(Received 22 August 2001; accepted for publication 6 December 2001)

A graphical formalism is introduced for describing subgroup type coordinates on n-dimensional Lorentzian hyperboloids imbedded into $n+1$ dimensional Minkowski spaces. The $O(n,1)$ group element is parametrized according to different subgroup chains, involving Lorentz, rotation, and Euclidean subgroups. The coordinates are then induced by the corresponding group action. Eigenfunctions of the Laplace–Beltrami operator are obtained as products of Jacobi functions, associated Legendre functions, and modified Bessel functions. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1467709]

I. INTRODUCTION

The purpose of this article is to study in a systematic manner all possible subgroup type coordinates on an n-dimensional Lorentzian hyperboloid, embedded into an $n+1$-dimensional Minkowski space. The isometry group of this space is the pseudo-orthogonal group $O(n,1)$, the Lorentz group in n space dimensions. The space itself can be identified as the quotient space $O(n,1)/O(n)$, or $O(n,1)/O(n-1,1)$, for the two-sheeted or one-sheeted hyperboloid, respectively.

By ''separable coordinates'' we mean curvlinear coordinates $(\xi_1,\xi_2,\ldots,\xi_n)$ on a hyperboloid H_n, such that the Laplace–Beltrami equation

$$\Delta_{\mathrm{LB}}\Psi(\xi_1,\xi_2,\ldots,\xi_n)=\nu(\nu+n-1)\,\Psi(\xi_1,\xi_2,\ldots,\xi_n), \tag{1.1}$$

allows the ''multiplicative'' separation

$$\Psi_{\lambda_1,\lambda_2,\ldots,\lambda_n}(\xi_1,\xi_2,\ldots,\xi_n)=\prod_{i=1}^{n}\Phi_i(\xi_i;\lambda_1,\lambda_2,\ldots,\lambda_n). \tag{1.2}$$

In Eq. (1.2) each function Φ_i depends only on one variable ξ_i, but can depend on all the separation constants λ_j.

We make use of an algebraic approach to the separation of variables in Riemannian or pseudo-Riemannian spaces.[1–10] In this approach the separated solutions $\Psi(\xi_1,\xi_2,\ldots,\xi_n)$ are simultaneous eigenfunctions of a complete set of commuting operators $\{Y_1,Y_2,\ldots,Y_n\}$, where n is the dimension of the space. The operators Y_i are second-order operators in the enveloping algebra of L, where L is the Lie algebra of the isometry group G of the corresponding space, and the Laplace–Beltrami operator Δ_{LB} is included in the set $\{Y_1,Y_2,\ldots,Y_n\}$. A classification of

a)Electronic mail: pogosyan@fis.unam.mx

different coordinate systems corresponds to a classification of such commuting sets of operators under the action of the group G. Subgroup type coordinates are obtained when we take a chain of subgroups

$$G \equiv G_1 \supset G_2 \supset \cdots \supset G_k \tag{1.3}$$

each of which has at least one second-order Casimir operator. The commuting operators $\{Y_1, Y_2, \ldots, Y_n\}$ are then taken as Casimir operators of the groups in the chain (1.3).

Subgroup type coordinates on homogeneous spaces associated with rotation groups $O(n)$ and unitary groups $SU(n)$ were studied by Vilenkin, Kuznetsov, Smorodinsky and others.[11–15] They introduced a graphical method, the ''method of trees,'' to describe subgroup coordinates on spheres $S_n \sim O(n+1)/O(n)$ and complex ''spheres'' $C_n \sim SU(n)/U(n-1)$.

The relation between tree diagrams and subgroup chains was explored in a recent publication,[15] devoted to Lie algebra contractions and the separation of variables. The method of trees was extended from spheres to Euclidean spaces in the same article.[15]

In this article we shall adapt the method of trees to a noncompact group, namely $O(n,1)$ and introduce a graphical method for coordinates on hyperboloids. We shall relate tree diagrams to subgroup diagrams, representing chains of subgroups. We show that the subgroup chains can be used to directly generate separable coordinates by acting on a chosen ''origin'' on the homogeneous space.

In Sec. II we introduce notation and review some basic facts on maximal subgroups of pseudo-orthogonal, orthogonal, and Euclidean Lie groups. Coordinate and subgroup diagrams and all types of separable subgroup coordinates are introduced in Sec. III, first for the low-dimensional groups O(2,1) and O(3,1), then for the general case of $O(n,1)$ for n arbitrary. Section IV is devoted to the eigenfunctions of the Laplace–Beltrami operator for O(2,1) and O(3,1). Eigenfunctions for the general case of $O(n,1)$ are presented in Sec. V and are associated with the different types of subgroup and coordinate diagrams.

II. SUBGROUP CHAINS AND SUBGROUP DIAGRAMS

A. General setting

We consider the upper sheet of the two-sheeted hyperboloid H_n,

$$u \cdot u = u^2 = u_0^2 - \mathbf{u}^2 = 1, \quad \mathbf{u}^2 = u_1^2 + u_2^2 + \cdots + u_n^2, \tag{2.1}$$

where u_μ, $\mu = 0,1,\ldots,n$ are Cartesian coordinates in the ambient Minkowski space $M_{n,1}$. The Laplace–Beltrami operator in curvilinear coordinates on H_n is written as

$$\Delta_{\mathrm{LB}} \equiv \Delta(H_n) = \frac{1}{\sqrt{g}} \frac{\partial}{\partial \xi^\mu} \sqrt{g}\, g^{\mu\nu} \frac{\partial}{\partial \xi^\nu}, \tag{2.2}$$

where the metric is

$$\mathrm{d}s^2 = g_{\mu\nu} \mathrm{d}\xi^\mu\, \mathrm{d}\xi^\nu, \quad g = |\det(g_{\mu\nu})|, \quad g_{\alpha\mu} g^{\mu\nu} = \delta_\alpha^\nu. \tag{2.3}$$

The relation between the metric tensor $G_{\mu\nu} = \mathrm{diag}(1,-1,-1,\ldots,-1)$, $(\mu,\nu = 0,1,2,\ldots,n)$ in the ambient space and $g_{\mu\nu}(\xi)$ of Eqs. (2.2) and (2.3) is

$$g_{\mu\nu}(\xi) = G_{ik} \frac{\partial u^i}{\partial \xi^\mu} \frac{\partial u^k}{\partial \xi^\nu}. \tag{2.4}$$

The isometry group is $SO(n,1)$, the proper Lorentz group. Its Lie algebra $o(n,1)$ is realized by vector fields with a standard basis $M_{\mu\nu}$, namely

$$M_{ik}=-\left(u_i\frac{\partial}{\partial u_k}-u_k\frac{\partial}{\partial u_i}\right),\quad M_{0k}=\left(u_0\frac{\partial}{\partial u_k}+u_k\frac{\partial}{\partial u_0}\right),\quad i,k=1,2,\ldots,n \tag{2.5}$$

with the commutation relations

$$[M_{\mu\nu},M_{\alpha\beta}]=G_{\nu\alpha}M_{\mu\beta}-G_{\nu\beta}M_{\mu\alpha}-G_{\mu\alpha}M_{\nu\beta}+G_{\mu\beta}M_{\nu\alpha},\quad \alpha,\beta,\mu,\nu=0,1,2,\ldots,n. \tag{2.6}$$

The Laplace–Beltrami operator and the second order Casimir operator of o(n,1) are related by

$$\Delta(H_n)=Q(n,1),\quad Q(n,1)=\sum_{i=1}^{n}M_{0i}^2-\sum_{1\leqslant i<k}^{n}M_{ik}^2. \tag{2.7}$$

B. Subgroups of O(n,1)

Since we are interested in subgroup type coordinates, we need a classification of subalgebras of the algebra o(n,1). Consider the defining representation of o(n,1), i.e., matrices X satisfying

$$XI_{1,n}+I_{1,n}X^T=0,\quad I_{n,1}=\begin{pmatrix}1 & 0\\ 0 & -I_n\end{pmatrix},\quad X\in R^{(n+1)\times(n+1)}. \tag{2.8}$$

A maximal subalgebra of o(n,1) can be embedded in this representation reducibly, or irreducibly.[16,17] A reducibly imbedded subalgebra will leave a proper vector subspace of R^{n+1} invariant, an irreducibly imbedded subalgebra will only leave R^{n+1}, and 0 invariant. Here we will only need reducibly imbedded subalgebras.

Maximal subalgebras are obtained if the invariant subspace is either completely isotropic (all vectors in the space are lightlike and mutually orthogonal with respect to the metric in the ambient space), or nondegenerate (no lightlike vectors in an orthogonal basis). For o(n,1), that means the following maximal subalgebras exist:

$$\mathrm{o}(n,1)\supset\mathrm{o}(n_1,1)\oplus\mathrm{o}(n_2),\quad n_1+n_2=n,\ n_1\geqslant 1,\ n_2\geqslant 2, \tag{2.9}$$

$$\mathrm{o}(n,1)\supset\mathrm{sim}(n-1), \tag{2.10}$$

where sim($n-1$) is the Lie algebra of the similitude group of the $n-1$ dimensional Euclidean space [the group $E(n-1)$ extended by dilations]. The subalgebra in Eq. (2.9) leaves invariant a space spanned by n_1 negative length vectors [in the metric (2.8)] and also its orthogonal complement in the Minkowski space $M_{n,1}$. We can choose the basis elements of subalgebra (2.9) to be

$$\{M_{ik},M_{j0}\},\ \{M_{ab}\}\ \ 1\leqslant i<k\leqslant n_1,\quad 1\leqslant j\leqslant n_1\ \ n_1+1\leqslant a<b\leqslant n_1+n_2=n. \tag{2.11}$$

It is to be remembered that the algebras o(1) and o(0,1) are empty. For $n_1\geqslant 1$ and $n_2\geqslant 2$ the subalgebras in Eq. (2.1) contribute two Casimir operators

$$C(n_1,1)=\sum_{i=1}^{n_1}M_{i0}^2-\sum_{1\leqslant i<k\leqslant n_1}M_{ik}^2,\quad C(n_2)=\sum_{n_1+1\leqslant a<b\leqslant n_1+n_2}M_{ab}^2. \tag{2.12}$$

The subalgebra sim($n-1$) leaves invariant a one-dimensional isotropic space in $M_{n,1}$ and is spanned by

$$\{M_{0n},M_{ik},M_{0i}+M_{ni}\},\quad 1\leqslant i<k\leqslant n-1,\quad 1\leqslant i\leqslant n-1. \tag{2.13}$$

The algebra sim($n-1$) does not have a second-order Casimir operator, but its maximal subalgebra $e(n-1)$, the Euclidean Lie algebra, does. The algebra $e(n-1)$ is obtained from (2.13) by omitting M_{0n}. The corresponding Casimir operator is

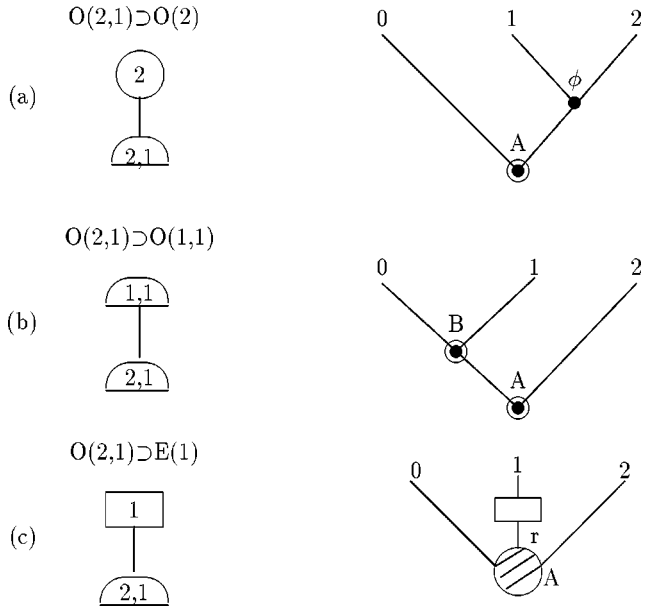

FIG. 1. All subgroup and coordinate diagrams for the O(2,1) hyperboloid.

$$P^2=(M_{01}+M_{n1})^2+(M_{02}+M_{n2})^2+\cdots+(M_{0n-1}+M_{nn-1})^2. \tag{2.14}$$

We shall use subgroup diagrams, first introduced in Ref. 3. A semicircle will denote an o(p,1) algebra with the number p indicated inside. A circle will denote an o(p) algebra, again with the number p indicated. Finally, a square with a number inside will indicate a Euclidean algebra $e(p)$.

Links in a subgroup chain can be of the following types (each indicated subgroup on the right is maximal in the group on the left):

$$\mathrm{O}(p,1)\supset \mathrm{O}(p), \quad \mathrm{O}(p,1)\supset \mathrm{O}(p-1,1), \tag{2.15}$$

$$\mathrm{O}(p,1)\supset E(p-1), \tag{2.16}$$

$$\mathrm{O}(p,1)\supset \mathrm{O}(p_1,1)\otimes \mathrm{O}(p_2), \quad p_1+p_2=p, \ p_1\geqslant 1, \quad p_2\geqslant 2, \tag{2.17}$$

$$\mathrm{O}(p)\supset \mathrm{O}(p-1), \tag{2.18}$$

$$\mathrm{O}(p)\supset \mathrm{O}(p_1)\otimes \mathrm{O}(p_2), \quad p_1+p_2=p, \quad p_1\geqslant p_2\geqslant 1, \tag{2.19}$$

$$E(p)\supset \mathrm{O}(p), \tag{2.20}$$

$$E(p)\supset E(p_1)\otimes E(p_2), \quad p_1+p_2=p, \ p_1\geqslant p_2\geqslant 1. \tag{2.21}$$

The group O(p,1) itself provides one second order operator, the Laplace operator itself. The subgroups on the right in Eqs. (2.15), (2.16), (2.18), and (2.20) provide one further Casimir operator each. The direct products on the right-hand sides of (2.17) and (2.19) provide two Casimir operators in each case. The group $E(p_1)\otimes E(p_2)$ in (2.21) provides two Casimir operators, however their sum is equal to the Casimir operator of the $E(p)$ group on the left-hand side of Eq. (2.21).

All ''allowed'' subalgebra chains and the corresponding Casimir operators for o(2,1) and o(3,1) are shown on the left-hand side of Figs. 1 and 2, respectively. The word ''allowed'' in the previous sentence means that each subalgebra has least one second-order Casimir operator and is maximal amongst those that have this property.

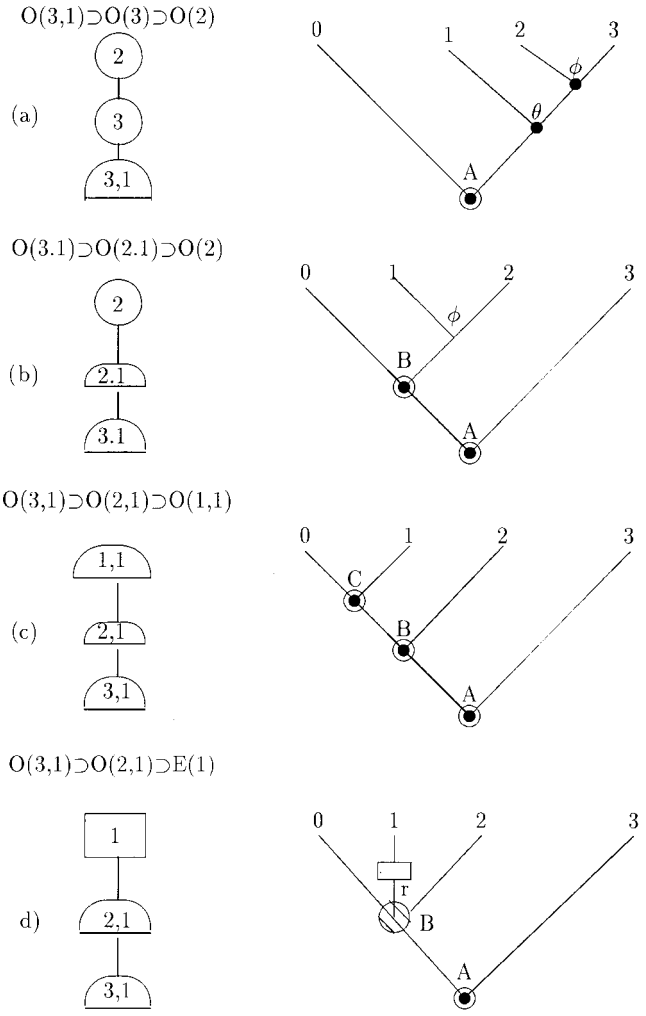

FIG. 2. All subgroup and coordinate diagrams for the O(3,1) hyperboloid.

The procedure of writing all subgroup chains for any p is recursive. From a circle, we can go to one or two circles. From a semicircle to a circle, a semicircle, a square, or a circle plus a semicircle. From a square we can go to a circle, or to two squares.

III. SUBGROUP TYPE COORDINATES AND COORDINATE DIAGRAMS

A. General procedure

Subgroup type coordinates can be interpreted quite literally. They can be obtained by successively applying a series of one-dimensional subgroups of the isometry group G to the origin of the considered space.

Let us consider the hyperboloid H_n [of Eq. (2.1)] and the isometry group O(n,1). We start from the origin which we choose to be the point $(u_0,u_1,\ldots,u_n)=(1,0,\ldots,0)\equiv\mathbb{1}$. Next, we parametrize an element of O(n,1) as

$$G=HG_1e^{M_{0k}A}G_0, \quad A\in R, \tag{3.1}$$

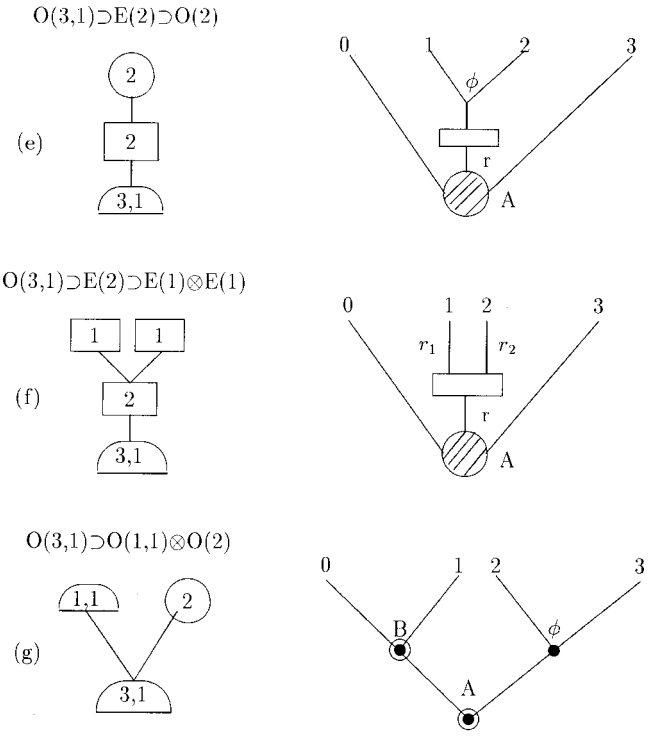

FIG. 2 (*Continued.*)

where $G_0 \sim O(n)$ is the isotropy group of the origin. The exponential represents a pseudorotation in the $(0k)$ plane. We will choose $k=n$, or $k=1$, as the case may be. The group $G_1 \sim O(n-1)$ leaves the space $\exp M_{ok}\mathbb{1}$ (a hyperbola) invariant. Finally H will act effectively on the hyperboloid and generate the coordinate system.

We will run through all different choices of the group HG_1 and relate subgroup diagrams, tree diagrams, and subgroup coordinates. We mention that H itself is not a group.

We shall first treat low dimensional examples, then return to the general case.

B. The group O(2,1)

1. O(2,1)⊃O(2)

Formula (3.1) reduces to

$$G = e^{M_{12}\phi} e^{M_{01}A} e^{M_{12}\alpha} \tag{3.2}$$

and the procedure $\mathbf{u} = G\mathbb{1}$ produces spherical coordinates $(0 \leqslant A < \infty, 0 \leqslant \phi < 2\pi)$

$$\begin{pmatrix} u_0 \\ u_1 \\ u_2 \end{pmatrix} = \begin{pmatrix} \cosh A \\ \sinh A \cos\phi \\ \sinh A \sin\phi \end{pmatrix}. \tag{3.3}$$

The commuting set of operators corresponding to this system is

$$Y_1 = M_{01}^2 + M_{02}^2 - M_{12}^2, \quad Y_2 = M_{12}^2.$$

2. O(2,1)⊃O(1,1)

We have

$$G=e^{M_{01}B}e^{M_{02}A}e^{M_{12}\alpha} \tag{3.4}$$

and we obtain hyperbolic coordinates $(-\infty<A<\infty,-\infty<B<\infty)$

$$\begin{pmatrix} u_0 \\ u_1 \\ u_2 \end{pmatrix}=\begin{pmatrix} \cosh A\cosh B \\ \cosh A\sinh B \\ \sinh A \end{pmatrix}. \tag{3.5}$$

The commuting set of operators is

$$Y_1=M_{01}^2+M_{02}^2-M_{12}^2,\quad Y_2=M_{01}^2.$$

3. O(2,1)⊃E(1)

We have

$$G=e^{(M_{01}+M_{21})r}e^{M_{02}A}e^{M_{12}\alpha} \tag{3.6}$$

and we obtain horospheric coordinates $(-\infty<A<\infty,-\infty<r<\infty)$

$$\begin{pmatrix} u_0 \\ u_1 \\ u_2 \end{pmatrix}=\begin{pmatrix} \cosh A+\dfrac{r^2}{2}e^{-A} \\ re^{-A} \\ \sinh A+\dfrac{r^2}{2}e^{-A} \end{pmatrix}. \tag{3.7}$$

The commuting set of operators is

$$Y_1=M_{01}^2+M_{02}^2-M_{12}^2,\quad Y_2=(M_{01}+M_{21})^2.$$

Notice that the group element $\exp(M_{01}A)$ in Eq. (3.2) and $\exp(M_{02}A)$ in (3.4) and (3.6) takes us onto a hyperbola in the 01 or 02 plane, respectively. The element on the left-hand side, $\exp(M_{12}\phi)$, $\exp(M_{01}B)$, or $\exp(M_{01}+M_{21})r$ completes the parametrization of the O(2,1) hyperboloid and introduces an "ignorable variable" ϕ, B, or r, respectively. Ignorable variables do not figure in the metric tensor, or in the coefficients of the Laplace–Beltrami operator. In the solutions of the Helmholtz equation they figure as exponentials.

For the group O(2,1) the group G_1 of Eq. (3.1) is $G_1=I$ and H is a one-dimensional subgroup.

In Fig. 1 we show the subgroup and coordinate diagrams for the group O(2,1) acting on the hyperboloid H_2. The coordinate diagrams of Figs. 1(a) and 1(b) are obvious extensions of the tree diagrams[13] for a sphere S_n. Each point at the top of a coordinate diagram corresponds to a point in the ambient space $M_{n,1}$ ($M_{2,1}$ in Fig. 1). The coordinate u_0 will always be chosen to be on the extreme left-hand side of the tree. All nodes on the branch leading to u_0 will be denoted by a double circle, as in Figs. 1(a) and 1(b). Nodes on branches leading to the coordinates u_i ($i=1,\ldots,n$) will be denoted by a single (full) circle [see Fig. 1(a)]. At each double circle (hyperbolic node) we introduce a hyperbolic "angle" A_i [A in Fig. 1(a), A and B in Fig. 1(b)]. At each single circle (trigonometric node) we introduce a trigonometric angle θ_i [ϕ in Fig. 1(a)]. The rules for writing coordinates corresponding to such tree diagrams are a slight modification of the rules for S_n spheres.[13] We move along a tree from the bottom to the top and write $\cos\theta_i$, or, respectively, $\cosh A_i$, when we go to the left at a node and $\sin\theta_i$, or, respectively, $\sinh A_i$ when we go to the right.

We mention that for the sphere S_2 the diagrams of Figs. 1(a) and 1(b) would be equivalent.

The subgroup diagrams involving squares (Euclidean subgroups) and the corresponding horospheric coordinates are a specific new feature arising for the noncompact group $O(n,1)$. The vertex in Fig. 1(c) is a three prong one. A variable A is asigned to the central prong. This prong leads to a rectangle, representing E_{n-1} [E_1 in Fig. 3(c)]. Further coordinates are introduced in E_{n-1}. For O(2,1) there is only one such coordinate, namely a Cartesian one which we call r. The general case $O(k,1)\supset E(k-1)$ is treated in the following.

C. The group O(3,1)

From now on we drop the groups G_0 and G_1 in Eq. (3.1) that act trivially, and hence do not produce coordinates.

1. O(3,1)⊃O(3)⊃O(2) [Fig. 2(a)]

In formula (3.1) we have

$$H=e^{M_{23}\phi}e^{M_{12}\theta}e^{M_{01}A} \tag{3.8}$$

and coordinates induced by the action $\mathbf{u}=G1$ are the spherical ones

$$\begin{aligned} u_0&=\cosh A, \quad 0\leqslant A<\infty,\\ u_1&=\sinh A\cos\theta, \quad 0\leqslant\theta\leqslant\pi,\\ u_2&=\sinh A\sin\theta\cos\phi, \quad 0\leqslant\phi<2\pi,\\ u_3&=\sinh A\sin\theta\sin\phi. \end{aligned} \tag{3.9}$$

The O(2) subgroup on the left in (3.8) provides the ignorable variable ϕ. The entire O(3) subgroup in the chain is given as $(\exp M_{23}\phi)(\exp M_{12}\theta)\ (\exp M_{23}\alpha)$, but we drop $(\exp M_{23}\alpha)$ in Eq. (3.8), since it acts trivially on the origin of the sphere $u_1^2+u_2^2+u_3^2=\sinh^2 A$.

The commuting set of operators corresponding to this system is

$$Y_1=\Delta(H_3), \quad Y_2=M_{13}^2+M_{12}^2+M_{23}^2, \quad Y_3=M_{23}^2.$$

2. O(3,1)⊃O(2,1)⊃(2) [Fig. 2(b)]

The action on the origin of H_3 is given by

$$H=e^{M_{12}\phi}e^{M_{01}B}e^{M_{03}A} \tag{3.10}$$

and the coordinates are

$$\begin{aligned} u_0&=\cosh A\cosh B, \quad -\infty<A<\infty,\\ u_1&=\sinh A\sinh B\cos\phi, \quad 0\leqslant B<\infty,\\ u_2&=\sinh A\sinh B\sin\phi, \quad 0\leqslant\phi<2\pi,\\ u_3&=\sinh A. \end{aligned} \tag{3.11}$$

The variable ϕ is ignorable, the others not. The O(2,1) subgroup is generated by M_{12}, M_{01} and M_{02}. The element $(\exp M_{02}C)$ is omitted in Eq. (3.10) since it acts trivially on $\exp M_{03}A\cdot 1$.

The commuting set of operators is

$$Y_1=\Delta(H_3), \quad Y_2=M_{01}^2+M_{02}^2-M_{12}^2, \quad Y_3=M_{12}^2.$$

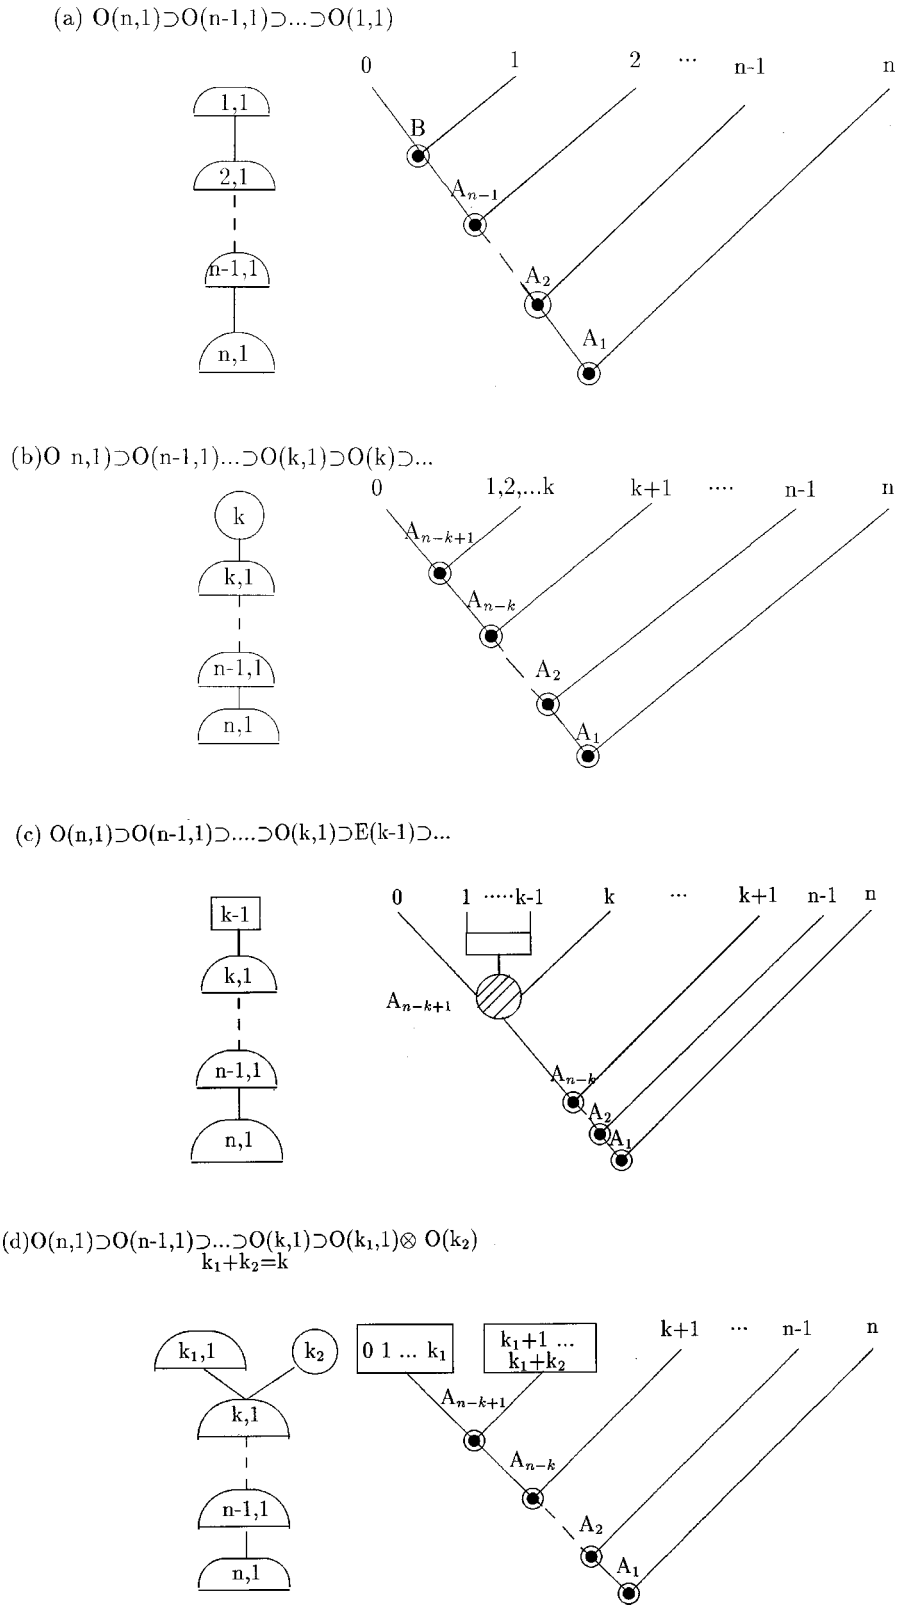

FIG. 3. Subgroup and coordinate diagrams for the O(n,1) hyperboloid.

3. O(3,1)⊃O(2,1)⊃O(1,1) [Fig. 2(c)]

The action on the origin of H_3 is given by

$$H=e^{M_{01}C}e^{M_{02}B}e^{M_{03}A} \tag{3.12}$$

and the corresponding hyperbolic coordinates are

$$\begin{gathered}u_0=\cosh A\cosh B\cosh C,\quad -\infty<A<\infty,\\ u_1=\sinh A\cosh B\sinh C,\quad -\infty<B<\infty,\\ u_2=\sinh A\sinh B,\quad -\infty<C<\infty,\\ u_3=\sinh A.\end{gathered} \tag{3.13}$$

The variable C is ignorable, A and B are not.

The commuting set of operators corresponding to this system is

$$Y_1=\Delta(H_3),\quad Y_2=M_{01}^2+M_{02}^2-M_{12}^2,\quad Y_3=M_{01}^2.$$

4. O(3,1)⊃O(2,1)⊃E(1) [Fig. 2(d)]

We take

$$H=e^{(M_{01}+M_{21})r}e^{M_{02}B}e^{M_{03}A} \tag{3.14}$$

and obtain

$$\begin{gathered}u_0=\cosh A\left(\cosh B+\frac{r^2}{2}e^{-B}\right),\quad -\infty<A<\infty,\\ u_1=\cosh A r e^{-B},\quad -\infty<B<\infty,\\ u_2=\cosh A\left(\sinh B+\frac{r^2}{2}e^{-B}\right),\quad -\infty<r<\infty,\\ u_3=\sinh A.\end{gathered} \tag{3.15}$$

The (only) ignorable variable is r. Notice that the rule for introducing the coordinates B and r coincides with that of Eq. (3.7) for O(2,1).

The commuting operators are

$$Y_1=\Delta(H_3),\quad Y_2=M_{01}^2+M_{02}^2-M_{12}^2,\quad Y_3=(M_{01}+M_{12})^2.$$

5. O(3,1)⊃E(2)⊃O(2) [Fig. 2(e)]

We have

$$H=e^{M_{12}\phi}e^{(M_{01}+M_{31})r}e^{M_{03}A} \tag{3.16}$$

and

$$\begin{gathered}u_0=\left(\cosh A+\frac{r^2}{2}e^{-A}\right),\quad -\infty<A<\infty,\\ u_1=re^{-A}\cos\phi,\quad 0\leqslant r<\infty,\end{gathered} \tag{3.17}$$

$$u_2 = re^{-A}\sin\phi, \quad 0 \leqslant \phi < 2\pi,$$

$$u_3 = \left(\sinh A + \frac{r^2}{2}e^{-A}\right)$$

where the only ignorable variable is ϕ.

The commuting set of operators are

$$Y_1 = \Delta(H_3), \quad Y_2 = M_{12}^2, \quad Y_3 = (M_{01}+M_{31})^2 + (M_{02}+M_{32})^2.$$

6. O(3,1)⊃E(2)⊃E(1)⊗E(1) [Fig. 2(f)]

The group parametrization is

$$H = e^{(M_{01}+M_{31})r_1}e^{(M_{02}+M_{32})r_2}e^{M_{03}A} \tag{3.18}$$

and we have

$$\begin{aligned} u_0 &= \cosh A + \frac{r^2}{2}e^{-A}, \quad -\infty < A < \infty, \\ u_1 &= r_1 e^{-A}, \quad -\infty < r_1 < \infty, \\ u_2 &= r_2 e^{-A}, \quad -\infty < r_2 < \infty, \\ u_3 &= \sinh A + \frac{r^2}{2}e^{-A}, \end{aligned} \tag{3.19}$$

where $r^2 = r_1^2 + r_2^2$. In this case the two exponentials on the left-hand side in Eq. (3.18) commute, i.e., $\{M_{01}+M_{31}, M_{02}+M_{32}\}$ is a (maximal) Abelian subalgebra of o(3,1). Hence we obtain two ignorable variables, r_1 and r_2.

The commuting set of operators is

$$Y_1 = \Delta(H_3), \quad Y_2 = (M_{01}+M_{31})^2, \quad Y_3 = (M_{02}+M_{32})^2.$$

7. O(3,1)⊃O(2)⊗O(1,1) [Fig. 2(g)]

The most convenient parametrization is

$$H = e^{M_{01}B}e^{M_{23}\phi}e^{M_{02}A}, \tag{3.20}$$

which yields

$$\begin{aligned} u_0 &= \cosh A \cosh B, \quad 0 \leqslant A < \infty, \\ u_1 &= \cosh A \sinh B, \quad -\infty < B < \infty, \\ u_2 &= \sinh A \cos\phi, \quad 0 \leqslant \phi < 2\pi, \\ u_3 &= \sinh A \sin\phi. \end{aligned} \tag{3.21}$$

The subalgebras M_{01} and M_{23} commute, hence both B and ϕ are ignorable variables and $\{M_{01}, M_{23}\}$ is a maximal Abelian subalgebra of O(3,1).

The commuting set of operators are

$$Y_1 = \Delta(H_3), \quad Y_2 = M_{01}^2, \quad Y_3 = M_{23}^2.$$

For a classification of maximal Abelian subalgebras of o(p,q) see Ref. 18, for those of the pseudo-Euclidean Lie algebras $e(p,q)$; see Refs. 19 and 20.

All subgroup and coordinate diagrams for O(3,1) and the hyperboloid H_3 are shown in Fig. 2. The ones that differ qualitatively from tree diagrams for O(4) are Figs. 2(d)–2(f), involving Euclidean subalgebras of O(3,1) and hence horospheric type coordinates.

Our parametrization of the group elements $G\sim$O(3,1) is such that we can read off coordinates on H_n, as in the case of O(2,1) from the coordinate diagrams (for $2\leqslant n$) as follows. For subgroup chains not involving $E(n)$ groups we start at the bottom of the coordinate diagram. When proceeding along the line leading to u_0 in the ambient space, we write $\cosh A_i$, when we go to the left, $\sinh A_i$ when we go to the right (toward a spacelike coordinate in the ambient space). When we proceed along a line toward a spacelike coordinate, then again for each vertex we write $\cos\theta_i$ when we go to the left, $\sin\theta_i$ when we go to the right [as for S_n (Refs. 13–15)]. The $E(n)$ subgroups always occur at the end of a chain. Before we come to the corresponding ''fork'' or ''tri-tail'' on the diagram we proceed as before ($\cosh A_i$ to the left, $\sinh A_i$ to the right). The fork and the box in it [see Fig. 3 for O$(n,1)$] corresponds to coordinates in a Euclidean space E_n.

D. Subgroup diagrams and coordinate diagrams for O(n,1)

The two cases considered previously, O(2,1) and O(3,1), have demonstrated two features of the general case. The first is that subgroup type coordinates are generated by successively applying the action of a chain of one-dimensional subgroups to the origin $\mathbb{1}$ of the hyperboloid. The second is that the process is recursive. To obtain all subgroup type coordinates on the hyperboloid $H_{n,1}$ we will need to know all subgroup type coordinates on hyperboloids $H_{k,1}$ $(2\leqslant k<n)$, spheres S_k $(3\leqslant k\leqslant n)$, and Euclidean spaces E_k, $(2\leqslant k\leqslant n-1)$.

The actual formula for generating the coordinates is

$$\mathbf{u}=He^{M_{0k}}\mathbb{1}, \tag{3.22}$$

where k is either $k=1$ or $k=n$ and HG_1 of Eq. (3.1) is the Lorentz group O$(n-1,1)$, the rotation group O(n), the Euclidean group $E(n-1)$, or a direct product O$(n_1,1)\otimes$O(n_2), $n_1+n_2=n$. The group $G_1\sim$O$(n-2)$ acts trivially, so we omit it in Eq. (3.22), even though H itself is not, in general, a group. Actually, H is a product of one-dimensional subgroups and we now proceed to discuss different choices of H.

1. Subgroup chain O(n,1)⊃O(n−1,1)⋯⊃O(2,1)⊃O(1,1) [see Fig. 3(a)]

We write Eq. (3.22) as

$$\mathbf{u}=e^{M_{01}B}e^{M_{02}A_{n-1}}\cdots e^{M_{0n}A_1}\mathbb{1} \tag{3.23}$$

and obtain the coordinates

$$\begin{aligned}
u_0&=\cosh A_1\cosh A_2\cdots\cosh A_{n-1}\cosh B,\\
u_1&=\cosh A_1\cosh A_2\cdots\cosh A_{n-1}\sinh B,\\
u_2&=\cosh A_1\cosh A_2\cdots\sinh A_{n-1},\\
&\cdots\\
&\cdots\\
u_{n-2}&=\cosh A_1\cosh A_2\sinh A_3,\\
u_{n-1}&=\cosh A_1\sinh A_2,\\
u_n&=\sinh A_1.
\end{aligned} \tag{3.24}$$

Only the last coordinate introduced, namely B, is ignorable.

2. Subgroup chain $O(n,1)\supset O(n-1,1)\cdots\supset O(k,1)\supset O(k)$ [see Fig. 3(b)]

Equation (3.22) in this case is

$$\mathbf{u}=Ge^{M_{01}A_{n-k+1}}e^{M_{0k+1}A_{n-k}}\cdots e^{M_{0n-1}A_2}e^{M_{0n}A_1}\rrbracket, \tag{3.25}$$

where $G\sim \mathrm{O}(k)$, $k\geqslant 2$. The coordinates are

$$\begin{aligned}
u_0&=\cosh A_1\cosh A_2\cdots\cosh A_{n-k+1},\quad 1\leqslant a\leqslant k,\\
u_a&=\cosh A_1\cosh A_2\cdots\cosh A_{n-k+1}s_a,\\
u_{k+1}&=\cosh A_1\cosh A_2\cdots\sinh A_{n-k},\\
&\cdots\\
&\cdots\\
u_{n-2}&=\cosh A_1\cosh A_2\sinh A_3,\\
u_{n-1}&=\cosh A_1\sinh A_2,\\
u_n&=\sinh A_1.
\end{aligned} \tag{3.26}$$

The variables s_a satisfy

$$s_1^2+s_2^2+\cdots+s_k^2=1 \tag{3.27}$$

and are parametrized by introducing spherical, or polyspherical coordinates on the sphere S_k.[11–15] The ignorable variables are "hidden" in s_a, $a=1,2,\ldots,k$. The number of ignorable variables N_I satisfies $1\leqslant N_I\leqslant[k/2]$ where we have $N_I=1$ for spherical coordinates on S_k, $N_I=[k/2]$ for cylindrical coordinates.

3. The subgroup chain $O(n,1)\supset O(n-1,1)\cdots\supset O(k,1)\supset E(k-1)$ [see Fig. 3(c)]

Equation (3.22) in this case

$$\mathbf{u}=Ge^{M_{0k}A_{n-k+1}}e^{M_{0n+1}A_{n-k}}\cdots e^{M_{0n}A_1}\rrbracket \tag{3.28}$$

with $G\sim E(k-1)$, $k\geqslant 2$. The coordinates are

$$\begin{aligned}
u_0&=\cosh A_1\cosh A_2\cdots\cosh A_{n-k}\left(\cosh A_{n-k+1}+\frac{r^2}{2}e^{-A_{n-k+1}}\right),\\
u_a&=\cosh A_1\cosh A_2\cdots\cosh A_{n-k}e^{-A_{n-k+1}}r_a,\quad 1\leqslant a\leqslant k-1,\\
u_k&=\cosh A_1\cosh A_2\cdots\cosh A_{n-k}\left(\sinh A_{n-k+1}+\frac{r^2}{2}e^{-A_{n-k+1}}\right),\\
u_{k+1}&=\cosh A_1\cosh A_2\cdots\sinh A_{n-k},\\
&\cdots\\
u_{n-2}&=\cosh A_1\cosh A_2\sinh A_3,
\end{aligned} \tag{3.29}$$

$$u_{n-1}=\cosh A_1 \sinh A_2,$$

$$u_n=\sinh A_1.$$

We have

$$r_1^2+r_2^2+\cdots+r_{k-1}^2=r^2, \quad -\infty<r_a<\infty \tag{3.30}$$

and r_a are coordinates in $k-1$ dimensional Euclidean space. The Euclidean Lie algebra $e(k-1)$ has the basis

$$\{M_{0a}+M_{ka}, M_{bc}\}, \quad 1\leqslant a\leqslant k-1, \quad 1\leqslant b<c\leqslant k-1. \tag{3.31}$$

Subgroup coordinates, subgroup diagrams, and coordinate diagrams (called "cluster diagrams") were discussed in detail in an earlier article.[15] In particular we can simply use r_a, $1\leqslant a\leqslant k-1$ as Cartesian coordinates, generated by $\exp(M_{0a}+M_{ka})r_a$. In this case $r_1,\ldots,r_{k-1}$ are ignorable variables since $\{M_{01}+M_{k1},\ldots,M_{0k-1}+M_{kk-1}\}$ is a maximal Abelian subalgebra[18] of O(k,1). The minimal number of ignorable variables in this case is $N_I=1$, obtained if we introduce spherical coordinates in the Euclidean space E_k.

4. The subgroup chain $O(n,1)\supset O(n-1,1)\cdots\supset O(k,1)\supset O(k_1,1)\otimes O(k_2)$, $k_1+k_2=k$, $3\leqslant k\leqslant n$, $1\leqslant k_1$, $2\leqslant k_2$

Equation (3.22) in this case

$$\mathbf{u}=G_1G_2e^{M_{0k_1+1}A_{n-k+1}}e^{M_{0k+1}A_{n-k}}\cdots e^{M_{0n-1}A_2}e^{M_{0n}A_1}\rceil \tag{3.32}$$

with $G_1\sim O(k_1,1)$, $1\leqslant k_1\leqslant k-2$, and $G_2\sim O(k_2)$, $2\leqslant k_2\leqslant k-1$,

$$u_\alpha=\cosh A_1\cosh A_2\cdots\cosh A_{n-k}\cosh A_{n-k+1}x_\alpha, \quad 0\leqslant\alpha\leqslant k_1,$$

$$u_a=\cosh A_1\cosh A_2\cdots\cosh A_{n-k}\sinh A_{n-k+1}s_a, \quad k_1+1\leqslant a\leqslant k_1+k_2=k,$$

$$u_{k+1}=\cosh A_1\cosh A_2\cdots\sinh A_{n-k},$$

$$\cdots \tag{3.33}$$

$$u_{n-2}=\cosh A_1\cosh A_2\sinh A_3,$$

$$u_{n-1}=\cosh A_1\sinh A_2,$$

$$u_n=\sinh A_1.$$

The coordinates x_α and s_a satisfy

$$x_0^2-x_1^2-x_2^2-\cdots-x_{k_1}^2=1, \tag{3.34}$$

$$s_{k_1+1}^2+s_{k_1+2}^2+\cdots+s_{k_1+k_2}^2=1. \tag{3.35}$$

The hyperboloid (3.34) must be parametrized according to some subgroup chain of $O(k_1,1)$, using the diagrams of Fig. 3 with n replaced by k_1 (a lower dimensional problem). Similarly, the sphere (3.35) is parametrized according to the "method of trees."[10–14]

The recursive character of the subgroup type coordinates is very clear in Fig. 3. The parametrization is complete only in Fig. 1(a) [see Eq. (3.24)]. In Figs. 1(b), 1(c), and 1(d) the spaces (3.27), (3.30), (3.34) and (3.35), respectively, remain to be parametrized.

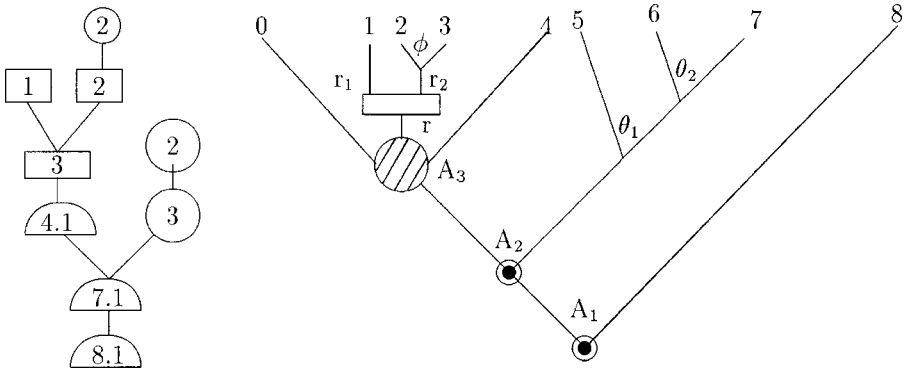

FIG. 4. Example of a subgroup and coordinate diagram for the O(8,1) hyperboloid.

The conventions are so chosen that the coordinate systems are obtained as for O(2,1) and O(3,1). We write $\cosh A_i$ when we go left at a vertex on the coordinate diagram, $\sinh A_i$ when we go right.

As an example, let us consider the subgroup and coordinate diagrams shown in Fig. 4 for the hyperboloid H_8. The coordinates and complete set of commuting operators are

$$
\begin{aligned}
u_0 &= \cosh A_1 \cosh A_2 (\cosh A_3 + \tfrac{1}{2}(r_1^2 + r_2^2) e^{-A_3}),\\
u_1 &= \cosh A_1 \cosh A_2 e^{-A_3} r_1,\\
u_2 &= \cosh A_1 \cosh A_2 e^{-A_3} r_2 \cos\phi,\\
u_3 &= \cosh A_1 \cosh A_2 e^{-A_3} r_2 \sin\phi,\\
u_4 &= \cosh A_1 \cosh A_2 (\sinh A_3 + \tfrac{1}{2}(r_1^2 + r_2^2) e^{-A_3}),\\
u_5 &= \cosh A_1 \sinh A_2 \cos\theta_1,\\
u_6 &= \cosh A_1 \sinh A_2 \sin\theta_1 \cos\theta_2,\\
u_7 &= \cosh A_1 \sinh A_2 \sin\theta_1 \sin\theta_2,\\
u_8 &= \sinh A_1,
\end{aligned}
\tag{3.36}
$$

$$
\begin{aligned}
&Y_1 = \Delta_{\mathrm{LB}}, \quad Y_2 = \sum_{i=1}^{7} M_{0i}^2 - \sum_{1 \le i < k \le 7}^{n} M_{ik}^2, \quad Y_3 = \sum_{i=1}^{4} M_{0i}^2 - \sum_{1 \le i < k \le 4}^{n} M_{ik}^2,\\
&Y_4 = \sum_{i=1}^{3} (M_{0i} + M_{4i})^2, \quad Y_5 = M_{01} + M_{41}, \quad Y_6 = M_{23}, \quad Y_7 = M_{56}^2 + M_{57}^2 + M_{67}^2, \quad Y_8 = M_{67}^2.
\end{aligned}
\tag{3.37}
$$

IV. SOLUTIONS OF THE LAPLACE–BELTRAMI EQUATION FOR THE GROUP O(2,1) AND O(3,1)

A. General comments

The general form of the Laplace–Beltrami operator for any Riemannian, or pseudo-Riemannian space is given in Eq. (2.2).

For the hyperboloid H_n we wish to solve Eq. (1.1) with Ψ as in Eq. (1.2). We will request that the function Ψ be normalizable with respect to the invariant measure for representations of the principal series of unitary representations of $O(n,1)$[12] when we have

$$\nu = -\frac{n-1}{2} + i\rho, \quad \rho \in \mathbb{R}. \tag{4.1}$$

For a (compact) rotation group $O(n+1)$ we have

$$\Delta_{LB}\Psi = \Delta(S_n)\Psi = -\ell(\ell+n-1)\Psi, \quad \ell \in I\mathbb{Z}, \tag{4.2}$$

and for a Euclidean group $E(n)$,

$$\Delta_{LB}\Psi = \Delta(E_n)\Psi = -k^2\Psi, \quad k \in \mathbb{R}, \tag{4.3}$$

where Δ is the Laplace operator.

We shall present normalizable eigenfunctions but do not give their normalization constants explicitly.

B. The group O(2,1)

The coordinates corresponding to Figs. 1(a), 1(b), and 1(c) are given in Eqs. (3.3), (3.5), and (3.7), respectively. In all cases, one coordinate is ignorable and figures only in an exponential. We take the solution as $\Psi(A,z) = f(A)e^{i\nu z}$ with $z = \phi$, B, or r, respectively. The equations for $f(A)$ and their normalizable solutions are, respectively,

(1) $O(2,1) \supset O(2)$,

$$\left[\frac{1}{\sinh A}\frac{\partial}{\partial A}\sinh A\frac{\partial}{\partial A} - \frac{m^2}{\sinh^2 A} - \nu(\nu+1)\right] f(A) = 0, \tag{4.4}$$

leading to

$$\Psi_{\nu m}(A,\phi) = P_\nu^m(\cosh A)e^{im\phi}, \quad m \in \mathbb{Z}, \quad \nu = -\tfrac{1}{2} + i\rho, \tag{4.5}$$

where $P_\nu^m(z)$ is an associated Legendre function.

(2) $O(2,1) \supset O(1,1)$,

$$\left[\frac{1}{\cosh A}\frac{\partial}{\partial A}\cosh A\frac{\partial}{\partial A} - \frac{k^2}{\cosh^2 A} - \nu(\nu+1)\right] f(A) = 0, \tag{4.6}$$

$$\Psi_{\nu k}(A,B) = \frac{1}{\sqrt{\cosh A}} P^{\nu+1/2}_{-1/2+ik}(\tanh A)e^{ikB}, \quad k \in \mathbb{R}, \quad \nu = -\frac{1}{2} + i\rho. \tag{4.7}$$

(3) $O(2,1) \supset E(1)$,

$$\left[e^A\frac{\partial}{\partial A}e^{-A}\frac{\partial}{\partial A} - k^2e^{2A} - \nu(\nu+1)\right] f(A) = 0, \tag{4.8}$$

$$\Psi_{\nu k}(A,r) = e^{A/2}K_{\nu+1/2}(ke^A)e^{ikr}, \tag{4.9}$$

where $K_\nu(z)$ is a modified Bessel function (of an imaginary argument), sometimes called a Macdonald function.[21,22]

C. The group O(3,1)

The coordinates corresponding to the diagrams in Figs. 2(a)–2(g) are (3.9), (3.11), (3.13), (3.15), (3.17), (3.19), and (3.21), respectively. The diagrams already indicate the recursive character of the procedure. The top row in the subgroup diagrams 2(a)–2(g) provides ignorable variables and hence exponentials in the solutions. The second row will provide functions that already occur in the separation of variables for the sphere S_2, the hyperboloid H_2, or the Euclidean space E_2. Figures 2(f) and 2(g) correspond to two ignorable variables. In all cases a new equation occurs only at the "ground level" of the diagrams and will involve the variable A. Let us run through all seven cases.

(1) $\mathrm{O}(3,1)\supset\mathrm{O}(3)\supset\mathrm{O}(2)$.

We put

$$\Psi_{n\ell m}(A,\theta,\phi)=f_{n\nu}(A)Y_{\ell m}(\theta,\phi). \tag{4.10}$$

In (4.10) $Y_{\ell m}(\theta,\phi)$ are spherical harmonics, coming from the O(3) subgroup with $\ell\in\mathbb{Z}$, $-\ell\leqslant m\leqslant\ell$. The function $f(A)$ satisfies

$$\left[\frac{1}{\sinh^2 A}\frac{\partial}{\partial A}\sinh^2 A\frac{\partial}{\partial A}-\frac{\ell(\ell+1)}{\sinh^2 A}-\nu(\nu+2)\right]f(A)=0, \tag{4.11}$$

and hence we obtain

$$f_{\nu\ell}(A)=\frac{1}{\sqrt{\sinh A}}P^{-\ell-1/2}_{1/2+\nu}(\cosh A),\quad \nu=-1+i\rho. \tag{4.12}$$

The negative sign in the superscript of the Legendre function was chosen to assure that the function is finite for $A=0$.

(2) $\mathrm{O}(3,1)\supset\mathrm{O}(2,1)$.

We consider diagrams of Figs. 2(b), 2(c), and 2(d) simultaneously, with $G\sim\mathrm{O}(2)$, O(1,1) and $E(1)$, respectively. We put

$$G\sim\mathrm{O}(2):\quad \Psi_{\nu_1\nu_2 m}(A,B,\phi)=f_{\nu_1\nu_2}(A)P^m_{\nu_2}(\cosh B)e^{im\phi}, \tag{4.13}$$

$$G\sim\mathrm{O}(1,1):\quad \Psi_{\nu_1\nu_2 k}(A,B,C)=f_{\nu_1\nu_2}(A)\frac{1}{\sqrt{\cosh B}}P^{\nu_2+1/2}_{-1/2+ik}(\tanh B)e^{ikC}, \tag{4.14}$$

$$G\sim E(1):\quad \Psi_{\nu_1\nu_2 k}(A,B,r)=f_{\nu_1\nu_2}(A)e^{B/2}K_{\nu_2+1/2}(ke^B)e^{ikr}. \tag{4.15}$$

The general form of the equations takes into account the results of Sec. IV B. The function $f_{\nu_1\nu_2}(A)$ is the same in all three cases. It satisfies

$$\left[\frac{1}{\cosh^2 A}\frac{\partial}{\partial A}\cosh^2 A\frac{\partial}{\partial A}+\frac{\nu_2(\nu_2+1)}{\cosh^2 A}-\nu_1(\nu_2+2)\right]f_{\nu_1\nu_2}(A)=0, \tag{4.16}$$

and is hence equal to

$$f_{\nu_1\nu_2}(A)=\frac{1}{\cosh A}P^{\nu_1+1}_{\nu_2}(\tanh A),\quad \nu_1=-1+i\rho,\quad \nu_2=-\frac{1}{2}+iq. \tag{4.17}$$

(3) $\mathrm{O}(3,1)\supset E(2)\supset G$.

We now consider diagrams of Figs. 2(e) and 2(f), with $G\sim\mathrm{O}(2)$ and $G\sim E(1)\otimes E(1)$, respectively. Subgroup coordinates in the Euclidean plane E_2 are either polar ($E(2)\supset\mathrm{O}(2)$) or Cartesian ($E(2)\supset E(1)\otimes E(1)$), so we put

$$\mathrm{O}(2): \quad \Psi_{\nu km}(A,r,\phi)=f_{\nu k}(A)J_m(kr)e^{im\phi}, \tag{4.18}$$

$$T(1)\otimes T(1): \quad \Psi_{\nu k_1 k_2}(A,r_1,r_2)=f_{\nu k}(A)e^{i(k_1 r_1+k_2 r_2)}, \quad k^2=k_1^2+k_2^2. \tag{4.19}$$

The function $f_{\nu k}(A)$ is the same in both cases and satisfies

$$\left[e^{2A}\frac{\partial}{\partial A}e^{-2A}\frac{\partial}{\partial A}-k^2e^{2A}-\nu(\nu+2)\right]f_{\nu k}(A)=0. \tag{4.20}$$

We obtain

$$f_{\nu k}(A)=e^A K_{\nu+1}(ke^A), \quad \nu=-1+i\rho. \tag{4.21}$$

(4) $\mathrm{O}(3,1)\supset \mathrm{O}(1,1)\otimes \mathrm{O}(2)$.
We have

$$\Psi_{\nu km}(A,B,\phi)=f_{\nu km}(A)e^{ikB}e^{im\phi}, \tag{4.22}$$

where $f_{\nu km}(A)$ satisfies

$$\left[\frac{1}{\sinh A\cosh A}\frac{\partial}{\partial A}\sinh A\cosh A\frac{\partial}{\partial A}-\frac{k^2}{\cosh^2 A}-\frac{m^2}{\sinh^2 A}-\nu(\nu+2)\right]f_{\nu km}(A)=0. \tag{4.23}$$

The solution can be written in terms of the hypergeometrical functions or in terms of Jacobi functions as

$$f_{\nu km}(A)=(\cosh A)^{ik}(\sinh A)^m P^{(m,ik)}_{(\nu-ik-m)/2}(\cosh 2A), \quad m\in\mathbb{Z}, \quad k\in\mathbb{R}, \quad \nu=-1+i\rho. \tag{4.24}$$

V. SOLUTIONS OF THE LAPLACE–BELTRAMI EQUATION FOR H_n

In Sec. IV we presented the separated solutions of the Laplace–Beltrami equation for all subgroup type coordinates on H_2 and H_3. The case of H_3 and the group O(3,1) illustrated the recursive character of the procedure. We will make use of this character to write out the solutions for the hyperboloid H_n for arbitrary n. To do this we need to know the basis functions for the spheres S_k, Euclidean spaces E_k, and hyperboloids H_k for $k\leqslant n-1$. The procedure depends only on the first link in the subgroup chain $\mathrm{O}(n,1)\supset G$ and we shall consider four cases separately.

A. $\mathrm{O}(n,1)\supset \mathrm{O}(n)$

This case is represented by Fig. 5(a). To the coordinates on S_{n-1} we add one hyperbolic angle A. The coordinates on H_n are

$$u_0=\cosh A, \quad u_i=s_i\sinh A, \quad s_1^2+s_2^2+\cdots+s_n^2=1. \tag{5.1}$$

The Laplace–Beltrami operator on H_n can be written as

$$\Delta(H_n)=\frac{1}{\sinh^{n-1}A}\frac{\partial}{\partial A}\sinh^{n-1}A\frac{\partial}{\partial A}+\frac{1}{\sinh^2 A}\Delta(S_{n-1}). \tag{5.2}$$

We write the solutions on H_n as

$$\Psi(A,\xi_1\cdots\xi_{n-1})=f_{\nu_n \diagup_{n-1}}(A)Y_{\diagup_{n-1},\ldots,\diagup_1}(\xi_1,\xi_2,\ldots,\xi_{n-1}) \tag{5.3}$$

where $f(A)$ satisfies

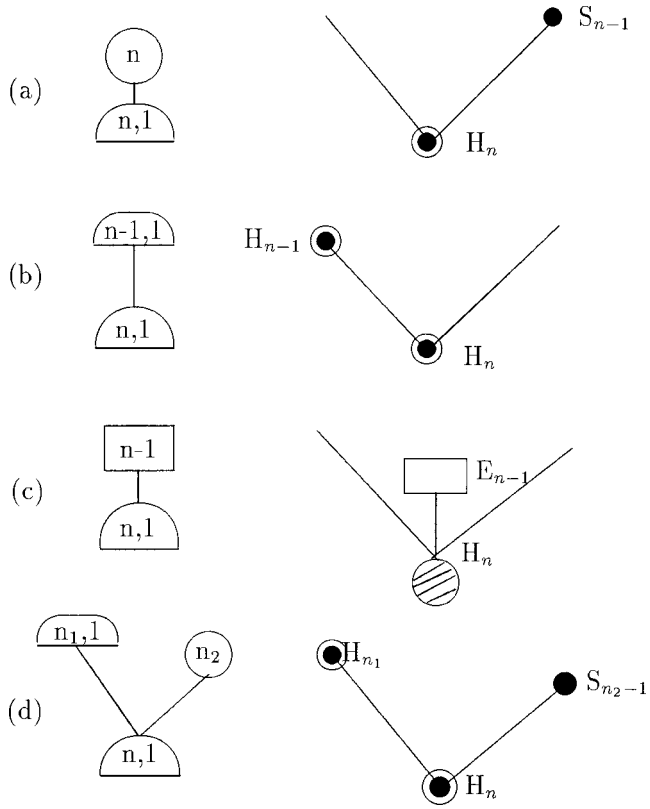

FIG. 5. Elementary links for H_n coordinate diagrams and O(n,1) subgroup diagrams.

$$\left[\frac{\partial^2}{\partial A^2}+(n-1)\coth A\frac{\partial}{\partial A}-\frac{\ell_{n-1}(\ell_{n-1}+n-2)}{\sinh^2 A}-\nu_n(\nu_n+n-1)\right]f_{\nu_n\ell_{n-1}}(A)=0. \tag{5.4}$$

The function $Y_{\ell_{n-1},\ldots,\ell_1}(\xi_1,\xi_2,\ldots,\xi_{n-1})$ is the solution of the Laplace–Beltrami equation on S_{n-1} in any one of the subgroup type coordinates on that space. That is, it corresponds to any one of the S_{n-1} tree diagrams.[13–15]

Equation (5.4) is easy to solve in terms of associated Legendre functions and we have

$$f_{\nu_n\ell_{n-1}}(A)=(\sinh A)^{(2-n)/2}P^{-\ell_{n-1}-(n-2)/2}_{\nu_n+(n-2)/2}(\cosh A). \tag{5.5}$$

The negative sign in the superscript was again chosen to assure that the function is finite for $A=0$. It should be remembered that ℓ_{n-1} refers to representations of the rotation group O(n) whereas ν_n to those of O(n,1). Hence, ℓ_{n-1} is an integer whereas ν_n satisfies $\nu_n=-(n-1)/2+ip_n$ for unitary representations of the principal series (with p_n real).

We mention that for the group O($n+1$) and the sphere S_n the corresponding formula can be written as

$$f_{l_n,l_{n-1}}(\theta)=(\sin\theta)^{(2-n)/2}P^{-l_{n-1}-(n-2)/2}_{l_n+(n-2)/2}(\cos\theta), \tag{5.6}$$

which corresponds to the diagrams in Fig. 6(a).

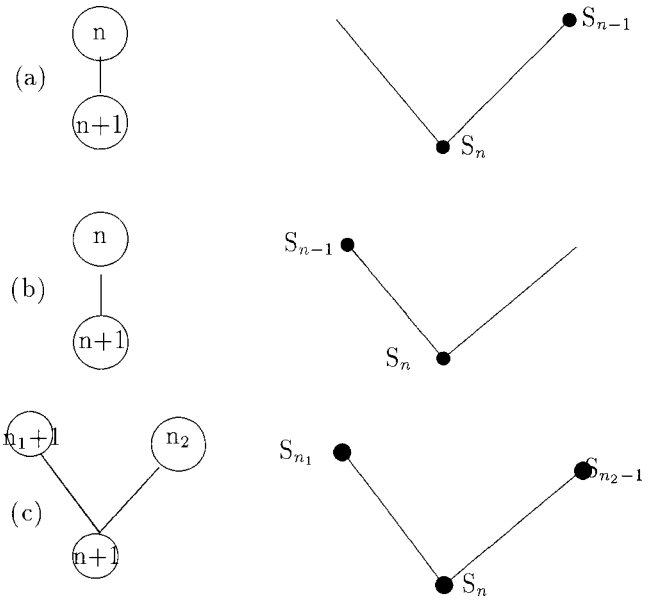

FIG. 6. Elementary links for S_n coordinate diagrams and $O(n+1)$ subgroup ones.

B. $O(n,1)\supset O(n-1,1)$

This case is represented in Fig. 5(b). We write coordinates on H_n as

$$u_\mu = x_\mu \cosh A, \quad u_n = \sinh A, \quad \mu = 0,1,2,\ldots,n-1, \quad x_0^2 - x_1^2 - \cdots - x_{n-1}^2 = 1. \tag{5.7}$$

The Laplace–Beltrami operator on H_n can be written in terms of the one on H_{n-1} as

$$\Delta(H_n) = \frac{1}{(\cosh^{n-1} A)} \frac{\partial}{\partial A}(\cosh^{n-1} A) \frac{\partial}{\partial A} + \frac{1}{\cosh^2 A} \Delta(H_{n-1}). \tag{5.8}$$

We again write the solutions on H_n as in Eq. (5.3), where $Y_{\ell_{n-1},\ldots,\ell_1}(\xi_1,\xi_2,\ldots,\xi_{n-1})$ is a set of eigenfunctions of $\Delta_{\mathrm{LB}}(H_{n-1})$ in some subgroup type coordinate system on H_{n-1}. The function $f(A)$ satisfies

$$\left[\frac{\partial^2}{\partial A^2} + (n-1)\tanh A \frac{\partial}{\partial A} + \frac{\nu_{n-1}(\nu_{n-1}+n-2)}{\cosh^2 A} - \nu_n(\nu_n+n-1)\right] f_{\nu_n \nu_{n-1}}(A) = 0. \tag{5.9}$$

The solution of this equation that is square integrable for representations of the principal series can again be expressed in terms of associated Legendre functions

$$f_{\nu_n \nu_{n-1}}(A) = (\cosh A)^{(1-n)/2} P^{\nu_n + (n-1)/2}_{\nu_{n-1} + (n-3)/2}(\tanh A). \tag{5.10}$$

Taking into account that we have $\nu_n = -(n-1)/2 + ip_n$, we can rewrite Eq. (5.10) as

$$f_{\nu_n \nu_{n-1}}(A) = (\cosh A)^{(1-n)/2} P^{ip_n}_{-1/2 + ip_{n-1}}(\tanh A). \tag{5.11}$$

For S_n, Eq. (5.10) is not convenient since the argument of the associated Legendre function would be imaginary. The contribution to the eigenfunction corresponding to the diagrams in Fig. 6(b) can be better written as

$$f_{l_n l_{n-1}}(\theta) = (\cos\theta)^{(-n+2)/2} P^{l_{n-1} + (n-2)/2}_{l_n + (n-2)/2}(\sin\theta). \tag{5.12}$$

C. $O(n,1)\supset E(n-1)$

We write coordinates corresponding to Fig. 5(c) as

$$u_0=\cosh A+\frac{r^2}{2}e^{-A},\quad r_1^2+r_2^2+\cdots+r_{n-1}^2=r^2,$$

$$u_i=r_i e^{-A},\quad i=1,2,\ldots,n-1, \tag{5.13}$$

$$u_n=\sinh A+\frac{r^2}{2}e^{-A}.$$

The Laplace–Beltrami operator on H_n is now expressed in terms of Laplace operator for the Euclidean space E_{n-1} as

$$\Delta(H_n)=e^{(n-1)A}\frac{\partial}{\partial A}e^{-(n-1)A}\frac{\partial}{\partial A}+e^{2A}\Delta(E_{n-1}). \tag{5.14}$$

The separated eigenfunctions have the form (5.3) where this time $Y_{\ell_n,\ldots,\ell_1}(\xi_1,\xi_2,\ldots,\xi_{n-1})$ are eigenfunctions of $\Delta(E_{n-1})$. The function $f_{\nu_n k}(A)$ satisfies

$$\left[\frac{\partial^2}{\partial A^2}-(n-1)\frac{\partial}{\partial A}-k^2e^{2A}-\nu_n(\nu_n+n-1)\right]f_{\nu_n k}(A)=0, \tag{5.15}$$

where we have put

$$\Delta Y=-k^2Y. \tag{5.16}$$

The function $f_{\nu_n k}$ satisfying Eq. (5.15) is best expressed in terms of modified Bessel functions as

$$f_{\nu_n k}(A)=e^{(n-1)/2A}K_{\nu_n+(n-1)/2}(ke^A) \tag{5.17}$$

or equivalently

$$f_{p_n k}(A)=e^{(n-1)/2A}K_{ip_n}(ke^A). \tag{5.18}$$

These formulas do not have an analog for the group $O(n+1)$.

D. $O(n,1)\supset O(n_1,1)\otimes O(n_2)$, $n_1+n_2=n$

We write the coordinates corresponding to Fig. 5(d) as

$$\begin{aligned} &u_\alpha=x_\alpha\cosh A,\quad \alpha=0,1,2,\ldots,n-1,\quad x_0^2-x_1^2-\cdots-x_{n_1}^2=1,\\ &u_n=s_i\sinh A,\quad i=n_1+1,..,n_1+n_2,\quad s_{n_1+1}^2+s_{n_1+2}^2+\cdots+s_{n_1+n_2}^2=1. \end{aligned} \tag{5.19}$$

The Laplace–Beltrami operator on H_n in this case is

$$\Delta(H_n)=\frac{1}{\cosh^{n_1}A\sinh^{n_2}A}\frac{\partial}{\partial A}\cosh^{n_1}A\sinh^{n_2}A\frac{\partial}{\partial A}+\frac{1}{\cosh^2 A}\Delta_{\mathrm{LB}}(H_{n_1})+\frac{1}{\sinh^2 A}\Delta_{\mathrm{LB}}(S_{n_2-1}). \tag{5.20}$$

The separated eigenfunctions of H_n have the form

$$\Psi(A,\xi_1,\ldots,\xi_{n_1},\eta_1,\ldots,\eta_{n_2-1})=f(A)\,Z(\xi_1,\ldots,\xi_{n_1})\,Y(\eta_1,\ldots,\eta_{n_2-1}), \tag{5.21}$$

where ξ_i and η_α are subgroup coordinates on H_{n_1} and S_{n_2-1}, respectively. The function $f(A)$ satisfies

$$\left[\frac{\partial^2}{\partial A^2}+[n_1\tanh A+(n_2-1)\coth A]\frac{\partial}{\partial A}+\frac{\nu_{n_1}(\nu_{n_1}+n_1-1)}{\cosh^2 A}-\frac{\ell_{n_2}(\ell_{n_2}+n_2-2)}{\sinh^2 A}-\nu_n(\nu_n+n-1)\right]f(A)=0. \tag{5.22}$$

The (normalizable) solutions of this equation can be expressed in terms of Jacobi functions as

$$f_{\nu_{n_1}\ell_{n_2}\nu_n}(A)=(\cosh A)^{\nu_{n_1}}(\sinh A)^{\ell_{n_2}}P_N^{(\alpha,\beta)}(\cosh 2A),$$
$$N=\frac{1}{2}(\nu_n-\nu_{n_1}-\ell_{n_1}),\quad \alpha=\ell_{n_2}+\frac{n_2-2}{2},\quad \beta=\nu_{n_1}+\frac{n_1-1}{2}. \tag{5.23}$$

The analog of Eq. (5.23) for the sphere S_n is

$$f_{\ell_n\ell_{n_1}\ell_{n_2}}(\theta)=(\cos\theta)^{\ell_{n_1}}(\sin\theta)^{\ell_{n_2}}P_N^{(\alpha,\beta)}(\cos 2\theta),$$
$$N=\frac{1}{2}(\ell_n-\ell_{n_1}-\ell_{n_2}),\quad \alpha=\ell_{n_2}+\frac{n_2-2}{2},\quad \beta=\ell_{n_1}+\frac{n_1-1}{2}. \tag{5.24}$$

It corresponds to the diagrams in Fig. 6(c) and $P_N^{(\alpha\beta)}$ is in this case a Jacobi polynomial.

VI. CONCLUSIONS

The main results of this article is that we have presented all separable subgroup type coordinates on a Lorentzian hyperboloid H_n, together with the corresponding separated eigenfunctions. We have introduced coordinate diagrams incorporating those introduced earlier for rotation groups[11–15] and Euclidian ones.[15] We have related the H_n coordinate diagrams to O(n,1) subgroup diagrams. Finally, we have shown that for arbitrary n the eigenfunctions of the Laplace operator involve products of the functions (5.5), (5.6), (5.10), (5.12), (5.17), (5.23) only. No new functions occur for higher dimensions, only associated Legendre functions and polynomials with various subscripts, superscripts and arguments, cylindrical functions, and Jacobi functions and polynomials.

The recursive formulas (5.2), (5.8), (5.14), and (5.20) bring out another feature of the separation of variables. Namely, they make it obvious that every separable coordinate system on the sphere S_{n-1} the hyperboloid H_{n-1}, the Euclidean space E_{n-1}, and the product space $H_{n1}\otimes S_{n_2-1}$ will provide separable coordinates on the hyperboloid H_n. We have emphasized this for subgroup type coordinates only, but we could also introduce ellipsoidal, paraboloidal, or other nonsubgroup coordinates on the lower dimentional manifolds and obtain ''semisubgroup'' [8] type coordinates on H_n.

This recursive character of separable coordinates in various spaces also gave rise to a different graphical formalism describing all coordinates in which the Laplace–Beltrami equation separates. The formalism was first introduced for the O($n+1$) spheres S_n and Euclidean spaces E_n,[23] then extended to n-dimensional hyperboloids.[10] In all cases certain ''irreducible'' types of coordinates

are introduced for any n. They are of ellipsoidal, or paraboloidal type. The graphs introduced by Kalnins and Miller then show how various coordinate systems in lower dimensions can be combined together to provide ''reducible'' type coordinates in higher dimensions. The diagrams introduced in the present paper can be directly mapped onto a proper subset of those used in Ref. 10.

The main new contributions are

(1) *The explicit relation between subgroup chains and subgroup type coordinates*.
(2) *The explicit construction of complete sets of invariant operators, their eigenfunctions, and eigenvalues*.

Finally, let us mention some directions for future research. In this article we have studied the separation of variables in the Laplace–Beltrami equation on H_n. We could also study the separation of variables in a Schrödinger equation, i.e., add a scalar potential, or scalar and a vector one to the Laplace–Beltrami operator. This would allow us to study quantum (and classical) integrable, or superintegrable, systems on hyperboloids. Another open problem is that of Lie algebra contractions in which the distance R, characterizing the hyperboloid $u_0^2-u_1^2-\cdots-u_n^2=R^2$ is subject to the limit $R\to\infty$. The hyperboloid will ''contract'' to a Euclidean, or pseudo-Euclidean space and we will obtain asymptotic formulas for the special functions involved (see Refs. 15, 24–26 for $S_n\to E_n$ contractions and Ref. 27 for $H_2\to E_2$ ones). Finally a systematic study of nonsubgroup type coordinates and their contractions is under consideration.

(Received 14 February 2002; accepted for publication 1 March 2002)

Coherent states in the time-energy plane provide a natural basis to study adiabatic scattering. We relate the (diagonal) matrix elements of the scattering matrix in this basis with the frozen on-shell scattering data. We describe an exactly solvable model, and show that the error in the frozen data cannot be estimated by the Wigner time delay alone. We introduce the notion of energy shift, a conjugate of Wigner time delay, and show that for incoming state $\rho(H_0)$ the energy shift determines the outgoing state. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1476952]

I. INTRODUCTION

Scattering from a slowly changing scatterer is described, to leading order, by a *time independent* scatterer frozen at the scattering time.[1] Although this seems like stating the obvious, it turns out that in trying to make precise how accurate this approximation is, one encounters both conceptual and technical difficulties. Our aim is to describe these difficulties and explain how they are resolved.

One conceptual difficulty is to understand what the frozen S matrix—a function of energy and scattering time—means. Strictly speaking, a function of both time and energy is in conflict with the uncertainty principle. A wave that is sharp in energy will have an ill-defined scattering time and, conversely, a wave with a well-defined scattering time is ill-defined in energy. What, then, is the meaning of the frozen S matrix?

The resolution of this problem is related to the fact that the adiabatic limit naturally leads to different parametrizations of time, and the right parametrization has small uncertainty. Specifically, the physical time t will parametrize the intrinsic ''fast'' dynamics and has the usual time-energy uncertainty $\hbar$. The slow variation in the external conditions will be parametrized by s. We refer to the latter as *epoch*. Since the epoch often plays the role of a parameter it is convenient to choose s dimensionless. The two parametrizations are related by $s=\omega t$, with ω a slow frequency—the adiabaticity parameter. The epoch-energy uncertainty then takes the form $\delta s\,\delta e \sim \hbar\omega$ and so arbitrarily small in the adiabatic limit.

Coherent states provide a convenient basis to analyze the semi-classical limit.[2,3] Semi-classical analysis is traditionally about the $\hbar\to 0$ limit, but is equally valid when $\hbar$ is fixed (and henceforth set equal to one) and $\omega\to 0$. Here we introduce coherent states labeled by points in the time-energy plane, with time being the scattering time. As we shall see, the frozen S matrix approximates the diagonal matrix elements of the dynamical scattering matrix in such coherent

c)Electronic mail: gmgraf@itp.phys.ethz.ch
d)Electronic mail: sadun@math.utexas.edu

states. This reconciles the time-energy uncertainty with the frozen scattering data. In a further step, matrix elements of the frozen S matrix can be approximated by the on-shell data.

Another thorny issue that we address is when a description in terms of frozen data is meaningful and how accurate it is. The question can also be rephrased as a question about the intrinsic time scale relevant to scattering. If τ denotes this time scale, then $\omega\tau$ is the error in the frozen data and $\omega\tau \ll 1$ characterizes the adiabatic regime.

The Wigner time delay[14] $\tau_w(E,s)$ conveys information about the time the particle spends near the scatterer. It is a function of the energy E and scattering epoch s. It is tempting to hope that τ might be estimated by $\tau_w(E,s)$, but there is no compelling argument for doing so. One cannot argue on the basis of dimensional analysis alone, since $\dot{\tau}_w$ and $\sqrt{\tau_w'}$, with dot a derivative with respect to the epoch and prime with respect to the energy, give additional and independent time scales. In fact, since Wigner time delay is a *comparison* of the arrival time at a faraway point, relative to the time of arrival in the free dynamics, it is not even positive-definite. This suggests that it cannot quite capture τ, which is more closely related to the ''dwell time'' near the scatterer.

The way to determine τ is to consider the error in approximating the scattering data by the frozen data. The error is, to leading order, proportional to the adiabaticity parameter ω. Since the error is, in general, complex, we identify τ with the absolute value of the error divided by ω. Calculating the error, to leading order in ω, is no harder, and reminiscent of, calculating the scattering in the lowest order of the Born approximation.

We shall see that, to leading order, the adiabatic time scale τ can be estimated from the scattering data and the derivative of the Hamiltonian H with respect to the epoch, Eq. (7.4) below, but not from the Wigner time delay alone. We show this by considering an exactly soluble model where the dynamical S matrix can be computed explicitly.

We introduce the *energy shift* operator $\mathcal{E}$. This is a measure of the energy change in time dependent scattering and is a natural dual of the Wigner time delay. As we shall see, in the case that the incoming state is $\rho(H_0)$, the outgoing state is $\rho(H_0-\omega\mathcal{E})$. In the adiabatic limit, the energy shift can be approximated by the frozen energy shift, which is related to the logarithmic derivative of the on-shell scattering matrix with respect to the epoch, Eq. (4.2). The energy shift then gives a handle on the exchange of energy[4,5] and the pumping of charge in adiabatic scattering.[6,15]

II. ELEMENTS OF SCATTERING THEORY

Scattering theory is a comparison of dynamics: One is the actual dynamics generated by the time dependent $H(t)=H_s$, $(s=\omega\, t)$, the other is a fiducial dynamics generated by a *time independent* Hamiltonian H_0. The Hamiltonian H_0 is the generator of dynamics for which there is trivial scattering and the S matrix is the identity.

The results of this section are true in general, without taking the adiabatic limit $\omega\to 0$. We shall assume that H and H_0 admit good scattering. Namely, we assume the existence of wave operators and the unitarity of the S matrix. For explicit conditions on H_0 and $H(t)$ that guarantee this, see, e.g., Refs. 7 and 8.

A. The wave operator

Let $U(t'',t')$ and $U_0(t'',t')=U_0(t''-t')$ denote the evolution from time t' to t'', generated by $H(t)$ and the time-independent H_0, respectively.

Definition 2.1: The wave operators, based at epoch s, are defined by the (strong) limit

$$\Omega_{\pm}(s;H,H_0)=\lim_{t'\to\pm\infty} U(t,t')U_0(t'-t) \quad (s=\omega t). \tag{2.1}$$

The existence of the limit, and the equation of motion imply the following.

Proposition 2.2: The dependence of the wave operator on the base point s satisfy the differential equation

$$-i\omega\dot{\Omega}_{\pm}(s)=H_s\Omega_{\pm}(s,H,H_0)-\Omega_{\pm}(s,H,H_0)H_0. \tag{2.2}$$

As we shall presently see, the notion of wave operator based at epoch s is only interesting in the case of a time dependent $H(t)$.

B. The frozen wave operators

The frozen Hamiltonian H_s is *time independent* so $U(t'',t')=e^{iH_s(t''-t')}$, in this case, and $\Omega_{\pm}(s_0,H_s,H_0)$ is independent of the base point $s_0=\omega t_0$. This follows from the existence of the limit in Eq. (2.1) since $t'\to\pm\infty$ is the same as $t'-t_0\to\pm\infty$. To stress this we write $\Omega_{\pm}(H_s,H_0)$. From Eq. (2.2) then follows the standard intertwining relation of time-independent scattering theory:

Corollary 2.3: The wave operators $\Omega_{\pm}(H_s,H_0)$ relating the frozen Hamiltonian at epoch s and H_0 are independent of the base point, and intertwine the two dynamics:

$$H_s\Omega_{\pm}(H_s,H_0)=\Omega_{\pm}(H_s,H_0)H_0. \tag{2.3}$$

C. The dynamical S matrix

The (dynamical) scattering matrix based at epoch s is defined by

$$\mathcal{S}_d(s;H,H_0)=\Omega_+^{\dagger}(s;H,H_0)\Omega_-(s;H,H_0). \tag{2.4}$$

The S matrices based on different points in time are all related by conjugation generated by the free evolution. Namely, we have the following.

Proposition 2.4: Suppose that the wave operators exist. Then

$$\mathcal{S}_d(s;H,H_0)=e^{-iH_0t}\mathcal{S}_d(0;H,H_0)e^{iH_0t}\quad(s=\omega\ t). \tag{2.5}$$

This follows from $U(s,t)\Omega_{\pm}(s;H,H_0)=\Omega_{\pm}(s;H,H_0)e^{-iH_0(s-t)}$. Under a change of the reference Hamiltonian, say to the frozen Hamiltonian H_s,

$$\mathcal{S}_d(s;H,H_0)=\Omega_+^{\dagger}(H_s,H_0)\mathcal{S}_d(s;H,H_s)\Omega_-(H_s,H_0). \tag{2.6}$$

D. The frozen S matrix

In the frozen S data the epoch is decoupled from time. As such it can also be studied using time independent methods, which are normally quite powerful.[8] Its basic properties are in marked contrast with that of the dynamical S matrix, namely:

Corollary 2.5: The frozen S matrix

$$\mathcal{S}_f(H_s,H_0)=\Omega_+^{\dagger}(H_s,H_0)\Omega_-(H_s,H_0) \tag{2.7}$$

is independent of the base point. It depends on freezing time parametrically through H_s.

E. The on-shell S matrix

H_0 provides a basis that spans the Hilbert space of scattering states. Let $|E,j)$ denote the generalized eigenvectors of H_0:

$$H_0|E,j)=E|E,j),\quad (E,j|E',j')=\delta(E-E')\delta_{j,j'}. \tag{2.8}$$

E is the energy and j labels the scattering channels. $\mathcal{S}_f$ commutes with H_0, by Eq. (2.3), hence

$$(E,j|\mathcal{S}_f(H_s,H_0)|E',j')=\delta(E-E')S_{jj'}(s,E). \tag{2.9}$$

$S_{jj'}(s,E)$ is the *on-shell* scattering matrix. Note that in the frozen Hamiltonian the physical time is decoupled from the epoch, which now has been relegated to the role of a parameter. The on-shell scattering matrix therefore is not in conflict with the uncertainty principle.

III. THE ENERGY SHIFT

By taking the s-derivatives of Eq. (2.5) one gets

$$i\omega\dot{\mathcal{S}}_d(s)\mathcal{S}_d(s)^\dagger = H_0 - \mathcal{S}_d(s)H_0\mathcal{S}_d(s)^\dagger = [H_0,\mathcal{S}_d(s)]\mathcal{S}_d^\dagger(s) = [H_0,\mathcal{S}_d(s) - \mathcal{S}_f(H_s,H_0)]\mathcal{S}_d^\dagger(s). \tag{3.1}$$

This equation may be interpreted as follows. If we think of H_0 as the asymptotic observable associated with the outgoing energy, then $H_{0,in} = \mathcal{S}_d(s)H_0\mathcal{S}_d(s)^\dagger$ represents the asymptotic observable[9] corresponding to the incoming energy. This motivates calling

$$\mathcal{E}_d(s) = i\dot{\mathcal{S}}_d(s)\mathcal{S}_d^\dagger(s) \tag{3.2}$$

the operator of energy shift.

The energy shift vanishes for time independent scattering, as it must. It gives a handle on changes in (certain) quantum states. By the functional calculus applied to Eq. (3.1), for any function ρ,

$$\mathcal{S}_d(s)\rho(H_0)\mathcal{S}_d(s)^\dagger = \rho(H_0 - \omega\mathcal{E}_s(s)). \tag{3.3}$$

This is interpreted as follows: If $\rho(H_0)$ is the incoming state, then the corresponding outgoing state is $\rho(H_0 - \omega\,\mathcal{E}_s(s))$. The energy shift is a first order quantity in the adiabaticity parameter and, as we shall see, it can be approximated, to leading order, by the frozen data. This then gives a handle on the outgoing state ρ to first order in the adiabaticity parameter.

Proposition 3.1: The energy shift based on time s is conjugate to the energy shift based on time zero

$$\mathcal{E}_d(s) = e^{iH_0t}\mathcal{E}_d(0)e^{-iH_0t} \quad (s=\omega t). \tag{3.4}$$

This follows directly from Eqs. (2.5) and (3.1).

IV. THE PROBLEM OF ADIABATIC SCATTERING

The dynamical S matrix has qualitatively different properties from the frozen S matrix: The dynamical S matrix has no freezing time—it does not ''know'' when the incoming wave is going to hit the scatterer. It does depend, however, by conjugation, on a choice of a base point. In contrast, the frozen S matrix is independent of the choice of a base point and depends nontrivially on the freezing time. The frozen scattering data for one epoch know nothing *a priori* about the corresponding data at any other epoch.

Matrix elements of the scattering matrix carry information about the time that the wave is near the scatterer. For such matrix elements, the adiabatic limit can be expressed in terms of the corresponding frozen matrix elements. However, the introduction of wave packets promotes the epoch from playing the role of a parameter, to that of real, albeit slow, time. One then needs to confront the uncertainty principle. We do that by considering matrix elements between coherent states labeled by points in the energy time plane.

A. The Wigner time delay

The Wigner time delay is defined in terms of the on-shell scattering matrix. When this definition is transcribed to the frozen, on-shell, S matrix it reads

$$\tau_w(s,E) = -iS'(s,E)S^\dagger(s,E). \tag{4.1}$$

Prime denotes partial derivative with respect to the energy. With this definition, the Wigner time delay is a Hermitian matrix.

B. The frozen energy shift

For the frozen, on-shell, Hamiltonian one can associate a matrix of energy shift which is a natural conjugate of the Wigner time delay:

$$\mathcal{E}(s,E)=i\dot{S}(s,E)S^{\dagger}(s,E), \tag{4.2}$$

where dot denotes derivative with respect to the epoch.

C. Time scales

The frozen on-shell S matrix defines several time scales, among them τ_w and the (dimensionless) time scale $\mathcal{E}^{-1}$. The coherent states provide us with yet another time scale related to the time width of the coherent states. One of the problems of adiabatic scattering is to study the relation between these time scales and the time scale τ such that $\omega\tau\ll 1$ characterizes the adiabatic regime.

V. TIME-ENERGY COHERENT STATES

A. The role of dispersion

For a particle moving on the line, its energy and the time that it crosses the origin are canonical coordinates. One can therefore construct energy-time coherent states in analogy with the usual phase space coherent states. The explicit construction, however, depends on the dispersion law. For linear dispersion the construction is particularly simple.

Consider a classical particle with dispersion law $e(p)$ moving freely on the line. The velocity of the particle is $e'(p)$ so the time of passage through the origin is $t=-q/e'(p)$. Time-energy are (local) canonical coordinates since

$$de\wedge dt=dq\wedge dp. \tag{5.1}$$

The global aspects of the energy-time phase space can be complicated. For example, for a free (massive) particle, with quadratic dispersion $e(p)=p^2$, the energy-time phase space is made of two copies of the half plane $e\geqslant 0$ depending on the direction of crossing of the origin.

A simpler situation is obtained in the case of linear dispersion, $e(p)=p$. There is now no ambiguity in the direction of crossing and the energy-time phase space is again the plane. The map $(q,p)\leftrightarrow(e,t)$ is, in fact, the identity

$$e=p,\quad t=-q. \tag{5.2}$$

The usual coherent states are then also the coherent states on the energy-time plane.

B. Coherent states for linear dispersion

The time-energy coherent states are

$$|t,e;\varepsilon\rangle=e^{i(tP+eX)}|g_{\varepsilon}\rangle,\quad [P,X]=-i, \tag{5.3}$$

with g_{ε} Gaussian:

$$\langle p|g_{\varepsilon}\rangle=\frac{1}{\sqrt[4]{\pi\varepsilon^2}}e^{-p^2/2\varepsilon^2}. \tag{5.4}$$

They have the following properties:[2]

(A) The states $|t,e;\varepsilon\rangle$ are normalized.

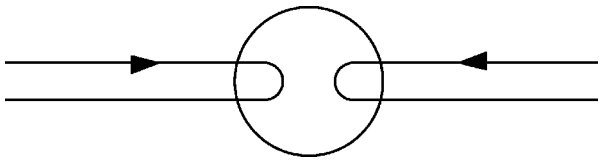

FIG. 1. A network of two channels. Each channel is chiral and lets particles propagate to and from infinity, according to the arrows. The circle denotes the region where the channels are coupled.

(B) $|t,e;\varepsilon\rangle$ have Gaussian localization in time and energy near the point (t,e) with width

$$\delta e \sim \varepsilon, \quad \delta t \sim \frac{1}{\varepsilon}, \quad \delta s \sim \frac{\omega}{\varepsilon}.$$

Hence ω plays the role of $\hbar$ in the epoch-energy plane.

(C) H_0 is the generator of shifts of the coherent states:

$$e^{-iH_0t'}|t,e;\varepsilon\rangle = e^{-it'e/2}|t-t',e;\varepsilon\rangle.$$

(D) The overlap of coherent states is

$$\langle t,e,\varepsilon|t',e',\varepsilon\rangle = e^{-(e-e')^2/4\varepsilon^2} e^{-\varepsilon^2(t-t')^2/4} e^{-i(et'-e't)/2}.$$

(E) The coherent states give a resolution of the identity

$$\int \frac{dtde}{2\pi} |t,e;\varepsilon\rangle\langle t,e;\varepsilon| = 1.$$

(F) The scalar product between coherent states and the eigenstates of $H_0 = P$ is

$$(E|t,e;\varepsilon\rangle = e^{-ite/2} e^{-itE} \frac{e^{-(E-e)^2/2\varepsilon^2}}{\sqrt[4]{\pi\varepsilon^2}}.$$

VI. SCATTERING BETWEEN CHANNELS WITH LINEAR DISPERSION

Linear dispersion approximates the low energy physics of electrons in one dimensional channels provided the Fermi energy is large. The price one pays is that the ''ultraviolet'' properties are pathological. In particular, the spectrum is unbounded below and this then leads to certain anomalies which must be correctly interpreted. With linear dispersion one can also solve certain models with interacting electrons.[10]

In the following we shall study adiabatic scattering for *noninteracting* particles with linear dispersion. The particles move on a collection of lines and are allowed to ''hop'' from one line to the other and scatter. Each line serves as an incoming and outgoing channel since the flow on it is unidirectional. An example with two channels is shown in Fig. 1. (Such models bear some resemblance to Schrödinger operators on graphs.)[11] The Hilbert space is $\oplus_{j=1}^{n} L^2(\mathbb{R})$, a finite direct sum. j labels the scattering channels. H_0 is then

$$(H_0\psi)(x,j) = -i\psi'(x,j), \quad x \in \mathbb{R}, \quad 1 \leqslant j \leqslant n.$$

For the interaction one may take, for example,

$$((H(s)-H_0)\psi)(x,j) = \sum_{j'} v_{j,j'}(x,s)\psi(x,j')$$

with $v_{jj'}$ Hermitian, and compactly supported. Alternatively, one may consider finite rank perturbations.

A. A soluble model

Here we describe a simple, time dependent, model for which the calculation of both the dynamical and frozen scattering matrices is reduced to quadrature.

Consider scattering on the line with

$$H_0 = P = -i\nabla, \quad H_s = P + f(s)V, \quad s = \omega\, t,$$

with $(V\psi)(x) = v(x)\psi(x)$ a potential (multiplication operator) which is sufficiently regular and short range so that $\int |v(x)|dx$, $\int |xv(x)|dx < \infty$. The model has one channel and should not be confused with the two-channel example pictured in Fig. 1.

To calculate the dynamical S matrix note that

$$\Omega(t,t') := U(t,t')U_0(t'-t), \tag{6.1}$$

satisfies the Volterra type equation:

$$\frac{\partial \Omega(t,t')}{\partial t'} = if(\omega t')\Omega(t,t')V(t-t'), \quad \Omega(t',t') = 1, \tag{6.2}$$

with $V(t)$ the (backward) free Heisenberg evolution of the potential, i.e.,

$$V(t) := U_0(t)VU_0(-t). \tag{6.3}$$

Since $H_0 = P$ is the generator of shifts, $V(t)$ is the shifted potential:

$$(V(t)\psi)(x) = v(x-t)\psi(x). \tag{6.4}$$

In particular, $V(t)$ at different times commute, and the solution of the Volterra type problem is given simply by

$$\Omega(t,t') = e^{-i\int_0^{t-t'} f(s-\omega t'')V(t'')dt''}, \quad s = \omega t. \tag{6.5}$$

From the definition of the wave operators based on time s, Eq. (2.1), we obtain for the dynamical wave operators

$$\Omega_-(s;H,H_0) = e^{-i\int_0^{\infty} f(s-\omega\, t')V(t')dt'}, \quad \Omega_+(s;H,H_0) = e^{i\int_{-\infty}^{0} f(s-\omega t')V(t')dt'}.$$

From this we obtain for the dynamical scattering matrix

$$S_d(s,H,H_0) = e^{-i\int_{-\infty}^{\infty} f(s-\omega t')V(t')dt'}. \tag{6.6}$$

The dynamical scattering matrix, as well as the wave operators, are local gauge transformations, i.e., multiplication by a *function* of position, of modulus one.

The wave operators and the S matrix reduce to the frozen ones upon replacing the function $f(s-\omega t')$ by its frozen value $f(s)$, hence,

$$S_f(H_s,H_0) = e^{-if(s)\int_{-\infty}^{\infty} V(t)dt} = e^{-if(s)\int_{-\infty}^{\infty} V_+(t)dt}, \tag{6.7}$$

where $2V_+(t) = V(t) + V(-t)$. S_f is just a number, not a function of position.

The frozen scattering matrix provides very little information on the potential $v(x)$, for it depends on just one number—the total weight of the potential (this is in sharp contrast with scattering problems where H_0 is the Laplacian[12]). The dynamical S matrix, in contrast, provides independent information about the potential for each value of s.

Since the frozen S matrix is independent of the incident energy, the Wigner time delay vanishes identically in this model: $\tau_w=0$. The (frozen) energy shift is just a real number (a multiple of the identity)

$$\mathcal{E}_f=\dot{f}(s)\int_{-\infty}^{\infty}v(x)dx.$$

In contrast, the dynamical energy shift is the multiplication operator:

$$\mathcal{E}_d=\int_{-\infty}^{\infty}\dot{f}(s-\omega\ t')V(t')dt'. \tag{6.8}$$

B. The on-shell scattering matrix and coherent states

For later purposes we shall need the matrix elements of the frozen S matrix. Since $\mathcal{S}_f$ commutes with H_0, the matrix elements are independent of t and are related to the on-shell matrix by

$$\langle t,e,j;\varepsilon|\mathcal{S}_f(H_s,H_0)|t,e,j';\varepsilon\rangle=\frac{1}{\sqrt{\pi}\varepsilon}\int dES_{jj'}(s,E)e^{-(E-e)^2/\varepsilon^2}=S_{jj'}(s,e)+O(\varepsilon^2\partial_{EE}S). \tag{6.9}$$

The estimate is obtained by observing that $S_{jj'}(s,E)-S_{jj'}(s,e)$ does not contribute to the integral to first order in $E-e$. Since

$$(\partial_{EE}S)S^{\dagger}=-\tau_w^2+i\tau_w'$$

(with prime denoting the derivative with respect to the energy), we see that the on-shell S matrix approximates the diagonal entries of the frozen S matrix, provided the Wigner time delay and its energy dependence are both small:

$$\varepsilon^2(\tau_w^2+|\tau_w'|)\ll 1. \tag{6.10}$$

VII. THE ADIABATIC TIME SCALE τ

In this section we compute, to leading order, the time scale τ relevant to adiabatic scattering. This time scale is defined so that $\omega\tau\ll 1$ characterizes the adiabatic regime in the sense that the frozen scattering data approximate the dynamical scattering data.

There are two results in this section, one positive and one negative. The positive result says that, at least to leading order, τ can be computed from time independent quantities alone, Eq. (7.4) below. The negative result is that τ cannot be computed from the on-shell scattering matrix and its derivatives. In particular, the Wigner time delay alone does not determine τ.

Using Eqs. (2.5)–(2.7) and property (C) in Sec. V B, one finds

$$\begin{aligned}&\langle t,e,j;\varepsilon|(\mathcal{S}_d(0;H,H_0)-\mathcal{S}_f(H_s,H_0))|t,e,j';\varepsilon\rangle\\&\quad=\langle 0,e,j;\varepsilon|\Omega_+^{\dagger}(H_s,H_0)(\mathcal{S}_d(s;H,H_s)-1)\Omega_-(H_s,H_0)|0,e,j;\varepsilon\rangle.\end{aligned} \tag{7.1}$$

The correction to the leading order of the S matrix can be approximated by an analog of the Born series:[8]

$$\mathcal{S}_d(s;H,H_s)-1\approx -i\int_{-\infty}^{\infty}e^{iH_st'}(H_{s+\omega\ t'}-H_s)e^{-iH_st'}dt'. \tag{7.2}$$

Since $H_{s+\omega t'}-H_s$ is supported near the origin, only small t' contribute to the matrix elements in Eq. (7.1). More precisely, this depends only on the time localization property of either the bra or the ket. We can therefore approximate $H_{s+\omega\, t'}-H_s \approx \omega\, t' \dot{H}_s$. Using property (C) in Sec. V B,

$$e^{-iH_s t}\Omega_-(H_s,H_0)|0,e,j;\varepsilon\rangle = e^{-iet/2}\Omega_-(H_s,H_0)|t,e,j;\varepsilon\rangle,$$

we finally get

$$\langle t,e,j;\varepsilon|(\mathcal{S}_d(0;H,H_0)-\mathcal{S}_f(H_s,H_0))|t,e,j';\varepsilon\rangle \approx -i\omega\tau(e,s;\varepsilon), \tag{7.3}$$

where

$$\tau(e,s;\varepsilon)=\int_{-\infty}^{\infty}\langle t',e,j;\varepsilon|\Omega_+^{\dagger}(H_s,H_0)\dot{H}_s\Omega_-(H_s,H_0)|t',e,j;\varepsilon\rangle t'\,dt'. \tag{7.4}$$

$\tau(e,s;\varepsilon)$ involves the frozen wave operators and the rate of change of the Hamiltonian at the epoch s. In particular, one can use methods of time-independent scattering theory to compute it. It is in general complex. The adiabatic time scale, $\tau=|\tau(e,s;\varepsilon)|$, is a measure of the error. $\omega\tau \ll 1$ then clearly characterizes the adiabatic regime.

Propagation estimates can, and have been, used[13] to bound the error in the frozen data. These estimates yield bounds on τ.

A. Example: The soluble model

For the case of one channel scattering with $H(s)=P+f(s)V$, by Eqs. (6.6) and (6.7)

$$\begin{aligned} S_d(s;H,H_0)-S_f(H_s,H_0) &= (e^{-i\int_{-\infty}^{\infty}(f(s-\omega t)-f(s))V(t)dt}-1)S_f(H_s,H_0) \\ &\approx i\omega\dot{f}(s)\left(\int_{-\infty}^{\infty} tV(t)dt\right)S_f(H_s,H_0). \end{aligned} \tag{7.5}$$

The adiabatic time scale τ is, in analogy with Eq. (7.3), the multiplication operator:

$$\tau \approx -\dot{f}(s)\left(\int_{-\infty}^{\infty} tV(t)dt\right)S_f(H_s,H_0) = -\dot{f}(s)\left(\int_{-\infty}^{\infty} tV_-(t)dt\right)S_f(H_s,H_0);$$

$$2V_-(t)=V(t)-V(-t). \tag{7.6}$$

By Eq. (6.7) the frozen S matrix only depends on V_+, while the error only depends on V_-. Since V_- and V_+ are independent this shows that the error term in the adiabatic expansion cannot be estimated in terms on the frozen scattering data alone.

Combining Eqs. (6.9) and (7.3) we obtain a relation between matrix elements of the dynamical S matrix and the on-shell S matrix:

$$\langle t,e,j;\varepsilon|\mathcal{S}_d(0;H,H_0)|t,e,j';\varepsilon\rangle = S_{jj'}(s,e)+O(\varepsilon^2(\tau_w^2+|\tau_w'|)+\omega\tau(e,s;\varepsilon)). \tag{7.7}$$

VIII. THE ENERGY SHIFT

The energy shift is a first order quantity; nevertheless, it is determined, to leading order, by the frozen data:

$$\langle t,e,j;\varepsilon|\mathcal{E}_d(0)|t,e,j';\varepsilon\rangle \approx i(\dot{S}(s,e)S^{\dagger}(s,e))_{jj'} \quad (s=\omega\, t). \tag{8.1}$$

We first remark that (7.3) and (7.4) generalize to off-diagonal matrix elements, i.e., the time t in the ket $|t,e,j';\varepsilon\rangle$ may be shifted to $t+\Delta t$ [resp. $t'+\Delta t$ in (7.4)] while leaving the bra unchanged. By the translation property of coherent states, property (C) in Sec. II B, multiplication by H_0 can be traded for derivative with respect to time. Hence

$$\begin{aligned}\langle t,e,j;\varepsilon|[H_0,\mathcal{S}_d(0;H,H_0)]|t+\Delta t,e,j';\varepsilon\rangle &= i\partial_t\langle t,e,j;\varepsilon|\mathcal{S}_d(0;H,H_0)|t+\Delta t,e,j';\varepsilon\rangle \\ &\approx i\partial_t\langle t,e,j;\varepsilon|\mathcal{S}_f(H_s,H_0)|t+\Delta t,e,j';\varepsilon\rangle \\ &= i\omega\langle t,e,j;\varepsilon|\dot{\mathcal{S}}_f(H_s,H_0)|t+\Delta t,e,j';\varepsilon\rangle. \quad (8.2)\end{aligned}$$

In principle, the order of the error in the frozen data in the passage from the second to the third line does not determine the order of the error in derivatives, but this can be justified in the present case. The last identity in the equation above can be seen from

$$\langle t,e,j;\varepsilon|\mathcal{S}_f(H_s,H_0)|t+\Delta t,e,j';\varepsilon\rangle = \frac{1}{\sqrt{\pi}\varepsilon}\int dE S_{jj'}(s,E)e^{-(E-e)^2/\varepsilon^2}e^{-i(\Delta t)e/2}e^{-i(\Delta t)E}.$$

We then multiply (8.2) with the complex conjugate of the mentioned generalization of (7.3) and integrate over Δt using property (E) of Sec. V B. The result then heuristically follows from Eq. (3.1) and the statement for $\mathcal{E}_f$ analogous to (6.9). An alternate derivation of (8.1) can be made, more directly, starting from the rhs of Eq. (3.1) and using Born's expansion.

The energy shift plays a role in the theory of adiabatic quantum pumps. In particular, the pumped charge, the entropy production and noise generation in quantum pumps can all be expressed in terms of the energy shift.[3] It is remarkable that basic properties of adiabatic quantum pumps can be understood, to leading order, in terms of the frozen scattering data alone.

(Received 4 February 2002; accepted for publication 13 March 2002)

We obtain a new family of coherent state representations of SU($n+1$), in which the coherent states are Wigner functions over a subgroup of SU($n+1$). For representations of SU($n+1$) of the type (λ, 0, 0,...), the basis functions are simple products of n exponential. The corresponding coherent state representations of the algebra su($n+1$) are also obtained, and provide a polar decomposition of su($n+1$) for any $n+1$. The su($n+1$) modules thus obtained are useful in understanding contractions of su($n+1$) and su($n+1$)-phase states of quantum optics. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1479301]

I. INTRODUCTION

In this paper, we wish to present a new kind of coherent state[1] construction for the groups SU($n+1$). The construction is applicable to unitary irreducible representations (unirreps) of SU($n+1$) characterized by integral highest weights of the type (λ, 0,...) for which there is no weight multiplicity, described by Young tableaux having a single row.

Our coherent states differ from the usual coherent states in that our basis functions are functions over a subgroup $\mathfrak{k}$ of SU($n+1$) rather than polynomials in holomorphic variables. Because there is no multiplicity of weights in SU($n+1$) unirreps of the type (λ, 0,...), we can choose $\mathfrak{k}$ to be the Cartan subgroup of SU($n+1$). Basis functions for our modules are simple products of n exponential factors, and are closely related to the $\mathrm{SU}(3)\supset\mathrm{SO}(3)$ construction of Ref. 2.

The realization of su($n+1$) that we obtain is particularly well-suited for a discussion of polar decompositions of su($n+1$) generators. We consider as an application a study of phase states,[3–6] and, in particular, of SU(2) and SU(3) phase states. The general case can be inferred from the discussion of the SU(3) case and from the results of Sec. III.

Coherent states are also useful in understanding the ''semiclassical'' behavior of systems.[7] Our construction can also be used to understand some of the possible asymptotic limits of quantum systems. For SU($n+1$) unirreps of the type (λ, 0,...), which are applicable to ($n+1$)-channel interferometry,[6] the asymptotic limit corresponds to taking the number of (unpolarized) photons λ to be arbitrarily large. The parameters which enter in the explicit realization of the su($n+1$) generators will be related to the partition of λ photons between $n+1$ channels.

The construction is presented first for SU(2) in Sec. II. The general construction, valid for the irreps (λ, 0,...) of SU($n+1$) is presented in Sec. III. Section IV contains an application to SU(3) of the general formalism. Our paper ends with a discussion containing further results and a short conclusion.

II. SU(2)

A. Coherent state representation of the su(2) algebra

A basis for A_1, the complex extension of the su(2) algebra, is given in the usual way, by the three operators $\{\hat{h}_1,\hat{e}_+,\hat{e}_-\}$ with nonzero commutation relations

$$[\hat{h}_1,\hat{e}_\pm]=\pm 2\hat{e}_\pm, \quad [\hat{e}_+,\hat{e}_-]=\hat{h}_1. \tag{1}$$

For λ any positive integer, a highest weight $|\chi_\lambda\rangle$ for an irrep of dimension $\lambda+1$ (the number λ is just twice the spin of the representation) is defined by

$$\hat{h}_1|\chi_\lambda\rangle=\lambda|\chi_\lambda\rangle, \quad \lambda\in\mathbb{Z}^+, \quad \hat{e}_+|\chi_\lambda\rangle=0. \tag{2}$$

Now it can be verified explicitly that the map Γ:

$$\begin{aligned}
&\hat{h}_1\mapsto\Gamma(\hat{h}_1)=-i\frac{\mathrm{d}}{\mathrm{d}\varphi},\\
&\hat{e}_+\mapsto\Gamma(\hat{e}_+)=-\frac{1}{2}e^{2i\varphi}(\tan\beta)^{-1}\left(\lambda+i\frac{\mathrm{d}}{\mathrm{d}\varphi}\right),\\
&\hat{e}_-\mapsto\Gamma(\hat{e}_-)=-\frac{1}{2}e^{-2i\varphi}(\tan\beta)\left(\lambda-i\frac{\mathrm{d}}{\mathrm{d}\varphi}\right),
\end{aligned} \tag{3}$$

preserves the commutation relations of su(2) and is therefore a realization of A_1. A carrier space for this representation is the span of exponential functions $\{e^{i\nu\theta},\nu=-\lambda,-\lambda+2,...,\lambda-2,\lambda\}$. The highest and lowest weight state proportional to $e^{i\lambda\theta}$ and $e^{-i\lambda\theta}$, respectively.

To obtain Eq. (3), one first chooses some fixed but otherwise arbitrary (generic) angle β in the range $0<\beta<2\pi$. With β fixed, the state $R_y(\beta)|\chi_\lambda\rangle$, where $R_y(\beta)=e^{(\hat{e}_+-\hat{e}_-)\beta}$, $R_z(\varphi)=e^{\varphi\hat{h}_1}$, is cyclic under the action of $R_z^{-1}(\varphi)$. $R_y(\beta)|\chi_\lambda\rangle$ then acts as a fiducial vector "translated" by $R_z^{-1}(\varphi)$.

Let $|\psi\rangle$ be an arbitrary state in the irrep with highest weight λ, and define the coherent state wave function for $|\psi\rangle$ by

$$|\psi\rangle\mapsto\psi_\beta(\varphi)\equiv\langle\chi_\lambda|R_y(\beta)R_z(\varphi)|\psi\rangle. \tag{4}$$

Since $\langle\chi_\lambda|\hat{e}_-=0$, it is convenient to write $R_y(\beta)$ in antinormal-ordered form, so that, ignoring a normalization and a phase factor,

$$\psi_\beta(\varphi)=\langle\chi_\lambda|R_y(\beta)R_z(\varphi)|\psi\rangle\propto\langle\chi_\lambda|e^{\tan\beta\hat{e}_+}R_z(\varphi)|\psi\rangle. \tag{5}$$

The coherent state realization $\Gamma(\hat{X})$ of an operator $\hat{X}$ in su(2) is defined by

$$\hat{X}|\psi\rangle\to[\Gamma(\hat{X})\psi]_\beta(\varphi)\equiv\langle\chi_\lambda|e^{\tan\beta\hat{e}_+}R_z(\varphi)\hat{X}|\psi\rangle. \tag{6}$$

Using $R_z(\varphi)=\exp(i\varphi\hat{h}_1)$, it follows immediately from this that

$$\hat{h}_1\mapsto\Gamma(\hat{h}_1)=-i\frac{\mathrm{d}}{\mathrm{d}\varphi}, \tag{7}$$

since

$$\Gamma(\hat{h}_1)\psi_\beta(\varphi)=\langle\chi_\lambda|e^{\tan\beta\hat{e}_+}R_z(\varphi)\hat{h}_1|\psi\rangle. \tag{8}$$

If $\hat{X}=\hat{e}_{\pm}$, we then have

$$[\Gamma(\hat{e}_{\pm})\psi_{\beta}](\varphi)=\langle\chi_{\lambda}|e^{\tan\beta\hat{e}_{+}}R_{z}(\varphi)\hat{e}_{\pm}|\psi\rangle=e^{\pm 2i\varphi}\langle\chi_{\lambda}|e^{\tan\beta\hat{e}_{+}}\hat{e}_{\pm}R_{z}(\varphi)|\psi\rangle. \tag{9}$$

The step which differentiates ours from the usual construction is to expand $\hat{e}_{\pm}$ as

$$\hat{e}_{\pm}=x_{\pm}e^{-\tan\beta\hat{e}_{+}}\hat{e}_{-}e^{\tan\beta\hat{e}_{+}}+y_{\pm}e^{-\tan\beta\hat{e}_{+}}\hat{h}_{1}e^{\tan\beta\hat{e}_{+}}+z_{\pm}\hat{h}_{1}, \tag{10}$$

where $x_{\pm}$, $y_{\pm}$, and $z_{\pm}$ are coefficients to be determined. This expansion is always possible since $\hat{e}_{\pm}$ is a traceless su(2) matrix and can therefore always be expanded in terms three linearly independent traceless matrices in A_1.

Before solving for the coefficients in Eq. (10), it is worth observing that, once substituted in Eq. (9), one obtains the simpler expression

$$\begin{aligned}[\Gamma(\hat{e}_{\pm})\psi_{\beta}](\varphi)&=e^{\pm 2i\varphi}(y_{\pm}\langle\chi_{\lambda}|\hat{h}_{1}e^{\tan\beta\hat{e}_{+}}R_{z}(\varphi)|\psi\rangle+z_{\pm}\langle\chi_{\lambda}|e^{\tan\beta\hat{e}_{+}}R_{z}(\varphi)\hat{h}_{1}|\psi\rangle)\\&=e^{\pm 2i\varphi}\left(\lambda y_{\pm}-iz_{\pm}\frac{\mathrm{d}}{\mathrm{d}\varphi}\right)\psi_{\beta}(\varphi),\end{aligned} \tag{11}$$

where Eq. (7), $\langle\chi_{\lambda}|\hat{h}_{1}=\lambda\langle\chi_{\lambda}|$ and $\langle\chi_{\lambda}|\hat{e}_{-}=0$ have been used.

Although they will depend on the parameter β, the coefficients $y_{\pm}$ and $z_{\pm}$ cannot depend on the particular choice of representation used to compute them, as long as the representation is faithful: if they did, commutation relations which would hold in a representation would not necessarily hold in another. Thus, one can compute these coefficients in the defining 2×2 representation, where

$$\hat{e}_{+}\mapsto\begin{pmatrix}0&1\\0&0\end{pmatrix},\quad \hat{e}_{-}\mapsto\begin{pmatrix}0&0\\1&0\end{pmatrix},\quad \hat{h}_{1}\mapsto\begin{pmatrix}1&0\\0&-1\end{pmatrix},\quad e^{\tan\beta\hat{e}_{+}}\mapsto\begin{pmatrix}1&\tan\beta\\0&1\end{pmatrix}. \tag{12}$$

For $\hat{X}=\hat{e}_{+}$, Eq. (10) yields the matrix system

$$\begin{pmatrix}0&1\\0&0\end{pmatrix}=x_{+}\begin{pmatrix}-\tan\beta&-\tan^{2}\beta\\1&\tan\beta\end{pmatrix}+y_{+}\begin{pmatrix}1&2\tan\beta\\0&-1\end{pmatrix}+z_{+}\begin{pmatrix}1&0\\0&-1\end{pmatrix}. \tag{13}$$

It is immediately possible to solve for x_{+}, as it multiplies the only matrix with a nonzero entry below the diagonal. Knowing x_{+}, it is then easy to solve for y_{+} and z_{+}. The solution is simply $y_{+}=-z_{+}=\frac{1}{2}(\tan\beta)^{-1}$ so that the final expression for $\Gamma(\hat{e}_{+})$ corresponds to that given in Eq. (3). Repeating the steps for $\hat{e}_{-}$ yields $x_{-}=1$ and $y_{-}=-z_{-}=\frac{1}{2}\tan\beta$ so that $\Gamma(\hat{e}_{-})$ has the form given in Eq. (3).

B. Basis functions

First, we claim that the set of states $\{R_{z}^{-1}(\varphi)R_{y}^{-1}(\beta)|\chi_{\lambda}\rangle,\ R_{z}^{-1}(\varphi)\in\mathrm{U}(1),\ \beta\ \text{fixed}\}$, obtained by U(1) rotation of the state $R_{y}^{-1}(\beta)|\chi_{\lambda}\rangle$ through all possible angle φ, spans the carrier space V_{λ} for an irrep of SU(2) with highest weight λ. To show this, recall that V_{λ} is generated from $|\chi_{\lambda}\rangle$ by repeated action of the lowering operator e_{-}. Now,

$$R_{z}^{-1}(\varphi)R_{y}^{-1}(\beta)|\chi_{\lambda}\rangle\propto R_{z}^{-1}(\varphi)e^{\tan\beta\hat{e}_{-}}|\chi_{\lambda}\rangle\propto e^{\tan\beta e^{-2i\varphi\hat{e}_{-}}}|\chi_{\lambda}\rangle e^{i\lambda\varphi} \tag{14}$$

by using the normal form of $e^{-\beta(\hat{e}_{+}-\hat{e}_{-})}$. This can be seen to indeed generate the whole of V_{λ} (provided that $\tan\beta\neq 0$, which is our assumption about β being generic).

Thus, to any state $|\psi\rangle$ in V_{λ} there corresponds a unique coherent state wave function

$$|\psi\rangle\mapsto\psi_{\beta}(\varphi)\equiv\langle\chi_{\lambda}|R_{y}(\beta)R_{z}(\varphi)|\psi\rangle, \tag{15}$$

which belongs to the set of U(1) square-integrable functions. In particular, the basis functions $|\lambda\nu\rangle$ are given by $\psi_{\beta;\lambda\nu}(\varphi)=\langle\chi_\lambda|R_y(\beta)|\lambda\nu\rangle e^{i\nu\varphi}$ and must be proportional to the only normalized function on the half-circle with weight ν:

$$\psi_{\beta;\lambda\nu}(\varphi)\propto\frac{1}{\sqrt{\pi}}e^{i\nu\varphi}. \tag{16}$$

Note that we can restrict to the half circle because the difference of two weights in an invariant subspace is always an even integer.

C. Making the representation Hermitian

The representation of su(2) given in Eq. (3) is not Hermitian with respect to the natural U(1) inner product. If, as usual, the adjoint of $\hat{e}_+$ is taken as $\hat{e}_-$, i.e., $\hat{e}_+^\dagger=\hat{e}_-$, then

$$\langle\lambda\nu'|\Gamma(\hat{e}_+)|\lambda\nu\rangle\neq\langle\lambda\nu|\Gamma(\hat{e}_-)|\lambda\nu'\rangle^* \tag{17}$$

if

$$\langle\psi_\beta|\psi'_\beta\rangle=\int_0^\pi d\varphi\,\psi^*_\beta(\varphi)\psi'_\beta(\varphi). \tag{18}$$

However, since λ is integral, the representation Γ must be equivalent to a Hermitian representation γ, i.e., there must exist an intertwining operator $\mathcal{K}$ such that

$$\mathcal{K}^{-1}\Gamma\mathcal{K}=\gamma,\quad\text{with}\quad\langle\lambda\nu'|\gamma(\hat{e}_+)|\lambda\nu\rangle=\langle\lambda\nu|\gamma(\hat{e}_-)|\lambda\nu'\rangle^*. \tag{19}$$

To construct the operator $\mathcal{K}$, note that $\Gamma(\hat{h}_1)$ is actually Hermitian in the representation of Eq. (3), so that $\mathcal{K}^{-1}\Gamma(\hat{h}_1)\mathcal{K}=\Gamma(\hat{h}_1)=\gamma(\hat{h}_1)$. Thus, $\mathcal{K}$ commutes with $\Gamma(\hat{h}_1)$ and weight eigenstates of $\Gamma(\hat{h}_1)$ are also weight eigenstates of $\mathcal{K}$. Let

$$\hat{h}_1|\lambda\nu\rangle=\nu|\lambda\nu\rangle,\quad\mathcal{K}|\lambda\nu\rangle=\mathcal{K}_\nu|\lambda\nu\rangle. \tag{20}$$

Using Eq. (19), the Hermiticity condition reads

$$\langle\lambda,\nu+2|\gamma(\hat{e}_+)|\lambda\nu\rangle=\frac{1}{2\tan\beta}(\lambda-\nu)\frac{\mathcal{K}_\nu}{\mathcal{K}_{\nu+2}}=\langle\lambda\nu|\gamma(\hat{e}_-)|\lambda,\nu+2\rangle^*=\frac{1}{2}\tan\beta(\lambda+\nu+2)\frac{\mathcal{K}^*_{\nu+2}}{\mathcal{K}^*_\nu} \tag{21}$$

from which we conclude that the ratio of $\mathcal{K}_{\nu+2}/\mathcal{K}_\nu$ must satisfy, up to a phase that we choose to be $+1$,

$$\frac{\mathcal{K}_{\nu+2}}{\mathcal{K}_\nu}=\frac{1}{\tan\beta}\sqrt{\frac{\lambda-\nu}{\lambda+\nu+2}}, \tag{22}$$

so that γ is indeed Hermitian and given explicitly by

$$\langle\lambda,\nu+2|\gamma(\hat{e}_+)|\lambda\nu\rangle=\frac{1}{2}\sqrt{(\lambda+\nu+2)(\lambda-\nu)}=\langle\lambda\nu|\gamma(\hat{e}_-)|\lambda,\nu+2\rangle. \tag{23}$$

D. Application: Phase operators and phase states

Any matrix M can be factorized in polar form $U\cdot D$, with U a unitary matrix and D a semipositive definite diagonal matrix.[8] The operator D is always well-defined. The unitary matrix U is the exponential of a Hermitian ''phase'' operator associated with the phase of the observable

described by the matrix M. The problems of constructing a phase operator in a finite or semi-infinite dimensional space are related to the lack of uniqueness in the definition of U which occurs when the rank of M is smaller than its dimension.

Our realization Γ acts in a natural way in the infinite dimensional irreducible space spanned by the set of U(1) functions (phase functions) $V_{\sigma_2}=\{e^{i(2p+\sigma_2)\varphi}/\sqrt{\pi}, p\in\mathbb{Z}\}$, where σ_2 is the "duality" of the representation: $\sigma_2=0$ for bosons and $\sigma_2=1$ for fermions. Furthermore, the realization Γ of $\hat{e}_+$ or $\hat{e}_-$ can obviously be factored as a product of two operators. One may easily show that the "diagonal" part of the decomposition of $\Gamma(\hat{e}_\pm)$ obtained, to within a sign, from $\sqrt{\Gamma^\dagger(\hat{e}_\pm)\Gamma(\hat{e}_\pm)}$.

We are primarily interested in the matrix representation of the operator $\hat{E}_\varphi \equiv e^{2i\varphi}$. In the infinite-dimensional space V_{σ_2}, the matrix representation of $\hat{E}_\varphi$ contains zeroes everywhere, except immediately above the diagonal. $\hat{E}_\varphi$ is unitary with respect to the inner product of Eq. (18). Since $[\Gamma(\hat{h}_1),\hat{E}_\varphi]=\hat{E}_\varphi, \hat{E}_\varphi$ is the exponential of an Hermitian "phase" operator that is conjugate to $\hat{h}_1$.

The eigenstates of $\hat{E}_\varphi$, known as phase states,[3] are labeled by the continuous variable $\theta_\circ$ and given by

$$|\theta_\circ\rangle=\sum_{p=-\infty}^{\infty} e^{i(2p+\sigma_2)(\theta_\circ+\varphi)}, \quad \hat{E}_\varphi|\theta_\circ\rangle=e^{-2i\theta_\circ}|\theta_\circ\rangle. \tag{24}$$

To obtain a finite dimensional Hermitian representation of su(2), we project from V_{σ_2} a finite dimensional subspace V^λ spanned by an appropriate subset of exponential functions. Rowe[9] has already observed that the appropriate projection operator is the intertwining operator $\mathcal{K}$ of Eq. (19). Since $\mathcal{K}_\nu=0$ for $|\nu|>\lambda$, $\mathcal{K}$ isolates from the set of all U(1) functions $\{e^{ip\varphi}, p=-\infty,\ldots,\infty\}$ a subset of pertinent functions which form a basis for the *physical* $SU(2)$ *subspace* for the representation. $\mathcal{K}$ also adjusts the matrix elements of the various generators of the algebra so as to make γ Hermitian. Thus, the expression of γ in terms of an intertwining operator which acts as a projector ties in nicely with the work by Popov and collaborators[10] on phase operators in a finite dimensional subspace.

The restriction of $\hat{E}_\varphi$ to the finite-dimensional space V^λ is no longer unitary: the highest weight is annihilated by $\hat{E}_\varphi$ so that $\hat{E}_\varphi$ is now nilpotent, with the last line of its matrix representation containing only zeroes:

$$\hat{E}_\varphi=\begin{pmatrix} 0 & 1 & 0 & \ldots & \\ & 0 & 1 & 0 & \\ \vdots & & \ddots & 1 & \ddots \\ & & & & 1 \\ 0 & 0 & \ldots & & 0 \end{pmatrix}. \tag{25}$$

We would like to transform $\hat{E}_\varphi$ into a unitary matrix, but that transformation is not unique, as the rank of the matrix representation of $\gamma(\hat{e}_\pm)$ in V^λ is less than the dimension of this matrix. It is nevertheless possible to obtain a unitary operator closely related to $\hat{E}_\varphi$. The choice

$$E_{\hat{\varphi}}(\xi)=\begin{pmatrix} 0 & 1 & 0 & \ldots & \\ & 0 & 1 & 0 & \\ \vdots & & \ddots & 1 & \ddots \\ & & & & 1 \\ e^{i\xi} & 0 & \ldots & & 0 \end{pmatrix} \tag{26}$$

will produce a unitary matrix with determinant $e^{i\xi}$. The factor ξ is related to the phase of the vacuum state, which cannot be determined.

Vourdas[4] has done an extensive analysis of the case where $\xi=0$, which amounts to imposing a cyclic boundary condition by identifying $|\lambda,\lambda+2\rangle\sim|\lambda,-\lambda\rangle$. The case of general ξ does not differ significantly from this particular case where $\xi=0$: the eigenvalues and eigenvectors of the matrix of Eq. (26) are simply shifted by inessential phase factors. Thus, we set $\xi=0$ and define

$$E_{\hat{\varphi}}\equiv E_{\hat{\varphi}}(0), \tag{27}$$

so that $\det(E_{\hat{\varphi}})=1$. The notation indicates that $E_{\hat{\varphi}}$ is the exponential of a Hermitian "phase" operator $\hat{\varphi}$.

Phase states in the finite dimensional subspace V^{λ} are eigenstates of $E_{\hat{\varphi}}$. They are obtained by restricting the sum in Eq. (24) to those values of ν that correspond to states occurring in the su(2) irrep with highest weight λ:

$$|\lambda;\theta_\lambda\rangle=\sum_{\nu=-\lambda,-\lambda+2,\ldots,\lambda} e^{i\nu\theta_\lambda}|\lambda\,\nu\rangle=\frac{\sin((\lambda+1)(\varphi+\theta_\lambda))}{\sin(\varphi+\theta_\lambda)},\quad \theta_\lambda=2\pi/(\lambda+1), \tag{28}$$

using $|\lambda\,\nu\rangle\mapsto e^{i\nu\varphi}$. The state $|\lambda;\theta_\lambda\rangle$ behaves like a periodic δ function as $\lambda\to\infty$, in accordance with the requirement of Ref. 5.

E. Application: Asymptotic SU(2) Wigner function

Let $\lambda\to\infty$ and set $\nu_0=\lambda\cos 2\beta$, i.e., set $\cos 2\beta=\nu_0/\lambda$ to its "classical value." Then

$$\lim_{\lambda\to\infty}\frac{\mathcal{K}_{\nu_0+p+2}}{\mathcal{K}_{\nu_0+p}}=\lim_{\lambda\to\infty}\tan\beta\sqrt{\frac{(\lambda+\nu_0+p+2)}{(\lambda-\nu_0-p)}}=\tan\beta\sqrt{\frac{1+\cos 2\beta}{1-\cos 2\beta}}=1+O(p/\lambda). \tag{29}$$

For finite values of p, we can therefore solve for $\mathcal{K}_{\nu_0+p}$ as $\mathcal{K}_{\nu_0+p}=1$. For finite p, the operators $\hat{e}_{\pm}$ are now represented by

$$\begin{aligned}\gamma(\hat{e}_+)&\to-\tfrac{1}{2}e^{2i\varphi}\lambda(1-\cos 2\beta)\operatorname{cotan}\beta=-\tfrac{1}{2}\lambda e^{2i\varphi}\sin 2\beta,\\ \gamma(\hat{e}_-)&\to-\tfrac{1}{2}e^{-2i\varphi}\lambda(1+\cos 2\beta)\tan\beta=-\tfrac{1}{2}\lambda e^{-2i\varphi}\sin 2\beta,\end{aligned} \tag{30}$$

and, in particular, we have $\gamma(\hat{L}_y)=i(\gamma(\hat{e}_+)-\gamma(\hat{e}_-))=\lambda\sin 2\beta\sin 2\varphi$. The reduced SU(2)-Wigner function, $\langle\lambda\,\nu|\exp(i\theta\hat{L}_y)|\lambda\,\nu'\rangle$, can therefore be written, in the limit, as

$$\begin{aligned}&\lim_{\lambda\to\infty}\langle\tfrac{1}{2}\lambda,\tfrac{1}{2}(\nu_0+p)|\exp(i\theta(\gamma(\hat{e}_+)-\gamma(\hat{e}_-)))|\tfrac{1}{2}\lambda,\tfrac{1}{2}(\nu_0+q)\rangle\\ &\quad\to\frac{1}{\pi}\int_0^{\pi}e^{i((1/2)(p-q))2\varphi}e^{i\theta\lambda\sin 2\beta\sin 2\varphi}\mathrm{d}\varphi\\ &\quad=J_{p-q}((-\lambda\sin 2\beta)\theta),\end{aligned} \tag{31}$$

where J_ν is a Bessel function and we have used an integral expression for J_ν found in Ref. 11. This result has been further investigated in Ref. 12.

III. GENERALIZATION TO SU($N+1$) IRREPS OF TYPE (λ, 0,...)

A. Algebraic formulation

In this section we generalize the above-mentioned construction to obtain a representation of su($n+1$) on the n-torus. We start by going to the complex extension of u($n+1$), spanned by the $(n+1)^2$ operators $\{\hat{C}_{ij}, i,j=1,...,n+1\}$ which satisfy the commutation relations

$$[\hat{C}_{ij},\hat{C}_{kl}]=\delta_{jk}\hat{C}_{il}-\delta_{il}\hat{C}_{kj}. \tag{32}$$

The complex extension of su($n+1$) is obtained by selecting from the above set the operators $\hat{C}_{ij}$, $i\neq j$ and $\hat{h}_k$, where

$$\hat{h}_k=\hat{C}_{kk}-\hat{C}_{k+1,k+1}, \quad k=1,...,n. \tag{33}$$

Let $\mathfrak{h}$ be the Cartan subalgebra of $\mathfrak{g}=sl(n+1,\mathbb{C})$ consisting of diagonal matrices. Let (λ, 0, ...) be a dominant integral weight (with respect to $\mathfrak{h}$) and $|\chi_\lambda\rangle$ the highest weight vector of a representation on the space V which has only trivial weight multiplicities. Let $\mathfrak{s}$ be the stabilizer subalgebra of $\langle\chi_\lambda|$, i.e.,

$$\mathfrak{s}=\{s\in g \quad s.t. \quad \langle\chi_\lambda|s=\alpha(s)\langle\chi_\lambda|\}, \tag{34}$$

where $\alpha(s)\in\mathbb{C}$. Note that the Cartan subalgebra $h\subset\mathfrak{s}$.

Choose and fix a generic element g in $SL(n+1,\mathbb{C})$ and construct another ''twisted'' copy of the Cartan subalgebra $g\mathfrak{h}g^{-1}$. The only condition on g must be that

$$\mathfrak{g}=\mathfrak{s}+g\mathfrak{h}g^{-1}, \tag{35}$$

i.e., it must be possible to expand an arbitrary element in $\mathfrak{g}$ as a sum of an element in $\mathfrak{s}$ and an element in $g\mathfrak{h}g^{-1}$. The coherent state representation of an operator $\hat{X}\in\mathfrak{g}$ is then defined by

$$\Gamma(\hat{X})\psi_g(k)\equiv\langle\chi_\lambda|g\,k\,\hat{X}|\psi\rangle, \quad k\in H. \tag{36}$$

Since H is just an n-dimensional torus, the group element $k\in H$ is parametrized by n angles $\varphi_1,\ldots,\varphi_n$ as in $k=\exp(i\Sigma_p\varphi_p\hat{h}_p)$, where p runs from $p=1,...,n$. We will abuse the notation and write the coherent state as a function of $\underline{\varphi}=[\varphi_1,\ldots,\varphi_n]$. With this notation we find that, for $\hat{X}=\hat{h}_k\in\mathfrak{h}$,

$$\Gamma(\hat{h}_k)=-i\frac{\partial}{\partial\varphi_k}. \tag{37}$$

If $\hat{X}=\hat{C}_{j\ell}$, $\ell\neq j$ so that $\hat{X}\notin\mathfrak{h}$, then we have

$$\begin{aligned}\Gamma(\hat{C}_{j\ell})\psi_g(\varphi)&=\langle\chi_\lambda|g\exp(i\Sigma_k\varphi_k\hat{h}_k)\hat{C}_{j\ell}|\psi\rangle,\\&=\exp(i\Sigma_k m^k_{j\ell}\varphi_k)\langle\chi_\lambda|g\hat{C}_{j\ell}\exp(i\Sigma\varphi_k\hat{h}_k)|\psi\rangle\\&=\exp(i\Sigma_k m^k_{j\ell}\varphi_k)\langle\chi_\lambda|(g\hat{C}_{j\ell}g^{-1})g\exp(i\Sigma_k\varphi_k\hat{h}_k)|\psi\rangle,\end{aligned} \tag{38}$$

where k runs from 1 to n and where

$$[\hat{h}_k,\hat{C}_{j\ell}]=m^k_{j\ell}\hat{C}_{j\ell}=\delta_{kj}\hat{C}_{k\ell}-\delta_{k+1,j}\hat{C}_{k+1,\ell}-\delta_{k\ell}\hat{C}_{jk}+\delta_{k+1,\ell}\hat{C}_{j,k+1} \tag{39}$$

for $j\neq k=1,...,n+1$. With the understanding that $\varphi_0=\varphi_{n+1}=0$, the sum $\Sigma_{k=1}^n m^k_{j\ell}\varphi_k$ can be rewritten as

$$\sum_{k=1}^{n} m_{j\ell}^{k}\varphi_k = \varphi_j - \varphi_{j-1} - \varphi_\ell + \varphi_{\ell-1}. \tag{40}$$

In order to complete the description of our coherent state representation of $\mathfrak{g}$, we need to compute explicitly, for every $(j\ell)$, the decomposition

$$g\hat{C}_{j\ell}g^{-1} = \overbrace{\hat{s}_{j\ell}}^{\epsilon_{\mathfrak{s}}} + \overbrace{g\hat{d}_{j\ell}g^{-1}}^{\epsilon_{g\mathfrak{h}g^{-1}}}, \quad \hat{d}_{j\ell} = \sum_{k=1}^{n} d_{j\ell}^{k}\hat{h}_k, \tag{41}$$

as per Eq. (35). It is simpler (and equivalent) to compute

$$\hat{C}_{j\ell} = g^{-1}\hat{s}_{j\ell g} + \hat{d}_{j\ell}. \tag{42}$$

Substitution of (42) into Eq. (38) then yields

$$\begin{aligned}\Gamma(\hat{C}_{j\ell})\psi_g(\varphi) &= \exp(i\Sigma_k m_{j\ell}^{k}\varphi_k)\langle\chi_\lambda|(\hat{s}_{j\ell}g + \hat{d}_{j\ell})\exp(i\Sigma_k\varphi_k\hat{h}_k)|\psi\rangle,\\ &= \exp(i\Sigma_k m_{j\ell}^{k}\varphi_k)\langle\chi_\lambda|(\hat{s}_{j\ell}g\,\exp(i\Sigma_k\varphi_k\hat{h}_k) + g\,\exp(i\Sigma_k\varphi_k\hat{h}_k)\hat{d}_{j\ell})|\psi\rangle.\end{aligned} \tag{43}$$

It follows therefore that, in accordance with Eq. (37), $\hat{d}_{j\ell}$ will be a sum of differential operators in the variables φ_k, while the action on the left of $\hat{s}_{j\ell}$ will yield back $\langle\chi_\lambda|$ to within a normalization factor.

Again we observe that the expansion coefficients cannot depend on the choice of representation, so that we choose to work in the $(n+1)\times(n+1)$ representation where $|\chi_\lambda\rangle = (1,0,...,0)^t$. The computation is further facilitated if we observe that the dependence on g is actually only up to left multiplication of $\mathcal{S}$; hence we can write $g = S\cdot\overline{g}$, with $S\in\mathcal{S}$ in the stabilizer subgroup and $\overline{g}$ a conveniently chosen coset representative in $\mathcal{S}\backslash G$; a different choice of the representative $g' = s\cdot g$ will produce equivalent representations in which the coherent states are multiplied by a character $\chi(s)$. Then,

$$\hat{C}_{j\ell} = (\overline{g})^{-1}\hat{s}_{j\ell}\,\overline{g} + \hat{d}_{j\ell}. \tag{44}$$

If the highest weight vector $\langle\chi_\lambda|$ is the vector (1, 0,..., 0), then a general element $\hat{s}\in\mathfrak{s}$ and coset representative $\overline{g}$ have respective the matrix forms

$$\hat{s}\mapsto\begin{pmatrix} y & \mathbf{0}\\ \mathbf{x}^t & Y\end{pmatrix}, \quad \overline{g} = \begin{pmatrix} 1 & -\mathbf{v}\\ \mathbf{0}^t & \mathbb{1}\end{pmatrix}, \tag{45}$$

where Y is an $n\times n$ complex matrix, $\mathbf{x} = (x_2, x_3, \ldots, x_{n+1})$ is a complex $1\times n$ vector, $\mathbf{0}$ is the $\mathbf{1}\times n$ null vector, $y = -\mathrm{Tr}(Y)$, $\mathbf{v} = (v_2, v_3, \ldots, v_{n+1})$ is a complex vector, and $\mathbb{1}$ is the $n\times n$ unit matrix. [The matrix form of $\overline{g}$ can be compared with Eq. (12).]

The product $\overline{g}^{-1}\hat{s}\overline{g}$ is a matrix of the form

$$\begin{pmatrix} y + \mathbf{v}\cdot\mathbf{x} & -(y + \mathbf{v}\cdot\mathbf{x})\mathbf{v} + \mathbf{v}Y\\ \mathbf{x}^t & -\mathbf{x}\otimes\mathbf{v} + Y\end{pmatrix}, \tag{46}$$

where $\mathbf{v}\cdot\mathbf{x}$ is the usual scalar product and $\otimes$ denotes the outer product so that $\mathbf{x}\otimes\mathbf{v}$ is an $n\times n$ matrix.

We therefore seek to match the matrix expression of $\hat{C}_{j\ell}$ with the expansion

$$\begin{pmatrix} y + \mathbf{v}\cdot\mathbf{x} & -(y + \mathbf{v}\cdot\mathbf{x})\mathbf{v} + \mathbf{v}Y\\ \mathbf{x}^t & -\mathbf{x}\otimes\mathbf{v} + Y\end{pmatrix} + d, \tag{47}$$

where d is a diagonal matrix $d=\mathrm{diag}(d^1,...,d^{n+1})$ of zero trace.

For every different pair of indices (j,ℓ), $j\neq\ell$, and with $\mathbf{v}$ appearing as parameter (which does not depend on j, ℓ), we need to solve the above-given equation for y, Y, $\mathbf{x}$, d. These unknowns depend on j, ℓ but, to avoid overburdening the notation, we will keep writing y for $y_{j\ell}$, d^k for $d^k_{j\ell}$, etc., until we reach final formulas.

Using the form of $\hat{s}$, the highest weight state $(1,0,...)^t$ and Eq. (43), we find that the only coefficient in $\hat{s}$ that enters in the expression of $\Gamma(\hat{C}_{j\ell})$ is y. The only element in $\mathfrak{s}$ to have nonzero entry in position (1,1) is $\hat{h}_1$. As $\langle\chi_\lambda|\hat{h}_1=\langle\chi_\lambda|\lambda$, Eq. (43) simplies to

$$\Gamma(\hat{C}_{j\ell})=y_{j\ell}\exp(i\Sigma_k m_k^{j\ell}\varphi_k)\left(\lambda-i\sum_{k=1}^{n}z^k\frac{\partial}{\partial\varphi_k}\right),\quad y_{j\ell}z^k=d^k. \tag{48}$$

We divide the straightforward search for the solution into three subcases. It is also useful at this point to introduce an auxiliary set of $n+1$ vectors in the Cartan Lie-algebra $\mathfrak{h}$, given by

$$\hat{\rho}_k=-\sum_{j=1}^{k-1}j\hat{h}_j+\sum_{j=k}^{n}(n-j+1)\hat{h}_j=\mathrm{diag}(-1,...,-1,\overbrace{\quad n\quad}^{k\text{th-term}},-1,...,-1),\quad k=1,...,n+1, \tag{49}$$

$$\Gamma(\hat{\rho}_k)=-i\left(\sum_{j=1}^{k-1}j\frac{\partial}{\partial\varphi_j}-\sum_{j=k}^{n}(n-j+1)\frac{\partial}{\partial\varphi_j}\right). \tag{50}$$

Note that, for $\hat{\rho}_{n+1}$, there is no contribution from the second sum in Eq. (49).

1. Case 1: $\hat{C}_{1\ell}$

Let $j=1$, $\mathbf{c}$ be the vector of components $(\mathbf{c})_k=\delta_{\ell k}$, $k=2,3,...,n+1$ and write

$$\hat{C}_{1\ell}=\begin{pmatrix}0 & \mathbf{c}\\ \mathbf{0}^t & \mathbf{0}\end{pmatrix}, \tag{51}$$

From Eq. (47), $\mathbf{x}=\mathbf{0}$, $y+d^1=0$, and $Y+d=0$; Y is a diagonal matrix with entries $y=Y_{kk}=-d^k$.

From $\mathbf{v}(-y\mathbb{1}+Y)=\mathbf{c}$, we find first that $Y_{kk}=y$ for $k\neq\ell$, and, using the condition $y_{1\ell}+\mathrm{Tr}(Y)=0$, that $Y_{\ell\ell}=-ny$. Finally, from the nonzero component $\ell=k$ of $\mathbf{c}$, one obtains

$$y=\frac{-1}{(n+1)v_\ell}. \tag{52}$$

If Eq. (35) is to hold, then we must have $v_\ell\neq 0\ \forall\ell$. The matrix d is given by

$$d=\mathrm{diag}\left(-y,-y,...,-y,\overbrace{\quad ny\quad}^{\ell\text{th}-\text{term}},-y...,-y\right)=-y\hat{\rho}_\ell=\frac{-1}{(n+1)v_\ell}\hat{\rho}_\ell. \tag{53}$$

Therefore we finally have

$$\Gamma(\hat{C}_{1\ell})=y_{1\ell}\,e^{i(\varphi_1-\varphi_\ell+\varphi_{\ell-1})}(\lambda+\Gamma(\hat{\rho}_\ell)),\quad y_{1\ell}=\frac{-1}{(n+1)v_\ell}, \tag{54}$$

where we have found $\Sigma_{k=1}^{n}m_k^{1\ell}\varphi_k=\varphi_1-\varphi_\ell+\varphi_{\ell-1}$ using $\varphi_{n+1}=0$ and Eq. (40).

2. Case 2: $\hat{C}_{j\ell}$, $\ell \neq j$, $\ell, j \geqslant 2$

We now write

$$\hat{C}_{j\ell} = \begin{pmatrix} 0 & \mathbf{0} \\ \mathbf{0}^t & c_{j\ell} \end{pmatrix}, \tag{55}$$

where $(c_{j\ell})_{mn} = \delta_{jm}\delta_{\ell n}$. Using Eq. (47), $\mathbf{x} = \mathbf{0}$ once more, so that $y + d^1 = 0$. Thus, the diagonal elements of Y are such that $Y_{kk} + d^k = 0$. The only off-diagonal entry in Y is a 1 in the jth row, ℓth column. (For consistency it is convenient to enumerate the entries of the $n \times n$ matrix Y_{jk} with j, $k = 2,...,n+1$.) From $\mathbf{v}(-y\mathbb{1} + Y) = 0$, we obtain the equations

$$v_k(-y + Y_{kk}) + v_j\delta_{\ell k} = 0, \tag{56}$$

from which we conclude that, if $k \neq \ell$, $Y_{kk} = y$. The coefficient $Y_{\ell\ell}$ is fixed by $y + \mathrm{tr}(Y) = 0$ to be $Y_{\ell\ell} = -ny$. Finally, from Eq. (56) with $\ell = k$, we conclude that

$$y = \frac{v_j}{(n+1)v_\ell}, \tag{57}$$

where $v_j \neq 0 \neq v_\ell$ by assumption. The diagonal matrix d is given by

$$d = \mathrm{diag}\Big(-y, -y, \ldots, -y, \overbrace{ny}^{\ell\text{th-term}}, -y \ldots, -y \Big) = -y\hat{\rho}_\ell = -\frac{v_j}{(n+1)v_\ell}\hat{\rho}_\ell \tag{58}$$

Summarizing, we find, using Eq. (40),

$$\Gamma(\hat{C}_{j\ell}) = y_{j\ell} e^{i(\varphi_j - \varphi_{j-1} - \varphi_\ell + \varphi_{\ell-1})}(\lambda + \Gamma(\hat{\rho}_\ell)), \quad y_{j\ell} = \frac{v_j}{(n+1)v_\ell}. \tag{59}$$

3. Case 3: $\hat{C}_{\ell 1}$, $\ell \neq 1$

In this case, the vector $\mathbf{x}^t$ has components $x_j = \delta_{\ell j}$. Thus, the scalar product $\mathbf{v}\cdot\mathbf{x} = v_\ell$, and the equation $y + v_\ell + d^1 = 0$ gives

$$d^1 = -(v_\ell + y). \tag{60}$$

From $\mathbf{v}(-y\mathbb{1} + v_\ell\mathbb{1} + \mathbf{Y}) = 0$, we conclude that

$$(-y - v_\ell)v_m + \sum_{k=1}^{n} v_k Y_{km} = 0, \quad m = 2,3,...,n+1. \tag{61}$$

Now, $(\mathbf{x}\otimes\mathbf{v})_{pm} = x_p v_m = \delta_{\ell p} v_m$. Thus, we have

$$0 = -(\mathbf{x}\otimes\mathbf{v})_{pm} + Y_{pm} + d^m\delta_{pm} = -\delta_{\ell p}v_m + Y_{pm} + d^m\delta_{pm}, \quad m = 2,3,...,n+1. \tag{62}$$

Multiplying Eq. (62) by v_p and summing over p, we obtain

$$0 = \sum_p (-\delta_{\ell p}v_p v_m) + \sum_p v_p Y_{pm} + \sum_p v_p d^m \delta_{pm}, \quad m = 2,3,...,n+1. \tag{63}$$

Using Eq. (61) and the fact that $v_m \neq 0$, this can be simplified to

$$0 = -v_\ell + y + v_\ell + d^m = y + d^m, \quad m = 2,3,...,n+1. \tag{64}$$

Now using the fact that $\Sigma_{k=1}^{n+1} d^k = 0$, we immediately find

$$y=-\frac{v_\ell}{n+1}, \tag{65}$$

so that, using Eq. (60), we find the matrix d to be

$$d=\mathrm{diag}(ny,-y,\ldots,-y)=-y\hat{\rho}_1=-\frac{v_\ell}{n+1}\hat{\rho}_1. \tag{66}$$

Hence,

$$\Gamma(\hat{C}_{\ell 1})=y_{\ell 1}e^{i(\varphi_\ell-\varphi_{\ell-1}-\varphi_1)}(\lambda+\Gamma(\hat{\rho}_1)),\quad y_{\ell 1}=\frac{v_\ell}{n+1},\quad \ell=2,\ldots,n+1,\quad \varphi_{n+1}\equiv 0. \tag{67}$$

B. Evaluating the v_k coefficients

The coefficients v_k are related to SU($n+1$) Wigner functions as follows. If $\nu=(\nu_1,\nu_2,\ldots,\nu_{n+1})$ denotes an ordered partition of λ, i.e., $\nu_1+\nu_2+\ldots+\nu_{n+1}=\lambda$ with ν_i a non-negative integer, then the set of states $\{\psi_\nu\}$, labeled by different partitions ν of λ, can be chosen as basis states for the irrep (λ, 0,..., 0) of su(n). These states satisfy

$$\hat{h}_k\psi_\nu=(\nu_k-\nu_{k+1})\psi_\nu, \tag{68}$$

and are uniquely identified by the set of eigenvalues of the operators $\hat{h}_k$.

Next, we need $g=\bar{g}\cdot S$, or $\bar{g}=S^{-1}g=\bar{g}$, with $\mathcal{S}^{-1}$ and G matrices of the form

$$S^{-1}=\begin{pmatrix} w & \mathbf{0} \\ \mathbf{Q}^t & X \end{pmatrix},\quad g=\begin{pmatrix} a & \mathbf{b} \\ \mathbf{c}^t & U \end{pmatrix}, \tag{69}$$

where $a=\langle\chi_\lambda|g|\chi_\lambda\rangle$ and $b_k=\langle\chi_\lambda|g|\psi_{\nu_k}\rangle$, with ψ_{χ_λ} the highest weight state of the $(n+1)$-dimensional defining representation (1, 0,..., 0) and ψ_{ν_k}, $k=2,\ldots,n+1$, the remaining basis states of this irrep. Thus we have

$$w=\frac{1}{\langle\chi_\lambda|g|\chi_\lambda\rangle},\quad v_k=\frac{\langle\chi_\lambda|g|\psi_{\nu_k}\rangle}{\langle\chi_\lambda|g|\chi_\lambda\rangle}. \tag{70}$$

C. Basis functions

We have already observed that, with $\bar{g}$ of the form of Eq. (45) and $v_j\neq 0\ \forall j$, then $(\bar{g})^{-1}|\chi_\lambda\rangle$ generates the whole representation space. Thus, the state $(\bar{g})^{-1}|\chi_\lambda\rangle$ acts as a cyclic vector for the irrep with highest weight (λ, 0, 0,...) under the action of any fixed element $k\in H$ in the Cartan subgroup. Hence, to every vector ψ in the representation space, there corresponds a unique function on H:

$$\psi\mapsto\psi_g(k)=\langle\chi_\lambda|g\,k|\psi\rangle. \tag{71}$$

The basis state ψ_ν of (λ, 0,..., 0) is mapped to the normalized element on the n-torus

$$\psi_\nu\mapsto\langle\chi_\lambda|\bar{g}k|\psi_\nu\rangle\propto\langle\chi_\lambda|\bar{g}|\psi_\nu\rangle\exp(i\Sigma_k(\nu_k-\nu_{k+1})\varphi_k)\mapsto\frac{\exp(i\Sigma_k(\nu_k-\nu_{k+1})\varphi_k)}{(2\pi)^{n/2}}. \tag{72}$$

The highest weight state ψ_{χ_λ} of (λ, 0,..., 0) is represented by $\psi_{\chi_\lambda}\mapsto e^{i\varphi_1}/(2\pi)^{n/2}$.

D. Making the representation Hermitian

States on the torus are naturally normalized with respect to the inner product

$$\langle \psi_{\nu'}|\psi_{\nu}\rangle = \frac{1}{(2\pi)^n}\int_0^{2\pi} d\varphi_1 \int_0^{2\pi} d\varphi_2 \cdots \int_0^{2\pi} d\varphi_n \exp(-i\Sigma_k(\nu'_k-\nu'_{k+1})\varphi_k)\exp(i\Sigma_p(\nu_p-\nu_{p+1})\varphi_p)$$

$$= \prod \delta_{\nu'_k-\nu_k-\nu'_{k+1}+\nu_{k+1}}. \tag{73}$$

However, with this inner product, the action of the operators $\Gamma(\hat{C}_{ij})$, $i\neq j$, is not Hermitian:

$$\langle \psi_{\nu'}|\Gamma(\hat{C}_{ij})|\psi_{\nu}\rangle \neq \langle \psi_{\nu'}|\Gamma^{\dagger}(\hat{C}_{ji})|\psi_{\nu}\rangle = \langle \psi_{\nu}|\Gamma(\hat{C}_{ji})|\psi_{\nu'}\rangle^*; \tag{74}$$

the resulting representation does not exponentiate to a unitary representation of the group. Since all representations of su$(n+1)$ having integral dominant weight are equivalent to Hermitian representations, there must exist an intertwining operator $\mathcal{K}$ that will transform Γ into a Hermitian representation γ, i.e., there exists $\mathcal{K}$

$$\gamma(\hat{C}_{ij}) = \mathcal{K}^{-1}\Gamma(\hat{C}_{ij})\mathcal{K}, \quad \text{such that} \quad \langle \psi_{\nu'}|\gamma(\hat{C}_{ij})|\psi_{\nu}\rangle = \langle \psi_{\nu}|\gamma(\hat{C}_{ji})|\psi_{\nu'}\rangle^*. \tag{75}$$

We find $\mathcal{K}$ by combining Eq. (75) with its Hermitian conjugate $\gamma^{\dagger}(\hat{C}_{ji}) = \mathcal{K}^{\dagger}\Gamma^{\dagger}(\hat{C}_{ji})(\mathcal{K}^{-1})^{\dagger}$, so that

$$\gamma(\hat{C}_{ij}) = \gamma^{\dagger}(\hat{C}_{ji}) \Rightarrow \Gamma(\hat{C}_{ij})\mathcal{S} = \mathcal{S}\Gamma^{\dagger}(\hat{C}_{ji}), \tag{76}$$

where $\mathcal{S}=\mathcal{K}\mathcal{K}^{\dagger}$ is a Hermitian operator. Noting that the Cartan elements $\hat{h}_k$ are represented under the map Γ by operators Hermitian with respect to the inner product of Eq. (73), we may take $\mathcal{S}$ to be diagonal in the weight basis: $\mathcal{S}|\psi_{\nu}\rangle = \mathcal{S}_{\nu}|\psi_{\nu}\rangle$. Thus, using Eq. (76), we obtain the condition

$$\langle \psi_{\nu'}|\Gamma(\hat{C}_{ij})\mathcal{S}|\psi_{\nu}\rangle = \langle \psi_{\nu'}|\mathcal{S}\Gamma^{\dagger}(\hat{C}_{ji})|\psi_{\nu}\rangle \Rightarrow \frac{\mathcal{S}_{\nu}}{\mathcal{S}_{\nu'}} = \frac{y^*_{ji}(\lambda+\rho_i(\nu'))}{y_{ij}(\lambda+\rho_j(\nu))} \equiv R_{\nu,\nu'}, \tag{77}$$

where $\nu_k = \nu'_k + \delta_{ik} - \delta_{jk}$ and

$$\rho_i(\nu) = \langle \psi_{\nu}|\hat{\rho}_i|\psi_{\nu}\rangle = \sum_{k=1}^{n+1} (\rho_i)_{kk}\nu_k, \tag{78}$$

where $(\rho_i)_{kk}$ is the kth entry in the diagonal matrix ρ_i defined in Eq. (49).

To construct the coefficients $\mathcal{S}_{\nu}$ from the ratios of Eq. (77), one starts by (arbitrarily) fixing to $+1$ the coefficient of the highest weight corresponding to the trivial partition $(\lambda, 0, 0,...)$; changing this would just change $\mathcal{S}$ by an overall multiplicative factor. Noting now that $\mathcal{S}=\mathcal{K}\mathcal{K}^{\dagger}$ is a positive Hermitian matrix, the ratio $\mathcal{K}_{\nu}/\mathcal{K}_{\nu'}$ can therefore be obtained, up to a phase, as the square root of the right-hand side of Eq. (77). The phase of the ratio $\mathcal{K}_{\nu}/\mathcal{K}_{\nu'}$ should be chosen so that the matrix elements of $\gamma(\hat{C}_{ij})$ are real, something that it is always possible to do. In practice, one chooses, without loss of generality, the element $g\in G$, from which y_{ij} is obtained, so that y_{ij} is always real. Assuming therefore that g is chosen in this way, we have v_k always real and

$$\frac{\mathcal{K}_{\nu}}{\mathcal{K}_{\nu'}} = \sqrt{\frac{y_{ji}(\lambda+\rho_i(\nu'))}{y_{ij}(\lambda+\rho_j(\nu))}}. \tag{79}$$

IV. APPLICATION TO SU(3)

A. Representation on the 2-torus

The su(3) Lie algebra is spanned in the usual way by the subset of u(3) operators comprising the ladder operators $\{\hat{C}_{ij}, i \neq j\}$ together with the Cartan generators $\hat{h}_1 = \hat{C}_{11} - \hat{C}_{22}$, $\hat{h}_2 = \hat{C}_{22} - \hat{C}_{33}$. The $\{\hat{C}_{ij}\}$ operators satisfy the general commutation relations $[\hat{C}_{ij}, \hat{C}_{kl}] = \delta_{jk}\hat{C}_{il} - \delta_{il}\hat{C}_{kj}$.

The highest weight state of the irrep $(\lambda,0)$ is mapped to the state $|\lambda,0,0\rangle \mapsto e^{i\lambda\varphi_1}/2\pi$. More generally, a state $|\nu_1,\nu_2,\nu_3\rangle$, with $\nu_1+\nu_2+\nu_3=\lambda$, is mapped to

$$|\nu_1,\nu_2,\nu_3\rangle \mapsto \frac{e^{i(\nu_1-\nu_2)\varphi_1 + i(\nu_2-\nu_3)\varphi_2}}{2\pi} = \frac{e^{i(\nu_1-\nu_2)\varphi_1 + i(2\nu_2+\nu_1-\lambda)\varphi_2}}{2\pi}, \tag{80}$$

where the condition $\nu_1+\nu_2+\nu_3=\lambda$ has been used.

Following the parametrization of Ref. 13 for SU(3) elements, and using the fact that we can choose g to be such that the matrix elements are real, we find

$$w = \frac{1}{\cos\frac{1}{2}\beta_2}, \quad v_2 = \cos\frac{1}{2}\beta_3 \tan\frac{1}{2}\beta_2, \quad v_3 = \sin\frac{1}{2}\beta_3 \tan\frac{1}{2}\beta_2. \tag{81}$$

Simple application of Eqs. (37), (54), (59), and (67) then yields

$$\Gamma(\hat{h}_1) = -i\frac{\partial}{\partial\varphi_1}, \quad \Gamma(\hat{h}_2) = -i\frac{\partial}{\partial\varphi_2},$$

$$\Gamma(\hat{C}_{12}) = \frac{-1}{3\cos\frac{1}{2}\beta_3 \tan\frac{1}{2}\beta_2} e^{i(2\varphi_1-\varphi_2)}\left[\lambda + i\frac{\partial}{\partial\varphi_1} - i\frac{\partial}{\partial\varphi_2}\right],$$

$$\Gamma(\hat{C}_{21}) = \frac{-\cos\frac{1}{2}\beta_3 \tan\frac{1}{2}\beta_2}{3} e^{-i(2\varphi_1-\varphi_2)}\left[\lambda - 2i\frac{\partial}{\partial\varphi_1} - \frac{\partial}{\partial\varphi_2}\right],$$

$$\Gamma(\hat{C}_{13}) = \frac{-1}{3\sin\frac{1}{2}\beta_3 \tan\frac{1}{2}\beta_2} e^{i(\varphi_1+\varphi_2)}\left[\lambda + i\frac{\partial}{\partial\varphi_1} + 2i\frac{\partial}{\partial\varphi_2}\right], \tag{82}$$

$$\Gamma(\hat{C}_{31}) = \frac{-\sin\frac{1}{2}\beta_3 \tan\frac{1}{2}\beta_2}{3} e^{-i(\varphi_1+\varphi_2)}\left[\lambda - 2i\frac{\partial}{\partial\varphi_1} - i\frac{\partial}{\partial\varphi_2}\right],$$

$$\Gamma(\hat{C}_{23}) = \frac{1}{3\tan\frac{1}{2}\beta_3} e^{i(-\varphi_1+2\varphi_2)}\left[\lambda + i\frac{\partial}{\partial\varphi_1} + 2i\frac{\partial}{\partial\varphi_2}\right],$$

$$\Gamma(\hat{C}_{32}) = \frac{\tan\frac{1}{2}\beta_3}{3} e^{i(\varphi_1-2\varphi_2)}\left[\lambda + i\frac{\partial}{\partial\varphi_1} - i\frac{\partial}{\partial\varphi_2}\right].$$

The ratios of $\mathcal{K}$ matrix elements required to compute the matrix elements of $\gamma(\hat{C}_{ij})$ are $\mathcal{K}_{\nu}/\mathcal{K}_{\nu'}$, with $\nu'_k=\nu_k+\delta_{ik}-\delta_{jk}$. Using $\nu_1+\nu_2+\nu_3=\lambda$, they are given explicitly by

$$\frac{\mathcal{K}_{\nu_1\nu_2\nu_3}}{\mathcal{K}_{\nu_1+1,\nu_2,\nu_3-1}}=v_3\sqrt{\frac{\lambda+\rho_1(\nu')}{\lambda+\rho_3(\nu)}}=\sin\frac{1}{2}\beta_3\tan\frac{1}{2}\beta_2\sqrt{\frac{\lambda+2(\nu_1+1-\nu_2)+(\nu_2-\nu_3+1)}{\lambda-(\nu_1-\nu_2)-2(\nu_2-\nu_3)}}$$
$$=\sin\frac{1}{2}\beta_3\tan\frac{1}{2}\beta_2\sqrt{\frac{\nu_1+1}{\nu_3}}, \tag{83}$$

$$\frac{\mathcal{K}_{\nu_1\nu_2\nu_3}}{\mathcal{K}_{\nu_1\nu_2-1,\nu_3+1}}=\frac{v_2}{v_3}\sqrt{\frac{\lambda+\rho_3(\nu')}{\lambda+\rho_2(\nu)}}=\frac{1}{\tan\frac{1}{2}\beta_3}\sqrt{\frac{\nu_3+1}{\nu_2}}, \tag{84}$$

$$\frac{\mathcal{K}_{\nu_1\nu_2\nu_3}}{\mathcal{K}_{\nu_1+1,\nu_2-1,\nu_3}}=v_2\sqrt{\frac{\lambda+\rho_1(\nu')}{\lambda+\rho_2(\nu)}}=\cos\frac{1}{2}\beta_3\tan\frac{1}{2}\beta_2\sqrt{\frac{\nu_1+1}{\nu_2}}. \tag{85}$$

To obtain the matrix element $\gamma(\hat{C}_{13})$, for instance, one computes

$$\begin{aligned}
&\langle\psi_{\nu_1+1,\nu_2,\nu_3-1}|\gamma(\hat{C}_{13})|\psi_{\nu_1,\nu_2,\nu_3}\rangle\\
&\quad=\int\frac{d\varphi_1}{2\pi}\int\frac{d\varphi_2}{2\pi}\exp[-i(\nu_1-\nu_2+1)\varphi_1-i(\nu_2-\nu_3-1)\varphi_2]\\
&\qquad\times(\mathcal{K}^{-1}\Gamma(\hat{C}_{13})\mathcal{K})\exp[i(\nu_1-\nu_2)\varphi_1+i(\nu_2-\nu_3)\varphi_2],\\
&\quad=\int\frac{d\varphi_1}{2\pi}\int\frac{d\varphi_2}{2\pi}\exp[-i(\nu_1-\nu_2+1)\varphi_1-i(\nu_2-\nu_3-1)\varphi_2]\\
&\qquad\times\left(\frac{1}{\mathcal{K}_{\nu_1+1,\nu_2,\nu_3-1}}e^{i(\varphi_1+\varphi_2)}\frac{-1}{3\sin\frac{1}{2}\beta_3\tan\frac{1}{2}\beta_2}\left[\lambda+i\frac{\partial}{\partial\varphi_1}+2i\frac{\partial}{\partial\varphi_2}\right]\mathcal{K}_{\nu_1,\nu_2,\nu_3}\right)\\
&\qquad\times\exp[-i(\nu_1-\nu_2)\varphi_1+i(\nu_2-\nu_3)\varphi_2]\\
&\qquad\times\frac{-1}{3\sin\frac{1}{2}\beta_3\tan\frac{1}{2}\beta_2}[\lambda-(\nu_1-\nu_2)-2(\nu_2-\nu_3)]\sin\frac{1}{2}\beta_3\tan\frac{1}{2}\beta_2\sqrt{\frac{\nu_1+1}{\nu_3}},\\
&\quad=-\sqrt{(\nu_1+1)\nu_3}.
\end{aligned} \tag{86}$$

B. Application: the SU(3)→[$\mathbb{R}^6$]U(1)^2 contraction

Consider the limit where $\lambda\to\infty$. Set

$$\overline{\nu_1}=\lambda\left(\cos\frac{1}{2}\beta_2\right)^2,\quad \overline{\nu_2}=\lambda\left(\sin\frac{1}{2}\beta_2\right)^2\left(\cos\frac{1}{2}\beta_3\right)^2,\quad \overline{\nu_3}=\lambda\left(\sin\frac{1}{2}\beta_2\right)^2\left(\sin\frac{1}{2}\beta_3\right)^2. \tag{87}$$

The angles β_2 and β_3 then provide a convenient way to parametrize the distribution of λ photons in three modes with mode i containing a large number ν_i of photons.

With this, it is readily seen that the values of the angles β_2, β_3 for which the representation Γ of Eq. (82) is singular correspond to a distribution such that at least one of the three fields contains no quanta. Provided that Γ is nonsingular, we then have, for values of ν and ν' sufficiently close to the average values $\overline{\nu}$,

$$\lim_{\lambda\to\infty}\frac{\mathcal{K}_\nu}{\mathcal{K}_{\nu'}}=1+O(1/\lambda). \tag{88}$$

The representation Γ is then Hermitian; the diagonal operators $\hat{h}_1$ and $\hat{h}_2$ remain unchanged, and the ladder generators become, in the limit where $\lambda\to\infty$,

$$\begin{aligned}
&\Gamma(\hat{C}_{12})\to -2\lambda e^{i(2\varphi_1-\varphi_2)}\sin\beta_2\cos\frac{1}{2}\beta_3,\\
&\Gamma(\hat{C}_{21})\to -2\lambda e^{-i(2\varphi_1-\varphi_2)}\sin\beta_2\cos\frac{1}{2}\beta_3,\\
&\Gamma(\hat{C}_{13})\to -2\lambda e^{i(\varphi_1+\varphi_2)}\sin\beta_2\sin\frac{1}{2}\beta_3,\\
&\Gamma(\hat{C}_{31})\to -2\lambda e^{-i(\varphi_1+\varphi_2)}\sin\beta_2\cos\frac{1}{2}\beta_3,\\
&\Gamma(\hat{C}_{23})\to 2\lambda e^{i(-\varphi_1+2\varphi_2)}\left(\sin\frac{1}{2}\beta_2\right)^2\sin\beta_3,\\
&\Gamma(\hat{C}_{32})\to 2\lambda e^{i(\varphi_1-2\varphi_2)}\left(\sin\frac{1}{2}\beta_2\right)^2\sin\beta_3.
\end{aligned} \tag{89}$$

All the ladder operators commute with one another, and the resultant algebra is $[\mathbb{R}^6]\mathrm{U}(1)^2$.

C. Application: Phase operators and SU(3) phase states

The realization Γ acts naturally in the irreducible infinite-dimensional space of functions V_{σ_3}, where a state $|n,m\rangle$, $n,m\in\mathbb{Z}$ is represented by the function over the 2-torus $|n,m\rangle\mapsto e^{i(2n-m)\varphi_1}e^{i(2m-n-\sigma_3)\varphi_2}/2\pi$. Here, $\sigma_3=0$, 1, or 2 is the "triality" of the representation.

We introduce three "phase-like" operators:

$$\hat{E}_{\varphi_{12}}=e^{i(2\varphi_1-\varphi_2)},\quad \hat{E}_{\varphi_{23}}=e^{i(-\varphi_1+2\varphi_2)},\quad \hat{E}_{\varphi_{13}}=e^{i(\varphi_1+\varphi_2)}. \tag{90}$$

In V_{σ_3}, the operators $\hat{E}_{\varphi_{12}}$ and $\hat{E}_{\varphi_{23}}$ are unitary with respect to the natural inner product over the 2-torus; they are the exponential of phase operators conjugate to $\hat{h}_1$ and $\hat{h}_2$, respectively, since

$$\left[\frac{1}{2}\Gamma(\hat{h}_1),\hat{E}_{\varphi_{12}}\right]=\hat{E}_{\varphi_{12}},\quad \left[\frac{1}{2}\Gamma(\hat{h}_2),\hat{E}_{\varphi_{23}}\right]=\hat{E}_{\varphi_{23}}. \tag{91}$$

Note that $[\frac{1}{2}\Gamma(\hat{h}_1),\hat{E}_{\varphi_{23}}]\neq 0$, $[\frac{1}{2}\Gamma(\hat{h}_2),\hat{E}_{\varphi_{12}}]\neq 0$.

The realization of an element of A_2, say, $\Gamma(\hat{C}_{12})$ can be expressed as products of a unitary and a diagonal matrix: $\Gamma(\hat{C}_{12})=-\hat{E}_{\varphi_{12}}\hat{e}_{12}$, where $\hat{e}_{12}=\sqrt{\Gamma^\dagger(\hat{C}_{12})\Gamma(\hat{C}_{12})}$.

In the infinite-dimensional space V_{σ_3}, the unitary operators $\hat{E}_{\varphi_{12}}$ and $\hat{E}_{\varphi_{23}}$ commute, and it is possible to find their common set of eigenvectors. It can be verified that, for any θ_1, θ_2, states of the type

$$|\theta_1,\theta_2\rangle = \sum_{n,m\in\mathbb{Z}} e^{i(2n-m)\theta_1} e^{i(2m-n)\theta_2} |n,m\rangle = \sum_{n,m\in\mathbb{Z}} e^{i(2n-m)(\varphi_1+\theta_1)} e^{i(2m-n)(\varphi_2+\theta_2)}, \tag{92}$$

are the simultaneous eigenstate of $\hat{E}_{\varphi_{12}}$, $\hat{E}_{\varphi_{23}}$, and $\hat{E}_{\varphi_{13}}$:

$$\begin{aligned} &\hat{E}_{\varphi_{12}}|\theta_1,\theta_2\rangle = e^{-i(2\theta_1-\theta_2)}|\theta_1,\theta_2\rangle, \quad \hat{E}_{\varphi_{23}}|\theta_1,\theta_2\rangle = e^{-i(-\theta_1+2\theta_2)}|\theta_1,\theta_2\rangle, \\ &\hat{E}_{\varphi_{13}}|\theta_1,\theta_2\rangle = e^{-i(\theta_1+\theta_2)}|\theta_1,\theta_2\rangle. \end{aligned} \tag{93}$$

The states $|\theta_1,\theta_2\rangle$ are therefore phase states.

Consider now the finite-dimensional subspace $V^\lambda \subset V_{\sigma_3}$ such that V^λ is the carrier space for a unirrep of highest weight $(\lambda, 0)$. This subspace is projected using the $\mathcal{K}$ operator from V_{σ_3}. In going from the infinite-dimensional space V_σ to the finite-dimensional V^λ, a number of problems arise in connection with the definition and properties of the phase operators.

We denote the states in V^λ by three non-negative integers as per Eq. (80). First, however, we note that it is not difficult to properly define the radial part of an operator. For instance, the radial part $\hat{J}_{12}$ of $\gamma(\hat{C}_{12})$ is found from $\hat{J}_{12} = \sqrt{\gamma^\dagger(\hat{C}_{12})\gamma(\hat{C}_{12})}$.

In V^λ, the restrictions of the operators $\hat{E}_{\varphi_{ij}}$ are nilpotent and therefore no longer unitary. The rank of $\hat{E}_{\varphi_{ij}}$ is equal to $\dim(V^\lambda)-(\lambda+1)$ as there are $(\lambda+1)$ states annihilated by $\hat{E}_{\varphi_{ij}}$ [one state in each $\mathrm{su}(2)_{ij}$ subrepresentation occurring in the su(3) irrep $(\lambda, 0)$].

In contrast with the SU(2) case, where a single entry of $\hat{E}_\varphi$ could be changed so as to obtain the unitary operator $E_{\hat{\varphi}}$, an arbitrary complex linear combination of the $(\lambda+1)$ states annihilated by $\hat{E}_{\varphi_{ij}}$ yields another state annihilated by $\hat{E}_{\varphi_{ij}}$. Thus, we are left with infinitely many ways of transforming $\hat{E}_{\varphi_{ij}}$ into a unitary phase operator $E_{\hat{\varphi}_{ij}}$, even if we insist that the determinant of $E_{\hat{\varphi}_{ij}}$ be 1. Furthermore, it can easily be verified that, for $\lambda \geqslant 2$, the restriction of $\hat{E}_{\varphi_{ij}}$ is an operator that does not necessarily commute with the other $\hat{E}_{\varphi_{kl}}$ operators: $[\hat{E}_{\varphi_{ij}}, \hat{E}_{\varphi_{kl}}] \neq 0$.

We point out that, in the matrix representation of $[\hat{E}_{\varphi_{12}}, \hat{E}_{\varphi_{23}}]$ there are precisely λ entries which are 1 rather than zero in this commutator. The ''faulty'' nonzero matrix elements appear in positions corresponding to matrix elements of the type $\langle \nu_1+1,0,\nu_3-1|\hat{E}_{\varphi_{13}}|\nu_1,0,\nu_3\rangle$, i.e., matrix elements involving vacuum states in mode 2: the familiar problems associated with the construction of unitary phase operators in the presence of vacuum states are still present.

Thus, the number of ''faulty'' nonzero matrix elements in commutators of the type $[\hat{E}_{\varphi_{ij}}, \hat{E}_{\varphi_{jk}}]$ will grow like λ, since the number of states having the vacuum in one mode grows like λ. On the other hand, the number of states in the irrep $(\lambda, 0)$ grows like λ^2. The classical limit where $\lambda \to \infty$ corresponds to the limit where the phases commute, provided that we ignore the relatively small number of ''faulty'' nonzero matrix elements compared to the number of ''correct'' zero matrix elements. This relative number grows like $1/\lambda$.

In particular, in the interpretation of Eq. (89), the realization Γ becomes singular for states near the vacuum state when $\lambda \to \infty$ limit. Hence, provided that the distribution of photons in an input state is such that the vacuum can be safely ignored, phase operators can be considered as commuting.

A similar result on the lack of commutativity between the *total* and relative su(2) phase operators in systems containing few photons has been obtained in Ref. 14. These authors found that commutativity was recovered in the classical limit. Our results are similar to those found in Ref. 14, albeit applicable to the case of noncommuting *relative* phases in a three-beam system.

The three-dimensional representation (1, 0) merits special attention. Besides providing an illustrative example for our previous discussion, this representation is the only one that allows commuting *unitary* phase operators while preserving the polar decomposition.

More precisely, in a system containing a total of $\lambda=\nu_1+\nu_2+\nu_3=1$ quantum, the explicit matrix realization of (some of) $\hat{C}_{ij}$ in terms of $\hat{E}_{\varphi_{ij}}\cdot\hat{J}_{ij}$ can easily be found:

$$
\begin{array}{lccc}
(ij) & \hat{E}_{\varphi_i} & \hat{J}_{ij} & \hat{C}_{ij}=\hat{E}_{\varphi_{ij}}\cdot\hat{J}_{ij} \\
(1,2) & \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} & \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \\
(2,3) & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \\
(1,3) & \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} & \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\end{array}
\tag{94}
$$

To compute $\hat{E}_{\varphi_{12}}$, for instance, one uses $\hat{E}_{\varphi_{12}}=e^{i(2\varphi_1-\varphi_2)}$, i.e., the "phase" part of $\Gamma(\hat{C}_{12})$, the basis states $\{\frac{1}{2\pi}e^{i\varphi_1},\frac{1}{2\pi}e^{i(-\varphi_1+\varphi_2)},\frac{1}{2\pi}e^{i\varphi_2}\}$, and the inner product

$$
\langle\Psi|\Phi\rangle=\int_0^{2\pi}\int_0^{2\pi}\mathrm{d}\varphi_1\,\mathrm{d}\varphi_2\,\Psi^*\Phi. \tag{95}
$$

The operators $\hat{E}_{\varphi_{ij}}$ are explicitly not unitary. Whereas $\hat{E}_{\varphi_{12}}\cdot\hat{E}_{\varphi_{23}}=\hat{E}_{\varphi_{13}}$ it is not true that $[\hat{E}_{\varphi_{12}},\hat{E}_{\varphi_{23}}]=\hat{E}_{\varphi_{13}}$: the phase operators do not commute.

There are many ways of turning $\hat{E}_{\varphi_{ij}}$ into a unitary operator $E_{\hat{\varphi}_{ij}}$ while still preserving the decomposition of $\hat{C}_{ij}$ into a phase and a diagonal part. What is unique of the (1,0) representation is that it is also possible to find unitary operators $\hat{E}_{\hat{\varphi}_{ij}}$ such that $\hat{E}_{\hat{\varphi}_{ij}}$ preserves the polar decomposition of $\hat{C}_{ij}$ and simultaneously produces commuting phase operators: $[\hat{E}_{\hat{\varphi}_{ij}},\hat{E}_{\hat{\varphi}_{kl}}]=0$. This remarkable choice is

$$
E_{\hat{\varphi}_{12}}=\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},\quad E_{\hat{\varphi}_{23}}=\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},\quad E_{\hat{\varphi}_{13}}=\begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}. \tag{96}
$$

It is not possible to convert $\hat{E}_{\varphi_{ij}}$ into a unitary operator $E_{\hat{\varphi}_{ij}}$ that will have all of the above enumerated properties when the total number of photons is greater than 1.

This result on the existence of commuting unitary phase operators is expected, as the representation (1,0) is pertinent to the classical description of a three-channel interferometer,[15] for which the phases are (of course) expected to commute.

V. DISCUSSION AND CONCLUSION

In deriving the representation Γ acting over the functions defined over the maximal torus H of $G=\mathrm{SU}(n+1)$, the main hinge is the decomposition of the Lie algebra as per Eq. (35). This is equivalent to requiring that the dimension of the subgroup H or, equivalently, the rank of the group G [i.e., n in the case of $\mathrm{SU}(n+1)$] is exactly of complementary dimension to the stabilizer of the highest weight state.

The question arises now as to whether there are other representations and/or groups G which allow a similar decomposition. The answer is—unfortunately—no, i.e., we need some extensions to the above-presented picture in order to accommodate other groups. We discuss why there is such an obstruction in the Appendix.

The technique adopted in this paper has been limited in scope to unirreps of $\mathrm{SU}(n+1)$ with highest weights of the type $(\lambda, 0,...)$. However, it is possible to extend the formalism presented here to general irreps by suitably enlarging the subgroup over which the coherent states are defined. Irreps of the type $(\lambda, \mu, 0,...)$ are particularly interesting as they can be expected to have applications to the description of polarized beams. For irreps with highest weight $(\lambda, \mu, 0,...)$, the appropriate subgroup $\mathfrak{k}$ of $\mathrm{SU}(n+1)$ is $S(U(2)\times U(1)\times\ldots\times U(1))$: the basis states and the representation Γ will then be expressed[16] in terms of Wigner functions over this subgroup.

The major result of this paper is a realization of the $\mathrm{su}(n+1)$ Lie algebra (or, more precisely, of the complex extension of this algebra), appropriate for irreps with integral highest weights of the form $(\lambda, 0,...)$, for which basis functions and generators are expressed in terms of exponential functions and derivatives of phase angles. This would appear to be particularly suitable for applications to phase states, and for the study of the asymptotic limits of a representation and the appropriate limit of Wigner functions.

Although this has been done explicitly only for SU(2) and SU(3), the parameters which enter in the realization can be generally interpreted as projective coordinates, related to $\mathrm{SU}(n+1)$ Wigner functions, and understood physically as related to the distribution of λ photons between $n+1$ fields.

H.d.G. would like to acknowledge further support from the Faculté Saint-Jean of the University of Alberta, where part of this work was done. We would finally like to thank Barry Sanders for numerous discussions throughout this project.

APPENDIX A: HOW TO COUNT THE DIMENSION OF THE STABILIZER

In this section, we show why our construction only works for algebras which have A_n as their complexification, and for which representations of A_n our construction is possible.

Let $\mathfrak{h}$ be the Cartan subalgebra of a Lie algebra of one of the classical groups [i.e., $\mathrm{SU}(n)$, $\mathrm{SO}(2n+1)$, $\mathrm{Sp}(2n)$, $\mathrm{SO}(2n)$ or their noncompact versions]. A good comprehensive review of Lie algebra structure is Refs. 17 and 18.

Let f_α be a lowering operator corresponding to the positive root α: in order that $f_\alpha\chi_\lambda\neq 0$ it is necessary and sufficient that $(\alpha,\lambda)\geqslant 0$, where $(,)$ is the Killing form. Notice that such lowering operators form a nilpotent subalgebra: we denote by $\mathfrak{t}_\lambda$ the subset of positive roots for which $(\lambda,\alpha)>0$.

Now, let $\{\alpha_i\}_{i=1\ldots l}$ be a set of simple (positive) roots, $\{\omega_i\}_{i=1\ldots l}$ the corresponding set of weights, i.e., $(\omega_i,\alpha_j)=\delta_{ij}$.

Any dominant weight and positive root can be written as

$$\lambda=\sum_{i=1}^{n}\lambda_i\omega_i,\quad \lambda_i\in\mathbb{N}_+,\quad \alpha=\sum_{i=1}^{n}m_i\alpha_i,\quad m_i\in\mathbb{N}_+. \tag{A1}$$

Let us fix a fundamental weight ω_k (which is equivalent to choosing a node on the Dynkin diagram).

For a given Lie algebra $\mathfrak{g}$ (i.e., for a given Dynkin diagram) one can compute the number of roots in $\mathfrak{t}_{\omega_k}$ and check to see, as we choose different nodes of the Dynkin diagram, if there are sufficiently many roots to allow a decomposition of the type proposed in Eq. (35).

The results are here below (we refer to the Planches in Ref. 18).

(1) SU($n+1$) (A_n): choosing the kth node there are $k(n+1-k)$ positive roots in $\mathfrak{t}_{\omega_k}$. The minimum for $\mathfrak{t}_{\omega_k}$ is n, which occurs when $k=1$ or $k=n$. These choices correspond, respectively, to the representations $(\lambda, 0,...)$ or $(0,..., 0,\lambda)$.

(2) SO($2n+1$) ($B_n, n>1$): choosing the kth node there are $k+k(n-k)+k(n+1-k)=2k(n+1-k)$ positive roots in $\mathfrak{t}_{\omega_k}$. The minimum is $2n$, which is bigger than the rank n of the group: it is impossible to construct SO($2n+1$) on the torus.

(3) Sp($2n$) ($C_n, n>2$): choosing the kth node there are $k(n-k)+k+k=k(n+2-k)$ positive roots. The minimum is $n+1$, and this is again greater than the rank n of Sp($2n$).

(4) SO($2n$) (D_n): choosing the kth node there are $k(n-k)+k+k=k(n+2-k)$ positive roots, the minimum is $n+1$, which is also greater than the rank of the group.

As we see, the minimal number is equal to the rank of the algebra only for A_n.

APPENDIX B: A COHOMOLOGICAL PERSPECTIVE ON $\mathcal{S}$-MATRIX THEORY

We wish to draw the attention of the reader to the following interesting ''cohomological'' interpretation of the solution for the operator $\mathcal{S}$.

In the construction of the coefficients $\mathcal{S}_\nu$ of the operator $\mathcal{S}$ from the ratios of Eq. (77) as described above, it is not *a priori* clear that the coefficient $\mathcal{S}_\nu$ corresponding to a nontrivial partition ν defined starting from the trivial partition does not depend on the particular ''path'' we have followed to reach the given partition ν. Indeed—in general—there are different ways of getting to a given partition ν starting from the trivial one; for instance, we have

$$(\lambda,0,0,0,...)\overset{C_{21}}{\mapsto}(\lambda-1,1,0,0,...)\overset{C_{31}}{\mapsto}(\lambda-2,1,1,0,...) \quad \text{or} \tag{B1}$$

$$(\lambda,0,0,0,...)\overset{C_{31}}{\mapsto}(\lambda-1,0,1,0,...)\overset{C_{21}}{\mapsto}(\lambda-2,1,1,0,...). \tag{B2}$$

We have to make sure that the coefficient $\mathcal{S}_{(\lambda-2,1,1,0,...)}$ defined along these two different ''paths'' does not depend on the choice of path. We observe here that this in particular implies that the following *cocycle* condition holds

$$R_{\nu,\nu'}R_{\nu',\nu''}R_{\nu'',\nu}=1 \tag{B3}$$

for any partitions ν, ν', ν'' which are adjacent in the following sense: Two partitions ν, ν' of λ are said to be *adjacent* if there exist $i\neq j$ such that

$$\nu_k=\nu'_k+\delta_{ik}-\delta_{jk}, \quad k=1,...,n+1. \tag{B4}$$

Let us verify this fact and consider the small loop

$$\nu\overset{C_{ij}}{\to}\nu'\overset{C_{jk}}{\to}\nu''\overset{C_{ki}}{\to}\nu, \tag{B5}$$

$$\nu'_r=\nu_r+\delta_{ir}-\delta_{jr}, \quad \nu''_r=\nu'_r+\delta_{jr}-\delta_{kr}=\nu_k+\delta_{ir}-\delta_{kr}, \tag{B6}$$

and the associated cocycle condition

$$R_{\nu\nu'}R_{\nu\nu'}R_{\nu'\nu''}=\frac{y_{ji}^{*}(\lambda+\rho_i(\nu'))}{y_{ij}(\lambda+\rho_j(\nu))}\frac{y_{kj}^{*}(\lambda+\rho_j(\nu''))}{y_{jk}(\lambda+\rho_k(\nu'))}\frac{y_{ik}^{*}(\lambda+\rho_k(\nu))}{y_{ki}(\lambda+\rho_i(\nu''))}, \tag{B7}$$

which, according to Eq. (B3), should be 1.

Using the expressions for y_{ij}, it can be verified explicitly that, if we set $v_1\equiv 1$, then

$$\frac{(y_{ji})^{*}}{y_{ij}}=\left(\frac{v_j^{*}v_j}{v_i^{*}v_i}\right), \quad v_1\equiv 1. \tag{B8}$$

Using Eq. (B8), one sees at once that the y dependence drops out Eq. (B7). Moreover, since i, j, k are distinct indices, one checks also that

$$\rho_i(\nu'')=\rho_i(\nu'), \quad \rho_j(\nu'')=\rho_j(\nu), \quad \rho_k(\nu)=\rho_k(\nu'). \tag{B9}$$

Therefore Eq. (B7) is consistent with Eq. (B3). In a similar way, one can easily check that $R_{\nu,\nu'}=(R_{\nu',\nu})^{-1}$. This equation, together with Eq. (B7), define a *cocycle* over partitions.

(Received 12 March 2002; accepted for publication 13 March 2002)

A new integrable model which is a variant of the one-dimensional Hubbard model is proposed. The integrability of the model is verified by presenting the associated quantum R-matrix which satisfies the Yang–Baxter equation. We argue that the new model possesses the SO(4) algebra symmetry, which contains a representation of the η-pairing SU(2) algebra and a spin SU(2) algebra. Additionally, the algebraic Bethe ansatz is studied by means of the quantum inverse scattering method. The spectrum of the Hamiltonian, eigenvectors, as well as the Bethe ansatz equations, are discussed. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1481956]

I. INTRODUCTION

Since the discovery of high temperature superconductivity in cuprates,[1] a tremendous effort has been made to uncover the mystery of this phenomenon. It is generally believed that the strongly correlated electron systems behaving as non-Fermi liquids are closely related to superconducting materials. This has caused an intense study in strongly correlated electron systems.[2–7] These systems possess various physical characteristics which are decisively dominated by the competing interactions; e.g., the Coulomb interaction in the Hubbard model, spin fluctuations through the antiferromagnetic coupling for the super-symmetric t-J model and current-density correlated interaction inducing hole pairs of Cooper type superconductors in the one-dimensional (1D) Bariev model. The 1D Hubbard model as a prototype among the strongly correlated electron systems has attracted a substantial deal of interest in the study of integrable quantum field theory, mathematical physics and condensed matter physics since its exact solution was achieved by Lieb and Wu[8] in 1968. Towards a complete understanding of the mathematical structure of the 1D Hubbard model in the framework of the quantum inverse scattering method (QISM), a fundamental advance was achieved by Shastry[9] in demonstrating the integrability of the model. Specifically, it was shown that a two-dimensional statistical covering model of two coupled symmetric six vertex models provides a one parameter family of transfer matrices commuting with the Hamiltonian of the 1D Hubbard model. The algebraic formulation with respect to the integrability leads to the quantum R-matrix[9–12] which facilitates not only the algebraic Bethe ansatz solution,[13] but also the construction of the boost operator[14] for the model. Remarkably, the Hamiltonian of the Hubbard model was proved to exhibit the SO(4) symmetry by Yang and Zhang[15] (see also Ref. 16). Besides the spin SU(2) algebra, the SO(4) algebra contains the η-pair SU(2) algebra with the

[a]Electronic mail: guan@if.ufrgs.br

raising operator creating an on-site pair of electrons with opposite spins. This can be interpreted as a localized Cooper pair. A complete set of eigenstates of the Hamiltonian can be obtained by exploiting the SO(4) symmetry.[17]

The 1D Hubbard Hamiltonian with more competing interactions may also be considered. Along this line, many extended Hubbard models have been constructed in the literature, such as a $u(2|2)$ extended Hubbard model,[5] supersymmetric $U_q(\mathrm{osp}(2|2))$ electronic systems[18] and SU(N) Hubbard models.[19] In this article, we present an alternative 1D Hubbard model such that the Hamiltonian has off-site Coulomb interaction instead of the on-site one of the standard Hubbard model. The integrability of this model is verified by presenting the associated quantum R-matrix which fulfills the Yang–Baxter equation (YBE). We show that the model exhibits the SO(4) symmetry with new representations of the η-pairing SU(2) algebra and the ζ-pairing spin SU(2) algebra. Moreover, the algebraic Bethe ansatz is formulated by means of the QISM. Though the model exhibits the same spectrum as the standard Hubbard model on a periodic lattice, the new quantum R-matrix, the hidden nesting structure associated with an asymmetric isotropic six-vertex model and the Bethe eigenvectors do distinguish this model from the standard one.[9,10] The essential differences between the two models manifest in the open lattice versions, which we will discuss in more depth in the conclusion.

The article is organized as follows. In Sec. II, we introduce a Lax operator associated with the new Hubbard model and construct a nontrivial higher conserved quantity commuting with the Hamiltonian. In Sec. III, we present the R-matrix associated with the model by solving the Yang–Baxter relation. The SO(4) symmetry is verified too. In Sec. IV, we formulate the algebraic Bethe ansatz solutions for the model with periodic boundary conditions. The eigenvectors and eigenvalues of the Hamiltonian are presented explicitly. Section V is devoted to a discussion and conclusion.

II. THE MODEL

Let us begin by introducing a variant of the 1D Hubbard model with the Hamiltonian

$$H=\sum_{j=1}^{L}\{(\sigma_j^+\sigma_{j+1}^-+\sigma_j^-\sigma_{j+1}^+)+(\sigma\to\tau)\}+\frac{U}{4}\sum_{j=1}^{L}\sigma_j^z\tau_{j+1}^z. \tag{1}$$

Above σ_j and τ_j are the two commuting species of Pauli matrices acting on site j, and U is a Coulomb coupling constant. Above and throughout, periodic boundary conditions are imposed on all summations evaluated over the lattice length L. The difference from the standard Hubbard model is that the model (1) exhibits the off-site Coulomb interaction instead of the on-site one. We shall see that it not only breaks the spin reflection symmetry but also specifies a new representation of η-pairing SU(2) algebra and spin SU(2) algebra in order to maintain the SO(4) symmetry. To verify the integrability of the model, we, at first, identify a relation between the Hamiltonian (1) and the transfer matrix which is defined by

$$\tau(u)=Tr_0T(u) \tag{2}$$

with

$$T(u)=L_{0L}(u)\cdots L_{01}(u). \tag{3}$$

The local Lax operators associated with model (1) have to be alternatively chosen as

$$L_{0j}(u)=L_{0j}^{\sigma}(u)I_0^2L_{0j}^{\tau}(u) \tag{4}$$

$$=\begin{pmatrix} e^{h(u)}P_j^+Q_j^+ & e^{h(u)}P_j^+\tau_j^- & e^{-h(u)}\sigma_j^-Q_j^+ & e^{-h(u)}\sigma_j^-\tau_j^- \\ e^{-h(u)}P_j^+\tau_j^+ & e^{-h(u)}P_j^+Q_j^- & e^{h(u)}\sigma_j^-\tau_j^+ & e^{h(u)}\sigma_j^-Q_j^- \\ e^{h(u)}\sigma_j^+Q_j^+ & e^{h(u)}\sigma_j^+\tau_j^- & e^{-h(u)}P_j^-Q_j^+ & e^{-h(u)}P_j^-\tau_j^- \\ e^{-h(u)}\sigma_j^+\tau_j^+ & e^{-h(u)}\sigma_j^+Q_j^- & e^{h(u)}P_j^-\tau_j^+ & e^{h(u)}P_j^-Q_j^- \end{pmatrix}, \tag{5}$$

where

$$P_j^{\pm}=w_4(u)\pm w_3(u)\sigma^z;$$

$$Q_j^{\pm}=w_4(u)\pm w_3(u)\tau^z$$

with a parametrization $\gamma(u)=w_4(u)-w_3(u)=\sin(u)$; $\alpha(u)=w_4(u)+w_3(u)=\cos(u)$. We would like to mention that the Lax operators

$$L_{0j}^{\sigma}(u)=w_4(u)+w_3(u)\sigma_j^z\sigma_0^z+\sigma_j^+\sigma_0^-+\sigma_0^+\sigma_j^-, \tag{6}$$

$$L_{0j}^{\tau}(u)=w_4(u)+w_3(u)\tau_j^z\tau_0^z+\tau_j^+\tau_0^-+\tau_0^+\tau_J^-, \tag{7}$$

$$I_0=\cosh\frac{h(u)}{2}+\sigma_0^z\tau_0^z\sinh\frac{h(u)}{2}, \tag{8}$$

have been chosen the same as that for the Hubbard model.[9–11] It follows that the Hamiltonian (1) is related to the transfer matrix (2) in the following way:

$$\ln\tau(u)=\ln\tau(0)+Hu+\frac{1}{2!}Ju^2+\cdots, \tag{9}$$

above the Hamiltonian $H=\Sigma_{j=1}^{L}H_{j(j+1)}$ with the Hamiltonian density

$$H_{j(j+1)}=L_{0(j+1)}(0)L_{0j}'(0)L_{0j}^{-1}(0))L_{0(j+1)}^{-1}(0), \tag{10}$$

and the second higher conserved current can be given as

$$J=\sum_{j=1}^{L}J_{j(j+1)(j+2)} \tag{11}$$

with

$$J_{j(j+1)(j+2)}=B_{j(j+1)}-H_{j(j+1)}^2-[H_{j(j+1)},H_{(j+1)(j+2)}], \tag{12}$$

$$B_{j(j+1)}=L_{0(j+1)}(0)L_{0j}''(0)L_{0j}^{-1}(0)L_{0(j+1)}^{-1}(0). \tag{13}$$

Here the prime denotes the derivative with respect to spectral parameter u. After a straightforward calculation, the equation (10) does provide us with the expression (1), whereas the second conserved quantity (11) has the form

$$J_{j(j+1)(j+2)}=\frac{U}{2}\{[-\sigma_j^+\sigma_{j+1}^-+\sigma_j^-\sigma_{j+1}^+]\tau_{j+1}^z+[-\tau_j^+\tau_{j+1}^-+\tau_{j+1}^+\tau_j^-]+\sigma_j^z[-\sigma_j^+\sigma_{j+1}^- +\sigma_j^-\sigma_{j+1}^+]\tau_{j+2}^z+[-\tau_{j+1}^+\tau_{j+2}^-+\tau_{j+2}^+\tau_{j+1}^-]\sigma_j^z\}+[-\sigma_{j+2}^+\sigma_j^-+\sigma_j^+\sigma_{j+2}^-]\sigma_{j+1}^z +[-\tau_{j+2}^+\tau_j^-+\tau_j^+\tau_{j+2}^-]\tau_{j+1}^z. \tag{14}$$

Here we would like to stress that both the Hamiltonian (1) and the conserved quantity (11) should be understood as global operators. It is meant that $[H,J]=0$ rather than $[H_{j(j+1)},J_{j(j+1)(j+2)}]=0$. The mutual commutativity of H and J convinces us of the existence of a quantum R-matrix associated with the model (1). We shall present a rigorous proof of the integrability of the model in the next section.

III. INTEGRABILITY OF THE MODEL

It has long been clarified that the existence of the quantum R-matrix which fulfills the Yang–Baxter relation is desirable for constructing integrable quantum chains. This suggests to us a way to verify the integrability of the model presented above. Indeed, following Ref. 11, we, after a cumbersome algebraic calculation, can find a class of solutions to the Yang–Baxter relation

$$\overset{\vee}{R}(u,v)L_{0j}(u)\otimes L_{0j}(v)=L_{0j}(v)\otimes L_{0j}(u)\overset{\vee}{R}(u,v), \tag{15}$$

which is given as

$$\overset{\vee}{R}(u,v) = \begin{pmatrix}
\rho_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & \rho_2^- & 0 & 0 & \rho_9 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & \rho_2^+ & 0 & 0 & 0 & 0 & 0 & \rho_9 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & \rho_5 & 0 & 0 & \rho_6^+ & 0 & 0 & \rho_6^- & 0 & 0 & \rho_8 & 0 & 0 & 0\\
0 & \rho_{10} & 0 & 0 & \rho_2^+ & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & \rho_4 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & \rho_6^- & 0 & 0 & \rho_3 & 0 & 0 & \rho_7 & 0 & 0 & \rho_6^+ & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & \rho_2^- & 0 & 0 & 0 & 0 & 0 & \rho_{10} & 0 & 0\\
0 & 0 & \rho_{10} & 0 & 0 & 0 & 0 & 0 & \rho_2^- & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & \rho_6^+ & 0 & 0 & \rho_7 & 0 & 0 & \rho_3 & 0 & 0 & \rho_6^- & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \rho_4 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \rho_2^+ & 0 & 0 & \rho_{10} & 0\\
0 & 0 & 0 & \rho_8 & 0 & 0 & \rho_6^- & 0 & 0 & \rho_6^+ & 0 & 0 & \rho_5 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & \rho_9 & 0 & 0 & 0 & 0 & 0 & \rho_2^+ & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \rho_9 & 0 & 0 & \rho_2^- & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \rho_1
\end{pmatrix}, \tag{16}$$

with the Boltzmann weights

$$\rho_1=(\cos u\cos v e^{l}+\sin v\sin u e^{-l})\rho_2,$$

$$\rho_4=(\cos u\cos v e^{-l}+\sin v\sin u e^{l})\rho_2,$$

$$\rho_9=(\sin u\cos v e^{-l}-\sin v\cos u e^{l})\rho_2,$$

$$\rho_{10}=(\sin u\cos v e^{l}-\sin v\cos u e^{-l})\rho_2,$$

$$\rho_2^{+}=e^{l}\rho_2,\quad \rho_2^{-}=e^{-l}\rho_2,$$

$$\rho_3=\frac{(\cos u\cos v e^{l}-\sin v\sin u e^{-l})}{\cos^2 u-\sin^2 v}\rho_2,$$

$$\rho_5=\frac{(\cos u\cos v e^{-l}-\sin v\sin u e^{l})}{\cos^2 u-\sin^2 v}\rho_2,$$

$$\rho_6^{+}=\frac{(\cos u\sin u e^{-l}-\sin v\cos v e^{l})}{\cos^2 u-\sin^2 v}\rho_2,$$

$$\rho_6^{-}=\frac{(\cos u\sin u e^{l}-\sin v\cos v e^{-l})}{\cos^2 u-\sin^2 v}\rho_2$$

and

$$\rho_8=\rho_3-\rho_1,$$

$$\rho_7=\rho_5-\rho_4, \tag{17}$$

$$l=h(u)-h(v),\quad i\qquad \frac{\sinh 2h(u)}{\sin 2u}=\frac{U}{2},$$

which enjoy the following identities:

$$\rho_4\rho_1+\rho_9\rho_{10}=1,$$

$$\rho_1\rho_5+\rho_3\rho_4=2,$$

$$\rho_6^{+}\rho_6^{-}=\rho_3\rho_5-1.$$

This R-matrix with more distinct Boltzmann weights is indeed different from the one for the standard Hubbard model[9–11] and a twisted version[20] which is associated with the Hubbard model with chemical potential terms. Running a Maple program we may check that the R-matrix satisfies the Yang–Baxter equation

$$R_{12}(u,v)R_{13}(u,w)R_{23}(v,w)=R_{23}(v,w)R_{13}(u,w)R_{12}(u,v). \tag{18}$$

So far we have built up the QISM mechanism for the alternative Hubbard model and concluded the integrability of the model as well. On the other hand, a fermionic model is always favorable in the study of the condensed matter physics due to the clear distinction between the fermionic degrees of freedom and bosonic degrees of freedom. By performing the Jordan–Wigner transformations,[11,21] one may obtain the Hamiltonian of a fermionic model which is equivalent to the Hubbard model (1):

$$H=-\sum_{j=1}^{N-1}\sum_{s}(a_{(j+1)s}^{\dagger}a_{js}+a_{js}^{\dagger}a_{(j+1)s})+U\sum_{j=1}^{N}\left(n_{j\uparrow}-\frac{1}{2}\right)\left(n_{(j+1)\downarrow}-\frac{1}{2}\right). \tag{19}$$

Above $a_{js}^{\dagger}$ and a_{js} are creation and annihilation operators with spins ($s=\uparrow$ or $\downarrow$) at site j satisfying the anti-commutation relations

$$\{a_{js},a_{j's'}\}=\{a_{js}^{\dagger},a_{j's'}^{\dagger}\}=0, \tag{20}$$

$$\{a_{js},a_{j's'}^{\dagger}\}=\delta_{jj'}\delta_{ss'}, \tag{21}$$

and $n_{js}=a_{js}^{\dagger}a_{js}$ is the density operator. The integrability of the fermionic model (19) requires that the graded Lax operator related to the Hamiltonian (19),

$$\mathcal{L}_{0j}(u)=\begin{pmatrix} -e^{h(u)}f_{j\uparrow}f_{j\downarrow} & -e^{h(u)}f_{j\uparrow}a_{j\downarrow} & \mathrm{i}e^{-h(u)}a_{j\uparrow}g_{j\downarrow} & \mathrm{i}e^{-h(u)}a_{j\uparrow}a_{j\downarrow} \\ -\mathrm{i}e^{-h(u)}f_{j\uparrow}a_{j\downarrow}^{\dagger} & e^{-h(u)}f_{j\uparrow}g_{j\downarrow} & e^{h(u)}a_{j\uparrow}a_{j\downarrow}^{\dagger} & \mathrm{i}e^{h(u)}a_{j\uparrow}g_{j\downarrow} \\ e^{h(u)}a_{j\uparrow}^{\dagger}f_{j\downarrow} & e^{h(u)}a_{j\uparrow}^{\dagger}a_{j\downarrow} & e^{-h(u)}g_{j\uparrow}f_{j\downarrow} & e^{-h(u)}g_{j\uparrow}a_{j\downarrow} \\ -\mathrm{i}e^{-h(u)}a_{j\uparrow}^{\dagger}a_{j\downarrow}^{\dagger} & e^{-h(u)}a_{j\uparrow}^{\dagger}g_{j\downarrow} & \mathrm{i}e^{h(u)}g_{j\uparrow}a_{j\downarrow}^{\dagger} & -e^{h(u)}g_{j\uparrow}g_{j\downarrow} \end{pmatrix}, \tag{22}$$

must generate the graded Yang–Baxter relation

$$\overset{\vee}{\mathcal{R}}(u,v)\mathcal{L}_{0j}(u)\otimes\mathcal{L}_{0j}(v)=\mathcal{L}_{0j}(v)\otimes\mathcal{L}_{0j}(u)\overset{\vee}{\mathcal{R}}(u,v), \tag{23}$$

with the graded R-matrix which is given by

$$\overset{\vee}{\mathcal{R}}(u,v)=W\overset{\vee}{R}(u,v)W^{-1}, \tag{24}$$

where

$$W=\sigma^{z}\otimes\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -\mathrm{i} & 0 & 0 \\ 0 & 0 & -\mathrm{i} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}\otimes I \tag{25}$$

and

$$f_{js}=\sin u-(\sin u-\mathrm{i}\cos u)n_{js},\quad g_{js}=\cos u-(\cos u+\mathrm{i}\sin u)n_{js}, \tag{26}$$

with the grading $P(1)=P(4)=0$, $P(2)=P(3)=1$. The monodromy matrix is defined by

$$\mathcal{T}(u)=\mathcal{L}_{0L}(u)\cdots\mathcal{L}_{01}(u), \tag{27}$$

such that the transfer matrices

$$\tau(u)=\mathrm{str}_{0}\mathcal{T}(u) \tag{28}$$

commute each other for different values of the parameter u. It can be verified that an expansion of the logarithm of the transfer matrix (28) in powers of u will lead to the Hamiltonian (19) as well as higher conserved quantities.

We would like to remark that the model possesses the SO(4) symmetry if we consider a new representation of the η-pair SU(2) algebra,

$$\eta=\sum_{i=1}^{L}(-1)^{i}a_{i\uparrow}a_{(i+1)\downarrow},\quad \eta^{\dagger}=(\eta)^{\dagger},\quad \eta_{z}=\frac{1}{2}\sum_{i=1}^{L}(n_{i\uparrow}+n_{i\downarrow})-\frac{1}{2}L, \tag{29}$$

and the ζ-pair spin SU(2) algebra

$$\zeta=\sum_{i=1}^{L} a_{i\uparrow}^{\dagger}a_{(i+1)\downarrow}, \quad \zeta^{\dagger}=(\zeta)^{\dagger}, \quad \zeta_z=\frac{1}{2}\sum_{i=1}^{L}(n_{(i+1)\downarrow}-n_{i\uparrow}), \tag{30}$$

which comprise the SO(4) algebra. Taking into account the globality of these operators, one may show that the Hamiltonian (19) commutes with the generators of the above two SU(2) algebras. This symmetry could be expected to complete all eigenstates of the Hubbard model like the case in the standard Hubbard model. Here the η-pairing raising operator creating a pair of electrons with opposite spin on different sites could be interpreted as a delocalized Cooper pair.

IV. ALGEBRAIC BETHE ANSATZ

Towards an exact solution of an integrable model, the algebraic Bethe ansatz seems to have more utility than the coordinate Bethe ansatz because the former not only provides us with the spectrum of all conserved quantities, but makes a close connection to the finite temperature properties of the model. There have been a lot of papers devoted to the study of the nested algebraic Bethe ansatz[22] for the multistate integrable models with Lie algebra (or Lie superalgebra) symmetry. Following the so-called ABCDF approach to solve the Hubbard-like models,[13,23] we shall formulate the algebraic Bethe ansatz for the model in that which follows. To this end, as usual, we have to perform the ansatz step by step. However, it is not necessary to restate all of the calculations used in solving our model because of the similarity to the routine proposed in Ref. 13.

In order to carry out the algebraic Bethe ansatz for this Hubbard model, we first need to find the eigenvalues and eigenvectors of the transfer matrix (28):

$$\tau|\Phi_n\rangle=\lambda|\Phi_n\rangle. \tag{31}$$

Following the prescription in Ref. 13, the eigenvectors of the transfer matrix are given by

$$|\Phi_n\rangle=\mathbf{\Phi_n}.\mathcal{F}|0\rangle, \tag{32}$$

where the components of $\mathcal{F}$ are coefficients of an arbitrary linear combination of vectors $\mathbf{\Phi_n}$ and $|0\rangle$ is the pseudovacuum state, chosen here as the standard ferromagnetic one

$$|0\rangle=\otimes_{j=1}^{N}|0\rangle_j, \tag{33}$$

where

$$|0\rangle_i=\begin{pmatrix}1\\0\end{pmatrix}_i\otimes\begin{pmatrix}1\\0\end{pmatrix}_i \tag{34}$$

which corresponds to the doubly occupied state. We write the monodromy matrix $\mathcal{T}(u)$ in (27) as

$$\mathcal{T}(u)=\begin{pmatrix} B(u) & B_1(u) & B_2(u) & F(u)\\ C_1(u) & A_{11}(u) & A_{12}(u) & E_1(u)\\ C_2(u) & A_{21}(u) & A_{22}(u) & E_2(u)\\ C_3(u) & C_4(u) & C_5(u) & D(u)\end{pmatrix} \tag{35}$$

such that the necessary commutation relations between the diagonal fields and the creation fields can be derived from the Yang–Baxter algebra

$$\mathcal{R}_{12}(u,v)\overset{1}{\mathcal{T}}(u)\overset{2}{\mathcal{T}}(v)=\overset{2}{\mathcal{T}}(v)\overset{1}{\mathcal{T}}(u)\mathcal{R}_{12}(u,v). \tag{36}$$

In the above,

$$\mathcal{R}_{12}(u,v)=\mathcal{P}\check{R}(u,v).$$

Here $\mathcal{P}$ is the graded permutation operator. Let us first display an important commutation role, which reveals to us a hidden nesting structure and the symmetry of eigenvectors,

$$\vec{B}(u)\vec{B}(v)=\frac{\rho_4(u,v)}{\rho_1(u,v)}\vec{B}(v)\vec{B}(u)\cdot\hat{r}(u,v)+\frac{\mathrm{i}}{\rho_8(u,v)\rho_1(u,v)}F(v)B(u)\vec{\xi}_1(u,v)$$
$$+\frac{\mathrm{i}}{\rho_8(u,v)}F(u)B(v)\vec{\xi}_2(u,v), \tag{37}$$

where

$$\vec{\xi}_1(u,v)=(0,f_1(u,v),f_2(u,v),0);\quad \vec{\xi}_2(u,v)=(0,\rho_6^+(u,v),\rho_6^-(u,v),0),$$

$$\hat{r}(u,v)=\begin{pmatrix}1&0&0&0\\0&a(u,v)&b(u,v)&0\\0&c(u,v)&d(u,v)&0\\0&0&0&1\end{pmatrix}, \tag{38}$$

with

$$f_1(u,v)=\rho_6^-(u,v)\rho_8(u,v)-\rho_6^+(u,v)\rho_5(u,v),$$

$$f_2(u,v)=\rho_6^-(u,v)\rho_5(u,v)-\rho_6^+(u,v)\rho_8(u,v),$$

$$a(u,v)=\frac{\rho_3(u,v)\rho_8(u,v)-\rho_6^+(u,v)^2}{\rho_4(u,v)\rho_8(u,v)},$$

$$d(u,v)=\frac{\rho_3(u,v)\rho_8(u,v)-\rho_6^-(u,v)^2}{\rho_4(u,v)\rho_8(u,v)},$$

$$b(u,v)=c(u,v)=\frac{\rho_6^+(u,v)\rho_6^-(u,v)-\rho_8(u,v)\rho_7(u,v)}{\rho_4(u,v)\rho_8(u,v)}.$$

It turns out that the auxiliary matrix $\hat{r}(u,v)$ is nothing but a gauged rational R-matrix of an isotropic six-vertex model. If we adopt the parametrization introduced in Ref. 13 or 24, explicitly,

$$\tilde{x}=-\frac{\sin x}{\cos x}e^{-2h(x)}+\frac{\cos x}{\sin x}e^{2h(x)},\quad x=u,v, \tag{39}$$

one may find that

$$a(u,v)=-\frac{Ue^{-\theta(u,v)}}{\tilde{u}-\tilde{v}-U},\quad d(u,v)=-\frac{Ue^{\theta(u,v)}}{\tilde{u}-\tilde{v}-U},$$

$$b(u,v)=c(u,v)=\frac{\tilde{u}-\tilde{v}}{\tilde{u}-\tilde{v}-U},$$

with

$$e^{-\theta(u,v)}=\frac{\cos v\,\sin u}{\sin v\cos u}.$$

We shall see that the $\hat{r}$-matrix (38) is related to the one of the isotropic six-vertex model via a proper gauge transformation, which does not change the spectrum of the spin sector. This seems to provide a new version of the R-matrix, which does not have the difference property, for the isotropic six-vertex model. In view of the commutation relation (37), the creation operators $\vec{B}_a$, $\vec{E}_a$ do not intertwine. So it is reasonable that the eigenvectors of the transfer matrices are generated only by the creation operators $\vec{B}_a(u)$ and $F(u)$. Following the argument in Ref. 13, we may find that the n-particle vector can be determined recursively by the following relation:

$$\Phi_n(v_1,\ldots,v_n)=\vec{B}(v_1)\otimes\Phi_{n-1}(v_2,\ldots,v_n)+\sum_{j=2}^{n}\frac{1}{\mathrm{i}\rho_8(v_1,v_j)}\prod_{k\neq j}^{n}\frac{\rho_1(v_k,v_j)}{\mathrm{i}\rho_9(v_k,v_j)}[\vec{\xi}_2(v_1,v_j)$$
$$\otimes F(v_1)\Phi_{n-2}(v_2,\ldots,v_{j-1},v_{j+1},\ldots,v_n)B(v_j)]\prod_{k=2}^{j-1}\frac{\rho_4(v_k,v_j)}{\rho_1(v_k,v_j)}\hat{r}_{k,k+1}(v_k,v_j). \tag{40}$$

Explicitly, the two-particle eigenvector reads

$$\Phi_2(v_1,v_2)=\vec{B}(v_1)\otimes\vec{B}(v_2)+\vec{\xi}_2(v_1,v_2)\otimes F(v_1)B(v_2)\frac{1}{\mathrm{i}\rho_8(v_1,v_2)}. \tag{41}$$

From the commutation relation (37), we can conclude that $\Phi_n(v_1,\ldots,v_n)$ satisfies an exchange symmetry relation

$$\Phi_n(v_1,\ldots,v_j,v_{j+1},\ldots,v_n)=\frac{\rho_4(v_j,v_{j+1})}{\rho_1(v_j,v_{j+1})}\Phi_n(v_1,\ldots,v_{j+1},v_j,\ldots,v_n)\cdot\hat{r}_{j,j+1}(v_j,v_{j+1}) \tag{42}$$

based on the following identity:

$$\frac{\rho_4(v_j,v_{j+1})}{\rho_1(v_{j+1},v_j)\rho_8(v_{j+1},v_j)\rho_1(v_j,v_{j+1})}\vec{\xi}_1(v_{j+1},v_j)\cdot\hat{r}(v_j,v_{j+1})$$
$$=-\frac{1}{\rho_8(v_j,v_{j+1})}\vec{\xi}_2(v_j,v_{j+1}). \tag{43}$$

In the above expressions, $\vec{\xi}$ plays the role of forbidding two spin up or two spin down electrons at same site. Also, $F(u)$ creates a local hole pair with opposite spins. In order to manipulate the eigenvalue of the transfer matrix (28) we need the commutation roles involving the diagonal fields over the creation fields. After some algebra, from the Yang–Baxter relation (36) we have

$$B(u)\vec{B}_a(v)=\frac{\rho_1(v,u)}{\mathrm{i}\rho_9(v,u)}\vec{B}_a(v)B(u)-\frac{1}{\mathrm{i}\rho_9(v,u)}\vec{B}_a(u)B(v)\cdot\hat{\eta}_1(v,u), \tag{44}$$

$$D(u)\vec{B}_a(v)=\frac{\mathrm{i}\rho_{10}(u,v)}{\rho_8(u,v)}\vec{B}_a(v)D(u)-\frac{1}{\rho_8(v,u)}F(v)\vec{C}^*_{a+3}(u)\cdot\hat{\eta}_1(u,v)$$
$$+\frac{\rho_5(u,v)}{\rho_8(u,v)}F(u)\vec{C}^*_{a+3}(v)+\frac{\mathrm{i}}{\rho_8(u,v)}\vec{\xi}_2(u,v)\cdot(\vec{E}^*(u)\otimes\hat{A}(v)), \tag{45}$$

$$\hat{A}_{ab}(u)\vec{B}_a(v)=\frac{\mathrm{i}\rho_4(u,v)}{\rho_9(u,v)}\vec{B}(v)\otimes\hat{A}(u)\cdot\hat{r}(u,v)-\frac{\mathrm{i}}{\rho_9(u,v)}\hat{\eta}_2(u,v)\cdot\vec{B}(u)\otimes\hat{A}(v)$$
$$+\frac{1}{\rho_9(u,v)\rho_8(u,v)}\{F(v)\vec{C}_{3-a}(u)\otimes\vec{\xi}_1(u,v)+\hat{\eta}_2(u,v)\cdot F(u)\vec{C}_{3-a}(v)$$
$$\otimes\vec{\xi}_2(u,v)\}+\frac{1}{\rho_8(u,v)}\vec{E}^*(u)B(v)\otimes\vec{\xi}_2(u,v). \tag{46}$$

Above we introduced the notations

$$\hat{\eta}_1(u,v)=\begin{pmatrix}\rho_2^+(u,v) & 0\\ 0 & \rho_2^-(u,v)\end{pmatrix},$$

$$\hat{\eta}_2(u,v)=\begin{pmatrix}\rho_2^-(u,v) & 0\\ 0 & \rho_2^+(u,v)\end{pmatrix},$$

$$\hat{A}(u)=\begin{pmatrix}A_{11}(u) & A_{12}(u)\\ A_{21}(u) & A_{22}(u)\end{pmatrix}, \tag{47}$$

$$\vec{B}=(B_1,B_2),\quad \vec{C}=\begin{pmatrix}C_1\\ C_2\end{pmatrix},$$

$$\vec{C}^*=(C_4,C_5),\quad \vec{E}^*=\begin{pmatrix}E_1\\ E_2\end{pmatrix}.$$

In order to determine the eigenvalue of the transfer matrix (28) acting on the mult-particle eigenstates we need to consider the commutation relations for the creation field $F(u)$:

$$B(u)F(v)=-\frac{\rho_1(v,u)}{\rho_8(v,u)}F(v)B(u)+\frac{\rho_5(v,u)}{\rho_8(v,u)}F(u)B(v)-\frac{\mathrm{i}}{\rho_8(v,u)}[\vec{B}(u)\otimes\vec{B}(v)]\cdot\vec{\xi}_2^t(v,u), \tag{48}$$

$$D(u)F(v)=-\frac{\rho_1(v,u)}{\rho_8(v,u)}F(v)D(u)+\frac{\rho_5(v,u)}{\rho_8(v,u)}F(u)D(v)+\frac{\mathrm{i}}{\rho_8(v,u)}\vec{\xi}_2(v,u)\cdot[\vec{E}^*(u)\otimes\vec{E}^*(v)], \tag{49}$$

$$\hat{A}(u)F(v)=\left[1-\frac{\rho_2^+(u,v)\rho_2^-(u,v)}{\rho_9(u,v)\rho_{10}(u,v)}\right]F(v)\hat{A}(u)+\frac{1}{\rho_9(u,v)\rho_{10}(u,v)}\hat{\eta}_2(u,v)\cdot F(u)\hat{A}(v)\cdot\hat{\eta}_2(u,v)$$
$$+\frac{1}{\mathrm{i}\rho_9(u,v)}\hat{\eta}_2(u,v)\cdot\vec{B}(u)\otimes\vec{E}^*(v)-\frac{1}{\mathrm{i}\rho_{10}(u,v)}\vec{E}^*(u)\otimes\vec{B}(v)\cdot\hat{\eta}_2(u,v), \tag{50}$$

$$\vec{B}(u)F(v)=\frac{\mathrm{i}\rho_9(u,v)}{\rho_1(u,v)}F(v)\vec{B}(u)+\frac{1}{\rho_1(u,v)}\hat{\eta}_2(u,v)\cdot\vec{B}(v)F(u), \tag{51}$$

$$F(u)\vec{B}(v)=-\frac{\mathrm{i}\rho_{10}(u,v)}{\rho_1(u,v)}\vec{B}(v)F(u)+\frac{1}{\rho_1(u,v)}\hat{\eta}_1(u,v)\cdot F(v)\vec{B}(u). \tag{52}$$

Finally, if we adopt the variables $z_\pm(v_i)$ used in Ref. 13, i.e.,

$$z_-(v_i)=\frac{\cos v_i}{\sin v_i}e^{2h(v_i)},\quad z_+(v_i)=\frac{\sin v_i}{\cos v_i}e^{2h(v_i)},\tag{53}$$

and make a shift on the spin rapidity $\tilde{\lambda}_j=\tilde{\lambda}_j+U/2$, the eigenvalue of the transfer matrix (28) is given as (up on a common factor)

$$\begin{aligned}\tau(u)|\Phi_n(v_1,\ldots,v_n)\rangle=\Bigg\{&[z_-(u)]^L\prod_{i=1}^{n}\frac{\sin u(1+z_-(v_i)/z_+(u))}{\cos u(1-z_-(v_i)/z_-(u))}\\&+[z_+(u)]^L\prod_{i=1}^{n}\frac{\sin u(1+z_-(v_i)z_-(u))}{\cos u(1-z_-(v_i)z_+(u))}\\&-\prod_{i=1}^{n}\frac{\sin u(1+z_-(v_i)/z_+(u))}{\cos u(1-z_-(v_i)/z_-(u))}\prod_{l=1}^{M}\frac{(\tilde{u}-\tilde{\lambda}_l+U/2)}{(\tilde{u}-\tilde{\lambda}_l-U/2)}\\&+\prod_{i=1}^{n}\frac{\sin u(1+z_-(v_i)z_-(u))}{\cos u(1-z_-(v_i)z_+(u))}\prod_{l=1}^{M}\frac{(\tilde{u}-\tilde{\lambda}_l-3U/2)}{(\tilde{u}-\tilde{\lambda}_l-U/2)}\Bigg\}|\Phi_n(v_1,\ldots,v_n)\rangle,\end{aligned}\tag{54}$$

provided that

$$[z_-(v_i)]^L=\prod_{l=1}^{M}\frac{(\tilde{v}_i-\tilde{\lambda}_l+U/2)}{(\tilde{v}_i-\tilde{\lambda}_l-U/2)},\tag{55}$$

$$\prod_{i=1}^{n}\frac{(\tilde{\lambda}_j-\tilde{v}_i+U/2)}{(\tilde{\lambda}_j-\tilde{v}_i-U/2)}=-\prod_{\substack{l=1,\\ l\neq j,}}^{M}\frac{(\tilde{\lambda}_j-\tilde{\lambda}_l+U)}{(\tilde{\lambda}_j-\tilde{\lambda}_l-U)},\tag{56}$$

where

$$j=1,\ldots M,\quad i=1,\ldots,n.$$

If we express the variable $z_-(u_i)$ in terms of the (hole) momenta k_i by $z_-(u_i)=e^{ik_i}$, from the relation (39), the energy is given by

$$E_n=-(N/2-n)U-\sum_{i=1}^{n}2\cos k_i.\tag{57}$$

Using the momenta k_i instead of the charge rapidity $\tilde{v}_i$ via the relation (39) and making a scaling on the spin rapidity $\tilde{\lambda}_j$ as $\lambda_j=-(i/2)\tilde{\lambda}_j$, then the Bethe equations (55) and (56) read

$$e^{iLk_i}=\prod_{l=1}^{M}\frac{(\sin k_i-\lambda_l-iU/4)}{(\sin k_i-\lambda_l+iU/4)},$$

$$\prod_{i=1}^{n}\frac{(\sin k_i-\lambda_j-iU/4)}{(\sin k_i-\lambda_j+iU/4)}=-\prod_{\substack{l=1,\\ l\neq j}}^{M}\frac{(\lambda_j-\lambda_l+iU/2)}{(\lambda_j-\lambda_l-iU/2)},\tag{58}$$

$$j=1,\ldots M,\quad i=1,\ldots,n.$$

V. CONCLUSIONS AND DISCUSSION

We have proposed an integrable variant of the Hubbard model with off-site Coulomb interaction. The integrability of the model was verified by showing that the quantum R-matrix satisfies the Yang–Baxter equation. It was argued that the model possess SO(4) symmetry, however, it contains a new representation of η-pairing SU(2) algebra and ζ-pair spin SU(2) algebra. By means of the nested Bethe ansatz, we have presented the spectrum of the Hamiltonian, eigenvectors and the Bethe ansatz equations for the model with periodic boundary conditions. We found that the model exhibits a gauged r-matrix of the isotropic XXX model, which plays a crucial role in solving the model. Under periodic boundary conditions the alternative model and the standard Hubbard model share the same spectrum and Bethe ansatz equations. However, the new R-matrix we obtained permits different boundary conditions from that for the usual one.[25,26] This is meant that there does not exist simple transformation or gauge transformation between the new R-matrix and the original one. In turn, the differences in spectrum for the two models would be apparent in the case of open boundary conditions. We would like to remark that the 1D Hubbard model with long range Coulomb interaction, i.e., $U\Sigma_{j=1}^{N}(n_{j\uparrow}-\frac{1}{2})(n_{(j+r)\downarrow}-\frac{1}{2})$, $r=1,2,\ldots$, instead of the on-site one in the standard Hubbard model would be also integrable. But this type of interaction would result in nondiagonal boundary scattering matrices which provide competing interaction terms in the Hamiltonain. This seems to open an opportunity to identify new boundary impurity effects[27–29] in a Luttinger liquid. An interesting problem is to identify the boost operator for the spectral parameter extension of this new model, which can iteratively generate all of the conserved currents, using the results of Ref. 14. We shall be focusing on these problems in the near future.

(Received 10 January 2002; accepted for publication 10 February 2002)

We give a rigorous renormalization analysis of the self-similarity of correlation functions in a quasiperiodically forced two-level system. More precisely, the system considered is a quantum two-level system in a time-dependent field consisting of periodic kicks with amplitude given by a discontinuous modulation function driven in a quasiperiodic manner at golden mean frequency. Mathematically, our analysis consists of a description of all piecewise-constant periodic orbits of an additive functional recurrence. We further establish a criterion for such orbits to be globally bounded functions. In a particular example, previously only treated numerically, we further calculate explicitly the asymptotic height of the main peaks in the correlation function. © *2002 American Institute of Physics.*

I. INTRODUCTION

A number of authors have investigated the possibility of the existence of dynamics with singular continuous spectrum in quasiperiodically forced two-level quantum systems.[2,5,10] In these works, such a spectrum—suggestive of a form of weak mixing—is observed in the presence of piecewise-constant discontinuous forcing. Moreover, for the forcing frequencies considered, the autocorrelation function is observed not only neither to decay to zero nor to return to unity repeatedly, but also to possess an asymptotic self-similar structure. (We shall confine our description of the form of the dynamics to one of the nature of the autocorrelation function.) This self-similarity suggests that a renormalization analysis is appropriate to help understand this phenomenon, and this is indeed the content of the analysis of Feudel *et al.* in Ref. 5. There have, in addition, been many other studies of the response of two-level systems to quasiperiodic forcing, but we shall concentrate on the self-similarity aspects here. (See, for instance, the references in Ref. 5, and also Refs. 1, 3, and 15 to mention but a few.)

As is implicit in some of the works cited above (and is explicitly acknowledged in Ref. 5), there is much in common between the response of these quantum systems and the nature of strange nonchaotic attractors. Consequently, our work here will have important implications in that context, too.

In this article we give a rigorous renormalization analysis explaining and generalizing the numerical results in Ref. 5. Because of its number-theoretic simplicity, most analysis has been concerned with the case of forcing at golden mean frequency, and this article will be no exception. The self-similar structure is then explained by means of the additive functional recurrence

$$Z_n(x) = Z_{n-1}(-\omega x) + Z_{n-2}(\omega^2 x + \omega), \tag{1.1}$$

where $\omega = (\sqrt{5}-1)/2$ is the golden mean.

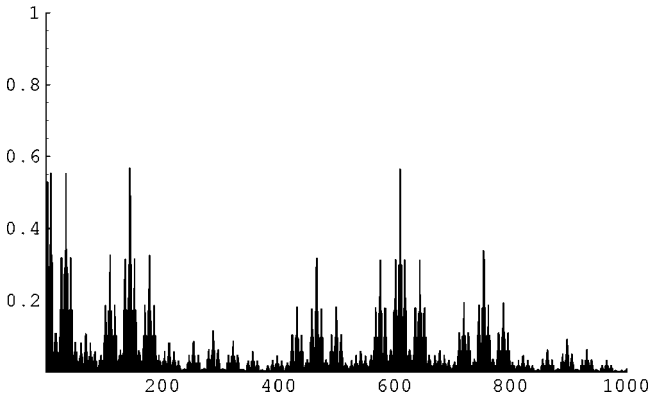

FIG. 1. Autocorrelation function K_{P_y} for modulation function (1.29) and $\kappa=\pi/2$.

The multiplicative version of (1.1) has been previously studied in some detail. It naturally appears in seemingly disparate contexts. First, it arises in the analysis of the self-similar fluctuations of the localized eigenstates of the Harper equation.[7] Second, it helps explain universal characteristics present in the birth of a strange nonchaotic attractor.[9] In Ref. 8 these two phenomena are indeed linked. It further arises in the analysis of the autocorrelation function of the orbit on a strange nonchaotic attractor.[4] (In each of these contexts the recurrence arises when the frequency parameter ω is taken to be the golden mean.)

In Ref. 11 we proved that there exists a fixed point of the multiplicative version of (1.1) of the type numerically found in Ref. 7. [To do this at times we considered the additive recurrence (1.1) in our proof.] In Ref. 12 we gave a description of all of its piecewise-constant periodic orbits, thereby providing a mathematical understanding of, and generalizing, the numerical observations in Ref. 4. In a forthcoming work[13] we give an analysis of its analytic periodic orbits, thereby explaining the beautiful ''orchid'' picture of Ketoja and Satija[7] arising in a generalized Harper equation. We expect this analysis can be adapted to the birth of a strange nonchaotic attractor scenario.[9]

In this article we describe all piecewise-constant periodic orbits of (1.1). Further, we characterize those periodic orbits which are globally bounded. As a consequence, it follows that the autocorrelation functions are indeed asymptotically self-similar for a wide class of piecewise-constant forcing functions. The precise locations of the discontinuities of these functions are, however, crucial. See Fig. 1 for an example of such an autocorrelation function. Much of our analysis of the multiplicative recurrence in Ref. 12 can be adapted to the additive case (1.1), and we begin by doing this in Sec. II. There are some important differences to be taken into account, too. The piecewise-constant periodic orbits of the multiplicative problem consist of functions taking values ± 1 only, and, as a consequence, an analysis of the discontinuities suffices to determine periodicity. In the additive problem there is no such restriction. In Sec. II F we establish a criterion to guarantee periodicity in this case. Moreover, it is quite simple to find piecewise-constant periodic orbits of the additive recurrence that are spatially unbounded. We identify the nature of the locations of the discontinuities of Z_n on the whole of $\mathbb{R}$ in Sec. III, and use this information, in Sec. IV, to establish a criterion to distinguish those periodic orbits that are spatially bounded. In Sec. V we look in detail at the particular example studied numerically by Feudel *et al.* in Ref. 5 resulting in the period-6 orbit shown in Fig. 2. For this example we calculate the averages of the function Z_n which give the asymptotic height of the main peaks in the corresponding correlation function, which is shown in Fig. 1. As a consequence, we show that the asymptotic height of the peaks in Fig. 1 is $1-1/\sqrt{5}=0.552\,786\ldots$.

In the remainder of this introduction we describe the system under consideration more precisely, and, following Ref. 5, indicate how the recurrence (1.1) arises in the analysis of its autocorrelation functions.

A. Formulation of the equations of motion

The Hamiltonian of a two-level system in a time-dependent magnetic field $B(t)$ takes the form $H=B(t)\cdot\sigma$, where $\sigma=(\sigma_x,\sigma_y,\sigma_z)$ consists of the Pauli spin matrices

$$\sigma_x=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_y=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma_z=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{1.2}$$

Following the previous authors, we consider the special case $B(t)=(S(t)/2,0,k/2)$, which gives the Hamiltonian

$$H(t)=\tfrac{1}{2}k\sigma_z+\tfrac{1}{2}S(t)\sigma_x. \tag{1.3}$$

Schrödinger's equation for the spinor $\psi=(\psi_1,\psi_2)$ is then

$$i\dot{\psi}_1=\tfrac{1}{2}k\psi_1+\tfrac{1}{2}S(t)\psi_2,\quad i\dot{\psi}_2=-\tfrac{1}{2}k\psi_2+\tfrac{1}{2}S(t)\psi_1. \tag{1.4}$$

(We take $\hbar=1$.) This is conveniently expressed in terms of the components of the polarization vector $P=\psi^*\sigma\psi$, the so-called Bloch variables,

$$P_x=\psi_2\psi_1^*+\psi_1\psi_2^*,\quad P_y=i(\psi_1\psi_2^*-\psi_2\psi_1^*),\quad P_z=\psi_1\psi_1^*-\psi_2\psi_2^*, \tag{1.5}$$

as the first-order linear time-dependent system

$$\dot{P}_x=-kP_y,\quad \dot{P}_y=kP_x-S(t)P_z,\quad \dot{P}_z=S(t)P_y, \tag{1.6}$$

which, from the normalization $\psi_1\psi_1^*+\psi_2\psi_2^*=1$, satisfies the constraint

$$P_x^2+P_y^2+P_z^2=1. \tag{1.7}$$

We suppose that the forcing consists of period-T δ-function kicks, so that we have

$$S(t)=\sum_{n=-\infty}^{\infty} R_n\delta(t-nT), \tag{1.8}$$

with variable amplitude R_n. Between kicks we have a rotation in the (P_x,P_y) plane, and at kicks a rotation in the (P_y,P_z) plane resulting in the linear kick-to-kick mapping

$$\begin{pmatrix} P_{x,n+1} \\ P_{y,n+1} \\ P_{z,n+1} \end{pmatrix} = \begin{pmatrix} \cos kT & -\sin kT\cos R_n & \sin kT\sin R_n \\ \sin kT & \cos kT\cos R_n & -\cos kT\sin R_n \\ 0 & \sin R_n & \cos R_n \end{pmatrix} \begin{pmatrix} P_{x,n} \\ P_{y,n} \\ P_{z,n} \end{pmatrix}, \tag{1.9}$$

where $(P_{x,n},P_{y,n},P_{z,n})$ denotes the value of the polarization vector at time step n.

Although the kicks occur periodically, they do so with variable amplitude R_n which we now take to be determined in a quasiperiodic manner governed by the rotation

$$\phi_{n+1}=\phi_n+\omega \pmod 1, \tag{1.10}$$

with the rotation number $\omega\notin\mathbb{Q}$. The amplitude R_n is then defined via a period-1 *modulation function* Φ to be

$$R_n=\kappa\Phi(\phi_n), \tag{1.11}$$

where κ is an amplitude. The precise form of the modulation function Φ is crucial for the resulting dynamics. It is the case of piecewise-constant discontinuous modulation function, where a singular continuous spectrum is observed, that will concern us in this article.

To simplify matters we assume that the time between kicks, T, is commensurate with the fundamental frequency k, setting

$$kT=2\pi m, \quad m\in\mathbb{Z}, \tag{1.12}$$

thereby decoupling the variable $P_{x,n}$ so that the resulting dynamics is merely a rotation in the (P_y,P_z) plane. (Numerical work in Ref. 5 indicates that this simplification may not be essential to witness the singular continuous spectrum.) Because of the constraint (1.7), without loss of generality, we may set $P_{x,n}=0$ (otherwise we can simply rescale the remaining variables). Thus, writing

$$P_{y,n}=\cos\theta_n, \quad P_{z,n}=\sin\theta_n, \tag{1.13}$$

we arrive at the skew-product system

$$\phi_{n+1}=\phi_n+\omega \pmod 1, \tag{1.14}$$

$$\theta_{n+1}=\theta_n+\kappa\Phi(\phi_n). \tag{1.15}$$

We remark that it is in such systems that early work on the appearance of strange nonchaotic attractors was undertaken,[6] and that, in some sense, such attractors lie intermediate between regular and chaotic dynamics. In particular, the presence of a singular continuous spectrum may be mooted as a candidate for their characterization.

Of course it is straightforward to ''solve'' the system (1.14) and (1.15):

$$\phi_n=\phi_0+n\omega \pmod 1, \tag{1.16}$$

$$\theta_n = \theta_0 + \kappa \sum_{l=0}^{n-1} \Phi(\phi_0 + l\omega), \tag{1.17}$$

but this does not help illuminate the behavior of the variable θ, i.e., (P_y, P_z). To this end we turn to an analysis of correlations.

B. Renormalization analysis of the autocorrelation function

For completeness we recall here the renormalization analysis of the autocorrelation function from Feudel *et al.*[5] The autocorrelation function of the (zero mean) observable P_y is

$$K_{P_y}(t) = \frac{\langle P_{y,n} P_{y,n+t} \rangle}{\langle P_{y,n}^2 \rangle}, \tag{1.18}$$

where we have defined the average

$$\langle f(n) \rangle = \lim_{N \to \infty} \frac{1}{N} \sum_{n=1}^{N} f(n). \tag{1.19}$$

Using the trigonometric identity $2 \cos A \cos B = \cos(A+B) + \cos(A-B)$, we have

$$\langle P_{y,n} P_{y,n+t} \rangle = \langle \cos\theta_n \cos\theta_{n+t} \rangle = \tfrac{1}{2} \langle \cos(\theta_{n+t} - \theta_n) \rangle = \tfrac{1}{2} \langle \cos \kappa Q_t(\phi_n) \rangle, \tag{1.20}$$

where we have averaged over the initial phase θ_0 to remove the average of $\cos(\theta_{n+t} + \theta_n)$, and then defined

$$Q_t(\phi) = \sum_{l=0}^{t-1} \Phi(\phi + l\omega), \quad Q_0(\phi) = 0. \tag{1.21}$$

Thus

$$K_{P_y}(t) = \langle \cos \kappa Q_t(\phi_n) \rangle = \int_0^1 \cos \kappa Q_t(\phi) d\phi, \tag{1.22}$$

where we have used the fact that for irrational ω the rotation (1.14) is ergodic with respect to Lebesgue measure to replace the time average by a space average.

We now specialize to the case of golden mean rotation number, setting $\omega = (\sqrt{5}-1)/2$, and accordingly consider Fibonacci times only. Then Q_n satisfies the recurrence relation

$$Q_{F_n}(\phi) = Q_{F_{n-1}}(\phi) + Q_{F_{n-2}}(\phi + F_{n-1}\omega), \tag{1.23}$$

where the Fibonacci numbers (F_n) are defined by $F_0 = 0$, $F_1 = 1$, and $F_n = F_{n-1} + F_{n-2}$ for $n \geqslant 2$. Using the identity

$$F_{n-1}\omega = F_{n-2} - (-\omega)^{n-1}, \tag{1.24}$$

and defining the rescaled variables

$$Z_n(y) = Q_{F_n}(y(-\omega)^n), \tag{1.25}$$

results in the iterative functional recurrence

$$Z_n(x) = Z_{n-1}(-\omega x) + Z_{n-2}(\omega^2 x + \omega), \tag{1.26}$$

with initial conditions

$$Z_0(x)=0, \quad Z_1(x)=\Phi(-\omega x). \tag{1.27}$$

This recurrence is the object of study in this article.

In terms of the functions Z_n, the autocorrelation function K_{P_y} at Fibonacci times is

$$K_{P_y}(F_n)=\frac{1}{(-\omega)^{-n}}\int_0^{(-\omega)^{-n}}\cos \kappa Z_n(y)\,dy. \tag{1.28}$$

For the particular choice of modulation function

$$\Phi(\phi)=\begin{cases}+1, & 0\leqslant\{\phi\}<\frac{1}{2},\\ -1, & \frac{1}{2}\leqslant\{\phi\}<1,\end{cases} \tag{1.29}$$

where $\{\phi\}$ denotes ϕ (mod 1), with the initial conditions given by (1.27), Feudel *et al.*[5] observe that iteration of (1.1) leads to a period-6 orbit as shown in Fig. 2. The corresponding autocorrelation function K_{P_y} (with $\kappa=\pi/2$) is shown in Fig. 1. Note that the height of the largest peaks is approximately 0.55 and is numerically calculated in Ref. 5 from an average of $|Z_n|$ with $n\equiv 0$ mod 3, i.e., either of the top two figures in Fig. 2, to be asymptotically approximately 0.552 79. By carefully describing the locations of the discontinuities in Fig. 2, in Sec. V we shall show that this value is in fact $1-1/\sqrt{5}=0.552\,786\ldots$.

Our analysis shows that self-similarity of the autocorrelation function occurs for many other choices of modulation function in addition to (1.29). However, the locations of the discontinuities of the modulation function must be preperiodic points of a map of the interval to be introduced in the next section.

II. PERIODIC ORBITS AND THEIR DISCONTINUITIES

We begin this section by adapting our previous analysis[12] of the multiplicative version of (1.1) to the problem at hand. We introduce an expanding piecewise-linear map of an interval whose periodic orbits correspond to the discontinuities of the piecewise-constant periodic orbits of (1.1), and show that the dynamics of this interval map ''drives'' the global behavior of periodic orbits of (1.1). We also give a detailed analysis of the periodicity of the discontinuities. We then give a necessary and sufficient criterion for the piecewise-constant orbits of (1.1) to be periodic.

A. Iterated function system and the inverse map *F*

Defining

$$\phi_1(x)=-\omega x, \quad \phi_2(x)=\omega^2 x+\omega, \tag{2.1}$$

we may write Eq. (1.1) in the form

$$Z_n(x)=Z_{n-1}(\phi_1(x))+Z_{n-2}(\phi_2(x)), \tag{2.2}$$

where $\omega=(\sqrt{5}-1)/2$ is the golden mean,

The iterated function system (IFS) on $\mathbb{R}$ given by ϕ_1, ϕ_2 has the following properties:

(1) ϕ_1 and ϕ_2 are linear contractions with fixed points 0 and 1, respectively, and with $\phi_1'(x)=-\omega$ and $\phi_2'(x)=\omega^2$.
(2) The *fundamental interval* $I=[-\omega,1]$ is the fixed point set for the IFS. Indeed $\phi_1(I)=[-\omega,\omega^2]$, $\phi_2(I)=[\omega^2,1]$, so that $\phi_1(I)\cup\phi_2(I)=I$.
(3) The fundamental interval I is the attractor for the IFS. Indeed given any compact subset $K\subset\mathbb{R}$ and any $\varepsilon>0$, there exists $N\in\mathbb{N}$ such that for any $k\geqslant N$ and any choice $i_1,\ldots,i_k\in\{1,2\}$ we have

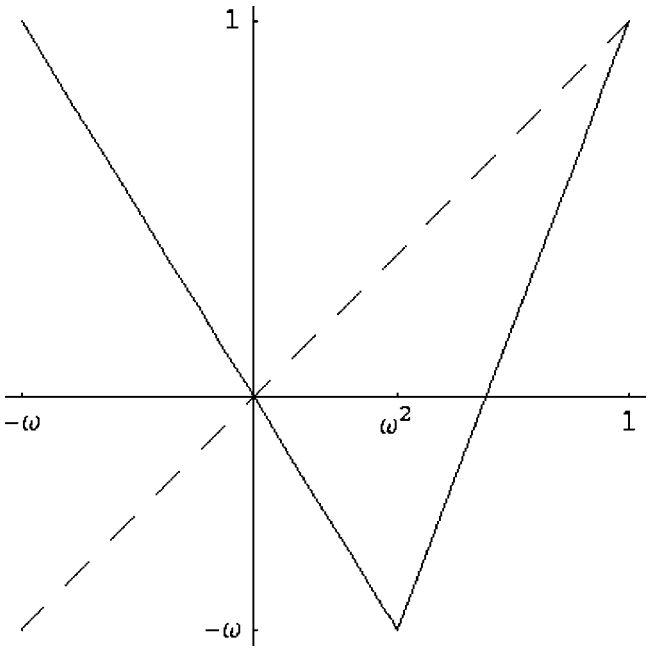

FIG. 3. The function F.

$$\phi_{i_1}\circ\cdots\circ\phi_{i_k}(x)\in[-\omega-\varepsilon,1+\varepsilon] \tag{2.3}$$

for any $x\in K$. This property will be important when we consider the behavior of Eq. (2.2) outside the fundamental interval.

Let $F:I\to I$ be defined by

$$F(x)=\begin{cases}\phi_1^{-1}(x)=-\omega^{-1}x, & x\in[-\omega,\omega^2];\\ \phi_2^{-1}(x)=\omega^{-2}x-\omega^{-1}, & x\in[\omega^2,1],\end{cases} \tag{2.4}$$

as drawn in Fig. 3. We shall see below that periodic points of F correspond to discontinuities of the periodic solutions of (2.2).

We note that for any periodic point $y\in I$, precisely one of $\phi_1(y)$, $\phi_2(y)$ is also a periodic point of F. This follows from the fact that each period point has two preimages, exactly one of which is a periodic point on the same orbit. (Note that ω^2 is not a periodic point of F.) We analyze the dynamics of F in terms of a code of a point $x\in I$. As in Ref. 12 we let the interval $[-\omega,\omega^2)$ be encoded with the symbol 1 and $(\omega^2,1]$ with the symbol 2. We define the code of $x\in I$ to be the sequence $(a_n)_{n\geqslant 0}$ in $\{1,2\}^{\mathbb{N}_0}$ given by

$$a_n=\begin{cases}1, & F^n(x)\in[-\omega,\omega^2);\\ 2, & F^n(x)\in(\omega^2,1],\end{cases} \tag{2.5}$$

and ignore the (countable) set of (nonperiodic) points whose orbits under F include the point ω^2. Hence the codes are all infinite sequences. In terms of the code $a_0a_1a_2\ldots$ of a point $x\in I$, we have

$$F(x)=(-\omega^{-1})^{a_0}x-(a_0-1)\omega^{-1}. \tag{2.6}$$

Since F is uniformly expanding ($|F'(x)|\geqslant\omega^{-1}$), every point $x\in I$ corresponds to a unique code and vice versa. In particular, periodic orbits of F correspond to periodic codes in $\{1,2\}^{\mathbb{N}_0}$ under the shift map σ:

$$\sigma(a_0a_1a_2\ldots)=a_1a_2\ldots. \tag{2.7}$$

A periodic orbit $y_0,y_1,\ldots,y_{k-1}$ of period k of F is given uniquely by a periodic code $\overline{a_0a_1\ldots a_{k-1}}$, which we henceforth denote as just $a_0a_1\ldots a_{k-1}$. Indeed, given a code $a_0a_1\ldots a_{k-1}$, it is straightforward to calculate the corresponding periodic orbit $y_0,y_1,\ldots,y_{k-1}$ of F. We have $\phi_{a_{k-1}}^{-1}\circ\cdots\circ\phi_{a_0}^{-1}(y_0)=y_0$, or, equivalently, $\phi_{a_0}\circ\cdots\circ\phi_{a_{k-1}}(y_0)=y_0$, whose (unique) solution is readily calculated to be

$$y_0=\frac{-\sum_{j=0}^{k-1}(a_j-1)(-\omega)^{1+\sum_{i=0}^{j-1}a_i}}{1-(-\omega)^{\sum a_j}}, \tag{2.8}$$

where empty sums are defined to be zero. The other points of the orbit may be calculated by applying this formula with the code $a_0a_1\ldots a_{k-1}$ cyclically permuted.

For example, $F(y)$ has two fixed points: $y=0$ with code 1, and $y=1$ with code 2. The period-2 orbit with code 21 is given by $y_0=\frac{1}{2}$ and $y_1=-\omega/2$. It is the fixed point $y=0$ and this period-2 orbit that are the discontinuity points in the fundamental interval of the period-6 orbit shown in Fig. 2.

B. Reduction of Z_n on $\mathbb{R}$ to the fundamental interval

In this section we consider Eq. (2.2) outside the fundamental interval $I=[-\omega,1]$, i.e., on the whole of $\mathbb{R}$. The fact that I is the attractor for the IFS leads to the conclusion that the global behavior of (2.2) is "driven" by its behavior in I.

The following result is a straightforward variation of the corresponding result in Ref. 12.

Lemma 1: Let Z_0, Z_1 be initial conditions for (2.2) on $\mathbb{R}$ and let $\varepsilon>0$ be such that $Z_0(x)=Z_1(x)=0$ for all $x\in[-\omega-\varepsilon,1+\varepsilon]$. Then for each $L>1$, there exists $N>0$ (depending only on L) such that $Z_n(x)=0$ for all $x\in[-L,L]$ and all $n>N$.

In other words, if the initial conditions on, and just outside, the fundamental interval are zero, then the value of Z_n at all points eventually becomes zero.

From the lemma we may prove the following proposition whose proof again follows mutatis mutandis the corresponding result in Ref. 12.

Proposition 1: Let Z_n be a piecewise-constant periodic orbit of (2.2) of period p on $\mathbb{R}$ with $Z_n(1+)=Z_n(1)$. Then Z_n is periodic with period p on the fundamental interval I. Conversely, suppose that Z_n is periodic with period p on I. Then there is a unique extension $\tilde{Z}_n$ of Z_n to $\mathbb{R}$ such that $\tilde{Z}_n$ is periodic with period p on $\mathbb{R}$.

Moreover, Lemma 1 further implies the following.

Proposition 2: Let Z_0, Z_1 be piecewise-constant initial conditions for (2.2) on $\mathbb{R}$ with $Z_0(1+)=Z_0(1)$, $Z_1(1+)=Z_1(1)$. Suppose Z_n is periodic of period p on the fundamental interval I. Then the sequence Z_n converges to the unique periodic extension $\tilde{Z}_n$ given by proposition 1, i.e., for all integers $r\geqslant 0$ we have $Z_{r+np}(x)\to\tilde{Z}_r(x)$ as $n\to\infty$.

In other words, initial data on the fundamental interval resulting in periodic behavior uniquely determines an asymptotic (right continuous at 1) global periodic behavior. It is important to realize, however, that such globally defined periodic orbits will not in general consist of bounded functions. We shall address this issue in Sec. IV.

C. Analysis of the discontinuities

In order to study the piecewise-constant periodic orbits of the recurrence (1.1) we first consider the dynamics of the discontinuities. We define, for each $x\in\mathbb{R}$ and $n\geqslant 0$,

$$D_n(x)=Z_n(x+)-Z_n(x-), \tag{2.9}$$

the difference of the right-hand limit at x to the left-hand limit at x, so that $D_n(x)\neq 0$ if and only if Z_n has a discontinuity at x. The recurrence (2.2) for Z_n naturally induces a recurrence for D_n:

$$\begin{aligned} D_n(x) &= Z_n(x+) - Z_n(x-) \\ &= Z_{n-1}(\phi_1(x+)) + Z_{n-2}(\phi_2(x+)) - Z_{n-1}(\phi_1(x-)) - Z_{n-2}(\phi_2(x-)) \\ &= Z_{n-1}(\phi_1(x)-) - Z_{n-1}(\phi_1(x)+) + Z_{n-2}(\phi_2(x)+) - Z_{n-2}(\phi_2(x)-) \\ &= -D_{n-1}(\phi_1(x)) + D_{n-2}(\phi_2(x)). \end{aligned} \tag{2.10}$$

Clearly if Z_n is periodic with period p, then D_n is also periodic with period m dividing p. Our task is to determine the possible periods m of D_n and relate m to p, the period of Z_n.

From now on we assume that Z_n is periodic with period p and that D_n is periodic with period m, and, in view of Proposition 1, we only consider the behavior of Z_n and D_n on the fundamental interval $I=[-\omega,1]$. We define the *restricted discontinuity set*

$$D=\{x\in I: D_n(x)\neq 0 \text{ for some } n\geqslant 0\}. \tag{2.11}$$

Then D is the finite set of points in I for which Z_n has a discontinuity for at least one $n\geqslant 0$. As in our analysis of the multiplicative recurrence,[12] the restricted discontinuity set D consists of finitely many periodic orbits of the map F as we now show.

Proposition 3: Let Z_n be a piecewise-constant periodic orbit of (2.2), and let D be the associated restricted discontinuity set. Then D consists of a finite collection of periodic orbits of the map F.

Proof: Suppose $y\in D$. Then $D_n(y)\neq 0$ for some $n\geqslant 0$. From (2.10) we have that $D_{n-i_1}(\phi_{i_1}(y))\neq 0$ for some $i_1\in\{1,2\}$. We therefore have $\phi_{i_1}(y)\in D$. Continuing in this way, we obtain a sequence $i_1,i_2,\ldots\in\{1,2\}$ such that $\phi_{i_k}\circ\cdots\circ\phi_{i_1}(y)\in D$ for each $k\in\mathbb{N}$. Since D is finite there exist r, $r'\in\mathbb{N}$ with $r>r'$ and $\phi_{i_{r'}}\circ\cdots\circ\phi_{i_1}(y)=\phi_{i_r}\circ\cdots\circ\phi_{i_1}(y)$. Applying F^r to this equation gives $F^{r-r'}(y)=y$, so that y is a periodic point of F of period j dividing $r-r'$.

Now let $y_0=y,y_1,\ldots,y_{k-1}$ be the points on the orbit of y_0 under F with $y_{i+1(\mathrm{mod}\,k)}=F(y_i)$ for $i=0,1,\ldots,k-1$, and let $a_0a_1\ldots a_{k-1}$ be the code of the orbit. Then for $0\leqslant i\leqslant k-1$ we have

$$\phi_{a_i}^{-1}(y_i)=y_{i+1}, \quad \text{or, equivalently,} \quad \phi_{a_{i-1}}(y_i)=y_{i-1}, \tag{2.12}$$

where here, and in what follows, we assume that expressions relating to the periodic orbit $y_0,y_1,\ldots,y_{k-1}$ are reduced modulo k.

Moreover, as we noted earlier, precisely one of $\phi_1(y_i)$, $\phi_2(y_i)$ is periodic. Thus, if $a_{i-1}=1$ then $\phi_2(y_i)\notin D$ and so $D_n(\phi_2(y_i))=0$ for all n, while if $a_{i-1}=2$, then $\phi_1(y_i)\notin D$ and so $D_{n-1}(\phi_1(y_i))=0$ for all n. The recurrence (2.10) may therefore be written

$$D_n(y_i)=\begin{cases} -D_{n-1}(y_{i-1}), & a_{i-1}=1, \\ D_{n-2}(y_{i-1}), & a_{i-1}=2, \end{cases} \tag{2.13}$$

which can be written as

$$D_n(y_i)=(-1)^{a_{i-1}}D_{n-a_{i-1}}(y_{i-1}). \tag{2.14}$$

Thus $D_{n+a_0+\cdots+a_{i-1}}(y_i)=(-1)^{a_0+\cdots+a_{i-1}}D_n(y_0)$, so that if $D_n(y_0)\neq 0$, then $D_{n+a_0+\cdots+a_{i-1}}(y_i)\neq 0$, i.e., if $y_0\in D$, then $y_i\in D$. We conclude that not only must every point $y\in D$ be a periodic point of F, but that every point on the periodic orbit of y also lies in D, so that D consists of complete orbits of F. □

D. Period of the discontinuities for a single periodic orbit of *F*

From (2.14) we see that over a complete periodic orbit with code $a_0a_1\ldots a_{k-1}$ the index n decreases by

$$l=\sum_{i=0}^{k-1} a_i, \tag{2.15}$$

and, moreover, we have $D_n(y_i)=(-1)^l D_{n-l}(y_i)$, for $0\leqslant i\leqslant k-1$. We therefore deduce the following result.

Proposition 4: Let m be the period of the discontinuity function D_n restricted to a periodic orbit $y_0,\ldots,y_{k-1}$ of F and let l *be the sum of the code over the orbit of F. Then m divides* lcm$\{2,l\}$, *i.e., if* l *is even m divides* l, *while if* l *is odd m divides* $2l$.

We define for any integer m

$$\hat{m}=\mathrm{lcm}\{2,m\}=\begin{cases} m, & m \quad \text{even;} \\ 2m, & m \quad \text{odd.} \end{cases} \tag{2.16}$$

A convenient representation of the discontinuity data is in terms of an $\hat{l}\times k$ matrix M, the *discontinuity matrix*, with entries defined by

$$M_{n,i}=D_n(y_i), \tag{2.17}$$

for $0\leqslant n\leqslant \hat{l}-1$, $0\leqslant i\leqslant k-1$, so that the entry in row n and column i is the value of D_n at the point y_i on the orbit $y_0,y_1,\ldots,y_{k-1}$.

The relation (2.14) above gives a special structure to the matrix M. Indeed (2.14) translates to

$$M_{n,i}=(-1)^{a_{i-1}}M_{n-a_{i-1},i-1}, \tag{2.18}$$

where here, and in what follows, indices referring to the periodicity of D_n are reduced modulo $\hat{l}$.

The structure of (2.18) can be more easily understood as follows. Column i of the matrix M is simply column $(i-1)$ cyclically permuted downwards by a_{i-1} single cyclic permutations with a change of sign if $a_{i-1}=1$. This observation also holds when $i=0$, for then (2.18) becomes

$$M_{n,0}=(-1)^{a_{k-1}}M_{n-a_{k-1},k-1}. \tag{2.19}$$

Let us denote the first column of M by $(X_0,X_1,\ldots,X_{\hat{l}-1})$, i.e., $M_{n,0}=X_n$ for $0\leqslant n\leqslant \hat{l}-1$. Then the relation (2.18) tells us that

$$M_{n,1}=(-1)^{a_0}M_{n-a_0,0}=(-1)^{a_0}X_{n-a_0}, \tag{2.20}$$

and, in general,

$$M_{n,i}=(-1)^{\Sigma_{j=0}^{i-1}a_j}M_{n-\Sigma_{j=0}^{i-1}a_j,0}=(-1)^{\Sigma_{j=0}^{i-1}a_j}X_{n-\Sigma_{j=0}^{i-1}a_j}, \tag{2.21}$$

so that each column of M is simply a cyclic permutation with an appropriate sign change of the first column of M. In the case of odd l, in order to satisfy (2.19), the first column of M must take the form $(X_0,X_1,\ldots,X_{l-1},-X_0,-X_1,\ldots,-X_{l-1})$.

Example 1: The period-2 orbit $\{\frac{1}{2},-\omega/2\}$ has code 21, so $k=2$, $l=3$, $\hat{l}=6$ and

$$M=\begin{pmatrix} X_0 & -X_1 \\ X_1 & -X_2 \\ X_2 & X_0 \\ -X_0 & X_1 \\ -X_1 & X_2 \\ -X_2 & -X_0 \end{pmatrix},$$

in which, since $a_0=2$, the second column is the first column shifted down two rows without sign change. Utilizing $a_1=1$ on the second column reproduces the first column by shifting down one and changing sign.

Example 2: The fixed point 0 of F has code 1 so here $k=l=1$, $\hat{l}=2$ and

$$M=\begin{pmatrix} X_0 \\ -X_0 \end{pmatrix}.$$

The combination of Examples 1 and 2 was our initial motivation for studying this problem, and enables us to give a precise description of the numerical results of Feudel *et al.*[5] We shall return again to this example later on in this article, after discussing how to treat discontinuity sets containing more than one periodic orbit of F in the next subsection.

Example 3: The fixed point 1 of F has code 2 so here $k=1$, $l=\hat{l}=2$ and

$$M=\begin{pmatrix} X_0 \\ X_1 \end{pmatrix}.$$

Example 4: When the code is 2112 we have $k=4$, $l=l'=6$ and

$$M=\begin{pmatrix} X_0 & X_4 & -X_3 & X_2 \\ X_1 & X_5 & -X_4 & X_3 \\ X_2 & X_0 & -X_5 & X_4 \\ X_3 & X_1 & -X_0 & X_5 \\ X_4 & X_2 & -X_1 & X_0 \\ X_5 & X_3 & -X_2 & X_1 \end{pmatrix}.$$

When l is even, by a suitable choice of first column, i.e., of the l numbers $X_0,X_1,\ldots,X_{l-1}$, we may arrange for the discontinuities to have any period dividing l. When l is odd, by suitably choosing X_0, $X_1,\ldots,X_{l-1}$, any period twice any divisor of l can be obtained (or the trivial period-1 case of no discontinuities). Moreover, in this latter case, the discontinuities satisfy $X_{n+l}=-X_n$.

We emphasize that our freedom of choice is in choosing the values of the discontinuities at each point of a periodic orbit of F. It is *not* the case that one may arbitrarily select the discontinuities of the initial conditions Z_0, Z_1. This would correspond to specifying the first two *rows* of the discontinuity matrix. As our analysis shows, however, the rows are not independent. However, we remark that each row of the discontinuity matrix contains each X_i at most once, and that any two adjacent rows together contain each X_i at least once. Indeed, given one row, it is clear that those entries which appear in the following row are simply those in the columns corresponding to y_i with code 1. Thus an alternative (equivalent) method of specifying a periodic discontinuity orbit may be given directly in terms of the discontinuities of Z_0 and Z_1 at each y_i. Namely, the discontinuities of Z_1, i.e., $D_1(y_i)$ may be chosen arbitrarily, as may the discontinuities $D_0(y_i)$ of Z_0 at each y_i with code 2. (This exhausts l freedoms.) The discontinuities of Z_0 at each y_i with code 1, however, are given as $D_0(y_i)=-D_1(y_{i+1})$ (with period k on the index). While useful for ensuring that initial conditions result in periodic behavior, this alternative description is less useful for determining the precise period. This description will, however, be useful in Sec. IV when we wish to analyze the global behavior of recurrence (2.2).

E. Multiple periodic orbits in *D*

In general, the restricted discontinuity set D will be composed of points of more than one periodic orbit of F. Let t be the number of periodic orbits of F in D. For $0\leqslant s\leqslant t-1$, we consider the periodic orbit s of F in D. We make the general convention that superscript s refers to the orbit s. Now, from the additive structure of (2.10), we have that a sum of solutions is again a

solution of the equation. Moreover, because the periodic orbits in D are distinct, and are never mapped to each other under the two maps ϕ_1, ϕ_2, we have that the dynamics of D_n on each of the periodic orbits in D are independent. Indeed, we may write

$$D_n(x)=\sum_{s=0}^{t-1} D_n^s(x), \tag{2.22}$$

where D_n^s is the restriction of D_n to the periodic orbit s, i.e.,

$$D_n^s(x)=\begin{cases} D_n(x), & x\in\{y_0^s,\ldots,y_{k^s-1}^s\};\\ 0, & \text{otherwise.}\end{cases} \tag{2.23}$$

We may then apply the analysis of the previous subsection to each of the functions D_n^s. This is because $D_n^s(x)=0$, except when x is one of the points on the periodic orbit $y_0^s\ldots y_{k^s-1}^s$ of F.

The theory for D_n that we discussed above carries over in a straightforward manner to the function D_n^s. In particular, for each orbit in D we can formulate an $\hat{l}^s\times k^s$ discontinuity matrix M^s, defined by $M_{n,i}^s=D_n^s(y_i^s)$ for $0\leqslant n\leqslant \hat{l}^s-1$ and $0\leqslant i\leqslant k^s-1$. To simplify notation, we adopt the convention that matrix indices are reduced modulo k^s when dealing with expressions relating to the periodic orbit $y_0^s,\ldots,y_{k^s-1}^s$ of F, while those relating to the periodicities of D_n are reduced modulo $\hat{l}^s$. These matrices are independent of each other since the dynamics of D_n on each periodic orbit in D are independent.

Thus, as in (2.18), we have

$$M_{n,i}^s=(-1)^{a_{i-1}^s}M_{n-a_{i-1}^s,i-1}^s, \tag{2.24}$$

for $0\leqslant n\leqslant \hat{l}^s-1$ and $0\leqslant i\leqslant k^s-1$, and the matrix M^s is determined by its first column $(X_0^s,X_1^s,\ldots,X_{\hat{l}^s-1}^s)$. [When l^s is odd this column takes the form $(X_0^s,X_1^s,\ldots,X_{l^s-1}^s,-X_0^s,-X_1^s,\ldots,-X_{l^s-1}^s)$.] Indeed, as in (2.21),

$$M_{n,i}^s=(-1)^{\Sigma_{j=0}^{i-1}a_j^s}X_{n-\Sigma_{j=0}^{i-1}a_j^s}^s, \tag{2.25}$$

and the period m^s of the first column is precisely the row period of M^s. We also have $m^s|\hat{l}^s$.Conversely, let $\hat{l}=\mathrm{lcm}(\hat{l}^0,\ldots,\hat{l}^{t-1})$. Then for any $m|\hat{l}$ we define $m^s=\gcd(m,\hat{l}^s)$. Then $m^s|\hat{l}^s$ and by appropriate choices of $(X_0^s,X_1^s,\ldots,X_{\hat{l}^s-1}^s)$ we may construct a matrix M^s with row period m^s if l^s is even, or $\hat{m}^s$ if l^s is odd, and, extending periodically to all $n\geqslant 0$, we have that D_n has period m^s if l^s is even, or $\hat{m}^s$ if l^s is odd, when restricted to the orbit $y_0^s,\ldots,y_{k^s-1}^s$.

We therefore have the following proposition.

Proposition 5: Let Z_n be a piecewise-constant periodic orbit of (2.2). Then the period m of the discontinuity function D_n is given by

$$m=\mathrm{lcm}(m^0,\ldots,m^{t-1}), \tag{2.26}$$

where m^s is the period of the function D_n^s, given by the period of $(X_0^s,X_1^s,\ldots,X_{\hat{l}^s-1}^s)$, i.e., the first column of the discontinuity matrix M^s. Furthermore, m divides

$$\hat{l}=\mathrm{lcm}(\hat{l}^0,\ldots,\hat{l}^{t-1}). \tag{2.27}$$

Moreover, by appropriate choices of $(X_0^s,X_1^s,\ldots,X_{\hat{l}^s-1}^s)$, for any m dividing $\hat{l}$ we may construct a periodic orbit of D_n with period $\hat{m}$ (and, if all l^s are even, we may construct a periodic orbit of odd period m).

F. The criterion for orbits to be periodic

In the previous subsection we dealt quite extensively with the periodicity of the discontinuities on the fundamental interval $I=[-\omega,1]$. It is perfectly feasible for the sequence of discontinuities D_n to be periodic while the sequence (Z_n) itself is not. The simple example $Z_0(x)=0$, $Z_1(x)=1$ for all x, with no discontinuities at all, generates the Fibonacci numbers as the values for Z_n. This sequence is clearly not periodic, growing without bound. In order to ensure that (Z_n) is itself periodic it suffices to ensure that the values at a single point are periodic. It will be convenient to choose an end point of I for this purpose. We consider then the values $Z_n(1)$. As we saw in Sec. II B, it is not just the fundamental interval, but also the right hand limit at the end point 1 of the interval that dictates the global behavior. With this in mind we take Z_n to be right continuous at 1 and write $Z_n^{1+}=Z_n(1)=Z_n(1+)$.

Iteration (2.2) gives

$$Z_n(1+)=Z_{n-1}(\phi_1(1+))+Z_{n-2}(\phi_2(1+)). \tag{2.28}$$

Now ϕ_2 is increasing and $\phi_2(1)=1$, so $\phi_2(1+)=1+$, and thus $Z_{n-2}(\phi_2(1+))=Z_{n-2}(1+)$. On the other hand ϕ_1 is decreasing and $\phi_1(1)=-\omega$, so now $\phi_1(1+)=-\omega-$. To relate $Z_{n-1}(\phi_1(1+))$ to $Z_{n-1}(1+)$ we therefore need to pass from $-\omega-$ to $1+$, which means that we need to add in the effect of all of the discontinuities of Z_{n-1} in I. Let us therefore write

$$Z_{n-1}(1+)=Z_{n-1}(-\omega-)+\Sigma_{n-1}, \tag{2.29}$$

where we denote

$$\Sigma_{n-1}=\sum_{y\in[-\omega,1]} D_{n-1}(y). \tag{2.30}$$

We thus have the following recurrence relation for Z_n^{1+}:

$$Z_n^{1+}=Z_{n-1}^{1+}+Z_{n-2}^{1+}-\Sigma_{n-1}. \tag{2.31}$$

This is a second-order inhomogeneous recurrence relation of a Fibonacci type. Its solution is

$$Z_n^{1+}=F_nZ_1^{1+}+F_{n-1}Z_0^{1+}-\sum_{i=2}^{n} F_{n+1-i}\Sigma_{i-1}. \tag{2.32}$$

If we now require Z_n to be a periodic orbit of period p of (2.2), then in particular we require Z_n^{1+} to have period p. The inhomogeneity is merely the sum of the discontinuities of Z_n and therefore this too has period p. Thus imposing periodicity of period p we can arrive at two simultaneous linear equations for Z_0^{1+} and Z_1^{1+}, namely,

$$Z_0^{1+}=Z_p^{1+}=F_pZ_1^{1+}+F_{p-1}Z_0^{1+}-\sum_{i=2}^{p} F_{p+1-i}\Sigma_{i-1}, \tag{2.33}$$

$$Z_1^{1+}=Z_{p+1}^{1+}=F_{p+1}Z_1^{1+}+F_pZ_0^{1+}-\sum_{i=2}^{p+1} F_{p+2-i}\Sigma_{i-1}. \tag{2.34}$$

When written in matrix form, the determinant of the matrix of coefficients of this system is $1+(-1)^p-F_{p+1}-F_{p-1}\neq 0$, thus these equations always possess a unique solution. The conclusion is that we may arbitrarily select the discontinuities over a set of periodic orbits of F on the fundamental interval (i.e., select the first columns of the discontinuity matrices), and then define Z_0^{1+}, Z_1^{1+}, i.e., $Z_0(1)$, $Z_1(1)$, by solving this system of linear equations, and the resulting orbit

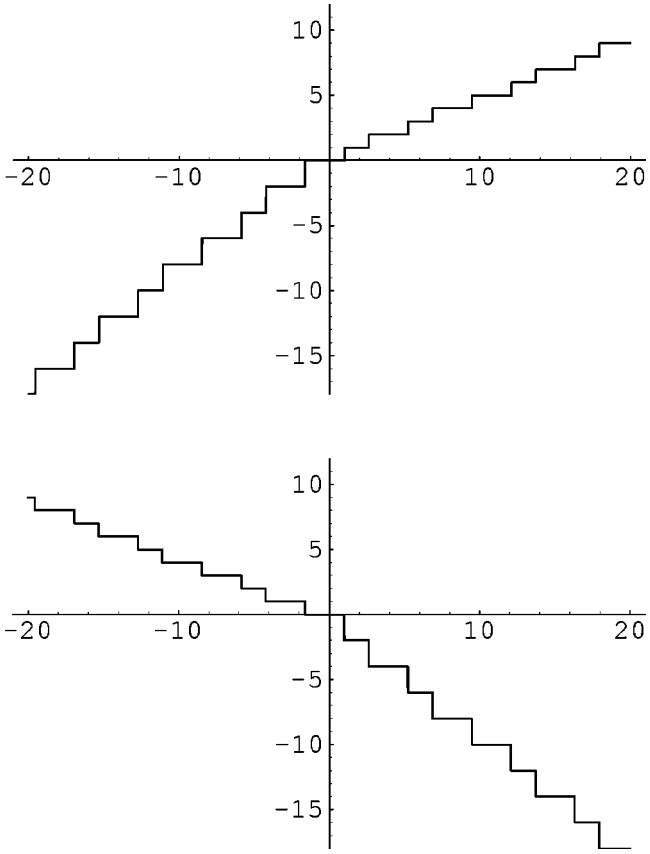

FIG. 4. Period-2 orbit of the recurrence (2.2).

is periodic on the fundamental interval. By the results of Sec. II B this local data determines the asymptotic (right continuous at 1) globally periodic orbit. In summary we have the following theorem.

Theorem 1: *A necessary and sufficient condition for a piecewise-constant, right-continuous at 1, orbit of (2.2) to be periodic (on the whole of* $\mathbb{R}$*) with period* p *is that its discontinuities have period* p *and that* Z_0^{1+}, Z_1^{1+} *satisfy Eqs. (2.33) and (2.34).*

For example, consider Example 3 above with arbitrary discontinuities X_0, X_1 at 1 of Z_0, Z_1, respectively. Solving (2.33) and (2.34) with $p=l=2$ gives $Z_0^{1+}=X_0$, $Z_1^{1+}=X_1$, i.e., that both Z_0 and Z_1 must be zero to the left of 1 on I. Figure 4 shows the case $X_0=1$, $X_1=-2$.

For the case of discontinuity set given by the union of Examples 1 and 2, $D=\{\frac{1}{2}, -\omega/2\}\cup\{0\}$, with discontinuities X_0^0, $-X_1^0$, X_0^1, and X_1^0, $-X_2^0$, $-X_0^1$ of Z_0 and Z_1 at $\frac{1}{2}$, $-\omega/2$, 0, respectively, for the period-6 orbit of the discontinuities to be a period-6 orbit of (2.2) we solve (2.33) and (2.34) with $p=6$, and thereby specify

$$Z_0^{1+}=(2X_0^0-X_1^0+X_2^0+2X_0^1)/2, \quad Z_1^{1+}=(-X_0^0+2X_1^0-X_2^0-2X_0^1)/2. \tag{2.35}$$

III. DISCONTINUITIES ON $\mathbb{R}$

Thus far we have a necessary and sufficient condition for orbits of (2.2) to be periodic on the whole of $\mathbb{R}$. We further wish to address the problem of the spatial boundedness of such orbits. The example shown in Fig. 4 demonstrates that orbits can be periodic (in time) but unbounded (in space). To find conditions for spatial boundedness we must understand both the locations and the sizes of the discontinuities of Z_n on the whole of $\mathbb{R}$, and that is the purpose of this section. The

sizes of the discontinuities will be straightforward to calculate, but identifying their locations presents some difficulty. Since recurrence (2.2) is linear, we may consider the contribution of each periodic orbit, and, indeed, each discontinuity of each periodic orbit, to the global discontinuity set of Z_n separately.

We shall return to the issue of spatial boundedness in Sec. IV. A precise identification of the locations of the discontinuities of Z_n will also enable us to calculate the autocorrelation functions. This we shall do in Sec. V.

A. Discontinuities and the field $\mathbb{Q}(\omega)$

Let L_n denote the set of locations of the discontinuities of Z_n, i.e.,

$$L_n=\{x\in\mathbb{R}:D_n(x)\neq 0\}. \tag{3.1}$$

From (2.2) it is clear that

$$L_n=\phi_1^{-1}(L_{n-1})\cup\phi_2^{-1}(L_{n-2}), \tag{3.2}$$

unless there is a cancellation of discontinuities (which, as we shall see below, may occur if both 1 and 0 are discontinuities). As we saw in Sec. II B, the global discontinuities of Z_n are generated from those in the fundamental interval I, and the latter consist of elements of periodic orbits of the map F. It is clear from (2.8) that such periodic orbits must be composed of elements of the field

$$\mathbb{Q}(\omega)=\{a+b\omega:a,b\in\mathbb{Q}\}. \tag{3.3}$$

As a consequence, the sets L_n consist of elements of $\mathbb{Q}(\omega)$, since the maps ϕ_1^{-1}, ϕ_2^{-1} act on $\mathbb{Q}(\omega)$ as

$$\phi_1^{-1}(a+b\omega)=-(a+b)-a\omega, \tag{3.4}$$

$$\phi_2^{-1}(a+b\omega)=2a+b-1+(a+b-1)\omega. \tag{3.5}$$

Rather than consider a periodic orbit itself, we shall consider initially an orbit asymptotic to it generated from discontinuity data on the fundamental interval only. By the results of Sec. II B this orbit is eventually periodic and identical to the desired periodic orbit on any bounded subset of $\mathbb{R}$.

Consider then the case of Z_0 having a single discontinuity of size X at $a+b\omega\in(-\omega,1]$, and Z_1 having discontinuity only at $\phi_1^{-1}(a+b\omega)$. This discontinuity will have size $-X$. If $a+b\omega\in(-\omega,\omega^2)$ (i.e., $a+b\omega$ has code 1), then $\phi_1^{-1}(a+b\omega)=F(a+b\omega)\in(-\omega,1)$, otherwise ($a+b\omega$ has code 2) $\phi_1^{-1}(a+b\omega)\notin(-\omega,1]$.

The first few discontinuity location sets are

$$\begin{aligned}
L_0&=\{a+b\omega\}=a+b\omega+\{0+0\omega\},\\
L_1&=\{-(a+b)-a\omega\}=-(a+b)-a\omega+\{0+0\omega\},\\
L_2&=2a+b+(a+b)\omega+\{-1-\omega,0+0\omega\},\\
L_3&=-(3a+2b)-(2a+b)\omega+\{-1-\omega,0+0\omega,2+\omega\},\\
L_4&=5a+3b+(3a+2b)\omega+\{-4-3\omega,-3-2\omega,-1-\omega,0+0\omega,2+\omega\},\\
L_5&=-(8a+5b)-(5a+3b)\omega+\{-4-3\omega,-3-2\omega,-1-\omega,0+0\omega,\\
&\quad 2+\omega,4+2\omega,5+3\omega,7+4\omega\},
\end{aligned} \tag{3.6}$$

where, when x is a number and S is a set of numbers, $x+S$ denotes the set $\{x+s:s\in S\}$. We shall write these sets in the form

$$L_n=c^{(n)}+d^{(n)}\omega+M_n. \tag{3.7}$$

We observe that the numbers $c^{(n)}$, $d^{(n)}$ obey a simple Fibonacci recurrence, and that the sets (M_n) grow in an alternating manner, appending successively on the right and left of the existing list, and that M_n contains F_{n+1} elements. Moreover, M_n consists of numbers of the form $a+b\omega$ in which b increases uniformly by 1 from $-F_{n-1}$ to F_n-1 when n is odd, and from $-F_n$ to $F_{n-1}-1$ when n is even. However, the component a has increments given by a sequence 1,2,1,2,2,1,2,..., ranging from $-(F_n-1)$ to $F_{n+1}-1$ when n is odd, and from $-(F_{n+1}-1)$ to F_n-1 when n is even. The size of each discontinuity in L_n is $(-1)^nX$.

We shall now identify the precise form of the set M_n, and then prove that the above observations hold for all n.

B. Discontinuities arising from a single discontinuity in *I*

We now state and prove the precise form of the sets L_n based on our preliminary observation in the previous subsection.

For $x\in\mathbb{R}$, we let $\lceil x\rceil$ denote the ceiling of x, namely $\min\{n\in\mathbb{Z}:n\geqslant x\}$, and $\lfloor x\rfloor$ denote the floor of x, namely $\max\{n\in\mathbb{Z}:n\leqslant x\}$. First, we have the following proposition.

Proposition 6: The discontinuity location sets (L_n) *arising from applying recurrence (2.2) to initial conditions in which* Z_0 *has a single discontinuity of size* X *at* $a+b\omega\in I$, *and* Z_1 *has a single discontinuity of size* $-X$ *at* $\phi_1^{-1}(a+b\omega)$, *are* $L_0=\{a+b\omega\}$ *and for* $n\geqslant 1$

$$L_n=c^{(n)}+d^{(n)}\omega+M_n, \tag{3.8}$$

where

$$M_n=\{\lceil i/\omega\rceil+i\omega:i=l_n,\ldots,r_n\}, \tag{3.9}$$

with

$$l_n,r_n=\begin{cases}-F_{n-1},F_n-1, & n\ \ odd,\\ -F_n,F_{n-1}-1, & n\ \ even,\end{cases} \tag{3.10}$$

and where

$$c^{(n)}=(-1)^n(F_{n+1}a+F_nb),\quad d^{(n)}=(-1)^n(F_na+F_{n-1}b). \tag{3.11}$$

Moreover, each discontinuity of L_n *is of size* $(-1)^nX$.

Proof: The proof is by induction with the base case being clear. Suppose now that L_{n-1} and L_{n-2} are given as in the statement of the proposition. As we noted earlier in (3.2) we have $L_n=\phi_1^{-1}(L_{n-1})\cup\phi_2^{-1}(L_{n-2})$. We readily calculate that

$$\phi_1^{-1}(L_{n-1})=c^{(n)}+d^{(n)}\omega+\phi_1^{-1}(M_{n-1}), \tag{3.12}$$

$$\phi_2^{-1}(L_{n-2})=c^{(n)}+d^{(n)}\omega+\phi_2^{-1}(M_{n-2}), \tag{3.13}$$

so that we need only establish that $M_n=\phi_1^{-1}(M_{n-1})\cup\phi_2^{-1}(M_{n-2})$ with M_n as given by (3.9). To do this it suffices to show that each element of M_n is in either $\phi_1^{-1}(M_{n-1})$ or $\phi_2^{-1}(M_{n-2})$, since M_n has F_{n+1} elements and $\phi_1^{-1}(M_{n-1})$, $\phi_2^{-1}(M_{n-2})$ have F_n, F_{n-1} elements, respectively. Suppose that n is even and let $i\in\{-F_n,\ldots,F_{n-1}-1\}$. Considering (3.4) and (3.5), we must show there exists either $j\in\{-F_{n-2},\ldots,F_{n-1}-1\}$ such that $i=-\lceil j/\omega\rceil$ and $\lceil i/\omega\rceil=-\lceil j/\omega\rceil-j$ or $k\in\{-F_{n-2},\ldots,F_{n-3}-1\}$ such that $i=\lceil k/\omega\rceil+k-1$ and $\lceil i/\omega\rceil=2\lceil k/\omega\rceil+k-1$.

Set $j=\lfloor -i\omega \rfloor$ so that $j+\varepsilon_1=-i\omega$, i.e.,

$$j/\omega+\varepsilon_1/\omega=-i, \tag{3.14}$$

for some $\varepsilon_1\in(0,1)$. We note that $j\in\{\lfloor -(F_{n-1}-1)\omega\rfloor,\ldots,\lfloor F_n\omega\rfloor\}$, for which the identity (1.24) (recalling that n is even) gives $\lfloor F_n\omega\rfloor=\lfloor F_{n-1}-\omega^n\rfloor=F_{n-1}-1$, and $\lfloor -(F_{n-1}-1)\omega\rfloor=\lfloor -F_{n-2}+\omega-\omega^{n-1}\rfloor=-F_{n-2}$, so that j is in the desired range.

Now (case 1) if $\varepsilon_1\in(0,\omega)$, then $\varepsilon_1/\omega\in(0,1)$ so that (3.14) gives $\lceil j/\omega\rceil=-i$, i.e., $i=-\lceil j/\omega\rceil$. We further have $i/\omega=i+i\omega=i-j-\varepsilon_1=-\lceil j/\omega\rceil-j-\varepsilon_1$, and thus $\lceil i/\omega\rceil=-\lceil j/\omega\rceil-j$ as desired.

On the other hand (case 2), if $\varepsilon_1\in(\omega,1)$, then $\varepsilon_1/\omega\in(1,\omega^{-1})$ and we deduce that $\lceil j/\omega\rceil=-i-1$, so that $i\neq-\lceil j/\omega\rceil$, and we thus need to define a suitable k. (Note that the case $\varepsilon_1=\omega$ is clearly impossible since ω is irrational. For the same reason we have $\varepsilon_1\neq 0$.) We set $k=\lfloor -j\omega\rfloor$ so that there exists $\varepsilon_2\in(0,1)$ such that

$$-j\omega=k+\varepsilon_2. \tag{3.15}$$

Since $j\in\{-F_{n-2},\ldots,F_{n-1}-1\}$, by an argument similar to that above, we deduce, as desired, that $k\in\{-F_{n-2},\ldots,F_{n-3}-1\}$. Addition of (3.14) and (3.15) gives $j+\varepsilon_1/\omega=-i+k+\varepsilon_2$ so that, since $\varepsilon_1/\omega\in(1,\omega^{-1})$ and $\varepsilon_2\in(0,1)$, we have $\varepsilon_2=\varepsilon_1/\omega-1$, and thus $\varepsilon_2\in(0,\omega)$, i.e., $\varepsilon_2/\omega\in(0,1)$. Equation (3.15) is $-j=k/\omega+\varepsilon_2/\omega$ which thus gives

$$-j=\lceil k/\omega\rceil. \tag{3.16}$$

Now addition of (3.15) and (3.16) gives $-j-j\omega-\varepsilon_2=k+\lceil k/\omega\rceil$, i.e., $-k-\lceil k/\omega\rceil=j/\omega+\varepsilon_2=\lceil j/\omega\rceil$ and so, since $\lceil j/\omega\rceil=-i-1$, we deduce that $i=\lceil k/\omega\rceil+k-1$. From $j+\varepsilon_1=-i\omega$ and $j=-\lceil k/\omega\rceil$, it immediately follows that $i/\omega=i+i\omega=i+\lceil k/\omega\rceil-\varepsilon_1=2\lceil k/\omega\rceil+k-1-\varepsilon_1$, and so $\lceil i/\omega\rceil=2\lceil k/\omega\rceil+k-1$ as desired.

The case n odd is established in a similar manner.

That each discontinuity of L_n is of size $(-1)^nX$ follows immediately from the facts that ϕ_1^{-1} is orientation reversing and ϕ_2^{-1} is orientation preserving. □

We have thus established the locations and sizes of the discontinuities of Z_n that arise from the presence of a discontinuity in Z_0 at $a+b\omega\in I$.

We must also consider the case in which Z_0 has no discontinuities and Z_1 has a single discontinuity in I. However, this situation is clearly identical to the case just considered, but with a reduction of one in all subscripts. More precisely, we have the following.

Proposition 7: The discontinuity location sets (L_n) *arising from applying recurrence (2.2) to initial conditions in which* Z_0 *has no discontinuities and* Z_1 *has a single discontinuity of size* $-X$ *at* $a+b\omega\in I$ *are* $L_0=\varnothing$, $L_1=\{a+b\omega\}$, *and for* $n\geqslant 2$

$$L_n=c^{(n-1)}+d^{(n-1)}\omega+M_{n-1}, \tag{3.17}$$

with $c^{(n)}$, $d^{(n)}$, M_n *as in the statement of Proposition 6. Moreover, each discontinuity of* L_n *is of size* $(-1)^nX$.

The proof of Proposition 7 is analogous to that of Proposition 6.

Thus far we have considered functions possessing only a finite number of discontinuities. A globally periodic orbit, however, possesses an infinite number of discontinuities, being the limit (defined by pointwise convergence) of the sets (L_n) considered thus far. It is clear from Proposition 6 what the discontinuity set generated by a single discontinuity at the fixed point zero is, namely

$$\{\lceil i/\omega\rceil+i\omega : i\in\mathbb{Z}\}, \tag{3.18}$$

this being the limit of the corresponding sets L_n with $a=b=0$, so that $c^{(n)}=d^{(n)}=0$ for all n. However, care is needed in the determination of these sets for other periodic orbits. We shall return to this issue in Sec. V where we consider the period-6 orbit of (2.2) generated by the period-2 orbit $\{\frac{1}{2},-\omega/2\}$ of F.

We remark that a symbolic formulation of the discontinuity locations is possible in terms of ''words'' with letters drawn from the ''alphabet'' {1, 2}. More precisely, a sequence of Fibonacci words with first few elements

$$\begin{gathered}1\\12\\1212\\1212212\\121221212212\end{gathered} \tag{3.19}$$

may be used to describe the increments in the elements of the discontinuity sets L_n. These words may be obtained by the following rules. We denote by $\diamondsuit$ the empty word, by S the substitution operator $1\mapsto 2$, $2\mapsto 12$, and by R the reversal operator $w_1\ldots w_k\mapsto w_k\ldots w_1$. The nth Fibonacci word w^n may be written as the concatenation $u^n v^n$ with the rule $u^1=v^1=\diamondsuit$, and, for $n\geqslant 1$, $u^{n+1}=R(S(v^n)1)$, $v^{n+1}=R(S(u^n))$. We index the ''letters'' in w^n by setting w_0^n to be the last letter of u^n and setting w_1^n to be the first letter of v^n. Then the words w^n are the words given in (3.19). As $n\to\infty$, $w^n\to w^*$, the biinfinite Fibonacci word. One may write the set (3.18) as $\{x_i+i\omega\}$ where $x_0=0$ and $x_i-x_{i-1}=w_i^*$.

IV. GLOBAL BOUNDEDNESS

In the previous section we determined the global effect of a single discontinuity in the fundamental interval. Each of the l variables $X_0,X_1,\ldots,X_{l-1}$ in the discontinuity matrix of a periodic orbit gives rise to such a discontinuity in the initial conditions Z_0, Z_1 in the form of one of the three following cases.

(1) Z_0 has a single discontinuity in I at $x\in(-\omega,\omega^2)$ and Z_1 has a single discontinuity at $F(x)\in I-\{1\}$.
(2) Z_0 has a single discontinuity in $(\omega^2,1]$ and Z_1 has no discontinuities in I.
(3) Z_0 has no discontinuities in I and Z_1 has a single discontinuity in I.

Case 1 corresponds to a discontinuity of Z_0 at a point y_i with code 1, so that y_{i+1} is a discontinuity location of Z_1 (having the same size, but opposite sign). Case 2 corresponds to a discontinuity location y_i of Z_0 with code 2. Case 3 corresponds to a discontinuity location y_i of Z_1 such that y_{i-1} has code 2. (It is illustrative to look at a discontinuity matrix such as that of Example 4 to understand these three cases.) Cases 1 and 2 are handled by Proposition 6, while Proposition 7 treats case 3.

The important thing to note from Propositions 6 and 7 is that each discontinuity generates an ordered set of discontinuities of the same size and sign in which the elements of each set have identical relative displacements: the elements of each set are separated from each other *by the same amount* $(1+\omega$ *or* $2+\omega)$ *in the same order*. Moreover, with the exception of the fixed point 1, each nonzero discontinuity causes an unbounded monotonic growth as we move further from the fundamental interval on both sides.

From Proposition 6 we see that if Z_0 has a discontinuity at 1 of size X (case 2), then this discontinuity gives rise to discontinuities in Z_n of size X at locations $\geqslant 1$ for even n and of size $-X$ at locations $\leqslant -1-\omega$ for odd n. Proposition 7 shows that if Z_1 has a discontinuity at 1 of

size $-X'$ (case 3), then *this* discontinuity gives rise to discontinuities in Z_n of size X' at locations $\leqslant -1-\omega$ for *even* n and of size $-X'$ at locations $\geqslant 1$ for *odd* n. This may be seen in Fig. 4, in which the discontinuities in the first figure (even n) are of size 1 on the right (corresponding to the discontinuity in Z_0), while those on the left are of size 2 (corresponding to the discontinuity in Z_1). The situation is reversed in the second figure (where n is odd).

For global boundedness we require there to be cumulative growth on neither the left nor the right hand sides of the fundamental interval.

Consider the case of even n. For boundedness on the right we must include the effect of 1 being a discontinuity location for Z_0. For boundedness on the left we must include the effect of 1 being a discontinuity location for Z_1.

We first look at the cumulative effect of the discontinuities contributing to growth to the right of the fundamental interval. We must consider all discontinuities from cases 1 and 2, and those of case 3 excluding the fixed point 1. The sum over all discontinuities of all periodic orbits of the type of case 2 is

$$\sum_{y\in(\omega^2,1]} D_0(y). \tag{4.1}$$

The combined contribution of all discontinuities of all periodic orbits of the type of cases 1 and 3 is

$$-\sum_{y\in(-\omega,1)} D_1(y), \tag{4.2}$$

the contributions from case 1 being of the form $+D_0(y_{i-1})=-D_1(y_i)$, and from case 3 of the form $-D_1(y_i)$. Note that 1 is excluded from the range of this sum since, as we noted above, discontinuities associated with 1 being a discontinuity of the type of case 3 are to the left of the fundamental interval for even n. Because of the same relative spacing of discontinuity locations, as we increase to the right the contributions from all three cases grow at the same rate. For boundedness we therefore require the sum of (4.1) and (4.2) to be zero, i.e., we require

$$\sum_{y\in(\omega^2,1]} D_0(y)=\sum_{y\in(-\omega,1)} D_1(y). \tag{4.3}$$

Now look to the left of the fundamental interval (with n still even). The sum over all discontinuities of all periodic orbits of the type of case 2 is now

$$\sum_{y\in(\omega^2,1)} D_0(y), \tag{4.4}$$

and the sum over all discontinuities of all periodic orbits of the type of cases 1 and 3 is

$$-\sum_{y\in(-\omega,1]} D_1(y), \tag{4.5}$$

where 1 is now excluded from the first sum since discontinuities associated with a 1 being a discontinuity of the type of case 2 are to the right of the fundamental interval for even n. For the same reasons as above, we require the sum of (4.4) and (4.5) to be zero, i.e., we require

$$\sum_{y\in(\omega^2,1)} D_0(y)=\sum_{y\in(-\omega,1]} D_1(y). \tag{4.6}$$

For even n, it is clear that if condition (4.3) is violated, there will be unbounded growth on the right, while if condition (4.6) is violated, there will be unbounded growth on the left. Thus our combined conditions are necessary and sufficient. [Consideration of boundedness for odd n results in the same two conditions (4.3) and (4.6).] We thus have the following.

Theorem 2: *A necessary and sufficient criterion for a piecewise-constant periodic orbit of (2.2) to be globally bounded is*

$$\sum_{y\in(-\omega,1]} D_1(y)=\sum_{y\in(\omega^2,1)} D_0(y) \quad \text{and} \quad \sum_{y\in(-\omega,1)} D_1(y)=\sum_{y\in(\omega^2,1]} D_0(y). \tag{4.7}$$

Note that in general the inclusion or exclusion of 1 from the intervals in these sums is crucial. (However, the points $-\omega$ and ω^2 are never discontinuities.) Further note that when 1 is not a discontinuity location these two conditions are identical. For instance, for the period-6 orbit resulting from Examples 1 and 2 the condition (4.7) is the single constraint $X_0^0-X_1^0+X_2^0+X_0^1=0$.

We remark that we may produce orbits that are unbounded, but *relatively globally bounded* by ensuring the condition of Theorem 2 is satisfied but the condition for periodicity of Sec. II F (Theorem 1) is violated. [We define the orbit (Z_n) to be relatively globally bounded if there exists a constant K such that $|Z_n(x)-Z_n(0)|\leqslant K$ for all $x\in\mathbb{R}$ and for all $n\in\mathbb{N}$.] The simplest example of such an orbit is that generated by the constant functions $Z_0(x)=0$, $Z_1(x)=1$ in which there are no discontinuities.

From the physical point of view we deduce that we may choose many forms for the modulation function in (1.11), and, provided the conditions for periodicity (Theorem 1) and global boundedness (Theorem 2) are satisfied, the resulting autocorrelation function will display asymptotic self-similarity. More precisely, provided the function Φ is chosen so that the initial conditions $Z_0(x)=0$, $Z_1(x)=\Phi(-\omega x)$ are periodic or preperiodic on the fundamental interval $[-\omega,1]$, and that two successive functions on this periodic orbit satisfy the periodicity and global boundedness conditions, then there is asymptotic self-similarity of the autocorrelation function.

We look in detail at the particular choice (1.29) in the next section.

V. THE PERIOD-6 ORBIT

As a further application of our work in Sec. III, we now look in detail at the particular example of Feudel *et al.*[5] briefly mentioned in the Introduction. The choice of modulation function (1.29) results in the period-6 orbit shown in Fig. 2. However, it is important to note that the discontinuities of the initial conditions (1.27) do not all form discontinuities of the period-6 orbit. In particular, the function $Z_1(x)=\Phi(-\omega x)$ has a discontinuity at $x=\omega^{-1}/2$ which is not periodic for F, but its image under F is $\frac{1}{2}$, which is part of the period-two orbit $\{\frac{1}{2},-\omega/2\}$. The other discontinuity of Z_1 in the fundamental interval $[-\omega,1]$ is the fixed point 0.

Henceforth, when we refer to the orbit (Z_n) we mean the global periodic orbit, and not the orbit asymptotic to it that we generate from the periodic orbit on the fundamental interval. This global period-6 orbit is generated from the restricted discontinuity set equal to the union of Examples 1 and 2, namely $\{\frac{1}{2},-\omega/2\}\cup\{0\}$ with discontinuity values $X_0^0=-2$, $X_1^0=0$, $X_2^0=0$, corresponding to $\{\frac{1}{2},-\omega/2\}$, and $X_0^1=2$ corresponding to $\{0\}$. This data means that Z_0 has discontinuities $X_0^0=-2$ at $\frac{1}{2}$, $-X_1^0=0$ at $-\omega/2$, and $X_0^1=2$ at 0, while Z_1 has discontinuities $X_1^0=0$ at $\frac{1}{2}$, $-X_2^0=0$ at $-\omega/2$, and $-X_0^1=-2$ at 0. The point 1 is not a discontinuity point, and to guarantee periodicity we specify $Z_0^{1+}=Z_0(1)=0$, and $Z_1^{1+}=Z_1(1)=-1$ according to (2.35). We further note that this data satisfies the condition $X_0^0-X_1^0+X_2^0+X_0^1=0$, which is the criterion of the previous section (Theorem 2) guaranteeing a globally bounded periodic orbit.

The value of the corresponding autocorrelation function K_{P_y} at Fibonacci times F_n will be calculated explicitly in terms of the amplitude κ. Figure 1 shows K_{P_y} for the case $\kappa=\pi/2$. In the cases $n\equiv 1, 2 \bmod 3$, since (as we shall show) $Z_n=\pm 1$, Eq. (1.28) gives us $K_{P_y}(F_n)=\cos\kappa\ (=0$

when $\kappa=\pi/2$). In the case $n\equiv 0 \bmod 3$, where now (again, as we shall show) $Z_n=0,\pm 2$, we have $K_{P_y}(F_n)=1-\alpha+\alpha\cos 2\kappa$ ($=1-2\alpha$ when $\kappa=\pi/2$) where 2α is the asymptotic average value of $|Z_n|$. In Ref. 5 it is numerically calculated that $\alpha\approx 0.2236$. In fact, this constant is $1/(2\sqrt{5})$ as we shall show in this section. As a consequence, when $\kappa=\pi/2$, for $n\equiv 0 \bmod 3$ we have $K_{P_y}(F_n)\to 1-1/\sqrt{5}=0.552\,786\ldots$ as $n\to\infty$.

A. The discontinuity location sets

1. Discontinuities arising from the fixed point 0

We have that Z_0 and Z_1 both have a single discontinuity at 0 ($=0+0\omega$) only, and so, taking the limit $n\to\infty$ in Proposition 6, the discontinuity location set associated with the fixed point 0 is

$$L^1=\{\lceil i/\omega\rceil+i\omega: i\in\mathbb{Z}\}. \tag{5.1}$$

2. Discontinuities arising from the period-two orbit $\{\frac{1}{2},-\omega/2\}$

The discontinuity location sets associated with the period-two orbit $\{\frac{1}{2},-\omega/2\}$ are generated from Z_0 having a discontinuity at $\frac{1}{2}$ and Z_1 having no discontinuities in fundamental interval $[-\omega,1]$. [Of course, Z_1 has a discontinuity at $\phi_1^{-1}(\frac{1}{2})=-\omega^{-1}/2$, but this is outside the fundamental interval.] The result is period-3 behavior. Let us define the sets

$$L^{0,0}=\{\lceil i/\omega+\tfrac{1}{2}\rceil-\tfrac{1}{2}+i\omega: i\in\mathbb{Z}\}, \tag{5.2}$$

$$L^{0,1}=\{\lceil (i-\tfrac{1}{2})/\omega+\tfrac{1}{2}\rceil-\tfrac{1}{2}+(i-\tfrac{1}{2})\omega: i\in\mathbb{Z}\}, \tag{5.3}$$

$$L^{0,2}=\{\lceil (i-\tfrac{1}{2})/\omega\rceil+(i-\tfrac{1}{2})\omega: i\in\mathbb{Z}\}. \tag{5.4}$$

Then we have the following.

Proposition 8: The discontinuity location sets L_n generated by the period-2 orbit $\{\frac{1}{2},-\omega/2\}$ satisfy

$$L^{0,0}\cap L_n=\{\lceil i/\omega+\tfrac{1}{2}\rceil-\tfrac{1}{2}+i\omega: i=l_n^0,\ldots,r_n^0\},\quad n\equiv 0 \bmod 3; \tag{5.5}$$

$$L^{0,1}\cap L_n=\{\lceil (i-\tfrac{1}{2})/\omega+\tfrac{1}{2}\rceil-\tfrac{1}{2}+(i-\tfrac{1}{2})\omega: i=l_n^1,\ldots,r_n^1\},\quad n\equiv 1 \bmod 3; \tag{5.6}$$

$$L^{0,2}\cap L_n=\{\lceil (i-\tfrac{1}{2})/\omega\rceil+(i-\tfrac{1}{2})\omega: i=l_n^2,\ldots,r_n^2\},\quad n\equiv 2 \bmod 3, \tag{5.7}$$

where, as $n\to\infty$, $l_n^k\to-\infty$, $r_n^k\to\infty$ for $k=0,1,2$, so that the sets $L^{0,0}$, $L^{0,1}$, $L^{0,2}$ are the limits as $m\to\infty$ of the sequences (L_{3m}), (L_{3m+1}), (L_{3m+2}), respectively.

Proof: We must consider the three residue classes modulo 3 separately. We shall use the readily established fact that the Fibonacci numbers have the following parity structure: $F_n\equiv 0 \bmod 2$ when $n\equiv 0 \bmod 3$, and $F_n\equiv 1 \bmod 2$ when $n\equiv 1,2 \bmod 3$.

(a) $n\equiv 0 \bmod 3$. We treat the two cases $n\equiv 0 \bmod 6$, $n\equiv 3 \bmod 6$, separately.

In the case $n\equiv 0 \bmod 6$, so that n is even, Proposition 6 gives

$$L_n=\{F_{n+1}/2+\lceil i/\omega\rceil+(F_n/2+i)\omega: i=-F_n,\ldots,F_{n-1}-1\}, \tag{5.8}$$

which by relabeling is

$$L_n=\{F_{n+1}/2+\lceil (i-F_n/2)/\omega\rceil+i\omega: i=-F_n/2,\ldots,F_n/2+F_{n-1}-1\}. \tag{5.9}$$

(Note that F_n is even.) To establish the result we must show that

$$F_{n+1}/2+\lceil (i-F_n/2)/\omega\rceil=\lceil i/\omega+\tfrac{1}{2}\rceil-\tfrac{1}{2} \tag{5.10}$$

for a suitable range of i. Now, since F_{n+1} is odd,

$$\begin{aligned}\tfrac{1}{2}+F_{n+1}/2+\lceil(i-F_n/2)/\omega\rceil&=\lceil\tfrac{1}{2}+F_{n+1}/2+(i-F_n/2)/\omega\rceil\\&=\lceil\tfrac{1}{2}+(i+(F_{n+1}\omega-F_n)/2)/\omega\rceil\\&=\lceil\tfrac{1}{2}+(i+\omega^{n+1}/2)/\omega\rceil=\lceil i/\omega+1/2+\omega^n/2)\rceil,\end{aligned}\tag{5.11}$$

where we have used the identity (1.24). We must show that for suitable i this equals $\lceil i/\omega+\frac{1}{2}\rceil$. Since $i/\omega=i+i\omega$ our desired equality may be written as $\lceil i\omega+\frac{1}{2}+\omega^n/2\rceil=\lceil i\omega+\frac{1}{2}\rceil$, which is true if, and only if, $\lceil i\omega+\frac{1}{2}\rceil-(i\omega+\frac{1}{2})\geqslant\omega^n/2$, in which we note that $\lceil i\omega+\frac{1}{2}\rceil-(i\omega+\frac{1}{2})=|i\omega+\frac{1}{2}-r|$, where $r=\lceil i\omega+\frac{1}{2}\rceil$.

Now since the ratios of successive Fibonacci numbers are the continued fraction approximants to ω we have that

$$|q\omega-p|\geqslant|F_n\omega-F_{n-1}|=\omega^n,\tag{5.12}$$

for all $p\in\mathbb{Z}$ and all integers q with $|q|\leqslant F_n$.

We thus have $|2i\omega+1-2r|\geqslant\omega^n$ for all integers i such that $2|i|\leqslant F_n$, i.e., $|i\omega+\frac{1}{2}-r|\geqslant\omega^n/2$, for all integers i such that $|i|\leqslant F_n/2$. This establishes our desired equality for a range of i of the desired type.

The case $n\equiv3$ mod 6 is similar, with minor modifications to take into account the oddness of n. Such modifications may be seen in the proof of the first part of the next case.

(b) $n\equiv1$ mod 3. We consider separately the two cases $n\equiv1$ mod 6, $n\equiv4$ mod 6.

In the case $n\equiv1$ mod 6, so that n is odd, Proposition 6 gives

$$L_n=\{-F_{n+1}/2+\lceil i/\omega\rceil+(i-F_n/2)\omega:i=-F_{n-1},\ldots,F_n-1\},\tag{5.13}$$

which by relabeling is

$$L_n=\{-F_{n+1}/2+\lceil(i+(F_n-1)/2)/\omega\rceil+(i-\tfrac{1}{2})\omega:i=-F_{n-1}-(F_n-1)/2,\ldots,(F_n-1)/2\}.\tag{5.14}$$

(Note that F_n is now odd.) To establish the result we must show that

$$-F_{n+1}/2+\lceil(i+(F_n-1)/2)/\omega\rceil=\lceil(i-\tfrac{1}{2})/\omega+\tfrac{1}{2}\rceil-\tfrac{1}{2}\tag{5.15}$$

for a suitable range of i. We now proceed as in case (a). First we have

$$1/2-F_{n+1}/2+\lceil(i+(F_n-1)/2)/\omega\rceil=\lceil i/\omega-\omega/2+\omega^n/2\rceil,\tag{5.16}$$

and so we must show that $\lceil i\omega-\omega/2+\omega^n/2\rceil=\lceil i\omega-\omega/2\rceil$ for suitable i, which is true if, and only if, $\lceil i\omega-\omega/2\rceil-(i\omega-\omega/2)>\omega^n/2$. Now $\lceil i\omega-\omega/2\rceil-(i\omega-\omega/2)=|i\omega-\omega/2-r|$, where $r=\lceil i\omega-\omega/2\rceil$, and we have $|2i\omega-\omega-2r|=|(2i-1)\omega-2r|\geqslant\omega^n$ for all integers i such that $|2i-1|<F_n$. This is just $|i\omega-\omega/2-r|>\omega^n/2$ for such a range of i as desired.

The case $n\equiv4$ mod 6 is similar.

(c) $n\equiv2$ mod 3. We omit the detail for this case which is similar to those above. □

B. Combining the discontinuities

Note that

$$L^{0,n}\subset\begin{cases}(\mathbb{Z}/2-\mathbb{Z})+\omega\mathbb{Z}, & n=0,\\(\mathbb{Z}/2-\mathbb{Z})+\omega(\mathbb{Z}/2-\mathbb{Z}), & n=1,\\\mathbb{Z}+\omega(\mathbb{Z}/2-\mathbb{Z}), & n=2,\end{cases}\tag{5.17}$$

while

$$L^1 \subset \mathbb{Z} + \omega\mathbb{Z}. \tag{5.18}$$

It follows that the discontinuity location sets generated from the period-two orbit $\{\frac{1}{2}, -\omega/2\}$ are disjoint from those associated with the fixed point 0. Thus, there can be no cancellation, or even modification, of the discontinuities generated by one periodic orbit ($\{\frac{1}{2}, -\omega/2\}$ or $\{0\}$) by the other. We further recall that the elements of each of these sets form an increasing sequence with separation either $1+\omega$ or $2+\omega$.

The initial conditions for the discontinuities are $X_0^0 = -2$, $X_1^0 = X_2^0 = 0$, and $X_0^1 = 2$. It follows that each discontinuity of Z_n due to the period-two orbit $\{\frac{1}{2}, -\omega/2\}$ is of size -2 when n is even, and of size 2 when n is odd. Each discontinuity of Z_n due to the fixed point 0 is of size 2 when n is even, and of size -2 when n is odd.

As well as specifying the initial discontinuity data, we have also specified the initial values $Z_0(1) = 0$ and $Z_1(1) = -1$, thereby giving us initial conditions asymptotic to a globally bounded periodic orbit of period-6. It is straightforward to check that $Z_2(1) = 1$, $Z_3(1) = 0$, $Z_4(1) = 1$, $Z_5(1) = -1$, so that, knowing from Sec. II that the discontinuities have period-6 satisfying $D_{n+3} = -D_n$, the periodic orbit (Z_n) itself satisfies $Z_{n+3} = -Z_n$.

C. Calculation of the autocorrelation function

Given this detailed knowledge of the locations and sizes of all discontinuities we can calculate the autocorrelation function (1.28). We denote the discontinuity locations associated with the fixed point 0 given in (5.1) as $a_i^1 + b_i^1\omega$, and those associated with the period-2 orbit $\{\frac{1}{2}, -\omega/2\}$ given in (5.2)–(5.4) as $a_i^0 + b_i^0\omega$.

We must consider the three residue classes modulo 3 separately.

1. n≡0 mod 3

When $n \equiv 0 \bmod 3$ we see from (5.1) and (5.2) that discontinuities may be matched by the coefficients of ω. The separation of matched discontinuities is then

$$a_i^1 + b_i^1\omega - (a_i^0 + b_i^0\omega) = \lceil i/\omega \rceil + i\omega - (\lceil i/\omega + \tfrac{1}{2} \rceil - \tfrac{1}{2} + i\omega) = \tfrac{1}{2} + \lceil i/\omega \rceil - \lceil i/\omega + \tfrac{1}{2} \rceil = \pm\tfrac{1}{2}, \tag{5.19}$$

and these discontinuities occur in strict alternation since the separation of elements in each sequence is either $1+\omega$ or $2+\omega$.

Now when, in addition, n is even so that $n \equiv 0 \bmod 6$, each discontinuity from $\{\frac{1}{2}, -\omega/2\}$ has size $X_0^0 = -2$, while each discontinuity from $\{0\}$ has size $X_0^1 = 2$. Moreover, we have that $Z_n(1) = 0$, so that the matched discontinuities combine to give an interval of height ± 2 and width $\frac{1}{2}$ in the graph of Z_n, as in the top two graphs in Fig. 2. For instance, the first pair after 1 is $2+\omega$ with discontinuity 2, and $\frac{5}{2}+\omega$ with discontinuity -2. Thus the graph of Z_n consists of intervals at height zero punctuated by excursions of width $\frac{1}{2}$ to a height ± 2. The analysis for odd n (i.e., so that now $n \equiv 3 \bmod 6$) is identical, but with all signs reversed.

The autocorrelation function values $K_{P_y}(F_n)$ may now be calculated.

Theorem 3: *Let* (Z_n) *be the globally bounded period-6 orbit of* (2.2) *generated by discontinuity set* $\{\frac{1}{2}, -\omega/2, 0\}$ *with initial data* $D_0(\frac{1}{2}) = -2$, $D_0(-\omega/2) = 0$, $D_0(0) = 2$, $D_1(\frac{1}{2}) = 0$, $D_1(-\omega/2) = 0$, $D_1(0) = -2$, *with* $Z_0^{1+} = Z_0(1) = 0$, *and* $Z_1^{1+} = Z_1(1) = -1$. *Then, for* $n \equiv 0 \bmod 3$,

$$\lim_{n\to\infty} K_{P_y}(F_n) = 1 - \alpha + \alpha\cos 2\kappa, \tag{5.20}$$

where

$$\alpha = \frac{1}{2\sqrt{5}}. \tag{5.21}$$

For the special case $\kappa=\pi/2$ shown in Fig. 1 we thus have $K_{P_y}(F_n)\to 1-1/\sqrt{5}=0.552\,786\ldots$ as $n\to\infty$ with $n\equiv 0 \bmod 3$.

Proof: We have already seen that Z_n takes values 0, ± 2. Note that

$$\cos \kappa Z_n(y)=\begin{cases}1, & Z_n(y)=0,\\ \cos 2\kappa, & |Z_n(y)|=2.\end{cases} \tag{5.22}$$

Thus, defining

$$\alpha_n=\frac{1}{(-\omega)^{-n}}\int_0^{(-\omega)^{-n}}\frac{|Z_n(y)|}{2}dy, \tag{5.23}$$

as the proportion of the interval $[0,\omega^{-n}]$ for even n, $[-\omega^{-n},0]$ for odd n, for which $|Z_n(y)|=2$, (1.28) becomes

$$K_{P_y}(F_n)=1-\alpha_n+\alpha_n\cos 2\kappa. \tag{5.24}$$

Now

$$F_n=\frac{\omega^{-n}}{\sqrt{5}}+O(1), \tag{5.25}$$

from which it is straightforward to deduce that

$$\omega^{-n}=F_{n+1}+F_n\omega+O(1). \tag{5.26}$$

We now recognize that $F_{n+1}+F_n\omega$, respectively $-(F_{n+1}+F_n\omega)$, is a discontinuity point generated by the fixed point 0, and thus the interval $[0,\omega^{-n}]$, respectively $[-\omega^{-n},0]$, contains $F_n+O(1)$ intervals of length $\frac{1}{2}$ with $|Z_n|=2$, and thus

$$\alpha_n=\frac{F_n+O(1)}{2\omega^{-n}}\to\frac{1}{2\sqrt{5}}. \tag{5.27}$$

Hence the result. □

2. $n\equiv 1$ mod 3

When $n\equiv 1 \bmod 3$ the discontinuity location sets are given by (5.1) and (5.3). We have

$$\begin{aligned}a_i^1+b_i^1\omega-(a_i^0+b_i^0\omega)&=\lceil i/\omega\rceil+i\omega-(\lceil(i-\tfrac{1}{2})/\omega+\tfrac{1}{2}\rceil-\tfrac{1}{2}+(i-\tfrac{1}{2})\omega)\\&=\omega^{-1}/2+\lceil i/\omega\rceil-\lceil i/\omega-\omega/2\rceil>0\end{aligned} \tag{5.28}$$

and

$$\begin{aligned}a_{i+1}^0+b_{i+1}^0\omega-(a_i^1+b_i^1\omega)&=\lceil(i+\tfrac{1}{2})/\omega+\tfrac{1}{2}\rceil-\tfrac{1}{2}+(i+\tfrac{1}{2})\omega-(\lceil i/\omega\rceil+i\omega)\\&=\lceil i/\omega+\omega/2\rceil-\lceil i/\omega\rceil+\omega^{-1}/2>0,\end{aligned} \tag{5.29}$$

so that the two sets of discontinuities alternate in a strict manner. (Note that the distance between discontinuities may be $\omega^{-1}/2$ or $1+\omega^{-1}/2$. See the second row of Fig. 2.)

When, in addition, n is odd, i.e., $n\equiv 1 \bmod 6$, each discontinuity from $\{\frac{1}{2},-\omega/2\}$ has size $-X_0^0=2$, while each discontinuity from $\{0\}$ has size $-X_0^1=-2$. We further have $Z_n(1)=-1$ in this case, and the first discontinuity after 1 is $\frac{3}{2}+\omega/2$ at which Z_n increases to $+1$. Thus Z_n oscillates between values ± 1 with discontinuity locations as calculated above.

The situation for the subcase in which n is even (i.e., $n \equiv 4 \bmod 6$) follows similarly, or more simply from the fact that $Z_{n+3} = -Z_n$.

It is a simple consequence of the fact that $Z_n = \pm 1$ that the autocorrelation function value $K_{P_y}(F_n)$ in Eq. (1.28) equals $\cos \kappa$.

3. $n \equiv 2 \bmod 3$

When $n \equiv 2 \bmod 3$ the discontinuity location sets are given by (5.1) and (5.4). We have

$$a_i^1 + b_i^1 \omega - (a_i^0 + b_i^0 \omega) = \lceil i/\omega \rceil + i\omega - (\lceil (i - \tfrac{1}{2})/\omega \rceil + (i - \tfrac{1}{2})\omega) = \omega/2 + \lceil i/\omega \rceil - \lceil i/\omega - \omega^{-1}/2 \rceil > 0 \tag{5.30}$$

and

$$a_{i+1}^0 + b_{i+1}^0 \omega - (a_i^1 + b_i^1 \omega) = \lceil (i + \tfrac{1}{2})/\omega \rceil + (i + \tfrac{1}{2})\omega - (\lceil i/\omega \rceil + i\omega) = \lceil i/\omega + \omega^{-1}/2 \rceil - \lceil i/\omega \rceil + \omega/2 > 0. \tag{5.31}$$

(Note now that the distance between discontinuities may be $\omega/2$ or $1 + \omega/2$. See the third row of Fig. 2.)

For both even and odd cases here, as in the previous case, we deduce that the two sets of discontinuities alternate in a strict manner, and, since $Z_{6l+2}(1) = -Z_{6l+5}(1) = 1$, that for all $n \equiv 2 \bmod 3$, Z_n oscillates between values ± 1 with discontinuity locations as calculated above.

Again, we immediately deduce that in this case (1.28) is simply $K_{P_y}(F_n) = \cos \kappa$.

VI. CONCLUSION

We have verified and generalized rigorously the numerical results in Ref. 5 concerning the asymptotic self-similarity of the autocorrelation function in a quasiperiodically forced two-level quantum system. As in studies of the self-similar fluctuations of the localized eigenstates of the Harper equation,[7] the birth of a strange nonchaotic attractor,[9] and of the autocorrelation function of a strange nonchaotic attractor,[4] this self-similarity is explained by means of a functional recurrence, the key to the understanding of which is the dynamics of a simple piecewise-linear map of the interval.[11–13]

To accomplish this task, a description of the piecewise-constant periodic orbits of the additive recurrence (1.1) has been completed. Moreover, a necessary and sufficient criterion for such orbits to be spatially bounded has been derived. As a consequence, provided the locations of its discontinuities are carefully chosen, a piecewise-constant modulation function gives rise to asymptotic self-similarity of the autocorrelation function. It seems likely that, as in the case of the generalized Harper equation with next-nearest-neighbor interactions,[7,13] there will be an underlying strange set on which these orbits lie. If so, an understanding of the form of the autocorrelation function in the presence of a general piecewise-constant modulation function will follow.

Our work has been in the case of golden mean frequency only, but numerical work in Ref. 5 for this problem indicates that the singular continuous spectrum is present for a wider class of irrationals. For the parallel problem of the autocorrelation function in strange nonchaotic attractors, there is evidence in Ref. 14 that, at least for certain quadratic irrational frequencies, the autocorrelation function displays self-similarity of the type studied here. Periodic orbits of a generalization of the functional recurrence (1.1) provide an explanation of this phenomenon in both settings, and will be the subject of a forthcoming paper.

(Received 16 October 2001; accepted for publication 11 April 2002)

We investigate particular models which can be $\mathcal{N}$-fold supersymmetric at specific values of a parameter in the Hamiltonians. The models to be investigated are a periodic potential and a parity-symmetric sextic triple-well potential. Through the quantitative analyses on the nonperturbative contributions to the spectra by the use of the valley method, we show how the characteristic features of $\mathcal{N}$-fold supersymmetry which have been previously reported by the authors can be observed. We also clarify the difference between quasi-exactly solvable and quasi-perturbatively solvable cases in view of the dynamical property, that is, dynamical $\mathcal{N}$-fold supersymmetry breaking. © *2002 American Institute of Physics*.
[DOI: 10.1063/1.1485115]

I. INTRODUCTION

In our previous paper,[1] we have formulated in formal and abstract ways *$\mathcal{N}$-fold supersymmetry* in quantum mechanics[2–6] and investigated general properties of the models which possess this symmetry. $\mathcal{N}$-fold supersymmetry is characterized by the supercharges which are $\mathcal{N}$-th order polynomials of momentum and similar generalizations of supercharges were also investigated in different contexts.[7–23] We have shown that $\mathcal{N}$-fold supersymmetric models have a lot of significant properties similar to the ordinary supersymmetric ones[24–27] such as degenerate spectral structure between bosonic states and fermionic ones, non-renormalization theorems for the generalized Witten index and for a part of the spectra, and so on. Furthermore, we have introduced the notion of *quasi-solvability* to identify an important aspect of $\mathcal{N}$-fold supersymmetry and have proved the equivalence between $\mathcal{N}$-fold supersymmetry and quasi-solvability. Recently, we have further shown[5] that *Type A* subclass of $\mathcal{N}$-fold supersymmetry, which was first introduced in Ref. 4, is equivalent to the quasi-solvable models constructed by sl(2) generators.[28] Then, it has turned out that the equivalence between them for special cases which had been reported previously in Refs. 2, 17, and 23 holds generically.

Quasi-solvability means the existence of a finite dimensional invariant subspace under the action of the Hamiltonian. As a consequence, a part of the spectra can be solved by a finite dimensional algebraic equation. In the case where the subspace is physical, that is, L^2, these spectra give the *true* eigenvalues of the Hamiltonian. In this case, the system is often called *quasi-exactly solvable*.[28–30] On the other hand, if the subspace is not physical, solvable spectra only give *perturbative* eigenvalues at most and thus we have dubbed this case *quasi-perturbatively solvable*.[4] This distinction is quite important, especially in view of dynamical $\mathcal{N}$-fold supersymmetry breaking; $\mathcal{N}$-fold supersymmetry is broken dynamically if a system is quasi-perturbatively solvable while it is not broken if a system is quasi-exactly solvable.

In this article, we analyze particular models which can be $\mathcal{N}$-fold supersymmetric more

quantitatively. Previously in Ref. 2, an asymmetric quartic double-well potential was investigated in detail by the valley method.[31–39] It was shown that the system possesses $\mathcal{N}$-fold supersymmetry at specific values of a parameter in the Hamiltonian where the leading Borel singularity of the perturbative corrections for the first $\mathcal{N}$-th energies disappear. This result is a consequence of a general property of $\mathcal{N}$-fold supersymmetry, namely, the non-renormalization theorem. It was also shown that the nonperturbative corrections for the first $\mathcal{N}$-th energies do not vanish even when the system becomes $\mathcal{N}$-fold supersymmetric. This result consistently reflects the fact that, in the case of an asymmetric quartic double-well potential, the solvable subspace is not physical, that is, the system is quasi-perturbatively solvable; nonvanishing nonperturbative effects break $\mathcal{N}$-fold supersymmetry dynamically.

These observations show that combining with the formal discussions in Ref. 1 quantitative analyses may give deeper and complement understanding on dynamical properties of the $\mathcal{N}$-fold supersymmetric models. As in the case of the ordinary supersymmetric models, nonperturbative analyses are quite important in the $\mathcal{N}$-fold supersymmetric case; dynamical $\mathcal{N}$-fold supersymmetry breaking can take place via purely nonperturbative effects, e.g., quantum tunneling. However, nonperturbative analyses are in general quite nontrivial even in the simple one-dimensional quantum mechanics. The valley method is one of the most successful tools for this kind of purpose. So we fully employ it in this work.

The article organizes as follows. In the next section, we summarize the general results and properties of the Type A subclass of $\mathcal{N}$-fold supersymmetry.[1,4–6] In Sec. III, we develop particular cases of the Type A models which are especially relevant for the analyses in this article. Sections IV and V are devoted to valley method analyses on a periodic and a sextic triple-well potential, respectively. We choose potentials to be investigated so that the systems can be Type A $\mathcal{N}$-fold supersymmetric at specific values of a parameter involved in the potentials. The way of the choice enables us to clarify the characteristic features of Type A $\mathcal{N}$-fold supersymmetry. The periodic potential is always quasi-exactly solvable when Type A N-fold supersymmetric while the triple-well potential can be either quasi-exactly or quasi-perturbatively solvable. In both the cases we show that the disappearance of the leading Borel singularity occurs. However, the nonperturbative corrections vanish when and only when the systems are quasi-exactly solvable. Finally, we give summary in the last section.

II. GENERAL PROPERTIES OF TYPE A $\mathcal{N}$-FOLD SUPERSYMMETRY

First of all, we summarize the general results and properties of Type A $\mathcal{N}$-fold supersymmetry. For details, e.g., derivation of the results, see Refs. 1 and 5. To define $\mathcal{N}$-fold supersymmetry, we introduce the following Hamiltonian $\mathbf{H}_{\mathcal{N}}$ and the $\mathcal{N}$-fold supercharges,

$$\mathbf{H}_{\mathcal{N}}=H_{\mathcal{N}}^{-}(p,q)\psi\psi^{\dagger}+H_{\mathcal{N}}^{+}(p,q)\psi^{\dagger}\psi, \tag{2.1}$$

$$Q_{\mathcal{N}}=P_{\mathcal{N}}^{\dagger}(p,q)\psi, \quad Q_{\mathcal{N}}^{\dagger}=P_{\mathcal{N}}(p,q)\psi^{\dagger}. \tag{2.2}$$

Here ψ and $\psi^{\dagger}$ are fermionic coordinates which satisfy

$$\{\psi,\psi\}=\{\psi^{\dagger},\psi^{\dagger}\}=0, \quad \{\psi,\psi^{\dagger}\}=1, \tag{2.3}$$

and are usually represented as the following 2×2 matrix form:

$$\psi=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}, \quad \psi^{\dagger}=\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix}. \tag{2.4}$$

The component of the $\mathcal{N}$-fold supercharges $P_{\mathcal{N}}$ is given by an $\mathcal{N}$-th order polynomial of $p=-id/dq$ and thus expressed as

$$P_{\mathcal{N}}=p^{\mathcal{N}}+w_{\mathcal{N}-1}(q)p^{\mathcal{N}-1}+\cdots+w_1(q)p+w_0(q), \tag{2.5}$$

without any loss of generality. Then, the system is said to be $\mathcal{N}$-fold supersymmetric if the Hamiltonian $\mathbf{H}_{\mathcal{N}}$ commutes with the $\mathcal{N}$-fold supercharges $Q_{\mathcal{N}}$ and $Q_{\mathcal{N}}^{\dagger}$:

$$[Q_{\mathcal{N}},\mathbf{H}_{\mathcal{N}}]=[Q_{\mathcal{N}}^{\dagger},\mathbf{H}_{\mathcal{N}}]=0. \tag{2.6}$$

The Type A $\mathcal{N}$-fold supersymmetry is characterized by a particular class of the $\mathcal{N}$-fold supercharges which can be expressed as the following form:[40]

$$\begin{aligned} P_{\mathcal{N}}&=\left(D+i\frac{\mathcal{N}-1}{2}E(q)\right)\left(D+i\frac{\mathcal{N}-3}{2}E(q)\right)\cdots\left(D-i\frac{\mathcal{N}-1}{2}E(q)\right)\\ &\equiv\prod_{k=-(\mathcal{N}-1)/2}^{(\mathcal{N}-1)/2}(D+ikE(q)),\quad D=p-iW(q). \end{aligned} \tag{2.7}$$

If we restrict $H_{\mathcal{N}}^{\pm}$ to be the following Schrödinger type,

$$H_{\mathcal{N}}^{\pm}=\tfrac{1}{2}p^2+V_{\mathcal{N}}^{\pm}(q), \tag{2.8}$$

we can show[5] that necessary and sufficient conditions of the Hamiltonian (2.1) with (2.8) to be Type A $\mathcal{N}$-fold supersymmetric, that is, to satisfy the relation (2.6), are as the following:

$$V_{\mathcal{N}}^{\pm}(q)=\frac{1}{2}W(q)^2+\frac{\mathcal{N}^2-1}{24}(E(q)^2-2E'(q))\pm\frac{\mathcal{N}}{2}W'(q), \tag{2.9a}$$

$$\left(\frac{d}{dq}-E(q)\right)\frac{d}{dq}\left(\frac{d}{dq}+E(q)\right)W(q)=0\quad(\mathcal{N}\geqslant 2), \tag{2.9b}$$

$$\left(\frac{d}{dq}-2E(q)\right)\left(\frac{d}{dq}-E(q)\right)\frac{d}{dq}\left(\frac{d}{dq}+E(q)\right)E(q)=0\quad(\mathcal{N}\geqslant 3). \tag{2.9c}$$

A. The solvable subspaces

Owing to the relation Eq. (2.6), the $\mathcal{N}$-dimensional vector spaces defined by

$$\mathcal{V}_{\mathcal{N}}^{-}=\ker P_{\mathcal{N}},\quad \mathcal{V}_{\mathcal{N}}^{+}=\ker P_{\mathcal{N}}^{\dagger} \tag{2.10}$$

are invariant under the action of $H_{\mathcal{N}}^{-}$ and $H_{\mathcal{N}}^{+}$, respectively. We can therefore define the matrices $\mathbf{S}^{\pm}$ as follows:

$$H_{\mathcal{N}}^{\pm}\phi_n^{\pm}=\sum_{m=1}^{\mathcal{N}}\mathbf{S}_{n,m}^{\pm}\phi_m^{\pm}, \tag{2.11}$$

where $\phi^{\pm}$ are bases of the $\mathcal{V}_{\mathcal{N}}^{\pm}$, respectively. It can be proved[1] for general $\mathcal{N}$-fold supersymmetry that the *mother Hamiltonian* $\mathcal{H}_{\mathcal{N}}$ defined by the anticommutator of the supercharges can be expressed as

$$\mathcal{H}_{\mathcal{N}}\equiv\frac{1}{2}\{Q_{\mathcal{N}}^{\dagger},Q_{\mathcal{N}}\}=\frac{1}{2}\begin{pmatrix}\det\mathbf{M}_{\mathcal{N}}^{+}(H_{\mathcal{N}}^{+})+p^{+}P_{\mathcal{N}}^{\dagger} & 0\\ 0 & \det\mathbf{M}_{\mathcal{N}}^{-}(H_{\mathcal{N}}^{-})+p^{-\dagger}P_{\mathcal{N}}\end{pmatrix}, \tag{2.12}$$

where

$$\mathbf{M}_{\mathcal{N}}^{\pm}(\lambda)=2(\lambda\mathbf{I}-\mathbf{S}^{\pm}), \tag{2.13}$$

and $p^{\pm}$ are at most $(\mathcal{N}-1)$-th order differential operators. From the definition of the mother Hamiltonian (2.12), the elements of the subspaces $\mathcal{V}_{\mathcal{N}}^{\pm}$ are also characterized as the zero-modes of the mother Hamiltonian.

In the case of Type A, we can obtain analytic expressions for these bases:

$$\phi_n^{\pm}(q)=h(q)^{n-1}h'(q)^{-(\mathcal{N}-1)/2}U(q)^{\pm 1}, \quad (n=1,\ldots,\mathcal{N}), \tag{2.14}$$

where[41]

$$U(q)=e^{\int dq W(q)}, \tag{2.15}$$

and $h(q)$ is a solution of the following linear differential equation:

$$h''(q)-E(q)h'(q)=0, \tag{2.16}$$

and thus generically given by

$$h(q)=c_1\int dq e^{\int dq E(q)}+c_2. \tag{2.17}$$

The appearance of the two arbitrary constants $c_{1,2}$ in Eq. (2.17) reflects the fact that the spaces $\mathcal{V}_{\mathcal{N}}^{\pm}$ spanned by the bases Eq. (2.14) are invariant under any linear transformations on $h(q)$. With the aid of these bases Eq. (2.14), the components of the matrices $\mathbf{S}_{n,m}^{\pm}$ defined by Eq. (2.11) can be determined (for each fixed $n=1,\ldots,\mathcal{N}$) by the following recurrence relations:

$$\mathbf{S}_{n,\mathcal{N}-m}^{-}=\frac{P_{\mathcal{N}-m-1}(H_{\mathcal{N}}^{-}\phi_n^{-}-\Sigma_{k=\mathcal{N}-m+1}^{\mathcal{N}}\mathbf{S}_{n,k}^{-}\phi_k^{-})}{P_{\mathcal{N}-m-1}\phi_{\mathcal{N}-m}^{-}}, \tag{2.18a}$$

$$\mathbf{S}_{n,\mathcal{N}-m}^{+}=\frac{P_{\mathcal{N}-m-1}^{\dagger}(H_{\mathcal{N}}^{+}\phi_n^{+}-\Sigma_{k=\mathcal{N}-m+1}^{\mathcal{N}}\mathbf{S}_{n,k}^{+}\phi_k^{+})}{P_{\mathcal{N}-m-1}^{\dagger}\phi_{\mathcal{N}-n}^{+}}, \tag{2.18b}$$

for $m=1,\ldots,\mathcal{N}-1$ with the initial conditions

$$\mathbf{S}_{n,\mathcal{N}}^{-}=\frac{P_{\mathcal{N}-1}H_{\mathcal{N}}^{-}\phi_n^{-}}{P_{\mathcal{N}-1}\phi_{\mathcal{N}}^{-}}, \quad \mathbf{S}_{n,\mathcal{N}}^{+}=\frac{P_{\mathcal{N}-1}^{\dagger}H_{\mathcal{N}}^{+}\phi_n^{+}}{P_{\mathcal{N}-1}^{\dagger}\phi_{\mathcal{N}}^{+}}. \tag{2.19}$$

From Eq. (2.11), the spectra $E_n^{\pm}$ of the Hamiltonians $H_{\mathcal{N}}^{\pm}$ in the subspaces $\mathcal{V}_{\mathcal{N}}^{\pm}$ are given by

$$\det \mathbf{M}_{\mathcal{N}}^{\pm}(E_n^{\pm})=0. \tag{2.20}$$

If $\phi_n(q)$'s are normalizable, linear combinations of them which diagonalize the matrix $\mathbf{S}$ are the *true* eigenstates of $H_{\mathcal{N}}$. In this case, the system is often called *quasi-exactly solvable*.[28–30] On the other hand, if $\phi_n(q)$'s are not normalizable, they have, at most, restricted meanings in the perturbation theory. In this case, the spectra determined by Eq. (2.20) only give perturbatively correct ones. For this reason, we dub the case *quasi-perturbatively solvable*.[1] Then, $\mathcal{N}$-fold supersymmetry of the total system $\mathbf{H}_{\mathcal{N}}$ is dynamically broken when *both* of the systems $H_{\mathcal{N}}^{\pm}$ are quasi-perturbatively solvable. Otherwise, that is, at least one of the systems $H_{\mathcal{N}}^{\pm}$ is quasi-exactly solvable, the elements of the corresponding solvable subspace give the $\mathcal{N}$-fold supersymmetric physical states and therefore $\mathcal{N}$-fold supersymmetry is preserved.

B. A non-renormalization theorem

A kind of the non-renormalization theorem holds for the Type A models. We first assume that we can set $W(0)=0$ by the redefinition of the origin of the coordinate q and the energy. To define a perturbation theory, we then introduce a coupling constant g as

$$W(q)=\frac{1}{g}w(gq),\quad E(q)=ge(gq), \tag{2.21}$$

so that, in the leading order of g, the potential $V_{\mathcal{N}}^{\pm}$ become harmonic with frequency $|w'(0)|$,

$$V_{\mathcal{N}}^{\pm}(q)=\tfrac{1}{2}w'(0)^2q^2+O(g). \tag{2.22}$$

From Eq. (2.14) with Eqs. (2.15), (2.17) and (2.21), we can easily see that the $\phi_n^{\pm}$ behave as

$$\phi_n^{\pm}(q)=U(0)^{\pm 1}(q^{n-1}+O(g))e^{\pm w'(0)q^2/2}. \tag{2.23}$$

Here, we choose the two arbitrary constants $c_{1,2}$ in Eq. (2.17) as $h(0)=0$, $h'(0)=1$. Thus, as far as $w'(0)>0(<0)$, all the $\phi_n^-(\phi_n^+)$ remain normalizable in *any finite* order of g even if $\phi_n^-(\phi_n^+)$ themselves are *not* normalizable. So, they stay the $\mathcal{N}$-fold supersymmetric vacua in any order of the perturbation theory and therefore any perturbative corrections do not break $\mathcal{N}$-fold supersymmetry.

III. SPECIAL CASES OF TYPE A $\mathcal{N}$-FOLD SUPERSYMMETRY

In this section, we illustrate some special cases of the Type A $\mathcal{N}$-fold supersymmetry by using the general results obtained in the previous section.

A. Exponential type potentials

At first, we will consider the case where $E(q)=\lambda$ (nonzero constant). This is a trivial solution of Eq. (2.9c). From Eq. (2.9b) we yield

$$W(q)=C_1e^{\lambda q}+C_2e^{-\lambda q}+C_3. \tag{3.1}$$

In this case, the Hamiltonians and the supercharge are given by

$$H_{\pm\mathcal{N}}=\frac{1}{2}p^2+\frac{1}{2}W(q)^2+\frac{\mathcal{N}^2-1}{24}\lambda^2\pm\frac{\mathcal{N}}{2}W'(q),\quad P_{\mathcal{N}}=\prod_{k=-(\mathcal{N}-1)/2}^{(\mathcal{N}-1)/2}(D+ik\lambda). \tag{3.2}$$

The function $h(q)$ can be chosen as

$$h(q)=\frac{e^{\lambda q}}{\lambda}. \tag{3.3}$$

Bases of the solvable subspaces $\mathcal{V}_{\mathcal{N}}^{\pm}$ are calculated as

$$\phi_n^{\pm}(q)=\frac{1}{\lambda^{n-1}}\exp\left[-\frac{1}{2}(\mathcal{N}-2n+1)\lambda q\pm C_3q\pm\frac{C_1}{\lambda}e^{\lambda q}\mp\frac{C_2}{\lambda}e^{-\lambda q}\right]. \tag{3.4}$$

Thus, normalizability of $\phi_n^{\pm}$ depends on the values of the constants C_i and λ. For example, provided that all the constants C_1, C_2 and λ are nonzero real numbers, either ϕ^+ or ϕ^- is normalizable when $C_1C_2<0$ while both of $\phi^{\pm}$ are not when $C_1C_2>0$. The correspondence between quasi-exact solvability and $\mathcal{N}$-fold supersymmetry in the case of the exponential type potentials Eq. (3.1) was recently discussed in Ref. 17.

The nonzero matrix elements of $\mathbf{S}^{\pm}$ can be calculated as follows. The direct action of the Hamiltonians Eq. (2.8), with the Type A potentials Eq. (2.9a), on the bases Eq. (2.14) reads

$$H_{\mathcal{N}}^{\pm}\phi_n^{\pm}=-\frac{1}{2}(n-1)(n-2)h'^2\phi_{n-2}^{\pm}+\frac{1}{2}(n-1)[(\mathcal{N}-2)h''\mp 2Wh']\phi_{n-1}^{\pm}$$
$$-\frac{\mathcal{N}-1}{12}[(\mathcal{N}-2)(E'+E^2)\mp 6(W'+EW)]\phi_n^{\pm}. \tag{3.5}$$

From Eqs. (3.1) and (3.3), the following relations hold:

$$h'^2=\lambda^2h^2, \tag{3.6a}$$

$$h''=\lambda^2h, \tag{3.6b}$$

$$E'+E^2=\lambda^2, \tag{3.6c}$$

$$Wh'=C_1\lambda^2h^2+C_3\lambda h+C_2, \tag{3.6d}$$

$$W'+EW=2C_1\lambda^2h+C_3\lambda. \tag{3.6e}$$

Substituting the above relations (3.6) for Eq. (3.5), we obtain

$$\mathbf{S}_{n,n-1}^{\pm}=\mp(n-1)C_2, \tag{3.7a}$$

$$\mathbf{S}_{n,n}^{\pm}=-\tfrac{1}{12}[(\mathcal{N}-1)(\mathcal{N}-2)+6(n-1)(n-\mathcal{N})]\lambda^2\pm\tfrac{1}{2}(\mathcal{N}-2n+1)C_3\lambda, \tag{3.7b}$$

$$\mathbf{S}_{n,n+1}^{\pm}=\mp(n-\mathcal{N})C_1\lambda^2. \tag{3.7c}$$

All the other matrix elements are zero.

The special choices $\lambda=ig$, $C_1=1/2ig$, $C_2=-1/2ig$ and $C_3=0$ lead to

$$W(q)=\frac{1}{g}\sin(gq), \quad E(q)=ig, \tag{3.8}$$

and correspond to the periodic potential in Ref. 3. We note that Eq. (3.8) is incorporated with the perturbation theory defined by Eq. (2.21). We will later carry out nonperturbative analysis of this special case in Sec. IV.

B. Sextic oscillator potentials

Next, we will consider the case where

$$E(q)=\frac{1}{q-q_0}. \tag{3.9}$$

This is also a solution of Eq. (2.9c). This special case corresponds to (one of) the cubic type in Ref. 4. The Hamiltonians and the supercharge are given by

$$H_{\mathcal{N}}^{\pm}=\frac{1}{2}p^2+\frac{1}{2}W(q)^2+\frac{\mathcal{N}^2-1}{8(q-q_0)^2}\pm\frac{\mathcal{N}}{2}W'(q), \tag{3.10}$$

$$P_{\mathcal{N}}=\prod_{k=-(\mathcal{N}-1)/2}^{(\mathcal{N}-1)/2}\left(D+i\frac{k}{q-q_0}\right), \tag{3.11}$$

with

$$W(q)=C_1(q-q_0)^3+C_2(q-q_0)+\frac{C_3}{q-q_0}. \tag{3.12}$$

We note that the Hamiltonians (3.10) are parity symmetric. The function $h(q)$ can be chosen as

$$h(q)=\frac{(q-q_0)^2}{2}. \tag{3.13}$$

Bases of the solvable subspaces $\mathcal{V}_{\mathcal{N}}^{\pm}$ are calculated as

$$\phi_n^{\pm}(q)=\frac{1}{2^{n-1}}(q-q_0)^{2n-\mathcal{N}/2-3/2\pm C_3}\exp\left[\pm\frac{C_1}{4}(q-q_0)^4\pm\frac{C_2}{2}(q-q_0)^2\right]. \tag{3.14}$$

Thus, either ϕ^+ or ϕ^- is normalizable unless $C_1=C_2=0$ and the corresponding system $H_{\mathcal{N}}^+$ or $H_{\mathcal{N}}^-$ is quasi-exactly solvable. The correspondence between quasi-exact solvability and $\mathcal{N}$-fold supersymmetry in the case of the sextic potential Eq. (3.10) was recently pointed out in Ref. 23.

The nonzero matrix elements of $\mathbf{S}^{\pm}$ can be obtained by Eq. (3.5). From Eqs. (3.9), (3.12) and (3.13), the following relations hold:

$$h'^2=2h, \tag{3.15a}$$

$$h''=1, \tag{3.15b}$$

$$E'+E^2=0, \tag{3.15c}$$

$$Wh'=4C_1h^2+2C_2h+C_3, \tag{3.15d}$$

$$W'+EW=8C_1h+2C_2. \tag{3.15e}$$

Substituting the above relations (3.15) for Eq. (3.5) we obtain

$$\mathbf{S}_{n,n-1}^{\pm}=\tfrac{1}{2}(n-1)[(\mathcal{N}-2n+2)\mp 2C_3], \tag{3.16a}$$

$$\mathbf{S}_{n,n}^{\pm}=\pm(\mathcal{N}-2n+1)C_2, \tag{3.16b}$$

$$\mathbf{S}_{n,n+1}^{\pm}=\mp 4(n-\mathcal{N})C_1. \tag{3.16c}$$

All the other matrix elements are zero.

If we rewrite Eq. (3.12) as

$$W(q)=w(q)+\frac{C_3}{q-q_0},\quad w(q)=C_1(q-q_0)^3+C_2(q-q_0), \tag{3.17}$$

the potential parts $V_{\mathcal{N}}^{\pm}(q)$ of the Hamiltonians (3.10) are, in terms of $w(q)$,

$$V_{\mathcal{N}}^{\pm}(q)=\frac{1}{2}w(q)^2+\frac{(2C_3\mp\mathcal{N}-1)(2C_3\mp\mathcal{N}+1)}{8(q-q_0)^2}\pm\left(\frac{\mathcal{N}}{2}\pm\frac{C_3}{3}\right)w'(q)+\frac{2}{3}C_2C_3. \tag{3.18}$$

We note that in the cases when $C_3=(\mathcal{N}\pm 1)/2$ and $-(\mathcal{N}\pm 1)/2$, one of the potential-pair $V_{\mathcal{N}}^{\pm}(q)$ becomes a genuine sixth order polynomial:

$$V_{\mathcal{N}}^{+}(q)=\frac{1}{2}w(q)^2+\frac{4\mathcal{N}\pm 1}{6}w'(q)\quad\left(C_3=\frac{\mathcal{N}\pm 1}{2}\right), \tag{3.19a}$$

$$V_{\mathcal{N}}^{-}(q)=\frac{1}{2}w(q)^2-\frac{4\mathcal{N}\pm 1}{6}w'(q) \quad \left(C_3=-\frac{\mathcal{N}\pm 1}{2}\right), \tag{3.19b}$$

where irrelevant constant terms are omitted. Conversely, a sextic anharmonic oscillator or a triple-well potential (with parity symmetry) can be one of the Type A $\mathcal{N}$-fold supersymmetric pair whenever the potential can be put in one of the forms of Eq. (3.19). When $C_3=(\mathcal{N}\pm 1)/2$, the bases Eq. (3.14) for $V_{\mathcal{N}}^{+}(q)$ read

$$\phi_n^{+}(q)=\frac{1}{2^{n-1}}(q-q_0)^{2n-3/2\pm 1/2}\exp\left[\frac{C_1}{4}(q-q_0)^4+\frac{C_2}{2}(q-q_0)^2\right]\left(C_3=\frac{\mathcal{N}\pm 1}{2}\right). \tag{3.20}$$

It is worth noting that the solvable subspace $\mathcal{V}_{\mathcal{N}}^{+}$ consists of the states with definite parity [odd for $C_3=(\mathcal{N}+1)/2$ and even for $C_3=(\mathcal{N}-1)/2$]. We will later see close relation between this fact and pattern of the nonperturbative spectral shifts. When $C_3=-(\mathcal{N}\pm 1)/2$, the bases Eq. (3.14) for $V_{\mathcal{N}}^{-}(q)$ are similarly

$$\phi_n^{-}(q)=\frac{1}{2^{n-1}}(q-q_0)^{2n-3/2\pm 1/2}\exp\left[-\frac{C_1}{4}(q-q_0)^4-\frac{C_2}{2}(q-q_0)^2\right]\left(C_3=-\frac{\mathcal{N}\pm 1}{2}\right). \tag{3.21}$$

Again, the subspace $\mathcal{V}_{\mathcal{N}}^{-}$ contains only odd-parity states for $C_3=-(\mathcal{N}+1)/2$ and only even-parity states for $C_3=-(\mathcal{N}-1)/2$.

C. Quartic oscillator potentials

In the next, we will consider the case where $E(q)=0$. This is also a trivial solution of Eq. (2.9c). From Eq. (2.9b) we yield

$$W(q)=C_1q^2+C_2q+C_3. \tag{3.22}$$

In this case, the Hamiltonians and the supercharge are given by

$$H_{\pm\mathcal{N}}=\frac{1}{2}p^2+\frac{1}{2}W(q)^2\pm\frac{\mathcal{N}}{2}W'(q), \quad P_{\mathcal{N}}=D^{\mathcal{N}}. \tag{3.23}$$

The function $h(q)$ reads

$$h(q)=q. \tag{3.24}$$

Bases of the solvable subspaces $\mathcal{V}_{\mathcal{N}}^{\pm}$ are calculated as

$$\phi_n^{\pm}(q)=q^{n-1}\exp\left[\pm\frac{C_1}{3}q^3\pm\frac{C_2}{2}q^2\pm C_3q\right]. \tag{3.25}$$

Thus, both of $\phi^{\pm}$ are not normalizable and therefore the system is quasi-perturbatively solvable as far as C_1 is a nonzero real number. The relation between quasi-perturbative solvability and $\mathcal{N}$-fold supersymmetry in a special case of the models was pointed out in Ref. 2.

The nonzero matrix elements of $\mathbf{S}^{\pm}$ can be obtained by Eq. (3.5). From Eqs. (3.22) and (3.24), the following relations hold:

$$h'^2=1, \tag{3.26a}$$

$$Wh'=C_1h^2+C_2h+C_3, \tag{3.26b}$$

$$W'+EW=2C_1h+C_2. \tag{3.26c}$$

Substituting the above relations (3.26) for Eq. (3.5) we obtain

$$\mathbf{S}^{\pm}_{n,n-2} = -\tfrac{1}{2}(n-1)(n-2), \tag{3.27a}$$

$$\mathbf{S}^{\pm}_{n,n-1} = \mp(n-1)C_3, \tag{3.27b}$$

$$\mathbf{S}^{\pm}_{n,n} = \pm\tfrac{1}{2}(\mathcal{N}-2n+1)C_2, \tag{3.27c}$$

$$\mathbf{S}^{\pm}_{n,n+1} = \mp(n-\mathcal{N})C_1. \tag{3.27d}$$

All the other matrix elements are zero.

IV. ANALYSIS OF A PERIODIC POTENTIAL

A. The valley method

Before proceeding to show the results of the analyses, we briefly review the valley method[31–39] which is employed in this research. For more details about the method, see Ref. 2.

The main problem in quantum theories concerns with the evaluation of the Euclidean partition function:

$$Z = \mathcal{J}\int \mathcal{D}q\, e^{-S[q]}. \tag{4.1}$$

Since the evaluation cannot be done exactly in general, one must find out a proper method which enables one to get a good estimation of the quantity. The semi-classical approximation is known to be one of the most established methods. Especially, the uses of instantons have been succeeded in analyzing nonperturbative aspects of various quantum systems which have degenerate vacua.[42] However, validity of the approximation comes into question when the fluctuations around the classical configuration contain a negative mode. Let us consider an asymmetric double-well potential as a typical example. For this potential, there is a so-called bounce solution as the classical solution which has a negative mode in the fluctuations. The negative mode contributes nonzero imaginary part of the spectra in the approximation, showing instability of the system. Since the spectra of the model must be real, the instability in the approximation must be *fake*.

The appearance of a negative mode indicates that the classical action does not give the minimum but rather a saddle point in the functional space. In this case, one may expect that the quantity (4.1) is dominated by the configurations along the negative mode, which may intuitively constitute a *valley* in the functional space. The valley method is a natural realization of this consideration.

At first, we give a geometrical definition of the valley in the functional space $q(\tau)$:[34]

$$\frac{\delta}{\delta q(\tau)}\left[\frac{1}{2}\int d\tau'\left(\frac{\delta S[q]}{\delta q(\tau')}\right)^2 - \lambda S[q]\right] = 0. \tag{4.2}$$

The above definition (4.2) can be interpreted as follows; for each fixed "height" $S[q]$, the valley is defined at the point where the norm of the gradient vector becomes extremal. Introducing an auxiliary field $F(q)$, we can make the valley equation (4.2) a more perspicuous form:

$$\frac{\delta S[q]}{\delta q(\tau)} = F(\tau), \tag{4.3a}$$

$$\int d\tau'\, D(\tau,\tau')F(\tau') = \lambda F(\tau), \tag{4.3b}$$

where the operator D is defined as

$$D(\tau,\tau')=\frac{\delta^2 S[q]}{\delta q(\tau)\,\delta q(\tau')}. \tag{4.4}$$

It is now evident that any solution of the equation of motion is also a solution of the valley equation (4.3) with $F(\tau)\equiv 0$.

Next, we separate the integration along the valley line from the whole functional integration. We parametrize the valley line by a parameter R and denote the valley configuration by $q_R(\tau)$. We then define Faddeev–Popov determinant $\Delta[\varphi_R]$ by the following:

$$\int dR\ \delta\left(\int d\tau\,\varphi_R(\tau)G_R(\tau)\right)\Delta[\varphi_R]=1, \tag{4.5}$$

where $\varphi_R(\tau)=q(\tau)-q_R(\tau)$ is the fluctuation over which we will be doing Gaussian integrations, and $G_R(\tau)$ is the normalized gradient vector,

$$G_R(\tau)=\frac{\delta S[q_R]}{\delta q_R(\tau)}\Bigg/\sqrt{\int d\tau'\left(\frac{\delta S[q_R]}{\delta q_R(\tau')}\right)^2}. \tag{4.6}$$

Inserting Eq. (4.5) into the functional integral (4.1), expanding the action $S[q]$ around $\varphi_R(\tau)=0$ and integrating up to the second order term in $\varphi_R(\tau)$, we finally obtain the one-loop order result:

$$Z=\mathcal{J}\int dR\int \mathcal{D}q\ \delta\left(\int d\tau\,\varphi_R(\tau)G_R(\tau)\right)\Delta[\varphi_R]e^{-S[q]}\simeq\mathcal{J}\int\frac{dR}{\sqrt{2\pi\det' D_R}}\Delta[\varphi_R]e^{-S[q_R]}, \tag{4.7}$$

where the Jacobian $\Delta[\varphi_R]$ is given by, in this approximation,

$$\Delta[\varphi_R]=\frac{dS[q_R]}{dR}\Bigg/\sqrt{\int d\tau'\left(\frac{\delta S[q_R]}{\delta q_R(\tau')}\right)^2}. \tag{4.8}$$

In the above, $\det'$ denotes the determinant in the functional subspace which is perpendicular to the gradient vector $G_R(\tau)$. The valley equation (4.3) ensure that the subspace does not contain the eigenvector of the eigenvalue λ. Therefore, we can safely perform the Gaussian integrations even when we encounter a nonpositive mode. The extension to the multi-dimensional valley, which will be needed when there are multiple nonpositive eigenvalues, is straightforward.

In this article, we only deal with one-dimensional quantum mechanics where the Euclidean action is given by

$$S[q]=\int d\tau\left[\frac{1}{2}\left(\frac{dq}{d\tau}\right)^2+V(q)\right]. \tag{4.9}$$

In this case, the valley equations (4.3) are explicitly written as

$$-\frac{d^2q(\tau)}{d\tau^2}+V'(q)=F(\tau), \tag{4.10a}$$

$$\left[-\frac{d^2}{d\tau^2}+V''(q)\right]F(\tau)=\lambda F(\tau). \tag{4.10b}$$

B. Valley-instantons

At first, we will analyze a periodic potential. The form of the potential to be analyzed is the following:

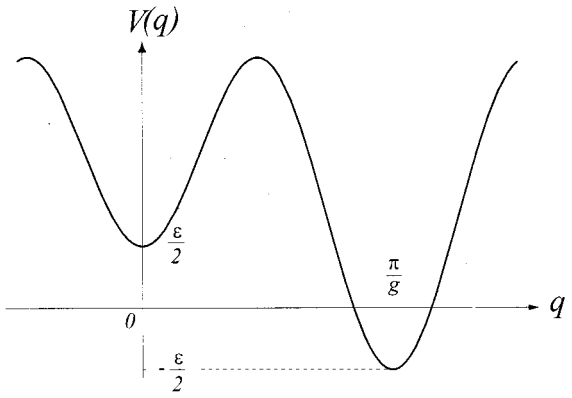

FIG. 1. The form of the periodic potential investigated in this section.

$$V(q;\epsilon)=\frac{1}{2g^2}\sin^2(gq)+\frac{\epsilon}{2}\cos(gq). \tag{4.11}$$

This is a periodic potential with periodicity $2\pi/g$ (unless $\epsilon=0$) and has two local minima at $q=2k\pi/g$ and $q=(2k+1)/g$ $(k=0,\pm1,\pm2,\ldots)$ in one period (see Fig. 1).

Comparing this potential with Eqs. (3.2) and (3.8), we find that the system has Type A $\mathcal{N}$-fold supersymmetry when

$$\epsilon=\pm\mathcal{N}. \tag{4.12}$$

Since the system is defined on a bounded region, all the bases of the solvable space $\mathcal{V}_{\mathcal{N}}^{\pm}$ are normalizable. Thus, certain linear combinations of them serve as physical eigenstates of the Hamiltonian and $\mathcal{N}$-fold supersymmetry is not broken dynamically. Therefore, we may expect that the nonperturbative corrections for certain $\mathcal{N}$ physical states will vanish and the perturbation series for the corresponding spectra will be convergent when $\epsilon=\pm\mathcal{N}$.

We note that the potential (4.11) has the following symmetry:

$$V\left(q-\frac{\pi}{g};\epsilon\right)=V(q;-\epsilon). \tag{4.13}$$

Therefore, we can restrict ϵ to be positive without any loss of generality.

In the case of $\epsilon=0$, there are (anti-)instanton solutions of the equation of motion which describe the quantum tunneling between the neighboring vacua. The instanton and anti-instanton which connect the two vacua at $q=k\pi/g$ and $q=(k+1)\pi/g$ are given by

$$q_0^{(I)}(\tau-\tau_0)=\frac{k\pi}{g}+\frac{1}{g}\arccos(-\tanh(\tau-\tau_0)), \tag{4.14a}$$

$$q_0^{\overline{(I)}}(\tau-\tau_0)=\frac{k\pi}{g}+\frac{1}{g}\arccos(\tanh(\tau-\tau_0)). \tag{4.14b}$$

When $\epsilon\neq0$, the classical solutions drastically change into the so-called bounce solutions which cause fake instability. On the other hand, the solutions of the valley equation (4.10) contain a continuously deformed (anti-)instanton which connects the two nondegenerate local minima and is called (*anti-*)*valley-instanton*.[2]

The solutions of the valley equation (4.10) also contain a family of the configurations, which tends to the trivial vacuum configuration in the one limit and tends to well-separated valley-instanton and anti-valley-instanton configuration in the other limit. The latter configuration is called $I\bar{I}$-valley. The bounce solution is also realized as an intermediate configuration of this family, which is consistent with the fact that the solution of the equation of motion is also a solution of the valley equations. For details, see the numerical result in Ref. 2. For the $I\bar{I}$-valley configuration, it turns out that $|\lambda| \ll 1$ and thus the asymptotic form of the configuration can be obtained by solving the valley equation (4.10) with perturbative expansion in λ:

$$q(\tau) = q_0(\tau) + \lambda q_1(\tau) + \cdots, \quad F(\tau) = \lambda F_1(\tau) + \lambda^2 F_2(\tau) + \cdots. \tag{4.15}$$

Indeed, if we denote the distance between the valley-instanton and the anti-valley-instanton as R, the lambda is order $\lambda \sim O(e^{-R})$ quantity. The action of the $I\bar{I}$-valley with the boundary condition $q(\pm T/2) = 2k\pi/g$ $(T \gg 1)$ is finally obtained as

$$S^{(I\bar{I})}(\tilde{R}) = S^{(\bar{I}I)}(\tilde{R}) = 2S_0^{(I)} - \frac{\epsilon}{2}\tilde{R} + \frac{\epsilon}{2}(T - \tilde{R}) - \frac{8}{g^2}e^{-\tilde{R}} + O(e^{-2\tilde{R}}), \tag{4.16}$$

while the one with $q(\pm T/2) = (2k+1)\pi/g$ $(T \gg 1)$ is

$$S^{(I\bar{I})}(R) = S^{(\bar{I}I)}(R) = 2S_0^{(I)} + \frac{\epsilon}{2}R - \frac{\epsilon}{2}(T - R) - \frac{8}{g^2}e^{-R} + O(e^{-2R}), \tag{4.17}$$

where $S_0^{(I)}$ denotes the Euclidean action of one (anti-)instanton Eq. (4.14) and amounts to

$$S_0^{(I)} = \frac{2}{g^2}. \tag{4.18}$$

In Eqs. (4.16) and (4.17), the fourth term can be interpreted as the interaction term between the valley-instanton and the anti-valley-instanton. Therefore, the minus sign indicates that the interaction is attractive.

The other type of the solutions emerges in this case, which is asymptotically composed of two successive valley-instantons or two successive anti-valley-instantons. We call them II-valley and $\overline{II}$-valley, respectively. These configurations do not appear in the case of double-well potentials since they connect every other vacuum. The Euclidean action of them with large separation R can be also calculated in the same way as

$$S^{(II)}(\tilde{R}) = S^{(\overline{II})}(\tilde{R}) = 2S_0^{(I)} - \frac{\epsilon}{2}\tilde{R} + \frac{\epsilon}{2}(T - \tilde{R}) + \frac{8}{g^2}e^{-\tilde{R}} + O(e^{-2\tilde{R}}), \tag{4.19}$$

for the configuration with $q(-T/2) = 2k\pi/g$ and $q(T/2) = (2k \pm 2)\pi/g$ $(T \gg 1)$, and

$$S^{(II)}(R) = S^{(\overline{II})}(R) = 2S_0^{(I)} + \frac{\epsilon}{2}R - \frac{\epsilon}{2}(T - R) + \frac{8}{g^2}e^{-R} + O(e^{-2R}), \tag{4.20}$$

for the one with $q(-T/2) = (2k+1)\pi/g$ and $q(T/2) = (2k+1 \pm 2)\pi/g$ $(T \gg 1)$. Note that the sign of the fourth term is plus and thus the interaction between the (anti-)valley-instantons in this case is repulsive.

C. Analysis of two-valley sector

From the results on the $I\bar{I}$-valley, the contribution of the $I\bar{I}$-valley to the partition function can be written as the following form:

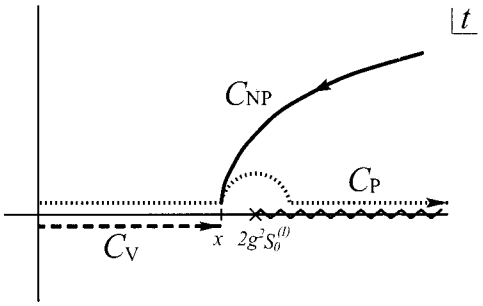

FIG. 2. Deformation of the contour C_V to the sum of C_P and C_{NP}.

$$\bar{Z^{(II)}}=\frac{4e^{-T/2}}{\pi g^2}\int_0^T dR\,(T-R)e^{-\bar{S^{II}}(R)}=\frac{4e^{-T/2}}{\pi g^2}\int_{C_V} dt\,\mathcal{F}(t)e^{-t/g^2}, \tag{4.21}$$

where we have changed the integration variable R to $t=g^2\bar{S^{II}}(R)$ in the second line. The integration contour C_V is $[0,2g^2S_0^{(I)})$ and the integrand $\mathcal{F}(t)$ has a singularity at $t=2g^2S_0^{(I)}$. The integral Eq. (4.21) contains both the perturbative contribution at $t\sim 0$ and the nonperturbative one at $t\sim 2g^2S_0^{(I)}$. To separate the perturbative and the nonperturbative contribution, we deform the contour C_V to the sum of C_P and C_{NP}:

$$\bar{Z^{(II)}}=\frac{4e^{-T/2}}{\pi g^2}\int_{C_P} dt\,\mathcal{F}(t)e^{-t/g^2}+\frac{4e^{-T/2}}{\pi g^2}\int_{C_{NP}} dt\,\mathcal{F}(t)e^{-t/g^2}=\bar{Z_P^{(II)}}(g^2)+\bar{Z_{NP}^{(II)}}(g^2), \tag{4.22}$$

as is shown in Fig. 2.

We identify the first term as the formal Borel summation of the perturbation series and the second term as the nonperturbative contribution. For the nonperturbative contribution, the following analytic property holds. If we perform the analytic continuation of $Z_{NP}(|g^2|e^{i\theta})$ from $\theta=0$ to $\theta=\pi$, the contour for Z_{NP} changes from $C_{NP}(0)$ to $C_{NP}(\pi)$, as shown in Fig. 3. In the weak coupling limit, the integral of $C_{NP}(\pi)$ can be well-approximated by that of C_V because the dominant contribution of the integral comes from $t\sim 2g^2S_0^{(I)}$. Therefore, in the case of $g^2=|g^2|e^{i\pi}$ when the interaction between valley-instantons is repulsive, the following relation holds approximately:

$$Z_{NP}(|g^2|e^{i\pi})\simeq Z(|g^2|e^{i\pi}). \tag{4.23}$$

This relation coincides with what Bogomolny suggested heuristically as a method of evaluation of the instanton–anti-instanton contribution.[43]

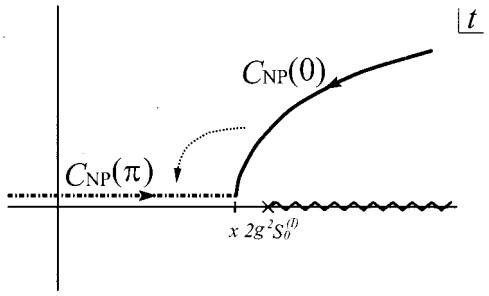

FIG. 3. The change of the contour $C_{NP}(\theta)$ as θ is changed from zero to π.

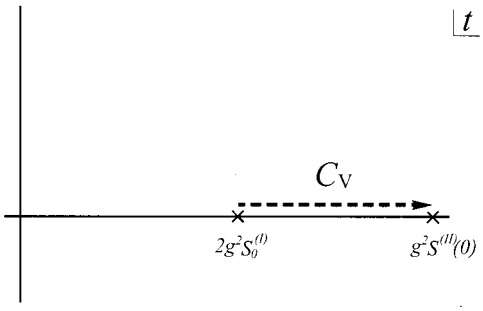

FIG. 4. The integration contour C_V in the case of the II-valley.

An immediate consequence of our decomposition of the perturbative and nonperturbative contribution is

$$\mathrm{Im}\, Z_P + \mathrm{Im}\, Z_{NP} = 0, \tag{4.24}$$

since $Z = Z_P + Z_{NP}$ is real. From the relation above, the dispersion relation becomes[2]

$$Z_P(g^2) = \frac{1}{2\pi i} \oint_{C_{g^2}} dz \frac{Z_P(z)}{z - g^2} \simeq -\frac{1}{\pi} \sum_{r=0}^{\infty} g^{2r} \int_0^{\infty} dz \frac{\mathrm{Im}\, Z_{NP}(z)}{z^{r+1}}, \tag{4.25}$$

where C_{g^2} is the counter around $z = g^2$ and we have neglected the contribution from the singularities far from the origin. The last line of Eq. (4.25) gives the relation between the coefficients of the perturbation series and the imaginary part of the nonperturbative contribution. Rewriting the above relation in terms of the energy spectra, we find for the perturbative part of the spectra $E_P(g^2) = \Sigma_{r=0}^{\infty} a^{(r)} g^{2r}$ that the coefficients $a^{(r)}$ can be estimated as

$$a^{(r)} = -\frac{1}{\pi} \int_0^{\infty} dg^2 \frac{\mathrm{Im}\, E_{NP}(g^2)}{g^{2r+2}}. \tag{4.26}$$

The situation in the case of $\overline{II}$-valley is completely the same as that in the $I\overline{I}$-valley.

On the other hand, the situation in the case of II-valley is different, reflecting the fact that the II-valley configuration cannot be deformed continuously to the trivial vacuum configuration. The contribution of the II-valley to the partition function has quite similar form to that of the $I\overline{I}$-valley:

$$Z^{(II)} = \frac{4e^{-T/2}}{\pi g^2} \int_{C_V} dt\, \mathcal{F}(t) e^{-t/g^2}. \tag{4.27}$$

However, the integration contour is now $C_V = (2g^2 S_0^{(I)}, g^2 S^{(II)}(0)]$ and thus is disconnected to the perturbative region $t \sim 0$ (see Fig. 4).

This means that Eq. (4.27) contains only the nonperturbative contribution,

$$Z_{NP}(g^2) = Z(g^2). \tag{4.28}$$

Therefore, we need not separate the integration as in the case of the $I\overline{I}$-valley. As a consequence, the II-valley configuration does not contribute to the imaginary part and also to the large order behavior of the perturbation series, which will be confirmed in the examples in Secs. IV and V. Furthermore, since the interaction for the II-valley configuration is repulsive, as has been observed in Eqs. (4.19) and (4.20), the integral is dominated around $t \sim 2g^2 S_0^{(I)}$ and can be approxi-

mated by the integral on the contour $[2g^2S_0^{(I)},\infty)$ in the weak coupling limit. Therefore, analytic continuation is not needed. The situation in the case of the $\overline{II}$-valley is completely the same as that in the II-valley.

D. Multi-valley calculus

Utilizing the knowledge of the (anti-)valley-instantons and the interactions between them obtained previously and applying the manipulation discussed in Sec. IV C, we will evaluate the partition function $Z=\mathrm{tr}\, e^{-HT}$ by summing over those configurations made of several (anti-)valley-instantons which satisfy a boundary condition in T. The periodic boundary condition for a configuration $q(\tau)$ is in general given by

$$q(\tau+T)=q(\tau). \tag{4.29}$$

For a system which has a periodic potential like Eq. (4.11), however, the condition (4.29) can be relaxed and be replaced with

$$q(\tau+T)=q(\tau)+\frac{2k\pi}{g} \quad (k=0,\pm 1,\pm 2,\ldots). \tag{4.30}$$

This condition restricts the number of the valley-instantons to be even, $2n$. The nonperturbative contributions from the multi-valley configurations satisfying Eq. (4.30) can be calculated by the extension of the technique developed in Ref. 44. We divide the time interval $0\leqslant\tau\leqslant T$ into n regions and put a valley-instanton pair on each of the region. In order to distinguish what kind of pairs, we introduce the indices ϵ_i and $\tilde{\epsilon}_i$ for the i-th region (mod n) as follows:

(i) $\epsilon_i=1$, $\tilde{\epsilon}_i=1$ for II-valley,
(ii) $\epsilon_i=1$, $\tilde{\epsilon}_i=-1$ for $I\overline{I}$-valley,
(iii) $\epsilon_i=-1$, $\tilde{\epsilon}_i=1$ for $\overline{I}I$-valley,
(iv) $\epsilon_i=-1$, $\tilde{\epsilon}_i=-1$ for $\overline{II}$-valley.

In this way, the allowed configurations for a given valley-instanton number $2n$ are exhausted by the allowed combinations of the set $\{\epsilon_i,\tilde{\epsilon}_i\}$ $(i=1,\ldots,n)$. Combining the results on well-separated valley-instanton pairs with the above conventions, the well-separated multiple valley-instanton action for given n and $\{\epsilon_i,\tilde{\epsilon}_i\}$ is expressed as

$$S_n=2nS_0^{(I)}+\frac{8}{g^2}\sum_{i=1}^{n}\epsilon_i\tilde{\epsilon}_i e^{-R_i}+\frac{8}{g^2}\sum_{i=1}^{n}\tilde{\epsilon}_i\epsilon_{i+1}e^{-\tilde{R}_i}+\frac{\epsilon}{2}\sum_{i=1}^{n}(R_i-\tilde{R}_i)+i\frac{\vartheta}{2}\sum_{i=1}^{n}(\epsilon_i+\tilde{\epsilon}_i), \tag{4.31}$$

where R_i is the distance between the $(2i-1)$-th and $2i$-th (anti-)valley-instanton and $\tilde{R}_i$ the one between the $2i$-th and the $(2i+1)$-th (anti-)valley-instanton (mod n) and $\epsilon_{n+1}=\epsilon_1$ (see Fig. 5).

The sum of the contributions from the $2n$ valley-instantons configuration can be written as

$$Z_{\mathrm{NP}}=\sum_{n=1}^{\infty}\alpha^{2n}J_n, \tag{4.32}$$

where α^2 denotes the contribution of the Jacobian and the R-independent part of the determinant for one valley-instanton-pair and is calculated as, in this case,

$$\alpha^2=\frac{4}{\pi g^2}e^{-4/g^2}. \tag{4.33}$$

The term J_n is given by

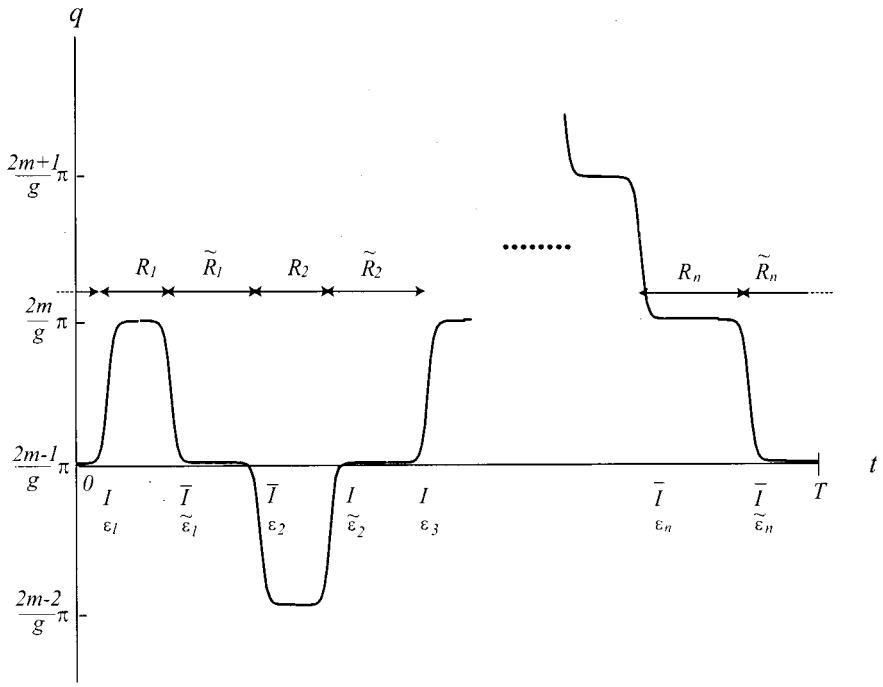

FIG. 5. The collective coordinates R_i and $\tilde{R}_i$ for a $2n$ valley-instantons configuration.

$$J_n=\frac{T}{n}\int_0^\infty\left(\prod_{i=1}^n dR_i\right)\left(\prod_{i=1}^n d\tilde{R}_i\right)\delta\left(\sum_{i=1}^n (R_i+\tilde{R}_i)-T\right)\sum_{\epsilon_i,\tilde{\epsilon}_i=\pm 1}\exp\left(-\frac{1+\epsilon}{2}\sum_{i=1}^n R_i-\frac{1-\epsilon}{2}\sum_{i=1}^n \tilde{R}_i\right.$$
$$\left.-\frac{8}{g^2}\sum_{i=1}^n \epsilon_i\tilde{\epsilon}_i e^{-R_i}-\frac{8}{g^2}\sum_{i=1}^n \tilde{\epsilon}_i\epsilon_{i+1}e^{-\tilde{R}_i}-i\frac{\vartheta}{2}\sum_{i=1}^n(\epsilon_i+\tilde{\epsilon}_i)\right). \tag{4.34}$$

To calculate the sum over the set $\{\epsilon_i,\tilde{\epsilon}_i\}$, we introduce the following transfer matrices:

$$T(R_i)=\begin{pmatrix}\exp\left(-\frac{8}{g^2}e^{-R_i}-i\vartheta\right) & \exp\left(\frac{8}{g^2}e^{-R_i}\right)\\ \exp\left(\frac{8}{g^2}e^{-R_i}\right) & \exp\left(-\frac{8}{g^2}e^{-R_i}+i\vartheta\right)\end{pmatrix}, \tag{4.35a}$$

$$\tilde{T}(\tilde{R}_i)=\begin{pmatrix}\exp\left(-\frac{8}{g^2}e^{-\tilde{R}_i}\right) & \exp\left(\frac{8}{g^2}e^{-\tilde{R}_i}\right)\\ \exp\left(\frac{8}{g^2}e^{-\tilde{R}_i}\right) & \exp\left(-\frac{8}{g^2}e^{-\tilde{R}_i}\right)\end{pmatrix}. \tag{4.35b}$$

Then, using these matrices we have

$$J_n=\frac{T}{2\pi i n}\int_{-i\infty-\eta}^{i\infty-\eta} ds\, e^{-Ts}\,\mathrm{tr}\left(\prod_{i=1}^n\int_0^\infty dR_i\, e^{(s-1/2-\epsilon/2)R_i}T(R_i)\int_0^\infty d\tilde{R}_i\, e^{(s-1/2+\epsilon/2)\tilde{R}_i}\tilde{T}(\tilde{R}_i)\right)$$
$$=\frac{T}{2\pi i n}\int_{-i\infty-\eta}^{i\infty-\eta} ds\, e^{-Ts}\,\mathrm{tr}[\mathcal{T}(s,\epsilon,\vartheta)^n], \tag{4.36}$$

where

$$\mathcal{T}(s,\epsilon,\vartheta)=\begin{pmatrix} K(s-\epsilon/2)e^{-i\vartheta} & I(s-\epsilon/2) \\ I(s-\epsilon/2) & K(s-\epsilon/2)e^{i\vartheta} \end{pmatrix}\begin{pmatrix} K(s+\epsilon/2) & I(s+\epsilon/2) \\ I(s+\epsilon/2) & K(s+\epsilon/2) \end{pmatrix}. \tag{4.37}$$

In the above, K and I are defined by

$$K(s)=\int_0^\infty dR\, e^{(s-1/2)R-(8/g^2)e^{-R}} \simeq \left(\frac{8}{g^2}\right)^{s-1/2}\Gamma\left(-s+\frac{1}{2}\right), \tag{4.38a}$$

$$I(s)=\int_0^\infty dR\, e^{(s-1/2)R+(8/g^2)e^{-R}} \simeq \left(-\frac{8}{g^2}\right)^{s-1/2}\Gamma\left(-s+\frac{1}{2}\right), \tag{4.38b}$$

where the manipulation explained in Sec. IV C is utilized for estimating each of the integration. The calculation of the trace in Eq. (4.36) can be done by diagonalizing $\mathcal{T}$. If we denote the two eigenvalues of $\mathcal{T}$ as $t_\pm$, we immediately yield

$$J_n=\frac{T}{2\pi i n}\int_{-i\infty-\eta}^{i\infty-\eta} ds\, e^{-Ts}(t_+(s)^n+t_-(s)^n). \tag{4.39}$$

From Eq. (4.37), $t_\pm$ is evaluated as

$$\begin{aligned} t_\pm(s)=&K(s+\epsilon/2)K(s-\epsilon/2)\cos\vartheta+I(s+\epsilon/2)I(s-\epsilon/2) \\ &\pm\{[I(s+\epsilon/2)^2-K(s+\epsilon/2)^2]K(s-\epsilon/2)^2\sin^2\vartheta,, \\ &+[K(s+\epsilon/2)I(s-\epsilon/2)+I(s+\epsilon/2)K(s-\epsilon/2)\cos\vartheta]^2\}^{1/2}. \end{aligned} \tag{4.40}$$

Finally, combining Eqs. (4.32) and (4.39) we obtain the nonperturbative contribution to the partition function:

$$Z_{\mathrm{NP}}=-\frac{T}{2\pi i}\int_{-i\infty-\eta}^{i\infty-\eta} ds\, e^{-Ts}\ln(1-\alpha^2 t_+(s))(1-\alpha^2 t_-(s)). \tag{4.41}$$

E. Nonperturbative contributions

From the results in Eqs. (4.38), (4.40) and (4.41), the nonperturbative contributions to the spectra are determined by the following equation:

$$\alpha^2\beta_\pm(E,\epsilon,\vartheta)\left(\frac{8}{g^2}\right)^{(E-1/2)2}\Gamma\left(-E+\frac{1}{2}-\frac{\epsilon}{2}\right)\Gamma\left(-E+\frac{1}{2}+\frac{\epsilon}{2}\right)=1, \tag{4.42}$$

where

$$\begin{aligned} \beta_\pm(E,\epsilon,\vartheta)=&\cos\vartheta+(-)^{(E-1/2)2} \\ &\pm\sqrt{(-)^{(E-1/2-\epsilon/2)2}+(-)^{(E-1/2+\epsilon/2)2}+(-)^{(E-1/2)2}2\cos\vartheta-\sin^2\vartheta}. \end{aligned} \tag{4.43}$$

We will solve the above equation by the series expansion in α:

$$E_{n_\pm}=E^{(0)}_{n_\pm}+\alpha E^{(1)}_{n_\pm}+\alpha^2 E^{(2)}_{n_\pm}+\cdots, \quad E^{(0)}_{n_\pm}=n_\pm+\frac{1}{2}\pm\frac{\epsilon}{2}, \tag{4.44}$$

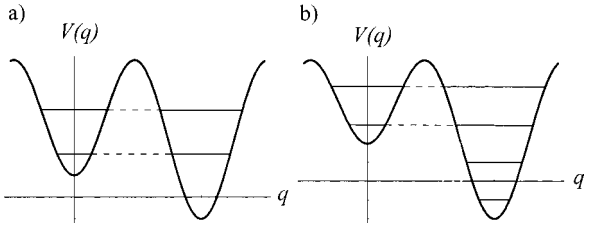

FIG. 6. Degeneracies of the harmonic spectra for (a) $\epsilon=1$ and (b) $\epsilon=2$.

where E_{n_+} stands for the spectra corresponding to, in the limit $g\to 0$, the eigenfunctions of the shallower potential wells and E_{n_-} stands for the ones corresponding to the eigenfunctions of the deeper potential wells. For $\epsilon\neq\mathcal{N}$ ($\mathcal{N}=1,2,3,\ldots$), the first order contributions vanish and the leading second order contributions are calculated as follows:

$$E^{(2)}_{n_\pm}=2[\cos\vartheta+(-)^{\pm\epsilon}]\frac{(-)^{n_\pm+1}}{n_\pm!}\left(\frac{8}{g^2}\right)^{2n_\pm\pm\epsilon}\Gamma(-n_\pm\mp\epsilon). \tag{4.45}$$

For $\epsilon=\mathcal{N}$ ($\mathcal{N}=1,2,3,\ldots$), all the harmonic spectra $E^{(0)}_{n_+}$ of the shallower wells and the higher harmonic spectra $E^{(0)}_{n_-}$ of the deeper wells degenerate for $n_-=n_++\mathcal{N}$; see Fig. 6 for $\epsilon=\mathcal{N}=1,2$. Between these degenerate states, resonant tunneling enhances the nonperturbative corrections, and results in order α^1 contributions to the spectra E_{n_-} and E_{n_+} with $n_-=n_++\mathcal{N}$:

$$E^{(1)}_{n_\pm}=\mp\sqrt{\frac{2[1+(-)^{\mathcal{N}}\cos\vartheta]}{n_+!\,n_-!}\left(\frac{8}{g^2}\right)^{n_++n_-}}, \tag{4.46}$$

$$E^{(2)}_{n_\pm}=\frac{E^{(1)2}_{n_\pm}}{2}\left[\frac{2\ln(-)}{1+(-)^{\mathcal{N}}\cos\vartheta}+2\ln\left(\frac{8}{g^2}\right)-\psi(n_++1)-\psi(n_-+1)\right], \tag{4.47}$$

where $\psi(z)=d\ln\Gamma(z)/dz$ is the digamma function. For the other spectra, say, the lower E_{n_-} with $n_-<\mathcal{N}$, the contributions are the same as Eq. (4.45). We see from Eq. (4.45) the nonperturbative corrections for these lower E_{n_-} vanish, at least up to order α^2, at $\vartheta=0(\pi)$ when $\epsilon=\mathcal{N}$ is odd(even) and thus, from Eq. (4.12), the system has $\mathcal{N}$-fold supersymmetry. This means that when the system is $\mathcal{N}$-fold supersymmetric with odd(even) $\mathcal{N}$, among the physical states for each of the lower $\mathcal{N}$ spectral bands, the state which satisfies the periodic(anti-periodic) boundary condition does not receive nonperturbative correction. From Eq. (3.4) in this case, these physical states are surely the elements of the solvable subspace $\mathcal{V}^-$. Therefore, the results are consistent with the fact that $\mathcal{N}$-fold supersymmetry in this case is not broken dynamically.

Finally, we make a remark on the resultant equation (4.42). The origin of the disappearance of the nonperturbative corrections discussed above comes from the factor $\beta_\pm$ in Eq. (4.42). Indeed, to make the lhs of Eq. (4.42) finite when $\beta_\pm=0$, the gamma functions must diverge adequately. This happens only when $E=E^{(0)}_{n_\pm}$ for certain values of $n_\pm$, and therefore the nonperturbative corrections must vanish.[45] From the derivation of Eq. (4.42), we can see that the appearance of the factor $\beta_\pm$ is achieved by taking into account both of the repulsive and attractive interactions between the valley-instantons properly. Therefore, we guess that naive application of the dilute-gas approximation can hardly lead to the correct results even for the ground-state energy.

F. Large order behavior of the perturbation series

The large order behavior of the perturbation series in g^2 for the spectra can be estimated by the same way as in the case of the double-well potential. From the nonperturbative contributions, Eqs. (4.45)–(4.47), we can easily see that the imaginary parts of them are continuous, at least up to the order α^2, in ϵ and yield

$$\mathrm{Im}\, E_{n_\pm} \sim -\alpha^2 \frac{2\pi}{n_\pm!\Gamma(n_\pm+1\pm\epsilon)}\left(\frac{8}{g^2}\right)^{2n_\pm\pm\epsilon}, \tag{4.48}$$

which are valid for arbitrary ϵ. Then, if we expand the spectra in power of g^2 such that

$$E_{n_\pm} = E^{(0)}_{n_\pm} + \sum_{r=1}^{\infty} a^{(r)}_{n_\pm} g^{2r}, \tag{4.49}$$

the large order behavior of the coefficients $a^{(r)}$ for sufficiently large r are calculated as, using Eqs. (4.26) and (4.48),

$$a^{(r)}_{n_\pm} \sim A_{n_\pm}(\epsilon)\, 4^{-r}\Gamma(r+2n_\pm+1\pm\epsilon), \tag{4.50}$$

where

$$A_{n_\pm}(\epsilon) = \frac{2}{\pi}\frac{2^{2n_\pm\pm\epsilon}}{n_\pm!\Gamma(n_\pm+1\pm\epsilon)}. \tag{4.51}$$

Equation (4.50) shows that the perturbative coefficients diverge factorially unless the prefactor $A(\epsilon)$ vanish. From Eq. (4.51), we can find the disappearance of the leading divergence takes place only when $\epsilon=\mathcal{N}$ ($\mathcal{N}=1,2,3,\ldots$). Comparing the results with Eq. (4.12) and taking the symmetry (4.13) into account, we see that the above cases completely coincide with the case where the system possesses Type A $\mathcal{N}$-fold supersymmetry. Therefore, the results of the valley method analyses are consistent with a consequence of Type A $\mathcal{N}$-fold supersymmetry, that is, the non-renormalization theorem.

V. ANALYSIS OF A TRIPLE-WELL POTENTIAL

In this section we will analyze a sextic triple-well potential. The form of the potential to be analyzed is the following:

$$V(q) = \frac{1}{2}q^2(1-g^2q^2)^2 + \frac{\epsilon}{2}(1-3g^2q^2). \tag{5.1}$$

This has three local minima at $q=0$ and $q\simeq\pm 1/g$ for $\epsilon g^2 \ll 1$ (see Fig. 7).

Comparing this potential with Eq. (3.19), C_1, C_2 and q_0 in $w(q)$ being

$$C_1 = -g^2, \quad C_2 = 1, \quad q_0 = 0, \tag{5.2}$$

we can easily see that the system has Type A $\mathcal{N}$-fold supersymmetry when

$$\epsilon = \pm\frac{4\mathcal{N}\pm 1}{3}. \tag{5.3}$$

More precisely, the system becomes one of the $\mathcal{N}$-fold supersymmetric pair $H^{\pm}_{\mathcal{N}}$; $H^{+}_{\mathcal{N}}$ when $\epsilon=(4\mathcal{N}\pm 1)/3$ and $H^{-}_{\mathcal{N}}$ when $\epsilon=-(4\mathcal{N}\pm 1)/3$. As has been explained in Sec. III B, $\mathcal{N}$-fold supersymmetry does not break in the cubic type because either bases of the solvable subspace $\mathcal{V}^{+}_{\mathcal{N}}$ or those of $\mathcal{V}^{-}_{\mathcal{N}}$ are normalizable in general. Since $C_1<0$ in this case, bases of the solvable subspace

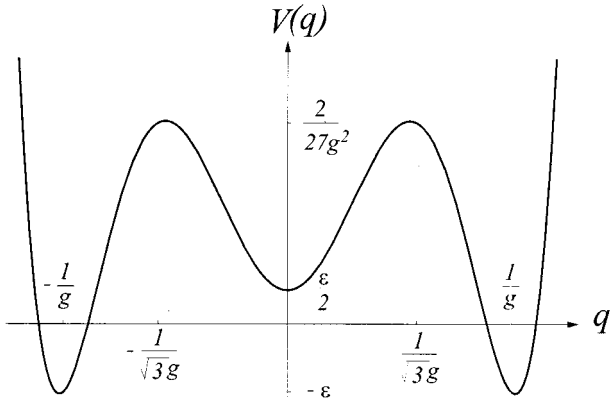

FIG. 7. The form of the triple-well potential investigated in this section.

$\mathcal{V}_{\mathcal{N}}^{+}$ are normalizable and physical while those of $\mathcal{V}_{\mathcal{N}}^{-}$ are not. Therefore, we may expect that the nonperturbative corrections for certain $\mathcal{N}$ states will vanish when $\epsilon=(4\mathcal{N}\pm 1)/3$ while those will not when $\epsilon=-(4\mathcal{N}\pm 1)/3$, though the perturbation series for the corresponding spectra will be in both the cases convergent.

As far as we know, little has been investigated for triple-well potentials. We have found only two references[46,47] on the subject, both of which employed the dilute-gas approximation. However, from the consideration mentioned at the end of Sec. IV E, we intend to analyze beyond the dilute-gas approximation using the same technique of the valley method as in Sec. IV.[48]

In the case of $\epsilon=0$, the three local minima of the potential have the same potential value. Thus, there are (anti-)instanton solutions of the equation of motion which describe the quantum tunneling between the neighboring vacua:

$$q_0^{(I)}(\tau-\tau_0)=\pm\frac{1}{g}\frac{1}{(1+e^{\mp 2(\tau-\tau_0)})^{1/2}},\quad q_0^{(\bar{I})}(\tau-\tau_0)=\pm\frac{1}{g}\frac{1}{(1+e^{\pm 2(\tau-\tau_0)})^{1/2}}. \tag{5.4}$$

When $\epsilon\neq 0$, the solutions of the valley equation now become the (anti-)valley-instantons. In this case, there are three kinds of the solutions of the valley equation which are asymptotically composed of two (anti-)valley-instantons. Contrary to the periodic potential in Sec. IV, there are two different $I\bar{I}$-valley or $\bar{I}I$-valley configurations in this case since the curvature at the central potential bottom (at $q=0$) is different, even at the leading order of g^2, from the one at the side potential bottoms (at $q\simeq\pm 1/g$); the $I\bar{I}$ ($\bar{I}I$)-valley which satisfy $q(\pm T/2)=0$ ($T\gg 1$) are different from the ones which satisfy $q(\pm T/2)\simeq 1/g$ or $-1/g$ ($T\gg 1$). The Euclidean action of the former with large separation R can be calculated by the perturbative expansion in $\lambda\sim O(e^{-2R})$ as follows:

$$S^{(I\bar{I})}(R)=S^{(\bar{I}I)}(R)=2S_0^{(I)}-\epsilon R+\frac{\epsilon}{2}(T-R)-\frac{1}{g^2}e^{-2R}+O(e^{-4R}), \tag{5.5}$$

while the one of the latter with large separation $\tilde{R}$ can be calculated in the same way as

$$S^{(I\bar{I})}(\tilde{R})=S^{(\bar{I}I)}(\tilde{R})=2S_0^{(I)}+\frac{\epsilon}{2}\tilde{R}-\epsilon(T-\tilde{R})-\frac{2}{g^2}e^{-\tilde{R}}+O(e^{-2\tilde{R}}), \tag{5.6}$$

where $S_0^{(I)}$ denotes the Euclidean action of one (anti-)instanton Eq. (5.4) and amounts to

$$S_0^{(I)}=\frac{1}{4g^2}. \tag{5.7}$$

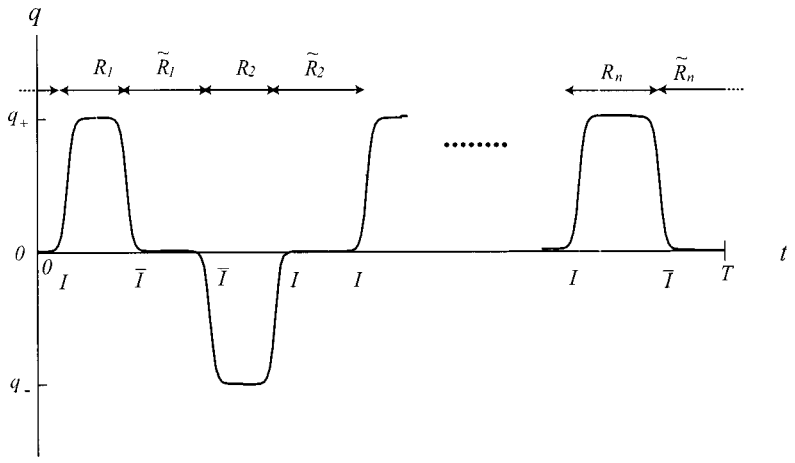

FIG. 8. The collective coordinates R_i and $\tilde{R}_i$ for a $2n$ valley-instantons configuration.

The other type is II-valley or $\overline{II}$-valley. The Euclidean action of them with large separation $\tilde{R}$ can be also calculated in the same way as

$$S^{(II)}(\tilde{R})=S^{(\overline{II})}(\tilde{R})=2S_0^{(I)}+\frac{\epsilon}{2}\tilde{R}-\epsilon(T-\tilde{R})+\frac{2}{g^2}e^{-\tilde{R}}+O(e^{-2\tilde{R}}). \tag{5.8}$$

A. Multi-valley calculus

The evaluation of the partition function $Z=\mathrm{tr}\,e^{-HT}$ by summing over multi-valley-instanton configurations can be done in the same manner as those for the double-well and the periodic potentials. One can easily see that in order to incorporate with the periodic boundary condition in T, the number of the valley-instantons in a period T must be even. For a given number $2n$ of the valley-instantons, however, there are still several configurations. If we regard a configuration as n valley-instanton pairs, we have four kinds of pair, II-, $I\bar{I}$-, $\bar{I}I$-, and $\overline{II}$-valleys. We denote the number of the II- and $\overline{II}$-valley as n_{II} and $n_{\overline{II}}$, respectively, and that of the others as $n_{I\bar{I}}$. Contrary to the periodic potential case, the particle must come back to the start point after the period T passes in this case. Therefore, we must impose Eq. (4.29) rather than Eq. (4.30). This condition results in $n_{II}=n_{\overline{II}}$. As a consequence we have

$$2n_{II}+n_{I\bar{I}}=n. \tag{5.9}$$

This restriction shows that for a given n there are $[n/2]+1$ variety of the n_{II} value. For n and n_{II} fixed, however, the configuration is not determined uniquely yet. There remains a freedom of the permutation of the pairs. The number of cases can be calculated if one notices that the configuration is uniquely determined as far as the position of the II- and $\overline{II}$-valleys among n area is fixed. We denote a set of the position as $\{i_{II}\}$. It is therefore clear that for given n and n_{II} there are ${}_nC_{2n_{II}}$ configurations of the multiple valley-instantons. Combining the results on well-separated valley-instanton pairs with the above considerations, the well-separated multi-valley-instanton action for given n, n_{II} and $\{i_{II}\}$ is expressed as

$$S^{\{i_{II}\}}_{n,n_{II}}=2nS_0^{(I)}-\epsilon\sum_{i=1}^{n}R_i+\frac{\epsilon}{2}\sum_{i=1}^{n}\tilde{R}_i-\frac{1}{g^2}\sum_{i=1}^{n}e^{-2R_i}+\frac{2}{g^2}\sum_{i\in\{i_{II}\}}e^{-\tilde{R}_i}-\frac{2}{g^2}\sum_{i\notin\{i_{II}\}}e^{-\tilde{R}_i}, \tag{5.10}$$

where R_i is the distance between the $(2i-1)$-th and $2i$-th (anti-)valley-instanton and $\tilde{R}_i$ is the one between the $2i$-th and the $(2i+1)$-th (anti-)valley-instanton (mod n) (see Fig. 8).

The sum of the contributions from the $2n$ valley-instantons configuration can be written as

$$Z_{\mathrm{NP}}=\sum_{n=1}^{\infty}\alpha^{2n}J_n,\quad J_n=\sum_{n_{II}=0}^{[n/2]}\sum_{\{i_{II}\}}\mathcal{J}_{n,n_{II}}^{\{i_{II}\}},\tag{5.11}$$

where α^2 denotes the contribution of the Jacobian and the R-independent part of the determinant for one valley-instanton-pair and is calculated as, in this case,

$$\alpha^2=\frac{\sqrt{2}}{\pi g^2}e^{-1/2g^2}.\tag{5.12}$$

The term $\mathcal{J}_{n,n_{II}}^{\{i_{II}\}}$ is given by

$$\begin{aligned}\mathcal{J}_{n,n_{II}}^{\{i_{II}\}}=\frac{T}{n}\int_0^{\infty}\left(\prod_{i=1}^{n}dR_i\right)\left(\prod_{i=1}^{n}d\tilde{R}_i\right)\delta\left(\sum_{i=1}^{n}(R_i+\tilde{R}_i)-T\right)\exp\Bigg[-(1-\epsilon)\sum_{i=1}^{n}R_i-\left(\frac{1}{2}+\frac{\epsilon}{2}\right)\sum_{i=1}^{n}\tilde{R}_i\\+\frac{1}{g^2}\sum_{i=1}^{n}e^{-2R_i}-\frac{2}{g^2}\sum_{i\in\{i_{II}\}}e^{-\tilde{R}_i}+\frac{2}{g^2}\sum_{i\notin\{i_{II}\}}e^{-\tilde{R}_i}\Bigg].\end{aligned}\tag{5.13}$$

In the above expression, we notice that for n and n_{II} fixed, the contribution $\mathcal{J}_{n,n_{II}}^{\{i_{II}\}}$ does not depend on the choice of the set $\{i_{II}\}$. This means the following equality,

$$\sum_{\{i_{II}\}}\mathcal{J}_{n,n_{II}}^{\{i_{II}\}}=\binom{n}{2n_{II}}\mathcal{J}_{n,n_{II}},\tag{5.14}$$

where $\mathcal{J}_{n,n_{II}}$ is the contribution $\mathcal{J}_{n,n_{II}}^{\{i_{II}\}}$ for a specific $\{i_{II}\}$ and is evaluated as

$$\begin{aligned}\mathcal{J}_{n,n_{II}}&=\frac{T}{n}\int_0^{\infty}\left(\prod_{i=1}^{n}dR_i\right)\left(\prod_{i=1}^{n}d\tilde{R}_i\right)\delta\left(\sum_{i=1}^{n}(R_i+\tilde{R}_i)-T\right)\exp\Bigg[-(1-\epsilon)\sum_{i=1}^{n}R_i-\left(\frac{1}{2}+\frac{\epsilon}{2}\right)\sum_{i=1}^{n}\tilde{R}_i\\&\quad+\frac{1}{g^2}\sum_{i=1}^{n}e^{-2R_i}-\frac{2}{g^2}\sum_{i=1}^{2n_{II}}e^{-\tilde{R}_i}+\frac{2}{g^2}\sum_{i=2n_{II}+1}^{n}e^{-\tilde{R}_i}\Bigg]\\&=\frac{T}{2\pi i n}\int_{-i\infty-\eta}^{i\infty-\eta}ds\,e^{-Ts}K_-(s)^nK_+^{(1)}(s)^{2n_{II}}K_+^{(2)}(s)^{n-2n_{II}}.\end{aligned}\tag{5.15}$$

In the last expression for $\mathcal{J}_{n,n_{II}}$, several K's are defined by

$$K_-(s)=\int_0^{\infty}dR\exp\left[(s-1+\epsilon)R+\frac{1}{g^2}e^{-2R}\right]\simeq\frac{1}{2}\left(-\frac{1}{g^2}\right)^{s/2-1/2+\epsilon/2}\Gamma\left(-\frac{s}{2}+\frac{1}{2}-\frac{\epsilon}{2}\right),\tag{5.16a}$$

$$K_+^{(1)}(s)=\int_0^{\infty}d\tilde{R}\exp\left[\left(s-\frac{1}{2}-\frac{\epsilon}{2}\right)\tilde{R}-\frac{2}{g^2}e^{-\tilde{R}}\right]\simeq\left(\frac{2}{g^2}\right)^{s-1/2-\epsilon/2}\Gamma\left(-s+\frac{1}{2}+\frac{\epsilon}{2}\right),\tag{5.16b}$$

$$K_+^{(2)}(s)=\int_0^{\infty}d\tilde{R}\exp\left[\left(s-\frac{1}{2}-\frac{\epsilon}{2}\right)\tilde{R}+\frac{2}{g^2}e^{-\tilde{R}}\right]\simeq\left(-\frac{2}{g^2}\right)^{s-1/2-\epsilon/2}\Gamma\left(-s+\frac{1}{2}+\frac{\epsilon}{2}\right),\tag{5.16c}$$

where the manipulation explained in Sec. IV C is again utilized for estimating each of the integrations. Eventually, from Eqs. (5.11), (5.14) and (5.15) we obtain

$$Z_{\mathrm{NP}}=\sum_{n=1}^{\infty}\alpha^{2n}\sum_{n_{II}=0}^{[n/2]}\binom{n}{2n_{II}}\mathcal{J}_{n,n_{II}}$$

$$=-\frac{T}{4\pi i}\int_{-i\infty-\eta}^{i\infty-\eta}ds e^{-Ts}\ln(1-\alpha^2K_-(s)K_+^{(+)}(s))(1-\alpha^2K_-(s)K_+^{(-)}(s)), \tag{5.17}$$

where

$$K_+^{(\pm)}(s)=K_+^{(2)}(s)\pm K_+^{(1)}(s). \tag{5.18}$$

B. Nonperturbative contributions

From the results in Eqs. (5.16)–(5.18), the nonperturbative contributions to the spectra are determined by the following equation:

$$\alpha^2\beta_{\pm}(E,\epsilon)\left(\frac{2}{g^2}\right)^{E-1/2-\epsilon/2}\Gamma\left(-E+\frac{1}{2}+\frac{\epsilon}{2}\right)\left(-\frac{1}{g^2}\right)^{E/2-1/2+\epsilon/2}\Gamma\left(-\frac{E}{2}+\frac{1}{2}-\frac{\epsilon}{2}\right)=1, \tag{5.19}$$

where

$$\beta_{\pm}(E,\epsilon)=\frac{(-)^{E-1/2-\epsilon/2}\pm 1}{2}. \tag{5.20}$$

We will solve the above equation by the series expansion in α:

$$E_{n_0}=E_{n_0}^{(0)}+\alpha E_{n_0}^{(1)}+\alpha^2E_{n_0}^{(2)}+\cdots,\quad E_{n_0}^{(0)}=n_0+\frac{1}{2}+\frac{\epsilon}{2}, \tag{5.21a}$$

$$E_{n_\pm}=E_{n_\pm}^{(0)}+\alpha E_{n_\pm}^{(1)}+\alpha^2E_{n_\pm}^{(2)}+\cdots,\quad E_{n_\pm}^{(0)}=2n_\pm+1-\epsilon, \tag{5.21b}$$

where E_{n_0} stands for the spectra corresponding to, in the limit $g\to 0$, the eigenfunctions of the center potential well and $E_{n_\pm}$ for the ones corresponding to the parity eigenstates obtained by the linear combinations of the eigenfunctions of each side potential well. For $\epsilon\neq\pm(2\mathcal{N}+1)/3$ ($\mathcal{N}=0,1,2,\ldots$), the first order contributions vanish and the leading second order contributions are calculated as follows:

$$E_{n_0}^{(2)}=-\frac{1}{n_0!}\left(\frac{2}{g^2}\right)^{n_0}\left(-\frac{1}{g^2}\right)^{n_0/2-1/4+(3/4)\epsilon}\Gamma\left(-\frac{n_0}{2}+\frac{1}{4}-\frac{3}{4}\epsilon\right), \tag{5.22}$$

$$E_{n_\pm}^{(2)}=-\left((-)^{(1-3\epsilon)/2}\pm 1\right)\frac{1}{n_\pm!}\left(\frac{2}{g^2}\right)^{2n_\pm+1/2-(3/2)\epsilon}\left(\frac{1}{g^2}\right)^{n_\pm}\Gamma\left(-2n_\pm-\frac{1}{2}+\frac{3}{2}\epsilon\right). \tag{5.23}$$

In this case, degeneracies of the harmonic oscillator spectra for each potential well only occur between both side wells. The different nonperturbative contributions for $n_\pm$ in Eq. (5.23) show the splitting of the degeneracies via the quantum tunneling as in the case of symmetric double-well potentials.

When $\epsilon=(4\mathcal{N}+1)/3$ ($\mathcal{N}=0,1,2,\ldots$), all the even-parity central harmonic spectra $E_{2m_0}^{(0)}$ and the higher side harmonic spectra $E_{n_\pm}^{(0)}$ degenerate for $n_\pm=m_0+\mathcal{N}$ [see Fig. 9(a) for $\epsilon=\frac{5}{3}$ ($\mathcal{N}=1$)].

It is interesting, however, that the interference due to the quantum tunneling only occurs between the same (even-)parity states. As a consequence, E_{2m_0} and E_{n_+} satisfying $n_+=m_0+\mathcal{N}$ acquire order α^1 contributions as follows:

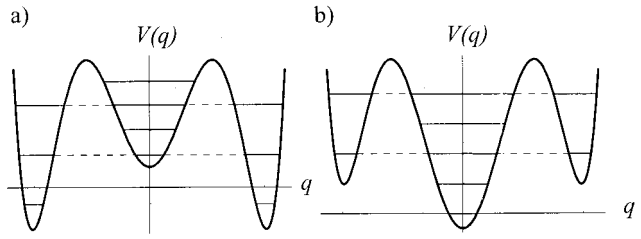

FIG. 9. Degeneracies of the harmonic spectra for (a) $\epsilon=\frac{5}{3}$ and (b) $\epsilon=-1$.

$$E^{(1)}_{n_+/2m_0}=\pm\sqrt{\frac{2}{n_+!(2m_0)!}\left(\frac{2}{g^2}\right)^{2m_0}\left(\frac{1}{g^2}\right)^{n_+}}, \tag{5.24}$$

$$E^{(2)}_{n_+/2m_0}=\frac{E^{(1)2}_{n_+/2m_0}}{4}\left[\ln\left(-\frac{2}{g^2}\right)+\ln\left(\frac{2}{g^2}\right)+\ln\left(-\frac{1}{g^2}\right)-\psi(n_++1)-2\psi(2m_0+1)\right]. \tag{5.25}$$

For the other spectra, say, E_{n_-}, E_{2m_0+1} and the lower E_{n_+} with $n_+<\mathcal{N}$, the contributions are the same as Eqs. (5.22) and (5.23). When $\epsilon=-(4\mathcal{N}-1)/3$ ($\mathcal{N}=1,2,3,\ldots$), all the side harmonic spectra $E^{(0)}_{n_\pm}$ and the higher even-parity central harmonic spectra $E^{(0)}_{2m_0}$ degenerate for $m_0=n_\pm+\mathcal{N}$ [see Fig. 9(b) for $\epsilon=-1$ ($\mathcal{N}=1$)]. In this case, the interference also occurs only between the same (even-)parity states. The contributions for E_{2m_0} and E_{n_+} satisfying $m_0=n_++\mathcal{N}$ are given by the same as Eqs. (5.24) and (5.25). For the other spectra, say, E_{n_-}, E_{2m_0+1} and the lower E_{2m_0} with $m_0<\mathcal{N}$, the contributions are the same as Eqs. (5.22) and (5.23).

When $\epsilon=(4\mathcal{N}-1)/3$ ($\mathcal{N}=1,2,3,\ldots$), all the odd-parity central harmonic spectra $E^{(0)}_{2m_0+1}$ and the higher side harmonic spectra $E^{(0)}_{n_\pm}$ degenerate for $n_\pm=m_0+\mathcal{N}$ [see Fig. 10(a) for $\epsilon=1$ ($\mathcal{N}=1$)].

In this case, only the odd-parity states interfere and yield order α^1 contributions for $n_-=m_0+\mathcal{N}$:

$$E^{(1)}_{n_-/2m_0+1}=\pm\sqrt{\frac{2}{n_-!(2m_0+1)!}\left(\frac{2}{g^2}\right)^{2m_0+1}\left(\frac{1}{g^2}\right)^{n_-}}, \tag{5.26}$$

$$E^{(2)}_{n_-/2m_0+1}=\frac{E^{(1)2}_{n_-/2m_0+1}}{4}\left[\ln\left(-\frac{2}{g^2}\right)+\ln\left(\frac{2}{g^2}\right)+\ln\left(-\frac{1}{g^2}\right)-\psi(n_-+1)-2\psi(2m_0+2)\right]. \tag{5.27}$$

The contributions for the other spectra, say, E_{n_+}, E_{2m_0} and the lower E_{n_-} with $n_-<\mathcal{N}$, are given by the same as Eqs. (5.22) and (5.23). When $\epsilon=-(4\mathcal{N}+1)/3$ ($\mathcal{N}=0,1,2,\ldots$), all the side har-

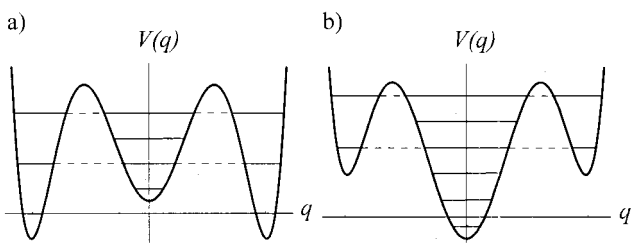

FIG. 10. Degeneracies of the harmonic spectra for (a) $\epsilon=1$ and (b) $\epsilon=-\frac{5}{3}$.

monic spectra $E^{(0)}_{n_\pm}$ and the higher odd-parity central harmonic spectra $E^{(0)}_{2m_0+1}$ degenerate for $m_0=n_\pm+\mathcal{N}$ [see Fig. 10(b) for $\epsilon=-\frac{5}{3}$ $(\mathcal{N}=1)$]. Only the odd-parity states interfere in the same way and the nonperturbative contributions for E_{2m_0+1} and E_{n_-} satisfying $m_0=n_-+\mathcal{N}$ are the same as Eqs. (5.26) and (5.27). Again, the expressions for the other spectra, say, E_{n_+}, E_{2m_0} and the lower E_{2m_0+1} with $m_0<\mathcal{N}$, are given by Eqs. (5.22) and (5.23).

From the whole result obtained here, we see that the nonperturbative corrections vanish only when $\epsilon=(4\mathcal{N}\pm1)/3$ $(\mathcal{N}=1,2,3,\ldots)$. More precisely, when $\epsilon=(4\mathcal{N}+1)/3$, Eq. (5.23) is applied for the even-parity states labeled by the quantum number n_- and results in $E^{(2)}_{n_-}=0$ for all $n_-<\mathcal{N}$. Similarly, when $\epsilon=(4\mathcal{N}-1)/3$, Eq. (5.23) is applied for the odd-parity states labeled by the quantum number n_+ and results in $E^{(2)}_{n_+}=0$ for all $n_+<\mathcal{N}$. It should be noted that in the case of $\epsilon=-(4\mathcal{N}\pm1)/3$ $(\mathcal{N}=1,2,3,\ldots)$ the nonperturbative corrections do remain although the models are $\mathcal{N}$-fold supersymmetric, reflecting the fact that they are only quasi-perturbatively solvable but are not quasi-exactly solvable. These results are just what we have expected from the general properties of $\mathcal{N}$-fold supersymmetry.

C. Large order behavior of the perturbation series

The large order behavior of the perturbation series in g^2 for the spectra can be estimated by the same way as in the case of the double-well and periodic potentials. From the nonperturbative contributions Eqs. (5.22)–(5.27), we can easily see that the imaginary parts of them are continuous, at least up to the order α^2, in ϵ and yield

$$\mathrm{Im}\,E_{n_0}\sim-\alpha^2\frac{\pi}{n_0!\Gamma\left(\frac{n_0}{2}+\frac{3}{4}+\frac{3}{4}\epsilon\right)}\left(\frac{2}{g^2}\right)^{n_0}\left(\frac{1}{g^2}\right)^{n_0/2-1/4+(3/4)\epsilon}, \tag{5.28a}$$

$$\mathrm{Im}\,E_{n_\pm}\sim-\alpha^2\frac{\pi}{n_\pm!\Gamma\left(2n_\pm+\frac{3}{2}-\frac{3}{2}\epsilon\right)}\left(\frac{2}{g^2}\right)^{2n_\pm+1/2-(3/2)\epsilon}\left(\frac{1}{g^2}\right)^{n_\pm}, \tag{5.28b}$$

which are valid for arbitrary ϵ. Then, if we expand the spectra in power of g^2 such that

$$E_{n_0/n_\pm}=E^{(0)}_{n_0/n_\pm}+\sum_{r=1}^{\infty}a^{(r)}_{n_0/n_\pm}g^{2r}, \tag{5.29}$$

the large order behavior of the coefficients $a^{(r)}$ for sufficiently large r are calculated as, using Eqs. (4.26) and (5.28),

$$a^{(r)}_{n_0}\sim A_{n_0}(\epsilon)2^r\Gamma\left(r+\frac{3}{2}n_0+\frac{3}{4}+\frac{3}{4}\epsilon\right), \tag{5.30a}$$

$$a^{(r)}_{n_\pm}\sim A_{n_\pm}(\epsilon)2^r\Gamma\left(r+3n_\pm+\frac{3}{2}-\frac{3}{2}\epsilon\right), \tag{5.30b}$$

where

$$A_{n_0}(\epsilon)=\frac{\sqrt{2}}{\pi}\frac{2^{(5/2)n_0+3/4+(3/4)\epsilon}}{n_0!\Gamma\left(\frac{n_0}{2}+\frac{3}{4}+\frac{3}{4}\epsilon\right)}, \tag{5.31a}$$

$$A_{n_\pm}(\epsilon)=\frac{\sqrt{2}}{\pi}\frac{2^{5n_\pm+2-3\epsilon}}{n_\pm!\Gamma\left(2n_\pm+\frac{3}{2}-\frac{3}{2}\epsilon\right)}. \tag{5.31b}$$

Equations (5.30) show that the perturbative coefficients diverge factorially unless the prefactor $A(\epsilon)$'s vanish. From Eq. (5.31), we can find the disappearance of the leading divergence takes place only when $\epsilon=\pm(2n+1)/3$ ($n=1,2,3,\ldots$). More precisely, we obtain the following results:

(1) $\epsilon=(4\mathcal{N}\pm1)/3(\mathcal{N}=1,2,3,\ldots)$

$$A_{n_\pm}(\epsilon)=0 \quad \text{for} \quad n_\pm<\mathcal{N}.$$

(2) $\epsilon=-(4\mathcal{N}+1)/3(\mathcal{N}=1,2,3,\ldots)$

$$A_{2m_0+1}(\epsilon)=0 \quad \text{for} \quad m_0<\mathcal{N}.$$

(3) $\epsilon=-(4\mathcal{N}-1)/3(\mathcal{N}=1,2,3,\ldots)$

$$A_{2m_0}(\epsilon)=0 \quad \text{for} \quad m_0<\mathcal{N}.$$

Comparing these results with Eq. (5.3), we see that the above cases completely coincide with the case where the system possesses Type A $\mathcal{N}$-fold supersymmetry. Again, the results of the valley method analyses are consistent with the non-renormalization theorem.

VI. SUMMARY

In this article, we have made nonperturbative analyses on the models which can be $\mathcal{N}$-fold supersymmetric at specific values of the parameter. Combining the results obtained in this article with the ones in Ref. 2, we get the following:

(1) For all the potentials investigated (double-well, triple-well, periodic), the leading divergence of the perturbation series disappears when and only when they are $\mathcal{N}$-fold supersymmetric. The non-renormalization theorem ensures that $\mathcal{N}$-fold supersymmetry is sufficient for the disappearance of the divergence. The results indicate that it may also be necessary.
(2) The nonperturbative corrections to the spectra for certain states vanish when and only when the models are quasi-exactly solvable (triple-well, periodic).
(3) For the quasi-perturbatively solvable potentials (double-well, triple-well), the nonperturbative corrections remain although they are $\mathcal{N}$-fold supersymmetric.

As was mentioned in Ref. 28 the quasi-solvable models constructed by sl(2) generators do not always have normalizable solvable states. Although the conditions on the normalizability of the models were fully investigated in Ref. 49, it remains unclear what is the role of the partial algebraization of the models without normalizable solvable states. The results listed above provide an answer to this problem. Even though the solvable wave functions are not normalizable, they can be normalizable and thus make sense in the perturbation theory. In this case, the spectra corresponding to the solvable states also make sense in the perturbation theory. As was shown in Ref. 1, the perturbation series for them are convergent since they are the solutions of a finite order algebraic equation. However, the fact that the solvable states and the corresponding spectra make sense only in the perturbation theory inevitably means the existence of the nonperturbative effects, which is in contrast to the case of the quasi-exactly solvable models. That is why we have called the case quasi-perturbatively solvable.

Finally, we would like to mention about applicability of the dilute-gas approximation. As has been mentioned previously, the dilute-gas approximation cannot give proper results, that is, con-

sistent results with $\mathcal{N}$-fold supersymmetry, for both the potentials Eqs. (4.11) and (5.1). Therefore, it seems that the success of the dilute-gas approximation for the symmetric double-well potential is rather exceptional and applicability of it is quite limited.

Quantum jump dynamics in cavity QED

D. Spehner[a] and M. Orszag
Facultad de Física, Pontificia Universidad Católica de Chile, Casilla 306, Santiago 22, Chile

(Received 18 December 2001; accepted for publication 25 February 2002)

We study the stochastic dynamics of the electromagnetic field in a lossless cavity interacting with a beam of two-level atoms, given that the atomic states are measured after they have crossed the cavity. The atoms first interact at the exit of the cavity with a classical laser field $\mathcal{E}$ and then enter into a detector which measures their states. Each measurement disentangles the field and the atoms and changes in a random way the state $|\psi(t)\rangle$ of the cavity field. For weak atom-field coupling, the evolution of $|\psi(t)\rangle$ when many atoms cross the cavity and the detector is characterized by a succession of quantum jumps occurring at random times, separated by quasi-Hamiltonian evolutions, both of which depend on the laser field $\mathcal{E}$. For $\mathcal{E}=0$, the dynamics is the same as in the Monte Carlo wave function model of Dalibard *et al.* [Phys. Rev. Lett. **68**, 580 (1992)] and Carmichael, *An Open System Approach to Quantum Optics*, Lecture Notes in Physics Vol. 18 (Springer, Berlin, 1991)]. The density matrix of the quantum field, obtained by averaging the projector $|\psi(t)\rangle\langle\psi(t)|$ over all results of the measurements, is independent of $\mathcal{E}$ and follows the master equation of the damped harmonic oscillator at finite temperature. We provide numerical evidence showing that for large $\mathcal{E}$, an arbitrary initial field state $|\psi(0)\rangle$ evolves under the monitoring of the atoms and the measurements toward squeezed states $|\alpha,re^{2i\phi}\rangle$, moving in the α-complex plane but with almost constant squeezing parameters r and ϕ. The values of r and ϕ are determined analytically. On the other hand, for $\mathcal{E}=0$, the dynamics transforms the initial state into Fock states $|n\rangle$ with fluctuating numbers of photons n, as shown in Kist *et al.* [J. Opt. B: Quantum Semiclassical Opt. **1**, 251 (1999)]. In the last part, we derive the quantum jump dynamics from the linear quantum jump model proposed in Spehner and Bellissard [J. Stat. Phys. **104**, 525 (2001)], for arbitrary open quantum systems having a Lindblad-type evolution. A careful derivation of the infinite jump rates limit, where the dynamics can be approximated by a diffusion process of the quantum state, is also presented. © *2002 American Institute of Physics.*

I. INTRODUCTION

The dissipative dynamics of an open quantum system S can be described in two different ways. The first one consists in coupling S with a reservoir R and assuming that the total system $S+R$ is isolated. Since one is concerned by the dynamics of S only, one traces out the degrees of freedom of R in the equation of motion of $S+R$. Within the Markov approximation, the reduced density matrix of S follows a first-order differential equation with time-independent coefficients. In many cases, a separation of time scales between the Hamiltonian (R-independent) and dissipative (R-dependent) evolutions allows one to perform a local averaging in time, which kills nonresonant terms.[1,2] The coarse-grained master equation obtained in this way has the Lindblad form.[3] An alternative approach to this density matrix description has been developed in the last two

[a]Present address: Universität Essen, Fachbereich Physik, D-45117 Essen, Germany; electronic mail: spehner@theophys.uni-essen.de

decades in quantum optics[4–8] (see, e.g., Ref. 9), quantum measurement theory,[10–13] quantum and classical stochastic calculus,[14–17] and electronic transport in solids.[18–20] This approach is based on stochastic evolutions of pure states. The system is described by a random wave function (RW) evolving according to a linear or nonlinear *stochastic Schrödinger equation*. Consistency with the density matrix approach requires that the pure state evolution gives the master equation back after averaging over the dynamical noise. Apart from being intuitively appealing, the RW models provide quite efficient tools for solving master equations numerically, since Schrödinger equations have N components, whereas master equations have $N\times N$ components, N being the dimension of the Hilbert space of S. However, the RW models are more than simple mathematical or numerical tools: they describe the *real* evolution of single quantum systems under continuous monitoring by measurements (photon counting, homodyne or heterodyne detections).[5,8,9] In recent years, the attainment of low temperature and low dissipation regimes, as well as the improvements of detection techniques, has allowed the investigation of the dynamics of such continuously monitored systems. Remarkable examples of these are single ions[21] and Bose–Einstein condensates[22] in electromagnetic traps, probed by laser beams, and electromagnetic fields in high Q-cavities,[23] probed by beams of highly excited atoms (Rydberg atoms). This new generation of experiments, combined with the difficulties usually encountered in solving the master equation, has strongly stimulated the developments of the RW approach in quantum optics.

The aim of this paper is to investigate a specific physical realization, which could be in principle realizable experimentally (although this question is not addressed here), of a class of RW models based on quantum jumps. The system we consider is the electromagnetic field of a high Q-cavity interacting with a beam of two-level atoms, which forms the reservoir of temperature T. The states of the atoms leaving the cavity are measured by a detector. A laser field $\mathcal{E}$ is placed between the cavity and the detector. The corresponding master equation, obtained by averaging over the results of the measurement on the atoms, is, for weak atom-field coupling, the equation of the damped harmonic oscillator with finite temperature. The same problem has been considered in Ref. 24 in the reverse situation where one knows exactly the state of each atom before it crosses the cavity and no measurement is performed on it at the exit (its final state thus being unknown). It has been shown in this reference that the cavity field evolves at large times to a state which is completely controlled by the atomic initial states.

We first introduce in Sec. II the class of quantum jump models studied in this work, for arbitrary open systems having a Lindblad-type evolution. The experimental scheme is presented in Sec. III, where we also compute the random evolution of the cavity field and its corresponding average evolution. We focus in Sec. IV on single quantum trajectories, i.e., single realizations of the measurements. The numerical simulations and analytical results presented in this section show that for $T>0$ and large laser fields $\mathcal{E}$, the state of the cavity field localizes at large times to squeezed states with an almost constant squeezing amplitude r which depends only on T. Section V is devoted to the derivation, for arbitrary open systems, of the nonlinear quantum jump schemes from the corresponding linear ones introduced in Ref. 18. Their relation with the so-called quantum state diffusion stochastic Schrödinger equations[10–12,15–17] is also established. Our conclusions are presented in Sec. VI.

II. THE QUANTUM JUMP SCHEMES

Let us first recall briefly a few basic facts about the master equation approach to open quantum systems. Consider an open system S interacting with a reservoir R. The density matrix σ of the total system $S+R$ is assumed to follow the Liouville–von Neumann equation of closed systems. A state of S is specified by the reduced density matrix ρ, defined as the partial trace of σ over the reservoir's Hilbert space. By tracing out the degrees of freedom of R in the Liouville–von Neumann equation, one obtains an integro-differential equation for ρ (Nakajima–Zwanzig equation).[25] Using a Born–Markov approximation and a local time averaging on a time scale much larger than the inverse Bohr frequencies of S, this equation is transformed into a simpler first-order linear differential equation, called the *master equation*.[1,25] This coarse-grained equation has in most cases the Lindblad form:[3]

$$\frac{d\rho}{dt} = -i[H,\rho] + \frac{1}{2}\sum_m ([L_m\rho, L_m^\dagger] + [L_m, \rho L_m^\dagger]). \tag{1}$$

H is the Hamiltonian of S (including the energy shifts due to the coupling with the reservoir), and L_m are some operators acting on the Hilbert space of S. The sum over the discrete indices m can be finite or infinite, depending on the nature of the problem.

We now describe the random wave function approach of Dalibard, Castin, and Mølmer[4] and Carmichael.[5] This approach, called in the former reference the Monte Carlo wave function method, has been introduced independently by several other authors.[6,7,13] It is based on quantum jumps, i.e., on discontinuous random evolutions of the wave function of S.

At some random times, quantum jumps (QJ) occur as a result of some continuous measurement on the system S (e.g., a detection of a photon emitted by a system constituted by an atom). If a jump occurs, the wave function $|\psi\rangle$ of S is modified discontinuously as follows:

$$\text{jump } m: \quad |\psi\rangle \to \frac{L_m|\psi\rangle}{\|L_m|\psi\rangle\|}, \tag{2}$$

where L_m are the Lindblad operators appearing in (1). The probability of occurrence of a jump of type m in the time interval $[t, t+\delta t]$ is

$$\delta p_m(t) = \|L_m|\psi(t)\rangle\|^2 \delta t. \tag{3}$$

One must choose δt small enough so that $\delta p_m(t) \ll 1$ for any $|\psi\rangle$ and all m's (this is fulfilled if δt^{-1} is much bigger than the damping constants γ_m appearing in the master equation, contained in the operators L_m). If no jump occurs between t and $t+\delta t$, the wave function evolves between these two times according to Schrödinger's equation with an effective Hamiltonian $H+K$, and is then normalized at $t+\delta t$:

$$\begin{aligned} |\psi(t+\delta t)\rangle &= \frac{|\varphi(t+\delta t)\rangle}{\|\varphi(t+\delta t)\|}, \\ |\varphi(t+\delta t)\rangle &= e^{-i\delta t(H+K)}|\psi(t)\rangle. \end{aligned} \tag{4}$$

K can be computed in special cases by first determining perturbatively the wave function of the total system $S+R$ and then projecting it onto the subspace corresponding to the no-jump measurement.[4,9] An easier (though less fundamental) way to compute K is to ask directly that the average $\mathsf{M}|\psi(t)\rangle\langle\psi(t)|$ satisfies the master equation (1) (see the following). This gives[4]

$$K = K_0 \equiv \frac{1}{2i}\sum_m L_m^\dagger L_m. \tag{5}$$

Note that K_0 is *not* self-adjoint. Hence the norm of the wave function is not conserved by the evolution operator $e^{-i\delta t(H+K_0)}$. This can be interpreted by invoking the gain of information on the system provided by the measurement, namely, by the knowledge that no jump occurred between t and $t+\delta t$. For instance, in the case of an atom coupled to the quantized electromagnetic field, we may infer from a no-photon detection that the atom has not emitted spontaneously a photon.

Since the wave function is normalized at each step δt in (2) and (4), the random dynamics is norm-preserving on the time resolution δt. These normalizations make the stochastic quantum evolution nonlinear. We will see in Sec. V that it is possible to define an equivalent linear model, in which the random wave function is not normalized.[18,14] The map $t \in [0,\infty[\mapsto |\psi(t)\rangle$ for a given outcome of the jumps is called a *quantum trajectory*.[5]

Let us consider the average density matrix $\rho(t) = \mathsf{M}|\psi(t)\rangle\langle\psi(t)|$, where M is the average over all realizations of the jumps. It can be easily shown[4] that $\rho(t)$ obeys the master equation (1) to lowest order in $\|L_m\|^2\delta t$. Actually, taking $H=0$ for simplicity, one has

$$\rho(t+\delta t)=\mathsf{M}_{t+\delta t}|\psi(t+\delta t)\rangle\langle\psi(t+\delta t)|$$
$$=\mathsf{M}_t\left(\left(1-\sum_m \delta p_m(t)\right)\frac{e^{-i\delta tK_0}|\psi(t)\rangle\langle\psi(t)|e^{i\delta tK_0^\dagger}}{\|e^{-i\delta tK_0}|\psi(t)\rangle\|^2}+\sum_m \delta p_m(t)\frac{L_m|\psi(t)\langle\psi(t)|L_m^\dagger}{\|L_m|\psi(t)\rangle\|^2}\right).$$

This equation is simplified by taking

$$e^{-i\delta tK_0}=\left(1-\delta t\sum_m L_m^\dagger L_m\right)^{1/2}. \tag{6}$$

Then, by (3):

$$\rho(t+\delta t)=\left(1-\delta t\sum_m L_m^\dagger L_m\right)^{1/2}\rho(t)\left(1-\delta t\sum_m L_m^\dagger L_m\right)^{1/2}+\delta t\sum_m L_m\rho(t)L_m^\dagger. \tag{7}$$

Expanding the square roots and keeping only terms of order one in δt, one obtains (1) and K_0 is given by (5). Note that, for an arbitrary time interval δt between consecutive measurements, $\rho(t+\delta t)$ is *not* given by integrating (1) from t to $t+\delta t$ (a different result is already obtained at the next order δt^2). This should be kept in mind when dealing with real or numerical experiments, where δt is always finite.

Consider a transformation $L_m\to L_m'$ on the operators L_m which does not change (1). The quantum jumps and the effective Hamiltonian K may be modified by this replacement. This leads to a different stochastic dynamics, which unravels the same master equation. A particular transformation leaving (1) invariant is[26]

$$L_m\to L_m'=L_m+\lambda_m,\quad H\to H'=H+\frac{1}{2i}\sum_m(\lambda_m^* L_m-\lambda_m L_m^\dagger)=H'^\dagger, \tag{8}$$

where λ_m's are complex numbers. This invariance of the Lindblad equation is not related to a particular symmetry of the system or its coupling with the reservoir. It simply expresses that the separation between the Hamiltonian part $-i[H,\rho]$ and the remaining dissipative part in (1) is not unique. The transformation (8) generates a whole family of distinct QJ models depending on the set of numbers λ_m. The modification of the wave function at a jump m is now given by

$$\text{jump } m:\quad |\psi\rangle\to\frac{W_m|\psi\rangle}{\|W_m|\psi\rangle\|} \tag{9}$$

with the jump operators W_m proportional to $(L_m+\lambda_m)$:

$$W_m=\gamma_m^{-1/2}(L_m+\lambda_m). \tag{10}$$

The new generalized Hamiltonian $H+K$ is obtained by replacing L_m by L_m' in (5) and adding to it $H'-H$:

$$K=\frac{1}{2i}\sum_m(L_m^\dagger L_m+2\lambda_m^* L_m+|\lambda_m|^2). \tag{11}$$

The last term in the sum, proportional to the identity operator, is written only for convenience: it is irrelevant because of the normalization in Eq. (4) giving the evolution between jumps. The probability of occurrence of a jump of type m becomes

$$\delta p_m(t)=\|(L_m+\lambda_m)|\psi(t)\rangle\|^2\delta t=\gamma_m\delta t\,\|W_m|\psi(t)\rangle\|^2. \tag{12}$$

Note that it increases like $|\lambda_m|^2$ for large λ_m.

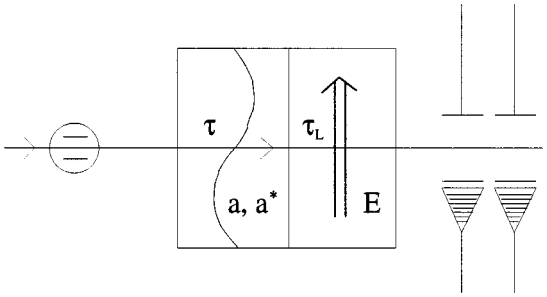

FIG. 1. The two-level atoms of the beam cross one by one a cavity containing the studied quantum field a, a second cavity containing a laser field $\mathcal{E}$, and a detector measuring their states.

III. FIELD MODE IN A CAVITY

It is shown in this section that the QJ schemes described in Sec. II can be physically realized by an atomic beam crossing a cavity with perfectly reflecting walls and interacting with the quantum field inside, which forms the system S. The measurements are performed on the outgoing atoms, after they have interacted with a classical laser field $\mathcal{E}$ placed between the cavity and the measuring apparatus.

A. Experimental scheme

Let us consider one mode of the quantized electromagnetic field of a lossless cavity coupled to its environment. The environment is a beam of atoms prepared in one of two Rydberg states $|g\rangle$ (''ground state'') and $|e\rangle$ (''excited state'') in resonance with the frequency ω of the mode. The fluxes r_g and r_e of atoms crossing the cavity, prepared, respectively, in states $|g\rangle$ and $|e\rangle$, are assumed to be such that at most one atom is in the cavity at any time. The time interval between the crossing of two consecutive atoms in the cavity is $\delta t=(r_g+r_e)^{-1}$. To simplify, all the atoms of the beam are supposed to have the same speed. They thus spend the same time $\tau<\delta t$ in the cavity, interacting with the field mode. The atom-mode interaction Hamiltonian is in the interaction picture (rotating-wave approximation):[1,2]

$$H_{\rm int}=-i\,(\lambda^*|g\rangle\langle e|\,a^\dagger-\lambda|e\rangle\langle g|\,a), \tag{13}$$

where $a^\dagger$ and a are the creation and annihilation operators of a photon. The coupling constant λ is equal to $\sqrt{q^2\omega/2\varepsilon_0 V}\,\vec{d}_{ge}\cdot\vec{\sigma}$, where $\vec{d}_{ge}$ is the matrix element of the atomic dipole, $\vec{\sigma}$ the polarization vector of the field mode, q the charge of the electron, and V the volume of the cavity.

At the exit of the cavity, the atoms enter into a second cavity, identical to the first but containing a classical laser field $\vec{\mathcal{E}}$ (Fig. 1). They spend a time $\tau_L<\delta t$ there, interacting with the laser field. Under the dipolar and rotating-wave approximations, the atom-laser interaction Hamiltonian is in the interaction picture:[1,2]

$$H_L=-\frac{i}{2}(\Omega^*|g\rangle\langle e|-\Omega|e\rangle\langle g|), \tag{14}$$

where $\Omega=i\,\vec{d}_{ge}\cdot\vec{\mathcal{E}}$ is the Rabi frequency. The Hamiltonian (14) describes the atom-laser interaction for a laser field in resonance with the atomic transition. The more general situation of nonzero detuning of the laser frequency will be discussed in the following.

Finally, the state of each atom at the exit of the second cavity is measured by a detector, telling us if it is in its ''ground'' or in its ''excited'' state. The corresponding experimental scheme is presented in Fig. 1. It has been considered in Ref. 27 without the laser field $\mathcal{E}$. The flight times of the atoms between the two cavities and between the second cavity and the detector are taken sufficiently small so that spontaneous emission of photons by the atoms can be neglected.

B. Stochastic dynamics of the field mode

Let us compute the evolution of the state of the field mode in the first cavity, for a given result of the measurements. If one looks at it with a time resolution equal or bigger than the time δt separating the entrance of consecutive atoms, the field mode is continuously monitored by the measurements on the atoms (continuous measurement). The coupling constant λ, the Rabi frequency Ω, and the interaction times τ, τ_L are assumed to satisfy

$$|\lambda|\tau \ll 1, \quad |\Omega|\tau_L \ll 1. \tag{15}$$

Let us first determine the change of the wave function $|\psi(t)\rangle$ of the field mode when one atom, initially in state $|i\rangle$, $i=g$ or e, crosses the two cavities and the detector. At the time t just prior to the entrance of the atom in the first cavity, the wave function $|\Psi(t)\rangle$ of the total system "atom+field mode" is a tensor product state $|\Psi(t)\rangle = |i\rangle|\psi(t)\rangle$ (the atom and the field did not yet interact). Since the two fields are in separated cavities, the atom interacts with the quantum field *before* interacting with the classical field $\mathcal{E}$. The total wave function at the exit of the second cavity (before the measurement) is thus, in the interaction picture,

$$|\Psi_{\text{ent}}\rangle = e^{-i\,\tau_L H_L}\, e^{-i\,\tau H_{\text{int}}} |i\rangle|\psi(t)\rangle. \tag{16}$$

Note that the evolution would be different if the laser field was placed in the first cavity (in this case, the product of exponentials must be replaced by the exponential of $H_{\text{int}}+H_L$). Because of their interaction, the quantum field and the atom are now entangled, i.e., $|\Psi_{\text{ent}}\rangle$ is not a product state. After the measurement on the atom has been performed, the field and the atom again become disentangled and the wave function of the total system is

$$|\Psi(t+\delta t)\rangle = |j\rangle|\psi(t+\delta t)\rangle, \quad |\psi(t+\delta t)\rangle = \frac{\langle j|\Psi_{\text{ent}}\rangle}{\|\langle j|\Psi_{\text{ent}}\rangle\|}, \tag{17}$$

with $j=g$ if the atom is detected in its ground state and $j=e$ if it is detected in its excited state. We have assumed for simplicity that the measurement is performed at a time $t+\tau_{\text{mes}} < t+\delta t$ earlier than the entrance of the next atom in the first cavity. Since we work in the interaction picture, $|\Psi(t+\tau_{\text{mes}})\rangle$ is then equal to $|\Psi(t+\delta t)\rangle$. The wave function $|\psi(t+\delta t)\rangle$ of the mode at the time $t+\delta t$ is thus well-defined and given by

$$\begin{aligned} |\psi(t+\delta t)\rangle &= \frac{|\varphi(t+\delta t)\rangle}{\|\varphi(t+\delta t)\|}, \\ |\varphi(t+\delta t)\rangle &= \langle j|e^{-i\tau_L H_L} e^{-i\tau H_{\text{int}}}|i\rangle|\psi(t)\rangle. \end{aligned} \tag{18}$$

The probability that the atom is detected in state $|j\rangle$, given that it enters in the cavity in state $|i\rangle$, is

$$p_{i\to j} = \|\langle j|\Psi_{\text{ent}}\rangle\|^2 = \|\varphi(t+\delta t)\|^2. \tag{19}$$

A straightforward computation leads to

$$\begin{aligned} e^{-i\tau H_{\text{int}}} = &\sum_{p=0}^{\infty} \frac{(-|\lambda|^2\tau^2)^p}{(2p)!}\left(|g\rangle\langle g|\, n^p + |e\rangle\langle e|\,(n+1)^p\right) \\ &+ \sum_{p=0}^{\infty} \frac{(-|\lambda|^2\tau^2)^p}{(2p+1)!}\left(\lambda\tau|e\rangle\langle g|\, a\, n^p - \lambda^*\tau|g\rangle\langle e|\, n^p\, a^\dagger\right), \end{aligned}$$

where $n=a^\dagger a$ is the number operator. Denoting by $n^{1/2}$ its square root, this formula can be rewritten in a more compact form:

$$e^{-i\tau H_{\rm int}} = |g\rangle\langle g|\cos(|\lambda|\tau n^{1/2}) + |e\rangle\langle e|\cos(|\lambda|\tau(n+1)^{1/2}) + \lambda\tau|e\rangle\langle g|\, a\,\mathrm{sinc}(|\lambda|\tau n^{1/2}) - \lambda^*\tau|g\rangle\langle e|\,\mathrm{sinc}(|\lambda|\tau n^{1/2})\, a^\dagger \tag{20}$$

with $\mathrm{sinc}(u) = (\sin u)/u$. Similarly,

$$e^{-i\tau H_L} = \cos\left(\frac{|\Omega|\tau_L}{2}\right) + \frac{\Omega\tau_L}{2}|e\rangle\langle g|\,\mathrm{sinc}\left(\frac{|\Omega|\tau_L}{2}\right) - \frac{\Omega^*\tau_L}{2}|g\rangle\langle e|\,\mathrm{sinc}\left(\frac{|\Omega|\tau_L}{2}\right).$$

Let us introduce the operator

$$\tilde{a} = a\,\mathrm{sinc}(|\lambda|\tau n^{1/2}) \tag{21}$$

and the complex numbers

$$\eta = \lambda\tau, \quad \epsilon = \frac{\Omega\tan(|\Omega|\tau_L/2)}{|\Omega|\lambda\tau}. \tag{22}$$

Four cases must be considered.

(1) The atom enters the first cavity in its ground state and is detected in the same state: $i=j=g$. Then,

$$|\varphi(t+\delta t)\rangle = (1+|\eta\epsilon|^2)^{-1/2}(\cos(|\eta|n^{1/2}) - |\eta|^2\epsilon^*\tilde{a})|\psi(t)\rangle \equiv (1 - i\,\delta t\, K_g)|\psi(t)\rangle. \tag{23}$$

(2) The atom enters the first cavity in its ground state and is detected in its excited state: $i=g$, $j=e$. Then,

$$|\varphi(t+\delta t)\rangle = \eta\,(1+|\eta\epsilon|^2)^{-1/2}\, W_-|\psi(t)\rangle, \quad W_- \equiv \tilde{a} + \epsilon\cos(|\eta|n^{1/2}). \tag{24}$$

(3) The atom enters the first cavity in its excited state and is detected in its ground state: $i=e$, $j=g$. Then,

$$|\varphi(t+\delta t)\rangle = -\,\eta^*(1+|\eta\epsilon|^2)^{-1/2}\, W_+|\psi(t)\rangle, \quad W_+ \equiv \tilde{a}^\dagger + \epsilon^*\cos(|\eta|(n+1)^{1/2}). \tag{25}$$

(4) The atom enters the first cavity in its excited state and is detected in the same state: $i=j=e$. Then,

$$|\varphi(t+\delta t)\rangle = (1+|\eta\epsilon|^2)^{-1/2}(\cos(|\eta|(n+1)^{1/2}) - |\eta|^2\epsilon\,\tilde{a}^\dagger)|\psi(t)\rangle \equiv (1 - i\,\delta t\, K_e)|\psi(t)\rangle. \tag{26}$$

Cases (2) and (3) correspond, respectively, to the absorption and the emission of a photon of the cavity mode or of the laser field by the atom. In order to have quantum jumps separated by ''continuous'' Hamiltonian evolutions on time scales bigger than δt, the probabilities of these events must be very small. The probability $\delta p_-(t)$ of case (2) is equal to $p_{g\to e}$ multiplied by the probability $r_g\,\delta t$ that the atom enters in the first cavity in state $|g\rangle$. With the help of (19) and (24), one gets

$$\delta p_-(t) = \frac{r_g\,\delta t\,|\eta|^2}{1+|\eta\epsilon|^2}\|W_-|\psi(t)\rangle\|^2 = r_g\,\delta t(\|\sin(|\eta|n^{1/2})|\psi(t)\rangle\|^2 + \mathcal{O}(\eta\epsilon)). \tag{27}$$

The probability $\delta p_+(t)$ of case (3) is given by a similar formula, replacing r_g by r_e, W_- by W_+, and n by $n+1$. The probabilities of cases (1) and (4) are, respectively, $r_g\,\delta t - \delta p_-(t)$ and $r_e\,\delta t - \delta p_+(t)$. We see that $\delta p_\pm(t)$ is small if $|\eta| = |\lambda|\tau \ll 1$ and $|\eta\epsilon| \simeq |\Omega|\tau_L/2 \ll 1$, provided that also

$$\langle\psi(t)|(|\eta|n^{1/2} - k\pi)^{2q}|\psi(t)\rangle = \mathcal{O}(\eta^q), \quad q = 1,2,\ldots, \tag{28}$$

with k a non-negative integer. This condition is met for $k=0$ if the maximal number of photons in the cavity is much smaller than $|\eta|^{-2}$ (of order $|\eta|^{-1}$ or smaller). This corresponds to the perturbative regime. If the condition is met for $k\geqslant 1$, the atom makes almost $k/2$ Rabi oscillations in the cavity and leaves it, with a high probability, nearly in the same state as it entered it. Indeed, neglecting terms of order η^2 and $\eta^4\epsilon^4$, it follows from (22), (23), and (26):

$$\begin{aligned}\delta t K_g &\simeq \frac{|\eta|^2}{2i}(\tilde{a}^\dagger\tilde{a}+2(-1)^k\epsilon^*\tilde{a}+|\epsilon|^2),\\ \delta t K_e &\simeq \frac{|\eta|^2}{2i}(\tilde{a}\,\tilde{a}^\dagger+2(-1)^k\epsilon\,\tilde{a}^\dagger+|\epsilon|^2),\end{aligned} \tag{29}$$

up to an irrelevant additional phase $k\pi$. When the atom is measured in the same state as its initial state [cases (1) and (4)], the normalized wave function of the mode is thus modified, up to a sign, by an amount of order $|\eta|+|\eta^{3/2}\epsilon|$. In the opposite cases (2) and (3), the mode wave function is modified by an amount of order 1. It suffers a quantum jump:

$$|\psi(t+\delta t)\rangle = \frac{W_\pm|\psi(t)\rangle}{\|W_\pm|\psi(t)\rangle\|}, \tag{30}$$

with the jump operators

$$\begin{aligned}W_- &\simeq \tilde{a}+(-1)^k\epsilon,\\ W_+ &\simeq \tilde{a}^\dagger+(-1)^k\epsilon^*.\end{aligned} \tag{31}$$

The signs $-$ and $+$ correspond to case (2) (absorption of a photon) and case (3) (emission of a photon), respectively. The probability that a jump $\pm$ occurs is of order $|\eta|+|\eta^{3/2}\epsilon|+|\eta\epsilon|^2$, see (27) and (28). It is given approximately by

$$\delta p_\pm(t) \simeq \gamma_\pm\,\delta t\|W_\pm|\psi(t)\rangle\|^2, \tag{32}$$

where we have introduced the damping rates:

$$\begin{aligned}\gamma_- &= r_g|\eta|^2 = r_g|\lambda|^2\tau^2,\\ \gamma_+ &= r_e|\eta|^2 = r_e|\lambda|^2\tau^2.\end{aligned} \tag{33}$$

The operator $\tilde{a}$ is given, up to terms of order $\eta^{1/2}$, by

$$\tilde{a} \simeq \begin{cases} a & \text{if } k=0\\ (-1)^k a\left(\dfrac{|\eta|n^{1/2}-k\pi}{k\pi}-\dfrac{(|\eta|n^{1/2}-k\pi)^2}{(k\pi)^2}\right) & \text{if } k\geqslant 1.\end{cases} \tag{34}$$

If $|\psi(t)\rangle=|n\rangle$ is a Fock state with $n=(k\pi/|\eta|)^2$ photons, the crossing of the atom of initial state $|i\rangle$ has no effect on the field if $i=g$ (since $\tilde{a}|\psi(t)\rangle=0$), and a small effect if $i=e$ and $|\eta|\ll 1$.

If condition (28) is not met, the atom strongly modifies the state of the field mode in all cases (1)–(4). Hence there is no ''continuous-like'' Hamiltonian evolution changing weakly the state of the mode, separated by unlikely jumps. For $\epsilon=0$, the evolutions for $i=g$ [Eq. (23)] and $i=e$ [Eq. (26)] have the form (6) (the jump operators $W_\pm$ are proportional to $\tilde{a}^\dagger$ and $\tilde{a}$, respectively, and $\cos^2(|\eta|n^{1/2})=1-|\eta|^2\tilde{a}^\dagger\tilde{a}$, $\cos^2(|\eta|(n+1)^{1/2})=1-|\eta|^2\tilde{a}\tilde{a}^\dagger$). Although there is *a priori* no conceptual difficulty in treating this case, the corresponding dynamics becomes cumbersome when many atoms cross the cavities. We thus restrict ourself in what follows to the simpler situation in which conditions (15) and (28) are fulfilled.

Let us determine the change of the wave function of the field mode when many atoms cross the cavities. Let Δt be such that the number $\Delta t/\delta t$ of atoms crossing the cavities in a time interval $[t,t+\Delta t]$ is large but much smaller than the inverse of the coupling strength $|\eta|$:

$$1 \ll \frac{\Delta t}{\delta t} \ll |\eta|^{-1}, |\eta^{3/2}\epsilon|^{-1}, |\eta\epsilon|^{-2}. \tag{35}$$

Assuming that r_g and r_e are of the same order of magnitude, the numbers of atoms entering in the first cavity in state $|g\rangle$ and $|e\rangle$ between t and $t+\Delta t$ are large and approximately equal to $r_g\Delta t$ and $r_e\Delta t$, respectively. Since the probabilities $\delta p_\pm(t)$ of occurrence of jumps when one atom crosses the cavities are assumed to be as small as $|\eta|+|\eta^{3/2}\epsilon|+|\eta\epsilon|^2$, the probability of occurrence of two or more jumps between t and $t+\Delta t$ is negligible. Suppose first that no jump occur between these two times, i.e., that only cases (1) and (4) occur for all atoms. Then,

$$|\varphi(t+\Delta t)\rangle = \cdots(1-i\,\delta t K_g)\cdots(1-i\,\delta t K_e)\cdots(1-i\,\delta t K_g)\cdots|\psi(t)\rangle. \tag{36}$$

There are $r_g\Delta t$ factors $(1-i\,\delta t K_g)$ and $r_e\Delta t$ factors $(1-i\,\delta t K_e)$. Let us expand the products and neglect terms of order $(\Delta t/\delta t)^2|\eta^{(4+m)/2}\epsilon^m|$, $m=0,\ldots,4$, which are small by (35). We find:

$$\begin{aligned} |\psi(t+\Delta t)\rangle &= \frac{|\varphi(t+\Delta t)\rangle}{\|\varphi(t+\Delta t)\|}, \\ |\varphi(t+\Delta t)\rangle &\simeq (1-i\Delta t K)|\psi(t)\rangle, \end{aligned} \tag{37}$$

with $K = r_g\delta t K_g + r_e\delta t K_e$. Note that the change $|\varphi(t+\Delta t)\rangle - |\varphi(t)\rangle$ is proportional to Δt. The effective Hamiltonian K is the average of the operators K_i, which describe the evolution of the quantum field as one *given* atom crosses the cavities without absorbing or emitting a photon, over its (unknown) initial state $|i\rangle$ ($i=g$ with probability $r_g\delta t$, and $i=e$ with probability $r_e\delta t$). This averaging is related to our assumption that many atoms cross the cavities between t and $t+\Delta t$; it is an average over the initial states of the atoms, and must be distinguished from the average over the results of the measurements. Equation (29) gives

$$K = \frac{1}{2i}(\gamma_-(\tilde{a}^\dagger\tilde{a} + 2(-1)^k\epsilon^*\tilde{a} + |\epsilon|^2) + \gamma_+(\tilde{a}\tilde{a}^\dagger + 2(-1)^k\epsilon\tilde{a}^\dagger + |\epsilon|^2)). \tag{38}$$

If a jump $\pm$ occurs between t and $t+\Delta t$, the change of the wave function is approximately

$$|\psi(t+\Delta t)\rangle = \frac{W_\pm|\psi(t)\rangle}{\|W_\pm|\psi(t)\rangle\|}. \tag{39}$$

Actually, the change due to atoms crossing the cavities without modifying their states [cases (1) and (4)] between t and $t+\Delta t$ is of order $(\Delta t/\delta t)(|\eta|+|\eta^{3/2}\epsilon|)$. It can be neglected with respect to the change due to an atom having emitted or absorbed a photon, of order 1. Similarly, the probability $\Delta p_\pm(t)$ of occurrence of a jump $\pm$ in the time interval $[t,t+\Delta t]$ is obtained by replacing δt by Δt in (32).

The above coarse-grained stochastic dynamics coincides for $\gamma_+ = r_e = 0$ with that considered by Wiseman and Milburn[8] for a damped mode monitored by homodyne detection. In the Schrödinger picture, the mode wave function $|\psi_S(t+\Delta t)\rangle$ is given by (39), in which $W_\pm$ is replaced by $W_\pm^S(t) = e^{-itH}W_\pm e^{itH}$, if a jump $\pm$ occurs between t and $t+\Delta t$. In the opposite (and much more probable) case, it is given by (37), with K replaced by $H+K_S(t)$, $K_S(t) = e^{-itH}Ke^{itH}$. Here $H = \omega(a^\dagger a + 1/2)$ is the free Hamiltonian of the field mode, and we have assumed $\omega\Delta t \ll 1$. The jump operators in the Schrödinger picture are, up to irrelevant phase factors, $W_-^S(t) = \tilde{a} + (-1)^k\epsilon e^{-i\omega t}$ and $W_+^S(t) = \tilde{a}^\dagger + (-1)^k\epsilon^* e^{i\omega t}$. Like the Hamiltonian $H_{\rm int}$, $W_\pm$ depends on time in the Schrödinger picture and is time-independent in the interaction picture. The dynamics in the

Schrödinger picture is the same as in the interaction picture provided that ϵ is replaced by an oscillating field $\epsilon(t)=\epsilon e^{-i\omega t}$. This is also true for the dynamics between jumps, $K_S(t)$ being obtained from (38) by the same rule.

For $\epsilon=0$, the random evolution of $|\psi_S(t)\rangle$ coincides with the random evolution in the model of Dalibard *et al.*,[4] in agreement with the results of Ref. 27. For $\epsilon\neq 0$, it coincides with the QJ evolution of Sec. II with the two Lindblad operators $L_-=\sqrt{\gamma_-}\tilde{a}$ and $L_+=\sqrt{\gamma_+}\tilde{a}^\dagger$, and with $\lambda_- = \sqrt{\gamma_-}(-1)^k\epsilon e^{-i\omega t}$, $\lambda_+=\sqrt{\gamma_+}(-1)^k\epsilon^* e^{i\omega t}$.

All the results of this section are actually valid for an arbitrary Hamiltonian H_L—describing the interaction of the two-level atoms with an arbitrary external field placed between the first cavity and the detector—such that $\|H_L\|\tau_L \ll 1$. In fact, if we define $\epsilon = \langle e|e^{-i\tau_L H_L}|g\rangle/\lambda\tau\langle e|e^{-i\tau_L H_L}|e\rangle$, the only change in the calculation is the replacement of the prefactor $(1-|\eta\epsilon|^2)^{-1/2}$ by $\langle g|e^{-i\tau_L H_L}|g\rangle$ in (23) and (25) and by $\langle e|e^{-i\tau_L H_L}|e\rangle$ in (24) and (26). In particular, the stochastic dynamics is not modified if the laser frequency is detuned from the atomic frequency by $\delta=\omega_L-\omega$, with $|\delta|\tau_L\ll 1$. This is because ϵ is independent of δ in leading order in $\|H_L\|\tau_L$, i.e., the interaction time τ_L is too short for the atoms to feel the frequency shift from the atomic transition.

C. Average dynamics of the field mode

In order to relate the random wave function dynamics with the familiar density matrix approach, let us compute the master equation satisfied by the field mode density matrix:

$$\rho(t)=\mathsf{M}|\psi(t)\rangle\langle\psi(t)|, \tag{40}$$

where M denotes the mean value over the results of the measurements on the atoms (i.e., over all quantum trajectories).

As is well known, averaging the projector $|\psi(t)\rangle\langle\psi(t)|$ over all results of the measurements is the same as not performing any measurement. One may therefore equivalently determine the differential equation for the reduced density matrix $\tilde{\rho}(t)$ of the photon mode, in the same experimental scheme as in Fig. 1 but *without the detector*. The reduced density matrix $\tilde{\rho}(t)$ is defined as the partial trace over the atomic Hilbert spaces of the density matrix $\sigma(t)$ of the total system "atoms+field mode" (see Sec. II):

$$\tilde{\rho}(t)=\operatorname*{tr}_A(\sigma(t)). \tag{41}$$

In order to justify the above-mentioned statement, let us show that the changes of $\rho(t)$ and $\tilde{\rho}(t)$ when one atom crosses the cavities are the same. The atom arrives in the first cavity in state $|i\rangle$, $i=g$ or $i=e$. Before it enters in the cavity, the total density matrix $\sigma(t)$ is a tensor product $|i\rangle\langle i|\otimes\tilde{\rho}(t)$. We assume that $\tilde{\rho}(t)=\rho(t)=\mathsf{M}|\psi(t)\rangle\langle\psi(t)|$. It follows from the second equality in (17), from (19), and from the fact that the measurements on the atoms are independent:

$$\rho(t+\delta t)=\mathsf{M}_{t+\delta t}|\psi(t+\delta t)\rangle\langle\psi(t+\delta t)|=\operatorname*{tr}_A(\mathsf{M}_t|\Psi_{\mathrm{ent}}\rangle\langle\Psi_{\mathrm{ent}}|), \tag{42}$$

where $|\Psi_{\mathrm{ent}}\rangle$ is given by (16). Thus,

$$\rho(t+\delta t)=\operatorname*{tr}_A(e^{-i\tau_L H_L}e^{-i\tau H_{\mathrm{int}}}|i\rangle\langle i|\rho(t)e^{i\tau H_{\mathrm{int}}}e^{i\tau_L H_L})=\tilde{\rho}(t+\delta t)=\operatorname*{tr}_A(e^{-i\tau H_{\mathrm{int}}}\sigma(t)e^{i\tau H_{\mathrm{int}}}). \tag{43}$$

Hence the changes of $\rho(t)$ and $\tilde{\rho}(t)$ are identical as one atom crosses the cavities. The two exponentials of H_L in (43) disappear by cyclicity of the trace, showing that $\tilde{\rho}(t+\delta t)=\rho(t+\delta t)$ does not depend on the laser field $\mathcal{E}$. This last point is actually clear, since if no measurement on the atoms is performed, their interaction with the laser field in the second cavity has no effect on the field in the first cavity.

Since they have the same time evolution, we identify in what follows $\rho(t)$ and $\tilde{\rho}(t)$ and compute the master equation for the usual density matrix (41). Two cases must be distinguished.

(1) The atom enters in the first cavity in its ground state: $i=g$. By replacing (20) into (43),

$$\rho(t+\delta t)=(1-|\eta|^2\tilde{a}^\dagger\tilde{a})^{1/2}\rho(t)(1-|\eta|^2\tilde{a}^\dagger\tilde{a})^{1/2}+|\eta|^2\tilde{a}\rho(t)\tilde{a}^\dagger\equiv(1+\delta t\mathcal{L}_g)\rho(t), \tag{44}$$

where $\tilde{a}$ is given by (21).

(2) The atom enters in the first cavity in its excited state: $i=e$. Then,

$$\rho(t+\delta t)=(1-|\eta|^2\tilde{a}\tilde{a}^\dagger)^{1/2}\rho(t)(1-|\eta|^2\tilde{a}\tilde{a}^\dagger)^{1/2}+|\eta|^2\tilde{a}^\dagger\rho(t)\tilde{a}\equiv(1+\delta t\mathcal{L}_e)\rho(t). \tag{45}$$

For a given initial state of the atom, the evolution in (44) and (45) has the general form (7). Under the conditions (15) and (28), one has

$$\begin{aligned}\delta t\mathcal{L}_g(\rho)&\simeq|\eta|^2(\tilde{a}\rho\tilde{a}^\dagger-\tfrac{1}{2}\{\tilde{a}^\dagger\tilde{a},\rho\}),\\ \delta t\mathcal{L}_e(\rho)&\simeq|\eta|^2(\tilde{a}^\dagger\rho\tilde{a}-\tfrac{1}{2}\{\tilde{a}\tilde{a}^\dagger,\rho\}),\end{aligned} \tag{46}$$

where the curly brackets denote the anticommutator $\{A,B\}=AB+BA$.

Let us determine the coarse-grained evolution of $\rho(t)$ on the time scale Δt satisfying (35). By the same arguments as in Sec. III B,

$$\rho(t+\Delta t)=\cdots(1+\delta t\mathcal{L}_g)\cdots(1+\delta t\mathcal{L}_e)\cdots(1+\delta t\mathcal{L}_g)\cdots\rho(t),$$

with $r_g\Delta t$ factors $(1+\delta t\mathcal{L}_g)$ and $r_e\Delta t$ factors $(1+\delta t\mathcal{L}_e)$. One can retain only the terms of order one in Δt in the expansion of the product:

$$\rho(t+\Delta t)\simeq\{1+\Delta t(r_g\delta t\mathcal{L}_g+r_e\delta t\mathcal{L}_e)\}\rho(t). \tag{47}$$

The superoperator inside the parentheses is the average of the superoperator $\mathcal{L}_i$ over the initial atomic states $|i\rangle$, $i=e$ or g. Writing $\Delta\rho/\Delta t=\mathrm{d}\rho/\mathrm{d}t$, the coarse-grained master equation in the interaction picture is therefore

$$\frac{\mathrm{d}\rho}{\mathrm{d}t}=\gamma_-(\tilde{a}\rho(t)\tilde{a}^\dagger-\tfrac{1}{2}\{\tilde{a}^\dagger\tilde{a},\rho(t)\})+\gamma_+(\tilde{a}^\dagger\rho(t)\tilde{a}-\tfrac{1}{2}\{\tilde{a}\tilde{a}^\dagger,\rho(t)\}). \tag{48}$$

Not surprisingly, this is the equation of the damped harmonic oscillator with finite temperature T. Here T is the temperature of the atomic beam:

$$\exp\left(-\frac{\omega}{k_BT}\right)=\frac{r_e}{r_g}=\frac{\gamma_+}{\gamma_-}, \tag{49}$$

where k_B is the Boltzmann constant. Equation (48) has the general form (1), with two Lindblad operators $L_-=\sqrt{\gamma_-}\tilde{a}$ and $L_+=\sqrt{\gamma_+}\tilde{a}^\dagger$. Recall that $\tilde{a}$ coincides with the usual annihilation operator a only if $k=0$ (perturbative regime).

In conclusion, if $|\lambda|\tau\ll1$ and condition (28) holds, i.e., if each atom modifies weakly the state of the field, the average density matrix (40) satisfies the master equation (48). Although the quantum trajectories of the mode depend on $\mathcal{E}$, the corresponding master equation is the same for all laser fields, in accordance with the general results of Sec. II.

IV. SINGLE QUANTUM TRAJECTORIES OF THE FIELD MODE

We focus in this section on single quantum trajectories of the field mode, corresponding to specific realizations of the measurements. The main question addressed in the following concerns the localization properties of the random dynamics at large times, for different laser fields $\mathcal{E}$. In the

case $\mathcal{E}=0$, i.e, for the ''standard'' Monte Carlo wave function dynamics, it has been shown in Ref. 27 that the field wave function evolves at large times toward Fock states $|n(t)\rangle$ [with a time fluctuating number of photons $n(t)$]. Note that it is straightforward to prove that Fock states form an invariant family of states under the stochastic dynamics. In fact, if $\epsilon=0$, the jump operators $W_{\pm}$ transform $|n\rangle$ into $|n\pm1\rangle$ (up to multiplicative constants), and $|n\rangle$ is an eigenvector of $H+K_0=\omega(n+1/2)-i(\gamma_-\sin^2(|\eta|n^{1/2})+\gamma_+\sin^2(|\eta|(n+1)^{1/2}))/(2|\eta|^2)$. The localization property is much more difficult to prove. For nonzero laser fields, Fock states do no longer form an invariant family and the localization is of different nature. In the case of zero temperature ($\gamma_+=0$), it has been shown in Ref. 8 that the field mode has a diffusive dynamics in the limit $\epsilon\to\infty$, given by a stochastic Schrödinger equation with real Wiener processes; we will prove in Sec. V that this remains true at any temperature. Such kind of dynamics has been widely studied in the literature.[11,12,15,26,28] It is expected that localization occurs toward coherent or squeezed states if the Lindblad operators are linear combinations of a and $a^\dagger$. However, this has only been proved in the case $L\propto(a+a^\dagger)$ as far as we are aware.[28] Here we present numerical results indicating that for $T>0$ and large enough ϵ, the mode wave function $|\psi(t)\rangle$ evolves toward squeezed states after some time $\Delta\tau$ of the order of the thermalization time in the absence of measurements. At large times, the squeezing amplitude $r(t)$ of the squeezed states is found to fluctuate slightly around a mean value $\overline{r}$, and the squeezing angle $\phi(t)$ evolves linearly in time, $\phi(t)=\overline{\phi_0}-\omega t$. Interestingly, $\overline{r}$ and $\overline{\phi_0}$ are independent of the realization and of the initial state, being, respectively, functions of the temperature T and the laser field $\mathcal{E}$ only. By letting $\epsilon\to\infty$, writing the corresponding quantum state diffusion equation (which is derived in the general case in Sec. V), and using a result due to Rigo and Gisin,[26] we obtain in Sec. IV B analytic expressions for $\overline{r}$ and $\overline{\phi_0}$ in good agreement with the numerical simulations.

A. Numerical results

Let us first look at the Husimi Q-function for the mode wave function in the interaction picture,

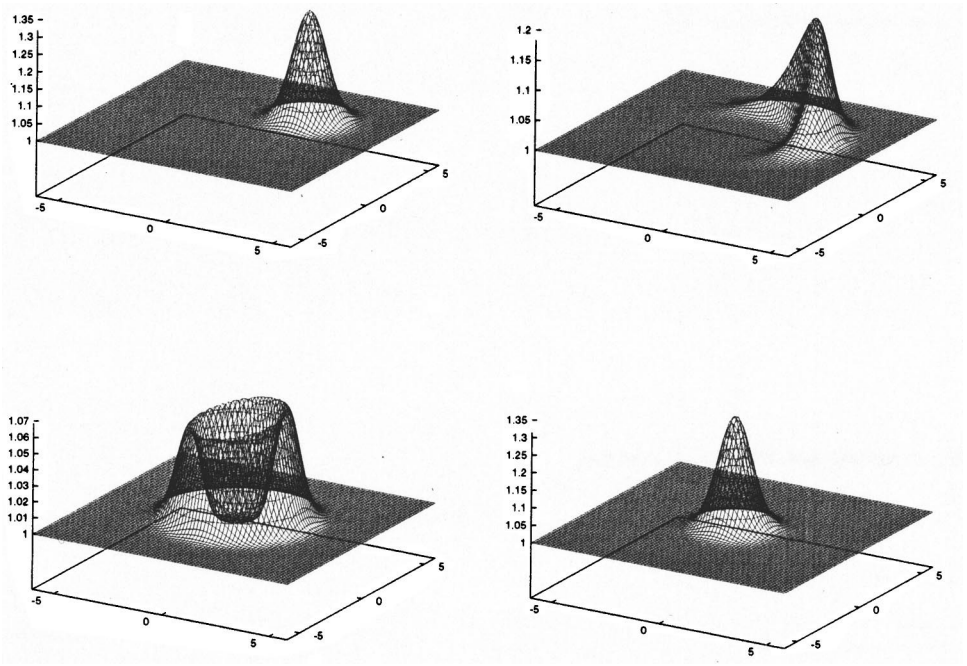

FIG. 2. $Q(\alpha,t)+1$ for $\epsilon=0$ and $\gamma_+/\gamma_-=3/4$, at four different times: $\gamma_- t=0$ (top left), $\gamma_- t=5$ (top right), $\gamma_- t=20$ (bottom left), and $\gamma_- t=60$ (bottom right).

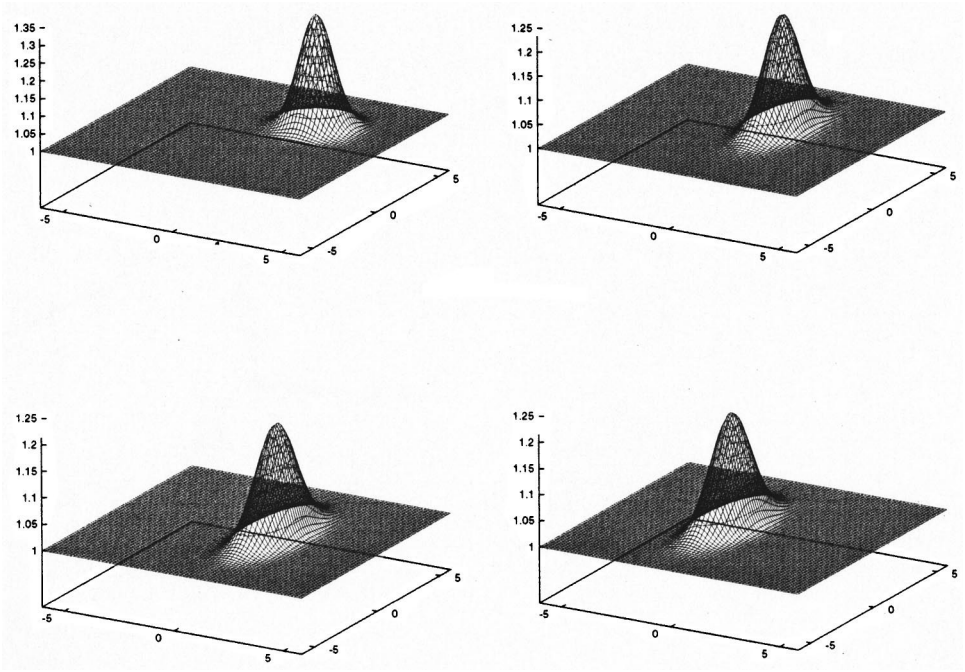

FIG. 3. $Q(\alpha,t)+1$ for $\epsilon=50$ and $\gamma_+/\gamma_-=3/4$, at the same times as in Fig. 2.

$$Q(\alpha,t)=\frac{1}{\pi}|\langle\alpha|\psi(t)\rangle|^2, \quad \alpha\in\mathbb{C}.$$

The simulations of single quantum trajectories for $\epsilon=0$ and $\epsilon=50$ give the results plotted in Figs. 2 and 3, respectively. Recall that for Fock states $|\psi\rangle=|n\rangle$, $Q(\alpha)$ is equal to $|\alpha|^{2n}\exp(-|\alpha|^2)/\pi n!$, and for squeezed states $|\psi\rangle=|\alpha_0,\xi\rangle$ with $\xi\in\mathbb{R}$, $|\xi|=r$,

$$Q(\alpha)=\frac{1}{\pi\cosh(r)}\exp\left(-\frac{2\Re(\alpha-\alpha_0)^2}{1+e^{-2r}}-\frac{2\Im(\alpha-\alpha_0)^2}{1+e^{2r}}\right)$$

(see Ref. 29). This asymmetric paraboloid becomes symmetric for a coherent state $|\psi\rangle=|\alpha_0\rangle$, which corresponds to $r=0$ in the above-mentioned formula. It is seen in Fig. 2 that in the case $\epsilon=0$, the initial coherent state $|\alpha=2+2i\rangle$ is transformed into states which are close to Fock states at times $t_3=20/\gamma_-$ $(n\neq 0)$ and $t_4=60/\gamma_-$ $(n=0)$. This is in agreement with the results of Ref. 27. On the other hand, for $\epsilon=50$, Fig. 3 shows that the same initial coherent state is transformed into states which are close to squeezed states $|\alpha,re^{i\phi}\rangle$. The squeezed states at t_3 and t_4 have approximately the same squeezing parameters r and $\phi=0$, but they have different centers α.

In order to study more precisely the localization toward squeezed states at large values of ϵ, let us follow the time evolution of the mean square deviations for a given quantum trajectory $t\mapsto|\psi(t)\rangle$:

$$\begin{aligned}\Delta x_\phi^2(t)&=\langle\psi_S(t)|X_\phi^2|\psi_S(t)\rangle-\langle\psi_S(t)|X_\phi|\psi_S(t)\rangle^2,\\ \Delta y_\phi^2(t)&=\langle\psi_S(t)|Y_\phi^2|\psi_S(t)\rangle-\langle\psi_S(t)|Y_\phi|\psi_S(t)\rangle^2.\end{aligned} \tag{50}$$

X_ϕ and Y_ϕ are the usual field quadrature operators rotated by an angle ϕ:

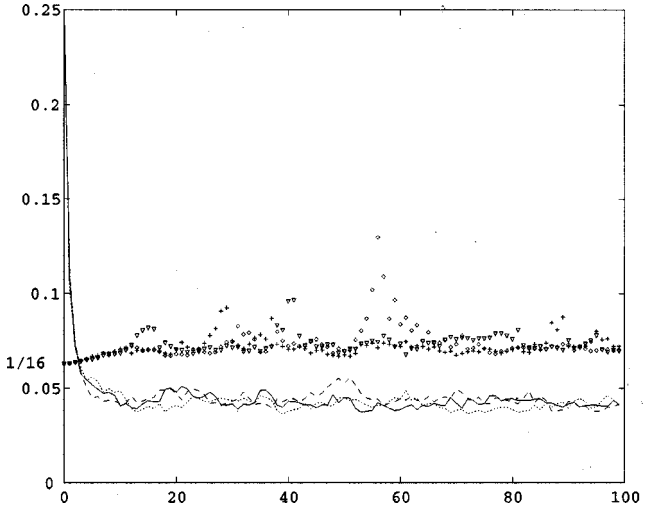

FIG. 4. $\Delta x^2(t)$ (solid, dashed, and dotted lines) and $\Delta x^2(t)\Delta y^2(t)$ [(+), ($\diamond$), and ($\triangledown$)] vs $\gamma_- t$ for three different quantum trajectories with initial coherent state. The values of the parameters are $\epsilon=20$ and $\gamma_+/\gamma_-=3/4$. The dotted line and the triangles correspond to the exact dynamics using the nonperturbative formulas (23)–(26) for K_g, $W_\pm$, and K_e, with $|\lambda|\tau=0.93\times10^{-2}$.

$$X_\phi=\frac{ae^{-i\phi}+a^\dagger e^{i\phi}}{2},\quad Y_\phi=X_{\phi+\pi/2}=\frac{ae^{-i\phi}-a^\dagger e^{i\phi}}{2i}. \tag{51}$$

We denote by $\phi_{\min}(t)$ the angle for which $\Delta x^2_\phi(t)$ is minimum. The minimum mean square deviation $\Delta x^2_{\phi_{\min}(t)}(t)$ is denoted by $\Delta x^2(t)$ and, similarly, $\Delta y^2_{\phi_{\min}(t)}(t)$ is denoted by $\Delta y^2(t)$. Obviously, $\Delta x^2(t)$ and $\Delta y^2(t)$ remain unchanged if the wave function $|\psi_S(t)\rangle$ in the Schrödinger picture is replaced in (50) by the wave function $|\psi(t)\rangle$ in the interaction picture. This replacement leads to an increase of $\phi_{\min}(t)$ by ωt.

The time evolutions of $\Delta x^2(t)$ and $\Delta x^2(t)\Delta y^2(t)$ are shown in Figs. 4 and 5, for different quantum trajectories starting from the same coherent state $|\psi(0)\rangle=|\alpha\rangle$. Note that the time scale is of order of the thermalization time of the density matrix $\rho(t)$. Figure 4 corresponds to $\epsilon=20$ and Fig. 5 to $\epsilon=100$. One sees in both Figs. 4 and 5 that $\Delta x^2(t)$ begins to fluctuate around a mean

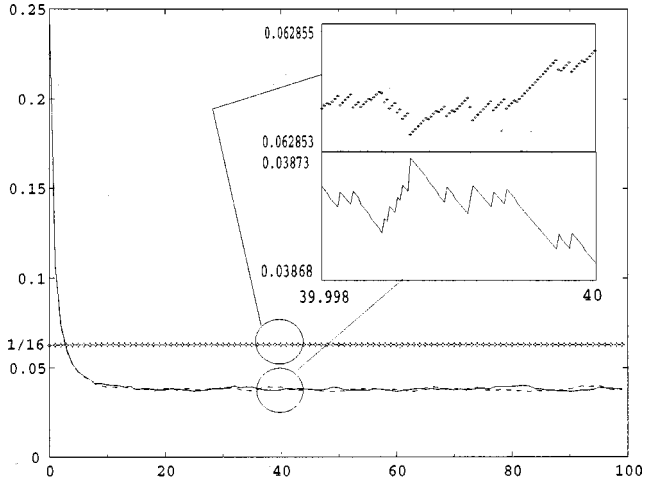

FIG. 5. Same as in Fig. 4 but with $\epsilon=100$ (the nonperturbative results are not shown but look similar). In the upper square, $\Delta x^2(t)$ and $\Delta x^2(t)\Delta y^2(t)$ are shown on a finer time scale, on which discontinuous quantum jumps can be seen separately.

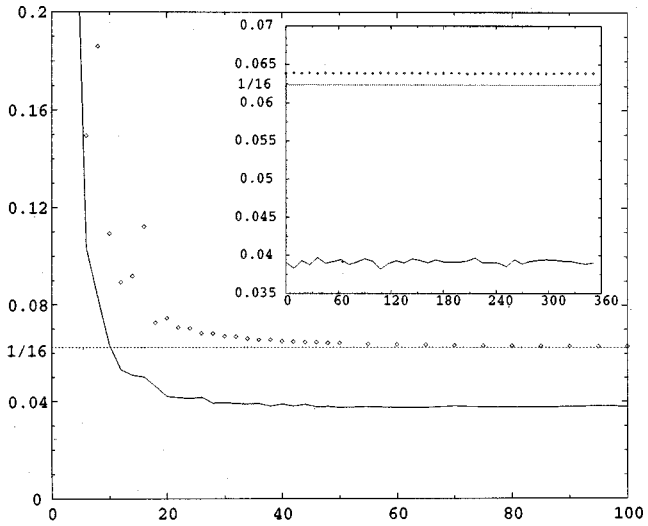

FIG. 6. Time averages $\overline{\Delta x^2}$ (plain line) and $\overline{\Delta x^2 \Delta y^2}$ ($\diamond$) for different values of $\Re\epsilon$ (shown in the horizontal axis) and $\Im\epsilon=0$. Inset: same for different values of $\arg\epsilon$ (shown in degrees in the horizontal axis) and fixed modulus $|\epsilon|=50$. The time average is taken on the interval $[10/\gamma_-, 100/\gamma_-]$ and $\gamma_+/\gamma_- = 3/4$.

value $\overline{\Delta x^2}$ after some transient time $\Delta\tau \simeq 10/\gamma_-$. The comparison of the numerical results for the different trajectories shows that $\overline{\Delta x^2}$ does not depend upon the specific realization. The fluctuations are considerably reduced in the case $\epsilon=100$ (Fig. 5) with respect to the case $\epsilon=20$ (Fig. 4). Moreover, in the former case, the product $\Delta x^2(t)\Delta y^2(t)$ is much closer to the minimum value 1/16 allowed by the Heisenberg uncertainty principle. The variation of $\overline{\Delta x^2}$ and $\overline{\Delta x^2 \Delta y^2}$ with ϵ for fixed temperature $T \simeq 0.288\omega/k_B$ is presented in Fig. 6. One observes that $\overline{\Delta x^2}$ is almost constant for $50 \leqslant \epsilon \leqslant 100$. Furthermore, the time average of $\Delta x^2(t)\Delta y^2(t)$ goes closer and closer to 1/16 as ϵ increases. The result presented in the inset shows moreover that $\overline{\Delta x^2}$ and $\overline{\Delta x^2 \Delta y^2}$ are independent of $\arg(\epsilon)$, up to small fluctuations.

Most numerical simulations were done using the approximations (31) and (38) for the jump operators $W_\pm$ and for K, together with $\tilde{a}=a$. This is justified if the maximum number of photons $n_{\max}$ is small with respect to $|\eta|^{-2}=|\lambda|^{-2}\tau^{-2}$, and $|\eta|^{-2}=|\lambda|^{-2}\tau^{-2}$, and $n_{\max}^{3/2} \ll |\eta|^{-4}|\epsilon|^{-1}$, $n_{\max}^{3/2} \ll |\eta|^{-2}|\epsilon|$ (see Sec. III B). Since we worked in the Fock states basis, $n_{\max}$ was bounded by the dimension of the Hilbert space (which was taken between 75 and 150). One may be worried, however, that, despite the smallness of the error made at each time step δt, the error made after many steps might be large and could invalidate our results in the long time limit. We checked that this is actually not the case by integrating numerically the exact dynamics, using formulas (23)–(26) for the evolution on each time step δt, and the exact possibilities of occurrence of the four cases. The curve in the dotted line and the triangles in Fig. 4 are the values of $\Delta x^2(t)$ and $\Delta x^2(t)\Delta y^2(t)$ obtained from a simulation of this nonperturbative dynamics. This means using the exact formulas (23)–(26) for the evolution on each time step δt, and the exact probabilities of occurrence of the four cases. The total number of atoms crossing the cavity in the whole time interval is 2×10^6, and $|\eta| = \sqrt{(\gamma_- + \gamma_+)\delta t} \simeq 0.0093$. The exact results show very similar fluctuations, around the same values $\overline{\Delta x^2}$ and $\overline{\Delta x^2 \Delta y^2}$, as the two trajectories obtained using the perturbative scheme. No systematic deviation increasing with time is seen. This result, together with other simulations for different values of ϵ and η,[31] shows errors in the considered time range. Note however that if $|\eta|$ is too large (for values in the range 0.06–0.09 or larger in Fig. 4, and 0.02–0.04 or larger in Fig. 5), large time fluctuations of $\Delta x^2(t)$ and $\Delta x^2(t)\Delta y^2(t)$ are observed and therefore the localization is of different nature.

In all our simulations, we found that $\overline{\Delta x^2}$ and $\overline{\Delta x^2 \Delta y^2}$ are insensitive to the initial state $|\psi(0)\rangle$ of the field mode. This is illustrated in Fig. 7 for $\epsilon=20$ and $\epsilon=20+10i$ (similar results are

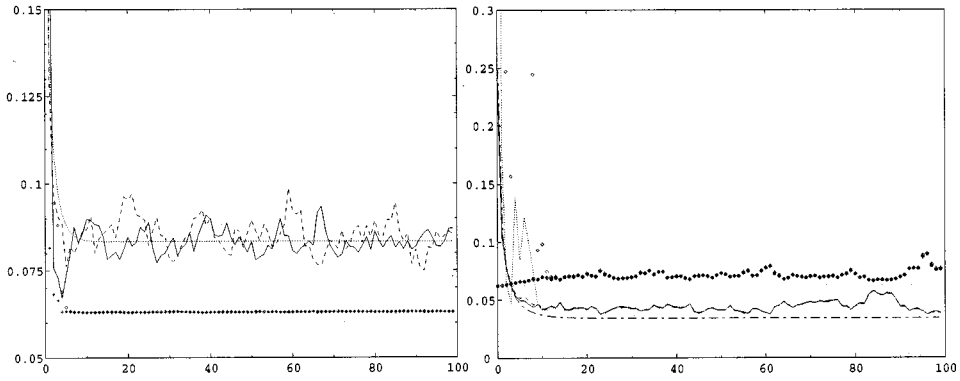

FIG. 7. $\Delta x^2(t)$ (lines) and $\Delta x^2(t)\Delta y^2(t)$ [(+), ($\diamond$), and ($\bigcirc$)] vs $\gamma_- t$ for trajectories with different initial states $|\psi(0)\rangle$. Left-hand side: in the two shown trajectories, $\langle n|\psi(0)\rangle$ is chosen randomly for $0\leqslant n\leqslant 20$ and vanishes for $n>20$; $|\psi(0)\rangle$ and the realization of the measurements are different in each trajectory; $\epsilon=20+10i$ and $\gamma_+/\gamma_-=1/2$. Right-hand side: (1) $|\psi(0)\rangle=|\alpha\rangle$ with $\alpha=\sqrt{3/2}(1+i)$ [plain line, ($\bigcirc$);] (2) id. with $\alpha=-1+5i$ [dashed line, (+);] (3) $|\psi(0)\rangle=|n=5\rangle$ [dotted line, ($\diamond$)]; in all cases, $\epsilon=20$ and $\gamma_+/\gamma_-=3/4$. The dotted line on the left-hand side and dot-dashed line on the right-hand side correspond to the theoretical result (64) for $\epsilon\to\infty$.

obtained for $\epsilon=100$). On the right-hand side of the Fig. 7, it is seen that $\Delta x^2(t)$ differs noticeably at small t's if $|\psi(0)\rangle$ is a coherent state [cases (1) and (2)] and if it is a Fock state [case (3); the first small time values are outside the range of the figure: $\Delta x^2(0)=2.75$]. However, the three curves are hard to distinguish for $\gamma_- t\gtrsim 10$. In the two trajectories shown on the left-hand side, the two distinct initial states are chosen by picking randomly the 20 first components $\langle n|\psi(0)\rangle$ in the Fock states basis (the realization of the measurements is also different in the two cases). For times bigger than $10/\gamma_-$, one observes that $\Delta x^2(t)$ fluctuates around the same value for both trajectories.

For the quantum trajectories studied in Figs. 3–5, the angle $\phi_{\min}(t)+\omega t$ is found to be zero at times $t\gtrsim\Delta\tau$. Nonvanishing angles are obtained if one considers non real ϵ's. The time dependence of $\phi_{\min}(t)+\omega t$ for $\epsilon=20+10i$ is presented in Fig. 8 for different initial states. It is seen that it evolves toward a constant value $\overline{\phi_0}$ which neither depends on $|\psi(0)\rangle$ nor on the ratio γ_+/γ_-. As shown in the inset, we obtain $\overline{\phi_0}=\arg(\epsilon)$.

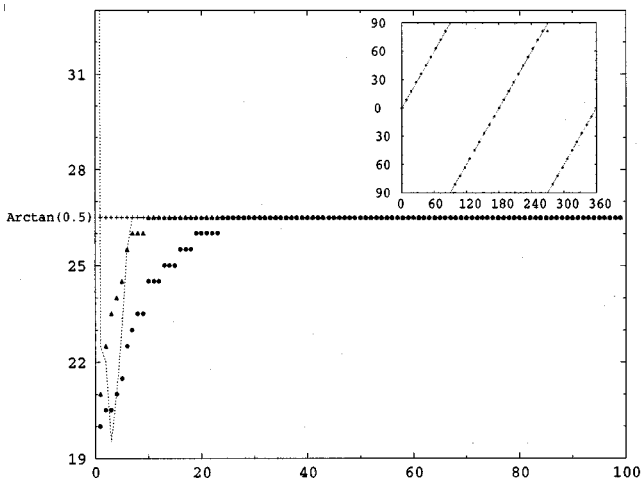

FIG. 8. Angle $\phi_{\min}(t)+\omega t$ (in degrees) vs $\gamma_- t$ for $\epsilon=20+10i$ and different initial states and temperatures: (1) $|\psi(0)\rangle=|\alpha\rangle$ with $\alpha=2-2i$; $\gamma_+/\gamma_-=1/4$ ($\triangle$); (2) $|\psi(0)\rangle=(2+2e^{-9})^{-1/2}(|\alpha\rangle+|\beta\rangle)$ with $\alpha=-3i$ and $\beta=3$; $\gamma_+/\gamma_-=3/4$ ($\bullet$); (3) $|\psi(0)\rangle=|n\rangle$ with $n=10$; $\gamma_+/\gamma_-=3/4$ (+); (4) $|\psi(0)\rangle$ is chosen randomly as in Fig. 7; $\gamma_+/\gamma_-=1/2$ (dashed line). Inset: time average of $\phi_0(t)=\phi_{\min}(t)+\omega t$ as function of $\arg\epsilon$ (both in degrees) for $|\epsilon|=50$ and $\gamma_+/\gamma_-=3/4$ (time average as in Fig. 6). The result is well fitted by the broken lines $\overline{\phi_0}=\arg(\epsilon)$ mod. 180.

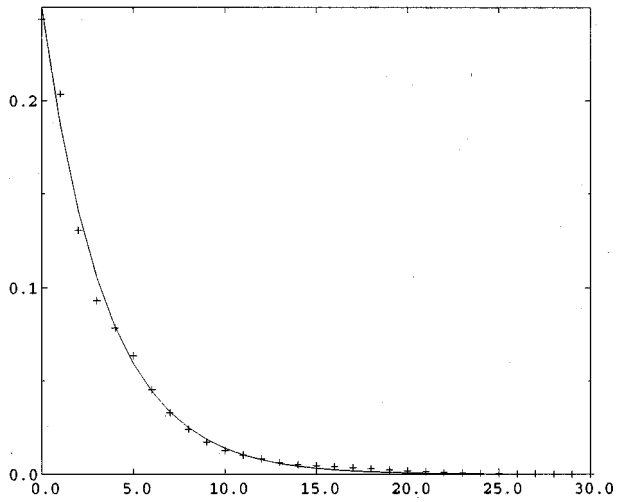

FIG. 9. Time average of the probability $|\langle n|\psi(t)\rangle|^2$ to find n photons for $\epsilon=50$, $\gamma_+/\gamma_-=3/4$ (+). The average is taken over 5000 discrete times in the interval $[0,100/\gamma_-]$. The solid line corresponds to the Bose–Einstein distribution.

Bringing together the above-mentioned results, we are led to the following conclusions. For large $|\epsilon|$ and small $|\eta|$ smaller than $\simeq 0.01$, the wave function $|\psi_S(t)\rangle$ of the field mode evolves, whatever its initial state $|\psi_S(0)\rangle$, to some almost minimum uncertainty states (MUS) at times $t \geqslant \Delta\tau$, where $\Delta\tau$ is a transient time. Moreover, if $T>0$,

$$\Delta x^2(t) \simeq \overline{\Delta x^2} < 1/4, \quad \phi_{\min}(t) \simeq \overline{\phi_0} - \omega t \tag{52}$$

at large times where both $\overline{\Delta x^2}$ and $\overline{\phi_0} = \arg(\epsilon)$ are independent of $|\psi_S(0)\rangle$ and of the realization of the measurements. Therefore, provided $|\epsilon|$ is big enough and $|\eta|$ small enough, the state of the field mode at times $t \geqslant \Delta\tau$ is close to a squeezed state:

$$|\psi_S(t)\rangle \simeq |\alpha(t), \xi(t)\rangle. \tag{53}$$

The squeezing amplitude $r(t)=|\xi(t)|$ fluctuates slightly around a time-independent value $r \simeq -\ln(4\overline{\Delta x^2})/2$ and $\arg(\xi(t)) \simeq 2(\overline{\phi_0} - \omega t)$. The center $\alpha(t)$ of the squeezed state moves around in the complex plane. Actually, by ergodicity, the time average of $|\psi_S(t)\rangle\langle\psi_S(t)|$ must coincide with the equilibrium density matrix $\rho^{(\mathrm{eq})} = Z^{-1}\exp(-\omega(a^\dagger a + 1/2)/k_B T)$. To check ergodicity, we have computed numerically the time average of $|\langle n|\psi(t)\rangle|^2$ on the interval $[0,100/\gamma_-]$ for a *single* quantum trajectory. It is indeed seen in Fig. 9 that it reproduces well the Bose–Einstein exponential distribution $\rho_{nn}^{(\mathrm{eq})}$.

B. Analytical results

The above-given numerical results suggest that the dynamics has the localization property toward squeezed states in the limit of large laser fields $|\epsilon| \to \infty$. In particular, the squeezed states should form an invariant family of states under the stochastic dynamics in this limit. The second statement can be shown analytically as follows. We restrict our analysis here to the perturbative regime where $|\eta| \ll 1$, $|\eta\epsilon| \ll 1$ and (28) holds with $k=0$, so that $\tilde{a} \simeq a$. As said previously, one can describe the mode's dynamics in the limit $|\epsilon| \to \infty$, $|\eta| \to 0$, $|\eta\epsilon| \to 0$ by a stochastic Schrödinger equation with real Wiener processes (quantum state diffusion). This is because the probability of occurrence of jumps grows like $|\epsilon|^2$ (for instance, in Figs. 4 and 5, the total number of jumps in the whole time interval $[0,100/\gamma_-]$ is close to 7×10^4 and 1.75×10^6, respectively). On the other hand, as is clear from (31) and (39), the change of the wave function during a jump is of order $1/\epsilon$. Hence there are infinitely many jumps with an infinitesimal impact on the wave function in the

limit $|\epsilon|\to\infty$. On a time scale much bigger than the inverse frequencies of jumps [but small enough so that $|\psi(t)\rangle$ does not change much on such a time scale], $|\psi(t)\rangle$ satisfies the following Itô stochastic differential equation in the limit $\epsilon\to\infty$, $\arg\epsilon=\theta$:

$$|\mathrm{d}\psi\rangle=\Big[\sqrt{\gamma_-}(e^{-i\theta}a-\Re\langle e^{-i\theta}a\rangle_t)\mathrm{d}w_-(t)+\sqrt{\gamma_+}(e^{i\theta}a^\dagger-\Re\langle e^{i\theta}a^\dagger\rangle_t)\mathrm{d}w_+(t)$$
$$+\Re\langle e^{i\theta}a^\dagger\rangle_t\Big(\gamma_-e^{-i\theta}a+\gamma_+e^{i\theta}a^\dagger-\frac{\gamma_-+\gamma_+}{2}\Re\langle e^{i\theta}a^\dagger\rangle_t\Big)\mathrm{d}t-iK_0\,\mathrm{d}t\Big]|\psi(t)\rangle. \quad (54)$$

The notation is as follows: $K_0=(\gamma_-a^\dagger a+\gamma_+aa^\dagger)/2i$, $\langle O\rangle_t=\langle\psi(t)|O|\psi(t)\rangle$ is the quantum expectation at time t and $\mathrm{d}w_\pm(t)$ are the stochastic infinitesimal increments of two independent real Wiener processes, which have zero mean and satisfy the Itô rules:[30]

$$\mathrm{d}w_\pm(t)\mathrm{d}w_\pm(t)=\mathrm{d}t,\quad \mathrm{d}w_-(t)\mathrm{d}w_+(t)=0,\quad \mathrm{d}w_\pm(t)\mathrm{d}t=0. \quad (55)$$

Equation (54) will be derived in Sec. V in the general case. It belongs to the class of stochastic Schrödinger equations studied in Refs. 11 and 12 and has been derived from the QJ dynamics by Wiseman and Milburn[8] (see also Refs. 5 and 9) in the case of a mode in a decaying cavity (corresponding here to $\gamma_+=0$). It can actually be derived directly from the stochastic dynamics of Sec. III B, Eqs. (23)–(26), with the probabilities (27), in the limit $|\epsilon|\to\infty$, $|\eta|\to0$, $|\epsilon\eta|=$const., under assumption (28) with $k=0$.[31] A related equation with complex Wiener processes has been studied in Ref. 10.

Rigo and Gisin[26] have shown that the stochastic Schrödinger equation (54) preserves squeezed states. Since (54) actually differs from the equation considered by these authors by some additional phase factors $e^{\pm i\theta}$, and the explicit solution of the evolution equations for the squeezing parameters is not given in Ref. 26, we briefly recall here their derivation. We use the Itô formalism of stochastic differential equations,[30] whereas Stratanovich formalism was used in Ref. 26. It is convenient to characterize squeezed states by the following criterion:

$$|\psi\rangle=\|\psi\||\alpha,\xi=re^{2i\phi}\rangle\Leftrightarrow(a-\Gamma a^\dagger-\beta)|\psi\rangle=0,\quad \Gamma=-e^{2i\phi}\tanh(r),\quad \beta=\alpha-\Gamma\alpha^*. \quad (56)$$

The family of the squeezed states is invariant under (54) if $|\psi\rangle+|d\psi\rangle$ remains a squeezed state for any $|\psi\rangle=|\alpha,\xi\rangle$, i.e., $(a-\Gamma a^\dagger-\mathrm{d}\Gamma\,a^\dagger-\beta-\mathrm{d}\beta)(|\psi\rangle+|\mathrm{d}\psi\rangle)=0$. This is equivalent to[26]

$$[a-\Gamma a^\dagger,D(\psi)]|\psi\rangle-(\mathrm{d}\Gamma\,a^\dagger+\mathrm{d}\beta)D(\psi)|\psi\rangle=(\mathrm{d}\Gamma\,a^\dagger+\mathrm{d}\beta)|\psi\rangle, \quad (57)$$

where $D(\psi)$ is the operator inside the square brackets in (54). The left-hand side is found to be

$$\Big(-\frac{\gamma_++\gamma_-}{2}(a+\Gamma\,a^\dagger)\mathrm{d}t+\Re\langle e^{i\theta}a^\dagger\rangle(\gamma_+e^{i\theta}\mathrm{d}t+\gamma_-e^{-i\theta}\Gamma\,\mathrm{d}t+\sqrt{\gamma_+}\mathrm{d}\beta\,\mathrm{d}w_++\sqrt{\gamma_-}\mathrm{d}\beta\,\mathrm{d}w_-)$$
$$+\sqrt{\gamma_+}\,e^{i\theta}(-a^\dagger\mathrm{d}\beta\,\mathrm{d}w_++\mathrm{d}w_+)+\sqrt{\gamma_-}e^{-i\theta}(-a\,\mathrm{d}\beta\,\mathrm{d}w_-+\Gamma\,\mathrm{d}w_-)\Big)|\psi\rangle. \quad (58)$$

We have thrown away all terms $\mathrm{d}\Gamma\,\mathrm{d}w_\pm$ since $\mathrm{d}\Gamma$ is proportional to $\mathrm{d}t$. This is because, by inspection of (58), the terms containing the noises $\mathrm{d}w_\pm$ on the left-hand side of (57) are proportional to $|\psi\rangle$. Multiplying both members of (57) by $\mathrm{d}w_\pm$ and using (55) and (58) gives

$$\mathrm{d}\beta\,\mathrm{d}w_+=\sqrt{\gamma_+}e^{i\theta}\mathrm{d}t,\quad \mathrm{d}\beta\,\mathrm{d}w_-=\sqrt{\gamma_-}e^{-i\theta}\Gamma\,\mathrm{d}t. \quad (59)$$

Now we use the well-known identity $S(-\xi)D(-\alpha)aD(\alpha)S(\xi)=a\cosh r+\Gamma\,a^\dagger\cosh r+\alpha$, where $S(\xi)=\exp(\xi^*a^2/2-\xi a^{\dagger2}/2)$ and $D(\alpha)=\exp(\alpha a^\dagger-\alpha^*a)$ are, respectively, the squeezing and the displacement operators.[2] The squeezed state $|\psi\rangle$ is equal to $D(\alpha)S(\xi)|0\rangle$. Let us multiply the two members of (57) by $S(-\xi)D(-\alpha)$ and substitute (58) and (59) into this equation. This leads to the two coupled stochastic differential equations:

$$
\begin{aligned}
d\Gamma &= -e^{2i\theta}(1+e^{-2i\theta}\Gamma)(\gamma_+ + \gamma_- e^{-2i\theta}\Gamma)dt, \\
d\beta &= -\left(\frac{\gamma_- + \gamma_+}{2} + \gamma_- e^{-2i\theta}\Gamma\right)\beta\, dt + 2\Re(e^{i\theta}a^*)(\gamma_+ e^{i\theta} + \gamma_- e^{-i\theta}\Gamma)dt \\
&\quad + \sqrt{\gamma_+}e^{i\theta}dw_+ + \sqrt{\gamma_-}e^{-i\theta}\Gamma\, dw_- .
\end{aligned}
\tag{60}
$$

These equations are equivalent to (57) and have a solution. Hence the squeezed states $|\alpha,\xi\rangle$ form an invariant family under the quantum state diffusion dynamics, and α and ξ evolve in time according to (60).

We now obtain the squeezing amplitudes $r(t)$ and angles $\phi(t)$ of the squeezed states by solving (60). They are determined by the first equation:

$$
\Gamma(t) = -e^{2i\theta}\frac{\gamma_+ e^{(\gamma_- - \gamma_+)t} + c}{\gamma_- e^{(\gamma_- - \gamma_+)t} + c} = -e^{2i\phi(t)}\tanh(r(t)), \tag{61}
$$

where c is an arbitrary complex constant. Thus $r(t)$ and $\phi(t)$ are deterministic, unlike $\alpha(t)$, which is given by the second equation. Going back to the Schrödinger picture, one has for $t(\gamma_- - \gamma_+) \gg 1$:

$$
\begin{aligned}
\tanh(r(t)) &\simeq \frac{\gamma_+}{\gamma_-} = \exp\left(-\frac{\omega}{k_B T}\right), \\
\phi(t) &\simeq \theta - \omega t.
\end{aligned}
\tag{62}
$$

It is worth noticing that perfect squeezing $[r(t)\to\infty]$ is obtained in the *high* temperature limit $k_B T \gg \omega$. The rate $(\gamma_- - \gamma_+)^{-1}$ of convergence of $\tanh r(t)$ to $\tanh \bar{r} = \exp(-\omega/k_B T)$ also tends to infinity in this limit. Since the number of photons in the cavity becomes very large at very high temperatures and long times, the perturbative approximation (28) should however break down at some point. This can put a limitation on the attainment of very large $r(t)$. A more detailed study of this apparently surprising result is the object in a separate work.[31]

As stated previously, the second equation in (62) agrees quite well with the results of the numerical simulations of Fig. 8. Using the minimum mean square deviation $\Delta x^2 = e^{-2r}/4$ of squeezed states[2] yields the time average $\overline{\Delta x^2}$:

$$
\overline{\Delta x^2} \simeq \frac{\gamma_- - \gamma_+}{4(\gamma_- + \gamma_+)}. \tag{63}
$$

In the particular case of an initial coherent state $|\psi(0)\rangle = |\alpha\rangle$, the constant c is equal to $-\gamma_+$, so that (62) is exact at all times $t \geqslant 0$ and

$$
\Delta x^2(t) \simeq \frac{\gamma_- - \gamma_+}{4\gamma_- + 4\gamma_+(1 - 2e^{-(\gamma_- - \gamma_+)t})}. \tag{64}
$$

This solution is compared in Fig. 7 with the numerical results for $|\epsilon| \sim 20$. The exact value of $\overline{\Delta x^2}$ is close to the approximated value 1/12 obtained from (63) for $\gamma_+/\gamma_- = 1/2$ (left-hand side of Fig. 7). It is a bit higher than the theoretical prediction $1/28 \simeq 0.0357$ for $\gamma_+/\gamma_- = 3/4$ (right-hand side). For $50 \leqslant \epsilon \leqslant 100$, one has a better agreement, as seen in Fig. 6. Hence the dynamics of the mode is well described by the quantum state diffusion equation (54) for $\epsilon \geqslant 50$, at this temperature.

V. STOCHASTIC SCHRÖDINGER EQUATIONS

In this section we discuss the mathematical link between the quantum jump dynamics of Sec. II and various stochastic Schrödinger equations found in the literature. The analysis is done for arbitrary open quantum systems having a Lindblad-type dynamics.

A. Linear quantum jump dynamics

A linear version of the QJ dynamics of Sec. II, in which the random wave function is not normalized at each time step δt, has been introduced in Ref. 18. The unormalized wave function $|\varphi(t)\rangle$ of the open system S satisfies the following Itô stochastic differential equation:

$$|\mathrm{d}\varphi\rangle=\left[-i(H+K)\mathrm{d}t+\sum_m\ (W_m-1)\mathrm{d}N_m(t)\right]|\varphi(t)\rangle, \tag{65}$$

where H is the Hamiltonian of S, the jump operators W_m are related to the Lindblad operators L_m by

$$L_m=\sqrt{\gamma_m}(W_m-1), \tag{66}$$

and $\mathrm{d}N_m(t)=0,1$ are the stochastic increments of independent Poisson processes N_m with parameters γ_m. These increments have mean $\mathsf{M}\,\mathrm{d}N_m(t)=\gamma_m\,\mathrm{d}t$ and satisfy the Itô rules:

$$\mathrm{d}N_m(t)\mathrm{d}N_n(t)=\delta_{n,m}\mathrm{d}N_m(t),\quad \mathrm{d}N_m(t)\mathrm{d}t=0. \tag{67}$$

Equation (65) has been first considered by Belavkin[14] with some jump operators W_m proportional to L_m [the relation with the jump operators (66) is given by the transformation (8)]. It has also been considered independently in Ref. 16. It is easy to show that $\rho(t)=\mathsf{M}|\varphi(t)\rangle\langle\varphi(t)|$ obeys the Lindblad equation (1) if K is appropriately chosen. In fact, by (65) and (67),

$$\begin{aligned}\mathrm{d}\rho&=\mathsf{M}(|\mathrm{d}\varphi\rangle\langle\varphi|+|\varphi\rangle\langle\mathrm{d}\varphi|+|\mathrm{d}\varphi\rangle\langle\mathrm{d}\varphi|)\\&=-i[H,\rho]\mathrm{d}t-iK\rho\,\mathrm{d}t+i\rho K^\dagger\,\mathrm{d}t+\sum_m\ \gamma_m((W_m-1)\rho+\rho(W_m^\dagger-1)+(W_m-1)\rho(W_m^\dagger-1))\mathrm{d}t.\end{aligned}$$

Replacing (66) into this equation yields

$$\mathrm{d}\rho=-i[H,\rho]\mathrm{d}t+\sum_m\ \left(L_m\rho L_m^\dagger-\frac{1}{2}\{L_m^\dagger L_m,\rho\}\right)\mathrm{d}t,$$

provided that

$$K=\frac{1}{2i}\sum_m\ \gamma_m(W_m^\dagger+1)(W_m-1)=\frac{1}{2i}\sum_m\ (L_m^\dagger L_m+2\sqrt{\gamma_m}L_m). \tag{68}$$

To give a physical meaning to the linear stochastic dynamics, one must choose the jump rates γ_m equal to the probability per unit time of the corresponding transitions. These are given by the Fermi golden rule to second order in perturbation theory. For instance, for the field mode considered in Sec. III, $\gamma_\pm$ are the damping rates (33) for the absorption and emission of a photon by the atoms.

Let us write (65) in the "dissipative interaction picture" $|\tilde{\varphi}(t)\rangle=U(t)|\varphi(t)\rangle$, where $U(t)=\exp(it(H+K))$. It reads $|\mathrm{d}\tilde{\varphi}\rangle=\Sigma_m(\tilde{W}_m(t)-1)\mathrm{d}N_m(t)|\tilde{\varphi}(t)\rangle$, with $\tilde{W}_m(t)=U(t)W_mU(-t)$. This implies:

$$|\tilde{\varphi}(t)\rangle=\tilde{W}_{m_p}(t_p)\cdots\tilde{W}_{m_1}(t_1)|\varphi(0)\rangle,$$

where $0\leqslant t_1\leqslant\cdots\leqslant t_p\leqslant\cdots$ are the jump times (times such that $\Sigma_m\,\mathrm{d}N_m(t)=1$), $t_p\leqslant t<t_{p+1}$, and m_q is the index of the jump occurring at time t_q ($\mathrm{d}N_{m_q}(t_q)=1$, $q=1,\ldots,p$). Hence the stochastic Schrödinger equation (65) admits the solution:

$$|\varphi(t)\rangle=e^{-i(t-t_p)(H+K)}W_{m_p}e^{-i(t_p-t_{p-1})(H+K)}\cdots W_{m_1}e^{-it_1(H+K)}|\varphi(0)\rangle,\quad t_p\leqslant t<t_{p+1}. \tag{69}$$

In other words, the evolution of the quantum state may be computed as follows.

(1) If there is a jump m between t and $t+\mathrm{d}t$, then

$$|\varphi(t+\mathrm{d}t)\rangle = W_m|\varphi(t)\rangle. \tag{70}$$

This occurs with a probability $\gamma_m \mathrm{d}t$ independent of $|\varphi(t)\rangle$.

(2) If no jump occurs between t and $t+\mathrm{d}t$, then

$$|\varphi(t+\mathrm{d}t)\rangle = (1 - i\,\mathrm{d}t(H+K))|\varphi(t)\rangle. \tag{71}$$

If $\gamma = \Sigma_m \gamma_m < \infty$, the time delays $t-t_p, t_p - t_{p-1}, \ldots, t_1$ and the jump indices $m_p, \ldots, m_1$ in (69) are independent random variables. The time delays are equally distributed, according to the exponential law $e^{-\gamma s}\,\mathrm{d}s$. Because of the independence of the Poisson processes N_m, the probability that $m_q = m$ is γ_m/γ.

It has been proven in Ref. 18 that, under appropriate hypothesis on W_m and γ_m, the wave function (69) is still well defined (as some limit of the right-hand side) if $\gamma = \infty$, in which case infinitely many jumps occur between 0 and t. This result is important for electrons in strongly disordered solids, where $m=(i,j)$ labels pairs of eigenstates $|i\rangle, |j\rangle$ of the electronic Hamiltonian, and L_{ij} is equal or "close" to $\sqrt{\gamma_{ij}}|j\rangle\langle i|$, i.e., $W_{ij} \simeq 1 + |j\rangle\langle i|$ (locality condition). Then, the number of jumps in a finite interval becomes infinite in the infinite volume limit, due to the divergence of the double sum $\Sigma_{i,j}\,\gamma_{ij}$. In this case, the presence of the identity operator inside the parentheses in (66) is necessary for the mathematical definiteness of $|\varphi(t)\rangle$.

B. Nonlinear quantum jump dynamics

The nonlinear QJ scheme of Sec. II can be deduced from the above-mentioned linear QJ dynamics in the following way. By comparing (9) and (4) with (70) and (71), it is clear that, for a given realization of the jumps, the normalized wave function

$$|\psi(t)\rangle = \frac{|\varphi(t)\rangle}{\|\varphi(t)\|} \tag{72}$$

evolves according to the nonlinear QJ scheme with $\lambda_m = \sqrt{\gamma_m}$. However, it was argued in Sec. II that the density matrix $\rho(t)$ is the mean value of $|\psi(t)\rangle\langle\psi(t)|$, whereas it has been seen earlier that $\rho(t) = \mathsf{M}|\varphi(t)\rangle\langle\varphi(t)|$. This means that the probability P' attached to $|\psi(t)\rangle$ is different from the probability P attached to $|\varphi(t)\rangle$, that is, to the Poisson processes N_m. This change of probability $P \to P'$ provides the link between the two random evolutions for $|\varphi(t)\rangle$ and $|\psi(t)\rangle$. We define it as follows. Let us denote by M' and M the mean values with respect to P' and P, respectively. Let F be an arbitrary (operator-valued) stochastic process such that $F(t)$ depends only upon the realizations of the jump times up to time t. Such F is said to be *adapted* to the filtration of the Poisson processes N_m.[33] We ask that

$$\mathsf{M}'(F(t)) = \mathsf{M}(F(t)\|\varphi(t)\|^2) \tag{73}$$

for any such process F. Taking $F(t) = |\psi(t)\rangle\langle\psi(t)|$, this implies in particular

$$\rho(t) = \mathsf{M}'|\psi(t)\rangle\langle\psi(t)| = \mathsf{M}|\varphi(t)\rangle\langle\varphi(t)|. \tag{74}$$

Let us compute the probability of occurrence of a jump m between times t and $t+\delta t$ for the new probability P':

$$\delta p_m(t) = \mathsf{M}'(\delta N_m(t)|\psi(t)). \tag{75}$$

The right-hand side is the conditional (mean) expectation of $\delta N_m(t)$ given $|\psi(t)\rangle$, for the probability P'. Indeed, the (P') probability of a jump between t and $t+\delta t$ depends upon the wave function $|\psi(t)\rangle$ at time t. Let $F(t)$ be an arbitrary stochastic force adapted to the filtration of the

N_m's. Then $F(t)\,\delta N_m(t)$ depends upon the realizations of the N_m's until time $t+\delta t$ [recall that $\delta N_m(t)=N_m(t+\delta t)-N_m(t)$]. Therefore, replacing $F(t)$ by $F(t)\,\delta N_m(t)$ in (73),

$$\mathsf{M}'(F(t)\,\delta N_m(t))=\mathsf{M}(F(t)\,\delta N_m(t)\|\varphi(t+\delta t)\|^2)=\mathsf{M}(F(t)\,\delta N_m(t)\|W_m|\varphi(t)\rangle\|^2).$$

Formula (70) together with the fact that $\delta N_m(t)=0,1$ have been used in the second line. By the independence of the forward increment $\delta N_m(t)$ and $F(t)\|W_m|\varphi(t)\rangle\|^2$, one gets

$$\mathsf{M}'(F(t)\,\delta N_m(t))=\mathsf{M}(\delta N_m(t))\mathsf{M}(F(t)\|W_m|\varphi(t)\rangle\|^2)=\gamma_m\,\delta t\,\mathsf{M}'(F(t)\|W_m|\varphi(t)\rangle\|^2\|\varphi(t)\|^{-2}). \tag{76}$$

But $F(t)$ is arbitrary, thus (76) implies the identity of the conditional expectations:

$$\delta p_m(t)=\mathsf{M}'(\delta N_m(t)|\psi(t))=\gamma_m\,\delta t\,\mathsf{M}'(\|W_m|\varphi(t)\rangle\|^2\||\varphi(t)\rangle\|^{-2}|\psi(t))=\gamma_m\,\delta t\|W_m|\psi(t)\rangle\|^2, \tag{77}$$

in accordance with (12). As a result, the stochastic evolution of the normalized wave function $|\psi(t)\rangle$ with probability P' coincides with that described in Sec. II for $\lambda_m=\sqrt{\gamma_m}$. It is moreover given by the nonlinear stochastic Schrödinger equation:[15]

$$|\mathrm{d}\psi\rangle=\left[-i\left(H+K+\frac{1}{2}\langle K^\dagger-K\rangle_t\right)\mathrm{d}t+\sum_m\left(\frac{W_m}{\sqrt{\langle W_m^\dagger W_m\rangle_t}}-1\right)\mathrm{d}N_m(t)\right]|\psi(t)\rangle, \tag{78}$$

with $\langle O\rangle_t=\langle\psi(t)|O|\psi(t)\rangle$. This equation is readily obtained by computing $|\psi(t+\mathrm{d}t)\rangle$ from (70) and (71).

C. Linear quantum state diffusion

It has been shown by Carmichael and Wiseman and Milburn[5,8] that the nonlinear QJ dynamics of the quantum field considered in Sec. III, with $\gamma_+=0$, is well described in limit $|\epsilon|\to\infty$ by a quantum state diffusion (QSD) stochastic equation involving real Wiener processes (white noise). The linear version of QSD is obtained in this section in the more general setting of arbitrary Markovian quantum open systems, by taking the limit of infinite jump rates $\gamma_m\to\infty$ in the linear QJ dynamics of Sec. V A.

Following Wiseman and Milburn,[8] we introduce a small dimensionless parameter $\varepsilon>0$ that will tend to zero. Our goal is to increase up to infinity the rates γ_m of the jumps in the linear QJ dynamics, without modifying the master equation giving the average dynamics. Hence the Lindblad operators L_m are here considered as *fixed*, i.e., independent of ε. So are the damping rates contained in the master equation, given by some ε-independent rates $\overline{\gamma}_m>0$. The jump rates γ_m are assumed to go to infinity like ε^{-4}:

$$\gamma_m=\varepsilon^{-4}\overline{\gamma}_m. \tag{79}$$

The magnitude of the negative power of ε is chosen for future convenience. Let $|\varphi(t)\rangle$ be the solution of the linear QJ stochastic equation (65). We are interested in the variation of $|\varphi(t)\rangle$ on a time interval $\Delta t\gg\gamma_m^{-1}$ such that infinitely many jumps occur between t and $t+\Delta t$ in the limit $\varepsilon\to0$. On the other hand, we want Δt to be small enough so that the change $|\Delta\varphi\rangle=|\varphi(t+\Delta t)\rangle-|\varphi(t)\rangle$ of the wave function goes to zero as $\varepsilon\to0$. A possible Δt realizing these two conditions is

$$\Delta t=\varepsilon^3\overline{\gamma}^{-1}, \tag{80}$$

where $\overline{\gamma}=\Sigma_m\,\overline{\gamma}_m$ is the sum of the fixed damping rates. Indeed, from (66),

$$W_m=1+\varepsilon^2\overline{\gamma}_m^{-1/2}L_m. \tag{81}$$

Since the L_m are ε-independent, the impact of each jump on $|\varphi\rangle$ is of order ε^2. Moreover, the number of jumps m between t and $t+\Delta t$ is of order $\gamma_m \Delta t = \varepsilon^{-1}\overline{\gamma_m}/\overline{\gamma}$. This means that the impact of the jumps between t and $t+\Delta t$ is of order $\varepsilon^{-1}\times\varepsilon^2=\varepsilon$, which is indeed small for small ε.

Let $\Delta N_m(t)$ be the number of jumps m in the time interval $[t,t+\Delta t]$. By dividing this interval into smaller intervals $[\tau_n,\tau_{n+1}]$ of length γ_m^{-1}, $\Delta N_m(t)$ can be written as a sum of $\gamma_m \Delta t = \mathcal{O}(\varepsilon^{-1})$ independent random variables $N_m([\tau_n,\tau_{n+1}])$ (number of jumps between τ_n and τ_{n+1}), which have mean and variance 1. Therefore, by the central limit theorem,

$$\Delta z_n = \frac{\Delta N_m - \gamma_m \Delta t}{\sqrt{\gamma_m}} \tag{82}$$

can be approximated for small ε by a Gaussian random variable of zero mean and variance Δt [the convergence as $\varepsilon\to 0$ actually holds for a fixed ε-independent Δt; for Δt given by (80), one gets an infinitesimal increment dz_n]. Shifting t by Δt or changing m leads to independent increments ΔN_m and Δz_m. It follows that Δz_m are the infinitesimal increments of some independent real Wiener processes z_m in the limit $\varepsilon\to 0$. Indeed, a Wiener process z is by definition a stochastic process with independent increments $\Delta z = z(t+\Delta t)-z(t)$ distributed according to a Gaussian law of variance Δt. The convergence of $(N_m-\gamma_m t)/\sqrt{\gamma_m}$ to a Wiener process can be shown more rigorously by using a theorem proven in Ref. 32.

The next step consists in evaluating both the mean and the fluctuating parts of $|\Delta\varphi\rangle$ to leading order in ε. Let $p=\Sigma_m \Delta N_m(t)$ be the total number of jumps between t and $t+\Delta t$. We denote by $s_q = t_{q+1}-t_q$, $q=1,\ldots,p-1$, the time delays between consecutive jumps and set $s_0=t_1-t$ and $s_p = t+\Delta t - t_p$. By (79) and (80), p and s_q have mean values $\gamma\Delta t$ and γ^{-1} of order ε^{-1} and ε^4, respectively. The generalized Hamiltonian (68) can be decomposed into two parts:

$$K = K_0 - i\varepsilon^{-2}R, \tag{83}$$

where K_0 and R are ε-independent:

$$K_0 = \frac{1}{2i}\sum_m L_m^\dagger L_m, \quad R = \sum_m \sqrt{\overline{\gamma_m}} L_m. \tag{84}$$

Let us set $V_q = \overline{\gamma_{m_q}}^{-1/2} L_{m_q}$ if $q=1,\ldots,p$ and $V_0=0$. With the help of (69), (81), and (83), one obtains

$$|\Delta\varphi\rangle = \left\{ \prod_{q=p}^{0} \left[\left(1-\varepsilon^{-2}s_q R + \frac{1}{2}\varepsilon^{-4}s_q^2 R^2 - i s_q (H+K_0) + \mathcal{O}(\varepsilon^6) \right)(1+\varepsilon^2 V_q) \right] - 1 \right\} |\varphi(t)\rangle, \tag{85}$$

where the product is taken in decreasing order in q. The terms of order ε in the expansion of the product are

$$\begin{aligned} |\Delta\varphi\rangle^{(f)} &= \sum_{q=0}^{p} (-\varepsilon^{-2}s_q R + \varepsilon^2 V_q)|\varphi(t)\rangle \\ &= \sum_m (-\varepsilon^{-2}\Delta t\,\overline{\gamma_m}^{1/2} + \varepsilon^2 \Delta N_m(t)\,\overline{\gamma_m}^{-1/2}) L_m |\varphi(t)\rangle = \sum_m \Delta z_m(t) L_m |\varphi(t)\rangle. \end{aligned} \tag{86}$$

These are the leading order fluctuating forces (of zero mean). Since fluctuating terms of higher order should not contribute in the limit $\varepsilon\to 0$, we may replace the product in (85) by its mean value in computing the terms of order ε^2 and more. This simplifies greatly the computation, because the order of the operators in the product then becomes of no importance. In fact, by the remark following (71), the random variables $s_0,\ldots,s_p$, $m_1,\ldots,m_p$ are independent, so that the mean of the product is the product of the means. Moreover, $\mathrm{M}V_q = \Sigma_m(\gamma_m/\gamma)\overline{\gamma_m}^{-1/2} L_m = R/\overline{\gamma}$. Therefore, one

can commute all operators in the product when computing the mean value. It is easy to show that the terms of order ε^2 cancel on average. The terms of order ε^3 are found to be proportional to Δt:

$$|\Delta\varphi\rangle^{(d)} = \mathsf{M}|\Delta\varphi\rangle = -i(H+K_0)\Delta t(1+\mathcal{O}(\varepsilon)). \tag{87}$$

This is the drift contribution to $|\Delta\varphi\rangle$.

The previous computation shows that the QJ dynamics is transformed as $\varepsilon \to 0$, if one looks at it with the time resolution $\Delta t = \overline{\gamma}^{-1}\varepsilon^3$, to a diffusive dynamics given by the linear Itô stochastic differential equation:[12,15,17]

$$|\mathrm{d}\varphi\rangle = \left[-i(H+K_0)\mathrm{d}t + \sum_m L_m \mathrm{d}z_m(t)\right]|\varphi(t)\rangle. \tag{88}$$

Here $K_0 = \Sigma_m L_m^\dagger L_m/2i$ and $\mathrm{d}z_m(t)$ are the infinitesimal increments of independent *real* Wiener processes z_m, which have zero mean and satisfy the Itô rules:

$$\mathrm{d}z_m(t)\mathrm{d}z_n(t) = \delta_{n,m}\,\mathrm{d}t, \quad \mathrm{d}z_m(t)\mathrm{d}t = 0. \tag{89}$$

D. Nonlinear quantum state diffusion

We have so far determined the linear stochastic Schrödinger equation for $|\varphi(t)\rangle$. The corresponding nonlinear equation for the normalized wave function $|\psi(t)\rangle$ is obtained by means of the above-mentioned change of probability $P \to P'$. This derivation of the nonlinear QSD equation from the linear one is actually well-known.[12,28] It is slightly more complicated than for the QJ dynamics, because $|\mathrm{d}\psi\rangle$ is to be expressed in terms of Wiener processes for the new probability P'. This can be done by using Girsanov's theorem,[33] which states that a Wiener differential $\mathrm{d}w_m$ for P' is obtained by adding an appropriate drift differential to $\mathrm{d}z_m$. For the change of probability defined by (73), the conditional (mean) expectation of $\mathrm{d}P'/\mathrm{d}P$ given $|\varphi(t)\rangle$ is $\|\varphi(t)\|^2$. The drift differential is then $-\|\varphi(t)\|^{-2}\mathrm{d}\|\varphi\|^2\mathrm{d}z_m$ (for more details, see Refs. 12, 28). From (88) and (89), one gets

$$\mathrm{d}\|\varphi\|^2 = 2\|\varphi(t)\|^2 \sum_m \Re\langle L_m\rangle_t \mathrm{d}z_m, \tag{90}$$

which implies that $\|\varphi(t)\|^2$ is a local martingale. Thus,

$$\mathrm{d}w_m(t) = \mathrm{d}z_m(t) - 2\Re\langle L_m\rangle_t \mathrm{d}t. \tag{91}$$

According to Itô's formula,[30] one has

$$\frac{|\mathrm{d}\varphi\rangle}{\|\varphi\|} = \frac{\mathrm{d}(\sqrt{\|\varphi\|^2}|\psi\rangle)}{\|\varphi\|} = |\mathrm{d}\psi\rangle + \left(\frac{\mathrm{d}\|\varphi\|^2}{2\|\varphi\|} - \frac{\mathrm{d}\|\varphi\|^2\mathrm{d}\|\varphi\|^2}{8\|\varphi\|^3}\right)\frac{|\psi\rangle + |\mathrm{d}\psi\rangle}{\|\varphi\|}.$$

The multiplication of both members by $\mathrm{d}z_m$ leads, with the help of (88)–(90), to $\mathrm{d}z_m|\mathrm{d}\psi\rangle = (L_m - \Re\langle L_m\rangle_t)|\psi\rangle\mathrm{d}t$. Going back to the original equation, it follows:

$$|\mathrm{d}\psi\rangle = \left[-i(H+K_0)\mathrm{d}t + \sum_m \Re\langle L_m\rangle_t\left(-L_m + \frac{3}{2}\Re\langle L_m\rangle_t\right)\mathrm{d}t + \sum_m (L_m - \Re\langle L_m\rangle_t)\mathrm{d}z_m\right]|\psi\rangle.$$

The nonlinear QDS equation is obtained by replacing (91) into this equation:[11,12,15]

$$|\mathrm{d}\psi\rangle = \left[-i(H+K_0)\mathrm{d}t + \sum_m \Re\langle L_m\rangle_t\left(L_m - \frac{1}{2}\Re\langle L_m\rangle_t\right)\mathrm{d}t + \sum_m (L_m - \Re\langle L_m\rangle_t)\mathrm{d}w_m(t)\right]|\psi(t)\rangle. \tag{92}$$

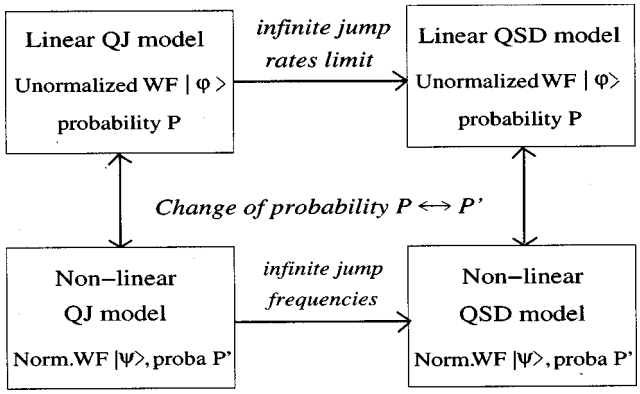

FIG. 10. The links between the different stochastic Schrödinger equations.

Let us come back to the mode dynamics of Sec. III. If one sticks to the norm-preserving QJ dynamics, the jump operators $W_{\pm}$ in (31) are defined up to a multiplicative constant. If $k=0$, $\tilde{a}\simeq a$, they can be obtained, up to such a constant, from the Lindblad operators $L_{+}=\sqrt{\overline{\gamma}_{+}}a^{\dagger}$ and $L_{-}=\sqrt{\overline{\gamma}_{-}}a$ by means of formula (66), provided that the transition rates are replaced by some effective rates $\gamma_{\pm}=\overline{\gamma}_{\pm}|\epsilon|^2$ and $L_{\pm}$ are multiplied by the phase factors $e^{\pm i\theta}$, $\theta=\arg\epsilon$. Thus the above-presented analysis can be used to compute the QSD equation for the normalized mode wave function $|\psi(t)\rangle$ in the limit of large laser fields $|\epsilon|\to\infty$. The introduction of the phase factors $e^{\pm i\theta}$ in (92) leads to the QSD equation (54).

E. Links between the stochastic Schrödinger equations

The summary of the results of this section is given in Fig. 10. The stochastic Schrödinger equations in Itô form for the linear and nonlinear QJ models are, respectively, Eqs. (65) and (78), and those for the linear and nonlinear QSD models are, respectively, Eqs. (88) and (92).

VI. CONCLUSION

We have shown that the nonlinear quantum jump (or Monte Carlo wave function) model applied to a simple optical system (damped harmonic oscillator at finite temperature T) can be generalized to describe the evolution of the quantum field in a cavity monitored by an atomic beam of two level atoms. These atoms cross one by one the cavity and interact at its exit first with a classical laser field $\mathcal{E}$, and then with a detector measuring their states. This kind of monitoring by measurements is similar to that obtained by homodyne measurement of the field in a decaying cavity,[5,8] the photon counting on the output field being replaced by the measurements on the atoms. Actually, if all atoms are sent in their ground state ($T=0$), the stochastic evolution of the wave function of the quantum field (quantum trajectories) is the same for the two kinds of monitoring. If the atoms form a beam of randomly prepared atoms with temperature $T>0$, they may also emit photons in the cavity and thus a new kind of quantum jump comes into play (creation of a photon). This has notable effects on the quantum trajectories. The effect of the laser field $\mathcal{E}$ is to modify the two jump operators. In fact, the measured atomic transitions can be driven by this field as well as by the interaction with the studied quantum field in the cavity. As a result, $\mathcal{E}$ also modifies the generalized Hamiltonian that rules the evolution between jumps. The average over all realizations of the measurements leads to an $\mathcal{E}$-independent dynamics, described by a density matrix satisfying the master equation of the damped harmonic oscillator with temperature T. Whereas the density matrix converges at large times to the Bose–Einstein equilibrium, the individual quantum trajectories for given realizations experience localization toward squeezed states at large $\mathcal{E}$. The squeezing parameters evolve to some almost constant values, up to small fluctuations going to zero in the infinite laser intensity limit. This localization occurs at large enough times, for any initial state of the quantum field. The centers of the squeezed states move

randomly in the complex plane, in such a way that the time averages of the quantum probabilities to find n-photons are distributed according to Bose–Einstein (ergodicity). The squeezing amplitude r and phase ϕ are controlled, respectively, by the temperature T and the laser field $\mathcal{E}$. r is found to increase with T, which means that the squeezing is enhanced by increasing the temperature of the atomic beam; however, the waiting time before r reaches its almost stationary value is also temperature increasing. On the other hand, no squeezing is obtained at $T=0$, and localization toward Fock states occurs if $\mathcal{E}=0$. As in the case of the homodyne measurement, the quantum trajectories are given in the infinite $\mathcal{E}$ limit by a so-called quantum state diffusion (QSD) stochastic Schrödinger equation, involving real white noise.[5,8,11,12] A precise mathematical derivation of this equation from the quantum jump dynamics was performed in Sec. V for arbitrary open quantum systems having a Lindblad-type dynamics. More precisely, this derivation starts from a linear version of the QJ dynamics proposed in Ref. 18, in which the wave function is not normalized at each step, which is proven to be related to the nonlinear QJ model by a simple change of probability.

(Received 31 January 2001; accepted for publication 12 March 2002)

We study a pair of canonoid (fouled) Hamiltonians of the harmonic oscillator which provide, at the classical level, the same equation of motion as the conventional Hamiltonian. These Hamiltonians, say K_1 and K_2, result to be explicitly time dependent and can be expressed as a formal rotation of two cubic polynomial functions, H_1 and H_2, of the canonical variables (q,p). We investigate the role of these fouled Hamiltonians at the quantum level. Adopting a canonical quantization procedure, we construct some quantum models and analyze the related eigenvalue equations. One of these models is described by a Hamiltonian admitting infinite self-adjoint extensions, each of them has a discrete spectrum on the real line. A self-adjoint extension is fixed by choosing the spectral parameter ε of the associated eigenvalue equation equal to zero. The spectral problem is discussed in the context of three different representations. For $\varepsilon=0$, the eigenvalue equation is exactly solved in all these representations, in which square-integrable solutions are explicitly found. A set of constants of motion corresponding to these quantum models is also obtained. Furthermore, the algebraic structure underlying the quantum models is explored. This turns out to be a nonlinear (quadratic) algebra, which could be applied for the determination of approximate solutions to the eigenvalue equations. [DOI: 10.1063/1.1479300]

I. INTRODUCTION

A few years ago, in Ref. 1 a method was devised to find alternative Lagrangians for the time-dependent oscillator

$$\ddot{q}+\omega(t)^2 q=0, \tag{1}$$

where $q=q(t)$, $\omega(t)$ is a given differentiable function, and the dot stands for time derivative. The method, which is based on the concept of fouling transformation,[2] is reviewed in Sec. II.

In this paper we study certain nonconventional quantum Hamiltonians corresponding to the classical fouled Hamiltonians associated with the Lagrangians derived in Ref. 1. This investigation is motivated by the fact that these nonconventional quantum Hamiltonians, having a polynomial structure in the operators a and $a^\dagger$, may play an important role in the context of quantum optics, especially in handling coherence and squeezing of multiphoton systems.

All the fouled Lagrangians of the hierarchy found in Ref. 1 lead to the same equation of motion (1) as occurs for the conventional Lagrangian $L_1=1/2(\dot{q}^2-\omega(t)^2q^2)$ [see (5)]. In Sec. III the fouled Hamiltonians $K_\pm$, related to the simplest fouled Lagrangians, $L_2^{(1)}$ and $L_2^{(2)}$, given by (23) and (24) are written down. By way of example, we have limited ourselves to considering the standard (harmonic) oscillator where $\omega(t)\equiv\lambda$ is a constant. Furthermore, it is shown that (at the classical level), as one expects, $K_\pm$ reproduce the same equation of motion coming from the conventional Hamiltonian $H_0=1/2(p^2+\lambda^2q^2)$. For brevity, we shall deal with K_+ only. It turns

[a]Also at: Dipartimento di Fisica dell'Università di Salerno, 84100 Baronissi, Salerno, Italy.
[b]Electronic mail: soliani@le.infn.it

out that K_+ (see Sec. IV) can assume two possible forms, denoted by $K_+^{(1)} \equiv K_1$ and $K_+^{(2)} \equiv K_2$ [see (39) and (40)], which are independent but depend explicitly on time via the coefficients $\cos \lambda t$ and $\sin \lambda t$. Consequently, K_1 and K_2 can be formally interpreted as the result of a *rotation* (of an angle λt) of the quantities $H_1 = \sqrt{\lambda}(p^2 + \lambda^2 q^2)q$ and $H_2 = (2/3\sqrt{\lambda})p^3$, which are *not* explicitly dependent on time. In other words, we have $K_1^2 + K_2^2 = H_1^2 + H_2^2$, and

$$\{K_1, K_2\}_{q,p} = \{H_1, H_2\}_{q,p}$$

(see Sec. IV), where the symbol {,} denotes the Poisson bracket with respect to the canonical variables (q,p), namely

$$\{A,B\}_{q,p} = \frac{\partial A}{\partial q}\frac{\partial B}{\partial p} - \frac{\partial A}{\partial p}\frac{\partial B}{\partial q}.$$

In Sec. V the canonical quantization procedure based on a bosonic couple of annihilation and creation operators, a and $a^\dagger$ (with $[a, a^\dagger] = 1$), is applied to the fouled Hamiltonians K_1 and K_2. In such a way K_1 and K_2 are converted into a pair of Hamiltonian operators, say $\mathcal{K}_1$ and $\mathcal{K}_2$. [Classically, as we know, K_1 and K_2 provide the same equation of motion (1).] Furthermore, since the canonical quantization procedure does affect only the cubic polynomial functions of (q,p), namely H_1 and H_2, here we limit ourselves to study the operators $\mathcal{H}_1$ and $\mathcal{H}_2$, which are the quantized versions of H_1 and H_2, respectively. The arising *quantum models* are investigated in Secs. VI and VII.

Precisely, in Sec. VI we show that the quantum model coming from $\mathcal{H}_1$ gives rise to a linear second-order eigenvalue equation of the Sturm–Liouville type (in the harmonic oscillator excitation number representation, or n-rep).

An interesting feature of the operator $\mathcal{H}_1$ is that it is connected with an undetermined Hamburger moment problem.[3–5] We show that this operator has deficiency indices (1,1) and allows a one-parameter family of self-adjoint extensions whose spectra are discrete and with no point in common. This goal has been achieved essentially by associating the operator $\mathcal{H}_1$ with a Jacobi matrix.[3,5] A possible physical interpretation of the operator $\mathcal{H}_1$ is provided by fixing, among the infinite self-adjoint extensions, the extension corresponding to $\varepsilon = 0$, where ε denotes the spectral parameter. In this case the eigenvalue equations for $\mathcal{H}_1$ can be solved exactly in all the following representations: the harmonic oscillator excitation number representation (n-rep), the coordinate space representation (q-rep), and the Fock–Bargmann holomorphic function representation (z-rep).[6–8] In all these representations, for $\varepsilon = 0$ square-integrable solutions of the eigenvalue equations are explicitly obtained.

In Sec. VII we deal with the eigenvalue equation for $\mathcal{H}_2$. The analysis of this Hamiltonian is trivial. It is exactly solvable,[9] its spectrum is on the whole line, and the related eigenfunctions can be easily found. Nevertheless, $\mathcal{H}_2$ has been involved in the construction of two quantum models described by the operators $\mathcal{H}_3$ and $\mathcal{H}_4$ [see (57) and (58)], where $\mathcal{H}_2 = \mathcal{H}_3 + \mathcal{H}_4$. One can attribute to $\mathcal{H}_3$ a physical meaning. Specifically, $\mathcal{H}_3$ can be interpreted as a special case of a class of Hamiltonians appearing in the higher order nonlinear optical processes.[5,10–12] This Hamiltonian is involved in the construction of third power squeezed states.[5,11,13]

On the other hand, as we can see in Sec. VII, the operator $\mathcal{H}_4$ is closely related to $\mathcal{H}_1$ so that the solutions of the corresponding eigenvalue equation can be derived from the solutions of the eigenvalue equation for $\mathcal{H}_1$.

In Sec. VIII some constants of motion involving the operators $\mathcal{H}_1$, $\mathcal{H}_2$, $\mathcal{H}_3$, $\mathcal{H}_4$, and $\mathcal{H}_5 \sim a^3 + a^{\dagger 3}$ are derived. Section IX contains a discussion on a possible algebraic framework which could be employed to analyze Eq. (69). This approach resorts to a quadratic algebra in terms of which the operator $\mathcal{H}_1$ can be naturally expressed. Finally, in Sec. X a few concluding remarks are presented, while in the Appendix a detail of a calculation is reported.

II. FOULED LAGRANGIANS

We recall that a fouling transformation is a transformation under which the coordinates in configuration space are preserved:

$$Q=q, \tag{2}$$

while

$$P_n=P_n(q,p,t); \tag{3}$$

P_n being a polynomial of degree n in the variables q and $p=\partial L_1/\partial\dot{q}=\dot{q}$, i.e.,

$$P_n=\sum_{j=0}^{n} a_j p^{n-j}q^j, \tag{4}$$

where

$$L_1=\tfrac{1}{2}(\dot{q}^2-\omega(t)^2q^2) \tag{5}$$

is the conventional Lagrangian, and $a_j=a_j(t)$ are (real) time-dependent coefficients.

In Ref. 1 it was proven that the function $L_n=L_n(q,\dot{q},t)$ expressed by

$$L_n=\sum_{j=0}^{n}\frac{1}{n-j+1}a_j\dot{q}^{n-j+1}q^j+(\dot{a}_n-\omega^2a_{n-1})\frac{q^{n+1}}{n+1} \tag{6}$$

satisfies

$$\frac{\partial L_n}{\partial\dot{q}}=P_n, \quad \frac{\partial L_n}{\partial q}=\dot{P}_n. \tag{7}$$

The compatibility condition for these equations provides

$$\dot{a}_0=-\frac{n-1}{n}a_1, \quad \dot{a}_j=(n-j+1)\omega^2a_{j-1}-(j+1)\frac{n-j-1}{n-j}a_{j+1}, \tag{8}$$

with $j=1,2,...,n-1$. Furthermore, we have

$$\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L_n}{\partial\dot{q}}-\frac{\partial L_n}{\partial q}=I_n(t)(\ddot{q}+\omega(t)^2q), \tag{9}$$

where $I_n(t)$ is a time-dependent constant of motion, viz., $(\mathrm{d}/\mathrm{d}t)I_n(t)=0$, given by

$$I_n(t)=\sum_{j=0}^{n}(n-j)a_jp^{n-j-1}q^j=\frac{\partial^2L_n}{\partial\dot{q}^2} \tag{10}$$

for any $n\geqslant 1$.

From Eq. (9) we deduce that corresponding to the solution q of the generalized oscillator (1), L_n satisfies the Euler–Lagrange equation. We notice that for $n=1$, Eq. (6) gives the conventional Lagrangian (5) (with $a_0=1$ and $a_1=0$). The related invariant is $I_1=\partial^2L_1/\partial_{\dot{q}}{}^2=1$.

Hereafter, by way of example, we are interested in the case $n=2$. Then, from (6) and (10) we obtain

$$L_2=\tfrac{1}{3}a_0\dot{q}^3+\tfrac{1}{2}a_1\dot{q}^2q+a_2\dot{q}q^2+\tfrac{1}{3}(\dot{a}_2-\omega^2a_1)q^3, \tag{11}$$

$$I_2 = 2a_0 p + a_1 q, \tag{12}$$

where [see (8)]

$$\dot{a}_0 = -\tfrac{1}{2} a_1, \quad \dot{a}_1 = 2\omega^2(t) a_0, \tag{13}$$

namely

$$\ddot{a}_0 + \omega^2(t) a_0 = 0. \tag{14}$$

The general solution of Eq. (14) can be written in the form

$$a_0 = \sqrt{2}\sigma\left(c_1 \cos\frac{\theta}{2} + c_2 \sin\frac{\theta}{2}\right). \tag{15}$$

where c_1, c_2 are constants, and σ, θ are defined by

$$\ddot{\sigma} + \omega^2(t)\sigma = \frac{1}{4\sigma^3}, \tag{16}$$

and

$$\dot{\theta} = \frac{1}{\sigma^2}. \tag{17}$$

In the following we shall limit ourselves to the choice $\omega(t) = \lambda = \text{const}$. Consequently, Eqs. (16) and (17) admit the solution

$$\sigma = \frac{1}{\sqrt{2\lambda}} \tag{18}$$

and

$$\theta = 2\lambda t. \tag{19}$$

Equation (15) has the two independent solutions

$$a_0^{(1)} = \frac{1}{\sqrt{\lambda}} \cos\lambda t, \quad a_0^{(2)} = \frac{1}{\sqrt{\lambda}} \sin\lambda t, \tag{20}$$

while the corresponding values $a_1^{(1)}$, $a_1^{(2)}$ are [see (13)]

$$a_l^{(1)} = 2\sqrt{\lambda} \sin\lambda t, \quad a_1^{(2)} = -2\sqrt{\lambda} \cos\lambda t. \tag{21}$$

On the other hand, the expressions of $a_2^{(1)}$, $a_2^{(2)}$ turn out to be (see Ref. 1)

$$a_2^{(1)} = \lambda^{3/2} \cos\lambda t, \quad a_2^{(2)} = \lambda^{3/2} \sin\lambda t. \tag{22}$$

Now, using (20)–(22), from (11) we obtain the two alternative fouled Lagrangians,

$$L_2^{(1)} = \frac{1}{3\sqrt{\lambda}} \cos\lambda t \dot{q}^3 + \sqrt{\lambda} \sin\lambda t \dot{q}^2 q + \lambda^{3/2} \cos\lambda t \dot{q} q^2 - \lambda^{5/2} \sin\lambda t q^3, \tag{23}$$

$$L_2^{(2)}=\frac{1}{3\sqrt{\lambda}}\sin\lambda t\dot{q}^3-\sqrt{\lambda}\cos\lambda t\dot{q}^2q+\lambda^{3/2}\sin\lambda t\dot{q}q^2+\lambda^{5/2}\cos\lambda tq^3, \tag{24}$$

which furnish the two independent invariants

$$I_2^{(1)}=\frac{\partial^2 L_2^{(1)}}{\partial\dot{q}^2}=\frac{2}{\sqrt{\lambda}}\cos\lambda t\dot{q}+2\sqrt{\lambda}\sin\lambda t\quad q, \tag{25}$$

$$I_2^{(2)}=\frac{\partial^2 L_2^{(2)}}{\partial\dot{q}^2}=\frac{2}{\sqrt{\lambda}}\sin\lambda t\dot{q}-2\sqrt{\lambda}\cos\lambda t\quad q, \tag{26}$$

respectively [see (10)].

Equations (25) and (26) provide the general solution q and the momentum $p=\dot{q}$ of the harmonic oscillator ($\omega\equiv\lambda$), i.e.,

$$q=\frac{1}{2\sqrt{\lambda}}(I_2^{(1)}\sin\lambda t-I_2^{(2)}\cos\lambda t), \tag{27}$$

$$p=\dot{p}=\frac{\sqrt{\lambda}}{2}(I_2^{(1)}\cos\lambda t+I_2^{(2)}\sin\lambda t), \tag{28}$$

from which, as one expects,

$$H_0=\frac{1}{2}(p^2+\lambda^2q^2)=\frac{\lambda}{8}[(I_2^{(1)})^2+(I_2^{(2)})^2]=\text{const}, \tag{29}$$

where H_0 is the conventional Hamiltonian.

III. FOULED HAMILTONIANS

At this point, we build up the Hamiltonian corresponding to the Lagrangian L_2 given by (11). Following the procedure of Ref. 1, we get

$$K_\pm=-\frac{a_1}{2a_0}qP\pm\frac{2}{3}a_0\left[\left(\frac{a_1^2}{4a_0^2}-\frac{a_2}{a_0}\right)q^2+\frac{P}{a_0}\right]^{3/2}+\left[\frac{a_1}{6a_0}\left(3a_2-\frac{a_1^2}{2a_0}\right)-\frac{1}{3}\left(\dot{a}_2-\lambda^2a_1\right)\right]q^3, \tag{30}$$

where

$$P=a_0p^2+a_1qp+a_2q^2. \tag{31}$$

For the sake of definiteness, later we shall study the Hamiltonian K_+ only.

The Hamilton equations for K_+ read

$$\dot{q}=-\frac{a_1}{2a_0}q+\frac{I_2}{2a_0}, \tag{32}$$

$$\dot{P}=\frac{a_1}{2a_0}P-\frac{a_1^2-4\lambda^2a_0^2}{4a_0^2}I_2q-3a_1\left(\lambda^2-\frac{a_1^2}{12a_0^2}\right)q^2, \tag{33}$$

where the relation

$$\left(\frac{a_1^2}{4a_0^2}-\frac{a_2}{a_0}\right)q^2+\frac{P}{a_0}=\left(\frac{I_2}{2a_0}\right)^2 \tag{34}$$

with $a_2=\lambda^2 a_0$ has been used (see Ref. 1).

By developing Eqs. (31) and (32) with the help of (12) and (30), we arrive at

$$I_2(\ddot{q}+\lambda^2 q)=0, \tag{35}$$

which tells us that the fouled Hamiltonian K_+, as it occurs for the related fouled Lagrangian L_2 [see (9)], gives rise to the same equation of motion emerging from the conventional Hamiltonian (29).

By virtue of (33), the Hamiltonians (30) take the form

$$K_+=\tfrac{1}{2}a_1(p^2+\lambda^2 q^2)q+\tfrac{2}{3}a_0 p^3, \tag{36}$$

$$K_-=-\frac{3}{2}a_1 p^2 q-\frac{a_1^2}{a_0}q^2 p+\left(\frac{a_1}{2}\lambda^2-\frac{a_1^3}{6a_0^2}\right)q^3-\frac{2}{3}a_0 p^3. \tag{37}$$

One can see that

$$K_\pm=P_p-L_2, \tag{38}$$

where P and L_2 are given by (31) and (11).

IV. THE FOULED HAMILTONIANS $K_+^{(1)}$ AND $K_-^{(2)}$

By using (20)–(22), from (36) we derive the pair of (explicitly time-dependent) Hamiltonians

$$K_+^{(1)}\equiv K_1=H_1\sin\lambda t+H_2\cos\lambda t, \tag{39}$$

$$K_+^{(2)}\equiv K_2=-H_1\cos\lambda t+H_2\sin\lambda t, \tag{40}$$

where H_1 and H_2 are defined by

$$H_1=\sqrt{\lambda}(p^2+\lambda^2 q^2)q=2\sqrt{\lambda}H_0 q, \tag{41}$$

$$H_2=\frac{2}{3\sqrt{\lambda}}p^3. \tag{42}$$

One can check straightforwardly that the following evolution equations:

$$\dot{K}_1=\{K_1,H_0\}_{q,p}+\frac{\partial K_1}{\partial t}, \tag{43}$$

$$\dot{K}_2=\{K_2,H_0\}_{q,p}+\frac{\partial K_2}{\partial t}, \tag{44}$$

$$\dot{H}_1=\{H_1,H_0\}_{q,p}, \tag{45}$$

$$\dot{H}_2=\{H_2,H_0\}_{q,p}, \tag{46}$$

hold, where H_0 is given by (29) and

$$\{H_1,H_0\}_{q,p}=2\sqrt{\lambda}pH_0, \tag{47}$$

$$\{H_2,H_0\}_{q,p}=-2\frac{\lambda^2}{\sqrt{\lambda}}p^2q. \tag{48}$$

We also have that the Poisson brackets between K_1, K_2 and H_1, H_2 concide, i.e.,

$$\{K_1,K_2\}_{q,p}=\{H_1,H_2\}_{q,p}. \tag{49}$$

This is a direct consequence of the rotation form of the transformations (39) and (40).

V. QUANTIZATION

Hereafter, we shall put for simplicity $\lambda=\hbar=1$.

In order to quantize the fouled Hamiltonians (39) and (40), let us introduce the operators

$$\hat{q}=\frac{1}{\sqrt{2}}(a+a^\dagger),\quad \hat{p}=-\frac{i}{\sqrt{2}}(a-a^\dagger), \tag{50}$$

where a and $a^\dagger$ denote a (boson) annihilation and a creation operator, respectively.

By means of (50), we can write the operators $\mathcal{H}_1$ and $\mathcal{H}_2$ corresponding to the classical functions (41) and (42). We obtain

$$\mathcal{H}_1=\sqrt{2}(a^{\dagger 2}a+a^\dagger a^2+a^\dagger+a), \tag{51}$$

$$\mathcal{H}_2=\frac{i}{\sqrt{2}}\left[\frac{1}{3}(a^3-a^{\dagger 3})+(a^{\dagger 2}a-a^\dagger a^2+a^\dagger-a)\right], \tag{52}$$

with the help of the commutation rule

$$[a,a^\dagger]=1 \tag{53}$$

or, in terms of the Heisenberg commutation relation: $[\hat{q},\hat{p}]=i$.

Now let us use the representation $\hat{q}=x$, $\hat{p}=-i(\mathrm{d}/\mathrm{d}x)$, so that the operators a and $a^\dagger$ can be written as [see (50)]

$$a=\frac{1}{\sqrt{2}}\left(x+\frac{\mathrm{d}}{\mathrm{d}x}\right),\quad a^\dagger=\frac{1}{\sqrt{2}}\left(x-\frac{\mathrm{d}}{\mathrm{d}x}\right). \tag{54}$$

In terms of these quantities, $\mathcal{H}_1$ and $\mathcal{H}_2$ take the forms

$$\mathcal{H}_1=-\left(x\frac{\mathrm{d}^2}{\mathrm{d}x^2}+\frac{\mathrm{d}}{\mathrm{d}x}\right)+x^3, \tag{55}$$

and

$$\mathcal{H}_2=\frac{2i}{3}\frac{\mathrm{d}^3}{\mathrm{d}x^3}. \tag{56}$$

For later convenience, we shall report also in the representation (54) the following operators appearing in (52):

$$\mathcal{H}_3\equiv\frac{i}{\sqrt{2}}\frac{1}{3}(a^3-a^{\dagger 3})=\frac{i}{2}\left[\frac{1}{3}\frac{\mathrm{d}^3}{\mathrm{d}x^3}+\left(x^2\frac{\mathrm{d}}{\mathrm{d}x}+x\right)\right], \tag{57}$$

$$\mathcal{H}_4 \equiv \frac{i}{\sqrt{2}}(a^{\dagger 2}a - a^\dagger a^2 + a^\dagger - a) = \frac{i}{2}\left[\frac{\mathrm{d}^3}{\mathrm{d}x^3} - \left(x^2\frac{\mathrm{d}}{\mathrm{d}x} + x\right)\right]. \tag{58}$$

In Sec. VI, we shall study the operators $\mathcal{H}_1$ and $\mathcal{H}_2$ by dealing with the corresponding eigenvalue problems.

VI. SELF-ADJOINT EXTENSIONS OF THE OPERATOR $\mathcal{H}_1$

In order to clarify the quantum-mechanical meaning of the Hamiltonian $\mathcal{H}_1$, it is crucial to establish whether $\mathcal{H}_1$ enjoys self-adjoint type properties. In doing so, first let us recall that one can provide different representations for the operator (51), which correspond to various forms of the related eigenvalue equations. We shall consider the following representations: the harmonic oscillator excitation number representation (n-rep), the coordinate representation (q-rep), and the Fock–Bargmann holomorphic function representation (z-rep).

For reader's convenience, we shall summarize in the following the main properties of these representations.[8]

Let $\mathfrak{h}$ denote the Hilbert space where the operators $\hat{q}$, $\hat{p}$ and $a^\dagger$, a act. In the n- rep, the vectors $\{|n\rangle\}$ form a basis in $\mathfrak{h}$. The following relations

$$a = \sqrt{n}|n-1\rangle, \quad a^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle, \quad a^\dagger a|n\rangle = n|n\rangle \tag{59}$$

hold.

On the other hand, in the q-rep a vector $|\psi\rangle$ belonging to the space $\mathfrak{h}$ is represented by a coordinate function $\langle q|\psi\rangle = \psi(q)$ which is square-integrable:

$$\int_{-\infty}^{+\infty} |\psi(q)|^2\,\mathrm{d}q < \infty. \tag{60}$$

The basic vector $|n\rangle$ is described by the function

$$\langle q|n\rangle = \varphi_n(q) = N_n H_n(q)\exp\left(-\frac{q^2}{2}\right), \tag{61}$$

where $N_n = (\sqrt{\pi}2^n n!)^{-1/2}$ and $H_n(q)$ is the Hermite polynomial of degree n. In the q-rep, formulas (59) become the standard recursion relations for the Hermite polynomials.

In order to introduce the Fock–Bargmann representation (or z-rep), let $|\psi\rangle$ be an arbitrary normalized vector in $\mathfrak{h}$, namely

$$|\psi\rangle = \sum_{n=0}^{\infty} c_n|n\rangle, \tag{62}$$

with $\langle\psi|\psi\rangle = \Sigma_{n=0}^{\infty}|c_n|^2 = 1$. Furthermore, taking into account the Glauber form

$$|z\rangle = \exp\left(-\frac{|z|^2}{2}\right)\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{n!}}|n\rangle, \tag{63}$$

the state $|\psi\rangle$ is completely determined by

$$\langle z|\psi\rangle = \exp\left(-\frac{|z|^2}{2}\right)\psi(\overline{z}), \tag{64}$$

where

$$\psi(z)=\sum_{n=0}^{\infty} c_n u_n(z), \tag{65}$$

with $u_n(z)=z^n/\sqrt{n!}$. Owing to the condition $\Sigma_{n=0}^{\infty}|c_n|^2=1$, the series in (65) converges uniformly in any compact domain of the complex z plane. Consequently, $\psi(z)$ turns out to be an entire holomorphic function in the z plane, and

$$\|\psi\|^2=\int \exp(-|z|^2)|\psi(z)|^2\,\mathrm{d}\mu(z)<\infty, \tag{66}$$

where $\mathrm{d}\mu(z)=\pi^{-1}\,\mathrm{d}x\,\mathrm{d}y$, $z=x+iy$.[8]

The scalar product of two entire functions $\psi_1(z)$ and $\psi_2(z)$ obeying the condition (66) is given by

$$\langle\psi_1|\psi_2\rangle=\int \exp(-|z|^2)\overline{\psi}_1(z)\psi_2(z)\mathrm{d}\mu(z). \tag{67}$$

As proven by Bargmann,[7] the Fock–Bargmann representation space with a scalar product provided by (67) is really a Hilbert space. We observe also that in the z-rep, the operator solution for the commutation relation $[a,a^\dagger]=1$[6] is

$$a\to\frac{\mathrm{d}}{\mathrm{dz}},\quad a^\dagger\to z. \tag{68}$$

Now let us consider the eigenvalue equation

$$(a^{\dagger 2}a+a^\dagger a^2+a+a^\dagger)|\chi\rangle=\varepsilon|\chi\rangle. \tag{69}$$

Starting from the n-rep and following the lines of Ref. 5, let us put

$$|\chi\rangle=\sum_{n=0} f_n(\varepsilon)|n\rangle \tag{70}$$

into Eq. (69). By using Eq. (59), after simple calculations we obtain the recursion formula

$$(n+1)^{3/2}f_{n+1}(\varepsilon)-\varepsilon f_n(\varepsilon)+n^{3/2}f_{n-1}(\varepsilon)=0 \tag{71}$$

for $n\geqslant 1$, and

$$f_1(\varepsilon)=\varepsilon f_0(\varepsilon) \tag{72}$$

(the boundary condition).

We remark that the sequence $\{f_n\}$ is such that the series $\Sigma_{n=0}|f_n|^2$ converges, i.e., the sequence $\{f_n\}\equiv(f_0,f_1,f_2,\ldots)$ belongs to the Hilbert space l^2.

To show this, first let us consider the case $\varepsilon=0$. Then, Eqs. (71) and (72) provide

$$f_{2n}=(-1)^n\left[\frac{(2n-1)!!}{(2n)!!}\right]^{3/2}f_0, \tag{73}$$

the odd terms being zero. Thus, from the asymptotic formula of gamma function (Ref. 14, p. 257), we deduce that for $n\to\infty$, $|f_{2n}|^2$ behaves as $n^{-3/2}$, so that $\Sigma_{n=0}|f_{2n}|^2<\infty$. In general, i.e., for $\varepsilon\neq 0$, Eq. (71) tells us that for great values of n, the sum of the first and the last term is leading with respect to the second term. This allows us to see easily that both even and odd terms, $|f_{2n}|^2$ and $|f_{2n+1}|^2$, behave asymptotically as $n^{-3/2}$. To conclude, the series $\Sigma_{n=0}|f_n|^2$ is convergent,

namely the sequence $\{f_n\}$ belongs to the Hilbert space l^2 for any value of the spectral parameter ε. Then, the equation $\mathcal{H}_1^\dagger|\chi\rangle=\varepsilon|\chi\rangle$, for $\mathrm{Im}\,\lambda\neq 0$, has nontrivial solutions (Ref. 3, p. 140).

Now, by introducing the notation $b_n=(n+1)^{3/2}$, we see that it is possible to associate with the difference equation (71) the (infinite) Jacobi matrix

$$A=\begin{pmatrix} 0 & b_0 & 0 & 0 & \cdots \\ b_0 & 0 & b_1 & 0 & \cdots \\ 0 & b_1 & 0 & b_2 & \cdots \\ 0 & 0 & b_2 & 0 & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \end{pmatrix}, \tag{74}$$

so that Eq. (69) is equivalent to the eigenvalue equation $Af=\varepsilon f$, with $f=(f_0,f_1,\ldots)^T$.

The Jacobi matrix (74) plays a crucial role in the study of the Hamburger moment problem (see, for example, Refs. 3, 5, and 15). Precisely, let us consider the moments

$$s_n=\int_{-\infty}^{+\infty} x^n\,\mathrm{d}\sigma(x), \quad n=0,1,2,..., \tag{75}$$

where σ denotes a (positive) measure on $\mathbb{R}$ (Ref. 15, p. 145). The Hamburger moment problem is to determine conditions on a sequence of real numbers $\{s_n\}_{n=0}^{\infty}$, so that there exists a measure satisfying (75). One can show that a sequence of real numbers $\{s_n\}$ are the moments of a positive measure on $\mathbb{R}$ if and only if for all N and all $\alpha_0,\alpha_1,\ldots,\alpha_N\in\mathbb{C}$, one has

$$\sum_{n,m=0}^{N} \overline{\alpha}_n\alpha_m s_{n+m}\geqslant 0. \tag{76}$$

From the Jacobi matrix (74) we get the limitations

$$\sum_{n=0}^{\infty}\frac{1}{b_n}=\sum_{n=0}^{\infty}\frac{1}{(n+1)^{3/2}}<\infty, \quad b_{n-1}b_{n+1}<b_n^2. \tag{77}$$

Consequently, the Jacobi matrix (74) belongs to the type *C* (limit circle case), and corresponds to an undetermined Hamburger moment problem (Refs. 3 and 5). So, the properties of the operator $\mathcal{H}_1\sim a^{\dagger 2}a+a^\dagger a^2+a+a^\dagger$ are similar to the properties of the operator $a^k+a^{\dagger k}$ $(k=3)$ discussed by Nagel.[5] In other words, the operator $\mathcal{H}_1$ has deficiency indices (1, 1) and allows a one-parameter family of self-adjoint extensions, each having a purely discrete spectrum on the real line.[4,16] The spectra of two different extensions turn out to have no point in common (Ref. 3, p. 152). We have that different self-adjoint extensions correspond to different dynamics.[15,17]

Since every self-adjoint extension of $\mathcal{H}_1$ has a discrete spectrum on the real line, and taking one eigenvalue determines the corresponding extension uniquely, let us choose $\varepsilon=0$.

In this case the eigenvalue equation underlying the operator $\mathcal{H}_1$ can be solved exactly in all the representations mentioned at the beginning of this section.

To show this, let us deal with the *q*-rep. With the help of (54), the eigenvalue equation (69) reads

$$x\phi''+\phi'+(\sqrt{2}\varepsilon-x^3)\phi=0, \tag{78}$$

where $\phi'\equiv(\mathrm{d}/\mathrm{d}x)\phi$.

Equation (78) can be written as the Sturm–Liouville equation (Ref. 18, p. 59)

$$\mathcal{L}[\phi(x)]=-\sqrt{2}\varepsilon\phi(x), \tag{79}$$

where $\mathcal{L}$ denotes the Sturm–Liouville operator

$$\mathcal{L}=\frac{\mathrm{d}}{\mathrm{d}x}\left[x\frac{\mathrm{d}}{\mathrm{d}x}\right]-x^3. \tag{80}$$

By using the transformation

$$\phi(x)=\exp\left(-\frac{x^2}{2}\right)\psi(x), \tag{81}$$

Eq. (78) becomes

$$x\psi''+(1-2x^2)\psi'+(\sqrt{2}\varepsilon-2x)\psi=0. \tag{82}$$

This equation is satisfied by

$$\psi(x)=\sum_{n=0}^{\infty} f_n N_n H_n(x), \tag{83}$$

where the coefficients f_n fulfill the recursion relations (71) and (72). We have already shown that $\{f_n\}\in l^2$. Then, the function $\psi(x)$ belongs to the Hilbert space $L^2_{e^{-x^2}}(-\infty,\infty)$ [$\exp(-x^2)$ is the weight function]. We point out that generally the relation (83) is not valid in the pointwise sense, but it holds in accordance with the metric of $L^2_{e^{-x^2}}(-\infty,\infty)$, namely

$$\lim_{n\to\infty}\int_{-\infty}^{+\infty}\left|\psi(x)-\sum_{k=0}^{n} f_k N_k H_k(x)\right|^2\exp(-x^2)\mathrm{d}x=0. \tag{84}$$

For $\varepsilon=0$, via the change of variable $\xi=x^2$ Eq. (82) can be written as a special case of a Kummer equation, whose independent solutions are $M(1/2,1;x^2)$ and $U(1/2,1;x^2)$ (Ref. 14, p. 504). In the case the solution $\psi(x)$ of Eq. (82) with the property $\psi(x)\in L^2_{e^{-x^2}}(-\infty,\infty)$ is given by

$$\psi(x)=cU\left(\frac{1}{2},1;x^2\right)=\sum_{n=0}^{\infty} f_{2n}N_{2n}H_{2n}(x), \tag{85}$$

where the constant c is such that $c\pi^{3/4}=f_0$, and

$$f_{2n}=f_0\pi^{-3/4}N_{2n}\int_{-\infty}^{+\infty}U\left(\frac{1}{2},1;x^2\right)H_{2n}(x)\exp(-x^2)\mathrm{d}x. \tag{86}$$

One can easily check that (86) is satisfied for any $n\in\mathbb{N}$

Finally, in the z-rep, i.e., for $|\chi\rangle\to\chi$, $a^\dagger\to z$, $a\to\mathrm{d}/\mathrm{d}z$, Eq. (69) gives

$$z\chi_{zz}+(1+z^2)\chi_z+(z-\varepsilon)\chi=0, \tag{87}$$

where

$$\chi=\sum_{n=0}^{\infty} f_n\frac{z^n}{\sqrt{n!}} \tag{88}$$

and f_n satisfies the recursion relations (71) and (72). For $\varepsilon=0$, the eigenvalue equation (87) as well can be exactly solved. In fact, by setting $z^2=y$, $\zeta=-y/2$, this equation becomes a special case of the Kummer equation.

Therefore, in the z-rep, where the eigenfunction should be a holomorphic (and normalizable) function in the whole z-plane, one has the solution $M(1/2,1;-z^2/2)$. The other solution, namely the Kummer function $U(1/2,1;-z^2/2)$, is not holomorphic at $z=0$.

To conclude this section, we observe that the solutions of the eigenvalue equation for $\mathcal{H}_1$ in the case $\varepsilon=0$ can be also found from Eqs. (71) and (72), obtained within the *n*-rep, by means of the standard integral representations of the confluent hypergeometric functions. An example of this procedure is displayed in Ref. 19.

VII. THE $\mathcal{H}_2$, $\mathcal{H}_3$, $\mathcal{H}_4$ MODELS

The eigenvalue problem for the operator $\mathcal{H}_2$ can be written as

$$\mathcal{L}\psi=\varepsilon\psi, \tag{89}$$

where $\mathcal{L}=(2i/3)D_x^3$ $(D_x=\mathrm{d}/\mathrm{d}x)$. The study of Eq. (89) is trivial. It is exactly solvable,[9] its spectrum is on the whole line, and the related eigenfunctions are of the exponential type.

The operator $\mathcal{H}_3$ [see (57)] belongs to the class of Hamiltonians

$$\mathcal{H}=i\kappa_n(a^n-a^{\dagger n}) \tag{90}$$

appearing in the higher order nonlinear optical processes. In particular, (57) describes a subharmonic generation process, in which a photon from a strong pump beam produces *n* photons of the signal beam in a nonlinear medium.[11] The constant κ_n is related to the *n*th nonlinear susceptibility coefficient and to the amplitude of the pump field, while a and $a^\dagger$ are the annihilation and the creation operators for the signal field. In this context, the evolution of an arbitrary initial state $|\Psi(0)\rangle$ of the signal field to the state $|\Psi(t)\rangle$ is governed by

$$|\psi(t)\rangle=\exp[\kappa_n t(a^n-a^{\dagger n})]|\Psi(0)\rangle. \tag{91}$$

The squeezing of this state was examined by Hillery, Zubairy, and Wódkiewicz.[11] They showed that to any order in the coupling constant κ_n, the vacuum state is not squeezed in the higher order nonlinear optical processes $(n\geqslant 3)$.

This important result stimulated the analysis of *n*th power squeezed states. Interesting (and, generally, not yet completely explored) questions arise in connection with this argument. Some of them are discussed in Refs. 5, 13, and 19, and references therein.

Now let us make some comments about the Hamiltonian $\mathcal{H}_4$. This operator is closely related to $\mathcal{H}_1$. This can be seen by means of the phase transformation $a'=ia$, $a'^\dagger=-ia^\dagger$, so that $\mathcal{H}_4$ takes the form

$$\mathcal{H}_4=-\frac{1}{\sqrt{2}}(a'^{2\dagger}a'+a'^\dagger a'^2+a'^\dagger+a'). \tag{92}$$

In other words, one has $\mathcal{H}_4=1/2\mathcal{H}_1$ (in terms of the primed operators). This corresponds to pick up $q'=-p$ and $p'=q$. In such a way $\mathcal{H}_4$ turns out to be the inverse Fourier transform of (55). Therefore, the solutions of the eigenvalue equation for the Hamiltonian operator $\mathcal{H}_4$ can be derived from the solutions of the eigenvalue equation for the Hamiltonian operator $\mathcal{H}_1$ [see (69)].

The eigenvalue equation for $\mathcal{H}_1$ $(\mathcal{H}_4)$ can be investigated by means of the algebraic approach outlined in Sec. IX.

VIII. EQUATIONS AND CONSTANTS OF MOTION RELATED TO THE OPERATORS $\mathcal{H}_j$

The equations of motion for the Hamiltonians $\mathcal{H}_j$ $(j=1,2,3,4)$ arise immediately by using the Heisenberg representation. In other words, by putting $a(t)=a(0)\exp(-it)$ and $a^\dagger(t)=a^\dagger(0)\exp(it)$ in the expressions (51) and (58), we easily find (as one expects) that $\mathcal{H}_1$ and $\mathcal{H}_4$ satisfy the same equation of motion (i.e., the equation for the harmonic oscillator of frequency $\lambda=1$):

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}\mathcal{H}_1+\mathcal{H}_1=0, \quad \frac{\mathrm{d}^2}{\mathrm{d}t^2}\mathcal{H}_4+\mathcal{H}_4=0. \tag{93}$$

On the other hand, for the operators $\mathcal{H}_3=(i/\sqrt{2})\frac{1}{3}(a^3-a^{\dagger 3})$ [see (57)] and $\mathcal{H}_5=(1/\sqrt{2})1/3(a^3+a^{\dagger 3})$, the same considerations made for $\mathcal{H}_1$ and $\mathcal{H}_4$ in Sec. VII hold. One has that $\mathcal{H}_3$ and $\mathcal{H}_5$ obey the same equation of motion (i.e., the equation for the harmonic oscillator of frequency 3):

$$\mathrm{d}t^2\mathcal{H}_3+9\mathcal{H}_3=0, \quad \frac{\mathrm{d}^2}{\mathrm{d}t^2}\mathcal{H}_5+9\mathcal{H}_5=0. \tag{94}$$

Some comments on Eqs. (93) and (94) are presented in Sec. X.

At this point, we observe that in addition to the constants of motion

$$\tilde{q}=e^{-it\hat{H}_0}\hat{q}e^{it\hat{H}_0}=\hat{q}\cos t-\hat{p}\sin t, \tag{95}$$

$$\tilde{p}=e^{-it\hat{H}_0}\hat{p}e^{it\hat{H}_0}=\hat{q}\sin t+\hat{p}\cos t, \tag{96}$$

where $[\hat{q},\hat{p}]=i$, $\hat{H}_0=1/2(\hat{p}^2+\hat{q}^2)$, and $\tilde{q}=-1/2I_2^{(2)}$, $\tilde{p}=1/2I_2^{(1)}$, we obtain also the following set of constants:

$$\tilde{H}_1=\mathcal{H}_1\cos t-2\mathcal{H}_4\sin t, \tag{97}$$

$$\tilde{H}_4=\frac{1}{4}\mathcal{H}_1\sin t+\mathcal{H}_4\cos t, \tag{98}$$

$$\tilde{H}_3=\mathcal{H}_3\cos 3t-\mathcal{H}_5\sin 3t, \tag{99}$$

$$\tilde{H}_5=\mathcal{H}_3\sin 3t+\mathcal{H}_5\cos 3t. \tag{100}$$

In terms of the arbitrary constants $\tilde{H}_j(j=1,4,3,5)$, one can express the general solutions of Eqs. (93) and (94), which can be easily found by inverting the transformations (97), (98) and (99), (100), respectively.

IX. A POSSIBLE ALGEBRAIC FRAMEWORK FOR THE STUDY OF EQ. (69)

For $\varepsilon\neq 0$, Eq. (69) could be investigated following different analytical techniques. Among these, an important role is played by the algebraic approach, which allows one to express Eq. (69) in terms of the generators of a *quadratic* algebra.[20,21]

As an example of a quadratic algebra, we can consider a nonlinear deformation of the (linear) $su(1,1)$ algebra, defined by

$$[J_0,J_\pm]=\pm J_\pm, \tag{101}$$

$$[J_+,J_-]=P(J_0), \tag{102}$$

where the Jacobi indentity holds. $J_\pm$ are the ladder operators, and $P(J_0)$ is a second-degree polynomial function of the diagonal operator J_0. $P(J_0)$ can be written in the form

$$P(J_0)=\alpha_1+\alpha_2 J_0+\alpha_3 J_0^2, \tag{103}$$

where α_i $(i=1,2,3)$ are arbitrary coefficients $(\alpha_3\neq 0)$.

Now let us introduce the (bosonic) realization

$$J_0 = a^\dagger a + \tfrac{1}{2}, \tag{104}$$

$$J_- = -(a^\dagger a^2 + a), \tag{105}$$

$$J_+ = a^{\dagger 2} a + a^\dagger, \tag{106}$$

with $J_+ = -(J_-)^\dagger$. Then, the operators (104)–(106) turn out to obey the commutation relations

$$[J_0, J_\pm] = \pm J_\pm, [J_+, J_-] = \tfrac{1}{4} + 3J_0^2. \tag{107}$$

We remark that the quadratic algebra (107) is a finite $W_3^{(2)}$-algebra,[20,21] which corresponds to choosing $\alpha_1 = 1/4$, $\alpha_2 = 0$, and $\alpha_3 = 3$ in (103).

By virtue of (104)–(106), Eq. (69) can be reexpressed as

$$\Omega(\varepsilon)|\chi\rangle = 0, \tag{108}$$

with

$$\Omega(\varepsilon) = J_+ - J_- - \varepsilon. \tag{109}$$

Therefore, the eigenvalue problem (69) can be formulated in terms of the generators $J_\pm$ of a quadratic algebra of the type $W_3^{(2)}$. The Casimir operator of the quadratic algebra (107) is considered in the Appendix.

X. CONCLUSIONS

In the context of the existence of an infinite set of fouled Lagrangians and Hamiltonians for the generalized (time-dependent) oscillator, we have studied a special case where the frequency of the oscillator is assumed to be a constant λ (harmonic oscillator). By way of example, we have considered a pair of independent fouled Lagrangians $(L_2^{(1)}, L_2^{(2)})$ [see (23) and (24)] and, in correspondence, a pair of fouled independent Hamiltonians (K_1, K_2) [see (39) and (40)] which lead, at the classical level, to the same equation of motion provided by the conventional Lagrangian and Hamiltonian. Both $(L_2^{(1)}, L_2^{(2)})$ and (K_1, K_2) are explicitly time-dependent. The method followed to find these alternative Lagrangians and Hamiltonians implies the construction of two independent invariants (constants of motion), $I_2^{(1)}$ and $I_2^{(2)}$; in terms of them the canonical variables q and p can be expressed. These invariants, which are of the Nöther type,[22] are connected with the "quadrature-phase amplitudes" appearing in the problem of generation of squeezed states in certain optical devices.[23]

In this paper we have focused our attention mainly on the quantized version of the fouled Hamiltonians (K_1, K_2). Since K_1 and K_2 are related to the cubic polynomials $H_1 = \sqrt{\lambda}(p^2 + \lambda^2 q)q$ and $H_2 = (2/3\sqrt{\lambda})p^3$ by a formal rotation, the canonical quantization prescription affects essentially H_1 and H_2. Our purpose has been to study, at the quantum level, the Hamiltonians $\mathcal{H}_1$ and $\mathcal{H}_2$ [see (51) and (52)] corresponding to H_1 and H_2. The model described by $\mathcal{H}_2$ is associated with an eigenvalue problem given by a (linear) third-order differential equation, with constant coefficients, which is exactly solvable.[9] Furthermore, we have put $\mathcal{H}_2 = \mathcal{H}_3 + \mathcal{H}_4$, where $\mathcal{H}_4$ [see (58)] turns out to be closely related to the quantum model $\mathcal{H}_1$ in the sense discussed in Sec. VII. On the other hand, the quantum model $\mathcal{H}_3$ has a well-defined physical interpretation. It belongs to a class of Hamiltonians which finds applications in the field of nth power squeezed states.

Finally, the operator $\mathcal{H}_1$, considered in Sec. VI, has deficiency indices (1, 1) and allows a one-parameter family of self-adjoint extensions, each having a purely discrete spectrum on the real line. The spectra of two different extensions have no point in common. Since different self-adjoint extensions correspond to different dynamics, we needed to fix a given dynamics. This has been carried out by choosing the value $\varepsilon = 0$ for the eigenvalue parameter. In this case all the differen-

tial equations coming from (69) in all the representations: *n*-rep, *q*-rep, and *z*-rep, can be solved exactly. In this case, square-integrable solutions of the eigenvalue equations are explicitly determined.

In order to investigate some properties of the Hamiltonians $\mathcal{H}_j$ $(j=1,2,3,4)$, in Sec. VIII we have introduced the operator $\mathcal{H}_5 \sim (a^3 + a^{3\dagger})$, which is connected with $\mathcal{H}_3$, as one can see by using the transformation $a' = ia$, $a'^{\dagger} = -ia^{\dagger}$. We have built up a set of constants of motion involving $(\mathcal{H}_1, \mathcal{H}_4)$ and $(\mathcal{H}_3, \mathcal{H}_5)$. These constants play the role of the arbitrary constants present in the general solution of two equations of the harmonic oscillator-type of frequencies 1 and 3, respectively, which are satisfied by $(\mathcal{H}_1, \mathcal{H}_4)$ and $(\mathcal{H}_3, \mathcal{H}_5)$ [see (93) and (94)].

To conclude, we point out that quadratic (and, more in general, polynomially deformed algebras) take place in quantum optics in relation to the construction of coherent states and in the description of multiphoton processes (see, for example Refs. 24 and 25, and references therein). Keeping in mind these problems, it should be of interest to deal with the quantization of fouled Hamiltonians (of the generalized oscillator) expressed by polynomials in the canonical variables (q,p) of degree higher than three.

ACKNOWLEDGMENT

APPENDIX: THE CASIMIR INVARIANT FOR THE QUADRATIC ALGEBRA (107)

We remind the reader that a standard form of a quadratic algebra, which is important in the treatment of coherent states of trilinear boson Hamiltonians,[26] is[24,25,27]

$$[N_0, N_\pm] = \pm N_\pm, \quad [N_+, N_-] = \pm 2N_0 + \delta N_0^2, \tag{A1}$$

where the positive (negative) sign of $2N_0$ indicates a polynomially deformed $su(2)$ $(su(1,1))$, and δ is a parameter.

The Casimir operator is given by[24,25,27]

$$C = N_- N_+ + N_0(N_0+1)\left[1 + \frac{\delta}{6}(2N_0+1)\right]. \tag{A2}$$

By setting

$$J_0 = a_0 N_0 + b_0, \tag{A3}$$

$$J_- = k_1 N_-, \tag{A4}$$

$$J_+ = k_2 N_+, \tag{A5}$$

and choosing, for example,

$$a_0 = 1, \quad b_0 = \frac{i}{2\sqrt{3}}, \quad k_1 k_2 = \frac{i\sqrt{3}}{2}, \tag{A6}$$

the commutator relations (107) are converted into

$$[N_0, N_\pm] = \pm N_\pm, \quad [N_+, N_-] = 2N_0 + \delta N_0^2, \tag{A7}$$

with $\delta = -2i\sqrt{3}$. Hence, the Casimir operator (A2) reads

$$C = N_- N_+ + N_0(N_0+1)\left[1 - \frac{i}{\sqrt{3}}(2N_0+1)\right]. \tag{A8}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 7 JULY 2002

Redefining spinors in Lorentz-violating quantum electrodynamics

Don Colladay[a] and Patrick McDonald[b]
New College of Florida, Sarasota, Florida 34243

(Received 6 February 2002; accepted for publication 8 March 2002)

An analysis of spinor redefinitions in the context of the Lorentz-violating quantum electrodynamics (QED) extension is performed. Certain parameters that apparently violate Lorentz invariance are found to be physically irrelevant as they can be removed from the Lagrangian using an appropriate redefinition of the spinor field components. It is shown that conserved currents may be defined using a modified action of the complex extension of the Lorentz group on the redefined spinors. This implies a natural correspondence between the apparently Lorentz-violating theory and conventional QED. Redefinitions involving derivatives are shown to relate certain terms in the QED extension to Lagrangians involving nonlocal interactions or skewed coordinate systems. The redundant parameters in the QED extension are identified and the Lagrangian is rewritten in terms of physically relevant coupling constants. The resulting Lagrangian contains only physically relevant parameters and transforms conventionally under Lorentz transformations. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1477938]

I. INTRODUCTION

The possibility of miniscule violations of Lorentz invariance arising from a more fundamental theory of nature has been of recent interest.[1] For example, such violations may arise in the low-energy limit of string theory,[2] or physically realistic noncommutative field theories.[3] The full standard model extension uses the general concept of spontaneous symmetry breaking to construct a Lagrangian consisting of all possible terms involving standard-model fields that are observer Lorentz scalars, including terms having coupling coefficients with Lorentz indices. At low energies, the relevant operators that are gauge invariant all have mass dimension $D \leqslant 4$, and are given in Ref. 4. At higher energy scales nonrenormalizable terms are expected to play a role in the theoretical consistency of the model.[5]

Various experiments have placed stringent bounds on parameters in the standard-model extension, including comparative tests of quantum electrodynamics (QED) in Penning traps and colliders,[6–11] spectroscopy of hydrogen and antihydrogen,[12,13] measurements of muon properties,[14,15] clock-comparison experiments,[16–20] observations of the behavior of a spin-polarized torsion pendulum,[21,22] measurements of cosmological birefringence,[23,4,24] studies of neutral-meson oscillations,[25–27] and observations of the baryon asymmetry.[28]

In the theoretical results involving experimentally observable quantities, some of the parameters in the standard model extension do not appear while others occur only in specific linear combinations. The reason behind this is that some parameters that apparently violate Lorentz invariance when the spinor field is assumed to transform in the standard way under the action of the Lorentz group do not in fact violate this symmetry when the action on the field is appropriately modified such that the associated Lorentz currents are conserved. The freedom to select spinor coordinates in different ways generates a natural equivalence relation on the collection of Lagrangians. Different Lagrangians in the same equivalence class are related by field redefinitions; that is, by an invertible map between fields used to describe the same physics. The explicit

[a]Electronic mail: colladay@ncf.edu
[b]Electronic mail: McDonald@ncf.edu

construction of the redefinition used in this paper appears in Eq. (5). All Lagrangians in the same class are physically equivalent and the spinor transformation properties can be implemented so that the Lorentz currents are as close to conserved as possible. In other words, redefinitions may be used to define the currents so that they absorb the apparently Lorentz-violating terms which are obstructions to conservation. This means that one can use the transformation properties to eliminate a subset of the parameters appearing in the standard model extension and no more.

In this paper, the effects of field redefinitions in the context of extended QED are examined in detail. Particular terms in the standard model extension are already known to be unobservable since explicit redefinitions of the spinor components have previously been considered.[4] It is the goal of this work to analyze a more general set of field redefinitions and use them to simplify the full Lorentz-violating Lagrangian as much as possible. The basic idea is to remove parameters that depend explicitly on the spinor coordinates. Once these redundant parameters have been eliminated, the remaining field transforms according to the standard action of the complex Lorentz group.

The paper is organized as follows. In Sec. II, the extended QED theory is summarized. In Sec. III, an analysis is presented of the field redefinitions that are used to generate specific terms in the QED extension. The effects of transformations which do not include terms involving differentiation as well as those that do are investigated. The currents associated with U(1) and Poincaré group transformations for the general QED extension are derived in Sec. IV. It is shown that conserved currents can be defined when only redundant parameters are present by using a similar representation to the conventional complex Lorentz group action. Section V contains the construction of the physical extended QED Lagrangian with all redundant parameters removed.

II. EXTENDED QED

To study the effects of specific field redefinitions, we restrict our attention to the QED subset involving only the electron and photon sectors of the full standard model extension presented in Ref. 4. In the pure-photon sector, there is one CPT-even (k_F) and one CPT-odd (k_{AF}) Lorentz-violating term. The free photon Lagrangian is

$$\mathcal{L}_{\text{photon}} = -\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu} - \tfrac{1}{4}(k_F)_{\kappa\lambda\mu\nu}F^{\kappa\lambda}F^{\mu\nu} + \tfrac{1}{2}(k_{AF})^{\kappa}\epsilon_{\kappa\lambda\mu\nu}A^{\lambda}F^{\mu\nu}, \tag{1}$$

where the coupling k_F is a real, dimensionless coupling that can be taken to have the symmetries of the Riemann tensor, and the coefficient k_{AF} is real and has dimensions of mass.

Denoting the four-component electron field by ψ and the electron mass by m, the general QED Lagrangian for electrons and photons including Lorentz-violating interactions arising from a generic spontaneous symmetry breaking mechanism is

$$\mathcal{L}^{\text{QED}}_{\text{electron}} = \frac{i}{2}\bar{\psi}\Gamma_{\nu}\overleftrightarrow{D}^{\nu}\psi - \bar{\psi}M\psi, \tag{2}$$

where $D_{\mu} = \partial_{\mu} + iqA_{\mu}$ is the usual covariant derivative,

$$\Gamma_{\nu} = \gamma_{\nu} + c_{\mu\nu}\gamma^{\mu} + d_{\mu\nu}\gamma_5\gamma^{\mu} + e_{\nu} + if_{\nu}\gamma_5 + \tfrac{1}{2}g_{\lambda\mu\nu}\sigma^{\lambda\mu}, \tag{3}$$

and

$$M = m + im_5\gamma_5 + a_{\mu}\gamma^{\mu} + b_{\mu}\gamma_5\gamma^{\mu} + \tfrac{1}{2}H_{\mu\nu}\sigma^{\mu\nu}. \tag{4}$$

Note that any Lorentz-*preserving* terms that arise from spontaneous symmetry breaking can be absorbed into the bare mass terms m, m_5, and the overall normalization of the Lagrangian. The normalization is chosen such that the coefficient of the γ_{ν} term in Eq. (3) is one. The coupling coefficients a, b, c, d, e, f, g, m_5, and H are real, constant parameters related to the vacuum expectation value of contributing tensor fields in the underlying theory.

Some of these parameters (or combinations of parameters) are only apparently Lorentz-violating as the Lagrangian containing them can be shown to be equivalent to the standard Lagrangian using the appropriate field redefinition. This question is taken up in Sec. III.

III. GENERAL FERMION FIELD REDEFINITIONS

Some of the Lorentz-violating couplings in Eq. (2) can in fact be eliminated through a redefinition of the spinor field. To determine precisely which terms can be removed in this manner, it is useful to begin with the standard Dirac Lagrangian in terms of ψ with no Lorentz-violating terms and perform a field redefinition of the form $\psi = R\chi$, where R is some operator. The Lagrangian in terms of χ will contain terms included in the full Lorentz-violating Lagrangian. In this section, we examine possible choices for the field redefinition and examine the resulting terms in the Lagrangian.

To see which terms can be removed from the theory, we consider generic redefinitions of the fermion fields of the form

$$\psi(x) = [1 + f(x,\partial)]\chi(x), \tag{5}$$

where $f(x,\partial)$ represents a general 4×4 matrix function of the coordinates and derivatives. Only lowest order terms in the field redefinition parameters are retained since the Lorentz-violating couplings in the full Lagrangian are assumed small. By applying this transformation to the conventional free fermion Lagrangian (containing no Lorentz-violating parameters) we will see which terms can be eliminated from the extended theory by applying the inverse transformation.

To simplify the task, note that the Lorentz-violating terms generated by this transformation must have no explicit dependence on the coordinates and must consist of dimension $D \leqslant 4$ operators.[29] Candidate terms for $f(x,\partial)$ up to second order in x and ∂ are of the form

$$f(x,\partial) = v\cdot\Gamma + i\theta + iA_\mu x^\mu + B_\mu \partial^\mu + \gamma_5 \tilde{B}_\mu \partial^\mu + C_{\mu\nu} x^\mu \partial^\nu, \tag{6}$$

where v represents a set of arbitrary complex constants multiplying an arbitrary gamma matrix, denoted Γ, in the set $\{i\gamma_5, \gamma^\mu, \gamma_5\gamma^\mu, \sigma^{\mu\nu}\}$, θ is a complex constant, while A_μ, B_μ, $\tilde{B}_\mu$, and $C_{\mu\nu}$ are arbitrary real constants. Note that this is a generalization of the field redefinitions previously considered in Ref. 4.

The terms Re θ, B_μ and the antisymmetric part of $C_{\mu\nu}$ (together with the appropriate spin components $v_{\mu\nu}$) are simply the generators of the U(1) and Poincaré groups and are symmetries of the conventional Lagrangian. These terms do not generate any artificial Lorentz-violating parameters. The term Im θ rescales the Lagrangian and can be absorbed into the other constants. This leaves several independent transformations that may generate artificial Lorentz-violating terms. We proceed to calculate these explicitly in the rest of this section. Since we are working to lowest order in Lorentz-violating parameters, we can consider each term independently.

First, we summarize the results obtained using the v terms which have been previously described in Ref. 4. An explicit example is presented to illustrate the general method. As shown in Sec. IV, a field redefinition of this type can be interpreted as selecting a new basis in spinor space for the representations of SL(2,C), the complex extension of the Lorentz group. The standard Lagrangian expressed in terms of the redefined field is given by

$$\begin{aligned}\mathcal{L} &= \frac{i}{2}\bar{\psi}\gamma^\mu \overleftrightarrow{\partial}_\mu \psi - m\bar{\psi}\psi \\ &= \mathcal{L}_0 + \frac{i}{2}\bar{\chi}[\{\gamma^\mu, \Gamma\cdot \mathrm{Re}\, v\} + i[\gamma^\mu, \Gamma\cdot \mathrm{Im}\, v]]\overleftrightarrow{\partial}_\mu \chi - 2m\, \mathrm{Re}\, v\cdot\bar{\chi}\Gamma\chi,\end{aligned} \tag{7}$$

where $\mathcal{L}_0$ is the conventional free field Lagrangian in terms of χ. For example, consider the field redefinition induced by $v\cdot\Gamma = v_\mu\gamma^\mu$. Using the above-given relation yields

TABLE I. Summary of terms generated by field redefinitions of the form $v\cdot\Gamma$.

$\mathbf{v}\cdot\mathbf{\Gamma}$	$\mathbf{v}\in\Re$ ($v\equiv\mathrm{Re}\,\mathbf{v}$)	$\mathbf{v}\in\Im$ ($v\equiv\mathrm{Im}\,\mathbf{v}$)
$v(i\gamma_5)$	Used to eliminate m_5 term	$d_{\mu\nu}=2vg_{\mu\nu}$
$v_\mu\gamma^\mu$	$e_\mu=2v_\mu$ and $a_\mu=2mv_\mu$	$g_{\lambda\mu\nu}=2(v_\mu g_{\lambda\nu}-v_\lambda g_{\mu\nu})$
$v_\mu\gamma_5\gamma^\mu$	$g_{\lambda\mu\nu}=-2\epsilon_{\lambda\mu\nu}{}^\alpha v_\alpha$ and $b_\mu=2mv_\mu$	$f_\mu=-2v_\mu$
$v_{\mu\nu}\sigma^{\mu\nu}$	$d_{\mu\nu}=-2\epsilon_{\mu\nu}{}^{\alpha\beta}v_{\alpha\beta}$ and $\frac{1}{2}H_{\mu\nu}=2mv_{\mu\nu}$	$c_{\mu\nu}=2v_{[\mu\nu]}$

$$\mathcal{L}=\mathcal{L}_0+\mathrm{Re}\,v_\mu[i\bar{\chi}\overleftrightarrow{\partial^\mu}\chi-2m\bar{\chi}\gamma^\mu\chi]-i\,\mathrm{Im}\,v_\mu[\bar{\chi}\sigma^{\mu\nu}\overleftrightarrow{\partial}_\nu\chi]. \tag{8}$$

Inspection of the term proportional to $\mathrm{Im}\,v_\mu$ indicates that the four terms in the extended Lagrangian (2) of the form

$$g_{\lambda\mu\nu}=2\,\mathrm{Im}(v_\mu g_{\lambda\nu}-v_\lambda g_{\mu\nu}), \tag{9}$$

do not contribute in lowest order to the free fermion Lagrangian. Examination of the terms multiplying $\mathrm{Re}\,v_\mu$ indicates that the simultaneous choice of

$$e^\mu=2\,\mathrm{Re}\,v^\mu,\quad a^\mu=2m\,\mathrm{Re}\,v^\mu \tag{10}$$

can be removed from the Lagrangian. This means that the field redefinition can remove either e^μ or a^μ, but not both, unless $a^\mu=me^\mu$ happens to hold in the original Lagrangian. Similar calculations can be done for the other choices of $v\cdot\Gamma$. The results are summarized in Table I. Note that a (finite) transformation of the form $e^{iv\gamma_5}$ with $v\in\Re$ is used to remove any term of the form m_5 in the original Lagrangian to all orders. The effect is an m_5 dependent mixing of some of the Lorentz-violating parameters, but the structure is essentially unchanged.

Next, we consider the A, B, $\tilde{B}$, and C redefinitions. To lowest order in these parameters, the transformed Lagrangian becomes

$$\begin{aligned}\mathcal{L}=\mathcal{L}_0-\bar{\chi}A_\mu\gamma^\mu\chi+B_\mu\partial^\mu\mathcal{L}_0-\tilde{B}_\mu\partial^\mu\left[\frac{i}{2}\bar{\chi}\gamma_5\gamma^\nu\overleftrightarrow{\partial}_\nu\chi\right]\\ -m\bar{\chi}\gamma_5\tilde{B}_\mu\overleftrightarrow{\partial^\mu}\chi+C_{\mu\nu}x^\mu\partial^\nu\mathcal{L}_0+\frac{i}{2}\,C_{\mu\nu}\bar{\chi}\gamma^\mu\overleftrightarrow{\partial^\nu}\chi.\end{aligned} \tag{11}$$

The A term can be used to eliminate a^μ as is discussed in detail in Ref. 4. The B term is a total divergence that drops out of the action. This is a direct consequence of translational invariance since under a (finite) translation of the coordinates by B,

$$\psi(x)=e^{B\cdot\partial}\chi(x)=\chi(x+B)=\chi(x'), \tag{12}$$

and the action takes the same form in the translated coordinate system. The first C term can be partially integrated to yield a total divergence and a rescaling of $\mathcal{L}_0$. The final C term is of the form c as defined in Eq. (2).

A few remarks are in order regarding the above-mentioned transformation involving C. First, note that such a field redefinition appears equivalent to changing fermion coordinates to a system with a new (constant) metric that skews the coordinates. We can see this by examination of the transformation

$$\psi(x)=(1+C^{\mu\nu}x_\mu\partial_\nu)\chi(x)\approx e^{C^{\mu\nu}x_\mu\partial_\nu}\chi(x)=\chi(x+C\cdot x)=\chi(x'), \tag{13}$$

where $x'^\mu=x^\mu+C_\nu{}^\mu x^\nu$ are the new field coordinates. This redefinition is therefore equivalent to transforming to a skewed coordinate system with a nondiagonal metric given by

$$g'^{\mu\nu} = \eta^{\mu\nu} + C^{(\mu\nu)}. \tag{14}$$

Rewriting the transformed Lagrangian in terms of this new metric yields

$$\mathcal{L} = \frac{i}{2}\overline{\chi}(x')\tilde{\gamma}^{\mu}\overleftrightarrow{\partial}'_{\mu}\chi(x') - m\overline{\chi}(x')\chi(x'), \tag{15}$$

where the modified matrices $\tilde{\gamma}^{\mu} = (\eta^{\mu}_{\nu} + c^{\mu}_{\nu})\gamma^{\nu}$ satisfy the relations $\{\tilde{\gamma}^{\mu}, \tilde{\gamma}^{\nu}\} = 2g'^{\mu\nu}$. The resulting Lagrangian can be related to the conventional one using the vierbein formalism of general relativity by performing the appropriate general coordinate transformation. This shows that there is a natural association between the theory containing a c term and a theory formulated in a skewed coordinate system defined by the above-given metric. If the free fermions are the only component to the theory it is possible to perform the appropriate general coordinate transformation on the skewed coordinates relating it to the conventional case. This is because it is not possible to distinguish the theory in a skewed coordinate system (with a c term) from a conventional theory in an orthonormal system since fermion propagation properties are the only tool available to define the coordinate system itself.

However, when photon interactions are incorporated through the covariant derivative, it is no longer possible to perform the general coordinate transformation without affecting the photon sector. There is now an alternate way to distinguish the coordinates physically so that the skewed coordinates become observable. Under the fermion field redefinition, the fermion–photon interaction term becomes

$$\mathcal{L}_{\text{int}} = -q\overline{\psi}(x)\gamma^{\mu}A_{\mu}(x)\psi(x) \rightarrow -q\overline{\chi}(x')\tilde{\gamma}^{\mu}A'_{\mu}(x)\chi(x'), \tag{16}$$

where the photon field is expressed as a function of the conventional coordinates x, but its components are resolved in the modified coordinates x'. In this picture, the theory exhibits a form of nonlocality since the fermion fields interact with the photon field at different space–time points. If the photon field is reexpressed in terms of the new coordinates x', the Lagrangian becomes local, but picks up an extra term that breaks the natural association between the theories. Yet another approach is to redefine the physical photon field $A'_{\mu}(x) \rightarrow A'_{\mu}(x')$, but the new metric introduces corrections of the form in Eq. (1) into the kinetic photon sector. Therefore, the photon interactions prevent the trivial elimination of symmetric c terms using the above-given field redefinition. Similar problems arise when using other derivative transformations, so these are not considered in detail in subsequent sections of this paper. For example, the term $\tilde{B}$ in Eq. (6) generates a term of the form f [defined in Eq. (2)] as well as a total divergence in the transformed Lagrangian of Eq. (11). This transformation corresponds to a shift in opposite directions for the left-handed and right-handed fields due to the presence of γ_5. There is therefore a natural correspondence between the Lagrangian with an f term and the conventional theory provided the left-handed and right-handed fields can be translated independently.[30] The interaction that breaks the correspondence with the conventional theory in this case is the fermion mass term that mixes left-handed and right-handed fields. A similar situation occurs when the above-discussed C transformation is multiplied by γ_5. Symmetric components of the form d defined in Eq. (2) arise in the transformed Lagrangian, but the mass term depends explicitly on x, therefore breaking the natural correspondence between the theories.

Finite field transformations can be constructed through exponentiation of Eq. (5). The results of these transformations are often much more complicated than the infinitesimal ones since several parameters can be mixed. As an example, consider a field redefinition of the form

$$\psi = e^{v_{\mu}\gamma^{\mu}}\chi = \left(\cosh v + \frac{v_{\mu}\gamma^{\mu}}{v}\sinh v\right)\chi, \tag{17}$$

with v_μ real, timelike, and the quantity v defined by $v=\sqrt{v_\mu v^\mu}$. Application of this transformation to the standard Lagrangian in terms of ψ yields a Lagrangian for χ with apparent Lorentz-violating parameters and a modified mass given by

$$e^\mu=\frac{v^\mu}{v}\sinh 2v, \quad c^{\mu\nu}=\frac{v^\mu v^\nu}{v^2}(\cosh 2v-1),$$
$$m'=m\cosh 2v, \quad a^\mu=\frac{mv^\mu}{v}\sinh 2v. \tag{18}$$

Note that the corrections to c and m terms appear only at second order in v.

Such a choice of parameters in the QED extension leaves the dispersion relation unaltered and therefore leads to no stability problems or microcausality violations. This is true for any finite field redefinition of the form $e^{v\cdot\Gamma}$ since the field redefinition commutes with the square of the conventional Dirac equation. The set of all such transformations generates a class of Lagrangians equivalent to the conventional one.

The derivative field redefinitions may also be exponentiated to yield finite transformations. In the cases of $\tilde{B}$ and C of Eq. (6), finite transformations correspond to finite coordinate transformations, possibly different for various spinor components. As in the infinitessimal case, interactions between various spinor components and other fields limit the usefulness of these transformations due to nonlocality problems.

To gain further insight into the invariance of the physics under the above-mentioned transformations, it is useful to compute the currents associated with the generators of the Poincaré group. We will see that it is necessary to redefine the action of the complex Lorentz group along with the field in order to yield maximally conserved Lorentz generators.

IV. POINCARÉ GENERATORS

We start with a general free fermion Lagrangian of the form

$$\mathcal{L}=\frac{i}{2}\overline{\chi}\Gamma^\nu\overleftrightarrow{\partial}_\nu\chi-\overline{\chi}M\chi, \tag{19}$$

and apply Noether's theorem to obtain the divergence of the currents associated with various continuous transformations of the field. Invariance under a global U(1) phase transformation yields a conserved current of

$$j^\mu=\overline{\chi}\Gamma^\mu\chi, \tag{20}$$

satisfying $\partial_\mu j^\mu=0$. Invariance under translations yields a conserved energy momentum tensor of

$$\Theta^{\mu\nu}=\frac{i}{2}\overline{\chi}\Gamma^\mu\overleftrightarrow{\partial}^\nu\chi, \tag{21}$$

satisfying $\partial_\mu\Theta^{\mu\nu}=0$.

The Lagrangian is no longer invariant under the conventional action of the Lorentz group, so the divergences of the corresponding currents will not vanish. These can be calculated using the standard technique of writing the action over an arbitrary four-volume in terms of boosted coordinates and fields at $x'^\mu=\Lambda^\mu{}_\nu x^\nu\approx x^\mu+\epsilon^\mu{}_\nu x^\nu$ and calculating the variation to lowest order in $\epsilon^\mu{}_\nu$. A choice must be made for the induced transformation properties of the spinor components of χ under the complex extension of the Lorentz group SL(2,C). Using the standard $S(\Lambda)=1-(i/4)\sigma_{\mu\nu}\epsilon^{\mu\nu}$ yields currents given by

$$\partial_\alpha j^{\alpha\mu\nu}=X^{\mu\nu}, \tag{22}$$

where

$$j^{\alpha\mu\nu}=x^{[\mu}\Theta^{\alpha\nu]}+\tfrac{1}{4}\overline{\chi}\{\Gamma^{\alpha},\sigma^{\mu\nu}\}\chi, \tag{23}$$

and

$$\begin{aligned}X^{\mu\nu}=&-a^{[\mu}\overline{\chi}\gamma^{\nu]}\chi-b^{[\mu}\overline{\chi}\gamma_5\gamma^{\nu]}\chi-\frac{i}{2}\overline{\chi}(c^{[\nu\alpha}\gamma^{\mu]}\overleftrightarrow{\partial}_{\alpha}+c^{\alpha[\nu}\gamma_{\alpha}\overleftrightarrow{\partial}^{\mu]})\chi-\frac{i}{2}\overline{\chi}(d^{[\nu\alpha}\gamma_5\gamma^{\mu]}\overleftrightarrow{\partial}_{\alpha}\\&+d^{\alpha[\nu}\gamma_5\gamma_{\alpha}\overleftrightarrow{\partial}^{\mu]})\chi+\frac{i}{2}e^{[\mu}\overline{\chi}\overleftrightarrow{\partial}^{\nu]}\chi-\frac{1}{2}f^{[\mu}\overline{\chi}\gamma_5\overleftrightarrow{\partial}^{\nu]}\chi\\&-\frac{i}{4}\overline{\chi}(2g^{[\nu\alpha\beta}\sigma^{\mu]}{}_{\alpha}\overleftrightarrow{\partial}_{\beta}+g^{\alpha\beta[\nu}\sigma_{\alpha\beta}\overleftrightarrow{\partial}^{\mu]})\chi-\overline{\chi}H^{[\mu\alpha}\sigma^{\nu]}{}_{\alpha}\chi.\end{aligned} \tag{24}$$

All of these equations can be verified by direct calculation.

It is expected that terms which can be eliminated using a field redefinition should also be removable from $X^{\mu\nu}$ with the appropriate redefinition of the associated currents. To explicitly construct the conserved currents, the field redefinition is applied to the conventional currents written in terms of ψ, satisfying the conventional Dirac equation. These conserved currents are reexpressed in terms of χ giving the proper conserved currents for the new Lagrangian.

Alternatively, the conserved currents of the modified Lagrangian may be computed from Nöether's theorem using a modified action of the Lorentz group on the spinor fields. Using a general finite field redefinition $\psi=e^{v\cdot\Gamma}\chi$, it is found that the action of U(1) and translations is the same on ψ and χ meaning that the four-current and energy-momentum tensors are computed as in Eqs. (20) and (21). However, the action of the Lorentz transformations is in fact modified due to the field redefinition. Under an infinitesimal Lorentz transformation of the coordinates, the ψ spinor components mix according to $\delta\psi=S(\Lambda)\psi$, while the corresponding change in χ is calculated to be $\delta\chi=e^{-v\cdot\Gamma}S(\Lambda)e^{v\cdot\Gamma}\chi=\tilde{S}(\Lambda)\chi$. This means that the χ components transform according to a similar representation of the complex Lorentz group. When the associated current is computed using this modified action of SL(2,C) on χ, it is indeed conserved.

As an example, consider the field redefinition used in Eq. (8) involving $\mathrm{Re}\,v_{\mu}$. If the conventional $S(\Lambda)$ is used to find the current associated with the Lorentz transformations, the result is $j_{\chi}^{\alpha\mu\nu}$ given by Eq. (23), which is not conserved. However, if $\tilde{S}(\Lambda)$ is used to transform the field χ, then the associated current is

$$\tilde{J}_{\chi}^{\alpha\mu\nu}=x^{[\mu}\Theta^{\alpha\nu]}+\tfrac{1}{4}\overline{\chi}\{\Gamma^{\alpha},\sigma^{\mu\nu}\}\chi+\tfrac{1}{2}\overline{\chi}e^{[\mu}\sigma^{\nu]\alpha}\chi, \tag{25}$$

which is in fact conserved. This shows that one must be careful to map the correct conserved generators into the proper associated currents written in terms of χ. Similar maps between generators can be performed using the derivative transformations, however, in this case the U(1) and translation currents may also be modified.

As a practical approach, the redundant parameters can first be removed from the Lagrangian and then the conventional $S(\Lambda)$ can be used to construct the currents in the redefined Lagrangian. We perform this removal of the redundant parameters in Sec. V.

V. ELIMINATION OF REDUNDANT PARAMETERS

In this section, we start with a general Lagrangian and apply field redefinitions to remove redundant parameters. The starting point is the Lagrangian given in Eq. (2). The parameters m_5, a_{μ}, e_{μ}, f_{μ}, and $c_{[\mu\nu]}$ can all be immediately removed using a combination of the transformations described in Sec. III. The parameter $g_{\lambda\mu\nu}$ can be replaced by the traceless $\tilde{g}_{\lambda\mu\nu}$ satisfying $g^{\lambda\nu}\tilde{g}_{\lambda\mu\nu}=g^{\mu\nu}\tilde{g}_{\lambda\mu\nu}=0$. The other transformations listed in Table I involve linear combinations of parameters.

To handle these terms, the Lagrangian must be reexpressed in terms of the new, physically relevant linear combinations of parameters. For example, the combination of antisymmetric d and H terms of Eq. (2) are reexpressed as

$$\frac{i}{4}\overline{\psi}d_{[\mu\nu]}\gamma_5\gamma^\mu\overleftrightarrow{\partial}^\nu\psi-\frac{1}{2}\overline{\psi}H_{\mu\nu}\sigma^{\mu\nu}\psi=v^+_{\alpha\beta}\left[\frac{i}{2}\overline{\psi}\epsilon_{\mu\nu}{}^{\alpha\beta}\gamma_5\gamma^\mu\overleftrightarrow{\partial}^\nu\psi-m\overline{\psi}\sigma^{\alpha\beta}\psi\right]$$
$$+v^-_{\alpha\beta}\left[\frac{i}{2}\overline{\psi}\epsilon_{\mu\nu}{}^{\alpha\beta}\gamma_5\gamma^\mu\overleftrightarrow{\partial}^\nu\psi+m\overline{\psi}\sigma^{\alpha\beta}\psi\right], \tag{26}$$

where $v^\pm_{\alpha\beta}=\frac{1}{4}(\tilde{d}_{\alpha\beta}\pm 1/m\,H_{\alpha\beta})$, and $\epsilon^{\alpha\beta}_{\mu\nu}\tilde{d}_{\alpha\beta}=d_{[\mu\nu]}$. The combination $v^-_{\alpha\beta}$ can be removed using a field redefinition, leaving only $v^+_{\alpha\beta}$ terms in the Lagrangian. The g and b terms can be similarly combined using the definition $v^\pm_\alpha=\frac{1}{2}(g_\alpha\pm 1/m\,b_\alpha)$

After all of these redefinitions have been performed, the form for the Lagrangian becomes

$$\mathcal{L}=\frac{i}{2}\overline{\psi}\left(\gamma_\nu+\frac{1}{2}c_{(\mu\nu)}\gamma^\mu+\frac{1}{2}d_{(\mu\nu)}\gamma_5\gamma^\mu+\frac{1}{2}\hat{g}_{\lambda\mu\nu}\sigma^{\lambda\mu}\right)\overleftrightarrow{\partial}^\nu\psi-m\overline{\psi}\psi+\frac{1}{4}\left(\tilde{d}_{\alpha\beta}+\frac{1}{m}H_{\alpha\beta}\right)$$
$$\times\left[\frac{i}{2}\overline{\psi}\epsilon_{\mu\nu}{}^{\alpha\beta}\gamma_5\gamma^\mu\overleftrightarrow{\partial}^\nu\psi-m\overline{\psi}\sigma^{\alpha\beta}\psi\right]-\frac{1}{2}\left(g_\alpha-\frac{1}{m}b_\alpha\right)\left[\frac{i}{2}\overline{\psi}\frac{1}{2}\epsilon_{\lambda\mu}{}^{\nu\alpha}\sigma^{\lambda\mu}\overleftrightarrow{\partial}_\nu\psi-m\overline{\psi}\gamma_5\gamma^\alpha\psi\right], \tag{27}$$

where $\hat{g}_{\lambda\mu\nu}$ is a traceless coupling with a vanishing totally antisymmetric piece. The totally antisymmetric component of $\tilde{g}$ is absorbed into $g_\alpha=-\epsilon_\alpha{}^{\lambda\mu\nu}\tilde{g}_{\lambda\mu\nu}$. This Lagrangian can be written in the form

$$\mathcal{L}=\frac{i}{2}\overline{\psi}\tilde{\Gamma}_\nu\overleftrightarrow{\partial}^\nu\psi-\overline{\psi}\tilde{M}\psi, \tag{28}$$

where

$$\tilde{\Gamma}_\nu=\gamma_\nu+\tfrac{1}{2}c_{(\mu\nu)}\gamma^\mu+(\tfrac{1}{2}d_{(\mu\nu)}+\epsilon_{\mu\nu}{}^{\alpha\beta}v^+_{\alpha\beta})\gamma_5\gamma^\mu+\tfrac{1}{2}(\hat{g}_{\lambda\mu\nu}-\epsilon_{\lambda\mu\nu}{}^\alpha v^-_\alpha)\sigma^{\lambda\mu}, \tag{29}$$

and

$$\tilde{M}=m(1+v^+_{\alpha\beta}\sigma^{\alpha\beta}-v^-_\alpha\gamma_5\gamma^\alpha), \tag{30}$$

where all distinct parameters are now physically relevant.

This Lagrangian is therefore the one for which ψ can be assumed to transform under the standard representation of SL(2,C), yielding maximally conserved currents.[31] The relevant currents are given as in Sec. IV with appropriately mapped constants found by comparison of Eqs. (2) and (28). The remaining terms cannot be removed by a redefinition of spinor coordinates. Other terms may be eliminated in the free theory using transformations involving derivatives of the fields as discussed in Sec. III, but interactions between the fermion fields and other fields often break the natural correspondence between the redefined Lagrangian and the original theory. This means that if these terms are removed from the free fermion sector, they will appear as modified interaction terms and will not be removed from the theory, only shifted to another sector.

Physical quantities should therefore depend only on the combinations occurring in the Lagrangian of Eq. (28). Therefore, it is not possible to obtain experimental bounds on all Lorentz-violating parameters of Eq. (2) independently, only on the combinations present in Eq. (28). For example, it is only the linear combination $v^+_{\alpha\beta}$ of the antisymmetric part of d and H that is observable. This implies that only one parameter should in fact be used to describe this quantity.

Comparison with previous calculations within the context of this model verify that this is indeed the case. For example, in applications to electrons and positrons in Penning traps,[6–9] the relevant experimental bound is obtained from the observable cyclotron and anomaly frequencies ($\tilde{g}_{\lambda\mu\nu}=0$ in this calculation)

$$\begin{aligned}\omega_c^{e^\pm} &\approx (1-c_{00}^e-c_{11}^e-c_{22}^e)\omega_c\,,\\ \omega_c^{e^\pm} &\approx \omega_a \mp 2b_3^e+2md_{30}^e+2H_{12}^e,\end{aligned} \tag{31}$$

which can place bounds only on the combinations of parameters found in Eq. (27), not on the parameters that can be removed by the field redefinitions. As another example, a calculation of the cross section for $e^+e^-\to 2\gamma$ within the QED extension[10] only depends on the symmetric components of c. Similar results have been obtained in other QED systems.[32]

For many practical calculations it is convenient to perform another field redefinition to normalize $\tilde{\Gamma}^0\to\gamma^0$. This has the effect of removing extra time derivative couplings ensuring that the resulting Schrödinger equation has a conventional time evolution.[6,17] Starting with a general Lagrangian of the form (2), the appropriate field redefinition that removes time derivative couplings to lowest order is $\psi=A\chi$ with

$$\begin{aligned}A&=1-\tfrac{1}{2}\gamma^0(\Gamma_0-\gamma_0)\\ &=1-\tfrac{1}{2}\gamma^0(c_{\mu 0}\gamma^\mu+d_{\mu 0}\gamma_5\gamma^\mu+e_0+if_0\gamma_5+\tfrac{1}{2}g_{\lambda\mu 0}\sigma^{\lambda\mu}).\end{aligned} \tag{32}$$

Note that these are in 1–1 correspondence with the nonunitary transformations of the form $v\cdot\Gamma$ examined in Sec. III. The unitary transformations of this type can be obtained by letting the coupling constants in Eq. (32) be pure imaginary rather than real. In this case, the time derivative structure is unaffected by the field redefinition. This provides an alternative perspective on the spinor component field redefinitions. The unitary transformations preserve the time derivative terms while the nonunitary transformations modify the time derivative structure. This can be seen directly from Eq. (7) by noting that the requirement that no time derivatives are introduced is equivalent to the condition $(v\cdot\Gamma)^\dagger=-v\cdot\Gamma$, hence making the field redefinition unitary to lowest order. The unitary transformations are used in the standard Dirac theory to transition between various representations of the gamma matrices, an alternative perspective to the explicit correction terms used in this paper. In other words, any apparent Lorentz-violating terms generated by a unitary transformation may be absorbed into a modified gamma matrix representation.

As a practical method for calculation, the procedure is therefore to first remove the redundant parameters to obtain Eq. (28), then perform the field redefinition of Eq. (32) (using $\tilde{\Gamma}^0$ in place of Γ^0). The resulting Lagrangian will therefore yeild a conventional Schrödinger equation time evolution and will not contain any redundant parameters.

VI. SUMMARY

In this paper, an analysis of field redefinitions in the context of the Lorentz-violating QED extension was presented. It was shown that a variety of parameters that apparently violate Lorentz invariance can be eliminated from the Lagrangian using suitable fermionic field redefinitions.

The approach taken to find these parameters was to begin with the conventional Dirac Lagrangian, introduce an arbitrary spinor redefinition, and examine the resulting transformed Lagrangian. Any parameters generated using this procedure can be removed by the corresponding inverse transformation. The action of SL(2,C) on the spinor fields is deduced using the conventional action on the ψ spinors and performing the field redefinition to determine the corresponding action on χ. The resulting transformation matrices of the new spinor are related by a similarity transformation to the original matrices. This modified action must be taken into account when defining the conserved generators in the modified Lagrangian.

This implies a procedure for elimination of redundant parameters from the original Lagrangian. By first identifying all possible terms that can be generated from the conventional Lagrangian by a field redefinition, these terms can be omitted from the physical Lagrangian. This procedure has been carried out in Sec. V. A further transformation may be implemented to normalize the time derivative structure of the theory to obtain conventional Schrödinger time evolution and physical particle states.

The possible nonderivative field redefinitions that can be applied to the QED extension fall into two general categories, unitary and nonunitary. The nonunitary transformations modify the time derivative structure of the Lagrangian and can be used to construct a hermitian hamiltonian and a Schrödinger equation with conventional time evolution. The time derivative couplings in a general bilinear Lagrangian of the form in Eq. (2) can always be removed using a suitable nonunitary transformation. Moreover, there is a one-to-one correspondence between these nonunitary transformations and the field redefinitions used to eliminate the extra time derivative couplings.

Redefinitions involving differentiation may be useful in the free fermion theory, but often lead to nonlocal interactions or skewed coordinate systems when interactions are present. These problems make it difficult to perform a generic analysis of all possible applications of these transformations. Derivative redefinitions may be applied on a case by case basis where they might be useful in simplification of calculations.

Stability and causality issues[5] cannot be effectively addressed using the above-presented arguments since the redefinition was only carried out to lowest order in Lorentz-violating parameters. Causality and stability problems appear either when the coupling constants are large, or when the momentum is significantly large to invalidate the linear approximations involved. However, the finite field redefinition considered in Eq. (17) leads to a finite set of parameters that maintain the conventional dispersion relation. The resulting theory must therefore be stable and microcausal. A class of apparently Lorentz-violating Lagrangians that are microcausal and stable may therefore be generated by applying finite versions of the field redefinitions discussed in this paper. A complete nonperturbative analysis would be of interest, but is beyond the scope of this work.

Application of a similar analysis to the entire standard model extension would be of interest. For example, cross-generational mixings would allow for a richer structure of possible field redefinitions than in QED.

[29] Actually, terms in the transformed Lagrangian may contain an explicit dependence on x or may be of dimension greater than four provided that the terms are total divergences and therefore can be removed from the action. For examples, see the relevant terms in Eq. (11).
[30] Actually, one of the redefinitions listed in Table I can also be used to eliminate the f term, so it is always removable from the Lagrangian.
[31] Note that field redefinitions involving the physically relevant coupling constants may still be performed yielding different definitions of the Lorentz currents. However, the physically irrelevant parameters have been removed. For example, a further field redefinition is convenient in removing extra time derivatives for calculational purposes as is described preceding Eq. (32).

Phase space structure and short distance behavior of local quantum field theories

Stephan Mohrdieck[a)]
Mathematisches Institut, Universität Basel, Rheinsprung 21, CH 4051 Basel, Switzerland

(Received 6 September 2000; accepted for publication 11 April 2002)

In this article a general relation between the short distance structure of quantum field theories and their phase space properties is exemplified by the simple class of generalized free fields. As is known, theories with decent phase space properties, resulting from a finite or moderately increasing infinite particle spectrum, always have non-trivial scaling (short distance) limits [cf. D. Buchholz and R. Verch, Rev. Math. Phys. **10**, 775 (1998)]. But, whereas in the finite particle case the phase space properties of the limit theories comply with strong nuclearity conditions, they violate in the infinite particle case even rather mild compactness assumptions. These results provide further evidence to the effect that relevant information on the short distance structure of a theory can be obtained by phase space analysis. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1486262]

I. INTRODUCTION

In quantum field theory the structure of a physical theory at small distances is an interesting issue in several respects. It is important for understanding the particle structure at small scales as well as the classification of the ultraviolet properties of the theory.

Recently, Buchholz and Verch presented a model independent approach to the investigation of these problems in Ref. 8, which is carried out in the framework of algebraic quantum field theory. There, they adapted the method of the renormalization group to this framework by introducing the notions of scaling algebra and scaling limit.

Before summarizing the ideas of Buchholz and Verch, let us give a brief account of the framework of algebraic quantum field theory (see, e.g., Ref. 12).

In this framework, a quantum field theory is given by the net of algebras of local observables $\mathfrak{A}$ together with a covariant action of the translation group by automorphisms $\alpha_{x,x\in\mathbb{R}^d}$. This is a map

$$\mathcal{O}\mapsto\mathfrak{A}(\mathcal{O}), \tag{1}$$

fulfilling certain properties. Here $\mathcal{O}\subset\mathbb{R}^{d=s+1}$ is an open bounded region in $d=s+1$ dimensional Minkowski-space and $\mathfrak{A}(\mathcal{O})$ is unital C^*-algebra, the algebra generated by all observables which can be measured in $\mathcal{O}$. The C^*-algebra generated by all the local algebras $\mathfrak{A}(\mathcal{O})$ (as C^*-inductive limit) is also denoted by $\mathfrak{A}$. Furthermore, we impose the following properties:

(1) *Locality:* Observables $A\in\mathfrak{A}(\mathcal{O}_1)$ and $B\in\mathfrak{A}(\mathcal{O}_2)$ corresponding to spacelike separated regions $\mathcal{O}_1$ and $\mathcal{O}_2$ should commute:

$$[A,B]=0. \tag{2}$$

(2) *Covariance:* The translation group $\mathbb{R}^d$ acts on the net by automorphisms $\alpha_x\in\mathrm{Aut}(\mathfrak{A})$, for $x\in R^d$:

$$\alpha_x(\mathfrak{A}(\mathcal{O}))=\mathfrak{A}(\mathcal{O}+x). \tag{3}$$

a)Electronic mail: mohrdis@math.unibas.ch

Furthermore, we require the representation of the translation group to be continuous in the strong topology, i.e., the maps $x \mapsto \alpha_x(A)$ to be continuous in the norm topology, for all $A \in \mathfrak{A}$.

(3) *Vacuum state:* In general, a physical state of the theory is a positive, linear, normalized functional σ on the net $\mathfrak{A}$. Such a state allows us to get a representation π_σ of the net $\mathfrak{A}$ on a Hilbert space $\mathcal{H}_\sigma$ via GNS-construction. If the corresponding state σ is invariant under the translation group, there exists a unitary representation $U_\sigma(x)$, $x \in \mathbb{R}^d$, of the translation group on $\mathcal{H}_\sigma$ implementing the representation α:

$$U_\sigma(x)\pi_\sigma(A)U_\sigma(-x) = \pi_\sigma(\alpha_x(A)), \tag{4}$$

for all $A \in \mathfrak{A}$. Let us assume that our theory has a vacuum state, i.e., that there exist a translation-invariant state σ, such that the joint spectrum of the generators of all implementors is contained in the forward light cone.

Now, let us briefly summarize the approach of Buchholz and Verch (for details we refer to Ref. 8):

Given a local, covariant net of observables $\mathfrak{A}$, $\alpha_{x, x \in \mathbb{R}^d}$ in d space–time dimensions we construct the scaling net $\underline{\mathfrak{A}}, \underline{\alpha}_{x, x \in \mathbb{R}^d}$, again a local covariant net, by the following rule: Let $\underline{A}: \mathbb{R}^{>0} \to \mathfrak{A}$ be a bounded function. Then we set

$$\underline{\mathfrak{A}}(\mathcal{O}) := \{\underline{A} \,|\, \underline{A}_\lambda \in \mathfrak{A}(\lambda \mathcal{O}),\ x \mapsto \underline{\alpha}_x(\underline{A}) \text{ continuous in norm topology}\},$$

$$\underline{\alpha}_x(\underline{A})_\lambda := \alpha_{\lambda x}(\underline{A}_\lambda).$$

The crucial point is that the scaling net carries a representation of the dilation group τ_λ, $\lambda \in \mathbb{R}^{>0}$. Starting with the vacuum state σ on the underlying theory, we define its *canonical lift* $\underline{\sigma}$ on the scaling net: $\underline{\sigma}(\underline{A}) := \sigma(\underline{A}_1)$. Then one considers the scaled states $\underline{\sigma} \circ \tau_\lambda$. This net of states on the scaling net has limit points $\underline{\sigma}^{(0,\nu)}$, $\nu \in \Xi$ for $\lambda \searrow 0$, in the weak*-topology. Here, Ξ is a suitable index set. Via GNS-construction, we get representations $\mathfrak{A}^{(0,\nu)}$, $\nu \in \Xi$, of the scaling net $\underline{\mathfrak{A}}$ corresponding to these states. The $\mathfrak{A}^{(0,\nu)}$, $\nu \in \Xi$ are called *the scaling limit nets* of the underlying theory.

Buchholz and Verch also provided a classification of the scaling limit. Since we do not need it here, we refer to Ref. 9.

Furthermore, it was observed by Buchholz,[1] that phase space properties should play an important role for the short distance structure of a theory. This can heuristically be illustrated by the following example, which was more thoroughly investigated by Lutz:[15]

Assume we have a quantum field theory exhibiting the following behavior: The energy-momentum transfer of local observable scales with λ^{-q} with $q > 1$ under renormalization group transformations, while its localization in space–time scales with λ. Since we require Planck's constant not to vary with the scale, its scaling limit theory should be a classical theory, i.e., all observables commute.

In this article we consider a generalized free field in $d \geqslant 3$ space–time dimensions with finite or moderately increasing infinite particle spectrum. To be more precise, we impose the following condition on the mass spectrum:

$$\forall \beta > 0: \quad \sum_{i \in I} e^{-\beta m_i} < \infty, \tag{5}$$

where I is either finite or $\mathbb{N}$. It was shown by Buchholz and Verch that these theories have nontrivial scaling limit, cf. Ref. 9. As is well known,[10] these theories fulfill the nuclearity condition.

Our aim is to show that its scaling limit theories exhibit the following phase space properties: If the mass spectrum is finite, all the scaling limit theories fulfill the strong nuclearity condition. But, none of its scaling limit theories complies with the weaker compactness criterion in the infinite case. Heuristically the situation can be understood as follows: In the finite case the scaling

limit should be the massless theory with finite multiplicity, which is known to fulfill the nuclearity condition. On the other hand, in the infinite case, the scaling limit theory is expected to contain the massless free field with infinite multiplicity, which does not comply with the compactness criterion.

Our analysis will be carried out by only investigating the phase space properties of the underlying theory.

The article is organized as follows:

In Sec. II we rephrase the mathematical tools for the investigation of phase space properties in quantum field theory. Afterwards, we describe the interaction between phase space properties and the structure of the scaling limit.

The models we are dealing with are introduced in Sec. III. There we also indicate upper bounds in the scaling limit of the nuclear norms of the phase space maps of our theories. Using this we show that all the scaling limit theories in the case of a finite mass spectrum fulfill the nuclearity condition. In Sec. IV, we prove that the scaling limit in the case of an infinite mass spectrum has no decent phase space behavior, and it violates the compactness criterion. This is carried out by considering lower bounds of the ϵ-contents of the phase space maps.

II. THE PHASE SPACE AND THE SCALING LIMIT

As was already pointed out in the Introduction, the phase space properties of the underlying theory should (partially) determine its short distance behavior. In fact, a link between properties of the scaling limit and the phase space properties of a local quantum field theory was established by Buchholz (cf. Ref. 1). Here, we want to summarize the main results of his article.

Let us start by recalling the main notions for the description of phase space properties in the framework of local quantum field theory (cf. Refs. 1, 2, 4, 17, and 18).

Let T be an arbitrary bounded linear operator between two Banach spaces $\mathcal{E}$ and $\mathcal{F}$.

Definition 2.1: (i) The ϵ-content $N_T(\epsilon)$ of T is the maximal number (or infinity) of elements $E_i \in \mathcal{E}_1$, such that

$$\forall i \neq j: \quad \|T(E_i - E_j)\| > \epsilon. \tag{6}$$

(ii) T is called p-nuclear, $p \in \mathbb{R}^{>0}$, if there exist sequences $e_n \in \mathcal{E}^*$ and $F_n \in \mathcal{F}$, $n \in \mathbb{N}$, such that

$$\begin{gathered} T = \sum_{n=1}^{\infty} e_n F_n, \\ \sum_{n=1}^{\infty} \|e_n\|^p \|F_n\|^p < \infty. \end{gathered} \tag{7}$$

The first sum should converge in the strong topology. We set $\||T|\|_p := \inf(\Sigma_{n=1}^{\infty} \|e_n\|^p \|F_n\|^p)^{1/p}$ and call this the nuclear p-norm. (To be precise, it is only a quasi-norm for $0 < p < 1$.) The infimum is taken over all decompositions of T as in Eq. (7).

Furthermore, we set $\|A\|_p := (\mathrm{Tr}|A|^p)^{1/p}$ for a bounded endomorphism A of a Hilbert space, if this trace exists. This will be called the pth *trace norm of* A. For further properties of and relations between these concepts, we refer to Refs. 1 and 2.

In the fr amework of local quantum field theory, ''decent'' phase space properties of a local, covariant net $\mathfrak{A}$ are described by the compactness criterion or, a sharpened version of it, the nuclearity criterion (cf. Refs. 13, 10, and 7): First let us define the *phase space maps* $\Theta_{\beta,\mathcal{O}}$, for each bounded region $\mathcal{O} \subset \mathbb{R}^d$ and $\beta \in \mathbb{R}^{>0}$:

$$\begin{aligned} &\Theta_{\beta,\mathcal{O}} : \mathfrak{A}(\mathcal{O}) \to \mathcal{H}, \\ &A \mapsto e^{-\beta H} A \Omega. \end{aligned} \tag{8}$$

Here, H is the Hamiltonian of the theory.

Compactness condition: A local covariant net $\mathfrak{A}$ fulfills the *compactness condition*, iff the phase space maps $\Theta_{\beta,\mathcal{O}}$ are compact, for every β and $\mathcal{O}$ as above.

Nuclearity Condition: A local covariant net fulfills the *nuclearity condition*, iff the phase space maps $\Theta_{\beta,\mathcal{O}}$ are p-nuclear, for every $p>0$, bounded region $\mathcal{O}$ and sufficiently large $\beta>0$.

We should mention that these conditions have a large variety of consequences for the particle interpretation and statistical and thermodynamical properties of the underlying theory. Since we do not need them here, we refer to Refs. 13, 10, 7, 6, 14, and 19.

With these tools we are able to give an account on the interplay between phase space properties of the underlying theory and the structure of the scaling limit. We only present the results. For the proofs, we refer to Ref. 1, Proposition 4.3 and Theorems 4.5 and 4.6.

Investigating the nuclear p-norms of the phase space maps we can decide whether the scaling limit theories fulfill the nuclearity condition or not:

Theorem 2.1: *Consider a quantum field theory with p-nuclear phase space maps $\Theta_{\beta,\mathcal{O}}$ for some $0<p<\frac{1}{3}$. Furthermore, assume that* $\limsup_{\lambda\searrow 0}\|\|\Theta_{\lambda\beta,\lambda\mathcal{O}}\|\|_p<\infty$. *Then we have the following.*

The phase space maps $\Theta^{(0,\nu)}_{\beta,\mathcal{O}}$ of every scaling limit net $\mathfrak{A}^{(0,\nu)}$, $\nu\in\Xi$, are q-nuclear, for $q>2p/(2-3p.)$ Furthermore, there exists a constant c depending only on p and q, such that

$$\|\|\Theta^{(0,\nu)}_{\beta,\mathcal{O}}\|\|_q\leqslant c\limsup_{\lambda\searrow 0}\|\|\Theta_{\lambda\beta,\lambda\mathcal{O}}\|\|_p\,. \tag{9}$$

Using the ϵ-contents the following sufficient and necessary conditions for the validity of the compactness criterion of the scaling limit theories hold. Here, the ϵ-content of $\Theta_{\beta,\mathcal{O}}$ will be denoted by $N_{\beta,\mathcal{O}}(\epsilon)$.

Proposition 2.1: All scaling limit theories of a given quantum field theory fulfill the compactness criterion, if $\limsup_{\lambda\searrow 0}N_{\lambda\beta,\lambda\mathcal{O}}(\epsilon)<\infty$, *for all $\epsilon>0$ and bounded regions $\mathcal{O}$. A necessary condition for the compactness criterion is that* $\liminf_{\lambda\searrow 0}N_{\lambda\beta,\lambda\mathcal{O}}(\epsilon)<\infty$, *for all $\epsilon>0$ and bounded regions $\mathcal{O}$.*

Remark: By investigating phase space properties it is also possible to decide whether the scaling limit theories are trivial (cf. Ref. 1). Using the techniques presented in this article even the nontriviality of the scaling limit of the models under consideration can be shown (cf. Ref. 16). We will not outline this here because of the stronger results in Ref. 9, where the scaling limit nets are directly constructed.

III. THE MODELS AND UPPER BOUNDS

In this section we first give a brief description of our models. Then we show that the nuclearity condition holds in the scaling limit, in the case of a finite mass spectrum. This is done by calculating upper bounds for the nuclear p-norms of the phase space maps $\Theta_{\beta,\mathcal{O}}$ and investigating their behavior in the limit $\lambda\searrow 0$.

Let us start by giving the construction of our quantum field theories in the Cauchy data formulation.

Let $\mathcal{K}$ be the one-particle Hilbert space:

$$\mathcal{K}:=\bigoplus_{i\in I}L^2(\mathbb{R}^s,\mathbb{C}), \tag{10}$$

where $s=d-1$ is the number of space-dimensions. On $\mathcal{K}$ we have a scalar product $\langle,\rangle$ in a canonical way. In addition, there is an antilinear involution J given by componentwise complex conjugation of the functions in $\mathcal{K}$. Our vacuum Hilbert space $\mathcal{H}$ will be the symmetric Fock space over $\mathcal{K}$. Its scalar product will be denoted by $(,)$.

The creation and annihilation operators $a^*(F)$ resp. $a(F)$, $F\in\mathcal{K}$, act on $\mathcal{H}$. We define the the Weyl operators $W(F)$, $F\in\mathcal{K}$:

$$W(F) := e^{i(a^*(F)+a(F))^-}, \quad F \in \mathcal{K}. \tag{11}$$

Here, $(a^*(F)+a(F))^-$ denotes the self-adjoint operator extending the densely defined (unbounded) operator $a^*(F)+a(F)$. The Weyl operators are subject to the canonical commutation relations:

$$W(F)W(G) = e^{i\Im\langle G,F\rangle} W(F+G). \tag{12}$$

Let $\mathbf{P}$ be the momentum operator on $L^2(\mathbb{R}^s,\mathbb{C})$. Then the one particle Hamiltonian $\underline{\omega}$ acts as follows:

$$\underline{\omega} F := \bigoplus_{i\in I} \omega_i f_i, \quad \omega_i := \sqrt{|\mathbf{P}|^2 + m_i^2}. \tag{13}$$

By second quantization we get the Hamiltonian H on $\mathcal{H}$. It is the generator of the time translations of our quantum field theory.

Let $\mathcal{O}_r \in \mathbb{R}^d$ be a double cone with Basis $\mathbf{O}_r = \{\mathbf{x}\in\mathbb{R}^s, |\mathbf{x}| < r\} \subset \mathbb{R}^s$, the ball of radius r centered at 0 in the $t=0$-plane. Then we define closed subspaces of $\mathcal{K}$ [Here $\mathcal{D}(\mathbf{O}_r)$ denotes the set of test function with support contained in $\mathbf{O}_r$):

$$\mathcal{L}_\phi^{m_i}(\mathcal{O}_r) := \overline{\omega_i^{-1/2}\mathcal{D}(\mathbf{O}_r)}^{\|\cdot\|_{L^2(\mathbb{R}^s,\mathbb{C})}}, \tag{14}$$

$$\mathcal{L}_\pi^{m_i}(\mathcal{O}_r) := \overline{\omega_i^{1/2}\mathcal{D}(\mathbf{O}_r)}^{\|\cdot\|_{L^2(\mathbb{R}^s,\mathbb{C})}}, \tag{15}$$

$$\mathcal{L}_\phi(\mathcal{O}_r) := \overline{\underline{\omega}^{-1/2}\bigoplus_{i\in I}\mathcal{D}(\mathbf{O}_r)}^{\|\cdot\|_{\mathcal{K}}} = \overline{\bigoplus_{i\in I}\mathcal{L}_\phi^{m_i}(\mathcal{O}_r)}^{\|\cdot\|_{\mathcal{K}}}, \tag{16}$$

$$\mathcal{L}_\pi(\mathcal{O}_r) := \overline{\underline{\omega}^{1/2}\bigoplus_{i\in I}\mathcal{D}(\mathbf{O}_r)}^{\|\cdot\|_{\mathcal{K}}} = \overline{\bigoplus_{i\in I}\mathcal{L}_\pi^{m_i}(\mathcal{O}_r)}^{\|\cdot\|_{\mathcal{K}}}. \tag{17}$$

The corresponding projectors are denoted by $E_\phi^{m_i}(r)$, $E_\pi^{m_i}(r)$, $\underline{E}_\phi(r)$, resp. $\underline{E}_\pi(r)$. Now we consider the real linear subspace $\mathcal{L}(\mathcal{O}_r)\subset\mathcal{K}$:

$$\mathcal{L}(\mathcal{O}_r) := (1+J)\mathcal{L}_\phi(\mathcal{O}_r) \oplus (1-J)\mathcal{L}_\pi(\mathcal{O}_r). \tag{18}$$

We define the local von Neumann algebras $\mathfrak{A}(\mathcal{O})$, for $\mathcal{O}$ as above, to be the von Neumann algebras generated by all Weyl operators located in $\mathcal{O}$:

$$\mathfrak{A}(\mathcal{O}_r) := \{W(F) | \quad F \in \mathcal{L}(\mathcal{O}_r)\}''. \tag{19}$$

Here the prime denotes the commutant. The local algebras for arbitrary bounded regions are defined by use of the translation operators and additivity:

$$\mathfrak{A}(\mathcal{O}) := \left(\bigcup_{x+\tilde{\mathcal{O}}\subset\mathcal{O}} \mathfrak{A}(x+\tilde{\mathcal{O}}) \right)''. \tag{20}$$

Here, $\tilde{\mathcal{O}}$ is a double cone of the shape as above. So, $\mathfrak{A}(\mathcal{O})$ is the smallest von Neumann algebra containing all translated algebras $\mathfrak{A}(x+\tilde{\mathcal{O}})$.

Before continuing we have to deal with the following rather subtle problem: The net of von Neumann algebras we have constructed so far complies with all of the assumptions made in the Introduction except for the norm continuity of the maps $x\mapsto\alpha_x(A)$. Now, one can obtain a net of C^*-algebras $\mathcal{O}\mapsto\mathcal{A}(\mathcal{O})$ fulfilling norm continuity by ''smearing out'' with test functions. The local algebras $\mathcal{A}(\mathcal{O})$ will be weakly dense in the algebras $\mathfrak{A}(\mathcal{O})$. Now, it is not *a priori* clear how

the phase space properties behave under this procedure. The following lemma shows that they do not change. Thus, we are allowed to work with the larger von Neumann algebras.

The phase space maps and the ϵ-contents for theory using the weakly dense subalgebras $\mathcal{A}(\mathcal{O})$ are denoted with a tilde.

Lemma 3.1: We have the following.

(i) The phase space map $\Theta_{\beta,\mathcal{O}}$ is p-nuclear, iff $\tilde{\Theta}_{\beta,\mathcal{O}}$ is p-nuclear and their nuclear p-norms coincide:

$$\| |\Theta_{\beta,\mathcal{O}}| \|_p = \| |\tilde{\Theta}_{\beta,\mathcal{O}}| \|_p . \tag{21}$$

(ii) For the corresponding ϵ-contents, the following chain of inequalities holds:

$$\tilde{N}_{\beta,\mathcal{O}}(\epsilon) \leqslant N_{\beta,\mathcal{O}}(\epsilon) \leqslant \tilde{N}_{\beta,\mathcal{O}}\left(\frac{\epsilon}{2}\right). \tag{22}$$

Proof: The proof of (i) is in analogy to the proof of Lemma 2.2. in Ref. 3. It can be found in Ref. 16.

(ii) follows by use of a 3ϵ-type argument from the Kaplansky density theorem and the definition of ϵ-content. ■

Our main result of this section is the following:

Theorem 3.1: *All scaling limit theories of the generalized free field with finite mass spectrum in $d \geqslant 3$ space–time dimensions fulfill the nuclearity condition.*

Proof: In $d=3,4$ space–time dimensions the theorem follows easily from Ref. 9: There it is proven that scaling limit of the theories in question is a generalized free field of mass zero with finite multiplicity. By Ref. 5 these theories fulfill the nuclearity condition.

In higher dimensions we use Theorem 2.1 to reduce the statement of the theorem to the following proposition:

Proposition 3.1: Let $\mathcal{O} \subset \mathcal{O}_r$ *be a double cone contained in a second one with a ball of radius r centered at 0 as a basis in the $t=0$-plane.*

Then, the following upper bounds hold for the nuclear p-norms of the phase space maps:

$$\|\Theta_{\beta,\mathcal{O}}\|_p \leqslant \begin{cases} \exp\left[\mathcal{C}(p,s) \left(\frac{r}{\beta}\right)^s \sum_{i \in I} e^{-(\beta/4)\, p m_i} \right], & \beta \leqslant r, \\ \exp\left[\mathcal{C}(p,s) \left(\frac{r}{\beta}\right)^{[(s-1)/2]\, p} \sum_{i \in I} e^{-(\beta/4)\, p m_i} \right], & \beta > r. \end{cases}$$

Remark: One easily sees that these upper bounds for $\lambda r, \lambda \beta$ diverge in the limit $\lambda \searrow 0$, if the mass spectrum is infinite.

Proof of the proposition: Analogously to the proof of the theorem in the Appendix of Ref. 10 and the proofs of Theorem 2.1 and Lemma 2.2 in Ref. 5 (see also Ref. 16, Lemma 4.2.1), we get

$$\| |\Theta_{\beta,\mathcal{O}}| \|_p \leqslant \exp\left\{ \frac{2}{p} \left(\sum_{n=1}^{\infty} \frac{1}{n} \left\| |\underline{E}_{\phi}(r) e^{-\beta \underline{\omega}}|^n \right\|_p^p + \sum_{n=1}^{\infty} \frac{1}{n} \left\| |\underline{E}_{\pi}(r) e^{-\beta \underline{\omega}}|^n \right\|_p^p \right) \right\}.$$

Now, we have the direct sum decomposition $\underline{E}_{\phi}(r) = \oplus_{i \in I} E_{\phi}^{m_i}(r)$, a corresponding one for $\underline{E}_{\pi}(r)$ and the following inequalities:

$$\| |\underline{E} e^{-\beta \underline{\omega}}|^r \|_1 \leqslant \| \underline{E} e^{-r \beta \underline{\omega}} \|_1, \quad \forall r \in \{1\} \cup \mathbb{R}^{\geqslant 2}, \tag{23}$$

$$\mathrm{Tr}(|A|^r) \leqslant \mathrm{Tr}(|A|^q), \quad \forall r \geqslant q, \|A\| \leqslant 1, \tag{24}$$

of which the first one is proven in Ref. 5, Lemma 2.2, while the second is immediate. Using these equations, we derive the following upper bound for the nuclear p-norm of $\Theta_{\beta,\mathcal{O}}$:

$$\|\|\Theta_{\beta,\mathcal{O}}\|\|_p \leqslant \exp\left\{ \frac{2}{p} \sum_{i\in I} \left[\left(\sum_{n=1}^{K} \frac{1}{n} \right) (\|E_\phi^{m_i}(r)e^{-\beta\omega_i}\|_p^p + \|E_\pi^{m_i}(r)e^{-\beta\omega_i}\|_p^p) \right.\right.$$
$$\left.\left. + \sum_{n=K+1}^{\infty} \frac{1}{n} (\|E_\phi^{m_i}(r)e^{-np\beta\omega_i}\|_1 + \|E_\pi^{m_i}(r)e^{-np\beta\omega_i}\|_1) \right] \right\}, \tag{25}$$

where K is the biggest natural number with $Kp<2$.

We only need to calculate the nuclear p-norms for $p=2/N$. Because of the formula above, it is sufficient to establish upper bounds for the trace norms of the operators $E_\phi^{m_i}(r)e^{-np\beta\omega_i}$ and $E_\pi^{m_i}(r)e^{-np\beta\omega_i}$. The basic idea is to decompose the above operators into N Hilbert–Schmidt operators, whose kernels can easily be estimated. We will describe this briefly for $E_\phi^{m_i}(r)e^{-np\beta\omega_i}$: Let $\chi\in\mathcal{D}(\mathbb{R}^s)$ be a test function, which is identical to 1 on $\mathbf{O}_1$ and set χ_r by $\chi_r(\mathbf{x}):=\chi(r^{-1}\mathbf{x})$. Denote by the same symbol the corresponding multiplication operator. Let us now define the following operators:

$$h_n^{m_i,r,\beta} := \omega_i^{1/2}(1+\lambda^2\omega_i^2)^{s(n-1)}\chi_r(1+\lambda^2\omega_i^2)^{-sn}\omega_i^{-1/2}, \tag{26}$$

$$k_n^{m_i,r,\beta} := \omega_i^{1/2}(1+\lambda^2\omega_i^2)^{s(n-1)}\chi_r\omega_i^{-1/2}e^{-\beta\omega_i}. \tag{27}$$

Now, set $\lambda:=\min\{r,\beta\}$. Using the identity $E_\phi^{m_i}(r)=E_\phi^{m_i}(r)\omega_i^{1/2}\chi_r\omega_i^{-1/2}$, we obtain the following decomposition for every $N\in\mathbb{N}$:

$$E_\phi^{m_i}(r)=E_\phi^{m_i}(r)h_1^{m_i,r,\beta}\cdots h_{N-1}^{m_i,r,\beta}k_N^{m_i,r,\beta}. \tag{28}$$

By an easy, but tedious, calculation, we obtain upper bounds for the p-trace-norms of $E_\phi^{m_i}(r)e^{-\beta\omega_i}$, where the constant C is independent of r,β and m_i:

$$\|E_\phi^{m_i}(r)e^{-\beta\omega_i}\|_p^p \leqslant \begin{cases} C\left(\dfrac{r}{\beta}\right)^s e^{-(\beta/4)pm_i}, & \beta\leqslant r, \\ C\left(\dfrac{r}{\beta}\right)^{[(s-1)/2]p} e^{-(\beta/4)pm_i}, & \beta>r. \end{cases} \tag{29}$$

Inserting this and a similar estimate for the trace norms of $E_\pi^{m_i}(r)e^{-\beta\omega_i}$ into Eq. (25), the claim follows. ■

IV. THE CASE OF AN INFINITE MASS SPECTRUM

In this section we will prove that the scaling limit theories violate the compactness criterion in the case of an infinite mass spectrum. For doing this we need lower bounds of the ϵ-content of the phase space maps. Since this investigation of lower bounds does not appear in the literature so far, our discussion will be more detailed in this part. Here is our final result:

Theorem 4.1: *Let $\mathfrak{A}$ be a generalized free scalar field in $d\geqslant 3$ space–time dimensions, having a discrete infinite mass spectrum, which fulfills the condition $\Sigma_{i\in\mathbb{N}}e^{-\beta m_i}<\infty$, for all $\beta>0$.*

Then none of its scaling limit theories fulfills the compactness criterion.

For the proof of this theorem we need some auxiliary results: First, let us fix our notation. Let $\chi\in\mathcal{D}(\mathbb{R}^s)$ be a test function with $\mathrm{Supp}(\chi)\subset\mathbf{O}_1$, which is identical to 1 on $\mathbf{O}_{1/2}$. Define χ_r by $\chi_r(\mathbf{x}):=\chi(r^{-1}\mathbf{x})$. We use the same notation for the corresponding multiplication operator. Now, let us set

$$K_{\phi,m_i}^{\beta}(r) := \omega_i^{1/2}\chi_r\omega_i^{-1}e^{-2\beta\omega_i}\chi_r\omega_i^{1/2}. \tag{30}$$

We can state a first auxiliary result:

Lemma 4.1: Keeping the definitions made above, the following estimate holds:

$$\liminf_{\lambda \searrow 0} \|K^{m_i}_{\phi,\lambda\beta}(\lambda r)\| \geqslant \|K^0_{\phi,\beta}(r)\|. \tag{31}$$

Proof: To obtain this, we first present the operators $K^{m_i}_{\phi,\lambda\beta}(\lambda r)$ as integral kernels in momentum space:

$$K^{m_i}_{\phi,\lambda\beta}(\lambda r) = \int d^s\mathbf{k} \frac{(|\mathbf{p}|^2+m_i^2)^{1/4}(|\mathbf{q}|^2+m_i^2)^{1/4}}{\sqrt{|\mathbf{k}|^2+m_i^2}} e^{-2\lambda\beta\sqrt{|\mathbf{k}|^2+m_i^2}} \times (\lambda r)^{2s}\tilde{\chi}((\lambda r)(\mathbf{p}-\mathbf{k}))\tilde{\chi}((\lambda r)(\mathbf{k}-\mathbf{q})). \tag{32}$$

Here the tilde denotes the Fourier transform. Now, let $f \in \mathcal{D}(\mathbb{R}^s)$ be an arbitrary test function with $\|f\|=1$. Then we define f_λ by $f_\lambda(\mathbf{x}) := \lambda^{-s/2} f(\lambda^{-1}\mathbf{x})$. This implies $\|f_\lambda\|=1$. Using the integral kernel presentation above and the self-adjointness of $K^{m_i}_{\phi,\lambda\beta}(\lambda r)$, we get

$$\|K^{m_i}_{\phi,\lambda\beta}(\lambda r)\| \geqslant \langle f_\lambda, K^{m_i}_{\phi,\lambda\beta}(\lambda r) f_\lambda\rangle = \langle f, K^{\lambda m_i}_{\phi,\beta}(r) f\rangle, \tag{33}$$

where the last equation follows by substitution. Now, there exists an integrable upper bound, uniform in the m_i. It is, up to a positive constant, given by

$$\frac{1}{1+|\mathbf{p}-\mathbf{k}|^{2s+2}} \frac{1}{1+|\mathbf{q}|^{s+1}} \left\{ \frac{\sqrt{|\mathbf{p}|}\sqrt{|\mathbf{q}|}}{|\mathbf{k}|} + \sqrt{\frac{|\mathbf{p}|}{|\mathbf{k}|}} + \sqrt{\frac{|\mathbf{q}|}{|\mathbf{k}|}} + 1 \right\} e^{-2\beta|\mathbf{k}|}. \tag{34}$$

Thus, applying Lebesgue's theorem, we can interchange the integral with the limit $\lambda \searrow 0$ to obtain

$$\liminf_{\lambda \searrow 0} \|K^{m_i}_{\phi,\lambda\beta}(\lambda r)\| \geqslant \lim_{\lambda \to 0} \langle f, K^{\lambda m_i}_{\phi,\beta}(r) f\rangle = \langle f, K^0_{\phi,\beta}(r) f\rangle. \tag{35}$$

Since $\mathcal{D}(\mathbb{R}^s)$ is dense in $L^2(\mathbb{R}^s,\mathbb{C})$ the lemma follows. ■

Before proving the main result of this section, we still need a lemma:

Lemma 4.2: There exists a constant C independent of r,β and the mass spectrum, such that the following estimate holds:

$$\underline{\omega}^{-1/2}\chi_r\underline{\omega}\chi_r\underline{\omega}^{-1/2} \leqslant C\underline{E}_\phi(r). \tag{36}$$

Proof: The inequality is obtained as follows:

Trivially, we have $\|\underline{\omega}^{-1/2}\chi_r\underline{\omega}\chi_r\underline{\omega}^{-1/2}\| = \sup_{i\in I}\|\omega_i^{-1/2}\chi_r\omega_i\chi_r\omega_i^{-1/2}\|$. We present $\omega_i^{-1/2}\chi_r\omega_i\chi_r\omega_i^{-1/2}$ as an integral kernel in momentum space:

$$\omega_i^{-1/2}\chi_r\omega_i\chi_r\omega_i^{-1/2} := (|\mathbf{p}|^2+m^2)^{-1/4} r^{2s} \int d^s\mathbf{k}\tilde{\chi}(r(\mathbf{p}-\mathbf{k})) \times (|\mathbf{k}|^2+m^2)^{1/2}\tilde{\chi}(r(\mathbf{k}-\mathbf{q}))(|\mathbf{q}|^2+m^2)^{-1/4}.$$

Now, we can indicate, after a long but straightforward calculation, an upper bound C for its norm, uniform in m_i and r. This is achieved by using the criterion of Schur (cf. Ref. 11), which we rephrase for convenience:

Let $I = I(\mathbf{p},\mathbf{q})$ be an integral kernel, such that the following estimates are finite:

$$N_1 := \sup_{\mathbf{p}\in\mathbb{R}^s} \int d^s\mathbf{q}\,|I(\mathbf{p},\mathbf{q})| < \infty,$$

$$N_2 := \sup_{\mathbf{q}\in\mathbb{R}^s} \int d^s\mathbf{p}\,|I(\mathbf{p},\mathbf{q})| < \infty.$$

Then, I defines a bounded operator and $\|I\| \leqslant \sqrt{N_1 N_2}$. ■

Proof of the theorem: We will prove this theorem using Proposition 2.1, by showing that $\liminf_{\lambda\searrow 0} N_{\lambda\beta,\lambda\mathcal{O}}(\epsilon) = \infty$, for some $\epsilon > 0$.

By the identity $|e^{-\beta\omega}\underline{E}_\phi(r)| = \oplus_{i\in\mathbb{N}}|e^{-\beta\omega_i}E_\phi^{m_i}(r)|$ we can find orthonormal eigenfunctions $F_{\phi,i}^{(\lambda)} \in \mathcal{L}_\phi(\mathcal{O}_{\lambda r})$, $i\in\mathbb{N}$, of $|e^{-\lambda\beta\omega}\underline{E}_\phi(\lambda r)|$ corresponding to the eigenvalues $\|e^{-\lambda\beta\omega_i}E_\phi^{m_i}(\lambda r)\|$. We define local operators $A_{\phi,i}^{(\lambda)} \in \mathfrak{A}(\lambda\mathcal{O})$, $\|A_{\phi,i}^{(\lambda)}\| = 1$:

$$A_{\phi,i}^{(\lambda)} := \frac{1}{1+e^{-1/2}}\left(W(F_{\phi,i}^{(\lambda)}) - e^{-1/2}1\right). \tag{37}$$

With these definitions, the following estimate holds, for $i \neq j$:

$$\begin{aligned}\|\Theta_{\lambda\beta,\lambda\mathcal{O}}(A_{\phi,i}^{(\lambda)} - A_{\phi,j}^{(\lambda)})\|^2 &= \frac{e^{-1}}{(1+e^{-1/2})^2}\left(\exp\{\|e^{-\lambda\beta\omega_i}E_\phi^{m_i}(\lambda r)\|^2\} + \exp\{\|e^{-\lambda\beta\omega_j}E_\phi^{m_j}(\lambda r)\|^2\} - 2\right)\\ &\geqslant \frac{e^{-1}}{(1+e^{-1/2})^2}\left(\|e^{-\lambda\beta\omega_i}E_\phi^{m_i}(\lambda r)\|^2 + \|e^{-\lambda\beta\omega_j}E_\phi^{m_j}(\lambda r)\|^2\right).\end{aligned} \tag{38}$$

Applying Lemma 4.2, we conclude with C independent of r,β and m_i:

$$\|e^{-\lambda\beta\omega_i}E_\phi^{m_i}(\lambda r)\|^2 = \|e^{-\lambda\beta\omega_i}E_\phi^{m_i}(\lambda r)e^{-\lambda\beta\omega_i}\| \geqslant C\|K_{\phi,\lambda\beta}^{m_i}(\lambda r)\|. \tag{39}$$

Combining the last two equations and Lemma 4.1, we get, for $i \neq j$,

$$\liminf_{\lambda\searrow 0} \|\Theta_{\lambda\beta,\lambda\mathcal{O}}(A_{\phi,i}^{(\lambda)} - A_{\phi,j}^{(\lambda)})\|^2 \geqslant C\|K_{\phi,\beta}^0(r)\|. \tag{40}$$

The constant C does not depend on r,β and i,j. Therefore the theorem follows. ■

ACKNOWLEDGMENT

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 7 JULY 2002

Conditions for the alignment of the principal null directions of two Weyl-like tensors

G. E. Sneddon[a)]
School of Mathematical and Physical Sciences, James Cook University, Townsville, 4811, Queensland, Australia

(Received 19 February 2002; accepted for publication 25 March 2002)

A possible means to classify the interaction between the Weyl and Ricci tensors is to look at the number of principal null directions that the Weyl and Plebanski tensors have in common. This paper presents algebraic conditions that can be used to determine this number without explicitly calculating the principal null directions themselves. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1483377]

I. INTRODUCTION

Over the past decade, considerable attention has been paid to understanding the invariants of the Riemann tensor and the relationships between them.[1–8] This renewed interest focused on the identities between the invariants and how they can be used to find information about the Riemann tensor. As a result of work by Sneddon[5–7] it is possible to write down a complete set of invariants for the Riemann tensor. Unfortunately, the number of elements required in a complete set is rather large and this limits the usefulness of such a set. Other workers[1,4] have sought to find a smaller set of invariants that is not necessarily complete, but which can be used to obtain information about all other invariants.

One reason for developing an understanding of these invariants is to enable a classification of the Riemann tensor that takes into account the interaction between the Weyl tensor and the Ricci tensor (the irreducible parts of the Riemann tensor). Most existing classifications classify each of these tensors separately. An exception is the work by Haddow,[3] who looked at the particular cases of Einstein–Maxwell fields and perfect fluids.

In Sec. II the main features of the existing classifications of the Weyl tensor and Ricci tensor are summarized. It is argued that in the first instance a classification of the interaction should be based on the principal spinors of the Weyl spinor Ψ and the Plebanski spinor L. In Sec. III the condition for Ψ and L to have at least one principal null direction (PND) in common is presented. This is essentially a condition on the scalar invariants of the Riemann tensor. In Sec. IV conditions for Ψ and L to have at least two PNDs in common are given. It is shown that these conditions can be expressed as a rotor equation, $X_{ABC}=0$. Each of the components of X can be expressed in terms of the NP components of Ψ and L, but the covariant expression for X in terms of Ψ and L is not determined at this stage. Similarly, Sec. V gives conditions for Ψ and L to have at least three PNDs in common. Also in this section, conditions for the spinors to have four PNDs in common are given. While this is really a trivial case (since then $\Psi \propto L$) it does lead to a means to find covariant expressions for the previous conditions in terms of Ψ and L. These conditions are presented in Sec. VI.

Most of the conditions were obtained using a numerical procedure rather than index manipulations. They were all checked subsequently by assigning symbolic values to the components of Ψ and L and evaluating the expressions using a computer algebra package.

Although the properties being investigated relate to principal spinors, in most instances the conditions are expressed in the language of self-dual bivectors or rotors. The main reason for this is that the smaller number of indices needed for these quantities usually leads to more compact

a)Electronic mail: Graeme.Sneddon@jcu.edu.au

expressions. On some occasions it is helpful to refer to both forms (almost interchangeably). Thus $A,B,\ldots$ will be used for rotor indices and will take values from 1 to 3. Spinor indices will be represented by $\mu,\nu,...$ and will take values 0 and 1. Finally, $k,l,\ldots$ will represent tensor indices.

II. PRELIMINARIES

The classification of the Riemann tensor proceeds by first separating the tensor into its irreducible parts, i.e.,

$$R_{klmn}=C_{klmn}+E_{klmn}+\tfrac{1}{6}g_{k[m}g_{n]l}R,$$

where C_{klmn} is the Weyl tensor, $E_{klmn}=2g_{[k[m}S_{n]l]}$ where S_{kl} is the trace-free Ricci tensor, and R is the trace of the Ricci tensor. Each of C_{klmn} and E_{klmn} (or S_{kl}) can be classified separately. There are several approaches to the classifications of these tensors. These have been described by Plebanski,[9] Kramer, Stephani and Herlt,[10] Hall,[11] Penrose and Rindler,[12] and Joly and MacCallum[13] (among others). The Weyl tensor can be classified according to the solutions of the eigenvalue equation $C^{kl}{}_{mn}V^{mn}=\lambda V^{kl}$ where V^{kl} is a bivector. Similarly, the trace free Ricci tensor can be classified by the solutions of the equation $E^{kl}{}_{mn}V^{mn}=\gamma V^{kl}$ or of $S^{k}{}_{l}v^{l}=\gamma v^{k}$.

Alternatively, the classification can be carried out on the spinor equivalents of these tensors. In the case of the Weyl tensor, the spinor equivalent is $\Psi_{\mu\nu\rho\sigma}$ which can be expressed in terms of its principal spinors by $\Psi_{\mu\nu\rho\sigma}=\alpha_{(\mu}\beta_{\nu}\gamma_{\rho}\delta_{\sigma)}$. The classification is according to the coincidences of the principal spinors and gives the same results as the approach in terms of eigenbivectors. Both approaches lead to the Petrov classification of the Weyl tensor.

The spinor equivalent of E_{klmn} is $\Phi_{\mu\nu\dot{\rho}\dot{\sigma}}$. The dotted indices appear because E_{klmn} is the anti-self-dual part of the Riemann tensor. This means that, unlike Ψ, the decomposition of Φ into principal spinors is not possible. Instead the classification can be based on the solutions of the eigenvalue equation $\Phi^{\mu\nu}{}_{\dot{\rho}\dot{\sigma}}\overline{\chi}^{\dot{\rho}\dot{\sigma}}=\gamma\chi^{\mu\nu}$, where the eigenspinor $\chi^{\mu\nu}$ can be scaled so that γ will be real. Again this gives essentially the same results as the direct classification of either E_{klmn} or S_{kl}. These approaches lead to the Plebanski classification or equivalently, a classification according to the Segré type of the Ricci tensor.

The classification of $\Phi_{\mu\nu\dot{\rho}\dot{\sigma}}$ can also be carried out according to the locus ω of complex null vectors $z^{k}\leftrightarrow\xi^{\mu}\eta^{\dot{\nu}}$ where the function

$$\Omega(\xi,\eta)=\Phi_{\mu\nu\dot{\rho}\dot{\sigma}}\xi^{\mu}\xi^{\nu}\eta^{\dot{\rho}}\eta^{\dot{\sigma}}$$

vanishes.[12] The resulting classification, together with the separation into various categories, is a refinement of the Plebanski classification.

The classification of these tensors can also be expressed in the language of complex self-dual bivectors (or rotors).[14] This is the notation that was used by Sneddon[5–7] to describe the relationships between the invariants of the Riemann tensor. A brief description of this notation is given in Ref. 5, but the main feature is that pairs of symmetric spinor indices are replaced by a single rotor index which can take values from 1 to 3. Thus $\Psi_{\mu\nu\rho\sigma}\rightarrow\Psi_{AB}$ and $\Phi_{\mu\nu\dot{\rho}\dot{\sigma}}\rightarrow\Gamma_{A\dot{B}}$, where Ψ_{AB} is symmetric and trace-free and $\Gamma_{A\dot{B}}$ is Hermitian. The metric in this space is denoted by α_{AB}. The symbols used are summarized in Table I. In this notation the relevant eigenvalue equations are

$$\Psi^{A}{}_{B}\phi^{B}=\lambda\phi^{B},\quad \Gamma^{A}{}_{\dot{B}}\overline{\chi}^{\dot{B}}=\gamma\chi^{A}.$$

One other classification scheme for the Ricci tensor is based on the Plebanski tensor

$$L_{klmn}=S_{[k[m}S_{n]l]}+g_{[k[m}S_{n]}{}^{p}S_{l]p}-\tfrac{1}{6}g_{k[m}g_{n]l}S_{pq}S^{pq}.$$

This tensor has the same symmetries as the Weyl tensor and it is trace-free. Its spinor equivalent (to within a factor) is given by $L_{\mu\nu\rho\sigma}=2\Phi_{(\mu\nu}{}^{\dot{\gamma}\dot{\delta}}\Phi_{\underline{\rho\sigma})\dot{\gamma}\dot{\delta}}$. In terms of rotors, $L_{\mu\nu\rho\sigma}$ is equivalent to L_{AB} which is the trace-free part of $K_{AB}=\Gamma_{A\dot{C}}\Gamma^{\dot{C}}{}_{B}$. It is clear that L_{AB} will have the same

TABLE I. The notation for the tensor, spinor, and rotor forms of the different entities.

	Weyl tensor	Ricci tensor	Plebanski tensor
Tensor form	C_{klmn}	S_{kl} $\downarrow$ E_{klmn}	L_{klmn}
Spinor form	$\Psi_{\mu\nu\rho\sigma}$	$\Phi_{\mu\nu\dot{\rho}\dot{\sigma}}$	$L_{\mu\nu\rho\sigma}$
Rotor form	Ψ_{AB}	$\Gamma_{A\dot{B}}$	$K_{AB}=\Gamma_{A\dot{C}}\overline{\Gamma^{C}}_{B}$ $\downarrow$ L_{AB}

symmetries as Ψ_{AB}. This means that the Petrov classification can be applied directly to the Plebanski tensor and $L_{\mu\nu\rho\sigma}$ can be expressed in terms of its principal spinors. Classifying the Ricci tensor according to the coincidences of these spinors gives rise to the Petrov–Plebanski (or PP) classification[9] of the Ricci tensor. As might be expected, the PP classification is not as fine as the Plebanski classification. Essentially, some of the detail available in Γ is lost when we take the square (and then remove the trace). However, provided $[K]$ (the trace of K) is still available, the only types that cannot be distinguished by the PP classification are the pairs

$$[11(1,1)] \text{ and } [(11)1,1], \quad [(11)(1,1)] \text{ and } [(11)2],$$

$$[1(11,1)] \text{ and } [(111),1], \quad [(111,1)] \text{ and } [(112)].$$

(See the table on page 1001 of Ref. 9.)

It should also be noted that the PP classification can be obtained from the eigenvalue equation for L (or K). The equation is $L^{A}{}_{B}\phi^{B}=\lambda\phi^{A}$. The relationship between the eigenbivectors ϕ^{A} (or their spinor equivalents) and the principal spinors of L has been given by Plebanski,[9] but it is not straightforward.

As noted by Penrose and Rindler (Ref. 12, p. 266), the separate classification of Ψ and Φ will not give the full story. There is still the interrelationship between the two parts to consider. In classifying this interrelationship, it is not essential that all possible information from the two entities be represented. An analogy might be with the classification of two matrices. Each matrix can be classified according to the nature of its eigenvalues and eigenvectors. The relationship between the matrices could then be classified according to the alignments of the two sets of eigenvectors. In that case the eigenvalues of the matrices would not affect the classification of the interrelationship.

There are two possibilities on which such a classification of Ψ and Φ might be based. These are the alignments of the eigenbivectors of Ψ and L and the coincidences between the principal spinors of Ψ and L. Given the nature of the relationship between the principal spinors and eigenbivectors, it is unlikely that the two approaches would be completely compatible. That is, neither could be seen as a refinement of the other. However, of the two approaches, it is the latter that is likely to result in a simpler classification scheme in the first instance. This is the approach taken by Haddow[3] for Einstein–Maxwell fields. In either case, it would be the properties of L, rather than Γ, that influence the classification. In other words, some of the information available in Γ would not influence the classification of the interaction between Ψ and Γ. Alternatively, the classification based on principal spinors could be viewed as asking how many of the principal spinors of $\Psi_{\mu\nu\rho\sigma}$ generate a family of complex null vectors that is tangent to (or touches) the curve ω formed from $\Phi_{\mu\nu\dot{\rho}\dot{\sigma}}$ (Ref. 12, p. 287).

With this in mind, the aim in the remainder of this paper is to find algebraic conditions for Ψ and L to have one, two, three, or four principal spinors in common.

III. THE CONDITION FOR ONE PND IN COMMON

The principal spinors (and hence the PNDs) of Ψ and L can most easily be obtained from the roots of the polynomials

$$P(z)=\Psi_0+4z\Psi_1+6z^2\Psi_2+4z^3\Psi_3+z^4\Psi_4,$$

$$Q(z)=L_0+4zL_1+6z^2L_2+4z^3L_3+z^4L_4,$$

respectively, where Ψ_i and L_i are the NP components of Ψ and L. Thus, the condition for one PND in common is just the condition that these two polynomials have a root in common. This condition is well known and is simply that the resultant of the two polynomials be zero. (See Cox, Little, and O'Shea,[15] for example.)

In our case, the quartic polynomials will have a root in common if and only if there are cubic polynomials, $A(z)$ and $B(z)$, such that

$$P(z)A(z)+Q(z)B(z)=0. \tag{1}$$

If the coefficients of $A(z)$ and $B(z)$ are $a_0\cdots a_3$ and $b_0\cdots b_3$, respectively, Eq. (1) can be expanded and the coefficients of the powers of z can be set equal to zero. This gives the following set of equations for the coefficients of $A(z)$ and $B(z)$:

$$\begin{pmatrix}
\Psi_0 & 0 & 0 & 0 & L_0 & 0 & 0 & 0\\
4\Psi_1 & \Psi_0 & 0 & 0 & 4L_1 & L_0 & 0 & 0\\
6\Psi_2 & 4\Psi_1 & \Psi_0 & 0 & 6L_2 & 4L_1 & L_0 & 0\\
4\Psi_3 & 6\Psi_2 & 4\Psi_1 & \Psi_0 & 4L_3 & 6L_2 & 4L_1 & L_0\\
\Psi_4 & 4\Psi_3 & 6\Psi_2 & 4\Psi_1 & L_4 & 4L_3 & 6L_2 & 4L_1\\
0 & \Psi_4 & 4\Psi_3 & 6\Psi_2 & 0 & L_4 & 4L_3 & 6L_2\\
0 & 0 & \Psi_4 & 4\Psi_3 & 0 & 0 & L_4 & 4L_3\\
0 & 0 & 0 & \Psi_4 & 0 & 0 & 0 & L_4
\end{pmatrix}
\begin{pmatrix} a_0\\ a_1\\ a_2\\ a_3\\ b_0\\ b_1\\ b_2\\ b_3 \end{pmatrix}
=\begin{pmatrix} 0\\ 0\\ 0\\ 0\\ 0\\ 0\\ 0\\ 0 \end{pmatrix}.$$

Since we need a nonzero solution, the determinant

$$R=\begin{vmatrix}
\Psi_0 & 0 & 0 & 0 & L_0 & 0 & 0 & 0\\
4\Psi_1 & \Psi_0 & 0 & 0 & 4L_1 & L_0 & 0 & 0\\
6\Psi_2 & 4\Psi_1 & \Psi_0 & 0 & 6L_2 & 4L_1 & L_0 & 0\\
4\Psi_3 & 6\Psi_2 & 4\Psi_1 & \Psi_0 & 4L_3 & 6L_2 & 4L_1 & L_0\\
\Psi_4 & 4\Psi_3 & 6\Psi_2 & 4\Psi_1 & L_4 & 4L_3 & 6L_2 & 4L_1\\
0 & \Psi_4 & 4\Psi_3 & 6\Psi_2 & 0 & L_4 & 4L_3 & 6L_2\\
0 & 0 & \Psi_4 & 4\Psi_3 & 0 & 0 & L_4 & 4L_3\\
0 & 0 & 0 & \Psi_4 & 0 & 0 & 0 & L_4
\end{vmatrix} \tag{2}$$

must be zero. This determinant is the resultant of $P(z)$ and $Q(z)$.

If the expression for R is expanded, there will be 219 terms, so this form will be quite cumbersome in the general case. Since the property of having a PND in common is an invariant property, it is to be expected that R can be written in terms of the invariants of Ψ and L. If so, this should provide a simpler expression than (2). Using a computer algebra package (in this case, MATHEMATICA) it is easy to show that R is invariant under a general Lorentz transformation as expected. For example, if $\{o^\mu,\iota^\mu\}$ forms a dyad for spin space then, under the transformation

$$o^\mu \to o^\mu + b\,\iota^\mu, \quad \iota^\mu \to \iota^\mu, \tag{3}$$

the components of Ψ undergo the transformation

$$\Psi_0 \to \Psi_0 + 4b\Psi_1 + 6b^2\Psi_2 + 4b^3\Psi_3 + b^4\Psi_4,$$

$$\Psi_1 \to \Psi_1 + 3b\Psi_2 + 3b^2\Psi_3 + b^3\Psi_4,$$

$$\Psi_2 \to \Psi_2 + 2b\Psi_3 + b^2\Psi_4,$$

$$\Psi_3 \to \Psi_3 + b\Psi_4,$$

$$\Psi_4 \to \Psi_4$$

and the components of L will change similarly. However, R is left unchanged by this transformation.

The method used to express R in terms of the invariants is the ''method of undetermined coefficients'' first used by Ouchterlony[16] and described in Ref. 7. To obtain the expression for R we start by writing down all products of invariants that have degree four in both Ψ and L. (It is sufficient to include only those invariants that belong to the complete set for Ψ and L given by Sneddon.[5]) Then R must be a linear combination of these terms. Equations for the coefficients of these terms can be found by giving random numerical values to the components of Ψ and L. These equations can be solved to give

$$\begin{aligned} R = &-48[\Psi^2L^2]^2 + 8[\Psi^2L^2][\Psi L]^2 - 32[\Psi L^2][\Psi^2 L][\Psi L] + 288\det(\Psi)\det(L)[\Psi L] \\ &- 6[\Psi^2][L^2][\Psi L]^2 - 96\det(\Psi)[\Psi L^2][L^2] - 96\det(L)[\Psi^2 L][\Psi^2] + [\Psi L]^4 \\ &+ 40[\Psi^2 L^2][\Psi^2][L^2] - 7[\Psi^2]^2[L^2]^2 + 32[L^2][\Psi^2 L]^2 + 32[\Psi^2][\Psi L^2]^2. \end{aligned} \tag{4}$$

(The notation is that $[\Psi^2 L^2]$ represents the trace of the matrix product $\Psi^2 L^2$, etc.) It can easily be confirmed that the right-hand side of this expression is equivalent to the determinant (2).

One disadvantage with this method is that it does not give any indication of the origin of this expression in terms of the components Ψ_{AB} and L_{AB} or the principal spinors of Ψ and L. In Sec. VI a covariant expression for R is obtained in terms of the components, but it is still unclear why this expression should imply that $\Psi_{\mu\nu\rho\sigma}$ and $L_{\mu\nu\rho\sigma}$ have a principal spinor in common. Presumably, if Ψ and L are each written as symmetrized products of their principal spinors, the expression for R will reduce to a product of all possible inner products of a principal spinor of Ψ with a principal spinor of L. If two such principal spinors are proportional to each other then their inner product will be zero and so R will be zero. On the other hand, if $R=0$, one of the inner products must be zero and so the corresponding spinors are proportional.

IV. THE CONDITIONS FOR TWO PNDS IN COMMON

The condition for two coincident PNDs is that there exist quadratics, $A(z)$ and $B(z)$, such that $P(z)A(z)+Q(z)B(z)=0$. (This will also include the case where the two common PNDs are actually equal.) In a similar fashion to the case for one PND in common, the equations for the coefficients of $A(z)$ and $B(z)$ will have a nonzero solution if the rank of the matrix

$$\begin{pmatrix} \Psi_0 & 0 & 0 & L_0 & 0 & 0 \\ 4\Psi_1 & \Psi_0 & 0 & 4L_1 & L_0 & 0 \\ 6\Psi_2 & 4\Psi_1 & \Psi_0 & 6L_2 & 4L_1 & L_0 \\ 4\Psi_3 & 6\Psi_2 & 4\Psi_1 & 4L_3 & 6L_2 & 4L_1 \\ \Psi_4 & 4\Psi_3 & 6\Psi_2 & L_4 & 4L_3 & 6L_2 \\ 0 & \Psi_4 & 4\Psi_3 & 0 & L_4 & 4L_3 \\ 0 & 0 & \Psi_4 & 0 & 0 & L_4 \end{pmatrix} \tag{5}$$

is less than or equal to 5. This means that the determinant of any 6×6 submatrix must be zero. While this gives seven separate conditions (one for each row that is to be removed) only two of these can be independent. The determinant of the submatrix with the $(7-i)$th row removed will be denoted by X_i.

Unlike the equation for one PND in common, the X_i are not invariant under a Lorentz transformation. This removes any hope of being able to write these conditions in terms of invariants. Instead, under the transformation (3) the X_i transform as

$$X_0 \to X_0 + 6bX_1 + 15b^2X_2 + 20b^3X_3 + 15b^4X_4 + 6b^5X_5 + b^6X_6,$$

$$X_1 \to X_1 + 5bX_2 + 10b^2X_3 + 10b^3X_4 + 5b^4X_5 + b^5X_6,$$

$$X_2 \to X_2 + 4bX_3 + 6b^2X_4 + 4b^3X_5 + b^4X_6,$$

$$X_3 \to X_3 + 3bX_4 + 3b^2X_5 + b^3X_6,$$

$$X_4 \to X_4 + 2bX_5 + b^2X_6,$$

$$X_5 \to X_5 + bX_6,$$

$$X_6 \to X_6.$$

This is precisely the transformation of the components of a six index, completely symmetric spinor $X_{\mu\nu\rho\sigma\gamma\delta}$. The corresponding rotor will be X_{ABC}, which is completely symmetric and trace-free.

In fact, X_{ABC} satisfies some other properties as well as being symmetric and trace-free. We have seen that only two of the conditions $X_i=0$ can be independent. The relations between these conditions can be found easily. For example, if the matrix (5) is augmented with the column $(\Psi_0,4\Psi_1,6\Psi_2,4\Psi_3,\Psi_4,0,0)^T$ the determinant of the resulting matrix is identically zero. Therefore,

$$\Psi_0X_6 + 4\Psi_1X_5 + 6\Psi_2X_4 + 4\Psi_3X_3 + \Psi_4X_2 \equiv 0. \tag{6}$$

Five similar identities can be found by augmenting (5) with $(0,\Psi_0,4\Psi_1,6\Psi_2,4\Psi_3,\Psi_4,0)^T$, $(0,0,\Psi_0,4\Psi_1,6\Psi_2,4\Psi_3,\Psi_4)^T$, and similar columns constructed from the components of L. In terms of rotors, these identities are

$$\Psi^{AB}X_{ABC} \equiv 0, \quad L^{AB}X_{ABC} \equiv 0.$$

There is still the task of writing X_{ABC} as a covariant expression in terms of Ψ_{AB} and L_{AB}. A sketch of one possible method for doing this is given at this stage. A different approach is used in Sec. IV, which leads to a simpler result. Each term in the expression for X_{ABC} must have three factors of Ψ_{AB} and three factors of L_{AB}. In order to get an odd number of indices the alternating tensor, e_{ABC}, must also appear in each term. Index contraction can be used to reduce the number of free indices to three. Terms of this type can have one of two possible forms. These are as follows.

TABLE II. The conditions for three coincident PNDs arranged as spinor components.

$U_{\mu\nu\rho\sigma\alpha\beta\gamma\delta}$	$V_{\mu\nu\rho\sigma}$	W
$U_0=D_{56}$		
$U_1=\frac{1}{2}D_{46}$		
$U_2=\frac{1}{14}(3D_{36}+5D_{45})$	$V_0=D_{36}-3D_{45}$	
$U_3=\frac{1}{14}(D_{26}+5D_{35})$	$V_1=\frac{1}{2}(D_{26}-2D_{35})$	
$U_4=\frac{1}{70}(D_{16}+15D_{25}+20D_{34})$	$V_2=\frac{1}{6}(D_{16}+D_{25}-8D_{34})$	$W=D_{16}-5D_{25}+10D_{34}$
$U_5=\frac{1}{14}(D_{15}+5D_{24})$	$V_3=\frac{1}{2}(D_{15}-2D_{24})$	
$U_6=\frac{1}{14}(3D_{14}+5D_{23})$	$V_4=D_{14}-3D_{23}$	
$U_7=\frac{1}{2}D_{13}$		
$U_8=D_{12}$		

(i) $se_{DEF}F^{D}{}_{(A}G^{E}{}_{B}H^{F}{}_{C)}$, where s is a scalar and F, G, and H are matrix products (all different) of Ψ and L. These matrix products can be chosen from the basis set of matrices, Eq. (3) of Sneddon.[6] It can further be shown that only terms with F equal to the identity matrix are needed.

(ii) $se_{DEF}F^{DE}G^{F}{}_{(A}H_{BC)}$ where s is a scalar, F is a skew-symmetric matrix, and H is a symmetric matrix. Again, G can be taken to be the identity.

There are a total of 62 such terms. Of these only 24 are irreducible. All other terms can be obtained from these. The method of undetermined coefficients can be used to find the coefficients of each of these terms in the expression for X_{ABC}. Unfortunately, the resulting expression gives little insight into why it should be zero if there are two PNDs in common.

V. THE CONDITIONS FOR THREE AND FOUR PNDS IN COMMON

The procedures of Secs. III and IV can be extended to the cases of three or four PNDs in common. If there are three PNDs in common the rank of the matrix

$$\begin{pmatrix} \Psi_0 & 0 & L_0 & 0 \\ 4\Psi_1 & \Psi_0 & 4L_1 & L_0 \\ 6\Psi_2 & 4\Psi_1 & 6L_2 & 4L_1 \\ 4\Psi_3 & 6\Psi_2 & 4L_3 & 6L_2 \\ \Psi_4 & 4\Psi_3 & L_4 & 4L_3 \\ 0 & \Psi_4 & 0 & L_4 \end{pmatrix} \tag{7}$$

is less than or equal to 3. Again, this means that the determinant of any 4×4 submatrix must be zero. It is clear that it cannot be a simple spinor involved on this occasion. In fact, these terms will separate into three different quantities, an eight index spinor, a four index spinor, and a scalar. These will be denoted by U, V, and W, respectively. If D_{ij} is the determinant of the submatrix obtained by removing the ith and jth rows, the components of U, V, and W are given in Table II. The terms in each of the first two columns transform as the components of a spinor under a Lorentz transformation.

The rotor equivalent of U will be a four index, completely symmetric, trace-free quantity. That of V will be a two index, completely symmetric, trace-free quantity. Again, there will be relationships connecting the conditions $U_{ABCD}=0$, $V_{AB}=0$, and $W=0$. Only three of these conditions can be independent. Also, each of these quantities will be expressible in terms of Ψ_{AB} and L_{AB}. This is not done at this stage, other than to note that the scalar W can be expressed as

$$W=24[\Psi^2L^2]-22[\Psi^2][L^2]+10[\Psi L]^2.$$

Finally, if there are four PNDs in common the rank of the matrix

$$\begin{pmatrix} \Psi_0 & L_0 \\ 4\Psi_1 & 4L_1 \\ 6\Psi_2 & 6L_2 \\ 4\Psi_3 & 4L_3 \\ \Psi_4 & L_4 \end{pmatrix} \tag{8}$$

is less than or equal to 1. The determinant of any 2×2 submatrix must be zero. This means that Ψ and L must be proportional to each other. This also follows immediately from the fact that there are four PNDs in common.

There are a total of ten conditions, not all independent. These can be arranged into a group of seven (that transform as the components of a six index spinor) and a group of three (that transform as the components of a two index spinor). The six index spinor will be equivalent to a three index rotor. The terms in the expression for this rotor must have one factor of Ψ_{AB}, one factor of L_{AB}, and one of e_{ABC}. Virtually the only quantity that meets these requirements and is symmetric is

$$Y_{ABC}=e_{DE(A}\Psi^{D}{}_{B}L^{E}{}_{C)}. \tag{9}$$

The trace-free part of this rotor gives the seven conditions that transform as a six index spinor. The trace of Y_{ABC} is $Y_A=Y_{AB}{}^{B}$. The remaining three conditions are given by $Y_A=0$. All ten conditions can be deduced from the single equation

$$Y_{ABC}=0.$$

These conditions also satisfy certain identities. An example of one such set of identities is

$$\Psi^{(A}{}_{D}Y^{BC)D}-\Psi^{(AB}Y^{C)}+\alpha^{(AB}\Psi^{C)}{}_{D}Y^{D}\equiv 0.$$

(This equation has been obtained using computer algebra rather than index manipulation.)

It turns out that Y_{ABC} also plays an important role in the expression of the conditions for one, two, and three PNDs in common. These expressions are obtained in Sec. VI.

The spinor form of rotors such as Y_{ABC}, that contain the alternating tensor, is not immediately apparent. However, because of the central role played by Y_{ABC} it is important to note its spinor equivalent. The spinor equivalent of $e_{DEA}\psi^{D}\phi^{E}$ is obtained in the Appendix. It follows that if the indices of Y_{ABC} correspond to spinor indices according to $A\leftrightarrow\mu\nu$, $B\leftrightarrow\rho\sigma$, and $C\leftrightarrow\gamma\delta$, then

$$e_{DEA}\Psi^{D}{}_{B}L^{E}{}_{C}\leftrightarrow 2\Psi_{\alpha\rho\sigma(\mu}L^{\alpha}{}_{\nu)\gamma\delta}.$$

Y_{ABC} will correspond to that part of this spinor that is symmetric under the interchange of any of the index pairs $\mu\nu$, $\rho\sigma$, and $\gamma\delta$. Note that this spinor will not be completely symmetric. Instead, the symmetric spinor $2\Psi_{\alpha(\rho\sigma\mu}L^{\alpha}{}_{\nu\gamma\delta)}$ will correspond to the trace-free part of Y which is $Y_{ABC}-\frac{3}{5}\alpha_{(AB}Y_{C)}$.

VI. COVARIANT EXPRESSIONS FOR THE CONDITIONS

The method used to obtain the conditions for coincident PNDs gives no insight into how they can be written in terms of covariant expressions. In the case of four coincidences though, it was possible to deduce that the conditions could be expressed as $Y^{ABC}=0$. It turns out that all of the conditions can be expressed in terms of Y^{ABC}.

Conditions with a certain degree in Ψ and L can be obtained by first writing down all possible combinations of Y^{ABC} that have that degree and the required number of free indices and the required symmetries. The method of undetermined coefficients can then be used to determine which linear combination of these will give the required condition. In the process, it is shown that Y^{ABC} also satisfies certain identities. These are noted along the way. Throughout, the rotor expression of the condition is given rather than the spinor form.

A. Conditions for three coincident PNDs

These conditions are all quadratic in Y. We look at the scalar W first. The only possible quadratic terms are $Y^{ABC}Y_{ABC}$ and $Y^{A}Y_{A}$. We find that

$$-\tfrac{1}{72}W=\widetilde{W}=Y^{ABC}Y_{ABC}+Y^{A}Y_{A}. \tag{10}$$

The possible quadratic two index quantities are $Y^{ABC}Y_{C}$, $Y^{ACD}Y^{B}{}_{CD}$, $Y^{A}Y^{B}$ and terms involving the metric. The components of V come from the trace-free part of $Y^{ABC}Y_{C}$. In fact,

$$\tfrac{1}{144}V^{AB}=\widetilde{V}^{AB}=Y^{ABC}Y_{C}-\tfrac{1}{3}\alpha^{AB}Y^{C}Y_{C}. \tag{11}$$

Equivalent expressions for V^{AB} can be found by using the identity

$$2Y^{ABC}Y_{C}-Y^{ACD}Y^{B}{}_{CD}+Y^{A}Y^{B}=\tfrac{1}{3}\alpha^{AB}(3Y^{C}Y_{C}-Y^{CDE}Y_{CDE}). \tag{12}$$

The four index, quadratic terms that can be formed are $Y^{E(AB}Y_{E}{}^{CD)}$, $Y^{(ABC}Y^{D)}$, and terms involving the metric. U^{ABCD} is proportional to the trace-free part of $-3Y^{E(AB}Y_{E}{}^{CD)}+4Y^{(ABC}Y^{D)}$. We have

$$\begin{aligned}\tfrac{1}{12}U^{ABCD}=\widetilde{U}^{ABCD}=&-3Y^{E(AB}Y_{E}{}^{CD)}+4Y^{(ABC}Y^{D)}+\tfrac{18}{7}\alpha^{(AB}Y^{CD)E}Y_{E}\\&+\tfrac{1}{35}\alpha^{(AB}\alpha^{CD)}(14Y^{EFG}Y_{EFG}-51Y^{E}Y_{E}).\end{aligned} \tag{13}$$

Any metric with four coincident PNDs must also have at least three coincident PNDs. Therefore, if the condition for four coincidences is satisfied, the condition for three coincidences should be automatically satisfied. In this case, it follows trivially that if $Y^{ABC}=0$ then each of U^{ABCD}, V^{AB} and W will also be zero.

B. Conditions for two coincident PNDs

These conditions are cubic in Y and have three rotor indices. There are several terms that meet this requirement. They are

$$Y^{DE(A}Y^{B}{}_{EF}Y^{C)F}{}_{D},\quad Y^{DE(A}Y^{BC)F}Y_{DEF},\quad Y^{DE(A}Y^{BC)}{}_{E}Y_{D},\quad Y^{DE(A}Y^{B}{}_{DE}Y^{C)},$$

$$Y^{D(AB}Y^{C)}Y_{D},\quad Y^{DEF}Y_{DEF}Y^{ABC},\quad Y^{D}Y_{D}Y^{ABC},\quad Y^{A}Y^{B}Y^{C},$$

and terms involving the metric. First, there are three identities connecting these terms,

$$Y^{DE(A}Y^{B}{}_{DE}Y^{C)}-2Y^{D(AB}Y^{C)}Y_{D}-Y^{A}Y^{B}Y^{C}=0,$$

$$-3Y^{DE(A}Y^{BC)F}Y_{DEF}+6Y^{DE(A}Y^{BC)}{}_{E}Y_{D}+3Y^{D(AB}Y^{C)}Y_{D}+Y^{DEF}Y_{DEF}Y^{ABC}-3Y^{D}Y_{D}Y^{ABC}=0,$$

and

$$\begin{aligned}&-6Y^{DE(A}Y^{B}{}_{EF}Y^{C)F}{}_{D}+Y^{DEF}Y_{DEF}Y^{ABC}+6Y^{A}Y^{B}Y^{C}+3Y^{D}Y_{D}Y^{ABC}\\&-\tfrac{3}{5}(-6Y^{DEF}Y_{DE}{}^{G}Y^{(A}{}_{FG}+Y^{DEF}Y_{DEF}Y^{(A}+9Y^{D}Y_{D}Y^{(A})\alpha^{BC)}=0.\end{aligned}$$

The first two can be obtained from Eq. (12), by multiplying by Y^{F} and $Y^{FG}{}_{C}$, respectively. The third identity is new and was found using the method of undetermined coefficients. The traces of the first two identities also give identities with one free index. The trace of the third is identically zero.

The expression for X^{ABC} comes from the trace-free part of $12Y^{DE(A}Y^{BC)}{}_{E}Y_{D}-Y^{DEF}Y_{DEF}Y^{ABC}-5Y^{D}Y_{D}Y^{ABC}$. We find

$$-\tfrac{1}{144}X^{ABC}=\tilde{X}^{ABC}=12Y^{DE(A}Y^{BC)}{}_{E}Y_{D}-Y^{DEF}Y_{DEF}Y^{ABC}-5Y^{D}Y_{D}Y^{ABC}$$
$$-(12Y_{E}Y_{D}Y^{ED(A}+Y^{DEF}Y_{DEF}Y^{(A}-3Y^{D}Y_{D}Y^{(A)})\alpha^{BD)}. \tag{14}$$

Again, we should be able to deduce that $X^{ABC}=0$ from the conditions for two coincident PNDs. This follows from

$$X^{ABC}=-12V^{D(A}Y^{BC)}{}_{D}-2WY^{ABC}+\tfrac{3}{5}(4V^{D(A}Y_{D}+8V^{DE}Y^{(A}{}_{DE}+2WY^{(A)})\alpha^{BC)}.$$

C. Condition for one coincident PND

In this case, there are eight possible terms in the expression for R. They are

$$Y^{ABC}Y_{ADE}Y^{DF}{}_{B}Y^{EF}{}_{C},\quad Y^{ABC}Y_{ABD}Y^{EF}{}_{A}Y^{D}{}_{EF},\quad Y^{ABC}Y^{D}{}_{BC}Y^{E}{}_{AD}Y_{E},$$
$$Y^{ABC}Y^{D}{}_{AB}Y_{C}Y_{E},\quad Y^{ABC}Y_{A}Y_{B}Y_{C},\quad (Y^{ABC}Y_{ABC})^{2},\quad (Y^{A}Y_{A})^{2},\quad (Y^{A}Y_{A})(Y^{BCD}Y_{BCD}).$$

There are four identities connecting these invariants. These are

$$6Y^{ABC}Y_{ADE}Y^{DF}{}_{B}Y^{EF}{}_{C}-24Y^{ABC}Y_{A}Y_{B}Y_{C}-(Y^{ABC}Y_{ABC})^{2}$$
$$+9(Y^{A}Y_{A})^{2}-6(Y^{A}Y_{A})(Y^{BCD}Y_{BCD})=0,$$

$$3Y^{ABC}Y_{ABD}Y^{EF}{}_{A}Y^{D}{}_{EF}-36Y^{ABC}Y_{A}Y_{B}Y_{C}-(Y^{ABC}Y_{ABC})^{2}$$
$$+6(Y^{A}Y_{A})^{2}-4(Y^{A}Y_{A})(Y^{BCD}Y_{BCD})=0,$$

$$Y^{ABC}Y^{D}{}_{BC}Y^{E}{}_{AD}Y_{E}-5Y^{ABC}Y_{A}Y_{B}Y_{C}+(Y^{A}Y_{A})^{2}-(Y^{A}Y_{A})(Y^{BCD}Y_{BCD})=0,$$

and

$$3Y^{ABC}Y^{D}{}_{AB}Y_{C}Y_{E}-6Y^{ABC}Y_{A}Y_{B}Y_{C}-(Y^{A}Y_{A})(Y^{BCD}Y_{BCD})=0.$$

The expression for R can be written as

$$-\tfrac{1}{144}R=\tilde{R}=48Y^{ABC}Y_{A}Y_{B}Y_{C}-(Y^{ABC}Y_{ABC})^{2}-9(Y^{A}Y_{A})^{2}+6(Y^{A}Y_{A})(Y^{BCD}Y_{BCD}), \tag{15}$$

although several other forms are possible.

Finally, it must be possible to obtain the condition, $R=0$, from $X_{ABC}=0$. In fact, it can be shown that

$$R=Y^{ABC}X_{ABC}. \tag{16}$$

We can also show

$$Y^{ABC}X_{ABD}=\tfrac{1}{3}R\delta^{C}{}_{D}. \tag{17}$$

VII. CONCLUSION

We have obtained algebraic conditions for the Weyl tensor and Ricci tensor to have a given number of PNDs in common. Initially, these conditions were given in terms of the determinants of certain matrices. They were also written in a covariant form in terms of rotors or complex bivectors. For one PND in common, we need $R=0$, where R is given by Eq. (15). For two PNDs in common, we need $X_{ABC}=0$ [Eq. (14)]. For three PNDs in common, we need $W=0$, $V_{AB}=0$, and $U_{ABCD}=0$ [Eqs. (10), (11), and (13)]. Finally, if $Y_{ABC}=0$ [Eq. (9)] there will be four PNDs in common. All of these conditions are expressed in terms of Y_{ABC}.

Although it is of theoretical interest that these conditions can be expressed in terms of covariant quantities, these expressions are generally fairly complex. In practice it may be the case that the expressions for these conditions in terms of the determinants will be of more use.

These results mean that it is possible to classify the Riemann tensor according to the number of PNDs the Weyl and Plebanski tensors have in common without calculating the PNDs explicitly. Such a classification would be additional to the separate classifications of the Weyl tensor and the Ricci tensor. It would be a first attempt at classifying the interaction between these tensors.

APPENDIX: ROTOR EXPRESSIONS CONTAINING e_{ABC}

It will be sufficient to consider the spinor equivalent of $e_{DEA}\psi^D\phi^E$. The notation used is that of Buchdahl[14] and is summarized in Ref. 5. The connection between spinors and rotors is given by

$$\phi_A=\lambda_{A\mu\nu}\phi^{\mu\nu}, \quad \phi_{\mu\nu}=\tfrac{1}{2}\lambda_{A\mu\nu}\phi^A.$$

In addition, we need the identities $\lambda^{A\mu\nu}\lambda_{A\alpha\rho}=2\,\delta^{(\mu}{}_{(\alpha}\delta^{\nu)}{}_{\rho)}$ and

$$\lambda^{[D}{}_{\rho\sigma}\lambda^{E]\alpha\beta}=e^{DEC}\lambda_C{}^{(\alpha}{}_{(\rho}\delta^{\beta)}{}_{\sigma)}. \tag{A1}$$

[Equation (A1) is from p. 417 of Ref. 14. It was not recorded in Ref. 5.] Then,

$$e_{DEA}\psi^D\phi^E=e_{DEA}\lambda^D{}_{\rho\sigma}\lambda^{E\alpha\beta}\psi^{\rho\sigma}\phi_{\alpha\beta}=e_{DEA}e^{DEC}\lambda_C{}^{(\alpha}{}_{(\rho}\delta^{\beta)}{}_{\sigma)}\psi^{\rho\sigma}\phi_{\alpha\beta}=2\lambda_{A\alpha\rho}\psi^\rho{}_\beta\phi^{\alpha\beta}.$$

The spinor equivalent is

$$\lambda^{A\mu\nu}\lambda_{A\alpha\rho}\psi^\rho{}_\beta\phi^{\alpha\beta}=2\,\delta^{(\mu}{}_{(\alpha}\delta^{\nu)}{}_{\rho)}\psi^\mu{}_\beta\phi^{\nu\beta}=2\,\psi^{(\mu}{}_\beta\phi^{\nu)\beta}.$$

(Received 22 December 2000; accepted for publication 28 March 2002)

A generic route is described for the modification of fractal basin boundaries in nonlinear systems by changing only the *shape* of a periodic (autonomous or non-autonomous) term in the dynamics equations. Two examples are used to illustrate the route: a non-invertible two-dimensional map, and a driven dissipative oscillator with a cubic potential that typically models a metastable system close to a fold. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1481546]

I. INTRODUCTION

The dynamics of generic physical systems is determined by their global structures such as strange attractors and the boundaries of basins of attraction. In particular, the existence of fractal basin boundaries (FBB)[1–8] has fundamental implications for the behavior since small uncertainties in initial conditions (or other system parameters) may lead to large uncertainties in the response of the system. Indeed, FBBs are of practical importance for the control of a wide class of chaotic systems such as coupled oscillator arrays. We here describe a generic route to control FBBs (i.e., to vary their fractal dimension) by solely varying the waveform of a periodic term in the dynamics equations.

To demonstrate the new technique in the simplest possible context, consider the following two-dimensional map:

$$\theta_{n+1}=\frac{4K(m)}{\pi}\theta_n \mod 2\pi, \tag{1a}$$

$$z_{n+1}=\lambda z_n+\mathrm{cn}\left[\frac{4K(m)}{\pi}\theta_n;m\right], \tag{1b}$$

where we assume $1<\lambda<2$, $0\leqslant\theta<2\pi$, $m\in[0,1[$, and where cn is the Jacobian elliptic function of parameter m and (real) period $4K(m)$, with $K(m)$ the complete elliptic integral of the first kind. When $m=0$, then $\mathrm{cn}[4K(m=0)\theta/\pi;m=0]=\cos(2\theta)$, i.e., we recover a map similar to that considered in Ref. 2. Increasing m makes the pulse given by $\mathrm{cn}[4K(m)\theta/\pi;m]$ progressively narrower. The Jacobian matrix of the map (1) has eigenvalues $4K(m)/\pi$ and λ, which are greater than 1 so that there can be no attractors with finite z. In fact, there exist only two attractors $-z=+\infty$ and $z=-\infty-$ and we wish to characterize the evolution of the fractality of their basin boundary, $z=f(\theta)$, as m varies over the range $[0,1[$. To find this boundary set, we note first that $\theta_n=[4K(m)/\pi]^n\theta_0 \mod (2\pi)$. The map (1) is two-to-one, i.e., given θ_{n+1}, it is not possible to find θ_n uniquely since there are two possible solutions of (1a), $\theta_n=\theta_{n+1}/[4K(m)/\pi]$ and $\theta_n=\pi^2/2K(m)+\theta_{n+1}/[4K(m)/\pi]$. However, we can select any z_n and find one orbit that ends at (z_N,θ_N), by using the above θ_n and taking $z_{n-1}=\lambda^{-1}z_n-\lambda^{-1}\mathrm{cn}\{[4K(m)/\pi]^n\theta_0;m\}$. For the given (z_N,θ_0) one finds that this orbit started at $z_0=\lambda^{-N}z_N-\Sigma_{i=1}^{N}\lambda^{-i}\mathrm{cn}\{[4K(m)/\pi]^i\theta_0;m\}$. The boundary between the two basins are those (z_0,θ_0) such that z_N is finite as $N\to\infty$, so these z and θ are related by

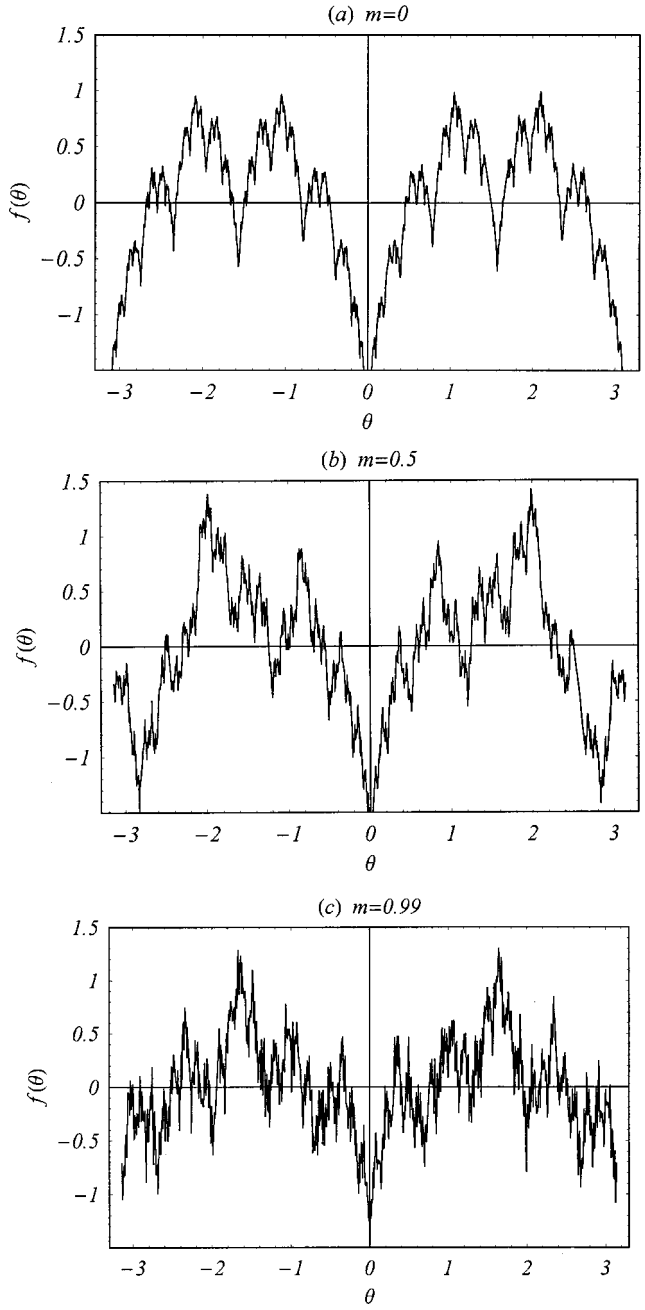

FIG. 1. Approximate plots of the fractal curve (2) (by computing the first 10^3 terms of the series) for $\lambda = 1.5$ and three values of the shape parameter m: (a) $m = 0$, (b) $m = 0.5$, and (c) $m = 0.99$.

$$z = -\sum_{n=1}^{\infty} \lambda^{-n} \mathrm{cn}\left\{\left[\frac{4K(m)}{\pi}\right]^n \theta; m\right\} \equiv f(\theta). \tag{2}$$

Since $\lambda > 1$ and $m \in [0,1[$, this sum converges absolutely and uniformly. One also has $df(\theta)/d\theta = \Sigma_{n=1}^{\infty}[4K(m)/\pi\lambda]^n \mathrm{sn}\{[4K(m)/\pi]^n\theta; m\}\mathrm{dn}\{[4K(m)/\pi]^n\theta; m\}$, where sn and dn are the Jacobian elliptic functions. The latter sum diverges $\forall m \in [0,1[$ because $\lambda < 2$. Hence $f(\theta)$ is nondifferentiable. Figure 1 shows approximate plots of the curve (2) for three values of the shape parameter $m = \{0, 0.5, 0.99\}$. It can be shown[9] that the box-counting dimension of the curve (2) is

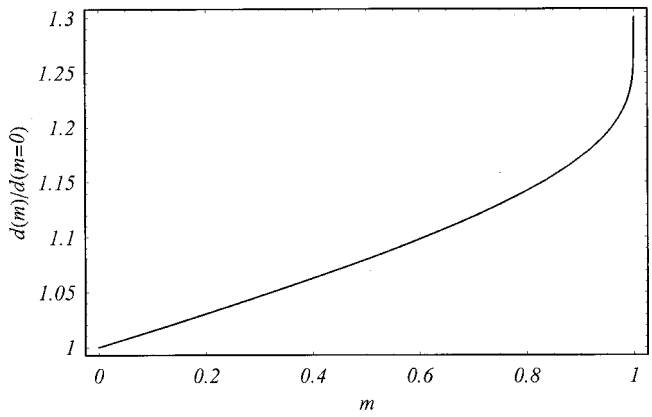

FIG. 2. Normalized fractal dimension of the curve (2), $d(m)/d(m=0)$ [cf. Eq. (3)], vs m for $\lambda=1.5$.

$$d=d(m)\equiv 2-\frac{\mathrm{Ln}\lambda}{\mathrm{Ln}[4K(m)/\pi]}. \tag{3}$$

For $m=0$, we recover the value $d(m=0)=2-(\mathrm{Ln}\lambda)(\mathrm{Ln}2)^{-1}$ reported, for a similar version of the trigonometric counterpart of the map (1), in Ref. 2, while we obtain $d(m\to 1)\to 2$ as the symmetric pulses modeled by the function $\mathrm{cn}[4K(m)\theta/\pi;m]$ become narrow. Figure 2 shows the normalized box-counting dimension $d(m)/d(m=0)$ versus m for $\lambda=\mathrm{const}$. One sees that the increase in the normalized box-counting dimension is especially noticeable for very narrow pulses ($m\lesssim 1$), which is a consequence of its dependence on $K(m)$. It is worth mentioning that similar results can be obtained[10] for other periodic functions instead of cn, i.e., the fractality of a basin boundary can be varied by reshaping a suitable periodic term in the map equations.

II. CONTROL OF CHAOTIC ESCAPE FROM A POTENTIAL WELL

To illustrate the same phenomenon in a physically motivated model equation, consider now the chaotic-escape problem of the dissipative driven oscillator

$$\ddot{x}=-x+\beta x^2-\delta\dot{x}+\gamma\,\mathrm{cn}(\omega t;m) \tag{4}$$

from the cubic potential well that typically models a metastable system close to a fold.[11,12] We assume that $\delta,\gamma\ll 1$ and $\omega=\omega(m)\equiv 4K(m)/T$, where T is the forcing period. This latter is fundamental in comparing the structural stability of the system when only the forcing shape is varied (i.e., by changing m in the range $[0,1[$). The forcing $\mathrm{cn}[4K(m)t/T;m]$ can induce escape in such a way that, before escape, chaotic transients of unpredictable duration—due to the fractal character of the basin boundary (of the attractor at infinity)—are usually observed. In order to characterize the evolution of such FBBs as the shape parameter is varied, we shall apply the Melnikov method (MM) to Eq. (4). The MM provides a criterion for the occurrence of homoclinic (and heteroclinic) chaos in a wide variety of dynamical systems. As is well known, its predictions for the appearance of strange attractors are both approximate and limited. However, it appears that the criterion for the homoclinic (and heteroclinic) orbits—accurately predicted by MM—in various systems[4,11] is coincident with the change from a smooth to an irregular FBB. This is the relevant result for our analysis of the evolution of the FBB as the shape parameter m is varied with the remaining parameters held constant. Since MM is today considered standard, we refer the interested reader to the abundant literature.[13–17]

The application of MM to Eq. (4) involves calculating the Melnikov function,

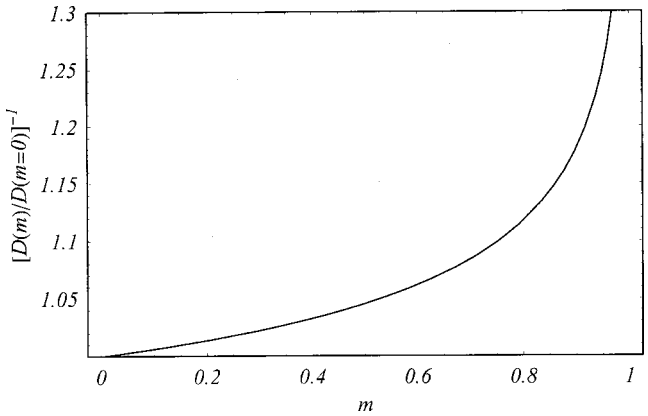

FIG. 3. Function $[D(m)/D(m=0)]^{-1}$ vs m in the range $m\in[0,m_{\text{threshold}}]$, where $D(m)\equiv U(\beta,m,T)-\delta/\gamma$ [cf. Eq. (9)], and $\delta=0.1$, $\gamma=0.08$, $\beta=1.0$, $T=2\pi/0.85$, and $m_{\text{threshold}}\approx 1$.

$$M(t_0)=\int_{-\infty}^{\infty}\left\{-\delta\dot{x}_0^2(t)+\gamma\dot{x}_0(t)\,\mathrm{cn}\left[\frac{4K(m)}{T}(t+t_0);m\right]\right\}dt, \tag{5}$$

where

$$x_0(t)=\frac{1}{\beta}\left(1-\frac{3}{1+\cosh(t)}\right),$$
$$\dot{x}_0(t)=\frac{3}{\beta}\frac{\sinh(t)}{[1+\cosh(t)]^2} \tag{6}$$

are the parametric equations of the separatrix of the underlying conservative system ($\delta=\gamma=0$).

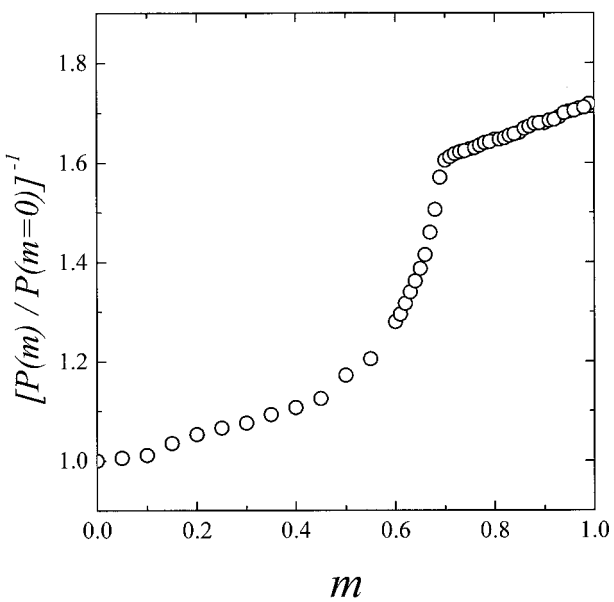

FIG. 4. Inverse normalized escape probability $[P(m)/P(m=0)]^{-1}$ vs m for the same parameters as in Fig. 3. To generate numerically the basins of attraction, we selected a grid of 300×300 starting points in the region of phase space $\{x(t=0)\in[-0.7,1.5],\dot{x}(t=0)\in[-1.0,0.7]\}$. From this grid of initial conditions, each integration was continued until either x exceeds 20, at which point the system is deemed to have escaped (i.e., to the attractor at infinity), or the maximum allowable number of cycles, here 30, is reached.

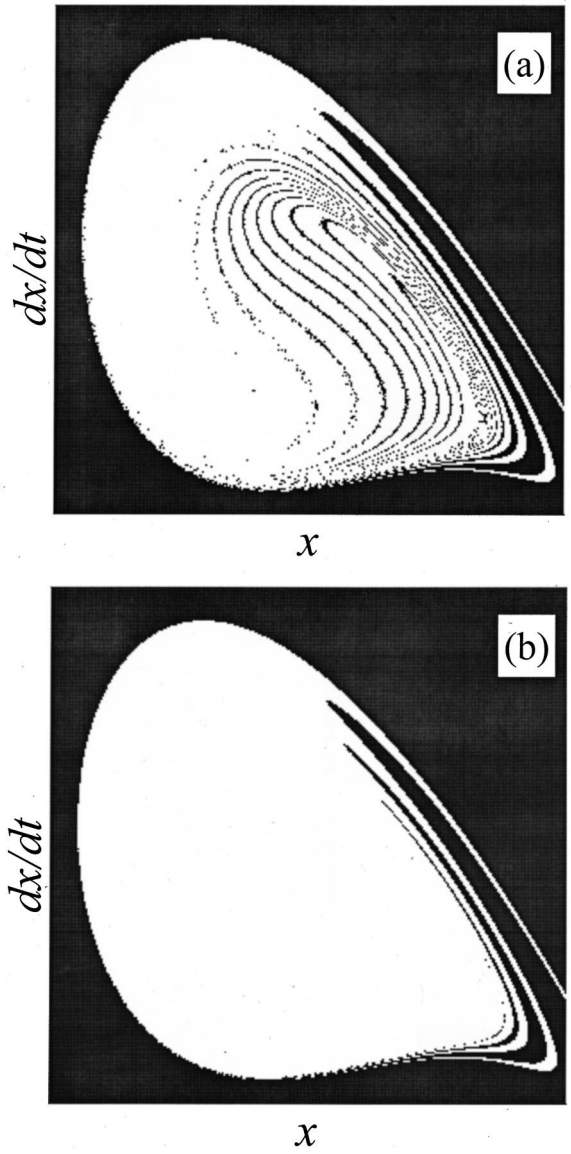

FIG. 5. Basin erosion of the system (4) for $\delta=0.1$, $\gamma=0.08$, $\beta=1.0$, and $T=2\pi/0.85$ in the window $-0.7<x<1.5$, $-1.0<\dot{x}<0.7$: (a) $m=0.68<m_c\approx 0.7$, (b) $m=0.72>m_c$.

After substituting Eq. (6) into Eq. (5), using the Fourier expansion of cn,[18] and computing the resulting integrals with the aid of standard integral tables,[19] Eq. (5) can be written as

$$M(t_0)=-\frac{6\delta}{5\beta^2}-\frac{96\pi^4\gamma}{\beta}\sum_{n=0}^{\infty}c_n(m)b_n(T)\sin\left[\frac{2\pi(2n+1)t_0}{T}\right], \tag{7}$$

with

$$\begin{aligned} c_n(m)&\equiv\frac{1}{\sqrt{m}K(m)}\operatorname{sech}\left[\left(n+\frac{1}{2}\right)\frac{\pi K(1-m)}{K(m)}\right],\\ b_n(T)&\equiv\frac{1}{T^2}\left(n+\frac{1}{2}\right)^2\operatorname{csch}\left[\left(n+\frac{1}{2}\right)\frac{4\pi^2}{T}\right]. \end{aligned} \tag{8}$$

It is straightforward to demonstrate that a homoclinic bifurcation is guaranteed if

$$\frac{\delta}{\gamma} < U(\beta,m,T) \equiv 80\beta\pi^4 \sum_{n=0}^{\infty} c_n(m) b_n(T), \tag{9}$$

where $U(\beta,m,T)$ is the threshold function. With δ,γ,β, and T constant, we can now define a "function distance" to fractality of the basin boundary, $D(m) \equiv U(\beta,m,T) - \delta/\gamma$, so that FBBs (do not) appear when $D(m) > 0 (D(m) \leqslant 0)$. Figure 3 shows a plot of the function $[D(m)/D(m=0)]^{-1}$ versus m for a set of parameters (δ,γ,β,T) such that a FBB already occurs for $m = m_{\text{threshold}}$, i.e., $D(m = m_{\text{threshold}}) > 0$, and *a fortiori* for $m \in [0, m_{\text{threshold}}]$ [cf. Eq. (9)]. It is worth noting that $D(m)$ provides a *qualitative* estimate for the variation of the fractality of the FBB (indeed, observe the similarity with Fig. 2). We can now discuss the connection between the function $D(m)/D(m=0)$ and the normalized escape probability $P(m)/P(m=0)$. We found two different regimes as m varies, as can be seen in Fig. 4. First, there is a *nonlinear* regime over the range $m \in [0, m_c]$, where the variation of the normalized escape probability is very similar to that of the function $D(m)/D(m=0)$ (compare Figs. 3 and 4). Second, there is a *linear* regime over the range $m \in]m_c, 1[$, where $P(m) = P(m=0)/(am+b)$, with a, b, m_c functions of the remaining system parameters. Note that the critical value m_c represents the threshold between having fractallike fingers protruding into the nonescaping basin [as in Fig. 5(a)] and their almost complete disappearance [as in Fig. 5(b)].

III. CONCLUSIONS

The analysis based on models (1) and (4) can be developed in two important ways.[10] First, the results extend to general nonautonomous systems with FBBs. Second, the manner of altering the geometrical shape of the periodic term can be chosen quite freely, which is fundamental in technological applications.

In sum, we have presented a generic way to reduce or increase the fractality of a FBB by only altering the waveform of a suitable periodic term. We connected it with the escape probability in a generic escape problem, where two distinct escape regimens were characterized.

(Received 7 March 2002; accepted for publication 20 March 2002)

Consider a classical Hamiltonian H in n dimensions consisting of a kinetic energy term plus a potential. If the associated Hamilton–Jacobi equation admits an orthogonal separation of variables, then it is possible to generate algorithmically a canonical basis $\mathbf{Q}$, $\mathbf{P}$ where $P_1=H, P_2,\ldots,P_n$ are the other second-order constants of the motion associated with the separable coordinates, and $\{Q_i,Q_j\}=\{P_i,P_j\}=0, \{Q_i,P_j\}=\delta_{ij}$. The $2n-1$ functions $Q_2,\ldots,Q_n,P_1,\ldots,P_n$ form a basis for the invariants. We show how to determine for exactly which spaces and potentials the invariant Q_j is a polynomial in the original momenta. We shed light on the general question of exactly when the Hamiltonian admits a constant of the motion that is polynomial in the momenta. For $n=2$ we go further and consider all cases where the Hamilton–Jacobi equation admits a second-order constant of the motion, not necessarily associated with orthogonal separable coordinates, or even separable coordinates at all. In each of these cases we construct an additional constant of the motion. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1484540]

I. INTRODUCTION

The quest for integrable systems has a long history. Basically, the question is, given a classical Hamiltonian $H=H(x,p)$ where $\mathbf{x}=(x_1,\ldots,x_n)$, $\mathbf{p}=(p_1,\ldots,p_n)$, how can one find all the solutions to the Poisson bracket condition

$$\{H,L\}=\sum_{i=1}^{n}\left(\frac{\partial H}{\partial p_i}\frac{\partial L}{\partial x_i}-\frac{\partial H}{\partial x_i}\frac{\partial L}{\partial p_i}\right)=0, \tag{1}$$

where $L=L(\mathbf{x},\mathbf{p})$.[1] There is no known comprehensive solution to this problem. However, if the associated Hamilton–Jacobi equation $H(\mathbf{x},\partial S/\partial\mathbf{x})=E$ is additively separable in the orthogonal variables $\mathbf{x}$, then a complete integral of the equation can be constructed by quadratures and one can find a basis of $2n-1$ functionally independent solutions to Eq. (1). Indeed there is an explicit canonical change of coordinates from the variables $\mathbf{x}$, $\mathbf{p}$ with $\{x_i,p_j\}=\delta_{ij}$ to variables $\mathbf{Q}$, $\mathbf{P}$ where $P_1=H, P_2,\ldots,P_n$ are the other second-order constants of the motion associated with the orthogo-

nal separable x-coordinates, and $\{Q_i,Q_j\}=\{P_i,P_j\}=0$, $\{Q_i,P_j\}=\delta_{ij}$. Thus the $2n-1$ functions $Q_2,\ldots,Q_n,P_1,\ldots,P_n$ form a basis for the invariants. Each invariant Q_j can be expressed as a sum of the form

$$Q_j=\sum_{k=1}^{n} M_k(x_k,\mathbf{P}), \tag{2}$$

see Ref. 1.

Numerous examples have been found through this approach, but important problems remain. Many of the known interesting dynamical systems have extra constants of the motion L which are *polynomial* in the canonical momenta $p_i, i=1,\ldots,n$. This often enables global statements to be made about the system in question, e.g., the existence of closed orbits. However, though many interesting results have been obtained, e.g., Refs. 2 and 3, an algorithmic way of generating all polynomial solutions to (1) is not known. In particular, from the x-based integrals in (2) it is difficult to tell if Q_j is a polynomial in the momenta p_i. In this article we adopt a p-based approach to the calculation of the invariants Q_j in which the term M_k take the form $M_k=M(p_k,\mathbf{P})$, and we can say in advance for exactly which separable metrics and potentials Q_j is a polynomial in the momenta. We give, in principle, a complete solution to this problem. Moreover, we show how to characterize each term M_k in (2) by the Poisson brackets $\{M_k,P_j\}$. [Note: Although the term $M_k(x_k,\mathbf{P})$ always exists, there are cases where it cannot be expressed as $M_k(p_k,\mathbf{P})$, i.e., as a function of p_k alone. These are exactly the cases where x_k is an *ignorable* variable, i.e., where the components of the metric tensor in the $\mathbf{x}$-coordinates do not depend on x_k and where, also, the potential V does not depend on x_k. However, these special cases where M_k and the invariant Q_i of which it is a component term always have polynomial dependence (after multiplication by a linear combination of second-order invariants) can be handled separately or by requiring that M_k depends on a variable with some x dependence, such as $M_k(r(x_k)p_k,\mathbf{P})$ treated below.]

Of course, the system could admit a polynomial invariant

$$L=R(\mathbf{P},Q_2,\ldots,Q_n)$$

such that $L,\mathbf{P}$ is functionally independent, even if $Q_2,\ldots,Q_n$ are not polynomials. It is a much more difficult problem to classify all such possibilities for polynomial L as functions of possibly nonpolynomial Q_j. We make some progress toward the solution of this problem, through the consideration of important examples. These questions of when a system with n second-order constants of the motion (generated by an orthogonal separation of variables) admits additional polynomial constants of the motion are closely related to the concept of superintegrability.[4–18]

For dimension $n=2$ in this article, we go beyond the formulation discussed above and consider all cases where the Hamilton–Jacobi equation admits a second-order constant of the motion, not necessarily associated with orthogonal separable coordinates, or even separable coordinates at all. In each of these cases we construct an additional constant of the motion.

II. CARTESIAN SYSTEMS IN TWO DIMENSIONS

Let us first consider two dimensional Euclidean space. In Cartesian coordinates the Hamiltonian H has the form

$$H=p_x^2+p_y^2+V(x,y).$$

If we have separation of variables in Cartesian coordinates the potential must take the form

$$V(x,y)=X(x)+Y(y). \tag{3}$$

We immediately observe that there are already two invariants arising from the separation, namely $L_1=p_x^2+X(x)$ and $L_2=p_y^2+Y(y)$. Our problem is to calculate a third invariant and determine when it can be chosen to be a polynomial in the canonical momenta. To do this we compute two functions $M(x,p_x)$ and $N(y,p_y)$ that satisfy the conditions

$$\{H,M\}=1, \quad \{H,N\}=1. \tag{4}$$

These equations can be solved in principle if we know the original functions X and Y. Indeed, if we write out the first of these conditions, we obtain

$$2p_x\frac{\partial M}{\partial x}-X'\frac{\partial M}{\partial p_x}=1.$$

This equation can be readily solved to give

$$M=-\int X'^{-1}dQ,$$

where $Q=p_x$ and $L_1=p_x^2+X$. [We consider $X'^{-1}=dx/dX$ to be a function of $X=L_1-Q^2$ to compute the integral. An arbitrary function $f(L_1,L_2)$ can be added to the integral, but this makes no difference since L_1,L_2 are invariants.] Once M and N have been determined, we see that $L_3=N-M$ must be an invariant. It is immediately clear that if $X=x^{1/p}$ where p is an integer, then M is a polynomial in p_x. As examples of this consider the following.

(1) $p=3$:

$$M=-3x^{2/3}p_x-4x^{1/3}p_x^3-\tfrac{8}{5}p_x^5.$$

(2) $p=4$:

$$M=-4x^{3/4}p_x-8x^{1/2}p_x^3-\tfrac{32}{5}x^{1/4}p_x^5-\tfrac{64}{35}p_x^7.$$

It follows from these two examples that the Hamiltonian

$$H=p_x^2+p_y^2+x^{1/3}+y^{1/4}$$

has, in addition to the obvious invariants

$$L_1=p_x^2+x^{1/3}, \quad L_2=p_y^2+y^{1/4},$$

the additional invariant

$$L_3=3x^{2/3}p_x+4x^{1/3}p_x^3+\tfrac{8}{5}p_x^5-4y^{3/4}p_y-8y^{1/2}p_y^3-\tfrac{32}{5}y^{1/4}p_y^5-\tfrac{64}{35}p_y^7. \tag{5}$$

From this observation we conclude that all potentials of the form

$$V=\alpha x^{1/p}+\beta y^{1/q} \tag{6}$$

have the superintegrability property with three functionally independent invariants which are polynomial in p_x and p_y. This includes the known examples corresponding to $p=1,2$. If $X(x)$ is determined by a polynomial relation of the form

$$\sum_{j=1}^{n} a_jX^j=x,$$

we can go even further. Then the function M is always a polynomial in the canonical momentum p_x. As an example consider

$$X(x)=2^{-1/3}[\{x+\sqrt{x^2+1}\}^{1/3}-\{x+\sqrt{x^2+1}\}^{-1/3}]. \tag{7}$$

The inverse function is

$$x=X^3+\frac{3}{2^{2/3}}X$$

and the corresponding function $M(x,p_x)$ is given by

$$-M(x,p_x)=\frac{8}{5}p_x^5+4Xp_x^3+3X^2p_x+\frac{3}{2^{2/3}}p_x.$$

It is clear that all that we have done applies also to potentials that separate in n dimensions, in Cartesian coordinates. There is only one further Cartesian case for which polynomial invariants can be generated. Let us consider the case when $X(x)=\omega_1^2x^2$. The corresponding function $M(x,p_x)$ is given by

$$M(x,p_x)=\frac{1}{4\omega_1}\arcsin\left(\frac{\omega_1^2x^2-p_x^2}{\omega_1^2x^2+p_x^2}\right).$$

If $Y(y)=\omega_2^2y^2$, this establishes that the Hamiltonian

$$H=p_x^2+p_y^2+\omega_1^2x^2+\omega_2^2y^2 \tag{8}$$

has the constant of motion

$$L_3=\frac{1}{4\omega_1}\arcsin\left(\frac{\omega_1^2x^2-p_x^2}{\omega_1^2x^2+p_x^2}\right)-\frac{1}{4\omega_2}\arcsin\left(\frac{\omega_2^2y^2-p_y^2}{\omega_2^2y^2+p_y^2}\right), \tag{9}$$

in addition to the constants $L_1=p_x^2+\omega_1^2x^2$ and $L_2=p_y^2+\omega_2^2y^2$. In general this invariant is not polynomial in the canonical momenta. However, if ω_1/ω_2 is a fraction p/q for integers p,q, then $\omega_1=ps,\omega_2=qs$ and $L_3'=\sin(4spqL_3)$ will be a rational invariant whose common denominator is a product of powers of L_1 and L_2. The numerator is then an additional polynomial invariant, e.g., consider $\omega_1=1,\omega_2=2$. Then

$$L_3'=\sin(8L_3)=\frac{L_1L_2^2-2(xp_y^2-4yp_xp_y-4xy^2)^2}{L_1L_2^2},$$

which indicates that $L_3''=xp_y^2-4yp_xp_y-4xy^2$ is an additional invariant. In general, $L_1^pL_2^q\sin(4spqL_3)$ will be a polynomial invariant, functionally independent of L_1 and L_2.

III. GENERAL TWO-DIMENSIONAL SEPARABLE SYSTEMS

If we extend this problem to the case of orthogonal separable coordinates in a general Riemannian space, we know that the Hamiltonian in a given set of coordinates with a separable potential has the form

$$H=L_1=\frac{p_x^2+p_y^2+v_1(x)+v_2(y)}{f_1(x)+f_2(y)}, \tag{10}$$

and, due to the separability, there is the invariant[19–21]

$$L_2=\frac{f_2(y)(p_x^2+v_1(x))-f_1(x)(p_y^2+v_2(y))}{f_1(x)+f_2(y)}.$$

We can implement the same ansatz as we have done previously by looking for a function $M(H,x,p_x)$ which satisfies

$$\{H,M\}=\frac{1}{f_1(x)+f_2(y)}. \tag{11}$$

The condition has the form

$$(-v_1'(x)+f_1'(x)H)\frac{\partial M}{\partial p_x}+2p_x\frac{\partial M}{\partial x}=1. \tag{12}$$

Assuming that $|v_1'|+|f_1'|>0$, we see that this equation has the solution

$$M(H,L_2,p_x)=\int U'^{-1}dQ,$$

where

$$Q=p_x,\quad L_2=v_1(x)-f_1(x)H+p_x^2,\quad U(x)=-v_1(x)+f_1(x)H+L_2.$$

[We consider $U'^{-1}=dx/dU$ to be a function of $U=Q^2$. An arbitrary function $f(L_1,L_2)$ can be added to the integral, but this makes no difference since $L_1=H$ and L_2 are invariants.] There is a similar condition for the function $N(H,L_2,y,p_y)$. The new invariant is $L_3=N-M$. It is straightforward to verify the condition

$$\{L_2,L_3\}=1. \tag{13}$$

Indeed, $\{L_2,M\}=f_2/(f_1+f_2)$, $\{L_2,N\}=-f_1/(f_1+f_2)$. This implies that the set L_1,L_2,L_3 is functionally independent.

Similarly, we can construct functions $M(H,x,p_x),N(H,y,p_y)$ that satisfy

$$\{H,M\}=\frac{f_1(x)}{f_1(x)+f_2(y)},\quad \{H,N\}=\frac{-f_2(y)}{f_1(x)+f_2(y)}. \tag{14}$$

Assuming that $|v_i'|+|f_i'|>0$ for $i=1,2$, we see that these equations have the solutions

$$M(H,L_2,p_x)=\int f_1(x)U_1'^{-1}dQ,\quad N(H,L_2,p_y)=-\int f_2(y)U_2'^{-1}dQ,$$

where

$$U_i=-v_i+f_iH+L_2.$$

Setting $L_4=N-M$, we see that L_4, not an invariant, satisfies

$$\{H,L_4\}=1,\quad \{L_2,L_4\}=0. \tag{15}$$

Let us illustrate what can happen with some examples.

(1) We choose parabolic coordinates in Euclidean space[22] $x'=1/2(\xi^2-\eta^2)$, $y'=\xi\eta$. First consider the parabolic-separable Hamiltonian

$$H=L_1=\frac{p_\xi^2+p_\eta^2+\xi}{\xi^2+\eta^2}. \tag{16}$$

We can immediately associate with this the extra invariant

$$L_2=\frac{\eta^2 p_\xi^2-\xi^2 p_\eta^2+\eta^2\xi}{\xi^2+\eta^2}.$$

If we look for our functions $M(\xi,p_\xi)$ and $N(\eta,p_\eta)$, as before we obtain

$$M(\xi,p_\xi)=\frac{1}{4\sqrt{H}}\ln\left(\frac{\sqrt{H}p_\xi+\frac{1}{2}-\xi H}{-\sqrt{H}p_\xi+\frac{1}{2}-\xi H}\right),$$

$$N(\eta,p_\eta)=\frac{1}{4\sqrt{H}}\ln\left(\frac{\sqrt{H}\eta+p_\eta}{\sqrt{H}\eta-p_\eta}\right).$$

If we now consider the constant $\cosh(4(M-N)\sqrt{H})$, we find that it can be written in the form

$$4\cosh(4(M-N)\sqrt{H})=\frac{L_3^2 H}{(1-4HL_2)L_2},$$

where

$$L_3=\frac{2\xi\eta}{\xi^2+\eta^2}(p_\xi^2+p_\eta^2)-2p_\xi p_\eta+\frac{\eta(\xi^2-\eta^2)}{\xi^2+\eta^2} \tag{17}$$

is an additional invariant quadratic in the canonical momenta. This is a special case of a more general example in Ref. 23.

(2) Consider the Hamiltonian in Cartesian coordinates

$$H=p_x^2+p_y^2+\frac{x}{\sqrt{x^2+y^2}}. \tag{18}$$

In parabolic coordinates this Hamiltonian has the form

$$H=L_1=\frac{p_\xi^2+p_\eta^2+\xi^2-\eta^2}{\xi^2+\eta^2}.$$

The second-order invariant associated with this separation is

$$L_2=\frac{\xi^2 p_\eta^2-\eta^2 p_\xi^2-2\xi^2\eta^2}{\xi^2+\eta^2}.$$

The additional invariant calculated by our method is given by

$$L_3=\frac{\operatorname{arccosh}([(H-1)\xi^2+p_\xi^2]/[(H-1)\xi^2-p_\xi^2])}{\sqrt{H-1}}+\frac{\operatorname{arccosh}([(H+1)\eta^2+p_\eta^2]/[(H+1)\eta^2-p_\eta^2])}{\sqrt{H+1}}, \tag{19}$$

which is clearly transcendental.

(3) If we consider the Hamiltonian

$$H=p_x^2+p_y^2+ib(x+iy), \tag{20}$$

then using the semihyperbolic coordinates[22]

$$x+iy=i(u+w), \quad x-iy=(-i/2)(u-w)^2$$

and applying our construction, we find

$$\frac{\exp(M-N)-i}{\exp(M-N)+i}=-i\frac{\sqrt{b-iX}}{\sqrt{b+iX}},$$

thus giving rise to the additional constant $X=p_x+ip_y$.

(4) Let us now look at an example of a potential where our construction yields elliptic integrals. We consider the potential $V=2x+\beta/y^2$. If we carry out the construction using parabolic coordinates $x=(\frac{1}{2})(\xi^2-\eta^2)$, $y=\xi\eta$, then the functions M and N are given by the integrals

$$M=\frac{1}{2}\int\frac{\xi d\xi}{\sqrt{-\xi^6+H\xi^4+L\xi^2-\beta}}, \quad N=\frac{1}{2}\int\frac{\eta d\eta}{\sqrt{\eta^6+H\eta^4+L\eta^2-\beta}},$$

where L is the quadratic constant associated with the separation of variables in parabolic coordinates. If we change variables according to $u=\xi^2$, $v=-\eta^2$, then both M and N are given by integrals of the form

$$I=\frac{1}{2}\int\frac{d\lambda}{\sqrt{(a-\lambda)(b-\lambda)(c-\lambda)}},$$

where $\lambda=u,v$ and

$$abc=-\beta, \quad L=ab+bc+ac, \quad H=a+b+c.$$

There are a variety of ways of evaluating elliptic integrals of this type. We recall that all our considerations are in the complex domain. As an example, we can choose to use the complex equivalent of the integral

$$\int_{-\infty}^{u}\frac{dx}{\sqrt{(a-x)(b-x)(c-x)}}=\frac{2}{\sqrt{a-c}}F(\alpha,p),$$

valid for $a>b>c\geqslant u$ and for which

$$\sqrt{\frac{a-c}{a-u}}=\sin\alpha=\mathrm{sn}(A,p), \quad p=\sqrt{\frac{a-b}{a-c}}.$$

Then if we calculate $\mathrm{sn}^2(\sqrt{a-c}(M-N),p)$ using the addition formulas for elliptic functions we obtain

$$\mathrm{sn}^2(\sqrt{a-c}(M-N),p)=\frac{c-a}{c+b+L_1},$$

where L_1 is the second quadratic constant associated with this super-integrable system. Because of the various ways of evaluating elliptic integrals, there are a number of ways of uncovering the presence of L_1.

In analogy with the constructions (5)–(7), we can find Riemannian spaces and potentials with polynomial invariants of arbitrarily high order. Set

$$x=P_n\left(\frac{U+A}{\alpha+\beta H}\right), \quad A=\delta+\phi H-L_2, \tag{21}$$

where P_n is a polynomial of order n and α,β,δ,ϕ are constants. Then there exists a function F_n, inverse to P_n, i.e., $F_n(P_n(y))=y$, such that

$$U=(\alpha+\beta H)F_n(x)-\delta-\phi H+L_2,$$

and $v_1(x)=-\alpha F_n(x)+\delta$, $f_1(x)=\beta F_n(x)-\phi$, where $(\alpha+\beta H)^n M(x,p_x)$ is a polynomial in the momenta. The Cartesian coordinate constructions (5)–(7) correspond to the special case $\beta=0$.

The solution of the equation (11) can be understood in a more general context. We have the dual relations

$$x=F(U-L_2,H), \quad U(x,H)=-v_1(x)+f_1(x)H+L_2, \quad U_x\neq 0. \tag{22}$$

(Since U and L_2 occur only as $U-L_2$, we will, without loss of generality, set $L_2=0$ in the theoretical developments to follow, and then replace U by $U-L_2$ in the examples.) Thus we have

$$1=F_U U_x, \quad F_U U_H+F_H=0.$$

The condition that $U(x,H)$ is linear in H, i.e., $U_{HH}=0$, leads to the following necessary and sufficient conditions that the function $x=F(U,H)$ correspond to an invariant M on a Riemannian manifold with potential:

$$F_{HH}F_U^2-2F_{UH}F_UF_H+F_{UU}F_H^2=0, \quad F_U\neq 0. \tag{23}$$

This equation admits an infinite dimensional conformal symmetry group. Indeed if $V=F(U,H)$ is a solution, then $G(V)$ is also a solution, for *any* nonconstant function G. Also, this group contains the subgroup of inhomogeneous affine symmetries: if $F(U,H)$ is a solution, then so is $F([a_{11}U+a_{12}H++a_{13}]/A,[a_{21}U+a_{22}H+a_{23}+a_{23}]/A)$, where a_{ij} are constants, $\det(a_{ij})\neq 0$ and

$$A=a_{31}U+a_{32}H++a_{33}.$$

Note that the function $V_1=(U+\delta+\phi H)/(\alpha+\beta H)$ satisfies (23), so any function of V_1 must also satisfy the requirement. This puts (21) in the proper context. A more general solution is $V_2=(U+\phi H+\delta)/(\alpha U+\beta H+\gamma)$, where again any function of V_2 also satisfies the requirement. Equation (23) also occurs in the theory of level sets, used in computational geometry and computer vision,[24] since it describes the family of functions F whose level sets are always straight lines in the (U,H) plane.

We have seen that the construction (21) always leads to a polynomial invariant L_3, up to multiplication by a polynomial in H and L_2. In fact these are the *only* polynomial invariants L_3 that can be constructed directly from the integration. This follows from the following theorem.

Theorem 1: *The function $F(U,H)$ with $F_U\neq 0$ is a solution of Eq. (21) with polynomial dependence on U if and only if it is of the form*

$$F(U,H)=P\left(\frac{U+\alpha H+\beta}{\gamma H+\delta}\right),$$

where P is a (nonconstant) polynomial and $\alpha,\beta,\gamma,\delta$ are constants with $|\gamma|^2+|\delta|^2>0$.

Proof: Let

$$F=a_0(H)U^N+a_1(H)U^{N-1}+\cdots+a_{N-1}(H)U+a_N(H)$$

be a solution of (21) with $N\geqslant 1$ and $a_0\neq 0$. Substituting this expression into (21) and equating the coefficient of U^{3N-2} on both sides of the resulting expression, we find the condition $a_0''a_0=((N+1)/N)a_0'^2$, so $a_0(H)=(\gamma H+\delta)^{-N}$. Now we make the change of variables $\tilde{U}=U/(\gamma H+\delta)$, $\tilde{H}=(\phi H+{}_\rho)/(\gamma H+\delta)$, where $\phi\delta-\gamma\rho\neq 0$. It follows that

$$F=\tilde{U}^N+\tilde{a}_1(\tilde{H})\tilde{U}^{N-1}+\cdots+\tilde{a}_{N-1}(\tilde{H})\tilde{U}+\tilde{a}_N(\tilde{H})$$

in the new coordinates, and F is a solution of

$$F_{\tilde{H}\tilde{H}}F_{\tilde{U}}^2-2F_{\tilde{U}\tilde{H}}F_{\tilde{U}}F_{\tilde{H}}+F_{\tilde{U}\tilde{U}}F_{\tilde{H}}^2=0. \tag{24}$$

Substituting the polynomial into (24) and equating coefficients of $\tilde{U}^{3N-3}$, we find $\tilde{a}_1''N^2=0$ or $\tilde{a}_1=\alpha_1\tilde{H}+\beta_1$. Using this information, we return to our original expression for the polynomial and make a new change of variables of the form

$$\tilde{U}=\frac{U+\alpha H+\beta}{\gamma H+\delta},\quad \tilde{H}=\frac{\chi H+\zeta}{\gamma H+\delta}, \tag{25}$$

where $\chi\delta-\gamma\zeta\neq 0$, and α, β are chosen such that the transformed coefficient of $\tilde{U}^{N-1}$ vanishes. In these variables

$$F=\tilde{U}^N+\tilde{a}_2(\tilde{H})\tilde{U}^{N-2}+\cdots+\tilde{a}_{N-1}(\tilde{H})\tilde{U}+\tilde{a}_N(\tilde{H}).$$

We substitute this expression into (24), and equating coefficients of $\tilde{U}^{3N-4}$ we find $\tilde{a}_2''=0$, so $\tilde{a}_2$ is a polynomial in $\tilde{H}$ of order $\leqslant 1$. Proceeding in this fashion to equate coefficients of $\tilde{U}^{3N-s}$ for $s=5,6,\ldots$ in order, we find that the first occurence of $\tilde{a}_k, k\geqslant 3$ in this sequence of equations takes the form $\tilde{a}_k''=p_k(\tilde{a}_2,\ldots,\tilde{a}_{k-1})$ where p_k is a polynomial of order 3 at most. It follows by induction on k that each $\tilde{a}_k$ is a polynomial in $\tilde{H}$.

At this point we have shown that F is a polynomial in both $\tilde{U}$ and in $\tilde{H}$. Let $\tilde{H}^M$ be the maximal power of $\tilde{H}$ that occurs in F. If $M=0$, we are done. Assume $M\geqslant 1$. If we use the argument of the first paragraph of this proof with $\tilde{U}$ and $\tilde{H}$ interchanged, we see that the coefficient of $\tilde{H}^M$ in F must take the form $\alpha_0/(\beta_1\tilde{U}+1)$ with $\alpha_0\neq 0$. Since F is a polynomial in $\tilde{U}$ we must have $\beta_1=0$.

Thus

$$F=\tilde{U}^N+\tilde{a}_2(\tilde{H})\tilde{U}^{N-2}+\cdots+\tilde{a}_{N-1}(\tilde{H})\tilde{U}+\alpha_0\tilde{H}^M.$$

Now substitute this expression into (24) and equate coefficients of $\tilde{U}^n\tilde{H}^m$ where $n+m$ is maximal. Suppose $N\geqslant M$. The highest power term in $F_{\tilde{H}\tilde{H}}F_{\tilde{U}}^2$ is $\alpha_N M(M-1)N^2\tilde{H}^{M-2}\tilde{U}^{2N-2}$. The highest power term in $F_{\tilde{U}\tilde{U}}F_{\tilde{H}}^2$ is $\alpha_N^2N(N-1)M^2\tilde{H}^{2M-2}\tilde{U}^{N-2}$, but this is of lower order. The highest power term in $2F_{\tilde{U}\tilde{H}}F_{\tilde{H}}F_{\tilde{U}}$ is $t=2\alpha_N a_{N_1,M_1}N_1M_1NM\tilde{U}^{N_1+N-2}\tilde{H}^{M_1+M-2}$ where a_{N_1,M_1} is the coefficient of $\tilde{U}^{N_1}\tilde{H}^{M_1}$ in F. Here $N_1<N, M_1<M$. If $N>N_1+M_1$, then the highest power term is the coefficient of $\tilde{H}^{M-2}\tilde{U}^{2N-2}$, so $M=1$. If $N\leqslant N_1+M_1$, then $t=0$, so $a_{N_1,M_1}=0$. Thus, the only possiblity is $M=1$, so

$$F=\tilde{U}^N+\alpha_2\tilde{U}^{N-2}+\cdots+\alpha_{N-1}\tilde{U}+\alpha_N\tilde{H}.$$

Substituting this expression into the differential equation we see that $F_{\tilde{U}\tilde{U}}=0$, or $F=\tilde{U}+\alpha_N\tilde{H}$. But this is impossible since $N=1$ and the coefficient of $\tilde{U}^{N-1}$ must be 0. Hence F depends only on $\tilde{U}$. There is a similar argument for the case $M>N$. **QED**

If we limit our search for potentials to a space in which $U_H=f_1(x)$ is prescribed, then the general conditions (23) are replaced by

$$F_H+f_1(F)F_U=0, \quad F_U\neq 0. \tag{26}$$

Equation (26) admits the complete integral

$$F(U,H,\alpha,\beta)=f_1^{-1}\left(\frac{U+\alpha}{H+\beta}\right),$$

where f_1^{-1} is the function inverse to f_1. From this one can use standard techniques (method of characteristics, envelopes of solutions) from the theory of quasilinear first-order partial differential equations to construct solutions of (26) that satisfy particular initial conditions or that depend on arbitrary functions (Ref. 25, Chap. II or Ref. 26, Sec. 88).

Note: Standard Hamilton–Jacobi theory gives essentially these same constants of the motion, but from a different viewpoint.[1] Our expression for L_3, for example, is

$$L_3=\int U_x'^{-1}dp_x-\int U_y'^{-1}dp_y=M-N,$$

where $U_x=-v_1(x)+f_1(x)H+L_2$, etc. Standard Hamilton–Jacobi theory gives

$$L_3=\frac{1}{2}\int\frac{dx}{\sqrt{-v_1+f_1H+L_2}}-\frac{1}{2}\int\frac{dy}{\sqrt{-v_2+f_2H-L_2}}=\tilde{M}-\tilde{N}.$$

In the standard theory $\tilde{M}=\tilde{M}(H,L_2,x)$, etc., whereas in our approach $M=M(H,L_2,p_x)$, etc. In both cases the condition (12) is satisfied. Our approach makes it easier in some cases to determine if polynomial invariants exist. It also points out the bracket relations between M,N and the operators L_j defining the separation, e.g., (11).

Examples abound of spaces for which these constructions apply. We illustrate this with a family of surfaces in Minkowski space: $ds^2=dz^2-dy^2-dx^2$. The surfaces involve a horispherical coordinate ξ and take the form

$$\mathbf{X}(t,\xi)=(x,y,z)=(2t\xi,g(t)+(\xi^2-1)t,g(t)+(\xi^2+1)t). \tag{27}$$

The metric on the surface is

$$ds^2=4[tg'(t)dt^2-t^2d\xi^2]=4t^2[d\rho^2-d\xi^2]=(f(\rho)+1)[d\rho^2-d\xi^2],$$

where $(d\rho/dt)^2=g'(t)/t^2$, and we can construct a polynomial invariant for the surface (and for an appropriate added potential) provided that the function $t^2=F(\rho)$ has a polynomial inverse function, i.e., $\rho=G(t^2)$ where G is a polynomial. Clearly $g'(t)=4t^4G'(t^2)^2$ and any polynomial G will determine a surface with a polynomial invariant. For example, choose $G(t^2)=\frac{1}{2}t^4+t^2$. Then we can take $g(t)=\frac{4}{9}t^9+\frac{8}{7}t^7+\frac{4}{5}t^5$ and $\rho(t)=\frac{1}{2}t^4+t^2$. The resulting M will be third-order polynomial in p_ξ and p_ρ. Similarly, we can determine a potential term $v(\rho)$ with $v'\neq 0$ such that N is a polynomial in p_ξ and p_ρ.

Rather than make either of the choices p_x or x for the independent variable in (12) we could choose some other function $w(x,p_x)$, adapted to the specific problem at hand. For example, let us take $w(x,p_x)=r'(x)p_x$ for some given function r, and require $M=M(H,L_2,w)$. Solving (12) in these variables we find

$$M=\int \frac{dr(x)}{dw^2}dw, \tag{28}$$

where

$$w^2=U=r'(x)^2p_x^2=r'(x)^2(-v_1+f_1H+L_2), \quad r(x)=F(U,H,L_2).$$

This approach will work even if v_1 and f_1 are constants; it is guaranteed to yield a polynomial invariant if we require

$$r=P_n\left(\frac{U+\alpha_1H+\alpha_2L_2+\alpha_3}{\alpha_4H+\alpha_5L_2+\alpha_6}\right), \tag{29}$$

where P_n is a polynomial of order n and the α_i are constants. Then there exists a function F_n, inverse to P_n, such that

$$U=(\alpha_4H+\alpha_5L_2+\alpha_6)F_n(r)-(\alpha_1H+\alpha_2L_2+\alpha_3)=r'^2(-v_1+f_1H+L_2).$$

Equating coefficients of L_2 we find the condition $r'(x)^2=\alpha_5F_n(r)-\alpha_2$ and we can solve for $r(x)$ by quadratures. Equating coefficients of H and the constant term, we obtain expressions for f_1 and v_1:

$$f_1(x)=\frac{\alpha_4F_n(r)-\alpha_1}{\alpha_5F_n(r)-\alpha_2}, \quad v_1(x)=\frac{\alpha_3-\alpha_6F_n(r)}{\alpha_5F_n(r)-\alpha_2}.$$

It follows that $(\alpha_4H+\alpha_5L_2+\alpha_6)^nM(rp_x)$ is a polynomial in the momenta.

IV. LIE FORM AND NONORTHOGONAL SEPARATION IN TWO DIMENSIONS

We know that if a Hamiltonian

$$H=\sum_{i,j=1}^{2} g^{ij}p_ip_j$$

admits a constant of the motion L that is quadratic in the momenta

$$L=\sum_{i,j=1}^{2} a^{ij}p_ip_j, \quad \{H,L\}=0, \tag{30}$$

and if the roots of the determinant $|a^{ij}-\lambda g^{ij}|$ are distinct, then the eigenforms define new (separable) variables ρ, μ and the Hamiltonian can be written in Liouville form

$$H=\frac{p_\rho^2+p_\mu^2}{f(\rho)+g(\mu)}.$$

However, it may be that the roots of this determinant are equal. In this case H cannot be put into Liouville form, but rather Lie form, which for a suitable choice of variables (nonseparable) is

$$H=\frac{p_xp_y}{x+B(y)}. \tag{31}$$

The associated quadratic constant of the motion is

$$L=p_x^2-2yH. \tag{32}$$

We now ask the question: When the roots of L are equal, how can we calculate the third invariant? We are interested in the the same question when a potential is added to the Hamiltonian. These questions can readily be answered. Indeed if we look for a function $N(H,L,y,p_y)$ that is in involution with H, we obtain the equation

$$(x+B(y))N_y+p_yB'(y)N_{p_y}=0. \tag{33}$$

If we solve (31) and (32) for x and p_x in terms of the variables H, L, y and p_y, we obtain

$$p_x=\sqrt{L+2yH}, \quad x=\frac{p_y}{H}\sqrt{L+2yH}-B(y).$$

The equation (33) for N then has the form

$$\frac{\sqrt{L+2yH}}{HB'(y)}N_y+N_{p_y}=0.$$

From this condition a second invariant can be readily obtained in the form

$$L'=H\int\frac{B'(y)}{\sqrt{L+2yH}}dy-p_y. \tag{34}$$

We now extend these considerations by considering the possibility of adding a potential. If we do this and have an extra quadratic constant, then H and L have the forms

$$H=\frac{p_xp_y+\frac{1}{2}K(y)}{x+B(y)}+\frac{1}{2}U'(y), \quad L=p_x^2-2yH+U(y). \tag{35}$$

Solving (35) for p_x and x gives

$$p_x=\sqrt{L-U(y)+2yH}, \quad x=\frac{p_y\sqrt{L-U(y)+2yH}+\frac{1}{2}K(y)}{H-\frac{1}{2}U'(y)}-B(y).$$

Then the equation for N has the form

$$\begin{aligned}2\sqrt{L-U(y)+2yH}(2H-U'(y))N_y+[-2U''(y)\sqrt{L-U(y)+2yH}p_y+B'(y)U'(y)^2\\ +4B'(y)H^2-U''(y)K(y)-4B'(y)U'(y)H+K'(y)U'(y)-2K'(y)H]N_{p_y}=0.\end{aligned} \tag{36}$$

This equation can, in principle, be solved directly. In fact, for suitable redefinition of the variables $y\to Y$, $p_y\to P_y$, Eq. (36) can be put in the form

$$N_Y+(P_Y+s(Y))N_{P_Y}=0 \tag{37}$$

that can be solved by the further transformation

$$P_{Y'}=P_Y+t(Y), \quad Y'=Y.$$

Then, provided that

$$t'(Y)-t(Y)+s(Y)=0,$$

(37) reduces to

$$N_{Y'}+P_{Y'}N_{P_{Y'}}=0.$$

From this we immediately deduce an extra constant of the motion of the form

$$L'=e^{Y'}/P_{Y'}. \tag{38}$$

The equation for $t(Y)$ has the solution

$$t(Y)=e^{Y}\int^{Y}e^{-u}s(u)du.$$

There is one remaining possibility for a quadratic constant of the motion (30) in two dimensions: the constant may be associated with *nonorthogonal* separation of variables. In two dimensions there is only one case: separation in light cone (null) coordinates.[27] For this case the Hamiltonian takes the form

$$H=p_zp_{\bar{z}}+f(\bar{z}),$$

and there is a Killing vector p_z, so p_z^2 is a second-order constant of the motion. In addition there is a quadratic constant

$$L=Mp_z+\frac{i}{2}\int\bar{z}\frac{df}{d\bar{z}}d\bar{z}.$$

Thus we have answered the following questions.

(1) If a Hamiltonian with potential admits a quadratic constant of the motion in two dimensions how does one calculate the third constant?
(2) A subset of problem 1 is when we require separation only and ask to calculate the third constant.

V. SYSTEMS IN THREE DIMENSIONS

Let us now look at how the orthogonal separation of variable considerations extend to three dimensions. If we have a general separable coordinate system in three dimensions, we could take the Hamiltonian to be[20,28,29]

$$H=L_1=\frac{g_2-g_3}{\Phi}(p_{x_1}^2+v_1(x_1))+\frac{g_3-g_1}{\Phi}(p_{x_2}^2+v_2(x_2))+\frac{g_1-g_2}{\Phi}(p_{x_3}^2+v_3(x_3)), \tag{39}$$

where $g_i=g_i(x_i), f_i=f(x_i)$ and Φ is the determinant of the Stäckel matrix

$$\begin{pmatrix}1 & f_1 & g_1\\ 1 & f_2 & g_2\\ 1 & f_3 & g_3\end{pmatrix}. \tag{40}$$

This automatically gives us two more invariants:

$$L_2=\frac{f_3-f_2}{\Phi}(p_{x_1}^2+v_1(x_1))+\frac{f_1-f_3}{\Phi}(p_{x_2}^2+v_2(x_2))+\frac{f_2-f_1}{\Phi}(p_{x_3}^2+v_3(x_3)), \tag{41}$$

$$L_3=\frac{f_2g_3-f_3g_2}{\Phi}(p_{x_1}^2+v_1(x_1))+\frac{f_3g_1-f_1g_3}{\Phi}(p_{x_2}^2+v_2(x_2))+\frac{f_1g_2-f_2g_1}{\Phi}(p_{x_3}^2+v_3(x_3)). \tag{42}$$

We need to find an additional two invariants, such that the five form a functionally independent set.

If we look for a function M_1 such that

$$\{H,M_1\}=\frac{g_2-g_3}{\Phi}, \tag{43}$$

then this function satisfies the equation

$$2p_{x_1}\partial_{x_1}M_1+[-v_1'(x_1)+f_1'H+g_1'L_2]\partial_{p_{x_1}}M_1=1, \tag{44}$$

which looks like the form we have been using in two dimensions. There are similar equations for the corresponding functions M_i for $i=2,3$. For $M_1(H,L_2,L_3,Q_1)$ with $Q_1=p_{x_1}$ this has the solution

$$M_1=\int U_1'^{-1}dQ_1,$$

where $U_1(x_1)=-v_1(x_1)+f_1H+g_1L_2+L_3$ and $L_3=v_1-f_1H-g_1L_2+p_{x_1}^2$. (Here, we consider $U_1'^{-1}=dx_1/dU_1$ to be a function of $U_1=Q_1^2$ to compute the integral. We also assume that $|v_1'|+|f_1'|+|g_1'|>0$.) The corresponding invariant that we can calculate from these three functions is $L_3'=M_1+M_2+M_3$. This is based on the obvious identity

$$(g_2-g_3)+(g_3-g_1)+(g_1-g_2)=0.$$

Note: As in the two dimensional case, the solution of the equation (44) can be understood in a more general context. We have the dual relations

$$x=F(U-L_3,H,L_2),\quad U(x,H,L_2)=-v_1(x)+f_1(x)H+g_1(x)L_2+L_3, \tag{45}$$

where $U_x\neq 0$. (Since U and L_3 occur only as $U-L_3$ we can, without loss of generality, set $L_3=0$ in the equations immediately following, and then replace U by $U-L_3$ in the examples.) Thus we have

$$1=F_UU_x,\quad F_UU_H+F_H=0,\quad F_UU_{L_2}+F_{L_2}=0.$$

The condition that $U(x,H,L_2)$ is linear in H and L_2, i.e., $U_{HH}=U_{L_2L_2}=U_{HL_2}=0$, leads to the following necessary and sufficient conditions that the function $x=F(U,H,L_2)$ correspond to an invariant M_1 on a Riemannian manifold with potential:

$$\begin{aligned}
&F_{HH}F_U^2-2F_{UH}F_UF_H+F_{UU}F_H^2=0,\quad F_U\neq 0,\\
&F_{UU}F_{L_2}^2-2F_{L_2U}F_{L_2}F_U+F_{L_2L_2}F_U^2=0,\\
&F_{L_2L_2}F_H^2-2F_{HL_2}F_HF_{L_2}+F_{HH}F_{L_2}^2=0.
\end{aligned} \tag{46}$$

These equations admit an infinite dimensional conformal symmetry group. Indeed, if $V=F(U,H,L_2)$ is a solution, then $G(V)$ is also a solution, for *any* nonconstant function G. Also, this group contains the subgroup of inhomogeneous affine symmetries: if $F(U,H,L_2)$ is a solution, then so is $F([a_{11}U+a_{12}H+a_{13}L_2+a_{14}]/A,[a_{21}U+a_{22}H+a_{23}L_2+a_{24}]/A,[a_{31}U+a_{32}H+a_{33}L_2+a_{24}]/A)$ where a_{ij} are constants, $\det(a_{ij})\neq 0$ and

$$A=a_{41}U+a_{42}H+a_{43}L_2+a_{44}.$$

As in the two dimensional case, the only polynomial functions F of U are of a very special form.

Theorem 2: *The function $F(U,H,L_2)$ with $F_U \neq 0$ is a solution of Eqs. (46) with polynomial dependence on U if and only if it is of the form*

$$F(U,H,L_2)=P\left(\frac{U+\alpha_1 H+\alpha_2 L_2+\beta}{\gamma_1 H+\gamma_2 L_2+\delta}\right),$$

where P is a (nonconstant) polynomial and $\alpha_i,\beta,\gamma_i,\delta$ are constants with $|\gamma_1|^2+|\gamma_2|^2+|\delta|^2>0$.

Proof: The proof is similar to that of Theorem 1. It follows from this theorem and the first two equations in (46) that

$$F=P^{(1)}(U^{(1)},L_2)=P^{(2)}(U^{(2)},H),$$

where the $P^{(i)}$ are polynomials of strict order N in their first arguments and

$$U^{(1)}=\frac{U+\alpha_1^{(1)}L_2H+\beta^{(1)}L_2}{\gamma_1^{(1)}L_2H+\delta^{(1)}L_2} \quad U^{(2)}=\frac{U+\alpha_1^{(2)}HL_2+\beta^{(2)}H}{\gamma_1^{(2)}HL_2+\delta^{(2)}H}.$$

Furthermore, the coefficients of the $N-1$-st power of their first arguments can be asumed to be zero. Comparing the coefficients of the highest power U^N of U in F, we see that this coefficient must be of the form

$$(\gamma_1 H+\gamma_2 L_2+\gamma_3 HL_2+\delta)^{-N},$$

where now the γ_i,δ are constants. Substituting this into the third equation in (46) and equating coefficients of U^{3N}, we see that $\gamma_3=0$.

Equating the coefficients of U^{N-1} in the $P^{(i)}$ we see that

$$U^{(1)}=U^{(2)}=\tilde{U}=\frac{U+\alpha_1 H+\alpha_2 L_2+\phi HL_2+\beta}{\gamma_1 H+\gamma_2 L_2+\delta},$$

where the coefficients are constants. Then, substituting this result into the third equation again and comparing coefficients of U^{3N-1} we see that $\phi=0$. At this point we have shown that $F=P(\tilde{U},H,L_2)$ where P is a polynomial of order exactly N in its first argument. The proof that P is independent of its second and third arguments follows exactly as in the last part of the proof of Theorem 1. **QED**

If we limit our search for potentials to a space in which $U_H=f_1(x),U_{L_2}=g_1(x)$ are prescribed, then the general conditions (46) are replaced by

$$F_H+f_1(F)F_U=0, \quad F_{L_2}+g_1(F)F_U=0, \quad F_U\neq 0. \tag{47}$$

From this one can use standard techniques (method of characteristics, envelopes of solutions) from the theory of systems of quasilinear first order partial differential equations to construct solutions of (47) that satisfy particular initial conditions or that depend on arbitrary functions.

The invariant $L_3'=M_1+M_2+M_3$ also commutes with L_2. Indeed, from the fact that

$$\partial_{x_1}L_2=\frac{f_3-f_2}{\Phi}(v_1'-f_1'H-g_1'L_2)$$

we can verify that (44) implies

$$\{L_2,M_1\}=\frac{f_3-f_2}{\Phi}. \tag{48}$$

The corresponding conditions are satisfied by M_2 and M_3. Then the fact that $\{L_2,L_3'\}=0$ is implied by the obvious identity

$$(f_3-f_2)+(f_1-f_3)+(f_2-f_1)=0.$$

Finally, from the fact that

$$\partial_{x_1}L_3=\frac{f_2g_3-f_3g_2}{\Phi}(v_1'-f_1'H-g_1'L_2)$$

we can verify that (44) implies

$$\{L_3,M_1\}=\frac{f_2g_3-f_3g_2}{\Phi}. \tag{49}$$

The corresponding conditions are satisfied by M_2 and M_3. Then the fact that $\{L_3,L_3'\}=1$ is implied by the identity

$$(f_2g_3-f_3g_2)+(f_3g_1-f_1g_3)+(f_1g_2-f_2g_1)=\Phi. \tag{50}$$

Similarly, we can define a new invariant L_2' by requiring that a new function M_1 satisfy

$$\{L_1,M_1\}=\frac{g_1(g_2-g_3)}{\Phi}, \tag{51}$$

with analogous conditions for M_2 and M_3. For $M_1(H,L_2,L_3,Q_1)$ with $Q_1=p_{x_1}$ this has the solution

$$M_1=\int g_1U_1'^{-1}dQ_1,$$

where $U_1(x_1)=-v_1(x_1)+f_1H+g_1L_2+L_3$.

[Note that for M_1 to be a polynomial in p_x,p_y,p_z we must have $g_1(F)F_U$ a polynomial in U. If $g_1'=0$, this reduces to requiring F to be a polynomial in U. If $g_1'\neq 0$, we can replace the variable x by $\tilde{x}_1=r(x_1)=\int g_1(x_1)dx_1$ with $\tilde{x}_1=G(U,H,L_2,L_3)$. Then $g_1(F)F_U=G_U$ and our original analysis goes through with F replaced by G. It is guaranteed to yield a polynomial invariant if we require

$$r=P_n\left(\frac{U+\alpha_1H+\alpha_2L_2+\alpha_3L_3+\alpha_4}{\alpha_5H+\alpha_6L_2+\alpha_7}\right),\quad g_1=r'(x_1), \tag{52}$$

where P_n is a polynomial of order n and the α_i are constants. Then there exists a function F_n, inverse to P_n, such that

$$U=(\alpha_5H+\alpha_6L_2+\alpha_7)F_n(r)-(\alpha_1H+\alpha_2L_2+\alpha_3L_3+\alpha_4)=-v_1+f_1H+g_1L_2+L_3.$$

Equating coefficients of L_2 we find the condition $r'=\alpha_6F_n(r)-\alpha_2$ and we can solve for $r(x_1)$ by quadratures. Equating coefficients of H, L_3 and the constant term, we find $\alpha_3=-1$ and

$$f_1(x)=\alpha_5F_n(r)-\alpha_1,\quad g_1(x)=\alpha_6F_n(r)-\alpha_2,\quad v_1(x)=\alpha_4-\alpha_7F_n(r).$$

It follows that $(\alpha_5H+\alpha_6L_2+\alpha_7)^nM_1$ is a polynomial in the momenta.]

The corresponding invariant that we can calculate from these three functions is $L_2'=M_1+M_2+M_3$. This is based on the obvious identity

$$g_1(g_2-g_3)+g_2(g_3-g_1)+g_3(g_1-g_2)=0.$$

Then it follows that

$$\{L_2,M_1\}=\frac{g_1(f_3-f_2)}{\Phi},\quad \{L_3,M_1\}=\frac{g_1(f_2g_3-f_3g_2)}{\Phi},$$

with analogous results for M_2, M_3. Thus, from the definition of Φ we see that $\{L_2,L_2'\}=1$.

Finally, we define a function $L_1'=M_1+M_2+M_3$ by requiring

$$\{L_1,M_1\}=\frac{f_1(g_2-g_3)}{\Phi},\tag{53}$$

with similar conditions for M_2 and M_3. For $M_1(H,L_2,L_3,Q_1)$ with $Q_1=p_{x_1}$ this has the solution

$$M_1=\int f_1U_1'^{-1}dQ_1.$$

Then it follows that

$$\{L_2,M_1\}=\frac{f_1(f_3-f_2)}{\Phi},\quad \{L_3,M_1\}=\frac{f_1(f_2g_3-f_3g_2)}{\Phi},$$

with analogous relations for M_2 and M_3.

In summary, all brackets between the six functions L_i,L_i' are zero except that

$$\{L_3,L_3'\}=\{L_2,L_2'\}=\{L_1,L_1'\}=1.\tag{54}$$

Thus the mapping $(x_1,x_2,x_3,p_{x_1},p_{x_2},p_{x_3})\to(L_1,L_2,L_3,L_1',L_2',L_3')$ is canonical.

Note: Standard Hamilton–Jacobi theory gives exactly these same constants of the motion, from a different viewpoint.[1] Our expression for L_3', for example, is

$$L_3'=\sum_j\int U_j'^{-1}dp_{x_j}=\sum_j M_j,$$

where $U_j=-v_j(x_j)+f_jL_1+g_jL_2+L_3$ and $U_j=p_{x_j}^2$. Standard Hamilton–Jacobi theory gives

$$L_3'=\frac{1}{2}\sum_j\int\frac{dx_j}{\sqrt{-v_j+f_jL_1+g_jL_2+L_3}}=\sum_j\tilde{M}_j.$$

In the standard theory $\tilde{M}_j=\tilde{M}_j(L_1,L_2,L_3,x_j)$, whereas in our approach $M_j=M_j(L_1,L_2,L_3,p_{x_j})$. In both cases the condition (44) is satisfied. Our approach makes it straightforward to determine exactly when the L_i' are polynomials in the momenta p_{x_j}. It also points out the bracket relations between the M_i and the operators L_j defining the separation, e.g., (43), (48), (49), (51), and (53).

The generalization to n dimensions is straightforward.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 7 JULY 2002

Conservation laws for a class of nonlinear equations with variable coefficients on discrete and noncommutative spaces

M. Klimek[a)]
Institute of Mathematics and Computer Science, Technical University of Częstochowa, ul.Dąbrowskiego 73, 42-200 Częstochowa, Poland

(Received 4 January 2001; accepted for publication 14 March 2002)

The conservation laws for a class of nonlinear equations with variable coefficients on discrete and noncommutative spaces are derived. For discrete models the conserved charges are constructed explicitly. The applications of the general method include equations on quantum plane, supersymmetric equations for chiral and antichiral supermultiplets, auxiliary equations of integrable models which means various cases of nonlinear Toda lattice equations and anomalous diffusion equation. [DOI: 10.1063/1.1480449]

I. INTRODUCTION

Our aim is to present the procedure of derivation of the conservation laws and consequently the conserved charges for a certain class of nonlinear equations with variable coefficients. In the classical field theory the conserved currents and charges follow from the Noether theorem and are connected with the symmetry of the action. In the case of linear equations of motion with constant coefficients the construction of conserved currents by Takahashi and Umezawa method[1] can be applied.

In previous papers[2–5] we have extended this procedure to the linear equations on discrete and noncommutative spaces including quantum Minkowski[6–9] and braided linear spaces.[10,11] It appears, however, that we can consider in a similar way a wide class of equations with variable coefficients built within framework of any differential calculus with the Leibniz's rule for partial derivatives deformed via the transformation operator which is multiplicative and invertible. The range of admissible spaces includes the classical space–time with continuous coordinates, the discrete space, the mixed space with discrete and continuous coordinates, superspace including space–time and spinor coordinates, and quantum Minkowski and braided linear spaces (with q-Minkowski as a special case).

The equations we shall investigate have the variable coefficients which fulfill the corresponding restriction (3) including the conjugated derivatives. The possibility of derivation of the conservation laws for some equations with variable coefficients on noncommutative spaces was indicated earlier,[4,5] but the proposed conditions for coefficients were too strong to construct useful examples. In constrast the new condition (as we show explicitly in the applications) appears to be identical with the nonlinear equations of some of the integrable models for which we derive the conserved currents via the auxiliary linear equations with variable coefficients.

Resuming the proposed method can be applied to nonlinear models in two ways: namely, we can consider the equation with nonlinear term free from the derivatives (in form of the potential) or alternatively we investigate the auxiliary linear equations with variable coefficients for nonlinear integrable models.

The article is organized as follows: Sec. II contains the description of the investigated models and the derivation of the conservation laws. In Sec. III we extend the procedure to discrete and mixed discrete and continuous models, including both types of derivatives initial ∂ and its conju-

a)Electronic mail: klimek@matinf.pcz.czest.pl

gation $\partial^\dagger$. For this class of equations we add the construction of conserved charges following the classical method of integrating the time-component of the conserved current over the subspace excluding the time-coordinate. This result is due to the fact that for the discrete and classical differential calculi the definite integral over mentioned subspace is known to commute with time-derivative (71).

Section IV includes applications of the derived procedure. We start with a simple example of an equation of the second order with variable coefficients on quantum plane, then we consider the conserved currents and charges for a pair of chiral and antichiral supermultiplets on $D=4$, $N=1$ superspace connected via a nonlinear equation of motion. We also review the conservation laws and conserved charges for various cases of the nonlinear Toda lattice equation for which we use our results for mixed discrete and continuous spaces in order to write explicitly the conserved currents and charges. The section is closed with the derivation of the conservation law for the equation of anomalous diffusion.

II. NONLINEAR EQUATIONS WITH VARIABLE COEFFICIENTS AND THEIR CONSERVATION LAW

In the previous papers we discussed the conservation laws for linear equations with constant coefficients for discrete differential calculus[2,3] as well as for a wider category of equations acting on noncommutative spaces, namely on quantum Minkowski spaces[4,12] and the braided linear ones.[5,13,14]

Now we would like to present our results for an extended class of equations with variable coefficients of the form

$$\Lambda(\partial)\Phi=0, \tag{1}$$

$$\Lambda(\partial)=\Lambda_0+\sum_{l=1}^{N}\Lambda_{\mu_1\cdots\mu_l}\partial^{\mu_1}\cdots\partial^{\mu_l}, \tag{2}$$

where coefficients (may be matrices) fulfill the condition

$$\partial^{\dagger\,\mu_1}\Lambda_{\mu_1\cdots\mu_l}=0 \tag{3}$$

for $l=1,\ldots,N$ and with the conjugated derivative described below (30).

In addition we assume the coefficients to obey symmetry properties with respect to the permutation of indices. Their exact form is connected with the commutation relations in the algebra of partial derivatives. In the classical case this algebra is commutative, thus the coefficients for such models are fully symmetric with respect to permutation of the set of indices. In the sequel we describe the symmetry properties of the discussed equation for specific differential calculus.

We include into considerations the nonlinear equations provided the only nonlinear term does not depend on derivatives, which means

$$\Lambda_0=\Lambda_0(\Phi). \tag{4}$$

As will be shown, this class of equations contains some of the equations of motion for supersymmetric models in superfield formulation as well as auxiliary linear equations yielded by nonlinear integrable models as, for example, Toda lattice equations.

Our construction presented below in Propositions 2.1 and 2.2 holds for any differential calculus with the following deformation of Leibniz's rule:

$$\partial^i(fg)=(\partial^i f)g+(\zeta^i_j f)\partial^j g, \tag{5}$$

where ζ is the invertible transformation operator.

We shall now discuss the admissible differential calculi. They include classical, discrete, noncommutative and supersymmetric models described below.

A. Differential calculi with Leibniz's rule of the form (5)

Starting with the classical commutative differential calculus (for which ζ is the identity operator) we can also include the discrete differential calculus with derivatives defined by one of the formulas:

$$\partial^i f_k = (\zeta^i - 1) f_k = f_{k+1} - f_k, \tag{6}$$

$$\partial^i f_k = (x_{k+1} - x_k)^{-1} (\zeta^i - 1) f_k = (x_{k+1} - x_k)^{-1} (f_{k+1} - f_k), \tag{7}$$

where k denotes the position on the lattice in the direction i.

The first one is widely used in the discrete models and measures the difference between the values of the function between two points of the lattice in the given direction i while the second one (introduced in Refs. 2 and 3) is a quotient of the change of value of the function over the distance between the two neighboring points of the lattice taken in the direction i. Both types of the derivatives obey (5) with the transformation operator being the shift operator along the lattice in the direction i:

$$\zeta^i f_k = f_{k+1}, \tag{8}$$

where k in the above formula denotes the value of the ith coordinate of the point on the lattice.

It is clear that we can also include mixed models depending both on classical commutative derivatives with respect to continuous coordinates and discrete derivatives (6) or (7) with respect to lattice dimensions.

Similarly to the classical differential calculus, the algebra of discrete derivatives in the form (6) or (7) is commutative, thus we consider in these models equations with coefficients fully symmetric with respect to permutation of each of the sets of indices $(\mu_1, \ldots, \mu_l)$.

The Leibniz's rule of the form (5) is also characteristic for noncommutative spaces. We have checked[4,5] that for quantum Minkowski spaces and for braided linear spaces (including the q-Minkowski space) it is given by the formula (5) with transformation operators determined by their multiplicity property:

$$\zeta^i_j(fg) = (\zeta^i_k f)(\zeta^k_j g) \tag{9}$$

and the action on monomials of the first order:

$$\zeta^i_j x^k = R^{ik}_{aj} x^a - (RZ)^{ik}_j, \tag{10}$$

$$\zeta^i_j x_k = R^{li}_{kj} x_l. \tag{11}$$

The first of the above formulas is valid on the quantum Minkowski space and the second on the braided linear space with R being the matrices fulfilling the QYBE.[9–11] For quantum Minkowski spaces introduced by Podleś and Woronowicz the R matrix is self-invertible $R^2 = 1$ and for braided linear spaces developed by Majid it is bi-invertible:

$$(R^{-1})^{ij}_{kl} R^{kl}_{ab} = R^{ij}_{kl} (R^{-1})^{kl}_{ab} = \delta^i_a \delta^j_b, \tag{12}$$

$$\tilde{R}^{ib}_{al} R^{ak}_{jb} = R^{ib}_{al} \tilde{R}^{ak}_{jb} = \delta^i_j \delta^k_l. \tag{13}$$

Let us recall the algebra of partial derivatives for both cases:

$$\partial^l \partial^k = R^{lk}_{ij} \partial^i \partial^j, \tag{14}$$

$$\partial^l \partial^k = (R')^{lk}_{ij} \partial^j \partial^i, \tag{15}$$

with the first relation valid for the quantum Minkowski case and the second for the braided differential calculus. The above commutation relations yield respectively for coefficients of Eqs. (1) and (2) the following symmetry properties ($l=1,\ldots,N$):

$$R_{\nu\rho}^{\mu_k\mu_{k+1}}\Lambda_{\mu_1\ldots\mu_k\mu_{k+1}\ldots\mu_l}=\Lambda_{\mu_1\ldots\nu\rho\ldots\mu_l}, \tag{16}$$

$$(R')_{\nu\rho}^{\mu_k\mu_{k+1}}\Lambda_{\mu_1\ldots\mu_k\mu_{k+1}\ldots\mu_l}=\Lambda_{\mu_1\ldots\rho\nu\ldots\mu_l}. \tag{17}$$

We should here point out that also the differential calculus on finite groups investigated by Sitarz and Majid and their collaborators[15–19] includes Leibniz's rule of the form (5). The partial derivatives in this calculus read as ($i=1,\ldots,n$):

$$\partial^i f(x)=f(xx_i)-f(x), \tag{18}$$

where elements x_i numbering the basis of partial derivatives belong to the cyclic conjugacy class of a certain finite group G and the x is an arbitrary element of group G. It is clear that the transformation operator ζ is in this case

$$\zeta^i f(x)=f(xx_i). \tag{19}$$

The commutation rules for partial derivatives (18) are rather complicated so we shall discuss only the inverse operator for ζ in the next section, leaving the derivation of the conservation laws for general equation on finite groups for further investigation.

Let us notice that the important category of models on noncommutative spaces are supersymmetric models in the superspace formulation. In this framework the noncommutative space is divided into the classical commutative Minkowski space coordinates x (with corresponding indices and metric) and the spinor coordinates θ (we shall not specify below the type of spinors—Majorana or Weyl). For all equations within this class the part connected with space–time is described using the classical commutative differential calculus while for spinor coordinates we have anticommuting derivatives. The first part of the components of the transformation operator looks as follows:

$$\zeta_\nu^\mu=\delta_\nu^\mu, \quad \zeta_\nu^\alpha=\zeta_\alpha^\nu=0, \tag{20}$$

where for the supersymmetric models we have denoted the space–time indices as μ, ν while we use α and β as spinor indices (Weyl or Majorana). The only nontrivial part of the transformation operator for the supersymmetric models are the components which act between the spinor indices, namely for the monomials of the first order they are of the form

$$\zeta_\beta^\alpha x_\mu=\delta_\beta^\alpha x_\mu, \quad \zeta_\beta^\alpha\theta_\gamma=-\delta_\beta^\alpha\theta_\gamma. \tag{21}$$

We can extend the supersymmetric transformation operator to an arbitrary function by its multiplicity property (9).

Respectively the coefficients of equations (1) and (2) should be antisymmetric under permutation of two spinor indices and symmetric for all the other permutations.

B. The modification of the Leibniz's rule

For all the considered differential calculi (discrete, supersymmetric, quantum Minkowski and braided) the transformation operators have one common feature, namely, they are invertible; for discrete models with derivatives (6) or (7) the inverse operators ζ^- are simply backshift operators in the given direction while for noncommutative models the inverses are given by their multiplicity property:

$$\zeta_j^{-\,i}(fg)=(\zeta_j^{-\,k}f)(\zeta_k^{-\,i}g) \tag{22}$$

together with their action on monomials of the first order:

$$\zeta_j^{-\,i} x^k = R_{ja}^{ki} x^a + Z_j^{ki}, \tag{23}$$

$$\zeta_j^{-\,i} x_k = \tilde{R}_{kj}^{li} x_l, \tag{24}$$

where $\tilde{R}$ is the second inverse of the R matrix characteristic for braided linear spaces.[10,11]

The inverse transformation operator for differential calculus on a finite group can be derived using the definition of the cyclic conjugacy class.[19] Namely it implies the existence of the special element x_1 such that Ad_{x_1} is a cyclic permutation of $\mathcal{C}-\{x_1\}$. If $x_1^{n-1}=e$ (e being the neutral element in the group G), then also $(x_i)^{n-1}=e$ for $i=2,\ldots,n$. Thus the inverse transformation operator is given by the following formula:

$$(\zeta^i)^{-1} = (\zeta^i)^{n-2}. \tag{25}$$

Now let us discuss the supersymmetric differential calculus. The inverse operator for supersymmetric models is given by

$$\zeta_\nu^{-\,\mu} = \delta_\nu^\mu, \quad \zeta_\nu^{-\,\alpha} = \zeta_\alpha^{-\,\nu} = 0, \tag{26}$$

with the spinor–spinor part defined by the multiplicity (22) and its action on monomials of the first order:

$$\zeta_\beta^{-\,\alpha} x_\mu = \delta_\beta^\alpha x_\mu, \quad \zeta_\beta^{-\,\alpha} \theta_\gamma = -\delta_\beta^\alpha \theta_\gamma. \tag{27}$$

All the described above inverse operators fulfill the condition

$$\zeta_j^k \zeta_k^{-\,i} = \zeta_j^{-\,k} \zeta_k^i = \delta_j^i. \tag{28}$$

The properties of the transformation operators ζ and ζ^- imply the following modification of Leibniz's rule:

$$\partial^k[(\zeta_k^{-\,i} f)g] = (-\partial^{\dagger\,i} f)g + f(\partial^i g) = f(-\overleftarrow{\partial}^{\dagger\,i} + \partial^i)g, \tag{29}$$

where the conjugated derivative $\partial^\dagger$ is defined as follows:

$$\partial^{\dagger\,i} := -\partial^k \zeta_k^{-\,i}, \tag{30}$$

and we take for the given type of the derivative the connected inverse transformation operator. We see that after modification we deal with Leibniz's rule where the right-hand side is analogous to the classical differential calculus:

$$\partial^i(fg) = f(-\overleftarrow{\partial}^{\dagger\,i} + \partial^i)g$$

for which the conjugated derivative is given by: $\partial^{\dagger\,i} = -\partial^i$.

The conjugated derivatives form the conjugated equation which for the class described by conditions (1)–(3) looks as follows:

$$\Lambda(\overleftarrow{\partial}^\dagger) = \Lambda_0(\Phi) + \sum_{l=1}^{N} \overleftarrow{\partial}^{\dagger\,\mu_1} \cdots \overleftarrow{\partial}^{\dagger\,\mu_l} (\zeta_{\mu_l}^{-\,\alpha_l} \cdots \zeta_{\mu_1}^{-\,\alpha_1} \Lambda_{\alpha_1 \ldots \alpha_l}). \tag{31}$$

The following propositions hold for Eqs. (1)–(3) and are the extension of results derived in Refs. 3–5.

C. Derivation of the conservation laws for admissible differential calculi

Proposition 2.1: The unique solution of the operator equation

$$\sum_{\mu} (-\overleftarrow{\partial}^{\dagger\,\mu}+\partial^{\mu})\circ\Gamma_{\mu}(\partial,\overleftarrow{\partial}^{\dagger})=\Lambda(\partial)-\Lambda(\overleftarrow{\partial}^{\dagger}) \tag{32}$$

in the class of polynomials of derivatives $\overleftarrow{\partial}^{\dagger}$ and ∂ for the equation operator Λ fulfilling (3) is of the form

$$\Gamma_{\mu}(\partial,\overleftarrow{\partial}^{\dagger})=(\zeta_{\mu}^{-\,\alpha}\Lambda_{\alpha}) + \sum_{l=1}^{N-1}\sum_{k=0}^{l} \overleftarrow{\partial}^{\dagger\,\mu_1}\cdots\overleftarrow{\partial}^{\dagger\,\mu_k}(\zeta_{\mu}^{-\,\alpha}\zeta_{\mu_k}^{-\,\alpha_k}\cdots\zeta_{\mu_1}^{-\,\alpha_1}\Lambda_{\alpha_1\cdots\alpha_k\alpha\mu_{k+1}\cdots\mu_l})\partial^{\mu_{k+1}}\cdots\partial^{\mu_l}. \tag{33}$$

Proof: Let us explain that the "$\circ$" operation describes the way the noncommuting derivatives work on monomials of derivatives $\overleftarrow{\partial}^{\dagger}$ and ∂, namely,

$$\begin{aligned}(-\overleftarrow{\partial}^{\dagger\,\mu}+\partial^{\mu})\circ\overline{[\nu_1,\ldots,\nu_l]}a(\vec{x})[\rho_1,\ldots,\rho_k] \\ :=-\overline{[\nu_1,\ldots,\nu_l,\mu]}a(\vec{x})[\rho_1,\ldots,\rho_k]+\overline{[\nu_1,\ldots,\nu_l]}\partial^{\mu}a(\vec{x})[\rho_1,\ldots,\rho_k],\end{aligned} \tag{34}$$

where the following notation for monomials was used:

$$[\rho_1,\ldots,\rho_k]:=\partial^{\rho_1}\cdots\ \partial^{\rho_k}, \tag{35}$$

$$\overline{[\nu_1,\ldots,\nu_l]}:=\overleftarrow{\partial}^{\dagger\,\nu_1}\cdots\ \overleftarrow{\partial}^{\dagger\,\nu_l}. \tag{36}$$

The further calculations base on the assumption that we consider the general operator of the order $N-1$ with respect to the derivatives and on the associativity of the algebra of derivatives. The explicit solution of the condition (32) is enclosed in the Appendix.

We modify the Γ operator due to the deformation of Leibniz's rule [Eqs. (5) and (29)] and obtain the operator $\hat{\Gamma}$:

$$\hat{\Gamma}_{\mu}(\partial,\overleftarrow{\partial}^{\dagger})=\overleftarrow{\zeta}_{\mu}^{-\,j}(\zeta_{j}^{-\,\alpha}\Lambda_{\alpha}) + \sum_{l=1}^{N-1}\sum_{k=0}^{l} \overleftarrow{\partial}^{\dagger\,\mu_1}\cdots\ \overleftarrow{\partial}^{\dagger\,\mu_k}\overleftarrow{\zeta}_{\mu}^{-\,j}(\zeta_{j}^{-\,\alpha}\zeta_{\mu_k}^{-\,\alpha_k}\cdots\ \zeta_{\mu_1}^{-\,\alpha_1}\Lambda_{\alpha_1\cdots\alpha_k\alpha\mu_{k+1}\cdots\mu_l})\partial^{\mu_{k+1}}\cdots\ \partial^{\mu_l}, \tag{37}$$

which for a pair of arbitrary functions f and g is connected with the Γ operator by the equality

$$\sum_{\mu}\partial^{\mu}f\hat{\Gamma}_{\mu}(\partial,\overleftarrow{\partial}^{\dagger})g=\sum_{\mu} f(-\overleftarrow{\partial}^{\dagger\,\mu}+\partial^{\mu})\circ\Gamma_{\mu}(\partial,\overleftarrow{\partial}^{\dagger})g. \tag{38}$$

The immediate consequence of Proposition 2.1 is therefore the construction of conserved currents yielded by the following statement.

Proposition 2.2: Let us assume that function Φ is an arbitrary solution of Eqs. (1) and (2) with coefficients fulfilling (3), which means

$$\Lambda(\partial)\Phi=0, \tag{39}$$

and function Φ' solves the conjugated equation with the operator of the form (31):

$$\Phi' \Lambda(\overleftarrow{\partial}^{\dagger}) = 0. \tag{40}$$

Then

$$J_{\mu} = \Phi' \hat{\Gamma}_{\mu}(\partial, \overleftarrow{\partial}^{\dagger}) \Phi, \tag{41}$$

where the operator $\hat{\Gamma}_{\mu}$ *is defined by (37), is a current which obeys the conservation law:*

$$\sum_{\mu} \partial^{\mu} J_{\mu} = 0. \tag{42}$$

Proof: This is a corollary from the (38) property of the $\hat{\Gamma}$ operator, from the operator equation (32) for Γ and finally from the fact that functions Φ and Φ' fulfill the respective equations (1) and (40).

Let us notice that the auxiliary conjugated equation for the nonlinear model is now the linear one with respect to the solution Φ':

$$\Phi' \left(\Lambda_0(\Phi) + \sum_{l=1}^{N} \overleftarrow{\partial}^{\dagger \mu_1} \cdots \overleftarrow{\partial}^{\dagger \mu_l} \zeta^{-}_{\mu_l}{}^{\alpha_l} \cdots \zeta^{-}_{\mu_1}{}^{\alpha_1} \Lambda_{\alpha_1 \ldots \alpha_l} \right) = 0. \tag{43}$$

The solution Φ' depends on the solution of the initial equation Φ which defines the potential for the conjugated equation $\Lambda_0(\Phi)$.

Now the interesting question arises whether the presented construction which works on a wide class of spaces can be extended to equations with operators including both ∂ and $\partial^{\dagger}$ derivatives. As we know from discrete models (see, for example, Refs. 20 and 21) the equations depend explicitly on the forth- and backshifts along the lattice. Also the equations of motion built within the framework of generalized difference derivatives (7) (which was discussed in Refs. 3 and 22) include both initial and conjugate derivatives as a consequence of the minimal action principle. The method of derivation of the conserved currents for the discrete and mixed models shall be described in the next section. It is based on the fact that acting on functions of commutative coordinates the operators (6) and (7) yield two symmetric formulas for Leibniz's rules (both for initial and conjugated derivative).

III. CONSERVED CURRENTS AND CHARGES FOR DISCRETE AND MIXED MODELS DEPENDING ON THE ∂ AND $\partial^{\dagger}$ DERIVATIVES

Our aim is now to extend the construction described in Propositions 2.1 and 2.2 to the equations depending on the initial and conjugated derivatives of the form

$$[\Lambda(\partial) + \tilde{\Lambda}(\partial^{\dagger})] \Phi = 0, \tag{44}$$

$$\Lambda(\partial) = \Lambda_0 + \sum_{l=1}^{N} \Lambda_{\mu_1 \ldots \mu_l} \partial^{\mu_1} \cdots \partial^{\mu_l}, \tag{45}$$

$$\tilde{\Lambda}(\partial^{\dagger}) = \tilde{\Lambda}_0 + \sum_{l=1}^{\tilde{N}} \tilde{\Lambda}_{\mu_1 \ldots \mu_l} \partial^{\dagger \mu_1} \cdots \partial^{\dagger \mu_l}. \tag{46}$$

Following the previous considerations we restrict the class of equations to variable coefficients fulfilling the extended version of the condition (3):

$$\partial^{\dagger \mu_1} \Lambda_{\mu_1 \ldots \mu_l} = 0, \quad \partial^{\mu_1} \tilde{\Lambda}_{\mu_1 \ldots \mu_k} = 0, \tag{47}$$

for all $l=1,\ldots,N$ and $k=1,\ldots,\tilde{N}$.

Furthermore, the coefficients Λ and $\tilde{\Lambda}$ are symmetric under permutation of indices.

We include the nonlinear equations provided the nonlinear terms do not depend on the derivatives, which means they have a form of potential:

$$\Lambda_0=\Lambda_0(\Phi),\quad \tilde{\Lambda}_0=\tilde{\Lambda}_0(\Phi). \tag{48}$$

As we shall see in the subsequent sections the class of equations fufilling (47) contains the widely studied in different context linear auxiliary equations connected with nonlinear integrable models such as equations of nonlinear Toda lattice models.

The important factor in our calculations is the fact that for discrete (or mixed—classical and discrete) differential calculus we can write the modified Leibniz's rule symmetrically in the following form:

$$\partial^{\alpha}(\zeta_{\alpha}^{-\beta}f)g=(-\partial^{\dagger\beta}f)g+f\partial^{\beta}g=f(-\tilde{\partial}^{\dagger\beta}+\partial^{\beta})g, \tag{49}$$

$$\partial^{\dagger\alpha}(\zeta_{\alpha}^{\beta}f)g=(-\partial^{\beta}f)g+f\partial^{\dagger\beta}g=f(-\tilde{\partial}^{\beta}+\partial^{\dagger\beta})g. \tag{50}$$

Equation (50) indicates that the statement analogous to Proposition 2.1 holds for the operator $\tilde{\Lambda}(\partial^{\dagger})$; namely, we shall prove that the operator equation (51) has the unique solution by virtue of Proposition 3.1:

$$\sum_{\mu}(-\tilde{\partial}^{\mu}+\partial^{\dagger\mu})\circ\tilde{\Gamma}_{\mu}(\partial^{\dagger},\tilde{\partial})=\tilde{\Lambda}(\partial^{\dagger})-\tilde{\Lambda}(\tilde{\partial}), \tag{51}$$

where the conjugated operator $\tilde{\Lambda}(\tilde{\partial})$ looks as follows:

$$\tilde{\Lambda}(\tilde{\partial})=\tilde{\Lambda}_0(\Phi)+\sum_{l=1}^{\tilde{N}}\tilde{\partial}^{\mu_1}\cdots\tilde{\partial}^{\mu_l}(\zeta_{\mu_l}^{\alpha_l}\cdots\zeta_{\mu_1}^{\alpha_1}\Lambda_{\alpha_1\ldots\alpha_l}). \tag{52}$$

Proposition 3.1: The unique solution of (51) in the class of polynomials of derivatives $\tilde{\partial}$ and $\partial^{\dagger}$ for the equation operator $\tilde{\Lambda}$ (46) with coefficients fulfilling (47) is of the form

$$\tilde{\Gamma}_{\mu}(\partial^{\dagger},\tilde{\partial})=(\zeta_{\mu}^{\alpha}\tilde{\Lambda}_{\alpha})+\sum_{l=1}^{\tilde{N}-1}\sum_{k=0}^{l}\tilde{\partial}^{\mu_1}\cdots\tilde{\partial}^{\mu_k}(\zeta_{\mu}^{\alpha}\zeta_{\mu_k}^{\alpha_k}\cdots\zeta_{\mu_1}^{\alpha_1}\tilde{\Lambda}_{\alpha_1\ldots\alpha_k\alpha\mu_{k+1}\ldots\mu_l})\partial^{\dagger\mu_{k+1}}\cdots\partial^{\dagger\mu_l}. \tag{53}$$

Proof: The formula (53) is the immediate consequence of the proof of Proposition 2.1 enclosed in the Appendix as the following connections between derivatives and transformation operators hold:

$$\partial^{\dagger\alpha}(fg)=(\partial^{\dagger\alpha}f)g+(\zeta_{\beta}^{-\alpha}f)\partial^{\dagger\beta}g, \tag{54}$$

$$(\zeta^{-})^{-1}=\zeta, \tag{55}$$

$$(\partial^{\dagger})^{\dagger\gamma}=-(-\partial^{\beta}\zeta_{\beta}^{-\alpha})\zeta_{\alpha}^{\gamma}=\partial^{\gamma}. \tag{56}$$

We notice that ζ^{-} is the transformation operator for the derivative $\partial^{\dagger}$, the operator ζ being its inverse. Therefore, all the calculations from the proof of Proposition 2.1 can be repeated with suitable replacements. In this way we obtain the formula for the $\tilde{\Gamma}$ operator (53) which is simply the (33) operator with new derivatives $\partial^{\dagger}$ and $\tilde{\partial}$ and the operator ζ acting now as the inverse transformation operator.

We modify the operator $\tilde{\Gamma}$ similarly as in (37) and obtain the operator $\hat{\tilde{\Gamma}}$:

$$\hat{\tilde{\Gamma}}_\mu(\partial^\dagger,\tilde{\partial})=\tilde{\xi}^j_\mu(\zeta^\alpha_j\Lambda_\alpha)+\sum_{l=1}^{\tilde{N}-1}\sum_{k=0}^{l}\tilde{\partial}^{\mu_1}\cdots\tilde{\partial}^{\mu_k}\tilde{\xi}^j_\mu(\zeta^\alpha_j\zeta^{\alpha_k}_{\mu_k}\cdots\zeta^{\alpha_1}_{\mu_1}\tilde{\Lambda}_{\alpha_1\ldots\alpha_k\alpha\mu_{k+1}\ldots\mu_l})\partial^{\dagger\,\mu_{k+1}}\cdots\partial^{\dagger\,\mu_l}, \tag{57}$$

which in turn fulfills the equality

$$\sum_\mu \partial^{\dagger\,\mu}(f\hat{\tilde{\Gamma}}_\mu(\partial^\dagger,\tilde{\partial})g)=\sum_\mu f((-\tilde{\partial}^\mu+\partial^{\dagger\,\mu})\circ\tilde{\Gamma}_\mu(\partial^\dagger,\tilde{\partial}))g \tag{58}$$

for a pair of arbitrary functions f and g.

We can use the constructed operators $\hat{\Gamma}$ and $\hat{\tilde{\Gamma}}$ to derive the conserved currents by the following proposition:

Proposition 3.2: Let us assume that the function Φ is an arbitrary solution of Eq. (44) with coefficients fulfilling (47), which means

$$[\Lambda(\partial)+\tilde{\Lambda}(\partial^\dagger)]\Phi=0, \tag{59}$$

and the function Φ' solves the conjugated equation with operators (31) and (52):

$$\Phi'[\Lambda(\tilde{\partial}^\dagger)+\tilde{\Lambda}(\tilde{\partial})]=0. \tag{60}$$

Then,

$$J_\mu=\Phi'\hat{\Gamma}_\mu\Phi,\quad \tilde{J}_\mu=\Phi'\hat{\tilde{\Gamma}}_\mu\Phi, \tag{61}$$

where the operators $\hat{\Gamma}$ and $\hat{\tilde{\Gamma}}$ are given by (37) and (57) are a current that obeys the conservation law:

$$\sum_\mu \partial^\mu J_\mu+\sum_\mu \partial^{\dagger\,\mu}\tilde{J}_\mu=0. \tag{62}$$

Proof: The conservation law (62) is implied by the properties (38) and (58) of the applied operators $\hat{\Gamma}$ and $\hat{\tilde{\Gamma}}$:

$$\partial^\mu\Phi'\hat{\Gamma}_\mu\Phi+\partial^{\dagger\,\mu}\Phi'\hat{\tilde{\Gamma}}_\mu\Phi=\Phi'\left(\sum_\mu(-\tilde{\partial}^{\dagger\,\mu}+\partial^\mu)\circ\Gamma_\mu(\partial,\tilde{\partial}^\dagger)+\sum_\mu(-\tilde{\partial}^\mu+\partial^{\dagger\,\mu})\circ\tilde{\Gamma}_\mu(\partial^\dagger,\tilde{\partial})\right)\Phi$$
$$=\Phi'(\tilde{\Lambda}(\partial^\dagger)-\tilde{\Lambda}(\tilde{\partial})+\Lambda(\partial)-\Lambda(\tilde{\partial}^\dagger))\Phi=0. \tag{63}$$

Corollary 3.3: The components of the conserved current for the equation (44) fulfilling the condition (47) can be written also in the form

$$J'_\mu=\Phi'\text{`}\hat{\Gamma}_\mu\Phi-\zeta^{-\ \nu}_\mu(\Phi'\hat{\tilde{\Gamma}}_\nu\Phi). \tag{64}$$

They obey the conservation law including only the ∂ derivatives:

$$\sum_{\mu} \partial^{\mu} J'_{\mu} = 0, \tag{65}$$

provided Φ *is the solution of (44) and the function* Φ' *solves the conjugate equation with operators (31) and (52).*

Let us notice that the presented construction holds when we work within the framework of classical commutative differential calculus (for which the conjugation means $\partial^{\dagger} = -\partial$ and the transformation operator is the identity) as well as for mixed models where part of the coordinates is continuous and the other part is discrete with suitable difference derivatives in the form (6) or (7).

In the sequel we shall use the construction (37), (57), and (61) in order to derive the conserved currents and in consequence the conserved charges for the mixed discrete nonlinear Toda model and for the double discrete Toda model as well.

As we know from the classical field theory we can use the conserved currents in construction of the conserved charges. This is also the case for our discrete and mixed discrete models with derivatives defined by (6) or (7). We shall integrate the time component of the conserved current over subspace excluding the time-coordinate. We use in derivation the conserved currents given by Proposition 3.2 or accordingly by Corollary 3.3 if the conjugated derivative with respect to the time-coordinate appears in the model. Integrating we must remember to take the corresponding integral. Namely for continuous coordinates we understand $\int dx_i$ as the Lebesque integral while for the discrete derivative (6) the definite integral is given by

$$\int dx_i := \sum_{k=-\infty}^{+\infty} (\zeta_i)^k. \tag{66}$$

If the equation includes the discrete derivative of the type (7), we use the definite integral in the form

$$\int dx_i := \sum_{k=-\infty}^{+\infty} (x^i_{k+1} - x^i_k)(\zeta_i)^k. \tag{67}$$

In the above formulas for discrete integrals the ζ_i is the shift operator in the direction i along the lattice.

Let us denote the integral over subspace with excluded time-coordinate as $\int_{\text{sub}}$. Then the conserved charges for discrete and mixed discrete models with variable coefficients can be derived using the following proposition:

Proposition 3.4: Let us assume that in the model described by the equation (44) the conjugated discrete derivative with respect to the time-coordinate does not appear. Then the charge

$$Q = \int_{\text{sub}} J_t, \tag{68}$$

where J_t *is the time component of the conserved current described in Proposition 3.2, is conserved:*

$$\partial^t Q = 0. \tag{69}$$

Proof: The conservation of the charge (68) is implied by the conservation law from Proposition 3.2, namely,

$$\partial^t Q = \int_{\text{sub}} \partial^t J_t = \int_{\text{sub}} -\sum_{k \neq t} (\partial^k J_k + \partial^{\dagger\, k} \tilde{J}_k) = \text{boundary terms} = 0, \tag{70}$$

provided the currents vanish at the infinity in the corresponding spacelike dimensions. We have used here also the property of the discrete and mixed discrete differential calculus:

$$\partial^t \int_{\mathrm{sub}} = \int_{\mathrm{sub}} \partial^t. \tag{71}$$

Let us point out that the equality (71) does not apply in general to noncommutative spaces (the superspace being an exception) and this fact is the major difficulty in construction of the conserved charges for an arbitrary model on noncommutative space.[13,14]

If in equation (44) both initial and conjugate time-derivatives appear, we derive the conserved charge using Corollary 3.3, namely the following statement is then valid (with proof being the copy of the above calculations for Proposition 3.4):

Corollary 3.5: Let us assume that in the model described by the equation (44) both discrete derivatives ∂^t and $\partial^{\dagger\, t}$ appear. Then the charge

$$Q = \int_{\mathrm{sub}} J'_t, \tag{72}$$

where J'_t is the time component of the conserved current described in Corollary 3.3, is conserved:

$$\partial^t Q = 0. \tag{73}$$

IV. APPLICATIONS

A. The second order equation on quantum plane with variable coefficients

Let us start with the simple example of the second order equation on quantum plane with coefficients depending on coordinates x and y.

The commutation relations for derivatives and coordinates look as follows:[10,11]

$$yx = qxy, \quad \partial^y \partial^x = q^{-1} \partial^x \partial^y. \tag{74}$$

Leibniz's rule (5) in differential calculus is defined by the following R-matrix:

$$R = \begin{bmatrix} q^2 & 0 & 0 & 0 \\ 0 & q & q^2-1 & 0 \\ 0 & 0 & q & 0 \\ 0 & 0 & 0 & q^2 \end{bmatrix}, \quad R' = q^{-2} R. \tag{75}$$

From the above matrix we can deduce the explicit action of the transformation operator ζ on the monomials of the first order (11). It yields the following formulas for the inverse transformation ζ^-:

$$\zeta_x^{-\,x} x = q^{-2} x, \quad \zeta_x^{-\,x} y = q^{-1} y, \quad \zeta_y^{-\,x} x = (q^{-2}-1) y, \quad \zeta_y^{-\,x} y = 0, \tag{76}$$

$$\zeta_y^{-\,y} y = q^{-2} y, \quad \zeta_y^{-\,y} x = q^{-1} x, \quad \zeta_x^{-\,y} y = 0, \quad \zeta_x^{-\,y} x = 0. \tag{77}$$

The conjugated derivatives are defined using the inverse transformation operator:

$$\partial^{\dagger\, x} = -\partial^x \zeta_x^{-\,x} - \partial^y \zeta_y^{-\,x}, \quad \partial^{\dagger\, y} = -\partial^x \zeta_x^{-\,y} - \partial^y \zeta_y^{-\,y}. \tag{78}$$

Now let us discuss an arbitrary equation of the second order with the coefficients depending on x and y and check which of them fufills the condition (3):

$$\Lambda(\partial^x, \partial^y) = \Lambda_{xx} \partial^x \partial^x + \Lambda_{yx} \partial^y \partial^x + \Lambda_{xy} \partial^x \partial^y + \Lambda_{yy} \partial^y \partial^y. \tag{79}$$

The condition (3) for our simple case reads as follows:

$$\partial^{\dagger x}\Lambda_{xx}+\partial^{\dagger y}\Lambda_{yx}=0, \quad \partial^{\dagger y}\Lambda_{yy}+\partial^{\dagger x}\Lambda_{xy}=0. \tag{80}$$

Let us assume $\Lambda_{xy}=\Lambda_{yx}=0$. Then we can show that $\Lambda_{xx}=\phi(y)$ and $\Lambda_{yy}=\psi(x)$ obey the conditions (3), namely,

$$\partial^{\dagger x}\Lambda_{xx}=(-\partial^{x}\zeta_{x}^{-\,x}-\partial^{y}\zeta_{y}^{-\,x})\phi(y)=-\partial^{x}\zeta_{x}^{-\,x}\phi(y)=-\partial^{x}\phi(q^{-1}y)=0, \tag{81}$$

$$\partial^{\dagger y}\Lambda_{yy}=(-\partial^{x}\zeta_{x}^{-\,y}-\partial^{y}\zeta_{y}^{-\,y})\psi(x)=-\partial^{y}\zeta_{y}^{-\,y}\psi(x)=-\partial^{y}\psi(q^{-1}x)=0. \tag{82}$$

Now we can apply our construction to obtain the Γ operator:

$$\Gamma_{x}=\tilde{\partial}^{\dagger\ x}\phi(q^{-2}y)+\phi(q^{-1}y)\partial^{x}, \quad \Gamma_{y}=\tilde{\partial}^{\dagger\ y}\psi(q^{-2}x)+\psi(q^{-1}x)\partial^{y}. \tag{83}$$

It is easy to check that this operator fulfills the operator equation (32):

$$\begin{aligned}(-\tilde{\partial}^{\dagger\ x}+\partial^{x})\circ\Gamma_{x}+(-\tilde{\partial}^{\dagger\ y}+\partial^{y})\circ\Gamma_{y}\\ =-(\tilde{\partial}^{\dagger x}\tilde{\partial}^{\dagger\ x}\phi(q^{-2}y)+\tilde{\partial}^{\dagger y}\tilde{\partial}^{\dagger\ y}\psi(q^{-2}x))+\phi(y)\partial^{x}\partial^{x}+\psi(x)\partial^{y}\partial^{y},\end{aligned} \tag{84}$$

where the operator $\Lambda(\tilde{\partial})$ gives the conjugated equation:

$$\Lambda(\tilde{\partial})=\tilde{\partial}^{\dagger x}\tilde{\partial}^{\dagger\ x}\phi(q^{-2}y)+\tilde{\partial}^{\dagger y}\tilde{\partial}^{\dagger\ y}\psi(q^{-2}x). \tag{85}$$

The modified $\hat{\Gamma}$ operator is given by the formula

$$\hat{\Gamma}_{x}=\tilde{\partial}^{\dagger x}\tilde{\zeta}_{x}^{-\,x}\phi(q^{-2}y)+\tilde{\zeta}_{x}^{-\,x}\phi(q^{-1}y)\partial^{x}, \tag{86}$$

$$\begin{aligned}\hat{\Gamma}_{y}=\tilde{\partial}^{\dagger x}\tilde{\zeta}_{y}^{-\,x}\phi(q^{-2}y)+\tilde{\zeta}_{y}^{-\,x}\phi(q^{-1}y)\partial^{x},\\ +\tilde{\partial}^{\dagger y}\tilde{\zeta}_{y}^{-\,y}\psi(q^{-2}x)+\tilde{\zeta}_{y}^{-\,y}\psi(q^{-1}x)\partial^{y}.\end{aligned} \tag{87}$$

Having the explicit form of the Γ and $\hat{\Gamma}$ operators we can construct the conserved currents:

$$J_{x}=\Phi'\hat{\Gamma}_{x}\Phi, \quad J_{y}=\Phi'\hat{\Gamma}_{y}\Phi, \tag{88}$$

where the functions Φ' and Φ solve the respective equations:

$$\Phi'(\tilde{\partial}^{\dagger x}\tilde{\partial}^{\dagger x}\phi(q^{-2}y)+\tilde{\partial}^{\dagger y}\tilde{\partial}^{\dagger y}\psi(q^{-2}x))=0, \tag{89}$$

$$(\phi(y)\partial^{x}\partial^{x}+\psi(x)\partial^{y}\partial^{y})\Phi=0. \tag{90}$$

According to Proposition 2.2 the above current obeys the conservation law:

$$\partial^{x}J_{x}+\partial^{y}J_{y}=0, \tag{91}$$

provided functions Φ' and Φ are the solutions of the corresponding equations (89) and (90).

B. Nonlinear equation of motion for chiral and antichiral supermultiplets

The supersymmetric models in the superfield formulation yield interesting examples of the equations of motion with coefficients depending on variables.[23] Let us recall that in such a frame-

work the fields depend on superspace coordinates including the space–time and spinor variables while in construction of the action the covariant derivatives are used which explicitly depend on spinor coordinates.

We shall study in this section the $D=4$ $N=1$ chiral and antichiral superfields obeying the nonlinear equation of motion resulting from the supersymmetric action:

$$I=\int d^4x d^2\theta d^2\overline{\theta}\overline{\Phi}\Phi+\int d^4x d^2\theta\left(\frac{m}{2}\Phi^2+\frac{g}{3}\Phi^3\right)+\int d^4x d^2\overline{\theta}\left(\frac{m}{2}\overline{\Phi}^2+\frac{g}{3}\overline{\Phi}^3\right). \tag{92}$$

The integration over spinor variables θ and $\overline{\theta}$ can be expressed in terms of the covariant derivatives:

$$\int d^2\theta=-\frac{1}{4}D^2, \quad \int d^2\overline{\theta}=-\frac{1}{4}\overline{D}^2, \tag{93}$$

$$\int d^2\theta d^2\overline{\theta}=\frac{1}{16}D^2\overline{D}^2=\frac{1}{16}\overline{D}^2D^2=\frac{1}{16}D^\alpha\overline{D}^2D_\alpha=\frac{1}{16}\overline{D}_{\dot\alpha}D^2\overline{D}^{\dot\alpha}. \tag{94}$$

The covariant derivatives used in supersymmetric models are built from the basic derivatives with respect to the space–time and spinor coordinates:

$$D_\alpha=\partial_\alpha+i\sigma^\mu_{\alpha\dot\beta}\overline{\theta}^{\dot\beta}\partial_\mu, \quad D^\alpha=\epsilon^{\alpha\beta}D_\beta, \tag{95}$$

$$\overline{D}_{\dot\alpha}=-\partial_{\dot\alpha}-i\theta^\beta\sigma^\mu_{\beta\dot\alpha}\partial_\mu, \quad \overline{D}^{\dot\alpha}=\epsilon^{\dot\alpha\dot\beta}\overline{D}_{\dot\beta}. \tag{96}$$

Due to the fact that chiral Φ and antichiral $\overline{\Phi}$ superfields fulfill the following condition,

$$\overline{D}_{\dot\alpha}\Phi=0, \quad D_\alpha\overline{\Phi}=0, \tag{97}$$

we obtain from the action (92) the equations of motion in the form

$$\begin{pmatrix} \frac{1}{4}D^2 & m+g\overline{\Phi} \\ m+g\Phi & \frac{1}{4}\overline{D}^2 \end{pmatrix}\begin{pmatrix}\Phi\\ \overline{\Phi}\end{pmatrix}=0. \tag{98}$$

We have written the equations for the superfields Φ and $\overline{\Phi}$ in the matrix form. In this example we deal with the coefficients of the equation depending explicitly on θ and $\overline{\theta}$ variables due to the form of the covariant derivatives (95) and (96):

$$D^2=D^\alpha D_\alpha=-\partial^\alpha\partial_\alpha+2i\overline{\theta}^{\dot\beta}\sigma^\mu_{\alpha\dot\beta}\partial_\mu\partial^\alpha-\overline{\theta}^2\Box, \tag{99}$$

$$\overline{D}^2=\overline{D}_{\dot\alpha}\overline{D}^{\dot\alpha}=-\overline{\partial}_{\dot\alpha}\overline{\partial}^{\dot\alpha}-2i\theta^\alpha\sigma^\mu_{\alpha\dot\beta}\partial_\mu\overline{\partial}^{\dot\beta}+\theta^2\Box. \tag{100}$$

The second important feature of the chiral–antichiral superfield equation of motion is its nonlinearity for $g\neq 0$. However, the nonlinear term does not depend on the derivatives so we can apply our method of derivation to the conservation law provided the condition (3) for the kinetic part of the operator is fulfilled. Let us extract the ζ and ζ^- operators from Leibniz's rule for basic derivatives:

$$\partial^\mu(fg)=(\partial^\mu f)g+f\partial^\mu g, \tag{101}$$

$$\partial^\alpha(fg)=(\partial^\alpha f)g+(\zeta^\alpha_\beta f)\partial^\beta g, \tag{102}$$

$$\overline{\partial}^{\alpha}(fg)=(\overline{\partial}^{\alpha}f)g+(\zeta_{\dot\beta}^{\dot\alpha}f)\overline{\partial}^{\dot\beta}g. \tag{103}$$

It is clear that $\zeta_{\nu}^{\mu}=\delta_{\nu}^{\mu}$ and the following components of the transformation operator vanish:

$$\zeta_{\alpha}^{\mu}=\zeta_{\mu}^{\alpha}=0,\quad \zeta_{\dot\alpha}^{\mu}=\zeta_{\mu}^{\dot\alpha}=0,\quad \zeta_{\alpha}^{\dot\alpha}=\zeta_{\dot\alpha}^{\alpha}=0. \tag{104}$$

The remaining components of the ζ operator are defined by its action on the monomials of the first order in superspace variables:

$$\zeta_{\beta}^{\alpha}x_{\nu}=\delta_{\beta}^{\alpha}x_{\nu},\quad \zeta_{\beta}^{\alpha}\theta_{\gamma}=-\delta_{\beta}^{\alpha}\theta_{\gamma},\quad \zeta_{\beta}^{\alpha}\overline{\theta}_{\dot\gamma}=-\delta_{\beta}^{\alpha}\overline{\theta}_{\dot\gamma}. \tag{105}$$

The analogous formulas hold also for dotted indices. Hence we get for the inverse transformation operator

$$\zeta_{\beta}^{-\ \alpha}x_{\nu}=\delta_{\beta}^{\alpha}x_{\nu},\quad \zeta_{\beta}^{-\ \alpha}\theta_{\gamma}=-\delta_{\beta}^{\alpha}\theta_{\gamma},\quad \zeta_{\beta}^{-\ \alpha}\overline{\theta}_{\dot\gamma}=-\delta_{\beta}^{\alpha}\overline{\theta}_{\dot\gamma}, \tag{106}$$

with the corresponding expressions with dotted indices of the same form.

Now having the explicitly derived inverse transformation operator we arrive at the conjugated derivatives given by the formulas

$$\partial^{\dagger\,\mu}=-\partial^{\mu},\quad \partial^{\dagger\,\alpha}=-\partial^{\beta}\zeta_{\beta}^{-\ \alpha},\quad \overline{\partial}^{\dagger\,\dot\alpha}=-\overline{\partial}^{\dot\beta}\zeta_{\dot\beta}^{-\ \dot\alpha}. \tag{107}$$

Using the conjugated derivatives we obtain the condition (3) written for our equation for the chiral and antichiral superfields:

$$\partial^{\dagger\,\alpha}\Lambda_{\alpha\mu}+\overline{\partial}^{\dagger\,\dot\alpha}\Lambda_{\dot\alpha\mu}+\partial^{\dagger\,\nu}\Lambda_{\nu\mu}=0, \tag{108}$$

$$\partial^{\dagger\,\alpha}\Lambda_{\alpha\beta}+\partial^{\dagger\,\mu}\Lambda_{\mu\beta}=0, \tag{109}$$

$$\overline{\partial}^{\dagger\,\dot\alpha}\Lambda_{\dot\alpha\dot\beta}+\partial^{\dagger\,\mu}\Lambda_{\mu\dot\beta}=0. \tag{110}$$

One can easily check that the above conditions are fulfilled using the explicit form of the coefficients from Eq. (98):

$$\Lambda_{\alpha\dot\beta}=\Lambda_{\dot\beta\alpha}=\begin{pmatrix}0&0\\0&0\end{pmatrix}, \tag{111}$$

$$\Lambda_{\alpha\beta}=-\epsilon_{\alpha\beta}\begin{pmatrix}\frac{1}{4}&0\\0&0\end{pmatrix}, \tag{112}$$

$$\Lambda_{\dot\alpha\dot\beta}=-\epsilon_{\dot\alpha\dot\beta}\begin{pmatrix}0&0\\0&\frac{1}{4}\end{pmatrix}, \tag{113}$$

$$\Lambda_{\mu\alpha}=\Lambda_{\alpha\mu}=\begin{pmatrix}\frac{i}{4}\overline{\theta}^{\dot\beta}\sigma^{\nu}_{\alpha\dot\beta}&0\\0&0\end{pmatrix}g_{\nu\mu}, \tag{114}$$

$$\Lambda_{\mu\dot\alpha}=\Lambda_{\dot\alpha\mu}=\begin{pmatrix}0&0\\0&-\frac{i}{4}\theta^{\beta}\sigma^{\nu}_{\beta\dot\alpha}\end{pmatrix}g_{\nu\mu}, \tag{115}$$

$$\Lambda_{\mu\nu}=\begin{pmatrix} -\frac{1}{4}\overline{\theta^2} & 0 \\ 0 & -\frac{1}{4}\theta^2 \end{pmatrix} g_{\mu\nu}. \tag{116}$$

The next step is therefore the application of the general formula (33) for the Γ operator to our model:

$$\Gamma_\mu=\overleftarrow{\partial}^{\dagger\,\nu}\Lambda_{\nu\mu}+\Lambda_{\mu\nu}\partial^\nu, \tag{117}$$

$$\Gamma_\alpha=-\overleftarrow{\partial}^{\dagger\,\mu}\Lambda_{\mu\alpha}+\overleftarrow{\partial}^{\dagger\,\gamma}\Lambda_{\gamma\alpha}+\Lambda_{\alpha\gamma}\partial^\gamma-\Lambda_{\alpha\mu}\partial^\mu, \tag{118}$$

$$\Gamma_{\dot\alpha}=-\overleftarrow{\partial}^{\dagger\,\mu}\Lambda_{\mu\dot\alpha}+\overleftarrow{\partial}^{\dagger\,\dot\gamma}\Lambda_{\dot\gamma\dot\alpha}+\Lambda_{\dot\alpha\dot\gamma}\partial^{\dot\gamma}-\Lambda_{\dot\alpha\mu}\partial^\mu. \tag{119}$$

The operator $\hat\Gamma$ differs from the Γ by insertion of the ζ^- operator in the middle of the monomials of derivatives:

$$\hat\Gamma_\mu=\Gamma_\mu, \tag{120}$$

$$\hat\Gamma_\beta=-\overleftarrow{\partial}^{\dagger\,\mu}\overleftarrow{\zeta}^{-\,\alpha}_{\beta}\Lambda_{\mu\alpha}+\overleftarrow{\partial}^{\dagger\,\gamma}\overleftarrow{\zeta}^{-\,\alpha}_{\beta}\Lambda_{\gamma\alpha}+\overleftarrow{\zeta}^{-\,\alpha}_{\beta}\Lambda_{\alpha\gamma}\partial^\gamma-\overleftarrow{\zeta}^{-\,\alpha}_{\beta}\Lambda_{\alpha\mu}\partial^\mu, \tag{121}$$

$$\hat\Gamma_{\dot\beta}=-\overleftarrow{\partial}^{\dagger\,\mu}\overleftarrow{\zeta}^{-\,\dot\alpha}_{\dot\beta}\Lambda_{\mu\dot\alpha}+\overleftarrow{\partial}^{\dagger\,\dot\gamma}\overleftarrow{\zeta}^{-\,\dot\alpha}_{\dot\beta}\Lambda_{\dot\gamma\dot\alpha}+\overleftarrow{\zeta}^{-\,\dot\alpha}_{\dot\beta}\Lambda_{\dot\alpha\dot\gamma}\partial^{\dot\gamma}-\overleftarrow{\zeta}^{-\,\dot\alpha}_{\dot\beta}\Lambda_{\dot\alpha\mu}\partial^\mu. \tag{122}$$

We apply the obtained operator $\hat\Gamma$ to derive the currents:

$$J_\mu=(\overline{\Phi}',\Phi')\hat\Gamma_\mu\begin{pmatrix}\Phi\\ \overline{\Phi}\end{pmatrix}, \tag{123}$$

$$J_\alpha=(\overline{\Phi}',\Phi')\hat\Gamma_\alpha\begin{pmatrix}\Phi\\ \overline{\Phi}\end{pmatrix}, \tag{124}$$

$$J_{\dot\alpha}=(\overline{\Phi}',\Phi')\hat\Gamma_{\dot\alpha}\begin{pmatrix}\Phi\\ \overline{\Phi}\end{pmatrix}, \tag{125}$$

which obey the conservation law:

$$\partial^\mu J_\mu+\partial^\alpha J_\alpha+\overline{\partial^\alpha}J_{\dot\alpha}=0, \tag{126}$$

provided the fields used in construction fulfill the corresponding equation of motion (98) and the pair of superfields $\overline{\Phi}'$ and Φ' its conjugated version:

$$(\overline{\Phi}',\Phi')\begin{pmatrix}\frac{1}{4}\overleftarrow{D}^{\dagger 2} & m+g\overline{\Phi}\\ m+g\Phi & \frac{1}{4}\overleftarrow{\overline{D}}^{\dagger 2}\end{pmatrix}=0. \tag{127}$$

Let us notice that this equation is linear with respect to superfields $\overline{\Phi}'$ and Φ' and its solution depends on the potential given by the chiral and antichiral superfields Φ and $\overline{\Phi}$.

Due to the properties of covariant derivatives built from the self-conjugated operators, we conclude that the conjugated set of equations for superfields $(\overline{\Phi}', \Phi')$ has at least following solutions:

(i) For the case $g \neq 0$ we can take $\overline{\Phi}' = \Phi$ and $\Phi' = \overline{\Phi}$ where Φ and $\overline{\Phi}$ are solutions for (98).

(ii) When $g = 0$, the superfield $\overline{\Phi}'$ is an arbitrary solution of the chiral part and Φ' of the antichiral part of the set of equations (98).

The above solutions give in turn the explicit form of the conserved currents (123)–(125) where we replace the multiplet $(\overline{\Phi}', \Phi')$ with $(\Phi, \overline{\Phi})$ for $g \neq 0$ and with $(\delta\Phi, \delta\overline{\Phi})$ for $g = 0$. Let us notice that for linear model $g = 0$ we obtain the full set of conserved currents connected with symmetry operators of chiral–antichiral supermultiplet equation:

$$J_\mu = (\delta\Phi, \delta\overline{\Phi})\hat{\Gamma}_\mu \begin{pmatrix} \Phi \\ \overline{\Phi} \end{pmatrix}, \tag{128}$$

$$J_\alpha = (\delta\Phi, \delta\overline{\Phi})\hat{\Gamma}_\alpha \begin{pmatrix} \Phi \\ \overline{\Phi} \end{pmatrix}, \tag{129}$$

$$J_{\dot{\alpha}} = (\delta\Phi, \delta\overline{\Phi})\hat{\Gamma}_{\dot{\alpha}} \begin{pmatrix} \Phi \\ \overline{\Phi} \end{pmatrix}, \tag{130}$$

where the symmetries δ include supersymmetric transformations:

$$Q_\alpha = -i\partial_\alpha - \sigma^l_{\alpha\dot{\beta}}\overline{\theta}^{\dot{\beta}}\partial_l, \quad \overline{Q}^{\dot{\alpha}} = -i\overline{\partial}^{\dot{\alpha}} + \sigma^{l\,\dot{\alpha}}_{\alpha}\theta^\alpha\partial_l, \tag{131}$$

and the operators from Poincarè algebra: momenta, angular momentum and boosts for four-dimensional Minkowski space.

We can use the obtained conserved current (123)–(125) to construct the integral of motion by integrating the time-component of the current (123) over the subspace,

$$Q = \int d^3x d^2\theta d^2\overline{\theta} J_0, \tag{132}$$

as the following equality holds:

$$\partial^0 Q = \int d^3x d^2\theta d^2\overline{\theta}\partial^0 J_0 = \int d^3x d^2\theta d^2\overline{\theta}(-\partial^k J_k - \partial^\alpha J_\alpha - \partial^{\dot{\alpha}} J_{\dot{\alpha}}) = \text{boundary terms} = 0. \tag{133}$$

Let us point out that the developed method allows immediate construction of conserved charges. The obtained charges are supermultiplets built from component charges which are also conserved separately. The application of our method to the equations obeying the condition (3) is an alternative to the procedure used in supersymmetric models (see, for example, Ref. 24 for chiral superfields and Ref. 25 for supersymmetric principal chiral model) where the conservation laws include covariant spinor derivatives D and $\overline{D}$ instead of basic derivatives ∂^μ, ∂^α and $\overline{\partial}^{\dot{\alpha}}$ which we have used. The consequence of the fact that the time-derivative does not appear explicitly in the conservation law is an additional procedure required to derive the component conservation laws and conserved charges.

C. Nonlinear integrable models and their consistency conditions

1. Nonlinear Toda lattice equation

The interesting case of application of Proposition 3.2 is the linear set of equations which originates from the nonlinear Toda lattice equation. The set of auxiliary equations derived in Ref. 21 from gauged bidifferential calculus reads as follows:

$$\dot{\chi}_k=\lambda(e^{q_{k-1}-q_k}\chi_{k-1}-\chi_k)\zeta, \tag{134}$$

$$\chi_{k+1}-\chi_k=-\lambda(\dot{\chi}_k+\dot{q}_k\chi_k)\zeta, \tag{135}$$

where we have used our notation for the transformation operator which for the mixed model like the one considered in this section is simply shifting along the lattice $\zeta f_k=f_{k-1}$ with respect to the spacelike dimension. We shall discuss the consistency condition which we obtain after elimination of the parameter λ and operator ζ from the set of equations (134) and (135). It is an equation of second order including classical derivative with respect to the time-variable and the discrete one with respect to the space-lattice variable:

$$\ddot{\chi}_k+\dot{q}_k\dot{\chi}_k-e^{q_{k-1}-q_k}(\chi_{k-1}-\chi_k)-(\chi_{k+1}-\chi_k)=0. \tag{136}$$

Let us notice that this equation is free of the parameter λ and the operator ζ.

We can rewrite this equation using the notation

$$\chi_{k-1}-\chi_k=(\zeta-1)\chi_k=\partial\chi_k, \quad \chi_{k+1}-\chi_k=(\zeta^{-}-1)\chi_k=\partial^{\dagger}\chi_k, \tag{137}$$

$$q_{k-1}-q_k=(\zeta-1)q_k=\partial q_k, \quad \dot{f}=\partial^t f, \tag{138}$$

and it has the following form:

$$[\partial^t\partial^t+(\partial^t q)\partial^t-e^{(\partial q)}\partial-\partial^{\dagger}]\chi=0. \tag{139}$$

In this form we see clearly that the equation involves both ∂ and $\partial^{\dagger}$ derivatives so we should follow the construction for discrete models given in Propositions 3.1 and 3.2.

Let us observe that the discussed equation fulfills the restriction (3) and it coincides in this case with the nonlinear Toda lattice equation:

$$\partial^{\dagger\,t}\Lambda_t+\partial^{\dagger}\Lambda_x=-\ddot{q}_k-e^{q_k-q_{k+1}}+e^{q_{k-1}-q_k}=0. \tag{140}$$

We construct the Γ operator according to (33), (37), (53), and (57) taking into account that the transformation operator acts as follows:

$$\zeta_t f_k(t)=f_k(t), \quad \zeta f_k(t)=f_{k-1}(t), \quad \zeta^{-}f_k(t)=f_{k+1}(t), \tag{141}$$

$$\hat{\Gamma}_t=\Gamma_t=-\tilde{\partial}^t+\partial^t+(\partial^t q), \tag{142}$$

$$\hat{\Gamma}_x=-\tilde{\zeta}^{-}e^{-(\partial^{\dagger}q)}, \tag{143}$$

$$\hat{\tilde{\Gamma}}_x=\tilde{\zeta}. \tag{144}$$

The components of the $\hat{\Gamma}$ operator yield the corresponding components of the current:

$$J_t^{\delta}=\delta\chi'\hat{\Gamma}_t\chi, \quad J_x^{\delta}=\delta\chi'\hat{\Gamma}_x\chi, \quad \tilde{J}_x^{\delta}=\delta\chi'\hat{\tilde{\Gamma}}_x\chi, \tag{145}$$

which obeys the conservation law including the conjugated derivative:

$$\partial^t J_t^\delta + \partial J_x^\delta + \partial^\dagger \tilde{J}_x^\delta = 0, \tag{146}$$

provided the field χ fulfills the consistency condition (139), and the field χ' its conjugation:

$$\chi'[\overleftarrow{\partial}^t \overleftarrow{\partial}^t - \overleftarrow{\partial}^t(\partial^t q) - \overleftarrow{\partial}^\dagger e^{-(\partial^\dagger q)} - \overleftarrow{\partial}] = 0, \tag{147}$$

and the operator δ is now the symmetry operator of the conjugated equation (147).

We proceed taking integrals with respect to the discrete spatial variable (we have denoted it as x) and obtain the charges

$$Q^\delta = \int dx J_t = \int dx\, \delta\chi' \hat{\Gamma}_t \chi, \tag{148}$$

which are also conserved:

$$\partial^t Q = 0. \tag{149}$$

In the above formula we understand the discrete definite integral $\int dx$ as given by (66).

We can check that the following operators transform solution χ' of equation (147) into the solution $\delta\chi'$:[26]

$$\delta^0 = c\frac{\partial}{\partial\chi'}, \quad \delta^1 = e^q \frac{\partial}{\partial\chi'}, \quad \delta^2 = [-\partial^{-1}(\partial^t q) + t]\frac{\partial}{\partial\chi'}, \tag{150}$$

where the indefinite discrete integral ∂^{-1} is given by

$$\partial^{-1} = \frac{1}{\zeta - 1} = -\sum_{k=0}^{\infty} \zeta^k, \tag{151}$$

and c is a constant.

The derived symmetries of the equation (139) lead to the following expressions for charges:

$$Q^0 = \int dx c\Gamma_t \chi, \tag{152}$$

$$Q^1 = \int dx e^q \Gamma_t \chi, \tag{153}$$

$$Q^2 = \int dx[-\partial^{-1}(\partial^t q) + t]\Gamma_t \chi. \tag{154}$$

After expanding the solutions χ with respect to powers of the operators $\lambda\zeta$ we shall be able to rewrite the expressions (148) as an infinite set of conserved charges:

$$Q^{0(m)} = \int dx c\Gamma_t \chi^{(m)}, \tag{155}$$

$$Q^{1(m)} = \int dx e^q \Gamma_t \chi^{(m)}, \tag{156}$$

$$Q^{2(m)} = \int dx[-\partial^{-1}(\partial^t q) + t]\Gamma_t \chi^{(m)}, \tag{157}$$

where the components $\chi^{(m)}$ read as follows:

$$\chi^{(m)}=(-1)^{m-1}[(\partial^{\dagger})^{-1}(\partial^{t}+(\partial^{t}q))]^{m-2}(\partial^{\dagger})^{-1}(\partial^{t}q), \quad m\geqslant 2. \tag{158}$$

2. Nonlinear Toda lattice equation—generalization

Our next example is the generalization of nonlinear Toda model sketched in Ref. 21. The functions depend now smoothly on one time variable t, one spacelike variable y and one discrete spacelike coordinate x. The bidifferential calculus is in this case defined as follows:[21]

$$\delta f=[S^{-1},f]\tau-f'\xi, \quad df=\dot{f}\tau+[S,f]\xi, \tag{159}$$

$$A=X\tau+(Y-1)S\xi, \tag{160}$$

where X and Y are matrices with entries being smooth functions of t and y and discrete in the coordinate x. The condition $\delta A=0$ leads to the following generalized Toda model nonlinear equations:

$$X_k'=Y_k-Y_{k-1}, \quad \dot{Y}_k=Y_kX_{k+1}-X_kY_k. \tag{161}$$

The linear version for auxiliary field χ can be deduced following Ref. 21 from the set of equations given by

$$\delta\chi=\lambda(d+A)\chi, \tag{162}$$

and looks as follows:

$$(S^{-1}-1)\chi=\lambda[\dot{\chi}+X\chi]S, \tag{163}$$

$$-\chi'=\lambda[(S-1)\chi+(Y-1)(S\chi)]S. \tag{164}$$

We can rewrite the above set of equations using our notations:

$$S=\zeta, \quad S^{-1}=\zeta^{-}, \tag{165}$$

$$\zeta\chi_k(t,y)=\chi_{k+1}(t,y), \quad \zeta^{-}\chi_k(t,y)=\chi_{k-1}(t,y), \tag{166}$$

$$(\zeta-1)\chi=\partial\chi, \quad (\zeta^{-}-1)\chi=\partial^{\dagger}\chi, \tag{167}$$

$$\chi'=\partial^{y}\chi, \quad \dot{\chi}=\partial^{t}\chi, \tag{168}$$

and they are given by the formulas

$$\partial^{\dagger}\chi=\lambda[\partial^{t}+X]\chi\zeta, \tag{169}$$

$$-\partial^{y}\chi=\lambda[\partial\chi+(Y-1)(\zeta\chi)]\zeta. \tag{170}$$

The consistency equation (in the symmetric form) for the above set of equations reads as

$$[\tfrac{1}{2}\partial^{y}\partial^{t}+\tfrac{1}{2}\partial^{t}\partial^{y}+X\partial^{y}-Y\partial-\partial^{\dagger}]\chi=0. \tag{171}$$

Let us point out that in the derivation of the consistency equation for the generalized Toda model not only Eqs. (169) and (170), but also the second of the Toda equations (161) were used.

We check now the condition (3) for the variable coefficients of the operator of the equation:

$$\partial^{\dagger\,y}\Lambda_y+\partial^{\dagger}\Lambda_x=-\partial^{y}X+Y-\zeta^{-}Y=0. \tag{172}$$

Our equation fulfills the restriction (3) due to the fact that X and Y obey the first of the equations of nonlinear Toda model (161). The condition (47) also holds as the coefficient for the derivative $\partial^{\dagger}$ is constant.

Similarly to the previous examples we can apply Propositions 3.1 and 3.2 for the discrete models depending on initial and conjugate discrete derivatives. In this way we obtain the $\hat{\Gamma}$ operator in the form

$$\hat{\Gamma}_t=\Gamma_t=\tfrac{1}{2}(-\tilde{\partial}^y+\partial^y),\quad \hat{\Gamma}_y=\Gamma_y=\tfrac{1}{2}(-\tilde{\partial}^t+\partial^t)+X, \tag{173}$$

$$\hat{\Gamma}_x=-\tilde{\zeta}^-(\zeta^- Y),\quad \hat{\tilde{\Gamma}}_x=-\tilde{\zeta}. \tag{174}$$

We use the above components of the $\hat{\Gamma}$ and $\hat{\tilde{\Gamma}}$ operators to construct the respective components of the currents:

$$J_t^{\delta}=\delta\chi'\hat{\Gamma}_t\chi,\quad J_y^{\delta}=\delta\chi'\hat{\Gamma}_y\chi, \tag{175}$$

$$J_x^{\delta}=\delta\chi'\hat{\Gamma}_x\chi,\quad \tilde{J}_x^{\delta}=\delta\chi'\hat{\tilde{\Gamma}}_x\chi, \tag{176}$$

where we have denoted δ as the symmetry operator of the conjugated equation (177) and χ is the solution of (169)–(171) while χ' solves its conjugation:

$$[-\tfrac{1}{2}\partial^y\partial^t-\tfrac{1}{2}\partial^t\partial^y+\partial]\chi'+(\partial^y\chi')X+(\partial^{\dagger}\chi')(\zeta^- Y)=0. \tag{177}$$

As the currents fulfill the conservation law,

$$\partial^t J_t^{\delta}+\partial^y J_y^{\delta}+\partial J_x^{\delta}+\partial^{\dagger}\tilde{J}_x^{\delta}=0, \tag{178}$$

they yield the conserved charges [with the integral $\int dx$ in the sense of (66)]:

$$Q^{\delta}=\int dydx J_t^{\delta}=\int dydx\,\delta\chi'\hat{\Gamma}_t\chi. \tag{179}$$

Following the procedure applied earlier we expand the solution χ in terms of powers of the operator $\lambda\zeta$:

$$\chi=\sum_{m=0}^{\infty}\chi^{(m)}(\lambda\zeta)^m. \tag{180}$$

After assuming the first components in the form of the unital $N\times N$ matrix,

$$\chi^{(0)}=\chi'^{(0)}=\chi^{(1)}=\chi'^{(1)}=\mathbf{1}_{N\times N}, \tag{181}$$

we obtain the following equations for the subsequent components:

$$\partial^{\dagger}\chi^{(m)}=[\partial^t+X]\chi^{(m-1)},\quad m\geqslant 2, \tag{182}$$

$$-\partial^y\chi^{(m)}=[\partial+(Y-1)\zeta]\chi^{(m-1)},\quad m\geqslant 2. \tag{183}$$

Inserting the expansion (180) into the expressions for currents and charges we arrive at the infinite towers of the conserved currents and charges:

$$J_{\mu}^{\delta(m)}=\delta\chi'\hat{\Gamma}_{\mu}\chi^{(m)}, \tag{184}$$

$$Q^{\delta\ (m)}=\int dxdy\,\delta\chi'\hat{\Gamma}_t\chi^{(m)}, \tag{185}$$

with the following explicit expressions for the components of the fields χ:

$$\chi^{(2)}=(\partial^{\dagger})^{-1}X, \tag{186}$$

$$\chi^{(m)}=[(\partial^{\dagger})^{-1}(\partial^t+X)]^{m-2}(\partial^{\dagger})^{-1}X, \quad m\geqslant 2, \tag{187}$$

and the initial solutions for the conjugated equation (177) related to the symmetry operators in the form

$$\delta^0\chi'=C, \quad \delta^1\chi'=\partial^{-1}X-y, \tag{188}$$

with C being a constant $N\times N$ matrix.

3. Double discrete nonlinear Toda lattice equation

Let us end the review of the integrable models with the fully discrete Toda lattice equation. The set of auxiliary linear equations given in Ref. 20 has the following form:

$$\chi_k(n)-\chi_k(n-1)=-\frac{\gamma}{c}[g_k^{-1}(n)g_{k+1}(n)\chi_{k+1}(n)-\chi_k(n)], \tag{189}$$

$$\chi_k(n)-\chi_{k-1}(n)=-\gamma c[g_k^{-1}(n)g_k(n+1)\chi_k(n+1)-\chi_k(n)]. \tag{190}$$

We rewrite the above equations using our notation:

$$f_k(n)-f_{k-1}(n)=-\partial^x f_k(n), \quad \zeta_x^- f_k(n)=f_{k+1}(n), \tag{191}$$

$$f_k(n)-f_k(n-1)=-\partial^t f_k(n), \quad \zeta_t^- f_k(n)=f_k(n+1). \tag{192}$$

Then the set of equations (189) and (190) looks as follows:

$$-\partial^t\chi=-\frac{\gamma}{c}[g^{-1}(\zeta_x^- g)(\zeta_x^-\chi)-\chi], \tag{193}$$

$$-\partial^x\chi=-\gamma c[g^{-1}(\zeta_t^- g)(\zeta_t^-\chi)-\chi]. \tag{194}$$

The consistency equation for the above set reads as

$$-g^{-1}(\zeta_x^- g)\partial^{\dagger\,x}\chi-\partial^x\chi+c^2g^{-1}(\zeta_t^- g)\partial^{\dagger\,t}\chi+c^2\partial^t\chi=0. \tag{195}$$

The condition (47) for our example is fulfilled:

$$\partial^{\dagger\,x}\Lambda_x+\partial^{\dagger\,t}\Lambda_t=0, \tag{196}$$

$$\partial^x\tilde{\Lambda}_x+\partial^t\tilde{\Lambda}_t=-\partial^x g^{-1}(\zeta_x^- g)+c^2\partial^t g^{-1}(\zeta_t^- g)=0, \tag{197}$$

provided the double discrete nonlinear Toda lattice equation is valid for the field g:

$$\partial^x g^{-1}(\zeta_x^- g)=c^2\partial^t g^{-1}(\zeta_t^- g). \tag{198}$$

We construct the conserved currents following Propositions 3.1 and 3.2. As both initial and conjugated derivatives appear in the equation we use the Γ and $\tilde{\Gamma}$ operators:

$$\Gamma_x = -1, \quad \tilde{\Gamma}_x = -(\zeta_x g^{-1})g, \tag{199}$$

$$\Gamma_t = c^2, \quad \tilde{\Gamma}_t = c^2(\zeta_t g^{-1})g, \tag{200}$$

and obtain the $\hat{\Gamma}$ and $\hat{\tilde{\Gamma}}$ operators with the following components:

$$\hat{\Gamma}_x = -\overleftarrow{\zeta}_x^-, \quad \hat{\tilde{\Gamma}}_x = -\overleftarrow{\tilde{\zeta}}_x(\zeta_x g^{-1})g, \tag{201}$$

$$\hat{\Gamma}_x = c^2\overleftarrow{\zeta}_t^-, \quad \hat{\tilde{\Gamma}}_t = c^2\overleftarrow{\tilde{\zeta}}_t(\zeta_t g^{-1})g. \tag{202}$$

The above operators give in turn the currents:

$$J_\mu^\delta = \delta\chi' \hat{\Gamma}_\mu \chi, \quad \tilde{J}_\mu^\delta = \delta\chi' \hat{\tilde{\Gamma}}_\mu \chi, \tag{203}$$

which are conserved according to Proposition 3.2:

$$\partial^t J_t^\delta + \partial^x J_x^\delta + \partial^{\dagger\, t}\tilde{J}_t^\delta + \partial^{\dagger\, x}\tilde{J}_x^\delta = 0, \tag{204}$$

provided the function χ solves the equation (195), χ' the conjugated equation:

$$\chi'[\overleftarrow{\partial}^x(\zeta_x g^{-1})g + \overleftarrow{\partial}^{\dagger\, x} - c^2\overleftarrow{\partial}^t(\zeta_t g^{-1})g - c^2\overleftarrow{\partial}^{\dagger\, t}] = 0, \tag{205}$$

and δ is the symmetry operator for the conjugated equation.

Following Corollary 3.3 we can reformulate the currents (203) in order to obtain the conservation law including only the ∂ derivatives:

$$J_x'^{\,\delta} = J_x^\delta - \zeta_x^-(\tilde{J}_x^\delta), \quad J_t'^{\,\delta} = J_t^\delta - \zeta_t^-(\tilde{J}_t^\delta). \tag{206}$$

The current J' obeys the conservation law:

$$\partial^t J_t'^{\,\delta} + \partial^x J_x'^{\,\delta} = 0. \tag{207}$$

Now we apply the (64) version of the conserved current so as to obtain the conserved charges:

$$Q^\delta = \int dx J_t'^{\,\delta} = \int dx(\delta\chi' \hat{\Gamma}_t \chi - \zeta_t^-(\delta\chi' \hat{\tilde{\Gamma}}_t \chi)), \tag{208}$$

where the integral $\int dx$ is defined as in (66).

D. Anomalous diffusion equation

Let us close the applications with an example of the equation built within the framework of standard differential calculus. In recent years the phenomenon of anomalous diffusion attracted more and more attention. In this context the general equation for anomalous diffusion was discussed in Refs. 27–29. It contains the fractional time-derivative.[30] We shall consider here the special case with standard partial derivatives:

$$\left[\partial^t - \frac{1}{r^{D-1}}\partial^r r^{-\Theta} r^{D-1}\partial^r - \frac{\alpha}{r^2}\right]P(r,t) = 0, \tag{209}$$

where D is the Hausdorff dimension of the underlying fractal structure and Θ is connected with the anomalous diffusion parameter d_w; $\Theta = d_w - 2$ and α is an arbitrary constant.

As the above equation is the partial differential equation we work with commuting derivatives and the transformation operator is the identity. The diffusion equation (209) can be rewritten to the form

$$[r^{\Theta}\partial^t-(\partial^r)^2-V(r)]W(r,t)=0, \tag{210}$$

with the new potential

$$V(r)=-r^{-2}\left[\frac{D-1-\Theta}{2}-\frac{(D-1-\Theta)^2}{4}\right]+\alpha r^{\Theta-2} \tag{211}$$

and the new density function

$$W(r,t)=r^{(D-1-\Theta)/2}P(r,t). \tag{212}$$

The transformed equation (210) obeys the main condition (3):

$$\partial^t\Lambda_t=0, \quad \partial^r\Lambda_{rr}=0. \tag{213}$$

Analogous transformation shall be applied to the conjugated equation:

$$\left[-\partial^t-\partial^r r^{-\Theta}r^{D-1}\partial^r\frac{1}{r^{D-1}}-\frac{\alpha}{r^2}\right]P'(r,t)=0. \tag{214}$$

Using the modified density function

$$W'(r,t)=r^{(-D+1-\Theta)/2}P'(r,t), \tag{215}$$

we arrive at the corresponding form of the conjugated equation:

$$[-r^{\Theta}\partial^t-(\partial^r)^2-V(r)]W'(r,t)=0. \tag{216}$$

As both the diffusion equation (210) and its conjugation (216) fulfill the condition (3) we can apply the general method to this partial differential equation. The components of the modified $\hat{\Gamma}$ operator coincide in our case with those of the Γ operator:

$$\hat{\Gamma}_t=\Gamma_t=r^{\Theta}, \quad \hat{\Gamma}_r=\Gamma_r=\overleftarrow{\partial}^r-\partial^r. \tag{217}$$

The current looks as follows:

$$J_t=W'(r,t)\Gamma_t W(r,t), \tag{218}$$

$$J_r=W'(r,t)\Gamma_r W(r,t). \tag{219}$$

It can be expressed in terms of the probability density functions,

$$J_t=P'(r,t)P(r,t), \tag{220}$$

$$J_r=r^{-\Theta}\left[P'(r,t)(\overleftarrow{\partial}^r-\partial^r)P(r,t)-\frac{D-1}{r}P'(r,t)P(r,t)\right], \tag{221}$$

and due to Proposition 2.2 is conserved:

$$\partial^t J_t+\partial^r J_r=0, \tag{222}$$

provided the probability density functions P and P' solve respective diffusion equations (209) and (214).

The conservation law for the fractional version of the diffusion equation

$$\left[D_t^{\gamma}-\frac{1}{r^{D-1}}\partial^r r^{-\Theta}r^{D-1}\partial^r-\frac{\alpha}{r^2}\right]P(r,t)=0 \tag{223}$$

is currently under investigation. We shall follow the results developed for fractional differential equations with constant coefficients.[31]

V. FINAL REMARKS

We have discussed the method of derivation of the conservation laws for a class of equations with variable coefficients. It can be applied to models built using supersymmetric, discrete, mixed discrete and noncommutative (quantum Minkowski or braided) differential calculus.

The conserved charges were constructed explicitly for considered supersymmetric and discrete equations. The problem of derivation of such charges for noncommutative models is open. The integration over noncommutative spaces, namely braided linear space (including q-Minkowski), is well developed,[32–34] but subintegrals and commutation rules for subintegrals and derivatives need further study. In particular, the generalized version of the property (71),

$$\partial^t \int_{\mathrm{sub}} = \int_{\mathrm{sub}} \partial^t,$$

must be derived. As we have shown for models on quantum planes,[13] it is crucial in the construction of the conserved charges.

APPENDIX: PROOF OF PROPOSITION 2.1

Let us recall the notation for monomials of derivatives:

$$[\rho_1 \dots \rho_k] := \partial^{\rho_1} \cdots \partial^{\rho_k}, \quad \overleftarrow{[\nu_1 \cdots \nu_m]} := \overleftarrow{\partial}^{\dagger\,\nu_1} \cdots \overleftarrow{\partial}^{\dagger\,\nu_m}. \tag{A1}$$

Due to the modification of Leibniz's rule we are to consider the solution of the operator equation for the Γ operator in the form of the polynomial of order $N-1$:

$$\Gamma_\mu(\partial, \overleftarrow{\partial}^\dagger) = a^0_\mu + \sum_{l=1}^{N-1} \sum_{k=0}^{l} \overleftarrow{[\mu_1, \dots, \mu_k]} a^k_{\mu\mu_1 \dots \mu_l} [\mu_{k+1}, \dots, \mu_l], \tag{A2}$$

where the coefficients a^k depend on the coordinates $\vec{x}$.

The condition (32) from Sec. II applied to the above polynomial yields the equations for coefficients $a^k_{\mu\mu_1 \dots \mu_l}$:

$$\begin{aligned}
\sum_\mu (-\overleftarrow{\partial}^{\dagger\,\mu} + \partial^\mu) \circ \Gamma_\mu(\partial, \overleftarrow{\partial}^\dagger) = &- \sum_{l=1}^{N-1} \sum_{k=0}^{l} \sum_\mu \overleftarrow{[\mu_1, \dots, \mu_k, \mu]} a^k_{\mu\mu_1 \dots \mu_l} [\mu_{k+1}, \dots, \mu_l] \\
&+ \sum_{l=1}^{N-1} \sum_{k=0}^{l} \overleftarrow{[\mu_1, \dots, \mu_k]} \sum_\mu (\zeta^\mu_\nu a^k_{\mu\mu_1 \dots \mu_l})[\nu, \mu_{k+1}, \dots, \mu_l] \\
&+ \sum_{l=1}^{N-1} \sum_{k=0}^{l} \overleftarrow{[\mu_1, \dots, \mu_k]} \sum_\mu (\partial^\mu a^k_{\mu\mu_1 \dots \mu_l})[\mu_{k+1}, \dots, \mu_l] \\
&- \sum_\mu \overleftarrow{[\mu]} a^0_\mu + \sum_\mu (\zeta^\mu_\nu a^0_\mu)[\nu] + \sum_\mu (\partial^\mu a^0_\mu) = \Lambda(\partial) - \Lambda(\overleftarrow{\partial}^\dagger).
\end{aligned} \tag{A3}$$

The procedure is analogous to the one used in the proof of Proposition 4.1 from Ref. 5, which describes the derivation of conservation law for the equation with constant coefficients or fulfilling the strong condition [see (23) and (24) from Ref. 5]. Now we have decided to change the form of the conjugated equation. This results in the weaker restrictions for coefficients of equation (1) and changes the set of equations for functions $a^k_{\mu\mu_1 \dots \mu_l}$ defining the operator Γ for the following one:

$$\partial^{\mu}a^{0}_{\mu}=0, \tag{A4}$$

$$a^{0}_{\mu}=\zeta^{-\ \alpha}_{\mu}\Lambda_{\alpha}, \tag{A5}$$

$$\partial^{\alpha}a^{0}_{\alpha\mu}+\zeta^{\nu}_{\mu}a^{0}_{\nu}=\Lambda_{\mu}, \tag{A6}$$

$$\zeta^{\alpha}_{\mu}a^{0}_{\alpha\mu_1\ldots\mu_l}+\partial^{\alpha}a^{0}_{\alpha\mu\mu_1\ldots\mu_l}=\Lambda_{\mu\mu_1\ldots\mu_l}, \tag{A7}$$

$$-a^{k}_{\mu\mu_1\ldots\mu_l}+\zeta^{\alpha}_{\mu_{k+1}}a^{k+1}_{\alpha\mu_1\ldots\mu_k\mu\mu_{k+2}\ldots\mu_l}+\partial^{\alpha}a^{k+1}_{\alpha\mu_1\ldots\mu_k\mu\mu_{k+1}\ldots\mu_l}=0, \tag{A8}$$

$$a^{l}_{\mu\mu_1\ldots\mu_l}+\partial^{\alpha}a^{l}_{\alpha\mu_1\ldots\mu_l\mu}=\zeta^{-\ \alpha}_{\mu}\zeta^{-\ \alpha_l}_{\mu_l}\ldots\zeta^{-\ \alpha_1}_{\mu_1}\Lambda_{\alpha_1\ldots\alpha_l\alpha}, \tag{A9}$$

with $l=1,\ldots,N-1$ and $k=0,\ldots,l-1$.

We see that equations (A4), (A5), and (A9) yielded by the coefficients of the conjugated equation differ from the case studied earlier in Refs. 4 and 5. We begin to solve this set of equations by deriving the coefficients $a^{0}_{\mu\mu_1\ldots\mu_l}$ from Eqs. (A5)–(A7). Namely for $l=N-1$ we have

$$\zeta^{\alpha}_{\mu}a^{0}_{\alpha\mu_1\ldots\mu_{N-1}}=\Lambda_{\mu\mu_1\ldots\mu_{N-1}}. \tag{A10}$$

Applying the inverse operator ζ^{-} we obtain

$$a^{0}_{\mu\mu_1\ldots\mu_{N-1}}=\zeta^{-\ \alpha}_{\mu}\Lambda_{\alpha\mu_1\ldots\mu_{N-1}}. \tag{A11}$$

We insert this solution into (A7) for $l=N-2$ and solve the next equation:

$$\zeta^{\alpha}_{\mu}a^{0}_{\alpha\mu_1\ldots\mu_{N-2}}-\partial^{\dagger\ \alpha}\Lambda_{\alpha\mu\mu_1\ldots\mu_{N-2}}=\Lambda_{\mu\mu_1\ldots\mu_{N-2}}. \tag{A12}$$

By assumption (3) after using ζ^{-} operator and (28) we derive $a^{0}_{\mu\mu_1\ldots\mu_{N-2}}$ as

$$a^{0}_{\mu\mu_1\ldots\mu_{N-2}}=\zeta^{-\ \alpha}_{\mu}\Lambda_{\alpha\mu_1\ldots\mu_{N-2}}. \tag{A13}$$

Passing to the next equation from the subset (A7) and solving them in the similar way we obtain the unique solution for coefficients a^{0}:

$$a^{0}_{\mu_1\ldots\mu_l}=\zeta^{-\ \alpha}_{\mu_1}\Lambda_{\alpha\mu_2\ldots\mu_l},\quad l=1,\ldots,N. \tag{A14}$$

This solution for initial coefficients allows us to evaluate the remaining ones using (A8) and (A9), namely we obtain the a^{1} coefficients after writing the subset (A8) for $k=0$ and solving it the way we solved the subset (A5)–(A7) for a^{0}. The result is unique and looks as follows:

$$a^{1}_{\mu\mu_1\mu_2\ldots\mu_l}=\zeta^{-\ \alpha}_{\mu}\zeta^{-\ \alpha_1}_{\mu_1}\Lambda_{\alpha_1\alpha\mu_2\ldots\mu_l},\quad l=1,\ldots,N-1. \tag{A15}$$

The same method applied to subsets of (A8) and (A9) for $k=1,\ldots,N-2$ produces the unique solution of the set of equations for coefficients in the form

$$a^{k}_{\mu\mu_1\ldots\mu_l}=\zeta^{-\ \alpha}_{\mu}\zeta^{-\ \alpha_k}_{\mu_k}\cdots\ \zeta^{-\ \alpha_1}_{\mu_1}\Lambda_{\alpha_1\ldots\alpha_k\alpha\mu_{k+1}\ldots\mu_l},\quad l=1,\ldots,N-1. \tag{A16}$$

The derivation of the explicit formulas for unique solution of the coefficients of the operator Γ_{μ} concludes the proof of Proposition 2.1.

Let us notice once more that in the derivation of coefficients for the Γ_{μ} operator the crucial factors were the properties of coefficients of the equations (1)–(3) which enabled us to solve the equation (32) in the explicit form.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 7 JULY 2002

Boundary values as Hamiltonian variables. II. Graded structures

Vladimir O. Soloviev[a)]
Institute for High Energy Physics, 142284 Protvino, Moscow Region, Russia

(Received 9 December 2001; accepted for publication 14 March 2002)

It is shown that the new formula for the field theory Poisson brackets arises naturally in the proposed extension of the formal variational calculus incorporating divergences. The linear spaces of local functionals, evolutionary vector fields, functional forms, multi-vectors and differential operators become graded with respect to divergences. The bilinear operations, such as the action of vector fields onto functionals, the commutator of vector fields, the interior product of forms and vectors and the Schouten–Nijenhuis bracket are compatible with the grading. A definition of the adjoint graded operator is proposed and antisymmetric operators are constructed with the help of boundary terms. The fulfilment of the Jacobi identity for the new Poisson brackets is shown to be equivalent to vanishing of the Schouten–Nijenhuis bracket of the Poisson bivector with itself. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1478144]

I. INTRODUCTION

The Hamiltonian formalism of classical mechanics may serve as the ideal model illustrating the harmony of physics and mathematics. Starting from the 1970s it was realized that a number of its mathematical constructions, for example, the Schouten–Nijenhuis bracket,[1] could be extrapolated to field theory.[2,3] This development made the search for new nonlinear integrable models much easier. More general constructions uniting the Schouten–Nijenhuis bracket with the Frolicher–Nijenhuis bracket were considered by A. Vinogradov.[4]

But these methods (initially called the formal variational calculus[5]) have some restrictions. Boundary conditions are limited by those allowing free integration by parts. As a rule, the periodic boundary conditions or the rapid decay of fields at spatial infinity are required. Of course, these are not all the physically interesting cases. For example, the Coulomb potential in electrodynamics does not tend to zero rapidly enough. The similar behavior is typical for Yang–Mills and gravitation fields. Nontrivial boundary problems arise also in the motion of material continua.

We consider the Hamiltonian treatment of nontrivial boundary problems as an interesting field of research where there is some place for new approaches and results. The field theory Poisson brackets which fulfill the Jacobi identity under arbitrary boundary conditions have been proposed in Ref. 6. Here we extend the formal variational calculus to the most general case when no one boundary term arising in integration by parts can be discarded. We present some physical applications of the methods developed here in the next paper of this series.[7] Let us also say that the interest in the role of divergences in field theory is vivid now as can be seen from related papers.[8–10]

We add that recently there has appeared a new proposal[11] for the Poisson bracket satisfying the Jacobi identity irrespective of boundary conditions. But this new formula still has no such a geometric background as the one developed here. For this reason it is not clear yet whether it can be applied, for example, to non-ultralocal brackets. We address the interested reader to Ref. 12 for a discussion.

As an example, illustrating the nonstandard nature of the problems to be considered, let us

a)Electronic mail: vosoloviev@mx.ihep.su

remind the history of the long discussion on the role of surface integrals in the canonical formulation of general relativity. During about 15 years Arnowitt, Deser and Misner,[13] Dirac,[14] Higgs,[15] Schwinger,[16] DeWitt,[17] and Regge and Teitelboim[18] were involved in it. The solution obtained in the last work[18] serves as the paradigm for the treatment of similar problems up to now. It has been proposed to work with the special class of the so-called ''differentiable'' functionals. These functionals are defined by the requirement that their variation should not have surface contributions under the prescribed boundary conditions. The Poisson brackets for these functionals are the standard ones, i.e., they are just the same as given in the formal variational calculus

$$\{F,G\}=\int_\Omega\left(\frac{\delta F}{\delta q^A(x)}\frac{\delta G}{\delta p_A(x)}-\frac{\delta G}{\delta q^A(x)}\frac{\delta F}{\delta p_A(x)}\right)d^nx,$$

but now nonzero surface contributions are allowed.

Here a natural question to ask is: do these brackets fulfill the standard axiomatic requirements, i.e., the Jacobi identity and the existence of the Poisson algebra on this space of admissible functionals? For the infinite domain of integration and the asymptotic boundary conditions the affirmative result for the second requirement was obtained by Brown and Henneaux.[19] The first requirement was partially analyzed by us and, in the case treated above, the answer is also positive.

It is more difficult to study the finite domain case. Let us take as a second example the motion of a fluid or plasma. It was shown by Lewis *et al.*[20] that the Jacobi identity for the standard Poisson bracket can be violated even in the case of fixed boundary, and so the Poisson brackets should be modified by surface terms. In the free boundary case it turns out to be natural to extend the space of admissible functionals so that their variation could include nonzero surface contributions. But according to Ref. 20 the presence of a nonzero term with δq^A in the boundary integral requires the absence of the corresponding term with δp_A and vice versa. A new formula for Poisson brackets arises as a result of a generalization of the variational derivative which is now allowed to contain a surface contribution

$$\delta H=\int_\Omega\frac{\delta^\wedge H}{\delta q^A}\delta q^A d^nx+\oint_{\partial\Omega}\frac{\delta^\vee H}{\delta q^A}\delta q^A\Big|_{\partial\Omega}dS+\int_\Omega\frac{\delta^\wedge H}{\delta p_A}\delta p_A d^nx+\oint_{\partial\Omega}\frac{\delta^\vee H}{\delta p_A}\delta p_A\Big|_{\partial\Omega}dS.$$

Unfortunately, it is not quite clear whether the Poisson bracket of the two functionals, admissible in this new sense, will be admissible functional itself.

As a third example, we would like to attract the reader's attention to consequences of the noncommutativity of the standard variational derivatives, i.e., the Euler–Lagrange derivatives. This point was discussed formally in publications by I. Anderson[21,22] and Aldersley.[23] We faced the problem independently, in the course of studying surface terms in the Poisson algebra of the Ashtekar formalism of canonical gravity.[24] There it was found that transformations of the type

$$q^A(x)\to q^A(x),\quad p_A(x)\to p_A(x)+\frac{\delta F[q]}{\delta q^A(x)},$$

were noncanonical ones if surface terms were not ignored. Tracing the connection of this calculation with the standard calculations with δ-functions,[25] we have found that the correspondence could be restored by introduction of θ_Ω—the characteristic function of the domain Ω

$$\theta_\Omega(x)=\begin{cases}1, & \text{if } x\in\Omega;\\ 0, & \text{otherwise.}\end{cases}$$

Then the standard relations

$$\left(\frac{\partial}{\partial x^i}+\frac{\partial}{\partial y^i}\right)\delta(x,y)=0$$

should be modified as

$$\left(\theta_\Omega(x)\frac{\partial}{\partial x^i}+\theta_\Omega(y)\frac{\partial}{\partial y^i}\right)\delta(x,y)=-\frac{\partial\theta_\Omega}{\partial x^i}\delta(x,y),$$

where the usually discarded surface term is preserved.

All the above examples lead us to the necessity to extend the formal variational calculus onto total divergences. This extension consists in the introduction of a new grading for the linear spaces of local functionals, vector fields, functional forms, multi-vectors and differential operators. To come back to the standard case one should put $\theta_\Omega(x)\equiv 1$ in $\mathbb{R}^n$.

The extension of the formal variational calculus naturally incorporates the new definition of local functionals (not modulo divergences now) and of their differentials (as a full variation, not restricted on the boundary). The Poisson bivectors are now defined in a more general way and they can include boundary contributions. The definition of pairing (interior product) is also revised and now the trace of two differential operators is used for it, so the pairing becomes compatible with the grading. The Poisson bracket found more or less heuristically in Ref. 6 arises now on the base of the geometrical constructions as

$$\{F,G\}=\mathrm{d}G\lrcorner\mathrm{d}F\lrcorner\Psi,$$

where Ψ is the Poisson bivector.

We show here that the Jacobi identity for the new Poisson brackets can be verified without the long calculations of binomial sums used in Ref. 6. Its fulfillment is equivalent to the vanishing of the Schouten–Nijenhuis bracket of the Poisson bivector with itself. And in its turn this condition can be easily tested along with the procedure proposed by Olver[2] with a minimal modification of it. More attention than in Ref. 6 is paid here to non-ultralocal Hamiltonian operators with non-constant coefficients, because now the technical obstacles are removed. It turns out to be that not all operators which are Hamiltonian with respect to the standard brackets remain Hamiltonian in relation to the new brackets. For example, the second structure of the Korteweg–de Vries equation is not automatically Hamiltonian with respect to the new formalism; the Jacobi identity in this case is valid only up to divergence. In this respect it strongly differs from the first KdV structure.

The content of this work is as follows. In Sec. II we introduce the grading for local functionals, and evolutionary vector fields. In Sec. III the differential, the functional m-forms, the interior product of vector fields onto m-forms and Lie derivative are defined. Section IV deals with graded differential operators and their adjoints. In Sec. V we discuss multi-vectors and the Schouten–Nijenhuis bracket. It is shown how one-vectors and evolutionary vector field spaces are isomorphic. Section VI contains the general definition of Poisson bracket, its realization in this formalism, the definition of Hamiltonian vector fields and the theorem on connection between the commutator of two Hamiltonian vector fields and the Poisson bracket of corresponding Hamiltonians. All constructions are illustrated by an example: the first Hamiltonian structure of the Korteweg–de Vries equation. The proof of Jacobi identity is postponed until Sec. VII. This new proof is applicable for all local Poisson brackets and so supersedes the proofs given earlier in Ref. 6. The proofs are easy to compare as notations are the same. At last, in Sec. VIII we consider two examples of the non-ultralocal Poisson brackets with field dependent coefficients (this class of brackets cannot be studied by the methods of Ref. 6). We show that the second structure of the Korteweg–de Vries equation is Hamiltonian only up to surface terms, whereas the two-dimensional flow of the ideal fluid is exactly described by Hamiltonian structure. This points to nontrivial character of the generalization of the formal variational calculus suggested here. A short summary is given in Sec. IX and the points remaining unclear are mentioned.

As a rule, we use below the same notations as in Ref. 6 except for a change in the notation of the Fréchet derivative (from D_f to f') and omitting the sign of summation according to the Einstein rule. We find it convenient to represent integrals over finite domain Ω through integrals over the infinite space $\mathbb{R}^n$ by inserting into all integrands the characteristic function θ_Ω. Then the formalism seems closer to the standard formal variational calculus where local functionals and functional forms are defined modulo divergences. But the formal divergences that we discard here are integrated to zero under arbitrary conditions on the boundary of the finite domain, whereas real divergences are incorporated into graded structures. All the operations introduced below are compatible both with discarding formal total divergences (if one object is a formal divergence, then the result of operation is also formal divergence) and with the grading (i.e., the same is valid for real divergences). Extension of the space of differential operators by admitting their grading permits us to use the concept of adjoint operator. So, antisymmetric operators can now be constructed and the Poisson bracket formulas become more compact than in Ref. 6, though their content is the same. Nevertheless, in the proof of the Jacobi identity we prefer to use old notations to make easier the comparison with not so general proofs of Ref. 6.

Henceforth we consider the space $\mathbb{R}^n$ and the multi-index notations $J=(j_1,\ldots,j_n)$ where $j_i\geqslant 0$:

$$\phi_A^{(J)}=\frac{\partial^{|J|}\phi_A}{\partial^{j_1}x^1\ldots\partial^{j_n}x^n},\quad |J|=j_1+\cdots+j_n.$$

The Fréchet derivative is defined as

$$f'_A=\frac{\partial f}{\partial\phi_A^{(J)}}D_J, \tag{1}$$

where

$$D_i=\frac{\partial}{\partial x^i}+\phi_A^{(J+i)}\frac{\partial}{\partial\phi_A^{(J)}},\quad D_J=D_1^{j_1}\cdots D_n^{j_n},\quad D_i^0=1,\quad D_i^{-1}=0.$$

Binomial coefficients for multi-indices are

$$\binom{J}{K}=\binom{j_1}{k_1}\ldots\binom{j_n}{k_n},$$

$$\binom{j}{k}=\begin{cases} j!/(k!(j-k)!), & \text{if } 0\leqslant k\leqslant j;\\ 0 & \text{otherwise.}\end{cases}$$

With the help of them we introduce the so-called higher Eulerian operators[2,23,26]

$$E_A^J(f)=(-1)^{|K|+|J|}\binom{K}{J}D_{K-J}\frac{\partial f}{\partial\phi_A^{(K)}}. \tag{2}$$

II. LOCAL FUNCTIONALS AND EVOLUTIONARY VECTOR FIELDS

Let us start with notions from the theory of graded spaces as they are given in Ref. 3. A *grading* in linear space L is a decomposition of it into a direct sum of subspaces, with a special value of some function p (grading function) assigned to all the elements of any subspace.

Below the function p takes its values in the set of all positive multi-indices $J=(j_1,\ldots,j_n)$ and so,

$$L=\bigoplus_{J=0}^{\infty} L^{\langle J\rangle}.$$

Elements of each subspace are called homogeneous.

A bilinear operation $x,y\mapsto x\circ y$, defined on L, is said to be *compatible with the grading* if the product of any homogeneous elements is also homogeneous, and if

$$p(x\circ y)=p(x)+p(y).$$

Now let us turn to the concrete structures.

There are two ways to write a local functional: as the integral of a smooth function $f^{\langle 0\rangle}(\phi_A^{(K)}(x))$ of fields and their derivatives up to some finite order over the prescribed domain Ω in $\mathbb{R}^n$, or as the integral over all the space $\mathbb{R}^n$ but with the characteristic function of the domain θ_Ω included into the integrand

$$F=\int_\Omega f^{\langle 0\rangle}(\phi_A^{(K)}(x))d^nx\equiv\int_{\mathbb{R}^n}\theta_\Omega f^{\langle 0\rangle}d^nx. \tag{3}$$

As in Ref. 6, let us denote the space of local functionals as $\mathcal{A}$. Here we shall call the expression given above the *canonical form of a local functional*. We formally extend that definition by allowing local functionals to be written as follows:

$$F=\int_{\mathbb{R}^n} D_J\theta_\Omega f^{\langle J\rangle}(\phi_A^{(K)}(x))d^nx\equiv\int\theta^{(J)}f^{\langle J\rangle}d^nx\equiv\int f d^nx,$$

where only a finite number of terms is allowed. Here and below we simplify the notation for derivatives of θ and remove Ω. All the integrals without the domain of integration shown explicitly are integrals over $\mathbb{R}^n$; below we shall omit d^nx. Of course, any functional can be transformed to the above form (3), exclusively used in Ref. 6, through integration by parts

$$F=\int\theta\tilde{f}^{\langle 0\rangle}\equiv\int_\Omega\tilde{f}^{\langle 0\rangle},$$

where

$$\tilde{f}^{\langle 0\rangle}=(-1)^{|J|}D_Jf^{\langle J\rangle}.$$

Evidently, the formal integration by parts over infinite space $\mathbb{R}^n$ changes the grading. It will be clear below that the general situation is the following: from one side we have the compatibility of all the bilinear operations with the grading and from the other side—with the formal integration by parts. So, basic objects (local functionals, etc.) are defined as equivalence classes modulo formal divergences (i.e., divergences of expressions containing θ-factors) and the unique decomposition into the homogeneous subspaces with the fixed grading function can be made only for representatives of these classes.

We call expressions of the form

$$\Psi=\int\theta^{(J)}D_K\psi_A^{\langle J\rangle}\frac{\partial}{\partial\phi_A^{(K)}}\equiv\int\theta^{(J)}\psi^{\langle J\rangle}\equiv\int\psi,$$

the *evolutionary vector fields*. The action of the evolutionary vector field on a local functional is given by the expression

$$\Psi F = \int \theta^{(I+J)} D_K \psi_A^{\langle J \rangle} \frac{\partial f^{\langle I \rangle}}{\partial \phi_A^{(K)}} \equiv \int \theta^{(I+J)} \psi^{\langle J \rangle} f^{\langle I \rangle} \equiv \int \psi f. \tag{4}$$

It is a straightforward calculation to check that this operation is compatible with the formal integration by parts, i.e.,

$$\psi D f = D(\psi f),$$

as it is in the standard formal variational calculus. This relation is, of course, valid for integrands.

It is easy to see that the evolutionary vector field with coefficients

$$\psi_A^{\langle J \rangle} = D_L \xi_B^{\langle I \rangle} \frac{\partial \lambda_A^{\langle J-I \rangle}}{\partial \phi_B^{(L)}} - D_L \lambda_B^{\langle I \rangle} \frac{\partial \xi_A^{\langle J-I \rangle}}{\partial \phi_B^{(L)}}$$

can be considered as the *commutator of the evolutionary vector fields* Ξ and Λ,

$$\Psi F = [\Xi, \Lambda] F = \int (\xi(\lambda f) - \lambda(\xi f)),$$

with the Jacobi identity fulfilled for the commutator operation, and so these vector fields form a Lie algebra.

Let us comment upon the representation of the evolutionary vector fields as integrals, which is different from the traditional notations.

The formal variational calculus[5] operates with the local functionals which are expressed by single integrals of functions of the specified class, for example, infinitely differentiable ones. The functional forms and multi-vectors are expressed by similar integrals. The pairing of two such objects gives us a single integral again.

At the same time, other notations are widespread, especially in physical literature, which use the δ-function and its derivatives. Then a result of the pairing of two single integrals is understood as a double integral. But as this double integral contains the δ-function, it always can be converted into the single one.

This conversion of a double integral into the single one with the help of the δ-function is trivial when no boundary terms could arise. The subject of this work is just a study of the opposite case. The new rule is necessary here and it has been proposed in Ref. 6 as Rule 4.2:

$$\int_\Omega \int_\Omega f(x) g(y) D_J^{(x)} D_K^{(y)} \delta(x,y) = \int_\Omega D_K f D_J g. \tag{5}$$

In this article we give really new and equivalent forms of these rules which help to avoid the usage of double integrals at all.

The concept of vector field appeared initially in the course of studying the evolutionary differential equations and their symmetries. In the formal variational calculus[5] functionals are, in fact, replaced by equivalence classes of functions, and so the action of evolutionary vector fields onto local functionals is replaced by their action on functions:

$$\psi f = D_K \psi_A \frac{\partial f}{\partial \phi_A^{(K)}}.$$

However, to represent functionals by integrals and to require that the result of the action of an evolutionary vector field onto a local functional is a local functional, i.e., an integral, it is absolutely natural to represent the evolutionary vector fields also as integrals,

$$\Psi = \int_\Omega D_K \psi_A(x) \frac{\partial}{\partial \phi_A^{(K)}(x)} \equiv \int \psi,$$

in combination with the standard rule

$$\frac{\partial \phi_A^{(J)}(y)}{\partial \phi_B^{(K)}(x)} = \delta(x,y)\,\delta_{AB}\delta_{JK}\,. \tag{6}$$

Another argument supporting our notations is the equivalence between evolutionary vector fields and one-vectors, which is demonstrated for the standard formal variational calculus in Ref. 2 and also for the graded case in Sec. V of this article. One-vectors as a partial case of multivectors are always written as integrals.

Apart from the notational revision we would like to mention a new feature in our treatment of the vector fields: now they are not derivations when applied to standard functions, but only to the graded ones. Of course, in the traditional approach the vector fields are not derivations when applied to functionals, because the multiplication of functionals is not defined. But these vector fields, traditionally written without the integral sign, are derivations of functions. This property is partially lost here. It can be restored formally if we consider integrands containing θ as functions and take a relation

$$D_I\theta \times D_J\theta = D_{I+J}\theta \tag{7}$$

as a definition of their multiplication.

In this context, formula (4), introduced as a definition, can be interpreted also as a consequence of the standard relation (6) and a new definition (7).

Therefore, it is evident that our ''rule for multiplication of distributions'' taken from Ref. 6, i.e., Eq. (7), is nothing more than another way to define the pairing compatible with the introduced grading.

At last, let us mention the possibility to use other notations in this formalism. It is, of course, possible to avoid θ-functions and to use integrals over the domain Ω only. Then any local functional can be given as

$$F = \int_\Omega D_J f^{\langle\langle J\rangle\rangle},$$

where

$$f^{\langle\langle J\rangle\rangle} = (-1)^{|J|} f^{\langle J\rangle},$$

with analogous rewriting of the other objects. Correspondingly, Eq. (4) will be written as

$$\Psi F = \int_\Omega D_{I+J}\left(D_K \psi_A^{\langle\langle J\rangle\rangle} \frac{\partial f^{\langle\langle I\rangle\rangle}}{\partial \phi_A^{(K)}} \right).$$

III. DIFFERENTIALS AND FUNCTIONAL FORMS

The *differential of a local functional* is simply the first variation of it,

$$\mathrm{d}F = \int \theta^{(J)} \frac{\partial f^{\langle J\rangle}}{\partial \phi_A^{(K)}}\,\delta\phi_A^{(K)} \equiv \int \theta^{(J)} \mathrm{d}f^{\langle J\rangle} \equiv \int \mathrm{d}f.$$

Here and below $\delta\phi_A^{(K)} = D_K\delta\phi_A$. It can also be expressed through the Fréchet derivative (1) or through the higher Eulerian operators (2):

$$\mathrm{d}F = \int \theta^{(J)} f^{\langle J\rangle\prime}(\delta\phi) = \int \theta^{(J)} D_K(E_A^K(f^{\langle J\rangle})\,\delta\phi_A).$$

This differential is a special example of functional one-form. A general functional one-form can be written as

$$\Sigma=\int \theta^{(J)}\sigma^{\langle J\rangle}_{AK}\delta\phi^{(K)}_{A}\equiv\int \theta^{(J)}\sigma^{\langle J\rangle}\equiv\int \sigma.$$

Of course, the coefficients $\sigma^{\langle J\rangle}_{AK}$ are not unique since we can make formal integration by parts. Let us call the following expression the *canonical form of a functional one-form*:

$$\Sigma=\int \theta^{(J)}\sigma^{\langle J\rangle}_{A}\delta\phi_{A}\,.$$

Analogously, we can define *functional m-forms* as integrals or equivalence classes modulo formal divergences of vertical m-forms:

$$\Sigma=\frac{1}{m!}\int \theta^{(J)}\sigma^{\langle J\rangle}_{A_1K_1,\ldots,A_mK_m}\delta\phi^{(K_1)}_{A_1}\wedge\cdots\wedge\delta\phi^{(K_m)}_{A_m}=\int \theta^{(J)}\sigma^{\langle J\rangle}=\int \sigma.$$

Define the *pairing* (or the *interior product*) of an evolutionary vector field and one-form as

$$\Sigma(\Xi)=\Xi\lrcorner\Sigma=\int \theta^{(I+J)}\sigma^{\langle J\rangle}_{AK}D_K\xi^{\langle I\rangle}_{A}=\int \theta^{(I+J)}\sigma^{\langle J\rangle}(\xi^{\langle I\rangle})=\int \sigma(\xi). \tag{8}$$

The interior product of an evolutionary vector field and a functional m-form will be given as follows:

$$\Xi\lrcorner\Sigma=\frac{1}{m!}(-1)^{i+1}\int \theta^{(I+J)}\sigma^{\langle J\rangle}_{A_1K_1,\ldots,A_mK_m}D_{K_i}\xi^{\langle I\rangle}_{A_i}\delta\phi^{(K_1)}_{A_1}$$

$$\wedge\cdots\wedge\delta\phi^{(K_{i-1})}_{A_{i-1}}\wedge\delta\phi^{(K_{i+1})}_{A_{i+1}}\wedge\cdots\wedge\delta\phi^{(K_m)}_{A_m}.$$

Then a value of the m-form on the m evolutionary vector fields will be defined by the formula

$$\Sigma(\Xi_1,\ldots,\Xi_m)=\Xi_m\lrcorner\cdots\Xi_1\lrcorner\Sigma.$$

It can be checked by straightforward calculation that

$$(D\sigma)(\xi_1,\ldots,\xi_m)=D(\sigma(\xi_1,\ldots,\xi_m)).$$

The *differential of the m-form*, which is given as

$$\mathrm{d}\Sigma=\frac{1}{m!}\int \theta^{(J)}\frac{\partial\sigma^{\langle J\rangle}_{A_1K_1,\ldots,A_mK_m}}{\partial\phi^{(K)}_{A}}\delta\phi^{(K)}_{A}\wedge\delta\phi^{(K_1)}_{A_1}\wedge\cdots\wedge\delta\phi^{(K_m)}_{A_m}=\int \theta^{(J)}\mathrm{d}\sigma^{\langle J\rangle}=\int \mathrm{d}\sigma,$$

satisfies standard properties

$$\mathrm{d}^2=0$$

and

$$\mathrm{d}\Sigma(\Xi_1,\ldots,\Xi_{m+1})=\sum_i(-1)^{i+1}\Xi_i\Sigma(\Xi_1,\ldots,\hat{\Xi}_i,\ldots,\Xi_{m+1})$$

$$+\sum_{i<j}(-1)^{i+j}\Sigma([\Xi_i,\Xi_j],\Xi_1,\ldots,\hat{\Xi}_i,\ldots,\hat{\Xi}_j,\ldots,\Xi_{m+1}).$$

The *Lie derivative* of a functional form Σ along the evolutionary vector field Ξ can be introduced by the standard formula

$$L_{\Xi}\Sigma = \Xi \lrcorner \mathrm{d}\Sigma + \mathrm{d}(\Xi \lrcorner \Sigma).$$

IV. GRADED DIFFERENTIAL OPERATORS AND THEIR ADJOINTS

We call linear matrix differential operators of the form

$$\hat{I}_{AB} = \theta^{(J)} I_{AB}^{\langle J \rangle N} D_N$$

the *graded differential operators*.

Let us call the linear differential operator $\hat{I}^*$ the *adjoint* to $\hat{I}$ if for an arbitrary set of smooth functions f_A, g_A

$$\int f_A \hat{I}_{AB} g_B = \int g_A \hat{I}^*_{AB} f_B .$$

For coefficients of the adjoint operator we can derive the expression

$$I^{*\langle J \rangle M}_{AB} = (-1)^{|K|} \binom{K}{L} \binom{K-L}{M} D_{K-L-M} I_{BA}^{\langle J-L \rangle K}. \tag{9}$$

It is easy to check that the relation

$$\hat{I}_{AB}(x)\,\delta(x,y) = \hat{I}^*_{BA}(y)\,\delta(x,y)$$

follows from Rule 4.2 of Ref. 6. For example, we have

$$\left(\theta(x) \frac{\partial}{\partial x^i} + \theta(y) \frac{\partial}{\partial y^i} \right) \delta(x,y) = -\theta^{(i)} \delta(x,y). \tag{10}$$

In one of our previous publications[24] we tried to connect the appearance of surface terms in Poisson brackets and the standard manipulations with the δ-function. The ansatz used there for the above simplest example coincided with (10) up to the sign. The reason for this difference laid in the other choice made there instead of Rule 4.2 of Ref. 6. That ansatz lead us to the standard Poisson brackets, which are not appropriate for nontrivial boundary problems.

Operators satisfying the relation

$$\hat{I}^* = -\hat{I}$$

will be called the *antisymmetric* ones. With the help of them it is possible to express two-forms (and also two-vectors to be defined below) in the canonical form

$$\Sigma = \frac{1}{2} \int \delta\phi_A \wedge \hat{I}_{AB} \delta\phi_B .$$

It is clear that we can consider representations of functional forms as decompositions over the basis derived as a tensor product of $\delta\phi_A$, with the totally antisymmetric multilinear operators

$$\hat{\sigma} = \theta^{(J)} \sigma^{\langle J \rangle}_{A_1 K_1, \ldots, A_m K_m} (D_{K_1} \cdot, \ldots, D_{K_m} \cdot)$$

as coefficients of these decompositions.

V. MULTI-VECTORS, MIXED TENSORS AND SCHOUTEN–NIJENHUIS BRACKET

Let us introduce dual basis to $|\delta\phi_A\rangle$ by the relation

$$\left\langle \frac{\delta}{\delta\phi_B(y)}, \delta\phi_A(x) \right\rangle = \delta_{AB}\delta(x,y) \tag{11}$$

and construct by means of the tensor product a basis

$$\frac{\delta}{\delta\phi_{B_1}(y)} \otimes \frac{\delta}{\delta\phi_{B_2}(y)} \otimes \cdots \otimes \frac{\delta}{\delta\phi_{B_m}(y)}.$$

Then by using totally antisymmetric multilinear operators described in the previous section we can define the *functional m-vectors* (or *multi-vectors*)

$$\Psi = \frac{1}{m!} \int \theta^{(J)} \psi^{\langle J\rangle}_{B_1 L_1, \ldots, B_m L_m} D_{L_1} \frac{\delta}{\delta\phi_{B_1}} \wedge \cdots \wedge D_{L_m} \frac{\delta}{\delta\phi_{B_m}} = \int \theta^{(J)} \psi^{\langle J\rangle}.$$

Here a natural question on the relation between evolutionary vector fields and one-vectors arises. Evidently, evolutionary vector fields lose their form when being integrated by parts whereas one-vectors preserve it. Let us make a partial integration in the expression of a general evolutionary vector field

$$\Xi = \int \theta^{(J)} D_K \xi^{\langle J\rangle}_A \frac{\partial}{\partial \phi^{(K)}_A}$$

by removing D_K from $\xi^{\langle J\rangle}_A$. Then we get

$$\Xi = \int \xi^{\langle J\rangle}_A \theta^{(J+L)} (-1)^{|K|} \binom{K}{L} D_{K-L} \frac{\partial}{\partial \phi^{(K)}_A}.$$

It is easy to see that by using (7), i.e., Rule 5.4 from Ref. 6, in the backward direction we can write

$$\Xi = \int (\theta^{(J)} \xi^{\langle J\rangle}_A)(\theta^{(L)} (-1)^{|L|} E^L_A) = \int \theta^{(J)} \xi^{\langle J\rangle}_A \frac{\delta}{\delta\phi_A},$$

where the higher Eulerian operators (2) and the full variational derivative (Definition 5.1 of Ref. 6)

$$\frac{\delta F}{\delta\phi_A} = \sum (-1)^{|J|} E^J_A(f) D_J \theta$$

are consequently used. Therefore, we arrive at the following statement.

Statement 5.1: There is a one-to-one correspondence between the evolutionary vector fields and the functional one-vectors. The coefficients of a one-vector in the canonical form $\xi^{\langle J\rangle}_A$ are equal to the characteristics of the evolutionary vector field.

It is not difficult to show that we can deduce the pairing (interior product) of one-forms and one-vectors and this pairing preserves the identification. Really, the definition of the dual basis (11) and (7), i.e., Rule 5.4 of Ref. 6, permits us to derive that

$$\Sigma(\Xi)=\Xi\lrcorner\Sigma=\int\int\theta^{(I)}(x)\theta^{(J)}(y)\sigma^{\langle I\rangle}_{AK}(x)\xi^{\langle J\rangle}_{BL}(y)\left\langle D_L\frac{\delta}{\delta\phi_B(y)},D_K\delta\phi_A(x)\right\rangle$$
$$=\int\theta^{(I+J)}D_L\sigma^{\langle I\rangle}_{AK}D_K\xi^{\langle J\rangle}_{AL}$$
$$=\int\theta^{(I+J)}\sigma^{\langle I\rangle}(\xi^{\langle J\rangle})=\int\sigma(\xi)=\int\theta^{(I+J)}\mathrm{Tr}(\sigma^{\langle I\rangle}\xi^{\langle J\rangle}),$$

and when a one-vector is in the canonical form (only $L=0$ term is nonzero), this result coincides with Eq. (8).

This formula for the pairing will be exploited below also for the interior product of one-vectors and m-forms or one-forms and m-vectors. Its importance comes from the fact that it is invariant under the formal partial integration both in forms and in vectors, i.e.,

$$(\mathrm{D}\sigma)(\xi)=\mathrm{D}(\sigma(\xi))=\sigma(\mathrm{D}(\xi)).$$

Evidently, it is the trace construction for convolution of differential operators (as coefficients of tensor objects in the proposed basis) that guarantees this invariance.

The interior product of a one-vector onto m-form and, analogously, of a one-form onto m-vector is defined as

$$\Xi\lrcorner\Sigma=\frac{1}{m!}(-1)^{(i+1)}\int\theta^{(I+J)}D_{K_i}\xi^{\langle I\rangle}_{A_iL}D_L(\sigma^{\langle J\rangle}_{A_1K_1,\ldots,A_mK_m}\delta\phi^{(K_1)}_{A_1}$$
$$\wedge\cdots\wedge\delta\phi^{(K_{i-1})}_{A_{i-1}}\wedge\delta\phi^{(K_{i+1})}_{A_{i+1}}\wedge\cdots\wedge\delta\phi^{(K_m)}_{A_m})$$
$$=(-1)^{(i+1)}\int\theta^{(I+J)}\xi^{\langle I\rangle}\lrcorner\sigma^{\langle J\rangle}. \tag{12}$$

Then we also can define the value of m-form on m one-vectors (or, analogously, m-vector on m one-forms)

$$\Sigma(\Xi_1,\ldots,\Xi_m)=\Xi_m\lrcorner\cdots\Xi_1\lrcorner\Sigma=\int\theta^{(J+I_1+\ldots+I_m)}\mathrm{Tr}(\sigma^{\langle J\rangle}\xi_1^{\langle I_1\rangle}\cdots\xi_m^{\langle I_m\rangle}),$$

where each entry of multilinear operator σ acts only on the corresponding ξ, whereas each derivation of the operator ξ acts on the product of σ and all the rest of the ξ's.

It is possible to define the *differential of m-vector*

$$\mathsf{d}\Psi=\frac{1}{m!}\int\theta^{(J)}\frac{\partial\psi^{\langle J\rangle}_{A_1K_1,\ldots,A_mK_m}}{\partial\phi^{(L)}_B}\delta\phi^{(L)}_BD_{K_1}\frac{\delta}{\delta\phi_{A_1}}\wedge\cdots\wedge D_{K_m}\frac{\delta}{\delta\phi_{A_m}},$$

as an example of a mixed $\binom{m}{1}$ object. Evidently, $\mathsf{d}^2\Psi=0$.

With the help of the previous constructions we can define the *Schouten–Nijenhuis bracket*

$$[\Xi,\Psi]_{SN}=\mathsf{d}\Xi\lrcorner\Psi+(-1)^{pq}\mathsf{d}\Psi\lrcorner\Xi$$

for two multi-vectors of orders p and q. The result of this operation is $p+q-1$-vector and it is analogous to the Schouten–Nijenhuis bracket in tensor analysis.[1] Its use in the formal variational calculus is described in Refs. 2 and 3. However, in cited references this bracket is usually defined for operators. We can recommend Ref. 27 as an interesting source for the treatment of the Schouten–Nijenhuis bracket of multi-vectors. Our construction of this bracket guarantees a compatibility with the equivalence modulo divergences

$$[D\xi,\psi]_{SN}=D[\xi,\psi]_{SN}=[\xi,D\psi]_{SN}.$$

Statement 5.2: The Schouten–Nijenhuis bracket of functional one-vectors up to a sign coincides with the commutator of the corresponding evolutionary vector fields.

Proof: Let us take the two one-vectors in canonical form without loss of generality,

$$\Xi=\int \theta^{(J)}\xi_A^{\langle J\rangle}\frac{\delta}{\delta\phi_A},\quad \Psi=\int \theta^{(K)}\psi_B^{\langle K\rangle}\frac{\delta}{\delta\phi_B},$$

and compute

$$[\Xi,\Psi]_{SN}=\mathsf{d}\Xi\lrcorner\Psi-\mathsf{d}\Psi\lrcorner\Xi.$$

We have

$$\mathsf{d}\Xi=\int \theta^{(J)}\xi_A^{\langle J\rangle\prime}(\delta\phi)\frac{\delta}{\delta\phi_A}=\int \theta^{(J)}\frac{\partial\xi_A^{\langle J\rangle}}{\partial\phi_C^{(L)}}\delta\phi_C^{(L)}\frac{\delta}{\delta\phi_A},$$

and

$$\mathsf{d}\Xi\lrcorner\Psi=-\int \theta^{(J+K)}\frac{\partial\xi_A^{\langle J\rangle}}{\partial\phi_B^{(L)}}D_L\psi_B^{\langle K\rangle}\frac{\delta}{\delta\phi_A}.$$

Therefore, we obtain

$$[\Xi,\Psi]_{SN}=-\int \theta^{(J+K)}\left(D_L\psi_B^{\langle K\rangle}\frac{\partial\xi_A^{\langle J\rangle}}{\partial\phi_B^{(L)}}-D_L\xi_B^{\langle K\rangle}\frac{\partial\psi_A^{\langle J\rangle}}{\partial\phi_B^{(L)}}\right)\frac{\delta}{\delta\phi_A}=-[\Xi,\Psi],$$

and the proof is completed.

Statement 5.3 (Olver's lemma[2]): The Schouten–Nijenhuis bracket for two bivectors can be expressed in the form

$$[\Lambda,\Psi]_{SN}=-\frac{1}{2}\int \xi\wedge\hat{I}'(\hat{K}\xi)\wedge\xi-\frac{1}{2}\int \xi\wedge\hat{K}'(\hat{I}\xi)\wedge\xi, \tag{13}$$

where the two differential operators $\hat{I}$, $\hat{K}$ are the coefficients of the bivectors in their canonical form.

Proof: Let us consider the Schouten–Nijenhuis bracket for the two bivectors and without loss of generality take them in the canonical form

$$\Lambda=\frac{1}{2}\int \theta^{(L)}\xi_A\wedge I_{AB}^{\langle L\rangle N}D_N\xi_B,$$

$$\Psi=\frac{1}{2}\int \theta^{(M)}\xi_C\wedge K_{CD}^{\langle M\rangle P}D_P\xi_D,$$

where $\xi_A=\delta/\delta\phi_A$ and operators $\hat{I}$, $\hat{K}$ are antisymmetric. Then we have

$$\mathsf{d}\Lambda=\frac{1}{2}\int \theta^{(L)}\frac{\partial I_{AB}^{\langle L\rangle N}}{\partial\phi_E^{(J)}}\delta\phi_E^{(J)}\xi_A\wedge D_N\xi_B$$

and

$$\mathrm{d}\Lambda \lrcorner \Psi = \frac{1}{4}\int \theta^{(L+M)} \frac{\partial I_{AB}^{\langle L\rangle N}}{\partial \phi_C^{(J)}} D_J(K_{CD}^{\langle M\rangle P} D_P \xi_D) \wedge \xi_A \wedge D_N \xi_B$$
$$- \frac{1}{4}\int \theta^{(L+M)} D_P\left(\frac{\partial I_{AB}^{\langle L\rangle N}}{\partial \phi_D^{(J)}} \xi_A \wedge D_N \xi_B \right) \wedge D_J(\xi_C K_{CD}^{\langle M\rangle P}).$$

Now let us make integration by parts in the second term:

$$\mathrm{d}\Lambda \lrcorner \Psi = -\frac{1}{4}\int \theta^{(L+M)} \xi_A \wedge (I_{AB}^{\langle L\rangle N})'(\hat{K}^{\langle M\rangle}\xi) \wedge D_N \xi_B$$
$$- \frac{1}{4}\int \theta^{(L+M+Q)} (-1)^{|P|} \binom{P}{Q} \frac{\partial I_{AB}^{\langle L\rangle N}}{\partial \phi_D^{(J)}} \xi_A \wedge D_N \xi_B \wedge D_{J+P-Q}(\xi_C K_{CD}^{\langle M\rangle P}).$$

At last we change the order of multipliers under wedge product in the second term, make a replacement $M \to M-Q$ and organize the whole expression in the form

$$\mathrm{d}\Lambda \lrcorner \Psi = -\frac{1}{4}\int \theta^{(L+M)} \xi_A \wedge (I_{AB}^{\langle L\rangle N})'_C \left(\hat{K}_{CD}^{\langle M\rangle} \xi_D + (-1)^{|P|} \binom{P}{Q} \right.$$
$$\left. \times \binom{P-Q}{R} D_{P-Q-R} K_{CD}^{\langle M-Q\rangle p} D_R \xi_C \right) \wedge D_N \xi_B .$$

Having in mind the definition of adjoint operator (9) we can represent the final result of the calculation as follows,

$$[\Lambda, \Psi]_{SN} = -\frac{1}{2}\int \theta^{(L+M)} \xi \wedge ((\hat{I}^{\langle L\rangle})'(\hat{K}^{\langle M\rangle}\xi) + (\hat{K}^{\langle M\rangle})'(\hat{I}^{\langle L\rangle}\xi)) \wedge \xi,$$

thus supporting in this extended formulation the method, proposed in Ref. 2 for testing the Jacobi identity (see Sec. VII). For the general procedure of testing Hamiltonian properties see also Ref. 28.

VI. POISSON BRACKETS AND HAMILTONIAN VECTOR FIELDS

Let us call the bivector

$$\Psi = \frac{1}{2}\int \frac{\delta}{\delta \phi_A} \wedge \hat{I}_{AB} \frac{\delta}{\delta \phi_B},$$

formed with the help of the graded antisymmetric differential operator

$$\hat{I}_{AB} = \theta^{(L)} I_{AB}^{\langle L\rangle N} D_N,$$

the *Poisson bivector* if

$$[\Psi, \Psi]_{SN} = 0.$$

The operator $\hat{I}_{AB}$ is then called the *Hamiltonian operator*. We call the value of the Poisson bivector on the differentials of two functionals F and G,

$$\{F, G\} = \Psi(\mathrm{d}F, \mathrm{d}G) = \mathrm{d}G \lrcorner \mathrm{d}F \lrcorner \Psi,$$

the *Poisson bracket* of these functionals.

The explicit form of the Poisson bracket can easily be obtained. It depends on the explicit form of the functional differential, which can be changed by the formal partial integration. Of course, all the possible forms are equivalent. Taking the extreme cases we get an expression through Fréchet derivatives,

$$\{F,G\}=\int \theta^{(J)}\mathrm{Tr}(f'_A\hat{I}^{\langle J\rangle}_{AB}g'_B), \tag{14}$$

or through higher Eulerian operators (2),

$$\{F,G\}=\int \theta^{(J)}D_{P+Q}(E^P_A(f)\hat{I}^{\langle J\rangle}_{AB}E^Q_B(g)). \tag{15}$$

Theorem 6.1: *The Poisson bracket defined above satisfies the standard requirements of the bilinearity, antisymmetry and closure on the space of local functionals $\mathcal{A}$, i.e., Definition 2.3 of Ref. 6.*

Proof: (1) From the previous formulas (14) and (15) it is clear that $\{F,G\}$ is a local functional, (2) antisymmetry of $\{F,G\}$ is evident and (3) equivalence of the Jacobi identity to the Poisson bivector property will be proved in Sec. VII.

The result of interior product of the differential of a local functional H on the Poisson bivector (up to the sign) will be called the *Hamiltonian vector field* (or the *Hamiltonian one-vector*)

$$\hat{I}\mathrm{d}H=-\mathrm{d}H\lrcorner\Psi$$

corresponding to the Hamiltonian H. Evidently, the standard relations take place:

$$\{F,H\}=\mathrm{d}F(\hat{I}\mathrm{d}H)=(\hat{I}\mathrm{d}H)F.$$

Theorem 6.2: *The Hamiltonian vector field corresponding to the Poisson bracket of the functionals F and H coincides up to the sign with the commutator of the Hamiltonian vector fields corresponding to these functionals.*

Proof: Consider a value of the commutator of Hamiltonian vector fields $\hat{I}\mathrm{d}F$ and $\hat{I}\mathrm{d}H$ on the arbitrary functional G,

$$\begin{aligned}[\hat{I}\mathrm{d}F,\hat{I}\mathrm{d}H]G&=\hat{I}\mathrm{d}F(\hat{I}\mathrm{d}H(G))-\hat{I}\mathrm{d}H(\hat{I}\mathrm{d}F(G))\\&=\hat{I}\mathrm{d}F(\{G,H\})-\hat{I}\mathrm{d}H(\{G,F\})\\&=\{\{G,H\},F\}-\{\{G,F\},H\}=-\{G,\{F,H\}\}=-\hat{I}\mathrm{d}\{F,H\}(G),\end{aligned}$$

where we have used the Jacobi identity and antisymmetry of Poisson bracket. Due to the arbitrariness of G the proof is completed.

Example 6.3: Let us consider the first structure

$$\{u(x),u(y)\}=\tfrac{1}{2}(D_x-D_y)\delta(x,y)$$

of the Korteweg–de Vries equation (Example 7.6 of Ref. 2)

$$u_t=u_{xxx}+uu_x.$$

Construct the adjoint graded operator to θD according to Eq. (9),

$$(\theta D)^*=-\theta D-D\theta,$$

and the antisymmetric operator is

$$\hat{I} = \tfrac{1}{2}(\theta D - (\theta D)^*) = \theta D + \tfrac{1}{2} D\theta.$$

The Poisson bivector has a form

$$\Psi = \frac{1}{2}\int \theta\left(\frac{\delta}{\delta u} \wedge D\frac{\delta}{\delta u}\right).$$

The differential of a local functional H (for simplicity it is written in canonical form)

$$H = \int \theta h$$

is equal to

$$\mathrm{d}H = \int \theta h'(\delta u) = \int \theta^{(k)}(-1)^k E^k(h)\,\delta u,$$

where the Fréchet derivative or higher Eulerian operators can be used. Therefore, the Hamiltonian vector field generated by H is

$$\hat{I}\mathrm{d}H = -\mathrm{d}H \lrcorner \Psi = -\frac{1}{2}\int \theta\left(h'\left(D\frac{\delta}{\delta u}\right) - Dh'\left(\frac{\delta}{\delta u}\right)\right),$$

or

$$-\frac{1}{2}\int \theta^{(k)}(-1)^k (E^k(h)D - DE^k(h))\frac{\delta}{\delta u},$$

or also

$$-\frac{1}{2}\int \theta^{(k)}(-1)^k D_i (E^k(h)D - DE^k(h))\frac{\partial}{\partial u^{(i)}}.$$

The value of this vector field on another functional F coincides with the Poisson bracket

$$-\mathrm{d}F \lrcorner \mathrm{d}H \lrcorner \Psi = \{F,H\} = \frac{1}{2}\int \theta^{(k+l)}(-1)^{k+l}(E^k(f)DE^l(h) - E^k(h)DE^l(f)).$$

VII. PROOF OF THE JACOBI IDENTITY

In this section we will prove that the Jacobi identity for the Poisson bracket is fulfilled if and only if the Schouten–Nijenhuis bracket of the corresponding Poisson bivector with itself is equal to zero. This should complete the proof of Theorem 6.1.

Let us use one of the possible forms of the Poisson brackets given in the Appendix of Ref. 6:

$$\{F,G\} = \frac{1}{2}\int \theta^{(J)}\mathrm{Tr}(f'(\hat{I}^{\langle J\rangle}g') - g'(\hat{I}^{\langle J\rangle}f')),$$

where the differential operator $\hat{I}$ is not supposed to be antisymmetric for the easier comparison of this proof with that given in Ref. 6. We remind that in less condensed notations

$$\mathrm{Tr}(f'(\hat{I}g')) = \binom{J}{M}\binom{K}{L} D_L \frac{\partial f}{\partial \phi_A^{(J)}} D_{J+K-L-M} I_{AB}^N D_{N+M} \frac{\partial g}{\partial \phi_B^{(K)}}$$

(in the Appendix of Ref. 6 the indices M and L in the binomial coefficients of the same formula are unfortunately given in the opposite order).

We will estimate the bracket

$$\{\{F,G\},H\}=\frac{1}{2}\int \theta^{(J)}\mathrm{Tr}(\{f,g\}'(\hat{I}^{\langle J\rangle}h')-h'(\hat{I}^{\langle J\rangle}\{f,g\}')),$$

where $\{f,g\}$ denotes the integrand of $\{F,G\}$. Since the Fréchet derivative is a derivation we have

$$\{f,g\}'=\tfrac{1}{2}\theta^{(K)}\mathrm{Tr}(f''(\hat{I}^{\langle K\rangle}g',\cdot)+f'\hat{I}'^{\langle K\rangle}(\cdot)g'+g''(f'\hat{I}^{\langle K\rangle},\cdot)-(f\leftrightarrow g))$$

and

$$\mathrm{Tr}(\{f,g\}'\hat{I}h')=\tfrac{1}{2}\mathrm{Tr}(f''(\hat{I}g',\hat{I}h')+f'\hat{I}'(\hat{I}h')g'+g''(f'\hat{I},\hat{I}h')-(f\leftrightarrow g)).$$

Let us explain that f'' denotes the second Fréchet derivative, i.e., the symmetric bilinear operator arising in calculation of the second variation of the local functional F (in the canonical form):

$$f''(\xi,\eta)=\frac{\partial^2 f}{\partial\phi_A^{(J)}\partial\phi_B^{(K)}}D_J\xi_A D_K\eta_B.$$

When we put into entries of f'' operators under the trace sign it should be understood that these operators act on everything except their own coefficients, for example,

$$\mathrm{Tr}(f''(\hat{I}g',\hat{I}h'))=\binom{L}{P}\binom{L-P}{Q}\binom{M}{S}\binom{M-S}{T}$$
$$\times D_{L+M-P-Q-S-T}\frac{\partial^2 f}{\partial\phi_A^{(J)}\partial\phi_B^{(K)}}D_{J+T}\left(D_P\hat{I}_{AC}\frac{\partial g}{\partial\phi_C^{(L)}}\right)D_{K+Q}\left(D_S\hat{I}_{BD}\frac{\partial h}{\partial\phi_D^{(M)}}\right)$$

and the expression remains symmetric under permutation of its entries

$$\mathrm{Tr}(f''(\hat{I}g',\hat{I}h'))=\mathrm{Tr}(f''(\hat{I}h',\hat{I}g')).$$

When the operator $\hat{I}$ stands to the right from the operator of Fréchet derivative f' as in expression

$$\mathrm{Tr}(g''(\hat{I}h',f'\hat{I})),$$

it acts on everything except f'. At last, for the Fréchet derivative of the operator we have

$$\hat{I}'(\hat{I}h')=\frac{\partial I_{AB}^K}{\partial\phi_C^{(J)}}D_J\left(I_{CD}^L D_L\frac{\partial h}{\partial\phi_D^{(M)}}D_M\right)D_K.$$

Making similar calculations we get

$$\mathrm{Tr}(h'\hat{I}\{f,g\}')=\tfrac{1}{2}\mathrm{Tr}(f''(h'\hat{I},\hat{I}g')+f'\hat{I}'(h'\hat{I})g'+g''(f'\hat{I},h'\hat{I})-(f\leftrightarrow g))$$

and therefore

$$\{\{F,G\},H\}=\frac{1}{4}\int \theta^{(J+K)}\mathrm{Tr}(f''(\hat{I}^{\langle J\rangle}g',\hat{I}^{\langle K\rangle}h')-f''(h'\hat{I}^{\langle J\rangle},\hat{I}^{\langle K\rangle}g')-f''(\hat{I}^{\langle J\rangle}h',g'\hat{I}^{\langle K\rangle})$$
$$+f''(g'\hat{I}^{\langle J\rangle},h'\hat{I}^{\langle K\rangle})+f'\hat{I}'^{\langle J\rangle}(\hat{I}^{\langle K\rangle}h'-h'\hat{I}^{\langle K\rangle})g'-(f\leftrightarrow g)).$$

Just the first four terms, apart from the fifth containing the Fréchet derivative of the operator $\hat{I}$, were present in our proof for the non-ultralocal case given in Ref. 6 (only terms with zero grading were allowed for $\hat{I}$ there). After cyclic permutation of F, G, H all terms with the symmetric operator of the second Fréchet derivative are mutually cancelled and

$$\{\{F,G\},H\}+\text{c.p.}=\frac{1}{4}\int \theta^{(J+K)}\mathrm{Tr}(f'\hat{I}'^{\langle J\rangle}(\hat{I}^{\langle K\rangle}h'-h'\hat{I}^{\langle K\rangle})g'-g'\hat{I}'^{\langle J\rangle}(\hat{I}^{\langle K\rangle}h'-h'\hat{I}^{\langle K\rangle})f'+\text{c.p.}),$$

where cyclic permutations of F, G, and H are abbreviated to c.p. When operator $\hat{I}$ is given in explicitly antisymmetric form all the four terms are equal. Taking into account Olver's Lemma (13) we get

$$\{\{F,G\},H\}+\text{c.p.}=-[\hat{I},\hat{I}]_{SN}(\mathrm{d}F,\mathrm{d}G,\mathrm{d}H),$$

so finishing the proof.

VIII. EXAMPLES: NON-ULTRALOCAL OPERATORS WITH NONCONSTANT COEFFICIENTS

The second structure of the Korteweg–de Vries equation may serve as a counterexample to the hypothesis[29] that all operators which are Hamiltonian (modulo divergences) with respect to the standard Poisson brackets should also be Hamiltonian (exactly) in the new brackets.

Example 8.1:

Let us start with the standard expression (Example 7.6 of Ref. 2)

$$\{u(x),u(y)\}=\left(\frac{d^3}{dx^3}+\frac{2}{3}u\frac{d}{dx}+\frac{1}{3}\frac{du}{dx}\right)\delta(x,y)$$

and construct the adjoint operator to

$$\hat{K}=\theta(D_3+\tfrac{2}{3}uD+\tfrac{1}{3}Du),$$

which is

$$\hat{K}^*=-\theta(D_3+\tfrac{2}{3}uD+\tfrac{1}{3}Du)-D\theta(3D_2+\tfrac{2}{3}u)-3D_2\theta D-D_3\theta.$$

Then the antisymmetric operator

$$\hat{I}=\tfrac{1}{2}(\hat{K}-\hat{K}^*)=\theta(D_3+\tfrac{2}{3}uD+\tfrac{1}{3}Du)+D\theta(\tfrac{3}{2}D_2+\tfrac{1}{3}u)+\tfrac{3}{2}D_2\theta D+\tfrac{1}{2}D_3\theta$$

can be used for forming the bivector

$$\Psi=\frac{1}{2}\int \xi\wedge\hat{I}\xi,$$

where $\delta/\delta u=\xi$. This bivector has a form

$$\Psi=\frac{1}{2}\int\left(\theta\xi\wedge D_3\xi+\frac{3}{2}D\theta\xi\wedge D_2\xi+\left(\frac{3}{2}D_2\theta+\frac{2}{3}\theta u\right)\xi\wedge D\xi\right).$$

Then evaluating the Schouten–Nijenhuis bracket for the bivector with the help of Statement 5.3,

$$[\Psi,\Psi]_{SN}=\int\left(\frac{2}{3}\theta\xi\wedge D_3\xi\wedge D\xi+D\theta\xi\wedge D_2\xi\wedge D\xi\right),$$

and integrating the first term by parts we get

$$[\Psi,\Psi]_{SN}=\frac{1}{3}\int \theta D(\xi\wedge D\xi\wedge D_2\xi).$$

Therefore, instead of the Jacobi identity we have

$$\{\{F,G\},H\}+c.p.=-\frac{1}{3}\int_\Omega D_{i+j+k+1}(E^i(f)DE^j(g)D_2E^k(h)+\text{c.p.})dx.$$

So, the second structure of KdV equation can be Hamiltonian only under special boundary conditions.

Example 8.2: Now let consider another example which is also non-ultralocal, but the operator remains to be Hamiltonian in the new brackets independently of boundary conditions. The Euler equations for the flow of ideal fluid can be written[2] in Hamiltonian form as follows (Example 7.10 of Ref. 2):

$$\frac{\partial\omega}{\partial t}=\mathcal{D}\frac{\delta H}{\delta\omega},$$

where

$$H=\int \frac{1}{2}|\mathbf{u}|^2d^2x,\quad \omega=\nabla\times\mathbf{u}.$$

Let us limit our consideration by the two-dimensional case when ω has only one component ω and

$$\mathcal{D}=\omega_xD_y-\omega_yD_x,$$

where $\omega_i=D_i\omega$, $i=(x,y)$. We can construct the antisymmetric operator

$$\hat{I}=\tfrac{1}{2}(\theta\mathcal{D}-(\theta\mathcal{D})^*)=\theta(\omega_xD_y-\omega_yD_x)+\tfrac{1}{2}(D_y\theta\omega_x-D_x\theta\omega_y),$$

and then the bivector

$$\Psi=\frac{1}{2}\int \xi\wedge\hat{I}\xi=\frac{1}{2}\int \theta(\omega_x\xi\wedge\xi_y-\omega_y\xi\wedge\xi_x),$$

where $\xi=\delta/\delta\omega$. Statement 5.3 gives us

$$[\Psi,\Psi]_{SN}=\int (\theta(\omega_x(\xi\wedge\xi_{xy}\wedge\xi_y-\xi\wedge\xi_{yy}\wedge\xi_x)+\omega_y(\xi\wedge\xi_{xy}\wedge\xi_x-\xi\wedge\xi_{xx}\wedge\xi_y))$$
$$+(D_y\theta\omega_x-D_x\theta\omega_y)\xi\wedge\xi_x\wedge\xi_y),$$

and after integration by parts the expression can be reduced to zero.

IX. CONCLUSION

We have shown that there exists an extension of the standard formal variational calculus which incorporates divergences (without any specification of boundary conditions). It would be important to understand how this formalism is related to the constructions of the variational bicomplex.[30] It seems also rather interesting to study if some physically relevant algebras can be realized with the help of new Poisson brackets as algebras of local functionals. One such example is considered in Ref. 31. This formalism may be also applied to free boundary problems as shown in the next article of this series.[7]

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 7 JULY 2002

Boundary values as Hamiltonian variables. III. Ideal fluid with a free surface

Vladimir O. Soloviev[a)]
Institute for High Energy Physics, 142284 Protvino, Moscow Region, Russia

(Received 9 December 2001; accepted for publication 14 March 2002)

An application of the approach to Hamiltonian treatment of boundary terms proposed in previous articles of this series is considered. Here the Hamiltonian formalism is constructed and the role of standard boundary conditions is revealed for a inviscid compressible fluid with surface tension which moves in a field of the Newtonian gravitational potential. It is shown that these boundary conditions guarantee absence of singular contributions to the equations of motion, i.e., to the Hamiltonian vector field. From the other side the Hamiltonian variation contains a nonzero boundary term. Such Hamiltonians are usually treated as ''nondifferentiable'' or ''inadmissible.'' We conclude that nondifferentiable functionals can be admissible Hamiltonians for non-ultralocal Poisson brackets. We give a four-sided picture of free surface dynamics: both in Lagrangian and in Eulerian variables and also both in variational and in Hamiltonian approaches. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1478145]

I. INTRODUCTION

In our previous publications[1,2] we have tried to construct a general field theory Hamiltonian formalism preserving all boundary terms arising from any integration by parts. We address the reader to these references for the detailed motivation and elaboration of the approach. The purpose of this article is to apply this formalism to a concrete problem—the ideal compressible fluid dynamics—in order to clarify the role played by boundary conditions in fixing the class of admissible functionals. A new and general result, if compared with the approach suggested by Regge and Teitelboim,[3] which is now the most popular one (see, for example, Ref. 4), is the fact that this class may differ from the class of ''differentiable'' functionals for non-ultralocal Poisson brackets. A very short and preliminary presentation of this result has already appeared in Ref. 5 with two examples considered: Ashtekar variables in canonical gravity and hydrodynamics of ideal fluid. The first example later was treated in detail in Ref. 6. Here we intend to thoroughly study the second one.

Let us remind the reader first of the history of applications of the Hamiltonian approach to surface waves in the ideal (inviscid) fluid. In 1967 Zakharov[7] was the first who suggested to apply the canonical formalism to the waves on the surface of the incompressible fluid in the case of the potential flow. Later, in 1977, this problem was discussed also by Miles[8] and Milder.[9] In 1986 Lewis, Marsden, Montgomery, and Ratiu (LMMR)[10] suggested a new approach to a more general problem where the incompressible ideal fluid flow was already not supposed to be potential. In 1988 Abarbanel *et al.*[11] treated the compressible fluid case. The approaches by these authors were rather different. It would be interesting to rederive all these results on the base of the formalism proposed in Refs. 1 and 2. But here we limit ourselves to the compressible fluid case.

Henceforth the main objective of our study will be the compressible inviscid fluid dynamics described in Eulerian coordinates and the main method will be the Hamiltonian formalism preserving all the boundary terms. For completeness of this presentation we will remind the reader here of the connections between the four possible ways of the hydrodynamics description: the

a)Electronic mail: vosoloviev@mx.ihep.su

variational approach and the Hamiltonian approach both in Lagrangian and in Eulerian coordinates. These connections may be illustrated by the following commutative diagram

Variational Principle in Lagrangian variables	*Legendre transform* $\longrightarrow$	Hamiltonian formalism in Lagrangian variables
Clebsch$\downarrow$*potentials*		$\downarrow$*reduction*
Variational Principle in Eulerian variables	*Legendre transform*+*reduction* $\longrightarrow$	Hamiltonian formalism in Eulerian variables

Our presentation is new in the part related to boundary terms. As it was already mentioned before,[11] the reduction of Hamiltonian formalism from Lagrangian variables to Eulerian ones, first made by LMMR,[10] requires here a small modification.

We will step by step consider each of the four angles and each of the four arrows of the above diagram. For every case we consider both a fixed boundary and a free boundary.

Section II concerns the variational principle in Lagrangian variables. The Lagrangian description of fluid dynamics is similar to the mechanical one and the fluid is considered as a huge number of identical mass points. The basic variables are here the coordinates of the mass points. But one needs to add to the usual potential energy of particles moving in an external field (in our case this is a field of the Newtonian gravitational potential) the internal energy which is supposed to depend on the fluid density and specific entropy. Therefore thermodynamics comes into play and a fluid temperature and pressure appear.

When dealing with the free boundary case we use the approach first proposed in Ref. 11. In particular it allows us to include into the action the surface tension energy by a suitable way for a further step to the Hamiltonian formalism.

In Sec. III we describe the transform from the Lagrangian to the Hamiltonian formalism in Lagrangian variables. Here this transformation does not create a lot of difficulties; it is only necessary to find the conjugate momenta to the coordinates of fluid particles and to make the Legendre transform.

In the case of free boundary we need not go beyond the Regge–Teitelboim criterion when deriving Hamiltonian equations of motion. This is a consequence of ultralocality of the Poisson brackets.

Section IV deals with the transform from Lagrangian variables to Eulerian ones in the framework of Hamiltonian formalism. The Eulerian description in contrast to the Lagrangian one looks like a field theory rather than mechanics. The transformation to new variables is rather nontrivial because this transformation mixes the ''dependent'' (fields) and the ''independent'' (spatial coordinates) variables. All formal calculations of the Poisson brackets are made by means of δ-functions, and this could not be understood as a rigorous deduction in the free boundary case. But results of this deduction are justified by their self-consistence. In the fixed boundary case we present explicit calculations based on our previous work[2] to demostrate the fulfillment of the Jacobi identity. This is not an easy way to prove a result as has been observed in Ref. 10. At the moment we have no such easy proof of the Jacobi identity for the free boundary case. Nevertheless, the formalism gives us the Hamiltonian equations (or the Hamiltonian vector field) by means of the internal product of the one-form (the Hamiltonian variation) and the bivector which define the Poisson bracket. At first we have a singular contribution to the Hamiltonian vector field which is proportional to the boundary δ-function. But if we put a regularity condition, i.e., require this term to be zero, we obtain the standard boundary condition for this problem (which is also the natural boundary condition following from the variational principle).

In Sec. V we construct the variational principle in Eulerian variables. The interesting story of this problem for the fixed boundary case can be found in a book by Kupershmidt.[12] After adding to the Lagrangian (which is initially taken from the Lagrangian variables approach) some constraints, there appear Clebsch variables which in the next section will serve as canonical variables of the Hamiltonian formalism.

In the free boundary case we add to the action (with minus sign) the surface energy term. But this is not enough to obtain correct boundary conditions from the variational principle and we are to add a new surface term. Then the Lagrangian density is equal to the pressure. In the particular case of the two-dimensional potential flow of incompressible fluid without surface tension the fact that the dynamical boundary conditions follow from the variational principle has been revealed by Luke.[13] Zakharov[7] has shown almost simultaneously that these boundary conditions are Hamiltonian equations.

Section VI treats the transform from the variational principle for Eulerian variables to the Hamiltonian formalism. In the fixed boundary case the Clebsch variables become canonical ones. We use here the Faddeev–Jackiw approach,[14] i.e., simply invert the symplectic matrix without looking for Dirac's "primary constraints." [15] It is easy to express the standard momenta of the Eulerian approach by means of Clebsch variables. Poisson brackets for these momenta represent the diffeomorphism algebra. The Hamiltonian also can be expressed through these momenta and a few of the Clebsch potentials: density and entropy. All this closes our diagram in its down right angle.

In the case of free boundary a new function arises which refers to the position of the boundary and so variables become noncanonical. This time we use the Dirac method for dealing with constraints and derive the Dirac brackets to construct the Poisson bivector. It is written in other variables and so differs from the one found in Sec. IV. But applying it to find the Hamiltonian vector field, i.e., to derive Hamiltonian equations, we again arrive at the result of Sec. IV. Therefore the diagram is commutative also for the free boundary case.

It is necessary to mention that recently there has appeared[16] another formula for the Poisson bracket exactly fulfilling the Jacobi identity. But this new proposal is still not general enough to include the treatment of non-ultralocal brackets and so cannot be used in this work.

II. VARIATIONAL PRINCIPLE IN LAGRANGIAN VARIABLES

The description of the continuum media in Lagrangian variables is such that the motion of each separate mass point is explicitly provided. It allows us to derive the media equations from equations of motion for mass points. Also, the thermodynamic characteristics (internal energy, temperature, pressure, entropy, etc.) are included. The particles could be numbered, for example, by their initial positions. Let the motion go on in some (fixed or changing with time) region Ω of Euclidean space $\mathbb{R}^n$, and let $\mathbf{r}\in\Omega_0$ be the particle "number," whereas $\mathbf{Y}(t)$ is its position at an arbitrary moment of time t. For simplicity we limit ourselves to Cartesian coordinates. Then the law of motion is given by the following function:

$$\mathbf{Y}=\mathbf{Y}(\mathbf{r},t), \quad \text{where} \quad \mathbf{r}\equiv\mathbf{Y}(\mathbf{r},0).$$

Classical mechanics is a deterministic theory, therefore the existence of inverse function is guaranteed:

$$\mathbf{R}=\mathbf{R}(\mathbf{x},t), \quad \text{and so} \quad \mathbf{r}\equiv\mathbf{R}(\mathbf{Y}(\mathbf{r},t),t).$$

A. Fixed boundary

It is rather natural to expect that the media Lagrangian is expressed as an integral of the difference of the kinetic and potential energy densities (with the internal energy density added to the last one) taken over the region Ω_0:

$$L=\int_{\Omega_0}\rho_0(\mathbf{r})\left[\frac{\dot{\mathbf{Y}}^2}{2}-\Phi(\mathbf{Y})-\varepsilon(\rho(\mathbf{Y}),s_0(\mathbf{r}))\right]d\mathbf{r}. \tag{1}$$

Here $\dot{\mathbf{Y}}=\partial\mathbf{Y}/\partial t(\mathbf{r},t)$; $\Phi(\mathbf{Y})$ is the potential; and $\varepsilon(\rho,s_0)$ is the internal energy per unit mass which is a function of the mass density $\rho(\mathbf{Y})$ and the specific entropy $s_0(\mathbf{r})$, where $\rho_0(\mathbf{r})$ is the mass density taken at the initial instant of time $t=0$. It is suitable to introduce the transformation matices

$$J_{ij}=\frac{\partial Y^i}{\partial r^j}, \quad J^{ij}=\frac{\partial r^i}{\partial Y^j}. \tag{2}$$

Let us denote $J=\det|J_{ij}|$. It is evident that the following relation takes place:

$$J_{ij}J^{jk}=\delta_i^k.$$

Due to the mass conservation law we have

$$\rho_0(\mathbf{r})d\mathbf{r}=\rho(\mathbf{Y})d\mathbf{Y}, \quad \text{therefore} \quad \rho_0=\rho J.$$

The entropy is supposed to be adjusted to any separate particle and additive,

$$s_0(\mathbf{r})=s(\mathbf{Y}(\mathbf{r},t),t).$$

Some additional information is given by the first law of thermodynamics

$$\delta\varepsilon=Tds_0-pd\frac{1}{\rho},$$

where T is the absolute temperature and p is the pressure, i.e.,

$$T=\frac{\partial\varepsilon}{\partial s_0}, \quad p=\rho^2\frac{\partial\varepsilon}{\partial\rho}.$$

Varying the action as a functional of $\mathbf{Y}(\mathbf{r},t)$,

$$\delta\int_{t_1}^{t_2}Ldt=\int_{t_1}^{t_2}\int_{\Omega_0}\rho_0(\mathbf{r})\left[\dot{\mathbf{Y}}\frac{\partial}{\partial t}\delta\mathbf{Y}-\frac{\partial\Phi}{\partial\mathbf{Y}}\delta\mathbf{Y}-\frac{\partial\varepsilon}{\partial\rho}\delta\rho\right]d\mathbf{r},$$

where

$$\delta\rho=\delta\left(\frac{\rho_0}{J}\right)=-\frac{\rho_0}{J^2}\delta J,$$

and therefore

$$-\rho_0\frac{\partial\varepsilon}{\partial\rho}\delta\rho=p\,\delta J$$

leads to equations of motion. Taking into account that the Jacobian variation is given by the following formula,

$$\delta J=JJ^{ji}\delta J_{ij}=JJ^{ji}\frac{\partial}{\partial r^j}\delta Y^i,$$

we obtain

$$p\,\delta J=\frac{\partial}{\partial r^j}(pJJ^{ji}\delta Y^i)-JJ^{ji}\frac{\partial p}{\partial r^j}\delta Y^i-p\frac{\partial}{\partial r^j}(JJ^{ji})\delta Y^i.$$

In the Appendix it is shown that the last term is, in fact, zero. Taking into account that

$$\frac{\partial p}{\partial Y^i}=\frac{\partial p}{\partial r^j}\frac{\partial r^j}{\partial Y^i}=J^{ji}\frac{\partial p}{\partial r^j},$$

we arrive at the following expression for the action variation:

$$\delta\int_{t_1}^{t_2}L\,dt=\int_{\Omega_0}d\mathbf{r}\rho_0\dot{\mathbf{Y}}\delta\mathbf{Y}\Big|_{t_1}^{t_2}+\int_{t_1}^{t_2}\int_{\Omega_0}\delta\mathbf{Y}\left[-\rho_0\ddot{\mathbf{Y}}-\rho_0\frac{\partial\Phi}{\partial\mathbf{Y}}-J\frac{\partial p}{\partial\mathbf{Y}}\right]d\mathbf{r}+\int_{t_1}^{t_2}dt\oint_{\partial\Omega_0}pJJ^{ji}\delta Y^i dS_j. \tag{3}$$

According to the variational principle by Hamilton we are to fix variables at the boundaries of the time interval:

$$\delta\mathbf{Y}(t_1)=\delta\mathbf{Y}(t_2)=0.$$

The term with variation $\delta\mathbf{Y}$ on the spatial boundary $\partial\Omega_0$ is zero due to the fixed boundary conditions for domain $\Omega=\Omega_0$,

$$n_jJ^{ji}\delta Y^i|_{\partial\Omega_0}=0,\quad\text{or}\quad\mathbf{n}\cdot\delta\mathbf{Y}|_{\partial\Omega}=0, \tag{4}$$

where n^j is the normal to the boundary $\partial\Omega_0$ (for the definiteness here and below it is the unit outside normal), which is supposed to be smooth; correspondingly, $\mathbf{n}$ is the same vector given in coordinates $\mathbf{Y}$.

The meaning of these boundary conditions is that particles which occur on the boundary at the initial moment of time will stay there forever.

As the volume integral in the variation of action should be zero, we obtain the Lagrangian equations of motion in Lagrangian coordinates:

$$\ddot{\mathbf{Y}}=-\frac{\partial\Phi}{\partial\mathbf{Y}}-\frac{1}{\rho}\frac{\partial p}{\partial\mathbf{Y}},\quad\text{or}\quad\ddot{Y}^i=-JJ^{ji}\frac{\partial\Phi}{\partial r^j}-\frac{JJ^{ji}}{\rho_0}\frac{\partial p}{\partial r^j}. \tag{5}$$

B. Free boundary

Suppose now that the fluid boundary or some part of it is free. Then position of the boundary $\partial\Omega=\partial\Omega_t$ is to be decribed by dynamical variables. In the Eulerian approach it requires us to introduce a new independent function, but here it is sufficient to use the same variable $\mathbf{Y}(\mathbf{r},t)$, though its variation on the boundary now is not constrained by condition (4). Moreover, some new terms given by boundary integrals may arise in the action, for example, the energy of surface tension

$$L\to L-E_{\text{surf}},$$

which is defined (up to a constant) by the following expression,

$$E_{\text{surf}}=\tau\int_{\partial\Omega_t}dS=\tau\int_{\partial\Omega_t}n^i dS_i=\tau\int_{\Omega_t}\nabla\cdot\mathbf{n}d\mathbf{Y}, \tag{6}$$

where n^i is unit outward normal to the boundary which is smoothly continued onto the whole domain Ω. It is possible to treat such problems on the base of the formalism suggested in our previous papers,[1,2] but it should be slightly generalized. Let us introduce function $P_\Omega(\mathbf{Y})$, which is positive everywhere in the region Ω, equal to zero on the boundary $\partial\Omega$ and negative outside. Then we can formally write the integral over our domain Ω as an integral over the whole space $\mathbb{R}^n$:

$$\int_{\Omega} f d\mathbf{Y} = \int \theta(P_{\Omega}) f d\mathbf{Y}. \tag{7}$$

The required generalization is that earlier[1,2] we have not treated P_{Ω} as a variable, whereas now we do so. If we suppose $\nabla P_{\Omega} \neq 0$ on $\partial\Omega$, the unit outward normal to the boundary surface is given by the following formula:

$$\mathbf{n} = -\frac{\nabla P_{\Omega}}{|\nabla P_{\Omega}|}.$$

Then the surface tension energy of the fluid (6) may be written as follows:

$$E_{\text{surf}} = \tau \int \theta(P_{\Omega}) \nabla \cdot \mathbf{n} d\mathbf{Y} = -\tau \int (\nabla \theta \cdot \mathbf{n}) d\mathbf{Y}.$$

From the other side,

$$\frac{\partial \theta(P_{\Omega})}{\partial Y^i} = \frac{d\theta(P_{\Omega})}{dP_{\Omega}} \frac{\partial P_{\Omega}}{\partial Y^i}, \quad \frac{d\theta(P_{\Omega})}{dP_{\Omega}} = \left(\nabla \theta(P_{\Omega}) \cdot \frac{\nabla P_{\Omega}}{|\nabla P_{\Omega}|^2} \right), \tag{8}$$

i.e.,

$$E_{\text{surf}} = \tau \int \frac{d\theta(P_{\Omega})}{dP_{\Omega}} |\nabla P_{\Omega}| d\mathbf{Y}.$$

Let us introduce a notion

$$K = \nabla \cdot \mathbf{n}.$$

It is easy to be convinced that on the boundary K is equal to the trace of a second fundamental form of a boundary surface. Then

$$E_{\text{surf}} = \tau \int_{\Omega_t} K d\mathbf{Y} = \tau \int \theta(P_{\Omega}) K d\mathbf{Y}.$$

To deduce a natural boundary condition we are to find a variation of this expression when function $\mathbf{Y}(\mathbf{r},t)$ is varied. First consider the surface energy variation due to varying P_{Ω}:

$$\delta E_{\text{surf}} = \tau \int \frac{d\theta(P_{\Omega})}{dP_{\Omega}} \delta P_{\Omega} K d\mathbf{Y} + \tau \int \theta(P_{\Omega}) \delta K d\mathbf{Y}.$$

Let us demonstrate that the second term is really zero (we omit $d\mathbf{Y}$),

$$\int \theta(P_{\Omega}) \delta K = \int \theta(P_{\Omega}) \delta \nabla \cdot \mathbf{n} = -\int \nabla \theta(P_{\Omega}) \delta \mathbf{n} = -\int \frac{d\theta}{dP_{\Omega}} |\nabla P_{\Omega}| (\mathbf{n} \cdot \delta \mathbf{n}) = 0, \tag{9}$$

as the only contribution to the integral comes from the boundary $\partial\Omega$, and the unit normal variation on the boundary is orthogonal to the normal itself. Therefore we obtain

$$\delta E_{\text{surf}} = \tau \int \frac{d\theta}{dP_{\Omega}} K \delta P_{\Omega} d\mathbf{Y}.$$

We will use this formula as it is when dealing with Eulerian coordinates. But here we are to find variation δE_{surf} induced by variation $\delta\mathbf{Y}$, as P_Ω is not an independent variable in the Lagrangian picture. The point is that the domain of definition for $\mathbf{r}$, i.e., Ω_0, does not change even in the case of the variable domain Ω.

Instead of function $P_\Omega(\mathbf{Y},t)$, corresponding to Ω, for the region Ω_0 we can use function

$$P_{\Omega_0}(\mathbf{r}) = P_\Omega(\mathbf{Y}(\mathbf{r},t),t)$$

or

$$P_\Omega(\mathbf{x},t) = P_{\Omega_0}(\mathbf{R}(\mathbf{x},t)).$$

Function $P_{\Omega_0}(\mathbf{r})$ should not be varied as also functions $\rho_0(\mathbf{r})$ and $s_0(\mathbf{r})$. Therefore we should take into account the following equation:

$$\delta P_\Omega = \frac{\partial P_\Omega}{\partial \mathbf{Y}}\,\delta\mathbf{Y} = \frac{\partial P_{\Omega_0}}{\partial r^j} J^{ji}\delta Y^i.$$

Then

$$\delta E_{\text{surf}} = \tau \int \frac{d\theta}{dP_\Omega}\frac{\partial P_\Omega}{\partial Y_i} K\,\delta Y^i d\mathbf{Y},$$

or, taking into account (8),

$$\delta E_{\text{surf}} = \tau \int \theta_{,j} K J J^{ji}\delta Y^i d\mathbf{r} = -\tau \int_{\Omega_0} \partial_j (K J J^{ji}\delta Y^i) d\mathbf{r}.$$

This term, together with the surface term from Eq. (3), give us the full surface contribution to the action variation in the free boundary case:

$$(\delta S)_{\text{surf}} = \int_{t_1}^{t_2} dt \int_{\Omega_0} \partial_j ((p-\tau K) J J^{ji}\delta Y^i) d\mathbf{r} = \int_{t_1}^{t_2} dt \oint_{\partial\Omega_0} (p-\tau K) J J^{ji}\delta Y^i dS_j\,.$$

The variational principle by Hamilton requires this term to be zero and as variation $\delta\mathbf{Y}$ is here arbitrary we obtain the so-called natural boundary conditions:[17,18]

$$(p-\tau K)\big|_{\partial\Omega_0} = 0. \tag{10}$$

As boundary maps to boundary after the coordinate transform $\mathbf{r}\to\mathbf{Y}(\mathbf{r},t)$, the last equality can be rewritten in the standard form:[19]

$$(p-\tau K)\big|_{\partial\Omega} = 0. \tag{11}$$

III. HAMILTONIAN FORMALISM IN LAGRANGIAN VARIABLES

A. Fixed boundary

It is easy to see from the action variation (3) that the momenta conjugated to variables $\mathbf{Y}(\mathbf{r},t)$ are as follows:

$$\mathbf{M}(\mathbf{r},t) = \rho_0(\mathbf{r})\dot{\mathbf{Y}}(\mathbf{r},t), \quad \{Y^i(\mathbf{r},t), M_j(\mathbf{r}',t)\} = \delta^i_j \delta(\mathbf{r},\mathbf{r}').$$

The standard Legendre transform of Lagrangian (1) leads to the following Hamiltonian:

$$\mathrm{H}=\int_{\Omega_0}\left(\frac{\mathbf{M}^2}{2\rho_0}+\rho_0\Phi(\mathbf{Y})+\rho_0\varepsilon(\rho(\mathbf{Y}),s_0)\right)d\mathbf{r}. \tag{12}$$

In the Hamiltonian variation

$$\delta\mathrm{H}=\int_{\Omega_0}\left(\delta\mathbf{M}\left[\frac{\mathbf{M}}{\rho_0}\right]+\delta\mathbf{Y}\left[\rho_0\frac{\partial\Phi}{\partial\mathbf{Y}}+J\frac{\partial p}{\partial\mathbf{Y}}\right]\right)d\mathbf{r}-\int_{\partial\Omega_0}pJJ^{ji}\delta Y^i dS_j$$

the last term becomes zero if boundary conditions (4) are valid. This result gives us an opportunity to treat the expressions in square brackets as variational derivatives. Then Hamiltonian equations reduce to the standard form

$$\dot{\mathbf{Y}}=\{\mathbf{Y},\mathrm{H}\}=\frac{\delta\mathrm{H}}{\delta\mathbf{M}},\quad \dot{\mathbf{M}}=\{\mathbf{M},\mathrm{H}\}=-\frac{\delta\mathrm{H}}{\delta\mathbf{Y}} \tag{13}$$

or, explicitly,

$$\dot{\mathbf{Y}}=\frac{\mathbf{M}}{\rho_0},\quad \dot{\mathbf{M}}=-\rho_0\frac{\partial\Phi}{\partial\mathbf{Y}}-J\frac{\partial p}{\partial\mathbf{Y}}. \tag{14}$$

It is easy to see that these equations are equivalent to Lagrangian ones (5). As to the Jacobi identity, canonical Poisson brackets defined in Refs. 1 and 2 satisfy it without any reference to boundary conditions as shown there.

B. Free boundary

Let us add to Hamiltonian (12) the surface energy

$$\mathrm{H}=\int_{\Omega_0}\left(\frac{\mathbf{M}^2}{2\rho_0}+\rho_0\Phi(\mathbf{Y})+\rho_0\varepsilon(\rho(\mathbf{Y}),s_0)\right)d\mathbf{r}+\tau\int_{\partial\Omega}n^i dS_i.$$

Now its variation is as follows,

$$\delta\mathrm{H}=\int_{\Omega_0}\left(\delta\mathbf{M}\left[\frac{\mathbf{M}}{\rho_0}\right]+\delta\mathbf{Y}\left[\rho_0\frac{\partial\Phi}{\partial\mathbf{Y}}+J\frac{\partial p}{\partial\mathbf{Y}}\right]\right)d\mathbf{r}-\int_{\partial\Omega_0}(p-\tau K)JJ^{ji}\delta Y^i dS_j,$$

where variation $\delta\mathbf{Y}$ is free on the boundary. Then we calculate the full variational derivatives

$$\frac{\delta\mathrm{H}}{\delta Y^i}=\theta(P_{\Omega_0})\left[\rho_0\frac{\partial\Phi}{\partial Y^i}+J\frac{\partial p}{\partial Y^i}\right]+\frac{\partial\theta(P_{\Omega_0})}{\partial r^i}[p-\tau K],$$

$$\frac{\delta\mathrm{H}}{\delta M^i}=\theta(P_{\Omega_0})\left[\frac{M^i}{\rho_0}\right].$$

The Hamiltonian vector field and equations of motion are formally the same as in the fixed boundary case (13). But now there is a singular contribution proportional to the δ-function. If we demand that this term has to be zero, we get standard boundary conditions (10). Here the Poisson bracket is canonical, and so, ultralocal,

$$\{\mathrm{F},\mathrm{G}\}=-\mathrm{d}\mathrm{F}\lrcorner\mathrm{d}\mathrm{G}\lrcorner\Psi=\int\left(\frac{\delta\mathrm{F}}{\delta Y^i}\frac{\delta\mathrm{G}}{\delta M_i}-\frac{\delta\mathrm{G}}{\delta Y^i}\frac{\delta\mathrm{F}}{\delta M_i}\right)d\mathbf{r},$$

therefore this requirement is equivalent to the disappearance of the surface term in the Hamiltonian variation, i.e., to the ''differentiability'' condition for the Hamiltonian in accordance with

Regge–Teitelboim approach.[3] Below we will see that these two requirements are not equivalent in the case of non-ultralocal Poisson brackets. As to the Jacobi identity the arguments given above for the fixed boundary are still valid because $\partial\Omega_0$ is not dynamical.

Let us mention as a curious thing that both in Ref. 10, and in our paper, Ref. 1, just similar nonzero surface terms in the Hamiltonian variation for incompressible fluid have served as a motivation to modify the standard formula for Poisson bracket. But in Ref. 11 it was reasonably stated that just this surface contribution should be zero as a consequence of boundary conditions. Such contributions, as we will see below, are important only for more complicated situations when Poisson brackets are non-ultralocal.

IV. HAMILTONIAN FORMALISM IN EULERIAN VARIABLES

A. Fixed boundary

The step from the Lagrangian description to the Eulerian one on the base of Hamiltonian formalism is a change of variables of the more general type than we used to do in the field theory. In some sense such a change is like general relativity transformations making coordinates dependent on the metric tensor (c-numbers become functions of q-numbers in quantum theory),

$$M_i(\mathbf{r},t)d\mathbf{r}=\pi_i(\mathbf{Y}(\mathbf{r},t),t)d\mathbf{Y},$$

or

$$\pi_i(\mathbf{x},t)=\int_{\Omega_0}\delta(\mathbf{x}-\mathbf{Y}(\mathbf{r},t))M_i(\mathbf{r},t)d\mathbf{r}.$$

Analogous relations are valid for mass densities in the two approaches

$$\rho_0(\mathbf{r})d\mathbf{r}=\rho(\mathbf{Y}(\mathbf{r},t),t)d\mathbf{Y},\quad \rho(\mathbf{x},t)=\int_{\Omega_0}\delta(\mathbf{x}-\mathbf{Y}(\mathbf{r},t))\rho_0(\mathbf{r})d\mathbf{r},$$

but equations for the specific entropy are different as it is a scalar, not a scalar density:

$$s(\mathbf{x},t)=s_0(\mathbf{R}(\mathbf{x},t)),\quad s(\mathbf{x},t)=\int_{\Omega_0}\delta(\mathbf{r}-\mathbf{R}(\mathbf{x},t))s_0(\mathbf{r})d\mathbf{r}. \tag{15}$$

Here

$$\mathbf{R}(\mathbf{Y}(\mathbf{r},t),t)\equiv\mathbf{r},\quad \mathbf{Y}(\mathbf{R}(\mathbf{x},t),t)\equiv\mathbf{x}.$$

Though momenta $M_i(\mathbf{r},t)$ are replaced in the Eulerian approach by an equal number of degrees of freedom $\pi_i(\mathbf{x},t)$, coordinates $Y^i(\mathbf{r},t)$ are replaced by new variables $\rho(\mathbf{x},t)$, $s(\mathbf{x},t)$, and their number in general is not equal to the spatial dimension. We will see, after all, that even for the new momenta π_i Poisson brackets are different from canonical ones.

To calculate the Poisson brackets for the new variables it is convenient to go to their linear functionals, as follows,

$$\pi(\lambda)=\int_\Omega d\mathbf{x}\lambda^i(\mathbf{x})\pi_i(\mathbf{x})=\int_\Omega d\mathbf{x}\int_{\Omega_0}d\mathbf{r}\lambda^i(\mathbf{x})\delta(\mathbf{x}-\mathbf{Y}(\mathbf{r},t))M_i(\mathbf{r},t)=\int_{\Omega_0}d\mathbf{r}\lambda^i(\mathbf{Y}(\mathbf{r},t))M_i(\mathbf{r},t).$$

Therefore

$$\{\pi(\lambda),\pi(\mu)\}=\int_{\Omega_0}d\mathbf{r}\int_{\Omega_0}d\mathbf{r}'\{\lambda^i(\mathbf{Y}(\mathbf{r},t))M_i(\mathbf{r},t),\mu^j(\mathbf{Y}(\mathbf{r}',t))M_j(\mathbf{r}',t)\}$$

$$=\int_{\Omega_0}d\mathbf{r}\int_{\Omega_0}d\mathbf{r}'\Big(\{\lambda^i(\mathbf{Y}(\mathbf{r},t)),M_j(\mathbf{r}',t)\}M_i(\mathbf{r},t)\mu^j(\mathbf{Y}(\mathbf{r}',t))$$

$$+\{M_i(\mathbf{r},t),\mu^j(\mathbf{Y}(\mathbf{r}',t))\}\lambda^i(\mathbf{Y}(\mathbf{r},t))M_j(\mathbf{r}',t)$$

$$=-\int_{\Omega_0}d\mathbf{r}[\lambda,\mu]^iM_i$$

$$=-\int_{\Omega}d\mathbf{x}[\lambda,\mu]^i\pi_i=-\pi([\lambda,\mu]),\tag{16}$$

where

$$[\lambda,\mu]^i=\lambda^j\mu^i_{,j}-\mu^j\lambda^i_{,j}.$$

In a similar way we obtain

$$\{\rho(\lambda),\pi(\mu)\}=\rho(\mu^i\lambda_{,i}).\tag{17}$$

By using results from previous papers[1,2] we come to the conclusion that Eqs. (16) and (17) locally are equivalent to the following equations:

$$\{\pi_i(\mathbf{x}),\pi_j(\mathbf{x}')\}=\pi_i(\mathbf{x}')\,\delta_{,j}(\mathbf{x}',\mathbf{x})-\pi_j(\mathbf{x})\,\delta_{,i}(\mathbf{x},\mathbf{x}'),\tag{18}$$

$$\{\rho(\mathbf{x}),\pi_i(\mathbf{x}')\}=\rho(\mathbf{x}')\,\delta_{,i}(\mathbf{x}',\mathbf{x}).\tag{19}$$

It is easy to see that these Poisson brackets correspond to the standard realization of the diffeomorphism algebra with generators given by variables $\pi_i(\mathbf{x})$.

The Poisson bracket for $\rho(\mathbf{x})$ corresponds to the scalar density transformation law. In contrast, $s(\mathbf{x})$ transforms as a scalar, i.e.,

$$\{s(\mathbf{x}),\pi(\mathbf{x}')\}=-s_{,i}\delta(\mathbf{x},\mathbf{x}').\tag{20}$$

Apparently all other brackets are zero.

Poisson brackets for arbitrary local functionals of variables $\pi_i(\mathbf{x})$, $\rho(\mathbf{x})$, $s(\mathbf{x})$ can be derived with account for all the boundary terms on the base of the Poisson bivector, interior product operation, and the full variation (differential) of local functional defined according to our formalism:[2]

$$\{\mathrm{F},\mathrm{G}\}=-\mathrm{dF}\lrcorner\mathrm{dG}\lrcorner\Psi.$$

For example, in the simplest case, if the boundary of domain Ω is fixed and if everything depends only on variables $\pi_i(\mathbf{x})$, $\rho(\mathbf{x})$, $s(\mathbf{x})$, but not on their spatial derivatives, we obtain

$$\{F,G\}=\int_{\Omega}d\mathbf{x}\Big[\rho\Big(\partial_i\Big(\frac{\partial f}{\partial\rho}\Big)\frac{\partial g}{\partial\pi_i}-\partial_i\Big(\frac{\partial g}{\partial\rho}\Big)\frac{\partial f}{\partial\pi_i}\Big)-s_{,i}\Big(\frac{\partial f}{\partial s}\frac{\partial g}{\partial\pi_i}-\frac{\partial g}{\partial s}\frac{\partial f}{\partial\pi_i}\Big)$$

$$+\pi_i\Big(\partial_j\Big(\frac{\partial f}{\partial\pi_i}\Big)\frac{\partial g}{\partial\pi_j}-\partial_j\Big(\frac{\partial g}{\partial\pi_i}\Big)\frac{\partial f}{\partial\pi_j}\Big)\Big].$$

The analytical form of the Hamiltonian practically does not change after the transform to Eulerian variables:

$$\mathrm{H}=\int_{\Omega} d\mathbf{x}\left(\frac{\pi^2}{2\rho}+\rho\Phi(\mathbf{x})+\rho\varepsilon(\rho,s)\right). \tag{21}$$

Its variational derivatives are as follows:

$$\frac{\delta \mathrm{H}}{\delta \pi_i}=\theta\frac{\pi_i}{\rho},$$

$$\frac{\delta \mathrm{H}}{\delta \rho}=\theta\left(-\frac{\pi^2}{2\rho^2}+\Phi+\varepsilon+\frac{p}{\rho}\right),$$

$$\frac{\delta \mathrm{H}}{\delta s}=\theta\rho\frac{\partial\varepsilon}{\partial s}=\theta\rho T.$$

The Hamiltonian equations are derived by means of the interior product of the Hamiltonian differential and the Poisson bivector according to the general formalism.[2] It is convenient to rewrite these equations in terms of the Eulerian velocity $v^i=\pi_i/\rho$,

$$\dot{\rho}=-(\rho v^i)_{,i}, \tag{22}$$

$$\dot{s}=-v^i s_{,i}, \tag{23}$$

$$\dot{v}^i=-v^j v^i_{,j}-\Phi_{,i}-\frac{p_{,i}}{\rho}, \tag{24}$$

where $p=\rho^2\partial\varepsilon/\partial\rho$. To test the Jacobi identity here we can exploit an approach presented and motivated in our previous work.[2] In fact, this calculation is different from the one presented, for example, in Olver's book[20] only by preserving all the boundary contributions. The bivector which determines the Poisson bracket is as follows:

$$\begin{aligned}\Psi&=\frac{1}{2}\int\int\frac{\delta}{\delta\phi_A(x)}\{\phi_A(x),\phi_B(y)\}\wedge\frac{\delta}{\delta\phi_B(y)}\\&=\frac{1}{2}\int\int\frac{\delta}{\delta\pi_i(x)}\{\pi_i(x),\pi_j(y)\}\wedge\frac{\delta}{\delta\pi_j(y)}+\frac{\delta}{\delta\rho(x)}\{\rho(x),\pi_i(y)\}\wedge\frac{\delta}{\delta\pi_i(y)}\\&\quad+\frac{\delta}{\delta\pi_i(x)}\{\pi_i(x),\rho(y)\}\wedge\frac{\delta}{\delta\rho(y)}+\frac{\delta}{\delta s(x)}\{s(x),\pi_i(y)\}\wedge\frac{\delta}{\delta\pi_i(y)}\\&\quad+\frac{\delta}{\delta\pi_i(x)}\{\pi_i(x),s(y)\}\wedge\frac{\delta}{\delta s(y)}.\end{aligned}$$

After some transformations and integrations we can get another form of it:

$$\Psi=\int\pi_i D_j\left(\frac{\delta}{\delta\pi_i}\right)\wedge\frac{\delta}{\delta\pi_j}+\rho D_i\left(\frac{\delta}{\delta\rho}\right)\wedge\frac{\delta}{\delta\pi_i}-s_{,i}\frac{\delta}{\delta s}\wedge\frac{\delta}{\delta\pi_i}.$$

Then it is easy to see that

$$\mathrm{d}\Psi=\int\delta\pi_i D_j\left(\frac{\delta}{\delta\pi_i}\right)\wedge\frac{\delta}{\delta\pi_i}+\delta\rho D_i\left(\frac{\delta}{\delta\rho}\right)\wedge\frac{\delta}{\delta\pi_i}-(\delta s)_{,i}\frac{\delta}{\delta s}\wedge\frac{\delta}{\delta\pi_i},$$

and therefore

$$\begin{aligned}\mathrm{d}\Psi \lrcorner \Psi = \int \pi_i D_k\left[D_j\left(\frac{\delta}{\delta\pi_i}\right)\wedge\frac{\delta}{\delta\pi_j}\right]\wedge\frac{\delta}{\delta\pi_k} - D_j\left(\frac{\delta}{\delta\pi_i}\right)\wedge\frac{\delta}{\delta\pi_j}\wedge\pi_k D_i\left(\frac{\delta}{\delta\pi_k}\right)\\ - D_j\left(\frac{\delta}{\delta\pi_i}\right)\wedge\frac{\delta}{\delta\pi_j}\wedge\rho D_i\left(\frac{\delta}{\delta\rho}\right) + s_{,i}D_j\left(\frac{\delta}{\delta\pi_i}\right)\wedge\frac{\delta}{\delta\pi_j}\wedge\frac{\delta}{\delta s}\\ + D_k\left[D_i\left(\frac{\delta}{\delta\rho}\right)\wedge\frac{\delta}{\delta\pi_i}\right]\wedge\rho\frac{\delta}{\delta\pi_k} + \frac{\delta}{\delta s}\wedge\frac{\delta}{\delta\pi_i}\wedge D_i\left(s_{,k}\frac{\delta}{\delta\pi_k}\right).\end{aligned}$$

By straightforward calculation, preserving all divergences, it is easy to check that this expression vanishes exactly (not up to divergences). It means that the Schouten–Nijenhuis bracket of bivector Ψ with itself becomes zero as for bivectors

$$[\Psi,\Psi]_{SN} = \mathrm{d}\Psi\lrcorner\Psi + (-1)^{2\cdot 2}\mathrm{d}\Psi\lrcorner\Psi = 2\,\mathrm{d}\Psi\lrcorner\Psi,$$

and as it has been proved in Ref. 2 that this is equivalent to the Jacobi identity fulfillment for arbitrary local functionals:

$$\{\{F,G\},H\}+\{\{H,F\},G\}+\{\{G,H\},F\} = -[\Psi,\Psi]_{SN}(\mathrm{d}F,\mathrm{d}G,\mathrm{d}H). \tag{25}$$

B. Free boundary

If we were working in Lagrangian coordinates, the same set of variables as in the case of fixed boundary was enough, but here we should add function $P_\Omega(\mathbf{x},t)$ introduced earlier in (7) as an independent dynamical variable. The following formulas analogous to (15) are valid:

$$P_\Omega(\mathbf{x},t) = P_0(\mathbf{R}(\mathbf{x},t)), \quad P_\Omega(\mathbf{x},t) = \int_{\Omega_0}\delta(\mathbf{r}-\mathbf{R}(\mathbf{x},t))P_0(\mathbf{r})d\mathbf{r},$$

therefore the Poisson brackets for $P_\Omega(\mathbf{x},t)$ are in close analogy with brackets for the entropy variable $s(\mathbf{x},t)$

$$\{P_\Omega(\mathbf{x},t),\pi^i(\mathbf{x}',t)\} = -P_{\Omega,i}\delta(\mathbf{x},\mathbf{x}'),$$

brackets of $P_\Omega(\mathbf{x},t)$ with other variables are zero.

In the free boundary case the Hamiltonian depends on function P_Ω both through the argument of θ-function and through the surface energy expression (6):

$$\mathrm{H} = \int \theta(P_\Omega)\left[\frac{\boldsymbol{\pi}^2}{2\rho}+\rho\Phi(\mathbf{x})+\rho\varepsilon(\rho,s)+\tau\nabla\cdot\mathbf{n}\right]d\mathbf{x}, \tag{26}$$

moreover in the last case it also depends on spatial derivatives of function P_Ω up to the second order. But taking into account relation (9), the full variational derivative of the Hamiltonian over function P_Ω is equal to the following expression:

$$\frac{\delta\mathrm{H}}{\delta P_\Omega} = \frac{d\theta}{dP_\Omega}\left[\frac{\pi^2}{2\rho}+\rho\Phi(\mathbf{x})+\rho\varepsilon(\rho,s)+\tau\nabla\cdot\mathbf{n}\right], \tag{27}$$

or

$$\frac{\delta\mathrm{H}}{\delta P_\Omega} = \theta_{,i}\frac{P_{\Omega,i}}{|P_{\Omega,i}|^2}\left[\frac{\pi^2}{2\rho}+\rho\Phi(\mathbf{x})+\rho\varepsilon(\rho,s)+\tau K\right].$$

The derivatives over other variables do not change if compared with the fixed boundary case.

According to our definitions,[1,2] from the Poisson bivector

$$\Psi = \frac{1}{2}\int\int \frac{\delta}{\delta\phi_A(\mathbf{x})}\wedge\frac{\delta}{\delta\phi_B(\mathbf{y})}\{\phi_A(\mathbf{x}),\phi_B(\mathbf{y})\}d\mathbf{x}d\mathbf{y}$$
$$= \int \pi_i D_j\left(\frac{\delta}{\delta\pi_i}\right)\wedge\frac{\delta}{\delta\pi_j} + \rho D_i\left(\frac{\delta}{\delta\rho}\right)\wedge\frac{\delta}{\delta\pi_i} - s_{,i}\frac{\delta}{\delta s}\wedge\frac{\delta}{\delta\pi_i} - P_{\Omega,i}\frac{\delta}{\delta P_\Omega}\wedge\frac{\delta}{\delta\pi_i},$$

and by means of the interior product operation we get the Hamiltonian vector field

$$-d\mathrm{H}\lrcorner\Psi = \int \theta[-v^i s_{,i}]\frac{\delta}{\delta s} + \theta[-v^i P_{\Omega,i}]\frac{\delta}{\delta P_\Omega} + \theta[-\pi_{i,i}]\frac{\delta}{\delta\rho}$$
$$+ \theta[-(\pi_i v_j)_{,j} - \rho\partial_i\Phi - \partial_i p]\frac{\delta}{\delta\pi_i} - \theta_{,i}[p-\tau K]\frac{\delta}{\delta\pi_i}.$$

The requirement of absence of any singular contributions to the Hamiltonian equations leads us to the already known boundary condition (11). It is easy to see that equations of motion do not change in comparison with (22), (24) and (23). But we also get the following new equation,

$$\dot{P}_\Omega = -(\mathbf{v}\cdot\nabla)P_\Omega. \tag{28}$$

Here it is evident that the requirement of disappearance of boundary terms in the Hamiltonian variation [or equivalently in the full variational derivatives (27)] leads to the boundary condition which is different from the standard one. It means that in the general statement of a problem, when the canonical choice of variables is not prescribed from the very beginning, the criterion by Regge and Teitelboim of choosing the surface contributions[3] should be replaced by the requirement of vanishing of the singular contributions to the Hamiltonian vector field, i.e., to the Hamiltonian equations of motion.

It should be stated that in the case of the dynamical domain of integration Ω we are unable to check the Jacobi identity by calculating $[\Psi,\Psi]_{SN}$ because the proof of Eq. (25) given in Ref. 2 is not valid here.

V. VARIATIONAL PRINCIPLE IN EULERIAN VARIABLES

It is natural to ask whether it is possible to derive the Hamiltonian formalism for Eulerian variables, considered in the previous section, directly from the corresponding variational principle, without appealing to the Hamiltonian formalism for Lagrangian variables. The answer will be definitely in the affirmative, but the construction of this variational principle is rather nontrivial and deserves a special discussion. It is interesting that such a discussion has been used by Kupershmidt as an intrigue for his book (see Ref. 12, Introduction). A discussion on this problem can also be found in Refs. 13, 21–23.

A. Fixed boundary

Let us first ask how to construct the Lagrangian and corresponding variables if we know a Hamiltonian [in our case as a functional of $\pi^i(\mathbf{x})$, $\rho(\mathbf{x})$ and $s(\mathbf{x})$] and Poisson brackets for Hamiltonian variables. If variables are canonical, then, certainly, it is sufficient to use the Legendre transform, but in the general case this may be a nontrivial task. Momenta $\pi^i(\mathbf{x})$ have nonzero Poisson brackets between themselves, Hamiltonian (21) does not imply variables conjugate to these momenta (''coordinates'') and the total number of variables is not in general even (for example, in case $\mathbb{R}^3$ it is equal to five). The solution may be to introduce some auxiliary variables.

Therefore, to move along the left vertical arrow of the diagram we add to the ''naive'' Lagrangian

$$L_0 = \int_\Omega d\mathbf{x}\rho\left(\frac{\mathbf{v}^2}{2} - \Phi(\mathbf{x}) - \varepsilon(\rho,s)\right),$$

derived from Lagrangian (1) by a trivial change of variables and formed as a difference of the kinetic and potential energies (with the internal energy added to the last one), some constraints together with the corresponding Lagrange multipliers.

As the first and the most evident constraint we take the continuity equation (the mass conservation law)

$$\frac{\partial\rho}{\partial t} + \mathrm{div}(\rho\mathbf{v}) = 0. \tag{29}$$

Also we use the entropy conservation law

$$\frac{\partial s}{\partial t} + (\mathbf{v}\cdot\nabla)s = 0, \tag{30}$$

which is possible to rewrite, combining with (29) also as follows:

$$\frac{\partial(\rho s)}{\partial t} + \mathrm{div}(\rho s\mathbf{v}) = 0.$$

At last, it is necessary to put a condition providing guarantee for existence of the Lagrangian coordinates. It means that any mass point having at the moment t position with coordinates $\mathbf{x}$, may be supplied by its "number" α_μ, for example, by the coordinates of its initial position $\mathbf{R}(\mathbf{x},t)$. This "number" should also be "conserved" in the process of the fluid motion

$$\frac{\partial\alpha_\mu}{\partial t} + (\mathbf{v}\cdot\nabla)\alpha_\mu = 0. \tag{31}$$

Here the number of degrees of freedom or the range for index μ, in general, does not coincide with the spatial dimension of $\mathbb{R}^n$, for example, in the case $n=3$ one variable α is enough. As a result, still up to surface terms, we arrive at the following Lagrangian,

$$L = L_0 + \int_\Omega d\mathbf{x}\left[\phi\left(\frac{\partial\rho}{\partial t} + \mathrm{div}(\rho\mathbf{v})\right) - \eta\left(\frac{\partial s}{\partial t} + (\mathbf{v}\cdot\nabla)s\right) - \beta_\mu\left(\frac{\partial\alpha_\mu}{\partial t} + (\mathbf{v}\cdot\nabla)\alpha_\mu\right)\right],$$

or at the following action

$$S = \int_{t_1}^{t_2} dt \int_\Omega d\mathbf{x}\left[\rho\left(\frac{\mathbf{v}^2}{2} - \Phi(\mathbf{x}) - \varepsilon(\rho,s)\right) + \phi\left(\frac{\partial\rho}{\partial t} + \mathrm{div}(\rho\mathbf{v})\right) - \eta\frac{Ds}{Dt} - \beta_\mu\frac{D\alpha_\mu}{Dt}\right], \tag{32}$$

where

$$\frac{D}{Dt} = \frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla),$$

and the signs in front of η, β_μ are taken for convenience, so that we get positive signs in formula (33). By varying action (32) over ϕ, η, β_μ we evidently get supplementary conditions (29)–(31).

By varying (32) over velocity $\mathbf{v}$ we get the so-called Clebsch representation for velocity variable,

$$\mathbf{v} = \nabla\phi + \frac{\eta}{\rho}\nabla s + \frac{\beta_\mu}{\rho}\nabla\alpha_\mu, \tag{33}$$

which means that velocity may be treated as an auxiliary variable.

By varying action (32) over density ρ we get the following equation,

$$\frac{\mathbf{v}^2}{2}-\Phi(\mathbf{x})-\varepsilon(\rho,s)-\rho\frac{\partial\varepsilon}{\partial\rho}-\dot{\phi}-(\mathbf{v}\cdot\nabla)\phi=0,$$

which may be understood as an equation for evolution of potential ϕ:

$$\dot{\phi}=-(\mathbf{v}\cdot\nabla)\phi+\frac{\mathbf{v}^2}{2}-\Phi(\mathbf{x})-\varepsilon(\rho,s)-\frac{p}{\rho}. \tag{34}$$

We get new independent equations of motion by varying (32) over s,

$$\dot{\eta}=-\operatorname{div}(\eta\mathbf{v})+\rho\frac{\partial\varepsilon}{\partial s}, \tag{35}$$

and over α_μ

$$\dot{\beta}_\mu=-\operatorname{div}(\beta_\mu\mathbf{v}). \tag{36}$$

It is easy to be convinced that equations of motion for "old" variables ρ, s are still the same (22) and (23).

It is possible to demonstrate that the same is true for velocity $\mathbf{v}$, Eq. (24). For this purpose we need to differentiate (33) over time and substitute into the derived expression values of $\dot{\rho}$, $\dot{\phi}$, $\dot{s}$, $\dot{\eta}$, $\dot{\alpha}_\mu$, $\dot{\beta}_\mu$ taken from equations of motion (29), (34), (30), (35), (31), and (36), correspondingly.

Of course, we do not yet touch surface terms arising from integration by parts in the action variation (32). Let us display them explicitly:

$$(\delta S)_{\mathrm{surf}}=\int_\Omega d\mathbf{x}[\phi\delta\rho-\eta\delta s-\beta_\mu\delta\alpha_\mu]_{t_1}^{t_2}+\int_{t_1}^{t_2}dt\oint_{\partial\Omega}[\mathbf{v}(\phi\delta\rho-\eta\delta s-\beta_\mu\delta\alpha_\mu)+\rho\phi\delta\mathbf{v}]\cdot\mathbf{n}dS. \tag{37}$$

Boundary condition

$$\mathbf{n}\cdot\mathbf{v}|_{\partial\Omega}=0,$$

which means, as in previous sections, fixed edge of the domain Ω, provides vanishing of all variation contributions at the spatial part of the boundary. The contribution from variations on the time boundary disappears because variables ρ, s, α_μ must be fixed at the initial and final instants of time.

B. Free boundary

Let us add to action (32) a surface energy contribution and let us, as before, describe the free boundary dynamics by means of function $P_\Omega(\mathbf{x},t)$

$$S=\int_{t_1}^{t_2}dt\int\theta(P_\Omega)\left[\rho\left(\frac{\mathbf{v}^2}{2}-\Phi(\mathbf{x})-\varepsilon(\rho,s)\right)+\phi\left(\frac{\partial\rho}{\partial t}+\operatorname{div}(\rho\mathbf{v})\right)-\eta\frac{Ds}{Dt}-\beta_\mu\frac{D\alpha_\mu}{Dt}-\tau\nabla\cdot\mathbf{n}\right]d\mathbf{x}. \tag{38}$$

The variation of this action will differ from the variation of action (32) by some new surface terms only. Let us display them separately:

$$(\delta' S)_{\mathrm{surf}}=\int_{t_1}^{t_2}dt\int\frac{d\theta}{dP_\Omega}\Bigg(\dot{P}_\Omega(-\phi\delta\rho+\eta\delta s+\beta_\mu\delta\alpha)$$
$$+\delta P_\Omega\Bigg[\rho\Bigg(\frac{\mathbf{v}^2}{2}-\Phi(\mathbf{x})-\varepsilon(\rho,s)\Bigg)+\phi\Bigg(\frac{\partial\rho}{\partial t}+\mathrm{div}(\rho\mathbf{v})\Bigg)-\eta\frac{Ds}{Dt}-\beta_\mu\frac{D\alpha_\mu}{Dt}-\tau K\Bigg]\Bigg)d\mathbf{x}.$$

First line terms arise as a result of integration by parts of partial time derivatives. Varying over K does not contribute, as shown before [see (9)].

By combining the derived expression with the contribution (37) found above, which may be rewritten as follows,

$$(\delta'' S)_{\mathrm{surf}}=\int_{t_1}^{t_2}\int d\mathbf{x}\frac{\partial}{\partial t}[\theta(P_\Omega)(\phi\delta\rho-\eta\delta s-\beta_\mu\delta\alpha_\mu)]$$
$$-\int_{t_1}^{t_2}dt\int\nabla\theta(P_\Omega)\cdot[\mathbf{v}(\phi\delta\rho-\eta\delta s-\beta_\mu\delta\alpha_\mu)+\rho\phi\delta\mathbf{v}]d\mathbf{x},$$

we obtain

$$(\delta S)_{\mathrm{surf}}=\int\theta(P_\Omega)(\phi\delta\rho-\eta\delta s-\beta_\mu\delta\alpha_\mu)d\mathbf{x}\Big|_{t_1}^{t_2}-\int_{t_1}^{t_2}dt\int\nabla\theta(P_\Omega)\cdot(\rho\phi\delta\mathbf{v})d\mathbf{x}$$
$$-\int_{t_1}^{t_2}dt\int\frac{d\theta}{dP_\Omega}(\dot{P}_\Omega+(\mathbf{v}\cdot\nabla)P_\Omega)(\phi\delta\rho-\eta\delta s-\beta_\mu\delta\alpha_\mu)d\mathbf{x}+\int_{t_1}^{t_2}dt\int\frac{d\theta}{dP_\Omega}\delta P_\Omega$$
$$\times\Bigg[\rho\Bigg(\frac{\mathbf{v}^2}{2}-\Phi(\mathbf{x})-\varepsilon(\rho,s)\Bigg)+\phi\Bigg(\frac{\partial\rho}{\partial t}+\mathrm{div}(\rho\mathbf{v})\Bigg)-\eta\frac{Ds}{Dt}-\beta_\mu\frac{D\alpha_\mu}{Dt}-\tau K\Bigg]d\mathbf{x}.$$

Some terms here give us a boundary condition

$$\dot{P}_\Omega+(\mathbf{v}\cdot\nabla)P_\Omega=0,$$

and some other terms disappear when fields on the time boundaries are fixed. But there are other terms which do not allow us to derive the famous boundary condition (10). It is well known[17,18] that actions which differ by boundary terms lead to different natural boundary conditions. So, action (38) should be modified by some surface integral. It is easy to get convinced that we will obtain the desired action after subtracting from (38) the following expression:

$$\Delta S=\int_{t_1}^{t_2}dt\int_\Omega\Bigg(\frac{\partial}{\partial t}(\rho\phi)+\nabla\cdot(\rho\phi\mathbf{v})\Bigg)d\mathbf{x}.$$

Therefore, the action which leads to correct equations of motion and boundary conditions for the free boundary case has the following form:

$$S=\int_{t_1}^{t_2}dt\int\theta(P_\Omega)\Bigg[\rho\Bigg(\frac{\mathbf{v}^2}{2}-\Phi(\mathbf{x})-\varepsilon(\rho,s)\Bigg)-\rho\frac{D\phi}{Dt}-\eta\frac{Ds}{Dt}-\beta_\mu\frac{D\alpha_\mu}{Dt}-\tau K\Bigg]d\mathbf{x}. \qquad (39)$$

If we compare the above expression with formula (34), we can see that the Lagrangian density up to the sign is equal to the pressure when equations of motion are satisfied. In a paper by Luke[13] for the two-dimensional

$$d\mathbf{x}=dxdy,\quad P_\Omega(x,y,t)=h(x,t)-y,$$

potential flow $\mathbf{v}=\nabla\phi$ of the incompressible fluid $\rho=1$, and $s=\text{const}$ without surface tension $\tau=0$ in a constant gravitational field $\Phi(\mathbf{x})=gy$, it was first pointed out that action (39), taking the following form

$$S=-\int_{t_1}^{t_2}dt\int dx\int^{h(x,t)}dy\left(\frac{1}{2}\phi_x^2+\frac{1}{2}\phi_y^2+\dot{\phi}+gy\right),$$

allowed us to derive not only equations of motion but also the dynamical boundary conditions for the free surface. The presence of $\dot{\phi}$ in the Lagrangian density is essential as it generates the symplectic form

$$\omega=\int d\mathbf{x}\delta h\wedge\delta\phi,$$

corresponding to the Poisson bracket discovered in an almost simultaneous paper by Zakharov.[7]

It is easy to see that action (39) can be also used in the fixed boundary case for domain Ω.

VI. AN ALTERNATIVE WAY TO THE HAMILTONIAN FORMALISM FOR EULERIAN VARIABLES

Let us show that starting from the variational principle for Eulerian variables discussed in the previous section, it is possible to construct a new Hamiltonian formalism which is equivalent to the one constructed above by means of reduction of the Hamiltonian formalism for Lagrangian variables. This construction may be provided both by Dirac method,[15] and by inverting the symplectic form matrix (Faddeev–Jackiw method[14]).

A. Fixed boundary

In the Dirac approach, action (39) with variable $\mathbf{v}$ eliminated by means of Eq. (33) leads to the appearance of primary constraints

$$\pi_\phi=-\rho,\quad \pi_\rho=0,$$

$$\pi_s=-\eta,\quad \pi_\eta=0,$$

$$\pi_\alpha=-\beta,\quad \pi_\beta=0.$$

Then we look for secondary constraints, and next we derive Dirac brackets and eliminate second class constraints.

The Faddeev–Jackiw approach looks simpler here. We determine the symplectic form

$$\omega=\int\theta(P)(\delta\phi\wedge\delta\rho+\delta s\wedge\delta\eta+\delta\alpha_\mu\wedge\delta\beta_\mu)d\mathbf{x}$$

(here and below we reduce notation P_Ω to P), which is explicitly canonical, and this allows us to find the Poisson brackets

$$\{\rho(\mathbf{x}),\phi(\mathbf{x}')\}=\delta(\mathbf{x},\mathbf{x}'),\quad \{\eta(\mathbf{x}),s(\mathbf{x}')\}=\delta(\mathbf{x},\mathbf{x}'),\quad \{\beta_\mu(\mathbf{x}),\alpha_\nu(\mathbf{x}')\}=\delta_{\mu\nu}\delta(\mathbf{x},\mathbf{x}'),$$

which coincide with the Dirac brackets. Let us introduce the following quantities,

$$\pi=\rho\nabla\phi+\eta\nabla s+\beta_\mu\nabla\alpha_\mu,$$

and calculate their Poisson brackets. The result is the same as given by Eq. (18). In an analogous way we may check the correspondence with formulas (19) and (20). The Hamiltonian can be obtained by the standard Legendre transform and it coincides with expression (21) being expressed in variables π.

Therefore, by using Clebsch potentials we can maintain the correspondence between the variational principle and the Hamiltonian formalism in Eulerian coordinates.

B. Free boundary

Here for simplicity we replace α_μ by α. In the free boundary case it is necessary to consider P as a dynamical variable. Time derivatives enter action (39) in the following form,

$$\int_{t_1}^{t_2} dt \int d\mathbf{x}\theta(P)(-\rho\dot{\phi}-\eta\dot{s}-\beta\dot{\alpha}),$$

so, the corresponding symplectic form is as follows:

$$\omega=-\int d\mathbf{x}(\theta(P)(\delta\rho\wedge\delta\phi+\delta\eta\wedge\delta s+\delta\beta\wedge\delta\alpha)+\theta'(P)\delta P\wedge(\rho\delta\phi+\eta\delta s+\beta\delta\alpha)).$$

In the case of the potential flow of incompressible fluid considered by Zakharov,[7] this form reduces (for $\rho=1$) to the following expression,

$$\omega=\int d\mathbf{x}\theta'(P)\delta\phi\wedge\delta P,$$

allowing us to use the canonical Poisson brackets for the pair of conjugate variables: velocity potential on the boundary and the position of the boundary.

Here in order to come to the Hamiltonian formalism we will use Dirac approach. Let us introduce conjugate momenta for all variables

$$\{\phi(x),\pi_\phi(y)\}=\{\rho(x),\pi_\rho(y)\}=\{s(x),\pi_s(y)\}=\delta(x,y),$$

$$\{\eta(x),\pi_\eta(y)\}=\{\alpha(x),\pi_\alpha(y)\}=\{\beta(x),\pi_\beta(y)\}=\{P(x),\pi_P(y)\}=\delta(x,y),$$

and find their values from action (39) by means of the standard formula

$$\pi_i=\frac{\partial\mathcal{L}}{\partial\dot{q}_i}.$$

As the Lagrangian density depends on velocities in a linear way we get as many primary constraints as many momenta we have introduced

$$\psi_1=\pi_\phi+\theta(P)\rho,\quad \psi_4=\pi_\rho,$$

$$\psi_2=\pi_s+\theta(P)\eta,\quad \psi_5=\pi_\eta,$$

$$\psi_3=\pi_\alpha+\theta(P)\beta,\quad \psi_6=\pi_\beta,$$

$$\psi_7=\pi_P.$$

The Legendre transform gives the initial Hamiltonian

$$\mathrm{H}_0=\int d\mathbf{x}\theta(P)\left(\frac{1}{2\rho}(\rho\nabla\phi+\eta\nabla s+\beta\nabla\alpha)^2+\rho\Phi+\rho\varepsilon(\rho,s)+\tau K\right),$$

coinciding with expression (26) with the only difference: momenta π_i expressed by means of Clebsch variables. But Hamiltonian H_0 when expressed in new variables does not provide the correct equations of motion and so should be accompanied by a linear combination of the primary constraints

$$\mathrm{H}=\mathrm{H}_0+\int d\mathbf{x}\sum_{i=1}^{7}\lambda_i\psi_i\,.$$

Evidently, the first six constraints are second class. The matrix of their Poisson brackets,

$$\{\psi_i,\psi_j\}=\begin{pmatrix}0 & I\\ -I & 0\end{pmatrix}\theta(P)\,\delta(x,y),$$

has an inverse [here we are to consider $\theta(P)\,\delta(\mathbf{x},\mathbf{y})$ as a unit operator]

$$C_{ij}(\mathbf{x},\mathbf{y})=\begin{pmatrix}0 & -I\\ I & 0\end{pmatrix}\theta(P)\,\delta(\mathbf{x},\mathbf{y}),$$

so it is possible to determine the Dirac brackets by the standard formula

$$\{f(\mathbf{x}),g(\mathbf{y})\}_D=\{f(\mathbf{x}),g(\mathbf{y})\}-\sum_{i,j=1}^{6}\int d\mathbf{z}\int d\mathbf{w}\{f(\mathbf{x}),\psi_i(\mathbf{z})\}C_{ij}(\mathbf{z},\mathbf{w})\{\psi_j(\mathbf{w}),g(\mathbf{y})\}.$$

Therefore, we exclude the first six momenta, and, correspondingly, the first six constraints from the Hamiltonian

$$\mathrm{H}=\int d\mathbf{x}\left[\theta(P)\left(\frac{1}{2\rho}(\rho\nabla\phi+\eta\nabla s+\beta\nabla\alpha)^2+\rho\Phi+\rho\varepsilon(\rho,s)+\tau K\right)+\lambda_P\pi_P\right].$$

The calculation of Dirac brackets for the other eight variables gives us the following results:

$$\{\rho(\mathbf{x}),\phi(\mathbf{y})\}_D=\theta(P)\,\delta(\mathbf{x},\mathbf{y}),\quad \{\rho(\mathbf{x}),\pi_P(\mathbf{y})\}_D=-\theta'(P)\rho\,\delta(\mathbf{x},\mathbf{y}),$$

$$\{\eta(\mathbf{x}),s(\mathbf{y})\}_D=\theta(P)\,\delta(\mathbf{x},\mathbf{y}),\quad \{\eta(\mathbf{x}),\pi_P(\mathbf{y})\}_D=-\theta'(P)\,\eta\,\delta(\mathbf{x},\mathbf{y}),$$

$$\{\beta(\mathbf{x}),\alpha(\mathbf{y})\}_D=\theta(P)\,\delta(\mathbf{x},\mathbf{y}),\quad \{\beta(\mathbf{x}),\pi_P(\mathbf{y})\}_D=-\theta'(P)\beta\,\delta(\mathbf{x},\mathbf{y}),$$

$$\{P(\mathbf{x}),\pi_P(\mathbf{y})\}=\delta(\mathbf{x},\mathbf{y}).$$

Therefore, we can now relate to the initial symplectic form the following Poisson bivector:

$$\Psi=\int d\mathbf{x}\left[\theta(P)\left(\frac{\delta}{\delta\rho}\wedge\frac{\delta}{\delta\phi}+\frac{\delta}{\delta\eta}\wedge\frac{\delta}{\delta s}+\frac{\delta}{\delta\beta}\wedge\frac{\delta}{\delta\alpha}\right)+\frac{\delta}{\delta\pi_P}\wedge\left(-\frac{\delta}{\delta P}+\theta'(P)\left(\rho\frac{\delta}{\delta\rho}+\eta\frac{\delta}{\delta\eta}+\beta\frac{\delta}{\delta\beta}\right)\right)\right].$$

The differential of the Hamiltonian has the following form,

$$\mathrm{d}\mathrm{H}=\int d\mathbf{x}\frac{\delta\mathrm{H}}{\delta\phi_A}\,\delta\phi_A\,, \tag{40}$$

where some full variational derivatives have nontrivial boundary contributions

$$\frac{\delta\mathrm{H}}{\delta\rho}=\theta(P)\left(\mathbf{v}\nabla\phi-\frac{v^2}{2}+\Phi+\varepsilon+\frac{p}{\rho}\right),$$

$$\frac{\delta\mathrm{H}}{\delta\eta}=\theta(P)\mathbf{v}\cdot\nabla s,$$

$$\frac{\delta \mathrm{H}}{\delta \beta} = \theta(P)\mathbf{v}\cdot\nabla\alpha,$$

$$\frac{\delta \mathrm{H}}{\delta \phi} = -\theta'(P)\rho\mathbf{v}\cdot\nabla P - \theta(P)\nabla(\rho\mathbf{v}),$$

$$\frac{\delta \mathrm{H}}{\delta s} = -\theta'(P)\eta\mathbf{v}\cdot\nabla P - \theta(P)(\nabla(\eta\mathbf{v}) - \rho T),$$

$$\frac{\delta \mathrm{H}}{\delta \alpha} = -\theta'(P)\beta\mathbf{v}\cdot\nabla P - \theta(P)\nabla(\beta\mathbf{v}),$$

$$\frac{\delta \mathrm{H}}{\delta P} = \theta'(P)\left(\frac{\rho v^2}{2} + \rho\Phi + \rho\varepsilon + \tau K\right), \quad \frac{\delta \mathrm{H}}{\delta \pi_P} = \lambda_P .$$

The interior product of this differential onto the Poisson bivector gives (up to the sign) the following Hamiltonian vector field

$$\begin{aligned} -\mathrm{dH}\lrcorner\Psi = {} & [-\theta'(P)\rho(\lambda_P + \mathbf{v}\cdot\nabla P) - \theta(P)\nabla(\rho\mathbf{v})]\frac{\delta}{\delta\rho} + [-\theta'(P)\eta(\lambda_P + \mathbf{v}\cdot\nabla P) \\ & - \theta(P)(\nabla(\eta\mathbf{v}) - \rho T)]\frac{\delta}{\delta\eta} + [-\theta'(P)\beta(\lambda_P + \mathbf{v}\cdot\nabla P) - \theta(P)\nabla(\beta\mathbf{v})]\frac{\delta}{\delta\beta} \\ & + \theta'(P)(p - \tau K)\frac{\delta}{\delta\pi} - \theta(P)\mathbf{v}\cdot\nabla\alpha\frac{\delta}{\delta\alpha} + \lambda_P\frac{\delta}{\delta P} \\ & + \theta(P)\left[\frac{v^2}{2} - \mathbf{v}\cdot\nabla\phi - \Phi - \varepsilon - \frac{p}{\rho}\right]\frac{\delta}{\delta\phi} - \theta(P)[\mathbf{v}\cdot\nabla s]\frac{\delta}{\delta s}, \end{aligned}$$

i.e., Hamiltonian equations of motion, for example,

$$\dot{P} = \lambda_P . \tag{41}$$

If we require that all terms singular on the boundary should be zero, we get the following two equations:

$$\theta'(P)(\lambda_P + \mathbf{v}\cdot\nabla P) = 0, \tag{42}$$

$$\theta'(P)(p - \tau K) = 0. \tag{43}$$

Taking into account (41) we recognize the same standard boundary conditions (11) and (28). If we start from Regge–Teitelboim criterion,[3] i.e., if we demand cancellation of boundary terms in the Hamiltonian variation (40), then we obtain incorrect boundary conditions, in particular, the requirement of stationarity for the boundary.

After cancellation of singular terms, derived equations coincide with the Lagrangian ones.

VII. CONCLUSION

We have demonstrated that the method proposed in Refs. 1 and 2 is applicable for Hamiltonian treatment of free boundary problems. The special features of this class of problems are explicit in the approach.

It is important to stress that the most popular now Regge–Teitelboim approach[3] is not adequate for non-ultralocal Poisson brackets as the requirement of the Hamiltonian ''differentiabil-

ity'' leads to boundary conditions different from those obtained on the base of the variational principle. At the same time, it does not exclude singular boundary contributions from equations of motion.

We require that boundary conditions must exclude the contributions proportional to the δ-function and its derivatives from the Hamiltonian equations of motion, i.e., from the Hamiltonian vector fields. At the same time such terms may be present in the Hamiltonian variation or in the Poisson bivector.

These conclusions are supported by some other examples.[5,6] We hope that the method discussed here will be useful in treating various free boundary problems.

APPENDIX: A PROOF OF ONE FORMULA USED IN SEC. II

Let us prove the following formula,

$$\frac{\partial}{\partial r^j}(JJ^{ji})=0,$$

for variables given in Eq. (2).

According to the standard variational rules we have for the determinant and for the inverse matrix the following relations, correspondingly,

$$\delta J=JJ^{lk}\delta J_{kl}, \quad \delta J^{ji}=-J^{jk}J^{li}\delta J_{kl}.$$

Then we obtain

$$\frac{\partial}{\partial r^j}(JJ^{ji})=J(J^{ji}J^{lk}-J^{jk}J^{li})\frac{\partial^2 Y^k}{\partial r^j\partial r^l}=J\left(\frac{\partial r^j}{\partial Y^i}\frac{\partial r^l}{\partial Y^k}-\frac{\partial r^j}{\partial Y^k}\frac{\partial r^l}{\partial Y^i}\right)\frac{\partial^2 Y^k}{\partial r^j\partial r^l}=J\left[\frac{\partial r^l}{\partial Y^k}\frac{\partial}{\partial r^j}\left(\frac{\partial Y^k}{\partial r^l}\right)\frac{\partial r^j}{\partial Y^i}\right.$$
$$\left.-\frac{\partial r^l}{\partial Y^i}\frac{\partial}{\partial r^j}\left(\frac{\partial Y^k}{\partial r^l}\right)\frac{\partial r^j}{\partial Y^k}\right]=J\left[\frac{\partial r^l}{\partial Y^k}\frac{\partial}{\partial Y^i}\left(\frac{\partial Y^k}{\partial r^l}\right)-\frac{\partial r^l}{\partial Y^i}\frac{\partial}{\partial Y^k}\left(\frac{\partial Y^k}{\partial r^l}\right)\right]=J\left[\frac{\partial}{\partial Y^i}\left(\frac{\partial Y^k}{\partial r^l}\frac{\partial r^l}{\partial Y^k}\right)\right.$$
$$\left.-\frac{\partial Y^k}{\partial r^l}\frac{\partial^2 r^l}{\partial Y^i\partial Y^k}-\frac{\partial}{\partial Y^k}\left(\frac{\partial Y^k}{\partial r^l}\frac{\partial r^l}{\partial Y^i}\right)+\frac{\partial Y^k}{\partial r^l}\frac{\partial^2 r^l}{\partial Y^k\partial Y^i}\right]=0.$$

On Keller theorem for anisotropic media

Leonid G. Fel[a)]
School of Physics and Astronomy, Raymond and Beverly Sackler Faculty of Exact Sciences, Tel Aviv University, Tel Aviv 69978, Israel

(Received 20 January 2002; accepted for publication 23 March 2002)

The Keller theorem in the problem of effective conductivity in anisotropic two-dimensional (2D) many-component composites makes it possible to establish a simple inequality $\sigma^e_{\mathrm{is}}(\sigma_i^{-1})\cdot\sigma^e_{\mathrm{is}}(\sigma_k)>1$ for the isotropic part $\sigma^e_{\mathrm{is}}(\sigma_k)$ of the second rank symmetric tensor $\hat{\sigma}^e_{i,j}$ of effective conductivity. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1480450]

The extension of the Keller theorem[1] in the problem of effective conductivity in the infinite 2D two-component composites on the many-component case[2] poses a new question on the duality relation for the second rank symmetric tensor $\hat{\sigma}^e_{i,j}$ of effective conductivity in anisotropic media. It is related to the restrictions imposed on the linear invariant of $\hat{\sigma}^e_{i,j}$ which is called an isotropic part $\sigma^e_{\mathrm{is}}(\sigma_k)$ of effective conductivity. Recently the perturbation theory for the infinite periodic three-component 2D checkerboard with twofold rotation lattice symmetry was developed[3] where the coincidence of $\sigma^e_{\mathrm{is}}(\sigma_k)$ with solution $\sigma_B(\sigma_k)$ of the Bruggemann equation was established up to the sixth order term. This fact is curious because it gives grounds to think that effective medium approximation (EMA) describes exactly $\sigma^e_{\mathrm{is}}(\sigma_k)$ in this certain structure. Here we will discuss this conclusion.

Let us define the isotropic part of conductivity tensor

$$\sigma^e_{\mathrm{is}}(\sigma_k)=\tfrac{1}{2}\ \mathrm{Tr}\ \hat{\sigma}^e_{i,j}(\sigma_k),\quad k=1,2,\ldots,n, \tag{1}$$

which is an invariant scalar with respect to the plane rotation. We recall the extension[2] of the Keller theorem for the principal values $\hat{\sigma}^{\mathrm{xx}}_e$, $\hat{\sigma}^{\mathrm{yy}}_e$ of diagonalized matrix $\hat{\sigma}^{ij}_e$ for 2D n-component composite

$$\begin{aligned}&\hat{\sigma}^{\mathrm{xx}}_e(\sigma_1^{-1},\sigma_2^{-1},\ldots,\sigma_n^{-1})\cdot\hat{\sigma}^{\mathrm{yy}}_e(\sigma_1,\sigma_2,\ldots,\sigma_n)=1,\\&\hat{\sigma}^{\mathrm{yy}}_e(\sigma_1^{-1},\sigma_2^{-1},\ldots,\sigma_n^{-1})\cdot\hat{\sigma}^{\mathrm{xx}}_e(\sigma_1,\sigma_2,\ldots,\sigma_n)=1.\end{aligned} \tag{2}$$

Both (1) and (2) make it possible to derive a simple inequality for $\Lambda^e_{\mathrm{is}}=\sigma^e_{\mathrm{is}}(\sigma_i^{-1})\cdot\sigma^e_{\mathrm{is}}(\sigma_k)\geqslant 1$. Indeed,

$$\Lambda^e_{\mathrm{is}}=\frac{1}{4}[2+\hat{\sigma}^{\mathrm{xx}}_e(\sigma_k)\cdot\hat{\sigma}^{\mathrm{xx}}_e(\sigma_k^{-1})+\hat{\sigma}^{yy}_e(\sigma_k)\cdot\hat{\sigma}^{\mathrm{yy}}_e(\sigma_k^{-1})]=\frac{1}{4}\left[2+\frac{\hat{\sigma}^{\mathrm{xx}}_e(\sigma_k)}{\hat{\sigma}^{\mathrm{yy}}_e(\sigma_k)}+\frac{\hat{\sigma}^{\mathrm{yy}}_e(\sigma_k)}{\hat{\sigma}^{\mathrm{xx}}_e(\sigma_k)}\right]\geqslant 1, \tag{3}$$

where the only isotropic media $\hat{\sigma}^{\mathrm{xx}}_e=\hat{\sigma}^{\mathrm{yy}}_e$ corresponds to the equality in (3). At the same time another isotropic invariant $\Delta^e_{\mathrm{is}}=\det\hat{\sigma}^e_{ij}(\sigma_k)$ satisfies the duality relation

$$\Delta^e_{\mathrm{is}}(\sigma_k)\cdot\Delta^e_{\mathrm{is}}(\sigma_k^{-1})=1.$$

The EMA theory of the infinite 2D n-component isotropic composite has as its consequence the Bruggemann equation[4]

a)Electronic mail: lfel@post.tau.ac.il

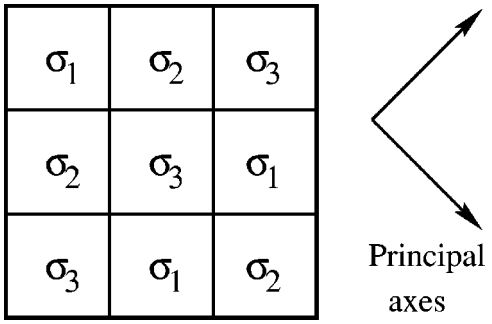

FIG. 1. A unit cell of periodic 2D three-component checkerboard considered in Ref. 3.

$$\sum_{k=1}^{n} \frac{\sigma_k - \sigma_B(\sigma_k)}{\sigma_k + \sigma_B(\sigma_k)} = 0, \tag{4}$$

which necessarily leads to the duality relation

$$\sigma_B(\sigma_k^{-1}) \cdot \sigma_B(\sigma_k) = 1. \tag{5}$$

The last formula means that σ_{is}^e can satisfy the Bruggemann equation only for isotropic S_n-permutation invariant media: $\hat{\sigma}_e^{xx} = \hat{\sigma}_e^{yy}$, $\hat{\sigma}_e^{xy} = 0$ in any reference frame $\{x,y\}$.

The infinite periodic 2D three-component checkerboard was considered in Ref. 3 for symmetrically related partial conductivities ($\sigma_1 = 1, \sigma_{2,3} = 1 \pm \delta$), see Fig. 1. Such structure does not possess an isotropy of the second rank conductivity tensor $\hat{\sigma}_e^{i,j}$ that follows from the simple crystallographical consideration[5] as well as from the straightforward calculation[3] of the nondiagonal term $\hat{\sigma}_e^{xy} \propto \delta^2$. Therefore $\sigma_{\mathrm{is}}^e(\sigma_k)$ for this structure cannot satisfy the Bruggemann equation (4) even if its coincidence with $\sigma_B(\sigma_k)$ reached the δ^6 term in the perturbation theory. In fact, the Bruggemann equation cannot provide an exact solution for the scalar linear invariant $\sigma_{\mathrm{is}}^e(\sigma_k)$ of the macroscopic conductivity tensor $\hat{\sigma}_{i,j}^e$ in any 2D problem where that tensor is nonscalar.

Resonance dynamics and partial averaging in a restricted three-body system

Nader Haghighipour[a)]
Department of Physics and Astronomy, Northwestern University, Evanston, Illinois 60208

(Received 20 November 2001; accepted for publication 19 March 2002)

Based on the value of the orbital eccentricity of an object and also its proximity to the exact resonant orbit in a three-body system, the pendulum approximation [S. F. Dermott and C. D. Murray, Nature (London) **319**, 201 (1983)] or the second fundamental model of resonance [M. H. Andoyer, Bull. Astron. **20**, 321 (1903); J. Henrard and A. Lemaître, Celest. Mech. **30**, 197 (1983)] are commonly used to study the motion of that object near its resonant state. In this paper, we present the method of partial averaging as an analytical approach to study the dynamical evolution of a body near a resonance. To focus attention on the capabilities of this technique, a restricted, circular and planar three-body system is considered and the dynamics of its outer planet while captured in a resonance with the inner body is studied. It is shown that the first-order partially averaged system resembles a mathematical pendulum whose librational motion can be viewed as a geometrical interpretation of the resonance capture phenomenon. The driving force of this pendulum corresponds to the gravitational attraction of the inner body and its contribution, at different resonant states, is shown to be proportional to e^s, where s is the order of the resonance and e is the orbital eccentricity of the outer planet. As examples of such systems, the cases of (1:1), (1:2), and (1:3) resonances are discussed and the results are compared with known planetary systems such as the Sun–Jupiter–Trojan asteroids. © *2002 American Institute of Physics.*

I. INTRODUCTION

The study of the dynamical evolution of a planetary system while captured in a resonance has a long history in dynamical astronomy. Since the pioneering work of Poincaré[1] on the study of the near-resonance motions in a restricted three-body system by means of a zeroth-order resonance Hamiltonian (i.e., a Hamiltonian with no perturbing terms other than the resonant ones), the body of literature produced on this subject has become so rich and extensive that it is virtually impossible to cite all the articles here. Recent discoveries of extrasolar planetary systems such as Gliese 876,[2] where two planets are locked in a near (2:1) commensurability, have also provided rich grounds for astrodynamicists to extend such studies to the systems beyond the boundaries of our solar system.[3–7]

There are two analytical approaches that are commonly taken in the study of the dynamics of the bodies of a three-body system while captured in a resonance. For an object with high orbital eccentricity ($\geqslant 0.15$) in a first-order resonance, or for an object at any higher order resonance, the pendulum model is used when the object's orbit is sufficiently close to the real resonance location.[8] The Hamiltonian model, or as it is often called, the second fundamental model of resonance,[9,10] is usually used for small eccentricities. A comparison of the results of the application of these two models to the study of the motion of a test particle in a first-order interior resonance as well as an exterior $(1:n')$, $n'=2,3,4,5$ commensurability, with the results of numerical integrations, can be found in a series of papers by Winter and Murray.[11,12] In these articles, as

a)Electronic mail: nader@dtm.ciw.edu

a part of their comprehensive project CRISS-CROSS on understanding the location and origin of chaotic regions in the phase space of our solar system, Winter and Murray present a detailed analysis of the dynamics of a test particle at resonance.

The purpose of this paper is to present a relatively new approach, namely the method of partial averaging near a resonance, to study analytically the dynamics of a system near a resonant state. This technique, which is based on the averaging theorem (see Refs. 13 and 14), enables one to avoid certain complexities by studying the behavior of the system averaged over a fast angular variable.[15–17] It is necessary to mention that a complete picture of the dynamical evolution of the system can only be obtained by direct analysis of its equations of motion. The partially averaged system allows one to focus attention on the slow-changing quantities. Such an idea is commonly used in celestial mechanics: the Hamiltonian of the system is averaged over a fast variable and the resulting averaged Hamiltonian is used to study the slow dynamics of the system. A review of this technique can be found in the work of Ferraz-Mello[18] and the references cited therein. To demonstrate the capabilities of the method of partial averaging, a restricted, circular and planar three-body system is considered here and the motion of its outer planet near an $(n:n')$ resonance is studied.

Although the method of partial averaging near a resonance has long been used by mathematicians in their studies of dynamical systems near resonances,[15–17] its application to astronomical systems is quite recent. One can find such applications in papers by this author on the study of the dynamical evolution of a planetary system in a uniform and homogeneous medium of planetesimals[19,20] and also in a series of articles by Chicone, Mashhoon, and Retzloff[21–26] on their extensive study of the dynamics of a binary system subject to incident gravitational radiation as well as gravitational radiation damping.

The system of interest in this paper is a hypothetical restricted, planar and circular three-body system consisting of a star and two planets. The equations of motion of the outer planet of this system are presented in Sec. II. Section III deals with the system at resonance. In Sec. IV, the method of partial averaging near a resonance is applied and the averaged dynamics of the outer planet, in the first order of perturbation, is studied. It is shown in this section that the contribution of the gravitational attraction of the inner planet on the averaged dynamics of the outer body at different resonant states is directly proportional to the orbital eccentricity of the latter with a power equal to the order of the resonance. As examples of such cases, the (1:1), (1:2), and (1:3) resonances are studied in detail and a comparison with the system of Sun–Jupiter–Trojan asteroids as an actual case of a near (1:1) commensurability is presented. Section V concludes this study by reviewing the results and presenting remarks on their applicability to other planetary systems.

II. THE SYSTEM

The system of interest in this study is a planar three-body system consisting of a star S and two planets P_1 and P_2 where P_2 is the outer planet and P_1, the more massive planet, orbits S uniformly along a circular path. The orbital period of P_1 is considered to be known and constant. It is also assumed that the mass of S is so much larger than P_1 and P_2 that the effect of their gravitational attraction on S can be neglected.

As mentioned earlier, it is the dynamics of P_2 that is of interest here. In an inertial coordinate system with its origin at S and its axes on the plane of the system, the equation of motion of the outer planet can be written as

$$m_2\frac{d^2\vec{r}_2}{dt^2}+\mathcal{G}\frac{Mm_2}{|\vec{r}_2|^3}\vec{r}_2+\mathcal{G}\frac{m_1m_2}{|\vec{r}_2-\vec{r}_1|^3}(\vec{r}_2-\vec{r}_1)=0. \tag{1}$$

In this equation, $\mathcal{G}$ is the gravitational constant, $\vec{r}_1$ and $\vec{r}_2$ are the position vectors of the two planets, m_1 and m_2 are their corresponding masses, and M is the mass of the central star. For future purposes, it is more convenient to write Eq. (1) in a dimensionless form. Introducing r_0 and t_0 as the quantities that carry units of length and time, respectively, Eq. (1) can be written as

$$\frac{d^2\vec{\hat{r}}}{d\hat{t}^2}+\hat{k}\frac{\vec{\hat{r}}}{|\vec{\hat{r}}|^3}+\mu\,\hat{k}\frac{(\vec{\hat{r}}-\vec{\hat{r}}_1)}{|\vec{\hat{r}}-\vec{\hat{r}}_1|^3}=0, \tag{2}$$

where $\vec{\hat{r}}$, $\vec{\hat{r}}_1$, and $\hat{t}$ are dimensionless quantities given by $\vec{r}_2=r_0\,\vec{\hat{r}}$, $\vec{r}_1=r_0\,\vec{\hat{r}}_1$, and $t=t_0\,\hat{t}$. In Eq. (2), $\hat{k}=\mathcal{G}Mt_0^2/r_0^3$ and $\mu=m_1/M$. The assumption of a uniform circular motion for P_1 allows one to set $\hat{k}=1$ by choosing $r_0=r_1$ and $t_0=T_1/2\pi$ where T_1 is the orbital period of P_1.

As mentioned in Sec. I, we would like to analyze Eq. (2) using the method of partial averaging. To do so, it is necessary to write Eq. (2) in terms of appropriate action-angle variables (Appendix A). The most appropriate action-angle variables for this purpose are the Delaunay variables given by $L=a^{1/2}$, $G=\mathcal{P}_\theta=[a(1-e^2)]^{1/2}$, $\ell=u-e\sin u$, and $g=\theta-v$, where $e=\mathcal{P}_r\mathcal{P}_\theta/\sin v$ and a are the eccentricity and the semimajor axis of the osculating ellipse of P_2, θ is its plane-polar angle, $\mathcal{P}_r$ and $\mathcal{P}_\theta$ are its radial and angular momenta, and u and v are its eccentric and true anomalies related as

$$r=\frac{G^2}{1+e\cos v}=a\,(1-e\cos u). \tag{3}$$

In order to write Eq. (2) in terms of the Delaunay variables, it is more convenient to first write this equation in terms of $\mathcal{P}_r$ and $\mathcal{P}_\theta$. That is,

$$\mathcal{P}_r=\dot{r}, \tag{4}$$

$$\mathcal{P}_\theta=r^2\,\dot{\theta}, \tag{5}$$

$$\dot{\mathcal{P}}_r=\frac{1}{r^3}\mathcal{P}_\theta^2-\frac{1}{r^2}-\frac{\mu}{|\vec{r}-\vec{\mathbf{r}}_1|^3}[\vec{r}-\cos(\theta-\theta_1)], \tag{6}$$

$$\dot{\mathcal{P}}_\theta=-\frac{\mu}{|\vec{r}-\vec{\mathbf{r}}_1|^3}r\sin(\theta-\theta_1), \tag{7}$$

where $\theta_1=\omega_1\hat{t}$ and $\omega_1=1$ is the dimensionless angular velocity of P_1. In Eqs. (4)–(7), the hat signs have been dropped for the sake of simplicity and the overdot indicates a derivative with respect to the dimensionless time $\hat{t}$. The vector $\vec{\mathbf{r}}_1$ in Eqs. (6) and (7) is the unit vector along $\vec{r}_1$. In terms of the Delaunay variables, Eqs. (4)–(7) can be written as

$$\dot{G}=r\,F_\theta, \tag{8}$$

$$\dot{L}=a\,(1-e^2)^{-1/2}[F_\theta+e\,(F_r\sin v+F_\theta\cos v)], \tag{9}$$

$$\dot{g}=\frac{1}{e}[a(1-e^2)]^{1/2}\left[F_\theta\left(\frac{\sin v}{1+e\cos v}\right)-(F_r\cos v-F_\theta\sin v)\right], \tag{10}$$

$$\dot{\ell}=a^{-3/2}+\frac{r}{e}a^{-1/2}\left\{(F_r\cos v-2\,F_\theta\sin v)+\frac{1}{2}e\,[(F_r\cos 2v-F_\theta\sin 2v)-3\,F_r]\right\}, \tag{11}$$

where

$$F_r=-\mu\frac{r-\cos(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_1|^3},\quad F_\theta=-\mu\frac{\sin(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_1|^3}. \tag{12}$$

III. SYSTEM AT RESONANCE

Consider an $(n:n')$ commensurability between the angular frequency of the inner planet ω_1, and $\omega_\ell = a^{-3/2}$, the Keplerian frequency of the osculating ellipse of the outer one. That is,

$$n\,\omega_1 = n'\,\omega_\ell\,. \tag{13}$$

For our restricted circular system with this resonance condition, the Keplerian frequency ω_ℓ, and therefore, the semimajor axis of the outer planet at resonance are constant. The constant value of the semimajor axis, denoted by $a_{(n:n')}$, corresponds to the resonant value of the action variable L as $L_{(n:n')} = a^{1/2}_{(n:n')}$. We would like to study the dynamics of the outer planet when L varies in the vicinity of this value. For this purpose, we need to introduce an appropriate transformation that renders Eqs. (8)–(11) in a form that includes deviations of L from $L_{(n:n')}$. Let D be an action variable measuring these deviations. We then write (Appendix A)

$$L = a^{1/2}_{(n:n')} + \mu^{1/2} D, \tag{14}$$

and

$$\ell = a^{-3/2}_{(n:n')}\,\hat{t} + \varphi, \tag{15}$$

where φ denotes the deviations of the mean anomaly ℓ from its Keplerian value. Such transformations have been repeatedly used in application of Hamiltonian averaging techniques to resonant systems.[18] It is important to mention that the choice of $\mu^{1/2}$ in Eq. (14) is to assure equal lowest order of perturbation for $\dot{D}$ and $\dot{\varphi}$ after writing Eqs. (8)–(11) for the system near resonance. Details on this can be found in Refs. 14 and 20.

For the purpose of writing Eqs. (8)–(11) near a resonance, it is more convenient to write these equations as (Appendix B)

$$\dot{L} = -\mu \frac{\partial H}{\partial \ell}, \quad \dot{G} = -\mu \frac{\partial H}{\partial g}, \tag{16}$$

and

$$\dot{\ell} = \omega_\ell + \mu \frac{\partial H}{\partial L}, \quad \dot{g} = \mu \frac{\partial H}{\partial G}, \tag{17}$$

where $H = -|\vec{r} - \vec{\mathbf{r}}_\mathbf{1}|^{-1}$ (hereafter, *external Hamiltonian*) represents the perturbative effect of the inner planet, P_1. The dynamical equations of the system near resonance can now be written as[19]

$$\dot{D} = -\mu^{1/2}\frac{\partial H}{\partial \ell} - \mu\, D\, \frac{\partial^2 H}{\partial \ell\, \partial L} + O(\mu^{3/2}), \tag{18}$$

$$\dot{\varphi} = -3\,\mu^{1/2}\, a^{-2}_{(n:n')}\, D + \mu \left[6 a^{-5/2}_{(n:n')}\, D^2 + \frac{\partial H}{\partial L} \right] + O(\mu^{3/2}), \tag{19}$$

$$\dot{G} = -\mu \frac{\partial H}{\partial g} + O(\mu^{3/2}), \tag{20}$$

$$\dot{g} = \mu \frac{\partial H}{\partial G} + O(\mu^{3/2}). \tag{21}$$

In these equations, all partial derivatives are evaluated at $(L_{(n:n')},G,L^{-3}_{(n:n')}\hat{t}+\varphi,g)$. The averaged dynamics of the system is obtained by applying the averaging technique presented in Appendix A to Eqs. (18)–(21).

IV. FIRST-ORDER AVERAGED SYSTEM

As mentioned before, we would like to study the averaged dynamics of the outer planet near a resonance, in the first order of the perturbation parameter $\mu^{1/2}$. In that order, Eqs. (18)–(21) are written as

$$\dot{D}=-\mu^{1/2}\mathcal{F},\quad \dot{\varphi}=-\mu^{1/2}\left[\frac{3D}{a^2_{(n:n')}}\right],\quad \dot{G}=\dot{g}=0, \tag{22}$$

where $\mathcal{F}=\partial H/\partial \ell$ is evaluated at $(L_{(n:n')},G,L^{-3}_{(n:n')}\hat{t}+\varphi,g)$.

In this section, we apply the method of partial averaging, as described in Appendix A, to Eq. (22). As mentioned in Appendix A, the analysis presented there is only valid for systems with one angular variable. An inspection of the main dynamical equations of the outer planet [i.e., Eqs. (16) and (17)] reveals that these equations along with $\dot{\theta}_1=1$ represent the time variations of two action variables L and G and three angular variables ℓ, g, and θ_1. However, as shown by Eq. (22), to the first order of $\mu^{1/2}$, $\dot{g}=0$. That is, the angular variable g is a constant. Also, from the resonance condition (13) and the transformation (15), the angular variables ℓ and $\theta_1=\hat{t}$ are related as $\ell=(n/n')\hat{t}+\varphi$. These relations imply that, in fact, Eq. (22) represents a dynamical system with an action variable $D(\hat{t})$ and an angular variable $\varphi(\hat{t})$. These equations are now in the correct form for applying the partial averaging technique.

The averaged dynamics of the outer planet, to the first order of perturbation, is obtained by averaging quantities D and φ in Eq. (22) using integral (A7). The result, after eliminating $\overline{D}$, can be written as

$$\ddot{\overline{\varphi}}-3\,\mu\, a^{-2}_{(n:n')}\overline{\mathcal{F}}(L_{(n:n')},G,\overline{\varphi},g)=0, \tag{23}$$

where the overbar denotes an averaged quantity. To study this equation, it is necessary to calculate $\overline{\mathcal{F}}$. From the definition of $\mathcal{F}$, however, one has to first write the *external Hamiltonian* H in terms of the mean anomaly ℓ. To do so, we start by writing H as

$$H=-[1+r^2-2\,r\cos(\theta-\theta_1)]^{-1/2}. \tag{24}$$

The dependence of H on the mean anomaly is, in fact, implied through the dependence of r and θ on the true anomaly v. That is, in order to write H as a function of ℓ, we need to substitute for r from Eq. (3) and replace θ by $g+v$. The mean anomaly ℓ appears when $\cos v$ and $\sin v$ are replaced by

$$\cos v=-e+2\left(\frac{1-e^2}{e}\right)\sum_{j=1}^{\infty}\cos(j\ell)J_j(je), \tag{25}$$

and

$$\sin v=(1-e^2)^{1/2}\sum_{j=1}^{\infty}\sin(j\ell)[J_{j-1}(je)-J_{j+1}(je)]. \tag{26}$$

Here J_j is the Bessel function of order j. The Hamiltonian H can, therefore, be written as

$$H=-\{[1+a^2-2a\cos(\ell+g-\theta_1)]-e\,a\,[2a\cos\ell+\cos(2\ell+g-\theta_1)-3\cos(g-\theta_1)]$$
$$+\tfrac{1}{4}a\,e^2[2a(3-\cos 2\ell)+4\cos(\ell+g-\theta_1)-3\cos(3\ell+g-\theta_1)-\cos(\ell-g+\theta_1)]$$
$$+O(e^3)\}^{-1/2}. \tag{27}$$

To calculate $\mathcal{F}$, we need to differentiate H with respect to the mean anomaly ℓ. From Eq. (27), we can see that such a differentiation will result in a very complex expression for the function $\mathcal{F}$, which makes the calculation of its averaged value through integral (A7), if not impossible, quite difficult. Traditionally in celestial mechanics, such complexities are avoided by expanding the gravitational effects of the perturbing bodies in terms of the osculating orbital elements such as eccentricity.[27] Such expansions are quite customary in studies of the dynamics of the bodies, such as planets of our solar system where, except Pluto, the mean orbital eccentricities range from 3% to 8%.

In this paper, the perturbative effect of the outer planet appears as function $\mathcal{F}$ in Eq. (23). One can consider this equation as the equation of a dynamical system written according to the Newton's second law where $\mathcal{F}$ represents its associated force. After differentiating Eq. (27) with respect to the mean anomaly and expanding the results in terms of the eccentricity of the outer planet, this force can be written as

$$\mathcal{F}=\mathcal{F}^{(0)}+e\,\mathcal{F}^{(1)}+e^2\,\mathcal{F}^{(2)}+O(e^3), \tag{28}$$

where

$$\mathcal{F}^{(0)}=a\,[1+a^2-2a\cos(\ell+g-\theta_1)]^{-3/2}\sin(\ell+g-\theta_1), \tag{29}$$

$$\mathcal{F}^{(1)}=a\,[1+a^2-2a\cos(\ell+g-\theta_1)]^{-3/2}[a\sin\ell+\sin(2\ell+g-\theta_1)]$$
$$+\tfrac{3}{2}a^2[1+a^2-2a\cos(\ell+g-\theta_1)]^{-5/2}\sin(\ell+g-\theta_1)$$
$$\times[2a\cos\ell+\cos(2\ell+g-\theta_1)-3\cos(g-\theta_1)], \tag{30}$$

and

$$\mathcal{F}^{(2)}=\tfrac{1}{8}a\,[1+a^2-2\,a\cos(\ell+g-\theta_1)]^{-3/2}[4a\sin 2\ell-4\sin(\ell+g-\theta_1)+9\sin(3\ell+g-\theta_1)$$
$$+\sin(\ell-g+\theta_1)]-\tfrac{3}{16}a^2[1+a^2-2\,a\cos(\ell+g-\theta_1)]^{-5/2}[20\,a\sin(\ell+g-\theta_1)$$
$$-14\,a\sin(3\ell+g-\theta_1)+14\,a\sin(\ell-g+\theta_1)+16\sin 2(\ell+g-\theta_1)-7\sin 2(2\ell+g-\theta_1)$$
$$+2(7-4a^2)\sin 2\ell-\sin 2(g-\theta_1)]+\tfrac{15}{32}a^3[1+a^2-2a\cos(\ell+g-\theta_1)]^{-7/2}[2(4a^2$$
$$+13)\sin(\ell+g-\theta_1)+(4a^2-7)\sin(3\ell+g-\theta_1)-(4a^2-15)\sin(\ell-g+\theta_1)+\sin(5\ell+3g$$
$$-3\theta_1)+9\sin(\ell+3g-3\theta_1)+4a\sin 2(2\ell+g-\theta_1)-16\,a\sin 2\ell-12\,a\sin 2(g-\theta_1)$$
$$-8\,a\sin 2(\ell+g-\theta_1)-6\sin 3(\ell+g-\theta_1)]. \tag{31}$$

Expansion of $\mathcal{F}$ in terms of e, as given by Eq. (28), enables us to simplify the calculations of $\overline{\mathcal{F}}$ by integrating only the terms that play more significant roles. The question is now how to identify such terms. In the following, we answer this question.

To compute the averaged value of $\mathcal{F}$, we need to integrate Eq. (28) using formula (A7). From Eqs. (29)–(31) one can see that because of the terms $[1+a^2-2a\cos(\ell+g-\theta_1)]^{-\lambda}$, $\lambda=3/2,5/2,7/2$, calculation of integral (A7) may not be quite doable. This difficulty can, however, be overcome taking into account that for the outer planet $r_2>r_1$, or in a dimensionless form and in terms of the osculating elements, $a>1$. Therefore, the above-mentioned quantity can be written as $a^{-2\lambda}[1+a^{-2}-2a^{-1}\cos(\ell+g-\theta_1)]^{-\lambda}$, which can, subsequently, be expanded using the identity

$$(1-2\,\xi\cos\alpha+\xi^2)^{-\lambda}=\sum_{q=0}^{\infty} C_q^{\lambda}(\cos\alpha)\xi^q, \quad |\xi|<1. \tag{32}$$

In this equation,

$$C_q^{\lambda}(\cos\alpha)=\sum_{h=0}^{q}\frac{\Gamma(\lambda+h)\Gamma(\lambda+q-h)}{h!\,(q-h)!\,[\Gamma(\lambda)]^2}\cos[(q-2h)\alpha] \tag{33}$$

are the Gegenbauer polynomials and α and ξ are equal to $\ell+g-\theta_1$ and a^{-1}, respectively.

An inspection of Eqs. (29)–(31) reveals that quantities $\mathcal{F}^{(0)}$, $\mathcal{F}^{(1)}$, and $\mathcal{F}^{(2)}$ share a common feature; the terms $[1+a^2-2a\cos(\ell+g-\theta_1)]^{-\lambda}$ are multiplied by sinus functions with angular arguments of a general form $[\nu\ell+\nu'(g-\theta_1)]$ where ν and ν' are integers. For instance, in Eq. (29), $\nu=\nu'=1$ and in the first term of Eq. (30), $\nu=1$ and $\nu'=0$. Therefore, a general term of Eqs. (29)–(31) can be written as

$$\begin{aligned}&[1+a^2-2a\cos(\ell+g-\theta_1)]^{-\lambda}\sin[\nu\ell+\nu'(g-\theta_1)]\\&\quad=\sum_{q=0}^{\infty}\sum_{h=0}^{q} a^{-(q+2\lambda)}\frac{\Gamma(\lambda+h)\Gamma(\lambda+q-h)}{h!(q-h)!\,[\Gamma(\lambda)]^2}\cos[(q-2h)(\ell+g-\theta_1)]\sin[\nu\ell+\nu'(g-\theta_1)].\end{aligned} \tag{34}$$

Consequently, $\mathcal{F}$ will be equal to the sum of terms proportional to $e^s\cos[(q-2h)(\ell+g-\theta_1)]\sin[\nu\ell+\nu'(g-\theta_1)]$ where $s=0,1,2$.

The above-mentioned quantity appeared in Eq. (28) after the Hamiltonian (27) was differentiated with respect to the mean anomaly ℓ. That means, the three components of this quantity, $\cos[(q-2h)(\ell+g-\theta_1)]$, $\sin[\nu\ell+\nu'(g-\theta_1)]$ and e^s, have their origins in H. A deeper look at Eq. (27) indicates what the nature of these components are and how they contribute to the averaged dynamics of the outer planet.

The first term in the curly braces in Eq. (27) is the term responsible for $[1+a^2-2a\cos(\ell+g-\theta_1)]^{-\lambda}$ and consequently, for the expansion (32). As seen from Eq. (27), this term is associated with the zeroth power of eccentricity. That is, it represents the effect of the inner planet as the $\mathcal{F}^{(0)}$ component of the force of the dynamical system (23). Later in this section, we will discuss this component in more detail and explain its contribution to the dynamics of the system while captured in a (1:1) resonance.

The $\sin[\nu\ell+\nu'(g-\theta_1)]$ term in the above-mentioned coupling has its roots in all terms of the Hamiltonian H. To study this term in more details, it proves useful to evaluate the averaged value of $\mathcal{F}$ using formula (A7). Using the expansion (34), a general term of $\overline{\mathcal{F}}$ will be proportional to

$$\begin{aligned}&\int_0^{2\pi n'}\sin[(\nu+q-2h)\ell+(\nu'+q-2h)(g-\theta_1)]\mathrm{d}\hat{t}\\&\quad+\int_0^{2\pi n'}\sin[(\nu-q+2h)\ell+(\nu'-q+2h)(g-\theta_1)]\mathrm{d}\hat{t}.\end{aligned}$$

Recall that in an $(n:n')$ resonance, $\ell=(n/n')\hat{t}+\varphi$. We also have $\theta_1=\hat{t}$. Therefore, because of their harmonic natures, the above-mentioned integrals will be equal to zero except for those cases where the variable $\hat{t}$ in the integrands vanishes. In the first integral, this corresponds to $\nu+q-2h=\pm n'$ and $\nu'+q-2h=\pm n$ and in the second integral we must have $\nu-q+2h=\pm n'$ and $\nu'-q+2h=\pm n$. These four equations imply that $(q-2h)$ has to be equal to one of the four integers $\pm(\nu\pm n')$ and, at the same time, one of the four integers $\pm(\nu'\pm n)$ with the same arrangement of $+$ and $-$ signs, in order for the quantity $\mathcal{F}$ to have a nonzero averaged value. In other words, we must have

TABLE I. The angular arguments of the contributing terms of expansion (28) for a Sun–protoJupiter–protoSaturn system in a (1:2) resonance.

Angular argument of the contributing terms	(ν,ν')	$\pm(q-2h)$
ℓ	(1,0)	3,1
$g-\theta_1$	(0,1)	2,0
$\ell+2g-2\theta_1$	(1,2)	3,1

$3\ell+2g-2\theta_1$	(3,2)	5,3,1

$$|\Delta\nu| = |\nu-\nu'| = n'-n. \tag{35}$$

Equation (35) is, indeed, a *selection rule*. That is, it can be used to identify the contributing terms of expansion (28) in the averaged dynamics of the outer planet in an $(n:n')$ resonance. To show this, we apply the above-mentioned analysis to a specific three-body system consisting of Sun, a proto-Jupiter, and a proto-Saturn. It was shown by Melita and Woolfson[28] and also by Haghighipour[19] that in a medium of planetesimals, the protoSaturn of the three-body system above undergo an inward migration when the dynamical friction force of the medium is taken into consideration. Recently Masset and Snellgrove[29] have also arrived at the same conclusion in their study of the migration of giant protoplanets embedded in a protoplanetary disk. As a result of this migration, the semimajor axis of the protoSaturn decreases until it is captured in a near (1:2) resonance with the protoJupiter. It has also been shown that under certain conditions, this body can migrate outward and become captured in higher order resonances of the form $(1:n')$ where $n' \geqslant 3$.[19,20,30] Equation (23) can, therefore, be used to study the averaged dynamics of the proto-Saturn above near a (1:2) and also near a higher order resonance of (1:3).

From the *selection rule* (35), it becomes evident that for the system in a (1:2) resonance, only $\mathcal{F}^{(1)}$ will have nonzero averaged value and when the system is captured in a (1:3) commensurability, only $\mathcal{F}^{(2)}$ will contribute. Tables I and II show the angular arguments of the sinus functions of the contributing terms of $\mathcal{F}^{(1)}$ and $\mathcal{F}^{(2)}$ and also their corresponding values of $(q-2h)$.

The quantity $|\Delta\nu|$ in the selection rule (35) is called the order of the resonance. The fact that $\mathcal{F}^{(1)}$ is the first contributing term of expansion (28) in a (1:2) resonance and $\mathcal{F}^{(2)}$ is its first contributing term in a (1:3) resonance imply that in a first-order exterior resonance such as (1:2), the first contributing term is proportional to e^1 and similarly, in a second-order resonance such as (1:3), the first contributing term is proportional to e^2. In general, by expanding $\mathcal{F}$ to higher orders of eccentricity, one can show that in an exterior $(n:n')$ resonance of order $|\Delta\nu|$, the first fulfillment of the condition (35) by the factor $\sin[\nu\ell+\nu'(g-\theta_1)]$ appears in a term proportional to e^s where s is equal to $|\Delta\nu|$. For instance, the contribution of expansion (28) to the averaged dynamics of the outer planet in a resonance of the form $(n:n+1)$ will first appear in its second term, $\mathcal{F}^{(1)}$, and the third term of this expansion, $\mathcal{F}^{(2)}$, will be the first term with a nonzero averaged

TABLE II. The angular arguments of the contributing terms of expansion (28) for a Sun–protoJupiter–protoSaturn system in a (1:3) resonance.

Angular argument of the contributing terms	(ν,ν')	$\pm(q-2h)$
2ℓ	(2,0)	5,1
$2(g-\theta_1)$	(0,2)	3,1
$\ell+3g-3\theta_1$	(1,3)	4,2
$\ell-g+\theta_1$	(1,−1)	4,2,0
$3\ell+g-\theta_1$	(3,1)	6,2,0

$5\ell+3g-3\theta_1$	(5,3)	8,4,2

value when the system is captured in an $(n:n+2)$ commensurability. The role of $\sin[\nu\ell+\nu'(g-\theta_1)]$ in the coupling term and, consequently, in the averaged dynamics of the outer planet is to differentiate the contributing terms of the expansion (28) for an $(n:n')$ resonance by determining the power of the eccentricity to which the disturbing force $\mathcal{F}$ has to be expanded, through the selection rule (35). The factor e^s in the coupling represents the strength of the contributing term associated with a resonance of order $s=\Delta\nu$. It is customary in celestial mechanics to call this resonant state an e^s-resonance.[27] For instance, the (1:2) resonant state in the Sun–protoJupiter–protoSaturn system studied previously is an e^1-resonance and the state of the system in a (1:3) commensurability corresponds to an e^2-resonance.

Let us now, just as examples of the first- and the second-order exterior resonances, study the averaged system near (1:2) and (1:3) commensurabilities. In general, after replacing ℓ by its equivalent value given by Eq. (15), substituting for $(q-2h)$ by $\pm(\nu\pm n')$ and $\pm(\nu'\pm n)$, and averaging the results, the product of $\cos[(q-2h)(\ell+g-\theta_1)]$ and $\sin[\nu\ell+\nu'(g-\theta_1)]$ will produce terms that are proportional to $\sin(n'\overline{\varphi}+ng)$. For instance, for a system near a (1:2) resonance,

$$\overline{\mathcal{F}}_{(1:2)}=\frac{e_{(1:2)}}{a^2_{(1:2)}}\sigma_{(1:2)}\sin(2\overline{\varphi}+g), \tag{36}$$

and for a (1:3) resonance,

$$\overline{\mathcal{F}}_{(1:3)}=\frac{e^2_{(1:3)}}{4a^2_{(1:3)}}\left[\sigma^{(3/2)}_{(1:3)}+3\sigma^{(5/2)}_{(1:3)}+\frac{15}{a^2_{(1:3)}}\sigma^{(7/2)}_{(3:1)}\right]\sin(3\overline{\varphi}+g). \tag{37}$$

In these equations,

$$\sigma_{(1:2)}=\sum_{h=0}^{\infty}\left[\frac{\Gamma\left(\frac{3}{2}+h\right)}{a^h_{(1:2)}h!\Gamma\left(\frac{3}{2}\right)}\right]^2\left\{1+\left(\frac{2h+3}{h+1}\right)\left[1-\frac{3}{4a^2_{(1:2)}}\left(\frac{2h+5}{h+2}\right)\right]\right\}, \tag{38}$$

$$\sigma^{(3/2)}_{(1:3)}=\sum_{h=0}^{\infty}\left[\frac{\Gamma\left(\frac{3}{2}+h\right)}{a^h_{(1:3)}h!\Gamma\left(\frac{3}{2}\right)}\right]^2\left\{\frac{9}{2}+\left(\frac{2h+3}{h+1}\right)\left[1+\frac{1}{8a^2_{(1:3)}}\left(\frac{2h+5}{h+2}\right)\right]\right\}, \tag{39}$$

$$\sigma^{(5/2)}_{(1:3)}=\sum_{h=0}^{\infty}\left[\frac{\Gamma\left(\frac{5}{2}+h\right)}{a^h_{(1:3)}h!\Gamma\left(\frac{5}{2}\right)}\right]^2\left\{\frac{7}{2}+\left[1-\frac{7}{8a^2_{(1:3)}}\right]\left(\frac{2h+5}{h+1}\right)-\frac{1}{8a^2_{(1:3)}}\left[7+\frac{1}{4a^2_{(1:3)}}\left(\frac{2h+9}{h+3}\right)\right]\frac{(2h+7)(2h+5)}{(h+2)(h+1)}\right\}, \tag{40}$$

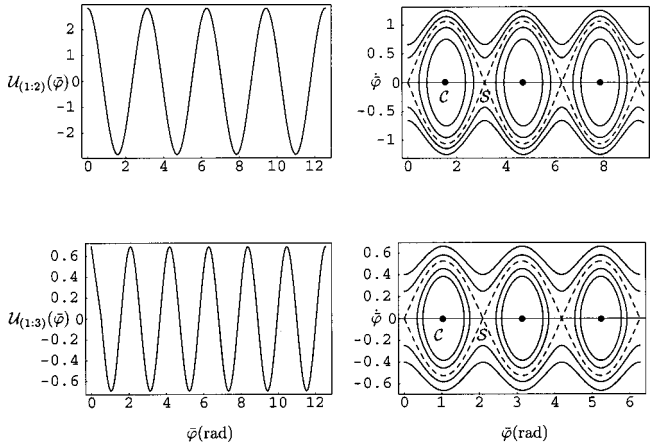

FIG. 1. Graphs of the potential function $\mathcal{U}_{(1:2)}(\overline{\varphi})$ (top left panel) and its phase diagram (top right panel) and the potential function $\mathcal{U}_{(1:3)}(\overline{\varphi})$ (bottom left panel) with its associated phase diagram (bottom right panel) for the system studied by Haghighipour (Ref. 19) at (1:2) and (1:3) resonances. The scale on all vertical axes is 0.01. The origins on the horizontal axes of the graphs of the (1:2) resonance have been shifted by -0.44(rad) and the corresponding origins of the graphs of the (1:3) resonance have been shifted by -1.7(rad).

$$\sigma^{(7/2)}_{(1:3)}=\sum_{h=0}^{\infty}\left[\frac{\Gamma\left(\frac{7}{2}+h\right)}{a^{h}_{(1:3)}h!\,\Gamma\left(\frac{7}{2}\right)}\right]^{2}\left\{\frac{1}{2}\left[a^{2}_{(1:3)}-\frac{7}{4}\right]-\frac{3}{4}\left(\frac{2h+7}{h+1}\right)\right.$$
$$+\left[\frac{1+15a^{2}_{(1:3)}-4a^{4}_{(1:3)}}{32a^{2}_{(1:3)}}\right]\frac{(2h+9)(2h+7)}{(h+2)(h+1)}$$
$$\left.+\frac{3}{16a^{2}_{(1:3)}}\left[1-\frac{3}{8a^{2}_{(1:3)}}\left(\frac{2h+13}{h+4}\right)\right]\frac{(2h+11)(2h+9)(2h+7)}{(h+3)(h+2)(h+1)}\right\}. \tag{41}$$

Because $\overline{\mathcal{F}}$ is proportional to $\sin(n'\overline{\varphi}+ng)$, Eq. (23) can be viewed as the equation of a mathematical pendulum with a potential function proportional to $\cos(n'\overline{\varphi}+ng)$ [see Eq. (A12)]. Such a pendulum, with its harmonic potential, is a characteristic of the first-order partially averaged system near a resonance where $e_{(n:n')}$ is considered to be constant.[13,14,19,31] For instance, for the cases of (1:2) and (1:3) resonances,

$$\mathcal{U}_{(1:2)}(\overline{\varphi})=\frac{3e_{(1:2)}}{2a^{4}_{(1:2)}}\sigma_{(1:2)}\cos(2\overline{\varphi}+g)+\text{constant}, \tag{42}$$

and

$$\mathcal{U}_{(1:3)}(\overline{\varphi})=\frac{e^{2}_{(1:3)}}{4a^{4}_{(1:3)}}\left[\sigma^{(3/2)}_{(1:3)}+3\,\sigma^{(5/2)}_{(1:3)}+\frac{15}{a^{2}_{(1:3)}}\sigma^{(7/2)}_{(1:3)}\right]\cos(3\overline{\varphi}+g)+\text{constant}. \tag{43}$$

Figure 1 shows the graphs of these two potential functions with their corresponding phase diagrams. In producing these graphs, the numerical values of the orbital eccentricity and the semimajor axis of P_2 have been taken from the restricted three-body system of Haghighipour[19] at (1:2) and (1:3) resonances.

The harmonic nature of the potential function of the pendulum (23) indicates that this pendulum can be in three dynamical states; stable equilibrium corresponding to the minimum of the potential function (centers $\mathcal{C}$ on the phase diagrams), unstable equilibrium corresponding to the

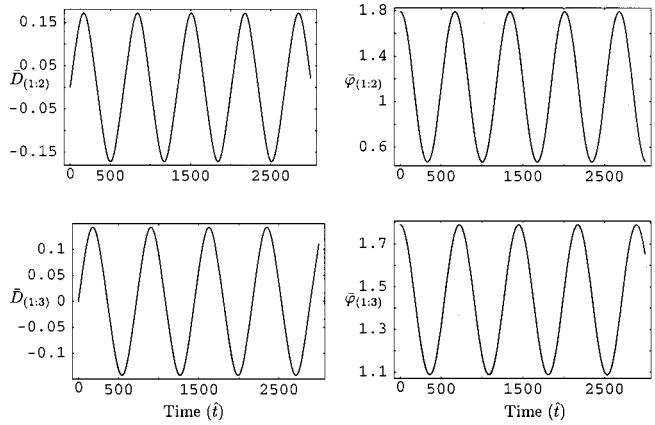

FIG. 2. Graphs of $\bar{D}(\hat{t})$ and $\bar{\varphi}(\hat{t})$ for the systems of Fig. 1, partially averaged to the first order.

maximum of the potential function (saddle points $\mathcal{S}$) or, an oscillatory (librational) motion around the stable equilibrium (the orbits inside the *separatrix*, the dashed orbit that passes through the saddle point $\mathcal{S}$). The resonance lock phenomenon is geometrically depicted by these librational motions.

The oscillatory variations in values of $\bar{\varphi}$ create a harmonic behavior for the action variable $\bar{D}$. From Eq. (22), for a system at an $(n:n')$ resonance where $\bar{\mathcal{F}}$ is proportional to $\sin(n'\bar{\varphi}+ng)$, $\bar{D}$ will be proportional to $\cos(n'\bar{\varphi}+ng)$. Figure 2 shows the graphs of $\bar{D}$ and $\bar{\varphi}$ against time for the systems of Fig. 1. As mentioned in Sec. III, D is the measure of changes in the action variable L or, in other words, an indication of the variations of the semimajor axis of the outer planet from its resonant value. From Eq. (A14), the width of the resonance band within which the semimajor axis of the outer planet varies around its resonant value is limited by the height of the separatrix and to the first order of perturbation can be written as

$$\Delta a_{(n:n')}=4\left[\tfrac{2}{3}\mu\, a^{3}_{(n:n')}\,\Delta\,\mathcal{U}_{(n:n')}(\bar{\varphi})\right]^{1/2}, \tag{44}$$

where $\Delta\,\mathcal{U}_{(n:n')}(\bar{\varphi})$ is equal to the difference between the maximum and the minimum values of $\mathcal{U}_{(n:n')}(\bar{\varphi})$.

It is necessary to mention that the procedure presented here for expansion of $[1+a^2-2a\cos(\ell+g-\theta_1)]^{-\lambda}$ using Gegenbauer polynomials, is not valid for a (1:1) resonance. At this state, from Eq. (13), the Keplerian period of the outer planet becomes nearly equal to T_1. That means, $a_{(1:1)}\simeq 1$ and expansion (32) is no longer applicable. However, it is still possible to use the method of averaging to study the dynamics of the outer planet near a (1:1) commensurability. The *external Hamiltonian* H, in this case, must be studied in its entirety as given by Eq. (25). Expanding H to the second order in eccentricity and integrating $\mathcal{F}$ in the vicinity of the (1:1) resonance, we have

$$\begin{aligned}\bar{\mathcal{F}}_{(1:1)}=&\tfrac{1}{2}a_{(1:1)}[2-e^2_{(1:1)}]\sin(\bar{\varphi}+g)\,[1+a^2_{(1:1)}-2a_{(1:1)}\cos(\bar{\varphi}+g)]^{-3/2}\\&-3\,a^2_{(1:1)}\,e^2_{(1:1)}\sin 2(\bar{\varphi}+g)\,[1+a^2_{(1:1)}-2a_{(1:1)}\cos(\bar{\varphi}+g)]^{-5/2}\\&+\tfrac{45}{4}a^3_{(1:1)}\,e^2_{(1:1)}\sin^3(\bar{\varphi}+g)[1+a^2_{(1:1)}-2a_{(1:1)}\cos(\bar{\varphi}+g)]^{-7/2}.\end{aligned} \tag{45}$$

The potential function associated with the first-order partially averaged system is given by

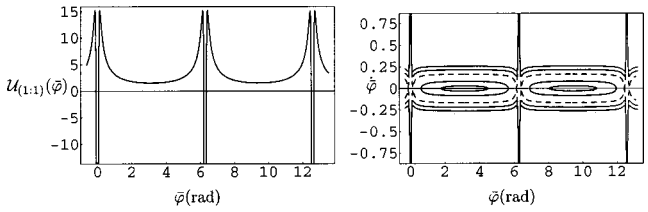

FIG. 3. Graphs of the potential function $\mathcal{U}_{(1:1)}(\bar{\varphi})$ (left panel) and its phase diagram (right panel) against $\bar{\varphi}$.

$$\mathcal{U}_{(1:1)}(\bar{\varphi})=\frac{3}{a_{(1:1)}^2}[1+a_{(1:1)}^2-2a_{(1:1)}\cos(\bar{\varphi}+g)]^{-1/2}-\frac{21}{2a_{(1:1)}}e_{(1:1)}^2\cos(\bar{\varphi}+g)$$
$$\times[1+a_{(1:1)}^2-2a_{(1:1)}\cos(\bar{\varphi}+g)]^{-3/2}+\frac{27}{4}e_{(1:1)}^2\sin^2(\bar{\varphi}+g)$$
$$\times[1+a_{(1:1)}^2-2a_{(1:1)}\cos(\bar{\varphi}+g)]^{-5/2}. \tag{46}$$

Figure 3 shows the graph of this potential for $g=0°$. The fact that $d\mathcal{U}_{(1:1)}(\bar{\varphi})/d\bar{\varphi}$ shows slight deviations from zero near the points of stable equilibrium is an indication of a slow-frequency librational motion in those neighborhoods. To see this, let us apply this analysis to the system of Sun–Jupiter–Trojan asteroid. Located at the L_4 and L_5 Lagrangian points of Jupiter's orbit, Trojan asteroids are in a near (1:1) resonance with Jupiter and have a librational motion with a period of approximately 148 years.[32,33] Substituting for a and e in Eq. (46) by the values of the semimajor axis and the eccentricity of Trojan asteroids and Taylor expanding $\mathcal{U}_{(1:1)}(\bar{\varphi})$ around its stable equilibrium, one will obtain a librational period of approximately 110 years. The difference between this period and the 148 years reported in the above-mentioned references can be attributed to several factors such as neglecting the gravitational effect of Saturn, restricting Jupiter to stay on a circular orbit, and also to the coupling between φ and the argument of the pericenter g. Studies are currently under way to extend the partially averaged equations of this system to the second order of perturbation where φ and g decouple. A closer value for the above-mentioned librational period is expected in this case.

The first-order partially averaged system near a resonance, presented by Eq. (23) is, in general, Hamiltonian. It portrays the phenomenon of resonance-lock as librational motion of a pendulum. However, with respect to an arbitrary perturbation, this Hamiltonian system is structurally unstable. In an actual system, in order to be able to draw conclusions on long-term behavior of quantities such as orbital eccentricity of the outer planet, its angular momentum and also the precession of its orbit, it is necessary to extend this analysis to higher orders of the perturbation parameter $\mu^{1/2}$. Such an extension will allow for the time variation of the angle g to be taken into consideration. This will render the system of Eqs. (18)–(21) in a set of equations with two angular variables, φ and g. In order to be able to apply the method of partial averaging near a resonance to this system, it is then necessary to introduce an averaging transformation that renders the equations of the system in a form that to the first order of perturbation, it becomes automatically equivalent to the first-order partially averaged system at resonance. The second-order partially averaged system is then obtained by averaging those equations using formula (A7). Such studies are currently in preparation for publication.

V. SUMMARY AND CONCLUDING REMARKS

Application of the method of partial averaging to the study of the dynamics of the outer body of a restricted three-body system while captured in a resonance has been presented here. Analysis of the first-order partially averaged system near a resonance has revealed that the equations of

motion of the outer planet, averaged over fast periodic motion at resonance, resemble a mathematical pendulum. Such a pendulum analogy can also be found in the comprehensive study of orbital resonances among planetary satellites by Peale[34] and also in the comprehensive study of the dynamical behavior of a test particle near an interior as well as an exterior resonance in a restricted three-body system by Winter and Murray.[11,12]

In the analysis presented here, the driving force of the pendulum-like first-order partially averaged system is obtained from the *external Hamiltonian H* [Eq. (24)] which involves the gravitational effect of the inner planet on the dynamics of the outer one. In writing the dynamical equations of the outer planet in terms of the Delaunay variables, this force appears as F_r and F_θ in Eqs. (8)–(11). It is important to mention that the form of these equations [i.e., Eqs. (8)–(11)] is quite general and independent of the physical nature of the perturbation. In a system where the perturbations are non-Hamiltonian, extra terms will be added to the functions F_r and F_θ as well as Eqs. (16) and (17). However, Eqs. (8)–(11) will keep their general form.[19,20] The procedure presented here regarding the application of the partial averaging technique and the analysis of the pendulum-like equation are also quite general and can be applied to non-Hamiltonian systems in a similar fashion. In fact, one of the most important features of the method of partial averaging near a resonance is that it presents a general analytical procedure that is equally applicable to both Hamiltonian and non-Hamiltonian systems. As examples of the systems where the method of partial averaging near a resonance has been used in conjunction with non-Hamiltonian perturbations, we refer the reader to Refs. 19, 23, and 24.

As mentioned in Sec. IV, the first-order partially averaged system near a resonance presents the first step in utilizing the method of averaging in the analytical study of the dynamics of a resonance-locked system. To this order of approximation, the argument of the pericenter g was assumed to be constant. In order to obtain a more comprehensive picture of the dynamics of a system near a resonance and the roles that perturbative effects play in its stability, one has to extend this analysis to higher orders of the perturbation parameter $\mu^{1/2}$. Such an extension is necessary to assure decoupling of the angles φ and g (see, e.g., Ref. 20). At that stage, one can apply the averaging technique presented here to the dynamics of the system at the second order of perturbation by averaging those equations over the fast-changing angular variable φ and studying the pendulum-like equation of the angular variable g. Such studies are currently under way for the case of (1:1) resonance and their applications to Trojan asteroids.

The choice of a restricted system as presented in this study was merely to focus attention on the method of partial averaging and its capabilities as another approach to analytical analysis of the dynamics of a system near a resonance. The analysis presented here is quite general and can be applied to any dynamical system at resonance. One can apply such analysis to the systems at interior resonances where $a<1$, by setting $\xi=a$ in Eq. (32) and changing the *selection rule* (35) to

$$|\Delta\nu| = n - n'. \tag{47}$$

An implication of this *selection rule* can be found in a recent paper by Michtchenko and Ferraz-Mello[35] on analytical modeling of the Jupiter–Saturn system near their (5:2) resonance. They show that at the lowest order, the contribution of the resonant part of the disturbing function appears as the third power of eccentricity, a result that is also implied by the *selection rule* (47).

Other interesting cases for application of the partial averaging technique are the study of the stability of the extrasolar planetary system Gliese 876[2] where its two planets are locked in a near (2:1) commensurability, the study of dynamical stability of P-type binary planetary systems where recent numerical integrations by Holman and Wiegert[36] have indicated the existence of islands of instabilities for eccentric binaries at $(n:1), n>3$, resonances and also the study of the dynamical evolution of pulsar planetary systems such as PSR B1257+12[37] and PSR B1620-26.[38–41] It appears that gravitational radiation reaction may play a vital role in the dynamical evolution of these system.[21–26]

APPENDIX A: METHOD OF PARTIAL AVERAGING NEAR A RESONANCE

A short introduction to the method of partial averaging near a resonance as used in this article is presented here. For more details on this technique, the reader is referred to Refs. 13, 14, 19, and 20.

Partial averaging near a resonance is based on the application of the method of averaging to the dynamical equations of a system in the vicinity of its resonant state.[13,14] These equations are usually written in one of the several standard forms.[13] In celestial mechanics, it is customary to write the dynamical equations of the system in terms of action-angle variables.

Consider a perturbation system with an action variable $\mathcal{B}$ and an angular variable β such that

$$\dot{\mathcal{B}}=\varepsilon\,\mathcal{M}(\mathcal{B},\beta,t,\varepsilon), \tag{A1}$$

and

$$\dot{\beta}=\omega_0(\mathcal{B})+\varepsilon\,\mathcal{Q}(\mathcal{B},\beta,t,\varepsilon), \tag{A2}$$

where $\mathcal{M}$ and $\mathcal{Q}$ are periodic in time with period $\mathcal{T}$ and ω_0 is the frequency of the unperturbed $(\varepsilon=0)$ system. At resonance $\mathcal{T}$ and ω_0 are related as

$$l\,\omega_0=l'\,\omega_{\mathcal{T}}, \tag{A3}$$

where $\omega_{\mathcal{T}}$ is the angular frequency associated with $\mathcal{T}$ and l and l' are positive integers. One can show that in the vicinity of the resonance state (A3), Eqs. (A1) and (A2) can be written as[14,20]

$$\dot{\mathcal{E}}=\varepsilon^{1/2}\,\mathcal{M}(\mathcal{B}_0,\beta,t),+\varepsilon\,\mathcal{E}\frac{\partial\mathcal{M}}{\partial\mathcal{B}}(\mathcal{B}_0,\beta,t)+O(\varepsilon^{3/2}) \tag{A4}$$

and

$$\dot{\Theta}=\varepsilon^{1/2}\,\mathcal{E}\frac{\partial\omega_0}{\partial\mathcal{B}}(\mathcal{B}_0)+\varepsilon\left[\mathcal{Q}(\mathcal{B}_0,\beta,t)+\frac{1}{2}\mathcal{E}^2\frac{\partial^2\omega_0}{\partial\mathcal{B}^2}(\mathcal{B}_0)\right]+O(\varepsilon^{3/2}), \tag{A5}$$

where

$$\mathcal{E}=\varepsilon^{-1/2}(\mathcal{B}-\mathcal{B}_0),\quad \Theta=\beta-\omega_0(\mathcal{B}_0)t, \tag{A6}$$

represent deviations of $\mathcal{B}$ and β from their resonant values $\mathcal{B}_0$ and $\omega_0(\mathcal{B}_0)t$, respectively. Equations (A6) are, indeed, the necessary transformations for writing Eqs. (A1) and (A2) in the neighborhood of the $(l:l')$ resonance. The averaged dynamics of the system at this neighborhood is obtained by averaging Eqs. (A4) and (A5) using the averaging integral

$$\overline{\mathcal{R}}=\frac{1}{l\mathcal{T}}\int_0^{l\mathcal{T}}\mathcal{R}[\mathcal{B}_0,\omega_0(\mathcal{B}_0)t+\Theta,t]\,\mathrm{d}t, \tag{A7}$$

where $\mathcal{R}$ is a general function.

The first order partially averaged system near $(l:l')$ resonance is obtained by neglecting the $O(\varepsilon)$ terms in Eqs. (A4) and (A5) and is given by

$$\dot{\bar{\mathcal{E}}} = \varepsilon^{1/2}\,\bar{\mathcal{M}}(\mathcal{B}_0, \bar{\Theta}), \tag{A8}$$

and

$$\dot{\bar{\Theta}} = \varepsilon^{1/2}\,\bar{\mathcal{E}}\frac{\partial \omega_0}{\partial \mathcal{B}}(\mathcal{B}_0), \tag{A9}$$

where the overbar indicates an averaged quantity. According to the principle of averaging[13,14,19,23] the dynamics of the system of Eqs. (A1) and (A2) can be approximated by the dynamics of the system (A8) and (A9) during the time interval $\varepsilon^{-1/2}t$. It is necessary to emphasize that in order to be able to make such an approximation, it is required by the principle of averaging that the main dynamical system [i.e., Eqs. (A1) and (A2)] have only one angular variable. Extension of the method of averaging to the systems with two or more angular variables can be found in the works of Grebenikov and Ryabov,[42] Arnold, Kozlov, and Neishtadt[43] and also in a recent paper by Cucu-Dumitrescu and Selaru[44] on the study of the equations of motion around an oblate planet. In the first order of perturbation, however, such an extension is not necessary.

Introducing $\mathcal{H}$, as

$$\mathcal{H} = \varepsilon^{1/2}\left[\frac{1}{2}\bar{\mathcal{E}}^2\frac{\partial \omega_0}{\partial \mathcal{B}}(\mathcal{B}_0) - \int \bar{\mathcal{M}}(\mathcal{B}_0, \bar{\Theta}, t)\, \mathrm{d}\bar{\Theta}\right], \tag{A10}$$

one can show that Eqs. (A7) and (A8) can be written as

$$\dot{\bar{\mathcal{E}}} = -\frac{\partial \mathcal{H}}{\partial \bar{\Theta}}, \quad \dot{\bar{\Theta}} = \frac{\partial \mathcal{H}}{\partial \bar{\mathcal{E}}}. \tag{A11}$$

Equation (A11) implies that $\mathcal{H}$ can be considered as the Hamiltonian of the first-order partially averaged system at resonance. To this Hamiltonian, one can attribute a potential function given by

$$V(\bar{\Theta}) = -\int \bar{\mathcal{M}}(\mathcal{B}_0, \bar{\Theta})\, d\bar{\Theta}. \tag{A12}$$

Differentiating Eqs. (A11) with respect to t and using the Hamiltonian $\mathcal{H}$, one can write

$$\ddot{\bar{\Theta}} - \varepsilon\left[\frac{\partial \omega_0}{\partial \mathcal{B}}(\mathcal{B}_0)\right]\bar{\mathcal{M}}(\mathcal{B}_0, \bar{\Theta}) = 0. \tag{A13}$$

Equation (A13) can be regarded as the equation of a mathematical pendulum with Hamiltonian $\mathcal{H}$ and potential function $V(\bar{\Theta})$. The librational motion of this pendulum presents a geometrical interpretation for the resonance-lock phenomenon. The maximum variation of the action variable $\mathcal{B}$ associated with these librational motions is given by[14]

$$\Delta\mathcal{B} = 2\left\{2\,\varepsilon\left[\frac{\partial \omega_0}{\partial \mathcal{B}}(\mathcal{B}_0)\right]^{-1}[V_{\max}(\bar{\Theta}) - V_{\min}(\bar{\Theta})]\right\}^{1/2} + O(\varepsilon). \tag{A14}$$

APPENDIX B: PROOF OF EQUATIONS (16) AND (17)

From the definition of H, we have

$$\frac{\partial H}{\partial L} = \frac{1}{|\vec{r} - \vec{\mathbf{r}}_1|^{-3}}\left\{[r - \cos(\theta - \theta_1)]\frac{\partial r}{\partial L} + r\sin(\theta - \theta_1)\frac{\partial \theta}{\partial L}\right\}, \tag{B1}$$

$$\frac{\partial H}{\partial G}=\frac{1}{|\vec{r}-\vec{\mathbf{r}}_{\mathbf{1}}|^{-3}}\left\{[r-\cos(\theta-\theta_1)]\frac{\partial r}{\partial G}+r\sin(\theta-\theta_1)\frac{\partial \theta}{\partial G}\right\}, \tag{B2}$$

$$\frac{\partial H}{\partial \ell}=\frac{1}{|\vec{r}-\vec{\mathbf{r}}_{\mathbf{1}}|^{-3}}\left\{[r-\cos(\theta-\theta_1)]\frac{\partial r}{\partial \ell}+r\sin(\theta-\theta_1)\frac{\partial \theta}{\partial \ell}\right\}, \tag{B3}$$

$$\frac{\partial H}{\partial g}=\frac{1}{|\vec{r}-\vec{\mathbf{r}}_{\mathbf{1}}|^{-3}}r\ \sin(\theta-\theta_1)\frac{\partial \theta}{\partial g}. \tag{B4}$$

From these equations it is evident that one needs to compute derivatives of r and θ with respect to all Delaunay variables. From Eq. (3), we have

$$\frac{\partial r}{\partial L}=-\left(\frac{G}{1+e\cos v}\right)^2\left(\cos v\frac{\partial e}{\partial L}-e\sin v\frac{\partial v}{\partial L}\right), \tag{B5}$$

$$\frac{\partial r}{\partial G}=2\left(\frac{G}{1+e\cos v}\right)-\left(\frac{G}{1+e\cos v}\right)^2\left(\cos v\frac{\partial e}{\partial G}-e\sin v\frac{\partial v}{\partial G}\right), \tag{B6}$$

$$\frac{\partial r}{\partial \ell}=ea\sin u\frac{\partial u}{\partial \ell} \tag{B7}$$

and $\partial r/\partial g=0$. On the other hand, from $\theta=g+v$, $\partial\theta/\partial g=1$ and the derivatives of θ with respect to L, G and ℓ will be equal to derivatives of v with respect to these variables. Using $\ell=u-e\sin u$ and $G=L(1-e^2)^{1/2}$ along with Eq. (3), the partial derivatives of r with respect to the Delaunay variables can be written as

$$\frac{\partial r}{\partial L}=\frac{r}{e}a^{-1/2}(2e-\cos v-e\cos^3 v), \tag{B8}$$

$$\frac{\partial r}{\partial G}=\frac{1}{e}[a(1-e^2)]^{1/2}\cos v, \tag{B9}$$

$$\frac{\partial r}{\partial \ell}=ea\,(1-e^2)^{-1/2}\sin v, \tag{B10}$$

and the partial derivatives of θ with respect to L,G, and ℓ will be equal to

$$\frac{\partial \theta}{\partial L}=\frac{G^2}{e\,L^3(1-e^2)}\sin v\,(2+e\cos v), \tag{B11}$$

$$\frac{\partial \theta}{\partial G}=-\frac{1}{e}[a(1-e^2)]^{1/2}\left[\frac{1}{r}+\frac{1}{a(1-e^2)}\right]\sin v, \tag{B12}$$

$$\frac{\partial \theta}{\partial \ell}=\left(\frac{a}{r}\right)^2(1-e^2)^{1/2}. \tag{B13}$$

Replacing the derivatives of r and θ in Eqs. (B1)–(B4) by their equivalent expressions given by Eqs. (B8)–(B13), one can write

$$\frac{\partial H}{\partial L}=\frac{r}{e}a^{-1/2}\left\{\left[\frac{r-\cos(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_{\mathbf{1}}|^3}\right](2e-\cos v-e\cos^3 v)+\left[\frac{\sin(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_{\mathbf{1}}|^3}\right](2+e\cos v)\sin v\right\}, \tag{B14}$$

$$\frac{\partial H}{\partial G}=\frac{1}{e}[a(1-e^2)]^{1/2}\left\{\left[\frac{r-\cos(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_\mathbf{1}|^3}\right]\cos v-\left[\frac{\sin(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_\mathbf{1}|^3}\right]\left[\frac{1}{r}+\frac{1}{a(1-e^2)}\right]\sin v\right\}, \tag{B15}$$

$$\frac{\partial H}{\partial \ell}=a\,(1-e^2)^{-1/2}\left\{e\,\sin v\left[\frac{r-\cos(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_\mathbf{1}|^3}\right]+\frac{a}{r}(1-e^2)\left[\frac{\sin(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_\mathbf{1}|^3}\right]\right\}, \tag{B16}$$

and

$$\frac{\partial H}{\partial g}=\frac{r\,\sin(\theta-\theta_1)}{|\vec{r}-\vec{\mathbf{r}}_\mathbf{1}|^3}, \tag{B17}$$

which along with Eq. (12) immediately results in expressions (16) and (17).

(Received 20 September 2001; accepted for publication 1 March 2002)

Current theory of gelation describes this process in terms of a set of nonlinear integral equations. In this article the uniqueness of nontrivial solutions of these equations within the unit functional hypercube has been proved. Besides, the convergence to this solution of iterations from an arbitrary point of the above hypercube has been established, which is of utmost importance for calculations of particular gelation processes. © *2002 American Institute of Physics.*

I. INTRODUCTION

Today mathematical methods are finding ever-increasing use in chemistry.[1–4] These methods prove to be especially efficient in the solution of theoretical problems of polymer chemistry. In view of the leading positions of polymer manufacturing in modern chemical industry the role of mathematical modeling of polymerization processes is hard to overestimate. Among them the most challenging for such a modeling are the processes of obtaining polymer networks. Such a network (gel) is a giant macromolecule occupying the whole of the reaction system.

In the present article considering the formation of a gel we will focus exclusively on the processes of polycondensation of monomers, at least one of which has more than two functional groups. This condition is, however, only a necessary prerequisite of the gelation occuring in the course of a branched polycondensation. Indeed, when this process is conducted in a dilute solution of monomers along with intermolecular reactions, which lead to the enlargement of polymers, intramolecular reactions will vigorously proceed. These latter are responsible for a retardation of gelation due to the decrease in polymer molecules' functionality. At sufficiently pronounced intensity of intramolecular reactions a polymer network will not be formed at all in the course of the synthesis. In this case a suspension of colloid polymer particles will be the product of the reaction.

Our theoretical approach is based on the kinetic model which neglects intramolecular reactions in molecules of finite size. The validity of this assumption, experimentally verified for many particular polycondensation processes,[3,4] is nowadays extensively used in polymer chemistry.

Initially there is a mixture of low-molecular compounds referred to as monomers. Each of them, $R_\alpha A_1^{f_{1\alpha}} A_2^{f_{2\alpha}} \cdots A_n^{f_{n\alpha}}$, is composed of monomeric unit R_α and adjacent functional groups $A_i (i=1,\ldots,n)$ whose numbers $\{f_{i\alpha}\}$ in this αth monomer represent elements of a rectangular matrix of functionalities $\mathbf{f}$ of this monomer. In the course of the stepwise polymerization (polycondensation) functional groups react with each other to form stable chemical bonds between monomeric units. Such chemical transformations in the reaction system result in the formation of polymer molecules involving different number of monomeric units $l_1,\ldots,l_\alpha,\ldots,l_m$, which may be regarded as components of composition vector $\mathbf{l}$. The probability that a monomeric unit chosen at random in the moment t constitutes polymer molecule with given vector $\mathbf{l}$ is known as composition distribution. The problem of finding of this distribution $F(\mathbf{l};t)$ or its generating function

[c]Electronic mail: kuchanov@orc.ru

$$G(\mathbf{s};t)=\sum_{l} F(\mathbf{l};t)\prod_{\alpha=1}^{m} s_{\alpha}^{l_\alpha} \tag{1}$$

represents one of the key problems of the theory of polymerization. In the course of this process the enlargement of polymer molecules takes place accompanied by the growth of their average size:

$$\overline{\mathbf{l}}(t)=\sum_{l}\sum_{\alpha=1}^{m} l_\alpha F(\mathbf{l},t)=\sum_{\alpha} s_\alpha \frac{\partial G}{\partial s_\alpha}\bigg|_{\mathbf{s}=1}. \tag{2}$$

At a certain moment $t=t^*$ the quantity $\overline{\mathbf{l}}$ turns into infinity. To such a situation there corresponds the appearance of infinite macromolecule of gel. Weight fraction $\omega_g(t)$ of this polymer network increases during the polymerization due to the decrease of the weight fraction $\omega_s(t)$ of molecules of finite sizes constituting sol:

$$\omega_s(t)=\sum_{l} F(\mathbf{l};t)=G(\mathbf{l};t). \tag{3}$$

Determination of the dependence $\omega_g(t)=1-\omega_s(t)$ along with the calculation of the gel point is a fundamental problem of the theory of gelation for polymerization processes.

The article is organized as follows. In Sec. II we give the description of the most popular kinetic model of gelation. In Sec. III we propose a convenient generalization of the main equation. In Sec. IV we prove uniqueness of a solution and in Sec. V we prove convergence of iterations.

II. MATHEMATICAL MODELS

The distribution $F(\mathbf{l};t)$ of sol molecules in a simple manner is related to the concentrations of the molecules $C(\mathbf{l};t)$ present at the instant t in the reaction system by

$$F(\mathbf{l};t)=\frac{1}{M}\sum_{\alpha} l_\alpha c(\mathbf{l};t), \quad \text{where} \quad M=\sum_{l}\sum_{\alpha} l_\alpha c(\mathbf{l};t). \tag{4}$$

The evolution of these concentrations with time can be described by material balance equations which resemble the discrete Boltzmann equation.[5] Its form is prescribed by the choice of a particular chemical model of polymerization.

The simplest among them is the ideal model[3] which suggests that the probability for every pair of groups A_i and A_j to react is controlled exclusively by their types i and j. In terms of this model monomeric units are differentiated not only by types α but by their kinds as well. Kind q of the αth type monomeric unit is specified by rectangular matrix $\mathbf{g}$ whose element $g_{i\alpha}$ equals the number of reacted groups A_i in the αth unit. Let us denote by $P_\alpha^q(t)$ the fraction of αth units of the kind q contained in polymers at moment t. Thus, the exact solution of the equation for generating function (1), obtained in Ref. 6 for the ideal model of stepwise polymerization, can be presented as follows:

$$G(\mathbf{s};t)=H(\mathbf{s};\mathbf{u}), \quad \text{where} \quad H(\mathbf{s};\mathbf{u})=\sum_{\alpha} s_\alpha \sum_{q} P_\alpha^q \prod_{i} u_i^{g_{i\alpha}}, \tag{5}$$

where the dependence of components $\{u_i\}$ of the vector $\mathbf{u}$ on components $\{s_\alpha\}$ of the vector $\mathbf{s}$ is possible to determine from the solution of the set of equations

$$u_i=\sum_{j} \pi_{ij} h_j(\mathbf{s};\mathbf{u}) (i=1,\ldots,n). \tag{6}$$

Here use is made of the following designations:

$$h_j(\mathbf{s};\mathbf{u})=\frac{H_j(\mathbf{s};\mathbf{u})}{H_j(\mathbf{1};\mathbf{1})},\quad \text{where}\quad H_j(\mathbf{s};\mathbf{u})=\frac{\partial H}{\partial u_j}, \tag{7}$$

while π_{ij} represents the fractions of all reacted groups A_i that formed chemical bond (ij) by reacting with groups A_j. Functions $P_\alpha^q(t)$ and $\pi_{ij}(t)$ can be found from the solution of the Cauchy problem for the set of the first-order ordinary differential equations whose coefficients are the parameters of ideal kinetic model which characterize the probabilities of reactions between different groups. Particular form of functions $P_\alpha^q(t)$ and $\pi_{ij}(t)$ is, however, beyond the scope of our present work. We will just make use of the fact that all their values belong to the segment [0,1] and meet obvious normalization conditions

$$\sum_\alpha \sum_q P_\alpha^q \equiv 1, \quad \sum_j \pi_{ij} \equiv 1. \tag{8}$$

Weight fraction of sol (3) is determined according to (5) and (6) by the expression

$$\omega_s = H(\mathbf{1};\mathbf{y}), \tag{9}$$

where the components of vector $\mathbf{y}$ are obtainable from the solution of the set of equations

$$y_i=\sum_j \pi_{ij} h_j(\mathbf{1};\mathbf{y})\,(i=1,\ldots,n). \tag{10}$$

It is easy to notice that in view of (8) this set always has trivial solution

$$y_1=y_2=\cdots=y_n=1, \tag{11}$$

which is the only one in unit hypercube $0\leqslant y_i\leqslant 1\,(i=1,\ldots,n)$ just up to the moment when a polymer network is formed. At this moment $t=t^*$ average size of polymers (2) becomes infinite to which there mathematically corresponds turning into unity of the largest eigenvalue of the matrix with elements

$$\theta_{ik}=\sum_j \pi_{ij}\left.\frac{\partial h_j(\mathbf{1};\mathbf{u})}{\partial u_k}\right|_{\mathbf{u}=\mathbf{1}}. \tag{12}$$

At gel point $t=t^*$ the bifurcation happens which results in forking $t>t^*$ from trivial solution (11) of the equation (6) and of a nontrivial one situated inside unit hypercube. The substitution of this solution into expression (3) enables one to find the dependence of the weight fraction of sol on time of polymerization.

The ideal model of stepwise polymerization being of prime importance in macromolecular chemistry fails, however, to describe some particular gelation processes. In such cases mathematical models normally resort to more sophisticated kinetic models. The most reputable among them is the ''substitution effect'' (SE) model,[7] which takes account of the dependence of a functional group reactivity on the number of groups of every type among its neighbors in monomeric unit which have already reacted with one or another groups of other molecules. As a result of such chemical transformations a group A_i reacts with group A_j to yield chemical bond (ij). The set of such bonds adjoined to the αth type unit characterizes in terms of the SE model the kind q of this unit. The following expression,[7]

$$G(\mathbf{s};\mathbf{t})=H(\mathbf{s};[\mathbf{u}]), \tag{13}$$

represents an extension of the expression (5) where H stands for the generating functional of the distribution P_α^q of the probabilities of *labeled* units for types α and kinds q:

$$H(\mathbf{s};[\mathbf{u}])=\sum_{\alpha} s_{\alpha}\sum_{q} \int\cdots\int P_{\alpha}^{q}(\{\tau_{\alpha}\})\prod_{\gamma} u_{\gamma}(\tau_{\gamma})d\tau_{\gamma}. \tag{14}$$

A unit is termed ''labeled'' if all bonds $\{\gamma\}=(\gamma_1,\gamma_2,\ldots,\gamma_r)$ adjoining to it are supplied by labels $\{\tau_{\gamma}\}=(\tau_{\gamma_1},\tau_{\gamma_2},\ldots,\tau_{\gamma_r})$ indicating the time of the formation of each of them. Since $P_{\alpha}^{q}(\{\tau_{\gamma}\})d\tau_1 d\tau_2\cdots d\tau_r$ has the meaning of the infinitesimal probability for a randomly chosen unit to have at instant t the type α and kind q with bonds $\{\gamma\}$ adjoining to it formed within the intervals $\{\tau_{\gamma},\tau_{\gamma}+d\tau_{\gamma}\}$, then the integration of this probability distribution over the whole possible set of variables $\{\tau_{\gamma}\}$ yields $P_{\alpha}^{q}(t)$.

The vector-function $\mathbf{u}(\tau)$ that should be substituted into functional (13) in order to get generating function (1) can be found from the solution of the set of equations

$$u_{\gamma}(\tau)=\sum_{\delta} \pi_{\gamma\delta}(\tau)h_{\delta}(\mathbf{s},[\mathbf{u}];\tau), \tag{15}$$

where the following designations are used:

$$h_{\delta}(\mathbf{s},[\mathbf{u}];\tau)=\frac{H_{\delta}(\mathbf{s},[\mathbf{u}];\tau)}{H_{\delta}(1,[1];\tau)},\quad H_{\delta}(\mathbf{s},[\mathbf{u}];\tau)=\frac{\delta H(\mathbf{s},[\mathbf{u}])}{\delta u_{\delta}(\tau)}. \tag{16}$$

Equations (15), unlike algebraic equations (6) of the ideal model, are integral ones. The structure of the first and the second equations is virtually the same with the only distinction that the role of the partial derivatives (7) is played here by variational derivatives (16).

In the case of the SE model the following expression,

$$\omega_s=H(\mathbf{1};[\mathbf{y}]), \tag{17}$$

extends the formula (9). Here the vector-function $\mathbf{y}(\tau)$ is the solution of the set of integral equations

$$y_{\gamma}(\tau)=\sum_{\delta} \pi_{\gamma\delta}(\tau)h_{\delta}(\mathbf{1},[\mathbf{y}];\tau). \tag{18}$$

Inasmuch as the matrix $\boldsymbol{\pi}(\tau)$ is stochastic one, this set always has the trivial solution (11), which as it will be proven below is unique within functional hypercube $0\leqslant y_{\gamma}(\tau)\leqslant 1$ up to the gelation moment. The attainment of unity by the largest eigenvalue of the integral operator with kernel

$$\theta_{\gamma\nu}(\tau',\tau'')=\sum_{\delta} \pi_{\gamma\delta}(\tau')\left.\frac{\delta h_{\delta}(\mathbf{1},[\mathbf{u}];\tau)}{\delta u_{\nu}(\tau'')}\right|_{\mathbf{u}(\tau)=\mathbf{1}} \tag{19}$$

will be the condition for the calculation of the gel point.

Proceeding from physical analogies the assertion was made[8] that the set of equations (18) at $t>t^*$ will have within unit functional hypercube the unique nontrivial solution $\mathbf{y}(\tau)$ whose insertion into formula (17) provides a possibility to calculate the decrease of the weight of sol with time. This assertion was verified[9] by the results of computer calculations for monomer RA^3 homopolymerization described by the SE model.

The prime objective of this work is to provide rigorous within the framework of this model mathematical proof of the validity of this assertion for arbitrary process of stepwise polymerization. Besides, we will demonstrate the convergence of the iterative process to this nontrivial solution $\mathbf{y}(\tau)$ and will prove that such a convergence is the case under numerical solution of the set of integral equations (18) irrespective of the choice of starting point within functional unit hypercube.

III. Operator *R*

Let Q be the set of continuous vector functions $\mathbf{u}(\tau)=(u_1(\tau),u_2(\tau),\ldots,u_n(\tau))$ on the segment $[0,t]$, satisfying the inequalities $0\leqslant u_k(\tau)\leqslant 1$, $k=1,\ldots,n$, $\tau\in[0;t]$.

We introduce the following notation for elements $\mathbf{u},\mathbf{v}\in Q$:

(1) $\mathbf{u}<\mathbf{v}$, if $u_k(\tau)<v_k(\tau)$ strictly for any k, τ;
(2) $\mathbf{u}=\mathbf{v}$, if $u_k(\tau)=v_k(\tau)$ for any k, τ;
(3) $\mathbf{u}\lneqq\mathbf{v}$, if $u_k(\tau)\leqslant v_k(\tau)$ for any k, τ but there exists point k',t' in which the inequality is strict;
(4) $\mathbf{u}\leqslant\mathbf{v}$, if $u_k(\tau)\leqslant v_k(\tau)$, i.e., either $\mathbf{u}=\mathbf{v}$ or $\mathbf{u}\lneqq\mathbf{v}$.

Let $\mathbf{0}\in Q$ be the vector function, for which $u_k(\tau)\equiv 0$ everywhere, and $\mathbf{1}\in Q$ is the vector function, with $u_k(\tau)\equiv 1$. We define an operator R on the set Q by the formula:

$$R_i[\mathbf{u}](\tau)=\int_{D_t} K_i(\tau,\mathbf{x},\mathbf{u}(x))dx,\quad i=1,\ldots,n. \tag{20}$$

Here $\mathbf{u}(x)=(u_1(x_1),u_2(x_2),\ldots u_n(x_n))$, $\mathbf{x}\in\mathbb{R}^n$, $D_t=\{\mathbf{x}|0\leqslant x_1\leqslant x_2\leqslant\cdots\leqslant x_n\leqslant t\}$. $K_i(\tau,x_2,x_2,\ldots x_n,r_1,r_2,\ldots,r_n)$ $i=1,\ldots,n$ are nonnegative functions possessing the following properties.

(1^0) $K_i\in\mathbb{C}^2([0,t]\times D_t\times[0,1]^n)$.

(2^0) For any i, $K_i\geqslant\mathbf{0}$ and $K_i\not\equiv\mathbf{0}$.

(3^0) $\int_{D_t}K_i(\tau,\mathbf{x},\mathbf{1})dx=1$, $i=1,\ldots,n$.

(4^0) K_i monotone increasing functions with respect to any $r_k:\partial K_i/\partial r_k>0$ for any $i=1,\ldots,n$, $k=1,\ldots,n$.

(5^0) K_i are strictly convex in non-negative directions, i.e., for any $\mathbf{b}\in\mathbb{R}^n$, $\mathbf{b}\gneqq 0$ the inequality $\Sigma_{j,k}\partial^2K_i/\partial r_j\partial r_k b_j b_k>0$ holds for any τ, $\mathbf{x}$, $\mathbf{r}$, $\mathbf{i}$.

The operator in the right-hand side of (18) has all the properties of the operator R in (20). Now we formulate the properties of R that follow from (1^0)–(5^0):

(A) $\mathbf{R}$ maps Q into Q and $\mathbf{R}[\mathbf{1}]=\mathbf{1}$.

(B) $\mathbf{R}$ is monotone: $\mathbf{u}\lneqq\mathbf{v}$ implies $\mathbf{R}[\mathbf{u}]<\mathbf{R}[\mathbf{v}]$.

(C) $\mathbf{R}$ is strictly convex in the non-negative directions, i.e., for $\theta\in[0;1]$, any $\tau\in[0;t]$, $k=1,\ldots n$ and for $\mathbf{h}\gneqq\mathbf{0}$, $\mathbf{h}\in Q$, $\mathbf{u}\in Q$, such that $\mathbf{u}+\theta\cdot\mathbf{h}\in Q$, the function $\varphi(\theta)=R_k[\mathbf{u}+\theta\cdot\mathbf{h}](\tau)$ is strictly convex: $\varphi''(\theta)>0$.

IV. A THEOREM ON THE UNIQUENESS OF A FIXED POINT

Theorem 1: If the equation

$$\mathbf{R}[\mathbf{u}]=\mathbf{u} \tag{21}$$

has a solution nonequal to $\mathbf{1}$, then this solution is unique on the set $Q\setminus\mathbf{1}$.

Proof:

Lemma 1 (on the convexity): Let $\mathbf{u}\lneqq\mathbf{v}$ and let there exist a point $(k,\aleph)$ such that $R_k[\mathbf{u}](\aleph)\leqslant u_k(\aleph)$ and $R_k[\mathbf{v}](\aleph)\leqslant v_k(\aleph)$. Let $\mathbf{w}=\mathbf{w}(\theta)=\mathbf{u}+\theta(\mathbf{v}-\mathbf{u})$ be the segment connecting $\mathbf{u}$ and $\mathbf{v}$. Then the formula $R_k[\mathbf{w}](\aleph)<\mathbf{w}_k(\aleph)$ is true for any $\theta\in(0;1)$.

Proof: Consider the function $\varphi(\theta)=R_k[\mathbf{w}(\theta)](\aleph)-\mathbf{w}_k(\theta)(\aleph)$. Clearly $\varphi(0)\leqslant 0$, $\varphi(1)\leqslant 0$ and $\varphi(\theta)$ is strictly convex due to property (C): $\varphi''(\theta)>0$, since $\mathbf{h}=\mathbf{v}-\mathbf{u}\gneqq 0$. Lemma 1 is proved.

We divide the proof of the theorem into three steps:

Step 1. Let us show that the solution $\mathbf{u}^0\neq 1$ of the equation $\mathbf{u}=R[\mathbf{u}]$ has the stronger property: $\mathbf{u}^0<1$. Let there be a point (l,λ), at which $\mathbf{u}^0_l(\lambda)=1$. Then $R_l[\mathbf{u}^0](\lambda)=1$ (since $\mathbf{u}^0$ is a solution) as well as $R_l[\mathbf{1}](\lambda)=1$. These two equalities contradict property (B) (monotonicity).

Step 2. Let us consider an element $\mathbf{u}^1<1$, which does not belong to the set $\Pi(\mathbf{u}^0)=\{\mathbf{u}|0\leqslant\mathbf{u}\lneqq\mathbf{u}^0\}$ the set of elements that are not strictly less then $\mathbf{u}^0$. We show that $\mathbf{u}^1$ is not a solution of

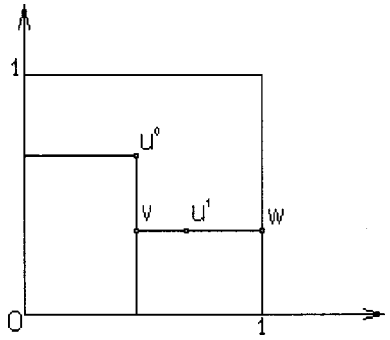

FIG. 1.

(21). Let us define **v** and **w** from Q (see Figs. 1 and 2) as follows. **v** is an element given by the formula: $v_i(\tau)=\min\{u_i^0(\tau);u_i^1(\tau)\}$; **w** is defined as an element from Q, which belongs to the straight line that connects **v** and $\mathbf{u}^1$ and is continued up to the upper bound of Q. So **w** is the point of intersection of the upper bound Q and these straight lines: $\mathbf{w}=\mathbf{v}+\theta\cdot(\mathbf{u}^1-\mathbf{v})$, $\theta>1$. Let (r,ρ) be such that $w_r(\rho)=1$.

We show that **v** and **w** satisfy the conditions of Lemma 1, i.e.,

$$R_r[\mathbf{v}](\rho)\leqslant v_r(\rho) \tag{22}$$

and

$$R_r[\mathbf{w}](\rho)\leqslant w_r(\rho). \tag{23}$$

Inequalities (22) and (23) and Lemma 1 imply the $\mathrm{R}_r[\mathbf{u}^1](\rho)<u_r^1(\rho)$. Inequality (23) is obvious since $w_r(\rho)=1$; inequality (22) follows from the monotonicity of **R** and the relation $\mathbf{v}\leqslant\mathbf{u}$: $\mathrm{R}_r[\mathbf{v}](\rho)\leqslant\mathrm{R}_r[\mathbf{u}^0](\rho)=u_r^0(\rho)=v_r(\rho)$. Thus we have proved that $\mathrm{R}[\mathbf{u}^1]\neq\mathbf{u}^1$.

Step 3. Let $\mathbf{u}^1<1$ and $\mathbf{u}^1\in\Pi(\mathbf{u}^0)$. We shall show that $\mathrm{R}[\mathbf{u}^1]\neq\mathbf{u}^1$. Assume the contrary and consider the set $\Pi(\mathbf{u}^1)$. We conclude that $\mathrm{R}[\mathbf{u}^0]\neq\mathbf{u}^0$ similar to step 2, that is a contradiction.

The theorem is proved.

Now we investigate iterations.

V. ITERATIONS

We consider the iterations $\mathbf{u}^{m+1}=\mathbf{R}[\mathbf{u}^m]$ $(m=0,1,\ldots)$ and show that the convergence properties depend strongly on the linearization $\mathbf{R}'[\mathbf{1}]$ at point **1**, fixed point of **R** ($\mathbf{R}[\mathbf{1}]=\mathbf{1}$, property (A) of the operator **R**).

Consider the linear operator $\mathbf{A}=\mathbf{R}'[\mathbf{1}]$:

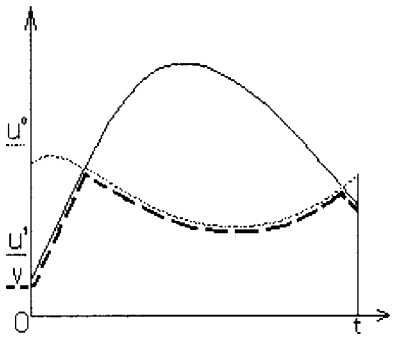

FIG. 2.

$$\mathbf{Ah}=\mathbf{R}'[\mathbf{1}]\mathbf{h}=\sum_{j=1}^{n}\int_{D_i}\frac{\partial\mathbf{K}(\tau,\mathbf{x},\mathbf{1})}{\partial r_j}h_j(x)dx. \tag{24}$$

Properties (A) and (B) of operator **R** provide the strong positivity[10,11] of operator **A** in the solid cone $K=\{\mathbf{v}=(v_1(\tau),v_2(\tau),\ldots,v_n(\tau))|v_i(\tau)\in\mathbb{C}([0,t]) \quad i=1,\ldots,n; \quad \mathbf{v}\geqslant 0\}$ of the space of continuous functions $\mathbb{C}([0,t])$. This means that every boundary point except zero is a mapping into the cone, i.e., $\mathbf{v}\gneqq\mathbf{0}$ implies $\mathbf{Av}>\mathbf{0}$. Indeed, the following decomposition is valid:

$$\mathbf{R}[\mathbf{1}]-\mathbf{R}[\mathbf{1}-\varepsilon\mathbf{v}]=\varepsilon\mathbf{R}'[\mathbf{1}]\mathbf{v}+\mathbf{O}(\varepsilon\mathbf{v})>\mathbf{0}, \quad \mathbf{v}\in \mathrm{K}\setminus\mathbf{0}.$$

Here $\mathbf{O}(\varepsilon\mathbf{v})$ is such that $\mathbf{O}(\varepsilon\mathbf{v})/\varepsilon$ tends to **0** in sup-norm as ε tends to 0. The last inequality follows from property (B). As $\varepsilon>0$ tends to zero, we have $\mathbf{R}'[\mathbf{1}]\mathbf{v}>\mathbf{0}$, i.e., $\mathbf{R}'[\mathbf{1}]\mathbf{v}\in K\setminus\partial$K.

Due to theorem 6.2 from Ref. 10 the operator A has a simple maximal positive eigenvalue (Perron eigenvalue), and the corresponding eigenfunction is positive (Perron eigenfunction).

We show below that the behavior of iterations depends upon the Perron eigenvalue ρ of **A**: cases $\rho\leqslant 1$ or $\rho>1$ specify two different types of behavior.

To prove the convergence of iterations we need the following lemma.

Lemma 2: Let ρ be an eigenvalue of a linear integral operator

$$\mathbf{A}_i[\mathbf{f}](\tau)=\sum_{j=1}^{n}\int_0^t A_{ij}(\tau,\sigma)f_j(\sigma)d\sigma$$

with positive continuous kernels $A_{ij}(\sigma,\tau)$. Let the eigenfunction **h** *corresponding to ρ be positive. And let* **g** *be an arbitrary positive element of* $[\mathbb{C}([0,t])]^n$. *Then there exists a point* (k,τ) [*respectively a point* (k',τ')], *such that* $[(\mathbf{A}-\rho\mathbf{E})\mathbf{g}]_k(\tau)\geqslant 0$ (*respectively* $[(\mathbf{A}-\rho\mathbf{E})\mathbf{g}]_{k'}(\tau')\leqslant 0$).

Proof:

Step 1. Let **f**, **f**′ be strictly positive elements of $\mathbb{C}([0,t])$. We shall show that the assertions $(\mathbf{A}-\rho\mathbf{E})\mathbf{f}>\mathbf{0}$ and $(\mathbf{A}-\rho\mathbf{E})\mathbf{f}'<\mathbf{0}$ exclude each other. Suppose that for any $i=1,\ldots,n$ and $\tau\in[0;t]$

$$-\rho f_i(\tau)+\sum_{j=0}^{n}\int_0^t A_{ij}(\tau,\sigma)f_j(\sigma)d\sigma>0, \tag{25}$$

$$\rho f_i'(\tau)-\sum_{j=0}^{n}\int_0^t A_{ij}(\tau,\sigma)f_j'(\sigma)d\sigma>0. \tag{26}$$

Define $\varepsilon_i(\tau)=f_i(\tau)/f_i'(\tau)>0$, and note that $\varepsilon_i\in\mathbb{C}([0,t])$. Multiplying (26) by $\varepsilon_i(\tau)$ and adding (25) we get

$$\sum_{j=0}^{n}\int_0^t A_{ij}(\tau,\sigma)(f_j(\sigma)-\varepsilon_i(\tau)f_j'(\sigma))d\sigma>0 \quad \text{for any} \quad (i,\tau). \tag{27}$$

Inequality (27) is violated at point (i',τ') of the maximum of $\varepsilon_i(\tau)$: if $\varepsilon_i(\tau)\leqslant\varepsilon_{i'}(\tau')$, then $f_j(\sigma)-\varepsilon_{i'}(\tau')f_j'(\sigma)\leqslant 0$ and all the terms in (27) are nonpositive.

Step 2. Suppose $(\mathbf{A}-\rho\mathbf{E})\mathbf{g}<\mathbf{0}$. Take $\mathbf{g}'=\lambda\mathbf{h}-\mathbf{g}$, where **h** is the eigenfunction of **A** and λ is large enough for $\lambda\mathbf{h}-\mathbf{g}>\mathbf{0}$. Then we get

$$(\mathbf{A}-\rho\mathbf{E})\mathbf{f}=-(\mathbf{A}-\rho\mathbf{E})\mathbf{f}',$$

consequently $(\mathbf{A}-\rho\mathbf{E})\mathbf{g}'>\mathbf{0}$. This contradicts to the step 1; hence $(\mathbf{A}-\rho\mathbf{E})\mathbf{g}'\not<\mathbf{0}$ and there exists a point (k,τ) satisfying the statement of the lemma. Similarly, supposing $(\mathbf{A}-\rho\mathbf{E})\mathbf{g}>\mathbf{0}$ we get existence of a point (k',τ') with desired properties.

There is an important property of the iterations $\mathbf{u}^{m+1}=\mathbf{R}[\mathbf{u}^m]$. If $\mathbf{u}^0 \lneqq \mathbf{u}^1$ $(\mathbf{u}^0 \leqslant \mathbf{u}^1)$, then $\mathbf{u}^k < \mathbf{u}^{k+1}$ $(\mathbf{u}^k \leqslant \mathbf{u}^{k+1})$ for $\mathbf{k}>0$. If $\mathbf{u}^0 \gneqq \mathbf{u}^1$ $(\mathbf{u}^0 \geqslant \mathbf{u}^1)$, then $\mathbf{u}^k > \mathbf{u}^{k+1}$ $(\mathbf{u}^k \geqslant \mathbf{u}^{k+1})$ for $k>0$.

Theorem 2: If $\rho \leqslant 1$, then the iterations $\mathbf{u}^{m+1}=\mathbf{R}[\mathbf{u}^m]$ $(m=0,1,\ldots)$ converge to $\mathbf{1}$ for any $\mathbf{u}^0 \in Q$.

Proof: Consider the sequence $\mathbf{v}^{m+1}=\mathbf{R}[\mathbf{v}^m]$ with $\mathbf{v}^0=\mathbf{0}$. $\mathbf{R}[\mathbf{0}] \geqslant \mathbf{0}$ and so the sequence increases monotonically $(\mathbf{v}^m \geqslant \mathbf{v}^{m-1})$. As $\mathbf{v}^m<1$ the limit $\mathbf{v}=\lim \mathbf{v}^m$ exists and is not continuous in general, and therefore it does not belong to Q. But $\mathbf{R}[\mathbf{u}](\tau)$ is equicontinuous over τ with respect to $\mathbf{u}$, in view of $|\mathrm{R}_i[u](\tau)-\mathrm{R}_i[u](\tau')| \leqslant \mathrm{M}t^n|\tau-\tau'|$ with $\mathrm{M}=\sup_{\tau,\mathbf{x},\mathbf{u}}|\partial K_i/\partial\tau|$. So $\{\mathbf{v}^m(\tau)\}$ is equicontinuous with respect to m, and $\mathbf{v} \in \mathrm{Q}$ due to the Arzela theorem (on the compactness of a subset of continuous functions[12]). Hence it follows that $\mathbf{v}$ is a fixed point of $\mathbf{R}$:$\mathbf{R}[\mathbf{v}]=\mathbf{v}$. Let us show that $\mathbf{v}=\mathbf{1}$.

If $\mathbf{v} \lneqq \mathbf{1}$, then by Lemma 1 for $\mathbf{u}(\theta)=\mathbf{v}+(\mathbf{1}-\mathbf{v})\theta$ and for any $(k,\aleph)$ $\varphi(\theta)=\mathrm{R}_k[\mathbf{u}(\theta)](\aleph) - u_k(\theta)(\aleph)$ we have $\varphi''(\theta)>0$, $\varphi(0)=\varphi(1)=0$ and hence $\varphi'(1)>0$ strictly. But $\varphi(1) =[\mathrm{R}'[\mathbf{1}]-\mathrm{E}]_k(\mathbf{1}-\mathbf{v})(\aleph)$, where E is the unit operator. In accordance with Lemma 2 the following inequality holds: $[(\mathrm{R}'[\mathbf{1}]-\rho\mathrm{E})(\mathbf{1}-\mathbf{v})]_k(\aleph) \leqslant 0$ at some point $(k,\aleph)$. Hence,

$$\varphi'(1)=[(\mathrm{R}'[\mathbf{1}]-\mathrm{E})(\mathbf{1}-\mathbf{v})]_k(\aleph) \leqslant [(\mathrm{R}'[\mathbf{1}]-\rho E)(\mathbf{1}-\mathbf{v})]_k(\aleph) \leqslant 0.$$

This contradiction shows that $\mathbf{v}=\mathbf{1}$. Any other sequence $\mathbf{u}^{m+1}=\mathrm{R}[\mathbf{u}^m]$ is bounded below by $\{\mathbf{v}^m\}$ and bounded above by $\mathbf{1}$, and hence tends to $\mathbf{1}$ as well.

Theorem 2 is proved.

Note: If $\rho<1$, then the theorem on spectrum radius[11] shows that there exists p for which $\|A^p\|<q<1$ and hence R^p is a contraction map. This shows that convergence to $\mathbf{1}$ is exponential in this case.

Theorem 3: If $\rho>1$, then the iteration $\mathbf{u}^{m+1}=\mathrm{R}[\mathbf{u}^m]$ with $\mathbf{u}^0 \neq \mathbf{1}$ converges to the unique solution in $\mathrm{Q}\setminus\mathbf{1}$ of the equation $\mathbf{u}=\mathrm{R}[\mathbf{u}]$, and $\mathbf{1}$ is a repelling fixed point.

Proof: For any $\mathbf{u}^0 \in \mathrm{Q}$ we shall construct two sequences $\{\mathbf{v}^m\}$ and $\{\mathbf{w}^m\}$ minorizing and majorizing $\{\mathbf{u}^m\}$ respectively: $\mathbf{0} \leqslant \mathbf{v}^m \leqslant \mathbf{u}^m \leqslant \mathbf{w}^m < 1$ $(m=1,2,\ldots)$.

We take $\mathbf{v}^0=\mathbf{0}$ and $\mathbf{v}^{m+1}=\mathbf{R}[\mathbf{v}^m]$. Then $\{\mathbf{v}^m\}$ is monotonically increasing: $\mathbf{v}^{m+1} \geqslant \mathbf{v}^m$ and has a limit $\mathbf{v}$, $\mathbf{v}=\mathbf{R}[\mathbf{v}]$ as in Theorem 2.

For $\mathbf{w}^1$ we take $\mathbf{w}^1=\mathbf{1}-\varepsilon\mathbf{h}$, $\mathbf{h}$ is the Perron eigenfunction of the operator A: $\mathrm{A}\mathbf{h}=\rho\mathbf{h}$. As $\mathbf{u}^1=\mathrm{R}[\mathbf{u}^0]<\mathbf{1}$ we get $\mathbf{w}^1=\mathbf{1}-\varepsilon\mathbf{h}$ for ε small enough, and so $\{\mathbf{w}^m\}$ majorizes $\{\mathbf{u}^m\}$. It decreases monotonically as $\mathrm{R}[\mathbf{w}^m]<\mathbf{w}^m$: $\mathrm{R}[\mathbf{1}-\varepsilon\mathbf{h}]=\mathbf{1}-\varepsilon\rho\mathbf{h}+\mathrm{O}(\varepsilon\mathbf{h})$.

Hence as in Theorem 2 $\{\mathbf{w}^m\}$ has the limit $\mathbf{w}$, that is the fixed point of the operator $\mathbf{R}$ also. From Theorem 1 (Sec. IV) we have $\mathbf{w}=\mathbf{v}$, and this completes the proof of the theorem.

VI. CONCLUSIONS

We have proved theorems that are infinite-dimentional analogs of ones from branching process theory.[13–15] We showed that they are useful for computations of statistical characteristics of a gel. These general results are of utmost importance for the quantitative theory of polymer networks. It would be interesting to use the correspondence between quantum Hamiltonians and kinetic equations.[16,17]

(Received 7 January 2002; accepted for publication 8 April 2002)

We develop a very simple method to study the high temperature, or equivalently high external field, behavior of the Sherrington–Kirkpatrick mean field spin glass model. The basic idea is to couple two different replicas with a quadratic term, trying to push out the two replica overlap from its replica symmetric value. In the case of zero external field, our results reproduce the well known validity of the annealed approximation, up to the known critical value for the temperature. In the case of nontrivial external field, we can prove the validity of the Sherrington–Kirkpatrick replica symmetric solution up to a line, which falls short of the Almeida–Thouless line, associated to the onset of the spontaneous replica symmetry breaking, in the Parisi ansatz. The main difference with the method, recently developed by Michel Talagrand, is that we employ a quadratic coupling, and not a linear one. The resulting flow equations, with respect to the parameters of the model, turn out to be very simple, and the parameter region, where the method works, can be easily found in explicit terms. As a straightforward application of cavity methods, we show also how to determine free energy and overlap fluctuations, in the region where replica symmetry has been shown to hold. It is a major open problem to give a rigorous mathematical treatment of the transition to replica symmetry breaking, necessarily present in the model. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1483378]

I. INTRODUCTION

The mean field spin glass model, introduced by Sherrington and Kirkpatrick in Ref. 1, is here considered in the high temperature regime, or, equivalently, for a large external field. It is very well known, on physical grounds, that in this region the replica symmetric solution holds, as shown for example in Ref. 2, and references quoted there. However, due to the very large fluctuations present in the model, it is not so simple to give a complete, mathematically rigorous, characterization of this region, especially when there are external fields. Rigorous work on this subject include Refs. 3–8. For other rigorous results on the structure of the model, we refer to Refs. 9–15.

The method developed in Ref. 8, by Michel Talagrand, is particularly interesting. The starting point is given by the very sound physical idea that the spontaneous replica symmetry breaking phenomenon can be understood by exploring the properties of the model, under the application of auxiliary interactions, which explicitly break the replica symmetry. In Ref. 8, the replica symmetric solution is shown to hold in a region, which (*probably*) coincides with the region found in the theoretical physics literature, as shown for example in Ref. 2, i.e., up to the Almeida–Thouless line.[16]

[a)]Electronic-mail: francesco.guerra@roma1.infn.it
[b)]Electronic-mail: f.toninelli@sns.it

The main tool in Talagrand's treatment is an additional minimal replica coupling, linear in the overlap between two replicas. Then, a kind of quadratic stability for the so modified free energy leads immediately, through a generalization of the methods developed in Ref. 15, to establish the validity of the replica symmetric solution in a suitable parameter region.

Here we propose a very different strategy, by introducing a quadratic replica coupling, attempting to push the overlap away from its replica symmetric value. In a sense, our method is the natural extension, with applications, of the ideas put forward in Ref. 15, where sum rules were introduced for the free energy, by expressing its deviation from the replica symmetric solution in terms of appropriate quadratic fluctuations for the overlap. We choose exactly these quadratic fluctuation terms to act as additional interaction between two replicas, thus explicitly breaking replica symmetry. Then, a generalization of the sum rules, given in Ref. 15, for this modified model, allows us immediately to prove that the free energy of the original model converges, in the infinite volume limit, to its replica symmetric value, at least in a parameter region, explicitly determined.

The organization of the article is as follows. In Sec. II, we recall the basic definitions of the mean field spin glass model, and introduce the overlap distribution structure. As a first introduction of our method of quadratic coupling, in Sec. III, we treat the well known case of zero external field, by showing that the annealed approximation holds, in the infinite volume limit, up to the true critical inverse temperature $\beta_c = 1$. Our proof shows explicitly that there is a strong connection between the critical value of the transition temperature for the zero external field model, and the analogous, and numerically equivalent, temperature for the well known ferromagnetic Curie–Weiss mean field model.

In Sec. IV, we consider the model with external field, and introduce the associated model with quadratic replica coupling. Then, simple stability estimates give immediately the convergence of the free energy to its replica symmetric value, in a suitable, well defined, region of the parameters.

Section V reports about results on the free energy and overlap fluctuations, in our determined replica symmetric region. We also sketch the method of proof, based on cavity considerations, as developed for example in Refs. 2 and 5. A more complete treatment will be found in a forthcoming paper.[17]

Finally, Sec. VI is dedicated to a short outlook about open problems and further developments.

For the relevance of the mean field spin glass model for the understanding of the physical properties of realistic spin glasses, we refer to Ref. 18, but see also Ref. 19.

II. THE GENERAL STRUCTURE OF THE MEAN FIELD SPIN GLASS MODEL

The generic configuration of the mean field spin glass model is defined by Ising spin variables $\sigma_i = \pm 1$, attached to each site $i = 1,2,\ldots,N$. The external quenched disorder is given by the $N(N-1)/2$ independent and identical distributed random variables J_{ij}, defined for each couple of sites. For the sake of simplicity, we assume each J_{ij} to be a centered unit Gaussian with averages

$$E(J_{ij}) = 0, \quad E(J_{ij}^2) = 1.$$

The Hamiltonian of the model, in some external field of strength h, is given by

$$H_N(\sigma, J) = -\frac{1}{\sqrt{N}} \sum_{(i,j)} J_{ij}\sigma_i\sigma_j - h\sum_i \sigma_i . \tag{1}$$

The first sum extends to all site couples, and the second to all sites. The normalizing factor $1/\sqrt{N}$ is typical of the mean field character of the model, and guarantees a good thermodynamic limit for the free energy per spin, i.e., the existence of a finite and nontrivial limit for the free energy as $N \to \infty$. The first term in (1) is a long range random two body interaction, while the second represents the interaction of the spins with a fixed external magnetic field h.

For a given inverse temperature β, we introduce the disorder dependent partition function $Z_N(\beta,J)$, the (quenched average of the) free energy per site $f_N(\beta)$, the internal energy per site $u_N(\beta)$, the Boltzmann state ω_J, and the auxiliary function $\alpha_N(\beta)$, according to the definitions

$$Z_N(\beta,J)=\sum_{\sigma_1 \dots \sigma_N} \exp(-\beta H_N(\sigma,J)), \tag{2}$$

$$-\beta f_N(\beta)=N^{-1}E \log Z_N(\beta,J)=\alpha_N(\beta), \tag{3}$$

$$\omega_J(A)=Z_N(\beta,J)^{-1}\sum_{\sigma_1 \dots \sigma_N} A \exp(-\beta H_N(\sigma,J)), \tag{4}$$

$$u_N(\beta)=N^{-1}E\omega_J(H_N(\sigma,J))=\partial_\beta(\beta f_N(\beta))=-\partial_\beta\alpha_N(\beta), \tag{5}$$

where A is a generic function of the σ's. In the notation ω_J, we have stressed the dependence of the Boltzmann state on the external noise J, but, of course, there is also a dependence on β, h and N.

We are interested in the thermodynamic limit $N\to\infty$.

Let us now introduce the important concept of replicas. Consider a generic number s of independent copies of the system, characterized by the Boltzmann variables $\sigma_i^{(1)}, \sigma_i^{(2)}, \dots$, distributed according to the product state

$$\Omega_J=\omega_J^{(1)}\omega_J^{(2)} \dots \omega_J^{(s)},$$

where all $\omega_J^{(\alpha)}$ act on each one $\sigma_i^{(\alpha)}$s, and are subject to the *same* sample J of the external noise. Clearly, the *Boltzmannfaktor* for the replicated system is given by

$$\exp(-\beta(H_N(\sigma^{(1)},J)+H_N(\sigma^{(2)},J)+\cdots+H_N(\sigma^{(s)},J))). \tag{6}$$

The overlaps between two replicas a, b are defined according to

$$q_{ab}(\sigma^{(a)},\sigma^{(b)})=\frac{1}{N}\sum_i \sigma_i^{(a)}\sigma_i^{(b)},$$

and they satisfy the obvious bounds

$$-1\leqslant q_{ab}\leqslant 1.$$

For a generic smooth function F of the overlaps, we define the $\langle\ \rangle$ averages

$$\langle F(q_{12},q_{13},\dots)\rangle=E\Omega_J(F(q_{12},q_{13},\dots)),$$

where the Boltzmann averages Ω_J act on the replicated σ variables, and E is the average with respect to the external noise J.

We remark here that the noise average E introduces correlations between different groups of replicas, which would be otherwise independent under the Boltzmann averages Ω_J, as for example q_{12} and q_{34}.

The $\langle\ \rangle$ averages are obviously invariant under permutations of the replicas.

Overlap distributions play a very important role in the theory. For example, by using integration by parts on the J integrals, a simple direct calculation[2,11] shows that

$$\partial_\beta\alpha_N(\beta)=\frac{\beta}{2}(1-\langle q_{12}^2\rangle). \tag{7}$$

In order to introduce our treatment, based on flow equations with respect to the parameters of the theory, it is convenient to start from a *Boltzmannfaktor* given by

$$\exp\left(\sqrt{\frac{t}{N}} \sum_{(i,j)} J_{ij}\sigma_i\sigma_j + \beta h \sum_i \sigma_i + \sqrt{x} \sum_i J_i\sigma_i \right). \tag{8}$$

Notice that we have introduced an auxiliary additional one body random interaction ruled by the strength $\sqrt{x}$, $x \geqslant 0$, and N quenched independent and identically distributed centered unit Gaussian random variables J_i, so that

$$E(J_i)=0, \quad E(J_i^2)=1.$$

In order to get the original model, we have to put $x=0$ at the end. Moreover, we have written $\beta=\sqrt{t}$, with $t \geqslant 0$. The variables t, and x, will play the role of time variable, and space variable, respectively, in our flow equations. Now we define the partition function Z by using the *Boltzmannfaktor* (8), and the auxiliary function $\alpha_N(x,t)$ in the form

$$\alpha_N(x,t)=N^{-1}E \log Z_N.$$

Then, as in the proof of (7), we have

$$\partial_t \alpha_N(x,t)= \tfrac{1}{4}(1-\langle q_{12}^2 \rangle), \tag{9}$$

$$\partial_x \alpha_N(x,t)= \tfrac{1}{2}(1-\langle q_{12} \rangle). \tag{10}$$

It is very simple to calculate explicitly the average $N^{-1}E \log Z_N$ for $t=0$, at a generic strength x_0 of the one body random interaction. In fact, at $t=0$, the interaction factorizes, and the spins at different sites become independent. Therefore we have

$$\alpha(x_0,0)=\log 2 + \int \log\cosh(\beta h + z\sqrt{x_0})\, d\mu(z), \tag{11}$$

independently of N, where $d\mu$ is the centered unit Gaussian, representing each single J_i,

$$d\mu(z)=\exp\left(-\frac{z^2}{2}\right) dz/\sqrt{2\pi}.$$

Starting from (11) and (10) at $t=0$, we can immediately calculate the order parameter $\overline{q}(x_0)$ according to

$$\overline{q}(x_0)=\langle q_{12} \rangle (x_0,0)= \int \tanh^2(\beta h + z\sqrt{x_0})\, d\mu(z).$$

Let us now consider linear trajectories at constant velocity given by

$$x(t)=x_0-\overline{q}(x_0)t, \tag{12}$$

where x_0 is the initial starting point. Consider the problem of inverting (12), i.e., to find the conditions such that, for a given point (x,t), $x \geqslant 0$, $t \geqslant 0$, there is only one trajectory arriving at x, at time t. A precise statement is given by the following theorem.

Theorem 1: *Consider first the case of nonzero external field h. Then, for any point (x,t), $x \geqslant 0$, $t \geqslant 0$, there exists a unique $x_0(x,t)$ such that*

$$x=x_0(x,t)-\overline{q}(x_0(x,t))t,$$

and a unique $\overline{q}(x,t)=\overline{q}(x_0(x,t))$, *such that*

$$\overline{q}(x,t)=\int \tanh^2(\beta h+z\sqrt{x+\overline{q}(x,t)t})d\mu(z).$$

If $h=0$, *then, for any point* (x,t), $x\geqslant 0$, $t\geqslant 0$, *with the exclusion of the segment* $x=0$, $0\leqslant t\leqslant 1$, *there exists a unique* $x_0(x,t)>0$, *such that the previous formulas hold.*

The proof is very simple, and can be found in Ref. 15.

By following the methods of Ref. 15, sum rules connecting α and its SK approximation can be easily found by using transport equations. They involve overlap fluctuations. In fact, let us consider α along the trajectories in (12), i.e., $\alpha(x(t),t)$. An easy calculation gives

$$\frac{d}{dt}\alpha_N(x(t),t)=\frac{1}{4}(1-\overline{q}(x_0))^2-\frac{1}{4}\langle(q_{12}-\overline{q}(x_0))^2\rangle. \tag{13}$$

Now we integrate along t, take into account the initial condition (11), and the invertibility of (12), and find the sum rule

$$\overline{\alpha}(x,t)=\alpha_N(x,t)+\frac{1}{4}\int_0^t\langle(q_{12}-\overline{q})^2\rangle_{x(t'),t'}dt'. \tag{14}$$

Here, we have defined the replica symmetric Sherrington–Kirkpatrick solution[1,2] in the form

$$\overline{\alpha}(x,t)=\log 2+\int \log\cosh(\beta h+z\sqrt{x_0})d\mu(z)+\frac{t}{4}(1-\overline{q}(x_0))^2, \tag{15}$$

where x_0 and $\overline{q}(x_0)$ are expressed in terms of (x,t), according to the invertibility assured by the previous theorem. A very simple, but important, consequence of the sum rule is that α_N is dominated by its replica symmetric solution, uniformly in N,

$$\alpha_N(x,t)=N^{-1}E\log Z_N\leqslant\overline{\alpha}(x,t). \tag{16}$$

This is a simple consequence of the positivity of the term under integration in (14). Notice that (16) is a lower bound for the free energy, so that it is not directly connected to any variational principle for the Boltzmann–Gibbs state.

It is our aim to explore the parameter region where the t'-integral in (14) can be neglected, in the thermodynamic limit.

Now, we are ready to explain our method of quadratic coupling, starting with the simple case of zero external field, and then going to the case of nontrivial external fields.

III. QUADRATIC COUPLING FOR ZERO EXTERNAL FIELD

The high temperature region ($\beta<1$) of the zero external field SK model is a very particular case where everything can be computed. As it is well known,[3] in this case the annealed approximation is exact in the infinite volume limit. In fact, we have

$$\lim_{N\to\infty}\frac{1}{N}E\ln Z_N(t,J)=\overline{\alpha}(t)\equiv\ln 2+\frac{t}{4}=\frac{1}{N}\ln EZ_N(t,J)+\frac{t}{4N}. \tag{17}$$

In this section we give a new proof of Eq. (17), based on sum rules for the free energy. Our method is very simple and can be easily extended to the case of nontrivial external field, considered in the next section.

When $h=0$, $x=0$, then also $\overline{q}=0$ and $x_0=0$. Then, the sum rule in (14) reads

$$\alpha_N(t)=\overline{\alpha}(t)-\frac{1}{4}\int_0^t\langle q_{12}^2\rangle_{t'}dt'. \tag{18}$$

The presence of $\langle q_{12}^2\rangle$, as order parameter, suggests to couple two replicas with a term proportional to the square of the overlap, the corresponding partition function being

$$\tilde{Z}_N(t,\lambda,J)=\sum_{\{\sigma,\sigma'\}}\exp\left(\sqrt{\frac{t}{N}}\sum_{(i,j)}J_{ij}(\sigma_i\sigma_j+\sigma_i'\sigma_j')+\frac{\lambda}{2}Nq_{12}^2\right), \tag{19}$$

with $\lambda\geqslant 0$. The effect of the added term is to give a larger weight to the configurations having $q_{12}\neq 0$, thus favoring non-self-averaging of the overlap. Of course, the system possesses spin-flip symmetry also for $\lambda\neq 0$, so that $\langle q_{12}\rangle=0$. Therefore, if $\langle q_{12}^2\rangle\neq 0$, then the overlap is non-self-averaging. Now replica symmetry is explicitly broken.

The basic idea of our method is to show that, as long as $t<1$ and λ is small enough, the term $\lambda N q_{12}^2$ does not change the value of the free energy in the thermodynamic limit. Therefore, ''most'' configuration must have $q_{12}=0$ and the overlap must be self-averaging. In order to implement this intuitive idea, one introduces the λ dependent auxiliary function

$$\tilde{\alpha}_N(t,\lambda)=\frac{1}{2N}E\ln\tilde{Z}_N,$$

where the normalization factor $\frac{1}{2}$ is chosen so that $\tilde{\alpha}_N(t,0)=\alpha_N(t)$. Through a simple explicit calculation, we can easily calculate the t derivative in the form

$$\partial_t\tilde{\alpha}_N=\tfrac{1}{4}(1+\langle q_{12}^2\rangle-2\langle q_{13}^2\rangle), \tag{20}$$

where now all averages $\langle\ \rangle$ involve the λ-dependent state with *Boltzmannfaktor* given in agreement with (19). Moreover, it is obvious that

$$\partial_\lambda\tilde{\alpha}_N=\tfrac{1}{4}\langle q_{12}^2\rangle.$$

Starting from some point $\lambda_0>0$, consider the linear trajectory $\lambda(t)=\lambda_0-t$, with obvious invertibility in the form $\lambda_0=\lambda+t$. Let us take the t derivative of $\tilde{\alpha}_N$ along this trajectory

$$\frac{d}{dt}\tilde{\alpha}_N(t,\lambda(t))=(\partial_t-\partial_\lambda)\tilde{\alpha}_N=\frac{1}{4}-\frac{1}{2}\langle q_{13}^2\rangle_{t,\lambda(t)}.$$

Notice that the term containing $\langle q_{12}^2\rangle$ disappeared. By integration we get the sum rule and the inequality

$$\tilde{\alpha}_N(t,\lambda)=\frac{t}{4}+\tilde{\alpha}_N(0,\lambda_0)-\frac{1}{2}\int_0^t\langle q_{13}^2\rangle_{t',\lambda(t')}dt'\leqslant\frac{t}{4}+\tilde{\alpha}_N(0,\lambda_0), \tag{21}$$

where $\langle q_{13}^2\rangle_{t',\lambda(t')}$ refers to $\lambda(t')=\lambda_0-t'=\lambda+t-t'$.

Next, we compute $\tilde{\alpha}_N(0,\lambda_0)$. We introduce an auxiliary unit Gaussian z, and perform simple rescaling, in order to obtain

$$\tilde{\alpha}_N(0,\lambda_0)=\frac{1}{2N}\ln\sum_{\{\sigma,\sigma'\}}e^{1/2\,\lambda_0 N q_{12}^2}=\frac{1}{2N}\ln\sum_{\{\sigma,\sigma'\}}\int e^{\sqrt{\lambda_0 N}q_{12}z}d\mu(z) \tag{22}$$

$$= \ln 2 + \frac{1}{2N} \ln \int \left(\cosh z \sqrt{\frac{\lambda_0}{N}} \right)^N d\mu(z)$$

$$= \ln 2 + \frac{1}{2N} \ln \int dy \sqrt{\frac{N\lambda_0}{2\pi}} \exp N \left(-\lambda_0 \frac{y^2}{2} + \ln \cosh(y\lambda_0) \right), \tag{23}$$

where we performed the change of variables z to $y\sqrt{N\lambda_0}$ in the last step. It is immediately recognized that the integral in (23) appears in the ordinary treatment of the well known ferromagnetic mean field Curie–Weiss model. The saddle point method gives immediately

$$\lim_{N\to\infty} \tilde{\alpha}_N(0,\lambda_0) = \ln 2 + \frac{1}{2} \max_y \left(-\lambda_0 \frac{y^2}{2} + \ln \cosh(y\lambda_0) \right). \tag{24}$$

Therefore, the critical value for λ_0 is $\lambda_c = 1$. For $\lambda_0 > 1$ we have

$$\lim_{N\to\infty} \tilde{\alpha}_N(0,\lambda_0) > \ln 2,$$

while for $\lambda_0 < 1$, one can use the elementary property $2 \ln \cosh x \leqslant x^2$ to find

$$\tilde{\alpha}_N(0,\lambda_0) \leqslant \ln 2 + \frac{1}{4N} \ln \frac{1}{1-\lambda_0}. \tag{25}$$

Notice that, when λ_0 approaches the value 1^-, the term of order $1/N$ diverges, since Gaussian fluctuations around the saddle point become larger and larger.

Thanks to (25), the inequality in (21) becomes

$$\tilde{\alpha}_N(t,\lambda) \leqslant \overline{\alpha}(t) + \frac{1}{4N} \ln \frac{1}{1-\lambda_0},$$

which holds for $0 \leqslant \lambda_0 < 1$, i.e., for $0 \leqslant t+\lambda < 1$.

Next, we use convexity of $\tilde{\alpha}_N(t,\lambda)$ with respect to λ and the fact that

$$\partial_\lambda \tilde{\alpha}_N(t,\lambda)|_{\lambda=0} = \tfrac{1}{4} \langle q_{12}^2 \rangle_t$$

to write

$$\alpha_N(t) + \frac{\lambda}{4} \langle q_{12}^2 \rangle_t \leqslant \tilde{\alpha}_N(t,\lambda) \leqslant \overline{\alpha}(t) + \frac{1}{4N} \ln \frac{1}{1-\lambda-t},$$

for $\lambda > 0$. For $0 \leqslant t \leqslant \overline{t} < 1$, choose $\lambda = (1-\overline{t})/2$, so that

$$\lambda + t \leqslant \overline{\lambda}_0 \equiv (1+\overline{t})/2 < 1,$$

and

$$\frac{1}{4} \langle q_{12}^2 \rangle_t \leqslant \frac{1}{\lambda} (\overline{\alpha}(t) - \alpha_N(t)) + \frac{1}{4N\lambda} \ln \frac{1}{1-\overline{\lambda}_0}. \tag{26}$$

Recalling Eq. (18), one has

$$\frac{d}{dt} (\overline{\alpha}(t) - \alpha_N(t)) = \frac{1}{4} \langle q_{12}^2 \rangle_t \leqslant \frac{1}{\lambda} (\overline{\alpha}(t) - \alpha_N(t)) + \frac{1}{4N\lambda} \ln \frac{1}{1-\overline{\lambda}_0}, \tag{27}$$

so that

$$\alpha_N(t)=\overline{\alpha}(t)+O(1/N),$$

uniformly for $0\leqslant t\leqslant\overline{t}<1$. Of course, from Eq. (21) and convexity of $\tilde{\alpha}_N$ one also has

$$\tilde{\alpha}_N(t,\lambda)=\overline{\alpha}(t)+O(1/N),$$

$$\langle q_{13}^2\rangle_{t,\lambda}=O(1/N),$$

for $0\leqslant t+\lambda\leqslant\overline{\lambda}_0<1$.

We have gained a complete control of the system in the triangular region $0\leqslant t<1$, $0\leqslant\lambda<1-t$. Note that we have not only proved Eq. (17) but we have also shown that the leading correction to annealing is of order at most $1/N$.

IV. THE GENERAL CASE

The method we follow for the general case, where the *Boltzmannfaktor* is given by (8), is a direct generalization of the one explained in the previous section. In fact, by taking into account the t derivative in (13), we are led to introduce the auxiliary function

$$\tilde{\alpha}_N(x,\lambda,t)=\frac{1}{2N}E\ln\tilde{Z}_N(x,\lambda,t;J),$$

where $\tilde{Z}_N$ is the partition function for a system of two replicas coupled by the term

$$\frac{\lambda}{2}N(q_{12}-\overline{q}(x,t))^2,$$

with $\lambda\geqslant 0$. In order to simplify notation, we omit the argument h.

Now the t derivative is given by

$$\partial_t\tilde{\alpha}_N=\frac{1}{4}(1+\langle q_{12}^2\rangle-2\langle q_{13}^2\rangle)+\frac{\lambda}{2}(\overline{q}-\langle q_{12}\rangle)\frac{\partial\overline{q}}{\partial t},$$

while the x and λ derivatives appear as

$$\partial_x\tilde{\alpha}_N=\frac{1}{2}(1+\langle q_{12}\rangle-2\langle q_{13}\rangle)+\frac{\lambda}{2}(\overline{q}-\langle q_{12}\rangle)\frac{\partial\overline{q}}{\partial x},$$

$$\partial_\lambda\tilde{\alpha}_N=\frac{1}{4}\langle(q_{12}-\overline{q}(x,t))^2\rangle.$$

Starting from points $\lambda_0>0$, x_0, consider the linear trajectories $\lambda(t)=\lambda_0-t$, $x(t)=x_0-\overline{q}(x_0)t$, as in (12), with obvious invertibility as explained before. Since $\overline{q}$ is constant along the trajectory, and therefore $\partial_t\overline{q}-\overline{q}\partial_x\overline{q}=0$, one finds for the total time derivative of $\tilde{\alpha}_N$

$$\frac{d}{dt}\tilde{\alpha}_N(x(t),\lambda(t),t)=(\partial_t-\overline{q}\partial x-\partial_\lambda)\tilde{\alpha}_N=\frac{1}{4}(1-\overline{q})^2-\frac{1}{2}\langle(q_{13}-\overline{q})^2\rangle.$$

Notice that in this case the term containing $\langle(q_{12}-\overline{q})^2\rangle$ disappeared.

By integration, we get the sum rule and the inequality

$$\tilde{\alpha}_N(x,\lambda,t)=\frac{t}{4}(1-\overline{q})^2+\tilde{\alpha}_N(x_0,\lambda_0,0)-\frac{1}{2}\int_0^t\langle(q_{13}-\overline{q})^2\rangle_{t',x(t'),\lambda(t')}dt'$$

$$\leqslant\frac{t}{4}(1-\overline{q})^2+\tilde{\alpha}_N(x_0,\lambda_0,0),$$

where $\langle(q_{13}-\overline{q})^2\rangle_{t',x(t'),\lambda(t')}$ refers to

$$\lambda(t')=\lambda_0-t'=\lambda+t-t',$$

$$x(t')=x_0-\overline{q}t'=x+\overline{q}(t-t').$$

If Ω_J is the product state for two replicas with the original *Boltzmannfaktor* given by (8), then we can write

$$\tilde{\alpha}_N(x,\lambda,t)-\alpha_N(x,t)\equiv\frac{1}{2N}E\ln\Omega_J\left(\exp\frac{1}{2}\lambda N(q_{12}-\overline{q})^2\right).$$

Therefore, by exploiting the Jensen inequality, we have, for $\lambda\geqslant 0$,

$$\frac{\lambda}{4}\langle(q_{12}-\overline{q})^2\rangle_{x,t}\leqslant\tilde{\alpha}_N(x,\lambda,t)-\alpha_N(x,t).$$

Let us also define

$$\Delta_N(x_0,\lambda_0)\equiv\tilde{\alpha}_N(x_0,\lambda_0,0)-\alpha(x_0,0)=\frac{1}{2N}E\ln\Omega_J^0\left(\exp\frac{1}{2}\lambda_0 N(q_{12}-\overline{q})^2\right),\tag{28}$$

where we have introduced the state Ω_J^0 for two replicas, corresponding to $t=0$, and $x=x_0$, in (8). Notice that Ω_J^0 is a factor state over the sites i.

By collecting all our definitions and inequalities, and taking into account the definition (15), we have

$$\frac{\lambda}{4}\langle(q_{12}-\overline{q})^2\rangle_{x,t}\leqslant\Delta_N(x_0,\lambda_0)+\overline{\alpha}(x,t)-\alpha_N(x,t).$$

Let us now introduce $\lambda_c(x_0)$ such that, for any $\lambda_0\leqslant\lambda_c(x_0)$, one has

$$\lim_{N\to\infty}\Delta_N(x_0,\lambda_0)=0.$$

Then, by the same reasoning already exploited starting from (26), and taking into account (13), we obtain the proof of the following.

Theorem 2: *For any $t\leqslant\lambda_c(x_0(x,t))$, where $x_0(x,t)$ is defined as in Theorem 1, we have the convergence*

$$\lim_{N\to\infty}\alpha_N(x,t)=\overline{\alpha}(x,t).\tag{29}$$

For the specification of $\lambda_c(x_0)$, we can easily establish the complete characterization of the Δ_N limit. In fact, the following holds.

Theorem 3: *The infinite volume limit of Δ_N is given by*

$$\lim_{N\to\infty}\Delta_N(x_0,\lambda_0)=\Delta(x_0,\lambda_0).$$

Here, $\Delta(x_0,\lambda_0)$ *is defined through the variational expression*

$$\Delta(x_0,\lambda_0)\equiv\frac{1}{2}\max_{\mu}\left(\int \ln(\cosh\mu+\tanh^2(\beta h+z\sqrt{x_0})\sinh\mu)d\rho(z)-\mu\overline{q}-\frac{\mu^2}{2\lambda_0}\right), \tag{30}$$

where $d\rho(z)$ *is the centered unit Gaussian measure.*

Of course, the expression (30) is in agreement with (24), when there are no external fields.

It is easy to realize that the value λ_c, in the general case, is strictly less than the expected value t_c, following from the Almeida–Thouless argument,

$$t_c\int \cosh^{-4}(\beta h+z\sqrt{x_0})d\mu(z)=1.$$

The proof of Theorem 3 is easy. First of all, let us establish the elementary bound, uniform in N,

$$\Delta_N(x_0,\lambda_0)\geqslant\Delta(x_0,\lambda_0). \tag{31}$$

In fact, starting from the definition of $\Delta_N(x_0,\lambda_0)$ given in (28), we can write, for $\lambda_0\neq 0$, and any μ,

$$(q_{12}-\overline{q})^2\geqslant 2\frac{\mu}{\lambda_0}(q_{12}-\overline{q})-\left(\frac{\mu}{\lambda_0}\right)^2,$$

and conclude that

$$\Delta_N(x_0,\lambda_0)\geqslant\alpha_0(\mu)-\frac{\mu^2}{4\lambda_0}, \tag{32}$$

where we have defined

$$\begin{aligned}\alpha_0(\mu)&\equiv\frac{1}{2N}E\ln\Omega_J^0(\exp\mu N(q_{12}-\overline{q}))\\&=\frac{1}{2}\int \ln(\cosh\mu+\tanh^2(\beta h+z\sqrt{x_0})\sinh\mu)d\rho(z)-\frac{1}{2}\mu\overline{q}.\end{aligned}$$

Of course, it is convenient to take the $\max_\mu$ on the rhs of (32), so that the bound in (31) is established. The proof that the bound is in effect the limit, as $N\to\infty$, can be obtained in a very simple way by using a Gaussian transformation on (28), as it was done in (22). In fact, we now have

$$\frac{1}{2N}E\ln\Omega_J^0\left(\exp\frac{1}{2}\lambda_0 N(q_{12}-\overline{q})^2\right)=\frac{1}{2N}E\ln\int\Omega_J^0(\exp\sqrt{\lambda_0 N}(q_{12}-\overline{q})z)d\rho(z). \tag{33}$$

Therefore, by exploiting the fact that also Ω_J^0 factorizes with respect to the sites i, we can write

$$\begin{aligned}\Delta_N(x_0,\lambda_0)=\frac{1}{2N}E\ln\int\prod_i&\left(\cosh\sqrt{\frac{\lambda_0}{N}}z+\tanh^2(\beta h+J_i\sqrt{x_0})\sinh\sqrt{\frac{\lambda_0}{N}}z\right)\\&\times\exp(-\sqrt{\lambda_0 N}\overline{q}z)d\rho(z).\end{aligned} \tag{34}$$

Now, we find it convenient to introduce a small $\epsilon>0$, so that

$$\frac{1}{\lambda_0}=\frac{1}{\lambda_0'}+\epsilon. \tag{35}$$

Notice that $\lambda_0<\lambda_0'$. We also introduce the auxiliary (random) function

$$\phi_N(y,\lambda_0')\equiv\frac{1}{N}\sum_i \ln(\cosh y+\tanh^2(\beta h+J_i\sqrt{x_0})\sinh y)-\overline{q}y-\frac{1}{2}\frac{y^2}{\lambda_0'}.$$

By the strong law of large numbers, as $N\to\infty$, for any y, we have the J almost sure convergence of $\phi_N(y,\lambda_0')$ to $\phi(y,\lambda_0')$ defined by

$$\phi(y,\lambda_0')\equiv\int \ln(\cosh y+\tanh^2(\beta h+z\sqrt{x_0})\sinh y)d\rho(z)-\overline{q}y-\frac{1}{2}\frac{y^2}{\lambda_0'}=E\,\phi_N(y,\lambda_0').$$

Here $d\rho(z)$ performs the averages with respect to the J_i variables. Let us also remark that the convergence is J almost surely uniform for any finite number of values of the variable y.

Now we can go back to (34), write explicitly the unit Gaussian measure $d\rho(z)$, perform the change of variables $y=z\sqrt{\lambda_0 N^{-1}}$, make the transformation (35), take the $\sup_y$ for the ϕ_N, and perform the residual Gaussian integration over y. We end up with the estimate

$$\Delta_N(x_0,\lambda_0)\leqslant\frac{1}{2}E\sup_y\phi_N(y,\lambda_0')+\frac{1}{2N}\ln\frac{1}{\sqrt{\lambda_0\epsilon}}. \tag{36}$$

Since the J-dependent $\sup_y$ is reached in some finite interval, for any fixed λ_0', and the function ϕ_N is continuous with respect to y, with bounded derivatives, we can perform the $\sup_y$ with y running over a finite discrete mesh of values, by tolerating a small error, which becomes smaller and smaller as the mesh interval is made smaller. But in this case the strong law of large numbers allows us to substitute ϕ_N with ϕ, in the infinite volume limit $N\to\infty$. On the other hand, the second term on the rhs of (36) vanishes in the limit. Therefore, we conclude that

$$\limsup_{N\to\infty}\Delta_N(x_0,\lambda_0)\leqslant\tfrac{1}{2}\sup_y\phi(y,\lambda_0').$$

From continuity with respect to λ_0, we can let λ_0' approach λ_0, and the theorem is proven.

V. FLUCTUATIONS OF OVERLAPS AND FREE ENERGY

In the previous sections we proved that, in a certain region of the parameters t, x, βh, the typical values of the free energy $\ln Z_N/N$ and of the overlap q_{ab} are the replica symmetric expressions $\overline{\alpha}$ and $\overline{q}$, respectively. In the same region, one can obtain a more precise characterization of the fluctuations of these quantities, for $N\to\infty$, showing that a central limit-type theorem holds, after suitable rescaling. This will be analyzed in detail in a subsequent paper.[17] Here, we just give the main results and sketch the ideas underlying the proof.

Concerning the fluctuations of the overlap around the Sherrington–Kirkpatrick order parameter $\overline{q}$, we prove the following.

Theorem 4:[17] *The rescaled overlap variables*

$$\xi_{ab}^N\equiv\sqrt{N}(q_{ab}-\overline{q})$$

tend in distribution, as $N\to\infty$, to centered, jointly Gaussian variables with covariances

$$\langle\xi_{ab}^2\rangle=A(t,x,h),$$

$$\langle\xi_{ab}\xi_{ac}\rangle=B(t,x,h),$$

$$\langle \xi_{ab}\xi_{cd}\rangle = C(t,x,h),$$

where $b\neq c$, $c\neq a,b$, *and* $d\neq a,b$. *The expressions of* A, B, C *are explicitly given and coincide with those found in Ref. 15.*

Recently, an analogous result was proved independently by Talagrand,[20] who computed the $N\to\infty$ limit for all moments of the ξ variables.

The scheme of our proof is as follows: The control we obtained on the coupled two replica system and concentration of measure inequalities for the free energy[21] imply that the fluctuations of q_{ab} from $\overline{q}$ are exponentially suppressed for N large. Then, by means of the cavity method[2] one can write a self-consistent closed equation for the characteristic function of the variables ξ^N_{ab}. This equation turns out to be linear, apart from error terms which vanish asymptotically for $N\to\infty$, thanks to the strong suppression of the overlap fluctuations. The solution, which is easily found, coincides with the characteristic function of a Gaussian distribution, with the correct covariance structure.

Concerning the free energy, the result we prove is the following:

Theorem 5:[17] *Define the rescaled free energy fluctuation as*

$$\hat{f}_N(t,x,h;J) \equiv \sqrt{N}\left(\frac{\ln Z_N(t,x,h;J)}{N} - \overline{\alpha}(t,x,h)\right).$$

Then,

$$\hat{f}_N(t,x,h;J) \overset{d}{\to} \mathcal{N}(0,\sigma^2(t,x,h)),$$

where $\mathcal{N}(m,\sigma^2)$ *denotes the Gaussian random variable of mean* m *and variance* σ^2, *and*

$$\sigma^2(t,x,h) = Var(\ln\cosh(z\sqrt{\overline{q}t+x}+\beta h)) - \frac{\overline{q}^2 t}{2}.$$

Here, $Var(.)$ *denotes the variance of a random variable and* $z=\mathcal{N}(0,1)$.

This result is a consequence of Theorem 4 and of concentration of measure inequalities for the free energy.

VI. OUTLOOK AND CONCLUSIONS

We obtained control on the thermodynamic limit of the model, in a region above the Almeida–Thouless line, by suitably coupling two replicas of the system and studying stability with respect to the coupling parameter. The question naturally arises, whether and how this method can be extended up to the expected critical line. This problem seems to be common to all approaches proposed so far.

The method can also be further generalized to the case where more and more replicas are mutually coupled. In this case, replica symmetry is explicitly broken at various levels, and it is possible to give a generalization of the Ghirlanda–Guerra relations.[13] We plan to report soon on these generalizations.[22]

(Received 6 July 2001; accepted for publication 11 April 2002)

Focusing of waves in one dimension is analyzed for the plasma-wave equation and the wave equation with variable speed. The existence of focusing causal solutions to these equations is established, and such wave solutions are constructed explicitly by deriving an orthogonality relation for the time-independent Schrödinger equation. The connection between wave focusing and inverse scattering is studied. The potential at any point is recovered from the incident wave that leads to focusing to that point. It is shown that focusing waves satisfy certain temporal-antisymmetry and support properties. Discontinuities in the spatial and temporal derivatives of the focusing waves are examined and related to the discontinuities in the potential of the Schrödinger equation. The theory is illustrated with some explicit examples. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1483894]

I. INTRODUCTION

Consider a (Dirac-delta) plane wave incident onto an inhomogeneous medium. As time progresses the plane wave is scattered by the inhomogeneity and consequently develops a ''tail'' that trails the wavefront. One of the questions considered in this article concerns the opposite process. Namely, ''Can one prepare an incident wave (consisting of a plane wave plus a tail) such that the tail vanishes at a specified instant due to the interaction with the inhomogeneity, i.e., the wave reduces to the plane wave at that instant?'' If this happens, we say that the wave focuses to the point being crossed by the wavefront at the specified instant. We are also interested in determining remotely the value of the inhomogeneity at any specified point in space from the incident wave that is going to focus to that point; this will be done by performing a measurement on the incident wave at some arbitrarily chosen moment in time before the wavefront reaches that point.

Mathematically speaking, our aim is to analyze focusing of causal solutions to the plasma-wave equation

$$\frac{\partial^2 u(x,t)}{\partial x^2} - \frac{\partial^2 u(x,t)}{\partial t^2} = V(x)u(x,t), \quad x,t \in \mathbf{R}, \tag{1.1}$$

where V is real valued and belongs to $L_1^1(\mathbf{R})$, the class of measurable potentials such that $\int_{-\infty}^{\infty} dx(1+|x|)|V(x)|$ is finite. In order to do this, we derive the orthogonality relation (3.6) for the associated Schrödinger equation

$$\frac{d^2\psi(k,x)}{dx^2} + k^2\psi(k,x) = V(x)\psi(k,x), \quad x \in \mathbf{R}, \tag{1.2}$$

and exploit the connection between (1.1) and (1.2) through the Fourier transformation

$$u(x,t) := \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\, \psi(k,x)e^{-ikt}. \tag{1.3}$$

We use the subscript "l" to indicate waves incident from the left (i.e., coming from $x=-\infty$) and use "r" for incidence from the right. Our focusing waves consist of a (Dirac-delta distribution) wavefront and a tail lying either to the left or right of the wavefront in such a way that the tail completely disappears at a certain moment in time and thus the whole wave reduces to the wavefront at the focusing point. There is no loss of generality in choosing the focusing moment as $t=0$, and we denote the focusing point by x_0. Hence, we are interested in constructing causal solutions to (1.1) incident either from the left or right such that $u(x,0)=\delta(x-x_0)$, where $\delta(x)$ denotes the Dirac delta distribution. In Sec. VII we display $\partial u(x,0)/\partial t$ explicitly for our focusing waves and hence show that it is also possible to view them as some specific solutions to (1.1) satisfying certain initial conditions. Clearly, unless $\partial u(x,0)/\partial t\equiv 0$ when $x\in\mathbf{R}\backslash\{x_0\}$ for our focusing waves, their energy is not concentrated at x_0 when $t=0$; hence, in general, focusing of waves is not the same as focusing of the wave energy.

Our analysis helps us to understand better the connection between (1.1) and (1.2). In our treatment we include bound states of V, whereas such states are usually excluded in the analysis of (1.1) by imposing further restrictions on V such as positivity. Throughout our article, unless otherwise stated, V is only assumed to be real valued and belonging to $L_1^1(\mathbf{R})$; any other assumptions on V will be explicitly stated.

In our article we also investigate the connection between wave focusing and inverse scattering. The inverse scattering problem for (1.1) and (1.2) consists of the recovery of V from an appropriate set of scattering data. The recovery in the time domain is usually achieved by using some layer-stripping methods, see, e.g., Burridge (1980), Bube and Burridge (1983), Morawetz and Kriegsmann (1983), Bayliss *et al.* (1989), and Sacks (1993), in terms of the impulse response to a plane wave sent onto $V(x)$ either from $x=-\infty$ or from $x=+\infty$. In these techniques one considers the solution to (1.1) satisfying $u(x,t)=\delta(x-t)+o(1)$ and $\partial u(x,t)/\partial t=\delta'(x-t)+o(1)$ when $t\to-\infty$ as the wave incident from the left, or $u(x,t)=\delta(x+t)+o(1)$ and $\partial u(x,t)/\partial t=\delta'(x+t)+o(1)$ when $t\to-\infty$ as the wave incident from the right. The contrast with our focusing waves can be visualized by considering waves incident from the left especially when $V\equiv 0$ for $x<0$: our focusing wave for $x<0$ and $t<-x_0$ consists of the wavefront $\delta(x-x_0-t)$ followed by [cf. (5.19)] the nontrivial tail $K_r(x_0,x-t)$, whereas the wave in the aforementioned references is $\delta(x-t)$ for $x<0$ and $t<0$. We show in Sec. VII that the value of $V(x_0)$ for any fixed $x_0>0$ is recovered from the incident wave that is going to focus to x_0 with a measurement performed at an arbitrary moment $t<-x_0$ (i.e., before the wavefront reaches the inhomogeneity); in contrast, in the layer-stripping methods one lets the incident wave penetrate the inhomogeneity during the time interval $0<t<2x_0$ in order to recover $V(x)$ for $0<x<x_0$. A heuristic discussion of the physics connecting focusing and inverse scattering appears in Rose (2002), which is a strictly time-domain analysis that avoids reference to scattering solutions to (1.2).

This article is organized as follows. In Sec. II we introduce the Jost solutions, scattering coefficients, and normalized bound-state solutions of (1.2). In Sec. III we derive the orthogonality relation (3.6), a key result for obtaining the causal focusing wave solutions to (1.1) (incident either from the left or right) explicitly in terms of the Jost solutions, transmission coefficient, and normalized bound-state solutions of (1.2). In Sec. IV, we construct such causal waves that focus at $t=0$, namely U_l incident from the left and U_r incident from the right, and we study some of their properties; we also indicate how the value of $V(x_0)$ can be recovered by using waves focusing to x_0 and its vicinity. In Sec. V we examine the connection between wave focusing and inverse scattering problem; in particular, we analyze the relationship between wave focusing and the Marchenko inversion method, construct our focusing waves in terms of the solutions to the Marchenko integral equations, and show that wave focusing can be viewed as a consequence of the Marchenko method. In Sec. VI we explore certain temporal antisymmetries satisfied by the tails of our focusing waves; in this section we also show that, for potentials vanishing on a half line, the tail of a focusing wave may vanish in some regions at certain times and that a gap may develop between the wavefront and the tail. In Sec. VII, under more restrictive conditions on V, we analyze the discontinuities in the spatial and temporal derivatives of our focusing waves and relate such discontinuities to jump discontinuities of V; we also show that $V(x_0)$ can be recovered

solely from the incident wave leading to focusing to x_0, where the measurement can be performed at one arbitrarily chosen moment before the wavefront reaches x_0; as a corollary we obtain the interesting identities (7.22) and (7.25) for the solutions to the Marchenko equations when the corresponding potential vanishes on a half line. In Sec. VIII we present some explicit examples to illustrate various aspects of wave focusing and the recovery of $V(x_0)$ via focusing, and we also provide some snapshots of focusing waves as their tails disappear and reappear. Finally, in Sec. IX we analyze wave focusing for the variable-speed wave equation (9.14).

II. PRELIMINARIES

Let $\mathbf{C}^+$ denote the upper-half complex plane and $\overline{\mathbf{C}^+} := \mathbf{C}^+ \cup \mathbf{R}$. There are two types of solutions to (1.2). The scattering solutions consist of linear combinations of e^{ikx} and e^{-ikx} as $x \to \pm\infty$, and they occur for $k \in \mathbf{R}\backslash\{0\}$; on the other hand, the bound-state solutions decay exponentially as $x \to \pm\infty$, and they can occur only at certain k-values on the imaginary axis in $\mathbf{C}^+$. Let us use N to denote the number of bound states, which is known to be finite, and suppose that the bound states occur at $k = i\kappa_j$ with $0 < \kappa_1 < \cdots < \kappa_N$.

Among the scattering solutions to (1.2) are the Jost solution from the left, f_l, and the Jost solution from the right, f_r, satisfying the respective boundary conditions

$$e^{-ikx} f_\mathrm{l}(k,x) = 1 + o(1), \quad e^{-ikx} f_\mathrm{l}'(k,x) = ik + o(1), \quad x \to +\infty, \tag{2.1}$$

$$e^{ikx} f_\mathrm{r}(k,x) = 1 + o(1), \quad e^{ikx} f_\mathrm{r}'(k,x) = -ik + o(1), \quad x \to -\infty, \tag{2.2}$$

where the prime is used for the derivative with respect to the spatial coordinate x. From the spatial asymptotics

$$f_\mathrm{l}(k,x) = \frac{e^{ikx}}{T(k)} + \frac{L(k)e^{-ikx}}{T(k)} + o(1), \quad x \to -\infty, \tag{2.3}$$

$$f_\mathrm{r}(k,x) = \frac{e^{-ikx}}{T(k)} + \frac{R(k)e^{ikx}}{T(k)} + o(1), \quad x \to +\infty, \tag{2.4}$$

we obtain the scattering coefficients, namely, the transmission coefficient T, and the reflection coefficients L and R from the left and right, respectively.

Each bound state corresponds to a pole of T in $\mathbf{C}^+$ and vice versa. It is known that the bound states are simple and there exists only one linearly independent solution to (1.2) at each $k = i\kappa_j$ belonging to $L^2(\mathbf{R})$. The bound-state norming constants $c_{\mathrm{l}j}$ and $c_{\mathrm{r}j}$ are defined as

$$c_{\mathrm{l}j} := \left[\int_{-\infty}^{\infty} dx\, f_\mathrm{l}(i\kappa_j, x)^2 \right]^{-1/2}, \quad c_{\mathrm{r}j} := \left[\int_{-\infty}^{\infty} dx\, f_\mathrm{r}(i\kappa_j, x)^2 \right]^{-1/2}, \tag{2.5}$$

and they are related to each other via the residues of T as

$$\mathrm{Res}(T, i\kappa_j) = ic_{\mathrm{l}j}^2 \gamma_j = i\frac{c_{\mathrm{r}j}^2}{\gamma_j}, \tag{2.6}$$

where γ_j is the dependency constant given by $\gamma_j := f_\mathrm{l}(i\kappa_j, x)/f_\mathrm{r}(i\kappa_j, x)$. The sign of γ_j is the same as that of $(-1)^{N-j}$ and hence $c_{\mathrm{r}j} = (-1)^{N-j}\gamma_j c_{\mathrm{l}j}$. The normalized bound-state solution $\varphi_j(x)$ at $k = i\kappa_j$ is defined as

$$\varphi_j(x) := c_{\mathrm{l}j} f_\mathrm{l}(i\kappa_j, x) = (-1)^{N-j} c_{\mathrm{r}j} f_\mathrm{r}(i\kappa_j, x). \tag{2.7}$$

III. AN ORTHOGONALITY IDENTITY

The scattering and bound-state solutions to (1.2) satisfy the completeness relation, see, e.g., Newton (1983) and Chadan amd and Sabatier (1989),

$$\frac{1}{4\pi}\int_{-\infty}^{\infty} dk[\,\psi_{\rm l}(k,x)\psi_{\rm l}(-k,x_0)+\psi_{\rm r}(k,x)\psi_{\rm r}(-k,x_0)\,]+\sum_{j=1}^{N}\varphi_j(x)\varphi_j(x_0)=\delta(x-x_0), \quad (3.1)$$

where $\psi_{\rm l}$ and $\psi_{\rm r}$ are the physical solutions to (1.2) related to the Jost solutions as

$$\psi_{\rm l}(k,x):=T(k)f_{\rm l}(k,x), \quad \psi_{\rm r}(k,x):=T(k)f_{\rm r}(k,x). \quad (3.2)$$

In the Jost solutions, physical solutions, and scattering coefficients, for real k, replacing k by $-k$ has the same effect as taking complex conjugation. Moreover, we have

$$f_{\rm l}(-k,x)=T(k)f_{\rm r}(k,x)-R(k)f_{\rm l}(k,x), \quad k\in\mathbf{R}, \quad (3.3)$$

$$f_{\rm r}(-k,x)=-L(k)f_{\rm r}(k,x)+T(k)f_{\rm l}(k,x), \quad k\in\mathbf{R}, \quad (3.4)$$

which are consequences of the fact that either $\{f_{\rm l}(k,\cdot),f_{\rm r}(k,\cdot)\}$ or $\{f_{\rm l}(-k,\cdot),f_{\rm r}(-k,\cdot)\}$ is a linearly independent set of solutions to (1.2) when $k\in\mathbf{R}\backslash\{0\}$ and that the functions in one set can be expressed as a linear combination of those in the other. It is known that

$$R(k)T(-k)=-L(-k)T(k), \quad k\in\mathbf{R}. \quad (3.5)$$

Next we prove an orthogonality identity for (1.2) that will be useful in the analysis of wave focusing for (1.1).

Theorem 3.1: *Assume V is real valued and belongs to $L^1_1(\mathbf{R})$. Then*

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dkT(k)f_{\rm l}(k,x)f_{\rm r}(k,x_0)+\sum_{j=1}^{N}\varphi_j(x)\varphi_j(x_0)=\delta(x-x_0). \quad (3.6)$$

Proof: The proof will be given by showing that the integral term in (3.6) is identical to the integral in (3.1). From (3.2)–(3.4) we get

$$\psi_{\rm r}(k,x)=f_{\rm l}(-k,x)+R(k)f_{\rm l}(k,x), \quad k\in\mathbf{R},$$

$$\psi_{\rm l}(-k,x_0)=f_{\rm r}(k,x_0)+L(-k)f_{\rm r}(-k,x_0), \quad k\in\mathbf{R}.$$

Thus, for $k\in\mathbf{R}$ we have

$$\begin{aligned}&\psi_{\rm l}(k,x)\psi_{\rm l}(-k,x_0)+\psi_{\rm r}(k,x)\psi_{\rm r}(-k,x_0)\\ &\quad=T(k)f_{\rm l}(k,x)[f_{\rm r}(k,x_0)+L(-k)f_{\rm r}(-k,x_0)]+[f_{\rm l}(-k,x)+R(k)f_{\rm l}(k,x)]T(-k)f_{\rm r}(-k,x_0)\\ &\quad=T(k)f_{\rm l}(k,x)f_{\rm r}(k,x_0)+T(-k)f_{\rm l}(-k,x)f_{\rm r}(-k,x_0), \end{aligned} \quad (3.7)$$

where we have used (3.5) in the last step for simplification. Replacing the dummy integration variable k by $-k$, we get

$$\int_{-\infty}^{\infty} dkT(-k)f_{\rm l}(-k,x)f_{\rm r}(-k,x_0)=\int_{-\infty}^{\infty} dkT(k)f_{\rm l}(k,x)f_{\rm r}(k,x_0),$$

and hence from (3.7) we obtain

$$\int_{-\infty}^{\infty} dk[\psi_l(k,x)\psi_l(-k,x_0)+\psi_r(k,x)\psi_r(-k,x_0)]=2\int_{-\infty}^{\infty} dkT(k)f_l(k,x)f_r(k,x_0).$$

Thus, the integral on the left-hand side of (3.6) is the same as that on the left-hand side of (3.1).■

IV. WAVE FOCUSING FOR THE PLASMA-WAVE EQUATION

In this section we construct focusing waves of (1.1) incident either from the left or right in terms of the Jost solutions, transmission coefficient, and bound states for (1.2). We also relate the discontinuities at the wavefront of such focusing waves to an integral of V and show how the value of $V(x)$ at any specific point can be extracted from waves focusing to that point and its vicinity.

In terms of the Jost solutions of (1.2), let us define

$$K_l(x,t):=\frac{1}{2\pi}\int_{-\infty}^{\infty} dk[f_l(k,x)-e^{ikx}]e^{-ikt}, \tag{4.1}$$

$$K_r(x,t):=\frac{1}{2\pi}\int_{-\infty}^{\infty} dk[f_r(k,x)-e^{-ikx}]e^{ikt}. \tag{4.2}$$

Using (2.7) and the inverse Fourier transforms on (4.1) and (4.2), we obtain

$$\varphi_j(x)=(-1)^{N-j}c_{rj}\left[e^{\kappa_j x}+\int_{-\infty}^{x} dsK_r(x,s)e^{\kappa_j s}\right]=c_{lj}\left[e^{-\kappa_j x}+\int_{x}^{\infty} dsK_l(x,s)e^{-\kappa_j s}\right]. \tag{4.3}$$

The properties of K_l and K_r stated in the following theorem are already known, see, e.g., Faddeev (1967), Marchenko (1986), Chadan and Sabatier (1989), Deift and Trubowitz (1979), and they are used later in our analysis.

Theorem 4.1: *Assume V is real valued and belongs to $L^1_1(\mathbf{R})$. Then*

(i) For each fixed $x\in\mathbf{R}$, $K_l(x,\cdot)$ and $K_r(x,\cdot)$ belong to $L^2(\mathbf{R})\cap L^1(\mathbf{R})$.

(ii) For any $a\in\mathbf{R}$, $K_l(x,t)$ is uniformly bounded in (x,t) for $x\geqslant a$; similarly, $K_r(x,t)$ is uniformly bounded in (x,t) for $x\leqslant a$. Moreover, we have

$$K_l(x,t)=0, \quad t<x; \quad K_r(x,t)=0, \quad t>x. \tag{4.4}$$

(iii) K_l and K_r are continuous in (x,t) except when $t=x$, and the jumps there are related to V as

$$K_l(x,x^+)=\frac{1}{2}\int_{x}^{\infty} dzV(z), \quad K_r(x,x^-)=\frac{1}{2}\int_{-\infty}^{x} dzV(z). \tag{4.5}$$

Define

$$\hat{L}(t):=\frac{1}{2\pi}\int_{-\infty}^{\infty} dkL(k)e^{ikt}, \quad \hat{R}(t):=\frac{1}{2\pi}\int_{-\infty}^{\infty} dkR(k)e^{ikt}. \tag{4.6}$$

When V is real valued and belongs to $L^1_1(\mathbf{R})$, each of $\hat{L}$ and $\hat{R}$ is continuous and belongs to $L^2(\mathbf{R})$. In fact, they are absolutely continuous and differentiable, and for each fixed $a\in\mathbf{R}$ their derivatives satisfy $\hat{L}'\in L^1_1(-\infty,a)$ and $\hat{R}'\in L^1_1(a,+\infty)$.

Let us define

$$P_l(x,t):=\frac{1}{2\pi}\int_{-\infty}^{\infty} dk[T(k)-1]f_l(k,x)e^{-ikt}, \tag{4.7}$$

$$P_{\rm r}(x,t) := \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[T(k)-1]f_{\rm r}(k,x)e^{ikt}, \tag{4.8}$$

$$\Phi_{\rm l}(x,t) := \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[\psi_{\rm l}(k,x)-e^{ikx}]e^{-ikt}, \tag{4.9}$$

$$\Phi_{\rm r}(x,t) := \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[\psi_{\rm r}(k,x)-e^{-ikx}]e^{ikt}. \tag{4.10}$$

Proposition 4.2: Assume V is real valued and belongs to $L^1_1(\mathbf{R})$. Then, for any fixed $x\in\mathbf{R}$, each of $P_{\rm l}(x,\cdot)$, $P_{\rm r}(x,\cdot)$, $\Phi_{\rm l}(x,\cdot)$, and $\Phi_{\rm r}(x,\cdot)$ belongs to $L^2(\mathbf{R})$. Moreover, we have

$$\Phi_{\rm l}(x,t) = P_{\rm l}(x,t) + K_{\rm l}(x,t), \quad \Phi_{\rm r}(x,t) = P_{\rm r}(x,t) + K_{\rm r}(x,t), \tag{4.11}$$

$$\Phi_{\rm l}(x,t) = P_{\rm l}(x,t) = -\sum_{j=1}^{N} (-1)^{N-j} c_{{\rm r}j}\varphi_j(x)e^{\kappa_j t}, \quad t<x, \tag{4.12}$$

$$\Phi_{\rm r}(x,t) = P_{\rm r}(x,t) = -\sum_{j=1}^{N} c_{{\rm l}j}\varphi_j(x)e^{-\kappa_j t}, \quad t>x, \tag{4.13}$$

$$\Phi_{\rm l}(x,t) = K_{\rm r}(x,t) + \hat{L}(-x-t) + \int_{-\infty}^{x} ds\,\hat{L}(-t-s)K_{\rm r}(x,s), \quad t\neq x, \tag{4.14}$$

$$\Phi_{\rm r}(x,t) = K_{\rm l}(x,t) + \hat{R}(x+t) + \int_{x}^{\infty} ds\,\hat{R}(t+s)K_{\rm l}(x,s), \quad t\neq x, \tag{4.15}$$

$$P_{\rm l}(x,x_0+t) + \int_{-\infty}^{x_0} ds\,P_{\rm l}(x,s+t)K_{\rm r}(x_0,s) + \sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t} = 0, \quad x>x_0+t, \tag{4.16}$$

$$P_{\rm r}(x,x_0-t) + \int_{x_0}^{\infty} ds\,P_{\rm r}(x,s-t)K_{\rm l}(x_0,s) + \sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t} = 0, \quad x<x_0-t. \tag{4.17}$$

Proof: We obtain (4.11) by using (3.2), (4.1), (4.2), and (4.7)–(4.10). With the help of (2.6), (2.7), (4.4), (4.7), (4.8), and (4.11), by using a contour integration along the infinite semicircle enclosing $\mathbf{C}^+$, we obtain (4.12) and (4.13). Using (4.2), (4.6), and a Fourier transform on (3.4) we get (4.14). Similarly, by using (3.3), (4.1), and (4.6) we get (4.15). With the help of (4.3) and (4.12) we establish (4.16). In the same manner, using (4.3) and (4.13) we get (4.17). ■

Define

$$U_{\rm l}(x,t;x_0) := \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,\psi_{\rm l}(k,x)f_{\rm r}(k,x_0)e^{-ikt} + \sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}, \tag{4.18}$$

$$U_{\rm r}(x,t;x_0) := \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,\psi_{\rm r}(k,x)f_{\rm l}(k,x_0)e^{-ikt} + \sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}, \tag{4.19}$$

$$\Upsilon_{\rm l}(x,t;x_0) := U_{\rm l}(x,t;x_0) - \delta(x-x_0-t), \tag{4.20}$$

$$\Upsilon_{\rm r}(x,t;x_0) := U_{\rm r}(x,t;x_0) - \delta(x-x_0+t). \tag{4.21}$$

Theorem 4.3: *Assume V is real valued and belongs to $L^1_1(\mathbf{R})$. Then U_l is a causal solution to (1.1) incident from the left and focusing to $x=x_0$ when $t=0$. Similarly, U_r is a causal solution to (1.1) that is incident from the right and that focuses to $x=x_0$ when $t=0$.*

Proof: First, ψ_l, ψ_r, f_l, and f_r are solutions to (1.2) and they are transformed from the k-domain to the t-domain as in (1.3). Thus, with the help of (2.7), we see that each of U_l and U_r is a solution to (1.1). Using (4.2), (4.9), (4.11), (4.18), and (4.20) we get

$$\Upsilon_l(x,t;x_0)=K_r(x_0,x-t)+K_l(x,x_0+t)+\int_{x-t}^{x_0} ds K_l(x,s+t)K_r(x_0,s)+P_l(x,x_0+t)$$
$$+\int_{-\infty}^{x_0} ds P_l(x,s+t)K_r(x_0,s)+\sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}. \tag{4.22}$$

Similarly, using (4.1), (4.10), (4.11), (4.19), and (4.21) we obtain

$$\Upsilon_r(x,t;x_0)=K_l(x_0,x+t)+K_r(x,x_0-t)+\int_{x_0}^{x+t} ds K_r(x,s-t)K_l(x_0,s)+P_r(x,x_0-t)$$
$$+\int_{x_0}^{\infty} ds P_r(x,s-t)K_l(x_0,s)+\sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}. \tag{4.23}$$

With the help of (4.4) it follows that at any fixed moment t each of the first three terms on the right-hand side of (4.22) vanishes when $x>x_0+t$; moreover, using (4.16) it follows that the last three terms add to zero when $x>x_0+t$. Thus, U_l consists of the wavefront $\delta(x-x_0-t)$ followed by the tail Υ_l on the left, and it is incident from the left. Similarly, at any fixed moment t each of the first three terms on the right-hand side of (4.23) vanishes when $x<x_0-t$; moreover, from (4.17) it follows that the last three terms add to zero when $x<x_0-t$. Hence, U_r is a wave consisting of the wavefront $\delta(x-x_0+t)$ followed by the tail Υ_r on the right and the wave is incident from the right. Each of the waves U_l and U_r focuses to $x=x_0$ at $t=0$ because $U_l(x,0;x_0)=\delta(x-x_0)$ and $U_r(x,0;x_0)=\delta(x-x_0)$, as readily seen by comparing (4.18) and (4.19) with (3.6). ■

Since (1.1) is linear and homogeneous, any linear combination of U_l and U_r also focuses at $t=0$. In fact, for the special choice U_l-U_r even the wavefronts cancel each other and the wave vanishes on the entire x-axis at $t=0$. On the other hand, for the special choice U_l+U_r the wavefronts superimpose on top of each other at $t=0$.

Proposition 4.4: Assume V is real valued and belongs to $L^1_1(\mathbf{R})$. Then the only discontinuities of P_l and P_r can occur when $x=t$. Such discontinuities are given by

$$P_l(x,x^-)=\Phi_l(x,x^-)=-\sum_{j=1}^{N} (-1)^{N-j}c_{rj}\varphi_j(x)e^{\kappa_j x}, \tag{4.24}$$

$$P_r(x,x^+)=\Phi_r(x,x^+)=-\sum_{j=1}^{N} c_{lj}\varphi_j(x)e^{-\kappa_j x}, \tag{4.25}$$

$$P_l(x,x^+)=-\frac{1}{2}\int_{-\infty}^{\infty} ds V(s)-\sum_{j=1}^{N} (-1)^{N-j}c_{rj}\varphi_j(x)e^{\kappa_j x}, \tag{4.26}$$

$$P_r(x,x^-)=-\frac{1}{2}\int_{-\infty}^{\infty} ds V(s)-\sum_{j=1}^{N} c_{lj}\varphi_j(x)e^{-\kappa_j x}. \tag{4.27}$$

Proof: Note that (4.24) and (4.25) are equivalent to (4.12) and (4.13), respectively. Since $\hat{L}$ and $K_r(x,\cdot)$ are square integrable, their product is integrable; hence the integral term in (4.14) is

continuous in (x,t) as a result of the Lebesgue dominated convergence theorem. Similarly, from the square-integrability of $\hat{R}$ and of $K_{\rm l}(x,\cdot)$ it follows that the integral term in (4.15) is continuous in (x,t). Using the fact that $\hat{L}$ and $\hat{R}$ are continuous, from (4.11), (4.14), and (4.15) we see that the discontinuities of $P_{\rm l}$ and $P_{\rm r}$ coincide with those of $K_{\rm l}$ and $K_{\rm r}$; hence, such discontinuities can occur only when $x=t$. In fact, with the help of (4.4) we get

$$P_{\rm l}(x,x^+)-P_{\rm l}(x,x^-)=-K_{\rm r}(x,x^-)-K_{\rm l}(x,x^+), \tag{4.28}$$

$$P_{\rm r}(x,x^+)-P_{\rm r}(x,x^-)=K_{\rm l}(x,x^+)+K_{\rm r}(x,x^-). \tag{4.29}$$

Thus, using (4.5), (4.24), (4.25), (4.28), and (4.29), we get (4.26) and (4.27). ■

Theorem 4.5: *Assume V is real valued and belongs to $L^1_1(\mathbf{R})$. Then the only discontinuities of $U_{\rm l}$ and $U_{\rm r}$ occur at the wavefront, and the jumps in the tails at the wavefront are related to V as*

$$\Upsilon_{\rm l}(x_0^-+t,t;x_0)=-\frac{1}{2}\int_{x_0}^{x_0+t}dz\,V(z), \tag{4.30}$$

$$\Upsilon_{\rm r}(x_0^+-t,t;x_0)=-\frac{1}{2}\int_{x_0-t}^{x_0}dz\,V(z). \tag{4.31}$$

Proof: From (4.22) and (4.23) we see that the discontinuities in $\Upsilon_{\rm l}$ and $\Upsilon_{\rm r}$ can come only from the first, second, and fourth terms on the right-hand sides of (4.22) and (4.23), respectively; the third and fifth terms are continuous in (x,t) because the integrands there, being products of L^2-functions, are integrable in s. Thus, with the help of Proposition 4.4 and the fact that $K_{\rm r}$ and $K_{\rm l}$ can have discontinuities only when $x=t$, we conclude that the discontinuities in $\Upsilon_{\rm l}$ and $\Upsilon_{\rm r}$ can only occur at the wavefront, and we have

$$\begin{aligned}\Upsilon_{\rm l}(x_0^-+t,t;x_0)-\Upsilon_{\rm l}(x_0^++t,t;x_0)&=K_{\rm r}(x_0,x_0^-)-K_{\rm r}(x_0,x_0^+)+K_{\rm l}(x_0+t,x_0^++t)-K_{\rm l}(x_0+t,x_0^-+t)\\&\quad+P_{\rm l}(x_0+t,x_0^++t)-P_{\rm l}(x_0+t,x_0^-+t),\end{aligned} \tag{4.32}$$

$$\begin{aligned}\Upsilon_{\rm r}(x_0^+-t,t;x_0)-\Upsilon_{\rm r}(x_0^--t,t;x_0)&=K_{\rm l}(x_0,x_0^+)-K_{\rm l}(x_0,x_0^-)+K_{\rm r}(x_0-t,x_0^--t)-K_{\rm r}(x_0-t,x_0^+-t)\\&\quad+P_{\rm r}(x_0-t,x_0^--t)-P_{\rm r}(x_0-t,x_0^+-t).\end{aligned} \tag{4.33}$$

Now using (4.4), (4.5), (4.28), and (4.29) in (4.32) and (4.33) and the fact that $U_{\rm l}$ and $U_{\rm r}$ are causal, we establish (4.30) and (4.31). ■

As an application of Theorem 4.5, let us show how one can recover the value of $V(x_0)$ by using waves focusing to x_0 and its vicinity. Consider the left-hand side of (4.30) at some fixed time t in the interval $(-\infty,-x_0)$; in fact, one can even consider it when $t\to-\infty$. Let

$$\Gamma_{\rm l}(x_0,t):=\Upsilon_{\rm l}(x_0^-+t,t;x_0). \tag{4.34}$$

Thus, $\Gamma_{\rm l}(x_0,t)$ indicates the height of the tail of $U_{\rm l}$ at the wavefront at some fixed time $t<-x_0$. From (4.30), if V is continuous at x_0 and x_0+t, we see that

$$V(x_0)-V(x_0+t)=2\,\frac{\partial\Gamma_{\rm l}(x_0,t)}{\partial x_0}. \tag{4.35}$$

Note that $V(x_0+t)$ can be made as small as we want by choosing t so that either x_0+t lies to the left of the support of V (if V is supported in a right-half line) or by letting $t\to-\infty$ (if the support of V extends to $x=-\infty$). Clearly, $\partial\Gamma_{\rm l}(x_0,t)/\partial x_0$ can be obtained by using waves focusing to x_0 and its vicinity. An explicit example in Sec. VIII illustrates the recovery of $V(x_0)$ by using the technique described here.

Note that in the recovery technique outlined above, we have not made any other assumptions on V besides $V \in L_1^1(\mathbf{R})$, its realness, and its continuity at x_0 and x_0+t for some fixed $t<-x_0$. In fact, even when V is not continuous but only sectionally continuous, this technique still holds provided we replace (4.35) by

$$V(x_0^-)-V(x_0^++t)=2\frac{\partial\Gamma_l(x_0,t)}{\partial x_0}, \quad t<-x_0.$$

Under some stronger assumptions on V in Sec. VII, we will see that we can recover $V(x_0)$ by only using the wave that focuses to x_0 without needing any waves focusing near x_0.

V. CONNECTION WITH THE MARCHENKO METHOD

In this section we explore the connection between wave focusing for (1.1) and the Marchenko method to solve the inverse scattering problem for (1.2). By presenting certain representations for U_l and U_r, we show that their focusing is a direct consequence of the Marchenko method.

Let us define

$$M_r(t):=\hat{L}(-t)+\sum_{j=1}^{N} c_{rj}^2 e^{\kappa_j t}, \quad M_l(t):=\hat{R}(t)+\sum_{j=1}^{N} c_{lj}^2 e^{-\kappa_j t}, \tag{5.1}$$

where $\hat{L}$ and $\hat{R}$ are as in (4.6), and c_{rj} and c_{lj} are as in (2.5). Using (4.3), (4.4), (4.12)–(4.15), and (5.1) we get the two Marchenko equations

$$K_r(x,t)+M_r(x+t)+\int_{-\infty}^{x} dsM_r(t+s)K_r(x,s)=0, \quad t<x, \tag{5.2}$$

$$K_l(x,t)+M_l(x+t)+\int_{x}^{\infty} dsM_l(t+s)K_l(x,s)=0, \quad t>x, \tag{5.3}$$

and using (4.4), (4.14), and (4.15) we obtain the two complementary equations

$$\Phi_l(x,t)=\hat{L}(-x-t)+\int_{-\infty}^{x} ds\hat{L}(-t-s)K_r(x,s), \quad t>x, \tag{5.4}$$

$$\Phi_r(x,t)=\hat{R}(x+t)+\int_{x}^{\infty} ds\hat{R}(t+s)K_l(x,s), \quad t<x. \tag{5.5}$$

Let

$$F_l(x,t):=K_l(x,t)+M_l(x+t)+\int_{x}^{\infty} dsM_l(t+s)K_l(x,s), \tag{5.6}$$

$$F_r(x,t):=K_r(x,t)+M_r(x+t)+\int_{-\infty}^{x} dsM_r(t+s)K_r(x,s), \tag{5.7}$$

$$Z_l(x,t):=\Phi_l(x,t)-\hat{L}(-x-t)-\int_{-\infty}^{x} ds\hat{L}(-t-s)K_r(x,s), \tag{5.8}$$

$$Z_r(x,t):=\Phi_r(x,t)-\hat{R}(x+t)-\int_{x}^{\infty} ds\hat{R}(t+s)K_l(x,s). \tag{5.9}$$

Using (4.4) we can write the Marchenko equations (5.2) and (5.3) as

$$F_{\mathrm{r}}(x,t)=0, \quad t<x; \quad K_{\mathrm{r}}(x,t)=0, \quad t>x, \tag{5.10}$$

$$F_{\mathrm{l}}(x,t)=0, \quad t>x; \quad K_{\mathrm{l}}(x,t)=0, \quad t<x, \tag{5.11}$$

and the complementary equations (5.4) and (5.5) as

$$Z_{\mathrm{l}}(x,t)=0, \quad t>x; \quad Z_{\mathrm{r}}(x,t)=0, \quad t<x. \tag{5.12}$$

The following proposition shows that the focusing wave U_{l} can be constructed from the scattering data $\{L,\{\kappa_j\},\{c_{\mathrm{r}j}\}\}$ via the solution K_{r} of the Marchenko equation (5.2); similarly, the focusing wave U_{r} can be constructed from the data $\{R,\{\kappa_j\},\{c_{\mathrm{l}j}\}\}$ via the solution K_{l} of the Marchenko equation (5.3).

Proposition 5.1: The waves U_{l} and U_{r} defined in (4.18) and (4.19) can be expressed in terms of the quantities defined in (4.1), (4.2), (5.6), and (5.7) as

$$U_{\mathrm{l}}(x,t;x_0)=\delta(x-x_0-t)+K_{\mathrm{r}}(x_0,x-t)+F_{\mathrm{r}}(x,x_0+t)+\int_{-\infty}^{x_0} ds F_{\mathrm{r}}(x,t+s)K_{\mathrm{r}}(x_0,s), \tag{5.13}$$

$$U_{\mathrm{r}}(x,t;x_0)=\delta(x-x_0+t)+K_1(x_0,x+t)F_{\mathrm{l}}(x,x_0-t)+\int_{x_0}^{\infty} ds F_1(x,s-t)K_{\mathrm{l}}(x_0,s). \tag{5.14}$$

Proof: Using (4.3), (4.14), (4.22), (5.1), and (5.7), we obtain (5.13). Similarly, using (4.3), (4.15), (4.23), (5.1), and (5.6), we obtain (5.14). ■

Let us define

$$\begin{aligned} A_{\mathrm{r}}(x,t;x_0) :=& K_{\mathrm{r}}(x_0,x-t)-K_{\mathrm{r}}(x_0,x+t)-F_{\mathrm{r}}(x_0,x-t)+F_{\mathrm{r}}(x_0,x+t) \\ &-\int_{-\infty}^{x} ds K_{\mathrm{r}}(x,s)[F_{\mathrm{r}}(x_0,s-t)-F_{\mathrm{r}}(x_0,s+t)] \\ &+\int_{-\infty}^{\max\{x,x_0\}} ds[K_{\mathrm{r}}(x_0,s)K_{\mathrm{r}}(x,s+t)-K_{\mathrm{r}}(x_0,s+t)K_{\mathrm{r}}(x,s)], \end{aligned} \tag{5.15}$$

$$\begin{aligned} A_{\mathrm{l}}(x,t;x_0) :=& K_{\mathrm{l}}(x_0,x+t)-K_{\mathrm{l}}(x_0,x-t)+F_{\mathrm{l}}(x_0,x-t)-F_{\mathrm{l}}(x_0,x+t) \\ &-\int_{x}^{\infty} ds K_{\mathrm{l}}(x,s)[F_{\mathrm{l}}(x_0,s+t)-F_{\mathrm{l}}(x_0,s-t)] \\ &+\int_{\min\{x,x_0\}}^{\infty} ds[K_{\mathrm{l}}(x_0,s)K_{\mathrm{l}}(x,s-t)-K_{\mathrm{l}}(x_0,s-t)K_{\mathrm{l}}(x,s)]. \end{aligned} \tag{5.16}$$

Note that at $t=0$ both $A_{\mathrm{r}}(x,t;x_0)$ and $A_{\mathrm{l}}(x,t;x_0)$ vanish.

Proposition 5.2: The waves U_{l} and U_{r} defined in (4.18) and (4.19) can be expressed in terms of the quantities defined in (4.1), (4.2), (5.6)–(5.9), (5.15), and (5.16) as

$$U_{\mathrm{l}}(x,t;x_0)=\delta(x-x_0-t)+Z_{\mathrm{l}}(x,x_0+t)+F_{\mathrm{r}}(x_0,x-t)+\int_{x_0+t}^{x} ds F_{\mathrm{r}}(x_0,s-t)K_{\mathrm{r}}(x,s)+A_{\mathrm{r}}(x,t;x_0), \tag{5.17}$$

$$\begin{aligned} U_{\mathrm{r}}(x,t;x_0) =& \delta(x-x_0+t)+Z_{\mathrm{r}}(x,x_0-t)+F_{\mathrm{l}}(x_0,x+t) \\ &+\int_{x}^{x_0-t} ds F_{\mathrm{l}}(x_0,s+t)K_{\mathrm{l}}(x,s)+A_{\mathrm{l}}(x,t;x_0). \end{aligned} \tag{5.18}$$

Proof: We obtain (5.17) by using (4.3), (4.11), (4.14), (5.1), (5.7), and (5.8) in (4.22). Similarly, (5.18) is obtained by using (4.3), (4.11), (4.15), (5.6), and (5.9) in (4.23). ■

Theorem 5.3: *Assume that V is real valued and belongs to $L_1^1(\mathbf{R})$. Then we have the following.*

(i) The causality of U_l is a consequence of the Marchenko equation (5.2).
(ii) The causality of U_r is a consequence of the Marchenko equation (5.3).
(iii) The focusing of U_l to x_0 at $t=0$ is a consequence of (5.2) and (5.4).
(iv) The focusing of U_r to x_0 at $t=0$ is a consequence of (5.3) and (5.5).

Proof: Recall that (5.2) and (5.3) are equivalent to (5.10) and (5.11), respectively; similarly, (5.4) and (5.5) are equivalent to the first and second equations in (5.12), respectively. Note that if (5.10) holds, then the right-hand side of (5.13) vanishes when $x>x_0+t$ and hence (i) is proved. Similarly, if (5.11) holds, then the right-hand side of (5.14) vanishes for $x<x_0-t$ and hence (ii) is proved. If (5.10) and the first equation in (5.12) hold, then each of the first four terms on the right-hand side of (5.17) vanishes when $x<x_0+t$; moreover, the last term $A_r(x,t;x_0)$ vanishes at $t=0$ and hence (iii) is proved. In the same manner, if (5.11) and the second equation in (5.12) hold, then each of the first four terms on the right-hand side of (5.18) vanishes when $x>x_0-t$; moreover, the last term $A_l(x,t;x_0)$ vanishes at $t=0$ and hence (iv) is also proved. ■

Let us comment on the roles that the complementary equations (5.4) and (5.5) play in the Marchenko method. For the recovery of V by solving (5.2), one uses the ''right'' scattering data $\{L,\{\kappa_j\},\{c_{rj}\}\}$ as the input and obtains the ''right'' quantity K_r, from which the ''right'' Jost solution f_r is obtained with the help of (4.1). The complementary equation (5.4) is a means to construct the ''left'' quantity Φ_l, from which the ''left'' physical solution ψ_l can be obtained via the inverse Fourier transform on (4.9). In a similar manner, the complementary equation (5.5) is a means to construct the ''right'' quantities such as ψ_r by using only the ''left'' scattering data $\{R,\{\kappa_j\},\{c_{lj}\}\}$ as the input to the Marchenko procedure. Hence, Theorem 5.3(iii) is equivalent to the statement that the focusing of U_l is a consequence of the Marchenko method using the ''right'' scattering data as the input. Similarly, Theorem 5.3(iv) is equivalent to saying that focusing of U_r is a consequence of the Marchenko method using the ''left'' scattering data as the input.

The following result and its proof are used in the proof of Theorems 6.4 and 6.5. Even though this result is already known, we include a brief proof for convenience because we later refer to the facts stated in it.

Proposition 5.4: Assume V is real valued and belongs to $L_1^1(\mathbf{R})$. If $V\equiv 0$ for $x>0$, then $M_l(t)=0$ for $t>0$, and if $V\equiv 0$ for $x<0$, then $M_r(t)=0$ for $t<0$, where M_l and M_r are the quantities defined in (5.1).

Proof: If $V\equiv 0$ for $x>0$, then R is meromorphic in $\mathbf{C}^+$ with simple poles at the bound states $k=i\kappa_j$ having the residues $\mathrm{Res}(R,i\kappa_j)=ic_{lj}^2$, and $R(k)e^{2ikx}=o(1/k)$ as $k\to\infty$ in $\overline{\mathbf{C}^+}$ for each $x\geqslant 0$. Similarly, if $V\equiv 0$ for $x<0$, then L is meromorphic in $\mathbf{C}^+$ with simple poles at the bound states $k=i\kappa_j$ having the residues $\mathrm{Res}(L,i\kappa_j)=ic_{rj}^2$, and $L(k)e^{-2ikx}=o(1/k)$ as $k\to\infty$ in $\overline{\mathbf{C}^+}$ for each $x\leqslant 0$. Thus, from (5.1) with the help of a contour integration, we directly get the conclusion of our proposition. ■

Let us make a contrast between an incident focusing wave and an incident plane wave; the latter is often used to probe an inhomogeneous medium. For simplicity, consider the special case $V\equiv 0$ for $x<0$. In this case, from (4.2) it follows that $K_r(x,t)=0$ for $x<0$. Thus, using (5.7) and Proposition 5.4 we get $F_r(x,x_0+t)=0$ for $x<0$ and $t<-x_0$. Hence, from (5.13) it follows that our focusing wave incident from the left is given by

$$U_l(x,t;x_0)=\delta(x-x_0-t)+K_r(x_0,x-t),\quad x<0,\quad t<-x_0. \tag{5.19}$$

From (5.19) we see that, if $x_0>0$, U_l contains some information about V even before the incident wave first encounters the potential at $x=0$ and $t=-x_0$. Using $x_0+t<0$ and $V(z)=0$ for $z<0$, from (4.30) we get $\Upsilon_l(x_0^-+t,t;x_0)=(1/2)\int_0^{x_0}dzV(z)$. This is in contrast to the case where a pure

plane wave is sent onto V from $x=-\infty$, in which case the incident wave consists solely of the Dirac-delta wavefront alone and a tail is nonexistent until the wave encounters the potential at $x=0$.

VI. TEMPORAL ANTISYMMETRIES AND SUPPORT PROPERTIES

In this section we are interested in showing that the focusing waves U_l and U_r satisfy certain temporal antisymmetries and support properties that are useful in understanding their focusing. We also show that for potentials vanishing on a half line, a gap may develop between the wavefront and the tail of these focusing waves. We present our results only for U_l because the corresponding results for U_r are obtained in a similar manner.

In terms of the Jost solutions of (1.2), let us define the Faddeev functions m_l and m_r as follows:

$$m_l(k,x) := e^{-ikx} f_l(k,x), \quad m_r(k,x) := e^{ikx} f_r(k,x).$$

Then, we can write Υ_l and Υ_r defined in (4.20) and (4.21), respectively, as

$$\Upsilon_l(x,t;x_0) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[T(k)m_l(k,x)m_r(k,x_0)-1]e^{ik(x-x_0-t)} + \sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}, \tag{6.1}$$

$$\Upsilon_r(x,t;x_0) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[T(k)m_r(k,x)m_l(k,x_0)-1]e^{-ik(x-x_0+t)} + \sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}. \tag{6.2}$$

From Theorem 4.3 we know that U_l and U_r are causal. Hence, from (6.1) and (6.2) we conclude the following.

Corollary 6.1: Assume V is real valued and belongs to $L^1_1(\mathbf{R})$. Then for $x>x_0+t$ we have

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[T(k)m_l(k,x)m_r(k,x_0)-1]e^{ik(x-x_0-t)} = -\sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}, \tag{6.3}$$

and for $x<x_0-t$ we have

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[T(k)m_r(k,x)m_l(k,x_0)-1]e^{-ik(x-x_0+t)} = -\sum_{j=1}^{N} \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}. \tag{6.4}$$

Theorem 6.2: *Assume V is real valued and belongs to $L^1_1(\mathbf{R})$. Then, for $t<x_0-x$, the tail Υ_l defined in (4.20) satisfies*

$$\Upsilon_l(x,t;x_0) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[m_l(k,x)m_l(-k,x_0)-1][e^{ik(x-x_0-t)} - e^{ik(x-x_0+t)}]. \tag{6.5}$$

Similarly, for $t<x-x_0$, the tail Υ_r defined in (4.21) satisfies

$$\Upsilon_r(x,t;x_0) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\,[m_r(k,x)m_r(-k,x_0)-1][e^{-ik(x-x_0+t)} - e^{-ik(x-x_0-t)}]. \tag{6.6}$$

Proof: From (3.3) we get

$$T(k)m_r(k,x_0) = m_l(-k,x_0) + R(k)e^{2ikx_0}m_l(k,x_0), \quad k\in\mathbf{R},$$

and, hence, for real k, we have

$$T(k)m_l(k,x)m_r(k,x_0)=m_l(k,x)m_l(-k,x_0)+R(k)m_l(k,x)e^{2ikx_0}m_l(k,x_0). \tag{6.7}$$

From (3.3) we see that

$$R(k)m_l(k,x)=e^{-2ikx}[T(k)m_r(k,x)-m_l(-k,x)], \quad k\in\mathbf{R}. \tag{6.8}$$

Thus, using (6.8) in the second term on the right-hand side of (6.7), we obtain

$$\begin{aligned}T(k)m_l(k,x)m_r(k,x_0)=&[T(k)m_r(k,x)-m_l(-k,x)]m_l(k,x_0)e^{2ik(x_0-x)}\\&+m_l(k,x)m_l(-k,x_0), \quad k\in\mathbf{R}.\end{aligned} \tag{6.9}$$

Using (6.9) in (6.1) we get

$$\Upsilon_l(x,t;x_0)=I_1-I_2+I_3-I_4+I_5+I_6,$$

where we have defined

$$I_1:=\frac{1}{2\pi}\int_{-\infty}^{\infty}dk m_l(k,x)m_l(-k,x_0)e^{ik(x-x_0-t)},$$

$$I_2:=\frac{1}{2\pi}\int_{-\infty}^{\infty}dk m_l(-k,x)m_l(k,x_0)e^{-ik(x-x_0+t)},$$

$$I_3:=\frac{1}{2\pi}\int_{-\infty}^{\infty}dk e^{-ik(x-x_0+t)}, \quad I_4:=\frac{1}{2\pi}\int_{-\infty}^{\infty}dk e^{ik(x-x_0-t)},$$

$$I_5:=\frac{1}{2\pi}\int_{-\infty}^{\infty}dk[T(k)m_r(k,x)m_l(k,x_0)-1]e^{-ik(x-x_0+t)},$$

$$I_6:=\sum_{j=1}^{N}\varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}.$$

Because of (6.4) we have $I_5+I_6=0$ when $x_0-t-x>0$. Changing the dummy integration variable k to $-k$ in I_2 and I_3 we obtain (6.5). The proof of (6.6) is similar to that of (6.5) and is obtained with the help of (3.4) and (6.3). ■

From (6.5) and (6.6) we get the following antisymmetry properties for Υ_l and Υ_r.

Corollary 6.3: Assume V is real valued and belongs to $L_1^1(\mathbf{R})$. *Then*

$$\Upsilon_l(x,-t;x_0)=-\Upsilon_l(x,t;x_0), \quad t\in(x-x_0,x_0-x),$$

$$\Upsilon_r(x,-t;x_0)=-\Upsilon_r(x,t;x_0), \quad t\in(x_0-x,x-x_0),$$

$$\Upsilon_l(x,-t;x_0)-\Upsilon_r(x,-t;x_0)=\Upsilon_r(x,t;x_0)-\Upsilon_l(x,t;x_0), \quad x,t,x_0\in\mathbf{R}.$$

We remark that the temporal antisymmetry is a key part of the physics underlying wave focusing. It is immediate from Corollary 6.3 that both Υ_l and Υ_r vanish at $t=0$.

Next, we present some results related to the support properties of Υ_l when the potential vanishes on a half line. Similar results hold for Υ_r although they are not listed here. In the next theorem, we show that, if the incident wave focuses to a point lying behind the support of the potential, a gap develops between the wavefront and the tail of the wave.

Theorem 6.4: *Assume V is real valued, belongs to* $L_1^1(\mathbf{R})$, *and vanishes for* $x>0$; *let* $x_0\geqslant 0$. *Then we have the following.*

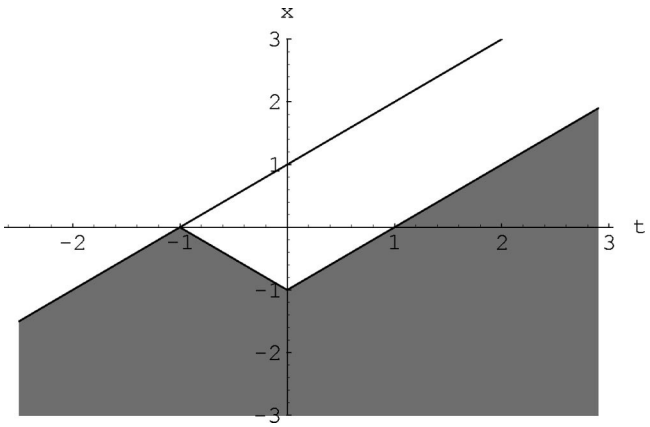

FIG. 1. The support of Υ_1 with $x_0=1$ in Theorem 6.4 is shaded in the tx-plane.

(i) *When* $t\geqslant 0$, *we have* $\Upsilon_1(x,t;x_0)=0$ *for* $x\geqslant -x_0+t$.
(ii) *When* $t\in[-x_0,0]$, *we have* $\Upsilon_1(x,t;x_0)=0$ *for* $x\geqslant -x_0-t$.
(iii) *Consequently, the wavefront* $\delta(x-x_0-t)$ *is in distance* $2x_0$ *ahead of the tail* Υ_1 *for* $t\geqslant 0$.
(iv) *Similarly, the wavefront* $\delta(x-x_0-t)$ *is in distance* $2(x_0+t)$ *ahead of the tail* Υ_1 *for* $t\in[-x_0,0]$.

Proof: The proof will be given by showing that Υ_1 vanishes on the closure of the rectangular region lying below the wavefront and above the shaded region exemplified in Fig. 1. If $V\equiv 0$ for $x>0$, then $m_1(k,x)=1$ for $x\geqslant 0$ and $T(k)m_r(k,x_0)=1+R(k)e^{2ikx_0}$. Thus, from (6.1), with the help of (2.7), we get

$$\Upsilon_1(x,t;x_0)=\hat{R}(x+x_0-t)+\sum_{j=1}^{N} c_{1j}^2 e^{-\kappa_j(x+x_0-t)}, \quad x\geqslant 0. \tag{6.10}$$

Comparing (6.10) with (5.1), we see that $\Upsilon_1(x,t;x_0)=M_1(x+x_0-t)$; hence, with the help of Proposition 5.4, we conclude that $\Upsilon_1(x,t;x_0)=0$ for $x>-x_0+t$ and $x\geqslant 0$. By the continuity of Υ_1 on the line $x=-x_0+t$, as indicated in Theorem 4.5, we get $\Upsilon_1(x,t;x_0)=0$ for $x\geqslant -x_0+t$.

On the other hand, when $x\leqslant 0$, using $T(k)m_r(k,x_0)=1+R(k)e^{2ikx_0}$, from (6.1) we get $\Upsilon_1(x,t;x_0)=I_7+I_8$, where we have defined

$$I_7:=\frac{1}{2\pi}\int_{-\infty}^{\infty} dk[m_1(k,x)-1]e^{ik(x-x_0-t)}, \tag{6.11}$$

$$I_8:=\frac{1}{2\pi}\int_{-\infty}^{\infty} dk R(k)m_1(k,x)e^{ik(x+x_0-t)}+\sum_{j=1}^{N}\varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}. \tag{6.12}$$

For $x>-x_0+t$, from (6.12) we obtain

$$I_8=i\sum_{j=1}^{N}\mathrm{Res}(R,i\kappa_j)m_1(i\kappa_j,x)e^{-\kappa_j(x+x_0-t)}+\sum_{j=1}^{N} c_{1j}^2 m_1(i\kappa_j,x)e^{-\kappa_j(x+x_0-t)}.$$

As mentioned in the proof of Proposition 5.4, we have $\mathrm{Res}(R,i\kappa_j)=ic_{1j}^2$, and hence $I_8=0$ for $x\leqslant 0$ and $x>-x_0+t$. Thus, from (4.1) and (6.11), we see that $\Upsilon_1(x,t;x_0)=K_1(x,x_0+t)$ for $x\leqslant 0$ and $x>-x_0+t$. From the Marchenko equation (5.3), we get

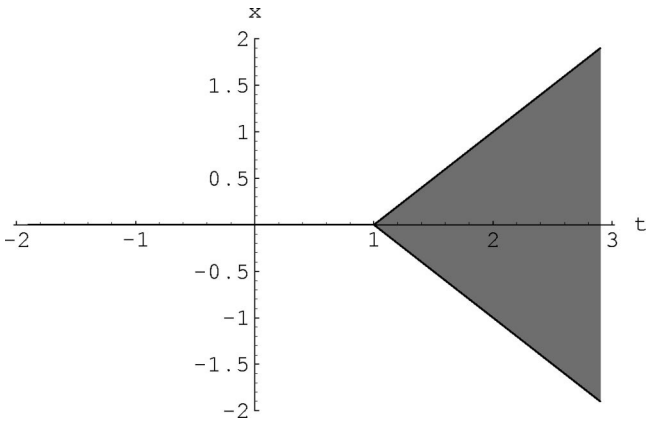

FIG. 2. The support of Υ_1 with $x_0=-1$ in Theorem 6.5 is shaded in the tx-plane.

$$K_1(x,x_0+t)+M_1(x+x_0+t)+\int_x^\infty dsM_1(x_0+t+s)K_1(x,s)=0, \quad x_0+t>x. \tag{6.13}$$

Note that in our region of interest, we have $x+x_0+t>0$, and hence by Proposition 5.4 each of the second and third terms on the left-hand side of (6.13) vanishes. Thus, from (6.13) we conclude $K_1(x,x_0+t)=0$, which in turn gives us $\Upsilon_1(x,t;x_0)=0$ for $x\leqslant 0$ and $x>\max\{-x_0-t,-x_0+t\}$. Again by the continuity of Υ_1 everywhere except at the wavefront of U_1, we get $\Upsilon_1(x,t;x_0)=0$ also on the line segment $x=-x_0+t$ for $t\in[0,x_0]$ and on the segment $x=-x_0-t$ for $t\in[-x_0,0]$. Therefore, we have proved (i) and (ii). Note that (iii) and (iv) directly follow from (i) and (ii). ■

In the next two theorems, when $V\equiv 0$ for $x<0$, we investigate the support properties of the focusing wave U_1.

Theorem 6.5: *Assume V is real valued, belongs to $L_1^1(\mathbf{R})$, and vanishes for $x<0$; let $x_0\leqslant 0$. Then we have the following.*

(i) *At each time $t\leqslant -x_0$, we have $\Upsilon_1(x,t;x_0)=0$.*
(ii) *At each time $t\geqslant -x_0$, we have $\Upsilon_1(x,t;x_0)=0$ for $x\leqslant -x_0-t$.*
(iii) *Consequently, at each fixed time $t>-x_0$, the support of $\Upsilon_1(\cdot,t;x_0)$ is the finite interval $(-x_0-t,x_0+t)$.*

Proof: The proof will be given by showing that the support of Υ_1 is confined to the interior of the region exemplified in Fig. 2. Because U_1 is a causal wave, in the region $x\leqslant \pm x_0\pm t$ we have $x\leqslant 0$; hence $T(k)m_1(k,x)=1+L(k)e^{-2ikx}$, and $m_r(k,x_0)=1$. Thus, from (6.3), with the help of (2.7), we get

$$\Upsilon_1(x,t;x_0)=\hat{L}(-x-x_0-t)+\sum_{j=1}^N c_{rj}^2 e^{\kappa_j(x+x_0+t)}, \quad x\leqslant 0. \tag{6.14}$$

From (5.1) and (6.14) we see that $\Upsilon_1(x,t;x_0)=M_r(x+x_0+t)$, and by Proposition 5.4 we conclude $\Upsilon_1(x,t;x_0)=0$ for $x<-x_0-t$. Because of the continuity of Υ_1 in the tx-plane off the wavefront, we also get $\Upsilon_1(x,t;x_0)=0$ on the line segment $x=-x_0-t$ for $t\geqslant -x_0$. ■

Theorem 6.6: *Assume V is real valued, belongs to $L_1^1(\mathbf{R})$, and vanishes for $x<0$; let $x_0\geqslant 0$. Then we have the following:*

(i) *At each time $t\leqslant 0$, we have $\Upsilon_1(x,t;x_0)=0$ for $x\leqslant -x_0+t$.*
(ii) *At each time $t\geqslant 0$, we have $\Upsilon_1(x,t;x_0)=0$ for $x\leqslant -x_0-t$.*

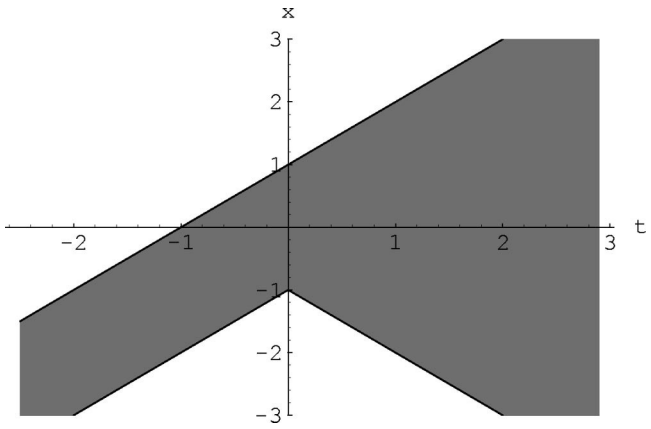

FIG. 3. The support of Υ_1 with $x_0=1$ in Theorem 6.6 is shaded in the tx-plane.

(iii) Consequently, at each fixed $t\leqslant 0$, *the support of* $\Upsilon_1(\cdot,t;x_0)$ *is the finite interval* $(-x_0+t,x_0+t)$. *Similarly, at each fixed* $t\geqslant 0$, *the support of* $\Upsilon_1(\cdot,t;x_0)$ *is the finite interval* $(-x_0-t,x_0+t)$.

Proof: The proof is obtained by using arguments similar to those used in the proof of Theorem 6.4 and by showing that the support of Υ_1 is confined to the interior of the shaded region exemplified in Fig. 3. ■

VII. DISCONTINUITIES IN DERIVATIVES OF FOCUSING WAVES

In this section, under more restrictions on V, we analyze the discontinuities in the spatial and temporal derivatives of our focusing waves, and we present some corollaries of our analysis. First, we show that we can recover $V(x_0)$ remotely by using only the wave that focuses to x_0 with a measurement taken at any fixed specified time $t<-x_0$; this complements our result in Sec. IV on the recovery of $V(x_0)$ from measurements on waves focusing to x_0 and its vicinity. Next, we examine the t-derivative of our focusing waves at $t=0$. Finally, for potentials vanishing on a half line, we derive an identity involving the temporal and spatial derivatives of the solutions to the Marchenko equations. We present the results mainly for the focusing wave incident from the left because the results for the incidence from the right can be obtained analogously.

In our analysis in the section, we put some or all of the following restrictions on V:

(H1) V is real valued and belongs to $L^1_1(\mathbf{R})$.

(H2) V is sectionally continuous with jump discontinuities at $x=a_j$ for $j=1,\ldots,n$.

(H3) V is piecewise continuously differentiable in each of the intervals $(-\infty,a_1)$, $(a_n,+\infty)$, and (a_j,a_{j+1}) with $j=1,\ldots,n-1$.

(H4) V' is integrable in each interval of its continuity.

(H5) V' is piecewise differentiable, and V'' is integrable in each interval it exists.

Paraphrasing, hypothesis (H2) states that V is continuous on $\mathbf{R}$ except perhaps at a finite number of points, and V has finite left and right limits at those points; (H3) is a similar statement for V'. Hypotheses (H4) and (H5) state that V' and V'' exist everywhere except perhaps at a finite number of points; moreover, if we remove those points from $\mathbf{R}$, V' and V'' are integrable on the resulting set.

Define

$$\alpha_l(x):=\int_x^\infty dy V(y), \quad \alpha_r(x):=\int_{-\infty}^x dy V(y), \quad \beta:=\int_{-\infty}^\infty dy V(y), \tag{7.1}$$

$$q_l(k,x):=V(x)+\sum_{a_j>x}[V(a_j^+)-V(a_j^-)]e^{2ik(a_j-x)}, \tag{7.2}$$

$$q_r(k,x) := -V(x) + \sum_{a_j^- < x} [V(a_j^+) - V(a_j^-)] e^{2ik(x-a_j)}. \tag{7.3}$$

In the next proposition we list the large-k asymptotics of the transmission coefficient and the Faddeev functions and their x-derivatives up to the orders needed in (7.15) and (7.16) [cf. p. 163 of Deift and Trubowitz(1979) where some expansions are given up to $o(1/k^2)$ as $k \to \infty$ in $\overline{\mathbf{C}^+}$].

Proposition 7.1: (i) Assume V satisfies hypotheses (H1)–(H4). Then, as $k \to \infty$ in $\overline{\mathbf{C}^+}$ we have

$$T(k) = 1 + \frac{\beta}{2ik} - \frac{\beta^2}{8k^2} + O(1/k^3), \tag{7.4}$$

$$m_l(k,x) = 1 - \frac{\alpha_l(x)}{2ik} - \frac{1}{8k^2}[\alpha_l(x)^2 - 2q_l(k,x)] + O(1/k^3), \tag{7.5}$$

$$m_r(k,x) = 1 - \frac{\alpha_r(x)}{2ik} - \frac{1}{8k^2}[\alpha_r(x)^2 + 2q_r(k,x)] + O(1/k^3). \tag{7.6}$$

(ii) In addition, if V satisfies also hypothesis (H5), then as $k \to \infty$ in $\overline{\mathbf{C}^+}$ we have

$$m_l'(k,x) = \frac{q_l(k,x)}{2ik} + O(1/k^2), \quad m_r'(k,x) = \frac{q_r(k,x)}{2ik} + O(1/k^2). \tag{7.7}$$

Proof: The proof is straightforward. For example, (7.5) is obtained by iterating the integral representation for m_l, see, e.g., Deift and Trubowitz (1979),

$$m_l(k,x) = 1 + \frac{1}{2ik}\int_x^\infty dy [e^{2ik(y-x)} - 1] V(y) m_l(k,y), \tag{7.8}$$

and using integration by parts on $\int_x^\infty dy e^{2ik(y-x)} V(y)$. Differentiating (7.8) with respect to x and using iteration and integration by parts, we obtain the asymptotics for m_l'. Similarly, with the help of the integral representations

$$m_r(k,x) = 1 + \frac{1}{2ik}\int_{-\infty}^x dy [e^{2ik(x-y)} - 1] V(y) m_r(k,y),$$

$$\frac{1}{T(k)} = 1 - \frac{1}{2ik}\int_{-\infty}^\infty dy V(y) m_l(k,y),$$

we obtain the large-k asymptotics for m_r, m_r', and T. ■

Let $\theta(x)$ denote the Heaviside function, and with the help of (7.1)–(7.3) let us define

$$D(x,x_0) := \beta[\alpha_l(x) + \alpha_r(x_0)] - \alpha_l(x)\alpha_r(x_0) - \frac{1}{2}[\beta^2 + \alpha_l(x)^2 + \alpha_r(x_0)^2]. \tag{7.9}$$

Using (7.1) we simplify the right-hand side in (7.9) to obtain

$$D(x,x_0) = -\frac{1}{2}\left[\int_x^{x_0} dy V(y)\right]^2. \tag{7.10}$$

Theorem 7.2: *Assume that V satisfies hypotheses (H1)–(H5). Then, the discontinuous part of $\partial \Upsilon_l(x,t;x_0)/\partial x$ is given by*

$$\frac{1}{4}[V(x_0)-V(x)+D(x,x_0)]\theta(x_0+t-x)-\frac{1}{4}\theta(x_0+t-x)\sum_{a_j>x}[V(a_j^+)-V(a_j^-)]$$
$$\times\theta(x-2a_j+x_0+t)-\frac{1}{4}\theta(x_0+t-x)\sum_{a_j<x_0}[V(a_j^+)-V(a_j^-)]\theta(-x+2a_j-x_0+t), \tag{7.11}$$

where $D(x,x_0)$ is the quantity in (7.10).

Proof: Consider the representation of Υ_1 given in (6.1), from which we get

$$\frac{\partial\Upsilon_1(x,t;x_0)}{\partial x}=\theta(x_0+t-x)\left[I_{10}+I_{11}+\sum_{j=1}^{N}\varphi_j'(x)\varphi_j(x_0)e^{\kappa_j t}\right], \tag{7.12}$$

where we have defined

$$I_{10}:=\frac{i}{2\pi}\int_{-\infty}^{\infty}dk\ k[T(k)m_{\rm l}(k,x)m_{\rm r}(k,x_0)-1]e^{ik(x-x_0-t)}, \tag{7.13}$$

$$I_{11}:=\frac{1}{2\pi}\int_{-\infty}^{\infty}dkT(k)m_{\rm l}'(k,x)m_{\rm r}(k,x_0)e^{ik(x-x_0-t)}. \tag{7.14}$$

When $V\in L_1^1(\mathbf{R})$, it is known that φ_j' is continuous; hence, the summation term within the brackets in (7.12) is continuous in (x,t). From the integrands in (7.13) and (7.14) let us separate the terms that are continuous in (k,x) and integrable in k; by the Lebesgue dominated convergence theorem, the integrals of such terms are continuous in (x,t). Using (7.1)–(7.7) and (7.9), as $k\to\infty$ in $\overline{\mathbf{C}^+}$ we obtain

$$ik[T(k)m_{\rm l}(k,x)m_{\rm r}(k,x_0)-1]=-\frac{1}{2}\int_x^{x_0}dyV(y)+\frac{i}{4(k+i0^+)}[D(x,x_0)+q_{\rm l}(k,x)-q_{\rm r}(k,x_0)]$$
$$+O(1/k^2), \tag{7.15}$$

$$T(k)m_{\rm l}'(k,x)m_{\rm r}(k,x_0)=\frac{q_{\rm l}(k,x)}{2i(k+i0^+)}+O(1/k^2), \tag{7.16}$$

where the $O(1/k^2)$-terms are continuous in (k,x) and integrable in k. When $x<x_0+t$, the $O(1)$-term in (7.15) does not contribute to the integral in (7.13). Using $\int_{-\infty}^{\infty}dke^{ikz}/(k+i0^+)=-2\pi i\theta(-z)$, we evaluate the contribution of the $O(1/k)$-terms in (7.13) and (7.14) to I_{10} and I_{11}, respectively, which, with the help of (7.10), results in (7.11). ■

Let us define

$$G(x,t;x_0):=-\frac{1}{4}[V(x_0)+V(x)+D(x,x_0)]\theta(x_0+t-x)$$
$$-\frac{1}{4}\theta(x_0+t-x)\sum_{a_j>x}[V(a_j^+)-V(a_j^-)]\theta(x-2a_j+x_0+t)$$
$$+\frac{1}{4}\theta(x_0+t-x)\sum_{a_j<x_0}[V(a_j^+)-V(a_j^-)]\theta(-x+2a_j-x_0+t), \tag{7.17}$$

where $D(x,x_0)$ is the quantity in (7.10).

Theorem 7.3: *Assume that V satisfies hypotheses (H1)–(H5). Then, the discontinuous part of $\partial\Upsilon_1(x,t;x_0)/\partial t$ is equal to $G(x,t;x_0)$ defined in (7.17).*

Proof: As in (7.12) we have

$$\frac{\partial \Upsilon_l(x,t;x_0)}{\partial t} = \theta(x_0+t-x)\left[-I_{10} + \sum_{j=1}^{N} \kappa_j \varphi_j(x)\varphi_j(x_0)e^{\kappa_j t}\right]. \tag{7.18}$$

Proceeding as in the proof of Theorem 7.2, we see that the only contribution to the discontinuities comes from the $O(1/k)$-term in (7.13), which gives us (7.17). ■

As a corollary of (7.18), we see that $U_l(x,t;x_0)$ is the solution to (1.1) satisfying the initial conditions $U_l(x,0;x_0)=\delta(x-x_0)$ and

$$\frac{\partial U_l(x,0;x_0)}{\partial t} = \delta'(x-x_0) + \sum_{j=1}^{N} \kappa_j \varphi_j(x)\varphi_j(x_0) - \frac{i}{2\pi}\int_{-\infty}^{\infty} dk\; k[T(k)m_l(k,x)m_r(k,x_0)-1]e^{ik(x-x_0)}. \tag{7.19}$$

With the help of (7.11)–(7.13), it is possible to identify the discontinuities on the right-hand side of (7.19) and hence also in $\partial U_l(x,0;x_0)/\partial t$. The initial value $\partial U_r(x,0;x_0)/\partial t$ can be obtained similarly and its discontinuities can be evaluated explicitly in an analogous manner.

Next, we turn our attention to the inverse scattering problem and describe the recovery of $V(x_0)$ by using only the wave $U_l(x,t;x_0)$ focusing to x_0. Assume that V satisfies hypotheses (H1)–(H5) and that x_0 is a point of continuity of V. As stated below (4.34), we know that the height of the tail Υ_l at the wavefront at any fixed time $t<-x_0$ is given by (4.30). Furthermore, from (7.11) we see that the x-derivative from the left for the tail Υ_l at the wavefront is given by

$$\frac{\partial \Upsilon_l(x_0^- + t,t;x_0)}{\partial x} = \frac{1}{4}[V(x_0)-V(x_0+t)] - \frac{1}{8}\left(\int_{x_0+t}^{x_0} dz V(z)\right)^2. \tag{7.20}$$

Eliminating the integral term in (4.30) and (7.20), we get

$$V(x_0) = V(x_0+t) + 2\Upsilon_l(x_0^- + t,t;x_0)^2 + 4\frac{\partial \Upsilon_l(x_0^- + t,t;x_0)}{\partial x}. \tag{7.21}$$

Note that all of the three terms on the right-hand side of (7.21) can be measured at some moment $t<-x_0$, where x_0+t is a point of continuity for V; in fact, we can even make our measurement when $t\to-\infty$, in which case $V(x_0+t)\to 0$. Thus, $V(x_0)$ can be remotely determined by using only the wave that focuses to x_0.

As a corollary of the arguments leading to (5.19) and (7.21) we obtain the following property for the solution to the Marchenko equation (5.2).

Theorem 7.4: *Assume V satisfies hypotheses (H1)–(H5) and $V\equiv 0$ for $x<0$. Then, for any point $x\in\mathbf{R}$ at which V is continuous, the solution $K_r(x,t)$ of the Marchenko equation (5.2) satisfies*

$$\frac{\partial K_r(x,x^-)}{\partial x} - \frac{\partial K_r(x,x^-)}{\partial t} = K_r(x,x^-)^2, \quad x\in\mathbf{R}. \tag{7.22}$$

Proof: Note that (7.22) holds trivially for all $x\leqslant 0$ because $K_r(x,t)=0$ for $x\leqslant 0$ as indicated above (5.19). From the Marchenko method, it is known that

$$V(x_0) = 2\frac{\partial K_r(x_0,x_0^-)}{\partial x} + 2\frac{\partial K_r(x_0,x_0^-)}{\partial t}, \quad x\in\mathbf{R}. \tag{7.23}$$

From (5.19) we see that $\Upsilon_1(x,t;x_0)=K_r(x_0,x-t)$ for all $x<0$ and $t<-x_0$; hence, we can write (7.21) with $x_0>0$ and $t<-x_0$ as

$$V(x_0)=2K_r(x_0,x_0^-)^2+4\frac{\partial K_r(x_0,x_0^-)}{\partial t}, \quad x_0>0. \tag{7.24}$$

Finally, comparing (7.23) and (7.24), we see that (7.22) also holds for $x>0$. ■

We next present the analog of Theorem 7.4 for K_l without a proof. It can also be obtained from (7.22) by changing the signs of x and t.

Theorem 7.5: *Assume V satisfies hypotheses (H1)–(H5) and $V\equiv 0$ for $x>0$. Then, for any point $x\in\mathbf{R}$ at which V is continuous, the solution $K_l(x,t)$ of the Marchenko equation (5.3) satisfies*

$$\frac{\partial K_l(x,x^+)}{\partial x}-\frac{\partial K_l(x,x^+)}{\partial t}=K_l(x,x^+)^2, \quad x\in\mathbf{R}. \tag{7.25}$$

VIII. EXAMPLES

In this section we illustrate wave focusing, various properties of focusing waves, and the recovery of a potential via wave focusing. An animated example of wave focusing can be found at the web site http://www.msstate.edu/~aktosun/publications.html.

Example 8.1: Consider the wave focusing for

$$V(x)=\theta(-x)\frac{16(\sqrt{2}+1)^2e^{-2\sqrt{2}x}}{[(\sqrt{2}+1)^2e^{-2\sqrt{2}x}-1]^2}.$$

Note that V, being non-negative, does not support any bound states; moreover, it is supported in $(-\infty,0)$ and hence the region $(0,+\infty)$ is the "free region." The corresponding scattering coefficients are rational functions of k, and one can obtain explicitly the scattering coefficients and Jost solutions of (1.2). We have $f_l(k,x)=e^{ikx}$ for $x\geqslant 0$,

$$f_r(k,x)=e^{-ikx}\left[1+\frac{i}{k+\sqrt{2}i}\frac{2\sqrt{2}}{(\sqrt{2}+1)^2e^{-2\sqrt{2}x}-1}\right], \quad x\leqslant 0,$$

$$T(k)=\frac{k(k+\sqrt{2}i)}{(k+i)^2}, \quad L(k)=-\frac{1}{(k+i)^2}\frac{k+\sqrt{2}i}{k-\sqrt{2}i}, \quad R(k)=\frac{1}{(k+i)^2}.$$

Using a contour integration in (4.18), we can evaluate U_l explicitly and verify that U_l focuses to x_0 at time $t=0$. When $x_0>0$, as indicated in Theorem 6.4, a gap develops between the wavefront and the tail, which is illustrated in Fig. 4. When $x_0<0$, the corresponding wave is illustrated in Fig. 5. It can be verified directly that the discontinuity in the tail at the wavefront, the discontinuities in the x-derivative of the tail, and the discontinuities in the t-derivative of the tail agree with the results in (4.30), (7.11), and (7.17), respectively.

Next, we illustrate the recovery of $V(x_0)$ by using the technique described in Sec. IV utilizing (4.35).

Example 8.2: Consider the wave focusing for the potential

$$V(x)=\theta(x)\frac{80(\sqrt{5}+1)(\sqrt{5}+2)e^{2\sqrt{5}x}}{[(\sqrt{5}+1)(\sqrt{5}+2)e^{2\sqrt{5}x}-2]^2}. \tag{8.1}$$

The corresponding scattering coefficients and Jost solutions can be evaluated explicitly as

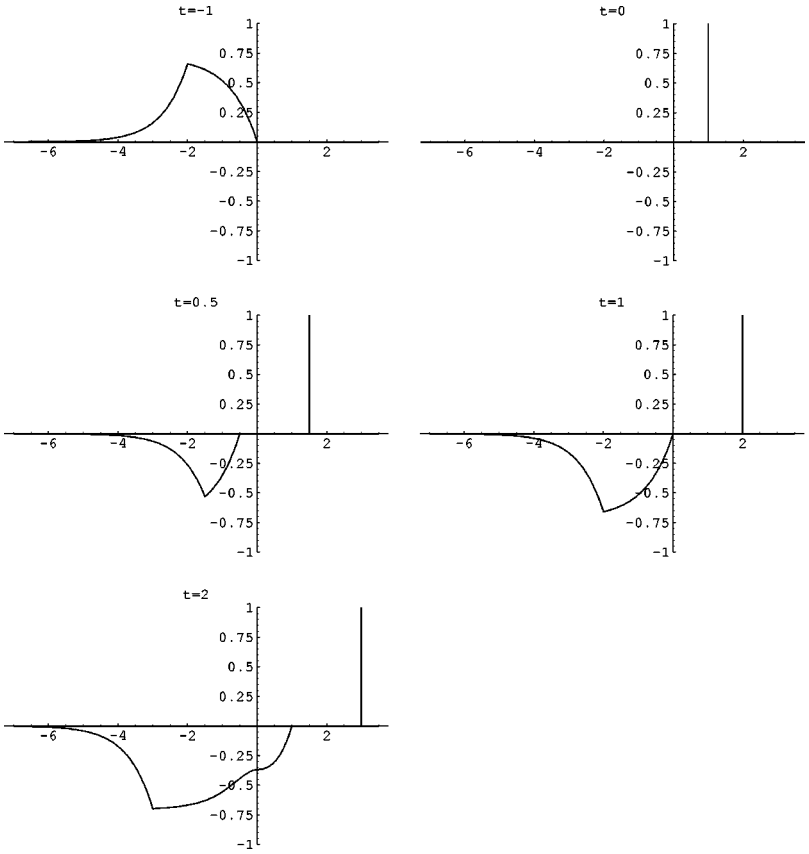

FIG. 4. The focusing wave of Example 8.1 with $x_0=1$ is shown at $t=-1,0,0.5,1,2$.

$$T(k)=\frac{k(k+\sqrt{5}i)}{(k+i)(k+2i)},\quad L(k)=\frac{2}{(k+i)(k+2i)},\quad R(k)=\frac{-2(k+\sqrt{5}i)}{(k+i)(k+2i)(k-\sqrt{5}i)},$$

$$f_{\mathrm{l}}(k,x)=e^{ikx}\left[1+\frac{iE(x)}{k+\sqrt{5}i}\right],\quad x\geqslant 0;\quad f_{\mathrm{r}}(k,x)=e^{-ikx},\quad x\leqslant 0,$$

$$f_{\mathrm{l}}(k,x)=\frac{(k+i)(k+2i)}{k(k+\sqrt{5}i)}e^{ikx}+\frac{2}{k(k+\sqrt{5}i)}e^{-ikx},\quad x\leqslant 0,$$

$$f_{\mathrm{r}}(k,x)=e^{-ikx}\left[1-\frac{iE(x)}{k-\sqrt{5}i}\right]-\frac{2(k+\sqrt{5}i)e^{ikx}}{(k+i)(k+2i)(k-\sqrt{5}i)}\left[1+\frac{iE(x)}{k+\sqrt{5}i}\right],\quad x\geqslant 0,$$

where

$$E(x):=\frac{4\sqrt{5}}{(1+\sqrt{5})(2+\sqrt{5})e^{2\sqrt{5}x}-2}.$$

Using (4.18) it is possible to construct $U_{\mathrm{l}}(x,t;x_0)$ explicitly. Since $V\equiv 0$ when $x<0$, we see that $V(x_0+t)=0$ for any fixed $t<-x_0$. Note that $\Gamma_{\mathrm{l}}(x_0,t)$ given in (4.34) can be computed as $\sqrt{5}-3+E(x_0)$. Then, using (4.35), we obtain $V(x_0)=2E'(x_0)$, agreeing with (8.1).

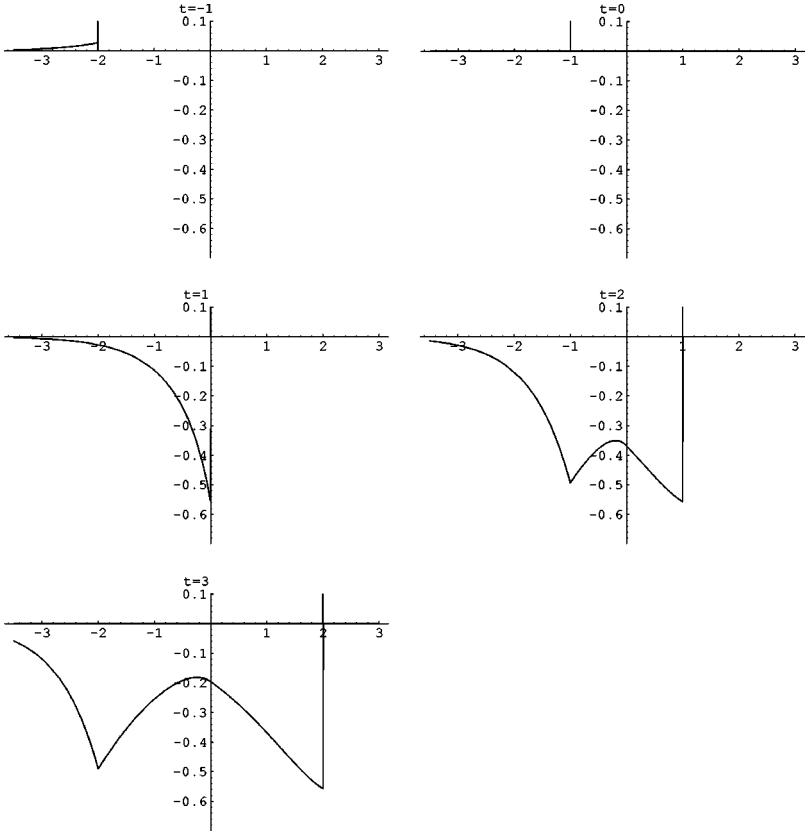

FIG. 5. The focusing wave of Example 8.1 with $x_0=-1$ is shown at $t=-1,0,1,2,3$.

Finally, we illustrate the recovery of $V(x_0)$ by using the technique described in Sec. VII utilizing (7.21).

Example 8.3: Consider the wave focusing for the potential

$$V(x)=-\frac{16c^2e^{2x}}{(2e^{2x}+c^2)^2}, \tag{8.2}$$

where $c>0$ is the bound-state norming constant. The corresponding scattering coefficients are $T(k)=(k+i)/(k-i)$, $L(k)=R(k)=0$, and the Jost solutions for $x\in\mathbf{R}$ are given by

$$f_{\rm l}(k,x)=e^{ikx}\left[1-\frac{2i}{k+i}\,\frac{c^2}{2e^{2x}+c^2}\right],\quad f_{\rm r}(k,x)=e^{-ikx}\left[1-\frac{4i}{k+i}\,\frac{e^{2x}}{2e^{2x}+c^2}\right].$$

Using (4.18) we get

$$U_{\rm l}(x,t;x_0)=\delta(x-x_0-t)+\theta(-x+x_0+t)\,\frac{4c^2e^{x+x_0}(e^t-e^{-t})}{(2e^{2x}+c^2)(2e^{2x_0}+c^2)}.$$

Hence,

$$\Upsilon_{\rm l}(x_0^-+t,t;x_0)=\frac{4c^2e^{t+x_0}(e^t-e^{-t})}{(2e^{2x_0}+c^2)(2e^{2(t+x_0)}+c^2)},$$

$$\lim_{t\to-\infty} \Upsilon_l(x_0^- + t, t; x_0) = -\frac{4e^{x_0}}{2e^{2x_0}+c^2}, \tag{8.3}$$

$$\frac{\partial \Upsilon_l(x_0^- + t, t; x_0)}{\partial x} = \frac{4c^2 e^{2x_0+t}(e^t - e^{-t})(c^2 - e^{2(t+x_0)})}{(2e^{2x_0}+c^2)(2e^{2(t+x_0)}+c^2)^2},$$

$$\lim_{t\to-\infty} \frac{\partial \Upsilon_l(x_0^- + t, t; x_0)}{\partial x} = \frac{4e^{2x_0}}{2e^{2x_0}+c^2}. \tag{8.4}$$

Since $\lim_{t\to-\infty} V(x_0+t)=0$, using (8.3) and (8.4) in (7.21), we can construct $V(x_0)$ explicitly, agreeing with its value obtained from (8.2).

IX. FOCUSING FOR THE VARIABLE-SPEED WAVE EQUATION

In this section we analyze focusing for the variable-speed wave equation given in (9.14) by using the corresponding results for (1.1).

Consider the generalized Schrödinger equation

$$\frac{d^2\psi(k,x)}{dx^2} + k^2 H(x)^2 \psi(k,x) = Q(x)\psi(k,x), \quad x \in \mathbf{R}, \tag{9.1}$$

where Q is real valued and belongs to $L^1_1(\mathbf{R})$, and H is bounded, strictly positive, $H-1 \in L^1(\mathbf{R})$, and $2HH''-3(H')^2 \in L^1_1(\mathbf{R})$. Via the Liouville transformation

$$y = y(x) := \int_0^x dz H(z), \quad \phi(k, y(x)) := \sqrt{H(x)}\,\psi(k,x), \tag{9.2}$$

we can transform (9.1) into the Schrödinger equation

$$\frac{d^2\phi(k,y)}{dy^2} + k^2\phi(k,y) = V(y)\phi(k,y), \quad y \in \mathbf{R}, \tag{9.3}$$

with

$$V(y) = V(y(x)) := \frac{Q(x)}{H(x)^2} + \frac{H''(x)}{2H(x)^3} - \frac{3H'(x)^2}{4H(x)^4}. \tag{9.4}$$

The aforementioned conditions on Q and H guarantee that V is real valued and belongs to $L^1_1(\mathbf{R})$, for which the direct and inverse scattering problems are well understood.

Let $f_l(k,x)$ and $f_r(k,x)$ denote the Jost solutions of (9.1) satisfying the boundary conditions (2.1) and (2.2), respectively. The scattering coefficients for (9.1) are obtained as in (2.3) and (2.4). For the analysis of the scattering and inverse scattering problems for (9.1), see, e.g., Aktosun *et al.* (1992a,b). It is known that the potential $V(y)$ has bound states if and only if $Q(x)$ has bound states. Since $H(x)$ is strictly positive, the mapping $x \mapsto y$ is one-to-one. Thus, for any x_0 there is a unique $y_0 := y(x_0)$, and conversely.

Let us denote the Jost solutions of (9.3) by $g_l(k,y)$ and $g_r(k,y)$, from the left and right, respectively. Let us use $\tau(k)$, $\rho(k)$, and $\ell(k)$ to denote the transmission coefficient and the reflection coefficients from the right and left, respectively, for (9.3). We have, see, e.g., Aktosun *et al.* (1992a),

$$g_l(k,y) = e^{-ikA_+}\sqrt{H(x)}\,f_l(k,x), \quad g_r(k,y) = e^{-ikA_-}\sqrt{H(x)}\,f_r(k,x), \tag{9.5}$$

$$\tau(k) = T(k)e^{ikA}, \quad \ell(k) = L(k)e^{2ikA_-}, \quad \rho(k) = R(k)e^{2ikA_+}, \tag{9.6}$$

where

$$A_{\pm} := \pm \int_0^{\pm\infty} dt[1-H(t)], \quad A := A_- + A_+ .$$

As seen from the first formula in (9.6) the bound states for (9.1) and (9.3) occur simultaneously at the same k-value on the positive imaginary axis, i.e., at the common poles of $T(k)$ and $\tau(k)$ in $\mathbf{C}^+$. We let N denote the number of bound states for (9.1) and let the bound states occur at $k = i\kappa_j$ with $0 < \kappa_1 < \cdots < \kappa_N$.

In terms of the Jost solutions of (9.3), as in (4.1) and (4.2), let us define

$$\tilde{K}_{\rm l}(y,t) := \frac{1}{2\pi} \int_{-\infty}^{\infty} dk[g_{\rm l}(k,y) - e^{iky}]e^{-ikt},$$

$$\tilde{K}_{\rm r}(y,t) := \frac{1}{2\pi} \int_{-\infty}^{\infty} dk[g_{\rm r}(k,y) - e^{-iky}]e^{ikt}.$$

As in (4.4) we have

$$\tilde{K}_{\rm l}(y,t) = 0, \quad t < y; \quad \tilde{K}_{\rm r}(y,t) = 0, \quad t > y.$$

For each fixed $y \in \mathbf{R}$, $\tilde{K}_{\rm l}(y,\cdot)$ and $\tilde{K}_{\rm r}(y,\cdot)$ belong to $L^2(\mathbf{R}) \cap L^1(\mathbf{R})$. They are discontinuous at $t = y$, and as in (4.5) the jumps there are related to V as

$$\tilde{K}_{\rm l}(y,y^+) = \frac{1}{2}\int_y^{\infty} dz V(z), \quad \tilde{K}_{\rm r}(y,y^-) = \frac{1}{2}\int_{-\infty}^{y} dz V(z).$$

Next we present the analog of Theorem 3.1 for (9.1).

Theorem 9.1: *Assume Q and H satisfy the conditions stated below (9.1). Then*

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dk T(k) f_{\rm l}(k,x)\, f_{\rm r}(k,x_0) + \sum_{j=1}^{N} \frac{\varphi_j(x)\varphi_j(x_0)}{H(x)H(x_0)} = \frac{\delta(x-x_0)}{H(x)H(x_0)}, \tag{9.7}$$

where $\varphi_j(x)$ are the normalized bound-state wave functions for (9.1) corresponding to the bound states at $k = i\kappa_j$ with $j = 1,\ldots,N$.

Proof: Using (9.5) and (9.6), from (3.6) we get

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dk \tau(k) g_{\rm l}(k,y) g_{\rm r}(k,y_0) + \sum_{j=1}^{N} \xi_j(y)\xi_j(y_0) = \delta(y-y_0), \tag{9.8}$$

where $\xi_j(y)$ are the normalized bound-state wave functions for (9.3). Using (9.5) and (9.6), we can write the first term on the left-hand side of (9.8) as

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dk \tau(k) g_{\rm l}(k,y) g_{\rm r}(k,y_0) = \frac{\sqrt{H(x)H(x_0)}}{2\pi}\int_{-\infty}^{\infty} dk T(k) f_{\rm l}(k,x) f_{\rm r}(k,x_0). \tag{9.9}$$

As in (2.5) and (2.7), for $j = 1,\ldots,N$ we have

$$\xi_j(y) = \frac{g_{\rm l}(i\kappa_j,y)}{\sqrt{\int_{-\infty}^{\infty} dz g_{\rm l}(i\kappa_j,z)^2}}, \quad \varphi_j(x) = \frac{H(x) f_{\rm l}(i\kappa_j,x)}{\sqrt{\int_{-\infty}^{\infty} dz H(z)^2 f_{\rm l}(i\kappa_j,z)^2}}. \tag{9.10}$$

With the help of (9.5) and (9.10), we see that $\xi_j(y)$ and $\varphi_j(x)$ are related to each other as

$$\xi_j(y)=\frac{\varphi_j(x)}{\sqrt{H(x)}}, \tag{9.11}$$

and thus the summation term on the left-hand side of (9.8) is expressed as

$$\sum_{j=1}^{N}\xi_j(y)\xi_j(y_0)=\sum_{j=1}^{N}\frac{\varphi_j(x)\varphi_j(x_0)}{\sqrt{H(x)H(x_0)}}. \tag{9.12}$$

Moreover, from $dy/dx=H(x)$ and the fact that $y=y_0$ if and only if $x=x_0$, we get

$$\delta(y-y_0)=\frac{\delta(x-x_0)}{\sqrt{H(x)H(x_0)}}. \tag{9.13}$$

Hence, using (9.9), (9.12), and (9.13) in (9.8), we obtain (9.7). ■

Using the Fourier transformation (1.3), we can transform (9.1) into the variable-speed wave equation

$$\frac{\partial^2 w(x,t)}{\partial x^2}-H(x)^2\frac{\partial^2 w(x,t)}{\partial t^2}=Q(x)w(x,t),\quad x,t\in\mathbf{R}, \tag{9.14}$$

where $1/H(x)$ corresponds to the variable wave speed. We are interested in wave focusing for (9.14); in other words, we would like to construct causal solutions to (9.14) incident either from the left or right such that they focus at time $t=0$ to any specified point x_0. In particular, we want to construct solutions to (9.14) satisfying $w(x,0)=\delta(x-x_0)/H(x_0)$.

Let us define

$$W_{\mathrm{l}}(x,t;x_0):=\frac{1}{2\pi}\int_{-\infty}^{\infty}dkT(k)f_{\mathrm{l}}(k,x)f_{\mathrm{r}}(k,x_0)e^{-ikt}+\sum_{j=1}^{N}\frac{\varphi_j(x)\varphi_j(x_0)}{H(x)H(x_0)}e^{\kappa_j t}, \tag{9.15}$$

$$W_{\mathrm{r}}(x,t;x_0):=\frac{1}{2\pi}\int_{-\infty}^{\infty}dkT(k)f_{\mathrm{r}}(k,x)f_{\mathrm{l}}(k,x_0)e^{-ikt}+\sum_{j=1}^{N}\frac{\varphi_j(x)\varphi_j(x_0)}{H(x)H(x_0)}e^{\kappa_j t}, \tag{9.16}$$

where φ_j are the normalized bound-state wave functions given in (9.10).

Theorem 9.2: Assume that Q and H satisfy the conditions stated below (9.1). Then W_{l} is a causal solution to (9.14) that is incident from the left and that focuses to $x=x_0$ when $t=0$. Similarly, W_{r} is a causal solution to (9.14) that is incident from the right and that focuses to $x=x_0$ when $t=0$.

Proof: Since $g_{\mathrm{l}}(k,y)$ is a solution to (9.3), with the help of (9.2), (9.10), and (9.11) we see that W_{l} defined in (9.15) is a solution to (9.14). Using (9.5), (9.6), and (9.12) in (9.15) we get

$$\sqrt{H(x)H(x_0)}W_{\mathrm{l}}(x,t;x_0)=\frac{1}{2\pi}\int_{-\infty}^{\infty}dk\tau(k)g_{\mathrm{l}}(k,y)g_{\mathrm{r}}(k,y_0)e^{-ikt}+\sum_{j=1}^{N}\xi_j(y)\xi_j(y_0)e^{\kappa_j t}. \tag{9.17}$$

By comparing the right-hand sides of (4.18) and (9.17) and applying Theorem 4.3, we see that the theorem is proved for W_{l}. The proof for W_{r} defined in (9.16) is similarly obtained. ■

We see from Theorem 9.2 that W_{l} consists of the wavefront $\delta(y-y_0-t)/\sqrt{H(x)H(x_0)}$ followed by a tail on the left and that it is incident from the left. Similarly, W_{r} consists of the wavefront $\delta(y-y_0+t)/\sqrt{H(x)H(x_0)}$ followed by a tail on the right and that it is incident from the right.

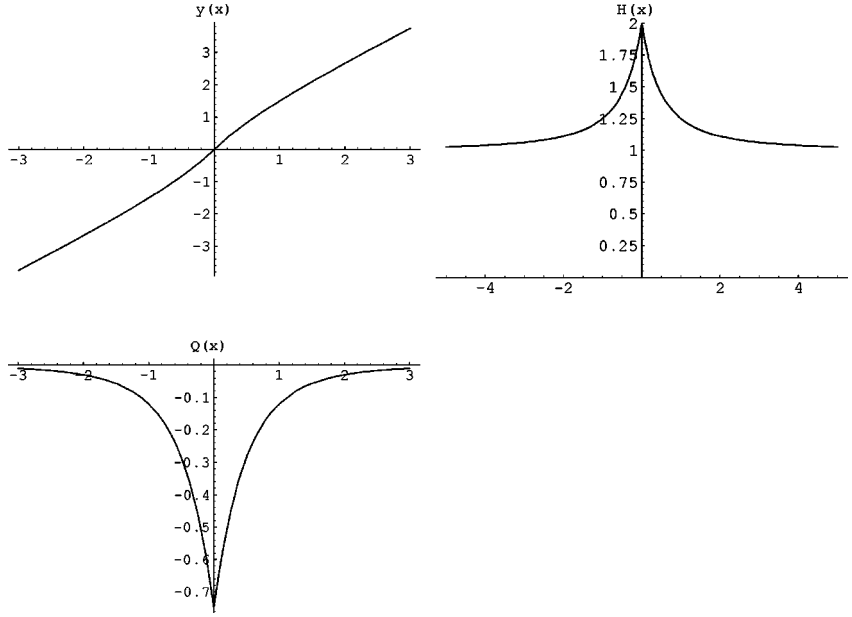

FIG. 6. The plots of $y(x)$, $H(x)$, and $Q(x)$ in Example 9.3.

The Marchenko equations associated with (9.1) were analyzed in Aktosun *et al.* (1992a). Using the results given in Secs. III and IV, it is possible to give various representations for W_l and W_r, similar to those in (4.22), (4.23), (5.13), (5.14), (5.17), and (5.18), and thus obtain the analogs of Theorems 4.5 and 5.3. We let the interested reader work out the details.

Next we present an example of focusing for (9.14).

Example 9.3: Consider

$$y(x)=\theta(-x)\left[x-1+\frac{1}{1-x}\right]+\theta(x)\left[x+1-\frac{1}{x+1}\right],$$

and hence

$$H(x)=\theta(-x)\,\frac{1+(1-x)^2}{(1-x)^2}+\theta(x)\,\frac{1+(1+x)^2}{(1+x)^2}.$$

Note that $H(x)$ is continuous, but $H'(x)$ has a discontinuity at $x=0$. Even though the focusing theory we outlined above is developed under the assumption that H'' exists, it can be extended in a straightforward manner when H'' contains some Dirac delta distributions. We have $H(0)=2$, $H'(0^+)=-2$, $H'(0^-)=2$, and hence H'' contains a delta distribution at $x=0$. Letting

$$Q(x)=\theta(-x)\,\frac{-3}{[1+(1-x)^2]^2}+\theta(x)\,\frac{-3}{[1+(1+x)^2]^2}, \tag{9.18}$$

from (9.4) we get $V(y)=-\delta(y)/2$. In Fig. 6 we show $y(x)$, $H(x)$, and $Q(x)$.

Using (9.5) and (9.6) we obtain

$$T(k)=\frac{4ke^{2ik}}{4k-i},\quad R(k)=\frac{4ie^{2ik}}{4k-i},\quad L(k)=\frac{4ie^{2ik}}{4k-i},$$

$$f_{\rm l}(k,x)=\begin{cases}\dfrac{e^{ik(y-1)}}{\sqrt{H(x)}}, & x\geqslant 0,\\ \left(1+\dfrac{1}{4ik}\right)\dfrac{e^{-ik(y+1)}}{\sqrt{H(x)}}-\dfrac{1}{4ik}\dfrac{e^{ik(y-1)}}{\sqrt{H(x)}}, & x\leqslant 0,\end{cases}$$

$$f_{\rm r}(k,x)=\begin{cases}\left(1+\dfrac{1}{4ik}\right)\dfrac{e^{-ik(y+1)}}{\sqrt{H(x)}}-\dfrac{1}{4ik}\dfrac{e^{ik(y-1)}}{\sqrt{H(x)}}, & x\geqslant 0,\\ \dfrac{e^{-ik(y+1)}}{\sqrt{H(x)}}, & x\leqslant 0.\end{cases}$$

Note that there is a bound state at $k=i/4$. Using (2.7) and (9.11) we get the normalized bound-state wave function as

$$\varphi(x)=\frac{\sqrt{H(x)}}{2}e^{-|y|/4}.$$

If the focusing point x_0 occurs in $[0,+\infty)$, with $y_0:=y(x_0)$ from (9.15) we get

$$W_{\rm l}(x,t;x_0)=\frac{\delta(y-y_0-t)}{\sqrt{H(x)H(x_0)}}+\frac{\theta(-x)w_-(x,t;x_0)+\theta(x)w_+(x,t;x_0)}{4\sqrt{H(x)H(x_0)}},$$

where

$$\begin{aligned}w_-(x,t;x_0):=&-\theta(-y+y_0+t)+\theta(y+y_0+t)+\theta(-y-y_0+t)-\theta(y-y_0+t)\\&+\theta(y-y_0+t)e^{(y-y_0+t)/4},\end{aligned}$$

$$w_+(x,t;x_0):=\theta(-y-y_0+t)e^{-(y+y_0-t)/4}.$$

It can directly be verified that $W_{\rm l}(x,0;x_0)=\delta(x-x_0)/[H(x)H(x_0)]$. This wave is illustrated in Fig. 7.

Now let us consider a slight modification of the above example.

Example 9.4: Suppose that $y(x)$ and hence $H(x)$ are as in Example 9.3. Let us assume that $Q(x)$ is given by

$$Q(x)=\delta(x)+\theta(-x)\frac{-3}{[1+(1-x)^2]^2}+\theta(x)\frac{-3}{[1+(1+x)^2]^2},$$

and hence differs from (9.18) by a delta distribution at $x=0$. From (9.4) it follows that $V(y)=0$ for all $y\in\mathbf{R}$, and hence $\tau(k)=1$ and $\rho(k)=\not{\ell}(k)=0$. Thus, we have a reflectionless case and there are no bound states. In this case, from (9.5) and (9.6) we get $T(k)=e^{2ik}$, $R(k)=L(k)=0$, and

$$f_{\rm l}(k,x)=\frac{e^{ik(y-1)}}{\sqrt{H(x)}},\quad f_{\rm r}(k,x)=\frac{e^{-ik(y+1)}}{\sqrt{H(x)}}.$$

Since Q contains a delta distribution, $f_{\rm l}'$ and $f_{\rm r}'$ are discontinuous in x at $x=0$. Using (9.15) we obtain

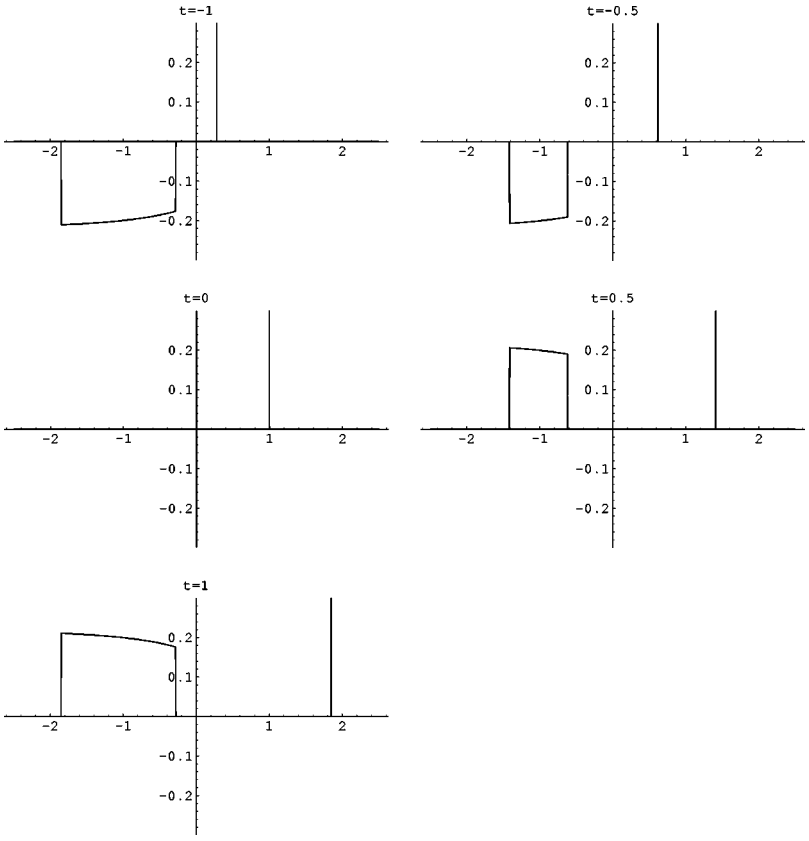

FIG. 7. The focusing wave of Example 9.3 with $x_0=1$ is shown at $t=-1,-0.5,0,0.5,1$.

$$W_1(x,t;x_0)=\frac{\delta(y-y_0-t)}{\sqrt{H(x)H(x_0)}}.$$

Thus, the wave W_1 is always focused, and there is no tail following the wave front due to the fact that there is no reflection.

We prove that the Frobenius–Perron operator U of the cusp map $F:[-1,1] \to [-1,1]$, $F(x)=1-2\sqrt{|x|}$ (which is an approximation of the Poincaré section of the Lorenz attractor) has no analytic eigenfunctions corresponding to eigenvalues different from 0 and 1. We also prove that for any $q \in (0,1)$ the spectrum of U in the Hardy space in the disk $\{z \in \mathbb{C}: |z-q|<1+q\}$ is the union of the segment $[0,1]$ and some finite or countably infinite set of isolated eigenvalues of finite multiplicity. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1483895]

I. INTRODUCTION

The so-called cusp map[1]

$$F:[-1,1]\to[-1,1], \quad F(x)=1-2\sqrt{|x|}$$

is an approximation of the Poincaré section of the Lorenz attractor.[2,3] This map is ergodic.[4] The unique absolutely continuous invariant probability measure μ has density $\rho(x)=(1-x)/2$.[1]

The Frobenius–Perron operator (F.P.O.) U of F is the adjoint of the Koopman operator V (Ref. 5) in the Hilbert space $L_2([-1,1],\mu)$:

$$Vf(x)=f(F(x)),$$

$$Uf(x)=\frac{1}{2}\left(1-\frac{(1-x)^2}{4}\right)f\left(\frac{(1-x)^2}{4}\right)+\frac{1}{2}\left(1+\frac{(1-x)^2}{4}\right)f\left(-\frac{(1-x)^2}{4}\right). \tag{1}$$

The spectral analysis of the F.P.O. in different function spaces is useful for the probabilistic approach to nonlinear dynamics. The spectrum of the F.P.O. known also as resonance spectrum gives estimates on the decay of correlation functions, see, e.g., Refs. 5–7. The spectral decomposition of the Koopman and Frobenius–Perron operators acquires meaning in locally convex topological spaces and allows for probabilistic prediction.[8–11]

[a)]Electronic mail: shkarin@math.uni-wuppertal.de
[b)]Electronic mail: eiarevsk@ulb.ac.be

The cusp map is not expanding.[6] In Refs. 12–14, the following family of maps depending analytically on the parameter $\varepsilon \in (0,1/2]$ is introduced and studied:

$$F_\varepsilon : [-1,1] \to [-1,1], \quad F_\varepsilon(x) = \frac{1-\sqrt{1-4\varepsilon(1-\varepsilon-2|x|)}}{2\varepsilon}, \quad \text{for } \varepsilon \in (0,\tfrac{1}{2}]. \tag{2}$$

This family consists of piecewise analytic expanding maps and has the cusp map as the limit case for $\varepsilon = \frac{1}{2}$. For any map (2), the spectrum of the F.P.O. in the space of C^∞ functions consists of a sequence of eigenvalues of finite multiplicity converging to 0, and the corresponding eigenfunctions are analytic.[15,6] The divergence of the eigenfunctions as the maps (2) approach the cusp map has been observed numerically.[13,14,16] These numerical results indicate that the F.P.O. (1) has no analytic eigenfunctions corresponding to eigenvalues different from 0 or 1. In the present article we give an analytic proof of this fact. Our result confirms the reliability of the numerical works.[13,14,16]

The spectral properties of the F.P.O. of piecewise analytic maps with one neutral fixed point (i.e., fixed point with derivative equal to 1; this is the point $x=-1$ for the cusp map) have been addressed by Rugh.[17] For each map satisfying certain properties, Rugh has constructed a map-dependent Banach space of functions, analytic everywhere except at the neutral fixed point. The spectrum of the Frobenius–Perron operator in this Banach space is the union of the segment $[0,1]$ and some isolated eigenvalues of finite multiplicity. However, Rugh's results do not specify the spectrum of the F.P.O. in the space of everywhere analytic functions. Moreover, the cusp map does not satisfy the properties of the class of maps considered by Rugh as a result of the cusp singularity. Nevertheless, we prove in this article that for any $q \in (0,1)$ the spectrum of the F.P.O. (1) in the usual Hilbert Hardy space in the disk $\{z \in \mathbb{C}: |z-q| < 1+q\}$ is the union of the segment $[0,1]$ and a finite or countable set of isolated eigenvalues of finite multiplicity.

The article is organized as follows. In Sec. II, we summarize in Theorems 1–4 our results about spectra of the operator U, and derive Theorems 1 and 2. We prove auxiliary lemmas in Sec. III, while the main proofs are presented in Secs. IV and V.

II. THE SPECTRUM OF THE F.P.O.

We shall use the following notations. $\mathcal{A}$ is the space of real-analytic functions $f:[-1,1]\to\mathbb{C}$ and $\mathcal{E}$ is the space of entire functions of one complex variable (endowed with their natural topologies[18]). $\mathcal{P}$ is the space of polynomials of one complex variable. As usual in algebra, we assume that the degree of zero polynomial is -1.

The spectral structure of the F.P.O. in the spaces $\mathcal{A}$ and $\mathcal{E}$ is given by the following two theorems.

Theorem 1: *The spectra of both operators $U_\mathcal{E} = U|_\mathcal{E}: \mathcal{E}\to\mathcal{E}$ and $U_\mathcal{A} = U|_\mathcal{A}: \mathcal{A}\to\mathcal{A}$ coincide with the whole complex plane.*

Theorem 2: *(I) The point spectra of both operators $U_\mathcal{E}$ and $U_\mathcal{A}$ coincide with the two-point set $\{0,1\}$. The eigenvalue 1 is simple and the eigenvalue 0 has infinite multiplicity for both operators.*

(II) Let $f \in \mathcal{A}$. Then $Uf \equiv 0$ if and only if $f(x) \equiv (1+x)g(x)$ for all $x \in [-1,1]$, where $g \in \mathcal{A}$ is odd.

(III) Let $\lambda \in \mathbb{C}$, $f \in \mathcal{A}$, $n \in \mathbb{N}$ and $(U-\lambda I)^n f = 0$ (where I is the identity operator).

(i) If $\lambda \notin \{0,1\}$, then $f=0$.
(ii) If $\lambda = 1$, then f is constant.

As we have already mentioned, Rugh's theorem[17] cannot be applied for the cusp map. Moreover, one cannot use the technique of Rugh's proof to prove a similar theorem for the cusp map. Indeed, the key element of Rugh's proof is a holomorphic function φ, defined in an open simply connected set, containing all points of the segment except the neutral fixed point such that $\varphi \circ \xi \circ \varphi^{-1}(z) \equiv z+1$, where ξ is a branch of the inverse map containing the neutral fixed point

[$\xi(z)=-(1-z)^2/4$ for the cusp map]. Such a map φ obviously does not exist if ξ' vanishes somewhere on the segment, which is the case for the cusp map since $\xi'(1)=0$. Nevertheless, using similar ideas but quite different technique, we prove that U has the spectral structure as in Rugh's theorem in appropriate Hardy spaces. The definitions of the Hardy spaces H^2 in the unit disk and in the upper half-plane $\{z:\mathrm{Im}\, z\geqslant 0\}$ can be found, e.g., in Ref. 19, Chaps. 3 and 8. These spaces are separable Hilbert spaces.

Theorem 3: *Let $q\in(0,1)$ and X be the Hardy space H^2 in the disk $\{z\in\mathbb{C}:|z-q|<1+q\}$. Then U is a bounded operator on the Hilbert space X and the spectrum of $U|_X:X\to X$ is the union of the segment $[0,1]$ and a finite or countable set of isolated eigenvalues of finite multiplicity.*

The proof of Theorem 3 is given in Sec. V. The Hardy spaces in any other disk or half-plane are the results of appropriate linear change of variables applied to the Hardy space in the unit disk or the upper half-plane.

For the sake of completeness we formulate here the following theorem proved in Ref. 16.

Theorem 4: *The spectrum of the operator $U|_X:X\to X$, where X is either $L_p([-1,1],\mu)$ $(1\leqslant p\leqslant+\infty)$ or $C^k[-1,1]$ $(k=0,1,\ldots,\infty)$, is the closed unit disk. The point spectrum of $U|_X$ is the set $\{z\in\mathbb{C}:|z|<1\}\cup\{1\}$. The eigenspace corresponding to the eigenvalue 1 is the one dimensional space of constants. The eigenspace corresponding to the eigenvalues $\{z:|z|<1\}$ is infinite dimensional.*

For the proof of Theorems 1 and 2 we need the following.

Proposition: (I) Let $\lambda\in\mathbb{C}\setminus\{0\}$, $g\in\mathcal{E}$, $f\in\mathcal{A}$ and

$$Uf(x)=\lambda f(x)+g(x), \tag{3}$$

for all $x\in[-1,1]$. Then $f\in\mathcal{E}$.

(II) If additionally $g\in\mathcal{P}$, then $f\in\mathcal{P}$ and $\deg f\leqslant\deg g+1$.

(III) If $g\in\mathcal{P}$ and $\deg g=4k+1$, $k=0,1,\ldots$, then the functional equation (3) has no solutions in $\mathcal{A}$.

The proof of the Proposition is given in Sec. IV.

Proof of Theorem 1: The number 0 is an eigenvalue of $U_{\mathcal{A}}$ and $U_{\mathcal{E}}$. For example, $Uf=0$ if $f(x)=(1+x)x$. Therefore, the number 0 belongs to the spectra of these operators. Let $\lambda\in\mathbb{C}\setminus\{0\}$. According to the proposition, the functional equation (3) has in the space $\mathcal{P}$ no solutions for g with degree of the form $4k+1$. Thus, the functional equation $Uf(x)=\lambda f(x)+x$ has no analytic solutions. Therefore, the function $g(x)=x$ does not belong to the image of the operator $U_{\mathcal{A}}-\lambda I$ (and to the smaller image of $U_{\mathcal{E}}-\lambda I$) for any $\lambda\in\mathbb{C}\setminus\{0\}$. Hence, operators $U_{\mathcal{A}}-\lambda I$ and $U_{\mathcal{E}}-\lambda I$ are non-invertible. Therefore the spectra of $U_{\mathcal{A}}$ and $U_{\mathcal{E}}$ coincide with the whole complex plane.

Proof of Theorem 2: Let $z\in\mathbb{C}\setminus\{0\}$, $c\in\mathbb{C}$ and $f\in\mathcal{A}$. The proposition implies that

$$\text{if } Uf-zf\equiv c, \quad \text{then } f \text{ is a constant.} \tag{4}$$

Let $\lambda\in\mathbb{C}$, $\lambda\neq 0$, $f\in\mathcal{A}$ and $(U-\lambda I)^n f=0$. Relation (4) implies consequently that the functions $h_1=(U-\lambda I)^{n-1}f$, $h_2=(U-\lambda I)^{n-2}f,\ldots,$ $h_{k-1}=(U-\lambda I)f$, $h_k=f$ are constants. In particular, $f\equiv a$ for some $a\in\mathbb{C}$. Since $U1=1$, we have that $0=(U-\lambda I)^n f=(1-\lambda)^n\cdot a$. Therefore either $\lambda=1$ or $f=0$. This proves part III of the theorem.

Let now $f\in\mathcal{A}$. According to (1), the equality $Uf=0$ can be written in the form

$$\left(1-\frac{(1-x)^2}{4}\right)f\left(\frac{(1-x)^2}{4}\right)+\left(1+\frac{(1-x)^2}{4}\right)f\left(-\frac{(1-x)^2}{4}\right)=0, \tag{5}$$

$x\in[-1,1]$. For $x=-1$ the equality (5) implies that $f(-1)=0$. Therefore $f(x)\equiv(1+x)g(x)$ for some $g\in\mathcal{A}$. Substituting $(1+x)g(x)$ instead of $f(x)$ into (5), we obtain

$$\left(1-\frac{(1-x)^4}{16}\right)\left(g\left(\frac{(1-x)^2}{4}\right)+g\left(-\frac{(1-x)^2}{4}\right)\right)=0 \tag{6}$$

for $x\in[-1,1]$. Denoting $y=(1-x)^2/4$, we arrive to $g(y)=g(-y)$ for $y\in[0,1)$. Hence, g is odd.

Suppose now that $f(x)\equiv(1+x)g(x)$ for odd $g\in\mathcal{A}$. This implies the validity of (6) and therefore (5), which is equivalent to $Uf=0$. Part II of the theorem is proved. Part I follows immediately from parts II and III. ■

III. ANALYTIC CONTINUATION OF EIGENFUNCTIONS

First, we introduce some notations, which we shall use in Secs. III and IV without additional comments. Let λ, g, and f be as in the proposition. For $z\in\mathbb{C}$ and $r\in(0,+\infty)$ we denote

$$D(z,r)=\{w\in\mathbb{C}:|w-z|<r\},\quad \overline{D}(z,r)=\{w\in\mathbb{C}:|w-z|\leqslant r\}.$$

By $\mathbb{C}_-$ we denote the set $\mathbb{C}\setminus(-\infty,0)$. We reserve the symbol $\sqrt{z}$ for the "positive" branch of the square root on the set $\mathbb{C}_-$, i.e., $\sqrt{z}=\sqrt{r}e^{i\varphi/2}$, where $z=re^{i\varphi}$, $-\pi<\varphi<\pi$.

For an infinite connected subset $A\subseteq\mathbb{C}$ we say that a function $\varphi:A\to\mathbb{C}$ is analytic if φ admits an analytic extension to some open set, containing A. In particular, $\mathcal{A}$ is the space of all functions analytic on $[-1,1]$. For a connected set $A\subseteq\mathbb{C}$ and a subset $B\subseteq A$, having at least one limit point in A, we say that a function $\varphi:B\to\mathbb{C}$ is analytic on A if φ admits a (unique) analytic extension on A. We shall also denote by φ the extension.

We shall show that the function f admits an analytic extension to the disk $D(0,2+\sqrt{3})$ in several steps.

Lemma 1: Let A and B be subsets of $\mathbb{C}$, $\varphi_1:A\to\mathbb{C}$ and $\varphi_2:B\to\mathbb{C}$ be analytic functions, and $M\subseteq A\cap B$ be a set having at least one limit point in $A\cap B$. Let also the set $A\cap B$ be connected and $\varphi_1|_M\equiv\varphi_2|_M$. Then the function

$$\varphi:A\cup B\to\mathbb{C},\quad \varphi(z)=\begin{cases}\varphi_1(z) & \text{if } z\in A;\\ \varphi_2(z) & \text{if } z\in B\end{cases}$$

is well defined and analytic on $A\cup B$.

Proof: Since M has a limit point in the connected set $A\cap B$, then according to the uniqueness theorem[20] $\varphi_1|_{A\cap B}\equiv\varphi_2|_{A\cap B}$. Therefore φ is well defined. Analyticity of φ follows from analyticity of φ_1 and φ_2. ■

Lemma 2: The analyticity of f on $\overline{D}(0,c)$ $(c\geqslant 1)$ implies the analyticity of f on $\overline{D}(0,c)\cup\overline{D}(1,2\sqrt{c})$.

Proof: Let f be analytic on $\overline{D}(0,c)$. Consider $h:\overline{D}(1,2\sqrt{c})\to\mathbb{C}$, $h(z)=(Uf(z)-g(z))/\lambda$. Clearly h is well defined and analytic. Since (3) is valid on $[-1,1]$, we have that $h(z)=f(z)$ for $z\in[-1,1]$. Lemma 1 implies that the function

$$q(y)=\begin{cases}f(y) & \text{if } y\in\overline{D}(0,c),\\ h(y) & \text{if } z\in\overline{D}(1,2\sqrt{c}),\end{cases}$$

is well defined and analytic on $\overline{D}(0,c)\cup\overline{D}(1,2\sqrt{c})$. This is the desired analytic extension of f. ■

Lemma 3: The function f is analytic on the closed disk $\overline{D}(1,2)$ and the functional equation (3) is valid for all $x\in\overline{D}(1,2)$.

Proof: It suffices to show that f is analytic on $\overline{D}(1,2)$ [the validity of the functional equation (3) for all $x\in\overline{D}(1,2)$ follows then from the uniqueness theorem[20]]. For this goal it suffices to show that f is analytic on $\overline{D}(0,1)$. Analyticity on $\overline{D}(1,2)$ then follows from Lemma 2. For $a\in(0,1]$ let

$$K_a=\{z\in\overline{D}(0,1):|\operatorname{Im} z|<a\},\quad \overline{K_a}=\{z\in\overline{D}(0,1):|\operatorname{Im} z|\leqslant a\}.$$

Suppose that f is not analytic on $\overline{D}(0,1)$. Let us denote

$$a=\sup\{b\in(0,1): f \text{ is analytic on } K_b\}.$$

Then $a\in(0,1]$, f is analytic on K_a and f is not analytic on $\overline{K_a}$.

Let $z\in\overline{K_a}$, $x=\operatorname{Re} z$, $y=\operatorname{Im} z$ and $w=(1-z)^2/4$. Since $|z|\leqslant 1$, we have that $|w|\leqslant(1+|z|)^2/4\leqslant 1$. Since $x^2+y^2\leqslant 1$ and $|y|\leqslant a$ we have that $|\operatorname{Im} w|=|(x-1)y|/2\leqslant a|x-1|/2$. Therefore $|\operatorname{Im} w|\leqslant a$. Moreover, $|\operatorname{Im} w|=a$ if and only if $x=-1$ and $|y|=a$. But then $|z|=\sqrt{1+a^2}>1$. Hence, $|\operatorname{Im} w|<a$. Thus, we have shown that

$$\pm(1-z)^2/4\in K_a \quad \text{for any} \quad z\in\overline{K_a}. \tag{7}$$

Formulas (7) and (1) imply that the function $h(z)=(Uf(z)-g(z))/\lambda$ is well defined and analytic on $\overline{K_a}$. The equation (3) implies that $f(x)=h(x)$ for $x\in[-1,1]$. Therefore h is an analytic continuation of f, i.e., f is analytic on $\overline{K_a}$. This contradiction completes the proof. ■

Lemma 4: (I) Let $c\in[2,+\infty)$, $z\in\overline{D}(-1,c)\setminus D(1,c)$. *Then* $1-2\sqrt{-z}\in\overline{D}(-1,c)$.

(II) Let $a\in[3,+\infty)$, $z\in\overline{D}(0,a)$, $\operatorname{Re} z\geqslant 0$. *Then* $w,u\in D(0,a)$, *where* $w=2\sqrt{z}-1$ *and* $u=z-w$.

Proof: (I) According to the maximum principle,[20] it suffices to show that

$$\sqrt{z}\in\overline{D}(1,c/2) \quad \text{for any} \quad z\in\partial M, \tag{8}$$

where ∂M is the boundary of the set $M=\{z\in\overline{D}(1,c):\operatorname{Re} z\geqslant 0\}$. Clearly (8) is equivalent to

$$\sqrt{z}\in\overline{D}(1,c/2) \quad \text{for any} \quad z\in\Gamma_1=\{it: t\in[-\sqrt{c^2-1},\sqrt{c^2-1}]; \tag{9}$$

$$\sqrt{z}\in\overline{D}(1,c/2) \quad \text{for any} \quad z\in\Gamma_2=\{z\in\mathbb{C}: |z-1|=c,\ \operatorname{Re} z\geqslant 0\}. \tag{10}$$

Parametrizing $z\in\Gamma_2$ by polar coordinates $z=re^{i\varphi}$, we obtain that (9) and (10) are equivalent to

$$\max\{t+1-\sqrt{2t}: t\in[0,\sqrt{c^2-1}]\}\leqslant c^2/4; \tag{11}$$

$$r+1\leqslant 2\sqrt{r}\cos(\varphi/2)+c^2/4 \ \text{ if } \ r^2-2r\cos\varphi=c^2-1, \quad \varphi\in[-\pi/2,\pi/2], \tag{12}$$

respectively. Since $r^2-2r\cos\varphi=c^2-1$, inequality from (12) is equivalent to

$$c^4/16+c^2(\sqrt{r}\cos(\varphi/2)-1)\geqslant 0.$$

As r and $\cos(\varphi/2)$ are decreasing with respect to $\varphi\in[0,\pi/2]$ and the function $t+1-\sqrt{2t}$ on the segment $[0,\sqrt{c^2-1}]$ takes the maximal value for $t=\sqrt{c^2-1}$, we obtain that inequalities (11) and (12) are respectively equivalent to

$$4\alpha^4-8\alpha^2+8\alpha-3\geqslant 0 \quad \text{for} \quad \alpha\in[(3/4)^{1/4},+\infty); \tag{13}$$

$$4\alpha^4+16\alpha-15\geqslant 0 \quad \text{for} \quad \alpha\in[(3/4)^{1/4},+\infty). \tag{14}$$

Since $4\alpha^4-8\alpha^2+8\alpha-3=(2\alpha^2+2\alpha-3)(2\alpha^2+2\alpha+1)$ and $4\alpha^4+16\alpha-15=(2\alpha^2+2\alpha-3)(2\alpha^2-2\alpha+5)$, the number $(\sqrt{7}-1)/2<(3/4)^{1/4}$ is the maximal real zero of both polynomials $4\alpha^4-8\alpha^2+8\alpha-3$ and $4\alpha^4+16\alpha-15$. This proves (13) and (14), which imply (8).

(II) We have to prove that $|w|<a$ and $|u|<a$. According to the maximum principle, it suffices to verify this for $z\in\Gamma$, where $\Gamma=\Gamma_1\cup\Gamma_2$, $\Gamma_1=\{it: t\in[-a,a]\}$ and $\Gamma_2=\{ae^{i\varphi}: \varphi\in[-\pi/2,\pi/2]\}$.

For $z\in\Gamma_1$ we have

$$|w|^2=4|t|-2\sqrt{2|t|}+1, \quad |u|^2=t^2-2\sqrt{2}|t|^{3/2}+4|t|-2\sqrt{2}|t|^{1/2}+1.$$

For $z \in \Gamma_2$ we have

$$|w|^2 = 4a + 1 - 4\sqrt{a}\cos(\varphi/2),$$

$$|u|^2 = a^2 - 4a^{3/2}\cos(\varphi/2) + 4a + 2a\cos\varphi - 4a^{1/2}\cos(\varphi/2) + 1.$$

Differentiating these functions with respect to t and φ, we find that both $|u|^2$ and $|w|^2$ for $z \in \Gamma_1$ are maximal when $t = \pm a$ and that both $|u|^2$ and $|w|^2$ for $z \in \Gamma_2$ are maximal when $\varphi = \pm \pi/2$. Thus, in any case,

$$|w|^2 \leqslant 4a - 2\sqrt{2a} + 1 \quad \text{and} \quad |u|^2 \leqslant a^2 - 2\sqrt{2}a^{3/2} + 4a - 2\sqrt{2}a^{1/2} + 1. \tag{15}$$

Hence, it suffices to verify that

$$a^2 - 4a + 2\sqrt{2a} - 1 > 0 \quad \text{and} \quad 2\sqrt{2}a^{3/2} - 4a + 2\sqrt{2}a^{1/2} - 1 > 0 \tag{16}$$

for $a \geqslant 3$. Both functions from (16) are increasing for $a \geqslant 3$. Hence, we should only prove (16) for $a = 3$, which is a simple arithmetic exercise. ■

Lemma 5: Let $c \in [2, +\infty)$. Then the analyticity of f on $\overline{D}(1,c)$ implies the analyticity of f on $\overline{D}(1,c) \cup \overline{D}(-1,c)$.

Proof: Let f be analytic on $\overline{D}(1,c)$. Pick $\varepsilon > 0$ such that f is analytic on $\overline{D}(1,c+\varepsilon)$ and let

$$\begin{gathered} S_0 = \overline{D}(1,c+\varepsilon) \cap (\overline{D}(1,c) \cup \overline{D}(-1,c)), \\ S_{n+1} = S_n \cup \{z \in \overline{D}(-1,c) : 1 - 2\sqrt{-z} \in S_n\} = S_n \cup (\{-(1-w)^2/4 : w \in S_n\} \cap \overline{D}(-1,c)). \end{gathered} \tag{17}$$

Evidently f is analytic on S_0. It is easy to see that S_n, $n = 0,1,2...$, is an increasing sequence of subsets of $\overline{D}(1,c) \cup \overline{D}(-1,c)$.

First, we shall show that analyticity of f on S_n implies analyticity of f on S_{n+1}. Let f be analytic on S_n. Consider the function $h : A_n \to \mathbb{C}$,

$$h(z) = \frac{1+z}{z-1} f(-z) + \frac{2\lambda}{1-z} f(1 - 2\sqrt{-z}) + \frac{2}{1-z} g(1 - 2\sqrt{-z}), \tag{18}$$

where $A_n = \{z \in \overline{D}(-1,c) : z \notin [0, +\infty), 1 - 2\sqrt{-z} \in S_n\}$. Clearly h is well defined and analytic. Moreover, from (3) and the definition of h it follows that $h|_{(-1,0)} = f|_{(-1,0)}$. Lemma 1 implies that the function

$$q : S_{n+1} = A_n \cup S_n \to \mathbb{C}, \quad q(z) = \begin{cases} f(z) & \text{if } z \in S_n, \\ h(z) & \text{if } z \in A_n, \end{cases}$$

is well defined and is an analytic extension of f to S_{n+1}. Therefore f is analytic on $\bigcup_{n=0}^{\infty} S_n$. It remains to show that

$$\overline{D}(1,c) \cup \overline{D}(-1,c) = \bigcup_{n=0}^{\infty} S_n. \tag{19}$$

From the definition of S_n, the point $z \in \overline{D}(-1,c) \setminus D(1,c+\varepsilon)$ belongs to $\bigcup_{n=0}^{\infty} S_n$, if and only if there exists $m \in \mathbb{N}$ such that $z_j \in \overline{D}(-1,c) \setminus D(1,c+\varepsilon)$ for $0 \leqslant j \leqslant m$ and $z_{m+1} \in S_0$, where

$$z_0 = z, \quad z_{j+1} = 1 - 2\sqrt{-z_j}. \tag{20}$$

Suppose that there exists $z\in\overline{D}(-1,c)\setminus D(1,c+\varepsilon)$ such that $z_n\in\overline{D}(-1,c)$ for all $n\in\mathbb{N}$. Let K be the closure of the set $\{z_n : n=0,1,\dots\}$. Then K is a closed subset of the compact set $A=\overline{D}(-1,c)\setminus D(1,c+\varepsilon)$, and $\varphi(K)\subseteq K$, where $\varphi(z)=1-2\sqrt{-z}$. Since $|\varphi'(u)|<1$ for any $u\in A$, $\varphi|_K : K\to K$ is a contraction. According to the contraction map theorem, there exists a fixed point of the map $\varphi|_K$. But the unique solution (in $\mathbb{C}\setminus[1,+\infty)$) of the equation $\varphi(w)=w$ is $w=-1\notin A$. This contradiction shows that for any $z\in\overline{D}(-1,c)\setminus D(1,c+\varepsilon)$ there exists the first positive integer m for which $z_m\notin\overline{D}(-1,c)\setminus D(1,c+\varepsilon)$. Then $z_{m-1}\in\overline{D}(-1,c)\setminus D(1,c+\varepsilon)$. According to Lemma 4 $z_m=1-2\sqrt{-z_{m-1}}\in\overline{D}(-1,c)\cap\overline{D}(1,c+\varepsilon)\subset S_0$. According to the description of the set $\bigcup_{n=0}^{\infty} S_n$, we have that $z\in\bigcup_{n=0}^{\infty} S_n$. This implies (19). ■

Lemma 6: The function f is analytic on the disk $D(0,2+\sqrt{3})$.

Proof: Let $c_0=1$, $c_{n+1}=\sqrt{4c_n-1}$ for $n=1,2,\dots$. This sequence strictly increases and converges to $2+\sqrt{3}$. From Lemma 3 it follows that f is analytic on $\overline{D}(0,c_0)$. According to Lemmas 2 and 5, analyticity of f on $\overline{D}(0,c_n)$ implies analyticity of f on $\overline{D}(1,2\sqrt{c_n})\cup\overline{D}(-1,2\sqrt{c_n})\supset\overline{D}(0,c_{n+1})$. Therefore f is analytic on $\overline{D}(0,c_n)$ for any $n=0,1,\dots$. Hence, f is analytic on the set $\bigcup_{n=0}^{\infty}\overline{D}(0,c_n)=D(0,2+\sqrt{3})$. ■

IV. PROOF OF THE PROPOSITION

(I) Without loss of generality we can assume that $g(-1)=0$ and $f(-1)=0$. If this is not the case, we can achieve these conditions just by adding suitable constants to f and g. Therefore $f(x)=\varphi(x)(1+x)$, $g(x)=\psi(x)(1+x)$ and $\psi\in\mathcal{E}$, $\varphi\in\mathcal{A}$. Moreover, analyticity of f on a connected set $A\supset[-1,1]$ implies analyticity of φ on the same set A. Let

$$\begin{aligned} f_0(x)&=(\varphi(x)+\varphi(-x))/2,\quad f_1(x)=(\varphi(x)-\varphi(-x))/2;\\ g_0(x)&=(\psi(x)+\psi(-x))/2,\quad g_1(x)=(\psi(x)-\psi(-x))/2. \end{aligned} \tag{21}$$

Then $g_0,g_1\in\mathcal{E}$, $f_0,f_1\in\mathcal{A}$. The analyticity of f on a connected symmetric (with respect to 0) set $A\supset[-1,1]$ implies the analyticity of f_0,f_1 on the same set. Thus, according to Lemma 6 f_0 and f_1 are analytic on $D(0,2+\sqrt{3})$.

Evidently f_0,g_0 are even, f_1,g_1 are odd and

$$f(x)=(1+x)(f_0(x)+f_1(x)),\quad g(x)=(1+x)(g_0(x)+g_1(x)). \tag{22}$$

From (3) and (22) it follows that

$$\left(1-\frac{(1-x)^4}{16}\right)f_0\left(\frac{(1-x)^2}{4}\right)=\lambda(1+x)(f_0(x)+f_1(x))+(1+x)(g_0(x)+g_1(x))$$

for any $x\in[-1,1]$. Dividing by $(1+x)$ we obtain

$$\frac{1}{16}(15-11x+5x^2-x^3)f_0\left(\frac{(1-x)^2}{4}\right)=\lambda(f_0(x)+f_1(x))+g_0(x)+g_1(x). \tag{23}$$

Adding (23) for x with (23) for $-x$ we obtain that for any $x\in[-1,1]$,

$$\frac{1}{32}(15-11x+5x^2-x^3)f_0\left(\frac{(1-x)^2}{4}\right)+\frac{1}{32}(15+11x+5x^2+x^3)f_0\left(\frac{(1+x)^2}{4}\right)=\lambda f_0(x)+g_0(x). \tag{24}$$

Let us prove that $f_0 \in \mathcal{E}$. Suppose that $f_0 \notin \mathcal{E}$. Since f_0 is analytic on $D(0,2+\sqrt{3})$, there exists $a \in [2+\sqrt{3}, +\infty)$ such that f_0 is analytic on $D(0,a)$ and is not analytic on $\overline{D}(0,a)$. Since f_0 is even, we have that f_0 is not analytic on the set $B=\{z \in \overline{D}(0,a): z \neq 0, \mathrm{Re}\, z \geqslant 0\}$. According to Lemma 4, $x=2\sqrt{y}-1 \in D(0,a)$ and $y-x \in D(0,a)$ for any $y \in B$. Since $15+11x+5x^2+x^3 \neq 0$ for $y \in B$, the function

$$h(y)=\frac{(x^3-5x^2+11x-15)f_0(y-x)+32\lambda f_0(x)+32g_0(x)}{15+11x+5x^2+x^3},$$

where $x=x(y)=2\sqrt{y}-1$, is well defined and analytic on B. On the other hand, (24) and the definition of h imply that $h(x)=f(x)$ for all $x \in (0,1)$. The uniqueness theorem implies that h is an analytic extension of f_0 from $(0,1]$ to B, which does not exist. This contradiction proves that $f_0 \in \mathcal{E}$.

From (23) it follows that

$$f_1(x)=\frac{1}{16\lambda}(15-11x+5x^2-x^3)f_0\left(\frac{(1-x)^2}{4}\right)-f_0(x)-\frac{1}{\lambda}(g_0(x)+g_1(x)). \tag{25}$$

Therefore $f_1 \in \mathcal{E}$. Formula (22) implies that f is entire and part I is proved.

(II) Let $g \in \mathcal{P}$. We have to prove that $f \in \mathcal{P}$. According to (21) $g_0, g_1 \in \mathcal{P}$. Let $k=\deg g_0$ if $g_0 \not\equiv 0$ and $k=0$ if $g_0 \equiv 0$. Let us show that $f_0 \in \mathcal{P}$ and $\deg f_0 \leqslant k/2-1$.

The functional equation (24) can be rewritten in the form

$$f_0\left(\frac{(1+x)^2}{4}\right)=\frac{32\lambda f_0(x)}{x^3+5x^2+11x+15}+\frac{32g_0(x)}{x^3+5x^2+11x+15}+\frac{x^3-5x^2+11x-15}{x^3+5x^2+11x+15}f_0\left(\frac{(1-x)^2}{4}\right). \tag{26}$$

Since f_0 is even

$$M(R)=\max_{|x|=R}|f_0(x)|=\max_{|x|=R,\ \mathrm{Re}\, x \geqslant 0}|f_0(x)|. \tag{27}$$

Let $y \in \mathbb{C}$, $|y|=R$, $\mathrm{Re}\, y \geqslant 0$, $x=2\sqrt{y}-1$, $w=y-x$. Then $|x|=2\sqrt{R}+O(1)$ and

$$|w|=|y|\left|1-\frac{y}{x}\right|=R\left|1-\frac{2}{\sqrt{y}}+\frac{1}{y}\right|=R\left|1-\frac{2}{\sqrt{y}}\right|+O(1).$$

All O-symbols are considered here for $R \to \infty$. The number $|1-(2/\sqrt{y})|$ for $|y|=R$, $\mathrm{Re}\, y \geqslant 0$, is maximal for $y=\pm Ri$. Therefore,

$$|w| \leqslant R\left|1-\frac{\sqrt{2}(1+i)}{\sqrt{R}}\right|+O(1)=R-\sqrt{2R}+O(1)$$

and

$$|w|<R-\sqrt{R}, \quad |x|=2\sqrt{R}+O(1)<R-\sqrt{R} \tag{28}$$

for sufficiently large R. Formula (26) implies that

$$f_0(y)=\frac{32\lambda f_0(x)}{x^3+5x^2+11x+15}+\frac{32g_0(x)}{x^3+5x^2+11x+15}+\frac{x^3-5x^2+11x-15}{x^3+5x^2+11x+15}f_0(w). \tag{29}$$

Note that

$$\left|\frac{x^3-5x^2+11x-15}{x^3+5x^2+11x+15}\right|=\left|1-\frac{10}{x}+O\left(\frac{1}{x^2}\right)\right|=\left|1-\frac{5}{\sqrt{y}}\right|+O(R^{-1}).$$

The number $|1-(5/\sqrt{y})|$ for $|y|=R$, $\operatorname{Re} y\geqslant 0$, is maximal for $y=\pm Ri$. Therefore,

$$\left|\frac{x^3-5x^2+11x-15}{x^3+5x^2+11x+15}\right|\leqslant 1-\frac{5}{\sqrt{2R}}+O(R^{-1}). \tag{30}$$

Formulas (29), (27), (28) and (30) imply that

$$M(R)\leqslant M(R-\sqrt{R})\left(1-\frac{5}{\sqrt{2R}}+O(R^{-1})\right)+O(R^{(k-3)/2}).$$

If f_0 is a polynomial of degree at most $k/2-1$, we have proved the statement. Otherwise $R^{k/2}=O(M(R))$. Hence $R^{(k-3)/2}=O(M(R-\sqrt{R})/R)$, and

$$M(R)\leqslant M(R-\sqrt{R})\left(1-\frac{5}{\sqrt{2R}}+O(R^{-1})\right). \tag{31}$$

Therefore $M(R)\leqslant M(R-c\sqrt{R})$ for sufficiently large R. Hence $M(R)=O(1)$ and f_0 is a constant according to the Liouville theorem.[20] Hence $M(R)$ is constant. Formula (31) implies then that $M(R)\equiv 0$. Therefore, $f_0\equiv 0$ and $k=0$ according to (26). Thus, anyway $f_0\in\mathcal{P}$ and $\deg f_0\leqslant k/2-1$.

From (25) we find that $f_1\in\mathcal{P}$ and

$$\deg f_1\leqslant\max\{k+1,\deg g_1\}.$$

Then using (22) we find that $f\in\mathcal{P}$ and $\deg f\leqslant\deg g+1$.

(III) Suppose that $g\in\mathcal{P}$ and $f\in\mathcal{A}$ satisfies (3). According to part II of the Proposition $f(x)=\Sigma_{k=0}^{n}a_kx^k$, $a_n\neq 0$. If n is odd, then according to (1) $\deg Uf=2n+2$ and $\deg g=\deg(Uf-\lambda f)=2n+2$ is even. If n is even and $n\neq\deg Uf$, then $\deg g=\max\{\deg f,\deg Uf\}$ is even. It remains to consider the case $\deg Uf=n$. Since $\deg Uf$ is always a multiple of 4, we have that $n=4m$, $m=0,1,\ldots$. According to (1)

$$Uf(x)=\sum_{l=1}^{2m}(a_{2l}-a_{2l-1})2^{-4l}(1-x)^{4l}+a_0. \tag{32}$$

Since $\deg Uf=4m$ we have that $a_{2l}=a_{2l-1}$ if $m<l\leqslant 2m$ and $a_{2m}\neq a_{2m-1}$. Substituting (32) into (3) and taking these relations into account, we obtain that $\deg g=4m$ or $\deg g=4m-1$. In any case $\deg g$ does not have form $4j+1$.

V. PROOF OF THEOREM 3

We start with two lemmas.

Lemma 7: Let $q\in(0,1)$ *and* $z\in\overline{D}(q,1+q)$. *Then* $(1-z)^2/4\in D(q,1+q)$.

Proof: We have to prove that

$$|(z-1)^2-4q|<4+4q. \tag{33}$$

Since $z\in\overline{D}(q,1+q)$, we find that $z=q+(1+q)u$, where $|u|\leqslant 1$. Obviously (33) is equivalent to

$$|1-6q+q^2-2(1-q^2)u+(1+2q+q^2)u^2|<4+4q. \tag{34}$$

If $1-6q+q^2\geqslant 0$, we have

$$|1-6q+q^2-2(1-q^2)u+(1+2q+q^2)u^2|\leqslant 1-6q+q^2+2(1-q^2)+(1+2q+q^2)$$
$$=4-4q<4+4q.$$

If $1-6q+q^2<0$, we have

$$|1-6q+q^2-2(1-q^2)u+(1+2q+q^2)u^2|\leqslant -1+6q-q^2+2(1-q^2)+(1+2q+q^2)$$
$$=4+4q-2(1-q)^2<4+4q.$$

■

Lemma 8: Let $\mathcal{H}$ be the Hardy space H^2 in the upper half-plane $\Pi=\{z\in\mathbb{C}:\mathrm{Re}\,z>\alpha\}$, $\alpha\in\mathbb{R}$, $\nu,\varphi:\overline{\Pi}\to\mathbb{C}$ be bounded analytic functions and $c,\varepsilon\in(0,+\infty)$ be such that

$$\mathrm{Re}\,\varphi(z)\geqslant\varepsilon \quad for\ \ all\ \ z\in\Pi; \tag{35}$$

$$\int_{-\infty}^{+\infty}|\nu(\alpha+is)|^2\,ds\leqslant A<\infty; \qquad \int_{-\infty}^{+\infty}|\varphi(\alpha+is)-c|^2\,ds\leqslant A<\infty. \tag{36}$$

Then the operator $S:\mathcal{H}\to\mathcal{H}$, $Sf(z)=(1+\nu(z))f(z+\varphi(z))$ is the sum of two operators A and B, where A is bounded, self-adjoint and has purely absolutely continuous spectrum $[0,1]$ and B is a Hilbert–Schmidt operator.

Proof: Without loss of generality we assume $\alpha=0$. According to the Paley–Wiener theorem (Ref. 19, Chap. 8), the Laplace transform

$$Lg(z)=\frac{1}{\sqrt{2\pi}}\int_0^{\infty}e^{-zt}g(t)\,dt$$

is a unitary operator from $L_2[0,+\infty)$ onto $\mathcal{H}$.

Let $\mathcal{D}_+$ be the subspace of $L_2[0,+\infty)$, consisting of infinitely differentiable functions with compact support lying in $(0,+\infty)$. Consider the operator $\widetilde{S}=L^{-1}SL:L_2[0,+\infty)\to L_2[0,+\infty)$. Using the standard formula for the inverse Laplace transform we obtain that

$$\widetilde{S}g(t)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\int_0^{+\infty}g(\tau)e^{is(t-\tau)}e^{-\varphi(is)\tau}(1+\nu(is))\,d\tau\,ds$$

for any $g\in\mathcal{D}_+$. Therefore,

$$\widetilde{S}g(t)=g(t)e^{-ct}+\int_0^{+\infty}g(\tau)K(\tau,t)\,d\tau, \tag{37}$$

where

$$K(\tau,t)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}e^{is(t-\tau)}[e^{-\varphi(is)\tau}(1+\nu(is))-e^{c\tau}]\,ds.$$

The existence of the last integral (in the principle value sense) for any τ and almost all t, follows from the Plancherel theorem, since formula (36) implies square integrability, with respect to s, of the function $e^{-is\tau}[e^{-\varphi(is)\tau}(1+\nu(is))-e^{c\tau}]$.

According to the Parseval identity and using formulas (35) and (36), we obtain

$$\int_{-\infty}^{+\infty}|K(\tau,t)|^2dt=\frac{1}{2\pi}\int_{-\infty}^{+\infty}|e^{-\varphi(is)\tau}(1+\nu(is))-e^{c\tau}|^2ds$$

$$\leqslant\frac{e^{-2\tau\varepsilon}}{\pi}\int_{-\infty}^{+\infty}(|e^{-(\varphi(is)-\varepsilon)\tau}-e^{(c+\varepsilon)\tau}|^2+|e^{-(\varphi(is)-\varepsilon)\tau}\nu(is)|^2)\,ds$$

$$\leqslant\frac{e^{-2\tau\varepsilon}}{\pi}\int_{-\infty}^{+\infty}(\tau^2|\varphi(is)-c|^2+|\nu(is)|^2)\,ds$$

$$\leqslant\frac{Ae^{-2\tau\varepsilon}(\tau^2+1)}{\pi}.$$

According to Fubini's theorem

$$\int_0^{+\infty}\int_0^{+\infty}|K(\tau,t)|^2dtd\tau\leqslant\int_0^{+\infty}\int_{-\infty}^{+\infty}|K(\tau,t)|^2dtd\tau\leqslant\frac{A}{\pi}\int_0^{+\infty}e^{-2\tau\varepsilon}(\tau^2+1)\,d\tau<+\infty.$$

Therefore, $K\in L_2([0,+\infty)^2)$. Since $\mathcal{D}_+$ is dense in $L_2[0,+\infty)$, formula (37) is valid for any $g\in L_2[0,+\infty)$. Therefore, $\widetilde{S}=\widetilde{A}+\widetilde{B}$, where

$$\widetilde{A}g(t)=g(t)e^{-ct}\quad\text{and}\quad\widetilde{B}g(t)=\int_0^{+\infty}g(\tau)K(\tau,t)\,d\tau,$$

the operator $\widetilde{A}$ is bounded, self-adjoint and has purely absolutely continuous spectrum $[0,1]$, and the operator $\widetilde{B}$ is a Hilbert–Schmidt operator. It remains to note that operators S and $\widetilde{S}$ are unitarily equivalent. ■

Now we can prove Theorem 3. Evidently $U=U^0+U^1$, where

$$U^0f(x)=\frac{1}{2}\left(1+\frac{(1-x)^2}{4}\right)f\left(-\frac{(1-x)^2}{4}\right),\tag{38}$$

$$U^1f(x)=\frac{1}{2}\left(1-\frac{(1-x)^2}{4}\right)f\left(\frac{(1-x)^2}{4}\right).\tag{39}$$

According to Lemma 7, there exists a $r>1+q$ such that for any $f\in X$ the function U^1f admits an analytic extension to $\overline{D}(q,r)$. Let X_r be the Hardy space in the disk $D(q,r)$. Then formula (39) defines a bounded linear operator U_r^1 from X to X_r. The operator $U_X^1:X\to X$ is the superposition of U_r^1 and the identity embedding J of X_r into X. Since the operator J is nuclear [J has the s-numbers $(1+q)^nr^{-n}$)], we find that $U_X^1=U^1|_X:X\to X$ is also nuclear and therefore compact.

Let $\mathcal{H}$ be the Hardy space in the upper half-plane $\{z\in\mathbb{C}:\mathrm{Re}\,z>(1+q)^{-1}\}$. One can easily verify that the operator $M:X\to\mathcal{H}$,

$$Mf(z)=\frac{1}{z}f\left(\frac{2}{z}-1\right),\tag{40}$$

is unitary up to a multiplication on a positive constant. Then the operators U_X^0 and $W^0=MU^0M^{-1}:\mathcal{H}\to\mathcal{H}$ are unitarily equivalent.

From the definitions of (38) and (40) we obtain that

$$M^{-1}f(z)=\frac{2}{z+1}g\left(\frac{2}{z+1}\right)\quad\text{and}\quad W^0f(z)=(1+\nu(z))f(z+\varphi(z)),$$

where

$$\nu(z)=\frac{1-z}{2z^2-z} \quad \text{and} \quad \varphi(z)=\frac{1}{2}+\frac{1}{4z-2}.$$

One can easily verify that φ and ν satisfy all conditions of Lemma 8 with $\varepsilon=c=\frac{1}{2}$. According to Lemma 8, W^0 is a sum of a self-adjoint operator with the purely absolutely continuous spectrum $[0,1]$ and a Hilbert–Schmidt operator. Since U_X^0 and W^0 are unitarily equivalent and U_X^1 is nuclear, we have that U_X is a sum of a self-adjoint operator with purely absolutely continuous spectrum $[0,1]$ and a Hilbert–Schmidt operator. Following Ref. 21, we say that $z\in\mathbb{C}$ is a normal point of a bounded linear operator on a separable Hilbert space if either z is a regular point or z is an isolated eigenvalue of finite multiplicity. According to Theorem 5.2 of Chap. 1 in Ref. 21, for any bounded self-adjoint operator A and any compact operator B acting on the same Hilbert space, the sets of normal points of A and $A+B$ coincide. It remains to apply this theorem. ■

VI. CONCLUDING REMARKS

(1) So far there exist very few results on the spectral properties of the F.P.O. of the maps with parabolic neutral fixed points. We would like to point out the result of H. Rugh,[17] who considered the F.P.O. of piecewise analytic maps, which are expanding everywhere except one parabolic fixed point. Namely, he constructed a specific map-dependent Banach space of analytic functions, where the spectrum of the F.P.O. consists of the segment $[0,1]$ and some isolated normal eigenvalues. This space is in fact the image of $L_1[0,+\infty)$ with respect to some map-dependent integral transformation similar to the Laplace transform.

The cusp map does not satisfy the conditions of Rugh's theorem because of the cusp-shaped singularity. Nevertheless, we proved that the F.P.O. of the cusp map has similar spectral properties in the Hardy spaces H^2 in the disks $D(q,1+q)$, $0<q<1$. We also conjecture that the spectrum of the F.P.O. U of the cusp map in the Hardy spaces H^2 in the disks $D(q,1+q)$, $0<q<1$ is precisely the segment $[0,1]$, i.e., the set of isolated eigenvalues of U is empty. Note that the functions of these Hardy spaces as well as the functions of Rugh's spaces are analytic in all points of the segment except at the parabolic fixed point ($x=-1$ in the case of the cusp map). However, we should notice that the spectrum of the F.P.O. of a map S in spaces of analytic functions with singularity at a fixed point of S may differ considerably from the spectrum in spaces of everywhere analytic functions. We have proved that this is precisely the case for the cusp map.

(2) The theory of the point spectrum for the maps has been recently developed in terms of locally convex topological vector spaces.[9] For different classes of observables the same evolution law may have different resonances, i.e., different rates of approach to equilibrium. However, once the class of observables is chosen, the resonance structure is unique.[9,10] In terms of the assumptions of Ref. 9, the admissible point spectra for a given map are described. Here we see that for the cusp map, we have continuous spectra in Hardy spaces. This type of spectra was not addressed in Ref. 9.

(3) We would like also to notice that Theorems 1 and 2 remain valid if one replaces the F.P.O. (1) of the cusp map by some positive transfer operator[6] of the cusp map, for example,

$$\tilde{U}f(x)=\frac{1}{2}f\left(\frac{(1-x)^2}{4}\right)+\frac{1}{2}f\left(-\frac{(1-x)^2}{4}\right).$$

Of course, Theorems 1 and 2 do not remain valid for all positive transfer operators in the class considered in Ref. 6. For example, let us consider the operator

$$Wf(x)=\left(\frac{1}{2}-\beta+\frac{a(x)}{4}\right)f(a(x))+\left(\frac{1}{2}+\beta-\frac{a(x)}{4}\right)f(-a(x)),$$

where $a(x)=(1-x)^2/4$. For the real parameter $\beta\in[-\frac{1}{4},\frac{1}{2}]$, this is a positive transfer operator for the cusp map, and $W1=1$. On the other hand, the function

$$f(x)=x-\frac{x^2}{2}+\frac{\beta}{2(1-\beta)}$$

is the eigenfunction of W corresponding to the eigenvalue β: $Wf=\beta f$. Hence Theorems 1 and 2 are not valid for the operator W.

(4) We do not consider Hardy spaces H^p, $p\neq 2$, although Theorem 3 can be generalized for such spaces. In order to do this, one has to generalize results of Chap. 1 of Ref. 21 for arbitrary continuous linear operators on Banach spaces. This can be done with minor modifications in proofs.[21]

(5) There are few questions which remain open for the cusp map. First, the question about the asymptotics of the autocorrelation function. As the eigenvalues of the F.P.O. of the family (2) tend to unity when $\varepsilon\to\frac{1}{2}$, one can expect nonexponential decrease of the autocorrelation function. The estimations in Ref. 14 show that the autocorrelation function $C(n)$ decreases as $1/n$, when $n\to\infty$. However, this conjecture has not yet been analytically proven. Another question addresses the choice of the space of analytic functions where the spectrum of the F.P.O. is naturally defined by the dynamics of the map.

(Received 2 November 2001; accepted for publication 7 February 2002)

A new formula relating the analytic continuation of the Hurwitz zeta function to the Euler gamma function and a polylogarithmic function is presented. In particular, the values of the first derivative of the real part of the analytic continuation of the Hurwitz zeta function for even negative integers and the imaginary one for odd negative integers are explicitly given. The result can be of interest both on mathematical and physical side, because we are able to apply our new formulas in the context of the spectral zeta function regularization, computing the exact pair production rate per space–time unit of massive Dirac particles interacting with a purely electric background field. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1481976]

I. INTRODUCTION

In 1951, Schwinger[1] computed the implicit effective Lagrangian for a Dirac charged spinor in a general electromagnetic background field using proper time approach. In particular, he applied the result to the physical case of a constant and uniform electric background and he was able to evaluate the exact pair-production rate per space–time unit, namely

$$w(E,e,m)=\frac{e^2E^2}{4\pi^3}\sum_{n=1}^{+\infty}\frac{e^{-n\,\pi m^2/eE}}{n^2}. \tag{1}$$

This result is well known and can be obtained by other ways (e.g., Itzykson and Zuber,[2] using the S-matrix approach, and by Beneventano and Santangelo[3]). In 1990 Blau *et al.*,[4] using the techniques of the spectral zeta function regularization, tried to obtain the same results obtained by Schwinger. However, they were able only to obtain nonexact results for the four dimensional case, using asymptotic analysis. In 1996, Soldati and Sorbo[5] obtained a new expression, but once again their methods were based on asymptotic analysis and the results were expressed in terms of asymptotic series.

The problem for general electromagnetic external field has been recently discussed by Schubert[6] and by Cho and Pak.[7] Schubert obtained the same action by Schwinger using proper time method and techniques of computation inspired by string theory. Cho and Pak obtained a renormalized action from the general one (non-renormalized) found by Schwinger, using the so-called Sitacaramachandrarao identity. Recently, Beneventano and Santangelo[8] have compared their results obtained using spectral zeta function methods with the general result obtained by Schwinger, showing that they agree.

In this article, we shall compute the imaginary part of the effective Lagrangian related to a Dirac field in a constant and uniform external electric field by making use of new formulas

a)Electronic mail: adesi@science.unitn.it
b)Author to whom correspondence should be addressed. Electronic mail: zerbini@science.unitn.it

concerning the analytic continuation of the first derivative of the Hurwitz zeta function.

The content of the article is the following. In Sec. II, we briefly introduce the spectral zeta function regularization procedure and illustrate the result obtained by Blau *et al.,* which will be our starting point for the application of the new formulas. In Sec. III, we derive a new expression for the analytic continuation of the Hurwitz zeta function, viewed as an analytic function of two complex variables. In Sec. IV, we use that result to recover the rate of pair creation of Dirac particles in constant and uniform electric background.

II. ZETA FUNCTION REGULARIZATION

In this section, we shall review the relation between the mathematical problem that we have solved and the physical problem associated with the Dirac pair creation. For a review of the method, see, for example, Refs. 9–11 and references quoted therein.

Within the context of quantum field theory (QFT) interacting with a classical gauge background field, one is forced to confront with the determinants of differential operators.
In the context of a Klein Gordon field interacting with an external gauge field A, this determinant is related to some physical quantities formally obtained from the *Euclidean* functional integral:

$$Z[A_E]=\int D\varphi e^{-(1/2)\int d^4x\varphi A_E\varphi}, \tag{2}$$

where A_E is the Euclidean Klein Gordon operator. In the definition of this integral we have to analytically continue some global Minkowski temporal coordinate x^0 into imaginary value $x^0\rightarrow ix^0$ and consider the analytical continuation of all relevant quantities.

The above Gaussian functional integral could be interpreted as a Wiener measure, but, for our purposes, we may interpret it in terms of a functional determinant, and rewrite the definition of (2) as

$$Z[A_E]=\left[\det\left(\frac{A_E}{\mu}\right)\right]^{-1/2}, \tag{3}$$

where μ is a constant with the same physical dimension of the operator A_E.

It is sometime useful to introduce two physical quantities: the effective action and the effective Lagrangian. The former is defined as the logarithm of Z. The latter is a function of space–time points and gives, after an integration on the whole space–time, the effective action. The physical interpretation of this determinant is found after a reanalytical continuation of the imaginary time into a real time. The result is the vacuum to vacuum transition amplitude.

We can use zeta function regularization to give a rigorous meaning to functional determinants. This regularization technique was introduced by Ray and Singer for elliptic differential operators.[12] Within the quantum field theory, it was used by by Dowker and Chritchley[13] and Hawking.[14] Given a compact Riemannian manifold M and for elliptic and second order operators acting on $L_2(M)$, it can be proved that such definition gives a useful extension of the notion of functional determinant.

Since the square of the Euclidean Dirac operator is an elliptic second order differential operator, making use of the zeta regularization technique, Blau *et al.*[4] arrived at the following effective Lagrangian for a Dirac field in an external constant and uniform electric field:

$$L_{\rm eff}(E,0)=-\frac{e^2E^2}{2\pi^2}\left\{\left[1-\ln\left(\frac{-2ieE}{\mu^2}\right)\right]\zeta_H\left(-1;1+i\frac{m^2}{2eE}\right)+\frac{d}{ds}\zeta_H\left(s;1+i\frac{m^2}{2eE}\right)_{s=-1}\right\}$$
$$+i\frac{m^2eE}{8\pi^2}\left[\ln\frac{m^2}{\mu^2}-1\right], \tag{4}$$

where $\zeta_H(s;x)$ is the Hurwitz zeta function defined by

$$\zeta_H(s;x) \coloneqq \sum_{n=0}^{\infty} \left(\frac{1}{n+x}\right)^s, \quad \mathrm{Re}\, s>1.$$

They were not able to find an explicit form for the analytic continuation of the derivatives of the Hurwitz zeta function at $s=-1$. Thus, a direct comparison between their result and the one obtained by Schwinger was missing.

III. ANALYTIC CONTINUATION OF THE HURWITZ ZETA FUNCTION

In this section, we discuss the analytical properties of the Hurwitz zeta function. Following Ref. 15, we obtain a new identity involving the Hurwitz zeta function, the Euler $\Gamma(s)$ function and a polylogarithmic function.

Recall that the Hurwitz zeta function is defined as follows:

$$\zeta_H(s;x) \coloneqq \sum_{n=0}^{+\infty} (n+x)^{-s}, \tag{5}$$

where $\mathrm{Re}\, s>1$, $x\neq 0,-1,-2,\ldots$. One can analytically extend it into an analytic function of two complex variables s and x.

In order to search for the analytical continuation in the double complex plane, we introduce the function $F(s;z)$ defined by the following series:

$$F(s;z) \coloneqq \lim_{k\to\infty} \sum_{n=-k}^{k} (-in+z)^{-s}. \tag{6}$$

Notice that the series above is absolutely convergent for $\mathrm{Re}\, s>1$, $z\neq \pm ik, k\in N$. Thus, one may write

$$F(s;z) \coloneqq \lim_{k\to\infty}\left[\sum_{n=0}^{k} (-in+z)^{-s} + \sum_{n=0}^{k} (in+z)^{-s}\right] - z^{-s}. \tag{7}$$

Using this definition for the series (6), we proceed in searching for its analytical continuation. With regard to this issue, previous attempts can be found in Refs. 16 and 17. Here the author obtained an expression different from ours, requiring, however, as far as physical applications were concerned, an *ad hoc* finite renormalization.

It is straightforward to prove the following relation between $F(s;z)$ and $\zeta_H(s;z)$:

$$F(s;z) = i^s \zeta_H(s;iz) + i^{-s}\zeta_H(s;-iz) - z^{-s}. \tag{8}$$

First, let us investigate the function $F(s;x)$. The following theorem gives an expression for the analytic continuation of $F(s;z)$ in terms of polylogarithmic function.

Theorem: Following the definition stated above, the analytic continuation of $F(s,z)$ for each $s\in C$ and $\mathrm{Re}\, z>0$ is given by

$$F(s;z) = \frac{(2\pi)^s}{\Gamma(s)} \sum_{n=1}^{+\infty} \frac{e^{-2n\pi z}}{n^{1-s}}. \tag{9}$$

Proof: Define the sequence $F_k(s;z)$:

$$F_k(s;x) \coloneqq \sum_{n=-k}^{k} (-in+z)^{-s}, \tag{10}$$

which obviously converges to $F(s;z)$.

Recall the definition of the Euler $\Gamma(s)$ function for $\mathrm{Re}\, s>0$,

$$\Gamma(s) := \int_0^\infty t^{s-1} e^{-t} dt.$$

Consider the product of this function and the sequence $F_k(s;x)$:

$$F_k(s;z)\Gamma(s) = \sum_{n=-k}^{+k} (-in+z)^{-s} \int_0^\infty t^{s-1} e^{-t} dt = \int_0^\infty \sum_{n=-k}^{+k} (-in+z)^{-s} t^{s-1} e^{-t} dt.$$

We may change variables according to $t=\tau(-in+z)$, which is allowed for z not purely imaginary integer since $|dt/d\tau| \neq 0$, and we obtain

$$F_k(s;z) = \frac{1}{\Gamma(s)} \int_0^{+\infty} d\tau e^{-\tau z} \tau^{s-1} \sum_{n=-k}^{+k} e^{in\tau}. \tag{11}$$

The part of the integrand in (11) multiplying the series *vanishes* in $\tau=0$ for $\mathrm{Re}\, s>1$. This implies that the integration may be interpreted as the action of the **k**-element of a sequence of distributions $g_k(\tau)$,

$$g_k(\tau) := \sum_{n=-k}^{+k} e^{in\tau} \tag{12}$$

on the continuous function $e^{-\tau z}\tau^{s-1}$. It is a well-known result of the theory of distribution that this sequence converges and gives the Poisson summation formula:

$$\lim_{k\to\infty} g_k(\tau) = \lim_{k\to\infty} \sum_{n=-k}^{+k} e^{in\tau} = 2\pi \sum_{n=-\infty}^{+\infty} \delta(\tau - 2n\pi).$$

Thus we obtain in the limit $k\to\infty$:

$$F(s;z) = \frac{1}{\Gamma(s)} \int_0^{+\infty} e^{-\tau z} \tau^{s-1} \sum_{n=-\infty}^{+\infty} e^{in\tau} = \frac{(2\pi)^s}{\Gamma(s)} \sum_{n=1}^{+\infty} \frac{e^{-2n\pi z}}{n^{1-s}},$$

which, as stated in the hypotheses of the theorem, makes sense as analytic continuation for each $s\in C$ and $\mathrm{Re}\, z>0$.

Recalling the relation (8) between $F(s;z)$ and $\zeta_H(s;z)$, we have the following corollary:

Corollary: The following formula is valid for each $s\in C$ and $\mathrm{Re}\, z>0$ in the sense of the analytic continuation:

$$(i)^s \zeta_H(s;iz) + i^{-s} \zeta_H(s;-iz) - z^{-s} = \frac{(2\pi)^s}{\Gamma(s)} \sum_{n=1}^{+\infty} \frac{e^{-2n\pi z}}{n^{1-s}}. \tag{13}$$

Proof: Direct use of Eqs. (8) and (9).

Equation (13) can be checked for $s=-n$. In this case the right hand side is vanishing and Eq. (13) gives

$$i^{-n} \zeta_H(-n,iz) + i^n \zeta_H(-n,-iz) - z^{-s} = 0. \tag{14}$$

Recall that the values of the Hurwitz zeta function are known for negative integers and are related to the Bernoulli's polynomials by the following formula:

$$\zeta_H(-n,z)=-\frac{B_{n+1}(z)}{n+1}. \tag{15}$$

It is easy to show that this equation is identically fulfilled.

Remark: We now notice that the series

$$\sum_{n=1}^{+\infty}\frac{e^{-2n\pi z}}{n^{1-s}} \tag{16}$$

and its derivatives are uniformly convergent in the variable s for $\mathrm{Re}\,z>0$ and $\mathrm{Re}\,s\in(-\infty,a)$ with $a<\infty$. A straightforward computation leads to the following lemma:

Lemma 1: The following formula holds for each $s\in\mathrm{C}$ and $\mathrm{Re}\,z>0$ in the sense of the analytic continuation:

$$\begin{aligned}(i)^s\frac{d}{ds}\zeta_H(s;iz)+(i)^{-s}\frac{d}{ds}\zeta_H(s;-iz)&\\ =(2\pi)^s\left(\frac{d}{ds}\frac{1}{\Gamma(s)}\right)\sum_{n=1}^{+\infty}\frac{e^{-2n\pi z}}{n^{1-s}}+\frac{(2\pi)^s}{\Gamma(s)}\sum_{n=1}^{+\infty}\frac{e^{-2n\pi z}\ln(2n\pi)}{n^{1-s}}&\\ +i\frac{\pi}{2}\left[-2(i)^s\zeta_H(s;iz)+z^{-s}+\frac{(2\pi)^s}{\Gamma(s)}\sum_{n=1}^{+\infty}\frac{e^{-2n\pi z}}{n^{1-s}}\right]-(z)^{-s}(\ln|z|+iarg\,z).&\end{aligned} \tag{17}$$

Proof: One simply applies the derivative on both sides of the formula obtained in the corollary above, then uses the remark above to exchange the series with the derivative with respect to s, and then analytically continues the result for all the values of s.

As a result, we shall derive formulas for the real and imaginary values of the first derivative of the Hurwitz zeta function respectively for even and odd negative integers.

Using parity properties of the real and the imaginary part of this polynomials it is easy to prove the following lemma.

Lemma 2: For $x\in R$, $x>0$, and for $n\in N$, $n<0$, the Hurwitz zeta function has the following parity properties:

$$\mathrm{Re}\,\zeta_H(-n;ix)=\mathrm{Re}\,\zeta_H(-n;-ix), \tag{18}$$

$$\mathrm{Im}\,\zeta_H(-n;ix)=-\mathrm{Im}\,\zeta_H(-n;-ix). \tag{19}$$

We have the following.

Proposition: For $x\in R$ and for $m\in N$, the following two formulas are valid for any natural number:

$$\begin{aligned}\mathrm{Im}\frac{d}{ds}\zeta_H(-(2m+1);ix)=\pi\,\mathrm{Re}\frac{B_{2m+2}(ix)}{4(m+1)}+\frac{(-1)^{m+1}x^{2m+1}}{2}\ln x&\\ +\frac{(-1)^{m+1}(2m+1)!}{2(2\pi)^{2m+1}}\sum_{n=1}^{+\infty}\frac{e^{-2n\pi x}}{n^{2(m+1)}},&\end{aligned} \tag{20}$$

$$\mathrm{Re}\frac{d}{ds}\zeta_H(-2m;ix)=-\pi\,\mathrm{Im}\frac{B_{2m+1}(ix)}{2(2m+1)}+\frac{(-1)^{m+1}x^{2m}}{2}\ln x+\frac{(-1)^m(2m)!}{2(2\pi)^{2m}}\sum_{n=1}^{+\infty}\frac{e^{-2n\pi x}}{n^{1+2m}}. \tag{21}$$

Proof: Simple computation using Lemma 1 and 2.

Note: It is possible to obtain other identities involving higher order derivatives of the Hurwitz zeta function starting from (13). As a consequence, it is possible to obtain the values of higher derivatives of either the imaginary or real part of the Hurwitz zeta function for negative integers using recursive formulas.

As far as we know only asymptotic values have been found by E. Elizalde[18,19] for the analytic continuation of the derivatives of the Hurwitz zeta function. Thus (20) and (21) are new formulas. In the next section, we use the second one for the application to the study of the Dirac pair creation in the pure electrical background field.

IV. APPLICATION TO SCHWINGER PAIR CREATION

In this last section we shall apply the formula (20) to the problem of Dirac pair creation in a purely electrical background field, recovering the Schwinger result. The starting point is the effective Lagrangian obtained by Blau *et al.*

$$L_{\mathrm{eff}}(E,0)=-\frac{e^2E^2}{2\pi^2}\left\{\left[1-\ln\left(\frac{-2ieE}{\mu^2}\right)\right]\zeta_H\left(-1;1+i\frac{m^2}{2eE}\right)\frac{d}{ds}\zeta_H\left(s;1+i\frac{m^2}{2eE}\right)_{s=-1}\right\}$$
$$+i\frac{m^2eE}{8\pi^2}\left[\ln\frac{m^2}{\mu^2}-1\right]. \tag{22}$$

We have to find the imaginary part of the right-hand side of (22). Making use of Eq. (20) to $s=-1$, we obtain

$$\mathrm{Im}\frac{d}{ds}\zeta_H(-1;ix)=-\frac{1}{4\pi}\sum_{n=1}^{+\infty}\frac{e^{-2n\pi x}}{n^2}-\frac{x}{2}\ln x+\frac{\pi}{24}-\frac{\pi x^2}{4}. \tag{23}$$

If we plug this formula in the effective Lagrangian expression, we obtain the Schwinger result:

$$w(E,e,m)=\frac{e^2E^2}{4\pi^3}\sum_{n=1}^{+\infty}\frac{e^{-n\,\pi m^2/eE}}{n^2}. \tag{24}$$

KT-geometry is the geometry of a Hermitian connection whose torsion is a 3-form. HKT-geometry is the geometry of a hyper-Hermitian connection whose torsion is a 3-form. We identify nontrivial conditions for a reduction theory for these types of geometry. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1487443]

I. INTRODUCTION

Symplectic reduction is a novel method of constructing symplectic manifolds from others that admit a group action of symplectic diffeomorphisms. To describe the main result, let G be a compact group of symplectic diffeomorphisms acting on the symplectic manifold (M,ω) and $\mathfrak{g}$ be the Lie algebra of G. It can be shown that under certain conditions, $N=\nu^{-1}(\zeta)/G$ is also a symplectic manifold, where $\zeta\in\mathfrak{g}^*$ and $\nu:M\to\mathfrak{g}^*$ is the moment map. The manifold N is also denoted with $M//G$. It is remarkable that symplectic reduction can be generalized in various ways. First, it can be shown that if M is a Kähler manifold admitting a G-action of holomorphic isometries, then $M//G$ is also a Kähler manifold. Furthermore, it can be shown that if M is a hyper-Kähler manifold admitting an G-action of triholomorphic isometries, then $M//G=\nu^{-1}(\zeta)$ is also hyper-Kähler, where $\nu=(\nu_1,\nu_2,\nu_3):M\to\mathbf{R}^3\otimes\mathfrak{g}^*$ and $\zeta=(\zeta_1,\zeta_2,\zeta_3)\in\mathbf{R}^3\otimes\mathfrak{g}^*$.[1] In the context of hyper-Kähler reduction there are three moment maps each associated to the three complex structures. One common feature of all symplectic, Kähler and hyper-Kähler reductions is that moment maps exist because the G-action preserves some symplectic form.

More generally it has been shown that if M is a hypercomplex manifold admitting a triholomorphic group action, then $M//G$ is also hypercomplex.[2] The details of this construction will be summarized in Sec. II B. Here it is worth mentioning that in the context of hypercomplex reductions, moment maps do not arise naturally because in the generic case there are no symplectic forms which are preserved by the group action. Instead it is assumed that one can find such functions on M which have the required properties.

In the next section, we assume the existence of a G-moment map on M and study the geometry on the reduced space N. The aim is to prove that the reduction of a KT-space is a KT-space and the reduction of a HKT-space is again a HKT-space. The definition and twistor construction of HKT spaces have been given in Ref. 3. The properties of KT and HKT manifolds have been widely investigated in the literature.[3–5] The result on KT-space in Sec. II is not surprising because a Hermitian structure can easily be found on a reduced space and every Hermitian structure has a unique KT-connection. The existence of HKT-connection on the reduction of a

HKT-space is less trivial. Examples of HKT-reduction in this regard are given at the end of this paper.

In the third section, we identify nontrivial and sufficient topological or cohomological constraints on either the manifold M or the group G to ensure the existence of a G-moment map on strong KT-manifolds and strong HKT-manifolds. In the absence of symplectic forms, this is a nontrivial result as one usually generates moment map through the Kähler form. In the fourth section, we discuss when a potential function on a HKT-space may descend to a potential function on the reduced HKT-space.

II. EXISTENCE OF HKT-STRUCTURES ON REDUCED SPACES

Assuming the existence of ''moment maps,'' we examine the geometry on the reduced space in the next two sections.

A. KT reduction

Before we explain HKT reduction, it is instructive to consider first the reduction of KT manifolds, i.e., Hermitian manifolds equipped with the hermitian connection whose torsion is a three-from.

Let M be a KT manifold and let G be a compact group of complex isometries on M. Denote the algebra of holomorphic vector fields by $\mathfrak{g}$. Next introduce a G-equivariant map $\nu: M \to \mathfrak{g}$ satisfying the transversality condition, i.e., $Id\,\nu(X) \neq 0$ for all $X \in \mathfrak{g}$. We remark that a map ν is equivariant if $\nu(g \cdot x) = \mathrm{Ad}\, g^*(\nu(x))$.

Definition 1: A map ν is called G-moment map if and only if (i) it is equivariant and (ii) it satisfies the transversality condition.

We remark that for simply connected Kähler manifolds the moment map can be constructed using the invariance of Kähler form and complex structure and it satisfies the transversality property. However additional conditions are required in order the moment map to be equivariant.

Next given a point $\zeta \in \mathfrak{g}$, denote the level set $\nu^{-1}(\zeta)$ by P. Since the map ν is G-equivariant, level sets are invariant if the group G is Abelian or if the point ς is invariant. Assuming that the level set P is invariant, and the action of G on P is free, then the quotient space $N = P/G$ is a smooth manifold. Let $\pi: P \to N$ be the quotient map.

It can be shown that in fact $N = P/G$ is a complex manifold. This construction can be done as follows. For each point m in the space P, its tangent space is

$$T_m P = \{t \in T_m M : d\nu(t) = 0\}.$$

Consider the vector subspace

$$\mathcal{U}_m = \{t \in T_m P : Id\,\nu(t) = 0\}.$$

Due to the transversality condition, this space is transversal to the vectors generated by elements in $\mathfrak{g}$. In addition, this space is a vector subspace of $T_m P$ with co-dimension $\dim \mathfrak{g}$, and hence it is a vector subspace of $T_m M$ with co-dimension $2 \dim \mathfrak{g}$. The same condition implies that, as a subbundle of $TM_{|P}$, $\mathcal{U}$ is closed under I. Moreover there is a G-invariant splitting,

$$TP = \mathcal{U} \oplus \mathcal{V}, \tag{1}$$

where $\mathcal{V}$ is the tangent space to the orbits of G and it is the bundle of kernels of $d\pi$. We use the terms ''horizontal'' and ''vertical'' for $\mathcal{U}$ and $\mathcal{V}$.

As the projection π is an isomorphism on $\mathcal{U}$, for any tangent vector $\hat{A}$ at $\pi(m)$, there exists a unique element A^u in $\mathcal{U}_m$ such that $d\pi(A^u) = \hat{A}$. We call A^u horizontal lift of $\hat{A}$. The complex structure on N is defined by

$$I\hat{A} = d\pi(IA^u), \quad \text{i.e.,} \quad (I\hat{A})^u = IA^u. \tag{2}$$

Theorem 1: *Let $(M,\mathcal{I},g)$ be a KT-manifold. Suppose that G is a compact group of complex isometries admitting a G-moment map ν. Then the complex reduced space $N=M//G$ inherits a KT structure.*

Proof: To show this, it suffices to find a complex structure I and a Hermitian metric g on N which are induced from M because for every Hermitian structure (I,g), there always exists a unique KT structure on N.[5,6]

To begin, since $\mathcal{U}$ is G-invariant, if X^u is tangent to P at m and is contained in $\mathcal{U}$, then for any element $f\in G$, $dL_f(X^u)$ is tangent to P at $f(m)$ and is contained in $\mathcal{U}$. Using $\pi\circ L_f=\pi$, if X^u is a horizontal lift of $\hat{X}$ to a point m, then $d\pi\circ dL_f(X^u)=d\pi(X^u)=\hat{X}$. Therefore, $dL_f(X^u)$ is the horizontal lift of $\hat{X}$ to $f(m)$.

Since G is also a group of isometries, $g(dL_f(X),dL_f(Y))=g(X,Y)$ for any vectors X and Y tangent to P. Define a metric $\hat{g}$ on N by

$$\hat{g}_{\pi(p)}(\hat{X},\hat{Y})=g_p(X^u,Y^u), \tag{3}$$

where X^u and Y^u are the horizontal lifts of $\hat{X}$ and $\hat{Y}$, respectively. From the analysis above, the metric $\hat{g}$ is independent from the choice of the reference point p of the orbit. Note that the "horizontal" and "vertical" spaces ARE NOT necessarily orthogonal.

To prove that $\hat{g}$ is Hermitian, we note that

$$\begin{aligned} g_{\pi(p)}(I\hat{X},I\hat{Y}) &= g_p((I\hat{X})^u,(I\hat{Y})^u) \\ &= g_p(I(\hat{X}^u),I(\hat{Y})^u)=g_p(\hat{X}^u,\hat{Y}^u)=g_{\pi(p)}(\hat{X},\hat{Y}). \end{aligned} \tag{4}$$

Q.E.D.

B. HKT reduction

We shall begin with a description of hypercomplex reduction developed by Joyce.[2] Let G be a compact group of hypercomplex automorphism on M. Denote the algebra of hyper-holomorphic vector fields by $\mathfrak{g}$. Suppose that $\nu=(\nu_1,\nu_2,\nu_3):M\to\mathbf{R}^3\otimes\mathfrak{g}$ is a G-equivariant map satisfying the following two conditions. The Cauchy–Riemann condition, $I_1d\nu_1=I_2d\nu_2=I_3d\nu_3$, and the transversality condition, $I_ad\nu_a(X)\neq 0$ for all $X\in\mathfrak{g}$. In analogy with a similar definition given in the previous section, any map satisfying these conditions is called a G-moment map. Given a point $\zeta=(\zeta_1,\zeta_2,\zeta_3)$ in $\mathbf{R}^3\otimes\mathfrak{g}$, denote the level set $\nu^{-1}(\zeta)$ by P. Assuming that the level set P is invariant, and the action of G on P is free, then the quotient space $N=P/G$ is a smooth manifold.

Joyce proved that the quotient space $N=P/G$ inherits a natural hypercomplex structure.[2] His construction runs as follows. For each point m in the space P, its tangent space is

$$T_mP=\{t\in T_mM: d\nu_1(t)=d\nu_2(t)=d\nu_3(t)=0\}.$$

Consider the vector subspace,

$$\mathcal{U}_m=\{t\in T_mP: I_1d\nu_1(t)=I_2d\nu_2(t)=I_3d\nu_3(t)=0\}. \tag{5}$$

Due to the transversality condition, this space is transversal to the vectors generated by elements in $\mathfrak{g}$. Due to the Cauchy–Riemann condition, this space is a vector subspace of T_mP with co-dimension $\dim\mathfrak{g}$, and hence it is a vector subspace of T_mM with co-dimension $4\dim\mathfrak{g}$.

The same condition implies that, as a subbundle of $TM_{|P}$, $\mathcal{U}$ is closed under I_a. Moreover there is a G-invariant splitting,

$$TP=\mathcal{U}\oplus\mathcal{V}, \tag{6}$$

where $\mathcal{V}$ is the tangent space to the orbits of G and it is the bundle of kernels of $d\pi$. Again, we use the terms ''horizontal'' and ''vertical'' for $\mathcal{U}$ and $\mathcal{V}$ although these two spaces are not necessarily orthogonal. Following techniques and notations of the last section, a hypercomplex structure on N is defined by

$$I_a\hat{A}=d\pi(I_aA^u), \quad \text{i.e.,} \quad (I_aA)^u=I_aA^u. \tag{7}$$

Theorem 2: *Let $(M,\mathcal{I},g)$ be a HKT-manifold. Suppose that G is a compact group of hypercomplex isometries admitting a G-moment map ν. Then hypercomplex reduced space $N=M//G$ inherits a HKT structure.*

Proof: Define hypercomplex structures I_a on $N=P/G$ as in (7). As in the previous section, define a metric $\hat{g}$ on N by

$$g_p(X^u,Y^u)=\hat{g}_{\pi(p)}(\hat{X},\hat{Y}), \tag{8}$$

where X^u and Y^u are the horizontal lifts of $\hat{X}$ and $\hat{Y}$, respectively. This is a hyper-Hermitian metric.

On M, define $F_a(X,Y)=g(I_aX,Y)$ and

$$\omega_1=F_2-iF_3. \tag{9}$$

This is a (0,2)-form with respect to I_1. Since the hyper-Hermitian structure on X admits a HKT-metric, $\overline{\partial}\omega_1=0$. Equivalently, the (0,3)-part of $d\omega_1$ vanishes.

Similarly, we define $\hat{\omega}_1$ on N. By (Ref. 5, Proposition 2), the hyper-Hermitian metric $\hat{g}$ is a HKT-metric if and only if $\overline{\partial}\hat{\omega}_1=0$. In other words, we need to prove that the type (0,3)-part of $d\hat{\omega}_1$ with respect to I_1 vanishes. This is equivalent to

$$\pi^*d\hat{\omega}_1(X^u,Y^u,Z^u)=0 \tag{10}$$

for any vectors X^u,Y^u,Z^u in $\mathcal{U}^{0,1}_{I_1}$. As

$$\pi^*\hat{\omega}_1(Y^u,Z^u)=\omega_1(Y^u,Z^u) \tag{11}$$

and we have the following computation:

$$\begin{aligned}
d\pi^*\hat{\omega}_1(X^u,Y^u,Z^u)&=X^u(\pi^*\hat{\omega}_1(Y^u,Z^u))-Y^u(\pi^*\hat{\omega}_1(Z^u,X^u))+Z^u(\pi^*\hat{\omega}_1(X^u,Y^u))\\
&\quad-\pi^*\hat{\omega}_1([X^u,Y^u],Z^u)-\pi^*\hat{\omega}_1([Y^u,Z^u],X^u)-\pi^*\hat{\omega}_1([Z^u,X^u],Y^u)\\
&=X^u(\omega_1(Y^u,Z^u))-Y^u(\omega_1(Z^u,X^u))+Z^u(\omega_1(X^u,Y^u))-\omega_1([X^u,Y^u]^u,Z^u)\\
&\quad-\omega_1([Y^u,Z^u]^u,X^u)-\omega_1([Z^u,X^u]^u,Y^u)=d\omega_1(X^u,Y^u,Z^u)\\
&\quad+\omega_1([X^u,Y^u]^v,Z^u)+\omega_1([Y^u,Z^u]^v,X^u)+\omega_1([Z^u,X^u]^v,Y^u)\\
&=\omega_1([X^u,Y^u]^v,Z^u)+\omega_1([Y^u,Z^u]^v,X^u)+\omega_1([Z^u,X^u]^v,Y^u).
\end{aligned}$$

To complete the proof of this theorem we claim that $[X^u,Y^u]^v=0$. Equivalently, $d_a\nu_a([X^u,Y^u])=0$ for $a=1,2,3$. Since X^u and Y^u are in the kernel of $d_a\nu_a$ for $a=1,2,3$,

$$dd_a\nu_a(X^u,Y^u)=X^u(d_a\nu_a(Y^u))-Y_a(d_a\nu_a(X^u))-d_a\nu_a([X^u,Y^u])=-d_a\nu_a([X^u,Y^u]).$$

As $dd_1\nu_1$ is of type-(1,1) with respect to I_1 and X^u and Y^u are type-(0,1) with respect to I_1, $dd_1\nu_1(X^u,Y^u)=0$. By the Cauchy–Riemann condition $d_1\nu_1=d_2\nu_2=d_3\nu_3$, our claim follows.

Q.E.D.

III. MOMENT MAPS FOR STRONG KT AND HKT SPACES

As we have seen, the construction of new HKT manifolds using HKT reduction requires the existence of a G-moment map satisfying the requirements of Theorem 2. This moment map is not specified within the theory, as it is the case for the hyper-Kähler reduction, but rather its existence is an additional assumption of the construction. However as we shall see in the special case of reduction for strong KT (and HKT) manifolds, under certain assumptions, there is such a moment map which arises naturally. The local construction of a moment map for KT and HKT geometries presented below parallels the construction of an action for two-dimensional (2,0)- and (4,0)-supersymmetric gauged sigma models with the Wess–Zumino term in Ref. 7, respectively. Again, we focus on a reduction theory for strong KT-structure first. The reduction theory for strong HKT-structures follow.

A. Local consideration

Let G a compact group of complex automorphisms on a *strong* KT manifold M. In particular G is a group of isometries on M which leaves in addition the torsion three-form H invariant. To continue we introduce a basis $\{e_a; a=1,\ldots,\dim \mathfrak{g}\}$ in the Lie algebra of $\mathfrak{g}$ and denote the associated vector fields of M with $\{X^a; a=1,\ldots,\dim \mathfrak{g}\}$; denote with $\{e^a; a=1,\ldots,\dim \mathfrak{g}^*\}$ the associated basis in the dual $\mathfrak{g}^*$ of $\mathfrak{g}$. The conditions for invariance of the KT structure can now be written as

$$\mathcal{L}_a g=0, \quad \mathcal{L}_a H=0, \quad \mathcal{L}_a I=0, \tag{12}$$

where $\mathcal{L}_a=\mathcal{L}_{X^a}$; similarly later for the inner derivation we have $i_a=i_{X^a}$.

Using the assumption that M is a strong KT manifold, $dH=0$, the last equation above implies that $d i_a H=0$ and so there is a locally defined one-form u_a such that

$$i_a H=d u_a .$$

Clearly u_a is uniquely defined up to the addition of a closed one-form.

Next let us denote with $\tilde{X}$ the one-form dual with the vector field X with respect to the KT metric. Using $\mathcal{L}_a I=0$, one can show that the two-form $d(\tilde{X}_a+u_a)$ is type-(1,1) with respect to the complex structure I. Therefore, by the $\overline{\partial}$-Poincare Lemma, there is a locally defined complex-valued function h_a on M such that $(\tilde{X}_a+u_a)^{1,0}=\partial h_a$. Let f_a be the real part of h_a. Define

$$w_a=\tilde{X}_a+u_a-d f_a . \tag{13}$$

Then $w_a^{1,0}=i\partial \nu_a$, where ν_a is a constant multiple of the imaginary part of h_a. Therefore, we can write

$$w_a=I d \nu_a . \tag{14}$$

Let $\xi=\xi^a e_a$ be any element in $\mathfrak{g}$. Define a map ν from M to $\mathfrak{g}^*$ by

$$\nu(x)(\xi) := \sum_a \xi^a \nu_a(x). \tag{15}$$

A necessary condition for ν to be well-defined on M is that the class of $i_a H$ in $H^2(M,\mathbf{R})$ should be trivial. If in addition M satisfies the $\partial\overline{\partial}$-lemma, then ν will be well-defined on M.

In the case when the group G is Abelian, the issue of equivariance is absent and hence the map ν so constructed is the moment map. Before we investigate equivariance in general, we consider the issue of nondegeneracy.

Definition 2: A holomorphic Killing vector field X is nondegenerate if $d\nu_X \neq 0$.

Therefore, a holomorphic Killing vector field is nondegenerate if its moment map is nonconstant. The following proposition is useful to determine when a holomorphic Killing vector field is nondegenerate.

Proposition 1: If the length of a holomorphic Killing vector field is nonconstant, then the vector field is nondegenerate.

Proof: Note that $d\nu_X = 0$ if and only if $d\tilde{X} + du = 0$, i.e., $d\tilde{X} + \iota_X H = 0$. It means that for any vector field Y and Z,

$$Y(g(X,Z)) - Z(g(X,Y)) - g(X,[Y,Z]) + H(X,Y,Z) = 0,$$

$$\text{i.e.,} \quad g(\nabla_Y X, Z) + g(X, \nabla_Y Z) - g(\nabla_Z X, Y) - g(X, \nabla_Z Y) - g(X,[Y,Z]) + H(X,Y,Z) = 0,$$

$$\text{or} \quad g(\nabla_Y X, Z) - g(\nabla_Z X, Y) + 2H(X,Y,Z) = 0.$$

On the other hand, since $\mathcal{L}_X g = 0$ and $\nabla g = 0$,

$$\begin{aligned} 0 &= X(g(Y,Z)) - g([X,Y],Z) - g(Y,[X,Z]) \\ &= g(\nabla_X Y, Z) + g(Y, \nabla_X Z) - g([X,Y],Z) - g(Y,[X,Z]) \\ &= g(\nabla_Y X, Z) + g([X,Y],Z) + H(X,Y,Z) + g(Y, \nabla_Z X) \\ &\quad + g(Y,[X,Z]) + H(Y,X,Z) - g([X,Y],Z) - g(Y,[X,Z]) \\ &= g(\nabla_Y X, Z) + g(Y, \nabla_Z X). \end{aligned}$$

Combining the above two identities, we find that for any vector fields Y, Z,

$$g(\nabla_Y X, Z) = -H(X,Y,Z) = -du_X(Y,Z). \tag{16}$$

In particular, $g(\nabla_Y X, X) = 0$ for any Y. Since $\nabla g = 0$. It implies that $dg(X,X) = 0$. Q.E.D.

B. Equivariance

Now we seek conditions for ν to be equivariant. This issue will be analyzed in the next few paragraphs. The map ν is equivariant if and only if $\nu(g \cdot x) = \mathrm{Ad}g^*(\nu(x))$. Let X be any element in $\mathfrak{g}$. The equivariance is determined by

$$\nu(g \cdot x)(X) = \nu(x)(\mathrm{Ad}\, g(X)). \tag{17}$$

The infinitesimal version of the above identity is

$$\mathcal{L}_Y \nu_X = \nu_{[V,X]}; \quad \text{equivalently} \quad \mathcal{L}_Y \nu_X - \nu_{[Y,X]} = 0. \tag{18}$$

Let $[X_b, X_a] = f^c_{ba} X_c$ be the structural equations for the algebra $\mathfrak{g}$ so that f^c_{ba} are constants. Apply the above formula to w_a and u_a, respectively, with respect to X_b, the equivariance conditions for w_a and u_a are

$$\mathcal{L}_b w_a - f^c_{ba} w_c = 0, \quad \mathcal{L}_b u_a - f^c_{ba} u_c = 0. \tag{19}$$

These are nontrivial conditions. Note that

$$\begin{aligned} d\mathcal{L}_b u_a &= \mathcal{L}_b du_a = \mathcal{L}_b \iota_a H = \iota_{\mathcal{L}_b X_a} H + \iota_a \mathcal{L}_b H \\ &= \iota_{\mathcal{L}_b X_a} H = f^c_{ba} \iota_c H = f^c_{ba} du_c = d(f^c_{ba} u_c). \end{aligned} \tag{20}$$

By Poincaré lemma, there exists a locally defined closed 1-form v_{ba} such that

$$\mathcal{L}_b u_a - f^c_{ba} u_c = v_{ba}. \tag{21}$$

Therefore, v_{ba} is the obstruction for u_a to be equivariant.

Next, note that $\mathcal{L}_a g = 0$,

$$\begin{aligned}(\mathcal{L}_b \tilde{X}_a)X &= \mathcal{L}_b(g(X_a, X)) - g(X_a, \mathcal{L}_b X) \\ &= g(\mathcal{L}_b X_a, X) + g(X_a, \mathcal{L}_b X) - g(X_a, \mathcal{L}_b X) \\ &= f^c_{ba} g(X_c, X) = f^c_{ba} \tilde{X}_c X.\end{aligned}$$

Therefore, the $\mathfrak{g}^*$-valued 1-form $w := w_a \eta^a$ is equivariant if and only if $u := u_a \eta^a$ is equivariant.

Assuming that u is equivariant. This implies that after a possible shift of u_a with respect to a closed one-form, u_a must satisfy the above equation. Note that even if u_a is equivariant, it is not unique but rather defined up to an equivariant *closed* one-form.

Next since dw_a is an (1,1)-form and if we assume that the $\partial\bar{\partial}$-lemma applies on the manifold M (see either Ref. 8, 5.11 or Ref. 9, Corollary 2.110), there is a function ν_a on M such that

$$dw_a = dd^c v_a = dId\nu_a. \tag{22}$$

Therefore, the 1-form,

$$z_a = w_a - Id\nu_a$$

is closed. In the above equation ν_a is not uniquely defined but rather it is defined up the addition of the real part of a *holomorphic* function.

As we have assumed that u_a is equivariant, w_a is equivariant. We obtain

$$Id\nu_{ba} + z_{ba} = 0, \tag{23}$$

where $\nu_{ba} = \mathcal{L}_b \nu_a - f_{ba}{}^c \nu_c$ and $z_{ba} = \mathcal{L}_b z_a - f_{ba}{}^c z_c$. Since $dz_{ba} = 0$, (23) implies that $dd^c \nu_{ba} = 0$. By $\partial\bar{\partial}$-Lemma again, ν_{ba} is a harmonic function and hence is the real part of a holomorphic function f_{ba}. If, in addition,

$$f_{ba} = \mathcal{L}_b F_a - f_{ba}{}^c F_c \tag{24}$$

for some holomorphic functions F_a, then redefining ν_a as $\nu_a - \mathrm{Re}\, F_a$ and z_a as $z_a - d\,\mathrm{Im}\, F_a$ both ν_a and z_a become equivariant. So there is a choice of u_a, such that $w_a = Id\nu_a$. Therefore, we have found an equivariant moment map $\nu: M \to \mathfrak{g}^*$.

C. Cohomology

The various conditions that we have found for the existence of a moment map in the previous section can be identified as classes in de-Rham H^*_{dR} and in H^*_δ cohomology, where δ will be defined shortly. Let δ_G be the map defining Lie algebra cohomology in the usual way.[10] In particular, for $\theta \in \mathfrak{g}^*$ and $\zeta,\ \eta \in \mathfrak{g}$,

$$\delta_G \theta(\zeta, \eta) = -\theta([\zeta, \eta]). \tag{25}$$

Therefore, (note the convention for wedge product) in terms of structural constants with respect to the dual basis θ^a,

$$\delta_G\theta^a=-\sum_{b,c} f^a_{bc}\theta^b\otimes\theta^c$$

$$=-\sum_{b<c} f^a_{bc}(\theta^b\otimes\theta^c-\theta^c\otimes\theta^b)=-\sum_{b<c} f^a_{bc}\theta^b\wedge\theta^c=-\frac{1}{2}\sum_{b,c} f^a_{bc}\theta^b\wedge\theta^c. \tag{26}$$

In particular, $\delta_G^2=0$. Next for ϕ in $\Lambda^l(M)$ and X in $\mathfrak{g}$, define

$$\hat{\delta}\phi(X):=\mathcal{L}_X\phi. \tag{27}$$

Equivalently, $\hat{\delta}\phi=\mathcal{L}_a\phi\cdot\theta^a$. Then we extend this operator to

$$\delta:\Lambda^l(M)\otimes\Lambda^k\mathfrak{g}^*\otimes\mathfrak{g}^*\to\Lambda^l(M)\otimes\Lambda^{k+1}\mathfrak{g}^*\otimes\mathfrak{g}^* \tag{28}$$

as follows. If ϕ is in $\Lambda^l(M)$, θ is in $\Lambda^k\mathfrak{g}^*$ and η is in $\mathfrak{g}^*$, then define

$$\begin{aligned}\delta(\phi\cdot\theta\otimes\eta):=&\hat{\delta}\phi\wedge\theta\otimes\eta+\phi\cdot\delta_G\theta\otimes\eta\\&+(-1)^k\phi\cdot\theta\wedge\delta_G\eta.\end{aligned} \tag{29}$$

This map generates a resolution.

$$\begin{aligned}\Lambda^l(M)\otimes\mathfrak{g}^*\xrightarrow{\delta_0}&\Lambda^l(M)\otimes\Lambda^1\mathfrak{g}^*\otimes\mathfrak{g}^*\cdots\\&\to\Lambda^l(M)\otimes\Lambda^k\mathfrak{g}^*\otimes\mathfrak{g}^*\\&\xrightarrow{\delta_k}\Lambda^l(M)\otimes\Lambda^{k+1}\mathfrak{g}^*\otimes\mathfrak{g}^*\cdots.\end{aligned}$$

We claim that this resolution is a complex, i.e., $\delta_k\circ\delta_{k+1}=\delta^2=0$. To check, notice that

$$\begin{aligned}\delta^2(\phi\cdot\theta\otimes\eta)=&\delta(\hat{\delta}\phi\wedge\theta)\otimes\eta+(-1)^{k+1}\hat{\delta}\phi\wedge\theta\wedge\delta_G\eta+\hat{\delta}\phi\wedge\delta_G\theta\otimes\eta\\&+\phi\cdot\delta_G^2\phi\otimes\eta+(-1)^{k+1}\phi\cdot\delta_G\theta\wedge\delta_G\eta+(-1)^k\hat{\delta}\phi\wedge\theta\wedge\delta_G\eta\\&+(-1)^k\phi\cdot\delta_G\theta\wedge\delta_G\eta+(-1)^{2k}\phi\cdot\theta\wedge\delta_G^2\eta\\=&\delta(\hat{\delta}\phi\wedge\theta)\otimes\eta+\hat{\delta}\phi\wedge\delta_G\theta\otimes\eta=(\delta(\hat{\delta}\phi\wedge\theta)+\hat{\delta}\phi\wedge\delta_G\theta)\otimes\eta\\=&(\delta(\hat{\delta}\phi)\wedge\theta-\hat{\delta}\phi\wedge\delta_G\theta+\hat{\delta}\phi\wedge\delta_G\theta)\otimes\eta\\=&(\delta(\mathcal{L}_a\phi\theta^a))\wedge\theta\otimes\eta\\=&(\mathcal{L}_b\mathcal{L}_a\phi\cdot\theta^b\wedge\theta^a+\mathcal{L}_c\phi\cdot\delta_G\theta^c)\wedge\theta\otimes\eta\\=&(\mathcal{L}_b\mathcal{L}_a\phi-\tfrac{1}{2}f^c_{ba}\mathcal{L}_c\phi)\cdot\theta^b\wedge\theta^a\wedge\theta\otimes\eta.\end{aligned}$$

Since $[\mathcal{L}_a,\mathcal{L}_a]\phi=f^c_{ba}\mathcal{L}_c\phi$ and $f^c_{ba}=-f^c_{ab}$,

$$\mathcal{L}_b\mathcal{L}_a\phi-\tfrac{1}{2}f^c_{ba}\mathcal{L}_c\phi=\mathcal{L}_a\mathcal{L}_b\phi+\tfrac{1}{2}f^c_{ba}\mathcal{L}_c\phi=\mathcal{L}_a\mathcal{L}_b\phi-\tfrac{1}{2}f^c_{ab}\mathcal{L}_c\phi. \tag{30}$$

It shows that the term $\mathcal{L}_b\mathcal{L}_a\phi-\frac{1}{2}f^c_{ba}\mathcal{L}_c\phi$ is symmetric in the indices ab while the term $\theta^b\wedge\theta^a$ is skew symmetric in ab. It follows that $\delta(\mathcal{L}_a\phi\theta^a)=0$ and hence $\delta^2=0$ as claimed.

One can now define a cohomology theory with respect to δ in the usual way and denote it with

$$H^k_\delta(\Lambda^l(M)\otimes\mathfrak{g}^*) := \frac{\ker \delta_k}{\text{image } \delta_{k-1}}. \tag{31}$$

Since δ commutes with d, one can also naturally define the cohomology groups $H^k_\delta(C^l(M)\otimes\mathfrak{g}^*)$, where $C^l(M)$ are the close l-forms on M.

A cohomology theory based on a resolution of $\mathcal{O}\otimes\mathfrak{g}^*$, where $\mathcal{O}$ is the sheaf of germs of holomorphic functions on M, is similarly defined. This is possible because the group G consists of holomorphic actions. In particular, $\overline{\partial}\circ\mathcal{L}_a=\mathcal{L}_a\circ\overline{\partial}$. This cohomology is

$$H^k_\delta(\mathcal{O}\otimes\mathfrak{g}^*) := \frac{\ker \delta:\mathcal{O}\otimes\Lambda^k\mathfrak{g}^*\otimes\mathfrak{g}^*}{\text{image } \delta:\mathcal{O}\otimes\Lambda^{k-1}\mathfrak{g}^*\otimes\mathfrak{g}^*}. \tag{32}$$

Returning now in the discussion of the previous section, we have seen a necessary condition for the existence of a moment map in the KT case is that i_aH is a trivial class in $H^2_{dR}(M)$. Now we write $i_aH=du_a$ and define $u=u_a\eta^a$. This is a section of $\Lambda^1(M)\otimes\mathfrak{g}^*$. Using (26),

$$\begin{aligned}\delta u &= (\delta u_a)\otimes\eta^a+\sum_c u_c\delta_G\eta^c \\ &= \mathcal{L}_b u_a\theta^b\otimes\eta^a-\sum_{a,b,c} f^c_{ba}u_c\theta^b\otimes\eta^a \qquad (33)\\ &= \sum_{a,b}\left(\mathcal{L}_b u_a-\sum_c f^c_{ba}u_c\right)\theta^b\otimes\eta^a. \qquad (34)\end{aligned}$$

Due to (20), the 1-form part is closed. Therefore δu is an element of $C^1(M)\otimes\Lambda^1\mathfrak{g}^*\otimes\mathfrak{g}$. Obviously, it is in the kernel of δ. It defines a class in $H^1_\delta(C^1(M)\otimes\mathfrak{g}^*)$. Since u is not necessarily a closed 1-form, this class is not necessarily trivial although it is represented by δu. Due to computation of previous paragraphs, this cohomology class is the obstruction for adjusting u by a closed 1-form so that it could be equivariant.

If this class vanishes, then as we have explained $\delta(w_a\eta^a)=0$ as well. Using this and assuming that ν_a is well-defined in $w=Id\nu+z$, where $\nu=\nu_a\eta^a$ and $z=z_a\eta^a$, we have $Id\delta\nu+\delta z=0$. As we have explained in the previous section the obstruction for both z and ν to be equivariant are δz and $\delta\nu$, respectively. The last identity implies that it suffices to find the condition for $\delta\nu=0$.

Due to identity (22), $\delta w=0$ and $\mathcal{L}_aI=0$, we have $dId\delta\nu=0$. Therefore, by $\partial\overline{\partial}$-Lemma, there exists holomorphic function f_{ba} such that $\nu_{ba}=\text{Re}\, f_{ba}$. Define

$$f := f_{ba}\theta^b\otimes\eta^a. \tag{35}$$

This is an element in $\mathcal{O}\otimes\Lambda^1\mathfrak{g}^*\otimes\mathfrak{g}^*$. The function part of δf is holomorphic as the group G consists of holomorphic actions.

However, the real part of δf is equal to $\delta\nu=0$. Therefore, δf is purely imaginary. This is possible only if $\delta f=0$. It follows that f defines a class in $H^1_\delta(\mathcal{O}\otimes\mathfrak{g}^*)$. Note that the class of f vanishes if and only if the equation $f=\delta F$ has a solution. In other words, there are solutions for Eq. (24).

Some of the conditions that we have derived above can be cast into an elegant form using equivariant cohomology.[11] In physics, it is known that the obstructions for gauging *bosonic* two-dimensional sigma models with the Wess–Zumino term[12,13] are elements of equivariant cohomology.[14] The theorem below provides sufficient conditions for KT reduction.

Theorem 3: *Let M be a strong KT manifold and G be a compact group acting on M and leaving invariant the KT structure. If the torsion three-form H admits an equivariant extension as a closed form in $EG\times_G M$, $H^1_\delta(\mathcal{O}\otimes\mathfrak{g}^*)=0$ and the $\partial\overline{\partial}$-lemma applies on M, then $M//G$ is a KT manifold.*

Proof: Note that EG is the universal classifying bundle space for the group G. It can be shown that a closed three-form H in M admits an equivariant extension in $EG\times_G M$, if H is invariant under the group action of G on M and there are equivariant one-forms $\{u_a;a=1,\ldots,\dim\mathfrak{g}\}$ on M such that

$$i_a H = du_a \quad \text{and} \quad i_a u_b + i_b u_a = 0. \tag{36}$$

Of course the one-form u_a is defined up to the addition of an equivariant closed one-form v_a. Because of this, the one-form $w_a = u_a + \tilde{X}_a$ is equivariant and dw_a is an (1,1) form on M. If the $\partial\overline{\partial}$-lemma applies, then $w_a = Id\nu_a + z_a$, where ν_a is a function on M and z_a is closed one-form. It can be shown that in fact z_a is equivariant. Indeed, since w_a is equivariant and the G-action preserves the complex structure, we have

$$Id\nu_{ba} + z_{ba} = 0, \tag{37}$$

where $\nu_{ba} = \mathcal{L}_b\nu_a - f_{ba}{}^c\nu_c$ and $z_{ba} = \mathcal{L}_b z_a - f_{ba}{}^c z_c$. We have seen that the obstruction for z_a and ν_a to be equivariant lies in $H^1_\delta(\mathcal{O}\otimes\mathfrak{g}^*)$. Since this vanishes z_a and ν_a are equivariant. So there is a choice of u_a, such that $w_a = Id\nu_a$.

It remains to prove the transversality condition. This follows from the last condition in (36) because it implies that $i_a u_b$ is skew-symmetric and so $i_a w_b$ is the sum of a nondegenerate symmetric matrix with $i_a u_b$. Therefore ν is a G-moment map and so $M//G$ is a KT manifold. Q.E.D.

D. Moment maps on strong HKT structures

The construction of G-moment maps for the reduction of strong HKT manifolds can proceed as in the case of strong KT manifolds above. The only difference is that for each complex structure $\{I_r;r=1,2,3\}$ one gets

$$w_a = I_r d(\nu^r)_a + z^r_a, \tag{38}$$

where z^r_a are again equivariant closed one-forms provided that the obstructions in $H^1_\delta(\mathcal{O}\otimes\mathfrak{g})$ vanish. In this case however it is not always possible to redefine u_a such that $w_a = I_r d(\nu^r)_a$ unless $z^1_a = z^2_a = z^3_a$. Nevertheless, we can still use the map $\nu: M\to\mathbf{R}^3\otimes\mathfrak{g}$ as defined in (38) as a moment map. This moment map is equivariant but neither transversality nor the Cauchy–Riemann conditions generically hold. Thus we have the following theorem:

Theorem 4: *Let M be a strong HKT manifold and G be a compact group acting on M and leaving invariant the HKT structure. If the torsion three-form H admits an extension as a closed form in $EG\times_G M$ such that $w_a = I_r d(\nu^r)_a$ with ν equivariant, then $M//G$ is a HKT manifold.*

Proof: The proof follows from that of reductions of strong KT manifolds and that of reductions of weak HKT manifolds. Q.E.D.

IV. POTENTIAL FUNCTIONS

Recall that if $(M,\mathcal{I},g)$ is a HKT manifold with Kähler forms ω_a, a *HKT potential* is a function ρ such that $2\omega_1 = dd_1\rho + d_2d_3\rho, 2\omega_2 = dd_2\rho + d_3d_1\rho, 2\omega_3 = dd_3\rho + d_1d_2\rho$. In this section, we follow the methods in Ref. 15 to find a potential function on reduced space. We continue to use the notations established in Sec. II B.

Theorem 5: *Let $(M,\mathcal{I},g)$ be a HKT manifold with HKT potential function ρ. Suppose that G is a compact group of hypercomplex isometries leaving ρ invariant with moment map $\nu=(\nu_1,\nu_2,\nu_3)$ such that the tangent vectors to the orbits of G in $\nu^{-1}(0)$ are in the* $\ker(d_a\rho)$, *for $a=1,2,3$. Then the function ρ induces a HKT potential function on the reduced space $N=M//G$.*

Proof: Let $P:=\nu^{-1}(0)$ and $i:P\to M$ be the inclusion map. Now we first check that $i^*dd_a\rho|_{\mathcal{U}}=dd_a i^*\rho|_{\mathcal{U}}$, where $\mathcal{U}$ is defined in (5). To this end notice that

$$i^*d\rho(X^u)=d\rho(X^u),\quad i^*d\rho([X^u,Y^u])=d\rho([X^u,Y^u]),$$

and $i^*I_a d\rho(X^u)=I_a d\rho(di(X^u))=-d\rho(I_aX^u)$ because $I_a d\rho(X)=-d\rho(I_aX)$. By direct computations after restricting on points of P we have

$$\begin{aligned}(i^*dd_a\rho)(X^u,Y^u)&=di^*d_a\rho(X^u,Y^u)\\&=X^u((i^*I_ad\rho)(Y^u))-Y^u((i^*I_ad\rho)(X^u))-i^*I_ad\rho([X^u,Y^u])\\&=-X^u(d\rho(I_aY^u))+Y^u(d\rho(I_aX^u))+d\rho(I_a[X^u,Y^u])\\&=-X^u(d\rho(I_aY^u))+Y^u(d\rho(I_aX^u))+d\rho(I_a[X^u,Y^u]^u).\end{aligned}$$

The last equality is due to $d\rho(I_a[X^u,Y^u]^v)=-d_a\rho([X^u,Y^u]^v)=0$. This is true because $[X^u,Y^u]^v$ is tangent to an orbit of G and the condition in the theorem. We shall use the same argument repeatedly and implicitly in subsequent computation.

As the map ρ is G-invariant, for x in P, we may define

$$\rho_N(\pi(x)):=\rho(x),\tag{39}$$

where π is the quotient map from P onto $N=P/G$. In other words, $\pi^*\rho_N=\rho$. It follows that

$$\begin{aligned}(\pi^*dd_a\rho_N)(X^u,Y^u)&=d\pi^*d_a\rho_N(X^u,Y^u)\\&=X^u(d_a\rho_N(d\pi(Y^u)))-Y^u(d_a\rho_N(d\pi(X^u))-d_a\rho_N(d\pi([X^u,Y^u]))\\&=-X^u(d\rho_N(I_ad\pi Y^u))+Y^u(d\rho_N(I_ad\pi X^u))+d\rho_N(I_ad\pi[X^u,Y^u]))\\&=-X^u(d\rho(I_aY^u))+Y^u(d\rho(I_aX^u))+d\rho_N(d\pi(I_a[X^u,Y^u]^u))\\&=-X^u(d\rho(I_aY^u))+Y^u(d\rho(I_aX^u))+d\rho(I_a[X^u,Y^u]^u).\end{aligned}$$

It follows that $i^*dd_a\rho_{|\mathcal{U}}=\pi^*dd_a\rho_{N|\mathcal{U}}$. Similarly,

$$\begin{aligned}(\iota^*d_ad_b\rho)(X^u,Y^u)&=(I_adI_cd\rho)(di(X^u),di(Y^u))\\&=(I_adI_cd\rho)(X^u,Y^u)\\&=dI_cd\rho(I_aX^u,I_aY^u)\\&=I_aX^u(d_c\rho(I_aY^u))-I_aY^u(d_c\rho(I_aX^u))-d_c\rho([I_aX^u,I_aY^u])\\&=I_aX^u(d_c\rho(I_aY^u))-I_aY^u(d_c\rho(I_aX^u))-d_c\rho([I_aX^u,I_aY^u]^u).\end{aligned}$$

On the other hand,

$$\begin{aligned}(\pi^*d_ad_b\rho_N)(X^u,Y^u)&=(I_adI_cd\rho_N)(d\pi(X^u),d\pi(Y^u))\\&=(dI_cd\rho_N)(I_ad\pi(X^u),I_ad\pi(Y^u))\\&=(dI_cd\rho_N)(d\pi I_a(X^u),d\pi I_a(Y^u))\\&=(\pi^*dI_cd\rho_N)(I_aX^u,I_aY^u)\\&=(d\pi^*I_cd\rho_N)(I_aX^u,I_aY^u)\\&=I_aX^u(\pi^*I_cd\rho_N(I_aY^u)-I_aY^u(\pi^*I_cd\rho_N(I_aX^u))-\pi^*I_cd\rho_N([I_aX^u,I_aY^u])\\&=I_aX^u(-d\rho_N(d\pi(I_cI_aY^u))-I_aY^u(-d\rho_N(d\pi(I_cI_aX^u))\\&\quad-d\rho_N(d\pi I_c[I_aX^u,I_aY^u])\\&=I_aX^u(I_cd\rho(I_aY^u))-I_aY^u(I_cd\rho(I_aX^u))+d\rho(d\pi I_c[I_aX^u,I_aY^u]^u)\\&=I_aX(d_c\rho(I_aY^u))-I_aY^u(d_c\rho(I_aX^u))-d_c\rho([I_aX^u,I_aY^u]^u).\end{aligned}$$

Therefore, $i^*d_bd_c\rho_{|\mathcal{U}}=\pi^*d_bd_c\rho_{N|\mathcal{U}}$ for all even permutations (abc) of (123). At the end we use the fact that the reduced Kähler forms $\overline{\omega}_a$ are characterized by the condition $(\pi^*\overline{\omega}_a)_{|\mathcal{U}}=(i^*\omega_a)_{|\mathcal{U}}$ and conclude that $2\overline{\omega}_a=dd_a\rho_N+d_bd_c\rho_N$. Q. E. D.

Remark: In the case of when the torsion vanishes the condition in the above theorem is equivalent to the one proposed by Kobak and Swann.[15] In both cases the crucial point is to ensure $i^*I_ad\rho=I_ai^*d\rho$. In both cases $d\rho(X^v)=0$ since ρ is invariant.

V. EXAMPLES

It is known that SU(3) admits invariant hypercomplex structure, constructed by Joyce. Moreover Pedersen and Poon[16] considered the deformation of this structure and succeeded to represent any ''small'' deformation as a hypercomplex reduced space of the space $S^1\times S^{11}$ under an appropriate S^1 action. As it is shown in Refs. 5 and 17, the space $S^1\times S^{11}$ is HKT and one can check that the S^1-actions considered in Ref. 16 Sec. 6.3 are HKT isometries. Now according to the theorem of Sec. II B we have:

Theorem 6: *Any small deformation of the invariant hypercomplex structure on* $SU(3)$ *admits a HKT structure*.

In the rest of this section, we will construct new HKT-metrics through a reduction process. We begin with a well-known metric, namely the Taub-NUT metric.

A. Taub-NUT metric

We use the notation of Ref. 18. Let $\mathcal{M}=\mathbb{H}\times\mathbb{H}$ with quaternionic coordinates (q,w). We identify points $(t,x,y,z)\in R^4$ with a quaternion $q\in H$: $q=t+ix+jy+kz$. The (quaternion) conjugate is $\overline{q}=t-ix-jy-kz$. The flat metric on M is

$$ds^2_{\text{flat}}=dqd\overline{q}+dwd\overline{w}. \tag{40}$$

Using left multiplication of the unit quaternions i,j, and k, we find the hypercomplex structure I,J, and K such that

$$Idt=dx,Idx=-dt,Idy=dz,Idz=-dy,$$

$$Jdt=dy,Jdx=-dz,Jdy=-dt,Jdz=dx,$$

$$Kdt=dz,Kdx=dy,Kdy=-dx,Kdz=-dt. \tag{41}$$

With respect to these complex structures, the Kähler form of the flat metric $dqd\overline{q}$ are

$$\omega_I=dt\wedge dx+dy\wedge dz,\quad \omega_J=dt\wedge dy+dz\wedge dx,\omega_K=dt\wedge dz+dx\wedge dy. \tag{42}$$

Let G be $\mathbb{R}$, $t\in\mathbb{R}$ with the action $(q,w)\to(qe^{it},w+\lambda t)$, for λ in $\mathbb{R}$. This is a group of hyper-Kähler isometries. It generates a moment map,

$$\nu=\frac{1}{2}qi\overline{q}+\frac{\lambda}{2}(w-\overline{w}). \tag{43}$$

We write $\mathbf{r}=qi\overline{q}$, $r=|\mathbf{r}|$ and $w=y+\mathbf{y}$ so $\mathbf{r}$ and $\mathbf{y}$ are in R^3. Moreover,

$$\nu=\tfrac{1}{2}\mathbf{r}+\lambda\mathbf{y}. \tag{44}$$

Define ψ by $q=\rho e^{i\psi/2}$, where ρ is a pure quaternion. Now using the coordinates $(\psi,\mathbf{r},y,\mathbf{y})$, we write the flat metric on M as

$$ds^2_{\text{flat}}=\frac{1}{4}\left(\frac{1}{r}d\mathbf{r}^2+r(d\psi+\omega\cdot d\mathbf{r})^2\right)+dy^2+d\mathbf{y}^2, \tag{45}$$

where curl $\omega = \text{grad}(1/r)$. In these coordinates the G-action is

$$(\psi, y) \to (\psi + 2t, y + \lambda t), \tag{46}$$

which leaves $\tau = \psi - 2y/\lambda$ invariant. On $\nu^{-1}(0)$, one has $\mathbf{y} = -(1/2\lambda)\,\mathbf{r}$. The induced metric in the coordinates $(\mathbf{r}, \tau, y)$ on $\nu^{-1}(0)$ is

$$ds^2_{\text{flat}} = \frac{1}{4}\left(\frac{1}{r}d\mathbf{r}^2 + r\left(d\tau + \frac{2}{\lambda}dy + \omega \cdot d\mathbf{r}\right)^2\right) + dy^2 + \frac{1}{4\lambda^2}d\mathbf{r}^2. \tag{47}$$

The quotient space $\nu^{-1}(0)/G$ is obtained by an orthogonal projection along the Killing vector field $\partial/\partial y$. It turns out that the quotient metric is the Taub–NUT metric,

$$ds^2_{\text{TN}} = \frac{1}{4}\left(\frac{1}{r} + \frac{1}{\lambda^2}\right)d\mathbf{r}^2 + \frac{1}{4}\left(\frac{1}{r} + \frac{1}{\lambda^2}\right)^{-1}(d\tau + \omega \cdot d\mathbf{r})^2. \tag{48}$$

B. A HKT-version of the Taub–NUT metric

Given the preparation of the last section, we are now ready to consider HKT-reduction. Let h be a function of r. We consider the metric on $\mathbb{H}\backslash\{0\} \times \mathbb{H}$ given by

$$ds^2_h = \frac{h(r)}{q\overline{q}}dq d\overline{q} + dw d\overline{w} = \frac{h(r)}{r}dq d\overline{q} + dw d\overline{w}. \tag{49}$$

As $[h(r)/r]\,dq d\overline{q}$ is a HKT-metric on $\mathbb{H}\backslash\{0\}$ and product of HKT metrics is again a HKT metric, ds^2 is a HKT metric. Since the hypercomplex structure does not change, the group G remains hypercomplex. It is again a group of isometries. Therefore, we again use the moment maps ν generated by the action G with respect to the hyper-Kähler metric ds^2_{flat}. On $\nu^{-1}(0)$ the induced metric with respect to ds^2_h is

$$\begin{aligned}
&\frac{h}{4r}\left(\frac{1}{r}d\mathbf{r}^2 + r\left(d\tau + \frac{2}{\lambda}dy + \omega \cdot d\mathbf{r}\right)^2\right) + dy^2 + \frac{1}{4\lambda^2}d\mathbf{r}^2 \\
&\quad = \frac{1}{4}\left(\frac{h}{r^2} + \frac{1}{\lambda^2}\right)d\mathbf{r}^2 + \left(1 + \frac{h}{\lambda^2}\right)dy^2 \\
&\qquad + \frac{h}{2\lambda}dy \odot (d\tau + \omega \cdot d\mathbf{r}) + \frac{h}{4}(d\tau + \omega \cdot d\mathbf{r})^2.
\end{aligned} \tag{50}$$

Here we used $\alpha \odot \beta = \alpha \otimes \beta + \beta \otimes \alpha$. So $\alpha \odot \alpha = 2\alpha \otimes \alpha$.

As hyper-Kähler reduction is also obtained by orthogonal projection, the horizontal distribution $\mathcal{U}$ is defined by $\ker \theta$. Therefore, the reduced metric is obtained by taking the restriction of ds^2 on $\nu^{-1}(0)$ modulo θ or μ, where

$$\theta = \iota_{\partial/\partial y} ds^2_{\text{flat}}, \quad \mu = dy + \frac{1}{2\lambda}\frac{(d\tau + \omega \cdot d\mathbf{r})}{\left(\frac{1}{r} + \frac{1}{\lambda^2}\right)}. \tag{51}$$

In other words, if $\hat{g}$ is the quotient metric, then there is a 1-form α and function a on $\nu^{-1}(0)$ such that

$$ds^2_h = a\,\mu \otimes \mu + (\alpha \otimes \mu + \mu \otimes \alpha) + \hat{g}. \tag{52}$$

It follows that $\iota_{\partial/\partial y} ds^2 = a\mu + \alpha$. In our example,

$$a=1+\frac{h}{\lambda^2},\quad \alpha=\frac{1}{2\lambda}\left(h-\left(1+\frac{h}{\lambda^2}\right)\left(\frac{1}{r}+\frac{1}{\lambda^2}\right)^{-1}\right)(d\tau+\omega\cdot d\mathbf{r}). \tag{53}$$

Therefore the quotient metric is

$$\begin{aligned}&\frac{1}{4}\left(\frac{h}{r^2}+\frac{1}{\lambda^2}\right)d\mathbf{r}^2+\left(1+\frac{h}{\lambda^2}\right)dy^2+\frac{h}{2\lambda}dy\odot(d\tau+\omega\cdot d\mathbf{r})+\frac{h}{4}(d\tau+\omega\cdot d\mathbf{r})^2\\&\quad-\left(1+\frac{h}{\lambda^2}\right)\left(dy+\frac{1}{2\lambda}\frac{(d\tau+\omega\cdot d\mathbf{r})}{\frac{1}{r}+\frac{1}{\lambda^2}}\right)^2-\left(dy+\frac{1}{2\lambda}\frac{(d\tau+\omega\cdot d\mathbf{r})}{\frac{1}{r}+\frac{1}{\lambda^2}}\right)\\&\quad\odot\frac{1}{2\lambda}\left(h-\left(1+\frac{h}{\lambda^2}\right)\left(\frac{1}{r}+\frac{1}{\lambda^2}\right)^{-1}\right)(d\tau+\omega\cdot d\mathbf{r})\\&\quad=\frac{1}{4}\left(\frac{h}{r^2}+\frac{1}{\lambda^2}\right)d\mathbf{r}^2+\frac{1}{4}\left(\frac{h}{r^2}+\frac{1}{\lambda^2}\right)\left(\frac{1}{r}+\frac{1}{\lambda^2}\right)^{-2}(d\tau+\omega\cdot d\mathbf{r})^2.\end{aligned} \tag{54}$$

$$=\left(\frac{h}{r^2}+\frac{1}{\lambda^2}\right)\left(\frac{1}{r}+\frac{1}{\lambda^2}\right)^{-1}ds^2_{\mathrm{TN}}. \tag{55}$$

In particular, the quotient metric is conformally equivalent to the Taub–NUT metric, a hyper-Kähler metric.

Amongst the class of weak HKT metrics that have been constructed above, there is a strong HKT metric which is complete. This is

$$ds^2=\left(\frac{1}{r}+\frac{1}{\lambda^2}\right)ds^2_{\mathrm{TN}}. \tag{56}$$

For this metric, the function h is

$$h(r)=1+\frac{2}{\lambda^2}r+\frac{1}{\lambda^2}\left(\frac{1}{\lambda^2}-1\right)r^2. \tag{57}$$

This metric is strong HKT because the conformal factor is a harmonic function with respect to the Taub-NUT hyper-Kähler metric. The asymptotic behavior of the metric is as follows: As $r\to\infty$, the metric (56) approaches the standard metric on $S^1\times\mathbf{R}^3$. As $r\to 0$, the metric (56) approaches

$$ds^2\sim\frac{1}{r}\left(r(d\tau+\omega\cdot d\mathbf{r})^2+\frac{1}{r}d\mathbf{r}^2\right).$$

Changing back to the quaternionic coordinates q, we find that the above metric can be rewritten as

$$ds^2=\frac{1}{q\bar{q}}dq\,d\bar{q}=du^2+ds^2(S^3)$$

with $r=q\bar{q}$ and $u=\log(|q|)$. So it is the standard metric on $\mathbf{R}\times S^3$. In physics language, the metric (56) interpolates between the ten-dimensional Kaluza–Klein vacuum and the near horizon geometry of the NS5-brane.

C. A HKT-version of the Lee–Weinberg–Yi metric

We are interested in examples beyond four-real dimension. As noted in Ref. 18, a high dimension analog of the Taub-NUT metric is the Lee–Weinberg–Yi (LWY) metric. We construct a family HKT-version of this metric. Moreover, these metrics are not conformal to the LWY-metric.

We first review the construction of the LWY-metric very briefly to fix notations. We take $\mathcal{M}=\mathbb{H}^m\times\mathbb{H}^m$ with coordinates (q_a,w_a), $a=1,\ldots,m$. Let $\Lambda=(\lambda_a^b)$ be a real nondegenerate $m\times m$-matrix. Let $V=(v_a^b)$ be the inverse matrix. For $G=\mathbb{R}^m=(t_1,\ldots,t_m)$, define an action by

$$q_a\mapsto q_a e^{it_a},\quad w_a\mapsto w_a+\sum_b \lambda_a^b t_b\,. \tag{58}$$

With respect to the flat metric $ds^2_{\text{flat}}=\Sigma_a dq_a d\overline{q}_a+\Sigma_a dw_a d\overline{w}_a$ and the hypercomplex structure defined as in (41), group G is a group hyperholomorphic isometry. The moment map

$$\nu=(\nu_1,\ldots,\nu_m):\mathcal{M}\to\mathbb{R}^m\otimes\mathbb{R}^3 \tag{59}$$

is given by

$$\nu_a=\frac{1}{2}q_a i\overline{q}_a+\frac{1}{2}\sum_b \lambda_a^b(w_b-\overline{w}_b). \tag{60}$$

Define $\mathbf{r}_a=q_a i\overline{q}_a$, $r_a=|\mathbf{r}_a|=q_a\overline{q}_a$, $\mathbf{y}_a=\frac{1}{2}(w_a-\overline{w}_a)$. It follows that $w_a=y_a+\mathbf{y}_a$. Now $\mathbf{r}_a$ and $\mathbf{y}_a$ are in $\mathbb{R}^3$ and the moment map is

$$\nu_a=\frac{1}{2}\mathbf{r}_a+\sum_b \lambda_a^b\mathbf{y}_b\,. \tag{61}$$

Define ψ_a by $q_a=\rho_a e^{i\psi_a/2}$, where ρ_a is a pure quaternion. Now using the coordinates $(\psi_a,\mathbf{r}_a,y_a,\mathbf{y}_a)$, one may construct explicitly a hyper-Kähler metric on the quotient space in the way the Taub-NUT metric is constructed. This is the LWY-metric.

For reference in subsequent computation, we note that in these coordinates the G-action is $(\psi_a,y_a)\to(\psi_a+2t_a,y_a+\Sigma_b\lambda_a^b t_b)$. It leaves the functions

$$\tau_a=\psi_a-2\sum_b v_a^b y_b \tag{62}$$

invariant. On the level set $\nu^{-1}(0)$, $\mathbf{r}_a=-2\Sigma_b\lambda_a^b\mathbf{y}_b$. Equivalently, $\mathbf{y}_a=-\frac{1}{2}\Sigma_b v_a^b\mathbf{r}_b$.

Next, consider a new metric on $\mathcal{M}$,

$$\begin{aligned} ds^2&=\sum_a f_a(q_a\overline{q}_a)dq_a d\overline{q}_a+\sum_a dw_a d\overline{w}_a\\ &=\sum_a f_a(r_a)dq_a d\overline{q}_a+\sum_a dw_a d\overline{w}_a\,. \end{aligned} \tag{63}$$

This is a HKT-metric. The group G is again a group of hyper-holomorphic isometries. We may use the G-moment map ν again to construct a quotient metric $\hat{g}$ with respect to ds^2.

The restriction of the metric ds^2 on $\nu^{-1}(0)$ with respect to the coordinates $(\mathbf{r}_a,\tau_a,y_a)$ is

$$\sum_a \left(\frac{f_a}{4r_a}d\mathbf{r}_a^2+\frac{f_a r_a}{4}\left(2\sum_b v_a^b dy_b+d\tau_a+A_a\right)^2+dy_a^2+\frac{1}{4}\left(\sum_b v_a^b d\mathbf{r}_b\right)^2\right)$$
$$=\frac{1}{4}\sum_{b,c}\left(\frac{\delta_b^c f_c}{r_c}+\sum_a v_a^b v_a^c\right)d\mathbf{r}_b\otimes d\mathbf{r}_c+\sum_{b,c}\left(\delta_b^c+\sum_a (f_a r_a v_a^b v_a^c)\right)dy_b\otimes dy_c$$
$$+\frac{1}{2}\sum_{a,b} f_a r_a v_a^b dy_b\odot(d\tau_a+A_a)+\frac{1}{4}\sum_a f_a r_a (d\tau_a+A_a)^2. \tag{64}$$

To find the quotient metric $\hat{g}$, it suffices to find functions F_{ab} and 1-forms α_a such that

$$ds^2=\sum_{a,b} F_{ab}\theta_a\otimes\theta_b+\sum_a (\theta_a\otimes\alpha_a+\alpha_a\otimes\theta_a)+\hat{g}. \tag{65}$$

Now the problem is that the Killing vector fields $\partial/\partial y_a$ generated by G on the zero level set in general are not mutually orthogonal.

From now on, we limit our discussion to the case when $\lambda_a^b=\lambda_a\delta_a^b$. Equivalently, Λ is a diagonal matrix whose nonzero entry is λ_a. Its inverse is a diagonal matrix whose non-zero entry is $v_a=1/\lambda_a$. In this case,

$$\theta_c:=\iota_{\partial/\partial y_c}ds^2=(1+r_c v_c^2)dy_c+\frac{1}{2}r_c v_c(d\tau_c+A_c)$$
$$=\left(1+\frac{r_c}{\lambda_c^2}\right)dy_c+\frac{r_c}{2\lambda_c}(d\tau_c+A_c), \tag{66}$$

where $A_c:=\omega(\mathbf{r}_a)\cdot d\mathbf{r}_a$. Since the vector fields $\partial/\partial y_a$ are mutually orthogonal with respect to ds^2,

$$\iota_{\partial/\partial y_c}ds^2=(1+r_c v_c^2)\left(\sum_a F_{ca}\theta_a+\alpha_c\right). \tag{67}$$

The restriction of the metric ds^2 on $\nu^{-1}(0)$ with respect to the coordinates $(\mathbf{r}_a,\tau_a,y_a)$ is

$$\sum_a\left(\frac{f_a}{4r_a}d\mathbf{r}_a^2+\frac{f_a r_a}{4}(2v_a dy_a+d\tau_a+A_a)^2+dy_a^2+\frac{v_a^2}{4}d\mathbf{r}_a^2\right)$$
$$=\sum_a\left(\frac{f_a}{4r_a}d\mathbf{r}_a^2+\frac{f_a r_a}{4}\left(\frac{2}{\lambda_a}dy_a+d\tau_a+A_a\right)^2+dy_a^2+\frac{1}{4\lambda_a^2}d\mathbf{r}_a^2\right)$$
$$=\sum_a\left(\tfrac{1}{4}(f_a r_a+v_a^2)d\mathbf{r}_a^2+(1+f_a r_a v_a^2)dy_a^2+\tfrac{1}{2}f_a r_a v_a dy_a\odot(d\tau_a+A_a)\right.$$
$$\left.+\tfrac{1}{4}f_a r_a(d\tau_a+A_a)^2\right).$$

Therefore,

$$\iota_{\partial/\partial y_a}ds^2=(1+f_a r_a v_a^2)dy_a+\tfrac{1}{2}v_a f_a r_a(d\tau_a+A_a)$$
$$=\frac{(1+f_a r_a v_a^2)}{(1+r_a v_a^2)}\theta_a+\tfrac{1}{2}f_a v_a r_a\left(1-\frac{1+f_a r_a v_a^2}{(1+r_a v_a^2)f_a}\right)(d\tau_a+A_a)=\frac{(1+f_a r_a v_a^2)}{(1+r_a v_a^2)}\theta_a$$
$$+\frac{v_a r_a}{2(1+r_a v_a^2)}(f_a-1)(d\tau_a+A_a).$$

It implies that the matrix (F_{ab}) is a diagonal matrix and

$$F_a = F_{aa} = \frac{(1+f_a r_a v_a^2)}{(1+r_a v_a^2)^2}, \quad \alpha_a = \frac{v_a r_a}{2(1+r_a v_a^2)^2}(f_a - 1)(d\tau_a + A_a). \tag{68}$$

Then the quotient metric is n

$$\begin{aligned}\hat{g} &= ds^2 - \sum_a (F_a \theta_a \otimes \theta_a + \theta_a \odot \alpha_a) \\ &= \frac{1}{4}\left(\frac{f_a}{r_a} + v_a^2\right) d\mathbf{r}_a^2 + \left(\frac{f_a r_a}{4} - \frac{r_a^2 v_a^2 (1+f_a r_a v_a^2)}{4(1+r_a v_a^2)^2} - \frac{v_a^2 r_a^2 (f_a - 1)}{2(1+r_a v_a^2)^2}\right)(d\tau_a + A_a)^2 \\ &= \frac{1}{4}\sum_a \left(\frac{f_a + r_a v_a^2}{1+r_a v_a^2}\right)\left(\left(\frac{1+r_a v_a^2}{r_a}\right) d\mathbf{r}_a^2 + \left(\frac{1+r_a v_a^2}{r_a}\right)^{-1} (d\tau_a + A_a)^2\right).\end{aligned} \tag{69}$$

When $f_a = 1$ for all a, we obtain a simple version of the LWY-metric,

$$ds^2_{\mathrm{LWY}} = \frac{1}{4}\sum_a \left(\left(\frac{1+r_a v_a^2}{r_a}\right) d\mathbf{r}_a^2 + \left(\frac{1+r_a v_a^2}{r_a}\right)^{-1} (d\tau_a + A_a)^2\right). \tag{70}$$

This is simple because this metric is a product metric.

In general, so long as not all the $\lambda_a = 1/v_a$ are equal, the quotient metric $\hat{g}$ is a HKT-metric. However, it is no longer conformal to the LWY-metric.

Contact metric 5-manifolds, CR twistor spaces and integrability

Mitsuhiro Itoh[a)]
Institute of Mathematics, University of Tsukuba, 305-8571, Ibaraki, Japan

(Received 28 August 2001; accepted for publication 4 March 2002)

The CR twistor space is defined over a contact metric 5-manifold M. Like the 4-dim twistor theory, the integrability of the almost CR twistor structure is discussed in terms of the Weyl conformal curvature and also the scalar curvature of M. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1476953]

I. INTRODUCTION AND MAIN THEOREMS

The twistor space for 4-manifolds stems from the idea of R. Penrose developed in mathematical physics of gravity (see Ref. 15). The twistor space is endowed with the canonical almost complex structure. The integrability of this almost complex structure is exhibited by Atiyah, Hitchin and Singer in terms of conformally half flatness of a base 4-manifold.

Theorem(Atiyah, Hitchin and Singer[2,3]): Let $\mathcal{Z}^-$ be the twistor space of an oriented Riemannian 4-manifold (M,g). Then, the almost complex structure on $\mathcal{Z}^-$ is integrable if and only if (M,g) is self-dual, namely, the anti-self-dual Weyl conformal tensor W^- vanishes.

The twistor space of a 4-manifold presents a profound link between 4-dimensional conformal geometry and theory of complex manifolds. For this direction, for instance, refer to Hitchin's paper[8] and the Ward correspondence.[19]

Twistor space is defined also on odd dimensional spaces, such as a mini-twistor space for Einstein-Weyl 3-manifolds, defined by N. Hitchin in Ref. 9. LeBrun defined in this direction a CR twistor space for conformal 3-manifolds in Ref. 14 as null cones over complexified tangent bundle.

We will focus on a contact 5-manifold in this article and investigate the twistor space defined on it. So, let M be a smooth 5-manifold and suppose that M be equipped with a contact metric structure (η,ξ,ϕ,g).

M admits then a particular direction along the characteristic field ξ in each tangent space and also the rank 4 contact bundle $\mathbf{E}=\mathrm{Ker}\ \eta$ so that $TM=\mathbf{E}\oplus\langle\xi\rangle$. The bundle $\mathbf{E}$ plays a role of the tangent bundle of a 4-manifold. To $\mathbf{E}$ is associated an SO(4)-principal bundle, the oriented orthonormal frame bundle $P_{\mathbf{E}}$.

We take as the CR twistor space $\mathcal{Z}$ the sphere bundle $\mathbf{U}(\Lambda^2_-(\mathbf{E}^*))=\{\alpha\in\Lambda^2_-(\mathbf{E}^*)\,|\,|\alpha|=2\}$ for the dual $\mathbf{E}^*$ of $\mathbf{E}$. Anti-self-dual two-forms α on $\mathbf{E}$ of norm $|\alpha|=2$ are identified with orthogonal almost complex structures J of $\mathbf{E}$. So, $\mathcal{Z}$ can be regarded as the space of orthogonal almost complex structures on the contact bundle $\mathbf{E}$.

To define an almost CR structure $\mathcal{J}$ on $\mathcal{Z}$ we utilize the contact splitting of TM and the tangent space decomposition of $\mathcal{Z}$ at $\alpha\in\mathcal{Z}$ into the vertical and horizontal subspaces: $T_\alpha\mathcal{Z}=\mathcal{V}_\alpha\oplus\mathcal{H}_\alpha$, where the vertical subspace $\mathcal{V}_\alpha\cong T\boldsymbol{P}^1(\mathbf{C})$ and the horizontal subspace $\mathcal{H}_\alpha\cong T_xM$, $x=\pi(\alpha)$. Here $\pi:\mathcal{Z}\to M$ is the projection.

At $\alpha\in\mathcal{Z}$ via the identification of α with J^α, an almost complex structure of $\mathbf{E}_x$, we define

$$\mathcal{J}_\alpha:\quad \mathcal{V}_\alpha\to\mathcal{V}_\alpha;\ \ \mathcal{J}_\alpha(V)=j(V),$$

$$\mathcal{H}'_\alpha\to\mathcal{H}'_\alpha;\ \ \pi_*(\mathcal{J}_\alpha(X'))=J^\alpha(\pi_*(X')),$$

a)Electronic mail: itohm@sakura.cc.tsukuba.ac.jp

$$\mathcal{H}''_\alpha \to \mathcal{H}''_\alpha; \quad \mathcal{J}_\alpha(X'') = 0.$$

Here j is the canonical almost complex structure of $P^1(\mathbf{C})$ and $\mathcal{H}$ has the splitting $\mathcal{H}_\alpha = \mathcal{H}'_\alpha \oplus \mathcal{H}''_\alpha$ according to the contact splitting of TM.

Set $\mathcal{E} = \mathcal{V} \oplus \mathcal{H}'$, the subbundle of the tangent bundle $T\mathcal{Z}$, on which $\mathcal{J}$ acts as an almost complex structure with the splitting $\mathcal{E} \otimes \mathbf{C} = \mathcal{E}^{1,0} \oplus \mathcal{E}^{0,1}$.

Definition: The almost CR structure $\mathcal{J}$ on $\mathcal{Z}$ is *integrable* if

$$[X - \sqrt{-1}\mathcal{J}X, Y - \sqrt{-1}\mathcal{J}Y] \in \Gamma(\mathcal{E}^{1,0})$$

for any smooth sections $X - \sqrt{-1}\mathcal{J}X, Y - \sqrt{-1}\mathcal{J}Y$ of $\mathcal{E}^{1,0}$.

The main purpose of this article is to exhibit an integrability of the almost CR structure $\mathcal{J}$ in terms of the base manifold curvature.

The curvature tensor $\mathcal{R}: \Lambda^2(T^*M) \to \Lambda^2(T^*M)$ of (M,g) enjoys the decomposition

$$\mathcal{R} = \mathcal{W} + \mathcal{B} - \frac{s}{20} id,$$

into the Weyl conformal curvature part $\mathcal{W}$, the trace free Ricci tensor part $\mathcal{B}$ and the scalar curvature part $-(s/20)\, id$.

In terms of the splitting of $\Lambda^2(T^*M)$,

$$\Lambda^2(T^*M) = \Lambda^2_+(\mathbf{E}^*) \oplus \Lambda^2_-(\mathbf{E}^*) \oplus \eta \wedge \Lambda^1(\mathbf{E}^*),$$

$\mathcal{R}$ has the block decomposition

$$\mathcal{R} = \begin{pmatrix} \mathcal{R}^+_+ & \mathcal{R}^-_+ & \mathcal{R}^0_+ \\ \mathcal{R}^+_- & \mathcal{R}^-_- & \mathcal{R}^0_- \\ \mathcal{R}^+_0 & \mathcal{R}^-_0 & \mathcal{R}^0_0 \end{pmatrix},$$

with the similar decompositions of $\mathcal{W}$, $\mathcal{B}$.[12]

The following theorem indicates the validity of contact geometrical analog of the theorem of Atiyah, Hitchin and Singer.

Theorem 1.1: Let (M, η, ξ, ϕ, g) be a K-contact 5-manifold and $\mathcal{Z} = \mathbf{U}(\Lambda^2_-(\mathbf{E}^*))$ its CR twistor space.

Then, $\mathcal{J}$ on $\mathcal{Z}$ is integrable if and only if (M,g) is self-dual contact-metric, in other words, the anti-self-dual Weyl conformal tensor $\mathcal{W}^-$ vanishes and the scalar curvature $s = -4$.

Here, a K-contact manifold is a contact metric manifold for which ξ is a Killing field (see Sec. II). The connection $\nabla^{\mathbf{E}}$, induced from the Levi-Civita connection, is utilized to define the vertical-horizontal splitting of $\mathcal{Z}$. However, it is observed that an arbitrary metric connection on $\mathbf{E}$, for example, a generalized Tanaka–Webster connection given by Tanno,[17] yields an almost CR structure on $\mathcal{Z}$, whose integrability may also be interesting.

The CR twistor space $\mathcal{Z}$ with the almost CR structure $(\mathcal{E}, \mathcal{J})$, even not integrable, admits a vector field $\tilde{\xi}$, the horizontal lift of ξ on M.

Theorem 1.2: Let $\mathcal{Z}$ be the CR twistor space of a K-contact 5-manifold (M, η, ξ, ϕ, g). Then, the following are equivalent.

(i) $\tilde{\xi}$ is a CR holomorphic vector field, i.e.,

$$[\tilde{\xi}, X - \sqrt{-1}\mathcal{J}X] \in \Gamma(\mathcal{E}^{1,0})$$

for any smooth section $X - \sqrt{-1}\mathcal{J}X$ of $\mathcal{E}^{1,0}$.

(ii) $\mathcal{R}^-_0 = \mathcal{W}^-_0 + \mathcal{B}^-_0 : \eta \wedge \Lambda^1(\mathbf{E}^*) \to \Lambda^2_-(\mathbf{E}^*)$ vanishes,

An almost CR structure $\mathcal{J}$ on $\mathcal{Z}$ induces an almost complex structure $\mathcal{I}$ on the product space $\mathcal{Z}\times\mathbf{R}$ or $\mathcal{Z}\times S^1$ such that $\mathcal{I}|_{\mathcal{E}}=\mathcal{J}$, $\mathcal{I}(\tilde{\xi})=\partial/\partial t$. It is not difficult to show that $\mathcal{I}$ on $\mathcal{Z}\times\mathbf{R}$ or $\mathcal{Z}\times S^1$ is integrable if and only if $\mathcal{J}$ on $\mathcal{Z}$ is integrable and also $\tilde{\xi}$ is CR holomorphic.

So an immediate consequence of Theorems 1.1 and 1.2 is the following integrability of the almost complex structure.

Corollary 1.1: Let (M,η,ξ,ϕ,g) be a K-contact 5-manifold. The almost complex manifold $(\mathcal{Z}\times\mathbf{R},\mathcal{I})$ is integrable if the following curvature conditions hold:

$$\mathcal{W}_-^-=0,$$

$$\mathcal{R}_0^-=\mathcal{W}_0^-+\mathcal{B}_0^-=0$$

and $s=-4$.

We exhibit certain examples of the K-contact 5-manifold for which the CR twistor space admits the integrable CR structure.

From its full curvature formula (see Ref. 4) a Sasakian 5-manifold (M,η,ξ,ϕ,g) with constant ϕ-sectional curvature $c=-3$ satisfies these three conditions in Corollary 1.1. So the CR twistor space of this manifold M admits the integrable almost CR structure with the CR holomorphic vector field $\tilde{\xi}$.

Restricting ourselves to a certain class of K-contact 5-manifolds, K-contact 5-manifolds admit an S^1-fibration with a connection η, the contact form. The above theorems are then transfered to the following.

Theorem 1.3: Let (M,η,ξ,ϕ,g) be a K-contact 5-manifold which is an S^1-principal bundle over a 4-manifold N with a connection η. Then, the CR twistor space $\mathcal{Z}$ of M is integrable if and only if N is self-dual, i.e., $W_N^-=0$ and has zero scalar curvature, $s_N=0$.

Moreover, the horizontal vector field $\tilde{\xi}$ is always CR holomorphic so that for a base 4-manifold N which is self-dual and of zero scalar curvature the product space $\mathcal{Z}\times\mathbf{R}$ or $\mathcal{Z}\times S^1$ is a complex 4-dimensional manifold.

From Boothby–Wang fibration theorem the base 4-manifold N in Theorem 1.3 must be an almost Kähler manifold with a Kähler form whose lift is $d\eta$. When M is moreover Sasakian, N is Kähler, due to the result of Hatakeyama (see Ref. 7). For a Kähler 4-manifold the scalar curvature $s=0$ if and only if the self-dual Weyl conformal tensor $W^+=0$ (see Refs. 10 and 5). Therefore the CR twistor space of a Sasakian 5-manifold M admitting a compatible S^1-bundle structure is integrable if and only if the base Kähler 4-manifold N of M is conformally flat $(W=0)$. Since N is self-dual, the twistor space $\mathcal{Z}$ of M is an S^1-fibration over the Penrose twistor space $\mathcal{Z}_N$ of N so that one gets a sequence of fibrations: $\mathcal{Z}\times\mathbf{R}\to\mathcal{Z}\to\mathcal{Z}_N$.

As a concrete example, we take a canonically defined circle bundle M over $N=S^2\times H^2$, the Riemannian product of S^2 and H^2. So, M is equipped with a Sasakian structure. N is geometrically conformally flat, Kähler and of $s_N=0$. Moreover, N is conformally equivalent to $\mathbf{R}\times(\mathbf{R}^3\backslash 0)$ and hence to $S^4\backslash C$, where C is a great circle so that $\mathcal{Z}_N$ is $P^3(\mathbf{C})\backslash\hat{C}$, where $\hat{C}$ is the set of twistor lines over C. The CR twistor space $\mathcal{Z}$ of M is then a certain circle bundle over $P^3(\mathbf{C})\backslash\hat{C}$. Namely we get the double fibration:

$$\mathcal{Z}\xrightarrow{S^1}P^3(\mathbf{C})\backslash\hat{C}\xrightarrow{P^1(\mathbf{C})}S^2\times H^2.$$

Dividing this by a certain discrete subgroup Γ of $\mathrm{SL}(2,\mathbf{R})$, one can get compact quotients. The details of the argument of Theorem 4 will be given elsewhere.[13]

Remarks: (i) Notice that $\tilde{\eta}=\pi^*\eta$, the pulled back one-form to $\mathcal{Z}$ of η, gives rise to the degeneracy of the Levi form $(Z_1,Z_2)\mapsto d\tilde{\eta}(\mathcal{J}Z_1,\overline{Z_2})$ so that our CR twistor space is not strongly pseudo-convex.

(ii) We have

$$\pi^*\Lambda^2_+(\mathbf{E}^*)=\Lambda^{(1,1)}(\mathcal{Z})\cap\pi^*\Lambda^2(\mathbf{E}^*)$$

similarly to the twistor space of a 4-manifold (see, for example, Ref. 2, p. 442), and contrarily $\Lambda^2_-(\mathbf{E}^*)$ lifts to $(\Lambda^{(2,0)}\oplus\Lambda^{(0,2)})(\mathcal{Z})$.

(iii) A contact CR analog of the Ward correspondence holds (see Ref. 2, p. 441 and Ref. 19). In fact, we easily observe that if V is a Hermitian vector bundle with a self-dual connection D, i.e., a connection D with curvature R^D satisfying $R^D\in\Gamma(\Lambda^2_+(\mathbf{E}^*)\otimes\mathrm{End}\,V)$ over a K-contact 5-manifold of $\mathcal{W}^-=0$ and $s=-4$, and if $\tilde{V}=\pi^*V$ is the pulled back bundle on $\mathcal{Z}$, then the lift $\tilde{D}=\pi^*D$ of D, a connection on $\tilde{V}$, satisfies two of the three properties of so-called Tanaka canonical connection, namely, (a) $i(\tilde{\xi})R^{\tilde{D}}=0$ and (b) $R^{\tilde{D}}\in\Gamma(\Lambda^{(1,1)}(\mathcal{Z})\otimes\mathrm{End}\,\tilde{V})$. See Refs. 16 and 18 for Tanaka canonical connection.

(iv) We can define, similarly to $\mathcal{Z}$, the positive type of CR twistor space $\mathcal{Z}^+$ over M as $\mathcal{Z}^+=\mathbf{U}(\Lambda^2_+(\mathbf{E}^*))$ which admits an almost CR structure $\mathcal{J}^+$. However, it can not be integrable, since the ϕ-invariance of $d\eta$ obstructs its integrability.

In Sec. II we will give a basic summary of contact-metric structure and almost CR structure. To investigate the integrability of the almost CR structure we take the projective spinor bundle description of the CR twistor space. We therefore provide in Sec. III a brief summary of Clifford algebra and spinors to define the projective spinor bundle. Integrability argument will be given in Sec. IV by lifting it up on the orthonormal frame bundle $P_{\mathbf{E}}$ of $\mathbf{E}$. We divide Sec. V into five small sections to accomplish a proof of Theorems 1. For this description and the argument of the integrability we owe much to Ref. 6. In Sec. VI we deal with the CR holomorphic condition of the horizontal characteristic field.

The author is indebted to the referee for valuable comments.

II. CONTACT METRIC STRUCTURE AND ALMOST CR STRUCTURE

We first introduce the notion of contact metric structure. For a reference of contact metric structures see Ref. 4 and also Ref. 11.

Definition 2.1: We call a quadruplet (η,ξ,ϕ,g) of tensors on a 5-manifold M a contact metric structure, if $\eta\in\Gamma(M;\Lambda^1(M))$, $\xi\in\mathcal{X}(M)$, $\phi\in\Gamma(M;\mathrm{End}TM)$ and a smooth metric g on M satisfy

(i) $\eta\wedge(d\eta)^2\neq 0$,
(ii) $\eta(\xi)=1$, $d\eta(\xi,\cdot)=0$,
(iii) $\phi^2(X)=-X+\eta(X)\xi$, and
(iv) $g(X,\phi Y)=\frac{1}{2}d\eta(X,Y)$, $g(\phi X,\phi Y)=g(X,Y)-\eta(X)\eta(Y)$.

Then $|\xi|=1$ and $\phi(\xi)=0$. So the contact bundle $\mathbf{E}=\mathrm{Ker}\,\eta$ carries a Hermitian structure $(g|_{\mathbf{E}},\phi|_{\mathbf{E}})$ and

$$TM=\mathbf{E}\oplus\langle\xi\rangle.$$

An orthonormal frame $e=(e_1,\ldots,e_4)$ of $(\mathbf{E},g|_{\mathbf{E}})$ is called ϕ-basis, if $e_2=\phi(e_1)$, $e_4=\phi(e_3)$.

Lemma 2.1: Let $e=(e_1,\ldots,e_4)$ be a ϕ-basis. Then for any odd permutation $(i_1,\ldots,i_4)$ of (1,2,3,4) the ξ-component of $[e_{i_1},e_{i_2}]+[e_{i_3},e_{i_4}]$ vanishes.

Proof: This is obvious, since

$$d\eta(\phi(X),\phi(Y))=d\eta(X,Y),\quad X,Y\in\mathbf{E},\tag{1}$$

and that the ξ-component of $[e_j,e_k]$ is $\eta([e_j,e_k])=-d\eta(e_j,e_k)$.

The contact bundle $\mathbf{E}$ inherits a metric connection $\nabla^{\mathbf{E}}$,

$$\nabla^{\mathbf{E}}_X Y=\mathrm{pr}^{\mathbf{E}}\nabla_X Y,$$

where $\mathrm{pr}^{\mathbf{E}}$ is the projection from TM onto $\mathbf{E}$ and ∇ is the Levi-Civita connection.

Lemma 2.2:

(i) For $Z\in\Gamma(\mathbf{E})$, and $X\in TM$,

$$\nabla_X Z=\nabla^{\mathbf{E}}_X Z+\alpha_X(Z),\quad \alpha_X(Z)=-g(Z,\nabla_X\xi)\xi,$$

and

(ii) the Gauss equation for the curvature $R^{\mathbf{E}}$ of $\nabla^{\mathbf{E}}$ is

$$R^{\mathbf{E}}(X,Y)Z=(R(X,Y)Z)^{\mathbf{E}}-g(Z,\nabla_X\xi)\nabla_Y\xi+g(Z,\nabla_Y\xi)\nabla_X\xi,\quad X,Y\in TM,\ Z\in\Gamma(\mathbf{E}).$$

Here the curvature tensor is defined as $R^{\mathbf{E}}(X,Y)Z=\nabla^{\mathbf{E}}_X\nabla^{\mathbf{E}}_Y Z-\nabla^{\mathbf{E}}_Y\nabla^{\mathbf{E}}_X Z-\nabla^{\mathbf{E}}_{[X,Y]}Z$.

A contact metric structure (η,ξ,ϕ,g) is called *K-contact* if ξ is a Killing field. Basic properties of a $(2n+1)$-dimensional K-contact structure are

$$\nabla_X\xi=-\phi(X),$$

$$R(\xi,X)\xi=-X,$$

$$Ric(\xi,\xi)=2n\quad\text{for}\quad X\in\mathbf{E}_x.$$

We have from Lemma 2.2, (ii) for a K-contact 5-manifold (M,η,ξ,ϕ,g) the components $R^{\mathbf{E}}_{ijk\ell}=g(R^{\mathbf{E}}(e_i,e_j)e_k,e_\ell)$ in terms of a ϕ-basis are given as follows.

Lemma 2.3:

$$R^{\mathbf{E}}_{ijk\ell}=R_{ijk\ell}-g(\phi e_i,e_k)g(\phi e_j,e_\ell)+g(\phi e_i,e_\ell)g(\phi e_j,e_k),$$

$$i,j,k,\ell=1,2,3,4.$$

Hence the curvature $R^{\mathbf{E}}$ enjoys the symmetries

$$R^{\mathbf{E}}_{ijk\ell}=R^{\mathbf{E}}_{k\ell ij}\ \text{ for }\ i,j,k,\ell=1,2,3,4.$$

Moreover, we get

$$R^{\mathbf{E}}_{ijk\ell}=R_{ijk\ell}$$

except for

$$R^{\mathbf{E}}_{1324}=R_{1324}-1,\quad R^{\mathbf{E}}_{1423}=R_{1423}+1.$$

A contact metric manifold (M,η,ξ,ϕ,g) is called *Sasakian* when the canonically defined almost complex structure on $M\times\mathbf{R}$ is integrable (see Ref. 4). This notion is equivalent to that ϕ satisfies $(\nabla_X\phi)Y=g(X,Y)\xi-\eta(Y)X$. A Sasakian manifold is K-contact. The curvature tensor of a Sasakian manifold satisfies

$$g(R(\xi,X)Y,Z)=0,\ X,Y,Z\in\mathbf{E},$$

giving rise to the partial vanishing of $\mathcal{R}$ as $\mathcal{R}^{+}_{0}=\mathcal{R}^{-}_{0}=0$.

Let N be a smooth orientable odd dimensional manifold.

In order to define a CR structure (i.e., an integrable almost CR structure) on N we take the complexified tangent bundle $TN\otimes\mathbf{C}$ and consider a special subbundle of it.

Let $\mathcal{S}$ be a complex vector subbundle of $TN\otimes\mathbf{C}$ satisfying $\mathcal{S}\cap\overline{\mathcal{S}}=\{0\}$ and $\dim_{\mathbf{C}}TN\otimes\mathbf{C}/\mathcal{S}\oplus\overline{\mathcal{S}}=1$. Then the pair $(N,\mathcal{S})$ or $\mathcal{S}$ is called an *almost CR structure* (see Ref. 1).

$\mathcal{S}$ is called *integrable* if $[\Gamma(\mathcal{S}),\Gamma(\mathcal{S})]\subset\Gamma(\mathcal{S})$.

Real hypersurfaces of a complex manifold are prototype of the CR manifold. From the equation on the structure tensor ϕ one can see that Sasakian manifolds are CR manifolds.

A vector field ζ on N is *CR holomorphic* when $[\zeta,\Gamma(\mathcal{S})]\subset\Gamma(\mathcal{S})$. For basic references of CR structure, see, for instance, Refs. 1, 16, and 18.

III. THE PROJECTIVE SPINOR DESCRIPTION

The contact bundle $\mathbf{E}$ of a contact metric 5-manifold (M,η,ξ,ϕ,g) is rank 4, oriented and carries the fiber inner product $g|_{\mathbf{E}}$. The oriented orthonormal frame bundle $P_{\mathbf{E}}$ associated to $\mathbf{E}$ has structure group SO(4).

The spinor group $\mathrm{Spin}(4)=\mathrm{SU}(2)_+\times\mathrm{SU}(2)_-$, the universal covering group of SO(4), enjoys, via the Clifford multiplication on $S=S^+\oplus S^-\cong\mathbf{C}^2\oplus\mathbf{C}^2$, the spinor representations $\rho^{\pm}:\mathrm{Spin}(4)\to\mathrm{SU}(S^{\pm})$ yielding the action r^- of SO(4) on $P^1(\mathbf{C})$.

So, we define the projective spinor bundle $\mathbf{P}(S^-(\mathbf{E}))$ associated to $\mathbf{E}$ as

$$\mathbf{P}(S^-(\mathbf{E}))=P_{\mathbf{E}}\times_{(\mathrm{SO}(4),r^-)}P(S^-).$$

From the basic Clifford multiplication property the CR twistor space $\mathcal{Z}=\mathbf{U}(\Lambda^2_-(\mathbf{E}^*))$ can be identified with the projectified negative spinor bundle $\mathbf{P}(S^-(\mathbf{E}))$. We will explain this in a natural way in Sec. IV.

To state more precisely we let $\mathrm{Cliff}(\mathbf{R}^4)$ denote the Clifford algebra over the Euclidean 4-space with the negative inner product $(\mathbf{R}^4,-\langle,\rangle)$.

$\mathrm{Cliff}(\mathbf{R}^4)$ is 16-dimensional and generated by the orthonormal basis e_1,e_2,e_3,e_4 of $\mathbf{R}^4$ with the relations $e_i\cdot e_i=-1$ for $i=1,\ldots,4$ and $e_i\cdot e_j+e_j\cdot e_i=0$ for $i\neq j$.

As is well known in Clifford algebra theory, the complexification $\mathrm{Cliff}^{\mathbf{C}}(\mathbf{R}^4)$ is isomorphic to the algebra $C(4)$ of all 4×4 complex matrices. We denote thus obtained isomorphism by $\rho:\mathrm{Cliff}^{\mathbf{C}}(\mathbf{R}^4)\to C(4)$. Then, ρ is defined as

$$e_1\mapsto I_2\otimes g_1,\ \ e_2\mapsto I_2\otimes g_2,\ \ e_3\mapsto g_1\otimes T,\ \ e_4\mapsto g_2\otimes T, \tag{2}$$

where

$$I_2=\begin{pmatrix}1&0\\0&1\end{pmatrix},\ \ T=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\ \ g_1=\begin{pmatrix}i&0\\0&-i\end{pmatrix},\ \ g_2=\begin{pmatrix}0&i\\i&0\end{pmatrix}. \tag{3}$$

We write $\rho(X)u$ as $X\cdot u$ for brevity, for $X\in\mathrm{Cliff}^{\mathbf{C}}(\mathbf{R}^4)$ and $u\in\mathbf{C}^4$.

The group Spin(4) is generated multiplicatively by all elements $x\cdot y$ with $x,y\in\mathbf{R}^4$ and $|x|=|y|=1$. The covering homomorphism $\lambda:\mathrm{Spin}(4)\to\mathrm{SO}(4)$ is given by

$$\lambda(z)x=z\cdot x\cdot z^{-1},\quad z\in\mathrm{Spin}(4),\ \ x\in\mathbf{R}^4. \tag{4}$$

The Lie algebra $\mathfrak{spin}(4)$ of Spin(4) is identified with the linear hull of the set $\{e_i\cdot e_j|i<j\}$. On the other hand, $\{E_{ij}|i<j\}$ is the standard basis of the Lie algebra $\mathfrak{so}(4)$. The differential $\rho_*:\mathfrak{spin}(4)\to\mathfrak{so}(4)$ of the map ρ is then given by $\rho_*(e_i\cdot e_j)=2E_{ij}$. Here E_{ij}, $i<j$, is the 4×4 skew-symmetric matrix whose (i,j)-entry is -1, while the (j,i)-entry is 1, and other ones are zero.

By restricting the map ρ to Spin(4), we get a complex representaion of Spin(4) on $\mathbf{C}^4\cong S$ for which we use the same ρ. This decomposes into two irreducible unitary representations, called the spinor representations $\rho^{\pm}:\mathrm{Spin}(4)\to\mathrm{SU}(S^{\pm})$, where $S=S^+\oplus S^-\cong\mathbf{C}^2\oplus\mathbf{C}^2$.

Notice that the differential of the representation $\rho:\mathrm{Spin}(4)\to\mathrm{GL}(S)$ is given by $\rho_*=\rho$.

With respect to a certain basis of $S=S^+\oplus S^-$ we have

$$\rho^-:\sum_{i<j}a_{ij}e_i\cdot e_j\mapsto\begin{pmatrix}i(a_{34}-a_{12})&(a_{13}+a_{24})+i(a_{14}-a_{23})\\-(a_{13}+a_{24})+i(a_{14}-a_{23})&i(a_{12}-a_{34})\end{pmatrix}. \tag{5}$$

The spinor representation ρ^- induces the transitive isometric action r^- of SO(4) on the complex projective line $P(S^-)\cong P^1(\mathbf{C})$ preserving the complex structure. So, we write

$$P(S^-)=\mathrm{SO}(4)/H^-,$$

where H^- is the isotropy group of this action at the reference point $[1:0]\in P^1(\mathbf{C})$.

To exploit the integrability of the almost CR structure $\mathcal{J}$ given in Sec. I we introduce bases of the Lie algebra $\mathfrak{h}^-$ of H^- and its orthogonal complement $\mathfrak{n}^-$ in $\mathfrak{so}(4)$.

The algebra $\mathfrak{h}^-$ is the image under $\lambda:\mathfrak{spin}(4)\to\mathfrak{so}(4)$ of the inverse image $(\rho^-)^{-1}(\mathfrak{s}^1)$, where $\mathfrak{s}^1$ is the isotropy subalgebra in $\mathfrak{su}(2)$ at the point [1:0].

Thus we get the following form of $\mathfrak{h}^-$ by the aid of the precise description of the spinor representation;

$$\mathfrak{h}^-=\left\{\sum_{i<j}a_{ij}E_{ij}\,\middle|\,a_{13}+a_{24}=0,\ a_{14}=a_{23}\right\}.$$

Its orthogonal complement $\mathfrak{n}^-$ with respect to the canonical inner product is

$$\mathfrak{n}^-=\mathbf{R}(E_{13}+E_{24})\oplus\mathbf{R}(E_{14}-E_{23})$$

giving the tangent space of $P^1(\mathbf{C})$ at the origin.

The complex structure j is now written as

$$j:E_{13}+E_{24}\mapsto-(E_{14}-E_{23}),\quad E_{14}-E_{23}\mapsto E_{13}+E_{24}.$$

The detailed argument of these descriptions is referred to Ref. 6.

IV. INTEGRABILITY OF THE ALMOST CR STRUCTURE

In their paper[2] Atiyah, Hitchin, and Singer proved the integrability by reducing the problem to the integrability on the spinor bundles S^- instead of $\mathbf{P}(S^-)$.

In this article, however, we will reduce the integrability to certain conditions on the frame bundle $P_{\mathbf{E}}$ with respect to a submersion $\Phi:P_{\mathbf{E}}\to\mathbf{P}(S^-(\mathbf{E}))$. The frame of argument we adopt here is almost similar to that in Ref. 6. But our CR twistor space situation is quite different from that in Ref. 6 and so we must proceed to observe the details of the argument.

Choose a point $x\in M$ and take a small neighborhood U of x diffeomorphic to $\mathbf{R}^5$. Then, $P_{\mathbf{E}}$ over U admits the associated Spin(4)-bundle $\tilde{P}_{\mathbf{E}}$ over U and hence the spinor bundle $S^-(\mathbf{E})_U=\tilde{P}_{\mathbf{E}}\times_{\mathrm{Spin}(4)}S^-$ over U.

The projection $p:S^-\to P(S^-);u\mapsto p(u)$ yields the canonical projection

$$\mathbf{p}:S^-(\mathbf{E})_U\to\mathbf{P}(S^-(\mathbf{E}))|_U;\hat{\psi}^-=[\tilde{e},u]\mapsto\psi^-=[e,p(u)],\quad\tilde{e}\in\tilde{P}_{\mathbf{E}}|_U,$$

where $\tilde{e}$ is a lift of $e\in P_{\mathbf{E}}|_U$.

To each ψ^- of $\mathbf{P}(S^-(\mathbf{E}))|_U$ at $x\in U$ we define an almost complex structure $J^{\psi^-}:\mathbf{E}_x\to\mathbf{E}_x$ in the following way.

Choose a nonzero $\hat{\psi}^-$ in $S^-(\mathbf{E})$ such that $\mathbf{p}(\hat{\psi}^-)=\psi^-$.

Then the Clifford multiplication induces the $\mathbf{R}$-linear isomorphism

$$\mathbf{E}_x\to S^-(\mathbf{E})_x;X\mapsto X\cdot\hat{\psi}^-.$$

The complex structure of $S^-(\mathbf{E})_x$ yields canonically a $g|_{\mathbf{E}}$-orthogonal almost complex structure J^{ψ^-} of $\mathbf{E}_x$ as

$$(J^{\psi^-}(X))\cdot\hat{\psi}^-=\sqrt{-1}(X\cdot\hat{\psi}^-).$$

Remark that this definition does not depend on any choice of negative spinors $\hat{\psi}^-$ for ψ^-.

So, $\mathbf{P}(S^-(\mathbf{E}))$ is identified with the space of reversely oriented, orthogonal, almost complex structures on $\mathbf{E}$ and hence with the twistor space $\mathcal{Z}=U(\Lambda^2_-(\mathbf{E}))$.

We decompose by the aid of the connection $\nabla^{\mathbf{E}}$ on $\mathbf{E}$ the tangent bundle $TP_{\mathbf{E}}$ into

$$TP_{\mathbf{E}}=\hat{\mathcal{V}}\oplus\hat{\mathcal{H}},$$

where $\hat{\mathcal{V}}$ and $\hat{\mathcal{H}}$ are the vertical and horizontal subbundles, respectively.

We further decompose $\hat{\mathcal{V}}$ into the isotropic vertical part $\hat{\mathcal{V}}^{\mathfrak{h}^-}=\{A^*|A\in\mathfrak{h}^-\}$ and its orthogonal complement $\hat{\mathcal{V}}^{\mathfrak{n}^-}=\{B^*|B\in\mathfrak{n}^-\}$. Here A^* means the fundamental vector field on $P_{\mathbf{E}}$ generated by $A\in\mathfrak{so}(4)$.

So we have the decomposition

$$TP_{\mathbf{E}}=\hat{\mathcal{V}}^{\mathfrak{h}^-}\oplus\hat{\mathcal{V}}^{\mathfrak{n}^-}\oplus\hat{\mathcal{H}}'\oplus\hat{\mathcal{H}}'',\quad \hat{\mathcal{H}}=\hat{\mathcal{H}}'\oplus\hat{\mathcal{H}}''$$

corresponding to the contact decomposition $TM=\mathbf{E}\oplus\langle\xi\rangle$.

Now we choose a point $q\in P(S^-)$ and take a nonzero spinor $u\in S^-$ such that $p(u)=q$.

So, associated to $u\in S^-$, we have a smooth submersion $\Phi=\Phi_u$: $P_{\mathbf{E}}\to\mathbf{P}(S^-(\mathbf{E}))$, $e\mapsto\psi^-=[e,p(u)]$.

Remark that these submersions Φ_u obey

$$\Phi_u(ea)=\Phi_{\hat{a}u}(e),e\in P_{\mathbf{E}}$$

for $a\in\mathrm{SO}(4)$ and $\hat{a}\in\mathrm{Spin}(4)$ with $\lambda(\hat{a})=a$.

We define an associated endomorphism $\hat{\mathcal{J}}:T_eP_{\mathbf{E}}\to T_eP_{\mathbf{E}}$ at $e\in P_{\mathbf{E}}$ by

(1) $\hat{\mathcal{J}}=0$ on $\hat{\mathcal{V}}^{\mathfrak{h}^-}$,

(2) $\hat{\mathcal{J}}=\hat{J}$ on $\hat{\mathcal{V}}^-$, where $\hat{J}$ is canonically defined as $\hat{J}(B^*)=(jB)^*$, $B\in\mathfrak{n}^-$,

(3) for $X\in\hat{\mathcal{H}}'$ $\hat{\mathcal{J}}(X)$ is the horizontal vector in $\hat{\mathcal{H}}'$ for which

$$(\pi_P)_*(\hat{\mathcal{J}}(X))=J^{\Phi(e)}((\pi_P)_*(X)),$$

where $J^{\Phi(e)}:\mathbf{E}_x\to\mathbf{E}_x$ is the almost complex structure defined by $\Phi(e)\in\mathbf{P}(S^-(\mathbf{E}))$, and

(4) $\hat{\mathcal{J}}=0$ on $\hat{\mathcal{H}}''$, i.e., $\hat{\mathcal{J}}(\hat{\xi})=0$ for the horizontal lift $\hat{\xi}$ of ξ.

The definition of $\hat{\mathcal{J}}$ on $P_{\mathbf{E}}$ yields the relation

$$\Phi_*(\hat{\mathcal{J}}(X))=\mathcal{J}(\Phi_*(X)),X\in TP_{\mathbf{E}}.$$

Remark that $\mathrm{Ker}\Phi_*=\hat{\mathcal{V}}^{\mathfrak{h}^-}$ and further Φ_* maps the subbundle $\hat{\mathcal{E}}=\hat{\mathcal{V}}^{\mathfrak{n}^-}\oplus\hat{\mathcal{H}}'$ isomorphically onto the subbundle $\mathcal{E}=\mathcal{V}\oplus\mathcal{H}'$ of $T\mathbf{P}(S^-(\mathbf{E}))$.

With respect to $\hat{\mathcal{J}}$ the complexified bundle $\hat{\mathcal{E}}\otimes\mathbf{C}=(\hat{\mathcal{V}}^{\mathfrak{n}^-}\oplus\hat{\mathcal{H}}')\otimes\mathbf{C}$ decomposes into the (1,0)-part and (0,1)-part as

$$\hat{\mathcal{E}}\otimes\mathbf{C}=\hat{\mathcal{E}}^{(1,0)}\oplus\hat{\mathcal{E}}^{(0,1)}.$$

Since the Φ is a submersion, the bracket operation $[\cdot,\cdot]$ is preserved through Φ for φ-related vector fields. So, we can state the integrability condition of the almost CR structure as follows.

Proposition 4.1: The almost CR structure $\mathcal{J}$ on $\mathcal{Z}=\mathbf{P}(S^-(\mathbf{E}))$ is integrable if and only if, for each $p(u)\in P(S^-)$, the endomorphism $\hat{\mathcal{J}}=\hat{\mathcal{J}}^{\Phi}$ associated to the $\Phi=\Phi_u$ fulfills

$$[Z-\sqrt{-1}\hat{\mathcal{J}}Z,W-\sqrt{-1}\hat{\mathcal{J}}W]\in\Gamma(\hat{\mathcal{V}}^{\mathfrak{h}^-}\otimes\mathbf{C}\oplus\hat{\mathcal{E}}^{(1,0)})$$

for any smooth sections $Z-\sqrt{-1}\hat{\mathcal{J}}Z,W-\sqrt{-1}\hat{\mathcal{J}}W$ of $\hat{\mathcal{E}}^{(1,0)}$.

Since the pair $(\mathfrak{h}^-,\mathfrak{n}^-)$ is a symmetric pair, that is, $[\mathfrak{n}^-,\mathfrak{n}^-]\subset\mathfrak{h}^-$, Proposition 4.1 reduces to the following.

Proposition 4.2: $\mathcal{J}$ on $\mathcal{Z}^-$ is integrable if and only if, with respect to any $\hat{\mathcal{J}}=\hat{\mathcal{J}}^{\Phi}$ associated to Φ_u, the following two conditions hold
(i)

$$[V-\sqrt{-1}\hat{\mathcal{J}}V,W-\sqrt{-1}\hat{\mathcal{J}}W]\in\Gamma(\hat{\mathcal{V}}^{\mathfrak{h}^-}\otimes\mathbf{C}\oplus\hat{\mathcal{E}}^{(1,0)})$$

for any smooth sections $V-\sqrt{-1}\hat{\mathcal{J}}V$ of $(\hat{\mathcal{V}}^{\mathfrak{n}^-})^{(1,0)}$ and $W-\sqrt{-1}\hat{\mathcal{J}}W$ of $(\hat{\mathcal{H}}')^{(1,0)}$.
(ii)

$$[Z-\sqrt{-1}\hat{\mathcal{J}}Z,W-\sqrt{-1}\hat{\mathcal{J}}W]\in\Gamma(\hat{\mathcal{V}}^{\mathfrak{h}^-}\otimes\mathbf{C}\oplus\hat{\mathcal{E}}^{(1,0)})$$

for any smooth sections $Z-\sqrt{-1}\hat{\mathcal{J}}Z,W-\sqrt{-1}\hat{\mathcal{J}}W$ of the same subbundle $(\hat{\mathcal{H}}')^{(1,0)}$.

V. THE CURVATURE CONDITIONS AND THE PROOF OF THEOREM 1.1

We will verify Theorem 1.1 by investigating the integrability hypothesis given in Proposition 4.2.

1. First we show by choosing appropriate negative spinors that the integrability condition implies the curvature conditions stated in Theorem 1.1, namely, that a K-contact 5-manifold (M,η,ξ,ϕ,g) satisfies $\mathcal{W}^-=0$ for the Weyl conformal curvature tensor $\mathcal{W}$ and the scalar curvature $s=-4$.

In fact, we will take three negative spinors in $S^-(\mathbf{E})$ such that the associated almost complex structures correspond to the three anti-self-dual forms $\theta_1\wedge\theta_2-\theta_3\wedge\theta_4,\theta_1\wedge\theta_3+\theta_2\wedge\theta_4,\theta_1\wedge\theta_4-\theta_2\wedge\theta_3$, respectively. Here $\{\theta_i\}$ is the dual frame of a ϕ-basis $\{e_i\}$.

We make use of the decomposition of $\mathfrak{so}(4)=\mathfrak{h}^-\oplus\mathfrak{n}^-$ and their bases given in Sec. III and set

$$Y_1=E_{12},\quad Y_2=E_{34},\quad Y_3=E_{13}-E_{24},\quad Y_4=E_{14}+E_{23},$$

$$Y_5=E_{13}+E_{24},\quad Y_6=E_{14}-E_{23},$$

so $\mathfrak{h}^-$ is spanned by $Y_i,i=1,\ldots,4$ and $\mathfrak{n}^-$ by Y_5,Y_6.

Let $x\in M$ and choose a neighborhood U containing x. Take an orthonormal frame field $e=(e_1,e_2,e_3,e_4)$ of $\mathbf{E}$, which is a ϕ-basis.

Thus, $e=(e_1,\ldots,e_4)$ gives a smooth section of $P_{\mathbf{E}}$ over U so that $P_{\mathbf{E}}$ admits a trivialization

$$P_{\mathbf{E}}|_U=U\times\mathrm{SO}(4).$$

Fix a u in $S^-\backslash\{0\}$ with the submersion $\Phi=\Phi_u:P_{\mathbf{E}}|_U\to\mathbf{P}(S^-(\mathbf{E}))|_U$. So $\Phi(e)\in\mathbf{P}(S^-(\mathbf{E}))|_U$ yields an almost complex structure $J=J^{\Phi(e)}:\mathbf{E}_y\to\mathbf{E}_y$ at $y=\pi_P(e)\in U$.

Then $\hat{\mathcal{H}}'$ is spanned by

$$Z_i=e_i-(\omega^{\mathbf{E}}(e_i))^*=e_i-\sum_{j<k}\omega^{\mathbf{E}}_{jk}(e_i)E^*_{jk},\quad i=1,\ldots,4,$$

where $\omega^{\mathbf{E}}=(\omega^{\mathbf{E}}_{jk})=\Sigma\omega_{jk}E_{jk}$ is the connection form of $\nabla^{\mathbf{E}}$ with respect to the frame field $e=(e_i)$;

$$\nabla^{\mathbf{E}}_X e_i=\sum_{j=1}^{4}\omega^{\mathbf{E}}_{ji}(X)e_j.$$

To simplify the argument we may assume $\omega^{\mathbf{E}}_{jk}=0$ at x.

From the definition of $\hat{\mathcal{J}}$ we have

$$\hat{\mathcal{J}}Z_i = J^{\Phi(e)}e_i - \sum \omega^{\mathbf{E}}_{jk}(J^{\Phi(e)}e_i)E^*_{jk}, \quad i=1,2,3,4.$$

Hence the integrability conditions of Proposition 4.2 reduce to the following two conditions at x:

$$\text{(i)}' \quad [Y^*_6 - \sqrt{-1}Y^*_5,\ Z_i - \sqrt{-1}\hat{\mathcal{J}}Z_i] \in \Gamma((\hat{\mathcal{V}}^{\mathfrak{h}^-})\otimes\mathbf{C}\oplus(\hat{\mathcal{E}})^{(1,0)}),\ \ i=1,\ldots,4$$

and

$$\text{(ii)}' \quad [Z_i - \sqrt{-1}\hat{\mathcal{J}}Z_i,\ Z_j - \sqrt{-1}\hat{\mathcal{J}}Z_j] \in \Gamma((\hat{\mathcal{V}}^{\mathfrak{h}^-})\otimes\mathbf{C}\oplus(\hat{\mathcal{E}})^{(1,0)}),\ \ i<j$$

hold.

Remark that (ii)′ is equivalent to

$$\text{(ii)}'' \quad \hat{\mathcal{J}}([Z_i - \sqrt{-1}\hat{\mathcal{J}}Z_i, Z_j - \sqrt{-1}\hat{\mathcal{J}}Z_j]) - \sqrt{-1}[Z_i - \sqrt{-1}\hat{\mathcal{J}}Z_i, Z_j - \sqrt{-1}\hat{\mathcal{J}}Z_j] \in \Gamma((\hat{\mathcal{V}}^{\mathfrak{h}^-})\otimes\mathbf{C}),$$

since $\hat{\mathcal{E}}^{(1,0)}$ is the $\sqrt{-1}$-eigenspace of $\hat{\mathcal{J}}$.

First we remark that $(i)'$ is always satisfied.

In fact, Y^*_5, Y^*_6 and E^*_{jk} are vector fields on $U\times\mathrm{SO}(4)$ having only $\mathrm{SO}(4)$-components which are constant along U, while e_i and $J^{\Phi(e)}e_i$ have only U-components, constant along $\mathrm{SO}(4)$. So

$$[Y^*_6 - \sqrt{-1}Y^*_5, Z_i - \sqrt{-1}\hat{\mathcal{J}}Z_i] = -\sum \omega^{\mathbf{E}}_{jk}(e_i)[Y^*_6 - \sqrt{-1}Y^*_5, E^*_{jk}] + \sqrt{-1}\sum \omega^{\mathbf{E}}_{jk}(J^{\Phi(e)}e_i)[Y^*_6 - \sqrt{-1}Y^*_5, E^*_{jk}].$$

The above vanishes at x, since $\omega^{\mathbf{E}}=0$. So the condition (i)′ is fulfilled.

2. To exploit (ii)″ we choose a $u\in S^-\backslash\{0\}$ such that $J=J^{\Phi(e)}$ associated to $\Phi(e)=\Phi_u(e)$ is given by

$$J(e_1)=e_2, \quad J(e_3)=-e_4.$$

So we have $\hat{\mathcal{J}}Z_1=Z_2$ and $\hat{\mathcal{J}}Z_4=Z_3$ and then $Z_1-\sqrt{-1}\hat{\mathcal{J}}Z_1=Z_1-\sqrt{-1}Z_2$ and $Z_3-\sqrt{-1}\hat{\mathcal{J}}Z_3=Z_3+\sqrt{-1}Z_4$.

The nontrivial conditions in (ii)″ are then only the one for $(i,j)=(1,3)$, namely,

$$\hat{\mathcal{J}}[Z_1-\sqrt{-1}Z_2, Z_3+\sqrt{-1}Z_4] - \sqrt{-1}[Z_1-\sqrt{-1}Z_2, Z_3+\sqrt{-1}Z_4] \in \Gamma((\hat{\mathcal{V}}^{\mathfrak{h}^-})\otimes\mathbf{C}).$$

At the e in $P_{\mathbf{E}}$ over x the bracket $[Z_1,Z_3]$ takes the value

$$\begin{aligned}[Z_1,Z_3] &= [e_1-(\omega^{\mathbf{E}}(e_1))^*, e_3-(\omega^{\mathbf{E}}(e_3))^*] \\ &= [e_1,e_3]-[e_1,(\omega^{\mathbf{E}}(e_3))^*]+[e_3,(\omega^{\mathbf{E}}(e_1))^*]+[(\omega^{\mathbf{E}}(e_1))^*,(\omega^{\mathbf{E}}(e_3))^*] \\ &= [e_1,e_3]-\left[e_1,\sum \omega^{\mathbf{E}}_{jk}(e_3)E^*_{jk}\right]+\left[e_3,\sum \omega^{\mathbf{E}}_{jk}(e_1)E^*_{jk}\right].\end{aligned}$$

It follows then from the assumption $\omega^{\mathbf{E}}=0$ at the x that

$$[Z_1,Z_3]=[e_1,e_3]-\sum e_1(\omega^{\mathbf{E}}_{jk}(e_3)))E^*_{jk}+\sum e_3(\omega^*_{jk}(e_1))E^*_{jk}$$

$$=[e_1,e_3]-\sum_{j<k}(d\omega^{\mathbf{E}}_{jk})(e_1,e_3)E^*_{jk}$$

$$=[e_1,e_3]-\sum_{j<k}\Omega^{\mathbf{E}}_{jk}(e_1,e_3)E^*_{jk}, \tag{6}$$

where $\Omega^{\mathbf{E}}$ denotes the curvature form of $\nabla^{\mathbf{E}}$ on $\mathbf{E}$. Thus we get the following.

Lemma 5.1: At e in $P_{\mathbf{E}}=U\times \mathrm{SO}(4)$ over x

$$[Z_1-\sqrt{-1}Z_2,Z_3+\sqrt{-1}Z_4]=-\sum\{\Omega^{\mathbf{E}}_{jk}(e_1,e_3)+\Omega^{\mathbf{E}}_{jk}(e_2,e_4)+\sqrt{-1}(\Omega^{\mathbf{E}}_{jk}(e_1,e_4)$$
$$-\Omega^{\mathbf{E}}_{jk}(e_2,e_3))\}E^*_{jk}. \tag{7}$$

For brevity we write this as

$$[Z_1-\sqrt{-1}Z_2,Z_3+\sqrt{-1}Z_4]=-\sum\Omega^{\mathbf{E}}_{jk}(e_1-\sqrt{-1}e_2,e_3+\sqrt{-1}e_4)E^*_{jk}. \tag{8}$$

Proof: From (2)

$$[Z_1-\sqrt{-1}Z_2,Z_3+\sqrt{-1}Z_4]=\{[e_1,e_3]+[e_2,e_4]\}+\sqrt{-1}\{[e_1,e_4]-[e_2,e_3]\}-\sum\{\Omega^{\mathbf{E}}_{jk}(e_1,e_3)$$
$$+\Omega^{\mathbf{E}}_{jk}(e_2,e_4)+\sqrt{-1}(\Omega^{\mathbf{E}}_{jk}(e_1,e_4)-\Omega^{\mathbf{E}}_{jk}(e_2,e_3))\}E^*_{jk}. \tag{9}$$

From Lemma 2.1, the first two terms on the rhs have no ξ-component. So, they vanish at x, since $[e_1,e_3]+[e_2,e_4]+\cdots$ is given by $\nabla^{\mathbf{E}}_{e_1}e_3-\nabla^{\mathbf{E}}_{e_3}e_1+\cdots$ which vanishes at x.

We now express (5) in terms of the basis $\{Y^*_i|i=1,\ldots,6\}$ as

$$[Z_1-\sqrt{-1}Z_2,Z_3+\sqrt{-1}Z_4]=-\Omega^{\mathbf{E}}_{12}(s,t)Y^*_1-\Omega^{\mathbf{E}}_{34}(s,t)Y^*_2-\tfrac{1}{2}\{\Omega^{\mathbf{E}}_{13}(s,t)-\Omega^{\mathbf{E}}_{24}(s,t)\}Y^*_3$$
$$-\tfrac{1}{2}\{\Omega^{\mathbf{E}}_{14}(s,t)+\Omega^{\mathbf{E}}_{23}(s,t)\}Y^*_4-\tfrac{1}{2}\{\Omega^{\mathbf{E}}_{13}(s,t)+\Omega^{\mathbf{E}}_{24}(s,t)\}Y^*_5$$
$$-\tfrac{1}{2}\{\Omega^{\mathbf{E}}_{14}(s,t)-\Omega^{\mathbf{E}}_{23}(s,t)\}Y^*_6,$$

where we set $s=e_1-\sqrt{-1}e_2$ and $t=e_3+\sqrt{-1}e_4$, for brevity.

So, by the definition of $\hat{\mathcal{J}}$,

$$\hat{\mathcal{J}}[Z_1-\sqrt{-1}Z_2,Z_3+\sqrt{-1}Z_4]=\tfrac{1}{2}\{\Omega^{\mathbf{E}}_{13}(s,t)+\Omega^{\mathbf{E}}_{24}(s,t)\}Y^*_6-\tfrac{1}{2}\{\Omega^{\mathbf{E}}_{14}(s,t)-\Omega^{\mathbf{E}}_{23}(s,t)\}Y^*_5. \tag{10}$$

On the other hand,

$$\sqrt{-1}[Z_1-\sqrt{-1}Z_2,Z_3+\sqrt{-1}Z_4]=-\frac{\sqrt{-1}}{2}\{\Omega^{\mathbf{E}}_{13}(s,t)+\Omega^{\mathbf{E}}_{24}(s,t)\}Y^*_5-\frac{\sqrt{-1}}{2}\{\Omega^{\mathbf{E}}_{14}(s,t)$$
$$-\Omega^{\mathbf{E}}_{23}(s,t)\}Y^*_6 \mod \hat{\mathcal{V}}^{(1)^-}. \tag{11}$$

Therefore the condition (ii)″ for $(i,j)=(1,3)$ is equivalent to

$$\hat{\mathcal{J}}[Z_1-\sqrt{-1}Z_2,Z_3+\sqrt{-1}Z_4]-\sqrt{-1}[Z_1-\sqrt{-1}Z_2,Z_3+\sqrt{-1}Z_4]$$
$$=\left\{-\frac{1}{2}(\Omega^{\mathbf{E}}_{14}(s,t)-\Omega^{\mathbf{E}}_{23}(s,t))+\frac{\sqrt{-1}}{2}(\Omega^{\mathbf{E}}_{13}(s,t)+\Omega^{\mathbf{E}}_{24}(s,t))\right\}Y_5^*$$
$$+\left\{\frac{1}{2}(\Omega^{\mathbf{E}}_{13}(s,t)+\Omega^{\mathbf{E}}_{24}(s,t))+\frac{\sqrt{-1}}{2}(\Omega^{\mathbf{E}}_{14}(s,t)-\Omega^{\mathbf{E}}_{23}(s,t))\right\}Y_6^*\in\Gamma(\hat{\mathcal{V}}^{\flat^-}\otimes\mathbf{C}).$$

Clearly this holds if and only if

$$-\frac{1}{2}(\Omega^{\mathbf{E}}_{14}(s,t)-\Omega^{\mathbf{E}}_{23}(s,t))+\frac{\sqrt{-1}}{2}(\Omega^{\mathbf{E}}_{13}(s,t)+\Omega^{\mathbf{E}}_{24}(s,t))=0, \tag{12}$$

$$\frac{1}{2}(\Omega^{\mathbf{E}}_{13}(s,t)+\Omega^{\mathbf{E}}_{24}(s,t))+\frac{\sqrt{-1}}{2}(\Omega^{\mathbf{E}}_{14}(s,t)-\Omega^{\mathbf{E}}_{23}(s,t))=0. \tag{13}$$

Equation (13) is reduced to (12) and one can see that, when one writes $\Omega^{\mathbf{E}}_{k\ell}(e_i,e_j)=R^{\mathbf{E}}_{\ell kij}$, (12) is written as the two real equations;

$$R^{\mathbf{E}}_{1341}+R^{\mathbf{E}}_{2441}-R^{\mathbf{E}}_{1332}-R^{\mathbf{E}}_{2432}+R^{\mathbf{E}}_{1431}-R^{\mathbf{E}}_{2331}+R^{\mathbf{E}}_{1442}-R^{\mathbf{E}}_{2342}=0 \tag{14}$$

and

$$R^{\mathbf{E}}_{1441}-R^{\mathbf{E}}_{2341}-R^{\mathbf{E}}_{1432}+R^{\mathbf{E}}_{2332}-R^{\mathbf{E}}_{1331}-R^{\mathbf{E}}_{2431}-R^{\mathbf{E}}_{1342}-R^{\mathbf{E}}_{2442}=0. \tag{15}$$

From the symmetry of the curvature $R^{\mathbf{E}}_{ijk\ell}$ in (i,j) and (k,ℓ) these are

$$-R^{\mathbf{E}}_{1413}+R^{\mathbf{E}}_{1323}-R^{\mathbf{E}}_{1424}+R^{\mathbf{E}}_{2324}=0 \tag{16}$$

and

$$-R^{\mathbf{E}}_{1414}+2R^{\mathbf{E}}_{1423}-R^{\mathbf{E}}_{2323}+R^{\mathbf{E}}_{1313}+2R^{\mathbf{E}}_{1324}+R^{\mathbf{E}}_{2424}=0. \tag{17}$$

By the aid of Lemma 2.3 and the remark there they can be further written in terms of the Riemannian curvature $R_{ijk\ell}$ of (M,η,ξ,ϕ,g) as

$$-R_{1413}+R_{1323}-R_{1424}+R_{2324}=0 \tag{18}$$

and

$$-R_{1414}+2(R_{1423}+1)-R_{2323}+R_{1313}+2(R_{1324}-1)+R_{2424}=0. \tag{19}$$

We now make use of the decomposition of $R_{ijk\ell}$ in terms of the Weyl conformal tensor $W_{ijk\ell}$, the Ricci tensor $R_{ij}=\Sigma_k R_{kijk}$ and the scalar curvature s:

$$R_{ijk\ell}=W_{ijk\ell}-\frac{1}{3}(R_{ik}\delta_{j\ell}+R_{j\ell}\delta_{ik}-R_{i\ell}\delta_{jk}-R_{jk}\delta_{i\ell})-\frac{s}{12}(\delta_{jk}\delta_{i\ell}-\delta_{j\ell}\delta_{ik}).$$

We then rewrite the above as follows:

$$-W_{1414}+2W_{1423}-W_{2323}+W_{1313}+2W_{1324}+W_{2424}=0$$
$$-W_{1413}+W_{1323}-W_{1424}+W_{2324}=0, \tag{20}$$

namely

$$\mathcal{W}(\theta_1\wedge\theta_4-\theta_2\wedge\theta_3,\theta_1\wedge\theta_4-\theta_2\wedge\theta_3)=\mathcal{W}(\theta_1\wedge\theta_3+\theta_2\wedge\theta_4,\theta_1\wedge\theta_3+\theta_2\wedge\theta_4), \tag{21}$$

$$\mathcal{W}(\theta_1\wedge\theta_4-\theta_2\wedge\theta_3,\theta_1\wedge\theta_3+\theta_2\wedge\theta_4)=0. \tag{22}$$

3. We next take another $u'\in S^-\backslash\{0\}$ such that J associated with $\Phi_{u'}$ is given

$$J(e_1)=e_3,\quad J(e_2)=e_4.$$

Just like the preceding case, we get

$$\mathcal{W}(\theta_1\wedge\theta_2-\theta_3\wedge\theta_4,\theta_1\wedge\theta_4-\theta_2\wedge\theta_3)=\mathcal{W}(\theta_1\wedge\theta_3-\theta_4\wedge\theta_2,\theta_1\wedge\theta_4-\theta_2\wedge\theta_3) \tag{23}$$

and

$$\mathcal{W}(\theta_1\wedge\theta_4-\theta_2\wedge\theta_3,\theta_1\wedge\theta_4-\theta_2\wedge\theta_3)+\mathcal{W}(\theta_1\wedge\theta_2-\theta_3\wedge\theta_4,\theta_1\wedge\theta_3+\theta_2\wedge\theta_4)=\frac{s}{6}+\frac{2}{3}. \tag{24}$$

Notice a K-contact metric 5-manifold M has the scalar curvature $s=\Sigma_{i=1}^4 R_{ii}+Ric(\xi,\xi)$ and $Ric(\xi,\xi)=4$.

Further, choose a $u''\in S^-\backslash\{0\}$ such that the associated almost complex structure J satisfies

$$J(e_1)=e_4,\quad J(e_3)=e_2.$$

In this case we write similarly the integrability condition as

$$\mathcal{W}(\theta_1\wedge\theta_3-\theta_4\wedge\theta_2,\theta_1\wedge\theta_4-\theta_2\wedge\theta_3)=\mathcal{W}(\theta_1\wedge\theta_2-\theta_3\wedge\theta_4,\theta_1\wedge\theta_3+\theta_2\wedge\theta_4) \tag{25}$$

and

$$\mathcal{W}(\theta_1\wedge\theta_3-\theta_4\wedge\theta_2,\theta_1\wedge\theta_3-\theta_4\wedge\theta_2)+\mathcal{W}(\theta_1\wedge\theta_4-\theta_2\wedge\theta_3,\theta_1\wedge\theta_2-\theta_3\wedge\theta_4)=\frac{s}{6}+\frac{2}{3}. \tag{26}$$

4. From the above equations altogether, we see that $\mathcal{W}_-^-$ has only diagonal components. Further, by making use of the symmetric consideration in indices $\{1,2,3,4\}$, that is, by taking account of the even permutation invariance of the integrability, it follows that $\mathcal{W}_-^-$ is a scalar multiple $c=s/6+\frac{2}{3}$ of the standard bilinear form. Notice that the permutational invariance is based on the ambiguity in choosing the isotropy subgroup H^- representing $P^1(\mathbf{C})$ as $\mathrm{SO}(4)/H^-$.

Therefore, from the trace free property of the Weyl conformal tensor $\mathcal{W}_-^-$ must vanish and $s/6+\frac{2}{3}=0$, that is, $s=-4$. In fact, we have the following.

Lemma 5.2:

$$\mathrm{tr}\mathcal{W}_-^-=0.$$

Proof: Since $\theta_1\wedge\theta_2-\theta_3\wedge\theta_4$, $\theta_1\wedge\theta_3-\theta_4\wedge\theta_2$ and $\theta_1\wedge\theta_4-\theta_2\wedge\theta_3$ form a basis of $\Lambda_-^2(\mathbf{E}^*)$,

$$\begin{aligned}\mathrm{tr}\mathcal{W}_-^-=&\mathcal{W}(\theta_1\wedge\theta_2-\theta_3\wedge\theta_4,\theta_1\wedge\theta_2-\theta_3\wedge\theta_4)+\mathcal{W}(\theta_1\wedge\theta_3-\theta_4\wedge\theta_2,\theta_1\wedge\theta_3-\theta_4\wedge\theta_2)\\&+\mathcal{W}(\theta_1\wedge\theta_4-\theta_2\wedge\theta_3,\theta_1\wedge\theta_4-\theta_2\wedge\theta_3),\end{aligned} \tag{27}$$

which reduces to

$$\mathrm{tr}\mathcal{W}_-^-=\sum_{i,j=1,\,i<j}^{4} W_{ijij}-2(W_{1234}+W_{1342}+W_{1423}).$$

Here the second term vanishes from the first Bianchi identity, since $W_{1234}+W_{1342}+W_{1423}=R_{1234}+R_{1342}+R_{1423}$. On the other hand, from the trace free property of the Weyl conformal tensor W we have $\Sigma_{a=1}^{4}W_{a1a1}=-W_{0101}$ where 0 means the ξ-direction. So, by using again the trace free property the half of the first term is

$$\sum_a W_{a1a1}+\sum_a W_{a2a2}+\sum_a W_{a3a3}+\sum_a W_{a4a4}=-\sum_a W_{0a0a}=0.$$

5. In order to verify the converse implication of Theorem 1.1 it suffices to show that under the curvature conditions in Theorem 1.1 $\mathcal{J}$ is integrable at an arbitrary $\psi\in\mathcal{Z}=\mathbf{P}(S^-(\mathbf{E}))$. Any ψ can be represented as $[e,p(v)]$, where $e=(e_1,\ldots,e_4)$ is an orthonormal ϕ-basis at the point $\pi(\psi)=x$ and $v\in S^-$. But there is an $\hat{a}=(\mathrm{id},a_-)\in\mathrm{Spin}(4)=\mathrm{SU}(2)_+\times\mathrm{SU}(2)_-$ such that $v=\hat{a}\cdot u$ for the appropriate negative spinor $u\in S^-$ which appeared in Sec. V B.

So $\psi=[e,p(\hat{a}\cdot u)]$ is $[ea,p(u)]$, $a\in\mathrm{SO}(4)$.

Since the property of ϕ-basis is invariant under the $\mathrm{SU}(2)_-$-action, ea is again a ϕ-basis.

Renaming ea as e, we have the induced almost complex structure $J=J^{\psi}:\mathbf{E}_x\to\mathbf{E}_x$ satisfying

$$J(e_1)=e_2,\quad J(e_3)=-e_4.$$

So, the integrability of $\mathcal{J}$ at ψ reduces to the one of $\mathcal{J}$ at a particular negative spinor, which is guaranteed by the curvature condition $\mathcal{W}_-=0$ and $s=-4$, as was shown in Sec. V B.

Thus Theorem 1.1 is completely proved.

VI. THE CR HOLOMORPHICITY OF $\tilde{\xi}$

To prove Theorem 1.2 we take, similarly as in the proof of Theorem 1.1, over $P_{\mathbf{E}}$ the horizontal lift $\hat{\xi}$ of ξ and consider the CR holomorphicity of $\tilde{\xi}$ in terms of $\hat{\xi}$.

$\tilde{\xi}$ on $\mathcal{Z}$ is CR holomorphic if and only if, for each $\Phi_u:P_{\mathbf{E}}\to\mathcal{Z}$, $u\in S^-$, it holds that $[\hat{\xi},Z]$ is a section of $\hat{\mathcal{E}}^{1,0}$ mod $\Gamma(\hat{\mathcal{V}}^{\mathfrak{h}^-}\otimes\mathbf{C})$ for each section Z of $\hat{\mathcal{E}}^{1,0}$.

This is equivalent to the following:

For each Φ_u

(i) $[\hat{\xi},Y_6^*-\sqrt{-1}Y_5^*]$ is a section of $\hat{\mathcal{E}}^{1,0}$ mod $\Gamma(\hat{\mathcal{V}}^{\mathfrak{h}^-}\otimes\mathbf{C})$, and

(ii) $[\hat{\xi},Z-\sqrt{-1}\hat{\mathcal{J}}Z]$ is a section of $\hat{\mathcal{E}}^{1,0}$ mod $\Gamma(\hat{\mathcal{V}}^{\mathfrak{h}^-}\otimes\mathbf{C})$ for any $Z\in\Gamma(\hat{\mathcal{H}}')$, where $\hat{\mathcal{J}}$ is the almost complex structure associated to Φ_u.

The first condition is always fulfilled.

It suffices for the proof of Theorem 1.2 to show the following.

Proposition 6.1: Let (M,η,ξ,ϕ,g) be a K-contact metric 5-manifold and $\mathcal{Z}$ be its CR twistor space.

$\tilde{\xi}$ is CR holomorphic on $\mathcal{Z}$ if and only if the curvature R of (M,η,ξ,ϕ,g) satisfies

$$R_{0i12}-R_{0i34}=R_{0i13}+R_{0i24}=R_{0i14}-R_{0i23}=0,\ \ i=1,\ldots,4, \tag{28}$$

where $(e_1,\ldots,e_4)$ is an orthonormal ϕ-basis and $e_0=\xi$.

Proof of Proposition 6.1: We will investigate condition (ii).

Assume $\tilde{\xi}$ is CR holomorphic.

Take a point $x\in M$ and an orthonormal frame field e of $\mathbf{E}$ around x which is a ϕ-basis and choose the spinor $u\in S^-\setminus\{0\}$ again such that the associated almost complex structure J satisfies

$$J(e_1)=e_2,\quad J(e_3)=-e_4.$$

As was shown in Sec. V $Z_i=e_i-(\omega^{\mathbf{E}}(e_i))^*$ is the horizontal lift of e_i and $Z_1-\sqrt{-1}Z_2$, $Z_4-\sqrt{-1}Z_3$ span $(\hat{\mathcal{H}}')^{1,0}$.

Then, the condition (ii) for vector fields $Z_1-\sqrt{-1}Z_2$, $Z_4-\sqrt{-1}Z_3$ is written in terms of the curvature $R^{\mathbf{E}}$ as

$$-(R^{\mathbf{E}}_{1014}-R^{\mathbf{E}}_{1023})+(R^{\mathbf{E}}_{2013}+R^{\mathbf{E}}_{2024})=0,$$

$$(R^{\mathbf{E}}_{2014}-R^{\mathbf{E}}_{2023})+(R^{\mathbf{E}}_{1013}+R^{\mathbf{E}}_{1024})=0$$

and

$$-(R^{\mathbf{E}}_{4014}-R^{\mathbf{E}}_{4023})+(R^{\mathbf{E}}_{3013}+R^{\mathbf{E}}_{3024})=0,$$

$$(R^{\mathbf{E}}_{3014}-R^{\mathbf{E}}_{3023})+(R^{\mathbf{E}}_{4013}+R^{\mathbf{E}}_{4024})=0.$$

Since $\phi(\xi)=0$, from the Gauss equations in Sec. II we get

$$(R_{1014}-R_{1023})-(R_{2013}+R_{2024})=0,$$

$$(R_{2014}-R_{2023})+(R_{1013}+R_{1024})=0$$

and

$$(R_{4014}-R_{4023})-(R_{3013}+R_{3024})=0,$$

$$(R_{3014}-R_{3023})+(R_{4013}+R_{4024})=0.$$

We take another negative spinor $u'\in S^-\backslash\{0\}$. Then the conditions for u' are written similarly. So, we obtain

$$R_{0i13}+R_{0i24}=R_{0i14}-R_{0i23}=0,\quad i=0,\ldots,4.$$

By the permutational argument we have also $R_{0i12}-R_{0i34}=0$, $i=1,\ldots,4$.

The converse implication of Proposition 6.1 is obtained without difficulty, just like the proof of Theorem 1.1. So we complete the proof.

Cyclic identities involving Jacobi elliptic functions

Avinash Khare[a] and Uday Sukhatme[b]
Department of Physics, University of Illinois at Chicago, Chicago, Illinois 60607-7059

(Received 22 March 2002; accepted for publication 5 April 2002)

We state and discuss numerous new mathematical identities involving Jacobi elliptic functions $\mathrm{sn}(x,m)$, $\mathrm{cn}(x,m)$, and $\mathrm{dn}(x,m)$, where m is the elliptic modulus parameter. In all identities, the arguments of the Jacobi functions are separated by either $2K(m)/p$ or $4K(m)/p$, where p is an integer and $K(m)$ is the complete elliptic integral of the first kind. Each p-point identity of rank r involves a cyclic homogeneous polynomial of degree r (in Jacobi elliptic functions with p equally spaced arguments) related to other cyclic homogeneous polynomials of degree $r-2$ or smaller. We algebraically demonstrate the derivation of several of our identities for specific small values of p and r by using standard properties of Jacobi elliptic functions. Identities corresponding to higher values of p and r are verified numerically using advanced mathematical software packages. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1484541]

I. INTRODUCTION

The Jacobi elliptic functions $\mathrm{sn}(x,m)$, $\mathrm{cn}(x,m)$, and $\mathrm{dn}(x,m)$ with real elliptic modulus parameter $m(0\leqslant m\leqslant 1)$ have been extensively studied and used in mathematics, science and engineering.[1,2] Recently, while studying[3,4] the properties of quantum mechanical periodic potentials,[5,6] we have discovered numerous new mathematical identities involving Jacobi elliptic functions. The purpose of this article is to tabulate, derive and discuss these identities.

To the best of our knowledge, our results are not discussed in the mathematics literature. However, we did find that geometrical constructions called the ''poristic polygons of Poncelet'' give rise to a few of our very simplest identities like Eqs. (3) and (40) involving just the Jacobi elliptic functions $\mathrm{dn}(x,m)$. For a discussion of this geometrical approach, see Refs. 7 and 8.

Our new identities play a crucial role in obtaining a large class of novel periodic solutions of both integrable and the nonintegrable nonlinear equations like the Korteweg–de Vries (KdV) and modified Korteweg–de Vries equations,[9] the nonlinear Schrödinger and KP equations, the sine–Gordon and Boussinesq equations, as well as the $\lambda\phi^4$ model.[10] The solutions obtained for the KdV equation[9] all correspond to one gap periodic potentials. This process can be generalized to obtain new solvable periodic potentials with a finite number of band gaps.[4]

If $K(m)$ denotes the complete elliptic integral of the first kind, the elliptic functions $\mathrm{sn}(x,m)$ and $\mathrm{cn}(x,m)$ have real periods $4K(m)$, whereas $\mathrm{dn}(x,m)$ has a period $2K(m)$. The $m=0$ limit gives $K(0)=\pi/2$ and trigonometric functions: $\mathrm{sn}(x,0)=\sin x$, $\mathrm{cn}(x,0)=\cos x$, $\mathrm{dn}(x,0)=1$. The $m\to 1$ limit gives $K(1)\to\infty$ and hyperbolic functions: $\mathrm{sn}(x,1)\to\tanh x$, $\mathrm{cn}(x,1)\to\mathrm{sech}\,x$, $\mathrm{dn}(x,1)\to\mathrm{sech}\,x$. Therefore, our new identities for Jacobi elliptic functions can be thought of as generalizations to arbitrary m of identities involving trigonometric and hyperbolic functions.

The plan of the article is as follows. In Sec. II, we discuss the general structure of the identities and various different ways of obtaining them. Each identity has two integer labels r and p. Here, r denotes the rank of the identity and p is the number of subdivisions of the period at which Jacobi elliptic functions are evaluated. In Sec. III, we algebraically derive some of the identities given in Tables I, II, and III for rank $r=2$, 3 and $p=2$, 3, 4. Finally, in Sec. IV, we offer several comments regarding the general patterns revealed by the identities. In Tables I and II, we have listed identities for ranks $r=2$ and 3, respectively. For clarity, we give explicit expressions

[b]Author to whom correspondence should be addressed. Electronic mail: sukhatme@tigger.cc.uic.edu

for $p=2$, 3, 4 and then given the general structure for arbitrary p. In Table III we have given some examples of identities of rank 4 and above. The algebraic proofs of identities with large rank r and $p>4$ are tedious, but we have numerically verified the identities using the mathematical software package Maple.

II. DESCRIPTION OF THE IDENTITIES

In all the identities discussed in this article, the arguments of the Jacobi functions are separated by either $2K(m)/p$ or $4K(m)/p$, where p is an integer ($p\geqslant 2$) depending on whether the left hand side of the identity is a periodic function of period $2K(m)/p$ or $4K(m)/p$. For any given choice of p, we define the quantities s_i, c_i and d_i as follows:

$$s_i\equiv \mathrm{sn}\left[x+\frac{2(i-1)K(m)}{p},m\right],\quad c_i\equiv \mathrm{cn}\left[x+\frac{2(i-1)K(m)}{p},m\right],\quad d_i\equiv \mathrm{dn}\left[x+\frac{2(i-1)K(m)}{p},m\right]. \tag{1}$$

Similarly, we define

$$\tilde{s}_i\equiv \mathrm{sn}\left[x+\frac{4(i-1)K(m)}{p},m\right],\quad \tilde{c}_i\equiv \mathrm{cn}\left[x+\frac{4(i-1)K(m)}{p},m\right],\quad \tilde{d}_i\equiv \mathrm{dn}\left[x+\frac{4(i-1)K(m)}{p},m\right]. \tag{2}$$

Each p-point identity which we discuss will involve a cyclic homogeneous polynomial of degree r (in Jacobi elliptic functions with p equally spaced arguments) expressed as a linear combination of other cyclic homogeneous polynomials of degree $r-2n$, where $1\leqslant n\leqslant r/2$. We designate this to be a p-point identity of rank r.

Let us consider a few examples to clarify the terminology and establish the notation. A simple p-point identity of rank 2 is

$$d_1d_2+c.p.\equiv d_1d_2+d_2d_3+\cdots+d_pd_1=A, \tag{3}$$

where we have used the notation "$+c.p.$" to denote cyclic permutations of the indices 1,2,...p. Later, we have also used the notation "$-c.p.$" to denote cyclic permutations with alternating positive and negative signs in a few identities where p is an even integer. For the special case $p=4$, the quantities in Eq. (3) are

$$d_1\equiv dn(x,m), d_2\equiv \mathrm{dn}(x+K(m)/2,m), d_3\equiv \mathrm{dn}(x+K(m),m), d_4\equiv \mathrm{dn}(x+3K(m)/2,m). \tag{4}$$

As discussed in the next section, for $p=4$, the constant A can be computed and shown to be $A=2\tilde{t}(1+\tilde{t}^2)$ where

$$\tilde{t}\equiv \mathrm{dn}(K(m)/2,m)=(1-m)^{1/4}. \tag{5}$$

Similarly, two examples of three-point identities of rank 2 and rank 3 are

$$\tilde{c}_1\tilde{c}_2+c.p.=-\frac{q(q+2)}{(1+q)^2},\quad \tilde{c}_1\tilde{d}_2\tilde{d}_3+c.p.=-q^2(\tilde{c}_1+\tilde{c}_2+\tilde{c}_3), \tag{6}$$

where

$$q\equiv \mathrm{dn}(2K(m)/3,m), \tag{7}$$

and the arguments are x, $x+4K(m)/3$ and $x+8K(m)/3$, respectively. Many more examples are given in Tables I, II, and III.

Although x-independent constants like A do depend on the number of points p, the rank r, the modulus parameter m, and the specific identity involved, for simplicity, we do not usually exhibit these dependences explicitly. In fact, the symbols A and B appearing in the identities given in Tables I, II, and III are just meant to denote generic constants. They do not all have the same values.

Given any p-point identity of rank r, one way of generating a new p-point identity of rank $r+1$ is by differentiation and use of the well-known formulas

$$\frac{d}{dx}\mathrm{sn}(x,m)=\mathrm{cn}(x,m)\mathrm{dn}(x,m), \quad \frac{d}{dx}\mathrm{cn}(x,m)=-\mathrm{sn}(x,m)\mathrm{dn}(x,m),$$

$$\frac{d}{dx}\mathrm{dn}(x,m)=-m\mathrm{sn}(x,m)\mathrm{cn}(x,m), \tag{8}$$

$$\mathrm{sn}^2(x,m)+\mathrm{cn}^2(x,m)=1, \quad \mathrm{dn}^2(x,m)+m\mathrm{sn}^2(x,m)=1. \tag{9}$$

For example, differentiation of the p-point rank 2 identity

$$d_1d_2+\ldots+d_pd_1=A \tag{10}$$

yields the rank 3 identity

$$s_1c_1(d_2+d_p)+c.p.=0, \tag{11}$$

which reduces to the well-known trigonometric identity

$$\sum_{i=1}^{p}\sin\left[2x+\frac{2(i-1)\pi}{p}\right]=0 \tag{12}$$

in the limit $m=0$.

Another p-point rank r identity of interest for $r\leqslant p$ is

$$d_1d_2\cdots d_r+c.p.=A \quad (r \text{ even}), \tag{13}$$

$$d_1d_2\cdots d_r+c.p.=B\sum_{i}^{p} d_i \quad (r \text{ odd}). \tag{14}$$

One also has similar identities involving $\tilde{s}_i$ or $\tilde{c}_i$ (instead of d_i) for any odd integer value of p. All these identities have the remarkable property of reducing the degree of the polynomial in the Jacobi functions from r to 0 (1) depending on whether r is even (odd). For small values of p and r, the constants A, B in Eqs. (13) and (14) are easily evaluated. Some results are

$$A(p=2,r=2)=2\sqrt{1-m}, A(p=3,r=2)=q(q+2), A(p=4,r=2)=2\tilde{t}(1+\tilde{t}^2),$$

$$B(p=3,r=3)=3\left(\frac{m}{1-q^2}-1\right), B(p=4,r=3)=\sqrt{1-m}, \tag{15}$$

$$A(p=4,r=4)=4(1-m).$$

For the special limiting cases $m=0$ and $m=1$, one gets

$$A(m=0,p,r)=p, \;\; B(m=0,p,r)=1, \;\; A(m=1,p,r)=B(m=1,p,r)=0. \tag{16}$$

Another way of obtaining additional identities is by manipulating established identities. For example, for $p=3$ and $r=3$, Eq. (14) is

$$d_1d_2d_3=\frac{B}{3}(d_1+d_2+d_3), \tag{17}$$

where $B\equiv B(p=3,r=3)$ is as given by eq. (15). Squaring identity (3) for $p=3$ and using Eqs. (15) and (17) yields the new identity

$$d_1^2d_2^2+c.p.=-2\left(\frac{m}{1-q^2}-1\right)\sum_{i=1}^{3} d_i^2+\left[(1-q^2)^2+\frac{6m}{1-q^2}-3-4m\right]. \tag{18}$$

A similar identity is also true for any p, and in fact we have used it in a crucial manner for obtaining new periodic solutions of the KdV equation.[9] However, to establish this p-point identity, one needs a generalization of identities (3) and (14). The generalized identities are

$$d_1 d_n + c.p. = A \quad (n = 2,3,4,...), \tag{19}$$

and

$$d_1 d_{j_1} d_{j_2} + c.p. = B \sum_{i=1}^{p} d_i \quad (1 < j_1 < j_2 \leqslant p). \tag{20}$$

which we have verified to be true numerically using Maple for many specific choices of the integers n, j_1, j_2, p.

III. DERIVATION OF IDENTITIES FOR $p=2$, 3, 4

For illustrative purposes, we now outline the proof of the p-point identity $d_1 d_2 + c.p. = A$, for $p=2$, 3, 4. The left hand side of this identity contains p terms. The proof for $p=2$ is trivial, since it is well known that $d_1 d_2 \equiv \mathrm{dn}(x,m)\mathrm{dn}(x+K(m),m) = \sqrt{1-m}$.[1,2] For $p=3$, one needs to compute $d_1 d_2 + d_2 d_3 + d_3 d_1 \equiv \mathrm{dn}(x,m)\mathrm{dn}(x+2K(m)/3,m) + \mathrm{dn}(x+2K(m)/3,m)\mathrm{dn}(x+4K(m)/3,m) + \mathrm{dn}(x+4K(m)/3,m)\mathrm{dn}(x,m)$. This can be accomplished by algebraic simplification after using the addition theorem[1,2]

$$\mathrm{dn}(u+v) = (\mathrm{dn}u \ \ \mathrm{dn}v - m \ \ \mathrm{sn}u \ \ \mathrm{cn}u \ \ \mathrm{sn}v \ \ \mathrm{cn}v)/(1 - m \ \ \mathrm{sn}^2 u \ \ \mathrm{sn}^2 v), \tag{21}$$

and the fact that

$$\begin{gathered} \mathrm{dn}(4K(m)/3,m) = \mathrm{dn}(2K(m)/3,m), \ \ \mathrm{sn}(4K(m)/3,m) = \mathrm{sn}(2K(m)/3,m), \\ \mathrm{cn}(4K(m)/3,m) = -\mathrm{cn}(2K(m)/3,m). \end{gathered} \tag{22}$$

The result is the constant A for the $p=3$ case. One gets $A = q(q+2)$, where q has been defined in Eq. (7). One has also made use of the fact that q satisfies the fourth order equation

$$q^4 + 2q^3 - 2(1-m)q - (1-m) = 0, \tag{23}$$

which follows by making use of Eqs. (21) and (8) with $u = v = 2K(m)/3$. Similarly, the result for $p=4$, as discussed following Eq. (3), can be easily derived.

In principle, an analogous algebraic procedure can be used for any value of p, but the algebra becomes increasingly lengthier. We have therefore verified identity (3) numerically using the advanced mathematical software package Maple. Note that for any chosen value of p, the constant A equals p in the limit $m=0$ and vanishes for $m \to 1$.

Proceeding in this way, and using the addition theorems

$$\mathrm{cn}(u+v) = (\mathrm{cn}u \ \ \mathrm{cn}v - \mathrm{sn}u \ \ \mathrm{dn}u \ \ \mathrm{sn}v \ \ \mathrm{dn}v)/(1 - m \ \ \mathrm{sn}^2 u \ \ \mathrm{sn}^2 v), \tag{24}$$

$$\mathrm{sn}(u+v) = (\mathrm{sn}u \ \ \mathrm{cn}v \ \ \mathrm{dn}v + \mathrm{sn}v \ \ \mathrm{cn}v \ \ \mathrm{dn}u)/(1 - m \ \ \mathrm{sn}^2 u \ \ \mathrm{sn}^2 v), \tag{25}$$

for $p=2$, 3, 4, we have derived all the identities of rank 2 as given by Eqs. (31)–(34). It may be noted that the identities for $p=4$ contain identities for $p=2$ as special cases.

In the limit of $m \to 0$, two of the identities in Eq. (32) reduce to the well known trigonometric identity

$$\cos x \cos(x + 2\pi/3) + \cos(x + 2\pi/3)\cos(x + 4\pi/3) + \cos(x + 4\pi/3)\cos x = -\tfrac{3}{4}. \tag{26}$$

Let us now turn our attention to the derivation of the identities of rank $r=3$ in case $p=2$, 3, 4. For $p=2$, 4 these identities are easily derived by using the identities of rank 2 as given by Eqs. (31) and (34) and these are listed as Eqs. (39) and (60)–(63). Note that for these cases, and in fact in general for any even integer case, one obtains identities with both $+c.p.$ and $-c.p.$ As an

illustration, we start from the identity (3) with $p=4$ and $A=2\tilde{t}(1+\tilde{t}^2)$ and $\tilde{t}=(1-m)^{1/4}$. On multiplying both sides of this identity by $(d_1-d_2+d_3-d_4)$ and using the relations $d_1d_3=d_2d_4=\sqrt{1-m}$, we immediately obtain the four-point identity

$$d_1^2(d_2+d_4)-c.p.=2\tilde{t}(1+\tilde{t}+\tilde{t}^2)(d_1-c.p.). \tag{27}$$

However, for $p=3$, all the identities of rank 3 cannot be derived from those of rank 2. We find that there are four basic identities of rank 3 [say those given by Eqs. (40)–(43)] which we have derived using the addition theorems [Eqs. (21), (24), and (25)] and relations (22) and (23). As an illustration, let us consider the derivation of identity (41),

$$\tilde{c}_1\tilde{c}_2\tilde{c}_3=\frac{q^2}{1-q^2}(\tilde{c}_1+\tilde{c}_2+\tilde{c}_3), \tag{28}$$

where q is as given by Eq. (7). On using the addition theorem (24) and the fact that $\mathrm{cn}(2K(m)/3,m)=q/(1+q)$ with q satisfying Eq. (23), the identity (28) is easily derived.

Using these four basic identities and those of rank 2, one can then derive the remaining 18 identities of rank 3 (for $p=3$) as given in Table II. For example, consider the identity (57). This is easily derived by starting from the rank 2 ($p=3$) identity

$$\tilde{c}_1\tilde{c}_2+c.p.=\frac{-q(2+q)}{(1+q)^2}, \tag{29}$$

multiplying both sides by $(\tilde{c}_1+\tilde{c}_2+\tilde{c}_3)$ and using identity (28) and Eq. (27).

Finally, let us consider identities of rank 4 and higher in case $p=2$, 3, 4, some of which have been given in Table III. We find that all these identities can be derived by using the identities of rank 2 and 3 as given in Tables II and III. For example, identities (77), (79) and (80) simply follow from the basic rank 3 identities (40)–(42).

IV. DISCUSSION AND COMMENTS

By the techniques described in the previous sections, we have obtained a large number of new identities, many of which are displayed in Tables I, II, and III. It should be noted that the modulus parameter m is not transformed and remains unchanged in all identities. Although it is not easy to give a complete systematic classification, we can comment on some general properties and patterns.

(i) For any identity of rank r, the left hand side is a cyclic homogeneous polynomial expression of degree r with p terms.

(ii) If the polynomial on the left hand side is periodic with period $2K(m)/p$ $[4K(m)/p]$, then the identity involves arguments spaced by $2K(m)/p$ $[4K(m)/p]$.

(iii) The right hand side involves polynomials of rank $r-2$, $r-4$,..., which are "irreducible," some examples being Σd_i, $\Sigma\tilde{s}_i$, $\Sigma\tilde{c}_i$, $\Sigma\tilde{c}_i\tilde{d}_i$, $\Sigma\tilde{s}_i\tilde{d}_i$, Σc_is_i, $\Sigma c_is_id_i$, etc., and all these irreducibles multiplied by d_i^{2n} where $n=1,2,\ldots$.

(iv) In general, many of the identities of higher rank can be obtained from those of lower rank by either differentiation or algebraic manipulation. Similarly, many identities of a given rank r ($r>2$) can be derived from lower rank identities as well as some identities of the same rank. For example, for $p=3$, using the identities of rank 2 and three of the rank 3 identities as given by Eqs. (40)–(42) one can obtain all other identities of rank 3 as given in Table II.

(v) The generic constants A, B, C in any identity can be determined by choosing specific, convenient values of x in the arguments. The value $x=0$ is a good choice in many cases. Note that for $p\leqslant 4$, we have given explicit values for all the constants appearing in the

identities—for three-point identities, all constants are expressed in terms of $q \equiv \mathrm{dn}(2K(m)/3,m)$, and for four-point identities, all constants are expressed in terms of $\tilde{t} \equiv \mathrm{dn}(K(m)/2,m) = (1-m)^{1/4}$.

(vi) Some identities for even values of p involve alternating positive and negative signs. The symbol "$-c.p.$" in these identities refers to cyclic permutations with alternating signs. Many of these identities, like $d_1^2(d_2+d_p)-d_2^2(d_3+d_1)+\cdots-d_p^2(d_1+d_{p-1})=A(d_1-d_2+\cdots-d_p)$, play a crucial role in determining band edge wave functions of solvable quantum mechanical periodic potentials.[4]

(vii) It should be noted that our identities involve cyclic permutations $\pm c.p.$ of terms which have no clockwise or anticlockwise "handedness." For example, for even p, there is no identity of the type $(d_1^2 d_2 - c.p.)$ proportional to $(d_1 - c.p.)$, since the term $d_1^2 d_2$ has a clockwise handedness. It is only when one adds on an anticlockwise handed term $d_1^2 d_p$ that the combination $[d_1^2(d_2+d_p)-c.p.]$ is indeed proportional to $(d_1-c.p.)$.

(viii) In the limit $m \to 0$, one recovers many known nontrivial trigonometric identities. In the limit $m \to 1$, since the period $K(1) \to \infty$, one usually gets trivial hyperbolic function identities. Both these limits serve as a useful check on all the new identities involving Jacobi elliptic functions obtained in this paper. Of course, as mentioned previously, software packages like Maple or Mathematica quickly provide confirmation of any identity to typically eight digit accuracy.

(ix) Identities for a given value of p contain identities of the factors of p as special cases. For example, for even p, only half of $d_1,\ldots,d_p$ are independent since they satisfy identities

$$d_1 d_{(p+2)/2} = \cdots = d_{p/2} d_p = \sqrt{1-m}, \tag{30}$$

coming from $p=2$. Similarly, the full list of $p=6$ identities contains $p=2$, 3 identities. For example, $d_1 d_4 = d_2 d_5 = d_3 d_6 = \sqrt{1-m}$ and similarly $d_1 d_3 + d_3 d_5 + d_5 d_1 = d_2 d_4 + d_4 d_6 + d_6 d_2 = q^2 + 2q$, where q is as given by Eq. (7).

TABLE I. **Identities of rank 2.** The symbols A in Eqs. (35) and (37) are used generically to denote constants independent of x; the constants are in general all different.

p=2:

$$d_1 d_2 = \sqrt{1-m}. \tag{31}$$

p=3: $[q \equiv \mathrm{dn}(2K(m)/3,m)]$

$$d_1 d_2 + c.p. = q(q+2),\ \tilde{c}_1\tilde{c}_2 + c.p. = \frac{-q(q+2)}{(1+q)^2},\ \tilde{s}_1\tilde{s}_2 + c.p. = \frac{1}{m}(q^2-1), \tag{32}$$

$$\tilde{c}_1(\tilde{d}_2+\tilde{d}_3)+c.p. = \tilde{s}_1(\tilde{d}_2+\tilde{d}_3)+c.p. = \tilde{c}_1(\tilde{s}_2+\tilde{s}_3)+c.p. = 0. \tag{33}$$

p=4: $[\tilde{t} \equiv \mathrm{dn}(K(m)/2,m) = (1-m)^{1/4}]$

$$d_1 d_3 = d_2 d_4 = \sqrt{1-m},\ d_1 d_2 + c.p. = 2\tilde{t}(1+\tilde{t}^2). \tag{34}$$

p=even integer:

$$d_1 d_2 + c.p. = A,\ d_1 d_3 + c.p. = A,\ \ldots,\ d_1 d_{p/2} + c.p. = A, \tag{35}$$

$$d_1 d_{p/2+1} = d_2 d_{p/2+2} = \cdots = d_{p/2} d_p = \sqrt{1-m}. \tag{36}$$

p=odd integer:

$$\begin{gathered} d_1 d_2 + c.p. = A,\ \tilde{c}_1\tilde{c}_2 + c.p. = A,\ \tilde{s}_1\tilde{s}_2 + c.p. = A, \\ \vdots \\ d_1 d_{(p+1)/2} + c.p. = A,\ \tilde{c}_1\tilde{c}_{(p+1)/2} + c.p. = A,\ \tilde{s}_1\tilde{s}_{(p+1)/2} + c.p. = A, \\ \tilde{c}_1(\tilde{d}_2+\tilde{d}_p)+c.p. = 0,\ \tilde{s}_1(\tilde{d}_2+\tilde{d}_p)+c.p. = 0,\ \tilde{c}_1(\tilde{s}_2+\tilde{s}_p)+c.p. = 0, \\ \vdots \\ \tilde{c}_1(\tilde{d}_{(p+1)/2}+\tilde{d}_{(p+3)/2})+c.p. = 0,\ \tilde{s}_1(\tilde{d}_{(p+1)/2}+\tilde{d}_{(p+3)/2})+c.p. \\ = 0,\ \tilde{c}_1(\tilde{s}_{(p+1)/2}+\tilde{s}_{(p+3)/2})+c.p. = 0. \end{gathered} \tag{37, 38}$$

TABLE II. **Identities of rank 3.** The symbols A in Eqs. (66)–(73) are used generically to denote constants independent of x; the constants are in general all different.

p=2:

$$d_1^2 d_2 \pm d_2^2 d_1 = \sqrt{1-m}\,(d_1 \pm d_2), \quad c_1 s_1 d_2 + c_2 s_2 d_1 = 0. \tag{39}$$

p=3: $[q \equiv \mathrm{dn}(2K(m)/3,m)]$

$$d_1 d_2 d_3 = \frac{(q^2+m-1)}{1-q^2}(d_1+d_2+d_3), \tag{40}$$

$$\tilde{c}_1\tilde{c}_2\tilde{c}_3 = \frac{q^2}{1-q^2}(\tilde{c}_1+\tilde{c}_2+\tilde{c}_3), \tag{41}$$

$$\tilde{s}_1\tilde{s}_2\tilde{s}_3 = \frac{-1}{1-q^2}(\tilde{s}_1+\tilde{s}_2+\tilde{s}_3), \tag{42}$$

$$\tilde{c}_1(\tilde{s}_2\tilde{d}_3+\tilde{s}_3\tilde{d}_2)+c.p.=0, \tag{43}$$

$$\tilde{c}_1\tilde{d}_2\tilde{d}_3+c.p.=-q^2(\tilde{c}_1+\tilde{c}_2+\tilde{c}_3), \tag{44}$$

$$m\tilde{c}_1\tilde{s}_2\tilde{s}_3+c.p.=-(1+q)^2(\tilde{c}_1+\tilde{c}_2+\tilde{c}_3), \tag{45}$$

$$\tilde{s}_1\tilde{d}_2\tilde{d}_3+c.p.=\frac{-(1-m)}{q^2}(\tilde{s}_1+\tilde{s}_2+\tilde{s}_3), \tag{46}$$

$$\tilde{s}_1\tilde{c}_2\tilde{c}_3+c.p.=\frac{q(q+2)}{1-q^2}(\tilde{s}_1+\tilde{s}_2+\tilde{s}_3), \tag{47}$$

$$\tilde{d}_1\tilde{c}_2\tilde{c}_3+c.p.=\frac{-q^2}{(1+q)^2}(\tilde{d}_1+\tilde{d}_2+\tilde{d}_3), \tag{48}$$

$$d_1^3(d_2+d_3)+c.p.=\frac{2mq}{1-q^2}(d_1^2+c.p.)-2(1-m), \tag{78}$$

$$\tilde{s}_1\tilde{d}_1\tilde{c}_2\tilde{c}_3+c.p.=\frac{q^2}{1-q^2}(\tilde{s}_1\tilde{d}_1+c.p.), \tag{79}$$

$$\tilde{c}_1\tilde{d}_1\tilde{s}_2\tilde{s}_3+c.p.=\frac{-1}{1-q^2}(\tilde{c}_1\tilde{d}_1+c.p.), \tag{80}$$

$$m^2c_1s_1c_2s_2+c.p.=\frac{2mq}{1-q^2}(d_1^2+c.p.)+[m-(2-m)(1+q)^2]. \tag{81}$$

r=5, p=3:

$$d_1^3(s_2c_2+s_3c_3)+c.p.=\frac{-2mq}{1-q^2}(s_1c_1d_1+c.p.), \tag{82}$$

$$m\tilde{s}_1^4(\tilde{s}_2+\tilde{s}_3)+c.p.=\frac{2(q^2+m-1)}{1-q}(\tilde{s}_1^3+c.p.)+\frac{2(q^3+q^2+mq-q+2m-1)}{(1-q^2)^2}$$
$$(\tilde{s}_1+c.p.). \tag{83}$$

r=6, p=6:

$$d_1^3(d_2^2d_3+d_6^2d_5)+c.p.=A(d_1^2+c.p.)+B. \tag{84}$$

r=8, p=6:

$$c_1d_1c_2d_2s_3s_4s_5s_6+c.p.=A(s_1s_2s_3s_4s_5s_6). \tag{85}$$

r, p:

$$m^ps_1^2s_2^2\cdots s_p^2=A(s_1^2+c.p.)+B\quad(r=2p). \tag{86}$$

TABLE III. (*Continued.*)

For indices $1<j_1<j_2<\cdots<j_{r-1}\leqslant p$:

$$d_1 d_{j_1} d_{j_2}\cdots d_{j_{r-1}}+c.p.=A \ (r=\text{even},p),$$
$$d_1 d_{j_1} d_{j_2}\cdots d_{j_{r-1}}+c.p.=B(d_1+c.p.) \ (r=\text{odd},p),$$
$$\tilde{s}_1\tilde{s}_{j_1}\tilde{s}_{j_2}\cdots\tilde{s}_{j_{r-1}}+c.p.=A,\ \tilde{c}_1\tilde{c}_{j_1}\tilde{c}_{j_2}\cdots\tilde{c}_{j_{r-1}}+c.p.=A \ (r=\text{even},\ p=\text{odd}), \tag{87}$$
$$\tilde{s}_1\tilde{s}_{j_1}\tilde{s}_{j_2}\cdots\tilde{s}_{j_{r-1}}+c.p.=B(\tilde{s}_1+c.p.),\ \tilde{c}_1\tilde{c}_{j_1}\tilde{c}_{j_2}\cdots\tilde{c}_{j_{r-1}}+c.p.=B(\tilde{c}_1+c.p.)$$
$$(r=\text{odd},\ p=\text{odd}),$$
$$d_1^{r-1}(d_2+d_p)+c.p.=A(d_1^{r-2}+c.p.)+B(d_1^{r-4}+c.p.)+\cdots.$$

The last equation ends with a constant if r is odd, and with a term proportional to $(d_1+c.p.)$ if r is even.

(x) It should be noted that in many applications like finding new solutions of the KdV equation,[9] the identities needed involve summations over all combinations of many (say two) indices $i,\ j=1,...,p$. These combinations correspond to the sum of several cyclic identities discussed in the tables.

(xi) In this article, we have concentrated our attention on cyclic identities in which the arguments are separated by fractions of the periods $2K(m)$ or $4K(m)$ on the real axis. However, each one of our identities can be easily translated into a corresponding one in which the arguments are separated by fractions of the periods $i2K'$ or $i4K'$ on the imaginary axis, where $K'\equiv K(1-m)$. For example, the simple two-point identity $\mathrm{dn}(x,m)\mathrm{dn}(x+K(m),m)=\sqrt{1-m}$ translates to the new identity $\mathrm{sn}(u,m)\mathrm{sn}(u+iK',m)=1/\sqrt{m}$. The general procedure consists of first replacing m by $1-m$ [which in alternative standard notation[2] corresponds to replacing $k\equiv\sqrt{m}$ by $k'\equiv\sqrt{1-m}$ and $K(m)$ by K'], then using the well known results

$$\mathrm{sn}(x,1-m)=\frac{i\,\mathrm{cn}(ix+K,m)}{\sqrt{1-m}\,\mathrm{sn}(ix+K,m)},\quad \mathrm{cn}(x,1-m)=\frac{\mathrm{dn}(ix+K,m)}{\sqrt{1-m}\,\mathrm{sn}(ix+K,m)},$$
$$\mathrm{dn}(x,1-m)=\frac{1}{\mathrm{sn}(ix+K,m)},$$

and finally changing to a new variable $u=ix+K$.

In conclusion, even though Jacobi elliptic functions have been studied for approximately two centuries, it is exciting to discover new cyclic identities connecting them. What makes our results doubly exciting is that the identities play a vital role in the study of periodic potentials[4] and in yielding new solutions of nonlinear differential equations of physical interest.[9]

(Received 31 May 2001; accepted for publication 31 January 2002)

The quasiclassical limit of the scalar nonlocal $\bar{\partial}$-problem is derived and a quasiclassical version of the $\bar{\partial}$-dressing method is presented. Dispersionless Kadomtsev–Petviashvili (KP), modified KP, and dispersionless two-dimensional Toda lattice (2DTL) hierarchies are discussed as illustrative examples. It is shown that the universal Whitham hierarchy is nothing but the ring of symmetries for the quasiclassical $\bar{\partial}$-problem. The reduction problem is discussed and, in particular, the d2DTL equation of B type is derived. © *2002 American Institute of Physics.*

I. INTRODUCTION

Considerable interest has been paid recently to dispersionless or quasiclassical limits of integrable equations and hierarchies (see, e.g., Refs. 1–13, and references therein). Study of dispersionless hierarchies is of great importance since they arise in the analysis of various problems in physics, mathematics, and applied mathematics from the theory of quantum fields and strings[14–16] to the theory of conformal maps on the complex plane.[17–18]

Different methods have been used to study dispersionless equations and hierarchies.[1–13] In particular, several $1+1$-dimensional equations and systems have been analyzed by the quasiclassical version of the inverse scattering transform, including the local Riemann–Hilbert problem approach.[2,3,11–13,19] Similar study of the $2+1$-dimensional equations and hierarchies, like Kadomtsev–Petviashvili (KP) and dispersionless two-dimensional Toda lattice (2DTL), has been missing. Recently this problem has been addressed in Ref. 20 and the quasiclassical $\bar{\partial}$-dressing approach to the dispersionless KP hierarchy has been proposed.

In this paper we consider a class of scalar dispersionless integrable hierarchies governed by the scalar $\bar{\partial}$-problem with the dispersionless KP (dKP), modified dkP (mdKP), and d2DTL hierarchies as particular cases. We derived the general form of the quasiclassical $\bar{\partial}$-problem. It is given by the system

$$\frac{\partial S}{\partial \bar{\lambda}} = W\left(\lambda, \bar{\lambda}; \frac{\partial S}{\partial \lambda}\right), \tag{1.1}$$

$$\frac{\partial \varphi}{\partial \bar{\lambda}} = W'\left(\lambda, \bar{\lambda}; \frac{\partial S}{\partial \lambda}\right)\frac{\partial \varphi}{\partial \lambda} + \tilde{W}\left(\lambda, \bar{\lambda}; \frac{\partial S}{\partial \lambda}\right)\frac{\partial^2 S}{\partial \lambda^2}\varphi, \tag{1.2}$$

for $\lambda \in G$, where G is a domain in the complex plane $\mathbb{C}$ and W and $\tilde{W}$ are some functions. The type of hierarchy is specified by the undressed part $S_0(\lambda, T)$ of S and the domain G. A quasiclaszsical $\bar{\partial}$-dressing method based on the system (1.1)–(1.2) allows us to construct dispersionless integrable hierarchies and provides us a method for finding their solutions. The dKP, dmKP, and d2DTL hierarchies are considered as illustrative examples.

[a)]Elecronic mail: luism@eucmos.sim.ucm.es

Symmetries of the quasiclassical $\bar{\partial}$-problem (1.1) and (1.2) are defined by linear Beltrami-type equations and form an infinite-dimensional ring. It is shown that this ring, parametrized by symmetry parameters, is nothing but the universal Whitham hierarchy introduced in Ref. 8. In particular, the dKP, mdKP, and m2DTL hierarchies are special subrings of symmetries for problems (1.1) and (1.2).

We also discuss the reduction of the dispersionless hierarchies and present the dispersionless 2DTL equation of B type.

Equations of the form (1.1) and (1.2) are well-known in the complex-analysis; in particular, in connection with quasiconformal mappings in the plane (see, e.g., Refs. 21–23). Thus, there is a close connection between the theory of quasiclassical integrable hierarchies and the theory of quasiconformal mappings.

II. DISPERSIONLESS HIERARCHIES AND UNIVERSAL WHITHAM HIERARCHY

We begin by recalling some relevant formulas for dispersionless hierarchies and choose the Kadomtsev–Petviashili (KP) hierarchy to illustrate their main features. The usual KP hierarchy is an infinite set of the compatibility condition for the system

$$L\psi=\lambda\psi, \tag{2.1}$$

$$\frac{\partial\psi}{\partial t_n}=(L^n)_+\psi, \tag{2.2}$$

where $L=\partial+u_1\partial^{-1}+u_2\partial^{-2}+\cdots,\partial=\partial/\partial t,(L^n)_+$ denotes the pure differential part of the operator L^n, λ is a spectral parameter, and ψ is a common KP wave function. The KP equation itself is the equation for coefficient u_1 as a function of the first three times t_1,t_2,t_3. For the modified KP (mKP) hierarchy the operator L is of the form $L=\partial+u_0+u_1\partial^{-1}+u_2\partial^{-2}+\cdots$ while for the two-dimensional Toda lattice (2DTL) hierarchy one needs two operators L_1 and L_2.[10]

The dispersionless KP (dKP) hierarchy is a formal limit $\varepsilon\to 0$ of the KP hierarchy for which[1–10]

$$u_k\left(\frac{T_n}{\varepsilon}\right)\xrightarrow[\varepsilon\to 0]{} u_{k_0}(T)+O(\varepsilon), \tag{2.3}$$

and

$$\psi\left(\frac{T_n}{\varepsilon}\right)\xrightarrow[\varepsilon\to 0]{} e^{(1/\varepsilon)\,S(\lambda,T)+O(\varepsilon)}, \tag{2.4}$$

where T_n are slow times.

Under such a limit, Eq. (2.1) gives rise to the Laurent series $\mathcal{L}=p+\Sigma_{n=1}^{\infty}u_n(T)p^{-n}$, where $p=\partial S/\partial T_1$ while Eq. (2.2) becomes

$$\frac{\partial p}{\partial T_n}=\frac{\partial B_n(p)}{\partial T_1} \tag{2.5}$$

where $B_n(p)=[\mathcal{L}^n(p)]_+$ and $[\mathcal{L}^n]_+$ denotes here a polynomial part of $\mathcal{L}^n$. The compatibility conditions for (2.5) are given by the infinite set of equations

$$\frac{\partial B_n}{\partial T_m}-\frac{\partial B_n}{\partial T_m}+\{B_n,B_m\}=0 \tag{2.6}$$

where the Poisson bracket $\{,\}$ is defined as

$$\{f,g\}=\frac{\partial f}{\partial p}\frac{\partial g}{\partial T_1}-\frac{\partial f}{\partial T_1}\frac{\partial g}{\partial p}. \tag{2.7}$$

Equation (2.5) or (2.6) represent the dKP hierarchy. Similarly, the dmKP hierarchy is given by equations of the form (2.5)–(2.7) with $\mathcal{L}=p+\Sigma_{n=1}^{\infty}u_n(T)p^{-n}$.[24] The d2DTL hierarchy can be written by a set of equations similar to (2.5)–(2.7) for two Laurent series $\mathcal{L}_1$ and $\mathcal{L}_2$ (Ref. 10) with the substitution $p\to e^p$.

A more general dispersionless-like hierarchy has been introduced in Ref. 8. This universal Whitham hierarchy is given by the infinite set of equations

$$\frac{\partial\Omega_A}{\partial T_B}-\frac{\partial\Omega_B}{\partial T_A}+\{\Omega_A,\Omega_B\}=0,\quad A,B=1,2,3,\ldots, \tag{2.8}$$

where $\Omega_A(p,T)$ are arbitrary holomorphic functions of p. As has been shown in Ref. 8, the dKP, d2DTL, and Benney hierarchies are particular cases.

III. QUASICLASSICAL $\bar{\partial}$-PROBLEM

The $\vec{\partial}$-dressing method is a powerful tool to study usual integrable equations and hierarchies.[25–27] In this paper we shall formulate its quasiclassical version. We shall demonstrate that it provides an effective method to construct and study dispersionless hierarchies.

We begin with the derivation of the quasiclassical limit of the basic $\bar{\partial}$-problem.

The usual scalar integrable hierarchies are associated with the following scalar linear nonlocal problem (see Refs. 24–26):

$$\frac{\partial\chi(\lambda,\bar{\lambda};t)}{\partial\bar{\lambda}}=\int\int_{\mathbb{C}}d\mu\wedge d\bar{\mu}\chi(\mu,\bar{\mu};t)g(\mu,t)R_0(\mu,\bar{\mu};\lambda,\bar{\lambda})g^{-1}(\lambda,t), \tag{3.1}$$

where λ is a complex variable ("spectral parameter"), $\bar{\lambda}$ denotes complex conjugation of λ, $\chi(\lambda,\bar{\lambda};\mu)$ is a complex-valued function on the complex plane $\mathbb{C}$ $(\lambda,\bar{\lambda}\in\mathbb{C})$, the kernel $R_0(\mu,\bar{\mu};\lambda,\bar{\lambda})$ is the $\bar{\partial}$-data. Usually, it is assumed that the function χ has a canonical normalization i.e.,

$$\chi\to 1+\frac{\chi_1}{\lambda}+\frac{\chi_2}{\lambda^2}+\cdots,\quad \lambda\to\infty,$$

and that the problem (3.1) is uniquely solvable. Concrete integrable hierarchies are specialized by the form of the function $g(\lambda,t)=\exp(S_0(\lambda,t))$ and by the domain G of the support for the $\bar{\partial}$-data R_0 ($R_0(\mu,\bar{\mu};\lambda,\bar{\lambda})=0$ for $\mu,\lambda\in\mathbb{C}/G$.) For the KP hierarchy $S_0=\Sigma_{k=1}^{\infty}\lambda^k t_k$ and G ia a disk with center at the origin, while for the 2DTL hierarchy $S_0(\lambda;x,y,n)=n\ln\lambda+\Sigma_{k=1}^{\infty}\lambda^k x_k+\Sigma_{k=1}^{\infty}\lambda^{-k}y_k$ where x_k and y_k are continuous variables and n is an integer discrete variable. The domain G in this case is an annulus $a\leqslant|\lambda|\leqslant b$. Given $g(\lambda)$ the $\bar{\partial}$-dressing method provides us with the corresponding hierarchy of nonlinear equations and their linear problems.[24–26] Solutions of nonlinear equations are given by the function χ evaluated at certain points λ_0. For instance, for the KP hierarchy $u_1=-2(\partial\chi_1(t)/\partial t_1)$.

In order to derive the quasiclassical limit of the $\bar{\partial}$-problem (3.1) we first introduce slow variables T ($t_i=T_i/\varepsilon$ for KP and mKP, $x_i=X_i/\varepsilon$, $y_i=Y_i/\varepsilon$, $n=T/\varepsilon$ for 2DTL) for small ε and proceed to the limit $\varepsilon\to 0$. In this limit $g(T/\varepsilon)=\exp[S_0(\lambda,T)/\varepsilon]$. Motivated by the formula of the type (2.4) and by the structure of Eq. (3.1) we will look for solutions χ of the form

$$\chi\left(\lambda,\overline{\lambda};\frac{T}{\varepsilon}\right)=\hat{\chi}(\lambda,\overline{\lambda};T;\varepsilon)\exp\left(\frac{\widetilde{S}(\lambda,\overline{\lambda};T)}{\varepsilon}\right), \tag{3.2}$$

where $\widetilde{S}(\lambda,\overline{\lambda};T)$ is a certain function and

$$\hat{\chi}(\lambda,\overline{\lambda};T;\varepsilon)=\sum_{n=0}^{\infty}\hat{\chi}_n(\lambda,\overline{\lambda};T)\varepsilon^n. \tag{3.3}$$

It is clear that only for special $\overline{\partial}$-data R_0 Eq. (3.1) will have a well-defined limit as $\varepsilon\to 0$. Thus, it is not difficult to see that the $\overline{\partial}$-data of the form

$$R_0(\mu,\overline{\mu};\lambda,\overline{\lambda};\varepsilon)=\sum_{k=0}^{\infty}\Gamma_k(\mu,\overline{\mu})\varepsilon^{k-1}\delta^{(k)}(\mu-\lambda-\varepsilon\alpha_k(\lambda,\overline{\lambda})) \tag{3.4}$$

do a job. Here $\Gamma_k(\mu,\overline{\mu})$, $\alpha_k(\lambda,\overline{\lambda})$ are arbitrary functions ($\Gamma_k=0$ at $\lambda\in\mathbb{C}/G$) and $\delta^{(k)}$ is the k-derivative Dirac delta-function ($\delta^{(k)}(\lambda)=(\partial^k/\partial\lambda^k)\,\delta(\lambda)$). Indeed, in the simplest case $\alpha_k=0$, substituting (3.4) into (3.1), one gets

$$\frac{\partial\hat{\chi}(\lambda,\overline{\lambda};T,\varepsilon)}{\partial\overline{\lambda}}+\frac{1}{\varepsilon}\frac{\partial S(\lambda,\overline{\lambda};T)}{\partial\overline{\lambda}}\hat{\chi}(\lambda,\overline{\lambda},T,\varepsilon)$$

$$=\int\int_{\mathbb{C}}d\mu\wedge d\overline{\mu}\hat{\chi}(\mu,\overline{\mu},\varepsilon)\exp\left(\frac{S(\mu,T)-S(\lambda,T)}{\varepsilon}\right)\sum_{k=0}^{\infty}\Gamma_k(\mu,\overline{\mu})\varepsilon^{k-1}\delta^{(k)}(\mu-\lambda) \tag{3.5}$$

where

$$S(\lambda,\overline{\lambda};T):=\widetilde{S}(\lambda,\overline{\lambda};T)+S_0(\lambda;T).$$

Evaluating in (3.5) the terms of the order $1/\varepsilon$, one obtains

$$\frac{\partial S(\lambda,\overline{\lambda};T)}{\partial\overline{\lambda}}=W\left(\lambda,\overline{\lambda};\frac{\partial S}{\partial\lambda}\right), \tag{3.6}$$

where

$$W\left(\lambda,\overline{\lambda};\frac{\partial S}{\partial\lambda}\right)=\sum_{k=0}^{\infty}(-1)^k\Gamma_k(\lambda,\overline{\lambda})\left(\frac{\partial S}{\partial\lambda}\right)^k. \tag{3.7}$$

Furthermore, the terms of zero order in ε in (3.5) give [the contribution proportional to $\hat{\chi}_1$ disappears due to (3.6)]:

$$\frac{\partial\varphi}{\partial\overline{\lambda}}=W'\left(\lambda,\overline{\lambda};\frac{\partial S}{\partial\lambda}\right)\frac{\partial\varphi}{\partial\lambda}+\widetilde{W}\left(\lambda,\overline{\lambda};\frac{\partial S}{\partial\lambda}\right)\frac{\partial^2 S}{\partial\lambda^2}\varphi, \tag{3.8}$$

where

$$\varphi:=\hat{\chi}_0,\quad W'(\lambda,\overline{\lambda};\xi):=\frac{\partial W(\lambda,\overline{\lambda};\xi)}{\partial\xi},$$

and

$$\widetilde{W}:=(-1)^2\Gamma_2+(-1)^3\Gamma_3 3\frac{\partial S}{\partial\lambda}+\cdots=\frac{1}{2}W''\left(\lambda,\overline{\lambda};\frac{\partial S}{\partial\lambda}\right). \tag{3.9}$$

Since $\partial S_0/\partial\overline{\lambda}=0$ at $\lambda\in G$, then Eqs. (3.6)–(3.9) for $\lambda\in G$ can be rewritten as

$$\frac{\partial S}{\partial\overline{\lambda}}=W\left(\lambda,\overline{\lambda};\frac{\partial S}{\partial\lambda}\right), \tag{3.10}$$

$$\frac{\partial\varphi}{\partial\overline{\lambda}}=W'\frac{\partial\varphi}{\partial\lambda}+\widetilde{W}\frac{\partial^2 S}{\partial\lambda^2}\varphi. \tag{3.11}$$

Equations (3.10) and (3.11) are the quasiclassical limit of the nonlocal $\overline{\partial}$-problem (3.1). One gets similar equations for the kernels (3.4) with $\alpha_k\neq 0$. The derivation given above suggests that the quasiclassical limit of the $\overline{\partial}$-problem (3.1) is given by Eqs. (3.10) and (3.11) also for a more general than (3.4) $\overline{\partial}$-data R_0.

The function S is widely used in the analysis of the dispersionless limits of the integrable hierarchies.[4–10] Within the $\overline{\partial}$-approach it is a nonholomorphic function of the ''spectral'' variable λ and obeys the nonlinear $\overline{\partial}$-equation (3.10) (for $\lambda\in G$). The function $\varphi=\hat{\chi}_0$ obeys the local $\overline{\partial}$-problem (3.11) of the Beltrami type. Note that the ratio ϕ of two solutions φ_1 and φ_2 of Eq. (3.11) satisfies the Beltrami equation

$$\frac{\partial\phi}{\partial\overline{\lambda}}=W'\left(\lambda,\overline{\lambda};\frac{\partial S}{\partial\lambda}\right)\frac{\partial\phi}{\partial\lambda}. \tag{3.12}$$

For the Orlov's function $M=\partial S/\partial\lambda$ Eqs. (3.10) and (3.11) take the form of quasilinear equations

$$\frac{\partial M}{\partial\overline{\lambda}}=\frac{\partial}{\partial\lambda}W(\lambda,\overline{\lambda};M), \tag{3.13}$$

$$\frac{\partial\varphi}{\partial\overline{\lambda}}=W'(\lambda,\overline{\lambda};M)\frac{\partial\varphi}{\partial\lambda}+\widetilde{W}(\lambda,\overline{\lambda};M)\frac{\partial M}{\partial\lambda}\varphi. \tag{3.14}$$

Quasiclassical $\overline{\partial}$-problems (3.10) and (3.11) are basic equations for our approach. The equations of the type (3.10) and (3.11) are well known and widely studied in the theory of nonlinear elliptic systems with two independent variables and in complex analysis (see, e.g., Refs. 27, 21–23). One theorem from the theory of such equations will be crucial for our further constructions. This theorem (see theorem 3.32 from Ref. 27) states that, under certain mild condition on A (see the appendix), the only solution of the Beltrami equation $\partial Z/\partial\overline{\lambda}=A(\partial Z/\partial\lambda)$ in $\mathbb{C}$ which vanish as $\lambda\to\infty$ is $Z\equiv 0$.

We would like to note that the systems of the type (1.1) and (1.2) arise also within the complex Wenthel–Kramers–Brillouin method: see, e.g., the general canonical system (1.14), (1.14′) in Ref. 28. This connection and the ''elliptic'' version of Maslov's method for the system (1.1) and (1.2) will be discussed elsewhere.

IV. QUASICLASSICAL $\bar{\partial}$-DRESSING METHOD

The principal goal of the $\bar{\partial}$-dressing method based on Eqs. (3.10) and (3.11) is the same as of the original $\bar{\partial}$-dressing method.[24–26] It is to extract the nonlinear differential equations from the quasiclassical $\bar{\partial}$-problems.

Now the time dependence of the functions S and φ is encoded in the undressed functions $S_0(\lambda, T)$. Since

$$\tilde{S} = 1 + \frac{S_1}{\lambda} + \frac{S_2}{\lambda^2} + \cdots$$

at $\lambda \to \infty$ then the behavior of $\partial S/\partial T_A$ for large λ is completely defined by

$$\frac{\partial S}{\partial T_A} = \frac{\partial S_0}{\partial T_A} + \frac{1}{\lambda}\frac{\partial S_1}{\partial T_A} + \cdots, \tag{4.1}$$

where T_A is a slow time.

A basic property of the nonlinear equation (3.10) is that it implies the linear Beltrami equation for the infinitesimal variations δS (symmetries):

$$\frac{\partial}{\partial \bar{\lambda}}(\delta S) = W'\left(\lambda, \bar{\lambda}; \frac{\partial S}{\partial \lambda}\right)\frac{\partial}{\partial \lambda}(\delta S). \tag{4.2}$$

In particular, for any time T_A,

$$\frac{\partial}{\partial \bar{\lambda}}\left(\frac{\partial S}{\partial T_A}\right) = W'\left(\lambda, \bar{\lambda}; \frac{\partial S}{\partial \lambda}\right)\frac{\partial}{\partial \lambda}\left(\frac{\partial S}{\partial T_A}\right). \tag{4.3}$$

Any power of solution of the Beltrami equation is a solution too as well as any differentiable function of two solutions. So together with $\partial S/\partial T_{A_1}, \ldots, \partial S/\partial T_{A_n}$ any differentiable function

$$f\left(\frac{\partial S}{\partial T_{A_1}}, \ldots, \frac{\partial S}{\partial T_{A_n}}\right)$$

with arbitrary n is a solution of Eq. (4.3). Thus the symmetries of the problem (3.10) form a ring.

Due to (4.1), the functions

$$f\left(\frac{\partial S}{\partial T_{A_1}}, \ldots, \frac{\partial S}{\partial T_{A_n}}\right)$$

have singularities in certain points. The functions

$$f_0\left(\frac{\partial S}{\partial T_{A_1}}, \ldots, \frac{\partial S}{\partial T_{A_n}}\right)$$

which are bounded in $\mathbb{C}$ and vanish as $\lambda \to \infty$ are very special. According to the Vekua's theorem mentioned at the end of Sec. III they vanish identicaly. So we have the nonlinear equations

$$f_0\left(\frac{\partial S}{\partial T_{A_1}}, \ldots, \frac{\partial S}{\partial T_{A_n}}\right) = 0. \tag{4.4}$$

Note that in contrast to the usual hierarchies we get nonlinear equations for the ''wave function'' S (the classical action).

Now we turn to the $\bar{\partial}$-problem (3.11). It is linear one. So the construction is similar to that of the usual case. Namely, suppose that one has found a solution φ_0 to Eq. (3.11) of the form $\varphi_0 = L\varphi$ where L is a certain linear operator and φ_0 is bounded and vanishes as $\lambda \to \infty$. Since $\varphi \to 1 + \varphi_1/\lambda + \cdots$ as $\lambda \to \infty$ the ratio φ_0/φ vanishes as $\lambda \to \infty$ and obeys the Beltrami equation

$$\frac{\partial}{\partial \bar{\lambda}}\left(\frac{\varphi_0}{\varphi}\right) = W' \frac{\partial}{\partial \lambda}\left(\frac{\varphi_0}{\varphi}\right). \tag{4.5}$$

Then according to the Vekua's theorem φ_0/φ vanishes identically and, consequently,

$$L\varphi = 0 \tag{4.6}$$

that is the desired linear problem for the wave function φ. Note that one can get the same results assuming that the problem (3.11) with canonically normalized φ is uniquely solvable.

Equations (4.4) and (4.6) are the basic equations associated with the quasiclassical $\bar{\partial}$-problems (3.10) and (3.11). They are compatible by construction. Equations (4.4) and (4.6) provide us also with equations for functions $u_k(T)$ which depend only on the times T. Usually one has infinite families of equations of the type (4.4) and (4.6). So the quasiclassical $\bar{\partial}$-problems (3.10) and (3.11) give rise to an infinite hierarchy of integrable quasiclassical (or dispersionless) equations.

V. dKP AND dmKP HIERARCHIES

Let us consider concrete examples to illustrate the general scheme. We start with the dKP hierarchy. In this case $S_0(\lambda, T) = \Sigma_{n=1}^{\infty} \lambda^n T_n$ and $\partial S/\partial T_n = \lambda^n + (1/\lambda)(\partial S_1/\partial T_n) + (1/\lambda^2) \times (\partial S_2/\partial T_n) + \ldots (n = 1, 2, \ldots)$. Since $\partial S/\partial T_n$ have power singularities at infinity the desired function f_0 will be, clearly, polynomials. Taking, for instance, the derivatives $\partial S/\partial T_2$ and $\partial S/\partial T$ we readily see that the difference $\partial S/\partial T_2 - (\partial S/\partial T_1)^2$ behaves as $-2(\partial S_1/\partial T_1) + O(1/\lambda)$ as $\lambda \to \infty$. Thus, the desired function f_0 is $\partial S/\partial T_2 - (\partial S/\partial T_1)^2 + 2(\partial S_1/\partial T_1)$. So we get

$$\frac{\partial S}{\partial T_2} - \left(\frac{\partial S}{\partial T_1}\right)^2 - u = 0, \tag{5.1}$$

where $u = -2(\partial S_1/\partial T_1)$.

Analogously, taking the derivatives $\partial S/\partial T_3$ and $\partial S/\partial T_1$ one easily concludes that the combination $\partial S/\partial T_3 - (\partial S/\partial T_1)^3 - V_1(\partial S/\partial T_1) - V_0$ vanishes at $\lambda \to 0$ if $V_1 = -3(\partial S/\partial T_1)$ and $V_0 = -3(\partial S_2/\partial T_1) = -\frac{3}{2}(\partial S_1/\partial T_2)$. So one gets the other function f_0 and

$$\frac{\partial S}{\partial T_3} - \left(\frac{\partial S}{\partial T_1}\right)^3 - V_1 \frac{\partial S}{\partial T_1} - V_0 = 0 \tag{5.2}$$

where $\partial V_0/\partial T_1 = \frac{3}{4}(\partial u/\partial T_2)$.

In a similar manner one constructs an infinite family of equations

$$\frac{\partial S}{\partial T_n} - \left(\frac{\partial S}{\partial T_1}\right)^n - \sum_{k=0}^{n-2} V_{nk}(T)\left(\frac{\partial S}{\partial T_1}\right)^k = 0, \quad n = 1, 2, 3, \ldots \tag{5.3}$$

with appropriate coefficients $V_{nk}(T)$.

Equation (5.3) is nothing but the Eq. (2.5) of the dKP hierarchy. Evaluating the left-hand sides of (5.3) at $\lambda \to \infty$, taking the term of the order $1/\lambda$ and using other equations (5.3), one gets the dKP hierarchy for the function u and, in particular, the dKP equation

$$u_{T_1T_3}=\tfrac{3}{2}(u\,u_{T_1})_{T_1}+\tfrac{3}{4}u_{T_2T_2}. \tag{5.4}$$

In a usual manner Eq. (5.4) arises as the compatibility conditions for Eqs. (5.1) and (5.2). Equation (5.3) implies the hierarchy of nonlinear equations for the function S only. Indeed, eliminating all coefficients $u_{nk}(T)$ from (5.3) one gets the family of equations

$$\frac{\partial S}{\partial T_n}=F_n\left(\frac{\partial S}{\partial T_1},\frac{\partial S}{\partial T_2}\right),\quad n=3,4,5,\ldots.$$

The lowest of these equations is of the form

$$\frac{\partial^2 S}{\partial T_1\partial T_3}=\frac{3}{4}\frac{\partial^2 S}{\partial T_2^2}+\frac{3}{2}\left[\frac{\partial S}{\partial T_2}-\left(\frac{\partial S}{\partial T_1}\right)^2\right]\frac{\partial^2 S}{\partial T_1^2}.$$

Now we proceed to the $\bar{\partial}$-problem (3.11). For simplicity we restrict ourselves to the case $\tilde{W}=\frac{1}{2}W''$. It is not difficult to show, differentiating (3.11) and using Eqs. (5.1) and (5.2), that the function $Z=L\varphi=\partial\varphi/\partial T_2-2(\partial S/\partial T_1)(\partial\varphi/\partial T_1)-(\partial^2 S/\partial T_1^2)\,\varphi+\tilde{u}\varphi$ where $\tilde{u}=-2(\partial\varphi_1/\partial T_1)$ obeys

$$\frac{\partial Z}{\partial\bar{\lambda}}=W'\frac{\partial Z}{\partial\lambda}+\frac{1}{2}W''\frac{\partial^2 S}{\partial\lambda^2}Z \tag{5.5}$$

and vanish at $\lambda\to 0$. Consequently the ratio Z/φ obeys the Beltrami equation $(\partial/\partial\bar{\lambda})(Z/\varphi)=W'(\partial/\partial\lambda)(Z/\varphi)$ and $Z/\varphi=O(1/\lambda)$ as $\lambda\to\infty$. According to the Vekua's theorem this ratio vanishes identically and, consequently, we get the linear problem $Z=0$, i.e.,

$$\frac{\partial\varphi}{\partial T_2}-2\frac{\partial S}{\partial T_1}\frac{\partial\varphi}{\partial T_1}-\frac{\partial^2 S}{\partial T_1^2}\varphi+\tilde{u}\varphi=0. \tag{5.6}$$

In a similar manner, one gets

$$\frac{\partial\varphi}{\partial T_3}-6\left[2\left(\frac{\partial S}{\partial T_1}\right)^2+\tilde{u}\right]\frac{\partial\varphi}{\partial T_1}-3\left[4\frac{\partial S}{\partial T_1}\frac{\partial^2 S}{\partial T_1^2}+\frac{\partial\tilde{u}}{\partial T_1}-2\tilde{u}\frac{\partial S}{\partial T_1}+\tilde{w}\right]\varphi=0 \tag{5.7}$$

and higher-time equations

$$\frac{\partial\varphi}{\partial T_n}-A_n\frac{\partial\varphi}{\partial T_1}-B_n\varphi=0,\quad n=1,2,3,\ldots. \tag{5.8}$$

All linear problems (5.6)–(5.8) are compatible by construction.

In the particular case $\tilde{u}=\tilde{w}=0$ Eq. (5.6) is known as the transport equation within the quasiclassical approximation in quantum mechanics (see, e.g., Ref. 28). Note that in the case $\tilde{u}=\tilde{w}=0$ Eqs. (5.6) and (5.7) [and also (5.8)] take the form of conservation laws

$$\begin{aligned}&\frac{\partial\phi}{\partial T_2}-\frac{\partial}{\partial T_1}\left(\frac{\partial S}{\partial T_1}\phi\right)=0,\\ &\frac{\partial\phi}{\partial T_3}-\frac{\partial}{\partial T_1}\left(12\left(\frac{\partial S}{\partial T_1}\right)^2\phi\right)=0.\end{aligned} \tag{5.9}$$

Considering the adjoint dKP hierarchy for which $\psi^*(T)=\tilde{\chi}^*(T,\lambda;\varepsilon)e^{-S/\varepsilon}$, one gets the same equation (4.1) for S and equations for φ^* which are adjoint to (5.6) and (5.7). It is interesting that the quantity $\varphi(\lambda,T)\varphi^*(\lambda,T)$ obeys exactly Eq. (5.9).

Our second example is given by the dmKP hierarchy. In this case $S_0=\Sigma_{k=1}^{\infty}\lambda^{-k}T_k$ and

$$\frac{\partial S}{\partial T_k}=\frac{1}{\lambda^k}+\frac{\partial\tilde{S}(\lambda,T)}{\partial T_k}$$

where $\tilde{S}(\lambda,T)$ is holomorphic around $\lambda=0$. So to construct required functions f_0 one has to cancel singularities around $\lambda=0$. Taking again the derivatives $\partial S/\partial T_1$ and $\partial S/\partial T_2$ one readily sees that the combination $\partial S/\partial T_2-(\partial S/\partial T_1)^2$ has only simple pole at $\lambda=0$. To cancel it, we subtract $V(T)(\partial S/\partial T_1)$ where $V(T)=-2(\partial\tilde{S}(\lambda=0)/\partial T_2)$. Then at $\lambda=0$ one has

$$\frac{\partial S}{\partial T_2}-\left(\frac{\partial S}{\partial T_1}\right)^2-V(T)\frac{\partial S}{\partial T_1}=O\left(\frac{1}{\lambda}\right).$$

So due to the Vekua's theorem we conclude

$$\frac{\partial S}{\partial T_2}-\left(\frac{\partial S}{\partial T_1}\right)^2-V(T)\frac{\partial S}{\partial T_1}=0, \tag{5.10}$$

where $V(T)=-2(\partial\tilde{S}(\lambda=0,T)/\partial T_2)$. Taking the derivatives $\partial S/\partial T_1$ and $\partial S/\partial T_3$, one finds

$$\frac{\partial S}{\partial T_3}-\left(\frac{\partial S}{\partial T_1}\right)^3-\frac{3}{2}V\left(\frac{\partial S}{\partial T_1}\right)^2-\left(\frac{3}{4}V^2-3W\right)\frac{\partial S}{\partial T_1}=0, \tag{5.11}$$

where $\tilde{S}(\lambda)=\tilde{S}(0)+\lambda W(T)+\cdots$ as $\lambda\to 0$. Analogously, one obtains the infinite hierarchy of equations

$$\frac{\partial S}{\partial T_n}-\left(\frac{\partial S}{\partial T_1}\right)^n-\sum_{k=1}^{n-1}V_{nk}(T)\left(\frac{\partial S}{\partial T_1}\right)^k=0,\quad n=1,2,3,\ldots. \tag{5.12}$$

Equations (5.12) give us the dmKP hierarchy (see, e.g., Ref. 29). The simplest of these equations is the dmKP equation

$$V_t+\tfrac{3}{2}V^2V_x-\tfrac{3}{4}V_x\partial_x^{-1}V_y-\tfrac{3}{4}\partial_x^{-1}V_{yy}=0. \tag{5.13}$$

Analogously to the KP case, one can also construct the hierarchy of linear problems for the function φ. The simplest of them is of the form

$$\frac{\partial\varphi}{\partial T_2}-\left(2\frac{\partial S}{\partial T_1}+V\right)\frac{\partial\varphi}{\partial T_1}-\frac{\partial^2 S}{\partial T_1^2}\varphi=0. \tag{5.14}$$

Analogously to the dKP case Eq. (5.12) implies the hierarchy of equations for S only.

VI. DISPERSIONLESS TWO-DIMENSIONAL TODA LATTICE (2DTL) HIERARCHY

Our third example is the d2DTL hierarchy. In this case $S_0(\lambda;X,Y,T)=T\ln\lambda+\Sigma_{n=1}^{\infty}\lambda^nX_n+\Sigma_{n=1}^{\infty}\lambda^{-n}Y_n$ and the domain G is the ring $D_{a,b}(a\leqslant|\lambda|\leqslant b)$ with the cutted piece of the real axis. The derivatives of S now have singularities both in the origin and at the infinity:

$$\frac{\partial S}{\partial T}=\ln\lambda+\frac{\partial\tilde{S}}{\partial T},$$

$$\frac{\partial S}{\partial X_n}=\lambda^n+\frac{\partial\tilde{S}}{\partial X_n}, \tag{6.1}$$

$$\frac{\partial S}{\partial Y_n}=\lambda^{-n}+\frac{\partial \widetilde{S}}{\partial Y_n},\quad n=1,2,3,\ldots.$$

Since

$$\begin{gathered}\widetilde{S}(\lambda;X,Y,T)=1+\frac{\widetilde{S}_1}{\lambda}+\frac{\widetilde{S}_2}{\lambda^2}+\ldots,\quad \lambda\to\infty,\\ \widetilde{S}(\lambda;X,Y,T)=S_0+\lambda S_1+\lambda^2 S_2+\ldots,\quad \lambda\to 0\end{gathered}\tag{6.2}$$

one has at $\lambda\to\infty$,

$$\begin{gathered}\frac{\partial S}{\partial X_n}=\lambda^n+\frac{1}{\lambda}\frac{\partial \widetilde{S}_1}{\partial X_n}+\ldots,\\ \frac{\partial S}{\partial Y_n}=\lambda^{-n}+\frac{1}{\lambda}\frac{\partial \widetilde{S}_1}{\partial X_n}+\ldots,\quad n=1,2,3,\ldots,\\ e^{\partial S/\partial T}=\lambda+\frac{\partial \widetilde{S}_1}{\partial T}+\frac{1}{\lambda}\left[\frac{\partial \widetilde{S}_2}{\partial T}+\frac{1}{2}\left(\frac{\partial \widetilde{S}_1}{\partial T}\right)^2\right],\\ e^{-\partial S/\partial T}=\frac{1}{\lambda}-\frac{1}{\lambda^2}\frac{\partial \widetilde{S}_1}{\partial T},\end{gathered}\tag{6.3}$$

while at $\lambda\to 0$,

$$\begin{gathered}\frac{\partial S}{\partial X_n}=\frac{\partial S_0}{\partial X_n}+O(\lambda)\\ \frac{\partial S}{\partial Y_n}=\frac{1}{\lambda^n}+\frac{\partial S_0}{\partial Y_n}+O(\lambda),\quad n=1,2,3,\ldots,\\ e^{\partial S/\partial T}=\lambda e^{\partial S_0/\partial T}+\lambda^2 e^{\partial S_0/\partial T}\frac{\partial S_1}{\partial T}+O(\lambda^3),\\ e^{-\partial S/\partial T}=\frac{1}{\lambda}e^{-\partial S_0/\partial T}-\frac{\partial S_1}{\partial T}e^{-\partial S_0/\partial T}+O(\lambda).\end{gathered}\tag{6.4}$$

The required function f_0 should not have singularities at $\lambda=0$ and at $\lambda=\infty$ and should vanish at $\lambda\to\infty$. Taking the derivatives $\partial S/\partial T$, $\partial S/\partial X_n$, $\partial S\partial Y_n$ and using (6.2), (6.3), one finds the following two equations:

$$\frac{\partial S}{\partial Y_1}-Ve^{-\partial S/\partial T}=0,\tag{6.5}$$

$$\frac{\partial S}{\partial X_1}-e^{\partial S/\partial T}-U=0,\tag{6.6}$$

where $V(X,Y,T)=e^{\partial S_0/\partial T}$ and $U(X,Y,T)=-\partial \widetilde{S}_1/\partial T$. The system (6.5) and (6.6) is the simplest system of equations for the function S associated with the d2DTL hierarchy. We note that in contrast to the papers of Ref. 10 we have only one function S.

To extract from the above-mentioned system nonlinear equations for the functions $V(X,Y,T)$ and $U(X,Y,T)$ we perform the expansion of the left-hand-side of (6.5) at large λ and of the left-hand-side of Eq. (6.6) around $\lambda=0$. The terms of the order $1/\lambda$ in (6.5) give $V=1+\partial\tilde{S}/\partial Y_1$ while vanishing of the zero-order terms in Eq. (5.6) provides us with the equation $\partial S_0/\partial X_1 - U = 0$. As a result, we get the system of equations

$$1+\frac{\partial \tilde{S}_1}{\partial Y_1}=e^{\partial S_0/\partial T}, \quad \frac{\partial S_0}{\partial X_1}+\frac{\partial \tilde{S}_1}{\partial T}=0. \tag{6.7}$$

To rewrite it in a more familiar form we introduce the function $\alpha=\partial S_0/\partial T$, differentiate twice the first equation in (6.7) with respect to T, and use the second equation in (6.7). One gets

$$\frac{\partial \alpha}{\partial X_1 \partial Y_1}+\frac{\partial^2}{\partial T^2}(e^{\alpha})=0, \tag{6.8}$$

which is the standard form of the dispersionless 2DTL equation.

It is easy to show that the formal compatibility conditions for (6.5), (6.6) are equivalent to the system

$$V_{X_1}-VU_T=0, \quad U_{Y_1}+V_T=0 \tag{6.9}$$

which, of course, again gives rise to Eq. (6.8) ($\alpha=\ln V$). In the form (6.9) the 2DTL equation has been derived in Ref. 8.

Higher equations for S can be obtained analogously. Taking the times X_2 and Y_2, one finds the following:

$$\frac{\partial S}{\partial Y_2}-V_2 e^{-2(\partial S/\partial T)}-V_1 e^{-\partial S/\partial T}=0, \tag{6.10}$$

$$\frac{\partial S}{\partial X_2}-e^{2(\partial S/\partial T)}-U_1 e^{(\partial S/\partial T)}=0, \tag{6.11}$$

where

$$V_2=e^{2(\partial S_0/\partial T)}, \quad V_1=2\frac{\partial S_1}{\partial T}e^{\partial S_0/\partial T},$$

$$U_1=-2\frac{\partial \tilde{S}_1}{\partial T}, \quad U_0=-2\frac{\partial \tilde{S}_2}{\partial T}. \tag{6.12}$$

Higher d2DTL equations have, consequently, the form

$$\begin{gathered}
\frac{\partial V_2}{\partial X_2}-2V_2\frac{\partial U_0}{\partial T}=0,\\
\frac{\partial V_1}{\partial X_2}-V_1\frac{\partial U_0}{\partial T}-2V_2\frac{\partial U_1}{\partial T}-U_1\frac{\partial V_2}{\partial T}=0,\\
\frac{\partial U_0}{\partial Y_2}+\frac{\partial}{\partial T}(U_1V_1)+2\frac{\partial V_2}{\partial T}=0,\\
\frac{\partial U_1}{\partial Y_2}+2V_1\frac{\partial V_1}{\partial T}=0.
\end{gathered} \tag{6.13}$$

The hierarchy of equations for S takes the form

$$\frac{\partial S}{\partial Y_n}-\sum_{k=1}^{n} V_{nk}(X,Y,T)e^{-k(\partial S/\partial T)}=0, \tag{6.14}$$

$$\frac{\partial S}{\partial X_n}-\sum_{k=0}^{n} U_{nk}(X,Y,T)e^{k(\partial S/\partial T)}=0, \tag{6.15}$$

where V_{nk} and $U_{nk}(U_{nn}=1)$ are appropriate functions. These equations provides us with the d2DTL hierarchy for the coefficients V_{nk} and U_{nk}.

The formulas (6.14) and (6.15) shows the role of the function $e^{\partial S/\partial T}$. In the $1+1$-dimensional case this fact was first noted in Ref. 5.

The d2DTL hierarchy clearly contains the dKP and dmKP hierarchies as subhierarchies. The first arises if one consider only times X_n putting $T_n=T=0$ while the dmKP hierarchy is associated only with times $Y_n(X_n=T=0)$.

Equations (6.14) and (6.15) imply the hierarchy of equations for the function S only. The lowest of them is of the form

$$\frac{\partial^2 S}{\partial X_1 \partial Y_1}+e^{\partial S/\partial T}\frac{\partial S}{\partial Y_1}\frac{\partial^2 S}{\partial T^2}=0. \tag{6.16}$$

VII. RING OF SYMMETRIES FOR THE QUASICLASSICAL $\bar{\partial}$-PROBLEM AND UNIVERSAL WHITHAM HIERARCHY

The results of Sec. VI demonstrate that the symmetries of the quasiclassical $\bar{\partial}$-problem have a rather special property. Namely, for the dKP, dmKP, and d2DTL hierarchies different symmetries $\omega_A=\partial S/\partial T_A$ are connected by certain algebraic relations [see formulas (5.3), (5.12) and (6.14), (6.15)].

This property of the symmetries of the quasiclassical $\bar{\partial}$-problem has, in fact, a deeper background and is of general character. This background is provided by certain theorems about the solutions of the Beltrami equation (see Ref. 27).

Thus, let us start with the general quasiclassical $\bar{\partial}$-problem,

$$\frac{\partial S}{\partial \bar{\lambda}}=W\left(\lambda,\bar{\lambda};\frac{\partial S}{\partial \lambda}\right), \tag{7.1}$$

where $W(\lambda,\bar{\lambda};\xi)$ is a certain function and dependence of S on parameters (times) is not specified yet.

Infinitesimal symmetries ω of the problem (7.1) are defined by the linear Beltrami equation

$$\frac{\partial \omega}{\partial \bar{\lambda}}=W'\left(\lambda,\bar{\lambda};\frac{\partial S}{\partial \lambda}\right)\frac{\partial \omega}{\partial \lambda}. \tag{7.2}$$

Linear Beltrami equation possesses a number of interesting properties. They have been studied in detail as a part of the theory of generalized analytic functions (see Ref. 27). The first important property is formulated in Sec. 3 (Chap. II) of Ref. 27. This Theorem 1 (see the Appendix) states that for measurable and bounded on the entire complex plane $\mathbb{C}$ functions W' which satisfies the condition $|W'|\leqslant W_0<1$ and some other mild conditions, Eq. (7.2) has a solution $\omega_0(\lambda)$ (so-called, basic homeomorphism) for which

$$\omega_0(\lambda)=\lambda+O\left(\frac{1}{\lambda}\right),\quad \lambda\to\infty. \tag{7.3}$$

Another Theorem (theorem 2.16 from Ref. 27—see the Appendix) says that all solutions (in some class) of Eq. (7.2) are given by

$$\omega(\lambda,\overline{\lambda})=\Omega(\omega_0(\lambda,\overline{\lambda})), \tag{7.4}$$

where $\Omega(\xi)$ is an arbitrary analytic function in the domain $\omega(D_0)$.

These two basic results allow us to construct infinite hierarchy associated with the problem (7.1). Indeed, let us assign the time t_A for each symmetry ω_A such that $\omega_A=\partial S/\partial T_A$. So for the basic solution (7.3) $\omega_0=\partial S/\partial T_0$. The first theorem now says that there exists a symmetry of Eq. (7.1) such that

$$\frac{\partial S}{\partial T_0}=\lambda+O\left(\frac{1}{\lambda}\right). \tag{7.5}$$

Then the second theorem states that for any symmetry $\partial S/\partial T_A$ one has

$$\frac{\partial S}{\partial T_A}=\Omega_A\left(\frac{\partial S}{\partial T_0}(\lambda,\overline{\lambda}),T\right), \tag{7.6}$$

where $\Omega(\xi,T)$ is an appropriate function of the first argument. Thus the above two theorems imply that under certain conditions the $\overline{\partial}$-equation (7.1) possesses an infinite ring of symmetries (deformations) given by

$$\frac{\partial S(\lambda,\overline{\lambda};T)}{\partial T_A}=\Omega_A\left(\frac{\partial S}{\partial T_0},T\right),\quad A=0,1,2,3,\ldots, \tag{7.7}$$

where $\Omega_A(\xi,T)$ are arbitrary analytic functions of the ξ. The set of equations (7.7) is compatible by construction. Equation (7.7) gives rise to certain nonlinear equations for functions $U_k(T)$ on which S may depend. These equations can be obtained also from the equations for Ω_A which follow from (7.7). They are

$$\frac{\partial\Omega_A}{\partial T_B}-\frac{\partial\Omega_B}{\partial T_A}+\{\Omega_A,\Omega_B\}=0,\quad A,B=0,1,2,\ldots, \tag{7.8}$$

where

$$\{f,g\}=\frac{\partial f}{\partial p}\frac{\partial g}{\partial T_1}-\frac{\partial f}{\partial T_1}\frac{\partial g}{\partial p}. \tag{7.9}$$

and we denoted $p=\partial S/\partial T_0$.

So we constructed an integrable hierarchy of equations out of the $\overline{\partial}$-problem (7.1). It is an infinite ring since $\Omega_A(\xi,T)$ are arbitrary analytic functions. To get a concrete hierarchy one has to specify the set of functions Ω_A. The set of functions $\Omega_A(p(\lambda,\overline{\lambda};T),T)$ such that $\Omega_k\sim\lambda^k+O(1/\lambda)$ as $\lambda\to\infty$ with identification $T_0=T_1$, $T_k=T_{A-1}$ gives rise to the dKP hierarchy.

In the above-given construction the time T_0 has played a special role being connected with the "basic" symmetry ω_0. Infinite ring of symmetries for the problem (7.1) admits more general and symmetric formulation. It is due to the already mentioned obvious fact that any differentiable function

$$f\left(\frac{\partial S}{\partial T_{A_1}},\frac{\partial S}{\partial T_{A_2}},\dots\right)$$

of any set of symmetries $\partial S/\partial T_{A_1},\partial S/\partial T_{A_2},\dots,$ is again a symmetry [i.e., a solution of Eq. (7.2)]. Then the implicit function theorem implies that any symmetry $\partial S/\partial T_A$ can be chosen as a basic one.

So, let us take (arbitrary) symmetry $p=\partial S/\partial T_0$. The infinite hierarchy of symmetries now takes the form

$$\frac{\partial S}{\partial T_A}=\Omega_A(p,T), \tag{7.10}$$

where $\Omega_A(\xi,T)$ are arbitrary differentiable functions of ξ. The compatibility conditions for Eq. (7.10) is of the form (7.8) and (7.9) where now T_0 and $p=\partial S/\partial T_0$ are arbitrary time and the corresponding symmetry.

The infinite set of equations (7.8) in this case is nothing but the universal Whitham hierarchy introduced in the different way in Ref. 8. So in our approach the universal Whitham hierarchy is an infinite ring of symmetries of the general quasiclassical $\overline{\partial}$-problem (7.1).

VIII. DISPERSIONLESS HIERARCHIES OF THE B TYPE

Various type of reductions for the dKP hierarchy have been considered in Refs. 5 and 10. Here we will discuss the dispersionless hierarchies of the so-called B type. The dispersionless BKP hierarchy has been discussed briefly in Ref. 30. The dBKP hierarchy is characterized by the constraint[30]

$$S(-\lambda,T)=-S(\lambda,T). \tag{8.1}$$

This constraint immediately implies that only odd powers of $\partial S/\partial T_1$ are allowed in Eq. (5.3). Since in this case $S_0(\lambda,T)=\lambda T_1+\lambda^3T_3+\lambda^5T_5+\cdots$ and $\tilde{S}=1+S_1/\lambda+S_3/\lambda^3+\cdots$ as $\lambda\to\infty$, the hierarchy of equations for S takes the form

$$\frac{\partial S}{\partial T_{2n+1}}-\left(\frac{\partial S}{\partial T_1}\right)^{2n+1}-\sum_{k=0}^{n-1}U_{nk}(T)\left(\frac{\partial S}{\partial T_1}\right)^{2k+1}=0. \tag{8.2}$$

The two lowest equations (8.2) are

$$\frac{\partial S}{\partial T_3}-\left(\frac{\partial S}{\partial T_1}\right)^3-U\frac{\partial S}{\partial T_1}=0, \tag{8.3}$$

$$\frac{\partial S}{\partial T_5}-\left(\frac{\partial S}{\partial T_1}\right)^5-V_3\left(\frac{\partial S}{\partial T_1}\right)^3-V_1\frac{\partial S}{\partial T_1}=0, \tag{8.4}$$

where

$$U=-3\frac{\partial S_1}{\partial T_1},\quad V_3=\frac{5}{3}U,\quad V_1=\frac{5}{9}U^2-\frac{\partial S_3}{\partial T_1}. \tag{8.5}$$

Equations (8.3) and (8.4) imply that

$$\frac{9}{5}\frac{\partial U}{\partial T_5}+U^2\frac{\partial U}{\partial T_1}-U\frac{\partial U}{\partial T_3}-\frac{\partial U}{\partial T_1}\partial_{T_1}^{-1}\left(\frac{\partial U}{\partial T_3}\right)-\partial_{T_1}^{-1}\left(\frac{\partial^2U}{\partial T_3^2}\right)=0. \tag{8.6}$$

Equation (8.5) is the dispersionless limit of the $2+1$-dimensional Sawada–Kotera (and also Kaup-Kupershmidt) equation.[31,32]

To get the d2DTL hierarchy of the B type we shall use the universal Whitham hierarchy equation (7.10) and (7.7). Due to constraint (8.1) only odd functions $\Omega_A(-p,T)=-\Omega(p,T)$ are admissible. Taking the time $t_1=X$ as the reference one (i.e., $p=\partial S/\partial X$) and two other equations (7.10) in the form

$$\frac{\partial S}{\partial Y}=\frac{V}{p-U}-\frac{V}{p+U},\quad \frac{\partial S}{\partial T}=\ln\frac{p-U}{p+U}, \tag{8.7}$$

where u and V are functions of X,Y,T, one obtains

$$\begin{aligned} &V_T+U_Y=0,\\ &U_T+\frac{U_X}{U}-\frac{V_X}{V}=0. \end{aligned} \tag{8.8}$$

Introducing the function $\beta=\ln(V/U)$, one can rewrite the system (8.8) as

$$\begin{aligned} &\beta_{XY}+(Ue^{\beta})_{TT}=0,\\ &\beta_X+U_T=0. \end{aligned} \tag{8.9}$$

It is the d2DTL equation of the B type. The analog of Eqs. (6.5) and (6.6) for the B-d2DTL equation (8.9) is rather interesting

$$\begin{aligned} &\frac{\partial S}{\partial Y}+\frac{V}{U}\,\mathrm{sh}\left(\frac{\partial S}{\partial T}\right)=0,\\ &\frac{\partial S}{\partial X}+U\,\mathrm{cth}\left(\frac{1}{2}\,\frac{\partial S}{\partial T}\right)=0. \end{aligned} \tag{8.10}$$

The compatibility condition for this system is equivalent to the system (8.8).

Note finally that the nonlinear equation for $S(z,\bar{z};X,Y,T)$ in this case is of the form

$$\frac{S_{TT}S_XS_Y}{1+\mathrm{ch}(S_T)}-\frac{S_{TX}S_Y}{\mathrm{sh}(S_T)}+S_{XY}=0. \tag{8.11}$$

APPENDIX: PROPERTIES OF THE BELTRAMI

There is a well-established theory of generalized solutions of the linear Beltrami equation (see for instance Refs. 21–23 and 28)

$$Z_{\bar{\lambda}}=AZ_{\lambda}, \tag{A1}$$

where A is any given measurable function $\|A\|_{\infty}<1$ on G. Obviously, for $A\equiv 0$ we get into the class of conformal mappings. To present these results we need to introduce the operators

$$Th(\lambda):=\frac{1}{2\pi i}\int\int_{\mathbb{C}\times\mathbb{C}}\frac{h(\lambda')}{\lambda'-\lambda}d\lambda'\wedge d\bar{\lambda}', \quad \Pi h(\lambda):=\frac{\partial Th}{\partial\lambda}(\lambda),$$

where the integral is taken in the sense of the Cauchy principal value. Then one has:

Lemma: For any $p>1$ *the operator* Π *defines a bounded operator in* $L^p(\mathbb{C})$ *and for any* $0\leqslant k<1$ *there exists* $\delta>0$ *such that*

$$k\|\Pi\|_p<1,$$

for all $|p-2|<\delta$.

The next theorem summarizes the properties of solutions of (A1) that we need in our discussion.

Theorem: *Given a measurable function A with compact support inside the circle* $|\lambda|<R$ *and such that* $\|A\|_\infty<k<1$. *Then, for any fixed exponent* $p=p(k)>2$ *such that* $k\|\Pi\|_p<1$, *it follows that*

(1) *There is a unique function* Z_0 *on* $\mathbb{C}$ *with distributional derivatives satisfying the Beltrami equation* (A1) *such that*

$$Z_0(\lambda)=\lambda+O\left(\frac{1}{\lambda}\right), \quad \lambda\to\infty, \tag{A2}$$

with $Z_{0,\bar{\lambda}}$ *and* $Z_{0,\lambda}-1$ *being elements of* $L^p(\mathbb{C})$.

(2) *Every solution of* (A2) *on a domain G* of $\mathbb{C}$ *can be represented as*

$$Z(\lambda)=\Phi(Z_0(\lambda)), \tag{A3}$$

where Φ *is an arbitrary analytic function on the image domain* $Z_0(G)$ *of G under* Z_0.

3*nj*-coefficients of su(1,1) as connection coefficients between orthogonal polynomials in *n* variables

S. Lievens[a] and J. Van der Jeugt[b]
Department of Applied Mathematics and Computer Science, University of Ghent, Krijgslaan 281-S9, B-9000 Gent, Belgium

(Received 21 February 2001; accepted for publication 29 March 2002)

In the tensor product of $n+1$ positive discrete series representations of su(1,1), a coupled basis vector can be described by a certain binary coupling tree. To every such binary coupling tree, polynomials $R_l^{(k)}(x)$ and $\mathcal{R}_l^{(k)}(x)$ are associated. These polynomials are n-variable Jacobi and continuous Hahn polynomials, and are orthogonal with respect to a weight function. The connection coefficients expressing such a polynomial associated with a given binary coupling tree in terms of those polynomials associated with another binary coupling tree are proportional to $3nj$-coefficients of su(1,1). © *2002 American Institute of Physics.*

I. INTRODUCTION

The $3nj$-coefficients of su(2) [or so(3)] play a dominant role in quantum theory of angular momentum[1–5] and its applications in nuclear, atomic, and molecular physics. For $3j$- and $6j$-coefficients of su(2) there exist expressions in terms of hypergeometric series,[5–7] explaining the close relation with orthogonal polynomials such as Hahn and Racah polynomials.[7] For example, the $6j$-coefficient of su(2) is expressed in terms of a terminating balanced ${}_4F_3$ series of unit argument. The parameters of the ${}_4F_3(1)$ series are written in terms of the six representation labels (angular momenta) of the $6j$-coefficient. By the nature of these representation labels (integer or half-integer positive numbers), the parameters of the ${}_4F_3(1)$ series are integers.[6,7] When identifying the $6j$-coefficient with a Racah polynomial $R_m(\lambda(x);\alpha,\beta,\gamma,\delta)$, it is not easy to decide which parameters correspond to the degree m, which to the variable x, and which to the parameters α, β, γ, δ of the polynomial. In a way, this identification becomes easier when dealing with positive discrete series representations of su(1,1) rather than with su(2) representations. This is, for us, one of the main reasons to consider couplings of such su(1,1) representations, their $3nj$-coefficients, and the connections with orthogonal polynomials in this article.

The Lie algebra su(1,1), or so(2,1), plays itself an important role in physical models. It has been extensively used as spectrum generating algebra in many simple quantum systems, such as the nonrelativistic Coulomb problem, the isotropic harmonic oscillator, Schrödinger's relativistic equation, and the Dirac–Coulomb problem (Ref. 8, and references therein). In certain boson models,[9,10] the relevant representations are the positive discrete series representations $\mathcal{D}^+(k)$. To fix the notation, let J_0, $J_\pm$ be the generators of su(1,1) subject to

$$[J_0,J_\pm]=\pm J_\pm, \quad [J_+,J_-]=-2J_0, \tag{1.1}$$

with the conditions $J_0^\dagger=J_0$ and $J_\pm^\dagger=J_\mp$. The positive discrete series representations[7] $\mathcal{D}^+(k)$ ($k>0$) have a basis $|k,n\rangle$, with $n=0,1,2,\ldots$, and the action of the generators is given by

$$J_0|k,n\rangle=(n+k)|k,n\rangle,$$

[a]Electronic mail: stijn.lievens@rug.ac.be
[b]Electronic mail: joris.vanderjeugt@rug.ac.be

$$J_+|k,n\rangle=\sqrt{(n+1)(2k+n)}|k,n+1\rangle, \tag{1.2}$$

$$J_-|k,n\rangle=\sqrt{n(2k+n-1)}|k,n-1\rangle.$$

[In the rest of the article, we always mean ''positive discrete series representations'' whenever we say ''representations'' of su(1,1).] The tensor product of two positive discrete series representations $(k_1)=\mathcal{D}^+(k_1)$ and $(k_2)=\mathcal{D}^+(k_2)$ [or the *coupling of two representations* (k_1) and (k_2)] decomposes as follows:[7]

$$(k_1)\otimes(k_2)=\bigoplus_{j=0}^{\infty}(k_1+k_2+j). \tag{1.3}$$

The ''coupled basis vectors'' are written in terms of the uncoupled ones by means of the su(1,1) Clebsch–Gordan coefficients:

$$|(k_1k_2)k,n\rangle=\sum_{n_1,n_2}C^{k_1,k_2,k}_{n_1,n_2,n}|k_1,n_1\rangle\otimes|k_2,n_2\rangle. \tag{1.4}$$

Herein, $k=k_1+k_2+j$ for some integer $j\geqslant 0$, and the sum is such that $n_1+n_2=j+n$. Explicit expressions for the Clebsch–Gordan coefficients are given, e.g., in Refs. 7, 11, and 12, in terms of a ${}_3F_2(1)$ series.

In this article we shall be dealing with the coupling or tensor product of $n+1$ such representations, labeled by positive integers $k_1,k_2,\ldots,k_{n+1}$. For the description of coupled basis vectors in such a tensor product, the notion of binary coupling trees is essential (see Ref. 4, Topic 12 and Refs. 13 and 14). Binary couplings find their origin in the recoupling theory of $n+1$ angular momenta (Ref. 4 Topic 12) [thus in the context of tensor products of $(n+1)$ su(2) representations], but apply also to the ''recoupling theory'' of $n+1$ positive discrete series representations of su(1,1).[13,14] Binary coupling trees describe the coupling scheme (the way of taking tensor products), i.e., the sequential pairwise coupling (Ref. 4 Topic 12). A $3nj$-coefficient of su(1,1) is then the coefficient of a unitary transformation which connects two basis vectors corresponding to different binary coupling schemes of $n+1$ representations.[4,6,13,14] Thus a $3nj$-coefficient is characterized by two binary trees T_1 and T_2 (with labeled leaves and nodes), and since it is the transformation coefficient or overlap coefficient, it is usually denoted by $\langle T_1,T_2\rangle$. For the reader not familiar with binary coupling trees, their meaning will become transparent from the examples given in this article.

The motivation for the work presented here stems from interpretations of identities involving orthogonal polynomials and su(1,1) Racah coefficients [or su(1,1) $6j$-coefficients]. One such identity appears already in the seminal work of Granovskiĭ and Zhedanov [Ref. 15, Eq. (9)]: this is a convolution identity involving products of Jacobi polynomials and Racah coefficients. The identity can be interpreted as a connection coefficient identity between orthogonal polynomials in two variables, with su(1,1) Racah coefficients as connection coefficients (see Refs. 11 and 12). It was later extended to the case of continuous Hahn polynomials (Ref. 12, Theorem 3.13): here the connection coefficients are the same [namely su(1,1) Racah coefficients], but the orthogonal polynomials in two variables are certain products of two continuous Hahn polynomials.

In the present article orthogonal polynomials in n variables will be associated with the tensor product of $n+1$ representations of su(1,1). A different class of orthogonal polynomials arises depending upon the (internal) binary coupling tree. Then, the connection coefficients relating two such orthogonal polynomials associated with a different binary coupling tree are given by $3nj$-coefficients (associated with the coupling trees). For the case of three couplings Jacobi polynomials and continuous Hahn polynomials appear. Also for the n-variable case, these two families are present: the orthogonal polynomials we are dealing with are either products of certain Jacobi polynomials, or products of continuous Hahn polynomials.

In general, orthogonal polynomials in several variables give rise to certain difficulties that are not present in the one variable situation. For example, orthogonal polynomials in n variables are no longer uniquely defined by the area Ω and the weight function on the area. This is closely related to the fact that there is no obvious natural order for polynomials in several variables.

The space of all polynomials in the variables $x_1,\ldots,x_n$ with real coefficients is denoted $\mathbb{R}[x_1,\ldots,x_n]$ or Π^n for short. The degree of a polynomial $P\in\Pi^n$ is the highest degree of any of its monomials. Let $\langle\cdot,\cdot\rangle$ be an inner product defined on Π^n. Then P is an orthogonal polynomial if $\langle P,Q\rangle=0$ for all polynomials Q with $\deg Q<\deg P$. This definition does not require that P is orthogonal with other (orthogonal) polynomials of the same degree.

In our case the inner product will be defined in terms of some (classical) weight function W on some (classical) area Ω in $\mathbb{R}^n$: $\langle P,Q\rangle=\int_\Omega P(x)Q(x)W(x)dx$.

The outline of the rest of this article is as follows. In Sec. II we confine ourselves to the two variable case. The basic identities are convolution identities involving su(1,1) Racah coefficients and Jacobi polynomials[15,11] or continuous Hahn polynomials.[12] The new aspect here is that we show how to deduce these identities from the Biedenharn–Elliott identity.[4] More particularly, we show how the Biedenharn–Elliott identity yields a new convolution identity involving the Wilson and Racah polynomials. The products of Wilson polynomials on both sides of the identity are shown to be orthogonal in $\mathbb{R}^2$ with respect to some weight function. Using limiting relations between the Wilson, continuous Hahn and Jacobi polynomials, two other (known) convolution identities are (re)derived.

Section III generalizes the result involving Jacobi polynomials to n variables. With the coupling of $n+1$ representations in su(1,1) we associate a set of orthogonal polynomials on the simplex with respect to the classical weight function $x_1^{\alpha_1}\cdots x_n^{\alpha_n}(1-x_1-\cdots-x_n)^{\alpha_{n+1}}$ $(\alpha_i>-1)$. For $n=2$ these polynomials are due to Proriol.[16] For arbitrary n, but associated to a special coupling tree, these polynomials appear in Ref. 17. The more general case was also considered by Rosengren[18] in the context of multilinear Hankel forms.

Section IV does the same for the result involving continuous Hahn polynomials. In this case the area is the complete space $\mathbb{R}^n$, and the weight function is in terms of gamma functions.

In Sec. V we prove that the sets of polynomials defined in the previous sections form bases for Π^n. Moreover, we show that the generalized recoupling coefficients of su(1,1), which are essentially sums of products of Racah coefficients, are the connection coefficients between the different bases.

In the rest of this article we will use the following abbreviations: k always stands for the $(n+1)$-tuple $(k_1,\ldots,k_{n+1})\in\mathbb{R}_+^{n+1}$, and l is an n-tuple $(l_1,\ldots,l_n)\in\mathbb{N}^n$. Moreover, we use $|k|=k_1+\cdots+k_{n+1}$ and $|l|=l_1+\cdots+l_n$. The Kronecker delta symbol $\delta_{l,l'}$ then stands for the product $\delta_{l_1,l_1'},\ldots,\delta_{l_n,l_n'}$, etc.

II. A CONVOLUTION IDENTITY INVOLVING WILSON POLYNOMIALS

In general recoupling theory of su(2), the Biedenharn–Elliott identity is well known.[4,1,6] In the case of positive discrete series representations of su(1,1), the identity is essentially the same. It is easily derived by considering the overlap or transformation coefficient (Ref. 4, pp. 456–457),[13,14]

$$\langle((((k_1,k_2)k_{12},k_3)k_{13},k_4)k_{14}|(k_1,(k_2,(k_3,k_4)k_{34})k_{24})k_{14}\rangle$$

and computing this in two different ways: either directly, yielding a product of two recoupling coefficients, or in three steps, introducing a summation variable and thus yielding a sum of a product of three recoupling coefficients. Explicitly we obtain

$$\sum_{k_{23}} U^{k_1,k_2,k_{12}}_{k_3,k_{13},k_{23}} U^{k_1,k_{23},k_{13}}_{k_4,k_{14},k_{24}} U^{k_2,k_3,k_{23}}_{k_4,k_{24},k_{34}} = U^{k_{12},k_3,k_{13}}_{k_4,k_{14},k_{34}} U^{k_1,k_2,k_{12}}_{k_{34},k_{14},k_{24}}, \tag{2.1}$$

where k_{23} is restricted to some range, and U stands for a Racah coefficient (or recoupling coefficient, or $6j$-coefficient) of su(1,1). All k_i's or k_{ij}'s refer to su(1,1) representation labels and are positive real numbers. An explicit form for the recoupling coefficients in terms of terminating balanced ${}_4F_3(1)$ series is known:[7,11,12]

$$U^{k_1,k_2,k_{12}}_{k_3,k_0,k_{23}}=\begin{pmatrix} j+j_{12} \\ j_{23} \end{pmatrix}\frac{(2k_2)_{j_{12}}(2k_3)_j(2k_1+2k_2+2k_3+j+j_{12}-1)_{j_{23}}}{(2k_3,2k_2+2k_3+j_{23}-1)_{j_{23}}(2k_2+2k_3+2j_{23})_{j'}}$$
$$\times\sqrt{\frac{j'!(2k_1,2k_{23},2k_1+2k_{23}+j'-1)_{j'}\,j_{23}!(2k_2,2k_3,2k_2+2k_3+j_{23}-1)_{j_{23}}}{j!(2k_{12},2k_3,2k_{12}+2k_3+j-1)_j\,j_{12}!(2k_1,2k_2,2k_1+2k_2+j_{12}-1)_{j_{12}}}}$$
$$\times{}_4F_3\left(\begin{matrix}2k_1+2k_2+j_{12}-1,2k_2+2k_3+j_{23}-1,-j_{12},-j_{23}\\ 2k_2,2k_1+2k_2+2k_3+j+j_{12}-1,-j-j_{12}\end{matrix};1\right), \tag{2.2}$$

with the following restrictions and definitions:

$$k_{12}=k_1+k_2+j_{12},\quad k_{23}=k_2+k_3+j_{23},$$

$$k_0=k_{12}+k_3+j=k_1+k_{23}+j',\quad j_{12},j,j_{23},j'\in\mathbb{N},\ \text{and}\ j_{12}+j=j_{23}+j'.$$

In (2.2), we follow the classical notation for Pochhammer symbols $(a)_n$ and for hypergeometric series ${}_pF_q$.[19–21]

Both the Racah and Wilson polynomials are defined in terms of terminating balanced ${}_4F_3(1)$ series. We will now perform an appropriate renaming of the nine free parameters and the summation variable in (2.1) to derive a convolution identity involving Wilson and Racah polynomials.

Wilson polynomials, denoted $W_m(x^2;a,b,c,d)$, are defined as follows:

$$W_m(x^2;a,b,c,d)=(a+b)_m(a+c)_m(a+d)_m\,{}_4F_3\left(\begin{matrix}-m,m+a+b+c+d-1,a+ix,a-ix\\ a+b,a+c,a+d\end{matrix};1\right), \tag{2.3}$$

while Racah polynomials, denoted $R_m(\lambda(x);\alpha,\beta,\gamma,\delta)$, are defined by

$$R_m(\lambda(x);\alpha,\beta,\gamma,\delta)={}_4F_3\left(\begin{matrix}-m,m+\alpha+\beta+1,-x,x+\gamma+\delta+1\\ \alpha+1,\beta+\delta+1,\gamma+1\end{matrix};1\right), \tag{2.4}$$

where $\lambda(x)=x(x+\gamma+\delta+1)$ and one of the denominator parameters equals $-M$ with $M\in\mathbb{N}$ and $0\leqslant m\leqslant M$.

Here (and in the rest of the article), we use the notation of Ref. 22 for Wilson and Racah polynomials (and for all other one variable orthogonal polynomials).

Theorem 1: *The Wilson polynomials satisfy the following convolution identity:*

$$\sum_{l=0}^{m+j}\begin{pmatrix} j+m \\ l \end{pmatrix}\frac{(2k_2)_m(2k_3)_j(2k_1+2k_2+2k_3+j+m-1)_l}{(2k_3)_l(2k_2+2k_3+l-1)_l(2k_2+2k_3+2l)_{j+m-l}}R_l(\lambda(m);2k_2-1,2k_3-1,$$
$$-j-m-1,2k_1+2k_2+j+m-1)W_{m+j-l}((x_1-t)^2;k_1+it,k_2+k_3+l-is+it,k_1-it,k_2+k_3$$
$$+l+is-it)W_l((x_1+x_2-t)^2;k_2-ix_1+it,k_3-is+it,k_2+ix_1-it,k_3+is-it)$$
$$=W_m((x_1-t)^2;k_1+it,k_2-i(x_1+x_2)+it,k_1-it,k_2+i(x_1+x_2)-it)$$
$$\times W_j((x_1+x_2-t)^2;k_1+k_2+m+it,k_3-is+it,k_1+k_2+m-it,k_3+is-it), \tag{2.5}$$

where $j,\ m\in\mathbb{N},\ k_1,\ k_2,\ k_3,\ x_1,\ x_2,\ x_3,\ t\in\mathbb{R}$ *and* $s=x_1+x_2+x_3$.

Proof: In the case of su(1,1), the summation range for k_{23} in (2.1) is from k_2+k_3 to $\min(k_{13}-k_1,k_{24}-k_4)$. The summation variable k_{23} thus takes *real* values, starting with k_2+k_3 and increasing in steps of one. Substituting (2.2) in (2.1) yields an identity between terminating balanced ${}_4F_3(1)$ series:

$$\begin{aligned}
&\sum_{k_{23}=k_2+k_3}^{\min(k_{13}-k_1,k_{24}-k_4)} f\times {}_4F_3\left(\begin{matrix}k_1+k_2+k_{12}-1,k_2+k_3+k_{23}-1,k_1+k_2-k_{12},k_2+k_3-k_{23}\\ 2k_2,k_{13}+k_1+k_2+k_3-1,k_1+k_2+k_3-k_{13}\end{matrix};1\right)\\
&\quad\times {}_4F_3\left(\begin{matrix}k_1+k_{23}+k_{13}-1,k_{23}+k_4+k_{24}-1,k_1+k_{23}-k_{13},k_{23}+k_4-k_{24}\\ k_1+k_{23}+k_4-k_{14},2k_{23},k_{14}+k_1+k_{23}+k_4-1\end{matrix};1\right)\\
&\quad\times {}_4F_3\left(\begin{matrix}k_2+k_3+k_{23}-1,k_2+k_3-k_{23},k_3+k_4+k_{34}-1,k_3+k_4-k_{34}\\ k_2+k_3+k_4-k_{24},2k_3,k_{24}+k_2+k_3+k_4-1\end{matrix};1\right)\\
&\quad={}_4F_3\left(\begin{matrix}k_3+k_4+k_{34}-1,k_{12}+k_3+k_{13}-1,k_3+k_4-k_{34},k_{12}+k_3-k_{13}\\ k_{12}+k_3+k_4-k_{14},2k_3,k_{14}+k_{12}+k_3+k_4-1\end{matrix};1\right)\\
&\qquad\times {}_4F_3\left(\begin{matrix}k_1+k_2+k_{12}-1,k_1+k_2-k_{12},k_2+k_{34}+k_{24}-1,k_2+k_{34}-k_{24}\\ 2k_2,k_1+k_2+k_{34}-k_{14},k_{14}+k_1+k_2+k_{34}-1\end{matrix};1\right),
\end{aligned}$$

where f is a numerical factor that is easily calculated from (2.2). Renaming the following positive integer differences as

$$m=k_{12}-k_1-k_2,\quad j=k_{13}-k_{12}-k_3\quad\text{and}\quad l=k_{23}-k_2-k_3,$$

and performing appropriate Bailey transformations (Ref. 23, Theorem 3.3.3) on the balanced ${}_4F_3(1)$'s, yields that (when $k_{13}-k_1\leqslant k_{24}-k_4$)

$$\begin{aligned}
&\sum_{l=0}^{j+m} f'\times {}_4F_3\left(\begin{matrix}-l,l+2k_2+2k_3-1,-m,m+2k_1+2k_2-1\\ 2k_2,2k_1+2k_2+2k_3+j+m-1,-j-m\end{matrix};1\right)\\
&\quad\times {}_4F_3\left(\begin{matrix}-m-j+l,m+j+l+2k_1+2k_2+2k_3-1,k_1+k_{14}+k_{24}-1,k_1+k_{14}-k_{24}\\ 2k_1,k_1+k_2+k_3+l+k_4+k_{14}-1,k_1+k_2+k_3+l+k_{14}-k_4\end{matrix};1\right)\\
&\quad\times {}_4F_3\left(\begin{matrix}-l,l+2k_2+2k_3-1,k_2+k_{24}+k_{34}-1,k_2+k_{24}-k_{34}\\ 2k_2,k_2+k_3+k_{24}-k_4,k_{24}+k_2+k_3+k_4-1\end{matrix};1\right)\\
&\quad={}_4F_3\left(\begin{matrix}-j,j+2m+2k_1+2k_2+2k_3-1,m+k_1+k_2+k_{14}-k_{34},m+k_1+k_2+k_{14}+k_{34}-1\\ 2m+2k_1+2k_2,m+k_1+k_2+k_3+k_4+k_{14}-1,m+k_1+k_2+k_3+k_{14}-k_4\end{matrix};1\right)\\
&\qquad\times {}_4F_3\left(\begin{matrix}-m,m+2k_1+2k_2-1,k_1+k_{14}+k_{24}-1,k_1+k_{14}-k_{24}\\ 2k_1,k_1+k_2+k_{14}-k_{34},k_1+k_2+k_{14}+k_{34}-1\end{matrix};1\right),
\end{aligned}$$

where, once again, f' is a numerical factor that is easily calculated.

This last identity can be written in terms of Wilson and Racah polynomials by putting

$$ix_1=k_{14}-k_{24},\quad ix_2=k_{24}-k_{34},\quad ix_3=k_{34}-k_4\quad\text{and}\quad it=k_4+i(x_1+x_2+x_3)-\tfrac{1}{2}.$$

Note that all the renamings are invertible. Determination of the factor f' now yields the desired result. Since (2.5) is a rational identity in the parameters k_i, x_i and t, it is valid for all values of these parameters. □

From Theorem 1 we can easily rederive a convolution identity for continuous Hahn polynomials. The continuous Hahn polynomials, denoted $p_m(x;a,b,c,d)$, are defined as[22]

$$p_m(x;a,b,c,d)=i^m\frac{(a+c)_m(a+d)_m}{m!}\,{}_3F_2\left(\begin{matrix}-m,m+a+b+c+d-1,a+ix\\ a+c,a+d\end{matrix};1\right);\qquad(2.6)$$

for their orthogonality [when $\Re(a,b,c,d)>0$, $\overline{c}=a$ and $\overline{d}=b$], see Ref. 22 or (4.3). Using the limit transition,[22]

$$\lim_{t\to-\infty}\frac{W_m((x-t)^2;a+it,b+it,c-it,d-it)}{(2t)^m m!}=p_m(x;a,b,c,d), \tag{2.7}$$

in (2.5), one finds the following corollary (see also Ref. 12, Theorem 3.13).

Corollary 2: The continuous Hahn polynomials satisfy the following convolution identity:

$$\begin{aligned}&\sum_{l=0}^{m+j}\binom{j+m}{m}\frac{(2k_2)_m(2k_3)_j(2k_1+2k_2+2k_3+j+m-1)_l}{(2k_3)_l(2k_2+2k_3+l-1)_l(2k_2+2k_3+2l)_{j+m-l}}R_l(\lambda(m);2k_2-1,2k_3-1,\\&\quad -j-m-1,2k_1+2k_2+j+m-1)p_{m+j-l}(x_1;k_1,k_2+k_3+l-is,k_1,k_2+k_3+l+is)\\&\quad\times p_l(x_2;k_2,k_3-i(s-x_1),k_2,k_3+i(s-x_1))\\&\quad=p_m(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2))\\&\qquad\times p_j(x_1+x_2;k_1+k_2+m,k_3-is,k_1+k_2+m,k_3+is),\end{aligned} \tag{2.8}$$

where $j,m\in\mathbb{N}$, $k_1,k_2,k_3,x_1,x_2,x_3\in\mathbb{R}$ and $s=x_1+x_2+x_3$. □

The classical Jacobi polynomials are defined by

$$P_m^{(\alpha,\beta)}(x)=\frac{(\alpha+1)_m}{m!}{}_2F_1\left(\begin{matrix}-m,m+\alpha+\beta+1\\ \alpha+1\end{matrix};\frac{1-x}{2}\right); \tag{2.9}$$

for $\alpha,\beta>-1$, they are orthogonal over the interval $[-1,1]$ for the weight function $(1-x)^\alpha(1+x)^\beta$. Replacing x_i by sx_i in (2.8) and letting s tend to infinity yields Corollary 3 (see also Ref. 12 Corollary 3.15, or Refs. 15 and 11):

Corollary 3: The Jacobi polynomials satisfy the following convolution identity:

$$\begin{aligned}&\sum_{l=0}^{m+j}\binom{j+m}{m}\frac{(2k_2)_m(2k_3)_j(2k_1+2k_2+2k_3+j+m-1)_l}{(2k_3)_l(2k_2+2k_3+l-1)_l(2k_2+2k_3+2l)_{j+m-l}}R_l(\lambda(m);2k_2-1,2k_3-1,\\&\quad -j-m-1,2k_1+2k_2+j+m-1)P_{m+j-l}^{(2k_1-1,2k_2+2k_3+2l-1)}(1-2x_1)\\&\quad\times(1-x_1)^l P_l^{(2k_2-1,2k_3-1)}\left(\frac{1-x_1-2x_2}{1-x_1}\right)\\&\quad=(x_1+x_2)^m P_m^{(2k_1-1,2k_2-1)}\left(\frac{x_2-x_1}{x_1+x_2}\right)P_j^{(2k_1+2k_2+2m-1,2k_3-1)}(1-2x_1-2x_2).\end{aligned}$$

□

Both Corollaries 2 and 3 can be written in a more symmetric (and unified) way using a different scaling for the continuous Hahn and Jacobi polynomials. Defining the polynomial $\mathcal{S}_m^{k_1,k_2}(x_1,x_2)$ as

$$\begin{aligned}\mathcal{S}_m^{k_1,k_2}(x_1,x_2)=&\sqrt{\frac{m!(2m+2k_1+2k_2-1)\Gamma(m+2k_1+2k_2-1)}{\Gamma(m+2k_1)\Gamma(m+2k_2)}}\\&\times p_m(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2)),\end{aligned} \tag{2.10}$$

we have the following identity [Ref. 12, Eq. (3.15)]:

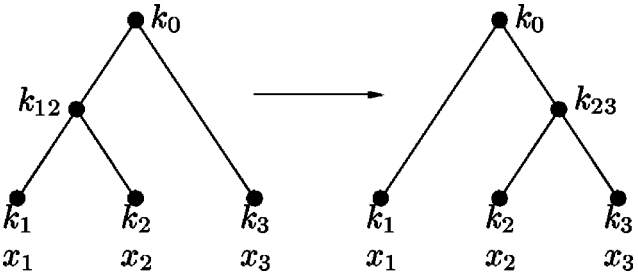

FIG. 1. Two possible ways of coupling three representations.

$$\mathcal{S}^{k_1,k_2}_{k_{12}-k_1-k_2}(x_1,x_2)\mathcal{S}^{k_{12},k_3}_{k_0-k_{12}-k_3}(x_1+x_2,x_3)$$
$$=\sum_{k_{23}=k_2+k_3}^{k_0-k_1} U^{k_1,k_2,k_{12}}_{k_3,k_0,k_{23}}\mathcal{S}^{k_2,k_3}_{k_{23}-k_2-k_3}(x_2,x_3)\mathcal{S}^{k_1,k_{23}}_{k_0-k_1-k_{23}}(x_1,x_2+x_3). \tag{2.11}$$

Formula (2.11) is easily remembered by considering two ways in which three su(1,1) representations can be coupled, as shown in Fig. 1. Notice how the left side of (2.11) follows from the tree on the left side of this figure. With each non-leaf node (i.e., with each intermediate or final coupling) one associates an $\mathcal{S}$-polynomial. The first (resp. second) variable of this $\mathcal{S}$-polynomial is the sum of all the variables associated with the leaves in the left (resp. right) subtree of the considered node. The upper parameters are determined by the value of the representation labels of the left and right child (in that order). The (positive integer) lower parameter is the difference between the value of the coupled representation label and the consisting labels. The $\mathcal{S}$-polynomials on the right side of (2.11) are formed in the same way but working with the tree on the right side of the figure. The recoupling coefficient appearing in (2.11) is that associated with a recoupling of three representations as shown in Fig. 1.

The $\mathcal{S}$-polynomials have the following property:

$$\mathcal{S}^{k_1,k_2}_m(x_1,x_2)=(-1)^m\mathcal{S}^{k_2,k_1}_m(x_2,x_1), \tag{2.12}$$

which is a direct consequence of Whipple's transformation for terminating ${}_3F_2(1)$ series (Ref. 23, p. 142).

If we define[15,11]

$$S^{k_1,k_2}_m(x_1,x_2)=(-1)^m\sqrt{\frac{m!}{(2k_1,2k_2,2k_1+2k_2+m-1)_m}}(x_1+x_2)^m P^{(2k_1-1,2k_2-1)}_m\left(\frac{x_2-x_1}{x_2+x_1}\right), \tag{2.13}$$

then relations (2.11) and (2.12) are still valid (after replacing $\mathcal{S}$ by S). This follows from the fact that

$$\lim_{u\to\infty}\frac{\mathcal{S}^{k_1,k_2}_m(ux_1,ux_2)}{u^m}=\sqrt{\frac{\Gamma(2m+2k_1+2k_2)}{\Gamma(2k_1)\Gamma(2k_2)}}S^{k_1,k_2}_m(x_1,x_2). \tag{2.14}$$

It is known[12] that the products of continuous Hahn polynomials on both the left and right sides of (2.8) [or (2.11)] are orthogonal on $\mathbb{R}^2$ for the weight function

$$\Gamma(k_1\pm ix_1)\Gamma(k_2\pm ix_2)\Gamma(k_3\pm i(s-x_1-x_2)), \tag{2.15}$$

where, for conciseness of notation, the product $\Gamma(k_j+ix)\Gamma(k_j-ix)$ is written as $\Gamma(k_j\pm ix)$. This convention is adopted throughout this article. Moreover, we will write $\Gamma(\pm k_j\mp ix)$ instead of $\Gamma(k_j-ix)\Gamma(-k_j+ix)$, etc. Observe that (2.11), with $x_3=s-x_1-x_2$, can thus be interpreted as a

connection coefficient formula between orthogonal polynomials in two variables, and the su(1,1) Racah coefficients are the connection coefficients. Similarly, replacing $\mathcal{S}$ by S in (2.11), one obtains again a connection coefficient formula. This time, the orthogonal polynomials are orthogonal on the simplex determined by $x_1, x_2 > 0$, $x_1 + x_2 < s$, and the weight function is $x_1^{2k_1-1} x_2^{2k_2-1} (s - x_1 - x_2)^{2k_3-1}$.

In this section we have shown how the Biedenharn–Elliott identity implies two connection coefficient formulas for orthogonal polynomials in two variables, one constructed with continuous Hahn polynomials, and one constructed with Jacobi polynomials. In the following sections this will be generalized to orthogonal polynomials in n variables. Finally, observe that also the products of Wilson polynomials in Theorem 1 are related to orthogonal polynomials in two variables (see Appendix A).

III. ORTHOGONAL POLYNOMIALS RELATED TO JACOBI POLYNOMIALS

When considering orthogonal polynomials in n variables, one of the classical areas is the simplex T_s^n:

$$T_s^n = \{x \in \mathbb{R}^n | 0 < x_j \text{ and } x_1 + \cdots + x_n < s\}. \tag{3.1}$$

Herein, s denotes some positive constant, and in almost all cases s is taken to be equal to 1. The classical weight function in this case is

$$x_1^{\kappa_1 - 1/2} \cdots x_n^{\kappa_n - 1/2} (s - |x|)^{\kappa_{n+1} - 1/2}, \tag{3.2}$$

where each $\kappa_i > -\frac{1}{2}$. In Ref. 24, Proposition 2.3.8, an explicit orthonormal basis is given associated with the weight function (3.2) on the simplex (3.1). Such a basis is not unique. In fact, with every binary coupling tree on $n+1$ leaves, a different basis can be constructed. In this section, an n-variable orthonormal polynomial will be constructed out of a product of n S-polynomials (2.13), and associated with a binary coupling of $n+1$ representations of su(1,1). We will show that this polynomial is orthogonal on the simplex T_s^n for the classical weight function. The outline of this proof is as follows: by a change of variables, we will transform the simplex into the cube on $\mathbb{R}^n$. This transformation will map the integral over the simplex into an integral over the cube, where one part can be interpreted as the multiple Jacobi weight function:

$$\prod_{i=1}^{n} (1 - x_i)^{a_i} (1 + x_i)^{b_i}, \tag{3.3}$$

while the other parts are the corresponding Jacobi polynomials.

Theorem 4: *With every coupling of* $(n+1)$ su(1,1) *representations labeled by* $k_1, \ldots, k_{n+1}$, *i.e., with every binary coupling tree with n internal nodes, we associate a set of polynomials* $R_l^{(k)}(x)$ *in n variables orthogonal on the simplex* T_s^n *for the weight function*

$$w^{(k)}(x) = x_1^{2k_1 - 1} \cdots x_n^{2k_n - 1} (s - |x|)^{2k_{n+1} - 1}, \tag{3.4}$$

where each $k_i > 0$. *Explicitly the orthogonality reads*

$$\int_{T_s^n} R_l^{(k)}(x) R_{l'}^{(k)}(x) w^{(k)}(x)\, dx = \delta_{l,l'} \frac{s^{2|k| + 2|l| - 1}}{\Gamma(2|k| + 2|l|)} \prod_{i=1}^{n+1} \Gamma(2k_i). \tag{3.5}$$

Note that in (3.5) *we also have orthogonality between polynomials of the same degree, which is more than the definition of orthogonality requires.*

Remark 5: In principal the notation of the polynomial should contain a reference to the binary coupling tree it corresponds to. For the moment, we can assume that the binary coupling tree is fixed, and we do not mention it in the notation of $R_l^{(k)}(x)$. When we want to emphasize the

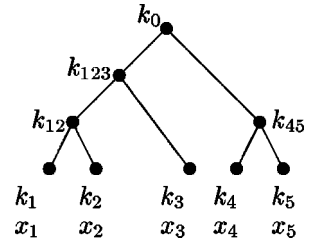

FIG. 2. Example binary coupling tree.

dependence of $R_l^{(k)}(x)$ on the given binary coupling tree T, we shall write $R_{l,T}^{(k)}(x)$. The meaning of the subscript l is related to the labeling of the internal nodes, and will soon become apparent.■

The association of a polynomial with a binary coupling tree is an extension of the method described after Eq. (2.11). For a given binary coupling tree, the polynomial $R_l^{(k)}(x)$ consists of a product of S-polynomials, each of these associated with a non-leaf node of the tree. Let us first describe an example.

Example 6: With the binary coupling tree shown in Fig. 2 we associate the following polynomial:

$$\begin{aligned}R(x_1,x_2,x_3,x_4,x_5) &= S^{k_1,k_2}_{k_{12}-k_1-k_2}(x_1,x_2)S^{k_{12},k_3}_{k_{123}-k_{12}-k_3}(x_1+x_2,x_3)S^{k_4,k_5}_{k_{45}-k_4-k_5}(x_4,x_5)\\ &\quad\times S^{k_{123},k_{45}}_{k_0-k_{123}-k_{45}}(x_1+x_2+x_3,x_4+x_5)\\ &= C\times(x_1+x_2)^{k_{12}-k_1-k_2}P^{(2k_1-1,2k_2-1)}_{k_{12}-k_1-k_2}\left(\frac{x_2-x_1}{x_2+x_1}\right)\\ &\quad\times(x_1+x_2+x_3)^{k_{123}-k_{12}-k_3}P^{(2k_{12}-1,2k_3-1)}_{k_{123}-k_{12}-k_3}\left(\frac{x_3-x_1-x_2}{x_3+x_1+x_2}\right)\\ &\quad\times(x_4+x_5)^{k_{45}-k_4-k_5}P^{(2k_4-1,2k_5-1)}_{k_{45}-k_4-k_5}\left(\frac{x_5-x_4}{x_5+x_4}\right)\\ &\quad\times(x_1+x_2+x_3+x_4+x_5)^{k_0-k_{123}-k_{45}}P^{(2k_{123}-1,2k_{45}-1)}_{k_0-k_{123}-k_{45}}\left(\frac{x_4+x_5-x_1-x_2-x_3}{x_4+x_5+x_1+x_2+x_3}\right).\end{aligned}$$

Herein, C is some numerical factor that can be determined from (2.13). ■

So the S-polynomial, associated to a non-leaf node of the tree, has as (upper) parameters the representation labels of left and right child of the node; as degree (the subindex) the difference between the representation label of the node and those of the children (this is a non-negative integer); and as left (resp. right) argument the sum of all the variables associated with the leaves in the left (resp. right) subtree of the considered node.

Such a polynomial $R(x_1,\ldots,x_{n+1})$, defined as a product of S-polynomials in this way, is homogeneous in the variables $x_1,\ldots,x_{n+1}$. So we can choose the constraint

$$x_1+x_2+\cdots+x_{n+1}=s, \tag{3.6}$$

where s is some arbitrary, positive constant. Note that this constraint is compatible with the definition of the weight function (3.4). The resulting polynomial will be denoted by $R_l^{(k)}(x)$. The subscript l in $R_l^{(k)}(x)$ stands for the sequence of degrees of the S-polynomials, in a chosen order (see later for this choice).

In order to prove (3.5), we shall transform variables from $(x_1,\ldots,x_n)$ to $(v_1,\ldots,v_n)$; determine the Jacobian and integration area for this transformation; determine the transformed weight function; and finally deduce the orthogonality. All of this can be done quite explicitly for any given binary coupling tree, and will be presented in the following subsections.

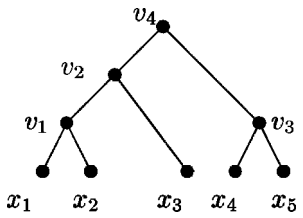

FIG. 3. Association of the variables v_i with non-leaf nodes.

A. Change of variables

We will change from variables x to variables v. The v_i are the arguments of the Jacobi polynomials appearing in the product expansion of $R_l^{(k)}(x)$ (see, for instance, Example 6).

Since each S-polynomial (and thus each Jacobi polynomial) in the product is associated with a specific non-leaf node of the tree, we can associate a variable v_i with each non-leaf node. The exact order is irrelevant but, for simplicity, we choose *postorder* (Ref. 25, Sec. 2.3.1). See Fig. 3 for an illustration.

Example 7: The arguments of the Jacobi polynomials in Example 6 are

$$\begin{aligned} v_1&=(x_2-x_1)/(x_2+x_1),\\ v_2&=(x_3-x_1-x_2)/(x_3+x_1+x_2),\\ v_3&=(x_5-x_4)/(x_5+x_4),\\ v_4&=(x_4+x_5-x_1-x_2-x_3)/(x_4+x_5+x_1+x_2+x_3). \end{aligned} \tag{3.7}$$

The set of equations (3.7), together with the constraint (3.6), has a unique solution:

$$\begin{aligned} x_1&=s(1-v_1)(1-v_2)(1-v_4)/8,\\ x_2&=s(1+v_1)(1-v_2)(1-v_4)/8,\\ x_3&=s(1+v_2)(1-v_4)/4,\\ x_4&=s(1-v_3)(1+v_4)/4,\\ x_5&=s(1+v_3)(1+v_4)/4. \end{aligned} \tag{3.8}$$

Notice how the solution (3.8) of (3.7) can easily be deduced from the tree in Fig. 3: each x_j consists of a factor s and factors $(1\pm v_i)/2$. There is a factor $(1+v_i)/2$ if x_j is in the right subtree of v_i, and there is a factor $(1-v_i)/2$ if x_j is in the left subtree of v_i. ■

This observation can be generalized to an arbitrary tree. Then we have

$$\begin{aligned} &v_i=\left(\sum_{\substack{\text{right leaves}\\ \text{of } v_i}} x_j-\sum_{\substack{\text{left leaves}\\ \text{of } v_i}} x_j\right)\Bigg/\sum_{\substack{\text{all leaves}\\ \text{of } v_i}} x_j, \quad \text{for } i=1,\ldots,n,\\ &x_1+x_2+\cdots+x_{n+1}=s. \end{aligned} \tag{3.9}$$

Lemma 8: The system (3.9) of $n+1$ (linear) equations for the variables x_j has the unique solution

$$x_j = s \prod_{\substack{\text{right ancestors} \\ \text{of } x_j}} \frac{1+v_i}{2} \prod_{\substack{\text{left ancestors} \\ \text{of } x_j}} \frac{1-v_i}{2}, \quad \text{for} \quad j=1,\ldots,n+1, \tag{3.10}$$

where we call v_i a right (resp. left) ancestor of x_j if x_j is in the right (resp. left) subtree of v_i.

Proof: By induction on n. It is easily verified that this statement is true when $n=1$. If $n>1$ and the left subtree of v_n has $0 \leqslant n_1 < n$ internal nodes, then the last two equations of (3.9) read

$$\begin{gathered} v_n = \left(\sum_{\substack{\text{right leaves} \\ \text{of } v_n}} x_j - \sum_{\substack{\text{left leaves} \\ \text{of } v_n}} x_j \right) \Bigg/ \sum_{j=1}^{n+1} x_j, \\ x_1 + x_2 + \cdots + x_{n+1} = s. \end{gathered} \tag{3.11}$$

These equations have the following unique solution for $\Sigma_{\substack{\text{right leaves} \\ \text{of } v_n}} x_j$ and $\Sigma_{\substack{\text{left leaves} \\ \text{of } v_n}} x_j$ (compare this with the case $n=1$):

$$\sum_{\substack{\text{right leaves} \\ \text{of } v_n}} x_j = s \frac{1+v_n}{2}, \qquad \sum_{\substack{\text{left leaves} \\ \text{of } v_n}} x_j = s \frac{1-v_n}{2}. \tag{3.12}$$

Using this solution for $\Sigma_{\substack{\text{left leaves} \\ \text{of } v_n}} x_j = \Sigma_{\substack{\text{leaves} \\ \text{of } v_{n_1}}} x_j$ with the first n_1 equations of (3.9), which involve only variables x that are in the left subtree of v_n, yields (by induction) the desired form of the unique solution for the variables x in the left subtree. The same applies to the variables x in the right subtree. This proves formula (3.10). We can even say more:

$$\sum_{\substack{\text{leaves} \\ \text{of } v_i}} x_j = s \prod_{\substack{\text{right ancestors} \\ \text{of } v_i}} \frac{1+v_m}{2} \prod_{\substack{\text{left ancestors} \\ \text{of } v_i}} \frac{1-v_m}{2}, \tag{3.13}$$

and

$$\sum_{\substack{\text{left leaves} \\ \text{of } v_i}} x_j = s \frac{1-v_i}{2} \prod_{\substack{\text{right ancestors} \\ \text{of } v_i}} \frac{1+v_m}{2} \prod_{\substack{\text{left ancestors} \\ \text{of } v_i}} \frac{1-v_m}{2}. \tag{3.14}$$

□

B. The Jacobian of the transformation

Example 9: The Jacobian $\partial x_j / \partial v_i$ of (the first four equations of) (3.8) is the following matrix:

$$\begin{pmatrix} -s(1-v_2)(1-v_4)/8 & -s(1-v_1)(1-v_4)/8 & 0 & -s(1-v_1)(1-v_2)/8 \\ s(1-v_2)(1-v_4)/8 & -s(1+v_1)(1-v_4)/8 & 0 & -s(1+v_1)(1-v_2)/8 \\ 0 & s(1-v_4)/4 & 0 & -s(1+v_2)/4 \\ 0 & 0 & -s(1+v_4)/4 & s(1-v_3)/4 \end{pmatrix}. \tag{3.15}$$

At first sight, this matrix is quite arbitrary. However, by taking linear combinations of rows and by swapping rows, it can be transformed into a simple upper triangular matrix. From (3.8) [or directly from (3.14)] we see that

$$\sum_{\substack{\text{left leaves}\\ \text{of } v_1}} x_j = x_1 = s(1-v_1)(1-v_2)(1-v_4)/8,$$

$$\sum_{\substack{\text{left leaves}\\ \text{of } v_2}} x_j = x_1 + x_2 = s(1-v_2)(1-v_4)/4,$$

$$\sum_{\substack{\text{left leaves}\\ \text{of } v_3}} x_j = x_4 = s(1-v_3)(1+v_4)/4,$$

$$\sum_{\substack{\text{left leaves}\\ \text{of } v_4}} x_j = x_1 + x_2 + x_3 = s(1-v_4)/2.$$

So, performing the row combinations $R_2 \leftarrow R_2 + R_1$, $R_3 \leftarrow R_3 + R_2$ and swapping the rows R_3 and R_4 of the Jacobian results in the following upper triangular matrix:

$$\begin{pmatrix} -s(1-v_2)(1-v_4)/8 & -s(1-v_1)(1-v_4)/8 & 0 & -s(1-v_1)(1-v_2)/8 \\ 0 & -s(1-v_4)/4 & 0 & -s(1-v_2)/4 \\ 0 & 0 & -s(1+v_4)/4 & s(1-v_3)/4 \\ 0 & 0 & 0 & -s/2 \end{pmatrix}. \tag{3.16}$$

The determinant of the Jacobian is thus

$$-s^4(1-v_2)(1-v_4)^2(1+v_4)/256. \tag{3.17}$$

Notice that the determinant only contains factors $s/2$ and $(1 \pm v_i)/2$. The power of each of these factors can easily be read from the tree in Fig. 3. There are four factors $s/2$, and the tree has four internal nodes. There are two factors $(1-v_4)/2$ and there are three leaves in the left subtree of v_4. There is one factor $(1+v_4)/2$ and there are two leaves in the right subtree of v_4. The same applies to v_1, v_2 and v_3.

Again, these observations can be generalized to an arbitrary tree.

Lemma 10: The absolute value of the determinant of the Jacobian, denoted J, of the transformation (3.10) (with $j=1,\ldots,n$) equals

$$J = \left| \det \frac{\partial x_j}{\partial v_i} \right| = \left(\frac{s}{2} \right)^n \prod_{i=1}^{n} \left(\frac{1+v_i}{2} \right)^{nr_i - 1} \left(\frac{1-v_i}{2} \right)^{nl_i - 1}, \tag{3.18}$$

where nr_i (resp. nl_i) is the number of leaves in the right (resp. left) subtree of v_i.

Proof: We will prove (3.18) by transforming the matrix $\partial x_j / \partial v_i$ into an upper triangular matrix by taking linear combinations of rows and by swapping rows. These manipulations do not change (up to a sign factor) the determinant of this matrix.

From (3.14) and the fact that we choose postorder, it is easily seen that $\Sigma_{\substack{\text{left leaves}\\ \text{of } v_i}} x_j$ depends on v_i but not on v_m when $m<i$. Therefore, we wish to perform row operations such that the mth row becomes

$$\frac{\partial\left(\sum_{\substack{\text{left leaves}\\ \text{of } v_m}} x_j\right)}{\partial v_i}. \tag{3.19}$$

We use induction on n to show that is possible. By the induction hypothesis, we can create the desired linear combinations in the left and right subtree. Note that the linear combinations in the right subtree do not depend on the variables $v_1,\ldots,v_{nl_n-1}$ (i.e., the variables v in the left subtree). In this process the row corresponding to the variable associated with the rightmost leaf of the left subtree is not used. For clarity, assume that this variable is x_{nl_n}. The Jacobian now has the following form:

$$x_{nl_n}\begin{array}{c} \begin{array}{ccccccccccc} v_1 & v_2 & v_3 & \cdots & v_{nl_n-1} & v_{nl_n} & v_{nl_n+1} & \cdots & v_{n-1} & v_n \end{array} \\ \left(\begin{array}{cccccccccc} * & \star & \star & \cdots & * & 0 & 0 & \cdots & 0 & * \\ 0 & * & \star & \cdots & * & 0 & 0 & \cdots & 0 & * \\ \vdots & & & & \vdots & \vdots & \vdots & & \vdots & \\ 0 & 0 & 0 & \cdots & * & 0 & 0 & \cdots & 0 & * \\ \star & \star & \star & \cdots & * & 0 & 0 & \cdots & 0 & * \\ 0 & 0 & 0 & \cdots & 0 & * & \star & \cdots & * & * \\ 0 & 0 & 0 & \cdots & 0 & 0 & * & \cdots & * & * \\ \vdots & \vdots & \vdots & & \vdots & \vdots & & & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & * & * \end{array}\right) \end{array}. \tag{3.20}$$

Herein, $*$ represents a nonzero value and $\star$ an arbitrary value.

We will now use the row $\partial x_{nl_n}/\partial v_i$ to create the sum of the variables corresponding to the leaves in the left subtree of the root, i.e., the row

$$\frac{\partial\left(\sum_{\substack{\text{left leaves}\\ \text{of } v_n}} x_j\right)}{\partial v_i} = \frac{\partial\left(\sum_{\substack{\text{left leaves}\\ \text{of } v_{nl_n-1}}} x_j\right)}{\partial v_i} + \frac{\partial\left(\sum_{\substack{\text{right leaves}\\ \text{of } v_{nl_n-1}}} x_j\right)}{\partial v_i}. \tag{3.21}$$

By induction, the first term on the rhs is already a row of the matrix. If x_{nl_n} is the only leaf in the right subtree of v_{nl_n-1}, then we are finished: simply add the row corresponding to the first term to the row corresponding to x_{nl_n}. If there is more than one leaf in the right subtree of v_{nl_n-1}, we call the root of this right subtree v_m and we have

$$\frac{\partial\left(\sum_{\substack{\text{right leaves}\\ \text{of } v_{nl_n-1}}} x_j\right)}{\partial v_i} = \frac{\partial\left(\sum_{\substack{\text{left leaves}\\ \text{of } v_n}} x_j\right)}{\partial v_i} + \frac{\partial\left(\sum_{\substack{\text{right leaves}\\ \text{of } v_m}} x_j\right)}{\partial v_i}. \tag{3.22}$$

The first term of the rhs of this equation is a row of the matrix (by induction). If x_{nl_n} is the only right leaf of v_m, we are finished; add the two rows corresponding to the first terms in (3.21) and (3.22) to the row corresponding to x_{nl_n}. It is clear that we can continue in this way to create the desired row.

By swapping the rows in this matrix, we have created an upper triangular matrix with the same determinant (up to a sign) as the original matrix.

From (3.14) it is clear that the elements of this upper triangular matrix consist only of factors $s/2$, $(1\pm v_i)/2$ (and -1). Each element on the diagonal of the upper triangular matrix has a single factor $-s/2$. There is a single factor $(1+v_i)/2$ for each variable v_m that is in the right subtree of

v_i. There are nr_i-1 (i.e., the number of internal nodes in the right subtree of v_i) such variables, so there are nr_i-1 entries on the diagonal that have a factor $(1+v_i)/2$. In the same way one sees that there are nl_i-1 entries on the diagonal that have a factor $(1-v_i)/2$. Multiplying the elements on the diagonal yields formula (3.18). □

C. Transformation of the area and weight function

The cube $\square^n$ in $\mathbb{R}^n$ is defined as

$$\square^n=\{v\in\mathbb{R}^n\,|\,-1<v_j<1\}. \tag{3.23}$$

Lemma 11: When x and v are connected through (3.9) and (3.10), then $x\in T_s^n \Leftrightarrow v\in\square^n$.

Note that, although the simplex T_n^s depends on s, the cube $\square^n$ does not. An explicit proof of this lemma is given in Appendix B.

Next, we consider the transformation of the weight function (3.4), first for an example, and then for an arbitrary binary coupling tree.

Example 12: For the tree of Fig. 2 the weight function is

$$w^{(k)}(x_1,x_2,x_3,x_4)=x_1^{2k_1-1}x_2^{2k_2-1}x_3^{2k_3-1}x_4^{2k_4-1}(s-x_1-x_2-x_3-x_4)^{2k_5-1}. \tag{3.24}$$

Rewriting this weight function in terms of the variables v, using (3.8), gives

$$\begin{aligned}\tilde{w}^{(k)}(v_1,v_2,v_3,v_4)=&\,s^{2k_1+2k_2+2k_3+2k_4+2k_5-5}\\ &\times\left(\frac{1+v_1}{2}\right)^{2k_2-1}\left(\frac{1+v_2}{2}\right)^{2k_3-1}\left(\frac{1+v_3}{2}\right)^{2k_5-1}\left(\frac{1+v_4}{2}\right)^{2k_4+2k_5-2}\\ &\times\left(\frac{1-v_1}{2}\right)^{2k_1-1}\left(\frac{1-v_2}{2}\right)^{2k_1+2k_2-2}\left(\frac{1-v_3}{2}\right)^{2k_4-1}\left(\frac{1-v_4}{2}\right)^{2k_1+2k_2+2k_3-3}.\end{aligned}$$

■

Lemma 13: The transformation of the weight function (3.4) under the substitution (3.10) becomes

$$\tilde{w}^{(k)}(v)=s^{2|k|-n-1}\prod_{i=1}^{n}\left(\frac{1+v_i}{2}\right)^{\sum_{\text{right leaves of }v_i}2k_j-mr_i}\left(\frac{1-v_i}{2}\right)^{\sum_{\text{left leaves of }v_i}2k_j-nl_i}. \tag{3.25}$$

Proof: Since the weight function is essentially equal to $\Pi_{j=1}^{n+1}x_j^{2k_j-1}$, it becomes a product of factors s, and $(1\pm v_i)/2$. Each x_j has a single factor s; the power of s is thus $\Sigma_{j=1}^{n+1}(2k_j-1)=2|k|-n-1$. Furthermore, each x_j which is in the right (resp. left) subtree of v_i has a factor $(1+v_i)/2$ [resp. $(1-v_i)/2$]. □

D. Verifying the orthogonality

If two su(1,1) representations k_1 and k_2 are coupled to k_{12}, then the difference $k_{12}-k_1-k_2$ is a non-negative integer [see (1.3)]. So, with each internal node, say v_i, of a binary coupling tree we can associate a non-negative integer, say l_i. Furthermore, we can associate a real positive value with each node of the tree; for the leaves this value is simply k_j, and for an internal node v_i the value equals the value of the left child plus the value of the right child plus l_i, or explicitly

$$\sum_{\substack{\text{leaves}\\ \text{of }v_i}}k_j+\sum_{\substack{\text{nodes in}\\ \text{subtree of }v_i}}l_j+l_i. \tag{3.26}$$

Example 14: In Fig. 4 the value of each node is indicated in the tree. ■

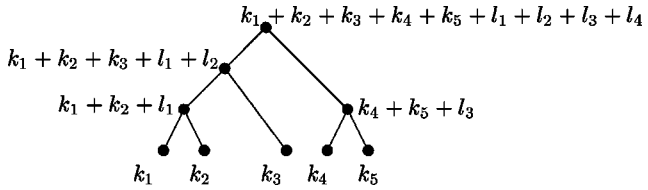

FIG. 4. Value of the nodes in the tree.

For a given binary coupling tree, the knowledge of $k=(k_1,k_2,\ldots,k_{n+1})$ and $l=(l_1,\ldots,l_n)$ completely determines the polynomial $R_l^{(k)}(x)$. Now we are in a position to prove Theorem 4.

As already mentioned, we will transform the integral over T_s^n into an integral over $\square^n$ by changing the variables from x to v. We will get a product of n integrals over the interval $(-1,1)$, each involving two Jacobi polynomials and a factor acting as weight function. Using the orthogonality of the Jacobi polynomials over this interval with respect to this weight function will yield the desired result. Explicitly, the orthogonality of the Jacobi polynomials reads

$$\int_{-1}^{1} P_m^{(a,b)}(t)P_n^{(a,b)}(t)(1-t)^a(1+t)^b dt=\delta_{m,n}h_m^{(a,b)}, \quad a,b>-1, \tag{3.27}$$

with

$$h_m^{(a,b)}=\frac{2^{a+b+1}\Gamma(m+a+1)\Gamma(m+b+1)}{(2m+a+b+1)m!\Gamma(m+a+b+1)}.$$

After transformation, using (3.13), the polynomial $R_l^{(k)}(x)$ becomes

$$\tilde{R}_l^{(k)}(v)=C\prod_{i=1}^{n}\left(s\prod_{\substack{\text{left ancestors}\\ \text{of } v_i}}\frac{1-v_m}{2}\prod_{\substack{\text{right ancestors}\\ \text{of } v_i}}\frac{1+v_m}{2}\right)^{l_i}P_{l_i}^{(a_i,b_i)}(v_i), \tag{3.28}$$

with

$$C=(-1)^{|l|}\prod_{i=1}^{n}\sqrt{\frac{l_i!}{(a_i+1,b_i+1,a_i+b_i+l_i+1)_{l_i}}}. \tag{3.29}$$

Herein, a_i equals two times the value of the node corresponding to the left child of v_i minus one, or explicitly

$$a_i=\sum_{\substack{\text{left leaves}\\ \text{of } v_i}}2k_j+\sum_{\substack{\text{nodes in left}\\ \text{subtree of } v_i}}2l_j-1. \tag{3.30}$$

Similarly, one finds

$$b_i=\sum_{\substack{\text{right leaves}\\ \text{of } v_i}}2k_j+\sum_{\substack{\text{nodes in right}\\ \text{subtree of } v_i}}2l_j-1. \tag{3.31}$$

Now we turn our attention to the transformed integrand of (3.5). Apart from the products

$$P_{l_i}^{(a_i,b_i)}(v_i)P_{l_i'}^{(a_i',b_i')}(v_i), \tag{3.32}$$

it consists of factors s and $(1\pm v_i)/2$. Let us determine the power of $(1-v_i)/2$. There are three contributing parts:

(i) the determinant of the Jacobian, yielding a term nl_i-1 [see (3.18)];
(ii) the transformed weight function, yielding a term $\sum_{\substack{\text{left leaves}\\ \text{of } v_i}} 2k_j-m_i$ [see (3.25)]; and
(iii) the transformed polynomials, yielding a term $\sum_{\substack{\text{nodes in left}\\ \text{subtree of } v_i}} l_j+\sum_{\substack{\text{nodes in left}\\ \text{subtree of } v_i}} l'_h$ [see (3.28)].

It is thus clear that the power p_i^- of $(1-v_i)/2$ is

$$p_i^-=\sum_{\substack{\text{left leaves}\\ \text{of } v_i}} 2k_j+\sum_{\substack{\text{nodes in left}\\ \text{subtree of } v_i}} l_j+\sum_{\substack{\text{nodes in left}\\ \text{subtree of } v_i}} l'_j-1. \tag{3.33}$$

In the same way one finds that the power p_i^+ of $(1+v_i)/2$ is

$$p_i^+=\sum_{\substack{\text{right leaves}\\ \text{of } v_i}} 2k_j+\sum_{\substack{\text{nodes in right}\\ \text{subtree of } v_i}} l_j+\sum_{\substack{\text{nodes in right}\\ \text{subtree of } v_i}} l'_j-1. \tag{3.34}$$

Example 15: In our example the transformed integral, denoted I, is, up to a constant factor, equal to the following product of four integrals:

$$\begin{aligned}
&\int_{-1}^{1} P_{l_1}^{(2k_1-1,2k_2-1)}(v_1)P_{l'_1}^{(2k_1-1,2k_2-1)}(v_1)\left(\frac{1-v_1}{2}\right)^{2k_1-1}\left(\frac{1+v_1}{2}\right)^{2k_2-1}dv_1\\
&\quad\times\int_{-1}^{1} P_{l_2}^{(2k_1+2k_2+2l_1-1,2k_3-1)}(v_2)P_{l'_2}^{(2k_1+2k_2+2l'_1-1,2k_3-1)}(v_2)\\
&\quad\times\left(\frac{1-v_2}{2}\right)^{2k_1+2k_2+l_1+l'_1-1}\left(\frac{1+v_2}{2}\right)^{2k_3-1}dv_2\\
&\quad\times\int_{-1}^{1} P_{l_3}^{(2k_4-1,2k_5-1)}(v_3)P_{l'_3}^{(2k_4-1,2k_5-1)}(v_3)\left(\frac{1-v_3}{2}\right)^{2k_4-1}\left(\frac{1+v_3}{2}\right)^{2k_5-1}dv_3\\
&\quad\times\int_{-1}^{1} P_{l_4}^{(2k_1+2k_2+2k_3+2l_1+2l_2-1,2k_4+2k_5+2l_3-1)}(v_4)\\
&\quad\times P_{l'_4}^{(2k_1+2k_2+2k_3+2l'_1+2l'_2-1,2k_4+2k_5+2l'_3-1)}(v_4)\\
&\quad\times\left(\frac{1-v_4}{2}\right)^{2k_1+2k_2+2k_3+l_1+l'_1+l_2+l'_2-1}\left(\frac{1+v_4}{2}\right)^{2k_4+2k_5+l_3+l'_3-1}dv_4.
\end{aligned}$$

Now, using the orthogonality (3.27) of the Jacobi polynomials, the first of these integrals is zero, except when $l_1=l'_1$. Assuming that $l_1=l'_1$, we see that the second integral is zero, except when $l_2=l'_2$. The third integral immediately implies that I is zero if $l_3\neq l'_3$. Assuming that $l_i=l'_i$, for $i=1,\ldots,3$, we see that I is zero, except when $l_4=l'_4$. We thus see that $I=\delta_{l,l'}h_l^{(k)}$, where h is some numerical constant. ■

In general, the transformation yields

$$
\begin{aligned}
I &= \int_{T_s^n} R_l^{(k)}(x) R_{l'}^{(k)}(x) w^{(k)}(x)\, dx \\
&= D \int_{\square} \prod_{i=1}^{n} P_{l_i}^{(a_i,b_i)}(v_i) P_{l_i'}^{(a_i',b_i')}(v_i) \left(\frac{1-v_i}{2}\right)^{p_i^-} \left(\frac{1+v_i}{2}\right)^{p_i^+} dv \\
&= D \prod_{i=1}^{n} \int_{-1}^{1} P_{l_i}^{(a_i,b_i)}(v_i) P_{l_i'}^{(a_i',b_i')}(v_i) \left(\frac{1-v_i}{2}\right)^{p_i^-} \left(\frac{1+v_i}{2}\right)^{p_i^+} dv_i . \qquad (3.35)
\end{aligned}
$$

Herein, the constant D equals

$$
D = C s^{|l|} \times C' s^{|l'|} \times s^{2|k|-n-1} \times \left(\frac{s}{2}\right)^n = \frac{C C' s^{|l|+|l'|+2|k|-1}}{2^n}. \qquad (3.36)
$$

The first two factors come from (3.28), the third factor comes from the transformed weight function (3.25), and the last factor originates from the Jacobian (3.18) of the transformation.

Notice that p_i^- equals a_i when $l_j = l_j'$ for the nodes in the left subtree of v_i. An analogous argument applies to p_i^+ and b_i. Suppose one computes the product of integrals (3.35) in the indicated order. At the moment that one is dealing with the integral involving v_i, the situation is so that I is zero if there is a $j<i$ so that $l_j \neq l_j'$. Therefore, we can at that moment assume that $a_i = p_i^-$ and $b_i = p_i^+$, and apply orthogonality (3.27) of the Jacobi polynomials, implying that l_i should equal l_i' in order to have a nonzero value of the integral I.

From (3.35) and (3.27) we have that

$$
\begin{aligned}
\int_{T_s^n} R_l^{(k)}(x) R_{l'}^{(k)}(x) w^{(k)}(x)\, dx &= D \prod_{i=1}^{n} \int_{-1}^{1} P_{l_i}^{(a_i,b_i)}(v_i) P_{l_i'}^{(a_i',b_i')}(v_i) \left(\frac{1-v_i}{2}\right)^{p_i^-} \left(\frac{1+v_i}{2}\right)^{p_i^+} dv_i \\
&= \delta_{l,l'} D \prod_{i=1}^{n} \frac{2\Gamma(l_i+a_i+1)\Gamma(l_i+b_i+1)}{(2l_i+a_i+b_i+1) l_i! \Gamma(l_i+a_i+b_i+1)} \\
&= \delta_{l,l'} s^{2|l|+2|k|-1} \prod_{i=1}^{n} \frac{\Gamma(l_i+a_i+1)}{(a_i+1)_{l_i}} \frac{\Gamma(l_i+b_i+1)}{(b_i+1)_{l_i}} \\
&\quad \times \frac{1}{(2l_i+a_i+b_i+1)\Gamma(l_i+a_i+b_i+1)(l_i+a_i+b_i+1)_{l_i}} \\
&= \delta_{l,l'} s^{2|l|+2|k|-1} \prod_{i=1}^{n} \frac{\Gamma(a_i+1)\Gamma(b_i+1)}{\Gamma(2l_i+a_i+b_i+2)} \\
&= \delta_{l,l'} \frac{s^{2|l|+2|k|-1}}{\Gamma(2|k|+2|l|)} \prod_{i=1}^{n+1} \Gamma(2k_i). \qquad (3.37)
\end{aligned}
$$

The last equation follows from the previous one by induction on n, using the result on the left and right subtree.

We thus have proved that with every binary coupling on n internal nodes there is an associated polynomial $R_l^{(k)}(x)$ in n variables that is orthogonal on the simplex T_s^n for the weight function $w^{(k)}(x)$.

As final comment, for $n=2$ the polynomials constructed here are due to Proriol.[16] The polynomials $R_l^{(k)}(x)$ associated with the special binary coupling tree in the shape of a *spine*[14] were already constructed in Ref. 17. The polynomials $R_l^{(k)}(x)$ associated with a general binary tree were also studied by Rosengren[18] in the context of multilinear Hankel forms. In his approach, orthogo-

nality of these polynomials follows quite easily. His methods, however, are less accessible for a mathematical physicist. Furthermore, the relation to classical $3nj$-coefficients (see Sec. V) is more explicit here.

IV. ORTHOGONAL POLYNOMIALS RELATED TO CONTINUOUS HAHN POLYNOMIALS

The notation in this section is as before, i.e., k stands for $(k_1,\ldots,k_{n+1})$ and l for $(l_1,\ldots,l_n)$. But we will also need a notation for parts of the components, so $\mathbf{k}_m=(k_1,\ldots,k_m)$, $\mathbf{k}^m=(k_m,\ldots,k_{n+1})$ [and similarly for $\mathbf{l}_m$ and $\mathbf{l}^m$, and $\mathbf{l}_m^j=(l_m,\ldots,l_j)$ $(m\leqslant j)$]. As usual, $|\mathbf{l}_m^j|=l_m+\cdots+l_j$.

In the way that a binary coupling tree defines $R_l^{(k)}(x)$ as a product of S-polynomials (Jacobi polynomials), we define new polynomials $\mathcal{R}_l^{(k)}(x)$ as the same product of $\mathcal{S}$-polynomials (continuous Hahn polynomials). In this section, we will prove the following theorem.

Theorem 16: *With every coupling of* $(n+1)$ su(1,1) *representations* $k_1,\ldots,k_{n+1}$, *i.e., with every binary coupling tree with n internal nodes, we associate a set of polynomials* $\mathcal{R}_l^{(k)}(x)$ *in n variables. This set is orthogonal on* $\mathbb{R}^n$ *for the weight function*

$$w^{(k)}(x)=\Gamma(k_1\pm ix_1)\cdots\Gamma(k_n\pm ix_n)\Gamma(k_{n+1}\pm i(s-|x|)). \tag{4.1}$$

Explicitly, the orthogonality reads

$$\int_{\mathbb{R}^n}\mathcal{R}_l^{(k)}(x)\mathcal{R}_{l'}^{(k)}(x)w^{(k)}(x)dx=\delta_{l,l'}(2\pi)^n\Gamma(|k|+|l|\pm is). \tag{4.2}$$

Recall that the $\mathcal{S}$-polynomials are defined by (2.10). The $\mathcal{S}$-polynomial in (2.10) is of degree m in the variables x_1 and x_2, but it is not homogeneous in these variables (see the proof of Lemma 19). This implies that the product $\mathcal{R}_l^{(k)}(x)$ is *not* homogeneous in the variables x_i, however, we still put $x_1+\cdots+x_{n+1}=s$. Note that this is consistent with the definition of the weight function (4.1).

Example 17: With the binary coupling tree shown in Fig. 2 we associate the following polynomial (before the replacement of x_5 by $s-x_1-x_2-x_3-x_4$):

$$\begin{aligned}
&\mathcal{R}(x_1,x_2,x_3,x_4,x_5)\\
&\quad=\mathcal{S}_{l_1}^{k_1,k_2}(x_1,x_2)\mathcal{S}_{l_2}^{k_{12},k_3}(x_1+x_2,x_3)\mathcal{S}_{l_3}^{k_4,k_5}(x_4,x_5)\mathcal{S}_{l_4}^{k_{123},k_{45}}(x_1+x_2+x_3,x_4+x_5)\\
&\quad=C\times p_{l_1}(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2))\\
&\qquad\times p_{l_2}(x_1+x_2;k_1+k_2+l_1,k_3-i(x_1+x_2+x_3),k_1+k_2+l_1,k_3+i(x_1+x_2+x_3))\\
&\qquad\times p_{l_3}(x_4;k_4,k_5-i(x_4+x_5),k_4,k_5+i(x_4+x_5))\\
&\qquad\times p_{l_4}(x_1+x_2+x_3;k_1+k_2+k_3+l_1+l_2,k_4+k_5+l_3-i(x_1+x_2+x_3+x_4+x_5),\\
&\qquad\ k_1+k_2+k_3+l_1+l_2,k_4+k_5+l_3+i(x_1+x_2+x_3+x_4+x_5)),
\end{aligned}$$

where C is some numerical factor that can be computed from (2.10). The subscripts l_i are the same as before. ■

It is well known that the continuous Hahn polynomials, appearing in the definition of the $\mathcal{S}$-polynomials, are orthogonal on $\mathbb{R}$ for the weight function $\Gamma(a+it)\Gamma(b+it)\Gamma(c-it)\Gamma(d-it)$ when $\Re(a,b,c,d)>0$, $c=\overline{a}$ and $d=\overline{b}$:

$$\int_{\mathbb{R}} \Gamma(a+it)\Gamma(b+it)\Gamma(c-it)\Gamma(d-it)p_m(t;a,b,c,d)p_j(t;a,b,c,d)dt$$
$$= 2\pi\delta_{m,j}\frac{\Gamma(j+a+c)\Gamma(j+b+d)\Gamma(j+a+d)\Gamma(j+b+c)}{j!(2j+a+b+c+d-1)\Gamma(j+a+b+c+d-1)}. \tag{4.3}$$

Using this orthogonality relation, (4.2) is easily established in the case $n=1$.

To investigate the general case, we introduce new variables u, but use a different approach than the one in the previous section. We do not define the variables u as the arguments of the continuous Hahn polynomials in the product, but we introduce essentially only one new variable, namely $x_1+\cdots+x_{nl_n}=y$ (and thus $x_{nl_n+1}+\cdots+x_{n+1}=s-y$). Here, we assumed for simplicity that the variables associated with the leaves in the left subtree are $x_1,\ldots,x_{nl_n}$. This will enable us to use induction on n. Again, it is constructive to consider first an example.

Example 18: For the tree in Fig. 2, we define the variables u_i as follows:

$$u_1=x_1, \quad u_2=x_2, \quad u_3=x_1+x_2+x_3, \quad u_4=x_4.$$

We thus leave all the variables x unchanged, except the rightmost variable of the left subtree (in this case thus x_3). We choose the sum of all the variables in the left subtree equal to a new variable (in this case u_3). Integrating last to this variable allows this variable to be viewed as a constant in the integrands of the other integrals, enabling us to use induction.

When integrating last to u_3, the integral becomes

$$\int_{\mathbb{R}^4} \mathcal{R}_l^{(k)}(x)\mathcal{R}_{l'}^{(k)}(x)w^{(k)}(x)dx$$
$$= \sqrt{\frac{l_4!(2|l|+2|k|-1)\Gamma(l_4+2|k|+2|\mathbf{l}_3|-1)}{\Gamma(l_4+2|\mathbf{k}_3|+2|\mathbf{l}_2|)\Gamma(l_4+2|\mathbf{k}^4|+2l_3)}}$$
$$\times \sqrt{\frac{l_4'!(2|l'|+2|k|-1)\Gamma(l_4'+2|k|+2|\mathbf{l}_3'|-1)}{\Gamma(l_4'+2|\mathbf{k}_3|+2|\mathbf{l}_2'|)\Gamma(l_4'+2|\mathbf{k}^4|+2l_3')}}$$
$$\times \int_{\mathbb{R}} p_{l_4}(u_3;|\mathbf{k}_3|+|\mathbf{l}_2|,|\mathbf{k}^4|+l_3-is,|\mathbf{k}_3|+|\mathbf{l}_2|,|\mathbf{k}^4|+l_3+is)$$
$$\times p_{l_4'}(u_3;|\mathbf{k}_3|+|\mathbf{l}_2'|,|\mathbf{k}^4|+l_3'-is,|\mathbf{k}_3|+|\mathbf{l}_2'|,|\mathbf{k}^4|+l_3'+is)I_{\text{left}}I_{\text{right}}du_3,$$

with

$$I_{\text{left}}= \sqrt{\frac{l_1!(2l_1+2|\mathbf{k}_2|-1)\Gamma(l_1+2|\mathbf{k}_2|-1)}{\Gamma(l_1+2k_1)\Gamma(l_1+2k_2)}}\sqrt{\frac{l_1'!(2l_1'+2|\mathbf{k}_2|-1)\Gamma(l_1'+2|\mathbf{k}_2|-1)}{\Gamma(l_1'+2k_1)\Gamma(l_1'+2k_2)}}$$
$$\times \sqrt{\frac{l_2!(2|\mathbf{l}_2|+2|\mathbf{k}_3|-1)\Gamma(l_2+2|\mathbf{k}_3|+2l_1-1)}{\Gamma(l_2+2|\mathbf{k}_2|+2l_1)\Gamma(l_2+2k_3)}}$$
$$\times \sqrt{\frac{l_2'!(2|\mathbf{l}_2'|+2|\mathbf{k}_3|-1)\Gamma(l_2'+2|\mathbf{k}_3|+2l_1'-1)}{\Gamma(l_2'+2|\mathbf{k}_2|+2l_1')\Gamma(l_2'+2k_3)}}$$
$$\times \int_{\mathbb{R}^2} p_{l_1}(u_1;k_1,k_2-i|\mathbf{u}_2|,k_1,k_2+i|\mathbf{u}_2|)p_{l_1'}(u_1;k_1,k_2-i|\mathbf{u}_2|,k_1,k_2+i|\mathbf{u}_2|)$$
$$\times p_{l_2}(|\mathbf{u}_2|;|\mathbf{k}_2|+l_1,k_3-iu_3,|\mathbf{k}_2|+l_1,k_3+iu_3)p_{l_2'}(|\mathbf{u}_2|;|\mathbf{k}_2|+l_1',k_3-iu_3,|\mathbf{k}_2|+l_1',k_3+iu_3)$$
$$\times \Gamma(k_1\pm iu_1)\Gamma(k_2\pm iu_2)\Gamma(k_3\pm i(u_3-|\mathbf{u}_2|))du_1du_2.$$

The integral I_{left} thus corresponds to the orthogonality relation (4.2) restricted to the left subtree of the tree in Fig. 2 and with s replaced by u_3. By induction, the value of this integral is

$$I_{\text{left}}=\delta_{l_1,l_1'}\delta_{l_2,l_2'}(2\pi)^2\Gamma(|\mathbf{k}_3|+|\mathbf{l}_2|\pm iu_3).$$

The integral I_{right} equals

$$\begin{aligned}I_{\text{right}}=&\sqrt{\frac{l_3!(2l_3+2|\mathbf{k}^4|-1)\Gamma(l_3+2|\mathbf{k}^4|-1)}{\Gamma(l_3+2k_4)\Gamma(l_3+2k_5)}}\sqrt{\frac{l_3'!(2l_3'+2|\mathbf{k}^4|-1)\Gamma(l_3'+|\mathbf{k}^4|-1)}{\Gamma(l_3'+2k_4)\Gamma(l_3'+2k_5)}}\\&\times\int_{\mathbb{R}}p_{l_3}(u_4;k_4,k_5-i(s-u_3),k_4,k_5+i(s-u_3))p_{l_3'}(u_4;k_4,k_5-i(s-u_3),k_4,\\&k_5+i(s-u_3))\Gamma(k_4\pm iu_4)\Gamma(k_5\pm i(s-u_3-u_4))du_4.\end{aligned}\tag{4.4}$$

The integral I_{right} corresponds to the orthogonality relation (4.2) restricted to the right subtree with s replaced by $s-u_3$. The value of this integral is thus

$$I_{\text{right}}=\delta_{l_3,l_3'}2\pi\Gamma(|\mathbf{k}^4|+l_3\pm i(s-u_3)).$$

Using the values of I_{left} and I_{right} enables us to use the orthogonality of the continuous Hahn polynomials when integrating over u_3, yielding the following:

$$\int_{\mathbb{R}^4}\mathcal{R}_l^{(k)}(x)\mathcal{R}_{l'}^{(k)}(x)w^{(k)}(x)dx=\delta_{l,l'}(2\pi)^4\Gamma(|k|+|l|\pm is).$$ ■

In the general case, assume that the variables associated with the leaves of the tree are (from left to right) $x_1,\ldots,x_{n+1}$. Define the variables u as follows:

$$u_j=x_j,\quad j\in\{1,\ldots,n\}\backslash nl_n\quad\text{and}\quad u_{nl_n}=x_1+\cdots+x_{nl_n}.\tag{4.5}$$

It is clear that the absolute value of the Jacobian of this transformation is 1 and that $u\in\mathbb{R}^n\Leftrightarrow x\in\mathbb{R}^n$.

Continuous Hahn polynomials associated with internal nodes of the left subtree only involve variables $x_1,\ldots,x_{nl_n}$, as do the gamma functions of the weight function associated with the leaves of the left subtree. Replacing x_{nl_n} by $u_{nl_n}-u_1-\cdots-u_{nl_n-1}$ [see (4.5)] yields an integral over $\mathbb{R}^{nl_n-1}$ involving the variables $u_1,\ldots,u_{nl_n-1}$, and with u_{nl_n} playing the role of s. The way in which this integral is constructed allows induction. Denoting this integral by I_{left}, we have

$$I_{\text{left}}=\delta_{\mathbf{l}_{nl_n-1},\mathbf{l}'_{nl_n-1}}(2\pi)^{nl_n-1}\Gamma(|\mathbf{k}_{nl_n}|+|\mathbf{l}_{nl_n-1}|\pm iu_{nl_n}).\tag{4.6}$$

On the other hand, continuous Hahn polynomials associated with internal nodes in the right subtree involve variables $x_{nl_n+1},\ldots,x_n$, but may also involve variables $x_1,\ldots,x_{nl_n}$. When the latter is the case, it is always the difference $-(x_1+\cdots+x_{nl_n})=-u_{nl_n}$ which occurs. So essentially, s is replaced by $s-u_{nl_n}$; this integral involving the variables $u_{nl_n+1},\ldots,u_n$ can also be calculated by induction. Denoting this integral over $\mathbb{R}^{nr_n-1}$ by I_{right} we have

$$I_{\text{right}} = \delta_{\mathbf{l}_{nl_n}^{n-1},\mathbf{l}'^{n-1}_{nl_n}} (2\pi)^{nr_n-1} \Gamma(|\mathbf{k}^{nl_n+1}| + |\mathbf{l}_{nl_n}^{n-1}| \pm i(s-u_{nl_n})). \tag{4.7}$$

The integral I, i.e., the left side of (4.2), then reduces to

$$\begin{aligned}
I &= \sqrt{\frac{l_n!(2|l|+2|k|-1)\Gamma(l_n+2|k|+2|\mathbf{l}_{n-1}|-1)}{\Gamma(l_n+2|\mathbf{k}_{nl_n}|+2|\mathbf{l}_{nl_n-1}|)\Gamma(l_n+2|\mathbf{k}^{nl_n+1}|+2|\mathbf{l}_{nl_n}^{n-1}|)}} \\
&\quad \times \sqrt{\frac{l'_n!(2|l'|+2|k|-1)\Gamma(l'_n+2|k|+2|\mathbf{l}'_{n-1}|-1)}{\Gamma(l'_n+2|\mathbf{k}_{nl_n}|+2|\mathbf{l}'_{nl_n-1}|)\Gamma(l'_n+2|\mathbf{k}^{nl_n+1}|+2|\mathbf{l}'^{n-1}_{nl_n}|)}} \int_{\mathbb{R}} p_{l_n}(u_{nl_n};|\mathbf{k}_{nl_n}|+|\mathbf{l}_{nl_n-1}|, \\
&\quad |\mathbf{k}^{nl_n+1}|+|\mathbf{l}_{nl_n}^{n-1}|-is,|\mathbf{k}_{nl_n}|+|\mathbf{l}_{nl_n-1}|,|\mathbf{k}^{nl_n+1}|+|\mathbf{l}_{nl_n}^{n-1}|+is) p_{l'_n}(u_{nl_n};|\mathbf{k}_{nl_n}|+|\mathbf{l}'_{nl_n-1}|, \\
&\quad |\mathbf{k}^{nl_n+1}|+|\mathbf{l}'^{n-1}_{nl_n}|-is,|\mathbf{k}_{nl_n}|+|\mathbf{l}'_{nl_n-1}|,|\mathbf{k}^{nl_n+1}|+|\mathbf{l}'^{n-1}_{nl_n}|+is) \times I_{\text{left}} \times I_{\text{right}} du_{nl_n} \\
&= \delta_{\mathbf{l}_{n-1},\mathbf{l}'_{n-1}} (2\pi)^{n-1} \sqrt{\frac{l_n!(2|l|+2|k|-1)\Gamma(l_n+2|k|+2|\mathbf{l}_{n-1}|-1)}{\Gamma(l_n+2|\mathbf{k}_{nl_n}|+2|\mathbf{l}_{nl_n-1}|)\Gamma(l_n+2|\mathbf{k}^{nl_n+1}|+2|\mathbf{l}_{nl_n}^{n-1}|)}} \\
&\quad \times \sqrt{\frac{l'_n!(2|l'|+2|k|-1)\Gamma(l'_n+2|k|+2|\mathbf{l}'_{n-1}|-1)}{\Gamma(l'_n+2|\mathbf{k}_{nl_n}|+2|\mathbf{l}'_{nl_n-1}|)\Gamma(l'_n+2|\mathbf{k}^{nl_n+1}|+2|\mathbf{l}'^{n-1}_{nl_n}|)}} \int_{\mathbb{R}} p_{l_n}(u_{nl_n};|\mathbf{k}_{nl_n}|+|\mathbf{l}_{nl_n-1}|, \\
&\quad |\mathbf{k}^{nl_n+1}|+|\mathbf{l}_{nl_n}^{n-1}|-is,|\mathbf{k}_{nl_n}|+|\mathbf{l}_{nl_n-1}|,|\mathbf{k}^{nl_n+1}|+|\mathbf{l}_{nl_n}^{n-1}|+is) \\
&\quad \times p_{l'_n}(u_{nl_n};|\mathbf{k}_{nl_n}|+|\mathbf{l}'_{nl_n-1}|,|\mathbf{k}^{nl_n+1}|+|\mathbf{l}'^{n-1}_{nl_n}|-is,|\mathbf{k}_{nl_n}|+|\mathbf{l}'_{nl_n-1}|,|\mathbf{k}^{nl_n+1}|+|\mathbf{l}'^{n-1}_{nl_n}|+is) \\
&\quad \times \Gamma(|\mathbf{k}_{nl_n}|+|\mathbf{l}_{nl_n-1}| \pm iu_{nl_n}) \Gamma(|\mathbf{k}^{nl_n+1}|+|\mathbf{l}_{nl_n}^{n-1}| \pm i(s-u_{nl_n})) du_{nl_n} \\
&= \delta_{l,l'} (2\pi)^n \Gamma(|k|+|l| \pm is).
\end{aligned}$$

Once again, we have used the orthogonality (4.3) of continuous Hahn polynomials. This completes the proof of Theorem 16.

V. CONNECTION COEFFICIENTS BETWEEN DIFFERENT BASES OF ORTHOGONAL POLYNOMIALS

We will show that the set of polynomials associated with a *fixed* binary coupling tree and *fixed* leaf values k_j, but varying values l_i, form a basis for Π^n.

Lemma 19: For any binary coupling tree T the degree of the polynomial $R_l^{(k)}(x)$ (*or* $\mathcal{R}_l^{(k)}(x)$) *associated with T is* $|l|$.

Proof: In the case of Jacobi polynomials, i.e., the case of S-polynomials, the result immediately follows from the fact that $S_m^{k_1,k_2}(x_1,x_2)$ is homogeneous of degree m in the variables x_1 and x_2.

Now consider the case of continuous Hahn polynomials. Although $p_m(t;a,b,c,d)$ is a polynomial of degree m in t, we have to be careful because, in the case of $\mathcal{S}$-polynomials, the variables x_i also appear in the parameters b and d. The polynomials associated with an internal node not on the path from the leaf x_{n+1} to the root are, up to a constant factor, $p_m(x;a,b-i(x+y),a,b+i(x+y))$ (x and y stand for a sum of variables x_j). Using the definition of the continuous Hahn polynomials we have

$$
\begin{aligned}
&p_m(x;a,b-i(x+y),a,b+i(x+y))\\
&\quad=i^m\frac{(2a)_m(a+b+i(x+y))_m}{m!}\,{}_3F_2\left(\begin{matrix}-m,m+2a+2b-1,a+ix\\ 2a,a+b+i(x+y)\end{matrix};1\right)\\
&\quad=i^m\frac{(2a)_m(a+b+i(x+y))_m}{m!}\sum_{j=0}^{m}\frac{(-m)_j(m+2a+2b-1)_j(a+ix)_j}{(2a)_j(a+b+i(x+y))_j j!}\\
&\quad=i^m\frac{(2a)_m}{m!}\sum_{j=0}^{m}\frac{(-m)_j(m+2a+2b-1)_j(a+ix)_j(a+b+i(x+y)+j)_{m-j}}{(2a)_j j!}.
\end{aligned}
$$

From this last equation one sees that the degree of this polynomial is at most m. It is easy to see that the coefficient of y^m is $(i^{2m}(2a)_m/m!)\neq 0$, since in our case $a>0$. The same can be done for a polynomial associated with an internal node on the path from x_{n+1} to the root. □

Theorem 20: *The polynomials* $R_l^{(k)}(x)$ and $\mathcal{R}_l^{(k)}(x)$ *associated with a fixed binary coupling tree* T *on* n *internal nodes form a basis for* Π^n.

Proof: Theorems 4 and 16 imply that the sets of polynomials associated with T are linearly independent.

The number of polynomials associated with T that have degree m equals the number of compositions $J(m,n)$ of m into n parts, i.e., the number of ways that one can write m as a sum of n non-negative integers whereby the order of the summands is important. There are thus $\Sigma_{k=0}^{m}J(k,n)$ polynomials of degree at most m associated with T. It is not difficult to see that this is exactly the dimension of Π_m^n, the set of polynomials in n variables with degree at most m. □

We recall the two properties (2.11) and (2.12) of the $\mathcal{S}$-polynomials. We can use these two properties to determine the connection coefficients between the different bases. This is stated in the following theorem.

Theorem 21: *Consider a binary coupling tree,* T_1, *with fixed values* k_j *and* l_i. *Consider another binary coupling tree* T_2 *with the same fixed values* k_j *but varying values* l_i', *such that* $|l|=|l'|$. *Then the polynomials* $R_{l,T_1}^{(k)}(x)$ [*resp.* $\mathcal{R}_{l,T_1}^{(k)}(x)$] *can be written as a linear combination of polynomials* $R_{l',T_2}^{(k)}(x)$ (*resp.* $\mathcal{R}_{l',T_2}^{(k)}$):

$$
R_{l,T_1}^{(k)}(x)=\sum_{|l'|=|l|}C_{l'}R_{l',T_2}^{(k)}(x);\quad \mathcal{R}_{l,T_1}^{(k)}(x)=\sum_{|l'|=|l|}C_{l'}\mathcal{R}_{l',T_2}^{(k)}(x). \tag{5.1}
$$

The connection coefficient $C_{l'}$ *is equal to the* 3nj*-coefficient* $\langle T_1(l),T_2(l')\rangle$ *(which is zero anyway if* $|l|\neq|l'|$).

Proof: This follows from Theorem 20 and the two basic properties of S- and $\mathcal{S}$-polynomials. These basic properties are given in (2.11) and (2.12). Observe that (2.11) simply expresses

$$
\mathcal{R}_{(l_1,l_2),T_1}^{(k_1,k_2,k_3)}(x_1,x_2)=\sum_{|l'|=|l|}U_{k_3,|k|+|l|,k_2+k_3+l_1'}^{k_1,k_2,k_1+k_2+l_1}\mathcal{R}_{(l_1',l_2'),T_2}^{(k_1,k_2,k_3)}(x_1,x_2), \tag{5.2}
$$

where T_1 (resp. T_2) is the tree on the left hand side (resp. right hand side) of Fig. 1 with $k_{12}=k_1+k_2+l_1$ and $k_0=|k|+|l|$ (resp. with $k_{23}=k_2+k_3+l_1'$ and $k_0=|k|+|l'|$). By definition the Racah coefficient (or 6j-coefficient) can be expressed as the overlap coefficient of two binary coupling trees, i.e.,

$$
U_{k_3,|k|+|l|,k_2+k_3+l_1'}^{k_1,k_2,k_1+k_2+l_1}=\langle T_1(l),T_2(l')\rangle.
$$

In the general case, let T_1 (with fixed values k_j and l_i) and T_2 (with the same fixed values k_j) be given. The expansion of $\mathcal{R}_{l,T_1}^{(k)}(x)$ in terms of $\mathcal{S}$-polynomials is then fixed. In order to express $\mathcal{R}_{l,T_1}^{(k)}(x)$ in terms of polynomials associated with the second tree T_2, one can use (2.11) and (2.12)

a number of times. Equation (2.11) corresponds to an elementary tree operation (the flop operation of Ref. 13), depicted in Fig. 1. Equation (2.12) corresponds to an exchange operation[13] on trees. So, to express $\mathcal{R}^{(k)}_{l,T_1}(x)$ in terms of polynomials $\mathcal{R}^{(k)}_{l',T_2}(x)$, one has to perform sufficiently many elementary tree operations on T_1 until one ends up with a tree of shape T_2. Each such operation corresponds to an application of (2.11), introducing a Racah coefficient and a summation index, or to an application of (2.12), introducing only a phase factor. As a consequence, the coefficient $C_{l'}$ in (5.1) stands for a certain sum over products of Racah coefficients. But this sum over products of Racah coefficients is just the $3nj$-coefficient defined by the left and right binary coupling trees, since the ''method of trees'' [13,14] yields that the expansion of a $3nj$-coefficient in terms of Racah coefficients is obtained exactly by such elementary tree operations. □

Observe there are some alternative ways of expressing the previous results. For example, for two n-variable Jacobi polynomials corresponding to the same binary coupling tree, their inner product is given by (3.5). For two n-variable Jacobi polynomials with different binary coupling tree, the inner product is essentially given by a $3nj$-coefficient:

$$\int_{T_s^n} R^{(k)}_{l,T_1}(x) R^{(k)}_{l',T_2}(x) w^{(k)}(x)\,dx = \langle T_1(l), T_2(l')\rangle \frac{s^{2|k|+2|l|-1}}{\Gamma(2|k|+2|l|)} \prod_{i=1}^{n+1} \Gamma(2k_i), \tag{5.3}$$

where $w^{(k)}(x)$ is the classical weight function (3.4).

In the same way, we have for n-variable continuous Hahn polynomials corresponding to different binary coupling trees that

$$\int_{\mathbb{R}^n} \mathcal{R}^{(k)}_{l,T_1}(x) \mathcal{R}^{(k)}_{l',T_2}(x) w^{(k)}(x)\,dx = \langle T_1(l), T_2(l')\rangle (2\pi)^n \Gamma(|k|+|l| \pm is), \tag{5.4}$$

where in this case $w^{(k)}(x)$ is given by (4.1).

APPENDIX A: ORTHOGONALITY OF PRODUCTS OF WILSON POLYNOMIALS

In this appendix we show that the products of Wilson polynomials in (2.5) also satisfy an orthogonality relation on $\mathbb{R}^2$; thus also (2.5) can be interpreted as a connection coefficient formula.

When $\Re(a,b,c,d)>0$ and nonreal parameters occur in conjugate pairs, Wilson polynomials are orthogonal on $\mathbb{R}_+$ for the weight function $|\Gamma(a+ix)\Gamma(b+ix)\Gamma(c+ix)\Gamma(d+ix)/\Gamma(2ix)|^2$:

$$\begin{aligned}\int_0^\infty \left|\frac{\Gamma(a+ix)\Gamma(b+ix)\Gamma(c+ix)\Gamma(d+ix)}{\Gamma(2ix)}\right|^2 & W_m(x^2;a,b,c,d) W_j(x^2;a,b,c,d)\,dx \\ &= 2\pi \frac{\Gamma(j+a+b)\Gamma(j+a+c)\Gamma(j+a+d)\Gamma(j+b+c)\Gamma(j+b+d)\Gamma(j+c+d)}{\Gamma(2j+a+b+c+d)} \\ &\quad \times (j+a+b+c+d-1)_j\, j!\, \delta_{m,j},\end{aligned} \tag{A1}$$

see, e.g., Ref. 22.

Theorem 22: *The products of Wilson polynomials on both the left and right sides of Eq. (2.5) are orthogonal on* $\mathbb{R}^2$ *for the weight function*

$$\begin{aligned}&\Gamma(k_1 \pm ix_1)\Gamma(k_2 \pm ix_2)\Gamma(k_3 \pm i(s-x_1-x_2)) \\ &\quad \times \frac{\Gamma(k_1 \pm i(x_1-2t))\Gamma(k_2 \pm i(2x_1+x_2-2t))\Gamma(k_3 \pm i(s-2t+x_1+x_2))}{\Gamma(\pm 2ix_1 \mp 2it)\Gamma(\pm 2ix_1 \pm 2ix_2 \mp 2it)},\end{aligned} \tag{A2}$$

if $k_1,k_2,k_3>0$.

Following the convention mentioned earlier, each factor in (A2) stands for the product of two gamma functions.

Proof: Consider the polynomial on the right side of (2.5). The parameters of the Wilson polynomials occur in conjugate pairs and the real parts of the parameters are positive. This allows us to use the orthogonality relation (A1).

Denoting the weight function (A2) by $w(x_1,x_2)$, we want to determine the value of

$$\begin{aligned}\int \int_{\mathbb{R}^2} & w(x_1,x_2) W_m((x_1-t)^2;k_1\pm it,k_2\pm i(x_1+x_2-t)) \\ & \times W_{m'}((x_1-t)^2;k_1\pm it,k_2\pm i(x_1+x_2-t)) \\ & \times W_j((x_1+x_2-t)^2;k_1+k_2+m\pm it,k_3\pm i(s-t)) \\ & \times W_{j'}((x_1+x_2-t)^2;k_1+k_2+m'\pm it,k_3\pm i(s-t))dx_1dx_2.\end{aligned}$$

The notation is obvious: each entry of the form $k_1\pm it$ stands for two parameters of the Wilson polynomial. In order to compute the integral, introduce two new variables, namely the arguments of the Wilson polynomials: $u_1=x_1-t$ and $u_2=x_1+x_2-t$. Changing variables and integrating first with respect to u_1 and then with respect to u_2 gives a constant times $\delta_{m,m'}\delta_{j,j'}$ for the above integral, if we use the facts that $\Gamma(\overline{z})=\overline{\Gamma(z)}$ and that the integrands are even functions.

Similar arguments yield the desired result for the Wilson polynomials on the left side of (2.5). □

APPENDIX B: PROOF OF LEMMA 11

In this appendix we prove Lemma 11. First, we show that if $x\in T_s^n$, then $-1<v_i<1$ for each v_i given by (3.9). The position of the variable v_i in the binary coupling tree plays a role in its expression. For a variable v_i not on the path from x_{n+1} to the root of the tree, the equation expressing v_i in terms of x is

$$v_i=\left(\sum_{\substack{\text{right leaves}\\ \text{of } v_i}} x_j-\sum_{\substack{\text{left leaves}\\ \text{of } v_i}} x_j\right)\Bigg/\sum_{\substack{\text{all leaves}\\ \text{of } v_i}} x_j,$$

which is of the form $f(y,z)=(y-z)/(y+z)$ with $0<y$, $0<z$ (and $y+z<s$). It is easy to see that $-1<f(y,z)<1$ if $y,z>0$. On the other hand, if v_i is on the path from x_{n+1} to the root, we have, after substitution of x_{n+1} by $s-|x|$, that

$$v_i=\left(s-\sum_{\substack{\text{non-leaves}\\ \text{of } v_i}} x_j-2\sum_{\substack{\text{left leaves}\\ \text{of } v_i}} x_j\right)\Bigg/\left(s-\sum_{\substack{\text{non-leaves}\\ \text{of } v_i}} x_j\right),$$

which is of the form $g(y,z)=(s-y-2z)/(s-y)$ with $0<y$, $0<z$ and $y+z<s$. A simple examination shows that $g(y,z)$ reaches its maximum $+1$ in this area when $z=0$, and its minimum -1 when $y+z=s$. Thus $-1<g(y,z)<1$ for $y,z>0$ with $y+z<s$. So we have that $-1<v_i<1$ for each $1\leqslant i<n$. For the variable v_n a completely analogous reasoning can be given.
Before proving $v\in\square^n\Rightarrow x\in T_s^n$ in general, consider an example.

Example 23: Let $v\in\square^4$ and consider Eqs. (3.7) with x_5 replaced by $s-x_1-x_2-x_3-x_4$:

$$\begin{aligned} v_1&=(x_2-x_1)/(x_2+x_1),\\ v_2&=(x_3-x_1-x_2)/(x_3+x_1+x_2),\\ v_3&=(s-x_1-x_2-x_3-2x_4)/(s-x_1-x_2-x_3),\\ v_4&=(s-2x_1-2x_2-2x_3)/s.\end{aligned} \tag{B1}$$

Since $-1<v_4<1$, the fourth equation of (B1) implies

$$-1<v_4<1\Rightarrow 0<x_1+x_2+x_3<s. \tag{B2}$$

The denominator of the second equation of (B1) is thus positive, and

$$-1<v_2\Rightarrow x_3>0 \quad \text{and} \quad v_2<1\Rightarrow x_1+x_2>0, \tag{B3}$$

hence

$$-1<v_1\Rightarrow x_2>0 \quad \text{and} \quad v_1<1\Rightarrow x_1>0. \tag{B4}$$

From (B2) it also follows that the denominator of the third equation of (B1) is positive, implying

$$-1<v_3\Rightarrow x_1+x_2+x_3+x_4<s \quad \text{and} \quad v_3<1\Rightarrow x_4>0. \tag{B5}$$

So we clearly have $v\in\square^4\Rightarrow x\in T_s^4$. ■

In general, let $v\in\square^n$. We know that

$$v_n=\left(s-2\sum_{\substack{\text{left leaves}\\ \text{of } v_n}} x_j\right)\Big/ s,$$

with $s>0$, and thus

$$-1<v_n<1\Rightarrow 0<\sum_{\substack{\text{left leaves}\\ \text{of } v_n}} x_j<s. \tag{B6}$$

Now consider the variable associated with the left child of v_n, that is, v_{nl_n-1}:

$$v_{nl_n-1}=\left(\sum_{\substack{\text{right leaves}\\ \text{of } v_{nl_n-1}}} x_j-\sum_{\substack{\text{left leaves}\\ \text{of } v_{nl_n-1}}} x_j\right)\Big/ \sum_{\substack{\text{all leaves}\\ \text{of } v_{nl_n-1}}} x_j.$$

From (B6) we know that the denominator of the previous formula is positive, and we have

$$-1<v_{nl_n-1}\Rightarrow \sum_{\substack{\text{right leaves}\\ \text{of } v_{nl_n-1}}} x_j>0 \tag{B7}$$

and

$$v_{nl_n-1}<1\Rightarrow \sum_{\substack{\text{left leaves}\\ \text{of } v_{nl_n-1}}} x_j>0. \tag{B8}$$

Continuing in this way for all internal nodes of the left subtree (in *in-order*[25]) yields that $x_j>0$ for every variable in the left subtree, since

$$-1<\frac{y-z}{y+z}<1\Rightarrow y>0 \quad \text{and} \quad z>0,$$

if $y+z>0$.

Consider the variable associated with the right child of v_n, i.e., v_{n-1}. For v_{n-1} we have the following expression:

$$v_{n-1}=\left(s-\sum_{\substack{\text{non-leaves}\\ \text{of } v_{n-1}}}x_j-2\sum_{\substack{\text{left leaves}\\ \text{of } v_{n-1}}}x_j\right)\Big/\left(s-\sum_{\substack{\text{non-leaves}\\ \text{of } v_{n-1}}}x_j\right).$$

The ''non-leaves of v_{n-1}'' are exactly the ''left leaves of v_n,'' so from (B6) we have once again that the denominator of the previous formula is positive. We thus have

$$-1<v_{n-1}\Rightarrow\sum_{\substack{\text{non-leaves}\\ \text{of } v_{n-1}}}x_j+\sum_{\substack{\text{left leaves}\\ \text{of } v_{n-1}}}x_j<s, \tag{B9}$$

and

$$v_{n-1}<1\Rightarrow\sum_{\substack{\text{left leaves}\\ \text{of } v_{n-1}}}x_j>0. \tag{B10}$$

Starting from this last equation, we can perform the same actions as in the left subtree to conclude that $x_j>0$ for all leaves in the left subtree of v_{n-1}. Continuing in this way we get that $x_j>0$, for $j=1,\ldots,n$ and $|x|<s$, since

$$-1<\frac{s-y-2z}{s-y}<1\Rightarrow y+z<s \quad\text{and}\quad z>0,$$

if $s-y>0$. This completes the proof that $v\in\square^n\Rightarrow x\in T_s^n$.

(Received 28 November 2001; accepted for publication 19 February 2002)

The properties of A-statistics, related to the class A of simple Lie algebras [T. D. Palev, preprint JINR E17-10550 (1977); hep-th/9705032], are further investigated. The description of each $sl(n+1)$ is carried out via generators $a_1^{\pm},\ldots,a_n^{\pm}$, which we call Jacobson generators. With respect to these generators, the definition of a Fock space of $sl(n+1)$ is given. It is proved that the Fock spaces W_p, $p\in\mathbb{N}$ are the simple symmetric (finite-dimensional) modules of $sl(n+1)$. The Pauli principle of the underlying statistics is formulated. Within each W_p operators $B(p)_i^{\pm}=a_i^{\pm}/\sqrt{p}$ $(i=1,\ldots,n)$, called quasi-Bose creation and annihilation operators (CAOs), are defined. Then $\lim_{p\to\infty}B(p)_i^{\pm}=B_i^{\pm}$, where $B_i^{\pm}$ are ordinary Bose CAOs. Therefore A-statistics appears as an approximation of Bose statistics with CAOs acting in finite-dimensional state spaces. We indicate that the $p=1$ quasi-Bose operators $B(1)_1^{\pm},\ldots,B(1)_n^{\pm}$ are natural operators for the description of hard-core Bose models and of the related Heisenberg spin models. We argue that (up to a certain natural assumption) A-statistics can be interpreted as an exclusion statistics. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1481544]

I. INTRODUCTION

During the last two decades quantum statistics became a field of increasing interest among field theorists and condensed matter theorists. Various new statistics were suggested, leading to generalizations or deviations from some of the first principles in quantum physics, such as the Heisenberg commutation relations, the Pauli exclusion principle, and the commutativity of space–time.

The literature on the subject is vast, especially in the part related to quantum groups.[1–5] In a paper entitled "Twisted second quantization," [6] Pusz and Woronowicz introduced multimode deformed Bose creation and annihilation operators (CAOs), covariant under the action of the quantum group $U_q[sl(n)]$ (for n pairs of them). Another deformation with commuting modes of CAOs was proposed in Ref. 7; the link between them was established in Ref. 8. A third deformation, which for one mode of CAOs was known for many years,[9] the so-called quon algebra,[10] was defined as an associative algebra, subject to relations $a_i^- a_j^+ - q a_j^+ a_i^- = \delta_{ij}$. This generalization (note that no relations among only creation operators or among only annihilation operators are required) was in the origin of a model proposed for a verification of small violations of Bose–Fermi statistics in quantum field theory (QFT).[11] The quon statistics, which in the classification of Doplicher, Haag, and Roberts[12] belongs to the class of "infinite statistics," was studied by several authors[13] from different points of view (see Ref. 14 for further discussions and references).

Recently string theory was also involved in discussions on quantum statistics, the latter related

[a)]Permanent address: Institute for Nuclear Research and Nuclear Energy, Boul. Tsarigradsko Chaussee 72, 1784 Sofia, Bulgaria; electronic mail: tpalev@inrne.bas.bg
[b)]Electronic mail: joris.vanderjeugt@rug.ac.be

to its prediction that Heisenberg's uncertainty principle has to be corrected at distances of order of the Planck length $k_P = 10^{-32}$ cm. Consequently there emerges an absolute minimum uncertainty in the measuring of any length.[15] These predictions motivated several authors to search for model independent arguments, leading to the same conclusions as string theory does (we refer to Ref. 16 for a survey on the subject). In particular it has been shown that the above-mentioned results can be reproduced on a purely kinematical level with appropriate deformations of the Heisenberg commutation relations,[17–20] i.e., of canonical quantum statistics. In all such cases the coordinates do not commute (see also Refs. 21–24), a result which is consistent with the spirit of noncommutative geometry.[25]

Turning to condensed matter physics we refer to anyons, ''particles'' with fractional statistics in two-dimensional systems.[26] The theoretical studies of this and other noncanonical statistics were strongly pushed forward after the discovery of the fractional quantum Hall effect in two-dimensional electron gases.[27] Its theoretical explanation led Laughlin[28] to the conclusion that there exist quasiparticles carrying fractional electric charges. The statistics of these particles (we write ''particles'' for the elementary excitations, the ''quasiparticles,'' when no confusion can arise) also turned out to be fractional statistics.[29]

A further breakthrough in the area of quantum statistics was marked with the 1991 paper of Haldane,[30] who proposed a generalized version of the Pauli exclusion principle. For only one kind of identical particles this new statistics, now called (fractional) exclusion statistics (ES), asserts that the change Δd in the dimension d of the single-particle Hilbert space is defined via the relation

$$\Delta d = -g \cdot \Delta N. \tag{1.1}$$

Here ΔN is an allowed increase of the number of particles. The constant g is called an exclusion statistics parameter.

Our approach to quantum statistics is strongly influenced by the ideas of Wigner, outlined in his 1950's work ''Do the equations of motion determine the quantum mechanical commutation relations?''[31] This was the first paper where it was clearly indicated that the canonical quantum statistics may, in principle, be generalized in a logically consistent way. Wigner demonstrated this on the example of a one-dimensional oscillator with a Hamiltonian $(m=\omega=\hbar=1)$ $H=\frac{1}{2}(p^2+q^2)$. Abandoning the requirement $[p,q]=-i$, Wigner was searching for all operators q and p, such that the ''classical'' equations of motion $\dot{p}=-q$, $\dot{q}=p$ are identical to the Heisenberg equations $\dot{p}=-i[p,H]$, $\dot{q}=-i[q,H]$. Apart from the canonical solution he found infinitely many other solutions. Let $\sqrt{2}B_1^{\pm}=q\mp ip$. It turns out[32] that all these different operators satisfy one and the same triple relation, namely (1.2) with $i=j=k=1$ (see the end of this section for the notation):

$$[\{B_i^{\xi},B_j^{\eta}\},B_k^{\epsilon}]=\delta_{ik}(\epsilon-\xi)B_j^{\eta}+\delta_{jk}(\epsilon-\eta)B_i^{\xi}, \quad i,j,k\in\mathbb{N}, \quad \xi,\eta,\epsilon=\pm, \quad \pm 1. \tag{1.2}$$

The operators $B_i^{\pm}$, $i=1,2,\ldots$ are para-Bose (pB) operators, discovered by Green[33] three years later as a possible generalization of statistics of tensor fields in QFT. Thus the infinitely many different solutions found by Wigner were in fact the Fock representations of one pair of para-Bose operators.

It is known that the linear span of all operators B_i^{ξ}, $\{B_j^{\eta},B_k^{\epsilon}\}$ is a Lie superalgebra[34] isomorphic to the orthosymplectic Lie superalgebra $osp(1/2n)$ for $i,j,k=1,\ldots,n$ and $\xi,\eta,\epsilon=\pm$.[35] The para-Bose operators constitute a basis in the odd subspace of this superalgebra and generate it. Consequently the representation theory of n pairs of pB operators is completely equivalent to the representation theory of $osp(1/2n)$. Hence Wigner found all Fock representations of $osp(1/2)$ long before Lie superalgebras (and supersymmetry) became of interest in physics.

Similarly, any n pairs of para-Fermi CAOs $F_1^{\pm},F_2^{\pm},\ldots,F_n^{\pm}$,[33] defined by

$$[[F_i^{\xi},F_j^{\eta}],F_k^{\epsilon}]=\tfrac{1}{2}\delta_{jk}(\epsilon-\eta)^2F_i^{\xi}-\tfrac{1}{2}\delta_{ik}(\epsilon-\xi)^2F_j^{\eta}, \quad i,j,k\in\mathbb{N}, \quad \xi,\eta,\epsilon=\pm, \quad \pm 1, \tag{1.3}$$

generate the Lie algebra $so(2n+1)$.[36,37] The key observation here is that both $so(2n+1)$ and $osp(1/2n)$ belong to class B of the basic Lie superalgebras in the classification of Kac.[38] Hence parastatistics (and in particular Bose and Fermi statistics) appear as particular Fock representations of Lie superalgebras from one and the same class, the Lie superalgebras of class B. In this sense Green's parastatistics could be called B-(para)statistics.

The clarification of the mathematical structure, hidden in parastatistics, provides a natural background for further searches of new quantum statistics. One such possibility is to consider deformations of parastatistics, namely deformations of $so(2n+1)$ and $osp(1/2n)$ in the sense of quantum groups. We refer to Ref. 39 for discussions and results along this line. Note that parastatistics associated with $so(2n+1)$ (parafermions: finite dimensional representations) and with $osp(1/2n)$ (parabosons: infinite dimensional representations) are not related to the known correspondence between $so(2n+1)$ and $osp(1/2n)$[40,41] where only finite dimensional representations play a role.

In another approach, initiated in Ref. 42, it was shown that to each infinite class A, B, C, and D of simple Lie algebras there corresponds quantum statistics. Examples from classes A and B of proper Lie superalgebras are also available. We have in mind Wigner quantum systems (WQSs).[32] Some such systems possess quite unconventional physical features. As an example we mention the $(n+1)$-particle WQS, based on the Lie superalgebra $sl(1/3n)$ from class A.[43] This WQS exhibits a quark-like structure: the composite system occupies a small volume V around the center of mass and no particles can be extracted out of V. Moreover the geometry within V is noncommutative. Another example is the $osp(3/2)$ WQS from class B.[44] It leads to a picture where two spinless point particles, ''curling'' around each other, produce an orbital (internal angular) momentum 1/2, a result which cannot be obtained in canonical quantum mechanics.

The present paper is also in the frame of quantum statistics. We study further the (microscopic) properties of A-statistics, introduced in Ref. 42 (see also Ref. 45), namely the statistics of Lie algebras $A_n \equiv sl(n+1)$, $n=1,2,\ldots$. Since Refs. 42 and 45 are not available as journal publications, we review the main issues of A-statistics in Secs. II and III and partially in Sec. IV omitting most of the proofs.

We begin (Sec. II) by recalling how the Lie algebra $sl(n+1)$ can be described via generators $a_1^{\pm},\ldots,a_n^{\pm}$ and relations; see (2.5). These generators, which we call Jacobson generators (JG), provide an alternative to the Chevalley description of $sl(n+1)$.

The Fock modules of the Jacobson generators, extended also to $gl(n+1)$-modules, are defined and classified in Sec. III. It is shown how they can be selected out of all irreducible $gl(n+1)$-modules on the ground of natural physical requirements; see Definition 1. All Fock modules W_p are finite-dimensional and are labeled by one positive integer $p \in \mathbb{N}$. More precisely, the signature (the highest weight) of the $gl(n+1)$-module W_p is $(p,0,0,\ldots,0)$, or equivalently, the representation of $gl(n+1)$ in W_p is a symmetric representation. The definition of the Fock spaces is given in such a way that within W_p each generator a_i^+ (respectively, a_i^-) can be interpreted as an operator creating (respectively, annihilating) a ''particle'' in a state i (on the orbital i).

The Pauli principle for A-statistics in W_p is formulated in Sec. IV (Corollary 3). It states that any number of particles up to p and no more than p can be distributed in an arbitrary way along the orbitals. This restriction leads to properties typical for exclusion statistics.[30] We show that under a certain natural assumption the A-statistics can be interpreted as an exclusion statistics in the form of Wu.[46]

Next, in Sec. V, representation-dependent creation and annihilation operators $B(p)_i^{\pm} = a_i^{\pm}/\sqrt{p}\,(i=1,\ldots,n)$ in W_p are defined. We prove that in an appropriate topology $\lim_{p\to\infty} B(p)_i^{\pm} = B_i^{\pm}$, where $B_1^{\pm},\ldots,B_n^{\pm}$ are Bose creation and annihilation operators. The operators $B(p)_1^{\pm},\ldots,B(p)_n^{\pm}$ possess also other Bose-type properties. For these reasons $B(p)_1^{\pm},\ldots,B(p)_n^{\pm}$ are referred to as quasi-Bose operators (of order p), the representations of $sl(n+1)$ and $gl(n+1)$ in W_p as quasiboson representations and the statistics as quasi-Bose statistics.

The Jacobson CAOs $a_1^{\pm},\ldots,a_n^{\pm}$ are ''bosonized'' in Sec. VI. These operators are expressed via n pairs of Bose CAOs $B_1^{\pm},\ldots,B_n^{\pm}$. The related realization of $gl(n+1)$ in W_p turns out to be the known Holstein–Primakoff realization.[47]

In Sec. VII we point out that the quasi-Bose operators can also be of more general interest. On the example of a two-leg $S=1/2$ Heisenberg spin ladder we show that the Bose realization of the Hamiltonian[48,49] together with the restrictions selecting the physical subspace simply means that the Bose operators related to each site have to be replaced by quasi-Bose operators of order $p=1$. This conclusion is of a more general nature. It holds for any hard-core Bose model,[50] since the $p=1$ particles are hard-core bosons (Proposition 5).

Section VIII is devoted to some conclusions and discussions.

Throughout the paper we use the following abbreviations and notation (some of them standard):

JGs	Jacobson generators;
CAOs	creation and annihilation operators;
UEA	universal enveloping algebra;
$\mathbb{N}$	all positive integers;
$\mathbb{Z}+$	all non-negative integers;
$[a,b]=ab-ba,$	$\{a,b\}=ab+ba;$
$\oplus$	direct sum of linear spaces or of Lie algebras.

II. JACOBSON GENERATORS OF $sl(n+1)$

The $sl(n+1)$-statistics, including $n=\infty$, was introduced in Ref. 42 (see also Ref. 45) as an alternative way for quantization of spinor fields in quantum field theory. References 42 and 45 are not available as journal publications. Therefore here and in Sec. III we outline the main features of this statistics in somewhat more details.

In order to define the Jacobson generators, it is convenient to consider $sl(n+1)$ as a subalgebra of the Lie algebra $gl(n+1)$. The universal enveloping algebra $U[gl(n+1)]$ of the latter can be defined as an associative algebra with unity of the generators $\{e_{ij}|i,j=0,1,\ldots,n\}$ subject to the relations

$$[e_{ij},e_{kl}]=\delta_{jk}e_{il}-\delta_{il}e_{kj}. \tag{2.1}$$

Then $gl(n+1)$ is a subalgebra of $U[gl(n+1)]$, considered as a Lie algebra, with generators e_{ij}, $i,j=0,1,\ldots,n$ and commutation relations (2.1).

The Cartan subalgebra H' of $gl(n+1)$ has a basis $h_i\equiv e_{ii}$, $i=0,1,\ldots,n$. Let $h^0,h^1,\ldots,h^n$ be the dual basis, $h^i(h_j)=\delta_{ij}$. The root vectors of both $gl(n+1)$ and $sl(n+1)$ are e_{ij}, $i\neq j=0,1,\ldots,n$. The root of each e_{ij} is h^i-h^j. Then

$$sl(n+1)=\mathrm{span}\{e_{ij},e_{ii}-e_{jj}|i\neq j=0,1,\ldots,n\}. \tag{2.2}$$

The Jacobson generators (JGs) of $sl(n+1)$ are part of the generators e_{ij}, namely

$$a_i^+=e_{i0},\quad a_i^-=e_{0i},\quad i=1,\ldots,n. \tag{2.3}$$

The correspondence with their roots reads

$$a_i^{\pm}\leftrightarrow\mp(h^0-h^i),\quad i=1,\ldots,n, \tag{2.4}$$

and therefore the JGs a_i^+ (a_i^-) are negative (positive) root vectors with respect to the natural ordering $h^0,h^1,\ldots,h^n$. Since any other root is a sum of the roots of a_j^- and a_i^+, namely

$$h^i-h^j=(h^0-h^j)-(h^0-h^i),\quad i\neq j=1,\ldots,n,$$

the JGs (2.3) generate $sl(n+1)$ in the sense of a Lie algebra.

From (2.1) and (2.3) one derives the triple relations

$$[[a_i^+,a_j^-],a_k^+]=\delta_{kj}a_i^+ + \delta_{ij}a_k^+, \tag{2.5a}$$

$$[[a_i^+,a_j^-],a_k^-]=-\delta_{ki}a_j^- - \delta_{ij}a_k^-, \tag{2.5b}$$

$$[a_i^+,a_j^+]=[a_i^-,a_j^-]=0. \tag{2.5c}$$

On the contrary, setting $e_{ij}-\delta_{ij}e_{00}=[a_i^+,a_j^-]$, one derives from (2.5) the commutation relation between all $sl(n+1)$ generators e_{ij}, $e_{ii}-e_{jj}$, $i\neq j=0,1,\ldots,n$.

The above-given description of $sl(n+1)$ via generators and relations is a particular case of describing Lie algebras via Lie triple systems, initiated by Jacobson.[51] For this reason the elements $a_i^{\pm}$ are referred to as Jacobson generators of $sl(n+1)$.

The presentation of simple Lie algebras in terms of generators and relations [as illustrated here by the JGs for $sl(n+1)$] is a topic of interest to physicists.[52,53] In fact, any simple finite dimensional Lie algebra can be generated by two elements only; this was first claimed by Jacobson (see also Ref. 54) and proved in Ref. 55. For this reason, these two generators are sometimes referred to as ''Jacobson's generators.'' We shall not use this terminology here, in order to avoid confusion with the Jacobson generators defined in this section. Observe that the nature of the relations becomes extremely complicated when using only these two generators. A simpler description was given in Ref. 56, in terms of three generators [by adding a third generator to the earlier two, which are related to a principal $sl(2)$ embedding]. The description of $sl(n)$, and other simple Lie algebras or superalgebras, is explicitly given in Ref. 56 in terms of such three generators and the corresponding relations (which are not triple relations, but of higher degree). Such a description (with three generators and a number of higher order relations) is appropriate to present the so-called Lie algebra of matrices of complex size $gl(\lambda)$, see Refs. 56 and 53, since for $gl(\lambda)$ or $sl(\lambda)$ there is no analog of a Cartan matrix or of Chevalley generators.

In the present paper, however, we shall only use the presentation of $sl(n+1)$ by means of the JGs (2.3) and the triple relations (2.5), which is essentially a description by means of Jacobson's Lie triple systems (LTSs).[51] The approach by means of LTSs was further developed to the $\mathbb{Z}_2$-graded case by Okubo.[57] Let us be more concrete. By definition[51] a Lie triple system $\mathcal{L}$ is a subspace of an associative algebra U, so that $\mathcal{L}$ is closed under the ternary operation $\omega:\mathcal{L}\otimes\mathcal{L}\otimes\mathcal{L}\to\mathcal{L}$ defined as $\omega(a\otimes b\otimes c)=[[a,b],c]$, $a,b,c\in\mathcal{L}$. The definiton of a Lie supertriple system (equivalent to the definition in Ref. 57) is similar. The difference is that $\mathcal{L}$ is a $\mathbb{Z}_2$-graded subspace of an associative superalgebra U and the commutators in the definition of ω are replaced by supercommutators.

The JGs of $sl(n+1)$ are closely related to the above-given definition. More precisely, let $\mathcal{L}_{sl}$ be the linear span of the generators (2.3) and U_{sl} be the associative unital algebra of the JGs subject to the relations (2.5). Then $\mathcal{L}_{sl}$ is a subspace of U_{sl}. Moreover $\omega:\mathcal{L}_{sl}\otimes\mathcal{L}_{sl}\otimes\mathcal{L}_{sl}\to\mathcal{L}_{sl}$ as a consequence of (2.5). Hence $\mathcal{L}_{sl}$ is a Lie triple system with a basis consisting of the JGs (2.3) and U_{sl} is the UEA of $sl(n+1)$. Similarly, the linear span $\mathcal{L}_{\rm pf}$ of para-Fermi CAOs $F_1^{\pm},F_2^{\pm},\ldots,F_n^{\pm}$ together with the associative algebra $U_{\rm pf}$ of these operators [subject to the relations (1.3)] is another example of a LTS. Hence the para-Fermi operators $F_1^{\pm},\ldots,F_n^{\pm}$ could be called JGs of $so(2n+1)$. In the same spirit the para-Bose operators $B_1^{\pm},\ldots,B_n^{\pm}$ are JGs of $osp(1/2n)$.

From a purely algebraic point of view the Jacobson generators provide an alternative to the Chevalley description of $sl(n+1)$, $so(2n+1)$, and $osp(1/2n)$. The JGs of $so(2n+1)$ and $osp(1/2n)$ however (contrary to the Chevalley generators) have a direct physical significance. These operators extend the canonical Fermi and Bose statistics to the more general parastatistics. In the following we proceed to show that the JGs of $sl(n+1)$ also introduce a new quantum statistics, different from Bose and Fermi statistics and their generalization—parastatistics. This statistics is intrinsically related to class A of simple Lie algebras in the same way as the para-Fermi statistics is related to class B of simple Lie algebras.

Typically the ''commutation relations'' between the creation and the annihilation operators (or the related position and momentum operators in case of finite degrees of freedom) are derived from (more precisely, are required to be consistent with) *the main quantization equation*

$$[H,a_i^{\pm}]=\pm\epsilon_i a_i^{\pm}, \tag{2.6}$$

where H is the Hamiltonian and i replaces all indices that may appear (momentum, spin, charge, etc.). In quantum field theory (2.6) expresses the translation invariance of the field (in infinitesimal form). In quantum mechanics the same equation appears as a compatibility condition (in the sense of Wigner[31]) between the Heisenberg equations of motion and the classical equations, if the system has a classical analog (for more details see Refs. 32 and 58). There are certainly several other conditions to be satisfied (Galilean or relativistic invariance, causality, etc.; we refer to Ref. 43 for discussions in case of noncanonical quantum mechanics). The possibility for choosing different statistics essentially depends upon the way one represents the Hamiltonian H. We are going to illustrate this on the example of para-Fermi statistics.

Consider a nonrelativistic free field locked in a finite volume. In the case of a Fermi field the Hamiltonian $\hat{H}$ is written in a normal-product form

$$\hat{H}=\sum_i \epsilon_i f_i^+ f_i^-, \tag{2.7}$$

so that the energy of the vacuum is zero. Here f_i^+ (f_i^-) are Fermi creation (annihilation) operators: $\{f_i^{\xi},f_j^{\eta}\}=\frac{1}{4}(\xi-\eta)^2\delta_{ij}$, $\xi,\eta=\pm$ or ± 1. Then (2.6) holds,

$$[\hat{H},f_i^{\pm}]=\pm\epsilon_i f_i^{\pm}, \tag{2.8}$$

and each f_i^{ξ} can be interpreted as an operator creating ($\xi=+$) or annihilating ($\xi=-$) a particle, i.e., a fermion with energy ϵ_i. Equation (2.8) is not fulfilled however, if the Fermi operators in (2.7) are replaced by para-Fermi operators (1.3): for $H=\Sigma_i \epsilon_i F_i^+ F_i^-$ the equation

$$[H,F_i^{\pm}]=\pm\epsilon_i F_i^{\pm} \tag{2.9}$$

does not hold. Why? In order to answer this question using proper Lie algebraic language assume that the sum in (2.7) is finite (finite number of Fermi oscillators),

$$\hat{H}=\sum_{i=1}^{n} \epsilon_i f_i^+ f_i^-. \tag{2.10}$$

This is only an intermediate step. The considerations in the following remain valid for $n=\infty$. Recall now that any n pairs of Fermi CAOs generate a particular Fermi representation of the Lie algebra $so(2n+1)\equiv B_n$, whereas the para-Fermi operators $F_1^{\pm},\ldots,F_n^{\pm}$ are (representation independent) generators of $so(2n+1)$.[36,37] Equation (2.8) is not preserved, when passing to other representations of B_n, because H is not an element from B_n and hence $[H,F_i^{\pm}]$ on the left-hand side of (2.9) is not a representation independent commutator. This observation also suggests the answer: one has to rewrite (2.10) in a representation independent form. In order to achieve this, represent (2.10) in the following identical form:

$$\hat{H}=\frac{1}{2}\sum_{i=1}^{n} \epsilon_i([f_i^+,f_i^-]+\{f_i^+,f_i^-\}). \tag{2.11}$$

Consider the Lie algebra generated from $f_1^{\pm},\ldots,f_n^{\pm}$ and $\{f_i^+,f_i^-\}$. Since $\{f_i^+,f_i^-\}=1$, we obtain a representation of the Lie algebra $B_n\oplus I$, where I is the one-dimensional center. Now $\hat{H}\in B_n\oplus I$ and therefore the commutation relations (2.8) hold for any other representation of $B_n\oplus I$. In other words, if we substitute $f_i^{\pm}\to F_i^{\pm}$ and $\{f_i^+,f_i^-\}\to\hat{p}$ in (2.11), i.e., set

$$H=\frac{1}{2}\sum_{i=1}^{n}\epsilon_i([F_i^+,F_i^-]+\hat{p}), \tag{2.12}$$

where $\hat{p}$ is a generator of the center I, then the quantization condition (2.8) will be fulfilled for any representation of $B_n\oplus I$ and in particular for the para-Fermi operators (1.3): $[H,F_i^{\pm}]=\pm\epsilon_i F_i^{\pm}$. The requirement $\hat{p}|0\rangle=p|0\rangle$, $p\in\mathbb{N}$ (and $F_i^-F_j^+|0\rangle=\delta_{ij}p|0\rangle$, $F_i^-|0\rangle=0$), leads to a representation with an order of the (para)statistics p.[59] Then the energy of the vacuum is also zero.

We shall now apply a similar approach for the algebra $sl(n+1)$. Let E_{ij}, $i,j=0,1,\ldots,n$, be the $(n+1)\times(n+1)$ matrix units. The map $\pi:e_{ij}\to E_{ij},i,j=0,1,\ldots,n$, gives a representation of $gl(n+1)$ (usually referred to as defining or identity representation). Its restriction to $sl(n+1)$ gives a representation of $sl(n+1)$. The operators $A_i^+=E_{i0}$, $A_i^-=E_{0i}$, $i=1,2,\ldots,n$ satisfy the triple relations (2.5). Set

$$\hat{H}=\sum_{i=1}^{n}\epsilon_i A_i^+A_i^-. \tag{2.13}$$

Then

$$[\hat{H},A_i^{\pm}]=\pm\epsilon_i A_i^{\pm}. \tag{2.14}$$

Hence A_i^{ξ} can be interpreted as an operator creating ($\xi=+$) or annihilating ($\xi=-$) a particle (quasiparticle, excitation) with energy ϵ_i for any $i=1,\ldots,n$. The representation π is an analog of the Fermi representation of para-Fermi statistics.

The commutation relations (2.14) do not hold for other representations of $sl(n+1)$. In order to extend the class of admissible representations we rewrite the Hamiltonian (2.13), like in the Fermi case, in the following identical form:

$$\hat{H}=\sum_{i=1}^{n}\epsilon_i([A_i^+,A_i^-]+E_{00}). \tag{2.15}$$

The Lie algebra generated from the operators $A_1^{\pm},\ldots,A_n^{\pm}$ and E_{00} is $gl(n+1)$ (in the representation π). Since $\hat{H}\in gl(n+1)$ (in this representation), (2.14) also holds for any other representation of $gl(n+1)$. In other words the Hamiltonian

$$H=\sum_{i=1}^{n}\epsilon_i([a_i^+,a_i^-]+e_{00})=\sum_{i=1}^{n}\epsilon_i([a_i^+,a_i^-]+h_0) \tag{2.16}$$

satisfies (2.6) for any other representation of $gl(n+1)$.

One may argue that expression (2.16) is not satisfactory, because the Hamiltonian H is not a function of the Jacobson generators only. In the following, in Corollary 1, we show that within every irreducible representation H can be written as a function of the JGs. Here we note that $[a_i^+,a_i^-]+e_{00}=h_i$ and therefore the Hamiltonian (2.16) can be represented manifestly as an element from the Cartan subalgebra of $gl(n+1)$:

$$H=\sum_{i=1}^{n}\epsilon_i h_i. \tag{2.17}$$

III. FOCK REPRESENTATIONS OF $sl(n+1)$

We proceed to outline those representations of the Jacobson generators that possess the main features of Fock space representations in ordinary quantum theory. In order to distinguish between the abstract generators and their representations, the JGs $a_1^{\pm},\ldots,a_n^{\pm}$, considered as operators in a certain $sl(n+1)$-module W, are called (Jacobson) creation and annihilation operators of $sl(n+1)$ [abbreviated also as Jacobson CAOs of $sl(n+1)$, $sl(n+1)$-CAOs, A-CAOs or simply CAOs].

Definition 1: Let $a_1^{\xi},\ldots,a_n^{\xi}$ be Jacobson creation ($\xi=+$) and annihilation ($\xi=-$) operators. The $sl(n+1)$-module W is said to be a Fock space of the algebra $sl(n+1)$ if it is a Hilbert space, so that the following conditions hold:

1. Hermiticity condition (A^* *denotes the operator conjugate to* A)

$$(a_i^+)^* = a_i^-, \quad i=1,\ldots,n. \tag{3.1}$$

2. Existence of vacuum. There exists a vacuum vector $|0\rangle \in W$ such that

$$a_i^-|0\rangle = 0, \quad i=1,\ldots,n. \tag{3.2}$$

3. The representation space W is spanned on vectors

$$a_{i_1}^+ a_{i_2}^+ \cdots a_{i_m}^+ |0\rangle, \quad m \in \mathbb{Z}_+ . \tag{3.3}$$

The Fock space of $sl(n+1)$ is also said to be an A_n-module of Fock or simply a Fock module.

Assume that W is a Fock space. Condition (3.1) asserts that any Fock representation is unitarizable with respect to this star operation, considered as an antilinear antiinvolution on $sl(n+1)$. It is known that all such representations are realized in direct sums of finite-dimensional irreducible $sl(n+1)$-modules. Then (3.3) yields that any Fock module is a finite-dimensional irreducible $sl(n+1)$-module.

We list a few propositions, proofs of which can be found in Refs. 42 and 45.

Proposition 1: The $sl(n+1)$-module W is a Fock space if and only if it is an irreducible finite-dimensional module with a highest weight Λ such that

$$a_i^- a_j^+ x_\Lambda = 0, \quad i \neq j = 1,\ldots,n. \tag{3.4}$$

The vacuum $|0\rangle$ is unique (up to a multiplicative constant) and can be identified with the highest weight vector x_Λ in W: $|0\rangle = x_\Lambda$.

For a proof see Theorem 1 in Ref. 45.

Recall that the Hamiltonian H, see (2.17), does not belong to $sl(n+1)$. It is an element from $gl(n+1)$. In order to define H as an operator in W, we extend each Fock module to an irreducible $gl(n+1)$-module. To this end we define the action of the $gl(n+1)$ central element [also $gl(n+1)$ Casimir operator] $h_0+h_1+\cdots+h_n$ in W, setting

$$(h_0+h_1+\cdots+h_n)x = px, \forall x \in W, \tag{3.5}$$

where p can be any number.

The next proposition classifies the Fock spaces. Unless otherwise stated, the roots and the weights are represented by their coordinates in the basis $h^0,h^1,\ldots,h^n$, i.e., $\lambda = \sum_{i=0}^n l_i h^i \equiv (l_0,l_1,\ldots,l_n)$.

Proposition 2: The irreducible $gl(n+1)$-module W_p is a Fock space, so that the energy of the vacuum is zero ($H|0\rangle = 0$), if and only if its highest weight (namely the weight of $|0\rangle$) is $\Lambda = ph^0 \equiv (p,0,\ldots,0)$, i.e., if

$$h_0|0\rangle = p|0\rangle, \quad h_i|0\rangle = 0, \quad i=1,\ldots,n, \tag{3.6}$$

where p is an arbitrary positive integer.

Let us add that a representation with a highest weight $(p,0,\ldots,0)$ is the pth symmetric power of the identity representation $(1,0,\ldots,0)$. It corresponds to a Young diagram with one row and p boxes.

From (2.3) and (3.5) $h_0+h_1+\cdots+h_n=p$, $h_0-h_i=[a_i^-,a_i^+]$, $i=1,\ldots,n$, which yields

$$h_0=\frac{1}{n+1}\left(p+\sum_{i=1}^{n}[a_i^-,a_i^+]\right),\quad h_i=\frac{1}{n+1}\left(p+n[a_i^+,a_i^-]-\sum_{k\neq i=1}^{n}[a_k^+,a_k^-]\right). \tag{3.7}$$

The last result shows that within any Fock module the generators e_{ij} can be expressed as functions of $a_1^{\pm},\ldots,a_n^{\pm}$. In view of this we say that $a_1^{\pm},\ldots,a_n^{\pm}$ are Jacobson CAOs of both $sl(n+1)$ and of $gl(n+1)$.

An immediate consequence of (2.16) and (3.7) is the following

Corollary 1: Within every Fock module W_p the Hamiltonian (2.16) can be expressed entirely via the Jacobson creation and annihilation operators:

$$H=\frac{1}{n+1}\sum_{i=1}^{n}\epsilon_i\left(p+n[a_i^+,a_i^-]-\sum_{k\neq i=1}^{n}[a_k^+,a_k^-]\right). \tag{3.8}$$

From (3.4), (3.6), and (3.7) one concludes:

Corollary 2: The Fock module W_p with a highest weight $\Lambda=(p,0,\ldots,0)$ is completely defined by the relations

$$a_i^-a_j^+|0\rangle=\delta_{ij}p|0\rangle,\quad a_k^-|0\rangle=0,\quad p\in\mathbb{N},\quad i,j,k=1,\ldots,n. \tag{3.9}$$

The above two conditions are the same as in the case of Green's parastatistics of order p.[33] Therefore p is referred to as an order of $sl(n+1)$-statistics (or A-statistics). The conclusion is that like in parastatistics the Fock spaces are labeled by a positive integer $p\in\mathbb{N}$. The representations corresponding to different orders of statistics have different highest weights and are therefore inequivalent.

Taking into account the second relation $a_k^-|0\rangle=0$ in (3.9), one can also define the Fock module W_p by means of the relations

$$[a_i^-a_j^+]|0\rangle=\delta_{ij}p|0\rangle,\quad a_k^-|0\rangle=0,\quad p\in\mathbb{N},\quad i,j,k=1,\ldots,n. \tag{3.10}$$

In view of this A-statistics and its Fock representations can be formulated in a somewhat more mathematical terminology. The latter is based on the observation that the linear span of all generators $[a_i^-a_j^+]$, a_i^-, $i,j=1,\ldots,n$, is a subalgebra $\mathcal{A}$ of $gl(n+1)$ [which contains as subalgebra also $gl(n)=\mathrm{span}\{[a_i^-a_j^+]|i,j=1,\ldots,n\}$]. Equation (3.10) defines one-dimensional representations of $\mathcal{A}$, spanned on the vacuum $|0\rangle$. Therefore the Fock modules W_p can be defined as those irreducible finite-dimensional $gl(n+1)$-modules, which are induced from trivial one-dimensional modules of $\mathcal{A}$ via Eq. (3.10). Then p labels the different, inequivalent one-dimensional modules of $\mathcal{A}$.

On the other hand one can define A-statistics by means of the triple relations (2.5). Then Eq. (3.9) defines completely the Fock modules W_p. All calculations can be carried out without even mentioning the underlying Lie algebraic structure of A-statistics (which is usually the case for parastatistics).

Let W_p be a Fock space with order of statistics p. From (3.3) and the fact that the creation operators commute with each other one concludes that W_p is a linear span of vectors $(a_1^+)^{l_1}(a_2^+)^{l_2}\cdots(a_n^+)^{l_n}|0\rangle$, $l_1,\ldots,l_n\in\mathbb{Z}_+$. The correspondence weight$\leftrightarrow$weight vector is one to one:

$$(a_1^+)^{l_1}(a_2^+)^{l_2}\cdots(a_n^+)^{l_n}|0\rangle \leftrightarrow \left| p-\sum_{k=1}^{n} l_k, l_1, l_2, \ldots, l_n \right\rangle, \tag{3.11}$$

i.e., all weight subspaces are one-dimensional.

Proposition 3: Let W_p be an $sl(n+1)$-module of Fock with order of statistics p. The vector

$$(a_1^+)^{l_1}(a_2^+)^{l_2}\cdots(a_n^+)^{l_n}|0\rangle \tag{3.12}$$

is not zero if and only if

$$l_1+l_2+\cdots+l_n \leqslant p. \tag{3.13}$$

The proof is a consequence of the properties of the roots in any finite-dimensional irreducible $sl(n+1)$-module W. If $\Lambda=(L_0,L_1,\ldots,L_n)$ is the highest weight in W, then for any other weight $\lambda=(l_0,l_1,\ldots,l_n)$ the following inequality holds:

$$l_{i_0}+l_{i_1}+\cdots+l_{i_m} \leqslant L_0+L_1+\cdots+L_m, \tag{3.14}$$

where $i_0 \neq i_1 \neq \ldots, \neq i_m = 0,1,\ldots,n$ and $m=0,1,\ldots,n$. Equation (3.14) is an equality for $m=n$. If W_p is a Fock space, $L_0+L_1+\cdots+L_m=p$.

Proposition 3 can be proved also by a direct, but rather long computation. One verifies that the infinite-dimensional module $\hat{W}_p$ spanned on all vectors (3.12) with $l_1,\ldots,l_n$ being arbitrary non-negative integers contains an invariant subspace V_p spanned on all vectors (3.12) with $l_1+l_2+\cdots+l_n>p$. Then W_p is the factor module $\hat{W}_p/V_p$ and all vectors (3.12), subject to (3.13) are (representatives of) the basis vectors in $W_p=\hat{W}_p/V_p$.

We proceed to recall how one defines a metric in W_p, so that it is a Hilbert space and the hermiticity condition (3.1) holds. Consider the vectors

$$(a_1^+)^{l_1}(a_2^+)^{l_2}\cdots(a_n^+)^{l_n}|0\rangle, \quad l_1+l_2+\cdots+l_n \leqslant p \tag{3.15}$$

from W_p. All such vectors have different weights. Consequently they are linearly independent and can be considered as a basis in W_p. Define a Hermitian form $(\ ,\ )$ on W_p in the usual way (for quantum theory), postulating [in addition to $a_i^-|0\rangle=0$, see (3.2)]:

$$(|0\rangle,|0\rangle) \equiv \langle 0|0\rangle = 1, \tag{3.16a}$$

$$\langle 0|a_i^+ = 0, \quad i=1,\ldots,n, \tag{3.16b}$$

$$\begin{aligned}&((a_1^+)^{m_1}(a_2^+)^{m_2}\cdots(a_n^+)^{m_n}|0\rangle,(a_1^+)^{l_1}(a_2^+)^{l_2}\cdots(a_n^+)^{l_n}|0\rangle)\\ &\quad=\langle 0|(a_n^-)^{m_n}\cdots(a_2^-)^{m_2}(a_1^-)^{m_1}(a_1^+)^{l_1}(a_2^+)^{l_2}\cdots(a_n^+)^{l_n}|0\rangle.\end{aligned} \tag{3.16c}$$

With respect to this form the vectors (3.15) are orthogonal. Moreover,

$$((a_1^+)^{l_1}(a_2^+)^{l_2}\cdots(a_n^+)^{l_n}|0\rangle,\ (a_1^+)^{l_1}(a_2^+)^{l_2}\cdots(a_n^+)^{l_n}|0\rangle) = \frac{p!}{(p-\Sigma_{j=1}^n l_j)!}\prod_{i=1}^{n} l_i! > 0. \tag{3.17}$$

Therefore all vectors

$$|p;l_1,\ldots,l_n\rangle = \sqrt{\frac{(p-\Sigma_{j=1}^n l_j)!}{p!}}\frac{(a_1^+)^{l_1}\cdots(a_n^+)^{l_n}}{\sqrt{l_1!l_2!\ldots l_n!}}|0\rangle, \quad l_1+l_2+\cdots+l_n \leqslant p \tag{3.18}$$

constitute an orthonormal basis in W_p, i.e., $(\ ,\ )$ is a scalar product. Then by construction the hermiticity condition (3.1) holds too.

The transformation of the basis (3.18) under the action of the Jacobson CAOs reads:

$$a_i^+|p;l_1,\ldots,l_i,\ldots,l_n\rangle=\sqrt{(l_i+1)\left(p-\sum_{j=1}^{n} l_j\right)}|p;l_1,\ldots,l_{i-1},l_i+1,l_{i+1}\ldots,l_n,\rangle, \tag{3.19}$$

$$a_i^-|p;l_1,\ldots,l_i,\ldots,l_n\rangle=\sqrt{l_i\left(p-\sum_{j=1}^{n} l_j+1\right)}|p;l_1,\ldots,l_{i-1},l_i-1,l_{i+1}\ldots,l_n\rangle. \tag{3.20}$$

Moreover,

$$h_0|p;l_1,l_2,\ldots,l_n\rangle=\left(p-\sum_{i=1}^{n} l_i\right)|p;l_1,l_2,\ldots,l_n\rangle, \tag{3.21}$$

$$h_i|p;l_1,l_2,\ldots,l_n\rangle=l_i|p;l_1,l_2,\ldots,l_n\rangle,\quad i=1,\ldots,n. \tag{3.22}$$

Let us consider in some more detail the $p=1$ representation. Denote by $b_i^{\pm}$ the Jacobson CAOs $a_i^{\pm}$ in this representation. In this particular case the representation space W_1 is $(n+1)$-dimensional with a basis

$$|1;l_1,\ldots,l_n\rangle,\quad l_1+\cdots+l_n\leqslant 1, \tag{3.23}$$

i.e., at most one of the labels $l_1,\ldots,l_n$ in $|1;l_1,\ldots,l_n\rangle$ is equal to 1 and all other are zeros. Then (3.19) and (3.20) reduce to

$$\begin{aligned} b_i^+|1;l_1,\ldots,l_{i-1},l_i,l_{i+1},\ldots,l_n\rangle&=(1-l_i)|1;l_1,\ldots,l_{i-1},l_i+1,l_{i+1},\ldots,l_n\rangle,\\ b_i^-|1;l_1,\ldots,l_{i-1},l_i,l_{i+1},\ldots,l_n\rangle&=l_i|1;l_1,\ldots,l_{i-1},l_i-1,l_{i+1},\ldots,l_n\rangle. \end{aligned} \tag{3.24}$$

The matrix elements of b_i^+ and b_i^-, in the basis ordered as $|1;0,0,0,\ldots,0\rangle,|1;1,0,0,\ldots,0\rangle,|1;0,1,0,\ldots,0\rangle,|1;0,0,1,\ldots,0\rangle,\ldots,|1;0,0,0,\ldots,1\rangle$ are the same as those of the matrix units E_{i0} and E_{0i} in the defining $(n+1)$-dimensional matrix representation of $gl(n+1)$. Hence the $p=1$ representation is the same as the defining representation and one can think of the operators $b_i^{\pm}$ as of matrices,

$$E_{i0}=b_i^+,\quad E_{0i}=b_i^-,\quad i=1,\ldots,n. \tag{3.25}$$

From here and (3.7) (with $p=1$) one can also express the rest of the generators via $p=1$ Jacobson creation and annihilation operators:

$$E_{00}=\frac{1}{n+1}\left(1-\sum_{i=1}^{n}[b_i^+,b_i^-]\right),\quad E_{ij}=[b_i^+,b_j^-]+\frac{\delta_{ij}}{n+1}\left(1-\sum_{k=1}^{n}[b_k^+,b_k^-]\right),\quad i,j=1,\ldots,n. \tag{3.26}$$

IV. THE PAULI PRINCIPLE FOR *A*-STATISTICS

The results obtained so far justify the terminology used. Equations (2.17) and (3.6) yield

$$H|p;l_1,\ldots,l_i,\ldots,l_n\rangle=\sum_{i=1}^{n} l_i\epsilon_i|p;l_1,\ldots,l_i,\ldots,l_n\rangle. \tag{4.1}$$

Therefore the state $|p;l_1,\ldots,l_i,\ldots,l_n\rangle$ can be interpreted as a many-particle state with l_1 particles on the first orbital, l_2 particles on the second orbital, etc. For reasons that will become clear soon,

we refer to these particles as A-particles or simply particles. The operator h_i, $i=1,\ldots,n$, see (3.22), is the number operator for the A-particles on the ith orbital, whereas $\hat{N}=h_1+\cdots+h_n$ counts all particles, accommodated in the state $|p;l_1,\ldots,l_i,\ldots,l_n\rangle$.

Since, see (3.19),

$$a_i^+|p;l_1,\ldots,l_i,\ldots,l_n\rangle\sim|p;l_1,\ldots,l_{i-1},l_i+1,l_{i+1},\ldots,l_n\rangle \quad \text{if } \sum_{i=1}^{n} l_i<p, \tag{4.2}$$

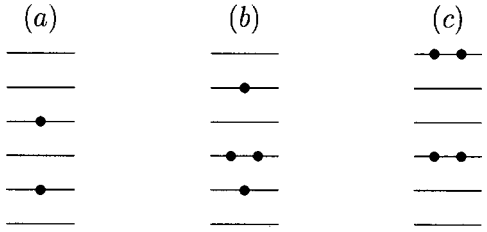
the operator a_i^+ creates an A-particle on the ith orbital, a particle with energy ϵ_i, if the state contains less than p particles. On the other hand, $a_i^+|p;l_1,\ldots,l_{i-1},l_i,l_{i+1},\ldots,l_n\rangle=0$, if $\Sigma_{i=1}^{n}l_i=p$, i.e., no more than p particles can be accommodated. Similarly, if $l_i>0$, a_i^- "kills" a particle with energy ϵ_i. Therefore, reformulating Proposition 3, one obtains:

Corollary 3 (Pauli principle for A-statistics): Let W_p be a Fock space of $sl(n+1)$, corresponding to an order of statistics p. Within W_p all states containing no more than p A-particles, namely all states

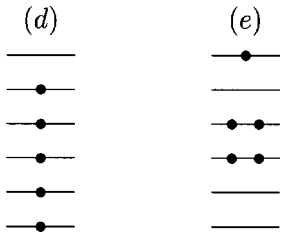
$$|p;l_1,\ldots,l_i,\ldots,l_n\rangle \quad with \quad 0\leqslant\sum_{i=1}^{n} l_i\leqslant p, \tag{4.3}$$

are allowed. There are no states accommodating more than p A-particles.

Let us consider, as an example, A-statistics of order $p=4$ with $n=6$ orbitals (for instance with six different energy levels). From (4.3), it follows that there is no restriction on the number of particles to be accommodated on a certain orbital as long as the total number of particles in any configuration does not exceed p. Hence, the following three states or configurations are allowed (the orbitals, for instance the energy levels, are represented by lines, and the particles by dots):



Note that the last two configurations (b) and (c) are already "saturated" in the sense that no more particles can be added, since the total number of them is already equal to $p=4$. The following two configurations correspond to forbidden states:



None of the states (d) and (e) is allowed since the total number of particles in the configuration exceeds $p=4$.

This example illustrates the statistical interaction between the orbitals: the filling of an orbital depends on how many particles are already accommodated on the other orbitals. This property is typical for Haldane's exclusion statistics.[30] Although Haldane's relation (1.1) does not hold for A-statistics, up to a certain natural assumption A-statistics can be viewed as a special case of exclusion statistics in the sense of Wu.

In Ref. 46 Wu proposed an "integral form" compatible with Haldane's relation (1.1):

$$d(N)=n-g(N-1). \tag{4.4}$$

This should be interpreted as follows: let n be the total number of orbitals that are available for the first particle, and suppose $N-1$ particles are already accommodated in the configuration, then $d(N)$ expresses the dimension of the single-particle space for the Nth particle (or the number of orbitals where the Nth particle can be ''loaded''). Bose statistics has $g=0$, and Fermi statistics has $g=1$.

The natural assumption mentioned previously is that the domain of definition of the function $d(N)$ consists of all *admissible* values of N, i.e., one does not require (4.4) to be applicable for values of N which the system cannot accommodate. Under this assumption A-statistics is a particular case of exclusion statistics, also with $g=0$:

$$d(N)=n, \quad \forall N\in\{1,2,\ldots,p\}. \tag{4.5}$$

If however one drops the condition for N to be an admissible value, one cannot satisfy Eq. (4.4). Indeed, (4.4) with $g=0$, does not hold for $N=p+1$, since $d(p+1)=0$.[60,61]

A-statistics is similar to Bose statistics in the sense that there is no restriction on the number of particles on an orbital apart from the general requirement that the total configuration should contain no more than p particles. This restriction leads perhaps to the simplest statistical interaction between the orbitals. Nevertheless the situation is not as easy as it sounds. As in any (nontrivial) model of an exclusion statistics (so also in this case) the orbitals cannot be considered anymore as independent (or quasiclosed) subsystems. In particular the grand partition function of the system cannot be represented anymore as a product of the partition functions of the orbitals. The latter makes the problem of studying the statistical properties of A-statistics more involved as compared to Bose or Fermi systems. From the point of view of statistical mechanics this is the main difference between A-statistics and Bose statistics.[62]

V. QUASI-BOSE CREATION AND ANNIHILATION OPERATORS

In the present section we show first approximately and then in a strict sense that A-statistics can be viewed as a good finite-dimensional approximation to Bose statistics for large values of order of statistics p. The terminology *finite-dimensional approximation* comes to remind one that the Fock spaces W_p of A-statistics are finite-dimensional linear spaces, whereas any Bose Fock space is infinite-dimensional.

Introduce new, representation-dependent, creation and annihilation operators

$$B(p)_i^{\pm}=\frac{a_i^{\pm}}{\sqrt{p}}, \quad i=1,\ldots,n, \quad p\in\mathbb{N}, \tag{5.1}$$

in W_p. The transformations following from (3.19) to (3.20) read

$$B(p)_i^{+}|p;l_1,\ldots,l_i,\ldots,l_n\rangle=\sqrt{(l_i+1)\left(1-\frac{\Sigma_{k=1}^{n}l_k}{p}\right)}|p;l_1,\ldots,l_i+1,\ldots,l_n\rangle, \tag{5.2}$$

$$B(p)_i^{-}|p;l_1,\ldots,l_i,\ldots,l_n\rangle=\sqrt{l_i\left(1+\frac{1-\Sigma_{k=1}^{n}l_k}{p}\right)}|p;l_1,\ldots,l_i-1,\ldots,l_n\rangle. \tag{5.3}$$

Consider the above-given equations for values of the order of statistics p, which are much greater than the number of accommodated particles, namely $l_1+l_2+\cdots+l_n\ll p$. In this approximation one obtains

$$B(p)_i^-|p;l_1,\ldots,l_{i-1},l_i,l_{i+1},\ldots,l_n\rangle \simeq \sqrt{l_i}|p;l_1,\ldots,l_{i-1},l_i-1,l_{i+1},\ldots,l_n\rangle,$$
$$B(p)_i^+|p;l_1,\ldots,l_{i-1},l_i,l_{i+1},\ldots,l_n\rangle \simeq \sqrt{l_i+1}|p;l_1,\ldots,l_{i-1},l_i+1,l_{i+1}\ldots,l_n\rangle, \tag{5.4}$$

which yields (an approximation to) the Bose commutation relations:

$$[B(p)_i^+,B(p)_j^+]=[B(p)_i^-,B(p)_j^-]=0 \quad \text{(exact commutators)}, \tag{5.5}$$

$$[B(p)_i^-,B(p)_j^+]\simeq \delta_{ij} \quad \text{if } l_1+l_2+\cdots+l_n \ll p. \tag{5.6}$$

Since for $l_1+l_2+\cdots+l_n\equiv\Sigma_k l_k \ll p$,

$$\frac{(p-\Sigma_k l_k)!}{p!}p^{\Sigma_k l_k}=\frac{p}{p-\Sigma_k l_k+1}\frac{p}{p-\Sigma_k l_k+2}\cdots\frac{p}{p}\simeq 1,$$

in a first approximation (3.18) reduces also to the well-known expressions for the orthonormed basis in a Fock space of n pairs of Bose creation and annihilation operators:

$$|p;l_1,\ldots,l_n\rangle=\frac{(B(p)_1^+)^{l_1}\cdots(B(p)_n^+)^{l_n}}{\sqrt{l_1!l_2!\cdots l_n!}}|0\rangle. \tag{5.7}$$

The conclusion is that the representations of $B(p)_i^{\pm}$ in (finite-dimensional) state spaces W_p with large values of p, restricted to states with a small amount $l_1+l_2+\cdots+l_n \ll p$ of accommodated particles, provide a good approximation to Bose creation and annihilation operators.[42,45] For this reason we refer to the operators $B(p)_i^{\pm}$ as *quasi-Bose creation and annihilation operators (of order p)* and to the corresponding particles as quasibosons.

In the remaining part of this section we will prove that in the limit $p\to\infty$ the quasi-Bose operators reduce to Bose creation and annihilation operators. To this end we proceed to introduce first an appropriate topology.

Let W be a Hilbert space with an orthonormed basis

$$|l_1,\ldots,l_i,\ldots,l_n\rangle\equiv|L\rangle, \quad \forall l_1,\ldots,l_n\in\mathbb{Z}_+. \tag{5.8}$$

Whenever possible we write $|L\rangle$ as an abbreviation for $|l_1,\ldots,l_i,\ldots,l_n\rangle$ and denote by $|L\rangle_{\pm i}$ a vector obtained from $|L\rangle$ by replacing l_i with $l_i\pm 1$, namely

$$|L\rangle_{\pm i}=|l_1,\ldots,l_{i-1},l_i\pm 1,l_{i+1},\ldots,l_n\rangle. \tag{5.9}$$

The space W consists of all vectors

$$\Phi=\sum_{l_1=0}^{\infty}\cdots\sum_{l_n=0}^{\infty}c(l_1,\ldots,l_n)|l_1,\ldots,l_n\rangle\equiv\sum_L c(L)|L\rangle, \tag{5.10}$$

where $c(l_1,\ldots,l_n)\equiv c(L)$ are complex numbers such that

$$\sum_{l_1=0}^{\infty}\cdots\sum_{l_n=0}^{\infty}|c(l_1,\ldots,l_n)|^2\equiv\sum_{l_1,\ldots,l_n=0}^{\infty}|c(l_1,\ldots,l_n)|^2\equiv\sum_L|c(L)|^2<\infty, \tag{5.11}$$

and this is in fact the square of the Hilbert space norm $(|\Phi|_0)^2$ of Φ.

Embed the $sl(n+1)$-module W_p in W via an identification of the basis vectors

$$|p;l_1,\ldots,l_i,\ldots,l_n\rangle\equiv|l_1,\ldots,l_i,\ldots,l_n\rangle\equiv|L\rangle, \quad \forall l_1+\cdots+l_n\leqslant p. \tag{5.12}$$

In order to turn the entire space W into an $sl(n+1)$-module, so that the restriction on $W_p \subset W$ coincides with (5.2) and (5.3), we set

$$B(p)_i^+ \Phi = \sum_{l_1+\cdots+l_n \leqslant p} c(L) \sqrt{(l_i+1)\left(1-\frac{\Sigma_{k=1}^n l_k}{p}\right)}|L\rangle_i, \tag{5.13}$$

$$B(p)_i^- \Phi = \sum_{l_1+\cdots+l_n \leqslant p} c(L) \sqrt{l_i\left(1+\frac{1-\Sigma_{k=1}^n l_k}{p}\right)}|L\rangle_{-i}, \tag{5.14}$$

where Φ is any vector (5.10) from W and $\Sigma_{l_1+\cdots+l_n \leqslant p}$ is a sum over all possible $l_1,\ldots,l_n \in \mathbb{Z}_+$ such that $l_1+\cdots+l_n \leqslant p$. Note that the sums in (5.13) and (5.14) are finite.

The transformation of the basis, following from (5.13) to (5.14), reads

$$B(p)_i^+ |L\rangle = \sqrt{(l_i+1)\left(1-\frac{\Sigma_{k=1}^n l_k}{p}\right)}|L\rangle_i, \quad \forall L \text{ such that } \sum_{k=1}^n l_k \leqslant p, \tag{5.15}$$

$$B(p)_i^- |L\rangle = \sqrt{l_i\left(1+\frac{1-\Sigma_{k=1}^n l_k}{p}\right)}|L\rangle_{-i}, \quad \forall L \text{ such that } \sum_{k=1}^n l_k \leqslant p, \tag{5.16}$$

$$B(p)_i^{\pm}|L\rangle = 0, \quad \forall L \text{ such that } \sum_{k=1}^n l_k > p. \tag{5.17}$$

Relations (5.15) and (5.16) are the same as (5.2) and (5.3) [via the identification (5.12)].

Since the quasi-Bose operators $B(p)_i^{\pm}$ take values in a finite-dimensional subspace of W, see (5.13) and (5.14), they are bounded and hence continuous linear operators in W. In view of this see (5.10), $B(p)_i^{\pm}\Phi = B(p)_i^{\pm}\Sigma_L c(L)|L\rangle = \Sigma_L c(L) B(p)_i^{\pm}|L\rangle$ and therefore (5.13) and (5.14) are a consequence of (5.15)–(5.17).

Next we proceed to define n pairs of Bose operators $B_i^{\pm}$, $i=1,\ldots,n$, in W. It is known that such operators cannot be realized as bounded operators in W (so that the corresponding position and momentum operators are selfadjoint operators in W; see, for instance, Ref. 63 or 64). Therefore care has to be taken about the common domain of definition Ω of the Bose operators. Following Ref. 65 we set Ω to be a dense subspace of W (with respect to the Hilbert space topology), consisting of all vectors (5.10) for which the series

$$(|\Phi|_r)^2 = \sum_{l_1,\ldots,l_n=0}^{\infty} \left(1+\sum_{k=1}^n l_k\right)^r |c(l_1,\ldots,l_n)|^2 \tag{5.18}$$

is convergent for any $r=0,1,2,\ldots$. Then the relations

$$B_i^-|L\rangle = \sqrt{l_i}|L\rangle_{-i}, \quad B_i^+|L\rangle = \sqrt{l_i+1}|L\rangle_i, \tag{5.19}$$

define a representation of n pairs of bosons $B_1^{\pm},\ldots,B_n^{\pm}$, namely of operators, which satisfy the relations

$$[B_i^-, B_j^+] = \delta_{ij}, \quad [B_i^+, B_j^+] = [B_i^-, B_j^-] = 0, \quad i,j=1,\ldots,n \tag{5.20}$$

in Ω (with Ω being a common domain of definition for all them). In terms of these operators

$$(|\Phi|_r)^2 = \left(\Phi, \left(1+\sum_{k=1}^n B_k^+ B_k^-\right)^r \Phi\right). \tag{5.21}$$

The norms $|\Phi|_r$, $r=0,1,2,\ldots$, turn Ω into a countably normed topological space (which can be viewed also as a metric space[66]). All balls

$$B(\Phi_0;r,\epsilon)=\{\Phi\in\Omega||\Phi-\Phi_0|_r<\epsilon\},\quad \forall\Phi_0\in\Omega,\quad \forall r\in\mathbb{Z}_+,\quad \forall\epsilon>0, \tag{5.22}$$

constitute a basis of open sets in the countably normed topological space Ω, whereas the balls (5.22) with a fixed r yield a basis in Ω, viewed as a $|\cdot|_r$-normed topological space. Clearly any $|\cdot|_r$-normed topology (*r-normed topology*) is weaker than the countably normed topology (*cn-topology*).

From now on we restrict the domain of definition of all quasi-Bose operators (5.1) to be Ω. The fact that each quasi-Bose operator maps Ω into a finite-dimensional subspace of Ω, see (5.13) and (5.14), indicates that each such operator is a bounded and hence a continuous linear operator with respect to the r-normed topology for any $r\in\mathbb{Z}_+$. A similar property however does not hold for the Bose creation and annihilation operators (5.19). These operators are not continuous with respect to any of the r-normed topologies in Ω. Therefore, if $\Sigma_{i=1}^{\infty}\Phi_i=\Phi$ converges in the sense of a certain r-normed topology, for instance in the Hilbert space topology ($r=0$), one cannot in general use relations like

$$B_i^{\pm}\sum_{i=1}^{\infty}\Phi_i=\sum_{i=1}^{\infty}B_i^{\pm}\Phi_i. \tag{5.23}$$

One of the advantages of the *cn*-topology is that it avoids the above-mentioned difficulties. Here are some of the properties of this topology, which will be relevant for the rest of the exposition:[65]

1. Ω is stable under the action of any polynomial of Bose operators,

$$P(B_1^{\pm},\ldots,B_n^{\pm})\Omega\subset\Omega. \tag{5.24}$$

2. Any polynomial of Bose CAOs is a continuous linear operator in Ω with respect to the *cn*-topology;

(5.25)

3. The scalar product in Ω is continuous with respect to the convergence defined by the *cn*-topology.

(5.26)

As a consequence, (5.23) holds for any series $\Sigma_{i=1}^{\infty}\Phi_i$ which converges in the *cn*-topology; moreover (5.26) yields $(\Sigma_{i=1}^{\infty}\Phi_i,\Psi)=\Sigma_{i=1}^{\infty}(\Phi_i,\Psi)$. The relevance of the *cn*-topology however goes far beyond the above-mentioned considerations. This topology, called nuclear topology, is of prime importance in the theory of generalized functions,[66,67] and their applications in quantum theory (see, for instance, Ref. 65).

Let $\mathcal{P}$ be the set of all linear operators in Ω defined everywhere in Ω, which are continuous in the *cn*-topology. With respect to the usual operations between operators $\mathcal{P}$ is an associative algebra.[66] According to (5.25) the Bose operators belong to $\mathcal{P}$. The quasi-Bose operators (5.1) (with domain of definition restricted to Ω) also belong to $\mathcal{P}$. Indeed $B(p)_i^{\pm}$ are bounded and hence continuous operators in Ω with respect to any r-normed topology. Let $B(\Phi_0;r,\epsilon)$ be an arbitrary open ball in the *cn*-topology; see (5.22). $B(\Phi_0;r,\epsilon)$ is an open ball also in the r-normed topology. Therefore the inverse image $O=[B(p)_i^{\pm}]^{-1}B(\Phi_0;r,\epsilon)$ of $B(\Phi_0;r,\epsilon)$ is an open set in the r-normed topology. Since the latter is weaker than the *cn*-topology, O is an open set also in the *cn*-topology. Thus, the inverse image $O=[B(p)_i^{\pm}]^{-1}B(\Phi_0;r,\epsilon)$ of any open ball (i.e., of any open set from the basis) in the *cn*-topology is an open set with respect to the same topology. Therefore $B(p)_i^{\pm}$ is a continuous operator in the *cn*-topology.

Introduce a topology on $\mathcal{P}$ in a way similar to the strong topology in the algebra $\mathcal{B}(\mathcal{H})$ of all bounded linear operators on a Hilbert space $\mathcal{H}$.[68] Let $\Phi_1,\ldots,\Phi_s$ be s different elements from Ω and ϵ be a positive number. A strong neighborhood $U(A_0;\Phi_1,\ldots,\Phi_s;\epsilon)$ of the operator $A_0\in\mathcal{P}$ is (defined as) the set of all operators $A\in\mathcal{P}$, which satisfy the inequalities

$$|(A-A_0)\Phi_k|_0<\epsilon, \quad \forall k=1,\ldots,s. \tag{5.27}$$

Definition 2: A strong topology on $\mathcal{P}$ is the topology with a basis of open sets consisting of all possible strong neighborhoods $U(A_0;\Phi_1,\ldots,\Phi_s;\epsilon)$ (namely the collection of strong neighborhoods, corresponding to any $A_0\in\mathcal{P}$, to any $\epsilon>0$, to any $s\in\mathbb{N}$, and to any sequence $\Phi_1,\ldots,\Phi_s$ of different elements from Ω).

Proposition 4: In the strong topology

$$\lim_{p\to\infty} B(p)_i^{\pm}=B_i^{\pm}, \quad i=1,\ldots,n. \tag{5.28}$$

Proof: In order to prove that (5.28) holds it is sufficient to show that every strong neighborhood $U(B_i^{\pm};\Phi_1,\ldots,\Phi_s;\epsilon)$ of $B_i^{\pm}$ contains all elements of the sequence $B(1)_i^{\pm},B(2)_i^{\pm},\ldots$ apart from a finite number of them. Since $U(B_i^{\pm};\Phi_1,\ldots,\Phi_s;\epsilon)=\cap_{k=1}^{s}U(B_i^{\pm};\Phi_k;\epsilon)$, it is sufficient to show that for any neighborhood $U(B_i^{\pm};\Phi;\epsilon)$ there exists an integer N such that $B(p)_i^{\pm}\in U(B_i^{\pm};\Phi;\epsilon)$ for any $p>N$ or, which is the same, see (5.27), that

$$|(B(p)_i^{\pm}-B_i^{\pm})\Phi|_0<\epsilon, \quad \forall p>N. \tag{5.29}$$

Equation (5.29) has to hold for any Φ and any ϵ. In general N depends on Φ and ϵ, $N=N(\Phi,\epsilon)$.

The fact that $B_i^{+}-B(p)_i^{+}$ is a continuous linear operator in Ω is essential since relations like (5.23) can be used. The latter together with (5.13)–(5.14) and (5.19) yields

$$(B_i^{+}-B(p)_i^{+})\Phi=\sum_{l_1+\cdots+l_n<p} c(L)\left(\sqrt{l_i+1}\left(1-\sqrt{1-\frac{\Sigma_k l_k}{p}}\right)|L\rangle_i+\sum_{l_1+\cdots+l_n\geqslant p} c(L)(\sqrt{l_i+1}|L\rangle_i\right). \tag{5.30}$$

The continuity of the scalar product with respect to the cn-topology and the fact that all terms on the right-hand side of (5.30) are orthogonal to each other yield

$$(|(B_i^{+}-B(p)_i^{+})\Phi|_0)^2=\sum_{l_1+\cdots+l_n<p}|c(L)|^2(l_i+1)\left(1-\sqrt{1-\frac{\Sigma_k l_k}{p}}\right)^2$$

$$+\sum_{l_1+\cdots+l_n\geqslant p}|c(L)|^2(l_i+1).$$

Let $\epsilon>0$. Select $p_0\in\mathbb{N}$ to be fixed. For any $p>p_0$,

$$\begin{aligned}(|(B_i^{+}-B(p)_i^{+})\Phi|_0)^2&=\sum_{l_1+\cdots+l_n\leqslant p_0}|c(L)|^2(l_i+1)\left(1-\sqrt{1-\frac{\Sigma_k l_k}{p}}\right)^2\\&+\sum_{p_0<l_1+\cdots+l_n<p}|c(L)|^2(l_i+1)\left(1-\sqrt{1-\frac{\Sigma_k l_k}{p}}\right)^2\\&+\sum_{l_1+\cdots+l_n\geqslant p}(1+l_i)|c(L)|^2\\&<\sum_{l_1+\cdots+l_n\leqslant p_0}|c(L)|^2(l_i+1)\left(1-\sqrt{1-\frac{\Sigma_k l_k}{p}}\right)^2\\&+\sum_{l_1+\cdots+l_n>p_0}(1+l_i)|c(L)|^2.\end{aligned} \tag{5.31}$$

Since the partial sums of $\Sigma_{l_1,\ldots,l_n=0}^{\infty}(1+l_i)|c(L)|^2$ constitute an increasing sequence of positive numbers, which is restricted from above, $\Sigma_{l_1,\ldots,l_n=0}^{\infty}(1+l_i)|c(L)|^2 \leqslant |\Phi|_1$, the series $\Sigma_{l_1,\ldots,l_n=0}^{\infty}(1+l_i)|c(L)|^2$ converges. Choose p_0 such that $\Sigma_{l_1+\cdots+l_n>p_0}(1+l_i)|c(L)|^2<\epsilon^2/2$. Then for any $p>p_0$,

$$
\begin{aligned}
(|(B_i^+ - B(p)_i^+)\Phi|_0)^2 &< \sum_{l_1+\cdots+l_n\leqslant p_0} |c(L)|^2(l_i+1)\left(1-\sqrt{1-\frac{\Sigma_k l_k}{p}}\right)^2+\frac{\epsilon^2}{2}\\
&< \sum_{l_1+\cdots+l_n\leqslant p_0} |c(L)|^2(l_i+1)\left(1-\sqrt{1-\frac{p_0}{p}}\right)^2+\frac{\epsilon^2}{2}\\
&< d\left(1-\sqrt{1-\frac{p_0}{p}}\right)^2+\frac{\epsilon^2}{2}, \qquad (5.32)
\end{aligned}
$$

where $d=\Sigma_{l_1+\cdots+l_n\leqslant p_0}|c(L)|^2(l_i+1)$ is a constant. Clearly there exists $N\in\mathbb{N}$ such that $d(1-\sqrt{1-p_0/p})^2<\epsilon^2/2$ for any $p>N$. Hence for every $\epsilon>0$ there exists a positive integer N such that $|(B_i^+ - B(p)_i^+)\Phi|_0<\epsilon$, $\forall p>N$, i.e., (5.29) holds.

In a similar way one proves that $\lim_{p\to\infty} B(p)_i^- = B_i^-$. This completes the proof. □

VI. BOSONIZATION OF *A*-STATISTICS

A simple comparison of (3.19)–(3.20) with (5.19) suggests that the Jacobson CAOs of any order p can be bosonized, namely that they can be expressed as functions of Bose CAOs $B_1^{\pm},\ldots,B_n^{\pm}$; see (5.20). Indeed, taking into account that $B_i^+B_i^-\equiv N_i$ is a number operator for bosons in a state i,

$$
N_i|L\rangle \equiv N_i|l_1,\ldots,l_i,\ldots,l_n\rangle = l_i|l_1,\ldots,l_i,\ldots,l_n\rangle, \quad i=1,\ldots,n, \qquad (6.1)
$$

one rewrites (3.19) as

$$
a_i^+|L\rangle = \sqrt{(l_i+1)\left(p-\sum_{k=1}^{n} N_k+1\right)}|L\rangle_i .
$$

In view of (5.19) the latter can also be represented as

$$
a_i^+|L\rangle = \sqrt{p+1-\sum_{k=1}^{n} N_k}\; B_i^+|L\rangle = B_i^+\sqrt{p-\sum_{k=1}^{n} B_k^+B_k^-}|L\rangle. \qquad (6.2)
$$

Since (6.2) holds for any $|L\rangle$,

$$
a_i^+ = B_i^+\sqrt{p-\sum_{k=1}^{n} B_k^+B_k^-}, \quad i=1,\ldots,n. \qquad (6.3)
$$

In a similar way one derives from (3.20):

$$
a_i^- = \sqrt{p-\sum_{k=1}^{n} B_k^+B_k^-}\; B_i^- , \quad i=1,\ldots,n. \qquad (6.4)
$$

Evidently also, see (3.21),

$$
h_0 = p-\sum_{k=1}^{n} B_k^+B_k^- . \qquad (6.5)
$$

Note that the entire Fock space W is reducible with respect to the Jacobson CAOs. Its finite-dimensional "physical" subspace W_p, see (5.12), is a simple (=irreducible) $gl(n+1)$-module and within this module $(a_i^+)^*=a_i^-$ holds.

After simple calculations and taking into account that $a_i^+=e_{i0}$, $a_i^-=e_{0i}$, $i=1,\ldots,n$, see (2.3), one can express all generators $\{e_{ij}|i,j=0,1,\ldots,n\}$ of $gl(n+1)$ via n pairs of Bose operators:

$$e_{ij}=B_i^+B_j^-, \quad i,j=1,\ldots,n, \tag{6.6a}$$

$$e_{i0}=B_i^+\sqrt{p-\sum_{k=1}^{n}B_k^+B_k^-}, \quad e_{0i}=\sqrt{p-\sum_{k=1}^{n}B_k^+B_k^-}\;B_i^-, \quad i=1,\ldots,n, \tag{6.6b}$$

$$e_{00}=p-\sum_{k=1}^{n}B_k^+B_k^-, \tag{6.6c}$$

where, we recall, p is any positive integer, $p\in\mathbb{N}$.

The above-presented bosonization of $gl(n+1)$ is not unknown. Up to a choice of notation it is the same as the so-called Holstein–Primakoff (HP) realization of $gl(n+1)$,[47] initially introduced for $sl(2)$.[69,70] Note that (6.6a) alone gives the known Jordan–Schwinger realization of $gl(n)$ via n pairs of Bose operators.

VII. QUASI-BOSE OPERATORS IN SPIN MODELS

In the present section we show that the Jacobson CAOs are implicitly present in various models. We demonstrate this on the example of a two-leg $S=1/2$ Heisenberg spin ladder.[48,49] The considerations in the following hold however for several other Heisenberg spin models (examples include lattice models with dimerization,[71–73] two-layer Heisenberg models[74–76]) and more generally for any hard-core Bose model[50] with degenerated orbitals per site (as for instance in Refs. 77 and 78).

The Hamiltonian of the model reads:

$$\hat{H}=\sum_i\,(J\hat{\mathbf{S}}_i^+\hat{\mathbf{S}}_{i+1}^++J\hat{\mathbf{S}}_i^-\hat{\mathbf{S}}_{i+1}^-+J_\perp\hat{\mathbf{S}}_i^+\hat{\mathbf{S}}_i^-). \tag{7.1}$$

Here $\hat{\mathbf{S}}_i^\pm\equiv(\hat{S}_{1i}^\pm,\hat{S}_{2i}^\pm,\hat{S}_{3i}^\pm)$ are two commuting spin-1/2 vector operators "sitting" on site i of the chain $\pm$ and the Hamiltonian is a scalar with respect to the total spin operator $\hat{\mathbf{S}}=\Sigma_i(\hat{\mathbf{S}}_i^++\hat{\mathbf{S}}_i^-)$:

$$[\hat{S}_{\alpha i}^\pm,\hat{S}_{\beta i}^\pm]=i\sum_\gamma\,\epsilon_{\alpha\beta\gamma}\hat{S}_{\gamma i}^\pm, \quad [\hat{S}_{\alpha i}^+,\hat{S}_{\beta j}^-]=0, \quad [\hat{H},\hat{\mathbf{S}}]=0. \tag{7.2}$$

Every local state space W_i related to site i is four-dimensional with a basis $|\uparrow,\uparrow\rangle$, $|\uparrow,\downarrow\rangle$, $|\downarrow,\uparrow\rangle$, $|\downarrow,\downarrow\rangle$ and $W=W_1\otimes W_2\otimes\cdots\otimes W_N$ is the global state space of the system (in the case of a ladder with N sites). The notation is standard: if A is any operator in W_i, then the operator corresponding to it in W is denoted as A_i, where $A_i\equiv id_1\otimes\ldots\otimes id_{i-1}\otimes A\otimes id_{i+1}\otimes\ldots\otimes id_N$.

If the system is in a disordered phase ($J_\perp\gg J$) its state is well described with the bond operator representation of spin operators,[71,79] which is a particular kind of bosonization:

$$\hat{S}_{\alpha i}^\pm=\tfrac{1}{2}(\pm B_{\alpha i}^-\pm B_{\alpha i}^+-i\epsilon_{\alpha\beta\gamma}B_{\beta i}^+B_{\gamma i}^-), \quad \alpha,\beta,\gamma=1,2,3. \tag{7.3}$$

Here $B_{1i}^\pm$, $B_{2i}^\pm$, $B_{3i}^\pm$ are three pairs of Bose CAOs related to site i and the vectors $|0\rangle_i$, $B_{1i}^+|0\rangle_i$, $B_{2i}^+|0\rangle_i$, $B_{3i}^+|0\rangle_i$ constitute another basis in W_i.

The treatment of the model in terms of bosonic operators is advantageous because of the simpler commutation rules of Bose statistics. However, it raises certain problems. As mentioned previously, any local state space W_i is four-dimensional, whereas the local Bose Fock space Φ_i is

infinite-dimensional. Moreover W_i is not invariant in Φ_i with respect to the Bose CAOs [and, as a result, with respect to the local spin operators (7.3)]. The physical state space W is not an invariant subspace of the global Fock space $\Phi=\Phi_1\otimes\Phi_2\otimes\cdots\otimes\Phi_N$ with respect to the Hamiltonian (7.1).

Various approaches have been proposed in order to overcome the problem. Following Ref. 71, additional scalar bosons $s_i^{\pm}$ were introduced in Ref. 48. Then the physical states are those which satisfy an additional constraint $s_i^+ s_i+\Sigma_\alpha B_{i\alpha}^+ B_{i\alpha}=1$. Another way is to keep the realization (7.3) but to introduce "by hands" a fictitious infinite on-site repulsion between the "bosons" [75] (first proposed in Ref. 50 for a nondegenerate case). This forbids configurations with two or more bosons accommodated on one and the same site. The latter leads to the "hard-core" condition $B_{\alpha i}^{\pm} B_{\beta i}^{\pm}=0$, i.e., the hard-core bosons are not quite bosons, since they satisfy fermionic-like conditions.

A third approach was worked out in Ref. 79 (see also Refs. 72–74). It proposes the Bose operators $B_{\alpha i}^{\pm}$ in (7.3) to be replaced throughout by new operators $b_{\alpha i}^{\pm}$ as follows:

$$B_{\alpha i}^+\to b_{\alpha i}^+=B_{\alpha i}^+\sqrt{1-\sum_{\beta=1}^{3} B_{\beta i}^+ B_{\beta i}^-},\quad B_{\alpha i}^-\to b_{\alpha i}^-=\sqrt{1-\sum_{\beta=1}^{3} B_{\beta i}^+ B_{\beta i}^-}\; B_{\alpha i}^-. \tag{7.4}$$

A simple comparison with (6.3) and (6.4) indicates the following.

1. The Bose operators related to site i, i.e., $B_{1i}^{\pm}$, $B_{2i}^{\pm}$, $B_{3i}^{\pm}$, are replaced by $p=1$ Jacobson CAOs (or, which is the same, by $p=1$ quasi-Bose operators),

$$B(1)_{\alpha i}^{\pm}\equiv b_{\alpha i}^{\pm},\quad \alpha=1,2,3, \tag{7.5}$$

in their Holstein–Primakov realization. Consequently (Proposition 3) the hard-core condition $b_{\alpha i}^+ b_{\beta i}^+=0$ holds.

2. The Jacobson CAOs from different sites commute:

$$[b_{\alpha i}^{\xi}, b_{\beta j}^{\eta}]=0 \quad \text{if } i\neq j \text{ for any } \xi,\eta=\pm \text{ and } \alpha,\beta=1,2,3. \tag{7.6}$$

It is essential that the substitution (7.4) does not change the commutation relations (7.2) between the new spin operators

$$S_{\alpha i}^{\pm}=\tfrac{1}{2}(\pm b_{\alpha i}^-\pm b_{\alpha i}^+-i\epsilon_{\alpha\beta\gamma} b_{\beta i}^+ b_{\gamma i}^-),\quad \alpha,\beta,\gamma=1,2,3, \tag{7.7}$$

and the corresponding new Hamiltonian

$$H=\sum_i (J\mathbf{S}_i^+\mathbf{S}_{i+1}^+ + J\mathbf{S}_i^-\mathbf{S}_{i+1}^- + J_\perp \mathbf{S}_i^+\mathbf{S}_i^-). \tag{7.8}$$

Moreover each local state space W_i is an invariant subspace of Φ_i with respect to the Jacobson CAOs and hence with respect to any function of them [in particular with respect to the spin operators (7.7)]. The Hamiltonian (7.8) is also a well-defined operator in W.

The conclusion is that replacing the Bose operators throughout the model with $p=1$ Jacobson CAOs $b_{\alpha i}^{\pm}$, which commute at different sites [see (7.6)], one obtains directly the physical state space and the correct expressions for the spin operators and the Hamiltonian.

Let us point out that the above-mentioned results can be also derived from the following proposition, which is of independent interest.

Proposition 5: Let $B_\alpha^{\pm}$, $\alpha=1,\ldots,n$, be n pairs of Bose CAOs with a Fock space $\mathcal{F}$ and a basis (5.8). Denote by $\mathcal{F}_1$ the subspace of $\mathcal{F}$ linearly spanned on the vacuum and all "single-particle" states,

$$\mathcal{F}_1=\mathrm{span}\{|l_1,\ldots,l_n\rangle | l_1+\cdots+l_n\leq 1\}. \tag{7.9}$$

Let $\mathcal{P}$ be a projection operator of $\mathcal{F}$ onto $\mathcal{F}_1$:

$$\mathcal{P}|l_1,\ldots,l_n\rangle=\begin{cases}|l_1,\ldots,l_n\rangle & if\ \ l_1+\cdots+l_n\leqslant 1\\ 0 & if\ \ l_1+\cdots+l_n>1.\end{cases} \tag{7.10}$$

Then the operators $\mathcal{P}B_\alpha^\pm\mathcal{P}$, $\alpha=1,\ldots,n$, considered as operators in $\mathcal{F}_1$, are $p=1$ Jacobson CAOs,

$$\mathcal{P}B_\alpha^\pm\mathcal{P}=B(1)_\alpha^\pm\equiv b_\alpha^\pm,\quad \alpha=1,\ldots,n. \tag{7.11}$$

Proof: One verifies directly that (2.5) and (3.24) hold. □

Coming back to the two-leg spin ladder model, introduce a projection operator $\mathcal{P}_w=\mathcal{P}_1\otimes\mathcal{P}_2\otimes\cdots\otimes\mathcal{P}_N$ of Φ onto W, where each $\mathcal{P}_i$ projects Φ_i onto W_i according to (7.10) with $n=3$. The projector $\mathcal{P}_w$ provides an alternative way for writing down the expressions for the spin operators (7.7) and the Hamiltonian (7.8). Instead of using the substitution (7.4), one can set:

$$H=\mathcal{P}_w\hat{H}\mathcal{P}_w,\quad S_{\alpha i}^\pm=\mathcal{P}_i\hat{S}_{\alpha i}^\pm\mathcal{P}_i,\quad i=1,\ldots,N. \tag{7.12}$$

The operator $\mathcal{P}_w$ is a Bose analog of the Gutzwiller projection operators,[80] extensively used in the t-J models in order to exclude the double occupation of fermions at each site (see, for instance, Ref. 81 where a similar problem, a t-J two-leg ladder is investigated).

VIII. CONCLUDING REMARKS

From a mathematical point of view the JGs $a_1^\pm,\ldots,a_n^\pm$ provide a new description of the Lie algebra $sl(n+1)$ in terms of generators and relations (2.5), based on the concept of Lie triple systems. For the same reason any n pairs of parafermions (respectively, parabosons) can be called Jacobson generators of the orthogonal Lie algebra $so(2n+1)$ [respectively, of the orthosymplectic Lie superalgebra $osp(1/2n)$]. The JGs provide an alternative to the Chevalley descriptions of these Lie (super)algebras.

From a physical point of view the interest in the JGs of $sl(n+1)$ stems from the observation that they indicate the possible existence of a new quantum statistics. Indeed, we have seen that within each Fock space W_p the operator a_i^+ (respectively, a_i^-) can be interpreted as an operator creating (respectively, annihilating) a particle in a state i (in particular with an energy ϵ_i).

In many respects the quasibosons behave as bosons. Similar to bosons, the quasibosons can be distributed along the orbitals in an arbitrary way as far as the number of accommodated particles M does not exceed p. The number of different states of $M\leqslant p$ quasibosons is the same as for bosons (the M-particle subspaces of quasibosons and bosons have one and the same dimension). There is however one essential difference: quasiboson systems of order p can accommodate at most p particles.

In order to use a proper Lie algebraic language we have restricted our consideration to finite-dimensional Lie algebras. In other words, we were studying systems with a finite number n of orbitals. Such systems certainly do exist. Examples are the local state spaces of spin systems (in particular the example considered in Sec. VII), $su(n)$ lattice models, etc. Nevertheless it is natural to ask whether A-statistics can be extended to incorporate infinitely many orbitals as this is usual in quantum theory. The answer to this question is positive and it is in fact evident from the results we have obtained so far. First of all the description of $sl(n+1)$ via generators (2.3) and relations (2.5) is well defined for $i,j,k\in\mathbb{Z}_+$, namely for $sl(\infty)=\mathrm{span}\{e_{ij}-\delta_{ij}e_{00}|i,j\in\mathbb{Z}_+\}$ [an equivalent definition is to say that $sl(\infty)$ is the algebra of all traceless infinite (in one direction) matrices containing no more than a finite number of nonzero entries]. Second, any Fock module W_p as given in Corollary 2 and in particular Eq. (3.9) are also well defined for $i,j,k\in\mathbb{N}$. In this case any W_p is an irreducible $sl(\infty)$ module, generated out of the vacuum by means of the Jacobson creation operators. Therefore each state $|p;l_1,\ldots,l_i,\ldots\rangle$ contains no more than a finite number of nonzero entries l_i. Moreover due to Proposition 3 the physical state space is a linear span of all vectors $|p;l_1,\ldots,l_i,\ldots\rangle$ with

$$\sum_{i=1}^{\infty} l_i \leqslant p. \tag{8.1}$$

All such states constitute an (orthonormal) basis in W_p. They transform according to the same relations (3.19) and (3.20) with $n=\infty$. It is straightforward to verify that any $sl(\infty)$ module W_p is a Fock space in the sense of Definition 1. Finally, the Pauli principle (Corollary 3) remains valid also for $n=\infty$: despite the infinitely many available orbitals, the infinitely many places to be occupied by the quasibosons, the system cannot accommodate more than p particles. [For an overview of commonly recognized definitions of $gl(\infty)$, see Ref. 82, where in particular several types of infinite dimensional Lie superalgebras of type gl are studied.]

We should point out that within A-statistics the main quantization equation (2.6) does not determine uniquely the creation and annihilation operators. The Jacobson generators (2.3) yield one possible solution of (2.6). For another possible choice (a causal A-statistics), we refer to Ref. 83.

The quasi-Bose operators $B(p)_1^{\pm},\ldots,B(p)_n^{\pm}$, introduced in Sec. V can be used as an approximation to Bose statistics for values of the order of statistics p, which is much bigger than the number of accommodated particles. An additional advantage of the quasi-Bose CAOs of any order p is that they are bounded linear operators, defined everywhere in the Fock space W_p. This property avoids the rather delicate questions of whether the operators under consideration can be defined on a common domain of definition Ω, so that any polynomial of them is also well defined in Ω.

The "opposite" to $p\to\infty$ case, namely the $p=1$ Jacobson CAOs (or, which is the same, the $p=1$ quasi-Bose operators) turns out to appear implicitly in various models simply because the hard-core bosons are $p=1$ quasibosons. We have illustrated this on a particular example from condensed matter physics. This observation does not lead to immediate new results as far as hard-core Bose models are concerned. Even so, we believe that the clarification of the hidden quasiboson structure of these models is of some interest. If, for instance, the Hamiltonian is written explicitly via quasibosons, then the model is representation independent. Considering instead of the hard-core bosons quasibosons with order of statistics $p=M$, one is led to a model where each site can accommodate up to M particles.

For applications of quasiboson representations in nuclear theory we refer to Ref. 60. As indicated there, the $p=1$ quasi-Bose operators reduce to Klein–Marshalek algebras,[84] which are extensively used in nuclear physics.

One way to enlarge the class of statistics studied here is to deform the relations (2.5) or, which is the same, to deform $sl(n+1)$ so that the main quantization equation (2.6) remains unaltered. The possibility for such deformations stems from the observation that the commutation relations between the Cartan elements [the Hamiltonian is a Cartan element; see (2.17)] and the root vectors [the Jacobson generators are root vectors; see (2.4)] remain unaltered upon quantum deformations (q-deformations). Therefore the problem actually is to express the known q-deformations of $sl(n+1)$ via deformed Jacobson generators. This is the first step. The second step will be to define the Fock representations and to write down the deformed analog of (3.19) and (3.20). Partial results in this respect were already announced.[85,86]

Erratum: "Euclidean Friedman–Robertson–Walker cosmology in Brans–Dicke-like theories of gravity" [J. Math. Phys. 43, 1487 (2002)]

Bertrand Chauvineau
UMR 6162 (ILGA), Observatoire de la Côte d'Azur, Avenue Copernic, 06130 Grasse, France

(Received 29 March 2002; accepted for publication 12 April 2002)

[DOI: 10.1063/1.1485116]

In a recent paper, I have studied the cosmological model in Brans–Dicke gravity, in the matter dominated area.[1] The set of equations considered in the paper, and often considered in papers dealing with this problem, is the equation BD(0,0), obtained replacing the indices i and j by zero in the Brans–Dicke equation,[2] the scalar field equation BD(Φ), and the conservation equation BD(C). BD(C) writes $\rho a^3 = Cste$ in the problem under consideration. The conservation equation BD(C) is a consequence of the full set of cosmological equations. This full set is BD(0,0), BD(1,1) and BD(Φ). BD(1,1) is obtained replacing the indices i and j by one in the Brans–Dicke equation, which gives

$$2\frac{\ddot{a}}{a}+\left(\frac{\dot{a}}{a}\right)^2+\frac{\omega}{2}\left(\frac{\dot{\Phi}}{\Phi}\right)^2+2\frac{\dot{a}}{a}\frac{\dot{\Phi}}{\Phi}+\frac{\ddot{\Phi}}{\Phi}=0.$$

The solutions of the system [BD(0,0), BD(Φ), BD(C)], studied in the paper, are

(a) a set $S_1(A,P)$, depending on two arbitrary constants, for $\omega > -3/2$; these solutions are referenced (13) and (14) in the paper;[1]
(b) a set $S_2(A,P)$, depending on two arbitrary constants, for $\omega < -3/2$; these solutions are referenced (19) and (20) in the paper;[1]
(c) a set $S_3(A)$, depending on one arbitrary constant, for $\omega < -3/2$; these solutions are referenced (9) and (10) in the paper.[1]

By inserting these solutions in the field equation BD(1,1), it turns out that this equation is not verified by $S_3(A)$ (while it is by both $S_1(A,P)$ and $S_2(A,P)$). $S_3(A)$ is then not a set of solutions of the full set of Brans–Dicke cosmological equations.

It could be worthwhile remarking that, while the system [BD(0,0), BD(Φ), BD(C)] is not strictly equivalent to the full system [BD(0,0), BD(1,1), BD(Φ)], it is equivalent up to a subset of solutions of zero measure. This is differs from what happens in general relativity, where there is strict equivalence between the two systems [EE(0,0), EE(1,1)] and [EE(0,0), EE(C)] (EE for Einstein equation) in the framework of Friedman–Robertson–Walker cosmology.

Symmetry breaking regime in the nonlinear Hartree equation

W. H. Aschbacher,[a] J. Fröhlich,[b] G. M. Graf,[c] K. Schnee,[d] and M. Troyer[e]
Theoretische Physik, ETH-Hönggerberg, CH-8093 Zürich, Switzerland

(Received 22 August 2001; accepted for publication 18 April 2002)

The present article is concerned with minimizers of the *attractive* Hartree energy functional $\mathcal{H}_g[\overline{\psi},\psi]=\frac{1}{2}\|\nabla\psi\|_2^2+(\psi,v\psi)_2+g(\psi,V*|\psi|^2\psi)_2$ on $\mathbb{R}^d$, $d\geqslant 2$, for a general class of external potentials v and two-body interactions V of positive type, with $g<0$. We prove spontaneous symmetry breaking in the large coupling limit. A numerical investigation visualizes this regime in the example of an external double well potential. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1488673]

I. INTRODUCTION

In this article we investigate the problem of *uniqueness* of minimizers of the Hartree energy functional

$$\mathcal{H}_g[\overline{\psi},\psi]:=\tfrac{1}{2}\|\nabla\psi\|_2^2+(\psi,v\psi)_2+g\,(\psi,V*|\psi|^2\psi)_2 \tag{1}$$

in an external potential v, for *attractive* two-body interaction gV, V of positive type (e.g., the Coulomb potential),

$$g<0. \tag{2}$$

The main results of this article are described in Theorems 1 and 2 in the next section: we prove that, for *small* couplings, there exists one and only one minimizer of the Hartree functional (1), whereas, for *large* enough couplings, minimizers of (1) are *not* unique!

The *existence* of minimizers of (1) is assured by the following well known facts: minimizers exist for all $g<0$, as soon as $|g|$ exceeds some critical value $g_*\geqslant 0$, $|g|\geqslant g_*$ (for vanishing v, or for a nonzero v); the existence of a g_* follows from standard arguments in the calculus of variations, whereas the size of g_* can be determined with the help of Birman–Schwinger theory of binding in quantum mechanics. For $v=0$, it implies that, in $d=1,2$ dimensions, the critical coupling vanishes, $g_*=0$. This also holds in $d\geqslant 3$ dimensions for *long range* two-body potentials V. For *short range* potentials V, the threshold is *strictly above zero*, $g_*>0$, for $d\geqslant 3$ (e.g., by the Cwikel–Lieb–Rozenblujm bound), cf. Ref. 1. In the case of a nonvanishing *confining* external potential, $v\neq 0$, a minimizer *always* exists (i.e., for all $g\geqslant g_*=0$). Nevertheless, there is a new *strictly positive* critical coupling, g_v, say, which relates the length scale, Δ_H, set by a minimizer to the length scale, Δ_v, of the external potential by

$$\Delta_H\approx\Delta_v,\ \text{for}\ |g|<g_v,\quad \Delta_H\ll\Delta_v,\ \text{for}\ |g|>g_v,$$

and Δ_H is *independent* of the external potential v.

[a]Electronic mail: aschbach@itp.phys.ethz.ch
[b]Electronic mail: juerg@itp.phys.ethz.ch
[c]Electronic mail: gmgraf@itp.phys.ethz.ch
[d]Electronic mail: schnee@itp.phys.ethz.ch
[e]Electronic mail: troyer@itp.phys.ethz.ch

We may compare the foregoing to the existence properties of minimizers of the following *local* functional (i.e., with $V=\delta$), called the *Gross–Pitaevskii functional*,

$$\mathcal{H}_g^{GP}[\overline{\psi},\psi] := \tfrac{1}{2}\|\nabla\psi\|_2^2 + g\,\|\psi\|_{p+1}^{p+1}, \quad p=3, \tag{3}$$

which does not possess any *global* minimizer for $g<0$: plugging the dilate wave function $\psi_\lambda(x) := \lambda^{d/2}\psi(\lambda x)$, $\lambda\in\mathbb{R}^+$, into (3), we arrive at

$$\mathcal{H}_g^{GP}[\overline{\psi_\lambda},\psi_\lambda] = \lambda^2\tfrac{1}{2}\|\nabla\psi\|_2^2 + g\,\lambda^{(d/2)(p-1)}\|\psi\|_{p+1}^{p+1}. \tag{4}$$

For *attractive* interaction, $g<0$, the scaled functional (4) diverges to $-\infty$ in the limit $\lambda\to\infty$ if $p>1+4/d$, in d dimensions. For $d\geqslant 3$ and $p=3$, this is the case [and (4) tends to $-\infty$ in the limit $\lambda\to\infty$, for $d=2$, provided $|g|$ is sufficiently large]!

One of our *physical motivations* for the investigation of the Hartree functional (1) comes from a description of Bose–Einstein condensation (BEC) based on an analysis of the *weak coupling limit of large bosonic systems*, cf. Refs. 2–4. In the standard BEC scenario, where the interatomic force is *repulsive* and the mean interboson distance is much larger than the range of the two-body potential V, low-energy scattering theory implies that the Hartree nonlinearity may be assumed to be *local*, $V=\delta$. However, for the case of *attractive* interatomic forces, $g<0$, e.g., for lithium ($^7_3$Li, with scattering length -1.45×10^{-9} m, cf. Ref. 5), the system undergoes a collapse, as soon as the number of condensate atoms exceeds a critical value, cf. Refs. 6 and 7. Using a nonlocal two-body potential V provides a less coarse-grained resolution of the boson–boson interaction (compared to $V=\delta$).

We stress that for a system of bosonic atoms close to collapse *collision processes* become important, see, e.g., Ref. 8. Such processes (as well as interactions of electrons and nuclei with the radiation field) are *not* taken into account in a description of the system in terms of Hartree theory. Furthermore, if we neglect short range repulsive (soft core or hard core) interactions between the atoms, such that the two-body forces are *purely attractive*, we are dealing with a system that is *not thermodynamically stable*.

Nevertheless, in the *mean-field regime*, a dilute gas of bosonic atoms is well described by Hartree theory, and, remarkably, this theory continues to be meaningful, *mathematically*, as the collapse point of a system with attractive two-body forces is approached, and even beyond that point. It may thus be expected to reproduce *qualitatively* some features of *structure formation* in a gas of bosonic atoms with attractive two-body forces, such as $^7_3$Li. One may expect that Hartree theory also provides a qualitatively valuable description of bosonic dwarf stars if the two-body potential gV is chosen to be the Newtonian gravitational potential. These features of Hartree theory contrast with the limited applicability of the *local* Gross–Pitaevskii functional, which does not have global minimizers for *attractive* two-body interactions.

In this article, we modestly study some variational problems associated with the Hartree energy functional. Our main results are rigorous, mathematically. They are important as ingredients for studies of Hartree *dynamics*. But we do not address dynamical problems in this article.

It was kindly brought to our attention that similar topics have been investigated in Refs. 9–13.

II. SYMMETRY BREAKING REGIME AT FINITE COUPLING

In this section we will prove that for large enough negative coupling g the minimizer of the functional (1) will break very general symmetries possibly induced by the external potential v. For convenience, we will formulate this statement for $N=\|\psi\|_2^2$ instead of g, which without loss of generality will be set equal to -1. Theorem 1 will be worked out for the case where V is a Coulomb potential, but at the end of the proof we will briefly discuss other potentials.

Our main theorem is the following.

Theorem 1: *Let V be the Coulomb potential in $\mathbb{R}^d$, $V=|x|^{-1}$, and $v\in C_b(\mathbb{R}^d)$, $d\geqslant 2$. Let $E(d)$ be the Euclidean group in d dimensions.*

If for some $R\in E(d)$, any minimizing sequence $x_k\in\mathbb{R}^d$ for the external potential v,

$$\lim_{k\to\infty} v(x_k) = \inf_{x\in\mathbb{R}^d} v(x), \tag{5}$$

fulfills

$$\liminf_{k\to\infty} |Rx_k - x_k| > 0,$$

then, for sufficiently large N, any minimizer Φ of the Hartree functional (1) satisfies

$$|\Phi\circ R|^2 \neq |\Phi|^2.$$

Remark: If the infimum of v is attained on its set X of minimima only, i.e., if (5) implies $\lim_{k\to\infty} \mathrm{dist}(x_k, X) = 0$, then the hypothesis simply means $\inf\{|Rx_* - x_*| \,|\, x_* \in X\} > 0$.

Corollary 1 (symmetry breaking): If $v \in C_b(\mathbb{R}^d)$ has a symmetry $R \in E(d)$, then Theorem 1 predicts symmetry breaking in the sense that no ground state wave function Φ is invariant under R.

The formulation of Theorem 1 is quite general. For illustration we consider more closely the particular cases of (a) a nonvanishing external potential consisting in a double well which has as discrete symmetry respective to the reflection at the axis orthogonal to the line between its two separate minima, (b) the Mexican hat and (c) a periodic potential. Case (a) is considered also in view of our numerical simulations. Note that Theorem 1 is not restricted to discrete symmetries at all. The corollary now tells us that for sufficiently large coupling g the ground state Φ of the case considered will not have the symmetry properties of (a) the double well, (b) the Mexican hat, resp. (c) the periodic potential. In the cases (a) and (b) this means that Φ can be localized either in one or the other well, resp. part of the Mexican hat. We mention that for a single well potential the hypotheses of the theorem are not fulfilled for any R which is a symmetry of the potential.

Proof of Theorem 1: The proof of Theorem 1 will be done in three steps corresponding to Lemma 1, Lemma 2 and the proof of the theorem itself: The first step of our proof is to show that an approximate minimizer of the *free* energy functional (i.e., without external potential),

$$\mathcal{E}_g[\overline{\psi}, \psi] = \tfrac{1}{2}\|\nabla\psi\|_2^2 + g(\psi, V*|\psi|^2\psi)_2, \quad g<0, \tag{6}$$

will be concentrated in a ball in space whose size can be arranged by varying the size of N. This is stated somewhat more accurately in the following lemma. There the term *η-approximate minimizer* (of the *free* functional) is used: Let $\eta>0$. An *η-approximate minimizer* is defined as a wave function ψ that satisfies

$$\|\psi\|_2^2 = N, \quad \mathcal{E}_{-1}[\overline{\psi}, \psi] \leqslant (1-\eta)E_N, \quad E_N := E[N, -1],$$

where

$$E[N,g] := \inf\{\mathcal{E}_g[\overline{\psi}, \psi] \,|\, \psi \in W^{1,2}(\mathbb{R}^d), \|\psi\|_2^2 = N\}.$$

Lemma 1 (concentration of approximate minimizer): Given $\delta>0$, there is $\eta>0$ such that, for N large enough, any η-approximate minimizer ψ obeys

$$\int_{B(y,\delta)} d^dx\, |\psi(x)|^2 \geqslant (1-\delta)N \quad \textit{for some} \quad y \in \mathbb{R}^d. \tag{7}$$

It will then be shown that the minimizer of the full energy functional (1) is an approximate minimizer of the free energy functional, in the sense of Lemma 1, and that they are localized around the minima of the potential:

Lemma 2 (localization): Let $v \in C_b(\mathbb{R}^d)$ and $\epsilon,\delta>0$ be fixed. Then, for N large enough, any minimizer Φ of

$$\mathcal{H}_{-1}[\overline{\psi},\psi]=\mathcal{E}_{-1}[\overline{\psi},\psi]+\int_{\mathbb{R}^d}d^dx\,v(x)|\psi(x)|^2,\quad \|\psi\|_2^2=N, \tag{8}$$

satisfies

$$\int_{B(y,\delta)}d^dx|\Phi(x)|^2\geqslant(1-\delta)N \tag{9}$$

and

$$\inf_{x\in B(y,\delta)}v(x)\leqslant\inf_{x\in\mathbb{R}^d}v(x)+\epsilon. \tag{10}$$

The last step of our proof will explicitly prove symmetry breaking.

In the following a scaling property of the wave function and the ground state energy will be used: The scaled function $\psi_{N,g}(x)=|g|^{d/2}N^{(1+d)/2}\psi_{1,1}(|g|Nx)$ satisfies for $d\geqslant 2$

$$\|\psi_{N,g}\|_2^2=N\|\psi_{1,1}\|_2^2,\quad E[N,g]=g^2N^3E[1,-1],\quad E[1,-1]<0. \tag{11}$$

The key ingredient for the proof of Lemma 1 is a partition of unity in the following form: For some $\chi\in C_0^\infty(\mathbb{R}^d)$ with $0\leqslant\chi\leqslant 1$, $\|\chi\|_2=1$, $\mathrm{supp}(\chi)\subset B(0,1)$, the ball of radius 1 with center at 0, the convolution of these approximate characteristic functions satisfies

$$\int_{\mathbb{R}^d}d^dy\,\chi^2(x-y)\chi^2(x'-y)\geqslant 1-\gamma, \tag{12}$$

for any $0<\gamma\leqslant 1$ and for $|x-x'|<\epsilon(\gamma)$ small enough. The functions

$$j_y(x)=\delta^{-d/2}\chi(\delta^{-1}(x-y))\equiv\delta^{-d/2}\chi_{y,\delta}(x)$$

indexed by $y\in\mathbb{R}^d$ form a partition of unity:

$$\int_{\mathbb{R}^d}d^dy\,j_y^2(x)=1.$$

Using the IMS-localization formula[14]

$$p^2=\int dy\,j_y p^2 j_y-\int dy(\nabla j_y)^2,$$

with p being the momentum operator, we get for the kinetic energy

$$\frac{1}{2}\|\nabla\psi\|_2^2=\frac{\delta^{-d}}{2}\int_{\mathbb{R}^d}d^dy\,\|\nabla(\chi_{y,\delta}\psi)\|_2^2-\frac{\delta^{-2}}{2}\|\nabla\chi\|_2^2\|\psi\|_2^2. \tag{13}$$

Proof of Lemma 1: Using (12) and taking $|x-x'|<\epsilon(\gamma)\delta$ we write for the nonlinearity

$$(\psi,V*|\psi|^2\psi)_2\leqslant -g\delta^{-d}\int_{|x-x'|<\epsilon\delta}\int_{\mathbb{R}^d}d^dy\,\frac{d^dx\,d^dx'}{|x-x'|}|\chi_{y,\delta}(x)\psi(x)|^2\,|\chi_{y,\delta}(x')\psi(x')|^2$$
$$+\int_{|x-x'|\geqslant\epsilon\delta}\frac{d^dx\,d^dx'}{|x-x'|}|\psi(x)|^2|\psi(x')|^2,$$

where we have set $0>g=-(1-\gamma)^{-1}$. The last term is obviously bounded by $(\epsilon\delta)^{-1}N^2$. Using (13) and extending the double integral in the first term to the whole space, which can be done because the integrand is positive, we get

$$\mathcal{E}_{-1}[\overline{\psi},\psi]\geqslant\delta^{-d}\int_{\mathbb{R}^d}d^dy\,\mathcal{E}_g[\overline{\chi_{y,\delta}\psi},\chi_{y,\delta}\psi]-(\epsilon\delta)^{-1}N^2-\frac{\delta^{-2}}{2}\|\nabla\chi\|_2^2N \tag{14}$$

with $g=-(1-\gamma)^{-1}$. Now we use (11) and obtain

$$\begin{aligned}\mathcal{E}_{-1}[\overline{\psi},\psi]+(\epsilon\delta)^{-1}N^2+\frac{\delta^{-2}}{2}\|\nabla\chi\|_2^2N&\geqslant g^2\delta^{-d}\left(\int_{\mathbb{R}^d}d^dy\,\|\chi_{y,\delta}\psi\|_2^6E[1,-1]\right)\\&\geqslant g^2\delta^{-d}\sup_y\|\chi_{y,\delta}\psi\|_2^4\left(\int_{\mathbb{R}^d}d^dy(\|\chi_{y,\delta}\psi\|_2^2)E[1,-1]\right)\\&=g^2N\sup_y\|\chi_{y,\delta}\psi\|_2^4E[1,-1].\end{aligned}$$

By assumption $(1-\eta)N^3E[1,-1]\geqslant\mathcal{E}_{-1}[\overline{\psi},\psi]$ and, since $E[1,-1]<0$,

$$N^{-2}(\sup_y\|\chi_{y,\delta}\psi\|_2)^4g^2\geqslant(1-\eta)+\left((\epsilon\delta)^{-1}N^{-1}+\frac{\delta^{-2}}{2}\|\nabla\chi\|_2^2N^{-2}\right)E[1,-1]^{-1}.$$

Choose now $\gamma(\eta)$ such that

$$g^{-2}=(1-\gamma)^2\geqslant1-\eta.$$

For $N>N_0(\eta)$ sufficiently large,

$$\left((\epsilon\delta)^{-1}N^{-1}+\frac{\delta^{-2}}{2}N^{-2}\|\nabla\chi\|_2^2\right)E[1,-1]^{-1}\geqslant-\eta.$$

So one gets

$$(\sup_y\|\chi_{y,\delta}\psi\|_2)^4N^{-2}\geqslant(1-2\eta)(1-\eta)\geqslant\left(1-\frac{\delta}{2}\right)^2$$

for $\eta(\delta)$ small enough. And, finally,

$$\int_{B(y,\delta)}d^dx|\psi(x)|^2\geqslant\|\chi_{y,\delta}\psi\|_2^2\geqslant(1-\delta)N \tag{15}$$

for some $y\in\mathbb{R}^d$.

Proof of Lemma 2: It is enough to prove this lemma for a $\delta_0=O(\epsilon)$ because it then holds for any $\delta\geqslant\delta_0$ as well.

We first show that a minimizer Φ of (1) is an approximate minimizer of (6) and so by Lemma 1 the first statement holds.

For any ψ with $\|\psi\|_2^2=N$ one has by assumption: $\mathcal{H}_{-1}[\overline{\Phi},\Phi]\leqslant\mathcal{H}_{-1}[\overline{\psi},\psi]$. This gives

$$\mathcal{E}_{-1}[\overline{\Phi},\Phi]-\mathcal{E}_{-1}[\overline{\psi},\psi]\leqslant\int_{\mathbb{R}^d}d^dx\,v(x)(|\psi(x)|^2-|\Phi(x)|^2)\leqslant2\|v\|_\infty N$$

and by passing to the infimum over ψ

$$\mathcal{E}_{-1}[\overline{\Phi},\Phi]\leqslant E_N\left(1-\frac{2\|v\|_\infty N}{(-E_N)}\right)=E_N\left(1-\frac{2\|v\|_\infty}{N^2|E[1,-1]|}\right).$$

For N large enough the bracket is $\geqslant(1-\eta)$, where η is as in Lemma 1, and so

$$\mathcal{E}_{-1}[\overline{\Phi},\Phi]\leqslant E_N(1-\eta).$$

Hence (7) holds true.

The second statement of Lemma 2 will be proved by contradiction.

In the following we denote $\inf_{x\in\mathbb{R}^d} v(x)$ by v_*. Pick $y_0\in\mathbb{R}^d$ and $\delta>0$ small enough, so that

$$v(x)\leqslant v_*+\frac{\epsilon}{2}\quad \forall x\in B(y_0,\delta),$$

and assume the second statement is false. For

$$\tilde{\Phi}(x)=\Phi(x-(y_0-y)),$$

the translate of Φ by (y_0-y), one has

$$\int_{B(y_0,\delta)} d^dx|\tilde{\Phi}(x)|^2\geqslant(1-\delta)N$$

and, since $\int_{\mathbb{R}^d\setminus B(y_0,\delta)} d^dx\,|\tilde{\Phi}(x)|^2\leqslant\delta N$,

$$\int_{\mathbb{R}^d} d^dx(v(x)-v_*)|\tilde{\Phi}(x)|^2\leqslant\frac{\epsilon}{2}N+\|v-v_*\|_\infty\delta N.$$

On the other hand, if (10) were false,

$$\int_{\mathbb{R}^d} d^dx\,(v(x)-v_*)|\Phi(x)|^2>\epsilon(1-\delta)N-\|v-v_*\|_\infty\delta N.$$

This gives

$$\begin{aligned}\mathcal{H}_{-1}[\bar{\tilde{\Phi}},\tilde{\Phi}]-\mathcal{H}_{-1}[\overline{\Phi},\Phi]&=\int_{\mathbb{R}^d} d^dx(v(x)-v_*)(|\tilde{\Phi}(x)|^2-|\Phi(x)|^2)\\&\leqslant-\frac{\epsilon}{2}(1-2\delta)N+2\|v-v_*\|_\infty\delta N\\&=-\left(\frac{\epsilon}{2}-\delta(2\|v-v_*\|_\infty+\epsilon)\right)N<0\end{aligned}$$

for $\delta<\epsilon/(4\|v-v_*\|+2\epsilon)$. This contradicts Φ being a minimizer and proves Lemma 2.

Proof of Theorem 1: By assumption, there is $0<\delta<\frac{1}{2}$ for ϵ sufficiently small such that

$$v(x)\leqslant\inf_{x'} v(x')+2\epsilon$$

implies

$$|Rx-x|>4\delta.$$

By Lemma 2,

$$\int_{B(y,\delta)} d^dx\,|\Phi(x)|^2\geqslant(1-\delta)N$$

holds for some y with

$$|Ry-y|>4\delta-2\delta=2\delta.$$

Assume $|\Phi(Rx)|\equiv|\Phi(x)|$. Then (9) also holds for y replaced by Ry. This leads to

$$N=\int_{\mathbb{R}^d}d^dx|\Phi(x)|^2\geqslant\int_{B(y,\delta)}d^dx|\Phi(x)|^2+\int_{B(Ry,\delta)}d^dx|\Phi(x)|^2\geqslant 2(1-\delta)N>N$$

since $B(y,\delta)$ and $B(Ry,\delta)$ are disjoint, which is a contradiction.

This proves Theorem 1.

We will now show how Theorem 1 can easily be extended to other potentials like the case where the two-body potential V is a potential of the form $V\in C_b(\mathbb{R}^d)$ such that $V(x)\to\sup V$ implies $x\to 0$. We first note that we have the following inequality for the energy of the minimizer:

$$E[N,-1]=E_N\leqslant -V(0)N^2+\rho,\quad \text{where}\ \ \rho=o(N^2)\ \ \text{as}\ \ N\to\infty. \tag{16}$$

The validity of this inequality can easily be seen by noting that the scaled function $\tilde{\phi}(x)=N^{1/2}a^{-d/2}\phi(a^{-1}x)$, $\|\phi\|_2^2=1$, satisfies

$$N^{-2}\mathcal{E}_g(\tilde{\phi})=a^{-2}N^{-1}\|\nabla\phi\|_2^2-\int_{\mathbb{R}^{2d}}d^d\tilde{x}d^d\tilde{x}'V(|\tilde{x}-\tilde{x}'|a)|\phi(\tilde{x})|^2|\phi(\tilde{x}')|^2,\quad \tilde{x}=a^{-1}x,$$

and $\|\tilde{\phi}\|_2=N$. Setting $a=N^{-1/3}$ and using dominated convergence in the limit of large N, one gets (16).

For the proof of Lemma 1 we note the following: We again split up the nonlinearity in (6) into two terms, one involving the integration over $|x-x'|<\epsilon\delta$ [with $\epsilon=\epsilon(\gamma)$ as in (12)] and the other over its complement. Noting that $\sup V:=V(0)>V(x)$ for $x\neq 0$ by assumption, we set $f(x,x')=|\psi(x)|^2|\psi(x')|^2$ and write

$$\begin{aligned}(\psi,V*|\psi|^2\psi)_2&\leqslant V(0)\int_{|x-x'|<\epsilon\delta}d^dxd^dx'f(x,x')+V^*\int_{|x-x'|\geqslant\epsilon\delta}d^dxd^dx'f(x,x')\\&=(V(0)-V^*)\int_{|x-x'|<\epsilon\delta}d^dxd^dx'f(x,x')+V^*N^2\\&=(V(0)-V^*)\left(\int_{|x-x'|<\epsilon\delta}d^dxd^dx'f(x,x')-N^2\right)+V(0)N^2,\end{aligned}$$

where we have set $V^*:=\sup_{|x-x'|\geqslant\epsilon\delta}V(x-x')$. Now we use (12) to get

$$(\psi,V*|\psi|^2\psi)_2\leqslant(V(0)-V^*)(-g\sup_{y\in\mathbb{R}^d}(\|\chi_{y,\delta}\psi\|_2^2)N-N^2)+V(0)N^2,$$

where again $g=-(1-\gamma)^{-1}$ and the first integral was evaluated as

$$\delta^{-d}\int_{|x-x'|<\epsilon\delta}\int_{\mathbb{R}^d}d^dyd^dxd^dx'|\chi_{y,\delta}(x)\psi(x)|^2|\chi_{y,\delta}(x')\psi(x')|^2\leqslant\sup_{y\in\mathbb{R}^d}(\|\chi_{y,\delta}\psi\|_2^2)N.$$

By assumption $(1-\eta)E[N,-1]\geqslant\mathcal{E}_{-1}(\overline{\psi},\psi)$ for an η-approximate ground state and using (16) we arrive at

$$(1-\eta)(V(0)N^2-\rho)\leqslant(V(0)-V^*)(-gN\sup_{y\in\mathbb{R}^d}(\|\chi_{y,\delta}\psi\|_2^2)-N^2)+V(0)N^2.$$

This is rewritten as

$$-g^{-1}\left(1-\frac{\eta V(0)+\rho N^{-2}}{V(0)-V^*}\right)\leqslant N^{-1}\sup_{y\in\mathbb{R}^d}(\|\chi_{y,\delta}\psi\|_2^2).$$

Setting now $\gamma=c^{-1}\delta$ with $c\gg\delta$ and choosing η small and N large enough, such that

$$\frac{\eta V(0)+\rho N^{-2}}{V(0)-V^*}<c^{-1}\delta,$$

we get

$$N^{-1}\sup_{y\in\mathbb{R}^d}(\|\chi_{y,\delta}\psi\|_2^2)\geqslant(1-c^{-1}\delta)^2\geqslant 1-\delta,$$

which gives the first lemma.

The proofs of the second lemma and of Theorem 1 are almost the same as before.

Remark: This is complemented by the following result, which conversely implies that no symmetry breaking of the ground state occurs at small coupling. This feature is reproduced by our numerical simulations.

Theorem 2: (positive critical coupling for $d\geqslant 1$): *Let the two-body potential* $V\in L^1(\mathbb{R}^d)\cap L^\infty(\mathbb{R}^d)$ *be real-valued, and the external potential* $v\in C_b(\mathbb{R}^d)$, $d\geqslant 1$, *such that*

$$H_0=-\tfrac{1}{2}\Delta+v \tag{17}$$

has an isolated ground state.

Then, for sufficiently small coupling $|g|$, *there exists a unique nonlinear ground state* ψ, $\|\psi\|_2=1$, *of*

$$H_g^{(\psi)}=H_0+gV*|\psi|^2. \tag{18}$$

This implies that, in any dimension $d\geqslant 1$, *symmetry breaking occurs above a strictly positive critical coupling* g_* *only,* $|g|>g_*$.

Proof of Theorem 2: The ground state energy E_0 of H_0 is nondegenerate by the Perron–Frobenius theorem (see, e.g., Ref. 1). Let ψ_0 (with $\|\psi_0\|\equiv\|\psi_0\|_2=1$) be the corresponding ground state, and P_0 its eigenprojection. The perturbation in (29) is bounded in operator norm since $\|V*|\psi|^2\|\leqslant\|V\|_\infty\|\psi\|^2$; hence, $H_g^{(\psi)}$ is an analytic family of type A. By the Kato–Rellich theorem[1] and its proof, we have the following.

(i) Let Γ be a circle around E_0 of small enough radius r, so that no other point in $\sigma(H_0)$ is encircled. Then

$$C\equiv\sup\|(H_g^{(\psi)}-z)^{-1}\|<\infty,$$

where the supremum is over $z\in\Gamma$, $|g|<g_*$ and $\|\psi\|\leqslant 1$, provided g_* is small enough.

(ii) For such g and ψ there is precisely one (nondegenerate) eigenvalue of $H_g^{(\psi)}$ within Γ. It is the ground state energy, and its eigenprojection is

$$P_g^{(\psi)}=-(2\pi i)^{-1}\oint_\Gamma dz(H_g^{(\psi)}-z)^{-1}.$$

A nonlinear ground state is the same (up to the phase) as a fixed point of the map

$$T:\ \mathcal{S}=\{\|\psi\|=1\}\to\mathcal{S},\quad \psi\mapsto\frac{P_g^{(\psi)}\psi_0}{\|P_g^{(\psi)}\psi_0\|}. \tag{19}$$

By the contraction mapping principle,[15] it suffices to prove that T is a *strict contraction*. Indeed,

$$P_g^{(\psi)}-P_g^{(\phi)}=(2\pi i)^{-1}\oint_\Gamma dz(H_g^{(\psi)}-z)^{-1}(gV*(|\psi|^2-|\phi|^2))(H_g^{(\phi)}-z)^{-1}$$

is estimated for $\|\psi\|,\|\phi\|\leqslant 1$ as

$$\|P_g^{(\psi)}-P_g^{(\phi)}\|\leqslant|g|C^2r\|V\|_\infty\||\psi|^2-|\phi|^2\|_1\leqslant 2|g|C^2r\|V\|_\infty\|\psi-\phi\|,$$

where the triangle inequality has been used on $|\psi|^2-|\phi|^2=\psi(\overline{\psi}-\overline{\phi})-(\psi-\phi)\overline{\phi}$. The same bound applies to

$$|\|P_g^{(\psi)}\psi_0\|-\|P_g^{(\phi)}\psi_0\||\leqslant\|(P_g^{(\psi)}-P_g^{(\phi)})\psi_0\|.$$

In particular for $\phi=0$, and hence $P_g^{(\phi)}=P_0$, $\|P_g^{(\phi)}\psi_0\|=1$, this shows that $\|P_g^{(\psi)}\psi_0\|\geqslant\frac{1}{2}$ for g_* small enough. Thus (19) is well defined. From

$$\begin{aligned}T(\psi)-T(\phi)=&\|P_g^{(\psi)}\psi_0\|^{-1}(P_g^{(\psi)}-P_g^{(\phi)})\psi_0\\&+\|P_g^{(\psi)}\psi_0\|^{-1}\|P_g^{(\phi)}\psi_0\|^{-1}(\|P_g^{(\psi)}\psi_0\|-\|P_g^{(\phi)}\psi_0\|)P_g^{(\phi)}\psi_0\end{aligned}$$

T is now seen to be a strict contraction on $\mathcal{S}$.

This proves Theorem 2.

III. NUMERICAL INVESTIGATION

The following simulation performed by a branch of our C++ HARTREE package[16] (using the extension BLITZ++, cf. Ref. 17) is built on a bilinear Lagrange finite element discretization of the numerical configuration space $\Omega\subset\mathbb{R}^2$, $\Omega=]0,D[^{\times 2}$, $D>0$, endowed with homogeneous Dirichlet boundary conditions leading to a Galerkin space of globally continuous functions in $W_0^{1,2}(\Omega)$.

Discretizing the Hartree equation by means of these bilinear finite elements, we arrive at the following nonlinear eigenvalue problem,

$$\frac{1}{(h^{(n)})^2}\left(\frac{1}{2}A^{(N)}+v^{(N)}+gW^{(N)}[\underline{\psi}^{(N)}]\right)\underline{\psi}^{(N)}=E^{(N)}\underline{\psi}^{(N)},\tag{20}$$

where $A^{(N)}$, $v^{(N)}$, and $W^{(N)}$ denote the finite element discretizations of the Laplacian $-\Delta$, the external potential v, and the Hartree energy $V*|\psi|^2$, respectively, on the square grid of $N=n^2$ vertices, and mass lumping saves us the inversion of the massmatrix. $\underline{\psi}^{(N)}$ denotes the component vector gained by expanding $\psi^{(N)}$ with respect to the finite element basis in the Galerkin space, and $h^{(n)}:=D/(n-1)$.

Since we would like to use a version of the fast Fourier transform algorithm (MFFT, cf. Ref. 18) for the fast evaluation of the Hartree energy term $W^{(N)}$, we depart from the finite element framework in the treatment of $W^{(N)}$ using a quadrature scheme for its computation. We denote by $\tilde{W}^{(N)}$ this nonconforming discretization. The two-body potentials V considered here are three-dimensional regularized Coulomb and Yukawa potentials

$$\tilde{W}^{(N)}[\underline{\psi}^{(N)}]_{(i,j),(k,l)}=\delta_{ik}\delta_{jl}(h^{(n)})^4\sum_{i',j'=0}^{n-1}|\psi_{i'j'}^{(N)}|^2\frac{e^{-(\alpha h^{(n)}\sqrt{(i-i')^2+(j-j')^2})}}{h^{(n)}\sqrt{(i-i')^2+(j-j')^2}+\delta}\tag{21}$$

depending on the falloff parameter α and the regularization δ. Here, the indices represent pairs of coordinates of the vertices in the two-dimensional grid.

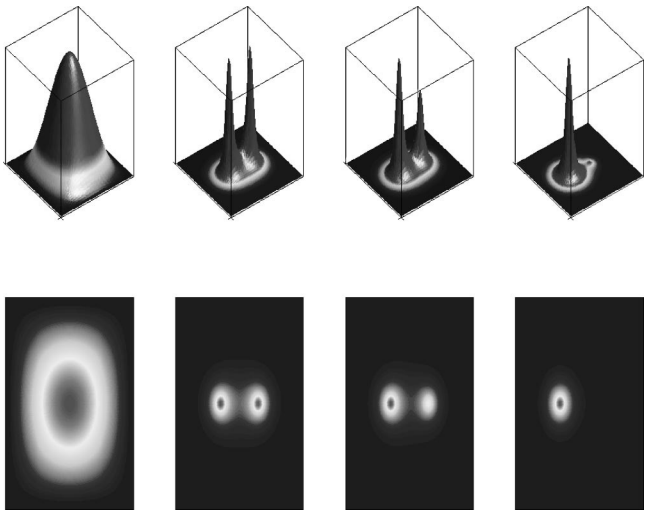

FIG. 1. Modulus squared of selected wave function iterates from the PC sequence converging to a symmetry broken minimizer. For the reason of visibility, the volumes of the boxes are determined by the maximal value of the modulus of the iterate.

The external potential v is chosen to consist of two smooth potential wells. The y-coordinates of their minima are equal whereas the x-coordinates are connected by a reflection at the axis orthogonal to the line joining the two local minimima of v. Hence, this external potential possesses a discrete symmetry, cf. Fig. 1.

The nonlinear eigenvalue problem (20) is solved by means of two interlocking iterative procedures

$$\Psi^{(N),p,q} \xrightarrow[q\to\infty]{\text{PM}} \Psi^{(N),p} \xrightarrow[p\to\infty]{\text{PC}} \Psi^{(N)} \tag{22}$$

for $\Psi^{(N),p,q} := (E^{(N),p,q}, \underline{\Phi}^{(N),p,q})$ and analogously for $\Psi^{(N),p}$ and $\Psi^{(N)}$. The superscript p is index of the Picard (PC) iteration sequence $\Psi^{(N),p}$ whose elements are the solutions of the sequence of *linearized* problems

$$\frac{1}{(h^{(n)})^2}\left(\frac{1}{2}A^{(N)} + v^{(N)} + g\tilde{W}^{(N)}[\underline{\Phi}^{(N),p}]\right)\underline{\Phi}^{(N),p+1} = E^{(N),p+1}\underline{\Phi}^{(N),p+1} \tag{23}$$

for some suitably chosen starting guess $\underline{\Phi}^{(N),0}$. Note that the Hartree energy $\tilde{W}^{(N)}$ depends on p only, and not on $p+1$!

Each element of this sequence of linear problems is solved by use of the power method (PM) consisting simply in a repeated application of the linearized operator on the rhs of (23) on a starting guess $\underline{\Phi}^{(N),p,0}$ for the linear problem, for all $p \in \mathbb{N}_0$. Subsequently, the iterate is normalized. This PM iteration is assigned the superscript q in $\Psi^{(N),p,q}$.

Although there is a *Lanczos algorithm* implemented in the HARTREE package[16] we discuss the elementary PM iteration for reasons of monitoring the iterates directly. For the Lanczos algorithm, cf. Refs. 19 and 20.

The PM iteration procedure works as follows. Given a linear real symmetric operator H on a complex finite N-dimensional Hilbert space $\mathcal{H}$ and a vector $\psi^0 \in \mathcal{H}$, PM provides us with the eigenvector whose corresponding eigenvalue is the eigenvalue with largest modulus of H restricted to the subspace determined by ψ^0. More precisely, if $\{\phi_k\}_{k=0}^{N-1}$ is an orthonormal eigenbasis of H in $\mathcal{H}$, $H\phi_k = E_k\phi_k$, in which ψ^0 may be expanded, $\psi^0 = \Sigma_{k=0}^{N-1} c_k\phi_k$, then PM computes a multiple of the eigenfunction $\phi_* \in \{\phi_k\}_{k=0}^{N-1}$ with eigenvalue E_*, for which

$$|E_*| = \max\{|E_k| | E_k \in \sigma(H|_{span\{\phi_k | c_k \neq 0\}})\} \tag{24}$$

holds (provided they are unique). This is achieved by iterating the application of H on ψ^0 with subsequent normalization of the iterate:

$$\psi^j := \frac{H^j \psi^0}{\|H^j \psi^0\|} = \sum_{k=0}^{N-1} \frac{c_k (E_k/E_*)^j}{(|c_*|^2 + \Sigma_{l=0, l\neq *}^{N-1} |c_l|^2 (E_l/E_*)^{2j})^{1/2}} \phi_k \xrightarrow{j\to\infty} \frac{c_*}{|c_*|} \phi_*, \tag{25}$$

$$(\psi^j, H\psi^j) = \sum_{k=0}^{N-1} \frac{|c_k|^2 (E_k/E_*)^{2j}}{|c_*|^2 + \Sigma_{l=0, l\neq *}^{N-1} |c_l|^2 (E_l/E_*)^{2j}} E_k \xrightarrow{j\to\infty} E_*. \tag{26}$$

As we can see in (24) the restriction to a subspace of $\mathcal{H}$ is determined by the choice of nonvanishing components in the eigenbasis expansion of the starting seed ψ^0. Now, depending on the location of the spectrum, we have to shift the linear operator H by an amount $s \in \mathbb{R}$ which, in our case, reads as

$$\begin{aligned} H_s^{(N)}[\underline{\Phi}^{(N),p}]\underline{\Phi}^{(N),p+1} &:= \left[\frac{1}{h^{(n)2}}\left(\frac{1}{2}A^{(N)} + v^{(N)} + g\tilde{W}^{(N)}[\underline{\Phi}^{(N),p}]\right) + s\mathbb{I}^{(N)}\right]\underline{\Phi}^{(N),p+1} \\ &= (E^{(N),p+1} + s)\underline{\Phi}^{(N),p+1} \end{aligned} \tag{27}$$

such that for the computation of the ground state energy, at most,

$$|\min \sigma(H_s^{(N)}[\underline{\Phi}^{(N),p}])| > |\max \sigma(H_s^{(N)}[\underline{\Phi}^{(N),p}])|. \tag{28}$$

Then, the ground state energy of $H_s^{(N)}[\underline{\Phi}^{(N),p}]$ has maximal modulus among all energies of $H_s^{(N)}[\underline{\Phi}^{(N),p}]$.

The *convergence speed characteristic* is determined by the quotient $q_{\tilde{k}}(s)$ in the numerator of (25) shifted by s, where $\hat{k} \in \{0, \ldots, N-1\}$ denotes the energy level for which the quotient $q_{\hat{k}}(s)$ is closest to one among all existing $q_k(s)$, $k \in \{0, \ldots, N-1\}$,

$$q_{\hat{k}}(s) := \left(\frac{E_{\hat{k}} + s}{E_* + s}\right)^j. \tag{29}$$

The length and energy scales l and E set by a minimizer are $l \propto |g|^{-1}$, and $E \propto g^2$. For numerical reasons, we have to allow grid resolutions with $l \gg h$ only ($h := h^{(n)}$ for some n). But the maximal kinetic energy on such a grid is roughly proportional to h^{-2}, which determines the scale of the coupling g, $|g| \ll h^{-1}$. This implies the existence of positive energy states on the grid since the depth of the Hartree energy well is $O(g^2)$. Hence,

$$\max \sigma(H^{(N)}[\underline{\Phi}^{(N),p}]) = O(h^{-2}) > 0.$$

Approximating the Hartree energy well around its minimum by a harmonic potential, we find the *level spacing* ΔE to be

$$\Delta E = O(g^2).$$

Since, on the length scale $|g|^{-1}$, the quadratic function changes as g^2 (depth of the energy well), it is of the form $O(g^4)x^2$ which results in a harmonic oscillator frequency $\omega = O(g^2)$. Therefore, we can set $E_0 = -\alpha_0 g^2$ and the first excited state $E_1 = -\alpha_1 g^2$ with $\alpha_0 - \alpha_1 > 0$. The convergence speed characteristic $q_1(s)$ from (29) is now expanded in $g^2 h^2 \ll 1$, with $(\alpha_0 - \alpha_1)$ is of order $O(1)$:

$$q_1(-h^{-2})^{1/j} = 1 - (\alpha_0 - \alpha_1) g^2 h^2 + O(g^4 h^4). \tag{30}$$

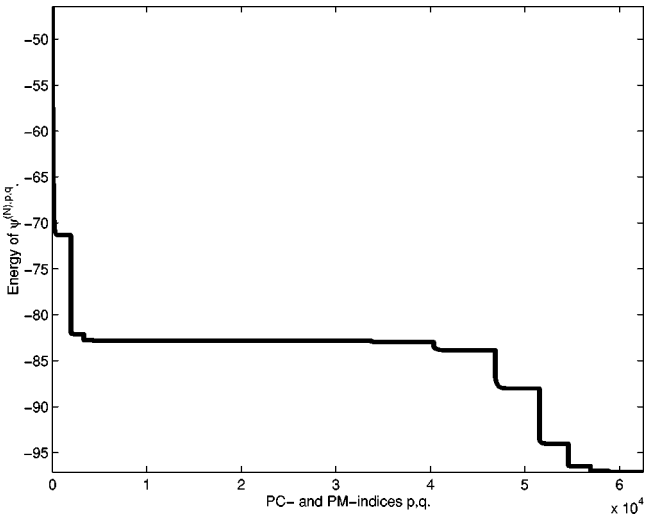

FIG. 2. Total energy of the interlocking PC iterates and PM iterates for the sequence in Fig. 1.

Now, in order to get an idea for the *size* of j, we can expand ψ^j up to first order, $k=0,1$, for example, and compute j approximately from

$$\left\| \frac{H_s\psi^j - (\psi^j, H_s\psi^j)\psi^j}{(\psi^j, (H_s - s\mathbb{1})\psi^j)} \right\| \leqslant \epsilon_{\text{rel}}, \tag{31}$$

which is the chosen *stopping criterion* for the PM iteration, given the relative error ϵ_{rel} (with $H_s := H + s1$). Note that this criterion does not depend on the shift $s \in \mathbb{R}$ if ψ^j is normalized for all j.

Clearly, (31) is satisfied for *any* eigenstate of H. But as soon as the $*$-component in the expansion of ψ^0 is nonvanishing (e.g., due to *finite precision arithmetic*), $c_* \neq 0$, the sequence ψ^j will eventually converge to a multiple of ϕ_*.

But, note that the chosen accuracy may be reached *before* a nonvanishing c_* is generated!

IV. FIGURES

In Fig. 1 we visualize some instructive elements of the PC iteration sequence $\{\Phi^{(N),p}\}_{p=0}^{\infty}$. The data specification for the simulation in Figs. 1 and 2 is as follows.

The grid is generated by six bisections leading to $n = 2^6 = 64$.

The external potential $v(x,y)$ is chosen to be a double well potential composed of two wells of the form

$$v(x,y) = V_0 / \cosh((x-x_0)^2/a^2 + (y-y_0)^2/b^2)$$

localized at

$$((x_1)_0, (y_1)_0) = (0.35, 0.5)$$

and

$$((x_2)_0, (y_2)_0) = (0.65, 0.5)$$

with widths

$$(a_1, b_1) = (a_2, b_2) = (0.03, 0.03)$$

and strengths

$$(V_1)_0=(V_2)_0=-0.1.$$

The two-body potential V has the form (21) with

$$\alpha=0 \quad \text{and} \quad \delta=0.1.$$

This Hartree energy is coupled by a coupling constant $g=-16$.

The starting guess $\Phi^{(N),0}$ for the iteration is chosen to be the ground state for the pure kinetic energy in Ω. With the additional rule

$$\underline{\Phi}^{(N),p+1,0}:=\underline{\Phi}^{(N),p,\infty}, \tag{32}$$

all the necessary starting approximations are determined, where $p\in\mathbb{N}_0$, and $\underline{\Phi}^{(N),0,\infty}:=\underline{\Phi}^{(N),0}$.

In the following simulation, $q=\infty$ means $q=O(10)-O(10^2)$ iterations, whereas $p=\infty$ is $p=O(10)$.

Figure 1 visualizes the density contours of selected iterates from the PC iteration sequence. The first picture shows the ground state for the pure kinetic energy. After a while, a state similar to the ground state of the linear operator $-\frac{1}{2}\Delta+v$ is approached. This state becomes unstable, such that, finally, one of the two possible nonlinear ground states results. The decision for the left or the right potential well is made by finite precision arithmetic.

The qualitative behavior of Fig. 1 is confirmed for different grid resolutions $n=2^m$, $m\in\mathbb{N}$, where the location and strength of the external potential v have been kept fixed.

On the chosen level of accuracy, $\epsilon_{\text{rel}}=10^{-6}$, and on this space discretization level, $n=64$, the critical coupling lies around

$$g_*\approx 16$$

(we are only interested in the qualitative behavior). Above g_*, the minimizer density looks as in the second picture of Fig. 1.

In Fig. 2 the expectation value of $H^{(N)}$ in the PC states from Fig. 1 and their underlying PM states is monitored. We note that the energy minimum for all these states is in fact reached in the final configuration.

Bound states in straight quantum waveguides with combined boundary conditions

J. Dittrich[a] and J. Kříž[b]
Nuclear Physics Institute, Academy of Sciences of the Czech Republic, 250 68 Řež, Czech Republic

(Received 7 December 2001; accepted for publication 8 May 2002)

We investigate the discrete spectrum of the Hamiltonian describing a quantum particle living in the two-dimensional straight strip. We impose the combined Dirichlet and Neumann boundary conditions on different parts of the boundary. Several statements on the existence or the absence of the discrete spectrum are compared for two models with combined boundary conditions. Examples of eigenfunctions and eigenvalues are computed numerically. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1491597]

I. INTRODUCTION

Quantum waveguides with Dirichlet boundary conditions were extensively studied (e.g., Refs. 1–7, and references therein). Their spectral properties essentially depend on the geometry of the waveguide, in particular the existence of bound states induced by curvature[1,2,3,5] or by coupling of straight waveguides through windows[4,6] were shown. The waveguides with Neumann boundary condition were also investigated in several papers, e.g., Refs. 8–10. The possible next generalization are waveguides with combined Dirichlet and Neumann boundary conditions on different parts of the boundary. Some very simple combinations of these conditions appear due to the symmetry of special configurations in systems studied, for example, in Refs. 4, 5, 6, 8, 10. Such ''combined'' systems might also be of interest in nanoscopic physics if interphases modeled by different conditions could be realized. The presence of different boundary conditions also gives rise to nontrivial spectral properties like the existence of bound states.

In the present paper, we compare two simple cases of straight planar waveguides of constant width with combined boundary conditions. We show the examples with[8] and without the presence of bound states. The systems we are going to study are sketched in Fig. 1. We consider a Schrödinger particle whose motion is confined to a planar strip of width d. For definiteness we assume that it is placed to the upper side of the x axis. On part of the boundary the Neumann condition is imposed (thin lines in the picture), while on the other part the Dirichlet one holds (thick lines). The length of the overlay of Neumann boundaries is 2δ and it is placed to both sides of the y axis in both cases. We shall denote this configuration space by $\Omega=\mathbb{R}\times(0,d)$ and its particular parts by $\Omega_{\mathrm{I}}=(-\infty,-\delta)\times(0,d)$, $\Omega_{\mathrm{II}}=(-\delta,\delta)\times(0,d)$ and $\Omega_{\mathrm{III}}=(\delta,\infty)\times(0,d)$.

In Sec. II we define the Hamiltonian as a Laplace operator with chosen boundary conditions with the help of a quadratic form. We also explicitly give the operator domain which contains functions not belonging to the Sobolev space $H^2(\Omega)$. For those functions $-\Delta f\in L^2(\Omega)$ but the separated second derivatives are not square integrable. Due to this fact the proof of the operator domain form is a little complicated. Similar functions are known to occur in the domains of the Dirichlet Laplacian in regions with boundaries having angles larger than π.[11] In Sec. III we study the question of bound state existence below the threshold of the essential spectrum for example A. For comparison, the known case B[8] is given to stress the different properties of two examples with

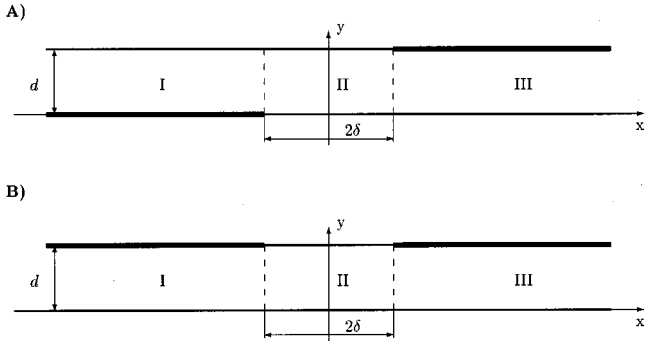

FIG. 1. Straight quantum waveguides with combined boundary conditions. The thin lines denote the Neumann boundary condition, the thick lines the Dirichlet one.

different symmetries. While in case B a bound states always exists, it appears for sufficiently large overlay 2δ only in case A. The proved results are illustrated in Sec. IV by numerical calculations. Some technical points are left to appendices.

II. THE HAMILTONIAN

As we are going to prove several statements that are valid for more general combinations of boundary conditions, let us define several objects. Let there be a finite number of points on the boundary $\partial\Omega$, where the boundary condition is changing, which we denote $P_k=\langle x_k,y_k\rangle$, $k=1,\ldots,M$. We can choose the numbering so as $y_k=d$ for $k=1,\ldots,M'$ and $x_1<x_2<\cdots<x_{M'}$ and $y_k=0$ for $k=M'+1,\ldots,M$ and $x_{M'+1}<x_{M'+2}<\cdots<x_M$. Let $\partial\Omega=\mathcal{D}\cup\mathcal{N}\cup\cup_{k=1}^{M}\{P_k\}$, where $\mathcal{D}$ is a union of finite number of intervals in $\partial\Omega$, where Dirichlet condition is imposed and $\mathcal{N}=(\partial\Omega\setminus\mathcal{D})^0$ is similar for the Neumann condition. For our examples we have
(A)

$$\mathcal{D}=\{\langle x,0\rangle|x<-\delta\}\cup\{\langle x,d\rangle|x>\delta\},$$

$$\mathcal{N}=\{\langle x,0\rangle|x>-\delta\}\cup\{\langle x,d\rangle|x<\delta\},$$

$$P_1=\langle\delta,d\rangle,\quad P_2=\langle-\delta,0\rangle,$$

(B)

$$\mathcal{D}=\{\langle x,d\rangle|(x<-\delta)\vee(x>\delta)\},$$

$$\mathcal{N}=\{\langle x,0\rangle|x\in\mathbb{R}\}\cup\{\langle x,d\rangle|-\delta<x<\delta\},$$

$$P_1=\langle-\delta,d\rangle;\quad P_2=\langle\delta,d\rangle.$$

Putting $\hbar^2/2m=1$, we may identify the particle Hamiltonian with the self-adjoint operator on the Hilbert space $L^2(\Omega)$, defined in the following way. Let us define a quadratic form

$$q_0(f,g)=\int_\Omega\overline{\nabla f}\cdot\nabla g\,\mathrm{d}^2x\quad\text{with domain}\quad Q(q_0)=\{f\in H^1(\Omega)|f\restriction\mathcal{D}=0\},\tag{2.1}$$

where $H^1(\Omega)=\{f\in L^2(\Omega)|\nabla f\in L^2(\Omega)\}$ is the standard Sobolev space and we denote as $f\restriction\mathcal{D}$ the trace of function f on $\mathcal{D}$. Now q_0 is obviously densely defined, symmetric, and below bounded quadratic form. The form q_0 is also closed as a direct consequence of Theorem 7.53 in Ref. 12.

There is the unique self-adjoint operator associated with this form (see, e.g., Ref. 13, Theorem 4.6.8). We denote this operator $-\Delta_{DN}^{\Omega}$ and its domain $D(\Omega)$. It is our Hamiltonian. We will show that this operator acts as the usual Laplace operator with the Dirichlet condition on $\mathcal{D}$ and Neumann condition on $\mathcal{N}$.

Theorem 1: *The domain of the operator* $-\Delta_{DN}^{\Omega}$ *is*

$$D(\Omega)=\left\{ f\in H^1(\Omega)\,\middle|\, -\Delta f\in L^2(\Omega), f\restriction\mathcal{D}=0, \frac{\partial f}{\partial y}\restriction\mathcal{N}=0\right\},$$
$$-\Delta_{DN}^{\Omega} f=-\Delta f \quad \text{for every} \quad f\in D(\Omega). \tag{2.2}$$

Proof: First, we know that $D(\Omega)\subset Q(q_0)$. Moreover $f\in D(\Omega)$ if and only if there exists a function $h\in L^2(\Omega)$ such that for all $g\in Q(q_0)$ the equality $q_0(g,f)=(g,h)_{L^2(\Omega)}$ holds. Then $h=-\Delta_{DN}^{\Omega} f$ (see Ref. 13, Theorem 4.6.8). Let g be any function from $C_0^{\infty}(\Omega)$. Then $g\in Q(q_0)$ and $(\nabla g,\nabla f)_{L^2(\Omega)}=(g,-\Delta f)_{L^2(\Omega)}$ using only definition of the distributional derivatives. So $-\Delta_{DN}^{\Omega} f=-\Delta f$ for all $f\in D(\Omega)$. We know now

$$D(\Omega)=\{f\in Q(q_0)\,|\,-\Delta f\in L^2(\Omega),(\forall g\in Q(q_0))((g,-\Delta f)_{L^2(\Omega)}=(\nabla g,\nabla f)_{L^2(\Omega)})\}. \tag{2.3}$$

Now we prove the implication $f\in D(\Omega)\Rightarrow \partial f/\partial y\restriction\mathcal{N}=0$. Let Ω_0 be an open subset of Ω, such that $P_k\notin\overline{\Omega}_0, k=1,\ldots,M$. We will show that every $f\in D(\Omega)$ belongs to $H^2(\Omega_0)$ for such subdomains. There exist real, positive numbers η_k, $k=1,\ldots,M$ such that the open balls $\underline{B(P_k,2\eta_k)}$ have empty intersections with Ω_0. We can choose η_k so small that even $\overline{B(P_k,2\eta_k)}\cap\overline{B(P_{k'},2\eta_{k'})}=\varnothing$ for $k\neq k'$. Let us denote

$$\omega_0=(-\infty,x_1-\eta_1)\times(d,2d),$$
$$\vdots$$
$$\omega_{M'-1}=(x_{M'-1}+\eta_{M'-1},x_{M'}-\eta_{M'})\times(d,2d),$$
$$\omega_{M'}=(x_{M'}+\eta_{M'},\infty)\times(d,2d),$$
$$\omega_{M'+1}=(-\infty,x_{M'+1}-\eta_{M'+1})\times(-d,0),$$
$$\vdots$$
$$\omega_{M+1}=(x_M+\eta_M,\infty)\times(-d,0)$$

and let $\tilde{\omega}_k$ be the reflection of ω_k to the domain Ω for $k=0,\ldots,M+1$, i.e., $\tilde{\omega}_k=\mathcal{R}_1(\omega_k)$ for $k=0,\ldots,M'$ and $\tilde{\omega}_k=\mathcal{R}_2(\omega_k)$ for $k=M'+1,\ldots,M+1$, where the bijections $\mathcal{R}_i:\mathbb{R}^2\to\mathbb{R}^2$, $i=1,2$ are defined as follows: $\mathcal{R}_1(\langle x,y\rangle)=\langle x,2d-y\rangle$ and $\mathcal{R}_2(\langle x,y\rangle)=\langle x,-y\rangle$. Let $\tilde{\Omega}=(\overline{\cup_{k=0}^{M+1}\omega_k\cup\Omega})^0$. In fact, we can say that $\tilde{\Omega}$ is the original domain Ω with its copy on each side of its boundary, from which we cut the columns $[x_k-\eta_k,x_k+\eta_k]\times[d,2d)$, respectively, $[x_k-\eta_k,x_k+\eta_k]\times(-d,0]$, above, respectively, below, the point P_k depending on which part of $\partial\Omega$ the point P_k lies. We construct a function $\tilde{f}\in L^2(\tilde{\Omega})$ as follows. For every point $\langle x,y\rangle\in\tilde{\Omega}\backslash\partial\Omega$ we define (so we see that the function will be defined almost everywhere in $\tilde{\Omega}$):

$$\tilde{f}(x,y)=\begin{cases} f(x,y) & \text{for} \quad \langle x,y\rangle\in\Omega \\ f(x,2d-y) & \text{for} \quad \langle x,2d-y\rangle\in\Omega, \quad \langle x,d\rangle\in\mathcal{N} \\ -f(x,2d-y) & \text{for} \quad \langle x,2d-y\rangle\in\Omega, \quad \langle x,d\rangle\in\mathcal{D} \\ f(x,-y) & \text{for} \quad \langle x,-y\rangle\in\Omega, \quad \langle x,0\rangle\in\mathcal{N} \\ -f(x,-y) & \text{for} \quad \langle x,-y\rangle\in\Omega, \quad \langle x,0\rangle\in\mathcal{D}. \end{cases}$$

Now for any $\varphi\in C_0^\infty(\tilde{\Omega})$ we can write

$$\begin{aligned}(-\Delta\tilde{f},\varphi)_{L^2(\tilde{\Omega})}&=(\tilde{f},-\Delta\varphi)_{L^2(\tilde{\Omega})}\\ &=(f,-\Delta\varphi)_{L^2(\Omega)}+\sum_{k=0}^{M+1}(\tilde{f},-\Delta\varphi)_{L^2(\omega_k)}\\ &=(f,-\Delta\varphi)_{L^2(\Omega)}\mp\sum_{k=0}^{M'}(-1)^k\int_{\tilde{\omega}_k}\overline{f(x,y)}\Delta\varphi(x,2d-y)\mathrm{d}^2x\\ &\quad+(-1)^s\sum_{k=M'+1}^{M+1}(-1)^k\int_{\tilde{\omega}_k}\overline{f(x,y)}\Delta\varphi(x,-y)\mathrm{d}^2x\\ &=(f,-\Delta\tilde{\varphi})_{L^2(\Omega)}, \end{aligned}\tag{2.4}$$

where we used the definition of the distributional derivatives and the substitution $y\mapsto 2d-y$, respectively, $y\mapsto -y$. The $-$ sign in $\mp$ is valid for these systems, where the Neumann condition is imposed on $\{\langle x,d\rangle|x\in(-\infty,x_1)\}$, the $+$ sign for others. The number s equals 0 or 1, so as $s+M'+1$ is odd for systems, where the Neumann condition is imposed on $\{\langle x,0\rangle|x\in(-\infty,x_{M'+1})\}$ and even for others. Finally, a new function is defined on the domain Ω as

$$\tilde{\varphi}(x,y)=\varphi(x,y)\pm\sum_{k=0}^{M'}(-1)^k\chi_{\tilde{\omega}_k}(x,y)\varphi(x,2d-y)-(-1)^s\sum_{k=M'+1}^{M+1}(-1)^k\chi_{\tilde{\omega}_k}(x,y)\varphi(x,-y),$$

where χ_ω is the standard characteristic function of the set ω. Taking into consideration the construction of the domain $\tilde{\Omega}$ and that supp $\varphi\subset\tilde{\Omega}$, we conclude that $\tilde{\varphi}\in C^\infty(\overline{\Omega})$ and it has a bounded support. Further, we know that the trace $\tilde{\varphi}\restriction\partial\Omega$ equals $\lim_{y\to d^-}\tilde{\varphi}(x,y)$ in the point $\langle x,d\rangle$ and similarly $\lim_{y\to 0^+}\tilde{\varphi}(x,y)$ in the point $\langle x,0\rangle$ for smooth functions (see the definition of traces, e.g., in Ref. 12). So the traces on $\mathcal{D}\cap\tilde{\Omega}$ are

$$(\tilde{\varphi}\restriction\partial\Omega)(x,d)=\lim_{y\to d^-}\tilde{\varphi}(x,y)=\lim_{y\to d^-}(\varphi(x,y)-\varphi(x,2d-y))=0,$$

$$(\tilde{\varphi}\restriction\partial\Omega)(x,0)=\lim_{y\to 0^+}\tilde{\varphi}(x,y)=\lim_{y\to 0^+}(\varphi(x,y)-\varphi(x,-y))=0.$$

In a similar way for parts of boundary $\partial\Omega$ with the Neumann condition inside $\tilde{\Omega}$,

$$\left(\frac{\partial\tilde{\varphi}}{\partial y}\restriction\partial\Omega\right)(x,d)=\lim_{y\to d^-}\frac{\partial\tilde{\varphi}}{\partial y}(x,y)=\lim_{y\to d^-}\frac{\partial}{\partial y}(\varphi(x,y)+\varphi(x,2d-y))=0,$$

$$\left(\frac{\partial\tilde{\varphi}}{\partial y}\restriction\partial\Omega\right)(x,0)=\lim_{y\to 0^+}\frac{\partial\tilde{\varphi}}{\partial y}(x,y)=\lim_{y\to 0^+}\frac{\partial}{\partial y}(\varphi(x,y)+\varphi(x,-y))=0.$$

On the rest of the boundary $\partial\Omega$, i.e., $\partial\Omega\backslash\tilde{\Omega}$, both Dirichlet and Neumann conditions are satisfied, which can be seen from the definition of $\tilde{\varphi}$. So it is clear that $\tilde{\varphi}\in H^2(\Omega)$ and it satisfies prescribed boundary conditions. It is easy to check that all such functions belong to $D(\Omega)$, using the Gauss theorem. Because both functions f and $\tilde{\varphi}$ are in $D(\Omega)$, which is a subset of $Q(q_0)$, we can continue the calculation from (2.4),

$$
\begin{aligned}
(f,-\Delta\tilde{\varphi})_{L^2(\Omega)}&=(\nabla f,\nabla\tilde{\varphi})_{L^2(\Omega)}=(-\Delta f,\tilde{\varphi})_{L^2(\Omega)}\\
&=(-\Delta f,\varphi)_{L^2(\Omega)}\mp\sum_{k=0}^{M'}(-1)^k\int_{\omega_k}\overline{\Delta f(x,2d-y)}\,\varphi(x,y)\,\mathrm{d}^2x\\
&\quad+(-1)^s\sum_{k=M'+1}^{M+1}(-1)^k\int_{\omega_k}\overline{\Delta f(x,-y)}\,\varphi(x,y)\,\mathrm{d}^2x=(F,\varphi)_{L^2(\tilde{\Omega})},
\end{aligned}
$$

where we used the ''reflection'' substitution again and F is a function defined by the last formula. Here $F\in L^2(\tilde{\Omega})$, because it is the sum of the finite number of L^2-functions. As we choose the function φ arbitrarily, we see that $-\Delta\tilde{f}=F\in L^2(\tilde{\Omega})$. Let $\psi\in C^\infty(\mathbb{R}^2)$, it is bounded together with its first and second derivatives, and let supp $\psi\subset\tilde{\Omega}$. Then $\psi\tilde{f}\in L^2(\mathbb{R}^2)$. Using the Leibnitz rule and several times a lemma from Sec. IX.6 in Ref. 14, we conclude that even $-\Delta(\psi\tilde{f})\in L^2(\mathbb{R}^2)$ [the Leibnitz rule itself does not give the result unless we know $\nabla\tilde{f}\in L^2(\tilde{\Omega})$]. We now use this lemma once more and we get the result that $\psi\tilde{f}\in H^2(\mathbb{R}^2)$. We can choose a function ψ so as $\psi\restriction\Omega_0=1$. It is possible, because $\Omega_0\subset\subset\tilde{\Omega}$ and our regions have a simple form at $x\to\pm\infty$. Let $r_1<r_2<r_3$ be the real positive numbers such that $[x_k-2\eta_k,x_k+2\eta_k]\subset(-r_1,r_1)$ for every $k=1,\ldots,M$ and denote $R_2=(-r_2,r_2)\times(0,d)$, $R_3=(-r_3,r_3)\times(-d,2d)$. Then using Ref. 15, Lemma XIV.2.1 we find a function $\psi_1\in C_0^\infty(\tilde{\Omega}\cap R_3)$, such that $0\leqslant\psi_1(x)\leqslant 1$ for all $x\in\tilde{\Omega}\cap R_3$ and $\psi_1(x)=1$ for $x\in\overline{\Omega_0\cap R_2}$. This function has compact support in $\tilde{\Omega}$, so its derivatives are bounded. Let now $\gamma\in C_0^\infty(-d,2d)$, such that $\gamma(y)=1$ for $y\in(0,d)$ (it can be constructed according to the same lemma as ψ_1). Let $\beta\in C^\infty(\mathbb{R})$ such that $\beta(x)=1$ for $|x|\geqslant r_2$, $\beta(x)=0$ on the interval $[-r_1,r_1]$ (we can again use the same lemma for construction of $1-\beta$). Then $\psi=\psi_1(1-\beta)+\gamma\beta$ satisfies all desired properties. Thus $\tilde{f}\psi\restriction\Omega_0=\tilde{f}\restriction\Omega_0=f\restriction\Omega_0$, so $f\in H^2(\Omega_0)$.

Now let us take any interval (a,b), such that $x_k\notin[a,b]$ for $k=1,\ldots,M$. Let $\xi\in C_0^\infty(a,b)$ be a real function. Because region $(a,b)\times(0,d)$ satisfies all conditions for Ω_0, $f\in H^2((a,b)\times(0,d))$. Using the Leibnitz rule we can see that $\xi f\in H^2((a,b)\times(0,d))$. For any $g\in Q(q_0)$ we have $g\xi\in Q(q_0)$ and

$$
\begin{aligned}
(\nabla g,\nabla(f\xi))_{L^2(\Omega)}&=(\nabla g,\xi\nabla f)_{L^2(\Omega)}+\left(\frac{\partial g}{\partial x},f\frac{d\xi}{dx}\right)_{L^2(\Omega)}\\
&=(\xi\nabla g,\nabla f)_{L^2(\Omega)}+\left(g\frac{d\xi}{dx},\frac{\partial f}{\partial x}\right)_{L^2(\Omega)}-\left(g\frac{d\xi}{dx},\frac{\partial f}{\partial x}\right)_{L^2(\Omega)}+\left(\frac{\partial g}{\partial x},f\frac{d\xi}{dx}\right)_{L^2(\Omega)}\\
&=(g\xi,-\Delta f)_{L^2(\Omega)}+\int_\Omega\frac{\partial(\overline{g(x,y)}f(x,y))}{\partial x}\frac{d\xi(x)}{dx}\mathrm{d}x\,\mathrm{d}y-2\left(g\frac{d\xi}{dx},\frac{\partial f}{\partial x}\right)_{L^2(\Omega)}\\
&=(g,-\xi\Delta f)_{L^2(\Omega)}-2\left(g,\frac{d\xi}{dx}\cdot\frac{\partial f}{\partial x}\right)_{L^2(\Omega)}-\left(g,f\frac{d^2\xi}{dx^2}\right)_{L^2(\Omega)}=(g,-\Delta(f\xi))_{L^2(\Omega)}.
\end{aligned}
\tag{2.5}
$$

Hence $\xi f\in D(\Omega)$. Using the Gauss theorem (it can be used for H^2-functions) we get for any $g\in Q(q_0)$,

$$(g,-\Delta(\xi f))_{L^2(\Omega)}=(\nabla g,\nabla(\xi f))_{L^2(\Omega)}-\int_a^b\left(\overline{g(x,d)}\xi(x)\frac{\partial f}{\partial y}(x,d)-\overline{g(x,0)}\xi(x)\frac{\partial f}{\partial y}(x,0)\right)\mathrm{d}x.$$

So due to (2.5)

$$\int_a^b\left(\overline{g(x,d)}\xi(x)\frac{\partial f}{\partial y}(x,d)-\overline{g(x,0)}\xi(x)\frac{\partial f}{\partial y}(x,0)\right)\mathrm{d}x=0$$

for any considered a,b and any $g\in Q(q_0),\xi\in C_0^\infty(a,b)$. Now we conclude that

$$\frac{\partial f}{\partial y}\restriction\mathcal{N}=0 \quad \text{a.e.}$$

This finishes the second part of proof.

It remains to show that if f satisfies all conditions from (2.2) then $f\in D(\Omega)$ [in the sense of definition (2.3)]. Let $\Omega_{0,\varepsilon}=\Omega\backslash\cup_{k=1}^M\overline{B(P_k,\varepsilon)}$, $\Omega_\varepsilon=\cup_{k=1}^M B(P_k,\varepsilon)\cap\Omega$. Because we know from the previous part of the proof that $f\in H^2(\Omega_{0,\varepsilon})$, we can use the Gauss theorem:

$$\begin{aligned}(\nabla g,\nabla f)_{L^2(\Omega)}+(g,\Delta f)_{L^2(\Omega)}&=(\nabla g,\nabla f)_{L^2(\Omega_{0,\varepsilon})}+(g,\Delta f)_{L^2(\Omega_{0,\varepsilon})}+(\nabla g,\nabla f)_{L^2(\Omega_\varepsilon)}\\&\quad+(g,\Delta f)_{L^2(\Omega_\varepsilon)}\\&=-\sum_{k=1}^M\int_0^\pi\frac{\partial\tilde f_k(\varepsilon,\theta)}{\partial r}\overline{\tilde g_k(\varepsilon,\theta)}\varepsilon\,\mathrm{d}\theta+(\nabla g,\nabla f)_{L^2(\Omega_\varepsilon)}\\&\quad+(g,\Delta f)_{L^2(\Omega_\varepsilon)},\end{aligned}\tag{2.6}$$

where $\tilde f_k$, $\tilde g_k$ are the transformations of f, g to the polar coordinates in the neighborhood of each P_k in the way, that the region $(0,\varepsilon)\times(0,\pi)\subset\Omega$, P_k is the origin of polar coordinates, and $\tilde f_k$ satisfies the Dirichlet condition for $\theta=0$. We can see that the last two terms in (2.6) go to zero as $\varepsilon\to0$, because ∇f, ∇g, $-\Delta f$, $g\in L^2(\Omega)$ and the measure of Ω_ε goes to zero. So we only have to prove that

$$\sum_{k=1}^M\int_0^\pi\frac{\partial\tilde f_k(r_n,\theta)}{\partial r}\overline{\tilde g_k(r_n,\theta)}r_n\mathrm{d}\theta\to0\quad\text{as}\quad n\to\infty\tag{2.7}$$

for some sequence $\{r_n\}_{n=0}^\infty$, $\lim_{n\to\infty}r_n=0$. We will show that each term in this sum tends to zero. For simplicity we will not write indices in the following text. We will decompose $\tilde f$ to the orthonormal transverse basis which respects our boundary conditions,

$$\tilde f(r,\theta)=\sum_{k=0}^\infty\sqrt{\frac{2}{\pi}}F_k(r)\sin\frac{2k+1}{2}\theta,\tag{2.8}$$

and in the same way

$$\tilde g(r,\theta)=\sum_{k=0}^\infty\sqrt{\frac{2}{\pi}}G_k(r)\sin\frac{2k+1}{2}\theta.\tag{2.9}$$

Let R be a small positive real number, so as $\min_{k\neq k'}\mathrm{dist}(P_k,P_{k'})>R$. It is easy to check the following equivalences:

$$f,g\in H^1(\Omega\cap B(P,R))\Leftrightarrow\tilde f,\tilde g,\frac{\partial\tilde f}{\partial r},\frac{\partial\tilde g}{\partial r},\frac{1}{r}\frac{\partial\tilde f}{\partial\theta},\frac{1}{r}\frac{\partial\tilde g}{\partial\theta}\in L^2((0,R)\times(0,\pi),r\,\mathrm{d}r\,\mathrm{d}\theta),\tag{2.10}$$

$$\Delta f\in L^2(\Omega\cap B(P,R))\Leftrightarrow\left(\frac{\partial^2\tilde f}{\partial r^2}+\frac{1}{r}\frac{\partial\tilde f}{\partial r}+\frac{1}{r^2}\frac{\partial^2\tilde f}{\partial\theta^2}\right)\in L^2((0,R)\times(0,\pi),r\,\mathrm{d}r\,\mathrm{d}\theta).\tag{2.11}$$

Using (2.10) we can decompose $(1/r)(\partial\tilde f/\partial\theta)$ to the orthonormal transverse basis

$$\frac{1}{r}\frac{\partial\tilde f}{\partial\theta}=\sum_{k=0}^{\infty}\sqrt{\frac{2}{\pi}}a_k(r)\cos\frac{2k+1}{2}\theta.$$

For almost every r we have

$$a_k(r)=\sqrt{\frac{2}{\pi}}\int_0^\pi\frac{1}{r}\frac{\partial\tilde f}{\partial\theta}(r,\theta)\cos\frac{2k+1}{2}\theta\,\mathrm{d}\theta$$

and

$$\begin{aligned}F_k(r)&=\sqrt{\frac{2}{\pi}}\int_0^\pi\tilde f(r,\theta)\sin\frac{2k+1}{2}\theta\,\mathrm{d}\theta\\&=-\sqrt{\frac{2}{\pi}}\frac{2}{2k+1}\int_0^\pi\tilde f(r,\theta)\frac{\partial}{\partial\theta}\cos\frac{2k+1}{2}\theta\,\mathrm{d}\theta\\&=\sqrt{\frac{2}{\pi}}\frac{2}{2k+1}\int_0^\pi\frac{\partial\tilde f}{\partial\theta}(r,\theta)\cos\frac{2k+1}{2}\theta\,\mathrm{d}\theta+\sqrt{\frac{2}{\pi}}\frac{2}{2k+1}\tilde f(r,0)=\frac{2}{2k+1}ra_k(r),\end{aligned}$$

due to the boundary condition $\tilde f(r,0)=0$. So

$$a_k(r)=\frac{1}{r}\frac{2k+1}{2}F_k(r).\tag{2.12}$$

Now we decompose in the same way $\partial\tilde f/\partial r$,

$$\frac{\partial\tilde f}{\partial r}=\sum_{k=0}^{\infty}\sqrt{\frac{2}{\pi}}b_k(r)\sin\frac{2k+1}{2}\theta.$$

Let $\{\xi_{k,n}\}_{n=1}^{\infty}$ be a sequence of $C_0^\infty(0,\pi)$ functions so as $\lim_{n\to\infty}\|\xi_{k,n}-\sqrt{(2/\pi)}\sin(2k+1)/2\,\theta\|_{L^2(0,\pi)}=0$ for $k=1,\ldots,M$ and let $\omega\in C_0^\infty(0,R)$. Then using twice the definition of the distributional derivatives, the definitions of F_k and b_k, and the fact that $\omega\xi_{k,n}\in C_0^\infty((0,R)\times(0,\pi))$ we get

$$\begin{aligned}\int_0^R\frac{d}{dr}F_k(r)\omega(r)\mathrm{d}r&=-\int_0^R F_k(r)\omega'(r)\mathrm{d}r\\&=-\int_0^R\omega'(r)\int_0^\pi\sqrt{\frac{2}{\pi}}\tilde f(r,\theta)\sin\frac{2k+1}{2}\theta\,\mathrm{d}\theta\,\mathrm{d}r\\&=-\lim_{n\to\infty}\int_0^R\int_0^\pi\omega'(r)\xi_{k,n}(\theta)\tilde f(r,\theta)\mathrm{d}\theta\,\mathrm{d}r\\&=\lim_{n\to\infty}\int_0^R\int_0^\pi\omega(r)\xi_{k,n}(\theta)\frac{\partial\tilde f}{\partial r}(r,\theta)\mathrm{d}\theta\,\mathrm{d}r\\&=\int_0^R\omega(r)\int_0^\pi\sqrt{\frac{2}{\pi}}\frac{\partial}{\partial r}\tilde f(r,\theta)\sin\frac{2k+1}{2}\theta\,\mathrm{d}\theta\,\mathrm{d}r=\int_0^R b_k(r)\omega(r)\mathrm{d}r.\end{aligned}$$

Because $\omega(r)$ was chosen arbitrarily, we conclude that

$$b_k(r)=\frac{dF_k(r)}{dr}=F_k'(r). \tag{2.13}$$

We can apply the same procedure to $\tilde{g}(r,\theta)$. Using (2.12) and (2.13) we know that the series (2.8) and (2.9) can be differentiated by terms. Now we use the similar derivation for Δf. Let

$$\left(\frac{\partial^2\tilde{f}}{\partial r^2}(r,\theta)+\frac{1}{r}\frac{\partial\tilde{f}}{\partial r}(r,\theta)+\frac{1}{r^2}\frac{\partial^2\tilde{f}}{\partial\theta^2}(r,\theta)\right)=\sqrt{\frac{2}{\pi}}\sum_{k=0}^{\infty}c_k(r)\sin\frac{2k+1}{2}\theta.$$

From the first part of the proof we know $\tilde{f}(r,.)\in H^2(0,\pi)$ for a.e. r and we can compute

$$\begin{aligned}
&\int_0^R\left(F_k''(r)+\frac{1}{r}F_k'(r)-\frac{1}{r^2}\left(\frac{2k+1}{2}\right)^2F_k(r)\right)r\omega(r)\,\mathrm{d}r\\
&\quad=-\int_0^R rF_k'(r)\omega'(r)\,\mathrm{d}r-\left(\frac{2k+1}{2}\right)^2\int_0^R\frac{1}{r}F_k(r)\omega(r)\,\mathrm{d}r\\
&\quad=\int_0^R(r\omega'(r))'\int_0^\pi\sqrt{\frac{2}{\pi}}\tilde{f}(r,\theta)\sin\frac{2k+1}{2}\theta\,\mathrm{d}\theta\,\mathrm{d}r\\
&\qquad-\left(\frac{2k+1}{2}\right)^2\int_0^R\frac{\omega(r)}{r}\int_0^\pi\sqrt{\frac{2}{\pi}}\tilde{f}(r,\theta)\sin\frac{2k+1}{2}\theta\,\mathrm{d}\theta\,\mathrm{d}r\\
&\quad=\lim_{n\to\infty}\int_0^R(r\omega'(r))'\int_0^\pi\tilde{f}(r,\theta)\xi_{k,n}(\theta)\mathrm{d}\theta\,\mathrm{d}r+\int_0^R\frac{\omega(r)}{r}\int_0^\pi\sqrt{\frac{2}{\pi}}\tilde{f}(r,\theta)\frac{d^2\sin\frac{2k+1}{2}\theta}{d\theta^2}\mathrm{d}\theta\,\mathrm{d}r\\
&\quad=-\lim_{n\to\infty}\int_0^R\int_0^\pi\omega'(r)\xi_{k,n}(\theta)r\frac{\partial\tilde{f}}{\partial r}(r,\theta)\mathrm{d}\theta\,\mathrm{d}r+\int_0^R\frac{\omega(r)}{r}\\
&\qquad\times\sqrt{\frac{2}{\pi}}\left(-\frac{2k+1}{2}\tilde{f}(r,0)-(-1)^k\frac{\partial\tilde{f}}{\partial\theta}(r,\pi)+\int_0^\pi\frac{\partial^2\tilde{f}}{\partial\theta^2}(r,\theta)\sin\frac{2k+1}{2}\theta\,\mathrm{d}\theta\right)\mathrm{d}r\\
&\quad=\lim_{n\to\infty}\int_0^R\int_0^\pi\omega(r)\xi_{k,n}(\theta)\frac{\partial}{\partial r}\left(r\frac{\partial\tilde{f}}{\partial r}(r,\theta)\right)\mathrm{d}\theta\,\mathrm{d}r\\
&\qquad+\int_0^R\frac{\omega(r)}{r}\sqrt{\frac{2}{\pi}}\int_0^\pi\frac{\partial^2\tilde{f}}{\partial\theta^2}(r,\theta)\sin\frac{2k+1}{2}\theta\,\mathrm{d}\theta\,\mathrm{d}r\\
&\quad=\int_0^R\int_0^\pi\sqrt{\frac{2}{\pi}}\omega(r)r\left(\frac{\partial^2\tilde{f}}{\partial r^2}(r,\theta)+\frac{1}{r}\frac{\partial\tilde{f}}{\partial r}(r,\theta)+\frac{1}{r^2}\frac{\partial^2\tilde{f}}{\partial\theta^2}(r,\theta)\right)\sin\frac{2k+1}{2}\theta\,\mathrm{d}\theta\,\mathrm{d}r\\
&\quad=\int_0^R c_k(r)r\omega(r)\mathrm{d}r,
\end{aligned}$$

so

$$c_k(r)=F_k''(r)+\frac{1}{r}F_k'(r)-\frac{1}{r^2}\left(\frac{2k+1}{2}\right)^2F_k(r)\quad\text{for a.e. } r. \tag{2.14}$$

Let us denote $\Delta_p \tilde{f}(r,\theta)=(\partial^2\tilde{f}/\partial r^2)(r,\theta)+(1/r)(\partial\tilde{f}/\partial r)(r,\theta)+(1/r^2)(\partial^2\tilde{f}/\partial\theta^2)(r,\theta)$. Taking into account (2.11) we will solve an equation $\Delta_p\tilde{f}(r,\theta)=h(r,\theta)$ for any $h\in L^2((0,R)\times(0,\pi),r\,\mathrm{d}r\,\mathrm{d}\theta)$. We are seeking, of course, only those solutions for which the function $f(x,y)$ corresponding to the function $\tilde{f}(r,\theta)$ remains in the set $H^1(B(P,R)\cap\Omega)$. If we decompose a function h to the series $h=\sqrt{(2/\pi)}\Sigma_{k=0}^{\infty}H_k(r)\sin(2k+1)/2\,\theta$ we get a set of equations:

$$F_k''(r)+\frac{1}{r}F_k'(r)-\frac{1}{r^2}\left(\frac{2k+1}{2}\right)^2F_k(r)=H_k,\quad k=0,\ldots.$$

We denote $\nu=k+1/2$. The solutions of these equations are

$$F_0=r^{1/2}\int_0^r H_0(z)z^{1/2}\mathrm{d}z-r^{-1/2}\int_0^r H_0(z)z^{3/2}\mathrm{d}z+C_1^{(0)}r^{1/2}+C_2^{(0)}r^{-1/2} \tag{2.15}$$

and for $k>0$,

$$F_k=\frac{1}{2\nu}r^{\nu}\int_R^r H_k(z)z^{-\nu+1}\mathrm{d}z-\frac{1}{2\nu}r^{-\nu}\int_0^r H_k(z)z^{\nu+1}\mathrm{d}z+C_1^{(k)}r^{\nu}+C_2^{(k)}r^{-\nu}. \tag{2.16}$$

We can compute the first derivatives

$$F_0'=\frac{1}{2}r^{-1/2}\int_0^r H_0(z)z^{1/2}\mathrm{d}z+\frac{1}{2}r^{-3/2}\int_0^r H_0(z)z^{3/2}\mathrm{d}z+\frac{1}{2}C_1^{(0)}r^{-1/2}-\frac{1}{2}C_2^{(0)}r^{-3/2} \tag{2.17}$$

and for $k>0$,

$$F_k'=\frac{1}{2}r^{\nu-1}\int_R^r H_k(z)z^{-\nu+1}\mathrm{d}z+\frac{1}{2}r^{-\nu-1}\int_0^r H_k(z)z^{\nu+1}\mathrm{d}z+\nu C_1^{(k)}r^{\nu-1}-\nu C_2^{(k)}r^{-\nu-1}. \tag{2.18}$$

Because $\tilde{f},\ \partial\tilde{f}/\partial r\in L^2((0,R)\times(0,\pi),r\,\mathrm{d}\theta\,\mathrm{d}r)$, the functions F_k and F_k' have to be in the set $L^2((0,R),r\,\mathrm{d}r)$ for all k. Taking the first two terms in (2.16) we get after application of the triangle and Schwarz inequalities

$$\begin{aligned}
&\left|\frac{1}{2\nu}r^{\nu}\int_R^r H_k(z)z^{-\nu+1}\mathrm{d}z-\frac{1}{2\nu}r^{-\nu}\int_0^r H_k(z)z^{\nu+1}\mathrm{d}z\right|\\
&\quad\leqslant\frac{1}{2\nu}\left(r^{\nu}\sqrt{\int_r^R|H_k(z)|^2z\,\mathrm{d}z}\sqrt{\int_r^R z^{-2\nu+1}\mathrm{d}z}+r^{-\nu}\sqrt{\int_0^r|H_k(z)|^2z\,\mathrm{d}z}\sqrt{\int_0^r z^{2\nu+1}\,\mathrm{d}z}\right)\\
&\quad\leqslant\frac{1}{2\nu}r\sqrt{\int_0^R|H_k(z)|^2z\,\mathrm{d}z}\left(\sqrt{\frac{1-\left(\frac{R}{r}\right)^{-2\nu+2}}{2\nu-2}}+\frac{1}{\sqrt{2\nu+2}}\right)\\
&\quad\leqslant\frac{r}{\nu\sqrt{2\nu-2}}\sqrt{\int_0^R|H_k(z)|^2z\,\mathrm{d}z}
\end{aligned}$$

for $0<r<R$. Using a similar procedure on (2.15), (2.17), and (2.18) we get the following inequalities holding for every $k=0,1,\ldots$:

$$|F_k-C_1^{(k)}r^{\nu}-C_2^{(k)}r^{-\nu}|\leqslant\frac{r}{\nu\sqrt{|2\nu-2|}}\sqrt{\int_0^R|H_k(z)|^2z\,\mathrm{d}z}, \tag{2.19}$$

$$|F_k' - \nu C_1^{(k)} r^{\nu-1} + \nu C_2^{(k)} r^{-\nu-1}| \leqslant \frac{1}{\sqrt{|2\nu-2|}} \sqrt{\int_0^R |H_k(z)|^2 z \, \mathrm{d}z}. \tag{2.20}$$

We conclude using this estimate that the first three terms in (2.16) belong to $L^2((0,R), r\,\mathrm{d}r)$ and thus the fourth term has to be in this set too. But it is obvious that $r^{-\nu} \notin L^2((0,R), r\,\mathrm{d}r)$ for $\nu \geqslant 3/2$. Hence $C_2^{(k)} = 0$ for $k \geqslant 1$. Applying the same arguments to (2.17) we have also $C_2^{(0)} = 0$. Moreover the condition $\int_0^R \Sigma_{k=0}^{\infty} |F_k'(r)|^2 r \, \mathrm{d}r < \infty$ must be satisfied. First we suppose $C_1^{(k)} = 0$ for all k. Then using estimate (2.20)

$$\begin{aligned}\int_0^R \sum_{k=0}^{\infty} |F_k'(r)|^2 r \, \mathrm{d}r &\leqslant \int_0^R r \, \mathrm{d}r \sum_{k=0}^{\infty} \frac{1}{2|\nu-1|} \int_0^R |H_k(z)|^2 z \, \mathrm{d}z \\ &\leqslant \|h\|^2_{L^2((0,R)\times(0,\pi), r\,\mathrm{d}\theta\,\mathrm{d}r)} \int_0^R r \, \mathrm{d}r \\ &= \frac{R^2}{2} \|h\|^2_{L^2((0,R)\times(0,\pi), r\,\mathrm{d}\theta\,\mathrm{d}r)}.\end{aligned}$$

Thus we must choose the constants $C_1^{(k)}$ so as

$$\sum_{k=0}^{\infty} \int_0^R |C_1^{(k)}|^2 \nu^2 r^{2\nu-2} r \, \mathrm{d}r = \sum_{k=0}^{\infty} |C_1^{(k)}|^2 \frac{\nu}{2} R^{2\nu} < \infty. \tag{2.21}$$

Now we turn our attention to the function $\tilde{g}(r,\theta)$. Using (2.10) we can write

$$u(r) := \sum_{k=0}^{\infty} \frac{1}{r^2} \left(\frac{2k+1}{2}\right)^2 |G_k(r)|^2 \in L^1((0,R), r\,\mathrm{d}r).$$

Denoting $v(r) = ru(r)$ we get a function $v \in L^1(0,R)$. Thus we can state $\liminf_{r\to 0^+} |rv(r)| = 0$. Otherwise $|rv(r)| \geqslant a > 0$ for a.e. small r, so $|v(r)| \geqslant a/r$ for some constant a and a.e. sufficiently small r, which is a contradiction of the fact that $v \in L^1(0,R)$. Hence we can find a sequence $\{r_n\}_{n=1}^{\infty}$ such that $r_n \to 0^+$ and

$$\lim_{n\to\infty} |r_n v(r_n)| = \lim_{n\to\infty} \sum_{k=0}^{\infty} \left(\frac{2k+1}{2}\right)^2 |G_k(r_n)|^2 = 0. \tag{2.22}$$

Now we are ready to return to (2.7). We rewrite the particular terms of this sum using (2.8) and (2.9),

$$\int_0^{\pi} \frac{\partial \tilde{f}_k(r_n,\theta)}{\partial r} \overline{\tilde{g}_k(r_n,\theta)} r_n \, \mathrm{d}\theta = \sum_{k=0}^{\infty} r_n F_k'(r_n) \overline{G_k(r_n)}.$$

The right-hand side of this equality can be estimated using (2.20), the triangle inequality and the Schwarz inequality in the space ℓ^2,

$$\begin{aligned}\left|\sum_{k=0}^{\infty} r_n F_k'(r_n) \overline{G_k(r_n)}\right| &\leqslant r_n \sum_{k=0}^{\infty} |G_k(r_n)| \left(\sqrt{\int_0^R |H_k(z)|^2 z \, \mathrm{d}z} \frac{1}{\sqrt{|2\nu-2|}} + \nu |C_1^{(k)}| r_n^{\nu-1} \right) \\ &\leqslant \sqrt{\sum_{k=0}^{\infty} |G_k(r_n)|^2} \left(r_n \|h\|_{L^2((0,R)\times(0,\pi), r\,\mathrm{d}\theta\,\mathrm{d}r)} + \sqrt{\sum_{k=0}^{\infty} \nu^2 |C_1^{(k)}|^2 r_n^{2\nu}} \right).\end{aligned} \tag{2.23}$$

Because of (2.22) it is enough to show that the last term in brackets in (2.23) is bounded and we will know that the statement (2.7) holds. Due to (2.21) it is sufficient to prove that the inequality $\nu r^{2\nu}<R^{2\nu}/2$ holds for all $\nu=1/2,3/2,\ldots$ and sufficiently small r. Rewriting the inequality to the form

$$\frac{r}{R}<\left(\frac{1}{2\nu}\right)^{1/2\nu} \tag{2.24}$$

we will study the function $\phi(x)=(1/x)^{1/x}$ on the interval $[1,\infty)$. It is obvious that ϕ is continuous and strictly positive on this interval. As

$$\frac{d}{dx}\phi(x)=\phi(x)\frac{\ln(x)-1}{x^2},$$

ϕ reaches its global minimum at the point $x=e$. Thus for $r/R<(1/e)^{1/e}$ the inequality (2.24) holds for every ν, which completes the proof. ■

Remark 1: The fact that all the functions from the domain of the Hamiltonian, which is defined by the quadratic form, satisfy the prescribed boundary condition is supposed to be well-known for domains with reasonable boundaries. But it is also very often supposed that the operator domain is the subset of the Sobolev space $H^2(\Omega)$, which satisfies the boundary conditions. The systems with combined boundary conditions are examples of operators for which this assertion is not true. The situation is similar to the systems studied in Ref. 11. It was shown there, that for bounded regions in the plane $\mathbb{R}^2$ with piecewise C^3-boundary, which has finite number of angles larger than π, there exists for each such angle one function, which is not in $H^2(\Omega)$ and which belongs to the operator domain with the Dirichlet boundary condition. The operator domain is then a span of the $H_0^2(\Omega)$ space and all these functions, called Guseva functions.

It is easy to check that similar functions belong to operator domain in our systems, too. Let us take the following function, written in polar coordinates with the origin in some P_k and $R<d$:

$$f(r,\theta)=\xi(r)r^{1/2}\sin\frac{\theta}{2}, \tag{2.25}$$

where $\xi(r)\in C^\infty(0,\infty)$, $\xi(r)=1$ on $(0,R/2)$, and $\xi(r)=0$ for $r>R$. This function satisfies the boundary conditions, $\Delta_p f\in L^2(\Omega)$ and $f\in H^1(\Omega)$, thus $f\in D(\Omega)$. But $f\notin H^2(\Omega)$. The trace on the part of the boundary $(-R/2,R/2)$ is

$$\frac{1}{r}\frac{\partial f}{\partial\theta}(r,\theta)=\begin{cases}\frac{1}{2}r^{-1/2} & \text{for } \theta=0\\ 0 & \text{for } \theta=\pi.\end{cases}$$

So even the trace of the normal derivatives on the boundary is not square integrable. These are the reasons why we cannot immediately use the Gauss theorem in the proof of Theorem 1.

The interesting open question arises whether all eigenfunctions have Guseva-like behavior near the points P_k.

III. BOUND STATES

Now we are going to study our specific systems from Fig. 1. First we localize the essential spectra of these systems and make the first estimate on the number of bound states below the essential spectrum threshold using the technique of the Dirichlet–Neumann bracketing (see, e.g., Ref. 14, Sec. XIII.15). Then we will continue with the specification of the number of bound states using variational methods.

A. Essential spectrum, number of bound states

The following arguments are the same for both our systems, so we do not distinguish between them in this section. Cutting the domain Ω by the additional Neumann or Dirichlet boundaries parallel to the y axis at $x=\pm\delta$, we get new operators $H^{(N)}$, $H^{(D)}$ defined in the standard way, using the quadratic form. We can decompose these operators $H^{(j)}=H_t^{(j)}\oplus H_c^{(j)}$, $j=N,D$, where the ''tail'' part corresponds to the two half strips and the rest to the central part with the Neumann and Dirichlet condition on the vertical boundaries, respectively. Using Dirichlet–Neumann bracketing we have $H_t^{(N)}\oplus H_c^{(N)}\leqslant -\Delta_{DN}^{\Omega}\leqslant H_t^{(D)}\oplus H_c^{(D)}$ in the sense of quadratic forms (see Ref. 14, Sec. XIII.15).

Now $\sigma_{\mathrm{ess}}(H_t^{(j)})=[\pi^2/4d^2,\infty)$, $j=N,D$ (we get this result after simple calculation using Example 4.9.6 in Ref. 13 and Corollary of Theorem VIII.33 in Ref. 14). By the minimax principle (see e.g., Ref. 14, Sec. XIII.1) $-\Delta_{DN}^{\Omega}$ has the same infimum of the essential spectrum. To verify that $\sigma_{\mathrm{ess}}(-\Delta_{DN}^{\Omega})$ is indeed the whole interval $[\pi^2/4d^2,\infty)$ we can use the same procedure as for $H_t^{(j)}$ (see Example 4.9.6 in Ref. 13). Possible isolated eigenvalues of $-\Delta_{DN}^{\Omega}$ are squeezed between those of $H_c^{(j)}$, $j=N,D$. Because the first eigenvalue of $H_c^{(N)}$ is zero, $-\Delta_{DN}^{\Omega}$ has an eigenvalue below the essential spectrum threshold provided $H_c^{(D)}$ does, which is true if $\delta>d$.

More generally, the number N_D of eigenvalues of $H_c^{(D)}$ smaller than $\pi^2/4d^2$ equals the largest integer number smaller than δ/d, i.e., $N_D=-[-\delta/d]-1$, where $[\cdot]$ denotes the entire part. The number of ''Neumann'' eigenvalues of $H_c^{(N)}$ is $N_N=1+N_D$. This means that the number of bound states of $-\Delta_{DN}^{\Omega}$ below the essential spectrum threshold satisfies the inequality

$$-\left[-\frac{\delta}{d}\right]-1\leqslant N\leqslant -\left[-\frac{\delta}{d}\right]. \tag{3.1}$$

We see that $-\Delta_{DN}^{\Omega}$ has isolated eigenvalues, at least for large enough δ. In the same way, one finds that the mth eigenvalue μ_m of $-\Delta_{DN}^{\Omega}$ is estimated by

$$\left(\frac{m-1}{\lambda}\right)^2\leqslant\frac{\mu_m}{\mu}\leqslant\left(\frac{m}{\lambda}\right)^2, \tag{3.2}$$

where $\lambda=\delta/d$ and $\mu=\inf(\sigma_{\mathrm{ess}})=\pi^2/4d^2$, and that the critical value $\lambda_m=\delta_m/d$ at which mth eigenvalue appears satisfies the bounds

$$m-1\leqslant\lambda_m\leqslant m. \tag{3.3}$$

To learn more about the dependence of the eigenvalues and the corresponding eigenfunctions on λ, we have to use a different technique.

B. Existence of bound states

The above-presented existence argument for $\lambda>1$ is a crude one. In fact, there is no lower bound on the length of the overlay of Neumann boundaries for case (B), which was shown in Ref. 8, Lemma 3.2. On the other hand we will show that in system (A) the discrete spectrum of the Hamiltonian is empty for small λ, but the ground state appears sooner than $\lambda=1$. We will distinguish the two cases writing $-\Delta_{DN}^{\Omega,\mathrm{A}}$, respectively, $-\Delta_{DN}^{\Omega,\mathrm{B}}$ instead of $-\Delta_{DN}^{\Omega}$ and $Q^{\mathrm{A}}(q_0)$, respectively, $Q^{\mathrm{B}}(q_0)$ instead of $Q(q_0)$.

Theorem 2: *The operator $-\Delta_{DN}^{\Omega,\mathrm{B}}$ has an isolated eigenvalue in $[0,\mu)$ for any $\delta>0$.*

The proof can be found in Ref. 8, Lemmas 2.2 and 3.1. We repeat the theorem here to show the difference with case (A), where the situation is more complicated.

Theorem 3: *There exists a real number $\Lambda_0\in(0,1)$, such that the discrete spectrum of the operator $-\Delta_{DN}^{\Omega,\mathrm{A}}(\lambda)$ is empty for all $\lambda\leqslant\Lambda_0$ and there exists at least one isolated eigenvalue in the spectrum of this operator for all $\lambda>\Lambda_0$.*

Proof: Taking into account that $\mu_1(\lambda)=\inf_{\varphi\in Q^A(q_0),\|\varphi\|=1} q_0(\varphi)$ is a nonincreasing continuous function of λ (see Appendix A) and the minimax principle,[14] it is sufficient to show that there are two real positive numbers $\Lambda_1<\Lambda_2$, Λ_1, $\Lambda_2\in(0,1)$, such that

(i) the discrete spectrum is empty for all $\lambda<\Lambda_1$,
(ii) there exists at least one isolated eigenvalue in the spectrum for all $\lambda>\Lambda_2$.

We know from Sec. III A that there exists a bound state for $\lambda>1$. Let us search for a better estimate $\Lambda_2<1$ by the variational technique. We are seeking the trial function $\Phi\in Q^A(q_0)$, for which the functional q defined by

$$q[\Phi]=q_0(\Phi,\Phi)-\mu\|\Phi\|^2_{L^2(\Omega)} \tag{3.4}$$

has a negative value (see, e.g., Ref. 16, Chap. 4). We can choose Φ continuous inside Ω, but not necessarily smooth. To make the longitudinal contribution to the kinetic energy small, we use an external scaling.

We start with the trial function

$$\Phi_\sigma(x,y)=\varphi_\sigma(x)\sin\frac{\pi y}{2d}+\psi_\sigma(x)\cos\frac{\pi y}{2d}+\eta(x)+\chi(x)\cos\frac{\pi y}{d}, \tag{3.5}$$

where

$$\varphi_\sigma(x)=\begin{cases}\varphi(x) & \text{for} \quad x\geqslant-\delta\\ \varphi(-\delta+\sigma(x+\delta)) & \text{for} \quad x\leqslant-\delta,\end{cases}$$

$$\psi_\sigma(x)=\begin{cases}\psi(x) & \text{for} \quad x\leqslant\delta\\ \psi(\delta+\sigma(x-\delta)) & \text{for} \quad x\geqslant\delta,\end{cases}$$

φ, $\psi\in\mathcal{S}(\mathbb{R})$, $\varphi(-\delta)=\psi(\delta)=1$; $\varphi(x)=0$ on $[\delta,\infty)$, $\psi(x)=0$ on $(-\infty,-\delta]$, η, $\chi\in C^\infty[-\delta,\delta]$ and $\eta(x)=\chi(x)=0$ for $|x|\geqslant\delta$. The value 1 of $\varphi(-\delta)$ and $\psi(\delta)$ is not important, it can be any constant without the influence on the result. We choose $\varphi(-\delta)=\psi(\delta)$, because we expect the ground state to be symmetric. We shall assume the functions φ, ψ, η, χ to be real. We decompose the functional q to three parts, in each of which one integrates over regions I, II, and III, respectively,

$$q[\Phi_\sigma]=q_{\mathrm{I}}[\Phi_\sigma]+q_{\mathrm{II}}[\Phi_\sigma]+q_{\mathrm{III}}[\Phi_\sigma]=\frac{d}{2}\sigma(\|\varphi'\|^2_{L^2(-\infty,-\delta)}+\|\psi'\|^2_{L^2(\delta,\infty)})+q_{\mathrm{II}}[\Phi_\sigma]. \tag{3.6}$$

We see that the first term here is always positive, but it can be arbitrarily small, due to the parameter σ, while the second term does not depend on σ. We easily compute

$$\begin{aligned}q_{\mathrm{II}}[\Phi_\sigma]=\int_{-\delta}^{\delta}\Bigg(&\frac{d}{2}(\varphi'(x)^2+\psi'(x)^2+\chi'(x)^2)+d\,\eta'(x)^2+\frac{2d}{\pi}\varphi'(x)\psi'(x)+\frac{4d}{3\pi}\chi'(x)(\psi'(x)\\&-\varphi'(x))+\frac{4d}{\pi}\eta'(x)(\varphi'(x)+\psi'(x))+\frac{\pi}{d}\chi(x)(\psi(x)-\varphi(x))+\frac{3\pi^2}{8d}\chi(x)^2\\&-\frac{\pi}{d}\varphi(x)\psi(x)-\frac{\pi^2}{4d}\eta(x)^2-\frac{\pi}{d}\eta(x)(\psi(x)+\varphi(x))\Bigg)\mathrm{d}x.\end{aligned} \tag{3.7}$$

We choose the solution of the Euler equations

$$d\varphi''(x)+\frac{2d}{\pi}\psi''(x)-\frac{4d}{3\pi}\chi''(x)+\frac{4d}{\pi}\eta''(x)+\frac{\pi}{d}(\psi(x)+\eta(x)+\chi(x))=0,$$

$$d\psi''(x)+\frac{2d}{\pi}\varphi''(x)+\frac{4d}{3\pi}\chi''(x)+\frac{4d}{\pi}\eta''(x)+\frac{\pi}{d}(\varphi(x)+\eta(x)-\chi(x))=0,$$

$$d\chi''(x)+\frac{4d}{3\pi}(\psi''(x)-\varphi''(x))-\frac{\pi}{d}(\psi(x)-\varphi(x))-\frac{3\pi^2}{4d}\chi(x)=0,$$

$$2d\eta''(x)+\frac{4d}{\pi}(\psi''(x)+\varphi''(x))+\frac{\pi}{d}(\psi(x)+\varphi(x))+\frac{\pi^2}{2d}\eta(x)=0$$

to be a trial function. By linear combinations of these equations we can obtain uncoupled second-order differential equations for $\varphi-\psi$ and $\varphi+\psi$. Then the solution with above-mentioned boundary condition is obtained,

$$\chi(x)=\frac{4}{3\pi}\left(\frac{\sinh\frac{\sqrt{3}\pi x}{2d}}{\sinh\frac{\sqrt{3}\pi\delta}{2d}}-\frac{\sinh\frac{\pi x}{d}\sqrt{3\frac{3\pi-8}{9\pi^2-18\pi-32}}}{\sinh\frac{\pi\delta}{d}\sqrt{3\frac{3\pi-8}{9\pi^2-18\pi-32}}}\right),$$

$$\varphi(x)=\frac{1}{2}\left(\frac{\cosh\frac{\pi x}{d}\sqrt{\frac{4-\pi}{\pi^2+2\pi-16}}}{\cosh\frac{\pi\delta}{d}\sqrt{\frac{4-\pi}{\pi^2+2\pi-16}}}-\frac{\sinh\frac{\pi x}{d}\sqrt{3\frac{3\pi-8}{9\pi^2-18\pi-32}}}{\sinh\frac{\pi\delta}{d}\sqrt{3\frac{3\pi-8}{9\pi^2-18\pi-32}}}\right),$$

$$\psi(x)=\frac{1}{2}\left(\frac{\cosh\frac{\pi x}{d}\sqrt{\frac{4-\pi}{\pi^2+2\pi-16}}}{\cosh\frac{\pi\delta}{d}\sqrt{\frac{4-\pi}{\pi^2+2\pi-16}}}+\frac{\sinh\frac{\pi x}{d}\sqrt{3\frac{3\pi-8}{9\pi^2-18\pi-32}}}{\sinh\frac{\pi\delta}{d}\sqrt{3\frac{3\pi-8}{9\pi^2-18\pi-32}}}\right), \tag{3.8}$$

$$\eta(x)=\frac{2}{\pi}\left(\frac{\cos\frac{\pi x}{2d}}{\cos\frac{\pi\delta}{2d}}-\frac{\cosh\frac{\pi x}{d}\sqrt{\frac{4-\pi}{\pi^2+2\pi-16}}}{\cosh\frac{\pi\delta}{d}\sqrt{\frac{4-\pi}{\pi^2+2\pi-16}}}\right).$$

As the quadratic form of the derivatives in (3.7) is positive definite this trial function is a good candidate for a minimum of the functional (3.7). Now we substitute (3.8) to (3.7) and after a tedious but straightforward calculation we obtain

$$q_{\mathrm{II}}[\Phi_\sigma]=\frac{\sqrt{(4-\pi)(\pi^2+2\pi-16)}}{2\pi}\tanh\frac{\pi\delta}{d}\sqrt{\frac{4-\pi}{\pi^2+2\pi-16}}+\frac{8}{3\sqrt{3}\pi}\coth\frac{\sqrt{3}\pi\delta}{2d}$$
$$+\frac{\sqrt{(3\pi-8)(9\pi^2-18\pi-32)}}{6\sqrt{3}\pi}\coth\frac{\pi\delta}{d}\sqrt{3\frac{3\pi-8}{9\pi^2-18\pi-32}}-\frac{4}{\pi}\tan\frac{\pi\delta}{2d}. \tag{3.9}$$

Now we can understand q_{II} like a function of a variable δ. We see that q_{II} is a continuous function on the interval $(0,d)$, $\lim_{\delta\to 0^+} q_{\mathrm{II}}(\delta)=+\infty$ and $\lim_{\delta\to d^-} q_{\mathrm{II}}(\delta)=-\infty$. So there must exist a point $\delta_0\in(0,d)$ and corresponding number $\Lambda_2=\delta_0/d$, such that $q_{\mathrm{II}}(\delta)<0$ for $\delta\in(\delta_0,d)$. Thus we can find for every δ from this interval a number σ small enough to have $q[\Phi_\sigma]<0$, which finishes the proof of the existence of Λ_2.

Now we are going to prove that the discrete spectrum of the operator $-\Delta_{DN}^{\Omega,A}(\lambda)$ is empty for all $\lambda\leqslant\Lambda_1$. It will be shown if we demonstrate that the functional $q[\Phi]\geqslant 0$ for all Φ from a suitable dense [in $H^1(\Omega)$ norm] set in $Q^A(q_0)$, say

$$\mathcal{Q}(\Omega)=\{\psi\in H^1(\Omega)\cap C(\overline{\Omega})\,|\,\psi\in C^2(\Omega_j), j=\mathrm{I,II,III}, \psi\restriction\mathcal{D}=0\},$$

where $C(\overline{\Omega})$ is just the set of functions continuous in the closure of Ω. It can be proven that this set is really dense in $Q^A(q_0)$ (See Appendix B). We again decompose q into three parts $q[\Phi]=q_{\mathrm{I}}[\Phi]+q_{\mathrm{II}}[\Phi]+q_{\mathrm{III}}[\Phi]$. The "tail" parts of $\Phi\in\mathcal{Q}(\Omega)$ we expand to the series

$$\Phi(x,y)=\sqrt{\frac{2}{d}}\sum_{k=0}^{\infty} a_k(x)\sin\frac{2k+1}{2d}\pi y \tag{3.10}$$

in the region Ω_{I} and

$$\Phi(x,y)=\sqrt{\frac{2}{d}}\sum_{k=0}^{\infty} b_k(x)\cos\frac{2k+1}{2d}\pi y \tag{3.11}$$

in region Ω_{III}. Using the same procedure like in the proof of Theorem 1, we know that these series can be differentiated by terms. Hence

$$q_{\mathrm{I}}[\Phi]=\sum_{k=0}^{\infty}\int_{-\infty}^{-\delta}\left(|a_k'(x)|^2+\frac{\pi^2}{d^2}(k^2+k)|a_k(x)|^2\right)\mathrm{d}x, \tag{3.12}$$

$$q_{\mathrm{III}}[\Phi]=\sum_{k=0}^{\infty}\int_{\delta}^{\infty}\left(|b_k'(x)|^2+\frac{\pi^2}{d^2}(k^2+k)|b_k(x)|^2\right)\mathrm{d}x, \tag{3.13}$$

and we see that $q_{\mathrm{I}}[\Phi]\geqslant 0$ and $q_{\mathrm{III}}[\Phi]\geqslant 0$ for all $\Phi\in\mathcal{Q}(\Omega)$. As we have seen previously above [similar to (3.6)] the contributions from the terms $|a_0'(x)|^2$ and $|b_0'(x)|^2$ can be arbitrarily small. We minimalize the rest of the functional using Euler equations, the general boundary conditions fixing the function values at $x=\delta$, $x=-\delta$, and the square integrability. As $\Phi\in C(\overline{\Omega})$ the Fourier coefficients a_k, b_k are continuous in $(-\infty,-\delta]$, $[\delta,\infty)$ and $a_k(-\delta)$, $b_k(\delta)$ are those of $\Phi(-\delta,\cdot)$, $\Phi(\delta,\cdot)$, respectively. The solution of the Euler equations will be really the absolute minimum of $q_{\mathrm{I}}+q_{\mathrm{III}}$. It is easy to see that for all Φ in the set $\mathcal{Q}(\Omega)$, $q_{\mathrm{I}}[\Phi]+q_{\mathrm{III}}[\Phi]=q_{\mathrm{I}}[\Phi_0]+q_{\mathrm{III}}[\Phi_0]+q_{\mathrm{I}}[\Phi-\Phi_0]+q_{\mathrm{III}}[\Phi-\Phi_0]$, where Φ_0 is given by Euler equations and we have seen previously that $q_{\mathrm{I}}[\Phi-\Phi_0]+q_{\mathrm{III}}[\Phi-\Phi_0]\geqslant 0$. For $k=1,2,\ldots$ we get

$$a_k''(x)-\frac{\pi^2}{d^2}k(k+1)a_k(x)=0,$$

$$b_k''(x)-\frac{\pi^2}{d^2}k(k+1)b_k(x)=0$$

and the square integrable solutions of these equations are

$$a_k(x)=A_k\exp\left(\frac{\pi}{d}\sqrt{k(k+1)}(x+\delta)\right), \tag{3.14}$$

$$b_k(x)=B_k\exp\left(\frac{\pi}{d}\sqrt{k(k+1)}(\delta-x)\right). \tag{3.15}$$

Putting these results to (3.12) and (3.13) we have

$$q_{\mathrm{I}}[\Phi]+q_{\mathrm{III}}[\Phi]\geqslant\frac{\pi}{d}\sum_{k=1}^{\infty}\sqrt{k(k+1)}(|A_k|^2+|B_k|^2). \tag{3.16}$$

Let us turn our attention to the functional q_{II}. First we estimate the value $\|\Phi\|^2_{L^2(\Omega_{\mathrm{II}})}$. Denoting $\Phi_-(y)=\Phi(-\delta,y)$ and $\Phi_+(y)=\Phi(\delta,y)$ we can write

$$\begin{aligned}
\|\Phi\|^2_{L^2(\Omega_{\mathrm{II}})}&=\int_0^d\int_{-\delta}^{\delta}\left|\Phi_-(y)+\int_{-\delta}^{x}\frac{\partial\Phi}{\partial x}(z,y)\,\mathrm{d}z\right|\left|\int_x^{\delta}\frac{\partial\Phi}{\partial x}(z,y)\,\mathrm{d}z-\Phi_+(y)\right|\mathrm{d}x\,\mathrm{d}y\\
&\leqslant\int_0^d\int_{-\delta}^{\delta}\left(|\Phi_-(y)|+\int_{-\delta}^{\delta}\left|\frac{\partial\Phi}{\partial x}(z,y)\right|\mathrm{d}z\right)\left(|\Phi_+(y)|+\int_{-\delta}^{\delta}\left|\frac{\partial\Phi}{\partial x}(z,y)\right|\mathrm{d}z\right)\mathrm{d}x\,\mathrm{d}y\\
&=2\delta\int_0^d\left(|\Phi_-(y)|\,|\Phi_+(y)|+(|\Phi_-(y)|+|\Phi_+(y)|)\int_{-\delta}^{\delta}\left|\frac{\partial\Phi}{\partial x}(z,y)\right|\mathrm{d}z\right.\\
&\quad\left.+\left(\int_{-\delta}^{\delta}\left|\frac{\partial\Phi}{\partial x}(z,y)\right|\mathrm{d}z\right)^2\right)\mathrm{d}y\leqslant 2\delta\left(\|\Phi_-\|_{L^2(0,d)}\|\Phi_+\|_{L^2(0,d)}+\||\Phi_-|\right.\\
&\quad\left.+|\Phi_+|\,\|_{L^2(0,d)}\sqrt{\int_0^d\left(\int_{-\delta}^{\delta}\left|\frac{\partial\Phi}{\partial x}(z,y)\right|\mathrm{d}z\right)^2\mathrm{d}y}+2\delta\left\|\frac{\partial\Phi}{\partial x}\right\|^2_{L^2(\Omega_{\mathrm{II}})}\right)\\
&\leqslant 2\delta\left(\|\Phi_-\|_{L^2(0,d)}\|\Phi_+\|_{L^2(0,d)}+\sqrt{2\delta}\||\Phi_-|+|\Phi_+|\,\|_{L^2(0,d)}\left\|\frac{\partial\Phi}{\partial x}\right\|_{L^2(\Omega_{\mathrm{II}})}\right.\\
&\quad\left.+2\delta\left\|\frac{\partial\Phi}{\partial x}\right\|^2_{L^2(\Omega_{\mathrm{II}})}\right),
\end{aligned}$$

where we used the fact that $\Phi\in C^2(\Omega_{\mathrm{II}})$ and the Schwarz inequality. Denoting $\kappa=\lambda\pi$, we use the last estimate and obtain

$$\begin{aligned}
q_{\mathrm{II}}[\Phi]&=\left\|\frac{\partial\Phi}{\partial x}\right\|^2_{L^2(\Omega_{\mathrm{II}})}+\left\|\frac{\partial\Phi}{\partial y}\right\|^2_{L^2(\Omega_{\mathrm{II}})}-\frac{\pi^2}{4d^2}\|\Phi\|^2_{L^2(\Omega_{\mathrm{II}})}\geqslant\left\|\frac{\partial\Phi}{\partial x}\right\|^2_{L^2(\Omega_{\mathrm{II}})}(1-\kappa^2)\\
&\quad-\sqrt{2\delta}\,\frac{\kappa\pi}{2d}\||\Phi_-|+|\Phi_+|\,\|_{L^2(0,d)}\left\|\frac{\partial\Phi}{\partial x}\right\|_{L^2(\Omega_{\mathrm{II}})}-\frac{\kappa\pi}{2d}\|\Phi_-\|_{L^2(0,d)}\|\Phi_+\|_{L^2(0,d)}.
\end{aligned} \tag{3.17}$$

Let us assume that there exists $\Phi\in\mathcal{Q}(\Omega)$ such that $q[\Phi]<0$. Taking into consideration (3.16) we conclude that $q_{\mathrm{II}}[\Phi]<0$ for considered $\Phi\in\mathcal{Q}$. Then also

$$\left\|\frac{\partial\Phi}{\partial x}\right\|^2_{L^2(\Omega_{\mathrm{II}})}(1-\kappa^2)-\sqrt{2\delta}\frac{\kappa\pi}{2d}\||\Phi_-|+|\Phi_+|\,\|_{L^2(0,d)}\left\|\frac{\partial\Phi}{\partial x}\right\|_{L^2(\Omega_{\mathrm{II}})}-\frac{\kappa\pi}{2d}\|\Phi_-\|_{L^2(0,d)}\|\Phi_+\|_{L^2(0,d)}<0.$$

This inequality holds obviously for $\kappa\geqslant 1$. Let us solve this inequality for $\kappa<1$. Then using the triangle inequality together with the inequality

$$2\|\Phi_-\|_{L^2(0,d)}\|\Phi_+\|_{L^2(0,d)} \leqslant \tfrac{1}{2}(\|\Phi_-\|_{L^2(0,d)}+\|\Phi_+\|_{L^2(0,d)})^2 \tag{3.18}$$

we get

$$\left\|\frac{\partial\Phi}{\partial x}\right\|_{L^2(\Omega_{\mathrm{II}})} < \frac{\kappa}{2\sqrt{2\,\delta}(1-\kappa)}(\|\Phi_-\|_{L^2(0,d)}+\|\Phi_+\|_{L^2(0,d)}). \tag{3.19}$$

We use this result in the following estimate:

$$\|\Phi_+-\Phi_-\|_{L^2(0,d)} = \sqrt{\int_0^d \left|\int_{-\delta}^{\delta}\frac{\partial\Phi}{\partial x}\mathrm{d}x\right|^2 \mathrm{d}y} \leqslant \sqrt{2\,\delta}\left\|\frac{\partial\Phi}{\partial x}\right\|_{L^2(\Omega_{\mathrm{II}})}$$

$$< \frac{\kappa}{2(1-\kappa)}(\|\Phi_-\|_{L^2(0,d)}+\|\Phi_+\|_{L^2(0,d)}). \tag{3.20}$$

Now we use estimates (3.16) and (3.17) together with inequality (3.18), the triangle inequality and

$$(\|\Phi_-\|_{L^2(0,d)}+\|\Phi_+\|_{L^2(0,d)})^2 \leqslant 2(\|\Phi_-\|^2_{L^2(0,d)}+\|\Phi_+\|^2_{L^2(0,d)}) \tag{3.21}$$

to estimate whole functional $q[\Phi]$. Denoting $A_0=a_0(-\delta)$, $B_0=b_0(\delta)$, we obtain

$$\begin{aligned} q[\Phi] &\geqslant \frac{\pi}{d}\sum_{k=1}^{\infty}\sqrt{k(k+1)}(|A_k|^2+|B_k|^2)+\left\|\frac{\partial\Phi}{\partial x}\right\|^2_{L^2(\Omega_{\mathrm{II}})}(1-\kappa^2)-\sqrt{2\,\delta}\frac{\kappa\pi}{2d}\||\Phi_-| \\ &\quad +|\Phi_+|\,\|_{L^2(0,d)}\left\|\frac{\partial\Phi}{\partial x}\right\|_{L^2(\Omega_{\mathrm{II}})}-\frac{\kappa\pi}{2d}\|\Phi_-\|_{L^2(0,d)}\,\|\Phi_+\|_{L^2(0,d)} \\ &\geqslant \frac{\pi\sqrt{2}}{d}\sum_{k=1}^{\infty}(|A_k|^2+|B_k|^2)+(1-\kappa^2)\left(\left\|\frac{\partial\Phi}{\partial x}\right\|_{L^2(\Omega_{\mathrm{II}})}-\sqrt{2\,\delta}\frac{\kappa\pi}{4d}\frac{\||\Phi_-|+|\Phi_+|\,\|_{L^2(0,d)}}{1-\kappa^2}\right)^2 \\ &\quad -\frac{\kappa^3\pi}{8d}\frac{\||\Phi_-|+|\Phi_+|\,\|^2_{L^2(0,d)}}{(1-\kappa^2)}-\frac{\kappa\pi}{4d}(\|\Phi_-\|^2_{L^2(0,d)}+\|\Phi_+\|^2_{L^2(0,d)}) \\ &\geqslant \frac{\pi\sqrt{2}}{d}\sum_{k=1}^{\infty}(|A_k|^2+|B_k|^2)-\frac{\kappa\pi}{4d(1-\kappa^2)}\sum_{k=0}^{\infty}(|A_k|^2+|B_k|^2), \end{aligned} \tag{3.22}$$

where we also used (3.10) and (3.11) together with (3.14) and (3.15). We assumed $q[\Phi]<0$, thus the same is true for the last expression in (3.22) and so we obtain for $\kappa<(\sqrt{129}-1)/8\sqrt{2}\doteq 0.92$,

$$\sum_{k=1}^{\infty}(|A_k|^2+|B_k|^2) < \frac{\kappa}{4\sqrt{2}(1-\kappa^2)-\kappa}(|A_0|^2+|B_0|^2). \tag{3.23}$$

Now we need estimates (3.21), (3.20), and (3.23) together with known inequalities for non-negative numbers

$$2ab \leqslant a^2+b^2,$$

$$(a+b+c)^2 \leqslant 3(a^2+b^2+c^2),$$

and the triangle inequality to do the last step of the proof. First notice, that

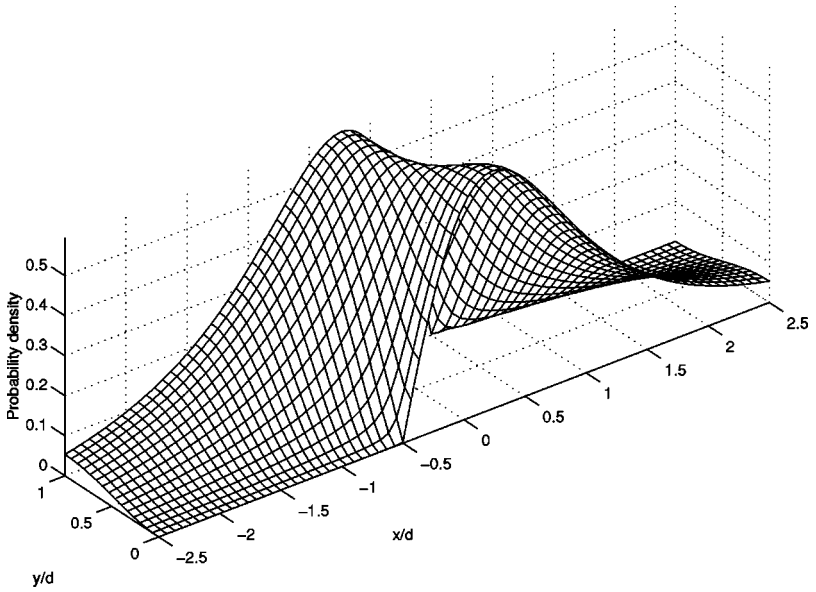

FIG. 2. Probability density $|\psi|^2$ (in units of d^{-2}) for the bound state in model A, $\lambda = 1/2$, coordinates x, y in the units of d. Only one discrete bound state exists here.

$$\frac{2}{d}\left\| A_0 \sin\frac{\pi y}{2d} - B_0 \cos\frac{\pi y}{2d}\right\|^2_{L^2(0,d)} = |A_0|^2 + |B_0|^2 - \frac{4}{\pi}\Re(A_0 B_0) \geqslant \left(1 - \frac{2}{\pi}\right)(|A_0|^2 + |B_0|^2). \tag{3.24}$$

On the other hand,

$$\begin{aligned}
&\frac{2}{d}\left\| A_0 \sin\frac{\pi y}{2d} - B_0 \cos\frac{\pi y}{2d}\right\|^2_{L^2(0,d)} \\
&\quad = \left\| \Phi_- - \Phi_+ - \sqrt{\frac{2}{d}}\sum_{k=1}^{\infty}\left(A_k \sin\frac{(2k+1)\pi y}{2d} - B_k \cos\frac{(2k+1)\pi y}{2d}\right)\right\|^2_{L^2(0,d)} \\
&\quad \leqslant \left(\|\Phi_- - \Phi_+\|_{L^2(0,d)} + \sqrt{\sum_{k=1}^{\infty}|A_k|^2} + \sqrt{\sum_{k=1}^{\infty}|B_k|^2}\right)^2 \\
&\quad \leqslant \left(\frac{\kappa}{2(1-\kappa)}(\|\Phi_-\|_{L^2(0,d)} + \|\Phi_+\|_{L^2(0,d)}) + \sqrt{\sum_{k=1}^{\infty}|A_k|^2} + \sqrt{\sum_{k=1}^{\infty}|B_k|^2}\right)^2 \\
&\quad < 3\left(\frac{\kappa^2}{2(1-\kappa)^2}\sum_{k=0}^{\infty}(|A_k|^2 + |B_k|^2) + \sum_{k=1}^{\infty}(|A_k|^2 + |B_k|^2)\right) \\
&\quad < 3\,\frac{2\sqrt{2}(1+\kappa)\kappa^2 + \kappa(1-\kappa)}{(1-\kappa)(4\sqrt{2}(1-\kappa^2) - \kappa)}(|A_0|^2 + |B_0|^2).
\end{aligned}$$

We compare this inequality with (3.24) and we have

$$1 - \frac{2}{\pi} < 3\kappa\,\frac{2\sqrt{2}(1+\kappa)\kappa + 1 - \kappa}{(1-\kappa)(4\sqrt{2}(1-\kappa^2) - \kappa)}. \tag{3.25}$$

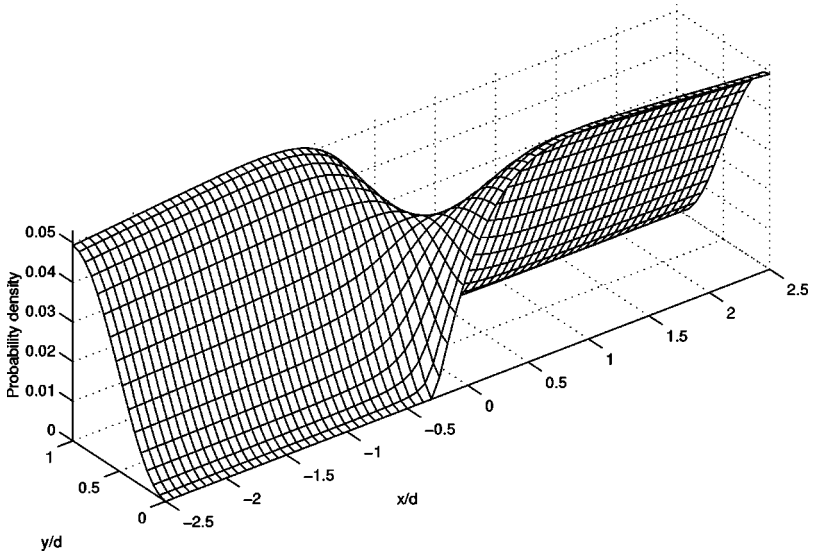

FIG. 3. The same as in Fig. 2 but $\lambda = 0.27$. It is close to the threshold for bound state appearance.

We recall that we investigate this inequality for $0 < \kappa < (\sqrt{129} - 1)/8\sqrt{2}$. The right-hand side of (3.25) is a positive, continuous function of κ on this interval and it goes to zero as κ does. Hence there must exist a number κ_0 (and so Λ_1), such that this inequality does not hold for $\kappa \in (0, \kappa_0)$, i.e., for $\lambda \in (0, \Lambda_1)$. Thus $q[\Phi] \geqslant 0$ for all $\Phi \in \mathcal{Q}(\Omega)$ for these values of the parameter λ, which has been to prove. ■

Remark 2: We also know that the discrete eigenvalues emerge at the essential spectrum threshold and they are continuous functions of λ *in both our specific cases. The rigorous formulation and the proof of this statement are given in Appendix A.*

IV. NUMERICAL RESULTS

We have solved the Schrödinger equation corresponding to our systems numerically. Since Ω consists of three rectangular regions, the easiest way to do that is the mode-matching method (see, e.g., Ref. 4). The results are shown in Figs. 2–5. In Figs. 4 and 5 we can notice that the first eigenvalue in model A appears for $\Lambda_0 > 0$. Our numerical results indicate that $\Lambda_0 \doteq 0.26$ in agreement with our analytical proofs. Solving numerically the equation $q_{\mathrm{II}}[\Phi_\sigma] = 0$ with the right-hand side given by (3.9) we get the result $\Lambda_2 \doteq 0.34$. In the same way from (3.25) we get after numerical computation $\Lambda_1 \doteq 0.08$. Hence $\Lambda_1 < \Lambda_0 < \Lambda_2$, which we have expected.

ACKNOWLEDGMENTS

The authors thank Professor Pavel Exner for discussions on the problem formulation and expected results. The work was supported by GA ASCR Grant No. IAA 1048101.

APPENDIX A: THE CONTINUITY OF THE EIGENVALUES

First we define some notations for purposes of this appendix. Let $\lambda > 0$ then

$$Q(\lambda) = \{f \in H^1(\Omega) \mid f \restriction \mathcal{D}(\lambda) = 0\},$$

where

$$\mathcal{D}(\lambda) = \{\langle x, 0\rangle \mid x < -\lambda d\} \cup \{\langle x, d\rangle \mid x > \lambda d\}$$

or

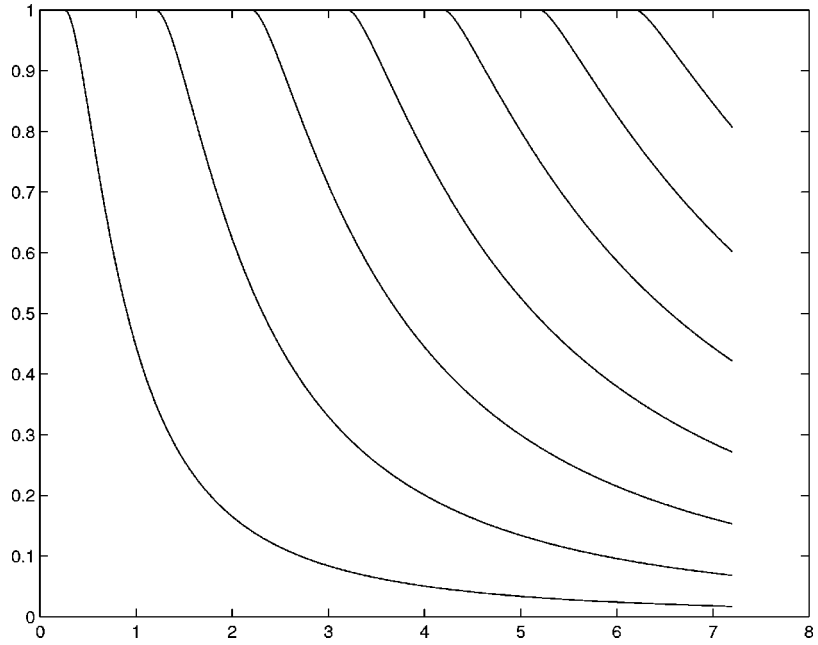

FIG. 4. Eigenvalues (in the units of $\mu = \pi^2/4d^2$) for model A in dependence on λ.

$$\mathcal{D}(\lambda) = \{\langle x,d\rangle \mid (x < -\lambda d) \vee (x > \lambda d)\}.$$

So we have stressed only the dependence of the form domain on the parameter λ. We define

$$U(\varphi_1,\ldots,\varphi_m;\lambda) = \inf_{\substack{\psi\in Q(\lambda),\psi\neq 0\\ \psi\perp\varphi_1,\ldots,\varphi_m}} \frac{\|\nabla\psi\|^2_{L^2(\Omega)}}{\|\psi\|^2_{L^2(\Omega)}},$$

$$\mu_n(\lambda) = \sup_{\varphi_1,\ldots,\varphi_{n-1}\in L^2(\Omega)} U(\varphi_1,\ldots,\varphi_{n-1};\lambda).$$

From the minimax principle,[14] we know that for every $n=1,2,\ldots$, $\mu_n(\lambda)$ is either the nth eigenvalue of the operator (counting multiplicity) or the bottom of its essential spectrum. The aim of this appendix is to show that $\mu_n(\lambda)$ are continuous functions in $(0,\infty)$.

Lemma 1: Functions $\mu_n : \lambda \mapsto \mu_n(\lambda)$ *are nonincreasing, finite, and continuous in* $(0,\infty)$ *for every* $n=1,2,\ldots$.

Proof: We know from the minimax principle and the Dirichlet–Neumann bracketing[14] that $0 \leq \mu_n(\lambda) \leq \pi^2/4d^2$ for all $\lambda > 0$ and $n=1,2,\ldots$. Let $\lambda_1 > \lambda_2$. Then $Q(\lambda_2) \subset Q(\lambda_1)$ and so for any $m=0,1,\ldots$ and any m-tuple $\varphi_1,\ldots,\varphi_m$,

$$U(\varphi_1,\ldots,\varphi_m;\lambda_1) \leq U(\varphi_1,\ldots,\varphi_m;\lambda_2) \leq \mu_{m+1}(\lambda_2).$$

Because these inequalities hold for every m-tuple $\varphi_1,\ldots,\varphi_m$ from our Hilbert space they must be fulfilled even for supremum over these m-tuples. Hence

$$\mu_{m+1}(\lambda_1) \leq \mu_{m+1}(\lambda_2) \tag{A1}$$

for every $m=0,1,\ldots$ and μ_{m+1} are thus nonincreasing.

For any $\varrho > 1$ we define $\varphi^{(\varrho)}(x,y) = \varphi(\varrho x, y)$. The equivalences $\varphi \in Q(\lambda) \Leftrightarrow \varphi^{(\varrho)} \in Q(\lambda/\varrho)$ and $\varphi \perp \psi \Leftrightarrow \varphi^{(\varrho)} \perp \psi^{(\varrho)}$ are obvious. Moreover

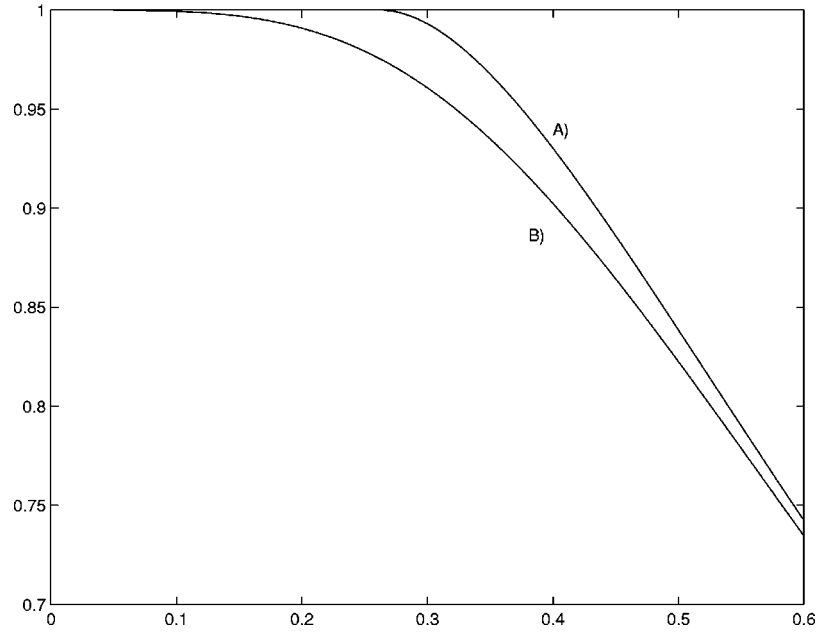

FIG. 5. First eigenvalues for models A and B in dependence of λ. While in model B the eigenvalue exists for any $\lambda>0$ in model A appears at $\Lambda>\Lambda_0$ (numerical calculations indicate $\Lambda_0\doteq 0.26$).

$$\frac{\|\nabla\varphi^{(\varrho)}\|^2_{L^2(\Omega)}}{\|\varphi^{(\varrho)}\|^2_{L^2(\Omega)}}=\frac{\varrho^2\|\dfrac{\partial\varphi}{\partial x}\|^2_{L^2(\Omega)}+\|\dfrac{\partial\varphi}{\partial y}\|^2_{L^2(\Omega)}}{\|\varphi\|^2_{L^2(\Omega)}}\leqslant\varrho^2\frac{\|\nabla\varphi\|^2_{L^2(\Omega)}}{\|\varphi\|^2_{L^2(\Omega)}}. \tag{A2}$$

Let integer $m\geqslant 0$, $\lambda>0$ and $\varphi_1,\ldots,\varphi_m\in L^2(\Omega)$ are chosen arbitrarily. Then for any $\varphi\in Q(\lambda)$ such that $\varphi\perp\varphi_1,\ldots,\varphi_m$ we know $\varphi_1^{(\varrho)},\ldots,\varphi_m^{(\varrho)}\in L^2(\Omega)$, $\varphi^{(\varrho)}\in Q(\lambda/\varrho)$, and $\varphi^{(\varrho)}\perp\varphi_1^{(\varrho)},\ldots,\varphi_m^{(\varrho)}$. Then using (A2) we get

$$U\left(\varphi_1^{(\varrho)},\ldots,\varphi_m^{(\varrho)};\frac{\lambda}{\varrho}\right)\leqslant\frac{\|\nabla\varphi^{(\varrho)}\|^2_{L^2(\Omega)}}{\|\varphi^{(\varrho)}\|^2_{L^2(\Omega)}}\leqslant\varrho^2\frac{\|\nabla\varphi\|^2_{L^2(\Omega)}}{\|\varphi\|^2_{L^2(\Omega)}}.$$

Because these inequalities hold for arbitrary m-tuple $\varphi_1,\ldots,\varphi_m$ it must hold even for the infimum of

$$\frac{\|\nabla\varphi\|^2_{L^2(\Omega)}}{\|\varphi\|^2_{L^2(\Omega)}}$$

and hence

$$U\left(\varphi_1^{(\varrho)},\ldots,\varphi_m^{(\varrho)};\frac{\lambda}{\varrho}\right)\leqslant\varrho^2U(\varphi_1,\ldots,\varphi_m;\lambda)\leqslant\varrho^2\mu_{m+1}(\lambda).$$

Passing again to the supremum over all m-tuples $\varphi_1^{(\varrho)},\ldots,\varphi_m^{(\varrho)}$ and taking into account (A1) we obtain

$$\mu_{m+1}(\lambda)\leqslant\mu_{m+1}\left(\frac{\lambda}{\varrho}\right)\leqslant\varrho^2\mu_{m+1}(\lambda), \tag{A3}$$

because $\lambda>\lambda/\varrho$. From the second inequality of (A3) and from (A1) we get

$$\frac{1}{\varrho^2}\mu_{m+1}(\lambda)\leqslant\mu_{m+1}(\lambda\varrho)\leqslant\mu_{m+1}(\lambda) \tag{A4}$$

using $\lambda\varrho>\lambda$. We recall that these inequalities hold for any $m\in\{0,1,\ldots\}$.

For any $0<\lambda'<\lambda$ we set $\varrho=\lambda/\lambda'$ and we put it to (A3)

$$\mu_{m+1}(\lambda)\leqslant\mu_{m+1}(\lambda')\leqslant\left(\frac{\lambda}{\lambda'}\right)^2\mu_{m+1}(\lambda).$$

We see that $\lim_{\lambda'\to\lambda^-}\mu_{m+1}(\lambda')=\mu_{m+1}(\lambda)$. We repeat the same procedure for $0<\lambda<\lambda'$ using the inequalities (A4) instead of (A3) and we get $\lim_{\lambda'\to\lambda^+}\mu_{m+1}(\lambda')=\mu_{m+1}(\lambda)$, which finishes the proof. ■

APPENDIX B: THE DENSE SET IN $Q^A(q_0)$

The goal of the appendix is to prove the following lemma.

Lemma 2: The set $\widetilde{Q}(\Omega)=\{\psi\in C^\infty(\overline{\Omega})\mid\psi=\widetilde{\psi}\restriction\Omega,\widetilde{\psi}\in C_0^\infty(\mathbb{R}^2),\psi\restriction\mathcal{D}=0\}$ *is dense in the set* $Q^A(q_0)$ *with respect to the* $H^1(\Omega)$ *norm.*

Proof: Let $\varphi\in Q^A(q_0)$. Then for every $\varepsilon>0$ we can find the function $\varphi_1^{(\varepsilon)}$ from the set $\{\psi\in C^\infty(\overline{\Omega})\mid\psi=\widetilde{\psi}\restriction\Omega,\widetilde{\psi}\in C_0^\infty(\mathbb{R}^2)\}$ such that $\|\varphi-\varphi_1^{(\varepsilon)}\|_{H^1(\Omega)}<\varepsilon$ (see, e.g., Ref. 12, Theorem 3.18). Due to Theorem 5.22 in Ref. 12 we can also write $\|(\varphi-\varphi_1^{(\varepsilon)})\restriction\mathcal{D}\|_{L^2(\mathcal{D})}<\sqrt{C}\varepsilon$, where C is a constant. Let γ be the function from the class $C^\infty(\mathbb{R})$ with the following properties: $0\leqslant\gamma(t)\leqslant1$ for $t\in\mathbb{R}$, $\gamma(t)=0$ for $t\leqslant1/2$, $\gamma(t)=1$ for $t\geqslant1$ and $|d\gamma(t)/dt|\leqslant\Gamma/5$ for some constant Γ and every $t\in\mathbb{R}$. For $\langle x,y\rangle\in\Omega$ and $\varepsilon<d/2$ we define

$$\omega_\varepsilon^{(1)}(x,y)=\begin{cases}\gamma\left(\dfrac{4(d-y)}{\varepsilon}\right)\gamma\left(\dfrac{\sqrt{(x-\delta)^2+(y-d)^2}}{\varepsilon}\right) & \text{for } x\geqslant\delta\\ \gamma\left(\dfrac{\sqrt{(x-\delta)^2+(y-d)^2}}{\varepsilon}\right) & \text{for } x\leqslant\delta,\end{cases}$$

$$\omega_\varepsilon^{(2)}(x,y)=\begin{cases}\gamma\left(\dfrac{4y}{\varepsilon}\right)\gamma\left(\dfrac{\sqrt{(x+\delta)^2+y^2}}{\varepsilon}\right) & \text{for } x\leqslant-\delta\\ \gamma\left(\dfrac{\sqrt{(x+\delta)^2+y^2}}{\varepsilon}\right) & \text{for } x\geqslant-\delta\end{cases}$$

and $\omega_\varepsilon=\omega_\varepsilon^{(1)}\omega_\varepsilon^{(2)}$. Obviously $\varphi_2^{(\varepsilon)}=\varphi_1^{(\varepsilon)}\omega_\varepsilon\in\widetilde{Q}(\Omega)$. Let us denote

$$\Omega_\varepsilon=\{\langle x,y\rangle\in\Omega\mid\operatorname{dist}(\langle x,y\rangle,\mathcal{D})<\varepsilon\},$$

$$\Omega_\varepsilon^1=((\delta,\infty)\times(d-\varepsilon,d))\cup((-\infty,-\delta)\times(0,\varepsilon)),$$

$$\Omega_\varepsilon^2=((\delta-\varepsilon,\delta)\times(d-\varepsilon,d))\cup((-\delta,-\delta+\varepsilon)\times(0,\varepsilon)),$$

$$\Omega_\varepsilon^3=((\delta-\varepsilon,\delta+\varepsilon)\times(d-\varepsilon,d))\cup((-\delta-\varepsilon,-\delta+\varepsilon)\times(0,\varepsilon)).$$

Now we are going to estimate $\|\varphi_2^{(\varepsilon)}-\varphi\|_{H^1(\Omega)}^2$,

$$\|\varphi_2^{(\varepsilon)}-\varphi\|_{H^1(\Omega)}^2=\|(\varphi_1^{(\varepsilon)}-\varphi)\omega_\varepsilon+\varphi(\omega_\varepsilon-1)\|_{L^2(\Omega)}^2+\|\nabla(\varphi_1^{(\varepsilon)}-\varphi)\omega_\varepsilon+\nabla\varphi(\omega_\varepsilon-1)+\varphi_1^{(\varepsilon)}\nabla\omega_\varepsilon\|_{L^2(\Omega)}^2\leqslant3\left(\|\varphi_1^{(\varepsilon)}-\varphi\|_{H^1(\Omega)}^2+\|\varphi\|_{H^1(\Omega_\varepsilon)}^2+\frac{\Gamma^2}{\varepsilon^2}\|\varphi_1^{(\varepsilon)}\|_{L^2(\Omega_\varepsilon)}^2\right).$$

Now we continue by estimating of $\|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon)}$,

$$\|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon)} \leqslant \|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon^1)} + \|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon^2)},$$

$$\|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon^1)} = \int_\delta^\infty \int_{d-\varepsilon}^d |\varphi_1^{(\varepsilon)}(x,y)|^2 \mathrm{d}y\, \mathrm{d}x + \int_{-\infty}^{-\delta} \int_0^\varepsilon |\varphi_1^{(\varepsilon)}(x,y)|^2 \mathrm{d}y\, \mathrm{d}x.$$

Because the estimates of the second term in the previous expression will be analogous to ones of the first term we will not write the second integral, but only ''second term'' instead of it,

$$\begin{aligned}
\|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon^1)} &= \int_\delta^\infty \int_{d-\varepsilon}^d \left| \varphi_1^{(\varepsilon)}(x,d) - \int_y^d \frac{\partial \varphi_1^{(\varepsilon)}}{\partial t}(x,t)\mathrm{d}t \right|^2 \mathrm{d}y\, \mathrm{d}x + \text{second term} \\
&\leqslant 2 \int_\delta^\infty \int_{d-\varepsilon}^d \left(|\varphi_1^{(\varepsilon)}(x,d)|^2 + \varepsilon \int_{d-\varepsilon}^d \left| \frac{\partial \varphi_1^{(\varepsilon)}}{\partial t}(x,t) \right|^2 \mathrm{d}t \right) \mathrm{d}y\, \mathrm{d}x + \text{second term} \\
&= 2 \left(\varepsilon \|\varphi_1^{(\varepsilon)} \restriction \mathcal{D}\|^2_{L^2(\mathcal{D})} + \varepsilon^2 \left\| \frac{\partial \varphi_1^{(\varepsilon)}}{\partial y} \right\|^2_{L^2(\Omega_\varepsilon^1)} \right) \\
&\leqslant 2\varepsilon^2 (C\varepsilon + \|\varphi_1^{(\varepsilon)}\|^2_{H^1(\Omega_\varepsilon^1)}) \leqslant 2\varepsilon^2 (C\varepsilon + 2(\|\varphi_1^{(\varepsilon)} - \varphi\|^2_{H^1(\Omega)} + \|\varphi\|^2_{H^1(\Omega_\varepsilon^1)})) \\
&\leqslant 2\varepsilon^2 (C\varepsilon + 2\varepsilon^2 + 2\|\varphi\|^2_{H^1(\Omega_\varepsilon^1)}).
\end{aligned}$$

For any $z \in (\delta, \delta+\varepsilon)$ we calculate

$$\begin{aligned}
\|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon^2)} &= \int_{\delta-\varepsilon}^\delta \int_{d-\varepsilon}^d \left| \int_x^z \frac{\partial \varphi_1^{(\varepsilon)}}{\partial t}(t,y)\mathrm{d}t + \int_y^d \frac{\partial \varphi_1^{(\varepsilon)}}{\partial s}(z,s)\mathrm{d}s - \varphi_1^{(\varepsilon)}(z,d) \right|^2 \mathrm{d}y\, \mathrm{d}x + \text{s.t.} \\
&\leqslant 3 \int_{\delta-\varepsilon}^\delta \int_{d-\varepsilon}^d \left(2\varepsilon \int_{\delta-\varepsilon}^{\delta+\varepsilon} \left| \frac{\partial \varphi_1^{(\varepsilon)}}{\partial t}(t,y) \right|^2 \mathrm{d}t + \varepsilon \int_{d-\varepsilon}^d \left| \frac{\partial \varphi_1^{(\varepsilon)}}{\partial s}(z,s) \right|^2 \mathrm{d}s \right. \\
&\quad \left. + |\varphi_1^{(\varepsilon)}(z,d)|^2 \right) \mathrm{d}y\, \mathrm{d}x + \text{second term}.
\end{aligned}$$

When we integrate the last inequality over z from δ to $\delta+\varepsilon$ we obtain

$$\varepsilon \|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon^2)} \leqslant 3 \left(2\varepsilon^3 \left\| \frac{\partial \varphi_1^{(\varepsilon)}}{\partial x} \right\|^2_{L^2(\Omega_\varepsilon^3)} + \varepsilon^3 \left\| \frac{\partial \varphi_1^{(\varepsilon)}}{\partial y} \right\|^2_{L^2(\Omega_\varepsilon^3)} + \varepsilon^2 \|\varphi_1^{(\varepsilon)} \restriction \mathcal{D}\|^2_{L^2(\mathcal{D})} \right)$$

and so

$$\|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon^2)} \leqslant 6\varepsilon^2 \|\varphi_1^{(\varepsilon)}\|^2_{H^1(\Omega_\varepsilon^3)} + 3C\varepsilon^3 \leqslant 12\varepsilon^2 (\varepsilon^2 + \|\varphi\|^2_{H^1(\Omega_\varepsilon^3)}) + 3C\varepsilon^3.$$

We give both these estimates together and we get

$$\|\varphi_1^{(\varepsilon)}\|^2_{L^2(\Omega_\varepsilon)} \leqslant 5C\varepsilon^3 + 16\varepsilon^4 + 16\varepsilon^2 \|\varphi\|^2_{H^1(\Omega_\varepsilon^1 \cup \Omega_\varepsilon^2)}.$$

Hence

$$\|\varphi_2^{(\varepsilon)} - \varphi\|^2_{H^1(\Omega)} \leqslant 3((1+16\Gamma^2)(\varepsilon^2 + \|\varphi\|^2_{H^1(\Omega_\varepsilon^1 \cup \Omega_\varepsilon^2)}) + 5C\Gamma^2\varepsilon).$$

Here $\lim_{\varepsilon\to 0^+}\|\varphi\|^2_{H^1(\Omega^1_\varepsilon\cup\Omega^2_\varepsilon)}=0$, e.g., by the dominated convergence. So $\|\varphi_2^{(\varepsilon)}-\varphi\|^2_{H^1(\Omega)}$ goes to zero as ε does which has been to show. ■

Remark 3: Our set $\tilde{Q}$ is obviously a subset of the set $\mathcal{Q}$ defined in the proof of the Theorem 3. Hence $\mathcal{Q}$ is a dense set in $Q^A(q_0)$ as well.

Bogoliubov transformations and exact isolated solutions for simple nonadiabatic Hamiltonians

C. Emary[a] and R. F. Bishop
Department of Physics, University of Manchester Institute of Science and Technology (UMIST), P.O. Box 88, Manchester M60 1QD, United Kingdom

(Received 10 December 2001; accepted for publication 25 April 2002)

We present a new method for finding isolated exact solutions of a class of nonadiabatic Hamiltonians of relevance to quantum optics and allied areas. Central to our approach is the use of Bogoliubov transformations of the bosonic fields in the models. We demonstrate the simplicity and efficiency of this method by applying it to the Rabi Hamiltonian. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1490406]

I. INTRODUCTION

There exists a class of simple, nonintegrable, nonadiabatic Hamiltonians of the type that find application as models of light–matter interactions, for which it is possible to find exact isolated solutions. Generally these models involve some atomic system, typically characterized by a simple two-level (or multilevel) system, interacting with a number of bosonic fields. Making the familiar rotating-wave approximation usually renders these models completely soluble, but avoiding this approximation maintains the nonintegrability of the models, and gives rise to the possibility of isolated exact solutions. This was first demonstrated for the Jahn–Teller model by Judd,[1] and these solutions are often referred to as Juddian solutions. Probably the simplest model for which these solutions have been found is the Rabi Hamiltonian (RH), which describes a two-level atom interacting with a single-mode bosonic field via a dipole interaction.[2] The Juddian solutions of the RH were first discovered by Reik and co-workers,[3] where they were seen to occur at the level crossings in the energy schema of the system. This turns out to be a general and important feature of these solutions.

Apart from being of interest for what they tell us about the structure and symmetries of these models, the Juddian solutions are of considerable further value. Simple quantum optics and related models, such as the RH, have long been utilized as test cases for various calculational techniques,[4–6] and the possession of exact solutions facilitates their accurate assessment. Furthermore, the existence of isolated exact solutions in nonintegrable quantum models is also of interest from the perspective of studying possible quantum chaos in such systems.[7,8] In addition, it is hoped that these exact solutions may serve as useful starting points for perturbative treatments of the entire spectra of these models.

In this paper we present a new and more general method for finding these isolated exact solutions, which we believe to have several advantages over the methods hitherto employed. Judd and Reik, working in the Bargmann representation, have used power series and Neumann series ansätze for the field mode. Neither of these approaches is particularly intuitive and the resulting algebra can become complicated. Kuś and Lewenstein[9] have given a more concise approach which, as we describe later, is clearly related to the method that we describe here. For models such as the RH they used Bargmann representation ansätze for the field consisting of a finite number of bosonic excitations on top of a coherent state. They have also extended their method to some further systems, such as a three-level system and an auto-ionizing ion.

We believe that the method we outline in this paper is both more intuitive and more efficient

[a]Electronic mail: emary@dirac.phy.umist.ac.uk

than those discussed previously, and that it reflects the essential physics of the systems to a greater degree. At the heart of the method is a simple canonical transformation of the bosonic field operators of the models. This transformation suggests the existence of exact solutions in a most direct manner. Our method also has the advantage that it is easy to generalize, and is readily able to be extended to ''two-photon'' type interactions, in which two photons are required to induce an atomic transition.[10]

The remainder of this paper is organized as follows. In Sec. II we outline our method for finding the Juddian solutions. We describe in some detail the theory of Bogoliubov transformations of a boson mode and pay particular attention to their relation to the coherent and squeezed states. We then use these transformations to investigate the displaced and squeezed harmonic oscillators, to develop insight into the reasoning behind this approach. In Sec. III we apply this method to the Rabi Hamiltonian, as an example of the use of this method. We then finish with some conclusions and indications of further work.

II. METHODOLOGY

The models that we consider here consist of an atomic system interacting with one or more bosonic modes. Each of these modes is described by annihilation and creation operators, b and $b^\dagger$, respectively, which obey the usual commutation relation,

$$[b,b^\dagger]=1. \tag{1}$$

In general the atomic system will be described in terms of a set of matrices. For example, the two-level system in the RH is described by the SU(2) Pauli matrices.

Our method for finding exact isolated solutions for such systems involves two components. First, one must choose an appropriate representation for the atomic matrices and then, crucially, one performs a Bogoliubov transformation of the operators of the field mode. The nature of this transformation depends upon the type of interaction being considered and, with the correct choice of parameters, it leaves the Schrödinger equation in a form that admits exact solutions with very simple ansätze.

A. Bogoliubov transformations

A Bogoliubov transformation is a transformation from one description of a field mode in terms of the bosonic operators, b and $b^\dagger$, to a description in terms of new bosonic operators, $\tilde{b}$ and $\tilde{b}^\dagger$, say. This transformation is canonical so that the new operators obey the same commutation relation as the old ones, namely

$$[\tilde{b},\tilde{b}^\dagger]=1. \tag{2}$$

The most general linear Bogoliubov transformation may be viewed as a rotation plus translation of the original oscillator Hilbert space to the new oscillator space,

$$\begin{aligned}\tilde{b}&=e^{-i\beta}(1-|\sigma|^2)^{-1/2}(b-\sigma b^\dagger-z),\\ \tilde{b}^\dagger&=e^{i\beta}(1-|\sigma|^2)^{-1/2}(b^\dagger-\sigma^* b-z^*),\end{aligned} \tag{3}$$

where σ and z are complex numbers describing the amplitudes of the rotation and translation, respectively. β is a simple, and usually rather unimportant, phase factor. From the outset it is important to note the restriction $|\sigma|<1$ in order to preserve the unitarity of the transformation. In the following we consider two specializations of this transformation, namely a pure translation and a pure rotation. These transformations may be very simply related to the familiar coherent and squeezed states of quantum optics and it is from this standpoint that we introduce the transformations.

B. Coherent bosons

The usual Glauber coherent states, $|z\rangle$, may be defined as eigenkets of the single-mode bosonic annihilation operator,[11]

$$b|z\rangle = z|z\rangle, \tag{4}$$

where z is a complex number. Such states are readily constructed as the following equivalent forms:

$$|z\rangle = e^{-1/2|z|^2} e^{zb^\dagger}|0\rangle \tag{5}$$

$$= e^{(zb^\dagger - z^* b)}|0\rangle, \tag{6}$$

where we have normalized the coherent state such that $\langle z|z\rangle = 1$. The exponential operator in Eq. (6) is denoted as follows:

$$D(z) \equiv e^{(zb^\dagger - z^* b)}, \tag{7}$$

and is called the displacement operator. It is a unitary operator and we may readily use it to perform a unitary transformation of the field operators,

$$\begin{aligned} D(z) b D^\dagger(z) &= b - z \equiv a, \\ D(z) b^\dagger D^\dagger(z) &= b^\dagger - z^* \equiv a^\dagger. \end{aligned} \tag{8}$$

The operators $D(z)$ form a representation of the Weyl (or Heisenberg–Weyl) group when multiplied by a trivial phase factor $\exp(i\phi)$, with ϕ real. The operators a and $a^\dagger$ obey the same commutator relation as the original operators, and thus we see this transformation to be a Bogoliubov transformation of the type described earlier as a pure translation. Equations (4) and (8) clearly imply

$$a|z\rangle = 0, \tag{9}$$

from which we see that the operator a annihilates the coherent state $|z\rangle$. Thus $|z\rangle$ may be considered as the vacuum state of the a-type bosons, and we rewrite it accordingly as $|0;z\rangle \equiv |z\rangle$,

$$a|0;z\rangle = 0. \tag{10}$$

We shall call these a-type bosons ''coherent bosons'' and write their number states as $|n;z\rangle$, such that $a^\dagger a|n;z\rangle = n|n;z\rangle$.

C. Displaced harmonic oscillator

The simplest application of the coherent bosons is to the displaced harmonic oscillator,

$$H_D = \tfrac{1}{2}(x + \sqrt{2}\lambda)^2 + \tfrac{1}{2}p^2, \tag{11}$$

in which the center of the oscillator is shifted by an amount $-\sqrt{2}\lambda$. Introducing the harmonic oscillator operators via

$$\begin{aligned} x &\equiv \frac{1}{\sqrt{2}}(b^\dagger + b), \\ p &\equiv \frac{i}{\sqrt{2}}(b^\dagger - b), \end{aligned} \tag{12}$$

the Hamiltonian reads

$$H_D = b^\dagger b + \lambda(b^\dagger + b) + \tfrac{1}{2} + \lambda^2. \tag{13}$$

By performing a Bogoliubov transformation of the original bosonic operators to a new set of coherent bosons, $a^\dagger$ and a, such that

$$a \equiv b + \lambda, \quad a \equiv b^\dagger + \lambda, \tag{14}$$

we may rewrite the Hamiltonian of Eq. (13) in the form

$$H_D = a^\dagger a + \tfrac{1}{2}. \tag{15}$$

The eigenstates of this Hamiltonian are thus clearly seen to be the number states of the a-type bosons, with corresponding eigenenergies $E_n = n + \frac{1}{2}$.

D. Squeezed bosons

Following Bishop and Vourdas[12] we construct the most general squeezed state, $|z;\rho,\theta,\beta\rangle$, by acting upon the bosonic vacuum $|0\rangle$ first with the displacement operator $D(z)$ of Eq. (7) and then with the pure squeezing operator $S(\rho,\theta,\beta)$,

$$|z;\rho,\theta,\beta\rangle = S(\rho,\theta,\beta)D(z)|0\rangle, \tag{16}$$

The squeezing operator is given by

$$S(\rho,\theta,\beta) \equiv \exp(-\tfrac{1}{4}\rho e^{-i\theta} b^{\dagger 2} + \tfrac{1}{4}\rho e^{i\theta} b^2)\exp(i\beta b^\dagger b), \tag{17}$$

where ρ,θ,β are real parameters. It is a unitary operator, $S^\dagger S = 1$, and provides a representation of the group SU(1,1). Using a relationship given by Perelomov,[13] we are able to write the squeezing operator in the equivalent form

$$S(\sigma,\beta) = \exp(\tfrac{1}{2}\sigma b^{\dagger 2})(1-|\sigma|^2)^{b^\dagger b/2 + 1/4}\exp(-\tfrac{1}{2}\sigma^* b^2)\exp(i\beta b^\dagger b), \tag{18}$$

where β is the same real parameter as above, and σ is a complex number with modulus $|\sigma| < 1$, given by $\sigma \equiv -e^{-i\theta}\tanh(\frac{1}{2}\rho)$. Using this expression, we can use the squeezing operator to make unitary transformations of the bosonic annihilation and creation operators,

$$\begin{aligned} S(\sigma,\beta) b S^\dagger(\sigma,\beta) &= e^{-i\beta}(1-|\sigma|^2)^{-1/2}(b - \sigma b^\dagger) \equiv c, \\ S(\sigma,\beta) b^\dagger S^\dagger(\sigma,\beta) &= e^{i\beta}(1-|\sigma|^2)^{-1/2}(b^\dagger - \sigma^* b) \equiv c^\dagger. \end{aligned} \tag{19}$$

The operators c and $c^\dagger$ satisfy the commutation relation $[c,c^\dagger] = 1$ and thus the transformation $b,b^\dagger \to c,c^\dagger$ is a Bogoliubov transformation of the rotation type. From Eq. (19), it follows that for any function $f(b,b^\dagger)$,

$$S f(b,b^\dagger) S^\dagger = f(c,c^\dagger) \leftrightarrow S f(b,b^\dagger) = f(c,c^\dagger) S. \tag{20}$$

Equation (20) implies that $Sb = cS$ and hence $|z;\sigma\beta\rangle \equiv |z;\rho\theta\beta\rangle$ are eigenstates of the annihilation operator c,

$$c|z;\sigma\beta\rangle = cS(\sigma,\beta)|z\rangle = S(\sigma,\beta)b|z\rangle = z|z;\sigma\beta\rangle. \tag{21}$$

If we consider the squeezed vacuum $S|0\rangle = |0;\sigma,\beta\rangle = |0;\sigma\rangle$, we see that it is independent of β and that

$$c|0;\sigma\rangle = 0. \tag{22}$$

The number states of the c-type bosons are denoted $|n;\sigma\beta\rangle$, such that $c^\dagger c|n;\sigma\beta\rangle = n|n;\sigma\beta\rangle$. We call the c-type bosons "squeezed" bosons.

E. Squeezed harmonic oscillator

In position representation the squeezed harmonic oscillator has the form

$$H_S = \tfrac{1}{2}(1+2\lambda)x^2 + \tfrac{1}{2}(1-2\lambda)p^2, \tag{23}$$

where the real parameter λ determines the degree of squeezing, with the restriction that $|\lambda| < \frac{1}{2}$. Translating this into the standard bosonic representation defined by Eq. (12) we have

$$H_S = b^\dagger b + \tfrac{1}{2} + \lambda(b^{\dagger 2} + b^2). \tag{24}$$

We introduce squeezed c-type bosons defined by

$$c^\dagger = \frac{b^\dagger + \sigma b}{\sqrt{1-\sigma^2}}, \qquad c = \frac{b + \sigma b^\dagger}{\sqrt{1-\sigma^2}}, \tag{25}$$

and leave σ real but undetermined for the moment. Making these substitutions into Eq. (24), we have

$$H_S = \frac{1}{(1-\sigma^2)}\left\{[-\sigma+\lambda+\lambda\sigma^2](c^2+c^{\dagger 2}) + (\sigma^2+1-4\lambda\sigma)\left(c^\dagger c + \frac{1}{2}\right)\right\}. \tag{26}$$

We eliminate the first term in this Hamiltonian by choosing

$$-\sigma+\lambda+\lambda\sigma^2 = 0, \tag{27}$$

giving, as one of the two solutions,

$$\sigma = \frac{(1-\Omega)}{2\lambda}, \qquad \Omega \equiv \sqrt{1-4\lambda^2}. \tag{28}$$

With this choice, the Hamiltonian becomes

$$H_S = \{c^\dagger c + \tfrac{1}{2}\}\Omega. \tag{29}$$

The eigenstates of this Hamiltonian are clearly the number states of the squeezed c-type bosons, with eigenenergies

$$E_n = \{n + \tfrac{1}{2}\}\Omega. \tag{30}$$

We note that the other solution of Eq. (27) with $\sigma = (1+\Omega)/2\lambda$ leads to the unphysical oscillator with $H_S = -(c^\dagger c + \frac{1}{2})\Omega$, and since this Hamiltonian does not have square-integrable solutions, we discard it.

III. APPLICATION TO THE RABI HAMILTONIAN

The Rabi Hamiltonian (RH) describes a two-level atom interacting with a single mode of quantized electromagnetic radiation via a dipole interaction.[2] It is usually written in the form

$$H_{\text{Rabi}} = \tfrac{1}{2}\omega_0\sigma_z + \omega b^\dagger b + g(b^\dagger + b)(\sigma_+ + \sigma_-), \tag{31}$$

where ω_0 is the atomic level splitting, ω is the frequency of the boson mode, and g is the coupling strength of the atom to the field. The two-level atom is described by the Pauli pseudo-spin operators, which satisfy the SU(2) commutation relations

$$[\sigma_k,\sigma_l]=2i\varepsilon_{klm}\sigma_m, \tag{32}$$

where $k,l,m\in\{x,y,z\}$ with $k\neq l$ and ε_{klm} is the antisymmetric Levi-Civita symbol. We have defined the raising and lowering operators as

$$\sigma_+\equiv\sigma_x+i\sigma_y, \quad \sigma_-\equiv\sigma_x-i\sigma_y. \tag{33}$$

It is convenient to rescale the Hamiltonian as $H_{\mathrm{Rabi}}=\omega\tilde{H}_{\mathrm{Rabi}}$, where

$$\tilde{H}_{\mathrm{Rabi}}=\tilde{\omega}\sigma_z+b^\dagger b+\lambda(b^\dagger+b)\sigma_x, \tag{34}$$

and $\tilde{\omega}\equiv\omega_0/(2\omega)$ and $\lambda\equiv 2g/\omega$. There is a conserved parity Π associated with the Hamiltonian,

$$\Pi\equiv\exp[i\pi(b^\dagger b+\tfrac{1}{2}(\sigma_z+1))]=-\sigma_z\cos(\pi b^\dagger b), \tag{35}$$

such that $[H_{\mathrm{Rabi}},\Pi]=0$. The parity operator Π has two eigenvalues, $\pi=\pm 1$. The RH is not known to be integrable, but isolated exact solutions do exist. Here we use the above-outlined technique to find these Juddian solutions.

In order to do this we first require an appropriate matrix representation for the Pauli matrices, which for this model is one in which σ_x is diagonal. We shall use

$$\sigma_x=\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}, \quad \sigma_y=\begin{bmatrix}0 & i\\ -i & 0\end{bmatrix}, \quad \sigma_z=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix}. \tag{36}$$

In terms of the two-component wave function, $|\Psi\rangle=\binom{|\Psi_1\rangle}{|\Psi_2\rangle}$, the time-independent Schrödinger equation for the system, $\tilde{H}_{\mathrm{Rabi}}|\Psi\rangle=E|\Psi\rangle$, then reads

$$\begin{aligned}\tilde{\omega}|\Psi_2\rangle+(b^\dagger b+\lambda(b^\dagger+b)-E)|\Psi_1\rangle=0,\\ \tilde{\omega}|\Psi_1\rangle+(b^\dagger b-\lambda(b^\dagger+b)-E)|\Psi_2\rangle=0.\end{aligned} \tag{37}$$

We now make the Bogoliubov transformation to the coherent bosons, $a^\dagger$ and a, specified by

$$a^\dagger=b^\dagger-\lambda, \quad a=b-\lambda. \tag{38}$$

The vacuum state of these bosons is the coherent state $|\lambda\rangle$. It should be noted that this choice of transformation may be intuited from considering the $\tilde{\omega}=0$ limit of the Hamiltonian, where the same transformation is used to solve the model exactly in this limit, which is essentially equivalent to the displaced oscillator considered earlier. With this transformation Eq. (37) becomes

$$\begin{aligned}\tilde{\omega}|\Psi_2\rangle+\{a^\dagger a+2\lambda(a^\dagger+a)+3\lambda^2-E\}|\Psi_1\rangle=0,\\ \tilde{\omega}|\Psi_1\rangle+\{a^\dagger a-\lambda^2-E\}|\Psi_2\rangle=0,\end{aligned} \tag{39}$$

where the kets $|\Psi_{1,2}\rangle$ are now in the transformed representation. For these kets we choose the ansatz

$$|\Psi_1\rangle=\sum_{n=0}^{N-1} p_n|n;\lambda\rangle=\sum_{n=0}^{N-1} p_n\frac{(a^\dagger)^n}{\sqrt{n!}}|0;\lambda\rangle=P_{N-1}(a^\dagger)|0;\lambda\rangle,$$
$$|\Psi_2\rangle=\sum_{n=0}^{N} q_n|n;\lambda\rangle=\sum_{n=0}^{N} q_n\frac{(a^\dagger)^n}{\sqrt{n!}}|0;\lambda\rangle=Q_N(a^\dagger)|0;\lambda\rangle, \tag{40}$$

where $|n;\lambda\rangle$ are number states of the coherent bosons, $a^\dagger a|n;\lambda\rangle=n|n;\lambda\rangle$, and we have introduced the polynomials P_{N-1} and Q_N of order $N-1$ and N, respectively. Making these substitutions we have

$$\begin{aligned}&\tilde{\omega}\sum_{n=0}^{N} q_n|n;\lambda\rangle+\sum_{n=0}^{N-1} p_n(n+3\lambda^2-E)|n;\lambda\rangle\\&\quad+2\lambda\sum_{n=0}^{N-1} p_n\sqrt{n+1}|n+1;\lambda\rangle+2\lambda\sum_{n=1}^{N-1} p_n\sqrt{n}|n-1;\lambda\rangle=0,\\&\tilde{\omega}\sum_{n=0}^{N-1} p_n|n;\lambda\rangle+\sum_{n=0}^{N} q_n(n-\lambda^2-E)|n;\lambda\rangle=0.\end{aligned} \tag{41}$$

Considering the highest number state, $|N;\lambda\rangle$, in the second of these equations, we see that for this equation to hold we require

$$(N-\lambda^2-E)q_N=0. \tag{42}$$

Since $q_N\neq 0$ by ansatz, we obtain a determination of the energy

$$E=N-\lambda^2. \tag{43}$$

This equation identifies the Juddian baseline energies, along which the Juddian solutions lie. Comparing the coefficients of the remaining number states gives us $2N+1$ linear equations for the $2N+1$ coefficients $(p_m, 0\leqslant m\leqslant N-1)$ and $(q_k, 0\leqslant k\leqslant N)$. To obtain nontrivial solutions, we clearly require the determinant of this equation set to be zero. This gives the compatibility condition, providing the locations of the Juddian points. The first two conditions ($N=1,2$) have the explicit forms

$$\tilde{\omega}^2+4\lambda^2=1, \qquad \text{for} \quad N=1, \tag{44}$$

$$\tilde{\omega}^4+(12\lambda^2-5)\tilde{\omega}^2+32\lambda^4-32\lambda^2+4=0, \qquad \text{for} \quad N=2, \tag{45}$$

as have been given by Kuś and Lewenstein.[9] Thus, for a given N, we have a polynomial of Nth order in λ^2 and $\tilde{\omega}^2$. Each of these has N roots for λ^2 in terms of $\tilde{\omega}^2$, which all turn out to be real, thus giving the location of N Juddian solutions. Before we look at these results, it is of interest to consider the other possible type of finite ansatz at the Juddian points. These are found by using the coherent bosons

$$a^\dagger=b^\dagger+\lambda, \quad a=b+\lambda, \tag{46}$$

and interchanging the roles of $|\Psi_1\rangle$ and $|\Psi_2\rangle$.

Results. By solving the complementary conditions we have calculated the first ten Juddian points for the resonant RH. These are displayed in Table I, listed to ten decimal places.

TABLE I. The couplings, energies, and N, of the first ten Juddian points of the resonant Rabi Hamiltonian ($\omega=\omega_0=1$).

g	E	N
0.216 506 351 0	0.812 500 000 0	1
0.166 164 073 2	1.889 558 003 1	2

0.758 249 241 5	1.700 232 351 1	4

The location of these Juddian points in the energy schema of the Hamiltonian is displayed in Fig. 1, where the schema was obtained by approximate numerical diagonalization via a standard configuration-interaction method, using a basis size of the lowest 101 harmonic oscillator states.[14] Also plotted are the Juddian baselines from Eq. (43).

From Fig. 1 we see that the Juddian points occur at the level crossings in this diagram. Thus we see that they occur when two solutions of different parity Π become degenerate in energy, and this degeneracy is the key to the existence of the Juddian solutions. The coherent-boson number states $|n;\lambda\rangle$ are not eigenstates of Π, and thus the ansätze (40) is not of definite parity. It is precisely because we can construct wave functions of mixed parity that allows us to find such simple ansatz at the Juddian points.

We are now able to make explicit the connection between this method and that used by Kuś and Lewenstein[9] in investigating the RH. They worked in the Bargmann representation,[15] in which the bosonic operators are represented by

$$b^\dagger \to z; \qquad b \to \frac{d}{dz} \tag{47}$$

and postulated the following forms for the two components of the wave function:

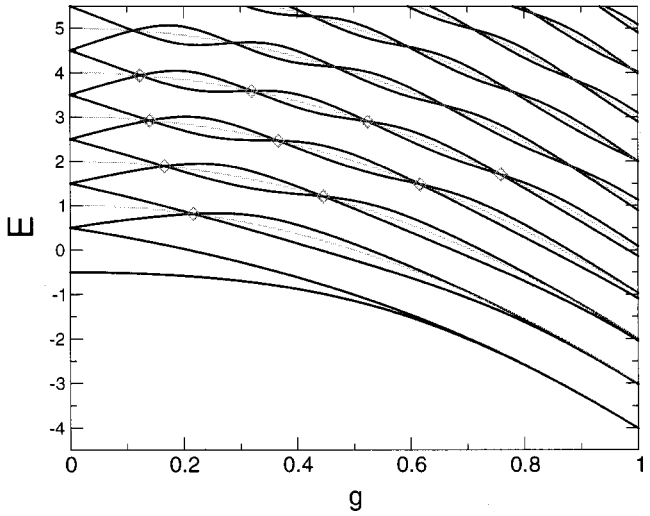

FIG. 1. The first ten Juddian points of the Rabi Hamiltonian (diamonds). Also plotted are the energy levels obtained by numerical diagonalization (dark lines), and the Juddian base lines (light lines). The Hamiltonian is resonant; $\omega=\omega_0=1$.

$$\Psi_1(z) = e^{-|z|^2/2}\langle z|\Psi_1\rangle = \tilde{P}_{N-1}(z)e^{\lambda z},$$
$$\Psi_2(z) = e^{-|z|^2/2}\langle z|\Psi_2\rangle = \tilde{Q}_N(z)e^{\lambda z}, \tag{48}$$

where $\tilde{P}_{N-1}(z)$ and $\tilde{Q}_N(z)$ are polynomials in z of order $N-1$ and N, respectively. Bearing in mind the form of the coherent state (6), these wave functions are simply seen to be of the form of polynomials in the bosonic creation operator, $b^\dagger$, acting upon a coherent state of amplitude λ. In our ansatz (40), we have the same coherent state but now being acted upon by polynomials in $a^\dagger = (b^\dagger - \lambda)$, which shares a closer connection to the coherent state than $b^\dagger$.

The polynomials of Kuś and Lewenstein are simply related to those of ansatz (40) by $\tilde{P}_N(z) = P_N(z-\lambda)$. In the present case where we have only used displacements of the boson mode, the difference between the two approaches is thus minimal. However, this is not the case when we require the use of squeezed bosons. Generally, an ansatz posited in the squeezed representation would contain polynomials of the form $P_N(c^\dagger)$, where $c^\dagger$ is the creation operator of the squeezed bosons. The analogous ansatz to Eq. (48) would still contain a polynomial in z, $\tilde{P}_N(z)$ say. If we assume the simplest type of squeezing and write $c^\dagger = (b^\dagger + \sigma b)/(\sqrt{1-\sigma^2})$ as in Eq. (25), then the Kuś and Lewenstein polynomial can be written

$$\tilde{P}_N(z) = P_N\left(\frac{z + \sigma\dfrac{d}{dz}}{\sqrt{1-\sigma^2}}\right), \tag{49}$$

which, crucially, contains both z and its derivative, and although formal relationships do exist between the polynomials of the two methods, these relationships are generally not trivial, especially if one considers the more general form of the Bogoliubov transformation. So the ansätze of the two methods are seen to be significantly different, and we conjecture that the one described here has several advantages which we shall discuss in the conclusion.

IV. CONCLUSIONS

We have presented a method for finding isolated exact solutions of a class of nonadiabatic models, of the type frequently used in quantum optics and related fields.

Compared with the original approaches of Judd and Reik, the above-mentioned method is more transparent and considerably simpler, advantages that it shares with the technique of Kuś and Lewenstein. However, we believe that the use of transformed bosons is more obviously physically meaningful than the use of wave functions in Bargmann space, especially given the connection of these bosons to the coherent and squeezed states, so important in quantum optics.

As an example of the use of this technique, we have applied it to the Rabi Hamiltonian and obtained in a simple fashion the known Juddian solutions of this model. In this example, we have used the coherent bosons to obtain Juddian solutions for a problem with an interaction of the type $\lambda(b^\dagger + b)\sigma_x$. It is hopefully now clear how one may apply this method to further problems containing the same type of interaction. We have not as yet mentioned the application of the squeezed bosons in performing this kind of calculation. This second type of Bogoliubov transformation is useful in finding Juddian solutions of models containing two-photon type interactions. An obvious example is the two-photon Rabi Hamiltonian,[16] which has the Hamiltonian

$$H = \tilde{\omega}\sigma_z + b^\dagger b + \lambda(b^{\dagger 2} + b^2)\sigma_x. \tag{50}$$

Using squeezed bosons we are able to obtain a set of Juddian solutions for this model and these results will be discussed in a future publication.

Due to the intuitive nature and simplicity of this technique it is easy to extend to other systems. For example, in view of their mode of construction we expect that our displaced and squeezed coherent states will be of particular use in any quantum field theory that has underlying

dynamical symmetry of the Weyl group or the SU(1,1) group, or to which the (inhomogeneous or homogeneous) Bogoliubov transformation may be profitably applied. The obvious group-theoretical foundations of the technique also point the way to other approximations, since, for example in the squeezed (two-photon) case, SU(1,1) is not the only relevant group. Thus, the three-dimensional Lorentz group SO(2,1), which is the group of rotations in three-dimensional Minkowski space with two space and one time dimensions, is locally isomorphic to SU(1,1). Similarly, both the groups $SL(2,\mathbb{R})$ of real second-order matrices with unit determinant and the symplectic group $Sp(2,\mathbb{R})$ are also locally isomorphic to SU(1,1).

One may also readily generalize the current approach for the two-level models involving linear or quadratic interactions with a single boson (or canonical quantum mode) to the corresponding case of linear or bilinear interactions involving several distinct bosons or modes. For the linear models involving only displacements this is essentially trivial. However, for models involving squeezing, in the case of n bosons or modes the various bilinear products of operators $b_i^\dagger b_j^\dagger$, $b_i b_j$ and $b_i^\dagger b_j$, $i,j=1,2,\ldots,n$ now form a realization of the higher symplectic algebra $Sp(2n,\mathbb{R})$. As before one can simply construct a unitary representation of this group by exponentiating the skew-adjoint operators in the algebra. For example, Bishop and Vourdas[17] have shown explicitly how to construct the most general two-mode squeezed states associated with a unitary representation of the group $Sp(4,\mathbb{R})$. Once again such states are the ordinary coherent states with respect to the new destruction operators c_1 and c_2, which are themselves general linear Bogoliubov transformations of the original destruction operators b_1, b_2 and their Hermitian-conjugate creation operators $b_1^\dagger$, $b_2^\dagger$. The $Sp(4,\mathbb{R})$ algebra has various subalgebras corresponding to different sorts of linear pairing terms. For example, whereas the single-mode paring operators $K_+^{(i)} \equiv \frac{1}{2}(b_i^\dagger)^2$; $K_-^{(i)} \equiv \frac{1}{2} b_i^2$; $K_0^{(i)} \equiv \frac{1}{2} b_i^\dagger b_i + \frac{1}{4}$ for $i=1,2$ correspond to the so-called $(\frac{1}{4}, \frac{3}{4})$ representations of SU(1,1), the mixed pairing operators $L_+ \equiv b_1^\dagger b_2^\dagger$; $L_- \equiv b_1 b_2$; $L_0 \equiv \frac{1}{2}(b_1^\dagger b_1 + b_2^\dagger b_2 + 1)$ correspond to the discrete-series representation of SU(1,1). By contrast, the mixed pairing operators $J_+ \equiv b_1^\dagger b_2$; $J_- \equiv b_1 b_2^\dagger$; $J_0 \equiv \frac{1}{2}(b_1^\dagger b_1 - b_2^\dagger b_2)$ correspond to the (Schwinger representation of) the angular momentum subalgebra SU(2). Bishop and Vourdas have shown in a separate publication[18] how squeezed (pair) coherent states can also be used in connection with a rather broad class of quantum Lagrangians which include the damped harmonic oscillator, and hence with problems involving ''quantum friction'' or fluctuation-dissipation phenomena in general. Within quantum optics for example, the quantum theory of lasers and photon detection provide obvious applications. Such problems can now also usefully be extended by our present treatment to the case of such damped systems coupled to two level atoms.

The possibility of using these solutions as the basis of a perturbative approach extends the method away from just the isolated exact points to the remainder of the spectrum of the system. The properties of such an approach are yet to be investigated. Finally we note that the extension to similar single-mode or multimode systems as considered earlier coupled to n-level atoms with $n \geqslant 2$ is also straightforward in principle.

(Received 26 October 2001; accepted for publication 15 April 2002)

We show that the spectral theory of the Dirac operator $D=i\not{\partial}-\sigma(x)-i\pi(x)\gamma_5$, in a static background $(\sigma(x),\pi(x))$ in $1+1$ space–time dimensions, is underlined by a certain novel generalization of supersymmetric quantum mechanics, and we explore some of its mathematical and physical consequences. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1485114]

I. INTRODUCTION: BAGS AND RESOLVENTS

In this article we prove that the spectral theory of the Dirac operator $D=i\not{\partial}-\sigma(x)-i\pi(x)\gamma_5$ in a static scalar and pseudo-scalar background $(\sigma(x),\pi(x))$ in $1+1$ space–time dimensions is governed by a pair of isospectral Strum–Liouville operators. This observation is a generalization of the well known fact that the spectral theory of the simpler Dirac operator in a purely scalar background $i\not{\partial}-\sigma(x)$ is equivalent to one dimensional supersymmetric quantum mechanics. We then explore some of the physical and mathematical consequences of these two isospectral Sturm–Liouville operators.

The spectral theory of $i\not{\partial}-\sigma(x)-i\pi(x)\gamma_5$ is most relevant in the physics of fermion bags, which we outline briefly in the rest of this section.

A central concept in particle physics states that fundamental particles acquire their masses through interactions with vacuum condensates. Thus, a massive particle may carve out around itself a spherical region[1] or a shell[2] in which the condensate is suppressed, thus reducing the effective mass of the particle at the expense of volume and gradient energy associated with the condensate. This picture has interesting phenomenological consequences.[1,3]

This phenomenon may be studied nonperturbatively in model field theories in $1+1$ space–time dimensions such as the Gross–Neveu (GN) model[4] and the multi-flavor Nambu–Jona–Lasinio (NJL)[5] model, in the large N limit.

Explicit calculations of fermion bag profiles in the GN and NJL models were given originally in Refs. 6–8.

Following these works, fermion bags in the GN and NJL models were discussed in the literature several other times.[9–12] For a recent review on these and related matters, see Ref. 13.

Very recently, static chiral fermion bag solitons[14] in a $1+1$ dimensional model, as well as nonchiral (real scalar) fermion bag solitons,[15] were discussed, in which the scalar field that couples to the fermions was dynamical already at the classical level.

Mathematical considerations similar to those involved in studying fermion bags appear also in other branches of theoretical physics, such as the theory of inhomogeneous superconductors,[16] and the results of this paper may be applicable there as well.

Studying the physics of fermion bags necessarily involves knowledge of the resolvent of the Dirac operator in the background of the bag. As an example, let us consider the $1+1$ dimensional NJL model (which contains the GN model as a special case).

a)Electronic mail: joshua@physics.technion.ac.il
b)Permanent address.

One version of writing the action of the $1+1$ dimensional NJL model is

$$S=\int d^2x\left\{\sum_{a=1}^{N}\overline{\psi}_a[i\partial\!\!\!/-(\sigma+i\pi\gamma_5)]\psi_a-\frac{1}{2g^2}(\sigma^2+\pi^2)\right\}, \tag{1.1}$$

where the $\psi_a(a=1,\ldots,N)$ are N flavors of massless Dirac fermions, with Yukawa couplings to the scalar and pseudoscalar auxiliary fields $\sigma(x),\pi(x)$.

The partition function associated with (1.1) is

$$\mathcal{Z}=\int \mathcal{D}\sigma\mathcal{D}\pi\mathcal{D}\overline{\psi}\mathcal{D}\psi\exp i\int d^2x\left\{\overline{\psi}[i\partial\!\!\!/-(\sigma+i\pi\gamma_5)]\psi-\frac{1}{2g^2}(\sigma^2+\pi^2)\right\}. \tag{1.2}$$

Integrating over the Grassmannian variables leads to $\mathcal{Z}=\int\mathcal{D}\sigma\mathcal{D}\pi\exp\{iS_{\text{eff}}[\sigma,\pi]\}$ where the bare effective action is

$$S_{\text{eff}}[\sigma,\pi]=-\frac{1}{2g^2}\int d^2x(\sigma^2+\pi^2)-iN\,\mathrm{Tr}\log[i\partial\!\!\!/-(\sigma+i\pi\gamma_5)] \tag{1.3}$$

and the trace is taken over both functional and Dirac indices.

This theory has been studied in the limit $N\to\infty$ with Ng^2 held fixed.[4] In this limit, (1.2) is governed by saddle points of (1.3) and the small fluctuations around them. The most general saddle point condition reads

$$\begin{aligned}\frac{\delta S_{\text{eff}}}{\delta\sigma(x,t)}&=-\frac{\sigma(x,t)}{g^2}+iN\mathrm{tr}\left[\langle x,t|\frac{1}{i\partial\!\!\!/-(\sigma+i\pi\gamma_5)}|x,t\rangle\right]=0,\\ \frac{\delta S_{\text{eff}}}{\delta\pi(x,t)}&=-\frac{\pi(x,t)}{g^2}-N\mathrm{tr}\left[\gamma_5\langle x,t|\frac{1}{i\partial\!\!\!/-(\sigma+i\pi\gamma_5)}|x,t\rangle\right]=0.\end{aligned} \tag{1.4}$$

Fermion bags are the space–time dependent solutions $(\sigma(x,t),\pi(x,t))$ of (1.4), subjected to appropriate boundary conditions at spatial infinity, and on which S_{eff}/N is finite.

Thus, studying fermion bags necessarily involves the resolvent of the Dirac operator in the background of the bag.

In this article we discuss some mathematical aspects of the much simpler problem of *static* fermion bags, namely, the static solutions $(\sigma(x),\pi(x))$ of (1.4).

For the usual physical reasons, we set boundary conditions on our static fields such that $\sigma(x)$ and $\pi(x)$ start from a point on the vacuum manifold $\sigma^2+\pi^2=m^2$ (with constant σ,π of course, and where m is the dynamical mass[4]) at $x=-\infty$, wander around in the $\sigma-\pi$ plane, and then relax back to another point on the vacuum manifold at $x=+\infty$. Thus, we must have the asymptotic behavior

$$\begin{aligned}\sigma&\xrightarrow[x\to\pm\infty]{} m\cos\theta_\pm, \quad \sigma'\xrightarrow[x\to\pm\infty]{}0,\\ \pi&\xrightarrow[x\to\pm\infty]{} m\sin\theta_\pm, \quad \pi'\xrightarrow[x\to\pm\infty]{}0,\end{aligned} \tag{1.5}$$

where $\theta_\pm$ are the asymptotic chiral alignment angles. Only the difference $\theta_+-\theta_-$ is meaningful, of course, and henceforth we use the axial U(1) symmetry of (1.1) to set $\theta_-=0$, such that $\sigma(-\infty)=m$ and $\pi(-\infty)=0$. We also omit the subscript from θ_+ and denote it simply by θ from now on. As typical of solitonic configurations, we expect that $\sigma(x)$ and $\pi(x)$ tend to their asymptotic boundary values (1.5) on the vacuum manifold at an exponential rate which is determined, essentially, by the mass gap m of the model.

Thus, in order to study static fermion bags, we need to invert the Dirac operator

$$D \equiv i\partial\!\!\!/ - (\sigma(x) + i\pi(x)\gamma_5) \tag{1.6}$$

in a given background of static field configurations $\sigma(x)$ and $\pi(x)$, subjected to the boundary conditions (1.5). In particular, we have to find the diagonal resolvent of (1.6) in that background. We stress that inverting (1.6) has nothing to do with the large N approximation, and consequently our results are valid for any value of N.

The rest of the article is organized as follows: In Sec. II we show that the Dirac equation $(i\partial\!\!\!/ - (\sigma(x) + i\pi(x)\gamma_5))\psi = 0$ in a given static $\sigma(x) + i\gamma_5\pi(x)$ background is equivalent to a pair of two isospectral Sturm–Liouville equations in one dimension, which generalize the well known one dimensional supersymmetric quantum mechanics. We use this generalized supersymmetry to express all four entries of the space-diagonal Dirac resolvent (i.e., the resolvent evaluated at coincident spatial coordinates) in terms of a single function. In Sec. III, we use the results of Sec. II to derive simple expressions for various bilinear fermion condensates in the given static $\sigma(x) + i\gamma_5\pi(x)$ background. In particular, we prove that each frequency mode of the spatial current $\langle \overline{\psi}(x)\gamma^1\psi(x)\rangle$ vanishes identically in the static background.

II. RESOLVENT OF THE DIRAC OPERATOR WITH STATIC BACKGROUND FIELDS

As was explained in the Introduction, we need to invert the Dirac operator (1.6), $D \equiv i\partial\!\!\!/ - (\sigma(x) + i\pi(x)\gamma_5)$, in a given background of static field configurations $\sigma(x)$ and $\pi(x)$, subjected to the boundary conditions (1.5).

In this article we use the Majorana representation

$$\gamma^0 = \sigma_2, \quad \gamma^1 = i\sigma_3 \quad \text{and} \quad \gamma^5 = -\gamma^0\gamma^1 = \sigma_1 \tag{2.1}$$

for γ matrices. In this representation (1.6) becomes

$$D = \begin{pmatrix} -\partial_x - \sigma & -i\omega - i\pi \\ i\omega - i\pi & \partial_x - \sigma \end{pmatrix} = \begin{pmatrix} -Q & -i\omega - i\pi \\ i\omega - i\pi & -Q^\dagger \end{pmatrix}, \tag{2.2}$$

where we introduced the pair of adjoint operators

$$Q = \sigma(x) + \partial_x, \quad Q^\dagger = \sigma(x) - \partial_x. \tag{2.3}$$

[To obtain (2.2), we have naturally transformed $i\partial\!\!\!/ - (\sigma(x) + i\pi(x)\gamma_5)$ to the ω plane, since the background fields $\sigma(x), \pi(x)$ are static.]

Inverting (2.2) is achieved by solving

$$\begin{pmatrix} -Q & -i\omega - i\pi(x) \\ i\omega - i\pi(x) & -Q^\dagger \end{pmatrix} \cdot \begin{pmatrix} a(x,y) & b(x,y) \\ c(x,y) & d(x,y) \end{pmatrix} = -i\mathbf{1}\delta(x-y) \tag{2.4}$$

for the Green's function of (2.2) in a given background $\sigma(x), \pi(x)$. By dimensional analysis, we see that the quantities a, b, c and d are dimensionless.

A. Generalized "supersymmetry" in a chiral bag background

We now show that the spectral theory of the Dirac operator (2.2) is underlined by a certain generalized one dimensional supersymmetric quantum mechanics. This generalized supersymmetry is very helpful in simplifying various calculations involving the Dirac operator and its resolvent.

The diagonal elements $a(x,y), d(x,y)$ in (2.4) may be expressed in terms of the off-diagonal elements as

$$a(x,y) = \frac{-i}{\omega - \pi(x)} Q^\dagger c(x,y), \quad d(x,y) = \frac{i}{\omega + \pi(x)} Q b(x,y), \tag{2.5}$$

which in turn satisfy the second order partial differential equations

$$\left[Q^\dagger \frac{1}{\omega+\pi(x)} Q-(\omega-\pi(x))\right] b(x,y)=$$
$$-\partial_x\left[\frac{\partial_x b(x,y)}{\omega+\pi(x)}\right]+\left[\sigma(x)^2+\pi(x)^2-\sigma'(x)-\omega^2+\frac{\sigma(x)\pi'(x)}{\omega+\pi(x)}\right]\frac{b(x,y)}{\omega+\pi(x)}=\delta(x-y),$$
$$\left[Q\frac{1}{\omega-\pi(x)} Q^\dagger-(\omega+\pi(x))\right] c(x,y)= \tag{2.6}$$
$$-\partial_x\left[\frac{\partial_x c(x,y)}{\omega-\pi(x)}\right]+\left[\sigma(x)^2+\pi(x)^2+\sigma'(x)-\omega^2+\frac{\sigma(x)\pi'(x)}{\omega-\pi(x)}\right]\frac{c(x,y)}{\omega-\pi(x)}=-\delta(x-y).$$

Thus, $b(x,y)$ and $-c(x,y)$ are simply the Green's functions of the corresponding second order Sturm–Liouville operators[17]

$$L_b(\omega)b(x)=-\partial_x\left[\frac{\partial_x b(x)}{\omega+\pi(x)}\right]+\left[\sigma(x)^2+\pi(x)^2-\sigma'(x)-\omega^2+\frac{\sigma(x)\pi'(x)}{\omega+\pi(x)}\right]\frac{b(x)}{\omega+\pi(x)},$$
$$L_c(\omega)c(x)=-\partial_x\left[\frac{\partial_x c(x)}{\omega-\pi(x)}\right]+\left[\sigma(x)^2+\pi(x)^2+\sigma'(x)-\omega^2+\frac{\sigma(x)\pi'(x)}{\omega-\pi(x)}\right]\frac{c(x)}{\omega-\pi(x)}, \tag{2.7}$$

in (2.6), namely,

$$b(x,y)=\frac{\theta(x-y)b_2(x)b_1(y)+\theta(y-x)b_2(y)b_1(x)}{W_b},$$
$$c(x,y)=-\frac{\theta(x-y)c_2(x)c_1(y)+\theta(y-x)c_2(y)c_1(x)}{W_c}. \tag{2.8}$$

Here $\{b_1(x),b_2(x)\}$ and $\{c_1(x),c_2(x)\}$ are pairs of independent fundamental solutions of the two equations $L_b b(x)=0$ and $L_c c(x)=0$, subjected to the boundary conditions

$$b_1(x),c_1(x)\xrightarrow[x\to-\infty]{} A^{(1)}_{b,c}(k)e^{-ikx},\quad b_2(x),c_2(x)\xrightarrow[x\to+\infty]{} A_{b,c}(k)^{(2)}e^{ikx}, \tag{2.9}$$

with some possibly k dependent coefficients $A^{(1)}_{b,c}(k),A^{(2)}_{b,c}(k)$ and with[18]

$$k=\sqrt{\omega^2-m^2},\quad \mathrm{Im}\,k\geqslant 0. \tag{2.10}$$

The purpose of introducing the (yet unspecified) coefficients $A^{(1)}_{b,c}(k),A^{(2)}_{b,c}(k)$ will become clear following Eqs. (2.13) and (2.14). The boundary conditions (2.9) are consistent, of course, with the asymptotic behavior (1.5) of σ and π due to which both L_b and L_c tend to a free particle Hamiltonian $[-\partial_x^2+m^2-\omega^2]$ as $x\to\pm\infty$.

The Wronskians of these pairs of solutions are

$$W_b(k)=\frac{b_2(x)b_1'(x)-b_1(x)b_2'(x)}{\omega+\pi(x)},$$
$$W_c(k)=\frac{c_2(x)c_1'(x)-c_1(x)c_2'(x)}{\omega-\pi(x)}. \tag{2.11}$$

As is well known, $W_b(k)$ and $W_c(k)$ are independent of x.

Note in passing that the canonical asymptotic behavior assumed in the scattering theory of the operators L_b and L_c corresponds to setting $A^{(1)}_{b,c}=A^{(2)}_{b,c}=1$ in (2.9). Thus, the Wronskians in (2.11) are *not* the canonical Wronskians used in scattering theory. As is well known in the literature,[19] the *canonical* Wronskians are proportional (with a k independent coefficient) to $k/t(k)$, where $t(k)$ is the transmission amplitude of the corresponding operator L_b or L_c. Thus, on top of the well-known features of $t(k)$, such as the fact that $t(k)$ has simple poles on the positive imaginary k-axis (corresponding to bound states), the Wronskians in (2.11) will have additional spurious k-dependence coming from the amplitudes $A^{(1)}_{b,c}(k),A^{(2)}_{b,c}(k)$ in (2.9).

Substituting the expressions (2.8) for the off-diagonal entries $b(x,y)$ and $c(x,y)$ into (2.5), we obtain the appropriate expressions for the diagonal entries $a(x,y)$ and $d(x,y)$. We do not bother to write these expressions here. It is useful, however, to note that, despite the ∂_x's in the Q operators in (2.5) that act on the step functions in (2.8), neither $a(x,y)$ nor $d(x,y)$ contains pieces proportional to $\delta(x-y)$. Such pieces cancel one another due to the symmetry of (2.8) under $x\leftrightarrow y$.

We will now prove that the spectra of the operators L_b and L_c are essentially the same. Our proof is based on the fact that we can factorize the eigenvalue equations $L_b b(x)=0$ and $L_c c(x)=0$ as

$$\frac{1}{\omega-\pi(x)}Q^{\dagger}\frac{1}{\omega+\pi(x)}Qb=b,$$
$$\frac{1}{\omega+\pi(x)}Q\frac{1}{\omega-\pi(x)}Q^{\dagger}c=c, \tag{2.12}$$

as should be clear from (2.6) and (2.7).

The factorized Eqs. (2.12) suggest the following map between their solutions. Indeed, given that $L_b b(x)=0$, then clearly

$$c(x)=\frac{1}{\omega+\pi(x)}Qb(x) \tag{2.13}$$

is a solution of $L_c c(x)=0$. Similarly, if $L_c c(x)=0$, then

$$b(x)=\frac{1}{\omega-\pi(x)}Q^{\dagger}c(x) \tag{2.14}$$

solves $L_b b(x)=0$.

Thus, in particular, given a pair $\{b_1(x),b_2(x)\}$ of independent fundamental solutions of $L_b b(x)=0$, we can obtain from it a pair $\{c_1(x),c_2(x)\}$ of independent fundamental solutions of $L_c c(x)=0$ by using (2.13), and vice versa. Therefore, with no loss of generality, we henceforth assume that the two pairs of independent fundamental solutions $\{b_1(x),b_2(x)\}$ and $\{c_1(x),c_2(x)\}$ are related by (2.13) and (2.14).

The coefficients $A^{(1)}_{b,c}(k),A^{(2)}_{b,c}(k)$ in (2.9) are to be adjusted according to (2.13) and (2.14), and this was the purpose of introducing them in the first place.

Thus, with no loss of generality, we may make the standard choice

$$A^{(1)}_b=A^{(2)}_b=1 \tag{2.15}$$

in (2.9). The coefficients $A^{(1)}_c,A^{(2)}_c$ are then determined by (2.13):

$$A_c^{(1)}=\frac{\sigma(-\infty)-ik}{\pi(-\infty)+\omega},$$
$$A_c^{(2)}=\frac{\sigma(\infty)+ik}{\pi(\infty)+\omega}. \tag{2.16}$$

We note that these $b(x)\leftrightarrow c(x)$ mappings can break only if

$$Qb=0 \quad \text{or} \quad Q^\dagger c=0, \tag{2.17}$$

for $b(x)$ or $c(x)$ that *solve* (2.12). Do such solutions exist? Let us assume, for example, that $Qb=0$ and that $L_b b=0$. From the first equation in (2.12) [or in (2.6)], we see that this is possible if and only if $\omega\pm\pi(x)\equiv 0$, which clearly cannot hold if $\partial_x\pi(x)\neq 0$. A similar argument holds for $Q^\dagger c=0$. Thus, if $\partial_x\pi(x)\neq 0$, the mappings (2.13) and (2.14) are one-to-one. In particular, a bound state in L_b implies a bound state in L_c (at the same energy) and vice versa.

An interesting related result concerns the Wronskians W_b and W_c. From (2.11), and from (2.13) and (2.14), it follows immediately that for pairs of independent fundamental solutions $\{b_1(x),b_2(x)\}$ and $\{c_1(x),c_2(x)\}$ we have

$$W_c=\frac{c_2\partial_x c_1-c_1\partial_x c_2}{\omega-\pi(x)}=c_1b_2-c_2b_1=\frac{b_2\partial_x b_1-b_1\partial_x b_2}{\omega+\pi(x)}=W_b. \tag{2.18}$$

The Wronskians of pairs of independent fundamental solutions of L_b and L_c, which are related via (2.13) and (2.14), are equal!

To summarize, if $\partial_x\pi(x)\neq 0$, L_b and L_c have the same set of energy eigenvalues and their eigenfunctions are in one-to-one correspondence.

If, however, $\pi=$const, then we are back to the familiar ''supersymmetric'' factorization

$$Q^\dagger Qb=(\omega^2-\pi^2)b, \quad QQ^\dagger c=(\omega^2-\pi^2)c, \tag{2.19}$$

and mappings

$$c(x)=\frac{1}{\omega+\pi}Qb(x), \quad b(x)=\frac{1}{\omega-\pi}Q^\dagger c(x). \tag{2.20}$$

As is well known from the literature on supersymmetric quantum mechanics, the mappings (2.20) break down if either $Qb=0$ or $Q^\dagger c=0$, in which case the two operators $Q^\dagger Q$ and $QQ^\dagger$ are isospectral, but only up to a ''zero-mode'' (or, rather, an $\omega^2=\pi^2$ mode), which belongs to the spectrum of only one of the operators.[20] The case $\pi(x)\equiv 0$ brings us back to the GN model. Supersymmetric quantum mechanical considerations were quite useful in the study of fermion bags in Ref. 10.

The ''Witten index'' associated with the pair of isospectral operators L_b and L_c is always null for backgrounds in which $\partial_x\pi(x)\neq 0$, since they are absolutely isospectral, and not only up to zero modes. There is no interesting topology associated with spectral mismatches of L_b and L_c. This is not surprising at all, since the NJL model, with its continuous axial symmetry, does not support topological solitons. This is in contrast to the GN model, for which $\pi\equiv 0$, which contains topological kinks, whose topological charge is essentially the Witten index of the pair of operators (2.19).

We note in passing that isospectrality of L_b and L_c, which we have just proved, is consistent with the γ_5 symmetry of the system of equations in (2.4), which relates the resolvent of D with that of $\tilde{D}=-\gamma_5 D\gamma_5$. Due to this symmetry, we can map the pair of equations $L_b b(x,y)=\delta(x-y)$ and $L_c c(x,y)=-\delta(x-y)$ [Eqs. (2.6)] on each other by

$$b(x,y)\leftrightarrow -c(x,y) \quad \text{together with} \quad (\sigma,\pi)\rightarrow(-\sigma,-\pi). \tag{2.21}$$

[Note that under these reflections we also have $a(x,y)\leftrightarrow -d(x,y)$, as we can see from (2.5).] The reflection $(\sigma,\pi)\rightarrow(-\sigma,-\pi)$ just shifts both asymptotic chiral angles $\theta_{\pm}$ by the same amount π, and clearly does not change the physics. Since this reflection interchanges $b(x,y)$ and $c(x,y)$ without affecting the physics, these two objects must have the same singularities as functions of ω, consistent with isospectrality of L_b and L_c.

Isospectrality of L_b and L_c realizes a concrete generalization of SUSY quantum mechanics. We should mention, in passing, the recent discussion in Ref. 21, made in a different context, with other generalizations of SUSY quantum mechanics.

B. The diagonal resolvent

Following Refs. 22 and 11 we define the diagonal resolvent $\langle x|iD^{-1}|x\rangle$ symmetrically as

$$\langle x|-iD^{-1}|x\rangle\equiv\begin{pmatrix} A(x) & B(x) \\ C(x) & D(x)\end{pmatrix}=\frac{1}{2}\lim_{\epsilon\rightarrow 0+}\begin{pmatrix} a(x,y)+a(y,x) & b(x,y)+b(y,x) \\ c(x,y)+c(y,x) & d(x,y)+d(y,x)\end{pmatrix}_{y=x+\epsilon}. \tag{2.22}$$

Here $A(x)$ through $D(x)$ stand for the entries of the diagonal resolvent, which following (2.5) and (2.8) have the compact representation[23]

$$\begin{aligned} B(x)&=\frac{b_1(x)b_2(x)}{W_b}, \quad D(x)=\frac{i}{2}\frac{[\partial_x+2\sigma(x)]B(x)}{\omega+\pi(x)}, \\ C(x)&=-\frac{c_1(x)c_2(x)}{W_c}, \quad A(x)=\frac{i}{2}\frac{[\partial_x-2\sigma(x)]C(x)}{\omega-\pi(x)}. \end{aligned} \tag{2.23}$$

We now use the generalized ''supersymmetry'' of the Dirac operator, which we discussed in the previous subsection, to deduce some important properties of the functions $A(x)$ through $D(x)$.

From (2.23) and from (2.3) we have

$$A(x)=\frac{i}{2}\frac{\partial_x-2\sigma(x)}{\omega-\pi(x)}\left(-\frac{c_1c_2}{W_c}\right)=\frac{i}{2W_c}\frac{c_2Q^{\dagger}c_1+c_1Q^{\dagger}c_2}{\omega-\pi(x)}.$$

Using (2.14) first, and then (2.13), we rewrite this expression as

$$A(x)=\frac{i}{2W_c}(c_2b_1+c_1b_2)=\frac{i}{2W_c}\frac{b_1Qb_2+b_2Qb_1}{\omega+\pi(x)}.$$

Then, using the fact that $W_c=W_b$ [Eq. (2.18)] and (2.23), we rewrite the last expression as

$$A(x)=\frac{i}{2}\frac{\partial_x+2\sigma}{\omega+\pi(x)}\left(\frac{b_1b_2}{W_b}\right)=\frac{i}{2}\frac{(\partial_x+2\sigma)B(x)}{\omega+\pi(x)}.$$

Thus, finally,

$$A(x)=D(x). \tag{2.24}$$

Supersymmetry renders the diagonal elements A and D equal.

Due to (2.23), $A=D$ is also a first order differential equation relating B and C. We can also relate the off diagonal elements B and C to each other more directly. From (2.23) and from (2.13) we find

$$C(x)=-\frac{c_1c_2}{W_c}=-\frac{(Qb_1)(Qb_2)}{(\omega+\pi)^2W_c}. \tag{2.25}$$

After some algebra, and using (2.18), we can rewrite this as

$$-(\omega+\pi)^2 C=\sigma^2 B+\sigma B'+\frac{b_1' b_2'}{W_b}.$$

The combination $b_1' b_2'/W_b$ appears in $B''=(b_1 b_2/W_b)''$. After using $L_b b_{1,2}=0$ to eliminate b_1'' and b_2'' from B'', we find

$$\frac{b_1' b_2'}{W_b}=\frac{1}{2}B''-\frac{\pi' B'}{2(\omega+\pi)}-\left(\sigma^2+\pi^2-\sigma'-\omega^2+\frac{\sigma\pi'}{\omega+\pi}\right)B.$$

Thus, finally, we have

$$-(\omega+\pi)^2 C=\frac{1}{2}B''+\left(\sigma-\frac{\pi'}{2(\omega+\pi)}\right)B'-\left(\pi^2-\sigma'-\omega^2+\frac{\sigma\pi'}{\omega+\pi}\right)B. \tag{2.26}$$

In a similar manner we can prove that

$$(\omega-\pi)^2 B=-\frac{1}{2}C''+\left(\sigma-\frac{\pi'}{2(\omega-\pi)}\right)C'+\left(\pi^2+\sigma'-\omega^2+\frac{\sigma\pi'}{\omega-\pi}\right)C. \tag{2.27}$$

We can simplify (2.26) and (2.27) further. After some algebra, and using (2.23), we arrive at

$$\begin{aligned} C(x)&=\frac{i}{\omega+\pi(x)}\partial_x D(x)-\frac{\omega-\pi(x)}{\omega+\pi(x)}B(x),\\ B(x)&=\frac{i}{\omega-\pi(x)}\partial_x A(x)-\frac{\omega+\pi(x)}{\omega-\pi(x)}C(x). \end{aligned} \tag{2.28}$$

Supersymmetry, namely, isospectrality of L_b and L_c, enables us to relate the diagonal resolvents of these operators, B and C, to each other.

Thus, we can use (2.23), (2.24) and (2.28) to eliminate three of the entries of the diagonal resolvent in (2.23), in terms of the fourth.

Note that the two relations in (2.28) transform into each other under

$$B\leftrightarrow -C \quad \text{simultaneously with} \quad (\sigma,\pi)\rightarrow(-\sigma,-\pi), \tag{2.29}$$

in consistency with (2.21). The relations in (2.28) are linear and homogeneous, with coefficients that for $\partial_x\pi(x)\neq 0$ do not introduce additional singularities in the ω plane. Thus, we see, once more, that B and C have the same singularities in the ω plane. We refer the reader to Sec. IV in Ref. 11 for concrete examples of such resolvents.

The case $\pi(x)\equiv 0$ brings us back to the GN model. In the GN model, our B and C coincide, respectively, with ωR_- and $-\omega R_+$ defined in Eqs. (9) and (10) in Ref. 10. With these identifications, the relation $A=D$ [Eq. (2.24)] coincides essentially with Eq. (18) of Ref. 10. The relations (2.26) and (2.27) were not discussed in Ref. 10, but one can verify them, for example, for the resolvents corresponding to the kink case $\sigma(x)=m\tanh mx$ [Eq. (29) in Ref. 10], for which

$$C=-\frac{\omega}{2\sqrt{m^2-\omega^2}}, \quad B=\left[\left(\frac{m\,\mathrm{sech}\,mx}{\omega}\right)^2-1\right]C.$$

III. BILINEAR FERMION CONDENSATES AND VANISHING OF THE SPATIAL FERMION CURRENT

Following basic principles of quantum field theory, we may write the most generic flavor-singlet bilinear fermion condensate in our static background as

$$\langle \overline{\psi}_{a\alpha}(t,x)\Gamma_{\alpha\beta}\psi_{a\beta}(t,x)\rangle_{\rm reg} = N\int \frac{d\omega}{2\pi}\,{\rm tr}\left[\Gamma\langle x|\,\frac{-i}{\omega\gamma^0 + i\gamma^1\partial_x - (\sigma + i\pi\gamma_5)}\,|x\rangle_{\rm reg}\right]$$
$$= N\int \frac{d\omega}{2\pi}\,{\rm tr}\left\{\Gamma\left[\begin{pmatrix} A(x) & B(x) \\ C(x) & D(x)\end{pmatrix} - \begin{pmatrix} A & B \\ C & D\end{pmatrix}_{\rm VAC}\right]\right\}, \qquad (3.1)$$

where we have used (2.22). Here $a=1,\ldots,N$ is a flavor index, and the trace is taken over Dirac indices α,β. As usual, we regularized this condensate by subtracting from it a short distance divergent piece embodied here by the diagonal resolvent

$$\langle x|-iD^{-1}|x\rangle_{\rm VAC} = \begin{pmatrix} A & B \\ C & D\end{pmatrix}_{\rm VAC} = \frac{1}{2\sqrt{m^2-\omega^2}}\begin{pmatrix} im\cos\theta & \omega + m\sin\theta \\ -\omega + m\sin\theta & im\cos\theta\end{pmatrix} \qquad (3.2)$$

of the Dirac operator in a vacuum configuration $\sigma_{\rm VAC} = m\cos\theta$ and $\pi_{\rm VAC} = m\sin\theta$.

In our convention for γ matrices (2.1) we have

$$\begin{pmatrix} A(x) & B(x) \\ C(x) & D(x)\end{pmatrix} = \frac{A(x)+D(x)}{2}\mathbf{1} + \frac{A(x)-D(x)}{2i}\gamma^1 + i\frac{B(x)-C(x)}{2}\gamma^0 + \frac{B(x)+C(x)}{2}\gamma_5. \qquad (3.3)$$

An important condensate is the expectation value of the fermion current $\langle j^\mu(x)\rangle$. In particular, consider its spatial component. In our static background $(\sigma(x),\pi(x))$, it must, of course, vanish identically

$$\langle j^1(x)\rangle = 0. \qquad (3.4)$$

Thus, substituting $\Gamma=\gamma^1$ in (3.1) and using (3.3) we find

$$\langle j^1(x)\rangle = iN\int \frac{d\omega}{2\pi}[A(x)-D(x)]. \qquad (3.5)$$

But we have already proved that $A(x)=D(x)$ in *any* static background $(\sigma(x),\pi(x))$ (Eq. (2.24)). Thus, each frequency component of $\langle j^1\rangle$ vanishes separately, and (3.4) holds identically. It is remarkable that the generalized supersymmetry of the Dirac operator guarantees the consistency of any static $(\sigma(x),\pi(x))$ background.

Expressions for other bilinear condensates may be derived in a similar manner (here we write the unsubtracted quantities). Thus, substituting $\Gamma=\gamma^0$ in (3.1) and using (3.3), (2.24) and (2.28), we find that the fermion density is

$$\langle j^0(x)\rangle = iN\int \frac{d\omega}{2\pi}[B(x)-C(x)] = iN\int \frac{d\omega}{2\pi}\,\frac{2\omega B(x) - i\partial_x D(x)}{\omega+\pi(x)}. \qquad (3.6)$$

Similarly, the scalar and pseudoscalar condensates are

$$\langle \overline{\psi}(x)\psi(x)\rangle = N\int \frac{d\omega}{2\pi}[A(x)+D(x)] = 2N\int \frac{d\omega}{2\pi}D(x), \qquad (3.7)$$

and

$$\langle \overline{\psi}(x)\gamma^5\psi(x)\rangle = N\int \frac{d\omega}{2\pi}[B(x)+C(x)] = N\int \frac{d\omega}{2\pi}\,\frac{2\pi(x)B(x)+i\partial_x D(x)}{\omega+\pi(x)}. \tag{3.8}$$

[17] Note that ω plays here a dual role: in addition to its role as the spectral parameter [the ω^2 terms in (2.7)], it also appears as a parameter in the definition of these operators, hence the explicit ω dependence in our notations for these operators in (2.7). For this reason, it is possible to completely factorize the operators L_b and L_c by additional obvious ω-dependent similarity transformations on Q and $Q^\dagger$. However, these similarity transformations are singular at points where $\pi(x) = \pm\omega$ and are thus ill defined, and we will avoid them.
[18] We see that if Im $k>0$, b_1 and c_1 decay exponentially to the left, and b_2 and c_2 decay to the right. Thus, if Im $k>0$, both $b(x,y)$ and $c(x,y)$ decay as $|x-y|$ tends to infinity.

Institute of Theoretical Physics, Warsaw University, Hoża 69, 00-681 Warszawa, Poland

(Received 5 April 2001; accepted for publication 14 May 2002)

It is shown that the renormalizability of the zero-range interaction in the two-dimensional space is always followed by the existence of a bound state, which is not true for odd-dimensional spaces. A renormalization procedure is defined and the exact retarded Green's function for electrons moving in two dimensions and interacting with both crossed magnetic and electric fields and an attractive zero-range interaction is constructed. Imaginary parts of poles of this Green's function determine lifetimes of quasibound (resonance) states. It is shown that for some particular parameters the stabilization against decay occurs even for strong electric fields. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1491596]

I. INTRODUCTION

The observations of the integer and fractional quantum Hall effects[1,2] are among the most important discoveries of recent years and have had a profound impact on both applied and fundamental physics. Many aspects of these discoveries are presented in the books edited by Prange and Girvin[3] and by Das Sarma and Pinczuk,[4] and in the monographs.[5,6] From the theoretical point of view the quantum Hall phenomenon is due to the two-dimensional dynamics of electrons moving under the influence of crossed magnetic and electric fields in the presence of impurities. Since the de Broglie wavelength of electrons scattered by impurities is much larger then the interaction range, therefore, it is legitimated to describe a scatterer by a zero-range potential. This, in fact, has been already proposed by Prange[7] shortly after the discovery of the quantum Hall effect, and discussed further in Refs. 8 and 9. In his seminal paper Prange studied electron states in two dimensions in perpendicular magnetic and in-plane electric fields in the presence of a single repulsive ''delta-like'' scatterer. Prange's model, with an attractive zero-range potential and zero electric field, has been reconsidered by Perez and Coutinho,[10] and by Cavalcanti and de Carvalho.[11] They showed that the attractive zero-range interaction can be rigorously defined by renormalizing the strength of the δ-function. Such a procedure cannot be developed for a repulsive two-dimensional δ-function (as it will follow shortly), for which an artificial cutoff has to be introduced, as described for instance in Ref. 12. The problem of electron scattering by a single impurity represented by a repulsive short-range potential in the presence of both magnetic and electric fields has been further studied from the classical point of view in Ref. 13, whereas the quantum description has been developed in Ref. 12 for a repulsive, and in Ref. 14 for an attractive δ-function potential. Both these quantum analyses show that due to external magnetic and electric fields new long living quasibound states appear in the positive part of the energy spectrum, the existence of which appears to be crucial for the explanation of the robustness of the quantum Hall effect.[7,12]

There has been shown[12,14] that in the limit of a very weak electric field the lifetime of these quasibound states tends to infinity and grow in a Gaussian way as the electric field tends to zero. This finding, not taking into account, however, the precisely determined functional dependence of the lifetime on the strength of the electric field, agrees with our common understanding of the decay problem in a weak electric field. The aim of this paper is to analyze this problem for strong electric fields. It is usually believed that with an increasing electric field the lifetimes of these quasibound states should decrease to zero. It appears, however, that such a behavior is not gen-

erally true and that for some particular values of magnetic and electric fields one observes a new phenomenon, the stabilization of these new quasibound states. We demonstrate this phenomenon for an attractive δ-function potential considered in Ref. 14.

In this paper we use units in which $\hbar=1$.

II. ATTRACTIVE δ-FUNCTION POTENTIAL

In this section we shall define the renormalized attractive δ-function potential for one-, two-, and three-dimensional cases. To this end let us assume that a quantum system without this interaction is described by the hamiltonian H_0. We introduce further a regularization of a zero-range potential such that the total hamiltonian is equal to

$$H=H_0+\lambda_\sigma\delta_\sigma(\mathbf{r}), \tag{1}$$

in which σ is a regularization parameter, λ_σ is a bare coupling constant, and $\delta_\sigma(\mathbf{r})$ tends to the Dirac distribution $\delta(\mathbf{r})$ in a d-dimensional space. Our aim is to construct the retarded Green's function satisfying the equation,

$$(E-H)G^{(+)}(\mathbf{r},\mathbf{r}';E)=\delta(\mathbf{r}-\mathbf{r}'), \tag{2}$$

provided that the range of a regularized potential is *very* small, i.e., is much smaller than the electron's de Broglie wavelength or the size of a bound state wave function. This means that in the Lippmann–Schwinger equation

$$G^{(+)}(\mathbf{r},\mathbf{r}';E)=G_0^{(+)}(\mathbf{r},\mathbf{r}';E) + \lambda_\sigma\int \mathrm{d}^d\mathbf{r}''G_0^{(+)}(\mathbf{r},\mathbf{r}'';E)\,\delta_\sigma(\mathbf{r}'')G^{(+)}(\mathbf{r}'',\mathbf{r}';E), \tag{3}$$

in which $G_0^{(+)}(\mathbf{r},\mathbf{r}';E)$ is the Green's function for the Hamiltonian H_0, we can approximate under the integral the full Green's function $G^{(+)}(\mathbf{r}'',\mathbf{r}';E)$ by $G^{(+)}(\mathbf{0},\mathbf{r}';E)$. This allows us to calculate $G^{(+)}(\mathbf{0},\mathbf{r}';E)$ and to arrive at the following expression for the retarded Green's function:

$$G^{(+)}(\mathbf{r},\mathbf{r}';E)=G_0^{(+)}(\mathbf{r},\mathbf{r}';E) + \frac{G_0^{(+)}(\mathbf{r},\mathbf{0};E)G_0^{(+)}(\mathbf{0},\mathbf{r}';E)}{\lambda_\sigma^{-1}-\int \mathrm{d}^d\mathbf{r}''G_0^{(+)}(\mathbf{0},\mathbf{r}'';E)\,\delta_\sigma(\mathbf{r}'')}. \tag{4}$$

In order to proceed further let us choose a particular regularization prescription for which all the space and momentum integrals, that will appear below, can be carried out and expressed in terms of elementary functions, namely,

$$\delta_\sigma(\mathbf{r})=\int \frac{\mathrm{d}^d\mathbf{k}}{(2\pi)^d}\exp(\mathrm{i}\mathbf{k}\cdot\mathbf{r}-\sigma^2\mathbf{k}^2). \tag{5}$$

Let us also assume for a moment that H_0 describes free electrons of a reduced mass m^*. For such a hamiltonian the retarded Green's function adopts the form

$$G_0^{(+)}(\mathbf{r},\mathbf{r}';E)=-\mathrm{i}\int_0^\infty \mathrm{d}t\,\mathrm{e}^{\mathrm{i}(E+\mathrm{i}\varepsilon)t} \times\int \frac{\mathrm{d}^d\mathbf{k}}{(2\pi)^d}\exp\left(\mathrm{i}\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')-\mathrm{i}\frac{\mathbf{k}^2}{2m^*}t\right), \tag{6}$$

in which ε is an infinitesimally small positive real number. Thus, after performing the Gauss integration over $\mathbf{k}$, the denominator in Eq. (4) becomes

$$D(E)=\lambda_\sigma^{-1}+\mathrm{i}\left(\frac{m^*}{2\pi\mathrm{i}}\right)^{d/2}\int_0^\infty \mathrm{d}t\,\frac{\mathrm{e}^{\mathrm{i}(E+\mathrm{i}\varepsilon)t}}{(t-2\mathrm{i}m^*\sigma^2)^{d/2}}. \tag{7}$$

As we see, for $d=1$ the last integral exists for $\sigma=0$, i.e., there is no need for the renormalization of a coupling constant λ_σ. On the other hand, for $d>1$ the integral in the equation above diverges for small t in the limit of a vanishing regularization parameter σ. It can be shown, however, that the divergent part of this integral can be absorbed into the bare coupling constant λ_σ. To this end let us consider in the beginning the case of $d=2$. Integrating by parts we end up in the limit of vanishing σ with

$$D(E)=\lambda_R^{-1}+\frac{m^*}{2\pi}\left(\ln(\mathrm{i})-\mathrm{i}E\int_0^\infty \mathrm{d}t\mathrm{e}^{\mathrm{i}(E+\mathrm{i}\varepsilon)t}\ln(t/t_0)\right), \tag{8}$$

where t_0 is an arbitrary positive real number of the same dimensionality as t, introduced only for dealing with a dimensionless argument of the logarithm function, and λ_R is the renormalized coupling constant,

$$\lambda_R^{-1}=\lim_{\sigma\to 0}\left[\lambda_\sigma^{-1}-\frac{m^*}{2\pi}\ln\left(\frac{2m^*\sigma^2}{t_0}\right)\right]. \tag{9}$$

As it follows from the equation above the bare coupling constant λ_σ has to be negative in order to carry out the renormalization procedure. Hence, the zero-range limit exists only for an attractive interaction. Performing the remaining integration we finally arrive at

$$D(E)=\lambda_R^{-1}+\frac{m^*}{2\pi}\ln\left(\frac{\mathrm{e}^{-\gamma}}{-Et_0}\right), \tag{10}$$

where γ is the Euler's constant. Since the energy of a bound state, $E_B<0$, supported by this interaction is determined by the zero of $D(E)$, therefore

$$E_B=-\frac{1}{t_0}\mathrm{e}^{-\gamma+2\pi/\lambda_R m^*}. \tag{11}$$

As one sees, the expression above is always negative, independently weather the renormalized coupling constant is negative or positive. This means that the zero-range potential in two-dimensional space always supports one bound state. Combining (10) with (11) we arrive at the following expression for the denominator $D(E)$:

$$D(E)=\frac{m^*}{2\pi}\ln\left(\frac{E_B}{E}\right), \tag{12}$$

in which an artificial parameter t_0 does not appear any more.

The existence of a bound state for a zero-range interaction, irrespectively of the sign of a renormalized coupling constant, can only happen for $d=2$. In order to show this let us consider the case of $d=3$. Now we do not need to introduce t_0 and end up with

$$D(E)=\lambda_R^{-1}+\frac{m^*}{2\pi}\sqrt{-2m^*E}, \tag{13}$$

where the renormalized coupling constant is equal to

$$\lambda_R^{-1}=\lim_{\sigma\to 0}\left(\lambda_\sigma^{-1}+\frac{m^*}{2\pi^{3/2}\sigma}\right). \tag{14}$$

Hence, it is clearly seen that again the renormalization procedure can be only performed for a negative bare coupling constant. Nevertheless, contrary to the two-dimensional case, a bound state exists only for a negative renormalized coupling constant λ_R. A similar situation occurs for the one-dimensional δ-function potential supporting one bound state just for negative coupling constants (renormalized and bare coupling constants are equal here and amount to $-\sqrt{2|E_B|/m^*}$).

Summarizing, for the two-dimensional zero-range interaction the renormalizability is followed by the existence of a bound state, irrespectively of the sign of the renormalized coupling constant. In our further discussion we shall limit ourselves to the two-dimensional renormalizable zero-range interaction. Let us also note in closing this section that the zero-range potential for an arbitrary dimensional space has been studied by Wódkiewicz[15] who also emphasized the difference between odd and even dimensions.

III. QUASIBOUND STATES IN CROSSED MAGNETIC AND ELECTRIC FIELDS

We can now include into our two-dimensional model external magnetic and electric fields. For this we need the exact form of the retarded Green's function for the Hamiltonian,

$$H_0=\frac{1}{2m^*}(-\mathrm{i}\boldsymbol{\nabla}-e\mathbf{A}(\mathbf{r}))^2-e\boldsymbol{\mathcal{E}}\cdot\mathbf{r}. \tag{15}$$

Let us assume that electrons move in the xy-plane, the magnetic field $\boldsymbol{\mathcal{B}}$ is perpendicular to this plane and the electric field $\boldsymbol{\mathcal{E}}$ points into the x-direction. For such a geometry and for the vector potential in the symmetric gauge, i.e., $\mathbf{A}=\frac{1}{2}\boldsymbol{\mathcal{B}}\times\mathbf{r}$,

$$H_0=\frac{1}{2m^*}\left[\left(-\mathrm{i}\partial_x+\frac{e\mathcal{B}}{2}y\right)^2+\left(-\mathrm{i}\partial_y-\frac{e\mathcal{B}}{2}x\right)^2\right]-e\mathcal{E}x, \tag{16}$$

and the Green's function adopts the form

$$\begin{aligned}G_0^{(+)}(\mathbf{r},\mathbf{r}';E)=&-\frac{m^*\omega}{4\pi}\int_0^\infty \mathrm{d}t\,\frac{\mathrm{e}^{\mathrm{i}(E+\mathrm{i}\varepsilon)t}}{\sin\dfrac{\omega t}{2}}\\&\times\exp\left[\frac{\mathrm{i}m^*\omega}{4}((x-x')^2+(y-y')^2)\cot\frac{\omega t}{2}+\frac{\mathrm{i}m^*\omega}{2}(xy'-x'y)+\frac{\mathrm{i}e\mathcal{E}t}{2}(x+x')\right.\\&\left.+\frac{\mathrm{i}e\mathcal{E}}{\omega}\left(\frac{\omega t}{2}\cot\frac{\omega t}{2}-1\right)\left(-y+y'+\frac{e\mathcal{E}t}{2m^*\omega}\right)\right],\end{aligned} \tag{17}$$

with $\omega=|e|\mathcal{B}/m^*$ being the cyclotron frequency. Since lifetimes of quasibound states are determined by poles of the Green's function, therefore, we shall concentrate in our further discussion on the denominator in Eq. (4). One can find that in this particular case $D(E)$ can be expressed as follows:

$$\begin{aligned}D(E)=&\lambda_\sigma^{-1}+\frac{m^*\omega}{4\pi}\int_0^\infty \mathrm{d}t\,\frac{\mathrm{e}^{\mathrm{i}(E+\mathrm{i}\varepsilon)t}}{\sin\dfrac{\omega t}{2}-\mathrm{i}m^*\omega\sigma^2\cos\dfrac{\omega t}{2}}\\&\times\exp\left[\frac{\mathrm{i}t}{2m^*}\left(\frac{e\mathcal{E}}{\omega}\right)^2\left(\frac{\omega t}{2}\cot\frac{\omega t}{2}-1\right)-\sigma^2\left(\frac{e\mathcal{E}}{\omega}\right)^2\frac{\left(\dfrac{\omega t}{2}\right)^2+\left(\dfrac{\omega t}{2}\cot\dfrac{\omega t}{2}-1\right)^2}{1-\mathrm{i}m^*\omega\sigma^2\cot\dfrac{\omega t}{2}}\right],\end{aligned} \tag{18}$$

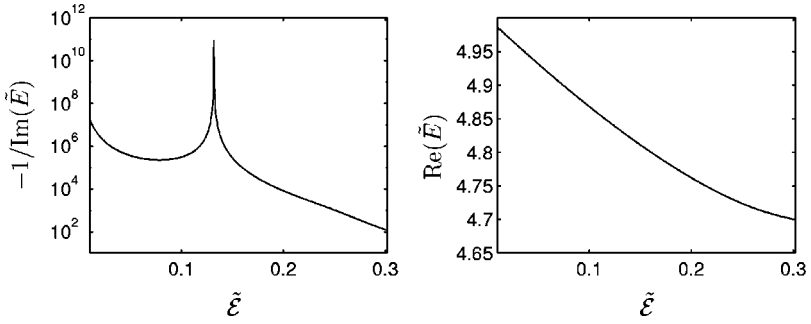

FIG. 1. Presents the dependence of the lifetime $\tau=-1/\mathrm{Im}(\tilde{E})$ and the real part of $\tilde{E}$ on the scaled electric field $\tilde{\mathcal{E}}$ for an impurity which supports one bound state of energy $\tilde{E}_B=-6.4$. For $\tilde{\mathcal{E}}=0.132$ we observe the stabilization of a resonance state located just below the third Landau level.

where the integral above diverges logarithmically for small values of t in the zero-range limit. However, as we have proved it in the previous section, this singularity can be removed by combining the divergent term with the bare coupling constant λ_σ.

For our further analysis it is convenient to introduce dimensionless variables, in which the length is measured in the units of $1/\sqrt{m^*\omega}$, whereas the electric field and the energy are scaled as $\tilde{\mathcal{E}}=|e|\mathcal{E}/\sqrt{m^*\omega^3}$ and $\tilde{E}=2E/\omega$, respectively. Changing the integration variable to $s=\omega t/2$ we obtain finally for $\sigma\to 0$,

$$D(E)=\frac{m^*}{2\pi}\left[\ln\left(\frac{\tilde{E}_B}{\tilde{E}}\right)+\int_0^\infty \mathrm{d}s\,\mathrm{e}^{\mathrm{i}(\tilde{E}+\mathrm{i}\varepsilon)s}\left(\frac{\exp(\mathrm{i}\tilde{\mathcal{E}}^2 s(s\cot s-1))}{\sin s}-\frac{1}{s}\right)\right]. \tag{19}$$

We shall demonstrate now that even in strong electric fields one can observe long living quasibound states. This nonperturbative result follows from the numerical determination of zeros of $D(E)$. It appears that for some particular values of the electric field and the binding energy there exist zeros of (19) with very small imaginary parts, although real parts remain positive. This phenomenon, which we call the stabilization, is presented in Figs. 1, 2, and 3. In Figs. 1 and 2 we draw the dependence of lifetimes, $\tau=-(2\,\mathrm{Im}(E))^{-1}=-(\omega\,\mathrm{Im}(\tilde{E}))^{-1}$, and real parts of E, $\mathrm{Re}(E)=(\omega/2)\mathrm{Re}(\tilde{E})$, in units of ω^{-1} and $\omega/2$, respectively. We see that with the increasing electric field the lifetime initially decreases, which is a commonly accepted result. We observe, however, that at a particular value for the electric field the lifetime starts increasing, approaches its maximum, and then monotonically decreases. In both presented cases the real part of E remains positive and is just below the third Landau level of energy $5\omega/2$ or above the second one of energy $3\omega/2$. In Fig. 3 we show the position of these poles of the Green's function in the complex energy plane. Only

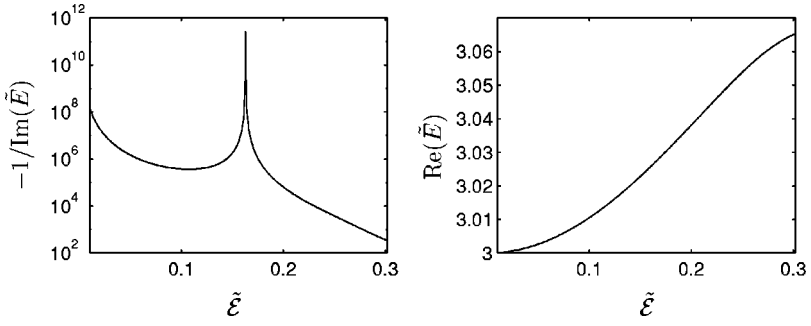

FIG. 2. The same as in Fig. 1 but for $\tilde{E}_B=-2.8$. The stabilization occurs for $\tilde{\mathcal{E}}=0.163$ for a resonance state located just above the second Landau level.

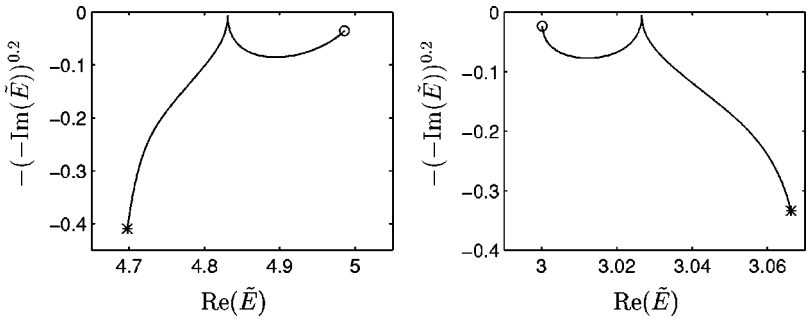

FIG. 3. Shows the trajectories of two resonances considered in Figs. 1 and 2 in the complex energy plane. For the visual purpose the imaginary part is raised to the power 1/5. The left frame corresponds to the binding energy $\tilde{E}_B=-6.4$ and the right one to $\tilde{E}_B=-2.8$. The circle marks the minimum value $\tilde{\mathcal{E}}=0.01$, whereas the asterisk indicates the maximum value $\tilde{\mathcal{E}}=3.1$. The stabilization occurs for $\tilde{\mathcal{E}}=0.132$, $\mathrm{Re}(\tilde{E})=4.83$, $\mathrm{Im}(\tilde{E})=-0.111\times10^{-10}$ and $\tilde{\mathcal{E}}=0.163$, $\mathrm{Re}(\tilde{E})=3.0266$, $\mathrm{Im}(\tilde{E})=-0.398\times10^{-11}$, respectively.

for the visual purpose the imaginary part is raised to the power 1/5. We see that with an increasing electric field the poles in the beginning depart from the real axis, but afterward start approaching it, reach minimum for the absolute value of the imaginary part of E (which appears to be almost equal to zero within the accuracy of our numerical calculation) and then again migrate downward. Such an unexpected nonmonotonic behavior happens for some particular values of the binding energies as well as the applied fields. At this point let us only mention that estimations of magnetic and electric fields show that they can be generated easily in experimental setups.

What we have checked in our numerical investigations is that the stabilization occurs only for states which are close to the excited Landau levels and does not appear for states near the first Landau level. Indeed, for very small electric fields resonances considered in this paper approach the second and the third Landau levels, i.e., the excited ones. This appears to be a general rule that the electric field generates new resonance states in a close vicinity of *excited* Landau levels. These states differ from the ones considered by Prange[7] and reinvestigated by Cavalcanti and de Carvalho.[11] In their case, when the electric field is switched off, the point interaction modifies only Landau states with the vanishing angular momentum, because only for these states the wave function does not vanish at the origin. The states with a nonzero angular momentum, i.e., the vortex Landau states, for which the wave functions explicitly depend on the polar angle φ and vanish at the origin, are not affected by a point interaction. The situation changes if a small electric field is applied. Then the vortex Landau states acquire small contributions which do not vanish at the origin, as follows for instance from perturbation theory. Hence, the interaction with a contact potential does not vanish, and apart from the well-known states considered previously[7,11] new resonance states emerge close to the excited Landau levels. These are the states for which the stabilization takes place. Since the wave function of them for small electric fields is predominantly composed of the vortex Landau states of nonzero angular momentum, therefore, one can call them the vortex resonance states. This fact suggests that the stabilization presented in this paper is due to the angular motion of electrons around the impurity, as it also happens in the classical considerations for a repulsive potential.[13] The analysis presented above can be applied to weak electric fields. For strong nonperturbative electric fields we can rather rely on the exact numerical analysis of this problem with the hope that the picture above still remains valid. However, the almost total suppression of ionization rates for some particular values of the electric field hardly can be explained only in terms of classical physics and we expect that its origin is due to complicated quantum interference effects which can only be studied numerically.

(Received 13 February 2002; accepted for publication 22 April 2002)

We show that a diagonalizable (non-Hermitian) Hamiltonian H is pseudo-Hermitian if and only if it has an antilinear symmetry, i.e., a symmetry generated by an invertible antilinear operator. This implies that the eigenvalues of H are real or come in complex conjugate pairs if and only if H possesses such a symmetry. In particular, the reality of the spectrum of H implies the presence of an antilinear symmetry. We further show that the spectrum of H is real if and only if there is a positive-definite inner-product on the Hilbert space with respect to which H is Hermitian or alternatively there is a pseudo-canonical transformation of the Hilbert space that maps H into a Hermitian operator. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1489072]

I. INTRODUCTION

The main reason for the recent interest in PT-symmetry[1] is that the eigenvalues of every PT-symmetric Hamiltonian are real or come in complex conjugate pairs. In particular, if the PT-symmetry is exact, the spectrum of the Hamiltonian is real. In Ref. 2, we introduced the concept of a pseudo-Hermitian operator and showed that the remarkable spectral properties of the PT-symmetric Hamiltonians follow from their pseudo-Hermiticity. Under the assumption of the diagonalizability (equivalently the existence of a complete biorthonormal set of energy eigenvectors), we obtained in Ref. 3 a complete characterization of all the (non-Hermitian) Hamiltonians that have a real spectrum. Here we also pointed out that the spectral properties of the PT-symmetric Hamiltonians are common to all Hamiltonians possessing an antilinear symmetry (a symmetry generated by an invertible antilinear operator). Therefore, at least for the class of diagonalizable Hamiltonians, presence of an antilinear symmetry implies pseudo-Hermiticity of the Hamiltonian. The main purpose of the present article is to show that the converse of this statement holds as well, that is, pseudo-Hermiticity of a Hamiltonian implies the existence of an antilinear symmetry. A direct consequence of this result is that if the spectrum of the Hamiltonian is real, then the system has an antilinear symmetry, PT-symmetry being the prime example.

The organization of the article is as follows. Section II includes a brief review of the necessary results reported in the companion articles.[2,3] Section III examines anti-pseudo-Hermiticity (pseudo-Hermiticity with an antilinear automorphism.) Here we prove that every (non-Hermitian) diagonalizable Hamiltonian is anti-pseudo-Hermitian and that the pseudo-Hermiticity of the Hamiltonian implies the presence of an antilinear symmetry. Section IV offers a description of the Hamiltonians with a real spectrum in terms of certain associated Hermitian operators. Section V presents a summary of the main results and the concluding remarks.

Throughout this article we shall consider (non-Hermitian) Hamiltonians H that are diagonalizable and have a discrete spectrum. As we explain below, this means that these Hamiltonians admit a complete biorthonormal set of eigenvectors $\{(|\psi_n,a\rangle,|\phi_n,a\rangle)\}$. The latter satisfy the following defining relations:[4]

a)Electronic mail: amostafazadeh@ku.edu.tr

$$H|\psi_n,a\rangle=E_n|\psi_n,a\rangle,\quad H^\dagger|\phi_n,a\rangle=E_n^*|\phi_n,a\rangle, \tag{1}$$

$$\langle\phi_m,b|\psi_n,a\rangle=\delta_{mn}\delta_{ab}, \tag{2}$$

$$\sum_n\sum_{a=1}^{d_n}|\psi_n,a\rangle\langle\phi_n,a|=1, \tag{3}$$

where n and a are, respectively, the spectral and degeneracy labels, d_n is the multiplicity (degree of degeneracy) of E_n, $\dagger$ and $*$, respectively, denote the adjoint and complex-conjugate, δ_{mn} stands for the Kronecker delta function, and 1 is the identity operator. In view of Eqs. (1)–(3), we also have

$$H=\sum_n\sum_{a=1}^{d_n}E_n|\psi_n,a\rangle\langle\phi_n,a|,\quad H^\dagger=\sum_n\sum_{a=1}^{d_n}E_n^*|\phi_n,a\rangle\langle\psi_n,a|. \tag{4}$$

In order to see the equivalence of the existence of a complete biorthonormal set of eigenvectors of H and its diagonalizability, we note that by definition a diagonalizable Hamiltonian H satisfies $A^{-1}HA=H_0$ for an invertible linear operator A and a diagonal linear operator H_0, i.e., there is an orthonormal basis $\{|n,\alpha\rangle\}$ in the Hilbert space and complex numbers E_n such that $H_0=\Sigma_n\Sigma_\alpha E_n|n,\alpha\rangle\langle n,\alpha|$. Then letting $|\psi_n,\alpha\rangle:=A|n,\alpha\rangle$ and $|\phi_n,\alpha\rangle:=(A^{-1})^\dagger|n,\alpha\rangle$, we can easily check that $\{|\psi_n,\alpha\rangle,|\psi_n,\alpha\rangle\}$ is a complete biorthonormal system for H. The converse is also true, for if such a system exists we may set $A:=\Sigma_n\Sigma_\alpha|\psi_n,\alpha\rangle\langle n,\alpha|$ for some orthonormal basis $\{|n,\alpha\rangle\}$ and check that $A^{-1}=\Sigma_n\Sigma_\alpha|n,\alpha\rangle\langle\phi_n,\alpha|$ and $A^{-1}HA=H_0$, i.e., H is diagonalizable.

We would like to emphasize that the diagonalizability condition may be viewed as a physical requirement without which an energy eigenbasis would not exist. To our knowledge all known non-Hermitian Hamiltonians that are used in physical applications are diagonalizable and therefore admit a complete biorthonormal set of eigenvectors. This in particular includes all the Hermitian Hamiltonians as well as the non-Hermitian Hamiltonians used in ionization optics,[5] the study of dissipative systems and resonant states,[6] two-component formulation of the minisuperspace quantum cosmology,[7] and also the PT-symmetric Hamiltonians whose spectral properties have been obtained using numerical methods.

II. PSEUDO-HERMITICITY

Let $H:\mathcal{H}\to\mathcal{H}$ be a linear operator acting in a Hilbert space $\mathcal{H}$ and $\eta:\mathcal{H}\to\mathcal{H}$ be a linear Hermitian automorphism (invertible transformation). Then the η-pseudo-Hermitian adjoint of H is defined by[2]

$$H^\sharp:=\eta^{-1}H^\dagger\eta. \tag{5}$$

H is said to be pseudo-Hermitian with respect to η or simply η-pseudo-Hermitian if $H^\sharp=H$. H is said to be pseudo-Hermitian if it is pseudo-Hermitian with respect to some linear Hermitian automorphism η.

The basic properties of pseudo-Hermitian operators are discussed in Refs. 2 and 3. Here we survey the properties that we shall make use of in this article. Let $H:\mathcal{H}\to\mathcal{H}$ be a diagonalizable linear operator. Then

(i) H is pseudo-Hermitian if and only if its eigenvalues are real or come in complex-conjugate pairs;[2] and

(ii) if H is pseudo-Hermitian with respect to two linear Hermitian automorphisms η_1 and η_2, then $\eta_1^{-1}\eta_2$ generates a symmetry of H, i.e., $[H,\eta_1^{-1}\eta_2]=0$.[2]

III. ANTI-PSEUDO-HERMITICITY

We first recall that a function $\tau:\mathcal{H}\to\mathcal{H}$ acting in a (complex) Hilbert space $\mathcal{H}$ is said to be an antilinear operator if for all $a,b\in\mathbb{C}$ and $|\xi\rangle,|\zeta\rangle\in\mathcal{H}$,

$$\tau(a|\xi\rangle+b|\zeta\rangle)=a^*\tau|\xi\rangle+b^*\tau|\zeta\rangle. \tag{6}$$

An antilinear operator $\tau:\mathcal{H}\to\mathcal{H}$ is said to be anti-Hermitian[8] if for all $|\xi\rangle,|\zeta\rangle\in\mathcal{H}$,

$$\langle\zeta|\tau|\xi\rangle=\langle\xi|\tau|\zeta\rangle. \tag{7}$$

Definition 1: A linear operator $H:\mathcal{H}\to\mathcal{H}$ acting in a Hilbert space $\mathcal{H}$ is said to be anti-pseudo-Hermitian if there is an antilinear anti-Hermitian automorphism $\tau:\mathcal{H}\to\mathcal{H}$ satisfying

$$H^\dagger=\tau H\tau^{-1}. \tag{8}$$

We begin our analysis by giving a characterization of antilinear anti-Hermitian operators with respect to which a given linear operator is anti-pseudo-Hermitian.

Theorem 1: Let $\mathcal{H}$ be a Hilbert space and $H:\mathcal{H}\to\mathcal{H}$ be a diagonalizable linear operator with a discrete spectrum and a complete biorthonormal set of eigenvectors $\{(|\psi_n,a\rangle,|\phi_n,a\rangle)\}$. Then $\tau:\mathcal{H}\to\mathcal{H}$ is an antilinear anti-Hermitian operator and H is τ-anti-pseudo-Hermitian if and only if there are symmetric invertible matrices $c^{(n)}$ with entries $c^{(n)}_{ab}$ such that for all $|\zeta\rangle\in\mathcal{H}$,

$$\tau|\zeta\rangle=\sum_n\sum_{a,b=1}^{d_n}c^{(n)}_{ab}\langle\zeta|\phi_n,a\rangle\,|\phi_n,b\rangle. \tag{9}$$

Proof: Suppose that $\tau:\mathcal{H}\to\mathcal{H}$ is a given antilinear anti-Hermitian operator and H is τ-anti-pseudo-Hermitian, i.e., (8) or equivalently

$$H^\dagger\tau=\tau H \tag{10}$$

holds. Letting both sides of (10) act on $|\psi_n,a\rangle$ and using (1) and (6), we have

$$H^\dagger(\tau|\psi_n,a\rangle)=E_n^*(\tau|\psi_n,a\rangle).$$

Comparing this equation with the second equation in (1), we find

$$\tau|\psi_n,a\rangle=\sum_{b=1}^{d_n}c^{(n)}_{ba}|\phi_n,b\rangle, \tag{11}$$

where $c^{(n)}_{ab}$ are defined by

$$c^{(n)}_{ab}:=\langle\psi_{n,a}|\tau|\psi_n,a\rangle. \tag{12}$$

We can also express (11) in the form

$$\langle\psi_m,b|\tau|\psi_n,a\rangle=\delta_{mn}c^{(n)}_{ba}. \tag{13}$$

Next note that because τ is an invertible operator, the matrix $c^{(n)}=(c^{(n)}_{ab})$ formed by $c^{(n)}_{ab}$ is nonsingular. In fact, applying $\langle\phi_{n,c}|\tau^{-1}$ to both sides of (11) and using (6) and the fact that τ^{-1} is also antilinear, we have

$$(c^{(n)^{-1}})_{ab}=\langle\phi_n,a|\tau^{-1}|\phi_n,b\rangle^*. \tag{14}$$

Furthermore, in view of (12) and (7), $c^{(n)}$ is a symmetric matrix. Now let $|\zeta\rangle$ be an arbitrary element of $\mathcal{H}$ and use (13), (3) and (7) to compute

$$\sum_n \sum_{a,b=1}^{d_n} c^{(n)}_{ab} \langle \zeta | \phi_n, a\rangle \, |\phi_n, b\rangle = \sum_{n,m} \sum_{a,b=1}^{d_n} |\phi_m, b\rangle \langle \zeta | \phi_n, a\rangle \langle \psi_n, a | \tau | \psi_m, b\rangle$$

$$= \sum_m \sum_b |\phi_m, b\rangle \langle \zeta | \tau | \psi_m, b\rangle$$

$$= \sum_m \sum_b |\phi_m, b\rangle \langle \psi_m, b | \tau | \zeta\rangle$$

$$= \tau |\zeta\rangle.$$

This establishes (9). Next, suppose that $c^{(n)}$ are given invertible symmetric matrices and τ is defined by (9). Then the antilinearity of τ follows from the antilinearity of the inner-product in its first entry. The following simple calculation shows that τ is anti-Hermitian. For all $|\xi\rangle, |\zeta\rangle \in \mathcal{H}$,

$$\langle \xi | \tau | \zeta\rangle = \sum_n \sum_{a,b=1}^{d_n} c^{(n)}_{ab} \langle \zeta | \phi_n, a\rangle \langle \xi | \phi_n, b\rangle$$

$$= \sum_n \sum_{a,b=1}^{d_n} c^{(n)}_{ab} \langle \zeta | \phi_n, b\rangle \langle \xi | \phi_n, a\rangle$$

$$= \sum_n \sum_{a,b=1}^{d_n} c^{(n)}_{ab} \langle \xi | \phi_n, a\rangle \langle \zeta | \phi_n, b\rangle$$

$$= \langle \zeta | \tau | \xi\rangle,$$

where we used (9) and the fact that $c^{(n)}$ are symmetric. In order to establish the τ-anti-pseudo-Hermiticity of H we first observe that (9) implies

$$\tau^{-1} |\zeta\rangle = \sum_n \sum_{a,b=1}^{d_n} (c^{(n)})^{-1*}_{ab} \langle \zeta | \psi_n, a\rangle \, |\psi_n, b\rangle. \tag{15}$$

This can be easily checked by applying τ to the right-hand side of (15) and using (9), (2), and (3) to show that the result is $|\zeta\rangle$. Next, we note that applying both sides of (9) to $|\psi_n, a\rangle$ we recover (11). Finally, we use (9), (15), (6), (1), (4), and (11) to compute, for all $|\zeta\rangle \in \mathcal{H}$,

$$\tau H \tau^{-1} |\zeta\rangle = \tau \sum_n \sum_{a,b=1}^{d_n} c^{(n)-1*}_{ab} \langle \zeta | \psi_n, a\rangle \, E_n |\psi_n, b\rangle$$

$$= \sum_n \sum_{a,b=1}^{d_n} E^*_n c^{(n)-1}_{ab} \langle \zeta | \psi_n, a\rangle^* \tau |\psi_n, b\rangle$$

$$= \sum_n \sum_{a,b,c=1}^{d_n} E^*_n \langle \psi_n, a | \zeta\rangle c^{(n)}_{ca} c^{(n)-1}_{ab} |\phi_n, c\rangle$$

$$= \sum_n \sum_{b=1}^{d_n} E^*_n |\phi_n, b\rangle \langle \psi_n, b | \zeta\rangle = H^\dagger |\zeta\rangle.$$

Therefore, $\tau H \tau^{-1} = H^\dagger$. □

We should emphasize that, unlike the case of pseudo-Hermitian Hamiltonians, the anti-pseudo-Hermiticity does not restrict the energy spectrum. In fact, we can use Theorem 1 to prove the following.

Corollary 1: Every diagonalazable linear operator $H:\mathcal{H}\to\mathcal{H}$ with a discrete spectrum is anti-pseudo-Hermitian.

Proof: Let $\{(|\psi_n,a\rangle,|\phi_n,a\rangle)\}$ be a complete biorthonormal set of eigenvectors, and $\tau:\mathcal{H}\to\mathcal{H}$ be defined by (9) with $c^{(n)}=1$ for all n, i.e., for all $|\zeta\rangle\in\mathcal{H}$,

$$\tau|\zeta\rangle:=\sum_n\sum_{a=1}^{d_n}\langle\zeta|\phi_n,a\rangle\,|\phi_n,a\rangle. \tag{16}$$

Then according to Theorem 1, τ is an antilinear anti-Hermitian operator and H is τ-anti-pseudo-Hermitian. □

Corollary 2: Every diagonalizable pseudo-Hermitian linear operator $H:\mathcal{H}\to\mathcal{H}$ with a discrete spectrum has an antilinear symmetry.

Proof: Let H be pseudo-Hermitian. Then according to Corollary 1 it is also anti-pseudo-Hermitian, i.e., there are a linear Hermitian automorphism $\eta:\mathcal{H}\to\mathcal{H}$ and an antilinear anti-Hermitian automorphism $\tau:\mathcal{H}\to\mathcal{H}$ such that

$$\eta H\eta^{-1}=H^\dagger=\tau H\tau^{-1}. \tag{17}$$

Hence, $[H,\eta^{-1}\tau]=0$. Clearly $\eta^{-1}\tau$ is an antilinear operator. □

Theorem 2: Let $H:\mathcal{H}\to\mathcal{H}$ be a diagonalizable linear operator acting in a Hilbert space $\mathcal{H}$ with a discrete spectrum. Then the following are equivalent.

(1) The eigenvalues of H are real or come in complex-conjugate pairs.
(2) H is pseudo-Hermitian.
(3) H has an antilinear symmetry.

Proof: The equivalence of (1) and (2) was established in Ref. 2; Corollary 2 shows that (2) implies (3); the fact that (3) implies (1) follows from a simple calculation given in Ref. 3. □

A class of PT-symmetric Hamiltonians is given by

$$H=\frac{p^2}{2m}+V_1(x)+iV_2(x), \tag{18}$$

where V_1 and V_2 are, respectively, even and odd real-valued functions and the classical phase space is assumed to be real, i.e., x and p are the standard Hermitian operators representing the position and momentum of a particle of mass m. As we point out in Ref. 2, the Hamiltonian (18) is P-pseudo-Hermitian. It is also easy to check that it is T-anti-pseudo-Hermitian. The P-pseudo-Hermiticity and T-anti-pseudo-Hermiticity of this Hamiltonian implies its $P^{-1}T=PT$ symmetry. In general, there are PT-symmetric Hamiltonians H that are neither P-pseudo-Hermitian nor T-anti-pseudo-Hermitian. According to Theorem 2, if we make the physical assumption that H is diagonalizable, so that it admits a complete biorthonormal set of energy eigenvectors, then H must be pseudo-Hermitian with respect to a linear Hermitian automorphism η. It turns out that the choice of η is not unique. But fixing an antilinear anti-Hermitian operator τ with respect to which H is anti-pseudo-Hermitian [namely, (9)], we can express η in terms of PT and τ according to

$$\eta=\tau PT. \tag{19}$$

One can easily check that PT-symmetry ($[PT,H]=0$) and anti-pseudo-Hermiticity (8) imply pseudo-Hermiticity of H with respect to (19).

Next we consider a general diagonalizable Hamiltonian H with a discrete spectrum and a symmetry generated by a general invertible antilinear operator X,

$$[H,X]=0. \tag{20}$$

The antilinearity of X implies η-pseudo-Hermiticity of H with respect to some linear Hermitian automorphism η. The anti-pseudo-Hermiticity of H with respect to an antilinear automorphism of the form (9) always holds. Hence Eqs. (17) are valid. Taking the adjoint of both sides of (20) and making use of (17), we can easily show that $X_\eta^\sharp := \eta^{-1} X \eta$ and $X_\tau^\sharp := \tau^{-1} X \tau$ commute with H, i.e., they generate antilinear symmetries of the system as well.

IV. NON-HERMITIAN HAMILTONIANS WITH A REAL SPECTRUM

We first recall the following results which we reported in Refs. 2 and 3.

(1) The (indefinite) inner-product defined by

$$\forall |\xi\rangle, |\zeta\rangle \in \mathcal{H}, \quad \langle\langle \xi|\zeta\rangle\rangle := \langle \xi|\eta|\zeta\rangle, \tag{21}$$

is invariant under the evolution generated by an η-pseudo-Hermitian Hamiltonian H.[2] It is also easy to check that such a Hamiltonian is Hermitian with respect to the (indefinite) inner-product (21). See also Ref. 9.

(2) A diagonalizable (non-Hermitian) Hamiltonian has a real spectrum if and only if it is pseudo-Hermitian with respect to a linear Hermitian automorphism of the form

$$\eta = OO^\dagger, \tag{22}$$

where $O:\mathcal{H}\to\mathcal{H}$ is a linear automorphism.[3]

These statements suggest the following characterization of the (non-Hermitian) Hamiltonians with a real spectrum. See also Ref. 10.

Theorem 3: A diagonalizable Hamiltonian H acting in a Hilbert space $\mathcal{H}$ has a real spectrum if and only if there is a positive-definite inner-product on $\mathcal{H}$ with respect to which H is Hermitian.

Proof: Suppose H has a real spectrum so that it is $OO^\dagger$-pseudo-Hermitian for a linear automorphism $O:\mathcal{H}\to\mathcal{H}$. Then the inner-product (21) with $\eta = OO^\dagger$ is clearly a positive-definite inner-product with respect to which H is Hermitian. Conversely, suppose that there is a positive-definite inner-product $(\ ,\ )$ with respect to which H is Hermitian. Then treating the spectral problem for H in the Hilbert space $\mathcal{H}$ with the inner-product $(\ ,\ )$, we find that H has a real spectrum.

Corollary: Suppose that H has an antilinear symmetry X. If X is an exact symmetry of H, then there is a positive-definite inner product on $\mathcal{H}$ with respect to which H is Hermitian. □

Proof: Exactness of an antilinear symmetry implies reality of the spectrum of H.[3] The conclusion then follows from Theorem 3. □

Next we give an alternative and in a sense equivalent characterization of the (non-Hermitian) Hamiltonians with a real spectrum.

Definition 2: Consider a quantum system with the Hilbert space $\mathcal{H}$ and the Hamiltonian $H:\mathcal{H}\to\mathcal{H}$. Then a linear automorphism $A:\mathcal{H}\to\mathcal{H}$ is said to be a *pseudo-canonical transformation* for the system if for all $|\zeta\rangle \in \mathcal{H}$ the transformation

$$|\zeta\rangle \to |\tilde{\zeta}\rangle := A|\zeta\rangle \tag{23}$$

leaves the Schrödinger equation,

$$i\frac{d}{dt}|\psi(t)\rangle = H|\psi(t)\rangle \tag{24}$$

form-invariant. A unitary pseudo-canonical transformation is called a (quantum) canonical transformation.[11]

Clearly the defining condition for a pseudo-canonical transformation implies the following transformation rule for the Hamiltonian:

$$H \to \tilde{H} := AHA^{-1} + i\dot{A}A^{-1}, \tag{25}$$

where a dot denotes a time-derivative. For a time-independent pseudo-canonical transformation A, the second term on the right-hand side of (25) drops and H transforms as

$$H\to\tilde{H}:=AHA^{-1}. \tag{26}$$

Theorem 4: A diagonalizable time-independent Hamiltonian H has a real spectrum if and only if there is a pseudo-canonical transformation that maps H into a Hermitian operator.

Proof: Suppose that H has a real spectrum. Then it is $OO^\dagger$-pseudo-Hermitian for a linear automorphism $O:\mathcal{H}\to\mathcal{H}$, i.e., $H^\dagger=OO^\dagger H(OO^\dagger)^{-1}$. Let $A:=O^\dagger$. Then, in view of (26) and the preceding equation, we have

$$\tilde{H}^\dagger=(AHA^{-1})^\dagger=(A^{-1})^\dagger H^\dagger A^\dagger=(A^{-1})^\dagger A^\dagger AHA^{-1}(A^\dagger)^{-1}A^\dagger=AHA^{-1}=\tilde{H}.$$

Hence the transformed Hamiltonian is Hermitian. Conversely suppose that there is a pseudo-canonical transformation $A:\mathcal{H}\to\mathcal{H}$ under which H transforms to a Hermitian Hamiltonian $\tilde{H}$ and let $O:=A^\dagger$. Then using (26) and $\tilde{H}^\dagger=\tilde{H}$, we have

$$OO^\dagger H(OO^\dagger)^{-1}=A^\dagger AA^{-1}\tilde{H}A(A^\dagger A)^{-1}=A^\dagger\tilde{H}^\dagger(A^\dagger)^{-1}=(A^{-1}\tilde{H}A)^\dagger=H^\dagger.$$

Therefore, H is $OO^\dagger$-pseudo-Hermitian, and its spectrum is real. □

Corollary: Suppose that H has an antilinear symmetry X. If X is an exact symmetry of H, then there is a pseudo-canonical transformation that maps H into a Hermitian operator.

Proof: Exactness of an antilinear symmetry implies reality of the spectrum of H.[3] The conclusion then follows from Theorem 4. □

V. DISCUSSION AND CONCLUSION

In this article we established the equivalence of the notion of pseudo-Hermiticity and presence of an antilinear symmetry for the class of diagonalizable (non-Hermitian) Hamiltonians. This required the study of pseudo-Hermiticity with respect to antilinear anti-Hermitian automorphisms. It turned that the latter does not restrict the choice of the Hamiltonian and such antilinear automorphisms always exist. In fact, we obtained the general form of these automorphisms. For a fixed complete biorthonormal eigenbasis, they are determined in terms of a sequence of complex symmetric matrices $c^{(n)}$. The choice of unity for all these matrices leads to a canonical antilinear anti-Hermitian automorphism, namely (16). Under an invertible transformation u of the basis

$$|\psi_n,a\rangle\to\sum_{b=1}^{d_n}u_{ba}|\psi_n,b\rangle,\quad |\phi_n,a\rangle\to\sum_{b=1}^{d_n}(u^{-1\dagger})_{ba}|\phi_n,b\rangle$$

that preserves its completeness and biorthonormality, the matrices $c^{(n)}$ transform according to

$$c^{(n)}\to u^{*t}c^{(n)}u^*=u^\dagger c^{(n)}u^{\dagger t},$$

where ^{t} denotes the transpose. We can transform to a basis where a general τ has the canonical form (16) if we can find invertible matrices $v=u^{-1\dagger}$ satisfying $c^{(n)}=vv^t$. As shown in Ref. 12 this is always possible. Therefore, up to the choice of the biorthonormal eigenbasis, τ is actually unique.

A simple consequence of our findings is that the reality of the spectrum of a Hamiltonian implies the presence of an antilinear symmetry. In view of the proof of Corollary 2 and Eq. (9) of this article and Eq. (23) of Ref. 2, we have in fact an explicit expression for the generator of such a symmetry in terms of the biorthonormal eigenvectors of the Hamiltonian. We also gave two characterizations of Hamiltonians with real spectrum. These characterizations show how a Hamiltonian with a real spectrum may be related to an associated Hermitian Hamiltonian. Another simple implication of our analysis is that every Hermitian Hamiltonian has an antilinear symmetry.

We aimed to obtain the energy levels of massive spin-1 particles moving in a constant magnetic field. The method used here is completely algebraic. In the process to obtain the energy levels the wave function is expressed in terms of Laguerre polynomials. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1489502]

I. INTRODUCTION

The problem of finding the states of a spinning particle moving in an external field has been solved for many different situations. The relativistic wave equation of spin-1 particles was at first derived by Kemmer in 1939.[1] Kemmer theory gives an entirely different aspect of the mesons. It is similar to the Dirac's equation of the electron. The similarity is very striking and the method investigated by Kemmer yields more than a mere restatement of the others. Kemmer equation is a Dirac type equation but involves matrices obeying a different scheme of commutation rules. These rules were first given by Duffin.[2] The theory can be developed in strikingly close correspondence to Dirac's electron theory; practically all the definitions of physical quantities like spin, magnetic moment etc., have their exact counterpart.

There are various wave equations to describe the spin-1 particles given in literature.[3–6] The methods used in these equations are quite complicated and give different results when they are compared. The method of Shay and Good is to expand the six-component wave function in terms of complete set of functions. This method leads to an invariant way to find the matrix elements, and it allows for arbitrary magnetic dipole moment and electric quadrupole moment of the particle. The eigenvalues of Shay and Good's equation have been obtained by Krase, Lu, and Good by using the quite complicated conventional method of solving the differential equation. A general method of obtaining the energy levels of any spin theory has been proposed by Tsai and Yildiz. They went on to obtain the energy levels of the spin-1 theory of Proca and Kemmer and observed that spin-1 theory is consistent only when there is no anomalous magnetic moment coupling.

The generally accepted method of approach is to define the Lagrange equation of motion and use the differential equation techniques to solve for the eigenfunctions and eigenvalues of the system. This method becomes complicated when higher spinning particles are handled.

In this study by starting from the Kemmer equation we used an algebraic method for obtaining the energy levels of massive spin-1 particles without anomolous magnetic moment moving in a homogeneous magnetic field.

The method we used does not require an explicit solution of the equation. The massive spin-1 particle will be considered as a two-identical particle system of spin-1/2 instead of a single spin-1 particle. This is the second quantization approach of Schrödinger applied to this problem. In the process to obtain the energy levels of the massive spin-1 particles, the solutions of spin-1/2 particles moving in a homogeneous magnetic field are used. The solutions of the Dirac equation in a magnetic field have been found in terms of Laguerre polynomials.[7] Since Kemmer matrices are expressed in terms of Dirac matrices and a massive spin-1 particle is considered as a two-identical fermion system, we used the Kemmer equation for obtaining the energy spectrum. To introduce

the method we first used it to obtain the energy levels of spin-1/2 particles moving in a homogeneous magnetic field in Sec. II. In the Conclusion we compared our results with the previous results and saw that they were in agreement with them.

The vector potential we used is

$$\vec{A}=-\tfrac{1}{2}yB\hat{x}+\tfrac{1}{2}xB\hat{y}, \tag{1}$$

where B is constant.

II. ENERGY SPECTRUM OF SPIN-1/2 PARTICLES

Covariant form of the Dirac equation for a spin-1/2 particle moving in an external field is

$$(\gamma^{\mu}\pi_{\mu}-M)\Psi(x)=0, \tag{2}$$

where γ^{μ} are 4×4 Dirac matrices; $\pi_{\mu}=(P_0-eA_0,\vec{P}-e\vec{A})$ is electrodynamical four-momentum vector; M is the mass of spin-1/2 particle, $\Psi(x)$ is the four-component spinor; $A^{\mu}=(A_0,\vec{A})$ is the four-vector electromagnetic potential and e is the charge of the electron. In the writing of the equation the Heaviside units $c=\hbar=1$ were used. The gamma matrices are given in the form

$$\gamma^0=\beta=\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}, \quad \vec{\gamma}=\beta\vec{\alpha}, \tag{3}$$

$$\vec{\alpha}=\gamma^0\vec{\gamma}=\begin{pmatrix} 0 & \vec{\sigma} \\ \vec{\sigma} & 0 \end{pmatrix}. \tag{4}$$

Equation (2) can be written as

$$(\vec{\alpha}\cdot\vec{\pi}+\beta M+e\Phi)\Psi(x)=\pi_0\Psi(x). \tag{5}$$

For steady states if we choose the wave function in the form

$$\Psi(x_0=t,\ \vec{x})=e^{-iEt}\begin{pmatrix} \varphi(\vec{x}) \\ \chi(\vec{x}) \end{pmatrix} \tag{6}$$

and use $\vec{\alpha}$ matrices, Eq. (5) takes the following form

$$\begin{pmatrix} M+e\Phi & \vec{\sigma}\cdot\vec{\pi} \\ \vec{\sigma}\cdot\vec{\pi} & -M+e\Phi \end{pmatrix}\begin{pmatrix} \varphi(\vec{x}) \\ \chi(\vec{x}) \end{pmatrix}=E\begin{pmatrix} \varphi(\vec{x}) \\ \chi(\vec{x}) \end{pmatrix}. \tag{7}$$

If the particle is chosen to be moving in a homogeneous magnetic field then $A_0=\Phi=0$. Since the particle is rotating around z-axis with a θ angle in the xy-plane and going forward in the z direction the geometry of the problem is cylindrically symmetrical.

By defining φ and χ as

$$\varphi=\begin{pmatrix} \varphi_+ \\ \varphi_- \end{pmatrix}, \quad \chi=\begin{pmatrix} \chi_+ \\ \chi_- \end{pmatrix}, \tag{8}$$

Eq. (7) takes the following form:

$$\begin{pmatrix} (E-M) & 0 & -P_z & -\pi_- \\ 0 & (E-M) & -\pi_+ & P_z \\ -P_z & -\pi_- & (E+M) & 0 \\ -\pi_+ & P_z & 0 & (E+M) \end{pmatrix}\begin{pmatrix} \varphi_+ \\ \varphi_- \\ \chi_+ \\ \chi_- \end{pmatrix}=0, \tag{9}$$

where φ_+ and χ_+ are the solutions with positive frequency and φ_- and χ_- are with negative frequency. Helicity raising and lowering operators are defined in cylindrical coordinates as

$$\pi_+ = \pi_1 + i\pi_2 = e^{i\theta}\left[-i\frac{\partial}{\partial\rho} + \frac{1}{\rho}\frac{\partial}{\partial\theta} - \frac{iB\rho e}{2}\right], \tag{10}$$

$$\pi_- = \pi_1 - i\pi_2 = e^{-i\theta}\left[-i\frac{\partial}{\partial\rho} - \frac{1}{\rho}\frac{\partial}{\partial\theta} + \frac{iB\rho e}{2}\right]. \tag{11}$$

The exact solutions of Dirac equation for a homogeneous magnetic field are given in terms of Laguerre polynomials. Before obtaining the energy levels of spin-1/2 particles we must note that the effect of helicity raising and lowering operators on Laguerre polynomials are given as follows:

(i) for $m>0$,

$$\pi_+ L_N^{|m|}(x)F_m(\rho,\theta,z) = 2i\omega^{1/2}x^{1/2}L_{N-1}^{|m|+1}(x)F_{m+1}(\rho,\theta,z), \tag{12}$$

$$\pi_- L_N^{|m|}(x)F_m(\rho,\theta,z) = -2iN\omega^{1/2}x^{-1/2}L_{N+1}^{|m|-1}(x)F_{m-1}(\rho,\theta,z), \tag{13}$$

and

(ii) for $m<0$

$$\pi_+ L_N^{|m|}(x)F_m(\rho,\theta,z) = -2i(N+|m|)\omega^{1/2}x^{1/2}L_N^{|m|-1}(x)F_{m+1}(\rho,\theta,z), \tag{14}$$

$$\pi_- L_N^{|m|}(x)F_m(\rho,\theta,z) = 2i\omega^{1/2}x^{1/2}L_N^{|m|+1}(x)F_{m-1}(\rho,\theta,z), \tag{15}$$

where m is quantum number of the system and

$$F_m(\rho,\theta,z) = (\sqrt{x})^{|m|}e^{im\theta+iP_z z-(x/2)}, \tag{16}$$

$$x = \frac{eB}{2}\rho^2. \tag{17}$$

The other index of Laguerre polynomials is defined in the form

$$N = \frac{1}{4\omega}(E^2 - M^2 - P_z^2) + \frac{(m-|m|)}{2}, \quad \text{for} \quad m>0, \tag{18}$$

$$N = \frac{1}{4\omega}(E^2 - M^2 - P_z^2) + \frac{(m-|m|-2)}{2}, \text{for} \quad m<0. \tag{19}$$

There are two possible cases due to spin orientations in magnetic field and each of them are related with the positive and negative values of m quantum number. Finally we have four different situations for the spin-1/2 particle:

Situation 1: Spin is parallel to the magnetic field and $m>0$.

If we choose the wave function in the form

$$\Psi = \begin{bmatrix} L_N^{|m|}(x)F_m(\rho,\theta,z) \\ 0 \\ c_1 L_N^{|m|}(x)F_m(\rho,\theta,z) \\ d_1 L_{N-1}^{|m|+1}(x)F_{m+1}(\rho,\theta,z) \end{bmatrix} \tag{20}$$

and use it in Eq. (9) we obtain the energy spectrum and c_1, d_1 coefficients as follows:

$$E_{\uparrow,m>0}^2 = P_z^2 + M^2 + 4\omega(N-1), \tag{21}$$

$$c_1=\frac{P_z}{(E+M)}, \tag{22}$$

$$d_1=\frac{2i\omega^{1/2}x^{1/2}}{(E+M)}. \tag{23}$$

Situation 2: Spin is parallel to the magnetic field and $m<0$.
If we choose the wave function in the form

$$\Psi=\begin{bmatrix} L_N^{|m|}(x)F_m(\rho,\theta,z) \\ 0 \\ c_2L_N^{|m|}(x)F_m(\rho,\theta,z) \\ d_2L_N^{|m|-1}(x)F_{m+1}(\rho,\theta,z) \end{bmatrix} \tag{24}$$

and use it in Eq. (9) we obtain the energy spectrum and c_2, d_2 coefficients as follows:

$$E^2_{\uparrow,m<0}=P_z^2+M^2+4\omega(N+|m|), \tag{25}$$

$$c_2=\frac{P_z}{(E+M)}, \tag{26}$$

$$d_2=\frac{-2i(N+|m|)\omega^{1/2}x^{-1/2}}{(E+M)}. \tag{27}$$

Situation 3: Spin is anti-parallel to the magnetic field and $m>0$.
If we choose the wave function in the form

$$\Psi=\begin{bmatrix} 0 \\ L_N^{|m|}(x)F_m(\rho,\theta,z) \\ c_3L_{N+1}^{|m|-1}(x)F_{m-1}(\rho,\theta,z) \\ d_3L_N^{|m|}(x)F_m(\rho,\theta,z) \end{bmatrix} \tag{28}$$

and use it in Eq. (9) we obtain the energy spectrum and c_3, d_3 coefficients as follows:

$$E^2_{\downarrow,m>0}=P_z^2+M^2+4\omega N, \tag{29}$$

$$c_3=\frac{-2iN\omega^{1/2}x^{-1/2}}{(E+M)}, \tag{30}$$

$$d_3=\frac{-P_z}{(E+M)}. \tag{31}$$

Situation 4: Spin is anti-parallel to the magnetic field and $m<0$.
If we choose the wave function in the form

$$\Psi=\begin{bmatrix} 0 \\ L_N^{|m|}(x)F_m(\rho,\theta,z) \\ c_4L_N^{m+1}(x)F_{m-1}(\rho,\theta,z) \\ d_4L_N^{|m|}(x)F_m(\rho,\theta,z) \end{bmatrix} \tag{32}$$

and use it in Eq. (9) we obtain the energy spectrum and c_4, d_4 coefficients as follows:

$$E^2_{\downarrow,m<0}=P_z^2+M^2+4\omega(N+|m|+1), \tag{33}$$

$$c_4=\frac{2i\omega^{1/2}x^{1/2}}{(E+M)}, \tag{34}$$

$$d_4=\frac{-P_z}{(E+M)}. \tag{35}$$

It can be seen that these results are in agreement with the results given in Ref. 7.

III. ENERGY SPECTRUM OF MASSIVE SPIN-1 PARTICLES

For massive spin-1 particles the Kemmer equation is given in the form

$$(\beta^\mu\pi_\mu-\tilde{M})\Psi_K(x)=0, \tag{36}$$

where 16×16 Kemmer matrices β^μ are given as

$$\beta^\mu=\gamma^\mu\otimes I+I\otimes\gamma^\mu \tag{37}$$

with the usual γ^μ Dirac matrices. $\tilde{M}$ is the total mass of two identical spin-1/2 particles and $\Psi_K(x)$ is the 16-component wave function of the Kemmer equation.

Since massive spin-1 particle will be considered as two-identical spin-1/2 particles, the wave function can be rewritten in the form

$$\Psi_K(x)=\Psi_D\otimes\Psi_D=\begin{pmatrix}A\\B\\C\\D\end{pmatrix}, \tag{38}$$

where $\Psi_D(x)$ is the solution of Dirac equation which was given in Sec. II and A, B, C, D are four component spinors given as

$$A=\begin{pmatrix}A_+\\A_0\\A_{\tilde{o}}\\A_-\end{pmatrix}=\begin{pmatrix}\varphi_+\varphi_+\\\varphi_+\varphi_-\\\varphi_-\varphi_+\\\varphi_-\varphi_-\end{pmatrix},\quad B=\begin{pmatrix}B_+\\B_0\\B_{\tilde{o}}\\B_-\end{pmatrix}=\begin{pmatrix}\varphi_+\chi_+\\\varphi_+\chi_-\\\varphi_-\chi_+\\\varphi_-\chi_-\end{pmatrix}, \tag{39}$$

$$C=\begin{pmatrix}C_+\\C_0\\C_{\tilde{o}}\\C_-\end{pmatrix}=\begin{pmatrix}\chi_+\varphi_+\\\chi_+\varphi_-\\\chi_-\varphi_+\\\chi_-\varphi_-\end{pmatrix},\quad D=\begin{pmatrix}D_+\\D_0\\D_{\tilde{o}}\\D_-\end{pmatrix}=\begin{pmatrix}\chi_+\chi_+\\\chi_+\chi_-\\\chi_-\chi_+\\\chi_-\chi_-\end{pmatrix}.$$

In these matrices the left and right elements of the right matrix indicate first and second particles, respectively. In this case we can see the following equalities:

$$B_0=C_{\tilde{o}},\quad B_{\tilde{o}}=C_0,$$

$$A_0=A_{\tilde{o}},\quad D_0=D_{\tilde{o}}. \tag{40}$$

Therefore, the wave function of the massive spin-1 particle is a ten-component spinor.

After some algebra Kemmer equation takes the following form:

$$[(\gamma_1^0\otimes I_2+I_1\otimes\gamma_2^0)E-(\gamma_1^0\otimes\vec{\alpha}_2+\vec{\alpha}_1\otimes\gamma_2^0)\cdot\vec{\pi}-\tilde{M}\gamma_1^0\otimes\gamma_2^0]\begin{pmatrix}A\\B\\C\\D\end{pmatrix}=0. \tag{41}$$

We obtain four linear algebraic equations, ultimately 16 equations from Eq. (41):

$$(2E-\tilde{M})A-\vec{\sigma}_{(1)}\cdot\vec{\pi}C-\vec{\sigma}_{(2)}\cdot\vec{\pi}B=0, \tag{42}$$

$$\vec{\sigma}_{(2)}\cdot\vec{\pi}A-\vec{\sigma}_{(1)}\cdot\vec{\pi}D-\tilde{M}B=0, \tag{43}$$

$$\vec{\sigma}_{(1)}\cdot\vec{\pi}A-\vec{\sigma}_{(2)}\cdot\vec{\pi}D-\tilde{M}C=0, \tag{44}$$

$$(2E+\tilde{M})D-\vec{\sigma}_{(1)}\cdot\vec{\pi}B-\vec{\sigma}_{(2)}\cdot\vec{\pi}C=0, \tag{45}$$

where

$$\vec{\sigma}_{(1)}\cdot\vec{\pi}=(\vec{\sigma}\otimes I)\cdot\vec{\pi}=\begin{pmatrix}P_z & 0 & \pi_- & 0\\ 0 & P_z & 0 & \pi_-\\ \pi_+ & 0 & -P_z & 0\\ 0 & \pi_+ & 0 & -P_z\end{pmatrix}, \tag{46}$$

$$\vec{\sigma}_{(2)}\cdot\vec{\pi}=(I\otimes\vec{\sigma})\cdot\vec{\pi}=\begin{pmatrix}P_z & \pi_- & 0 & 0\\ \pi_+ & -P_z & 0 & 0\\ 0 & 0 & P_z & \pi_-\\ 0 & \pi_+ & \pi_+ & -P_z\end{pmatrix}. \tag{47}$$

By using these matrices in Eqs. (42)–(45) and eliminating one of the same equations we obtain ten linear algebraic equations in the form

$$(2E-\tilde{M})A_+-2P_zB_+-2\pi_-B_0=0, \tag{48}$$

$$(2E-\tilde{M})A_0-\pi_+B_+-\pi_-B_-+P_z(B_0-B_{\tilde{o}})=0, \tag{49}$$

$$(2E-\tilde{M})A_-+2P_zB_--2\pi_+B_{\tilde{o}}=0, \tag{50}$$

$$(2E-\tilde{M})D_+-2P_zB_+-2\pi_-B_{\tilde{o}}=0, \tag{51}$$

$$(2E-\tilde{M})D_0-\pi_+B_+-\pi_-B_-+P_z(B_{\tilde{o}}-B_0)=0, \tag{52}$$

$$(2E-\tilde{M})D_-+2P_zB_--2\pi_+B_0=0, \tag{53}$$

$$P_z(A_+-D_+)+\pi_-(A_0-D_0)-\tilde{M}B_+=0, \tag{54}$$

$$P_z(D_--A_-)+\pi_+(A_0-D_0)-\tilde{M}B_-=0, \tag{55}$$

$$P_z(A_0+D_0)+\pi_-A_--\pi_+D_+-\tilde{M}B_{\tilde{o}}=0, \tag{56}$$

$$P_z(A_0+D_0)-\pi_+A_++\pi_-D_-+\tilde{M}B_0=0. \tag{57}$$

In order to find the energy eigenvalues we will choose B_0 and $B_{\tilde{o}}$ in terms of Laguerre polynomials:

$$B_0 = L_N^{|m|}(x) F_m(\rho,\theta,z), \tag{58}$$

$$B_{\tilde{o}} = -L_N^{|m|}(x) F_m(\rho,\theta,z). \tag{59}$$

(i) For $m>0$:

If we use $B_0 = L_N^{|m|}(x) F_m(\rho,\theta,z)$ and $B_{\tilde{o}} = -L_N^{|m|}(x) F_m(\rho,\theta,z)$ in Eqs. (48)–(53) we find A, B, C, D spinors in the form

$$B = \begin{pmatrix} b_+ \omega^{1/2} x^{-1/2} L_{N+1}^{|m|-1}(x) F_{m-1}(\rho,\theta,z) \\ L_N^{|m|}(x) F_m(\rho,\theta,z) \\ -L_N^{|m|}(x) F_m(\rho,\theta,z) \\ b_- \omega^{1/2} x^{1/2} L_{N-1}^{|m|+1}(x) F_{m+1}(\rho,\theta,z) \end{pmatrix}, \tag{60}$$

$$C = \begin{pmatrix} b_+ \omega^{1/2} x^{-1/2} L_{N+1}^{|m|-1}(x) F_{m-1}(\rho,\theta,z) \\ -L_N^{|m|}(x) F_m(\rho,\theta,z) \\ L_N^{|m|}(x) F_m(\rho,\theta,z) \\ b_- \omega^{1/2} x^{1/2} L_{N-1}^{|m|+1}(x) F_{m+1}(\rho,\theta,z) \end{pmatrix}, \tag{61}$$

$$A = \begin{pmatrix} \dfrac{2}{2E-\tilde{M}} (P_z b_+ - 2iN) \omega^{1/2} x^{-1/2} L_{N+1}^{|m|-1}(x) F_{m-1}(\rho,\theta,z) \\ \dfrac{1}{2E-\tilde{M}} [2i\omega(b_+ - (N-1)b_-) - 2P_z] L_N^{|m|}(x) F_m(\rho,\theta,z) \\ \dfrac{1}{2E-\tilde{M}} [2i\omega(b_+ - (N-1)b_-) - 2P_z] L_N^{|m|}(x) F_m(\rho,\theta,z) \\ -\dfrac{2}{2E-\tilde{M}} (P_z b_- + 2i) \omega^{1/2} x^{1/2} L_{N-1}^{|m|+1}(x) F_{m+1}(\rho,\theta,z) \end{pmatrix}, \tag{62}$$

$$D = \begin{pmatrix} \dfrac{2}{2E+\tilde{M}} (P_z b_+ + 2iN) \omega^{1/2} x^{-1/2} L_{N+1}^{|m|-1}(x) F_{m-1}(\rho,\theta,z) \\ \dfrac{1}{2E+\tilde{M}} [2i\omega(b_+ - (N-1)b_-) + 2P_z] L_N^{|m|}(x) F_m(\rho,\theta,z) \\ \dfrac{1}{2E+\tilde{M}} [2i\omega(b_+ - (N-1)b_-) + 2P_z] L_N^{|m|}(x) F_m(\rho,\theta,z) \\ -\dfrac{2}{2E+\tilde{M}} (P_z b_- - 2i) \omega^{1/2} x^{1/2} L_{N-1}^{|m|+1}(x) F_{m+1}(\rho,\theta,z) \end{pmatrix}. \tag{63}$$

We obtain four algebraic equations given below by using these spinors in Eqs. (54)–(57):

$$\left[E^2 - P_z^2 - \frac{\tilde{M}^2}{4} - 2\omega N \right] b_+ + 2N(N-1)\omega b_- = 0, \tag{64}$$

$$\left[E^2 - P_z^2 - \frac{\tilde{M}^2}{4} - 2\omega(N-1) \right] b_- + 2\omega b_+ = 0, \tag{65}$$

$$\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}+4\omega\left(\frac{E}{\tilde{M}}-\left(N-\frac{1}{2}\right)\right)\right]+i\omega P_z(N-1)b_-+i\omega P_z b_+=0, \tag{66}$$

$$\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}-4\omega\left(\frac{E}{\tilde{M}}+\left(N-\frac{1}{2}\right)\right)\right]-i\omega P_z(N-1)b_--i\omega P_z b_+=0. \tag{67}$$

From Eqs. (64) and (66) we find

$$b_+=\frac{2N\omega\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}+4\omega\left(\frac{E}{\tilde{M}}-\left(N-\frac{1}{2}\right)\right)\right]}{i\omega P_z\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}-4\omega N\right]}, \tag{68}$$

$$b_-=\frac{-\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}+4\omega\left(\frac{E}{\tilde{M}}-\left(N-\frac{1}{2}\right)\right)\right]\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}-2\omega N\right]}{i\omega P_z(N-1)\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}-4\omega N\right].}. \tag{69}$$

If we substitute these into Eqs. (65) and (67) we obtain the energy levels as follows

$$E=\pm\frac{1}{2}\sqrt{4P_z^2+\tilde{M}^2+16\omega\left(N-\frac{1}{2}\right)}, \tag{70}$$

$$E=\frac{2\omega}{\tilde{M}}\pm\frac{1}{2}\sqrt{\frac{16\omega^2}{\tilde{M}^2}+\tilde{M}^2+4P_z^2+16\omega\left(N-\frac{1}{2}\right)}, \tag{71}$$

$$E=-\frac{2\omega}{\tilde{M}}\pm\frac{1}{2}\sqrt{\frac{16\omega^2}{\tilde{M}^2}+\tilde{M}^2+4P_z^2+16\omega\left(N-\frac{1}{2}\right)}. \tag{72}$$

(ii) For $m<0$:

If we use $B_0=L_N^{|m|}(x)F_m(\rho,\theta,z)$ and $B_{\tilde{o}}=-L_N^{|m|}(x)F_m(\rho,\theta,z)$ in Eqs. (48)–(53) we find A, B, C, D spinors in the form

$$B=\begin{pmatrix} b_+\omega^{1/2}x^{1/2}L_N^{|m|+1}(x)F_{m-1}(\rho,\theta,z) \\ L_N^{|m|}(x)F_m(\rho,\theta,z) \\ -L_N^{|m|}(x)F_m(\rho,\theta,z) \\ b_-\omega^{1/2}x^{-1/2}L_N^{|m|-1}(x)F_{m+1}(\rho,\theta,z)\end{pmatrix}, \tag{73}$$

$$C=\begin{pmatrix} b_+\omega^{1/2}x^{1/2}L_N^{|m|+1}(x)F_{m-1}(\rho,\theta,z) \\ -L_N^{|m|}(x)F_m(\rho,\theta,z) \\ L_N^{|m|}(x)F_m(\rho,\theta,z) \\ b_-\omega^{1/2}x^{-1/2}L_N^{|m|-1}(x)F_{m+1}(\rho,\theta,z)\end{pmatrix}, \tag{74}$$

$$A=\begin{pmatrix} \dfrac{2}{2E-\tilde{M}}(P_z b_+ +2i)\omega^{1/2}x^{1/2}L_N^{|m|+1}(x)F_{m-1}(\rho,\theta,z) \\ \dfrac{1}{2E-\tilde{M}}[-2i\omega(N+|m|+1)b_+ +2i\omega b_- -2P_z]L_N^{|m|}(x)F_m(\rho,\theta,z) \\ \dfrac{1}{2E-\tilde{M}}[-2i\omega(N+|m|+1)b_+ +2i\omega b_- -2P_z]L_N^{|m|}(x)F_m(\rho,\theta,z) \\ \dfrac{2}{2E-\tilde{M}}[-P_z b_- +2i(N+|m|)]\omega^{1/2}x^{-1/2}L_N^{|m|-1}(x)F_{m+1}(\rho,\theta,z) \end{pmatrix}, \tag{75}$$

$$D=\begin{pmatrix} \dfrac{2}{2E-\tilde{M}}(P_z b_+ -2i)\omega^{1/2}x^{1/2}L_N^{|m|+1}(x)F_{m-1}(\rho,\theta,z) \\ \dfrac{1}{2E-\tilde{M}}[-2i\omega(N+|m|+1)b_+ +2i\omega b_- +2P_z]L_N^{|m|}(x)F_m(\rho,\theta,z) \\ \dfrac{1}{2E-\tilde{M}}[-2i\omega(N+|m|+1)b_+ +2i\omega b_- +2P_z]L_N^{|m|}(x)F_m(\rho,\theta,z) \\ -\dfrac{2}{2E-\tilde{M}}[P_z b_- +2i(N+|m|)]\omega^{1/2}x^{-1/2}L_N^{|m|-1}(x)F_{m+1}(\rho,\theta,z) \end{pmatrix}. \tag{76}$$

We obtain four algebraic equations given below by using these spinors in Eqs. (54)–(57) in the form

$$\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}-2\omega(N+|m|+1)\right]b_+ +2\omega b_- =0 \tag{77}$$

$$\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}+4\omega\left(\frac{E}{\tilde{M}}-\left(N+|m|+\frac{1}{2}\right)\right)\right]-i\omega P_z b_- -i\omega\left(N+|m|+\frac{1}{2}\right)P_z b_+ =0, \tag{78}$$

$$\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}-4\omega\left(\frac{E}{\tilde{M}}+\left(N+|m|+\frac{1}{2}\right)\right)\right]+i\omega P_z b_- +i\omega\left(N+|m|+\frac{1}{2}\right)P_z b_+ =0, \tag{79}$$

$$\left[E^2-P_z^2-\frac{\tilde{M}^2}{4}-2\omega(N+|m|)\right]b_- +2\omega(N+|m|)(N+|m|+1)b_+ =0. \tag{80}$$

From Eqs. (77)–(79) we find

$$b_+ =\frac{2\omega\left[E^2-P_z^2-\dfrac{\tilde{M}^2}{4}-4\omega\left(\dfrac{E}{\tilde{M}}+\left(N+|m|+\dfrac{1}{2}\right)\right)\right]}{i\omega P_z\left[E^2-P_z^2-\dfrac{\tilde{M}^2}{4}-4\omega(N+|m|+1)\right]}, \tag{81}$$

$$b_- =\frac{-\left[E^2-P_z^2-\dfrac{\tilde{M}^2}{4}-4\omega\left(\dfrac{E}{\tilde{M}}+\left(N+|m|+\dfrac{1}{2}\right)\right)\right]\left[E^2-P_z^2-\dfrac{\tilde{M}^2}{4}-2\omega(N+|m|+1)\right]}{i\omega P_z\left[E^2-P_z^2-\dfrac{\tilde{M}^2}{4}-4\omega(N+|m|+1)\right]}. \tag{82}$$

If we substitute these into Eqs. (78)–(80) we obtain the energy levels as follows:

$$E=\pm\frac{1}{2}\sqrt{4P_z^2+\tilde{M}^2+16\omega\left(N+|m|+\frac{1}{2}\right)}, \tag{83}$$

$$E=\frac{2\omega}{\tilde{M}}\pm\frac{1}{2}\sqrt{\frac{16\omega^2}{\tilde{M}^2}+\tilde{M}^2+4P_z^2+16\omega\left(N+|m|+\frac{1}{2}\right)}, \tag{84}$$

$$E=-\frac{2\omega}{\tilde{M}}\pm\frac{1}{2}\sqrt{\frac{16\omega^2}{\tilde{M}^2}+\tilde{M}^2+4P_z^2+16\omega\left(N+|m|+\frac{1}{2}\right)}. \tag{85}$$

IV. CONCLUSIONS

There are several techniques developed for understanding the behavior of spin-1 particles moving in a constant magnetic field. These techniques are quite complicated. Because there is no availablity of experimental tests of these techniques we do not know which one is the best.

We used here a simple algebraic method for obtaining the energy levels of a massive spin-1 particle moving in a constant magnetic field. Spin-1 particle was considered as a two-identical fermion system and in the process to obtain the energy levels the wave functions of spin-1/2 particle which are written in terms of Laguerre polynomials were used.

The nonrelativistic approximation applies when the energies p_z^2/M and eB/M are small compared to the rest energy M. On taking the positive roots of E^2 to first order only, one finds, as approximations to Eqs. (70)–(72),

$$E=M+\frac{P_Z^2}{2M}+\frac{eB}{2M}(2N-1), \tag{86}$$

$$E=M+\frac{P_Z^2}{2M}+\frac{eB}{2M}(2N-1)+\frac{eB}{2M}(\pm 1), \tag{87}$$

and Eqs. (83)–(85),

$$E=M+\frac{P_Z^2}{2M}+\frac{eB}{2M}(2N+2|m|+1), \tag{88}$$

$$E=M+\frac{P_Z^2}{2M}+\frac{eB}{2M}(2N+2|m|+1)+\frac{eB}{2M}(\pm 1), \tag{89}$$

where we used $\tilde{M}=2M$. These are the exact results those obtained by Krase, Lu, and Good. The first of these energy spectra can be interpreted as corresponding to $m_s=0$ and the of second are for $m_s=\pm 1$. Our results are more general those were obtained by W. Tsai, W. Tsai, and A. Yildiz. They found the energy spectrum in the limit $\pi_3=0$, ultimately in two dimensions. In this limit the first of these energy spectra are the same as the result obtained by them, only $2N+2|m|$ has been replaced by $2n$ for $m<0$.

If the magnetic field is quite weak, we see that the difference of the second from the first energy level is $\pm eB/2M$. This is the interaction energy of the spin with the magnetic field. From these spectra we can see that the magnetic moment of the massive spin-1 particle is

$$\mu_s=(\pm 1)\frac{e}{\tilde{M}}. \tag{90}$$

The energy spectra given in Eqs. (87) and (89) can be interpreted as corresponding to the spins of particle and anti-particle being parallel and anti-parallel to the magnetic field, respectively. From these spectra it is seen that for all values of magnetic field the energy difference between the spin $s=1$ to $s=-1$ is equal to

$$\Delta E_{\pm}=\frac{eB}{M}. \tag{91}$$

The propagator for the radial Dirac equation is explicitly constructed. It turns out to be a distribution of order zero, but it is shown that there exists no path-space measure associated with this equation. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1486263]

I. INTRODUCTION

It is always of interest to know whether or not there is a path-space measure associated with an initial-value problem for an evolution equation in mathematical physics, so that we may represent its solution by a path integral, that is, an integral with respect to a σ-additive set function defined on some σ-algebra of subsets of a suitable function space of ''paths.'' Then perturbations to the original equation have solutions represented by a path integral, too, and we can derive information about the solution by means of this representation.

A broad class of initial-value problems can be treated by semigroup theory, but the precise relationship of the idea of a path integral to these problems is somewhat ill-defined. Unfortunately, no such path-space measure exists as a mathematically rigorous measure associated with the Schrödinger equation, although it was with this equation in mind that Feynman conceived the very concept of *path integration* (Feynman, 1948).

However, as is well-known, for the imaginary-time Schrödinger equation, that is, the heat equation or more general evolution equations appearing in a Markov process in probability theory, the solution semigroup $S(t)$, $t\geqslant 0$, is a positivity preserving operator on some space $L^{\infty}(\Sigma)$ of bounded measurable functions on a certain set Σ, and there exists an associated path integral or path-space measure.

It is, roughly speaking, because there exists an integral kernel or transition function $p_t(x,dy)$ such that $S(t)$ is given by

$$(S(t)f)(x)=\int_{\Sigma}p_t(x,dy)f(y), \quad x\in\Sigma, \ \ t\geqslant 0,$$

for $f\in L^{\infty}(\Sigma)$ and that the bound $\|S(t)f\|_{\infty}\leqslant\|f\|_{\infty}$ holds for all $f\in L^{\infty}(\Sigma)$.

The aim of this article is to discuss this issue for the Dirac equation, in particular, the radial Dirac equation. Before going to the situation in three space dimensions, we first consider the Dirac operator D_1 with mass $m>0$ in one space dimension, defined in the space $L^2(\mathbb{R},\mathbb{C}^2)$ of $\mathbb{C}^2$-valued square-integrable functions in $\mathbb{R}$ by

$$D_1=\alpha\frac{1}{i}\frac{\partial}{\partial x}+m\beta, \tag{1}$$

for two (2×2) Hermitian matrices α and β satisfying $\alpha^2=\beta^2=1$ and $\alpha\beta+\beta\alpha=0$. Here and in the following, we are using a coordinate system where the speed of light c and Planck's constant

a)Electronic mail: ichinose@kappa.s.kanazawa-u.ac.jp
b)Electronic mail: b.jefferies@unsw.edu.au

$\hbar$ are equal to one. In Ichinose (1982, 1984) and Ichinose and Tamura (1984, 1987, and 1988), T. Ichinose and H. Tamura showed that the group of operators $e^{-iD_1 t}$, $t \in \mathbb{R}$, acting on $L^2(\mathbb{R},\mathbb{C}^2)$, is similar to a strongly continuous group $S(t)$ of operators for which the bound

$$\|S(t)f\|_\infty \leqslant e^{m|t|}\|f\|_\infty \tag{2}$$

holds for all $t \in \mathbb{R}$ and all bounded continuous functions $f = {}^t(f_1, f_2)$ in $L^2(\mathbb{R},\mathbb{C}^2)$, where $\|f\|_\infty = \max\{\|f_1\|_\infty, \|f_2\|_\infty\}$ stands for the norm of f as an element of the space $L^\infty(\mathbb{R},\mathbb{C}^2)$ of $\mathbb{C}^2$-valued bounded functions in $\mathbb{R}$, endowed with $\mathscr{C}^\infty$-norm on $\mathbb{C}^2$. As in the case of a Markov process above, the bound (2) is sufficient to ensure that there exist matrix-valued path-space measures $\nu_{x,t}$ such that

$$\int_\Omega \nu_{x,t}(d\omega) f(\omega(0)) = (e^{-itD_1} f)(x), \quad \text{almost all } x \in \mathbb{R}, \ t \geqslant 0, \tag{3}$$

for every bounded function f in $L^2(\mathbb{R},\mathbb{C}^2)$. It should be mentioned here that the integral kernel of e^{-itD_1} is a matrix-valued distribution of order zero or a matrix-valued *measure* in $\mathbb{R}\times\mathbb{R}$. For each $x \in \mathbb{R}$ and $t \geqslant 0$, the measure $\nu_{x,t}$, defined on the cylindrical σ-algebra of the space $\Omega_{x,t}$ of all paths $\omega:[0,t] \to \mathbb{R}$ with $\omega(t) = x$, takes values in the space $M_2(\mathbb{C})$ of (2×2) complex matrices. Further analysis in Ichinose and Tamura (1988) or Ichinose and Tamura (1987) shows that $\nu_{x,t}$ is a σ-additive Borel measure concentrated on the space $\Omega'_{x,t}$ of all Lipschitz-continuous paths $\omega:[0,t] \to \mathbb{R}$ with $\omega(t) = x$ and with velocity ± 1 and finitely many changes of direction in each finite time interval.

Initial-value problems for which the associated evolution $S(t)$, $t \geqslant 0$, satisfies a bound of the form (2) are comparatively rare. Together with the wave equation in one space dimension, the examples mentioned above are the most studied in the literature.

This article is concerned with $\mathbb{C}^2$-valued solutions $u(r,t)$ of the initial-value problem for the *radial Dirac equation*:

$$\frac{\partial u}{\partial t}(r,t) = -i(\tau_k u)(r,t), \quad u(r,0) = u_0(r), \tag{4}$$

for all $r \in \mathbb{R}_+ := (0,\infty)$ and $t \in \mathbb{R}$. The differential operator τ_k is defined for $k = \pm 1, \pm 2, \ldots$ by

$$\tau_k : u \mapsto \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} u_1'(r) \\ u_2'(r) \end{pmatrix} + \begin{pmatrix} m & -k/r \\ -k/r & -m \end{pmatrix} \begin{pmatrix} u_1(r) \\ u_2(r) \end{pmatrix}, \tag{5}$$

for suitably smooth $u \in L^2(\mathbb{R}_+,\mathbb{C}^2)$. The nonzero integer k represents an eigenvalue of the "spin-orbit operator" (see Thaller 1992, pp. 125–130). The radial Dirac operator (5) arises from the spin-angular momentum decomposition of the free Dirac operator in three space dimensions, defined as follows.

The *Dirac operator* D_3 in three space dimensions is defined in the space $L^2(\mathbb{R}^3,\mathbb{C}^4)$ of $\mathbb{C}^4$-valued square-integrable functions in $\mathbb{R}^3$ by means of the differential expression

$$D_3 = \sum_{j=1}^{3} \alpha_j \mathbf{p}_j + \alpha_4 m,$$

where $m > 0$ is the mass of the particle as in (1),

$$\mathbf{p}_j = \frac{1}{i}\frac{\partial}{\partial x_j}, \quad \alpha_j = \begin{pmatrix} 0 & \sigma_j \\ \sigma_j & 0 \end{pmatrix}, \quad \text{for } j = 1,2,3,$$

with the *Pauli matrices*

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}$$

and

$$\alpha_4=\begin{pmatrix}\sigma_0 & 0\\ 0 & -\sigma_0\end{pmatrix},\quad \text{with}\ \ \sigma_0=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}.$$

Here we have taken the standard representation of the Dirac operator [Thaller, 1992), Eq. (1.213), p. 36]. Then via the spin-angular momentum decomposition, the operator D_3 is equal to the direct sum of operators unitarily equivalent to the operators (5) with $k=\pm 1,\pm 2,\ldots$.

The fact that τ_k defines a self-adjoint operator acting in $L^2(\mathbb{R}_+,\mathbb{C}^2)$ follows from the spin-angular momentum decomposition of D_3 (Thaller, 1992, Theorem 4.14), hence, $e^{-it\tau_k}$, $t\in\mathbb{R}$, is a strongly continuous unitary group of operators acting on $L^2(\mathbb{R}_+,\mathbb{C}^2)$.

The initial-value problem (4) is a worthy object of study, because on adding a Coulomb potential $\sigma_0 e/r$, $e\in\mathbb{R}$, to τ_1, we get an essentially self-adjoint operator if and only if $|e|\leqslant\sqrt{3}/2$ (Weidmann, 1987, Theorem 6.9). For $\sqrt{3}/2<|e|<1$, there is a distinguished self-adjoint extension. In this respect, the operator $\tau_1+\sigma_0 e/r$ has properties similar to the Laplacian plus an attractive potential proportional to $1/r^2$ treated by a Feynman path integral in Nelson (1964). For larger values of $|e|$ close to one, the boundary conditions near $r=0$ need to take into account the effects of the nuclear dimensions and particle pair-production in quantum field theory (Popov, 1971).

The initial-value problem (4) has a superficial appeal from the point of view of analysis by path integrals because of the following line of reasoning. The operator

$$i\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\frac{\partial}{\partial x}$$

is unitarily similar to the generator

$$\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\frac{\partial}{\partial x} \tag{6}$$

of the direct sum of groups of translations acting on $L^\infty(\mathbb{R},\mathbb{C}^2)$. This is obviously a group of isometries of $L^\infty(\mathbb{R},\mathbb{C}^2)$.

For each $t\in\mathbb{R}$ and $r>0$, the matrix

$$\exp\left[-it\begin{pmatrix}m & -k/r\\ -k/r & -m\end{pmatrix}\right] \tag{7}$$

is unitary. The operator of multiplication by a function taking its values in the unitary (2×2) matrices is obviously an isometry of $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$.

Thus, one might hope to apply the Trotter product formula

$$e^{-it\tau_k}=\lim_{N\to\infty}\left[\exp\left(\frac{-it}{N}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\frac{\partial}{\partial r}\right)\exp\left(\frac{-it}{N}\begin{pmatrix}m & -k/r\\ -k/r & -m\end{pmatrix}\right)\right]^N$$

to show that $e^{-it\tau_k}$ is $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$-bounded and the operator norm is one. Standard arguments would then enable one to construct a σ-additive path-space measure associated with $e^{-it\tau_k}$, $t\in\mathbb{R}$. As seen in Ichinose and Tamura (1984), such a scalar measure representing $(e^{-it\tau_k}f,g)$ actually exists for states f and g with supports sufficiently separated from zero. The evidence seems to suggest that the initial-value problem (4) possesses a path-space measure.

However, the argument above is *false*. The mistake is as follows. In order that multiplication by the matrix-valued function (7) be unitary, we need to give $\mathbb{C}^2$ the usual Euclidean norm, that is, the ℓ^2-norm. But equipped with this norm, the operator

$$\exp\left[-it\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\frac{\partial}{\partial r}\right]$$

is *not* a contraction on $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$ (to make sense of this exponential, a boundary condition at $r=0$ must be added). The group generated by (6) is a continuous group of isometries on $L^\infty(\mathbb{R},\mathbb{C}^2)$ only if we endow $\mathbb{C}^2$ with the *ℓ^∞-norm*.

The conflict between the two norms for $\mathbb{C}^2$ means that the Trotter product formula cannot be used in $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$. Intuitively, we would *not* expect a path-space measure for (4) to exist, otherwise path-integrals would select a distinguished self-adjoint extension for *every* perturbation by a Coulomb potential $\sigma_0 e/r$ by virtue of a type of Feynman–Kac formula, whereas we know that an essentially self-adjoint perturbed operator exists only for $|e|\leqslant\sqrt{3}/2$. The main purpose of this work is to clarify the situation: we show in Sec. IV, Corollary 1, that the operator $e^{-it\tau_1}$ is not actually bounded on $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$ for any $t\neq 0$.

It is not hard to see that $e^{-it\tau_1}$ *is* bounded on $L^p(\mathbb{R}_+,\mathbb{C}^2)$ for all $1<p<\infty$ and $t\in\mathbb{R}$. By contrast, for the Laplacian Δ in $\mathbb{R}^n$ and the Dirac operator D_3 in $\mathbb{R}^3$, for each $t\neq 0$, the operator $e^{it\Delta}$ is bounded on $L^p(\mathbb{R}^n)$ and the operator e^{-itD_3} is bounded on $L^p(\mathbb{R}^3,\mathbb{C}^4)$, only for $p=2$ (Hörmander, 1960; Brenner, 1966).

In order to obtain information about the group $e^{-it\tau_1}$, $t\in\mathbb{R}$, of operators, we need an explicit formula for the propagator, that is, the integral kernel $\mathcal{K}_t$ of the operator $e^{-it\tau_1}$ for each $t\in\mathbb{R}$. Although $e^{-it\tau_1}$ is a unitary operator acting on $L^2(\mathbb{R}_+,\mathbb{C}^2)$ for each $t\in\mathbb{R}$, its kernel $\mathcal{K}_t$ may well be a matrix-valued distribution defined on $\mathbb{R}_+\times\mathbb{R}_+$. Explicit formulas are known for the propagator of the group e^{-itD_3}, $t\in\mathbb{R}$ (Prosser, 1963; Vladimirov, 1971; Rosen, 1983; Brzeźniak, 1990). For each $t\neq 0$, this is a matrix-valued distribution of order one, from which it follows that there is no path-space measure associated with the Dirac equation in four space–time dimensions.

The main result of this article, given in Theorem 1 of Sec. IV, is an explicit formula for the propagator $\mathcal{K}_t$ associated with the radial Dirac equation. From this we deduce that there is no path-space measure associated with the radial Dirac equation like the one that exists for the Dirac equation in two space–time dimensions. More formally, we show that $e^{-it\tau_1}$ does not map $L^2(\mathbb{R}_+,\mathbb{C}^2)\cap L^\infty(\mathbb{R}_+,\mathbb{C}^2)$ into $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$ for any $t\neq 0$. Nevertheless, a path integral approach to this equation is given in Jefferies (1994, 1996a) along the mathematical lines developed in Jefferies (1996b) for integration with respect to unbounded set functions.

Although the propagator associated with D_3 is a matrix-valued distribution of order one on $\mathbb{R}^3\times\mathbb{R}^3$, it is somewhat surprising to learn that $\mathcal{K}_t$ is a matrix-valued distribution of order *zero* on $\mathbb{R}_+\times\mathbb{R}_+$. In the course of the derivation of the formula for $\mathcal{K}_t$, it is apparent that averaging over the unit sphere smooths out the kernel.

It can be verified directly that $\partial/\partial t\mathcal{K}_t(r,\rho)=-i\tau_1\mathcal{K}_t(r,\rho)$, for all $r>0$, $\rho>0$, with $\mathcal{K}_0(r,\rho)=\delta(r-\rho)\sigma_0$ from the formula (19) for the distribution $\mathcal{K}_t$ we obtain in Sec. IV, but the proof of Theorem 1 may be applied to obtain the kernel of $e^{-it\tau_k}$ for integer values of k other than one.

A key part of our derivation is the representation (14) of the kernel of e^{-itD_3} obtained in Sec. III. The representation first appears in Rosen (1983), but we give a formal proof in Proposition 2. Using this representation, we obtain a regularization of e^{-itD_3} which preserves the reducing subspaces of D_3 with respect to the "spin-orbit" operator [Thaller, 1992, Eq. (4.105), p. 125]. The regularization simplifies our computations because we can deal with functions rather than distributions.

II. PRELIMINARIES

We first briefly fix some notation and terminology concerning function spaces and distributions.

A. Function notation

Let n be a positive integer. The sesquilinear inner product of $\mathbb{C}^n$ is denoted by $(\cdot,\cdot)$, which is linear in the first component and antilinear in the second. The corresponding inner product of two $\mathbb{C}^n$-valued functions $f(x)={}^t(f_1(x),\ldots,f_n(x))$ and $g(x)={}^t(g_1(x),\ldots,g_n(x))$ in $\mathbb{R}^d$ is denoted by

$$(f,g)=\int_{\mathbb{R}^d}(f(x),g(x))dx=\int_{\mathbb{R}^d}\sum_{j=1}^{n} f_j(x)\overline{g_j(x)}dx.$$

We shall also use the bilinear inner product $\langle\cdot,\cdot\rangle$.

For an open subset U of $\mathbb{R}^d$, $C_c^\infty(U,\mathbb{C}^n)$ denotes the space of $\mathbb{C}^n$-valued C^∞-functions with compact support in U. $\mathcal{S}(\mathbb{R}^d,\mathbb{C}^n)$ is the space of $\mathbb{C}^n$-valued rapidly decreasing C^∞ functions on $\mathbb{R}^d$. For $n=1$, they are the usual function spaces $C_c^\infty(U)$ and $\mathcal{S}(\mathbb{R}^d)$. The notation $C_0(\mathbf{R}^d,\mathbf{C}^n)$ is used for the space of $\mathbf{C}^n$-valued continuous functions vanishing at infinity on $\mathbb{R}^d$. It has the supremum norm.

For two locally convex topological linear spaces X and Y, $\mathcal{L}(X,Y)$ denotes the topological linear space of all continuous linear mappings of X into Y.

Since $\mathbb{C}^{n^2}$ is identified with the space $M_n(\mathbb{C})$ of $(n\times n)$ matrices, we denote the space of all $M_n(\mathbb{C})$-valued distributions with compact support in U by $\mathcal{L}(C_c^\infty(U),M_n(\mathbb{C}))$, which is the dual space of the space $C_c^\infty(U,M_n(\mathbb{C}))$. We denote also the space of $M_n(\mathbb{C})$-valued tempered distributions on $\mathbb{R}^d$ by $\mathcal{L}(\mathcal{S}(\mathbb{R}^d),M_n(\mathbb{C}))$, which is the dual space of the space $\mathcal{S}(\mathbb{R}^d,M_n(\mathbb{C}))$. For $n=1$, they are nothing but the usual spaces $C_c^\infty(U)'$ of Schwartz distributions in U, and $\mathcal{S}(\mathbb{R}^d)'$ of tempered distributions on $\mathbb{R}^d$.

B. Kernels of bounded linear operators

Let U be an open subset of $\mathbb{R}^d$. An $M_n(\mathbb{C})$-valued distribution K defined in $U\times U$, i.e., an element in $\mathcal{L}(C_c^\infty(U\times U),M_n(\mathbb{C}))$, is called the *integral kernel* or just the *kernel*, of a bounded linear operator T of $L^2(U,\mathbb{C}^n)$ into itself, if for every $f,g\in C_c^\infty(U)$ and $j,l=1,\ldots,n$, the equality

$$(T(fe_j),\overline{g}e_l)=(K(g\otimes f)e_j,e_l)$$

holds for the standard basis vectors $e_1,\ldots,e_n$ of $\mathbb{C}^n$. Here $g\otimes f$ is the function $(x,y)\mapsto g(x)f(y)$, $x,y\in U$. Thus, if $T:L^2(U,\mathbb{C}^n)\to L^2(U,\mathbb{C}^n)$ is a bounded linear operator and the $M_n(\mathbb{C})$-valued function $(x,y)\mapsto k(x,y)$, $x,y\in U$, is measurable and locally integrable in $U\times U$, then k is the kernel of T if, for every $f\in C_c^\infty(U)$ and $j=1,\ldots,n$, we have

$$T(fe_j)(x)=\int_U [k(x,y)e_j]f(y)dy$$

for almost all $x\in U$.

It follows that if k is a matrix-valued distribution defined in $\mathbb{R}$, i.e., an element of the space $\mathcal{L}(C_c^\infty(\mathbb{R}),M_n(\mathbb{C}))$, then the operator of convolution with respect to k has the distribution $k(x-y)$ defined in $\mathbb{R}^2$ as its kernel. The identity operator acting on $L^2(U,\mathbb{C}^n)$ has the distribution $\delta(x-y)I$ as its kernel. Here I is the $(n\times n)$ identity matrix and $\delta:f\mapsto f(0)$, $f\in C_c^\infty(\mathbb{R})$, is the Dirac distribution at zero.

III. REPRESENTATION OF THE PROPAGATOR OF THE DIRAC EQUATION

The kernel of e^{-itD_3} is known from Prosser (1963), Vladimirov (1971), Rosen (1983), and Brzeźniak (1990). It is simply obtained by applying the Dirac operator to the known propagator for the Klein–Gordon equation in four space–time dimensions [for the Klein–Gordon propagator, see, for example, De Jager (1963)].

The derivation of the kernel of $e^{-it\tau_1}$ is achieved by computing the restriction of the unitary operator e^{-itD_3} to the eigenspace corresponding to the eigenvalue $k=1$ of the "spin-orbit" operator [Thaller, 1992, Eq. (4.105), p. 125]. As we see below, the calculation is not entirely straightforward and the formula for the kernel is not simple.

We first obtain a representation of the kernel of e^{-itD_3} that simplifies the task of calculating its restriction to the eigenspace of the "spin-orbit" operator by looking at the Dirac equation in two space–time dimensions. The idea originates in Rosen (1983), where a certain one-dimensional character of the motion of a Dirac particle is emphasized.

A. The 1-D Dirac equation

The first statement is a simple consequence of perturbation theory for linear operators. It is the basis of the proof that there is a path-space measure associated with the Dirac equation in two space–time dimensions (Ichinose and Tamura, 1984). Although we have formula (9) below for the kernel of e^{-itD_1}, it is not obvious that it gives the operator bounds set out in Proposition 1 below.

Proposition 1: Let $\partial/\partial\xi$ be the operator acting in $L^2(\mathbb{R},\mathbb{C}^2)$, with domain $\mathcal{D}(\partial/\partial\xi)=H^1(\mathbb{R},\mathbb{C}^2)$ consisting of all functions $f={}^t(f_1,f_2)\in L^2(\mathbb{R},\mathbb{C}^2)$, for which f_1 and f_2 are absolutely continuous and f' is square-integrable.

Then the operator $-[\sigma_3\partial/\partial\xi+im\sigma_1]:\mathcal{D}(\partial/\partial\xi)\to L^2(\mathbb{R},\mathbb{C}^2)$ is the generator of a unitary group $e^{-t(\sigma_3\partial/\partial\xi+im\sigma_1)}$, $t\in\mathbb{R}$, such that for every $1\leqslant p\leqslant\infty$,

$$\|e^{-t(\sigma_3\partial/\partial\xi+im\sigma_1)}f\|_p\leqslant e^{m|t|}\|f\|_p,\quad t\in\mathbb{R},\tag{8}$$

for all $f\in L^2(\mathbb{R},\mathbb{C}^2)\cap L^p(\mathbb{R},\mathbb{C}^2)$.

Furthermore, the operator $e^{-t(\sigma_3\partial/\partial\xi+im\sigma_1)}$ leaves (the subspace) $C_0(\mathbb{R},\mathbb{C}^2)$ in $L^\infty(\mathbb{R},\mathbb{C}^2)$ invariant for each $t\in\mathbb{R}$.

Here note that whether a bound like (8) holds for every $1\leqslant p\leqslant\infty$ amounts essentially to the same thing as whether it holds for $p=1$ or $p=\infty$. Because if it holds for $p=1$ or $p=\infty$, by duality it also holds for the other p, and then for every $1\leqslant p\leqslant\infty$ by interpolation.

Proof of Proposition 1: The operator $\partial/\partial\xi$ is the infinitesimal generator of the group of translations on $L^2(\mathbb{R})$, so $\sigma_3\partial/\partial\xi$ acting in $L^2(\mathbb{R},\mathbb{C}^2)$ is the generator of that continuous group $T(t)$ of isometries on $L^2(\mathbb{R},\mathbb{C}^2)$ which maps the function $\xi\mapsto{}^t(f_1(\xi),f_2(\xi))$, $\xi\in\mathbb{R}$, to the function $\xi\mapsto{}^t(f_1(\xi+t),f_2(\xi-t))$, $\xi\in\mathbb{R}$.

Then $T(t)$ also defines a group of isometries $T_p(t)$ of $L^p(\mathbb{R},\mathbb{C}^2)$, for $1\leqslant p\leqslant\infty$. Clearly $T_p(t)$ is continuous for $1\leqslant p<\infty$. The group of isometries $T_\infty(t)$ leaves the space $C_0(\mathbb{R},\mathbb{C}^2)$ invariant, and defines a continuous group of isometries there.

Because $-im\sigma_1$ is a bounded perturbation of the operator $-\sigma_3\partial/\partial\xi$ acting in $L^p(\mathbb{R},\mathbb{C}^2)$ (or $C_0(\mathbb{R},\mathbb{C}^2)$), it follows from Reed and Simon (1975, Sec. X.2) that $-\sigma_3\partial/\partial\xi-im\sigma_1$ is the generator of a group $S(t)=e^{-t(\sigma_3\partial/\partial\xi+im\sigma_1)}$, $t\in\mathbb{R}$, of operators satisfying $\|S(t)\|\leqslant e^{m|t|}$, for all $t\in\mathbb{R}$. Here the same symbol $S(t)$ is used for the group of operators so defined on each space $L^p(\mathbb{R},\mathbb{C}^2)$, $1\leqslant p<\infty$, and $C_0(\mathbb{R},\mathbb{C}^2)$, and $\|\cdot\|$ denotes the operator norm of $\mathcal{L}(L^p(\mathbb{R},\mathbb{C}^2))$, for $1\leqslant p<\infty$, or of $\mathcal{L}(C_0(\mathbb{R},\mathbb{C}^2))$. □

In the following, we consider the case for $t>0$. Similar considerations apply to the case $t<0$. The integral kernel of the operator $e^{-t(\sigma_3\partial/\partial\xi+im\sigma_1)}$ is given [Ichinose and Tamura, 1984, (3.2)] by convolution with respect to the distribution

$$H(\xi,t)=\frac{1}{2}\left(\sigma_0\frac{\partial}{\partial t}-\sigma_3\frac{\partial}{\partial\xi}-im\sigma_1\right)J_0(m(t^2-\xi^2)^{1/2})\,\theta(t-|\xi|).$$

Here $J_0(t)$ is the Bessel function of order zero and θ is the Heaviside function—the characteristic function of the interval $[0,\infty)$. The distributional notation means that if $\phi:\mathbb{R}\to\mathbb{C}$ is a rapidly decreasing function, then $H(\cdot,t)(\phi)\in M_2(\mathbb{C})$ is the matrix

$$H(\cdot,t)(\phi)=\frac{1}{2}\int_{-t}^{t}\left[\left(\sigma_0\frac{\partial}{\partial t}-\sigma_3\frac{\partial}{\partial\xi}-im\sigma_1\right)J_0(m(t^2-\xi^2)^{1/2})\right]\phi(\xi)d\xi$$
$$+\frac{1}{2}(\phi(t)+\phi(-t))\sigma_0+\frac{1}{2}(\phi(t)-\phi(-t))\sigma_3. \tag{9}$$

Now the derivatives after the integral sign are interpreted in the pointwise sense. Then for each $t>0$, the convolution $H(\cdot,t)*\psi$ belongs to $C_0(\mathbb{R},\mathbb{C}^2)$ for every ψ belonging to the space $\mathcal{S}(\mathbb{R},\mathbb{C}^2)$ of rapidly decreasing $\mathbb{C}^2$-valued functions, and

$$[H(\cdot,t)*\psi](\xi)=[e^{-t(\sigma_3\partial/\partial\xi+im\sigma_1)}\psi](\xi),\quad \xi\in\mathbb{R}. \tag{10}$$

Since $dJ_0(t)/dt=-J_1(t)$ is bounded, it is clear from the representation (9) that $H(\cdot,t)$ is a matrix-valued distribution of order zero, that is, a matrix-valued measure, so we shall sometimes write $\int_{\mathbb{R}}H(d\xi,t)\phi(\xi)$ for (9) and $\int_{\mathbb{R}}H(d\eta,t)\psi(\xi-\eta)$ for (10). It follows from the representation (9) that for each $\xi\in\mathbb{R}$, the matrix-valued measure $H(d\xi,t)$ is supported by the interval $[-t,t]$.

B. The kernel of e^{-itD_3}

A bound like (8) with $p=\infty$ in Proposition 1 does not hold for the 3-D Dirac operator D_3, as noted in Ichinose (1984), because the initial-value problem for the hyperbolic system of the first order in $d+1$ space–time dimensions is L^∞ well-posed if and only if $d=1$ (cf. Brenner, 1966; Zastawniak, 1989; Brzeźniak, 1990). It is simply because the kernel of e^{-itD_3} is a distribution of order *one*, as is easily seen from the explicit representation obtained in Proposition 2 below.

It is convenient to take an equivalent representation of the Dirac operator D_3, so that

$$\alpha_j'=\begin{pmatrix}\sigma_j & 0\\ 0 & -\sigma_j\end{pmatrix},\quad \text{for } j=1,2,3,\quad \alpha_4'=\begin{pmatrix}0 & \sigma_0\\ \sigma_0 & 0\end{pmatrix}, \tag{11}$$

obtained from the Dirac matrices α_j by the similarity transformation $\alpha_j'=Q\alpha_jQ$, $j=1,2,3,4$, with

$$Q=2^{-1/2}\begin{pmatrix}\sigma_0 & \sigma_0\\ \sigma_0 & -\sigma_0\end{pmatrix}. \tag{12}$$

Let $\{e_1,e_2\}$ be the standard basis of $\mathbb{C}^2$. The tensor product $A\otimes B$ of two 2×2 matrices A and B is the 4×4 matrix of the associated linear transformation with respect to the basis $\mathcal{E}=\{e_1\otimes e_1,e_2\otimes e_1,e_1\otimes e_2,e_2\otimes e_2\}$ of $\mathbb{C}^4$. Linear transformations are identified with matrices with respect to these fixed bases. Then $\alpha_j'=\sigma_j\otimes\sigma_3$ for $j=1,2,3$ and $\alpha_4'=\sigma_0\otimes\sigma_1$ and, in this representation, the Dirac operator becomes

$$D_3=\sum_{j=1}^{3}(\sigma_j\otimes\sigma_3)\mathbf{p}_j+m\sigma_0\otimes\sigma_1. \tag{13}$$

The following result appears in Rosen (1983) in a somewhat compressed form. In the remainder of this section, we translate into the present notation and give a proof of this statement. We first give some additional notation.

Let μ_r be the uniform surface probability on the sphere S_r of radius $r>0$ in $\mathbb{R}^3$. For $r>0$, the μ_r-integral of a function f over S_r is denoted by $\mu_r(f)$. For a smooth function ϕ on $\mathbb{R}^3$, we have $\partial/\partial r\,\phi(x)=|x|^{-1}\langle x,\nabla\rangle\phi(x)$, $r=|x|\neq0$. For $r=0$, we understand $\mu_0=\delta$, the delta measure at $x=0$. For any $M_2(\mathbb{C})$-valued Borel measure λ on $\mathbb{R}$ and $M\in M_2(\mathbb{C})$, the set function $M\otimes\lambda:A\mapsto M\otimes[\lambda(A)]$, with A a Borel set in $\mathbb{R}$, is an $M_4(\mathbb{C})$-valued measure.

Proposition 2: Let D_3 be Dirac operator in the representation (13). *Then for each $t\in\mathbb{R}$, the operator e^{-itD_3} is convolution with respect to the matrix-valued distribution $K_t\in\mathcal{L}(\mathcal{S}(\mathbb{R}^3),M_4(\mathbb{C}))$ of order one, given for each test function $\phi\in\mathcal{S}(\mathbb{R}^3)$, by*

$$K_t(\phi)=\int_{-t}^{t}[\mu_{|\xi|}(\phi)+|\xi|\mu_{|\xi|}(\partial/\partial r\,\phi)][\sigma_0\otimes H(d\xi,t)]+\int_{-t}^{t}\xi\mu_{|\xi|}(\langle\sigma,\nabla\phi\rangle)\otimes H(d\xi,t), \tag{14}$$

or, as an $M_4(\mathbb{C})$*-valued distribution in* $\mathbb{R}^3$*, by*

$$K_t(x)=-\frac{1}{4\pi r}\sigma_0\otimes\left(\frac{\partial H(r,t)}{\partial r}+\frac{\partial H(-r,t)}{\partial r}\right)-\frac{1}{4\pi}\langle\sigma,\nabla\rangle\otimes\left(\frac{H(r,t)}{r}-\frac{H(-r,t)}{r}\right),\quad \text{for } r=|x|. \tag{15}$$

The representation (14) is proved by applying the Fourier transform $\mathcal{F}:L^2(\mathbb{R}^3)\to L^2(\mathbb{R}^3)$, defined for every $f\in L^2(\mathbb{R}^3)\cap L^1(\mathbb{R}^3)$ by

$$\mathcal{F}f(p)=\int_{\mathbb{R}^3}e^{-i\langle x,p\rangle}f(x)dx,\quad \text{for all } p\in\mathbb{R}^3.$$

Then $\mathcal{F}^{-1}f(x)=(2\pi)^{-3}\int_{\mathbb{R}^3}e^{i\langle x,p\rangle}f(p)\,dp$ defines the inverse operator. The same symbols are used for the operators defined on $L^2(\mathbb{R}^3,\mathbb{C}^n)$ by taking tensor products with the identity map on $\mathbb{C}^n$. Sometimes $\mathcal{F}f$ is written as $\hat{f}$ and $\mathcal{F}^{-1}f$ as $\check{f}$.

If $\Phi:\mathbb{R}^3\to M_n(\mathbb{C})$ is a matrix-valued Borel measurable function, then the operator of *multiplication* by Φ sends the element $f\in L^2(\mathbb{R}^3,\mathbb{C}^n)$ to $x\mapsto\Phi(x)f(x)$, $x\in\mathbb{R}^3$. This is a bounded linear operator on $L^2(\mathbb{R}^3,\mathbb{C}^n)$ if and only if Φ is essentially bounded.

The integral $\int_{\mathbb{R}^3}\Phi(x)\otimes\mu(dx)\in M_4(\mathbb{C})$ of a matrix-valued function $\Phi:\mathbb{R}^3\to M_2(\mathbb{C})$ with respect to an $M_2(\mathbb{C})$-valued Borel measure μ on $\mathbb{R}^3$ is taken componentwise with respect to the basis $\mathcal{E}$ of $\mathbb{C}^4$.

Lemma 1: The operator $\mathcal{F}e^{-itD_3}\mathcal{F}^{-1}$ *acting on* $L^2(\mathbb{R}^3,\mathbb{C}^4)$ *is the operator of multiplication by the matrix-valued function* $p\mapsto\int_{\mathbb{R}}e^{-i\langle\sigma,p\rangle\xi}\otimes H(d\xi,t)$, $p\in\mathbb{R}^3$, *where* $\sigma=(\sigma_1,\sigma_2,\sigma_3)$ *and* $\langle\sigma,p\rangle=\Sigma_{j=1}^{3}\sigma_j p_j$.

Proof: The integral converges because $H(d\xi,t)$ is a matrix-valued Borel measure on $\mathbb{R}$ and in the matrix norm $\|e^{-i\langle\sigma,p\rangle\xi}\|=1$ for all $\xi\in\mathbb{R}$ and $p\in\mathbb{R}^3$. By the functional calculus for the self-adjoint operator D_3, the operator $\mathcal{F}e^{-itD_3}\mathcal{F}^{-1}$ acting on $L^2(\mathbb{R}^3,\mathbb{C}^4)$ is the operator of multiplication by the matrix-valued function $p\mapsto e^{-it(\langle\sigma,p\rangle\otimes\sigma_3+m\sigma_0\otimes\sigma_1)}$, so it suffices to prove that

$$e^{-it(\langle\sigma,p\rangle\otimes\sigma_3+m\sigma_0\otimes\sigma_1)}=\int_{\mathbb{R}}e^{-i\langle\sigma,p\rangle\xi}\otimes H(d\xi,t). \tag{16}$$

To do so, rewrite the $M_4(\mathbb{C})$-valued function on the right-hand side by a formal integral with respect to $d\xi$:

$$w(p,t):=\int_{\mathbb{R}}e^{-i\langle\sigma,p\rangle\xi}\otimes H(\xi,t)d\xi,$$

each of whose (j,k) entries with $j,k=1,2$ makes sense as the bilinear inner product between a C^∞ function and a distribution with compact support in $\xi\in\mathbb{R}$. Then we have by (10)

$$\begin{aligned}\frac{\partial w(p,t)}{\partial t}&=-\int_{\mathbb{R}}e^{-i\langle\sigma,p\rangle\xi}\otimes\left(\sigma_3\frac{\partial}{\partial\xi}+im\sigma_1\right)H(\xi,t)d\xi\\&=-i\int_{\mathbb{R}}[\langle\sigma,p\rangle\otimes\sigma_3+m\sigma_0\otimes\sigma_1](e^{-i\langle\sigma,p\rangle\xi}\otimes H(\xi,t))d\xi\\&=-i[\langle\sigma,p\rangle\otimes\sigma_3+m\sigma_0\otimes\sigma_1]w(p,t).\end{aligned}$$

It follows that $w(p,t)$ is nothing but the left-hand side of Eq. (16). □

Lemma 2: The inverse Fourier transform of $p \mapsto e^{-i\langle \sigma,p\rangle \xi}$ *in the sense of distributions is* $\mu_{|\xi|} - \langle \nabla, x\rangle \mu_{|\xi|} - \xi\langle \sigma, \nabla\rangle \mu_{|\xi|}$ *for all* $\xi \in \mathbb{R}$.

Proof: The Fourier transform $p \mapsto \hat{\mu}_r(p)$, $p \in \mathbb{R}^3$, of μ_r is the function $p \mapsto \sin(r|p|)/r|p|$ [Vladimirov, 1971, p. 135, (38)] as may be seen by calculating $\hat{\mu}_r(p) = \int_{\mathbb{R}^3} e^{-i\langle x,p\rangle} \mu_r(dx)$ directly.

Suppose that $\xi \neq 0$. It follows from the commutation relations of the Pauli matrices $\sigma = (\sigma_1, \sigma_2, \sigma_3)$ that $e^{-i\langle \sigma,p\rangle \xi} = \cos(|\xi||p|) - i\langle \sigma, p\rangle \xi \sin(|\xi||p|)/|\xi||p|$. The operation of multiplication of the Fourier transform $\hat{T}(p)$ of a distribution T by ip corresponds to taking the gradient ∇T of T, so $(i\langle \sigma, p\rangle \xi \sin(|\xi|\,|p|)/|\xi|\,|p|) = \xi\langle \sigma, \nabla\rangle \mu_{|\xi|}$.

The term $\cos(|\xi|\,|p|)$ can be expressed as

$$\cos(|\xi||p|) = \left[\frac{\partial}{\partial r} r \frac{\sin(|\xi| r)}{|\xi| r}\right]_{r=|p|} = \frac{\sin(|\xi||p|)}{|\xi||p|} + \langle p, \nabla\rangle \frac{\sin(|\xi||p|)}{|\xi||p|}.$$

The operation of forming the distribution $(1/i)\nabla \hat{T}$ from the Fourier transform $\hat{T}$ of a distribution T corresponds to multiplying the distribution $T(x)$ by $-x$, so taking the inverse Fourier transform gives $\cos(|\xi|\,|p|)^{\vee} = \mu_{|\xi|} - \langle \nabla, x\rangle \mu_{|\xi|}$ and we obtain the stated formula. In the case that $\xi = 0$, we have $-[\langle \nabla, x\rangle \mu_0](\phi) = \delta(r\partial/\partial r \phi) = 0$ for all $\phi \in \mathcal{S}(\mathbb{R}^3)$ and the formula still holds. □

Proof of Proposition 2: Let $t \in \mathbb{R}$. According to Lemma 1 the operator e^{-itD_3} corresponds to convolution with respect to the inverse Fourier transform $K_t \in \mathcal{L}(\mathcal{S}(\mathbb{R}^3), M_4(\mathbb{C}))$ of $p \mapsto \int_{\mathbb{R}} e^{-i\langle \sigma,p\rangle \xi} \otimes H(d\xi, t)$, $p \in \mathbb{R}^3$. The distribution K_t is evaluated as follows.

The map $\Phi: \xi \mapsto e^{-i\langle \sigma, \cdot\rangle \xi}$, $\xi \in \mathbb{R}$, may be viewed as a function taking its values in the space $\mathcal{L}(\mathcal{S}(\mathbb{R}^3), M_2(\mathbb{C}))$ of matrix-valued tempered distributions. An application of (the vector-valued) Fubini's theorem shows that for each $\phi \in \mathcal{S}(\mathbb{R}^3)$

$$K_t(\phi) = \int_{\mathbb{R}^3} \check{\phi}(p) \left[\int_{\mathbb{R}} e^{-i\langle \sigma,p\rangle \xi} \otimes H(d\xi, t)\right] dp = \int_{\mathbb{R}} [\Phi(\xi)^{\vee}(\phi)] \otimes H(d\xi, t).$$

By Lemma 2, $\Phi(\xi)^{\vee} = \mu_{|\xi|} - \langle \nabla, x\rangle \mu_{|\xi|} - \xi\langle \sigma, \nabla\rangle \mu_{|\xi|}$ for every $\xi \in \mathbb{R}$.

If $\phi \in \mathcal{S}(\mathbb{R}^3)$ is a test function, then

$$K_t(\phi) = \int_{\mathbb{R}} [\mu_{|\xi|}(\phi) + |\xi| \mu_{|\xi|}(\partial/\partial r \phi)] \sigma_0 \otimes H(d\xi, t) + \int_{\mathbb{R}} \xi \mu_{|\xi|}(\langle \sigma, \nabla\rangle \phi) \otimes H(d\xi, t),$$

so that Eq. (14) holds.

We now verify the representation (15) of the distribution K_t. Let $\phi \in \mathcal{S}(\mathbb{R}^3)$. In terms of the uniform probability measure μ_r on the sphere S_r with radius $r > 0$, we have

$$
\begin{aligned}
K_t(\phi) &= \int_{\mathbb{R}}\int_{S_{|\xi|}} \sigma_0 \otimes H(\xi,t)\,\phi(x)\,d\mu_{|\xi|}(x)\,d\xi + \int_{\mathbb{R}}\int_{S_{|\xi|}} |\xi|\sigma_0 \otimes H(\xi,t)\,\frac{\partial \phi}{\partial r}(x)\,d\mu_{|\xi|}(x)\,d\xi \\
&\quad + \int_{\mathbb{R}} \xi \int_{S_{|\xi|}} [(\langle \sigma,\nabla\rangle \phi)(x) \otimes H(\xi,t)]\,d\mu_{|\xi|}(x)\,d\xi \\
&= \int_0^\infty \int_{S_1} \sigma_0 \otimes [H(r,t)+H(-r,t)] \left[\frac{\partial}{\partial r} r\phi(r\omega)\right] d\mu_1(\omega)\,dr \\
&\quad + \int_0^\infty r \int_{S_1} [\langle \sigma,\nabla\rangle \phi](r\omega) \otimes [H(r,t)-H(-r,t)]\,d\mu_1(\omega)\,dr \\
&= -\int_{S_1}\int_0^\infty \sigma_0 \otimes \left[\frac{\partial H(r,t)}{\partial r} + \frac{\partial H(-r,t)}{\partial r}\right] \phi(r\omega)\,r\,dr\,d\mu_1(\omega) \\
&\quad - \int_0^\infty \int_{S_1} \phi(r\omega)(\langle \sigma,\nabla\rangle \otimes [r^{-1}H(r,t) - r^{-1}H(-r,t)])\,r^2\,d\mu_1(\omega)\,dr,
\end{aligned}
$$

using the change of variables $r=|x|$, $\omega = x/r$ for $x \in \mathbb{R}^3$ and Fubini's theorem. Here note that $d\mu_1(\omega) = (1/4\pi)\,d\omega$, with $d\omega$ the surface measure on S_1. □

IV. THE PROPAGATOR OF THE RADIAL DIRAC OPERATOR

In this section, we present the calculation of the kernel of the group generated by (the closure of) the operator $i\tau_1$ defined by (5). The characteristic function of the interval $[0,\infty)$ is denoted by θ. The open interval $(0,\infty)$ is written as $\mathbb{R}_+$.

The function $D(\xi,t) = \frac{1}{2} J_0(m\sqrt{t^2-\xi^2})\,\theta(t^2-\xi^2)$, $\xi \in \mathbb{R}$, $t \in \mathbb{R}$, is the solution, in the sense of distributions, of the initial-value problem

$$
\frac{\partial^2 g}{\partial t^2}(\xi,t) - \frac{\partial^2 g}{\partial \xi^2}(\xi,t) + m^2 g(\xi,t) = 0, \quad g(\xi,0) = 0, \quad \frac{\partial g}{\partial t}(\xi,0) = \delta(\xi), \tag{17}
$$

for the one-dimensional Klein–Gordon equation (Vladimirov, 1971).

For each $t \in \mathbb{R}$, let

$$
\begin{aligned}
E(\xi,t) &= \left(\frac{\partial}{\partial t} + im\right) D(\xi,t), \\
\overline{E}(\xi,t) &= \left(\frac{\partial}{\partial t} - im\right) D(\xi,t), \\
F(\xi,t) &= \frac{\partial D}{\partial \xi}(\xi,t)
\end{aligned} \tag{18}
$$

in the sense of distributions belonging to $C_c^\infty(\mathbb{R})'$. These distributions are of order zero and involve unit point masses at $\pm t$. Note that as $D(\cdot,t)$ is an even function, so are $E(\cdot,t)$ and $\overline{E}(\cdot,t)$, while $F(\cdot,t)$ is an odd function.

The following representation for the integral kernel $\mathcal{K}_t$ of $e^{-it\tau_1}$ holds.

Theorem 1: *For each $t \in \mathbb{R}\setminus\{0\}$, $\mathcal{K}_t$ is an $M_2(\mathbb{C})$-valued distribution defined in $\mathbb{R}_+ \times \mathbb{R}_+$, i.e., an element in $\mathcal{L}(C_c^\infty(\mathbb{R}_+ \times \mathbb{R}_+), M_2(\mathbb{C}))$ of order zero such that for all $f,g \in C_c^\infty(\mathbb{R}_+)$, the equality $\langle e^{-it\tau_1}(fe_j), \overline{g}e_k\rangle = \langle \mathcal{K}_t(g \otimes f)e_j, e_k\rangle$ holds for $j,k=1,2$ with respect to the standard basis vectors e_1, e_2 of $\mathbb{C}^2$.*

The distribution $e^{-it\tau_1}(r,\rho) := \mathcal{K}_t(r,\rho)$ is given by the matrix

$$\begin{pmatrix} \overline{E}(r-\rho,t)-\overline{E}(r+\rho,t) & iW_{12}(r,\rho;t) \\ -iW_{21}(r,\rho;t) & E(r-\rho,t)+E(r+\rho,t)-W_{22}(r,\rho;t) \end{pmatrix} \tag{19}$$

of distributions of order zero belonging to $C_c^\infty(\mathbb{R}_+\times\mathbb{R}_+)'$, *where*

$$W_{12}(r,\rho;t)=\left[F(r-\rho,t)+F(r+\rho,t)+\frac{1}{\rho}(D(r-\rho,t)-D(r+\rho,t))\right],$$

$$W_{21}(r,\rho;t)=\left[F(r-\rho,t)-F(r+\rho,t)-\frac{1}{r}(D(r-\rho,t)-D(r+\rho,t))\right],$$

$$W_{22}(r,\rho;t)=(r\rho)^{-1}\left(\frac{\partial}{\partial t}+im\right)\int_{|r-\rho|}^{r+\rho}D(\xi,t)\xi d\xi.$$

The differentiation in the t-variable is interpreted in the sense of distributions.

A. Regularization

Let $\xi\mapsto v(\xi)$ be a non-negative smooth even function in $\mathbb{R}$, with support in the interval $[-1,1]$ and with the property that $\int_{\mathbb{R}}v(\xi)d\xi=1$. Set $v(\xi)=\varepsilon^{-1}v(\xi/\varepsilon)$ for $\varepsilon>0$. Then the function $D_\varepsilon(\cdot,t)=v_\varepsilon^{*}D(\cdot,t)$ is the solution of the Klein-Gordon equation (17) but with the initial conditions $g(\xi,0)=0$ and $\partial g/\partial t(\xi,0)=v_\varepsilon(\xi)$, $\xi\in\mathbb{R}$. The function $(\xi,t)\mapsto D_\varepsilon(\xi,t)$, $\xi\in\mathbb{R}$, $t>0$, is smooth in ξ and t and for each $t>0$, the function $D_\varepsilon(\cdot,t)$ has support in the interval $[-(t+\varepsilon),t+\varepsilon]$.

Then, as $\varepsilon\to 0+$, the smooth matrix-valued function H_ε defined by

$$H_\varepsilon(\xi,t)=\left(\sigma_0\frac{\partial}{\partial t}-\sigma_3\frac{\partial}{\partial\xi}-im\sigma_1\right)D_\varepsilon(\xi,t),\quad \xi\in\mathbb{R},\ \ t\geqslant 0, \tag{20}$$

converges in the space $\mathcal{L}(\mathcal{S}(\mathbb{R}),M_2(\mathbb{C}))$ of matrix-valued distributions to the distribution $H(\xi,t)$ defined by formula (9). Furthermore, because $H(\xi,t)$ is actually a distribution of order zero with compact support, as $\varepsilon\to 0+$, the matrix-valued measure $H_\varepsilon(\xi,t)d\xi$ converges to $H(d\xi,t)$ in the topology of the Banach space $\mathcal{L}(C_b(\mathbb{R}),M_2(\mathbb{C}))$ of all continuous linear mappings of $C_b(\mathbb{R})$ into $M_2(\mathbb{C})$. Here $C_b(\mathbb{R})$ is the Banach space of all bounded continuous functions on $\mathbb{R}$.

Let $K_t^{(\varepsilon)}\in\mathcal{L}(\mathcal{S}(\mathbb{R}^3),M_4(\mathbb{C}))$ be defined by

$$K_t^{(\varepsilon)}(\phi)=\int_{\mathbb{R}}[\mu_{|\xi|}(\phi)+|\xi|\mu_{|\xi|}(\partial/\partial r\,\phi)]\sigma_0\otimes H_\varepsilon(\xi,t)d\xi+\int_{\mathbb{R}}\xi\mu_{|\xi|}(\langle\sigma,\nabla\rangle\phi)\otimes H_\varepsilon(\xi,t)d\xi, \tag{21}$$

for every test function $\phi\in\mathcal{S}(\mathbb{R}^3)$. As a consequence of the smoothing operation of convolution with respect to v_ε, we can use integration by parts in the integral above. In order to derive the representation (19) of the kernel of $e^{-it\tau_1}$, we calculate the kernel of $K_t^{(\varepsilon)}$ and take the limit as $\varepsilon\to 0+$.

Lemma 3: As $\varepsilon\to 0+$,

(i) the distribution $K_t^{(\varepsilon)}$ *converges to* K_t *in* $\mathcal{L}(\mathcal{S}(\mathbb{R}^3),M_4(\mathbb{C}))$,

(ii) for any function $\psi\in\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$, *the convolution* $K_t^{(\varepsilon)}*\psi$ *belongs to* $\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$ *and converges to* $e^{-itD_3}\psi=K_t*\psi$ *in the topology of* $\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$, *and*

(iii) for any function $\psi\in L^2(\mathbb{R}^3,\mathbb{C}^4)$, *the convolution* $K_t^{(\varepsilon)}*\psi$ *belongs to* $L^2(\mathbb{R}^3,\mathbb{C}^4)$ *and converges to* $e^{-itD_3}\psi=K_t*\psi$ *in the topology of* $L^2(\mathbb{R}^3,\mathbb{C}^4)$. *The operator norm of* $\psi\mapsto K_t^{(\varepsilon)}*\psi$, $\psi\in L^2(\mathbb{R}^3,\mathbb{C}^4)$, *is bounded by* e^{mt}.

Proof: Given $\phi\in\mathcal{S}(\mathbb{R}^3)$, the function $\xi\mapsto[\mu_{|\xi|}(\phi)+|\xi|\mu_{|\xi|}(\partial/\partial r\phi)]$, $\xi\in\mathbb{R}$, is a bounded, continuous scalar-valued function and $\xi\mapsto\mu_{|\xi|}(\langle\sigma,\nabla\rangle\phi)$, $\xi\in\mathbb{R}$, is a bounded, continuous $M_2(\mathbb{C})$-valued function. The first assertion (i) now follows from the observation that $H_\varepsilon(\xi,t)d\xi$ converges to $H(d\xi,t)$ in $\mathcal{L}(C_b(\mathbb{R}),M_2(\mathbb{C}))$.

Observe that the distribution $K_t^{(\varepsilon)}$ is obtained from K_t by replacing H by H_ε. Let $T_\varepsilon(t)$ denote the operator of convolution with respect to $K_t^{(\varepsilon)}$ acting on $\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$. The proof of Lemma 1 shows that $\mathcal{F}T_\varepsilon(t)\mathcal{F}^{-1}$ is the operator of multiplication by the matrix-valued function $p\mapsto\int_{\mathbb{R}}e^{-i\langle\sigma,p\rangle\xi}\otimes H_\varepsilon(\xi,t)\,d\xi$.

Then for every $\psi\in\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$, the function $p\mapsto[\int_{\mathbb{R}}e^{-i\langle\sigma,p\rangle\xi}\otimes H_\varepsilon(\xi,t)\,d\xi]\psi(p)$, $p\in\mathbb{R}^3$, also belongs to $\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$ and $\mathcal{F}T_\varepsilon(t)\mathcal{F}^{-1}\psi\to\mathcal{F}e^{-itD_3}\mathcal{F}^{-1}\psi$ in $\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$ as $\varepsilon\to0+$ because $H_\varepsilon(\xi,t)d\xi$ converges to $H(d\xi,t)$ in $\mathcal{L}(C_b(\mathbb{R}),M_2(\mathbb{C}))$. Statement (ii) now follows from the observation that the Fourier transform leaves the space $\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$ invariant. A similar argument proves (iii). The bound

$$\left\|\int_{\mathbb{R}}e^{-i\langle\sigma,p\rangle\xi}\otimes H_\varepsilon(\xi,t)d\xi\right\|_{\mathcal{L}(\mathbb{C}^4)}\leqslant\|v_\varepsilon*H(\cdot,t)\|_{L^1(\mathbb{R},M_2(\mathbb{C}))}\leqslant e^{mt}$$

for each $p\in\mathbb{R}^3$ follows from (20) and Proposition 1, so $\|T_\varepsilon(t)\|\leqslant e^{mt}$. □

Let $\phi\in\mathcal{S}(\mathbb{R}^3)$. In terms of the uniform probability measure μ_r on the sphere S_r with radius $r>0$, we have

$$K_t^{(\varepsilon)}(\phi)=-\int_0^\infty r\int_{S_1}\sigma_0\otimes\left[\left.\frac{\partial H_\varepsilon(\xi,t)}{\partial\xi}\right|_{\xi=r}-\left.\frac{\partial H_\varepsilon(\xi,t)}{\partial\xi}\right|_{\xi=-r}\right]\phi(r\omega)d\mu_1(\omega)dr$$
$$+\int_0^\infty r\int_{S_1}[\langle\sigma,\nabla\rangle\phi](r\omega)\otimes[H_\varepsilon(r,t)-H_\varepsilon(-r,t)]d\mu_1(\omega)dr$$

by an appeal to Fubini's theorem and integrating by parts as in the proof of Proposition 2. On converting to Cartesian coordinates, the convolution $K_t^{(\varepsilon)}*\psi(x)$ of the distribution $K_t^{(\varepsilon)}$ with $\psi\in\mathcal{S}(\mathbb{R}^3,\mathbb{C}^4)$ is equal to

$$K_t^{(\varepsilon)}*\psi(x)=-1/4\pi\int_{\mathbb{R}^3}|x-y|^{-1}\sigma_0\otimes\left[\left.\frac{\partial H_\varepsilon(\xi,t)}{\partial\xi}\right|_{\xi=|x-y|}-\left.\frac{\partial H_\varepsilon(\xi,t)}{\partial\xi}\right|_{\xi=-|x-y|}\right]\psi(y)dy \tag{22}$$

$$-1/4\pi\int_{\mathbb{R}^3}|x-y|^{-1}\sigma_0\otimes[H_\varepsilon(|x-y|,t)-H_\varepsilon(-|x-y|,t)][\langle\sigma,\nabla\rangle\otimes\sigma_0]\psi(y)dy, \tag{23}$$

for all $x\in\mathbb{R}^3$.

B. Reducing subspaces

According to Thaller (1992, Sec. 4.6.4) [see also Bjorken and Drell (1964, p. 52ff)], for every $m_k=-|k|,\ldots,|k|-1$ and $k=\pm1,\pm2,\ldots$, the operators e^{-itD_3}, $t\in\mathbb{R}$, leave the subspace $\mathcal{H}(k,m_k)$ of $L^2(\mathbb{R}^3,\mathbb{C}^4)$ invariant. The subspace $\mathcal{H}(k,m_k)$ equals the orthogonal sum $\mathcal{H}(k,m_k)_+\oplus\mathcal{H}(k,m_k)_-$ with

$$\mathcal{H}(k,m_k)_+=\left\{\Phi^{(+)}(k,m_k)\otimes\frac{u(r)}{r}:u\in L^2(\mathbb{R}_+)\right\},$$

$$\mathcal{H}(k,m_k)_-=\left\{\Phi^{(-)}(k,m_k)\otimes\frac{u(r)}{r}:u\in L^2(\mathbb{R}_+)\right\},$$

for certain $\mathbb{C}^4$-valued eigenfunctions $\Phi^{(\pm)}(k,m_k)$ on S_1. If $u={}^t(u_1,u_2)\in L^2(\mathbb{R}_+,\mathbb{C}^2)$ are functions and c_+,c_- are complex numbers such that the element

$$\psi(x)=c_+\Phi^{(+)}(k,m_k)\otimes\frac{u_1(r)}{r}+c_-\Phi^{(-)}(k,m_k)\otimes\frac{u_2(r)}{r},\quad r=|x|,$$

of $L^2(\mathbb{R}^3,\mathbb{C}^4)$ belongs to the domain of D_3, then

$$(D_3\psi)(x)=c_+\Phi^{(+)}(k,m_k)\otimes\frac{(\tau_k u)_1(r)}{r}+c_-\Phi^{(-)}(k,m_k)\otimes\frac{(\tau_k u)_2(r)}{r},\quad r=|x|,$$

for the differential operator τ_k given by formula (5). Moreover,

$$(e^{-itD_3}\psi)(x)=c_+\Phi^{(+)}(k,m_k)\otimes\frac{(e^{-it\tau_k}u)_1(r)}{r}+c_-\Phi^{(-)}(k,m_k)\otimes\frac{(e^{-it\tau_k}u)_2(r)}{r},\quad r=|x|,$$

for all $\psi\in\mathcal{H}(k,m_k)$. The function $e^{-itD_3}\psi$ is also expressed as a convolution $K_t*\psi$.

It turns out that convolution with respect to the regularized kernel $K_t^{(\varepsilon)}$ also leaves the reducing subspaces $\mathcal{H}(k,m_k)$ invariant—the first integral (22) leaves the subspaces $\mathcal{H}(k,m_k)_+$ and $\mathcal{H}(k,m_k)_-$ invariant, and the second integral (23) maps $\mathcal{H}(k,m_k)_+$ to $\mathcal{H}(k,m_k)_-$ and $\mathcal{H}(k,m_k)_-$ to $\mathcal{H}(k,m_k)_+$. We shall only prove this for the case $k=1$ and $m_k=0$. A similar argument works for $k=-1$ with only changes in signs. We compute the distributional kernel of $e^{-it\tau_1}$ by taking the limit as $\varepsilon\to 0+$ of ${K^{(\varepsilon)}}_t*\psi$ for $\psi\in\mathcal{H}(1,0)$.

In the usual representation of the Dirac matrices,

$$\Phi^{(+)}(k,m_k)=\begin{pmatrix} i\psi(k,m_k)\\ 0\\ 0\end{pmatrix},\quad \Phi^{(-)}(k,m_k)=\begin{pmatrix} 0\\ 0\\ \psi(-k,m_k)\end{pmatrix},$$

$$\psi(k,m_k)=\frac{1}{\sqrt{2k-1}}\begin{pmatrix}\sqrt{k+m_k}\,Y(k-1,m_k)\\ \sqrt{k-m_k-1}\,Y(k-1,m_k+1)\end{pmatrix},\quad \text{for } k>0,$$

$$\psi(k,m_k)=\frac{1}{\sqrt{2|k|+1}}\begin{pmatrix}\sqrt{|k|-m_k}\,Y(|k|,m_k)\\ -\sqrt{|k|+m_k+1}\,Y(|k|,m_k+1)\end{pmatrix},\quad \text{for } k<0,$$

for the spherical harmonic functions $Y(l,j)$.

For $k=1$ and $m_1=-1,0$, we have

$$\Phi^{(+)}(1,0)=\begin{pmatrix} iY(0,0)\\ 0\\ 0\\ 0\end{pmatrix},\quad \Phi^{(-)}(1,0)=\frac{1}{\sqrt{3}}\begin{pmatrix} 0\\ 0\\ Y(1,0)\\ -\sqrt{2}Y(1,1)\end{pmatrix},$$

$$\Phi^{(+)}(1,-1)=\begin{pmatrix} 0\\ iY(0,0)\\ 0\\ 0\end{pmatrix},\quad \Phi^{(-)}(1,-1)=\frac{1}{\sqrt{3}}\begin{pmatrix} 0\\ 0\\ \sqrt{2}Y(1,-1)\\ -Y(1,0)\end{pmatrix}.$$

The spherical harmonic functions in this formula are given, with $0\leqslant\theta\leqslant\pi$ and $0\leqslant\varphi\leqslant 2\pi$, by

$$Y(0,0)=\frac{1}{\sqrt{4\pi}},\quad Y(1,0)=\frac{\sqrt{3/\pi}\cos\theta}{2},$$

$$Y(1,1)=-\frac{e^{i\varphi}\sqrt{3/2\pi}\sin\theta}{2},\quad Y(1,-1)=\frac{e^{-i\varphi}\sqrt{3/2\pi}\sin\theta}{2},$$

so that

$$\Phi^{(+)}(1,0)=\frac{i}{2\sqrt{\pi}}\begin{pmatrix}1\\0\\0\\0\end{pmatrix},\quad \Phi^{(-)}(1,0)=\frac{1}{2\sqrt{\pi}}\begin{pmatrix}0\\0\\\cos\theta\\e^{i\varphi}\sin\theta\end{pmatrix}.$$

With respect to the block-diagonal matrix representation (11) of the Dirac matrices, the new eigenvectors are $Q\Phi^{\pm}(1,0)$, $Q\Phi^{\pm}(1,-1)$, with Q in Eq. (12) used to define the α_j' in Sec. III B. For the purposes of the following computation, it is simpler to represent the tensor products $\sigma_j\otimes\sigma_3$, $j=1,2,3$ and $\sigma_0\otimes\sigma_1$ with respect to the permuted basis $\mathcal{E}'=\{e_1\otimes e_1, e_1\otimes e_2, e_2\otimes e_1, e_2\otimes e_2\}$ of $\mathbb{C}^4$ so that $\sigma_0\otimes\sigma_j=\left(\begin{smallmatrix}\sigma_j & 0\\ 0 & \sigma_j\end{smallmatrix}\right)$ for $j=1,2,3$. With respect to this new basis, the eigenvectors $Q\Phi^{\pm}(1,0)$, $Q\Phi^{\pm}(1,-1)$ are represented by the column vectors

$$\Psi^{(+)}(1,0)=\frac{i}{2\sqrt{2\pi}}\begin{pmatrix}1\\1\\0\\0\end{pmatrix},\quad \Psi^{(-)}(1,0)=\frac{1}{2\sqrt{2\pi}}\begin{pmatrix}\cos\theta\\-\cos\theta\\e^{i\varphi}\sin\theta\\-e^{i\varphi}\sin\theta\end{pmatrix},$$

$$\Psi^{(+)}(1,-1)=\frac{i}{2\sqrt{2\pi}}\begin{pmatrix}0\\0\\1\\1\end{pmatrix},\quad \Psi^{(-)}(1,-1)=\frac{1}{2\sqrt{2\pi}}\begin{pmatrix}e^{-i\varphi}\sin\theta\\-e^{-i\varphi}\sin\theta\\-\cos\theta\\\cos\theta\end{pmatrix}.$$

Proof of Theorem 1: According to Thaller (1992, Theorem 4.1.4), the matrix elements of (19) we are trying to calculate are the limiting distributions as $\varepsilon\to 0+$ corresponding to the action of the convolutions (22) and (23) on the subspaces $\mathcal{H}(1,0)_+$ and $\mathcal{H}(1,0)_-$ of $L^2(\mathbb{R}^3,\mathbb{C}^4)$. We look at each subspace separately.

1. The subspace $\mathcal{H}(1,0)_+$

On setting $\psi(y)=\Psi^{(+)}(1,0)\otimes\rho^{-1}u(\rho)$ in polar cordinates (ρ,θ,φ) in the integral (22), we have

$$\begin{aligned}&-1/4\pi\int_0^\infty\int_0^\pi\int_0^{2\pi}|r^2+\rho^2-2r\rho\cos\theta|^{-1/2}\sigma_0\otimes\left[\left.\frac{\partial H_\varepsilon(\xi,t)}{\partial\xi}\right|_{\xi=|r^2+\rho^2-2r\rho\cos\theta|^{1/2}}\right.\\&\quad\left.-\left.\frac{\partial H_\varepsilon(\xi,t)}{\partial\xi}\right|_{\xi=-|r^2+\rho^2-2r\rho\cos\theta|^{1/2}}\right]\Psi^{(+)}(1,0)u(\rho)\,\rho\sin\theta d\varphi d\theta d\rho\\&=-1/2\int_0^\infty\int_0^\pi|r^2+\rho^2-2r\rho\cos\theta|^{-1/2}\sigma_0\otimes\left[\left.\frac{\partial H_\varepsilon(\xi,t)}{\partial\xi}\right|_{\xi=|r^2+\rho^2-2r\rho\cos\theta|^{1/2}}\right.\\&\quad\left.-\left.\frac{\partial H_\varepsilon(\xi,t)}{\partial\xi}\right|_{\xi=-|r^2+\rho^2-2r\rho\cos\theta|^{1/2}}\right]\Psi^{(+)}(1,0)u(\rho)\rho\sin\theta d\theta d\rho.\end{aligned}$$

Let $\xi=(r^2+\rho^2-2r\rho\cos\theta)^{1/2}$. Then $\xi=r+\rho$ when $\theta=\pi$ and $\xi=|r-\rho|$ when $\theta=0$. The integral (22) becomes

$$-\frac{1}{2r}\int_0^\infty\left[\int_{|r-\rho|}^{r+\rho}\sigma_0\otimes\left(\left(\frac{\partial H_\varepsilon}{\partial\xi}\right)(\xi,t)-\left(\frac{\partial H_\varepsilon}{\partial\xi}\right)(-\xi,t)\right)d\xi\right]\Psi^{(+)}(1,0)u(\rho)d\rho$$

$$=-\frac{1}{2r}\int_0^\infty\sigma_0\otimes[H_\varepsilon(r+\rho,t)-H_\varepsilon(|r-\rho|,t)+H_\varepsilon(-(r+\rho),t)$$

$$-H_\varepsilon(-|r-\rho|,t)]\Psi^{(+)}(1,0)u(\rho)d\rho.$$

Now $D(\cdot,t)$ is an even function and we chose v_ε to be even, so $D_\varepsilon(\cdot,t)$ is also an even function. In the expression (20) for H_ε, the components of $(\sigma_0\partial/\partial t-im\sigma_1)D_\varepsilon(\xi,t)$ are even functions of ξ and the components of $\sigma_3\partial D_\varepsilon(\xi,t)/\partial\xi$ are odd functions of ξ. Furthermore, in the chosen basis, the application of either of the matrices $\sigma_0\otimes\sigma_0$ and $\sigma_0\otimes\sigma_1$ does not change the vector $\Psi^{(+)}(1,0)$.

On setting $\overline{E_\varepsilon}(\xi,t)=(\partial/\partial t-im)D_\varepsilon(\xi,t)$ for $\xi\in\mathbb{R}$ and $t>0$, the integral (22) is therefore equal to

$$-\frac{\Psi^{(+)}(1,0)}{r}\int_0^\infty[\overline{E_\varepsilon}(r+\rho,t)-\overline{E_\varepsilon}(r-\rho,t)]u(\rho)d\rho.$$

The matrix element corresponding to (22) is therefore $\overline{E_\varepsilon}(r-\rho,t)-\overline{E_\varepsilon}(r+\rho,t)$.

The integrand of (23) consists of the odd components of $H_\varepsilon(\cdot,t)$. Set $F_\varepsilon(\xi,t)=\partial D_\varepsilon(\xi,t)/\partial\xi$, for all $\xi\in\mathbb{R}$ and $t\geqslant 0$. Then note that

$$H_\varepsilon(\xi,t)-H_\varepsilon(-\xi,t)=-\sigma_3(F_\varepsilon(\xi,t)-F_\varepsilon(-\xi,t))=-2\sigma_3F_\varepsilon(\xi,t).$$

Then in polar coordinates, the integral (23) becomes

$$2\int_0^\infty\left[\int_{S_1}\langle\sigma,\omega\rangle\otimes\sigma_3\Psi^{(+)}(1,0)\,\frac{F_\varepsilon([r^2+\rho^2-2r\rho\langle\omega,\hat r\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat r\rangle]^{1/2}}\,\mu_1(d\omega)\right]\left[\frac{d}{d\rho}\,\frac{u(\rho)}{\rho}\right]\rho^2d\rho \tag{24}$$

for $r=|x|$ and $\hat r=x/r$. Here we have used the fact that $\Psi^{(+)}(1,0)$ is a *constant* vector.

Suppose that $\{\hat e_1,\hat e_2,\hat r\}$ is an orthonormal basis of $\mathbb{R}^3$ and $e_j=a_{j1}\hat e_1+a_{j2}\hat e_2+a_{j3}\hat r$ for the standard basis vectors e_j, $j=1,2,3$, of $\mathbb{R}^3$. Then

$$\langle\sigma,\omega\rangle=\sum_{j=1}^3\sigma_j[a_{j1}\langle\omega,\hat e_1\rangle+a_{j2}\langle\omega,\hat e_2\rangle+a_{j3}\langle\omega,\hat r\rangle].$$

Because $\int_{S_1}f(\langle\omega,\hat r\rangle)\langle\omega,\hat e_j\rangle d\mu(\omega)=0$, for $j=1,2$ and any bounded measurable function f, only the integral over the term $\Sigma_{j=1}^3\sigma_ja_{j3}\langle\omega,\hat r\rangle$ of $\langle\sigma,\omega\rangle$ in (24) remains. But $\hat r=\Sigma_{j=1}^3e_ja_{j3}$ because $[a_{j\kappa}]_{j,\kappa=1}^3$ is an orthogonal matrix, that is, $a_{j3}=\hat r_j$ for $j=1,2,3$, so the integral (24) is equal to

$$2\int_0^\infty\left[\int_{S_1}\langle\omega,\hat r\rangle\,\frac{F_\varepsilon([r^2+\rho^2-2r\rho\langle\omega,\hat r\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat r\rangle]^{1/2}}\,\mu_1(d\omega)\right]\left[\frac{d}{d\rho}\,\frac{u(\rho)}{\rho}\right]\rho^2d\rho$$

times the vector $[\langle\sigma,\hat r\rangle\otimes\sigma_3]\Psi^{(+)}(1,0)$.

With the substitution $\xi=[r^2+\rho^2-2r\rho\cos\theta]^{1/2}$, $\cos\theta=\langle\omega,\hat r\rangle$ and integration by parts, we have

$$
\begin{aligned}
&-2\int_0^\infty d\rho\,\frac{u(\rho)}{\rho}\,\frac{\partial}{\partial\rho}\rho^2\int_{S_1}\langle\omega,\hat r\rangle\,\frac{F_\varepsilon([r^2+\rho^2-2r\rho\langle\omega,\hat r\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat r\rangle]^{1/2}}\,\mu_1(d\omega)\\
&\quad=-\frac{2}{4\pi}\int_0^\infty d\rho\,\frac{u(\rho)}{\rho}\,\frac{\partial}{\partial\rho}\rho^2\int_0^\pi\int_0^{2\pi}\cos\theta\,\frac{F_\varepsilon([r^2+\rho^2-2r\rho\cos\theta]^{1/2},t)}{[r^2+\rho^2-2r\rho\cos\theta]^{1/2}}\sin\theta d\varphi d\theta\\
&\quad=-\int_0^\infty d\rho\,\frac{u(\rho)}{\rho}\,\frac{\partial}{\partial\rho}\rho^2\int_{|r-\rho|}^{r+\rho}\frac{r^2+\rho^2-\xi^2}{2r^2\rho^2}F_\varepsilon(\xi,t)d\xi\\
&\quad=-\frac{1}{2r^2}\int_0^\infty d\rho\,\frac{u(\rho)}{\rho}\,\frac{\partial}{\partial\rho}\int_{|r-\rho|}^{r+\rho}(r^2+\rho^2-\xi^2)F_\varepsilon(\xi,t)d\xi.
\end{aligned}
$$

In the region $\rho>r$, we have

$$
\begin{aligned}
&-\frac{1}{2r^2}\int_0^\infty d\rho\,\frac{u(\rho)}{\rho}\,\frac{\partial}{\partial\rho}\int_{\rho-r}^{r+\rho}(r^2+\rho^2-\xi^2)F_\varepsilon(\xi,t)d\xi\\
&\quad=-\frac{1}{2r^2}\int_0^\infty d\rho\,\frac{u(\rho)}{\rho}\left([(r^2+\rho^2-\xi^2)F_\varepsilon(\xi,t)]_{\rho-r}^{r+\rho}+2\rho\int_{\rho-r}^{r+\rho}F_\varepsilon(\xi,t)d\xi\right)\\
&\quad=-\frac{1}{r}\int_0^\infty d\rho u(\rho)\left[-(F_\varepsilon(r+\rho,t)+F_\varepsilon(\rho-r,t))+\frac{1}{r}(D_\varepsilon(r+\rho,t)-D_\varepsilon(\rho-r,t))\right]\\
&\quad=-\frac{1}{r}\int_0^\infty d\rho u(\rho)\left[F_\varepsilon(r-\rho,t)-F_\varepsilon(r+\rho,t)+\frac{1}{r}(D_\varepsilon(r+\rho,t)-D_\varepsilon(r-\rho,t))\right],
\end{aligned}
$$

because F_ε is an odd function. The same expression is obtained for $\rho<r$.

A calculation [cf. Thaller 1992, Eq. (4.122) p. 127] shows that

$$
[\langle\sigma,\hat r\rangle\otimes\sigma_3]\Psi^{(+)}(1,0)=i\Psi^{(-)}(1,0)(\hat r). \tag{25}
$$

Indeed,

$$
\langle\sigma,\hat r\rangle\otimes\sigma_3=\begin{pmatrix}\hat r_3 & \hat r_1-i\hat r_2\\ \hat r_1+i\hat r_2 & -\hat r_3\end{pmatrix}\otimes\sigma_3=\begin{pmatrix}\hat r_3\sigma_3 & (\hat r_1-i\hat r_2)\sigma_3\\ (\hat r_1+i\hat r_2)\sigma_3 & -\hat r_3 s_3\end{pmatrix}.
$$

The sum of the first two columns of $\langle\sigma,\hat r\rangle\otimes\sigma_3$ is

$$
\begin{pmatrix}\hat r_3\\ -\hat r_3\\ \hat r_1+i\hat r_2\\ -(\hat r_1+i\hat r_2)\end{pmatrix}=\begin{pmatrix}\cos\theta\\ -\cos\theta\\ e^{i\varphi}\sin\theta\\ -e^{i\varphi}\sin\theta\end{pmatrix},
$$

which is a constant multiple of $\Psi^{(-)}(1,0)(\hat r)$. The integral (23) is equal to

$$
-i\frac{\Psi^{(-)}(1,0)(\hat r)}{r}\int_0^\infty d\rho u(\rho)\left[F_\varepsilon(r-\rho,t)-F_\varepsilon(r+\rho,t)-\frac{1}{r}(D_\varepsilon(r-\rho,t)-D_\varepsilon(r+\rho,t))\right],
$$

so that the corresponding matrix element is

$$
-iW_{21}^{(\varepsilon)}(r,\rho;t)=-i\left[F_\varepsilon(r-\rho,t)-F_\varepsilon(r+\rho,t)-\frac{1}{r}(D_\varepsilon(r-\rho,t)-D_\varepsilon(r+\rho,t))\right].
$$

2. The subspace $\mathcal{H}(1,0)_-$

On the other hand, for $\psi(y)=\Psi^{(-)}(1,0)\otimes\rho^{-1}u(\rho)$, (23) is

$$-2\int_0^\infty\left[\int_{S_1}\sigma_0\otimes\frac{\frac{\partial G_\varepsilon}{\partial\xi}([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}\Psi^{(-)}(1,0)(\omega)d\mu_1(\omega)\right]u(\rho)\rho d\rho$$

for $G_\varepsilon(\xi,t)=(\sigma_0\partial/\partial t-im\sigma_1)D_\varepsilon(\xi,t)$, for all $\xi\in\mathbb{R}$ and $t>0$. Note here that

$$\frac{\partial}{\partial\xi}H_\varepsilon(\xi,t)-\frac{\partial}{\partial\xi}H_\varepsilon(-\xi,t)=2\left(\sigma_0\frac{\partial}{\partial t}-im\sigma_1\right)\frac{\partial}{\partial\xi}D_\varepsilon(\xi,t)=2\frac{\partial}{\partial\xi}G_\varepsilon(\xi,t).$$

Now

$$\begin{aligned}
&\int_{S_1}\sigma_0\otimes\frac{(\partial G_\varepsilon/\partial\xi)([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}\Psi^{(-)}(1,0)(\omega)d\mu_1(\omega)\\
&\quad=-i\int_{S_1}\sigma_0\otimes\frac{(\partial G_\varepsilon/\partial\xi)([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}[\langle\sigma,\omega\rangle\otimes\sigma_3]\Psi^{(+)}(1,0)d\mu_1(\omega)\\
&\quad=-i\int_{S_1}\sigma_0\otimes\frac{(\partial G_\varepsilon/\partial\xi)([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}[\langle\sigma,\hat{r}\rangle\otimes\sigma_3]\Psi^{(+)}(1,0)\langle\omega,\hat{r}\rangle d\mu_1(\omega)\\
&\quad=\int_{S_1}\sigma_0\otimes\frac{(\partial G_\varepsilon/\partial\xi)([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}\Psi^{(-)}(1,0)(\hat{r})\langle\omega,\hat{r}\rangle d\mu_1(\omega)\\
&\quad=\Psi^{(-)}(1,0)(\hat{r})\int_{S_1}\frac{(\partial E_\varepsilon/\partial\xi)([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}\langle\omega,\hat{r}\rangle d\mu_1(\omega)\\
&\quad=4^{-1}\Psi^{(-)}(1,0)(\hat{r})(r\rho)^{-2}\int_{|r-\rho|}^{r+\rho}\frac{\partial E_\varepsilon(\xi,t)}{\partial\xi}(r^2+\rho^2-\xi^2)d\xi,
\end{aligned}$$

where we have used the identity (25) and the fact that $(\sigma_0\otimes\sigma_0)\Psi^{(-)}(1,0)=\Psi^{(-)}(1,0)$ and $(\sigma_0\otimes\sigma_1)\Psi^{(-)}(1,0)=-\Psi^{(-)}(1,0)$. Integrating by parts, we have

$$-2^{-1}(r\rho)^{-1}\int_{|r-\rho|}^{r+\rho}\frac{\partial E_\varepsilon(\xi,t)}{\partial\xi}(r^2+\rho^2-\xi^2)d\xi=E_\varepsilon(r+\rho)+E_\varepsilon(r-\rho)-(r\rho)^{-1}\int_{|r-\rho|}^{r+\rho}E_\varepsilon(\xi)\xi d\xi,$$

which is the matrix element corresponding to the convolution (22) acting on $\mathcal{H}(1,0)_-$.

For the other integral (23), appealing to the identity (25), we have

$$\begin{aligned}
[\langle\sigma,\nabla\rangle]\otimes\sigma_3]\psi(y)&=[\langle\sigma,\nabla\rangle\otimes\sigma_3][\Psi^{(-)}(1,0)(\omega)\rho^{-1}u(\rho)]\\
&=\frac{u(\rho)}{\rho}[\langle\sigma,\nabla\rangle\otimes\sigma_3]\Psi^{(-)}(1,0)(\omega)+\langle\sigma,\omega\rangle\otimes\sigma_3\Psi^{(-)}(1,0)(\omega)\frac{d}{d\rho}\frac{u(\rho)}{\rho}\\
&=\frac{1}{i}\left[\frac{u(\rho)}{\rho}[\langle\sigma,\nabla\rangle\otimes\sigma_3][\langle\sigma,\omega\rangle\otimes\sigma_3]\Psi^{(+)}(1,0)+\Psi^{(+)}(1,0)\frac{d}{d\rho}\frac{u(\rho)}{\rho}\right],
\end{aligned}$$

in coordinates $\omega=y/|y|$ and $\rho=|y|$.

The function $\Psi^{(+)}(1,0)$ is a constant vector and a calculation shows that

$$[\langle\sigma,\nabla\rangle\otimes\sigma_3]\langle\sigma,\omega\rangle\otimes\sigma_3=\frac{2}{\rho}\sigma_0\otimes\sigma_0.$$

One integral in (23) is therefore

$$
\begin{aligned}
&-2i\Psi^{(+)}(1,0)\int_0^\infty\left[\int_{S_1}\frac{F_\varepsilon([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}\mu_1(d\omega)\right]\left[\frac{d}{d\rho}\frac{u(\rho)}{\rho}\right]\rho^2 d\rho\\
&=2i\Psi^{(+)}(1,0)\int_0^\infty\frac{1}{\rho}\frac{\partial}{\partial\rho}\rho^2\left[\int_{S_1}\frac{F_\varepsilon([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}\mu_1(d\omega)\right]u(\rho)d\rho\\
&=\frac{i\Psi^{(+)}(1,0)}{r}\int_0^\infty\frac{u(\rho)}{\rho}\frac{\partial}{\partial\rho}\rho\left[\int_{|r-\rho|}^{r+\rho}F_\varepsilon(\xi,t)d\xi\right]d\rho\\
&=\frac{i\Psi^{(+)}(1,0)}{r}\int_0^\infty\frac{u(\rho)}{\rho}\frac{\partial}{\partial\rho}\rho[D_\varepsilon(r+\rho,t)-D_\varepsilon(r-\rho,t)]d\rho\\
&=\frac{i\Psi^{(+)}(1,0)}{r}\int_0^\infty\left[F_\varepsilon(r-\rho,t)+F_\varepsilon(r+\rho,t)-\frac{1}{\rho}[D_\varepsilon(r-\rho,t)-D_\varepsilon(r+\rho,t)]u(\rho)d\rho\right.
\end{aligned}
$$

and the other is

$$
\begin{aligned}
&-4i\Psi^{(+)}(1,0)\int_0^\infty\left[\int_{S_1}\frac{F_\varepsilon([r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2},t)}{[r^2+\rho^2-2r\rho\langle\omega,\hat{r}\rangle]^{1/2}}\mu_1(d\omega)\right]u(\rho)d\rho\\
&=-\frac{2i\Psi^{(+)}(1,0)}{r}\int_0^\infty\frac{u(\rho)}{\rho}\int_{|r-\rho|}^{r+\rho}F_\varepsilon(\xi,t)d\xi d\rho\\
&=\frac{2i\Psi^{(+)}(1,0)}{r}\int_0^\infty\frac{u(\rho)}{\rho}[D_\varepsilon(r-\rho,t)-D_\varepsilon(r+\rho,t)]d\rho.
\end{aligned}
$$

Adding the two terms, the integral (23) becomes

$$
\frac{i\Psi^{(+)}(1,0)}{r}\int_0^\infty\left[F_\varepsilon(r-\rho,t)+F_\varepsilon(r+\rho,t)+\frac{1}{\rho}[D_\varepsilon(r-\rho,t)-D_\varepsilon(r+\rho,t)]u(\rho)d\rho,\right.
$$

so that the corresponding matrix element is

$$
iW_{12}^{(\varepsilon)}(r,\rho;t)=i\left[F_\varepsilon(r-\rho,t)+F_\varepsilon(r+\rho,t)+\frac{1}{\rho}[D_\varepsilon(r-\rho,t)-D_\varepsilon(r+\rho,t)].\right.
$$

The operator of convolution with respect to $K_t^{(\varepsilon)}$ therefore leaves the subspace $\mathcal{H}(1,0)$ invariant and its action on the radial components is the operator $e^{-it\tau_1}$ whose kernel is given by

$$
\begin{pmatrix}\overline{E_\varepsilon}(r-\rho,t)-\overline{E_\varepsilon}(r+\rho,t) & iW_{12}^{(\varepsilon)}(r,\rho;t)\\ -iW_{21}^{(\varepsilon)}(r,\rho;t) & E_\varepsilon(r-\rho,t)+E_\varepsilon(r+\rho,t)-W_{22}^{(\varepsilon)}(r,\rho;t)\end{pmatrix}, \tag{26}
$$

where

$$W_{12}^{(\varepsilon)}(r,\rho;t)=\left[F_\varepsilon(r-\rho,t)+F_\varepsilon(r+\rho,t)+\frac{1}{\rho}(D_\varepsilon(r-\rho,t)-D_\varepsilon(r+\rho,t))\right],$$

$$W_{21}^{(\varepsilon)}(r,\rho;t)=\left[F_\varepsilon(r-\rho,t)-F_\varepsilon(r+\rho,t)-\frac{1}{r}(D_\varepsilon(r-\rho,t)-D_\varepsilon(r+\rho,t))\right],$$

$$W_{22}^{(\varepsilon)}(r,\rho;t)=(r\rho)^{-1}\int_{|r-\rho|}^{r+\rho}E_\varepsilon(\xi,t)\xi d\xi.$$

By virtue of Lemma 3 and the observation that the operator of convolution with respect to $K_t^{(\varepsilon)}$ leaves the subspace $\mathcal{H}(1,0)$ invariant, the operator $e^{-it\tau_1}$ is the limit in the strong operator topology on $L^2(\mathbb{R}_+,\mathbb{C}^2)$, as $\varepsilon\to 0+$, of bounded linear operators with kernels given by (26).

It is readily verified that as $\varepsilon\to 0+$, the components of (26) converge in the space $C_c^\infty(\mathbb{R}_+\times\mathbb{R}_+)'$ of distributions to the components of (19). The proof of Theorem 1 is complete. □

The explicit form of the kernel $e^{-it\tau_1}(r,\rho)$ given in Theorem 1 enables us to show that $e^{-it\tau_1}$ is not a bounded operator on $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$ for $t\neq 0$.

Proposition 3: For each $\delta>0$ *and* $t\neq 0$, $e^{-it\tau_1}(\chi_{(0,\delta)}.e_2)\notin L^\infty(\mathbb{R}_+,\mathbb{C}^2)$.

Proof: Let $t>0$. A similar argument holds for $t<0$. It is enough to show that the function

$$r\mapsto\int_0^\delta W_{12}(r,\rho;t)d\rho,\quad 0<r<t, \tag{27}$$

is not bounded near $r=t$. The distribution of order zero with the kernel $F(r-\rho,t)+F(r+\rho,t)$ is associated with the sum of convolutions with respect to measures, giving a uniformly bounded function of r, so we examine the integral

$$\int_0^\delta\frac{D(r-\rho,t)-D(r+\rho,t)}{\rho}d\rho.$$

In the region $\{(r,\rho)\in(\mathbb{R}_+)^2:|r+\rho|<t\}$, there exists a constant $C>0$ such that

$$\begin{aligned}|D(r-\rho,t)-D(r+\rho,t)|&\leqslant C|\sqrt{t^2-(r-\rho)^2}-\sqrt{t^2-(r+\rho)^2}|\\&=\frac{4Cr\rho}{\sqrt{t^2-(r-\rho)^2}+\sqrt{t^2-(r+\rho)^2}}\\&\leqslant\frac{4Cr\rho}{\sqrt{t^2-(r-\rho)^2}}.\end{aligned}$$

It follows that $r\mapsto\int_0^{\delta\wedge(t-r)}\rho^{-1}[D(r-\rho,t)-D(r+\rho,t)]\,d\rho$ is a uniformly bounded function for all $0<r<t$.

In the region $\rho>t-r$, the term $\rho^{-1}D(r+\rho,t)$ in the kernel $W_{12}(r,\rho;t)$ is zero. Suppose that $t-\delta<r<t$. Then

$$\int_{t-r}^\delta\frac{D(r-\rho,t)}{\rho}d\rho=\frac{1}{2}\int_{t-r}^{\delta\wedge(t+r)}\frac{J_0(m\sqrt{t^2-(\rho-r)^2})}{\rho}d\rho. \tag{28}$$

Because $J_0(0)=1$ and J_0 is continuous, it follows that the function (28) and hence (27) has a logarithmic divergence at $r=t$. □

Corollary 1: The operator $e^{-it\tau_1}$ *is not bounded from* $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$ *to* $L^\infty(\mathbb{R}_+,\mathbb{C}^2)$ *for any* $t\neq 0$.

According to the following corollary, the group $e^{-it\tau_1}$, $t>0$, does not have path-space measures, somewhat in the same sense that the heat equation $e^{tD\Delta}$ with nonreal diffusion constant D as well as the Schrödinger group $e^{it\Delta/2}$ do not possess path-space measures (cf. Cameron, 1960/61).

The path-space $\Omega_{r,t}$ consists of all functions $\omega:[0,t]\to\mathbb{R}_+$ with $\omega(t)=r$ and we are looking for a family of $M_2(\mathbb{C})$-valued measures $\nu_{r,t}$ defined on the σ-algebra generated by cylinder sets in $\Omega_{r,t}$, such that the equations (29) below hold.

Corollary 2: There does not exist a family $\{\nu_{r,t}\}$ *of matrix-valued path-space measures on the path-space* $\Omega_{r,t}$ *such that*

$$\int_{\Omega_{r,t}} \nu_{r,t}(d\omega) f(\omega(0)) = (e^{-it\tau_1} f)(r), \quad \text{for all } r>0,\ t>0, \tag{29}$$

for every continuous function $f:[0,\infty)\to\mathbb{C}^2$ *with compact support.*

Proof: By smoothing out the function $\chi_{(0,\delta)}.e_2$ used in Proposition 3, we can find a continuous function $f:[0,\infty)\to\mathbb{C}^2$ with compact support such that $(e^{-it\tau_1}f)(r)$ diverges as $r\to t$. Hence, a formula like (29) cannot hold for *all* $r>0$. □

By duality, $e^{-it\tau_1}$ cannot be bounded from $L^1(\mathbb{R}_+,\mathbb{C}^2)$ to $L^1(\mathbb{R}_+,\mathbb{C}^2)$ either. Moreover, a construction similar to that above shows one can find a function f with an integrable singularity at $\rho=t$ such that the function

$$r\mapsto \int_{t-\delta}^{t} W_{21}(r,\rho;t) f(\rho)\, d\rho, \quad 0<r<t,$$

is not integrable at $r=0$ state.

(Received 11 September 2001; accepted for publication 11 March 2002)

We continue a previous analysis of the covariant Hamiltonian symplectic structure of general relativity for spatially bounded regions of space–time. To allow for wide generality, the Hamiltonian is formulated using any fixed hypersurface, with a boundary given by a closed spacelike two-surface. A main result is that we obtain Hamiltonians associated with Dirichlet and Neumann boundary conditions on the gravitational field coupled to matter sources, in particular a Klein–Gordon field, an electromagnetic field, and a set of Yang–Mills–Higgs fields. The Hamiltonians are given by a covariant form of the Arnowitt–Deser–Misner (ADM) Hamiltonian modified by a surface integral term that depends on the particular boundary conditions. The general form of this surface integral involves an underlying ''energy-momentum'' vector in the space–time tangent space at the spatial boundary two-surface. We give examples of the resulting Dirichlet and Neumann vectors for topologically spherical two-surfaces in Minkowski space–time, spherically symmetric space–times, and stationary axisymmetric space–times. Moreover, we establish the relation between these vectors and the ADM energy-momentum vector for a two-surface taken in a limit to be spatial infinity in asymptotically flat space–times. We also discuss the geometrical properties of the Dirichlet and Neumann vectors and obtain several striking results relating these vectors to the mean curvature and normal curvature connection of the two-surface. Most significantly, the part of the Dirichlet vector normal to the two-surface depends only on the space–time metric at this surface and thereby defines a geometrical normal vector field on the two-surface. We show that this normal vector is orthogonal to the mean curvature vector, and its norm is the mean null extrinsic curvature, while its direction is such that there is zero expansion of the two-surface, i.e., the Lie derivative of the surface volume form in this direction vanishes. This leads to a direct relation between the Dirichlet vector and the condition for a spacelike two-surface to be (marginally) trapped.

I. INTRODUCTION

In a previous paper[1] we began an investigation of the covariant symplectic structure associated with the Einstein equations for the gravitational field in any fixed spatially compact region $\Sigma\times\mathbb{R}$ of space–time whose spacelike slices Σ posses a closed two-surface boundary $\partial\Sigma$, with a fixed time-flow vector field tangent to the timelike boundary hypersurface $\partial\Sigma\times\mathbb{R}$. Through an analysis of boundary conditions required for the existence of a Hamiltonian variational principle, we derived Dirichlet, Neumann, and mixed type boundary conditions for the space–time metric at the spatial boundary two-surface $\partial\Sigma$. The corresponding Hamiltonians we obtained are given by a

a)Electronic mail: sanco@brocku.ca
b)Electronic mail: roh@gr.uchicago.edu

covariant form of the Arnowitt–Deser–Misner (ADM) Hamiltonian plus a surface integral term whose form depends on the boundary conditions. We also showed that these Hamiltonians naturally yield covariant field equations which are equivalent to a $3+1$ split of the Einstein equations into the well-known constraint equations and geometrical time-evolution equations for the space–time metric.

The present paper continues the previous analysis in two significant ways. First, in Sec. II, we investigate the covariant symplectic structure of the Einstein equations coupled to matter sources in any fixed spatially bounded region of space–time. Specifically, we consider Dirichlet and Neumann boundary conditions for a scalar field, an electromagnetic field, and a set of Yang–Mills/Higgs fields. Furthermore, we allow the fixed time-flow vector field on space–time to have an arbitrary direction (i.e., not necessarily timelike) in the space–time region. Such freedom in the choice of the time-flow vector field is useful for relating the Hamiltonian boundary terms to expressions for total energy, momentum, angular momentum associated with the gravitational and matter fields on given hypersurfaces in space–time.

Next, in Sec. III, we discuss in detail the geometrical structure of the gravitational part of the Dirichlet and Neumann Hamiltonian boundary terms. In particular, as noted in Ref. 1, these each involve an underlying locally constructed ''energy-momentum'' vector at each point in the tangent space at the two-surface. We show that the form of the boundary term vectors is closely related to the mean curvature vector and normal curvature connection one-form which describe the extrinsic geometry of the spatial boundary two-surface in space–time. Most striking, we further show that the part of the Dirichlet boundary term vector orthogonal to the two-surface yields a direction in which the two-surface has zero expansion in space–time.

Finally, through several examples, we illustrate the properties of the Dirichlet and Neumann boundary term vectors for topologically spherical two-surfaces in various physically interesting space–times in Sec. IV. As a main result, we show that in asymptotically flat space–times the Dirichlet vector at spatial infinity can be identified in a natural way with the ADM energy-momentum vector.

We make some concluding remarks in Sec. V. (The notation and conventions of Ref. 1 are used throughout.)

II. MATTER FIELDS

It is convenient here to employ the tetrad formulation of the Einstein equations, since this simplifies the analysis of boundary conditions and Hamiltonian boundary terms as shown in Ref. 1. We focus on Dirichlet and Neumann boundary conditions and make some remarks on more general boundary conditions at the end.

A. Preliminaries

On a given smooth orientable space–time (M, g_{ab}), let ξ^a be a complete, smooth time-flow vector field, allowed to be timelike, spacelike, or null. Let Σ be a region contained in a fixed hypersurface in M such that the boundary of the region is a closed orientable spacelike two-surface $\partial\Sigma$ (with the hypersurface allowed to be otherwise arbitrary).

For treatment of boundary conditions when the time-flow ξ^a is not necessarily timelike, it is helpful to introduce the following structure associated with the boundary two-surface $\partial\Sigma$.

Let $\mathcal{P}_{\partial\Sigma}$ and $\mathcal{P}^{\perp}_{\partial\Sigma}$ denote projection operators onto the tangent subspaces $T(\partial\Sigma)$ and $T(\partial\Sigma)^{\perp}$ with respect to the surface $\partial\Sigma$ in local coordinates in M. Note $\mathcal{P}_{\partial\Sigma}+\mathcal{P}^{\perp}_{\partial\Sigma}$ is the identity map on the tangent space $T(M)$ at $\partial\Sigma$. Define the metric on $\partial\Sigma$ by

$$\sigma^{ab}=\mathcal{P}_{\partial\Sigma}(g^{ab}), \quad \sigma_{ab}=g_{ac}g_{bd}\sigma^{bc}. \tag{2.1}$$

Let ϵ_{ab} be the metric volume form on $\partial\Sigma$, and define

$$*\epsilon_{ab}=\epsilon^{cd}\epsilon_{abcd}(g) \tag{2.2}$$

in terms of the space–time volume form $\epsilon_{abcd}(g)$. Note that $\mathcal{P}_{\partial\Sigma}(*\epsilon_{ab})=\mathcal{P}^{\perp}_{\partial\Sigma}(\epsilon_{ab})=0$. A useful identity is given by

$$2(\mathcal{P}_{\partial\Sigma})_{[a}{}^{c}(\mathcal{P}_{\partial\Sigma})_{b]}{}^{d}=\epsilon_{ab}\epsilon^{cd}. \tag{2.3}$$

Let

$$\zeta^a=\mathcal{P}^{\perp}_{\partial\Sigma}(\xi^a), \quad N^a=\mathcal{P}_{\partial\Sigma}(\xi^a), \tag{2.4}$$

so $\xi^a=\zeta^a+N^a$ decomposes into a sum of normal and tangential vectors with respect to $\partial\Sigma$. We now suppose ξ^a is not tangential to $\partial\Sigma$, i.e., $\zeta^a\neq 0$ everywhere on the surface $\partial\Sigma$. In this situation, much of the formalism and results given in Sec. 3 of Ref. 1 can be paralleled.

Let $\mathcal{B}$ denote the hypersurface given by the image of $\partial\Sigma$ under a one-parameter diffeomorphism generated by ξ^a on M. Note that the dual vector field $*\epsilon_{ab}\xi^b$ is hypersurface orthogonal since it is annihilated by all tangent vectors (in particular ξ^a) in $\mathcal{B}$. Define a basis $\{s_a,t_a\}$ for $T^*(\partial\Sigma)^{\perp}$ by diagonalization of the identity map

$$\delta^b_a=\sigma_a{}^b+s_a s^{*b}+t_a t^{*b}, \tag{2.5}$$

such that $s_a\propto *\epsilon_{ab}\xi^b$ is hypersurface orthogonal to $\mathcal{B}$, with $\{s^{*a},t^{*a}\}$ denoting a basis for $T(\partial\Sigma)^{\perp}$ that is dual to $\{s_a,t_a\}$. In particular, $s^{*a}s_a=t^{*a}t_a=1$, and $s^{*a}t_a=t^{*a}s_a=0$. This leads to a corresponding decomposition of the space–time metric

$$g_{ab}=\sigma_{ab}+s_a s^*_a+t_a t^*_b \tag{2.6}$$

with $s^*_a=g_{ab}s^{*b}$ and $t^*_a=g_{ab}t^{*b}$. Now, define a projection operator $\mathcal{P}_{\mathcal{B}}$ with respect to $\mathcal{B}$ by

$$h_a{}^b=\delta^b_a-s_a s^{*b} \tag{2.7}$$

satisfying

$$h_a{}^b s_b=0, \quad h_a{}^b s^{*a}=0. \tag{2.8}$$

Then

$$h_{ab}=g_{ab}-s_a s^*_a=\sigma_{ab}+t_a t^*_a \tag{2.9}$$

defines the induced metric on $\mathcal{B}$. Also, define the volume form on $\mathcal{B}$ by

$$\epsilon_{abc}(h)=\epsilon_{abcd}(g)s^{*d}=3t_{[a}\epsilon_{bc]}. \tag{2.10}$$

Finally, note that

$$*\epsilon_{ab}=4t_{[a}s_{b]}, \quad \epsilon_{abcd}=3\epsilon_{[ab}*\epsilon_{cd]}=4\epsilon_{[abc}(h)s_{d]}, \tag{2.11}$$

$$\zeta^a=-Nt^{*a}, \quad \zeta^a t_a=-N, \quad \zeta^a s_a=\zeta^a\epsilon_{ab}=0, \tag{2.12}$$

for some scalar function N. This yields the identities

$$\xi^a=-Nt^{*a}+N^a, \tag{2.13}$$

$$\xi^a\epsilon^{bc}\epsilon_{abcd}(g)=\xi^a*\epsilon_{ad}=-2Ns_d, \tag{2.14}$$

$$\xi^a\epsilon^{bc}\epsilon_{abc}(h)=-2N, \quad \mathcal{P}_{\partial\Sigma}(\xi^a\epsilon_{abc}(h))=-N\epsilon_{bc}. \tag{2.15}$$

These will be important in the analysis of boundary conditions for both the gravitational field and matter fields.

Now we introduce an orthonormal frame for g_{ab} given by

$$\theta^\mu_a = \sigma^\mu_a + s_a s^{*\mu} + t_a t^{*\mu}, \tag{2.16}$$

where $\sigma^\mu_a = \sigma_a{}^b \theta^\mu_b$ is an orthonormal frame for σ_{ab}, with the coefficients

$$s^{*\mu} = s^{*a}\theta^\mu_a, \quad t^{*\mu} = t^{*a}\theta^\mu_a \tag{2.17}$$

defined to satisfy $\mp t^{*\mu}t^{*\nu} \pm s^{*\mu}s^{*\nu} = \mathrm{diag}(-1,1,0,0)$ if ξ^a is timelike or spacelike, or $2s^{*(\mu}t^{*\nu)} = \mathrm{diag}(-1,1,0,0)$ if ξ^a is null. Consequently, the frame components of s^a, t^a, σ^{ab}, g^{ab} are given by

$$s^\mu = s^a \theta^\mu_a, \quad t^\mu = t^a \theta^\mu_a, \tag{2.18}$$

$$\sigma^{\mu\nu} = \sigma^{ab}\theta^\mu_a\theta^\nu_b = \mathrm{diag}(0,0,1,1), \quad \eta^{\mu\nu} = g^{ab}\theta^\mu_a\theta^\nu_b = \mathrm{diag}(\mp 1, \pm 1, 1, 1), \tag{2.19}$$

where $\{s^\mu, t^\mu\}$ are dual to $\{s^*_\mu = \eta_{\mu\nu}s^{*\nu}, t^*_\mu = \eta_{\mu\nu}t^{*\nu}\}$. Hereafter we fix the frame coefficients (2.17) and (2.18) to be independent of the space–time metric g_{ab}, so therefore under a variation δg_{ab}, the induced variations δs_a, δt_a, $\delta\sigma^\mu_a$, $\delta\theta^\mu_a$ satisfy

$$\delta\theta^\mu_a = \delta\sigma^\mu_a + s^{*\mu}\delta s_a + t^{*\mu}\delta t_a, \tag{2.20}$$

$$\delta s_a = s_\mu \delta\theta^\mu_a, \quad \delta t_a = t_\mu \delta\theta^\mu_a, \quad \delta\sigma^\mu_a = \sigma_\nu{}^\mu \delta\sigma^\nu_a, \tag{2.21}$$

$$\delta\sigma_{ab} = 2\sigma_{\mu\nu}\theta^\mu_{(a}\delta\theta^\nu_{b)} = \sigma^\mu_{(a}\delta\sigma_{b)\mu}, \quad \delta g_{ab} = 2\eta_{\mu\nu}\theta^\mu_{(a}\delta\theta^\nu_{b)}. \tag{2.22}$$

Note, by hypersurface orthogonality of s_a, it also follows that

$$\mathcal{P}_{\mathcal{B}}(\delta s_a) = 0, \quad \mathcal{P}_{\partial\Sigma}(\delta t_a) = 0, \quad \mathcal{P}^\perp_{\partial\Sigma}(\delta\sigma_{ab}) = 0. \tag{2.23}$$

Let

$$h^\mu_a = h_a{}^b\theta^\mu_b = \theta^\mu_a - s_a s^{*\mu}, \tag{2.24}$$

which yields a decomposition of the frame with respect to $\mathcal{B}$, satisfying

$$\mathcal{P}_{\partial\Sigma}(h^\mu_a) = \sigma^\mu_a, \quad \mathcal{P}^\perp_{\partial\Sigma}(h^\mu_a) = t_a t^{*\mu}. \tag{2.25}$$

It is convenient for later to also introduce a fixed frame adapted to $\partial\Sigma$ and ξ^a. Let

$$\vartheta^0_a = t_a, \quad \vartheta^1_a = s_a, \quad \vartheta^2_{[a}\vartheta^3_{b]} = \epsilon_{ab}, \quad \vartheta^2_a = \epsilon_a{}^b\vartheta^3_b, \tag{2.26}$$

which defines the frame ϑ^μ_a uniquely up to rotations of ϑ^2_a, ϑ^3_a. Thus, in this formalism, ϑ^μ_a is an orthonormal frame when ξ^a is timelike or spacelike, and a null frame when ξ^a is null.

In the case when ζ^a is timelike, the previous formalism reduces to that in Ref. 1. Most important, the formalism here applies equally well to the cases when ζ^a is spacelike or null.

Finally, in the case that $\zeta^a = 0$, i.e., ξ^a is tangential to $\partial\Sigma$, we simply fix any basis $\{s_a, t_a\}$ of $T^*(\partial\Sigma)^\perp$ and define a frame θ^μ_a to satisfy the previous equations (2.16)–(2.19). This yields the same formalism as in the case that ξ^a is not tangential to $\partial\Sigma$, except that there does not exist a hypersurface $\mathcal{B}$ generated by $\zeta^a = 0$.

Now, with the frame θ^μ_a used as the gravitational field variable, the Lagrangian for the vacuum Einstein equations is given by

$$L_{abcd}(\theta) = \epsilon_{abcd}(\theta)R(\theta). \tag{2.27}$$

Here $R(\theta)=\theta^b_\nu R^\nu_b(\theta)$ and $R_a{}^\mu(\theta)=\theta^b_\nu R_{ab}{}^{\mu\nu}(\theta)$ are the scalar curvature and Ricci curvature obtained from the curvature two-form

$$R_{ab}{}^{\mu\nu}(\theta)=2\partial_{[a}\Gamma_{b]}{}^{\mu\nu}(\theta)+2\Gamma_{[a}{}^{\mu\sigma}(\theta)\Gamma_{b]\sigma}{}^{\nu}(\theta) \tag{2.28}$$

in terms of the frame connection given by

$$\Gamma_a{}^{\mu\nu}=\theta^{b\mu g}\nabla_a\theta^\nu_b=2\,\theta^{b[\mu}\partial_{[a}\theta^{\nu]}_{b]}-\theta^{b\mu}\theta^{c\nu}\theta_{a\alpha}\partial_{[b}\theta^\alpha_{c]}. \tag{2.29}$$

A variation of $L_{abcd}(\theta)$ yields

$$\delta L_{abcd}(\theta)=\mathcal{E}^\mu_{[bcd}(\theta)\,\delta\theta^\mu_{a]}+\partial_{[a}\Theta_{bcd]}(\theta,\delta\theta), \tag{2.30}$$

where

$$\mathcal{E}^\mu_{bcd}(\theta)=8\epsilon_{bcda}(\theta)(R^{a\mu}(\theta)-\tfrac{1}{2}\theta^{a\mu}R(\theta))=0 \tag{2.31}$$

are the vacuum Einstein field equations for θ^μ_a, and where

$$\Theta_{bcd}(\theta,\delta\theta)=8\epsilon_{abcd}(g)\,\theta^e_\nu\theta^a_\mu\delta\Gamma_e{}^{\mu\nu}(\theta) \tag{2.32}$$

is the symplectic potential three-form. It follows that the Noether current associated with ξ^a is given by the three-form

$$J_{abc}(\xi,\theta)=\Theta_{abc}(\theta,\mathcal{L}_\xi\theta)+4\xi^dL_{abcd}(\theta)=\epsilon_{abcd}(g)(8\,\theta^e_\mu\theta^d_\nu\mathcal{L}_\xi\Gamma_e{}^{\mu\nu}(\theta)+4\xi^dR(\theta)), \tag{2.33}$$

which simplifies to

$$J_{abc}(\xi;\theta)=3\partial_{[a}Q_{bc]}(\xi;\theta)-\xi^e\theta_{e\mu}\mathcal{E}^\mu_{abc}(\theta), \tag{2.34}$$

where

$$Q_{bc}(\xi;\theta)=4\xi^e\epsilon_{bcda}(g)\,\theta^d_\mu\theta^a_\nu\Gamma_e{}^{\mu\nu}(\theta) \tag{2.35}$$

is the Noether charge potential.

The gravitational Noether charge associated with $\partial\Sigma$ is determined by the pullback of $Q_{bc}(\xi;\theta)$. A simple expression for the pullback is obtained through identities (2.2) and (2.11), yielding

$$\epsilon^{bc}\xi^a\epsilon_{debc}(g)\,\theta^d_\mu\theta^e_\theta\Gamma_a{}^{\mu\nu}(\theta)=*\epsilon_{de}\theta^d_\mu\theta^e_\nu\xi^a\Gamma_a{}^{\mu\nu}(\theta)=4t_\mu s_\nu\xi^a\theta^{e\mu g}\nabla_a\theta^\nu_e=4\xi^as_\nu t^{e\,g}\nabla_a\theta^\nu_e, \tag{2.36}$$

where, recall, ϵ_{bc} is the volume form on $\partial\Sigma$. Hence, the surface integral

$$Q_\Sigma(\xi;\theta)=\int_{\partial\Sigma}Q_{bc}(\xi;\theta)=8\int_{\partial\Sigma}\epsilon_{bc}s_\nu t^e\xi^{a\,g}\nabla_a\theta^\nu_e \tag{2.37}$$

gives the gravitational Noether charge.

When ξ^a is not tangential to $\partial\Sigma$, the pullback of $\Theta_{bcd}(\theta,\delta\theta)$ to the hypersurface $\mathcal{B}$ can be simplified similarly by the identities (2.14) and (2.11) and the frame decomposition (2.24),

$$\begin{aligned}\tfrac{1}{8}\epsilon^{ab}\xi^c\Theta_{abc}(\theta,\delta\theta)&=\epsilon^{ab}\xi^c\epsilon_{abcd}(g)\,\theta^d_\mu\theta^e_\nu\delta\Gamma_e{}^{\nu\mu}(\theta)\\&=-2Ns_\mu\theta^e_\nu\delta(\theta^{c\nu g}\nabla_e\theta^\mu_c)\\&=-2Nh^e_\nu\delta(s_\mu h_e{}^d h^{c\nu g}\nabla_d\theta^\mu_c)\\&=\epsilon^{ab}\xi^c\epsilon_{abc}(h)h^e_\nu\delta K_e{}^\nu,\end{aligned} \tag{2.38}$$

where we define

$$K_a{}^\mu = s_\nu h_a{}^d h^{c\mu\, g} \nabla_d \theta_c^\nu . \tag{2.39}$$

(Note these expressions have the same form as those obtained in Ref. 1 when ξ^a is timelike.) Hence, one obtains

$$\mathcal{P}_{\mathcal{B}} \Theta_{abc}(\theta, \delta\theta) = 8\, \epsilon_{abc}(h) h_\nu^e \delta K_e{}^\nu . \tag{2.40}$$

This expression leads to a simple form for the gravitational symplectic flux associated with $\mathcal{B}$,

$$\begin{aligned} \int_{\mathcal{B}} \omega_{abc}(\theta, \delta_1\theta, \delta_2\theta) &= \int_{\mathcal{B}} \delta_1 \Theta_{abc}(\theta, \delta_2\theta) - \delta_2 \Theta_{abc}(\theta, \delta_1\theta) \\ &= 8 \int_{\mathcal{B}} \epsilon_{abc}(h) ((\delta_1 h_\mu^d - h_\mu^d h_e^\nu \delta_1 h_\nu^e)\, \delta_2 K_d{}^\mu \\ &\quad - (\delta_2 h_\mu^d - h_\mu^d h_e^\nu \delta_2 h_\nu^e)\, \delta_1 K_d{}^\mu). \end{aligned} \tag{2.41}$$

The vanishing of this flux determines the allowed boundary conditions on the frame θ_c^μ at the boundary hypersurface $\mathcal{B}$.

We remark that in a frame (2.26) adapted to $\partial\Sigma$, one sees that $K_a{}^\mu = h^{c\mu} h_a{}^{d\, g} \nabla_d s_c$ represents the frame components of the extrinsic curvature tensor $K_{ab} = h_a{}^d h_b{}^{c\, g} \nabla_d s_c$ of the boundary hypersurface $\mathcal{B}$. Moreover, the Noether charge (2.37) is simply $Q_\Sigma(\xi;\theta) = 8 \int_{\partial\Sigma} \epsilon_{bc} \xi^a t_\mu K_a{}^\mu = 8 \int_{\partial\Sigma} \epsilon_{bc} \xi^a t^e K_{ae}$.

For the sequel, we now introduce Dirichlet and Neumann symplectic vectors,

$$P_a^{\mathrm{D}}(\theta) = s_\nu t^c \sigma_a{}^{dg} \nabla_d \theta_c^\nu - s_\nu t_a \sigma^{bd\, g} \nabla_b \theta_d^\nu + t_\nu s_a \sigma^{bd\, g} \nabla_b \theta_d^\nu = \tfrac{1}{2} \epsilon^{bc} \epsilon_{acde} \theta_\mu^d \theta_\nu^e \Gamma_b{}^{\mu\nu}(\theta), \tag{2.42}$$

$$P_a^{\mathrm{N}}(\theta) = s_\nu t^{a\, g} \nabla_a \theta_c^\nu = \tfrac{1}{4} \epsilon^{bc} \epsilon_{bcde} \theta_\mu^d \theta_\nu^e \Gamma_a{}^{\mu\nu}(\theta), \tag{2.43}$$

associated with the boundary two-surface $\partial\Sigma$ and the frame θ_a^μ. In a frame (2.26) adapted to the hypersurface $\mathcal{B}$, these vectors take the more geometrical form

$$P_a^{\mathrm{D}}(\vartheta) = t^c \sigma_a{}^{d\, g} \nabla_d s_c - t_a \sigma^{bd\, g} \nabla_b s_d + s_a \sigma^{bd\, g} \nabla_b t_d , \tag{2.44}$$

$$P_a^{\mathrm{N}}(\vartheta) = t^{cg} \nabla_a s_c . \tag{2.45}$$

Similarly to the derivation in Ref. 1 holding for the situation when $\mathcal{B}$ is timelike, here the projection of the vectors (2.42) and (2.43) along ξ^a yields the respective boundary terms required to define a covariant Hamiltonian for the vacuum Einstein equations with ξ^a as the time-flow vector field in a space–time region with spatial boundary two-surface $\partial\Sigma$, subject to Dirichlet or Neumann boundary conditions on the frame θ_a^μ, for a timelike, spacelike, or null boundary hypersurface $\mathcal{B}$. The significance and properties of the full vectors (2.42) and (2.43) will be discussed in Sec. III.

Lastly, we make some remarks on the gauge invariance of the preceeding results, which follow from the detailed gauge transformation analysis given in Sec. 3 of Ref. 1. Under a local $SO(3,1)$ transformation on the frame θ_a^μ, the Noether charge $Q_{bc}(\xi;\theta)$ transforms inhomogeneously due to its explicit dependence on the frame connection. However, the curvature $R_{ab}{}^{\mu\nu}(\theta)$ is invariant, and consequently so is the Lagrangian $L_{abcd}(\theta)$. Therefore the symplectic current $\omega_{abc}(\theta, \delta_1\theta, \delta_2\theta)$ is necessarily gauge invariant. As a result, up to addition of a locally constructed exact two-form, the symplectic current obtained here for the frame formulation of the vacuum Einstein equations must agree with the analogous current derived from the standard metric formulation. This means that the presymplectic forms $\Omega_\Sigma(\theta, \delta\theta, \mathcal{L}_\xi\theta)$ and $\Omega_\Sigma(g, \delta g, \mathcal{L}_\xi g)$ in the two formulations differ by only a boundary term (i.e., a locally constructed two-form integrated over the two-surface $\partial\Sigma$). Correspondingly, the Dirichlet and Neumann symplectic vectors associated

with $\Omega_\Sigma(g,\delta g,\mathcal{L}_\xi g)$ in the metric formulation are found to be the same as the ones given here for the frame formulation, up to certain gradient terms. Furthermore, if ξ^a is timelike and orthogonal to $\partial\Sigma$, then these gradient terms can be shown to vanish. In this situation, $\xi^a P_a^{\mathrm{D}}(\vartheta)$ and $\xi^a P_a^{\mathrm{N}}(\vartheta)$ are precisely the Dirichlet and Neumann boundary terms in the covariant Hamiltonian determined by the metric formulation of the vacuum Einstein equations (see Ref. 2 for a discussion of this Hamiltonian). Consequently, as noted in Ref. 1, we find that the expression $\xi^a P_a^{\mathrm{D}}(\vartheta)$ reduces to the boundary term derived by Brown and York[3,4] in the standard canonical formalism, with Dirichlet boundary conditions on the canonical variables in the case of a hypersurface boundary $\mathcal{B}$ where ξ^a is timelike. In comparison, the covariant formulation we have presented here applies equally well when ξ^a is null or spacelike.

B. Electromagnetic field

We start by considering a free electromagnetic field A_a on (M,g_{ab}), coupled to the gravitational field, generalizing the Minkowski background space–time considered in Sec. 2 in Ref. 1. The Lagrangian four-form for A_a is given by

$$L_{abcd}(A;\theta)=\tfrac{1}{2}\epsilon_{abcd}(g)F_{mn}F^{mn}=3F_{[ab}{}^*F_{cd]}, \tag{2.46}$$

where $F_{ab}={}^g\nabla_{[a}A_{b]}=\partial_{[a}A_{b]}$ is the electromagnetic field strength and ${}^*F_{ab}=\epsilon_{abcd}(g)F^{cd}$ is the dual field strength in terms of $F^{cd}=g^{ca}g^{db}F_{bd}$, with $g_{ab}=\theta_a^\mu\theta_b^\nu\eta_{\mu\nu}$. A useful fact here is that ${}^g\nabla_a$ reduces to ∂_a in any skew derivative expression on M. By variation of A_a and θ_a^μ in this Lagrangian, one obtains

$$\delta L_{abcd}(A;\theta)=\epsilon_{abcd}(g)({}^g\nabla_m(\delta A_n F^{mn})-\delta A_n{}^g\nabla_m F^{mn}-T_\mu{}^e(A;\theta)\,\delta\theta_e^\mu), \tag{2.47}$$

where $T_\mu{}^e(A;\theta)\,\theta_e^\mu=T_d{}^e(A;g)$ is the electromagnetic stress–energy tensor given by

$$T_a{}^b(A;g)=2F_{ac}F^{bc}-\tfrac{1}{2}\delta_a^b F_{mn}F^{mn}. \tag{2.48}$$

From the coefficient of the variation δA_a in $\delta L_{abcd}(A;\theta)$, the field equation for A_a is given by the Maxwell equations

$${}^*\mathcal{E}_a(A;g)={}^g\nabla^b F_{ba}={}^g\nabla^b\partial_{[b}A_{a]}=0. \tag{2.49}$$

The symplectic potential three-form obtained from $L_{abcd}(A;\theta)$ is given by the total derivative term in Eq. (2.47), which yields

$$\Theta_{bcd}(A,\delta A;\theta)=4\epsilon_{abcd}(g)\,\delta A_e F^{ae}. \tag{2.50}$$

Hence, the Noether current associated with ξ^a for A_a is given by the three-form

$$\begin{aligned}J_{abc}(\xi,A;g)&=\Theta_{abc}(A,\mathcal{L}_\xi A;\theta)+4\xi^d L_{abcd}(A;\theta)\\&=\epsilon_{abcd}(g)(-4F^{de}\mathcal{L}_\xi A_e+2\xi^d F_{mn}F^{mn})\\&=4\epsilon_{dabc}(g)(\xi^e T_e{}^d(A;g)+\xi^e A_e{}^*\mathcal{E}^d(A;g))+6\partial_{[a}({}^*F_{bc]}\xi^e A_e)\end{aligned} \tag{2.51}$$

by a similar derivation as in Minkowski space–time, with

$$\mathcal{L}_\xi A_a=\xi^{eg}\nabla_e A_a+A_e{}^g\nabla_a\xi^e=2\xi^{eg}\nabla_{[e}A_{a]}+{}^g\nabla_a(\xi^e A_e). \tag{2.52}$$

This yields the electromagnetic Noether charge

$$Q_\Sigma(\xi;A)=\int_\Sigma J_{abc}(\xi,A;g)=4\int_\Sigma\xi^e\epsilon_{dabc}(g)T_e{}^d(A;g)+2\int_{\partial\Sigma}\epsilon_{bcda}F^{da}\xi^e A_e \tag{2.53}$$

for solutions A_a of the Maxwell equations (2.49).

The total Lagrangian for the Maxwell equations coupled to the Einstein equations

$$R_\mu{}^a(\theta)-\tfrac{1}{2}\theta^\mu_a R(\theta)=T_\mu{}^a(A;\theta) \tag{2.54}$$

using the field variables A_a and θ^μ_a is given by $L_{abcd}(\theta,A)=L_{abcd}(\theta)-L_{abcd}(A;\theta)$ from Eqs. (2.27) and (2.46). One then obtains the total Noether current

$$\begin{aligned} J_{abc}(\xi,\theta,A)&=J_{abc}(\xi,\theta)-J_{abc}(\xi,A;\theta)\\ &=8\epsilon_{dabc}(g)\xi^e\theta^\mu_e(R_\mu{}^d(\theta)-\tfrac{1}{2}\theta^d_\mu R(\theta)-T_\mu{}^d(A;\theta))+3\partial_{[a}Q_{bc]}(\xi,\theta,A), \end{aligned} \tag{2.55}$$

where

$$Q_{bc}(\xi,\theta,A)=\xi^a\epsilon_{bcde}(g)(4\theta^d_\mu\theta^e_\nu\Gamma_a{}^{\mu\nu}(\theta)-2F^{de}A_a) \tag{2.56}$$

is the Noether charge potential. Hence, on solutions of the coupled Einstein–Maxwell equations, the total Noether charge is given by the surface integral

$$Q_\Sigma(\xi;\theta,A)=\int_{\partial\Sigma}Q_{bc}(\xi,\theta,A). \tag{2.57}$$

The electromagnetic part of this expression simplifies through identities (2.2) and (2.11), yielding

$$\epsilon^{bc}{*}F_{bc}\xi^dA_d={*}\epsilon_{bc}F^{bc}\xi^dA_d=4t_bs_cF^{bc}\xi^dA_d\,. \tag{2.58}$$

Then, substituting Eq. (2.36) for the gravitational part, one obtains

$$Q_\Sigma(\xi;\theta,A)=\int_{\partial\Sigma}\epsilon_{bc}\xi^a(8s_\nu t^{eg}\nabla_a\theta^\nu_e-4t_ds_eF^{de}A_a). \tag{2.59}$$

The Noether current gives a Hamiltonian conjugate to ξ^a on Σ under compact support variations $\delta\theta^\mu_a$ and δA_a,

$$H(\xi;\theta,A)=8\int_\Sigma\epsilon_{dabc}(g)\xi^e\theta^\mu_e(R_\mu{}^d(\theta)-\tfrac{1}{2}\theta^d_\mu R(\theta)-T_\mu{}^d(A;\theta)) \tag{2.60}$$

up to a boundary term (2.59). For variations $\delta\theta^\mu_a$ and δA_a with support on $\partial\Sigma$, after taking into account boundary terms, one has

$$\delta H(\xi;\theta,A)=\int_{\partial\Sigma}\delta Q_{ab}(\xi,\theta,A)-\xi^c\Theta_{abc}(\theta,A,\delta\theta,\delta A) \tag{2.61}$$

for Einstein–Maxwell solutions, where

$$\Theta_{abc}(\theta,A,\delta\theta,\delta A)=\Theta_{abc}(\theta,\delta\theta)-\Theta_{abc}(A,\delta A;\theta)=\epsilon_{dabc}(g)(8\theta^d_\mu\theta^e_\nu\delta\Gamma_e{}^{\mu\nu}(\theta)-4F^{de}dA_e) \tag{2.62}$$

is the total symplectic potential three-form from Eqs. (2.32) and (2.50). The electromagnetic part of the symplectic potential terms in the Hamiltonian variation (2.61) can be simplified similarly to expression (2.38) for the gravitational part, yielding

$$\tfrac{1}{4}\epsilon^{ab}\xi^c\Theta_{abc}(A,\delta A;\theta)=\epsilon^{ab}\xi^c\epsilon_{dabc}(g)F^{de}\delta A_e=2Ns_dF^{de}\delta A_e=-\epsilon^{ab}\xi^c\epsilon_{abc}(h)s_dF^{de}\delta A_e \tag{2.63}$$

through identities (2.14) and (2.15). Thus, one obtains

$$\mathcal{P}_{\partial\Sigma}(\xi^c\Theta_{abc}(\theta,A,\delta\theta,\delta A))=\mathcal{P}_{\partial\Sigma}(\xi^c\epsilon_{abc}(h)(8h^e_\nu\delta K_e{}^\nu+4s_dF^{de}\delta A_e))$$
$$=-N\epsilon_{ab}(8h^e_\nu\delta K_e{}^\nu+4s_dF^{de}\delta A_e). \tag{2.64}$$

Hence, for the existence of a Hamiltonian conjugate to ξ^a on Σ, there must exist a locally constructed three-form $\tilde{B}_{abc}(\theta,A)$ such that

$$\mathcal{P}_{\partial\Sigma}(\xi^c\Theta_{abc}(\theta,A,\delta\theta,\delta A))=\mathcal{P}_{\partial\Sigma}(\xi^c\delta\tilde{B}_{abc}(\theta,A)-\partial_{[a}\alpha_{b]}(\xi,\theta,\delta\theta,\delta A)) \tag{2.65}$$

for some locally constructed one-form $\alpha_b(\xi,\theta,A,\delta\theta,\delta A)$ in $T^*(\partial\Sigma)$. Then the total Hamiltonian is given by $H(\xi;\theta,A)$ plus a boundary term

$$H_B(\xi;\theta,A)=\int_{\partial\Sigma}Q_{ab}(\xi,\theta,A)-\xi^c\tilde{B}_{abc}(\theta,A). \tag{2.66}$$

We now consider Dirichlet and Neumann type boundary conditions on the fields θ^μ_a and A_a at $\partial\Sigma$.

First, consider the case when ξ^a is tangential to $\partial\Sigma$. Then one finds $\mathcal{P}_{\partial\Sigma}(\xi^c\Theta_{abc}(\theta,A,\delta\theta,\delta A))=0$, which leads to the following result.

Proposition 2.1: Suppose ξ^a is tangential to $\partial\Sigma$. Then no *boundary conditions are necessary for existence of a Hamiltonian conjugate to ξ^a on Σ. Consequently, a Hamiltonian is given by $H_\Sigma(\xi;\theta,A)=H(\xi;\theta,A)+Q_\Sigma(\theta,A)$.*

Next, assume ξ^a is not tangential to $\partial\Sigma$, and consider Dirichlet and Neumann boundary conditions on the electromagnetic and gravitational field variables.

Theorem 2.2: *Suppose ξ^a is nowhere tangential to $\partial\Sigma$. Let*

$$\text{(D)}\quad \delta(h_a{}^bA_b)|_{\partial\Sigma}=0,\quad \delta(h^\mu_a)|_{\partial\Sigma}=0, \tag{2.67}$$

$$\text{(N)}\quad \delta(|h|s_bh_c{}^aF^{cb})|_{\partial\Sigma}=0,\quad \delta(K_a{}^\mu)|_{\partial\Sigma}=0, \tag{2.68}$$

where $|h|=\det(h^\mu_a)$ is the determinant of the components of the frame h^μ_a associated with $\mathcal{B}$. Under Dirichlet (D) or Neumann (N) boundary conditions for both A_a and θ^μ_a, there exists a Hamiltonian $H(\xi;\theta,A)+H_B(\xi;\theta,A)$ conjugate to ξ^a on Σ, with the boundary term (2.66) given by

$$H^{\mathrm{D}}(\xi;\theta,A)=8\int_{\partial\Sigma}\xi^a(P^{\mathrm{D}}_a(\theta)-\tfrac{1}{2}t_ds_eF^{de}A_a)\mathrm{d}S, \tag{2.69}$$

$$H^{\mathrm{N}}(\xi;\theta,A)=8\int_{\partial\Sigma}\xi^a(P^{\mathrm{N}}_a(\theta)-\sigma_{[a}{}^ct_{d]}s_eF^{de}A_c)\mathrm{d}S, \tag{2.70}$$

in terms of the Dirichlet and Neumann symplectic vectors (2.42) and (2.43).

Proof: For case (D), first note from Eq. (2.63) that $\epsilon^{bc}\xi^a\Theta_{abc}(A,\delta A;\theta)=8Ns_dF^{de}h_e{}^c\delta A_c$. Now, using the boundary condition (D) on δA_a, one has

$$h_e{}^c\delta A_c=h_e{}^c\delta(s_cs^{*b}A_b)=s^{*b}A_bh_e{}^c\delta s_c=0 \tag{2.71}$$

by the hypersurface orthogonality relations (2.7) and (2.23). Thus,

$$\mathcal{P}_{\partial\Sigma}(\xi^a\Theta_{abc}(A,\delta A;\theta))=0. \tag{2.72}$$

Then, in Eq. (2.38), since $\delta\epsilon_{abc}(h)=\delta\epsilon_{bc}=0$ by the boundary condition (D) on $\delta\theta^\mu_a$, one has

$$\epsilon^{bc}\xi^a\Theta_{abc}(\theta,\delta\theta)=\epsilon^{bc}\delta(8\xi^a\epsilon_{abc}(h)K) \tag{2.73}$$

and thus,

$$\mathcal{P}_{\partial\Sigma}(\xi^a\Theta_{abc}(\theta,\delta\theta)-\delta(8\xi^a\epsilon_{abc}(h)K))=0, \tag{2.74}$$

where $K=h^e_\nu K_e{}^\nu$. Hence, substitution of Eqs. (2.72) and (2.74) into Eq. (2.65) yields

$$\xi^a\tilde{B}_{abc}(\theta,A)=8\xi^a\epsilon_{abc}(h)K \tag{2.75}$$

and $\alpha_b=0$. This leads to the boundary term (2.69) through Eq. (2.66) as follows. The pullback of $\xi^a\tilde{B}_{abc}(\theta,A)$ to $\partial\Sigma$ is given by

$$8\xi^a\epsilon^{bc}\epsilon_{abc}(h)K=8\xi^a t_a s_\nu h_d{}^e{}^g\nabla_e\theta^{d\nu}=16\xi^a t_a s_\nu h_d{}^e{}^g\nabla_e\theta^{d\nu}, \tag{2.76}$$

which, when combined with expression (2.36) for the pullback of $Q_{bc}(\xi,\theta)$, yields

$$\begin{aligned}\epsilon^{bc}(Q_{bc}(\xi,\theta)-\xi^a\tilde{B}_{abc}(\theta,A))&=16\xi^a(s_\nu t^e{}^g\nabla_a\theta^\nu_e-t_a s_\nu h_d{}^e{}^g\nabla_e\theta^{d\nu})\\&=16\xi^a s_\nu(t^d\sigma_a{}^e-t_a\sigma^{de})^g\nabla_e\theta^\nu_d=16\xi^a P^{\mathrm{D}}_a(\theta)\end{aligned} \tag{2.77}$$

by the metric decompositions (2.6) and (2.9) and the orthogonality $\xi^a s_a=0$. Finally, combining this expression with the pullback of $Q_{bc}(\xi,A)$ given by Eq. (2.58), we obtain Eq. (2.69).

For case (N), one has from Eq. (2.63) that

$$\epsilon^{bc}\xi^a\Theta_{abc}(A,\delta A;\theta)=\epsilon^{bc}\delta(4\xi^a\epsilon_{abc}(h)s_e A_d F^{de})+4\epsilon^{bc}A_e\xi^a\delta(\epsilon_{abc}(h)s_d F^{de}). \tag{2.78}$$

Now, since

$$\delta(\epsilon_{abc}(h)s_d F^{de})=\epsilon_{abc}(h)(\delta(s_d h_m{}^e F^{dm})+\delta\ln|h|s_d h_m{}^e F^{dm}), \tag{2.79}$$

this term vanishes by boundary condition (N) for δF^{ab}, and thus

$$\mathcal{P}_{\partial\Sigma}(\xi^a\Theta_{abc}(A,\delta A;\theta)-\delta(4\xi^a\epsilon_{abc}(h)s_e A_d F^{de}))=0. \tag{2.80}$$

Next, $\mathcal{P}_{\partial\Sigma}(\xi^a\Theta_{abc}(\theta,\delta\theta))=0$ holds immediately by boundary condition (N) for $\delta K_a{}^\mu$. Hence, from Eqs. (2.65) and (2.80), one has $\alpha_b=0$ and

$$\xi^a\tilde{B}_{abc}(\theta,A)=4\xi^a\epsilon_{abc}(h)s_e A_d F^{de}. \tag{2.81}$$

Then this leads to the boundary term (2.70) through Eq. (2.66) similarly to the derivation of the boundary term (2.69) above. □

C. Klein–Gordon scalar field

We next consider a free Klein–Gordon scalar field φ coupled to the gravitational field on (M,g_{ab}), with the standard Lagrangian four-form given by

$$L_{abcd}(\varphi;\theta)=\tfrac{1}{2}\epsilon_{abcd}(g)({}^g\nabla_e\varphi{}^g\nabla^e\varphi+m^2\varphi^2), \tag{2.82}$$

where $m=$const is the mass. Note, here ${}^g\nabla_a\varphi=\partial_a\varphi$, ${}^g\nabla^a\varphi=g^{ab}\partial_b\varphi$, and $g_{ab}=\theta^\mu_a\theta^\nu_b\eta_{\mu\nu}$. A variation of this Lagrangian with respect to φ and θ^μ_a yields

$$\delta L_{abcd}(\varphi;\theta)=\epsilon_{abcd}(g)({}^g\nabla_e(\delta\varphi{}^g\nabla^e\varphi)-\delta\varphi({}^g\nabla^e{}^g\nabla_e\varphi-m^2\varphi)-T_\mu{}^e(\varphi;\theta)\delta\theta^\mu_e), \tag{2.83}$$

where $T_\mu{}^e(\varphi;\theta)\theta^\mu_e=T_d{}^e(\varphi;g)$ is the Klein–Gordon stress–energy tensor given by

$$T_a{}^b(\varphi;g)={}^g\nabla^b\varphi{}^g\nabla_a\varphi-\tfrac{1}{2}\delta^b_a({}^g\nabla_e\varphi{}^g\nabla^e\varphi+m^2\varphi^2). \tag{2.84}$$

Hence, from the coefficient of the variation $\delta\varphi$ in Eq. (2.83), the Klein–Gordon field equation for φ is given by

$$*\mathcal{E}(\varphi;g) = {}^g\nabla^a\partial_a\varphi - m^2\varphi = 0. \tag{2.85}$$

The symplectic potential three-form obtained from $L_{abcd}(\varphi;\theta)$ is given by

$$\Theta_{bcd}(\varphi,\delta\varphi;\theta) = 4\epsilon_{abcd}(g)\,{}^g\nabla^a\varphi\,\delta\varphi. \tag{2.86}$$

This yields the Noether current associated with ξ^a,

$$\begin{aligned} J_{abc}(\xi,\varphi;g) &= \Theta_{abc}(\varphi,\mathcal{L}_\xi\varphi;\theta) + 4\xi^d L_{abcd}(\varphi;\theta) \\ &= \epsilon_{abcd}(g)(-4\,{}^g\nabla^d\varphi\,\mathcal{L}_\xi\varphi + 2\xi^d({}^g\nabla_e\varphi\,{}^g\nabla^e\varphi + m^2\varphi^2) \\ &= 4\epsilon_{dabc}(g)\xi^e T_e{}^d(\varphi;g), \end{aligned} \tag{2.87}$$

where $\mathcal{L}_\xi\varphi = \xi^e\,{}^g\nabla_e\varphi = \xi^e\partial_e\varphi$. Hence, one obtains the Noether charge

$$Q_\Sigma(\xi;\varphi) = \int_\Sigma J_{abc}(\xi,\varphi;g) = 4\int_\Sigma \epsilon_{dabc}(g)\xi^e T_e{}^d(\varphi;g). \tag{2.88}$$

In contrast to the situation for the electromagnetic field, here, due to the scalar nature of the Klein–Gordon field, the Noether charge does not have a surface integral term.

The total Lagrangian for the Klein–Gordon equation coupled to the Einstein equations

$$R_\mu{}^a(\theta) - \tfrac{1}{2}\theta_a^\mu R(\theta) = T_\mu{}^a(\varphi;\theta) \tag{2.89}$$

using the field variables φ and θ_a^μ is obtained through Eqs. (2.27) and (2.82) by $L_{abcd}(\theta,\varphi) = L_{abcd}(\theta) - L_{abcd}(\varphi;\theta)$. The resulting total Noether current is given by

$$\begin{aligned} J_{abc}(\xi,\theta,\varphi) &= J_{abc}(\xi,\theta) - J_{abc}(\xi,\varphi;\theta) \\ &= 8\epsilon_{dabc}(g)\xi^e\theta_e^\mu(R_\mu{}^d(\theta) - \tfrac{1}{2}\theta_\mu^d R(\theta) - T_\mu{}^d(\varphi;\theta)) + 3\partial_{[a}Q_{bc]}(\xi,\theta), \end{aligned} \tag{2.90}$$

where $Q_{bc}(\xi,\theta)$ is the gravitational Noether charge potential (2.35). Thus, there is no contribution from φ to the total Noether charge.

The Noether current gives a Hamiltonian conjugate to ξ^a on Σ under compact support variations $\delta\theta_a^\mu$ and $\delta\varphi$,

$$H(\xi;\theta,\varphi) = 8\int_\Sigma \epsilon_{dabc}(g)\xi^e\theta_e^\mu(R_\mu{}^d(\theta) - \tfrac{1}{2}\theta_\mu^d R(\theta) - T_\mu{}^d(\varphi;\theta)) \tag{2.91}$$

up to a boundary term $\int_{\partial\Sigma} Q_{ab}(\xi,\theta)$. For variations $\delta\theta_a^\mu$ and $\delta\varphi$ with support on $\partial\Sigma$, one has for Einstein–Klein–Gordon solutions,

$$\delta H(\xi;\theta,\varphi) = \int_{\partial\Sigma} \delta Q_{ab}(\xi,\theta) - \xi^c\Theta_{abc}(\theta,\delta\theta), \tag{2.92}$$

where $\Theta_{abc}(\theta,\delta\theta)$ is the expression (2.38) for the gravitational symplectic potential. Thus, there exists a Hamiltonian conjugate to ξ^a on Σ if

$$\mathcal{P}_{\partial\Sigma}(\xi^c\Theta_{abc}(\theta,\varphi,\delta\theta,\delta\varphi)) = \mathcal{P}_{\partial\Sigma}(\xi^c\delta\tilde{B}_{abc}(\theta,\varphi) - \partial_{[a}\alpha_{b]}(\xi,\theta,\varphi,\delta\theta,\delta\varphi)) \tag{2.93}$$

holds for a locally constructed three-form $\tilde{B}_{abc}(\theta,\varphi)$ and one-form $\alpha_b(\xi,\theta,\varphi,\delta\theta,\delta\varphi)$. Then the total Hamiltonian is given by $H(\xi;\theta,\varphi)$ plus a boundary term

$$H_B(\xi;\theta,\varphi)=\int_{\partial\Sigma} Q_{ab}(\xi,\theta)-\xi^c\tilde{B}_{abc}(\theta,\varphi). \tag{2.94}$$

Now, by an analysis similar to that for the Einstein–Maxwell equations, we obtain the following results.

Proposition 2.3: Suppose ξ^a *is tangential to* $\partial\Sigma$. *Then* no *boundary conditions are necessary for existence of a Hamiltonian conjugate to* ξ^a *on* Σ. *Consequently, a Hamiltonian is given by* $H_\Sigma(\xi;\theta,\varphi)=H(\xi;\theta,\varphi)+Q_\Sigma(\theta)$.

Theorem 2.4: *Suppose* ξ^a *is nowhere tangential to* $\partial\Sigma$. *Let*

$$\text{(D)}\quad \delta(\varphi)|_{\partial\Sigma}=0,\quad \delta(h_a^\mu)|_{\partial\Sigma}=0, \tag{2.95}$$

$$\text{(N)}\quad \delta(|h|s^a\partial_a\varphi)|_{\partial\Sigma}=0,\quad \delta(K_a{}^\mu)|_{\partial\Sigma}=0, \tag{2.96}$$

where $|h|=\det(h_a^\mu)$ *is the determinant of the components of the frame* h_a^μ *associated with* $\mathcal{B}$. *Under Dirichlet (D) or Neumann (N) boundary conditions for both* φ *and* θ_a^μ, *there exists a Hamiltonian* $H(\xi;\theta,\varphi)+H_B(\xi;\theta,\varphi)$ *conjugate to* ξ^a *on* Σ, *with the boundary term (2.94) given by*

$$H^{\mathrm{D}}(\xi;\theta,\varphi)=8\int_{\partial\Sigma}\xi^a P_a^{\mathrm{D}}(\theta)\mathrm{d}S, \tag{2.97}$$

$$H^{\mathrm{N}}(\xi;\theta,\varphi)=8\int_{\partial\Sigma}\xi^a(P_a^{\mathrm{N}}(\theta)-\tfrac{1}{2}t_a\varphi s^d\partial_d\varphi)\mathrm{d}S, \tag{2.98}$$

in terms of the Dirichlet and Neumann symplectic vectors (2.42) and (2.43).

D. Yang–Mills and Higgs fields

Last, we generalize the previous two examples by considering on (M,g_{ab}) a set of Yang–Mills fields A_a^{Υ} and Higgs fields φ^{Υ}, $\Upsilon=1,\ldots,n$, with a gauge group given by any n-dimensional semi-simple Lie group $\mathcal{G}$, $n\geqslant 3$. Let $C_{\Delta\Lambda}{}^{\Upsilon}$ be the commutator structure constants of the Lie algebra $\mathcal{A}$ of $\mathcal{G}$ (in a fixed basis). The structure constants are skew $C_{\Delta\Lambda}{}^{\Upsilon}=-C_{\Lambda\Delta}{}^{\Upsilon}$ and satisfy the Jacobi relation $C_{[\Delta\Lambda}{}^{\Upsilon}C_{\Pi]\Upsilon}{}^{\Phi}=0$. Let $\Gamma_{a\Delta}^{\Upsilon}(A)=C_{\Lambda\Delta}{}^{\Upsilon}A_a^{\Lambda}$ be the Yang–Mills connection, and define $k_{\Delta\Upsilon}=-1/2C_{\Delta\Lambda}{}^{\Pi}C_{\Upsilon\Pi}{}^{\Lambda}$, which denotes the positive definite Cartan–Killing metric on $\mathcal{A}$.

The Yang–Mills Lagrangian for A_a^{Υ} is given by the four-form

$$L_{abcd}(A;\theta)=\tfrac{1}{2}\epsilon_{abcd}(g)k_{\Lambda\Upsilon}F_{mn}^{\Lambda}F^{\Upsilon mn}=3k_{\Lambda\Upsilon}F_{[ab}^{\Lambda}{}^*F_{cd]}^{\Upsilon}, \tag{2.99}$$

where

$$F_{ab}^{\Lambda}={}^g\nabla_{[a}A_{b]}^{\Lambda}+\tfrac{1}{2}C_{\Delta\Upsilon}{}^{\Lambda}A_a^{\Delta}A_b^{\Upsilon} \tag{2.100}$$

is the Yang–Mills field strength, ${}^*F_{ab}^{\Lambda}=\epsilon_{abcd}(g)F^{\Lambda cd}$ is the dual field strength in terms of $F^{\Lambda cd}=g^{ca}g^{db}F_{bd}^{\Lambda}$, with $g_{ab}=\theta_a^\mu\theta_b^\nu\eta_{\mu\nu}$. For φ^{Υ}, it is convenient to introduce the gauge-covariant Higgs field strength

$$W_a^{\Lambda}={}^g\nabla_a\varphi^{\Lambda}+e\Gamma_{a\Upsilon}^{\Lambda}(A)\varphi^{\Upsilon}. \tag{2.101}$$

In terms of this field strength the Higgs Lagrangian is given by the four-form

$$L_{abcd}(\varphi;\theta)=\epsilon_{abcd}(g)(\tfrac{1}{2}k_{\Lambda\Upsilon}W_m^{\Lambda}W^{m\Upsilon}+V(|\varphi|)), \tag{2.102}$$

where $V(|\varphi|)$ is a Higgs potential with $|\varphi|^2=k_{\Lambda\Upsilon}\varphi^{\Lambda}\varphi^{\Upsilon}$, and $e=\text{const}$ is a coupling constant. These Lagrangians are gauge invariant under Yang–Mills gauge symmetries on the fields A_a^{Υ} and

φ^{Υ}. (In particular, if ${U^{\Upsilon}}_{\Lambda}$ denotes a homomorphism of $\mathcal{A}$ given by a function of the space–time coordinates x^{μ}, it is straightforward to show that the Yang–Mills gauge symmetry is then given by $A_a^{\Upsilon} \to {U^{-1\Upsilon}}_{\Lambda} A_a^{\Lambda} - {C^{*\Upsilon\Delta}}_{\Lambda} {U^{-1\Lambda}}_{\Pi} \partial_a {U^{\Pi}}_{\Delta}$ and $\varphi^{\Upsilon} \to {U^{-1\Upsilon}}_{\Lambda} \varphi^{\Lambda}$, where ${C^{*\Upsilon\Delta}}_{\Lambda} = k^{\Upsilon\Pi} C_{\Lambda\Pi}{}^{\Delta}$ denotes the structure constants of the dual Lie algebra $\mathcal{A}^*$ and $k^{\Upsilon\Pi}$ is the inverse of the Cartan–Killing metric. Under these transformations, the field strengths are gauge covariant, $F_{ab}^{\Upsilon} \to {U^{-1\Upsilon}}_{\Lambda} F_{ab}^{\Lambda}$ and $W_a^{\Upsilon} \to {U^{-1\Upsilon}}_{\Lambda} W_a^{\Lambda}$.)

To proceed, we consider the combined Yang–Mills–Higgs Lagrangian,

$$L_{abcd}(A,\varphi;\theta) = L_{abcd}(A;\theta) + L_{abcd}(\varphi;\theta). \tag{2.103}$$

First, the coefficient of the variation δA_a^{Υ} yields the Yang–Mills field equations

$$k^{\Upsilon\Lambda} {}^*\mathcal{E}_{a\Upsilon}(A;g) = {}^g\nabla^b F_{ba}^{\Lambda} + \Gamma^{b\Lambda}{}_{\Upsilon}(A) F_{ba}^{\Upsilon} - e C_{\Pi\Upsilon}{}^{\Lambda} \varphi^{\Pi} W_a^{\Upsilon} = 0, \tag{2.104}$$

where $e C_{\Pi\Upsilon}{}^{\Lambda} \varphi^{\Pi} W_a^{\Upsilon}$ has the role of a current source. The coefficient of the variation $\delta\varphi^{\Upsilon}$ similarly yields the Higgs field equations

$$k^{\Upsilon\Lambda} {}^*\mathcal{E}_{\Upsilon}(A;g) = {}^g\nabla^a W_a^{\Lambda} + \Gamma^{a\Lambda}{}_{\Upsilon}(A) W_a^{\Upsilon} - \frac{1}{|\varphi|} V'(|\varphi|) \varphi^{\Lambda} = 0. \tag{2.105}$$

Next, by variation of θ_a^{μ}, one obtains the Yang–Mills–Higgs stress–energy tensor ${T_{\mu}}^{e}(A,\varphi;\theta)\theta_e^{\mu} = {T_d}^{e}(A,\varphi;g)$ where

$${T_a}^{b}(A,\varphi;g) = k_{\Lambda\Upsilon}(2F_{ac}^{\Lambda} F^{\Upsilon bc} + W_a^{\Lambda} W^{\Upsilon b}) - \tfrac{1}{2}\delta_a^b k_{\Lambda\Upsilon}(F_{mn}^{\Lambda} F^{\Upsilon mn} + W_m^{\Lambda} W^{m\Upsilon}) - \delta_a^b V(|\varphi|). \tag{2.106}$$

The symplectic potential three-form arising from the Lagrangian (2.103) is given by

$$\Theta_{bcd}(A,\varphi,\delta A,\varphi;\theta) = 4\epsilon_{abcd}(g) k_{\Lambda\Upsilon}(\delta A_e^{\Lambda} F^{\Upsilon ae} + \delta\varphi^{\Lambda} W^{\Upsilon a}). \tag{2.107}$$

This yields the Noether current

$$\begin{aligned} J_{abc}(\xi,A,\varphi;g) &= \Theta_{abc}(A,\varphi,\mathcal{L}_{\xi}A,\mathcal{L}_{\xi}\varphi;\theta) + 4\xi^d L_{abcd}(A,\varphi;\theta) \\ &= \epsilon_{abcd}(g)(k_{\Lambda\Upsilon}(-4F^{\Lambda de}\mathcal{L}_{\xi}A_e^{\Upsilon} + \xi^d 2F_{mn}^{\Lambda} F^{\Upsilon mn}) \\ &\quad + k_{\Lambda\Upsilon}(-4W^{\Lambda d}\mathcal{L}_{\xi}\varphi^{\Upsilon} + 2W_m^{\Lambda} W^{m\Upsilon})) + 4V(|\varphi|)) \\ &= 4\epsilon_{dabc}(g)(\xi^e {T_e}^{d}(A,\varphi;g) + 6\partial_{[a}(k_{\Lambda\Upsilon} {}^*F_{bc]}^{\Lambda} \xi^e A_e^{\Upsilon}) \end{aligned} \tag{2.108}$$

for Yang–Mills–Higgs solutions. Hence, one obtains the Noether charge

$$Q_{\Sigma}(\xi;A,\varphi) = \int_{\Sigma} J_{abc}(\xi,A,\varphi;g) = 4\int_{\Sigma} \xi^e \epsilon_{dabc}(g) {T_e}^{d}(A,\varphi;g) + 2\int_{\partial\Sigma} k_{\Lambda\Upsilon}\epsilon_{bcda} F^{\Lambda da}\xi^e A_e^{\Upsilon}. \tag{2.109}$$

For the Yang–Mills–Higgs equations coupled to the Einstein equations

$$R_{\mu}^{a}(\theta) - \tfrac{1}{2}\theta_a^{\mu} R(\theta) = {T_{\mu}}^{a}(A,\varphi;\theta) \tag{2.110}$$

using the field variables A_a^{Υ}, φ^{Υ}, θ_a^{μ}, the total Lagrangian is given by $L_{abcd}(\theta,A,\varphi) = L_{abcd}(\theta) - L_{abcd}(A,\varphi;\theta)$ from Eqs. (2.27) and (2.103).

Through the same analysis as used in the Maxwell and Klein–Gordon examples, we obtain the following results.

Proposition 2.5: Suppose ξ^a is tangential to $\partial\Sigma$. Then no *boundary conditions are necessary for existence of a Hamiltonian conjugate to ξ^a on Σ. Consequently, a Hamiltonian is given by*

$$H(\xi;\theta,A,\varphi)=8\int_\Sigma \epsilon_{dabc}(g)\xi^e\theta^\mu_e(R_\mu{}^d(\theta)-\tfrac{1}{2}\theta^d_\mu R(\theta)-T_\mu{}^d(A,\varphi;\theta)) \tag{2.111}$$

up to an unessential boundary term.

Theorem 2.6: *Suppose ξ^a is nowhere tangential to $\partial\Sigma$. Let*

$$\text{(D)}\quad \delta(A^{\mathrm{Y}}_a)|_{\partial\Sigma}=0,\quad \delta(\varphi^{\mathrm{Y}})|_{\partial\Sigma}=0,\quad \delta(h^\mu_a)|_{\partial\Sigma}=0, \tag{2.112}$$

$$\text{(N)}\quad \delta(|h|s_b h_c{}^a F^{\mathrm{Y}cb})|_{\partial\Sigma}=0,\quad \delta(|h|s^a W^{\mathrm{Y}}_a)|_{\partial\Sigma}=0,\quad \delta(K_a{}^\mu)|_{\partial\Sigma}=0, \tag{2.113}$$

where $|h|=\det(h^\mu_a)$ is the determinant of the components of the frame h^μ_a associated with $\mathcal{B}$. Under Dirichlet (D) or Neumann (N) boundary conditions for both φ and θ^μ_a, there exists a Hamiltonian $H(\xi;\theta,A,\varphi)+H_B(\xi,\theta,A,\varphi)$ conjugate to ξ^a on Σ, with the boundary term given by

$$H^{\mathrm{D}}(\xi;\theta,A,\varphi)=8\int_{\partial\Sigma}\xi^a(P^{\mathrm{D}}_a(\theta)-P^{\mathrm{D}}_a(A))\mathrm{d}S, \tag{2.114}$$

$$H^{\mathrm{N}}(\xi;\theta,A,\varphi)=8\int_{\partial\Sigma}\xi^a(P^{\mathrm{N}}_a(\theta)-P^{\mathrm{N}}_a(A,\varphi))\mathrm{d},S, \tag{2.115}$$

where

$$P^{\mathrm{D}}_a(A)=\tfrac{1}{2}k_{\Lambda\mathrm{Y}}t_d s_e F^{\mathrm{Y}de}A^\Lambda_a, \tag{2.116}$$

$$P^{\mathrm{N}}_a(A,\varphi)=k_{\Lambda\mathrm{Y}}(\sigma_{[a}{}^c t_{d]}s_e F^{\mathrm{Y}de}A^\Lambda_c+\tfrac{1}{2}t_a s^d W^{\mathrm{Y}}_d\varphi^\Lambda), \tag{2.117}$$

and $P^{\mathrm{D}}_a(\theta)$, $P^{\mathrm{N}}_a(\theta)$ are the symplectic vectors given by (2.42) *and* (2.43).

E. Remarks

Clearly, the previous results when ξ^a is not tangential to $\partial\Sigma$ are easily generalized to mixed Dirichlet–Neumann boundary conditions on the tetrad and matter fields similar to Theorem 2.3 and Theorems 3.5 and 3.6 in Ref. 1. In particular, for allowed boundary conditions, note that one can have the tetrad satisfying (D) while the matter fields satisfy (N), and vice versa.

III. PROPERTIES OF THE SYMPLECTIC VECTORS

We first review some geometry of spatial two-surfaces in space–time (most of this material is standard, e.g., Ref. 5–8). Then we describe the properties of the Dirichlet and Neumann symplectic vectors regarded as locally constructed geometrical vector fields associated with a fixed spatial two-surface in space–time, independent of any Hamiltonian structure.

A. Two-surface geometry

Let (S,σ_{ab}) be a closed, orientable, smooth spacelike two-surface in a space–time (M,g_{ab}), where σ_{ab} is the pullback of g_{ab} to S. Let $T(S)$ and $T(S)^\perp$ denote, respectively, the tangent space of S and the normal space to S [defined by the orthogonal complement of $T(S)$ in $T(M)$]. Since $T(S)\oplus T(S)^\perp=T(M)$, every vector in $T(M)$ has a unique decomposition into vectors tangent and normal to $T(S)$, given by projection operators $\mathcal{P}_S:T(M)\to T(S)$, $\mathcal{P}^\perp_S:T(M)\to T(S)^\perp$.

Fix an oriented orthonormal frame $\{t^a,s^a\}$ for $T(S)^\perp$,

$$t^a s_a=0,-t^a t_a=s^a s_a=1, \tag{3.1}$$

with t^a being a future timelike unit vector and s^a being an outward spacelike unit vector. (If M is spatially noncompact, we define the ''outward'' direction by the exterior of the set $M-S$. If M is spatially compact, there is no preferred way in general to distinguish the sets S and $M-S$, so we then make an arbitrary consistent choice for an ''outward'' direction.) The metric on S is given by

$$\sigma_{ab} = g_{ab} + t_a t_b - s_a s_b . \tag{3.2}$$

The compatible volume form on S is given by

$$\epsilon_{ab} = \epsilon_{abcd}(g) s^c t^d, \tag{3.3}$$

satisfying $\sigma_{c[a}\sigma_{b]d} = \epsilon_{ab}\epsilon_{cd}$. The projection operators for $T(S)$ and $T(S)^\perp$ are given by

$$(\mathcal{P}_S)_a{}^b = \sigma_a{}^b + \epsilon_{ac}\epsilon^{bc}, \quad (\mathcal{P}_S^\perp)_a{}^b = s_a s^b - t_a t^b = \sigma_a^{\perp b} = \epsilon_{ac}^\perp \epsilon^{\perp bc}, \tag{3.4}$$

where $\epsilon_{ab}^\perp = 2 s_{[a} t_{b]}$ and

$$\sigma_{ab}^\perp = s_a s_b - t_a t_b . \tag{3.5}$$

Both σ_{ab} and ϵ_{ab} are independent of choice of the orthonormal frame. Since $\sigma_{ab}^\perp$ is a two-dimensional Lorentz metric, any two oriented orthonormal frames $\{t^a, s^a\}$ and $\{t'^a, s'^a\}$ differ by a local boost

$$t'^a = (\cosh\chi) t^a + (\sinh\chi) s^a, \quad s'^a = (\cosh\chi) s^a + (\sinh\chi) t^a, \tag{3.6}$$

where χ is a function on S. Under an arbitrary boost (3.6), σ_{ab} and ϵ_{ab} are invariant.

The intrinsic geometry of the two-surface S is completely determined by the metric σ_{ab}. In particular, the intrinsic curvature of S is given by

$$[\mathcal{D}_a, \mathcal{D}_b] v_c = \mathcal{R}_{abc}{}^d v_d , \tag{3.7}$$

where v_c is any dual tangent vector field on S, and $\mathcal{D}_a$ denotes the metric compatible (torsion-free) derivative operator on S defined by $\mathcal{D}_a \sigma_{bc} = 0$. Since S is two-dimensional, it follows that the intrinsic curvature tensor has only one linearly independent component

$$\mathcal{R}_{abc}{}^d = \tfrac{1}{2}\sigma_{c[a}\sigma_{b]}{}^d \mathcal{R} = \tfrac{1}{2}\epsilon_{ab}\epsilon_c{}^d \mathcal{R} \tag{3.8}$$

where $\mathcal{R}$ denotes the scalar curvature of S.

The two-surface S also has an extrinsic geometry with respect to (M, g_{ab}), which is characterized by the following curvatures.[5,8] Let $\nabla_a^S = \sigma_a{}^b \nabla_b$ where ∇_b is the metric compatible (torsion-free) derivative operator on (M, g_{ab}). Then ∇_a^S can be decomposed into the tangential derivative operator $\mathcal{D}_a$ and a normal derivative operator $\mathcal{D}_a^\perp$, with $\nabla_a^S = \mathcal{D}_a + \mathcal{D}_a^\perp$, defined by $\mathcal{D}_a^\perp v^b = \sigma_c^{\perp b} \nabla_a^S v^c$ for any vector field v^a in $T(M)$ at S. Now consider $\nabla_a^S t_b$ and $\nabla_a^S s_b$. The tangential parts yield the extrinsic curvature tensors of S with respect to the orthonormal frame

$$\kappa_{ab}(t) = \mathcal{D}_a t_b , \quad \kappa_{ab}(s) = \mathcal{D}_a s_b , \tag{3.9}$$

which are symmetric tensors on S. These measure the spatial rotation of the orthonormal frame in $T(S)^\perp$ under displacement on S. The normal parts of $\nabla_a^S t_b$ and $\nabla_a^S s_b$ give

$$\mathcal{D}_a^\perp t_b = s_b \mathcal{J}_a^\perp , \quad \mathcal{D}_a^\perp s_b = - t_b \mathcal{J}_a^\perp , \tag{3.10}$$

where

$$\mathcal{J}_a^\perp = s^c \nabla_a^S t_c , \tag{3.11}$$

which measures the boost of the orthonormal frame in $T(S)^\perp$ under displacement on S. The commutator of $\mathcal{D}_a^\perp$ defines the *normal curvature* of S,

$$[\mathcal{D}_a^\perp, \mathcal{D}_b^\perp] v_c = \mathcal{R}_{abc}^\perp{}^d v_d , \tag{3.12}$$

with

$$\mathcal{R}^{\perp}_{abcd} = 2\mathcal{D}_{[a}\mathcal{J}^{\perp}_{b]}\epsilon^{\perp}_{cd}, \tag{3.13}$$

where v_c is any dual normal vector field on S. Hence, $\mathcal{J}^{\perp}_a$ is geometrically a connection one-form on S associated with the normal curvature of S. Since S is two-dimensional, note $\mathcal{R}^{\perp}_{abcd}$ has only one linearly independent component, which is proportional to $\epsilon^{ab}\nabla^S_a\mathcal{J}^{\perp}_b$.

The trace of the extrinsic curvatures (3.9) of S,

$$\kappa(t) = \sigma^{ab}\kappa_{ab}(t), \quad \kappa(s) = \sigma^{ab}\kappa_{ab}(s), \tag{3.14}$$

measures how the two-surface area changes under infinitesimal dragging of S along each direction of the orthonormal frame. In particular, for any vector field v^a in $T(S)^{\perp}$,

$$\mathcal{L}_v\epsilon_{ab} = \kappa(v)\epsilon_{ab}, \tag{3.15}$$

with

$$\kappa(v) = \mathcal{D}_a v^a = \tfrac{1}{2}\sigma^{ab}\mathcal{L}_v\sigma_{ab}. \tag{3.16}$$

Thus, S is ''expanding'' or ''contracting'' in the direction v^a according to whether its trace extrinsic curvature $\kappa(v)$ is positive or negative. [More precisely, $\kappa(v)$ equals the rate of change of the area of the image of S under any diffeomorphism of M whose generator agrees with v^a at S.] We say that the expansion of S defined by (3.15) for a direction v^a is spacelike, timelike, or null, if $v^a v_a$ is, respectively, positive, negative, or zero. If v^a is non-null, we refer to $|\kappa(v)|/|v|$ as the *absolute expansion* of S in the direction v^a (with $|v| = \sqrt{|v^a v_a|}$).

A preferred direction in $T(S)^{\perp}$ is given by the mean curvature vector[5,8]

$$H^a = \kappa(s)s^a - \kappa(t)t^a. \tag{3.17}$$

If H^a is spacelike or timelike, then this is the direction of, respectively, minimum absolute spacelike or minimum absolute timelike expansion of S. Furthermore, the minimum value of the absolute expansion is given by the mean extrinsic curvature of S, $|\kappa(H)|/|H| = \sqrt{|\kappa(s)^2 - \kappa(t)^2|}$ Note, here, the norm of H^a is $H^a H_a = \kappa(s)^2 - \kappa(t)^2 \equiv H^2$.

The mean curvature vector and normal curvature tensor of S are each independent of choice of the orthonormal frame, namely, H^a and $\mathcal{R}^{\perp}_{abcd}$ are invariant under boosts (3.6) of $\{t^a, s^a\}$. In contrast, the extrinsic curvatures of S are not invariant but instead transform like the orthonormal frame, while the normal connection transforms like an SO(1, 1) connection

$$\mathcal{J}'^{\perp}_a = \mathcal{J}^{\perp}_a + \nabla^S_a\chi \tag{3.18}$$

with respect to the SO(1, 1) group generated by the boosts (3.6).

B. Dirichlet symplectic vector

It is convenient to work with a null frame for $T(S)^{\perp}$. Let

$$\sqrt{2}\,\theta^+_a = t_a + s_a, \quad \sqrt{2}\,\theta^-_a = t_a - s_a, \tag{3.19}$$

which define, respectively, outgoing and ingoing future pointing null dual vectors satisfying

$$\theta^+_a\,\theta^{-a} = -1. \tag{3.20}$$

Note that any two such oriented null frames $\{\theta^+_a, \theta^-_a\}$ and $\{\theta'^+_a, \theta'^-_a\}$ are related by a local boost

$$\theta'^+_a = e^{\chi}\theta^+_a, \quad \theta'^-_a = e^{-\chi}\theta^-_a, \tag{3.21}$$

where χ is a boost parameter given by a function on S.

The extrinsic curvatures of S in the $\theta_a^{\pm}$ directions are given by

$$\kappa_{ab}^{\pm} = \mathcal{D}_a \theta_b^{\pm} . \tag{3.22}$$

Then

$$\kappa^{\pm} = \mathcal{D}_a \theta^{\pm a} = \tfrac{1}{2} \sigma^{ab} \mathcal{L}_{\theta^{\pm}} \sigma_{ab} \tag{3.23}$$

are the trace extrinsic curvatures which measure the expansion of S in the $\theta_a^{\pm}$ directions. Specifically, $\kappa^{\pm}$ is the rate of change of two-surface area of S,

$$\mathcal{L}_{\theta^{\pm}} \epsilon_{ab} = \kappa^{\pm} \epsilon_{ab} , \tag{3.24}$$

under any diffeomorphism of M whose generator is given by $\theta_a^{\pm}$ at S. Equivalently, $\kappa^{\pm}$ measures the focusing of a congruence of null geodesics normal to S.

The mean curvature vector of S is given by

$$H^a = -(\kappa^- \theta^{+a} + \kappa^+ \theta^{-a}) \tag{3.25}$$

and the connection for the normal curvature of S is given by

$$\mathcal{J}_a^{\perp} = \theta^{+b} \nabla_a^S \theta_b^- . \tag{3.26}$$

We now consider the Dirichlet symplectic vector (2.44) associated with S in the frame $\{t^a, s^a\}$, and separate it into vectors that are normal and tangential to S,

$$(P_{\perp})^a = \mathcal{P}_S^{\perp}(P^a) = \kappa^+ \theta^{-a} - \kappa^- \theta^{+a}, \tag{3.27}$$

$$(P_{\parallel})^a = \mathcal{P}_S(P^a) = \sigma^{ac} \theta^{-b} \nabla_c^S \theta^+{}_b . \tag{3.28}$$

We call $(P_{\perp})^a$ the *Dirichlet normal vector* associated with S. It has the important property that it is independent of choice of the null frame at S.[7–9]

Proposition 3.1: $(P_{\perp})^a$ *is invariant under arbitrary boosts* (3.21) *of the oriented null frame*.

Consequently, $(P_{\perp})^a$ depends only on the two-surface S and the space–time metric g_{ab}. (In particular, its components in any coordinate system can be locally constructed out of the components of g and their partial derivatives, but not in a coordinate invariant form.) Moreover, $(P_{\perp})^a$ has three significant geometrical properties.

First of all, we consider the extrinsic curvature of S in the direction $(P_{\perp})^a$,

$$\kappa_{ab}^{\perp} = \mathcal{D}_a (P_{\perp})_b . \tag{3.29}$$

Remarkably, the trace of this extrinsic curvature vanishes

$$\kappa^{\perp} = \mathcal{D}_a (P_{\perp})^a = \kappa^+ \mathcal{D}_a \theta^{-a} - \kappa^- \mathcal{D}_a \theta^{+a} = 0 \tag{3.30}$$

by Eq. (3.23) and $\theta^{\pm a} \nabla_a^S = 0$. Then we have

$$\mathcal{L}_{P_{\perp}} \epsilon_{ab} = \kappa^+ \mathcal{L}_{\theta-} \epsilon_{ab} - \kappa^- \mathcal{L}_{\theta+} \epsilon_{ab} = \kappa^{\perp} \epsilon_{ab} = 0. \tag{3.31}$$

This result yields the following key geometrical property of $(P_{\perp})^a$.

Theorem 3.2: *The normal direction* $(P_{\perp})^a$ *to S in the space–time* (M, g_{ab}) *is area preserving, i.e., S has zero expansion in the direction* $(P_{\perp})^a$.

Moreover, this property essentially characterizes the directional part of $(P_{\perp})^a$ since there is a unique area-preserving normal direction at all points of S, except, if any, where $\kappa^+ = \kappa^- = 0$ (in which case all normal directions to S are area-preserving).

Second, we find that the norm of $(P_\perp)^a$ is given by

$$(P_\perp)^2 = 2\kappa^+\kappa^-. \tag{3.32}$$

Hence, the direction of $(P_\perp)^a$ is timelike, spacelike, or null if the expansions $\kappa^\pm$ of S are, respectively, opposite sign, same sign, or at least one is zero. (These are boost invariant properties.) In general, the signs of $\kappa^\pm$ can vary on S even if the space–time curvature satisfies positive energy conditions. Therefore, the sign of $(P_\perp)^2$ need not be the same everywhere on S. We note that the situation $(P_\perp)^2 > 0$ characterizes S as a trapped surface, related to the formation of black holes.[10] Further remarks on this aspect of $(P_\perp)^a$ will be made in Sec. V.

Third, we see that $(P_\perp)^a$ is closely related to the mean curvature vector of S.

Proposition 3.3:

$$(P_\perp)^a H_a = 0, \ (P_\perp)^2 = -H^2. \tag{3.33}$$

Thus, $(P_\perp)^a$ is, respectively, timelike, spacelike, or null as H^a is spacelike, timelike, or null. Let $|H| = \sqrt{|H^2|}$, $|P_\perp| = \sqrt{|(P_\perp)^2|}$ denote the absolute norms of H^a and $(P_\perp)^a$. Then, in the non-null case, the relations (3.33) give a unique characterization of $(P_\perp)^a$ (up to a sign) as a vector in $T(S)^\perp$ orthogonal to H^a and with the same absolute norm as H^a. Consequently, we will write $(P_\perp)^a = H^a_\perp$ and refer to

$$H^a_\perp = \kappa^+\theta^{-a} - \kappa^-\theta^{+a} \tag{3.34}$$

as the *normal mean curvature vector* of S, with $H^a_\perp H_a = 0$, $H^2_\perp = -H^2$.

Lemma 3.4: Suppose $|H| \neq 0$ or equivalently $|P_\perp| \neq 0$, i.e., H^a and $H^a_\perp = (P_\perp)^a$ are non-null. Then $\{H^a/|H|, H^a_\perp/|H|\}$ is an orthonormal frame for $T(S)^\perp$. Correspondingly, the pair of vectors

$$\hat{\theta}^{+a} \equiv \frac{1}{\sqrt{2}|H|}(H^a + H^a_\perp) = \frac{-\kappa^-}{\sqrt{|\kappa^+\kappa^-|}}\theta^{+a}, \tag{3.35}$$

$$\hat{\theta}^{-a} \equiv \frac{1}{\sqrt{2}|H|}(H^a - H^a_\perp) = \frac{-\kappa^+}{\sqrt{|\kappa^+\kappa^-|}}\theta^{-a}, \tag{3.36}$$

is a null frame for $T(S)^\perp$.

Thus, in the non-null case, H^a and $H^a_\perp = (P_\perp)^a$ determine a preferred orthonormal frame (or null frame) of $T(S)^\perp$ which depends just on the two-surface S and space–time metric g_{ab}. Then we can summarize the geometrical properties of these vectors in terms of the following orthonormal vectors in $T(S)^\perp$:

$$\hat{H}^a = \frac{1}{\sqrt{2|\kappa^+\kappa^-|}}(\kappa^-\theta^{+a} + \kappa^+\theta^{-a}), \tag{3.37}$$

$$\hat{H}^a_\perp = \frac{1}{\sqrt{2|\kappa^+\kappa^-|}}(\kappa^-\theta^{+a} - \kappa^+\theta^{-a}). \tag{3.38}$$

Theorem 3.5: *Suppose $\kappa^+\kappa^- \neq 0$ on S, i.e., H^a and $H^a_\perp$ are non-null. Then:*

(1) The expansion of S is zero in the unique normal direction $\hat{H}^a_\perp$, which is spacelike or timelike as $\kappa^+\kappa^-$ is positive or negative on S.

(2) The absolute expansion of S in the orthogonal normal direction $\hat{H}^a$ is $\sqrt{2|\kappa^+\kappa^-|}$. This is the minimum absolute spacelike expansion or minimum absolute timelike expansion where $\kappa^+\kappa^-$ is, respectively, positive or negative on S.

We now turn to consider the geometrical properties of $(P_\parallel)^a$. To begin, $(P_\parallel)^a$ can be identified[6,7] with the connection $\mathcal{J}_a^\perp$ for the normal curvature of S, in the null frame $\{\theta_a^+, \theta_a^-\}$.

Proposition 3.6:

$$(P_\parallel)^a = -\sigma^{ab}\mathcal{J}_b^\perp, \tag{3.39}$$

where

$$\mathcal{J}_a^\perp = \theta^{+c}\nabla_a^S\theta_c^-. \tag{3.40}$$

Hence, in contrast to the invariance of $(P_\perp)^a$ under boosts (3.21) of the null frame, $(P_\parallel)^a$ is not invariant but instead transforms as an SO(1, 1) connection,

$$(P_\parallel)'_a = (P_\parallel)_a - \nabla_a^S\chi, \tag{3.41}$$

where χ is a boost parameter given by a function on S. This describes a gauge transformation of $(P_\parallel)^a$ associated with the boosts (3.21) acting on $T(S)^\perp$ as an SO(1,1) gauge group. Consequently, the curl of $(P_\parallel)^a$ has the role of the gauge invariant curvature.

Proposition 3.7:

$$-\mathcal{D}_{[a}(P_\parallel)_{b]} = \tfrac{1}{4}\mathcal{R}^\perp_{abcd}\epsilon^{\perp cd} \tag{3.42}$$

is invariant under arbitrary boosts (3.21) of the null frame, where $\mathcal{R}^\perp_{abcd}$ is the normal curvature of S.

Thus, the curvature $\mathcal{D}_{[a}(P_\parallel)_{b]}$ depends only on the two-surface S and the space–time metric g_{ab}.

Interestingly, in the case when H^a is non-null, we can use the preferred orthonormal frame or null frame given by Lemma 3.4 to gauge-fix $(P_\parallel)^a$. We introduce

$$(\hat{P}_\parallel)_a = \frac{1}{H^2}H_\perp^b\mathcal{D}_a H_b = \frac{1}{H_\perp^2}H^b\mathcal{D}_a H_{\perp b} = (P_\parallel)_a + \tfrac{1}{2}\nabla_a^S\ln(\kappa^+/\kappa^-) \tag{3.43}$$

related to $(P_\parallel)_a$ by a gauge transformation (3.41) with boost parameter $\chi = \frac{1}{2}\ln(\kappa^-/\kappa^+)$ on S.

Proposition 3.8: $(\hat{P}_\parallel)_a$ *is invariant under arbitrary boosts (3.21) of the oriented null frame.*

Consequently, we call $(\hat{P}_\parallel)_a$ the *invariant Dirichlet tangent vector* associated with S. In particular, $(\hat{P}_\parallel)_a$ depends only on the two-surface S and the space–time metric g_{ab}. We now state the main geometrical property of $(\hat{P}_\parallel)_a$, which follows from Eq. (3.43).

Theorem 3.9: *Suppose $\kappa^+\kappa^- \neq 0$ on S, i.e., H^a and $H_\perp^a$ are non-null. Then the boost [with respect to $T(S)^\perp$] of the area-preserving unit normal vector $\hat{H}_\perp^a$ to S under displacement on S is a maximum in the direction $(\hat{P}_\parallel)_a$. By orthogonality of H^a and $H_\perp^a$, this is equivalent to the tangent direction on S in which the boost of the unit mean curvature vector $\hat{H}^a$ under displacement on S is a maximum.*

Finally, from Propositions 3.1 and 3.8, when the mean curvature vector is non-null we can define an invariant locally constructed Dirichlet four-vector associated with S by

$$\hat{P}^a = (P_\perp)^a + (\hat{P}_\parallel)^a = \kappa^+\theta^{-a} - \kappa^-\theta^{+a} + \sigma^{ac}\theta^{-b}\nabla_c^S\theta_b^+ + \tfrac{1}{2}\nabla_a^S\ln(\kappa^+/\kappa^-). \tag{3.44}$$

Note that this vector depends only on S and g_{ab} and is independent of the choice of null frame $\{\theta_a^+, \theta_a^-\}$. Indeed, in terms of purely geometrical structure associated with S,

$$\hat{P}^a = H_\perp^a + \frac{1}{H^2}H_\perp^b\mathcal{D}^a H_b, \tag{3.45}$$

where H^a is the mean curvature vector (3.25) and $H^a_\perp$ is the normal mean curvature vector (3.34) of S.

C. Neumann symplectic vector

Finally, we consider the Neumann symplectic vector (2.45) associated with S,

$$P^a = g^{ac}\theta^{-b}\nabla_c\theta^+_b\,. \tag{3.46}$$

Notice, first of all, the tangential part of P^a with respect to S,

$$(P_\parallel)^a = \mathcal{P}_S(P^a) = \sigma^{ac}\theta^{-b}\nabla^S_c\theta^+_b\,, \tag{3.47}$$

is identically equal to the tangential part of the Dirichlet symplectic vector (3.38). Hence, similar to Theorem 3.9, $(P_\parallel)^a$ gives the direction in which the boost of the null frame $\theta^\pm_a$ under displacement on S is a maximum. In contrast, the normal part of P^a with respect to S,

$$(P_\perp)^a = \mathcal{P}^\perp_S(P^a) = \sigma^{\perp ac}\theta^{-b}\nabla_c\theta^+_b = -\sigma^{\perp ac}\theta^{+b}\nabla_c\theta^-_b\,, \tag{3.48}$$

involves derivatives of the null frame $\theta^\pm_a$ in normal directions to S. In particular, note through substitution of

$$\sigma^{\perp b}_a = -(\theta^+_a\theta^{-b} + \theta^-_a\theta^{+b}) \tag{3.49}$$

that

$$(P_\perp)^a = -\theta^{+a}\theta^{-b}\theta^{-c}\nabla_c\theta^+_b + \theta^{-a}\theta^{+b}\theta^{+c}\nabla_c\theta^-_b = \sigma^{\perp a}_c[\theta^-,\theta^+]^c \tag{3.50}$$

since $\theta^{+b}\nabla_c\theta^+_b = \theta^{-b}\nabla_c\theta^-_b = 0$.

Proposition 3.10: $(P_\perp)^a$ *is the normal part of the commutator* $[\theta^-,\theta^+]^a$ *of the null frame,* $(P_\perp)^a = \mathcal{P}^\perp_S[\theta^-,\theta^+]^a$.

Consequently, unlike $(P_\parallel)^a$, which is well-defined given just the two-surface S and a null frame $\theta^{\pm a}$ of $T(S)^\perp$, it is necessary to consider "nearby" two-surfaces S', diffeomorphic to S, to extend the null frame $\theta^\pm_a$ of $T(S)^\perp$ off S so that $(P_\perp)^a$ is well-defined.

Let $S_{(\lambda_+,\lambda_-)}$ denote a two-parameter (λ_+,λ_-) local null congruence of two-surfaces S' diffeomorphic to S in (M,g_{ab}) with $S_{(0,0)} = S$. [The congruence is defined to be ingoing as a function of λ_- and outgoing as a function of λ_+.] Extend the null frame $\{\theta^{+a},\theta^{-a}\}$ off $T(S)^\perp$ to $T(S')^\perp$. This extension is unique up to boosts (3.21). Then $(P_\perp)^a = \sigma^{\perp ac}\theta^{-b}\nabla_c\theta^+_b$ is a well-defined normal vector at each point on S. We call $(P_\perp)^a$ the *Neumann normal vector* associated with S in a null congruence $S_{(\lambda_+,\lambda_-)} \simeq S\times(\lambda_+,\lambda_-)$. It depends, of course, on the congruence but also on the choice of null frame for $T(S_{(\lambda_+,\lambda_-)})^\perp$.

Proposition 3.11: Under boosts (3.21) of the null frame on the two-surfaces $S_{(\lambda_+,\lambda_-)} \simeq S(\lambda_+,\lambda_-)$, $(P_\perp)^a$ *transforms as*

$$(P_\perp)'_a = (P_\perp)_a - \sigma^{\perp b}_a\nabla_b\chi, \tag{3.51}$$

where χ *is a boost parameter given by a function of* (λ_+,λ_-).

By Proposition 3.6, $(P_\parallel)^a$ has a similar boost transformation property, which has the geometrical meaning of an SO(1,1) connection for the normal curvature of S. This suggests that, geometrically, $P^a = (P_\perp)^a + (P_\parallel)^a$ is also related to an SO(1, 1) connection associated with an extrinsic curvature of S.

Consider the derivative operator $\nabla^\perp_a$ defined by $\nabla^\perp_a v^b = \sigma^{\perp b}_c\nabla_a v^c$ for any normal vector field v^a on the two-surfaces $S_{(\lambda_+,\lambda_-)}$. The commutator of $\nabla^\perp_a$ gives the curvature

$$[\nabla_a^\perp, \nabla_b^\perp] v_c = R^\perp_{abc}{}^d v_d . \tag{3.52}$$

[Note that, on functions, $[\nabla_a^\perp, \nabla_b^\perp] f = 2\nabla_{[a}\nabla_{b]} f = 0$.] Clearly, $\mathcal{P}_S^\perp([\nabla_a^\perp, \nabla_b^\perp]) v_c = [\mathcal{D}_a^\perp, \mathcal{D}_b^\perp] v_c = \mathcal{R}^\perp_{abc}{}^d v_d$ yields the normal curvature of S. Hence, $R^\perp_{abcd}$ is a generalization of $\mathcal{R}^\perp_{abcd}$, which we call the *sectional curvature normal to S* in the null congruence $S_{(\lambda_+, \lambda_-)}$.

Proposition 3.12:

$$R^\perp_{abcd} = 2\nabla^\perp_{[a} J^\perp_{b]} \epsilon^\perp_{cd} , \tag{3.53}$$

where $J_a^\perp = \theta^{+b} \nabla_a \theta_b^-$.

Here $J_a^\perp$ is geometrically a connection one-form for $R^\perp_{abcd}$. In particular, boosts of the null frame act as an SO(1, 1) gauge group on $T(S_{(\lambda_+, \lambda_-)})^\perp$ under which $J_a^\perp$ transforms as $J'^\perp_a = J_a^\perp + \nabla_a \chi$ where χ is a function on $S_{(\lambda_+, \lambda_-)} \simeq S \times (\lambda_+, \lambda_-)$. Note that the curvature $R^\perp_{abcd}$ is invariant under these boosts. This leads to the main geometrical result concerning P^a.

Theorem 3.13: *In any null congruence of two-surfaces* $S_{(\lambda_+, \lambda_-)}$, $P_a = 2J_a^\perp$ *is a connection one-form for the sectional curvature normal to S,*

$$-\nabla^\perp_{[a} P_{b]} = \tfrac{1}{4} R^\perp_{abcd} \epsilon^{\perp cd} . \tag{3.54}$$

Thus the curl $\nabla^\perp_{[a} P_{b]}$ is invariant under arbitrary boosts of the null frame on $S_{(\lambda_+, \lambda_-)}$. It depends, still, on the choice of null congruence $S_{(\lambda_+, \lambda_-)} \simeq S \times (\lambda_+, \lambda_-)$.

In general, there is no unique null congruence determined just by S and g_{ab}. However, a natural choice is given by ingoing and outgoing null geodesics congruences $S_{\lambda_\pm}$ through S, with $S_{(\lambda_+, \lambda_-)}$ defined as $(S_{\lambda_+})_{\lambda_-}$ or $(S_{\lambda_-})_{\lambda_+}$ corresponding to constructing successive one-parameter ingoing and outgoing congruences.[11]

If $S_{(\lambda_+, \lambda_-)} \simeq S \times (\lambda_+, \lambda_-)$ is chosen to be a null geodesic congruence, then the geodesic equation implies that $\theta^{\pm a}$ satisfies $\theta'^{\pm b} \nabla_b \theta'^{\pm a} = 0$ where $\theta'^{\pm a}$ is given by a boost (3.21) for some function χ of (λ_+, λ_-). Thus,

$$\theta^{+b} \nabla_b \theta^{+a} = -\theta^{+a} \theta^{+b} \nabla_b \chi , \quad \theta^{-b} \nabla_b \theta^{-a} = \theta^{-a} \theta^{-b} \nabla_b \chi . \tag{3.55}$$

This leads to a simplification of $(P_\perp)^a$ from Eq. (3.50),

$$(P_\perp)^a = \theta^{+a} \theta^{+b} \theta^{-c} \nabla_c \theta_b^- - \theta^{-a} \theta^{-b} \theta^{+c} \nabla_c \theta_b^+ = -\theta^{+a} \theta^{-c} \nabla_c \chi - \theta^{-a} \theta^{+c} \nabla_c \chi . \tag{3.56}$$

Proposition 3.14: In a null geodesic congruence, $(P_\perp)^a = \sigma^{\perp ab} \nabla_b \chi$, *and consequently,* $\mathcal{P}_S^\perp(R^\perp_{abcd}) = 0$.

The converse of this result also holds, since if the normal part of $R^\perp_{abcd}$ vanishes, then $(P_\perp)_a$ is a gradient and hence $\theta^{\pm a}$ satisfies the geodesic equation (3.55) so that the congruence $S_{(\lambda_+, \lambda_-)}$ arises from null geodesics through S.

Geometrically, the boost function χ in the geodesic equation (3.55) is related to the choice of parametrization of the null congruence. Indeed, we can fix the parametrization in a natural way by $\chi = 0$, which implies a corresponding gauge-fixing of $(P_\perp)^a$,

$$(\hat{P}_\perp)^a = 0 . \tag{3.57}$$

To conclude, we remark that the use of ingoing and outgoing null congruences in defining $(P_\perp)^a$ can be replaced by using timelike and spacelike congruences, denoted S_{λ_s} and S_{λ_t}, through S. Moreover, if g_{ab} has isometries then it may be possible to fix a unique local two-parameter congruence $S_{(\lambda_s, \lambda_t)}$ constructed in a natural way from the Killing vectors and invariant surfaces of the isometries. In general, then $(P_\perp)^a$ is no longer just a gradient. This will be illustrated in the examples in Sec. IV.

Finally, it is important to note that there is no ambiguity in $(P_\perp)^a$ appearing in the Neumann Hamiltonian boundary term (2.43), since this involves only the component of $(P_\perp)^a$ in the direction of the time-flow vector, which is well-defined using the unique timelike congruence through S generated by the time-flow vector on M.

IV. EXAMPLES

We now consider examples for the Dirichlet and Neumann symplectic vectors described in Sec. III. In particular, we calculate these vectors and their properties for spacelike, topologically spherical two-surfaces in (a) Minkowski space–time, (b) spherically symmetric space–times, (c) axisymmetric space–times, (d) homogeneous isotropic space–times, (e) asymptotically flat space–times.

A. Minkowski space–time

Consider a closed orientable spacelike two-surface S embedded in a spacelike hyperplane in Minkowski space–time $(\mathbb{R}^4, \eta)$, using spherical coordinates

$$\eta_{ab} = -(\mathrm{d}t)_a(\mathrm{d}t)_b + (\mathrm{d}r)_a(\mathrm{d}r)_b + r^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b + \sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b), \tag{4.1}$$

where S is given by $t=t_0$, $r=R(\theta,\phi)$ for some function $R(\theta,\phi)$ and constant t_0. Fix an orthonormal frame ϑ_a^μ adapted to S in (R^4,η) by

$$\vartheta_a^0 = (\mathrm{d}t)_a, \quad \vartheta_a^1 = \frac{1}{\psi}((\mathrm{d}r)_a - \partial_a R), \tag{4.2}$$

$$\vartheta_a^2 = \frac{1}{\mu}\left(r(\mathrm{d}\theta)_a + \frac{\partial_\theta R}{r}(\mathrm{d}r)_a\right), \quad \vartheta_a^3 = \frac{\mu}{\psi}\left(r\sin\theta(\mathrm{d}\phi)_a + \frac{\partial_\phi R}{\mu^2 r\sin\theta}((\mathrm{d}r)_a - \partial_\theta R(\mathrm{d}\theta)_a)\right), \tag{4.3}$$

where

$$\mu = \sqrt{1 + r^{-2}(\partial_\theta R)^2}, \quad \psi = \sqrt{1 + r^{-2}((\partial_\theta R)^2 + (\partial_\phi R/\sin\theta)^2)}. \tag{4.4}$$

Note the metric associated with S is given in spherical coordinates by

$$\begin{aligned}\sigma_{ab} = {} & (1-\psi^{-2})(\mathrm{d}r)_a(\mathrm{d}r)_b + 2\psi^{-2}(\mathrm{d}r)_{(a}\partial_{b)}R - \psi^{-2}\partial_a R\partial_b R \\ & + r^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b + \sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b).\end{aligned} \tag{4.5}$$

The pullback of σ_{ab} to S yields the induced metric on S,

$$\sigma_{ab}|_S = (R^2 + (\partial_\theta R)^2)(\mathrm{d}\theta)_a(\mathrm{d}\theta)_b + (R^2\sin^2\theta + (\partial_\phi R)^2)(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b + 2\partial_\theta R\partial_\phi R(\mathrm{d}\theta)_{(a}(\mathrm{d}\phi)_{b)}. \tag{4.6}$$

Correspondingly, let $\psi_S = \psi|_S = \sqrt{1 + R^{-2}((\partial_\theta R)^2 + (\partial_\phi R/\sin\theta)^2)}$.

The trace of the extrinsic curvatures of (S,σ_{ab}) with respect to the frame on $T(S)^\perp$

$$t_a = \vartheta_a^0|_S = (\mathrm{d}t)_a, \quad s_a = \vartheta_a^1|_S = \frac{1}{\psi_S}((\mathrm{d}r)_a - \partial_a R), \tag{4.7}$$

are, respectively,

$$\kappa(t) = \sigma^{ab}\nabla_a t_b = -(\Gamma_2{}^{02}(\vartheta) + \Gamma_3{}^{03}(\vartheta))|_S = 0 \tag{4.8}$$

and

$$\kappa(s) = \sigma^{ab}\nabla_a s_b = -(\Gamma_2{}^{12}(\vartheta) + \Gamma_3{}^{13}(\vartheta))|_S = 2(\vartheta_1^a\vartheta_2^b\partial_{[a}\vartheta_{b]}^2 + \vartheta_1^a\vartheta_3^b\partial_{[a}\vartheta_{b]}^3)|_{r=R(\theta,\phi)}, \tag{4.9}$$

calculated in terms of the Ricci rotation coefficients

$$\Gamma_\lambda{}^{\mu\nu}(\vartheta)=\vartheta^a_\lambda\vartheta^{b\nu}\nabla_a\vartheta^\mu_b=2\,\vartheta^a_\lambda\vartheta^{b[\mu}\partial_{[a}\vartheta^{\nu]}_{b]}-\vartheta^{b\mu}\vartheta^{c\nu}\partial_{[b}\vartheta_{c]\lambda}\,. \tag{4.10}$$

Here $\kappa(s)$ is the standard Euclidean extrinsic curvature of S in $\mathbb{R}^3$.[5] [The explicit expression for $\kappa(s)$ as a function of the spherical coordinates is lengthy and will be omitted.]

A preferred direction in $T(S)^\perp$ is given by the mean curvature vector

$$H^a=s^a\kappa(s)-t^a\kappa(t)=\frac{\kappa(s)}{\psi_S}\left((\partial_r)^a-\frac{\partial_\theta R}{R^2}(\partial_\theta)^a-\frac{\partial_\phi R}{R^2\sin^2\theta}(\partial_\phi)^a\right), \tag{4.11}$$

which is spacelike. This vector gives the direction of the minimum absolute spacelike expansion of S in $(\mathbb{R}^4,\eta)$. Furthermore, the value of the expansion is the mean extrinsic curvature of S given by

$$\frac{1}{\sqrt{H^2}}\kappa(H)=|\kappa(s)|=\sqrt{H^2}. \tag{4.12}$$

Note S is convex or concave according to where the sign of $\kappa(s)$ is negative or positive.

The normal part of the Dirichlet symplectic vector is given by the normal mean curvature vector

$$(P^{\mathrm{D}}_\perp)^a=H^a_\perp=t^a\kappa(s)-s^a\kappa(t)=\kappa(s)(\partial_t)^a. \tag{4.13}$$

Note that $(P^{\mathrm{D}}_\perp)^a$ is timelike, orthogonal to H^a, with the same absolute norm as H^a. Most significant, $(P^{\mathrm{D}}_\perp)^a$ gives the direction of zero expansion of S.

A preferred orthonormal frame for $T(S)^\perp$ is

$$\hat t^a=\frac{1}{\sqrt{H^2}}H^a_\perp=(\partial_t)^a|_S,\quad \hat s^a=\frac{1}{\sqrt{H^2}}H^a=\frac{1}{\psi}\left((\partial_r)^a-\frac{\partial_\theta R}{r^2}(\partial_\theta)^a-\frac{\partial_\phi R}{r^2\sin^2\theta}(\partial_\phi)^a\right)|_S, \tag{4.14}$$

which depend only on S and η_{ab} but not on the Minkowski frame ϑ^μ_a. In the preferred frame (4.14), the tangential part of the Dirichlet symplectic vector is

$$(P^{\mathrm{D}}_\parallel)^a=\sigma^{ac}\hat t^b\nabla_c\hat s_b=-\frac{1}{\psi_S}\sigma^{ac}\left((\partial_r)^b-\frac{\partial_\theta R}{R^2}(\partial_\theta)^b-\frac{\partial_\phi R}{R^2\sin^2\theta}(\partial_\phi)^b\right)\nabla_c(\mathrm{d}t)_b=0, \tag{4.15}$$

and thus the normal curvature of S is zero.

Hence the complete Dirichlet symplectic vector is

$$P^a=(P^{\mathrm{D}}_\perp)^a+(P^{\mathrm{D}}_\parallel)^a=\kappa(s)(\partial_t)^a, \tag{4.16}$$

which depends only on S and η_{ab}. In particular, it is independent of choice of original orthonormal frame (4.2) and (4.3) on Minkowski space and of the normals (4.7) in $T(S)^\perp$.

To define the Neumann symplectic vector, it is natural to extend the preferred orthonormal frame (4.14) off S by using the obvious isometries of η_{ab}. With respect to this extension, the normal part of the Neumann symplectic vector is given by the commutator

$$(P^{\mathrm{N}}_\perp)^a=\mathcal{P}^\perp_S[\hat t,\hat s]^a=\frac{1}{\psi_S}\mathcal{P}^\perp_S\left([(\partial_t),(\partial_r)]^a-\frac{1}{R^2\sin^2\theta}[(\partial_t),\sin^2\theta\,\partial_\theta R(\partial_\theta)+\partial_\phi R(\partial_\phi)]^a\right)=0. \tag{4.17}$$

[Alternatively, the same result for $(P^{\mathrm{N}}_\perp)^a$ is obtained by extending (4.14) off S to the congruence of two-surfaces $t=\text{const}$, $r-R(\theta,\phi)=\text{const}$, which lie in parallel hyperplanes to S and are iso-

metric to S.] Then, since $(P^{\mathrm{N}}_{\parallel})^a=(P^{\mathrm{D}}_{\parallel})^a=0$, the complete Neumann symplectic vector in the congruence of two-surfaces associated with S under isometries of η_{ab} is given by

$$P^a=(P^{\mathrm{N}}_{\perp})^a+(P^{\mathrm{N}}_{\parallel})^a=0. \tag{4.18}$$

Thus the sectional curvature normal to S vanishes, reflecting the fact that S lies in a flat hyperplane.

1. Light cone two-sphere

Next, consider a closed orientable spacelike two-surface S embedded in a light cone in $(\mathbb{R}^4,\eta)$. Let $u=(t-r)/\sqrt{2}$, $v=(t+r)/\sqrt{2}$, θ, ϕ be light cone coordinates (i.e., r, θ, ϕ are spherical coordinates with respect to the origin point for the cone), with

$$\eta_{ab}=-2(\mathrm{d}u)_{(a}(\mathrm{d}v)_{b)}+\tfrac{1}{2}(v-u)^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b+\sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b). \tag{4.19}$$

Then S is given by $u=u_0$, $v=V(\theta,\phi)$ for some function $V(\theta,\phi)$ and constant u_0. Note that $(\mathrm{d}u)_a$ and $(\mathrm{d}v)_a-\partial_a V$ are, respectively, a null normal and spacelike normal for S, while $(\partial_\theta)^a+\partial_\theta V(\partial_v)^a$ and $(\partial_\phi)^a+\partial_\phi V(\partial_v)^a$ are orthogonal tangent vectors on S.

Fix a null frame ϑ^μ_a adapted to S in $(\mathbb{R}^4,\eta)$ by

$$\vartheta^0_a=(\mathrm{d}u)_a,\quad \vartheta^1_a=\tfrac{1}{2}\psi^2(\mathrm{d}u)_a+(\mathrm{d}v)_a-\partial_a V, \tag{4.20}$$

$$\vartheta^2_a=r(\mathrm{d}\theta)_a-\frac{\partial_\theta V}{r}(\mathrm{d}u)_a,\quad \vartheta^3_a=r\sin\theta(d\phi)_a-\frac{\partial_\phi V}{r\sin\theta}(\mathrm{d}u)_a \tag{4.21}$$

satisfying $\vartheta^\mu_a\vartheta^\nu_b\eta^{ab}=-2\delta^{(\mu}_0\delta^{\nu)}_1+\delta^\mu_2\delta^\nu_2+\delta^\mu_3\delta^\nu_3$, where

$$\psi=|\mathrm{d}V|=r^{-1}\sqrt{(\partial_\theta V)^2+(\partial_\phi V/\sin\theta)^2}. \tag{4.22}$$

Note the metric associated with S is given by

$$\sigma_{ab}=\psi^2(\mathrm{d}u)_a(\mathrm{d}u)_b-2(\mathrm{d}u)_{(a}(\partial_\theta V(\mathrm{d}\theta)_{b)}+\partial_\phi V(\mathrm{d}\phi)_{b)})+r^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b+\sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b), \tag{4.23}$$

where

$$\sigma_{ab}|_S=\tfrac{1}{2}(V-u_0)^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b+\sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b) \tag{4.24}$$

yields the induced metric on S.

The trace of the extrinsic curvatures of (S,σ_{ab}) with respect to the null frame on $T(S)^\perp$

$$u_a=\vartheta^0_a|_S=(\mathrm{d}u)_a, \tag{4.25}$$

$$v_a=\vartheta^1_a|_S=\psi^2_S(\mathrm{d}u)_a+(\mathrm{d}v)_a-\partial_\theta V(\mathrm{d}\theta)_a-\partial_\phi V(\mathrm{d}\phi)_a, \tag{4.26}$$

are, respectively,

$$\kappa(u)=\sigma^{ab}\nabla_a u_b=-(\Gamma_2{}^{02}(\vartheta)+\Gamma_3{}^{03}(\vartheta))|_S=-\frac{2}{R} \tag{4.27}$$

and

$$\kappa(v)=\sigma^{ab}\nabla_a v_b=-(\Gamma_2{}^{12}(\vartheta)+\Gamma_3{}^{13}(\vartheta))|_S=\frac{2}{R}(1+\psi^2_S)-\frac{2\partial_\theta R}{R^2}\frac{\cos\theta}{\sin\theta}-\frac{2\partial^2_\theta R}{R^2}-\frac{2\partial^2_\phi R}{R^2\sin^2\theta}, \tag{4.28}$$

where

$$\psi_S=\frac{1}{\sqrt{2}}\,\psi|_S=R^{-1}\sqrt{(\partial_\theta R)^2+(\partial_\phi R/\sin\theta)^2},\quad R=\sqrt{2}r|_S=V-u_0. \tag{4.29}$$

A preferred direction in $T(S)^\perp$ is given by the mean curvature vector

$$H^a=-u^a\kappa(v)-v^a\kappa(u) \tag{4.30}$$

in terms of the null vectors

$$u^a=-(\partial_v)^a|_S,\quad v^a=-\left((\partial_u)^a+\frac{\psi^2}{2}(\partial_v)^a+\frac{\partial_\theta V}{r^2}(\partial_\theta)^a+\frac{\partial_\phi V}{r^2\sin^2\theta}(\partial_\phi)^a\right)\Big|_S. \tag{4.31}$$

The norm of H^a gives the mean extrinsic curvature of S,

$$\frac{1}{|H|}|\kappa(H)|=\sqrt{2|\kappa(u)\kappa(v)|}=|H|. \tag{4.32}$$

Now, the normal part of the Dirichlet symplectic vector is given by the normal mean curvature vector $(P^{\mathrm{D}}_\perp)^a=H^a_\perp=v^a\kappa(u)-u^a\kappa(v)$, which simplifies to

$$(P^{\mathrm{D}}_\perp)^a=-\kappa(u)(\partial_u)^a-(\kappa(u)\psi_S^2-\kappa(v))(\partial_v)^a-\kappa(u)\frac{2\partial_\theta R}{R^2}(\partial_\theta)^a-\kappa(u)\frac{2\partial_\phi R}{R^2\sin^2\theta}(\partial_\phi)^a. \tag{4.33}$$

This vector gives the direction of zero expansion of S in $(\mathbb{R}^4,\eta)$.

A preferred null frame for $T(S)^\perp$ consists of

$$\hat{u}^a=\frac{1}{\sqrt{2}|H|}(H^a_\perp+H^a)=\sqrt{\frac{\kappa(v)}{\kappa(u)}}(\partial_v)^a, \tag{4.34}$$

$$\hat{v}^a=\frac{1}{\sqrt{2}|H|}(H^a_\perp-H^a)=\sqrt{\frac{\kappa(u)}{\kappa(v)}}\left((\partial_u)^a+\psi_S^2(\partial_v)^a+\frac{2\partial_\theta R}{R^2}(\partial_\theta)^a+\frac{2\partial_\phi R}{R^2\sin^2\theta}(\partial_\phi)^a\right), \tag{4.35}$$

which depend only on S and η_{ab} but not on the Minkowski frame ϑ^μ_a. In the preferred frame (4.34) and (4.35), the tangential part of the Dirichlet symplectic vector is given by

$$(P^{\mathrm{D}}_\parallel)^a=\sigma^{ac}\hat{v}^b\nabla_c\hat{u}_b=\sigma^{ac}v^b\nabla_c(\mathrm{d}u)_b+\tfrac{1}{2}\sigma^{ac}\partial_c\ln(\kappa(u)/\kappa(v)). \tag{4.36}$$

This simplifies to

$$\begin{aligned}(P^{\mathrm{D}}_\parallel)^a=&\frac{1}{R^2}((\partial_\theta)^a+\partial_\theta R(\partial_v)^a)\partial_\theta\ln(\kappa(u)/\kappa(v))\\&+\frac{1}{R^2\sin^2\theta}((\partial_\phi)^a+\partial_\phi R(\partial_v)^a)\partial_\phi\ln(\kappa(u)/\kappa(v)).\end{aligned} \tag{4.37}$$

Therefore, since the dual vector $(P^{\mathrm{D}}_\parallel)_a=\nabla^S_a\ln(\kappa(u)/\kappa(v))$ is a gradient on S, the normal curvature of S is zero.

The complete Dirichlet symplectic vector is

$$P^a=(P^{\mathrm{D}}_\perp)^a+(P^{\mathrm{D}}_\parallel)^a, \tag{4.38}$$

which depends only on S and η_{ab}. In particular, it is independent of choice of the original null frame (4.20) and (4.21) on Minkowski space and of the corresponding frame (4.25) and (4.26) on $T(S)^{\perp}$. Geometrically, the dual vector $(P_{\perp}^{\mathrm{D}})_a$ provides a preferred normal direction for a family of hypersurfaces defined to cut the light cone at S, with vanishing normal curvature.

Finally, the commutator of the null frame (4.31) yields the normal part of the Neumann symplectic vector,

$$\begin{aligned}(P_{\perp}^{\mathrm{N}})^a = P_S^{\perp}[v,u]^a &= \mathcal{P}_S^{\perp}\left[\partial_u + \frac{\psi^2}{2}\partial_v + \frac{\partial_\theta V}{r^2}\partial_\theta + \frac{\partial_\phi V}{r^2\sin^2\theta}\partial_\phi, \partial_v\right]^a\Bigg|_S \\ &= \frac{\sqrt{2}}{r}\mathcal{P}_S^{\perp}\left(\frac{\psi^2}{2}(\partial_v)^a + \frac{\partial_\theta V}{r^2}(\partial_\theta)^a + \frac{\partial_\phi V}{r^2\sin^2\theta}(\partial_\phi)^a\right)\Bigg|_S \\ &= -2\,\frac{\psi_S^2}{R}(\partial_v)^a, \end{aligned} \tag{4.39}$$

through $\partial_v\psi^2 = -\sqrt{2}\psi^2/r$. The tangential part of the Neumann symplectic vector is simply $(P_{\parallel}^{\mathrm{N}})^a = (P_{\parallel}^{\mathrm{D}})^a$. Hence, this yields the complete Neumann symplectic vector

$$P^a = (P_{\perp}^{\mathrm{N}})^a + (P_{\parallel}^{\mathrm{N}})^a, \tag{4.40}$$

which depends only on the congruence of spacelike two-surfaces $u=\text{const}$, $v - V(\theta,\phi) = \text{const}$, lying on the light cones in Minkowski space.

2. Constant curvature two-sphere

In the special case of a constant curvature two-sphere S, viewed as embedded either in a hyperplane $t=t_0=\text{const}$, $r=R=r_0=\text{const}$, or in a light cone, $u=u_0=(t_0-r_0)/\sqrt{2}$, $v=V=v_0=(t_0+r_0)/\sqrt{2}$, the mean curvature vector of S is simply $H^a=(2/r_0)(\partial_r)^a$, and the complete Dirichlet symplectic vector reduces to

$$P^a = H_{\perp}^a = \frac{2}{r_0}(\partial_t)^a, \tag{4.41}$$

while the complete Neumann symplectic vector vanishes.

B. Spherically symmetric space–times

In a spherically symmetric space–time $(\mathbb{R}\times\Sigma, g_{ab})$,

$$g_{ab} = -e^{2\psi}(\mathrm{d}t)_a(\mathrm{d}t)_b + e^{-2\nu}(\mathrm{d}r)_a(\mathrm{d}r)_b + r^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b + \sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b), \tag{4.42}$$

where $\psi=\psi(t,r)$ and $\nu=\nu(t,r)$, consider a spacelike two-surface S given by an isometry sphere $r=r_0=\text{const}$ and $t=t_0=\text{const}$. The metric on S is

$$\sigma_{ab} = r_0^2(\mathrm{d}\theta)_a(\mathrm{d}\theta)_b + r_0^2\sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b \tag{4.43}$$

and the area of S is $A(S)=4\pi r_0^2$. Fix an orthonormal frame adapted to S by

$$\vartheta_a^0 = e^{\psi}(\mathrm{d}t)_a, \quad \vartheta_a^1 = e^{-\nu}(\mathrm{d}r)_a, \quad \vartheta_a^2 = r(\mathrm{d}\theta)_a, \quad \vartheta_a^3 = r\sin\theta(\mathrm{d}\phi)_a. \tag{4.44}$$

The Ricci rotation coefficients of the frame

$$\Gamma_{\lambda}^{\mu\nu}(\vartheta) = \vartheta_{\lambda}^a\vartheta^{b\nu}\nabla_a\vartheta_b^{\mu} = 2\,\vartheta_{\lambda}^a\vartheta^{b[\mu}\partial_{[a}\vartheta_{b]}^{\nu]} - \vartheta^{b\mu}\vartheta^{c\nu}\partial_{[b}\vartheta_{c]\lambda} \tag{4.45}$$

have the following nonvanishing components:

$$\Gamma_0{}^{10} = -(\partial_r e^{\psi})e^{\nu}e^{-\psi}, \tag{4.46}$$

$$\Gamma_1{}^{01} = -(\partial_t e^{\nu})e^{-\nu}e^{-\psi}, \tag{4.47}$$

$$\Gamma_2{}^{12} = -\frac{e^{\nu}}{r} = \Gamma_3{}^{13}, \tag{4.48}$$

$$\Gamma_3{}^{23} = -\frac{\cos\theta}{r\sin\theta}. \tag{4.49}$$

The trace of the extrinsic curvatures of (S, σ_{ab}) with respect to the frame on $T(S)^{\perp}$

$$t_a = \vartheta^0_a|_S, \quad s_a = \vartheta^1_a|_S, \tag{4.50}$$

are, respectively,

$$\kappa(t) = \sigma^{ab}\nabla_a t_b = -(\Gamma_2{}^{02} + \Gamma_3{}^{03})|_S = 0, \tag{4.51}$$

and

$$\kappa(s) = \sigma^{ab}\nabla_a s_b = -(\Gamma_2{}^{12} + \Gamma_3{}^{13})|_S = \frac{2e^{\nu(t_0,r_0)}}{r_0}. \tag{4.52}$$

A preferred direction in $T(S)^{\perp}$ is given by the mean curvature vector

$$H^a = s^a\kappa(s) - t^a\kappa(t) = \frac{2e^{2\nu(t_0,r_0)}}{r_0}(\partial_r)^a, \tag{4.53}$$

which is spacelike. This vector gives the direction of the minimum absolute spacelike expansion of S. Furthermore, the value of the expansion is given by the trace extrinsic curvature of S with respect to the unit vector in the direction H^a,

$$\frac{1}{\sqrt{H^2}}\kappa(H) = |\kappa(t)| = \frac{2e^{\nu(t_0,r_0)}}{r_0}, \tag{4.54}$$

which is equal to the norm of H^a.

The normal part of the Dirichlet symplectic vector is given by the normal mean curvature vector

$$(P^{\mathrm{D}}_{\perp})^a = H^a_{\perp} = t^a\kappa(s) - s^a\kappa(t) = 2\frac{e^{\nu(t_0,r_0)}e^{-\psi(t_0,r_0)}}{r_0}(\partial_t)^a. \tag{4.55}$$

Here $(P^{\mathrm{D}}_{\perp})^a$ is timelike, orthogonal to H^a, with the same absolute norm as H^a. Most significant, $(P^{\mathrm{D}}_{\perp})^a$ gives the direction of zero expansion of S.

A preferred orthonormal frame for $T(S)^{\perp}$ is

$$\hat{t}^a = \frac{1}{\sqrt{H^2}}H^a_{\perp} = e^{-\psi}(\partial_t)^a, \quad \hat{s}^a = \frac{1}{\sqrt{H^2}}H^a = e^{\nu}(\partial_r)^a, \tag{4.56}$$

which depend only on S and η_{ab} but not on the chosen frame ϑ^{μ}_a. In the preferred frame (4.56) the tangential part of the Dirichlet symplectic vector is

$$(P^{\mathrm{D}}_{\parallel})^a = \sigma^{ac}\hat{t}^b\nabla_c\hat{s}_b = (\vartheta^{2a}\Gamma_2{}^{10} + \vartheta^{3a}\Gamma_3{}^{10})|_S = 0, \tag{4.57}$$

and thus the normal curvature of S is zero.

Hence the complete Dirichlet symplectic vector is

$$P^a=(P_\perp^{\mathrm{D}})^a+(P_\parallel^{\mathrm{D}})^a=2\,\frac{e^{\nu(t_0,r_0)-\psi(t_0,r_0)}}{r_0}(\partial_t)^a, \tag{4.58}$$

which depends only on S and η_{ab}. In particular, it is independent of choice of the original orthonormal frame (4.44) for g_{ab} and (4.50) for $\sigma^{\perp}_{ab}$.

To define the Neumann symplectic vector, it is natural to use the orthonormal frame (4.56) extended off S to the congruence of isometry spheres $t=\text{const}$, $r=\text{const}$. Then, for this extension, the normal part of the Neumann symplectic vector is given by the commutator

$$(P_\perp^{\mathrm{N}})^a=\mathcal{P}_S^{\perp}[\hat{t},\hat{s}]^a=(\hat{t}^a\Gamma_0{}^{10}+\hat{s}^a\Gamma_1{}^{10})|_S=(-(\partial_r e^{\psi})e^{\nu}e^{-2\psi}(\partial_t)^a+(\partial_t e^{\nu})e^{-\psi}(\partial_r)^a)|_S\,. \tag{4.59}$$

Since $(P_\parallel^{\mathrm{N}})^a=(P_\parallel^{\mathrm{D}})^a=0$, the complete Neumann symplectic vector with respect to the congruence of isometry spheres associated with S is given by

$$P^a=(P_\perp^{\mathrm{N}})^a+(P_\parallel^{\mathrm{N}})^a=e^{\nu(t_0,r_0)-\psi(t_0,r_0)}(-\partial_r\psi(t_0,r_0)(\partial_t)^a+\partial_t\nu(t_0,r_0)(\partial_r)^a). \tag{4.60}$$

Finally, as a special case, consider the Reissner–Nordström black hole space–time obtained for

$$e^{\psi}=e^{\nu}=\sqrt{1-2m/r+q^2/r^2}, \tag{4.61}$$

where $m=\text{const}$ and $q=\text{const}$ are the black hole mass and charge; $q=0$ yields the Schwarzschild black hole. The mean curvature vector of an isometry sphere S, $t=\text{const}$, $r=\text{const}$, is given by

$$H^a=\frac{2}{r}\left(1-\frac{2m}{r}+\frac{q^2}{r^2}\right)(\partial_r)^a, \tag{4.62}$$

which gives the direction of the minimum absolute spacelike expansion of S. Furthermore, the value of the expansion is given by the norm of H^a,

$$|\kappa(s)|=\frac{2}{r}\sqrt{1-\frac{2m}{r}+\frac{q^2}{r^2}}. \tag{4.63}$$

The complete Dirichlet symplectic vector is given by

$$P^a=\frac{2}{r}(\partial_t)^a, \tag{4.64}$$

which depends only on S and η_{ab}. Note that P^a is timelike, orthogonal to H^a, with the same absolute norm as H^a, and it gives the direction of zero expansion of S.

With respect to the congruence of isometry spheres associated to S, the complete Neumann symplectic vector is given by

$$P^a=-\left(\frac{m}{r^2}-\frac{q^2}{r^3}\right)\left(1-\frac{2m}{r}+\frac{q^2}{r^2}\right)^{-1}(\partial_t)^a. \tag{4.65}$$

The curl of this vector yields the sectional curvature normal to S.

C. Axisymmetric space–times

Now consider a stationary axisymmetric space–time $(\mathbb{R}\times\Sigma,g_{ab})$,

$$\begin{aligned} g_{ab}=&-e^{2\psi}(\mathrm{d}t)_a(\mathrm{d}t)_b+e^{-2\nu}(\mathrm{d}r)_a(\mathrm{d}r)_b+e^{-2\mu_1}(\mathrm{d}\theta)_a(\mathrm{d}\theta)_b\\ &+e^{-2\mu_2}((\mathrm{d}\phi)_a-w(\mathrm{d}t)_a)((\mathrm{d}\phi)_b-w(\mathrm{d}t)_b), \end{aligned} \tag{4.66}$$

where[12] $w=w(r,\theta)$, $\psi=\psi(r,\theta)$, $\nu=\nu(r,\theta)$, $\mu_1=\mu_1(r,\theta)$, and $\mu_2=\mu_2(r,\theta)$. Let S be a spacelike two-surface given by $r=r_0=\text{const}$ and $t=t_0=\text{const}$, which has the metric

$$\sigma_{ab}=e^{-2\mu_1(r_0,\theta)}(\mathrm{d}\theta)_a(\mathrm{d}\theta)_b)+e^{-2\mu_2(r_0,\theta)}(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b\,. \tag{4.67}$$

The area of S is $A(S)=2\pi\int_0^\pi e^{-\mu_1(r_0,\theta)-\mu_2(r_0,\theta)}\mathrm{d}\theta$. A natural orthonormal frame adapted to S is given by

$$\vartheta^0_a=e^{\psi}(\mathrm{d}t)_a\,,\quad \vartheta^1_a=e^{-\nu}(\mathrm{d}r)_a\,,\quad \vartheta^2_a=e^{-\mu_1}(\mathrm{d}\theta)_a\,,\quad \vartheta^3_a=e^{-\mu_2}((\mathrm{d}\phi)_a-w(\mathrm{d}t)_a). \tag{4.68}$$

The Ricci rotation coefficients of the frame

$$\Gamma^{\mu\nu}_{\lambda}(\vartheta)=\vartheta^a_\lambda\vartheta^{b\nu}\nabla_a\vartheta^\mu_b=2\,\vartheta^a_\lambda\vartheta^{b[\mu}\partial_{[a}\vartheta^{\nu]}_{b]}-\vartheta^{b\mu}\vartheta^{c\nu}\partial_{[b}\vartheta_{c]\lambda} \tag{4.69}$$

have the following nonvanishing components:

$$\Gamma_0{}^{01}=e^{-\psi}e^{\nu}\partial_r e^{\psi},\quad \Gamma_3{}^{01}=\tfrac{1}{2}e^{-\psi}e^{\nu}e^{-\mu_2}\partial_r w, \tag{4.70}$$

$$\Gamma_0{}^{02}=e^{-\psi}e^{\mu_1}\partial_\theta e^{\psi},\quad \Gamma_3{}^{02}=\tfrac{1}{2}e^{-\psi}e^{\mu_1}e^{-\mu_2}\partial_\theta w, \tag{4.71}$$

$$\Gamma_1{}^{03}=\tfrac{1}{2}e^{-\psi}e^{\nu}e^{-\mu_2}\partial_r w,\quad \Gamma_2{}^{03}=\tfrac{1}{2}e^{-\psi}e^{\mu_1}e^{-\mu_2}\partial_\theta w, \tag{4.72}$$

$$\Gamma_1{}^{12}=e^{\nu}e^{\mu_1}\partial_\theta e^{-\nu},\quad \Gamma_2{}^{12}=-e^{\nu}e^{\mu_1}\partial_r e^{-\mu_1}, \tag{4.73}$$

$$\Gamma_0{}^{13}=\tfrac{1}{2}e^{-\psi}e^{\nu}e^{-\mu_2}\partial_r w,\quad \Gamma_3{}^{13}=-e^{\nu}e^{\mu_2}\partial_r e^{-\mu_2}, \tag{4.74}$$

$$\Gamma_0{}^{23}=\tfrac{1}{2}e^{-\psi}e^{\mu_1}e^{-\mu_2}\partial_\theta w,\quad \Gamma_3{}^{23}=-e^{\mu_1}e^{\mu_2}\partial_\theta e^{-\mu_2}. \tag{4.75}$$

The trace of the extrinsic curvatures of (S,σ_{ab}) with respect to the frame on $T(S)^\perp$

$$t_a=\vartheta^0_a|_S\,,\quad s_a=\vartheta^1_a|_S\,, \tag{4.76}$$

are, respectively,

$$\kappa(t)=\sigma^{ab}\nabla_a t_b=-(\Gamma_2{}^{02}+\Gamma_3{}^{03})|_S=0, \tag{4.77}$$

and

$$\kappa(s)=\sigma^{ab}\nabla_a s_b=-(\Gamma_2{}^{12}+\Gamma_3{}^{13})|_S=-e^{\nu(r_0,\theta)}\partial_r\mu(r_0,\theta), \tag{4.78}$$

where $\mu(r,\theta)=\mu_1+\mu_2$. A preferred direction in $T(S)^\perp$ is given by the mean curvature vector

$$H^a=s^a\kappa(s)-t^a\kappa(t)=-e^{2\nu(r_0,\theta)}\partial_r\mu(r_0,\theta)(\partial_r)^a, \tag{4.79}$$

which is spacelike. This vector gives the direction of the minimum absolute spacelike expansion of S. Furthermore, the value of the expansion is given by the trace extrinsic curvature of S with respect to the unit vector in the direction H^a,

$$\frac{1}{\sqrt{H^2}}\,\kappa(H)=|\kappa(s)|=e^{\nu(r_0,\theta)}|\partial_r\mu(r_0,\theta)|, \tag{4.80}$$

which is equal to the norm of H^a.

The normal part of the Dirichlet symplectic vector is given by the normal mean curvature vector

$$(P^{\mathrm{D}}_\perp)^a=H^a_\perp=t^a\kappa(s)-s^a\kappa(t)=-e^{-\psi(r_0,\theta)}e^{\nu(r_0,\theta)}\partial_r\mu(r_0,\theta)((\partial_t)^a+w(\partial_\phi)^a). \tag{4.81}$$

Here $(P_\perp^{\mathrm{D}})^a$ is timelike, orthogonal to H^a, with the same absolute norm as H^a. Most significant, $(P_\perp^{\mathrm{D}})^a$ gives the direction of zero expansion of S.

A preferred orthonormal frame for $T(S)^\perp$ is

$$\hat{t}^a=\frac{1}{\sqrt{H^2}}H_\perp^a=e^{-\psi}((\partial_t)^a+w(\partial_\phi)^a),\quad \hat{s}^a=\frac{1}{\sqrt{H^2}}H^a=e^{\nu}(\partial_r)^a, \tag{4.82}$$

which depend only on S and η_{ab} but not on the chosen frame ϑ_a^μ. In the preferred frame (4.82) the tangential part of the Dirichlet symplectic vector is

$$(P_\parallel^{\mathrm{D}})^a=\sigma^{ac}\hat{t}^b\nabla_c\hat{s}_b=(\vartheta^{2a}\Gamma_2{}^{10}+\vartheta^{3a}\Gamma_3{}^{10})|_S=\tfrac{1}{2}e^{-\psi(r_0,\theta)}e^{\nu(r_0,\theta)}\partial_r w(r_0,\theta)(\partial_\phi)^a. \tag{4.83}$$

The curl of this vector yields the normal curvature of S.

Hence the complete Dirichlet symplectic vector is

$$P^a=(P_\perp^{\mathrm{D}})^a+(P_\parallel^{\mathrm{D}})^a=e^{-\psi(r_0,\theta)+\nu(r_0,\theta)}(-\partial_r\mu(r_0,\theta)((\partial_t)^a+w(\partial_\phi)^a)+\tfrac{1}{2}\partial_r w(r_0,\theta)\,(\partial_\phi)^a), \tag{4.84}$$

which depends only on S and η_{ab}. In particular, it is independent of choice of the original orthonormal frame (4.68) for g_{ab} and (4.76) for $\sigma_{ab}^\perp$.

To define the Neumann symplectic vector, it is natural to use the orthonormal frame (4.82) extended off S to the congruence of two-surfaces $t=\text{const}$, $r=\text{const}$. With respect to this extension, the normal part of the Neumann symplectic vector is given by the commutator

$$(P_\perp^{\mathrm{N}})^a=\mathcal{P}_S^\perp[\hat{t},\hat{s}]^a=(\hat{t}^a\Gamma_0{}^{10}+\hat{s}^a\Gamma_1{}^{10})|_S=-e^{-\psi(r_0,\theta)}e^{\nu(r_0,\theta)}\partial_r\psi(r_0,\theta)((\partial_t)^a+w(\partial_\phi)^a). \tag{4.85}$$

Since $(P_\parallel^{\mathrm{N}})^a=(P_\parallel^{\mathrm{D}})^a$, the complete Neumann symplectic vector in this congruence of two-surfaces associated with S is given by

$$P^a=(P_\perp^{\mathrm{N}})^a+(P_\parallel^{\mathrm{N}})^a=e^{-\psi(r_0,\theta)+\nu(r_0,\theta)}(-\partial_r\psi(r_0,\theta)((\partial_t)^a+w(\partial_\phi)^a)+\tfrac{1}{2}\partial_r w(r_0,\theta)\,(\partial_\phi)^a). \tag{4.86}$$

The curl of this vector yields the sectional curvature normal to S.

As a special case, consider the Kerr black hole space–time obtained for

$$e^{\psi}=\frac{\sqrt{\Delta}\rho}{\Upsilon},\quad e^{-\nu}=\frac{\rho}{\sqrt{\Delta}},\quad e^{-\mu_1}=\rho,\quad e^{-\mu_2}=\frac{\Upsilon\sin\theta}{\rho},\quad w=\frac{2amr}{\Upsilon^2}, \tag{4.87}$$

where

$$\Upsilon^2=(r^2+a^2)^2-a^2\Delta\sin^2\theta,\quad \Delta=r^2-2mr+a^2,\quad \rho^2=r^2+a^2\cos^2\theta. \tag{4.88}$$

Here $m=\text{const}$ and $a=\text{const}$ are the black hole mass and angular momentum; $a=0$ yields the Schwarzschild black hole. The mean curvature vector of a two-surface S, $t=\text{const}$, $r=\text{const}$, is given by

$$H^a=\frac{\Delta}{\rho^2}\frac{\partial_r\Upsilon}{\Upsilon}(\partial_r)^a=\frac{\Delta}{\rho^2\Upsilon^2}(2r(r^2+a^2)-a^2(r-m)\sin^2\theta)(\partial_r)^a, \tag{4.89}$$

which gives the direction of the minimum absolute spacelike expansion of S. Furthermore, the value of the expansion is given by the norm of H^a,

$$|\kappa(s)| = \frac{\sqrt{\Delta}}{\rho \Upsilon^2}(2r(r^2+a^2) - a^2(r-m)\sin^2\theta). \tag{4.90}$$

The complete Dirichlet symplectic vector is given by

$$\begin{aligned} P^a &= \frac{\Upsilon}{\rho^2}\left(\frac{\partial_r \Upsilon}{\Upsilon}((\partial_t)^a + w(\partial_\phi)^a) + \frac{\partial_r w}{2}(\partial_\phi)^a\right) \\ &= \frac{2r(r^2+a^2) - a^2(r-m)\sin^2\theta}{\rho^2 \Upsilon}(\partial_t)^a + \frac{am}{\rho^2 \Upsilon}(\partial_\phi)^a, \end{aligned} \tag{4.91}$$

which depends only on S and η_{ab}. Note that P^a is timelike, orthogonal to H^a, with the same absolute norm as H^a, and it gives the direction of zero expansion of S.

With respect to this congruence of two-surfaces S, the complete Neumann symplectic vector is given by

$$\begin{aligned} P^a &= \frac{\Upsilon}{\rho^2}\left(\left(\frac{\partial_r \Upsilon}{\Upsilon} - \frac{\partial_r \Delta}{2\Delta} - \frac{\partial_r \rho}{2\rho}\right)((\partial_t)^a + w(\partial_\phi)^a) + \frac{\partial_r w}{2}(\partial_\phi)^a\right) \\ &= -\frac{2m}{\rho^4 \Upsilon \Delta}((r^2+a^2)^2(r^2-a^2) + a^2((r^2+a^2)^2 - 4mr^3)\sin^2\theta)(\partial_t)^a \\ &\quad + \frac{am}{\rho^4 \Upsilon \Delta}((r^2-a^2)^2 - 4r^3(r-m) - a^2(a^2-r^2)\sin^2\theta)(\partial_\phi)^a. \end{aligned} \tag{4.92}$$

D. Homogeneous isotropic space–times

Next, consider a Friedmann–Robertson–Walker space–time $(\mathbb{R}\times\Sigma, g_{ab})$,

$$g_{ab} = -(\mathrm{d}t)_a(\mathrm{d}t)_b + a^2(t)\left(\frac{1}{1-kr^2}(\mathrm{d}r)_a(\mathrm{d}r)_b + r^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b + \sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b)\right), \tag{4.93}$$

where $k=0, 1, -1$ [Σ is $\mathbb{R}^3$ if $k=0, -1$ or S^3 if $k=1$] corresponding to a spatially flat, spherical, or hyperbolic geometry on Σ. Let S be a spacelike two-surface given by an isometry sphere $r = r_0 = \text{const}$ and $t = t_0 = \text{const}$. The metric on S is

$$\sigma_{ab} = a^2(t_0) r_0{}^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b + \sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b) \tag{4.94}$$

and the area of S is $A(S) = 4\pi a(t_0) r_0^2$. Fix an orthonormal frame adapted to S by

$$\vartheta^0_a = (\mathrm{d}t)_a, \quad \vartheta^1_a = \frac{a(t)}{\sqrt{1-kr^2}}(\mathrm{d}r)_a, \quad \vartheta^2_a = a(t) r (\mathrm{d}\theta)_a, \quad \vartheta^3_a = a(t) r \sin\theta (\mathrm{d}\phi)_a. \tag{4.95}$$

The Ricci rotation coefficients of the frame

$$\Gamma_\lambda{}^{\mu\nu}(\vartheta) = \vartheta^a_\lambda \vartheta^{b\nu} \nabla_a \vartheta^\mu_b = 2\vartheta^a_\lambda \vartheta^{b[\mu} \partial_{[a} \vartheta^{\nu]}_{b]} - \vartheta^{b\mu} \vartheta^{c\nu} \partial_{[b} \vartheta_{c]\lambda} \tag{4.96}$$

have the following nonvanishing components:

$$\Gamma_0{}^{01} = \frac{\dot{a}(t)}{a(t)} = \Gamma_2{}^{02} = \Gamma_3{}^{03}, \tag{4.97}$$

$$\Gamma_1{}^{12} = \frac{\sqrt{1-2kr}}{a(t) r} = \Gamma_3{}^{13}, \tag{4.98}$$

$$\Gamma_3{}^{23} = -\frac{\cos\theta}{a(t) r \sin\theta}. \tag{4.99}$$

(Here, an over-dot denotes a derivative with respect to t.)

The trace of the extrinsic curvatures of (S, σ_{ab}) with respect to the frame on $T(S)^{\perp}$

$$t_a = \vartheta^0_a|_S, s_a = \vartheta^1_a|_S, \tag{4.100}$$

are, respectively,

$$\kappa(t) = \sigma^{ab}\nabla_a t_b = -(\Gamma_2{}^{02} + \Gamma_3{}^{03})|_S = \frac{2\dot{a}(t_0)}{a(t_0)} \tag{4.101}$$

and

$$\kappa(s) = \sigma^{ab}\nabla_a s_b = -(\Gamma_2{}^{12} + \Gamma_3{}^{13})|_S = \frac{2\sqrt{1-kr_0{}^2}}{r_0 a(t_0)}. \tag{4.102}$$

A preferred direction in $T(S)^{\perp}$ is given by the mean curvature vector

$$H^a = s^a\kappa(s) - t^a\kappa(t) = 2\left(\frac{1-kr_0{}^2}{a(t_0)^2 r_0}(\partial_r)^a - \frac{\dot{a}(t_0)}{a(t_0)}(\partial_t)^a\right). \tag{4.103}$$

This vector gives the direction of the minimum absolute spacelike expansion of S. Furthermore, the value of the expansion is given by the trace extrinsic curvature of S with respect to the unit vector in the direction H^a,

$$\frac{1}{\sqrt{H^2}}\kappa(H) = |\kappa(s)| = \frac{2}{a(t_0)}\sqrt{\frac{1-kr_0{}^2}{r_0{}^2} - \dot{a}^2(t_0)}, \tag{4.104}$$

which is equal to the norm of H^a.

The normal part of the Dirichlet symplectic vector is given by the normal mean curvature vector

$$(P^{\mathrm{D}}_{\perp})^a = H^a_{\perp} = t^a\kappa(s) - s^a\kappa(t) = \frac{2\sqrt{1-kr_0{}^2}}{a(t_0)}\left(\frac{1}{r_0}(\partial_t)^a - \frac{\dot{a}(t_0)}{a(t_0)}(\partial_r)^a\right). \tag{4.105}$$

Here $(P^{\mathrm{D}}_{\perp})^a$ is orthogonal to H^a, with the same absolute norm as H^a. Most significant, $(P^{\mathrm{D}}_{\perp})^a$ gives the direction of zero expansion of S. Note that $(P^{\mathrm{D}}_{\perp})^a$ is timelike (and H^a is spacelike) if and only if the acceleration of Σ satisfies $|\dot{a}(t_0)| \leqslant \sqrt{1-kr_0{}^2}/r_0$, depending on the radius of S.

A preferred orthonormal frame for $T(S)^{\perp}$ is

$$\hat{t}^a = \frac{1}{\sqrt{H^2}}H^a_{\perp} = (\partial_t)^a, \quad \hat{s}^a = \frac{1}{\sqrt{H^2}}H^a = \frac{\sqrt{1-kr^2}}{a(t)}(\partial_r)^a, \tag{4.106}$$

which depend only on S and η_{ab} but not on the chosen frame ϑ^{μ}_a. In the preferred frame (4.56) the tangential part of the Dirichlet symplectic vector is

$$(P^{\mathrm{D}}_{\parallel})^a = \sigma^{ac}\hat{t}^b\nabla_c\hat{s}_b = (\vartheta^{2a}\Gamma_2{}^{10} + \vartheta^{3a}\Gamma_3{}^{10})|_S = 0, \tag{4.107}$$

and thus the normal curvature of S is zero.

Hence the complete Dirichlet symplectic vector is

$$P^a=(P^{\mathrm{D}}_{\perp})^a+(P^{\mathrm{D}}_{\parallel})^a=\frac{\sqrt{1-kr_0{}^2}}{a(t_o)}\left(\frac{1}{r_0}(\partial_t)^a-\frac{\dot a(t_0)}{a(t_0)}(\partial_r)^a\right), \tag{4.108}$$

which depends only on S and η_{ab}. In particular, it is independent of choice of the original orthonormal frame (4.95) for g_{ab} and (4.100) for $\sigma^{\perp}_{ab}$.

To define the Neumann symplectic vector, it is natural to use to the orthonormal frame (4.106) extended off S to the congruence of isometry spheres $t=\mathrm{const}$, $r=\mathrm{const}$. Then, for this extension, the normal part of the Neumann symplectic vector is given by the commutator

$$(P^{\mathrm{N}}_{\perp})^a=\mathcal{P}^{\perp}_S[\hat t,\hat s]^a=(\hat t^a\Gamma_0{}^{10}+\hat s^a\Gamma_1{}^{10})|_S=-\left(\frac{\sqrt{1-kr_0{}^2}}{a(t_0)^2}\right)\dot a(t_0)(\partial_r)^a. \tag{4.109}$$

Since $(P^{\mathrm{N}}_{\parallel})^a=(P^{\mathrm{D}}_{\parallel})^a=0$, the complete Neumann symplectic vector with respect to the congruence of isometry spheres associated with S is given by

$$P^a=(P^{\mathrm{N}}_{\perp})^a+(P^{\mathrm{N}}_{\parallel})^a=-\sqrt{1-kr_0{}^2}\frac{\dot a(t_0)}{a(t_0)^2}(\partial_r)^a. \tag{4.110}$$

For an isometry sphere S, $r=\mathrm{const}$, $t=\mathrm{const}$, in a time-symmetric hypersurface Σ, since $\dot a(t)=0$ it follows that H^a is spacelike, $(P^{\mathrm{D}}_{\perp})^a$ is timelike. Then the complete Dirichlet symplectic vector is

$$P^a=\frac{2\sqrt{1-kr^2}}{ra(t)}(\partial_t)^a, \tag{4.111}$$

while the complete Neumann symplectic vector vanishes.

E. Asymptotically flat space–times

Consider an asymptotically flat space–time (M,g_{ab}) with $g_{ab}=\eta_{ab}+O(1/r)$ and $\partial_c g_{ab}=O(1/r^2)$ as $r\to\infty$ at fixed t, where η_{ab} is a flat metric (4.1) in Minkowski spherical coordinates t, r, θ, ϕ. Suppose the total ADM mass, m, of the space–time (M,g_{ab}) is finite and positive. Then, the metric has the asymptotic form[13,14]

$$\begin{aligned}g_{ab}=&-(1-2m/r+O(1/r^2))(\mathrm{d}t)_a(\mathrm{d}t)_b+(1+2m/r+O(1/r^2))(\mathrm{d}r)_a(\mathrm{d}r)_b+r^2((\mathrm{d}\theta)_a(\mathrm{d}\theta)_b\\&+\sin^2\theta(\mathrm{d}\phi)_a(\mathrm{d}\phi)_b+O(1/r^3))\quad\text{as } r\to\infty \text{ at fixed } t.\end{aligned} \tag{4.112}$$

[Note that any gravitational radiation terms vanish in this limit.] We first discuss the ADM energy–momentum vector.[11] In the space–time (M,g_{ab}), spatial infinity, ι^0, can be represented as the set of asymptotic two-spheres S_∞ given by $t=\mathrm{const}$, $r=\to\infty$, which are regarded as being identified under asymptotic time translations generated by the Killing vector $(\partial_t)^a$ of η_{ab}. Now, for a spacelike hypersurface Σ_t, $t=\mathrm{const}$, the ADM energy and momentum in standard asymptotic Minkowski coordinates x^μ on M are given by[15]

$$P_\mu=\begin{cases}\displaystyle\sum_{\nu,\rho\neq 0}\frac{1}{16\pi}\int_{S_\infty}s_\nu(\partial_\rho g_{\rho\nu}-\partial_\nu g_{\rho\rho})\mathrm{d}S=m, & \mu=0\\ \displaystyle\sum_{\nu\neq 0}\frac{1}{16\pi}\int_{S_\infty}(s_\nu\partial_t g_{\mu\nu}-s_\mu\partial_t g_{\nu\nu})\mathrm{d}S=0, & \mu=1,2,3.\end{cases} \tag{4.113}$$

Hence, the ADM energy-momentum vector at spatial infinity is represented by $(P^{\mathrm{ADM}})_a=m(\mathrm{d}t)_a|_{S_\infty}$. Let $n^a=(\partial_t)^a|_{S_\infty}$. Then, geometrically, the vector

$$\frac{1}{m}(P^{\mathrm{ADM}})^a = -n^a \tag{4.114}$$

corresponds to an asymptotic stationary unit-norm Killing vector of the asymptotically flat metric (4.112).

To proceed, let S be any family of spacelike two-surfaces that approaches the two-sphere S_∞ as $r\to\infty$ at fixed t. Since the space–time metric is asymptotic to the Schwarzschild metric, we may use the results obtained in example (B) to calculate the Dirichlet and Neumann symplectic vectors in this limit.

The Dirichlet symplectic vector is given by

$$(P^{\mathrm{D}})^a = \frac{2}{r}(1-m/r)t^a + O(1/r^3), \tag{4.115}$$

where $t^a = (1+m/r+O(1/r^2))(\partial_t)^a$ is a unit timelike vector of (M,g_{ab}). For a comparison with $(P^{\mathrm{ADM}})^a$, we scale $(P^{\mathrm{D}})^a$ by the area of S, $A(S)=4\pi r^2+O(1/r)$, which yields

$$A(S)(P^{\mathrm{D}})^a = 8\pi(r-m+O(1/r))t^a. \tag{4.116}$$

Note that the first term in this expression is singular as $r\to\infty$. It corresponds to the Dirichlet symplectic vector for S_∞ with respect to the flat metric η_{ab} on M. We extend this vector in a natural geometrical manner from S_∞ to S by

$$(P^{\mathrm{D}}_{\mathrm{flat}})^a = \frac{2}{r}t^a, \tag{4.117}$$

which depends only on the radius of S and the timelike unit vector t^a with respect to g_{ab}. We now subtract $(P^{\mathrm{D}}_{\mathrm{flat}})^a$ from $(P^{\mathrm{D}})^a$ to obtain the normalized Dirichlet symplectic vector

$$(\overline{P^{\mathrm{D}}})^a = A(S)((P^{\mathrm{D}})^a - (P^{\mathrm{D}}_{\mathrm{flat}})^a) = (-8\pi m + O(1/r))t^a. \tag{4.118}$$

Then the limit $r\to\infty$ yields a well-defined (finite) vector associated to S_∞ in terms of $t^a\to n^a$. This establishes our main result.

Theorem 4.1: *For an asymptotically flat space–time (M,g_{ab}), at spatial infinity the normalized Dirichlet symplectic vector (4.118) is equal to 8π times the ADM energy-momentum vector (4.114),*

$$\frac{1}{8\pi}(\overline{P^{\mathrm{D}}})^a|_{S_\infty} = (P^{\mathrm{ADM}})^a = -mn^a. \tag{4.119}$$

[The 8π factor reflects the normalization chosen for the Hamiltonian variational principle for the Einstein equations in Sec. II.]

We remark that the ADM vector $(P^{\mathrm{ADM}})^a$ can be derived[16] directly from the symplectic structure of the Einstein equations similarly to the analysis given in Sec. 3 in Ref. 1 by using asymptotically flat boundary conditions at S_∞ in place of the Dirichlet boundary condition at S on the space–time metric.

Finally, we discuss the Neumann symplectic vector. Note that the normalized symplectic vector (4.118) is obtained from the locally constructed Dirichlet symplectic vector $(P^{\mathrm{D}})^a$ associated with a spacelike two-surface S, where $(P^{\mathrm{D}})^a$ depends only on S and g_{ab}. In contrast, the Neumann symplectic vector $(P^{\mathrm{N}})^a$ associated with S also depends on a choice of congruence of two-surfaces S' diffeomorphic to S. If a suitably parametrized null geodesic congruence through S is used to define $(P^{\mathrm{N}})^a$, it follows from Proposition 3.14 that the normal part of $(P^{\mathrm{N}})^a$ vanishes. Moreover, the tangential part of $(P^{\mathrm{N}})^a$ is equal to the tangential part of $(P^{\mathrm{D}})^a$. Thus for any

topological two-sphere S that approaches S_∞ as $r\to\infty$, by Eq. (4.115) the resulting vector $(P^{\mathrm{N}})^a$ is at most $O(1/r^3)$ and is tangential to S. Consequently, if we consider the normalized symplectic vector

$$(\overline{P}^{\mathrm{N}})^a = A(S)((P^{\mathrm{N}})^a - (P^{\mathrm{N}}_{\mathrm{flat}})^a) \tag{4.120}$$

defined analogously to $(\overline{P}^{\mathrm{D}})^a$, then

$$(\overline{P}^{\mathrm{N}})^a|_{S_\infty} = 0. \tag{4.121}$$

Note that for an asymptotically flat metric (4.112), as S approaches S_∞, all null geodesic congruences through S approach future and past null infinity, $\mathcal{I}^{\pm}$, and thereby provide a natural congruence of spacelike two-spheres $S_{\mathcal{I}^{\pm}}$ associated with the two-sphere S_∞ representing spatial infinity, $\imath^0$. In particular, $S_{\mathcal{I}^{\pm}}$ are related to S_∞ by null geodesic asymptotic isometries of g_{ab}. Hence, the normalized symplectic vector (4.121) effectively depends only on S and g_{ab} (including its asymptotic structure), similar to the vector (4.118).

V. CONCLUDING REMARKS

In this paper we have considered the covariant symplectic structure associated with the Einstein equations with matter sources. One main result is that we derive a covariant Hamiltonian under Dirichlet and Neumann type boundary conditions for both the gravitational field and matter fields in any fixed spatially bounded region of spacetime (M, g_{ab}), allowing the time-flow vector ξ^a to be timelike, spacelike, or null.

The Dirichlet and Neumann Hamiltonians evaluated on solutions of the coupled gravitational and matter field equations reduce to a surface integral over the spatial boundary two-surface, S. [In fact, this result is known to hold for any diffeomorphism covariant space–time field theory.[17]] For each of the boundary conditions this surface integral has the form of $\int_S \xi^a P_a \mathrm{d}S$ where P_a is a locally constructed dual vector field associated with the two-surface S and boundary conditions, which we call the Dirichlet and Neumann symplectic vectors. Similar results are discussed in Ref. 18.

Our principle result is to show that the purely gravitational part of the Dirichlet symplectic vector $(P^{\mathrm{D}})^a$ has very interesting geometrical properties when decomposed into its normal and tangential parts, $(P^{\mathrm{D}}_\perp)^a$ and $(P^{\mathrm{D}}_\parallel)^a$, with respect to S. First, $(P^{\mathrm{D}}_\perp)^a$ depends only on the two-surface S and space–time metric g_{ab} and thus yields a geometrical vector field normal to S in space–time. This vector $(P^{\mathrm{D}}_\perp)^a$ is shown to be orthogonal to the mean curvature vector of S and, most importantly, it gives the direction of zero expansion of S in space–time, i.e., $\mathcal{L}_{P_\perp}\epsilon_{ab}(S) = 0$ where $\epsilon_{ab}(S)$ is the area volume form of S. Furthermore, the norm of the vector $(P^{\mathrm{D}}_\perp)^a$ is equal to the product of the expansions of S with respect to ingoing and outgoing null geodesics, θ^{-a} and θ^{+a} (and is independent of parametrization of the geodesics). This expression is obviously related to the condition for a spatial two-surface S to be trapped (or marginally trapped), namely, $\kappa^+\kappa^-$ is positive (or zero) on S, where $\mathcal{L}_{\theta^\pm}\epsilon_{ab}(S) = \kappa^\pm\epsilon_{ab}(S)$. Consequently, S is trapped (or marginally trapped) precisely when $(P^{\mathrm{D}}_\perp)^a$ is spacelike (or null) on S. If this notion is applied to the ingoing and outgoing null geodesics at each point p on S [i.e., the pair of null geodesics through p is "trapped" (or "marginally trapped") if $\kappa^+\kappa^-$ is positive (or zero) at p], then, in this sense, $(P^{\mathrm{D}}_\perp)^a$ measures pointwise how close S is to being a trapped surface.

In contrast, $(P^{\mathrm{D}}_\parallel)^a$ depends not only on the two-surface S and space–time metric g_{ab} but also on a choice of orthonormal frame or null frame for the normal tangent space $T(S)^\perp$ of S. Geometrically, $(P^{\mathrm{D}}_\parallel)^a$ is shown to be a connection for the normal curvature of S in space–time and consequently changes by a gradient under a boost of the frame. However, if the normal vector $(P^{\mathrm{D}}_\perp)^a$ is non-null, then $(P^{\mathrm{D}}_\perp)^a$ and the mean curvature vector of S comprise a preferred frame for $T(S)^\perp$ and hence there exists a corresponding preferred, tangential vector $(P^{\mathrm{D}}_\parallel)^a$ (evaluated in this

frame). Thus, in this situation, the complete Dirichlet symplectic vector is a well-defined geometrical vector field depending only on S and g_{ab}. We refer to this as the invariant Dirichlet symplectic vector associated with S.

Apart from its geometrical interest, the Dirichlet symplectic vector is also related to definitions of canonical energy, momentum, and angular momentum given by the value of the Dirichlet Hamiltonian for solutions of the Einstein (and matter) equations. In particular, we have shown that in an asymptotically flat space–time in the limit of S approaching spatial infinity S_∞, the Dirichlet symplectic vector reduces in a suitable sense to the ADM energy-momentum vector. Hence, the integral $\int_{S_\infty} \xi^a (P^{\mathrm{D}})_a \mathrm{d}S$ yields total energy, momentum, angular momentum of the space–time when ξ^a is chosen to be an asymptotic Killing vector associated to time-translations, space-translations, or rotations of the asymptotic flat background metric.

In addition, for a compact spatial two-surface S in (M, g_{ab}), it follows from results in Ref. 2 that the quasilocal quantities $\int_S \xi^a (P^{\mathrm{D}})_a \mathrm{d}S$ for ξ^a chosen to be normal and tangential to S reproduce Brown and York's[3,4] quasilocal energy, momentum, and angular momentum quantities. (See also Refs. 1 and 6.) Furthermore, we have obtained matter contributions to these quantities, for an electromagnetic field and a set of Yang–Mills–Higgs fields. In a forthcoming paper we will explore geometrical quasilocal quantities defined purely in terms of $(P^{\mathrm{D}}_\perp)^a$ and $(P^{\mathrm{D}}_\parallel)^a$. We will also explore the use of $(P^{\mathrm{D}})^a$ as a time flow vector for a boundary-initial value formulation of the Einstein equations.

On the problem of algebraic completeness for the invariants of the Riemann tensor. III.

J. Carminati and E. Zakhary
School of Computing and Mathematics, Deakin University, Waurn Ponds, Victoria 3217, Australia

(Received 25 October 2001; accepted for publication 14 March 2002)

We study the set CZ of invariants [Zakhary and Carminati, J. Math. Phys. **42**, 1474 (2001)] for the class of space–times whose Ricci tensors possess a null eigenvector. We show that all cases are maximally backsolvable, in terms of sets of invariants from CZ, but that some cases are not completely backsolvable and these all possess an alignment between an eigenvector of the Ricci tensor with a repeated principal null vector of the Weyl tensor. We provide algebraically complete sets for each canonically different space–time and hence conclude with these results and those of a previous article [Carminati, Zakhary, and McLenaghan, J. Math. Phys. **43**, 492 (2002)] that the CZ set is determining or maximal. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1478803]

I. INTRODUCTION

In the first article of this series,[1] we introduced a new set CZ of polynomial Riemann invariants, satisfying the minimum degree property, which was claimed to be ''determining.'' The main purpose of the second article[2] in this series was to rigorously establish this fact for class A space–times whose Ricci tensors did not possess a null eigenvector. Further, for each canonically different space–time, we gave algebraically complete sets. (This was established by showing that the given sets were curvature complete and minimal in number, by a simple real count. The various new definitions which are used here were introduced in the previous articles.) In this article we will study class B space–times (Ricci tensor possesses a null eigenvector) and show that each canonically different case is maximally backsolvable in terms of sets of invariants from CZ. Interestingly, not all members of this class are completely backsolvable[3] and, in fact, we will show that such NCB space–times, in general, possess an alignment (necessary but not sufficient) between a null eigenvector of the Ricci tensor with a repeated principal null vector of the Weyl tensor. We will give, in some cases,[4] the necessary and/or sufficient invariant conditions (in terms of algebraic relations) for these to occur, together with a maximal independent set. For the NCB cases, we will also indicate, in the Ricci (or Weyl) canonical frames, the Weyl (or Ricci) information [by component(s)] which is missing. In all cases, we do provide algebraically complete sets for each canonically different space–time in class B and hence conclude with these results and those of a previous article[2] that the CZ set is determining or maximal. As before, we will establish all of our results by an implicit backsolving technique described previously.[1,2] Most of the calculations were done using Maple.

The set CZ of invariants and the relations between the various sets, in the literature, and the syzygies for the different Petrov and Segre types of the Weyl and Ricci tensors, have been given in a previous article.[1] For future use, the trace-free Ricci tensor can be written in the form

$$S_{ab} = -2[\Phi_{00} n_a n_b - 2\Phi_{01} n_{(a}\overline{m}_{b)} + \Phi_{02}\overline{m}_a\overline{m}_b - 2\Phi_{10} n_{(a} m_{b)} + 2\Phi_{11}(l_{(a} n_{b)} + m_{(a}\overline{m}_{b)}) - 2\Phi_{12} l_{(a}\overline{m}_{b)} + \Phi_{20} m_a m_b - 2\Phi_{21} l_{(a} m_{b)} + \Phi_{22} l_a l_b]. \quad (1)$$

II. RICCI CANONICAL FRAMES FOR CLASS B

Tables I–V give the canonical forms for the Ricci tensor when it possesses a null eigenvector. A summary of the notation and complete details where the Ricci tensor does not possess a null eigenvector have been given previously.[2]

At this point, we would like to again compare our canonical forms with those as given by McIntosh *et al.*[5] and Joly and MacCallum.[6] As before,[2] apart from possible changes due to $\mathbf{l}\leftrightarrow\mathbf{n}$ interchange and other minor frame changes, our work differs from theirs in that Φ_{11} could be zero for the Segre types [2,11] and [(1,1)11], whereas they report that Φ_{11} is necessarily nonzero for these types.

III. MAXIMAL BACKSOLVING

In this section, we will prove that the CZ set is determining for class B by explicitly showing that maximal backsolving is always possible for each Segre type, with certain chosen subsets of CZ. Further, we will show that these subsets are algebraically complete. As before, regarding our method of proof, after having established that a set of invariants is maximal or determining by backsolving and if necessary using the index theorem (when the subset is not curvature complete), we then check that we have retained the minimum possible number of invariants ["minimal number" property, i.e., that it cannot be further reduced (in number[7] of invariants) and still achieve the same "measure" [8] of backsolving, after all of the possible remaining tetrad freedom which can act on the curvature components, is completely used up]. It follows that once this is done, we have

established that the subset is algebraically complete. Note that if lower degree invariants (in CZ) are not used in the backsolving process, this means they are dependent for the particular case at hand (the proof of dependency will be given in a future article).

In cases where we have curvature complete sets, the minimal number property is established by simply observing that the number[7] of invariants is the same as the number of unknown functions in the curvature components (after all of the possible remaining tetrad freedom, which can act on the curvature components, is completely used up). In the cases where we do not have curvature complete sets but which are maximal, the missing amount of information is shown to be absent in all second order polynomial invariants using the index theorem. The minimal number property is then established by a simple real count modulo the mandatory missing curvature information.

We note that for the Segre types [2,11], [2,(11)], [(2,1)1] and [(2,11)], $\Phi_{22}=\pm 1$ in their respective canonical frames. In all of these cases, we have chosen $\Phi_{22}=1$ in the backsolving procedures. The backsolving when $\Phi_{22}=-1$ is identical to the case when $\Phi_{22}=1$ except for minor insignificant sign changes. Similarly, for the Segre types [3,1] and [(3,1)], we have chosen $\Phi_{12}=1$.

A. Segre type [2,11]

For this type, a complete set of invariants is $\{R, w_1, w_2, r_1, r_2, m_1, m_2, m_3\}$, and we will show that complete backsolving is always possible, at least in principle, except when $\Psi_0=\Psi_1=0$. This exceptional case occurs when the null eigenvector of the Ricci tensor aligns with the repeated

principal null direction of the Weyl tensor. As we shall see, for this and other Segre types, complete backsolving is, in general, not possible when such alignments occur. However, maximal backsolving is always achievable with certain invariants from CZ.

We begin with the backsolving for the Ricci components Φ_{ab}. In our canonical frame, the independent Ricci invariants are $r_1=\frac{2}{3}(\Phi_{02}^2+2\Phi_{11}^2)$ and $r_2=-2\Phi_{02}^2\Phi_{11}$. Since the Jacobian $J=-\frac{8}{3}\Phi_{02}(\Phi_{02}-2\Phi_{11})(\Phi_{02}+2\Phi_{11})\neq 0$, it follows that the Ricci invariants r_1, r_2 are always backsolvable for Φ_{ab}.

The Weyl and mixed invariants, in this case, take the form

$$w_1=\tfrac{1}{3}(\Psi_0\Psi_4-4\Psi_1\Psi_3+3\Psi_2^2),$$

$$w_2=2\Psi_1\Psi_2\Psi_3-\Psi_2^3-\Psi_0\Psi_3^2-\Psi_1^2\Psi_4+\Psi_0\Psi_2\Psi_4,$$

$$m_1=2\Psi_0\Phi_{02}+2\Psi_2\Phi_{02}^2-8\Psi_2\Phi_{11}^2,$$

$$m_2=\tfrac{2}{3}\Phi_{02}^2\Psi_0\Psi_4+\tfrac{4}{3}\Phi_{02}^2\Psi_1\Psi_3+4\Phi_{02}\Psi_0\Psi_2+8\Phi_{11}^2\Psi_2^2-\tfrac{16}{3}\Phi_{11}^2\Psi_1\Psi_3 -\tfrac{8}{3}\Phi_{11}^2\Psi_0\Psi_4-4\Phi_{02}\Psi_1^2-2\Phi_{02}^2\Psi_2^2,$$

$$m_3=-8\Phi_{11}^2\Phi_{02}\Psi_0+8\Phi_{11}^2\Phi_{02}^2\Psi_2-2\Phi_{02}^4\Psi_2.$$

Next, we begin the backsolving procedure for the Weyl components by noting that the system $\{m_1,m_3\}$, which contains only the Weyl components Ψ_0 and Ψ_2, has a Jacobian equal to $-9J^2/(16\Phi_{02})$ which is nonzero. Therefore, we may always solve for Ψ_0 and Ψ_2 in terms of m_1 and m_3 and Φ_{ab} (which in turn are determined by the Ricci invariants). We proceed by eliminating the product $\Psi_1\Psi_3$ between w_1 and m_2 to obtain an expression for Ψ_1^2 in terms of Ψ_0, Ψ_2, Ψ_4, Φ_{ab}, and invariants. This can always be done. In order to continue, we need to treat the cases when $\Psi_0=0$ separately.

Case 1: $\Psi_0\neq 0$: In this case, $m_3\neq-\Phi_{02}^2 m_1$. Since $\Psi_0\neq 0$, we may use the above expression for Ψ_1^2 and the combination of w_1 and w_2 which eliminates the product $\Psi_1\Psi_3$ to obtain an expression for Ψ_3^2 in terms of Ψ_0, Ψ_2, Ψ_4, Φ_{ab}, and invariants. Finally, solving w_1 for $\Psi_1\Psi_3$, squaring this expression and then substituting the above expressions for Ψ_1^2 and Ψ_3^2 yields a polynomial equation of degree 3 in Ψ_4 with the coefficients being polynomials in Ψ_0, Ψ_2, Φ_{ab}, and invariants. This polynomial can always be solved for Ψ_4, since the coefficient of Ψ_4^3 is $\Psi_0 J^2\neq 0$. It follows that complete backsolving has been achieved.

Case 2A: $\Psi_0=0$ & $\Psi_1\neq 0$: We note that, in this case, $m_3=-\Phi_{02}^2 m_1$. Also $(m_1^2+36r_1^2-36r_3)^2\neq 144m_2(r_2^2-r_3)$ and, together with $m_1=m_3=0$ or $m_1^3r_2^2-3m_1m_3^2r_1-2m_3^3=0$ when

$m_1 m_3 \neq 0$, provides the necessary and sufficient conditions for this case to occur. By a simple backsolving procedure, it is easily established that a complete set of invariants is $\{R, w_1, w_2, r_1, r_2, m_1, m_2\}$.

Case 2B: $\Psi_0 = \Psi_1 = 0$: The necessary and sufficient conditions for this case to occur are $w_2^2 = w_1^3$, $m_1^2 = 36(r_1^2 - r_3)w_1$, $m_2^2 = 36(r_1^2 - r_3)w_1^2$ and $m_1^3 r_2^2 - 3m_1 m_3^2 r_1 - 2m_3^3 = 0$. We can only backsolve for Ψ_2, where $\Psi_2^2 = w_1$, but cannot backsolve for Ψ_3 or Ψ_4. This is because these components do not appear in our invariants. It follows from the index theorem previously given (see the Appendix) that no other polynomial invariant formed from the Riemann tensor can contain these components (in our canonical frame). Hence, complete backsolving is not possible, in general, but maximal backsolving is possible with the (algebraically complete) set $\{R, w_1, r_1, r_2\}$.

B. Segre type [3,1]

The backsolving for this Segre type is very similar to [2,11]. A complete set of invariants is $\{R, w_1, w_2, r_1, m_1, m_2, m_3\}$ and, as will be shown below, complete backsolving is always possible, at least in principle, except when $\Psi_0 = \Psi_1 = 0$. As before, this exceptional case occurs when the null eigenvector of the Ricci tensor aligns with the repeated principal null direction of the Weyl tensor. However, maximal backsolving is always achievable using certain invariants from CZ.

In our canonical frame, the independent Ricci invariant is $r_1 = 4\Phi_{11}^2$ and, hence, $\Phi_{11} = \frac{1}{2}\sqrt{r_1}$. The Weyl and mixed invariants, in this case, take the form

$$w_1 = \tfrac{1}{3}(\Psi_0\Psi_4 - 4\Psi_1\Psi_3 + 3\Psi_2^2),$$

$$w_2 = 2\Psi_1\Psi_2\Psi_3 - \Psi_2^3 - \Psi_0\Psi_3^2 - \Psi_1^2\Psi_4 + \Psi_0\Psi_2\Psi_4,$$

$$m_1 = 16\Psi_1\Phi_{11} - 2\Psi_0,$$

$$m_2 = 4\Psi_1^2 - 4\Psi_0\Psi_2 - 16\Phi_{11}\Psi_1\Psi_2 + 16\Phi_{11}\Psi_0\Psi_3,$$

$$m_3 = -24\Phi_{11}^2\Psi_0 - 64\Phi_{11}^3\Psi_1.$$

We begin by noting that the system $\{m_1, m_3\}$ contains only the Weyl components Ψ_0 and Ψ_1. It can always be solved to give $\Psi_0 = -(m_1 r_1 + m_3)/(8r_1)$, $\Psi_1 = (3m_1 r_1 - m_3)/(32\sqrt{r_1^3})$. In order to continue, we need to treat the cases when $\Psi_0 = 0$ separately.

Case 1: $\Psi_0 \neq 0$: In this case, $m_3 \neq -m_1 r_1$. Since $\Psi_0 \neq 0$, we can solve m_2 for Ψ_3 in terms of Ψ_0, Ψ_1, Ψ_2, Φ_{11}, and m_2. Using this expression to eliminate Ψ_3 from w_1, we can solve w_1 for Ψ_4 in terms of Ψ_0, Ψ_1, Ψ_2, Φ_{11}, w_1, and m_2. Substituting these expressions for Ψ_3 and Ψ_4 into w_2 yields a polynomial equation of degree 3 in Ψ_2. This polynomial can always be solved for Ψ_2, since the coefficient of Ψ_2^3 is $\Psi_0^2\Phi_{11}^2$ which is nonzero. It follows that complete backsolving has been achieved.

Case 2A: $\Psi_0 = 0$ & $\Psi_1 \neq 0$: In this case, $m_3 = -m_1 r_1$. This condition together with $m_1 \neq 0$ provides the necessary and sufficient conditions for this case to occur. A complete set of invariants is $\{R, w_1, w_2, r_1, m_1, m_2\}$ and is completely backsolvable (CB).

Case 2B: $\Psi_0 = \Psi_1 = 0$: In this case, $w_2^2 = w_1^3$. The necessary and sufficient conditions for this case to occur are $m_1 = m_2 = m_3 = 0$. We can only backsolve for Ψ_2, where $\Psi_2^2 = w_1$, but cannot backsolve for Ψ_3 or Ψ_4. This is because these components do not appear in our invariants. It follows from the index theorem that no other polynomial invariant formed from the Riemann tensor can contain these components (see the Appendix). Hence, complete backsolving is not possible (NCB), but maximal backsolving is possible with the (algebraically complete) set $\{R, w_1, r_1\}$.

C. Segre type [(1,1)11]

In our canonical frame, the independent Ricci invariants are $r_1=\frac{2}{3}(\Phi_{02}^2+2\Phi_{11}^2)$ and $r_2=-2\Phi_{02}^2\Phi_{11}$. It follows that the Ricci invariants r_1, r_2 are always backsolvable for Φ_{ab}.

Case 1: $\Psi_0\neq 0$: In this case, we may use the tetrad freedom to make $\Psi_0\overline{\Psi}_0=1$. Further, we shall need to treat the cases where $\Psi_3=0$ or $\Psi_4=0$ separately.

Case 1A: $\Psi_3\Psi_4\neq 0$: We will now show that a complete set is $\{R,w_1,w_2,r_1,r_2,m_1,m_2,m_4\}$ and complete backsolving is always possible. The invariants in this frame are

$$w_1=\tfrac{1}{3}(\Psi_0\Psi_4-4\Psi_1\Psi_3+3\Psi_2^2),$$

$$w_2=2\Psi_1\Psi_2\Psi_3-\Psi_2^3-\Psi_0\Psi_3^2-\Psi_1^2\Psi_4+\Psi_0\Psi_2\Psi_4,$$

$$m_1=2\Psi_2(\Phi_{02}^2-4\Phi_{11}^2),$$

$$m_2=\tfrac{2}{3}(\Phi_{02}^2\Psi_0\Psi_4+2\Phi_{02}^2\Psi_1\Psi_3+12\Phi_{11}^2\Psi_2^2-4\Phi_{11}^2\Psi_0\Psi_4-3\Phi_{02}^2\Psi_2^2-8\Phi_{11}^2\Psi_1\Psi_3),$$

$$m_4=(16\Psi_2\Phi_{11}^2\overline{\Psi}_2\Psi_0+\Phi_{02}^2\Psi_4+8\Psi_3\Phi_{11}\overline{\Psi}_1\Phi_{02}\Psi_0+2\Psi_2\Phi_{02}^2\overline{\Psi}_2\Psi_0 +8\Psi_1\Phi_{11}\overline{\Psi}_3\Phi_{02}\Psi_0+\Psi_0^2\Phi_{02}^2\overline{\Psi}_4)/\Psi_0.$$

m_1 can always be solved for Ψ_2 since $\Phi_{02}^2-4\Phi_{11}^2\neq 0$. We can always solve w_1 and m_2 to get $\Psi_1=C_1/\Psi_3$ and $\Psi_4=C_4/\Psi_0$, where C_1, C_4 are given by Φ_{ab}, Ψ_2 and invariants. Substituting these expressions into w_2 we get the quadratic polynomial equation $\psi^2+(w_2-2C_1\Psi_2-C_4\Psi_2+\Psi_2^3)\psi+C_1^2C_4=0$, where $\psi=\Psi_0\Psi_3^2\neq 0$. This can always be solved for ψ in terms of Φ_{ab}, Ψ_2 and invariants. Substituting $\Psi_3=\sqrt{\psi/\Psi_0}$ into m_4, we get the following quartic polynomial equation in Ψ_0:

$$\Psi_0^4\Phi_{02}^2\overline{C}_4\sqrt{\psi\overline{\psi}}+8C_1\Phi_{02}\Psi_0^3\overline{\psi}\Phi_{11}-\sqrt{\psi\overline{\psi}}(m_4-2\Psi_2\Phi_{02}^2\overline{\Psi}_2-16\Psi_2\Phi_{11}^2\overline{\Psi}_2)\Psi_0^2 +8\psi\Psi_0\Phi_{11}\overline{C}_1\Phi_{02}+\Phi_{02}^2C_4\sqrt{\psi\overline{\psi}}=0,$$

which can always be solved for Ψ_0 since the coefficient of Ψ_0^4 is nonzero. Thus, Ψ_0 is determined in terms of Φ_{ab}, Ψ_2, ψ and invariants which in turn are all determinable by the invariants. Therefore, complete backsolving has been achieved.

Case 1B(i): $\Psi_3\Psi_1\Phi_{11}\neq 0$ & $\Psi_4=0$: For this case, a complete set is $\{R,w_1,w_2,r_1,r_2,m_1,m_4\}$ and complete backsolving is always possible. It is similar to case 1A except that m_2 is dependent (since $\Psi_4=C_4=0$).

Case 1B(ii): $\Psi_3\Phi_{11}\neq 0$ and $\Psi_1=\Psi_4=0$: A complete set is $\{R,\ w_1,\ w_2,\ r_1,\ r_2,\ \tilde{m}_5/\bar{\tilde{m}}_5\}$ and complete backsolving is again always possible. The Weyl and mixed invariants in this frame are

$$w_1=\Psi_2^2,\quad w_2=-\Psi_2^3-\Psi_0\Psi_3^2,$$

$$m_5=2(\Psi_2^2\Phi_{02}^2\overline{\Psi}_2\Psi_0-4\Psi_3\Phi_{11}\overline{\Psi}_3\Phi_{02}\Psi_0^2+8\Psi_2^2\Phi_{11}^2\overline{\Psi}_2\Psi_0+\Psi_3^2\Phi_{02}^2)/\Psi_0.$$

w_1 determines Ψ_2 and w_2 gives $\Psi_3^2=-(\Psi_2^3+w_2)/\Psi_0$. Finally, we need to determine Ψ_0. Substituting this expression into m_5 we get the cubic polynomial equation in Ψ_0: $8\Phi_{02}\Phi_{11}\overline{Q}_1\Psi_0^3-Q_0\Psi_0^2+2\Phi_{02}^2Q_1=0$ where $Q_0=[m_5+2\Psi_2^2\overline{\Psi}_2(\Phi_{02}^2+8\Phi_{11}^2)]/Q_1$ and $Q_1^2=\Psi_2^3+w_2\neq 0$. From this equation and its complex conjugate, we eliminate Ψ_0^3 (this can always be done) to obtain $\Phi_{02}Q_0\Psi_0^2-4\Phi_{11}\overline{Q}_0\Psi_0+2\Phi_{02}(16\Phi_{11}^2-\Phi_{02}^2)Q_1=0$. First, we consider the special case when $Q_0=0$. It then follows that m_5 is dependent and, from the original cubic, we obtain $\Psi_0^3=-\Phi_{02}Q_1/(4\Phi_{11}\overline{Q}_1)$ with the condition $\Phi_{02}^2=16\Phi_{11}^2$. Henceforth, we shall assume $Q_0\neq 0$. Eliminating Ψ_0^2 from the quadratic equation and its complex conjugate yields $4\Phi_{11}(Q_0^2$

$-\overline{Q}_0\overline{Q}_2)\Psi_0=\Phi_{02}(Q_0\overline{Q}_0-Q_2\overline{Q}_2)$ where $Q_2=2(16\Phi_{11}^2-\Phi_{02}^2)Q_1$. If $Q_0^2-\overline{Q}_0\overline{Q}_2=0$ (i.e., $Q_2\overline{Q}_2=Q_0\overline{Q}_0$ which is the real syzygy eliminating "half" of the information in m_5), then the quadratic equation becomes $\Phi_{02}Q_0^2\Psi_0^2-4\Phi_{11}Q_0\overline{Q}_0\Psi_0+\Phi_{02}\overline{Q}_0^2=0$ which has the two possible solutions $\Psi_0=(2\Phi_{11}\pm i\sqrt{\Phi_{02}^2-4\Phi_{11}^2})\overline{Q}_0/(\Phi_{02}Q_0)$ with the condition $\Phi_{02}^2>4\Phi_{11}^2$. In this case, $\tilde{m}_5\equiv\overline{Q}_0$. If $Q_0^2-\overline{Q}_0\overline{Q}_2\neq 0$, then we obtain $\Psi_0^2=\tilde{m}_5/\bar{\tilde{m}}_5$ where $\tilde{m}_5\equiv(Q_2\overline{Q}_2-Q_0\overline{Q}_0)/(Q_0^2-\overline{Q}_0\overline{Q}_2)$ with the real syzygy $\tilde{m}_5\bar{\tilde{m}}_5=16\Phi_{11}^2/\Phi_{02}^2$. In this case, the independent information resides in the composite invariant $\tilde{m}_5/\bar{\tilde{m}}_5$ which contains "half" of the information in m_5. The other "half" of the information in m_5 is not independent but is determined by the values of the other invariants $\{w_1,w_2,r_1,r_2\}$ via the real syzygy previously given.

Case 1B(iii): $\Psi_3\Psi_1\neq 0$ and $\Psi_4=\Phi_{11}=0$: A complete set is $\{R,w_1,w_2,r_1,m_1,\overline{m}_5^*/m_5^*\}$ and complete backsolving is always possible. The Weyl and mixed invariants in this frame are

$$w_1=\tfrac{1}{3}(3\Psi_2^2-4\Psi_1\Psi_3),\quad w_2=2\Psi_1\Psi_2\Psi_3-\Psi_2^3-\Psi_0\Psi_3^2,$$

$$m_1=2\Psi_2\Phi_{02}^2,\quad m_5=2\Phi_{02}^2(2\Psi_1\Psi_3\overline{\Psi}_2\Psi_0-3\Psi_2^2\overline{\Psi}_2\Psi_0-3\Psi_3^2)/(3\Psi_0).$$

m_1 determines Ψ_2 and then w_1 and w_2 give $\Psi_1=3(\Psi_2^2-w_1)/(4\Psi_3)$ and $\Psi_3^2=(m_1^3-12m_1w_1\Phi_{02}^4-16w_2\Phi_{02}^6)/(16\Psi_0\Phi_{02}^6)$. After substituting these expressions into m_5 and solving for Ψ_0, we obtain $\Psi_0^4=\overline{m}_5^*/m_5^*$ (or $\Psi_0^2=-\overline{m}_5^*$) where $m_5^*\overline{m}_5^*=1$ and m_5^* is defined by

$$m_5^*\equiv(8\Phi_{02}^4m_5+m_1^2\overline{m}_1+4\Phi_{02}^4w_1\overline{m}_1)/(m_1^3-12m_1w_1\Phi_{02}^4-16w_2\Phi_{02}^6).$$

In this case, the independent information resides in the composite invariant $\overline{m}_5^*/m_5^*$ which contains "half" of the information in m_5. The other "half" of the information in m_5 is not independent but is determined by the values of the other invariants $\{w_1,w_2,r_1,m_1\}$ via the real syzygy $m_5^*\overline{m}_5^*=1$.

Case 1B(iv): $\Psi_3\neq 0$ and $\Psi_1=\Psi_4=\Phi_{11}=0$: This case is similar to case 1B(iii) with basically the same equations holding, except that m_1 is now dependent because $m_1^2=4\Phi_{02}^4w_1$. Hence, a complete set is $\{R,w_1,w_2,r_1,\overline{m}_5^*/m_5^*\}$ and complete backsolving has been established.

Case 1C: $\Psi_3=0$ and $\Psi_4\neq 0$: A complete set is $\{R,w_1,w_2,r_1,r_2,m_1,m_4\}$ as complete backsolving can be easily carried out.

Case 1D: $\Psi_3=\Psi_4=0$: A maximal (complete) set in this case is $\{R,w_1,r_1,r_2\}$ and NCB. Clearly complete backsolving is impossible since only Ψ_2 can be solved for using w_1, while Ψ_0 and Ψ_1 remain undetermined (see the Appendix). All mixed invariants are dependent.

Case 2: $\Psi_0=0$ and $\Psi_1\neq 0$: We may use the tetrad freedom to make $\Psi_1\overline{\Psi}_1=1$. Further, we shall need to treat the cases where $\Psi_3=0$ or $\Psi_4=0$ separately.

Case 2A(i): $\Psi_3\Phi_{11}\neq 0$: A complete set is $\{R,w_1,w_2,r_1,r_2,m_1,m_4\}$ and is CB.

Case 2A(ii): $\Psi_3\Psi_4\neq 0$ and $\Phi_{11}=0$: A complete set is $\{R,w_1,w_2,r_1,m_1,\hat{\bar{m}}_5/\hat{m}_5\}$. The invariants in this frame are

$$w_1=\tfrac{1}{3}(3\Psi_2^2-4\Psi_1\Psi_3),\quad w_2=2\Psi_1\Psi_2\Psi_3-\Psi_2^3-\Psi_1^2\Psi_4,$$

$$m_1=2\Psi_2\Phi_{02}^2,\ \ m_5=\tfrac{2}{3}\Phi_{02}^2(2\Psi_1\overline{\Psi}_2\Psi_3-3\Psi_2^2\overline{\Psi}_2-3\Psi_1^2\overline{\Psi}_4).$$

m_1 can always be solved for Ψ_2 since $\Phi_{02}\neq 0$. We can always solve w_1 and w_2 to get $\Psi_3=3(\Psi_2^2-w_1)/(4\Psi_1)\neq 0$ and $\Psi_4=(\Psi_2^3-3\Psi_2w_1-2w_2)/(2\Psi_1^2)$. Substituting these expressions into m_5 we obtain the polynomial equation

$$\Phi_{02}^2(\overline{\Psi}_2^3-3\overline{\Psi}_2\overline{w}_1-2\overline{w}_2)\Psi_1^4+m_5+\Phi_{02}^2\overline{\Psi}_2(\Psi_2^2+w_1)=0.$$

This gives $\Psi_1^4=\hat{m}_5/\overline{Q_3}$ together with the real syzygy $\hat{m}_5\overline{\hat{m}}_5=Q_3\overline{Q_3}$, where $\hat{m}_5\equiv 18r_1^2m_5+9r_1^2w_1\overline{m}_1+m_1^2\overline{m}_1$ and $Q_3\equiv 27r_1^2w_1m_1+54r_1^3w_2-m_1^3$. Alternatively, $\Psi_1^8=\hat{m}_5Q_3/(\overline{\hat{m}}_5\overline{Q_3})$. Note that $Q_3\neq 0$ since $\Psi_4\neq 0$. Hence, backsolving is complete.

Case 2A(iii): $\Psi_3\neq 0$ and $\Psi_4=\Phi_{11}=0$: A complete set is $\{R,w_1,w_2,r_1,m_6\}$ and is CB.

Case 2B(i): $\Psi_3=0$ and $\Psi_4\neq 0$: A complete set is $\{R,w_1,w_2,r_1,r_2,\overline{m}_5'/m_5'\}$ and complete backsolving is always possible. The Weyl and mixed invariants in this frame are

$$w_1=\Psi_2^2,\quad w_2=-\Psi_2^3-\Psi_1^2\Psi_4,$$

$$m_5=2(4\Psi_4\Phi_{02}\Phi_{11}-\Psi_2^2\Phi_{02}^2\overline{\Psi}_2-8\Psi_2^2\Phi_{11}^2\overline{\Psi}_2-\Psi_1^2\Phi_{02}^2\overline{\Psi}_4).$$

The invariant w_1 determines Ψ_2 and Ψ_4 is determined, in terms of Ψ_1 and w_1 and w_2, by $\Psi_4=-(\Psi_2^3+w_2)/\Psi_1^2$. Substituting these expressions into m_5 we obtain the polynomial equation

$$2\Phi_{02}^2(\overline{w}_2+\overline{\Psi}_2^3)\Psi_1^6-Q_4\Psi_1^2-8\Phi_{02}\Phi_{11}(w_2+\Psi_2^3)=0,$$

where $Q_4\equiv m_5+2(\Phi_{02}^2+8\Phi_{11}^2)\Psi_2\overline{\Psi}_2$.

If $Q_4=0$, then necessarily $\Phi_{11}\neq 0$ and m_5 is dependent. In this case, we have $\Psi_1^6=4\Phi_{11}(w_2+\Psi_2^3)/[\Phi_{02}(\overline{w}_2+\overline{\Psi}_2^3)]$ with the condition $\Phi_{02}^2=16\Phi_{11}^2$. Henceforth, we shall assume that $Q_4\neq 0$. Combining the sixth degree equation together with its complex conjugate to eliminate Ψ_1^6 yields the quartic equation $\Phi_{02}\overline{Q}_4\Psi_1^4+4\Phi_{11}Q_4\Psi_1^2-\Phi_{02}Q_5=0$ where $Q_5\equiv 2(\Phi_{02}^2-16\Phi_{11}^2)\times(w_2+\Psi_2^3)$. If $\Phi_{11}=0$, then $Q_4Q_5\neq 0$ and $\Psi_1^8=m_5'/\overline{m}_5'$ (or $\Psi_1^4=m_5'$) together with the real syzygy $m_5'\overline{m}_5'=1$, where, in this case, $m_5'\equiv Q_4/\overline{Q}_5$. Next, we assume that $\Phi_{11}\neq 0$. It follows that if $Q_4^2+\overline{Q}_4Q_5=0\Leftrightarrow Q_4\overline{Q}_4-Q_5\overline{Q}_5=0$ (which is the real syzygy eliminating "half" of the information in m_5), then we obtain the bi-quadratic equation $\Phi_{02}\overline{Q}_4^2\Psi_1^4+4\Phi_{11}Q_4\overline{Q}_4\Psi_1^2+\Phi_{02}Q_4^2=0$ which has the two possible solutions $\Psi_0^2=(-2\Phi_{11}\pm i\sqrt{\Phi_{02}^2-4\Phi_{11}^2})Q_4/(\Phi_{02}\overline{Q}_4)$ with the condition $\Phi_{02}^2>4\Phi_{11}^2$. In this case, $m_5'=Q_4$.

Finally, we consider the case when $\Phi_{11}Q_4(Q_4\overline{Q}_4-Q_5\overline{Q}_5)\neq 0$. Combining the above quartic equation together with its complex conjugate yields $\Psi_1^4=m_5'/\overline{m}_5'$ (or equivalently $\Psi_1^2=-4\Phi_{11}m_5'/\Phi_{02}$) together with the real syzygy $16m_5'\overline{m}_5'=\Phi_{02}^2/\Phi_{11}^2$, where, in this case, $m_5'\equiv(Q_4^2+\overline{Q}_4Q_5)/(Q_4\overline{Q}_4-Q_5\overline{Q}_5)$.

Case 2B(ii): $\Psi_3=\Psi_4=0$: It immediately follows that a maximal (complete) set is $\{R,w_1,r_1,r_2\}$ and complete backsolving is impossible, since only Ψ_2 can be solved for using w_1 while the argument of Ψ_1 remains undetermined (see the Appendix).

Case 3: $\Psi_0=\Psi_1=0$ and $\Psi_3\neq 0$: We may use the tetrad freedom to make $\Psi_3\overline{\Psi}_3=1$. It follows that a maximal (complete) set is $\{R,w_1,r_1,r_2\}$ and NCB, since only Ψ_2 can be solved for using w_1 while the argument of Ψ_3 and Ψ_4 remain undetermined (see the Appendix).

Case 4: $\Psi_0=\Psi_1=\Psi_3=0$: If $\Psi_4\neq 0$, then we may use the tetrad freedom to make $\Psi_4\overline{\Psi}_4=1$. In this case, a maximal set is $\{R,w_1,r_1,r_2\}$ and NCB, since only Ψ_2 can be solved for using w_1 while the argument of Ψ_4 remains undetermined (see the Appendix). This case corresponds to an alignment between the eigenvector of the Ricci tensor and the repeated PND of the Weyl tensor. On the other hand, if $\Psi_4=0$,[3] then the set $\{R,w_1,r_1,r_2\}$ is complete.

D. Segre type [(1,1)(11)]

In our canonical frame, the only nonzero Ricci component is Φ_{11}. Hence, the only independent Ricci invariant is $r_1=4/3\Phi_{11}^2$ which determines Φ_{11}.

Case 1: $\Psi_0\neq 0$: We use the tetrad freedom to make $\Psi_0=1$. Further, we shall need to treat the cases where $\Psi_3=0$ or $\Psi_4=0$ separately.

Case 1A: $\Psi_3\neq 0$: A complete set is $\{R,w_1,w_2,r_1,m_1,m_2\}$ and is CB.

Case 1B(i): $\Psi_3=0$ and $\Psi_4\neq 0$: A complete set is $\{R,w_1,w_2,r_1,m_1\}$ and is CB.

Case 1B(ii): $\Psi_3=\Psi_4=0$: In this case all mixed invariants are dependent and $w_1=\Psi_2^2$ is the only independent Weyl invariant. Hence, a maximal (complete) set is $\{R,w_1,r_1\}$ and is NCB (see the Appendix).

Case 2: $\Psi_0=0$ and $\Psi_1\neq 0$: We use the tetrad freedom to make $\Psi_1=1$. It follows that a complete set is $\{R,w_1,w_2,r_1,m_1\}$ and is CB.

Case 3: $\Psi_0=\Psi_1=0$: If $\Psi_3=0$, we can make $\Psi_4=1$ (provided $\Psi_4\neq 0$), and then the complete set is $\{R,w_1,r_1\}$ with $w_1=\Psi_2^2$ determining Ψ_2. If $\Psi_3=\Psi_4=0$, then the same set is complete. In both of these cases, backsolving is complete. On the other hand, if $\Psi_3\neq 0$, we can make $\Psi_3=1$, and then a maximal (complete) set is $\{R,w_1,r_1\}$ with $w_1=\Psi_2^2$, while Ψ_4 is still undetermined (see the Appendix).

E. Segre type [2,(11)]

In our canonical frame, the only nonzero Ricci components are Φ_{11} and $\Phi_{22}=1$. Hence, the only independent Ricci invariant is $r_1=4/3\Phi_{11}^2$ which determines Φ_{11}.

Case 1: $\Psi_0\neq 0$: We use the tetrad freedom to make Ψ_0 real. Further, we shall need to treat the cases where $\Psi_3=0$ or $\Psi_4=0$ separately.

Case 1A: $\Psi_3\neq 0$: A complete set is $\{R,w_1,w_2,r_1,m_1,m_2,m_4\}$ and is CB.

Case 1B(i): $\Psi_3=0$ and $\Psi_4\neq 0$: In this case a complete set is $\{R,w_1,w_2,r_1,m_1,m_4\}$ since m_2 is dependent, and complete backsolving is again always possible.

Case 1B(ii): $\Psi_3=\Psi_4=0$: A complete set is $\{R,w_1,r_1,m_4,m_5\}$ and is CB.

Case 2: $\Psi_0=0$ and $\Psi_1\neq 0$: A complete set is $\{R,w_1,w_2,r_1,m_1,m_4\}$ and is CB. This is more easily established in a frame where Ψ_1 is real.

Case 3: $\Psi_0=\Psi_1=0$: In this case, a maximal (complete) set is $\{R,w_1,r_1\}$ with $w_1=\Psi_2^2$, while Ψ_3 (which can be made real if nonzero) and Ψ_4 are still undetermined (see the Appendix). Complete backsolving is not, in general, possible.

F. Segre type [(2,1)1]

In our canonical frame, the only nonzero Ricci components are $\Phi_{02}=-2\Phi_{11}=\Phi_{20}$ and $\Phi_{22}=1$. Hence, the only independent Ricci invariant is $r_1=4\Phi_{11}^2$, which determines Φ_{11}.

Case 1: $\Psi_0\neq 0$: We may use the tetrad freedom to make Ψ_1 real or imaginary, depending on the structure of Ψ_0. We note that m_1 being either not real or real invariantly distinguishes case 1A from case 1B.

Case 1A: $\mathrm{Im}(\Psi_0)\neq 0$: A complete set is $\{R,w_1,w_2,r_1,m_1,m_2,m_4\}$ and is CB. This is easily shown in a frame where Ψ_1 is real.

Case 1B: $\mathrm{Im}(\Psi_0)=0$ and $\mathrm{Re}(\Psi_0)\neq 0$: In this case m_1 is real. It can be shown that a complete set is $\{R,w_1,w_2,r_1,m_1,m_2,m_4\}$ and CB, which is more easily established in a frame where Ψ_1 is imaginary.

Case 2: $\Psi_0=0$ and $\Psi_1\neq 0$: In this case, we may use the tetrad freedom to make Ψ_2 real or imaginary, depending on the structure of Ψ_1. Also $m_1=0$ and the nature of m_2 invariantly distinguishes case 2A from case 2B.

Case 2A: $\mathrm{Im}(\Psi_1)\neq 0$: A complete set is $\{R,w_1,w_2,r_1,m_2,m_4\}$ and is CB, which is easily established in a frame where Ψ_2 is real.

Case 2B: $\mathrm{Im}(\Psi_1)=0$ and $\mathrm{Re}(\Psi_1)\neq 0$: In this case m_2 is real. It can be shown that a complete set is $\{R,w_1,w_2,r_1,m_2,m_4\}$ and is CB, which is easily established in a frame where Ψ_2 is imaginary.

Case 3: $\Psi_0=\Psi_1=0$: A maximal (complete) set is $\{R,w_1,r_1\}$ with $w_1=\Psi_2^2$, while Ψ_3 and Ψ_4 remain, in general, not completely determined (even though there still remains tetrad freedom to remove one unknown "part" of Ψ_3 or Ψ_4). Complete backsolving is, in general, not possible (see the Appendix).

G. Segre type [(3,1)]

In our canonical frame, the only nonzero Ricci components are $\Phi_{12}=\Phi_{21}=1$. All Ricci invariants vanish.

Case 1: $\Psi_0\neq 0$: We will use the tetrad freedom to make Ψ_1 real or imaginary, depending on the structure of Ψ_0. We note that m_1 being either not imaginary or imaginary invariantly distinguishes case 1A from case 1B.

Case 1A: $\mathrm{Re}(\Psi_0)\neq 0$: A complete set is $\{R,w_1,w_2,m_1,m_2,m_4\}$ and is CB. This is easily established in a frame where Ψ_1 is real.

Case 1B: $\mathrm{Re}(\Psi_0)=0$ and $\mathrm{Im}(\Psi_0)\neq 0$: In this case m_1 is imaginary. A complete set is $\{R,w_1,w_2,m_1,m_2,m_4\}$ and is CB. This is readily shown in a frame where Ψ_1 is imaginary.

Case 2: $\Psi_0=0$ and $\Psi_1\neq 0$: In this case $m_1=0$ and we may use the tetrad freedom to make Ψ_2 real or imaginary, depending on the structure of Ψ_1. We note that the nature of m_2 invariantly distinguishes case 2A from case 2B.

Case 2A: $\mathrm{Re}(\Psi_1)\neq 0$: We now use the tetrad freedom to make Ψ_2 real and will show that a complete set is $\{R,w_1,w_2,m_2,|m_5|\}$ and complete backsolving is always possible. The Weyl and mixed invariants in this frame are

$$w_1=\tfrac{1}{3}(3\Psi_2^2-4\Psi_1\Psi_3),\quad w_2=2\Psi_1\Psi_2\Psi_3-\Psi_1^2\Psi_4-\Psi_2^3,$$

$$m_2=4\Psi_1^2,\quad m_5=-8\Psi_1\Psi_2(\Psi_1+\bar{\Psi}_1).$$

This system of invariants can be solved (implicitly) for the NP Weyl components to yield

$$\Psi_1^2=m_2/4,\quad \Psi_2^2=|m_5|^2/[64\Psi_1\bar{\Psi}_1(\Psi_1+\bar{\Psi}_1)^2],$$

$$\Psi_3=3(\Psi_2^2-w_1)/(4\Psi_1)\ \text{and}\ \Psi_4=(2\Psi_1\Psi_2\Psi_3-\Psi_2^3-w_2)/\Psi_1^2.$$

Note that the invariant m_5 satisfies the real syzygy $\bar{m}_2m_5^2=m_2\bar{m}_5^2$. Also, the real invariant m_6 could be used instead of $|m_5|$.

Case 2B: $\mathrm{Re}(\Psi_1)=0$ and $\mathrm{Im}(\Psi_1)\neq 0$: In this case m_2 is real and negative and we may use the tetrad freedom to make Ψ_2 imaginary. Following the same procedure as in case 2A (with some sign differences), it can be shown that a complete set is $\{R,w_1,w_2,m_2,|m_5|\}$ and complete backsolving is always possible.

Case 3: $\Psi_0=\Psi_1=0$: A maximal (complete) set is $\{R,w_1\}$ with $w_1=\Psi_2^2$, while Ψ_3 and Ψ_4 remain, in general, not completely determined (even though there still remains tetrad freedom to remove one unknown "part" of Ψ_3 or Ψ_4). Complete backsolving is, in general, not possible (see the Appendix).

H. Segre type [(1,11)1]

For this Segre type, it is easier to use the Weyl canonical frame. The Ricci components, in general, are[9] $\Phi_{00}=\pm 2\alpha^2$, $\Phi_{01}=\pm 2\alpha\beta$, $\Phi_{02}=\pm 2\beta^2$, $\Phi_{11}=\pm(\alpha\gamma+\beta\bar{\beta})$, $\Phi_{12}=\pm 2\beta\gamma$, $\Phi_{22}=\pm 2\gamma^2$ (with the same sign all throughout) where α and γ are real, β is complex and $\alpha\gamma<\beta\bar{\beta}$. The only independent Ricci invariant is $r_1=4(\alpha\gamma-\beta\bar{\beta})^2$, therefore, $\gamma=(2\beta\bar{\beta}-\sqrt{r_1})/(2\alpha)$ if $\alpha\neq 0$, otherwise, $\beta\bar{\beta}=\frac{1}{2}\sqrt{r_1}$. In the analysis that follows, we will choose the "+" sign throughout. The analysis with the opposite sign only differs trivially in the intermediate steps, but the final conclusion does not differ.

For this Segre type and Petrov types I, II, and III, the backsolving calculations for when $\alpha\neq 0$ are virtually identical to the ones in Segre type [1,(111)] and corresponding Petrov types.[2] However, here we need to consider the case when $\alpha=0$, as well. Hence, for these Petrov types, we shall present only the backsolving for the Ricci components for when $\alpha=0$.

1. Segre type [(1,11)1], Petrov type I

Case 1: $\alpha\neq 0$: A complete set is $\{R,w_1,w_2,r_1,m_4,m_5\}$ and is CB.

Case 2: $\alpha=0$: In this case, $\beta\neq 0$, m_4 is dependent with $\beta\overline{\beta}=\frac{1}{2}\sqrt{r_1}$ and

$$m_5=8\Psi_0^2\beta^2(\overline{\Psi}_2\overline{\beta}^2+\overline{\Psi}_0\gamma^2)+8\Psi_0\Psi_2(\overline{\Psi}_0\gamma^4+\overline{\Psi}_0\beta^4+\overline{\Psi}_0\overline{\beta}^4+6\overline{\beta}^2\overline{\Psi}_2\gamma^2)$$
$$-24\Psi_2^2\beta^2(\overline{\Psi}_2\overline{\beta}^2+\overline{\Psi}_0\gamma^2).$$

Substituting $\overline{\beta}=\sqrt{r_1}/(2\beta)$ into m_5 and $\overline{m}_5$ and then eliminating γ from m_5 and $\overline{m}_5$ we get a polynomial of degree 16 in β with the coefficient of β^{16} being $256\Psi_0\overline{\Psi}_0^3\overline{\Psi}_2^2(3\Psi_2-\Psi_0)^2(3\Psi_2+\Psi_0)^2\neq 0$. Hence, we can determine β and then γ. Thus complete backsolving has been achieved.

2. Segre type [(1,11)1], Petrov type II

Case 1: $\alpha\neq 0$: A complete set is $\{R,w_1,r_1,m_4,m_5\}$ and is CB.

Case 2: $\alpha=0$: In this case, $m_4^2=36r_1w_1\overline{w}_1$, $m_5^2=36r_1w_1^2\overline{w}_1$, $\beta\overline{\beta}=\frac{1}{2}\sqrt{r_1}$ and a maximal (complete) set is $\{R,w_1,r_1\}$. We can only determine $|\beta|$ and the argument of β and γ are still undetermined, hence, is NCB. Using the index theorem, it can be shown that no invariants can determine these unknown quantities (see the Appendix). Further, we have, using (1), $S_{ab}l^b=-2\Phi_{11}l_a$. Hence, l^a is an eigenvector of the Ricci tensor as well as the repeated eigenvector of the Weyl tensor.

3. Segre type [(1,11)1], Petrov type III

Case 1: $\alpha\neq 0$: A complete set is $\{R,r_1,m_4,m_5\}$ and is CB.

Case 2: $\alpha=0$: In this case, $m_4=m_5=0$, $|\beta|=\frac{1}{2}\sqrt{r_1}$ and a maximal (complete) set is $\{R,r_1\}$. We can only determine $|\beta|$ and the argument of β, and γ are still undetermined, hence, is NCB. Using the index theorem, it can be shown that no invariants can determine these unknown quantities (see the Appendix). Again, we obtain $S_{ab}l^b=-2\Phi_{11}l_a$. Thus, l^a is an eigenvector of the Ricci tensor as well as the repeated eigenvector of the Weyl tensor.

4. Segre type [(1,11)1], Petrov type D

For this type $w_1=\Psi_2^2$ which determines Ψ_2. In our Weyl canonical frame, the only nonzero Weyl component is Ψ_2. In all type D cases below, complete backsolving is achievable.

Case 1: $\alpha\beta\neq 0$: We can make $\beta=1/\alpha$ (real) and it can be easily shown that the complete set is $\{R,w_1,r_1,m_4\}$. Note that $m_5^2=w_1m_4^2$.

Case 2: $\alpha\gamma\neq 0$ and $\beta=0$: We can make $\alpha=\pm 1$ and, hence, $\gamma=\mp\frac{1}{2}\sqrt{r_1}$. A complete set, in this case, is $\{R,w_1,r_1\}$. Note that $m_5^2=w_1m_4^2=36w_1^2\overline{w}_1r_1^2$.

Case 3: $\beta\gamma\neq 0$ and $\alpha=0$: We can make $\beta=1/\gamma$ (real) and, hence, $\beta^2=1/\gamma^2=\frac{1}{2}\sqrt{r_1}$. A complete set, in this case, is $\{R,w_1,r_1\}$. Note that $m_5^2=w_1m_4^2=36w_1^2\overline{w}_1r_1^2$.

Case 4: $\beta\neq 0$ and $\alpha=\gamma=0$: We can make β real and, hence, $\beta^2=\frac{1}{2}\sqrt{r_1}$. A complete set, in this case, is $\{R,w_1,r_1\}$. Note that $m_5^2=w_1m_4^2=36w_1^2\overline{w}_1r_1^2$.

5. Segre type [(1,11)1], Petrov type N

For this Petrov type, $w_1=w_2=0$. In our Weyl canonical frame, the only nonzero Weyl component is $\Psi_4=1$. We can use the remaining tetrad freedom to make $\beta=0$ if $\alpha\neq 0$, otherwise, we can make $\gamma=0$

Case 1: $\alpha\neq 0$ and $\beta=0$: In this case, $m_4=4\alpha^4$, $m_5=0$ and $\gamma=-\sqrt{r_1}/(2\alpha)$. Hence, a complete set is $\{R,r_1,m_4\}$ and complete backsolving is always possible.

Case 2: $\alpha=\gamma=0$ and $\beta\neq 0$: In this case, $m_4=m_5=0$, $\beta\overline{\beta}=\frac{1}{2}\sqrt{r_1}$ and a maximal (complete) set is $\{R,r_1\}$. We can only determine $|\beta|$ and the argument of β is still undetermined, in general, hence, backsolving is incomplete. Using the index theorem, it can be shown that no invariants can

TABLE VI. Algebraically complete sets for Segre type [(1,11)1] with the different Petrov types.

Petrov type	Conditions (in Weyl canonical frame)	Complete sets (and subsets thereof)	CB/NCB
I	-	$\{R,w_1,w_2,r_1,m_4,m_5\}$	CB
II	$\Phi_{00}=\Phi_{01}=0$	$\{R,w_1,r_1\}$	NCB
	Otherwise	$\{R,w_1,r_1,m_4,m_5\}$	CB
III	$\Phi_{00}=\Phi_{01}=0$	$\{R,r_1\}$	NCB
	Otherwise	$\{R,r_1,m_4,m_5\}$	CB
D	-	$\{R,w_1,r_1,m_4,m_5\}$	CB
N	$\Phi_{00}=\Phi_{01}=\Phi_{12}=\Phi_{22}=0$	$\{R,r_1\}$	NCB
	Otherwise	$\{R,r_1,m_4,m_5\}$	CB
O	-	$\{R,r_1\}$	CB

determine these unknown quantities (see the Appendix). Also, $S_{ab}l^b=-2\Phi_{11}l_a$ and, therefore, l^a is an eigenvector of the Ricci tensor as well as the repeated eigenvector of the Weyl tensor.

6. Segre type [(1,11)1], Petrov type O

For this Petrov type $w_1=w_2=0$ and $\Psi_i=0$. We can use the tetrad freedom to make $\alpha=\gamma=0$ and β real, i.e., the Ricci canonical frame as well. In this case, $m_4=m_5=0$ and $\beta^2=\frac{1}{4}r_1$. Hence, a complete set is $\{R,r_1\}$ and complete backsolving is always possible.

See Table VI for a complete summary for this Segre type.

I. Segre type [(2,11)]

In our canonical frame, the only nonzero Ricci component is $\Phi_{22}=1$. Hence, all Ricci invariants vanish.

Case 1: $\Psi_0\neq 0$: A complete set is $\{R,w_1,w_2,m_4,m_5\}$ and is CB, which is easily established in a frame where Ψ_0 is real and $\Psi_1=0$.

Case 2: $\Psi_0=0$, and $\Psi_1\neq 0$: In this case, $m_4=m_5=0$. A complete set is $\{R,w_1,w_2,m_6\}$ and is CB, which is easily established in a frame where Ψ_1 is real and $\Psi_2=0$.

Case 3: $\Psi_0=\Psi_1=0$: In this case, a maximal (complete) set is $\{R,w_1\}$ with $w_1=\Psi_2^2$. If $\Psi_2\neq 0$, we can make $\Psi_3=0$ and with Ψ_4 being real (rotation freedom if necessary), it still remains undetermined. If $\Psi_2=0$ and $\Psi_3\neq 0$, then we can make Ψ_3 real and $\Psi_4=0$. In this case Ψ_3 remains undetermined. If $\Psi_2=\Psi_3=0$ and $\Psi_4\neq 0$, then we can make Ψ_4 real and it remains undetermined[3] (also, see the Appendix).

J. Segre type [(1,111)]

We can use the tetrad freedom to reduce the Weyl components to standard forms. In this case, all Ricci and mixed invariants vanish (since all $\Phi_{ab}=0$). Complete backsolving is always possible using the Weyl invariants w_1 and w_2.[9]

Table VII summarizes our results and Fig. 1 characterizes a set S of invariants according to our definitions.

IV. CONCLUSION

In this third article on the problem of algebraic completeness for the invariants of the Riemann tensor, we have exhaustively analyzed all canonically different space–times in which the Ricci tensor does have a null eigenvector. In each case we have given algebraically complete sets. It follows from this and the previous two articles[1,2] that the set CZ is determining, as was previously claimed. Interestingly, we have also shown that complete backsolving is, in general, not possible (but maximal backsolving has been achieved) when there is an alignment between an eigenvector of the Ricci tensor with the repeated principal null direction of the Weyl tensor.[3] In such cases all the mixed invariants are either zero or always dependent. Also, there is at most one complex Weyl invariant (w_1) and two real Ricci invariants (r_1 and r_2) together with R. As previously mentioned,

we suspect that some space–times within such classes will, in general, prove to be more difficult to distinguish as inequivalent. As a final point, there still remains to fully clarify the geometric meaning of the invariants, principally the mixed ones. This will be the main focus of our work in the next article in this series.

APPENDIX: APPLICATION OF THE INDEX THEOREM

In one of our previous articles,[1] an Index theorem was presented regarding the general structure of any invariant formed from the Weyl and Ricci spinors:

$$\Psi_{ABCD}=\Psi_0\iota_A\iota_B\iota_C\iota_D-4\Psi_1 o_{(A}\iota_B\iota_C\iota_{D)}+6\Psi_2 o_{(A}o_B\iota_C\iota_{D)}-4\Psi_3 o_{(A}o_B o_C\iota_{D)}+\Psi_4 o_A o_B o_C o_D,$$

$$\Phi_{AB\dot{A}\dot{B}}=\Phi_{00}\iota_A\iota_B\bar{\iota}_{\dot{A}}\bar{\iota}_{\dot{B}}-2\Phi_{01}\iota_A\iota_B\bar{\iota}_{(\dot{A}}\bar{o}_{\dot{B})}+\Phi_{02}\iota_A\iota_B\bar{o}_{\dot{A}}\bar{o}_{\dot{B}}-2\Phi_{10}o_{(A}\iota_{B)}\bar{\iota}_{\dot{A}}\bar{\iota}_{\dot{B}}+4\Phi_{11}\iota_{(A}o_{B)}\bar{\iota}_{(\dot{A}}\bar{o}_{\dot{B})}$$
$$-2\Phi_{12}\iota_{(A}o_{B)}\bar{o}_{\dot{A}}\bar{o}_{\dot{B}}+\Phi_{20}o_A o_B\bar{\iota}_{\dot{A}}\bar{\iota}_{\dot{B}}-2\Phi_{21}o_A o_B\bar{\iota}_{(\dot{A}}\bar{\iota}_{\dot{B})}+\Phi_{22}o_A o_B\bar{o}_{\dot{A}}\bar{o}_{\dot{B}}.$$

Index Theorem: Let a,b,c be non-negative integers and let $\boldsymbol{\Psi}^a\overline{\boldsymbol{\Psi}}^b\boldsymbol{\Phi}^c$ represent any of the complete contractions (invariant) of a copies of the Weyl spinor, b copies of its complex conjugate and c copies of the Ricci spinor. Then any term in the expansion of these invariants has the form

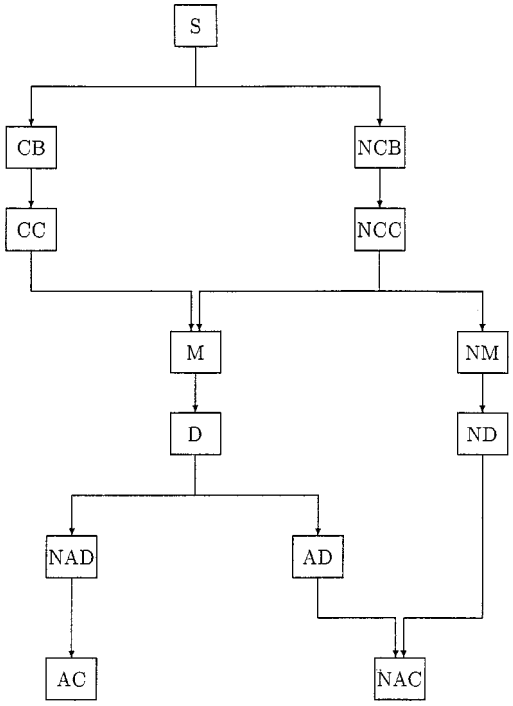

FIG. 1. Characterization of a set S of Riemann invariants. CB=completely backsolvable, NCB=not completely backsolvable, CC=curvature complete, NCC=not curvature complete, M=maximal, NM=not maximal, D=determining, ND=not determining, NAD=not always dependent, AD=always dependent, AC=algebraically complete, and NAC =not algebraically complete.

$$\Psi_0^{a_0}\Psi_1^{a_1}\Psi_2^{a_2}\Psi_3^{a_3}\Psi_4^{a_4}\overline{\Psi}_0^{b_0}\overline{\Psi}_1^{b_1}\overline{\Psi}_2^{b_2}\overline{\Psi}_3^{b_3}\overline{\Psi}_4^{b_4}\Phi_{00}^{c_{00}}\Phi_{01}^{c_{01}}\Phi_{02}^{c_{02}}\Phi_{10}^{c_{10}}\Phi_{11}^{c_{11}}\Phi_{12}^{c_{12}}\Phi_{20}^{c_{20}}\Phi_{21}^{c_{21}}\Phi_{22}^{c_{22}},$$

where $a_0,\ldots,a_4,b_0,\ldots,b_4,c_{00},\ldots,c_{22}$ are non-negative integers which must satisfy the following conditions:

$$a_0+a_1+a_2+a_3+a_4=a,\quad b_0+b_1+b_2+b_3+b_4=b,$$

$$c_{00}+c_{01}+c_{02}+c_{10}+c_{11}+c_{12}+c_{20}+c_{21}+c_{22}=c,$$

$$a_1+2a_2+3a_3+4a_4+c_{10}+c_{11}+c_{12}+2c_{20}+2c_{21}+2c_{22}=2a+c,$$

$$b_1+2b_2+3b_3+4b_4+c_{01}+2c_{02}+c_{11}+2c_{12}+c_{21}+2c_{22}=2b+c,$$

When applying the index theorem, note the following:

(1) If $\Phi_{ij}=0$ (or $\Psi_i=0$), we set $c_{ij}=0$ (or $a_i=b_i=0$).
(2) If an invariant does not include $\overline{\Psi}_i$'s, we set all $b_i=0$ and $b=0$.
(3) If $\Phi_{ij}=1$ (or $\Psi_i=1$), we do not set $c_{ij}=0$ (or $a_i=b_i=0$).
(4) If $\Phi_{ij}=\Phi_{kl}$, we do not set $c_{ij}=c_{kl}$.

We shall use this index theorem to prove the claims of non-backsolvability made above.

We begin by eliminating a, b and c to obtain the two conditions

$$2a_0+a_1+c_{00}+c_{01}+c_{02}=2a_4+a_3+c_{20}+c_{21}+c_{22}, \tag{A1}$$

$$2b_0+b_1+c_{00}+c_{10}+c_{20}=2b_4+b_3+c_{02}+c_{12}+c_{22}. \tag{A2}$$

Next, adding we obtain

$$2(a_0+b_0+c_{00})+(a_1+b_1+c_{01}+c_{10})=2(a_4+b_4+c_{22})+(a_3+b_3+c_{12}+c_{21}) \tag{A3}$$

For Segre type [2,11] with $\Psi_0=\Psi_1=0$ (in the Ricci canonical frame), we set $a_0=a_1=b_0=b_1=c_{00}=c_{01}=c_{10}=c_{12}=c_{21}=0$. Then Eq. (A3) gives $a_3+b_3+2(a_4+b_4+c_{22})=0$, which means that $a_3=b_3=a_4=b_4=c_{22}=0$, i.e., Ψ_3, $\bar{\Psi}_3$, Ψ_4 and $\bar{\Psi}_4$ (and Φ_{22}) will not appear in any invariant and hence, they cannot be determined. A similar argument can be used for the non-backsolvable cases in Segre types [3,1], [(1,1)11], [(1,1)(11)], [2,(11)], [(21)1], [(3,1)] and [(2,11)].

For Petrov type II and Segre type [(1,11)1] with $\alpha=0$, i.e., $\Phi_{00}=\Phi_{01}=0$ (in the Weyl canonical frame), we set $a_0=a_1=a_3=a_4=b_0=b_1=b_3=b_4=c_{00}=c_{01}=0$. Then Eq. (A3) gives $c_{12}+c_{21}+2c_{22}=0$, which means that $c_{12}=c_{21}=c_{22}=0$, i.e., Φ_{22}, Φ_{12}, and Φ_{21} will not appear in any invariant and hence, γ cannot be determined. Also, Eq. (A1) or (A2) gives $c_{02}=c_{20}$. Hence, any invariant will only involve $(\Phi_{02}\Phi_{20})^{c_{02}}$, which means that only $|\beta|$ can be determined. A similar argument can be used for the non-backsolvable cases in Segre type [(1,11)1] with Petrov types III and N (in the Weyl canonical frame).

[2] J. Carminati, E. Zakhary, and R. McLenaghan, J. Math. Phys. **43**, 492 (2002).
[3] However, if further information like additional structure of the Weyl tensor is supplied, then the case could become completely backsolvable. For example, if we impose the condition that the Weyl tensor is Petrov type D and aligned, then $\Psi_3=\Psi_4=0$ and the case would become completely backsolvable. This comment would obviously also apply to other not completely backsolvable cases. Thus an alignment between an eigenvector of the Ricci tensor with a repeated principal null vector of the Weyl tensor is a necessary but not sufficient condition to prevent complete backsolving.
[4] A complete analysis of the necessary and/or sufficient conditions for all the not completely backsolvable cases to occur will be done in future work.

[9] E. Zakhary, Ph.D thesis, Monash University, 1995.
[10] In the Ricci canonical frame, backsolving is not, in general, complete for Segre type [(1, 11)1] if $\Psi_0=\Psi_1=0$ or $\Psi_3=\Psi_4=0$, i.e., for degenerate Petrov types where the repeated PNDs coinside with an eigenvector of the Ricci tensor. Therefore, backsolving is always complete for Petrov type I, and also for type O (since $\Psi_a=0$). For Petrov types II, III, and N, backsolving is not, in general, always complete. On the other hand, since more conditions have been imposed on Ψ_a for Petrov type D, backsolving in this case is, understandably, complete.

(Received 19 November 2001; accepted for publication 25 March 2002)

We show that the reduced Dubrovin–Novikov hydrodynamic type models are integrable Nambu mechanical systems admitting Lax triples. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1481955]

I. INTRODUCTION

In a remarkable paper, Nambu[1] initiated the study of multi-Hamiltonian systems. Apparently Nambu mechanics presents a new alternative view to classical mechanics. Nambu's paper was followed by a number of papers which essentially carry the idea from the physical point of view by showing that the classical part of it could be cast into the framework of classical mechanics with Dirac constraint.[2,3]

Recently, this research was revitalized and carried forward again by Takhtajan.[4] He gave rise to a beautiful theory, revealing deep and nontrivial connection with algebra and differential geometry. Note that, until now, the main activity in the theory of Nambu–Poisson geometry was concentrated around the algebraic aspects of Nambu structure—see, e.g., the papers of Alekseevsky,[5] de Azcárraga,[6,7] Grabowski, Marmo, Michor, Vaisman, Vinogradov, etc.[8–14] Somehow, the applications of Nambu dynamics is not fully explored yet. R. Chatterjee[15] had shown that several Hamiltonian systems possessing dynamical or hidden symmetries can be realized within the framework of Nambu mechanics. Among the notable examples are the SU(n) isotropic harmonic oscillator and the SO(4) Kepler problem. Most recently, Gonera and Nutku[16] showed that the Nambu structure can be extracted also from the rational Calogero–Moser system.

Some attempts have been made from the point of view of foliation theory by Dufour, Zung, and Zhitomerski.[17–19] Hence it would be rewarding to find some interesting applications of Nambu–Poisson geometry. In this article we are continuing to explore the potentiality of the application of Nambu mechanics in integrable systems.[20,21]

In this article we explore a higher dimensioanl analog of a 2D incompressible Euler equation in terms of Nambu dynamics. Thus a novel Nambu type integrable system is proposed. By generalizing Charles Li's[22,23] method we derive the corresponding linear equations or Lax triple of this equation. Surprisingly, this theory can be applied to reduced Dubrovin–Novikov type hydrodynamic systems.[24] Recently these system of equations are poping up in D-Brane theory[25–27] with the celebrated Born–Infeld action.[28]

The rest of this article is organized as follows: Since Nambu mechanics is an exotic subject, so, in the next section we will address some definitions of this subject. In Sec. III, we will discuss our Nambu integrable system.

II. PRELIMINARIES

The modern concept of Nambu–Poisson structure was proposed by Takhtajan in 1994 in order to find an axiomatic formulation for the n-bracket operation. Let M denote a smooth n-dimensional manifold and $C^{\infty}(M)$ the algebra of infinitely differentiable real valued functions on M.

Definition 2.1: A manifold M is called a Nambu–Poisson manifold if there exits a $\mathbb{R}$-multilinear map

$$\{\ ,\ldots,\ \}\ :\ [C^\infty(M)]^{\otimes n}\to C^\infty(M). \tag{1}$$

This is called Nambu–Poisson bracket of order n $\forall f_1,f_2,\ldots,f_{2n-1}\in C^\infty(M)$. *This bracket satisfies*

(1) $\{f_1,\ldots,f_n\}=(-1)^{\epsilon(\sigma)}\{f_{\sigma(1)},\ldots,f_{\sigma(n)}\}$,
(2) $\{f_1f_2,f_3,\ldots,f_{n+1}\}=f_1\{f_2,f_3,\ldots,f_{n+1}\}+\{f_1,f_3,\ldots,f_{n+1}\}f_2$, *and*
(3) fundamental identity

$$\{\{f_1,\ldots,f_{n-1},f_n\},f_{n+1},\ldots,f_{2n-1}\}+\{f_n,\{f_1,\ldots,f_{n-1},f_{n+1}\},f_{n+2},\ldots,f_{2n-1}\}+\cdots$$
$$+\{f_n,\ldots,f_{2n-2},\{f_1,\ldots,f_{n-1},f_{2n-1}\}\}=\{f_1,\ldots,f_{n-1},\{f_n,\ldots,f_{2n-1}\}\}, \tag{2}$$

where $\sigma\in S_n$*—the symmetric group of n elements—and* $\epsilon(\sigma)$ *is its parity*.

This fundamental identity is called Takhtajan identity.

Let $\{.,.,\ldots,.\}:C^\infty(M)\times C^\infty(M)\cdots\times C^\infty(M)\to C^\infty(M)$ be a multi-derivation that satisfies the Takhtajan identity if

(1) $\{.,.,.,.,.\}$ satisfies Takhtajan identity for generators
(2) satisfies quadratic identities.

$$\sum_{k=1}^{n}\{\phi,f_1,\ldots,f_{n-2},f_{n+k-1}\}\{\phi',f_n,\ldots,\widehat{f_{n+k-1}},\ldots,f_{2n-1}\}+\{\phi',f_1,\ldots,f_{n-2},f_{n+k-1}\}$$
$$\times\{\phi,f_{n+1},\ldots,\widehat{f_{n+k-1}},\ldots,f_{2n-1}\}=0. \tag{3}$$

It is known that the Nambu dynamics on a Nambu–Poisson phase space involves $n-1$ so-called Nambu–Hamiltonians $H_1,\ldots,H_{n-1}\in C^\infty(M)$ and is governed by the following equations of motion:

$$\frac{df}{dt}=\{f,H_1,\ldots,H_{n-1}\},\ \ \forall f\in C^\infty(M). \tag{4}$$

A solution to the Nambu–Hamilton equations of motion produces an evolution operator U_t which by virtue of the fundamental identity preserves the Nambu bracket structure on $C^\infty(M)$.

Definition 2.2: $f\in C^\infty(M)$ *is a first integral of* $X_{H_1,\cdots H_{n-1}}$ *if and only if*

$$\{f,H_1,H_2,\ldots,H_{n-1}\}=0.$$

III. LAX TRIPLE AND NAMBU INTEGRABLE SYSTEMS

Vladimir Arnold realized that the Euler equation is a Hamiltonian system. The Lax pair of the 2D Euler equation was first given by Friedlander and Vishik[29,30] in terms of Lagragian coordinates, and most recently by Li in terms of Eulerian coordinates.

The three-dimensional incompressible Euler equation can be expressed in vorticity form,

$$\partial_t\Omega+(u\cdot\nabla)\Omega-(\Omega\cdot\nabla)u=0, \tag{5}$$

where $u=(u_1,u_2,u_3)$ is the velocity, $\Omega=(\Omega_1,\Omega_2,\Omega_3)$ is the vorticity, $\nabla=(\partial_x,\partial_y,\partial_z)$, $\Omega=\nabla\times u$, and $\nabla\cdot u=0$.

Dropping the third subscript of Ω, the 2D euler equation can be written as

$$\partial_t\Omega+\{\Omega,\chi\}=0, \tag{6}$$

where the bracket is given by $\{f,g\}=\partial_xf\partial_yg-\partial_yf\partial_xg$, and χ is the stream function given by

$$u=-\partial_y\chi,\quad v=\partial_x\chi.$$

Thus the vorticity is connected to the stream function by

$$\Omega = \partial_x v - \partial_y u = \Delta \chi.$$

Let us introduce our Nambu integrable system. The idea of this equation is stimulated from the work of Li, Friedlander and Vishik. This equation is a higher dimensional analog of the 2D Euler equation, although it is not a 3D Euler equation (see Remark 3)

Defintion 3.1: The generalized (or Nambu) integrable system is given by

$$\partial_t \Omega + \{\Omega, \chi_1, \chi_2\} = 0,$$

where χ_1 *and* χ_2 *are two Hamiltonians and*

$$\{\Omega, \chi_1, \chi_2\} = \frac{\partial(\Omega, \chi_1, \chi_2)}{\partial(x,y,z)}.$$

Proposition 3.2: The Lax triple of the Nambu integrable equation is
(1) $\{\Omega, \phi_1, \phi_2\} = \lambda \phi_2$,
(2) $\partial \phi_1 = \{\chi_1, \chi_2, \phi_1\}$,
(3) $\partial \phi_2 = \{\chi_1, \chi_2, \phi_2\}$.

Sketch of the Proof: Let us differentiate the first equation. We obtain

$$\{\Omega_t, \phi_1, \phi_2\} + \{\Omega, \phi_{1_t}, \phi_2\} + \{\Omega, \phi_1, \phi_{2_t}\} = \{\chi_1, \chi_2, \{\Omega, \phi_1, \phi_2\}\},$$

$$\{\Omega_t, \phi_1, \phi_2\} + \{\Omega, \{\chi_1, \chi_2, \phi_1\}, \phi_2\} + \{\Omega, \phi_1, \{\chi_1, \chi_2, \phi_2\}\} = \{\chi_1, \chi_2, \{\Omega, \phi_1, \phi_2\}\}.$$

Using the Takhtajan identity

$$\{\{f_1, f_2, f_3\}, f_4, f_5\} + \{f_3, \{f_1, f_2, f_4\}, f_5\} + \{f_3, f_4, \{f_1, f_2, f_5\}\} = \{f_1, f_2, \{f_3, f_4, f_5\}\}. \quad (7)$$

we obtain our desired result. □

Remark 3.3: An ordinary Poisson integrable system is obtained from the compatibility condition of two linear equations. These equations are called the Lax pair. In the case of a Nambu (triple bracket) integrable system we need three linear equations or Lax triple.

Remark 3.4: For $n = 2$*, this coincides with the 2D Euler equation. The Lax pair of the 2D Euler equation given by Li is*

$$L\phi = \lambda \phi, \quad \partial_x \phi + A\phi = 0, \quad (8)$$

where $L\phi = \{\Omega, \phi\}$, $A\phi + \{\chi, \phi\} = 0$*, and the compatibility yields*

$$\partial_x L + [A, L] = \partial_x \Omega + \{\Omega, \chi\} = 0.$$

Remark 3.5 (Connection to n dimensional Euler equation): The higher dimensional incompressible Euler equation is given by

$$\partial_t \Omega + (u \cdot \nabla)\Omega - (\Omega \cdot \nabla)u = 0, \quad \nabla \cdot u = 0.$$

This equation can be expressed as

$$\partial_t(\partial_j u^i - \partial_i u^j) + u \cdot \nabla(\partial_j u^i - \partial_i u^j) - \sum_{k=1}^{n} (\partial_j u^k \partial_k u^i - \partial_i u^k \partial_k u^j) = 0, \quad (9)$$

where $\Omega^i_j = \partial_j u^i - \partial_i u^j$*, and* $\Omega(u) = (\Omega^i_j)_{1 \leqslant i,j \leqslant n}$.

When the dimension is equal to 2*, Eq. (9) boils down to*

$$\partial_t\Omega + u\cdot\nabla\Omega - (\partial_1 u^1\partial_1 u^2 + \partial_1 u^2\partial_2 u^2 - \partial_2 u^1\partial_1 u^1 - \partial_2 u^2\partial_2 u^1) = 0,$$

where $\Omega(u) = \partial_1 u^2 - \partial_2 u^1$. *One can express this as*

$$\partial_t\Omega + u\cdot\nabla\Omega - \Omega(\nabla\cdot u) = 0. \tag{10}$$

As the divergence of the vector field is zero, we get the well known relation

$$\partial_t\Omega + u\cdot\nabla\Omega = 0. \tag{11}$$

This equality is extremely interesting—by this one can distinguish the two dimensional case from the $n \geqslant 3$ *case.*

Hence, because of the presence of the term $(\Omega\cdot\nabla)u$ in a higher dimensional incompressible Euler equation, our Nambu integrable system does not coincide with it.

A. Applications to Dubrovin–Novikov systems

Dubrovin and Novikov considered an arbitrary $n\times n$ system of hydrodynamic type

$$u^i_t = v^i_j(x)u^j_x, \quad i,j = 1,\ldots,n, \tag{12}$$

which are nondiagonalizable but integrable.

Let us consider a special set $(n=3)$ of above hyperbolic differential equations:

$$\frac{\partial u}{\partial x_1} = u\frac{\partial u}{\partial x_4} + v\frac{\partial u}{\partial x_3} + w\frac{\partial u}{\partial x_2}, \tag{13}$$

$$\frac{\partial v}{\partial x_1} = u\frac{\partial v}{\partial x_4} + v\frac{\partial v}{\partial x_3} + w\frac{\partial v}{\partial x_2}, \tag{14}$$

$$\frac{\partial w}{\partial x_1} = u\frac{\partial w}{\partial x_4} + v\frac{\partial w}{\partial x_3} + w\frac{\partial w}{\partial x_2}. \tag{15}$$

These are examples of what Dubrovin and Novikov call ''equations of hydrodynamic type'' and these are fully integrable—for explicit solutions, any functions homogeneous of degree 1 are automatically solutions of these set, though the general solution can be found only in implicit form.

Let us combine all the equations (13)–(15). We obtain

$$\frac{\partial(u+\iota_1 v+\iota_2 w)}{\partial x_1} = u\frac{\partial(u+\iota_1 v+\iota_2 w)}{\partial x_4} + v\frac{\partial(u+\iota_1 v+\iota_2 w)}{\partial x_3} + w\frac{\partial(u+\iota_1 v+\iota_2 w)}{\partial x_2}. \tag{16}$$

Let us set $\Omega = u+\iota_1 v+\iota_2 w$:

$$\frac{\partial\Omega}{\partial x_1} = u\frac{\partial\Omega}{\partial x_4} + v\frac{\partial\Omega}{\partial x_3} + w\frac{\partial\Omega}{\partial x_2}. \tag{17}$$

Suppose

$$u = -\frac{\partial(\chi_1,\chi_2)}{\partial(x_2,x_3)}, \quad v = \frac{\partial(\chi_1,\chi_2)}{\partial(x_4,x_2)}, \quad w = \frac{\partial(\chi_1,\chi_2)}{\partial(x_3,x_4)}, \tag{18}$$

where χ_1 and χ_2 are some potential functions. Hence we obtain the reduced form of Dubrovin–Novikov equation as

$$\frac{\partial \Omega}{\partial x_1} + \{\Omega, \chi_1, \chi_2\} = 0. \tag{19}$$

Systems related 2D systems: In this case we obtain

$$\frac{\partial (u + \iota v)}{\partial x} = u \frac{\partial (u + \iota v)}{\partial z} + v \frac{\partial (u + \iota v)}{\partial y}. \tag{20}$$

Let us set $\Omega = u + \iota v$:

$$\frac{\partial \Omega}{\partial x} = u \frac{\partial \Omega}{\partial z} + v \frac{\partial \Omega}{\partial y}. \tag{21}$$

Suppose

$$u = -\frac{\partial \chi}{\partial y}, \quad v = \frac{\partial \chi}{\partial z}, \tag{22}$$

where χ is some potential function.

After this transformation the equation becomes

$$\frac{\partial \Omega}{\partial x} + \{\Omega, \chi\} = 0, \tag{23}$$

where the bracket {,} is defined as

$$\{f, g\} = (\partial_z f)(\partial_y g) - (\partial_y f)(\partial_z g).$$

The relation between Ω and χ is

$$\Omega = u + \iota v = -\partial_y \chi + \iota \partial_z \chi.$$

IV. CONCLUSION

In this article, using Nambu mechanics we have proposed a Lax representation of the reduced Dubrovin–Novikov type hydrodynamic systems. The most promising applications from this Lax triple should be along the direction of Darboux transformations, group theoretic applications, etc. Moreover, we hope that Lax representation and the Darboux transformations can be useful in investigating finite time blow up solutions of reduced Dubrovin–Novikov type systems.

Two-dimensional Hamiltonian systems admitting second invariants which are quartic in the momenta are investigated using the Jacobi geometrization of the dynamics. This approach allows for a unified treatment of invariants at both arbitrary and fixed energy. In the differential geometric picture, the quartic invariant corresponds to the existence of a fourth rank Killing tensor. Expressing the Jacobi metric in terms of a Kähler potential, the integrability condition for the existence of the Killing tensor at fixed energy is a nonlinear equation involving the Kähler potential. At arbitrary energy, further conditions must be imposed which lead to an overdetermined system with isolated solutions. We obtain several new integrable and superintegrable systems in addition to all previously known examples. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1483107]

I. INTRODUCTION

The study of Hamiltonian systems by means of geometric techniques provides fruitful clues about their integrability.[1–3] In particular, geometrization of the dynamics by using the Jacobi metric,[4,5] is a standard tool to turn a natural Hamiltonian system into a geodesic flow over a suitable Riemannian manifold. Therefore it is natural to investigate integrability of two-dimensional systems by looking for invariants corresponding to Killing tensors of a conformal Riemannian geometry. These geometric objects in fact directly produce invariants polynomial in the momenta: the degree of this polynomial is the same as the rank of the Killing tensor. Since the energy enters in the Jacobi metric as a parameter, the conditions for the existence of a Killing tensor may happen to be satisfied only at a fixed value of energy. In this case we speak of integrability at fixed energy in distinction to the usual notion of integrability which is understood to be valid at arbitrary energy.

In Ref. 2, quadratic invariants at arbitrary and fixed energy (respectively, *strongly* and *weakly* conserved phase-space functions) for two-dimensional Hamiltonian systems were treated in a unified way. The integrability condition for quadratic invariants involves an arbitrary analytic function $S(z)$. For invariants at arbitrary energy, the function $S(z)$ is a second degree polynomial with real second derivative, and the integrability condition then reduces to the classical Darboux condition for quadratic invariants at arbitrary energy.[6] Thereafter, the possibility of searching for linear and quadratic invariants at fixed energy was addressed and some examples of a system admitting a second quadratic invariant at zero energy were provided.

Weak invariants, also called *configurational invariants*, have been discussed by Hall[7] and by

Sarlet, Leach and Cantrijn.[8] Hietarinta,[9] in his account of the direct methods for the search of the second invariant, also provides a review of all the known systems admitting one or more configurational invariants. Generalizing the approach of Ref. 2, Karlovini and Rosquist[10] have discussed the existence of invariants *cubic in the momenta* at both fixed and arbitrary energy. Beside giving a list of all known systems admitting a cubic strong invariant, they also find a superintegrable system admitting a cubic invariant related to an energy dependent linear invariant. In the present article we are going to discuss the case of the quartic invariant associated with the existence of a fourth-rank Killing tensor. Fourth-rank Killing tensors have previously been studied by one of the authors (see Ref. 11) in the Lorentzian case.

In analogy to the third-rank case, it turns out that it is natural to introduce a Kähler potential for the Jacobi metric. Expressing the conditions imposed on the geometry by Killing tensor equations in terms of this Kähler potential, there remains a system of nonlinear partial differential equations. Imposing the condition of strong integrability, it turns out that in general this system becomes overdetermined, so that, like for cubic invariants, only isolated mechanical systems exist with a second invariant quartic in the momenta. Due to the complexity of the system of equations, it is impossible to get a fully general solution. However, with our approach we are able to find some new integrable and superintegrable cases. In particular, one may wonder if the knowledge of a weak invariant can provide information about the global dynamical behavior of the system. We introduce a method which, starting from a family of weakly integrable systems, leads to finding a higher-order invariant for isolated members of the family which are therefore strongly integrable. The second invariant depends on the energy as a parameter.

The plan of the article is as follows: in Sec. II we recall the necessary and sufficient conditions for the existence of a Killing tensor in the Jacobi geometry and their application in problems of analytical mechanics. In Sec. III we examine the particular case of fourth-rank Killing tensors. In Sec. IV we analize the conditions for strong integrability with a quartic invariant. In Sec. V we present the method by which, starting from a family of weakly integrable systems, isolated examples of strongly integrable systems with quartic second invariant can be found. In Sec. VI we give tables of integrable systems admitting a quartic invariant which include new integrable and superintegrable systems in addition to all known cases. In Sec. VII we give our conclusions.

II. JACOBI GEOMETRY AND KILLING TENSORS

A. Geometric representation of the dynamics

We are interested in the classical two-dimensional systems with Hamiltonian function

$$\mathcal{H}=\tfrac{1}{2}(p_x^2+p_y^2)+V(x,y). \tag{1}$$

The approach followed in studying the integrability properties of these systems is based on the Jacobi geometrization procedure which associates to the Hamiltonian flow produced by (1), a geodesic flow on a Riemannian manifold endowed with a positive definite metric

$$ds_J^2=g_{\alpha\beta}dq^\alpha dq^\beta, \quad \alpha,\beta=1,2. \tag{2}$$

It can be shown (see, e.g., Ref. 4) that the Jacobi metric

$$g_{\alpha\beta}=2(E-V)h_{\alpha\beta}, \tag{3}$$

where $h_{\alpha\beta}$ is the metric of the flat space, generates a geodesic flow corresponding to the natural mechanical system with potential $V=V(q)$ at energy E. In fact, if we introduce the geodesic, or ''Jacobi,'' Hamiltonian

$$\mathcal{H}_J=\frac{1}{2}\,\frac{1}{2(E-V)}h^{\alpha\beta}p_\alpha p_\beta\equiv\frac{1}{2}, \tag{4}$$

the corresponding geodesic equations

$$\frac{dq^\alpha}{ds_J}=\frac{\partial \mathcal{H}_J}{\partial p_\alpha}=\frac{1}{2(E-V)}h^{\alpha\beta}p_\beta, \quad \frac{dp_\alpha}{ds_J}=-\frac{\partial \mathcal{H}_J}{\partial q^\alpha}=-\frac{1}{2(E-V)}\frac{\partial V}{\partial q^\alpha}, \tag{5}$$

are equivalent to the canonical equations of motion given by the Hamiltonian (1),

$$\frac{dq^\alpha}{dt}=\frac{\partial \mathcal{H}}{\partial p_\alpha}, \quad \frac{dp_\alpha}{dt}=-\frac{\partial \mathcal{H}}{\partial q^\alpha}, \tag{6}$$

if the natural identification of canonical coordinates

$$q^1=x, \quad q^2=y, \quad p_1=p_x, \quad p_2=p_y \tag{7}$$

is made. The phase-space trajectories are parametrized by the affine parameter s_J that is related to the standard time variable by

$$ds_J=2[E-V(q(t))]dt. \tag{8}$$

The Jacobi geometry corresponding to Hamiltonian (1) is then

$$ds^2=2G(dx^2+dy^2)=2Gdzd\overline{z}, \quad G=E-V, \tag{9}$$

where we have introduced null variables $z=x+iy$ and $\overline{z}=x-iy$.

All tensor calculations will be done in the standard null frame defined as

$$\Omega^0=\sqrt{G}dz, \quad \Omega^{\overline{0}}=\sqrt{G}d\overline{z}, \tag{10}$$

in which the metric takes the simplest possible form

$$ds^2=2d\Omega^0 d\Omega^{\overline{0}}. \tag{11}$$

We use the convention that tensor indices in this frame take the values 0 and $\overline{0}$, while in any coordinate frame the values will be the names of the coordinates (e.g., z and $\overline{z}$).

B. Invariants polynomial in the momenta and Killing tensors

One of the standard tools of the geometric approach is the investigation of integrability by looking for invariants generated by *Killing tensors*. Let us see the simple case of second-order Killing tensor equations

$$K_{(\alpha\beta;\gamma)}=0. \tag{12}$$

The existence of a second-rank Killing tensor, that is a symmetric tensor which satisfies Eq. (12), implies the existence of a conserved quadratic function

$$I_J=K^{\alpha\beta}p_\alpha p_\beta \tag{13}$$

commuting with the Jacobi Hamiltonian. In fact, it is easy to check that the vanishing of the Poisson bracket of this function with the Hamiltonian implies Eq. (12). In analogy with the theory of second order invariants, the Jacobi geometry approach leads, as it stands, to the determination of higher-order invariants. Generalizing Eq. (12), an *mth rank* Killing tensor is a symmetric tensor satisfying the equation

$$K_{(\mu_1\mu_2\ \cdots\ \mu_m;\mu_{m+1})}=0. \tag{14}$$

It gives rise to the *mth order* (in the momenta) invariant

$$I_J = K^{\mu_1 \mu_2 \cdots \mu_m} p_{\mu_1} \cdots p_{\mu_m}. \tag{15}$$

Two remarks are in order here:

(1) The function (15) is a *weak invariant*, in the sense that, in general, it is a conserved quantity in the dynamics fixed by the given value of the energy appearing in the definition of the Jacobi geometry (9). To grant it the full title of strong invariant, it must satisfy the additional requirement of satisfying the Killing tensor equations at arbitrary energy.
(2) The function (15), let us call it the *Jacobi invariant*, is a homogeneous polynomial of degree equal to the rank of the corresponding Killing tensor. To transform it into the ordinary invariant in the physical time gauge there is a straightforward recipe consisting in replacing the parameter E appearing in I_J with the corresponding Hamiltonian function (1). As a consequence, the physical invariant

$$I = I_J|_{E \to \mathcal{H}} \tag{16}$$

becomes a polynomial which is either even or odd in the momenta.

Karlovini and Rosquist[10] have discussed the existence of third-rank Killing tensors, giving a list of all known integrable or superintegrable systems admitting a cubic strong invariant. Here we are going to discuss the case of the quartic invariant associated with the existence of a fourth-rank Killing tensor. Moreover, we want to exploit the results concerning the existence of higher-order invariants to generate new solutions starting from the assumption of the existence of a second-rank Killing tensor.

III. QUARTIC INVARIANTS CORRESPONDING TO FOURTH-RANK KILLING TENSORS

In this section we derive the necessary and sufficient integrability condition for the Jacobi metric to admit a fourth-rank Killing tensor at a fixed value of the energy parameter E. In the following section we proceed by finding the conditions that ensure that the Killing tensor equations be satisfied at arbitrary values of the energy, with the restriction to the case in which the energy dependence of the Killing tensor is such that the corresponding invariant of the physical Hamiltonian is quartic in the momenta. As usual in our approach (see Ref. 11), we decompose the fourth-rank Killing tensor in the form

$$K_{\alpha\beta\gamma\delta} = P_{\alpha\beta\gamma\delta} + P_{(\alpha\beta} g_{\gamma\delta)} + \tfrac{3}{8} K g_{(\alpha\beta} g_{\gamma\delta)} \tag{17}$$

or equivalently

$$K_{\alpha\beta\gamma\delta} = P_{\alpha\beta\gamma\delta} + K_{(\alpha\beta} g_{\gamma\delta)} - \tfrac{1}{8} K g_{(\alpha\beta} g_{\gamma\delta)}, \tag{18}$$

where $K_{\alpha\beta} = K^{\gamma}_{\alpha\beta\gamma}$ and $K = K^{\gamma}_{\gamma}$. $P_{\alpha\beta\gamma\delta}$ is the trace-free (conformal) part, $P_{\alpha\beta} = P^{\gamma}_{\alpha\beta\gamma}$ its trace and K the full trace of the Killing tensor. In this way, the Killing tensor equations are split into the trace-free ''components'' and the equation for the trace

$$P_{(\alpha\beta\gamma\delta;\mu)} - \tfrac{1}{2} P^{\nu}{}_{(\alpha\beta\gamma;\nu} g_{\delta\mu)} = 0, \tag{19}$$

$$P_{(\alpha\beta;\gamma)} - \tfrac{1}{2} P^{\nu}{}_{(\alpha;\nu} g_{\gamma\delta)} + \tfrac{1}{2} P^{\nu}{}_{\alpha\beta\gamma;\nu} = 0, \tag{20}$$

$$K_{,\alpha} = -\tfrac{4}{3} P^{\beta}_{\alpha;\beta}. \tag{21}$$

It is advantageous to employ also the coordinate frame components of the conformal part and of its trace when parametrizing the five independent components of $K_{\alpha\beta\gamma\delta}$. Thus, the components of the Killing tensor can be written as

$$\begin{gathered} K_{0000}=G^2P^{\overline{zzzz}}=G^2\overline{S}, \quad K_{000\overline{0}}=\tfrac{1}{2}P_{00}=\tfrac{1}{2}GP^{\overline{zz}}=\tfrac{1}{2}G\overline{R(z,\overline{z})}, \\ K_{00\overline{00}}=\tfrac{1}{4}K, \quad K_{0\overline{000}}=\tfrac{1}{2}P_{\overline{00}}=\tfrac{1}{2}GP^{zz}=\tfrac{1}{2}GR(z,\overline{z}), \quad K_{\overline{0000}}=G^2P^{zzzz}=G^2S, \end{gathered} \tag{22}$$

where, as usual, $S=S(z)$ is a holomorphic function, so that $\overline{S}=\overline{S}(\overline{z})$ comes from (19), but the function $R=R(z,\overline{z})$ is a generic function of the arguments. With this parametrization, the equation for the trace (21) has the integrability condition

$$2(G_{,zz}R-G_{,\overline{zz}}\overline{R})+3(G_{,z}R_{,z}-G_{,\overline{z}}\overline{R}_{,\overline{z}})+G(R_{,zz}-\overline{R}_{,\overline{zz}})=0, \tag{23}$$

which is analogous to that obtained for the second-rank case (but now R is not holomorphic!).

We now proceed to solve the Killing tensor equations. Equation (20) gives

$$S^{-3/4}R_{,\overline{z}}+2(S^{1/4}G)_{,z}=0 \tag{24}$$

and its complex conjugate. In analogy with the approach followed in Refs. 2 and 10, we make a coordinate transformation to put the conformal Killing tensor in the simplest (*standard*) form. Using a conformal transformation of the form

$$w=H(z), \quad w=X+iY, \quad z=x+iy, \tag{25}$$

the transformation of the conformal tensor is such that

$$\tilde{S}(w):=P^{wwww}=[H'(z)]^4P^{zzzz}=[H'(z)]^4S(z). \tag{26}$$

If we make the standard choice

$$\tilde{S}(w):=P^{wwww}=1, \tag{27}$$

the conformal transformation is then provided by the function

$$H'(z)=[S(z)]^{-1/4}. \tag{28}$$

Equation (24) becomes

$$(S^{-1/2}R)_{,\overline{w}}+2\tilde{G}_{,w}=0, \tag{29}$$

with

$$\tilde{G}=|H'(z)|^{-2}G=\sqrt{|S|}G. \tag{30}$$

Moreover, under the conformal transformation generated by Eq. (28), the function R transforms as

$$\tilde{R}=P^{ww}=[H'(z)]^2P^{zz}=S^{-1/2}R. \tag{31}$$

Inserting $\tilde{R}$ into Eq. (29), we have the set

$$\tilde{R}_{,\overline{w}}+2\tilde{G}_{,w}=0, \quad \bar{\tilde{R}}_{,w}+2\tilde{G}_{,\overline{w}}=0. \tag{32}$$

The solution of this system can be found in terms of a real Kähler potential $\mathcal{K}(w,\overline{w})$:

$$\tilde{G}=\mathcal{K}_{,w\overline{w}}, \quad \tilde{R}=-2\mathcal{K}_{,ww}. \tag{33}$$

The integrability condition (23) determines the following equation for the Kähler potential:

$$\Im\{(\mathcal{K}_{,www}\mathcal{K}_{,w\bar{w}}+2\mathcal{K}_{,ww\bar{w}}\mathcal{K}_{,ww})_{,w}\}=0. \tag{34}$$

This is the necessary and sufficient condition for the existence of a fourth-rank Killing tensor. In analogy to the third-rank case (see Ref. 10) and in contrast to the first- and second-rank cases,[2] the condition is highly nonlinear. The same condition has been already found in Ref. 7 and treated in Ref. 9, even if not in the context of the present geometric approach. Note that in Ref. 9, Eq. (7.5.15), there is a misprint for a factor 2 missing.

In the standardized coordinate frame the second invariant can be written in the form

$$I_J=2\Re\{p_w^4+2\tilde{R}\mathcal{H}_J p_w^2\}+\tfrac{3}{2}\mathcal{H}_J^2 K, \tag{35}$$

whereas in the original null coordinate frame the second invariant is

$$I_J=2\Re\{Sp_z^4+2R\mathcal{H}_J p_z^2\}+\tfrac{3}{2}\mathcal{H}_J^2 K, \tag{36}$$

where

$$\mathcal{H}_J=\frac{1}{G}p_z p_{\bar{z}}=\frac{1}{\tilde{G}}p_w p_{\bar{w}}=p_0 p_{\bar{0}}\equiv\frac{1}{2} \tag{37}$$
