as independent fields. We use the notation $\sigma^{\check{A}}=(\tau,\sigma^{\check{r}})$ of Refs. 9 and 26. The $z^\mu_{\check{A}}(\sigma)=\partial z^\mu(\sigma)/\partial\sigma^{\check{A}}$ are flat cotetrad fields on Minkowski space–time with the $z^\mu_{\check{r}}$'s tangent to Σ_τ [note that in metric gravity the $z^\mu_{\check{A}}\neq\partial z^\mu/\partial\sigma^{\check{A}}$ are not cotetrad fields since no holonomic coordinates $z^\mu(\sigma)$ exist].

From the rewritten Lagrangian [see Eq. (2.3) for the case of N free scalar particles], it follows that: (i) the possible constraints of the system are Lorentz scalars; (ii) four primary first class constraints are added to assure the independence of the description from the choice of the foliation with spacelike hypersufaces:

$$\mathcal{H}_\mu(\tau,\vec{\sigma})=\rho_\mu(\tau,\vec{\sigma})-l_\mu(\tau,\vec{\sigma})T^{\tau\tau}_{\rm system}(\tau,\vec{\sigma})-z_{\check{r}\mu}(\tau,\vec{\sigma})T^{\tau\check{r}}_{\rm system}(\tau,\vec{\sigma})\approx 0. \tag{A8}$$

Here $T^{\tau\tau}_{\rm system}(\tau,\vec{\sigma})$, $T^{\tau\check{r}}_{\rm system}(\tau,\vec{\sigma})$, are the components of the energy–momentum tensor in the holonomic coordinate system on Σ_τ corresponding to the energy– and momentum–density of the isolated system. These four constraints satisfy an Abelian Poisson algebra since they are solved in the four-momenta $\rho_\mu(\tau,\vec{\sigma})$ conjugate to the embedding variables $z^\mu(\tau,\vec{\sigma})$: $\{\mathcal{H}_\mu(\tau,\vec{\sigma}),\mathcal{H}_\nu(\tau,\vec{\sigma}')\}=0$. This shows that the embedding fields $z^\mu(\tau,\vec{\sigma})$ are the *gauge* variables associated with this kind of general covariance.

The Dirac Hamiltonian is

$$H_D=H_{(c)}+\int \mathrm{d}^3\sigma\lambda^\mu(\tau,\vec{\sigma})\mathcal{H}_\mu(\tau,\vec{\sigma})+(\text{system-dependent primary constraints}), \tag{A9}$$

with $\lambda^\mu(\tau,\vec{\sigma})$ arbitrary Dirac multipliers and with $H_{(c)}$ the canonical Hamiltonian (it is either zero or weakly vanishing due to system-dependent secondary constraints). By using Eq. (A6) we can write

$$\begin{aligned}\lambda_\mu(\tau,\vec{\sigma})\mathcal{H}^\mu(\tau,\vec{\sigma})&=[(\lambda_\mu l^\mu)(l_\nu\mathcal{H}^\nu)-(\lambda_\mu z^\mu_{\check{r}})({}^3g^{\check{r}\check{s}}z_{\check{s}\nu}\mathcal{H}^\nu)](\tau,\vec{\sigma})\\ &\overset{\text{def}}{=}N_{(\rm flat)}(\tau,\vec{\sigma})(l_\mu\mathcal{H}^\mu)(\tau,\vec{\sigma})-N_{(\rm flat)\check{r}}(\tau,\vec{\sigma})({}^3g^{\check{r}\check{s}}z_{\check{s}\nu}\mathcal{H}^\nu)(\tau,\vec{\sigma}),\end{aligned} \tag{A10}$$

with the (nonholonomic form of the) constraints $\tilde{\mathcal{H}}(\tau,\vec{\sigma})=(l_\mu\mathcal{H}^\mu)(\tau,\vec{\sigma})\approx 0$, $\tilde{\mathcal{H}}_{\check{r}}(\tau,\vec{\sigma})=(z_{\check{r}\mu}\mathcal{H}^\mu)(\tau,\vec{\sigma})\approx 0$, satisfying the universal Dirac algebra like the ADM super-Hamiltonian and supermomentum constraints.

We have thereby defined new flat lapse and shift functions

$$\begin{aligned}N_{(\rm flat)}(\tau,\vec{\sigma})&=\lambda_\mu(\tau,\vec{\sigma})l^\mu(\tau,\vec{\sigma}),\\ N_{(\rm flat)\check{r}}(\tau,\vec{\sigma})&=\lambda_\mu(\tau,\vec{\sigma})z^\mu_{\check{r}}(\tau,\vec{\sigma}).\end{aligned} \tag{A11}$$

which have the same content of the arbitrary Dirac multipliers $\lambda_\mu(\tau,\vec{\sigma})$: they multiply primary first class constraints satisfying the Dirac algebra. In Minkowski spacetime they are quite distinct from the lapse and shift functions $N_{[z](\mathrm{flat})}(\tau,\vec{\sigma})=\sqrt{g(\tau,\vec{\sigma})/\gamma(\tau,\vec{\sigma})}$, $N_{[z](\mathrm{flat})\check{r}}(\tau,\vec{\sigma})={}^4g_{\tau\check{r}}(\tau,\vec{\sigma})$, defined by starting from the metric (they are functionals of the embeddings). Only by using the Hamilton equations $z^\mu_\tau(\tau,\vec{\sigma})\overset{\circ}{=}\{z^\mu(\tau,\vec{\sigma}),H_D\}=\lambda^\mu(\tau,\vec{\sigma})$ it follows that $N_{[z](\mathrm{flat})}(\tau,\vec{\sigma})\overset{\circ}{=}N_{(\mathrm{flat})}(\tau,\vec{\sigma})$, $N_{[z](\mathrm{flat})\check{r}}(\tau,\vec{\sigma})\overset{\circ}{=}N_{(\mathrm{flat})\check{r}}(\tau,\vec{\sigma})$.

Therefore, when we consider arbitrary $3+1$ splittings of space–time with arbitrary spacelike hypersurfaces, the descriptions of metric gravity plus matter and the parametrized Minkowski description of the same matter do not seem to follow the same pattern. The situation changes, however, if the allowed $3+1$ splittings of space–time in ADM metric gravity are restricted to have the leaves approaching Minkowski spacelike hyperplanes at spatial infinity and if parametrized Minkowski theories are restricted to spacelike hyperplanes.

The restriction of parametrized Minkowski theories to flat hyperplanes in Minkowski space–time is done by adding the gauge-fixings[9]

$$z^\mu(\tau,\vec{\sigma})-x^\mu_s(\tau)-b^\mu_{\check{r}}(\tau)\sigma^{\check{r}}\approx 0. \tag{A12}$$

Here $x^\mu_s(\tau)$ denotes a point on the hyperplane Σ_τ chosen as an arbitrary origin for the three-coordinates; the $b^\mu_{\check{r}}(\tau)$'s form an orthonormal triad at $x^\mu_s(\tau)$, and the τ-independent normal to the family of spacelike hyperplanes is $l^\mu=b^\mu_\tau=\epsilon^\mu{}_{\alpha\beta\gamma}b^\alpha_{\check{1}}(\tau)b^\beta_{\check{2}}(\tau)b^\gamma_{\check{3}}(\tau)$. Each hyperplane is described by ten configuration variables, $x^\mu_s(\tau)$ and the six independent degrees of freedom contained in the triad $b^\mu_{\check{r}}(\tau)$, and by the ten conjugate momenta: p^μ_s and six variables hidden in a spin tensor $S^{\mu\nu}_s$.[9] With these twenty canonical variables it is possible to build ten Poincaré generators $\overline{p^\mu_s}=p^\mu_s$, $\overline{J^{\mu\nu}_s}=x^\mu_s p^\nu_s-x^\nu_s p^\mu_s+S^{\mu\nu}_s$.

After the restriction to spacelike hyperplanes, the part $\int \mathrm{d}^3\sigma\lambda^\mu(\tau,\vec{\sigma})\mathcal{H}_\mu(\tau,\vec{\sigma})$ of the Dirac Hamiltonian is reduced to

$$\tilde{\lambda}^\mu(\tau)\tilde{\mathcal{H}}_\mu(\tau)-\tfrac{1}{2}\tilde{\lambda}^{\mu\nu}(\tau)\tilde{\mathcal{H}}_{\mu\nu}(\tau), \tag{A13}$$

because the time constancy of the gauge-fixings $z^\mu(\tau,\vec{\sigma})-x^\mu_s(\tau)-b^\mu_{\check{r}}(\tau)\sigma^{\check{r}}\approx 0$ implies (the overdot means $d/d\tau$)

$$\lambda_\mu(\tau,\vec{\sigma})=\tilde{\lambda}_\mu(\tau)+\tilde{\lambda}_{\mu\nu}(\tau)b^\nu_{\check{r}}\sigma^{\check{r}}, \tag{A14}$$

with

$$\tilde{\lambda}^\mu(\tau)=-\dot{x}^\mu_s(\tau),\quad \tilde{\lambda}^{\mu\nu}(\tau)=-\tilde{\lambda}^{\nu\mu}(\tau)=\frac{1}{2}\sum_{\check{r}}\,[\dot{b}^\mu_{\check{r}}b^\nu_{\check{r}}-b^\mu_{\check{r}}\dot{b}^\nu_{\check{r}}](\tau).$$

Since at this stage we have $z^\mu_{\check{r}}(\tau,\vec{\sigma})\approx b^\mu_{\check{r}}(\tau)$, we get

$$\begin{aligned} z^\mu_\tau(\tau,\vec{\sigma})&\approx N_{[z](\mathrm{flat})}(\tau,\vec{\sigma})l^\mu(\tau,\vec{\sigma})+N^{\check{r}}_{[z](\mathrm{flat})}(\tau,\vec{\sigma})b^\mu_{\check{r}}(\tau,\vec{\sigma})\\ &\approx\dot{x}^\mu_s(\tau)+\dot{b}^\mu_{\check{r}}(\tau)\sigma^{\check{r}}=-\tilde{\lambda}^\mu(\tau)-\tilde{\lambda}^{\mu\nu}(\tau)b_{\check{r}\nu}(\tau)\sigma^{\check{r}}. \end{aligned} \tag{A15}$$

Note that the coincidence of the two definitions of flat lapse and shift functions, independently of the equations of motion, is recovered at this stage only; actually

$$N_{[z](\mathrm{flat})}(\tau,\vec{\sigma})\approx N_{(\mathrm{flat})}(\tau,\vec{\sigma}),\quad N_{[z](\mathrm{flat})\check{r}}(\tau,\vec{\sigma})\approx N_{(\mathrm{flat})\check{r}}(\tau,\vec{\sigma}). \tag{A16}$$

The independence of our description on arbitrary foliations with spacelike hyperplanes, from the choice of the particular foliation, is assured by the remaining ten first class constraints

$$\tilde{\mathcal{H}}^{\mu}(\tau)=\int \mathrm{d}^3\sigma\,\mathcal{H}^{\mu}(\tau,\vec{\sigma})=p_s^{\mu}-p_{\rm sys}^{\mu}=p_s^{\mu}$$
$$-[\text{total momentum of the system inside the hyperplane}]^{\mu}\approx 0,$$
$$\tilde{\mathcal{H}}^{\mu\nu}(\tau)=b_{\check{r}}^{\mu}(\tau)\int d^3\sigma\,\sigma^{\check{r}}\mathcal{H}^{\nu}(\tau,\vec{\sigma})-b_{\check{r}}^{\nu}(\tau)\int d^3\sigma\,\sigma^{\check{r}}\mathcal{H}^{\mu}(\tau,\vec{\sigma})=S_s^{\mu\nu}-S_{sys}^{\mu\nu}=S_s^{\mu\nu}$$
$$-[\text{intrinsic angular momentum of the system inside the hyperplane}]^{\mu\nu},\tag{A17}$$

so that it follows

$$N_{(\rm flat)}(\tau,\vec{\sigma})=\lambda_{\mu}(\tau,\vec{\sigma})l^{\mu}(\tau,\vec{\sigma})\mapsto N_{(\rm flat)}(\tau,\vec{\sigma})=N_{[z](\rm flat)}(\tau,\vec{\sigma})=-\tilde{\lambda}_{\mu}(\tau)l^{\mu}-l^{\mu}\tilde{\lambda}_{\mu\nu}(\tau)b_{\check{s}}^{\nu}(\tau)\sigma^{\check{s}}$$
$$=-\lambda(\tau)-\tfrac{1}{2}\lambda_{\tau\check{s}}(\tau)\sigma^{\check{s}},$$

$$N_{(\rm flat)\check{r}}(\tau,\vec{\sigma})=\lambda_{\mu}(\tau,\vec{\sigma})z_{\check{r}}^{\mu}(\tau,\vec{\sigma})\mapsto N_{(\rm flat)}(\tau,\vec{\sigma})=N_{[z](\rm flat)\check{r}}(\tau,\vec{\sigma})=-\tilde{\lambda}_{\mu}(\tau)b_{\check{r}}^{\mu}(\tau)$$
$$-b_{\check{r}}^{\mu}(\tau)\tilde{\lambda}_{(\mu)(\nu)}(\tau)b_{\check{s}}^{\nu}(\tau)\sigma^{\check{s}}=-\lambda_{\check{r}}(\tau)-\tfrac{1}{2}\lambda_{\check{r}\check{s}}(\tau)\sigma^{\check{s}},$$

$$\lambda_A(\tau)=\tilde{\lambda}_{\mu}(\tau)b_A^{\mu}(\tau),\quad \tilde{\lambda}_{\mu}(\tau)=b_{\mu}^{A}(\tau)\lambda_A(\tau),\tag{A18}$$

$$\lambda_{AB}(\tau)=\tilde{\lambda}_{\mu\nu}(\tau)[b_A^{\mu}b_B^{\nu}-b_A^{\nu}b_B^{\mu}](\tau)=2[\tilde{\lambda}_{\mu\nu}b_A^{\mu}b_B^{\nu}](\tau),$$

$$\tilde{\lambda}_{\mu\nu}(\tau)=\tfrac{1}{4}[b_{\mu}^{A}b_{\nu}^{B}-b_{\mu}^{B}b_{\nu}^{A}](\tau)\lambda_{AB}(\tau)=\tfrac{1}{2}[b_{\mu}^{A}b_{\nu}^{B}\lambda_{AB}](\tau).$$

This is the main difference of the present approach with respect to the treatment of parametrized Minkowski theories given in standard references: there, no configuration action is defined but only a phase space action, in which people use, wrongly, $N_{[z](\rm flat)}$, $N_{[z](\rm flat)\check{r}}$ instead of $N_{(\rm flat)}$, $N_{(\rm flat)\check{r}}$ not only on spacelike hyperplanes but also on arbitrary spacelike hypersurfaces.

The embedding canonical variables $z^{\mu}(\tau,\vec{\sigma})$, $\rho_{\mu}(\tau,\vec{\sigma})$ are reduced to:

(i) $x_s^{\mu}(\tau),p_s^{\mu}$ with $\{x_s^{\mu},p_s^{\nu}\}=-{}^4\eta^{\mu\nu}$, parametrizing the arbitrary origin of the coordinates on the family of spacelike hyperplanes. The four constraints $\mathcal{H}^{\mu}(\tau)\approx p_s^{\mu}-p_{\rm sys}^{\mu}\approx 0$ mean that p_s^{μ} is determined by the four-momentum of the isolated system.

(ii) $b_A^{\mu}(\tau)$ [momentarily we do not identify the τ-dependent $b_{\tau}^{\mu}(\tau)$ with the normal l^{μ}] and $S_s^{\mu\nu}=-S_s^{\nu\mu}$, with the orthonormality constraints $b_A^{\mu}\,{}^4\eta_{\mu\nu}b_B^{\nu}={}^4\eta_{AB}$. The nonvanishing Dirac brackets enforcing the orthonormality constraints[55,9] for the b_A^{μ}'s are

$$\{b_A^{\rho},S_s^{\mu\nu}\}={}^4\eta^{\rho\mu}b_A^{\nu}-{}^4\eta^{\rho\nu}b_A^{\mu},$$
$$\{S_s^{\mu\nu},S_s^{\alpha\beta}\}=C_{\gamma\delta}^{\mu\nu\alpha\beta}S_s^{\gamma\delta},\tag{A19}$$

with $C_{\gamma\delta}^{\mu\nu\alpha\beta}$ the structure constants of the Lorentz algebra.

Then p_s^{μ}, $J_s^{\mu\nu}=x_s^{\mu}p_s^{\nu}-x_s^{\nu}p_s^{\mu}+S_s^{\mu\nu}$, satisfy the algebra of the Poincaré group, with $S_s^{\mu\nu}$ playing the role of the spin tensor. The other six constraints $\mathcal{H}^{\mu\nu}(\tau)\approx S_s^{\mu\nu}-S_{\rm sys}^{\mu\nu}\approx 0$ entail that $S_s^{\mu\nu}$ coincides with the spin tensor of the isolated system.

The velocity of the origin $x_s^{\mu}(\tau)$ is

$$\dot{x}_s^\mu(\tau) \overset{\circ}{=} \{x_s^\mu(\tau), H_D\} = \tilde{\lambda}_\nu(\tau)\{x_s^\mu(\tau), \mathcal{H}^\mu(\tau)\} = -\tilde{\lambda}^\mu(\tau) = [u^\mu(p_s)u^\nu(p_s) - \epsilon_r^\mu(u(p_s))\epsilon_r^\nu(u(p_s))]\dot{x}_{s\nu}(\tau) = -u^\mu(p_s)\lambda(\tau) + \epsilon_r^\mu(u(p_s))\lambda_r(\tau),$$

$$\dot{x}_s^2(\tau) = \lambda^2(\tau) - \vec{\lambda}^2(\tau) > 0, \quad \dot{x}_s \cdot u(p_s) = -\lambda(\tau),$$

$$U_s^\mu(\tau) = \frac{\dot{x}_s^\mu(\tau)}{\sqrt{\epsilon \dot{x}_s^2(\tau)}} = \frac{-\lambda(\tau)u^\mu(p_s) + \lambda_r(\tau)\epsilon_r^\mu(u(p_s))}{\sqrt{\lambda^2(\tau) - \vec{\lambda}^2(\tau)}}, \tag{A20}$$

$$\Rightarrow x_s^\mu(\tau) = x_s^\mu(0) - u^\mu(p_s)\int_0^\tau d\tau_1\, \lambda(\tau_1) + \epsilon_r^\mu(u(p_s))\int_0^\tau d\tau_1\, \lambda_r(\tau_1).$$

For each configuration of an isolated system with timelike total four-momentum there is a privileged family of Wigner hyperplanes orthogonal to p_s^μ ($\epsilon p_s^2 > 0$), namely that corresponding to the *intrinsic rest-frame* of the isolated system. If we choose these hyperplanes by means of suitable gauge fixings for the constraints $\tilde{\mathcal{H}}^{\mu\nu}(\tau) \approx 0$,[9] we are left with the four constraints $\mathcal{H}^\mu(\tau) \approx 0$, which can be rewritten as

$$\epsilon_s = \sqrt{\epsilon p_s^2} \approx [\text{invariant mass of the isolated system under investigation}] = M_{\text{sys}},$$

$$\vec{p}_{\text{sys}} = [3 - \text{momentum of the isolated system inside the Wigner hyperplane}] \approx 0, \tag{A21}$$

$$H_D = H_{(c)} + \tilde{\lambda}^\mu(\tau)\tilde{\mathcal{H}}_\mu(\tau) + (\text{system-dependent primary constraints}) = H_{(c)} + \lambda(\tau)[\epsilon_s - M_{\text{sys}}] - \vec{\lambda}(\tau)\cdot\vec{p}_{\text{sys}} + (\text{system-dependent primary constraints}).$$

There is no other restriction on p_s^μ, because $u_s^\mu(p_s) = p_s^\mu/\sqrt{\epsilon p_s^2}$ gives the orientation of the Wigner hyperplanes containing the isolated system, with respect to an arbitrarily given external inertial observer.

In this special gauge, after the projection to Dirac brackets, we have $b_A^\mu \equiv L^\mu{}_A(p_s, \mathring{p}_s)$ (the standard Wigner boost for timelike Poincaré orbits) and $S_s^{\mu\nu} \equiv S_{sys}^{\mu\nu}$, $\tilde{\lambda}_{\mu\nu}(\tau) \equiv 0$. The origin $x_s^\mu(\tau)$ does not belong to the canonical basis for these Dirac brackets anymore and is replaced by the noncovariant canonical variable[9]

$$\tilde{x}_s^\mu(\tau) = x_s^\mu(\tau) - \frac{1}{\epsilon_s(p_s^0 + \epsilon_s)}\left[p_{s\nu}S_s^{\nu\mu} + \epsilon_s\left(S_s^{0\mu} - S_s^{0\nu}\frac{p_{s\nu}p_s^\mu}{\epsilon_s^2}\right)\right].$$

In general, we have the problem that in the gauges where $\tilde{\lambda}_{\mu\nu}(\tau)$ or $\tilde{\lambda}_{AB}(\tau)$ are different from zero, the foliations with leaves Σ_τ associated with arbitrary $3+1$ splittings of Minkowski space–time are geometrically *ill-defined* at spatial infinity. Therefore, the variational principle describing the isolated system can make sense only for those $3+1$ splittings having these parts of Dirac's multipliers vanishing. The problem is that, since on hyperplanes $\dot{l}^\mu = 0$ and $l^\mu b_{\check{r}\mu}(\tau) = 0$ imply $l^\mu \dot{b}_{\check{r}\mu}(\tau) = 0$, Eq. (A15) implies $\lambda_{\tau\check{r}}(\tau) = 0$ [i.e., only three $\tilde{\lambda}_{\mu\nu}(\tau)$ are independent] on spacelike hyperplane, because otherwise Lorentz boosts could generate crossing of the foliation leaves. This suggests that, to avoid inconsistencies, the reduction be done from arbitrary spacelike hypersurfaces either directly to the Wigner hyperplanes or to spacelike hypersurfaces approaching Wigner hyperplanes asymptotically.[56] Therefore, the $3+1$ splittings of Minkowski space–time whose leaves are Wigner hyperplanes are the only ones for which the foliation is well defined at spatial infinity: both the induced proper time interval and shift functions are finite there.

In this way we have obtained a new kind of instant form of the dynamics, the *Wigner-covariant one-time rest-frame instant form*.[9,38] For any isolated system, all the variables become

Wigner covariant except for the *external* canonical center of mass $\tilde{x}^\mu_s$, which loses Lorentz covariance. This does not matter, however, being a completely decoupled variable. Our approach realizes the special relativistic generalization of the nonrelativistic separation of the center of mass from the relative motion $[H=\vec{P}^2/2M+H_{\rm rel}]$. The role of the center of mass is taken by the Wigner hyperplane, identified by a point $\tilde{x}^\mu(\tau)$ and its normal p^μ_s.

Let us close the Appendix quoting some notions concerning the *standard Wigner boosts for timelike Poincaré orbits*.

The rest frame form of a timelike four-vector p^μ is $\mathring{p}^\mu=\eta\sqrt{\epsilon p^2}(1;\vec{0})=\eta^{\mu 0}\eta\sqrt{\epsilon p^2}$, $\mathring{p}^2=p^2$, where $\eta=\mathrm{sign}\,p^0$. The standard Wigner boost transforming $\mathring{p}^\mu$ into p^μ is

$$\begin{aligned}
L^\mu{}_\nu(p,\mathring{p}) &= \epsilon^\mu_\nu(u(p)) \\
&= \eta^\mu_\nu + 2\frac{p^\mu \mathring{p}_\nu}{\epsilon p^2} - \frac{(p^\mu+\mathring{p}^\mu)(p_\nu+\mathring{p}_\nu)}{p\cdot\mathring{p}+\epsilon p^2} \\
&= \eta^\mu_\nu + 2u^\mu(p)u_\nu(\mathring{p}) - \frac{(u^\mu(p)+u^\mu(\mathring{p}))(u_\nu(p)+u_\nu(\mathring{p}))}{1+u^o(p)}, \\
&\nu=0, \quad \epsilon^\mu_0(u(p))=u^\mu(p)=p^\mu/\eta\sqrt{\epsilon p^2}, \\
&\nu=r, \quad \epsilon^\mu_r(u(p))=\left(-u_r(p);\delta^i_r-\frac{u^i(p)u_r(p)}{1+u^o(p)}\right).
\end{aligned} \tag{A22}$$

The inverse of $L^\mu{}_\nu(p,\mathring{p})$ is $L^\mu{}_\nu(\mathring{p},p)$, the standard boost to the rest frame, defined by

$$L^\mu{}_\nu(\mathring{p},p)=L_\nu{}^\mu(p,\mathring{p})=L^\mu{}_\nu(p,\mathring{p})|_{\vec{p}\to-\vec{p}}. \tag{A23}$$

Therefore, we can define the following cotetrads and tetrads:[57]

$$\begin{aligned}
&\epsilon^\mu_A(u(p))=L^\mu{}_A(p,\mathring{p}), \\
&\epsilon^A_\mu(u(p))=L^A{}_\mu(\mathring{p},p)=\eta^{AB}\eta_{\mu\nu}\epsilon^\nu_B(u(p)), \\
&\bar{\epsilon^o_\mu}(u(p))=\eta_{\mu\nu}\epsilon^\nu_o(u(p))=u_\mu(p), \quad \epsilon^A_o(u(p))=u_A(p), \\
&\epsilon^r_\mu(u(p))=-\delta^{rs}\eta_{\mu\nu}\epsilon^\nu_r(u(p))=\left(\delta^{rs}u_s(p);\delta^r_j-\delta^{rs}\delta_{jh}\frac{u^h(p)u_s(p)}{1+u^o(p)}\right), \\
&\epsilon^A_\mu(u(p))\epsilon^\nu_A(u(p))=\eta^\mu_\nu, \quad \epsilon^A_\mu(u(p))\epsilon^\mu_B(u(p))=\eta^A_B, \\
&\eta^{\mu\nu}=\epsilon^\mu_A(u(p))\eta^{AB}\epsilon^\nu_B(u(p))=u^\mu(p)u^\nu(p)-\sum_{r=1}^3\epsilon^\mu_r(u(p))\epsilon^\nu_r(u(p)).
\end{aligned} \tag{A24}$$

The *Wigner rotation* corresponding to the Lorentz transformation Λ is

$$\begin{aligned}
&R^\mu{}_\nu(\Lambda,p)=[L(\mathring{p},p)\Lambda^{-1}L(\Lambda p,\mathring{p})]^\mu{}_\nu=\begin{pmatrix}1 & 0\\ 0 & R^i{}_j(\Lambda,p)\end{pmatrix}, \\
&R^i{}_j(\Lambda,p)=(\Lambda^{-1})^i{}_j-\frac{(\Lambda^{-1})^i{}_o p_\beta(\Lambda^{-1})^\beta{}_j}{p_\rho(\Lambda^{-1})^\rho{}_o+\eta\sqrt{\epsilon p^2}}-\frac{p^i}{p^o+\eta\sqrt{\epsilon p^2}}\left[(\Lambda^{-1})^o{}_j-\frac{((\Lambda^{-1})^o{}_o-1)p_\beta(\Lambda^{-1})^\beta{}_j}{p_\rho(\Lambda^{-1})^\rho{}_o+\eta\sqrt{\epsilon p^2}}\right].
\end{aligned} \tag{A25}$$

The polarization vectors transform under the Poincaré transformations (a,Λ) as

$$\epsilon_r^\mu(u(\Lambda p))=(R^{-1})_r{}^s\Lambda^\mu{}_\nu\epsilon_s^\nu(u(p)). \tag{A26}$$

APPENDIX B: THE GARTENHAUS–SCHWARTZ TRANSFORMATION FOR SPINNING PARTICLES

Reference 58 contains the rest-frame instant form description of a system of N spinning positive-energy particles with the intrinsic spin described by Grassmann variables.

The N spinning particles are described on the Wigner hyperplane by a canonical basis including the center-of-mass variables $\tilde{x}_s^\mu$, p_s^μ, the pairs $\vec{\eta}_i$, $\vec{\kappa}_i$, $i=1,..,N$, of Eq. (2.16) and three Grassmann variables $\xi_i^r\equiv\epsilon_\mu^r(u(p_s))\xi_i^\mu$[58] satisfying $\{\xi_i^r,\xi_j^s\}=-i\delta^{rs}\delta_{ij}$ for each spin, and having vanishing Poisson bracket with all of the other variables.

The rest-frame *external* realization of the Poincaré algebra is built in analogy to Eq. (2.14) but with a modified spin tensor $\tilde{S}_s^{\mu\nu}$,

$$\begin{aligned}&\vec{\overline{S}}_s=\sum_{i=1}^N(\vec{\eta}_i\times\vec{\kappa}_i+\vec{\overline{S}}_{i\xi}),\\ &\overline{S}_{i\xi}^r=-\frac{i}{2}\epsilon^{ruv}\xi_i^u\xi_i^v,\quad \{\overline{S}_{i\xi}^r,\overline{S}_{j\xi}^s\}=\delta_{ij}\epsilon^{rsu}\overline{S}_{i\xi}^u.\end{aligned} \tag{B1}$$

In the absence of interactions Eqs. (2.7), (2.8), and (2.16) remain valid.

By using the expression of $\overline{S}_s^{\mu\nu}$ on the Wigner hyperplane given in Ref. 58 and the methodology of Ref. 31, the *internal* realization (2.15) of the Poincaré algebra becomes

$$\begin{aligned}&M_{\rm sys}=\sum_{i=1}^N\sqrt{m_i^2+\vec{\kappa}_i^2}=\sum_{i=1}^N H_i,\quad H_i=\sqrt{m_i^2+\vec{\kappa}_i^2},\\ &\vec{\kappa}_+=\sum_{i=1}^N\vec{\kappa}_i\quad(\approx 0),\\ &\vec{J}=\vec{\overline{S}}_s=\sum_{i=1}^N(\vec{\eta}_i\times\vec{\kappa}_i+\vec{\overline{S}}_{i\xi})=\vec{J}_B+\vec{J}_S,\quad \vec{J}_S=\sum_{i=1}^N\vec{\overline{S}}_{i\xi},\\ &\vec{K}=-\sum_{i=1}^N\vec{\eta}_iH_i+\sum_{i=1}^N\frac{\vec{\overline{S}}_{i\xi}\times\vec{\kappa}_i}{m_i+H_i}=\vec{K}_B+\vec{K}_s,\quad \vec{K}_B=-\sum_{i=1}^N\vec{\eta}_iH_i.\end{aligned} \tag{B2}$$

If, following Ref. 31, we put

$$\begin{aligned}&\vec{K}=-M_{\rm sys}\vec{q}_+ +\frac{\vec{S}_q\times\vec{\kappa}_+}{\sqrt{\Pi}+M_{\rm sys}},\quad \Pi=H_M^2-\vec{\kappa}_+^2,\\ &\vec{S}_q=\vec{J}-\vec{q}_+\times\vec{\kappa}_+,\end{aligned} \tag{B3}$$

we get consistently the expression of the *internal* canonical center of mass $\vec{q}_+$ given in Eq. (4.4), with $\vec{S}_q$ as the associated spin vector.

As in Sec. VI, we apply the Gartenhaus–Schwartz transformation leading from the internal canonical basis $\vec{\eta}_i$, $\vec{\kappa}_i$, $\vec{\xi}_i$ (with $\vec{\kappa}_+\approx 0$) to the center-of-mass basis $\vec{q}_+$, $\vec{\kappa}_+$, $\vec{\rho}_{qa}$, $\vec{\pi}_{qa}$, $\vec{\xi}_{qi}$ (being again $\vec{\kappa}_+\approx 0$) with $\vec{\overline{S}}_{i\xi}\mapsto\vec{S}_{qi\xi}$. Using Eqs. (5.1) and (5.4) with $\vec{K}=\vec{K}_B+\vec{K}_S$ of Eq. (B2), it is possible to find the differential equations for the α-dependence of the various quantities.

Since $\{\vec{\pi}_a,\vec{K}_S\}=0$, $\vec{\pi}_{qa}=\lim_{\alpha\to\infty}\vec{\pi}_a(\alpha)$ is the same as in the spinless case; the $\vec{\pi}_{qa}$'s are given in Eq. (5.13). Here too Π is an invariant and it holds $\sqrt{\Pi}=H_M(\infty)=H_{(\mathrm{rel})}=\Sigma_{i=1}^N H_i(\infty)$ with $H_i(\infty)=(M_{\mathrm{sys}}H_i-\vec{\kappa}_+\cdot\vec{\kappa}_i)/\sqrt{\Pi}$. Moreover, $\vec{n}_+=\vec{\kappa}_+/|\vec{\kappa}_+|$ is invariant.

For the spin variables $\vec{\vec{S}}_{i\xi}$ we obtain

$$\begin{aligned}\frac{\mathrm{d}\overline{S}^r_{i\xi}(\alpha)}{\mathrm{d}\alpha}&=\{\overline{S}^r_{i\xi}(\alpha),\vec{q}_+(\alpha)\cdot\vec{\kappa}_+(\alpha)\}=\left\{\frac{\vec{K}(\alpha)\cdot\vec{\kappa}_+(\alpha)}{H_M(\alpha)},\overline{S}^r_{i\xi}\right\}=\frac{\kappa^s_+(\alpha)}{H_M(\alpha)}\{K^s_S(\alpha),\overline{S}^r_{i\xi}(\alpha)\}\\&=\frac{[(\vec{\kappa}_+(\alpha)\times\vec{\kappa}_i(\alpha))\times\vec{\vec{S}}_{i\xi}(\alpha)]^r}{H_M(\alpha)(m_i+H_i(\alpha))},\\&\Rightarrow\frac{\mathrm{d}\vec{\vec{S}}_{i\xi}(\alpha)}{\mathrm{d}\theta(\alpha)}=\frac{(\vec{n}_+\times\vec{\kappa}_i(\alpha))\times\vec{\vec{S}}_{i\xi}(\alpha)}{m_i+H_i(\alpha)}.\end{aligned}\tag{B4}$$

This equation coincides with Eq. (3.10) of Ref. 45. By using Eq. (3.11) of Ref. 45, its integration provides the *Thomas precession* of the spin variable $\vec{\vec{S}}_{i\xi}$ about an axis $\vec{\kappa}_i\times\vec{n}_+$ in the instantaneous center-of-mass frame:[59]

$$\begin{aligned}&\vec{\vec{S}}_{i\xi}(\alpha)=\cos\gamma(\alpha)\vec{\vec{S}}_{i\xi}+[1-\cos\gamma(\alpha)](\vec{v}_i\cdot\vec{\vec{S}}_{i\xi})\vec{v}_i-\sin\gamma(\alpha)\vec{v}_i\times\vec{\vec{S}}_{i\xi},\\&\vec{v}_i=\frac{\vec{\kappa}_i\times\vec{n}_+}{|\vec{\kappa}_i\times\vec{n}_+|},\\&\mathrm{tg}\frac{\gamma(\alpha)}{2}=\frac{1-\cos\gamma(\alpha)}{\sin\gamma(\alpha)}=\frac{|\vec{\kappa}_i\times\vec{n}_+|}{(m_i+H_i)\mathrm{ctgh}\frac{\theta(\alpha)}{2}-\vec{\kappa}_i\cdot\vec{n}_+}\\&\quad\to_{\alpha\to\infty}\frac{|\vec{\kappa}_i\times\vec{\kappa}_+|}{(m_i+H_i)(M_{\mathrm{sys}}+\sqrt{\Pi})-\vec{\kappa}_i\cdot\vec{\kappa}_+}\approx 0,\quad\left[\mathrm{tg}\frac{\gamma(\infty)}{2}=\frac{M_{\mathrm{sys}}+\sqrt{\Pi}}{|\vec{\kappa}_+|}\right],\\&\sin\gamma(\alpha)=2\frac{(m_i+H_i)\mathrm{ctgh}\frac{\theta(\alpha)}{2}-\vec{\kappa}_i\cdot\vec{n}_+}{|\vec{\kappa}_i\times\vec{n}_+|^2+\left[(m_i+H_i)\mathrm{ctgh}\frac{\theta(\alpha)}{2}-\vec{\kappa}_i\cdot\vec{n}_+\right]^2}|\vec{\kappa}_i\times\vec{n}_+|,\\&\cos\gamma(\alpha)=1-2\frac{|\vec{\kappa}_i\times\vec{n}_+|^2}{|\vec{\kappa}_i\times\vec{n}_+|^2+\left[(m_i+H_i)\mathrm{ctgh}\frac{\theta(\alpha)}{2}-\vec{\kappa}_i\cdot\vec{n}_+\right]^2}.\end{aligned}\tag{B5}$$

Therefore, we obtain

$$\begin{aligned}\vec{S}_{qi\xi}=\lim_{\alpha\to\infty}\vec{\vec{S}}_{i\xi}(\alpha)&=\left[1-\frac{|\vec{\kappa}_i\times\vec{\kappa}_+|^2}{(m_i+H_i)(m_i+H_i(\infty))(M_{\mathrm{sys}}+\sqrt{\Pi})\sqrt{\Pi}}\right]\vec{\vec{S}}_{i\xi}\\&+\frac{\vec{\kappa}_i\times\vec{\kappa}_+\cdot\vec{\vec{S}}_{i\xi}\vec{\kappa}_i\times\vec{\kappa}_+}{(m_i+H_i)(m_i+H_i(\infty))(M_{\mathrm{sys}}+\sqrt{\Pi})\sqrt{\Pi}}-\frac{(m_i+H_i)(M_{\mathrm{sys}}+\sqrt{\Pi})-\vec{\kappa}_i\cdot\vec{\kappa}_+}{(m_i+H_i)(m_i+H_i(\infty))(M_{\mathrm{sys}}+\sqrt{\Pi})\sqrt{\Pi}}(\vec{\kappa}_i\\&\times\vec{\kappa}_+)\times\vec{\vec{S}}_{i\xi}\approx\vec{\vec{S}}_{i\xi}.\end{aligned}\tag{B6}$$

For the Grassmann variables $\vec{\xi}_i$, we get the same differential equation

$$\frac{d\xi_i^r(\alpha)}{d\alpha}=\{\xi_i^r(\alpha),\vec{q}_+(\alpha)\cdot\vec{\kappa}_+(\alpha)\}=\frac{[(\vec{\kappa}_+(\alpha)\times\vec{\kappa}_i(\alpha))\times\vec{\xi}_i]^r}{H_M(\alpha)(m_i+H_i(\alpha))},$$

$$\Rightarrow\frac{d\vec{\xi}_i(\alpha)}{d\theta(\alpha)}=\frac{(\vec{n}_+\times\vec{\kappa}_i(\alpha))\times\vec{\xi}_i(\alpha)}{m_i+H_i(\alpha)},\tag{B7}$$

$$\Downarrow$$

$$\vec{\xi}_{qi}=\lim_{\alpha\to\infty}\vec{\xi}_i(\alpha)=\left[1-\frac{|\vec{\kappa}_i\times\vec{\kappa}_+|^2}{(m_i+H_i)(m_i+H_i(\infty))(M_{\rm sys}+\sqrt{\Pi})\sqrt{\Pi}}\right]\vec{\xi}_i$$
$$+\frac{\vec{\kappa}_i\times\vec{\kappa}_+\cdot\vec{\xi}_i\vec{\kappa}_i\times\vec{\kappa}_+}{(m_i+H_i)(m_i+H_i(\infty))(M_{\rm sys}+\sqrt{\Pi})\sqrt{\Pi}}$$
$$-\frac{(m_i+H_i)(M_{\rm sys}+\sqrt{\Pi})-\vec{\kappa}_i\cdot\vec{\kappa}_+}{(m_i+H_i)(m_i+H_i(\infty))(M_{\rm sys}+\sqrt{\Pi})\sqrt{\Pi}}(\vec{\kappa}_i\times\vec{\kappa}_+)\times\vec{\xi}_i\approx\vec{\xi}_i\,.$$

Let us remark that now, besides the invariants $I_i^{(1)}$ and $I^{(2)}$ of Eqs. (5.14) of the spinless case (we have $I^{(2)}=I_B^{(2)}+I_S^{(2)}$ since $\vec{K}=\vec{K}_B+\vec{K}_S$), we have the additional invariants

$$I_i^{(3)}=(\vec{\kappa}_i\times\vec{n}_+)\cdot\vec{\bar{S}}_{i\xi},$$
$$I^{(2)}=I_B^{(2)}+I_S^{(2)},\quad I_S^{(2)}=\frac{|\vec{\kappa}_+|}{H_M}\sum_{i=1}^N\frac{I_i^{(3)}}{m_i+H_i}.\tag{B8}$$

Consider now the position vectors. As in the spinless case, the preliminary calculations for Eq. (5.19) now give

$$\frac{d}{d\alpha}\vec{n}_+\cdot\vec{\eta}_i(\alpha)=-\frac{\vec{n}_+\cdot\vec{\eta}_i(\alpha)}{H_i(\alpha)}\frac{dH_i(\alpha)}{d\alpha}-\frac{I_i^{(1)}I^{(2)}}{H_i(\alpha)}\frac{dJ^{(1)}(\alpha)}{d\alpha}-\frac{1}{H_i(\alpha)}\frac{dH_i(\alpha)}{d\alpha}\frac{I_i^{(3)}}{(m_i+H_i(\alpha))^2}.\tag{B9}$$

These equations have the solution

$$\vec{n}_+\cdot\vec{\eta}_i(\alpha)=\frac{H_i}{H_i(\alpha)}\vec{n}_+\cdot\vec{\eta}_i-\frac{I^{(2)}}{|\vec{\kappa}_+|}\left(e^\alpha-\frac{H_i}{H_i(\alpha)}\right)+\frac{I_i^{(3)}}{H_i(\alpha)}\left(\frac{1}{m_i+H_i(\alpha)}-\frac{1}{m_i+H_i}\right).\tag{B10}$$

For $\vec{\eta}_i(\alpha)$ it follows

$$\frac{\mathrm{d}\vec{\eta}_i(\alpha)}{\mathrm{d}\alpha}=\{\vec{\eta}_i(\alpha),\vec{\kappa}_+(\alpha)\cdot\vec{q}_+(\alpha)\}=-n^s_+\frac{\partial}{\partial\vec{\kappa}_i(\alpha)}\frac{|\vec{\kappa}_+(\alpha)|K^s(\alpha)}{H_M(\alpha)}=\vec{n}_+\cdot\vec{\eta}_i(\alpha)\frac{|\vec{\kappa}_+(\alpha)|\vec{\kappa}_i(\alpha)}{H_i(\alpha)H_M(\alpha)}$$
$$+\frac{\Sigma^N_{j=1}H_j(\alpha)\vec{n}_+\cdot\vec{\eta}_j(\alpha)}{H_M(\alpha)}\left[\frac{|\vec{\kappa}_+(\alpha)|\vec{\kappa}_i(\alpha)}{H_i(\alpha)H_M(\alpha)}-\vec{n}_+\right]+\frac{\vec{n}_+\cdot(\vec{\vec{S}}_{i\xi}(\alpha)\times\vec{\kappa}_i(\alpha))|\vec{\kappa}_+(\alpha)|\vec{\kappa}_i(\alpha)}{H_M(\alpha)H_i(\alpha)(m_i+H_i(\alpha))^2}$$
$$-\frac{|\vec{\kappa}_+(\alpha)|\vec{n}_+\times\vec{\vec{S}}_{i\xi}(\alpha)}{H_M(\alpha)(m_i+H_i(\alpha))}=\frac{H_i|\vec{\kappa}_+(\alpha)|\vec{\kappa}_i(\alpha)}{H_i^2(\alpha)H_M(\alpha)}\left[\vec{n}_+\cdot\vec{\eta}_i+\frac{I^{(2)}}{|\vec{\kappa}_+|}\right]-\frac{\vec{n}_+\cdot\vec{K}(\alpha)\vec{n}_+}{H_M(\alpha)}$$
$$+\frac{\vec{\kappa}_i(\alpha)|\vec{\kappa}_+(\alpha)|}{H_i(\alpha)H_M(\alpha)}\frac{\vec{n}_+\cdot(\vec{\vec{S}}_{i\xi}(\alpha)\times\vec{\kappa}_i(\alpha))}{(m_i+H_i(\alpha))^2}+\frac{I^{(3)}_i}{H_i(\alpha)}\left[\frac{1}{m_i+H_i(\alpha)}-\frac{1}{m_i+H_i}\right]$$
$$-\frac{|\vec{\kappa}_+(\alpha)|\vec{n}_+\times\vec{\vec{S}}_{i\xi}(\alpha)}{H_M(\alpha)(m_i+H_i(\alpha))}. \tag{B11}$$

The equations for $\vec{\rho}_a(\alpha)=\sqrt{N}\Sigma^N_{i=1}\gamma_{ai}\vec{\eta}_i(\alpha)$ are [see Eq. (3.21) of Ref. 45]

$$\frac{\mathrm{d}\vec{\rho}_a(\alpha)}{\mathrm{d}\alpha}=\sqrt{N}\sum_{i=1}^N\gamma_{ai}\frac{\mathrm{d}\vec{\eta}_i(\alpha)}{\mathrm{d}\alpha}=\sqrt{N}\sum_{i=1}^N\gamma_{ai}\frac{H_i|\vec{\kappa}_+(\alpha)|\vec{\kappa}_i(\alpha)}{H_i^2(\alpha)}\left(\vec{n}_+\cdot\vec{\eta}_i+\frac{I^{(2)}}{|\vec{\kappa}_+|}\right)$$
$$+\sqrt{N}\sum_{i=1}^N\gamma_{ai}\frac{\vec{\kappa}_i(\alpha)}{H_i(\alpha)}\left[\frac{|\vec{\kappa}_+(\alpha)|}{H_M(\alpha)}\frac{\vec{n}_+\cdot(\vec{\vec{S}}_{i\xi}\times\vec{\kappa}_i(\alpha))}{(m_i+H_i(\alpha))^2}+\frac{I^{(3)}_i|\vec{\kappa}_+(\alpha)|}{H_iH_M(\alpha)}\left(\frac{1}{m_i+H_i(\alpha)}\right.\right.$$
$$\left.\left.-\frac{1}{m_i+H_i}\right)\right]+\sqrt{N}\sum_{i=1}^N\gamma_{ai}\frac{|\vec{\kappa}_+(\alpha)|\vec{n}_+\times\vec{\vec{S}}_{i\xi}(\alpha)}{H_M(\alpha)(m_i+H_i(\alpha))}. \tag{B12}$$

By using the results contained in Ref. 45 this equation can be integrated and the final result is

$$\vec{\rho}_a(\alpha)=\vec{\rho}_a-\sum_{i,j=1}^N\sum_{b=1}^{N-1}\gamma_{aj}(\gamma_{bi}-\gamma_{bj})\frac{H_iH_j}{M_{\mathrm{sys}}}\vec{J}^{(2)}_j(\alpha)\vec{n}_+\cdot\vec{\rho}_b$$
$$+\sqrt{N}\sum_{i=1}^N\frac{I^{(3)}_i}{M_{\mathrm{sys}}(m_i+H_i)}\sum_{j=1}^N\gamma_{aj}\frac{\vec{k}_j(\alpha)}{H_j(\alpha)}\,\mathrm{sh}\,\theta(\alpha)$$
$$+\sqrt{N}\sum_{i=1}^N\frac{\gamma_{ai}}{(m_i+H_i(\alpha))(m_i+H_i)}\left[\frac{I^{(3)}_i(\vec{\kappa}_i-|\vec{n}_+\cdot\vec{\kappa}_i|\vec{n}_+\mathrm{sh}\,\theta(\alpha)}{H_i(\alpha)}+\frac{I^{(3)}_i[H_i-H_i(\alpha)]\vec{n}_+}{H_i(\alpha)}\right.$$
$$\left.+[\mathrm{ch}\,\theta(\alpha)-1]\vec{n}_+\cdot\vec{\vec{S}}_{i\xi}\vec{\kappa}_i\times\vec{n}_+-\mathrm{sh}\,\theta(\alpha)\frac{(m_i+H_i)[\mathrm{ch}\,\theta(\alpha)+1]-\vec{n}_+\cdot\vec{k}_i\mathrm{sh}\,\theta(\alpha)}{\mathrm{ch}\,\theta(\alpha)+1}\right]. \tag{B13}$$

Finally we get

$$\vec{\rho}_{qa}=\lim_{\alpha\to\infty}\vec{\rho}_a(\alpha)=\vec{\rho}_a-\sum_{i,j=1}^{N}\sum_{b=1}^{N-1}\gamma_{aj}(\gamma_{bi}-\gamma_{bj})\frac{H_i}{M_{\rm sys}}\left[\frac{|\vec{\kappa}_+|\vec{\kappa}_j(\infty)}{H_j(\infty)\sqrt{\Pi}}+\left(\frac{M_{\rm sys}}{\sqrt{\Pi}}-1\right)\vec{n}_+\right]\vec{n}_+\cdot\vec{\rho}_b$$

$$+\sqrt{N}\sum_{i=1}^{N}\frac{I_i^{(3)}}{M_{\rm sys}(m_i+H_i)}\sum_{j=1}^{N}\gamma_{aj}\frac{|\vec{\kappa}_+|\vec{\kappa}_j(\infty)}{H_j(\infty)\sqrt{\Pi}}+\sqrt{N}\sum_{i=1}^{N}\frac{\gamma_{ai}}{(m_i+H_i)(m_i+H_i(\infty))}\left[\frac{|\vec{\kappa}_+|I_i^{(3)}}{H_i(\infty)\sqrt{\Pi}}(\vec{\kappa}_i\right.$$

$$-\vec{n}_+\cdot\vec{\kappa}_i\vec{n}_+)+\frac{I_i^{(3)}(H_i-H_i(\infty))}{H_i(\infty)}+\frac{(M_{\rm sys}-\sqrt{\Pi})\vec{n}_+\cdot\vec{\vec{S}}_{i\xi}}{\sqrt{\Pi}}\vec{\kappa}_i\times\vec{n}_+$$

$$\left.-\frac{|\vec{\kappa}_+|}{\sqrt{\Pi}}\frac{(m_i+H_i)(M_{\rm sys}+\sqrt{\Pi})-|\vec{\kappa}_+|\vec{n}_+\cdot\vec{\kappa}_i}{M_{\rm sys}-\sqrt{\Pi}}\vec{n}_+\times\vec{\vec{S}}_{i\xi}\right]\approx\vec{\rho}_a\,. \tag{B14}$$

In the same way we obtain, as in the spinless case:

$$\vec{J}_S(\alpha)=\sum_{i=1}^{N}\left[\vec{\eta}_i(\alpha)\times\vec{\kappa}_i(\alpha)+\vec{\vec{S}}_{i\xi}(\alpha)\right]$$

$$\to_{\alpha\to\infty}\vec{S}_q=\sum_{a=1}^{N-1}\vec{\rho}_{qa}\times\vec{\pi}_{qa}+\sum_{i=1}^{N}\vec{S}_{qi\xi}\,. \tag{B15}$$

[25] This is true for scalar positive-energy particles (Ref. 26). For spinning positive-energy particles we must add (Ref. 27) some nonminimal coupling of the spin to the electric field. This would disappear in the projection from the Lorentz covariant theory (with 2^N branches of the mass spectrum) to the theory describing only the branch coresponding to positive energy for all of the particles. This can be done by performing an approximate Foldy–Wouthuysen transformation of the Lorentz covariant theory in the presence of electromagnetic fields, because the electric field is the source of possible crossings of the deformed 2^N branches (classical counterpart of pair production). The additional spin–electric field coupling is the source of the spin–orbit term in the quantum Hamiltonian for the electron.

[32] The same problem arises when one considers the rest-frame description of fields. A basis with a *center of phase* has already been found for a real Klein–Gordon field both in the covariant approach (Ref. 33) and on spacelike hypersurfaces (Ref. 34) (in this paper there is a first treatment of the topics of Secs. III and IV). In the Klein–Gordon case the *internal* center of mass has been found, but not yet a canonical basis containing it.

[48] The singular limit $\alpha\to\infty$ is very similar to a contraction of a Lie algebra.
[49] Note that at the nonrelativistic level only one such matrix appears, namely $k_{ab}^{-1}=\Sigma_{i=1}^N(1/m_i)K_{(i)ab}^{-1}$, see Eq. (2.9) of Ref. 2.
[50] The first line defines the *body frame components* $\breve{\rho}_{qa}^r$ of the vectors $\vec{\rho}_{qa}$ in this approach (θ^α are Euler angles). The body frame components of the relative velocities are the $\breve{v}_{qa}^r$ of the second line, while those of the spin and of the angular velocity are $\breve{S}_q^r$ and $\breve{\omega}^r$, respectively.
[51] Let us remark that any pair of orthonormal vectors $\vec{N}$, $\vec{\chi}$ depending only on the relative coordinates can be used to build a body frame. This freedom is connected to the possibility of redefining a body frame by using a configuration-dependent arbitrary rotation, which leaves $\vec{N}$ in the $\vec{S}$–$\hat{R}$ plane.
[52] The two expressions of α given above are consistent with the fact that $\hat{S}_q$, $\hat{R}$, and $\hat{N}$ are coplanar, so that $\hat{R}$ and $\hat{N}$ differ by a term in $\hat{S}_q$.
[53] Recall that a different Hamiltonian *right* SO(3) action on the relative phase space corresponds to each of them.
[54] The notation $\breve{A}=(\tau,\check{r})$ with $\check{r}=1,2,3$ will be used; note that $\breve{A}=\tau$ and $\breve{A}=\check{r}=1,2,3$ are Lorentz-scalar indices.
[55] A. J. Hanson and T. Regge, Ann. Phys. (N.Y.) **87**, 498 (1974).

[56] Asymptotically, we must fix the gauge freedom generated by the spin part of Lorentz boosts, see Eq. (A14); how this can be done before the restriction to spacelike hyperplanes still has to be studied.
[57] The $\epsilon_r^\mu(u(p))$'s are also called *polarization vectors*; the indices r, s will be used for $A=1,2,3$ and $\overline{o}$ for $A=o$.

(Received 13 June 2001; accepted for publication 11 January 2002)

Using the Streit–Hida formulation where the Feynman path integral is realized in the framework of white noise analysis, we evaluate the quantum propagator for systems with boundaries and topological constraints. In particular, the Feynman integrand is given as generalized white noise functionals for systems with flat wall boundaries and periodic constraints. Under a suitable Gauss–Fourier transform of these functionals the quantum propagator is obtained for: (a) the infinite wall potential; (b) a particle in a box; (c) a particle constrained to move in a circle; and (d) the Aharonov–Bohm system. The energy spectrum and eigenfunctions are obtained in all four cases. © *2002 American Institute of Physics.*

I. INTRODUCTION

In 1983, Streit and Hida[1] used white noise analysis[2–4] to provide a more rigorous basis for the Feynman path integral.[5] This approach, where the Feynman integrand is identified as a generalized white noise functional, was subsequently developed[6] and applied to various quantum mechanical systems including time-dependent potentials.[7–12] In this paper, we shall employ the same white noise functional approach[1] to evaluate the Feynman path integral for systems with constraints brought about by specified boundary and topological conditions. We begin with a brief review of the white noise functional approach in Sec. II. The free particle propagator is then evaluated as an example and basic tool in the treatment of the constrained systems. Section III presents the evaluation of the propagator for flat wall boundaries such as a quantum particle in a region bounded by an infinite wall. Then the Feynman integral for a particle in a one-dimensional box[13,14] is examined, where we employ the Poisson sum formula to evaluate the propagator. Section IV considers systems with periodic constraints exemplified by the quantum particle constrained to move in a circle.[15] Here we again utilize the Poisson sum formula instead of introducing smeared wave packets as done in Ref. 16, where a white noise approach was also used. In the Aharonov–Bohm setup, a charged particle is constrained to move in a circle around a solenoid containing a magnetic flux Φ situated at the center. We obtain the propagator for this system which readily yields the Aharonov–Bohm energy spectrum and eigenfunctions. In the limit where the flux Φ vanishes, one obtains the expected result for a quantum particle in a circle.[15,16]

II. BRIEF REVIEW

A. The Feynman path integral

The quantum mechanical propagator, $\langle x_1|\exp(-iHt)|x_0\rangle = K(x_1,t|x_0,0)$, in nonrelativistic quantum mechanics can be calculated using Feynman's prescription of summing over all possible paths or ''histories'' of the particle which start at x_0 and end at x_1. This prescription is symbolically written as

[a]Electronic mail: cbernido@mozcom.com

$$K(x_1,t|x_0,0)=\int \exp\left(\frac{i}{\hbar}S\right)D[x], \tag{2.1}$$

where S is the classical action for a particle of mass μ subjected to a potential $V(x)$ given by

$$S=\int_0^t\left[\frac{1}{2}\mu\dot{x}^2-V(x)\right]\mathrm{d}t. \tag{2.2}$$

A useful procedure in the explicit calculation of the path integral equation (2.1) is to slice the time interval N times, i.e., $t/N=t_j-t_{j-1}=\epsilon_j(j=1,\ldots,N)$, to obtain the time-sliced form,[5]

$$K(x_1,t|x_0,0)=\lim_{N\to\infty}\int\prod_{j=1}^{N}A_j\exp\left(\frac{i}{\hbar}S_j\right)\prod_{j=1}^{N-1}\mathrm{d}[x_j], \tag{2.3}$$

where, $x_j=x(t_j)$, S_j is the short-time action, and $A_j=\sqrt{\mu/2\pi i\hbar\epsilon_j}$ is the normalization. Although numerous quantum mechanical problems are solved using this prescription of Feynman,[17] there is still continuing effort to investigate the mathematical meaning of the Feynman path integral. Specifically, the integral, Eq. (2.1) or Eq. (2.3), with its infinite-dimensional flat ''measure'' $D[x]$ or $\Pi\mathrm{d}[x_j]$ is not mathematically well defined. There are several approaches for providing the Feynman integral with a more solid mathematical foundation,[18] but what we shall follow in this paper is the approach of Streit and Hida,[1] which utilizes the infinite-dimensional white noise calculus.

B. White noise analysis and the Feynman integral

What is referred to as white noise $\omega(t)$ is a random process defined as the time derivative of the Brownian motion $B(t)$, i.e.,

$$\omega(t)=\mathrm{d}B(t)/\mathrm{d}t. \tag{2.4}$$

Therefore, the white noise $\omega(t)$ may be viewed as the ''velocity'' of a Brownian motion. Alternatively, Wiener's Brownian motion $B(t)$ is represented by

$$B(t)=\int_0^t\omega(\tau)\mathrm{d}\tau. \tag{2.5}$$

White noise calculus was introduced by Hida in 1975[19] as a novel approach to infinite dimensional analysis. The basic idea was to take the collection of infinitely many independent random variables, $\{\omega(t);t\in\mathbf{R}\}$, and treat them as the coordinate system of an infinite dimensional space. One then proceeds to investigate generalized white noise functionals, $\Phi(\omega(t);t\in\mathbf{R})$, instead of functionals of Brownian motion, $f(B(t);t\in\mathbf{R})$.

In the framework of white noise analysis, the Feynman integral is treated as the ''average over all paths'' with a well-defined generalized white noise functional, or Hida distribution, as the weight.[2,6] The paths $x(t)$ which start at x_0 are parametrized as

$$x(t)=x_0+\left(\frac{\hbar}{\mu}\right)^{1/2}\int_0^t\omega(\tau)\mathrm{d}\tau, \tag{2.6}$$

in terms of the white noise random variable $\omega(t)$. Here, μ is the mass of the particle. With this, the velocity of the particle becomes $(\mathrm{d}x/\mathrm{d}t)=\sqrt{\hbar/\mu}\omega$, enabling us to write the exponential of $(i/\hbar)S_0$, where S_0 is the action for the free particle, as

$$\exp\left(\frac{i}{\hbar}S_0\right)=\exp\left[\frac{i}{\hbar}\int_0^t\left(\frac{1}{2}\mu\dot{x}^2\right)\mathrm{d}\tau\right]=\exp\left[\frac{i}{2}\int_0^t\omega(\tau)^2\,\mathrm{d}\tau\right]. \tag{2.7}$$

The next step is to interpret the Feynman integration over all paths, $\lim_{N\to\infty}\Pi\mathrm{d}[x_j]$ or $\mathrm{d}^\infty x$, in terms of integration over the Gaussian white noise measure $\mathrm{d}\mu(\omega)$:[2,6]

$$\mathrm{d}\mu(\omega)=N_\omega \exp\left(-\frac{1}{2}\int \omega(\tau)^2\,\mathrm{d}\tau\right)\mathrm{d}^\infty\omega. \tag{2.8}$$

We observe that, in the framework of white noise analysis, Feynman's flat "measure" $\mathcal{N}\mathrm{d}^\infty x$ would correspond to $N_\omega \mathrm{d}^\infty\omega=\exp[(1/2)\int\omega(\tau)^2\,\mathrm{d}\tau]\mathrm{d}\mu(\omega)$. With this, we also get the correspondence ($\hbar=1$),

$$\exp(iS_0)D[x]\rightarrow N\exp\left[\left(\frac{i+1}{2}\right)\int_0^t \omega(\tau)^2\,\mathrm{d}\tau\right]\mathrm{d}\mu(\omega), \tag{2.9}$$

where N is a suitable normalization factor.

The paths in the Feynman integral begin at x_0 and end at x_1. However, the parametrization of the paths $x(t)$ in Eq. (2.6) shows that only the initial point x_0 is fixed from where the random Brownian motion begins. We, therefore, fix the end point of the trajectories by means of the Donsker delta function,[2,16] $\delta(x(t)-x_1)$, where $x(t)$ is given by Eq. (2.6), such that at time t the particle is at the final point x_1. The Feynman integrand can now be represented by

$$I(x_1,t|x_0,0)=N\exp\left[\left(\frac{i+1}{2}\right)\int_0^t \omega(\tau)^2\,\mathrm{d}\tau\right]\delta\left(x_0+(\hbar/\mu)^{1/2}\int_0^t \omega(\tau)\mathrm{d}\tau-x_1\right), \tag{2.10}$$

in terms of the Gauss kernel,

$$I_0=N\exp\left[\left(\frac{i+1}{2}\right)\int_0^t \omega(\tau)^2\,\mathrm{d}\tau\right]. \tag{2.11}$$

Equipped with the Feynman integrand as a generalized white noise functional, and the measure in white noise space, the path integral is obtained by performing a "T-transform" of the Feynman integrand. Explicitly, this is defined as[2–4]

$$(T\Phi)(\xi)=\int \exp\left(i\int \omega(\tau)\xi(\tau)\mathrm{d}\tau\right)\Phi(\omega)\mathrm{d}\mu(\omega), \tag{2.12}$$

with $\xi\in S$, $\Phi\in S^*$, for the triple $S\subset L^2(\mu)\subset S^*$, the S^* being the white noise measure space. Here $\mathrm{d}\mu(\omega)$ is the Gaussian white noise measure[2–4] characterized by its Fourier transform,

$$\int \exp(i\langle\omega,\xi\rangle)d\mu(\omega)=\exp\left(-\frac{1}{2}\int \xi^2\,\mathrm{d}\tau\right)=C(\xi), \tag{2.13}$$

where $C(\xi)$ is the characteristic functional. For example, the T-transform of I_0, Eq. (2.11), is[2,6]

$$(TI_0)(\xi)=\exp\left(-\frac{i}{2}\int \xi^2\,\mathrm{d}\tau\right). \tag{2.14}$$

Similarly, the T-transform of the functional $I(x_1,t|x_0,0)$, Eq. (2.10), is given by $(\hbar=\mu=1)$[2]

$$(TI)(\xi)=\frac{1}{(2\pi it)^{1/2}}\exp\left[-\frac{i}{2}\int_0^t \xi^2(\tau)\mathrm{d}\tau\right]\times\exp\left[\frac{i}{(2t)}\left(\int_0^t \xi(\tau)\mathrm{d}\tau+x_1-x_0\right)^2\right]. \tag{2.15}$$

The $I(x_1,t|x_0,0)$, identified as the Feynman integrand, exists as a Hida distribution.[2,6] For $\xi=0$, this yields the free particle propagator,

$$K(x_1,t|x_0,0)=(TI)(0)=\frac{1}{(2\pi it)^{1/2}}\exp\left[\frac{i}{(2t)}(x_1-x_0)^2\right]. \tag{2.16}$$

We shall now employ this white noise approach to problems with boundaries and systems involving topologically inequivalent paths.

III. FLAT WALL BOUNDARIES

A. Infinite wall

We first consider a quantum particle of mass μ in a potential which describes an infinite wall at the origin, i.e.,

$$V(x)=\infty \quad \text{for } x\leqslant 0$$
$$=0 \quad \text{for } x>0. \tag{3.1}$$

Classically, for a particle which goes from x_0 to x_1 there are two possible paths: the first is a path that goes directly from the initial to the final point, and the second describes a path from x_0 that is reflected by the wall before arriving at x_1. Quantum mechanically, the particle propagator should satisfy the boundary condition,

$$K(x_1,x_0)=0$$
$$\text{at } x_1=0 \text{ or } x_0=0, \tag{3.2}$$

together with

$$\lim_{t\to 0} K(x_1,x_0;t)=\delta(x_1-x_0). \tag{3.3}$$

To obtain the propagator for the infinite wall problem we use the path parametrization of Eq. (2.6) and write the linear combination of white noise functionals,

$$I^W(x_1,t|x_0,0)=I_0\delta\left(x_0+(1/\mu)^{1/2}\int_0^t\omega(\tau)\mathrm{d}\tau-x_1\right)-I_0\delta\left(-x_0+(1/\mu)^{1/2}\int_0^t\omega(\tau)\mathrm{d}\tau-x_1\right), \tag{3.4}$$

where I_0 is the Gauss kernel given by Eq. (2.11). For a propagator which satisfies the boundary condition, Eq. (3.2), the combination of the type given by Eq. (3.4) has been discussed in the literature,[15,20,21] where the second term arises from particle trajectories originating from an image point, $-x_0$, and arriving at x_1.

Writing the delta function in terms of its Fourier representation we express the functional in Eq. (3.4) as ($\hbar=1$)

$$I^W(x_1,t|x_0,0)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\{\exp[ik(x_0-x_1)]-\exp[-ik(x_0+x_1)]\}$$
$$\times I_0\exp\left[(ik/\sqrt{\mu})\int_0^t\omega(\tau)\mathrm{d}\tau\right]\mathrm{d}k. \tag{3.5}$$

We then perform the T-transform of Eq. (3.5) following the definition in Eq. (2.12),

$$(TI^W)(\xi)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\{\exp[ik(x_0-x_1)]-\exp[-ik(x_0+x_1)]\}T\left(I_0\left(\xi+\frac{k}{\sqrt{\mu}}\right)\right)\mathrm{d}k$$
$$=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\{\exp[ik(x_0-x_1)]-\exp[-ik(x_0+x_1)]\}\exp\left(-\frac{i}{2}\int_0^t[\xi+(k/\sqrt{\mu})]^2\,\mathrm{d}\tau\right)\mathrm{d}k. \tag{3.6}$$

With $\xi=0$, the usual quantum propagator $(TI^W)(0)=K^W(x_1,t|x_0,0)$ can be obtained:

$$K^W(x_1,t|x_0,0)=\int_{-\infty}^{+\infty}\Psi_k(x_0)\Psi_k(x_1)\exp(-iE_kt)\mathrm{d}k, \tag{3.7}$$

where the energy is, $E_k=(k^2/2\mu)$, and the eigenfunction is given by $\Psi_k(x)=(1/\sqrt{\pi})\sin(kx)$.

B. Particle in a box

We next consider the Feynman integral for a particle of mass μ confined to move in a one-dimensional box of length L, with sides located at $x=0$ and $x=L$. Classically, the paths of the particle in a box can be categorized into four classes.[15] The first goes directly from x_0 to x_1 without hitting the walls; the second type of path hits the wall at $x=0$ before arriving at x_1; the third leaves x_0 and is reflected from the wall at $x=L$ before reaching x_1; and the fourth class describes a path which bounces once from the boundary at $x=0$ and also once from the wall at $x=L$ before reaching x_1. The other paths belonging to any of the four classes describe a particle bouncing back and forth inside the box of length L and, therefore, traveling an additional distance of $2Ln(n=0,1,2,\ldots)$.

Quantum mechanically, the particle propagator $K(x_1,x_0;t)$ has to satisfy the boundary conditions

$$K(x_1,0;t)=K(x_1,L;t)=K(0,x_0;t)=K(L,x_0;t)=0, \tag{3.8}$$

aside from the requirement

$$\lim_{t\to 0}K(x_1,x_0;t)=\delta(x_1-x_0). \tag{3.9}$$

Using the form of the Feynman functional for a free particle, Eq. (2.10), the white noise functional for a particle in a box can be written as

$$I^B(x_1,t|x_0,0)=\sum_{n=-\infty}^{+\infty}I_0C_n(x_1,t|x_0,0), \tag{3.10}$$

where[14]

$$\begin{aligned}2C_n(x_1,t|x_0,0)=&\,\delta(x(t)-x_1+2Ln)+\delta(-x(t)+x_1+2Ln)-\delta(x(t)+x_1+2Ln)\\&-\delta(-x(t)-x_1+2Ln)\end{aligned} \tag{3.11}$$

with $x(t)$ given by Eq. (2.6). The $(2Ln)$ in the delta function describes the fact that the particle leaving x_0 can bounce back and forth inside the box of length L before arriving at x_1. In Eq. (3.11) we observe that the first two terms, as well as the last two terms can be combined, respectively, so that Eq (3.10) can be written as

$$\begin{aligned}I^B(x_1,t|x_0,0)=\sum_{n=-\infty}^{+\infty}I_0\Bigg\{&\,\delta\Bigg(x_0+(1/\mu)^{1/2}\int_0^t\omega(\tau)\,\mathrm{d}\tau-x_1+2Ln\Bigg)\\&-\delta\Bigg(x_0+(1/\mu)^{1/2}\int_0^t\omega(\tau)\,\mathrm{d}\tau+x_1+2Ln\Bigg)\Bigg\}.\end{aligned} \tag{3.12}$$

We now write $\delta(x(t)-x_1+2Ln)=(\pi/L)\,\delta((\pi/L)[x(t)-x_1]+2\pi n)$, where $x(t)$ is given by Eq. (2.6). We can then apply the Poisson sum formula,[22]

$$\sum_{n=-\infty}^{\infty}\delta(\phi+2\pi n)=(1/2\pi)\sum_{m=-\infty}^{\infty}\exp(im\phi), \tag{3.13}$$

and write Eq. (3.12) as

$$I^B(x_1,t|x_0,0)=(1/2L)\sum_{m=-\infty}^{+\infty} I_0 \exp\left[(im\pi/L\sqrt{\mu})\int_0^t \omega(\tau)\,d\tau\right] \times\{\exp[(im\pi/L)(x_0-x_1)]-\exp[(im\pi/L)(x_0+x_1)]\}. \tag{3.14}$$

Taking the T-transform of the functional in Eq. (3.14) we get

$$\begin{aligned}(TI^B)(\xi)&=(1/2L)\sum_{m=-\infty}^{+\infty}(TI_0)(\xi+(m\pi/L\sqrt{\mu})) \times\{\exp[(im\pi/L)(x_0-x_1)]-\exp[(im\pi/L)(x_0+x_1)]\}\\ &=(1/2L)\sum_{m=-\infty}^{+\infty}\exp\left[-\frac{i}{2}\int_0^t\left(\xi+\frac{m\pi}{L\sqrt{\mu}}\right)^2 d\tau\right] \times\{\exp[(im\pi/L)(x_0-x_1)]-\exp[(im\pi/L)(x_0+x_1)]\}.\end{aligned} \tag{3.15}$$

Taking $\xi=0$, we obtain the propagator,

$$\begin{aligned}K^B(x_1,t|x_0,0)=(TI^B)(0)&=(1/2L)\sum_{m=-\infty}^{+\infty}\exp[-(i/2)(m\pi/L\sqrt{\mu})^2t] \times\{\exp[(im\pi/L)(x_0-x_1)]-\exp[(im\pi/L)(x_0+x_1)]\}\\ &=(1/2L)\sum_{m=-\infty}^{+\infty}\exp[-(i/2)(m\pi/L\sqrt{\mu})^2t] \times\left[\cos\left(\frac{m\pi}{L}(x_0-x_1)\right)-\cos\left(\frac{m\pi}{L}(x_0+x_1)\right)\right],\end{aligned} \tag{3.16}$$

with the sum over terms such as $\sin((m\pi/L)(x_0-x_1))$ giving a zero contribution. Equation (3.16) can be written in the symmetrized form,

$$K^B(x_1,t|x_0,0)=\sum_{m=-\infty}^{+\infty}\phi_m(x_0)\,\phi_m(x_1)\exp(-iE_mt), \tag{3.17}$$

where $E_m=m^2\pi^2/2\mu L^2$ and $\phi_m(x)=(1/\sqrt{L})\sin(m\pi x/L)$ are the energy eigenvalues and eigenfunctions for a quantum particle in a one-dimensional box.

IV. SYSTEMS WITH TOPOLOGICAL CONSTRAINTS

A. Quantum particle in a circle

In this section, we consider white noise functionals for a quantum system in a space which is multiply connected.[15,23–25] In particular, we treat the case of a particle constrained to move in a circle. This has been examined in the context of white noise analysis using smeared wave packets in Ref. 16. In contrast to this earlier work, we shall employ the Poisson sum formula, Eq. (3.13), to facilitate the evaluation of the propagator.

Let us begin by expressing the paths of the particle in a circle as ($\hbar=1;\ t_0=0$),

$$\vartheta(t)=\vartheta_0+\frac{1}{\sqrt{I}}\int_0^t\omega(\tau)\,d\tau, \tag{4.1}$$

where $I=\mu R^2$, for a particle of mass μ and a circle of radius R. We then note that the particle starting at a point ϑ_0 can move clockwise, or counterclockwise, before reaching a final point ϑ_1. The particle may even wind around the circle n times counterclockwise (for n positive), or $|n+1|$ times clockwise (for n negative) before stopping at ϑ_1. In contrast to Eq. (2.10) for the free particle, we must sum over all possible paths with different winding numbers and utilize the winding number decomposition of the propagator[15,23,24] to write

$$I^C(\vartheta_1,t|\vartheta_0,0)=\sum_{n=-\infty}^{+\infty} I_0\,\delta\left(\vartheta_0+\frac{1}{\sqrt{I}}\int_0^t\omega(\tau)\,d\tau-\vartheta_1+2\pi n\right), \tag{4.2}$$

where n is the winding number, and the kinetic part I_0 is given by Eq. (2.11).

Use of the Poisson sum formula, Eq. (3.13), in the functional Eq. (4.2) gives

$$I^C(\vartheta_1,t|\vartheta_0,0)=(1/2\pi)\sum_{m=-\infty}^{+\infty} I_0\exp\left[im\left(\vartheta_0+\frac{1}{\sqrt{I}}\int_0^t\omega(\tau)\,d\tau-\vartheta_1\right)\right]. \tag{4.3}$$

Taking the T-transform we get

$$\begin{aligned}(TI^C)(\xi)&=(1/2\pi)\sum_{m=-\infty}^{+\infty}\exp[im(\vartheta_0-\vartheta_1)]\left(T\left[I_0\exp\left((im/\sqrt{I})\int_0^t\omega(\tau)\,d\tau\right)\right]\right)(\xi)\\&=(1/2\pi)\sum_{m=-\infty}^{+\infty}\exp[im(\vartheta_0-\vartheta_1)]\,[(TI_0)(\xi+(m/\sqrt{I}))]\\&=(1/2\pi)\exp\left(\frac{-i}{2}\int\xi^2\,d\tau\right)\sum_{m=-\infty}^{+\infty}\exp[im(\vartheta_0-\vartheta_1)]\exp\left[\frac{-im^2t}{2I}-\frac{im}{\sqrt{I}}\int_0^t\xi(\tau)d\tau\right].\end{aligned} \tag{4.4}$$

For $\xi=0$, this yields the propagator for a charged particle constrained to move in a circle,

$$K(\vartheta_1,t|\vartheta_0,0)=(TI^C)(0)=(1/2\pi)\sum_{m=-\infty}^{+\infty}\exp[im(\vartheta_0-\vartheta_1)-iE_mt], \tag{4.5}$$

where the energy is $E_m=m^2/2\mu R^2$ in terms of the angular quantum number, m.

B. The Aharonov–Bohm set up

The Aharonov–Bohm setup[26–28] can be described by a charged particle which moves in a space with an impenetrable solenoid of radius R_0 that carries a flux Φ. For a solenoid oriented along the z axis, we can make use of the symmetry of the problem and look at the cross section, or the $(x-y)$ plane, where the Lagrangian for the particle is given by

$$L=\frac{1}{2}\mu\dot{\vec{r}}^2+\frac{e}{c}\vec{A}\cdot\dot{\vec{r}}. \tag{4.6}$$

Here, μ is the mass of the particle, $\dot{\vec{r}}=(d\vec{r}/dt)$, and the vector potential is given by

$$\vec{A}=\frac{\Phi}{2\pi}\frac{(-y\hat{i}+x\hat{j})}{x^2+y^2},\quad x^2+y^2>R_0, \tag{4.7}$$

such that the magnetic field is, $\vec{B}=\vec{\nabla}\times\vec{A}=0$, outside the solenoid. In polar coordinates, $\vec{r}=(r,\vartheta)$, the potential in the Lagrangian has the form

$$\frac{e}{c}\vec{A}\cdot\dot{\vec{r}}=\frac{e\Phi}{2\pi c}\,\dot{\vartheta}. \tag{4.8}$$

By constraining the particle to move in a circle with the solenoid at the center and located at the origin, the Lagrangian, Eq. (4.6), acquires the following form:

$$L=\frac{1}{2}I\dot{\vartheta}^2+\frac{e\Phi}{2\pi c}\,\dot{\vartheta}, \tag{4.9}$$

where, $I=\mu R^2$. The problem can now be cast in the language of white noise by modeling the paths of the particle using Eq. (4.1), such that Eq. (4.9) can be written as

$$L=\frac{1}{2}\omega^2+\frac{e\Phi}{2\pi c\sqrt{I}}\omega. \tag{4.10}$$

As in the case of a particle in a circle discussed previously, we can again use the winding number decomposition of the propagator,[15,23,24] with n being the winding number, and use the Lagrangian, Eq. (4.10), for the Aharonov–Bohm setup to write

$$I^{\mathrm{AB}}(\vartheta_1,t|\vartheta_0,0)=\sum_{n=-\infty}^{+\infty}I_0\,\delta\left(\vartheta_0+\frac{1}{\sqrt{I}}\int_0^t\omega(\tau)\,d\tau-\vartheta_1+2\pi n\right)\exp\left[i(\alpha/\sqrt{I})\int_0^t\omega(\tau)\,\mathrm{d}\tau\right], \tag{4.11}$$

where I_0 is given by Eq. (2.11) and the last factor contains the potential term with the magnetic flux, $\alpha=e\Phi/2\pi c$. Using the Poisson sum formula, Eq. (3.13), the functional, Eq. (4.11), becomes

$$I^{\mathrm{AB}}(\vartheta_1,t|\vartheta_0,0)=(1/2\pi)\sum_{m=-\infty}^{+\infty}I_0\exp[im(\vartheta_0-\vartheta_1)]\exp\left[i[(m+\alpha)/\sqrt{I}]\int_0^t\omega(\tau)\mathrm{d}\tau\right], \tag{4.12}$$

whose T-transform gives us

$$\begin{aligned}(TI^{\mathrm{AB}})(\xi)&=(1/2\pi)\sum_{m=-\infty}^{+\infty}\exp[im(\vartheta_0-\vartheta_1)]\left(T\left[I_0\exp\left(\frac{i(m+\alpha)}{\sqrt{I}}\int_0^t\omega(\tau)\,\mathrm{d}\tau\right)\right]\right)(\xi)\\&=(1/2\pi)\sum_{m=-\infty}^{+\infty}\exp[im(\vartheta_0-\vartheta_1)]\left[(TI_0)\left(\xi+\frac{(m+\alpha)}{\sqrt{I}}\right)\right]\\&=(1/2\pi)\exp\left(\frac{-i}{2}\int\xi^2\,\mathrm{d}\tau\right)\sum_{m=-\infty}^{+\infty}\exp[im(\vartheta_0-\vartheta_1)]\\&\quad\times\exp\left[\frac{-i(m+\alpha)^2t}{2I}-\frac{i(m+\alpha)}{\sqrt{I}}\int_0^t\xi(\tau)\mathrm{d}\tau\right].\end{aligned} \tag{4.13}$$

For $\xi=0$, this yields the Aharonov–Bohm propagator for a charged particle constrained to move in a circle,

$$K^{\mathrm{AB}}(\vartheta_1,t|\vartheta_0,0)=(TI^{\mathrm{AB}})(0)=(1/2\pi)\sum_{m=-\infty}^{+\infty}\exp[im(\vartheta_0-\vartheta_1)-iE_mt], \tag{4.14}$$

where the energy is $E_m=[m+(e\Phi/2\pi c)]^2/2\mu R^2$, with m the angular quantum number modified by the magnetic flux $e\Phi/2\pi c$. For the case where the magnetic flux $\Phi=0$, the Aharonov–Bohm propagator reduces to that of the particle in a circle discussed in the previous section.

V. CONCLUSION

In this paper, Feynman integrals for some systems with boundaries or constraints have been explicitly evaluated using the white noise functional approach. This approach was first introduced by Streit and Hida in Ref. 1, where they constructed the Feynman integral in the framework of white noise analysis. This infinite dimensional calculus provides a natural setting for the ''sum over all trajectories'' while quantum analysis is done in real time without resort to time slicing.[5] Several quantum systems have been treated explicitly using this method,[7–12] and this paper adds topologically constrained systems to the list. These solvable examples should shed more light on the true mathematical meaning of the Feynman integral, as well as pave the way for the treatment of more complicated systems with boundaries and nontrivial non-Gaussian systems.

(Received 25 September 2001; accepted for publication 11 January 2002)

We analyze the expansion of the fuzzy sphere noncommutative product in powers of the noncommutativity parameter. To analyze this expansion we develop a graphical technique that uses spin networks. This technique is potentially interesting in its own right as introducing spin networks of Penrose into noncommutative geometry. Our analysis leads to a clarification of the link between the fuzzy sphere noncommutative product and the usual deformation quantization of the sphere in terms of the ⋆-product. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1456255]

I. INTRODUCTION

This paper originated from an observation that manipulating with functions on the fuzzy sphere is equivalent to manipulating with certain SU(2) spin networks. Although this observation is nothing more than a reinterpretation of the construction[1] of noncommutative sphere spherical harmonics, it does bring spin networks of Penrose[2] into the subject of noncommutative geometry, and is thus interesting as providing an unusual perspective on noncommutative manifolds.

In this paper we would like to illustrate the usage of spin networks by deriving some facts about the noncommutative product on the fuzzy sphere. The fuzzy sphere of Ref. 3 gives one of the simplest examples of noncommutative spaces. In this reference the fuzzy sphere is constructed by replacing the algebra of polynomials on the sphere by the noncommutative algebra generated by Pauli matrices taken in a fixed irreducible representation of SU(2). More precisely, the algebra of functions from $L^2(S^2)$ is thought of as the algebra of polynomials in $x_i \in \mathbb{R}^3$ modulo the relation $\|x\|^2=1$. We set the radius of the sphere to be 1. One then quantizes the coordinates x_i via

$$x_i \to \hat{X}^i := \frac{\hat{J}^i}{\sqrt{\frac{N}{2}\left(\frac{N}{2}+1\right)}}, \tag{1.1}$$

where $\hat{J}^i$ are the generators of $\mathfrak{su}(2)$, satisfying $[\hat{J}^i,\hat{J}^j]=i\epsilon^{ijk}\hat{J}^k$, taken in the $(N+1)$-dimensional irreducible representation of SU(2). The factor in (1.1) is adjusted precisely in such a way that the "quantized" coordinates $\hat{X}^i$ square to one. The rule (1.1) gives quantization of the monomials of order one in coordinates. Monomials of order up to N are quantized by replacing the products of the coordinates x_i by the symmetrized products of matrices $\hat{X}^i$ (see more on this map in Sec. III). Monomials of order $(N+1)$ and higher become linearly dependent of lower order monomials, so that the algebra of functions on the fuzzy sphere is finite dimensional. The integral over S^2 is replaced by the trace:

[a)]Electronic mail: freidel@ens-lyon.fr
[b)]UMR 5672 du CNRS
[c)]Electronic mail: krasnov@cosmic.physics.ucsb.edu

$$\int_{S^2} \to \frac{1}{(N+1)} \mathrm{Tr}. \tag{1.2}$$

When $1/N$, which plays the role of the parameter of noncommutativity, is taken to zero, the commutator of $\hat{X}^i$ vanishes, and the algebra of functions on the noncommutative sphere reduces to the commutative algebra. The trace (1.2) then reduces to the usual integral. It is in this sense that the fuzzy sphere reduces to the usual S^2 when the noncommutativity parameter is sent to zero. For more details on this construction see, e.g., Ref. 3.

In practice one would like to have a more explicit description of the above-noted quantization map. In particular, any function on the sphere can be decomposed into the basis of spherical harmonics, and one would like to know the matrices into which the spherical harmonics are sent under the quantization map. This was described in Ref. 1, where it was realized that the components of these matrices are given by certain Clebsch–Gordan coefficients. Interestingly, Ref. 1 appeared before the introduction of the notion of fuzzy sphere in Ref. 3, and contained essentially all the ingredients of the construction.

Let us now explain why one should expect the appearance of Clebsch–Gordan coefficients, or $3j$-symbols, as the result of the quantization map. Consider the following simple chain of isomorphisms:

$$\mathrm{End}(V^{N/2}) \sim V^{N/2} \times (V^{N/2})^* \sim \oplus_{l=1}^{N} V^l. \tag{1.3}$$

Here V^l is the space of the irreducible representation of SU(2) of the dimension $(2l+1)$. The Clebsch–Gordan coefficients relate a basis on the right-hand side of (1.3) to a basis on the left-hand side. A particular basis in V^l is given by the usual spherical harmonics $Y_{lm}(\theta, \phi)$. Thus, the isomorphism in (1.3) implies that every Y_{lm}, $l \leqslant N$ must be representable as an element of $\mathrm{End}(V^{N/2})$, that is, as an $(N+1)\times(N+1)$ matrix. The components of this matrix are given by the corresponding Clebsch–Gordan coefficients. We shall write down the corresponding formulas in Sec. II.

The appearance of the Clebsch–Gordan coefficients, or $3j$-symbols, as components of the matrices representing the spherical harmonics indicates that spin networks must play some role. Indeed, spin networks are exactly the quantities constructed from $3j$-symbols, corresponding to their vertices, with their indices contracted in some way, the contraction being represented by the spin network edges. As we shall see, the problem of calculation of the noncommutative analog of the integral of a product of a number of spherical harmonics always reduces to the evaluation of a particular spin network. One of the goals of the present paper is to develop the corresponding techniques. We do this by studying in some detail the $\star$-product on the fuzzy sphere.

Our paper partially overlaps with Ref. 4. In particular, the formula for the $\star$-product on the fuzzy sphere in terms of the $6j$-symbol is also contained in Ref. 4. What is new in this paper is the expression for the expansion of this $\star$-product in powers of the noncommutativity parameter. Our approach also allows us to clarify the link between the fuzzy sphere product and the deformation quantization $\star$-product. Finally, we would like to mention Ref. 5, which also studies the quantization of the space of functions on S^2.

A large part of the paper deals with the expansion of the $\star$-product in powers of the noncommutativity parameter. As we have already mentioned, the role of noncommutativity parameter is played by $1/N$: the commutative limit corresponds to $N \to \infty$. The limit of large size matrices also plays a key role[6] in the at first seemingly unrelated subject of SU(N) Yang–Mills theories. It is tempting to speculate that this is not a coincidence and that there are some relations between the two subjects. Glimpses of such a relation have started appearing in work on noncommutative geometry in string theory, see, e.g., Ref. 7. Unfortunately, we do not have more to say about this in the present paper.

II. SETUP

Under the quantization map the spherical harmonics $Y_{lm}(x)$, $x \in S^2$ are mapped into certain $(N+1)\times(N+1)$ matrices, and, as explained in Sec. I, components of these matrices are given by the Clebsch–Gordan coefficients. Before we spell out what these matrices are, let us fix our conventions as to what basis of spherical harmonics is used. Let us introduce, for integer l,

$$\overline{\Theta}^l_m(x) := i^{-m}\langle l,m|T_g|\omega\rangle, \tag{2.1}$$

where the bar denotes the complex conjugation, $|l,m\rangle$ form a highest weight normalized basis in the irreducible representation of the dimension $(2l+1)$, and $|\omega\rangle$ is the vector (unique up to a phase) that is invariant under the action of some fixed SO(2) subgroup of SO(3). It is given by $|\omega\rangle = |l,0\rangle$. Then (2.1) is a function on the homogeneous space $\mathrm{SO}(3)/\mathrm{SO}(2) \sim S^2$. Using formula (A1) for the integral of a product of two matrix elements, one gets the orthogonality relation for Θ:

$$\int_{S^2} \mathrm{d}x\, \overline{\Theta}^l_m \Theta^{l'}_{m'} = \frac{\delta^{ll'}\delta_{mm'}}{\dim_l}, \tag{2.2}$$

where $\mathrm{d}x$ is the normalized measure on the sphere. The presence of the factor of $\dim_l = (2l+1)$ in this formula (and also the usage of the normalized measure $\mathrm{d}x$) is what makes our Θ^l_m different from the usual spherical harmonics Y_{lm}. The basis (2.1) satisfies

$$\overline{\Theta}^l_m = (-1)^m \Theta^l{}_{-m}. \tag{2.3}$$

Note that the same relation is satisfied by the usual Y_{lm}, so our basis is indeed only different by a normalization.

Along with the orthogonality relation (2.2), we will need the value of the integral of a product of three spherical harmonics. It is easily computed using formula (A2) for the integral of a product of three matrix elements and definition (2.1) of the spherical harmonics. We have

$$\int_{S^2} \mathrm{d}x\, \overline{\Theta^{l_3}_{m_3}(x)} \Theta^{l_1}_{m_1}(x) \Theta^{l_2}_{m_2}(x) = \overline{\hat{C}^{l_3 l_1 l_2}_{0\,0\,0}} \hat{C}^{l_3 l_1 l_2}_{m_3 m_1 m_2}. \tag{2.4}$$

Here $\hat{C}$ are Clebsch–Gordan coefficients, and we have used the fact that the right-hand side is only nonzero when $m_1 + m_2 = m_3$. Our choice of normalization for Clebsch–Gordan's is such that the so-called theta-symbol is always equal to one, see (2.12). For reference, let us mention that our coefficients $\hat{C}^l$ are given by $1/\sqrt{\dim_l}$ times the Clebsch–Gordan coefficients used by Vilenkin and Klimyk.[8] The caret over the symbol of the coefficient is used precisely to indicate this difference in normalizations. It is now not hard to see that (2.4), together with (2.2), implies that

$$\Theta^{l_1}_{m_1}(x) \Theta^{l_2}_{m_2}(x) = \sum_{l_3 = |l_1 - l_2|}^{l_1 + l_2} \sum_{m_3} \dim_{l_3} \hat{\Theta}^{l_3}_{m_3}(x) \overline{\hat{C}^{l_3 l_1 l_2}_{0\,0\,0}} \hat{C}^{l_3 l_1 l_2}_{m_3 m_1 m_2}. \tag{2.5}$$

Note that, in this formula, the commutativity of the product comes from the symmetry relations for the Clebsch–Gordan, namely:

$$\hat{C}^{l_3 l_2 l_1}_{m_3 m_2 m_1} = (-1)^{l_3 - l_1 - l_2} \hat{C}^{l_3 l_1 l_2}_{m_3 m_1 m_2}. \tag{2.6}$$

The group SO(3) acts on functions on S^2 by left shifts $T_g f(x) = f(g^{-1}x)$, and the functions $\Theta^l_m(x)$ for fixed l span the vector space V^l, in which the representation by shifts is irreducible. In view of the isomorphisms (1.3), functions $\Theta^l_m(x)$, $l \leqslant N$ can be mapped to $(N+1)\times(N+1)$ matrices, whose components must be given by Clebsch–Gordan coefficients. These matrices are

$$[\hat{\Theta}^{l}_{m}]_{ij}=\sqrt{N+1}\,\hat{C}^{l(N/2)(N^*/2)}_{mij}, \tag{2.7}$$

where $\hat{C}^{l(N/2)(N^*/2)}_{mij}$ are Clebsch–Gordan coefficients with properties:

$$\sum_{mij}\overline{\hat{C}^{l(N/2)(N^*/2)}_{mij}}\hat{C}^{(N/2)(N^*/2)}_{mij}=1, \tag{2.8}$$

$$\overline{\hat{C}^{l(N/2)(N^*/2)}_{mji}}=(-1)^m\hat{C}^{l(N/2)(N^*/2)}_{-mij}. \tag{2.9}$$

Here $(N/2)^*$ is the conjugate representation to $N/2$. The first of these properties is a normalization condition that will be explained in the following, while the second is a ''quantum'' analog:

$$(\hat{\Theta}^{l}_{m})^{\dagger}=\widehat{\overline{\Theta^{l}_{m}}} \tag{2.10}$$

of the classical property (2.3).

We are now in the position to introduce the graphic notations that will lead us to spin networks and somewhat explain the normalization choices made previously. We shall denote Clebsch–Gordan's by a tri-valent vertex, with its three edges representing the three pairs of indices of $\hat{C}$, so that

$[\hat{\Theta}^{l}_{m}]_{ij}=\sqrt{N+1}$ 
. (2.11)

Each edge corresponds to a pair of indices: an irreducible representation (spin) and a basis vector in this representation. If no spin is indicated, as for the bottom edges in (2.11), then $N/2$ is assumed. Edges are oriented. The operation of complex conjugation is represented by changing the orientation of all the edges. The origin of the graphic notation (2.11) is evident: the Clebsch–Gordan coefficients it represents are just the matrix elements of the intertwiner between the tensor product of $V^{N/2}\times(V^{N/2})^*$ and the representation V^l; this intertwiner is represented by a trivalent vertex.

Using the graphical notation introduced, the normalization condition (2.8) is a statement about the value of the so-called theta graph:

$=1.$ (2.12)

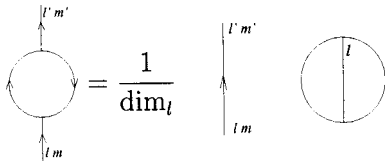
This graph is constructed taking the product of two $3j$-symbols and summing over the ''internal'' indices, as in (2.8). The theta graph is the simplest spin network, and the $3j$ symbols we use are normalized in precisely such a way that the value of this graph is always one.

As we mentioned in Sec. I, for the noncommutative sphere, the integral over S^2 goes into the trace. Let us now find the quantum analog of the orthogonality relation (2.2). The corresponding quantity is graphically represented as

$$\frac{1}{N+1}\mathrm{Tr}\left(\hat{\Theta}^{l}_{m}\right)^{\dagger}\hat{\Theta}^{l'}_{m'}=$$ 
. (2.13)

Here † denotes the operation of taking the Hermitian conjugation, and its effect is exactly such that all ''internal'' indices are contracted as in the above-given diagram. Now using an elementary

fact that



(2.14)

where a straight line represents the matrix element of the intertwiner between representations l and l', that is, a product of Kronecker deltas, we see that the "quantum" spherical harmonics $\hat{\Theta}$ satisfy exactly the same orthogonality relation (2.2) as the classical ones. The factor of $\sqrt{N+1}$ in (2.7) was adjusted precisely in such a way that this property holds.

We hope that the reader has already started appreciating the convenience of our graphical notations. Using these notations, complicated expressions are calculated by using elementary facts from representation theory. Thus, the property (2.14) is proved by noticing that the left-hand side of this equation is an intertwiner between representations l and l'. Such an intertwiner only exists when $l=l'$, which means that the result must be proportional to the straight line. The proportionality coefficient can be calculated by taking the trace of the whole expression, which is graphically represented by "closing" the open ends of the diagram. Performing this operation on the left-hand side, one gets the theta graph. The right-hand side gives a loop, whose value is just the dimension of the corresponding representation. We shall see other examples of such proofs in the sequel.

Let us now, before we go to our discussion of the ⋆-product on the fuzzy sphere, prove that the quantization rule (2.7) does give the correct quantization of the sphere, that is, the one given by (1.1). To this end, we must calculate the commutator of the noncommuting coordinates $\hat{X}^i$. Recall that classically the coordinates x_i are just the spherical harmonics corresponding to $l=1$:

$$x_1=\frac{1}{\sqrt{2}}(\Theta^1_1-\Theta^1_{-1}),\quad x_2=\frac{1}{i\sqrt{2}}(\Theta^1_1+\Theta^1_{-1}),\quad x_3=\Theta^1_0. \tag{2.15}$$

In the quantum case we replace the harmonics Θ^1 by the corresponding matrices (2.7). We then must have

$$[\hat{X}^i,\hat{X}^j]=i\epsilon^{ijk}\hat{X}^k\frac{1}{\sqrt{\frac{N}{2}\left(\frac{N}{2}+1\right)}}. \tag{2.16}$$

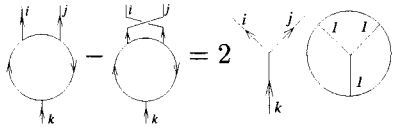
Let us show that this property indeed holds. We have

$$\frac{1}{N+1}[\hat{X}^i,\hat{X}^j]=$$

(2.17)

where the spin 1 is assumed on the vertical lines, and

$$\frac{1}{(N+1)^{3/2}}\mathrm{Tr}\left((\hat{X}^k)^\dagger[\hat{X}^i,\hat{X}^j]\right)=$$



. (2.18)

To get the last equality we used the fact that each of the two terms is an intertwiner from a single representation of spin 1 to the tensor product of two such representations. Such an intertwiner must be proportional to the unique intertwiner that is given by the tri-valent vertex on the right-hand side of (2.18). The proportionality coefficient is easily determined by closing all the open

edges, and is given by the $6j$-symbol on the right-hand side. The second term equals minus the first one, see (2.5), which explains the factor of 2. The $3j$-symbol is given by

$$= \frac{(-i)}{\sqrt{3!}}\epsilon^{ijk}, \tag{2.19}$$

and the $6j$-symbol can be calculated using formula (A3). The result is

$$= (-1)\frac{1}{\sqrt{3!}}\frac{1}{\sqrt{N+1}}\frac{1}{\sqrt{\frac{N}{2}(\frac{N}{2}+1)}}. \tag{2.20}$$

Combining all this together, we see that (2.16) indeed holds.

We thus learn that the quantization rule (2.7) coincides with the standard quantization map (1.1), at least for the spherical harmonics of the first order. Interestingly, the result of the commutator in the quantum case turns out to be expressed through the $6j$-symbol. In the case considered when all the spins were taken to be $l=1$, the commutator coincides with the classical result. However, for higher modes l one expects a deviation from the classical expressions. This is summarized in the notion of the $\star$-product. We shall now illustrate the described spin network techniques by deriving some facts about this $\star$-product.

III. THE $\star_N$-PRODUCT

As we have stated in Sec. I, our aim is to illustrate the spin network construction by deriving some facts about the fuzzy sphere noncommutative product. However, before we introduce and study this product, let us review the usual $\star$-product that arises in the deformation quantization of $\mathbb{R}^3$ equipped with Poisson structure invariant under the rotation group. We will then discuss a relation between this, and the fuzzy sphere product.

Let us start by recalling some general facts about $\star$-products. A $\star$-product gives a noncommutative deformation of the usual (pointwise) multiplication of functions. Let $\mathcal{A}=\mathcal{C}^\infty(M)$ be the space of smooth functions on a manifold M, and suppose that M is equipped with a Poisson bracket $\{\cdot,\cdot\}$. Let us denote by $A[[\hbar]]$ the space of formal power series with coefficients in $\mathcal{A}$. A star product on $\mathcal{A}$ is an associative, $\mathbb{R}[[\hbar]]$-linear product on $A[[\hbar]]$. The product of two functions on M is given by

$$\phi\star\psi=\sum_n \hbar^n B_n(f,g), \tag{3.1}$$

$B_n(\cdot,\cdot)$ being bidifferential operators. The first term in the expansion is the usual commutative product $B_0(f,g)=fg$, while the first term in the commutator is the Poisson bracket $B_1(f,g)-B_1(g,f)=\{f,g\}$. The Poisson bracket therefore gives the germ of deformation of the commutative product towards the $\star$-product. There is a notion of gauge transformation that can be defined on the set of $\star$-products and Poisson brackets. The group of these gauge transformations consists of linear automorphisms of $\mathcal{A}[[\hbar]]$ of the following form:

$$f\to U(f)=f+\hbar U_1(f)+\cdots\hbar^n U_n(f), \tag{3.2}$$

where $U_i(f)$ are differential operators. It acts on the set of star product as

$$\phi\star_U\psi=U^{-1}(U(\phi)\star U(\psi)). \tag{3.3}$$

Products related by such a transformation are called equivalent.

As is well known, when M is the dual of a Lie algebra $M=\mathfrak{g}^*$, there is the so-called Kirillov–Lie Poisson structure on it, whose symplectic leaves are coadjoint orbits. The bracket is

$$\{\phi,\psi\}(x)=x^k C_k^{ij}\partial_i\phi(x)\partial_j\psi(x), \tag{3.4}$$

where x^i are the components of $x\in\mathfrak{g}^*$. Using the natural identification between linear functions on $\mathfrak{g}^*$ and $\mathfrak{g}$ one can equivalently view x^i as a basis e^i in $\mathfrak{g}$. Then C_k^{ij} are the structure constants with respect to this basis. This identification extends to a natural isomorphism between the space $\mathrm{Pol}(\mathfrak{g}^*)$ of polynomials in x^i and symmetric algebra $\mathrm{Sym}(\mathfrak{g}^*)$. There are several equivalent ways to introduce a deformation quantization of the Kirillov bracket. We shall refer to the arising ⋆-product as Kirillov ⋆-product.

A. Universal enveloping algebra

The standard way to introduce a ⋆-product in $\mathfrak{g}^*$ is by using the universal enveloping algebra $\mathfrak{U}(\mathfrak{g})$. Recall that the universal enveloping algebra $\mathfrak{U}(\mathfrak{g})$ of the Lie algebra $\mathfrak{g}$ with generators e^i satisfying

$$[e^i,e^j]=\hbar C_k^{ij}e^k, \tag{3.5}$$

where C_k^{ij} are the structure constants, is the algebra generated by all polynomials in the generators e^i modulo the relation $XY-YX=[X,Y]$ for all $X,\ Y\in\mathfrak{g}$. The Poincare–Birkhoff–Witt theorem states that $\mathfrak{U}$ is isomorphic to the algebra $\mathrm{Sym}(\mathfrak{g})\sim\mathrm{Pol}(\mathfrak{g}^*)$ generated by all completely symmetrized polynomials in the generators: $\mathfrak{U}(\mathfrak{g})\sim\mathrm{Sym}(\mathfrak{g})$. Since the algebra $\mathrm{Sym}(\mathfrak{g})$ is naturally isomorphic to the algebra $\mathrm{Pol}(\mathfrak{g}^*)$ of polynomial functions on the dual space $\mathfrak{g}^*$, we have the one-to-one map

$$\sigma:\mathrm{Pol}(\mathfrak{g}^*)\to\mathfrak{U}(\mathfrak{g}),$$

$$x^{k_1}\cdots x^{k_n}\to\frac{1}{n!}\sum_s\ e^{k_{s(1)}}\cdots e^{k_{s(n)}},$$

where the sum is taken over all permutations s of n integers, x^i are linear functionals on $\mathfrak{g}^*$, and e^i are the corresponding elements in $\mathfrak{g}$. Using the map σ, one can define the following noncommutative product on $\mathrm{Pol}(\mathfrak{g}^*)$:

$$(\phi\star\psi)(x)=\sigma^{-1}[\sigma(\phi)\sigma(\psi)]. \tag{3.6}$$

Note that this ⋆-product explicitly depends on the deformation parameter $\hbar$ because the latter enters the commutator (3.5). What is not so straightforward to see is that this product can be expanded in terms of differential operators. For example, one can prove the following formula:

$$(e^X\star Y)(x)=e^{X(x)}\left[\frac{\mathrm{ad}\,X}{1-e^{-\mathrm{ad}\,X}}\cdot Y\right](x). \tag{3.7}$$

B. Baker–Campbell–Haussdorf formula

The Baker–Campbell–Haussdorf formula states that, given two Lie algebra elements X,Y, the product of the corresponding group elements can be expressed as

$$e^X\cdot e^Y=e^{X+Y+\Psi(X,Y)}, \tag{3.8}$$

where $X,Y,\ \Psi(X,Y)\in\mathfrak{g}$ and

$$X+Y+\Psi(X,Y)=\sum_{m=1}^{\infty}\frac{(-1)^{(m-1)}}{m}\sum_{\substack{k_i+l_i\geqslant 1\\ k_i\geqslant 0,l_i\geqslant 0}}\frac{[X^{k_1}Y^{l_1}\cdots X^{k_m}Y^{l_m}]}{k_1!l_1!\cdots k_m!l_m!},\tag{3.9}$$

and $[X_1\cdots X_n]$, $X_i\in\mathfrak{g}$ denotes $(1/n)[\cdots[[X_1,X_2],X_3],\ldots,X_n]$. This is the so-called Campbell–Hausdorff formula in the Dynkin form, see, e.g., Ref. 9. Representing the commutator as $[X,Y]=XY-YX$, one can think of $\Psi(X,Y)$ as a complicated sum of polynomials in the components X_i, Y_i:

$$\Psi_i(X,Y)=\sum_{i\vec{n}j\vec{m}}A_i^{i\vec{n}j\vec{m}}X_{i_1}\cdots X_{i_n}Y_{j_1}\cdots Y_{j_m}.\tag{3.10}$$

One then defines a $\star$-product on the space of functions on $\mathbb{R}^3=\mathfrak{g}^*$ by

$$(\phi\star\psi)(x)=\phi e^{(1/\hbar)(x|\Psi(\hbar\partial,\hbar\partial))}\psi,\tag{3.11}$$

where we have replaced the argument X_i of $\Psi(X,Y)$ by $\hbar$ times the derivative $\partial/\partial x^i$ acting on the left on ϕ, and the argument Y_i by the derivative acting on the right on ψ. The quantity $(x|\Psi)$ in the exponential stands for the contraction $x^i\Psi_i$. One can prove that the product (3.11) is, in fact, the same as (3.6). A good exposition of the relation between these two quantizations, and also of the relation of both to the Kontsevich deformation quantization, is given in Ref. 10.

C. Path integral

The third way to define the Kirillov $\star$-product uses a version of the Cattaneo–Felder[11] path integral. For the case in question, the function $\alpha^{ij}(x)$ that determines the Poisson structure:

$$\{\phi,\psi\}=\sum_{ij}\alpha^{ij}(x)\partial_i\phi(x)\partial_j\psi(x),\tag{3.12}$$

is linear in x, and the action used in Ref. 11 can be given a simple form of the action of the so-called BF theory. Thus, let us consider the following theory on the unit disk. It has two dynamical fields: the field B_i, which is $\mathfrak{g}^*$ valued, this field is the analog of the field X^i of Ref. 11, and the G-connection A^i, with curvature $F^i(A)$. This connection is the analog of the one-form field η of Ref. 11. The action is then given by

$$S[B,A]=\int_U B_iF^i(A),\tag{3.13}$$

where the integral is taken over the unit disk U. The $\star$-product is then given by the following path integral:

$$(\phi\star\psi)(x)=\langle\phi(B(0))\psi(B(1))\rangle_x\equiv\int_{B(\infty)=x}\mathcal{D}B\mathcal{D}A\,\phi(B(0))\psi(B(1))\exp\left(\frac{1}{\hbar}\int \mathrm{BF}\right).\tag{3.14}$$

Thus, the $\star$-product is obtained by computing the correlation function of two operators in this theory. The operators are given by functions ϕ, ψ on the values of the B field at two boundary points $0,1\in\partial U$. The value of B at the third boundary point ∞ is kept fixed in the path integral. One also has the boundary conditions for the connection: it is required that the connection one-form vanishes on ∂U on vectors tangent to the boundary. Then the perturbative expansion of the path integral (3.14) gives a noncommutative product in $\mathbb{R}^3$, which can be checked to be associative, and, thus, is a $\star$-product. Since the BF action (3.13) is essentially the one used by Cattaneo and Felder[11] product (3.14) is the Kontsevich product.[12] It can then be shown, see Ref. 10, that this product is equivalent to the one defined using the Campbell–Hausdorff formula.

D. $\star_N$-product

Having reviewed the usual ⋆-product, let us introduce the noncommutative product that is relevant in the context of the fuzzy sphere. The square integrable functions on S^2 can be decomposed into the basis of spherical harmonics:

$$\phi(x)=\sum_{lm}\ \phi^l_m\Theta^l_m(x). \tag{3.15}$$

We have a quantization map, which sends spherical harmonics Θ^l_m, $l\leqslant N$ to matrices (2.11). Under this map, functions are sent to matrices:

$$\phi(x)\to\hat{\phi}=\sum_{l=0}^{N}\ \sum_m\ \phi^l_m\hat{\Theta}^l_m \tag{3.16}$$

Note that this map is insensitive to the ''high frequency'' behavior of the function, for it cuts off all the harmonics with $l>N$.

Let us also construct the inverse map. To this end, we introduce a noncommutative analog of the δ function:

$$\hat{\delta}_x=\sum_{l=0}^{N}\ \sum_m\ \dim_l(\hat{\Theta}^l_m)^\dagger\Theta^l_m(x). \tag{3.17}$$

Thus, the ''quantum'' δ-function is a matrix that in addition depends on a point $x\in S^2$. Note that the δ-function is ''real'': $\hat{\delta}^\dagger=\hat{\delta}$. Given an arbitrary operator (matrix) $\hat{\phi}$ one can construct from it a square integrable function:

$$\hat{\phi}\to\phi(x)=\frac{1}{N+1}\mathrm{Tr}(\hat{\delta}_x\hat{\phi}). \tag{3.18}$$

The resulting functions, of course, contain only the modes with $l\leqslant N$. Using the δ-function (3.17) one can give another expression for the quantization rule (3.16). Indeed, we have

$$\hat{\phi}=\int_{S^2}\mathrm{d}x\ \hat{\delta}_x\phi(x). \tag{3.19}$$

One can easily check that the composition of the quantization map (3.16) and its inverse (3.18) give, back the function one started from with all its modes $l>N$ cut off. Let us formalize this introducing the notion of the projector $\mathcal{P}_N$:

$$\phi\to\hat{\phi}\to\frac{1}{N+1}\mathrm{Tr}(\hat{\delta}_x\hat{\phi})=\mathcal{P}_N\phi. \tag{3.20}$$

Thus, the maps (3.16) and (3.18) are one-to-one on the space of functions that only contain modes up to N. Let us denote this space by $\mathcal{A}^N$. Note that $\mathcal{A}^N=\mathcal{A}^\infty/\mathrm{Ker}\,\mathcal{P}_N$, where $\mathcal{A}^\infty$ is the algebra of all L^2 functions on S^2.

Having defined the quantization map, we can use it to define a noncommutative product on the space $\mathcal{A}^N$ via

$$\widehat{\phi\star_N\psi}=\hat{\phi}\hat{\psi}. \tag{3.21}$$

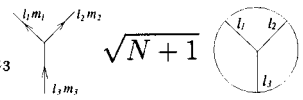
Let us emphasize that this is well defined only in $\mathcal{A}^N$ since $\hat{\phi}=\widehat{\mathcal{P}_N\phi}$ and the product $\star_N$ does not coincide with the usual ⋆-product reviewed previously, because they are defined on different

spaces. While $\star_N$ is the product on the space of functions $\mathcal{A}^N$, the "real" $\star$-product acts on the space of all square integrable functions $\mathcal{A}^\infty$. However, we are going to show that the $\star_N$-product is related to the usual $\star$-product via

$$\phi \star_N \psi = \mathcal{P}_N[\phi \star_\hbar \psi]|_{\hbar = 2/(N+1)}. \tag{3.22}$$

Let us note that the interplay between the noncommutative product and deformation quantization was studied before, see, e.g., Ref. 13. What is new in this paper is the justification for formula (3.22) coming from an explicit expression for the asymptotic expansion of the $\star_N$-product in powers of the noncommutativity parameter. To find this expansion we consider the $\star_N$-product of the modes. The product of two matrices $\hat{\Theta}$ can be decomposed into a sum of $\hat{\Theta}$. A simple calculation, similar to the one performed in (2.17), (2.18), gives

$$\Theta^{l_1}_{m_1} \star_N \Theta^{l_2}_{m_2} = \sum_{l_3=0}^{N} \sum_{m_3} \dim_{l_3} \Theta^{l_3}_{m_3}$$



$$\sqrt{N+1}$$

. (3.23)

Let us notice that the right-hand side depends on N only through the $6j$-symbol (and the square root), and the cutoff in the sum. Therefore, the nontrivial information about the $1/N$ expansion of the $\star_N$-product is all contained in the $6j$-symbol. Thus, the fuzzy sphere gives us an interesting example of a noncommutative manifold for which the $\star$-product is not only known in terms of its $1/N$ derivative expansion, but also in closed form, in terms of the $6j$-symbol in (3.23).

Let us note that (3.23) can also be written as

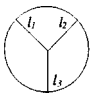
$$\Theta^{l_1}_{m_1} \star_N \Theta^{l_2}_{m_2} = \sum_{l_3=0}^{N} \mathcal{P}^{(l_3)}(\Theta^{l_1}_{m_1} \cdot \Theta^{l_2}_{m_2}) \Psi_{(N)}(l_1, l_2, l_3), \tag{3.24}$$

where $\mathcal{P}^{(l)}$ is the projector on the lth representation

$$\mathcal{P}_N = \sum_{l \leqslant N} \mathcal{P}^{(l)}, \tag{3.25}$$

and

$$\Psi_{(N)}(l_1, l_2, l_3) := \frac{\sqrt{N+1}}{\hat{C}^{l_3 l_1 l_2}_{000}}$$



. (3.26)

As we show below

$$\lim_{N\to\infty} \sqrt{N+1}$$

$$= \hat{C}^{l_3 l_1 l_2}_{000}. \tag{3.27}$$

This implies that the expansion of the function $\Psi_{(N)}(l_1, l_2, l_3)$ in powers of $1/N$ starts from unity. This fact, together with relation (2.5) means that the zeroth-order term in the $1/N$ expansion of the $\star_N$-product of two modes Θ is given by the usual product, which is what one expects.

Before we look more closely into the details of the asymptotic expansion, let us show that the noncommutative product defined by (3.23) is indeed an associative product. Interestingly, the

associativity follows from the so-called Biedenharn–Elliott (or pentagon) identity, which reads

$$\sum_l \dim_l$$  (3.28)

Note that although one has to sum over all l in this formula, only the terms with $l \leqslant N$ survive. We are also going to use the following recoupling identity:

 (3.29)

Here the sum is taken over all l_6. A proof of the associativity is then as follows:

$$\left(\Theta^{l_1} \star_N \Theta^{l_2}\right) \star_N \Theta^{l_3} = \sum_{l_3'} \dim_{l_3'} \Theta^{l_3'} \star_N \Theta^{l_3}$$ 
$$\sum_{l_3' l_4} \dim_{l_3'} \dim_{l_4} \Theta^{l_4}$$ 
$$\sum_{l_3' l_3'' l_4} \dim_{l_3'} \dim_{l_3''} \dim_{l_4} \Theta^{l_4}$$ 
$$\sum_{l_3'' l_4} \dim_{l_3''} \dim_{l_4} \Theta^{l_4}$$  $= \Theta^{l_1} \star_N \left(\Theta^{l_2} \star_N \Theta^{l_3}\right).$ (3.30)

Here we used the recoupling identity (3.29) to get the third line, and the pentagon identity (3.28) to get the last line. Note that, although in the third line the sum is taken over all l_3'', in the last line, after we used the pentagon identity, only the terms with $l_3'' \leqslant N$ are nonzero. Thus, the associativity of the product $\star_N$ is intimately related to the associativity in the category of irreducible representations of SU(2), of which the Biedenharn–Elliot identity is a manifestation.

Let us now study the asymptotic expansion of the $\star_N$-product more closely. To this end, let us rewrite formula (A3) for the $6j$-symbol in a form that is convenient for taking the large N-limit. It is convenient to introduce, for $N+a \geqslant 0$:

$$\gamma(a;N) = \frac{(N+a)!}{N!(N+1)^a}. \tag{3.31}$$

[It is not hard to recognize this function as related to the one appearing in the infinite limit Euler definition of the Γ function. Indeed, $\gamma(z;n) = \Gamma(z-1)/F(z-1,n+1)$, where $F(z,n) = n^z n!/(z(z+1)\cdots(z+n)) = n^z \int_0^1 (1-u)^n u^{z-1} du$, and $\lim_{n\to\infty} F(z,n) = \Gamma(z)$]. Since, for $a > 0$

$$\gamma(a;N)=\prod_{k=1}^{a}\left(1+\frac{k-1}{N+1}\right), \tag{3.32}$$

this function is analytic in $1/(N+1)$, and, for positive a, is a polynomial of degree $a-1$. We have

$$\gamma(a;N)=1+\frac{1}{N+1}\frac{a(a-1)}{2}+\cdots+\left(\frac{1}{N+1}\right)^{a-1}(a-1)! \tag{3.33}$$

One can similarly rewrite the function $\gamma(-a;N)$, $a>0$ as one over a polynomial of degree a:

$$\gamma(a;N)=\frac{1}{\Pi_{k=1}^{a}\left(1-\frac{k}{N+1}\right)}. \tag{3.34}$$

Using this function, the $6j$-symbol can be rewritten as

$$= (-1)^{l_1}(N+1)^{-1/2} l_3! \left[\frac{(l_1+l_2-l_3)!}{(l_1-l_2+l_3)!(l_2-l_1+l_3)!(l_1+l_2+l_3+1)!}\right]^{1/2}$$
$$\left[\frac{\gamma(-l_1;N)\gamma(l_1+1;N)\gamma(l_3+1;N)}{\gamma(-l_2;N)\gamma(-l_3;N)\gamma(l_2+1;N)}\right]^{1/2}$$
$$\sum_k \frac{(-1)^k}{k!}\frac{(l_1+k)!(l_2+l_3-k)!}{(l_1-k)!(l_2-l_3+k)!(l_3-k)!}\frac{\gamma(-l_3+k;N)}{\gamma(k+1;N)}. \tag{3.35}$$

The sum here is restricted to those k for which the quantities inside the factorials are non-negative. Using the representations (3.32), (3.34) for the γ function, it is not hard to deduce the analyticity properties of the $6j$-symbol as a function of $1/(N+1)$. We will need these properties in the following, when we discuss the relation between $\star_N$ and the usual $\star$-product. Function $\gamma(a+1;N)$, $a>0$, viewed as a function of $1/(N+1)$, has simple zeros on the negative axes, with the closest to origin zero located at $1/(N+1)=-1/a$. Function $\gamma(-a;N)$, a has simple poles on the positive axes, with the closest to the origin pole located at $1/(N+1)=1/a$. Then, the expression under the square root in (3.35) can be shown to have at most simple poles and zeros on the positive axes and at most second-order zeros on the negative axes. The function inside the sum in (3.35) has simple poles both on the positive and negative axes. The proves that the $6j$-symbol times $\sqrt{N+1}$ (3.35) is an analytic function of $1/(N+1)$ in the open disk of radius $\min(1/l_1,1/l_2,1/l_3)$ around zero. Moreover, all singularities are located on the positive and negative axes. This means that the function $\Psi_{(N)}(l_1,l_2,l_3)$ introduced in (3.26) can be analytically continued, as a function of $1/(N+1)$, to the whole complex plane. Introducing $\hbar=2/(N+1)$ we shall denote the analytic continuation of $\Psi_{(N)}(l_1,l_2,l_3)$ by $\Psi(l_1,l_2,l_3:\hbar)$.

It is not hard to find first terms of the expansion of $6j$ in powers of $1/(N+1)$. We get

$$\sqrt{N+1}\ \begin{Bmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{Bmatrix} = \hat{C}^{l_1 l_2 l_3}_{0\,0\,0}\left(1+\frac{1}{(N+1)}\frac{1}{2}\left(C_{l_1}-C_{l_2}+C_{l_3}\right)\right)$$
$$-\frac{(-1)^{l_1}}{(N+1)}(l_3+1)!\left[\frac{(l_1+l_2-l_3)!}{(l_1-l_2+l_3)!(l_2-l_1+l_3)!(l_1+l_2+l_3+1)!}\right]^{1/2}$$
$$\sum_k \frac{(-1)^k}{k!}k\frac{(l_1+k)!(l_2+l_3-k)!}{(l_1-k)!(l_2-l_3+k)!(l_3-k)!}+O(1/N^2), \tag{3.36}$$

where we have introduced a notation $C_l=l(l+1)$ and we have used expression (A4) for $C^{l_3 l_1 l_2}_{0\,0\,0}$. This proves that the zeroth-order term is given by the usual commutative product.

Let us introduce a notation for the prefactor in front of the sum in (3.36):

$$\rho(l_3,l_1,l_2)=(-1)^{l_2}l_3!\left[\frac{(l_1+l_2-l_3)!}{(l_1-l_2+l_3)!(l_2-l_1+l_3)!(l_1+l_2+l_3+1)!}\right]^{1/2}. \tag{3.37}$$

It can be noted that the sum in (3.36) is related to a certain Clebsch–Gordan coefficient. Namely,

$$\hat{C}^{l_3 l_1 l_2}_{1\,1\,0}=\frac{1}{l_3}\left(\frac{C_3}{C_1}\right)^{1/2}\rho(l_3,l_1,l_2)\sum_k \frac{(-1)^k}{k!}\frac{(l_1+k)!(l_2+l_3-k)!}{(l_1-k)!(l_2-l_3+k)!}\frac{k}{(l_3-k)!}. \tag{3.38}$$

Therefore, the first-order term in the expansion, that is, the coefficient of $1/(N+1)$ term in (3.36) can be written as

$$\tfrac{1}{2}(C_1-C_2+C_3)\hat{C}^{l_3 l_1 l_2}_{0\,0\,0}-(C_1C_3)^{1/2}\hat{C}^{l_3 l_1 l_2}_{1\,1\,0}. \tag{3.39}$$

It is now possible to prove the following two identities on Clebsch–Gordan coefficients.

$$(C_1-C_2+C_3)\hat{C}^{l_3 l_1 l_2}_{0\,0\,0}=(C_1C_3)^{1/2}(\hat{C}^{l_3 l_1 l_2}_{1\,1\,0}+\hat{C}^{l_3 l_1 l_2}_{-1\,-1\,0}). \tag{3.40}$$

$$\hat{C}^{l_3 l_1 l_2}_{1\,1\,0}=(-1)^{l_1+l_2+l_3}\hat{C}^{l_3 l_1 l_2}_{-1\,-1\,0}.$$

The first equality is just the expression of the intertwining property of the Clebsch–Gordan coefficient, and the second is a symmetry relation.

These two identities imply that (3.39) is equal to zero if $l_1+l_2+l_3$ is even. It is also clear that for odd $l_1+l_2+l_3$ it equals

$$-(C_1C_3)^{1/2}\hat{C}^{l_3 l_1 l_2}_{1\,1\,0}. \tag{3.41}$$

However, as is shown in the Appendix, this quantity is just $P(l_1,l_2,l_3)$, which is the coefficient that appears in the decomposition of the Poisson bracket of two spherical harmonics. This proves that the first-order term is given by the Poisson bracket.

We can summarize all of the above-mentioned results in a form of the following theorem.

Theorem 1: *There exists a function* $\Psi(l_1,l_2,l_3;\hbar)$*, given by the analytic continuation of the function* $\Psi_{(N)}(l_1,l_2,l_3)$ *introduced in (3.26), which is analytic in* $\hbar$ *in the open disk of radius* $\min(1/l_1,1/l_2,1/l_3)$ *around zero, and*

$$\Psi(l_1,l_2,l_3;\hbar)=1+\hbar\Psi_1(l_1,l_2,l_3)+(\hbar)^2\Psi_2(l_1,l_2,l_3)+\cdots. \tag{3.42}$$

For $N\geqslant l_1,l_2,l_3$,

$$\Psi(l_1,l_2,l_3;\hbar)|_{\hbar=2(N+1)}=\Psi_{(N)}(l_1,l_2,l_3). \tag{3.43}$$

The product defined via

$$\Theta^{l_1}_{m_1}\star_\hbar\Theta^{l_2}_{m_2}=\sum_{l_3=0}^{N}\mathcal{P}^{(l_3)}(\Theta^{l_1}_{m_1}\cdot\Theta^{l_2}_{m_2})\Psi(l_1,l_2,l_3;\hbar), \tag{3.44}$$

is an associative product. Moreover,

$$\begin{aligned}&\phi\star_\hbar\psi-\psi\star_\hbar\phi=\hbar\{\phi,\psi\}+o(\hbar),\\ &\mathcal{P}_N[\phi]\star_N\mathcal{P}_N[\psi]=\mathcal{P}_N[\phi\star_\hbar\psi]|_{\hbar=2/(N+1)}.\end{aligned} \tag{3.45}$$

The associativity follows from an analytic continuation of the Biedenharn–Elliot identity, see (3.28). What we did not prove is that the noncommutative product (3.44) is indeed a $\star$-product, that is given by an expansion in terms of derivatives. This is, in principle, possible with our techniques by considering the higher terms in the expansion of the $6j$-symbol. Thus, modulo this caveat, the $\star_\hbar$-product gives a deformation quantization of Kirillov bracket, and must thus be equivalent to the usual Kirillov $\star$-product. Formula (3.45) then establishes a relation between the fuzzy sphere product and Kirillov product.

We conclude by observing that expressions (3.23), (3.24) for the $\star_N$-product can be used to define a noncommutative product on the so-called q-deformed fuzzy sphere. While the usual fuzzy sphere is defined as the structure covariant under the action of the group SU(2), its q-deformed analog is covariant under the action of the quantum group $U_q(su(2))$. For a definition of the q-deformed fuzzy sphere see, e.g., Ref. 14. Expression (3.23) can then be used to get a product on the q-deformed sphere. To this end, one should replace all objects appearing on the right-hand side of (3.23)—the dimension, the $3j$ and $6j$-symbols—by the corresponding q-deformed quantities. One gets a q-deformed product. This product is still associative, for the proof (3.30) of associativity based on the pentagon identity holds for the quantum group as well. This q-deformed product was discussed in Ref. 4, where the usual fuzzy sphere version (3.23) is also mentioned. It would be quite interesting to obtain an analog of our asymptotic formula for the q-deformed product.

APPENDIX A: SOME FORMULAS

In the main text we use values of the integrals of a product of two and three matrix elements. These are given by

$$\int_G \mathrm{d}g\overline{\langle l_1,m_1|T_g|l_1,m_1'\rangle}\langle l_2,m_2|T_g|l_2,m_2'\rangle=\frac{\delta^{l_1l_2}\delta_{m_1m_2}\delta_{m_1'm_2'}}{\dim_{l_1}}, \tag{A1}$$

and

$$\int_G \mathrm{d}g\overline{\langle l_3,m_3|T_g|l_3,m_3'\rangle}\langle l_1,m_1|T_g|l_1,m_1'\rangle\langle l_2,m_2|T_g|l_2,m_2'\rangle=\hat{C}^{l_3l_1l_2}_{m_3'm_1'm_2'}\overline{\hat{C}^{l_3l_1l_2}_{m_3m_1m_2}}. \tag{A2}$$

Let us now give some explicit formulas for the $3j$- and $6j$-symbols. All these formulas are from Ref. 8, with normalizations properly adjusted to match our conventions. We have

$$= (-1)^{l_1}l_3!\left[\frac{(l_1+l_2-l_3)!}{(l_1-l_2+l_3)!(l_2-l_1+l_3)!(l_1+l_2+l_3+1)!}\right]^{1/2}$$
$$\left[\frac{(N-l_1)!(N+l_1+1)!(N+l_3+1)!}{(N+l_2+1)!(N-l_2)!(N-l_3)!}\right]^{1/2}$$
$$\sum_k \frac{(-1)^k}{k!}\frac{(l_1+k)!(l_2+l_3-k)!}{(l_1-k)!(l_2-l_3+k)!(l_3-k)!}\frac{(N-l_3+k)!}{(N+k+1)!}. \tag{A3}$$

Here the sum is taken over all k such that the factorials are taken of non-negative integers. Using this formula it is not hard to get the value (2.20) of the $6j$-symbol for all spins being equal to 1. In this case the sum in (A3) is taken only over two values $k=0$, 1 and the calculation leading to (2.20) is straightforward.

Let us also give an expression for the $3j$-symbol $C^{l_3 l_1 l_2}_{0\,0\,0}$. It can be obtained from the general expression for the $3j$-symbol (in terms of a finite sum) given in Ref. 8. Taking into account the difference in normalizations, we get

$$\hat{C}^{l_3 l_1 l_2}_{0\,0\,0} = \rho(l_3, l_1, l_2) \sum_k \frac{(-1)^k}{k!} \frac{(l_1+k)!(l_2+l_3-k)!}{(l_1-k)!(l_2-l_3+k)!(l_3-k)!}, \tag{A4}$$

where

$$\rho(l_3, l_1, l_2) = (-1)^{l_1} l_3! \left[\frac{(l_1+l_2-l_3)!}{(l_1-l_2+l_3)!(l_2-l_1+l_3)!(l_1+l_2+l_3+1)!} \right]^{1/2}. \tag{A5}$$

We should also note the formula:

$$\hat{C}^{l l_1 l_2}_{0\,0\,0} = \frac{(-1)^{g-1} g! \Delta(l_1, l_2, l)}{(g-l_1)!(g-l_2)!(g-l)!}, \tag{A6}$$

where $l_1+l_2+l=2g$, $g \in \mathbb{Z}$, and $\Delta(l_1, l_2, l)$ is given by

$$\Delta(l_1, l_2, l) = \left[\frac{(l_1+l_2-l)!(l_1-l_2+l)!(l_2-l_1+l)!}{(l_1+l_2+l+1)!} \right]^{1/2}. \tag{A7}$$

APPENDIX B: POISSON BRACKET OF SPHERICAL HARMONICS

In this section we calculate the Poisson bracket of two spherical harmonics. The result we obtain here is compared in Sec. III with the first-order term in the expansion of the $6j$-symbol in powers of $1/N$. We were not able to find a result for this Poisson bracket in the literature, so we sketch the calculation here.

We begin with some notations. Let J_i be generators of the Lie algebra of SU(2): $[J_i, J_j] = i\epsilon_{ijk} J_k$. These generators can be realized as vector fields in $\mathbb{R}^3$. Denoting by x_i the usual Cartesian coordinates in $\mathbb{R}^3$, we get

$$J_i = \frac{1}{i} \epsilon_i{}^{jk} x_j \partial_k. \tag{B1}$$

To calculate the Poisson bracket, it is convenient to introduce a set of complex coordinates in $\mathbb{R}^3$. We define $z = (x_1 + i x_2)/\sqrt{2}$, $x = x_3$ and $J_\pm = (J_1 \pm i J_2)/\sqrt{2}$, $J = J_3$. These new generators can be expressed in terms of the complex vector fields ∂_z, $\partial_{\overline{z}}$, ∂_x. We have

$$J_+ = x\partial_{\overline{z}} - z\partial_x, \quad J_- = \overline{z}\partial_x + x\partial_z, \quad J = z\partial_z - \overline{z}\partial_{\overline{z}}. \tag{B2}$$

These vector fields satisfy

$$[J_+, J_-] = J, \quad [J, J_\pm] = \pm J_\pm, \tag{B3}$$

and

$$\overline{J_+} = -J_-, \quad \overline{J} = -J. \tag{B4}$$

The spherical harmonics Θ^l_m are given by

$$\Theta^l_m = \alpha^l_m J_-^{l-m} v, \tag{B5}$$

where v is the highest weight vector $v = z^l$. To calculate the normalization factor α^l_m let us consider the norm $\|J_-^{l-m} v\|^2$. Using

$$[J_+, J_-^n]v = \frac{n}{2}(2l-n+1)J_-^{n-1}v, \tag{B6}$$

we get

$$\|J_-^{l-m}v\|^2 = (-1)^{l-m}\langle v|J_+^{l-m}J_-^{l-m}|v\rangle = (-1)^{l-m}\frac{1}{2^{l-m}}\frac{(l-m)!}{(l+m)!}(2l)!\|v\|^2. \tag{B7}$$

An explicit calculation, using the normalized measure on S^3, gives

$$\|v\|^2 = \|z^l\|^2 = \int \sin^{2l}\theta = \frac{1}{(2l+1)}\frac{l!}{(2l-1)!!}. \tag{B8}$$

Combining these two facts, and taking into account the normalization of Θ_m^l (2.2), we see that α_m^l is, up to a phase, given by

$$\frac{1}{l!}\left(\frac{(l+m)!}{2^m(l-m)!}\right)^{1/2}. \tag{B9}$$

We choose the phase factor in such a way that Θ_m^l coincide with the ones given by (2.1). This gives

$$\alpha_m^l = \frac{(-1)^{l-m}}{l!}\left(\frac{(l+m)!}{2^m(l-m)!}\right)^{1/2}. \tag{B10}$$

It is now straightforward to work out the action of vector fields ∂_z, $\partial_{\bar z}$, ∂_x on Θ_m^l. We get

$$\begin{aligned}
\partial_z\Theta_m^l &= \sqrt{\frac{1}{2}(l+m)(l+m-1)}\,\Theta_{m-1}^{l-1},\\
\partial_{\bar z}\Theta_m^l &= -\sqrt{\frac{1}{2}(l-m)(l-m-1)}\,\Theta_{m+1}^{l-1},\\
\partial_x\Theta_m^l &= \sqrt{(l+m)(l-m)}\,\Theta_m^{l-1}.
\end{aligned} \tag{B11}$$

We will also need the action of SU(2) generators on Θ_m^l:

$$\begin{aligned}
J_+\Theta_m^l &= -\sqrt{\frac{1}{2}(l-m)(l+m+1)}\,\Theta_{m+1}^l,\\
J_-\Theta_m^l &= -\sqrt{\frac{1}{2}(l+m)(l-m+1)}\,\Theta_{m-1}^l,\\
J\Theta_m^l &= m\Theta_m^l.
\end{aligned} \tag{B12}$$

The Poisson bracket is given by

$$\{f,g\} = \frac{i}{\sin\theta}\left(\frac{\partial f}{\partial\theta}\frac{\partial g}{\partial\varphi} - \frac{\partial g}{\partial\theta}\frac{\partial f}{\partial\varphi}\right). \tag{B13}$$

It is normalized so that $\{x_1, x_2\} = ix_3$. It can be expressed in terms of vector fields and generators as

$$\{f,g\} = \partial_z f J_+ g + \partial_{\bar z} f J_- g + \partial_x f J g. \tag{B14}$$

Using expressions (B11) and (B12) it is now straightforward to compute the Poisson bracket of two spherical harmonics. We have

$$\{\Theta^{l_1}_{m_1},\Theta^{l_2}_{m_2}\}=-\frac{1}{2}\Big(\sqrt{(l_1+m_1)(l_1+m_1-1)(l_2-m_2)(l_2+m_2+1)}\,\Theta^{l_1-1}_{m_1-1}\Theta^{l_2}_{m_2+1}$$
$$-\sqrt{(l_1-m_1)(l_1-m_1-1)(l_2+m_2)(l_2-m_2+1)}\,\Theta^{l_1-1}_{m_1+1}\Theta^{l_2}_{m_2-1}$$
$$-2\sqrt{(l_1+m_1)(l_1-m_1)}\,m_2\Theta^{l_1-1}_{m_1}\Theta^{l_2}_{m_2}\Big). \tag{B15}$$

Thus, using (2.4) we have

$$\int\{\Theta^{l_1}_{m_1},\Theta^{l_2}_{m_2}\}\overline{\Theta^{l}_{m}}=-\frac{1}{2}\overline{\hat{C}^{ll_1-1l_2}_{0\,0\,0}}\Big(\sqrt{(l_1+m_1)(l_1+m_1-1)(l_2-m_2)(l_2+m_2+1)}\,\hat{C}^{ll_1-1l_2}_{m\,m_1-1\,m_2+1}$$
$$-\sqrt{(l_1-m_1)(l_1-m_1-1)(l_2+m_2)(l_2-m_2+1)}\,\hat{C}^{l\,l_1-1\,l_2}_{m\,m_1+1\,m_2-1}$$
$$-2\sqrt{(l_1+m_1)(l_1-m_1)}\,m_2\hat{C}^{l\,l_1-1\,l_2}_{m\,m_1m_2}\Big). \tag{B16}$$

The requirement of gauge invariance implies that the quantity in brackets is proportional to the Clebsch–Gordan coefficient $\hat{C}^{l\,l_1l_2}_{m\,m_1m_2}$, with the proportionality coefficient depending only on l_1, l_2, l. In other words, we must have

$$\int\{\Theta^{l_1}_{m_1},\Theta^{l_2}_{m_2}\}\overline{\Theta^{l}_{m}}=P(l_1,l_2,l)\hat{C}^{l\,l_1l_2}_{m\,m_1m_2}. \tag{B17}$$

The coefficient $P(l_1,l_2,l)$ is proportional to $\hat{C}^{l\,l_1-1l_2}_{0\,0\,0}$ and thus is nonzero only when $l_1+l_2+l=2g-1$, $g\in\mathbb{Z}$. Since

$$\hat{C}^{l\,l_2l_1}_{m\,m_2m_1}=(-1)^{l-l_1-l_2}\hat{C}^{l\,l_1l_2}_{m\,m_1m_2}, \tag{B18}$$

for values of l_1, l_2, l summing up to an odd integer the Clebsch–Gordan coefficient changes sign under the exchange of l_1 with l_2. Because the Poisson bracket must be antisymmetric, the coefficient $P(l_1,l_2,l)$ must be symmetric under the exchange of l_1 with l_2. Let us now determine this coefficient. It can be determined, for example, by choosing $l=m$ and using

$$\hat{C}^{ll_1l_2}_{ljl-j}=(-1)^{l_1-j}\frac{(l_1+l_2-l)!}{(l_1+l_2+l+1)!\Delta(l_1,l_2,l)}\left[\frac{(l_1+j)!(l_2+l-j)!}{(l_1-j)!(l_2-l+j)!}\right]^{1/2}, \tag{B19}$$

where

$$\Delta(l_1,l_2,l)=\left[\frac{(l_1+l_2-l)!(l_1-l_2+l)!(l_2-l_1+l)!}{(l_1+l_2+l+1)!}\right]^{1/2}. \tag{B20}$$

After some algebraic manipulations this gives

$$P(l_1,l_2,l)=(-1)^{(l_1+l_2-l_{+1}/2)}(2g+2)\,\frac{g!\Delta(l_1,l_2,l)}{(g-l_1)!(g-l_2)!(g-l)!}. \tag{B21}$$

Here $2g+1=l_1+l_2+l$ and we have used formula (A6) for $\hat{C}^{ll_1\,-1l_2}_{0\,0\,0}$. Expression (B17) together with (B21) is our final result for the Poisson bracket of two spherical harmonics. Let us also note that $P(l_1,l_2,l)$ can be written as a certain Clebsch-Gordan coefficient:

$$P(l_1,l_2,l)=-\sqrt{l_1(l_1+1)l(l+1)}\hat{C}^{ll_1l_2}_{1\,1\,0}. \tag{B22}$$

This equality is analogous to formula (A6).

Observable effects and parametrized scaling limits of a model in nonrelativistic quantum electrodynamics

Fumio Hiroshima[a)]

(Received 2 July 2001; accepted for publication 12 December 2001)

Scaling limits of the Hamiltonian H of a system of N charged particles coupled to a quantized radiation field are considered. Ultraviolet cutoffs, $\hat{\lambda}_1,\ldots,\hat{\lambda}_N$, are imposed on the radiation field and the Coulomb gauge is taken. It is the so-called Pauli–Fierz model in nonrelativistic quantum electrodynamics. We mainly consider two cases: (i) all the ultraviolet cutoffs are identical, $\hat{\lambda}_1=\cdots=\hat{\lambda}_N$, (ii) supports of ultraviolet cutoffs have no intersection, $\mathrm{supp}\,\hat{\lambda}_i\cap\mathrm{supp}\,\hat{\lambda}_j=\varnothing$, $i\neq j$. The Hamiltonian acts on $L^2(\mathbb{R}^{dN})\otimes\mathcal{F}$, where $\mathcal{F}$ is a symmetric Fock space, and has the form $H=H_{\mathrm{el}}\otimes 1+B+1\otimes H_{\mathrm{quad}}$. Here H_{el} denotes a particle Hamiltonian, H_{quad} a quadratic field operator, and B an interaction term. The scaling is introduced as $H(\kappa)=H_{\mathrm{el}}\otimes 1+\kappa^l B+\kappa^2 1\otimes H_{\mathrm{quad}}$, where κ is a scaling parameter and $l\leqslant 2$ a parameter of the scaling. Performing a mass renormalization we consider the scaling limit of $H(\kappa)$ as $\kappa\to\infty$ in the strong resolvent sense. Then effective Hamiltonians H_{eff} in $L^2(\mathbb{R}^{dN})$ infected with reaction of effect of the radiation field is derived. In particular (1) effective Hamiltonians with an effective potential for $l=2$, and (2) effective Hamiltonians with an observed mass for $l=1$, are obtained. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1447590]

I. PRELIMINARIES

A. Observable effects and scaling limits

In this paper we consider the Hamiltonian H of a system of N nonrelativistic charged particles interacting with a quantized radiation field. Ultraviolet cutoffs are imposed on the radiation field and recoil of the particles and the radiation field (photons) are excluded, i.e., the dipole approximation is made. Taking scaling limits of the Hamiltonian, we derive effective Hamiltonians. The main idea is to diagonalize H by a canonical transformation derived from a symplectic structure.

The Schrödinger Hamiltonian of one charged particle with external potential V is of the form

$$\frac{1}{2m}p^2+V, \tag{1.1}$$

where p denotes the momentum operator and m the bare mass of the particle. To interpret the Lamb shift[1] intuitively, Welton[2] formally derived an effective Schrödinger Hamiltonian taking into account effects of a radiation field. He expected that a position fluctuation of a particle by a radiation field will effectively modify the external potential V. A fluctuation was thought of as a Gaussian random variable Δx, then a effective potential is formally given by the mean value of $V(x+\Delta x)$,

$$V_{\mathrm{eff}}(x):=\langle V(x+\Delta x)\rangle_{\mathrm{AVE}}=(2\pi)^{-3/2}\int_{\mathbb{R}^3}\hat{V}(k)e^{ikx}\langle e^{ik\Delta x}\rangle_{\mathrm{AVE}}=(2\pi C)^{-3/2}\int_{\mathbb{R}^3}V(y)e^{-|x-y|^2/2C}\,dy,$$

a)Electronic mail: hiroshima@mpg.setsunan.ac.jp

with a certain positive constant C. Then (1.1) effectively turns out to be the effective Hamiltonian, Welton's Hamiltonian, given by

$$\frac{1}{2m}p^2+V_{\mathrm{eff}}. \tag{1.2}$$

He gave an interpretation of the Lamb shift as the difference of the spectrum between the original Hamiltonian and the effective one.

On the other hand it was found in Ref. 3 that photons enhance the bare mass m. Then m amounts to an observed mass $m+\delta m$, $\delta m>0$, through a coupling to a radiation field. Then (1.1) formally turns out to be

$$\frac{1}{2(m+\delta m)}p^2+V. \tag{1.3}$$

In this paper performing a mass renormalization to eliminate a divergence contribution, we present a rigorous derivation of (1.2) and (1.3) by parametrized scaling limits of Hamiltonians describing an interaction between particles and radiation fields. Thus we interpolate (1.2) and (1.3). We suppose that N particles move in the d-dimensional space and a radiation field has the helicity $d-1$. Throughout this paper we assume

$$d\geqslant 3.$$

$\mathcal{F}$ denotes the Boson Fock space over $W:=\oplus^{d-1}L^2(\mathbb{R}^d)$, which is defined by

$$\mathcal{F}:=\bigoplus_{n=0}^{\infty}[\otimes_s^n W],$$

where $\otimes_s^n W$ denotes the n-fold symmetric tensor product of W, and $\otimes_s^0 W:=\mathbb{C}$. The bare vacuum Ω is defined by

$$\Omega:=\{1,0,0,\ldots\}.$$

Hamiltonians under consideration are of the form

$$H:=H_{\mathrm{el}}\otimes 1+B+1\otimes H_{\mathrm{quad}}$$

acting on the Hilbert space

$$\mathcal{H}:=L^2(\mathbb{R}^{dN})\otimes\mathcal{F}.$$

Here H_{el} describes the particle Hamiltonian of the form

$$H_{\mathrm{el}}:=\sum_{j=1}^{N}\frac{1}{2m_j}p_j^2+V.$$

Here $p_j:=-i\hbar\vec{\nabla}_j$ denotes the momentum operator of the jth particle canonically conjugate to the position operator x_j, $V:\mathbb{R}^{dN}\to\mathbb{R}$ an external potential, $\hbar$ the Planck constant divided by 2π, m_j the mass of the jth particle. H_{quad} a quadratic field operator in $\mathcal{F}$, and B an interaction term. We scale H as follows:

$$H(\kappa):=H_{\mathrm{el}}\otimes 1+\kappa^l B+\kappa^2 1\otimes H_{\mathrm{quad}}.$$

Davies[4,5] considered the scaling limit $\kappa\to\infty$ of the case of

$$l=1$$

for certain simple models to derive N-body Schrödinger Hamiltonians. He called this scaling limit *the weak coupling limit*. See also Refs. 6 and 7. On the other hand Arai[8] considered the case of

$$l=2$$

for the one particle Pauli–Fierz model in the dipole approximation without the self-interacting term A^2. Then he derived effective Hamiltonians with an effective potential. In this paper we consider scaling limits of

$$l\leqslant 2$$

for the N-particle Pauli–Fierz model in the dipole approximation. In particular, performing a mass renormalization, subtracting from $H(\kappa)$ some energy reset, and taking $\kappa\to\infty$ in the resolvent sense, we derive, for $l=2$, Welton's Hamiltonians, and for $l=1$, Hamiltonians with an observed mass.

B. Nonrelativistic models

Let $a^\dagger(f)$ and $a(f)$, $f\in W$, denote the smeared creation and annihilation operators acting on $\mathcal{F}$, respectively. $a^\sharp$ stands for a or $a^\dagger$. We set

$$a^{\sharp r}(f):=a^\dagger(\underbrace{0\oplus 0\cdots\oplus}_{d-1\,\text{times}}\overset{r_{\text{th}}}{f}\oplus\cdots 0\oplus 0).$$

They satisfy the canonical commutation relations,

$$[a^r(g),a^{\dagger s}(f)]=\delta_{rs}\int_{\mathbb{R}^d} f(k)g(k)\mathrm{d}k,$$

$$[a^{\dagger r}(f),a^{\dagger s}(g)]=[a^r(f),a^s(g)]=0$$

on the finite particle subspace of $\mathcal{F}$. We take the Coulomb gauge. The radiation field with the ultraviolet cutoff $\hat{\lambda}_j\in L^2(\mathbb{R}^d)$ is defined by

$$A_{j\mu}(x_j):=A_\mu(x_j,\hat{\lambda}_j):=\frac{1}{\sqrt{2}}\sum_{r=1}^{d-1}\{a^{\dagger r}(e^r_\mu e^{-ikx_j}\tilde{\hat{\lambda}}_j)+a^r(e^r_\mu e^{ikx_j}\hat{\lambda}_j)\},$$

where $e^r(k)=(e^r_1(k),\ldots,e^r_d(k))$ denotes polarization vectors satisying $e^r(k)\cdot e^s(k)=\delta_{rs}$ and $e^r(k)\cdot k=0$,

$$\tilde{\hat{\lambda}}_j(k):=\hat{\lambda}_j(-k),$$

and $\hat{f}$ denotes the Fourier transform of f. We assume

$$\hat{\lambda}_j(k)=\hat{\lambda}_j(-k),\quad j=1,...,N,$$

to ensure that $A_{j\mu}(x_j)$ is symmetric for each $x_j\in\mathbb{R}^d$. The physically reasonable choice of the ultraviolet cutoff is

$$\hat{\lambda}_j(k)=\frac{\sqrt{c}\hbar\hat{\rho}_j(k)}{\sqrt{(2\pi)^d\omega(k)}},$$

where $\hat{\rho}_j$ denotes the Fourier transform of the charge distribution ρ_j of the jth particle and c denotes the speed of the light. The dispersion relation $\omega(k)$ is given by

$$\omega(k) := |k|.$$

The free Hamiltonian H_f in $\mathcal{F}$ is defined by

$$H_f := \hbar c \sum_{r=1}^{d-1} \int \omega(k) a^{\dagger r}(k) a^r(k) \mathrm{d}k,$$

where $a^{\dagger r}(k)$ and $a^r(k)$ denote the kernels of $a^{\dagger r}(f)$ and $a^r(f)$, respectively. The total Hamiltonian is given by

$$H_{\text{total}} := \sum_{j=1}^{N} \frac{1}{2m_j} \left(p_j \otimes 1 - \frac{\alpha_j}{c} A_j(x_j) \right)^2 + 1 \otimes H_f + V \otimes 1,$$

where α_j's are nonzero coupling constants. We take the dipole approximation, i.e., we replace $A_j(x_j)$ with

$$A_j := A_j(0).$$

Then the Hamiltonian in the dipole approximation is given by

$$H := \sum_{j=1}^{N} \frac{1}{2m_j} \left(p_j \otimes 1 - \frac{\alpha_j}{c} 1 \otimes A_j \right)^2 + 1 \otimes H_f + V \otimes 1.$$

We work with the unit $c = \hbar = 1$ in what follows. Since

$$[p_{j\mu}, A_{j\nu}] = 0,$$

we have

$$H = H_{\text{el}} \otimes 1 - \sum_{j=1}^{N} \frac{\alpha_j}{m_j} p_j \otimes A_j + 1 \otimes \left(\sum_{j=1}^{N} \frac{\alpha_j^2}{2m_j} A_j^2 + H_f \right).$$

It is of mathematical interest to see A_j^2-corrections in scaling limits. Then we define, for $\epsilon \geqslant 0$,

$$H_\epsilon := H_{\text{el}} \otimes 1 - \sum_{j=1}^{N} \frac{\alpha_j}{m_j} p_j \otimes A_j + 1 \otimes \left(\sum_{j=1}^{N} \frac{\epsilon \alpha_j^2}{2m_j} A_j^2 + H_f \right)$$

with the domain

$$D(H_\epsilon) = D(H_{\text{el}} \otimes 1) \cap D(1 \otimes H_f) \cap D\left(1 \otimes \sum_{j=1}^{N} \frac{\epsilon \alpha_j^2}{2m_j} A_j^2 \right).$$

Actually, for $\epsilon < 1$, H_ϵ turns out to be an unphysical Hamiltonian for sufficiently large coupling constants, since in this case H_ϵ is unbounded from below. See Remark 3.10 for details. Let

$$\kappa > 1$$

be a scaling parameter. We introduce the scaled Hamiltonian $H_\epsilon(\kappa)$ as follows:

$$H_\epsilon(\kappa) := H_{\text{el}} \otimes 1 - \kappa^l \sum_{j=1}^{N} \frac{\alpha_j}{m_j} p_j \otimes A_j + \kappa^2 1 \otimes \left(\sum_{j=1}^{N} \frac{\epsilon \alpha_j^2}{2m_j} A_j^2 + H_f \right),$$

where

$$l \leqslant 2.$$

In particular we set

$$H(\kappa) := H_1(\kappa).$$

Unless confusion arises we omit $\otimes 1$ and $1 \otimes$ for simplicity in what follows. Throughout this paper we suppose that V satisfies Hypothesis **V**:

Hypothesis **V**: V is infinitesimally small with respect to $\Sigma_{j=1}^{N}(p_j^2/2m_j)$.

First of all we have to establish self-adjointness of $H_\epsilon(\kappa)$. Note that if we assume that $\hat{\lambda}_j/\sqrt{\omega}, \hat{\lambda}_j, \omega\hat{\lambda}_j \in L^2(\mathbb{R}^d)$, then

$$\left\| \left(-\sum_{j=1}^{N} \frac{\alpha_j}{m_j} p_j A_j + \sum_{j=1}^{N} \frac{\epsilon \alpha_j^2}{2m_j} A_j^2 \right) \Psi \right\| \leqslant a' \left\| \left(\sum_{j=1}^{N} \frac{p_j^2}{2m_j} + H_f \right) \Psi \right\| + b' \|\Psi\|$$

for $\Psi \in D(H_f)$ with some a' and b'. Let

$$\mathcal{D} := D\left(\sum_{j=1}^{N} \frac{p_j^2}{2m_j} \otimes 1 \right) \cap D(1 \otimes H_f).$$

Proposition 1.1: Let $\epsilon = 1$. *We suppose that* $\hat{\lambda}_j/\sqrt{\omega}, \hat{\lambda}_j, \omega\hat{\lambda}_j \in L^2(\mathbb{R}^d)$. *(1)* H_{total} *and* H *are self-adjoint on* $\mathcal{D}$ *and bounded from below. (2) Let* $l = 1$. *Then* $H(\kappa)$ *is self-adjoint on* $\mathcal{D}$ *and bounded from below for all* κ.

Proof: See Refs. 9 and 10 for (1). In the case of $l = 1$, $H(\kappa)$ is derived from the scaling $\alpha_j \to \kappa\alpha_j$ and $\omega \to \kappa\omega$ in H. Thus the self-adjointness follows from (1) □

Proposition 1.2: Let $\epsilon \neq 1$ *and* $V = 0$. *Suppose* $\hat{\lambda}_j/\sqrt{\omega}, \hat{\lambda}_j, \omega\hat{\lambda}_j \in L^2(\mathbb{R}^d)$. *Then* $H_\epsilon(\kappa)$ *is essentially self-adjoint on any core of* $\Sigma_{j=1}^{N} p_j^2/(2m_j) + H_f$.

Proof: The proof is due to Arai (Ref. 11 Theorem 2.2). Let $L := \Sigma_{j=1}^{N} p_j^2/(2m_j) + H_f + 1$. Then we see that

$$\|H_\epsilon(\kappa)\Psi\| \leqslant c\|L\Psi\|,$$

and

$$|(H_\epsilon(\kappa)\Psi, L\Psi) - (L\Psi, H_\epsilon(\kappa)\Psi)| \leqslant c'\|L^{1/2}\Psi\|\|L^{1/2}\Psi\|$$

with some constants c and c'. Thus, by the Nelson commutator theorem (Ref. 12, Theorem X.36), $H_\epsilon(\kappa)$ is essentially self-adjoint on any core of L. Thus the proposition follows. □

Self-adjointness of $H_\epsilon(\kappa)$ for $\epsilon < 1$ or $l \neq 1$ is discussed later (Theorem 3.11) in this paper. Since H_ϵ and $H_\epsilon(\kappa)$ are essentially self-adjoint, we take their self-adjoint extensions and denote them by the same symbols.

C. Problems

For the case of $N \geqslant 2$ we have to take care of the choice of ultraviolet cutoffs. For simplicity we mainly consider two cases: identical case, $\hat{\lambda}_1 = \cdots = \hat{\lambda}_N := \hat{\lambda}$, and independent case, $\operatorname{supp}\hat{\lambda}_j \cap \operatorname{supp}\hat{\lambda}_i = \varnothing$ for $i \neq j$.

Arai[8] considered the scaling limit of the case of $l = 2$, $\epsilon = 0$, and $N = 1$. Moreover in Refs. 13 and 14 distinct scaling limits were studied, but unfortunately A^2-corrections did not appear in scaling limits. In this paper we want to improve it and to see the relationship between Davies' scaling limit and Arai's one. As was seen in Sec. I A, Davies' scaling limits correspond to $l = 1$.

We set

$$H_\epsilon^0 := H_\epsilon \restriction_{V=0}.$$

Since H_ϵ^0 commutes with $p_{j\mu}$, H_ϵ is decomposable with respect to the spectrum of the particle momentum operators,

$$H_\epsilon^0 = \int_{\mathbb{R}^{dN}}^{\oplus} H_\epsilon^0(q)\mathrm{d}q.$$

$H_\epsilon^0(q)$ acts on $\mathcal{F}$. The ground state energy for each $q \in \mathbb{R}^{dN}$ is denoted by

$$E(q) := \inf \sigma(H_\epsilon^0(q)).$$

Then we call

$$m^*(\mu,\nu,j) := \left(\frac{\partial^2}{\partial q_{j\mu}\partial q_{j\nu}} E(q) \restriction_{q=0} \right)^{-1}$$

an *observed mass*. In this paper we explicitly give the ground state energy of H_ϵ^0 and its observed mass.

Thus the list of problems considered in this paper is epitomized as follows.

(1) Explicit ground state energy, $\inf \sigma(H_\epsilon^0)$.
(2) Observed mass, $m^*(\mu,\nu,j)$.
(3) Deriving effective Hamiltonians H_{eff} through scaling limits of $H_\epsilon(\kappa)$ subtracting a divergent contribution $E_{\mathrm{ren}}(\kappa)$: $s-\lim_{\kappa\to\infty}(H_\epsilon(\kappa)-E_{\mathrm{ren}}(\kappa)-z)^{-1} = (H_{\mathrm{eff}}-z)^{-1}\otimes P_\epsilon$ for $z \in \mathbb{C}\backslash\mathbb{R}$, where P_ϵ denotes a projection to the subspace spanned by ground states of $\Sigma_{j=1}^N \epsilon\alpha_j^2 A_j^2/(2m_j) + H_f$.
(4) What is a reasonable choice of $E_{\mathrm{ren}}(\kappa)$?
(5) l-dependence of H_{eff}.
(6) A_j^2-dependence (i.e., ϵ-dependence) of H_{eff}.
(7) Ultraviolet cutoff dependence of H_{eff}.

We give answers for (1) in Lemma 3.3, (2) in Corollary 3.7, (3) in Theorems 4.9–4.12, (4) in (4.5), (5), (6), and (7) in (4.7).

This paper is organized as follows. In Sec. II we discuss symplectic group structures of H_ϵ^0. In Sec. III we construct a canonical transformation and diagonalize H_ϵ^0. In Sec. IV we derive effective Hamiltonians by scaling limits. In Sec. V we give a remark on g-factor shift. Sections VI and VII are appendices.

II. SYMPLECTIC GROUP STRUCTURES

A. Unitary representations

$B(W)$ denotes the set of bounded operators on W. We define for $K \in B(W)$,

$$\overline{K}f := \overline{Kf}.$$

We introduce a notation. For $A,B,C,D \in B(W)$ we define

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} a(f) \\ a^\dagger(g) \end{pmatrix} := \begin{pmatrix} a(Af)+a^\dagger(Bg) \\ a(Cf)+a^\dagger(Dg) \end{pmatrix}.$$

Set

$$^{T}\begin{pmatrix} A & B \\ C & D \end{pmatrix} := \begin{pmatrix} A & C \\ B & D \end{pmatrix}.$$

Definition 2.1: Let $S,T \in B(W)$ *and set*

$$\xi := \begin{pmatrix} S & \overline{T} \\ T & \overline{S} \end{pmatrix} : W \oplus W \to W \oplus W.$$

(1) We say that ξ *is of symplectic group* Σ *if*

$$\xi^* J \xi = \xi J \xi^* = J, \tag{2.1}$$

where

$$\xi^* = \begin{pmatrix} S^* & T^* \\ \overline{T}^* & \overline{S}^* \end{pmatrix}, \quad J := \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}.$$

(2) We say that ξ *is of* Σ_{B} *if (i)* $\xi \in \Sigma$ *and (ii)* T *is a Hilbert–Schmidt operator.*

Σ_{B} is a subgroup of Σ. We define

$$\mathcal{H}_m := L^2(\mathbb{R}^m) \otimes \mathcal{F} \cong \int_{\mathbb{R}^m}^{\oplus} \mathcal{F} \mathrm{d}q.$$

Suppose that

$$\xi = \begin{pmatrix} S & \overline{T} \\ T & \overline{S} \end{pmatrix} \in \Sigma_{\mathrm{B}},$$

and

$$L = (L_1, \ldots, L_m) \in \oplus^m W.$$

For $f \in W$ we let

$$\begin{pmatrix} b(f) \\ b^{\dagger}(f) \end{pmatrix} := {}^{T}\begin{pmatrix} S & \overline{T} \\ T & \overline{S} \end{pmatrix} \begin{pmatrix} a(f) \\ a^{\dagger}(f) \end{pmatrix}$$

and

$$B(f) := 1 \otimes b(f) + \sum_{l=1}^{m} (L_l, f) p_l \otimes 1,$$

$$B^{\dagger}(f) := 1 \otimes b^{\dagger}(f) + \sum_{l=1}^{m} (\overline{L_l, f}) p_l \otimes 1,$$

where p_l, $l = 1, \ldots, m$, denote the momentum operators in $L^2(\mathbb{R}^m)$. It follows that

$$[b(f), b^{\dagger}(g)] = (\overline{f}, g),$$

$$[b(f), b(g)] = [b^{\dagger}(f), b^{\dagger}(g)] = 0.$$

Moreover since

$$\xi^{-1}=J\xi^{*}J=\begin{pmatrix} S^{*} & -T^{*} \\ -\overline{T}^{*} & \overline{S}^{*} \end{pmatrix},$$

we have

$$\begin{pmatrix} a(f) \\ a^{\dagger}(f) \end{pmatrix}={}^{T}\begin{pmatrix} S^{*} & -T^{*} \\ -\overline{T}^{*} & \overline{S}^{*} \end{pmatrix}\begin{pmatrix} b(f) \\ b^{\dagger}(f) \end{pmatrix} \tag{2.2}$$

and

$$\begin{pmatrix} 1\otimes a(f) \\ 1\otimes a^{\dagger}(f) \end{pmatrix}={}^{T}\begin{pmatrix} S^{*} & -T^{*} \\ -\overline{T}^{*} & \overline{S}^{*} \end{pmatrix}\begin{pmatrix} B(f) \\ B^{\dagger}(f) \end{pmatrix}-\sum_{l=1}^{m}\begin{pmatrix} (SL_l-\overline{TL_l},f)p_l\otimes 1 \\ (\overline{SL_l}-TL_l,f)p_l\otimes 1 \end{pmatrix}. \tag{2.3}$$

Define

$$R_l:=TL_l-\overline{SL_l},$$

and

$$\theta(q,\xi,L):=\exp\left\{\sum_{l=1}^{m} q_l\{a^{\dagger}(R_l)-a(\overline{R}_l)\}\right\},\quad q=(q_1,\ldots,q_m)\in\mathbb{R}^m.$$

Furthermore set

$$\theta(\xi,L):=\int_{\mathbb{R}^m}^{\oplus}\theta(q,\xi,L)\,dq=\exp\left\{\sum_{l=1}^{m} p_l\otimes\{a^{\dagger}(R_l)-a(\overline{R}_l)\}\right\},$$

where p_l, $l=1,...m$, denote the momentum operators.

Proposition 2.2: Suppose $\xi=\left(\begin{smallmatrix} S & \overline{T} \\ T & \overline{S} \end{smallmatrix}\right)\in\Sigma_{\mathrm{B}}$. *Then there exists a unitary operator* $U(\xi)$ *of* $\mathcal{F}$ *such that for all* $f\in W$

(1) $U(\xi)^{-1}b^{\sharp}(f)U(\xi)=a^{\sharp}(f)$,
(2) $U(\xi)^{-1}\theta(\xi,L)^{-1}B^{\sharp}(f)\theta(\xi,L)U(\xi)=a^{\sharp}(f)$.

Proof: See Refs. 15–17 for details. [We easily see that for $\xi_1:=\left(\begin{smallmatrix} S & \overline{T} \\ T & \overline{S} \end{smallmatrix}\right)\in\Sigma_{\mathrm{B}}$ and $\xi_2:=\left(\begin{smallmatrix} U & \overline{V} \\ V & \overline{U} \end{smallmatrix}\right)\in\Sigma_{\mathrm{B}}$: $U(\xi_2)U(\xi_1)a(f)U(\xi_1)^{-1}U(\xi_2)^{-1}=a((US+\overline{VT})f)+a^{\dagger}((VS+\overline{UT})f)$; $U(\xi_2)U(\xi_1)a^{\dagger}(f)U(\xi_1)^{-1}U(\xi_2)^{-1}=a((U\overline{T}+\overline{VS})f)+a^{\dagger}((V\overline{T}+\overline{US})f)$; and $\xi_2\cdot\xi_1=\left(\begin{smallmatrix} US+\overline{VT} & U\overline{T}+\overline{VS} \\ VS+\overline{UT} & V\overline{T}+\overline{US} \end{smallmatrix}\right)$. Then $U(\xi_2)U(\xi_1)=\omega(\xi_2\xi_1)U(\xi_2\xi_1)$, where $\omega(\xi_2\xi_1)$ is a constant. Hence the map $\Sigma_{\mathrm{B}}\ni\xi\mapsto U(\xi)$ defines a projective unitary representation of Σ_{B}.] □

We set

$$\mathcal{U}(q,\xi,L):=\theta(q,\xi,L)U(\xi):\mathcal{F}\to\mathcal{F},$$

and

$$\mathcal{U}(\xi,L):=\theta(\xi,L)U(\xi):\mathcal{H}_m\to\mathcal{H}_m.$$

We call $\mathcal{U}(\xi,L)$ the canonical transformation associated with $\{\xi,L\}\in\Sigma_{\mathrm{B}}\times\oplus^{m}W$.

B. Average of fluctuations

Define

$$\pi(f) := i\{a^\dagger(\overline{f}) - a(f)\}, \quad f \in W.$$

We want to obtain the average of fluctuation $F_{\xi L}$ of a function $F: \mathbb{R}^m \to \mathbb{C}$;

$$F_{\xi L} := \mathcal{U}(\xi, L)^{-1} F \mathcal{U}(\xi, L) = U(\xi)^{-1} F(x_1 + \pi(R_1), \ldots, x_m + \pi(R_m)) U(\xi),$$

with respect to the bare vacuum. Let Γ be the $m \times m$ symmetric matrix defined by

$$\Gamma := ((L_\mu, L_\nu)_W)_{1 \leqslant \mu, \nu \leqslant m},$$

and $\langle a, b \rangle$ denote the scalar product on $\mathbb{C}^m$. Suppose

$$\text{Rank } \Gamma = n \leqslant m$$

and T is a unitary matrix such that

$$T \Gamma T^{-1} = \text{diag}\{\mu_1, \ldots, \mu_n, 0, \ldots, 0\}, \quad \mu := \mu_1 \cdots \mu_n \neq 0.$$

Let

$$F_{T^{-1}}(x) := F(T^{-1}x), \quad x \in \mathbb{R}^m.$$

We define

$$F_{\text{eff}}(x) := (2\pi\mu)^{-m/2} \int_{\mathbb{R}^n} F_{T^{-1}}(y_1, \ldots, y_n, (Tx)_{n+1}, \ldots, (Tx)_m) \times \exp\left(-\sum_{j=1}^{n} |(Tx)_j - y_j|^2/(2\mu) \right) dy.$$

In particular if Rank $\Gamma = n$, then

$$F_{\text{eff}}(x) = (2\pi \det \Gamma)^{-m/2} \int_{\mathbb{R}^m} F(y) e^{-|x-y|^2/(2 \det \Gamma)} dy.$$

Lemma 2.3: Let $\xi = \begin{pmatrix} S & \overline{T} \\ T & \overline{S} \end{pmatrix} \in \Sigma_B$ *and* $(L_1, \ldots, L_m) \in \oplus^m W$. *Suppose that* F *is such that*

$$\int_{\mathbb{R}^n} |F_{T^{-1}}|(y_1, \ldots, y_n, (Tx)_{n+1}, \ldots, (Tx)_m) \exp\left(-\sum_{j=1}^{n} |(Tx)_j - y_j|^2/(2\mu) \right) dy \in L^1_{\text{loc}}(\mathbb{R}^m, dx).$$

Then for $f \in L^2(\mathbb{R}^m)$, *and* $g \in L^2(\mathbb{R}^m)$ *such that* $\mathcal{U}(\xi, L) g \otimes \Omega \in D(F)$, *we see that* $g \in D(F_{\text{eff}})$ *and*

$$(f \otimes \Omega, F_{\xi L} g \otimes \Omega)_{\mathcal{H}_m} = (f, F_{\text{eff}} g)_{L^2(\mathbb{R}^m)}. \tag{2.4}$$

Proof: We see that by (2.2)

$$a(\overline{R_l}) = b(S^* \overline{R_l}) - b^\dagger(\overline{T}^* \overline{R_l}),$$

$$a^\dagger(R_l) = -b(T^* R_l) + b^\dagger(\overline{S}^* R_l).$$

Thus we have

$$a^\dagger(R_l)-a(\overline{R_l})=b^\dagger(\overline{S}^*R_l+\overline{T}^*\overline{R_l})-b(T^*R_l+S^*\overline{R_l}):=b^\dagger(R_l')-b(\overline{R_l'}).$$

It follows from $\xi^*J\xi=\xi J\xi^*$ that

$$R_l'=\overline{S}^*(TL_l-\overline{SL_l})+\overline{T}^*(\overline{TL_l}-SL_l)=(\overline{S}^*T-\overline{T}^*S)L_l+(\overline{T}^*\overline{T}-\overline{S}^*\overline{S})\overline{L_l}=-\overline{L_l}.$$

Hence

$$\pi(R_l)=i\{a^\dagger(R_l)-a(\overline{R_l})\}=i\{b(L_l)-b^\dagger(\overline{L_l})\}.$$

Then we have

$$U(\xi)^{-1}\pi(R_l)U(\xi)=i\{a(L_l)-a^\dagger(\overline{L_l})\}=-\pi(L_l). \tag{2.5}$$

Let

$$F_N(x):=\begin{cases}F(x), & |x|<N,\\ 0, & |x|\geqslant N.\end{cases}$$

Moreover

$$F_{N\epsilon}:=\rho_\epsilon * F_N, \quad \epsilon>0,$$

where $\rho_\epsilon(x):=\rho(x/\epsilon)/\epsilon^m$, $\rho(x)\geqslant 0$, $\operatorname{supp}\rho\subset\{x\in\mathbb{R}^m||x|\leqslant 1\}$, and $\int_{\mathbb{R}^m}\rho(x)\mathrm{d}x=1$. (2.5) leads to

$$\begin{aligned}(f\otimes\Omega,(F_{N\epsilon})_{\xi L}g\otimes\Omega)&=(2\pi)^{-m/2}\int_{\mathbb{R}^m}\mathrm{d}k\, e^{ikx}\check{F}_{N\epsilon}(k)(f\otimes\Omega,U(\xi)^{-1}e^{i\langle k,x+\pi(R)\rangle}U(\xi)g\otimes\Omega)\\ &=(2\pi)^{-m/2}\int_{\mathbb{R}^d}\mathrm{d}k\, e^{ikx}\check{F}_{N\epsilon}(k)(f\otimes\Omega,e^{i\langle k,x-\pi(\overline{L})\rangle}g\otimes\Omega)\\ &=(2\pi)^{-m/2}\int_{\mathbb{R}^m}\mathrm{d}k\, e^{ikx}\check{F}_{N\epsilon}(k)\overline{f(x)}g(x)e^{-\langle k,\Gamma k\rangle/2}=(f,(F_{N\epsilon})_{\mathrm{eff}}g).\end{aligned}$$

Taking $\epsilon\to 0$, we have $(F_{N\epsilon})_{\mathrm{eff}}(x)\to(F_N)_{\mathrm{eff}}(x)$, and $(F_{N\epsilon})_{\xi L}\to(F_N)_{\xi L}$ strongly. Then the lemma follows for F_N. Let $f\in C_0^\infty(\mathbb{R}^m)$. Then taking $N\to\infty$, we also have $(f,(F_N)_{\xi L}g)\to(f,F_{\xi L}g)$ and $(f,(F_N)_{\mathrm{eff}}g)\to(f,F_{\mathrm{eff}}g)$ by the dominated convergence theorem. Hence the lemma follows. □

Remark 2.4: F_{eff} is independent of ξ.

C. Physical vacuum

Let $\xi=\left(\begin{smallmatrix}S & \overline{T}\\ T & \overline{S}\end{smallmatrix}\right)\in\Sigma_{\mathrm{B}}$ and $L\in\oplus^{dN}W$. We define

$$\Omega(q,\xi,L):=\mathcal{U}(q,\xi,L)\Omega.$$

Let K be a Hilbert–Schmidt operator. Then there exist complete orthonormal systems (CONS) $\{\psi_i\}$, $\{\phi_i\}$, and a positive sequence $\{\mu_i\}$ such that

$$Kf=\sum_{i=1}^\infty \mu_i(\psi_i,f)\phi_i, \quad f\in\mathcal{H}_m,$$

with

$$\sum_{i=1}^\infty \mu_i^2=\|K\|_{\mathrm{HS}}^2,$$

where $\|\cdot\|_{\mathrm{HS}}$ denotes the Hilbert–Schmidt norm. We define for a finite particle vector Ψ,

$$\langle a^\dagger|K|a^\dagger\rangle\Psi := s-\lim_{n\to\infty}\sum_{i=1}^{n}\mu_i a^\dagger(\overline{\psi_i})a^\dagger(\phi_i)\Psi.$$

The above-presented strong limit actually exists. It is well known that if

$$(1)K \text{ is a Hilbert–Schmidt operator,}\quad (2)\overline{K}^*=K,\quad (3)\|K\|<1,$$

then

$$U_0(K) := s-\lim_{N\to\infty}\sum_{n=1}^{N}\frac{1}{n!}\left(-\frac{1}{2}\langle a^\dagger|K|a^\dagger\rangle\right)^n\Psi$$

exists for a finite particle vector Ψ. See Ref. 18.

Lemma 2.5: We have

$$\Omega(q,\xi,L)=\det(1-(TS^{-1})^*TS^{-1})^{1/4}\theta(q,\xi,L)U_0(TS^{-1})\Omega.$$

Proof: See Ref. 13 for details. □

III. CANONICAL TRANSFORM OF THE HAMILTONIANS

A. Fixed particle-momentum Hamiltonians

We define the fixed particle-momentum Hamiltonian by

$$H_\epsilon^0(q) := \sum_{j=1}^{N}\frac{1}{2m_j}q_j^2-\sum_{j=1}^{N}\frac{\alpha_j}{m_j}q_j\cdot A_j+\sum_{j=1}^{N}\frac{\epsilon\alpha_j^2}{2m_j}A_j^2+H_f.$$

Here q is a fixed particle-momentum:

$$q=(q_1,\ldots,q_N)\in\mathbb{R}^{dN}.$$

By a canonical transformation $\mathcal{U}(q)$, we will diagonalize $H_\epsilon^0(q)$ as

$$\mathcal{U}(q)^{-1}H_\epsilon^0(q)\mathcal{U}(q)=E(q)+H_f \tag{3.1}$$

with some constant $E(q)$. In Ref. 13, (3.1) was established for $N=1$, in Ref. 14 for $N\geqslant 1$ but sufficiently small $|\alpha_j|$'s. In this section we improve it as follows:

(1) we extend (3.1) to $N\geqslant 1$ and arbitrary α_j's,
(2) we derive an explicit form of $E(q)$,
(3) we show analytic properties of $E(q)$ in each α_j's.

Proposition 3.1: Suppose that $\hat{\lambda}_j/\sqrt{\omega},\hat{\lambda}_j,\omega\hat{\lambda}_j\in L^2(\mathbb{R}^d)$ *for* $j=1,\ldots,N$. *Then for all* $\{\alpha_1,\ldots,\alpha_N\}$ *and all* $q\in\mathbb{R}^{dN}$, $H_\epsilon^0(q)$ *is self-adjoint on* $D(H_f)$ *and bounded from below.*

Proof: The proof is similar to Proposition 1.2. Let $L:=H_f+1$. Then we easily have

$$\|H_\epsilon^0(q)\Psi\|\leqslant c\|L\Psi\|,$$

and

$$|(H_\epsilon^0(q)\Psi,L\Phi)-(L\Psi,H_\epsilon^0(q)\Phi)|\leqslant c'\|L^{1/2}\Psi\|\|L^{1/2}\Phi\|$$

with some constants c and c' for $\Psi,\ \Phi\in D(H_f)$. Hence $H_\epsilon^0(q)$ is essentially self-adjoint on $D(H_f)$ by the Nelson commutator theorem. Moreover it is seen that

$$c''\left(\|H_f\Psi\|^2+\left\|\sum_{j=1}^N\left(\frac{q_j^2}{2m_j}-\frac{\alpha_j}{m_j}q_j\cdot A_j+\frac{\epsilon\alpha_j}{2m_j}A_j^2\right)\Psi\right\|^2\right)\leqslant\|H_\epsilon^0(q)\Psi\|^2+c'''\|\Psi\|^2$$

with some constants c'' and c'''. Then $H_\epsilon^0(q)$ is closed on $D(H_f)$. Thus $H_\epsilon^0(q)$ is self-adjoint on $D(H_f)$. □

B. Assumptions on ultraviolet cutoffs and coupling constants

In this section we introduce assumptions on $\hat{\lambda}_j$ and α_j. We suppose the following assumptions on $\hat{\lambda}_j$'s.

(A.1) $\hat{\lambda}_j$ is rotation invariant, i.e., there exists a function $\varphi_j:[0,\infty)\to\mathbb{R}$ such that $\hat{\lambda}_j(k)=\varphi_j(|k|)$,

(A.2) $\hat{\lambda}_j/\omega,\omega\hat{\lambda}_j\in L^2(\mathbb{R}^d)$,

(A.3) $\varphi_{ij}(s):=\varphi_i(\sqrt{s})\varphi_j(\sqrt{s})s^{(d-1)/2}\in L^\delta([0,\infty),\mathrm{d}s)$ for some $0<\delta<1$, and there exists $0<C_{ij}<1$ such that, for arbitrary $s,t\geqslant 0$, $|\varphi_{ij}(s)-\varphi_{ij}(t)|\leqslant C_{ij}|s-t|$,

(A.4) $\|\hat{\lambda}_j\omega^{(d-2)/2}\|_\infty<\infty$ and $\|\hat{\lambda}_j\omega^{d/2}\|_\infty<\infty$, where $\|g\|_\infty:=\sup_{x\in\mathbb{R}^d}|g(x)|$.

The above-mentioned assumptions are sufficient conditions to construct a canonical transformation. Let

$$m_{ab}:=\begin{cases}m_j, & a=b=j\\ 0, & a\neq b\end{cases}.$$

Define

$$\begin{aligned}D_{ij}(k)&:=m_{ij}-\epsilon\alpha_i\alpha_jK\lim_{\eta\downarrow 0}\int_{\mathbb{R}^d}\frac{\omega(k')\hat{\lambda}_i(k')\hat{\lambda}_j(k')}{\omega(k)^2-\omega(k')^2+i\eta}\mathrm{d}k'\\&=m_{ij}-\epsilon\alpha_i\alpha_j\frac{K}{2}S_{d-1}\left(\lim_{\eta\downarrow 0}\int_{|\omega(k)^2-x|>\eta,x>0}\frac{\varphi_{ij}(x)}{\omega(k)^2-x}\mathrm{d}x-2\pi i\varphi_{ij}(\omega(k)^2)\right),\end{aligned}\tag{3.2}$$

where S_{d-1} denotes the volume of the $(d-1)$-dimensional unit sphere and

$$K:=\frac{d-1}{d}.$$

We define

$$D:=D(k)=(D_{ij}(k))_{1\leqslant i,j\leqslant N}:\overset{N}{\oplus}L^2(\mathbb{R}^d)\to\overset{N}{\oplus}L^2(\mathbb{R}^d).$$

We introduce two assumptions of ultraviolet cutoffs, I_λ and II_λ, as follows:

Hypothesis I_λ*:* $\hat{\lambda}_1=\cdots=\hat{\lambda}_N:=\hat{\lambda}$ and $\Im\hat{\lambda}(k)\neq 0$ for all $k\in\mathbb{R}^d$.

Hypothesis II_λ*:* Each $\hat{\lambda}_j$ has a compact support such that $\mathrm{supp}\,\hat{\lambda}_j\cap\mathrm{supp}\,\hat{\lambda}_i=\varnothing$ for $i\neq j$, and $|\hat{\lambda}_j(k)/D_{jj}(k)|\to 0$ as k converges to the boundary of $\mathrm{supp}\,\hat{\lambda}_j$.

In what follows we mainly study above two cases. The next assumptions are needed to see the boundedness of the Hamiltonians from below.

Hypothesis $I_\lambda^\alpha(\epsilon)$*:* Ultraviolet cutoffs satisfy I_λ, and $\{\alpha_1,\cdots,\alpha_N\}$ satisfy that

$$\begin{cases}\displaystyle\sum_{j=1}^N\frac{\alpha_j^2}{m_j}<\frac{1}{\|\hat{\lambda}/\sqrt{\omega}\|^2}\frac{1}{1-\epsilon}, & 0\leqslant\epsilon<1,\\ \{\alpha_1,\ldots,\alpha_N\}\in\mathbb{R}^N, & \epsilon\geqslant 1.\end{cases}$$

Hypothesis $II_\lambda^\alpha(\epsilon)$*:* Ultraviolet cutoffs satisfy II_λ, and $\{\alpha_1,\ldots,\alpha_N\}$ satisfy that

$$\begin{cases} \dfrac{\alpha_j^2}{m_j} \leqslant \dfrac{1}{\|\hat{\lambda}_j/\sqrt{\omega}\|^2}\dfrac{1}{1-\epsilon}, \quad j=1,\ldots,N, \quad 0\leqslant\epsilon<1, \\ \{\alpha_1,\ldots,\alpha_N\}\in\mathbb{R}^N, \quad \epsilon\geqslant 1. \end{cases}$$

C. Diagonalization of $H_\epsilon^0(q)$

Since

$$D_{ij}(0)=m_{ij}+\epsilon\alpha_i\alpha_j\frac{K}{2}S_{d-1}\int_0^\infty\frac{\varphi_{ij}(x)}{x}\mathrm{d}x,$$

we easily see that $D(0)^{-1}$ exists as an $N\times N$ matrix for I_λ and II_λ. Set

$$\begin{pmatrix} R_1 \\ \vdots \\ R_N \end{pmatrix} := \sqrt{\omega}D(0)^{-1}\begin{pmatrix} \hat{\lambda}_1 \\ \vdots \\ \hat{\lambda}_N \end{pmatrix}.$$

We define

$$\theta(q):=\exp\left(\sum_{j=1}^N\sum_{r=1}^{d-1}\sum_{\mu=1}^d\frac{\alpha_j q_{j\mu}}{\sqrt{2}}\left\{a^r\left(\overline{\frac{e_\mu^r R_j}{\omega^{3/2}}}\right)-a^{\dagger r}\left(\frac{e_\mu^r R_j}{\omega^{3/2}}\right)\right\}\right).$$

Proposition 3.2: Suppose I_λ *or* II_λ.

(1) *There exist* $\mathbb{W}\in\Sigma_{\mathrm{B}}$ *and* Q_j, $j=1,\ldots,N$, *such that*

$$\theta(q,\mathbb{W},L)=\theta(q),$$

where $L=(L_1^1,\ldots,L_1^d,\ldots,L_N^1,\ldots,L_N^d)\in\oplus^{dN}W$ *with*

$$L_j^\mu:=\frac{\alpha_j}{\sqrt{2}}\oplus_{r=1}^{d-1}\frac{e_\mu^r Q_j}{\omega^{3/2}}.$$

(2) *Let*

$$\mathcal{U}(q):=\theta(q)U(\mathbb{W}).$$

Then $\mathcal{U}(q)$ *maps* $D(H_f)$ *onto itself, and*

$$\mathcal{U}(q)^{-1}H_\epsilon^0(q)\mathcal{U}(q)=E(q)+H_f$$

with some $E(q)$.

(3) $E(q)$ *can be analytically continued to a neighborhood* $\mathcal{O}$ *of* $\mathbb{R}$ *in each* α_j*'s*.

Proof: See Sec. VI. □

D. Ground state energy

In this section we show an explicit form of $E(q)$ for both cases I_λ and II_λ. In the case of $N=1$ it is shown in Ref. 19. For the case of $N\geqslant 2$ one needs a slight modification of Ref. 19. We do not, however, need to go into the minor details for the moment. So a proof of the following lemma is taken up in Sec. VII.

Lemma 3.3: (1) Suppose I_λ. *Then we have*

$$E(q)=\frac{1}{2}\sum_{j=1}^{N}\frac{q_j^2}{m_j}-\frac{1}{2}E_{\mathrm{I}}\left|\sum_{j=1}^{N}\frac{\alpha_j}{m_j}q_j\right|^2+g_{\mathrm{I}}(m),$$

where

$$E_{\mathrm{I}}:=\frac{K\|\hat{\lambda}/\sqrt{\omega}\|^2}{1+\epsilon\rho\|\hat{\lambda}/\sqrt{\omega}\|^2},$$

$$g_{\mathrm{I}}(m):=\frac{d}{2\pi}\int_{-\infty}^{\infty}\frac{\epsilon\rho s^2\|\sqrt{\omega}\hat{\lambda}/(s^2+\omega^2)\|^2}{1+\epsilon\rho\|\sqrt{\omega}\hat{\lambda}/\sqrt{s^2+\omega^2}\|^2}\mathrm{d}s,$$

$$\rho:=K\sum_{j=1}^{N}\frac{\alpha_j^2}{m_j}.$$

(2) Suppose II_λ *. Then we have*

$$E(q)=\frac{1}{2}\sum_{j=1}^{N}\frac{q_j^2}{m_j}-\frac{1}{2}\sum_{j=1}^{N}\frac{q_j^2}{m_j}E_{\mathrm{II}}^{j}+g_{\mathrm{II}}(m),$$

where

$$E_{\mathrm{II}}^{j}:=\frac{\rho_j\|\hat{\lambda}_j/\sqrt{\omega}\|^2}{1+\epsilon\rho_j\|\hat{\lambda}_j/\sqrt{\omega}\|^2},$$

$$g_{\mathrm{II}}(m):=\sum_{j=1}^{N}\frac{d}{2\pi}\int_{-\infty}^{\infty}\frac{\epsilon\rho_j s^2\|\sqrt{\omega}\hat{\lambda}_j/(s^2+\omega^2)\|^2}{1+\epsilon\rho_j\|\sqrt{\omega}\hat{\lambda}_j/\sqrt{s^2+\omega^2}\|^2}\mathrm{d}s,$$

$$\rho_j:=K\frac{\alpha_j^2}{m_j}.$$

Proof: See Sec. VII. □

It is an interesting case where $\epsilon=1$.

Corollary 3.4: (1) Suppose II_λ *and* $\epsilon=1$*. Then*

$$E(q)=\sum_{j=1}^{N}\frac{1}{2m_j^{\mathrm{eff}}}q_j^2+\sum_{j=1}^{N}\frac{d}{2\pi}\int_{-\infty}^{\infty}\frac{\rho_j s^2\|\sqrt{\omega}\hat{\lambda}_j/(s^2+\omega^2)\|^2}{1+\rho_j\|\sqrt{\omega}\hat{\lambda}_j/\sqrt{s^2+\omega^2}\|^2}\mathrm{d}s,$$

where

$$m_j^{\mathrm{eff}}:=m_j+\alpha_j^2K\|\hat{\lambda}_j/\sqrt{\omega}\|^2.$$

(2) Suppose $N=1$ *and* $\epsilon=1$*. Then*

$$E(q)=\frac{1}{2m^{\mathrm{eff}}}q^2+\frac{d}{2\pi}\int_{-\infty}^{\infty}\frac{K\alpha_1^2s^2\|\sqrt{\omega}\hat{\lambda}_1/(s^2+\omega^2)\|^2}{m+K\alpha_1^2\|\sqrt{\omega}\hat{\lambda}_1/(s^2+\omega^2)\|^2}\mathrm{d}s,$$

where

$$m^{\mathrm{eff}}:=m_1+\alpha_1^2K\|\hat{\lambda}_1/\sqrt{\omega}\|^2.$$

Lemma 3.5: (1) Suppose $\mathrm{I}_\lambda^\alpha(\epsilon)$. *Then for all* $q\in\mathbb{R}^{dN}$,

$$\sum_{j=1}^N \frac{q_j^2}{2m_j}-\frac{1}{2}E_{\mathrm{I}}\left|\sum_{j=1}^N \frac{\alpha_j}{m_j}q_j\right|^2>0.$$

(2) Suppose $\mathrm{II}_\lambda^\alpha(\epsilon)$. *Then for all* $q\in\mathbb{R}^{dN}$,

$$\sum_{j=1}^N \frac{q_j^2}{2m_j}-\frac{1}{2}\sum_{j=1}^N \frac{q_j^2}{m_j}E_{\mathrm{II}}^j>0.$$

Proof: By the Schwartz inequality we have

$$\frac{1}{2}E_{\mathrm{I}}\left|\sum_{j=1}^N \frac{\alpha_j}{m_j}q_j\right|^2\leqslant\frac{\rho\|\hat{\lambda}/\sqrt{\omega}\|^2}{1+\epsilon\rho\|\hat{\lambda}/\sqrt{\omega}\|^2}\sum_{j=1}^N \frac{q_j^2}{2m_j}.$$

Hence

$$\sum_{j=1}^N \frac{q_j^2}{2m_j}-\frac{1}{2}E_{\mathrm{I}}\left|\sum_{j=1}^N \frac{\alpha_j}{m_j}q_j\right|^2\geqslant\frac{1}{2}\left(1-\frac{\rho\|\hat{\lambda}/\sqrt{\omega}\|^2}{1+\epsilon\rho\|\hat{\lambda}/\sqrt{\omega}\|^2}\right)\sum_{j=1}^N \frac{q_j^2}{2m_j}.$$

Since Hypothesis $\mathrm{I}_\lambda^\alpha(\epsilon)$ implies that

$$1-\frac{\rho\|\hat{\lambda}/\sqrt{\omega}\|^2}{1+\epsilon\rho\|\hat{\lambda}/\sqrt{\omega}\|^2}>0,$$

(1) follows. (2) is similarly proven. □

E. Observed mass

We define the observed mass by

$$m^*(\mu,\nu,j):=\left(\frac{\partial^2}{\partial q_{j\mu}\partial q_{j\nu}}E(q)\bigg|_{q=0}\right)^{-1}.$$

Put

$$m^*(\mu,\mu,j):=m^*(\mu,j).$$

By Lemma 3.3 we have the following corollaries.

Corollary 3.6: (1) Suppose I_λ. *Then*

$$m^*(\mu,\nu,j)=\delta_{\mu\nu}m_j\left(\frac{1+K\left(\epsilon\Sigma_{i=1}^N\frac{\alpha_i^2}{m_i}-\frac{\alpha_j^2}{m_j}\right)\|\hat{\lambda}/\sqrt{\omega}\|^2}{1+\epsilon K\Sigma_{j=1}^N\frac{\alpha_j^2}{m_j}\|\hat{\lambda}/\sqrt{\omega}\|^2}\right)^{-1}.$$

In particular for the case of $\epsilon=1$,

$$m^*(\mu,\nu,j)=\delta_{\mu\nu}m_j\left(\frac{1+K\Sigma_{i\neq j}\dfrac{\alpha_i^2}{m_i}\|\hat{\lambda}/\sqrt{\omega}\|^2}{1+K\Sigma_{j=1}^N\dfrac{\alpha_j^2}{m_j}\|\hat{\lambda}/\sqrt{\omega}\|^2}\right)^{-1}.$$

(2) Suppose II_λ. *Then*

$$m^*(\mu,\nu,j)=\delta_{\mu\nu}\frac{m_j+\epsilon K\alpha_j^2\|\hat{\lambda}_j/\sqrt{\omega}\|^2}{1+(\epsilon-1)K\dfrac{\alpha_j^2}{m_j}\|\hat{\lambda}_j/\sqrt{\omega}\|^2}.$$

In particular for the case of $\epsilon=1$,

$$m^*(\mu,\nu,j)=\delta_{\mu\nu}(m_j+K\alpha_j^2\|\hat{\lambda}_j/\sqrt{\omega}\|^2).$$

Proof: It is a direct calculation. □

It is interesting to compare the sizes of observed masses for I_λ and II_λ.

Corollary 3.7: Suppose $\epsilon=1$. *Let* $m_{\mathrm{I}}^*(\mu,j)$ *be the observed mass for* I_λ *and* $m_{\mathrm{II}}^*(\mu,j)$ *for* II_λ. *Suppose that* $\|\hat{\lambda}/\sqrt{\omega}\|\leqslant\|\hat{\lambda}_j/\sqrt{\omega}\|$ *for a certain* j. *Then*

$$m_{\mathrm{I}}^*(\mu,j)<m_{\mathrm{II}}^*(\mu,j).$$

Proof: Note that

$$f(x)=\frac{x}{a+x},\quad a\geqslant 0,$$

is a monotonously increasing function of x. Directly we have

$$\frac{1}{m_{\mathrm{I}}^*(\mu,j)}=\frac{1}{m_j}\left(\frac{1+K\Sigma_{i\neq j}\dfrac{\alpha_i^2}{m_i}\|\hat{\lambda}/\sqrt{\omega}\|^2}{1+K\Sigma_{j=1}^N\dfrac{\alpha_j^2}{m_j}\|\hat{\lambda}/\sqrt{\omega}\|^2}\right)>\frac{1}{m_j}\left(\frac{1}{1+K\dfrac{\alpha_j^2}{m_j}\|\hat{\lambda}/\sqrt{\omega}\|^2}\right)$$
$$\geqslant\frac{1}{m_j}\left(\frac{1}{1+K\dfrac{\alpha_j^2}{m_j}\|\hat{\lambda}_j/\sqrt{\omega}\|^2}\right)=\frac{1}{m_{\mathrm{II}}^*(\mu,j)}.$$

Hence the corollary follows. □

F. Diagonalization of H_ϵ^0 and its self-adjointness

We define

$$\theta:=\exp\left(\sum_{j=1}^N\sum_{r=1}^{d-1}\sum_{\mu=1}^d\frac{\alpha_j}{\sqrt{2}}p_{j\mu}\otimes\left\{a^r\left(\overline{\frac{e_\mu^rR_j}{\omega^{3/2}}}\right)-a^{\dagger r}\left(\frac{e_\mu^rR_j}{\omega^{3/2}}\right)\right\}\right)$$

and

$$\mathcal{U}:=\theta U(\mathbb{W}).$$

Note that $\mathcal{U}$ maps $\mathcal{D}$ onto itself:

$$\mathcal{U}:\mathcal{D}\to\mathcal{D}.$$

Moreover we define $E(p)$ by the pseudodifferential operator with the kernel $E(q)$ in $L^2(\mathbb{R}^{dN})$.

Lemma 3.8: Suppose I_λ *or* II_λ. *Then for* $\Phi\in C_0^\infty(\mathbb{R}^{dN})\hat{\otimes}D(H_f)$,

$$\mathcal{U}^{-1}H_\epsilon^0\mathcal{U}\Phi=(E(p)\otimes 1+1\otimes H_f)\Phi. \tag{3.3}$$

Proof: Let $\Phi=g\otimes\psi$ *and* $\Psi=f\otimes\phi$, $g,\ f\in C_0^\infty(\mathbb{R}^{dN})$, $\psi,\phi\in D(H_f)$. We note that $\mathcal{U}\Phi\in\mathcal{D}$. Then the left-hand side of (3.3) is well defined. We have by Proposition 3.2

$$\begin{aligned}(\Psi,\mathcal{U}^{-1}H_\epsilon^0\mathcal{U}\Phi)_{\mathcal{H}}&=\int_{\mathbb{R}^{dN}}(\widehat{\mathcal{U}\Psi}(q),\widehat{H_\epsilon^0\mathcal{U}\Phi}(q))_{\mathcal{F}}\,dq\\&=\int_{\mathbb{R}^{dN}}(\mathcal{U}(q)\,\hat{\Psi}(q),H_\epsilon^0(q)\mathcal{U}(q)\,\hat{\Phi}(q))_{\mathcal{F}}\,dq\\&=\int_{\mathbb{R}^{dN}}\overline{\hat{f}}(q)\hat{g}(q)(\mathcal{U}(q)\psi,H_\epsilon^0(q)\mathcal{U}(q)\phi)_{\mathcal{F}}\,dq\\&=\int_{\mathbb{R}^{dN}}\hat{f}(q)\hat{g}(q)(\psi,(E(q)+H_f)\phi)_{\mathcal{F}}\,dq=(\Psi,(E(q)\otimes 1+1\otimes H_f)\Phi)_{\mathcal{H}}.\end{aligned}$$

Thus the lemma follows. □

Lemma 3.9: Suppose $\mathrm{I}_\lambda^\alpha(\epsilon)$ *or* $\mathrm{II}_\lambda^\alpha(\epsilon)$. *Then*

$$\mathcal{U}^{-1}H_\epsilon^0\mathcal{U}=E(p)\otimes 1+1\otimes H_f \tag{3.4}$$

holds on $\mathcal{D}$. *In particular* H_ϵ *is self-adjoint on* $\mathcal{D}$ *and bounded from below*.

Proof: By the assumption on $\{\alpha_1,\ldots,\alpha_N\}$, $E(p)$ is non-negative. Then $E(p)+H_f$ is self-adjoint on $\mathcal{D}$ and bounded from below. For $\Phi\in\mathcal{D}$, we can take a sequence $\Phi_n\in C_0^\infty(\mathbb{R}^{dN})\,\hat{\otimes}D(H_f)$ such that $\Phi_n\to\Phi$ and $(E(p)\otimes 1+1\otimes H_f)\Phi_n\to(E(p)\otimes 1+1\otimes H_f)\Phi$ strongly as $n\to\infty$. Since H_ϵ is closed, $H_\epsilon^0\mathcal{U}\Phi_n\to H_\epsilon^0\mathcal{U}\Phi$ as $n\to\infty$. Thus (3.4) holds. Since $\mathcal{U}$ maps $\mathcal{D}$ onto itself, H_ϵ^0 is self-adjoint on $\mathcal{D}$ and bounded from below. □

Remark 3.10: Let $\epsilon<1$. *Then* $E(p)$ *is unbounded from below for sufficiently large coupling constants. Actually in the case of* $N=1$, *for*

$$\alpha_1^2\geqslant m_1(\|\hat{\lambda}_1/\sqrt{\omega}\|^2(1-\epsilon))^{-1},$$

$E(p)$ *is unbounded from below. Hence* H_ϵ^0 *is unbounded from below for sufficiently large coupling constants. We should not overlook that the approximation of neglecting the self-interaction* A^2 *in* H *is not reasonable for sufficiently large coupling constants*.

Theorem 3.11: *Suppose* $\mathrm{I}_\lambda^\alpha(\epsilon)$ *or* $\mathrm{II}_\lambda^\alpha(\epsilon)$. *Then* H_ϵ *is self-adjoint on* $\mathcal{D}$ *and bounded from below*.

Proof: By Lemma 3.9 and the closed graph theorem there exists a constant c such that

$$\left\|\left(\sum_{j=1}^N\frac{p_j^2}{2m_j}+H_f\right)\Psi\right\|\leqslant c(\|H_\epsilon^0\Psi\|+\|\Psi\|),\quad \Psi\in\mathcal{D}.$$

Thus

$$\|V\Psi\|\leqslant ac(\|H_\epsilon^0\Psi\|+\|\Psi\|)+b\|\Psi\|$$

with some sufficiently small a, and some b, the Kato–Rellich theorem leads to the lemma. □

Corollary 3.12: Suppose I_λ. *Then*

$$\inf\sigma(H_\epsilon^0)=g_{\rm I}(m)=\frac{d}{2\pi}\int_{-\infty}^{\infty}\frac{\epsilon K\Sigma_{j=1}^N\frac{\alpha_j^2}{m_j}s^2\|\sqrt{\omega}\hat{\lambda}/(s^2+\omega^2)\|^2}{1+\epsilon K\Sigma_{j=1}^N\frac{\alpha_j^2}{m_j}\|\sqrt{\omega}\hat{\lambda}/\sqrt{s^2+\omega^2}\|^2}{\rm d}s.$$

Suppose II_λ. *Then*

$$\inf\sigma(H_\epsilon^0)=g_{\rm II}(m)=\sum_{j=1}^N\frac{d}{2\pi}\int_{-\infty}^{\infty}\frac{\epsilon K\frac{\alpha_j^2}{m_j}s^2\|\sqrt{\omega}\hat{\lambda}_j/(s^2+\omega^2)\|^2}{1+\epsilon K\frac{\alpha_j^2}{m_j}\|\sqrt{\omega}\hat{\lambda}_j/\sqrt{s^2+\omega^2}\|^2}{\rm d}s.$$

Proof: It follows from Lemmas 3.3 and 3.8. □

IV. EFFECTIVE HAMILTONIAN

A. Scaled Hamiltonians

Here we recall the scaled Hamiltonian $H_\epsilon(\kappa)$,

$$H_\epsilon(\kappa):=H_{\rm el}\otimes 1-\kappa^l\sum_{j=1}^N\frac{\alpha_j}{m_j}p_j\otimes A_j+\kappa^2 1\otimes\left(\sum_{j=1}^N\frac{\epsilon\alpha_j^2}{2m_j}A_j^2+H_f\right).$$

$H_\epsilon(\kappa)$ is derived from H_ϵ scaled as

$$\omega\to\kappa^2\omega, \tag{4.1}$$

$$\alpha_j\to\kappa^l\alpha_j, \tag{4.2}$$

$$\epsilon\to\kappa^{2-2l}\epsilon. \tag{4.3}$$

Replacing ω,α_j,ϵ as in (4.1)–(4.3), we see that

$$\theta\to\exp\left(\kappa^{l-2}\sum_{j=1}^N\sum_{r=1}^{d-1}\sum_{\mu=1}^d\frac{\alpha_j}{\sqrt{2}}p_{j\mu}\otimes\left\{a^r\left(\frac{\overline{e_\mu^r R_j}}{\omega^{3/2}}\right)-a^{\dagger r}\left(\frac{e_\mu^r R_j}{\omega^{3/2}}\right)\right\}\right), \tag{4.4}$$

$$-\frac{1}{2}E_{\rm I}\left|\sum_{j=1}^N\frac{\alpha_j}{m_j}q_j\right|^2\to-\kappa^{2l-2}\frac{1}{2}E_{\rm I}\left|\sum_{j=1}^N\frac{\alpha_j}{m_j}q_j\right|^2,$$

$$-\frac{1}{2}\sum_{j=1}^N\frac{q_j^2}{m_j}E_{\rm II}^j\to-\kappa^{2l-2}\frac{1}{2}\sum_{j=1}^N\frac{q_j^2}{m_j}E_{\rm II}^j,$$

$$g_{\rm I}(m)\to g_{\rm I}(m/k^2),$$

$$g_{\rm II}(m)\to g_{\rm II}(m/k^2).$$

Lemma 4.1: $U(\mathbb{W})$ *leaves invariant under the scaling* (4.1), (4.2), *and* (4.3).
Proof: See Lemma 6.5. □
Let

$$E_{\mathrm{ren}}(p) := \begin{cases} -\frac{1}{2} E_{\mathrm{I}} \left| \sum_{j=1}^{N} \frac{\alpha_j}{m_j} p_j \right|^2 & \text{for } \mathrm{I}_\lambda \\ -\frac{1}{2} \sum_{j=1}^{N} \frac{p_j^2}{m_j} E_{\mathrm{II}}^j & \text{for } \mathrm{II}_\lambda . \end{cases} \tag{4.5}$$

Moreover we set

$$g(m) := \begin{cases} g_{\mathrm{I}}(m) & \text{for } \mathrm{I}_\lambda \\ g_{\mathrm{II}}(m) & \text{for } \mathrm{II}_\lambda . \end{cases}$$

We define $\mathcal{U}_\kappa$ by $\mathcal{U}$ with ω, α_j, and ϵ replaced as in (4.1),(4.2), and (4.3), respectively.

Lemma 4.2: Suppose $\mathrm{I}_\lambda^\alpha(\kappa^{2l-2}\epsilon)$ *or* $\mathrm{II}_\lambda^\alpha(\kappa^{2l-2}\epsilon)$. *Then*

$$\mathcal{U}_\kappa^{-1} H_\epsilon(\kappa) \mathcal{U}_\kappa = \frac{1}{2} \sum_{j=1}^{N} \frac{p_j^2}{m_j} + \kappa^{2l-2} E_{\mathrm{ren}}(p) + \kappa^2 H_f + g(m/\kappa^2) + \mathcal{U}_\kappa^{-1} V \mathcal{U}_k .$$

In particular $H_\epsilon(\kappa)$ *is self-adjoint on* $\mathcal{D}$ *and bounded from below.*

Proof: It follows from Lemma 3.9. □

Lemma 4.3: Suppose I_λ *or* II_λ. *Then there exists the unique ground state* Ω_ϵ *of* $\Sigma_{j=1}^N \epsilon \alpha_j^2 A_j^2/(2m_j) + H_f$. *Moreover*

$$P_\epsilon := U(\mathbb{W}) P_\Omega U(\mathbb{W})^{-1} \tag{4.6}$$

is the projection to the eigenspace spanned by Ω_ϵ.

Proof: Set $q=0$ in Lemma 3.2 (2). Then

$$\mathcal{U}(0)^{-1} \left(\epsilon \sum_{j=1}^{N} \frac{\alpha_j^2}{2m_j} A_j^2 + H_f \right) \mathcal{U}(0) = H_f + g(m).$$

The right-hand side has the unique ground state Ω. Thus $\mathcal{U}(0)\Omega = U(\mathbb{W})\Omega = \Omega_\epsilon$ is the unique ground state of $\Sigma_{j=1}^N \epsilon \alpha_j^2 A_j^2/(2m_j) + H_f$. Hence the lemma follows. □

Lemma 4.4: (1) Suppose $l=2$. *Then* $\mathcal{U}_\kappa$ *is independent of* κ. (2) *Suppose* $l<2$. *Then s* $-\lim_{\kappa\to\infty} \mathcal{U}_\kappa = U(\mathbb{W})$.

Proof: It follows from (4.1) and (4.4). □

We write as

$$\mathcal{U}_\infty := \begin{cases} \mathcal{U}, & l=2, \\ U(\mathbb{W}), & l<2 . \end{cases}$$

B. Effective potentials

Define V_{eff} acting on $L^2(\mathbb{R}^{dN})$ by

$$(f, V_{\mathrm{eff}} g)_{L^2(\mathbb{R}^{dN})} := (f \otimes \Omega, (\mathcal{U}_\infty^{-1} V \mathcal{U}_\infty) g \otimes \Omega)_{\mathcal{H}} .$$

Note

$$D(V_{\mathrm{eff}}) \supset D\left(\sum_{j=1}^{N} \frac{p_j^2}{2m_j} \right).$$

We define the $N \times N$ correlation matrix $\Delta = (\Delta_{ij})_{1 \le i,j \le N}$ by

$$\Delta_{ij} := \frac{1}{2}\alpha_i\alpha_j K\left(\frac{Q_i}{\omega^{3/2}}, \frac{Q_j}{\omega^{3/2}}\right).$$

Note that

$$(L_i^\mu, L_j^\nu) = \frac{\alpha_i\alpha_j}{2} K\delta_{\mu\nu}\left(\frac{Q_i}{\omega^{3/2}}, \frac{Q_j}{\omega^{3/2}}\right) = \delta_{\mu\nu}\Delta_{ij}.$$

Suppose that $\mathrm{Rank}\Delta = M$ and $T = T_\Delta$ is an $N\times N$ unitary matrix such that

$$T\Delta T^{-1} = \mathrm{diag}\{\mu_1,\ldots,\mu_M,0,\ldots,0\}, \quad \mu = \mu_1\cdots\mu_M \neq 0.$$

Let

$$\tilde{T} := \begin{pmatrix} T_{11}1_d & \cdots & T_{1N}1_d \\ \vdots & & \vdots \\ T_{N1}1_d & \cdots & T_{NN}1_d \end{pmatrix}.$$

Here 1_d denotes the $d\times d$ identity matrix.

Lemma 4.5: Let $l=2$. Suppose

$$\int_{\mathbb{R}^{dM}} |V_{\tilde{T}^{-1}}|(y_1,\ldots,y_M,(\tilde{T}x)_{M+1},\ldots,(\tilde{T}x)_N)\exp\left(-\sum_{j=1}^K |(\tilde{T}x)_j - y_j|^2/(2\mu)\right)dy \in L^1_{\mathrm{loc}}(\mathbb{R}^{dN}).$$

(1) Suppose that $\mathrm{Rank}\Delta = N$. *Then we have*

$$V_{\mathrm{eff}}(x) = (2\pi)^{-dN/2}(\det\Delta)^{-d/2}\int_{\mathbb{R}^{dN}} e^{-|x-y|^2/(2\,\det\Delta)}V(y)dy.$$

(2) *Suppose that* $\mathrm{Rank}\Delta = M < N$. *Then we have*

$$V_{\mathrm{eff}}(x) = (2\pi)^{-dN/2}\mu^{-d/2}\int_{\mathbb{R}^{dM}} V_{\tilde{T}^{-1}}(y_1,\ldots,y_M,(\tilde{T}x)_{M+1},\ldots,(\tilde{T}x)_N)$$
$$\times\exp\left(-\sum_{j=1}^K |(\tilde{T}x)_j - y_j|^2/(2\mu)\right)dy.$$

Proof: It follows from Lemma 2.3. □

Lemma 4.6: Let $l<2$. Then $V_{\mathrm{eff}} = V$.

Proof: Since $\mathcal{U}_\infty$ and V is commutative, the lemma follows. □

C. Scaling limits

Let

$$V_\kappa := \mathcal{U}_\kappa^{-1} V \mathcal{U}_\kappa.$$

We define

$$H_\epsilon^{\mathrm{ren}}(\kappa) := \begin{cases} H_\epsilon(\kappa) - \kappa^{2l-2}E_{\mathrm{ren}}(p) - g(m/\kappa^2), & 1 < l \leqslant 2, \\ H_\epsilon(\kappa) - g(m/\kappa^2), & l \leqslant 1, \end{cases}$$

and

$$H_{\mathrm{eff}}:=\begin{cases}\displaystyle\sum_{j=1}^{N}\frac{p_j^2}{2m_j}+V_{\mathrm{eff}}, & l=2,\\ \displaystyle\sum_{j=1}^{N}\frac{p_j^2}{2m_j}+V, & 1<l<2,\\ \displaystyle\sum_{j=1}^{N}\frac{p_j^2}{2m_j}+E_{\mathrm{ren}}(p)+V, & l=1,\\ \displaystyle\sum_{j=1}^{N}\frac{p_j^2}{2m_j}+V, & l<1.\end{cases}\tag{4.7}$$

Lemma 4.7: Let κ be sufficiently large. Define

$$H_{\mathrm{eff}}(\kappa):=\begin{cases}\displaystyle\sum_{j=1}^{N}\frac{p_j^2}{2m_j}+\kappa^2H_f+V, & 1<l\leqslant 2,\\ \displaystyle\sum_{j=1}^{N}\frac{p_j^2}{2m_j}+\kappa^{2l-2}E_{\mathrm{ren}}(p)+\kappa^2H_f+V, & l\leqslant 1.\end{cases}$$

(1) Suppose I_λ *and* II_λ, *and* $l\neq 1$. *Then*

$$\mathcal{U}_\kappa H_\epsilon^{\mathrm{ren}}(\kappa)\mathcal{U}_\kappa=H_{\mathrm{eff}}(\kappa).\tag{4.8}$$

In particular, for all $\{\alpha_1,\ldots,\alpha_N\}$, $H_\epsilon^{\mathrm{ren}}(\kappa)$ *is self-adjoint on* $\mathcal{D}$ *and bounded from below. (2) Suppose* $\mathrm{I}_\lambda^\alpha(\epsilon)$ *or* $\mathrm{II}_\lambda^\alpha(\epsilon)$, *and* $l=1$. *Then* (4.8) *holds. In particular* $H_\epsilon^{\mathrm{ren}}(\kappa)$ *is self-adjoint on* $\mathcal{D}$ *and bounded from below.*

Proof: By Hypothesis **V** we see that for $\Psi\in\mathcal{D}$,

$$\|V_\kappa\Psi\|\leqslant a\left\|\sum_{j=1}^{N}\frac{p_j^2}{2m_j}\Psi\right\|+b\|\Psi\|.$$

Thus by the Kato–Rellich theorem $H_{\mathrm{eff}}(\kappa)$ for $1<l\leqslant 2$ is self-adjoint on $\mathcal{D}$ and bounded from below. For $l<1$, since κ is sufficiently large, we have $\Sigma_{j=1}^N(p_j^2/2m_j)+\kappa^{2l-2}E_{\mathrm{ren}}(p)$ is positive and

$$\left\|\left(\sum_{j=1}^{N}\frac{p_j^2}{2m_j}+\kappa^{2l-2}E_{\mathrm{ren}}(p)\right)f\right\|\geqslant\epsilon(\alpha_1,\ldots,\alpha_N)\left\|\sum_{j=1}^{N}\frac{p_j^2}{2m_j}f\right\|$$

with some $\epsilon(\alpha_1,\ldots,\alpha_N)>0$ independent of large κ. Then

$$\|V_\kappa\Psi\|\leqslant\frac{a}{\epsilon(\alpha_1,\ldots,\alpha_N)}\left\|\left(\sum_{j=1}^{N}\frac{p_j^2}{2m_j}+\kappa^{2l-2}E_{\mathrm{ren}}(p)\right)\Psi\right\|+b\|\Psi\|.\tag{4.9}$$

Hence $H_{\mathrm{eff}}(\kappa)$ for $l\neq 1$ is self-adjoint on $\mathcal{D}$ and bounded from below. By (3.8), (4.8) holds on $C_0^\infty(\mathbb{R}^{dN})\hat{\otimes}D(H_f)$, and $\mathcal{U}_\kappa$ maps $\mathcal{D}$ onto itself. Then (4.8) holds on $\mathcal{D}$ by a limiting argument. Thus (1) follows. For $l=1$, $\Sigma_{j=1}^N p_j^2/(2m_j)+E_{\mathrm{ren}}(p)$ is a nonnegative self-adjoint operator. Thus $H_{\mathrm{eff}}(\kappa)$ is self-adjoint on $\mathcal{D}$ and bounded from below. Thus (2) follows. □

Lemma 4.8: (1) Suppose $\mathrm{I}_\lambda^\alpha(\epsilon)$ *or* $\mathrm{II}_\lambda^\alpha(\epsilon)$, *and* $l=1$. *Then* H_{eff} *is self-adjoint on* $D(\Sigma_{j=1}^N p_j^2/(2m_j))$ *and bounded from below. (2) Let* $l\neq 1$. *Then* H_{eff} *is self-adjoint on* $D(\Sigma_{j=1}^N p_j^2/(2m_j))$ *and bounded from below.*

Proof: It is clear. We omit it. □

TABLE I. Effective Hamiltonians.

	$H_\epsilon^{\mathrm{ren}}(\kappa)+g(m/\kappa^2)$	H_{eff}
$l=2$, I_λ	$H_\epsilon(\kappa)+\frac{\kappa^2}{2}E_{\mathrm{I}}\left\vert\Sigma_{j=1}^N\frac{\alpha_j}{m_j}p_j\right\vert^2$	$\frac{1}{2m}p^2+V_{\mathrm{eff}}$
$l=2$, II_λ	$H_\epsilon(\kappa)+\frac{\kappa^2}{2}\Sigma_{j=1}^N\frac{p_j^2}{m_j}E_{\mathrm{II}}^j$	$\frac{1}{2m}p^2+V_{\mathrm{eff}}$
$1<l<2$, I_λ	$H_\epsilon(\kappa)+\frac{\kappa^{2l-2}}{2}E_{\mathrm{I}}\left\vert\Sigma_{j=1}^N\frac{\alpha_j}{m_j}p_j\right\vert^2$	$\frac{1}{2m}p^2+V$
$1<l<2$, II_λ	$H_\epsilon(\kappa)+\frac{\kappa^{2l-2}}{2}\Sigma_{j=1}^N\frac{p_j^2}{m_j}E_{\mathrm{II}}^j$	$\frac{1}{2m}p^2+V$
$l=1$, I_λ	$H_\epsilon(\kappa)$	$\Sigma_{j=1}^N\frac{p_j^2}{2m_j}-\frac{1}{2}E_{\mathrm{I}}\left\vert\Sigma_{j=1}^N\frac{\alpha_j}{m_j}p_j\right\vert^2+V$
$l=1$, II_λ	$H_\epsilon(\kappa)$	$\Sigma_{j=1}^N\frac{p_j^2}{2m_j}-\frac{1}{2}\Sigma_{j=1}^N\frac{p_j^2}{m_j}E_{\mathrm{II}}^j+V$
$l<1$	$H_\epsilon(\kappa)$	$\frac{1}{2m}p^2+V$

Let P_ϵ denote the projection to the subspace spanned by the unique ground state of $\Sigma_{j=1}^N\epsilon\alpha_j^2/2m_jA_j^2+H_f$. Note $P_0:=P_\Omega$ is the projection to Ω.

Theorem 4.9: *Let $l=2$. Suppose I_λ or II_λ. Moreover suppose $\vert V_{\mathrm{eff}}\vert\in L^1_{\mathrm{loc}}(\mathbb{R}^{dN})$. Then for all $\{\alpha_1,\ldots,\alpha_N\}$ and $z\in\mathbb{C}\backslash\mathbb{R}$,*

$$s-\lim_{\kappa\to\infty}(H_\epsilon^{\mathrm{ren}}(\kappa)-z)^{-1}=\theta\{(H_{\mathrm{eff}}-z)^{-1}\otimes P_\epsilon\}\theta^{-1}.$$

Theorem 4.10: *Let $1<l<2$. Suppose I_λ or II_λ. Then for all $\{\alpha_1,\ldots,\alpha_N\}$ and $z\in\mathbb{C}\backslash\mathbb{R}$,*

$$s-\lim_{\kappa\to\infty}(H_\epsilon^{\mathrm{ren}}(\kappa)-z)^{-1}=(H_{\mathrm{eff}}-z)^{-1}\otimes P_\epsilon. \tag{4.10}$$

Theorem 4.11: *Let $l=1$. Suppose $\mathrm{I}_\lambda^\alpha(\epsilon)$ or $\mathrm{II}_\lambda^\alpha(\epsilon)$. Then* (4.10) *holds.*

Theorem 4.12: *Let $l<1$. Suppose I_λ or II_λ. Then for all $\{\alpha_1,\ldots,\alpha_N\}$ and $z\in\mathbb{C}\backslash\mathbb{R}$,* (4.10) *holds. (See Table I).*

Before proving Theorems 4.9–4.12 we show a lemma.

Lemma 4.13: Suppose $z\in\mathbb{C}\backslash\mathbb{R}$.

(1) *Let $l=2$. Suppose $\vert V\vert_{\mathrm{eff}}\in L^1_{\mathrm{loc}}(\mathbb{R}^{dN})$, and I_λ or II_λ. Then for all $\{\alpha_1,\ldots,\alpha_N\}$,*

$$s-\lim_{\kappa\to\infty}(H_{\mathrm{eff}}(\kappa)-z)^{-1}=(H_{\mathrm{eff}}-z)^{-1}\otimes P_\Omega. \tag{4.11}$$

(2) *Let $1<l<2$. Suppose I_λ or II_λ. Then for all $\{\alpha_1,\ldots,\alpha_N\}$,* (4.11) *holds.*

(3) *Let $l=1$. Suppose $\mathrm{I}_\lambda^\alpha(\epsilon)$ or $\mathrm{II}_\lambda^\alpha(\epsilon)$. Then* (4.11) *holds.*

(4) *Let $l<1$. Suppose I_λ or II_λ. Then for all $\{\alpha_1,\ldots,\alpha_N\}$,* (4.11) *holds.*

Proof: By an abstract theorem in [Ref. 8 p. 2654, (i),(ii),(iii)] it is enough to prove that

(1) $D(V_\kappa)\supset D(H_{\mathrm{eff}})$ and $V_\kappa(H_{\mathrm{eff}}-z)^{-1}$ is a bounded operator for sufficiently large $-z$ with $\lim_{z\to-\infty}\Vert V_\kappa(H_{\mathrm{eff}}-z)^{-1}\Vert=0$ uniformly in κ,

(2) $V_\kappa(H_{\mathrm{eff}}-z)^{-1}$ is strongly continuous in κ and $s-\lim_{\kappa\to\infty}V_\kappa(H_{\mathrm{eff}}-z)^{-1}=V_{\mathrm{eff}}(H_{\mathrm{eff}}-z)^{-1}$.

By the definition of V_{eff} and Hypothesis **V**, we have

$$\Vert V_{\mathrm{eff}}f\Vert\leq a'\left\Vert\sum_{j=1}^N\frac{p_j^2}{2m_j}f\right\Vert+b'\Vert f\Vert$$

with some positive a' and b'. Together with (4.9) we get

$$\|V_\kappa f\| \leqslant a''\|H_{\mathrm{eff}} f\| + b''\|f\|$$

with some positive a'' and b''. Moreover

$$\|V_\kappa (H_{\mathrm{eff}} - z)^{-1} f\| \leqslant a''\|H_{\mathrm{eff}}(H_{\mathrm{eff}} - z)^{-1} f\| + b''\|(H_{\mathrm{eff}} - z)^{-1} f\|.$$

Hence $V_\kappa (H_{\mathrm{eff}} - z)^{-1} f \to 0$ as $z \to -\infty$. Then (1) follows. Since $\mathcal{U}_\kappa$ is continuous in κ and $s - \lim_{\kappa\to\infty} \mathcal{U}_k = \mathcal{U}_\infty$, we have

$$\begin{aligned}
\|(V_\kappa - V_{\kappa'})f\| &\leqslant \|\mathcal{U}_\kappa^{-1} V \mathcal{U}_k f - \mathcal{U}_\kappa^{-1} V \mathcal{U}_{\kappa'} f\| + \|\mathcal{U}_\kappa^{-1} V \mathcal{U}_{\kappa'} f - \mathcal{U}_{\kappa'}^{-1} V \mathcal{U}_{\kappa'} f\| \\
&\leqslant \|V(\mathcal{U}_\kappa - \mathcal{U}_{\kappa'})f\| + \|(\mathcal{U}_\kappa^{-1} - \mathcal{U}_{\kappa'}^{-1}) V \mathcal{U}_{\kappa'} f\| \\
&\leqslant a \left\| (\mathcal{U}_\kappa - \mathcal{U}_{\kappa'}) \sum_{j=1}^{N} \frac{p_j^2}{2m_j} f \right\| + b\|(\mathcal{U}_\kappa - \mathcal{U}_{\kappa'})f\| + \|(\mathcal{U}_\kappa^{-1} - \mathcal{U}_{\kappa'}^{-1}) V \mathcal{U}_{\kappa'} f\|.
\end{aligned}$$

Here in the third inequality we use that $\mathcal{U}_k$ and $p_j, j = 1,...,N$ are commutative. Then the first statement of (2) follows. The second statement is also proven similarly. □

Proof of Theorems 4.9–4.12: Suppose $l = 2$. Then $\mathcal{U}_\kappa = \mathcal{U}$ is independent of κ. We have by (4.8)

$$(H_\epsilon^{\mathrm{ren}}(\kappa) - z)^{-1} = \mathcal{U}(H_{\mathrm{eff}}(\kappa) - z)^{-1} \mathcal{U}^{-1}.$$

Taking $\kappa \to \infty$, we have

$$\lim_{\kappa\to\infty} (H_\epsilon^{\mathrm{ren}}(\kappa) - z)^{-1} = \mathcal{U}\{(H_{\mathrm{eff}} - z)^{-1} \otimes P_\Omega\}\mathcal{U}^{-1} = \theta\{(H_{\mathrm{eff}} - z)^{-1} \otimes U(\mathbb{W}) P_\Omega U(\mathbb{W})^{-1}\}\theta^{-1}.$$

Since $U(\mathbb{W}) P_\Omega U(\mathbb{W})^{-1} = P_\epsilon$, Theorem 4.9 follows. Next suppose $l = 1$,

$$(H_\epsilon^{\mathrm{ren}}(\kappa) - z)^{-1} = \mathcal{U}_\kappa (H_{\mathrm{eff}}(\kappa) - z)^{-1} \mathcal{U}_\kappa^{-1}.$$

Since

$$s - \lim_{\kappa\to\infty} \mathcal{U}_\kappa = U(\mathbb{W}),$$

taking $k \to \infty$, we have

$$\lim_{\kappa\to\infty} (H_\epsilon^{\mathrm{ren}}(\kappa) - z)^{-1} = U(\mathbb{W})\{(H_{\mathrm{eff}} - z)^{-1} \otimes P_\Omega\} U(\mathbb{W})^{-1}.$$

Hence Theorem 4.11 follows. Theorems 4.10 and 4.12 are proven similarly. □

D. Examples

In this section we assume that $|V_{\mathrm{eff}}| \in L^1_{\mathrm{loc}}(\mathbb{R}^{dN})$. A typical example is for $N = 1$ and $\epsilon = 1$. Put $A_1 = A$, $m_1 = m$, $p_1 = p$, $\alpha_1 = \alpha$.

Corollary 4.14: Let $N = 1$ and $\epsilon = 1$. Suppose I_λ *or* II_λ. *Then for all $\alpha \in \mathbb{R}$ and $z \in \mathbb{C}\backslash\mathbb{R}$:* ($l = 2$)

$$s - \lim_{\kappa\to\infty} \left(H(\kappa) + \kappa^2 \frac{1}{2(m + \delta m)} \frac{\delta m}{m} p^2 - g(m/\kappa^2) - z \right)^{-1} = \theta \left\{ \left(\frac{1}{2m} p^2 + V_{\mathrm{eff}} - z \right)^{-1} \otimes P_1 \right\} \theta^{-1};$$

$(1<l<2)$

$$s-\lim_{\kappa\to\infty}\left(H(\kappa)+\kappa^{2l-2}\frac{1}{2(m+\delta m)}\frac{\delta m}{m}p^2-g(m/\kappa^2)-z\right)^{-1}=\left(\frac{1}{2m}p^2+V-z\right)^{-1}\otimes P_1;$$

$(l=1)$

$$s-\lim_{\kappa\to\infty}(H(\kappa)-g(m/\kappa^2)-z)^{-1}=\left(\frac{1}{2(m+\delta m)}p^2+V-z\right)^{-1}\otimes P_1;$$

$(l<1)$

$$s-\lim_{\kappa\to\infty}(H(\kappa)-g(m/\kappa^2)-z)^{-1}=\left(\frac{1}{2m}p^2+V-z\right)\otimes P_1.$$

By virtue of Corollary 4.14 we see that in the case of $l=2$ the Welton Hamiltonian does appear and in the case of $l=1$ the Hamiltonian with observed mass does. (See Table II.)

Corollary 4.15: Suppose I_λ *and* $l=2$. *Moreover we assume that* $\alpha_1=\cdots=\alpha_N:=\alpha$ *and* $m_1=\cdots=m_N:=m$. *Then*

$$V_{\mathrm{eff}}=(2\pi C)^{-d/2}\int_{\mathbb{R}^d}V_{\tilde{T}^{-1}}(y,(\tilde{T}x)_2,\ldots,(\tilde{T}x)_N))e^{-|(\tilde{T}x)_1-y|^2/2C}\mathrm{d}y,$$

where

$$C:=\frac{N\alpha^2}{2}\frac{d-1}{d}\left\|\frac{Q}{\omega^{3/2}}\right\|^2,$$

Proof: Since the correlation matrix is given by

$$\Delta=\frac{\alpha^2}{2}\left\|\frac{Q}{\omega^{3/2}}\right\|^2K\begin{pmatrix}1&\cdots&1\\ \vdots&\ddots&\vdots\\ 1&\cdots&1\end{pmatrix},$$

where

$$Q=\sqrt{\omega}D^{-1}\begin{pmatrix}\hat{\lambda}\\ \vdots\\ \hat{\lambda}\end{pmatrix},$$

we have Rank $\Delta=1$. Thus the corollary follows. □

Corollary 4.16: Suppose II_λ *and* $l=2$. *Then*

$$V_{\mathrm{eff}}=(2\pi C)^{-d/2}\int_{\mathbb{R}^{dN}}V(y)e^{-|x-y|^2/2C}\mathrm{d}y,$$

where

$$C:=\Pi_{j=1}^N\left(\frac{d-1}{2d}\frac{\alpha_j^2}{m_j}\int_{\mathbb{R}^d}\frac{|\hat{\lambda}_j(k)|^2}{\omega(k)^2(m_j-\epsilon\delta C_j)}\mathrm{d}k\right),$$

TABLE II. Effective Hamiltonians for $N=1$ and $\epsilon=1$.

	$H^{\mathrm{ren}}(\kappa)+g(m/\kappa^2)$	H_{eff}
$l=2$	$H(\kappa)+\kappa^2\frac{1}{2(m+\delta m)}\frac{\delta m}{m}p^2$	$\frac{1}{2m}p^2+V_{\mathrm{eff}}$
$1<l<2$	$H(\kappa)+\kappa^{2l-2}\frac{1}{2(m+\delta m)}\frac{\delta m}{m}p^2$	$\frac{1}{2m}p^2+V$
$l=1$	$H(\kappa)$	$\frac{1}{2(m+\delta m)}p^2+V$
$l<1$	$H(\kappa)$	$\frac{1}{2m}p^2+V$

Proof: Since the correlation matrix is given by

$$\Delta=\mathrm{diag}\left\{\frac{1}{2}\alpha_1^2K\left\|\frac{Q_1}{\omega^{3/2}}\right\|^2,\ldots,\frac{1}{2}\alpha_N^2K\left\|\frac{Q_N}{\omega^{3/2}}\right\|^2\right\},$$

where

$$Q_j=\frac{\sqrt{\omega}\hat{\lambda}_j}{D_{jj}},$$

the corollary follows. □

V. CONCLUDING REMARKS (*g*-FACTOR SHIFT)

For simplicity we set $\epsilon=1$, $N=1$, and $d=3$. Put $A_1=A$, $m_1=m$, $p_1=p$, $\alpha_1=\alpha$. We suppose that spin 1/2 is included in the particle and an external vector potential $a(x)$ is imposed. Thus the Hamiltonian is read

$$H_{\mathrm{spin}}:=\frac{1}{2m}\{\sigma\cdot(p-a(x)-\alpha A)\}^2+V+H_f$$

acting on the Hilbert space

$$\mathbb{C}^2\otimes L^2(\mathbb{R}^3)\otimes\mathcal{F}.$$

Here $\sigma=(\sigma_1,\sigma_2,\sigma_3)$ denotes the Pauli matrices:

$$\sigma_1:=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \sigma_2:=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad \sigma_3:=\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

We have

$$H_{\mathrm{spin}}=\frac{1}{2m}(p-\alpha A)^2+H_f+V-\frac{g}{4m}\sigma\cdot\ \mathrm{curl}\,a+H_{\mathrm{I}},$$

where

$$g=2$$

and

$$H_{\mathrm{I}} := -\frac{1}{2m}\{(p-\alpha A)\cdot a - a\cdot(p-\alpha A)\} + \frac{1}{2m}a^2 - \frac{\alpha}{2m}\sigma\cdot\mathrm{curl}\,A,$$

and

$$\mathrm{curl}\,A := \frac{-i}{\sqrt{2}}\sum_{r=1}^{2}\{a^{\dagger r}((k\times e^r)\,\tilde{\lambda}) + a^r((-k\times e^r)\hat{\lambda})\}.$$

For simplicity we neglect H_{I}. Then our Hamiltonian is defined by

$$H = \frac{1}{2m}(p-\alpha A)^2 + H_f + V - \frac{g}{4m}\sigma\cdot\mathrm{curl}\,a.$$

Let $l=1$. Then the scaled Hamiltonian is given by

$$H(\kappa) := \frac{1}{2m}(p-\kappa\alpha A)^2 + \kappa^2 H_f + V - \frac{g}{4m}\sigma\cdot\mathrm{curl}\,a.$$

Corollary 5.1: Suppose that a is sufficiently smooth and that a is infinitesimally small with respect to p^2. Then $H(\kappa)$ is self-adjoint on $\mathcal{D}$ and bounded from below. Furthermore for $z \in \mathbb{C}\backslash\mathbb{R}$,

$$s-\lim_{\kappa\to\infty}(H(\kappa) - g(m/\kappa^2) - z)^{-1} = (H_{\mathrm{eff}} - z)^{-1}\otimes P_1.$$

Here

$$H_{\mathrm{eff}} = \frac{1}{2(m+\delta m)}p^2 - \frac{g_{\mathrm{eff}}}{4(m+\delta m)}\sigma\cdot\mathrm{curl}\,a + V,$$

and

$$g_{\mathrm{eff}} := \frac{m+\delta m}{m}g > 2.$$

Proof: The self-adjointness follows from Proposition 1.1. Since σ_j and $\mathcal{U}_k$ are commutative, by Theorem 4.11, we have

$$s-\lim_{\kappa\to\infty}(H(\kappa) - g(m/\kappa^2) - z)^{-1} = \left(\frac{1}{2(m+\delta m)}p^2 - \frac{g}{4m}\sigma\cdot\mathrm{curl}\,a + V - z\right)^{-1}\otimes P_1.$$

Hence the corollary follows. □

VI. PROOF OF PROPOSITION 3.2

A. Construction of canonical transformations

We recall

$$D_{ij} := m_{ij} - \epsilon\alpha_i\alpha_j\frac{K}{2}S_{d-1}\left(\lim_{\eta\downarrow 0}\int_{|\omega(k)^2-x|>\eta, x>0}\frac{\varphi_{ij}(x)}{\omega(k)^2-x}\mathrm{d}x - 2\pi i\varphi_{ij}(\omega(k)^2)\right).$$

Lemma 6.1: Suppose I_λ *or* II_λ. *Then* $\|D_{ij}\|_\infty < \infty$.

Proof: Set

$$\tilde{\varphi}_{ij}(s) := \lim_{\eta \downarrow 0} \int_{|s-x|>\eta, x>0} \frac{\varphi_{ij}(x)}{s-x} \mathrm{d}x.$$

Then by (A.3) and Ref. 20 we see that for $s,t \geqslant 0$,

$$|\tilde{\varphi}_{ij}(s) - \tilde{\varphi}_{ij}(t)| \leqslant C_{ij}|s-t|.$$

Hence $\tilde{\varphi}_{ij}$ is continuous. Since

$$\lim_{|s|\to\infty} \tilde{\varphi}_{ij}(s) = 0,$$

it follows that $\|D_{ij}\|_\infty < \infty$. □

Lemma 6.2: Suppose I_λ. *Then there exists*

$$Q = \begin{pmatrix} Q_1 \\ \vdots \\ Q_N \end{pmatrix} \in \oplus^N L^2(\mathbb{R}^d)$$

such that

$$(1)\ DQ = \sqrt{\omega}\begin{pmatrix} \hat{\lambda}_1 \\ \vdots \\ \hat{\lambda}_N \end{pmatrix},\ (2)\ \|\omega^{(d-1)/2} Q_j\|_\infty < \infty,\ and\ \|\omega^{(d-3)/2} Q_j\|_\infty < \infty,\ (3)\ Q_j/\omega^{3/2} \in L^2(\mathbb{R}^d).$$

Proof: We set

$$D(k) := M - \epsilon K g(k) A(\alpha_1, \ldots, \alpha_N),$$

where

$$M := \mathrm{diag}\{m_1, \ldots, m_N\},$$

$$A(\alpha_1, \ldots, \alpha_N) := \begin{pmatrix} \alpha_1\alpha_1 & \cdots & \alpha_1\alpha_N \\ \vdots & \ddots & \vdots \\ \alpha_N\alpha_1 & \cdots & \alpha_N\alpha_N \end{pmatrix},$$

and

$$g(k) := \lim_{\eta \downarrow 0} \int_{\mathbb{R}^d} \frac{\omega(k')|\hat{\lambda}(k')|^2}{\omega(k)^2 - \omega(k')^2 + i\eta} \mathrm{d}k'.$$

A is a positive definite matrix and we denote its eigenvalues by

$$\{a_1, \ldots, a_M, 0, \ldots, 0\}, \quad a_j > 0, \quad j = 1, \ldots, M, \tag{6.1}$$

with some $M \leqslant N$. A_M denotes the M-dimensional space spanned by eigenvectors with eigenvalues $a_1, \ldots, a_M$, and its orthogonal complement by $A_M^\perp$. Set $m = \min\{m_1, \ldots, m_N\}$, $a = \min\{a_1, \ldots, a_M\}$. For $z \in A_M^\perp$ we have

$$(z, D(k)z) = (z, Mz) \geqslant m|z|^2.$$

For $z \in A_M$, we have

$$|(z, D(k)z)| \geqslant \epsilon K |\Im g(k)||(z, Az)| \geqslant \epsilon a K |\Im g(k)||z|^2.$$

Hence for $\epsilon_0<|k|<\epsilon_1$ with $0<\epsilon_0$ and $0<\epsilon_1$ there exists $d'=d'(\epsilon_0,\epsilon_1)>0$ such that

$$|(z,D(k)z)|\geqslant d'|z|^2.$$

For $k=0$ it follows that

$$(z,D(0)z)=(z,Mz)-\epsilon Kg(0)(z,Az)\geqslant m|z|^2, \tag{6.2}$$

and as $|k|\to\infty$,

$$(z,D(k)z)\to(z,Mz)\geqslant m|z|^2. \tag{6.3}$$

Combining (6.2) with (6.3) we see that for $|k|\leqslant\epsilon_0$ or $|k|\geqslant\epsilon_1$ with some sufficiently small ϵ_0 and sufficiently large ϵ_1 there exists d'' such that

$$|(z,D(k)z)|>d''|z|^2.$$

Hence for all $k\in\mathbb{R}^d$,

$$|(z,D(k)z)|>\min\{d',d''\}|z|^2.$$

In particular the inverse D^{-1} of D exists as a bounded operator of $\oplus^N L^2(\mathbb{R}^d)$. Putting

$$Q:=\sqrt{\omega}D^{-1}\begin{pmatrix}\hat{\lambda}_1\\ \vdots\\ \hat{\lambda}_N\end{pmatrix},$$

we see that Q satisfies (1). It is seen that

$$\|\omega^n Q_j\|_\infty\leqslant\|D^{-1}\|\|\omega^{n+(1/2)}\hat{\lambda}_j\|_\infty.$$

From $\|\hat{\lambda}_j\omega^{(d-2)/2}\|_\infty<\infty$ and $\|\hat{\lambda}_j\omega^{d/2}\|_\infty<\infty$ [see (A.4)], (2) follows. Moreover from

$$\|\omega^n Q_j\|_{L^2(\mathbb{R}^d)}\leqslant\|D^{-1}\|\|\omega^{n+(1/2)}\hat{\lambda}_j\|_{L^2(\mathbb{R}^d)},$$

(3) follows, since $\hat{\lambda}/\omega\in L^2(\mathbb{R}^d)$ [see (A.2)]. Thus the lemma follows. □

Lemma 6.3: Suppose II_λ. *Then there exists Q such that (1)–(3) in Lemma 6.2 are satisfied.*

Proof: Note that

$$D_{jj}(k)\neq 0,\quad \text{for } k\in\{k\in\mathbb{R}^d|\hat{\lambda}_j(k)\neq 0\}.$$

Hence we can define $Q=(Q_1,\ldots,Q_N)$ by

$$Q_j(k):=\begin{cases}\dfrac{\sqrt{\omega(k)}\hat{\lambda}_j(k)}{D_{jj}(k)}, & k\in\{k\in\mathbb{R}^d|\hat{\lambda}_j(k)\neq 0\}\\ 0, & k\notin\mathrm{supp}\hat{\lambda}_j.\end{cases}$$

Since $|\hat{\lambda}_j(k)/D_{jj}(k)|\to 0$ as k converges to the boundary of $\mathrm{supp}\hat{\lambda}_j$, $Q(k)$ is well defined for all $k\in\mathbb{R}^d$, and we can easily check that Q satisfies (1)–(3). Thus the lemma follows. □

Let

$$R_j:=\sqrt{\omega}D(0)^{-1}\begin{pmatrix}\hat{\lambda}_1\\ \vdots\\ \hat{\lambda}_N\end{pmatrix}.$$

Define

$$Gf(k) := \lim_{\eta \downarrow 0} \int_{\mathbb{R}^d} \frac{f(k')}{(\omega(k)^2 - \omega(k')^2 + i\eta)(\omega(k)\omega(k'))^{(d-2)/2}} \mathrm{d}k'.$$

G is a skew symmetric bounded operator of $L^2(\mathbb{R}^{dN})$. Let

$$T_{\mu\nu} f := \delta_{\mu\nu} f + \epsilon \sum_{j=1}^{N} \alpha_j^2 Q_j \omega^{(d-2)/2} G \omega^{(d-2)/2} d_{\mu\nu} \sqrt{\omega} \hat{\lambda}_j f.$$

Lemma 6.4: Suppose I_λ *or* II_λ. *Then the following algebraic relations hold:*

(1) $\Sigma_{\beta=1}^{d} T^*_{\mu\beta} d_{\beta\nu} (1/\omega^2) Q_j = d_{\mu\nu} R_j / \omega^{3/2}$.
(2) $[\omega^2, T^*_{\mu\nu}] f = -\Sigma_{j=1}^{N} \alpha_j^2 (Q_j, f)_{L^2(\mathbb{R}^d)} d_{\mu\nu} \sqrt{\omega} \hat{\lambda}_j$.
(3) $T_{\mu\nu} \sqrt{\omega} \hat{\lambda}_j = \delta_{\mu\nu} m_j Q_j$.
(4) $T^*_{\mu\nu} d_{\nu\beta} T_{\beta\gamma} = d_{\mu\gamma}$.
(5) $e^r_\mu T_{\mu\nu} d_{\nu\beta} T_{\beta\gamma} e^s_\gamma = \delta_{rs}$.

Proof: By (1) of Lemmas 6.2 and 6.3, it is proven. See (Ref. 13, Lemma 2.6) for details. □

We define the bounded operator $W_\pm = (W^{rs}_\pm)_{1 \leqslant r,s \leqslant d-1} : W \to W$ by

$$W^{rs}_+ f := \tfrac{1}{2} e^r_\mu (\omega^{-1/2} T^*_{\mu\nu} \omega^{1/2} + \omega^{1/2} T^*_{\mu\nu} \omega^{-1/2}) e^s_\nu f,$$

$$W^{rs}_- f := \tfrac{1}{2} e^r_\mu (\omega^{-1/2} T^*_{\mu\nu} \omega^{1/2} - \omega^{1/2} T^*_{\mu\nu} \omega^{-1/2}) \widetilde{e^s_\nu f}.$$

It is checked by (A.4), Lemmas 6.2 and 6.3 that

$$\|W^{rs}_\pm f\| \leqslant c \|f\|,$$

where

$$c = 1 + \tfrac{1}{2} \sum_{j=1}^{d} (\|\omega^{(d-3)/2} Q_j\|_\infty \|\omega^{d/2} \hat{\lambda}_j\|_\infty + \|\omega^{(d-1)/2} Q_j\|_\infty \|\omega^{(d-2)/2} \hat{\lambda}_j\|_\infty) \|G\|.$$

We define

$$\mathbb{W} := \begin{pmatrix} W_+ & \overline{W_-} \\ W_- & \overline{W_+} \end{pmatrix}.$$

Lemma 6.5: Suppose I_λ or II_λ. *Then* $\mathbb{W} \in \Sigma_{\mathrm{B}}$. *Moreover* $\mathbb{W}$ *is invariant under the scaling* $\omega \to \kappa^2 \omega$, $\alpha_j \to \kappa^l \alpha_j$, and $\epsilon \to \kappa^{2l-2} \epsilon$.

Proof: It follows from Lemmas 6.4 (4) and (5). □

We define

$$\begin{pmatrix} b(f) \\ b^\dagger(f) \end{pmatrix} := {}^T\mathbb{W} \begin{pmatrix} a(f) \\ a^\dagger(f) \end{pmatrix}.$$

Let

$$L(q) := \sum_{j=1}^{N} \sum_{\mu=1}^{d} q_{j\mu} L^\mu_j \in W$$

with

$$L_j^\mu := \frac{\alpha_j}{\sqrt{2}} \overset{d-1}{\underset{r=1}{\oplus}} \frac{e_\mu^r Q_j}{\omega^{3/2}}.$$

L_j^μ is well defined by Lemmas 6.2 and 6.3. We define

$$\begin{pmatrix} B_q(f) \\ B_q^\dagger(f) \end{pmatrix} := \begin{pmatrix} b(f) \\ b^\dagger(f) \end{pmatrix} + \begin{pmatrix} (L(q),f)_W \\ \overline{(L(q),f)_W} \end{pmatrix}.$$

By (2.2) we have

$$\begin{pmatrix} a(f) \\ a^\dagger(f) \end{pmatrix} = {}^T(\mathbb{W}^{-1}) \begin{pmatrix} B_q(f) \\ B_q^\dagger(f) \end{pmatrix} - \begin{pmatrix} (W_+ L(q) - \overline{W_- \overline{L(q)}}, f)_W \\ \overline{(W_+ L(q) - \overline{W_- \overline{L(q)}}, f)_W} \end{pmatrix}.$$

By Proposition 2.2 there exists a unitary operator $U(\mathbb{W})$ such that

$$U(\mathbb{W})^{-1} b^\sharp(f) U(\mathbb{W}) = a^\sharp(f).$$

Recall

$$\theta(q) := \exp\left(\sum_{j=1}^N \sum_{r=1}^{d-1} \sum_{\mu=1}^d \frac{\alpha_j q_{j\mu}}{\sqrt{2}} \left\{ a^r\left(\overline{\frac{e_\mu^r R_j}{\omega^{3/2}}} \right) - a^{\dagger r}\left(\frac{e_\mu^r R_j}{\omega^{3/2}} \right) \right\} \right)$$

and

$$\mathcal{U}(q) := \theta(q) U(\mathbb{W}).$$

A proof of Proposition 3.2 (1): By Lemma 6.4 (1), we have

$$W_- L(q) - \overline{W_+ L(q)} = -\sum_{j=1}^N \sum_{\mu=1}^d q_{j\mu} \frac{\alpha_j}{\sqrt{2}} \oplus_{r=1}^{d-1} \frac{e_\mu^r R_j}{\omega^{3/2}}.$$

Hence $\theta(q, \mathbb{W}, L) = \theta(q)$ follows. □

A proof of Proposition 3.2 (2): It is seen that by Lemmas 6.4 (2) and (3), for $f \in W$,

$$[H_\epsilon^0(q), B_q(f)] = -B_q((\overset{d-1}{\oplus} \omega) f),$$

$$[H_\epsilon^0(q), B_q^\dagger(f)] = B_q^\dagger((\overset{d-1}{\oplus} \omega) f)$$

on some dense domain. Using these commutation relations we can prove that

$$e^{itH_\epsilon^0(q)} B^\dagger(f) e^{-itH_\epsilon^0(q)} = B^\dagger(e^{it\oplus^{d-1}\omega} f), \tag{6.4}$$

$$e^{itH_\epsilon^0(q)} B(f) e^{-itH_\epsilon^0(q)} = -B(e^{it\oplus^{d-1}\omega} f). \tag{6.5}$$

Then we have

$$B(f) e^{itH_\epsilon^0(q)} \mathcal{U}(q)\Omega = 0,$$

for all $f \in W$. It implies that $e^{itH_\epsilon^0(q)} \mathcal{U}(q)\Omega = \text{constant} \times \mathcal{U}(q)\Omega$. Since $e^{itH_\epsilon^0(q)}$ is one parameter unitary group,

$$e^{itH_\epsilon^0(q)}\mathcal{U}(q)\Omega = e^{itE(q)}\mathcal{U}(q)\Omega \tag{6.6}$$

with some constant $E(q)$. Hence by (6.4),(6.5), and (6.6) we obtain that

$$\mathcal{U}(q)^{-1}e^{itH_\epsilon^0(q)}\mathcal{U}(q)a^\dagger(f_1)\cdots a^\dagger(f_n)\Omega = e^{it(H_f-E(q))}a^\dagger(f_1)\cdots a^\dagger(f_n)\Omega.$$

Then

$$\mathcal{U}(q)^{-1}e^{itH_\epsilon^0(q)}\mathcal{U}(q) = e^{it(H_f-E(q))}.$$

Since $H_\epsilon^0(q)$ is self-adjoint on $D(H_f)$, we see that $\mathcal{U}(q)$ maps $D(H_f)$ onto itself and $\mathcal{U}(q)^{-1}H_\epsilon^0(q)\mathcal{U}(q) = H_f - E(q)$ holds by Stone's theorem. □

B. Analytic continuation

Lemma 6.6: Suppose I_λ. *Let* $f \in L^2(\mathbb{R}^d)$. *Then* $Q_j f$ *can be strongly analytically continued to a neighborhood* $\mathcal{O}$ of $\mathbb{R}$ *in each* α_i's.

Proof: We fix j. We can find a neighborhood $\mathcal{O}$ of $\mathbb{R}$ such that, for $z_j \in \mathcal{O}$,

$$D(z_j) = D(z_j,k) := M - \epsilon K g(k) A(\alpha_1,\ldots,z_j,\ldots,\alpha_N)$$

is a strongly analytic bounded operator on $\oplus^N L^2(\mathbb{R}^d)$, and

$$\inf_{k\in\mathbb{R}^d} |(w, D(z_j,k)w)| > \delta |w|^2, \quad \text{for } w \in \mathbb{C}^N,$$

with some positive constant δ. Hence $D(z_j)^{-1}$ exists as a bounded operator for $z_j \in \mathcal{O}$ and

$$\|D(z_j)^{-1}\| \leqslant \frac{1}{\delta}.$$

We can take a sufficiently small neighborhood $\mathcal{O}(z_j) \subset \mathcal{O}$ of z_j such that

$$\inf_{z_j \in \mathcal{O}(z_j)} \|D(z_j)^{-1}\| < \infty. \tag{6.7}$$

Since

$$\frac{D(z_j)^{-1} - D(z_j')^{-1}}{z_j - z_j'} = D(z_j)^{-1}\left(\frac{D(z_j') - D(z_j)}{z_j - z_j'}\right)D(z_j')^{-1},$$

by (6.7) we conclude that $D(z_j)^{-1}$ is strongly differentiable in $\mathcal{O}$. Thus $D(z_j)^{-1}$ is a strongly analytic bounded operator. Hence the lemma follows. □

Lemma 6.7: Suppose II_λ. *Let* $f \in L^2(\mathbb{R}^d)$. *Then* $Q_j f$ *can be strongly analytically continued to a neighborhood* $\mathcal{O}$ *of* $\mathbb{R}$ *in each* α_i's.

Proof: Note

$$Q_j(k) = \frac{1}{\epsilon K \alpha_j^2}\,\frac{1}{\dfrac{m_j}{\epsilon K \alpha_j^2} - g_j(k)}.$$

Here

$$g_j(k) := \lim_{\eta \downarrow 0} \int_{\mathbb{R}^d} \frac{\omega(k')|\hat{\lambda}_j(k')|^2}{\omega(k)^2 - \omega(k')^2 + i\eta}\,dk'.$$

It is seen that

(1) $g_j(0)<0$, (2) $\Im g_j(k)<0$ for $k\in \mathrm{supp}\hat{\lambda}_j$, (3) $g_j(k)=0$ for $k\notin \mathrm{supp}\hat{\lambda}_j$,
(4) g_j is continuous.

Hence, for arbitrary $\delta>0$,

$$\mathrm{dist}(\mathrm{Ran} g_j,[\delta,\infty))>M$$

with some positive constant M. Thus $Q_j f$ can be analytically continued to

$$\mathcal{O}' := \{a+ib, a\in\mathbb{R}, b\in\mathbb{R} \,|\, |a|>\delta, |b|<M\}$$

in $z_j := m_j/(\epsilon K \alpha_j^2)$. Thus $Q_j f$ can be strongly analytically continued in a neighborhood $\mathcal{O}$ of $\mathbb{R}$ in each α_j. □

A proof of Lemma 3.2 (3): Note that

$$E(q)=\frac{(\Omega, H_\epsilon(q)\mathcal{U}(q)\Omega)}{(\Omega,\mathcal{U}(q)\Omega)}. \tag{6.8}$$

It is proven in Refs. 11 and 13 that by Lemma 2.5 $E(q)$ can be expressed as

$$E(q)=\sum_{j=1}^{N}\frac{1}{2m_j}(q_j+\tilde{q}_j)^2+\Delta,$$

where

$$\tilde{q}_{j\nu} := \sum_{i=1}^{N}\sum_{r=1}^{d-1}\sum_{s=1}^{d-1}\sum_{\mu=1}^{d}\frac{1}{2}q_{\mu i}\alpha_i\alpha_j(e_\mu^r R_j/\omega^{3/2}, (1+W_-W_+^{-1})_{rs}e_\nu^s\hat{\lambda}_i),$$

$$\Delta=\sum_{j=1}^{N}\sum_{r=1}^{d-1}\sum_{\mu=1}^{d}\frac{\alpha_j^2}{4m_j}(e_\mu^r\hat{\lambda}_j,(1-W_-W_+^{-1})_{rs}e_\mu^s\hat{\lambda}_j).$$

By Lemmas 6.6 and 6.7 we see that $T_{\mu\nu}$ can be strongly analytically continued to some $\mathcal{O}\subset\mathbb{R}$ in each α_j's. Moreover $W_\pm$ also can be done. By the identities derived from the symplectic structure,

$$W_+^* W_+ - \overline{W_-^* W_-} = I,$$

$$W_+ W_+^* - \overline{W_- W_-^*} = I,$$

taking a sufficiently small neighborhood $\mathcal{O}'\subset\mathcal{O}$, we see that W_+^{-1} can be extended to $\alpha_j\in\mathcal{O}'$ as a bounded operator $W_+^{-1}(\alpha_j)$. Moreover it is seen that $\sup_{\alpha_j\in\mathcal{O}(\alpha_j)}\|W_+^{-1}(\alpha_j)\|<\infty$ for sufficiently small neighborhood $\mathcal{O}(\alpha_j)$ of α_j. Thus $W_+^{-1}(\alpha_j)$ is strongly differentiable in α_j, and hence strongly analytic on $\mathcal{O}'$. □

VII. PROOF OF LEMMA 3.3

A proof of Lemma 3.3 (1): We take a momentum lattice approximation. The momentum lattice approximated Hamiltonian (7.1) can be identified with a harmonic oscillator. Then its ground state energy can be explicitly obtained. By a limiting argument we get $E(q)$. First we assume that $|\alpha_j|$'s are sufficiently small and replace $\omega(k)$ with

$$\omega_\delta(k) := \omega(k)+\delta, \quad \delta>0.$$

Let $1/a>0$ be the width of the momentum lattice, and some $L>0$ be fixed. For

$$l=(l^1,\ldots,l^d)\in(2\pi\mathbb{Z}/a)^d$$

we define

$$\Gamma(l):=\left[l^1,l^1+\frac{2\pi}{a}\right)\times\cdots\times\left[l^d,l^d+\frac{2\pi}{a}\right).$$

Let $|l|:=\max_r|l^r|$. Suppose

$$|l|\leqslant 2\pi L.$$

Set

$$D:=(2[aL]+1)^d,$$

where $[z]$ denotes the integer part of z. We named the lattice points of the rectangle with width $2[aL]$ centered at the origin as

$$l_1,l_2,\ldots,l_D.$$

We set

$$\vec{q}:=\frac{1}{\sqrt{2}}\frac{1}{\sqrt{\omega_\delta(l)}}\{a^{\dagger r}(\chi_{\Gamma(l)})+a^r(\chi_{\Gamma(l)})\}_{1\leqslant r\leqslant d-1,|l|\leqslant 2\pi L},$$

$$\vec{p}:=\frac{i}{\sqrt{2}}\sqrt{\omega_\delta(l)}\{a^{\dagger r}(\chi_{\Gamma(l)})-a^r(\chi_{\Gamma(l)})\}_{1\leqslant r\leqslant d-1,|l|\leqslant 2\pi L},$$

where χ_I denotes the characteristic function of $I\subset\mathbb{R}^d$. Define

$$H_\epsilon(q,\delta,a,L):=\sum_{j=1}^N\left\{\frac{1}{2m_j}q_j^2-\frac{\alpha_j}{m_j}\sum_{\mu=1}^d(q_{j\mu}v_\mu^j,\vec{q})+\epsilon\sum_{\mu=1}^d\frac{\alpha_j^2}{2m_j}(\vec{q},v_\mu^j)(v_\mu^j,\vec{q})\right\}$$
$$+\frac{1}{2}\{(\vec{p},\vec{p})+(\vec{q},A_0\vec{q})\}-\frac{1}{2}\operatorname{tr}\sqrt{A_0}. \tag{7.1}$$

Here A_0 is the $(d-1)D\times(d-1)D$ symmetric matrix defined by

$$A_0:=(1_{(d-1)}\delta_{ll'}\omega_\delta(l)^2)_{|l|,|l'|\leqslant 2\pi L}=\begin{pmatrix}\omega_\delta(l_1)1_{(d-1)} & & & \\ & \omega_\delta(l_2)1_{(d-1)} & & \\ \vdots & \cdots & \ddots & \vdots \\ & & & \omega_\delta(l_D)1_{(d-1)}\end{pmatrix}, \tag{7.2}$$

and

$$v_\mu := \begin{pmatrix} \sqrt{\omega_\delta(l_1)}\hat{\lambda}(l_1)e^1_\mu(l_1) \\ \vdots \\ \sqrt{\omega_\delta(l_1)}\hat{\lambda}(l_1)e^{(d-1)}_\mu(l_1) \\ \vdots \\ \vdots \\ \sqrt{\omega_\delta(l_D)}\hat{\lambda}(l_D)e^1_\mu(l_D) \\ \vdots \\ \sqrt{\omega_\delta(l_D)}\hat{\lambda}(l_D)e^{(d-1)}_\mu(l_D) \end{pmatrix} \in \mathbb{R}^{(d-1)D}.$$

Here $1_{(d-1)}$ denotes the $(d-1)\times(d-1)$ identity matrix. It is seen that

$$(H_\epsilon(q,\delta,a,L)-z)^{-1} \to (H_\epsilon(q,\delta)-z)^{-1} \tag{7.3}$$

uniformly as $a\to\infty$ and then $L\to\infty$. Here $H_\epsilon(q,\delta)$ denotes $H^0_\epsilon(q)+\delta N$. We define the projection P by

$$P := \epsilon \sum_{j=1}^{N} \sum_{\mu=1}^{d} \frac{\alpha_j^2}{m_j} |v_\mu\rangle\langle v_\mu|.$$

Then

$$H_\epsilon(q,\delta,a,L) = \sum_{j=1}^{N} \left\{ \frac{1}{2m_j} q_j^2 - \frac{\alpha_j}{m_j} \sum_{\mu=1}^{d} (q_{j\mu} v_\mu, \vec{q}) \right\} + \frac{1}{2}(\vec{q}, P\vec{q}) + \frac{1}{2}(\vec{p},\vec{p}) + \frac{1}{2}(\vec{q}, A_0\vec{q}) - \frac{1}{2}\mathrm{tr}\sqrt{A_0}.$$

Set

$$A := A_0 + P.$$

Since $\omega_\delta(k) \geqslant \delta > 0$, the inverse of A_0 exists, and hence A also has the inverse, and it is symmetric. Then we have

$$= \sum_{j=1}^{N} \frac{1}{2m_j} q_j^2 - \sum_{j=1}^{N} \sum_{\mu=1}^{d} \frac{\alpha_j}{m_j} (AA^{-1} q_{j\mu} v_\mu, \vec{q}) + \frac{1}{2}(\vec{q}, A\vec{q}) + \frac{1}{2}(\vec{p},\vec{p}) - \frac{1}{2}\mathrm{tr}\sqrt{A_0}$$

$$= \sum_{j=1}^{N} \frac{1}{2m_j} q_j^2 + \frac{1}{2}((\vec{q}-\vec{f}), A(\vec{q}-\vec{f})) - \frac{1}{2}(\vec{f}, A\vec{f}) + \frac{1}{2}(\vec{p},\vec{p}) - \frac{1}{2}\mathrm{tr}\sqrt{A_0}.$$

Here we put

$$f := \sum_{j=1}^{N} \sum_{\mu=1}^{d} \frac{\alpha_j}{m_j} A^{-1} q_{j\mu} v_\mu.$$

By the commutation relation on $e^{is\vec{p}}$ and $e^{it\vec{q}}$:

$$e^{is\vec{p}_{rl_n}} e^{it\vec{q}_{r'l'_n}} = e^{its\delta_{rr'}\delta_{l_n l'_n}} e^{it\vec{q}_{r'l'_n}} e^{is\vec{p}_{rl_n}},$$

and the von Neumann uniqueness theorem, we can identify $\vec{p}$ and $\vec{q}$ with the momentum and position operators, respectively,

$$\vec{p}_{t,l_n} \cong -i\frac{\partial}{\partial x_{r,n}}, \quad \vec{q}_{r,l_n} \cong x_{r,n},$$

for $r=1,\ldots,d-1$ and $n=1,\ldots,D$. Hence we identify $H_\epsilon(q,\delta,a,L)$ as a harmonic oscillator in $L^2(\mathbb{R}^{(d-1)D})$. Generally for the harmonic oscillator

$$H_T := \tfrac{1}{2}(\vec{p},\vec{p}) + \tfrac{1}{2}(\vec{q},T\vec{q})$$

with non-negative symmetric matrix T, we have

$$\inf\sigma(H_T) = \operatorname{tr}\sqrt{T}.$$

Then it follows that

$$\begin{aligned} E(q) &= \inf\sigma(H_\epsilon(q,\delta,a,L)) \\ &= \inf\sigma\left(\frac{1}{2}(\vec{p},\vec{p}) + \frac{1}{2}((\vec{q}-\vec{f}),A(\vec{q}-\vec{f}))\right) + \sum_{j=1}^{N}\frac{1}{2m_j}q_j^2 - \frac{1}{2}(\vec{f},A\vec{f}) - \frac{1}{2}\operatorname{tr}\sqrt{A_0} \\ &= \sum_{j=1}^{N}\frac{1}{2m_j}q_j^2 - \frac{1}{2}(f,Af) + \frac{1}{2}\operatorname{tr}(\sqrt{A}-\sqrt{A_0}). \end{aligned}$$

Separately we calculate

(1) $\Sigma_{j=1}^{N}(1/2m_j)\,q_j^2 - 1/2(f,Af)$,
(2) $\frac{1}{2}\operatorname{tr}(\sqrt{A}-\sqrt{A_0})$.

First we calculate (1). We give a remark. Let

$$d_{\mu\nu}(k) := \sum_{r=1}^{d-1} e_\mu^r(k)e_\nu^r(k) = \left(1 - \frac{k}{|k|}\otimes\frac{k}{|k|}\right)_{\mu\nu} = \delta_{\mu\nu} - \frac{k_\mu k_\nu}{|k|^2}.$$

For rotation invariant functions f and g it follows that

$$(d_{\mu\nu}f,g) = \delta_{\mu\nu}K(f,g).$$

We have

$$(f,Af) = \sum_{i,j=1}^{N}\sum_{\mu,\nu=1}^{d}\frac{\alpha_i}{m_i}\frac{\alpha_j}{m_j}q_{i\mu}q_{j\nu}(A^{-1}v_\mu,v_\nu).$$

Note that we assume that $|\alpha_j|^2$ are sufficiently small. Then

$$A^{-1} = \sum_{n=1}^{\infty}(-1)^{n-1}A_0^{-1}(PA_0^{-1})^{n-1}.$$

Hence

$$\begin{aligned} (A^{-1}v_\mu,v_\nu) &= \sum_{n=1}^{\infty}(-1)^{n-1}(A_0^{-1}(PA_0^{-1})^{n-1}v_\mu,v_\nu) \\ &= \sum_{n=1}^{\infty}(-1)^{n-1}\sum_{j_1,\ldots,j_{n-1}=1}^{N}\sum_{\mu_1,\ldots,\mu_{n-1}=1}^{d}\epsilon^{n-1}\frac{\alpha_{j_1}^2}{m_{j_1}}\cdots\frac{\alpha_{j_{n-1}}^2}{m_{j_{n-1}}}(v_\mu A_0^{-1}v_{\mu_1}) \\ &\quad\times(v_{\mu_1},A_0^{-1}v_{\mu_2})(v_{\mu_2},A_0^{-1}v_{\mu_3})\cdots(v_{\mu_{n-2}},A_0^{-1}v_{\mu_{n-1}})(v_{\mu_{n-1}},A_0^{-1}v_\nu) \end{aligned}$$

$$= \delta_{\mu\nu} \sum_{n=1}^{\infty} (-1)^{n-1} \sum_{j_1,\ldots,j_{n-1}=1}^{N} \sum_{\mu_1,\ldots,\mu_{n-1}=1}^{d} \epsilon^{n-1} K^n \frac{\alpha_{j_1}^2}{m_{j_1}} \cdots \frac{\alpha_{j_{n-1}}^2}{m_{j_{n-1}}} \xi^n,$$

where

$$\xi := \sum_{|l| \leqslant 2\pi L} \frac{|\hat{\lambda}(l)|^2}{\omega_\delta(l)}.$$

Then it follows that

$$(A^{-1} v_\mu, v_\nu) = \delta_{\mu\nu} \sum_{n=1}^{\infty} (-1)^{n-1} K\xi \left\{ \epsilon K \xi \sum_{j=1}^{N} \frac{\alpha_j^2}{m_j} \right\}^{n-1}$$

$$= \delta_{\mu\nu} \frac{K\xi}{1 + \epsilon K \xi \Sigma_{j=1}^{N} \frac{\alpha_j^2}{m_j}}.$$

We have

$$(f, Af) = \sum_{i,j=1}^{N} \sum_{\mu,\nu=1}^{d} \delta_{\mu\nu} \frac{\alpha_i}{m_i} \frac{\alpha_j}{m_j} q_{i\nu} q_{j\mu} \frac{K\xi}{1 + \epsilon K \xi \Sigma_{j=1}^{N} \frac{\alpha_j^2}{m_j}} = \frac{K\xi}{1 + \epsilon K \xi \Sigma_{j=1}^{N} \frac{\alpha_j^2}{m_j}} \left| \sum_{j=1}^{N} \frac{\alpha_j}{m_j} q_j \right|^2.$$

Hence we have

$$(1) = \frac{1}{2} \sum_{j=1}^{N} \frac{q_j^2}{m_j} - \frac{1}{2} \frac{K\xi}{1 + \epsilon K \xi \Sigma_{j=1}^{N} \frac{\alpha_j^2}{m_j}} \left| \sum_{j=1}^{N} \frac{\alpha_j}{m_j} q_j \right|^2.$$

Next we calculate (2). Using the formula for non-negative self-adjoint operator B,

$$\sqrt{B} = \frac{1}{\pi} \int_{-\infty}^{\infty} B(s^2 + B)^{-1} \, \mathrm{d}s,$$

we see that

$$(2) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \mathrm{tr}\{A(s^2 + A)^{-1} - A_0(s^2 + A_0)^{-1}\} \mathrm{d}s.$$

Since

$$(s^2 + A)^{-1} = (s^2 + A_0)^{-1} \sum_{n=1}^{\infty} (-1)^{n-1} \{P(s^2 + A_0)^{-1}\}^{n-1},$$

we have

$$A(s^2 + A)^{-1} - A_0(s^2 + A_0)^{-1} = (\mathrm{I}) + (\mathrm{II}).$$

Here we put

$$(\mathrm{I}) := A_0(s^2+A_0)^{-1}\sum_{n=1}^{\infty}(-1)^n\{P(s^2+A_0)^{-1}\}^n, \tag{7.4}$$

$$(\mathrm{II}) := P(s^2+A)^{-1}. \tag{7.5}$$

It follows that

$$\mathrm{tr}(\mathrm{I}) = \sum_{n=1}^{\infty}(-1)^n \sum_{\varphi:\mathrm{CONS}} (\varphi, A_0(s^2+A_0)^{-1}\{P(s^2+A_0)^{-1}\}^n\varphi),$$

where $\Sigma_{\varphi:\mathrm{CONS}}$ means to sum up vectors in a complete orthonormal system. Then

$$= \sum_{n=1}^{\infty}(-1)^n \sum_{\varphi:\mathrm{CONS}} (\varphi, A_0(s^2+A_0)^{-1}\underbrace{P(s^2+A_0)^{-1}P(s^2+A_0)^{-1}\cdots P(s^2+A_0)^{-1}}_{n \text{ times}}\varphi)$$

$$= \sum_{n=1}^{\infty}(-1)^n \sum_{\varphi:\mathrm{CONS}} \sum_{j_1,\ldots,j_n=1}^{N} \sum_{\mu_1,\ldots,\mu_n=1}^{d} \epsilon^n \frac{\alpha_{j_1}^2}{m_{j_1}}\cdots\frac{\alpha_{j_n}^2}{m_{j_n}} (\varphi, A_0(s^2+A_0)^{-1}v_{\mu_1})$$
$$\times (v_{\mu_1}, (s^2+A_0)^{-1}v_{\mu_2})\times\cdots\times(v_{\mu_{n-1}}, (s^2+A_0)^{-1}v_{\mu_n})(v_{\mu_n}, (s^2+A_0)^{-1}\varphi).$$

We take as a CONS

$$\left\{\varphi_1 := \frac{(s^2+A_0)^{-1}v_{\mu_n}}{\|(s^2+A_0)^{-1}v_{\mu_n}\|}, \varphi_2, \varphi_3, \ldots,\right\}.$$

Then

$$\mathrm{tr}(\mathrm{I}) = \sum_{n=1}^{\infty}(-1)^n \sum_{j_1,\ldots,j_n=1}^{N} \sum_{\mu_1,\ldots,\mu_n=1}^{d} \epsilon^n \frac{\alpha_{j_1}^2}{m_{j_1}}\cdots\frac{\alpha_{j_n}^2}{m_{j_n}} (v_{\mu_n}, A_0(s^2+A_0)^{-2}v_{\mu_1})$$
$$\times (v_{\mu_1}, (s^2+A_0)^{-1}v_{\mu_2})\times\cdots\times(v_{\mu_{n-1}}, (s^2+A_0)^{-1}v_{\mu_n})\frac{(v_{\mu_n}, (s^2+A_0)^{-2}v_{\mu_n})}{\|(s^2+A_0)^{-1}v_{\mu_n}\|^2}$$
$$= d\sum_{n=1}^{\infty}(-1)^n\left(\sum_{j=1}^{N}\frac{\alpha_j^2}{m_j}\right)^n \epsilon^n K^n \xi(s)^{n-1}\eta(s),$$

where

$$\xi(s) := \sum_{|l|\leqslant 2\pi L} \frac{\omega_\delta(l)|\hat{\lambda}(l)|^2}{s^2+\omega_\delta(l)^2},$$

and

$$\eta(s) := \sum_{|l|\leqslant 2\pi L} \frac{\omega_\delta(l)^3|\hat{\lambda}(l)|^2}{(s^2+\omega_\delta(l)^2)^2}.$$

Hence

$$\mathrm{tr}(\mathrm{I}) = d\sum_{n=1}^{\infty}(-1)^n\left(\epsilon K\xi(s)\sum_{j=1}^{N}\frac{\alpha_j^2}{m_j}\right)^n \frac{\eta(s)}{\xi(s)}$$

$$= d\frac{-\epsilon K\xi(s)\Sigma_{j=1}^{N}\dfrac{\alpha_j^2}{m_j}}{1+\epsilon K\xi(s)\Sigma_{j=1}^{N}\dfrac{\alpha_j^2}{m_j}}\frac{\eta(s)}{\xi(s)} = d\frac{-\epsilon\rho\,\eta(s)}{1+\epsilon\rho\xi(s)}.$$

Next we see that

$$\begin{aligned}\mathrm{tr}(\mathrm{II}) &= \sum_{\varphi:\mathrm{CONS}}(\varphi,P(s^2+A)^{-1}\varphi) = \sum_{n=1}^{\infty}(-1)^{n-1}\sum_{\varphi:\mathrm{CONS}}(\varphi,P(s^2+A_0)^{-1}(P(s^2+A_0)^{-1})^{n-1}\varphi)\\ &= \sum_{n=1}^{\infty}(-1)^{n-1}\sum_{\varphi:\mathrm{CONS}}\sum_{j_1,\ldots,j_n=1}^{N}\sum_{\mu_1,\ldots,\mu_n=1}^{d}\frac{\alpha_{j_1}^2}{m_{j_1}}\cdots\frac{\alpha_{j_n}^2}{m_{j_n}}\epsilon^n\\ &\quad\times(\varphi,v_{\mu_1})(v_{\mu_1},(s^2+A_0)^{-1}v_{\mu_2})\cdots(v_{\mu_{n-1}},(s^2+A_0)^{-1}v_{\mu_n})(v_{\mu_n},(s^2+A_0)^{-1}\varphi).\end{aligned}$$

Take as a CONS

$$\left\{\varphi_1 := \frac{(s^2+A_0)^{-1}v_{\mu_n}}{\|(s^2+A_0)^{-1}v_{\mu_n}\|},\varphi_2,\varphi_3,\ldots,\right\}.$$

Then we have

$$\begin{aligned}\mathrm{tr}(\mathrm{II}) &= \sum_{n=1}^{\infty}(-1)^{n-1}\sum_{j_1,\ldots,j_n=1}^{N}\sum_{\mu_1,\ldots,\mu_n=1}^{d}\frac{\alpha_{j_1}^2}{m_{j_1}}\cdots\frac{\alpha_{j_n}^2}{m_{j_n}}\epsilon^n\times(v_{\mu_n},(s^2+A_0)^{-1}v_{\mu_1})\\ &\quad\times(v_{\mu_1},(s^2+A_0)^{-1}v_{\mu_2})\times\cdots\times(v_{\mu_{n-1}},(s^2+A_0)^{-1}v_{\mu_n})\frac{(v_{\mu_n},(s^2+A_0)^{-2}v_{\mu_n})}{\|(s^2+A_0)^{-1}v_{\mu_n}\|^2}\\ &= \sum_{n=1}^{\infty}(-1)^{n-1}\sum_{j_1,\ldots,j_n=1}^{N}\sum_{\mu_1,\ldots,\mu_n=1}^{d}\frac{\alpha_{j_1}^2}{m_{j_1}}\cdots\frac{\alpha_{j_n}^2}{m_{j_n}}\epsilon^n K^n\,\mathrm{d}\xi(s)^n\\ &= d\sum_{n=1}^{\infty}(-1)^{n-1}\left(\epsilon K\xi(s)\sum_{j=1}^{N}\frac{\alpha_j^2}{m_j}\right)^n = d\frac{\epsilon\rho\xi(s)}{1+\epsilon\rho\xi(s)}.\end{aligned}$$

Hence

$$\mathrm{tr}((\mathrm{I})+(\mathrm{II})) = \frac{d\epsilon\rho}{1+\epsilon\rho\xi(s)}(\xi(s)-\eta(s)).$$

From

$$\xi(s)-\eta(s) = \sum_{|l|\leqslant 2\pi L}\left\{\frac{|\hat{\lambda}(l)|^2\omega_\delta(l)}{s^2+\omega_\delta(l)^2}-\frac{\omega_\delta(l)^3|\hat{\lambda}(l)|^2}{(s^2+\omega_\delta(l)^2)^2}\right\} = \sum_{|l|\leqslant 2\pi L}\frac{s^2|\hat{\lambda}(l)|^2\omega_\delta(l)}{(s^2+\omega_\delta(l)^2)^2} := \eta'(s),$$

it follows that

$$(2) = \frac{\epsilon}{2\pi}\int_{-\infty}^{\infty}\frac{\epsilon\rho\,\eta'(s)}{1+\epsilon\rho\xi(s)}\mathrm{d}s.$$

As was mentioned in (7.3), as $a\to\infty$ and then $L\to\infty$, $H_\epsilon(q,\delta,a,L)$ uniformly converges to $H_\epsilon^0(q)+\delta N$ in the resolvent sense. Thus as $a\to\infty$ and then $L\to\infty$, it follows that

$$E(q,\delta,a,L)\to\inf\sigma(H_\epsilon(q)+\delta N)\coloneqq E(q,\delta).$$

Since $N\geqslant 0$, we have

$$\liminf_{\delta\to 0} E(q,\delta)\geqslant E(q)$$

and the strong resolvent convergence of $H^0_\epsilon(q)+\delta N$ to $H_\epsilon(q)$ as $\delta\to 0$ implies that

$$E(q)\geqslant\limsup_{\delta\to 0}E(q,\delta).$$

Thus

$$E(q,\delta)\to E(q)$$

as $\delta\to 0$. Thus the lemma follows for sufficiently small $|\alpha_j|$'s. By Proposition 3.2(3), $\inf\sigma(H^0_\epsilon(q))$ can be analytically continued in each α_j's to $\mathcal{O}$, and clearly $E(q)$ also can be done. Hence the lemma follows for all α_j's in $\mathbb{R}$. □

A proof of Lemma 3.3(2): The proof is similar to Lemma 3.3. Define the projection operator

$$P\coloneqq\epsilon\sum_{j=1}^{N}\sum_{\mu=1}^{d}\frac{\alpha_j^2}{m_j}|v^j_\mu\rangle\langle v^j_\mu|,$$

and

$$A\coloneqq A_0+P,$$

where A_0 is defined in (7.2). Here

$$v^j_\mu\coloneqq\begin{pmatrix}\sqrt{\omega_\delta(l_1)}\hat{\lambda}_j(l_1)e^1_\mu(l_1)\\ \vdots\\ \sqrt{\omega_\delta(l_1)}\hat{\lambda}_j(l_1)e^{(d-1)}_\mu(l_1)\\ \vdots\\ \vdots\\ \sqrt{\omega_\delta(l_D)}\hat{\lambda}_j(l_D)e^1_\mu(l_D)\\ \vdots\\ \sqrt{\omega_\delta(l_D)}\hat{\lambda}_j(l_D)e^{(d-1)}_\mu(l_D)\end{pmatrix}\in\mathbb{R}^{(d-1)D}.$$

Let

$$f\coloneqq\sum_{j=1}^{N}\sum_{\mu=1}^{d}\frac{\alpha_j}{m_j}A^{-1}q_{j\mu}v^j_\mu.$$

Similarly to Lemma 3.3 it is enough to calculate

(1) $\Sigma_{j=1}^{N}(1/2)m_jq_j^2-1/2(Af,f)$,
(2) $\frac{1}{2}\mathrm{tr}(\sqrt{A}-\sqrt{A_0})$.

First we calculate (1). We have

$$(A^{-1}v^i_\mu,v^j_\nu)=\delta_{\mu\nu}\delta_{ij}\sum_{n=1}^{\infty}(-1)^{n-1}K^n\epsilon^{n-1}\left(\frac{\alpha_j^2}{m_j}\right)^{n-1}\xi_j^n=\delta_{\mu\nu}\delta_{ij}\frac{K\xi_j}{1+\epsilon K\xi_j\dfrac{\alpha_j^2}{m_j}},$$

where

$$\xi_j := \sum_{|l| \leqslant 2\pi L} \frac{|\hat{\lambda}_j(l)|^2}{\omega_\delta(l)}.$$

Note that, for function g,

$$(\hat{\lambda}_j, g\hat{\lambda}_i) = \delta_{ij}(\hat{\lambda}_j, g\hat{\lambda}_j).$$

Then

$$\begin{aligned}(Af,f) &= \sum_{i,j=1}^{N} \sum_{\mu,\nu=1}^{d} (A^{-1}v_\mu^i, v_\nu^j) \\ &= \sum_{i,j=1}^{N} \sum_{\mu,\nu=1}^{d} \delta_{\mu\nu}\delta_{ij} \frac{\alpha_i}{m_i}\frac{\alpha_j}{m_j} q_{i\nu}q_{j\mu} \frac{K\xi_j}{1+\epsilon K\xi_j \dfrac{\alpha_j^2}{m_j}} \\ &= \sum_{j=1}^{N} \left(\frac{\alpha_j}{m_j}\right)^2 q_j^2 \frac{K\xi_j}{1+\epsilon K\xi_j \dfrac{\alpha_j^2}{m_j}}.\end{aligned}$$

Then

$$\frac{1}{2}\sum_{j=1}^{N} \frac{q_j^2}{m_j} - \frac{1}{2}(Af,f) = \frac{1}{2}\sum_{j=1}^{N} \frac{q_j^2}{m_j}\left(\frac{m_j - (1-\epsilon)K\alpha_j^2\xi_j}{m_j + \epsilon K\alpha_j^2\xi_j}\right).$$

Next we calculate (2). Let (I) and (II) be as in (7.4) and (7.5), respectively. We define

$$\xi_j(s) := \sum_{|l| \leqslant 2\pi L} \frac{\omega_\delta(l)|\hat{\lambda}_j(l)|^2}{s^2 + \omega_\delta(l)^2},$$

$$\eta_j(s) := \sum_{|l| \leqslant 2\pi L} \frac{\omega_\delta(l)^3|\hat{\lambda}_j(l)|^2}{(s^2 + \omega_\delta(l)^2)^2},$$

and

$$\eta_j'(s) := \sum_{|l| \leqslant 2\pi L} \frac{s^2|\hat{\lambda}_j(l)|^2\omega_\delta(l)}{(s^2 + \omega_\delta(l)^2)^2}.$$

We have

$$\begin{aligned}\mathrm{tr(I)} &= d\sum_{j=1}^{N} \sum_{n=1}^{\infty} (-1)^n \left(\frac{\alpha_j^2}{m_j}\right)^n \epsilon^n K^n \xi_j(s)^{n-1}\eta_j(s) \\ &= -d\sum_{j=1}^{N} \eta_j(s)\epsilon\frac{\alpha_j^2}{m_j}K\frac{1}{1+\epsilon\xi_j(s)K\dfrac{\alpha_j^2}{m_j}} \\ &= -d\sum_{j=1}^{N} \frac{\epsilon\rho_j\eta_j(s)}{1+\epsilon\rho_j\xi_j(s)}.\end{aligned}$$

Moreover

$$\mathrm{tr}(\mathrm{II})=\sum_{j=1}^{N}\sum_{n=1}^{\infty}(-1)^{n-1}\frac{\alpha_j^2}{m_j}\epsilon^n K^n \xi_j(s)^n = d\sum_{j=1}^{N}\frac{\epsilon\rho_j\xi_j(s)}{1+\epsilon\rho_j\xi_j(s)}.$$

Hence

$$(\mathrm{I})+(\mathrm{II})=d\sum_{j=1}^{N}\frac{\epsilon\rho_j}{1+\epsilon\rho_j\xi_j(s)}(\xi_j(s)-\eta_j(s))=d\sum_{j=1}^{N}\frac{\epsilon\rho_j}{1+\epsilon\rho_j\xi_j(s)}\eta_j'(s).$$

Then

$$\frac{1}{2}\mathrm{tr}(\sqrt{A}-\sqrt{A_0})=\frac{1}{2}\mathrm{tr}((\mathrm{I})+(\mathrm{II}))=\sum_{j=1}^{N}\frac{d}{2\pi}\int_{-\infty}^{\infty}\frac{\epsilon\rho_j\eta_j'(s)}{1+\epsilon\rho_j\xi_j(s)}\mathrm{d}s.$$

The same limiting argument on a, L, δ as in Lemma 3.3 leads to the desired results. □

(Received 27 July 2001; accepted for publication 11 December 2001)

The local Gauss law of quantum chromodynamics (QCD) on a finite lattice is investigated. It is shown that it implies a gauge invariant, additive law giving rise to a gauge invariant $\mathbb{Z}_3$-valued global charge in QCD. The total charge contained in a region of the lattice is equal to the flux through its boundary of a certain $\mathbb{Z}_3$-valued, additive quantity. Implications for continuum QCD are discussed. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1447310]

I. INTRODUCTION

Quantum chromodynamics (QCD) is one of the basic building blocks of the standard model for describing elementary particle interactions. During the last decades QCD was quite successful, e.g., in describing deep inelastic scattering processes within the framework of perturbation theory on the one hand and ''measuring'' certain types of observables using (nonperturbative) lattice approximation techniques on the other hand. Nonetheless, we are still facing the basic challenge, which consists in constructing an effective microscopic theory of interacting hadrons out of this gauge theory. For this purpose, nonperturbative methods for describing the low energy regime should be developed. In particular, the observable algebra and the superselection structure of this theory should be investigated. The present paper is a step in this direction.

We stress that standard methods from algebraic quantum field theory for models which do not contain massless particles, see Ref. 1, do not apply here. Some progress toward an implementation of similar ideas for theories with massless particles has been made; for the case of quantum electrodynamics (QED) see Refs. 2 and 3 and further references therein. In particular, Buchholz developed the concept of so-called charge classes and found a criterion for distinguishing between the electric charge (carried by massive particles) and additional superselection sectors corresponding to inequivalent asymptotic infrared clouds of photons. For some attempts to deal with the non-Abelian case we refer to papers by Strocchi and Wightman, see Refs. 4 and 5.

In QED, the notion of *global* (electric) charge is easy to understand. This is due to the fact that in this theory we have a *local* Gauss law, which is built from gauge invariant operators and which is linear. Thus, one can ''sum up'' the local Gauss laws over all points of a given (spacelike) hyperplane in space–time yielding the following gauge invariant conservation law: The global electric charge is equal to the electric flux through a two-sphere at infinity. On the contrary, in QCD the local Gauss law is neither built from gauge invariant operators nor is it linear. The main point of the present paper is to show that it is possible to extract from the local Gauss equation of QCD a gauge invariant, additive law for operators with eigenvalues in $\mathbb{Z}_3$ [which is canonically identified with the dual of the center of SU(3)]. This implies—as in QED—a gauge invariant conservation law: The global $\mathbb{Z}_3$-valued charge is equal to a $\mathbb{Z}_3$-valued gauge invariant quantity obtained from the color electric flux at infinity.

a)Electronic mail: kijowski@cft.edu.pl

This color charge, often called *triality*, was invented a long time ago. On the level of lattice gauge theories, this notion is already implicitly contained in a paper by Kogut and Susskind, see Ref. 6. In particular, Mack[7] used it to propose a certain (heuristic) scheme of color screening and quark confinement, based upon a dynamical Higgs mechanism with Higgs fields built from gluons. For similar ideas we also refer to papers by 'tHooft, see Ref. 8, and references therein. This concept was also used in a paper by Borgs and Seiler,[9] where the confinement problem for Yang–Mills theories with static quark sources at nonzero temperature was discussed. In this context, also the Gauss law for color charge was analyzed. Finally, we mention a paper by Fredenhagen and Marcu, see Ref. 10, dealing with a $\mathbb{Z}_2$-gauge theory (with $\mathbb{Z}_2$-valued matter fields) on the lattice. These authors were able to construct the ground state and charged states of this model. For some regions in the space of coupling constants, the thermodynamic limit of charged states was controlled.

In this paper, we consider QCD (with fermions) in the Hamiltonian approach. To be rigorous we restrict ourselves to its approximation on a finite (regular cubic) lattice. For basic notions concerning lattice gauge theories (including fermions) we refer to Ref. 11. The Hamiltonian formulation of lattice gauge theories was first proposed in Refs. 12 and 6. The paper is organized as follows: In Sec. II, we define the algebra of field operators. Since, to our knowledge, this has never been published, we discuss it in some detail. Next, by imposing the local Gauss law and gauge invariance, we obtain the observable algebra $\mathcal{O}(\Lambda)$ for lattice QCD, see Sec. III. In Sec. IV we analyze the local Gauss law and invent the gauge invariant notion of the local charge densitiy. We prove that there exists an operator function, built from the Casimir invariants of the theory under consideration, which—applied to the Gauss law—yields the additive, gauge invariant Gauss law for color charge. Using this notion, in Sec. V the global charge is defined and the flux law for QCD is discussed. Finally, we discuss some perspectives of this approach, including heuristic remarks concerning the continuum case.

For an analogous investigation of QED on the lattice, including its charge superselection structure, we refer to Refs. 13 and 14.

II. THE FIELD ALGEBRA FOR LATTICE QCD

We consider QCD in the Hamiltonian framework on a finite, regular three-dimensional lattice Λ. We denote the set of oriented, i-dimensional elements of Λ by Λ^i, $i=0,1,2,3$. Such elements are (in increasing order of i) called sites, links, plaquettes, and cubes. The set of nonoriented i-dimensional elements will be denoted by $|\Lambda|^i$. If, for instance, $(x,y)\in\Lambda^1$ is an oriented link, then by $|(x,y)|\in|\Lambda|^1$ we mean the corresponding nonoriented link. Instead of using a concrete Hilbert space representation (e.g., the Schrödinger representation), we give an abstract definition of the field algebra in terms of generators and defining relations.

The basic fields of lattice QCD are quarks living at lattice sites and gluons living on links. The field algebra is thus, by definition, the tensor product of local fermionic and bosonic algebras:

$$\mathcal{F}(\Lambda) := \bigotimes_{x\in|\Lambda|^0} \mathcal{F}_x \bigotimes_{|(x,y)|\in|\Lambda|^1} \mathcal{F}_{|(x,y)|}\,. \tag{2.1}$$

We impose locality of the lattice quantum fields by postulating that the local algebras corresponding to different elements of Λ commute with each other.

The fermionic field algebra $\mathcal{F}_x$ associated with a lattice site x is generated from the algebra $\mathcal{L}_x$ of canonical anticommutation relations of quarks. In terms of coordinates, the quark field is given by

$$|\Lambda|^0 \ni x \to (\psi^{aA}(x)) \in \mathcal{L}_x\,, \tag{2.2}$$

where a stands for bispinorial and (possibly) flavor degrees of freedom and $A=1,2,3$ is the color index corresponding to the fundamental representation of SU(3). The conjugate quark field is

denoted by $\psi^{*a}{}_A(x)$, where we raise and lower indices by the help of the canonical Hermitian metric tensor g_{AB} in $\mathbb{C}^3$. Finally, the (nontrivial) canonical anticommutation relations for elements of $\mathcal{L}_x$ read

$$[\psi^{*a}{}_A(x), \psi^{bB}(x)]_+ = \delta^B{}_A \delta^{ab}. \tag{2.3}$$

Passing to self-adjoint generators (real and imaginary parts of ψ), we observe that $\mathcal{F}_x$ is a Clifford algebra.

The bosonic field algebra $\mathcal{F}_{|(x,y)|}$ associated with the nonoriented link $|(x,y)|$ will be constructed in terms of its equivalent copies $\mathcal{F}_{(x,y)}$ and $\mathcal{F}_{(y,x)}$, corresponding to the two orientations of the link (x,y). We will see that there is a natural identification of these two algebras, induced from the vector character of both the gluonic potential A and the color electric field E of the underlying continuum theory: under the change of orientation of the kth axis both A_k and E^k change their signs.

The bosonic field algebra $\mathcal{F}_{(x,y)}$ is, by definition, the tensor product

$$\mathcal{F}_{(x,y)} := \tilde{\mathcal{E}}_{(x,y)} \otimes \mathcal{A}_{(x,y)}, \tag{2.4}$$

where $\tilde{\mathcal{E}}_{(x,y)}$ is the enveloping algebra of the (real) Lie algebra $\mathcal{E}_{(x,y)} \cong \mathrm{su}(3)$ and $\mathcal{A}_{(x,y)} \cong C^\infty(\mathrm{SU}(3))$ is the commutative $*$-algebra of smooth functions on the Lie group SU(3). We note that the above-mentioned tensor product is naturally endowed with the structure of a crossed product of Hopf algebras, given by the action of generators of $\tilde{\mathcal{E}}_{(x,y)}$ on functions, see Ref. 15. We identify the tensor product of elements of $\tilde{\mathcal{E}}_{(x,y)}$ and functions with their product as differential operators on SU(3). This way, $\mathcal{F}_{(x,y)}$ gets identified with the algebra of differential operators on the group manifold. For our purposes, we endow $\mathcal{F}_{(x,y)}$ with a Lie algebra structure. Thus, we have to define the commutator between a generator $e \in \mathcal{E}_{(x,y)}$ of $\tilde{\mathcal{E}}_{(x,y)}$ and a function $f \in \mathcal{A}_{(x,y)}$,

$$[e,f] := e^R(f), \tag{2.5}$$

where $e^R(f)$ denotes the derivative of f with respect to the right-invariant vector field e^R generated by e,

$$e^R(f)(g) := \left.\frac{\mathrm{d}}{\mathrm{d}s}\right|_{s=0} f(\exp(se)\cdot g), \quad g \in \mathrm{SU}(3). \tag{2.6}$$

Now we give an explicit description of $\mathcal{F}_{(x,y)}$ in terms of generators and defining relations. The algebra $\mathcal{A}_{(x,y)}$ is generated by matrix elements of the gluonic gauge potential on the link (x,y),

$$\Lambda^1 \ni (x,y) \to U^A{}_B(x,y) \in \mathcal{A}_{(x,y)}, \tag{2.7}$$

where $A,B = 1,2,3$ are color indices. Being functions on SU(3), these generators fulfill the following relations:

$$(U^A{}_B(x,y))^* U_A{}^C(x,y) = \delta^C{}_B \mathbf{1}, \tag{2.8}$$

$$\epsilon_{ABC} U^A{}_D(x,y) U^B{}_E(x,y) U^C{}_F(x,y) = \epsilon_{DEF} \mathbf{1}. \tag{2.9}$$

The algebra $\tilde{\mathcal{E}}_{(x,y)}$ is generated by color electric fields, spanning the Lie algebra $\mathcal{E}_{(x,y)}$. Choosing a basis $\{t_i\}$, $i = 1,\ldots,8$, of su(3) we denote by $\{E_i(x,y)\}$ the corresponding basis of $\mathcal{E}_{(x,y)}$,

$$\Lambda^1 \ni (x,y) \to E_i(x,y) := t_i \in \mathcal{E}_{(x,y)}. \tag{2.10}$$

These generators are self-adjoint (real), $E_i^* = E_i$. In the sequel we take as the basis the Hermitean, traceless Gell–Mann matrices ${t_i}^A{}_B$, normalized as follows:

$$\sum_i {t_i}^A{}_B {t_i}^C{}_D = \delta^A_D \delta^C_B - \frac{1}{3}\delta^A_B \delta^C_D, \tag{2.11}$$

or, equivalently, ${t_i}^A{}_B\, {t_j}^B{}_A = \delta_{ij}$. We will also use the following traceless matrix built from these fields:

$$E^A{}_B(x,y) = \sum_i E_i(x,y) {t_i}^A{}_B. \tag{2.12}$$

Since the coefficients ${t_i}^A{}_B$ are complex, these fields are no longer self-adjoint:

$$(E^A{}_B(x,y))^* = E_B{}^A(x,y). \tag{2.13}$$

The commutation relations between elements of su(3) translated to the language of these fields read

$$[E^A{}_B(x,y), E^C{}_D(x,y)] = \delta^C{}_B E^A{}_D(x,y) - \delta^A{}_D E^C{}_B(x,y), \tag{2.14}$$

whereas the commutation relations (2.5) between Lie algebra elements and functions, rewritten in terms of generators, take the following form:

$$[E^A{}_B(x,y), U^C{}_D(x,y)] = \delta^C{}_B U^A{}_D(x,y) - \tfrac{1}{3}\delta^A{}_B U^C{}_D(x,y). \tag{2.15}$$

Observe that, for every link (x,y), we have a model of quantum mechanics with configuration space being the group manifold SU(3). The matrix elements of the gluonic potential play the role of functions of position variables, whereas the color electric fields play the role of (noncommuting) canonically conjugate momenta. Formula (2.15) is the analog of the canonical commutation relation $[p,q] = -i$.

Now, we describe the transformation law of these objects under the change of the link orientation. The vector character of the continuum gauge potential implies that the (classical) SU(3)-valued parallel transporter $g(x,y)$ on (x,y) transforms to $g^{-1}(x,y)$ under the change of orientation. Thus, the change of orientation on (x,y) induces the transformation

$$\mathrm{SU}(3) \ni g \to i(g) = g^{-1} \in \mathrm{SU}(3) \tag{2.16}$$

on configuration space. This transformation lifts naturally to a mapping

$$\mathcal{I}_{(x,y)} : \mathcal{F}_{(x,y)} \to \mathcal{F}_{(y,x)} \tag{2.17}$$

of field algebras, defined by

$$\mathcal{I}_{(x,y)}(e,f) := (-i_*(e), i^*(f)). \tag{2.18}$$

We have $i^*(f)(g) \equiv \check{f}(g) := f(g^{-1})$ and $-i_*(e) = e^L$, where e^L is the left invariant vector field on SU(3) generated by $-e$. It acts on functions in the following way:

$$e^L(f)(g) = \left.\frac{\mathrm{d}}{\mathrm{d}s}\right|_{s=0} f(g \cdot \exp(-se)). \tag{2.19}$$

Observe that e^L is not an element of $\mathcal{E}_{(y,x)}$, but it can be expanded with respect to right-invariant vector fields with coefficients being functions on the group. Actually, the following formula is easily proved:

$$e^L = -\sum_{i=1}^{8} \mathrm{Tr}(geg^{-1}t_i)t_i^R, \tag{2.20}$$

where t_i is any orthonormal basis of su(3).

Lemma 1: The mapping $\mathcal{I}_{(x,y)}$ is an isomorphism of algebras.

Proof: We observe that $\mathcal{I}_{(x,y)}$ is obviously a bijective mapping between generators. It extends to an isomorphism of field algebras if we prove that it preserves the commutator. This is obvious for elements, which either belong both to $\mathcal{A}_{(x,y)}$ or to $\mathcal{E}_{(x,y)}$. Thus, it is sufficient to consider the commutator of a Lie algebra element e with a function f. Using the identity

$$e^R(f)(g) = \frac{\mathrm{d}}{\mathrm{d}s}\bigg|_{s=0} f(\exp(se)\cdot g) = \frac{\mathrm{d}}{\mathrm{d}s}\bigg|_{s=0} \check{f}(g^{-1}\cdot\exp(-se)) = e^L(\check{f})(g^{-1}), \tag{2.21}$$

and applying $\mathcal{I}_{(x,y)}$ to the functions on both sides, we obtain due to (2.5) and (2.18)

$$\mathcal{I}_{(x,y)}([e,f]) = \mathcal{I}_{(x,y)}(e^R(f)) = e^L(\check{f}) = [\mathcal{I}_{(x,y)}(e), \mathcal{I}_{(x,y)}(f)]. \tag{2.22}$$

This ends the proof. □

Field configurations, which are related under $\mathcal{I}_{(x,y)}$ will be identified as different representations of the same object. Thus, the bosonic field algebra $\mathcal{F}_{|(x,y)|}$, associated with the nonoriented link $|(x,y)|$, is defined as the subalgebra of $\mathcal{F}_{(x,y)}\times\mathcal{F}_{(y,x)}$, obtained by this identification:

$$\mathcal{F}_{|(x,y)|} := \{(l_{(x,y)}, k_{(y,x)}) \in \mathcal{F}_{(x,y)}\times\mathcal{F}_{(y,x)} : k_{(y,x)} = \mathcal{I}_{(x,y)}(l_{(x,y)})\}. \tag{2.23}$$

Projection onto the first (respectively, second) component gives us an isomorphism of $\mathcal{F}_{|(x,y)|}$ with $\mathcal{F}_{(x,y)}$ (respectively, $\mathcal{F}_{(y,x)}$).

The above-mentioned transformation law yields relations between generators of the two algebras. For functions on SU(3), formula (2.8) enables us to rewrite (2.18) as follows:

$$U^A{}_B(y,x) = (U_B{}^A(x,y))^*. \tag{2.24}$$

For Lie algebra elements, formula (2.20) applied to $e = t_i$ reads

$$E_j(y,x) = -\sum_{i=1}^{8} U^A{}_B(x,y)t_j{}^B{}_C U^C{}_D(y,x)t_i{}^D{}_A E_i(x,y), \tag{2.25}$$

or, in terms of generators $E^A{}_B(x,y)$,

$$E^A{}_B(y,x) = -U^A{}_D(y,x)U^C{}_B(x,y)E^D{}_C(x,y). \tag{2.26}$$

To summarize, the field algebra $\mathcal{F}(\Lambda)$ is the $*$-algebra, generated by elements

$$\{\psi^{aA}(x), U^A{}_B(x,y), E^A{}_B(x,y)\},$$

fulfilling relations (2.8), (2.9), (2.13), (2.24), and (2.26), together with canonical (anti) commutation relations

$$[\psi^{*a}{}_A(x), \psi^{bB}(y)]_+ = \delta(x-y)\,\delta^B{}_A\,\delta^{ab},$$

$$[E^A{}_B(x,y), E^C{}_D(u,z)] = \delta(x-u)\,\delta(y-z)(\delta^C{}_B E^A{}_D(x,y) - \delta^A{}_D E^C{}_B(x,y)),$$

$$[E^A{}_B(x,y), U^C{}_D(u,z)] = +\delta(x-u)\,\delta(y-z)(\delta^C{}_B U^A{}_D(x,y) - \tfrac{1}{3}\delta^A{}_B U^C{}_D(x,y)) - \delta(x-z)\,\delta(y-u)$$
$$\times(\delta^A{}_D U^C{}_B(y,x) - \tfrac{1}{3}\delta^A{}_B U^C{}_D(y,x)).$$

III. THE OBSERVABLE ALGEBRA

The observable algebra $\mathcal{O}(\Lambda)$ is defined by imposing the local Gauss law and gauge invariance.

The group of local gauge transformations acts on $\mathcal{F}(\Lambda)$ by automorphisms $x \to g^A{}_B(x)$ as follows:

$$\psi^{aA}(x) \to g^A{}_B(x)\psi^{aB}(x), \tag{3.1}$$

$$U^A{}_B(x,y) \to g^A{}_C(x)U^C{}_D(x,y)(g^{-1})^D{}_B(y), \tag{3.2}$$

$$E^A{}_B(x,y) \to g^A{}_C(x)E^C{}_D(x,y)(g^{-1})^D{}_B(x). \tag{3.3}$$

It is easy to check that these transformations are generated by

$$\mathcal{G}^A{}_B(x) := \rho^A{}_B(x) - \sum_y E^A{}_B(x,y), \tag{3.4}$$

where

$$\rho^A{}_B(x) = \sum_a \left(\psi^{*aA}(x)\psi^a{}_B(x) - \frac{1}{3}\delta^A_B \psi^{*aC}(x)\psi^a{}_C(x) \right) \tag{3.5}$$

is the local matter charge density. Observe that $\rho^A{}_A(x) = 0$.

To implement gauge invariance we have to take those elements of $\mathcal{F}(\Lambda)$, which commute with all generators $\mathcal{G}^A{}_B(x)$. Thus, the subalgebra of gauge invariant fields is, by definition, the commutant $\mathcal{A}(\mathcal{G})'$ of the algebra $\mathcal{A}(\mathcal{G})$, generated by the set $\{\mathcal{G}^A{}_B(x)\}$.

The local Gauss law at $x \in \Lambda^0$ has the form

$$\sum_y E^A{}_B(x,y) = \rho^A{}_B(x), \tag{3.6}$$

with the sum taken over all points y adjacent to x. Imposing it on the subalgebra $\mathcal{A}(\mathcal{G})'$ of gauge invariant fields means factorizing the latter with respect to $\mathcal{I}(\Lambda) \cap \mathcal{A}(\mathcal{G})'$, where $\mathcal{I}(\Lambda)$ is the ideal generated by (3.6). Thus, the observable algebra is defined as follows:

$$\mathcal{O}(\Lambda) := \mathcal{A}(\mathcal{G})'/\{\mathcal{I}(\Lambda) \cap \mathcal{A}(\mathcal{G})'\}. \tag{3.7}$$

Obviously, every element of $\mathcal{O}(\Lambda)$ is represented by a gauge invariant element of $\mathcal{F}(\Lambda)$ and $\mathcal{O}(\Lambda)$ can be viewed as a $*$-subalgebra of $\mathcal{F}(\Lambda)$ generated by gauge invariant bosonic combinations of U and E and by gauge invariant combinations of ψ and ψ^* of mesonic and baryonic type, with the Gauss law inducing some identities between those generators.

It will be shown in Sec. IV that there is a (gauge invariant), *additive* law, obtained by combining these two equations, which characterizes the local color charge density carried by the lattice quantum fields. Additivity will allow us to obtain the global color charge by adding up the local Gauss laws. In a subsequent paper we will show that the irreducible representations of $\mathcal{O}(\Lambda)$ are labeled by this global charge. This way, we get the physical Hilbert space $\mathcal{H}^{\text{phys}}$ as a direct sum of color charge superselection sectors. The similar problem for QED on the lattice was solved in Ref. 13.

IV. THE LOCAL CHARGE DENSITY

In this section we are going to analyze the local Gauss law (3.6). Suppose, for that purpose, that we are given a collection of operators $F^A{}_B$ in a Hilbert space $\mathcal{H}$, fulfilling $F^A{}_A = 0$ and $(F^A{}_B)^* = F_B{}^A$, realizing the canonical commutation relations for the Lie algebra su(3):

$$[F^A{}_B, F^C{}_D] = \delta^C{}_B F^A{}_D - \delta^A{}_D F^C{}_B . \tag{4.1}$$

The field algebra $\mathcal{F}(\Lambda)$ provides us with two basic examples of this type: the electric field $E^A{}_B(x,y)$ on each lattice link, see (2.14), and the charge operator $\rho^A{}_B(x)$ at each lattice site, given by formula (3.5). Indeed, due to canonical anticommutation relation (2.3), the latter fulfills (4.1). Thus, the operators occurring on both sides of the local Gauss law fulfill (4.1).

Throughout this paper, we assume integrability of the Lie algebra representations under consideration. This means that for each F there exists a unitary representation of the group SU(3),

$$\mathrm{SU}(3) \ni g \to \overline{F}(g) \in B(\mathcal{H}), \tag{4.2}$$

associated with F.

It is easy to check that if F and G are two commuting representations of su(3) then so is $F+G$. Indeed, if $\overline{F}(g)$ and $\overline{G}(g)$ are representations of SU(3) corresponding to F and G, then $F+G$ may be obtained by differentiating the representation $\mathrm{SU}(3) \ni g \to \overline{F}(g)\overline{G}(g) \in B(\mathcal{H})$, where $B(\mathcal{H})$ denotes the C^*-algebra of bounded operators on $\mathcal{H}$. Moreover, $-F^*$ is also a representation of su(3), corresponding to the following representation of SU(3): $\mathrm{SU}(3) \ni g \to (\overline{F}(g^{-1}))^* \in B(\mathcal{H})$.

Such a collection of operators is an *operator domain* in the sense of Woronowicz (see Ref. 16). We are going to construct an operator function on this domain, i.e., a mapping $F \to \varphi(F)$ which satisfies $\varphi(UFU^{-1}) = U\varphi(F)U^{-1}$ for an arbitrary isometry U. This function will be built from the two gauge-invariant, self-adjoint and commuting (Casimir) operators K_2 and K_3 of F:

$$K_2 = F^A{}_B F^B{}_A , \tag{4.3}$$

$$K_3 = \tfrac{1}{2}(F^A{}_B F^B{}_C F^C{}_A + F^A{}_B F^C{}_A F^B{}_C). \tag{4.4}$$

The Hilbert space $\mathcal{H}$ splits into the direct sum of subspaces $\mathcal{H}_\alpha$ on which F acts irreducibly. Each of these subspaces is a common eigenspace of K_2 and K_3. Denoting the highest weight characterizing a given irreducible representation by (m,n), with m and n being non-negative integers, the eigenvalues k_2 and k_3 of K_2 and K_3 are given by

$$k_2 = \tfrac{2}{3}(m^2 + mn + n^2 + 3m + 3n), \tag{4.5}$$

$$k_3 = \tfrac{1}{9}(m-n)(3+2m+n)(3+m+2n). \tag{4.6}$$

It is easy to check that the above-given formulas may be uniquely solved with respect to m and n yielding

$$\begin{aligned} m &= M(k_2,k_3) \\ &:= \sqrt{\frac{2}{3}(k_2+2)}\left(\cos\left(\frac{1}{3}\arccos\frac{\sqrt{6}k_3}{\sqrt{(k_2+2)^3}} + \frac{2}{3}\pi\right)\right. \\ &\quad \left. + 2\cos\left(\frac{1}{3}\arccos\frac{\sqrt{6}k_3}{\sqrt{(k_2+2)^3}}\right)\right) - 1, \end{aligned} \tag{4.7}$$

$$
\begin{aligned}
n &= N(k_2,k_3) \\
&:= -\sqrt{\frac{2}{3}(k_2+2)}\left(2\cos\left(\frac{1}{3}\arccos\frac{\sqrt{6}k_3}{\sqrt{(k_2+2)^3}}+\frac{2}{3}\pi\right)\right. \\
&\quad \left.+\cos\left(\frac{1}{3}\arccos\frac{\sqrt{6}k_3}{\sqrt{(k_2+2)^3}}\right)\right)-1. \qquad (4.8)
\end{aligned}
$$

Using these functions we may define a function with values in $\mathbb{Z}_3$, which will be identified with the dual to the center $\mathcal{C}$ of the gauge group SU(3):

$$f(k_2,k_3) := (M(k_2,k_3)-N(k_2,k_3)) \mod 3. \qquad (4.9)$$

For our purposes it is convenient to use the parametrization $\mathbb{Z}_3=(-1,0,1)$. Obviously, we have

$$f(k_2,-k_3) = -f(k_2,k_3). \qquad (4.10)$$

Since K_2 and K_3 are commuting and self-adjoint, there exists an operator-valued function:

$$\varphi(F) = f(K_2(F),K_3(F)). \qquad (4.11)$$

This means that $\varphi(F)$ may take eigenvalues $-1,0,1$ and that every irreducible subspace $\mathcal{H}_\alpha$ is an eigenspace of $\varphi(F)$ with eigenvalue $m-n \mod 3$.

Theorem 1: *The operator function φ has the following properties:*

$$\varphi(-F^*) = -\varphi(F), \qquad (4.12)$$

$$\varphi(F+G) = \varphi(F)+\varphi(G), \qquad (4.13)$$

for F and G commuting.

Proof: To show property (4.12) observe that $K_2(-F^*)=K_2(F)$, whereas $K_3(-F^*) = -K_3(F)$. Consequently, due to (4.5) and (4.6), we have $M(k_2,-k_3)=N(k_2,k_3)$ and $N(k_2,-k_3)=M(k_2,k_3)$ which implies (4.12). It remains to prove property (4.13). Let there be given two commuting representations, F and G, of su(3) in $\mathcal{H}$. Denote the irreducible components of F by $\{\mathcal{H}^F_\alpha\}$ and of G by $\{\mathcal{H}^G_\beta\}$. The irreducible spaces may be chosen in such a way that $\mathcal{H}$ decomposes as follows:

$$\mathcal{H} = \bigoplus_{\alpha,\beta} \mathcal{H}^F_\alpha \cap \mathcal{H}^G_\beta. \qquad (4.14)$$

Take $0 \neq x \in \mathcal{H}^F_\alpha \cap \mathcal{H}^G_\beta$ and consider the space $\mathcal{H}^{F+G}_x \subset \mathcal{H}$ generated by vectors $\{\overline{F}(g)\overline{G}(g)x\}$, $g \in \mathrm{SU}(3)$, where $\overline{F}$ and $\overline{G}$ are the corresponding (''integrated'') representations of SU(3). By construction, $\mathcal{H}^{F+G}_x$ carries an irreducible representation of $\overline{FG}$. There exists a canonical embedding

$$\mathcal{H}^{F+G}_x \ni y \to T(y) \in \mathcal{H}^F_\alpha \otimes \mathcal{H}^G_\beta, \qquad (4.15)$$

given by

$$T(\overline{F}(g)\overline{G}(g)x) := \overline{F}(g)x \otimes \overline{G}(g)x, \qquad (4.16)$$

intertwining the representation $\overline{FG}$ with $\overline{F}\otimes\overline{G}$. This means that $\overline{FG}$, acting on $\mathcal{H}^{F+G}_x$, is equivalent to one of the irreducible components of $\overline{F}\otimes\overline{G}$. Passing again to representations of the Lie

algebra su(3), we conclude that $F+G$, acting on $\mathcal{H}_x^{F+G}$, is equivalent to one of the irreducible components of $F\otimes\mathbf{1}+\mathbf{1}\otimes G$, acting on $\mathcal{H}_\alpha^F\otimes\mathcal{H}_\beta^G$. Now, property (4.13) follows from the following

Lemma 2: Let there be given two irreducible representations (m,n) *and* (m',n') *of* $su(3)$, *together with the decomposition of their tensor product into irreducible components,*

$$(m,n)\otimes(m',n')=(m_1,n_1)\oplus\cdots\oplus(m_p,n_p). \tag{4.17}$$

Then we have

$$(m-n)\mod 3+(m'-n')\mod 3=(m_i-n_i)\mod 3, \tag{4.18}$$

for every $i=1,\ldots,p$.

Proof: We use the classification of irreducible representations in terms of Young-tableaux. For su(3), the following two equations hold:

(1) The number of boxes constituting the Young-tableau of (m_i,n_i) equals the sum of boxes of the tableaux corresponding to (m,n) and (m',n') minus $3p$, where p is a non-negative integer.
(2) The number of boxes of an arbitrary irreducible representation of su(3) is equal to $m+2n\equiv m-n+3n$.

Taking the first equation modulo three and using the second equation yields the thesis. This ends the proof of the Lemma and of the Theorem. □

Applying the operator function φ to the local Gauss law (3.6) and using additivity (4.13) of φ we obtain

$$\sum_y \varphi(E(x,y))=\varphi(\rho(x)). \tag{4.19}$$

This is a gauge invariant equation for operators with eigenvalues in $\mathbb{Z}_3$, valid at every lattice site x. The quantity on the right-hand side is the (gauge invariant) local color charge density carried by the quark field.

We complete this section by giving another definition[17] of the function φ. Consider the center $\mathcal{C}=\{\rho\cdot\mathbf{1}_3;\rho^3=1,\rho\in\mathbb{C}\}$ of SU(3), where $\mathbf{1}_3$ is the unit matrix. If $\overline{F}$ is a representation of SU(3), then the center $\mathcal{C}$ acts as a multiple of the identity on each irreducible subspace $\mathcal{H}_\alpha$: $\mathcal{C}\ni c\to\overline{F}(c)|_{\mathcal{H}_\alpha}=f(c)\cdot\mathbf{1}_{\mathcal{H}_\alpha}$. Obviously, f is a character and, therefore, $(f(c))^3=1$. The formula $f(\rho\cdot\mathbf{1}_3)=\rho^k$, $k=-1,0,1$, gives an identification of the group of characters on $\mathcal{C}$ with $\mathbb{Z}_3$. Hence, there exists an operator function φ, whose values on every $\mathcal{H}_\alpha$ belong to $\mathbb{Z}_3$, defined by

$$f(\rho\cdot\mathbf{1}_3)=:\rho^{\varphi(F)}|_{\mathcal{H}_\alpha}. \tag{4.20}$$

To prove that this definition coincides with the previous one we use the equivalence of the irreducible representation (n,m) of SU(3) with the tensor representation in the space $\mathbb{T}_n^m(\mathbb{C}^3)$ of m-contravariant, n-covariant, completely symmetric and traceless tensors over $\mathbb{C}^3$. The center acts here as a multiple of the unit matrix and it is obvious that

$$f(\rho\cdot\mathbf{1}_3)=\rho^{m-n}. \tag{4.21}$$

The advantage of this formulation is that the above-mentioned properties of φ follow directly from the group properties of the characters. On the other hand, expression (4.11) for φ in terms of the fields F is explicit and gives deeper insight into the relation between the global charge and the invariants (Casimirs) of the theory.

V. THE GLOBAL CHARGE AND THE FLUX LAW

Using the commutation relation between E and U, transformation law (2.26) for $E(x,y)$ may be rewritten in three equivalent ways:

$$E^A{}_B(y,x) = U^A{}_D(y,x)E^D{}_C(x,y)U^C{}_B(x,y) + \tfrac{8}{3}\delta^A_B \tag{5.1}$$

$$= -U^C{}_B(x,y)E^D{}_C(x,y)U^A{}_D(y,x) - \tfrac{8}{3}\delta^A_B \tag{5.2}$$

$$= -E^D{}_C(x,y)U^A{}_D(y,x)U^C{}_B(x,y). \tag{5.3}$$

These equations imply that

$$K_2(E(x,y)) = K_2(E(y,x)), \quad K_3(E(x,y)) = -K_3(E(y,x)). \tag{5.4}$$

Hence, due to (4.10), we have

$$\varphi(E(x,y)) + \varphi(E(y,x)) = 0, \tag{5.5}$$

for every lattice bond (x,y).

Now we take the sum of Eq. (4.19) over all lattice sites $x \in \Lambda$. Due to the above-given identity, all terms on the left-hand side cancel, except for contributions coming from the boundary. This way we obtain the total flux through the boundary $\partial\Lambda$ of Λ:

$$\Phi_{\partial\Lambda} := \sum_{x \in \partial\Lambda} \varphi(E(x,\infty)), \tag{5.6}$$

where by $E(x,\infty)$ we denote the color electric charge along the external link, connecting the point x on the boundary of Λ with the ''rest of the world.'' On the right-hand side we get the (gauge invariant) global color charge, carried by the matter field

$$Q_\Lambda = \sum_{x \in \Lambda} \varphi(\rho(x)). \tag{5.7}$$

Both quantities appearing in the global Gauss law

$$\Phi_{\partial\Lambda} = Q_\Lambda, \tag{5.8}$$

take values in the center $\mathbb{Z}_3$ of SU(3). The ''sum modulo three'' is the composition law in $\mathbb{Z}_3$.

In the above-presented discussion we have admitted nonzero values of $E(x,\infty)$ at boundary points $x \in \partial\Lambda$. In the remainder of this section we make some heuristic remarks on the nature of these objects.

(1) One may treat Λ as a piece of a bigger lattice $\tilde{\Lambda}$. Then the boundary flux operators $E(x,\infty)$ belong to $\mathcal{F}(\tilde{\Lambda})$ and commute with $\mathcal{F}(\Lambda)$ [and also with $\mathcal{O}(\Lambda)$]. They are external from the point of view of $\mathcal{F}(\Lambda)$ and measure the ''violation of the local Gauss law'' on the boundary $\partial\Lambda$:

$$E(x,\infty) := \rho(x) - \sum_y E(y,x). \tag{5.9}$$

Nonvanishing of this element is equivalent to gauge dependence of quantum states under the action of boundary gauges $g(x) \in \mathrm{SU}(3)$, $x \in \partial\Lambda$. Let us discuss this point in more detail. Every irreducible representation of SU(3) is equivalent to some tensor representation. More precisely, denote by $T^m_n(\mathbb{C}^3)$ the space of m-contravariant, n-covariant tensors over $\mathbb{C}^3$, endowed with the

natural scalar product induced by the scalar product on $\mathbb{C}^3$. Let $\mathbb{T}^m_n(\mathbb{C}^3) \subset T^m_n(\mathbb{C}^3)$ be the subspace of *irreducible*, i.e., completely symmetric and traceless tensors. These tensors form a Hilbert space $\mathcal{T}(\mathbb{C}^3)$ defined as the direct sum

$$\mathcal{T}(\mathbb{C}^3) := \bigoplus_{m,n} \mathbb{T}^m_n(\mathbb{C}^3). \tag{5.10}$$

Under gauge transformations at $x \in \partial\Lambda$, physical states of QCD on Λ behave like elements of $\mathcal{T}(\mathbb{C}^3)$, whereas the subspaces $\mathbb{T}^m_n(\mathbb{C}^3)$ correspond to eigenspaces of the invariant operators $N(E(x,\infty))$ and $M(E(x,\infty))$, constructed from external fluxes (5.9). If one wants to include all these gauge invariant operators into an axiomatic formulation, as given in Sec. II, one has different options. The remarks at the beginning of this point suggest to postulate that these operators commute with all elements of the observable algebra $\mathcal{O}(\Lambda)$. This corresponds to treating external fluxes as purely *classical objects*, describing extra superselection rules (cf. Refs. 3–5).

(2) Our results concerning the charge superselection structure of QED on a finite lattice[13] suggest, however, a second option. In Ref. 13 all irreducible representations of the observable algebra were classified in terms of the global electric charge Q_Λ contained in Λ. Representations differing only by the local electric flux distribution over the boundary $\partial\Lambda$, but having the same value of the global flux $\Phi_{\partial\Lambda}$ were proved to be equivalent. The redistribution of fluxes is obtained by the action of certain unitary operators, see Ref. 13, acting on the quantum state under consideration. Such a *redistribution operator* has the following (heuristic) counterpart in continuum QED:

$$U(n) := \exp\left(\frac{i}{\hbar} \int_\Sigma n(x) \cdot A(x) \mathrm{d}^3x \right), \tag{5.11}$$

where $n=(n^k)$ is a divergence-free (i.e., fulfilling $\partial_k n^k \equiv 0$) vector-density on $\Sigma \subset \mathbb{R}^3$. Formally, we have

$$\tilde{E}^k(x) := (U^*(n) E(x) U(n))^k = E^k(x) + n^k(x). \tag{5.12}$$

It is obvious that replacing the field E by $\tilde{E}$ and leaving all other observables unchanged gives an equivalent representation of the observable algebra. Nevertheless, the flux field on the boundary $\partial\Sigma$ of the domain Σ is changed by $n^\perp(x)$, where "$\perp$" denotes the component orthogonal to $\partial\Sigma$.

In a subsequent paper we are going to present a similar result for lattice QCD. We shall prove that all irreducible representations of the observable algebra $\mathcal{O}(\Lambda)$ of QCD on a finite lattice are classified by the value of the global color charge Q_Λ, yielding three different superselection sectors labeled by elements of $\mathbb{Z}_3$. However, the local distribution of the (gauge invariant) gluon and antigluon fluxes $M(E(x,\infty))$ and $N(E(x,\infty))$ over the boundary $\partial\Lambda$ may be arbitrarily changed within one sector. The redistribution of fluxes is obtained by the following procedure. Take an arbitrary pair of points $\xi, \eta \in \partial\Lambda$ at the boundary and a path (collection of lattice links) $\gamma = \{(\xi, x_1), (x_1, x_2), \ldots, (x_k, \eta)\}$, connecting them. Define the following operator-valued matrix $U(\gamma) = (U^A{}_B(\gamma))$, where

$$U^A{}_B(\gamma) := \frac{1}{\sqrt{3}} U^A{}_{C_1}(\xi, x_1) U^{C_1}{}_{C_2}(x_1, x_2) \ldots U^{C_k}{}_B(x_k, \eta). \tag{5.13}$$

The action of $U(\gamma)$ on a quantum state ψ is, by definition, a collection $(U^A{}_B(\gamma)\psi)$ with an extra contravariant index A at ξ and an extra covariant index B at η. In general, the new state does not belong to any irreducible representation of SU(3) at ξ and η, even if ψ did. This means that $U(\gamma)\psi$ *is not* an eigenstate of operators $M(E(\xi,\infty))$, $N(E(\xi,\infty))$, $M(E(\eta,\infty))$, and $N(E(\eta,\infty))$, even if ψ was. Decomposing it into irreducible representations, we observe, however, that the value of $\varphi(E(\xi,\infty))$ has been changed by plus one and the value of $\varphi(E(\eta,\infty))$ has been changed by

minus one by this procedure. This suggests that these objects could also be treated as *quantum* and not as classical quantities. Then, only their sum, the global flux $\Phi_{\partial\Lambda}$, would be a classical object proportional to the identity on every superselection sector. This point of view was strongly advocated by Staruszkiewicz already a decade ago (see Ref. 18). We also refer to Ref. 19, where decoherence phenomena in QED in terms of *quantum* fluxes at infinity were discussed. We underline, however, that at the moment it is unclear, whether and if, then in which sense, intertwining operators of the type (5.13) survive in the thermodynamic limit.

(3) Finally, we stress that it does not make sense to attribute any physical meaning to the external gluon or antigluon fluxes M and N themselves. It is only the quantity $(M-N)$ ''modulo three'' which makes sense. This would hold also for the continuum theory, provided such a theory would be constructed in the future. Assume, for a moment, that a rigorous continuum QCD has been obtained as a limit of lattice theories, with surface fluxes $E^A{}_B(\Sigma) := \int_S E^A{}_B$ defined via the projective limit of finite sums corresponding to appropriate lattice approximations. Then it would not make sense to calculate quantities $N(E(\Sigma))$ or $M(E(\Sigma))$, because of the nonadditivity of functions (4.7) and (4.8). Indeed, if S has been divided into small portions, $S=\cup_\alpha S_\alpha$, we have

$$\int_S E = \sum_\alpha \int_{S_\alpha} E, \tag{5.14}$$

but the functions M, N [or even $(M-N)$] give, in general, different results when applied to both sides of Eq. (5.14). On the other hand, the function φ is additive and gives the same result when applied to both sides. This suggests that, in principle, the $\mathbb{Z}_3$-valued flux through S (equal to the sum of fluxes corresponding to its small portions S_α) could possibly survive in the continuum limit. The same argument applies to the color charge density $\varphi(\rho)$. We would then expect that the global $\mathbb{Z}_3$-valued Gauss law (5.8) could possibly survive in this ''would be'' continuum theory.

VI. DISCUSSION

We add some remarks concerning the perspectives of our approach, in which the notion of the observable algebra plays a central role. Often, one defines the observable algebra as the algebra of gauge invariant operators and imposes the Gauss law as a constraint to be fulfilled by physical states. If one discusses, for instance, the quark confinement problem in the somewhat simplified setting of QCD with infinitely heavy external charges, then this seems to be the appropriate choice. However, in our approach, we start with dynamical quarks and our final goal is a quantum theory of interacting hadrons, built from gluons and quarks. Within this strategy, all relations between (composite) physical fields, including the Gauss constraint, should be implemented on the level of the observable algebra. This point of view is strongly supported by our results for lattice QED, see Refs. 13, 14, and 20. The same strategy, applied there, yields exactly the charge superselection sectors of the theory. In these papers, we found that the observable algebra is generated by a certain Lie algebra, $u(2N)$ for spinorial QED and $u(N,N)$ for scalar QED. QCD seems to be generated by a certain Lie superalgebra—a conjecture we are actually working on. The characterization of the observable algebra in terms of a Lie (super)algebra is extremely helpful for the classification of its irreducible representations. It should be also helpful for constructing the thermodynamic limit, because for taking the limit $N\to\infty$ in the generating Lie (super)algebras there seems to exist appropriate mathematical tools for studying the resulting representations, see Ref. 21.

Finally, we stress that this work is part of a larger program, which includes both the study of gauge theoretical models in terms of gauge invariants within the functional integral approach, see Ref. 22, and the investigation of the structure of the full gauge orbit space, including singular strata, see Ref. 23. In the future, a rigorous study of singular strata within the lattice quantum theory discussed previously is also planned.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 4 APRIL 2002

Renormalization of Poincaré transformations in Hamiltonian semiclassical field theory

O. Yu. Shvedov[a)]
Sub-Department of Quantum Statistics and Field Theory, Department of Physics, Moscow State University, Vorobievy gory, Moscow 119899, Russia

(Received 21 June 2001; accepted for publication 7 January 2002)

Semiclassical Hamiltonian field theory is investigated from the axiomatic point of view. A notion of a semiclassical state is introduced. An ''elementary'' semiclassical state is specified by a set of classical field configurations and quantum states in this external field. ''Composed'' semiclassical states viewed as formal superpositions of ''elementary'' states are nontrivial only if the Maslov isotropic condition is satisfied; the inner product of ''composed'' semiclassical states is degenerate. The mathematical proof of Poincaré invariance of semiclassical field theory is obtained for ''elementary'' and ''composed'' semiclassical states. The notion of semiclassical field is introduced; its Poincaré invariance is also mathematically proved. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1453497]

I. INTRODUCTION

Different approaches to semiclassical field theory have been developed. Most of them were based on the functional integral technique: physical quantities were expressed via functional integrals which were evaluated with the help of saddle-point or stationary-phase technique. Since energy spectrum and *S*-matrix elements can be found from the functional integral,[1,2] this approach appeared to be useful for the soliton quantization theory.[1–5]

Another important partial case of the semiclassical field theory is the theory of quantization in a strong external background classical field[6] or in curved space–time:[7] one decomposes the field as a sum of a classical *c*-number component and a quantum component. Then the theory is quantized.

The one-loop approximation,[8–11] the time-dependent Hartree–Fock approximation,[8,9,12,13] and the Gaussian approximation developed in Refs. 14–17 may also be viewed as examples of applications of semiclassical conceptions.

On the other hand, the axiomatic field theory[18–20] tells us that the main objects of quantum field theory (QFT) are states and observables. The Poincaré group is represented in the Hilbert state space, so that evolution, boosts, and other Poincaré transformations are viewed as unitary operators.

The purpose of this paper is to introduce the semiclassical analogs of such QFT notions as states, fields, and Poincaré transformations. The analogs of Wightman Poincaré invariance and field axioms for the semiclassical field theory are to be formulated and checked.

Unfortunately, ''exact'' QFT is mathematically constructed for a restricted class of models only (see, e.g., Refs. 21–24). Therefore, formal approximate methods such as perturbation theory seem to be ways to quantize the field theory rather than to construct approximations for the exact solutions of QFT equations. The conception of field quantization within the perturbation framework is popular.[25,26] One can expect that the semiclassical approximation plays an analogous role.

To construct the semiclassical formalism based on the notion of a state, one should use the equation-of-motion formulation of QFT rather than the usual *S*-matrix formulation. It is well-known that additional difficulties such as Stueckelberg divergences[27] and problems associated with the Haag theorem[28,19,20] arise in the equation-of-motion approach. There are some ways to

a)Electronic mail: shvedov@qs.phys.msu.su

overcome them. The vacuum divergences can be eliminated in the perturbation theory with the help of the Faddeev transformation.[29] Stueckelberg divergences can be treated analogously[30] (exactly solvable models with Stueckelberg divergences have been suggested recently[31,32]). These investigations are important for the semiclassical Hamiltonian field theory.[33]

The semiclassical approaches are formally applicable to the quantum field theory models if the Lagrangian depends on the fields φ and the small parameter λ as follows (see, for example, Ref. 4):

$$\mathcal{L}=\frac{1}{2}\partial_\mu\varphi\partial_\mu\varphi-\frac{m^2}{2}\varphi^2-\frac{1}{\lambda}V(\sqrt{\lambda}\varphi), \tag{1.1}$$

where V is an interaction potential. To illustrate the *formal* semiclassical ansatz for the state vector, use the functional Schrödinger representation (see, e.g., Refs. 12, 13, 16, and 17). States at fixed moment of time are represented as functionals $\psi[\varphi(\cdot)]$ depending on fields $\varphi(\mathbf{x})$, $\mathbf{x}\in\mathbf{R}^d$, the field operator $\hat{\varphi}(\mathbf{x})$ is the operator of multiplication by $\varphi(\mathbf{x})$, while the canonically conjugated momentum $\hat{\pi}(\mathbf{x})$ is represented as a differentiation operator $-i\delta/\delta\varphi(\mathbf{x})$. The functional Schrödinger equation reads

$$i\frac{\mathrm{d}\psi^t}{\mathrm{d}t}=\mathcal{H}\psi^t, \tag{1.2}$$

where

$$\mathcal{H}=\int \mathrm{d}\mathbf{x}\left[-\frac{1}{2}\frac{\delta^2}{\delta\varphi(\mathbf{x})\,\delta\varphi(\mathbf{x})}+\frac{1}{2}(\nabla\varphi)^2(\mathbf{x})+\frac{m^2}{2}\varphi^2(\mathbf{x})+\frac{1}{\lambda}V(\sqrt{\lambda}\varphi(\mathbf{x}))\right].$$

The simplest semiclassical state corresponds to the Maslov theory of complex germ in a point.[34–36] It depends on the small parameter λ as

$$\begin{aligned}\psi^t[\varphi(\cdot)]&=\exp\left(\frac{i}{\lambda}S^t\right)\exp\left(\frac{i}{\lambda}\int \mathrm{d}x\,\Pi^t(\mathbf{x})[\varphi(\mathbf{x})\sqrt{\lambda}-\Phi^t(\mathbf{x})]\right)f^t\left(\varphi(\cdot)-\frac{\Phi^t(\cdot)}{\sqrt{\lambda}}\right)\\&\equiv(K_{S^t,\Pi^t,\Phi^t}f^t)[\varphi(\cdot)],\end{aligned} \tag{1.3}$$

where S^t, $\Pi^t(\mathbf{x})$, $\Phi^t(\mathbf{x})$, $t\in\mathbf{R}$, $\mathbf{x}\in\mathbf{R}^d$ are smooth real functions which rapidly damp with all their derivatives as $\mathbf{x}\to\infty$, $f^t[\phi(\cdot)]$ is a t-dependent functional.

As $\lambda\to 0$, the substitution (1.3) satisfies Eq. (1.2) in the leading order in λ if the following relations are obeyed. First, for the ''action'' S^t one finds

$$\frac{\mathrm{d}S^t}{\mathrm{d}t}=\int \mathrm{d}\mathbf{x}\left[\Pi^t(\mathbf{x})\dot{\Phi}^t(\mathbf{x})-\frac{1}{2}(\Pi^t(\mathbf{x}))^2-\frac{1}{2}(\nabla\Phi^t(\mathbf{x}))^2-\frac{m^2}{2}(\Phi^t(\mathbf{x}))^2-V(\Phi^t(\mathbf{x}))\right]. \tag{1.4}$$

Second, Π^t, Φ^t obeys the classical Hamiltonian system

$$\dot{\Phi}^t=\Pi^t,\ -\dot{\Pi}^t=(-\Delta+m^2)\Phi^t+V'(\Phi^t). \tag{1.5}$$

Finally, the functional f^t satisfies the functional Schrödinger equation with the quadratic Hamiltonian

$$i\dot{f}^t[\phi(\cdot)]=\int \mathrm{d}\mathbf{x}\left[-\frac{1}{2}\frac{\delta^2}{\delta\phi(\mathbf{x})\,\delta\phi(\mathbf{x})}+\frac{1}{2}(\nabla\phi(\mathbf{x}))^2+\frac{m^2}{2}\phi^2(\mathbf{x})+\frac{1}{2}V''(\Phi^t(\mathbf{x}))\phi^2(\mathbf{x})\right]f^t[\phi(\cdot)]. \tag{1.6}$$

There are more complicated semiclassical states that also approximately satisfy the functional Schrödinger equation (1.2). These ansatzes correspond to the Maslov theory of Lagrangian manifolds with complex germs.[34–36] They are discussed in Sec. V.

However, the QFT divergences lead to the following difficulties.

It is not evident how one should specify the class of possible functionals f and introduce the inner product on such a space via functional integral. This class was constructed in Ref. 33. In particular, it was found when the Gaussian functional

$$f[\phi(\cdot)]=\text{const}\exp\left(\frac{i}{2}\int \mathrm{d}\mathbf{x}\,\mathrm{d}\mathbf{y}\,\phi(x)\,\phi(\mathbf{y})\mathcal{R}(\mathbf{x},\mathbf{y})\right) \tag{1.7}$$

belongs to this class. The condition on the quadratic form $\mathcal{R}$ which was obtained in Ref. 33 depends on Φ, Π and differs from the analogous condition in the free theory. This is in agreement with the statement of Refs. 37 and 38 that nonequivalent representations of the canonical commutation relations at different moments of time should be considered if QFT in the strong external field is investigated in the leading order in λ. However, this does not lead to nonunitarity of the exact theory: the simple example has been presented in Ref. 32.

Another problem is to formulate the semiclassical theory in terms of the axiomatic field theory. Section II deals with formulation of axioms of relativistic invariance and field for the semiclassical theory. Section III is devoted to construction of Poincaré transformations. In Sec. IV the notion of semiclassical field is investigated. More complicated semiclassical states are constructed in Sec. V. Section VI contains concluding remarks.

II. AXIOMS OF SEMICLASSICAL FIELD THEORY

In the Wightman axiomatic approach the main object of QFT is a notion of a state space.[18–20] Formula (1.3) shows us that in the semiclassical field theory a state at fixed moment of time should be viewed as a set $(S,\Pi(\cdot),\Phi(\cdot),f[\phi(\cdot)])$ of a real number S, real functions $\Pi(\mathbf{x})$, $\Phi(\mathbf{x})$, $\mathbf{x}\in\mathbf{R}^d$, and a functional $f[\phi(\cdot)]$ from some class. This class depends on Π and Φ. Superposition of semiclassical states (S_1,Π_1,Φ_1,f_1) and (S_2,Π_2,Φ_2,f_2) is of the semiclassical type (1.3) if and only if $S_1=S_2$, $\Phi_1=\Phi_2$, $\Pi_1=\Pi_2$.

Thus, one introduces[39,40] the structure of a vector bundle (called a ''semiclassical bundle'' in Ref. 40) on the set of semiclassical states of the type (1.3). The base of the bundle being a space of sets (S,Π,Φ) (''extended phase space'' [39]) will be denoted as $\mathcal{X}$. The fibers are classes of functionals which depend on Φ and Π. Making use of the result concerning the class of functionals,[33] one makes the bundle trivial as follows. Consider the Φ, Π-dependent mapping V, which defines a correspondence between functionals f and elements of the Fock space $\mathcal{F}$:

$$V:\Psi\mapsto f,\quad \Psi\in\mathcal{F},\quad f=f[\phi(\cdot)],$$

as follows (see, e.g., Ref. 41). Let $\tilde{\mathcal{R}}(x,y)$ be an Φ, Π-dependent symmetric function such that its imaginary part is a kernel of a positively definite operator and the condition of Ref. 33 [see Eq. (3.41) in Sec. III F] is satisfied. By $\hat{\mathcal{R}}$ we denote the operator with kernel $\tilde{\mathcal{R}}$, while $\hat{\Gamma}$ has a kernel $i^{-1}(\tilde{\mathcal{R}}-\tilde{\mathcal{R}}^*)$. The vacuum vector of the Fock space corresponds to the Gaussian functional (1.7). The operator V is uniquely defined from the relations

$$\begin{aligned} V^{-1}\phi(\mathbf{x})V&=i(\hat{\Gamma}^{-1/2}(A^+-A^-))(\mathbf{x}),\\ V^{-1}\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}V&=i(\hat{\mathcal{R}}\hat{\Gamma}^{-1/2}A^+-\hat{\mathcal{R}}^*\hat{\Gamma}^{-1/2}A^-)(\mathbf{x}).\end{aligned} \tag{2.1}$$

Here $A^{\pm}(\mathbf{x})$ are creation and annihilation operators in the Fock space.

Definition 2.1: A semiclassical state is a point on the trivial bundle $\mathcal{X}\times\mathcal{F}\to\mathcal{X}$.

An important postulate of QFT is Poincaré invariance. This means that a representation of the Poincaré group in the state space should be specified. For each Poincaré transformation of the form

$$x'^{\mu}=\Lambda^{\mu}_{\nu}x^{\nu}+a^{\mu}, \quad \mu,\nu=\overline{0,d}, \tag{2.2}$$

which is denoted as (a,Λ), the unitary operator $\mathcal{U}_{a,\Lambda}$ should be specified. The group property

$$\mathcal{U}_{(a_1,\Lambda_1)}\mathcal{U}_{(a_2,\Lambda_2)}=\mathcal{U}_{(a_1,\Lambda_1)(a_2,\Lambda_2)}$$

with

$$(a_1,\Lambda_1)(a_2,\Lambda_2)=(a_1+\Lambda_1 a_2,\Lambda_1\Lambda_2)$$

should be satisfied.

Formulate an analog of the Poincaré invariance axiom for the semiclassical theory. Suppose that the Poincaré transformation $\mathcal{U}_{a,\Lambda}$ takes any semiclassical state (X,f) to a semiclassical state $(\tilde{X},\tilde{f})$ in the leading order in $\lambda^{1/2}$. Denote $\tilde{X}=u_{a,\Lambda}X$, $\tilde{f}=U(u_{a,\Lambda}X\leftarrow X)f$.

Axiom 1 (Poincaré invariance):

(*a*) *The mappings* $u_{a,\Lambda}\colon \mathcal{X}\to\mathcal{X}$ *are specified, the group properties for them* $u_{a_1,\Lambda_1}u_{a_2,\Lambda_2}=u_{(a_1,\Lambda_1)(a_2,\Lambda_2)}$ *are satisfied*;

(*b*) *for all* $X\in\mathcal{X}$ *the unitary operators* $U_{a,\Lambda}(u_{a,\Lambda}X\leftarrow X)\colon \mathcal{F}\to\mathcal{F}$, *obeying the group property*

$$\begin{aligned}&U_{a_1,\Lambda_1}(u_{(a_1,\Lambda_1)(a_2,\Lambda_2)}X\leftarrow u_{(a_2,\Lambda_2)}X)U_{a_2,\Lambda_2}(u_{(a_2,\Lambda_2)}X\leftarrow X)\\&\quad=U_{(a_1,\Lambda_1)(a_2,\Lambda_2)}(u_{(a_1,\Lambda_1)(a_2,\Lambda_2)}X\leftarrow X)\end{aligned} \tag{2.3}$$

are specified.

An important feature of QFT is the notion of a field: it is assumed that an operator distribution $\hat{\varphi}(\mathbf{x},t)$ is specified. Investigate it in the semiclassical theory. Applying the operator $\varphi(\mathbf{x})$ to the semiclassical state (1.3), we obtain an analogous state:

$$\exp\left(\frac{i}{\lambda}S^t\right)\exp\left(\frac{i}{\lambda}\int d\mathbf{x}\Pi^t(\mathbf{x})[\varphi(\mathbf{x})\sqrt{\lambda}-\Phi^t(\mathbf{x})]\right)\tilde{f}^t\left(\varphi(\cdot)-\frac{\Phi^t(\cdot)}{\sqrt{\lambda}}\right),$$

where

$$\tilde{f}^t[\phi(\cdot)]=(\lambda^{-1/2}\Phi^t(\mathbf{x})+\phi(\mathbf{x}))f^t[\phi(\cdot)].$$

As $\lambda\to 0$, one has

$$\hat{\varphi}(\mathbf{x},t)=\lambda^{-1/2}\Phi^t(\mathbf{x})+\hat{\phi}(\mathbf{x},t{:}X),$$

where $\hat{\phi}(\mathbf{x},t{:}X)$ is a Π,Φ-dependent operator in $\mathcal{F}$, $\Phi^t(\mathbf{x})\equiv\Phi(x{:}X)$ is a solution to the Cauchy problem for Eq. (1.5). The field axiom can be reformulated as follows.

Axiom 2: For each $X\in\mathcal{X}$ *the operator distribution* $\phi(\mathbf{x},t;X)\colon \mathcal{F}\to\mathcal{F}$ *is specified.*

An important feature of the relativistic quantum field theory is the property of Poincaré invariance of fields. The operator distribution $\hat{\varphi}(\mathbf{x},t)$ should obey the following property:

$$\mathcal{U}_{a,\Lambda}\hat{\varphi}(x)=\hat{\varphi}(\Lambda x+a)\mathcal{U}_{a,\Lambda}.$$

Apply this identity to a semiclassical state (X,f). In leading orders in $\lambda^{1/2}$, one obtains

$$\lambda^{-1/2}\Phi(x{:}X)(u_{a,\Lambda}X, U_{a,\Lambda}(u_{a,\Lambda}X{\leftarrow}X)f)+(u_{a,\Lambda}X, U_{a,\Lambda}(u_{a,\Lambda}X{\leftarrow}X)\hat{\phi}(x{:}X)f)$$
$$=\lambda^{-1/2}\Phi(\Lambda x+a{:}u_{a,\Lambda}X)(u_{a,\Lambda}X, U_{a,\Lambda}(u_{a,\Lambda}X{\leftarrow}X)f)$$
$$+(u_{a,\Lambda}X, \hat{\phi}(\Lambda x+a{:}u_{a,\Lambda}X)U_{a,\Lambda}(u_{a,\Lambda}X{\leftarrow}X)f).$$

Therefore, we formulate the following axiom.

Axiom 3 (Poincaré invariance of fields): The following properties are satisfied:

$$\Phi(x{:}X)=\Phi(\Lambda x+a{:}u_{a,\Lambda}X), \tag{2.4}$$

$$\hat{\phi}(\Lambda x+a{:}u_{a,\Lambda}X)U_{a,\Lambda}(u_{a,\Lambda}X{\leftarrow}X)=U_{a,\Lambda}(u_{a,\Lambda}X{\leftarrow}X)\hat{\phi}(x{:}X). \tag{2.5}$$

III. SEMICLASSICAL POINCARÉ TRANSFORMATIONS

A. Construction of Poincaré transformations in the functional representation

(1) Let us construct the mappings $u_{a,\Lambda}$ and unitary operators $U_{a,\Lambda}(u_{a,\Lambda}X{\leftarrow}X)$. Since any Poincaré transformation is a composition of time and space translations, boost and spatial rotations,

$$(a,\Lambda)=(a^0,1)(\mathbf{a},1)(0,\exp(\alpha^k I^{0k}))(0,\exp(\tfrac{1}{2}\theta_{sm}I^{sm}))$$

with $\theta_{sm}=-\theta_{ms}$,

$$(I^{\lambda\mu})^{\alpha}_{\beta}=-g^{\lambda\alpha}\delta^{\mu}_{\beta}+g^{\mu\alpha}\delta^{\lambda}_{\beta},$$

it is sufficient to specify operators $U_{a,\Lambda}$ for these special cases and then apply a group property.

In the ''exact'' theory, the operator $\mathcal{U}_{a,\Lambda}$ has the form

$$\mathcal{U}_{a,\Lambda}=\exp[i\mathcal{P}^0a^0]\exp[-i\mathcal{P}^ja^j]\exp[i\alpha^k\mathcal{M}^{0k}]\exp\left[\frac{i}{2}\mathcal{M}^{lm}\theta_{lm}\right]. \tag{3.1}$$

The momentum and angular momentum operators entering to formula (3.1) have the well-known form (see, e.g., Ref. 25)

$$\mathcal{P}^{\mu}=\int d\mathbf{x}\, T^{\mu 0}(\mathbf{x}), \quad \mathcal{M}^{\mu\lambda}=\int d\mathbf{x}[x^{\mu}T^{\lambda 0}(\mathbf{x})-x^{\lambda}T^{\mu 0}(\mathbf{x})], \tag{3.2}$$

where formally

$$T^{00}=\frac{1}{2}\hat{\pi}^2+\frac{1}{2}\partial_i\hat{\varphi}\partial_i\hat{\varphi}+\frac{m^2}{2}\hat{\varphi}^2+\frac{1}{\lambda}V(\sqrt{\lambda}\hat{\varphi}), \quad T^{k0}=-\partial_k\hat{\varphi}\hat{\pi}.$$

We are going to apply the operator (3.1) to the semiclassical state (1.3). Note that the operators $\mathcal{P}^{\mu}$ and $\mathcal{M}^{\mu\nu}$ (3.2) depend on field $\hat{\varphi}$ and momentum $\hat{\pi}$ semiclassically,

$$\mathcal{P}^{\mu}=\frac{1}{\lambda}P^{\mu}(\sqrt{\lambda}\hat{\pi}(\cdot),\sqrt{\lambda}\hat{\varphi}(\cdot)), \quad \mathcal{M}^{\mu\nu}=\frac{1}{\lambda}M^{\mu\nu}(\sqrt{\lambda}\hat{\pi}(\cdot),\sqrt{\lambda}\hat{\varphi}(\cdot)),$$

It is convenient to consider the more general problem (cf. Ref. 35). Let us find as $\lambda\to 0$ the state

$$\exp(-i\mathcal{A})K_{S^0,\Pi^0,\Phi^0}f^0, \tag{3.3}$$

where $K_{S,\Pi,\Phi}$ has the form (1.3),

$$\mathcal{A}=\frac{1}{\lambda}A(\sqrt{\lambda}\,\hat{\pi}(\cdot),\sqrt{\lambda}\,\hat{\varphi}(\cdot)).$$

Note that the state functional (3.3) may be viewed as a solution to the Cauchy problem of the form

$$\begin{gathered} i\frac{\partial\Psi^{\tau}}{\partial\tau}=\frac{1}{\lambda}A\left(\frac{\sqrt{\lambda}}{i}\frac{\delta}{\delta\varphi(\cdot)},\sqrt{\lambda}\,\varphi(\cdot)\right)\Psi^{\tau}, \\ \Psi^{0}[\varphi(\cdot)]=(K_{S^0,\Pi^0,\Phi^0}f^0)[\varphi(\cdot)] \end{gathered} \tag{3.4}$$

at $\tau=1$. Let us look for the asymptotic solution to Eq. (3.4) in the following form:

$$\Psi^{\tau}[\varphi(\cdot)]=(K_{S^{\tau},\Pi^{\tau},\Phi^{\tau}}f^{\tau})[\varphi(\cdot)]. \tag{3.5}$$

Substitution of functional (3.5) to Eq. (3.4) gives us the following relation:

$$\begin{aligned} &\left[-\frac{1}{\lambda}\left(\dot{S}^{\tau}-\int \mathrm{d}x\,\Pi^{\tau}(\mathbf{x})\dot{\Phi}^{\tau}(\mathbf{x})\right)-\frac{1}{\sqrt{\lambda}}\int \mathrm{d}\mathbf{x}\left(\dot{\Pi}^{\tau}(\mathbf{x})\phi(\mathbf{x})+\dot{\Phi}^{\tau}(\mathbf{x})i\frac{\delta}{\delta\phi(\mathbf{x})}\right)+i\frac{\partial}{\partial\tau}\right]f^{\tau}[\phi(\cdot)] \\ &\quad=\frac{1}{\lambda}A\left(\Pi^{\tau}(\cdot)-i\sqrt{\lambda}\frac{\delta}{\delta\phi(\cdot)},\Phi^{\tau}(\cdot)+\sqrt{\lambda}\,\phi(\cdot)\right)f^{\tau}[\phi(\cdot)]. \end{aligned} \tag{3.6}$$

Considering the terms of the orders $O(\lambda^{-1})$, $O(\lambda^{-1/2})$ and $O(1)$ in Eq. (3.6), we obtain

$$\dot{S}^{\tau}=\int \mathrm{d}\mathbf{x}(\Pi^{\tau}(\mathbf{x})\dot{\Phi}^{\tau}(\mathbf{x})-A(\Pi^{\tau}(\cdot),\Phi^{\tau}(\cdot)), \tag{3.7}$$

$$\dot{\Phi}^{\tau}(\mathbf{x})=\frac{\delta A(\Pi^{\tau}(\cdot),\Phi^{\tau}(\cdot))}{\delta\Pi(\mathbf{x})},\quad \dot{\Pi}^{\tau}(\mathbf{x})=-\frac{\delta A(\Pi^{\tau}(\cdot),\Phi^{\tau}(\cdot))}{\delta\Phi(\mathbf{x})}, \tag{3.8}$$

$$\begin{aligned} i\frac{\partial f^{\tau}[\Phi(\cdot)]}{\partial\tau}=&\left(\int \mathrm{d}\mathbf{x}\,\mathrm{d}\mathbf{y}\left[\frac{1}{2}\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}\frac{\delta^2A}{\delta\Pi(\mathbf{x})\delta\Pi(\mathbf{y})}\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{y})}+\phi(\mathbf{x})\frac{\delta^2A}{\delta\Phi(\mathbf{x})\delta\Pi(\mathbf{y})}\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{y})}\right.\right. \\ &\left.\left.+\frac{1}{2}\phi(\mathbf{x})\frac{\delta^2A}{\delta\Phi(\mathbf{x})\delta\Phi(\mathbf{y})}\phi(\mathbf{y})\right]+A_1\right)f^{\tau}[\phi(\cdot)]. \end{aligned} \tag{3.9}$$

Here A_1 is a c-number quantity which depends on the ordering of the operators $\hat{\varphi}$ and $\hat{\pi}$ and is relevant to the renormalization problem.

We see that for the cases $\mathcal{A}=-\mathcal{P}^0a^0$, $\mathcal{A}=\mathcal{P}^ja^j$, $\mathcal{A}=-\alpha^k\mathcal{M}^{0k}$, $\mathcal{A}=(1/2)\theta_{sm}\mathcal{M}^{sm}$ the mapping $u_{a,\Lambda}$ takes the initial condition for the system (3.7), (3.8) to the solution of the Cauchy problem for this system at $\tau=1$. The operators $\tilde{U}_{a,\Lambda}$ transform the initial condition for Eq. (3.9) to the solution at $\tau=1$.

(2) The classical mappings $u_{a,\Lambda}$ for our partial cases are presented in Table I.

One can write down the following general formula. Let (a,Λ) be an arbitrary Poincaré transformation. It happens that the mapping $u_{a,\Lambda}:(S,\Pi,\Phi)\mapsto(\tilde{S},\tilde{\Pi},\tilde{\Phi})$ has the following form. Let $\Phi(\mathbf{x},t)\equiv\Phi(x)$ be a solution of the Cauchy problem

$$\begin{gathered} \partial_{\mu}\partial^{\mu}\Phi(x)+m^2\Phi(x)+V'(\Phi(x))=0, \\ \Phi(\mathbf{x},0)=\Phi(\mathbf{x}),\quad \frac{\partial}{\partial t}\Phi(\mathbf{x},t)\big|_{t=0}=\Pi(\mathbf{x}). \end{gathered} \tag{3.10}$$

Denote

TABLE I. Poincaré transformations in classical theory.

Element of Poincaré group (a_τ,Λ_τ)	Classical Poincaré transformation $u_{a_\tau,\Lambda_\tau}:(S^0,\Pi^0,\Phi^0)\mapsto(S^\tau,\Pi^\tau\Phi^\tau)$	Classical Lie derivative $\delta F(S,\Pi,\Phi)=\frac{\mathrm{d}}{\mathrm{d}\tau}\Big\vert_{\tau=0} F(S^\tau,\Pi^\tau,\Phi^\tau)$

$\mathbf{a}_\tau=\mathbf{b}\tau$	$\Pi^\tau(\mathbf{x})=\Pi^0(\mathbf{x}-\mathbf{b}\tau)$	
Spatial translation	$S^\tau=S^0$	
$a^0=-\tau\,\mathbf{a}=0$	Resolving operator for the Cauchy problem $\dot\Phi^\tau=\Pi^\tau$	$-\delta_H=\int \mathrm{d}\mathbf{x}\left[\Pi(\mathbf{x})\frac{\delta}{\delta\Phi(\mathbf{x})}-(-\Delta\Phi(\mathbf{x})+m^2\Phi(\mathbf{x})+V'(\Phi(\mathbf{x})))\frac{\delta}{\delta\Pi(\mathbf{x})}\right]-i\mathrm{d}\mathbf{x}\left[\frac{1}{2}\Pi^2(\mathbf{x})-\frac{1}{2}(\nabla\Phi(\mathbf{x}))^2-\frac{m^2}{2}\Phi^2(\mathbf{x})-V(\Phi(\mathbf{x}))\right]\frac{\partial}{\partial S}.$
$\Lambda=1$	$-\dot\Pi^\tau=(-\Delta+m^2)\Phi^\tau+V'(\Phi^\tau)$	
Evolution	$\dot S^\tau=\int \mathrm{d}\mathbf{x}\left[\Pi^\tau\dot\Phi^\tau-\frac{1}{2}(\Pi^\tau)^2-\frac{1}{2}(\nabla\Phi_\tau)^2-\frac{m^2}{2}(\Phi^\tau)^2-V(\Phi^\tau)\right].$	
$a_\tau=0$	Resolving operator for the Cauchy problem $\dot\Phi^\tau=n^kx^k\Pi^\tau$	$-n^m\delta^m_B=n^m\int \mathrm{d}\mathbf{x}\left[x^m\Pi(\mathbf{x})\frac{\delta}{\delta\Phi(\mathbf{x})}-(-\partial_ix^m\partial_i\Phi(\mathbf{x})+x^mm^2\Phi(\mathbf{x})+x^mV'(\Phi(\mathbf{x})))\frac{\delta}{\delta\Pi(\mathbf{x})}\right]+n^m\int \mathrm{d}\mathbf{x}\,x^m\left[\frac{1}{2}\Pi^2(\mathbf{x})-\frac{1}{2}(\nabla\Phi(\mathbf{x}))^2-\frac{m^2}{2}\Phi^2(\mathbf{x})-V(\Phi(\mathbf{x}))\right]\frac{\partial}{\partial S}.$
$\Lambda_\tau=\exp[-\pi m^kl^{k0}]$	$-\dot\Pi^\tau=-\nabla x^kn^k\nabla\Phi^\tau+x^kn^k(m^2\Phi^\tau+V'(\Phi^\tau))$	
Boost	$\dot S^\tau=\int \mathrm{d}\mathbf{x}\left[\Pi^\tau\dot\Phi^\tau-x^kn^k\frac{1}{2}(\Pi^\tau)^2+\frac{1}{2}(\nabla\Phi^\tau)^2+\frac{m^2}{2}(\Phi^\tau)^2+V(\Phi^\tau)\right]$	

$$\check{\Phi}(x)=\Phi(\Lambda^{-1}(x-a)).$$

It appears that

$$\tilde{\Phi}(\mathbf{x})=\check{\Phi}(\mathbf{x},0),\quad \tilde{\Pi}(\mathbf{x})=\frac{\partial}{\partial t}\check{\Phi}(\mathbf{x},t)\big|_{t=0},$$

$$\tilde{S}=S+\int \mathrm{d}x[\,\theta(x^0)\,\theta(-(\Lambda x+a)^0)-\theta(-x^0)\,\theta((\Lambda x+a)^0)]$$
$$\times\left[\frac{1}{2}\,\partial_\mu\Phi(x)\partial^\mu\Phi(x)-\frac{m^2}{2}\Phi^2(x)-V(\Phi(x)).\right. \tag{3.11}$$

For spatial translations, rotations, and evolution, agreement between (3.11) and Table I is evident. Consider the x^1-boost case, $n^k=(1,0,...,0)$. One has

$$\tilde{\Phi}_\tau(\mathbf{x})=\Phi(x^1\cosh\tau+x^0\sinh\tau,x^2,\ldots,x^d,x^0\cosh\tau+x^1\sinh\tau)\big|_{x^0=0},$$

$$\tilde{\Pi}_\tau(\mathbf{x})=\frac{\partial}{\partial x^0}\Phi(x^1\cosh\tau+x^0\sinh\tau,x^2,\ldots,x^d,x^0\cosh\tau+x^1\sinh\tau)\big|_{x^0=0}.$$

The functions Φ_τ, Π_τ obey the system presented in Table I. For the integral for $\tilde{S}$, consider the substitution $x^0=y^1\sinh\tilde{\tau}$, $x^1=y^1\cosh\tilde{\tau}$, $x^2=y^2,\ldots,x^d=y^d$. One finds

$$\tilde{S}^\tau=S+\int_0^\tau \mathrm{d}\tilde{\tau}y^1\,\mathrm{d}\mathbf{y}\left[\frac{1}{2}(\tilde{\Pi}_\tau(y))^2-\frac{1}{2}(\nabla\tilde{\Phi}_\tau(\mathbf{y}))^2-\frac{m^2}{2}\tilde{\Phi}_\tau^2(\mathbf{y})-V(\tilde{\Phi}_\tau(\mathbf{y}))\right],$$

which agrees with Table I.

One can also notice that the group property for Eq. (3.11) is satisfied.

Let us make more precise the definition of the space χ.

Definition 3.1: χ *is a space of sets* (S,Π,Φ) *of a number S and functions* $\Pi,\Phi\in S(\mathbf{R}^d)$ *such that there exists a unique solution of the Cauchy problem (3.10) such that the functions* $\Phi(\Lambda x+a)\big|_{x^0=0}$ *and* $\partial_\mu\Phi(\Lambda x+a)\big|_{x^0=0}$ *are of the class* $S(\mathbf{R}^d)$ *for all* $a.\Lambda$.

We see that the transformation $u_{a,\Lambda}:\chi\to\chi$ is defined.

(3) The operators $\tilde{U}_{a,\Lambda}(u_{a,\Lambda}X\leftarrow X)$ are presented in Table II.

However, it is not easy to check the group property (2.3). It is much more convenient to investigate the infinitesimal Poincaré transformations and check the algebraic analog of (2.3).

It happens that operators $\tilde{U}_{a,\Lambda}(u_{a,\Lambda}X\leftarrow X)$ induce a Poincaré group representation in a specific space. It is a space of sections $f(x;\phi(\cdot))$ of the semiclassical bundle. The operators $\check{\tilde{U}}_{a,\Lambda}$ act as

$$(\check{\tilde{U}}_{a,\Lambda}f)(X)=\tilde{U}_{a,\Lambda}(X\leftarrow u_{a,\Lambda}^{-1}X)f(u_{a,\Lambda}^{-1}X). \tag{3.12}$$

The group property for the operators $\check{\tilde{U}}$ is equivalent to relation (2.3). Let $(a_{\mathrm{tau}},\Lambda_\tau)$ be a one-parametric subgroup of the Poincaré group with the tangent vector A being an element of the Poincaré algebra. Since the operator $\tilde{U}_{a_\tau,\Lambda_\tau}(u_{a_\tau,\Lambda_\tau}X\leftarrow X)$ takes the initial condition for the Cauchy problem for

$$i\dot{f}_\tau=\tilde{H}(A:u_{a_\tau\Lambda_\tau}X)f_\tau$$

to the solution of this equation, therefore, the generator of representation (3.12) is

TABLE II. Semiclassical Poincaré transformations in functional representation.

Element of Poincaré group (a_τ,Λ_τ)	Semiclassical operator $U_{a_\tau,\Lambda_\tau}(u_{a_\tau,\Lambda_\tau}X\leftarrow X)$: $f_0\mapsto f_\tau$ in the functional representation takes the initial condition for the Cauchy problem to the solution of the Cauchy problem for the equation:
$a_\tau=0$	$i\dot{f}^\tau[\phi(\cdot)]=-\frac{1}{2}\theta_{sm}\tilde{M}^{sm}(X_\tau)f_\tau[\phi(\cdot)]$
$\Lambda_\tau=\exp\left(\frac{\tau}{2}I^{sm}\theta_{sm}\right)$;	$\tilde{M}^{sm}=-\int d\mathbf{x}[(x^s\partial_m-x^m\partial_s)\phi(\mathbf{x})]\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}$
Spatial rotation	
$a^0_\tau=0\ \Lambda_\tau=1$	$i\dot{f}^\tau[\phi(\cdot)]=b^k\tilde{P}^k(X_\tau)f_\tau[\phi(\cdot)]$
$\mathbf{a}_\tau=\mathbf{b}\tau$	$\tilde{P}^k=-\int d\mathbf{x}\,\partial_k\phi(\mathbf{x})\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}$
Spatial translation	
$a^0=-\tau\ \mathbf{a}=0$	$i\dot{f}^\tau[\phi(\cdot)]=\tilde{H}(X_\tau)f_\tau[\phi(\cdot)]$
$\Lambda=1$	$\tilde{H}=\int d\mathbf{x}\left[-\frac{1}{2}\frac{\delta^2}{\delta\phi(\mathbf{x})\delta\phi(\mathbf{x})}+\frac{1}{2}(\nabla\phi)^2(\mathbf{x})+\frac{m^2}{2}\phi^2(\mathbf{x})+\frac{1}{2}V''(\Phi(\mathbf{x}))\phi^2(\mathbf{x})\right]$
Evolution	
$a_\tau=0$	$i\dot{f}^\tau[\phi(\cdot)]=n^m\tilde{B}^m(X_\tau)f_\tau[\phi(\cdot)]$
$\Lambda_\tau=\exp[-\tau n^k l^{k0}]$;	$\tilde{B}^m=\int d\mathbf{x}\,x^m\left[-\frac{1}{2}\frac{\delta^2}{\delta\phi(\mathbf{x})\delta\phi(\mathbf{x})}+\frac{1}{2}(\nabla\phi)^2(\mathbf{x})+\frac{m^2}{2}\phi^2(\mathbf{x})+\frac{1}{2}V''(\Phi(\mathbf{x}))\phi^2(\mathbf{x})\right]$
Boost	

$$(\check{\tilde{H}}(A)f)(X)=i\frac{d}{d\tau}|_{\tau=0}(\check{\tilde{u}}_{a_\tau,\Lambda_\tau}f)(X)=[\tilde{H}(A:X)-i\delta[A]]f(X),$$

where

$$\delta[A]=\frac{d}{d\tau}|_{\tau=0}f(u_{a_\tau,\Lambda_\tau}X)$$

is a Lie derivative presented in Table I. Therefore, the infinitesimal analog of the group property (2.3) is

$$[\tilde{H}(A_1:X)-i\delta[A_1];\tilde{H}(A_2:X)-i\delta[A_2]]=i(\tilde{H}([A_1;A_2]:X)-i\delta[A_1;A_2]]). \tag{3.13}$$

It follows from the notations of Tables I and II that relation (3.13) can be rewritten for the Poincaré algebra as

$$\begin{gathered}[\check{\tilde{P}}^\lambda,\check{\tilde{P}}^\mu]=0,\quad [\check{\tilde{M}}^{\lambda\mu},\check{\tilde{P}}^\sigma]=i(g^{\mu\sigma}\check{\tilde{P}}^\lambda-g^{\lambda\sigma}\check{\tilde{P}}^\mu)\\ [\check{\tilde{M}}^{\lambda\mu},\check{\tilde{M}}^{\rho\sigma}]=-i(g^{\lambda\rho}\check{\tilde{M}}^{\mu\sigma}-g^{\mu\rho}\check{\tilde{M}}^{\lambda\sigma}+g^{\mu\sigma}\check{\tilde{M}}^{\lambda\rho}-g^{\lambda\sigma}\check{\tilde{M}}^{\mu\rho})\end{gathered} \tag{3.14}$$

for operators

$$\check{\tilde{M}}^{ms}=\tilde{M}^{ms}+i\delta^{ms}_M,\quad \check{\tilde{P}}^m=\tilde{P}^m+i\delta^m_P,\quad \check{\tilde{P}}^0=\check{H}+i\delta_H,\quad \check{M}^{k0}=\tilde{B}^k+i\delta^k_B.$$

It is checked by direct calculations that Eq. (3.14) is *formally* satisfied. However, there is a problem of divergences and renormalization which requires more careful investigations.

B. Semiclassical Poincaré transformations in Fock space

For renormalization, let us construct the semiclassical Poincaré transformations in the Fock space. They are related with the constructed operators $\tilde{U}_{a,\Lambda}(u_{a,\Lambda}X \leftarrow X)$ by

$$\tilde{U}_{a,\Lambda}(u_{a,\Lambda}X \leftarrow X) = V_{u_{a,\Lambda}X} U_{a,\Lambda}(u_{a,\Lambda}X \leftarrow X) V_X^{-1}. \tag{3.15}$$

The operator V taking the Fock space vector $\Psi \in \mathcal{F}$ to the functional $f[\phi(\cdot)]$ is defined from the relation

$$V: |0\rangle \mapsto c \exp\left[\frac{i}{2}\int \mathrm{d}\mathbf{x}\,\mathrm{d}\mathbf{y}\tilde{\mathcal{R}}(\mathbf{x},\mathbf{y})\phi(\mathbf{x})\phi(\mathbf{y})\right] \tag{3.16}$$

and from formula (2.1), which can be rewritten as

$$\begin{aligned} VA^+(\mathbf{x})V^{-1} &= \mathcal{A}^+(\mathbf{x}) \equiv \left(\hat{\Gamma}^{-1/2}\hat{\mathcal{R}}^*\phi - \hat{\Gamma}^{-1/2}\frac{1}{i}\frac{\delta}{\delta\phi}\right)(\mathbf{x}), \\ VA^-(\mathbf{x})V^{-1} &= \mathcal{A}^-(\mathbf{x}) \equiv \left(\hat{\Gamma}^{-1/2}\hat{\mathcal{R}}_\phi - \hat{\Gamma}^{-1/2}\frac{1}{i}\frac{\delta}{\delta\phi}\right)(\mathbf{x}). \end{aligned} \tag{3.17}$$

$|c|$ can be formally found from the normalization condition

$$|c|^2 \int D\phi \left|\exp\left[\frac{i}{2}\int \mathrm{d}\mathbf{x}\,\mathrm{d}\mathbf{y}\phi(\mathbf{x})\tilde{\mathcal{R}}(\mathbf{x},\mathbf{y})\phi(\mathbf{y})\right]\right|^2 = 1. \tag{3.18}$$

The argument can be chosen to be arbitrary, for example,

$$\operatorname{Arg} c = 0. \tag{3.19}$$

Notice that the operator V is defined from the relations (3.16)–(3.19) uniquely.

Namely, any element of the Fock space can be presented[42] via its components, vacuum state and creation operators as

$$\Psi = \sum_{n=0}^{\infty} \frac{1}{\sqrt{n!}} \int \mathrm{d}\mathbf{x}_1 \cdots \mathrm{d}\mathbf{x}_n \Psi_n(\mathbf{x}_1,\ldots,\mathbf{x}_n) A^+(\mathbf{x}_1)\cdots A^+(\mathbf{x}_n)|0\rangle$$

Specify

$$V\Psi = \sum_{n=0}^{\infty} \frac{1}{\sqrt{n!}} \int \mathrm{d}\mathbf{x}_1 \cdots \mathrm{d}\mathbf{x}_n \Psi_n(\mathbf{x}_1,\ldots,\mathbf{x}_n) \mathcal{A}^+(\mathbf{x}_1)\cdots\mathcal{A}^+(\mathbf{x}_n)V|0\rangle.$$

The problem of divergence of the series is related with the problem of correctness of the functional Schrödinger representation. It is not investigated here.

Since the operators $\mathcal{A}^\pm(\mathbf{x})$ satisfy usual canonical commutation relations and $\mathcal{A}^-(\mathbf{x})|0\rangle = 0$, we obtain $VA^\pm(\mathbf{x}) = \mathcal{A}^\pm(\mathbf{x})V$.

The operator V depends on $\mathcal{R}$. It is useful to find an explicit form of the operator $V^{-1}\delta V$.

It happens that the following property is satisfied:

$$\begin{aligned} V^{-1}\delta V = &-\frac{i}{2}A^+\hat{\Gamma}^{-1/2}\delta\hat{\mathcal{R}}\hat{\Gamma}^{-1/2}A^+ - \frac{i}{2}A^-\hat{\Gamma}^{-1/2}\delta\hat{\mathcal{R}}^*\hat{\Gamma}^{-1/2}A^- \\ &+ A^+[\hat{\Gamma}^{1/2}\delta\hat{\Gamma}^{-1/2} + i\hat{\Gamma}^{-1/2}\delta\hat{\mathcal{R}}^*\hat{\Gamma}^{-1/2}]A^- + \frac{i}{4}\operatorname{Tr}[\delta(\hat{\mathcal{R}}+\hat{\mathcal{R}}^*)\hat{\Gamma}^{-1}]. \end{aligned} \tag{3.20}$$

The notations of the type $A^+\hat{\mathcal{B}}A^-$ are used for the operators like $\int d\mathbf{x}\,d\mathbf{y}A^+(\mathbf{x})\tilde{\mathcal{B}}(\mathbf{x},\mathbf{y})A^-(\mathbf{y})$, where $\tilde{\mathcal{B}}(\mathbf{x},\mathbf{y})$ is a kernel of the operator $\hat{\mathcal{B}}$.

To check formula (3.20), consider the variation of the formula (2.1) if $\mathcal{R}$ is varied:

$$[A^{\pm}(\mathbf{x});V^{-1}\delta V]=(\hat{\Gamma}^{1/2}\delta\hat{\Gamma}^{-1/2}A^{\pm})(\mathbf{x})-i(\hat{\Gamma}^{-1/2}\delta\hat{\mathcal{R}}\hat{\Gamma}^{-1/2}A^{+})(\mathbf{x})+i(\hat{\Gamma}^{-1/2}\delta\hat{\mathcal{R}}^{*}\hat{\Gamma}^{-1/2}A^{-})(\mathbf{x}).$$

Therefore, formula (3.20) is correct up to an additive constant. To find it, note that

$$\delta V|0\rangle=\left[\frac{i}{2}\int d\mathbf{x}\,d\mathbf{y}\;\phi(\mathbf{x})\,\delta\tilde{\mathcal{R}}(\mathbf{x},\mathbf{y})\,\phi(\mathbf{y})+\delta\ln c\right]V|0\rangle.$$

This relation and formula (2.1) imply

$$\langle 0|V^{-1}\delta V|0\rangle=\frac{i}{2}\mathrm{Tr}(\delta\hat{\mathcal{R}}\hat{\Gamma}^{-1})+\delta\ln c.$$

It follows from the normalization conditions (3.18) and (3.19) that $c=(\det\hat{\Gamma})^{1/4}$. Therefore, $\delta\ln c=\frac{1}{4}\mathrm{Tr}\,\delta\hat{\Gamma}\hat{\Gamma}^{-1}$. Thus, $\langle 0|V^{-1}\delta V|0\rangle=(i/4)\mathrm{Tr}\,\delta(\hat{\mathcal{R}}+\hat{\mathcal{R}}^{*})\Gamma^{-1}$. Formula (3.20) is checked.

It follows from formula (3.15) that the generators $H(A:X)$ in the Fock representation are related with $\tilde{H}(A:X)$ by the following relation:

$$\breve{H}(A:X)=H(A:X)-i\,\delta[A]=V_x^{-1}(\tilde{H}[A:X]-i\,\delta[A])V_x.$$

We see that commutation relations (3.13) are invariant under change of representation.

An explicit form of operators $H(A:X)$ will be simplified if we consider the case when the quadratic form $\mathcal{R}$ is invariant under spatial translations and rotations:

$$\tilde{\mathcal{R}}(\mathbf{x},\mathbf{y}:u_{(\mathbf{a},L)}X)=\tilde{\mathcal{R}}(L^{-1}(\mathbf{x}-\mathbf{a}),L^{-1}(\mathbf{y}-\mathbf{a}):X). \tag{3.21}$$

This property implies that

$$\begin{gathered}[\partial_k;\hat{\mathcal{R}}]=\delta_P^k\hat{\mathcal{R}},\quad [\partial_k;\hat{\Gamma}^{1/2}]=\delta_P^k\hat{\Gamma}^{1/2},\\ [(x^k\partial_l-x^l\partial_k);\hat{\mathcal{R}}]=\delta_M^{kl}\hat{\mathcal{R}},\quad [(x^k\partial_l-x^l\partial_k);\hat{\Gamma}^{1/2}]=\delta_M^{kl}\hat{\Gamma}^{1/2}.\end{gathered} \tag{3.22}$$

The generators $H(A:X)$ are presented in Table III.

We see that renormalization is necessary since the evolution and boost generators contain divergent terms $\frac{1}{4}\mathrm{Tr}\,\hat{\Gamma}$ and $\frac{1}{4}\mathrm{Tr}\,x^k\hat{\Gamma}$ which are to be changed by finite renormalizaed terms $\frac{1}{4}\mathrm{Tr}_R\hat{\Gamma}$ and $\frac{1}{4}\mathrm{Tr}_R x^k\hat{\Gamma}$.

Let us check the commutation relations between $\breve{H}(A:X)$. Since the divergences arise in terms $\overline{B^k}$ and $\overline{H}$ only, we suppose them to be arbitrary and then find the conditions that provide Poincaré invariance.

Let

$$\breve{H}_k=\tfrac{1}{2}A^+\mathcal{H}_k^{++}A^++A^+\mathcal{H}^{+-}A^-+\tfrac{1}{2}A^-\mathcal{H}^{--}A^-+\overline{H_k+}\,i\,\delta_k$$

be arbitrary quadratic Hamiltonians. Then the property $[\breve{H}_1,\breve{H}_2]=i\breve{H}_3$ under condition $[i\,\delta_1,i\,\delta_2]=i^2\delta_3$ means that

$$\mathcal{H}_3^{++}=-i[\mathcal{H}_1^{+-}\mathcal{H}_2^{++}+\mathcal{H}_2^{++}(\mathcal{H}_1^{+-})^{*}-\mathcal{H}_1^{++}(\mathcal{H}_2^{+-})^{*}-\mathcal{H}_2^{+-}\mathcal{H}_1^{++}]+\delta_1\mathcal{H}_2^{++}-\delta_2\mathcal{H}_1^{++}, \tag{3.23}$$

TABLE III. Semiclassical Poincaré transformations in Fock representation.

Element of Poincaré group (a_τ,Λ_τ)	Semiclassical operator $U_{a_\tau,\Lambda_\tau}(u_{a_\tau,\Lambda_\tau}X\leftarrow X):\Psi_0\mapsto\Psi_\tau$ in the Fock representation takes the initial condition for the Cauchy problem to the solution of the Cauchy problem for the equation:
$a_\tau=0$	$i\dot{\Psi}^\tau=-\frac{1}{2}\theta_{sm}M^{sm}\Psi_\tau$
$\Lambda_\tau=\exp\left(\frac{\tau}{2}I^{sm}\theta_{sm}\right)$	$M^{kl}=-iA^+(x^k\partial_l-x^l\partial_k)A^-$
Spatial rotation	
$a_\tau^0=0\ \Lambda_\tau=1$	$i\Psi^\tau=b^kP^k\Psi_\tau$
$\mathbf{a}_\tau=\mathbf{b}\tau$	$P^k=-iA^+\partial_kA^-$
Spatial translation	
$a^0=-\dot{\tau},\ \mathbf{a}=0$	$i\dot{\Psi}^\tau=H(X_\tau)\Psi_\tau$
$\Lambda=1$	$H(X)=\frac{1}{2}A^-\mathcal{H}^{--}(X)A^-+A^+(\hat{\omega}+\mathcal{H}(X))A^-+\frac{1}{2}A^+\mathcal{H}^{++}(X)A^++\overline{H}$
	$\mathcal{H}^{++}(X)=\hat{\Gamma}^{-1/2}[\delta_H\hat{\mathcal{R}}-\hat{\mathcal{R}}\hat{\mathcal{R}}-(-\Delta+m^2+V''(\Phi(\mathbf{x}))]\hat{\Gamma}^{-1/2}$
	$\mathcal{H}^{--}(X)=(\mathcal{H}^{++})^+$
	$\mathcal{H}(X)=\hat{\Gamma}^{-1/2}(\hat{\mathcal{R}}\hat{\mathcal{R}}^*+(-\Delta+m^2+V'')\Phi(\mathbf{x}))-\frac{1}{2}\delta_H(\hat{\mathcal{R}}+\hat{\mathcal{R}}^x)$ $+\frac{i}{2}[\delta_H\hat{\Gamma}^{1/2};\hat{\Gamma}^{1/2};\hat{\Gamma}^{1/2}])\hat{\Gamma}^{-1/2}-\hat{\omega}$
	$\hat{\omega}=\sqrt{-\Delta+m^2}$
	Formally $\overline{H}=\overline{H}_{\mathrm{reg}}+\frac{1}{4}\mathrm{Tr}\hat{\Gamma}$
	$\overline{H}_{\mathrm{reg}}=-\frac{1}{4}\mathrm{Tr}[\mathcal{H}^{++}+\mathcal{H}^{--}]$
	$i\dot{\Psi}^\tau=n^mB^m(X_\tau)\Psi_\tau$
Evolution	
$a_\tau=0$	$B^k(X)=\frac{1}{2}A^-\mathcal{B}^{k--}(X)A^-+A^+(L_k+\mathcal{B}^k(X))A^-+\frac{1}{2}A^+\mathcal{B}^{k++}(X)A^++\overline{B^k}$
$\Lambda_\tau=\exp[-\tau m^kl^{k0}];$	$\mathcal{B}^{k++}(X)=\hat{\Gamma}^{-1/2}[\delta_k^B\hat{\mathcal{R}}-\hat{\mathcal{R}}x^k\hat{\mathcal{R}}-(-\partial_ix^k\partial_i+x^km^2+x^kV''(\Phi(\mathbf{x})))]\hat{\Gamma}^{-1/2}$
	$\mathcal{B}^{k--}=(\mathcal{B}^{++})^+$
	$\mathcal{B}^k=\hat{\Gamma}^{-1/2}\Big[\hat{\mathcal{R}}x^k\hat{\mathcal{R}}^*+(-\partial_ix^k\partial_i+x^km^2+x^kV''(\Phi(\mathbf{x})))$ $-\frac{1}{2}\delta_B^k(\hat{\mathcal{R}}+\hat{\mathcal{R}}^*)+\frac{i}{2}[\delta_k^B\hat{\Gamma}^{1/2},\hat{\Gamma}^{1/2}]\Big]\hat{\Gamma}^{-1/2}-L_k$
	$L_k=\frac{1}{2}\hat{\omega}^{-1/2}[\hat{\omega}x^k\hat{\omega}+(-\partial_ix^k\partial_i+x^km^2)]\hat{\omega}^{-1/2}$
	Formally $\overline{B^k}=\overline{B^k_{\mathrm{reg}}}+\frac{1}{4}\mathrm{Tr}\,x^k\hat{\Gamma}$
	$\overline{B^k_{\mathrm{reg}}}=-\frac{1}{4}\mathrm{Tr}[\mathcal{B}^{k++}+\mathcal{B}^{k--}]$
Boost	

$$\mathcal{H}_3^{+-}=-i\{\mathcal{H}_2^{++}(\mathcal{H}_1^{++})^*-\mathcal{H}_1^{++}(\mathcal{H}_2^{++})^*+[\mathcal{H}_1^{+-};(\mathcal{H}_2^{+-})]\}+\delta_1\mathcal{H}_2^{+-}-\delta_2\mathcal{H}_1^{+-},\quad(3.24)$$

$$\overline{H_3}=-\frac{i}{2}\mathrm{Tr}[\mathcal{H}_2^{++}(\mathcal{H}_1^{++})^*-\mathcal{H}_1^{++}(\mathcal{H}_2^{++})^*]+\delta_1\overline{H_2}-\delta_2\overline{H_1}.\quad(3.25)$$

Relations (3.23)–(3.25) are treated in sense of bilinear forms on $D(T)$.

Consider now the commutation relations.

(1) The relations

$$[\check{P}^k,\check{P}^l]=0, \quad [\check{M}^{lm},\check{P}^s]=i(g^{ms}\check{P}^l-g^{ls}\check{P}^m)$$

are satisfied automatically since

$$[\partial_k,\partial_l]=0, \quad -[x^l\partial_m-x^m\partial_l,\partial_s]=g^{ms}\partial_l-g^{ls}\partial_m.$$

(2) The relation

$$[\check{M}^{lm},\check{M}^{rs}]=-i(g^{lr}\check{M}^{ms}-g^{mr}\check{M}^{ls}+g^{ms}\check{M}^{lr}-g^{ls}\check{M}^{mr})$$

is also satisfied.

(3) For the relation

$$[\check{P}^k,\check{P}^0]=0$$

Eqs. (3.23)–(3.25) take the form

$$\delta_P^k\mathcal{H}^{++}-[\partial_k;\mathcal{H}^{++}]=0, \quad \delta_P^k\mathcal{H}^{+-}-[\partial_k;\mathcal{H}^{+-}]=0, \tag{3.26}$$

$$\delta_P^k\overline{H}=0. \tag{3.27}$$

(4) For the relation

$$[\check{M}^{kl},\check{P}^0]=0,$$

Eqs. (3.23)–(3.25) are written as

$$\delta_M^{kl}\mathcal{H}^{++}-[x^k\partial_l-x^l\partial_k;\mathcal{H}^{++}]=0, \quad \delta_M^{kl}\mathcal{H}^{+-}-[x^k\partial_l-x^l\partial_k;\mathcal{H}^{+-}]=0, \tag{3.28}$$

$$\delta_M^{kl}\overline{H}=0. \tag{3.29}$$

(5) Consider the relation

$$[\check{M}^{k0},\check{P}^s]=-ig^{ks}\check{P}^0.$$

We write Eqs. (3.23)–(3.25) as follows:

$$[\partial_s,\mathcal{B}^{k++}]-\delta_P^s\mathcal{B}^{k++}=-g^{ks}\mathcal{H}^{++}, \quad [\partial_s,\mathcal{B}^{k+-}]-\delta_P^s\mathcal{B}^{k+-}=-g^{ks}\mathcal{H}^{+-}, \tag{3.30}$$

$$\delta_P^s\overline{B^k}=g^{ks}\overline{H}. \tag{3.31}$$

(6) The commutation relation

$$[\check{M}^{lm},\check{M}^{k0}]=-i(g^{lk}\check{M}^{m0}-g^{mk}\check{M}^{l0})$$

is equivalent to

$$\begin{aligned}&[x^l\partial_m-x^m\partial_l;\mathcal{B}^{k++}]-\delta_M^{lm}\mathcal{B}^{k++}=g^{lk}\mathcal{B}^{m++}-g^{mk}\mathcal{B}^{l++},\\&[x^l\partial_m-x^m\partial_l;\mathcal{B}^{k+-}]-\delta_M^{lm}\mathcal{B}^{k+-}=g^{lk}\mathcal{B}^{m+-}-g^{mk}\mathcal{B}^{l+-},\end{aligned} \tag{3.32}$$

$$-\delta_M^{kl}\overline{B^k}=g^{lk}\overline{B^m}-g^{mk}\overline{B^l}. \tag{3.33}$$

(7) The most nontrivial commutation relations are

$$[\check{M}^{k0};\check{P}^{0}]=i\check{P}^{k},\quad [\check{M}^{k0};\check{M}^{l0}]=-i\check{M}^{kl}.$$

They can be rewritten as follows:

$$\begin{aligned}0&=-i\{\mathcal{B}^{k+-}\mathcal{H}^{++}+\mathcal{H}^{++}(\mathcal{B}^{k+-})^{*}-\mathcal{B}^{k++}(\mathcal{H}^{+-})^{*}-\mathcal{H}^{+-}(\mathcal{B}^{k++})\}+\delta_{B}^{k}\mathcal{H}^{++}-\delta_{H}\mathcal{B}^{k++},\\ -i\partial_{k}&=-i\{\mathcal{H}^{++}\mathcal{B}^{k++}-\mathcal{B}^{k++}(\mathcal{H}^{++})^{*}+[\mathcal{B}^{k+-};\mathcal{H}^{+-}]\}+\delta_{B}^{k}\mathcal{H}^{+-}-\delta_{H}\mathcal{B}^{k+-},\end{aligned}\tag{3.34}$$

$$0=-\frac{i}{2}\mathrm{Tr}[\mathcal{H}^{++}(\mathcal{B}^{k++})^{*}-\mathcal{B}^{k++}(\mathcal{H}^{++})^{*}]+\delta_{B}^{k}\overline{H}-\delta_{H}\overline{B^{k}},\tag{3.35}$$

and

$$\begin{aligned}0&=-i\{\mathcal{B}^{k+-}\mathcal{B}^{l++}+\mathcal{B}^{l++}(\mathcal{B}^{k+-})^{*}-\mathcal{B}^{k++}(\mathcal{B}^{l+-})^{*}-\mathcal{B}^{l+-}(\mathcal{B}^{k++})\}+\delta_{B}^{k}\mathcal{B}^{l++}-\delta_{B}^{l}\mathcal{B}^{k++},\\ i(x^{k}\partial_{l}-x^{l}\partial_{k})&=-i\{\mathcal{B}^{l++}\mathcal{B}^{k++}-\mathcal{B}^{k++}(\mathcal{B}^{l++})^{*}+[\mathcal{B}^{k+-};\mathcal{B}^{l+-}]\}+\delta_{B}^{k}\mathcal{B}^{l+-}-\delta_{B}^{l}\mathcal{B}^{k+-},\end{aligned}\tag{3.36}$$

$$0=-\frac{i}{2}\mathrm{Tr}[\mathcal{B}^{l++}(\mathcal{B}^{k++})^{*}-\mathcal{B}^{k++}(\mathcal{B}^{l++})^{*}]+\delta_{B}^{k}\overline{B^{l}}-\delta_{B}^{l}\overline{B^{k}}.\tag{3.37}$$

(3) Properties (3.26), (3.28), (3.30), and (3.32) are obvious corollaries of relation (3.22). Properties (3.34) and (3.36) are checked by nontrivial but also direct computations.

Properties (3.27), (3.29), (3.31), (3.33), (3.35), (3.37) will be satisfied if the renormalized trace satisfies the following properties:

$$\begin{gathered}\delta_{k}^{P}\,\mathrm{Tr}_{R}\hat{\Gamma}=0,\quad \delta_{kl}^{M}\,\mathrm{Tr}_{R}\hat{\Gamma}=0,\\ \delta_{l}^{P}\,\mathrm{Tr}_{R}x^{k}\hat{\Gamma}=-\delta^{kl}\,\mathrm{Tr}_{R}\hat{\Gamma},\quad \delta_{kl}^{M}\,\mathrm{Tr}_{R}x^{k}\hat{\Gamma}=\delta^{kl}\,\mathrm{Tr}_{R}x^{m}\hat{\Gamma}-\delta^{mk}\,\mathrm{Tr}_{R}x^{l}\hat{\Gamma},\\ \mathrm{Tr}[x^{l}(\delta_{k}^{B}\hat{\Gamma}-\hat{\mathcal{A}}x^{k}\hat{\Gamma}-x^{k}\hat{\mathcal{A}})-x^{k}(\delta_{l}^{B}\hat{\Gamma}-\hat{\mathcal{A}}x^{l}\hat{\Gamma}-\hat{\Gamma}x^{l}\hat{\mathcal{A}})]+\delta_{l}^{B}\,\mathrm{Tr}_{R}x^{k}\hat{\Gamma}-\delta_{k}^{B}\,\mathrm{Tr}_{R}x^{l}\hat{\Gamma}=0,\\ \mathrm{Tr}[x^{l}(\delta^{H}\hat{\Gamma}-\hat{\mathcal{A}}\hat{\Gamma}-\hat{\Gamma}\hat{\mathcal{A}})-(\delta_{l}^{B}\hat{\Gamma}-\hat{\mathcal{A}}x^{l}\hat{\Gamma}-\hat{\Gamma}x^{l}\hat{\mathcal{A}})]+\delta_{l}^{B}\,\mathrm{Tr}_{R}\hat{\Gamma}-\delta^{H}\mathrm{Tr}_{R}x^{l}\hat{\Gamma}=0,\end{gathered}\tag{3.38}$$

where $\hat{\mathcal{A}}=\frac{1}{2}(\hat{\mathcal{R}}+\hat{\mathcal{R}}^{*})$.

Thus, algebraic commutation relations are checked.

C. Conditions of integrability

The problem of reconstructing a representation of a local Lie group from a representation of a Lie algebra (''integrability problem'') is mathematically nontrivial. Different conditions of integrability were presented in Refs. 43–47.

The problem of reconstructing the operators $U_{g}(u_{g}X\leftarrow X)$ and checking the group property was discussed in detail in Ref. 48. It has been shown that the operators $U_{g}(u_{g}X\leftarrow X)$ are correctly defined under the following sufficient conditions.

Let $h(\alpha)$ be an arbitrary smooth curve on the Poincaré group.

P1. *For self-adjoint operators*

$$A_{k}=L_{k},\quad A_{d+k}=-i\partial_{k},\quad A_{2d+kd+l}=-i(x^{k}\partial_{l}-x^{l}\partial_{k}),\quad A_{2d+d^{2}+1}=\hat{\omega}$$

there exists such a positively definite operator T that

(1) $\|T^{-1/2}A_{j}T^{-1/2}\|<\infty$, $\|A_{j}T^{-1}\|<\infty$,

(2) *for all* t_{1} *there exists such a constant C that* $\|T^{1/2}e^{iA_{j}t}T^{-1/2}\|\leqslant C$, $\|Te^{-iA_{j}t}T^{-1}\|\leqslant C$, $t\in[-t_{1},t_{1}]$.

P2. *The α-dependent operator functions $T\mathcal{B}^{k++}(u_{h(\alpha)}X)$ and $T\mathcal{H}^{++}(u_{h(\alpha)}X)$ are continuous in the Hilbert–Schmidt topology $\|\cdot\|_2$.*

P3. *The α-dependent operator functions $\mathcal{B}^{k++}(u_{h(\alpha)}X)$ and $\mathcal{H}^{++}(u_{h(\alpha)}X)$ are continuously differentiable with respect to α in the Hilbert–Schmidt topology.*

P4. *The α-dependent operator functions $\mathcal{B}^{k}(u_{h(\alpha)}X)$, $\mathcal{H}(u_{h(\alpha)}X)$, $T\mathcal{B}^{k}(u_{h(\alpha)}X)T^{-1}$, $T^{1/2}\mathcal{B}^{k}(u_{h(\alpha)}X)T^{-1/2}$, $T\mathcal{H}(u_{h(\alpha)}X)T^{-1}$, $T^{1/2}\mathcal{H}(u_{h(\alpha)}X)T^{-1/2}$ are strongly continuous.*

P5. *The α-dependent operator functions $T^{-1/2}\mathcal{H}(u_{h(\alpha)}X)T^{-1/2}$, $T^{-1/2}\mathcal{B}^{k}(u_{h(\alpha)}X)T^{-1/2}$, $\mathcal{H}(u_{h(\alpha)}X)T^{-1}$, $\mathcal{B}^{k}(u_{h(\alpha)}X)T^{-1}$ are continuously differentiable with respect to α in the operator norm $\|\cdot\|$ topology.*

P6. *The functions $\overline{H}(u_{h(\alpha)}X)$ and $\overline{B^{k}}(u_{h(\alpha)}X)$ are continuous.*

The property P6 can be substituted by the following property.

P6′. (*a*) *The operators $\mathcal{B}^{k++}$ and $\mathcal{H}^{++}$ are of the trace class and* $\mathrm{Tr}\,\mathcal{B}^{k++}(u_{h(\alpha)}X)$ *and* $\mathrm{Tr}\mathcal{H}^{++}(u_{h(\alpha)}X)$ *are continuous functions of α.*

(*b*) *The functions* $\mathrm{Tr}_R\Gamma(u_{h(\alpha)}X)$ *and* $\mathrm{Tr}_R x^k\Gamma(u_{h(\alpha)}X)$ *are continuous.*

Let us first justify property P1.

Let

$$\hat{K}=\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}.$$

This is a bounded self-adjoint positively definite operator without zero eigenvalues. Therefore, $\hat{K}^{-1}\equiv T^{1/2}$ is a (nonbounded) self-adjoint operator and

$$T=\hat{\omega}^{1/4}(\mathbf{x}^2+1)\hat{\omega}^{1/2}(\mathbf{x}^2+1)\hat{\omega}^{1/4};$$

$T\geqslant c>0$ for some c.

The first part of property P1 is justified as follows. One should check that the following norms are finite:

$$\|\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\hat{\omega}\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\|,$$

$$\|\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\hat{\omega}x^s\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\|,$$

$$\|\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}(\hat{k}^jx^s-\hat{k}^sx^j)\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\|,$$

$$\|\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\hat{k}^j\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\|,$$

$$\|\hat{\omega}\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\|,$$

$$\|\hat{\omega}x^s\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\|,$$

$$\|(\hat{k}^jx^s-\hat{k}^sx^j)\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\|,$$

$$\|\hat{k}^j\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\hat{\omega}^{-1/4}(\mathbf{x}^2+1)^{-1}\hat{\omega}^{-1/4}\|,$$

where $\hat{k}^j=-i\partial/\partial x^j$.

To check this statement, it is sufficient to notice that lemma A6 implies that the operators

$$[\hat{\omega}^{\alpha};(x^2+1)^{-1}],\quad [\hat{\omega}^{\alpha};x^s(\mathbf{x}^2+1)^{-1}],\quad [\hat{\omega}^{\alpha};x^lx^s(\mathbf{x}^2+1)^{-1}] \tag{3.39}$$

are bounded if $\alpha\leqslant 1$.

To prove the second part of P1, represent it in the following form:

$$\|e^{iA_j+}T^{1/2}e^{-iA_jt}T^{-1/2}\|\equiv\|T_j^{1/2}(t)T^{-1/2}\|\leqslant C,\quad \|T_j(t)T^{-1}\|\leqslant C. \tag{3.40}$$

It is necessary to investigate the Poincaré transformation properties of the operators $\hat{x}^j$ and $\hat{k}^j$.

Notice that the following relations are satisfied:

$$e^{i\hat{\omega}t}\hat{x}^l e^{-i\tilde{\omega}t}=\hat{x}^l+\hat{k}^l\hat{\omega}^{-1}t,\quad e^{i\tilde{\omega}t}\hat{k}^l e^{-i\tilde{\omega}t}=\hat{k}^l,$$

$$e^{i\hat{k}^s a^s}\hat{x}^l e^{-i\hat{k}^s a^s}=\hat{x}^l+a^l,\quad e^{i\hat{k}^s a^s}\hat{k}^l e^{-i\hat{k}^s a^s}=\hat{k}^l,$$

$$\exp\left(\frac{i\tau}{2}\theta_{\mathrm{ms}}(\hat{x}^m\hat{k}^s-\hat{x}^s\hat{k}^m)\right)\hat{x}^l\exp\left(-\frac{i\tau}{2}\theta_{\mathrm{ms}}(\hat{x}^m\hat{k}^s-\hat{x}^s\hat{k}^m)\right)=(e^{-\tau\theta}\hat{x})^l,$$

$$\exp\left(\frac{i\tau}{2}\theta_{\mathrm{ms}}(\hat{x}^m\hat{k}^s-\hat{x}^s\hat{k}^m)\right)\hat{k}^l\exp\left(-\frac{i\tau}{2}\theta_{\mathrm{ms}}(\hat{x}^m\hat{k}^s-\hat{x}^s\hat{k}^m)\right)=(e^{-\tau\theta}\hat{k})^l;$$

$$e^{iL^1\tau}\hat{k}^l e^{-iL^1\tau}=\hat{k}^l,\quad l\geqslant 2;\quad e^{iL^1\tau}\hat{k}^1 e^{-iL^l\tau}=\hat{k}^l\cosh\tau-\hat{\omega}\sinh\tau.$$

The operators $\hat{X}^l(\tau)=e^{iL^1\tau}\hat{x}^l e^{-iL^1\tau}$ have the following Weyl symbols:

$$X^1=\frac{\omega_{\mathbf{k}}}{\omega_{\mathbf{k}}\cosh\tau-k^1\sinh\tau}x^1,\quad X^\alpha=x^\alpha+\frac{k^\alpha\sinh\tau x^1}{\omega_{\mathbf{k}}\cosh\tau-k^1\sinh\tau}.$$

To check the properties, it is sufficient to show that they are satisfied at $\tau=0$ and show that the derivatives of the left-hand and right-hand sides of these relations coincide.

Making use of commutation relations $[x^s,f(\hat{k})]=i(\partial_f/\partial k^s)(\hat{k})$ and boundedness of the operators (3.39), we find that operators (3.40) are bounded uniformly with respect to $t\in[0,t_1]$. Property P1 is checked.

D. Choice of the operator $\mathcal{R}$

Let us choose operator $\mathcal{R}$ in order to satisfy properties P1–P5, P7. We will use the notions of Appendix A. First, we construct such an asymptotic expansion of a Weyl symbol $\underset{\sim}{\mathcal{R}}_N$ that for $\underset{\sim}{\mathcal{R}}=\underset{\sim}{\mathcal{R}}_N$,

$$\begin{gathered}\deg[\,\delta_B^l\underset{\sim}{\mathcal{R}}-\underset{\sim}{\mathcal{R}}*x^l*\underset{\sim}{\mathcal{R}}-x^l(\omega_k^2+V''(\Phi(\mathbf{x})))]\rangle\max\{d/2,d-1\},\\ \deg[\,\delta_H\underset{\sim}{\mathcal{R}}-\underset{\sim}{\mathcal{R}}*\underset{\sim}{\mathcal{R}}-(\omega_k^2+V''(\Phi(\mathbf{x})))]\rangle\max\{d/2,d-1\}.\end{gathered}\tag{3.41}$$

Next, we will construct another asymptotic expansion of a Weyl symbol $\mathcal{R}$ which obeys the condition $\mathrm{Im}\,\underset{\sim}{\mathcal{R}}>0$ and approximately equals to $\underset{\sim}{\mathcal{R}}_N$ at large, $|k|$ so that Eqs. (3.41) are satisfied. This will imply that properties P2–P5, P6′ are satisfied.

Let us define the expansions $\underset{\sim}{\mathcal{R}}_N$ with the help of the following recursive relations. Set

$$\begin{gathered}\underset{\sim}{\mathcal{R}}_0=i\omega_k,\\ \underset{\sim}{\mathcal{S}}_n=-\delta_H\underset{\sim}{\mathcal{R}}_n+\underset{\sim}{\mathcal{R}}_n*\underset{\sim}{\mathcal{R}}_n+\omega_k^2+V''(\Phi(\mathbf{x})),\\ \underset{\sim}{\mathcal{R}}_{n+1}=\underset{\sim}{\mathcal{R}}_n+\frac{i}{2\omega_k}\underset{\sim}{\mathcal{S}}_n.\end{gathered}\tag{3.42}$$

Lemma 3.1: The following relation is satisfied:

$$\deg\underset{\sim}{\mathcal{S}}_n=n.$$

Proof: For $n=0$, $\underset{\sim}{\mathcal{S}}_0=V''(\Phi(\mathbf{x}))$, so that statement of lemma is satisfied. Suppose that statement of lemma is justified for $n<N$. Check it for $n=N$. One has

$$\underline{\mathcal{S}}_N=\underline{\mathcal{S}}_{N-1}+\underline{\mathcal{R}}_N*\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)+\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)*\underline{\mathcal{R}}_N+\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)*\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)-\frac{i}{2\omega_k}\delta_H\underline{\mathcal{S}}_{N-1}.$$

Since

$$\deg\left[\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)*\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)-\frac{i}{2\omega_k}\delta_H\underline{\mathcal{S}}_{N-1}\right]\geqslant\deg\underline{\mathcal{S}}_{N-1}+1=N$$

and

$$\begin{aligned}\underline{\mathcal{S}}_N&=\underline{\mathcal{S}}_{N-1}+\underline{\mathcal{R}}_N*\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)+\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)*\underline{\mathcal{R}}_N\\&\approx\underline{\mathcal{S}}_{N-1}+\underline{\mathcal{R}}_N\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)+\left(\frac{i}{2\omega_k}\underline{\mathcal{S}}_{N-1}\right)\underline{\mathcal{R}}_N=0\end{aligned}$$

up to terms of the degree N, one finds

$$\deg\underline{\mathcal{S}}_N=N.$$

Lemma 3.1 is proved.

Denote

$$\underline{X}^l_n=-\delta^l_B\underline{\mathcal{R}}_n+\underline{\mathcal{R}}_n*x^l*\underline{\mathcal{R}}_n+x^l(\omega_k^2+V''(\Phi(\mathbf{x}))).$$

Lemma 3.2: The following property is obeyed:

$$\delta^l_B\underline{\mathcal{S}}_n-\delta_H\underline{X}^l_n=-\underline{X}^l_n*\underline{\mathcal{R}}_n-\underline{\mathcal{R}}_n*\underline{X}^l_n+\underline{\mathcal{S}}_n*x^l*\underline{\mathcal{R}}_n+\underline{\mathcal{R}}_n*x^l*\underline{\mathcal{S}}_n. \tag{3.43}$$

Proof: Denote

$$\underline{F}^l_n=\delta^l_B\underline{\mathcal{S}}_n-\delta_H\underline{X}^l_n+\underline{X}^l_n*\underline{\mathcal{R}}_n+\underline{\mathcal{R}}_n*\underline{X}^l_n-\underline{\mathcal{S}}_n*x^l*\underline{\mathcal{R}}_n-\underline{\mathcal{R}}_n*x^l*\underline{\mathcal{S}}_n.$$

One has

$$\begin{aligned}\underline{F}^l_n=&(\delta^l_B-x^l\delta_H)V''(\Phi(\mathbf{x}))+[\delta_H;\delta^l_B]\underline{\mathcal{R}}_n-[x^l(\omega_k^2+V''(\Phi(\mathbf{x}))-(\omega_k^2+V''(\Phi(\mathbf{x}))*x^l]*\underline{\mathcal{R}}_n\\&+\underline{\mathcal{R}}_n*[x^l(\omega_k^2+V''(\Phi(\mathbf{x}))-x^l*(\omega_k^2+V''(\Phi(\mathbf{x}))].\end{aligned}$$

It follows from the definition of the Weyl symbol that

$$x^l*f(x,k)=\left(x^l+\frac{i}{2}\frac{\partial}{\partial k^l}\right)f(x,k).$$

One also has

$$(\delta^l_B-x^l\delta_H)V''(\Phi(\mathbf{x}))=0.$$

Thus,

$$\underline{F}^l_n=[\delta_H;\delta^l_B]\underline{\mathcal{R}}_n+ik^l*\underline{\mathcal{R}}_n-\underline{\mathcal{R}}_n*ik^l=\frac{\partial\underline{\mathcal{R}}_n}{\partial x^l}-\delta^l_P\underline{\mathcal{R}}_n.$$

However, the property

$$\frac{\partial \underline{\mathcal{R}}_n}{\partial x^l} = \delta_P^l \underline{\mathcal{R}}_n ,$$

which means that Eq. (3.21) is satisfied as checked by induction. Lemma 3.2 is proved.

Lemma 3.3: The following properties are satisfied:

(1) $\deg \underline{X}_n^l = n$.
(2) $\deg (\underline{X}_n^l - x^l \underline{\mathcal{S}}_n) \geqslant n+1$.

Proof: It follows from the results of the Appendix that X_n^l is an asymptotic expansion of a Weyl symbol. Let $\deg \underline{X}_n^l = \alpha$.

Suppose that $\alpha < n$. Then the left-hand side of Eq. (3.43) is of the degree α, the degree of the right-hand side of Eq. (3.43) is greater than or equal to $\alpha - 1$. In the leading order in $1/|k|$ the right-hand side has the form one has $(-2i\omega_k \underline{X}_n^l)$ and its degree should be greater than or equal to α. Therefore, $\deg \underline{X}_n^l \geqslant \alpha + 1$. We obtain a contradiction.

Suppose $\alpha > n$. Then the left-hand side of Eq. (3.43) is of the degree n, the right-hand side in the leading order in $1/|k|$ has the form $2i\omega_k x^l \underline{\mathcal{S}}_n$. So that $\deg \underline{\mathcal{S}}_n$ should obey the inequality $\deg \underline{\mathcal{S}}_n \geqslant n+1$. We also obtain a contradiction.

Thus, $\alpha = n$. In the leading order in $1/|k|$ one has

$$0 \approx -2i\omega_k (\underline{X}_n^l - x^l \underline{\mathcal{S}}_n)$$

up to terms of the degree n, so that $\deg(\underline{X}_n^l - x^l \underline{\mathcal{S}}_n) \geqslant n+1$. Lemma 3.3 is proved.

We see that for $N \geqslant \max\{d/2, d-1\}$ the properties (3.41) are satisfied.

Lemma 3.4: Let $\underline{\mathcal{R}}^{(1)}$ *and* $\underline{\mathcal{R}}^{(2)}$ *be asymptotic expansions of Weyl symbols,* $\deg \underline{\mathcal{R}}^{(1)} = \deg \underline{\mathcal{R}}^{(2)} = -1$ *and* $\deg(\underline{\mathcal{R}}^{(1)} - \underline{\mathcal{R}}^{(2)}) = N+1$. *Then*

$$\deg(\underline{X}^{(1)l} - \underline{X}^{(2)l}) = N$$

and

$$\deg(\underline{\mathcal{S}}^{(1)} - \underline{\mathcal{S}}^{(2)}) = N.$$

Proof: Denote $\underline{\mathcal{R}} - \underline{\mathcal{R}}^{(2)} = \underline{D}$. Then

$$\underline{X}^{(1)l} - \underline{X}^{(2)l} = -\delta_B^l \underline{D} + \underline{\mathcal{R}}^{(1)} * x^l * \underline{D} + \underline{D} * x^l * \underline{\mathcal{R}}^{(1)} + \underline{D} * \underline{D} * x^l * \underline{D}.$$

We see that $\deg(\underline{X}^{(1)l} - \underline{X}^{(2)l}) = N$. The second statement is checked analogously. Lemma 3.4 is proved.

Let us construct such an asymptotic expansion $\underline{\mathcal{R}}$ that $\deg(\underline{\mathcal{R}} - \underline{\mathcal{R}}_N) = N+1$ and $\operatorname{Im} \underline{\mathcal{R}} > 0$. We will look for $\underline{\mathcal{R}}$ as follows (cf. Ref. 36),

$$\underline{\mathcal{R}} = \underline{\mathcal{A}} + i\omega_k^{1/4} * \exp \underline{\mathcal{B}} * \omega_k^{1/4} * \exp \underline{\mathcal{B}} * \omega_k^{1/4},$$

where $\underline{\mathcal{A}}$ and $\underline{\mathcal{B}}$ are *real* asymptotic expansions. Then

$$\underline{\Gamma}^{1/2} = \omega_k^{1/4} * \exp \underline{\mathcal{B}} * \omega_k^{1/4},$$

$$\underline{\Gamma}^{-1/2} = \omega_k^{-1/4} * \exp(-\underline{\mathcal{B}}) * \omega_k^{-1/4},$$

are also asymptotic expansions of Weyl symbols. Choose $\underline{\mathcal{A}}$ and $\underline{\mathcal{B}}$ to be polynomials,

$$\underline{\mathcal{A}} = \sum_{s=1}^{S_1} \frac{A_s(\mathbf{x}, \mathbf{k}/\omega_{\mathbf{k}})}{\omega_{\mathbf{k}}^{2s}}, \quad \underline{\mathcal{B}} = \sum_{s=1}^{S_2} \frac{B_s(\mathbf{x}, \mathbf{k}/\omega_{\mathbf{k}})}{\omega_{\mathbf{k}}^{2s}},$$

where $S_1=[N/2]$, $S_2=[(N+1)/2]$.

Lemma 3.5: There exists unique functions $A_1,\ldots,A_{S_1},B_1,\ldots,B_{S_2}$ *such that* $\deg(\underline{\mathcal{R}}-\underline{\mathcal{R}}_N)=N+1$.

Proof: It follows from recursive relations (3.42) that

$$\operatorname{Re}\underline{\mathcal{R}}_N=\sum_{s=1}^{\infty}\frac{A_{N,s}(\mathbf{x},\mathbf{k}/\omega_{\mathbf{k}})}{\omega_{\mathbf{k}}^{2s}},$$

$$\operatorname{Im}\underline{\mathcal{R}}_N=\omega_{\mathbf{k}}+\sum_{s=1}^{\infty}\frac{C_{N,s}(\mathbf{x},\mathbf{k}/\omega_{\mathbf{k}})}{\omega_{\mathbf{k}}^{2s}}.$$

Therefore, $A_s=A_{N,s}$, so that $\underline{\mathcal{A}}$ is uniquely defined. Denote

$$\underline{\mathcal{B}_s}=\frac{B_s(\mathbf{x},\mathbf{k}/\omega_{\mathbf{k}})}{\omega_{\mathbf{k}}^{2s}}.$$

Show that $\underline{\mathcal{B}_s}$ is uniquely defined. In the leading order in $1/|\mathbf{k}|$, one has

$$\operatorname{Im}\underline{\mathcal{R}}\approx\omega_{\mathbf{k}}+2\underline{\mathcal{B}_1}\omega_{\mathrm{k}},$$

so that $B_1=C_{N,1}/2$. Suppose that one can choose $\underline{\mathcal{B}_1},\ldots,\underline{\mathcal{B}_{s-1}}$ in such a way that the degree of the asymptotic expansion of a Weyl symbol

$$\underline{F}_{N,s}=\operatorname{Im}\underline{\mathcal{R}}_N-\omega_{\mathbf{k}}^{1/4}*\exp(\underline{\mathcal{B}_1}+\cdots+\underline{\mathcal{B}_{s-1}})*\omega_{\mathbf{k}}^{1/2}*\exp(\underline{\mathcal{B}_1}+\ldots+\underline{\mathcal{B}_{s-1}})*\omega_{\mathbf{k}}^{1/4}$$

satisfies the inequality

$$\deg\underline{F}_{N,s}\geqslant 2s-1.$$

Choose $\underline{\mathcal{B}_s}$ in such a way that $\deg\underline{F}_{N,s}\geqslant 2s-1$. One has

$$\underline{F}_{N,s+1}=\operatorname{Im}\underline{\mathcal{R}}_N-\omega_{\mathbf{k}}^{1/4}*\sum_{l_1=0}^{\infty}\frac{(\underline{\mathcal{B}_1}+\cdots+\underline{\mathcal{B}_{s-1}}+\underline{B_s})^{l/1}}{l_1!}*\omega_{\mathbf{k}}^{1/2}*\sum_{l_2=0}^{\infty}\frac{(\underline{\mathcal{B}_1}+\cdots+\underline{\mathcal{B}_{s-1}}+\underline{\mathcal{B}_s})^{1/2}}{l_2!}*\omega_{\mathbf{k}}^{1/4}.$$

Up to terms of the degree $2s+1$, one has

$$\begin{aligned}\underline{F}_{N,s+1}&\approx\operatorname{Im}\underline{\mathcal{R}}_N\\&\quad-\omega_{\mathbf{k}}^{1/4}*\left(\sum_{l_1=0}^{\infty}\frac{(\underline{\mathcal{B}_1}+\cdots+\underline{\mathcal{B}_{s-1}})^{l/1}}{l_1!}+\underline{\mathcal{B}_s}\right)*\omega_{\mathbf{k}}^{1/2}*\left(\sum_{l_2=0}^{\infty}\frac{(\underline{\mathcal{B}_1}+\cdots+\underline{\mathcal{B}_{s-1}})^{l/2}}{l_2!}+\underline{\mathcal{B}_s}\right)*\omega_{\mathbf{k}}^{1/4}\\&\approx\underline{F}_{N,s}-2\underline{\mathcal{B}_s}\omega_{\mathbf{k}}.\end{aligned}$$

Since

$$\underline{F}_{N,s}=\frac{1}{\omega_{\mathbf{k}}^{2s-1}}\sum_{l=0}^{\infty}\frac{F_{N,s,l}(\mathbf{x},\mathbf{k}/\omega_{\mathbf{k}})}{\omega_{\mathbf{k}}^{l}},$$

one finds that

$$\underline{\mathcal{B}_s}=\frac{1}{2\omega_k^{2s}}F_{N,s,0}(\mathbf{x},\mathbf{k}/\omega_{\mathbf{k}})$$

is uniquely defined. Lemma 3.5 is proved.

Thus, we have constructed the operator $\mathcal{R}$ such that properties (3.41) are satisfied. We obtain the following theorem.

Theorem 3.6: *Properties* (3.21), $P2-P5$, $P6'(a)$ *are satisfied.*

This theorem is a direct corollary of the results of the Appendix. Property P1 is satisfied because of construction of the operator $\mathcal{R}$. Properties $P2-P5$, $P6'(a)$ are corollaries of Theorems A8, A9, A10, properties (3.41) and theorem A2.

E. Regularization and renormalization of a trace

The purpose of this section is to specify functionals $\mathrm{Tr}_R\Gamma$ and $\mathrm{Tr}_R x^k\Gamma$ of arguments Φ, Π in order to satisfy properties $P6'(b)$, (3.38). We want the renormalized trace to satisfy properties like these:

(i) $\mathrm{Tr}_R\hat{A}=\mathrm{Tr}\,\hat{A}$ if $\hat{A}$ is of the trace class,
(ii) $\mathrm{Tr}_R(\hat{A}+\lambda\hat{B})=\mathrm{Tr}_R\hat{A}+\lambda\,\mathrm{Tr}_R\hat{B}$,
(iii) $\mathrm{Tr}_R[\hat{A};\hat{B}]=0$,
(iv) $\mathrm{Tr}_R\hat{A}_n\to 0$ if $A_n\to 0$

for such class of operators that is as wide as possible. Under these conditions, properties $P6'(b)$ and (3.38) are satisfied. However, one cannot specify such a renormalized trace. Namely, one should have

$$\mathrm{Tr}_R\left[\hat{x}_j;\mathcal{W}\left(\frac{k_j}{\omega_{\mathbf{k}}^l}f(\mathbf{x})\right)\right]=0, \tag{3.44}$$

where $f\in S(\mathbf{R}^d)$. $\mathcal{W}(A)$ is a Weyl quantization of the function A (see the appendix). Property (3.44) means that

$$\mathrm{Tr}_R\mathcal{W}\left(i\frac{\partial}{\partial k_i}\frac{k_j}{\omega_{\mathbf{k}}^l}f(\mathbf{x})\right)=0.$$

Therefore,

$$\delta_{ij}\,\mathrm{Tr}_R\mathcal{W}\left(\frac{f(\mathbf{x})}{\omega_{\mathbf{k}}^l}\right)-l\,\mathrm{Tr}_R\mathcal{W}\left(\frac{k_ik_j}{\omega_{\mathbf{k}}^{l+2}}f(\mathbf{x})\right)=0. \tag{3.45}$$

Choose $l=d$. Consider $i=j$ in Eq. (3.45) and perform the summation over i. Making use of the relation $\omega_{\mathbf{k}}^2-k_ik_i=m^2$, we find

$$\mathrm{Tr}_R\mathcal{W}(m^2\omega_{\mathbf{k}}^{-d-2}f(\mathbf{x}))=0.$$

However, the operator with Weyl symbol $m^2f(\mathbf{x})\omega_{\mathbf{k}}^{-d-2}$ is of the trace class. Its trace is nonzero, provided that $\int d\mathbf{x}\,f(x)\neq 0$.

However, we can introduce a notion of a trace for *asymptotic expansions of Weyl symbols*. The trace will be specified not only by operator but also by its asymptotic expansion which is not unique (see the remark after definition A6).

Let $\underline{A}=(A,\check{A})$ be asymptotic expansion of a Weyl symbol. Suppose that the coefficients A_l of the formal asymptotic expansion

$$\check{A}\equiv\sum_{l=0}^{\infty}\omega_{\mathbf{k}}^{-\alpha-l}A_l(x,\mathbf{k}/\omega_{\mathbf{k}})$$

are polynomial in $\mathbf{k}/\omega_{\mathbf{k}}$. One formally has

$$\mathrm{Tr}_R \underline{A} = \sum_{l=0}^{l_0} \int \frac{\mathrm{d}\mathbf{k}\, d\mathbf{x}}{(2\pi)^d} \frac{1}{\omega_{\mathbf{k}}^{\alpha+l}} A_l(\mathbf{x}, \mathbf{k}/\omega_{\mathbf{k}}) + \int \frac{\mathrm{d}\mathbf{k}\, \mathrm{d}\mathbf{x}}{(2\pi)^d} \left(A(\mathbf{x}, \mathbf{k}) - \sum_{l=0}^{l_0} \frac{1}{\omega_{\mathbf{k}}^{\alpha+l}} A_l(\mathbf{x}, \mathbf{k}/\omega_{\mathbf{k}}) \right). \tag{3.46}$$

For $\alpha + l_0 + 1 > d$, the last integral on the right-hand side of Eq. (3.46) converges. To specify trace, it is sufficient then to specify values of integrals

$$I^{s,n}_{i_1 \ldots i_n} = \int \frac{\mathrm{d}\mathbf{k}}{\omega_{\mathbf{k}}^s} \frac{k_{i_1}}{\omega_{\mathbf{k}}} \cdots \frac{k_{i_n}}{\omega_{\mathbf{k}}} \tag{3.47}$$

for $s \leqslant d$ which are divergent. We will define the quantities (3.47), making use of the following argumentation.

(1) We are going to specify trace in such a way that

$$\mathrm{Tr}_R \frac{\partial}{\partial k_i} \underline{A} = 0. \tag{3.48}$$

Let

$$\underline{A} = \frac{1}{\omega_{\mathbf{k}}^{s-1}} \frac{k_{j_1}}{\omega_{\mathbf{k}}} \cdots \frac{k_{j_{n+1}}}{\omega_{\mathbf{k}}},$$

property (3.48) implies the following recursive relations:

$$\sum_{s=1}^{n+1} \delta_{ij_s} I^{s,n}_{j_1 \ldots j_{s-1} j_{s+1} \ldots j_{n+1}} = (s+n) I^{s,n+2}_{i j_1 \ldots j_{n+1}}. \tag{3.49}$$

Therefore, $I^{s,n} = 0$ for odd n, while for even n $I^{s,n}$ is defined from Eq. (3.49), for example, $I^{s,2}_{ij} = (1/s)\, \delta_{ij} I^{s,0}$. Therefore, it is sufficient to define integrals

$$I^{s,0} = \int \mathrm{d}\mathbf{k}\, \omega_{\mathbf{k}}^{-s}. \tag{3.50}$$

Let us use the approach based on the dimensional regularization.[49,50] It is based on considering integrals (3.50) at arbitrary dimensionality of space–time. Expression (3.50) appears to be a meromorphic function of d. Subtracting the poles corresponding to sufficiently small positive integer values of d, we obtain a finite expression.

Formally, one has

$$I^{s,0} = \frac{1}{\Gamma(s/2)} \int_0^\infty \mathrm{d}\alpha\, \alpha^{s/2-1} \int \mathrm{d}\mathbf{k}\, e^{-\alpha(\mathbf{k}^2 + m^2)} = \frac{\pi^{d/2}}{\Gamma(s/2)} \frac{\Gamma\left(\frac{s-d}{2}\right)}{m^{s-d}}.$$

If $(s-d)/2 = -N$ is a nonpositive integer number, one should modify the definition of $I^{s,0}$. Change $d \to d - 2\varepsilon$. One finds

$$\begin{aligned} I^{s,0} &= \frac{\pi^{d/2}}{\Gamma(s/2) m^{s-d}} \frac{\Gamma(1+\varepsilon)(\pi m^2)^{-\varepsilon}}{(-N+\varepsilon)\cdots(-1+\varepsilon)\varepsilon} \\ &\approx \frac{\pi^{d/2}(-1)^N}{\Gamma(s/2) m^{s-d} N! \varepsilon} (1 + \varepsilon(-\ln(\pi m^2) + \Gamma'(1) + 1 + \cdots + N^{-1})) + O(\varepsilon). \end{aligned}$$

In the *MS* renormalization scheme,[50] one should omit the term $O(\varepsilon^{-1})$. There is also an $\overline{MS}$ renormalization scheme in which one omits also a fixed term of order $O(1)$. Let us omit the term $-\ln(\pi m^2)+\Gamma'(1)$. We obtain the following renormalized value of the integral:

$$I^{s,0}_{\mathrm{ren}}=\frac{\pi^{d/2}}{\Gamma(s/2)m^{s-d}}\frac{(-1)^N}{N!}(1+\cdots+1/N),$$

provided that $N=(d-s)/2$ is a non-negative integer number.

Therefore, we have defined the renormalized trace of an asymptotic expansion of a Weyl symbol by formula (3.46), provided that the coefficient functions are polynomials in $\mathbf{k}/\omega_{\mathbf{k}}$.

Let us investigate properties of the renormalized trace. Some properties are direct corollaries of definition (3.46).

Lemma 3.7: The following properties are satisfied:

(i) $\mathrm{Tr}_R(\underline{A}+\lambda\underline{B})=0$.
(ii) $\mathrm{Tr}_R(\partial\underline{A}/\partial k_i)=0$, $\mathrm{Tr}_R(\partial\underline{A}/\partial x_i)=0$.
(iii) *Let* $E-\lim_{n\to\infty}\underline{A}_n=\underline{A}$. *Then* $\lim_{n\to\infty}\mathrm{Tr}_R\underline{A}_n=\mathrm{Tr}_R\underline{A}$.
(iv) *Let* $\deg\underline{A}>d$. *Then* $\mathrm{Tr}_R\underline{A}=\mathrm{Tr}A$.

Corollary: The property P9 is satisfied.

Let us check that $\mathrm{Tr}_R(\underline{A}*\underline{B}-\underline{B}*\underline{A})=0$. First of all, prove the following statement.

Lemma 3.8: $\mathrm{Tr}_R\underline{A}*\underline{B}=\mathrm{Tr}_RAB$.

Proof: Making use of Eq. (A2), we find

$$\begin{aligned}
&(A*B)(\mathbf{x},\mathbf{k})-(AB)(\mathbf{x},\mathbf{k})\\
&\quad=\int\frac{d\mathbf{P}_1d\mathbf{p}_2d\mathbf{y}_1d\mathbf{y}_2}{(2\pi)^{2d}}\int_0^1 d\alpha\frac{\partial}{\partial\alpha}\left[A\left(\mathbf{x}+\mathbf{y}_1;\mathbf{k}+\alpha\frac{\mathbf{p}_2}{2}\right)B\left(\mathbf{x}+\mathbf{y}_2,\mathbf{k}_2-\alpha\frac{\mathbf{p}_1}{2}\right)\right]e^{-i\mathbf{p}_1\mathbf{y}_1-i\mathbf{p}_2\mathbf{y}_2}\\
&\quad=-\frac{i}{2}\int\frac{d\mathbf{p}_1d\mathbf{P}_2d\mathbf{y}_1d\mathbf{y}_2}{(2\pi)^{2d}}\int_0^1 d\alpha\left[\frac{\partial}{\partial k^i}A\left(\mathbf{x}+\mathbf{y}_1;\mathbf{k}+\alpha\frac{\mathbf{p}_2}{2}\right)\frac{\partial}{\partial x^i}B\left(\mathbf{x}+\mathbf{y}_2,\mathbf{k}_2-\alpha\frac{\mathbf{p}_1}{2}\right)\right.\\
&\qquad\left.-\frac{\partial}{\partial x^i}A\left(\mathbf{x}+\mathbf{y}_1;\mathbf{k}+\alpha\frac{\mathbf{p}_2}{2}\right)\frac{\partial}{\partial k^i}B\left(\mathbf{x}+\mathbf{y}_2,\mathbf{k}_2-\alpha\frac{\mathbf{p}_1}{2}\right)\right]e^{-i\mathbf{p}_1\mathbf{y}_1-i\mathbf{p}_2\mathbf{y}_2}\\
&\quad=-\frac{i}{2}\frac{\partial C^i(\mathbf{x},\mathbf{k})}{\partial k^i}
\end{aligned}$$

with

$$\begin{aligned}
C^i(\mathbf{x},\mathbf{k})=f\frac{d\mathbf{p}_1d\mathbf{p}_2d\mathbf{y}_1d\mathbf{y}_2}{(2\pi)^{2d}}\int_0^1 d\alpha\left[A\left(\mathbf{x}+\mathbf{y}_1;\mathbf{k}+\alpha\frac{\mathbf{p}_2}{2}\right)\frac{\partial}{\partial x^i}B\left(\mathbf{x}+\mathbf{y}_2,\mathbf{k}_2-\alpha\frac{\mathbf{p}_1}{2}\right)\right.\\
\left.-B\left(\mathbf{x}+\mathbf{y}_2,\mathbf{k}_2-\alpha\frac{\partial}{\partial x^i}A\left(\mathbf{x}+\mathbf{y}_1;\mathbf{k}+\alpha\frac{\mathbf{p}_2}{2}\right)\frac{\mathbf{p}_1}{2}\right)\right]e^{-i\mathbf{p}_1\mathbf{y}_1-i\mathbf{p}_2\mathbf{y}_2}.
\end{aligned}$$

One also has

$$\check{A}*\check{B}-\check{A}\check{B}=-\frac{i}{2}\frac{\partial\check{C}^j}{\partial k^j}$$

with

$$\check{C}^j(\mathbf{x},\mathbf{k})=\sum_{s=0}^{\infty}\sum_{l_1 l_2\geqslant 0;l_1+l_2=s}\frac{(-i)^{l_1}}{2l_1 l_1!}\frac{i^{l_2}}{2^{l/2}l_2!}\frac{1}{l_1+l_2+1}$$
$$\times\left[\frac{\partial^{l_1+l_2}\check{A}}{\partial k^i 1\ldots\partial k^{il_1}\partial x^{j1}\ldots\partial x^{jl_2}}\frac{\partial}{\partial x^i}\frac{\partial^{l_1+l_2}\check{B}}{\partial k^j 1\ldots\partial k^{jl_2}\partial x^{i_1}\ldots\partial x^{i_{l_1}}}\right.$$
$$\left.-\frac{\partial_{l_1}+l_2\check{B}}{\partial k^{j_1}\ldots\partial k^{j_{i_2}}\partial x^{i_1}\ldots\partial x^{i_{l_1}}}\frac{\partial}{\partial x^i}\frac{\partial^{l_1+l_2}\check{A}}{\partial k^{i_1}\ldots\partial k^{i_{l_1}}\partial x^{j_1}\ldots\partial x^{jl_2}}\right].$$

Analogously to the Appendix, one finds that $(C^j,\check{C}^j)\equiv\check{C}^j$ is an asymptotic expansion of a Weyl symbol. It follows from lemma 3.7 that $\mathrm{Tr}_R(\partial\underline{C}^j/\partial k^j)=0$. We obtain statement of lemma 3.8.

Lemma 3.9: For $\deg\underline{B}\geqslant 2$, $\mathrm{Tr}_R x^k\omega_{\mathbf{k}}*\underline{B}=\mathrm{Tr}_R x^k\omega_{\mathbf{k}}\underline{B}$ *and* $\mathrm{Tr}_R\omega_{\mathbf{k}}*\underline{B}=\mathrm{Tr}_R\omega_{\mathbf{k}}\underline{B}$. The proof is analogous.

Corollary 1: The following relations are satisfied:

(1) $\mathrm{Tr}_R(\underline{A}*\underline{B}-\underline{B}*\underline{A})=0$,
(2) $\mathrm{Tr}_R(x^k\omega_{\mathbf{k}}*\underline{B}-\underline{B}x^k\omega_{\mathbf{k}})=0$,
(3) $\mathrm{Tr}_R(\omega_{\mathbf{k}}*\underline{B}-\underline{B}*\omega_{\mathbf{k}})=0$.

Corollary 2: Property (3.38) *is satisfied.*

Thus, we have constructed functionals $\mathrm{Tr}_R x^k\hat{\Gamma}\equiv\mathrm{Tr}_R x^k\underline{\Gamma}$ and $\mathrm{Tr}_R\hat{\Gamma}\equiv\mathrm{Tr}_R\underline{\Gamma}$ such that properties (3.38) and P6′(b) are satisfied.

Note that the "finite renormalization"[25] can also be made. One can add quantities $\Delta\,\mathrm{Tr}_R x^k\hat{\Gamma}$ and $\Delta\,\mathrm{Tr}_R\hat{\Gamma}$ to renormalized traces in such a way that

$$\delta_k^P\Delta\,\mathrm{Tr}_R\hat{\Gamma}=0,\quad \delta_{kl}^M\Delta\,\mathrm{Tr}_R\hat{\Gamma}=0,$$

$$\delta_P^l\Delta\,\mathrm{Tr}_R x^k\hat{\Gamma}=-\delta^{kl}\Delta\,\mathrm{Tr}_R\hat{\Gamma},\quad \delta_{kl}^M\Delta\,\mathrm{Tr}_R x^k\hat{\Gamma}=\delta^{kl}\Delta\,\mathrm{Tr}_R x^m\hat{\Gamma}-\delta^{mk}\Delta\,\mathrm{Tr}_R x^l\hat{\Gamma},$$

$$\delta_l^B\Delta\,\mathrm{Tr}_R x^k\hat{\Gamma}-\delta_k^B\Delta\,\mathrm{Tr}_R x^l\hat{\Gamma}=0,$$

$$\delta_l^B\Delta\,\mathrm{Tr}_R\hat{\Gamma}-\delta^H\Delta\,\mathrm{Tr}_R x^l\hat{\Gamma}=0.$$

This corresponds to the possibility of adding the finite one-loop counterterm to the Lagrangian.

IV. SEMICLASSICAL FIELD

An important feature of QFT is a notion of field. In this section we introduce the notion of a semiclassical field and check its Poincaré invariance.

A. Definition of semiclassical field

First of all, introduce the notion of a semiclassical field $\tilde{\phi}(\mathbf{x},t:X)$ in the functional Schrödinger representation. At $t=0$, this is the operator of multiplication by $\phi(\mathbf{x})$. For arbitrary t, one has

$$\tilde{\phi}(\mathbf{x},t:X)=\tilde{U}_{-t}(X\leftarrow u_t X)\,\phi(\mathbf{x})\,\tilde{U}_t(u_t X\leftarrow X),$$

where $\tilde{U}_t(u_t X\leftarrow X)$ is the operator transforming the initial condition for the Cauchy problem for Eq. (1.6) to the solution to the Cauchy problem.

The field operator in the Fock representation is related to $\tilde{\phi}$ by the transformation (2.1),

$$\tilde{\phi}(\mathbf{x},t:X)=V_X^{-1}\tilde{\phi}(\mathbf{x},t:X)V_X.$$

Making use of Eq. (3.15), one finds

$$\hat{\phi}(\mathbf{x},t:X)=(U_H^t(X))^{-1}\tilde{\phi}(\mathbf{x},u_tX)U_H^t(X). \tag{4.1}$$

Here $\hat{\phi}(\mathbf{x}:X)=i(\Gamma^{-1/2}(A^+-A^-))(\mathbf{x})$, while

$$U_H^t(X)\equiv U_{a,\Lambda}(u_{a,\Lambda}X\leftarrow X),\quad \Lambda=1,\quad \mathbf{a}=0,\quad a^0=-t.$$

Let us define $\hat{\phi}$ mathematically as an operator distribution.

Let $S(\mathbf{R}^d)$ be a space of complex smooth functions $u:\mathbf{R}^d\to\mathbf{C}$ such that

$$\|u\|_{l,m}=\max_{\alpha_1+\cdots+\alpha_d\leqslant l}\sup_{\mathbf{x}\in\mathbf{R}^d}(1+|\mathbf{x}|)^m\left|\frac{\partial^{\alpha_1+\cdots+\alpha_d}}{\partial x^{\alpha_1}\cdots\partial x^{\alpha_d}}u(\mathbf{x})\right|\to_{k\to\infty}0.$$

We say that the sequence $\{u_k\}\in S(\mathbf{R}^n)$, $k=\overline{1,\infty}$ tends to zero if $\|u_k\|_{l,m}\to_{k\to\infty}0$ for all l,m.

Denote $\mathcal{D}=\{\Psi\in\mathcal{F}\|A^+TA^-\Psi\|<\infty\}$ (cf. Ref. 48).

Definition 4.1 (cf. Ref. 20): (1) An operator distribution ϕ defined on $\mathcal{D}\in\mathcal{F}$ is a linear mapping taking functions $f\in S(\mathbf{R}^d)$ to the linear operator $\phi[f]:\mathcal{D}\to\mathcal{F}$,

$$\phi:f\in S(\mathbf{R}^d)\mapsto\phi[f]:\mathcal{D}\to\mathcal{F},$$

such that $\|\phi[f_n]\Phi\|\to_{n\to\infty}0$ if $f_n\to_{n\to\infty}0$.

(2) Λ sequence of operator distributions ϕ_n is called convergent to the operator distribution ϕ if

$$\|\phi_n[f]\Phi-\phi[f]\Phi\|\to_{n\to\infty}0$$

for all $\Phi\in\mathcal{D}$, $f\in S(\mathbf{R}^d)$.

We will write

$$\phi[f]\equiv\int \mathrm{d}\mathbf{x}\phi(\mathbf{x})f(\mathbf{x}),\quad \mathbf{x}\in\mathbf{R}^d.$$

Consider the mapping $f\mapsto\phi_t\{f\}$, $f\in S(\mathbf{R}^d)$ of the form

$$\phi_t\{f:X\}=\int \mathrm{d}\mathbf{x}\,\hat{\phi}(\mathbf{x},t:X)f(\mathbf{x}).$$

It follows from the results of Ref. 48 that ϕ_t is an operator distribution being continuous with respect to t.

Consider the mapping $f\mapsto\phi[f]$, $f\in S(\mathbf{R}^{d+1})$ of the form

$$\phi[f:X]=\int \mathrm{d}t\,\phi_t\{f(\cdot,t):X\}.$$

Analogously, note also that ϕ is an operator distribution.

B. Poincaré invariance of the semiclassical field

1. Algebraic properties

To check the property of Poincaré invariance, notice that it is sufficient to check it for partial cases: spatial translations, rotations, evolution, boost, since any Poincaré transformation can be presented as a composition of these transformations. Let $g_B(\tau)=(a(\tau),\Lambda(\tau))$ be a one-parametric subgroup of Poincaré group corresponding to the element B of the Poincaré algebra. The Poincaré invariance property can be rewritten as

$$\hat{\phi}[f:X]=(U_B^\tau(X))^+\phi[v_{g_B(\tau)}f:U_{g_B(\tau)}X]U_B^\tau[X], \tag{4.2}$$

where

$$(v_{g_B(\tau)}f)(x)=f(\Lambda^{-1}(\tau)(x-a(\tau))).$$

Obviously, $v_{g_1}v_{g_2}=v_{g_1g_2}$.

Let us check relation (4.2). It is convenient to reduce the group property to an algebraic property. The formal derivative with respect to τ of the right-hand side of Eq. (4.2) is

$$(U_B^\tau(X))^+\left\{i[H(B:u_{g_B(\tau)}X);\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]]+\frac{\partial}{\partial\tau}\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]\right\}U_B^\tau(X). \tag{4.3}$$

If the quantity (4.3) vanishes, the property (4.2) will be satisfied since it is obeyed at $\tau=0$. Making use of the group property $g_B(\tau+\delta\tau)=g_B(\delta\tau)g_B(\tau)$, we find that vanishing of expression (4.3) is equivalent to the property:

$$\left.\frac{\partial}{\partial\tau}\right|_{\tau=0}\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]-i[\phi[f:X];H(B:X)]=0. \tag{4.4}$$

We obtain the following lemma.

Lemma 4.1: Let the bilinear form (4.4) vanish on $\mathcal{D}$. Then the property (4.2) is satisfied on $\mathcal{D}$.

Proof: Consider the matrix element

$$\chi^\tau=(U_B^\tau(X)\Psi_1,\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]U_B^\tau(X)\Psi_2)-(\Psi_1,\hat{\phi}[f:X]\Psi_2),$$

where Ψ_1, $\Psi_2\in\mathcal{D}$. Show it to be differentiable with respect to τ. Let us check that for $\Psi\in\mathcal{D}$, the vector $\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]\Psi$ is strongly continuously differentiable with respect to τ.

One has

$$\frac{\phi[v_{g_B(\tau+\delta\tau)}f:u_{g_B(\tau+\delta\tau)}X]-\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]}{\delta\tau}\Psi$$

$$=\phi\left[\frac{v_{g_B(\delta\tau)}-1}{\delta\tau}v_{g_B(\tau)}f:u_{g_B(\tau+\delta\tau)}X\right]\Psi+\frac{\phi[v_{g_B(\tau)}f:u_{g_B(\delta\tau)g_B(\tau)}X]-\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]}{\delta\tau}\Psi.$$

It follows from Ref. 48 that the first term tends to $\phi[(\partial/\partial t)|_{t=0}v_{g_B(t)}v_{g_B(\tau)}f:u_{g_B(\tau)}X]\Psi$, while the second term tends to $\delta[B]\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]\Psi$.

Notice that

$$\frac{\chi^{\tau+\delta\tau}-\chi^\tau}{\delta\tau}=\left(\phi[v_{g_B(\tau+\delta\tau)}f:u_{g_B(\tau+\delta\tau)}X]U_B^{\tau+\delta\tau}(X)\Psi_1;\frac{U_B^{\tau+\delta\tau}(X)-U_B^\tau}{\delta\tau}\Psi_2\right)$$
$$+(U_B^{\tau+\delta\tau}(X)\Psi_1;(\phi[v_{g_B(\tau+\delta\tau)}f:u_{g_B(\tau+\delta\tau)}X]-\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X])U_B^\tau(X)\Psi_2)$$
$$+((U_B^{\tau+\delta\tau}(X)-U_B^\tau(X))\Psi_1;\phi[v_{g_B(\tau)}f:u_{g_B(\tau)}X]U_B^\tau(X)\Psi_2).$$

This quantity tends as $\delta\tau\to0$ to the matrix element of the bilinear form (4.3) and vanishes under condition (4.4). Lemma 4.1 is proved.

2. Check of invariance

One should check property (4.2) for spatial translations and rotations, evolution, and boost transformations.

For spatial translations and rotations, property (4.2) reads

$$\hat{\phi}(\mathbf{x},t:X)=U_{0,\mathbf{a},L}^{-1}\hat{\phi}(L\mathbf{x}+\mathbf{a},t:u_{0,\mathbf{a},L}X)U_{0,\mathbf{a},L}\,. \tag{4.5}$$

It follows from commutativity of $U_{0,\mathbf{a},L}$ and U_t and Table III that property (4.5) is satisfied.

For evolution operator, property (4.2) is rewritten as

$$\hat{\phi}(\mathbf{x},t:X)=(U_H^{\tau}(X))^{-1}\hat{\phi}(\mathbf{x},t-\tau:u_{\tau}X)U_H^{\tau}(X). \tag{4.6}$$

Relation (4.6) is a direct corollary of definition (4.1) and group property for evolution operators.

Consider now the **n**-boost transformation. Check property (4.4). It can be presented as

$$[\check{B}^k;\hat{\phi}(\mathbf{x},t;X)]=-i\left(x^k\frac{\partial}{\partial t}+t\frac{\partial}{\partial x^k}\right)\hat{\phi}(\mathbf{x},t:X)$$

or

$$\begin{aligned}&[B^k(X);(U_H^t(X))^{-1}\phi(\mathbf{x}:u_tX)U_H^t(X)]+i\delta_B^k\{(U_H^t(X))^{-1}\phi(\mathbf{x}:u_tX)U_H^t(X)\}\\&\quad=-i\left(x^k\frac{\partial}{\partial t}+t\frac{\partial}{\partial x^k}\right)(U_H^t(X))^{-1}\phi(\mathbf{x}:u_tX)U_H^t(X).\end{aligned} \tag{4.7}$$

Let us make use of the property

$$U_H^t(X)B^K(X)=i(\delta_B^kU_H^t)(X)+[B^k(u_tX)-tP^k(u_tX)]U_H^t(X), \tag{4.8}$$

which can be checked by multiplication by $(U_H^t(X))^{-1}$ and differentiation with respect to t in a weak sense (cf. Ref. 48). We take relation (4.7) to the form

$$[\check{B}^k(Y)-\check{P}^k(Y)t;\phi(\mathbf{x}:Y)]=x^k[\check{H}(Y);\phi(\mathbf{x}:Y)]-it\frac{\partial\phi(\mathbf{x}:Y)}{\partial x^k},$$

where $Y=u_tX$. The property

$$i\frac{\partial\phi(\mathbf{x}:Y)}{\partial x^k}=[\check{P}^k(Y);\phi(\mathbf{x}:Y)]$$

is a corollary of relation (3.22). The relation

$$[\check{B}^k(Y)-x^k\check{H}(Y);\phi(\mathbf{x}:Y)]=0$$

is also checked by direct calculation.

Thus, we have obtained that the invariance property (2.5) is satisfied.

V. REMARKS ON COMPOSED SEMICLASSICAL STATES

In the soliton quantization theory and in gauge field theories, the zero-mode problem arises.[2] To resolve it, one can consider the superposition of the ''elementary'' quantum field semiclassical states (1.3) of the form (cf. Ref. 36)

$$\psi[\varphi(\cdot)]=\int\frac{\mathrm{d}\alpha}{\lambda^{k/4}}\exp\left(\frac{i}{\lambda}S(\alpha)\right)\exp\left(\frac{i}{\lambda}\Pi(\alpha;\mathbf{x})[\varphi(\mathbf{x})\sqrt{\lambda}-\Phi(\alpha,\mathbf{x})]\right)g\left(\alpha,\varphi(\cdot)-\frac{\Phi(\alpha,\cdot)}{\sqrt{\lambda}}\right), \tag{5.1}$$

where $\alpha\in\mathbf{R}^k$, $S(\alpha)$, $\Pi(\alpha;\mathbf{x})$, $\Phi(\alpha;\mathbf{x})$ are smooth functions. Calculate (formally) the functional integral for (ψ,ψ):

$$(\psi,\psi)=\int \frac{\mathrm{d}\alpha\,\mathrm{d}\gamma}{\lambda^{k/2}}\int D\varphi\exp\left(-\frac{i}{\lambda}S(\alpha)\right)\exp\left(-\frac{i}{\lambda}\Pi(\alpha;\mathbf{x})[\varphi(\mathbf{x})\sqrt{\lambda}-\Phi(\alpha,\mathbf{x})]\right)g^*\left(\alpha,\varphi(\cdot)-\frac{\Phi(\alpha,\cdot)}{\sqrt{\lambda}}\right)\exp\left(\frac{i}{\lambda}S(\gamma)\right)\exp\left(\frac{i}{\lambda}\Pi(\gamma;\mathbf{x})[\varphi(\mathbf{x})\sqrt{\lambda}-\Phi(\gamma,\mathbf{x})]\right)g\left(\gamma,\varphi(\cdot)-\frac{\Phi(\gamma,\cdot)}{\sqrt{\lambda}}\right).$$

After substitution $\gamma=\alpha+\sqrt{\lambda}\beta$, $\varphi(\cdot)=\Phi(\alpha,\cdot)/\sqrt{\lambda}+\phi(\cdot)$ we obtain as $\lambda\to 0$:

$$(\psi,\psi)\simeq\int d\alpha d\beta e^{(i/\sqrt{\lambda})\beta_s(\partial S/\partial g a_s-\int dx\Pi(a,\mathbf{x})\partial\Phi(\alpha,\mathbf{x})/\partial\alpha_s)}e^{(i/2)\beta_s(\partial/\partial\alpha_s)(\partial S/\partial\alpha_l-\int d\mathbf{x}\Pi(\alpha,\mathbf{x})\partial\Phi(\alpha,\mathbf{x})/\partial\alpha_l)\beta_l}$$
$$\times\int D\phi g^*(a,\phi(\cdot))e^{i\beta_l\int d\mathbf{x}((\partial\Pi(\alpha,\mathbf{x})/\partial\alpha_l)\phi(\mathbf{x})-(\partial\Phi(\alpha,\mathbf{x})/\partial\alpha_l)1/i\,(\delta/\delta\phi(\mathbf{x}))}g(\alpha,\phi(\cdot)). \tag{5.2}$$

The condition

$$\frac{\partial S}{\partial\alpha_s}=\int \mathrm{d}\mathbf{x}\,\Pi(\alpha,\mathbf{x})\frac{\partial\Phi(\alpha,\mathbf{x})}{\partial\alpha_s} \tag{5.3}$$

should be satisfied. Otherwise, the integral (5.2) will be exponentially small as $\lambda\to 0$, so that state (5.1) will be trivial. Under condition (5.3), one has

$$(\psi,\psi)\to_{\lambda\to 0}\int \mathrm{d}\alpha\,\mathrm{d}\beta\int D\phi g^*(\alpha,\phi(\cdot))$$
$$\times\exp\left(i\beta_l\int d\mathbf{x}\left(\frac{\partial\Pi(\alpha,\mathbf{x})}{\partial\alpha_l}\phi(\mathbf{x})-\frac{\partial\Phi(\alpha,\mathbf{x})}{\partial\alpha_l}\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}\right)\right)g(\alpha,\phi(\cdot)). \tag{5.4}$$

To specify the composed semiclassical state in the functional representation, one should:

(i) specify the smooth functions $(S(\alpha),\Pi(\alpha,\mathbf{x}),\Phi(\alpha,\mathbf{x}))\equiv X(\alpha)$ obeying Eq. (5.3) (determine the k-dimensional isotropic manifold in the extended phase space $\mathcal{X}$);
(ii) specify the α-dependent functional $g(\alpha,\phi(\cdot))$.

The inner product of composed semiclassical states is given by expression (5.4).

Since the inner product (5.4) may vanish for nonzero g, one should factorize the space of composed semiclassical states. Such functional g that obey the property

$$\int \mathrm{d}\alpha\left(g^*(\alpha,\cdot)\prod_l\delta\left[\int d\mathbf{x}\left(\frac{\partial\Pi(\alpha,\mathbf{x})}{\partial\alpha_l}\phi(\mathbf{x})-\frac{\partial\Phi(\alpha,\mathbf{x})}{\partial\alpha_l}\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}\right)\right]g(\alpha,\cdot)=0 \tag{5.5}$$

should be set to be equal to zero, $g\sim 0$.

One can define the Poincaré transformation of the composed semiclassical state as follows. The transformation of $(S(\alpha),\Pi(\alpha,\cdot),\Phi(\alpha,\cdot))$ is $u_{a,\Lambda}(S(\alpha),\Pi(\alpha,\cdot),\Phi(\alpha,\cdot))$. The transformation of $g(\alpha,\phi(\cdot))$ is

$$\tilde{U}_{a,\Lambda}(u_{a,\Lambda}(S,\Pi,\Phi)\leftarrow(S,\Pi,\Phi))g(\alpha,\phi(\cdot)).$$

One should check that the inner product entering to Eq. (5.5) is invariant under Poincaré transformations. This will also imply that equivalent states are taken to equivalent.

Since the functional Schrödinger representation is not well-defined, let us consider the Fock representation. One should then specify the α-dependent Fock vector $Y(\alpha)=V^{-1}g(\alpha,\cdot)$ instead of the α-dependent functional $g(\alpha,\phi(\cdot))$. Making use of formulas (2.1), we find that the inner product (5.4) takes the form

$$\left(\begin{pmatrix}\Lambda^k\\ Y(\cdot)\end{pmatrix},\begin{pmatrix}\Lambda^k\\ Y(\cdot)\end{pmatrix}\right)=\int \mathrm{d}\alpha\,\mathrm{d}\beta\left(Y(\alpha),\exp\left(\beta_s\int \mathrm{d}\mathbf{x}(B_s(\alpha,\mathbf{x})A^+(\mathbf{x})-B_s^*(\alpha,\mathbf{x})A_s^-(\mathbf{x}))\right)Y(\alpha)\right), \tag{5.6}$$

where

$$B_s(\alpha,\cdot)=\hat{\Gamma}^{-1/2}\left(\hat{\mathcal{R}}\frac{\partial\Phi(\alpha,\cdot)}{\partial\alpha_s}-\frac{\partial\Pi(\alpha,.)}{\partial\alpha_s}\right), \tag{5.7}$$

$\hat{\Gamma}=\hat{\Gamma}(\Phi(\alpha,\cdot),\Pi(\alpha,\cdot))$, $\hat{\mathcal{R}}=\hat{\mathcal{R}}(\Phi(\alpha,\cdot),\Pi(\alpha,\cdot))$. If the isotropic manifold $(\Phi(\alpha,\cdot),\Pi(\alpha,\cdot))$ is nondegenerate, the functions $B_s(\alpha,\mathbf{x})$ are linearly independent.

The Poincaré transformation of the composed semiclassical state

$$\begin{pmatrix}\{X(\alpha)\}\\ Y(\alpha)\end{pmatrix}$$

is

$$\begin{pmatrix}\{u_{a,\Lambda}X(\alpha)\}\\ U_{a,\Lambda}(u_{a,\Lambda}X(\alpha)\leftarrow X(\alpha))Y(\alpha)\end{pmatrix}.$$

Consider the quantity

$$\begin{aligned}(B_s,B_l)-(B_l,B_s)&=\left(\frac{\partial\Phi}{\partial\alpha_s},(\hat{\mathcal{R}}^*-\hat{\mathcal{R}})\hat{\Gamma}^{-1}\frac{\partial\Pi}{\partial\alpha_l}\right)-\left(\frac{\partial\Phi}{\partial\alpha_l},(\hat{\mathcal{R}}^*-\hat{\mathcal{R}})\hat{\Gamma}^{-1}\frac{\partial\Pi}{\partial\alpha_s}\right)\\&=i\int \mathrm{d}\mathbf{x}\left(\frac{\partial\Phi(\alpha,\mathbf{x})}{\partial\alpha_l}\frac{\partial\Pi(\alpha,\mathbf{x})}{\partial\alpha_s}-\frac{\partial\Phi(\alpha,\mathbf{x})}{\partial\alpha_s}\frac{\partial\Pi(\alpha,\mathbf{x})}{\partial\alpha_l}\right).\end{aligned} \tag{5.8}$$

Differentiating (5.3) with respect to α_l, we obtain that quantity (5.8) vanishes. Thus, operators $\beta_s\int \mathrm{d}\mathbf{x}(B_s(\alpha,\mathbf{x})A^+(\mathbf{x})-B_s^*(\alpha,\mathbf{x})A_s^-(\mathbf{x}))$ commute each other.

It follows from the results of Ref. 48 that the inner product (5.7) is correctly defined, while Poincaré transformations of composed semiclassical states satisfy the group property and conserve the inner product (5.7).

VI. CONCLUSIONS

In this paper a notion of a semiclassical state is introduced. ''Elementary'' semiclassical state are specified by a set (X,Ψ) of classical field configuration X (point on the infinite-dimensional manifold $\mathcal{X}$, see Sec. II and III B and element Ψ of the space $\mathcal{F}$. The set of all ''elementary'' semiclassical states may be viewed as a semiclassical bundle.

The physical meaning of classical field X is evident. Discuss the role of Ψ. In the soliton quantization language[1,2] Ψ specifies whether the quantum soliton is in the ground or excited state. For the Gaussian approach,[14–17] Ψ specifies the form of the Gaussian functional, while for QFT in the strong external classical field[6,7] Ψ is a state of a quantum field in the classical background.

The ''composed'' semiclassical states have also been introduced (Sec. V). They can be viewed as superpositions of ''elementary'' semiclassical states and are specified by the functions $(X(\tau),\Psi(\tau))$ defined on some domain of $\mathbf{R}^k$ with values on the semiclassical bundle.

Not arbitrary superposition of elementary semiclassical states is nontrivial. The isotropic condition (5.3) should be satisfied. Moreover, the inner product of the ''composed'' semiclassical states [Eq. (5.6)] is degenerate, so that there is a ''gauge freedom'' (5.5) in specifying composed semiclassical states.

The composed semiclassical states are used[36] in soliton quantization, since there are translation zero modes and solitons can be shifted. They are useful if there are conserved integrals of

motion like charges. The correspondence between composed and elementary semiclassical states in QFT resembles the relationship between WKB and wave packet approximations in quantum mechanics.

An important feature of QFT is the property of Poincaré invariance. In this paper an explicit check of this property is presented for semiclassical QFT. The Poincaré transformations of elementary and composed semiclassical states have been constructed as follows. First, the simplest Poincaré transformations like spatial translations and rotations, evolution and boost are considered. The infinitesimal transformations are investigated, the Lie algebraic commutation relations have been checked and the group properties have been justified.

For the ''composed'' states, conservation of the degenerate inner product and isotropic condition under Poincaré transformation have been checked.

An important feature of QFT is a notion of field. In this paper this notion is introduced for semiclassical QFT. The property of Poincaré invariance of semiclassical field is checked.

APPENDIX: WEYL CALCULUS

The purpose of this appendix is to formulate some properties of Weyl symbols of operators which are useful in justification of properties P1–P6. The detailed proofs can be found in Ref. 51.

1. Definition and some properties of Weyl symbols

First of all, recall the definition of the Weyl symbol of operator (Refs. 52–54, for reviews see e.g., Refs. 34 and 55). Let $A(x,k)$, $x,k\in\mathbf{R}^d$ be a classical observable depending on coordinates $x=(x_1,\ldots,x_d)$ and momenta $k=(k_1,\ldots,k_d)$. To specify the corresponding quantum observable $\hat{A}$ (to ''quantize'' the observable A), one should present it as a superposition of exponents,

$$A(x,k)=\int \mathrm{d}\alpha\,\mathrm{d}\beta\tilde{A}(\alpha,\beta)e^{i\alpha k+i\beta x}$$

and set

$$\hat{A}=\int \mathrm{d}\alpha\,\mathrm{d}\beta\tilde{A}(\alpha,\beta)e^{i\alpha\hat{k}+i\beta\hat{x}}.$$

Applying the formula for the inverse Fourier transformation, we find

$$(\hat{A}f)(x)=\int \frac{\mathrm{d}\alpha\,\mathrm{d}p}{(2\pi)^d}A\left(x+\frac{\alpha}{2};p\right)e^{-i\alpha p}f(x+\alpha). \tag{A1}$$

We denote the operator $\hat{A}$ of the form (A1) as $\hat{A}=\mathcal{W}(A)$. We will also write $A=\overline{\mathcal{W}}(\hat{A})$ if $\hat{A}=\mathcal{W}(A)$.

Definition A1: The operator $\mathcal{W}(A)$ is called a Weyl quantization of the function A. The function $\overline{\mathcal{W}}(\hat{A})$ is called a Weyl symbol of the operator $\hat{A}$.

For investigations of QFT ultraviolet divergences, we are interested in the behavior of Weyl symbols of operators at large values of momenta. Let us introduce some important spaces. Let $\omega_k=\sqrt{k^2+m^2}$ for some m.

Definition A2: (1) We say that a smooth function $A(x,k)$ is of the class $\mathcal{B}_N$ if and only if the functions $\omega_k^{N+s}(\partial^s A/\partial k^{i_1}\cdots\partial k^{i_s})$ are bounded for all $s,i_1,\ldots,i_s$.

(2) Let $A_n\in\mathcal{B}_N$, $n=1,\infty$, $A\in\mathcal{B}_N$. We say that $\mathcal{B}_N-\lim_{n\to\infty}A_n=A$ if and only if $\lim_{n\to\infty}\max_{k,x}\omega_k^{N+s}(\partial^s(A_n-A)/\partial k^{i_1}\ldots\partial k^{i_s})=0$ for all $s,i_1,\ldots,i_s$.

(3) We say that a function $A\in\mathcal{B}_N$ *is of the class* $\mathcal{A}_N$ *if and only if* $x_{j_1}\ldots x_{j_R}(\partial/\partial x_{s_1})\ldots(\partial/\partial x_{s_P})A\in\mathcal{B}_N$ *for all R, P,* $j_1,\ldots,j_R$, $s_1,\ldots,s_P$.

(4) Let $A_n\in\mathcal{A}_N$, $A\in\mathcal{A}_N$. *We say that* $\mathcal{A}_N-\lim_{n\to\infty}A_n=A$ *if and only if* $\mathcal{B}_N-\lim_{n\to\infty}x_{j_1}\cdots x_{j_R}(\partial/\partial x_{s_1})\cdots(\partial/\partial x_{s_P})\,(A_n-A)=0$ *for all R, P,* $j_1,\ldots,j_R$, $s_1,\ldots,s_P$.

The introduced classes $\mathcal{A}_N$ and $\mathcal{B}_N$ obey the following properties.

Lemma A1: (1) $\mathcal{A}_{N+R}\subseteq\mathcal{A}$, $\mathcal{B}_{N+R}\subseteq\mathcal{B}$ *for* $R\geqslant 0$.

(2) Let $\mathcal{A}_{N+R}-\lim_{n\to\infty}A_n=A$ and $R\geqslant 0$. *Then* $\mathcal{A}_N-\lim_{n\to\infty}A_n=A$.

(3) Let $\mathcal{B}_{N+R}-\lim_{n\to\infty}A_n=A$ *and* $R\geqslant 0$. *Then* $\mathcal{B}_N-\lim_{n\to\infty}A_n=A$.

(4) Let $A\in\mathcal{B}_N$. *Then* $(\partial/\partial k_i)A\in\mathcal{B}_{N+1}$.

(5) Let $A\in\mathcal{A}_N$. *Then* $x_iA\in\mathcal{A}_N$, $(\partial A/\partial x_i)\in\mathcal{A}_N$, $(\partial/\partial k_i)A\in\mathcal{A}_{N+1}$, $f(x)A\in\mathcal{A}_N$ *for smooth bounded function* $f(x)$.

(6) Let $\mathcal{B}_N-\lim_{n\to\infty}A_n=A$. *Then* $\mathcal{B}_{N+1}-\lim_{n\to\infty}(\partial/\partial k_i)A_n=(\partial/\partial k_i)A$.

(7) Let $\mathcal{A}_N-\lim_{n\to\infty}A_n=A$. *Then* $\mathcal{A}_N-\lim_{n\to\infty}x_iA_n=x_iA$, $\mathcal{A}_N-\lim_{n\to\infty}(\partial A_n/\partial x_i)=\partial A/\partial x_i$, $\mathcal{A}_{N+1}-\lim_{n\to\infty}(\partial/\partial k_i)A_n=(\partial/\partial k_i)A$, $\mathcal{A}_N-\lim_{n\to\infty}f(x)A_n=f(x)A$ *for smooth bounded function* $f(x)$.

(8) Let $A_1\in\mathcal{B}_{N_1}$, $A_2\in\mathcal{B}_{N_2}$. *Then* $A_1A_2\in\mathcal{B}_{N_1N_2}$.

(9) The following properties are satisfied: $k_i\in\mathcal{B}_{-1}$, $\omega_k^{\alpha}\in\mathcal{B}_{-\alpha}$.

(10) Let $A\in\mathcal{B}_N$. *Then* $k_iA\in\mathcal{B}_{N-1}$, $\omega_k^{-\alpha}A\in\mathcal{B}_{N+\alpha}$, $(\partial A/\partial k_i)\in\mathcal{B}_{N+1}$.

(11) Let $A\in\mathcal{A}_N$. *Then* $k_iA\in\mathcal{A}_{N-1}$, $\omega_k^{-\alpha}A\in\mathcal{A}_{N+\alpha}$, $\partial A/\partial k_i\in\mathcal{A}_{N+1}$.

(12) Let $\mathcal{B}_N-\lim_{n\to\infty}A_n=A$. *Then* $\mathcal{B}_{N-1}-\lim_{n\to\infty}k_iA_n=k_iA$, $\mathcal{B}_{N+\alpha}-\lim_{n\to\infty}\omega_k^{-\alpha}A_n=\omega_k^{-\alpha}A$, $\mathcal{B}_{N+1}-\lim_{n\to\infty}(\partial A_n/\partial k_i)=\partial A/\partial k_i$.

(13) Let $\mathcal{A}_N-\lim_{n\to\infty}A_n=A$. *Then* $\mathcal{A}_{N-1}-\lim_{n\to\infty}k_iA_n=k_iA$, $\mathcal{A}_{N+\alpha}-\lim_{n\to\infty}\omega_k^{-\alpha}A_n=\omega_k^{-\alpha}A$, $\mathcal{A}_{N+1}-\lim_{n\to\infty}(\partial A_n/\partial k_i)=\partial A/\partial k_i$.

(14) Let $A_1\in\mathcal{A}_{N_1}$, $A_2\in\mathcal{A}_{N_2}$. *Then* $A_1A_2\in\mathcal{A}_{N_1+N_2}$.

(15) Let $\mathcal{A}_{N_1}-\lim_{n\to\infty}A_{1,n}=A_1$, $\mathcal{A}_{N_2}-\lim_{n\to\infty}A_{2,n}=A_2$. *Then* $\mathcal{A}_{N_1+N_2}-\lim_{n\to\infty}A_{1,n}A_{2,n}=A_1A_2$.

Theorem A.2: *(1) Let* $A\in\mathcal{A}_0$. *Then the operator* $\mathcal{W}(A)$ (A1) *is bounded.*

(2) Let $\mathcal{A}_0-\lim_{n\to\infty}A_n=0$. *Then* $\lim_{n\to\infty}\|\mathcal{W}(A_n)\|=0$.

(3) Let $A\in\mathcal{A}_N$, $N>d/2$. *Then* $\mathcal{W}(A)$ *is a Hilbert–Schmidt operator.*

(4) Let $\mathcal{A}_N-\lim_{n\to\infty}A_n=0$, $N>d/2$. *Then* $\lim_{n\to\infty}\|\mathcal{W}(A_n)\|_2=0$.

(5) Let $A\in\mathcal{A}_N$, $N>d$. *Then* $\mathcal{W}(A)$ *is of the trace class.*

(6) Let $\mathcal{A}_N-\lim_{n\to\infty}A_n=0$, $N>d$. *Then* $\lim_{n\to\infty}\mathrm{Tr}\,\mathcal{W}(A_n)=0$.

Recall that the Weyl symbol of the product of operators

$$A*B=\overline{\mathcal{W}}(\mathcal{W}(A)\mathcal{W}(B))$$

can be presented as[34,55]

$$(A*B)(x,k)=\int\frac{\mathrm{d}\beta_1\,\mathrm{d}\beta_2\,\mathrm{d}\xi_1\,\mathrm{d}\xi_2}{(2\pi)^{2d}}A\left(x+\xi_1,k+\frac{\beta_2}{2}\right)B\left(x+\xi_2,k-\frac{\beta_1}{2}\right)e^{-\beta_1\xi_1-i\beta_2\xi_2}. \quad \text{(A2)}$$

Formula (A2) can be obtained from definition (A1).

Let us investigate some properties of formula (A2). Let us find an expansion of formula (A2) as $|k|\to\infty$. Formally, one has

$$A\left(x+\xi_1,k+\frac{\beta_2}{2}\right)=\sum_{n_2=0}^{\infty}\frac{1}{2^{n_2}n_2!}\frac{\partial^{n_2}A(x+\xi_1,k)}{\partial k^{i_1}\cdots\partial k^{i_{n_2}}}\beta_2^{i_1}\cdots\beta_2^{i_{n_2}};$$

$$B\left(x+\xi_2,k-\frac{\beta_1}{2}\right)=\sum_{n_1=0}^{\infty}\frac{(-1)^{n_1}}{2^{n_1}n_1!}\frac{\partial^{n_1}B(x+\xi_2,k)}{\partial k^{j_1}\cdots\partial k^{j_{n_1}}}\beta_1^{j_1}\cdots\beta_1^{j_{n_1}}.$$

Therefore,

$$(A^*B)(x,k)=\sum_{n_1n_2=0}^{\infty}\frac{(-1)^{n_1}}{2^{n_1+n_2}n_1!n_2!}\int\frac{d\beta_1\,d\beta_2\,d\xi_1\,d\xi_2}{(2\pi)^{2d}}e^{-i\beta_1\xi_1-i\beta_2\xi_2}\frac{\partial^{n_2}A(x+\xi_1,k)}{\partial k^{i_1}\cdots\partial k^{i_{n_2}}}\beta_2^{i_1}\cdots\beta_2^{i_{n_2}}$$
$$\times\frac{\partial^{n_1}B(x+\xi_2,k)}{\partial k^{j_1}\cdots\partial k^{j_{n_1}}}\beta_1^{j_1}\cdots\beta_1^{j_{n_1}}$$
$$=\sum_{n_1n_2=0}^{\infty}\frac{i^{n_1-n_2}}{2^{n_1+n_2}n_1!n_2!}\frac{\partial^{n_1+n_2}A(x,k)}{\partial k^{i_1}\cdots\partial k^{i_{n_2}}\partial x^{j_1}\cdots\partial x^{j_{n_1}}}\frac{\partial^{n_1+n_2}B(x,k)}{\partial x^{i_1}\cdots\partial x^{i_{n_2}}\partial k^{j_1}\cdots\partial k^{j_{n_1}}}. \tag{A3}$$

Denote

$$(A\overset{K}{*}B)(x,k)=\sum_{n_1n_2\geqslant 0,n_1+n_2\leqslant K}\frac{i^{n_1-n_2}}{2^{n_1+n_2}n_1!n_2!}\frac{\partial^{n_1+n_2}A(x,k)}{\partial k^{i_1}\cdots\partial k^{i_{n_2}}\partial x^{j_1}\cdots\partial x^{i_{n_1}}}\frac{\partial^{n_1+n_2}B(x,k)}{\partial x^{i_1}\cdots\partial x^{i_{n_2}}\partial k^{j_1}\cdots\partial k^{j_{n_1}}}.$$

This is an asymptotic expansion in $1/|k|$ as $|k|\to\infty$. One can estimate an accuracy of the asymptotic series.

Definition A3: We say that the function $f(x)$, $x\in\mathbf{R}^d$ is of the class $\mathcal{C}$ if f is a smooth function such that for each set $(i_1,\ldots,i_l)$ there exists $m>0$ such that the function $(x^2+1)^{-m}(\partial^l/\partial x^{i_1}\ldots\partial x^{i_l})f$ is bounded.

Theorem A3: *(1) Let $f\in\mathcal{C}$, $B\in\mathcal{A}_N$. Then $f^*B=f\overset{K}{*}B+R_K$ with $R_K\in\mathcal{A}_{N+K+1}$.*

(2) Let $f\in\mathcal{C}$, $\mathcal{A}_N-\lim_{n\to\infty}B_n=0$. Then $\mathcal{A}_{N+K+1}-\lim_{n\to\infty}(f^*B_n-f\overset{K}{*}B_n)=0$.

(3) Let $A=A(k)$, $A\in\mathcal{B}_{M_1}$, $B\in\mathcal{A}_{M_2}$. Then $A^*B=A\overset{K}{*}B+R_K$ with $R_K\in\mathcal{A}_{M_1+M_2+K+1}$.

(4) Let $A=A(k)$, $A\in\mathcal{B}_{M_1}$, $\mathcal{A}_{M_2}-\lim_{n\to\infty}B_n=B$. Then $\mathcal{A}_{M_1+M_2+K+1}-\lim_{n\to\infty}(A^*B_n-A\overset{K}{*}B_n)=0$.

(5) Let $A\in\mathcal{A}_{M_1}$, $B\in\mathcal{A}_{M_2}$. Then $A^*B=A\overset{K}{*}B+R_K$ with $R_K\in\mathcal{A}_{M_1+M_2+K+1}$.

(6) Let $A_n\in\mathcal{A}_{M_1}$, $B_n\in\mathcal{A}_{M_2}$. Then $\mathcal{A}_{M_1+M_2+K+1}-\lim_{n\to\infty}(A_n{}^*B_n-A_n\overset{K}{*}B_n)=A^*B-A\overset{K}{*}B$.

Let us now investigate the properties of the exponent of the operator $\exp\mathcal{W}(A)\equiv\mathcal{W}(*\exp A)$. It is convenient to consider the Fourier transformations of Weyl symbols,

$$\tilde{A}(\gamma,k)=\int\frac{dx}{(2\pi)^d}e^{-i\gamma x}A(x,k).$$

Introduce the following norms for Weyl symbols,

$$\|A\|_{I,K}=\max_{J+M+N\leqslant K}\max_{\gamma,K}\left|\omega_k^{I+J}\frac{\partial^J}{\partial k_{j_1}\cdots\partial k_{jj}}\gamma_{m_1}\cdots\gamma_{m_M}\frac{\partial^N\tilde{A}}{\partial\gamma_{n_1}\cdots\partial\gamma_{n_N}}\right|. \tag{A4}$$

Lemma A4: (1) $A\in\mathcal{A}_1$ if and only if $\|A\|_{1,K}<\infty$ for all $k=\overline{0,\infty}$.

(2) For arbitrary integer numbers K, $L>d/2$ there exists such a constant b_K that $\|A^*B\|_{0,K}\leqslant b_K\|A\|_{0,K+2L}\|B\|_{0,K}$.

Consider the Weyl symbol of the exponent

$$*\exp At-1=\sum_{n=1}^{\infty}\frac{A^{*n}t^n}{n!} \tag{A5}$$

with $A^{*n}=A^*\cdots^*A$.

Lemma A5: (1) Let $A\in\mathcal{A}_M$, $M>0$. *Then the expansion* (A5) *is convergent in the* $\|\cdot\|_{0,K}$*-norm. The estimation* $\|*\exp At-1\|_{0,K}\leqslant C_K$ *is satisfied for* $t\in[0,T]$.

(2) Let $A\in\mathcal{A}_M$, $M>0$. *Then* $\Sigma_{m=N}^{\infty}(A^{*m}/m!)\in\mathcal{A}_{MN}$.

(3) Let $A_n\in\mathcal{A}_M$, $M>0$ *and* $\mathcal{A}_M-\lim_{n\to\infty}A_n=A$. *Then* $\mathcal{A}_{MN}-\lim_{n\to\infty}\Sigma_{m=N}^{\infty}(A_n^{*m}/m!)=\Sigma_{m=N}^{\infty}(A^{*m}/m!)$.

Let $\hat{A}=f(\hat{x})$, $\hat{B}=g(\hat{k})$. Investigate the properties of the commutator $\hat{K}=[\hat{A};\hat{B}]$.

Lemma A6: Let $\partial^n f/\partial x^{i_1}\cdots\partial x^{i_n}$, $\partial^n g/\partial k^{i_n}\ldots\partial k^{i_n}$ *be bounded functions,* $m,n=\overline{1,L}$, *while*

$$\frac{\partial^{L+1}f}{\partial x^{i_1}\cdots\partial x^{i_{L+1}}}\in L^2,\quad \frac{\partial^{L+1}g}{\partial k^{i_1}\cdots\partial k^{i_{L+1}}}\in L^2.$$

Then $[f(\hat{x}),g(\hat{k})]$ *is a bounded operator.*

2. Asymptotic expansions of Weyl symbol

To check the property of Poincaré invariance, it is important to investigate the large-k expansion of the Weyl symbols. Introduce the corresponding definitions.

Definition A4: (1) We say that a smooth function $A(x,n)$, x, $n\in\mathbf{R}^d$, $|n|<1$, *is of the class* $\mathcal{L}$ *if the functions*

$$\frac{\partial^I}{\partial n_{i_1}\cdots\partial n_{i_I}}x_{j_1}\cdots x_{j_J}\frac{\partial^M}{\partial x_{m_1}\cdots\partial x_{m_M}}A \tag{A6}$$

are bounded.

(2) *Let* $A_s\in\mathcal{L}$, $s=\overline{1,\infty}$. *We say that* $\mathcal{L}-\lim_{s\to\infty}A_s=0$ *if*

$$\sup_{|n|\leqslant 1}\lim_{s\to\infty}\left|\frac{\partial^I}{\partial n_{i_1}\cdots\partial n_{i_I}}x_{j_1}\cdots x_{j_J}\frac{\partial^M}{\partial x_{m_1}\cdots\partial x_{m_M}}A\right|=0.$$

Definitions A2 and A4 imply the following statement.

Lemma A.7: (1) Let $A\in\mathcal{L}$. *Then the function* $B(x,k)=A(x,k/\omega_k)$ *is of the class* $\mathcal{B}_0$.

(2) *Let* $\mathcal{L}-\lim_{s\to\infty}A_s=0$. *Then* $\mathcal{B}_0-\lim_{s\to\infty}A_s(x,k/\omega_k)=0$.

Making use of definition A2 and lemma A5, we obtain the following corollary.

Corollary: (1) Let $A\in\mathcal{L}$. *Then the function* $\omega_k^{-\alpha}A(x,k/\omega_k)$ *is of the class* $\mathcal{A}_\alpha$.

(2) *Let* $\mathcal{L}-\lim_{s\to\infty}A_s=0$. *Then* $\mathcal{A}_\alpha-\lim_{s\to\infty}\omega_k^{-\alpha}A_s(x,k/\omega_k)=0$.

Definition A5: (1) A formal asymptotic expansion is a set $\breve{A}$ $\alpha\in\mathbf{R}$ *and functions* $A_0,A_1,\ldots\in\mathcal{L}$. *We say that the formal asymptotic expansions* $\breve{A}=(\alpha,A_0,A_1,\ldots)$ *and* $\breve{B}=(\beta,B_0,B_1,\ldots)$ *are equivalent if* $\alpha-\beta$ *is an integer number and* $A_{l-\alpha+\beta}=B_l$ *for all* $l=\overline{-\infty,+\infty}$ (*we assume* $A_l=0$ *and* $B_l=0$ *for* $l<0$. *We denote formal asymptotic expansions of Weyl symbols as*

$$\breve{A}\equiv\sum_{n=0}^{\infty}\omega_k^{-n-\alpha}A_n(x,k/\omega_k).$$

If $A_0=0,\ldots,A_{l-1}=0$, $A_l\neq 0$, *the quantity* $\deg\breve{A}\equiv\alpha+n$ *is called a degree of a formal asymptotic expansion* $\breve{A}$.

(2) *Let* $\breve{A}_s$, $s=\overline{1,\infty}$ *and* $\breve{A}$ *be formal asymptotic expansions of Weyl symbols. We say that* $F.E-\lim_{s\to\infty}\breve{A}_s=A$ *if* $\alpha_s=\alpha$ *and* $\mathcal{L}-\lim_{s\to\infty}(A_{s,n}-A_s)=0$.

The summation and multiplication by numbers are obviously defined:

$$\breve{A}+\lambda\breve{B}=\sum_{n=0}^{\infty}\omega_k^{-n-\alpha}(A_n(x,k\omega_k)+\lambda B_n(x,k/\omega_k)).$$

The product of formal asymptotic expansions of Weyl symbols

$$\check{A}\equiv\sum_{n=0}^{\infty}\omega_k^{-n-\alpha}A_n(x,k/\omega_k),\quad \check{B}\equiv\sum_{n=0}^{\infty}\omega_k^{-n-\beta}B_n(x,k/\omega_k)$$

is defined as

$$\check{A}\check{B}\equiv\sum_{n=0}^{\infty}\omega_k^{-n-\alpha-\beta}\sum_{s,l\geqslant 0;s+l=n}A_s(x,k/\omega_k)B_l(x,k/\omega_k).$$

Let $f=f(x), f\in\mathcal{C}$. Then

$$f(x)\check{A}\equiv\sum_{n=0}^{\infty}\omega_k^{-n-\alpha}f(x)A_n(x,k/\omega_k).$$

One also defines

$$\omega_k^{-\beta}\check{A}\equiv\sum_{n=0}^{\infty}\omega_k^{-n-\alpha-\beta}A_n(x,k/\omega_k)$$

and

$$\frac{\partial\check{A}}{\partial k_s}=\sum_{l=0}^{\infty}\omega_k^{-l-\alpha-1}\left[-(l+\alpha)A_l(x,n)+\frac{\partial A_l}{\partial n_p}(x,n)(\delta_{ps}-n_pn_s)\right]_{|n=k/\omega_k}.$$

The *-product of formal asymptotic expansions is introduced as

$$\check{A}*\check{B}\equiv\sum_{K=0}^{\infty}\sum_{n_1n_2\geqslant 0,n_1+n_2=K}\frac{i^{n_1-n_2}}{n_1!n_2!2^{n_1+n_2}}\frac{\partial^{n_1+n_2}}{\partial x^{i_1}\cdots\partial x^{i_{n_2}}\partial k^{j_1}\cdots\partial k^{j_{n_1}}}\sum_{l_1=0}^{\infty}\omega_k^{-l_1-\alpha_1}A_{l_1}(x,k/\omega_k)$$
$$\times\frac{\partial^{n_1+n_2}}{\partial x^{j_1}\cdots\partial x^{j_{n_1}}\partial k^{i_1}\cdots\partial k^{i_{n_2}}}\sum_{l_2=0}^{\infty}\omega_k^{-l_2-\alpha_2}A_{l_2}(x,k/\omega_k).$$

The formal asymptotic expansions $\check{A}*\omega_k^{\alpha}$, $\check{A}*f(x)$ are defined analogously. The *-exponent of a formal asymptotic expansion $\check{A}$ is defined as

$$*\exp\check{A}-1=\sum_{n=1}^{\infty}\frac{\check{A}^{*n}}{n!}$$

provided that $\deg A$ is a positive integer number.

Definition A6: (1) An asymptotic expansion of the Weyl symbol is a set $\underline{A}\equiv(A,\check{A})$ *of the Weyl symbol A and a formal asymptotic expansion* $\check{A}$ *such that*

$$A(x,k)-\sum_{l=0}^{n-1}\frac{A_l(x,k/\omega_k)}{\omega_k^{l+\alpha}}\in\mathcal{A}_{n+\alpha}$$

for all $n=\overline{0,\infty}$.

(2) We say that $E-\lim_{s\to\infty}\underline{A_s}=\underline{A}$ *if* $F.E-\lim_{s\to\infty}\check{A}_s=\check{A}$ *and*

$$\mathcal{A}_{n+\alpha}-\lim_{s\to\infty}\left(A_s(x,k)-\sum_{l=0}^{n-1}\frac{A_{s,l}(x,k/\omega_k)}{\omega_k^{l+\alpha}}\right)=A(x,k)-\sum_{l=0}^{n-1}\frac{A_l(x,k/\omega_k)}{\omega_k^{l+\alpha}}$$

for all $n=\overline{0,\infty}$.

Remark: For given Weyl symbol A, the asymptotic expansion is not unique. For example, let

$$A(x,k)=m^2 f(x)/\omega_k .$$

One can choose $\alpha=2$, $A_0(x,n)=m^2 f(x)$ and find $A(x,k)=\omega_k^{-2}A_0(x,k/\omega_k)$. On the other hand, one can set $\alpha=0$, $A_0(x,n)=f(x)(1-n_i n_i)$ and obtain $A(x,k)=A_0(x,k/\omega_k)$ since $\omega_k^2-k_i k_i=m^2$. We see that a degree is a characteristic feature of an expansion rather than of a symbol.

Let $\underline{A}=(A,\check{A})$, $\underline{B}=(B,\check{B})$. Denote $\underline{A}*\underline{B}\equiv(A*B,\check{A}*\check{B})$, $\omega_k^\alpha*\underline{A}\equiv(\omega_k^\alpha*A,\omega_k^\alpha*\check{A})$, $f(x)*\underline{A}\equiv(f(x)*A,f(x)*\check{A})$, $*\exp\underline{A}-1\equiv(*\exp A-1,*\exp\check{A}-1)$.

Theorem A3 and lemma A5 imply the following statements.

Theorem A8: *(1) Let* $\underline{A}$ *be an asymptotic expansion of a Weyl symbol. Then* $\omega_k^\alpha*\underline{A}$ *and* $f(x)*\underline{A}$ *are asymptotic expansions of Weyl symbols under conditions of theorem A3, while* $*\exp\underline{A}-1$ *is an asymptotic expansion of a Weyl symbol, provided that* $\deg\check{A}$ *is a positive integer number.*

(2) Let $\underline{A}$ *and* $\underline{B}$ *be asymptotic expansions of Weyl symbols. Then* $\underline{A}*\underline{B}$ *is an asymptotic expansion of a Weyl symbol.*

Theorem A9: *(1) Let* $E-\lim_{n\to\infty}\underline{A}_n=\underline{A}$. *Then:*

(*a*) $E-\lim_{n\to\infty}\omega_k^\alpha*\underline{A}_n\omega_k^\alpha*\underline{A}$,
(*b*) $E-\lim_{n\to\infty}f(x)*\underline{A}_n f(x)*\underline{A}$ *under conditions of theorem A3,*
(*c*) $E-\lim n\to\infty(*\exp\underline{A}_n-1)=*\exp\underline{A}-1$ *if* $\deg\check{A}_n$, $\deg\check{A}$ *are positive integer numbers.*

(2) Let $E-\lim_{n\to\infty}\underline{A}_n=\underline{A}$ *and* $E-\lim_{n\to\infty}\underline{B}_n=\underline{B}$. *Then* $E-\lim_{n\to\infty}\underline{A}_n*\underline{B}_n=\underline{A}*\underline{B}$.

The time derivative of the asymptotic expansion $\underline{A}(t)$ with respect to t is defined in a standard way

$$E-\lim_{\delta t\to 0}\frac{\underline{A}(t+\delta t)-\underline{A}(t)}{\delta t}=\frac{\mathrm{d}\underline{A}(t)}{\mathrm{d}t}.$$

The integral $\int_{t_1}^{t_2}\underline{A}(t)\mathrm{d}t$ is also defined in a standard way.

Theorem A9 implies the following statement.

Theorem A10: (1) *Let* $\underline{A}(t)$ *be a continuously differentiable asymptotic expansion of a Weyl symbol. Then*

(*a*) $(\mathrm{d}/\mathrm{d}t)(\omega_k^\alpha*\underline{A})=\omega_k^\alpha*(\mathrm{d}A/\mathrm{d}t)$,
(*b*) $(\mathrm{d}/\mathrm{d}t)(f(x)*\underline{A})=f(x)*(\mathrm{d}A/\mathrm{d}t)$ *under conditions of theorem A3.*
(*c*) $(\mathrm{d}/\mathrm{d}t)(*\exp\underline{A}-1)=\int_0^1\mathrm{d}\tau e^{\underline{A}(t-\tau)}*\mathrm{d}\underline{A}/\mathrm{d}t*e^{\underline{A}\tau}$,
(*d*) $(\mathrm{d}/\mathrm{d}t)(\underline{A}*\underline{B})=(\mathrm{d}/\mathrm{d}t)\underline{A}*\underline{B}+\underline{A}*(\mathrm{d}/\mathrm{d}t)\underline{B}$.

The only nontrivial statement is (c). It is proved by using the identity[55]

$$*\exp\underline{A}_1-*\exp\underline{A}_2=\int_0^1\mathrm{d}\tau*\exp(\underline{A}_1(1-\tau))*(\underline{A}_1-\underline{A}_2)*\exp(\underline{A}_2\tau).$$

We consider quantum systems with variable but finite number of particles. For such systems we develop geometric and commutator techniques. We use these techniques to find the location of the spectrum, to prove absence of singular continuous spectrum, and identify accumulation points of the discrete spectrum. The fact that the total number of particles is bounded allows us to give relatively elementary proofs of these basic results for an important class of many-body systems with nonconserved number of particles. © *2002 American Institute of Physics.*

I. INTRODUCTION

This paper is a contribution toward a geometrical theory of quantum systems with variable number of particles. Such systems occur naturally in quantum field theory, condensed matter physics, and the theory of chemical reactions. Though often, as in cases involving photons (see, e.g., Ref. 1), the number of particles can take arbitrary large values, in other cases such as scattering of spin waves on defects, scattering of massive particles and chemical reactions, there are only a few participants at any given time, though their number can change. It is the situations of the second kind that are addressed in this paper. Having the limitation on the total number of particles involved allows us to apply more sophisticated geometrical and positive commutative techniques than is usually the case (see, e.g., Ref. 1), while keeping the proof rather simple and obtaining stronger results. In this paper we obtain some basic results for the above-described systems by developing for them the method of conjugate operators.

The conjugate operator method consists in obtaining diverse spectral properties of a self-adjoint operator H in the Hilbert $\mathcal{H}$ assuming the existence of a self-adjoint operator A such that the commutator $[iH, A]$ has a definite sign when localized in a small spectral interval of H. More precisely, if τ is a closed subset of $\mathbf{R}$ then A is called locally conjugate for H on $\mathbf{R}\backslash\tau$ if and only if for every $\lambda \in \mathbf{R}\backslash\tau$ there is $c>0$ and a compact operator K such that the Mourre estimate

$$E_{[\lambda-c,\lambda+c]}(H)[iH,A]E_{[\lambda-c,\lambda+c]}(H) \geqslant cE_{[\lambda-c,\lambda+c]}(H)+K \tag{1.1}$$

holds, where $E_Z(H)$ denotes the spectral projector of H on a Borel set $Z\subset\mathbf{R}$ and the intersection of domains $D(H)\cap D(A)$ is assumed dense in $\mathcal{H}$ allowing one to understand the left-hand side as a quadratic form.

The method has appeared to be a remarkably fruitful tool in many recent investigations in spectral and scattering theory of many-body Hamiltonians, cf. Refs. 2–4, see also Refs. 5 and 6.

a)Electronic mail: soffer@math.rutgers.edu

If X is a finite-dimensional Euclidean space and H_X is the Schrödinger operator in $L^2(X)$ of the form

$$H_X = -\Delta_X + V_X, \tag{1.2}$$

where Δ_X is the Beltrami–Laplace operator on X and V_X has a many-body structure with interaction potentials satisfying some regularity and decay hypotheses, then there exists a closed, countable set $\tau(H_X) \subset \mathbf{R}$ [called the threshold set of H_X] such that the dilation generator

$$A_X = x \cdot D_x + D_x \cdot x \tag{1.3}$$

is locally conjugate for H_X in $\mathbf{R} \setminus \tau(H_X)$. Moreover the eigenvalues of H_X may accumulate (with multiplicities) only at $\tau(H_X)$ and the singular continuous spectrum of H_X is empty. It is also useful to adopt the convention that $H_X = 0$ in $L^2(X) = \mathbf{C}$ in the case $X = \{0\}$.

The aim of this paper is to obtain similar results for a class of Hamiltonians acting in the Hilbert space

$$\mathcal{H} = \bigoplus_{1 \leqslant n \leqslant N} L^2(X(n)), \tag{1.4}$$

where $\mathbf{X} = \{X(n)\}_{1 \leqslant n \leqslant N}$ is a family of configuration spaces which are finite dimensional Euclidean spaces. The Hamiltonians we consider,

$$\mathbf{H_X} = \mathbf{H_X^{diag}} + \mathbf{W_X}, \tag{1.5}$$

are perturbations of the diagonal operator formed by many-body Schrödinger operators in $L^2(X(n))$,

$$\mathbf{H_X^{diag}} = \bigoplus_{1 \leqslant n \leqslant N} H_{X(n)} = \bigoplus_{1 \leqslant n \leqslant N} (-\Delta_{X(n)} + V_{X(n)}). \tag{1.6}$$

Such Hamiltonians describe a quantum system of at most N particles and the interaction terms can change the number of particles between 1 and N. Hence $\mathbf{H_X}$ acts on the Fock subspace $\mathcal{H}$. In the second-quantized formulation the above-given interaction can contain any power of creation and annihilation operators leaving the above-mentioned Fock subspace invariant:

$$\mathbf{W_X} = P_N \mathbf{W_X} P_N,$$

where P_N is the projection of the Fock subspace of at most N particles. The locally conjugate operator for $\mathbf{H_X}$ is the diagonal operator

$$\mathbf{A_X} = \bigoplus_{1 \leqslant n \leqslant N} A_{X(n)}, \tag{1.7}$$

where $A_{X(n)}$ are dilation generators in $X(n)$ [defined in (1.3)].

The model is motivated by field theoretical and solid state systems, where the particle number is not conserved. This type of problem has recently attracted much attention, see, e.g., Refs. 7, 1, 8, 9, and 10. In Ref. 9 the two state atom coupled to a massive free field was studied, spectral and scattering theory was developed using conjugate operators and other N-body techniques. Previously the authors of Ref. 7 considered a truncated model of the two state atom where, like in this work, the total number of particles is at most $N < \infty$. The work of Ref. 9 was then generalized to a general molecule in a bound state, replacing the two-state atom in Ref. 8.

References 1 and 10 deal with the massless photon/boson field interacting with a bound atom. References 1, 8, and 9 use the dilation as conjugate operator; Refs. 7 and 10 use dilations modified by terms depending on the interaction.

In this work we generalize some of the above-mentioned models in that we allow the ''boson'' system to be interacting. We also allow the interaction between the atomic and boson field to be of general nature. (In all of the above-mentioned models the interaction is linear in the boson fields.)

Our construction of the conjugate operator is different from the above-noted works as it is more geometric in spirit. Our construction uses the geometry of N-body systems as the guiding principle; in particular we can modify the dilation generator using Graf's construction to allow local singularities in the interactions.[11,12] Furthermore our interactions are of a more general nature, and so we can cover the case of pair annihilation in some cases, e.g., the positronium system, when a bound electron and positron pair are annihilated when coupled to a field.

If X, X' are Euclidean spaces then $X' \subseteq X$ denotes the inclusion together with the fact that the Euclidean structure of X' is inherited from the structure of X and $X' \subset X$ denotes the strict inclusion, i.e., $X' \subset X \Leftrightarrow (X' \subseteq X$ and $X' \neq X)$.

Further on we assume that Euclidean spaces $X(n)$ satisfy[13]

$$X(N) \subset \cdots \subset X(2) \subset X(1). \tag{1.8}$$

The configuration space of the system, $X(1)$, is assumed to be Euclidean space, and corresponds to N particles, of various types or masses, e.g.,

$$X(1) = \{x = \{x_1, \ldots, x_N\} \,|\, x_i \in \mathbf{R}^m, i = 1, \ldots, N\},$$

endowed with the metric

$$x, y \in X(1), x \cdot y = \sum_{i=1}^{N} m_i x_i y_i, \quad m_i > 0.$$

$X' \subseteq X(1)$ then denotes a subspace of $X(1)$ endowed with the induced metric of $X(1)$.

Then we take $X(j)$ to denote the subspace of $X(1)$ with the $j-1$ particles x_N to x_{n-j+1} removed (namely, the corresponding coordinates are set to zero)

$$X(j) = \{x = (x_1, \ldots, x_{N-j+1})\}.$$

We then have subspaces $X(j)$ such that

$$X(N) \subset X(N-1) \subset \cdots X(2) \subset X(1).$$

This notation, while nonstandard, will allow us to do the inductive proofs in a standard way, and also emphasizes the generality of the N-body type systems involved: the subspaces $X(j)$ can be chosen more generally for X, so we can cover the generalized N-body systems of Agmon.[14]

To describe the many-body structure of the considered operators we assume that $\mathbf{Y}_0$ is a finite subset of Euclidean spaces contained in $X(1)$ (with inherited Euclidean structures) and for every $Y \in \mathbf{Y}_0$ the associated interaction potential $v_Y \in L^2_{\mathrm{loc}}(Y)$ is real-valued and satisfies some regularity and decay hypotheses (to be described later). For every $X \subseteq X(1)$ we define $V_X : H^2(X) \to L^2(X)$ as the operator of multiplication by

$$V_X(x) = \sum_{Y \in \mathbf{Y}_0, Y \subseteq X} v_Y(\pi^Y x), \tag{1.9}$$

where $x \in X$, π^Y is the orthogonal projection onto Y and $H^s(X)$ denotes the Sobolev space on X.

To describe the perturbation $\mathbf{W}_\mathbf{X}$ we also consider operators $W : H^2(X') \to L^2(X)$ with $X' \subset X$, saying that W is the operator of multiplication by $w \in L^2_{\mathrm{loc}}(X)$ if

$$(W\varphi)(x) = w(x)\varphi(\pi^{X'} x). \tag{1.10}$$

Such interaction terms allow quite general nonparticle number conserving terms. The decay assumptions on $w(x)$ imply that the created particle by the interaction have localized wave function. This is natural as local field theories of massive particles satisfy this condition. It may be violated by massless theories with (strong) infrared interactions.

The simplest case is when the interaction creates "one particle" (linear in the creation/annihilation term):

$$w(x)=f(x_\alpha),x_\alpha\in\mathbf{R}^3,f\in L^2(\mathbf{R}^3)\cap L^\infty(\mathbf{R}^3),$$

$$X'=\mathbb{R}^3\oplus\cdots\mathbb{R}^3,n-times,$$

$$X=X'\oplus\mathbb{R}^3.$$

In this case,

$$(W_\varphi)(x)=f(x_\alpha)\varphi(\Pi^{X'}x)$$

is the operator that creates a particle with wave function $f(x_\alpha)$, acting on the space of n particles into the space of $n+1$ particles.

The construction (1.10) allows much more general type of interactions, e.g., creating pairs of particles in some subspaces of other particles, this can be achieved by choosing

$$w(x)=f(x_\alpha,x_\beta),x_\alpha,x_\beta\in\mathbf{R}^3,$$

which corresponds to a (sum of) products of two creation operators.

We define $\tilde{\mathbf{X}}=\{\tilde{X}(n)\}_{2\leqslant n\leqslant N}$ by

$$X(n-1)=X(n)\oplus\tilde{X}(n)\ \text{ for }\ 2\leqslant n\leqslant N. \tag{1.11}$$

We assume that for $2\leqslant n\leqslant N$ and $Y\in\mathbf{Y}_0$ such that $Y\subseteq X(n)$ we have $w_{n-1,Y}\in L^2_{\mathrm{loc}}(Y\oplus\tilde{X}(n))$ satisfying some regularity and decay hypotheses [to be described later] and $W_{n-1}:H^2(X(n))\to L^2(X(n-1))$ is the operator of multiplication by $w_{n-1}\in L^2_{\mathrm{loc}}(X(n-1))$ of the form

$$w_{n-1}(x(n),\tilde{x}(n))=\sum_{Y\in Y_0,\{0\}\subset Y\subseteq X(n)} w_{n-1,Y}(\pi^Y x(n),\tilde{x}(n)), \tag{1.12}$$

where $(x(n),\tilde{x}(n))\in X(n)\oplus\tilde{X}(n)=X(n-1)$. We assume that $\mathbf{W}_\mathbf{X}$ is the self-adjoint operator in $\mathcal{H}$ defined by the quadratic form

$$\mathbf{W}_{\mathbf{X}[\varphi,\varphi]}=(\mathbf{W}^+_\mathbf{X}\varphi,\varphi)+(\varphi,\mathbf{W}^+_\mathbf{X}\varphi), \tag{1.13}$$

where $\mathbf{W}^+_\mathbf{X}(\varphi)=(W_1\varphi_2,\ldots,W_{N-1}\varphi_N,0)$ for $\varphi=(\varphi_1,\ldots,\varphi_N)\in\mathcal{H}$.

We shall prove:

Theorem I.1: *Let* $\mathbf{H}_\mathbf{X}$ *be defined as previously, let* $\mu>0$ *and* $\mu(n)>\dim\tilde{X}(n)/2$ *for* $2\leqslant n\leqslant N$. *We assume that for all*

$$Y\in Y_0,$$

$$\langle y\rangle^{\mu+|\alpha|}\partial_y^\alpha v_Y(y)(I-\Delta_Y)^{-1} \tag{1.14}$$

are compact operators on $L^2(Y)$ *for* $|\alpha|\leqslant 1$ *and*

$$\langle\tilde{x}(n)\rangle^{\mu(n)+|\tilde{\alpha}|}\langle y\rangle^{\mu+|\alpha|}\partial_y^\alpha\partial^{\tilde{\alpha}}_{\tilde{x}(n)}\omega_{n-1,Y}(y,\tilde{x}(n))(I-\Delta_{Y\oplus\tilde{X}(n)})^{-1} \tag{1.15}$$

are compact operators on $L^2(Y\oplus\tilde{X}(n))$ *for* $|\alpha|+|\tilde{\alpha}|\leqslant 1$, *where we denote* $\langle x\rangle=(1+|x|^2)^{1/2}$. *Then there exists a closed, countable set* $\tau(\mathbf{H_X})\subset\mathbf{R}$ *such that* $\mathbf{A_X}$ *is locally conjugate for* $\mathbf{H_X}$ *in* $\mathbf{R}\backslash\tau(\mathbf{H_X})$ *and the eigenvalues of* $\mathbf{H_X}$ *may accumulate (with multiplicities) only at* $\tau(\mathbf{H_X})$.

Theorem I.2: *We make the same hypotheses as in Theorem I.1 and assume moreover that the operators given by (1.14) are compact for* $|\alpha|\leqslant 2$ *and the operators given by (1.15) are compact for* $|\alpha|+|\tilde{\alpha}|\leqslant 2$. *Then the singular continuous spectrum of* $\mathbf{H_X}$ *is empty. Moreover, the point spectrum outside the threshold set consists of discrete eigenvalues of finite multiplicities. The operator* $\mathbf{H_X}$ *satisfies the limiting absorption principle with respect to either the operator* $\mathbf{A_X}$ *or the operator* $\langle x\rangle$.

II. DESCRIPTION OF THE LATTICE AND ASSOCIATED SUB-HAMILTONIANS

For Banach spaces X_1, X_2 we denote by $B(X_1,X_2)$ and $B_\infty(X_1,X_2)$ the set of bounded and compact operators $X_1\to X_2$, respectively, and $B(X_1)=B(X_1,X_1)$, $B_\infty(X_1)=B_\infty(X_1,X_1)$.

For every $X\subseteq X(1)$ we denote by $X^\perp$ the orthogonal complement of X in $X(1)$, i.e.,

$$X(1)=X\oplus X^\perp. \tag{2.1}$$

Without any loss of generality we may replace $\mathbf{Y}_0$ by $\mathbf{Y}$ being a larger finite family of subspaces of $X(1)$ (it suffices to set $v_Y=0$, $w_{n-1,Y}=0$ identically for $Y\in\mathbf{Y}\backslash\mathbf{Y}_0$). Setting

$$\begin{aligned}\mathbf{Y}_1&=\{Y_1+\cdots+Y_n: n\in\mathbf{N} \text{ and } Y_1,\ldots,Y_n\in\mathbf{Y}_0\cup\mathbf{X}\cup\tilde{\mathbf{X}}\cup\{0\}\},\\ \mathbf{Y}&=\{\pi^{X(1)}Y_1+\cdots+\pi^{X(N)}Y_N: Y_1,\cdots,Y_n\in\mathbf{Y}_1\},\end{aligned} \tag{2.2}$$

we have the following properties:

$$X(n)\in\mathbf{Y} \text{ for } 1\leqslant n\leqslant N,\quad \tilde{X}(n)\in\mathbf{Y} \text{ for } 2\leqslant n\leqslant N, \tag{2.3i}$$

$$Y_1,Y_2\in\mathbf{Y}\Rightarrow Y_1+Y_2\in\mathbf{Y}, \tag{2.3ii}$$

$$Y\in\mathbf{Y}\Rightarrow\pi^{X(n)}Y\in\mathbf{Y} \text{ for } 1\leqslant n\leqslant N. \tag{2.3iii}$$

If $Y\subseteq X\subseteq X(1)$, $Y\in\mathbf{Y}$, then we denote

$$\sharp_X Y=\max\{n\in\mathbf{N}: Y\subseteq Y_1\subset Y_2\subset\cdots\subset Y_n\subseteq X \text{ for some } Y_1,\ldots,Y_n\in\mathbf{Y}\}. \tag{2.4}$$

We denote by $S^m_{\mathrm{hg}}(X)$ the set of smooth functions which are homogeneous of degree m outside a bounded region, i.e.,

$$\begin{aligned}S^m_{\mathrm{hg}}(X)=\{&f\in C^\infty(X): \text{there is } R>0 \text{ such that}\\ &f(\lambda x)=\lambda^m f(x) \text{ hold for } \lambda>1 \text{ and } |x|>R\}.\end{aligned} \tag{2.5}$$

For $r>0$, $\tilde{r}>0$, $X'\in\mathbf{Y}$, $X'\subset X$, we define

$$\begin{aligned}U_X^{X'}(r,\tilde{r})=\{&x\in X: |\pi^{X'}x|<r|x| \text{ and}\\ &|\pi^Y x|>\tilde{r}|x| \text{ for all } Y\in\mathbf{Y} \text{ satisfying } Y\subset X, Y\not\subset X'\}\end{aligned} \tag{2.6}$$

if $X'\neq\{0\}$ and $U_X^{\{0\}}(r,\tilde{r})=U_X^{\{0\}}(\tilde{r})$ with

$$U_X^{\{0\}}(\tilde{r})=\{x\in X: |x|<1\}\cup\{x\in X: |\pi^Y x|>\tilde{r}|x| \text{ for all } Y\in\mathbf{Y} \text{ satisfying } Y\subset X\}. \tag{2.7}$$

If $X'\in\mathbf{Y}$, $X'\subseteq X$ then we may define the following self-adjoint operators in $L^2(X)$:

$$V_X^{X'}(x)=\sum_{Y\in\mathbf{Y},Y\subseteq X'} v_Y(\pi^Y x), \tag{2.8}$$

$$H_X^{X'}=-\Delta_X+V_X^{X'}, \tag{2.8'}$$

where in the case $X'=\{0\}$ we adopt the convention that $V_X^{X'}=0$ and $H_X^{X'}=-\Delta_X$.

Let $J_X^{X'}\in S^0_{\mathrm{hg}}(X)$ be such that supp $J_X^{X'}\subset U_X^{X'}(r,\tilde{r})$ for certain $r>0$, $\tilde{r}>0$. Then

$$(V_X^X-V_X^{X'})J_X^{X'}\in B_\infty(H^2(X),L^2(X)). \tag{2.9}$$

For $X'\in\mathbf{Y}$, $X'\subseteq X(n)$, $2\leqslant n\leqslant N$, we define $W_{n-1}^{X'}:H^2(X(n))\to L^2(X(n-1))$ as the operators of multiplication by

$$w_{n-1}^{X'}(x(n),\tilde{x}(n))=\sum_{Y\in\mathbf{Y},Y\subseteq X'} w_{n-1,Y}(\pi^Y x(n),\tilde{x}(n)) \tag{2.10}$$

and we adopt the convention that $W_{n-1}^{X'}=0$ if $X'=\{0\}$.

Let $J_{X(n)}^{X'}\in S^0_{\mathrm{hg}}(X(n))$ be such that supp $J_{X(n)}^{X'}\subset U_{X(n)}^{X'}(r,\tilde{r})$ for certain $r>0$, $\tilde{r}>0$. Then

$$(W_{n-1}-W_{n-1}^{X'})J_{X(n)}^{X'}\in B_\infty(H^2(X(n)),L^2(X(n-1))). \tag{2.11}$$

For $X'\in\mathbf{Y}$, $X'\subseteq X(N)$ we denote $\mathbf{X}(X')=\{X'(n)\}_{1\leqslant n\leqslant N}$ taking $X'(N)=X'$ and defining successively $X'(N-1)$, $X'(N-2),\ldots,X'(1)\in\mathbf{Y}$ by

$$X'(n-1)=X'(n)\oplus\tilde{X}(n) \quad \text{for} \quad 2\leqslant n\leqslant N. \tag{2.12}$$

Assume moreover $X'\neq\{0\}$ and introduce

$$\mathbf{H}_{\mathbf{X}}^{X'\mathrm{diag}}=\bigoplus_{1\leqslant n\leqslant N} H_{X(n)}^{X'(n)}. \tag{2.13}$$

Still assuming $X'\neq\{0\}$ we define $\mathbf{W}_{\mathbf{X}}^{X'}$ as the self-adjoint operator in $\mathcal{H}$ given by the quadratic form

$$\mathbf{W}_{\mathbf{X}}^{X'}[\varphi,\varphi]=(\mathbf{W}_{\mathbf{X}}^{X'+}\varphi,\varphi)+(\varphi,\mathbf{W}_{\mathbf{X}}^{X'+}\varphi), \tag{2.14}$$

where for $\varphi=(\varphi_1,\ldots,\varphi_N)\in\mathcal{H}$ we have

$$\mathbf{W}_{\mathbf{X}}^{X'+}(\varphi_1,\ldots,\varphi_N)=(W_1^{X'(2)}\varphi_2,\ldots,W_{N-1}^{X'(N)}\varphi_N,0)$$

and set

$$\mathbf{H}_{\mathbf{X}}^{X'}=\mathbf{H}_{\mathbf{X}}^{X'\mathrm{diag}}+\mathbf{W}_{\mathbf{X}}^{X'}. \tag{2.15}$$

In the case $X'\neq\{0\}$ we define $\mathbf{H}_{\mathbf{X}}^{\{0\}}$ according to (2.15), where we set

$$\mathbf{H}_{\mathbf{X}}^{\{0\}\mathrm{diag}}=\left(\bigoplus_{1\leqslant n\leqslant N-1} H_{X(n)}\right)\oplus(-\Delta_{X(N)}) \tag{2.13'}$$

and $\mathbf{W}_{\mathbf{X}}^{\{0\}}$ defined by (2.14), where for $\varphi=(\varphi_1,\ldots,\varphi_N)\in\mathcal{H}$ we take

$$\mathbf{W}_{\mathbf{X}}^{\{0\}+}(\varphi_1,\ldots,\varphi_N)=(W_1^{X'(2)}\varphi_2,\ldots,W_{N-2}^{X'(N-1)}\varphi_{N-1},0,0).$$

The next aim is to construct a suitable partition of unity described in

Proposition II.1: There exists a family $\{\mathbf{J}_{\mathbf{X}}^{X'}\}_{X'\in\mathbf{Y},X'\subset X(N)}$ *of operators of the form*

$$\mathbf{J}_{\mathbf{X}}^{X'}=\bigoplus_{1\leqslant n\leqslant N} J_n^{X'}, \tag{2.16}$$

where every $J_n^{X'}$ *is an operator of multiplication by real-valued* $J_n^{X'}\in S^0_{\mathrm{hg}}(X(n))$, *satisfying*

$$\sum_{X'\in\mathbf{Y},X'\subset X(N)} (\mathbf{J}_{\mathbf{X}}^{X'})^2=I \tag{2.17}$$

and such that for every X', $X''\in\mathbf{Y}$, X', $X''\subset X(N)$, *the following operators*

$$(i+\mathbf{H}_{\mathbf{X}})^{-1}[\mathbf{J}_{\mathbf{X}}^{X'},\mathbf{H}_{\mathbf{X}}^{X''}], \tag{2.18i}$$

$$(i+\mathbf{H}_{\mathbf{X}})^{-1}(\mathbf{H}_{\mathbf{X}}-\mathbf{H}_{\mathbf{X}}^{X'})\mathbf{J}_{\mathbf{X}}^{X'}, \tag{2.18ii}$$

$$(i+\mathbf{H}_{\mathbf{X}})^{-1}[\mathbf{J}_{\mathbf{X}}^{X'},[\mathbf{H}_{\mathbf{X}}^{X''},\mathbf{A}_{\mathbf{X}}]](i+\mathbf{H}_{\mathbf{X}})^{-1}, \tag{2.18iii}$$

$$(i+\mathbf{H}_{\mathbf{X}})^{-1}[\mathbf{H}_{\mathbf{X}}-\mathbf{H}_{\mathbf{X}}^{X'},\mathbf{A}_{\mathbf{X}}]\mathbf{J}_{\mathbf{X}}^{X'}(i+\mathbf{H}_{\mathbf{X}})^{-1} \tag{2.18iv}$$

are compact.

III. PROOF OF PROPOSITION II.1

If $r>0$, then $F(\cdot\leqslant r)$ denotes a smoothed characteristic function of $]-\infty,r]$, i.e., $\lambda\to F(\lambda\leqslant r)$ is a non-negative, smooth function on $\mathbf{R}$ which equals 1 on $]-\infty,r/2]$ and equals 0 on $[r,\infty[$.

Lemma III.1: Let $X'\in\mathbf{Y}$, $\{0\}\subset X'\subset X(N)$ *and* $J_N^{X'}\in S^0_{\mathrm{hg}}(X(N))$. *If* $r>0$ *then the relation*

$$J_{n-1}^{X'}(x(n),\tilde{x}(n))=J_n^{X'}(x(n))F\left(\frac{|\tilde{x}(n)|}{|x(n-1)|}\leqslant r\right) \tag{3.1}$$

allows one to define successively $J_{N-1}^{X'}\in S^0_{\mathrm{hg}}(X(N-1))$, $J_{N-2}^{X'}\in S^0_{\mathrm{hg}}(X(N-2)),\ldots,J_1^{X'}\in S^0_{\mathrm{hg}}(X(1))$. *If moreover* $\mathrm{supp}\ J_N^{X'}\subset U_{X(N)}^{X'}(r_{X'},\tilde{r}_{X'})$ *and* $r_{X'}>0$, $r>0$ *are small enough, then*

$$\mathrm{supp}\ J_n^{X'}\subset U_{X(N)}^{X'(n)}(r_{X'}+(N-n)r,\tilde{r}_{X'}/(1+N-n)) \tag{3.2n}$$

holds for every $1\leqslant n\leqslant N$.

Proof: We assume (3.2n) for a certain $2\leqslant n\leqslant N$ and we show (3.2n−1). Due to (3.2n), for $(x(n),\tilde{x}(n))\in\mathrm{supp}\ J_{n-1}^{X'}$ we have

$$|\tilde{x}(n)|\leqslant r|x(n)| \quad\text{and}\quad |\pi^{X'(n)}x(n)|<(r_{X'}+(N-n)r|x(n)|, \tag{3.3}$$

which implies

$$\begin{aligned}|\pi^{X'(n-1)}x(n-1)|&\leqslant|\pi^{X'(n)}x(n)|+|\tilde{x}(n)|\\&<(r_{X'}+(N-n)r+r)|x(n)|\leqslant(r_{X'}+(N-n+1)r)|x(n-1)|.\end{aligned} \tag{3.4}$$

Now we fix $Y\in\mathbf{Y}$ satisfying $Y\subset X(n-1)$, $Y\not\subseteq X'(n-1)$, and it remains to show that

$$|\pi^{Y}x(n-1)|>\frac{\tilde{r}_{X'}}{2+N-n}|x(n-1)|. \tag{3.5}$$

We define $Y_1 \in \mathbf{Y}$, $Y_1 \subseteq X(n)$ by

$$Y_1 = \pi^{X(n)} Y + X'(n) \tag{3.6}$$

and $Y_2 \subseteq X(n)$ by

$$X(n) = Y_1 \oplus Y_2 . \tag{3.7}$$

We note that $x \in X(n) \cap Y^{\perp} \Leftrightarrow (0 = (x,y) = (x, \pi^{X(n)} y)$ for all $y \in Y) \Leftrightarrow x \in X(n) \cap (\pi^{X(n)} Y)^{\perp}$. Therefore

$$Y_2 = Y_1^{\perp} \cap X(n) = (\pi^{X(n)} Y)^{\perp} \cap X'(n)^{\perp} \cap X(n) = Y^{\perp} \cap X''(n) \tag{3.8}$$

with $X''(n) = X'(n)^{\perp} \cap X(n)$, i.e., with $X''(n)$ satisfying

$$X(n) = X'(n) \oplus X''(n). \tag{3.9}$$

Clearly $Y_2 \subseteq X''(n)$ and we are going to check that the inclusion is strict. Indeed, $Y_2 = X''(n) \Rightarrow Y_1 = X'(n) \Rightarrow \pi^{X(n)} Y \subseteq X'(n) \Rightarrow Y = \pi^{X(n)} Y + \pi^{\tilde{X}(n)} Y \subseteq X'(n) + \tilde{X}(n) \subseteq X'(n-1)$, which is in contradiction with the assumption made on Y.

Thus we have $Y_2 \subset X''(n)$, which implies $X'(n) \subset Y_1$, hence $Y_1 \not\subseteq X'(n)$ and due to (3.2n),

$$|\pi^{Y_1} x(n)|^2 > \left(\frac{\tilde{r}_{X'}}{1+N-n} \right)^2 |x(n)|^2 \tag{3.10}$$

and since $|\pi^{Y_1} x(n)|^2 + |\pi^{Y_2} x(n)|^2 = |x(n)|^2$, (3.10) is equivalent to

$$|\pi^{Y_2}(n)|^2 < \left(1 - \left(\frac{\tilde{r}_{X'}}{1+N-n} \right)^2 \right) |x(n)|^2 . \tag{3.11}$$

Therefore using (3.8), (3.11), and (3.3) we obtain

$$\begin{aligned} |\pi^{Y^{\perp}} x(n-1)| &\leq |\pi^{Y^{\perp} \cap X''(n)} x(n-1)| + |\pi^{Y^{\perp} \cap X'(n)} x(n-1)| + |\pi^{Y^{\perp} \cap \tilde{X}(n)} x(n-1)| \\ &\leq |\pi^{Y_2} x(n)| + |\pi^{X'(n)} x(n)| + |\tilde{x}(n)| \Bigg(\left(1 - \left(\frac{\tilde{r}_{X'}}{1+N-n} \right)^2 \right)^{1/2} \\ &\quad + r_{X'} + (N-n+1) r \Bigg) |x(n)| \end{aligned} \tag{3.12}$$

and taking $r_{X'} > 0$, $r > 0$ small enough, we have

$$\left(1 - \left(\frac{\tilde{r}_{X'}}{1+N-n} \right)^2 \right)^{1/2} + r_{X'} + (N-n+1) r \leq \left(1 - \left(\frac{\tilde{r}_{X'}}{2+N-n} \right)^2 \right)^{1/2} . \tag{3.13}$$

Now it is clear that (3.12) and (3.13) give

$$|\pi^{Y^{\perp}} x(n-1)|^2 < \left(1 - \left(\frac{\tilde{r}_{X'}}{2+N-n} \right)^2 \right) |x(n-1)|^2 , \tag{3.14}$$

which gives (3.5) due to $|\pi^{Y} x(n-1)|^2 + |\pi^{Y^{\perp}} x(n-1)|^2 = |x(n-1)|^2$. □

Lemma III.2: Let $X' \in \mathbf{Y}$, $\{0\} \subset X' \subset X(N)$ *and assume that* $\{J_n^{X'}\}_{1 \leq n \leq N}$ *are as in Lemma 3.1 and (3.2n) holds for* $1 \leq n \leq N$. *If* $\mathbf{J}_{\mathbf{X}}^{X'}$ *is given by* (2.16), *then the operators (2.18i,ii,iii,iv) are compact*.

Proof: (i) Clearly it suffices to consider $\mathbf{H}_{\mathbf{X}}$ instead of $\mathbf{H}_{\mathbf{X}}^{X''}$ in (2.18i). Since the commutators $[J_n^{X'},\Delta_{X(n)}]$ are first-order differential operators with coefficients in $S_{\mathrm{hg}}^{-1}(X(n))$, i.e., $\Delta_{X(n)}$-compact operators, it is clear that

$$[\mathbf{J}_{\mathbf{X}}^{X'},\mathbf{H}_{\mathbf{X}}^{\mathrm{diag}}]=\bigoplus_{1\leqslant n\leqslant N}[J_n^{X'},-\Delta_{X(n)}] \tag{3.15}$$

is $\mathbf{H}_{\mathbf{X}}$-compact. In order to prove that $[\mathbf{J}_{\mathbf{X}}^{X'},\mathbf{W}_{\mathbf{X}}]$ is $\mathbf{H}_{\mathbf{X}}$-compact, it suffices to show that for $2\leqslant n\leqslant N$ one has

$$J_{n-1}^{X'}W_{n-1}-W_{n-1}J_n^{X'}\in B_\infty(H^2(X(n)),L^2(X(n-1))). \tag{3.16}$$

However $J_{n-1}^{X'}W_{n-1}-W_{n-1}J_n^{X'}$ is the operator of multiplication by

$$g(x(n),\tilde{x}(n))=\left(F\left(\frac{|\tilde{x}(n)|}{|x(n-1)|}\leqslant r\right)-1\right)w_{n-1}(x(n),\tilde{x}(n))J_n^{X'}(x(n)) \tag{3.17}$$

and we may write $g=g_3g_2g_1$ with

$$g_1(x(n),\tilde{x}(n))=\langle\tilde{x}(n)\rangle^{-\mu(n)+\epsilon}J_n^{X'}(x(n)), \tag{3.18i}$$

$$g_2(x(n),\tilde{x}(n))=\langle x(n)\rangle^{-\epsilon}\langle\tilde{x}(n)\rangle^{\mu(n)}w_{n-1}(x(n),\tilde{x}(n)), \tag{3.18ii}$$

$$g_3(x(n),\tilde{x}(n))=\left(F\left(\frac{|\tilde{x}(n)|}{|x(n-1)|}\leqslant r\right)-1\right)\langle x(n)\rangle^{\epsilon}\langle\tilde{x}(n)\rangle^{-\epsilon}, \tag{3.18iii}$$

where $\epsilon>0$ is chosen such that $\mu(n)-\epsilon>\dim\tilde{X}(n)/2$, which implies that the multiplication by g_1 is a bounded operator $H^2(X(n))\to H^2(X(n-1))$. Next the compactness hypotheses concerning the operators (1.15) guarantee that the multiplication by g_2 is a compact operator $H^2(X(n-1))\to L^2(X(n-1))$ and we complete the proof noting that the multiplication by g_3 is a bounded operator in $L^2(X(n-1))$ due to the definition of F.

(ii) Clearly (2.9) implies that $(\mathbf{H}_{\mathbf{X}}^{\mathrm{diag}}-\mathbf{H}_{\mathbf{X}}^{X'\,\mathrm{diag}})\mathbf{J}_{\mathbf{X}}^{X'}$ is $\mathbf{H}_{\mathbf{X}}$-compact. For $1\leqslant n\leqslant N$ let $\tilde{J}_n^{X'}\in S_{\mathrm{hg}}^0(X(n))$ be such that $\tilde{J}_n^{X'}=1$ on supp $J_n^{X'}$ and supp $\tilde{J}_n^{X'}\subset U_{X(n)}^{X'(n)}(r_{(n)}^{X'},\tilde{r}_n^{X'})$ for certain $r_n^{X'}>0$, $\tilde{r}_n^{X'}>0$. Setting

$$\tilde{\mathbf{J}}_{\mathbf{X}}^{X'}=\bigoplus_{1\leqslant n\leqslant N}\tilde{J}_n^{X'}, \tag{3.19}$$

it is clear that (2.11) implies the fact that $\tilde{\mathbf{J}}_{\mathbf{X}}^{X'}(\mathbf{W}_{\mathbf{X}}-\mathbf{W}_{\mathbf{X}}^{X'})\mathbf{J}_{\mathbf{X}}^{X'}$ is $\mathbf{H}_{\mathbf{X}}$-compact. Since $(I-\tilde{\mathbf{J}}_{\mathbf{X}}^{X'})\mathbf{J}_{\mathbf{X}}^{X'}=0$, it suffices to note that the operator

$$(I-\tilde{\mathbf{J}}_{\mathbf{X}}^{X'})(\mathbf{W}_{\mathbf{X}}-\mathbf{W}_{\mathbf{X}}^{X'})\mathbf{J}_{\mathbf{X}}^{X'}=(I-\tilde{\mathbf{J}}_{\mathbf{X}}^{X'})[\mathbf{W}_{\mathbf{X}}-\mathbf{W}_{\mathbf{X}}^{X'},\mathbf{J}_{\mathbf{X}}^{X'}] \tag{3.20}$$

is $\mathbf{H}_{\mathbf{X}}$-compact due to (i).

(iii) and (iv) We may define $\tilde{V}_X^{X'}$, $\tilde{H}_X^{X'}$, $\tilde{W}_{n-1}^{X'}$ according to (2.8), (2.10), where v_Y, $w_{n-n,Y}$ are replaced by

$$\tilde{v}_Y(y)=-y\cdot\Delta_y v_Y(y), \tag{3.21}$$

$$\tilde{w}_{n-1,Y}(y,\tilde{x}(n))=-\left(y\cdot\Delta_y+\tilde{x}(n)\cdot\Delta_{\tilde{x}(n)}+\frac{\dim\tilde{X}(n)}{2}\right)w_{n-1,Y}(y,\tilde{x}(n)). \tag{3.21$'$}$$

It is clear we still have

$$(\tilde{V}_X^X - \tilde{V}_X^{X'}) J_X^{X'} \in B_\infty(H^2(X), L^2(X)), \tag{3.22}$$

$$(\tilde{W}_{n-1} - \tilde{W}_{n-1}^{X'}) J_{X(n)}^{X'} \in B_\infty(H^2(X)(n)), L^2(X(n-1))), \tag{3.23}$$

where $\tilde{V}_X = \tilde{V}_X^X$, $\tilde{W}_{n-1} = \tilde{W}_{n-1}^X$.

Thus it suffices to follow the proof of (i) and (ii) noting that

$$\frac{i}{2}[\mathbf{H}_\mathbf{X}^{X'}, \mathbf{A}_\mathbf{X}] = \tilde{\mathbf{H}}_\mathbf{X}^{X'} = \tilde{\mathbf{H}}_\mathbf{X}^{X' \text{ diag}} + \tilde{\mathbf{W}}_\mathbf{X}^{X'}, \tag{3.24}$$

where $\tilde{\mathbf{H}}_\mathbf{X}^{X' \text{ diag}}$ and $\tilde{\mathbf{W}}_\mathbf{X}^{X'}$ are defined according to (2.13), (2.14) with $H_{X(n)}^{X'(n)}$, $W_{n-1}^{X'(n)}$ replaced by $\tilde{H}_{X(n)}^{X'(n)}$, $\tilde{W}_{n-1}^{X'(n)}$. □

Proof of Proposition II.1: Fix $0 < \tilde{r}_2 < 1$, set $\tilde{r}_{X'} = \tilde{r}_2$ for every X' such that $\sharp_{X(N)} X' = 2$ and choose $r_2 = r_2(\tilde{r}_2) > 0$ small enough to guarantee (3.2n) for $1 \leqslant n \leqslant N$ with $r_{X'} = r_2$. Assuming that we have chosen $r_{X'} = r_{\sharp_{X(N)} X'} > 0$, $\tilde{r}_{X'} = \tilde{r}_{\sharp_{X(N)} X'} > 0$ for every X' such that $\sharp_{X(N)} X' \leqslant k$, we choose sufficiently small $\tilde{r}_{k+1} = \tilde{r}_{k+1}(\tilde{r}_2, r_2, \ldots, \tilde{r}_k, r_k) > 0$ and $r_{k+1} = r_{k+1}(\tilde{r}_2, r_2, \ldots, \tilde{r}_k, r_k, \tilde{r}_{k+1}) > 0$ small enough to guarantee (3.2n) for $1 \leqslant n \leqslant N$ with $\tilde{r}_{X'} = \tilde{r}_{k+1}$, $r_{X'} = r_{k+1}$ for every X' such that $\sharp_{X(N)} X' = k+1$. A simple geometric reasoning based on the fact that for $X' \subset X$ and $r > 0$ small, $\{x \in X : |\pi^{X'} x| < r|x|\}$ is a small conical neighborhood of $X'^{\perp} \cap (X \setminus \{0\})$ in $X \setminus \{0\}$, allows one to find $\tilde{r}_{\{0\}} = r_{\{0\}} > 0$ such that $\{U_{X(N)}^{X'}(r_{X'}, \tilde{r}_{X'})\}_{X' \in \mathbf{Y}, X' \subset X(N)}$ is a covering of $X(N)$. Therefore there exists a partition of unity

$$\sum_{X' \in \mathbf{Y}, X' \subset X(N)} \tilde{J}_N^{X'} = 1 \tag{3.25}$$

composed of $\tilde{J}_N^{X'} \in S_{\text{hg}}^0(X(N))$ such that $\operatorname{supp} \tilde{J}_N^{X'} \subset U_{X(N)}^{X'}(r_{X'}, \tilde{r}_{X'})$ and $\tilde{J}_N^{X'} \geqslant 0$.

For $X' \neq \{0\}$ we define successively $\tilde{J}_{N-1}^{X'} \in S_{\text{hg}}^0(X(N-1))$, $\tilde{J}_{N-2}^{X'} \in S_{\text{hg}}^0(X(N-2)), \ldots, \tilde{J}_1^{X'} \in S_{\text{hg}}^0(X(1))$, using relation (3.1) with $\tilde{J}_n^{X'}$ instead of $J_n^{X'}$ and let $\tilde{\mathbf{J}}_\mathbf{X}^{X'}$ be defined as in (3.19). Due to the assertion of Lemma 2.1 we may assume that (3.2n) holds for $1 \leqslant n \leqslant N$ with $\tilde{J}_n^{X'}$ instead of $J_n^{X'}$ and due to Lemma 3.2 the commutator $[\tilde{\mathbf{J}}_\mathbf{X}^{X'}, \mathbf{H}_\mathbf{X}]$ is $\mathbf{H}_\mathbf{X}$-compact.

Defining $\tilde{\mathbf{J}}_\mathbf{X}^{\{0\}}$ by

$$\sum_{X' \in \mathbf{Y}\{0\} \subset X' \subset X(N)} \tilde{\mathbf{J}}_\mathbf{X}^{X'} = 1 - \tilde{\mathbf{J}}_\mathbf{X}^{\{0\}}, \tag{3.26}$$

it is clear that $[\tilde{\mathbf{J}}_\mathbf{X}^{\{0\}}, \mathbf{H}_\mathbf{X}]$ is still $\mathbf{H}_\mathbf{X}$-compact and

$$\tilde{\mathbf{J}}_\mathbf{X}^{\{0\}} = \bigoplus_{1 \leqslant n \leqslant N} \tilde{J}_n^{\{0\}}, \tag{3.27}$$

with $\tilde{J}_n^{\{0\}} \in S_{\text{hg}}^0(X(n))$ for $1 \leqslant n \leqslant N$ and $\operatorname{supp} \tilde{J}_N^{\{0\}} \subset U_{X(N)}^{\{0\}}(\tilde{r}_{\{0\}})$, hence the operators (2.18ii), (2.18iv) are compact for $X' = \{0\}$ as well.

It is clear that (3.26) implies existence of a constant $c_0 > 0$ such that

$$\mathbf{S}_\mathbf{X} = \sum_{X' \in \mathbf{Y}, X' \subset X(N)} (\tilde{\mathbf{J}}_\mathbf{X}^{X'})^2 \geqslant c_0 I \tag{3.28}$$

and then clearly $[\mathbf{S}_\mathbf{X}, \mathbf{H}_\mathbf{X}]$ is $\mathbf{H}_\mathbf{X}$-compact. Hence

$$[f(\mathbf{S_X}),\mathbf{H_X}](i+\mathbf{H_X})^{-1}\in B_\infty(\mathcal{H}) \tag{3.29}$$

if $f(\lambda)=(\lambda\pm i)^{-1}$ and Stone–Weierstrass theorem (see, e.g., Ref. 4) allows one to affirm that (3.26) still holds for every $f\in C(\mathbf{R})$ such that $f(\lambda)\to 0$ when $\lambda\to\infty$. We complete the proof noting that all assertions of Proposition 2.1 are satisfied if we set $\mathbf{J}_\mathbf{X}^{X'}=\tilde{\mathbf{J}}_\mathbf{X}^{X'}\mathbf{S}_\mathbf{X}^{-1/2}$. □

IV. PROOFS OF THEOREMS 1.1 AND 1.2

Let $\mathbf{X}=\{X(n)\}_{1\leqslant n\leqslant N}$ be as before a finite family of Euclidean spaces satisfying (1.8) and let $\mathbf{X}'=\{X'(n)\}_{1\leqslant n\leqslant N'}$ be another finite family of Euclidean spaces satisfying

$$X'(N')\subset\cdots\subset X'(2)\subset X'(1). \tag{4.1}$$

We shall write $\mathbf{X}'\leqslant\mathbf{X}$ if and only if the following three conditions hold:

$$\text{(i)}\quad N'\leqslant N,$$

$$\text{(ii)}\quad X'(1)\subseteq X(1),$$

$$\text{(iii)}\quad \tilde{X}'(n)=\tilde{X}(n)\ \text{ for }\ 2\leqslant n\leqslant N',$$

where $\tilde{X}(n)$ is given by (1.11) and $\tilde{X}'(n)$ by

$$X'(n-1)=X'(n)\oplus\tilde{X}'(n)\ \text{ for }\ 2\leqslant n\leqslant N'. \tag{4.2}$$

Moreover we shall write $\mathbf{X}'<\mathbf{X}\Leftrightarrow(\mathbf{X}'\leqslant\mathbf{X}$ and $\mathbf{X}'\neq\mathbf{X})$.

The idea of the proof of Theorem 1.1 is to show the assertion for $\mathbf{H_X}$ with

$$\tau(\mathbf{H_X})=\bigcup_{\mathbf{X'}<\mathbf{X}}\overline{\sigma_{pp}(\mathbf{H}_{X'})} \tag{4.3}$$

[where $\sigma_{pp}(H)$ denotes the set of eigenvalues of H], assuming that the analogical statement holds for every $\mathbf{H}_{\mathbf{X}'}$ with $\mathbf{X}'<\mathbf{X}$. We note first that Proposition 2.1 has the following

Corollary IV.1: Assume that $\mathbf{J}_\mathbf{X}^{X'}$ satisfies the assertions of Proposition 2.1. If $f\in C_0^\infty(\mathbf{R})$ then for every X', $X''\in\mathbf{Y}$, X', $X''\subset X(N)$, the operators

$$(i+\mathbf{H_X})[\mathbf{J}_\mathbf{X}^{X'},f(\mathbf{H}_\mathbf{X}^{X''})], \tag{4.4}$$

$$(i+\mathbf{H_X})(f(\mathbf{H_X})-f(\mathbf{H}_\mathbf{X}^{X'}))\mathbf{J}_\mathbf{X}^{X'}, \tag{4.4'}$$

are compact. Moreover there exist compact operators K_1, K_2, such that

$$f(\mathbf{H_X})=\sum_{X'\in\mathbf{Y},X'\subset X(N)}\mathbf{J}_\mathbf{X}^{X'}f(\mathbf{H}_\mathbf{X}^{X'})\mathbf{J}_\mathbf{X}^{X'}+K_1, \tag{4.5}$$

$$f(\mathbf{H_X})[i\mathbf{H_X},\mathbf{A_X}]f(\mathbf{H_X})=\sum_{X'\in\mathbf{Y},X'\subset X(N)}\mathbf{J}_\mathbf{X}^{X'}f(\mathbf{H}_\mathbf{X}^{X'})[i\mathbf{H}_\mathbf{X}^{X'},\mathbf{A_X}]f(\mathbf{H}_\mathbf{X}^{X'})\mathbf{J}_\mathbf{X}^{X'}+K_2. \tag{4.6}$$

Indeed, Proposition 2.1 allows one to get the compactness of operators (4.4)–(4.4′) for $f(\lambda)=(\lambda\pm i)^{-1}$ and the general case follows as before via Stone–Weierstrass theorem (cf. Ref. 4). Using (2.18) and (4.4)–(4.4′) we get (4.5–6) as in Ref. 4. We note first that the assertion of Theorem 1.1 holds in the case $N=1$ corresponding to the case of a standard scalar many-body operator treated in Ref. 3 or 4, where

$$\tau(H_X)=\bigcup_{X'\subset X}\overline{\sigma_{pp}(H_{X'})}. \tag{4.7}$$

Consider now the case $N\geqslant 2$ and assume that the assertion of Theorem 1.1 with (4.3) holds for all $\mathbf{X}'$ such that $\mathbf{X}'<\mathbf{X}$. Clearly we may exclude the case $X(N)=\{0\}$, because the corresponding operator may be replaced by $\mathbf{H}_{\mathbf{X}(N-1)}$ with

$$\mathbf{X}(N-1)=\{X(n)\}_{1\leqslant n\leqslant N-1}<\mathbf{X} \tag{4.8}$$

for which the assertion of Theorem 1.1 holds due to our induction hypothesis. It remains to consider the case $X(N)\neq\{0\}$ applying Corollary 4.1 similarly as in Ref. 4. Then for every $X'\in\mathbf{Y}$, $\{0\}\subset X'\subset X(N)$, we use the direct decomposition

$$\mathbf{H}_{\mathbf{X}}^{X'}=\int_{\xi\in X''}^{\oplus}\mathbf{H}_{\mathbf{X}(X')}(\xi)\mathrm{d}\xi, \tag{4.9}$$

where X'' is such that $X(N)=X'\oplus X''$ and

$$\mathbf{H}_{\mathbf{X}(X')}(\xi)=\xi^2+\mathbf{H}_{\mathbf{X}(X')}, \tag{4.9$'$}$$

where $\mathbf{H}_{\mathbf{X}(X')}$ is the Hamiltonian associated with the family of Euclidean subspaces $\mathbf{X}(X')$ defined by (2.12) with $X'(N)=X'$. Thus for $X'\in\mathbf{Y}$, $\{0\}\subset X'\subset X(N)$ we have $\mathbf{X}(X')<\mathbf{X}$ and the assertion of Theorem 1.1 holds for $\mathbf{H}_{\mathbf{X}(X')}$ due to our induction hypothesis. It remains to note that in the case $X'=\{0\}$,

$$\mathbf{H}_{\mathbf{X}}^{\{0\}}=\mathbf{H}_{\mathbf{X}(N-1)}\oplus(-\Delta_{X(N)}), \tag{4.10}$$

with $\mathbf{X}(N-1)$ given by (4.8), hence satisfies the assertion of Theorem 1.1. Therefore we may complete the proof similarly as in the reasoning described in Ref. 4. Here we point out that compactness is (in general) used in the Fock space with differing number of particles. So compactness of the relevant contribution from the W terms is between two spaces. Smallness of the remainder terms, after fibration, follows as in the usual case. The assertion of Theorem 1.2 follows from Theorem 1 and from the boundedness of $[[\mathbf{H}_{\mathbf{X}},\mathbf{A}_{\mathbf{X}}],\mathbf{A}_{\mathbf{X}}](i+\mathbf{H}_{\mathbf{X}})^{-1}$ (cf. Refs. 2 and 13).

SU(N) skyrmions from harmonic maps $S^2 \to \mathrm{Gr}(2,N)$

H. J. Wospakrik[a] and W. J. Zakrzewski[b]
Department of Mathematical Sciences, University of Durham, Durham DH1 3LE, United Kingdom

(Received 18 June 2001; accepted for publication 3 January 2002)

We construct multiskyrmion fields of the SU(N) Skyrme models by using harmonic maps of S^2 to the Grassmannian Gr(2,N), which we express in terms of rank-2 projectors. Within this construction we derive some approximate spherically symmetric solutions of SU(N) Skyrme models and show that their energies are marginally higher than those for the rank-one cases. We also discuss the possibility of generating exact spherically symmetric solutions using this construction. In particular, we present arguments which suggest that the only solutions obtained in this way are embeddings. © *2002 American Institute of Physics.*

I. INTRODUCTION

The SU(N) Skyrme models are minimal generalizations of the SU(N) chiral models in (3 +1)-dimensional space–time which possess static finite energy solutions called multiskyrmions. They are examples of topological solitons in three spatial dimensions. Recently, they have received a great deal of attention, especially for the $N=2$ case, since, it has been argued[1,2] that they describe, at a classical level, low energy states of nuclei.

The SU(N) Skyrme models are described by SU(N) group valued functions U of space–time coordinates $x^\mu=(\vec{x},t)$. Their dynamics is determined by the Lagrangian density

$$\mathcal{L}=-\frac{F^2}{16}\mathrm{Tr}(L_\mu L^\mu)+\frac{1}{32a^2}\mathrm{Tr}([L_\mu,L_\nu][L^\mu,L^\nu])+\frac{F^2}{16}M_\pi^2\,\mathrm{Tr}(U^{-1}+U-2I), \tag{1}$$

where

$$L_\mu=U^{-1}\partial_\mu U \tag{2}$$

are the SU(N) algebra valued currents, $F\cong 189\,\mathrm{MeV}$ is the pion decay constant, and a is a dimensional constant. The last term in (1) describes the mass term where M_π is the pion mass.

Multiskyrmions are stationary points (minima or saddle points) of the corresponding static energy functional. The requirement of the finiteness of the multiskyrmions energy imposes the condition that the field $U(\vec{x},t)$ goes to a constant matrix U_0 at spatial infinity. As by a global SU(N) transformation, this U_0 can be brought to the identity matrix I, so without the loss of generality we can impose the following boundary condition on U: $U\to I$ as $|\vec{x}|\to\infty$.

As this boundary condition is effectively a mapping from $S^3\to\mathrm{SU}(N)$ we see that each multiskyrmion configuration can be classified by an integer valued winding number

$$B=\frac{1}{24\pi^2}\int_{R^3}\epsilon_{ijk}\mathrm{Tr}(L_iL_jL_k)\mathrm{d}^3\vec{x}. \tag{3}$$

[a]Electronic mail: H.J.Wospakrik@durham.ac.uk
[b]Electronic mail: W.J.Zakrzewski@durham.ac.uk

This number is a topological invariant, i.e., an element of the third homotopy group $\pi_3(\mathrm{SU}(N))\equiv Z$, which classifies the solitonic sectors of the model. Following Skyrme[1] and Witten,[2,3] B is identified with the baryon number of the multiskyrmion configuration.

In what follows we express the energy in the same units as the baryon number B. This is achieved by rescaling the spatial coordinates[4,5] $\vec{x}\to 2\vec{x}/aF$ and by taking $F/4a=1/12\pi^2$. In these units the energy functional is given by

$$E=\frac{1}{12\pi^2}\int_{R^3}\left[-\frac{1}{2}\mathrm{Tr}(L_i^2)-\frac{1}{16}\mathrm{Tr}([L_i,L_j]^2)-\frac{m_\pi^2}{2}\mathrm{Tr}(U^{-1}+U-2I)\right]\mathrm{d}^3\vec{x}, \tag{4}$$

where $m_\pi=2M_\pi/aF$. From (4) we find the equation for the stationary points:

$$\partial_i\left(L_i-\frac{1}{4}[L_j,[L_i,L_j]]\right)-\frac{m_\pi^2}{2}(U-U^{-1})=0. \tag{5}$$

The first exact solution of (5), in the SU(2) case, was found by Skyrme.[1] This solution, also known as a hedgehog solution, describes a spherically symmetric energy lump and has the baryon number $B=1$. Since Witten's suggestion that the Skyrme model arises in the large N_c limit of QCD,[2] most of the studies involving SU(N) for $N>2$ considered configurations which were embeddings of the SU(2) fields.

The first nonembedding solution, for $N=3$, was presented by Balachandran *et al.*,[6] who found an SO(3) subgroup soliton which has baryon number $B=2$. Another configuration, which has a large strangeness content was then found by Kopeliovich *et al.*[7]

A more systematic study, using the harmonic map ansatz method, for any N, was then carried out by Ioannidou *et al.*[8,9] This method enabled the construction of new static spherically symmetric solutions. The method was, in fact, a generalization of the rational map approach of Houghton *et al.*[10] In their seminal work,[10] Houghton *et al.* have shown how to use rational maps of $S^2\to S^2$ to construct field configurations for the SU(2) Skyrme model which have arbitrary baryon number B and, for low values of B, are close to the exact solutions of the model. In Ref. 9, Ioannidou *et al.* took the SU(2) ansatz of Houghton *et al.* and rewrote it in terms of a projector of $S^2\to CP^1$ and then generalized it to more general projectors of $S^2\to CP^{N-1}$ of rank-one.

In this paper we generalize the method of Ioannidou *et al.* further by considering projectors of S^2 into the Grassmannian Gr(2,N), i.e., using projectors of higher rank (we concentrate our attention on the rank-2 projectors). We find that, in contradistinction to the rank-1 case, in which exact spherically symmetric solutions can be found (numerically) by using the Veronese sequence of N mutually orthogonal vector fields in CP^{N-1}, such a construction is now more involved.

In Sec. II, we discuss the harmonic maps of R^2 into the Grassmannian Gr(n,N) in terms of the ($N\times N$) projectors of rank-n, with $1<n<N$ and then present our generalization of the harmonic map ansatz. In Sec. III we rewrite various quantities of the SU(N) Skyrme models in spherical polar coordinates and then, using the harmonic map ansatz, reexpress them in terms of rank-n projectors. Next, in Sec. IV, we derive the stationary equations of the approximate energy functional which we then use to study various field configurations for the $N=3$, 4, and 5 cases using one and two rank-2 projectors in Secs. V and VI, respectively. Then, in Sec. VII, we formulate a condition on the sequence of N mutually orthogonal ($N\times n$) matrix fields in Gr(n,N) which would give exact spherically symmetric solutions of the SU(N) Skyrme models. In Secs. VIII and IX, we analyze this condition further, consider some special configurations, and present arguments suggesting that its only solutions are embeddings.

II. HARMONIC MAPS INTO GRASSMANN MANIFOLDS

Let $\xi\in C$ be a complex variable and $M_k=M_k(\xi,\overline{\xi})$, $k=0,1,...,\lambda$ where $\lambda\leqslant(N-1)$, be a set of $(\lambda+1)$ mutually orthogonal $(N\times n)$ matrices $(n<N)$, i.e.,

$$M_k^\dagger M_l=|M_k|^2\delta_{kl}, \tag{6}$$

where δ_{kl} is the Kronecker's delta, and where

$$|M_k|^2 = M_k^\dagger M_k \tag{7}$$

are $(n\times n)$ nonsingular matrices. Then the corresponding projector $P_k(n)$ onto each matrix M_k is given by

$$P_k(n) = M_k |M_k|^{-2} M_k^\dagger . \tag{8}$$

Clearly, $\mathrm{Tr}\, P_k(n) = \mathrm{Tr}\, I_n = n$, where I_n is an $(n\times n)$ unit matrix which means that each projector $P_k(n)$ has rank-n. From (8), we see that the projectors $P_k(n)$ are mutually orthogonal, i.e., $P_k(n)P_l(n) = \delta_{kl}P_l(n)$, and are Hermitian, i.e., $P_k(n)^\dagger = P_k(n)$, as by definition M_k are mutually orthogonal and, by construction (7), $|M_k|^2$ are Hermitian.

In the following we want to present a generalized harmonic map ansatz. To do this we use a sequence of mutually orthogonal matrices $(M_0, M_1, \ldots, M_\lambda)$ obtained from a sequence of holomorphic (analytic) matrices $(M, \partial_\xi M, \ldots, \partial_\xi^\lambda M), \partial_{\bar\xi} M = 0$, via the Gram–Schmidt orthogonalization process.

We can do this using the operator P_+ (Ref. 11) defined by its action on any matrix $M \in C^{N\times n}$ as

$$P_+ M = \partial_\xi M - M|M|^{-2}(M^\dagger \partial_\xi M). \tag{9}$$

Then we have

$$M_0 = M, \quad M_1 = P_+ M, \quad \ldots, \quad M_k = P_+^k M = P_+(P_+^{k-1} M), \quad \ldots, \quad M_\lambda = P_+^\lambda M. \tag{10}$$

With this construction the following properties of the matrices M_k hold when M_0 is holomorphic:[11]

$$\partial_{\bar\xi} M_k = -M_{k-1}|M_{k-1}|^{-2}|M_k|^2, \tag{11}$$

$$\partial_\xi (M_k |M_k|^{-2}) = M_{k+1}|M_k|^{-2}. \tag{12}$$

Geometrically, the matrices M_k define harmonic maps $R^2 \to \mathrm{Gr}(n,N)$, i.e., in terms of the projectors $P_k(n)$, where $\mathrm{Gr}(n,N)$ is the Grassmann manifold of n-dimensional planes in C^N.[11]

For rank-2 projectors which we are considering in this paper, the matrix M_k is given by

$$M_k = (M_{k1}, M_{k2}), \tag{13}$$

where M_{k1} and M_{k2} are two N-component column vector fields and $|M_k|^2$ is a (2×2) matrix.

Using this column vector notation the entries of the projector $P_k(2)$ are given by

$$(P_k(2))_{ab} = \frac{1}{D_k}[|M_k|^2_{22}(M_{k1})_a(\overline{M}_{k1})_b + |M_k|^2_{11}(M_{k2})_a(\overline{M}_{k2})_b - |M_k|^2_{12}(M_{k1})_a(\overline{M}_{k2})_b - |M_k|^2_{21}(M_{k2})_a(\overline{M}_{k1})_b], \tag{14}$$

where $a,b = 1,2,\ldots,N$, $(\overline{M}_{kj})_a$, $j = 1,2$ is the complex conjugate of $(M_{kj})_a$, and where

$$D_k = \mathrm{Det}|M_k|^2. \tag{15}$$

Clearly, $\mathrm{Tr}\, P_k(2) = 2$. Furthermore, if we let

$$P_{kj}(1) = M_{kj}|M_{kj}|^{-2} M_{kj}^\dagger , \tag{16}$$

then from (14) it follows that

$$P_k(2)=P_{k1}(1)+\tilde{P}_{k2}(1), \tag{17}$$

where

$$\tilde{P}_{k2}(1)=\tilde{M}_{k2}|\tilde{M}_{k2}|^{-2}\tilde{M}_{k2}^{\dagger}, \tag{18}$$

with

$$\tilde{M}_{k2}=[I-P_{k1}(1)]M_{k2}, \tag{19}$$

which is orthogonal to M_{k1}, i.e., $M_{k1}^{\dagger}\tilde{M}_{k2}=0$. Thus, we see from (17) that each projector of $\mathrm{Gr}(2,N)$ is really a sum of two mutually orthogonal rank-1 projectors.

Note that for some cases this construction does not work. To see this take the case where the initial $(N\times 2)$ matrix M_0 is chosen to be given by

$$M_0=(M_{01},\partial_{\xi}M_{01}), \tag{20}$$

i.e., M_{02} is a derivative of M_{01}. Then it follows from (10) that

$$M_1=(0,M_{12}). \tag{21}$$

Thus, in this special case, $|M_1|^2$ is singular, and so the projector $P_1(2)$ does not exist.

Let ξ now be related to the θ, φ, which locally parameterize S^2, via $\xi=\tan(\theta/2)e^{i\varphi}$. Then the matrices M_k define harmonic maps $S^2\to\mathrm{Gr}(n,N)$. Taking our sequence of projectors $P_k(n)=P_k$ in (8) we can now formulate our generalized harmonic map ansatz for the SU(N) Skyrme fields in three dimensions. Namely, we take the matrix $U\in\mathrm{SU}(N)$ of the form

$$U=\exp\left[i\sum_{k=0}^{\lambda-1}g_k\left(P_k-\frac{nI}{N}\right)\right]=\exp\left(-ni\sum_{k=0}^{\lambda-1}g_k/N\right)\left(I+\sum_{l=0}^{\lambda-1}A_lP_l\right), \tag{22}$$

where $g_k=g_k(r)$ for $k=0,...,\lambda-1$ are the profile functions and

$$A_k=(e^{ig_k}-1). \tag{23}$$

The profile functions $g_k(r)$ are required to satisfy the boundary conditions: $g_k(\infty)=0$ and $g_k(0)=2\alpha\pi$, where $\alpha=0$ or ± 1.

III. SU(N) MODEL-FOR THE GENERALIZED HARMONIC MAP ANSATZ

In this section, we first rewrite the energy (4) and the topological charge (3) in the spherical polar coordinates (r,θ,φ). Later we introduce the harmonic map ansatz—so it is convenient to replace the angular coordinates by the complex (or holomorphic) coordinates $(\xi,\bar{\xi})$.

A. Energy

The energy (4), when written in the spherical (holomorphic) coordinates $(r,\xi,\bar{\xi})$, takes the form

$$E=-\frac{i}{12\pi^2}\int \mathrm{d}\xi\,\mathrm{d}\bar{\xi}\,\mathrm{d}r\,r^2\,\mathrm{Tr}\left[\frac{1}{(1+|\xi|^2)^2}L_r^2+\frac{1}{r^2}L_{\xi}L_{\bar{\xi}}+\frac{1}{4r^2}[L_r,L_{\xi}][L_r,L_{\xi}]\right.$$
$$\left.-\frac{(1+|\xi|^2)^2}{16r^4}[L_{\xi},L_{\bar{\xi}}]^2\right], \tag{24}$$

where, for simplicity, we have put the pion (meson) mass $m_{\pi}=0$.

With the matrix $U \in \mathrm{SU}(N)$ given by the harmonic map ansatz (22), the currents L_a''s in (2) take the following form:

$$L_r = i \sum_{k=0}^{\lambda-1} \dot{g}_k \left(P_k - \frac{nI}{N} \right), \tag{25}$$

where $\dot{g}_k = \mathrm{d}g_k/\mathrm{d}r$ and

$$L_\xi = \left[I + \sum_{k=0}^{\lambda-1} (e^{-ig_k} - 1) P_k \right] \left[\sum_{l=0}^{\lambda-1} (e^{ig_l} - 1) P_{l\xi} \right] = \sum_{k=0}^{\lambda-1} [e^{i(g_k - g_{k+1})} - 1](M_{k+1}|M_k|^{-2} M_k^\dagger), \tag{26}$$

where by definition $g_\lambda = 0$, and that $L_{\bar{\xi}} = -(L_\xi)^\dagger$.

Using the expressions for L_r and L_ξ in (25) and (26), respectively, we find that the traces in the energy functional (24) become

$$\mathrm{Tr}(L_r^2) = \frac{n^2}{N} \left(\sum_{k=0}^{\lambda-1} \dot{g}_k \right)^2 - n \sum_{k=0}^{\lambda-1} \dot{g}_k^2, \tag{27}$$

$$\mathrm{Tr}(L_\xi L_{\bar{\xi}}) = -2 \sum_{k=0}^{\lambda-1} S_k \, \mathrm{Tr}(|M_{k+1}|^2 |M_k|^{-2}), \tag{28}$$

$$\mathrm{Tr}([L_r, L_\xi][L_r, L_{\bar{\xi}}]) = -2 \sum_{k=0}^{\lambda-1} (\dot{g}_k - \dot{g}_{k+1})^2 S_k \, \mathrm{Tr}(|M_{k+1}|^2 |M_k|^{-2}), \tag{29}$$

$$\mathrm{Tr}([L_\xi, L_{\bar{\xi}}]^2) = 8 \sum_{k=0}^{\lambda-1} [S_k^2 \, \mathrm{Tr}([|M_{k+1}|^2 |M_k|^{-2}]^2) - S_k S_{k-1} \, \mathrm{Tr}(|M_{k+1}|^2 |M_{k-1}|^{-2})], \tag{30}$$

where by definition $S_{-1} = 0$ and for $k = 0, \ldots, \lambda - 1$:

$$S_k = [1 - \cos(g_k - g_{k+1})]. \tag{31}$$

B. Topological charge

The topological charge (3) in the spherical (holomorphic) coordinate system takes the form

$$B = \frac{1}{8\pi^2} \int \mathrm{d}r \, \mathrm{d}\xi \, \mathrm{d}\bar{\xi} \, \mathrm{Tr}(L_r [L_\xi, L_{\bar{\xi}}]). \tag{32}$$

Using the expression for L_ξ in (26) we find that

$$[L_\xi, L_{\bar{\xi}}] = 2 \sum_{k=0}^{\lambda-1} S_k (M_k |M_k|^{-2} |M_{k+1}|^2 |M_k|^{-2} M_k^\dagger - M_{k+1} |M_k|^{-2} M_{k+1}^\dagger), \tag{33}$$

and so, using this commutator and L_r as given in (25), the topological charge (32) becomes

$$B = -\frac{1}{2\pi} \int \mathrm{d}r \sum_{k=0}^{\lambda-1} (\dot{g}_k - \dot{g}_{k+1})(1 - \cos(g_k - g_{k+1})) \mathcal{N}_k, \tag{34}$$

where

$$\mathcal{N}_k=\frac{i}{2\pi}\int \mathrm{d}\xi\,\mathrm{d}\bar{\xi}\,\mathrm{Tr}(|M_{k+1}|^2|M_k|^{-2}). \tag{35}$$

As $g_k(\infty)=0$, we finally obtain

$$B=\frac{1}{2\pi}\sum_{k=0}^{\lambda-1}\mathcal{N}_k(g_k(0)-g_{k+1}(0)), \tag{36}$$

and so we see that the only contributions to the topological charge comes from $g_k(0)$.

In Appendix A we show that if $D_k=\mathrm{Det}|M_k|^2$ is nonsingular in the whole complex ξ plane, then $\mathcal{N}_k$ obey the recurrence relations

$$\mathcal{N}_k-\mathcal{N}_{k-1}=\omega_k, \tag{37}$$

where ω_k is the highest degree of $|\xi|^2$ in D_k, i.e.,

$$\lim_{|\xi|\to\infty}D_k\to(|\xi|^2)^{\omega_k}, \tag{38}$$

and where by definition $\mathcal{N}_{-1}=0$.

Thus, if we know ω_k then we can determine $\mathcal{N}_k$. In fact, if

$$H_0=M_{01}\wedge M_{02}\wedge\cdots\wedge M_{0n} \tag{39}$$

is the exterior product of the column vectors of M_0 which form the n-dimensional subspace of C^N, then

$$\omega_0=\deg(H_0), \tag{40}$$

i.e., is the highest degree of ξ in H_0.

IV. APPROXIMATE FORMULATIONS

In this section, we derive field equations for the profile functions g_k from the energy (24) into which we have inserted the expressions of the generalized harmonic map ansatz.

To do this we, first of all, take a holomorphic matrix $M_0=M(\xi)$ and then evaluate the sequence $(M_1,M_2,\ldots,M_\lambda)$ using the formulation of Sec. II. Then we compute the angular integrals $\mathcal{N}_k$ in (35),

$$\mathcal{I}_k=\frac{i}{2\pi}\int \mathrm{d}\xi\,\mathrm{d}\bar{\xi}(1+|\xi|^2)^2\,\mathrm{Tr}([|M_{k+1}|^2|M_k|^{-2}]^2), \tag{41}$$

and

$$\mathcal{H}_k=\frac{i}{2\pi}\int \mathrm{d}\xi\,\mathrm{d}\bar{\xi}(1+|\xi|^2)^2\,\mathrm{Tr}(|M_{k+1}|^2|M_{k-1}|^{-2}) \tag{42}$$

for $k=0,\ldots,\lambda-1$, where by definition $\mathcal{H}_0=0$.

In terms of $\mathcal{N}_k$, $\mathcal{I}_k$, and $\mathcal{H}_k$, the energy (24), for our ansatz (22), reduces to

$$E=\frac{1}{6\pi}\int \mathrm{d}r\left(r^2\left[-\frac{n^2}{N}\left(\sum_{k=0}^{\lambda-1}\dot{g}_k\right)^2+n\sum_{k=0}^{\lambda-1}\dot{g}_k^2\right]+2\sum_{k=0}^{\lambda-1}\mathcal{N}_k\left[1+\frac{1}{4}(\dot{g}_k-\dot{g}_{k+1})^2\right]S_k\right.$$
$$\left.+\frac{1}{2r^2}\sum_{k=0}^{\lambda-1}[\mathcal{I}_kS_k^2-\mathcal{H}_kS_kS_{k-1}]\right). \tag{43}$$

Introducing

$$F_k = g_k - g_{k+1}, \tag{44}$$

with $g_\lambda = 0$ we find that, in terms of F_k, the energy integral (43) becomes

$$E = \frac{1}{6\pi}\int \mathrm{d}r\Bigg(r^2\Bigg[-\frac{n^2}{N}\Bigg(\sum_{k=0}^{\lambda-1}(k+1)\dot{F}_k\Bigg)^2 + n\sum_{k=0}^{\lambda-1}\Bigg(\sum_{l=k}^{\lambda-1}\dot{F}_l\Bigg)^2\Bigg] + \frac{1}{2}\sum_{k=0}^{\lambda-1}\mathcal{N}_k(4+\dot{F}_k^2)(1-\cos F_k)$$
$$+ \frac{1}{2r^2}\sum_{k=0}^{\lambda-1}\left[\mathcal{I}_k(1-\cos F_k)^2 - \mathcal{H}_k(1-\cos F_k)(1-\cos F_{k-1})\right]\Bigg), \tag{45}$$

and the topological charge (36) becomes

$$B = \frac{1}{2\pi}\sum_{k=0}^{\lambda-1}\mathcal{N}_k F_k(0). \tag{46}$$

To derive the equations for the profile functions g_k from (45) we note that

$$\frac{\partial \mathcal{E}}{\partial \dot{F}_l} = r^2\Bigg[-\frac{2n^2(l+1)}{N}\sum_{i=0}^{\lambda-1}(i+1)\dot{F}_i + 2n\sum_{i=0}^{l}\Bigg(\sum_{j=i}^{\lambda-1}\dot{F}_j\Bigg)\Bigg] + \mathcal{N}_l\dot{F}_l(1-\cos F_l), \tag{47}$$

where $\mathcal{E}$ denotes the integrand of E.

Thus our field equations for the functions F_i and so also for g_i are given by

$$\Bigg[-\frac{2n^2(l+1)}{N}\sum_{i=0}^{\lambda-1}(i+1)\ddot{F}_i + 2n\sum_{i=0}^{l}\sum_{j=i}^{\lambda-1}\ddot{F}_j\Bigg] + \frac{1}{r^2}\mathcal{N}_l\ddot{F}_l(1-\cos F_l)$$
$$+ \frac{2}{r}\Bigg[-\frac{2n^2(l+1)}{N}\sum_{i=0}^{\lambda-1}(i+1)\dot{F}_i + 2n\sum_{i=0}^{l}\sum_{j=i}^{\lambda-1}\dot{F}_j\Bigg] + \frac{\sin F_l}{2r^2}\Bigg[\mathcal{N}_l(\dot{F}_l^2-4) - \frac{2\mathcal{I}_l(1-\cos F_l)}{r^2}$$
$$+ \frac{\mathcal{H}_l(1-\cos F_{l-1})}{r^2} + \frac{\mathcal{H}_{l+1}(1-\cos F_{l+1})}{r^2}\Bigg]$$
$$= 0. \tag{48}$$

Now a question arises: what is the best choice of the initial matrix M_0 that would yield low energy field configurations which, hopefully, are close to the exact solutions of the full equations of the model, i.e., Eq. (5)? To answer this question we note that each $\mathcal{N}_k$ is, in fact, the energy of the Grassmannian $\mathrm{Gr}(n,N)$ models. Thus in order to have minimal $\mathcal{N}_k$, and so also energy to be close to the exact multiskyrmion energy, the entries of the matrix M_0 must be *polynomials* in ξ.[11,12]

In the following sections we make this choice for M_0 and consider various fields for the SU(3), SU(4), and SU(5) cases with one and two rank-2 projector approximations. Our choices are dictated by simplicity and they lead to energy density distributions which are spherically symmetric. Moreover, looking at the general case we see that they also correspond to setting some g_i functions in (22) equal to zero.

V. ONE PROJECTOR APPROXIMATIONS

In this case, we take only one profile function $g_0 = F_0 = F$, i.e., $\lambda = 1$, and so the approximate energy (45) with the mass term reduces to

$$E=\frac{1}{6\pi}\int \mathrm{d}r\left(\frac{1}{2}\dot{F}^2[A_N(n)r^2+\mathcal{N}_0(1-\cos F)]+2\mathcal{N}_0(1-\cos F)+\frac{\mathcal{I}_0(1-\cos F)^2}{2r^2}\right.$$
$$\left.+m_\pi^2\left[(N-n)\left(1-\cos\left[\frac{nF}{N}\right]\right)+n\left(1-\cos\left[\frac{(N-n)F}{N}\right]\right)\right]\right), \tag{49}$$

where

$$A_N(n)=\frac{2n(N-n)}{N}, \tag{50}$$

and the field equation for the approximate function F becomes

$$\ddot{F}\left[A_N(n)+\frac{\mathcal{N}_0(1-\cos F)}{r^2}\right]+\frac{2A_N(n)}{r}\dot{F}+\frac{\sin F}{2r^2}\left[\mathcal{N}_0(\dot{F}^2-4)-\frac{2\mathcal{I}_0(1-\cos F)}{r^2}\right]$$
$$-m_\pi^2A_N(n)\left[\sin\left(\frac{nF}{N}\right)+\sin\left(\frac{(N-n)F}{N}\right)\right]=0. \tag{51}$$

In the following we restrict our attention to the rank-2 case only, i.e., $n=2$. To solve (51) we impose the boundary conditions: $F(0)=2\pi$ and $F(\infty)=0$. Thus, the baryon number of these configurations is $B=\mathcal{N}_0$. Finally, we compare the approximate energies of each subcase with the corresponding energies of the one rank-1 projector approximations.[8]

As a first attempt to solve (51), let us take the initial matrix $M_0=(M_{01},M_{02})$, where both column vectors are given by the following Veronese type form:

$$M_{01}=(1,\sqrt{C_1^{N-1}}\xi,\ldots,\sqrt{C_k^{N-1}}\xi^k,\ldots,\xi^{N-1})^T,\quad M_{02}=\partial_\xi M_{01}, \tag{52}$$

where C_k^{N-1} denotes the binomial coefficients, and the superscript T denotes transposition.

This special form of M_0 enables us to express the determinant D_0 of $|M_0|^2$ in the following closed form:

$$D_0=(N-1)(1+|\xi|^2)^{2(N-2)}. \tag{53}$$

Then from (38) we conclude that $\mathcal{N}_0=2(N-2)$, which is consistent with (40). This result can be verified explicitly using definition (35) with the help of the recurrence relations (A4), which yields

$$\mathrm{Tr}(|M_1|^2|M_0|^{-2})=\frac{2(N-2)}{(1+|\xi|^2)^2}. \tag{54}$$

For this case, according to (21), $D_1=0$, and so according to formula (B3), $\mathcal{I}_0=\mathcal{N}_0^2=4(N-2)^2$.

In the SU(3) case, we find that $A_3(2)=\frac{4}{3}$, $\mathcal{N}_0=2$, and so $\mathcal{I}_0=4$, which all coincide with the values of the corresponding quantities in the rank-1 projector approximation.[8] Thus, we conclude that their energies also coincide, i.e., $E=2.444\,04$ $(m_\pi=0)$. This equality holds for $m_\pi\neq 0$ as well. This is to be expected as in this case our rank-2 projector is really a sum of two rank-1 projectors constructed from the first two vectors of the Veronese sequence.

It is clear that, for SU(N) with $N>3$ we have: $A_N(2)>A_N(1)$, $\mathcal{N}_0>(N-1)$, and $\mathcal{I}_0>(N-1)^2$. Thus, this Veronese type configuration for $N>3$ will lead to energies higher in comparison with those for the rank-1 projector approximations.[8]

So, in the following, we look only at M_0 with $\mathcal{N}_0=(N-1)$ and $\mathcal{I}_0<(N-1)^2$ in order to compensate $A_N(2)>A_N(1)$ in the energy integral (49). More specifically, we look at the following two subcases for which the determinant of $|M_0|^2$ is of the form,

$$D_0=c(1+|\xi|^2)^{N-1}, \tag{55}$$

or

$$D_0 = c(1+\sigma|\xi|^2)^{N-3}(1+|\xi|^2)^2, \tag{56}$$

where c and σ are some constants. For the subcase (56) we choose the column vector M_{01} to have the Veronese type form (52) while $M_{02} = \partial_\xi^{N-2} M_{01}$.

A. SU(3)

As here we have $N=3$, so subcase (56) is the same with the Veronese type subcase that we have discussed previously. Thus in this section we consider only subcase (55).

In this subcase, we can choose the initial matrix M_0 to be given by

$$M_0 = \begin{bmatrix} 1 & \sqrt{a}\xi & \sqrt{b}\xi^2 \\ 0 & 1 & \sqrt{c}\xi \end{bmatrix}^T. \tag{57}$$

If we now require that $D_0 = (1+|\xi|^2)^2$, then $c=2$ while there is an infinite number of solutions for a and b as here we have only one equation for a and b. In the following we restrict our attention to the solution: $a=0$ and $b=1$.

Starting from the corresponding initial matrix M_0 we find that

$$M_1 = \frac{\sqrt{2}}{D_0}\begin{bmatrix} \sqrt{2}\xi(-\bar{\xi}^2 - \sqrt{2}\bar{\xi}1) \\ -\bar{\xi}^2 - \sqrt{2}\bar{\xi}1 \end{bmatrix}^T, \tag{58}$$

which is orthogonal to M_0, i.e., $M_0^\dagger M_1 = 0$. Note that $|M_1|^2$ is singular, i.e., $D_1 = 0$.

Using these two basis matrices, M_0 and M_1, we find from (35) that $\mathcal{N}_0 = 2$, and from (41) $\mathcal{I}_0 = 4$. These results coincide with the corresponding numbers in the one rank-1 projector approximation of the SU(3) case described by the initial vector field[8]

$$f_0 = (1, \sqrt{2}\xi, \xi^2)^T. \tag{59}$$

As $A_3(2) = \frac{2}{3} = A_3(1)$ both rank-1 and rank-2 projector approximations have equal energy, i.e., $E = 2.444\,04$ $(m_\pi = 0)$. This equality holds for $m_\pi \neq 0$ as well.

The result $D_1 = 0$ that we have encountered previously is in fact a general property for SU(3) case with rank-2 projectors ansatz, which can be seen as follows. Using the splitting relation (17) we see that

$$M_1 = ([I - P_{01}(1) - \tilde{P}_{02}(1)]\partial_\xi M_{01}, [I - P_{01}(1) - \tilde{P}_{02}(1)]\partial_\xi M_{02}). \tag{60}$$

As the case $\partial_\xi M_{02} = 0$ is trivial so we will only consider the nonzero case. We observe that

$$\begin{aligned} V_0 &= M_{01}, \\ V_1 &= [I - P_{01}(1)]M_{02}, \\ V_2 &= [I - P_{01}(1) - \tilde{P}_{02}(1)]\partial_\xi M_{02} \end{aligned} \tag{61}$$

are mutually orthogonal and so they span C^3. Thus,

$$\partial_\xi M_{01} = \alpha V_0 + \beta V_1 + \gamma V_2, \tag{62}$$

where α, β, and γ are expansion coefficients which depend on ξ and $\bar{\xi}$. As

$$[I - P_{01}(1) - \tilde{P}_{02}(1)][\alpha V_0 + \beta V_1 + \gamma V_2] = \gamma V_2, \tag{63}$$

TABLE I.

m_π	$E(1)$	$E(2)$
0.0	3.644 10	3.813 87
0.2	3.682 91	3.861 58
1.0	4.172 41	4.420 30
2.23	5.001 86	5.334 05
7.0	7.471 87	8.023 36
30.0	14.339 3	15.428 7

so

$$M_1=(\gamma V_2, V_2), \tag{64}$$

and it clearly follows that $|M_1|^2$ has a vanishing determinant.

B. SU(4)

1. $D_0=c(1+|\xi|^2)^3$

In this subcase we can choose the initial matrix M_0 to be given by

$$M_0=\begin{bmatrix} 1 & 0 & \sqrt{a}\,\xi & \sqrt{b}\,\xi^2 \\ 0 & 1 & \sqrt{c}\,\xi & \sqrt{d}\,\xi^2 \end{bmatrix}^T. \tag{65}$$

If we require $D_0=(1+|\xi|^2)^3$, then there is an infinite number of solutions for a, b, c and d as here we have only three equations for the four parameters a, b, c, and d. In the following we consider the solution: $a=2$, $b=1$, $c=1$, $d=2$.

Then, starting from M_0 in (65) we have computed the corresponding mutually orthogonal matrix M_1 and by using these two basis matrices, M_0 and M_1, we have computed explicitly the integrals $\mathcal{N}_0$ and $\mathcal{I}_0$ in expressions (35) and (41), respectively and we have found that $\mathcal{N}_0=3$ and $\mathcal{I}_0=\frac{23}{3}$. We note that, in the one projector rank-1 case with initial vector field

$$f_0=(1,\sqrt{3}\,\xi,\sqrt{3}\,\xi^2,\xi^3)^T, \tag{66}$$

$\mathcal{I}_0=9$ which is larger than the above-given result. However, as $A_4(2)=2$ while $A_4(1)=\frac{3}{4}$ it is not clear which energy is larger. To assess this we have solved numerically Eq. (51) for F. In Table I we present our results for the energies $E(2)$ and compare them with the results using one rank-1 projector, $E(1)$,[8] for different values of the mass m_π.

From Table I we see that for all the masses (at least to $m_\pi=30.0$) we always have $E(2)>E(1)$. When we have solved (51) for the approximate profile function $F=g_0$, we found that it is very close to that found in Ref. 8 using rank-1 projector ansatz.

2. $D_0=c(1+\sigma|\xi|^2)(1+|\xi|^2)^2$

In this subcase, we choose the initial matrix M_0 to be given by the following Veronese type form:

$$M_0=\begin{bmatrix} 1 & \sqrt{3}\,\xi & \sqrt{3}\,\xi^2 & \xi^3 \\ 0 & 0 & 2\sqrt{3} & 6\,\xi \end{bmatrix}^T, \tag{67}$$

which has $D_0=12(1+4|\xi|^2)(1+|\xi|^2)^2$. For this configuration, we have found that it has $\mathcal{N}_0=3$ but $\mathcal{I}_0=7.143\,57$ and its energy is $E=3.769\,29$ ($m_\pi=0$), which is a little lower than the energy of Sec. V B 1, but it is still higher than the energy of the one rank-1 projector approximation, i.e., $E=3.644\,10$.

C. SU(5)

1. $D_0 = c(1+|\xi|^2)^4$

In this subcase we can choose the initial matrix M_0 to be

$$M_0 = \begin{bmatrix} 1 & \sqrt{a}\xi & \sqrt{b}\xi^2 & \sqrt{c}\xi^3 & \sqrt{d}\xi^4 \\ 0 & 0 & 0 & 1 & \sqrt{e}\xi \end{bmatrix}^T. \tag{68}$$

If we require $D_0 = (1+|\xi|^2)^4$, then there is an infinite number of solutions for a, b, c, d, and e as here we have only four equations for these five parameters. Here we consider only the solution: $a = b = c = e = \sqrt{2}$ and $d = 1$.

For this configuration, we have found that $\mathcal{N}_0 = 4$ but $\mathcal{I}_0 = 12.2667$, which is much lower than 16. However, as $A_5(2) = \frac{12}{5}$, we see that its energy is $E = 5.105\,80$ $(m_\pi = 0)$, which is still higher than $E = 4.837\,92$ in the rank-1 projector approximation.[13] When we have solved the equations for the approximate profile function $F = g_0$ for each rank (1 and 2), we found that their difference is very small.

2. $D_0 = c(1+\sigma|\xi|^2)^2(1+|\xi|^2)^2$

In this subcase we choose the initial matrix M_0 to have the following Veronese type form:

$$M_0 = \begin{bmatrix} 1 & 2\xi & \sqrt{6}\xi^2 & 2\xi^3 & \xi^4 \\ 0 & 0 & 0 & 12 & 24\xi \end{bmatrix}^T, \tag{69}$$

which has $D_0 = 144(1+3|\xi|^2)^2(1+|\xi|^2)^2$.

We have found that this configuration has $\mathcal{N}_0 = 4$ but $\mathcal{I}_0 = 12.4444$ and its energy is $E = 5.118\,75$ $(m_\pi = 0)$ which is higher than the energy of the case in Sec. V C 1.

VI. TWO PROJECTOR APPROXIMATIONS

Now we consider the case of two projectors. Here we have two profile functions: F_0 and F_1, i.e., $\lambda = 2$, and so the energy integral (45) becomes

$$E = \frac{1}{12\pi}\int \mathrm{d}r\Big(r^2[A_N(n)\dot{F}_0^2 + A_N(2n)\dot{F}_0\dot{F}_1 + A_N(2n)\dot{F}_1^2] + \mathcal{N}_0(4+\dot{F}_0^2)(1-\cos F_0) + \mathcal{N}_1(4+\dot{F}_1^2)$$
$$\times(1-\cos F_1) + \frac{1}{r^2}[\mathcal{I}_0(1-\cos F_0)^2 - \mathcal{H}_1(1-\cos F_0)(1-\cos F_1) + \mathcal{I}_1(1-\cos F_1)^2]\Big), \tag{70}$$

where now, for simplicity, we have set $m_\pi = 0$.

The field equations for F_0 and F_1 are

$$\ddot{F}_0\left[A_N(n) + \frac{\mathcal{N}_0(1-\cos F_0)}{r^2}\right] + \frac{1}{2}A_N(2n)\ddot{F}_1 + \frac{2}{r}\left[A_N(n)\dot{F}_0 + \frac{1}{2}A_N(2n)\dot{F}_1\right]$$
$$+ \frac{\sin F_0}{2r^2}\left[\mathcal{N}_0(\dot{F}_0^2 - 4) - \frac{2\mathcal{I}_0(1-\cos F_0)}{r^2} + \frac{\mathcal{H}_1(1-\cos F_1)}{r^2}\right] = 0, \tag{71}$$

$$\frac{1}{2}A_N(2n)\ddot{F}_0 + \ddot{F}_1\left[A_N(2n) + \frac{\mathcal{N}_1(1-\cos F_1)}{r^2}\right] + \frac{2}{r}\left[\frac{1}{2}A_N(2n)\dot{F}_0 + A_N(2n)\dot{F}_1\right]$$
$$+ \frac{\sin F_1}{2r^2}\left[\mathcal{N}_1(\dot{F}_1^2 - 4) - \frac{2\mathcal{I}_1(1-\cos F_1)}{r^2} + \frac{\mathcal{H}_1(1-\cos F_0)}{r^2}\right] = 0. \tag{72}$$

In the following, we take $n=2$ and solve these equations (numerically) by imposing the boundary conditions: $F_0(0)=2\pi$, $F_1(0)=0$, and $F_0(\infty)=F_1(\infty)=0$. Thus, the baryon number of these configurations is $B=\mathcal{N}_0$. We then compare the approximate energies of each of these cases with the corresponding energies of the one rank-1 projector approximations.[8]

For the SU(3) configurations, we have shown that $|M_1|^2$ is singular. Thus for this case the projector P_1 does not exist. As for the SU(4) and SU(5) cases that we have considered previously, $|M_1|^2$ is nonsingular, so in this section we consider these two cases only.

A. SU(4)

Starting from the initial matrix M_0 in (65), we find that

$$M_2=0, \tag{73}$$

so from (35), (41), and (42) we have $\mathcal{N}_1=0$, $\mathcal{I}_1=0$, and $\mathcal{H}_1=0$. As for this case, $N=4$ and $n=2$, the energy integral (70) reduces to the energy integral (49) for the corresponding one projector of rank-2 projector approximation.

We note that $M_2=0$ is in fact a general property for SU(4) with rank-2 projectors ansatz. To prove this it is convenient to note that $M_k=P_+^k M_0$ is given by

$$M_k=[I-P_0-P_1-\cdots-P_{k-1}]\partial_\xi^k M_0. \tag{74}$$

Then using the splitting relation (17) in (74) for M_2 gives

$$\begin{aligned} M_2&=[I-P_0(2)-P_1(2)]\partial_\xi^2 M_0,\\ &=[I-(P_{01}(1)+\tilde{P}_{02}(1))-(P_{11}(1)+\tilde{P}_{12}(1))]\partial_\xi^2 M_0. \end{aligned} \tag{75}$$

Now, $M_2=0$ follows from the completeness relation for the rank-1 projectors in C^4, i.e.,

$$P_{01}(1)+\tilde{P}_{02}(1)+P_{11}(1)+\tilde{P}_{12}(1)=I. \tag{76}$$

B. SU(5)

As Sec. V C 1 in the one projector approximation has lower energy, we restrict our attention to this subcase. Starting from the matrix M_0 in (69), we have computed the corresponding matrices M_1 and M_2, and we have found that $\mathcal{N}_1=2.0$, $\mathcal{I}_1=4.289\,89$, and $\mathcal{H}_1=3.573\,57$.

Solving Eq. (72) with the correct values for $\mathcal{N}_k$, $\mathcal{I}_k$, and $\mathcal{H}_k$, $k=0$ and 1, we have found that, as $A_5(2)=\frac{12}{5}$ and $A_5(4)=\frac{8}{5}$, this configuration has energy: $E=5.024\,69$. This is higher than the energy of the one rank-1 projector approximation case, i.e., $E=4.837\,92$; however, they are marginally higher than the exact energy of the SU(2) case with $B=4$, i.e., $E=4.464$.[5]

VII. CONDITION FOR AN EXACT SPHERICALLY SYMMETRIC SOLUTION

In this section we consider whether one could also construct exact spherically symmetric solutions of the SU(N) Skyrme field equations (5) using λ rank-2 projectors. When written in the spherical (holomorphic) coordinates, Eq. (5) without the mass term becomes

$$\begin{aligned} &\partial_r\left[r^2 L_r+\frac{(1+|\xi|^2)^2}{8}([L_{\bar\xi},[L_r,L_\xi]]+[L_\xi,[L_r,L_{\bar\xi}]])\right]+\frac{(1+|\xi|^2)^2}{2}(\partial_{\bar\xi}L_\xi+\partial_\xi L_{\bar\xi})\\ &\quad+\frac{(1+|\xi|^2)^2}{8}(\partial_\xi([L_r,[L_{\bar\xi},L_r]])+\partial_{\bar\xi}([L_r,[L_\xi,L_r]]))+\frac{(1+|\xi|^2)^2}{16r^2}[\partial_{\bar\xi}((1\\ &\quad+|\xi|^2)^2[L_\xi,[L_\xi,L_{\bar\xi}]])-\partial_\xi((1+|\xi|^2)^2[L_{\bar\xi},[L_\xi,L_{\bar\xi}]])]=0. \end{aligned} \tag{77}$$

Now, let us look in detail at all the terms in these equations in our generalized harmonic map ansatz (22) case. We find that

$$\partial_{\bar{\xi}} L_{\xi} + \partial_{\xi} L_{\bar{\xi}} = 2i \sum_{l=0}^{\lambda-1} \sin F_l [M_{l+1} |M_l|^{-2} M_{l+1}^{\dagger} - M_l |M_l|^{-2} |M_{l+1}|^2 |M_l|^{-2} M_l^{\dagger}], \tag{78}$$

$$[L_{\bar{\xi}}, [L_r, L_{\xi}]] = -2i \sum_{l=0}^{\lambda-1} S_l \dot{F}_l [M_{l+1} |M_l|^{-2} M_{l+1}^{\dagger} - M_l |M_l|^{-2} |M_{l+1}|^2 |M_l|^{-2} M_l^{\dagger}], \tag{79}$$

$$[L_r, [L_{\xi}, L_r]] = \sum_{l=0}^{\lambda-1} \dot{F}_l^2 b_l M_{l+1} |M_l|^{-2} M_l^{\dagger}, \tag{80}$$

$$\begin{aligned} [L_{\xi}, [L_{\xi}, L_{\bar{\xi}}]] = 2 \sum_{l=0}^{\lambda-1} & [2 S_l b_l M_{l+1} |M_l|^{-2} |M_{l+1}|^2 |M_l|^{-2} M_l^{\dagger} - S_l b_{l+1} M_{l+2} |M_l|^{-2} M_{l+1}^{\dagger} \\ & - S_{l+1} b_l M_{l+1} |M_{l+1}|^{-2} |M_{l+2}|^2 |M_l|^{-2} M_l^{\dagger}], \end{aligned} \tag{81}$$

where S_l is given by (31) and where

$$b_l = (e^{iF_l} - 1). \tag{82}$$

We have checked that none of the configurations that we have considered so far in this paper is an exact solution of (77). This can be seen as follows. First, we multiply (77) by M_l from the right, which results in a set of equations for M_l. As the terms $\partial_r (r^2 L_r) M_l$ are proportional to M_l while the others are not, the contracted equations have the following general structure:

$$a_l M_l + \sum_{k=0}^{\lambda-1} M_k A_{kl} = 0, \tag{83}$$

where a_l depend only on N, n, $\dot{g}_i$, $\ddot{g}_i$, and r while the $(n \times n)$ matrices A_{kl} depend on g_i, ξ, and $\bar{\xi}$ as well. Clearly, these equations are inconsistent, unless each matrix A_{kl} is proportional to the $(n \times n)$ unit matrix I_n, i.e., $A_{kl} = b_{kl} I_n$, where each b_{kl} is independent of ξ and $\bar{\xi}$.

Armed with this observation we can now ask the following question: for which forms of the matrices M_k do the SU(N) Skyrme field equations (77) have exact solutions? In Appendix C, we have looked at the SU(N) chiral models and we found that, if we are able to find the matrices M_k which satisfy the condition

$$|M_{k+1}|^2 |M_k|^{-2} = \mathcal{K}_k (1 + |\xi|^2)^{-2} I_n, \tag{84}$$

where $\mathcal{K}_k$ are some constants which depend on N, n, and k, then this configuration could possibly give exact solutions for the profile functions g_k.

To see how this may work in our case we have put the condition (84) into (78)–(81), which has turned the field equations (77) into the following reduced set

$$\sum_{k=0}^{\lambda-1} \left[\left(P_k - \frac{nI}{N} \right) \alpha_k + (P_{k+1} - P_k) \beta_k + (P_{k+2} - P_{k+1}) \gamma_k \right] = 0, \tag{85}$$

where α_k, β_k, and γ_k are some functions of the profile functions g_i and their derivatives, r and $\mathcal{K}_k$. In the appendix of Ref. 13 we have analyzed this type of equation for the case of the rank-1 projectors [for the alternative SU(N) Skyrme model in Ref. 13, $\gamma_k = 0$] and we have found that these equations do, indeed, yield consistent and compatible equations for the corresponding profile functions g_l.

To show whether this is also true for the case of rank-n projectors, we put the condition (84) into (35), (41), and (42), which yields the following relations:

$$\mathcal{N}_k = n\mathcal{K}_k, \tag{86}$$

$$\mathcal{I}_k = n\mathcal{K}_k^2, \tag{87}$$

$$\mathcal{H}_k = n\mathcal{K}_k\mathcal{K}_{k-1}. \tag{88}$$

Using these relations in (85) and following the procedure of the appendix of Ref. 13, we have found that the resulting equations for the profile functions g_k do, indeed, coincide with (48). This also means that the energy integral (24), in this case, is exact (i.e., not an approximation).

VIII. FURTHER ANALYSIS OF THE CONDITION (84)

As the matrices M_k for $k\neq 0$ are generated from the initial matrix M_0, so in this section, we derive the conditions that M_0 should satisfy in order for condition (84) to hold. To do so, we put (84) into (A3) and (A4) with $k=0$, and obtain

$$\partial_{\bar{\xi}}[(\partial_{\bar{\xi}}|M_0|^2)|M_0|^{-2}] = \mathcal{K}_0(1+|\xi|^2)^{-2}I_n, \tag{89}$$

and

$$\partial_\xi\partial_{\bar{\xi}}[\log D_0] = n\mathcal{K}_0(1+|\xi|^2)^{-2}, \tag{90}$$

respectively.

The general solution of Eq. (89) is

$$|M_0|^2 = (1+|\xi|^2)^{\mathcal{K}_0}G(\bar{\xi},\xi), \tag{91}$$

where $G(\bar{\xi},\xi)$ is an $(n\times n)$ Hermitian matrix satisfying

$$\partial_{\bar{\xi}}[(\partial_{\bar{\xi}}G)G^{-1}] = 0. \tag{92}$$

Equation (92) has the general solution[14]

$$G(\bar{\xi},\xi) = \bar{H}(\bar{\xi})H(\xi), \tag{93}$$

where H and $\bar{H}=H^\dagger$ are arbitrary $(n\times n)$ matrices of one variable.

Thus, with $G(\bar{\xi},\xi)$ given by (93), solution (91) becomes

$$|M_0|^2 = (1+|\xi|^2)^{\mathcal{K}_0}\bar{H}(\bar{\xi})H(\xi), \tag{94}$$

and from condition (84) it follows that (for $l\geqslant 1$)

$$|M_l|^2 = \mathcal{K}_0\mathcal{K}_1\cdots\mathcal{K}_{l-1}(1+|\xi|^2)^{\mathcal{K}_0-2l}\bar{H}(\bar{\xi})H(\xi). \tag{95}$$

Furthermore, from (91) it follows that

$$D_0 = (1+|\xi|^2)^{n\mathcal{K}_0}\mathrm{Det}[\bar{H}(\bar{\xi})]\mathrm{Det}[H(\xi)] \tag{96}$$

is a solution of (90). By putting D_0 into (A6) we have found that $\mathcal{N}_0=n\mathcal{K}_0$, as we have assumed that $\mathrm{Det}[H(\xi)]$ is holomorphic (and $\mathrm{Det}[\bar{H}(\bar{\xi})]$ is antiholomorphic) with the only singularity at $|\xi|\to\infty$, which is consistent with (86). Thus, we can choose $\mathrm{Det}[G(\bar{\xi},\xi)]=1$, and so from (95) it follows that

$$D_l=(\mathcal{K}_0\mathcal{K}_1\cdots\mathcal{K}_{l-1})^n(1+|\xi|^2)^{n(\mathcal{K}_0-2l)}, \tag{97}$$

from which, according to (38),

$$\omega_l=n(\mathcal{K}_0-2l). \tag{98}$$

Using the recurrence relations (37), with ω_l given by (98), we derive

$$\mathcal{N}_l=(l+1)(\mathcal{N}_0-nl). \tag{99}$$

Now, with $|M_0|^2$ given by (94), the projector $P_0(n)=M_0|M_0|^{-2}M_0^\dagger$ becomes

$$P_0(n)=(1+|\xi|^2)^{-\mathcal{K}_0}\tilde{M}_0\tilde{M}_0^\dagger, \tag{100}$$

where $\tilde{M}_0=M_0H^{-1}$. Using (94) then it follows that the matrix $\tilde{M}_0$ satisfies

$$|\tilde{M}_0|^2=\overline{H}^{-1}|M_0|^2H^{-1}=(1+|\xi|^2)^{\mathcal{K}_0}I_n. \tag{101}$$

Equation (101) implies that the column vectors of the matrix $\tilde{M}_0=(\tilde{M}_{01},\tilde{M}_{02},\ldots,\tilde{M}_{0n})$ are mutually orthogonal. Thus, using the SU(N) global symmetry, we can bring the column vectors $\tilde{M}_{0j}$, $(j=1,2,...,n)$ to live in n-disjoint subspaces. In this case, the projector $P_0(n)$ has a block diagonal form. For example, in the rank-2 projector ansatz, i.e., $n=2$, for $N=even$, we have

$$P_0(2)=\begin{bmatrix} P_{01}(1) & 0 \\ 0 & P_{02}(1) \end{bmatrix}, \tag{102}$$

where

$$P_{0s}(1)=\frac{\tilde{M}_0\tilde{M}_0^\dagger}{|\tilde{M}_0|^2}, \tag{103}$$

$s=0$, 1, are rank-1 projectors. For $N=odd$, still in the rank-2 projector ansatz, Eq. (101) requires that one of the entries of $\tilde{M}_{0j}$ should be zero, so if we choose $(\tilde{M}_{0j})_N=0$, then the $((N-1)\times(N-1))$ submatrix of $P_0(2)$ has the block form (102) while $P_0(2)_{NN}=0$.

Thus, as far as condition (84) is concerned, it seems that the only exact spherically symmetric solutions of the SU(N) Skyrme models using projectors of rank-2 are embeddings of a pair of SU($[N]/2$) solutions of rank-1 projector ansatz, where $[N]=N$, or $(N-1)$ for N even or odd, respectively.

IX. SOME SPECIFIC CONFIGURATIONS

In this final section we consider only the rank-2 projector ansatz, i.e., $n=2$. Thus, here, the SU(3) case should be excluded, as from our analysis in Sec. V A, $|M_1|^2$ is singular so it is automatically not proportional to the nonsingular matrix $|M_0|^2$ as required by (84). For the same reason, we also exclude the case $M_{02}=\partial_\xi M_{01}$, i.e., Eq. (21). Next, we have a look at some specific forms of the initial matrix M_0, for the $N=4$ and 6 cases.

A. SU(4)

In this case, we can choose the initial matrix M_0 to be given by

$$M_0=\begin{bmatrix} 1 & \xi & f(\xi) & \xi f(\xi) \\ 0 & 0 & 1 & \xi \end{bmatrix}^T, \tag{104}$$

where $f(\xi)$ is an arbitrary polynomial function of only ξ. Then

$$|M_0|^2=(1+|\xi|^2)\begin{bmatrix}1 & \overline{f(\xi)}\\ 0 & 1\end{bmatrix}\begin{bmatrix}1 & 0\\ f(\xi) & 1\end{bmatrix}, \tag{105}$$

which is of the form (94).

For the corresponding projector $P_0(2)$, we have found by direct evaluation that it has the block form (102) with

$$P_{0s}(1)=\frac{1}{(1+|\xi|^2)}\begin{bmatrix}1 & \overline{\xi}\\ \xi & |\xi|^2\end{bmatrix}, \tag{106}$$

$s=0$, 1, which clearly are the rank-1 projectors of a one skyrmion SU(2) solution. As $D_0=(1+|\xi|^2)^2$, this configuration has $\mathcal{N}_0=2$, or $\mathcal{K}_0=1$, and so according to (87), $\mathcal{I}_0=2$. Then from (99) we obtained $\mathcal{N}_1=0$ or $\mathcal{K}_1=0$ [according to (86)] so from (95) we conclude that $M_l=0$, for $l\geqslant 2$, which is consistent with our general result in Sec. VI A. Thus, this configuration has only one projector, i.e., $P_0(2)$.

Substituting $\mathcal{N}_0=\mathcal{I}_0=A_4(2)=2$ in the 1-projector energy integral (49) we found that it has energy: $E=2E_{\mathrm{SU}(2)}$, where $E_{\mathrm{SU}(2)}$ is the energy of the SU(2) Skyrme model,[9] as we would have been expected.

B. SU(6)

In this case, we can choose the initial matrix M_0 to be given by

$$M_0=\begin{bmatrix}1 & \sqrt{2}\xi & \xi^2 & f(\xi) & \sqrt{2}\xi f(\xi) & \xi^2 f(\xi)\\ 0 & 0 & 0 & 1 & \sqrt{2}\xi & \xi^2\end{bmatrix}^T, \tag{107}$$

from which it follows that $|M_0|^2$ is of the form (94) as well with $\mathcal{K}_0=2$.

We have also found that the corresponding projector, $P_0(2)$, has the block form (102) with $P_{0s}(1)$, $s=0$, 1, are the rank-1 projectors of the SU(3) solution.[9] As $D_0=(1+|\xi|^2)^4$, this configuration has $\mathcal{N}_0=4$, from which we derived that $\mathcal{I}_0=8$, $\mathcal{N}_1=4$, $\mathcal{I}_1=8$, $\mathcal{H}_1=8$, but $\mathcal{N}_2=0$ or $\mathcal{K}_2=0$ and so $M_l=0$ for $l\geqslant 3$. Thus, this configuration has only two projectors, i.e., $P_0(2)$ and $P_1(2)$.

Substituting the correct values for $\mathcal{N}_k$, $\mathcal{I}_k$, and $\mathcal{H}_k$, $k=0$, 1, into the 2 projectors energy integral (70) we have found that, as $A_6(2)=A_6(4)=\frac{8}{3}$, this configuration has energy: $E=2E_{\mathrm{SU}(3)}$, where $E_{\mathrm{SU}(3)}$ is the energy of the SU(3) Skyrme model.[9]

X. CONCLUSIONS

In this paper we have studied the SU(N) Skyrme models by constructing SU(N) multiskyrmions fields using the harmonic mappings method where we have generalized the method of Ioannidou *et al.*[9] by considering projectors of S^2 into the Grassmannian Gr(n,N), i.e., using projectors of rank $n>1$. In this approach a rank-n projector $P_k(n)$ is constructed from a member of a set of mutually orthogonal $(N\times n)$ matrix fields M_k. In particular, here we have concentrated our attention only on the rank-2 projectors.

Using our construction we have studied some approximate spherically symmetric configurations of SU(N) Skyrme models. When we have solved the equations for the profile functions for configurations with baryon number $B=(N-1)$ we found that they are very close to those for the rank-1 cases and that they have marginally higher energies. These results indicate that the rank-1 projector ansatz[8] is the best way to approximate energy minima of the SU(N) Skyrme models.

We have also discussed the possibility of generating exact spherically symmetric solutions using this construction. However, we have found that, in contradistinction to the rank-1 projector ansatz in which exact spherically symmetric solutions can be found (numerically) by using the Veronese sequence of N mutually orthogonal vector fields in CP^{N-1}, such a construction is more involved in our case. In particular, we have found that if the sequence of the $(N\times n)$ matrix fields

M_k satisfy condition (84) then it seems that the only possible exact solutions are embeddings. For example, for the rank-2 projector ansatz these are embeddings of a pair of SU($[N]/2$) solutions of rank-1 projector ansatz, where $[N]=N$, or $(N-1)$ for N even or odd, respectively.

It is not clear whether there exist other conditions than (84) for the $(N\times n)$ matrix fields M_k that might lead to nonembedding solutions.

APPENDIX A: RECURRENCE RELATIONS FOR Tr($|M_k|^2|M_{k-1}|^{-2}$) AND $\mathcal{N}_k$

In this appendix, we derive recurrence relations for $\mathrm{Tr}(|M_k|^2|M_{k-1}|^{-2})$ appearing in the integral $\mathcal{N}_k$ of (35). To do this we rewrite the definition of M_{k+1} in (10) as follows:

$$\partial_\xi M_k = M_{k+1} + M_k|M_k|^{-2}(M_k^\dagger \partial_\xi M_k). \tag{A1}$$

As $\partial_{\bar\xi} M_k$ is given by (11) so from the integrability condition

$$\partial_\xi \partial_{\bar\xi} M_k = \partial_{\bar\xi}\partial_\xi M_k, \tag{A2}$$

we derive the recurrence relations

$$\partial_\xi[(\partial_{\bar\xi}|M_k|^2)|M_k|^{-2}] = |M_{k+1}|^2|M_k|^{-2} - |M_k|^2|M_{k-1}|^{-2}. \tag{A3}$$

We note that for the $n=1$ case, i.e., when M_k are a sequence of N-component vector fields, Eq. (A3) gives the celebrated *Toda equation*.[15] Thus, for $n\neq 1$ our Eq. (A3) could be considered as its generalization to the *non-Abelian* case.[16]

Furthermore, taking the trace of Eq. (A3) we obtain

$$\partial_\xi\partial_{\bar\xi}[\log \mathrm{Det}|M_k|^2] = \mathrm{Tr}(|M_{k+1}|^2|M_k|^{-2}) - \mathrm{Tr}(|M_k|^2|M_{k-1}|^{-2}), \tag{A4}$$

i.e., our recurrence relations for $\mathrm{Tr}(|M_k|^2|M_{k-1}|^{-2})$.

Next, if $D_k = \mathrm{Det}|M_k|^2 \neq 0$ in the whole complex plane C then by applying Stokes' theorem in the plane to (A4), i.e.,

$$\int \mathrm{d}\xi\,\mathrm{d}\bar\xi(\psi)_{\bar\xi\xi} = \frac{1}{2}\oint_{|\xi|\to\infty}[\mathrm{d}\bar\xi\,\psi_{\bar\xi} - \mathrm{d}\xi\,\psi_\xi], \tag{A5}$$

we obtain

$$\frac{i}{4\pi}\oint_{|\xi|\to\infty}\left[\mathrm{d}\bar\xi\frac{\partial_{\bar\xi}D_k}{D_k} - \mathrm{d}\xi\frac{\partial_\xi D_k}{D_k}\right] = \mathcal{N}_k - \mathcal{N}_{k-1}. \tag{A6}$$

Thus, if ω_k is the highest degree of $|\xi|^2$ in D_k, i.e., $\lim_{|\xi|\to\infty} D_k \to |\xi|^{2\omega_k}$, then (A6) reduces to the following simple recurrence relations for $\mathcal{N}_k$, i.e.:

$$\omega_k = \mathcal{N}_k - \mathcal{N}_{k-1}. \tag{A7}$$

However, if $D_k = 0$ at some points, these recurrence relations cease to hold.

APPENDIX B: REDUCED FORMULA FOR EVALUATING Tr($[|M_{k+1}|^2|M_k|^{-2}]^2$)

In this appendix, we derive a formula for simplifying the calculation of the trace in $\mathcal{I}$ for the case $n=2$. Using the formula,

$$\mathrm{Tr}(H^2)=(\mathrm{Tr}H)^2-2\,\mathrm{Det}\,H, \tag{B1}$$

which is true for any (2×2) matrix H we note that for $D_k=\mathrm{Det}|M_k|^2\neq 0$, we have

$$\mathrm{Tr}([|M_{k+1}|^2|M_k|^{-2}]^2)=(\mathrm{Tr}[|M_{k+1}|^2|M_k|^{-2}])^2-2\,\frac{D_{k+1}}{D_k}. \tag{B2}$$

Thus, if $D_{k+1}=0$, then from (B2) we have

$$\mathrm{Tr}([|M_{k+1}|^2|M_k|^{-2}]^2)=(\mathrm{Tr}[|M_{k+1}|^2|M_k|^{-2}])^2. \tag{B3}$$

APPENDIX C: CONDITION (84) FROM THE SU(N) CHIRAL MODELS

To simplify our search for finding a condition for exact solution of the SU(N) Skyrme model Eqs. (77), in this appendix, we look at the corresponding SU(N) chiral model equations,

$$\partial_r(r^2L_r)+\frac{(1+|\xi|^2)^2}{2}(\partial_{\bar{\xi}}L_{\xi}+\partial_{\xi}L_{\bar{\xi}})=0, \tag{C1}$$

i.e., (77) without the Skyrme terms. In terms of the rank-n projectors P_k, Eq. (C1), after we have put in (25) and (78), becomes

$$\sum_{k=0}^{\lambda-1}\left[\left(P_k-\frac{nI}{N}\right)\partial_r(r^2\dot{g}_k)+(1+|\xi|^2)^2\sin F_k(M_{l+1}|M_l|^{-2}Mk_{l+1}^{\dagger}-M_l|M_l|^{-2}|M_{l+1}|^2|M_l|^{-2}M_l^{\dagger})\right]$$
$$=0, \tag{C2}$$

where $F_k=g_k-g_{k+1}$, $g_\lambda=0$.

Next we multiply Eq. (C2) from the right by M_s, and noting that M_s are independent matrix fields, we obtain

$$\partial_r\left[r^2\left(\dot{g}_s-\frac{n}{N}\sum_{k=0}^{\lambda-1}\dot{g}_k\right)\right]I_n+(1+|\xi|^2)^2(|M_{s-1}|^{-2}|M_s|^2\sin F_{s-1}-|M_s|^{-2}|M_{s+1}|^2\sin F_s)=0. \tag{C3}$$

Finally, summing over s from 0 to l, and noting that $M_{-1}=0$ (by definition), we find that (C3) gives us

$$\partial_r\left[r^2\left(\sum_{p=0}^{l}\sum_{q=p}^{\lambda-1}\dot{F}_q-\frac{n(l+1)}{N}\sum_{p=0}^{\lambda-1}(p+1)\dot{F}_p\right)\right]I_n-(1+|\xi|^2)^2|M_l|^{-2}|M_{l+1}|^2\sin F_l=0. \tag{C4}$$

Thus, in order to have a compatible and a consistent set of equations for the functions F_l in (C4), the matrices M_l must satisfy

$$|M_l|^{-2}|M_{l+1}|^2=\mathcal{K}_l(1+|\xi|^2)^{-2}I_n, \tag{C5}$$

i.e., condition (84).

A parabolic approximation method with application to global wave propagation

David R. Palmer[a)]
NOAA/Atlantic Oceanographic and Meteorological Laboratory, 4301 Rickenbacker Causeway, Miami, Florida 33149

(Received 18 July 2001; accepted for publication 17 January 2002)

Motivated by the difficulty in using the splitting matrix method to obtain parabolic approximations to complicated wave equations, we have developed an alternative method. It is three dimensional, does not *a priori* assume a preferred direction or path of propagation in the horizontal, determines spreading factors, and results in equations that are energy conserving. It is an extension of previous work by several authors relating parabolic equations to the horizontal ray acoustics approximation. Unlike previous work it applies the horizontal ray acoustics approximation to the propagator rather than to the Green's function or the homogenous field. The propagator is related to the Green's function by an integral over the famous ''fifth parameter'' of Fock and Feynman. Methods for evaluating this integral are equivalent to narrow-angle approximations and their wide-angle improvements. When this new method is applied to simple problems it gives the standard results. In this paper it is described by applying it to a problem of current interest—the development of a parabolic approximation for modeling global underwater and atmospheric acoustic propagation. The oceanic or atmospheric waveguide is on an Earth that is modeled as an arbitrary convex solid of revolution. The method results in a parabolic equation that is energy conserving and has a spreading factor that describes field intensification for antipodal propagation. Significantly, it does not have the singularities in its range-sliced version possessed by many parabolic equations developed for global propagation. We then discuss two extensions of the method; first to propagation along refracted geodesics and second to a description involving discrete, local, normal modes. [DOI: 10.1063/1.1458060]

I. INTRODUCTION

In the years following the introduction of the parabolic equation method and the split-step Fourier algorithm to wave propagation [Tappert and Hardin (1973); Hardin and Tappert (1973)], a great deal of work was done not only in applying it to propagation problems in the ocean and atmosphere but also in developing improvements on the method. Approximations and computational schemes were developed that more realistically account for the characteristics of the propagation medium and its boundaries and reduce the restriction to narrow-angle propagation. Fortunately several excellent early [Tappert (1977)] and recent [Brekhovskikh and Godin (1999); Lee and Pierce (1995)] reviews are available since the literature is too large to provide citations to all the relevant work.

A common technique for deriving the standard parabolic equation and improvements to it has been the splitting matrix method where a wave equation is factored into two contributions representing forward and backward propagating waves. This method was first developed by Bremmer (1951) for the one-dimensional problem and the latter generalized to three dimensions by Corones (1975) and Tappert (1977). In this approach it is assumed a particular direction in the ocean

[a)]Electronic mail: david.r.palmer@noaa.gov

medium is singled out by the nature of the source excitation and the dominant portion of the acoustic energy propagates in this direction without significant backscatter. For a discussion of this point of view, see Corones, DeFacio, and Krueger (1982). The square-root differential operator in the forward-propagating one is then approximated in some fashion to obtain a useful parabolic equation. Many times this approximation is done so as to reduce the dependence of the solution on the reference wave speed thus relaxing the narrow-angle approximation. The appropriate mathematical formalism for analysis of the one-way equation is in terms of pseudodifferential and Fourier integral operators. For a review, see Fishman (1992), where this mathematical formalism is applied to various equations having an index of refraction quadratic in a subset of the coordinate variables.

Most of these early studies applied the parabolic approximation to the Helmholtz equation

$$[\nabla^2 + k_0^2 n^2(\vec{x})]\, p(\vec{x}) = 0 \tag{1}$$

in Cartesian coordinates. Here a source radiates at angular frequency ω, where $k_0 = \omega/c_0$ with c_0 some reference wave speed, $n(\vec{x}) = c_0/c(\vec{x})$ is the index of refraction, and $c(\vec{x})$ is the wave speed at the point $\vec{x} = (x,y,z)$ in the medium. Sometimes the Laplacian was modified to account for a variable density field, $\nabla^2 \to \rho(\vec{x})\vec{\nabla}\cdot((1/\rho(\vec{x}))\vec{\nabla})$, and sometimes currents were included by introducing an effective wave speed equal to the actual speed shifted by the component of the current in the direction of propagation.

When one considers more complicated wave equations, however, progress has been slow in developing useful parabolic approximations using the splitting matrix method. We illustrate this with three examples. First is the problem of obtaining parabolic approximations to the elastic wave equation [Corones, DeFacio, and Krueger (1982); Hudson (1980); Landers and Claerbout (1972); Wales and McCoy (1983); Greene (1985); Wetton and Brooke (1990); Collins (1991); Collins (1993a)]. Although considerable effort has been devoted to this problem, parabolic equations have only been developed under limiting conditions that include consideration of a two-dimensional rather than a three-dimensional medium, Lamé parameters that are range independent or have very small spatial gradients, or very special types of propagation.

Second is the problem of obtaining parabolic equations for propagation in a moving inhomogeneous fluid. As a result of the work by Brekhovskikh and Godin (1999) and Godin (1987), it is now known that many of the earlier approximations, including the use of an effective wave speed, cannot adequately account for the effects of the motion in many important and practical situations. The appropriate wave equation, correct to first order in the Mach number, is complicated and considerable ingenuity has been devoted developing parabolic approximations that are wide angle, conserve energy, obey the flow reversal theorem and boundary conditions consistent with the parabolic approximation (a requirement ignored in most studies) [Godin (1991); Godin and Mokhov (1992); Godin (1998a); (1998b); (1999)]. Most progress on this problem was obtained using the multiple-scales approach (see the following) rather than with the splitting matrix method because of the problems associated with the splitting matrix method discussed here (Godin, private conversation).

A final example is the problem of developing parabolic approximations for wave equations in curvilinear coordinates with the purpose of modeling global wave propagation [Collins (1993b); McDonald *et al.* (1994); Collins *et al.* (1995a); (1995b); (1996)]. It is common to reduce the problem to a two-dimensional one by introducing local normal modes and by ignoring, to some degree, mode coupling. The matrix splitting method is then applied to the resulting equation in the horizontal coordinates to obtain a forward-propagating parabolic equation. The range-sliced version of this equation, needed to obtain a marching algorithm, has singularities [Collins *et al.* (1996)]. These singularities result from the fact that the commutators in the Baker–Campbell–Hausdorff formula used to develop the range-sliced expression cannot be dropped for small range intervals. They actually become more singular with order, regardless of the size of the range interval. The range-sliced marching algorithm, as well as the closely-related range-sliced path integral representation, are only valid in Cartesian coordinates. This point has been discussed in

detail by Kleinert (1995), who refers to this type of singularity as ''path collapse'' and who has developed techniques for dealing with it by scaling variables. These scaling techniques are only now being applied to wave propagation problems. This problem of singularities would exist even if the three-dimensional wave equation had been considered rather than the reduced two-dimensional one.

For these complicated wave equations, the splitting matrix method is not very easy to apply. It is not always obvious how the factorization should be done nor is it obvious how the resulting differential operators should be approximated to obtain wide-angle equations. Normalizations and spreading factors are not easy to obtain. [The quantity $1/\sqrt{r}$ in Eq. (2) in the following is a spreading factor.] With few exceptions, e.g., Tappert, Spiesberger, and Boden (1995), studies that use the splitting matrix method ignore the determination of the spreading factor.

It seems worthwhile then to consider new approaches to developing parabolic approximations that might have application to complicated wave equations. In developing them we are guided by four principles (prejudices actually).

(A) One should start with equations that are three dimensional. By starting with two-dimensional equations one has already made an assumption about the nature of the propagation. One has assumed there is no significant scattering of the wave field out of the surface defined by the two coordinates. If this is a valid assumption, it should be a consequence of the process of making the parabolic approximation and not something imposed on the problem from the outset and considered as a separate, unjustified approximation. One should also not approach the three-dimensional problem by patching together solutions to the two-dimensional one. One should be able to start with the three-dimensional problem and show that its solution can be written, with appropriate approximations, in terms of solutions to the two-dimensional problem if this patching process is valid.

(B) One should not assume any preferred horizontal direction or path for the propagation. In Corones, DeFacio and Krueger (1982), one reads, ''*...the parabolic approximation is used when a particular direction is singled out in the medium by the nature of the excitation*..... *The direction is distinguished by the excitation, not by the medium*.'' While this statement may be valid for laser propagation through the atmosphere where the radiation is emitted in a narrow beam, it cannot be valid in general. In particular, it cannot be valid for low-frequency sound propagation in the ocean because low-frequency sources (excitations) are essentially omnidirectional. It is possible for either the source or the medium to determine a preferred direction. In this paper we consider that class of problems for which the preferred direction or path, if it exists, is determined by the characteristics of the medium and defined in the process of making the parabolic approximation.

When one writes a wave equation in terms of cylindrical coordinates (r,φ,z) and discards derivatives with respect to φ, one has already assumed a preferred direction. It is the direction of the straight line along the radial connecting the source to the receiver. When one writes

$$p(r,\varphi,z)=\frac{e^{ik_0 r}}{\sqrt{r}}\psi(r,\varphi,z) \tag{2}$$

for the pressure field and assumes ψ varies slowly with r, one has also defined a preferred direction. This is an important point because more complicated wave equations may not have a preferred direction along the radial but in some other direction in the horizontal plane. If horizontal multipaths are present the preferred direction is not unique or it is undefined.

(C) The approach should provide a way for determining spreading factors. While for some applications spreading factors are not important, it is difficult to imagine a systematic, general method for developing parabolic equations that only determines part of the field.

(D) A general parabolic approximation method should consist of two distinct types of approximations: those related to horizontal variation; a preferred direction of propagation along a horizontal multipath, no backscattering, no out-of-plane propagation, etc., and those related to vertical variation; narrow-angle and wide-angle approximations. When one considers the application of the parabolic method to simple problems these two types of approximations are distinct. For example,

only the first type is needed to develop a parabolic equation for the propagation of a single adiabatic mode in a range-dependent waveguide while only the second type is needed for propagation of a field in a range-independent waveguide described by a modal sum. One might expect that a method applicable to more complicated problems as well as these simple ones would not mix the two types of approximations.

In developing an alternative to the splitting matrix method based on the above-mentioned considerations we are motivated by three observations. First, by working order-by-order in perturbation theory in the range-dependent part of the index of refraction, it was found many years ago [Palmer (1976)] that the solution to the Helmhotz equation can be written in terms of the solution to the standard parabolic equation by making a horizontal eikonal approximation followed by the stationary-phase approximation of an integral over the ''fifth parameter'' of Fock (1937) and Feynman (1951). The stationary-phase approximation was shown to be equivalent to the narrow-angle approximation. A completely different approach, based on the use of path integrals rather than perturbation theory, gave the same result [Palmer (1979)]. (In this case, horizontal ray theory was assumed rather than the closely related horizontal eikonal approximation.) Second, an alternative to the splitting matrix method is the method of multiple scales in which the horizontal variables are scaled differently from the depth variable [Tappert (1977); Siegmann, Kreigsmann, and Lee (1985); Kreigsmann (1985); Orchard, Siegmann, and Jacobson (1992)]. This method leads to the factorization of the field into a function that obeys the parabolic equation (e.g., ψ) and a kinematic factor that is dependent on only the horizontal coordinates [e.g., $\exp(ik_0 r)/\sqrt{r}$]. The multiple scales method is closely related to the method used by Brekhovskikh and Godin (1999, Sec. 7.2) to develop horizontal ray theory for a weakly range-dependent, three-dimensional medium. Finally, it is well known that there is a close relationship between ray theory (geometric optics) and parabolic equations [Myers and McAninch (1978); McAninch (1986); Babič and Buldyrev (1991), Chap. 6].

The method we propose then amounts to a horizontal ray theory approximation followed by the approximation of the integral over the Fock–Feynman parameter. It satisfies the four principles we discussed previously. Its validity is based on the fact that horizontal scales of variability in the ocean and atmosphere are much greater than vertical ones. The only aspect of this method that is different from what others have done is that we apply the horizontal ray theory approximation not to the wave equation but to the equation satisfied by the propagator. The two are related by an integral over the Fock–Feynman parameter. This is the key aspect of the method because this propagator obeys (exactly) a four-coordinate parabolic equation. Approximations such as the horizontal ray theory approximation essentially reduce its dimensionality.

Our procedure then for developing parabolic approximations is to express the solution to the wave equation as a one-dimensional integral transform and to apply the horizontal ray acoustics approximation to the transform function. It is worth noting that the work by Klauder (1987), and earlier, Maslov and Fedoriuk (1981) demonstrates that this procedure also has great advantage in avoiding the caustic singularities associated with the ray acoustics approximation, which in a quantum mechanic context is referred to as the semiclassical approximation.

In this paper we apply this method to the problem of developing a parabolic approximation for the wave equation in curvilinear coordinates appropriate for modeling global wave propagation. Our primary interest is acoustic propagation in the ocean although the analysis has application to ultrasonic propagation in the atmosphere. We do not assume the Earth is spherical or even ellipsoidal but only that it is a convex solid of revolution.

This paper is organized as follows. In Sec. II we characterize the waveguide on an Earth modeled as a solid of revolution. In Sec. III the propagator for the Helmholtz equation (modified to include a depth-dependent density variation) and the Fock–Feynman parameter are introduced. In Sec. IV we factor the propagator and apply the horizontal ray theory approximation. The eikonal and transport equations are derived and solved. We provide a detailed solution to the transport equation that determines the spreading factor for this problem. Section V treats the vertical equation and the stationary phase approximation. When applied to the simple Helmhotz equation in Cartesian coordinates it produces the standard narrow-angle parabolic equation. In

many situations one wants to do better. One extension would be to include the possibility of horizontal refraction and horizontal multipaths. Another extension would be the description of the depth dependence of the pressure field by use of normal modes. Section VI contains a discussion of these possibilities. Finally, in Sec. VII we summarize the approach used in the paper.

II. THE EARTH AS A SOLID OF REVOLUTION

The Earth is assumed to be a solid of revolution with, when viewed from space, a convex surface everywhere. The origin of the Cartesian coordinate system is centered in the Earth with the axis of rotation the z axis. The position vector from the origin of this coordinate system to a point on the Earth's surface is

$$\vec{x}_S = x_S\hat{x} + y_S\hat{y} + z_S\hat{z}, \tag{3}$$

where $\hat{x}$, $\hat{y}$, and $\hat{z}$ are unit vectors along the coordinate axes. Since the axis of rotation is the z axis, one can write

$$x_S = \rho_S(\varphi_g)\cos\lambda,$$

$$y_S = \rho_S(\varphi_g)\sin\lambda$$

where φ_g is the *geocentric latitude*

$$\varphi_g \equiv \arctan\left(\frac{z_S}{\sqrt{x_S^2+y_S^2}}\right)$$

and λ is the longitude.

Consider the directed line segment from the point on the surface with coordinates (φ_g,λ) to the nearby point $(\varphi_g+\delta\varphi_g,\lambda+\delta\lambda)$,

$$\delta\vec{x}_S = \delta x_S\hat{x} + \delta y_S\hat{y} + \delta z_S\hat{z}, \tag{4}$$

where $\delta x_S = x_S(\varphi_g+\delta\varphi_g,\lambda+\delta\lambda) - x_S(\varphi_g,\lambda)$, etc. To second order in the quantities $\delta\varphi_g$ and $\delta\lambda$ we have

$$\begin{aligned}
\delta x_S &= \rho_S'\cos\lambda\,\delta\varphi_g - \rho_S\sin\lambda\,\delta\lambda \\
&\quad + \tfrac{1}{2}\rho_S''\cos\lambda(\delta\varphi_g)^2 - \tfrac{1}{2}\rho_S\cos\lambda(\delta\lambda)^2 - \rho_S'\sin\lambda\,\delta\varphi_g\delta\lambda, \\
\delta y_S &= \rho_S'\sin\lambda\,\delta\varphi_g + \rho_S\cos\lambda\,\delta\lambda \\
&\quad + \tfrac{1}{2}\rho_S''\sin\lambda(\delta\varphi_g)^2 - \tfrac{1}{2}\rho_S\sin\lambda(\delta\lambda)^2 + \rho_S'\cos\lambda\,\delta\varphi_g\delta\lambda, \\
\delta z_S &= z_S'\delta\varphi_g + \tfrac{1}{2}z_S''(\delta\varphi_g)^2,
\end{aligned}$$

where a prime indicates differentiation with respect to φ_g. The terms linear in the infinitesimals are used to derive expressions for unit vectors and the quadratic terms are used to derive expressions for radii of curvature.

The unit vector tangent to the surface and in the direction of increasing λ is

$$\hat{\lambda} = \frac{\partial\vec{x}_S}{\partial\lambda} \Big/ \left|\frac{\partial\vec{x}_S}{\partial\lambda}\right| = -\sin\lambda\,\hat{x} + \cos\lambda\,\hat{y}. \tag{5}$$

It is convenient to define a second unit vector in the $x-y$ plane orthogonal to $\hat{\lambda}$,

$$\hat{\rho}_S = \cos\lambda\,\hat{x} + \sin\lambda\,\hat{y}. \tag{6}$$

The unit vector tangent to the surface in the direction of increasing φ_g is

$$\hat{\varphi}_g = \frac{\partial \vec{x}_S}{\partial \varphi_g} \Big/ \left|\frac{\partial \vec{x}_S}{\partial \varphi_g}\right| = \frac{\rho_S' \hat{\rho}_S + z_S' \hat{z}}{\xi} \tag{7}$$

with

$$\xi \equiv \sqrt{(\rho_S')^2 + (z_S')^2}. \tag{8}$$

Finally, the unit vector normal to the surface is

$$\hat{n} = \hat{\lambda} \times \hat{\varphi}_g = \frac{z_S' \hat{\rho}_S - \rho_S' \hat{z}}{\xi}. \tag{9}$$

In terms of these unit vectors we have

$$\vec{x}_S = \rho_S(\varphi_g)\hat{\rho}_S + z_S(\varphi_g)\hat{z}, \tag{10}$$

$$\hat{x}_S = \frac{\vec{x}_S}{|\vec{x}_S|} = \cos\varphi_g \hat{\rho}_S + \sin\varphi_g \hat{z}, \tag{11}$$

and

$$\begin{aligned}\delta\vec{x}_S = {} & \xi\,\delta\varphi_g \hat{\varphi}_g + (\rho_S + \rho_S'\delta\varphi_g)\,\delta\lambda\,\hat{\lambda} \\ & + \frac{1}{2\xi}[(\rho_S'\rho_S'' + z_S' z_S'')(\delta\varphi_g)^2 - \rho_S \rho_S'(\delta\lambda)^2]\hat{\varphi}_g \\ & + \frac{1}{2\xi}[(z_S'\rho_S'' - \rho_S' z_S'')(\delta\varphi_g)^2 - \rho_S z_S'(\delta\lambda)^2]\hat{n}.\end{aligned} \tag{12}$$

The differential line segment tangent to the surface is

$$\mathrm{d}\vec{x}_S = \xi\,\mathrm{d}\varphi_g\,\hat{\varphi}_g + \rho_S\,\mathrm{d}\lambda\,\hat{\lambda} \tag{13}$$

and the differential arc length is

$$\mathrm{ds} \equiv |d\vec{x}_S| = \sqrt{\xi^2(\mathrm{d}\varphi_g)^2 + \rho_S^2(\mathrm{d}\lambda)^2}. \tag{14}$$

At a point on the surface (φ_g, λ), there are two principal radii of curvature; the *meridional*, describing curvature in the $\hat{\varphi}_g - \hat{n}$ plane and the *prime vertical*, describing curvature in the $\hat{\lambda} - \hat{n}$ plane. We discuss first the meridional. Consider two points in the meridional plane at (φ_g, λ) and at $(\varphi_g + \delta\varphi_g, \lambda)$. The directed line segment from the first point to the second can be written as

$$\delta\vec{x}_S = \delta x_\varphi \hat{\varphi}_g + \delta x_n \hat{n}. \tag{15}$$

The meridional radius of curvature μ is given by

$$\mu = -\frac{1}{2}\,\mathrm{Lim}_{\delta\varphi_g \to 0}\frac{(\delta x_\varphi)^2}{\delta x_n} \tag{16}$$

provided the limit exists. If $\mu>0$ the surface is convex at the point (φ_g,λ) with respect to the origin (like a sphere's outer surface) and if $\mu<0$ the surface is concave. By setting $\delta\lambda=0$ in Eq. (12) we find

$$\delta x_\varphi=\xi\delta\varphi_g+\frac{1}{2\xi}(\rho_S'\rho_S''+z_S'z_S'')(\delta\varphi_g)^2$$

and

$$\delta x_n=\frac{1}{2\xi}(z_S'\rho_S''-\rho_S'z_S'')(\delta\varphi_g)^2.$$

Substituting into Eq. (16) gives

$$\mu=\frac{\xi^3}{\rho_S'z_S''-z_S'\rho_S''}. \tag{17}$$

The prime vertical radius of curvature is determined in a similar fashion to be

$$\nu=\frac{\rho_S\xi}{z_S'}. \tag{18}$$

The differential line segment, Eq. (13), can now be written

$$d\vec{x}_S=\frac{\mu}{\xi^2}(\rho_S'z_S''-z_S'\rho_S'')d\varphi_g\,\hat{\varphi}_g+\frac{\nu z_S'}{\xi}d\lambda\,\hat{\lambda}. \tag{19}$$

The geocentric latitude is the angle between the position vector and the equatorial plane

$$\varphi_g=\arcsin(\hat{x}_S\cdot\hat{z}). \tag{20}$$

The *geodetic latitude* φ is defined to be the angle the normal to the surface makes with respect to the equatorial plane

$$\varphi=\arcsin(\hat{n}\cdot\hat{z}). \tag{21}$$

Clearly

$$\sin\varphi=-\frac{\rho_S'}{\xi},\quad \cos\varphi=\frac{z_S'}{\xi}. \tag{22}$$

The geocentric and geodetic latitudes are equal only if the Earth is modeled as a sphere. In terms of the geodetic latitude,

$$\hat{\varphi}_g=-\sin\varphi\hat{\rho}_S+\cos\varphi\hat{z}$$

and

$$\hat{n}=\cos\varphi\hat{\rho}_S+\sin\varphi\hat{z}.$$

From Eq. (13),

$$\frac{d\vec{x}_S}{d\varphi}=\frac{\xi}{\varphi'}\hat{\varphi}_g,$$

so

$$\hat{\varphi} = \pm \hat{\varphi}_g , \tag{23}$$

where the sign is determined by the sign of $\varphi' = d\varphi/d\varphi_g$ since $\xi > 0$. This derivative can be expressed in terms of the derivatives of ρ_S and z_S by differentiating both sides of the equation $\tan\varphi = -\rho_S'/z_S'$ with respect to φ_g. That is

$$\varphi' = -\frac{\sin\varphi z_S'' + \cos\varphi \rho_S''}{\xi} = \frac{\rho_S' z_S'' - \rho_S'' z_S'}{\xi^2}$$

or

$$\mu\varphi' = \xi. \tag{24}$$

We are assuming the Earth has a convex surface everywhere, $\mu > 0$. Therefore $\varphi' > 0$, $\hat{\varphi} = \hat{\varphi}_g$, and there is a one-to-one relationship between the two latitudes enabling us to replace φ_g with φ as the independent variable. This is an advantage since geophysical data are referenced to the geodetic rather than the geocentric latitude.

The basic coordinate transformation equations can be rewritten as

$$x_S = \nu \cos\varphi \cos\lambda, \tag{25}$$

$$y_S = \nu \cos\varphi \sin\lambda, \tag{26}$$

$$z_S = \chi \sin\varphi. \tag{27}$$

The differential line segment is

$$d\vec{x}_S = \mu\, d\varphi\, \hat{\varphi} + \nu \cos\varphi\, d\lambda\, \hat{\lambda}. \tag{28}$$

Observing from this relation that

$$\mu^2 = \left| \frac{d\vec{x}_S}{d\varphi} \right|^2$$

we obtain

$$\mu^2 = \left(\frac{d}{d\varphi}(\nu\cos\varphi) \right)^2 + \left(\frac{d}{d\varphi}(\chi\sin\varphi) \right)^2. \tag{29}$$

Since

$$z_S' \sin\varphi + \rho_S' \cos\varphi = 0$$

we have

$$\sin\varphi \frac{d(\chi\sin\varphi)}{d\varphi} + \cos\varphi \frac{d(\nu\cos\varphi)}{d\varphi} = 0.$$

These equations yield

$$\mu = \nu \left| 1 - \frac{\cot\varphi}{\nu} \frac{d\nu}{d\varphi} \right| \tag{30}$$

and the useful relations

$$\frac{\mathrm{d}}{\mathrm{d}\varphi}(\nu\cos\varphi)=-\mu\sin\varphi,\quad \frac{\mathrm{d}}{\mathrm{d}\varphi}(\chi\sin\varphi)=+\mu\cos\varphi. \tag{31}$$

The arclength is

$$\mathrm{d}s=\sqrt{\mu^2(\mathrm{d}\varphi)^2+\nu^2\cos^2\varphi(\mathrm{d}\lambda)^2}. \tag{32}$$

The unit vector directed from the point with coordinates (φ, λ) to the one with coordinates $(\varphi+\mathrm{d}\varphi,\lambda+\mathrm{d}\lambda)$ is

$$\hat{s}=\frac{\mathrm{d}\vec{x}_S}{\mathrm{d}s}=\mu\frac{\mathrm{d}\varphi}{\mathrm{d}s}\hat{\varphi}+\nu\cos\varphi\frac{\mathrm{d}\lambda}{\mathrm{d}s}\hat{\lambda}. \tag{33}$$

The unit vector $\hat{s}$ can also be written in terms of the angle α the differential line segment makes with respect to $\hat{\varphi}$, i.e., the angle between $\mathrm{d}\vec{x}_S$ and "north"

$$\hat{s}=\cos\alpha\hat{\varphi}+\sin\alpha\hat{\lambda}, \tag{34}$$

where $\cos\alpha=\mu(\mathrm{d}\varphi/\mathrm{d}s)$ and $\sin\alpha=\nu\cos\varphi(\mathrm{d}\lambda/\mathrm{d}s)$.

We define

$$R(\varphi)\equiv\sqrt{\mu(\varphi)\nu(\varphi)}. \tag{35}$$

The length $R(\varphi)$ will play an important role in the development of the parabolic approximation. Since the Earth is almost spherical, it is possible to write

$$\frac{1}{R(\varphi)}=\frac{1}{\overline{R}}(1+\eta g(\varphi)), \tag{36}$$

where $\overline{R}$ is the mean radius of the Earth and g is a function of order unity. The small parameter η is a measure of the deviation of the solid from a sphere. If the Earth is taken to be an ellipsoid, η would be the eccentricity squared, $\eta\approx 1/150$ [see, e.g., Dworski and Mercer (1990)].

We summarize here the unit vectors that have been introduced with their differentials. We have

$$\hat{\varphi}=-\sin\varphi\hat{\rho}_S+\cos\varphi\hat{z}, \tag{37}$$

$$\hat{\lambda}=-\sin\lambda\hat{x}+\cos\lambda\hat{y}, \tag{38}$$

$$\hat{n}=\cos\varphi\hat{\rho}_S+\sin\varphi\hat{z}, \tag{39}$$

$$\begin{aligned}\hat{\rho}_S&=\cos\lambda\hat{x}+\sin\lambda\hat{y},\\ &=\cos\varphi\hat{n}-\sin\varphi\hat{\varphi}.\end{aligned} \tag{40}$$

For the differentials we have

$$\mathrm{d}\hat{\varphi}=-\sin\varphi\hat{\lambda}\,\mathrm{d}\lambda-\hat{n}\,\mathrm{d}\varphi, \tag{41}$$

$$\mathrm{d}\hat{\lambda}=-\hat{\rho}_S\,\mathrm{d}\lambda, \tag{42}$$

$$\mathrm{d}\hat{n}=\cos\varphi\hat{\lambda}\,\mathrm{d}\lambda+\hat{\varphi}\,\mathrm{d}\varphi, \tag{43}$$

and

$$d\hat{\rho}_S = \hat{\lambda}\, d\lambda. \tag{44}$$

The position vector to a general point in the ocean, below the surface, is

$$\vec{x} = \vec{x}_S - \zeta \hat{n},$$

where $\vec{x}_S$ is the position vector of the point on the surface directly over the point of interest, ζ ($\geqslant 0$) is the depth at that point. Propagation in the atmosphere can be considered by simply changing the sign of ζ. The differential line element is

$$d\vec{x} = d\vec{x}_S - d\zeta\, \hat{n} - \zeta\, d\hat{n} = (\mu - \zeta) d\varphi\, \hat{\varphi} + (\nu - \zeta)\cos\varphi\, d\lambda \hat{\lambda} - d\zeta\, \hat{n},$$

where we have used Eq. (43). The differential volume element is

$$d^3\vec{x} = (\mu - \zeta)(\nu - \zeta)\cos\varphi\, d\varphi\, d\lambda\, d\zeta.$$

Also

$$\nabla^2 = \frac{1}{(\mu-\zeta)(\nu-\zeta)\cos\varphi} \frac{\partial}{\partial\varphi}\left(\frac{\nu-\zeta}{\mu-\zeta}\cos\varphi \frac{\partial}{\partial\varphi}\right) + \frac{1}{(\mu-\zeta)^2\cos^2\varphi}\frac{\partial^2}{\partial\lambda^2} + \frac{1}{(\mu-\zeta)(\nu-\zeta)}\frac{\partial}{\partial\zeta}\left((\mu-\zeta)(\nu-\zeta)\frac{\partial}{\partial\zeta}\right) \tag{45}$$

and

$$\delta^{(3)}(\vec{x} - \vec{x}_0) = \frac{1}{(\mu-\zeta)(\nu-\zeta)}\delta(\sin\varphi - \sin\varphi_0)\,\delta(\lambda - \lambda_0)\,\delta(\zeta - \zeta_0).$$

In writing these relations we have used the fact that ν and μ are functions of φ but not of λ and ζ. For many problems it is not ∇^2 which is of concern but rather $\rho\nabla\cdot(\rho^{-1}\nabla)$, where ρ is the density of the medium. Because of stratification ρ is usually assumed to depend only on the depth variable ζ. If this is the case, the last term in Eq. (45) is replaced with

$$\frac{\rho(\zeta)}{(\mu-\zeta)(\nu-\zeta)}\frac{\partial}{\partial\zeta}\left(\frac{(\mu-\zeta)(\nu-\zeta)}{\rho(\zeta)}\frac{\partial}{\partial\zeta}\right).$$

In most work on global propagation, a ''thin-medium'' approximation is made. That is, since the thickness or depth of the medium is much less than the radii of curvature, $\zeta \ll \nu$ and $\zeta \ll \mu$, it is valid to replace $\nu - \zeta$ with ν and $\mu - \zeta$ with μ everywhere in the above-mentioned expressions, even before differentiation with respect to ζ or φ. With this approximation, we have

$$d\vec{x} = \mu d\varphi\hat{\varphi} + \nu\cos\varphi\, d\lambda\, \hat{\lambda} - d\zeta\, \hat{n} \tag{46}$$

and

$$d^3\vec{x} = J(\varphi) d\varphi\, d\lambda\, d\zeta, \tag{47}$$

where

$$J(\varphi) \equiv \mu\nu\cos\varphi. \tag{48}$$

Moreover

$$\rho\nabla\cdot(\rho^{-1}\nabla) = \nabla_S^2 + \rho\frac{\partial}{\partial\zeta}\left(\frac{1}{\rho}\frac{\partial}{\partial\zeta}\right), \tag{49}$$

where

$$\nabla_S^2 = \frac{1}{J(\varphi)}\left[\frac{\partial}{\partial\varphi}\left(\frac{\nu\cos\varphi}{\mu}\frac{\partial}{\partial\varphi}\right)+\frac{\mu}{\nu\cos\varphi}\frac{\partial^2}{\partial\lambda^2}\right] \tag{50}$$

and

$$\delta^{(3)}(\vec{x}-\vec{x}_0)=\frac{1}{J(\varphi)}\,\delta(\varphi-\varphi_0)\,\delta(\lambda-\lambda_0)\,\delta(\zeta-\zeta_0). \tag{51}$$

The thin-medium approximation can be relaxed by scaling and redefining the index of refraction, see, e.g., Tappert (1977) or Collins (1993b). If we had done this scaling the analysis would be unchanged; we would have simply ended up with expressions involving the redefined index of refraction.

III. GREEN'S FUNCTION AND THE PROPAGATOR

The equation for G the Green's function or impulse response function for the time-independent problem is

$$\left[\rho(\vec{x})\vec{\nabla}\cdot\left(\frac{1}{\rho(\vec{x})}\vec{\nabla}\right)+k_0^2 n^2(\vec{x})\right]G(\vec{x}|\vec{x}_0)=-\delta^{(3)}(\vec{x}-\vec{x}_0) \tag{52}$$

for a point source located at $\vec{x}_0=(x_0,y_0,z_0)$. The Green's function will also satisfy appropriate boundary conditions at the top and bottom of the ocean or atmosphere. In developing parabolic approximations, many authors begin with the wave equation appropriate for a source-free region of space [e.g., Eq. (1)]. We prefer to begin with Eq. (52) so that a separate analysis is not needed to account for a source. This analysis involves solving for the field on a surface close to the source and then matching boundary conditions on that surface. It should be noted in this regard that general, linear equations for wave propagation were derived in Brekhovskikh and Godin (1999) [Eqs. (4.1.9)–(4.1.11)] by including source terms from the outset.

It is not Green's functions, however, that obey parabolic equations and marching algorithms, but propagators. The two are related by an integral over τ, the Fock–Feynman parameter [Fock (1937); Feynman (1951)]

$$G(\vec{x}|\vec{x}_0)=\frac{i}{2k_0}\int_0^\infty d\tau\, e^{i\tau k_0/2}\Phi(\tau;\vec{x}). \tag{53}$$

The propagator function Φ is defined by

$$\left[2ik_0\frac{\partial}{\partial\tau}+\rho\vec{\nabla}\cdot\left(\frac{1}{\rho}\vec{\nabla}\right)-2k_0^2V(\vec{x})\right]\Phi(\tau;\vec{x})=0,\quad \tau>0, \tag{54}$$

and

$$\mathrm{Lim}_{\tau\to0}\Phi(\tau;\vec{x})=\delta^{(3)}(\vec{x}-\vec{x}_0), \tag{55}$$

where the wave speed variation is

$$V(\vec{x})\equiv-\tfrac{1}{2}[n^2(\vec{x})-1].$$

In terms of the curvilinear coordinates introducted in Sec. II, Eqs. (54) and (55) become

$$\left[2ik_0\frac{\partial}{\partial\tau}+\nabla_S^2+\rho\frac{\partial}{\partial\zeta}\left(\frac{1}{\rho}\frac{\partial}{\partial\zeta}\right)-2k_0^2V(\varphi,\lambda,\zeta)\right]\Phi(\tau;\varphi,\lambda,\zeta)=0 \tag{56}$$

and

$$\mathrm{Lim}_{\tau\to 0}\Phi(\tau;\varphi,\lambda,\zeta)=\frac{1}{J(\varphi)}\,\delta(\varphi-\varphi_0)\,\delta(\lambda-\lambda_0)\,\delta(\zeta-\zeta_0) \tag{57}$$

with ∇_S^2 given by Eq. (50).

IV. HORIZONTAL RAY THEORY

We write Φ as the product of two factors,

$$\Phi=H\Psi, \tag{58}$$

and require that H be independent of the depth coordinate and obey a parabolic equation in the horizontal coordinates

$$\left[2ik_0\frac{\partial}{\partial\tau}+\nabla_S^2\right]H(\tau,\varphi,\lambda)=0, \tag{59}$$

$$\mathrm{Lim}_{\tau\to 0}H(\tau,\varphi,\lambda)=\frac{1}{J(\varphi_0)}\,\delta(\varphi-\varphi_0)\,\delta(\lambda-\lambda_0). \tag{60}$$

As we shall see, the field H will determine spreading factors and the path along which the field Ψ propagates. The field Ψ, on the other hand, will reflect the dynamic effects associated with a variable wave speed. The factorization in Eq. (58) of the solution to a wave equation into functions having different coordinate dependencies has been used by many authors in the development of parabolic approximations [Myers and McAninch (1978); McAninch (1986); Babič and Buldyrev (1991)]. It is analogous to the factorization of the solution to the Helmholtz equation [Eq. (2)] that is often the starting point in the development of the standard parabolic approximation for the two-dimensional propagation problem in range and depth. In the path integral approach [Palmer (1978); (1979)] where it is as easy to develop ray theory approximations in one or two of the three coordinates as in all three, the factorization is not an *ansätz* but rather a consequence of making the horizontal ray theory approximation.

We assume horizontal spatial scales are large enough compared to the wavelength that the ray theory approximation is valid when considering horizontal wave motion. We do not make any assumption about the vertical scales of variability. Following Weinberg's (1962) matrix approach, we write Eq. (59) as a system of first-order equations,

$$\begin{bmatrix} 2ik_0J\partial/\partial\tau & \partial/\partial\varphi & \partial/\partial\lambda \\ \partial/\partial\varphi & -\mu/(\nu\cos\varphi) & 0 \\ \partial/\partial\lambda & 0 & -(\nu\cos\varphi)/\mu \end{bmatrix}\begin{bmatrix} H \\ H_\varphi \\ H_\lambda \end{bmatrix}=0, \tag{61}$$

and assume a common exponential factor

$$\begin{bmatrix} H \\ H_\varphi \\ H_\lambda \end{bmatrix}=\begin{bmatrix} \hat{H} \\ \hat{H}_\varphi \\ \hat{H}_\lambda \end{bmatrix}\exp(ik_0A), \tag{62}$$

so that

$$\begin{bmatrix} 2ik_0J(ik_0\partial A/\partial\tau+\partial/\partial\tau) & ik_0\partial A/\partial\varphi+\partial/\partial\varphi & ik_0\partial A/\partial\lambda+\partial/\partial\lambda \\ ik_0\partial A/\partial\varphi+\partial/\partial\varphi & -\mu/(\nu\cos\varphi) & 0 \\ ik_0\partial A/\partial\lambda+\partial/\partial\lambda & 0 & -\nu\cos\varphi/\mu \end{bmatrix}\times\begin{bmatrix} \hat{H} \\ \hat{H}_\varphi \\ \hat{H}_\lambda \end{bmatrix}=0. \tag{63}$$

Consider one element in the above-presented square array, say the element in the top row and middle column, $ik_0\partial A/\partial\varphi+\partial/\partial\varphi$. This element will contribute to the differential equation the expression

$$\hat{H}\left(ik_0\frac{\partial A}{\partial\varphi}+\frac{\partial\ln\hat{H}}{\partial\varphi}\right).$$

In this matrix approach, the rule for developing the lowest-order ray theory approximation is to ignore in the matrix elements gradients of $\hat{H}$ (or $\hat{H}_\varphi$ and $\hat{H}_\lambda$) in comparison to terms involving k_0 times the corresponding gradients of A. This rule is justified by using the traditional approach, i.e., writing the matrix equation as a single equation, expanding the $\hat{H}$ in a series in $1/k_0$, separating real and imaginary parts, and equating like powers of k_0. It cannot be justified by considering individual matrix elements such as the one above because the terms involving A and $\hat{H}$ are in general complex. In the present case the advantage of using the matrix approach over the traditional approach is that it is very easy to apply the ray theory approximation to individual coordinates.

Applying this rule to Eq. (63), we obtain, in lowest order,

$$\begin{bmatrix} -2k_0^2J\partial A/\partial\tau & ik_0\partial A/\partial\varphi & ik_0\partial A/\partial\lambda \\ ik_0\partial A/\partial\varphi & -\mu/(\nu\cos\varphi) & 0 \\ ik_0\partial A/\partial\lambda & 0 & -\nu\cos\varphi/\mu \end{bmatrix}\begin{bmatrix}\hat{H}\\ \hat{H}_\varphi\\ \hat{H}_\lambda\end{bmatrix}=0 \tag{64}$$

and

$$[\hat{H}\quad\hat{H}_\varphi\quad\hat{H}_\lambda]\begin{bmatrix} 2ik_0J\partial/\partial\tau & \partial/\partial\varphi & \partial/\partial\lambda \\ \partial/\partial\varphi & 0 & 0 \\ \partial/\partial\lambda & 0 & 0 \end{bmatrix}\begin{bmatrix}\hat{H}\\ \hat{H}_\varphi\\ \hat{H}_\lambda\end{bmatrix}=0. \tag{65}$$

Equation (64) gives the *eikonal equation*

$$\frac{\partial A}{\partial\tau}+\frac{1}{2\mu^2}\left(\frac{\partial A}{\partial\varphi}\right)^2+\frac{1}{2\nu^2\cos^2\varphi}\left(\frac{\partial A}{\partial\lambda}\right)^2=0, \tag{66}$$

which determines A. The factor $\hat{H}$ is determined by the *transport equation*

$$\left(\frac{\partial}{\partial\tau}+\frac{1}{\mu^2}\frac{\partial A}{\partial\varphi}\frac{\partial}{\partial\varphi}+\frac{1}{\nu^2\cos^2\varphi}\frac{\partial A}{\partial\lambda}\frac{\partial}{\partial\lambda}\right)\ln\hat{H}^2+\nabla_S^2A=0, \tag{67}$$

which follows from Eq. (65) after Eq. (64) is used to express $\hat{H}_\varphi$ and $\hat{H}_\lambda$ in terms of $\hat{H}$,

$$\hat{H}_\varphi=ik_0\frac{\nu\cos\varphi}{\mu}\frac{\partial A}{\partial\varphi}\hat{H},\quad \hat{H}_\lambda=ik_0\frac{\mu}{\nu\cos\varphi}\frac{\partial A}{\partial\lambda}\hat{H}. \tag{68}$$

The eikonal equation, Eq. (66), is solved in the usual way by introducing ray path coordinates, i.e., auxilliary functions $q_\tau(\sigma)$, $q_\varphi(\sigma)$, $q_\lambda(\sigma)$ and their conjugate momenta $p_\tau(\sigma)$, $p_\varphi(\sigma)$, $p_\lambda(\sigma)$ of a variable σ defined on an interval, $\sigma_0\leqslant\sigma\leqslant\sigma_1$, that satisfy the end-point conditions

$$q_\tau(\sigma_0)=0,\quad q_\tau(\sigma_1)=\tau, \tag{69}$$

$$q_\varphi(\sigma_0)=\varphi_0,\quad q_\varphi(\sigma_1)=\varphi, \tag{70}$$

$$q_\lambda(\sigma_0)=\lambda_0,\quad q_\lambda(\sigma_1)=\lambda, \tag{71}$$

$$p_\tau(\sigma_1)=\frac{\partial A}{\partial \tau}, \tag{72}$$

$$p_\varphi(\sigma_1)=\frac{\partial A}{\partial \varphi}, \tag{73}$$

$$p_\lambda(\sigma_1)=\frac{\partial A}{\partial \lambda}. \tag{74}$$

The initial values for the momenta are picked so that $\mathcal{E}(\sigma_0)=0$ where

$$\mathcal{E}(\sigma)\equiv p_\tau(\sigma)+\frac{1}{2}\frac{1}{h_\varphi^2(\sigma)}(p_\varphi(\sigma))^2+\frac{1}{2}\frac{1}{h_\lambda^2(\sigma)}(p_\lambda(\sigma))^2 \tag{75}$$

is the Hamiltonian function. Here we introduce the notation

$$h_\varphi(\sigma)\equiv\mu(q_\varphi(\sigma)),\quad h_\lambda(\sigma)\equiv\nu(q_\varphi(\sigma))\cos(q_\varphi(\sigma)). \tag{76}$$

The eikonal equation is equivalent to $\mathcal{E}(\sigma_1)=0$ and will be satisfied provided

$$\frac{\mathrm{d}\mathcal{E}(\sigma)}{\mathrm{d}\sigma}=0.$$

This condition, in turn, is assured if the path variables satisfy Hamilton's equations

$$\frac{\mathrm{d}q_\tau}{\mathrm{d}\sigma}=1, \tag{77}$$

$$\frac{\mathrm{d}q_\varphi}{\mathrm{d}\sigma}=\frac{1}{h_\varphi^2}p_\varphi, \tag{78}$$

$$\frac{\mathrm{d}q_\lambda}{\mathrm{d}\sigma}=\frac{1}{h_\lambda^2}p_\lambda \tag{79}$$

and

$$\frac{\mathrm{d}p_\tau}{\mathrm{d}\sigma}=0, \tag{80}$$

$$\frac{\mathrm{d}p_\varphi}{\mathrm{d}\sigma}=-\frac{1}{2}\left[\frac{\partial}{\partial q_\varphi}\left(\frac{1}{h_\varphi^2}\right)p_\varphi^2+\frac{\partial}{\partial q_\varphi}\left(\frac{1}{h_\lambda^2}\right)p_\lambda^2\right], \tag{81}$$

$$\frac{\mathrm{d}p_\lambda}{\mathrm{d}\sigma}=0. \tag{82}$$

From Eqs. (69) and (77) we have

$$q_\tau(\sigma)=\sigma-\sigma_0,\quad \sigma_1-\sigma_0=\tau. \tag{83}$$

In general, the eikonal A is given by the integral

$$A=\int_{\sigma_0}^{\sigma_1}\mathrm{d}\sigma\left[p_\tau\frac{\mathrm{d}q_\tau}{\mathrm{d}\sigma}+p_\varphi\frac{\mathrm{d}q_\varphi}{\mathrm{d}\sigma}+p_\lambda\frac{\mathrm{d}q_\lambda}{\mathrm{d}\sigma}\right]. \tag{84}$$

According to Eqs. (77)–(80), this integral can be rewritten as

$$A=\tau p_\tau+\int_{\sigma_0}^{\sigma_1}\mathbf{v}^2\,\mathrm{d}\sigma, \tag{85}$$

where

$$\mathbf{v}=\frac{\mathrm{d}s}{\mathrm{d}\sigma}=\sqrt{\frac{1}{h_\varphi^2}p_\varphi^2+\frac{1}{h_\lambda^2}p_\lambda^2}. \tag{86}$$

Because $\mathcal{E}=0$,

$$-2p_\tau=\mathbf{v}^2=\text{constant}.$$

Therefore

$$A=-\tau p_\tau. \tag{87}$$

Consider now the path length

$$s(\sigma)=\int_{\sigma_0}^{\sigma}\mathrm{d}s=\int_{\sigma_0}^{\sigma}\mathbf{v}(\sigma')\mathrm{d}\sigma'=(\sigma-\sigma_0)\sqrt{-2p_\tau}\,. \tag{88}$$

Equation (87) becomes

$$A=\frac{S^2}{2\tau}. \tag{89}$$

Here $S=s(\sigma_1)$ is the total path length along the ray path. This expression gives the functional dependence of A on τ since S is independent of τ.

Consider a function $f=f(q_\tau,q_\varphi,q_\lambda,\zeta)$ of the depth variable ζ and the path variables. The derivative of f along the path is

$$\frac{\mathrm{d}f}{\mathrm{d}\sigma}=\frac{\mathrm{d}q_\tau}{\mathrm{d}\sigma}\frac{\partial f}{\partial q_\tau}+\frac{\mathrm{d}q_\varphi}{\mathrm{d}\sigma}\frac{\partial f}{\partial q_\varphi}+\frac{\mathrm{d}q_\lambda}{\mathrm{d}\sigma}\frac{\partial f}{\partial q_\lambda}=\frac{\partial f}{\partial q_\tau}+\frac{1}{h_\varphi^2}p_\varphi\frac{\partial f}{\partial q_\varphi}+\frac{1}{h_\lambda^2}p_\lambda\frac{\partial f}{\partial q_\lambda}.$$

If this expression is evaluated at the end point $\sigma=\sigma_1$, we have

$$\frac{\mathrm{d}f}{\mathrm{d}\sigma}\Big|_{\sigma=\sigma_1}=\frac{\partial f(\tau,\varphi,\lambda,\zeta)}{\partial\tau}+\frac{1}{\mu^2}\frac{\partial A}{\partial\varphi}\frac{\partial f(\tau,\varphi,\lambda,\zeta)}{\partial\varphi}+\frac{1}{\nu^2\cos^2\varphi}\frac{\partial A}{\partial\lambda}\frac{\partial f(\tau,\varphi,\lambda,\zeta)}{\partial\lambda}. \tag{90}$$

One can change the independent variable in the ray paths from σ to the path length s since $\mathbf{v}(s)=\mathrm{d}s/\mathrm{d}\sigma$ does not change sign. It is, in fact, a constant equal to S/τ. Equation (88) is first solved for σ in terms of s,

$$\sigma(s)=\sigma_0+\int_0^s\frac{1}{\mathbf{v}}\mathrm{d}s'=\sigma_0+s\frac{\tau}{S} \tag{91}$$

and new ray path coordinates are introduced

$$\tau_{\mathrm{ray}}(s)\equiv q_\tau(\sigma(s)),$$

$$\varphi_{\mathrm{ray}}(s)\equiv q_\varphi(\sigma(s)),$$

$$\lambda_{\mathrm{ray}}(s)\equiv q_\lambda(\sigma(s))$$

defined on the interval, $0 \leqslant s \leqslant S$, that satisfies the same end-point conditions satisfied by q_τ, q_φ, and q_λ. In terms of these new path variables, a function $f(s,\zeta)=f(\tau_{\text{ray}}(s),\varphi_{\text{ray}}(s),\lambda_{\text{ray}}(s),\zeta)$ has a derivative with respect to path length given by

$$\mathbf{v}\frac{\partial f}{\partial s}=\left[\frac{\mathrm{d}q_\tau}{\mathrm{d}\sigma}\frac{\partial f}{\partial \tau_{\text{ray}}}+\frac{\mathrm{d}q_\varphi}{\mathrm{d}\sigma}\frac{\partial f}{\partial \varphi_{\text{ray}}}+\frac{\mathrm{d}q_\lambda}{\mathrm{d}\sigma}\frac{\partial f}{\partial \lambda_{\text{ray}}}\right],$$

where the derivatives with respect to σ are evaluated at $\sigma(s)$. At the end point of the path this expression becomes

$$\frac{S}{\tau}\left[\frac{\partial f}{\partial s}\right]_{s=S}=\frac{\partial f(\tau,\varphi,\lambda,\zeta)}{\partial \tau}+\frac{1}{\mu^2}\frac{\partial A}{\partial \varphi}\frac{\partial f(\tau,\varphi,\lambda,\zeta)}{\partial \varphi}+\frac{1}{\nu^2\cos^2\varphi}\frac{\partial A}{\partial \lambda}\frac{\partial f(\tau,\varphi,\lambda,\zeta)}{\partial \lambda}. \tag{92}$$

We have reverted to using a partial derivative on the left-hand side of this equation to remind ourselves that f can be a function of depth as well as of the path variables. By making this change in the independent variable, we will end up with equations that, unlike Eqs (59) and (67), involve τ as a parameter rather than as an independent variable, thus simplifying the evaluation of Eq. (53).

The unit vector along the ray path can be constructed from Eq. (33),

$$\hat{s}(\sigma)=\left(h_\varphi(\sigma)\frac{\mathrm{d}q_\varphi(\sigma)}{\mathrm{d}\sigma}\hat{\varphi}+h_\lambda(\sigma)\frac{\mathrm{d}q_\lambda(\sigma)}{\mathrm{d}\sigma}\hat{\lambda}\right)\Big/\frac{\mathrm{d}s}{\mathrm{d}\sigma}, \tag{93}$$

which at the end point of the path becomes

$$\frac{S}{\tau}\hat{s}(\sigma_1)=\frac{1}{\mu^2}\frac{\partial A}{\partial \varphi}\hat{\varphi}+\frac{1}{\nu^2\cos^2\varphi}\frac{\partial A}{\partial \lambda}\hat{\lambda}. \tag{94}$$

If we make the identification in Eq. (90)

$$f(\sigma_1)=f(\tau,\varphi,\lambda)=\ln \hat{H}^2,$$

Eq. (67) becomes

$$\frac{\mathrm{d}f}{\mathrm{d}\sigma}\Big|_{\sigma=\sigma_1}+\nabla_S^2 A=0. \tag{95}$$

For this expression to be useful, we must write $\nabla_S^2 A$ in terms of path variables evaluated at the end point $\sigma=\sigma_1$. To this end we define

$$A_\varphi(\sigma)\equiv\frac{h_\lambda(\sigma)}{h_\varphi(\sigma)}p_\varphi(\sigma)$$

and

$$A_\lambda(\sigma)\equiv\frac{h_\varphi(\sigma)}{h_\lambda(\sigma)}p_\lambda(\sigma),$$

so that

$$\nabla_S^2 A=\frac{1}{J(\varphi)}\left[\frac{\partial A_\varphi(\sigma_1)}{\partial \varphi}+\frac{\partial A_\lambda(\sigma_1)}{\partial \lambda}\right].$$

Because $\nabla_S^2 A$ involves derivatives with respect to φ and λ, the end-point values of the path coordinates q_φ and q_λ, it is clear it cannot be written as a function of the path (evaluated at the

end point). What is needed, in addition, is a perturbed path whose coordinates differ at the end point from φ and λ by infinitesimal amounts $\delta\varphi$ and $\delta\lambda$. The perturbations δA_φ and δA_λ evaluated at the end points will involve derivatives of A_φ and A_λ with respect to φ and λ. These derivatives can be used to construct $\nabla_S^2 A$. In addition, since $\nabla_S^2 A$ does not involve a derivative with respect to τ, it can be held fixed.

There is some freedom in the choice of how the path is perturbed. The perturbation can be induced by changes in any set of parameters that, together with φ_0 and λ_0, characterize the ray. Here we will use a set that exploits the fact that p_τ and p_λ are constant along the ray path

$$W \equiv \sqrt{-2p_\tau}, \quad P = \frac{p_\lambda}{W}. \tag{96}$$

The derivatives of the paths can be written in terms of W and P as follows:

$$\frac{\mathrm{d}q_\varphi}{\mathrm{d}\sigma} = \frac{A_\varphi}{J} = \frac{W}{J}\sqrt{h_\lambda^2 - P^2}, \quad \frac{\mathrm{d}q_\lambda}{\mathrm{d}\sigma} = \frac{A_\lambda}{J} = \frac{WP}{h_\lambda^2}. \tag{97}$$

Now $A_\varphi(\sigma_1)$ and $A_\lambda(\sigma_1)$ depend on φ and λ (as well as τ) so we can write the matrix equation

$$\begin{bmatrix} \partial A_\varphi(\sigma_1)/\partial W & \partial A_\varphi(\sigma_1)/\partial P \\ \partial A_\lambda(\sigma_1)/\partial W & \partial A_\lambda(\sigma_1)/\partial P \end{bmatrix} = \begin{bmatrix} \partial A_\varphi(\sigma_1)/\partial \varphi & \partial A_\varphi(\sigma_1)/\partial \lambda \\ \partial A_\lambda(\sigma_1)/\partial \varphi & \partial A_\lambda(\sigma_1)/\partial \lambda \end{bmatrix} Q(\sigma_1), \tag{98}$$

where

$$Q(\sigma) \equiv \begin{bmatrix} \partial q_\varphi(\sigma)/\partial W & \partial q_\varphi(\sigma)/\partial P \\ \partial q_\lambda(\sigma)/\partial W & \partial q_\lambda(\sigma)/\partial P \end{bmatrix}. \tag{99}$$

Equation (98) can be inverted provided that the determinant of Q,

$$\det(Q(\sigma)) = \frac{\partial q_\varphi(\sigma)}{\partial W}\frac{\partial q_\lambda(\sigma)}{\partial P} - \frac{\partial q_\varphi(\sigma)}{\partial P}\frac{\partial q_\lambda(\sigma)}{\partial W}, \tag{100}$$

does not vanish at $\sigma = \sigma_1$. (Caustics are located where $\det Q = 0$.) By taking the trace after inverting Eq (98) we obtain

$$\nabla_S^2 A = \frac{1}{J(\varphi)}\mathrm{trace}\left\{ \begin{bmatrix} \partial A_\varphi(\sigma_1)/\partial \varphi & \partial A_\varphi(\sigma_1)/\partial \lambda \\ \partial A_\lambda(\sigma_1)/\partial \varphi & \partial A_\lambda(\sigma_1)/\partial \lambda \end{bmatrix} \right\} = \frac{\mathrm{d}\ln D(\sigma)}{\mathrm{d}\sigma}\Big|_{\sigma=\sigma_1}, \tag{101}$$

where

$$D(\sigma) \equiv J(q_\varphi(\sigma))\det(Q(\sigma)). \tag{102}$$

This result was arrived at by using the relation

$$\frac{\mathrm{d}D}{\mathrm{d}\sigma} = \frac{\partial A_\varphi}{\partial W}\frac{\partial q_\lambda}{\partial P} - \frac{\partial A_\lambda}{\partial W}\frac{\partial q_\varphi}{\partial P} - (W \leftrightarrow P), \tag{103}$$

which follows from the equations of motion. Except for the presence of the function $J(q_\varphi)$, the derivation of Eq. (101) is identical to the usual derivation for the Cartesian problem using Liousville's formula [see, e.g., Brekhovskikh and Godin (1999), Sec. 5.1].

Combining Eq. (101) with Eq. (95) gives

$$\left.\frac{df}{d\sigma}\right|_{\sigma=\sigma_1}+\left.\frac{d}{d\sigma}\ln D(\sigma)\right|_{\sigma=\sigma_1}=0.$$

This equation can be solved by solving the more general one

$$\frac{df(\sigma)}{d\sigma}+\frac{d}{d\sigma}\ln D(\sigma)=0$$

and evaluating the result at $\sigma=\sigma_1$,

$$\hat{H}=\mathcal{C}\sqrt{\frac{1}{D(\sigma_1)}},$$

where $\mathcal{C}$ is an integration constant. It can be determined by considering the solution to the parabolic equation at a point $(\varphi',\lambda',\tau')$ where φ' and λ' are located in a neighborhood of the source at φ_0 and λ_0 taken small enough so that μ and $\nu\cos\varphi$ can be considered constant within it. The solution to the horizontal parabolic equation at $(\varphi',\lambda',\tau')$ that satisfies Eq. (60) is simply

$$H(\tau';\varphi',\lambda')=\left(\frac{k_0}{2\pi i\tau'}\right)\exp\left\{\frac{ik_0}{2\tau'}[\mu_0^2(\varphi'-\varphi_0)^2+\nu_0^2\cos^2\varphi_0(\lambda'-\lambda_0)^2]\right\},$$

where $\mu_0=\mu(\varphi_0)$ and $\nu_0=\nu(\varphi_0)$. We take the point $(\varphi',\lambda',\tau')$ to be along the ray path from $(\varphi_0,\lambda_0,0)$ to (φ,λ,τ),

$$\varphi'=q_\varphi(\sigma'),\quad \lambda'=q_\lambda(\sigma'),\quad \tau'=\sigma'-\sigma_0.$$

The variable $\sigma'-\sigma_0\lesssim\tau'$ is necessarily small enough so that the ray paths can be approximated by straight lines,

$$q_\varphi(\sigma')-\varphi_0=(\sigma'-\sigma_0)\frac{dq_\varphi}{d\sigma}(\sigma_0)=(\sigma'-\sigma_0)\frac{W}{J(\varphi_0)}\sqrt{\nu_0^2\cos^2\varphi_0-P^2},$$

$$q_\lambda(\sigma')-\lambda_0=(\sigma'-\sigma_0)\frac{dq_\lambda}{d\sigma}(\sigma_0)=(\sigma'-\sigma_0)\frac{WP}{\nu_0^2\cos^2\varphi_0}.$$

It is clear from these expressions that $D(\sigma')$ can be written in the form

$$D(\sigma')=\frac{1}{2}(\sigma'-\sigma_0)^2\frac{d^2D}{d\sigma^2}(\sigma_0). \tag{104}$$

[The second derivative in this expression is, in fact, equal to $2W^2/A_\varphi(\sigma_0)$.] Since

$$\hat{H}(\sigma')=\frac{k_0}{2\pi i(\sigma'-\sigma_0),}$$

we have

$$\mathcal{C}=\hat{H}(\sigma')\sqrt{D(\sigma')}=\frac{k_0}{2\pi i}\sqrt{\frac{1}{2}\frac{d^2D}{d\sigma^2}(\sigma_0)}.$$

The amplitude factor is, therefore,

$$\hat{H}=\frac{k_0}{2\pi i}\sqrt{\frac{1}{2D(\sigma_1)}\frac{d^2D}{d\sigma^2}(\sigma_0)}.$$

If both sides of Eq. (97) are differentiated with respect to W and P, we obtain

$$\frac{\partial A_\varphi}{\partial W}=\frac{A_\varphi}{W}+J\Omega\frac{\partial q_\varphi}{\partial W}, \tag{105}$$

$$\frac{\partial A_\varphi}{\partial P}=-\frac{W^2P}{A_\varphi}+J\Omega\frac{\partial q_\varphi}{\partial P}, \tag{106}$$

$$\frac{\partial A_\lambda}{\partial W}=\frac{A_\lambda}{W}+\frac{\partial A_\lambda}{\partial q_\varphi}\frac{\partial q_\varphi}{\partial W}, \tag{107}$$

$$\frac{\partial A_\lambda}{\partial P}=\frac{A_\lambda}{P}+\frac{\partial A_\lambda}{\partial q_\varphi}\frac{\partial q_\varphi}{\partial P}, \tag{108}$$

with

$$\Omega=\frac{1}{J}\frac{\partial A_\varphi}{\partial q_\varphi}=\frac{W^2}{2A_\varphi}\frac{\partial h_\lambda^2}{\partial q_\varphi} \tag{109}$$

and

$$\frac{\partial A_\lambda}{\partial q_\varphi}=A_\lambda\frac{\partial}{\partial q_\varphi}\ln\left(\frac{J}{h_\lambda^2}\right). \tag{110}$$

Substituting these expressions into Eq. (103) yields

$$\frac{\mathrm{d}}{\mathrm{d}\sigma}\left(\frac{D}{A_\varphi}\right)=\frac{D_1}{A_\varphi}+\frac{D_2}{A_\varphi}, \tag{111}$$

where

$$D_1=\frac{1}{W}\left(\frac{W^2(h_\lambda^2-P^2)}{A_\varphi}\frac{\partial q_\lambda}{\partial P}-A_\lambda\frac{\partial q_\varphi}{\partial P}\right) \tag{112}$$

and

$$D_2=\frac{1}{P}\left(\frac{W^2P^2}{A_\varphi}\frac{\partial q_\lambda}{\partial W}+A_\lambda\frac{\partial q_\varphi}{\partial W}\right). \tag{113}$$

The derivatives of D_1 and D_2 with respect to σ can be calculated by again using Eqs. (97) and (105)–(108) with the result

$$\frac{\mathrm{d}}{\mathrm{d}\sigma}\left(\frac{D_1}{A_\varphi}\right)=\frac{W^2}{A_\varphi^2} \tag{114}$$

and

$$\frac{\mathrm{d}}{\mathrm{d}\sigma}(A_\varphi D_2)=W. \tag{115}$$

Equation (115) can be solved for D_2:

$$D_2=(\sigma-\sigma_0)\frac{W^2}{A_\varphi}. \tag{116}$$

Using Eqs. (114) and (116) one sees that $(\sigma-\sigma_0)D_1$ obeys the same equation obeyed by D [Eq. (111)]. Since D and $(\sigma-\sigma_0)D_1$ satisfy the same initial conditions, we have

$$D(\sigma)=(\sigma-\sigma_0)D_1(\sigma). \tag{117}$$

Differentiating both sides of Eq. (114) gives

$$\frac{\mathrm{d}^2 D_1}{\mathrm{d}\sigma^2}-\left(\frac{\mathrm{d}\Omega}{\mathrm{d}\sigma}+\Omega^2\right)D_1=0. \tag{118}$$

The term in parentheses can be written in a particularly convenient form by differentiating Ω using the relations $\mathrm{d}A_\varphi/\mathrm{d}\sigma=-W^2\sin(q_\varphi)$ and $\partial h_\lambda^2/\partial q_\varphi=-2J\sin(q_\varphi)$, which follow from Eqs. (97) and (31). One finds

$$-\left(\frac{\mathrm{d}\Omega}{\mathrm{d}\sigma}+\Omega^2\right)=\frac{W^2}{\mu\nu}>0. \tag{119}$$

Referring to Eq. (35), we can write Eq. (118) as

$$\frac{\mathrm{d}^2 D_1}{\mathrm{d}\sigma^2}+\frac{W^2}{R^2}D_1=0. \tag{120}$$

If the Earth is modeled as a sphere, both μ and ν would be equal to its radius, $\overline{R}$, and the solution for D_1 is immediately found without approximation to be

$$D_1(\sigma)=\frac{1}{2}\frac{\mathrm{d}^2 D}{\mathrm{d}\sigma^2}(\sigma_0)\frac{\overline{R}}{W}\sin\left[\frac{W}{\overline{R}}(\sigma-\sigma_0)\right].$$

At the end of the path the argument of the sine function becomes $S/\overline{R}$, which is easily seen to be the angle at the center of the Earth subtended by the arc that ends at source and receiver positions

$$\cos\left(\frac{S}{\overline{R}}\right)=\cos\varphi\cos\varphi_0\cos(\lambda-\lambda_0)+\sin\varphi\sin\varphi_0.$$

Equation (120) cannot be solved exactly for an arbitrary volume of revolution. However, if

$$\frac{1}{W}\left|\frac{\mathrm{d}R}{\mathrm{d}\sigma}\right|\ll 1, \tag{121}$$

we can approximate D_1 with its WKB solution

$$D_1(\sigma)\approx D_1^{\mathrm{WKB}}(\sigma)=\frac{1}{2W}\frac{\mathrm{d}^2 D}{\mathrm{d}\sigma^2}(\sigma_0)\sqrt{R(\sigma)R(\sigma_0)}\sin\left(W\int_{\sigma_0}^{\sigma}\frac{\mathrm{d}\sigma'}{R(\sigma')}\right). \tag{122}$$

The overall normalization has been determined using Eq. (104).

To explore the validity of condition (121), we use the parametrization equation (36) to find

$$\frac{\mathrm{d}R}{\mathrm{d}\sigma}=-\frac{\overline{R}\eta}{2(1+\eta g(q_\varphi))^{3/2}}\frac{\partial g(q_\varphi)}{\partial q_\varphi}\frac{\mathrm{d}q_\varphi}{\mathrm{d}\sigma}.$$

Since

$$\left|\frac{dq_\varphi}{d\sigma}\right| \leqslant \frac{W}{h_\varphi} \approx \frac{W}{\bar{R}},$$

we have

$$\frac{1}{W}\left|\frac{dR}{d\sigma}\right| \lesssim \frac{1}{2}\eta\left|\frac{\partial g(q_\varphi)}{\partial q_\varphi}\right|. \tag{123}$$

Condition (121) will be satisfied if the smallest scale of variability in latitude of the surface is larger than the deviation of the Earth's shape from that of a sphere. If we (arbitrarily) require that the right-hand side of Eq. (123) be less than 1/10, the condition is satisfied provided one can consider the Earth spherical on horizontal scales of order $10(\bar{R}\eta/2) \approx 210$ km. Clearly Eq. (121) is valid since over distances of a few hundred kilometers it is safe to assume the Earth is flat—one does not need to even assume it is spherical.

Collecting expressions gives

$$\hat{H} = \frac{k_0\sqrt{W}}{2\pi i(R(\sigma_1)R(\sigma_0))^{1/4}}\left[(\sigma_1-\sigma_0)\sin\left(W\int_{\sigma_0}^{\sigma_1}\frac{d\sigma'}{R(\sigma')}\right)\right]^{-1/2}.$$

Changing the independent variable from σ to s and introducing the path-averaged quantity

$$\frac{1}{R_{\text{ave}}} = \frac{1}{S}\int_0^S \frac{ds'}{R(s')} = \frac{1}{S}\int_0^S \frac{ds'}{\sqrt{\mu(\varphi_{\text{ray}}(s'))\,\nu(\varphi_{\text{ray}}(s'))}} \tag{124}$$

results in

$$\hat{H} = \frac{k_0}{2\pi i\tau}\left(\frac{R_{\text{ave}}}{R(S)}\,\frac{R_{\text{ave}}}{R(0)}\right)^{1/4}\left[\frac{S/R_{\text{ave}}}{\sin(S/R_{\text{ave}})}\right]^{1/2}. \tag{125}$$

The ray theory approximation to Eq. (59) is therefore

$$H \simeq H_{\text{ray}} = \frac{k_0}{2\pi i\tau}\left(\frac{R_{\text{ave}}}{R(S)}\,\frac{R_{\text{ave}}}{R(0)}\right)^{1/4}\left[\frac{S/R_{\text{ave}}}{\sin(S/R_{\text{ave}})}\right]^{1/2}\exp\left(\frac{ik_0}{2\tau}S^2\right). \tag{126}$$

V. THE VERTICAL EQUATION AND STATIONARY PHASE

The horizontal ray theory approximation for Φ is slightly more involved than for H because no assumptions are made about the magnitude of the scales of variability of the depth coordinate. For Eqs. (56) and (59) to be satisfied, Ψ must satisfy the matrix equation

$$\begin{bmatrix} 2ik_0J(ik_0V+\partial/\partial\tau) & 2ik_0\partial A/\partial\varphi+\partial/\partial\varphi & 2ik_0\partial A/\partial\lambda+\partial/\partial\lambda & J\rho\partial/\partial\zeta \\ \partial/\partial\varphi & -\mu/(\nu\cos\varphi) & 0 & 0 \\ \partial/\partial\lambda & 0 & -(\nu\cos\varphi)/\mu & 0 \\ J\rho\partial/\partial\zeta & 0 & 0 & -J\rho^2 \end{bmatrix} \times \begin{bmatrix} \Psi \\ \Psi_\varphi \\ \Psi_\lambda \\ \Psi_\zeta \end{bmatrix} = 0 \tag{127}$$

and the initial condition

$$\text{Lim}_{\tau\to 0}\Psi(\tau;\varphi,\lambda,\zeta) = \delta(\zeta-\zeta_0). \tag{128}$$

Just as before we drop the horizontal gradients of the amplitude factors in comparison to the corresponding gradients of A, multiplied by k_0. While the derivative $\partial/\partial\tau$ can be dropped in the matrix in Eq. (63) we are not justified in dropping it in Eq. (127). The result is

$$\begin{bmatrix} 2ik_0J(ik_0V+\partial/\partial\tau) & 2ik_0\partial A/\partial\varphi & 2ik_0\partial A/\partial\lambda & J\rho\partial/\partial\zeta \\ \partial/\partial\varphi & -\mu/(\nu\cos\varphi) & 0 & 0 \\ \partial/\partial\lambda & 0 & -(\nu\cos\varphi)/\mu & 0 \\ J\rho\partial/\partial\zeta & 0 & 0 & -J\rho^2 \end{bmatrix} \times \begin{bmatrix} \Psi \\ \Psi_\varphi \\ \Psi_\lambda \\ \Psi_\zeta \end{bmatrix} = 0,$$

which is equivalent to the single second-order equation

$$\left[2ik_0\left(\frac{\partial}{\partial\tau}+\frac{1}{\mu^2}\frac{\partial A}{\partial\varphi}\frac{\partial}{\partial\varphi}+\frac{1}{\nu^2\cos^2\varphi}\frac{\partial A}{\partial\lambda}\frac{\partial}{\partial\lambda}\right)+\rho\frac{\partial}{\partial\zeta}\left(\frac{1}{\rho}\frac{\partial}{\partial\zeta}\right)-2k_0^2V\right]\Psi=0. \tag{129}$$

Comparison of Eqs. (129) and (92) gives

$$2ik_0\frac{S}{\tau}\left[\frac{\partial\Psi(\tau;\varphi_{\text{ray}}(s),\lambda_{\text{ray}}(s),\zeta)}{\partial s}\right]_{s=S} + \left[\rho\frac{\partial}{\partial\zeta}\left(\frac{1}{\rho}\frac{\partial}{\partial\zeta}\right)-2k_0^2V(\varphi_{\text{ray}}(S),\lambda_{\text{ray}}(S),\zeta)\right]\Psi(\tau;\varphi_{\text{ray}}(S),\lambda_{\text{ray}}(S),\zeta)=0.$$

This equation can be solved by solving the more general one

$$\left[2ik_0\frac{S}{\tau}\frac{\partial}{\partial s}+\rho\frac{\partial}{\partial\zeta}\left(\frac{1}{\rho}\frac{\partial}{\partial\zeta}\right)-2k_0^2V(\varphi_{\text{ray}}(s),\lambda_{\text{ray}}(s),\zeta)\right]\Psi(\tau;\varphi_{\text{ray}}(s),\lambda_{\text{ray}}(s),\zeta)=0 \tag{130}$$

and evaluating the result at $s=S$.

If we require that

$$\text{Lim}_{s\to0}\Psi(\tau;\varphi_{\text{ray}}(s),\lambda_{\text{ray}}(s),\zeta)=\delta(\zeta-\zeta_0), \tag{131}$$

then the initial condition, Eq. (128), will be satisfied because of relation (91). In fact, independent of the ray theory approximation, it is not difficult to see that Ψ has support only in a small neighborhood of ζ about ζ_0 and τ about 0 as $s\to0$.

Collecting expressions and substituting into Eq. (53) give

$$G(\vec{x}|\vec{x}_0)\approx\frac{1}{4\pi}\left(\frac{R_{\text{ave}}}{R(S)}\frac{R_{\text{ave}}}{R(0)}\right)^{1/4}\left[\frac{S/R_{\text{ave}}}{\sin(S/R_{\text{ave}})}\right]^{1/2} \times\int_0^\infty\frac{d\tau}{\tau}\exp\frac{ik_0}{2}\left(\tau+\frac{S^2}{\tau}\right)\Psi(\tau;\varphi,\lambda,\zeta). \tag{132}$$

One can evaluate the integral over the Fock–Feynman parameter in Eq. (132) using the method of stationary phase. The single stationary phase point is at $\tau=S$. If $\Psi(\tau;\varphi,\lambda,\zeta)$ has a phase which is a slowly varying function of τ at $\tau=S$, justifying the stationary phase approximation, then the wave number spectrum of $\Psi(S;\varphi,\lambda,\zeta)$ in path length—the horizontal wave number spectrum—will be dominated by values near the reference wave number k_0. That is, the stationary-phase approximation is equivalent to the narrow-angle approximation [Palmer (1976)].

The stationary phase approximation yields

$$G(\vec{x}|\vec{x}_0)\approx \frac{1}{4\pi}\left(\frac{R_{\rm ave}}{R(S)}\,\frac{R_{\rm ave}}{R(0)}\right)^{1/4}\left[\frac{2\pi i}{k_0 R_{\rm ave}\sin(S/R_{\rm ave})}\right]^{1/2} e^{ik_0 S}\psi(S,\zeta), \tag{133}$$

where

$$\psi(s,\zeta)\equiv\Psi(S;\varphi_{\rm ray}(s),\lambda_{\rm ray}(s),\zeta)$$

satisifies the two-dimensional parabolic equation

$$\left[2ik_0\frac{\partial}{\partial s}+\rho\frac{\partial}{\partial\zeta}\left(\frac{1}{\rho}\,\frac{\partial}{\partial\zeta}\right)-2k_0^2V(s,\zeta)\right]\Psi(s,\zeta)=0 \tag{134}$$

and the initial condition

$$\mathrm{Lim}_{s\to 0}\psi(s,\zeta)=\delta(\zeta-\zeta_0). \tag{135}$$

It being understood that s is measured along the ray path and that

$$V(s,\zeta)=V(\varphi_{\rm ray}(s),\lambda_{\rm ray}(s),\zeta). \tag{136}$$

If the Earth is modeled as a sphere with radius $\overline{R}$, Eq. (133) reduces to

$$G(\vec{x}|\vec{x}_0)\approx \frac{1}{4\pi}\left[\frac{2\pi i}{k_0\overline{R}\sin(S/\overline{R})}\right]^{1/2} e^{ik_0 S}\psi(S,\zeta)\quad(\text{sphere}).$$

It is worth noting that $\psi(s,\zeta)$ does not depend on the total path length S because $\Psi(\tau;\varphi_{\rm ray}(s),\lambda_{\rm ray}(s),\zeta)$ depends on S and τ only through the ratio S/τ. Equation (134) is clearly energy conserving and can be solved numerically using a standard range-sliced marching algorithm. Moreover, it does not possess any kinematic singularities of the type experienced by Collins *et al.* (1996). Caustics in the horizontal are located at $S\approx\pi R_{\rm ave}$ and correspond to the focusing that occurs for near antipodal propagation.

VI. REFRACTED GEODESICS AND NORMAL MODES

In this section we consider two extensions of the method we have presented.

A. Refracted geodesics

The factorization of Φ, Eq. (58), into a term H that depends on the horizontal coordinates and a remainder is not unique. One can always define H by

$$\left[2ik_0\frac{\partial}{\partial\tau}+\nabla_\perp^2-2k_0^2U(\varphi,\lambda)\right]H(\tau;\varphi,\lambda)=0, \tag{137}$$

where

$$U(\varphi,\lambda)=-\tfrac{1}{2}[n_{\rm refr}^2(\varphi,\lambda)-1] \tag{138}$$

is a function of φ and λ but not of the depth coordinate ζ. In Eq. (127) and all subsequent equations $V(\varphi,\lambda,\zeta)$ would be replaced with $\tilde{V}(\varphi,\lambda,\zeta)$ where

$$\tilde{V}(\varphi,\lambda,\zeta)=V(\varphi,\lambda,\zeta)-U(\varphi,\lambda). \tag{139}$$

We want to indicate how the above-presented analysis is modified by the presence of the function U.

The horizontal ray-theory approximation for H now involves a ray path that is a refracted geodesic. The eikonal equation and the expression for the Hamiltonian function become, respectively,

$$\frac{\partial A}{\partial \tau}+\frac{1}{2\mu^2}\left(\frac{\partial A}{\partial \varphi}\right)^2+\frac{1}{2\nu^2\cos^2\varphi}\left(\frac{\partial A}{\partial \lambda}\right)^2+U=0 \tag{140}$$

and

$$\mathcal{E}=p_\tau+\tfrac{1}{2}\mathbf{v}^2+U=0, \tag{141}$$

where $\mathbf{v}$ is now no longer a constant. The equations for p_φ and p_λ become

$$\frac{\mathrm{d}p_\varphi}{\mathrm{d}\sigma}=-\frac{1}{2}\left[\frac{\partial}{\partial q_\varphi}\left(\frac{1}{h_\varphi^2}\right)p_\varphi^2+\frac{\partial}{\partial q_\varphi}\left(\frac{1}{h_\lambda^2}\right)p_\lambda^2\right]-\frac{\partial U}{\partial q_\varphi}$$

and

$$\frac{\mathrm{d}p_\lambda}{\mathrm{d}\sigma}=-\frac{\partial U}{\partial q_\lambda}.$$

The equations for all the other ray-path variables are unchanged. The eikonal is now

$$A=\tau p_\tau+\tilde{A}, \tag{142}$$

where $\tilde{A}$ is the horizontal eikonal function

$$\tilde{A}=\int_{\sigma_0}^{\sigma_1}\mathbf{v}^2\,\mathrm{d}\sigma=\int_0^S\mathbf{v}\,\mathrm{d}s. \tag{143}$$

Since Eq. (142) can be written as

$$A-\tau\frac{\partial A}{\partial \tau}=\tilde{A} \tag{144}$$

it defines a Legendre transform which can be used to change the independent variables from (φ,λ,τ) to (φ,λ,p_τ). The variable τ is then given by

$$\tau=-\frac{\partial \tilde{A}}{\partial p_\tau}=\int_0^S\frac{\mathrm{d}s}{\sqrt{(-2)(p_\tau+U(s))}}.$$

The exponent in Eq. (132) is now

$$ik_0\left(\frac{\tau}{2}+A\right)$$

instead of $ik_0(\tau+S^2/\tau)/2$. At the stationary-phase point $\tau=\tau_{\mathrm{sp}}$ we have

$$\frac{\partial A}{\partial \tau}=p_\tau=-\frac{1}{2} \tag{145}$$

so

$$\mathbf{v}|_{\tau=\tau_{\mathrm{sp}}}=\sqrt{1-2U}=n_{\mathrm{refr}}$$

and

$$\tau_{\mathrm{sp}}=\int_0^S \frac{\mathrm{ds}}{n_{\mathrm{refr}}}.$$

We then have

$$ik_0\left(\frac{\tau}{2}+A\right)_{\tau=\tau_{\mathrm{sp}}}=ik_0\tilde{A}_{\tau=\tau_{\mathrm{sp}}}=ik_0\int_0^S n_{\mathrm{refr}}\,\mathrm{ds}.$$

The stationary-phase approximation then gives

$$\begin{aligned}G(\vec{x}|\vec{x}_0)&\propto\int_0^\infty \hat{H}\exp\left[ik_0\left(\frac{\tau}{2}+A\right)\right]\Psi(\tau;\varphi,\lambda,\zeta)\\&\propto\left[\hat{H}\left(\frac{\partial^2 A}{\partial\tau^2}\right)^{-1/2}\right]_{\tau=\tau_{\mathrm{sp}}}\exp\left[ik_0\int_0^S n_{\mathrm{refr}}\,\mathrm{ds}\right]\Psi(\tau_{\mathrm{sp}};\varphi,\lambda,\zeta).\end{aligned}\tag{146}$$

In calculating $\hat{H}$ it is no longer useful to use the set W and P to characterize ray-path variations. Instead we use

$$v_\varphi\equiv p_\varphi(\sigma_0)=-\frac{\partial A}{\partial\varphi_0},\tag{147}$$

$$v_\lambda\equiv p_\lambda(\sigma_0)=-\frac{\partial A}{\partial\lambda_0}.\tag{148}$$

The relationship between these initial values for the momenta and the derivatives of the eikonal with respect to the coordinates of the source position follow easily from the defining equation, Eq. (84). We still have

$$\hat{H}\propto\sqrt{\frac{1}{D(\sigma_1)}},$$

but now

$$D(\sigma)\equiv J(q_\varphi(\sigma))\det\begin{bmatrix}\partial q_\varphi(\sigma)/\partial v_\varphi & \partial q_\varphi(\sigma)/\partial v_\lambda\\ \partial q_\lambda(\sigma)/\partial v_\varphi & \partial q_\lambda(\sigma)/\partial v_\lambda\end{bmatrix}.$$

We next consider the variation in the ray path due to a change in receiver position

$$\begin{bmatrix}\partial q_\varphi(\sigma)/\partial\varphi & \partial q_\varphi(\sigma)/\partial\lambda\\ \partial q_\lambda(\sigma)/\delta\varphi & \partial q_\lambda(\sigma)/\partial\lambda\end{bmatrix}=-O\times\begin{bmatrix}\partial q_\varphi(\sigma)/\partial v_\varphi & \partial q_\varphi(\sigma)/\partial v_\lambda\\ \partial q_\lambda(\sigma)/\partial v_\varphi & \partial q_\lambda(\sigma)/\partial v_\lambda\end{bmatrix},$$

where

$$O=\begin{bmatrix}\partial^2 A/\partial\varphi_0\partial\varphi & \partial^2 A/\partial\varphi_0\partial\lambda\\ \partial^2 A/\partial\lambda_0\partial\varphi & \partial^2 A/\partial\lambda_0\partial\lambda\end{bmatrix}.\tag{149}$$

(We have used $\partial v_\varphi/\partial\varphi=-\partial^2 A/\partial\varphi_0\partial\varphi$, etc.) At $\sigma=\sigma_1$ the left-hand side of this equation becomes equal to the identity matrix and we have

$$D(\sigma_1)=\frac{J(\varphi)}{\det O}.$$

We now turn to consideration of $\partial^2 A/\partial\tau^2$ in Eq. (146). At $\sigma=\sigma_0$, Eq. (141) becomes

$$p_\tau+\frac{1}{2h_\varphi^2(\varphi_0)}v_\varphi^2+\frac{1}{2h_\lambda^2(\varphi_0)}v_\lambda^2+U(\varphi_0,\lambda_0)=0.$$

Differentiating with respect to τ gives

$$\frac{\partial^2 A}{\partial\tau^2}+\frac{\partial v_\varphi}{\partial\tau}\frac{dq_\varphi}{d\sigma}(\varphi_0)+\frac{\partial v_\lambda}{\partial\tau}\frac{dq_\lambda}{d\sigma}(\varphi_0)=0.$$

The change in the eikonal equation due to a change in source location, keeping the receiver location fixed, is given by

$$\frac{\partial^2 A}{\partial\varphi_0\partial\varphi}\frac{dq_\varphi}{d\sigma}(\varphi)+\frac{\partial^2 A}{\partial\varphi_0\partial\lambda}\frac{dq_\lambda}{d\sigma}(\varphi)=\frac{\partial v_\varphi}{\partial\tau}$$

and

$$\frac{\partial^2 A}{\partial\lambda_0\partial\varphi}\frac{dq_\varphi}{d\sigma}(\varphi)+\frac{\partial^2 A}{\partial\lambda_0\partial\lambda}\frac{dq_\lambda}{d\sigma}(\varphi)=\frac{\partial v_\lambda}{\partial\tau}.$$

Combining these last three equations gives

$$\frac{\partial^2 A}{\partial\tau^2}=e(\sigma_0)^T\cdot O\cdot e(\sigma_1), \tag{150}$$

where

$$e(\sigma)=\begin{bmatrix} dq_\varphi(\sigma)/d\sigma \\ dq_\lambda(\sigma)/d\sigma \end{bmatrix}.$$

Therefore

$$\left[\hat{H}\left(\frac{\partial^2 A}{\partial\tau^2}\right)^{-1/2}\right]_{\tau=\tau_{sp}}=\left(\frac{1}{J(\varphi)}\frac{\det O}{e(\sigma_0)\cdot O\cdot e(\sigma_1)}\right)^{1/2}_{\tau=\tau_{sp}}. \tag{151}$$

[For an alternative way of writing this amplitude factor see Gutzwiller (1990), Eq. (2.10).]

The evaluation of the derivatives of A with respect to source and receiver coordinates that make up the components of O are done at the stationary-phase point

$$A_{\tau=\tau_{sp}}=\frac{1}{2}\int_0^S\left[\frac{2n_{refr}^2-1}{n_{refr}}\right]ds \tag{152}$$

The derivatives can be performed once Hamilton's equations have been solved for the refracted geodesic and the variation of n_{refr} along the path is determined. Collecting expressions gives

$$G(\vec{x}|\vec{x}_0)\propto\left(\frac{1}{J(\varphi)}\frac{\det O}{e(\sigma_0)\cdot O\cdot e(\sigma_1)}\right)^{1/2}_{\tau=\tau_{sp}}\exp\left[ik_0\int_0^S n_{refr}ds\right]\Psi(s,\zeta), \tag{153}$$

where

$$\left[2ik_0 n_{\text{refr}}\frac{\partial}{\partial s}+\rho\frac{\partial}{\partial\zeta}\left(\frac{1}{\rho}\frac{\partial}{\partial\zeta}\right)-2k_0^2\tilde{V}(s,\zeta)\right]\Psi(s,\zeta)=0. \tag{154}$$

This parabolic equation differs from Eq. (134) in two respects—the s-dependent scale factor n_{refr} and the replacement of V with $\tilde{V}$.

B. Modal analysis

Much of the work done to model global propagation has assumed a description involving discrete, local, normal modes propagating without coupling [see, e.g., Munk, Worcester, and Wunsch (1995)]. In this section we discuss how this description can be incorporated into the formalism presented in the previous sections.

We begin with some preliminaries. The local modes satisfy

$$\left[\rho(\zeta)\frac{\partial}{\partial\zeta}\left(\frac{1}{\rho(\zeta)}\frac{\partial}{\partial\zeta}\right)+k_0^2 n^2(\varphi,\lambda,\zeta)\right]Z_m(\varphi,\lambda,\zeta)=k_0^2\varkappa_m^2(\varphi,\lambda)Z_m(\varphi,\lambda,\zeta), \tag{155}$$

where $\varkappa_m$ is the (dimensionless) normal-mode wave number. As a result of the self-adjoint nature of Eq. (155), we have the orthogonal relation

$$\int\frac{d\zeta}{\rho(\zeta)}Z_n(\varphi,\lambda,\zeta)Z_m(\varphi,\lambda,\zeta)=\delta_{nm} \tag{156}$$

and the completeness relation

$$\sum_m Z_m(\varphi,\lambda,\zeta)Z_m(\varphi,\lambda,\zeta_0)=\rho(\zeta_0)\,\delta(\zeta-\zeta_0).$$

We expand Φ in Eq. (56) in terms of these modes

$$\Phi(\tau;\varphi,\lambda,\zeta)=\frac{1}{\rho(\zeta_0)}\sum_m \mathcal{C}_m(\tau;\varphi,\lambda)Z_m(\varphi,\lambda,\zeta)Z_m(\varphi,\lambda,\zeta_0)$$

so that

$$\text{Lim}_{\tau\to 0}\mathcal{C}_m(\tau;\varphi,\lambda)=\frac{1}{J(\varphi)}\,\delta(\varphi-\varphi_0)\,\delta(\lambda-\lambda_0)$$

independent of the index m. We have for the Green's function

$$G(\vec{x}\,|\,\vec{x}_0)=\frac{1}{\rho(\zeta_0)}\sum_m Z_m(\varphi,\lambda,\zeta)Z_m(\varphi,\lambda,\zeta_0)G_m(\varphi,\lambda\,|\,\varphi_0,\lambda_0), \tag{157}$$

where

$$G_m=\frac{i}{2k_0}\int_0^\infty d\tau\, e^{i\tau k_0/2}\mathcal{C}_m(\tau;\varphi,\lambda). \tag{158}$$

The equation satisfied by the model coefficients is

$$\left[2ik_0\frac{\partial\mathcal{C}_m}{\partial\tau}+\nabla_S^2\mathcal{C}_m-2k_0^2W_m\mathcal{C}_m\right]Z_m(\varphi,\lambda,\zeta_0)+\sum_l\left[B_{ml}\mathcal{C}_l+2\vec{F}_{ml}\cdot\nabla_S\mathcal{C}_l\right]=0, \tag{159}$$

where

$$W_m(\varphi,\lambda) = -\tfrac{1}{2}[\varkappa_m^2(\varphi,\lambda) - 1],$$

$$B_{ml} = \int \frac{d\zeta}{\rho} Z_m \nabla_S^2 (Z_l(\varphi,\lambda,\zeta) Z_l(\varphi,\lambda,\zeta_0)),$$

and

$$\vec{F}_{ml} = \int \frac{d\zeta}{\rho} Z_m \nabla_S (Z_l(\varphi,\lambda,\zeta) Z_l(\varphi,\lambda,\zeta_0)).$$

Generally speaking, a modal analysis for the types of wave propagation problems we are considering is useful only if mode coupling can be ignored. If this is the case, then $B_{ml}=0$ and $\vec{F}_{ml}=0$ and Eq. (159) reduces to

$$\left[2ik_0 \frac{\partial}{\partial \tau} + \nabla_S^2 - 2k_0^2 W_m\right] \mathcal{C}_m = 0. \tag{160}$$

With preliminaries out of the way, we develop a method for solving Eq. (160) based on the ideas introduced earlier. We write

$$\mathcal{C}_m(\tau;\varphi,\lambda) = \Psi_m(\tau;\varphi,\lambda) H(\tau;\varphi,\lambda), \tag{161}$$

where H obeys

$$\left[2ik_0 \frac{\partial}{\partial \tau} + \nabla_S^2\right] H = 0$$

and

$$\mathrm{Lim}_{\tau\to 0} H(\tau;\varphi,\lambda) = \frac{1}{J(\varphi)} \delta(\varphi-\varphi_0)\,\delta(\lambda-\lambda_0).$$

The ray theory solution for H is given by Eq. (126). The equation satisfied by Ψ_m is

$$2ik_0 \frac{\partial \Psi_m}{\partial \tau} + \nabla_S^2 \Psi_m + 2\frac{\nabla_S H}{H} \cdot \nabla_S \Psi_m - 2k_0^2 W_m \Psi_m = 0 \tag{162}$$

and

$$\mathrm{Lim}_{\tau\to 0} \Psi_m(\tau;\varphi,\lambda) = 1.$$

We know

$$\frac{2}{H}\nabla_S H = \frac{2ik_0 S}{\tau}\left[\mu \frac{dq_\varphi}{ds}(\sigma_1)\hat{\varphi} + \nu \cos\varphi \frac{dq_\lambda}{ds}(\sigma_1)\hat{\lambda}\right] = \frac{2ik_0 S}{\tau}\hat{s}(\sigma_1) \tag{163}$$

and

$$\frac{S}{\tau}\frac{\partial}{\partial s} = \frac{\partial}{\partial \tau} + \frac{S}{\tau}\hat{s}(\sigma_1)\cdot\nabla_\perp, \tag{164}$$

so that

$$2ik_0 \frac{S}{\tau}\frac{\partial \Psi_m}{\partial s} + \nabla_S^2 \Psi_m - 2k_0^2 W_m \Psi_m = 0. \tag{165}$$

Consistently apply the horizontal ray approximation and replace Eq. (165) with

$$2ik_0\frac{S}{\tau}\frac{\partial\Psi_m}{\partial s}-2k_0^2W_m\Psi_m=0 \tag{166}$$

giving

$$\Psi_m=\exp\left[-ik_0\frac{\tau}{S}\int_0^S \mathrm{d}s\ W_m\right). \tag{167}$$

Combining terms

$$G_m=\frac{1}{4\pi}\left(\frac{R_{\mathrm{ave}}}{R(S)}\frac{R_{\mathrm{ave}}}{R(0)}\right)^{1/4}\left[\frac{S/R_{\mathrm{ave}}}{\sin(S/R_{\mathrm{ave}})}\right]^{1/2}\int_0^\infty\frac{\mathrm{d}\tau}{\tau}\exp\left[\frac{ik_0}{2}\left(\frac{S^2}{\tau}+\tau\langle\varkappa_m^2\rangle\right)\right],$$

where $\langle\varkappa_m^2\rangle$ is the mean-square-average of $\varkappa_m$ over the horizontal ray path

$$\langle\varkappa_m^2\rangle=\frac{1}{S}\int_0^S \mathrm{d}s\ \varkappa_m^2. \tag{168}$$

For $k_0S\gg1$ the integral over τ is approximately equal to

$$\left(\frac{2\pi i}{k_0S^2}\right)^{1/2}\left(\frac{\langle\varkappa_m^2\rangle}{S^2}\right)^{1/4}\exp[ik_0S\sqrt{\langle\varkappa_m^2\rangle}],$$

so that

$$G_m=\frac{1}{4\pi}\left(\frac{R_{\mathrm{ave}}}{R(S)}\frac{R_{\mathrm{ave}}}{R(0)}\frac{\langle\varkappa_m^2\rangle}{S^2}\right)^{1/4}\left[\frac{2\pi i}{k_0SR_{\mathrm{ave}}\sin(S/R_{\mathrm{ave}})}\right]^{1/2}\exp[ik_0S\sqrt{\langle\varkappa_m^2\rangle}]. \tag{169}$$

Alternative approaches to the modal problem are discussed in Burridge and Weinberg (1977); Collins (1993b); McDonald *et al.* (1994); and Collins *et al.* (1995a); (1995b); (1996).

VII. SUMMARY

In this paper we have proposed a method for obtaining parabolic approximations consisting of the following steps

(1) The Green's function for the problem of interest is written as a Laplace or Mellon transform over the corresponding propagator. The transform variable is the Fock–Feynman parameter.

(2) The propagator is factored into a term that is assumed to be a rapidly varying function of the horizontal coordinates and obeys a parabolic equation in those coordinates, and an envelope function that is assumed to be a slowly varying function of the horizontal coordinates.

(3) The dependence on the horizontal coordinates is determined using the ray theory approximation.

(4) The equation for the envelop function is cast into the form of a parabolic equation with the horizontal direction of propagation along the ray path determined in step (3).

(5) The integral over the Fock–Feynman parameter is approximated using the method of stationary phase.

If one applies this method to the Helmhotz equation in Cartesian coordinates, one obtains the standard narrow-angle parabolic equation in two coordinate variables. One can easily derive improved approximations because the proposed method separates the parabolic approximation into two separate approximations: one involving the characteristics of the field in the horizontal and the other its characteristics in the vertical. The horizontal ray-theory approximation can be relaxed in

any number of ways. One possibility is to use the Rytov approximation instead of the ray-theory one [Palmer (1976)]. This results in replacing the index of refraction by an effective one that is constructed by integration over the Fresnel ray tube surrounding the ray path. Another possibility is to allow for horizontal refraction and horizontal multipaths. In Sec. VI we indicate how this might be done.

There are many ways of relaxing the narrow-angle approximation by improving on the stationary-phase approximation. One possibility is to evalute the integral numerically in the same way that the integral over frequency is evaluated in the Fourier representation of the solution to the parabolic equation for a broadband source. One obtains the solution to Eq. (92) for a range of values of τ using a marching algorithm. The integral in Eq. (92) is then evaluated using a fast Fourier transform. Other than those relating to the numerical evaluation, the only approximations made in the development of the global problem considered here are the horizontal ray theory approximation and, of less importance, the WKB approximation for the amplitude.

ACKNOWLEDGMENTS

I am particularly grateful to O. A. Godin for his careful reading of an early version of the manuscript and his many valuable comments. This paper is dedicated to the memory of Fredrick D. Tappert who was always very generous sharing his knowledge and ideas about the parabolic equation method as well as about many other subjects.

(Received 23 May 2001; accepted for publication 15 January 2002)

The generalized Hénon–Heiles Hamiltonian $H=1/2(P_X^2+P_Y^2+c_1X^2+c_2Y^2)+aXY^2-bX^3/3$ with an additional nonpolynomial term μY^{-2} is known to be Liouville integrable for three sets of values of $(b/a,c_1,c_2)$. It has been previously integrated by genus two theta functions only in one of these cases. Defining the separating variables of the Hamilton–Jacobi equations, we succeed here, in the two other cases, to integrate the equations of motion with hyperelliptic functions. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1456948]

I. INTRODUCTION

The generalization of the Hénon–Heiles Hamiltonian defined by

$$H\equiv\frac{1}{2}(P_X^2+P_Y^2+c_1X^2+c_2Y^2)+aXY^2-\frac{b}{3}X^3+\frac{1}{32a^2}\frac{\mu}{Y^2},\quad a\neq 0, \tag{1}$$

$$X'=P_X,\quad Y'=P_Y, \tag{2}$$

$$X''=-aY^2+bX^2-c_1X, \tag{3}$$

$$Y''=-2aXY-c_2Y+\frac{1}{16a^2}\frac{\mu}{Y^3},\quad \mu \text{ arbitrary}, \tag{4}$$

is integrable in the sense of Liouville in three cases,[1–3] namely,

$$\frac{b}{a}=-1,\quad c_1=c_2, \tag{5}$$

$$\frac{b}{a}=-6,\quad c_1,c_2 \text{ arbitrary}, \tag{6}$$

$$\frac{b}{a}=-16,\quad c_1=16c_2, \tag{7}$$

and is equivalent to the reduction $\xi=x-ct$ of three fifth order soliton equations,[4] respectively the Sawada–Kotera (SK), KdV_5 and Kaup–Kupershmidt (KK) equations, by applying the translation

[a]Electronic mail: cverhoev@vub.ac.be
[b]Electronic mail: mmusette@vub.ac.be
[c]Electronic mail: Conte@drecam.saclay.cea.fr

$$\text{SK:}\quad u=X+\frac{c_2}{2a},\quad c=c_1c_2, \tag{8}$$

$$\text{KdV}_5\text{:}\quad u=X+\frac{c_1+4c_2}{20a},\quad c=\frac{1}{10}(-3c_1^2-16c_1c_2+48c_2^2), \tag{9}$$

$$\text{KK:}\quad u=X+\frac{c_2}{2a},\quad c=c_1c_2. \tag{10}$$

The reduced partial differential equations (PDEs) are respectively

$$\text{SK:}\quad u^{(4)}+10auu''+\frac{20}{3}a^2u^3-cu+4aE-\frac{c_1c_2^2}{3a}=0, \tag{11}$$

$$\text{KdV}_5\text{:}\quad u^{(4)}+20auu''+40a^2u^3+10au'^2-cu+4aE+\frac{1}{100a}(c_1+4c_2)(c_1^2-12c_1c_2+16c_2^2)=0, \tag{12}$$

$$\text{KK:}\quad u^{(4)}+40auu''+\frac{320}{3}a^2u^3+30au'^2-cu+4aE-\frac{c_1c_2^2}{3a}=0, \tag{13}$$

in which E is the constant value of the Hamiltonian H. Therefore we will further use these names for referring to the respective integrable cases of the Hamiltonian.

The problem which we address is to find the separating variables and to explicitly integrate.

The general solution for the KdV_5 case has been obtained in terms of hyperelliptic functions[5–7] by separation of the variables of the Hamilton–Jacobi equation in parabolic coordinates.

For $\mu=0$, the equations of motion for the SK and KK cases have been integrated[8–10] in terms of elliptic functions.

In this article we give the general solution of the equations of motion for the SK and KK cases in terms of hyperelliptic functions. This is achieved by separation of the variables of the Hamilton–Jacobi equation, where the canonical transformation between SK and KK[11] plays an important role.

In Sec. II, we consider the SK case with $\mu=0$ as a starting point to treat the general case (μ arbitrary). In Sec. III, we recover the canonical transformation between SK and KK, starting from the factorization of the scattering operator associated with these equations and using the link with the Fordy–Gibbons equation.[12] In Sec. IV, we give the general solution for KK, using the canonical transformation previously obtained. In Sec. V, we use the fact that the canonical transformation is invertible for obtaining the general solution of the SK case. In both cases, in the limit $\mu\to 0$, we recover the previous results.[9,10] In Sec. VI, we compare the present method of integration, starting from the Hamiltonian system, with the method used by Cosgrove[13] for integrating the fourth order ODEs (11) and (13).

II. PARTICULAR CASE: SAWADA–KOTERA FOR $\mu=0$

This is the simplest case and it will be our starting point to define the separation of variables of the Hamilton–Jacobi equation for KK.

Consider the Hamiltonian in the SK case derived from (1) by setting $a=\frac{1}{2}$ and defining $U=X+c_2$, $V=Y$, $c=c_1c_2$,

$$H\equiv K_{1,0}=\frac{1}{2}(P_U^2+P_V^2)+\frac{1}{2}UV^2+\frac{1}{6}U^3-\frac{c}{2}U, \tag{14}$$

which is a constant of motion of the equations

$$U''=-\frac{1}{2}(V^2+U^2)+\frac{c}{2},$$
$$V''=-UV, \tag{15}$$

where U,V and the derivatives $U'=P_U$, $V'=P_V$ are functions of the independent variable ξ ($'\equiv \mathrm{d}/\mathrm{d}\xi$).

This system possesses a second constant of motion[9]

$$K_{2,0}=-2P_UP_V-U^2V-\frac{V^3}{3}+cV, \tag{16}$$

which is in involution with the Hamiltonian, i.e., $\{K_{1,0},K_{2,0}\}=0$.

The separation of variables is defined as

$$Q_1=U+V, \quad Q_2=U-V,$$
$$P_1=\tfrac{1}{2}(P_U+P_V), \quad P_2=\tfrac{1}{2}(P_U-P_V), \tag{17}$$

and in those new variables the expressions of $K_{1,0}$ and $K_{2,0}$ are

$$K_{1,0}=P_1^2+P_2^2+\frac{1}{12}(Q_1^3+Q_2^3)-\frac{c}{4}(Q_1+Q_2), \tag{18}$$

$$K_{2,0}=2(P_2^2-P_1^2)+\frac{1}{6}(Q_2^3-Q_1^3)-\frac{c}{2}(Q_2-Q_1), \tag{19}$$

such that the equations of motion become

$$Q_1'^2=-\tfrac{1}{3}Q_1^3+cQ_1-K_{2,0}+2K_{1,0},$$
$$Q_2'^2=-\tfrac{1}{3}Q_2^3+cQ_2+K_{2,0}+2K_{1,0}. \tag{20}$$

They possess the general solution

$$Q_1=-12\wp\left(\xi-\xi_1,\frac{c}{12},-\frac{1}{144}(2K_{1,0}-K_{2,0})\right)\equiv-12\wp_1(\xi),$$
$$Q_2=-12\wp\left(\xi-\xi_2,\frac{c}{12},-\frac{1}{144}(2K_{1,0}+K_{2,0})\right)\equiv-12\wp_2(\xi), \tag{21}$$

in terms of the Weierstrass elliptic function $\wp(x-x_0,g_2,g_3)$, solution of the first order differential equation

$$\wp'^2=4\wp^3-g_2\wp-g_3, \tag{22}$$

such that the solutions become

$$U=-6(\wp_1(\xi)+\wp_2(\xi)),$$
$$V=-6(\wp_1(\xi)-\wp_2(\xi)). \tag{23}$$

III. CANONICAL TRANSFORMATION BETWEEN SK AND KK

Let us consider, for μ arbitrary, the equations and the constants of motion associated with the SK and KK Hamiltonians[14,15]

$$\text{SK:}\quad U'=P_U,\quad V'=P_V, \tag{24}$$

$$U''=-\frac{1}{2}(V^2+U^2)+\frac{c}{2},\quad V''=-UV+\frac{\mu}{4V^3}, \tag{25}$$

$$K_1=\frac{1}{2}(P_U^2+P_V^2)+\frac{1}{2}UV^2+\frac{1}{6}U^3-\frac{c}{2}U+\frac{\mu}{8V^2}, \tag{26}$$

$$K_2^2=K_{2,0}^2+\frac{2}{3}\mu U+\mu\frac{P_U^2}{V^2}, \tag{27}$$

$$\text{KK:}\quad a=\tfrac{1}{4},\quad c_1=16c_2,\quad c=c_1c_2,\quad u=X+2c_2,\quad v=Y, \tag{28}$$

$$u'=p_u,\quad v'=p_v, \tag{29}$$

$$u''=-\frac{1}{4}v^2-4u^2+c,\quad v''=-\frac{1}{2}uv+\frac{\mu}{v^3}, \tag{30}$$

$$k_1=\frac{1}{2}(p_u^2+p_v^2)+\frac{1}{4}uv^2+\frac{4}{3}u^3-cu+\frac{1}{2}\frac{\mu}{v^2}, \tag{31}$$

$$k_{2,0}^2=p_v^4-\frac{1}{72}v^6-\frac{1}{12}u^2v^4+up_v^2v^2-\frac{1}{3}p_up_vv^3+\frac{c}{12}v^4, \tag{32}$$

$$k_2^2=k_{2,0}^2+\frac{\mu}{3}u+2\mu\frac{p_v^2}{v^2}+\frac{\mu^2}{v^4}. \tag{33}$$

The reason why the expressions $k_{2,0}$ and k_2 are defined by their square will appear soon.

The two nonlinear partial differential equations SK and KK,

$$\text{SK:}\quad U_t+(U_{xxxx}+5UU_{xx}+\tfrac{5}{3}U^3)_x=0, \tag{34}$$

$$\text{KK:}\quad u_t+(u_{xxxx}+10uu_{xx}+\tfrac{20}{3}u^3+\tfrac{15}{2}u_x^2)_x=0, \tag{35}$$

whose reductions $\xi=x-ct$ are (11) and (13), respectively obtained from the systems (25)–(26) and (30)–(31) by elimination of the variables V and v, possess a Lax pair with a third order scattering problem $(L\psi=\lambda\psi)$.[16,17] The scattering operators can be factorized in the following way,

$$\text{SK:}\quad L\equiv\partial_x^3+U\partial_x=(\partial_x-w)(\partial_x+w)\partial_x, \tag{36}$$

$$\text{KK:}\quad L\equiv\partial_x^3+2u\partial_x+u_x=(\partial_x+w)(\partial_x)(\partial_x-w), \tag{37}$$

such that the solutions of the PDEs are related through a Bäcklund transformation

$$\text{SK:}\quad U=w_x-w^2, \tag{38}$$

$$\text{KK:}\quad u=-w_x-\tfrac{1}{2}w^2 \tag{39}$$

with the solution w of the Fordy–Gibbons equation[12]

$$w_t+(w_{xxxx}-5w_xw_{xx}-5w^2w_{xx}-5ww_x^2+w^5)_x=0. \tag{40}$$

The reduction $\xi=x-ct$ of this equation can be solved for $w(\xi)$, either by eliminating U and w' between (38) and the equations of motion (25),

$$w=\frac{1}{2}\frac{\sqrt{-\mu}}{V^2}-\frac{V'}{V}, \tag{41}$$

or by eliminating u and w' between (39) and the equations of motion (30),

$$w=2\frac{\sqrt{-\mu}}{v^2}+2\frac{v'}{v}, \tag{42}$$

such that, defining $\lambda^2=-\mu$ and

$$\Gamma=6(VK_{2,0}+\lambda P_U), \tag{43}$$

$$\Omega=48(3v^4k_{2,0}^2+6\lambda uv^5p_v+12\lambda p_v^3v^3-\lambda v^6p_u+3\lambda^2uv^4+18\lambda^2v^2p_v^2+12\lambda^3vp_v+3\lambda^4), \tag{44}$$

the canonical transformation is given by[11,18]

$$u=-\frac{3}{2}\left(-\frac{P_V}{V}+\frac{\lambda}{2V^2}\right)^2-U,\quad v^2=\frac{\Gamma}{V^2}, \tag{45}$$

$$p_u=\frac{1}{V^3}(3P_V^3+3UV^2P_V-P_UV^3)-\frac{3\lambda}{2V^6}\left(UV^4+3V^2P_V^2-\frac{3}{2}\lambda VP_V+\frac{\lambda^2}{4}\right),$$

$$p_v=\frac{1}{4V^2}\left(-2P_V+\frac{\lambda}{V}\right)\sqrt{\Gamma}-\lambda\frac{V}{\sqrt{\Gamma}}, \tag{46}$$

$$U=-6\left(\frac{p_v}{v}+\frac{\lambda}{v^2}\right)^2-u,\quad V^2=\frac{\Omega}{4v^8}, \tag{47}$$

$$P_U=\frac{1}{v^3}(12p_v^3+6uv^2p_v-v^3p_u)+\frac{3\lambda}{v^6}(2uv^4+12v^2p_v^2+12\lambda vp_v+4\lambda^2),$$

$$P_V=-\frac{1}{v^5}\left(p_v+\frac{\lambda}{v}\right)\sqrt{\Omega}+\lambda\frac{v^4}{\sqrt{\Omega}}. \tag{48}$$

IV. GENERAL SOLUTION OF THE KAUP–KUPERSHMIDT CASE

Starting from the separation of variables (17) and the canonical transformation (47) and (48) in the case $\mu=0$, we consider the transformation defined by Ref. 10 on the basis of Painlevé analysis

$$
\begin{aligned}
q_1 &= -6\frac{p_v^2 - k_{2,0}}{v^2} - u,\\
q_2 &= -6\frac{p_v^2 + k_{2,0}}{v^2} - u,\\
p_1 &= \frac{1}{2v^3}(12p_v^3 + 6uv^2p_v - v^3p_u - 12p_vk_{2,0}),\\
p_2 &= \frac{1}{2v^3}(12p_v^3 + 6uv^2p_v - v^3p_u + 12p_vk_{2,0}).
\end{aligned}
\tag{49}
$$

This inverts to

$$
\begin{aligned}
u &= -6\left(\frac{p_2 - p_1}{q_2 - q_1}\right)^2 - \frac{1}{2}(q_1 + q_2),\\
v^2 &= \frac{12k_{2,0}}{q_1 - q_2},\\
p_u &= 24\left(\frac{p_1 - p_2}{q_1 - q_2}\right)^3 + 2(p_1 - p_2)\frac{q_1 + q_2}{q_1 - q_2} + 2\frac{p_1q_2 - p_2q_1}{q_1 - q_2},\\
p_v^2 &= 12k_{2,0}\frac{(p_2 - p_1)^2}{(q_1 - q_2)^3}.
\end{aligned}
\tag{50}
$$

Taking account that $k_{2,0}$ is no longer a constant of motion, this change of variables will appear to be useful to find the general solution for KK. In those new variables, the Hamiltonian system (31) becomes

$$
H \equiv k_1 = p_1^2 + p_2^2 + \frac{1}{12}(q_1^3 + q_2^3) - \frac{c}{4}(q_1 + q_2) + \frac{\mu}{24}\frac{q_1 - q_2}{k_{2,0}}, \tag{51}
$$

$$
k_{2,0} = 2(p_2^2 - p_1^2) + \frac{1}{6}(q_2^3 - q_1^3) - \frac{c}{2}(q_2 - q_1), \tag{52}
$$

$$
q_1' = 2p_1 + \frac{\mu}{6}\frac{(q_1 - q_2)p_1}{k_{2,0}^2}, \tag{53}
$$

$$
q_2' = 2p_2 - \frac{\mu}{6}\frac{(q_1 - q_2)p_2}{k_{2,0}^2}. \tag{54}
$$

Therefore, defining $f(q_i, p_i) \equiv p_i^2 + \frac{1}{12}q_i^3 - (c/4)\,q_i$ $(i = 1,2)$, the Hamilton–Jacobi equation is separated

$$
k_1(f(q_1, p_1) - f(q_2, p_2)) = f^2(q_1, p_1) - f^2(q_2, p_2) + \frac{\mu}{48}(q_1 - q_2), \tag{55}
$$

$$
p_i = \frac{\partial S}{\partial q_i}. \tag{56}
$$

We can express the second constant of motion k_2^2 in two equivalent ways

$$k_2^2=-\frac{\mu}{3}q_1+\left(k_{2,0}+\frac{\mu}{12}\frac{q_1-q_2}{k_{2,0}}\right)^2, \tag{57}$$

or

$$k_2^2=-\frac{\mu}{3}q_2+\left(k_{2,0}-\frac{\mu}{12}\frac{q_1-q_2}{k_{2,0}}\right)^2, \tag{58}$$

so that the elimination of $\mu(q_1-q_2)/k_{2,0}$ between (51), (57) and (51), (58) yields

$$k_2^2=-\frac{\mu}{3}q_1+\left(-4p_1^2-\frac{q_1^3}{3}+cq_1+2k_1\right)^2, \tag{59}$$

or

$$k_2^2=-\frac{\mu}{3}q_2+\left(4p_2^2+\frac{q_2^3}{3}-cq_2-2k_1\right)^2. \tag{60}$$

The elimination of p_1 between (59) and (53), and of p_2 between (60) and (54), yields

$$q_1'=\sqrt{2k_1-\frac{q_1^3}{3}+cq_1-\sqrt{k_2^2+\frac{\mu}{3}q_1}}\left(1+\frac{\mu}{3}\frac{q_1-q_2}{(\sqrt{k_2^2+(\mu/3)\,q_2}+\sqrt{k_2^2+(\mu/3)\,q_1})^2}\right), \tag{61}$$

$$q_2'=\sqrt{2k_1-\frac{q_2^3}{3}+cq_2+\sqrt{k_2^2+\frac{\mu}{3}q_2}}\left(1-\frac{\mu}{3}\frac{q_1-q_2}{(\sqrt{k_2^2+(\mu/3)\,q_2}+\sqrt{k_2^2+(\mu/3)\,q_1})^2}\right). \tag{62}$$

In the case $\mu=0$, the differential equations for q_1 and q_2 are separated and their solution is expressed in terms of the Weierstrass elliptic function

$$q_{1,0}=-12\wp\left(\xi-\xi_1,\frac{c}{12},-\frac{1}{144}(2k_{1,0}-k_{2,0})\right)\equiv-12\wp_1(\xi), \tag{63}$$

$$q_{2,0}=-12\wp\left(\xi-\xi_2,\frac{c}{12},-\frac{1}{144}(2k_{1,0}+k_{2,0})\right)\equiv-12\wp_2(\xi), \tag{64}$$

so that the solution for (30) in the case $\mu=0$ is[10]

$$u=-\frac{3}{2}\left(\frac{\wp_1'(\xi)-\wp_2'(\xi)}{\wp_1(\xi)-\wp_2(\xi)}\right)^2+6(\wp_1(\xi)+\wp_2(\xi)), \tag{65}$$

$$v^2=\frac{k_{2,0}}{\wp_2(\xi)-\wp_1(\xi)}. \tag{66}$$

In the case $\mu\neq0$, let us introduce the new variables

$$s_1=\sqrt{3\frac{k_2^2}{\mu}+q_1},\quad s_2=-\sqrt{3\frac{k_2^2}{\mu}+q_2}, \tag{67}$$

which transform Eqs. (61) and (62) into

$$s_1' = \sqrt{2k_1 - \frac{1}{3}\left(s_1^2 - 3\frac{k_2^2}{\mu}\right)^3 + c\left(s_1^2 - 3\frac{k_2^2}{\mu}\right) - \sqrt{\frac{\mu}{3}}s_1}\left(\frac{1}{s_1 - s_2}\right), \tag{68}$$

$$s_2' = -\sqrt{2k_1 - \frac{1}{3}\left(s_2^2 - 3\frac{k_2^2}{\mu}\right)^3 + c\left(s_2^2 - 3\frac{k_2^2}{\mu}\right) - \sqrt{\frac{\mu}{3}}s_2}\left(\frac{1}{s_1 - s_2}\right). \tag{69}$$

Defining

$$P(s) = 2k_1 - \frac{1}{3}\left(s^2 - 3\frac{k_2^2}{\mu}\right)^3 + c\left(s^2 - 3\frac{k_2^2}{\mu}\right) - \sqrt{\frac{\mu}{3}}s, \tag{70}$$

the system (68) and (69) can be solved by inversion of the hyperelliptic integrals

$$\int_\infty^{s_1} \frac{ds}{\sqrt{P(s)}} + \int_\infty^{s_2} \frac{ds}{\sqrt{P(s)}} = k_3, \tag{71}$$

$$\int_\infty^{s_1} \frac{s\,ds}{\sqrt{P(s)}} + \int_\infty^{s_2} \frac{s\,ds}{\sqrt{P(s)}} = \xi + k_4, \tag{72}$$

which define s_1 and s_2 as multivalued functions of ξ.[19,20]

The general solution of the equations of motion (30) in the case $\mu \neq 0$ is

$$u = -\frac{1}{2}(s_1^2 + s_2^2) + \frac{3}{\mu}k_2^2 - \frac{3}{2}\left(\frac{s_1' + s_2'}{s_1 + s_2}\right)^2, \tag{73}$$

$$v^2 = \frac{2\sqrt{3\mu}}{s_1 + s_2}. \tag{74}$$

As they are rational symmetric combinations of s_1 and s_2 and their derivatives, u and v^2 are single-valued functions of ξ.

In the variables q_1, q_2 this solution is expressed as

$$u = -\frac{3}{2}\left(\frac{\sqrt{2k_1 - (q_1^3/3) + cq_1 - \sqrt{k_2^2 + (\mu/3)q_1}} - \sqrt{2k_1 - (q_2^3/3) + cq_2 + \sqrt{k_2^2 + (\mu/3)q_2}}}{q_1 - q_2}\right)^2 - \frac{1}{2}(q_1 + q_2), \tag{75}$$

$$v^2 = 6\frac{\sqrt{k_2^2 + (\mu/3)q_1} + \sqrt{k_2^2 + (\mu/3)q_2}}{q_1 - q_2}, \tag{76}$$

which clearly goes to (65) and (66) in the limit $\mu \to 0$.

V. GENERAL SOLUTION OF THE SAWADA–KOTERA CASE

We start from the general solution (73) and (74) for KK and apply the canonical transformation (47) to obtain the general solution for the SK Hamiltonian system

$$U = \sqrt{-3}(s_1' + s_2') + s_1^2 + s_1 s_2 + s_2^2 - \frac{3}{\mu}K_2^2, \tag{77}$$

$$V^2=-2\sqrt{-3}(s_1+s_2)(s_1s_1'+s_2s_2')+2(s_1+s_2)^2\left(s_1^2+s_2^2-\frac{9K_2^2}{2\mu}\right). \tag{78}$$

Let us check that the limit of this solution when $\mu\to 0$ is (23). The expression (77) for U can also be written as

$$U=\frac{1}{2}(s_1^2+s_2^2)-\frac{3}{\mu}K_2^2+\frac{3}{2}\left(\frac{s_1'+s_2'}{s_1+s_2}\right)^2-\frac{3}{2}\left(\frac{s_1'+s_2'}{s_1+s_2}+\sqrt{-\frac{1}{3}}(s_1+s_2)\right)^2. \tag{79}$$

Since in the limit $\mu\to 0$

$$s_1+s_2=\mathcal{O}(\sqrt{\mu}),$$

$$\frac{s_1'+s_2'}{s_1+s_2}\to\frac{\wp_1'(\xi)-\wp_2'(\xi)}{\wp_1(\xi)-\wp_2(\xi)},$$

one has

$$\lim_{\mu\to 0} U=\tfrac{1}{2}(Q_1+Q_2). \tag{80}$$

Next, for V^2, the expansions

$$2(s_1+s_2)^2\left(s_1^2+s_2^2-\frac{9K_2^2}{2\mu}\right)=\frac{1}{4}(Q_1-Q_2)^2+\mathcal{O}(\mu),\quad \mu\to 0,$$

$$(s_1+s_2)(s_1s_1'+s_2s_2')=\mathcal{O}(\sqrt{\mu}),\quad \mu\to 0,$$

provide the limit of V^2 in (78). Therefore,

$$\lim_{\mu\to 0} V^2=\tfrac{1}{4}(Q_1-Q_2)^2. \tag{81}$$

VI. COMPARISON WITH THE RESULTS OF COSGROVE

Cosgrove[13] recently integrated the ODEs (11) and (13) with hyperelliptic functions, using the postmultiplier method.

To compare the two different ways of integration, let us recall the vocabulary introduced in Painlevé analysis of nonlinear differential equations, making the distinction between fixed and movable constants. A constant is called *fixed* if it appears explicitly in the differential equation, while it is *movable* if it is a constant of integration and therefore depends on the initial data.

In the Hamiltonian formalism, described by the system (28)–(33) and (24)–(27), k_1 (resp. K_1) and k_2 (resp. K_2) are movable constants, while μ is fixed (it appears in the equations of motion).

In Cosgrove's paper, the first integrals of the fourth order equation he obtained in formulas (4.3)–(4.4) and (5.6)–(5.7), which are therefore movable constants, correspond in the Hamiltonian formalism to k_2 (resp. K_2) and μ, respectively introduced as movable and fixed constants. In order to integrate the resulting second order sixth degree differential equation and transform it in a coupled system of first order equations for applying the postmultiplier method, Cosgrove defined ''suitable'' auxiliary variables chosen in a ''subjective'' way. Here the link between the canonical variables and its expressions (4.5)–(4.6) and (5.3)–(5.4) can be clearly established. Those expressions, which are ''hidden'' variables for the fourth order differential equation, are nothing else than the canonical variables v^2 (resp. V^2) and p_v^2 (resp. P_V^2) explicitly defined in the Hamiltonian formalism.

VII. CONCLUSION

We proved that the three integrable cases (SK, KdV_5, and KK) of the Hénon–Heiles Hamiltonian can be integrated in terms of hyperelliptic functions.

We will take advantage of the method developed here to integrate other Hamiltonian systems with two degrees of freedom and additional nonpolynomial terms.

Generalized sine-Gordon/massive Thirring models and soliton/particle correspondences

José Acosta and Harold Blas[a)]
Instituto de Física Teórica, Universidade Estadual Paulista, Rua Pamplona 145, 01405-900-São Paulo, S.P., Brazil

(Received 25 September 2001; accepted for publication 8 January 2002)

We consider a real Lagrangian off-critical submodel describing the soliton sector of the so-called conformal affine $sl(3)^{(1)}$ Toda model coupled to matter fields. The theory is treated as a constrained system in the context of Faddeev–Jackiw and the symplectic schemes. We exhibit the parent Lagrangian nature of the model from which generalizations of the sine-Gordon (GSG) or the massive Thirring (GMT) models are derivable. The dual description of the model is further emphasized by providing the relationships between bilinears of GMT spinors and relevant expressions of the GSG fields. In this way we exhibit the strong/weak coupling phases and the (generalized) soliton/particle correspondences of the model. The $sl(n)^{(1)}$ case is also outlined. © *2002 American Institute of Physics.*

I. INTRODUCTION

Integrable theories in two dimensions have been an extraordinary laboratory for the understanding of basic nonperturbative aspects of physical theories and various aspects, relevant in more realistic four-dimensional models, have been tested.[1] In particular the conformal affine Toda models coupled to (Dirac) matter fields (CATM)[2] for the $sl(2)^{(1)}$ and $sl(3)^{(1)}$ cases are discussed in Refs. 3, 4, and 5, respectively. The interest in such models comes from their integrability and duality properties,[2,4] which can be used as toy models to understand some phenomena; such as a confinement mechanism in quantum chromodynamics (QCD)[3,5] and the electric–magnetic duality in four-dimensional gauge theories, conjectured in Ref. 6 and developed in Ref. 7. The affine Toda model coupled to matter field (ATM) type systems may also describe some low dimensional condensed matter phenomena, such as self-trapping of electrons into solitons, see, e.g., Ref. 8, tunneling in the integer quantum Hall effect,[9] and, in particular, polyacteline molecule systems in connection with fermion number fractionization.[10]

Off-critical submodels, such as the $sl(2)$ ATM, can be obtained at the classical or quantum mechanical level through some convenient reduction processes starting from CATM.[4,11] In the $sl(2)$ case, using bosonization techniques, it has been shown that the classical equivalence between the $U(1)$ vector and topological currents holds true at the quantum level, and then leads to a bag model like mechanism for the confinement of the spinor fields inside the solitons; in addition, it has been shown that the $sl(2)$ ATM theory decouples into a sine-Gordon model (SG) and a free scalar.[3,12] These facts indicate the existence of a sort of duality in these models involving solitons and particles.[6] The symplectic structure of the $sl(2)$ ATM model has recently been studied[11] in the context of Faddeev–Jackiw (FJ)[13] and (constrained) symplectic methods.[14,15] Imposing the equivalence between the $U(1)$ vector and topological currents as a constraint there have been obtained the SG or the massive Thirring (MT) model.

One of the difficulties with generalizations of complex affine Toda field theories, beyond $su(2)$ and its associated SG model, has to do with unitarity. Whereas for practical applications

a)Electronic mail: blas@ift.unesp.br

such as low dimensional condensed matter systems (see Ref. 16 and references therein) and N-body problems in nuclear physics,[17] the properties of interest are usually integrability and nonperturbative results of multifield Lagrangians. Therefore, integrable quantum field theories with several fields (bosons and/or fermions) are of some importance.

In this paper we construct many field generalizations of SG/MT models based on soliton/particle duality and unitarity. Beyond the well-known $sl(2)$ case the related $sl(n)^{(1)}$ CATM model does not possess a local Lagrangian, therefore we resort to an off-critical submodel Lagrangian with well behaved classical solutions making use of the results of Ref. 5. In Ref. 5 the authors studied the $sl(3)^{(1)}$ CATM soliton solutions and some of their properties up to general two-soliton. Using the FJ and symplectic methods we show the parent Lagrangian[18] nature of the $sl(3)$ ATM model from which the generalized sine-Gordon (GSG) or the massive Thirring (GMT) models are derivable. We thus show that there are (at least classically) two equivalent descriptions of the model, by means of either the Dirac or the Toda type fields. The duality exchange of the coupling regimes $g \to 1/g$ and the generalized soliton/particle correspondences in each $sl(2)$ ATM submodel will also be clear, which we uncover by providing explicit relationships between the GSG and GMT fields. We also outline the steps toward the $sl(n)$ affine Lie algebra generalizations. In this way we give a precise field content of both sectors; namely, the correct GMT/GSG duality, first undertaken in Ref. 19.

The paper is organized as follows. In Sec. II we define the $sl(3)$ ATM model. Section III deals with the model in the FJ framework, the outcome is the GMT model. In Sec. IV, we attack the same problem from the point of view of symplectic quantization[14,15] giving the Poisson brackets of the GMT and GSG models. Section V deals with the soliton/particle and strong/weak coupling correspondences. Section VI outlines the relevant steps toward the generalization to $sl(n)$ ATM. In the appendix we present the construction of $sl(3)^{(1)}$ CATM model and its relationship to the (two-loop) Wess–Zumino–Novikov–Witten (WZNW) model.

II. DESCRIPTION OF THE MODEL

In affine Toda type theories the question of whether all mathematical solutions are physically acceptable deserves a careful analysis, especially if any consistent quantization of the models is discussed. The requirement of real energy density leads to certain reality conditions on the solutions of the model. In general, a few soliton solutions survive the reality constraint, if in addition one also demands positivity. These kind of issues are discussed in Refs. 20. Here we follow the prescription to restrict the model to a subspace of classical solutions which satisfy the physical principles of reality of energy density and soliton/particle correspondence.

In CATM models associated with the principal gradation of an affine Lie algebra we have a one-soliton solution (real Toda field) for each pair of Dirac fields ψ^i and $\tilde{\psi}^i$.[2] This fact allows us to make the identifications $\tilde{\psi}^i \sim (\psi^i)^*$, and take real Toda fields. In the case of $sl(2)^{(1)}$ CATM theory, this procedure does not spoil the particle–soliton correspondence.[3,4]

We consider the $sl(3)^{(1)}$ CATM theory (see the Appendix) with the conformal symmetry gauge fixed[21] by setting $\eta = 0$ and the reality conditions

$$\tilde{\psi}^j = -(\psi^j)^*, \quad (j = 1,2,3), \quad \varphi_a^* = \varphi_a \quad (a = 1,2), \tag{2.1}$$

or

$$\tilde{\psi}^j = (\psi^j)^*, \quad j = 1,2, \quad \tilde{\psi}^3 = -(\psi^3)^*,$$

$$\varphi_{1,2} \to \varphi_{1,2} - \pi \ \text{(the new } \varphi_a\text{'s being real fields)}, \tag{2.2}$$

where an asterisk means complex conjugation. The condition (2.2) must be supplied with $x^\mu \to -x^\mu$. Moreover, for consistency of the equations of motion (A15)–(A23) under the reality conditions (2.1) and (2.2), from Eqs. (A16) to (A18), (A20), (A21), and (A23), we get the relationships

$$\tilde{\psi}_L^j \psi_R^3 - \tilde{\psi}_R^j \psi_L^3 e^{-3i\varphi_j} = 0, \quad j = 1,2, \quad \psi_L^1 \psi_R^2 e^{-3i\varphi_1} - \psi_L^2 \psi_R^1 e^{-3i\varphi_2} = 0. \tag{2.3}$$

Then, the above-given reality conditions and constraints allow us to define a suitable physical Lagrangian. Equations (A13), (A15)–(A23), supplied with (2.1) [or (2.2)] and (2.3), follow from the Lagrangian

$$\frac{1}{k}\mathcal{L} = \sum_{j=1}^{3} \left[\frac{1}{24} \partial_\mu \phi_j \partial^\mu \phi_j + i \overline{\psi^j} \gamma^\mu \partial_\mu \psi^j - m_\psi^j \overline{\psi^j} e^{i\phi_j \gamma_5} \psi^j \right], \tag{2.4}$$

where $\overline{\psi^j} \equiv (\psi^j)^\dagger \gamma_0$, $\phi_1 \equiv 2\varphi_1 - \varphi_2$, $\phi_2 \equiv 2\varphi_2 - \varphi_1$, $\phi_3 \equiv \phi_1 + \phi_2$, $m_\psi^3 = m_\psi^1 + m_\psi^2$, k is an overall coupling constant and the φ_j are real fields.

Equation (2.4) defines the $sl(3)$ *affine Toda theory coupled to matter fields* (ATM). Notice that the space of solutions of $sl(3)^{(1)}$ CATM model satisfying conditions (2.1)–(2.3) must be solutions of the $sl(3)$ ATM theory (2.4). Indeed, it is easy to verify that the three species of one-soliton solutions [$S \equiv 1$-soliton($\overline{S} \equiv 1$-antisoliton)]:[5] $\{(\varphi_1, \psi^1)_{S/\overline{S}}, \varphi_2 = 0, \psi^2 = 0, \psi^3 = 0\}$, $\{(\varphi_2, \psi^2)_{S/\overline{S}}, \varphi_1 = 0, \psi^1 = 0, \psi^3 = 0\}$, and $\{(\varphi_1 + \varphi_2, \psi^3)_{S/\overline{S}}, \varphi_1 = \varphi_2, \psi^1 = 0, \psi^2 = 0\}$ satisfy the equations of motion, i.e., each positive root of $sl(3)$ reproduces the $sl(2)$ ATM case.[3,4] Moreover, these solutions satisfy the above-given reality conditions and constriants (2.1)–(2.3) [with (2.1) and (2.2) for S and $\overline{S}$, respectively], and the equivalence between the $U(1)$ vector and topological currents (A29). Then, the soliton/particle correspondences survive the above-given reduction processes performed to define the $sl(3)$ ATM theory.

The class of two-soliton solutions of $sl(3)^{(1)}$ CATM[5] behave as follows: (i) they are given by six species associated with the pair (α_i, α_j), $i \leqslant j$; $i,j = 1,2,3$; where the α's are the positive roots of $sl(3)$ Lie algebra. Each species (α_i, α_i) solves the $sl(2)$ CATM submodel;[22] (ii) satisfy the $U(1)$ vector and topological currents equivalence (A29).

III. THE GENERALIZED MASSIVE THIRRING MODEL (GMT)

Let us consider the following Lagrangian:

$$\frac{1}{k}\mathcal{L} = \sum_{j=1}^{3} \left[\frac{1}{24} \partial_\mu \phi_j \partial^\mu \phi_j + i \overline{\psi^j} \gamma^\mu \partial_\mu \psi^j - m_\psi^j \overline{\psi^j} e^{i\phi_j \gamma_5} \psi^j + \lambda_\mu^j (m^j \overline{\psi^j} \gamma^\mu \psi^j - \epsilon^{\mu\nu} \partial_\nu (q_j \phi_j)) \right], \tag{3.1}$$

where the ATM Lagrangian (2.4) is supplied with the constraints, $(m^l \overline{\psi^l} \gamma^\mu \psi^l + (m^3/2) \overline{\psi^3} \gamma^\mu \psi^3 - \epsilon^{\mu\nu} \partial_\nu \phi_l)$, $(l = 1,2)$, with the help of the Lagrange multipliers λ_μ^j ($\lambda_\mu^3 \equiv (\lambda_\mu^1 + \lambda_\mu^2)/2$, $q_1 \equiv q_2 \equiv 1$, $q_3 \equiv 0$). Their total sum bears an intriguing resemblance to the $U(1)$ vector and topological currents equivalence (A29); however, the m^j's here are some arbitrary parameters. The same procedure has been used, for example, to incorporate the left-moving condition in the study of chiral bosons in two dimensions.[23] The constraints in (3.1) will break the left–right local symmetries (A25)–(A28) of $sl(3)$ ATM (2.4). In order to apply the FJ method we should write (3.1) in the first-order form in time derivative, so let us define the conjugated momenta

$$\begin{gathered} \pi_1 \equiv \pi_{\phi_1} = \tfrac{1}{12}(2\dot{\phi}_1 + \dot{\phi}_2) + \lambda_1^1, \quad \pi_2 \equiv \pi_{\phi_2} = \tfrac{1}{12}(2\dot{\phi}_2 + \dot{\phi}_1) + \lambda_1^2, \\ \pi_{\lambda_\mu^1} = 0, \quad \pi_{\lambda_\mu^2} = 0, \quad \pi_R^j \equiv \pi_{\psi_R}^j = -i\tilde{\psi}_R^j, \quad \pi_L^j \equiv \pi_{\psi_L}^j = -i\tilde{\psi}_L^j. \end{gathered} \tag{3.2}$$

We are assuming that Dirac fields are anticommuting Grasmannian variables and their momenta variables defined through *left* derivatives. Then, as usual, the Hamiltonian is defined by (sum over repeated indices is assumed)

$$\mathcal{H}_c = \pi_1 \dot{\phi}_1 + \pi_2 \dot{\phi}_2 + \dot{\psi}_R^j \pi_R^j + \dot{\psi}_L^j \pi_L^j - \mathcal{L}. \tag{3.3}$$

Explicitly the Hamiltonian density becomes

$$\mathcal{H}_c = 2(\pi_j)^2 + 4(\lambda_1^1)^2 + 4(\lambda_1^2)^2 - \lambda_1^1 \mathcal{J}_1 - \lambda_1^2 \mathcal{J}_2 - 4(\lambda_1^1 \lambda_1^2) + \tfrac{1}{24}(\phi_{j,x})^2 - \pi_R^j \psi_{R,x}^j + \pi_L^j \psi_{L,x}^j + i m_\psi^j (e^{-\phi_j} \tilde{\psi}_R^j \psi_L^j - e^{\phi_j} \tilde{\psi}_L^j \psi_R^j) + \lambda_0^1 [J_1^0 - \phi_{1,x}] + \lambda_0^2 [J_2^0 - \phi_{2,x}], \tag{3.4}$$

where $\pi_3 \equiv \pi_1 - \pi_2$, $\mathcal{J}_1 \equiv J_1^1 + 4(2\pi_1 - \pi_2)$, $\mathcal{J}_2 \equiv J_2^1 + 4(2\pi_2 - \pi_1)$, and

$$J_1^\mu = m^1 j_l^\mu + \frac{m^3}{2} j_3^\mu, \quad J_2^\mu = m^2 j_2^\mu + \frac{m^3}{2} j_3^\mu, \quad j_l^\mu \equiv \overline{\psi^l} \gamma^\mu \psi^l, \quad l = 1,2,3. \tag{3.5}$$

Let us observe that each $U(1)$ Noether current of the $sl(3)$ ATM theory defined in (2.4) is conserved separately, i.e., $\partial_\mu j_l^\mu = 0$, $l = 1,2,3$.

Next, the same Legendre transform (3.3) is used to write the first-order Lagrangian

$$\mathcal{L} = \pi_1 \dot{\phi}_1 + \pi_2 \dot{\phi}_2 + \dot{\psi}_R^j \pi_R^j + \dot{\psi}_L^j \pi_L^j - \mathcal{H}_c. \tag{3.6}$$

Our starting point for the FJ analysis will be this first-order Lagrangian. Then the Euler–Lagrange equations for the Lagrange multipliers allow one to solve two of them

$$\lambda_1^1 = \frac{2\mathcal{J}_1 + \mathcal{J}_2}{12}, \quad \lambda_1^2 = \frac{2\mathcal{J}_2 + \mathcal{J}_1}{12} \tag{3.7}$$

and the remaining equations lead to two constraints,

$$\Omega_1 \equiv J_1^0 - \phi_{1,x} = 0, \quad \Omega_2 \equiv J_2^0 - \phi_{2,x} = 0. \tag{3.8}$$

The Lagrange multipliers λ_1^1 and λ_1^2 must be replaced back in (3.6) and the constraints (3.8) solved. First, let us replace the λ_1^1 and λ_1^2 multipliers into $\mathcal{H}_c$, then one gets

$$\mathcal{H}_c' = 2(\pi_j)^2 - \tfrac{1}{12}\{(\mathcal{J}_1)^2 + (\mathcal{J}_2)^2 + (\mathcal{J}_1 \mathcal{J}_2)\} + \tfrac{1}{24}(\phi_{j,x})^2 + i \tilde{\psi}_R^j \psi_{R,x}^j - i \tilde{\psi}_L^j \psi_{L,x}^j + i m_\psi^j (e^{-i\phi_j} \tilde{\psi}_R^j \psi_L^j - e^{i\phi_j} \tilde{\psi}_L^j \psi_R^j). \tag{3.9}$$

The new Lagrangian becomes

$$\mathcal{L}' = \pi_1 \dot{\phi}_1 + \pi_2 \dot{\phi}_2 + \dot{\psi}_R^j \pi_R^j + \dot{\psi}_L^j \pi_L^j - \mathcal{H}_c'. \tag{3.10}$$

We implement the constraints (3.8) by replacing in (3.10) the fields ϕ_1, ϕ_2 in terms of the space integral of the current components J_1^0, J_2^0. Then we get the Lagrangian

$$\mathcal{L}'' = \pi_1 \partial_t \int^x J_1^0 + \pi_2 \partial_t \int^x J_2^0 + \dot{\psi}_R^j \pi_R^j + \dot{\psi}_L^j \pi_L^j - i \tilde{\psi}_R^j \psi_{R,x}^j + i \tilde{\psi}_L^j \psi_{L,x}^j - i m_\psi^j (e^{-i\int^x J_j^0} \tilde{\psi}_R^j \psi_L^j - e^{i\int^x J_j^0} \tilde{\psi}_L^j \psi_R^j) - \tfrac{1}{12}((J_1)^2 + (J_2)^2 + J_1 . J_2) + \pi_1 J_1^1 + \pi_2 J_2^1, \tag{3.11}$$

where $J_3^0 \equiv J_1^0 + J_2^0$. Observe that the terms containig the π_a's in Eq. (3.11) cancel to each other if one uses the current conservation laws. Notice the appearances of various types of current–current interactions. The following Darboux transformation:

$$\psi_R^j \to \exp\left(-\frac{i}{2}\int^x J_j^0\right) \psi_R^j, \quad \psi_L^j \to \exp\left(\frac{i}{2}\int^x J_j^0\right) \psi_L^j, \quad j = 1,2,3 \tag{3.12}$$

is used to diagonalize the canonical one-form. Then, the kinetic terms will give additional current–current interactions, $-\frac{1}{2}[J_1\cdot(j_1+j_3)+J_2\cdot(j_2+j_3)]$. We are, thus, after defining $k\equiv 1/g$, and rescaling the fields $\psi^j\to 1/\sqrt{k}\,\psi^j$, left with the Lagrangian

$$\mathcal{L}[\psi,\overline{\psi}]=\sum_{j=1}^{3}\{i\overline{\psi^j}\gamma^\mu\partial_\mu\psi^j+m_\psi^j\,\overline{\psi^j}\psi^j\}-\sum_{\substack{k,l=1\\k\leqslant l}}^{3}[\overline{a_{kl}}j_k\cdot j_l], \tag{3.13}$$

where $\overline{a_{kl}}=g\,a_{kl}$, with

$$a_{33}=\frac{1}{2}\left(\frac{(m^3)^2}{8}+m^3\right),\quad a_{12}=\frac{1}{12}m^1m^2,\quad a_{ii}=\frac{1}{2}\left(\frac{(m^i)^2}{6}+m^i\right),$$

$$a_{i3}=\frac{1}{2}\left(\frac{m^im^3}{4}+m^i+\frac{m^3}{2}\right),\quad i=1,2.$$

This defines the *generalized massive Thirring model* (GMT). The canonical pairs are $(-i\tilde{\psi}_R^j,\psi_R^j)$ and $(-i\tilde{\psi}_L^j,\psi_L^j)$.

IV. THE SYMPLECTIC FORMALISM AND THE ATM MODEL

A. The (constrained) symplectic formalism

We give a brief overview of the basic notations of symplectic approach.[24] The geometric structure is defined by the closed (pre)symplectic two-form

$$f^{(0)}=\tfrac{1}{2}f_{ij}^{(0)}(\xi^{(0)})\mathrm{d}\xi^{(0)i}\wedge\mathrm{d}\xi^{(0)j}, \tag{4.1}$$

where

$$f_{ij}^{(0)}(\xi^{(0)})=\frac{\partial}{\partial\xi^{(0)i}}\mathbf{a}_j^{(0)}(\xi^{(0)})-\frac{\partial}{\partial\xi^{(0)j}}\mathbf{a}_i^{(0)}(\xi^{(0)}) \tag{4.2}$$

with $\mathbf{a}^{(0)}(\xi^{(0)})=\mathbf{a}_j^{(0)}(\xi^{(0)})\mathrm{d}\xi^{(0)j}$ being the canonical one-form defined from the original first-order Lagrangian

$$L^{(0)}\mathrm{d}t=\mathbf{a}^{(0)}(\xi^{(0)})-V^{(0)}(\xi^{(0)})\mathrm{d}t. \tag{4.3}$$

The superscript (0) refers to the original Lagrangian, and is indicative of the iterative nature of the computations. The constraints are imposed through Lagrange multipliers which are velocities, and in such case one has to extend the configuration space.[14,15] The corresponding Lagrangian gets modified and consequently the superscript also changes. The algorithm terminates once the symplectic matrix turns out to be nonsingular.

B. The generalized massive Thirring model (GMT)

Next, we will consider our model in the framework of the symplectic formalism. Let $\mathcal{L}'$, Eq. (3.10), be the zeroth-iterated Lagrangian $\mathcal{L}^{(0)}$. Then the first iterated Lagrangian will be

$$\mathcal{L}^{(1)}=\pi_1\dot{\phi}_1+\pi_2\dot{\phi}_2+\dot{\psi}_R^j\pi_R^j+\dot{\psi}_L^j\pi_L^j+\dot{\eta}^1\Omega_1+\dot{\eta}^2\Omega_2-\mathcal{V}^{(1)}, \tag{4.4}$$

where the once-iterated symplectic potential is defined by

$$\mathcal{V}^{(1)}=\mathcal{H}_c'|_{\Omega_1=\Omega_2=0}, \tag{4.5}$$

and the stability conditions of the symplectic constraints, Ω_1 and Ω_2, under time evolution have been implemented by making $\lambda_0^1 \to \dot{\eta}^1$ and $\lambda_0^2 \to \dot{\eta}^2$. Consider the once-iterated set of symplectic variables in the following order

$$\xi^{(1)} = (\eta^1, \eta^2, \phi_1, \phi_2, \psi_R^1, \psi_L^1, \psi_R^2, \psi_L^2, \psi_R^3, \psi_L^3, \pi_1, \pi_2, \pi_R^1, \pi_L^1, \pi_R^2, \pi_L^2, \pi_R^3, \pi_L^3), \tag{4.6}$$

and the components of the canonical one-form

$$\mathbf{a}^{(1)} = (\Omega_1, \Omega_2, \pi_1, \pi_2, -\pi_R^1, -\pi_L^1, -\pi_R^2, -\pi_L^2, -\pi_R^3, -\pi_L^3, 0,0,0,0,0,0,0,0,0). \tag{4.7}$$

These result in the singular symplectic two-form 18×18 matrix

$$f_{AB}^{(1)}(x,y) = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \delta(x-y), \tag{4.8}$$

where the 9×9 martices are

$$a_{11} = \begin{pmatrix} 0 & 0 & \partial_x & 0 & im^1\tilde{\psi}_R^1 & im^1\tilde{\psi}_L^1 & 0 & 0 & \frac{im^3}{2}\tilde{\psi}_R^3 \\ 0 & 0 & 0 & \partial_x & 0 & 0 & im^2\tilde{\psi}_R^2 & im^2\tilde{\psi}_L^2 & \frac{im^3}{2}\tilde{\psi}_R^3 \\ \partial_x & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \partial_x & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ im^1\tilde{\psi}_R^1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ im^1\tilde{\psi}_L^1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & im^2\tilde{\psi}_R^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & im^2\tilde{\psi}_L^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_R^3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$a_{12} = \begin{pmatrix} \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & m^1\psi_R^1 & m^1\psi_L^1 & 0 & 0 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_L^3 \\ \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & 0 & 0 & m^2\psi_R^2 & m^2\psi_L^2 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_L^3 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \vdots & 0 & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix},$$

$$a_{21}=\begin{pmatrix} \frac{im^3}{2}\tilde{\psi}^3_L & \frac{im^3}{2}\tilde{\psi}^3_L & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ m^1\psi^1_R & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ m^1\psi^1_L & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & m^2\psi^2_R & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & m^2\psi^2_L & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ \frac{m^3}{2}\psi^3_R & \frac{m^3}{2}\psi^3_R & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ \frac{m^3}{2}\psi^3_L & \frac{m^3}{2}\psi^3_L & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$a_{22}=\begin{pmatrix} 0 & 0 & \cdots & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & \cdots & 0 & 0 \end{pmatrix}.$$

This matrix has the zero modes

$$\mathbf{v}^{(1)T}(x)=\left(\frac{-u}{m^1},\frac{-v}{m^2},0,0,u\psi^1_R,u\psi^1_L,v\psi^2_R,v\psi^2_L,\frac{m^3}{2}\left(\frac{u}{m^1}+\frac{v}{m^2}\right)\psi^3_R,\frac{m^3}{2}\left(\frac{u}{m^1}+\frac{v}{m^2}\right)\psi^3_L,-\frac{u'}{m^1},\right.$$
$$\left.-\frac{v'}{m^2},iu\tilde{\psi}^1_R,iu\tilde{\psi}^1_L,iv\tilde{\psi}^2_R,iv\tilde{\psi}^2_L,i\frac{m^3}{2}\left(\frac{u}{m^1}+\frac{v}{m^2}\right)\tilde{\psi}^3_R,\frac{im^3}{2}\left(\frac{u}{m^1}+\frac{v}{m^2}\right)\tilde{\psi}^3_L\right), \tag{4.9}$$

where u and v are arbitrary functions. The zero-mode condition gives

$$\int \mathrm{d}x\mathbf{v}^{(1)T}(x)\frac{\delta}{\delta\xi^{(1)}(x)}\int \mathrm{d}y\mathcal{V}^{(1)}\equiv 0. \tag{4.10}$$

Thus, the gradient of the symplectic potential happens to be orthogonal to the zero-mode $\mathbf{v}^{(1)}$. Since the equations of motion are automatically validated no symplectic constraints appear. This happens due to the presence of the symmetries of the action

$$\delta\xi^{(1)}_A=\mathbf{v}^{(1)}_{\mathbf{A}}(x),\quad A=1,2,\ldots,18. \tag{4.11}$$

So, in order to deform the symplectic matrix into an invertible one, we have to add some gauge fixing terms to the symplectic potential. One can choose any consistent set of gauge fixing conditions.[15] In our case we have two symmetry generators associated with the parameters u and v, so there must be two gauge conditions. Let us choose

$$\Omega_3\equiv\phi_1=0,\quad \Omega_4\equiv\phi_2=0. \tag{4.12}$$

These conditions gauge away the fields ϕ_1 and ϕ_2, so only the remaining field variables will describe the dynamics of the system. Other gauge conditions, which eventually gauge away the spinor fields ψ^i, will be considered in Sec. IV C.

Implementing the consistency conditions by means of Lagrange multipliers η^3 and η^4 we get the twice-iterated Lagrangian

$$\mathcal{L}^{(2)}=\pi_1\dot{\phi}_1+\pi_2\dot{\phi}_2+\dot{\psi}_R\pi_R^j+\dot{\psi}_L\pi_L^j+\dot{\eta}^1\Omega_1+\dot{\eta}^2\Omega_2+\dot{\eta}^3\Omega_3+\dot{\eta}^4\Omega_4-\mathcal{V}^{(2)}, \tag{4.13}$$

where

$$\mathcal{V}^{(2)}=\mathcal{V}^{(1)}|_{\Omega_3=\Omega_4=0}.$$

Assuming now that the new set of symplectic variables is given in the following order,

$$\xi^{(2)}=(\eta^1,\eta^2,\eta^3,\eta^4,\phi_1,\phi_2,\psi_R^1,\psi_L^1,\psi_R^2,\psi_L^2,\psi_R^3,\psi_L^3,\pi_1,\pi_2,\pi_R^1,\pi_L^1,\pi_R^2,\pi_L^2,\pi_R^3,\pi_L^3), \tag{4.14}$$

and the nonvanishing components of the canonical one-form

$$\mathbf{a}^{(2)}=(\Omega_1,\Omega_2,\Omega_3,\Omega_4,\pi_1,\pi_2,-\pi_R^1,-\pi_L^1,-\pi_R^2,-\pi_L^2,-\pi_R^3,-\pi_L^3,0,0,0,0,0,0,0,0), \tag{4.15}$$

one obtains the singular twice-iterated symplectic 20×20 matrix

$$f_{AB}^{(2)}(x,y)=\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}\delta(x-y), \tag{4.16}$$

where the 10×10 matrices are

$$a_{11}=\begin{pmatrix}
0 & 0 & 0 & 0 & \partial_x & 0 & im^1\tilde{\psi}_R^1 & im^1\tilde{\psi}_L^1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \partial_x & 0 & 0 & im^2\tilde{\psi}_R^2 & im^2\tilde{\psi}_L^2 \\
0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\
\partial_x & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & \partial_x & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
im^1\tilde{\psi}_R^1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
im^1\tilde{\psi}_L^1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & im^2\tilde{\psi}_R^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & im^2\tilde{\psi}_L^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix},$$

$$a_{12}=\begin{pmatrix}
\frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & m^1\psi_R^1 & m^1\psi_L^1 & 0 & 0 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_L^3 \\
\frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & 0 & 0 & m^2\psi_R^2 & m^2\psi_L^2 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_L^3 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0
\end{pmatrix},$$

$$a_{21}=\begin{pmatrix}
\frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_R^3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{im^3}{2}\tilde{\psi}_L^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
m^1\psi_R^1 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\
m^1\psi_L^1 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\
0 & m^2\psi_R^2 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\
0 & m^2\psi_L^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\
\frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_R^3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix},$$

$$a_{22}=\begin{pmatrix}
0 & 0 & 0 & \cdots & 0 & -1 & 0 \\
0 & 0 & 0 & \cdots & 0 & 0 & -1 \\
0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
\multicolumn{7}{c}{\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots} \\
0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
-1 & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & -1 & 0 & \cdots & 0 & 0 & 0
\end{pmatrix}.$$

The zero-modes are

$$\mathbf{v}^{(2)T}(x)=\Big(u,\ v,\ \omega,\ \chi,\ 0,\ 0,\ m^1u\psi_R^1,\ m^1u\psi_L^1,\ m^2v\psi_R^2,\ m^2v\psi_L^2,\ \frac{m^3}{2}(u+v)\psi_R^3,$$
$$\frac{m^3}{2}(u+v)\psi_L^3,\ u'+\omega,\ v'+\chi,\ im^1\tilde{\psi}_R^1u,\ im^1\tilde{\psi}_L^1u,\ im^2\tilde{\psi}_R^2v,im^2\tilde{\psi}_L^2v,$$
$$\frac{im^3}{2}\tilde{\psi}_R^3(u+v),\ i\frac{m^3}{2}\tilde{\psi}_L^3(u+v)\Big). \tag{4.17}$$

The zero-mode condition gives no constraints, implying the symmetries of the action

$$\delta\xi_{\mathbf{A}}^{(2)}=\mathbf{v}_{\mathbf{A}}^{(2)}(x),\quad A=1,2,\ldots,20. \tag{4.18}$$

Now, let us choose the gauge conditions

$$\Omega_5\equiv\pi_1J_1^1+\tfrac{1}{2}J_1\cdot(j_1+j_3)=0,\quad \Omega_6\equiv\pi_2J_2^1+\tfrac{1}{2}J_2\cdot(j_2+j_3)=0, \tag{4.19}$$

and impose the consistency conditions with the Lagrange multipliers η^5,η^6, then

$$\mathcal{L}^{(3)}=\pi_1\dot{\phi}_1+\pi_2\dot{\phi}_2+\dot{\psi}_R\pi_R^j+\dot{\psi}_L\pi_L^j+\dot{\eta}^1\Omega_1+\dot{\eta}^2\Omega_2+\dot{\eta}^3\Omega_3+\dot{\eta}^4\Omega_4+\dot{\eta}^5\Omega_5+\dot{\eta}^6\Omega_6-\mathcal{V}^{(3)}, \tag{4.20}$$

where

$$\mathcal{V}^{(3)}=\mathcal{V}^{(2)}|_{\Omega_5=\Omega_6=0}, \tag{4.21}$$

or explicitly

$$\mathcal{V}^{(3)}=\tfrac{1}{12}((J_1)^2+(J_2)^2+J_1\cdot J_2)+\tfrac{1}{2}[J_1\cdot(j_1+j_3)+J_2\cdot(j_2+j_3)]+i\tilde{\psi}_R^j\psi_{R,x}^j-i\tilde{\psi}_L^j\psi_{L,x}^j+im_\psi^j\overline{\psi^j}\psi^j. \tag{4.22}$$

The symplectic two-form for this Lagrangian is a nonsingular matrix, then our algorithm has come to an end. Collecting the canonical part and the symplectic potential $\mathcal{V}^{(3)}$ one has

$$\mathcal{L}[\psi,\overline{\psi}]=\sum_{j=1}^{3}\{i\overline{\psi^j}\gamma^\mu\partial_\mu\psi^j+m_\psi^j\overline{\psi^j}\psi^j\}-\sum_{\substack{k,l=1\\k\leqslant l}}^{3}[\overline{a}_{kl}j_k.j_l]+\sum_{l=1}^{3}m^l\nu_lj_l^0, \tag{4.23}$$

where $\nu_3\equiv(\nu_1+\nu_2)/2$. We have made the same choice, $k=1/g$, and the field rescalings $\psi^j\to1/\sqrt{k}\,\psi^j$ as in the last section. This is the same GMT Lagrangian as (3.13). As a bonus, we get the chemical potentials $\mu_l\equiv m^l\nu_l$ ($\dot{\eta}^{1,2}\to\nu_{1,2}$) times the charge densities. These terms are related to the charges $Q_F^l=1/2\pi\int_{-\infty}^{+\infty}dx\,j_l^0(t,x)$, and their presence is a consequence of the symplectic method.[11]

C. The generalized sine-Gordon model (GSG)

One can choose other gauge fixings, instead of (4.12), to construct the twice-iterated Lagrangian. Let us make the choice

$$\Omega_3\equiv J_1^0=0,\quad \Omega_4\equiv J_2^0=0, \tag{4.24}$$

which satisfies the nongauge invariance condition as can be verified by computing the brackets $\{\Omega_a,J_b^0\}=0$; $a,b=1,2$. The twice-iterated Lagrangian is obtained by bringing back these constraints into the canonical part of $\mathcal{L}^{(1)}$, then

$$\mathcal{L}^{(2)}=\pi_1\dot{\phi}_1+\pi_2\dot{\phi}_2+\dot{\psi}_R\pi_R^j+\dot{\psi}_L\pi_L^j+\dot{\eta}^1\Omega_1+\dot{\eta}^2\Omega_2+\dot{\eta}^3\Omega_3+\dot{\eta}^4\Omega_4-\mathcal{V}^{(2)}, \tag{4.25}$$

where the twice-iterated symplectic potential becomes

$$\mathcal{V}^{(2)}=\mathcal{V}^{(1)}\big|_{\Omega_3=\Omega_4=0}. \tag{4.26}$$

Considering the set of symplectic variables in the following order:

$$\xi_A^{(2)}=(\eta^1,\eta^2,\eta^3,\eta^4,\phi_1,\phi_2,\psi_R^1,\psi_L^1,\psi_R^2,\psi_L^2,\psi_R^3,\psi_L^3,\pi_1,\pi_2,\pi_R^1,\pi_L^1,\pi_R^2,\pi_L^2,\pi_R^3,\pi_L^3) \tag{4.27}$$

and the components of the canonical one-form

$$a_A^{(2)}=(\Omega_1,\Omega_2,\Omega_3,\Omega_4,\pi_1,\pi_2,-\pi_R^1,-\pi_L^1,-\pi_R^2,-\pi_L^2,-\pi_R^3,-\pi_L^3,0,0,0,0,0,0,0,0), \tag{4.28}$$

the (degenerated) 20×20 symplectic matrix is found to be

$$f_{AB}^{(2)}(x,y)=\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}\delta(x-y), \tag{4.29}$$

where

$$a_{11}=\begin{pmatrix}
0 & 0 & 0 & 0 & \partial_x & 0 & im^1\tilde{\psi}_R^1 & im^1\tilde{\psi}_L^1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \partial_x & 0 & 0 & im^2\tilde{\psi}_R^2 & im^2\tilde{\psi}_L^2 \\
0 & 0 & 0 & 0 & 0 & 0 & im^1\tilde{\psi}_R^1 & im^1\tilde{\psi}_L^1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & im^2\tilde{\psi}_R^2 & im^2\tilde{\psi}_L^2 \\
\partial_x & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & \partial_x & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
im^1\tilde{\psi}_R^1 & 0 & im^1\tilde{\psi}_R^1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
im^1\tilde{\psi}_L^1 & 0 & im^1\tilde{\psi}_L^1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & im^2\tilde{\psi}_R^2 & 0 & im^2\tilde{\psi}_R^2 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & im^2\tilde{\psi}_L^2 & 0 & im^2\tilde{\psi}_L^2 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix},$$

$$a_{12}=\begin{pmatrix}
\frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & m^1\psi_R^1 & m^1\psi_L^1 & 0 & 0 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_L^3 \\
\frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & 0 & 0 & m^2\psi_R^2 & m^2\psi_L^2 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_L^3 \\
\frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & m^1\psi_R^1 & m^1\psi_L^1 & 0 & 0 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_L^3 \\
\frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & 0 & 0 & m^2\psi_R^2 & m^2\psi_L^2 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_L^3 \\
0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0
\end{pmatrix},$$

$$a_{21}=\begin{pmatrix}
\frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_R^3 & \frac{im^3}{2}\tilde{\psi}_R^3 & 0 & 0 & 0 & 0 & 0 & 0\\
\frac{im^3}{2}\tilde{\psi}_L^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & \frac{im^3}{2}\tilde{\psi}_L^3 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0\\
m^1\psi_R^1 & 0 & m^1\psi_R^1 & 0 & 0 & 0 & -1 & 0 & 0 & 0\\
m^1\psi_L^1 & 0 & m^1\psi_L^1 & 0 & 0 & 0 & 0 & -1 & 0 & 0\\
0 & m^2\psi_R^2 & 0 & m^2\psi_R^2 & 0 & 0 & 0 & 0 & -1 & 0\\
0 & m^2\psi_L^2 & 0 & m^2\psi_L^2 & 0 & 0 & 0 & 0 & 0 & -1\\
\frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_R^3 & 0 & 0 & 0 & 0 & 0 & 0\\
\frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix},$$

$$a_{22}=\begin{pmatrix}
0 & 0 & 0 & \cdots & 0 & -1 & 0\\
0 & 0 & 0 & \cdots & 0 & 0 & -1\\
0 & 0 & 0 & \cdots & 0 & 0 & 0\\
\multicolumn{7}{c}{\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots}\\
0 & 0 & 0 & \cdots & 0 & 0 & 0\\
-1 & 0 & 0 & \cdots & 0 & 0 & 0\\
0 & -1 & 0 & \cdots & 0 & 0 & 0
\end{pmatrix}.$$

Its zero modes are

$$\begin{aligned}\mathbf{v}^{(2)T}(x)=\Big(&u,\ v,\ \omega,\ \chi,\ 0,\ 0,\ m^1(u+\omega)\psi_R^1,\ m^1(u+\omega)\psi_L^1,\ m^2(v+\chi)\psi_R^2,\ m^2(v+\chi)\psi_L^2,\\
&\frac{m^3}{2}(u+v+\omega+\chi)\psi_R^3,\ \frac{m^3}{2}(u+v+\omega+\chi)\psi_L^3,\ u',\ v',\ im^1\tilde{\psi}_R^1(u+\omega),\\
&im^1\tilde{\psi}_L^1(u+\omega),\ im^2\tilde{\psi}_R^2(v+\chi),\ im^2\tilde{\psi}_L^2(v+\chi),\ \frac{im^3}{2}\tilde{\psi}_R^3(u+v+\omega+\chi),\\
&\frac{im^3}{2}\tilde{\psi}_L^3(u+v+\omega+\chi)\Big),\end{aligned}\tag{4.30}$$

where u, v, ω, and χ are arbitrary functions. The zero-mode condition becomes

$$\int \mathrm{d}x\,\mathbf{v}^{(2)T}(x)\frac{\delta}{\delta\xi^{(2)}}\int \mathrm{d}y'\,\mathcal{V}^{(2)}=\int \mathrm{d}x\,J_a^1\,\partial_x f_a\equiv 0,\quad f_a\equiv(\omega,\chi),\quad a=1,2.$$

Since the functions f_a are arbitrary we end up with the following constraints:

$$\Omega_5\equiv J_1^1=0,\quad \Omega_6\equiv J_2^1=0.\tag{4.31}$$

Notice that by solving the constraints, $\Omega_3=\Omega_4=\Omega_5=\Omega_6=0$, Eqs. (4.24) and (4.31), we may obtain

$$\tilde{\psi}_R^j = \psi_R^j, \quad \tilde{\psi}_L^j = \psi_L^j. \tag{4.32}$$

So, at this stage, we have Majorana spinors, the scalars ϕ_1 and ϕ_2, and the auxiliary fields. Next, introduce a third set of Lagrange multipliers into $\mathcal{L}^{(2)}$, then

$$\mathcal{L}^{(3)} = \pi_1\dot{\phi}_1 + \pi_2\dot{\phi}_2 + \dot{\psi}_R\pi_R^j + \dot{\psi}_L\pi_L^j + \dot{\eta}^1\Omega_1 + \dot{\eta}^2\Omega_2 + \dot{\eta}^3\Omega_3 + \dot{\eta}^4\Omega_4 + \dot{\eta}^5\Omega_5 + \dot{\eta}^6\Omega_6 - \mathcal{V}^{(3)}, \tag{4.33}$$

where

$$\mathcal{V}^{(3)} = \mathcal{V}^{(2)}|_{\Omega_5=\Omega_6=0} \tag{4.34}$$

or

$$\mathcal{V}^{(3)} = \tfrac{1}{24}\phi_{j,x}^2 + i\psi_R^j\psi_{R,x}^j - i\psi_L^j\psi_{L,x}^j + im_\psi^j\psi_R^j\psi_L^j(e^{-i\phi_j} + e^{i\phi_j}). \tag{4.35}$$

The new set of symplectic variables is assumed to be ordered as

$$\xi_A^{(3)} = (\eta^1, \eta^2, \eta^3, \eta^4, \eta^5, \eta^6, \phi_1, \phi_2, \psi_R^1, \psi_L^1, \psi_R^2, \psi_L^2, \psi_R^3, \psi_L^3, \pi_1, \pi_2, \pi_R^1, \pi_L^1, \pi_R^2, \pi_L^2, \pi_R^3, \pi_L^3).$$

The components of the canonical one-form are

$$a_A^{(3)} = (\Omega_1, \Omega_2, \Omega_3, \Omega_4, \Omega_5, \Omega_6, \pi_1, \pi_2, -\pi_R^1, -\pi_L^1, -\pi_R^2, -\pi_L^2, -\pi_R^3, -\pi_L^3, 0,0,0,0,0,0,0,0).$$

After some algebraic manipulations we get the third-iterated 22×22 symplectic two-form

$$f_{AB}^{(3)}(x,y) = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \delta(x-y), \tag{4.36}$$

where

$$a_{11} = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & \partial_x & 0 & im^1\tilde{\psi}_R^1 & im^1\tilde{\psi}_L^1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & \partial_x & 0 & 0 & im^2\tilde{\psi}_R^2 \\

m^1\psi_L^1 & 0 & m^1\psi_L^1 & 0 & m^1\psi_L^1 & 0 & 0 & 0 & 0 & -1 & 0 \\
0 & m^2\psi_R^2 & 0 & m^2\psi_R^2 & 0 & -m^2\psi_R^2 & 0 & 0 & 0 & 0 & -1 \\
0 & m^2\psi_L^2 & 0 & m^2\psi_L^2 & 0 & m^2\psi_L^2 & 0 & 0 & 0 & 0 & 0 \\
\frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_R^3 & \frac{m^3}{2}\psi_R^3 & -\frac{m^3}{2}\psi_R^3 & -\frac{m^3}{2}\psi_R^3 & 0 & 0 & 0 & 0 & 0 \\
\frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & \frac{m^3}{2}\psi_L^3 & 0 & 0 & 0 & 0 & 0
\end{pmatrix},$$

$$a_{22}=\begin{pmatrix}
0 & 0 & 0 & 0 & \cdots & 0 & -1 & 0 & 0 \\
0 & 0 & 0 & 0 & \cdots & 0 & 0 & -1 & 0 \\
0 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & -1 \\
0 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\
 & & & & \cdots\cdots & & & & \\
0 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\
0 & -1 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & \cdots & 0 & 0 & 0 & 0
\end{pmatrix}.$$

It can be checked that this matrix has the zero modes

$$\mathbf{v}^{(3)}(x)=\Big(u,\ v,\ \omega,\ \chi,\ y,\ z,\ 0,\ 0,\ m^1a_1^-\psi_R^1,\ m^1a_1^+\psi_L^1,\ m^2a_2^-\psi_R^2,\ m^2a_2^+\psi_L^2,\ \frac{m^3}{2}a_3^-\psi_R^3,$$
$$\frac{m^3}{2}a_3^+\psi_L^3,\ u',\ v',\ im^1a_1^-\tilde{\psi}_R^1,\ im^1a_1^+\tilde{\psi}_L^1,\ im^2a_2^-\tilde{\psi}_R^2,\ im^2a_2^+\tilde{\psi}_L^2,$$
$$i\frac{m^3}{2}a_3^-\tilde{\psi}_R^3,\ i\frac{m^3}{2}a_3^+\tilde{\psi}_L^3\Big), \tag{4.37}$$

where $a_1^+\equiv u+\omega+y$, $a_2^+\equiv v+\chi+z$, $a_3^+\equiv u+\omega+y+v+\chi+z$, $a_1^-\equiv u+\omega-y$, $a_2^-\equiv v+\chi-z$, $a_3^+\equiv u+\omega+y+v-\chi-z$, and u, v, ω, χ, y, and z are arbitrary functions. The relevant zero-mode condition gives no constraints. Then the action has the following symmetries:

$$\delta\xi_A^{(3)}=\mathbf{v_A^{(3)}}(x),\quad A=1,2,\ldots,22. \tag{4.38}$$

These symmetries allow us to fix the bilinears $i\psi_R^j\psi_L^j$ to be constants. By taking $\psi_R^j=-iC_j\overline{\theta}_j$ and $\psi_L^j=\theta_j$ $(j=1,2,3)$ with C_j being real numbers, we find that $i\psi_R^j\psi_L^j$ indeed becomes a constant. Note that θ_j and $\overline{\theta}_j$ are Grassmannian variables, while $\overline{\theta}_j\theta_j$ is an ordinary commuting number.

The two form $f_{AB}^{(3)}(x,y)$, Eq. (4.36), in the subspace $(\phi_1,\phi_2,\pi_{\phi_1},\pi_{\phi_2})$ defines a canonical symplectic structure modulo canonical transformations. The coordinates ϕ_a and π_{ϕ_a} $(a=1,2)$ are not unique. Consider a canonical transformation from (ϕ_a,π_{ϕ_a}) to $(\hat{\phi}_a,\hat{\pi}_{\hat{\phi}_a})$ such that $\phi_a=\partial F/\partial\pi_{\phi_a}$ and $\hat{\phi}_a=\partial F/\partial\hat{\pi}_{\hat{\phi}_a}$. Then, in particular if $\phi_a=\hat{\phi}_a$ one can, in principle, solve for the function F such that a manifestly covariant kinetic term appears in the new Lagrangian.

Then choosing $k=1/g$ as the overall coupling constant, we are left with

$$\mathcal{L}''=\sum_{j=1}^{3}\left[\frac{1}{24g}\partial_\mu\phi_j\partial^\mu\phi_j+\frac{M_j}{g}\cos\phi_j\right]+\mu_1\partial_x\phi_1+\mu_2\partial_x\phi_2, \tag{4.39}$$

where $M_j=m_\psi^jC_j$. This defines the *generalized sine-Gordon model* (GSG). In addition we get the terms multiplied by chemical potentials μ_1 and μ_2 $(\dot{\eta}^{1,2}\rightarrow-\mu_{1,2})$. These are just the topological charge densities, and are related to the conservation of the number of kinks minus antikinks $Q^a_{\text{topol}}=1/\pi\int_{-\infty}^{+\infty}\mathrm{d}x\,\partial_x\phi_a$.

In the above-mentioned gauge fixing procedures the possibility of Gribov-type ambiguities deserves a careful analysis. See Ref. 11 for a discussion in the $sl(2)$ ATM case. However, in Sec. V, we provide indirect evidence of the absence of such ambiguities, at least for the soliton sector of the model.

V. THE SOLITON/PARTICLE CORRESPONDENCES

The $sl(2)$ ATM theory contains the sine-Gordon (SG) and the massive Thirring (MT) models describing the soliton/particle correspondence of its spectrum.[3,11,12] The ATM one-(anti)soliton solution satisfies the remarkable SG and MT classical correspondence in which, apart from the Noether and topological currents equivalence, MT spinor bilinears are related to the exponential of the SG field.[25] The last relationship was exploited in Ref. 4 to decouple the $sl(2)$ ATM equations of motion into the SG and MT ones. Here we provide a generalization of that correspondence to the $sl(3)$ ATM case. In fact, consider the relationships

$$\frac{\psi_R^1\tilde{\psi}_L^1}{i}=-\frac{1}{4\Delta}[(m_\psi^1p_1-m_\psi^3p_4-m_\psi^2p_5)e^{i(\varphi_2-2\varphi_1)}+m_\psi^2p_5e^{3i(\varphi_2-\varphi_1)}+m_\psi^3p_4e^{-3i\varphi_1}-m_\psi^1p_1], \tag{5.1}$$

$$\psi_R^2\tilde{\psi}_L^2=-\frac{1}{4\Delta}[(m_\psi^2p_2-m_\psi^1p_5-m_\psi^3p_6)e^{i(\varphi_1-2\varphi_2)}+m_\psi^1p_5e^{3i(\varphi_1-\varphi_2)}-m_\psi^3p_6e^{-3i\varphi_2}-m_\psi^2p_2], \tag{5.2}$$

$$\frac{\tilde{\psi}_R^3\psi_L^3}{i}=-\frac{1}{4\Delta}[(m_\psi^3p_3-m_\psi^1p_4+m_\psi^2p_6)e^{i(\varphi_1+\varphi_2)}+m_\psi^1p_4e^{3i\varphi_1}-m_\psi^2p_6e^{3i\varphi_2}-m_\psi^3p_3], \tag{5.3}$$

where $\Delta\equiv\overline{a}_{11}\overline{a}_{22}\overline{a}_{33}+2\overline{a}_{12}\overline{a}_{23}\overline{a}_{13}-\overline{a}_{11}(\overline{a}_{23})^2-(\overline{a}_{12})^2\overline{a}_{33}-(\overline{a}_{13})^2\overline{a}_{22}$; $p_1\equiv(\overline{a}_{23})^2-\overline{a}_{22}\overline{a}_{33}$; $p_2\equiv(\overline{a}_{13})^2-\overline{a}_{11}\overline{a}_{33}$; $p_3\equiv(\overline{a}_{12})^2-\overline{a}_{11}\overline{a}_{22}$; $p_4\equiv\overline{a}_{12}\overline{a}_{23}-\overline{a}_{22}\overline{a}_{13}$; $p_5\equiv\overline{a}_{13}\overline{a}_{23}-\overline{a}_{12}\overline{a}_{33}$; $p_6\equiv\overline{a}_{11}\overline{a}_{23}-\overline{a}_{12}\overline{a}_{13}$ and the $\overline{a}_{ij}$'s being the current–current coupling constants of the GMT model (3.13). Relationships (5.1)–(5.3) supplied with the conditions (2.1)–(2.3) and conveniently substituted into Eqs. (A13) and (A15)–(A23) decouple the $sl(3)^{(1)}$ CATM equations into the GSG (4.39) and GMT (3.13) equations of motion, respectively.

Moreover, one can show that the GSG (4.39) M_j parameters and the GMT (3.13) couplings $\overline{a}_{ij}$ are related by

$$\frac{2\Delta M_1}{g(m_\psi^1)^2}=\overline{a}_{22}\left(-\frac{m_\psi^3}{m_\psi^1}\overline{a}_{13}+\overline{a}_{33}\right)+\overline{a}_{23}\left(-\overline{a}_{23}+\frac{m_\psi^3}{m_\psi^1}\overline{a}_{12}\right), \tag{5.4}$$

$$\frac{2\Delta M_2}{g(m_\psi^2)^2}=\overline{a}_{11}\left(-\frac{m_\psi^3}{m_\psi^2}\overline{a}_{23}+\overline{a}_{33}\right)+\overline{a}_{13}\left(-\overline{a}_{13}+\frac{m_\psi^3}{m_\psi^2}\overline{a}_{12}\right), \tag{5.5}$$

$$\frac{2\Delta M_3}{g(m_\psi^3)^2}=-\frac{m_\psi^1m_\psi^2}{(m_\psi^3)^2}(\overline{a}_{12}\overline{a}_{33}-\overline{a}_{13}\overline{a}_{23})-\overline{a}_{11}\overline{a}_{22}+(\overline{a}_{12})^2. \tag{5.6}$$

Various limiting cases of the relationships (5.1)–(5.3) and (5.4)–(5.6) are possible. First, let us consider

$$\overline{a}_{jk}\to\begin{cases}\infty & j=k\neq l \quad (\text{for a given } l)\\ \text{finite} & \text{other cases}\end{cases} \tag{5.7}$$

then one has

$$\frac{\psi_R^l\tilde{\psi}_L^l}{i}=\frac{m_\psi^l}{4}(e^{-i\phi_l}-1), \quad \psi_R^j\tilde{\psi}_L^j=0, \quad j\neq l \tag{5.8}$$

for $\overline{a}_{ll}=\delta_l g$ ($\delta_{1,2}=1$, $\delta_3=-1$). The three species of one-soliton solutions of the $sl(3)$ ATM theory (2.4), found in Ref. 5 and described in Sec. II, satisfy the relationship (5.8).[4] Moreover, from Eqs. (5.4) to (5.6) taking the same limits as in (5.7) one has

$$M_l=\frac{(m_\psi^l)^2}{2}, \quad M_j=0, \quad j\neq l. \tag{5.9}$$

Therefore, relationships (5.1)–(5.3) incorporate each $sl(2)$ ATM submodel (particle/soliton) weak/strong coupling phases, i.e., the MT/SG correspondence.[4,11]

Then, the currents equivalence (A29), relationships (5.1)–(5.3), and conditions (2.1)–(2.3) satisfied by the one-soliton sector of CATM theory allowed us to establish the correspondence between the GSG and GMT models, thus extending the MT/SG result.[25] It could be interesting to obtain the counterpart of Eqs. (5.1)–(5.3) for the $N_S\geqslant 2$ solitons, e.g., along the lines of Ref. 25. For $N_S=2$, Eq. (A29) still holds;[5] and Eqs. (2.1)–(2.3) are satisfied for the species (α_i,α_i).

Second, consider the limit

$$\overline{a}_{ik}\to\begin{cases}\infty & i=k=j \quad (\text{for a chosen } j;\ j=1,2)\\ \text{finite} & \text{other cases}\end{cases}, \tag{5.10}$$

one gets $M_j=0$ and

$$4\overline{\Delta}\frac{\psi_R^l\tilde{\psi}_L^l}{i}=(m_\psi^3\overline{a}_{l3}-m_\psi^l\overline{a}_{33})e^{-i\phi_l}-m_\psi^3\overline{a}_{l3}e^{-3i\varphi_l}+m_\psi^l\overline{a}_{33}, \quad l\neq j,$$
$$4\overline{\Delta}\frac{\psi_R^3\tilde{\psi}_L^3}{i}=(m_\psi^3\overline{a}_{ll}-m_\psi^l\overline{a}_{l3})e^{-i\phi_3}+m_\psi^l\overline{a}_{l3}e^{-3i\varphi_l}+m_\psi^3\overline{a}_{ll}, \tag{5.11}$$

$$\psi_R^j\tilde{\psi}_L^j=0, \tag{5.12}$$

where $\overline{\Delta}\equiv 4(\overline{a}_{ll}\overline{a}_{33}-(\overline{a}_{l3})^2)$. The parameters are related by $(m_\psi^3)^2\overline{a}_{ll}M_l=m_\psi^l(m_\psi^3\overline{a}_{l3}-m_\psi^l\overline{a}_{33})M_3$. In the case $M_l=M_3=M$ and redefining the fields as $\phi_l=\sqrt{12g}(A+B)$, $\phi_j=-\sqrt{12g}B$ in the GSG sector, one gets the Lagrangian

$$\mathcal{L}_{\mathrm{BL}}=\frac{1}{2}(\partial_\mu A)^2+\frac{1}{2}(\partial_\mu B)^2+2\frac{M}{g}\cos\sqrt{24g}A\cos\sqrt{72g}B, \tag{5.13}$$

which is a particular case of the Bukhvostov–Lipatov model (BL).[26] It corresponds to a GMT-type theory with two Dirac spinors. The BL model is not classically integrable,[27] and some discussions have appeared in the literature about its quantum integrability.[28]

Alternatively, if one allows the limit $\overline{a}_{33}\to\infty$ one gets $\psi_R^3\tilde{\psi}_L^3=0$, and additional relations for the ψ^1,ψ^2 spinors and the φ_a scalars. The parameters are related by

$$\frac{M_1}{(m_\psi^1)^2\overline{a}_{22}}=\frac{M_2}{(m_\psi^2)^2\overline{a}_{11}}=-\frac{M_3}{m_\psi^1m_\psi^2\overline{a}_{12}}.$$

Then we left with two Dirac spinors in the GMT sector and all the terms of the GSG model. The later resembles the 2-cosine model studied in Ref. 29 in some submanifold of its renormalized parameter space.

VI. GENERALIZATION TO HIGHER RANK LIE ALGEBRA

The procedures presented so far can directly be extended to the CATM model for the affine Lie algebra $sl(n)^{(1)}$ furnished with the principal gradation. According to the construction of Ref. 2, these models have soliton solutions for an off-critical submodel, possess a $U(1)$ vector current proportional to a topological current, apart from the conformal symmetry they exhibit a $(U(1)_R)^{n-1}\otimes(U(1)_L)^{n-1}$ left–right local gauge symmetry, and the equations of motion describe the dynamics of the scalar fields φ_a, η, $\tilde{\nu}$ $(a=1,\ldots,n-1)$ and the Dirac spinors ψ^{α_j}, $\tilde{\psi}^{\alpha_j}$ $(j=1,\ldots,N;\ N\equiv(n/2)\ (n-1)=$number of positive roots α_j of the simple Lie algebra $sl(n))$ with one-(anti)soliton solution associated with the field $\alpha_j\cdot\vec{\varphi}$ $(\vec{\varphi}=\Sigma_{a=1}^{n-1}\varphi_a\alpha_a$, $\alpha_a=$simple roots of $sl(n))$ for each pair of Dirac fields $(\psi^{\alpha_j},\ \tilde{\psi}^{\alpha_j})$.[2] Therefore, it is possible to define the off-critical real Lagrangian $sl(n)$ ATM model for the solitonic sector of the theory. The reality conditions would generalize Eqs. (2.1)–(2.3), i.e., the new φ's real and the identifications $\tilde{\psi}^{\alpha_j}\sim(\psi^{\alpha_j})^*$ (up to $\pm$ signs). To apply the symplectic analysis of $sl(n)$ ATM one must impose $(n-1)$ constraints in the Lagrangian, analogous to (3.1), due to the above-given local symmetries. The outcome will be a parent Lagrangian of a generalized massive Thirring model (GMT) with N Dirac fields and a generalized sine-Gordon model (GSG) with $(n-1)$ fields. The decoupling of the Toda fields and Dirac fields in the equations of motion of $sl(n)^{(1)}$ CATM, analogous to (A13) and (A15)–(A23), could be performed by an extension of the relationships (5.1)–(5.3) and (2.1)–(2.3).

VII. DISCUSSIONS AND OUTLOOK

We have shown, in the context of FJ and symplectic methods, that the $sl(3)$ ATM (2.4) theory is a parent Lagrangian[18] from which both the GMT (3.13) and the GSG (4.39) models are derivable. From (3.13) and (4.39), it is also clear the duality exchange of the couplings: $g \to 1/g$. The various soliton/particle species correspondences are uncovered. The soliton sector satifies the $U(1)$ vector and topological currents equivalence (A29) and decouples the equations of motion into both dual sectors, through the relationships (5.1)–(5.3) [supplied with (2.1)–(2.3)]. Relationships (5.1)–(5.3) contain each $sl(2)$ ATM submodel soliton solution. In connection to these points, recently a parent Lagrangian method was used to give a generalization of the dual theories concept for non-p-form fields.[30] In Ref. 30, the parent Lagrangian contained both types of fields, from which each dual theory was obtained by eliminating the other fields through the equations of motion.

On the other hand, in non-Abelian bosonization of massless fermions,[31] the fermion bilinears are identified with bosonic operators. Whereas, in Abelian bosonization[32] there exists an identification between the massive fermion operator (charge nonzero sector) and a nonperturbative bosonic soliton operator.[33] Recently, it has been shown that symmetric space sine-Gordon models bosonize the massive non-Abelian (free) fermions providing the relationships between the fermions and the relevant solitons of the bosonic model.[34] The ATM model allowed us to establish these types of relationships for interacting massive spinors in the spirit of particle/soliton correspondence. We hope that the quantization of the ATM theories and the related WZNW models, and in particular relationships (A34), would provide the bosonization of the nonzero charge sectors of the GMT fermions in terms of their associated Toda and WZNW fields. In addition, the above-given approach to the GMT/GSG duality may be useful to construct the conserved currents and the algebra of their associated charges in the context of the CATM $\to$ ATM reduction. These currents in the MT/SG case were constructed treating each model as a perturbation on a conformal field theory (see Ref. 35 and references therein).

Moreover, two-dimensional models with four-fermion interactions have played an important role in the understanding of QCD (see, e.g., Ref. 36 and references therein). Besides, the GMT model contains explicit mass terms: most integrable models such as the Gross–Neveu, SU(2), and U(1) Thirring models all present spontaneous mass generation, the exception being the massive Thirring model. A GMT submodel with $a_{ii}=0$, $a_{ij}=1$ $(i>j)$ and equal m_{ψ}^{j}'s defines the so-called extended Bukhvostov–Lipatov model (BL) and has recently been studied by means of a bosonization technique.[37] Finally, BL type models were applied to N-body problems in nuclear physics.[17]

APPENDIX: THE $sl(3)^{(1)}$ CATM MODEL

We summarize the construction and some properties of the CATM model relevant to our discussions.[38] More details can also be found in Ref. 5. Consider the zero curvature condition $\partial_+ A_- - \partial_- A_+ + [A_+, A_-] = 0$. The potentials take the form

$$A_+ = -BF^+B^{-1}, \quad A_- = -\partial_- BB^{-1} + F^-, \tag{A1}$$

with

$$F^+ = E^3 + F_1^+ + F_2^+, \quad F^- = E^{-3} + F_1^- + F_2^-, \tag{A2}$$

where $E^{\pm 3}\equiv \mathbf{m}\cdot H^{\pm}=\frac{1}{6}[(2m^1_\psi+m^2_\psi)H_1^{\pm 1}+(2m^2_\psi+m^1_\psi)H_2^{\pm 1}]$ and the $F_i^{\pm}$'s and B contain the spinor fields and scalars of the model, respectively,

$$F_1^+=\sqrt{im^1_\psi}\psi^1_R E^0_{\alpha_1}+\sqrt{im^2_\psi}\psi^2_R E^0_{\alpha_2}+\sqrt{im^3_\psi}\tilde{\psi}^3_R E^1_{-\alpha_3}, \tag{A3}$$

$$F_2^+=\sqrt{im^3_\psi}\psi^3_R E^0_{\alpha_3}+\sqrt{im^1_\psi}\tilde{\psi}^1_R E^1_{-\alpha_1}+\sqrt{im^2_\psi}\tilde{\psi}^2_R E^1_{-\alpha_2}, \tag{A4}$$

$$F_1^-=\sqrt{im^3_\psi}\psi^3_L E^{-1}_{\alpha_3}-\sqrt{im^1_\psi}\tilde{\psi}^1_L E^0_{-\alpha_1}-\sqrt{im^2_\psi}\tilde{\psi}^2_L E^0_{-\alpha_2}, \tag{A5}$$

$$F_2^-=\sqrt{im^1_\psi}\psi^1_L E^{-1}_{\alpha_1}+\sqrt{im^2_\psi}\psi^2_L E^{-1}_{\alpha_2}-\sqrt{im^3_\psi}\tilde{\psi}^3_L E^0_{-\alpha_3}, \tag{A6}$$

$$B=e^{i\varphi_1 H_1^0+i\varphi_2 H_2^0}e^{\tilde{\nu}C}e^{\eta Q_{ppal}}, \tag{A7}$$

where $E^n_{\alpha_i}$, H_1^n, H_2^n, and C $(i=1,2,3;\ n=0,\pm 1)$ are some generators of $sl(3)^{(1)}$; Q_{ppal} being the principal gradation operator. The commutation relations for an affine Lie algebra in the Chevalley basis are

$$[H_a^m,H_b^n]=mC\frac{2}{\alpha_a^2}K_{ab}\delta_{m+n,0}, \tag{A8}$$

$$[H_a^m,E^n_{\pm\alpha}]=\pm K_{\alpha a}E^{m+n}_{\pm\alpha}, \tag{A9}$$

$$[E^m_\alpha,E^n_{-\alpha}]=\sum_{a=1}^{r} l_a^\alpha H_a^{m+n}+\frac{2}{\alpha^2}mC\delta_{m+n,0}, \tag{A10}$$

$$[E^m_\alpha,E^n_\beta]=\varepsilon(\alpha,\beta)E^{m+n}_{\alpha+\beta};\quad \text{if } \alpha+\beta \text{ is a roo}, \tag{A11}$$

$$[D,E^n_\alpha]=nE^n_\alpha,\quad [D,H^n_a]=nH^n_a, \tag{A12}$$

where $K_{\alpha a}=2\alpha.\alpha_a/\alpha_a^2=n_b^\alpha K_{ba}$, with n_a^α and l_a^α being the integers in the expansions $\alpha=n_a^\alpha\alpha_a$ and $\alpha/\alpha^2=l_a^\alpha\alpha_a/\alpha_a^2$, and $\varepsilon(\alpha,\beta)$ the relevant structure constants.

Take $K_{11}=K_{22}=2$ and $K_{12}=K_{21}=-1$ as the Cartan matrix elements of the simple Lie algebra $sl(3)$. Denoting by α_1 and α_2 the simple roots and the highest one by $\psi(=\alpha_1+\alpha_2)$, one has $l_a^\psi=1(a=1,2)$, and $K_{\psi 1}=K_{\psi 2}=1$. Take $\varepsilon(\alpha,\beta)=-\varepsilon(-\alpha,-\beta)$, $\varepsilon_{1,2}\equiv\varepsilon(\alpha_1,\alpha_2)=1$, $\varepsilon_{-1,3}\equiv\varepsilon(-\alpha_1,\psi)=1$ and $\varepsilon_{-2,3}\equiv\varepsilon(-\alpha_2,\psi)=-1$.

One has $Q_{ppal}\equiv\Sigma_{a=1}^2\mathbf{s}_a\lambda_a^v.H+3D$, where λ_a^v are the fundamental co-weights of $sl(3)$, and the principal gradation vector is $\mathbf{s}=(1,1,1)$.[39]

The zero curvature condition gives the following equations of motion

$$\frac{\partial^2\varphi_a}{4i\,e^\eta}=m^1_\psi[e^{\eta-i\phi_a}\tilde{\psi}^l_R\psi^l_L+e^{i\phi_a}\tilde{\psi}^l_L\psi^l_R]+m^3_\psi[e^{-i\phi_3}\tilde{\psi}^3_R\psi^3_L+e^{\eta+i\phi_3}\tilde{\psi}^3_L\psi^3_R],\quad a=1,2, \tag{A13}$$

$$-\frac{\partial^2\tilde{\nu}}{4}=im^1_\psi e^{2\eta-\phi_1}\tilde{\psi}^1_R\psi^1_L+im^2_\psi e^{2\eta-\phi_2}\tilde{\psi}^2_R\psi^2_L+im^3_\psi e^{\eta-\phi_3}\tilde{\psi}^3_R\psi^3_L+\mathbf{m}^2e^{3\eta}, \tag{A14}$$

$$-2\partial_+\psi^1_L=m^1_\psi e^{\eta+i\phi_1}\psi^1_R,\quad -2\partial_+\psi^2_L=m^2_\psi e^{\eta+i\phi_2}\psi^2_R, \tag{A15}$$

$$2\partial_-\psi^1_R=m^1_\psi e^{2\eta-i\phi_1}\psi^1_L+2i\left(\frac{m^2_\psi m^3_\psi}{im^1_\psi}\right)^{1/2}e^\eta(-\psi^3_R\tilde{\psi}^2_L e^{i\phi_2}-\tilde{\psi}^2_R\psi^3_L e^{-i\phi_3}), \tag{A16}$$

$$2\partial_- \psi_R^2 = m_\psi^2 e^{2\eta - i\phi_2}\psi_L^2 + 2i\left(\frac{m_\psi^1 m_\psi^3}{i m_\psi^2}\right)^{1/2} e^{\eta}(\psi_R^3 \tilde{\psi}_L^1 e^{i\phi_1} + \tilde{\psi}_R^1 \psi_L^3 e^{-i\phi_3}), \tag{A17}$$

$$-2\partial_+ \psi_L^3 = m_\psi^3 e^{2\eta + i\phi_3}\psi_R^3 + 2i\left(\frac{m_\psi^1 m_\psi^2}{i m_\psi^3}\right)^{1/2} e^{\eta}(-\psi_L^1 \psi_R^2 e^{i\phi_2} + \psi_L^2 \psi_R^1 e^{i\phi_1}), \tag{A18}$$

$$2\partial_- \psi_R^3 = m_\psi^3 e^{\eta - i\phi_3}\psi_L^3, \quad 2\partial_- \tilde{\psi}_R^1 = m_\psi^1 e^{\eta + i\phi_1}\tilde{\psi}_L^1, \tag{A19}$$

$$-2\partial_+ \tilde{\psi}_L^1 = m_\psi^1 e^{2\eta - i\phi_1}\tilde{\psi}_R^1 + 2i\left(\frac{m_\psi^2 m_\psi^3}{i m_\psi^1}\right)^{1/2} e^{\eta}(-\psi_L^2 \tilde{\psi}_R^3 e^{-i\phi_3} - \tilde{\psi}_L^3 \psi_R^2 e^{i\phi_2}), \tag{A20}$$

$$-2\partial_+ \tilde{\psi}_L^2 = m_\psi^2 e^{2\eta - i\phi_2}\tilde{\psi}_R^2 + 2i\left(\frac{m_\psi^1 m_\psi^3}{i m_\psi^2}\right)^{1/2} e^{\eta}(\psi_L^1 \tilde{\psi}_R^3 e^{-i\phi_3} + \tilde{\psi}_L^3 \psi_R^1 e^{i\phi_1}), \tag{A21}$$

$$2\partial_- \tilde{\psi}_R^2 = m_\psi^2 e^{\eta + i\phi_2}\tilde{\psi}_L^2, \quad -2\partial_+ \tilde{\psi}_L^3 = m_\psi^3 e^{\eta - i\phi_3}\tilde{\psi}_R^3, \tag{A22}$$

$$2\partial_- \tilde{\psi}_R^3 = m_\psi^3 e^{2\eta + i\phi_3}\tilde{\psi}_L^3 + 2i\left(\frac{m_\psi^1 m_\psi^2}{i m_\psi^3}\right)^{1/2} e^{\eta}(\tilde{\psi}_R^1 \tilde{\psi}_L^2 e^{i\phi_2} - \tilde{\psi}_R^2 \tilde{\psi}_L^1 e^{i\phi_1}), \tag{A23}$$

$$\partial^2 \eta = 0, \tag{A24}$$

where $\phi_1 \equiv 2\varphi_1 - \varphi_2$, $\phi_2 \equiv 2\varphi_2 - \varphi_1$, $\phi_3 \equiv \varphi_1 + \varphi_2$.

Apart from the *conformal invariance* the above-presented equations exhibit the $(U(1)_L)^2 \otimes (U(1)_R)^2$ *left–right local gauge symmetry*

$$\varphi_a \to \varphi_a + \theta_+^a(x_+) + \theta_-^a(x_-), \quad a = 1,2, \tag{A25}$$

$$\tilde{\nu} \to \tilde{\nu}, \quad \eta \to \eta, \tag{A26}$$

$$\psi^i \to e^{i(1+\gamma_5)\Theta_+^i(x_+) + i(1-\gamma_5)\Theta_-^i(x_-)}\psi^i, \tag{A27}$$

$$\tilde{\psi}^i \to e^{-i(1+\gamma_5)(\Theta_+^i)(x_+) - i(1-\gamma_5)(\Theta_-^i)(x_-)}\tilde{\psi}^i, \quad i = 1,2,3, \tag{A28}$$

$$\Theta_\pm^1 \equiv \pm\theta_\pm^2 \mp 2\theta_\pm^1, \quad \Theta_\pm^2 \equiv \pm\theta_\pm^1 \mp 2\theta_\pm^2, \quad \Theta_\pm^3 \equiv \Theta_\pm^1 + \Theta_\pm^2.$$

One can get global symmetries for $\theta_\pm^a = \mp\theta_\mp^a =$ constants. For a model defined by a Lagrangian these would imply the presence of two vector and two chiral conserved currents. However, it was found only half of such currents.[5] This is a consequence of the lack of a Lagrangian description for the $sl(3)^{(1)}$ CATM; however see the following.

The gauge fixing of the conformal symmetry, by setting the field η to a constant, is used to stablish the $U(1)$ vector, $J^\mu = \Sigma_{j=1}^3 m_\psi^j \overline{\psi^j}\gamma^\mu \psi^j$, and topological currents equivalence.[2,11] Moreover, it has been shown that the soliton solutions are in the orbit of the solution $\eta = 0$. The remarkable equivalence is

$$\sum_{j=1}^{3} m_\psi^j \overline{\psi^j}\gamma^\mu \psi^j \equiv \epsilon^{\mu\nu}\partial_\nu(m_\psi^1 \varphi_1 + m_\psi^2 \varphi_2), \quad m_\psi^3 = m_\psi^1 + m_\psi^2, \quad m_\psi^i > 0. \tag{A29}$$

The CATM theory has a local Lagrangian in terms of the B and the (two-loop) WZNW fields.[2] The relations between their fields can be obtained from

$$F^- = B\partial_- M M^{-1} B^{-1}, \quad F^+ = B^{-1} N^{-1}\partial_+ N B, \tag{A30}$$

where

$$M=\exp\left(\sum_{s>0}\zeta_s\right),\quad N=\exp\left(\sum_{s>0}\xi_{-s}\right), \tag{A31}$$

provided that the following constraints are imposed:

$$(\partial_- MM^{-1})_{-3}=B^{-1}(\mathbf{m}\cdot H^{-1})B,\quad (\partial_- MM^{-1})_{<-3}=0. \tag{A32}$$

and

$$(N^{-1}\partial_+ N)_3=B\,(\mathbf{m}\cdot H^1)B^{-1},\quad (N^{-1}\partial_+ N)_{>3}=0. \tag{A33}$$

In (A31) and (A32) and (A33) s and the subscripts denote the principal gradation structure of the relevant group elements.

The relationships are

$$\sqrt{im_\psi^3}\psi_L^3=e^{-\eta+i\phi_3}\partial_-\xi_{-1}^3,\quad -\sqrt{im_\psi^1}\tilde{\psi}_L^1=e^{-\eta-i\phi_1}\partial_-\xi_{-1}^1,$$

$$-\sqrt{im_\psi^2}\tilde{\psi}_L^2=e^{-\eta-i\phi_2}\partial_-\xi_{-1}^2,\quad \sqrt{im_\psi^3}\psi_R^1=e^{\eta-i\phi_1}\partial_+\zeta_1^1,$$

$$\sqrt{im_\psi^2}\psi_R^2=e^{\eta-i\phi_2}\partial_+\zeta_1^2,\quad \sqrt{im_\psi^3}\tilde{\psi}_R^3=e^{\eta+i\phi_3}\partial_+\zeta_1^3,$$

$$\sqrt{im_\psi^1}\psi_L^1e^{2\eta}=e^{i\phi_1}\partial_-\xi_{-2}^1+\tfrac{1}{2}(\xi_{-1}^3\partial_-\xi_{-1}^2\epsilon_{3,-2}+\xi_{-1}^2\partial_-\xi_{-1}^3\epsilon_{-2,3})e^{i\phi_1},$$

$$\sqrt{im_\psi^2}\psi_L^2e^{2\eta}=e^{i\phi_2}\partial_-\xi_{-2}^2+\tfrac{1}{2}(\xi_{-1}^3\partial_-\xi_{-1}^1\epsilon_{3,-1}+\xi_{-1}^1\partial_-\xi_{-1}^3\epsilon_{-1,2})e^{i\phi_2}, \tag{A34}$$

$$-\sqrt{im_\psi^3}\tilde{\psi}_L^3e^{2\eta}=e^{-i\phi_3}\partial_-\xi_{-2}^3+\tfrac{1}{2}(\xi_{-1}^1\partial_-\xi_{-1}^2\epsilon_{-1,-2}+\xi_{-1}^2\partial_-\xi_{-1}^1\epsilon_{-2,-1})e^{-i\phi_3},$$

$$\sqrt{im_\psi^3}\psi_R^3e^{-2\eta}=e^{-i\phi_3}\partial_+\zeta_2^3-\tfrac{1}{2}(\zeta_1^1\partial_+\zeta_1^2\epsilon_{1,2}+\zeta_1^2\partial_+\zeta_1^1\epsilon_{2,1})e^{-i\phi_3},$$

$$\sqrt{im_\psi^1}\tilde{\psi}_R^1e^{-2\eta}=e^{i\phi_1}\partial_+\zeta_2^1-\tfrac{1}{2}(\zeta_1^3\partial_+\zeta_1^2\epsilon_{-3,2}+\zeta_1^2\partial_+\zeta_1^3\epsilon_{2,-3})e^{i\phi_1},$$

$$\sqrt{im_\psi^2}\tilde{\psi}_R^2e^{-2\eta}=e^{i\phi_2}\partial_+\zeta_2^2-\tfrac{1}{2}(\zeta_1^3\partial_+\zeta_1^1\epsilon_{-3,1}+\zeta_1^1\partial_+\zeta_1^3\epsilon_{1,-3})e^{i\phi_2}.$$

We observe that the WZNW fields ξ_{-1}^i, ξ_{-2}^i, ζ_1^i, ζ_2^i $(i=1,2,3)$ are nonlocal in terms of the spinors and scalars $\{\psi_i, \widetilde{\psi}_i, \varphi_1, \varphi_2, \tilde{\nu}, \text{ and } \eta\}$. Then the CATM model Lagrangian must be nonlocal when written in terms of its fields.

(Received 23 April 2001; accepted for publication 4 January 2002)

The system of evolution equations for general motion of surfaces in orthogonal coordinates is analyzed to reduce the number of variables as well as equations. The explicit expression of the Lund–Regge surface is obtained. When the surface corresponds to the Lund–Regge equation, we prove that some components of velocity satisfy the linearizations of the Lund–Regge equation. The soliton solution is derived and one special case of the Lund–Regge surface is studied.
 [DOI: 10.1063/1.1452776]

I. INTRODUCTION

Dynamics of surfaces, interfaces, and front is an important ingredient of numerous nonlinear phenomena in classical physics.[1–4] In some cases, many dynamics can be modeled by the nonlinear partial differential equations which describe an evolution of surfaces in time.[3–5] Moreover, a local evolution law may be established in terms of a velocity field on the surface.[4] In addition, interesting papers by Nakayama *et al.*,[5,6] Mclachlan and Segur,[7] Konopelchenko,[8,9] and Szwabowicz[10] concerned the motion of surfaces and linked it to solitonic equations. Among them, Nakayama and Wadati[5] discussed the motion of surfaces. They calculated time evolutions for sphere, surface of revolution, and developable surface in details. In the appendix, they derived the Lund–Regge (LR) equation, but because of over-restrictions on the metric and the curvature tensor, they did not solve the time evolution of this system by using their theory. It is known that the LR equation is one soliton equation.[11–13] Sym *et al.*[14–16] developed the theory of the soliton surface which provided a geometrical interpretation for many integrable physical systems and is very useful to explicitly construct large classes of surfaces. Bobenko[17] reformulated it in a form familiar to the soliton theory which made it easier to apply the analytical method of this theory to integrable cases. Fokas *et al.*[18] show that the problem of the immersion of a two-dimensional surface into a three-dimensional Euclidean space is related to the problem of studying surfaces in Lie groups and Lie algebras, and proposed a more general formula for surface immerse into Lie algebra. Cieslinski *et al.*[19] generalized it and proved that many results concerning immersion on Lie algebra can be reduced to or interpreted within the soliton surfaces approach. We find that the above-mentioned method can be used to study the motion of surfaces and integrable system. So, we identify R^3 with su(2) and use the soliton theory to discuss the surfaces associated with the LR equation. Making use of one coordinate's transformation and spin transformation, we calculated the explicit expression of the surface.

In Ref. 20, Li suggested one approach to consider the motion of surfaces with constant negative curvature in asymptotic coordinates. Then in Refs. 21 and 22 we generalized this approach to discuss the evolution of surfaces in geodesic coordinates. In this paper, we will use this method to consider the system of evolution equation for general motion of surfaces in orthogonal

a)Electronic mail: ysli@ustc.edu.cn

coordinates, especially for the surfaces associated with the LR equation. We shall prove that when the surface corresponds to the LR equation, some components of velocity satisfy the linearizations of the LR equation. The evolution equation associated with the motion of this surface is derived as $2+1$ dimensional integrable equations.

In Sec. II, we describe the correspondence between R^3 and su(2). The explicit expression of the surface corresponding to the LR equation is obtained. In Sec. III, we analyze the system of evolution equations for general motion of surfaces in orthogonal coordinates and obtain one system with eight functions and twelve equations. So, under suitable conditions, we prove a fundamental theorem: this system can be reduced to an equivalent system with eight functions and eight equations. In Sec. IV, we prove that some velocity components of the motion of the LR surface should satisfy the linearization equation of the LR equation. Its corresponding motion equation is also derived. In Sec. V, given special velocity, $2+1$ dimensional integrable equations are obtained, which recovers the relations between the motion of surfaces and the soliton equations, the soliton solution is derived too. In Sec. VI, we study one special case of the LR surface. We conclude and give some remarks in Sec. VII.

II. THE SURFACES IN ORTHOGONAL COORDINATES AND THE LR EQUATION

Let $F(x,y)$ be a smooth surface in a three-dimensional Euclidean space, which is given by a vector-valued function

$$F=(F_1,F_2,F_3):R^2\to R^3.$$

To construct and investigate the surface in R^3 by analytical methods, we use 2×2 matrices instead of 3×3 matrices. More explicitly, we characterize the surface in terms of su(2). Let $\{e_1,e_2,e_3\}$ be the orthonormal bases of R^3 and $\{f_1,f_2,f_3\}$ be the orthonormal bases of su(2),

$$f_1=\frac{1}{2}\begin{pmatrix}0 & i\\ i & 0\end{pmatrix},\quad f_2=\frac{1}{2}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix},\quad f_3=\frac{1}{2}\begin{pmatrix}i & 0\\ 0 & -i\end{pmatrix}.$$

Then $\sigma_j=-2if_j(j=1,2,3)$ are Pauli matrices. Map the vector space R^3 with su(2),

$$F=\sum_{j=1}^{3}F_je_j\mapsto\sum_{j=1}^{3}F_jf_j$$

(the inner product $\langle F,G\rangle=-2\,\mathrm{tr}\,F\cdot G$ defines a Euclidean scalar product in R^3 and the Lie bracket corresponds to the vector product in R^3). So we identify three-dimensional Euclidean space with su(2). In the sequel we will follow the notation of Ref. 18.

Similarly to the method which Fokas and Gelfand mentioned in Ref. 18, in orthogonal coordinates, the first fundamental form of surfaces can be expressed by

$$Ih^2\,\mathrm{d}x^2+g^2\,\mathrm{d}y^2,$$

where

$$F_x=\psi^{-1}hf_1\psi,\quad F_y=\psi^{-1}gf_2\psi,\quad bfN=\psi^{-1}f_3\psi \tag{1}$$

and $\psi\in\mathrm{SU}(2)$ satisfies

$$\psi_x=U\psi,\quad \psi_y=V\psi, \tag{2}$$

$$U=\sum_{j=1}^{3}u_jf_j,\quad V=\sum_{j=1}^{3}v_jf_j, \tag{3}$$

where u_j, v_j, $(j=1, 2, 3)$ are functions of (x,y). Then the second fundamental form of surface can be obtained

$$II = L\,\mathrm{d}x^2 + 2M\,\mathrm{d}x\,\mathrm{d}y + N\mathrm{d}y^2,$$

$$L = -\langle F_x, \mathbf{N}_x\rangle = hu_2, \quad N = -\langle F_y, \mathbf{N}_y\rangle = -gv_1,$$

$$M = -\langle F_x, \mathbf{N}_y\rangle = -\langle F_y, \mathbf{N}_x\rangle = hv_2.$$

From the compatibility condition $F_{xy}=F_{yx}$, it yields

$$u_3 = \frac{h_y}{g}, \quad v_3 = -\frac{g_x}{h}, \quad hv_2 = -gu_1 \tag{4}$$

and from the compatibility condition $\psi_{xy}=\psi_{yx}$, we can derive that

$$u_{1y} - v_{1x} - \frac{g_x}{h}u_2 + \frac{h_y}{h}u_1 = 0, \tag{5}$$

$$u_{2y} + \left(\frac{g}{h}u_1\right)_x + \frac{h_y}{g}v_1 + \frac{g_x}{h}u_1 = 0, \tag{6}$$

$$\left(\frac{h_y}{g}\right)_y + \left(\frac{g_x}{h}\right)_x - \frac{g}{h}u_1^2 - u_2v_1 = 0. \tag{7}$$

It is the Gauss–Codazzi equation. Same as the appendix of Ref. 5, let

$$h = \cos\theta, \quad g = \sin\theta \tag{8}$$

and

$$L = p_x\cot\theta + \cos\theta\sin\theta,$$

$$M = p_y\cot\theta, \tag{9}$$

$$N = p_x\cot\theta - \cos\theta\sin\theta,$$

then from (4),

$$u_3 = -\theta_y, \quad v_3 = -\theta_x, \quad v_2 = -u_1\tan\theta.$$

Meanwhile, we have

$$u_1 = -p_y\frac{\cot\theta}{\sin\theta}, \quad v_1 = -p_x\frac{\cot\theta}{\sin\theta} + \cos\theta,$$

$$u_2 = p_x\frac{1}{\sin\theta} + \sin\theta, \quad v_2 = p_y\frac{1}{\sin\theta}.$$

Then from the Gauss–Codazzi equation, it can be derived that θ and p satisfy the LR equation[5,12,13]

$$\theta_{xx}-\theta_{yy}+\frac{\cos\theta}{\sin^3\theta}(p_x^2-p_y^2)=\cos\theta\sin\theta,$$
$$\frac{\partial}{\partial x}(p_x\cot^2\theta)=\frac{\partial}{\partial y}(p_y\cot^2\theta). \tag{10}$$

Gauss curvature and mean curvature are

$$K=-\frac{\theta_{xx}-\theta_{yy}}{\sin\theta\cos\theta},$$
$$H=\frac{p_x}{\sin^3\theta\cos\theta}-2\cot(2\theta),$$

respectively.

We call the surface associated with the LR equation the LR surface. It is known that the LR equation is a one soliton equation. To prove the LR surface is a one soliton surface[14,15] and calculate the explicit expression of the surfaces, we need to introduce one spectral parameter and prove F can be expressed by ψ. So, we do the coordinate transformation

$$\bar{x}=\frac{1}{2\lambda}(x-y),\quad \bar{y}=\frac{\lambda}{2}(x+y) \tag{11}$$

at that time, the LR equation (10) is changed to

$$\theta_{\bar{x}\bar{y}}+\frac{\cos\theta}{\sin^3\theta}p_{\bar{x}}p_{\bar{y}}=\cos\theta\sin\theta,$$
$$\frac{\partial}{\partial\bar{x}}(p_{\bar{y}}\cot^2\theta)+\frac{\partial}{\partial\bar{y}}(p_{\bar{x}}\cot^2\theta)=0. \tag{12}$$

It is another form of the LR equation.[11] Its Gauss curvature and mean curvature are

$$K=-\frac{\theta_{\bar{x}\bar{y}}}{\sin\theta\cos\theta},$$
$$H=\frac{p_{\bar{x}}+\lambda^2 p_{\bar{y}}}{2\lambda\sin^3\theta\cos\theta}-2\cot(2\theta),$$

respectively. Meanwhile Eqs. (2) and (3) can be rewritten as

$$\psi_{\bar{x}}=\bar{M}\psi=\frac{1}{2}\begin{pmatrix} i\theta_{\bar{x}} & -i\lambda e^{-i\theta}+ip_{\bar{x}}\dfrac{\cos\theta}{\sin^2\theta}-\dfrac{p_{\bar{x}}}{\sin\theta} \\ -i\lambda e^{-i\theta}+ip_{\bar{x}}\dfrac{\cos\theta}{\sin^2\theta}+\dfrac{p_{\bar{x}}}{\sin\theta} & -i\theta_{\bar{x}} \end{pmatrix}\psi,$$
$$\psi_{\bar{y}}=\bar{N}\psi=\frac{1}{2}\begin{pmatrix} -i\theta_{\bar{y}} & i\dfrac{e^{i\theta}}{\lambda}-ip_{\bar{y}}\dfrac{\cos\theta}{\sin^2\theta}-\dfrac{p_{\bar{y}}}{\sin\theta} \\ i\dfrac{e^{-i\theta}}{\lambda}-ip_{\bar{y}}\dfrac{\cos\theta}{\sin^2\theta}+\dfrac{p_{\bar{y}}}{\sin\theta} & i\theta_{\bar{y}} \end{pmatrix}\psi, \tag{13}$$

and the tangent vectors Eq. (1) are

$$F_{\bar{x}}=\frac{i\lambda}{2}\psi^{-1}\begin{pmatrix}0 & e^{-i\theta}\\ e^{i\theta} & 0\end{pmatrix}\psi,\quad F_{\bar{y}}=\frac{i}{2\lambda}\psi^{-1}\begin{pmatrix}0 & e^{i\theta}\\ e^{-i\theta} & 0\end{pmatrix}\psi. \tag{14}$$

Let $\lambda=e^{\Lambda}$, then we have

Proposition 1: Let

$$F=-\psi^{-1}\psi_{\Lambda}. \tag{15}$$

If ψ satisfies Eq. (13), then F satisfies Eq. (14).

Proof: It is easy to calculate that

$$F_{\bar{x}}=-\psi^{-1}\bar{M}_{\Lambda}\psi,\quad F_{\bar{y}}=-\psi^{-1}\bar{N}_{\Lambda}\psi$$

So, Eq. (14) can be obtained. □

So, if θ and p is a solution of the LR equation (12), the spectral problem of Eq. (13) can be solved, i.e., we can get the solution ψ in explicit form. Furthermore, the exact expression of the motion of the LR surface can be calculated from expression (15).

Similar to Ref. 20, using the spin transformation

$$T:\psi\rightarrow\varphi=T\psi,\quad T=\frac{1}{\sqrt{2}}\begin{pmatrix}e^{-i/2\,\theta} & e^{-i/2\,\theta}\\ -e^{i/2\,\theta} & e^{i/2\,\theta}\end{pmatrix}, \tag{16}$$

we map the spectral problem (13) to the Ablowitz–Kaup–Newell–Seger (AKNS) system

$$\begin{aligned}\varphi_{\bar{x}}&=\frac{1}{2}\begin{pmatrix} i\left(\lambda-p_{\bar{x}}\frac{\cos(2\theta)}{\sin^2\theta}\right) & 2i\theta_{\bar{x}}-2p_{\bar{x}}\cot\theta\\ 2i\theta_{\bar{x}}+2p_{\bar{x}}\cot\theta & -i\left(\lambda-p_{\bar{x}}\frac{\cos(2\theta)}{\sin^2\theta}\right)\end{pmatrix}\varphi,\\ \varphi_{\bar{y}}&=\frac{1}{2}\begin{pmatrix} -i\left(\frac{\cos 2\theta}{\lambda}-\frac{p_{\bar{y}}}{\sin^2\theta}\right) & -\frac{\sin 2\theta}{\lambda}\\ \frac{\sin 2\theta}{\lambda} & i\left(\frac{\cos 2\theta}{\lambda}-\frac{p_{\bar{y}}}{\sin^2\theta}\right)\end{pmatrix}\varphi.\end{aligned} \tag{17}$$

Given one soliton solution of the LR equation (12),[11,13]

$$\theta=\arcsin[d\,\mathrm{sec}\,h(d\alpha)],\quad p=\arctan\left[\frac{d}{A}\tanh(d\alpha)\right],$$

$$\alpha=c\bar{x}+\frac{\bar{y}}{c},\quad d^2+A^2=1,$$

the basic solution of the spectral problem (17) can be calculated that

$$\varphi=\begin{pmatrix}\varphi_1 & -\varphi_2^{\star}\\ \varphi_2 & \varphi_1^{\star}\end{pmatrix},$$

$$\varphi_1=[\lambda-cA+icd\tanh(d\alpha)]\exp\left[\frac{i}{2}(p+2\beta)\right],$$

$$\varphi_2=-icd\,\mathrm{sec}\,h(d\alpha)\exp\left[\frac{i}{2}(2\beta-p)\right],\quad \beta=\frac{\lambda-cA}{2}\bar{x}+\left(\frac{A}{2c}-\frac{1}{2\lambda}\right)\bar{y}.$$

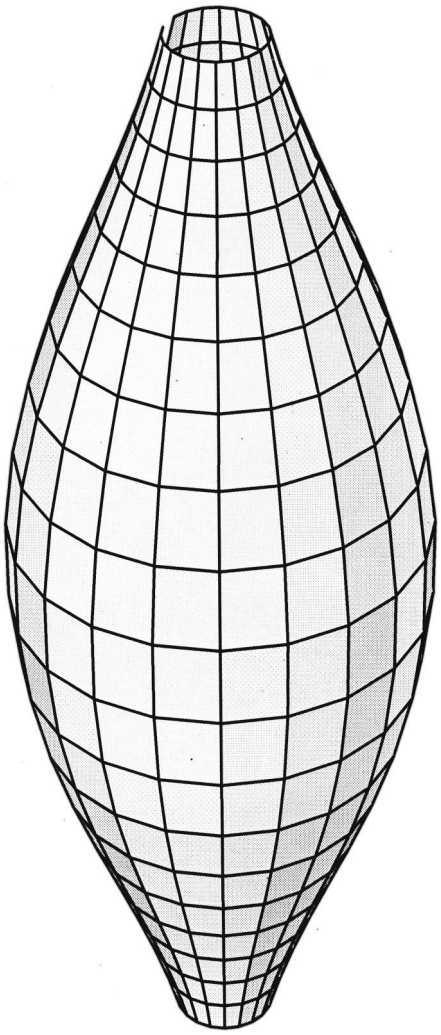

FIG. 1. $c=\lambda=\frac{1}{2}$; $A=\sqrt{2}/2$; $x\in[-3,3]$; $y\in[-10,10]$.

So making use of Eqs. (15) and (16), it can be derived that $F(\overline{x},\overline{y})$ is

$$F(\overline{x},\overline{y})=\frac{1}{2}\begin{pmatrix} iF_3(\overline{x},\overline{y}) & iF_1(\overline{x},\overline{y})-F_2(\overline{x},\overline{y}) \\ iF_1(\overline{x},\overline{y})+F_2(\overline{x},\overline{y}) & -iF_3(\overline{x},\overline{y}) \end{pmatrix},$$

$$F_1(\overline{x},\overline{y})=-\frac{2cd\lambda}{\lambda^2-2cA+c^2}\sec h(d\alpha)\cos(2\beta),$$

$$F_2(\overline{x},\overline{y})=\frac{2cd\lambda}{\lambda^2-2cA+c^2}\sec h(d\alpha)\sin(2\beta), \tag{18}$$

$$F_3(\overline{x},\overline{y})=\frac{2cd\lambda\tanh(d\alpha)}{\lambda^2-2cA+c^2}-\left(\frac{\lambda}{2}\overline{x}+\frac{\overline{y}}{2\lambda}\right).$$

Substituting (11) into (18), the surface corresponding to the first and second fundamental quantities (8) and (9) can be obtained. It is displayed in Figs. 1–5.

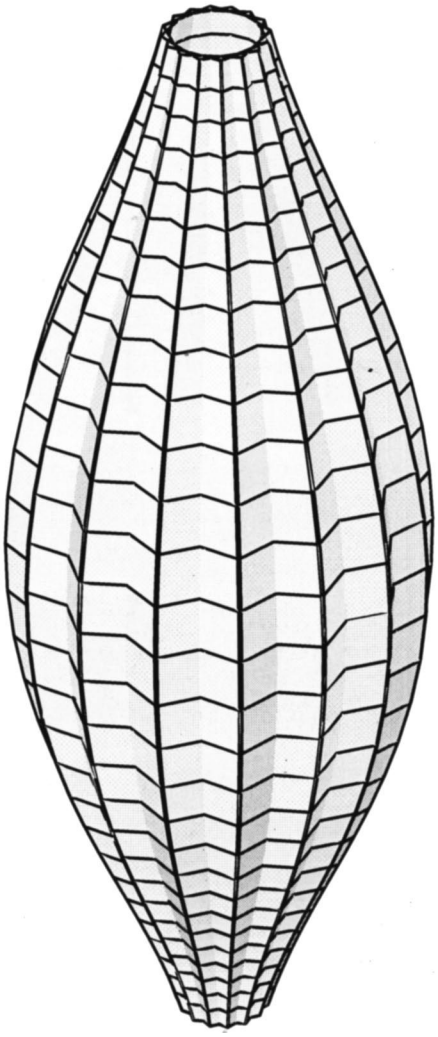

FIG. 2. $c=-\lambda=\frac{1}{2}$; $A=\sqrt{2}/2$; $x\in[-3,3]$; $y\in[-10,10]$.

III. THE MOTION OF SURFACE IN ORTHOGONAL COORDINATES

To discuss the motion of surfaces, we assume the velocity of the motion as

$$F_t=\psi^{-1}C\psi=uF_x+vF_y+w\mathbf{N}$$

and ψ satisfies

$$\psi_t=W\psi,\quad W=\sum_{j=1}^{3}w_jf_j, \tag{19}$$

where u, v, w are functions of (x,y,t) and are projections of F_x, F_y, $\mathbf{N}$, respectively. Then from the compatibility conditions of F_x, F_y, F_t, ψ_x, ψ_y, and ψ_t, it can be calculated that w_1, w_2, w_3 satisfy

$$w_1=-\frac{w_y}{g}+u_1u+v_1v,$$

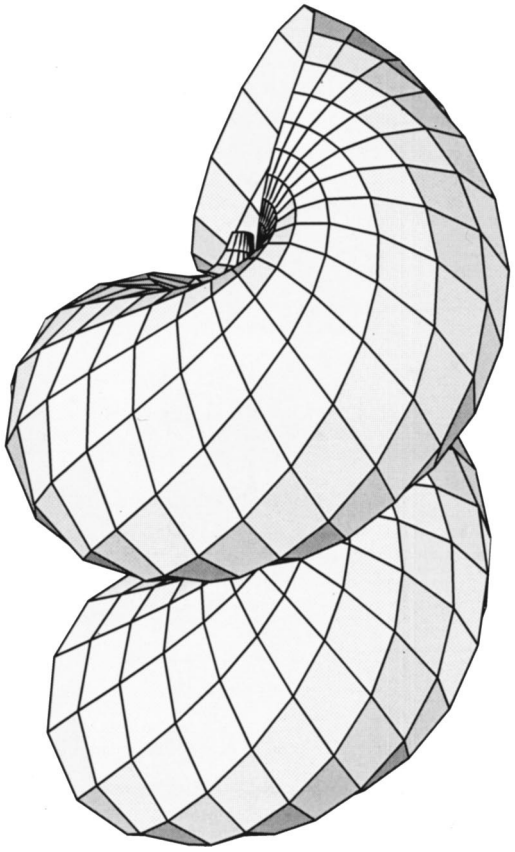

FIG. 3. $c=\frac{1}{2}$; $\lambda=\frac{3}{4}$; $A=\sqrt{2}/2$; $x\in[-10,10]$, $y\in[-15,15]$.

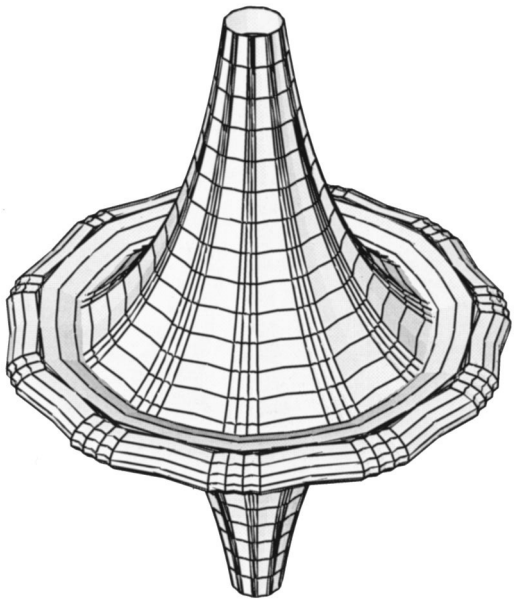

FIG. 4. $c=\lambda=1$; $A=\frac{1}{4}$; $x\in[-3,3]$, $y\in[-15,15]$.

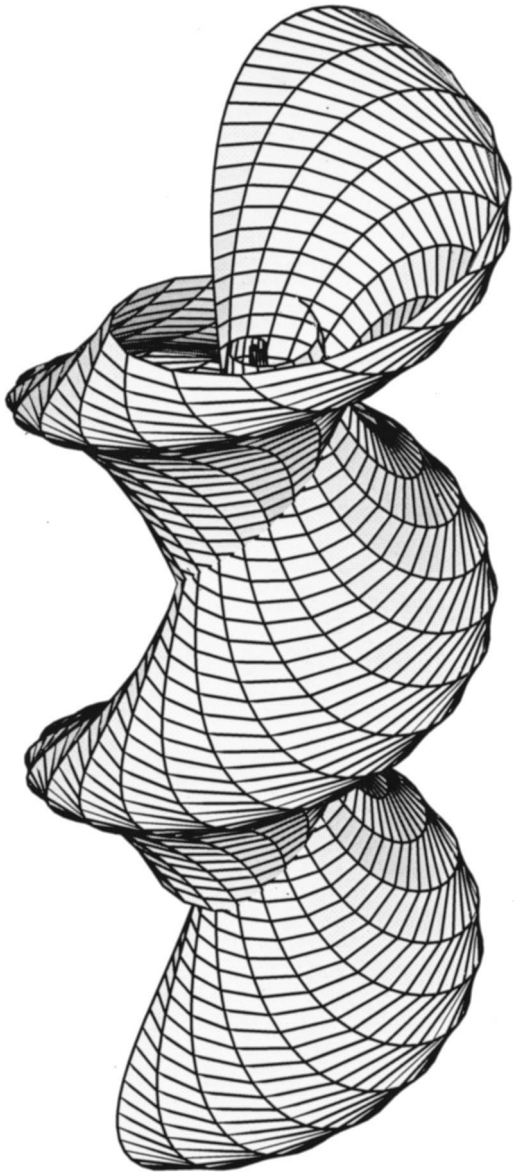

FIG. 5. $c=\frac{1}{2}$; $\lambda=-1$; $A=\sqrt{2}/2$; $x\in[-3,3]$, $y\in[-5,5]$.

$$
\begin{aligned}
w_2&=\frac{1}{h}(w_x+uu_2h-u_1vg),\\
w_3&=-\frac{1}{h}\left[(vg)_x-u\frac{hh_y}{g}+wu_1\right],\\
&=\frac{1}{g}\left[(uh)_y-v\frac{gg_x}{h}+wu_1\frac{g}{h}\right]
\end{aligned}
\tag{20}
$$

and besides the Gauss–Codazzi equation (5)–(7), the eight functions u, v, w, h, g, u_1, u_2, v_1 should satisfy the following equations:

$$h_t=(uh)_x+vh_y-wu_2, \tag{21}$$

$$h^2u_y=-g^2v_x-2gwu_1, \tag{22}$$

$$g_t=(vg)_y+ug_x+wv_1, \tag{23}$$

$$u_{1t}-w_{1x}+u_2w_3-\frac{h_y}{h}w_2=0, \tag{24}$$

$$u_{2t}-w_{2x}+\frac{h_y}{g}w_1-u_1w_3=0, \tag{25}$$

$$\left(\frac{g}{h}u_1\right)_t+w_{2y}+\frac{g_x}{h}w_1+v_1w_3=0, \tag{26}$$

$$\left(\frac{g_x}{h}\right)_t+w_{3y}-v_1w_2-\frac{g}{h}u_1w_1=0, \tag{27}$$

$$\left(\frac{h_y}{g}\right)_t-w_{3x}+u_1w_2-u_2w_1=0, \tag{28}$$

$$v_{1t}-w_{1y}-\frac{h}{g}u_1w_3+\frac{g_x}{h}w_2=0. \tag{29}$$

Among them, Eq. (22) is deduced from the two expressions of w_3 Eq. (20). In the following, we will discuss the reduction of this problem and clarify the relation between the velocities and the surfaces.

Theorem 1: *If $u_2\neq 0$, and w_1, w_2, w_3 are defined by Eq. (20), then Eqs. (26)–(29) can be derived from the Gauss–Codazzi equation (5)–(7) and Eqs. (21)–(25), i.e., in orthogonal coordinates, the motion of surfaces depends on eight functions u, v, w, h, g, u_1, u_2, and v_1, which satisfy the eight fundamental equations (5)–(7), (21)–(25).*

Lemma 1: Equation (26) can be derived from Eqs. (21) to (24).

Proof: By direct calculation, it can be deduced from Eqs. (23) and (24) that

$$\begin{aligned}\left(\frac{gu_1}{h}\right)_t=&\frac{u_1}{h}[(vg)_y+ug_x+wv_1]+\frac{gu_2}{h^2}[wu_1+v_xg+vg_x]\\&+\frac{g}{h}\left(u_{1x}u+u_1u_x+v_{1x}v-v_1v_x-\frac{w_{xy}}{g}+\frac{w_yg_x}{g^2}\right)\\&+\frac{h_y}{h^2}(w_x-vgu_1)-\frac{gu_1}{h^2}[(uh)_x+vh_y-wu_2].\end{aligned} \tag{30}$$

Meanwhile, from Eq. (20), it yields that

$$-w_{xy}=-hw_{2y}-h_yw_2+u_yu_{2y}h+uu_{2y}h+uu_2h_y-u_1(vg)_y-u_{1y}vg.$$

So, by using Eqs. (5), (6), and (22), it can be rewritten as

$$-w_{xy}=-hw_{2y}+\frac{u_2}{h}(-g^2v_x-2gwu_1)+uh\left[-u_1\frac{g_x}{h}-\left(\frac{gu_1}{h}\right)_x-\frac{h_y}{g}v_1\right]$$
$$-vg\left(v_{1x}+u_2\frac{g_x}{h}-\frac{h_y}{h}u_1\right)-u_1(vg)_y-h_yw_2+uu_2h_y.$$

Substituting it into Eq. (30), it yields that

$$\left(\frac{gu_1}{h}\right)_t=-w_{2y}+\frac{g_x}{h}\left(\frac{w_y}{g}-uu_1-v_1v\right)+\frac{v_1}{h}\left(wu_1+gv_x+g_xv-uh\frac{h_y}{g}\right).$$

So, Eq. (26) is obtained and this lemma is proved. □

Lemma 2: Equation (27) can be derived from Eqs. (5), (7), (21)–(23).

Proof: From Eqs. (21) and (23), g_t and h_t can be expressed. So, from Eqs. (7) and (22), it can be calculated that

$$h\left[\left(\frac{g_x}{h}\right)_t+w_{3y}-v_1w_2-\frac{g}{h}u_1w_1\right]=ug_{xx}+(wv_1)_x+v_1(w_x+uhu_2)+guu_1^2+wu_{1y}$$
$$+\frac{1}{h}(wu_1h_y+gv_xh_y)+\frac{g_x}{h}wu_2+\frac{hh_yu_y}{g}+hu\left(\frac{h_y}{g}\right)_y$$
$$=w\left[v_{1x}-u_{1y}+u_1\frac{h_y}{h}+u_1\frac{g_x}{h}-wu_1\frac{h_y}{h}\right].$$

Substituting Eq. (5) into it, the right-hand side of the above-given expression is zero, so Eq. (27) is obtained. This lemma is proved. □

Lemma 3: Equation (28) can be derived from Eqs. (6), (7) and (21)–(25).

Proof: By using Eqs. (6), (21), and (23), the left-hand side of Eq. (28) can be rewritten as

$$\left(\frac{h_y}{g}\right)_t-w_{3x}+u_1w_2-u_2w_1$$
$$=\frac{1}{g}\left[vh_{yy}-wu_{2y}+\left(\frac{gv}{h}g_x-wu_1\frac{g}{h}\right)_x\right]-\frac{h_y}{g}(vg_y+ug_x+wv_1)+\frac{u_1}{h}(w_x-vgu_1)$$
$$+\frac{g_x}{g}\left(uh_y+u_yh-vg\frac{g_x}{h}+wu_1\frac{g}{h}\right)+\frac{h_y}{g^2}(g_yv+g_xu)$$
$$=\frac{1}{g}\left(vh_{yy}+wu_1\frac{g_x}{h}+g_xw_3\right)+\frac{(vg_x)_x}{h}-\frac{vu_1^2g}{h}-\frac{vg_xh_x}{h^2}+\frac{vg_x^2}{gh}. \tag{31}$$

Then from Eq. (27), it yields that

$$\frac{h_{yy}}{g}=\frac{h_xg_x}{h^2}+\frac{gu_1^2}{h}-\frac{g_{xx}}{h}+u_2v_1.$$

Substituting it into Eq. (31), the left-hand side of Eq. (28) is equal to zero, so this lemma is proved. □

Lemma 4: If $u_2\neq 0$, Eq. (29) can be derived from Eqs. (5)–(7) and (21)–(23).

Proof: From Lemmas 1–3, Eqs. (26)–(28) yield. So they can be used to prove this lemma. From Eqs. (24) to (28), Eq. (7) can be rewritten as

$$(u_2w_1-u_1w_2)_y+\left(v_1w_2+\frac{g}{h}u_1w_1\right)_x-\left(\frac{g}{h}\right)_t u_1^2-u_2v_{1t}+2u_1\frac{g}{h}\left(u_2w_3-w_{1x}-\frac{h_y}{g}w_2\right)$$
$$+v_1\left(\frac{h_y}{g}w_1-w_{2x}-u_1w_3\right)=0.$$

Substituting h_t, g_t into it and using Eqs. (5) and (6), we have

$$u_1\left[\frac{g}{h}(u_2w_3-w_{1x})-\frac{g_x}{h}w_1-w_{2y}-\frac{g_t}{h}u_1+\frac{gh_t}{h^2}-v_1w_3\right]\times u_2\left(w_{1y}+\frac{g}{h}u_1w_2+\frac{g_x}{h}u_2w_2-v_{1t}\right)=0.$$

Then using (24) and (26), it can be directly calculated that if $u_2\neq 0$, (29) yields. This lemma is proved. □

From Lemmas 1–4, the theorem is proved.

Remark 1: Note that, among the eight equations, Eqs. (21)–(23) are derived from the compatibility conditions of F_x, F_y, F_t, Gauss–Codazzi equations are from $\psi_{xy}=\psi_{yx}$ and the remaining two are from the compatibility conditions $\psi_{xt}=\psi_{tx}$.

IV. THE MOTION OF THE LUND–REGGE SURFACE

To decide the equations of the surface evolution, we should clarify the relation between the velocity and the surface. First of all, from Eq. (20), we know

$$\begin{aligned}
w_1&=-\frac{w_y}{\sin\theta}-p_yu\frac{\cot\theta}{\sin\theta}+\left(\cos\theta-p_x\frac{\cot\theta}{\sin\theta}\right)v,\\
w_2&=\frac{w_x}{\cos\theta}+p_x\frac{u}{\sin\theta}+\sin\theta u+p_y\frac{v}{\sin\theta},\\
w_3&=-v_x\tan\theta-v\,\theta_x-u\,\theta_y+p_y\frac{w}{\sin^2\theta},\\
&=u_y\cot\theta-v\,\theta_x-u\,\theta_y-p_y\frac{w}{\sin^2\theta}.
\end{aligned}\tag{32}$$

Proposition 2: If the surface satisfies Eqs. (8) and (9), then besides the LR equation, θ and p should satisfy

$$\begin{aligned}
\theta_t&=-u_x\cot\theta+u\,\theta_x+v\,\theta_y+w\left(1+\frac{p_x}{\sin^2\theta}\right),\\
&=v_y\tan\theta+u\,\theta_x+v\,\theta_y+w\left(1-\frac{p_x}{\sin^2\theta}\right),
\end{aligned}\tag{33}$$

$$\left(p_y\frac{\cot\theta}{\sin\theta}\right)_t+w_{1x}-u_2w_3-\theta_yw_2=0.\tag{34}$$

In fact Eq. (34) is just Eq. (24), and from Eq. (21) or (23), it is easy to know that θ_t satisfies Eq. (33).

Proposition 3: The velocity u, v, and w should satisfy

$$\cos^2\theta u_y+\sin^2\theta v_x=2p_yw\frac{\cos\theta}{\sin\theta},\tag{35}$$

$$\cos^2\theta u_x+\sin^2\theta v_y=2wp_x\cot\theta, \tag{36}$$

$$w_{xx}-w_{yy}-w(p_x^2-p_y^2)\left(\csc^2\theta+3\frac{\cos^2\theta}{\sin^4\theta}\right)+2\frac{\cos\theta}{\sin^3\theta}(p_xu_x-p_yu_y)=w\cos 2\theta. \tag{37}$$

Proof: Equation (35) follows from Eq. (32) or (22). And from Eq. (33), Eq. (36) yields. In the following, we should prove that Eq. (37) is satisfied. From Eqs. (32) and (33), Eq. (25) can be rewritten as

$$p_{xt}\cot\theta-w_{xx}-w_x\theta_x\tan\theta-p_{xx}u\cot\theta-2p_yv_x\cot\theta+\theta_yw_y\cot\theta+w(p_y^2-p_x^2)\frac{\cos^2\theta}{\sin^4\theta}+w\cos^2\theta$$
$$+p_xu_x\cot\theta\frac{\cos 2\theta}{\sin^2\theta}-u_x\cot\theta=0. \tag{38}$$

Similarly, by direct calculation, Eq. (29) can be rewritten as

$$-p_{xt}\cot\theta+w_{yy}+w_x\theta_x\tan\theta-\theta_yw_y\cot\theta+p_{yy}u\cot\theta+2p_yu_y\cot\theta+p_{xy}v\cot\theta-wp_y^2\frac{1}{\sin^2\theta}$$
$$-p_x^2w\frac{1}{\sin^2\theta}(1+2\cot\theta)-w\sin^2\theta-2p_y\theta_yu\frac{1}{\sin^2\theta}-v_y\tan\theta+p_xv_y(\tan\theta+3\cot\theta)$$
$$+2wp_x\frac{1}{\sin^2\theta}+2p_x\theta_xu\frac{1}{\sin^2\theta}=0. \tag{39}$$

Then from Eqs. (38) and (39) and noting that θ, p satisfy the LR equation, it follows that

$$w_{yy}-w_{xx}+w\cos 2\theta-w(p_x^2-p_y^2)\frac{3+\cos^2\theta}{\sin^2\theta}+2(\tan\theta+\cot\theta)(p_xv_y-p_yv_x)=0. \tag{40}$$

On the other hand, by using Eqs. (35) and (36), it follows that

$$p_xv_y-p_yv_x=2w\frac{\cos\theta}{\sin^3\theta}(p_x^2-p_y^2)-\cot^2\theta(u_xp_x-u_yp_y).$$

Substituting it into Eq. (40), it yields Eq. (37). □

Then from Eqs. (35) and (36), v_y and v_x can be expressed by u, w, θ, and p. The compatibility condition of $v_{xy}=v_{yx}$ can be written as

$$\frac{\partial}{\partial y}\left(2wp_x\frac{\cos\theta}{\sin^3\theta}-u_x\cot^2\theta\right)=\frac{\partial}{\partial x}\left(2wp_y\frac{\cos\theta}{\sin^3\theta}-u_y\cot^2\theta\right). \tag{41}$$

Proposition 4: u, w satisfy the linearization of the LR equation.

Proof: Replacing θ and p with $\theta+\varepsilon w$, $p+\varepsilon u$ in the LR equation and then keep the $O(\varepsilon)$ terms. It is just Eqs. (37) and (41), that is, u w satisfy the linearization of the LR equation. □

So, if θ, p are a solution of LR equation, then θ_x, p_x are the solution of Eqs. (37) and (41), and θ_y, p_y are too.

V. EVOLUTION EQUATION OF THE LR SURFACE UNDER SPECIAL VELOCITY

Based on the previous text, for p not a constant, we can take the normal velocity component w and the tangent velocity component u as follows:

$$w=a_1\theta_x+a_2\theta_y,\quad u=a_1p_x+a_2p_y, \tag{42}$$

where a_1 and a_2 are constants. From Eqs. (35) and (36) we find that

$$v=-(a_1p_y+a_2p_x)\cot^2\theta. \tag{43}$$

Substituting u, v and w into Eqs. (33) and (34), the evolution equation of surface related to the time can be derived that

Proposition 5: The evolution equation of the LR equation for the velocity equations (42) and (43) is

$$\theta_t=a_1[\theta_x(p_x+1)-(p_x\cot\theta)_x-p_y\theta_y\cot^2\theta]+a_2[\theta_y(p_x+1)+\theta_xp_y-p_{xy}\cot\theta], \tag{44}$$

$$\begin{aligned}p_{yt}=&a_1\left[\theta_{xxy}\tan\theta+\theta_y\theta_{xx}\tan^2\theta-\theta_x\theta_{xy}+p_{xy}+4p_y^2\theta_y\frac{\cos\theta}{\sin^3\theta}+p_xp_{xy}(2-\cot^2\theta)-3p_yp_{yy}\cot^2\theta\right]\\&+a_2\left[\theta_{xyy}\tan\theta+\theta_y\theta_{xy}\tan^2\theta-\theta_x\theta_{yy}+p_{yy}+4p_yp_x\theta_y\frac{\cos\theta}{\sin^3\theta}\right.\\&\left.+(1-2\cot^2\theta)(p_xp_{yy}+p_yp_{xy})\right].\end{aligned} \tag{45}$$

It is 2+1 dimensional nonlinear integrable equations.

Proposition 6:

$$\begin{gathered}\theta=\arcsin[d\sec h(d\eta)],\quad p=\arctan\left[\frac{d}{A}\tanh(d\eta)\right],\\ \eta=c_1x+c_2y+c_3t,\quad c_1=\frac{c}{2\lambda}+\frac{\lambda}{2c},\quad c_2=-\frac{c}{2\lambda}+\frac{\lambda}{2c},\\ c_3=\frac{\lambda}{2c^2}(c-A\lambda)(a_1+a_2)-\frac{c}{2\lambda^2}(Ac-\lambda)(a_1-a_2)\end{gathered} \tag{46}$$

is one soliton solution of the LR equations (10), (44), and (45).

Proof: From the relation among Eqs. (10), (11), and (12), it is easy to know that Eq. (46) satisfies the LR equation (10). So we only need to prove that Eq. (46) satisfies (44) and (45),

$$\theta_x=-\frac{d^2c_1\sec h(d\eta)\tanh(d\eta)}{\sqrt{1-d^2\sec h^2(d\eta)}},\quad p_x=\frac{d^2c_1\sec h^2(d\eta)}{A\left[1+\frac{d^2}{A^2}\tanh^2(d\eta)\right]},$$

$$\cos\theta=\sqrt{1-d^2\sec h^2(d\eta)},\quad \sin\theta=d\sec h(d\eta),$$

$$p_{xy}=-\frac{4Ad^3c_1c_2\sinh(2d\eta)}{[2A^2-1+\cosh(2d\eta)]^2}.$$

So,

$$\theta_xp_x-(p_x\cot\theta)_x-p_y\theta_y\cot^2\theta+\theta_x=\frac{\sqrt{2}d^2(Ac_1^2+Ac_2^2-c_1)\sec h(d\eta)\tanh(d\eta)}{\sqrt{(2A^2-1+\cosh(2d\eta)\sec h^2(d\eta)}},$$

$$\theta_xp_y+\theta_yp_x-p_{xy}\cot\theta+\theta_y=\frac{\sqrt{2}d^2(2Ac_1-1)c_2\sec h(d\eta)\tanh(d\eta)}{\sqrt{[2A^2-1+\cosh(2d\eta)]\sec h^2(d\eta)}}.$$

Meanwhile,

$$[2A^2-1+\cosh(2d\eta)]\sec h^2(d\eta)=2[1-d^2\sec h^2(d\eta)].$$

So, by calculation, it can be proved that Eq. (46) satisfies Eq. (44). Moreover,

$$p_{yt}=-\frac{4Ad^3c_2c_3\sinh(2d\eta)}{[2A^2-1+\cos h(2d\eta)]^2},$$

$$\theta_{xxy}\tan\theta+\theta_y\theta_{xx}\tan^2\theta-\theta_x\theta_{xy}=\frac{16A^2d^5c_1^2c_2\sinh(2d\eta)}{[2A^2-1+\cosh(2d\eta)]^3},$$

$$p_{xy}-3p_yp_{yy}\cot^2\theta=\frac{4Ad^3c_2(3Ac_2^2-c_1)\sinh(2d\eta)}{[2A^2-1+\cosh(2d\eta)]^2},$$

$$4p_y^2\theta_y\frac{\cos\theta}{\sin^3\theta}+p_xp_{xy}(2-\cot^2\theta)$$
$$=-\frac{4A^2d^3c_2[(5-6A^2)c_1^2+2(2A^2-1)c_2^2-(c_1^2-2c_2^2)\cosh(2d\eta)]\sinh(2d\eta)}{[2A^2-1+\cosh(2d\eta)]^3},$$

$$\theta_{xyy}\tan\theta+\theta_y\theta_{xy}\tan^2\theta-\theta_x\theta_{yy}=\frac{16A^2d^5c_1c_2^2\sinh(2d\eta)}{[2A^2-1+\cosh(2d\eta)]^3},$$

$$p_{yy}+4p_yp_x\theta_y\frac{\cos\theta}{\sin^3\theta}=-\frac{4Ad^3(1+2Ac_1)c_2^2\sinh(2d\eta)}{[2A^2-1+\cosh(2d\eta)]^2},$$

$$(1-2\cot^2\theta)(p_xp_{yy}+p_yp_{xy})=\frac{16A^2d^3c_1c_2^2[-2+3A^2\cosh(2d\eta)]\sinh(2d\eta)}{[2A^2-1+\cosh(2d\eta)]^3}.$$

Then substituting them into Eq. (45), this proposition is proved. □

VI. SPECIAL CASE OF *p* BEING CONSTANT

For the LR equation (10), if p is constant, it is just Sine–Gorden (SG) equation

$$\theta_{xx}-\theta_{yy}=\cos\theta\sin\theta \tag{47}$$

and Gauss curvature $K=-1$, mean curvature $H=\tan\theta-\cot\theta$. It is the surface with constant negative curvature. At that time, the equations that velocity u, v, and w satisfy should change and we can not take the velocity at that case. So in the following, we clarify the relation between the velocity and the surface, and give an other set of velocity. From Eq. (37), it yields

$$w_{xx}-w_{yy}=w\cos 2\theta,$$

it is just the linearization of the SG equation. So we can take the normal velocity component w as

$$w=b_1\theta_x+b_2\theta_y.$$

To find the tangent velocity, we should clarify the relation between u, v and w further. From Eqs. (35) and (36), it is easy to know that u, v satisfy

$$\cos^2\theta u_y+\sin^2\theta v_x=0,$$

$$\cos^2\theta u_x+\sin^2\theta v_y=0.$$

And from Eq. (38), it is easy to know that u_x and w satisfy

$$w_{xx}+w_x\theta_x\tan\theta-w_y\theta_y\cot\theta+u_x\cot\theta=w\cos^2\theta.$$

From Eq. (39), it can be derived that v_y and w satisfy

$$w_{yy}+w_x\theta_x\tan\theta-w_y\theta_y\cot\theta-v_y\tan\theta=w\sin^2\theta.$$

So we find the tangent velocity u, v,

$$u=b_1\left(\frac{\theta_x^2}{2}+\frac{\theta_y^2}{2}-\frac{\cos 2\theta}{4}-\theta_{xx}\tan\theta\right)+b_2(\theta_x\theta_y-\theta_{xy}\tan\theta),$$

$$v=b_2\left(\frac{\theta_x^2}{2}+\frac{\theta_y^2}{2}+\frac{\cos 2\theta}{4}+\theta_{yy}\cot\theta\right)+b_1(\theta_x\theta_y+\theta_{xy}\cot\theta).$$

From Eq. (33), the time evolution of θ reads

$$\begin{aligned}\theta_t=&b_1\left[\frac{3}{4}\theta_{xxx}+\frac{1}{4}\theta_{xyy}+\sin^2\theta\theta_x+\frac{\theta_x}{2}(\theta_x^2+3\theta_y^2)\right]\\&+b_2\left[\frac{5}{4}\theta_{xxy}-\frac{1}{4}\theta_{yyy}+\sin^2\theta\theta_y+\frac{\theta_y}{2}(3\theta_x^2+\theta_y^2)\right].\end{aligned}\tag{48}$$

It is one $2+1$ dimensional integrable equation.

Proposition 7:

$$\begin{aligned}\theta&=2\arctan(\exp\delta),\\\delta&=\frac{x}{\sin a}+\frac{\cos a}{\sin a}y+\frac{t\csc^3 a}{4}[b_1(3+\cos^2 a)+b_2\cos a(4+\sin^2 a)]\end{aligned}\tag{49}$$

is one soliton solution of Eqs. (47) and (48), where a is constant.

Proof: Note that

$$\cos\theta=\frac{1-\exp 2\delta}{1+\exp 2\delta},\quad \sin\theta=\frac{2\exp 2\delta}{1+\exp 2\delta},$$

$$\theta_x=\frac{2\csc a\exp\delta}{1+\exp 2\delta},\quad \theta_y=\frac{2\cot a\exp\delta}{1+\exp 2\delta},$$

$$\theta_{xx}=\frac{2\csc^2 a\exp\delta}{1+\exp 2\delta}\left(1-\frac{2\exp 2\delta}{1+\exp 2\delta}\right),$$

$$\theta_{yy}=\frac{2\cot^2 a\exp\delta}{1+\exp 2\delta}\left(1-\frac{2\exp 2\delta}{1+\exp 2\delta}\right),$$

so

$$\theta_{xx}-\theta_{yy}=2\exp\delta\frac{\exp 2\delta-1}{(1+\exp 2\delta)^2}=\cos\theta\sin\theta.$$

Equation (49) is one soliton solution of Eq. (47). Continuously, by direct calculation,

$$w=b_1\theta_x+b_2\theta_y=\frac{2\exp\delta}{1+\exp 2\delta}(b_1\csc a+b_2\cot a)$$

$$u=-\frac{b_1}{4},\quad v=\frac{b_1\cos a}{\sin^2 a}+b_2\cot^2 a+\frac{b_2}{4}.$$

Substituting them into Eq. (33), it yields that

$$\theta_t=\frac{\exp\delta\csc^3 a}{2(1+\exp(2\delta))}[b_1(3+\cos^2 a)+b_2\cos a(4+\sin^2 a)].$$

So, Eq. (48) is satisfied. This proposition is proved. □

VII. CONCLUSION AND REMARKS

In this paper, we discussed the LR surface and its evolution equation. We calculated the explicit expression of the LR surface when θ and p are chosen as solition solution of the LR equation. We obtained the motion equation from the compatibility conditions of some linear equations. Because there are many compatibility equations among them, we reduced the number of equations in orthogonal coordinates and proved Theorem 1. Based on this theorem, it is proved that some velocity components satisfy the linearization of the LR equation. But because the Sym formulation fails in the t term, it is difficult to calculate the explicit expression for the evolution equations of the LR surface. As the special case of the LR surface, we mentioned the surface with $K=-1$, which is the case of the LR equation with p being constant. Comparing this case with Ref. 20, it can be found that we studied a different form of the SG equation with different coordinates. Moreover, when $h=1$, this coordinate is geodesic and this reduction related to Theorem 1 includes the reduction of that Theorem 1 in Ref. 21 in some degree. However, there are many questions deserving further investigation, for instance, solving the spectral problem (19), (32) and obtaining the explicit expression of the motion of LR surface.

k-constraint for the modified Kadomtsev–Petviashvili system

Deng-yuan Chen[a)]
Department of Mathematics, Shanghai University, Shanghai 200436, People's Republic of China

(Received 19 July 1999; accepted for publication 6 December 2001)

By imposing constraint $(L^k)_- = q\partial^{-1}r\partial$ on the pseudo-differential operator L^k, the k constrained modified Kadomtsev–Petviashvili (KP) hierarchy and their corresponding Lax pair are obtained from the linear problem and its adjoint of the modified KP system. Especially, the modified KdV system, the GNS system with derivative coupling, the Burgers system, and a new 3×3 integrable system are presented as examples. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1446665]

I. INTRODUCTION

Many integrable equations important in physics can be generated from the Kadomtsev–Petviashvili (KP) hierarchy by imposing some restrictions on the pseudo-differential operator,[1–3]

$$L=\partial+u_2\partial^{-1}+u_3\partial^{-2}+\cdots+u_j\partial^{-j+1}+\cdots. \tag{1.1}$$

The k constraint $(L^k)_- = q\partial^{-1}r$ is a typical example, which leads the KP hierarchy to the so-called k constrained KP equations.[4] Such a reduced approach has an advantage that from this reduction, one can obtain directly the spectral problems of constrained systems with the help of the linear problem of the KP hierarchy. Consequently, the correspondent recursion operator, the bi-Hamiltonian structure, and other some features characteristic of the integrability of soliton equations are also derived.

In this letter, we would like to consider one kind of constraint on a general pseudo-differential operator,

$$L=\partial+u_1+u_2\partial^{-1}+\cdots+u_j\partial^{-j+1}+\cdots, \tag{1.2}$$

which is analogous to the above "k-constraint." If we redefine $(L^n)_-$ [or $(L^n)_+$] as the residual part with the functional term (or pure differential part) of operator L^n [see (2.1) in Sec. II], such a constraint can be expressed as $(L^k)_- = q\partial^{-1}r\partial$ and it makes the modified KP isospectral hierarchy the k constrained modified KP equations. These equations include a lot of interesting soliton hierarchies, such as the modified KdV hierarchy, the generalized nonlinear Schrödinger (GNS) hierarchy with derivative coupling, the Burgers hierarchy for one-constraint, and a new 3×3 integrable hierarchy for two-constraints. Moreover, the associated spectral problems and recursion operators for constrained systems are also obtained from the reduced theory.

II. SATO THEORY OF THE MODIFIED KP SYSTEM

Let $x,y,t_j(j=1,2,\ldots)\in R$, and $S(R^\infty)$ denote the Schwartz space composed of all rapidly decreasing functions $u=u(x,y,t)$ with infinitely many variables $(x,y,t)=(x,y,t_1,t_2,\ldots)$. For $u_j \in S(R^\infty)(j=1,2,\ldots)$, we take the pseudo-differential operator (1.2). Write

a)Electronic mail: dychen@mail.shu.edu.cn

$$L^n=\sum_{j\leqslant n} p_{nj}(u)\partial^j, \tag{2.1a}$$

$$A_n=(L^n)_+=\sum_{j=1}^{n} p_{nj}(u)\partial^j, \tag{2.1b}$$

$$(L^n)_-=L^n-(L^n)_+, \tag{2.1c}$$

namely, $(L^n)_+$ is the pure differential part of L^n and $(L^n)_-$ is the residual part with the functional term.[5] The coefficients $p_{nj}(u)$ in (2.1a) are uniquely determined by the coordinates u_j,$(j=1,2,\ldots)$ and their derivatives. The first few explicit forms of the operators A_n are listed below,

$$A_1=\partial, \tag{2.2}$$

$$A_2=\partial^2+2u_1\partial, \tag{2.3}$$

$$A_3=\partial^3+3u_1\partial^2+3(u_2+u_{1,x}+u_1^2)\partial, \tag{2.4}$$

$$A_4=\partial^4+4u_1\partial^3+(4u_2+6u_{1,x}+6u_1^2)\partial^2+(4u_3+6u_{2,x}+4u_{1,xx}+12u_1u_2+12u_1u_{1,x}+4u_1^3)\partial. \tag{2.5}$$

Consider the linear problem,

$$L\phi=\eta\phi, \tag{2.6a}$$

$$\phi_{t_m}=A_m\phi, \tag{2.6b}$$

where ϕ is an eigenfunction and η is a spectral parameter. If $\eta_{t_m}=0$, then the compatibility condition of (2.6) gives rise to the Lax equation for A_m,

$$L_{t_m}=[A_m,L], \tag{2.7}$$

or equivalent zero-curvature equation

$$A_{m,t_n}-A_{n,t_m}=[A_n,A_m]. \tag{2.8}$$

The modified KP hierarchy is obtained from (2.7) or from (2.8). For example, from (2.7) with $m=2,\ 3$, we have

$$u_{1,t_2}=2u_{2,x}+u_{1,xx}+2u_1u_{1,x}, \tag{2.9a}$$

$$u_{2,t_2}=2u_{3,x}+u_{2,xx}+2(u_1u_2)_x, \tag{2.9b}$$

$$u_{3,t_2}=2u_{4,x}+u_{3,xx}+2u_1u_{3,x}+4u_{1,x}u_3-2u_{1,xx}u_2, \tag{2.9c}$$

$$\ldots,$$

$$u_{1,t_3}=3u_{3,x}+3u_{2,xx}+u_{1,xxx}+6(u_1u_2)_x+3(u_1u_{1,x})_x+3u_1^2u_{1,x}, \tag{2.10a}$$

$$u_{2,t_3}=3u_{4,x}+3u_{3,xx}+u_{2,xxx}+6(u_1u_3)_x+3(u_1u_{2,x})_x+6u_2u_{2,x}+3(u_1^2u_2)_x, \tag{2.10b}$$

$$\ldots.$$

Eliminating u_2, u_3 from (2.9a), (2.9b), and (2.10a), we obtain the modified KP equation ($u_1 = u$),[6]

$$u_{t_3} = \tfrac{1}{4} u_{xxx} - \tfrac{3}{2} u^2 u_x + \tfrac{3}{2} u_x \partial^{-1} u_{t_2} + \tfrac{3}{4} \partial^{-1} u_{t_2 t_2}. \tag{2.11}$$

Equation (2.11) can also be obtained from (2.8) with $n=2$, $m=3$.

III. NOTION OF THE *K*-CONSTRAINT

Let L be the pseudo-differential operator (1.2) and A_m be the differential operator (2.1b). Set $\psi = \partial^{-1}\phi^*$, then it satisfies

$$\overline{L}\psi = \eta\psi, \tag{3.1a}$$

$$\psi_{t_m} = -\overline{A}_m \psi, \tag{3.1b}$$

where

$$\overline{L} = \partial^{-1} L^* \partial, \tag{3.2a}$$

$$\overline{A}_m = \partial^{-1} A_m^* \partial, \tag{3.2b}$$

in which operators L^* and A_m^* denote the adjoint of L and A_m, respectively. The linear problem (3.1) is called the generalized adjoint of (2.6). Its compatibility condition is

$$\overline{L}_{t_m} = [\overline{A}_m, \overline{L}], \tag{3.3}$$

or equivalently

$$\overline{A}_{m,t_n} - \overline{A}_{n,t_m} = [\overline{A}_m, \overline{A}_n]. \tag{3.4}$$

After introducing the adjoint of (2.6), we can turn to two kinds of k reductions for the modified KP system. The starting point of our method is to consider the more general linear problem,

$$L^k \phi = \lambda \phi, \tag{3.5a}$$

$$\phi_m = A_m \phi, \tag{3.5b}$$

for a fixed positive integer k and $\lambda = \eta^k$. If we impose the condition $L^k = A_k$ or $(L^k)_- = 0$ upon operator L^k, then the linear problem (3.5) becomes

$$A_k \phi = \lambda \phi, \tag{3.6a}$$

$$\phi_{t_m} = A_m \phi, \quad m \neq 0 \ (\mathrm{mod}\, k), \tag{3.6b}$$

and the modified KP hierarchy is reduced to the integrable system which is the compatibility condition of (3.6). When $k=2$, one obtains the modified KdV system.

In order to introduce the concept of another reduction, let us recall the linear problem of the modified KP equation,[7]

$$\phi_{t_2} = \phi_{xx} + 2u\phi_x, \tag{3.7a}$$

$$\phi_{t_3} = \phi_{xxx} + 3u\phi_{xx} + \tfrac{3}{2}(u_x + u^2 - \partial^{-1} u_{t_2})\phi_x, \tag{3.7b}$$

and its adjoint

$$\psi_{t_2} = -\psi_{xx} + 2u\psi_x, \tag{3.8a}$$

$$\psi_{t_3} = \psi_{xxx} - 3u\psi_{xx} - \tfrac{3}{2}(u_x - u^2 - \partial^{-1}u_{t_2})\psi_x. \tag{3.8b}$$

If the potential u is subject to the symmetry,

$$u = \phi\psi = qr, \tag{3.9}$$

where $\phi = q$, $\psi = r$, for convenience, then (3.7a) and (3.8a) become

$$q_{t_2} = q_{xx} + 2qrq_x, \tag{3.10a}$$

$$r_{t_2} = -r_{xx} + 2qrr_x, \tag{3.10b}$$

which is the GNS equation with derivative coupling given by Chen *et al.* in Ref. 8. Also (3.7b) and (3.8b) become

$$q_{t_3} = q_{xxx} + 3qrq_{xx} + 3(q_x r + q^2 r^2)q_x, \tag{3.11a}$$

$$r_{t_3} = r_{xxx} - 3qrr_{xx} - 3(qr_x - q^2 r^2)r_x, \tag{3.11b}$$

which is the higher order equation of (3.10). As a result, one can obtain the special solutions of the modified KP equation by solving both (3.10) and (3.11).

Substituting constraint (3.9) ($u_1 = u$) into (2.9), and by using (3.10) and (3.11), we can easily obtain

$$u_2 = -qr_x, \quad u_3 = qr_{xx}, \quad \ldots. \tag{3.12}$$

In this way, the pseudo-differential operator (1.2) becomes

$$L = \partial + q\partial^{-1}r\partial, \tag{3.13}$$

and here the following formula

$$\partial^{-1}\theta = \sum_{j=0}^{\infty} (-1)^j (\partial^j \theta)\partial^{-(j+1)} \tag{3.14}$$

is used. Conversely, with L given by (3.13), we construct the family of equations as

$$q_{t_m} = A_m q = (\partial + q\partial^{-1}r\partial)_+^m q, \tag{3.15a}$$

$$r_{t_m} = -\overline{A_m} r = -(-\partial + r\partial^{-1}q\partial)_+^m r. \tag{3.15b}$$

It can be verified that for $m = 2,3$, (3.15) is just (3.10) and (3.11). In Sec. IV we will prove the coincidence of (3.15) with the whole GNS hierarchy with derivative coupling.

Expression (3.13) (or $L_- = q\partial^{-1}r\partial$) is named as the one constraint of the pseudo-differential operator L. The above idea can be extended to the operator L^k, which leads to the notion of the k constraint.

Now we impose a general restraint on L^k by

$$L^k = A_k + q\partial^{-1}r\partial \quad \text{or} \quad (L^k)_- = q\partial^{-1}r\partial, \tag{3.16}$$

such that the coordinates $u_{k+1},u_{k+2},\ldots$ in L can be expressed by the coordinates $u_1,u_2,\ldots,u_k,q,r$ and their derivatives. Then we take the coupled linear problem,

$$L^k\phi=A_k\phi+q\psi=\lambda\phi, \tag{3.17a}$$

$$\psi_x=r\phi_x, \tag{3.17b}$$

and

$$\phi_{t_m}=A_m\phi, \tag{3.18a}$$

$$\psi_{t_m}=C_m\phi, \tag{3.18b}$$

with a finite number of coordinates $u_1,u_2,\ldots,u_k$, q, and r. Here $\lambda=\eta^k$ and C_m is the polynomial in ∂ satisfying

$$\partial C_m=r\partial A_m-\overline{A}_m r\partial. \tag{3.19}$$

The compatibility conditions of (3.17a) and (3.18a), also (3.17b) and (3.18b) with (3.19), yield, respectively,

$$L^k_{t_m}=[A_m,L^k] \tag{3.20a}$$

and

$$r_{t_m}=-\overline{A}_m r. \tag{3.20b}$$

Substituting (3.16) into (3.20a), and comparing the coefficient of the functional term we have

$$q_{t_m}=A_m q, \tag{3.20c}$$

where formulas (3.14) and (3.20b) are used. For the different time variables, the compatibility conditions of (3.18a), or (3.18b), are just Eq. (2.8).

Expression (3.16) is called the k constraint of the pseudo-differential operator L defined by (1.2). When $q=r=0$, (3.16) is reduced to $L^k=A_k$.

IV. ONE-CONSTRAINT AND RELATED EVOLUTION EQUATIONS

In this case, the pseudo-differential operator L is in the form of (3.13), and the spectral problem (3.17) can be written as

$$\phi_x-\lambda q\psi=-\lambda^2\phi, \tag{4.1a}$$

$$-\lambda\psi_x=r\phi_x, \tag{4.1b}$$

or equivalently

$$\phi_x=-\lambda^2\phi+\lambda q\psi, \tag{4.2a}$$

$$\psi_x=\lambda r\phi-qr\psi. \tag{4.2b}$$

By letting

$$\phi=e^{-1/2(\lambda^2 x+\partial^{-1}qr)}\phi_1, \tag{4.3a}$$

$$\psi=e^{-1/2(\lambda^2 x+\partial^{-1}qr)}\psi_1, \tag{4.3b}$$

(4.2) becomes

$$\phi_{1,x}=-\tfrac{1}{2}(\lambda^2-qr)\phi_1+\lambda q\psi_1, \tag{4.4a}$$

$$\psi_{1,x}=\lambda r\phi_1+\tfrac{1}{2}(\lambda^2-qr)\psi_1. \tag{4.4b}$$

After replacing derivatives with respect to x by using (4.4) repeatedly, we can suppose the time evolution for ϕ_1 and ψ_1 in (3.18) with (4.3) as follows:

$$\phi_{1,t_n}=A\phi_1+B\psi_1, \tag{4.5a}$$

$$\psi_{1,t_n}=C\phi_1-A\psi_1, \tag{4.5b}$$

where A, B, and C are polynomials in λ. From the compatibility conditions of (4.4) and (4.5), we can obtain the evolution equations,

$$\begin{pmatrix} q \\ r \end{pmatrix}_{t_n}=\Phi^n\begin{pmatrix} q \\ -r \end{pmatrix}. \tag{4.6a}$$

Here,

$$\Phi=\begin{pmatrix} \partial+qr+q_x\partial^{-1}r-q\partial^{-1}r_x & q_x\partial^{-1}q+q\partial^{-1}q_x \\ r_x\partial^{-1}r+r\partial^{-1}r_x & -\partial+qr+r_x\partial^{-1}q-r\partial^{-1}q_x \end{pmatrix}, \tag{4.6b}$$

and (4.6) is just the GNS hierarchy with the derivative coupling, while (4.4) is its standard spectral problem. When $n=2,3$, (4.6) becomes (3.10) and (3.11).

In what follows, we shall verify that Eq. (3.15) obtained by one constraint coincides with the hierarchy (4.6) indeed. To this end, we require two auxiliary formulas.

Lemma 1: Let the differential operator A_m be defined by (2.1b), and $\overline{A}_m=\partial^{-1}A_m^*\partial$, then

$$(q\partial^{-1}rA_m)_+=q\partial^{-1}rA_m+q\partial^{-1}\overline{A}_m(\partial^{-1}r)\partial. \tag{4.7}$$

Proof: By use of (3.14), we obtain easily

$$\begin{aligned}(q\partial^{-1}rA_m)_-&=\left(q\sum_{j=1}^{m}\partial^{-1}rp_{mj}(u)\partial^j\right)_- \\ &=q\sum_{j=1}^{m}\sum_{i=j}^{\infty}(-1)^{i-1}(\partial^{i-1}rp_{mj}(u))\partial^{j-i} \\ &=-q\sum_{l=0}^{\infty}(-1)^l[\partial^l(\overline{A}_m\partial^{-1}r)]\partial^{-l} \\ &=-q\partial^{-1}\overline{A}_m(\partial^{-1}r)\partial. \end{aligned} \tag{4.8}$$

Therefore, (4.7) holds.

Lemma 2: Let q and r satisfy Eq. (3.20b) and (3.20c), then the functional term $p_{m0}(u)$ of $(L^m)_-$ in (2.1c) can be expressed as

$$p_{m0}(u)=\partial^{-1}(-q\overline{A}_mr+rA_mq). \tag{4.9}$$

Proof: In Eq. (3.20a) with $k=1$,

$$L_{t_m}=[A_m,L]=-[(L^m)_-,L], \tag{4.10}$$

by equating the functional term yields

$$u_{1t_m}=(qr)_{t_m}=p_{m0,x}(u). \tag{4.11}$$

Inserting (3.20b) and (3.20c) into (4.11), one can easily know that (4.9) holds.

Let us now return to verify the coincidence of (3.15) and (4.6).

For $m=1$, the conclusion obviously holds. If it is also true for general m, then for $m+1$ we have

$$A_{m+1}=[(\partial+q\partial^{-1}r\partial)(A_m+p_{m0}(u))]_+=\partial A_m+qrA_m+p_{m0}(u)\partial-(q\partial^{-1}r_xA_m)_+. \tag{4.12}$$

By use of (4.7) and (4.9) yields

$$A_{m+1}q=(\partial+qr+q_x\partial^{-1}r-q\partial^{-1}r_x)A_mq-(q_x\partial^{-1}q+q\partial^{-1}q_x)\overline{A}_mr. \tag{4.13}$$

Similarly,

$$\overline{A}_{m+1}r=-(r_x\partial^{-1}r+r\partial^{-1}r_x)A_mq+(-\partial+qr+r_x\partial^{-1}q-r\partial^{-1}q_x)\overline{A}_mr. \tag{4.14}$$

The above two equalities are just the desired coincidence for $m+1$.

We make the following remarks:

(1) If we choose $r=1$, then the one constraint is reduced to

$$L=\partial+q, \tag{4.15}$$

and the constrained Eq. (3.15) are reduced to

$$q_{t_n}=(\partial+q)^n_+q, \tag{4.16}$$

which is the Burgers hierarchy. In fact, its spectral problem is

$$\phi_x+q\phi=\lambda\phi, \tag{4.17}$$

so, (4.16) can also be written as the following explicit formula:

$$q_{t_n}=(\partial+q+q_x\partial^{-1})^nq_x. \tag{4.18}$$

(2) Setting

$$\phi_1=e^{1/2\,\partial^{-1}qr}\phi_2, \qquad \psi_1=e^{-1/2\,\partial^{-1}qr}\psi_2, \tag{4.19}$$

(4.4) becomes the Kaup–Newell (KN) spectral problem, so we can prove that two kinds of evolution equations [GNS hierarchy (4.6) and KN hierarchy[9]] associated with these spectral problems are equivalent.

V. TWO-CONSTRAINT AND RELATION EVOLUTION EQUATIONS

In this case, the pseudo-differential operator L^2 takes the form,

$$L^2=\partial^2+2u_1\partial+q\partial^{-1}r\partial, \tag{5.1}$$

from which we find that the coordinates $u_2,u_3,\ldots$ in L can be determined by the coordinates u_1, q, r and their x derivatives as

$$u_2=-\tfrac{1}{2}(u_{1,x}+u_1^2-qr), \tag{5.2a}$$

$$u_3=\tfrac{1}{4}(u_{1,xx}+4u_1u_{1,x}+2u_1^3-2qru_1-q_xr-3qr_x), \tag{5.2b}$$

....

Consider the spectral problems given by

$$\phi_{xx}+2u\phi_x+q\psi=\lambda\phi, \tag{5.3a}$$

$$\psi_x=r\phi_x, \tag{5.3b}$$

where $u=u_1$ and $\lambda=\eta^2$. If we replace the x derivatives which are higher than one by (5.3a) repeatedly, then the time evolution for ϕ and ψ in (3.18) can be written as

$$\phi_{t_n}=A\phi_x+B\phi+C\psi, \tag{5.4a}$$

$$\psi_{t_n}=D\phi_x+E\phi+F\psi, \tag{5.4b}$$

where A, B, C, D, E, and F are certain undetermined polynomials in λ. The compatibility of (5.3) and (5.4) requires that $A,B,\ldots,F$ satisfy $(t=t_n)$,

$$2u_t+A_{xx}-2uA_x-(2u_x+qr)A+2B_x+2rC_x+r_xC+qD=0, \tag{5.5a}$$

$$q_t-2qA_x-q_xA-qB+C_{xx}+2uC_x-qrC-\lambda C+qF=0, \tag{5.5b}$$

$$r_t+rA_x-2ruA+rB+r^2C-D_x+2uD-E-rF=0, \tag{5.5c}$$

and

$$2\lambda A_x+B_{xx}+2uB_x+\lambda rC+qE=0, \tag{5.6a}$$

$$\lambda rA+rB_x-\lambda D-E_x=0, \tag{5.6b}$$

$$qrA-rC_x-qD+F_x=0. \tag{5.6c}$$

From these equations one finds that all $A,B,\ldots,F$ can be taken as the nth-order polynomials. Let $a_j,b_j,\ldots,f_j$ be their coefficients of λ^{n-j}, respectively, then by equating the same powers of λ in (5.5) and (5.6), we obtain for $b_n=e_n=0$,

$$g_t=\theta\begin{pmatrix} a_n \\ c_n \\ d_n \end{pmatrix}, \tag{5.7a}$$

$$\begin{pmatrix} a_{j+1} \\ c_{j+1} \\ d_{j+1} \end{pmatrix}=J\theta\begin{pmatrix} a_j \\ c_j \\ d_j \end{pmatrix} \quad (j=0,1,2,\ldots,n-1), \tag{5.7b}$$

and

$$(a_0,c_0,d_0)=(1,0,r), \tag{5.7c}$$

where

$$g=(2u,q,r)^T, \tag{5.8a}$$

$$\theta=\begin{pmatrix} -\partial^2+2u\partial+2u_x+qr & -2r\partial-r_x & -q \\ 2q\partial+q_x+q\partial^{-1}qr & -\partial^2-2u\partial+q\partial^{-1}r_x & -q\partial^{-1}q \\ -r\partial+2ur-r\partial^{-1}qr & -r\partial^{-1}r_x & \partial-2u+r\partial^{-1}q \end{pmatrix}, \tag{5.8b}$$

$$J=\frac{1}{4}\begin{pmatrix} -(1+2\partial^{-1}u) & 2\partial^{-1}r & 2\partial^{-1}q \\ -2q\partial^{-1} & -4 & 0 \\ -(r+2r_x\partial^{-1}+2r\partial^{-1}u) & 2r\partial^{-1}r & 2r\partial^{-1}q+4\partial \end{pmatrix}. \tag{5.8c}$$

The coefficients b_j, e_j $(j=0,1,\ldots,n-1)$ and f_j $(j=0,1,\ldots,n)$ can be determined by a_j, c_j, and d_j according to (5.5) and (5.6). From (5.7), the evolution equations with odd time variables can be given by

$$g_{t_{2n+1}}=\Phi^n g_x, \tag{5.9}$$

where

$$\Phi=\theta J=(\omega_{ij})_{3\times 3}, \tag{5.10}$$

with

$$\omega_{11}=\tfrac{1}{4}\partial^2+\partial qr\partial^{-1}-\partial u\partial^{-1}u, \quad \omega_{12}=\tfrac{3}{2}r\partial+\tfrac{1}{2}r_x+\partial u\partial^{-1}r,$$

$$\omega_{13}=-\tfrac{3}{2}q\partial-\tfrac{1}{2}q_x+\partial u\partial^{-1}q, \quad \omega_{21}=\tfrac{3}{4}q_x+\tfrac{1}{2}q_{xx}\partial^{-1}-\tfrac{1}{2}q_x\partial^{-1}u+uq_x\partial^{-1},$$

$$\omega_{22}=\partial^2+2u\partial+qr-q\partial^{-1}r_x+\tfrac{1}{2}q_x\partial^{-1}r, \quad \omega_{23}=\tfrac{1}{2}q_x\partial^{-1}q+q\partial^{-1}q_x,$$

$$\omega_{31}=-\tfrac{3}{4}r_x-\tfrac{1}{2}r_{xx}\partial^{-1}-\tfrac{1}{2}r_x\partial^{-1}u+ur_x\partial^{-1}, \quad \omega_{32}=\tfrac{1}{2}r_x\partial^{-1}r+r\partial^{-1}r_x,$$

$$\omega_{33}=\partial^2-2u\partial+qr-r\partial^{-1}q_x+\tfrac{1}{2}r_x\partial^{-1}q. \tag{5.11}$$

Especially, when $n=0,1$ we have

$$u_{t_1}=u_x, \quad q_{t_1}=q_x, \quad r_{t_1}=r_x, \tag{5.12}$$

and

$$u_{t_3}=\tfrac{1}{4}u_{xxx}-\tfrac{3}{2}u^2u_x+\tfrac{3}{2}(uqr)_x+\tfrac{3}{4}(q_xr-qr_x)_x, \tag{5.13a}$$

$$q_{t_3}=q_{xxx}+3uq_{xx}+\tfrac{3}{2}(u_x+u^2+qr)q_x, \tag{5.13b}$$

$$r_{t_3}=r_{xxx}-3ur_{xx}-\tfrac{3}{2}(u_x-u^2-qr)r_x. \tag{5.13c}$$

If one takes that A, C, and D are the nth-order polynomials, while B, E, and F, are the $n+1$th-order polynomials in λ, then the evolution equations with the even time variables can be deduced by comparing the coefficient's method from (5.5) and (5.6),

$$g_{t_{2n}}=\Phi^n\theta g_0, \quad g_0=-(0,q,r_x)^T, \tag{5.14}$$

where Φ and θ are defined by (5.10) and (5.8b), respectively. When $n=0$, Eq. (5.14) becomes

$$u_{t_2}=(qr)_x, \tag{5.15a}$$

$$q_{t_2}=q_{xx}+2uq_x, \tag{5.15b}$$

$$r_{t_2}=-r_{xx}+2ur_x. \tag{5.15c}$$

Similar to that in the one constraint, Eqs. (5.9) and (5.14) obtained by linear problems (5.3) and (5.4) coincide with the equations defined by formula (3.20) for $k=2$.

To our knowledge, the constrained Eqs. (5.9) and (5.14) have not been reported in any literature.

ACKNOWLEDGMENTS

The author thanks Mr. Hongwei Xin for his helpful discussions and careful computation concerning the two-constraints. This project is supported by the National Science Foundation of China.

Shear-free relativistic fluids and the absence of movable branch points

R. G. Halburd[a)]
Department of Mathematical Sciences, Loughborough University, Loughborough, Leics, LE11 3TU, United Kingdom

(Received 19 November 2001; accepted for publication 10 January 2002)

The problem of determining the metric for a nonstatic shear-free spherically symmetric fluid (either charged or neutral) reduces to the problem of determining a one-parameter family of solutions to a second-order ordinary differential equation (ODE) containing two arbitrary functions f and g. Choices for f and g are determined such that this ODE admits a one-parameter family of solutions that have poles as their only movable singularities. This property is strictly weaker than the Painlevé property and it is used to identify classes of solvable models. It is shown that this procedure systematically generates many exact solutions including the Vaidya metric, which does not arise from the standard Painlevé analysis of the second-order ODE. Interior solutions are matched to exterior Reissner–Nordstrøm metrics. Some solutions given in terms of second Painlevé transcendents are described. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1455688]

I. INTRODUCTION

Several authors have shown that the problem of finding a nonstatic solution of the Einstein–Maxwell equations for a shear-free spherically symmetric charged fluid is equivalent to the problem of finding a t-dependent solution to the equation

$$\frac{\partial^2 y(x,t)}{\partial x^2} = f(x)y^2(x,t) + g(x)y^3(x,t), \tag{1}$$

where f and g are arbitrary functions of x only[1,2] (see also Ref. 3 and the references therein). Given a solution y of Eq. (1), define $r=\sqrt{x}$, $Y(r,t)=1/y(x,t)$, and

$$T(r,t) = h(t)\frac{\partial}{\partial t}\ln y(r^2,t), \tag{2}$$

where h is an arbitrary nonvanishing function of t. In terms of these variables, the metric for the fluid is given by

$$ds^2 = T^2(r,t)dt^2 - Y^2(r,t)\{dr^2 + r^2 d\Omega^2\}, \tag{3}$$

where $d\Omega^2 = d\theta^2 + \sin^2\theta d\phi^2$ is the standard metric on the two-sphere. The density ρ and pressure p are given by

$$8\pi\rho = 3h^{-2} - 12xy_x^2 + 12yy_x + 8xfy^3 + 6xgy^4, \tag{4}$$

$$8\pi p = 4y(y-2xy_x)\frac{y_{xt}}{y_t} + 12xy_x^2 - 8yy_x + 2xgy^4 - 2h^{-3}h_t\frac{y}{y_t} - 3h^{-2}. \tag{5}$$

a)Electronic mail: r.g.halburd@lboro.ac.uk

The only nonvanishing components of the electromagnetic field are

$$F_{01}=-F_{10}=-h(t)E(r)\frac{\partial y}{\partial t},$$

where $E^2(r)=2xg(x)$.

Although y is a function of two variables x and t, Eq. (1) is essentially an ODE for y as a function of x. As an ODE, the general solution of Eq. (1) contains two arbitrary constants. The general solution of Eq. (1) viewed as a partial differential equation (PDE) is obtained by replacing these arbitrary constants with arbitrary functions of t. Since T is a metric coefficient, it cannot be identically zero, so from Eq. (2) we see that y must have a nonconstant t-dependence. This leads us to the problem of finding families of solutions to Eq. (1) viewed as an ODE which depend on (at least) one parameter.

The connection between integrable systems (equations that are solvable, either explicitly or via a related linear problem) was first used by Kowlevskaya in her work on spinning tops.[4,5] She considered the equations of motion for a spinning top which depend on six parameters (the center of mass and the moments of inertia). Kowalevskaya noticed that in the known cases for which the equations could be integrated, the general solution was a meromorphic function of time when extended to the complex plane. She used local series analysis to determine all choices of the parameters for which the general solution was a meromorphic function of time and found a new set of values for the parameters for which she was then able to solve the equations in terms of ratios of hyper-elliptic functions.

The requirement that all solutions are meromorphic throughout the complex plane may be replaced with the requirement that all solutions be meromorphic on the covering space of **C** with a discrete set of points removed. In this way, branching of solutions is allowed at fixed singularities (singularities of the solutions that cannot occur at arbitrary locations in the complex plane but only at locations at which the equation itself is in some sense singular). An ODE is said to possess the Painlevé property if all movable singularities of all solutions are poles. This property is closely connected with the integrability (solvability) of the ODE. All ODEs that are known to possess the Painlevé property are integrable, either explicitly in terms of classically known functions, or via an associated linear problem. In particular, Painlevé, Gambier, and Fuchs classified all equations of the form

$$\frac{d^2y}{dx^2}=F\left(x;y,\frac{dy}{dx}\right), \tag{6}$$

where F is rational in y and dy/dx and analytic in x, that have the Painlevé property. They showed that each such equation could be transformed via a change of independent variable and an x-dependent Möbius transformation of y to 1 of 50 canonical equations. With the exception of six equations (the Painlevé equations P_I–P_{VI}) each of these canonical equations were solved in terms of classically known functions (see, e.g., Refs. 6 and 7). The first two Painlevé equations are

$$\frac{d^2\eta}{d\zeta^2}=6\eta^2+\zeta, \tag{7}$$

$$\frac{d^2\eta}{d\zeta^2}=2\eta^3+\zeta\eta+\alpha, \tag{8}$$

where α is an arbitrary complex constant. It was later shown that each Painlevé equation is the compatibility condition for a (linear) spectral problem. The Painlevé equations are considered to be integrable because of the underlying structure that emerges from these isomonodromy problems.[7,8]

It is important to note that the transformation of one the equations of the form (6) that possesses the Painlevé property to one of the canonical forms is itself determined by the solutions of a system of differential equations. A weaker definition of the Painlevé property is that all solutions are single-valued about all movable singularities. However, for equations of the form (6) this definition yields the same class of equations.

Shah and Vaidya,[1] Wyman,[9,10] Chatterjee,[11] Maharaj, Leach, and Maartens[12] and Srivastava[13] have studied Eq. (1) to determine choices of f and g for which the general solution has no movable critical points. In particular, Wyman[9] determined all choices of f in the uncharged ($g=0$) case. In Ref. 14 the author found all choices of f and g such that Eq. (1) possesses the Painlevé property. In particular, we have the following.

Proposition 1.1: Equation (1) possesses the Painlevé property (as an ODE in x) if and only if either

(1)

$$f(x)=6w^5(z), \quad g(x)=0, \tag{9}$$

where $w\neq 0$ and v are any solutions of

$$\frac{d^2v}{dz^2}=6v^2+az+b/2, \tag{10}$$

$$\frac{d^2w}{dz^2}=12vw, \tag{11}$$

where a, b are constants and z is given by

$$x=\int w^{-2}(z)dz, \tag{12}$$

or

(2)

$$f(x)=6v(z)w^5(z), \quad g(x)=2w^6(z), \tag{13}$$

where $w\neq 0$ and v are any solutions of

$$\frac{d^2v}{dz^2}=2v^3+(az+b)v+c/2, \tag{14}$$

$$\frac{d^2w}{dz^2}=(6v^2+az+b)w, \tag{15}$$

where a, b, c are constants and z is given by Eq. (12).

Furthermore, in both the above cases, the general solution of Eq. (1) is given by

$$y(x,t)=\frac{u(z,t)-v(z)}{w(z)}, \tag{16}$$

where u (in which t is treated as a parameter) is the general solution of the same second-order equation as v [i.e., in case 1, $u(z,t_0)$, where t_0 is a constant, solves Eq. (10) and in case 2 it solves Eq. (14)].

Note that Eq. (11) [resp. (15)] is the linearization of Eq. (10) [resp. (14)]. So if $v(z)=V(z;\epsilon)$ is a one-parameter family of solutions to Eq. (10) [resp. (14)], then $w(z):=V_\epsilon(z;\epsilon)$ is a solution to Eq. (11) [resp. (15)]. A second independent solution to Eq. (11) [resp. (15)] then

follows by reduction of order. Equation (12) shows that $x=\hat{w}(z)/w(z)$, where $\hat{w}$ is a second solution of Eq. (11) [resp. (15)] satisfying the Wronskian condition $W(w,\hat{w})=w\hat{w}_z-\hat{w}w_z=1$.

If $a=0$, then the general solution to Eq. (10) [resp. (14)] can be given explicitly in terms of elliptic functions. In particular, the case in which $a=0$ and the fixed solution v of Eq. (14) is a constant corresponds to the large class of solutions found by Sussman.[15] In fact, most of the solutions that have appeared in the literature to date are special cases of Sussman's solutions. The case in which v is not constant is solved explicitly in Ref. 14. If $a\neq 0$, then Eq. (10) [resp. (14)] can be mapped to Eq. (7) [resp. (8)]. A class of solutions to Eq. (1) corresponding to the Airy function solutions to Eq. (8) is also described in Ref. 14.

Recall that we wish to find one-parameter families of solutions to Eq. (1). When f and g are chosen so that Eq. (1) possesses the Painlevé property then the equation is integrable and we can find a two-parameter family of solutions. In the present article a property, weaker than the Painlevé property but still complex-analytic in nature, is considered. Namely, we wish to find all one-parameter families of solutions $\mathcal{F}$ to Eq. (1) such that all movable singularities of all solutions in $\mathcal{F}$ are poles. In Sec. II we will find all solutions to Eq. (1) that are simultaneously solutions of a Riccati equation. This class of solutions contains the well-known solutions due to Shah and Vaidya,[16] which does not arise in a regular Painlevé analysis of Eq. (1). A class of solutions that generalizes that due to Shah and Vaidya which is given in terms of solutions to linear equations is also derived.

Sections III and IV address the question of whether the solutions found in Sec. II exhaust the set of all one-parameter families of solutions $\mathcal{F}$ described above. In Sec. V, boundary conditions are determined such that the Riccati solutions can be matched to the Reissner–Nordstrøm external solution. In Sec. VI we find solutions to Eq. (1) corresponding to $a\neq 0$ but $v\equiv 0$ in Eq. (14). In this case the general solution to Eq. (15) is given in terms of Airy functions. From this solution, families of solutions are obtained using the Bäcklund transformation of the second Painlevé equation.

II. RICCATI SOLUTIONS

One way of finding a one-parameter family of solutions to Eq. (1) such that the only movable singularities are poles is to find a family of solutions that are also solutions of a first-order equation of Painlevé type. In this section, solutions to Eq. (1) are found that are also solutions to a first-order differential equation of the form

$$\frac{dy}{dx}=R(x,y), \tag{17}$$

where R is rational in y and locally analytic in x. Fuchs[17] showed that the only equation of the form (17) with the Painlevé property is the Riccati equation,

$$\frac{dy}{dx}=\alpha(x)y^2+\beta(x)y+\gamma(x), \tag{18}$$

where α, β, and γ are (locally) analytic functions of x. The general solution of Eq. (18) is given by

$$y(x)=-\frac{1}{\alpha(x)}\frac{d}{dx}\ln\Phi(x),$$

where Φ is the general solution of the linear equation

$$\frac{d^2\Phi}{dx^2}-\left(\beta+\frac{\alpha_x}{\alpha}\right)\frac{d\Phi}{dx}+\alpha\gamma\Phi=0. \tag{19}$$

Differentiating Eq. (18) with respect to x and again using Eq. (18) to eliminate dy/dx in the resulting expression gives

$$\frac{d^2y}{dx^2}=2\alpha^2y^3+(\alpha_x+3\alpha\beta)y^2+(\beta_x+\beta^2+2\alpha\gamma)y+(\gamma_x+\beta\gamma). \tag{20}$$

It follows that every solution of Eq. (18) is a solution of Eq. (1) if and only if the equations

$$\gamma_x+\beta\gamma=0, \tag{21}$$

$$\beta_x+\beta^2+2\alpha\gamma=0, \tag{22}$$

$$\alpha_x+3\alpha\beta=f, \tag{23}$$

$$2\alpha^2=g, \tag{24}$$

are satisfied.

Solving Eqs. (21)–(24) gives three classes of Riccati equations.

Case 1: $\beta\equiv 0$, $\gamma\equiv 0$. The Riccati equation (18) becomes

$$\frac{dy}{dx}=\alpha y^2,$$

which has the general solution

$$y(x,t)=\frac{1}{H(x)+G(t)}, \tag{25}$$

where $H'(x)=-\alpha(x)$ and G is an arbitrary function of t.

Case 2: $\beta\not\equiv 0$, $\gamma\equiv 0$. The Riccati equation (18) becomes

$$\frac{dy}{dx}=\alpha y^2+\frac{1}{x+C}y,$$

where C is an arbitrary constant, which has the general solution

$$y(x,t)=\begin{cases}\dfrac{x}{H(x)+G(t)}, & H'(x)=-x\alpha(x), \quad \text{if } C=0,\\[2ex] \dfrac{1+kx/4}{H(x)+G(t)}, & H'(x)=-(1+kx/4)\alpha(x), \quad \text{if } C=4/k\neq 0,\end{cases} \tag{26}$$

where G is an arbitrary function of t.

Case 3: $\gamma\not\equiv 0$. The Riccati equation (18) becomes

$$\frac{dy}{dx}+\frac{1}{2}(\gamma^{-1})_{xx}y^2+\frac{\gamma'}{\gamma}y-\gamma=0. \tag{27}$$

In Sec. V, these Riccati solutions will be matched to an external Reissner–Nordstrøm metric.

Note that Eq. (25) corresponds to setting $k=0$ in Eq. (26b). Under the transformation

$$\tilde{r}=\frac{r}{1+kr^2/4}$$

(recall $x=r^2$) the solutions corresponding to Eq. (26b) give rise to the metric

$$ds^2=[F(\tilde{r})+G(t)]^{-2}dt^2-[F(\tilde{r})+G(t)]^2\left[\frac{d\tilde{r}^2}{1-k\tilde{r}^2}+\tilde{r}^2d\Omega^2\right], \tag{28}$$

where $F(\tilde{r})=H(r^2)$ and we have set $h(t)=1/\dot{G}(t)$. The metric (28) was obtained by Shah and Vaidya.[16] This metric does not arise from the standard Painlevé analysis of Eq. (1).

Solutions found in this section will be referred to as Riccati solutions.

III. LOCAL SERIES ANALYSIS

In this section we will analyze Eq. (1) as an ODE in the complex domain. In particular, we will determine necessary conditions that Eq. (1) possesses a one-parameter family of Laurent series solutions. We begin by considering the case in which $g=0$. Under the transformation (16) in which w is given by Eq. (9), v is given by Eq. (11), and z is given implicitly by Eq. (12), Eq. (1) becomes

$$\frac{d^2u}{dz^2}=6u^2+A(z), \tag{29}$$

where

$$A(z)=\frac{d^2v}{dz^2}-6v^2.$$

We will only consider a one-parameter family of solutions $\mathcal{G}$ such that there exists an open connected bounded set $\Omega\in\mathbf{C}$ such that at each point $z_0\in\Omega$ there is a function $u\in\mathcal{G}$ with a pole at $z=z_0$. We will now find a necessary condition on the function A such that Eq. (29) admits a formal Laurent series solution with a pole at a point $z_0\in\Omega$, where A is analytic. Substituting the Laurent series

$$u(z)=\sum_{n=0}^{\infty}a_n(z-z_0)^{n-p}, \tag{30}$$

where p is a positive integer and $a_0\neq 0$, into Eq. (29) gives, to leading order,

$$p(p+1)a_0(z-z_0)^{-(p+2)}+\ldots=6a_0^2(z-z_0)^{-2p}+\ldots.$$

Equating the powers and coefficients of these leading-order terms gives

$$p=2,\quad a_0=1. \tag{31}$$

Using Eqs. (30) and (31) in Eq. (29) and equating coefficients of like powers of $z-z_0$ gives

$$(n+1)(n-6)a_n=P_n(a_0,a_1,\ldots,a_{n-1}), \tag{32}$$

where

$$P_n(a_0,a_1,\ldots,a_{n-1})=6\sum_{m=1}^{n-1}a_ma_{n-m}+\alpha_n(z_0),$$

and

$$\alpha_n(z_0)=\begin{cases}0, & n<4,\\ \dfrac{A^{(n-4)}(z_0)}{(n-4)!}, & n\geqslant 4,\end{cases}$$

is polynomial in its arguments and we have expanded A as a power series about $z=z_0$. The recurrence relation (32) shows that a_n is uniquely determined in terms of $\{a_0,\ldots,a_{n-1}\}$, except in the case when $n=6$. In this case, the left side of Eq. (32) vanishes while the right side is a known function of $(a_0,\ldots,a_5)$. If the right side does not vanish, then there is no solution to Eq. (29) with a pole of any order at $z=z_0$. If the right side of Eq. (32) does vanish, then a formal Laurent series solution exists in which z_0 and a_6 are arbitrary constants. A direct calculation shows that the right side of Eq. (32) vanishes if and only if

$$A''(z_0)=0. \tag{33}$$

Now since Eq. (33) must be satisfied for all z_0 in the open set Ω, this implies that $A(z)=az+b/2$, for some constants a and b. So, we reproduce precisely those solutions given in case 1 of Proposition 1.1.

Now we consider the local series analysis of Eq. (1) when g is not identically zero. In particular, g does not vanish identically on Ω. From Sec. 2 we see that the requirement that there is a one-parameter family of solutions such that all movable singularities are poles yields more solutions than requiring that Eq. (1) possesses the Painlevé property.

Let v and w be defined by Eq. (13) where z is given by Eq. (12). [Note that we are not assuming that Eqs. (14) and (15) hold.] The transformation (16) gives

$$\frac{d^2u}{dz^2}=2u^3+B(z)u+C(z), \tag{34}$$

where

$$B(z)=\frac{w_{zz}}{w}-6v^2, \quad C(z)=v_{zz}-vB(z)-2v^3.$$

We now look for a local Laurent series solution to Eq. (34) with a pole at $z=z_0\in\Omega$. Leading order analysis shows that any such solution u must have a simple pole at $z=z_0$ with residue ±1. Hence we substitute the series

$$u(z)=\sum_{n=0}^{\infty}a_n(z-z_0)^{n-1}, \quad a_0=\varepsilon=\pm1,$$

into Eq. (34) and equate coefficients of like powers of $z-z_0$ to obtain the recurrence relation

$$(n+1)(n-4)a_n=Q_n(a_0,\ldots,a_{n-1}), \tag{35}$$

where

$$Q_n(a_0,\ldots,a_{n-1})=2\left[\sum_{m=0}^{n}\sum_{m'=0}^{n-m}a_ma_{m'}a_{n-m-m'}-3a_n\right]+\beta_n(z_0)+\gamma_n(z_0),$$

and

$$\beta_n(z_0)=\begin{cases}0, & n<2,\\ \displaystyle\sum_{m=0}^{n-2}\frac{B^{(n-m-2)}(z_0)}{(n-m-2)!}a_m, & n\geqslant2,\end{cases} \qquad \gamma(z_0)=\begin{cases}0, & n<3,\\ \dfrac{C^{(n-3)}(z_0)}{(n-3)!}, & n\geqslant3.\end{cases}$$

Note that Q is polynomial in its arguments. The left side of Eq. (35) shows that a necessary and sufficient condition for the existence of a formal Laurent series solution with a pole at $z=z_0$ is $Q_4(a_0,a_1,a_2,a_3)=0$, which is equivalent to $B''(z_0)=-2\varepsilon C'(z_0)$, where $\varepsilon=\pm1=a_0$.

Now the general solution of Eq. (34) will have movable singularities with leading order behaviors that include both $+1$ and -1 residue poles (although, in general, these solutions will not be meromorphic and the Laurent series will have to be augmented by logarithm terms). So if we demand that all movable singularities of all solutions are poles [i.e., if we demand that Eq. (34) possess the Painlevé property], then $B''(z_0)=2'C(z_0)$ and $B''(z_0)=-2C'(z_0)$, for all $z_0\in\Omega$, leading to $B(z)=az+b$, and $C(z)=c/2$, where a, b, and c are arbitrary constants. So u satisfies Eq. (14).

Rather than demand that all movable singularities of all solutions of Eq. (34) are poles, we restrict our consideration to a subset of solutions $\mathcal{G}$ such that given any $z_0\in\Omega$, there is a solution in $\mathcal{G}$ with a pole at $z=z_0$. The above analysis shows that either we are left with Eq. (14) or we must consider the class of solutions where all movable singularities are poles and all but a finite number of these poles in ω have the same residue $\varepsilon=\pm 1$. A necessary condition in this case is the differential equation $B''(z)=-2\varepsilon C'(z)$. In terms of $q(z):=B(z)/2$, we now restrict ourselves to the study of the subset of solutions to the equation

$$\frac{d^2u}{dz^2}=2u^3+2qu+(\kappa-\varepsilon q_z),\quad \varepsilon=\pm 1, \tag{36}$$

where κ is an arbitrary constant, that admit only poles with residue ε in Ω.

IV. THE UNIQUENESS OF THE RICCATI SOLUTIONS

The only Riccati equation for which all solutions u are also solutions of Eq. (36) is

$$\frac{du}{dz}+\varepsilon(u^2+q)=0,\quad \kappa=0. \tag{37}$$

The general solution of equation (37) is given by

$$u=\varepsilon\frac{d}{dz}\ln\Phi, \tag{38}$$

where Φ is the general solution of the linear equation

$$\frac{d^2\Phi}{dz^2}+q\,\Phi=0. \tag{39}$$

We will show that these Riccati type solutions are identical to those found in Sec. II. All movable singularities of any solution to Eq. (37) are simple poles with residue ε. So the general solution to Eq. (37) is a one-parameter family of solutions to Eq. (36) of the kind considered at the end of the previous section. The perturbation argument described below suggests that this is the only such one-parameter family. We will then provide a proof based on Wiman–Valiron theory for the case in which q is a polynomial. Wiman–Valiron theory is particularly useful for finding entire solutions of analytic differential equations.[18]

We will now show how the Riccati equations derived in Sec. II are related to the solutions of Eq. (36) described at the end of Sec. III. It may be verified that the identity

$$w(u_z+\varepsilon[u^2+q])=y_x+\varepsilon w^3y^2+w(w_z+2\varepsilon vw)y+w(v_z+\varepsilon[v^2+q]) \tag{40}$$

follows from Eqs. (12) and (16). Furthermore, given Eqs. (12) and (13), where v and w satisfy

$$v_{zz}=2v^3+2qv-\varepsilon q_z \tag{41}$$

and

$$w_{zz}=(6v^2+2q)w, \tag{42}$$

respectively, it can be shown that Eqs. (21)–(24) are equivalent to

$$\alpha=-\varepsilon w^3, \tag{43}$$

$$\beta=-w(w_z+2\varepsilon v w), \tag{44}$$

$$\gamma=-w(v_z+\varepsilon[v^2+q]). \tag{45}$$

Equations (40) and (43)-(45) show that the Riccati solutions found in Sec. II are the same as those constructed using (16) where u is the general solution of Eq. (37) and v, w satisfy Eqs. (41) and (42), respectively. It is interesting to note that the solution by Shah and Vaidya discussed in Sec. II corresponds to the case in which v also satisfies the Ricatti equation (37). The $\gamma\neq 0$ case (case 3 in Sec. II) corresponds to a non-Ricatti solution v of Eq. (41) (although u still satisfies a Riccati equation).

Next we address the question of whether the class $\mathcal{G}$ consists only of Riccati solutions. Consider Eq. (36) with $q(z)=q_0+hQ(z)$, where q_0 is a complex constant and h is a small complex parameter. To leading order in h, Eq. (36) is

$$\frac{d^2u}{dz^2}=2u^3+2q_0u+\kappa.$$

If u is not constant, then

$$\left(\frac{du}{dz}\right)^2=u^4+2q_0u^2+2\kappa u+C, \tag{46}$$

where C is an integration constant. The nonconstant solutions of Eq. (46) are elliptic functions with simple poles of residue ± 1. The only solutions with poles of residue $\varepsilon=\pm 1$ but no poles of residue $-\varepsilon=\mp 1$ correspond to the case in which $\kappa=0$ and $C=q_0^2$ in which case Eq. (46) factors into two Riccati equations and u satisfies

$$\frac{du}{dz}+\varepsilon(u^2+q_0)=0.$$

The arguments given above assume that the one-parameter family of solutions $\mathcal{G}$ have poles in an open set Ω. In the following we show rigorously that we have found all one-parameter families of solutions that have only poles as their movable singularities under the assumption that q is a polynomial.

Consider the system of first-order equations

$$\frac{du}{dz}=\tilde{u}-\varepsilon u^2-\varepsilon q, \tag{47}$$

$$\frac{d\tilde{u}}{dz}=\kappa+2\varepsilon u\tilde{u}. \tag{48}$$

Differentiating Eq. (47) with respect to z and using Eq. (48) to eliminate $d\tilde{u}/dz$ gives Eq. (36). We wish to show that if there is a one-parameter family of solutions u having only movable poles with residue ε, then $\tilde{u}$ is identically zero. Note that if $\tilde{u}$ is identically zero, then Eq. (47) becomes Eq. (37) and Eq. (48) implies that $\kappa=0$. If $\tilde{u}$ does not vanish identically, then we can solve Eq. (48) for u and substitute it into Eq. (47) to give

$$2\tilde{u}\frac{d^2\tilde{u}}{dz^2}=\left(\frac{d\tilde{u}}{dz}\right)^2+4\tilde{u}^2(\varepsilon\tilde{u}-q)-\kappa^2. \tag{49}$$

We will prove the following.

Proposition 4.1: If q is a polynomial, then either any entire solution of Eq. (49) is a constant or

$$q=q_0+q_1z+q_2z^2,$$

where

$$q_1^2-4q_0q_2=\kappa^2 \tag{50}$$

and

$$\tilde{u}=\varepsilon q. \tag{51}$$

Note that if $\tilde{u}$ is one of the solutions given in Proposition 4.1 but $\tilde{u}\not\equiv 0$, then since $\tilde{u}$ contains no free parameters (i.e., no parameters other than those in the equation itself) u is given by Eq. (48) and so does not represent a one-parameter family of solutions to Eq. (36).

Proof: We will begin by showing that any polynomial solution of Eq. (49) is either a constant or the solution (51). We will then use the central index from Wiman–Valiron theory to show that there are no transcendental (i.e., nonpolynomial) solutions.

Let q and $\tilde{u}$ be polynomials of degree M and N, respectively. Furthermore, we assume that $\tilde{u}$ is not constant (i.e., $N\geqslant 1$ and $\tilde{a}_N\neq 0$). Then q and $\tilde{u}$ have expansions of the form

$$q(z)=\sum_{m=0}^{M}q_mz^m,\quad \tilde{u}(z)=\sum_{n=0}^{N}\tilde{a}_nz^n. \tag{52}$$

Substituting the expansions (52) into Eq. (49) and balancing the dominant terms for large z gives $M=N$. Equation (49) then becomes

$$\sum_{i,j=0}^{N}i(2i-j-2)\tilde{a}_i\tilde{a}_jz^{i+j-2}+\kappa^2=\sum_{i,j,k=0}^{N}4\tilde{a}_i\tilde{a}_j(\varepsilon\tilde{a}_k-q_k)z^{i+j+k}. \tag{53}$$

Now the polynomial on the left side of Eq. (53) is of degree at most $2N-2$ while the degree of the polynomial on the right side is of degree at most $3N$. Since $\tilde{a}_N\neq 0$, then the coefficient of z^{3N} in Eq. (49) gives $\tilde{a}_N=\varepsilon q_N$. Arguing by induction, equating the coefficients of $z^{3M-1},z^{3M-2},\ldots,z^{2N+1}$ to zero gives $\tilde{a}_{N-n}=\varepsilon q_{N-n}$, $n=1,\ldots,N$. Hence $\tilde{u}=\varepsilon q$ and the right side of Eq. (53) vanishes identically. On equating all coefficients of powers of z to zero on the left side of Eq. (49) we find that $N=2$ and q_0, q_1, and q_2 satisfy Eq. (50).

Now we will use Wiman–Valiron theory to show that all entire solutions to Eq. (49) are polynomials. Since $\tilde{u}$ is entire it has an expansion of the form

$$\tilde{u}(z)=\sum_{n=0}^{\infty}\tilde{a}_nz^n.$$

The *central index* $\nu(r,\tilde{u})$ is the greatest non-negative integer m such that

$$|\tilde{a}_m|r^m=\max_{n\geqslant 0}|\tilde{a}_n|r^n.$$

If $\tilde{u}$ is nonpolynomial, then $\nu(r,\tilde{u})$ is increasing, piecewise constant, right-continuous, and tends to $+\infty$ as $r\to+\infty$.

In terms of the central index we have the following lemma (see, e.g., Ref. 19).

Lemma 4.2: Let $\tilde{u}$ be a nonpolynomial entire function, and $\nu=\nu(r,\tilde{u})$ be its central index. Let $0<\delta<1/4$ and z be such that $|z|=r$ and

$$|\tilde{u}(z)|>\nu(r,\tilde{u})^{-(1/4)+\delta}\max_{|z|=r}|\tilde{u}(z)| \tag{54}$$

holds. Then there exists a set $F\subset\mathbf{R}$ of finite logarithmic measure, i.e., $\int_F dt/t<+\infty$ such that

$$\tilde{u}^{(m)}(z)=\left(\frac{\nu(r,\tilde{u})}{z}\right)^m(1+o(1))\tilde{u}(z) \tag{55}$$

holds for all $m\geqslant 0$ and $r\notin F$.

Lemma 4.2 says that for all positive r outside of the set F (which has finite logarithmic measure), the estimate (55) holds near the maximum of $|\tilde{u}|$ on the circle $|z|=r$ [where "near the maximum" means the set of z satisfying Eq. (54)].

Assume that there is a nonpolynomial solution $\tilde{u}$ of Eq. (49). Applying the estimate (55) to Eq. (49) gives

$$\left(\frac{\nu(r,\tilde{u})}{z}\right)^2\tilde{u}^2\sim 4\varepsilon\tilde{u}^3. \tag{56}$$

Since $\nu(r,\tilde{u})$ grows much slower than $\tilde{u}$,[20] it follows that Eq. (56) cannot be balanced. Thus the only entire solutions to Eq. (49) are polynomials. ■

V. BOUNDARY CONDITIONS FOR THE RICCATI SOLUTIONS

In this section we will match the Riccati solutions introduced in Sec. II to an external Reissner–Nordstrøm metric

$$ds^2=\hat{\Gamma}d\hat{t}^2-\hat{\Gamma}^{-1}d\hat{r}^2-\hat{r}^2d\Omega^2, \tag{57}$$

where $d\Omega^2$ is the standard metric on the two-sphere and

$$\hat{\Gamma}=1-\frac{2m}{\hat{r}}+\frac{4\pi e^2}{\hat{r}^2},$$

and m and e are constants. Let Σ_0 be the interface $r=r_0$ between the two solutions. The two metrics (3) and (57) can be matched across Σ_0 provided

$$p(r_0,t)=0, \tag{58}$$

$$g(r_0^2)=2\pi\left(\frac{e}{r_0^3}\right)^2, \tag{59}$$

$$2m=\left[\frac{4\pi e^2}{r}y+\frac{r^3}{h^2y^3}+2\frac{r^2}{y^2}y_r-\frac{r^3}{y^3}y_r^2\right]_{r=r_0}, \tag{60}$$

for all t.[2]

Equation (59) is equivalent to

$$\alpha^2(r_0^2)=\pi\left(\frac{e}{r_0^3}\right)^2. \tag{61}$$

Using Eq. (18) to eliminate y_x and $y_{xt}=(2\alpha y+\beta)y_t$ from Eq. (5) gives

$$8\pi p = 4\{(\beta^2 + 2\alpha\gamma)x - \beta)y^2 + 2\gamma(2\beta x - 1)y + 3x\gamma^2\} - 3h^{-2} - 2h^{-3}h_t\frac{y}{y_t}. \tag{62}$$

Using Eq. (18) to eliminate $y_r = 2ry_x$ from Eq. (60) and using Eq. (62) in Eq. (58), we see that Eqs. (58) and (60) are equivalent to

$$h^{-2}(t) = 4\left[r^2\gamma + \gamma(2r^2\beta - 1)y + \{(\beta^2 + 2\alpha\gamma)r^2 - \beta\}y^2 + \left(\frac{m}{2r^3} + 2r^2\alpha\beta - \alpha\right)y^3\right]_{r=r_0}. \tag{63}$$

A. Dust solutions

Setting p identically zero in Eq. (62) and solving for h^{-2} gives

$$h^{-2} = 4[x\gamma + \gamma(2x\beta - 1)y + \{(\beta^2 + 2\alpha\gamma)x - \beta\}y^2 + \delta y^3], \tag{64}$$

where δ is a function of x only. Recall that h is a function of t only. Differentiating Eq. (64) with respect to x and using Eqs. (21) and (22) gives

$$3\alpha\delta y^2 + \{\delta_x + 3\beta\delta + 2\alpha[(\beta^2 + 2\alpha\gamma)x - \beta]\}y + \gamma\{2x\alpha_x + 3[\alpha + \delta]\} = 0, \tag{65}$$

for all t. Since y must have nonconstant t-dependence, the coefficients of different powers of y in Eq. (65) must vanish identically. If $\alpha = 0$, then $g = 0$ and there are no Riccati solutions. Therefore the coefficient of y^2 in Eq. (65) shows that δ is identically zero. The constant term in Eq. (65) shows that either $\gamma \equiv 0$ or $\alpha(x) = \kappa x^{-3/2}$, where κ is a constant.

If $\gamma = 0$, then the coefficient of y in Eq. (65) shows that either $\beta = 0$ or $\beta = 1/x$. These solutions correspond to the solutions (25) and (26), respectively. Finally, if $\gamma \neq 0$ and $\alpha \neq 0$, then recall from Sec. II (case 3) that for any Riccati solution we must have $\alpha = -(\gamma^{-1})_{xx}$ and $\beta = -\gamma_x/\gamma$. It follows that the coefficient of y and the constant term in Eq. (65) cannot both vanish identically.

VI. BÄCKLUND TRANSFORMATIONS AND SPECIAL SOLUTIONS

In this section we will construct what is perhaps the simplest solution of Eq. (1) involving a genuine transcendent of the second Painlevé equation. It is simple in the sense that we have an explicit formula for the dependence of x on z. We will then use the well-known Bäcklund transformation of the second Painlevé equation to construct a countable family of equations of the form (1) together with their general solutions in terms of second Painlevé transcendents.

If $a \neq 0$, then, after rescaling z and v, Eqs. (14) and (15) become

$$\frac{d^2v}{dz^2} = 2v^3 + zv + \alpha, \tag{66}$$

$$\frac{d^2w}{dz^2} = (6v^2 + z)w, \tag{67}$$

where α is an arbitrary constant. Equation (66) is the standard form of the second Painlevé equation. We will denote the general solution of Eq. (66) by $v(z) = P_{II}(z;\alpha;c_1,c_2)$, where c_1 and c_2 are independent parameters (e.g., $c_1 = v(0)$ and $c_2 = v'(0)$).

Recall that, apart from the solution due to Shah and Vaidya [(Eq. (28)], many of the solutions that appear in the literature are special cases of the solutions of Sussman,[15] which correspond to the special case of Proposition 1.1 in which $a = 0$ and v is a constant. Note that if $a \neq 0$, then Eq. (66) [which is a rescaled version of Eq. (14)] admits a constant solution if and only if $\alpha = 0$. In this case the constant solution is $v \equiv 0$, which is equivalent to the case $f \equiv 0$.

If $v \equiv 0$, then Eq. (67) has the general solution

$$w(z)=\mu \mathrm{Ai}(z)+\nu \mathrm{Bi}(z),$$

where Ai and Bi are the Airy functions and μ and ν are arbitrary constants which are not both zero. From Eq. (12) we have

$$x=\pi \frac{\rho \mathrm{Ai}(z)+\sigma \mathrm{Bi}(z)}{\mu \mathrm{Ai}(z)+\nu \mathrm{Bi}(z)},$$

where ρ and σ are arbitrary constants satisfying $\mu\sigma-\nu\rho=1$. [Note the identity $\mathrm{Ai}(z)\mathrm{Bi}'(z)-\mathrm{Bi}(z)\mathrm{Ai}'(z)=\pi^{-1}$.] In particular, choosing $\mu=\sigma=1$ and $\nu=\rho=0$, we see that the general solution of $y_{xx}=\mathrm{Bi}^6(z)y^3$ is

$$y(x)=\frac{P_{II}(z;0;c_1,c_2)}{\mathrm{Bi}(z)},$$

where c_1 and c_2 are arbitrary constants (or functions of t, viewing the equation as a PDE) and z is given by

$$\frac{\mathrm{Bi}(z)}{\mathrm{Ai}(z)}=\frac{x}{\pi}.$$

Now we will see how to generate other solutions from the $v=0$ case just described. Let v be a solution of Eq. (66) where $\alpha\neq-\frac{1}{2}$. Then it is well known[21] that

$$\tilde{v}:=-v-\frac{1+2\alpha}{2v_z+2v^2+z} \tag{68}$$

satisfies Eq. (66) with α replaced by $\alpha+1$. Equation (68) is the standard Bäcklund transformation of Eq. (66). Let $V(z;\epsilon)$ be a one-parameter (i.e., ϵ) family of solutions to Eq. (66). Since Eq. (67) is the linearization of Eq. (66), it follows that $W(z;\epsilon):=V_\epsilon(z;\epsilon)$ is a solution to Eq. (67). Substituting $v=V(z;\epsilon)$ into Eq. (68) and differentiating with respect to ϵ shows that

$$\tilde{w}:=-w+2(1+2\alpha)\frac{w_z+2vw}{(2v_z+2v^2+z)^2} \tag{69}$$

satisfies Eq. (67) with v replaced by $\tilde{v}$, whenever w satisfies Eq. (67).

Applying the Bäcklund transformations (68) and (69) to $v(z)=0$, $w(z)=\mathrm{Ai}(z)$, described above, yields $\tilde{v}(z)=-z^{-1}$ and $\tilde{w}(z)=2z^{-2}\mathrm{Ai}'(z)-\mathrm{Ai}(z)$. It follows that

$$y(x)=\frac{z^2P_{II}(z;1;c_1,c_2)+z}{2\mathrm{Ai}'(z)-z^2\mathrm{Ai}(z)}$$

is the general solution of Eq. (1) with $f(x)=6\tilde{v}(z)\tilde{w}^5(z)$ and $g(x)=2\tilde{w}^6(z)$, where

$$\frac{2\mathrm{Bi}'(z)-z^2\mathrm{Bi}(z)}{2\mathrm{Ai}'(z)-z^2\mathrm{Ai}(z)}=\frac{x}{\pi}.$$

Repeated application of the Bäcklund transformations (68) and (69) will generate a countable family of equations of the form (1) and solutions in which v is a rational function of z and w is a rational function of z, the Airy functions Ai and Bi and their first derivatives.

VII. DISCUSSION

The search for metrics modeling nonstatic shear-free spherically symmetric charged fluids naturally leads to the problem of finding one-parameter families of solutions to Eq. (1). The

Painlevé property is a very powerful detector of the integrability of ODEs. Indeed, most of the solutions to Eq. (1) that have appeared in the literature to date arise naturally from the Painlevé analysis of Eq. (1) (see Ref. 14). However, since Eq. (1) is second-order while we only require a one-parameter family of solutions, it is not necessary for us to describe the general solution. From this point of view, requiring the Painlevé property is too restrictive.

In this article we have considered the problem of determining one-parameter families of solutions to Eq. (1) whose only movable singularities are poles. Besides the solutions covered by Proposition 1.1 [which corresponds to the cases in which Eq. (1) possesses the full Painlevé property] we found one-parameter families of solutions that satisfy Riccati equations. In particular, this class of solutions contains those of Shah and Vaidya, which do not arise in the standard Painlevé analysis of Eq. (1). The procedure for matching the Riccati solutions to an external Reissner–Nordstrøm metric was also described.

Finally, a special subclass of solutions that arise in Proposition 1.1 were described. In general, when $a \neq 0$, the transformation between x and z involves derivatives of a second Painlevé transcendent. In the class of solutions described in Sec. VI, v, w, and x are given explicitly in terms of Airy functions and there first derivatives—only u is a genuine Painlevé transcendent. Presumably this is the simplest class of solutions characterized by Proposition 2 that contains a genuine Painlevé transcendent.

Associated Lamé and various other new classes of elliptic potentials from sl(2,$\mathbb{R}$) and related orthogonal polynomials

Asish Ganguly[a)]

(Received 5 June 2001; accepted for publication 10 January 2002)

Using representations of sl(2,$\mathbb{R}$) generators which yield associated Lamé Hamiltonians we obtain new classes of elliptic potentials. We explicitly calculate eigenstates and spectra for these potentials and construct the associated orthogonal polynomials. We show that in the proper limit these potentials reduce to well-known exactly solvable potentials. © *2002 American Institute of Physics.*

I. INTRODUCTION

The study of band-edge energies and wave functions for the class of periodic potentials plays an important role in quantum mechanics.[1–6] Recently, it was shown[1] within the framework of supersymmetric quantum mechanics[2] that the bosonic and fermionic sectors for a periodic superpotential $W(x)$ possess an identical spectra (including the zero mode) provided $\int_{\text{period}} W(x)\,dx = 0$. A wide class of solvable periodic potentials was obtained[3] by applying supersymmetry transformations on Lamé and associated Lamé equation,[7,8] and it turned out that the superpartners of Lamé potentials are not physically identical except for some particular cases. On the other hand, periodic potentials belonging to the quasi-exactly solvable (QES) class have also been well studied in the literature.[9–19] It is useful to note that an early treatment on the noncompact sl(2,$\mathbb{R}$) Lie-algebraic scheme is due to Turbiner who formulated the basics of this formalism, gave the first classification of one-dimensional QES, and proposed multidimensional generalizations. Indeed, in Ref. 12 the connection between one-dimensional QES problems and the sl(2,$\mathbb{R}$) algebra was discovered (see also the review by Shifman[13]). Later in this formalism Lamé equation was algebraized[14,15] for integer as well as half-integer values of the potential parameter. Here it may be mentioned that a connection of periodic QES Hamiltonian within a compact Lie-algebraic approach was made by Alhassid *et al.*[16] by expressing the Hamiltonian as a quadratic in su(2) generators.

Recently we have proposed[17] an algebraization of the associated Lamé equation, namely

$$-\psi''(x)+[m(m+1)sn^2x+l(l+1)cn^2x/dn^2x]k^2\psi(x)=E\psi(x) \tag{1.1}$$

for $m,\ l\in\mathbb{R}$ and (m,l) lying in at least one algebraic line (AL) in the m-l plane. Here $snx \equiv sn(x,k)$, $cnx\equiv cn(x,k)$, $dnx\equiv dn(x,k)$ are three Jacobian elliptic functions of real modulus $k(0<k^2<1)$ and $k'^2=1-k^2$ is the complementary modulus. An associated Lamé equation provides a more general class of periodic potentials due to the presence of two parameters m,l and reduces to an ordinary Lamé equation when either of l and m takes the value 0 or -1. The explicit solutions were obtained by us for two cases: (i) m, l are both non-negative integers and (ii) m is a half-integer and l is an integer or half-integer. One of the aims of the present work is to extend our method of algebraization to the third new case when m is an integer but l is a half-integer. To the

a)Electronic mail: asish@cucc.ernet.in, gangulyasish@rediffmail.com

best of our knowledge, our solutions of associated Lamé equation for integer and half-integer combinations of the parameters m and l are new. We also generate two new classes of elliptic potentials and discuss their implications to the exactly solvable class. We also calculate band-edge eigenstates and energies for these new potentials.

The organization of the article is as follows. In Sec. II we discuss the basic method of generating a wide range of families of elliptic potentials within sl(2,$\mathbb{R}$), thereby obtaining three new classes of potentials. In Sec. III we algebraize the associated Lamé equation as a special case of one of them and make a systematic analysis to find the effective combination of two parameters m and l. Section IV is devoted to the construction of associated orthogonal polynomials. In Sec. V the solutions of associated Lamé equations are obtained for various values of m and l. Several new solutions are obtained here. In Sec. VI we calculate band-edge eigenstates and spectra for the two new classes of potentials obtained in Sec. II and show their connection to the known exactly solvable potentials. Finally, our conclusions are presented in Sec. VII.

II. VARIOUS FAMILIES OF ELLIPTIC POTENTIALS GENERATED BY sl(2,$\mathbb{R}$) ALGEBRA

QES models have been studied mainly from the point of view of two approaches. One approach is to find out a suitable Lie-algebraic representation of a QES Hamiltonian[12,13] and then to compute a finite part of the spectrum by diagonalizing a matrix having finite block structure. A slight variation of this approach has been proposed in Ref. 19 where a class of QES rational potentials with normalizable zero energy state is generated from standard so(2,1) representation of an exactly solvable model through a suitable coordinate transformation. Another approach, first suggested by Bender and Dunne,[20,21] is to generate an orthogonal family of polynomials $\{P_j(E)\}$ in the energy variable E and then to find the roots of a critical polynomial $P_n(E)$ (where n is some positive integer) giving the energy eigenvalues of the QES Hamiltonian. In fact, the existence of such a critical polynomial is evidence for a Hamiltonian to be QES.

Let us briefly recall the basic setup within an sl(2,$\mathbb{R}$) Lie algebra to generate the Schrödinger potential. The sl(2,$\mathbb{R}$) algebra is governed by the commutation relations

$$[T^+, T] = -2T^0, \quad [T^0, T^\pm] = \pm T^\pm, \tag{2.1}$$

where the three generators $T^\pm$, T^0 may be realized as

$$T^+ = \xi^2 \partial_\xi - n\xi, \quad T^0 = \xi \partial_\xi - \tfrac{1}{2}n, \quad T^- = \partial_\xi, \tag{2.2}$$

n being a non-negative integer. These generators act on polynomials in real variable ξ of degree $\leqslant n$.

The gauged Hamiltonian is taken as general quadratic combination of the generators in the form

$$H_G = -\sum_{a,b=0,\pm} C_{ab} T^a T^b - \sum_{a=0,\pm} C_a T^a - d, \tag{2.3}$$

which, using (2.2), can be expressed as

$$H_G(\xi) = -\sum_{j=2}^{4} B_j(\xi) \partial_\xi^{j-2}. \tag{2.4}$$

$B_j(\xi)$ are the jth degree polynomials in ξ given by

$$B_4(\xi)=C_{++}\xi^4+2C_{+0}\xi^3+C_{00}\xi^2+2C_{0-}\xi+C_{--},$$

$$B_3(\xi)=2(1-n)C_{++}\xi^3+\{3(1-n)C_{+0}+C_+\}\xi^2+\{(1-n)C_{00}+C_0\}\xi+(1-n)C_{0-}+C_-, \tag{2.5}$$

$$B_2(\xi)=n(n-1)C_{++}\xi^2+n\{(n-1)C_{+0}-C_+\}\xi+\frac{n^2}{4}C_{00}-\frac{1}{2}nC_0+d.$$

Here the numerical parameters C_{ij} $(i,j=0,\pm)$ are symmetric with $C_{+-}=C_{-+}=0$ and d is a suitably chosen constant.

Let us now convert H_G to the form

$$H_G(x)=-\partial_x{}^2+\left.\frac{B'_4-2B_3}{2\sqrt{B_4}}\right|_{\xi=\xi(x)}\partial_x-B_2|_{\xi=\xi(x)}, \tag{2.6}$$

through a coordinate transformation

$$x(\xi)=\int^{\xi}\frac{d\tau}{\sqrt{B_4(\tau)}}, \tag{2.7}$$

where the prime denotes derivative with respect to ξ.

Now the Schrödinger Hamiltonian with potential $V(x)$,

$$H(x)\psi(x)\equiv[-\partial_x{}^2+V(x)]\psi(x)=E\psi(x), \tag{2.8}$$

can be gauge transformed to the form

$$H_G(x)\chi(x)\equiv\left[-\partial_x{}^2+2\mathcal{A}\partial_x+\frac{d\mathcal{A}}{dx}-\mathcal{A}^2+V\right]\chi(x)=E\chi(x), \tag{2.9}$$

through an imaginary phase transformation

$$\psi(x)=e^{-\int\mathcal{A}(x)\,dx}\chi(x). \tag{2.10}$$

Comparing Eqs. (2.6) and (2.9), the potential $V(x)$ is obtained as

$$V(x)=\mathcal{A}^2-\left.\frac{d\mathcal{A}}{dx}-B_2\right|_{\xi=\xi(x)}, \tag{2.11}$$

where the gauge function $\mathcal{A}(x)$ is

$$\mathcal{A}(x)=\left.\frac{B'_4-2B_3}{4\sqrt{B_4}}\right|_{\xi=\xi(x)}. \tag{2.12}$$

The Schrödinger potential $V(x)$ can be written in terms of $B_j(\xi)$ in the following form:

$$V(x)=\left.\left[\frac{(B'_4-2B_3)(3B'_4-2B_3)}{16B_4}-\frac{1}{4}(B''_4-2B'_3+4B_2)\right]\right|_{\xi=\xi(x)}. \tag{2.13}$$

It is clear that the polynomial $B_4(\xi)$ determines the functional relation between ξ and x through Eq. (2.7). Table I contains all 12 forms of $B_4(\xi)$ which relate ξ to x through the elliptic functions.[22,23] Since our goal is to generate elliptic potentials these forms will facilitate our

TABLE I. Different coordinate transformations based on the choice of $B_4(\xi)$ and path of integration giving $\xi=\xi(x)$ in terms of three Jacobi elliptic functions $snx\equiv sn(x,k)$, $cnx\equiv cn(x,k)$ and $dnx\equiv dn(x,k)$ of real modulus $k(0<k^2<1,k'^2=1-k^2)$ are given.

Transformation no.	$B_4(\xi)$	Zeros of $B_4(\xi)$	ξ_0	$x(\xi)=\int_{\xi_0}^{\xi} B_4^{-1/2}(\tau)\,d\tau$ gives $\xi=\xi(x)$	$B_4(\xi(x))$
1	$(1+\xi^2)(1+k'^2\xi^2)$	$\pm i,\pm i/k'$	0	snx/cnx	dn^2x/cn^4x
2	$(1-\xi^2)(1-k^2\xi^2)$	$\pm 1,\pm 1/k$	0	snx	cn^2xdn^2x
3	$(1-\xi^2)(k'^2+k^2\xi^2)$	$\pm 1,\pm ik'/k$	1	$-cnx$	sn^2xdn^2x
4	$(1-\xi^2)(\xi^2-k'^2)$	$\pm 1,\pm k'$	1	$-dnx$	$k^4sn^2xcn^2x$
5	$(1+k^2\xi^2)(1-k'^2\xi^2)$	$\pm i/k,\pm 1/k'$	0	snx/dnx	cn^2x/dn^4x
6	$(\xi^2-1)(\xi^2-k^2)$	$\pm 1,\pm k$	$-\infty$	$-1/snx$	cn^2xdn^2x/sn^4x
7	$(\xi^2-1)(k'^2\xi^2+k^2)$	$\pm 1,\pm ik/k'$	1	$1/cnx$	sn^2xdn^2x/cn^4x
8	$(\xi^2-1)(1-k'^2\xi^2)$	$\pm 1,\pm 1/k'$	1	$1/dnx$	$k^4sn^2xcn^2x/dn^4x$
9	$(1+\xi^2)(k'^2+\xi^2)$	$\pm i,\pm ik'$	$-\infty$	$-cnx/snx$	dn^2x/sn^4x
10	$(\xi^2+k^2)(\xi^2-k'^2)$	$\pm ik,\pm k'$	$-\infty$	$-dnx/snx$	cn^2x/sn^4x
11	$(1-\xi^2)(1-k^2\xi^2)$	$\pm 1,\pm 1/k$	-1	$-cnx/dnx$	k'^4sn^2x/dn^4x
12	$(\xi^2-1)(\xi^2-k^2)$	$\pm 1,\pm k$	-1	dnx/cnx	k'^4sn^2x/cn^4x

purpose. Note that once B_4 is chosen, Eq. (2.13) gives various families of elliptic potentials containing four parameters C_+, C_-, C_0, and n. In particular, for the transformation 1 of Table I we get a new class of periodic potentials

$$V(x)=Psn^2x+Qsnxcnx+R\frac{snx\ \ cnx}{dn^2x}+S\frac{cn^2x}{dn^2x}, \tag{2.14}$$

where

$$\begin{aligned} P&=\frac{k^2}{4}n(n+2)-\frac{C_0}{2}(n+1)+\frac{1}{4k^2}[C_0{}^2-(C_+-C_-)^2],\\ Q&=\frac{1}{2k^2}(C_+-C_-)[k^2(n+1)-C_0],\\ R&=\frac{1}{2k^2}(C_+-k'^2C_-)[k^2(n+1)+C_0],\\ S&=\frac{k^2}{4}n(n+2)+\frac{C_0}{2}(n+1)+\frac{1}{4k^2}\left[C_0{}^2-\frac{1}{k'^2}(C_+-k'^2C_-)^2\right]. \end{aligned} \tag{2.15}$$

Here the constant d is chosen as

$$d=\frac{1}{4k^2}\left[C_-{}^2-(C_0{}^2+2C_+C_-)+\left(\frac{C_+}{k'}\right)^2\right]-\frac{n(n+2)}{2}. \tag{2.16}$$

Again, for the second and third choices of $B_4(\xi)$ from Table I, we are led to

$$V(x)=\begin{cases} k'^2\left[\dfrac{2}{cn^2x}-\dfrac{(n+3)(n+2)}{dn^2x}\right], & (2.17)\\[2ex] \dfrac{2}{sn^2x}-\dfrac{k'^2(n+3)(n+2)}{dn^2x}, & (2.18) \end{cases}$$

where we have taken

TABLE II. The solutions of a system of four nonlinear equations for four parameters n, $C_\pm$ and C_0 given by (3.1) are provided. Proper restrictions on m, l are essential to restrict the spin parameter n to a non-negative integer. It is interesting to note that the solutions 7–12 can be obtained from 1–6 under the translations $m\to m'=-m-1$, $l\to l'=-l-1$.

Solution no.	n	C_+	C_-	C_0	Restrictions on m,l
1	$l+m$	0	0	$k^2(l-m)$	$l+m\in\mathbb{N}-1$
2	$m-l-1$	0	0	$-k^2(l+m+1)$	$m-l\in\mathbb{N}$
3	$m-1/2$	$ik'(2l+1)$	$ik'(2l+1)$	$-k^2(m+1/2)$	$m\in\mathbb{N}-1/2, l\in\mathbb{R}$
4	$m-1/2$	$-ik'(2l+1)$	$-ik'(2l+1)$	$-k^2(m+1/2)$	$m\in\mathbb{N}-1/2, l\in\mathbb{R}$
5	$l-1/2$	$ik'^2(2m+1)$	$i(2m+1)$	$k^2(l+1/2)$	$l\in\mathbb{N}-1/2, m\in\mathbb{R}$
6	$l-1/2$	$-ik'^2(2m+1)$	$-i(2m+1)$	$k^2(l+1/2)$	$l\in\mathbb{N}-1/2, m\in\mathbb{R}$
7	$-(l+m+2)$	0	0	$-k^2(l-m)$	$-(l+m)\in\mathbb{N}+1$
8	$l-m-1$	0	0	$k^2(l+m+1)$	$l-m\in\mathbb{N}$
9	$-(m+3/2)$	$ik'(2l+1)$	$ik'(2l+1)$	$k^2(m+1/2)$	$-m\in\mathbb{N}+1/2, l\in\mathbb{R}$
10	$-(m+3/2)$	$-ik'(2l+1)$	$-ik'(2l+1)$	$k^2(m+1/2)$	$-m\in\mathbb{N}+1/2, l\in\mathbb{R}$
11	$-(l+3/2)$	$ik'^2(2m+1)$	$i(2m+1)$	$-k^2(l+1/2)$	$-l\in\mathbb{N}+1/2, m\in\mathbb{R}$
12	$-(l+3/2)$	$-ik'^2(2m+1)$	$-i(2m+1)$	$-k^2(l+1/2)$	$-l\in\mathbb{N}+1/2, m\in\mathbb{R}$

$$C_+=C_-=0,\quad C_0=\begin{cases}-k'^2(n+4)\\ -(n+4)\end{cases},\quad d=\begin{cases}\dfrac{1}{4}[3n^2+12n+8-k^2(n^2+8n+8)], & (2.19)\\[2mm] \dfrac{1}{4}(3n^2+12n+8)-\dfrac{k^2}{2}n(n+2). & (2.20)\end{cases}$$

Other choices of $B_4(\xi)$ can be similarly used. Later we will show that the families of elliptic potentials (2.14), (2.17), and (2.18) coincide with certain known potentials in the proper limit.

We now discuss the boundary conditions in the corresponding spectral problem. We see that the Schrödinger equation (2.8) for the potential (2.14) can be defined over the entire x axis. It follows from the oscillation theorem[8] that for a periodic potential of period $2K$ (where $K=\int_o^{\pi/2}d\alpha/\sqrt{1-k^2\sin^2\alpha}$) there exists a sequence $\{E_j\}_{j\geq 0}$ such that $E_o<E_1\leqslant E_2<E_3\leqslant E_4\ldots$, which are called the characteristic values of the energy parameter E and the periodic solutions of period $2K$ (or $4K$) exist for $E=E_j$. The intervals of stability of the solutions are (E_{2j},E_{2j+1}). For the $2K$-periodic potentials (2.17) and (2.18) which are singular at $x=\pm K$ and $x=0$, $2K$, respectively, the domains of corresponding equations may be taken as $(-K,K)$ and $(0,2K)$. Our choice of parameters guarantees that the wave functions vanish at boundary points.

III. ALGEBRAIZATION OF ASSOCIATED LAMÉ EQUATION

Associated Lamé potential (1.1) is a special case of the family of elliptic potentials (2.14) where

$$P=k^2m(m+1),\quad Q=R=0,\quad S=k^2l(l+1). \tag{3.1}$$

Equation (3.1) gives the system of constraints determining the four parameters C_+, C_-, C_0, and n. Table II contains the exhaustive list of 12 sets of solutions for them. Since the spin parameter n is restricted to be a non-negative integer, the sixth column of Table II gives the corresponding restrictions on m,l for validity of the solutions. Now 12 solutions for n represent four systems of parallel lines (see Fig. 1) in the $m-l$ plane: in the following these lines will be referred to as algebraic lines (ALs). Each point (m,l) on an ith AL gives (η_i+1) algebraic eigenstates, where η_i is a non-negative integer given by the numerical value of the spin parameter n associated with ith AL. Clearly, if a point lies in the intersection of r ALS, we get $\Sigma_{i=1}^{r}(\eta_i+1)$ eigenstates, all of which are not necessarily distinct. [It should be mentioned that the oblique ALs are discontinuous at half-integer points that is, they do not meet axis-parallel ALs for the reason explained in Sec. IV (see Table IV).]

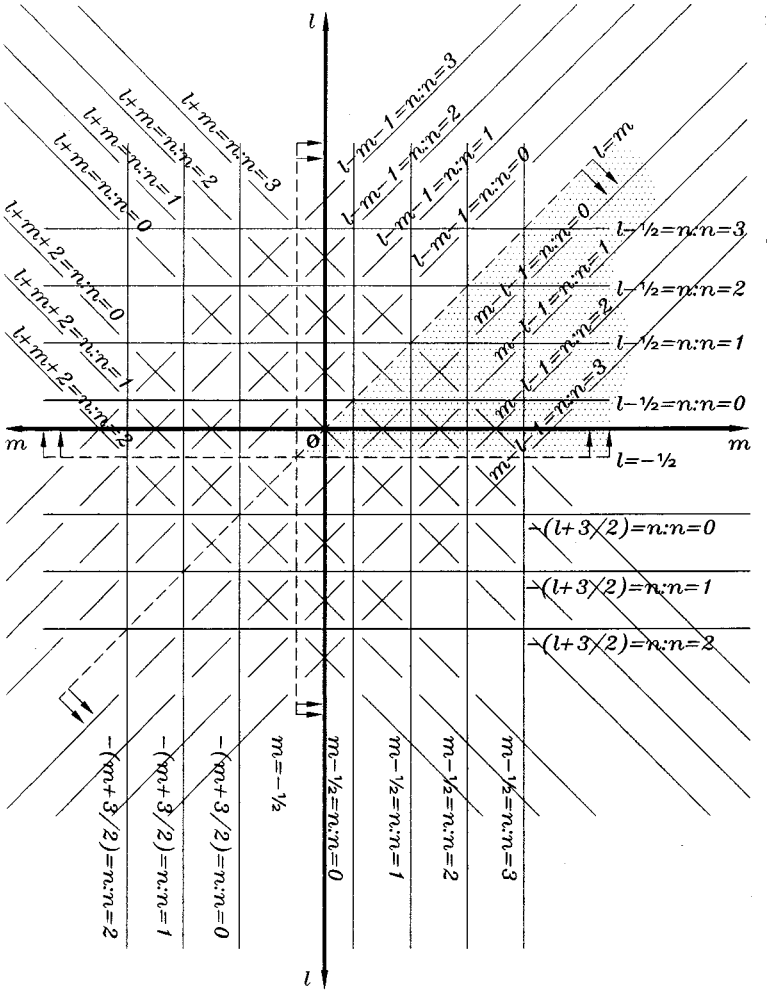

FIG. 1. Algebraic lines (ALs) for the associated Lamé equation are drawn in the $m-l$ plane for some non-negative integer values of n. Three dashed lines determine a triangular infinite region as effective region (shaded area). Oblique ALs are discontinuous at half-integer points.

We now determine the effective region in the $m-l$ plane. Denoting $p\equiv m(m+1)$ and $q\equiv l(l+1)$, we see that p,q are invariant under the translation $m,\ l\to m',\ l'$ where $m'=-m-1$, $l'=-l-1$. Thus it is sufficient to take $l,\ m\geqslant-\frac{1}{2}$. In Fig. 1 these two inequations give a square infinite region. Further, due to the relations $sn(x+2K)=-snx,\ sn(x+K)=cnx/dnx$ ($K=\int_0^{\pi/2}d\alpha/\sqrt{1-k^2\sin^2\alpha}$ is called complete elliptic integral of first kind), we can consider only $p\geqslant q$ without loss of generality. The restriction $p\geqslant q$ in turn implies that $m\geqslant l$. In Fig. 1 this inequation gives a triangular infinite region in the $m-l$ plane. For any point outside this triangular region there exists a point in the region giving the same associated Lamé potential. We call this region (shaded area in Fig. 1) as an effective region. Clearly the ALs lying entirely outside the effective region are not required for our purpose. It is easy to verify that those ALs correspond the solutions 7–12 of Table II. It turns out that we need to consider the first six solutions of Table II: indeed the solutions 7–12 can be generated from the solutions 1–6 by the translation $l,\ m\to l',\ m'$ where $l'=-l-1,\ m'=-m-1$.

The analysis discussed so far reveals that the three-parameter family of associated Lamé potentials $V(x;m,l,k)=m(m+1)k^2sn^2x+l(l+1)k^2cd^2x$ (we use the customary notation $cdx\equiv cnx/dnx$) are generated from sl(2, $\mathbb{R}$) algebra for $0<k^2<1$ and (m,l) lying in at least one AL in the effective region of the $m-l$ plane. We call the points in the effective region not lying in any

TABLE III. Lie-algebraic representations of the linear part H_{linear} of associated Lamé Hamiltonian H_G are given for different solutions of n, in terms of the three sl(2,$\mathbb{R}$) generators $T^{\pm},T^0$. The quadratic part is given by $H_{\text{quadratic}} = -k'^2T^{+2}-(1+k'^2)T^{02}-T^{-2}$.

Solution no.	n	H_{linear}
1	$m+l$	$-k^2(l-m)T^0+\frac{k^2}{4}(l-m)^2+\frac{n(n+2)}{2}$
2	$m-l-1$	$k^2(l+m+1)T^0+\frac{k^2}{4}(l+m+1)^2+\frac{n(n+2)_-}{2}$
3	$m-\frac{1}{2}$	$-ik'(2l+1)(T^+-T^-)+k^2\left(m+\frac{1}{2}\right)T^0+\frac{(2l+1)^2}{4}+\frac{k^2}{4}\left(m+\frac{1}{2}\right)^2+\frac{n(n+2)}{2}$
4	$m-\frac{1}{2}$	$ik'(2l+1)(T^+-T^-)+k^2\left(m+\frac{1}{2}\right)T^0+\frac{(2l+1)^2}{4}+\frac{k^2}{4}\left(m+\frac{1}{2}\right)^2+\frac{n(n+2)}{2}$
5	$l-\frac{1}{2}$	$-i(2m+1)(k'^2T^+-T^-)-k^2\left(l+\frac{1}{2}\right)T^0+\frac{(2m+1)^2}{4}+\frac{k^2}{4}\left(l+\frac{1}{2}\right)^2+\frac{n(n+2)}{2}$
6	$l-\frac{1}{2}$	$i(2m+1)(k'^2T^+-T^-)-k^2\left(l+\frac{1}{2}\right)T^0+\frac{(2m+1)^2}{4}+\frac{k^2}{4}\left(l+\frac{1}{2}\right)^2+\frac{n(n+2)}{2}$

AL as critical points. For instance, though the point $(-\frac{1}{2},-\frac{1}{2})$ lies in the effective region, we cannot algebraize the corresponding associated Lamé equation $-\psi''(x)-(sn^2x+cd^2x)k^2\psi(x)/4=E\psi(x)$ in this scheme, as no ALs pass through this point. In the following sections we consider four cases namely when (i) m and l are both integers, (ii) m is an integer and l is a half-integer, (iii) m and l are both half integers, and (iv) m is a half-integer and l is an integer.

The gauge Hamiltonian can be written in terms of sl(2, $\mathbb{R}$) generators in the form

$$H_G=H_{\text{quadratic}}+H_{\text{linear}}, \tag{3.2}$$

where

$$H_{\text{quadratic}}=-k'^2T^{+^2}-(1+k'^2)T^{0^2}-T^{-^2}, \tag{3.3}$$

and for each of six solutions 1–6 of Table II, H_{linear} is given in Table III. It is to be noted that the generators $T^{\pm}$, T^0 are computed from (2.2) for the corresponding n in Table III.

Before concluding the section, we wish to remark that the associated Lamé potential has two interesting limits:

$$V(x)\xrightarrow[k\to 0]{} 0 \quad (\text{free particle}),$$

$$V(x)\xrightarrow[k\to 1]{} -m(m+1)\text{sech}^2x+l(l+1)+m(m+1) \quad (\text{Pöschl–Teller potential}).$$

In above we have used the following limiting results:

$$sn(x,k)\xrightarrow[k\to 0]{k\to 1}\begin{cases}\tanh x\\ \sin x\end{cases},\quad cn(x,k)\xrightarrow[k\to 0]{k\to 1}\begin{cases}\text{sech}x\\ \cos x\end{cases},\quad dn(x,k)\xrightarrow[k\to 0]{k\to 1}\begin{cases}\text{sech}x\\ 1\end{cases}. \tag{3.4}$$

It may be mentioned that the present results are related to the ones obtained recently by Shifman and Turbiner.[24] Indeed the Hamiltonians 1 and 2 of Table III possess the so-called energy-reflection symmetry.

IV. ORTHOGONAL POLYNOMIALS IN ENERGY VARIABLE GENERATED BY EIGENSTATES OF A QES POTENTIAL

It is well known[15,20,21] that eigenfunctions of almost every one-dimensional QES Hamiltonian generate a family of orthogonal polynomials $\{P_j(E)\}$ in the energy variable E satisfying a three-term recursion relation of the form

$$P_{j+1}(E)=(\alpha_j E+\beta_j)P_j+\gamma_j P_{j-1}, \quad j\geqslant 0, \tag{4.1}$$

where α_j, β_j, γ_j are independent of E, and $\alpha_j\neq 0$, and $\gamma_0=0$, and $\gamma_n=0$ for some positive integer n, provided we expand the algebraic eigenfunction (2.10) as power series in terms of suitable variable $y=y(\xi)$. Simple observation of Eq. (2.5) shows that we can separate the numerical parameters C_{ij} and C_i in $B_3(\xi)$ and $B_2(\xi)$ by rewriting them as

$$B_3(\xi)=\frac{1-n}{2}B_4'(\xi)+A_2(\xi), \quad B_2(\xi)=\frac{n(n-1)}{12}B_4''(\xi)-\frac{n}{2}A_2'(\xi)+\frac{n(n+2)}{12}C_{00}+d, \tag{4.2}$$

where $A_2(\xi)$ is a second degree polynomial in ξ given by

$$A_2(\xi)=C_+\xi^2+C_0\xi+C_-. \tag{4.3}$$

Now, due to the GL(2) symmetry, the form of $H_G(\xi)$ in (2.4) remains invariant under the coordinate transformation

$$\xi=\frac{ey+f}{gy+h}, \quad \begin{pmatrix} e & f \\ g & h \end{pmatrix}\in \mathrm{GL}(2,\mathbb{C}), \tag{4.4}$$

accompanied by the gauge transformation

$$\hat{\chi}(y)=\hat{\mu}(y)\chi\left(\frac{ey+f}{gy+h}\right), \quad \hat{\mu}(y)=(gy+h)^n. \tag{4.5}$$

The transformed Hamiltonian $\hat{H}_G(y)$ can be written as

$$-\hat{H}_G(y)=\hat{B}_4(y)\partial_y^2+\left[\frac{1-n}{2}\hat{B}_4'(y)+\hat{A}_2(y)\right]\partial_y+\frac{n(n-1)}{12}\hat{B}_4''(y)-\frac{n}{2}\hat{A}_2'(y)+\frac{n(n+2)}{12}\hat{C}_{00}+d_1, \tag{4.6}$$

where the prime now denotes derivative wrt y. The transformed polynomials $\hat{B}_4(y)$ and $\hat{A}_2(y)$ are respectively of fourth and second degree and may be written as

$$\hat{B}_4(y)=\hat{C}_{++}y^4+2\hat{C}_{+0}y^3+\hat{C}_{00}y^2+2\hat{C}_{0-}y+\hat{C}_{--}, \qquad \hat{A}_2(y)=\hat{C}_+y^2+\hat{C}_0y+\hat{C}_-. \tag{4.7}$$

In (4.7) the transformed numerical parameters $\hat{C}_{ij}$, $\hat{C}_i$ are determined from the relations

$$\hat{B}_4(y)=\frac{(gy+h)^4}{(eh-fg)^2}B_4\left(\frac{ey+f}{gy+h}\right), \quad \hat{A}_2(y)=\frac{(gy+h)^2}{eh-fg}A_2\left(\frac{ey+f}{gy+h}\right), \tag{4.8}$$

while the constant d_1 in (4.6) is given by

$$d_1=d+\frac{n(n+2)}{12}(C_{00}-\hat{C}_{00}). \tag{4.9}$$

Let us now consider the eigenvalue equation

$$\hat{H}_G(y)\hat{\chi}(y)=E\hat{\chi}(y), \tag{4.10}$$

which is the transformed version of original gauged eigenvalue equation

$$H_G(\xi)\chi(\xi)=E\chi(\xi), \tag{4.11}$$

Here we have identified $\chi(\xi(x))\equiv\chi(x)$ in (2.10). The transformed eigenfunction $\hat{\chi}(y)$ may be taken as power series in y, namely

$$\hat{\chi}(y)=\sum_{j=0}^{\infty} P_j(E)\frac{y^j}{j!}. \tag{4.12}$$

It is straightforward to check that the coefficients $\{P_j(E)\}$, in general, satisfy a five-term recursion relation and to reduce this to a useful three-term recursion relation of the form (4.1), we require $\hat{C}_{++}=\hat{C}_{--}=0$. This means that $\hat{B}_4(y)$ must vanish at 0 and ∞. It is clear from Eq. (4.8) that our problem remains to choose e,f,g,h in (4.4) in such a manner that the two distinct roots ξ_1, ξ_2 of $B_4(\xi)$ are mapped to 0, ∞ of $\hat{B}_4(y)$. Our choice corresponds to the set $e=\xi_2$, $f=-\xi_1$, $g=1$, $h=-1$ so that $eh-fg=\xi_1-\xi_2\neq 0$. We are then led to a three-term recursion relation satisfied by $\{P_j(E)\}$,

$$\begin{aligned}&-[(2j-n+1)\hat{C}_{0-}+\hat{C}_{-}]P_{j+1}\\&\quad=\left[E+d_1+\hat{C}_0\left(j-\frac{n}{2}\right)+\hat{C}_{00}\left(j-\frac{n}{2}\right)^2\right]P_j+j(j-1-n)[(2j-n-1)\hat{C}_{+0}+\hat{C}_{+}]P_{j-1},\quad j\geqslant 0,\end{aligned} \tag{4.13}$$

where $P_{-1}\equiv 0$, $P_0\equiv 1$. Note that the relation (4.13) is of the form (4.1) provided that

$$(2j-n+1)\hat{C}_{0-}+\hat{C}_{-}\neq 0,\quad \forall j\geqslant 0. \tag{4.14}$$

We now examine whether (4.14) trivially holds or some additional restrictions need to be imposed on the spin parameter n. Clearly three cases are relevant which we discuss below.

A. Case 1. Associated Lamé potential (1.1)

This case corresponds to transformation 1 of Table I where $B_4(\xi)$ has four distinct complex roots $\pm i$, $\pm i/k'$. Once the pair of the roots ξ_1, ξ_2 is chosen, the transformed numerical parameters $\hat{C}_{ij}$, $\hat{C}_i$ can be computed from (4.7) and (4.8) corresponding to each of the six solutions 1–6 of Table II as follows:

Solutions 1 and 2: For the choice $\xi_1=-i$, $\xi_2=i$,

$$\hat{C}_{++}=0,\quad \hat{C}_{+0}=k^2/2,\quad \hat{C}_{00}=2(k^2-2),\quad \hat{C}_{0-}=k^2/2,\quad \hat{C}_{--}=0,$$

$$\hat{C}_{+}=\begin{cases}k^2(m-l)/2,\\ k^2(l+m+1)/2,\end{cases}\quad C_0=0,\quad \hat{C}_{-}=\begin{cases}k^2(l-m)/2,\\ -k^2(l+m+1)/2.\end{cases}$$

Then Eq. (4.14) gives

$$\tfrac{1}{2}k^2(2m-2j-1)\neq 0,\quad \forall j\geqslant 0.$$

We thus impose an additional restrictions on m as

$$m\neq \tfrac{1}{2},\tfrac{3}{2},\ldots\ . \tag{4.15}$$

Solutions 3 and 4: For the choice $\xi_1=\pm i/k'$, $\xi_2=\mp i/k'$,

$$\hat{C}_{++}=0,\quad \hat{C}_{+0}=-k^2/2,\quad \hat{C}_{00}=2(k^2-2),\quad \hat{C}_{0-}=-k^2/2,\quad \hat{C}_{--}=0$$

$$\hat{C}_{+}=k^2(m-2l-\tfrac{1}{2})/2,\quad \hat{C}_{0}=(2l+1)(k^2-2),\quad \hat{C}_{-}=-k^2(2l+m+\tfrac{3}{2})/2.$$

Then Eq. (4.14) gives

$$k^2(2j+2l+3)/2\neq 0,\quad \forall j\geqslant 0$$

This is always true in our effective region in the $m-l$ plane (see Fig. 1).

Solutions 5 and 6: For the choice $\xi_1=\pm i$, $\xi_2=\mp i$,

$$\hat{C}_{++}=0,\quad \hat{C}_{+0}=k^2/2,\quad \hat{C}_{00}=2(k^2-2),\quad \hat{C}_{0-}=k^2/2,\quad \hat{C}_{--}=0,$$

$$\hat{C}_{+}=k^2(2m-l+\tfrac{1}{2})/2,\quad \hat{C}_{0}=(2m+1)(k^2-2),\quad \hat{C}_{-}=k^2(2m+l+\tfrac{3}{2})/2.$$

Then Eq. (4.14) gives

$$-k^2(2j+2m+3)/2\neq 0,\quad \forall j\geqslant 0.$$

This is also true in our effective region.

B. Case 2. Potential (2.17)

This case corresponds to transformation 2 of Table I and the solution (2.19). Here $B_4(\xi)$ has four distinct real roots ± 1, $\pm 1/k$. For the choice $\xi_1=1$, $\xi_2=-1$,

$$\hat{C}_{++}=0,\quad \hat{C}_{+0}=-k'^2/2,\quad \hat{C}_{00}=2(1+k^2),\quad \hat{C}_{0-}=-k'^2/2,\quad \hat{C}_{--}=0,$$

$$\hat{C}_{+}=\frac{k'^2}{2}(n+4),\quad \hat{C}_{0}=0,\quad \hat{C}_{-}=-\frac{k'^2}{2}(n+4).$$

Then Eq. (4.14) gives

$$-\frac{k'^2}{2}(2j+5)\neq 0,\quad \forall j\geqslant 0. \tag{4.16}$$

C. Case 3. Potential (2.18)

This case corresponds to transformation 3 of Table I and solution (2.10). The polynomial $B_4(\xi)$ has two real and two complex roots ± 1, $\pm ik'/k$. For the choice $\xi_1=1$, $\xi_2=-1$,

$$\hat{C}_{++}=0,\quad \hat{C}_{+0}=-\tfrac{1}{2},\quad \hat{C}_{00}=2(1-2k^2),\quad \hat{C}_{0-}=-\tfrac{1}{2},\quad \hat{C}_{--}=0,$$

$$\hat{C}_{+}=\tfrac{1}{2}(n+4),\quad \hat{C}_{0}=0,\quad \hat{C}_{-}=-\tfrac{1}{2}(n+4).$$

Then Eq. (4.14) gives

$$-\tfrac{1}{2}(2j+5)\neq 0,\quad \forall_j\geqslant 0. \tag{4.17}$$

Hence we have proved that in every case the eigenfunction generates a family of orthogonal polynomials, provided an additional restriction (4.15) is imposed on potential parameters for case 1 and the roots ξ_1, ξ_2 of the polynomial $B_4(\xi)$ are suitably chosen. The family $\{P_j(E)\}$ can be expressed in terms of monic polynomials $\{\tilde{P}_j(E)\}$ satisfying a recurrence relation of the type

TABLE IV. The coefficients ρ_j, λ_j, and ω_j of the recurrence relation (4.17) and (4.18) are given for different cases. The choice of roots ξ_1, ξ_2 and the restrictions on m,l are also provided for each case.

Solution no.	n	ρ_j	λ_j	ω_j	(ξ_1,ξ_2)	Restrictions on m,l
1	$m+l$	$(\frac{1}{2}k^2)^2 j(l+m+1-j)(2j-2l-1)\times(2m-2j+1)$	$\frac{1}{2}k^2\{l(l+1)+m(m+1)\}+\frac{1}{2}(2-k^2)(l+m-2j)^2$	$\dfrac{(k^2/2)^j\Pi_{i=0}^{m-1}(2m-2i-1)}{\Pi_{i=0}^{m-1-j}(2m-2j-2i-1)}$	$(-i,i)$	$m\notin\mathbb{N}-\frac{1}{2}, l\in\mathbb{R}$ $m+l\in\mathbb{N}-1$
2	$m-l-1$	$(\frac{1}{2}k^2)^2 j(m-l-j)(2m-2j+1)\times(2j+2l+1)$	$\frac{1}{2}k^2\{l(l+1)+m(m+1)\}+\frac{1}{2}(2-k^2)(m-l-1-2j)^2$	$''$	$(-i,i)$	$m\notin\mathbb{N}-\frac{1}{2}, l\in\mathbb{R}$ $m-l\in\mathbb{N}$
3	$m-\frac{1}{2}$	$(\frac{1}{2}k^2)^2 j(j-m-\frac{1}{2})(2j-2m+2l)\times(2j+2l+1)$	$\dfrac{k^2}{4}\left(2m^2+2m-\frac{1}{2}\right)+\dfrac{(2l+1)^2}{4}+\dfrac{1}{2}(2-k^2)\left(2j-m+\dfrac{1}{2}\right)\times\left(2j-m+2l+\dfrac{3}{2}\right)$	$\dfrac{(k^2/2)^j\Pi_{i=1}^{m+3/2}(2l+2i+1)}{\Pi_{i=1}^{m+3/2-j}(2l+2j+2i+1)}$	$\left(\dfrac{i}{k'},\dfrac{-i}{k'}\right)$	$m\in\mathbb{N}-\frac{1}{2}, l\in\mathbb{R}$
4	$m-\frac{1}{2}$	$''$	$''$	$''$	$\left(\dfrac{-i}{k'},\dfrac{i}{k'}\right)$	$m\in\mathbb{N}-\frac{1}{2}, l\in\mathbb{R}$
5	$l-\frac{1}{2}$	$(\frac{1}{2}k^2)^2 j(j-l-\frac{1}{2})(2j-2l+2m)\times(2j+2m+1)$	$\dfrac{k^2}{4}\left(2l^2+2l-\dfrac{1}{2}\right)+\dfrac{(2m+1)^2}{4}+\dfrac{1}{2}(2-k^2)\left(2j-l+\dfrac{1}{2}\right)\times\left(2j-l+2m+\dfrac{3}{2}\right)$	$\dfrac{(-k^2/2)^j\Pi_{i=1}^{l+3/2}(2m+2i+1)}{\Pi_{i=1}^{l+3/2-j}(2m+2j+2i+1)}$	$(i,-i)$	$l\in\mathbb{N}-\frac{1}{2} m\in\mathbb{R}$
6	$l-1/2$	$''$	$''$	$''$	$(-i,i)$	$l\in\mathbb{N}-\frac{1}{2} m\in\mathbb{R}$
7		$(\frac{1}{2}k'^2)^2 j(j-n-1)(2j-2n-5)\times(2j+3)$	$-\dfrac{k'^2}{2}(n+1)(n+4)-\dfrac{1}{2}(1+k^2)(n-2j)^2$	$\dfrac{(k'^2/2)^j\Pi_{i=0}^{j+1}(2j+3-2i)}{3}$	$(1,-1)$	$n\in\mathbb{N}-1$
8		$\frac{1}{4}j(j-n-1)(2j-2n-5)(2j+3)$	$-\dfrac{1}{2}(n+1)(n+4)-\dfrac{1}{2}(1-2k^2)(n-2j)^2$	$\dfrac{(\frac{1}{2})^j\Pi_{i=0}^{j+1}(2j+3-2i)}{3}$	$(1,-1)$	$n\in\mathbb{N}-1$

$$\tilde{P}_{j+1}=(E-\lambda_j)\tilde{P}_j-\rho_j\tilde{P}_{j-1}, \tag{4.18}$$

$$\tilde{P}_j=\omega_j P_j, \quad j\geqslant 0. \tag{4.19}$$

The explicit expressions of ρ_j, λ_j, ω_j together with the choice of roots (ξ_1,ξ_2) and overall restrictions on potential parameters for all cases are contained in Table IV. Note that the last two rows correspond to the potential (2.17) and (2.18). Further restriction (4.15) is reflected in Fig. 1 showing discontinuities of oblique ALs at half-integer points. We see that $\rho_0=0$ and $\rho_{n+1}=0$, so that the critical polynomial is $\tilde{P}_{n+1}$ and the energy eigenvalues of a QES Hamiltonian are precisely the zeros of $\tilde{P}_{n+1}$, provided all the zeros are real and simple.

Let us now turn to the construction of wave functions. From (2.10) and (4.5), the Schrödinger wave function $\psi(x)$ reads

$$\psi(x)=\mu(x)\frac{1}{\hat{\mu}(y)}\hat{\chi}(y)\big|_{y=y(\xi(x))}, \tag{4.20}$$

where

$$\mu(x)=e^{-\int \mathcal{A}(x)\,dx}. \tag{4.21}$$

The gauge function $\mathcal{A}(x)$ can be computed from (2.12) and by using (4.2)

$$\mu(x)=B_4^{-n/4}(\xi)\exp\left[\int^{\xi}\frac{A_2(\tau)}{2B_4(\tau)}d\tau\right]\Bigg|_{\xi=\xi(x)}. \tag{4.22}$$

Finally, the $(n+1)$ eigenfunctions can be computed from (4.4), (4.5), (4.12), and (4.20) at the roots $E=E_i$ $(i=0,1,...,n)$ of $\tilde{P}_{n+1}$ giving the final form

$$\psi_{E_i}(x)=\mu(x)(\xi(x)-\xi_2)^n\sum_{j=0}^{n}\frac{P_j(E_i)}{j!}\left(\frac{\xi(x)-\xi_1}{\xi(x)-\xi_2}\right)^j \quad (i=0,1,...,n). \tag{4.23}$$

It should be mentioned that the infinite power series expansion in (4.12) terminates after $(n+1)$ terms since the coefficients $P_j(E_i)$ vanishes for $j>n$.

V. ALGEBRAIC EIGENFUNCTIONS AND ENERGY SPECTRA OF ASSOCIATED LAMÉ POTENTIAL

Let us recall that here $B_4(\xi(x))=dn^2x/cn^4x$ where $\xi=snx/cnx$ (transformation 1 of Table I). We have already obtained the explicit expression [cf. Eq. (4.23)] of the eigenfunctions. It remains to calculate the gauge factor $\mu(x)$ for each of the six solutions 1–6 of Table II. From (4.22) and (4.3), $\mu(x)$ is given by

$$\mu(x)=\begin{cases} cn^{m+l}x\ dn^{-l}x, \quad n=m+l, & (5.1)\\ cn^{m-l-1}x\ dn^{l+1}x, \quad n=m-l-1, & (5.2)\\ \left.\begin{array}{l} cn^{m-1/2}x\ dn^{-l}x(cnx+ik'snx)^{l+1/2}\\ cn^{m-1/2}x\ dn^{-l}x(cnx-ik'snx)^{l+1/2}\end{array}\right\}, \quad n=m-\frac{1}{2}, & \begin{array}{l}(5.3a)\\(5.3b)\end{array}\\ \left.\begin{array}{l} cn^{l-1/2}x\ dn^{-l}x(cnx+isnx)^{m+1/2}\\ cn^{l-1/2}x\ dn^{-l}x(cnx-isnx)^{m+1/2}\end{array}\right\}, \quad n=l-\frac{1}{2}. & \begin{array}{l}(5.4a)\\(5.4b)\end{array}\end{cases}$$

Besides the elliptic modulus parameter $k(0<k^2<1)$, the associated Lamé potential depends on two other real parameters m, l. In Sec. III we have shown that it is sufficient to consider the points (m, l) in effective region (see Fig. 1). The associated Lamé equation for any point (m, l) lying in at least one AL in the effective region thus gives an algebraic QES potential. In the following we

shall confine ourselves to the case where $m,l \in (\mathbb{N}-1)\cup(\mathbb{N}-\frac{1}{2})$. This can be decomposed into the following four categories. It is to be noted that all points in the m axis give Lamé potential.

A. Case 1: *m* and *l* are both non-negative integers

For $m \neq l$, the point (m, l) lies in two ALs belonging to two different systems given by $m+l=n$ and $m-l-1=n$ and for $m=l$, the point lies in one AL belonging to the system $m+l=2m=n$, for $n=0,1,2,\ldots$. Each AL gives (η_i+1) algebraic eigenstates, where η_i is the numerical value of the spin parameter n associated with the particular AL. Hence in either case, associated Lamé Hamiltonian possesses $(2m+1)$ band-edge eigenstates corresponding to $(2m+1)$ band-edge energies. This emphasizes the fact that the associated Lamé potential is a periodic QES and when m, l are both non-negative integers there are m bound bands followed by a continuum band. The eigenstates for $m \neq l$ generate two distinct families of orthogonal polynomials of the form (4.18) where ρ_j, λ_j, ω_j are given by the entries 1 and 2 of Table IV. The solutions for $m=1,2$ where l is restricted to take $(m+1)$ values $0,1,\ldots,m$, have been obtained by us elsewhere[17] and it has been shown that the so-called Lamé potential is contained in the scheme as a particular case for $l=0$.

B. Case 2: *m* and *l* are both half an odd positive integer

The point (m, l) lies in the intersection of two ALs belonging to two different systems given by $m-\frac{1}{2}=n$ and $l-\frac{1}{2}=n$. Since these two systems correspond to two pairs of algebraizations [see solutions 3–6 of Table II], Eqs. (4.23), (5.3), and (5.4) imply that each of the two algebraizations for each system gives $(m+\frac{1}{2})$ and $(l+\frac{1}{2})$ complex eigenstates, respectively, which are conjugate to one another. Further, the expressions of ρ_j, λ_j, ω_j [see entries 3–6 of Table IV] imply that the complex eigenstates arising from two algebraizations of each system generate the same families of orthogonal polynomials in the energy variable E. It turns out that there are $(m+\frac{1}{2})$ and $(l+\frac{1}{2})$ characteristic values of E for each of which we get two linearly independent solutions given by real and imaginary parts of the complex eigenstates. But we see that the solutions obtained from the system $l-\frac{1}{2}=n$ are included in the solutions obtained from the system $m-\frac{1}{2}=n$ (note that $m \geqslant l$ in the effective region). Hence when m and l are both half-integers, there are $(m+\frac{1}{2})$ characteristics values of E which are doubly degenerate. It may be mentioned that the point (m, l) in this case does not lie in the ALs belonging to the systems $m+l=n$ and $m-l-1=n$ due to the discontinuities of oblique ALs at half-integer points (see Fig. 1). The solutions for $(\frac{1}{2}, \frac{1}{2})$, $(\frac{3}{2}, \frac{1}{2})$, and $(\frac{3}{2}, \frac{3}{2})$ have already been reported.[17] However, for some half-integer combinations of m, l, for instance, $(\frac{3}{2}, \frac{1}{2})$, we notice that only highest energy is doubly degenerate.

C. Case 3: *m* is half an odd positive integer and *l* is a non-negative integer

The point (m, l) lies in one AL belonging to the system $m-\frac{1}{2}=n$. Thus, as before, there are $(m+\frac{1}{2})$ characteristics values of E which are doubly degenerate. The solutions for $(\frac{1}{2}, 0)$, $(\frac{3}{2}, 0)$, and $(\frac{3}{2}, 1)$ are explicitly obtained by us in Ref. 17 and the first two give Lamé potentials.

D. Case 4: *m* is a non-negative integer and *l* is half an odd positive integer

This case is new and corresponds to the system $l-\frac{1}{2}=n$. Two algebraizations given by entires 5 and 6 of Table IV yield $(l+\frac{1}{2})$ characteristics values of E for each of which there are two linearly independent solutions. Here l takes values $\frac{1}{2}, \frac{3}{2},\ldots$ and for each of them m is allowed to take an infinite set of values $l+\frac{1}{2}, l+\frac{3}{2},\ldots$ in the effective region.

From the above discussions it is clear that in the effective region when $m \in \mathbb{N}\cup\mathbb{N}-\frac{1}{2}$, l is restricted to take $(2m+1)$ values $0,\frac{1}{2},1,\frac{3}{2},\ldots,m-\frac{1}{2},m$. In the following examples $\phi_r(x)$ and e_r denote the ordered levels of eigenstates and energy spectra. Note that in the half-integer cases, the parenthesized superscript in the eigenstate indicates the degeneracy of the eigenvalues.

We now consider the following examples.

(a) $m=1$. l is allowed to take three values 0, $\frac{1}{2}$, 1. Solutions for $l=0$, 1 were reported in Ref. 17. The new case corresponds $m=1$, $l=\frac{1}{2}$ and gives the associated Lamé potential as

$$V(x)=2k^2sn^2x+\tfrac{3}{4}k^2cd^2x. \tag{5.5}$$

The wave functions and energy are

$$\phi_0{}^{(1)}(x)=\frac{\sqrt{1+cnx}}{\sqrt{dnx}}(2cnx-1),\quad \phi_0{}^{(2)}(x)=\frac{\mathrm{sgn}(snx)\sqrt{1-cnx}}{\sqrt{dnx}}(2cnx+1),\quad e_0=\frac{1}{4}(k^2+9).$$

(b) $m=2$. l is allowed to take five values 0, $\frac{1}{2}$, 1, $\frac{3}{2}$, 2. The integer values of l have already been given in Ref. 17.

(i) $l=\frac{1}{2}$: Associated Lamé potential

$$V(x)=6k^2sn^2x+\tfrac{3}{4}k^2cd^2x,$$

$$\phi_0{}^{(1)}(x)=\frac{\sqrt{1+cnx}}{\sqrt{dnx}}(4cn^2x-2cnx-1),\quad \phi_0{}^{(2)}(x)=\frac{\mathrm{sgn}(snx)\sqrt{1-cnx}}{\sqrt{dnx}}(4cn^2x+2cnx-1), \tag{5.6}$$

$$e_0=(k^2+25)/4.$$

(ii) $l=\frac{3}{2}$: Associated Lamé potential

$$V(x)=6k^2sn^2x+\frac{15}{4}k^2cd^2x,$$

$$e_{0,1}=\tfrac{1}{4}[49-5k^2+2f_{\mp}(k)],\quad f_{\pm}(k)=5(k^2-2)\pm\sqrt{k^4+25k'^2}, \tag{5.7}$$

$$\phi_{0,1}{}^{(1)}(x)=\frac{\sqrt{1+cnx}}{dn^{3/2}x}[8f_{\pm}(k)cn^3x-4f_{\pm}(k)cn^2x-2\{2f_{\pm}(k)+7k^2\}cnx+\{f_{\pm}(k)+7k^2\}],$$

$$\phi_{0,1}{}^{(2)}(x)=\frac{\mathrm{sgn}(snx)\sqrt{1-cnx}}{dn^{3/2}x}[8f_{\pm}(k)cn^2x+4f_{\pm}(k)cn^2x-2\{2f_{\pm}(k)+7k^2\}cnx$$
$$-\{f_{\pm}(k)+7k^2\}].$$

(c) $m=3$. l is allowed to take seven values 0, $\frac{1}{2}$, 1, $\frac{3}{2}$, 2, $\frac{5}{2}$, 3.

(i) $l=0$: Lamé potential

$$V(x)=12k^2sn^2x,$$

$$\phi_{0,4}(x)=dnx[5k^2sn^2x-f_{\pm}(k)],\quad e_{0,4}=2f_{\mp}(k)+k^2,$$

$$\phi_{1,5}(x)=cnx[5k^2sn^2x-g_{\pm}(k)],\quad e_{1,5}=2g_{\mp}(k)+1, \tag{5.8}$$

$$\phi_{2,6}(x)=snx[5k^2sn^2x-\eta_{\pm}(k)],\quad e_{2,6}=\eta_{\mp}(k)+3(1+k^2),$$

$$\phi_3(x)=snx\ \ cnx\ \ dnx,\quad e_3=4(1+k^2),$$

where $f_{\pm}(k)=2k^2+1\pm\sqrt{4k^4+k'^2}$, $g_{\pm}(k)=k^2+2\pm\sqrt{4-k^2k'^2}$, and $\eta_{\pm}(k)=2(k^2+1)\pm\sqrt{4k^4-7k^2+4}$.

(ii) $l=\frac{1}{2}$: Associated Lamé potential

$$V(x)=12k^2sn^2x+\tfrac{3}{4}k^2cd^2x,$$

$$\phi_0{}^{(1)}(x)=\frac{\sqrt{1+cnx}}{\sqrt{dnx}}[8cn^3x-4cn^2x-4cnx+1],\quad e_0=\frac{1}{4}(k^2+49),\tag{5.9}$$

$$\phi_0{}^{(2)}(x)=\frac{\mathrm{sgn}(snx)\sqrt{1-cnx}}{\sqrt{dnx}}[8cn^3x+4cn^3x-4cnx-1].$$

(iii) $l=1$: Associated Lamé potential

$$\begin{aligned}V(x)&=12k^2sn^2x+2k^2cd^2x,\\ \phi_0(x)&=cnx\ \ dn^2x,\quad e_0=1+4k^2,\\ \phi_1(x)&=snx\ \ dn^2x,\quad e_1=1+9k^2,\\ \phi_{2,3}(x)&=\frac{snx\ \ cnx}{dnx}\left[sn^2x-\frac{1}{5k^2}(k^2+3\pm\sqrt{k^4+9k'^2})\right],\quad e_{2,3}=10+2k^2\mp2\sqrt{k^4+9k'^2}.\end{aligned}\tag{5.10}$$

The remaining three eigenstates can be expressed as

$$\begin{aligned}\phi_i(x)=\frac{1}{dnx}\Bigg[&sn^4x-\frac{1}{10k^2}(9k^2+16-e_i)sn^2x\\&+\frac{1}{15k^4}\{e_i{}^2-2(5k^2+18)e_i+(9k^4+156k^2+320)\}\Bigg],\end{aligned}$$

where the eigenvalues e_i $(i=4,5,6)$ are the roots of the cubic

$$e^3-(11k^2+20)e^2+(19k^4+216k^2+64)e-(9k^6+388k^4+448k^2)=0.$$

(iv) $l=\frac{3}{2}$: Associated Lamé potential

$$\begin{aligned}V(x)&=12k^2sn^2x+\tfrac{15}{4}k^2cd^2x,\\ e_{0,1}&=\tfrac{1}{4}[81-9k^2+2h_{\mp}(k)],\quad h_{\pm}(k)=7(k^2-2)\pm2\sqrt{k^4+49k'^2}\\ \phi_{0,1}{}^{(1)}&=\frac{\sqrt{1+cnx}}{dn^{3/2}x}[16h_{\pm}(k)cn^4x-8h_{\pm}(k)cn^3x-12\{h_{\pm}(k)+3k^2\}cn^2x\\&\quad+2\{2h_{\pm}(k)+9k^2\}cnx+\{h_{\pm}(k)+9k^2\}],\\ \phi_{0,1}{}^{(2)}(x)&=\frac{\mathrm{sgn}(snx)\sqrt{1-cnx}}{dn^{3/2}x}[16h_{\pm}(k)cn^4x+8h_{\pm}(k)cn^3x-12\{h_{\pm}(k)+3k^2\}cn^2x\\&\quad-2\{2h_{\pm}(k)+9k^2\}cnx+\{h_{\pm}(k)+9k^2\}].\end{aligned}\tag{5.11}$$

(v) $l=2$: Associated Lamé potential

$$\begin{aligned}V(x)&=12k^2sn^2x+6k^2cd^2x,\\ \phi_0(x)&=dn^3x,\quad e_0=9k^2.\end{aligned}\tag{5.12}$$

The three eigenstates can be expressed as

$$\phi_i(x)=\frac{cnx}{dn^2x}\left[sn^4x-\frac{1}{10k^2}(4k^2+25-e_i)sn^2x\right.$$
$$\left.+\frac{1}{120k^4}\left\{e_i^2-2(2k^2+17)e_i-\frac{75}{2}k^4+156k^2+225\right\}\right],$$

where the three energies e_i are the roots of the cubic

$$2e^3-2(8k^2+35)e^2-(43k^4-640k^2-518)e+(525k^6-1365k^4-3312k^2-450)=0.$$

The remaining three energies e_r are the roots of the cubic

$$2e^3-2(11k^2+35)e^2-(37k^4-844k^2-518)e+732k^6-1851k^4-4662k^2-450=0,$$

and the three eigenstates are given by

$$\phi_r(x)=\frac{snx}{dn^2x}\left[sn^4x-\frac{1}{10k^2}(9k^2+25-e_r)sn^2x\right.$$
$$\left.+\frac{1}{120k^4}\left\{e_r{}^2-2(5k^2+17)e_r-\frac{57}{2}k^4+306k^2+225\right\}\right].$$

(vi) $l=\frac{5}{2}$: Associated Lamé potential

$$V(x)=12k^2sn^2x+\tfrac{35}{4}k^2cd^2x. \tag{5.13}$$

Three eigenvalues e_i are the roots of the cubic

$$64e^3-16(35k^2+179)e^2+4(39k^4+7398k^2+7459)e+(7915k^6-66871k^4-229507k^2-53361)=0,$$

and two linearly independent solutions for each e_i are

$$\phi_i^{(1)}(x)=\frac{\sqrt{1+cnx}}{dn^{5/2}x}[32\beta_icn^5x-16\beta_icn^4x-16(\gamma_i+2\beta_i)cn^3x+4(2\gamma_i+3\beta_i)cn^2x$$
$$+2(4\gamma_i+3\beta_i+792k^4)cnx-(2\gamma_i+\beta_i+792k^4)],$$

$$\phi_i^{(2)}(x)=\frac{\mathrm{sgn}(snx)\sqrt{1-cnx}}{dn^{5/2}x}[32\beta_icn^5x+16\beta_icn^4x-16(\gamma_i+2\beta_i)cn^3x-4(2\gamma_i+3\beta_i)cn^2x$$
$$+2(4\gamma_i+3\beta_i+792k^4)cnx+(2\gamma_i+\beta_i+792k^4)],$$

where

$$\gamma_i(k)=22k^2(37k^2+9-4e_i),$$

$$\beta_i(k)=16e_i{}^2-8(27k^2+29)e_i+845k^4+1966k^2+441.$$

(vii) $l=3$: Associated Lamé potential

$$V(x)=12k^2sn^2x+12k^2cd^2x. \tag{5.14}$$

Three band-edge eigenstates are given by

$$\phi_i(x)=\frac{snx\ cnx}{dn^3x}\left[sn^4x-\frac{1}{10k^2}(4k^2+36-e_i)sn^2x\right.$$
$$\left.+\frac{1}{120k^4}\{e_i{}^2-4(k^2+13)e_i+24(11k^2+24)\}\right]\quad(i=0,1,2)$$

where the three eigenvalues e_i are the roots of the cubic

$$e^3-8(k^2+7)e^2+16(k^4+35k^2+49)e-192(7k^4+31k^2+12)=0.$$

In particular, for $k^2=\frac{2}{3}$, the energies and eigenvalues can be obtained in exact form:

$$\phi_0(x)=\frac{snx\ cnx}{dn^3x}\left[sn^4x-4sn^2x+\frac{9}{2}\right],\quad e_0=12,$$

$$\phi_1(x)=\frac{snx\ cnx}{dn^3x}\left[sn^4x-3sn^2x+\frac{3}{2}\right],\quad e_1=\tfrac{56}{3},$$

$$\phi_2(x)=\frac{snx\ cnx}{dn^3x}\left[sn^4x-\frac{6}{5}sn^2x+\frac{3}{10}\right],\quad e_2=\tfrac{92}{3}.$$

The remaining four energies e_r are the roots of the biquadratic

$$e^4-4(5k^2+14)e^3+2(59k^4+616k^2+392)e^2-12(15k^6+698k^4+1280k^2+192)e$$
$$+9k^2(9k^6+1824k^4+8320k^2+3072)=0,$$

and the corresponding four eigenstates can be expressed as

$$\phi_r(x)=\frac{1}{dn^3x}\left[sn^6x-\frac{1}{10k^2}(9k^2+36-e_r)sn^4x+\frac{1}{120k^4}\right.$$
$$\times\{e_r{}^2-2(5k^2+26)e_r+9k^4+480k^2+576\}sn^2x+\frac{1}{720k^6}$$
$$\left.\times\{e_r{}^3-(11k^2+56)e_r{}^2+(19k^4+716k^2+784)e_r-3(3k^6+604k^4+2560k^2+768)\}\right].$$

Higher values of m and l can be similarly considered, in principle. But, in practice, as m,l increases, calculations become very complicated due to the fact that the analytical solutions of higher degree critical polynomials are quite lengthy. However, it may be mentioned that our algebraization scheme discovers several new families of associated Lamé potentials for integer and half-integer combinations of m,l, e.g., the potentials (5.5)–(5.7), (5.9), (511), and (5.13), whose solutions can be written analytically.

VI. ELLIPTIC GENERALIZATIONS OF GENDENSHTEIN AND OTHER EXACTLY SOLVABLE PERIODIC POTENTIALS

In Sec. II we have obtained two new families of potentials (2.17) and (2.18) for the second and third choices (transformations 2 and 3 of Table I) of $B_4(\xi)$. For the choice $B_4(\xi)=(1-\xi^2)\times(1-k^2\xi^2)$, we get

$$V(x)=k'^2\left[\frac{2}{cn^2x}-\frac{(n+3)(n+2)}{dn^2x}\right].\tag{6.1}$$

Here $V(x)$ depends on two parameters k $(0<k^2<1, k'^2=1-k^2)$ and n $(\in \mathbb{N}-1)$. Further, we choose the domain $(-K,K)$ where $2K$ is the period of the potential and given by $K=\int_0^{\pi/2} d\alpha/\sqrt{1-k^2\sin^2\alpha}$. We may note that as $k\to 1$, 0 the domain reduces to $(-\infty,\infty)$ and $(-\pi/2, \pi/2)$. It is interesting to observe following two limits:

$$V(x) \xrightarrow[k\to 1]{} 0, \quad x\in(-\infty,\infty) \quad \text{(free particle)}, \tag{6.2}$$

$$V(x) \xrightarrow[k\to 0]{} 2\tan^2 x-(n+1)(n+4), \quad x\in(-\pi/2,\pi/2), \tag{6.3}$$

which is an exactly solvable periodic potential.[25]

Again, for the choice $B_4(\xi)=(1-\xi^2)(k'^2+k^2\xi^2)$ (transformation 3 of Table I), we obtain

$$V(x)=\frac{2}{sn^2x}-\frac{k'^2(n+3)(n+2)}{dn^2x}, \quad x\in(0,2K), \tag{6.4}$$

where n $(\epsilon\mathbb{N}-1)$ and k $(0<k^2<1)$ are two parameters. The following two limits of (6.4) are noted:

$$V(x) \xrightarrow[k\to 1]{} 2\,\text{cosech}^2 x+2, \quad x\in(0,\infty), \tag{6.5}$$

which is singular Gendenshtein potential[26] and

$$V(x) \xrightarrow[k\to 0]{} 2\cot^2 x-(n+1)(n+4), \quad x\in(0,\pi), \tag{6.6}$$

which also belongs to the exactly solvable class. Note that in the above we have used the limiting results (3.4).

The elliptic potentials (6.1) and (6.4) are thus new families of periodic potentials belonging to QES class and can be considered as generalized versions of exactly solvable $\tan^2 x$, $\cot^2 x$, and $\text{cosech}^2 x$ potentials. These potentials are generated from a standard homogeneous quadratic combination of $\text{sl}(2,\mathbb{R})$ generators plus a linear operator. The gauged Hamiltonian can be written explicitly in terms of $\text{sl}(2,\mathbb{R})$ generators as

$$\begin{aligned}\text{Potential (6.1):} \quad H_G=&-k^2T^{+^2}+(1+k^2)T^{0^2}-T^{-^2}+k'^2(n+4)T^0\\ &-\tfrac{1}{4}[3n^2+12n+8-k^2(n^2+8n+8)],\end{aligned} \tag{6.7}$$

$$\begin{aligned}\text{Potential (6.4):} \quad H_G=&k^2T^{+^2}+(1-2k^2)T^{0^2}-k'^2T^{-^2}+(n+4)T^0\\ &-\tfrac{1}{4}[3n^2+12n+8-2k^2n(n+2)],\end{aligned} \tag{6.8}$$

where the generators $T^{\pm}$, T^0 are computed from (2.2) for $n\in\mathbb{N}-1$. The gauge factor $\mu(x)$ is obtained from (4.22), (2.19), and (2.20) for the corresponding choice of $B_4(\xi)$ (transformation 2 and 3 of Table I) as

$$\text{Potential (6.1):} \quad \mu(x)=cn^2x/dn^{n+2}x, \tag{6.9}$$

$$\text{Potential (6:4):} \quad \mu(x)=sn^2x/dn^{n+2}x. \tag{6.10}$$

The $(n+1)$ band-edge eigenstates and spectra can now be easily computed by constructing orthogonal polynomials using entries 7 and 8 of Table IV.

We now consider the following examples.

(a) The class of potentials given by Eq. (6.1)

(i) $n=0$:

$$V(x)=2k'^2\left(\frac{1}{cn^2x}-\frac{3}{dn^2x}\right),$$
$$\phi_0(x)=\frac{cn^2x}{dn^2x},\quad e_0=-2k'^2. \tag{6.11}$$

(ii) $n=1$:

$$V(x)=2k'^2\left(\frac{1}{cn^2x}-\frac{6}{dn^2x}\right),$$
$$\phi_0(x)=\frac{cn^2x}{dn^3x},\quad e_0=7k^2-8, \tag{6.12}$$
$$\phi_1(x)=\frac{snxcn^2x}{dn^3x},\quad e_1=2k^2-3.$$

(b) The class of potentials given by Eq. (6.4)
(i) $n=0$:

$$V(x)=\frac{2}{sn^2x}-\frac{6k'^2}{dn^2x},$$
$$\phi_0(x)=\frac{sn^2x}{dn^2x},\quad e_0=-2. \tag{6.13}$$

(ii) $n=1$:

$$V(x)=\frac{2}{sn^2x}-\frac{12k'^2}{dn^2x},$$
$$\phi_0(x)=\frac{sn^2x}{dn^3x},\quad e_0=k^2-8, \tag{6.14}$$
$$\phi_1(x)=\frac{sn^2xcnx}{dn^3x},\quad e_1=k^2-3.$$

Higher values of m can be similarly considered. We have thus found two new families of QES periodic potentials, which in the proper limit reduce to well-known exactly, solvable class.

VII. CONCLUSION

In this article we have systematically studied the basic method of generating various classes of elliptic potentials within an sl(2,$\mathbb{R}$) Lie-algebraic formulation. We have given a wide range of choice of coordinate transformation in Table I. Using transformations 1–3 of Table I we have obtained three new classes of QES periodic potentials, which, in the limits $k\to 0,1$, reduce to Pöschl–Teller, singular Gendenshtein and other known exactly solvable classes. Other choices from Table I can be similarly used to generate various new classes of elliptic potentials. Further, we have shown that the associated Lamé potential can be derived as a special case. This certainly adds an important member in the list of algebraic QES. We have explicitly obtained the eigenstates and spectra for these potentials. In fact, our algebraic approach discovers a new class of associated Lamé potential when either of the two parameters m and l are integers and other half-integers. It is shown that the eigenfunctions of our QES Hamiltonians generate a family of orthogonal poly-

nomials $\{Pj(E)\}$ satisfying a three-term recurrence relation of the form (4.18). It is to be mentioned that the coefficients ρ_j are not strictly positive for $1 \leqslant j \leqslant n$, in contrast to the cases discussed in Ref. 15. However, the $(n+1)$ roots of the critical polynomial are all real and simple.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 4 APRIL 2002

Irreducible modules of finite dimensional quantum algebras of type *A* at roots of unity

Toshiki Nakashima[a)]
Department of Mathematics, Sophia University, Tokyo 102-8554, Japan

(Received 25 April 2001; accepted for publication 7 January 2002)

Properly specializing the parameters contained in the maximal cyclic representation of the nonrestricted *A*-type quantum algebra at roots of unity, we find the unique primitive vector in it. In this case, the representation is no longer irreducible. We show that the submodule generated by the primitive vector is the unique irreducible submodule and can be identified with an irreducible highest weight module of the finite dimensional *A*-type quantum algebra, which is defined as the subalgebra of the restricted quantum algebra at roots of unity. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1453498]

I. INTRODUCTION

The quantum group $U_q(\mathfrak{g})$ associated with a simple Lie algebra $\mathfrak{g}$ is an associative algebra over the rational function field $\mathbf{C}(q)$ (q is an indeterminate) and we can define its ''integral'' form over the Laurant polynomial ring $\mathbf{C}[q,q^{-1}]$, which enables us to specialize q to any nonzero complex number ε. We are going to see two types of such integral forms and accordingly, we obtain two types of specializations; one is called the ''restricted specialization,'' denoted by $U_\varepsilon^{\mathrm{res}}$, and the other is called the ''nonrestricted specialization,'' denoted by U_ε. Both coincide if ε is transcendental. But we are interested in the case where ε is the lth primitive root of unity, l being an odd integer greater than 1. In this case, they do not. The former is initiated by Lusztig[1,2] and the latter is introduced in Ref. 3 by DeConcini and Kac. Their representation theories are quite different: Irreducible $U_\varepsilon^{\mathrm{res}}$-modules are highest weight modules in some sense and the classification of the irreducible modules is same as for simple Lie algebras or ordinary quantum algebras (see Theorem 3.5). Furthermore, irreducible modules possess the remarkable property ''tensor product theorem'' (see Theorem 3.6), which claims that the arbitrary irreducible highest weight module $V(\lambda)$ with the highest weight λ is divided into the tensor product of two irreducible modules, $V(\lambda^{(0)})$ and $V(l\lambda)^{(1)}$, where $\lambda^{(0)}$ and $\lambda^{(1)}$ are as in Theorem 3.6. Here the module $V(\lambda^{(0)})$ is identified with the irreducible $U_\varepsilon^{\mathrm{fin}}$-module, where $U_\varepsilon^{\mathrm{fin}}$ is some finite dimensional subalgebra of $U_\varepsilon^{\mathrm{res}}$ (see Sec. II B) and the module $V(l\lambda^{(1)})$ can be identified with the irreducible highest weight $U(\mathfrak{g})$-module $V(\lambda^{(1)})$, whose structure is known very well. Thus, if the structure of $V(\lambda^{(0)})$ is clarified, we can analyze the detailed feature of $V(\lambda)$. Indeed, the character of $V(\lambda)$ is given by the famous Kazhdan–Lusztig formula. But structures as a module, e.g., explicit descriptions of basis vectors or actions of the generators on them, are still unclear.

On the other hand, irreducible U_ε-modules are not necessarily highest or lowest weight modules. They are characterized by many continuous parameters and if they are ''generic,'' their dimensions are all same (see Refs. 3 and 4). But if we specialize the parameters properly, the modules become reducible. In Ref. 5, Date *et al.*, explicitly constructed such U_ε-modules for A_n-type, which is called the ''maximal cyclic representations'' that are realized in the vector space $\mathcal{V}:=(\mathbf{C}^l)^{(1/2)n(n+1)}$. They contains the continuous parameters and it is shown that if those parameters are generic, they are irreducible. Here we consider certain nongeneric specialization of the parameters so that $\mathcal{V}$ becomes a reducible U_ε-module. Moreover, we shall observe that such a module includes the unique primitive vector (see Proposition 4.9). The submodule generated by

a)Electronic mail: toshiki@mm.sophia.ac.jp

this primitive vector can be seen as an irreducible $U_\varepsilon^{\mathrm{fin}}$-module and isomorphic to $V(\lambda^{(0)})$ for some λ (Theorem 5.5).

From the physical point of view, the cyclic representations at roots of 1 are deeply related to certain physical models, e.g., chiral Potts models,[6,7] via *R*-matrices obtained as intertwining operators of tensor product.[8–10] On the other hand, the algebra $U_\varepsilon^{\mathrm{fin}}$ has the corresponding universal *R*-matrix.[11] So, we can consider its image on $\mathcal{V}$ or the irreducible submodule. The explicit form of the universal *R*-matrix for $U_\varepsilon^{\mathrm{fin}}$ cannot be directly deduced from the usual formula of the universal *R*-matrix for $U_q(\mathfrak{g})$. So, it might be interesting to see whether the image of the universal *R*-matrix of $U_\varepsilon^{\mathrm{fin}}$ can be obtained by specializing the parameters of the *R*-matrix related to the chiral Potts type models.

The organization of the paper is as follows. In Sec. II we review the quantum algebras at roots of unity. In Sec. III, we see the maximal cyclic representations of the *A*-type following Ref. 5 and review the representation theory of $U_\varepsilon^{\mathrm{res}}$. In Sec. IV, we specialize the parameters properly and show that under the specialization, there exists a unique primitive vector in the module. Finally, in Sec. V, it is shown that the representation space becomes the module of the finite dimensional algebra $U_\varepsilon^{\mathrm{fin}}$ and the submodule generated by the primitive vector is irreducible.

II. ALGEBRAS AT ROOTS OF UNITY

In the following, we review the algebras treated in this article.

A. Restricted integral forms and specializations

Let $\mathbf{C}(q)$ be the rational function field in an indeterminate q and denote the ring $\mathbf{C}[q,q^{-1}]$ by $\mathcal{A}$. We use the following notations:

$$[a]_q := \frac{q^a - q^{-a}}{q - q^{-1}}, \quad [a]_q! := [a]_q[a-1]_q \cdots [2]_q[1]_q, \quad \begin{bmatrix} m \\ k \end{bmatrix}_q := \frac{[m]_q!}{[k]_q![m-k]_q!}.$$

Let $I := \{1,2,\ldots,n\}$ be the index set and $(a_{ij})_{i,j\in I}$ be the Cartan matrix of type A_n, i.e., $a_{ii}=2$ $(1 \leqslant i \leqslant n)$, $a_{ii+1}=a_{i+1i}=-1$ $(1 \leqslant i \leqslant n-1)$, and $a_{ij}=0$ otherwise. Let us denote the set of roots (respectively, positive roots) by Δ (respectively, Δ_+). Let $\{h_i\}_{i\in I}$ be the set of simple co-roots and $\{\alpha_i\}_{i\in I}$ the set of simple roots. Define the weight lattice $P := \{\lambda \mid \langle h_i, \lambda \rangle \in \mathbf{Z}\}$ (respectively, the set of dominant integral weights $P_+ := \{\lambda \mid \langle h_i, \lambda \rangle \in \mathbf{Z}_{\geqslant 0}\}$). Let $\{\Lambda_i\}_{i\in I}$ be the fundamental weights which satisfy $\langle h_i, \Lambda_j \rangle = \delta_{ij}$ and then $P = \oplus_i \mathbf{Z}\Lambda_i$. Let W be the Weyl group of type A_n, which is generated by the simple reflections s_i $(i \in I)$. The *quantum algebra* $U_q(\mathfrak{g})$ is the associative algebra generated by e_i, f_i, $t_i^{\pm 1}$ $(i \in I)$ and the following relations:

$$t_i t_i^{-1} = t_i^{-1} t_i = 1, \quad t_i t_j = t_j t_i, \tag{2.1}$$

$$t_i e_j t_i^{-1} = q^{a_{ij}} e_j, \tag{2.2}$$

$$t_i f_j t_i^{-1} = q^{-a_{ij}} f_j, \tag{2.3}$$

$$e_i f_j - f_j e_i = \delta_{ij} \frac{t_i - t_i^{-1}}{q - q^{-1}} \tag{2.4}$$

$$\sum_{k=0}^{1-a_{ij}} (-1)^k e_i^{(k)} e_j e_i^{(1-a_{ij}-k)} = \sum_{k=0}^{1-a_j} (-1)^k f_i^{(k)} f_j f_i^{(1-a_{ij}-k)} = 0 \quad (i \neq j), \tag{2.5}$$

where $e_i^{(k)} := e_i^k/[k]_q!$ and $f_i^{(k)} := f_i^k/[k]_q!$.
Here we set

$$\begin{bmatrix} t_i,p \\ r \end{bmatrix}_q := \prod_{s=1}^{r} \frac{t_i q^{p+1-s} - t_i^{-1} q^{s-p-1}}{q^s - q^{-s}}.$$

The algebra $U_{\mathcal{A}}^{\mathrm{res}}$ is the $\mathcal{A}$-subalgebra of $U_q(\mathfrak{g})$ generated by $e_i^{(k)}$, $f_i^{(k)}$, $t_i^{\pm 1}$, and $\begin{bmatrix} t_{i,p} \\ k \end{bmatrix}$ ($i \in I$, p, $k \in \mathbf{Z}$, and $k \geqslant 0$), which is called the restricted integral form.

Here we can define the *restricted specializations* for any $\varepsilon \in \mathbf{C}^{\times}$;

$$U_{\varepsilon}^{\mathrm{res}} := U_{\mathcal{A}}^{\mathrm{res}} \otimes_{\mathcal{A}} \mathbf{C}_{\varepsilon}, \tag{2.6}$$

where $\mathcal{A}$ acts on $\mathbf{C}_{\varepsilon} := \mathbf{C}$ by $f(q)c := f(\varepsilon)c$ ($c \in \mathbf{C}$).

B. Finite dimensional quantum algebra

For $\varepsilon \in \mathbf{C}^{\times}$ we use

$$[a] := \frac{\varepsilon^a - \varepsilon^{-a}}{\varepsilon - \varepsilon^{-1}}, \quad [a]! := [a][a-1]\cdots[2][1], \quad \begin{bmatrix} m \\ k \end{bmatrix} := \begin{bmatrix} m \\ k \end{bmatrix}_{q=\varepsilon}.$$

Since $\begin{bmatrix} m \\ k \end{bmatrix}_q \in \mathbf{C}[q, q^{-1}]$, the definition of $\begin{bmatrix} m \\ k \end{bmatrix}$ is valid.

As for the specializations of q, we shall be interested in the case where ε is a root of unity. So in what follows, suppose that l is the odd integer greater than 1 and ε is the primitive lth root of unity.

Under this setting, we can find an interesting finite dimensional subalgebra $U_{\varepsilon}^{\mathrm{fin}}$ of $U_{\varepsilon}^{\mathrm{res}}$. $U_{\varepsilon}^{\mathrm{fin}}$ is defined as the subalgebra of $U_{\varepsilon}^{\mathrm{res}}$ generated by e_i, f_i, and $t_i^{\pm 1}$ ($i \in I$). We know that this algebra is finite dimensional over $\mathbf{C}$ with the dimension $2^n l^{n^2+2n}$ (see Proposition 2.2).

This $U_{\varepsilon}^{\mathrm{fin}}$ is also defined by "generators and relations" as follows:

Proposition 2.1 (Refs. 1 and 4): The algebra $U_{\varepsilon}^{\mathrm{fin}}$ is isomorphic to the associative $\mathbf{C}$*-algebra with generators e_α, f_α ($\alpha \in \Delta_+$), and $t_i^{\pm 1}$ ($1 \leqslant i \leqslant n$) satisfying the following relations;*

$$t_i t_i^{-1} = t_i^{-1} t_i = 1, \quad t_i t_j = t_j t_i, \tag{2.7}$$

$$t_i e_j t_i^{-1} = \varepsilon^{a_{ij}} e_j, \tag{2.8}$$

$$t_i f_j t_i^{-1} = \varepsilon^{-a_{ij}} f_j, \tag{2.9}$$

$$e_i f_j - f_j e_i = \delta_{ij} \frac{t_i - t_i^{-1}}{\varepsilon - \varepsilon^{-1}}. \tag{2.10}$$

If $(\alpha_i, \alpha) = 0$ and $i < g(\alpha)$,

$$e_i e_\alpha = e_\alpha e_i, \tag{2.11}$$

$$f_i f_\alpha = f_\alpha f_i. \tag{2.12}$$

If $(\alpha_i, \alpha) = -1$ and $i < g(\alpha)$,

$$e_{\alpha+\alpha_i} = \varepsilon^{-1} e_i e_\alpha - e_\alpha e_i, \tag{2.13}$$

$$\varepsilon e_i e_{\alpha+\alpha_i} = e_{\alpha+\alpha_i} e_i, \tag{2.14}$$

$$\varepsilon e_{\alpha+\alpha_i} e_\alpha = e_\alpha e_{\alpha+\alpha_i}, \tag{2.15}$$

$$f_{\alpha+\alpha_i} = \varepsilon f_\alpha f_i - f_i f_\alpha, \tag{2.16}$$

$$\varepsilon f_i f_{\alpha+\alpha_i} = f_{\alpha+\alpha_i} f_i, \tag{2.17}$$

$$\varepsilon f_{\alpha+\alpha_i} f_\alpha = f_\alpha f_{\alpha+\alpha_i}. \tag{2.18}$$

$$e_\alpha^l = f_\alpha^l = 0 \quad for\ \ any\ \ \alpha \in \Delta_+, \tag{2.19}$$

$$t_i^{2l} = 1 \quad for\ \ any\ \ i \in I, \tag{2.20}$$

where we define $g(\alpha)$ $(\alpha \in \Delta_+)$ *to be the largest index satisfying* $c_i \neq 0$ *if we write* $\alpha = \Sigma_i c_i \alpha_i$ *and set* $e_i := e_{\alpha_i}$ *and* $f_i := f_{\alpha_i}$.

Define $(U_\varepsilon^{\mathrm{fin}})^+$ [respectively $(U_\varepsilon^{\mathrm{fin}})^-$, $(U_\varepsilon^{\mathrm{fin}})^0$] to be the subalgebra of $U_\varepsilon^{\mathrm{fin}}$ generated by e_i (respectively, f_i, $t_i^{\pm 1}$). Fix a reduced expression $w_0 = s_{i_1} s_{i_2} \cdots s_{i_N}$ of the longest element of the Weyl group W and set $\beta_k := s_{i_1} s_{i_2} \cdots s_{i_{k-1}} (\alpha_{i_k})$ for $k \in \{1,...,N\}$ where $N := \frac{1}{2} n(n+1)$ is the number of positive roots. Here we have the following Poincaré–Birkhoff–Witt type theorem:

Proposition 2.2 (Refs. 1 and 4): (*i*) *The algebra* $(U_\varepsilon^{\mathrm{fin}})^+$ *is a finite dimensional* **C***-vector space with the basis*

$$\{e_{\beta_N}^{r_N} e_{\beta_{N-1}}^{r_{N-1}} \cdots e_{\beta_1}^{r_1}\}_{0 \leqslant r_1,\ldots,r_N < l}. \tag{2.21}$$

(*ii*) *The algebra* $(U_\varepsilon^{\mathrm{fin}})^-$ *is a finite dimensional* **C***-vector space with the basis*

$$\{f_{\beta_N}^{r_N} f_{\beta_{N-1}}^{r_{N-1}} \cdots f_{\beta_1}^{r_1}\}_{0 \leqslant r_1,\ldots,r_N < l}. \tag{2.22}$$

(*iii*) *The algebra* $(U_\varepsilon^{\mathrm{fin}})^0$ *is a finite dimensional* **C***-vector space with the basis*

$$\{t_n^{r_n} t_{n-1}^{r_{n-1}} \cdots t_1^{r_1}\}_{0 \leqslant r_l,\ldots,r_n < 2l}. \tag{2.23}$$

(*iv*) *Multiplication defines an isomorphism of* **C***-vector space,*

$$(U_\varepsilon^{\mathrm{fin}})^- \otimes (U_\varepsilon^{\mathrm{fin}})^0 \otimes (U_\varepsilon^{\mathrm{fin}})^+ \xrightarrow{\sim} U_\varepsilon^{\mathrm{fin}}. \tag{2.24}$$

C. Nonrestricted specializations

Here we see another type of specialization of q to a root of unity.

Introduce the elements

$$[t_i; m] := \frac{t_i q^m - t_i^{-1} q^{-m}}{q - q^{-1}} \in U_q(\mathfrak{g}).$$

The algebra $U_{\mathcal{A}}$ is the $\mathcal{A}$-subalgebra of $U_q(\mathfrak{g})$ generated by the elements e_i, f_i, $t_i^{\pm 1}$, and $[t_i; 0]$ $(1 \leqslant i \leqslant n)$.

Remark: The defining relations for $U_{\mathcal{A}}$ are as in Sec. II A, but replacing (2.4) by

$$e_i f_j - f_j e_i = \delta_{ij} [t_i; 0] \tag{2.25}$$

and adding the relation $(q - q^{-1})[t_i; 0] = t_i - t_i^{-1}$.

Now for the lth root of unity ε we define the **C**-algebra

$$U_\varepsilon := U_{\mathcal{A}} \otimes_{\mathcal{A}} \mathbf{C}_\varepsilon,$$

where $\mathcal{A}$ acts on $\mathbf{C}_\varepsilon = \mathbf{C}$ by $f(q)c = f(\varepsilon)c$ $(c \in \mathbf{C})$. This U_ε is called the *nonrestricted specialization*.

III. REPRESENTATIONS

A. Maximal cyclic representations of U_ε

The representation theory of U_ε is discussed in Ref. 3 in which the maximal dimension of irreducible representations for A_n-type is given by $l^{(1/2)n(n+1)}$ in the case where ε is the lth root of unity, and in Ref. 5 it is constructed explicitly and called the ''maximal cyclic representations.'' Here we subtly modify the presentations in Ref. 5 in order to simplify the arguments in Sec. IV.

Let H be the group generated by $\{x_{ij},z_{ij}\}_{1\leqslant i\leqslant j\leqslant n}$ and the center ε with the relations $z_{ij}x_{ij}=\varepsilon x_{ij}z_{ij}$ and all others commute each other, and set $\mathcal{W}:=\mathbf{C}[H]$ the group ring of H. For $r:=(r_1,\ldots,r_n)$, $s:=(s_1,\ldots,s_n)\in(\mathbf{C}^\times)^n$, we define the map $\varphi_{r,s}: U_\varepsilon\to\mathcal{W}$ by (see Ref. 5)

$$\varphi_{r,s}(e_i):=\sum_{k=i}^{n} x_{ik}x_{ik+1}\cdots x_{in}\{r_i z_{ik}z_{ik-1}z_{i-1\,k-1}^{-1}z_{i+1\,k}^{-1}\}, \tag{3.1}$$

$$\varphi_{r,s}(f_i):=\sum_{k=1}^{i} x_{i+1-k\,n+1-k}^{-1}x_{i+2-k\,n+2-k}^{-1}\cdots x_{in}^{-1} \times\{s_i z_{i+1-k\,n-k}z_{i+1-k\,n+1-k}^{-1}z_{i-k\,n+1-k}z_{i-k\,n-k}^{-1}\}, \tag{3.2}$$

$$\varphi_{r,s}(t_i):=\frac{r_i}{s_i}z_{in}^2 z_{i-1\,n}^{-1}z_{i+1\,n}^{-1}, \tag{3.3}$$

where we use the notation $\{z\}=(z-z^{-1})/(\varepsilon-\varepsilon^{-1})$ and set $x_{ij}^{\pm1}=z_{ij}^{\pm1}=1$ unless $1\leqslant i\leqslant j\leqslant n$.

Let $*:\mathcal{W}\to\mathcal{W}$ be the $\mathbf{C}$-linear involution defined by

$$x_{jk}^*:=x_{k+1-j\,k}^{-1},\quad z_{jk}^*:=z_{k+1-j\,k}^{-1},$$

and set

$$A_{ik}:=x_{ik}x_{ik+1}\cdots x_{in},\quad B_{ik}:=z_{ik}z_{ik-1}z_{i-1\,k-1}^{-1}z_{i+1\,k}^{-1}.$$

Then, (3.1) and (3.2) can be written in the following forms:

$$\varphi_{r,s}(e_i)=\sum_{k=i}^{n} A_{ik}\{r_i B_{ik}\},\quad \varphi_{r,s}(f_i)=\sum_{k=1}^{i} A_{n+1-i\,n+1-k}^*\{s_i B_{n+1-i\,n+1-k}^*\}. \tag{3.4}$$

Proposition 3.1: The map $\varphi_{r,s}$ defines a $\mathbf{C}$-linear algebra homomorphism from U_ε to $\mathcal{W}$.

Lemma 3.2: The following commutation relations hold [see Ref. 5, (2.5)]:

$$\begin{aligned} A_{ij}B_{ik}&=\varepsilon^{-2}B_{ik}A_{ij}\quad \text{if } j<k\\ &=\varepsilon^{-1}B_{ik}A_{ij}\quad \text{if } j=k\\ &=B_{ik}A_{ij}\quad \text{if } j>k. \end{aligned}$$

Proof of Proposition 3.1: We have $A_{ik}B_{ik}=\varepsilon^{-1}B_{ik}A_{ik}$ and then

$$\varphi_{r,s}(e_i)=\sum_{k=i}^{n}\{r_i\varepsilon^{-1}B_{ik}\}A_{ik},\quad \varphi_{r,s}(f_i)=\sum_{k=1}^{i}\{s_i\varepsilon^{-1}B_{n+1-i\;n+1-k}^*\}A_{n+1-i\;n+1-k}^*.$$

This implies $\varphi_{r,s}=\rho_{\varepsilon^{-1}r,\varepsilon^{-1}s}$ ($\rho_{r,s}$ is given in Ref. 5). Thus, by Theorem 2.2 in Ref. 5, we obtained the desired result. □

Proposition 3.3: For any $m\in\mathbf{Z}_{>0}$, we have

$$\varphi_{r,s}(e_i^m)=[m]!\sum_{p=1}^{m}\sum_{\substack{i\leqslant k_p<\cdots<k_1\leqslant n\\ 1\leqslant\nu_p<\cdots<\nu_1=m}}\prod_{r=1}^{p}A_{ik_r}^{\nu_r-\nu_{r+1}}\prod_{r=1}^{p}\begin{Bmatrix} r_iB_{ik_r};\nu_r-1\\ \nu_r-\nu_{r+1}\end{Bmatrix},\tag{3.5}$$

$$\varphi_{r,s}(f_i^m)=[m]!\sum_{p=1}^{m}\sum_{\substack{i\leqslant k_p<\cdots<k_1\leqslant n\\ 1\leqslant\nu_p<\cdots<\nu_1=m}}\prod_{r=1}^{p}A^{*\nu_r-\nu_{r+1}}_{n+1-i\ n+1-k_r}\prod_{r=1}^{p}\begin{Bmatrix} s_iB^*_{n+1-i\ n+1-k_r};\nu_r-1\\ \nu_r-\nu_{r+1}\end{Bmatrix},\tag{3.6}$$

where $\nu_{p+1}=0$ and we set

$$\begin{Bmatrix} a;b\\ c\end{Bmatrix}:=\frac{\{a\varepsilon^b\}\{a\varepsilon^{b-1}\}\cdots\{a\varepsilon^{b-c+1}\}}{[c]!}.$$

Remark: The definition of $\{{a;b\atop c}\}$ is invalid for ε such that $[c]!=0$. But on the right-hand side of (3.5) and (3.6) we see that the term

$$\frac{[m]!}{\Pi_{r=1}^{p}[\nu_r-\nu_{r+1}]!}\quad(1\leqslant\nu_p<\cdots<\nu_1=m)$$

is valid since $[m]_q!/\Pi_{r=1}^{p}[\nu_r-\nu_{r+1}]_q!\in\mathbf{Z}[q,q^{-1}]$.

Proof: In Ref. 5, the following formula is given:

$$\rho_{r,s}(e_i^m)=[m]!\sum_{p=1}^{m}\sum_{\substack{i\leqslant k_p<\cdots<k_1\leqslant n\\ 1\leqslant\nu_p<\cdots<\nu_1=m}}\prod_{r=1}^{p}\begin{Bmatrix} r_iB_{ik_r};-\nu_{r+1}\\ \nu_r-\nu_{r+1}\end{Bmatrix}\prod_{r=1}^{p}A_{ik_r}^{\nu_r-\nu_{r+1}},\tag{3.7}$$

where $\nu_{p+1}=0$. Since $\varphi_{r,s}=\rho_{\varepsilon^{-1}r,\varepsilon^{-1}s}$, it follows from (3.7)

$$\varphi_{r,s}(e_i^m)=\rho_{\varepsilon^{-1}r,\varepsilon^{-1}s}(e_i^m)=[m]!\sum_{p=1}^{m}\sum_{\substack{i\leqslant k_p<\cdots<k_1\leqslant n\\ 1\leqslant\nu_p<\cdots<\nu_1=m}}\prod_{r=1}^{p}\begin{Bmatrix} \varepsilon^{-1}r_iB_{ik_r};-\nu_{r+1}\\ \nu_r-\nu_{r+1}\end{Bmatrix}\prod_{r=1}^{p}A_{ik_r}^{\nu_r-\nu_{r+1}}.\tag{3.8}$$

Here by Lemma 3.2 we obtain for $i\leqslant k_p<\cdots<k_1\leqslant n$ and $1\leqslant r\leqslant p$,

$$\begin{Bmatrix} \varepsilon^{-1}r_iB_{ik_r};-\nu_{r+1}\\ \nu_r-\nu_{r+1}\end{Bmatrix}\left(\prod_{r=1}^{p}A_{ik_r}^{\nu_r-\nu_{r+1}}\right)=\left(\prod_{r=1}^{p}A_{ik_r}^{\nu_r-\nu_{r+1}}\right)\begin{Bmatrix} \varepsilon^{-1+\nu_r+\nu_{r+1}-2\nu_{p+1}}r_iB_{ik_r};-\nu_{r+1}\\ \nu_r-\nu_{r+1}\end{Bmatrix}$$
$$=\left(\prod_{r=1}^{p}A_{ik_r}^{\nu_r-\nu_{r+1}}\right)\begin{Bmatrix} r_iB_{ik_r};\nu_r-1\\ \nu_r-\nu_{r+1}\end{Bmatrix},$$

where we use $\nu_{p+1}=0$. Thus, we obtain (3.5). Similarly we also get (3.6). □

Let V_{ij} $(1\leqslant i\leqslant j\leqslant n)$ be a copy of the vector space $\mathbf{C}^l$ and set $\mathcal{V}:=\otimes_{1\leqslant i\leqslant j\leqslant n}V_{ij}$. Let $u_0,\ldots,u_{l-1}$ be the standard basis of $\mathbf{C}^l$. Now we define the representation $(\psi_{a,b},\mathcal{V})$ of $\mathcal{W}$ as follows: Let Z_{jk}, $X_{jk}\in\mathrm{End}(\mathcal{V})$ be the matrices defined as

$$Z_{jk}u_i=\varepsilon^iu_i,\quad X_{jk}u_i=u_{i+1}$$

on the component V_{jk} and as the identity on the other component. For nonzero parameters $a:=(a_{ij})_{1\leqslant i\leqslant j\leqslant n}$ and $b:=(b_{ij})_{1\leqslant i\leqslant j\leqslant n}\in(\mathbf{C}^\times)^{n(n+1)/2}$, define $\psi_{a,b}(x_{ij})$, $\psi_{a,b}(z_{ij})\in\mathrm{End}(\mathcal{V})$ to be

$$\psi_{a,b}(x_{ij})=a_{ij}X_{ij},\quad \psi_{a,b}(z_{ij})=b_{ij}Z_{ij}.\tag{3.9}$$

We can easily check that these define the representation of $\mathcal{W}$:

$$\psi_{a,b};\mathcal{W}\to\mathrm{End}(\mathcal{V}). \tag{3.10}$$

Composing $\varphi_{r,s}$ and $\psi_{a,b}$,

$$\Phi_{r,s,a,b}:=\psi_{a,b}\circ\varphi_{r,s}:U_\varepsilon\overset{\varphi_{r,s}}{\to}\mathcal{W}\overset{\psi_{a,b}}{\to}\mathrm{End}(\mathcal{V}),$$

we obtain the representation of U_ε denoted by $(\Phi_{r,s,a,b},\mathcal{V})$. The representation introduced in Ref. 5 is just as $(\Phi_{\varepsilon r,\varepsilon s,a,b},\mathcal{V})$ in our notation since we have $\varphi_{r,s}=\rho_{\varepsilon^{-1}r,\varepsilon^{-1}s}$ in the proof of Proposition 3.1.

It is shown in Ref. 5 that the representation $(\Phi_{r,s,a,b},\mathcal{V})$ is irreducible for generic parameters *r, s, a, b*. We are interested in specializations of these parameters so that the representation $(\Phi_{r,s,a,b},\mathcal{V})$ is not necessarily irreducible.

B. Representations of $U_\varepsilon^{\mathrm{res}}$ and $U_\varepsilon^{\mathrm{fin}}$

We review the representation theory of $U_\varepsilon^{\mathrm{res}}$. The classification of the irreducible representations of $U_\varepsilon^{\mathrm{res}}$ is given by Lusztig.[2] Before seeing it, let us recall the notions of highest weight modules. A $U_\varepsilon^{\mathrm{res}}$ or $U_\varepsilon^{\mathrm{fin}}$-module M is said to be of type **1**, if $t_i^l=1$ $(i\in I)$ on M.

Definition 3.4: Let V be a $U_\varepsilon^{\mathrm{res}}$-module of type **1**.

(*i*) *The weight spaces V_λ $(\lambda=\Sigma_i m_i\Lambda_i\in P)$ of V are defined by*

$$V_\lambda:=\left\{v\in V\,\middle|\,t_iv=\varepsilon^{m_i^{(0)}}v,\quad \begin{bmatrix}t_i;0\\ l\end{bmatrix}v=\begin{bmatrix}m_i^{(1)}\\ l\end{bmatrix}v\right\}, \tag{3.11}$$

where $m_i=m_i^{(0)}+lm_i^{(1)}$ and $0\leqslant m_i^{(0)}<l$.

(*ii*) *V is a highest weight module if V is generated by a primitive vector, i.e., a vector $v\in V_\lambda$ for some $\lambda\in P$, such that $e_iv=e_i^{(l)}v=0$ for any $i\in I$. In that case, λ is called the highest weight and v is called the highest weight vector of V.*

Let $V(\lambda)$ be the irreducible highest weight $U_q(\mathfrak{g})$-module given by $V(\lambda)=U_q(\mathfrak{g})/\mathcal{I}$ where $\lambda\in P_+$ and $\mathcal{I}$ is the left ideal generated by e_i, $f_i^{1+\langle h_i,\lambda\rangle}$, and $t_i-q^{\langle h_i,\lambda\rangle}$ $(1\leqslant i\leqslant n)$. Here denote the generator of $V(\lambda)$ by v_λ. Let $V_{\mathcal{A}}^{\mathrm{res}}(\lambda)$ be the $U_{\mathcal{A}}^{\mathrm{res}}$-submodule of $V(\lambda)$ generated by v_λ. Set $W_\varepsilon^{\mathrm{res}}(\lambda):=V_{\mathcal{A}}^{\mathrm{res}}(\lambda)\otimes_{\mathcal{A}}\mathbf{C}_\varepsilon$, which is naturally $U_\varepsilon^{\mathrm{res}}$-module. Note that $W_\varepsilon^{\mathrm{res}}(\lambda)$ is not necessarily irreducible. So, let Y be its maximal proper submodule and define $V_\varepsilon^{\mathrm{res}}(\lambda):=W_\varepsilon^{\mathrm{res}}(\lambda)/Y$ to be the irreducible quotient, which is type **1** highest weight module with the highest weight λ.

Theorem 3.5 (Ref. 2): *Arbitrary finite-dimensional irreducible $U_\varepsilon^{\mathrm{res}}$-module V of type* **1** *is isomorphic to $V_\varepsilon^{\mathrm{res}}(\lambda)$ for a unique $\lambda\in P_+$.*

Note that arbitrary finite-dimensional irreducible $U_\varepsilon^{\mathrm{res}}$-module V of type **1** is a direct sum of its weight spaces.

Here we call a weight $\lambda\in P_+$ satisfying $0\leqslant\langle h_i,\lambda\rangle<l$ for $i\in I$ an *l-restricted weight*.

Theorem 3.6 (Refs. 2 and 4, Proposition 11.2.10): (*i*) *For $\lambda=\Sigma_i m_i\Lambda_i\in P_+$, define $\lambda^{(0)}:=\Sigma_i m_i^{(0)}\lambda_i$ and $\lambda^{(1)}:=\Sigma_i m_i^{(1)}\lambda_i$ where $m_i=m_i^{(0)}+lm_i^{(1)}$ with $0\leqslant m_i^{(0)}<l$ (and then $\lambda=\lambda^{(0)}+l\lambda^{(1)}$). The $U_\varepsilon^{\mathrm{res}}$-module $V_\varepsilon^{\mathrm{res}}(\lambda)$ is isomorphic to $V_\varepsilon^{\mathrm{res}}(\lambda^{(0)})\otimes V_\varepsilon^{\mathrm{res}}(l\lambda^{(1)})$.*

(*ii*) *By restricting to $U_\varepsilon^{\mathrm{fin}}$, we obtain the one-to-one correspondence between the family of the finite-dimensional irreducible $U_\varepsilon^{\mathrm{res}}$-modules of type* **1** *with l-restricted highest weight and the family of irreducible $U_\varepsilon^{\mathrm{fin}}$-modules of type* **1**.

As we have stated in Sec. I, the module $V_\varepsilon^{\mathrm{res}}(\lambda^{(0)})$ is an irreducible $U_\varepsilon^{\mathrm{fin}}$-module and $V_\varepsilon^{\mathrm{res}}(l\lambda^{(1)})$ is identified with the irreducible highest weight $\mathfrak{sl}_{n+1}$-module $V(\lambda^{(1)})$. Since we know the structure of the irreducible $\mathfrak{sl}_{n+1}$-module well, this theorem implies that the structure of the module $V_\varepsilon^{\mathrm{res}}(\lambda)$ can be clarified if we shall make clear the one for $V_\varepsilon^{\mathrm{res}}(\lambda^{(0)})$.

IV. PRIMITIVE VECTORS

Let l and ε be same as in Sec. III.

A. Specializations of parameters

Let $M:=\{\mathrm{m}=(m_{jk})_{1\leqslant j\leqslant k\leqslant n} | 0\leqslant m_{jk}\leqslant l-1\}$ be the index set of the standard basis of $\mathcal{V}$. We can consider the additive structure on M via the natural identification $M\cong(\mathbf{Z}/l\mathbf{Z})^{(1/2)n(n+1)}$. For $\mathrm{m}\in M$ we write $u_{\mathrm{m}}:=\otimes_{1\leqslant j\leqslant k\leqslant n}u_{m_{jk}}(u_{m_{jk}}\in V_{jk})$.

We consider the following specialization of parameters *r, s, a, b*:

$$a_{ik}a_{ik+1}\cdots a_{in}=1, \tag{4.1}$$

$$r_i b_{ik}b_{ik-1}b^{-1}_{i-1k-1}b^{-1}_{i+1k}=1 \quad (1\leqslant i\leqslant k\leqslant n), \tag{4.2}$$

$$\frac{r_i}{s_i}b^2_{in}b^{-1}_{i-1n}b^{-1}_{i+1n}=\dot{\varepsilon}^{\lambda_i}, \tag{4.3}$$

where integers $\{\lambda_i\}_{1\leqslant i\leqslant n}$ satisfy $0\leqslant\lambda_i<l$. Here we set $a_{ik}=b_{ik}=1$ unless $1\leqslant i\leqslant k\leqslant n$.

Remark: Note that the set of parameters satisfying (4.1)–(4.3) is never empty. Indeed, if we set $a_{jk}=b_{jk}=1$ for any (j,k) and $r_i=1$ and $s_i=\varepsilon^{-\lambda_i}$ for any i, it is trivial to see that these satisfy (4.1)–(4.3). [By (4.1), we have $a_{jk}=1$ for all $1\leqslant j\leqslant k\leqslant n$].

Lemma 4.1: Under the specialization (4.2) and (4.3), we have

$$s_i b_{i+1-k\ n-k}b^{-1}_{i+1-k\ n+1-k}b_{i-k\ n+1-k}b^{-1}_{i-k\ n-k}=\varepsilon^{-\lambda_i}(1\leqslant k\leqslant i\leqslant n). \tag{4.4}$$

Proof: Using (4.2), we have $r_i b_{ik}b_{ik-1}b^{-1}_{i-1k-1}b^{-1}_{i+1k}=1=r_i b_{ik-1}b_{ik-2}b^{-1}_{i-1k-2}b^{-1}_{i+1k-1}$ and then $b_{i+1k-1}b^{-1}_{i+1k}=b_{ik-2}b^{-1}_{ik}b_{i-1k-1}b^{-1}_{i-1k-2}$. Changing $i\to i-k$ and $k\to n-k+1$, we get

$$b_{i+1-k\ n-k}b^{-1}_{i+1-k\ n+1-k}=b_{i-k\ n-k-1}b^{-1}_{i-k\ n+1-k}b_{i-k-1\ n-k}b^{-1}_{i-k-1\ n-k-1}. \tag{4.5}$$

By (4.2) with $k=n$ and (4.3), we have $s_i b_{in-1}b^{-1}_{in}b_{i-1n}b^{-1}_{i-1n-1}=\varepsilon^{-\lambda_i}$ which is (4.4) in the case $k=1$. Suppose that (4.4) holds and substitute (4.5) into (4.4). Then we obtain

$$s_i b_{i-k\ n-k-1}b^{-1}_{i-k\ n-k}b_{i-k-1\ n-k}b^{-1}_{i-k-1\ n-k-1}=\varepsilon^{-\lambda_i}.$$

Thus, the induction on k proceeds and then we prove (4.4) for any $k\in\{1,2,...,i\}$.

□

Under conditions (4.1)–(4.3), by this lemma we have

$$\Phi_{r,s,a,b}(e_i):=\sum_{k=i}^{n}X_{ik}X_{ik+1}\cdots X_{in}\{Z_{ik}Z_{ik-1}Z^{-1}_{i-1k-1}Z^{-1}_{i+1k}\}, \tag{4.6}$$

$$\Phi_{r,s,a,b}(f_i):=\sum_{k=1}^{i}X^{-1}_{i+1-k\ n+1-k}X^{-1}_{i+2-k\ n+2-k}\cdots X^{-1}_{in}$$
$$\times\{\varepsilon^{-\lambda_i}Z_{i+1-k\ n-k}Z^{-1}_{i+1-k\ n+1-k}Z_{i-k\ n+1-k}Z^{-1}_{i-k\ n-k}\}, \tag{4.7}$$

$$\Phi_{r,s,a,b}(t_i):=\varepsilon^{\lambda_i}Z^2_{in}Z^{-1}_{i-1n}Z^{-1}_{i+1n}, \tag{4.8}$$

B. Primitive vectors in $\mathcal{V}$

Under the specialization in Sec. IV A, we get the following:

Proposition 4.2: Under the specialization (4.1) and (4.2), $v\in\mathcal{V}$ satisfies the condition

$$e_i v=0 \quad \text{for any } i=1,...,n, \tag{4.9}$$

if and only if $v=cu_{\vec{0}}(c\in\mathbf{C})$ *where* $\vec{0}=(0,0,...,0)\in M$.

Proof: By (4.1) and (4.2), the action of e_i on $u_{\mathrm{m}}\in\mathcal{V}\,(\mathrm{m}=(m_{gh})\in M)$ is given by

$$e_iu_{\mathrm{m}}=\sum_{i\leqslant k\leqslant n}[m_{ik}+m_{ik-1}-m_{i-1k-1}-m_{i+1k}]u_{\mathrm{m}+\epsilon_{ik}+\cdots\epsilon_{in}}, \tag{4.10}$$

where $\epsilon_{jk}\in M$ satisfies that the (j,k)-entry is 1 and all others are 0. If $\mathrm{m}=\vec{0}$, we have $m_{ik}+m_{ik-1}-m_{i-1k-1}-m_{i+1k}=0$ for all $i\leqslant k\leqslant n$, which implies that $e_iu_{\vec{0}}=0$ for any i.

Conversely, assume that $v=\Sigma_{\mathrm{m}\in M}c_{\mathrm{m}}u_{\mathrm{m}}$ $(c_{\mathrm{m}}\in\mathbf{C})$ satisfies (4.9). First, we have

$$0=e_nv=X_{nn}\{Z_{n-1n-1}^{-1}Z_{nn}\}v=\sum_{\mathrm{m}\in M}c_{\mathrm{m}}[m_{nn}-m_{n-1n-1}]u_{m+\epsilon_{nn}} \tag{4.11}$$

This implies that

$$m_{n-1n-1}\neq m_{nn}\Rightarrow c_{\mathrm{m}}=0, \tag{4.12}$$

and then we have $v=\Sigma_{\mathrm{m}\in M,m_{n-1n-1}=m_{nn}}c_{\mathrm{m}}v_{\mathrm{m}}$.

Next, by $e_{n-1}v=0$ we have

$$\begin{aligned}0=e_{n-1}v&=(X_{n-1n-1}X_{n-1n}\{Z_{n-1n-1}Z_{n-2n-2}^{-1}\}+X_{n-1n}\{Z_{n-1n}Z_{n-1n-1}Z_{n-2n-1}^{-1}Z_{nn}^{-1}\})v\\&=\sum_{\substack{\mathrm{m}\in M.\\ m_{n-1n-1}=m_{nn}}}c_{\mathrm{m}}[m_{n-1n-1}-m_{n-2n-2}]u_{m+\epsilon_{n-1n-1}+\epsilon_{n-1n}}\\&\quad+c_{\mathrm{m}}[m_{n-1n}+m_{n-1n-1}-m_{n-2n-1}-m_{nn}]u_{m+\epsilon_{n-1n}}.\end{aligned}$$

This implies that

$$c_{\mathrm{m}}[m_{n-1n-1}-m_{n-2n-2}]=c_{\mathrm{m}}[m_{n-1n}+m_{n-1n-1}-m_{n-2n-1}-m_{nn}]=0 \tag{4.13}$$

for any $\mathrm{m}\in M$ satisfying $m_{n-1n-1}=m_{nn}$ since all vectors appearing in the summation are linearly independent under the condition $m_{n-1n-1}=m_{nn}$, that is, the indices $\mathrm{m}+\epsilon_{n-1n-1}+\epsilon_{n-1n}$ and $\mathrm{m}'+\varepsilon_{n-1n}$ never coincide for arbitrary m, m′ under the conditions $m_{n-1n-1}=m_{nn}$ and $m'_{n-1n-1}=m'_{nn}$. Thus, by (4.12) and (4.13) we have $c_{\mathrm{m}}=0$ unless

$$m_{n-2n-2}=m_{n-1n-1}=m_{nn},$$

$$m_{n-2n-1}=m_{n-1n}.$$

Here we assume that $c_{\mathrm{m}}=0$ in v unless

$$\begin{aligned}&m_{ii}=m_{i+1i+1}=\cdots=m_{nn},\\&m_{ii+1}=m_{i+1i+2}=\cdots=m_{n-1n},\\&\vdots\\&m_{in-1}=m_{i+1n}.\end{aligned} \tag{4.14}$$

By $e_iv=0$ we get

$$
\begin{aligned}
0 &= \sum_{k=i}^{n} X_{ik}X_{ik+1}\cdots X_{in}\{Z_{ik}Z_{ik-1}Z_{i-1k-1}^{-1}Z_{i+1k}^{-1}\}v \\
&= \sum_{\substack{\mathrm{m}\in M. \\ \mathrm{m}\ \text{satisfies}\ (4.14)}} \sum_{k=i}^{n} c_{\mathrm{m}}[m_{ik}+m_{ik-1}-m_{i-1k-1}-m_{i+1k}]u_{\mathrm{m}+\epsilon_{ik}+\cdots+\epsilon_{in}} \\
&= \sum_{\substack{\mathrm{m}\in M, \\ \mathrm{m}\ \text{satisfies}\ (4.14)}} (c_{\mathrm{m}}[m_{ii}-m_{i-1i-1}]u_{m+\epsilon_{ii}+\cdots+\epsilon_{in}} \\
&\quad + c_{\mathrm{m}}[m_{ii+1}+m_{ii}-m_{i-1i}-m_{i+1i+1}]u_{m+\epsilon_{i+1}+\cdots+\epsilon_{in}} \\
&\quad + \cdots + c_{\mathrm{m}}[m_{in}+m_{in-1}-m_{i-1n-1}-m_{i+1n}]u_{\mathrm{m}+\epsilon_{in}}).
\end{aligned} \tag{4.15}
$$

It follows from (4.14) that all vectors appearing in the summation (4.15) are linearly independent. Therefore, we obtain that $c_{\mathrm{m}}=0$, unless

$$
\begin{gathered}
m_{ii}-m_{i-1i-1}=0, \\
m_{ii+1}+m_{ii}-m_{i-1i}-m_{i+1i+1}=0, \\
\vdots \\
m_{in}+m_{in-1}-m_{i-1n-1}-m_{i+1n}=0.
\end{gathered}
$$

Thus, from this and (4.14) we get $c_{\mathrm{m}}=0$ unless

$$
\begin{gathered}
m_{i-1i-1}=m_{ii}=m_{i+1i+1}=\cdots=m_{nn}, \\
m_{i-1i}=m_{ii+1}=m_{i+1i+2}=\cdots=m_{n-1n}, \\
\vdots \\
m_{i-1,n-2}=m_{in-1}=m_{i+1n}, \\
m_{i-1n-1}=m_{in}.
\end{gathered} \tag{4.16}
$$

Thus, using $e_2v=e_3v=\cdots=e_{n-1}v=e_nv=0$ we have $c_{\mathrm{m}}=0$ unless

$$
\begin{gathered}
m_{11}=m_{22}=m_{33}=\cdots=m_{nn}, \\
m_{12}=m_{23}=m_{34}=\cdots=m_{n-1n}, \\
\vdots \\
m_{1,n-2}=m_{2n-1}=m_{3n}, \\
m_{1n-1}=m_{2n}.
\end{gathered} \tag{4.17}
$$

Finally, using $e_1v=0$, we have

$$
\begin{aligned}
0 &= \sum_{k=1}^{n} X_{1k}X_{1k+1}\cdots X_{1n}\{Z_{1k}Z_{1k-1}Z_{2k}^{-1}\}v \\
&= \sum_{\substack{\mathrm{m}\in M,\\ \mathrm{m}\ \text{satisfies}\ (4.17)}} \sum_{k=1}^{n} c_{\mathrm{m}}[m_{1k}+m_{1k-1}-m_{2k}]u_{\mathrm{m}+\epsilon_{1k}+\cdots+\epsilon_{1n}} \\
&= \sum_{\substack{\mathrm{m}\in M,\\ \mathrm{m}\ \text{satisfies}\ (4.17)}} (c_{\mathrm{m}}[m_{11}]u_{m+\epsilon_{11}+\cdots+\epsilon_{1n}} + c_{\mathrm{m}}[m_{12}+m_{11}-m_{22}]u_{m+\epsilon_{12}+\cdots+\epsilon_{1n}} \\
&\quad +\cdots+c_{\mathrm{m}}[m_{1n}+m_{1n-1}-m_{2n}]u_{\mathrm{m}+\epsilon_{1n}}). \qquad (4.18)
\end{aligned}
$$

Under the condition (4.17), we get that $c_{\mathrm{m}}=0$, unless

$$0=m_{11}=m_{12}=\cdots=m_{1n}. \qquad (4.19)$$

Therefore, it follows from (4.17) and (4.19) that $c_{\mathrm{m}}=0$ unless

$$
\begin{gathered}
0=m_{11}=m_{22}=m_{33}=\cdots=m_{nn}, \\
0=m_{12}=m_{23}=m_{34}=\cdots=m_{n-1n}, \\
\vdots \qquad (4.20) \\
0=m_{1,n-2}=m_{2n-1}=m_{3n}, \\
0=m_{1n-1}=m_{2n}, \\
0=m_{1n},
\end{gathered}
$$

which implies that $v=cu_{\vec{0}}(c\in\mathbf{C})$.

Remark: In the proof of the proposition, we easily see that we do not need (4.1) essentially. It is required for simplification of the proof or the presentations. So it is possible to proceed with the same argument for generic a_{jk}'s.

The primitive vector $u_{\vec{0}}$ possesses the following property:

Proposition 4.3: Under the conditions (4.1), (4.2) *and* (4.3), *we have* $t_iu_{\vec{0}}=\varepsilon^{\lambda_i}u_{\vec{0}}$ *and* $f_i^{\lambda_i+1}u_{\vec{0}}=0$.

Proof: The first formula is the immediate consequence of (4.8). We obtain the explicit form of $f_i^{\lambda_i+1}$ on $\mathcal{V}$ by (3.6) in Proposition 3.3 taking $m=\lambda_i+1$. By Lemma 4.1, under the specialization (4.1), (4.2), and (4.3), we have $s_ib_{i+1-kn-k}b_{i+1-kn+1-k}^{-1}b_{i-kn+1-k}b_{i-kn-k}^{-1}=\varepsilon^{-\lambda_i}$. Thus, on $u_{\vec{0}}$ we have

$$f_i^{\lambda_i+1}u_{\vec{0}}=[\lambda_i+1]!\sum_{p=1}^{\lambda_i+1}\sum_{\substack{i\leqslant k_p<\cdots<k_1\leqslant n\\ 1\leqslant\nu_p<\cdots<\nu_1=\lambda_i+1}}\prod_{r=1}^{p}A^{*\nu_r-\nu_r+1}_{n+1-i\ \ n+1-k_r}\prod_{r=1}^{p}\begin{Bmatrix}\varepsilon^{-\lambda_i};\nu_r-1\\ \nu_r-\nu_{r+1}\end{Bmatrix}u_{\vec{0}}.$$

For any $p\in\{1,2,...,\lambda_i+1\}$ and any $\nu_p,\ldots,\nu_1$ satisfying $1\leqslant\nu_p<\cdots<\nu_1=\lambda_i+1$, there exists $r\in\{1,2,...,p\}$ such that $\nu_{r+1}\leqslant\lambda_i<\nu_r$. Therefore, for such r we have

$$\begin{Bmatrix}\varepsilon^{-\lambda_i};\nu_r-1\\ \nu_r-\nu_{r+1}\end{Bmatrix}=\frac{\{\varepsilon^{-\lambda_i+\nu_r-1}\}\{\varepsilon^{-\lambda_i+\nu_r-2}\}\cdots\{\varepsilon^{-\lambda_i+\nu_{r+1}}\}}{[\nu_r-\nu_{r+1}]!}=0.$$

Thus, we obtain $f_i^{\lambda_i+1}u_{\vec{0}}=0$. □

Here for $\lambda:=(\lambda_1,\ldots,\lambda_n)$ $(0\leqslant\lambda_i<l)$ we define the U_ε-submodule $L(\lambda)$ of $\mathcal{V}$ by $L(\lambda):=U_\varepsilon u_{\vec{0}}$.

Let $V(\lambda)$ be the irreducible highest weight $U_q(\mathfrak{g})$-module as in Sec. III B. Let $V_{\mathcal{A}}(\lambda)$ be the $U_{\mathcal{A}}$-submodule of $V(\lambda)$ generated by v_λ. Set $V_\varepsilon(\lambda)$ be the U_ε-submodule of $V_{\mathcal{A}}(\lambda)\otimes_{\mathcal{A}}\mathbf{C}_\varepsilon$ generated by v_λ. Note that $V_\varepsilon(\lambda)$ is not necessarily irreducible. By Proposition 4.3, $t_i u_0^{\vec{}} = \varepsilon^{\lambda_i} u_0^{\vec{}}$ and $f_i^{\langle h_i,\lambda\rangle+1} u_0^{\vec{}} = 0$ $(i\in I)$, so we hope to have the surjective U_ε-linear map $\pi: V_\varepsilon(\lambda)\to L(\lambda)$ given by $\pi: v_\lambda \mapsto u_0^{\vec{}}$. It seems that the module $L(\lambda)$ is in the similar stream of the theory of $U_\varepsilon^{\mathrm{res}}$-modules. Here we expect that $L(\lambda)$ is an irreducible highest weight U_ε-module. Surprisingly, in Sec. IV C we will obtain the more interesting results that $L(\lambda)$ can be seen as an irreducible $U_\varepsilon^{\mathrm{fin}}$-module. By Theorem 3.6 this means that we get irreducible $U_\varepsilon^{\mathrm{res}}$ (or $U_\varepsilon^{\mathrm{fin}}$)-modules directly from U_ε-modules.

C. Shifts of parameters

Let $r^{(0)}=(r_j^{(0)})$, $s^{(0)}=(s_j^{(0)})\in(\mathbf{C}^\times)^n$ and $a^{(0)}=(a_{jk}^{(0)})$, $b^{(0)}=(b_{jk}^{(0)})\in(\mathbf{C}^{\mathrm{x}})^N$ be the parameters satisfying (4.1)–(4.3).

Fix a basis vector $u_\xi\in\mathcal{V}(\xi=(\xi_{jk})\in M)$ arbitrarily and set $b^{(\xi)}=(b_{jk}^{(\xi)}):=(\varepsilon^{-\xi_{jk}}b_{jk}^{(0)})\in(\mathbf{C}^\times)^N$. In this setting we obtain the following:

Proposition 4.4: For any $\mu=(\mu_{jk})\in M$ and any $X\in U_\varepsilon$, set

$$\Phi_{r^{(0)}s^{(0)},a^{(0)},b^{(0)}}(X)u_\mu=\sum_{\mathrm{m}\in M} C_{\mathrm{m}}u_{\mathrm{m}}. \tag{4.21}$$

Then we have

$$\Phi_{r^{(0)},s^{(0)},a^{(0)},b^{(\xi)}}(X)u_{\mu+\xi}=\sum_{\mathrm{m}\in M} C_{\mathrm{m}}u_{\mathrm{m}+\xi}. \tag{4.22}$$

Proof: It is shown easily from the formula

$$\psi_{a^{(0)},b^{(0)}}(x_{jk})u_\mu=a_{jk}^{(0)}u_{\mu+\varepsilon_{jk}}\quad \psi_{a^{(0)},b^{(0)}}(z_{jk})u_\mu=b_{jk}^{(0)}\varepsilon^{\mu_{jk}}u_\mu,$$

$$\psi_{a^{(0)},b^{(\xi)}}(x_{jk})u_{\mu+\xi}=a_{jk}^{(0)}u_{\mu+\xi+\varepsilon_{jk}},$$

$$\psi_{a^{(0)},b^{(\xi)}}(z_{jk})u_{\mu+\xi}=b_{jk}^{(\xi)}\varepsilon^{\mu_{jk}+\xi_{jk}}u_{\mu+\xi}=b_{jk}^{(0)}\varepsilon^{\mu_{jk}}u_{\mu+\xi}.$$

□

By Proposition 4.2, Proposition 4.3, and Proposition 4.4, we have the following result.

Proposition 4.5: We consider the representation $(\Phi_{r^{(0)},s^{(0)},a^{(0)},b^{(\varepsilon)}},\mathcal{V})$.

(*i*) *A vector $v\in\mathcal{V}$ satisfies the condition*

$$e_i v=0\quad \text{for any } i=1,\ldots,n, \tag{4.23}$$

if and only if $v=cu_\xi$ $(c\in\mathbf{C})$ where $u_\xi\in\mathcal{V}$ is the fixed basis vector as above.

(*ii*) *We have $t_i u_\xi=\varepsilon^{\lambda_i}u_\xi$ and $f_i^{\lambda_i+1}u_\xi=0$ $(i\in I)$.*

By this proposition, if we take the parameters properly, any basis vector $u_\xi\in\mathcal{V}$ can be the unique (up to constant) primitive vector in $\mathcal{V}$.

V. IRREDUCIBLE $U_\varepsilon^{\mathrm{fin}}$-MODULE

Suppose that parameter *r, s, a, b* satisfy conditions (4.1)–(4.3). In this case $u_0^{\vec{}}$ is the unique (up to constant) primitive vector in $\mathcal{V}$. As we defined in Sec. IV, set $L(\lambda):=U_\varepsilon u_0^{\vec{}}(\lambda=(\lambda_1,\lambda_2,\ldots,\lambda_n),0\leqslant\lambda_i\leqslant l-1)$, which is a U_ε-submodule of $\mathcal{V}$. In this section we shall see several properties of this module and it amounts to an irreducible $U_\varepsilon^{\mathrm{fin}}$-module.

A. Root vectors

First, we see higher root vectors in U_ε. There are several definitions for them. We shall introduce two of them here and discuss their relations.

The first one is defined by using (2.13) and (2.16) inductively. We also denote them by e_α and f_α $(\alpha\in\Delta_+)$.

Lemma 5.1: The root vectors e_α and $f_\alpha\in U_\varepsilon$ $(\alpha\in\Delta_+)$ defined by (2.13) *and* (2.16) *satisfy the relations* (2.11), (2.12), (2.14), (2.15), (2.17), *and* (2.18) *in* U_ε.

Proof: This lemma is easily obtained by using the results in, e.g., Refs. 12, 13, Sec. 3. Indeed, as for the element E_α $(\alpha\in\Delta_+)$ in Ref. 12, Chap. 4, we have the simple relation

$$e_\alpha=(q^{\mathrm{height}(\alpha)-1}E_\alpha)|_{q=\varepsilon^{-1}}. \tag{5.1}$$

Thus, the relations (2.11), (2.14), and (2.15) are immediate from Ref. 12, Proposition 3.2. The remaining relations are also derived similarly.

We introduce the alternative definition of root vectors:[5] For roots $\alpha=\alpha_i+\alpha_{i+1}+\cdots\alpha_j$ and $\beta=\alpha_{j+1}+\alpha_{j+2}+\cdots+\alpha_k$ $(i<j<k)$, we define

$$\overline{e}_{\alpha+\beta}=\overline{e}_\alpha\overline{e}_\beta-\varepsilon\overline{e}_\beta\overline{e}_\alpha, \tag{5.2}$$

$$\overline{f}_{\alpha+\beta}=\overline{f}_\alpha\overline{F}_\beta-\varepsilon^{-1}\overline{f}_\beta\overline{f}_\alpha, \tag{5.3}$$

where we set $\overline{e}_{\alpha_i}:=e_i$ and $\overline{f}_{\alpha_i}:=f_i$. Note that these definitions are well-defined, that is, these do not depend on the choice of j.

Those two types of the root vectors possess the following simple relations:

Lemma 5.2: For any $\alpha\in\Delta_+$, we have

$$\overline{e}_\alpha=\varepsilon^{\mathrm{height}(\alpha)-1}e_\alpha,\quad \overline{f}_\alpha=\varepsilon^{-\mathrm{height}(\alpha)+1}f_\alpha, \tag{5.4}$$

$$\overline{e}_\alpha^{\,l}=e_\alpha^l,\quad \overline{f}_\alpha^{\,l}=f_\alpha^l. \tag{5.5}$$

Proof: The proof of (5.4) is done by using induction on the height of roots and (5.5) is an immediate consequence of (5.4) since $\varepsilon^l=1$. □

B. $U_\varepsilon^{\mathrm{fin}}$-module structure on $\mathcal{V}$

For $\alpha\in\Delta_+$ we define the actions of e_α and f_α recursively by using the formulas (2.13) and (2.16) as in Sec. V A.

Proposition 5.3: For any $\alpha\in\Delta_+$ and $i\in I$, we have

$$e_\alpha^l=f_\alpha^l=0\ \text{ and }\ t_i^l=1\ \text{ on }\ \mathcal{V}. \tag{5.6}$$

Proof: Since $\Phi_{r,s,a,b}(t_i)=\varepsilon^{\lambda_i}Z_{in}^2Z_{i-1n}^{-1}Z_{i+1n}^{-1}$ on $\mathcal{V}$ and $Z_{ij}^l=1$, it is trivial that $t_i^l=1$.

To show the nilpotency of e_α and f_α, we need the following lemma:

Lemma 5.4 (Ref. 5, Proposition 3.4): For $\alpha=\alpha_i+\alpha_{i+1}+\cdots+\alpha_j$, the actions of $\overline{e}_\alpha^{\,l}$ and $\overline{f}_\alpha^{\,l}$ on $\mathcal{V}$ are given by

$$\overline{e}_\alpha^{\,l}=\frac{1}{(\varepsilon-\varepsilon^{-1})^l}\Bigg(\sum_{k_1\geqslant i,\ldots,k_{j-i+1}\geqslant j}\ \sum_{p=1}^{j-i+1}(-1)^{p-1}\theta(k_1\geqslant\cdots\geqslant k_p<\cdots<k_{j-i+1})$$

$$\times C_{ik_1\ldots k_{p-1}}(C_{i+p-1k_p}-C_{i+p-1k_p}^{-1})C_{i+pk_{p+1}\ldots k_{j-i+1}}^{-1}D_{ik_i\ldots k_{j-i+1}}\Bigg)\cdot\mathrm{id},$$

$$\overline{f}^{l}_{\alpha}=\frac{-1}{(\varepsilon-\varepsilon^{-1})^{l}}\Bigg(\sum_{k_1\geqslant n+1-j,\ldots,k_{j-1+1}\geqslant n+1-i}\ \sum_{p=1}^{j-i+1}(-1)^{p-1}\theta(k_1\geqslant\cdots\geqslant k_p<\cdots<k_{j-i+1})$$

$$\times\overline{C}_{n+1-j\ k_1\cdots k_{p-1}}(\overline{C}_{n-j+p\ k_p}-\overline{C}^{-1}_{n-j+p\ k_p})\overline{C}^{-1}_{n-j+p+1k_{p+1}\cdots k_{j-i+1}}\overline{D}_{n-j+1k_1\cdots k_{j-i+1}}\Bigg)\cdot\mathrm{id},$$

where $\theta(X)=1$ *if* X *is true and* $\theta(X)=0$ *otherwise, and we set*

$$C_{i\ k}:=(\varepsilon^{-1}r_ib_{ik}b_{ik-1}b^{-1}_{i-1k-1}b^{-1}_{i+1k})^{l}, \tag{5.7}$$

$$\overline{C}_{ik}:=(\varepsilon^{-1}s_{n-i+1}b_{k+1-i\ k}b_{k-i\ k-1}b^{-1}_{k+1-i\ k-1}b^{-1}_{k-i\ k})^{l}, \tag{5.8}$$

$$D_{ik}:=\prod_{p=k}^{n}(a_{ip})^{l},\overline{D}_{ik}:=\prod_{p=k}^{n}(a^{-1}_{p+1-ip})^{l}, \tag{5.9}$$

and $\phi_{ik_1\cdots k_p}:=\phi_{ik_1}\cdots\phi_{ik_p}$ *for* $\phi=C,\ \overline{C},\ D,\ \overline{D}$.
(Note that in the definition of $\overline{\eta}_{ik}$ [5], s_i must be changed to s_{n+1-i}.).

Applying the specializations of the parameters (4.2) and (4.4) to C_{ik} and $\overline{C}_{ik}$ we have $C_{ik}=\overline{C}_{ik}=1$ for all $1\leqslant i\leqslant k\leqslant n$, which implies that $C_{i+p-1k_p}-C^{-1}_{i+p-1k_p}=\overline{C}_{n-j+p\ k_p}-\overline{C}^{-1}_{n-j+p\ k_p}=0$ and then $\overline{e}^{l}_{\alpha}=\overline{f}^{l}_{\alpha}=0$. Since we have $e^{l}_{\alpha}=\overline{e}^{l}_{\alpha}$ and $f^{l}_{\alpha}=\overline{f}^{l}_{\alpha}$ by Lemma 5.2, we obtain that $e^{l}_{\alpha}=f^{l}_{\alpha}=0$ on $\mathcal{V}$. □

Theorem 5.5: *(i) If we define the actions of* e_α *and* f_α $(\alpha\in\Delta_+)$ *by using* (2.13) *and* (2.16), *the vector space* $\mathcal{V}$ *becomes* $U^{\mathrm{fin}}_{\varepsilon}$*-module of type 1.*

(*ii*) *The subspace* $L(\lambda)$ $(\lambda=(\lambda_1,\ldots,\lambda_n),\ \lambda_i\in\{0,1,...,l-1\})$ *is the unique irreducible* $U^{\mathrm{fin}}_{\varepsilon}$*-submodule of* $\mathcal{V}$.
