Eigenfunctions $\psi_{N,E}^{(\beta)}(x)$ of the Hamiltonians $H_C, H_D, H_{\mathrm{CS}}$ with eigenenergy E for arbitrary β are known. Essentially, these solutions are products of the ground state wave function and symmetric polynomials in the coordinates x of the N particles. In case of the Calogero–Sutherland Hamiltonian H_{CS}, these polynomials are the Jack polynomials.[34–36] In this approach, the energy eigenvalues E are labeled by a partition of length N. The crucial difference to the matrix Bessel functions is that the Jack polynomials are symmetric polynomials in one set of variables x only whereas the matrix Bessel functions $\Phi_N^{(\beta)}(x,k)$ are symmetric in two sets of variables x and k. Importantly, they are, in addition, symmetric under interchange of the two sets of variables, $\Phi_N^{(\beta)}(x,k)=\Phi_N^{(\beta)}(k,x)$. This is reflected in the fact that the operator $L_{x,\omega(k)}$ emerging in the Hankel ansatz depends on k while H_D does not. Due to their symmetry, the matrix Bessel func-

tions $\Phi_N^{(\beta)}(x,k)$ are, at least for H_D, the more natural eigenfunctions. This is so, because, to obtain orthogonality conditions, one has to sum the $\psi_{N,E}^{(\beta)}(x)$ over an infinite number of partitions. On the other hand, orthogonality relations are an inherent feature of the $\Phi_N^{(\beta)}(x,k)$ due to their meaning in the Fourier–Bessel analysis, as discussed in Appendix C.

In other words, the functions $\psi_{N,E}^{(\beta)}(x)$ can be viewed as a basis in an expansion of the $\Phi_N^{(\beta)}(x,k)$. We can consider the variables k as a set of real numbers corresponding to the energies E labeling the eigenstates of H_D. The matrix Bessel functions (3.15) are solutions of the Schrödinger equation with Hamiltonian H_D for the coupling parameters $\beta=1,2,4$. The recursion formula (5.5) represents an analytic continuation of these integral solutions to arbitrary positive β. All these functions $\Phi_N^{(\beta)}(x,k)$ have for arbitrary β additional features: the symmetry in x and k, which has no analog in the functions $\psi_{N,E}^{(\beta)}(x)$. The merit of our recursion formula lies in the fact that, *a priori*, no infinite resummation is required to obtain functions of the type $\Phi_N^{(\beta)}(x,k)$. Nevertheless Forrester[35] and Forrester and Nagao[37] showed that such resummed expressions can successfully be used in certain cases. They treated the case of Poissonian initial conditions[37] for the Calogero–Sutherland Hamiltonian H_{CS} and derived exact expressions for the correlation functions for arbitrary β for one or two particles. This is also related to the works of Muirhead[20] and Pandey.[38]

VIII. SUMMARY AND CONCLUSION

We presented a recursive construction for certain spherical functions. We referred to them as matrix Bessel functions because, first, they are a natural extension of vector Bessel functions in the sense that the integration over a group corresponds to the integration over a solid angle and, second, they satisfy a partial differential equation generalizing the Bessel ordinary differential equation. For matrices, the index β labeling the groups appears analogous to the dimension d in the case of vectors. The introduction of radial Gelfand–Tzetlin coordinates, which are related to but different from the ordinary angular ones, was crucial for the recursion. The Cayley transformation ought to provide a connection between the angular and the radial Gelfand–Tzetlin coordinates.[39] As evident from its construction, the recursion maps an integral over a group fully onto an iteration which exclusively takes place in the radial space.

Remarkably, the recursion turned out to be far more general than was to be expected, at first sight, from the proof which involved Lie groups. We showed that our recursion is also the iterative solution of the corresponding partial differential equation for arbitrary values of β. We introduced the term radial functions for this generalization of matrix Bessel functions. We expect that one has to employ the theory of quantum groups to give a group theoretical derivation of the recursion formula for arbitrary values of β.

Using the recursion formula, we discussed the structure of radial Bessel functions. We conjectured that, for even β, they can be written as finite sums involving only exponential and rational functions. We illustrated that by working out, for $\beta=4$, the cases of $N=3$ and $N=4$ distinct eigenvalues. Further evaluation of explicit formulas for arbitrary N and, maybe, for all even β does not seem impossible. Work is in progress. The extension of the stationary phase approach by Duistermaat and Heckman[13] to higher orders could, for even β, be an alternative to derive such explicit results, because the expansion terminates. In this context, we mention that the radial functions for higher values of β are, to some extent, but not fully, the higher order radial functions for lower values of β. This also generalizes the situation for ordinary Bessel functions. However, there are many more higher order radial functions; they are not at all exhausted by this mapping between values of β.

In the present contribution, we only focused on ordinary spaces, i.e., spaces which are built upon commuting numbers. In a second study[40] we also address superspaces which involve commuting and anticommuting variables.

APPENDIX A: ALTERNATIVE INTEGRAL REPRESENTATION FOR VECTOR BESSEL FUNCTIONS

The Bessel functions $\chi^{(d)}(kr)$ are defined as an integral over angles in Eq. (2.1), but they can also be written as integrals over the entire or half real axis.[21] To make possible an instructive comparison with the matrix case, we quote and rederive the representation

$$\chi^{(d)}(kr)=\frac{\Gamma(d/2)}{i2\pi}\left(\frac{2}{ikr}\right)^{(d-2)/2}\int_{-\infty}^{+\infty}\exp\left(-i\frac{kr}{2}\left(t+\frac{1}{t}\right)\right)\frac{\mathrm{d}t}{t^{d/2}}. \tag{A1}$$

The singularities have to be treated properly.

The position vector in the d dimensional space is $\vec{r}=r\vec{e}_r$, where the vector $\vec{e}_r$ parametrizes the unit sphere. To integrate over its orientation, i.e., over the solid angle Ω, one can reexpress the measure as

$$\mathrm{d}\Omega=\frac{\Gamma(d/2)}{\pi^{d/2}}\,\delta(\vec{e}_r^{\,2}-1)\mathrm{d}^d e_r\,. \tag{A2}$$

Here, the vector $\vec{e}_r$ is reinterpreted: its components live on the entire real axis and the domain of integration is the full d dimensional space with the Cartesian measure $\mathrm{d}^d e_r$. The δ distribution confines the vector to the unit sphere. Writing this distribution as a Fourier transform, we obtain from Eq. (2.1)

$$\begin{aligned}\chi^{(d)}(kr)&=\frac{\Gamma(d/2)}{\pi^{d/2}}\,\frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}t\int\mathrm{d}^d e_r\exp(it(\vec{e}_r^{\,2}-1))\exp(i\vec{k}\cdot r\vec{e}_r)\\&=\frac{\Gamma(d/2)}{2\pi}\int_{-\infty}^{+\infty}\frac{\exp(-it)}{(it)^{d/2}}\exp\left(-i\frac{(kr)^2}{4t}\right)\mathrm{d}t,\end{aligned} \tag{A3}$$

where the integral over $\vec{e}_r$ gave a Gaussian in d dimensions. The contour for the integration over t has to be chosen appropriately. Upon a trivial change of variables, this result yields Eq. (A1).

APPENDIX B: ALTERNATIVE INTEGRAL REPRESENTATION FOR MATRIX BESSEL FUNCTIONS

The matrix Bessel functions $\Phi_N^{(\beta)}(x,k)$ for $\beta=1,2,4$ can be be written in an alternative way. Although we can hardly believe that this representation is completely new, we could not find it in the literature. Similar to Eq. (A1) in the vector case, we can write

$$\Phi_N^{(\beta)}(x,k)=A_N^{(\beta)}\int\mathrm{d}[T]\exp(i\,\mathrm{Tr}\,T)\,\mathrm{Det}^{-\beta/2}(x\otimes\hat{k}-T\otimes 1_N), \tag{B1}$$

where 1_N is the $N\times N$ unit matrix. The normalization constant is given by

$$A_N^{(\beta)}=\frac{i^{\beta N^2/2}\pi^{\beta N(N-1)/4}}{\beta^{N+\beta N(N-1)/2}}\prod_{n=1}^{N}\Gamma(\beta n/2). \tag{B2}$$

The matrix T in Eq. (B1) is real symmetric, Hermitian, or Hermitian self-dual, respectively, for $\beta=1,2,4$. The measure $\mathrm{d}[T]$ is Cartesian and given by Eq. (3.3). All independent variables in T are integrated over the entire real axis. To ensure convergence, the diagonal elements of T have to be given a proper imaginary increment. We notice that x and T are $N\times N$ matrices for $\beta=1,2$ and $2N\times 2N$ for $\beta=4$ with doubly degenerated eigenvalues. The matrix $\hat{k}$ is, in all three cases β, just the $N\times N$ matrix $\hat{k}=\mathrm{diag}(k_1,k_2,...,k_N)$, as defined following Eq. (3.10).

The integral representation (B1) leads to an interesting integral equation for the matrix Bessel functions,

$$\Phi_N^{(\beta)}(x,k)=B_N^{(\beta)}\,\mathrm{Det}^{1-\beta/2}x\int \mathrm{d}[t]\,|\Delta_N(t)|^{\beta}\frac{\Phi_N^{(\beta)}(x,t)}{\Pi_{n,m}(k_m-t_n)^{\beta/2}}, \tag{B3}$$

where the normalization constant reads

$$B_N^{(\beta)}=\frac{i^{\beta N^2/2}\Gamma^N(\beta/2)}{(2\pi)^N N!}. \tag{B4}$$

The t_n in Eq. (B3) have a proper imaginary increment and their domain of integration is the real axis. Due to the symmetry relation (3.16), the variables x and k can be interchanged in Eqs. (B1) and (B3).

It is not difficult to see from the integral equation (B3) that the product in the denominator of its right-hand side can, in the case $\beta=2$, be written as

$$\frac{B_N^{(2)}}{\Pi_{n,m}(k_m-t_n)}=\frac{\det[\,\delta(x_n-t_m)]_{n,m=1,\ldots,N}}{|\Delta_N(k)\Delta_N(t)|^{1/2}}. \tag{B5}$$

For $\beta\neq 2$, the term $\mathrm{Det}^{1-\beta/2}x$ contributes. Nevertheless, the product still shares features with a δ distribution.

To derive this alternative integral representation, we proceed analogously to Eq. (A2) by rewriting the invariant measure of $U\in \mathrm{U}(N;\beta)$ using δ distributions. The invariance simply means that all columns U_n, $n=1,\ldots,N$ are orthonormal, $\mathrm{Tr}\,U_n^{\dagger}U_m=\delta_{nm}$. The trace Tr is only needed for $\beta=4$, because the entries of U are quaternions in this case. Thus, we may write

$$\mathrm{d}\mu(U)=M_N^{(\beta)}\,\mathrm{d}[U]\prod_{n=1}^{N}\delta(\mathrm{Tr}\,U_n^{\dagger}U_n-1)\prod_{n<m}\delta(\mathrm{Tr}\,U_n^{\dagger}U_m), \tag{B6}$$

where $\mathrm{d}[U]$ is the Cartesian measure of all entries of U and the integration is for all variables over the entire real axis. The constant $M_N^{(\beta)}$ will be determined later. Ullah[41,42] used such forms for the measure to work out certain probability density functions. The bilinear forms in the δ distributions have β components for $n\neq m$,

$$U_n^{\dagger}U_m=\sum_{\alpha=0}^{\beta-1}[U_n^{\dagger}U_m]^{(\alpha)}\tau^{(\alpha)}. \tag{B7}$$

We notice that $[U_n^{\dagger}U_n]^{(\alpha)}=0$ for $\alpha>0$ in the case $n=m$, because the length of every vector is real. Thus, because of Eq. (B7), the δ distributions in the measure (B6) have to be products of δ distributions for every nonzero component $[U_n^{\dagger}U_m]^{(\alpha)}$. We now introduce Fourier representations

$$\delta([U_n^{\dagger}U_m]^{(\alpha)})=\frac{1}{\pi}\int_{-\infty}^{+\infty}\mathrm{d}T_{nm}^{(\alpha)}\exp(-i2[U_n^{\dagger}U_m]^{(\alpha)}T_{nm}^{(\alpha)}), \tag{B8}$$

$$\delta([U_n^\dagger U_n]^{(0)}-1)=\frac{1}{2\pi}\int_{-\infty}^{+\infty} dT_{nn}^{(0)}\exp(-i([U_n^\dagger U_n]^{(0)}-1)T_{nm}^{(0)})$$

for $n\neq m$ and $n=m$, respectively. The Fourier variables form the elements

$$T_{nm}=\sum_{\alpha=0}^{\beta-1} T_{nm}^{(\alpha)}\,\tau^{(\alpha)} \tag{B9}$$

of a matrix T which is real-symmetric, Hermitian or Hermitian self-dual according to $\beta=1,2,4$. We notice that the diagonal elements $T_{nn}=T_{nn}^{(0)}$ are always real,

$$\delta(\mathrm{Tr}\,U_n^\dagger U_m)=\frac{1}{\pi^\beta}\int d^\beta T_{nm}\exp(-i\,\mathrm{Tr}\,U_n^\dagger(T_{nm}\otimes 1_N)U_m-i\,\mathrm{Tr}\,U_m^\dagger(T_{nm}^*\otimes 1_N)U_n),$$
$$\delta(\mathrm{Tr}\,U_n^\dagger U_n-1)=\frac{1}{2\pi}\int_{-\infty}^{+\infty} dT_{nn}\exp(i\,\mathrm{Tr}\,T_{nn}-i\,\mathrm{Tr}\,U_n^\dagger(T_{nn}\otimes 1_N)U_n) \tag{B10}$$

for $n\neq m$ and $n=m$, as previously. Just as for the trace Tr, the direct product is only needed in the case $\beta=4$.

We order the columns U_n, $n=1,\ldots,N$ of the matrix U in a vector $\vec{U}=(U_1,U_2,\ldots,U_N)^T$ with N^2 elements. For $\beta=1,2$, the elements are scalars; for $\beta=4$, they are quaternions. Collecting everything, we can rewrite the measure (B6) in the form

$$d\mu(U)=\frac{M_N^{(\beta)}d[U]}{(2\pi)^N\pi^{\beta N(N-1)/2}}\int d[T]\exp(i\,\mathrm{Tr}\,T-i\,\mathrm{Tr}\,\vec{U}^\dagger(T\otimes 1_N)\vec{U}). \tag{B11}$$

For the unitary case, a related Fourier integral form for integration measures was used by Fyodorov and Khoruzhenko[43] in the context of quantum chaotic scattering. To use the measure (B11) in the integral (3.15) for the matrix Bessel functions $\Phi_N^{(\beta)}(x,k)$, we also take advantage of the relation

$$\mathrm{Tr}\,U^{-1}xUk=\mathrm{Tr}\,\vec{U}^\dagger(x\otimes\hat{k})\vec{U}, \tag{B12}$$

which allows us to write

$$\Phi_N^{(\beta)}(x,k)=\frac{M_N^{(\beta)}}{(2\pi)^N\pi^{\beta N(N-1)/2}}\int d[U]\int d[T]\exp(i\,\mathrm{Tr}\,T)\exp(i\,\mathrm{Tr}\,\vec{U}^\dagger(x\otimes\hat{k}-T\otimes 1_N)\vec{U})$$
$$=\frac{M_N^{(\beta)}i^{\beta N^2}\pi^{\beta N/2}}{(2\pi)^N}\int d[T]\exp(i\,\mathrm{Tr}\,T)\,\mathrm{Det}^{-\beta/2}(x\otimes\hat{k}-T\otimes 1_N). \tag{B13}$$

Thus, the integration over U could be done as a Gaussian one and gave the result (B1). Obviously, the Gaussian integrals over $\vec{U}$ only converge, if the diagonal elements of T have a proper imaginary increment.

Formula (B13) yields immediately the integral equation (B3). Upon making the change of variables

$$T=x^{1/2}T'x^{1/2},$$
$$\text{implying}\quad d[T]=\mathrm{Det}^{1+\beta(N-1)/2}x\,d[T'], \tag{B14}$$

we bring x into the exponential function and remove it from the determinant. We diagonalize $T'=V'^{-1}t'V'$ and find

$$\mathrm{Det}^{-\beta/2}(x\otimes\hat{k}-T\otimes 1_N)=\mathrm{Det}^{-\beta N/2}x\prod_{n,m}(k_m-t'_n)^{-\beta/2}. \tag{B15}$$

The integral over V' is then just the integral definition (3.15) of the matrix Bessel function $\Phi_N^{(\beta)}(x,t')$ and we arrive at Eq. (B3).

The normalization constants remain to be derived. Conveniently, they nicely relate to a special form of Selberg's integral which is given in Eq. (17.5.2) of Mehta's book,[15]

$$\begin{aligned}J_N&=\int \mathrm{d}[t]|\Delta_N(t)|^{2\gamma}\prod_{n=1}^{N}(a_1+it_n)^{-b_1}(a_2-it_n)^{-b_2}\\&=\frac{(2\pi)^N}{(a_1+a_2)^{(b_1+b_2)N-\gamma N(N-1)-N}}\\&\quad\times\prod_{n=0}^{N-1}\frac{\Gamma(1+(n+1)\gamma)\Gamma(b_1+b_2-(N+n-1)\gamma-1)}{\Gamma(1+\gamma)\Gamma(b_1-n\gamma)\Gamma(b_2-n\gamma)}.\end{aligned} \tag{B16}$$

We now put $x=0$ or $k=0$ and have $\Phi_N^{(\beta)}(0,k)=1$ or $\Phi_N^{(\beta)}(x,0)=1$ on the left-hand side of Eq. (B13). We diagonalize $T=V^{-1}tV$ and use the invariance of the integral. Employing the measure (3.7) and the constant $C_N^{(\beta)}$ given in Eq. (3.9), we find the condition

$$1=\frac{M_N^{(\beta)}C_N^{(\beta)}\pi^{\beta N/2}}{(2\pi)^N}\int \mathrm{d}[t]|\Delta_N(t)|^{\beta}\prod_{n=1}^{N}\frac{\exp(it_n)}{(it_n)^{\beta N/2}}. \tag{B17}$$

We map this onto Selberg's integral (B16) by setting $\gamma=\beta/2$, $b_1=\beta N/2$, and $a_2=b_2$, by using

$$\lim_{a_2\to\infty}\frac{a_2^{a_2}}{(a_2-it_n)^{a_2}}=\exp(it_n) \tag{B18}$$

and by considering $a_2^{Na_2}J_N$ in the limits $a_1\to 0$ and $a_2\to\infty$. With the help of some standard asymptotic formulas for the Γ function, we obtain $M_N^{(\beta)}$ and, eventually, the constants $A_N^{(\beta)}$ and $B_N^{(\beta)}$ in Eqs. (B2) and (B4).

APPENDIX C: FOURIER–BESSEL ANALYSIS

The Fourier–Bessel analysis involving matrix Bessel functions was discussed by Harish-Chandra[4] in a general and formal way. To show the connection to our results, we summarize here some essential features of the Fourier–Bessel analysis on an explicit level.

We write the Fourier transform of a function $f(H)$ as

$$F(K)=D_N^{(\beta)}\int \mathrm{d}[H]\exp(i\,\mathrm{Tr}\,HK)f(H), \tag{C1}$$

where the matrices H and K have the same symmetries. If we choose a symmetric normalization,

$$D_N^{(\beta)}=\frac{1}{(2\pi)^{N/2}\pi^{\beta N(N-1)/4}}, \tag{C2}$$

we can write the inverse transform as

$$f(H)=D_N^{(\beta)}\int \mathrm{d}[K]\exp(-i\mathrm{Tr}KH)F(K). \tag{C3}$$

We notice that, according to Eq. (3.11), the Fourier transform of the constant $D_N^{(\beta)}$ is the δ distribution $\delta(K)$ and vice versa.

If f is an invariant function such that $f(H)=f(x)$, its Fourier transform turns out to be invariant as well, $F(K)=F(k)$. Introducing eigenvalue-angle coordinates, we easily find

$$F(k)=D_N^{(\beta)}C_N^{(\beta)}\int \mathrm{d}[x]|\Delta_N(x)|^{\beta}\Phi_N^{(\beta)}(x,k)f(x) \tag{C4}$$

for the Fourier transform and

$$f(x)=D_N^{(\beta)}C_N^{(\beta)}\int \mathrm{d}[k]\,|\Delta_N(k)|^{\beta}\Phi_N^{(\beta)*}(k,x)F(k) \tag{C5}$$

for its inverse. We now insert the transform (C4) into the inverse (C5) and conclude that

$$(D_N^{(\beta)}C_N^{(\beta)})^2\int \mathrm{d}[k]|\Delta_N(k)|^{\beta}\,\Phi_N^{(\beta)}(x,k)\,\Phi_N^{(\beta)*}(k,y)=\frac{\det[\,\delta(x_n-y_m)\,]_{n,m=1,\ldots,N}}{|\Delta_N(x)\Delta_N(y)|^{\beta/2}}. \tag{C6}$$

This is the analog of Hankel's expansion of the δ distribution. From Eq. (C6), the formula

$$\int \mathrm{d}\mu(U)\,\delta(U^{\dagger}xU-y)=\frac{1}{C_N^{(\beta)}}\,\frac{\det[\,\delta(x_n-y_m)\,]_{n,m=1,\ldots,N}}{|\Delta_N(x)\Delta_N(y)|^{\beta/2}} \tag{C7}$$

obtains. To see this, we introduce a matrix G having the same symmetries as H and write

$$\delta(H-G)=(D_N^{(\beta)})^2\int \mathrm{d}[K]\exp(-i\,\mathrm{Tr}\,K(H-G)). \tag{C8}$$

Averaging over the diagonalizing matrix U of H yields

$$\int \mathrm{d}\mu(U)\,\delta(H-G)=(D_N^{(\beta)})^2\int \mathrm{d}[K]\,\Phi_N^{(\beta)*}(x,k)\exp(i\,\mathrm{Tr}\,KG), \tag{C9}$$

by using the invariance of the measure. We now introduce eigenvalue-angle coordinates for K and do the integral over V, the diagonalizing matrix of K,

$$\int \mathrm{d}\mu(U)\,\delta(H-G)=(D_N^{(\beta)})^2C_N^{(\beta)}\int \mathrm{d}[k]|\Delta_N(k)|^{\beta}\,\Phi_N^{(\beta)*}(x,k)\Phi_N^{(\beta)}(k,y), \tag{C10}$$

where we have, once more, employed the invariance of the measure. Since the right-hand side of this equation does only depend on the eigenvalues y of G, we may replace G on the left-hand side with y. Together with Eq. (C6), this gives formula (C7).

For the convolution in matrix space of two functions $f_1(H)$ and $f_2(H)$, we straightforwardly find the generalization of the standard convolution theorem,

$$f(H)=\int \mathrm{d}[G]f_1(G)f_2(H-G)=\int \mathrm{d}[K]\exp(-i\,\mathrm{Tr}\,HK)F_1(K)F_2(K), \tag{C11}$$

where G has the same symmetries as H. The functions $F_1(K)$ and $F_2(K)$ are the Fourier transforms of $f_1(H)$ and $f_2(H)$, respectively. If the functions are invariant, the second equation of (C11) acquires the form

$$f(x)=C_N^{(\beta)}\int \mathrm{d}[k]|\Delta_N(k)|^{\beta}\,\Phi_N^{(\beta)*}(x,k)F_1(k)F_2(k). \tag{C12}$$

On the other hand, we find from the first equation of (C11)

$$f(x)=C_N^{(\beta)}\int \mathrm{d}[y]|\Delta_N(y)|^\beta f_1(y)\hat{f}_2(x,y), \tag{C13}$$

where y are the eigenvalues of G. This formula is a convolution in the curved space of the eigenvalues. The second function is given by

$$\hat{f}_2(x,y)=\int \mathrm{d}\mu(U) f_2(x-U^\dagger y U). \tag{C14}$$

We insert the Fourier integral for $F_1(k)$ according to Eq. (C4) into Eq. (C12), compare with Eq. (C13) and obtain the Fourier decomposition

$$\hat{f}_2(x,y)=D_N^{(\beta)}C_N^{(\beta)}\int \mathrm{d}[k]|\Delta_N(k)|^\beta \Phi_N^{(\beta)*}(x,k)F_2(k)\Phi_N^{(\beta)}(k,y). \tag{C15}$$

Formulas (C6) and (C7) can be viewed as special cases of these results.

APPENDIX D: ACTION OF THE LAPLACIAN ON THE RADIAL FUNCTIONS FOR ARBITRARY β

We make the notation more compact by defining

$$\tilde{\mu}(x',x)\mathrm{d}[x']=\mathrm{d}\mu(x',x)\exp\left(i\left(\sum_{n=1}^{N}x_n-\sum_{n=1}^{N-1}x_n'\right)k_N\right), \tag{D1}$$

where the measure is given in Eq. (5.6). To prove the identity (5.9), we write the integral using Θ functions. The left hand side of Eq. (5.9) reads

$$\Delta_x\int \tilde{\mu}(x',x)\Phi_{N-1}^{(\beta)}(x',\tilde{k})\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x_l)\mathrm{d}[x'], \tag{D2}$$

where now the integration domain is the real axis for all variables. Thus, we can directly calculate the action of the operator Δ_x onto the integral. We find

$$\begin{aligned}
&\Delta_x\int \tilde{\mu}(x',x)\Phi_{N-1}^{(\beta)}(x',\tilde{k})\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x_l)\mathrm{d}[x']\\
&\quad=\int \Phi_{N-1}^{(\beta)}(x',\tilde{k})\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x_l)\\
&\qquad\times\left(\Delta_{x'}^{(-)}+\beta\sum_{n\neq m}\frac{1}{(x_n'-x_m')^2}-k_N^2\right)\tilde{\mu}(x',x)\mathrm{d}[x']\\
&\qquad+\int \Phi_{N-1}^{(\beta)}(x',\tilde{k})\tilde{\mu}(x',x)\Delta_x\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x)\mathrm{d}[x']\\
&\qquad+2\int \Phi(x',\tilde{k})\sum_{n=1}^{N}\frac{\partial}{\partial x_n}\tilde{\mu}(x',x)\frac{\partial}{\partial x_n}\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x_l)\mathrm{d}[x'],
\end{aligned} \tag{D3}$$

where we define the operator

$$\Delta_{x'}^{(-)}=\sum_{n=1}^{N}\frac{\partial^2}{\partial x_n^2}-\sum_{n<m}\frac{\beta}{x_n-x_m}\left(\frac{\partial}{\partial x_n}-\frac{\partial}{\partial x_m}\right). \tag{D4}$$

By a series of integrations by parts, the operator $\Delta_{x'}^{(-)}$ acting on $\tilde{\mu}(x',x)$ is transformed to $\Delta_{x'}$ acting only on $\Phi(x',\tilde{k})$. At taking the derivative of the Θ functions, we notice that only adjacent levels contribute, because otherwise terms like $\Theta(x_i-x_j)$ with $i<j$ arise which annihilate the integral due to the chosen ordering. Therefore, we can write

$$\frac{\partial}{\partial x_n}\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x_l)=\prod(\Theta_{\neq nn'},\Theta_{\neq(n-1)'n})(\delta(x_n-x_n')\Theta(x_{n-1}'-x_n) - \delta(x_{n-1}'-x_n)\Theta(x_n-x_n')), \tag{D5}$$

where $\Pi(\Theta_{\neq nn'},\Theta_{\neq(n-1)'n})$ is short-hand for the product on the left-hand side of Eq. (D5) without the two factors $\Theta(x_{n-1}'-x_n)\Theta(x_n-x_n')$. Importantly, this product is symmetric in x_{n-1}' and x_n'. The second derivatives yield

$$\frac{\partial}{\partial x_n}\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x_l)=\prod(\Theta_{\neq nn'},\Theta_{\neq(n-1)'n})(\delta'(x_n-x_n')\Theta(x_{n-1}'-x_n) + \delta'(x_{n-1}'-x_n)\Theta(x_n-x_n')+\delta(x_{n-1}'-x_n)\delta(x_n-x_n')). \tag{D6}$$

The last term vanishes upon integration, since it is symmetric in x_{n-1}' and x_n', whereas the rest of the integrand is antisymmetric due to the Vandermonde determinant $\Delta_{N-1}(x')$ in the measure (5.6). Differentiation with respect to x_n' gives

$$\frac{\partial}{\partial x_n'}\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x_l)=\prod(\Theta_{\neq n'(n+1)},\Theta_{\neq nn'})(\delta(x_n'-x_{n+1})\Theta(x_n-x_n') - \delta(x_n-x_n')\Theta(x_n'-x_{n+1})). \tag{D7}$$

Integration by parts of the first term of the right hand side of Eq. (D3) yields

$$\begin{aligned}\Delta_x\int\tilde{\mu}(x',x)\Phi_{N-1}^{(\beta)}(x',\tilde{k})\prod_{i>j}\Theta(x_i-x_j')\prod_{j\geqslant l}\Theta(x_j'-x_l)\mathrm{d}[x'] \\ =\int\tilde{\mu}(x',x)\Delta_{x'}\Phi_{N-1}^{(\beta)}(x',\tilde{k})\mathrm{d}[x']-k_N^2\int\tilde{\mu}(x',x)\Phi_{N-1}^{(\beta)}(x',\tilde{k})\mathrm{d}[x'] \\ +2\int\Phi_{N-1}^{(\beta)}(x',\tilde{k})\sum_{n=1}^{N-1}\Bigg(\prod(\Theta_{\neq n'(n+1)},\Theta_{\neq nn'}) \\ \times(\delta(x_n-x_n')\Theta(x_n'-x_{n+1})+\delta(x_n'-x_{n+1})\Theta(x_n-x_n')) \\ \times\left(\frac{\partial}{\partial x_n}+\frac{\partial}{\partial x_n'}+\frac{1}{2}\sum_{m\neq n}\frac{\beta}{x_n-x_m}+-\frac{1}{2}\sum_{m\neq n}\frac{\beta}{x_n'-x_m'}\right)\Bigg)\tilde{\mu}(x',x)\mathrm{d}[x'].\end{aligned} \tag{D8}$$

Inserting in Eq. (D8) the function $\tilde{\mu}(x',x)$ as given in Eq. (D1) and (5.6) we find after a straightforward calculation

$$\Delta_x \int \tilde{\mu}(x',x)\Phi_{N-1}^{(\beta)}(x',\tilde{k})\mathrm{d}[x']$$

$$= \int \tilde{\mu}(x',x)\Delta_{x'}\Phi_{N-1}^{(\beta)}(x',\tilde{k})\mathrm{d}[x'] - k_N^2 \int \tilde{\mu}(x',x)\Phi_{N-1}^{(\beta)}(x',\tilde{k})\mathrm{d}[x']$$

$$+2\int \Phi_{N-1}^{(\beta)}(x',\tilde{k})\sum_{n=1}^{N-1}\Bigg(\prod\,(\Theta_{\neq n'(n+1)},\Theta_{\neq nn'})(g(x_n';y_n;x,x')-g(x_n';x_n;x,x'))$$

$$\times(\delta(x_n-x_n')\Theta(x_n'-x_{n+1})+\delta(x_n'-x_{n+1})\Theta(x_n-x_n'))\Bigg)\tilde{\mu}(x',x)\mathrm{d}[x'], \tag{D9}$$

with

$$g(x_n;x_n';x,x') = (\beta/2-1)\left(\sum_{m=1}^{N-1}\frac{1}{x_n-x_m'}-\sum_{m\neq n}\frac{1}{x_n-x_m}\right),$$
$$g(x_n';x_n;x,x') = (\beta/2-1)\left(\sum_{m\neq n}\frac{1}{x_n'-x_m'}-\sum_{m=1}^{N}\frac{1}{x_n'-x_m}\right). \tag{D10}$$

We now can perform the integration of the δ distributions in Eq. (D9). We notice that the difference $(g(x_n';x_n;x,x')-g(x_n';x_n;x,x'))$ vanishes linearly, whenever x_n' approaches one of the boundaries of its integration domain. Thus the second integral in Eq. (D9) yields zero as long as the measure diverges less than $(x_n-x_n')^{-1}$ when x_n' approaches x_n. This is always the case for $\beta>0$. Collecting everything, we arrive at the identity (5.9).

APPENDIX E: SYMMETRY OF THE RADIAL FUNCTIONS FOR ARBITRARY β

Applying the recursion formula (5.5) to all $N-1$ levels, we can extend Eq. (4.5) to arbitrary β and write

$$\Phi_N^{(\beta)}(x,k) = \int \prod_{n=1}^{N-1}\mathrm{d}\mu(x^{(n)},x^{(n-1)})\exp\left(i\left(\sum_{m=1}^{N-n+1}x_m^{(n-1)}-\sum_{m=1}^{N-n}x_m^{(n)}\right)k_{N-n+1}\right)\exp(ix_1^{(N-1)}k_1), \tag{E1}$$

where $x^{(0)}=x$. Analogously, we also find

$$\Phi_N^{(\beta)}(k,x) = \int \prod_{n=1}^{N-1}\mathrm{d}\mu(k^{(n)},k^{(n-1)})\exp\left(i\left(\sum_{m=1}^{N-n+1}k_m^{(n-1)}-\sum_{m=1}^{N-n}k_m^{(n)}\right)x_{N-n+1}\right)\exp(ik_1^{(N-1)}x_1) \tag{E2}$$

with $k^{(0)}=k$ for the solution of the differential equation which results from Eq. (5.1) by interchanging x and k. We have to show that these two radial functions (E1) and (E2) are identical. To this end, we change in Eq. (E1) on the nth level the variables $x_m^{(n)}, m=1,\ldots,(N-n)$ to $k_m^{(n)}, m=1,\ldots,(N-n)$ by setting

$$\frac{\Pi_{l=1}^{N-n-1}(x_m^{(n-1)}-x_l^{(n)})}{\Pi_{l\neq m}(x_m^{(n-1)}-x_l^{(n-1)})} = r_m^{(n)} = \frac{\Pi_{l=1}^{N-n-1}(k_m^{(n-1)}-k_l^{(n)})}{\Pi_{l\neq m}(k_m^{(n-1)}-k_l^{(n-1)})} \tag{E3}$$

for $n=1,\ldots,(N-1)$. These are, on the nth level, $N-n+1$ equations for making a change of $N-n$ variables. However, one has

$$\sum_{m=1}^{N-n+1} r_m^{(n)} = 1 \tag{E4}$$

on all levels which eliminates one of the $N-n+1$ equations.

Of course, the substitution (E3) is motivated by the radial Gelfand–Tzetlin coordinates which we introduced to construct the recursion formula for $\beta=1,2,4$. In this case, the $r_m^{(n)}$ are the moduli squared of a column of a matrix $U\in \mathrm{U}(N-n;\beta)$. Here, we do not use this connection to matrices and groups. We simply view Eq. (E3) as a standard change of variables in an integral. We underline that Eq. (E3) does not involve β at all. Equation (E4) is just the normalization of a column of U for $\beta=1,2,4$. Since it is independent of β, it also holds for arbitrary β. One can also verify Eq. (E4) by a direct calculation.

The original domains of integration are $x_m^{(n-1)}\leqslant x_m^{(n)}\leqslant x_{m+1}^{(n-1)}$. In these boundaries, the $r_m^{(n)}$ are positive definite. Hence, to satisfy this when changing the variables, we must have $k_m^{(n-1)}\leqslant k_m^{(n)}\leqslant k_{m+1}^{(n-1)}$ for the new domains of integration.

To work out the measure in the new variables $k_m^{(n)}$, we interpret Eq. (E3) as a change to the integration variables $r_m^{(n)}$, too. This yields immediately

$$\frac{\Delta_{N-n}(x^{(n)})}{\Delta_{N-n+1}(x^{(n-1)})}\,\mathrm{d}[x^{(n)}]=\mathrm{d}\mu(r^{(n)})=\frac{\Delta_{N-n}(k^{(n)})}{\Delta_{N-n+1}(k^{(n-1)})}\,\mathrm{d}[k^{(n)}]. \tag{E5}$$

The first equality sign goes back to the radial Gelfand–Tzetlin coordinates. We may use this piece of information, because it is independent of β. The second equality sign is simply due to Eq. (E3). Using this result, we find for the full and β dependent measure

$$\begin{aligned}\mathrm{d}\mu(x^{(n)},x^{(n-1)})&=G_{N-n+1}^{(\beta)}\left(\frac{\Pi_{l,m}(x_m^{(n-1)}-x_l^{(n)})}{\Delta_{N-n+1}^2(x^{(n-1)})}\right)^{(\beta-2)/2}\frac{\Delta_{N-n}(x^{(n)})}{\Delta_{N-n+1}(x^{(n-1)})}\,\mathrm{d}[x^{(n)}]\\&=G_{N-n+1}^{(\beta)}\left(\prod_{m=1}^{N-n+1}r_m^{(n)}\right)^{(\beta-2)/2}\frac{\Delta_{N-n}(x^{(n)})}{\Delta_{N-n+1}(x^{(n-1)})}\,\mathrm{d}[x^{(n)}]\\&=G_{N-n+1}^{(\beta)}\left(\frac{\Pi_{l,m}(k_m^{(n-1)}-k_l^{(n)})}{\Delta_{N-n+1}^2(k^{(n-1)})}\right)^{(\beta-2)/2}\\&\quad\times\frac{\Delta_{N-n}(k^{(n)})}{\Delta_{N-n+1}(k^{(n-1)})}\,\mathrm{d}[k^{(n)}]=\mathrm{d}\mu(k^{(n)},k^{(n-1)}).\end{aligned} \tag{E6}$$

For $\beta=1,2,4$, this result is a direct consequence of the invariance of the group measure $\mathrm{d}\mu(U)$. Here, we have derived it for arbitrary β. This, in turn, implies that the invariance of the group measure $\mathrm{d}\mu(U)$ is embedded into and reflects much more general features.

We now collect all these intermediate results and plug them into Eq. (E1). Apart from the expressions in the exponential functions, we have full agreement with the right-hand side of Eq. (E2). Hence, it remains to be shown that the change of variables (E3) leads to the identity

$$\begin{aligned}&\sum_{n=1}^{N-1}\left(\sum_{m=1}^{N-n+1}x_m^{(n-1)}-\sum_{m=1}^{N-n}x_m^{(n)}\right)k_{N-n+1}+x_1^{(N-1)}k_1\\&\quad=\sum_{n=1}^{N-1}\left(\sum_{m=1}^{N-n+1}k_m^{(n-1)}-\sum_{m=1}^{N-n}k_m^{(n)}\right)x_{N-n+1}+k_1^{(N-1)}x_1.\end{aligned} \tag{E7}$$

Since the symmetry relation (5.3) holds for $\beta=1,2,4$, we know that Eq. (E7) must be true in these cases. However, as Eq. (E7) does not involve β at all, it must also be valid for arbitrary β. Inserting this into the right-hand side of Eq. (E1), we recover Eq. (E2), as desired. We notice that this line of arguing cannot be spoiled by any other contribution to the argument of the exponential functions, because all other terms in the integrand are purely algebraic. This completes the proof of the symmetry relation (5.3) for arbitrary β.

APPENDIX F: CALCULATION OF THE NORMALIZATION CONSTANT $G_N^{(\beta)}$

In Appendix E, we introduced the coordinates $r_n'=r_n^{(1)}, n=1,\ldots,N$ on the first level of the recursion. They are the moduli squared of the coordinates on the unit sphere in the complex N dimensional space. Thus, it is natural to use the following type of hyper spherical coordinates

$$\begin{aligned}\sqrt{r_n'}&=\cos\vartheta_n\prod_{\nu=1}^{n-1}\sin\vartheta_\nu,\quad n=1,\ldots,(N-1),\\ \sqrt{r_N'}&=\sin\vartheta_{N-1}\prod_{\nu=1}^{N-2}\sin\vartheta_\nu,\end{aligned}\tag{F1}$$

where the positive semidefiniteness of the r_n' restricts the domain of integration to $0\leqslant\vartheta_n<\pi/2$, $n=1,\ldots,(N-1)$. Thus, we integrate over a (2^N)th segment of the unit sphere. The measure

$$\mathrm{d}\mu(r')=\prod_{n=1}^{N-1}\sin^{2(N-n)-1}\vartheta_n\cos\vartheta_n\,\mathrm{d}\vartheta_n\tag{F2}$$

is, apart from the phase angles, the measure on the unit sphere. Collecting everything, we have

$$\begin{aligned}1=\int\mathrm{d}\mu(x',x)&=G_N^{(\beta)}\int\left(\prod_{n=1}^{N}\sqrt{r_n'}\right)^{\beta-2}\mathrm{d}\mu(r')\\&=G_N^{(\beta)}\prod_{n=1}^{N-1}\int_0^{\pi/2}\sin^{(N-n)\beta-1}\vartheta_n\cos^{\beta-1}\vartheta_n\,\mathrm{d}\vartheta_n\\&=G_N^{(\beta)}\prod_{n=1}^{N-1}\frac{\Gamma((N-n)\beta/2)\Gamma(\beta/2)}{2\Gamma((N-n+1)\beta/2)}=G_N^{(\beta)}\frac{\Gamma^N(\beta/2)}{2^{N-1}\Gamma(N\beta/2)},\end{aligned}\tag{F3}$$

where the integral over ϑ_n is just Euler's integral of the first kind.

APPENDIX G: TRANSLATION INVARIANCE OF $W_{N,\omega}^{(\beta)}(x,k)$

We shift every x_n in the the recursion formula (5.5) for arbitrary β by a constant $\overline{x}$ and obtain

$$\Phi_N^{(\beta)}(x+\overline{x},k)=\int\mathrm{d}\mu(x',x+\overline{x})\exp\left(i\left(\sum_{n=1}^{N}x+N\overline{x}-\sum_{n=1}^{N-1}x'\right)k_N\right)\Phi_{N-1}^{(\beta)}(x',\tilde{k})\tag{G1}$$

with $x_n+\overline{x}\leqslant x_n'\leqslant x_{n+1}+\overline{x}$ as the domains of integration. The change of variables $x_n'\to x_n'+\overline{x}$ removes $\overline{x}$ from the measure given in Eq. (5.6) and the domains of integration, we find

$$\Phi_N^{(\beta)}(x+\overline{x},k)=\exp(i\overline{x}k_N)\int\mathrm{d}\mu(x',x)\exp\left(i\left(\sum_{n=1}^{N}x-\sum_{n=1}^{N-1}x'\right)k_N\right)\Phi_{N-1}^{(\beta)}(x'+\overline{x},\tilde{k}).\tag{G2}$$

We want to employ an induction. We assume that the radial functions for arbitrary β have the property

$$\Phi_N^{(\beta)}(x+\overline{x},k)=\exp\left(i\overline{x}\sum_{n=1}^{N}k_n\right)\Phi_N^{(\beta)}(x,k).\tag{G3}$$

If this is correct for $N-1$, formula (G2) implies that it is also true for N. The induction starts with $N=2$ where the correctness of Eq. (G3) is immediately obvious from the explicit solution (3.21) for arbitrary β. Thus, Eq. (G3) is valid for all N.

Since the k_n are arbitrary and since the sum over all k_n is invariant under the permutations $\omega(k)$, the property (G3) must also be true for every function $\Phi^{(\beta)}_{N,\omega}(x,k)$ with $\omega \in S_N$. We compare this with

$$\Phi^{(\beta)}_{N,\omega}(x+\overline{x},k)=\exp\left(i\overline{x}\sum_{n=1}^{N} k_n \right)\frac{\exp(i\Sigma_{n=1}^{N}x_n k_{\omega(n)})}{|\Delta_N(x)\Delta_N(k)|^{\beta/2}}\, W^{(\beta)}_{N,\omega}(x+\overline{x},k), \tag{G4}$$

which results from the Hankel ansatz (5.10). Hence, we conclude that we necessarily have

$$W^{(\beta)}_{N,\omega}(x+\overline{x},k)=W^{(\beta)}_{N,\omega}(x,k). \tag{G5}$$

This is the translation invariance.

APPENDIX H: CALCULATION OF $\Phi^{(4)}_4(x,k)$

We perform the calculation for $\Phi^{(4)}_4(-ix,k)$ to avoid inconvenient factors of i. The operator $L_{x,\omega(k)}$ defined in Eq. (5.13) splits into two parts. The first part

$$\tilde{\Delta}_{x,\omega(k)}=\sum_{n=1}^{N}\frac{\partial^2}{\partial x_n^2}-4\sum_{n<m}\frac{1}{(x_n-x_m)^2} \tag{H1}$$

does not change the order in k, while the second one,

$$\Lambda_{x,\omega(k)}=2\sum_{n=1}^{N} k_{\omega(n)}\frac{\partial}{\partial x_n}, \tag{H2}$$

raises the order in k by one. Since we can restrict ourselves to one element of the permutation group, we discuss only the identity permutation in the sequel. The symmetry of x and k together with the result for $\Phi^{(4)}_3(x,k)$ suggests that one try an expansion in the composite variable z_{ij} as defined in Eq. (6.8). To this end we define the elementary symmetric functions

$$e_\nu(z)=\sum_{i_1j_1<i_2j_2<\cdots<i_\nu j_\nu}\prod_{l=1}^{\nu} z_{i_lj_l}. \tag{H3}$$

Here, we assume the following ordering of the composite index $\{i_lj_l\}$, $i_l<j_l$. We say $\{i_lj_l\}<\{i_mj_m\}$ if $i_l<i_m$ or $i_l=i_m$ and $j_l<j_m$. All indices run to N. The highest order elementary symmetric function is of order $N(N-1)/2$ and is given by $\Delta_N(x)\Delta_N(k)$. The asymptotic formula (5.14) yields the leading term for large arguments. It is the starting point for a recursion in powers of z^{-1},

$$W^{(4)}_N(z)=\sum_{\nu=0}^{N(N-1)/2} p_\nu(z^{-1}), \tag{H4}$$

where $p_\nu(z)$ is a symmetric function of order ν in x_i and k_i. We investigate the action of the two operators defined in Eqs. (H1) and (H2) and find

$$\Lambda_{x,k}e_\nu(z^{-1})=-2\sum_{n<m}^{N}\frac{1}{(x_n-x_m)^2}e_{\nu-1}(z^{-1}_{\neq nm}), \tag{H5}$$

$$\tilde{\Delta}_{x,k} e_\nu(z^{-1}) = -4 \sum_{n<m}^{N} \frac{1}{(x_n - x_m)^2} e_\nu(z^{-1}_{\neq nm}) - 2 \sum_{\substack{n<m \\ k\neq n \\ k\neq m}}^{N} \frac{1}{(x_n - x_m)^2} z_{nk}^{-1} z_{mk}^{-1} e_{\nu-2}(z^{-1}_{\substack{\neq nm \\ \neq nk \\ \neq mk}}). \quad \text{(H6)}$$

The function $e_\nu(z_{\neq nm})$ is the elementary symmetric function $e_\nu(z)$ with all terms containing z_{nm} omitted. For $\nu = 0,1,2$ we simply have $p_\nu(z^{-1}) = (-2)^\nu e_\nu(z^{-1})$. For $\nu \geqslant 3$ the last term in Eq. (H5) causes corrections to the elementary symmetric functions. This arises due to the mixed derivatives which have to be taken into account in the action of $\tilde{\Delta}_{x,k}$ onto $e_\nu(z^{-1})$ for $\nu \geqslant 3$. Because of this term the Hankel ansatz becomes increasingly cumbersome as higher values of N are considered. More and more correction terms have to be constructed. So far, the construction was only possible for $N=4$. To construct the correction terms explicitly for the case $N=4$, we define a new set of symmetric functions as follows:

$$f_\nu(z^{-1}) = \sum_{k<l<m}^{N} z_{kl}^{-1} z_{km}^{-1} z_{lm}^{-1} e_{\nu-3}(z^{-1}_{\substack{\neq kl \\ \neq km \\ \neq lm}}). \quad \text{(H7)}$$

Again we have to investigate the action of $\Lambda_{x,k}$ and $\tilde{\Delta}_{x,k}$ on $f_\nu(z^{-1})$. We find

$$\tilde{\Delta}_{x,k} f_3(z^{-1}) = -4 \sum_{n<m}^{N} \frac{1}{(x_n - x_m)^2} f_3(z^{-1}_{\neq nm}) \quad \text{(H8)}$$

and

$$\Lambda_{x,k} f_3(z^{-1}) = -2 \sum_{\substack{n<m \\ k\neq n \\ k\neq m}}^{N} \frac{1}{(x_n - x_m)^2} z_{nk}^{-1} z_{mk}^{-1}, \quad \text{(H9)}$$

thus $f_3(z^{-1})$ is the desired correction term. We have

$$p_3(z^{-1}) = -2^3 (e_3(z^{-1}) + \tfrac{1}{2} f_3(z^{-1})). \quad \text{(H10)}$$

Fortunately, due to Eq. (H8) in the next step the correction term itself does not have to be corrected and we find

$$p_4(z^{-1}) = 2^4 (e_4(z^{-1}) + \tfrac{1}{2} f_4(z^{-1})). \quad \text{(H11)}$$

Up to now these results are valid for arbitrary N. The action of $\tilde{\Delta}_{x,k}$ onto the symmetric function $f_4(z^{-1})$ is not as simple as Eq. (H8). After a series of manipulations we arrive at

$$\tilde{\Delta}_{x,k} f_4(z^{-1}) = -4 \sum_{n<m}^{N} \frac{1}{(x_n - x_m)^2} f_4(z^{-1}_{\neq nm}) \quad \text{(H12)}$$

$$-2 \sum_{\substack{n<m \\ k\neq n \\ k\neq m}}^{N} \frac{1}{(x_n - x_m)^2} z_{nk}^{-1} z_{mk}^{-1} f_2(z^{-1}_{\substack{\neq nm \\ \neq nk \\ \neq mk}}). \quad \text{(H13)}$$

The contribution (H6) has to be added to this expression stemming from the action of $\tilde{\Delta}_{x,k}$ onto $e_4(z^{-1})$. On the other hand we calculate

$$\Lambda_{x,k} f_5(z^{-1}) = -2 \sum_{n<m}^{N} \frac{1}{(x_n - x_m)^2} f_4(z^{-1}_{\neq nm}) \tag{H14}$$

$$-2 \sum_{\substack{n<m \\ k\neq n \\ k\neq m}}^{N} \frac{1}{(x_n - x_m)^2} z_{nk}^{-1} z_{mk}^{-1} e_2(z^{-1}_{\substack{\neq nm \\ \neq nk \\ \neq mk}}). \tag{H15}$$

Thus, we have to find yet another correction term to compensate the second term in Eq. (H13). We define

$$f_5'(z^{-1}) = \sum_{i_1<i_2<i_3<i_4} \prod_{r<j} z^{-1}_{i_r i_j} \sum_{r<j} z_{i_r i_j} = \sum_{\substack{j<k \\ l<m}} z_{jl}^{-1} z_{jm}^{-1} z_{kl}^{-1} z_{km}^{-1} z_{lm}^{-1} \tag{H16}$$

and see that $\Lambda_{x,k} f_5'(z^{-1})$ yields exactly the desired second term of Eq. (H13). Pushing forward this procedure becomes more complicated step by step. There seems to be no obvious way of constructing the additional terms. Apparently for higher orders the correction terms also involve an increasing amount of indices. Nevertheless for $N=4$ we are already at the end of the procedure. Then the general expression

$$p_5(z^{-1}) = -2^5 (e_5(z^{-1}) + \tfrac{1}{2} f_5(z^{-1}) + \tfrac{1}{4} f_5'(z^{-1})) \tag{H17}$$

reduces to

$$p_5(z^{-1}) = -72 e_5(z^{-1}). \tag{H18}$$

The last step can readily be done, since the action of $\tilde{\Delta}_{x,k}$ onto $e_5(z^{-1})$ is already known by Eq. (H6). Thus we arrive at

$$p_6(z^{-1}) = 288 e_6(z^{-1}). \tag{H19}$$

Importantly, we have

$$\tilde{\Delta}_{x,k} e_6(z^{-1}) = \tilde{\Delta}_{x,k} \frac{1}{\Delta_4(x)\Delta_4(k)} = 0. \tag{H20}$$

That means, the sequence finishes after the sixth step. Collecting everything and observing that, for $N=4$, $f_5(z) = 2e_5(z)$ and $f_6(z) = 4e_6(z)$, we obtain

$$W_4^{(4)}(x,k) = \sum_{\nu=1}^{6} (-2)^{\nu} e_\nu(z^{-1}) + \sum_{\nu=3}^{6} (-2)^{\nu-1} f_\nu(z^{-1}) - 8e_5(z^{-1}) + 96 e_6(z^{-1}). \tag{H21}$$

This can be rewritten in a more compact way as

$$W_4^{(4)}(x,k) = \frac{1}{\Delta_4(x)\Delta_4(k)} \times \left(\prod_{i<j} (2 - z_{ij}) + 2^2 \sum_{l<m<n} \prod_{\substack{i<j \\ \neq lm \\ \neq ln \\ \neq mn}} (2 - z_{ij}) + 2^3 \sum_{\substack{l<m \\ k<n}} \prod_{\substack{i<j \\ \neq mk}} \prod_{\substack{\neq lk \\ \neq mn}} \prod_{\substack{\neq ln \\ \neq kn}} (2 - z_{ij}) \right), \tag{H22}$$

which yields Eq. (6.10).

(Received 19 October 2001; accepted for publication 1 February 2002)

We extend the recursion formula for matrix Bessel functions, which we obtained previously, to superspace. It is sufficient to do this for the unitary orthosymplectic supergroup. By direct computations, we show that fairly explicit results can be obtained, at least up to dimension 8×8 for the supermatrices. Since we introduce a new technique, we discuss various of its aspects in some detail. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1463218]

I. INTRODUCTION

In a previous work, we studied properties of matrix Bessel functions in ordinary space.[1] Here, we generalize these investigations to superspace. For the introductory remarks and the mathematical and physical background relevant for the ordinary space, and also relevant as the basis for the present study, we refer the reader to Ref. 1.

In mathematics, supersymmetry was pioneered by Berezin[2] and, in particular group theoretical aspects, by Kac.[3,4] The theory of nonlinear σ models in spaces of supermatrix fields was developed in physics of disordered systems by Efetov.[5,6] Verbaarschot, Weidenmüller, and Zirnbauer[7,8] used his approach to study models in random matrix theory. In Ref. 9, the first supersymmetric generalization of the Itzykson–Zuber integral[10] was given. In Ref. 11, Gelfand–Tzetlin coordinates[12] were constructed for the unitary supergroup. Extending Shatashvili's[13] method, the supersymmetric Itzykson–Zuber integral was also rederived in Ref. 11 in its most general form. Using the techniques of Ref. 9, such a calculation was also performed in Ref. 14.

From a mathematical viewpoint, Efetov's work[5] is the basis for a harmonic analysis in certain supersymmetric coset spaces, the Efetov spaces, which are relevant for the nonlinear σ models. In the full superspaces, a technique involving convolution integrals and ingredients of the corresponding harmonic analysis was introduced in Ref. 15. In the Efetov spaces, the theory of harmonic analysis, in both its mathematical and physical aspects, was developed by Zirnbauer[16] and was applied to disordered systems in Refs. 17 and 18. In the present contribution, we do not focus on the Efetov spaces, rather we address the full supergroup spaces. The supersymmetric Itzykson–Zuber integral[9] and its application in Ref. 15 is the simplest example of a supermatrix Bessel function appearing in this kind of harmonic analysis.

The matrix Bessel functions in superspace find direct application in random matrix theory. For general reviews, see Refs. 19–21. In Ref. 22 it was shown that they are the kernels for the supersymmetric analog of Dyson's Brownian motion.

The paper is organized as follows: In Sec. II, we introduce the supermatrix Bessel functions and collect basic definitions and notations. In Sec. III, we extend the recursion formula of Ref. 1 to superspaces. Since it is one of our goals to demonstrate that explicit results for supermatrix

[a)]Electronic mail: thomas@matfys.lth.se
[b)]Electronic mail: heiner.kohler@uam.es

Bessel functions can indeed be obtained, we present, in some detail, such calculations for certain supermatrix Bessel functions in Secs. IV and V, respectively. The asymptotics and the normalization are discussed in Sec. VI. We briefly comment on applications in Sec. VII and we summarize and conclude in Sec. VIII. Various calculations are shifted to the appendices.

II. SUPERMATRIX BESSEL FUNCTIONS

Similar to ordinary spaces,[1] the superunitary case, i.e., integration over the supergroup $\mathrm{U}(k_1/k_2)$, is the simplest one. Since this was already discussed in detail in Refs. 9, 11, and 22, we refrain from reconsidering it here. Thus, it turns out that we may restrict ourselves to the supermatrix Bessel function of the unitary orthosymplectic group $\mathrm{UOSp}(k_1/2k_2)$. As discussed by Kac,[3,4] the supergroups $\mathrm{U}(k_1/k_2)$ and $\mathrm{UOSp}(k_1/2k_2)$ exhaust almost all classical compact supergroups, apart from some exotic exceptions which are of little relevance for applications. Hence, the integral we have to deal with is given by

$$\Phi_{k_1 2k_2}(s,r)=\int_{u\in \mathrm{UOSp}(k_1/2k_2)} \exp(i\,\mathrm{trg}\,u^{-1}sur)\mathrm{d}\mu(u), \tag{2.1}$$

where $\mathrm{d}\mu(u)$ is the invariant measure. The arguments of the function (2.1) are the diagonal matrices $s=\mathrm{diag}(\sqrt{c}s_1,\sqrt{-c}s_2)$ and $r=\mathrm{diag}(\sqrt{c}r_1,\sqrt{-c}r_2)$. Here, we use Wegner's notation[23] and introduce the label $c=\pm 1$ to distinguish the two possible forms. We will return to this issue. The matrices s_1, s_2 and r_1, r_2 are given by

$$\begin{aligned} s_1&=\mathrm{diag}(s_{11},s_{21},\ldots,s_{k_1 1}), \quad s_2=\mathrm{diag}(s_{12}1_2,\ldots,s_{k_2 2}1_2),\\ r_1&=\mathrm{diag}(r_{11},r_{21},\ldots,r_{k_1 1}), \quad r_2=\mathrm{diag}(r_{12}1_2,\ldots,r_{k_2 2}1_2). \end{aligned} \tag{2.2}$$

There is a twofold degeneracy in s_2 and r_2, because the matrix $u^{-1}su$ or, equivalently, uru^{-1} has to be a *real Hermitian* supermatrix[23] of the form

$$\sigma=\begin{bmatrix} \sqrt{c}\sigma^{(R)} & \sigma^{(A)\dagger} \\ \sigma^{(A)} & \sqrt{-c}\sigma^{(HSd)} \end{bmatrix}, \quad c=\pm 1. \tag{2.3}$$

The matrices $\sigma^{(R)}$ and $\sigma^{(HSd)}$ have ordinary commuting entries, i.e., bosons, they are real symmetric and Hermitian self-dual, respectively. The matrix $\sigma^{(A)}$ has anticommuting or Grassmann entries, i.e., fermions, and is of the form

$$\sigma^{(A)}=[\sigma_1^{(A)},\ldots,\sigma_{k_1}^{(A)}], \quad \sigma_i^{(A)}=\begin{bmatrix} \sigma_{1i}^{(A)} \\ \sigma_{1i}^{(A)*} \\ \vdots \\ \sigma_{k_2 i}^{(A)} \\ \sigma_{k_2 i}^{(A)*} \end{bmatrix}. \tag{2.4}$$

We can now appreciate the meaning of the parameter c which enters the definition (2.3) of the real Hermitian matrices. For $c=1$, it yields the real symmetric and for $c=-1$ the Hermitian self-dual matrix as boson–boson block, and vice versa for the fermion–fermion block. In the framework of random matrix theory, we find the supermatrices corresponding to the Gaussian orthogonal ensemble (GOE) for $c=+1$ and those for the Gaussian symplectic ensemble (GSE) for $c=-1$.

The infinitesimal volume element is given by

$$\mathrm{d}[\sigma]=\prod_{i=1}^{k_1}\prod_{j=1}^{k_2}\mathrm{d}\sigma_{ij}^{(A)*}\mathrm{d}\sigma_{ij}^{(A)}\prod_{i<j}\mathrm{d}\sigma_{ij}^{(R)}\prod_{i=1}^{k_1}\mathrm{d}\sigma_{ii}^{(R)}\prod_{i<j}\mathrm{d}[\sigma_{ij}^{(HSd)}]\prod_{i=1}^{k_2}\mathrm{d}\sigma_{ii}^{(HSd)}, \tag{2.5}$$

where $d[\sigma_{ij}^{(HSd)}]$ is the product of the differentials of all independent elements of the quaternion $\sigma_{ij}^{(HSd)}$.

The supermatrix Bessel functions (2.1) are eigenfunctions of a wave equation in the curved space of the eigenvalues s or r. As in the ordinary case, a supermatrix gradient $\partial/\partial\sigma$ is introduced and the Laplace operator is defined by

$$\Delta = \mathrm{trg}\left(\frac{\partial}{\partial\sigma}\right)^2. \tag{2.6}$$

The plane waves $\exp(i\,\mathrm{trg}\,\sigma\rho)$ are the eigenfunctions, i.e., we have

$$\Delta\,\exp(i\,\mathrm{trg}\,\sigma\rho) = -\,\mathrm{trg}\,\rho^2\exp(i\,\mathrm{trg}\,\sigma\rho). \tag{2.7}$$

Here, both σ and ρ are real Hermitian. As in ordinary space, the supermatrix Bessel functions are obtained by averaging over the angular coordinates, i.e., over the diagonalizing group. The Laplacian commutes with the average and we arrive at the differential equation

$$\Delta_s\Phi_{k_1 2k_2}(s,r) = -\,\mathrm{trg}\,r^2\Phi_{k_1 2k_2}(s,r), \tag{2.8}$$

where the radial part of of the Laplacian (2.6) reads

$$\Delta_s = \frac{1}{\tilde{B}^{(c)}_{k_1k_2}(s)}\left(\sum_{p=1}^{k_1}\frac{\partial}{\partial s_{p1}}\tilde{B}^{(c)}_{k_1k_2}(s)\frac{\partial}{\partial s_{p1}} + \frac{1}{2}\sum_{p=1}^{k_2}\frac{\partial}{\partial s_{p2}}\tilde{B}^{(c)}_{k_1k_2}(s)\frac{\partial}{\partial s_{p2}}\right). \tag{2.9}$$

The Jacobian or Berezinian is given by[22]

$$\tilde{B}^{(1)}_{k_1k_2}(s) = \frac{|\Delta_{k_1}(s_1)|\Delta^4_{k_2}(is_2)}{\Pi_{p=1}^{k_1}\Pi_{q=1}^{k_2}(s_{p1}-is_{q2})^2}, \quad \tilde{B}^{(-1)}_{k_1k_2}(s) = \frac{|\Delta_{k_1}(is_1)|\Delta^4_{k_2}(s_2)}{\Pi_{p=1}^{k_1}\Pi_{q=1}^{k_2}(is_{p1}-s_{q2})^2}. \tag{2.10}$$

One easily convinces oneself that Δ_s depends on c only through a factor $\sqrt{c}$. Thus, without loss of generality, we set $c=1$ and omit the index c.

At this point, an important comment is in order. The normalization in ordinary space according to Eq. (3.17) in Ref. 1, $\Phi_N^{(\beta)}(x,0)=1$ and $\Phi_N^{(\beta)}(0,k)=1$, does not carry over to the supersymmetric case. This is due to the fact that the volume of some supergroups is zero[2] resulting in the vanishing of $\Phi_{k_1 2k_2}(0,s)$ for certain values of k_1 and k_2. This collides with the normalization of the plane waves (2.7) to unity at the origin. The reason for this contradiction is a well-known phenomenon in superanalysis. In going from Cartesian to angle eigenvalue coordinates, one has to add additional terms to the measure to preserve the symmetries of the original integral. These are called Efetov–Wegner–Parisi–Sourlas terms in the physics literature. A full-fledged mathematical theory of these boundary terms was given by Rothstein.[24]

To solve this normalization problem, we use the following strategy. First, we evaluate the supermatrix Bessel functions without taking care of the normalization. We just multiply the integrals with a normalization constant $\hat{G}_{k_1 2k_2}$. Having done the integrals, we determine the normalization by comparing the asymptotics of the supermatrix Bessel function for large arguments with the Gaussian integral.

III. SUPERSYMMETRIC RECURSION FORMULA

We extend the recursion formula in ordinary space[1] to superspace. After stating the result in Sec. III A, we present the derivation and the calculation of the invariant measure in Secs. III B and III C, respectively.

A. Statement of the result

Let $\Phi_{k_1 2 k_2}(s,r)$ be defined through the group integral in Eq. (2.1). It has two diagonal matrices defined as in Eq. (2.2) as arguments. It can be calculated iteratively by the *recursion formula*

$$\Phi_{k_1 2 k_2}(s,r) = \hat{G}_{k_1 2 k_2} \int \mathrm{d}\mu(s',s)\, \exp(i(\mathrm{trg}\, s - \mathrm{trg}\, s')r_{11}) \Phi_{(k_1-1)2k_2}(s',\tilde{r}), \tag{3.1}$$

where $\Phi_{(k_1-1)2k_2}(s',\tilde{r})$ is the group integral (2.1) over $\mathrm{UOSp}((k_1-1)/2k_2))$ and $\hat{G}_{k_1 2 k_2}$ is a normalization constant, see Secs. II and VI. As in the ordinary case,[1] the coordinates s' are *radial* Gelfand–Tzetlin coordinates. Again, they are different from the *angular* Gelfand–Tzetlin coordinates, which will be discussed elsewhere.[25] We also introduced the diagonal matrix

$$\tilde{r} = \mathrm{diag}(r_{21},\ldots,r_{k_1 1}, i r_2) = \mathrm{diag}(\tilde{r}_1, i\tilde{r}_2) \tag{3.2}$$

such that $r = \mathrm{diag}(r_{11},\tilde{r})$ and the diagonal matrix

$$s' = \mathrm{diag}(s'_{11},\ldots,s'_{(k_1-1)1}, i s'_2) = \mathrm{diag}(s'_1, i s'_2). \tag{3.3}$$

The invariant measure reads

$$\begin{aligned}
\mathrm{d}\mu(s',s) &= 2^{k_2+1} \mu_B(s'_1,s_1)\mu_F(s'_2,s_2)\mu_{BF}(s',s)\mathrm{d}[\xi']\mathrm{d}[s'_1], \\
\mu_B(s'_1,s_1) &= \frac{\Delta_{k_1}(s'_1)}{\sqrt{-\prod_{p=1}^{k_1}\prod_{q=1}^{k_1-1}(s_{p1}-s'_{q1})}}, \\
\mu_F(s'_2,s_2) &= \frac{\Delta^4_{k_2}(i s'_2)}{\prod_{p=1}^{k_2}\prod_{q=1}^{k_2}(i s_{p2} - i s'_{q2})^2}, \\
\mu_{BF}(s',s) &= \frac{\prod_{p=1}^{k_1}\prod_{l=1}^{k_2}\prod_{q=1}^{k_1-1}(i s'_{l2}-s_{p1})(i s_{l2}-s'_{q1})}{\prod_{p=1}^{k_1-1}\prod_{l=1}^{k_2}(i s'_{l2}-s'_{p1})^2}.
\end{aligned} \tag{3.4}$$

Here, we have introduced

$$\mathrm{d}[\xi'] = \prod_{p=1}^{k_2} \mathrm{d}\xi'^*_p\, \mathrm{d}\xi'_p, \quad \mathrm{d}[s'_1] = \prod_{p=1}^{k_1-1} \mathrm{d}s'_{p1}. \tag{3.5}$$

The domain of integration for the bosonic variables is compact and given by

$$s_{p1} \leqslant s'_{p1} \leqslant s_{(p+1)1}, \quad p = 1,\ldots,(k_1-1). \tag{3.6}$$

The fermionic eigenvalues $i s'_{p2}$ are related to Grassmann variables ξ'_p and ξ'^*_p through

$$|\xi'_p|^2 = i s'_{p2} - i s_{p2}. \tag{3.7}$$

The Jacobian or Berezinian consists of three parts. One of them, $\mu_B(s'_1,s_1)$, depends only on bosonic eigenvalues and one, $\mu_F(s'_1,s_1)$, only on fermionic eigenvalues, i.e., only on Grassmann variables. The third part mixes commuting and anticommuting integration variables. To underline once more the difference between radial and angular Gelfand–Tzetlin coordinates which is also present in superspace, we mention that the radial measure (3.4) is quite different from the angular one.[25]

As in ordinary space, the recursion formula is an exact map of the group integration onto an iteration exclusively in the radial space. Having done the iteration on the first k_1 levels, we have treated all Grassmann variables. Thus, in the integrand, we are left with the matrix Bessel function $\Phi_{k_2}^{(4)}(-i2s_2^{(k_1-1)},r_2)$ for USp$(2k_2)$ in ordinary space.[1] We notice the occurrence of the factor $-i2$ in the argument of $\Phi_{k_2}^{(4)}(-i2s_2^{(k_1-1)},r_2)$. Collecting everything, we arrive at

$$\Phi_{k_1 2k_2}(s,r)=\int \prod_{n=1}^{k_1-1} \mathrm{d}\mu(s^{(n)},s^{(n-1)})\exp(i(\mathrm{trg}\, s^{(n-1)}-\mathrm{trg}\, s^{(n)})r_{n1}) \times \exp(is_{11}^{(k_1-1)}r_{k_1 1})\Phi_{k_2}^{(4)}(-i2s_2^{(k_1-1)},r_2). \tag{3.8}$$

We have set $s=s^{(0)}$ and $s'=s^{(1)}$. It is worthwhile to notice that the radial Gelfand–Tzetlin coordinates have a highly appreciated and valuable property: The Grassmann variables only appear as moduli squared in the integrand. Thus, the number of integrals over anticommuting variables is only *half* the number of the independent Grassmann variables. Moreover, advantageously, the exponential is a simple function of the integration variables. Thus, we may conclude that the radial Gelfand–Tzetlin coordinates are the natural coordinates of the matrix and the supermatrix Bessel functions, because their intrinsic features are reflected.

B. Derivation

All crucial steps needed for the derivation of the supersymmetric recursion formula (3.1) carry over from the ordinary recursion formula in Ref. 1. We order the columns of the matrix $u \in \mathrm{UOSp}(k_1/2k_2)$ in the form $u=[u_1 u_2 \cdots u_{k_1} u_{k_1+1}\cdots u_{k_1+k_2}]$. We also introduce a rectangular matrix $b=[u_2\cdots u_{k_1} u_{k_1+1}\cdots u_{k_1+k_2}]$ such that $u=[u_1 b]$. Analogous to the ordinary case, we have

$$\begin{aligned} b^\dagger b &= 1_{(k_1-1)2k_2}, \\ bb^\dagger &= \sum_{p=2}^{k_1} u_p u_p^\dagger + \sum_{p=k_1+1}^{k_1+k_2} u_p u_p^\dagger = 1_{k_1 2k_2} - u_1 u_1^\dagger . \end{aligned} \tag{3.9}$$

We define the square matrix $\tilde{\sigma}=b^\dagger s b$ and rewrite the trace in the exponent as

$$\mathrm{trg}\, u^\dagger s u r = \mathrm{trg}\, \tilde{\sigma}\tilde{r} + \sigma_{11} r_{11}, \tag{3.10}$$

with $\sigma_{11}=u_1^\dagger s u_1$. Similar to the ordinary case, the first term on the right-hand side of Eq. (3.10) depends on the last k_1-1+k_2 columns u_p collected in b and the second term depends only on u_1. Thus, it is useful to decompose the invariant measure,

$$\mathrm{d}\mu(u)=\mathrm{d}\mu(b)\mathrm{d}\mu(u_1), \tag{3.11}$$

and to write Eq. (2.1) in the form

$$\Phi_{k_1 2k_2}(s,r)=\int \mathrm{d}\mu(u_1)\exp(i\sigma_{11}r_{11})\int \mathrm{d}\mu(b)\exp(i\,\mathrm{trg}\,\tilde{\sigma}\tilde{r}). \tag{3.12}$$

Since the coordinates b are locally orthogonal to u_1, the measure $\mathrm{d}\mu(b)$ also depends on u_1.

We now generalize the radial Gelfand–Tzetlin coordinates introduced in Ref. 1 for the ordinary spaces to the superspace. Naturally, the projector reads $(1_{k_1 2k_2}-u_1 u_1^\dagger)$ and we have the defining equation

$$(1_{k_1 2k_2}-u_1 u_1^\dagger)s(1_{k_1 2k_2}-u_1 u_1^\dagger)e_p'=s_p' e_p', \quad p=1,\ldots,k_1-1,k_1+1,\ldots,k_1+k_2 \tag{3.13}$$

for the (k_1-1+k_2) radial Gelfand–Tzetlin coordinates s'_p and the corresponding vectors e'_p as eigenvalues and eigenvectors of the matrix $(1_{k_1 2k_2}-u_1u_1^\dagger)s(1_{k_1 2k_2}-u_1u_1^\dagger)$ which has the generalized rank k_1-1+k_2. Due to $u_1^\dagger e'_p=0$, we find

$$(1_{k_1 2k_2}-u_1u_1^\dagger)se'_p=s'_pe'_p, \quad p=1,\ldots,k_1-1,k_1+1,\ldots,k_2. \tag{3.14}$$

As in Ref. 11, the eigenvalues s'_p are calculated from the characteristic function

$$z(s'_p)=\mathrm{detg}((1_{k_1 2k_2}-u_1u_1^\dagger)s-s'_p)=-s'_p\,\mathrm{detg}(s-s'_p)u_1^\dagger\frac{1_{k_1 2k_2}}{s-s'_p}u_1, \tag{3.15}$$

which has to be discussed in the limits

$$z(s'_p)\to\begin{cases}0 & \text{for } p=1,\ldots,k_1-1\\ \infty & \text{for } p=k_1+1,\ldots,k_1+k_2.\end{cases} \tag{3.16}$$

Thus, together with the normalization $u_1^\dagger u_1=1$, these are k_1+k_2 equations for the elements of u_1.

The two parts of the integral (3.12) have to be expressed in terms of the radial Gelfand–Tzetlin coordinates s'_p. In a calculation fully analogous to the ordinary case, we find

$$\sigma_{11}=\mathrm{trg}\,s-\mathrm{trg}\,s'. \tag{3.17}$$

The eigenvalues t_p, $p=1,\ldots,k_1-1,k_1+1,\ldots,k_1+k_2$ of $\tilde{\sigma}$ obtain from the characteristic function

$$w(t_p)=\mathrm{detg}(\tilde{\sigma}-t_p)=-\frac{1}{t_p}\mathrm{detg}((1_{k_1 2k_2}-u_1u_1^\dagger)s-t_p). \tag{3.18}$$

Comparison with Eq. (3.15) shows that the characteristic functions $w(t_p)$ and $z(s'_p)$ are, apart from the nonzero factor $-t_p$, identical. This implies $t_p\equiv s'_p$, $p=1,\ldots,k_1-1,k_1+1,\ldots,k_1+k_2$. Thus, by introducing the square matrix $\tilde{u}$ which diagonalizes $\tilde{\sigma}$, we may write

$$\tilde{\sigma}=b^\dagger sb=\tilde{u}^\dagger s'\tilde{u}. \tag{3.19}$$

By construction, $\tilde{u}$ must be in the group $\mathrm{UOSp}(k_1-1/2k_2)$, because σ and $\tilde{\sigma}$ share the same symmetries.

These intermediate results allow us to transform Eq. (3.12) into

$$\Phi_{k_1 2k_2}(s,r)=\int \mathrm{d}\mu(s',s)\exp(i(\mathrm{trg}\,s-\mathrm{trg}\,s')r_{11})\int \mathrm{d}\mu(b)\exp(i\,\mathrm{trg}\,\tilde{u}^\dagger s'\tilde{u}\tilde{r}), \tag{3.20}$$

where $\mathrm{d}\mu(s',s)$ is, apart from phase angles, the invariant measure $\mathrm{d}\mu(u_1)$, expressed in the radial Gelfand–Tzetlin coordinates s'. To do the integration over b, we view, for the moment, the vector u_1 as fixed and observe that the measure $\mathrm{d}\mu(b)$ is the invariant measure of the group $\mathrm{UOSp}(k_1-1/2k_2)$ under the constraint that b is locally orthogonal to u_1. The matrix $\tilde{u}\in\mathrm{UOSp}(k_1-1/2k_2)$ is constructed from b under the same constraint. Thus, since b and $\tilde{u}$ cover the same manifold, the integral over b in Eq. (3.20) must yield the supermatrix Bessel function $\Phi_{(k_1-1)2k_2}(s',\tilde{r})$ and we arrive at the supersymmetric recursion formula (3.1). In the last step, we used a line of arguing slightly different from the derivation in ordinary space. In this way we avoided a discussion related to the ill-defined supergroup volume. The invariance of the measure is the crucial property we need for the proof and this holds both in superspace and in ordinary space.

C. Invariant measure

In order to evaluate the invariant measure, we have to solve the system of equations (3.15) for $|v_p^{(1)}|^2=|u_{p1}|^2$, $p=1,\ldots,k_1$ and $|\alpha_p^{(1)}|^2=|u_{(k_1+2p)1}|^2+|u_{(k_1+2p-1)1}|^2$, $p=1,\ldots,k_2$ in terms of the bosonic eigenvalues $s_p'=s_{p1}'$, $p=1,\ldots,k_1-1$ and the fermionic eigenvalues $s_{k_1+2p}'=s_{k_1+2p-1}'=is_{p2}'$, $p=1,\ldots,k_2$,

$$1=\sum_{p=1}^{k_1}|v_p^{(1)}|^2+\sum_{p=1}^{k_2}|\alpha_p^{(1)}|^2, \tag{3.21}$$

$$0=\sum_{q=1}^{k_1}\frac{|v_q^{(1)}|^2}{s_{q1}-s_{p1}'}+\sum_{q=1}^{k_2}\frac{|\alpha_q^{(1)}|^2}{is_{q2}-s_{p1}'},\quad p=1,\ldots,k_1-1, \tag{3.22}$$

$$z_p=is_{p2}'\frac{\Pi_{q=1}^{k_1}(s_{q1}-is_{p2}')}{\Pi_{q=1}^{k_2}(is_{q2}-is_{p2}')^2}\left(\sum_{q=1}^{k_1}\frac{|v_q^{(1)}|^2}{s_{q1}-is_{p2}'}+\sum_{q=1}^{k_2}\frac{|\alpha_q^{(1)}|^2}{is_{q2}-is_{p2}'}\right),\quad z_p\to\infty,\quad p=1,\ldots,k_2. \tag{3.23}$$

In Appendix A, we sketch the solution of this system for small dimensions. Inspired by these solutions one can conjecture the general solutions and verify them by plugging them directly into Eqs. (3.21)–(3.23); one finds

$$\begin{aligned}|v_p^{(1)}|^2&=\frac{\Pi_{q=1}^{k_1-1}(s_{p1}-s_{q1}')\Pi_{q=1}^{k_2}(s_{p1}-is_{q2})^2}{\Pi_{q=1}^{k_2}(s_{p1}-is_{q2}')^2\Pi_{q=1,q\neq p}^{k_1}(s_{p1}-s_{q1})},\quad p=1,\ldots,k_1,\\ |\alpha_p^{(1)}|^2&=2(is_{p2}'-is_{p2})\frac{\Pi_{q=1}^{k_1-1}(is_{p2}-s_{q1}')\Pi_{q=1,q\neq p}^{k_2}(is_{p2}-is_{q2})^2}{\Pi_{q=1,q\neq p}^{k_2}(is_{p2}-is_{q2}')^2\Pi_{q=1}^{k_1}(is_{p2}-s_{q1})},\quad p=1,\ldots,k_2.\end{aligned} \tag{3.24}$$

These expressions are reminiscent of the ones derived in Ref. 11 for unitary matrices. However, importantly, all products in (3.24) involving fermionic eigenvalues are squared. This reflects the degeneracy of s in the fermion–fermion block. We have introduced new anticommuting variables $\xi_p',\xi_p'^*$ with $|\xi_p'|^2=is_{p2}'-is_{p2}$ according to definition (3.7).

From this point on, the invariant measure can be calculated in the same way as for the angular Gelfand–Tzetlin coordinates, see Ref. 11 for details. The result is summarized in Eq. (3.4).

IV. THE FUNCTION $\Phi_{22}(s,r)$

We use the recursion formula (3.1) to calculate the supermatrix Bessel function for UOSp(2/2). To avoid the imaginary unit in the exponent, we study $\Phi_{22}(-is,r)$. The recursion formula reads

$$\Phi_{22}(-is,r)=\hat{G}_{22}\int \mathrm{d}\mu(s',s)\exp((\mathrm{trg}\,s-\mathrm{trg}\,s')r_{11})\Phi_{12}(-is',\tilde{r}). \tag{4.1}$$

The function $\Phi_{12}(-is',\tilde{r})$ is easily found to be

$$\Phi_{12}(-is',\tilde{r})=\hat{G}_{12}(1-2(r_{21}-ir_{12})(s_{11}'-is_{12}'))\exp(2r_{12}s_{12}). \tag{4.2}$$

The measure of the coset UOSp(2/2)/UOSp(1/2) is according to formula (3.4) given by

$$\mathrm{d}\mu(s',s)=\frac{(is_{12}-s_{11}')\Pi_{n=1}^{2}(is_{12}'-s_{n1})}{\sqrt{-\Pi_{n=1}^{2}(s_{11}'-s_{n1})}(is_{12}'-s_{11}')^2}\mathrm{d}s_{11}'\,\mathrm{d}\xi_1'^*\,\mathrm{d}\xi_1'. \tag{4.3}$$

We do the Grassmann integration and find

$$\Phi_{22}(-is,r)=\hat{G}_{22}\exp(r_{11}(s_{11}+s_{21})-2is_{12}ir_{12})$$
$$\times\int_{s_{11}}^{s_{21}}\mu_B(s',s)\prod_{q=1}^{2}(is_{12}-s_{q1})\Bigg(4\prod_{j=1}^{2}(ir_{12}-r_{j1})-2(ir_{12}-r_{11})$$
$$\times\sum_{q=1}^{2}\frac{1}{is_{12}-s_{q1}}+2M_{11}(s_1',s_1)\Bigg)\exp(s_{11}'(r_{21}-r_{11}))\mathrm{d}s_{11}', \tag{4.4}$$

where we have introduced the operator

$$M_{mj}(s_1',s_1)=\frac{1}{(is_{m2}-s_{j1}')}\left(\frac{1}{2}\sum_{n=1}^{k_1}\frac{1}{is_{m2}-s_{n1}}-\frac{1}{is_{m2}-s_{j1}'}-\sum_{\substack{n=1\\n\neq j}}^{k_1}\frac{1}{s_{j1}'-s_{n1}'}-\frac{\partial}{\partial s_{j1}'}\right). \tag{4.5}$$

For later purposes, we introduced general indices m and j. Obviously, the Grassmann integration yielded eigenvalues in the denominator. This is somewhat surprising because of the following observation: we can always parametrize the group element $u\in\mathrm{UOSp}(2/2)$ in a noncanonical coset parametrization in the spirit of an Euler parametrization in ordinary space. Inserting this parametrization into the defining equation of the supermatrix Bessel function (2.1) one can expand the trace in all Grassmann variables. The expansion coefficients are polynomials in the commuting integration variables and—more important—in the matrix elements of s and r. The invariant measure can be expanded in the Grassmann variables as well. It does not depend on r and s. Although this procedure gets rapidly out of hand even for small groups, it is clear that the outcome of this expansion will be polynomial in the eigenvalues of s and r. In other words: eigenvalues can only appear in the denominator by an integration over commuting variables and never by a Grassmann integration. Therefore, before performing any integral over commuting variables, there must exist a form of $\Phi_{22}(-is,r)$, which is polynomial in the eigenvalues of s and r.

To remove the denominators and to obtain such a polynomial expression, we use the following result. Let $f(s_1')$ be an analytic, symmetric function in s_{1i}', $i=1,\ldots,k_1$. Furthermore, define the operator

$$L_m(s)=\sum_{j=1}^{k_1}\frac{1}{is_{m2}-s_{j1}}\frac{\partial}{\partial s_{j1}}. \tag{4.6}$$

Then the action of the operator on the integral over the bosonic part of the measure is given by

$$L_m(s)\int_{s_{11}}^{s_{21}}\cdots\int_{s_{(k_1-1)1}}^{s_{k_11}}\mu_B(s',s)f(s_1')\mathrm{d}[s_1']$$
$$=-\int_{s_{11}}^{s_{21}}\cdots\int_{s_{(k_1-1)1}}^{s_{k_11}}\mu_B(s',s)\sum_{j=1}^{k_1-1}M_{mj}(s_1',s_1)f(s_1')\mathrm{d}[s_1']. \tag{4.7}$$

This formula is derived in Appendix B.

We now set $f(s_1')=\exp(-s_{11}'(r_{21}-r_{11}))$ and insert Eq. (4.7) into Eq. (4.4), we arrive at

$$\Phi_{22}(-is,r)=\hat{G}_{22}\exp(-2is_{12}ir_{12})\Bigg(4\prod_{j=1}^{2}(ir_{12}-r_{j1})(is_{12}-s_{j1})$$
$$-2\sum_{q=1}^{2}(is_{12}-s_{q1})\left(ir_{12}-r_{21}-r_{11}-\frac{\partial}{\partial s_{q1}}\right)\Bigg)\Phi_2^{(1)}(-is_1,r_1), \tag{4.8}$$

where $\Phi_2^{(1)}(s_1,r_1)$ is the matrix Bessel function of the orthogonal group O(2) in ordinary space as defined in Ref. 1. Although this can already be taken as the result, we underline the symmetry between s and r by using the explicit form (3.21) of Ref. 1 for $\Phi_2(s_1,r_1)$,

$$\Phi_{22}(-is,r)=\hat{G}_{22}\exp\left(\mathrm{trg}\,rs-\frac{z}{2}\right)$$
$$\times\left(4\prod_{j=1}^{2}(ir_{12}-r_{j1})(is_{12}-s_{j1})-\sum_{q=1}^{2}(is_{12}-s_{q1})\sum_{p=1}^{2}(ir_{12}-r_{p1})-z\frac{\mathrm{d}}{\mathrm{d}z}\right)2\pi I_0(z/2), \tag{4.9}$$

where we have introduced $z=(s_{11}-s_{21})(r_{11}-r_{21})$ and the modified Bessel function I_0 as defined in Ref. 26.

The result (4.7) was crucial in the derivation of $\Phi_{22}(-is,r)$. By means of this formula, the denominator problem was overcome in one step. Because of its importance, we want to gain more insight into this problem: In Appendix C, we rederive $\Phi_{22}(-is,r)$ in two other ways. It is clear that the methods of Appendix C cannot be used for higher dimensions k_1 and $2k_2$, but it will help to understand the mechanisms needed when working with radial Gelfand–Tzetlin coordinates.

V. THE SERIES OF FUNCTIONS $\Phi_{k_14}(s,r)$

We calculate iteratively the four supermatrix Bessel functions $\Phi_{k_14}(s,r)$ for $k_1=1,2,3,4$. We do this in Secs. V A–V D, respectively.

A. First level $k_1=1$

According to the recursion formulas (3.1) and (3.8), the starting point is the matrix Bessel function for the unitary symplectic group $\Phi_2^{(4)}(s_2,r_2)$, which was already calculated in Ref. 1. Up to a normalization, we have

$$\Phi_2^{(4)}(i2s_2,r_2)=\sum_{\omega\in S_2}\left(\frac{1}{\Delta_2^2(is_2)\Delta_2^2(\omega(ir_2))}-\frac{1}{\Delta_2^3(is_2)\Delta_2^3(\omega(ir_2))}\right)\exp(-\mathrm{tr}is_2\omega(ir_2)). \tag{5.1}$$

Since the subgroup O(1) of UOSp(1/4) is trivial, no commuting integral has to be performed to derive $\Phi_{14}(-is,r)$. Inserting the measure (3.4) into the recursion formula and performing the Grassmann integrations yields straightforwardly

$$\Phi_{14}(-is,r)=\hat{G}_{14}\exp(\mathrm{trg}\,rs)\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)(2(is_{21}-s_{11})(ir_{21}-r_{11})-1)$$
$$\times(2(is_{22}-s_{11})(ir_{22}-r_{11})-1)-\hat{G}_{14}\frac{\exp(\mathrm{trg}(rs))}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}+(ir_{12}\leftrightarrow ir_{22}). \tag{5.2}$$

The exchange term $(ir_{12}\leftrightarrow ir_{22})$ accounts for the permutation group S_2 in Eq. (5.1). Anticipating that the structure of $\Phi_{14}(-is,r)$ will, remarkably, survive on all levels up to $\Phi_{44}(-is,r)$, we state that $\Phi_{14}(-is,r)$ essentially consists of two parts. A comparison with Eqs. (4.2), and (5.1) shows that the first part of $\Phi_{14}(-is,r)$ is a product of an exponential with three other terms. The first one,

$$\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right), \tag{5.3}$$

stems from the integral over the USp(4) subgroup. The other two terms can be identified with the supermatrix Bessel functions

$$\Phi_{12}(-is,r) \quad \text{with} \quad s=\mathrm{diag}(s_{11},is_{12},is_{12}), \quad r=\mathrm{diag}(r_{11},ir_{12},ir_{12}) \tag{5.4}$$

and

$$\Phi_{12}(-is,r) \quad \text{with} \quad s=\mathrm{diag}(s_{11},is_{22},is_{22}), \quad r=\mathrm{diag}(r_{11},ir_{22},ir_{22}). \tag{5.5}$$

The second part can be considered as a correction term, which destroys the product structure of $\Phi_{14}(-is,r)$. We may identify the different parts of the product with the integrations over the corresponding subsets of the group. Thus, $\Phi_2^{(4)}(-is_2,r_2)$ arises from the integration over the USp(4) subgroup, the O(1) integration yields unity, and the other two factors come from the integration over the coset $\mathrm{UOSp}(1/4)/(\mathrm{USp}(4)\otimes\mathrm{O}(1))$.

B. Second level $k_1=2$

We now have to do one integration over a commuting variable. After the Grassmann integration, we are left with a considerable amount of terms. To arrange them in a convenient way, we introduce the following notation for the product of two operators $D_1(s)D_2(s)$ acting on a function $f(s)$, we define

$$[D_1^{\rightarrow}(s)D_2(s)]f(s)=D_1(s)D_2(s)f(s)-(D_1(s)D_2(s))f(s). \tag{5.6}$$

This means, an operator with an arrow only acts on the terms outside the squared bracket. With this notation we can write

$$\begin{aligned}
\Phi_{24}(-is,r)=\hat{G}_{24}\exp(\mathrm{tr}(r_2s_2)+r_{21}(s_{11}+s_{21}))\int_{s_{11}}^{s_{21}}\mathrm{d}\mu_B(s_1',s_1)\Bigg[&\prod_{i=1}^{2}\prod_{j=1}^{2}(is_{i2}-s_{j1})\\
&\times\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)\\
&\times\left(4\prod_{i=1}^{2}(ir_{12}-r_{i1})+2\sum_{k=1}^{2}\frac{r_{21}-ir_{12}}{is_{12}-s_{k1}}+2M_{11}(s_1',s_1)\right)\\
&\times\left(4\prod_{i=1}^{2}(ir_{22}-r_{i1})+2\sum_{k=1}^{2}\frac{r_{21}-ir_{22}}{is_{22}-s_{k1}}+2M_{21}(s_1',s_1)\right)\\
&+\left(\frac{1}{\Delta_2^2(ir_2)\Delta_3^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\right)\\
&\times\left(\frac{4}{is_{12}-s_{11}'}M_{21}(s_1',s_1)-\frac{2}{is_{22}-s_{11}'}M_{11}(s_1',s_1)\right)\\
&+\frac{2}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\left(2\,\mathrm{tr}\,r_1-\mathrm{tr}\,ir_2+\sum_{i=1}^{2}\frac{1}{is_{22}-s_{i1}}\right)M_{11}(s_1',s_1)\\
&-\frac{2}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\left(2\,\mathrm{tr}\,r_1-\mathrm{tr}\,ir_2+\sum_{i=1}^{2}\frac{1}{is_{12}-s_{i1}}\right)M_{21}(s_1',s_1)\\
&-\frac{4}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\sum_{k=1}^{2}\prod_{j=1}^{2}\frac{r_{21}-ir_{j2}}{s_{k1}-is_{j2}}\Bigg]\exp(s_{11}'(r_{11}-r_{21}))+(ir_{12}\leftrightarrow ir_{22}).
\end{aligned} \tag{5.7}$$

As in Sec. IV, a denominator problem occurs. It becomes obvious in the product $M_{11}^{\rightarrow}(s_1',s_1)M_{21}(s_1',s_1)$. Thus, we expect an identity similar to formula (4.7). This identity should map a product of operators $L_1(s)L_2(s)$ acting on the integral onto a product of operators

$M_{11}(s_1',s_1)M_{21}(s_1',s_1)$ acting under the integral. Neither the outer operators, $L_m(s)$, nor the inner ones, $M_{mj}(s)$, commute. Hence, the desired identity must be a nontrivial one. It is given by the following result.

We have the same conditions as in formula (4.7), furthermore we define

$$[L_m^{\rightarrow}(s)L_l(s)]=\sum_{n=1}^{k_1}\sum_{q=1}^{k_1}\frac{1}{(is_{m2}-s_{n1})(is_{l2}-s_{q1})}\frac{\partial^2}{\partial s_{n1}\partial s_{q1}}. \tag{5.8}$$

Then the following formula holds

$$\begin{aligned}
&[L_m^{\rightarrow}(s)L_l(s)]\int_{s_{11}}^{s_{21}}\cdots\int_{s_{(k_1-1)1}}^{s_{k_1 1}}\mu_B(s',s)\,\mathrm{d}[s_1']\,f(s_1')\\
&\quad=\int_{s_{11}}^{s_{21}}\cdots\int_{s_{(k_1-1)1}}^{s_{k_1 1}}\mu_B(s',s)\Bigg[\sum_{j=1}^{k_1-1}\sum_{k=1}^{k_1-1}M_{mj}(s_1',s_1)M_{lk}(s_1',s_1)\\
&\qquad-\frac{1}{is_{l2}-is_{m2}}\sum_{j=1}^{k_1-1}\left(\frac{1}{is_{m2}-s_{j1}'}M_{lj}(s_1',s_1)-\frac{1}{is_{l2}-s_{j1}'}M_{mj}(s_1',s_1)\right)\\
&\qquad-\frac{1}{2}\sum_{k\neq j}^{k_1-1}\frac{1}{(is_{m2}-s_{k1}')(is_{m2}-s_{j1}')(is_{l2}-s_{k1}')(is_{l2}-s_{j1}')}\Bigg]f(s_1')\,\mathrm{d}[s_1'].
\end{aligned}\tag{5.9}$$

The derivation is along the same lines as the one for formula (4.7), it also involves formula (4.7). With the identities (5.9) and (4.7) the denominator problem is again solved in one step. After some further manipulations we arrive at

$$\begin{aligned}
\Phi_{24}(-is,r)&=2\pi\hat{G}_{24}\exp\left(\mathrm{trg}\,rs-\frac{z}{2}\right)\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)\\
&\quad\times\Bigg[\left(4\prod_{i=1}^{2}(r_{i1}-ir_{12})(s_{i1}-is_{12})-\sum_{\substack{i=1\\j=1}}^{2}(s_{j1}-is_{12})(r_{i1}-ir_{12})-z\frac{\partial^{\rightarrow}}{\partial z}\right)\\
&\quad\times\left(4\prod_{i=1}^{2}(r_{i1}-ir_{22})(s_{i1}-is_{22})-\sum_{\substack{i=1\\j=1}}^{2}(s_{j1}-is_{22})(r_{i1}-ir_{22})-z\frac{\partial}{\partial z}\right)\Bigg]I_0(z/2)\\
&\quad-2\pi\hat{G}_{24}\exp\left(\mathrm{trg}\,rs-\frac{z}{2}\right)\frac{2}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\\
&\quad\times\sum_{\substack{i=1\\k=1}}^{2}\prod_{j=1}^{2}(s_{i1}-is_{j2})(r_{k1}-ir_{j2})I_0(z/2)-2\pi\hat{G}_{24}\exp\left(\mathrm{trg}\,rs-\frac{z}{2}\right)\\
&\quad\times\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}((\mathrm{trg}\,s)(\mathrm{trg}\,r)-1)z\frac{\partial}{\partial z}I_0(z/2)+(ir_{12}\leftrightarrow ir_{22}).
\end{aligned}\tag{5.10}$$

As in Sec. IV, we used the composite variable $z=(s_{11}-s_{12})(r_{11}-r_{12})$. A comparison with Eqs. (4.8) and (5.2) shows the similarity in the structures of $\Phi_{24}(-is,r)$ and $\Phi_{14}(-is,r)$. The former also decomposes into two parts. The first part is a product, whose factors can be assigned to the integrations over the different submanifolds of the group in the same way as in the case of $\Phi_{14}(-is,r)$. The other one can be interpreted as a correction term due to the noncommutativity of the operators L_m in formula (5.9).

C. Third level $k_1=3$

This structure of $\Phi_{k_14}(-is,r)$ emerging in the previous calculations is likely to also be present for arbitrary k_1. However, for $k_1>2$, we have so far not been able to treat the general case. Fortunately, in important physics applications, one matrix argument of the supermatrix Bessel function has an additional twofold degeneracy in the boson–boson block. In this case, it is possible to carry on the recursion up to $\Phi_{44}(-is,r)$ by extending the techniques developed for $k_1=1$ and $k_2=2$. Thus, from now on, we restrict ourselves to this case.

At first sight, one might hope to achieve some simplification by applying the projection procedure onto the degenerate matrix, because this results in a considerable simplification of the invariant measure. However, it turned out that the integrations are easier if one does the recursion with the nondegenerate coordinates. Hence, we use the measure as it stands in Eq. (3.4). We consider $\Phi_{34}(-is,r)$ in the case that

$$r_1=\mathrm{diag}(r_{11},r_{21},r_{21}). \tag{5.11}$$

Having performed the Grassmann integral, one can arrange the terms in a way similar to Eq. (5.7). The complete expression and further details are given in Appendix D. We then can use formula (5.9) and find after some further algebra

$$\begin{aligned}
\Phi_{34}(-is,r)=4\ \hat{G}_{34}\exp(\mathrm{tr}\, r_2s_2)(r_{21}-ir_{12})(r_{21}-ir_{22})\Bigg[&\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)\\
&\times\Bigg(4\prod_{k=1}^{2}(r_{k1}-ir_{12})\prod_{k=1}^{3}(s_{k1}-is_{12})+2\sum_{k=1}^{3}\prod_{j\neq k}^{3}(s_{j1}-is_{12})\\
&\times\left(r_{11}+r_{21}-ir_{12}-\frac{\partial^{\rightarrow}}{\partial s_{k1}}\right)\Bigg)\\
&\times\Bigg(4\prod_{k=1}^{2}(r_{k1}-ir_{22})\prod_{k=1}^{3}(s_{k1}-is_{22})+2\sum_{k=1}^{3}\prod_{j\neq k}^{3}(s_{j1}-is_{22})\\
&\times\left(r_{11}+r_{21}-ir_{22}-\frac{\partial}{\partial s_{k1}}\right)\Bigg)-\frac{4}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\sum_{i=1}^{3}\prod_{\substack{j=1\\j\neq i}}^{3}(s_{j1}-is_{12})(s_{j1}-is_{22})\\
&\times\Bigg(r_{11}^2+r_{21}^2+r_{11}r_{21}-(r_{11}+r_{21})(ir_{12}+ir_{22})+ir_{12}ir_{22}\\
&-(r_{11}+r_{21}-ir_{12}-ir_{22})\frac{\partial}{\partial s_{i1}}\Bigg)-\frac{2}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\\
&\times\sum_{i,k}^{3}\prod_{\substack{j=1\\j\neq i}}^{3}\prod_{\substack{l=1\\l\neq k}}^{3}(s_{j1}-is_{12})(s_{l1}-is_{22})\left(\frac{\partial}{\partial s_{i1}}-\frac{\partial}{\partial s_{k1}}\right)\Bigg]\\
&\times\Phi_3^{(1)}(-is_1,r_1),\quad +(ir_{12}\leftrightarrow ir_{22}),
\end{aligned}\tag{5.12}$$

where $\Phi_3^{(1)}(s_1,r_1)$ is the matrix Bessel function of the orthogonal group O(3). We notice that the structure of $\Phi_{14}(-is,r)$ and $\Phi_{24}(-is,r)$ reappears in $\Phi_{34}(-is,r)$.

D. Fourth level $k_1=4$

In the calculation of $\Phi_{44}(-is,r)$, we again consider the case that the matrix r is degenerate,

$$r_1=\mathrm{diag}(r_{11},r_{11},r_{21},r_{21}). \tag{5.13}$$

The main problem is to find a convenient representation for the matrix Bessel function $\Phi_3^{(1)}(-is_1',\tilde{r}_1)$ appearing on the third level in Eq. (5.12). It turns out that the representation derived in Appendix B of Ref. 1 is very well suited to our purpose. Due to the degeneracy in $\tilde{r}_1$, the original threefold integral can be reduced to an integral over just one single variable

$$\Phi_3^{(1)}(-is_1',\tilde{r}_1)=\frac{\exp(r_{21}\,\mathrm{tr}\,s_1')}{\sqrt{|r_{11}-r_{21}|}}\int_{-\infty}^{+\infty}\mathrm{d}t\,\frac{\exp(i(r_{11}-r_{21})t)}{\Pi_{i=1}^3\sqrt{s_{i1}'-it}}. \tag{5.14}$$

Here, we again neglected the normalization because we want to fix it afterwards as explained previously. Similarly, $\Phi_4^{(1)}(-is_1,r_1)$ can be written as a double integral,

$$\Phi_4^{(1)}(-is_1,r_1)=\frac{\exp(r_{21}\,\mathrm{tr}\,s_1)}{|r_{11}-r_{21}|}\int_{-\infty}^{+\infty}\mathrm{d}t_1\int_{-\infty}^{+\infty}\mathrm{d}t_2|t_1-t_2|\,\frac{\exp(i(r_{11}-r_{21})(t_1+t_2))}{\Pi_{i=1}^4\Pi_{n=1}^2\sqrt{s_{i1}-it_n}}. \tag{5.15}$$

Singularities have to be taken care of appropriately. After inserting Eq. (5.10) into the recursion formula and performing the Grassmann integration, one can arrange the terms in a similar way as in the case of $\Phi_{34}(-is,r)$. At this point, we notice that formulas (4.7) and (5.9) need to be supplemented by further identities. We state the most important one in the following.

The same conditions as for formula (4.7) apply. Moreover, we define the operator

$$\tilde{L}_m(s)=\sum_{q=1}^{k_1}\frac{1}{is_{m2}-s_{q1}}\frac{\partial^2}{\partial s_{q1}^2}+\frac{1}{2}\sum_{q\neq n}\frac{1}{(is_{m2}-s_{q1})(s_{q1}-s_{n1})}\left(\frac{\partial}{\partial s_{q1}}-\frac{\partial}{\partial s_{n1}}\right). \tag{5.16}$$

Then we have

$$\begin{aligned}&\tilde{L}_m(s)\int_{s_{11}}^{s_{11}}\cdots\int_{s_{(k_1-1)1}}^{s_{k_1 1}}\mu_B(s',s)\mathrm{d}[s_1']f(s_1')\\&\quad=-\int_{s_{11}}^{s_{21}}\cdots\int_{s_{(k_1-1)1}}^{s_{k_1 1}}\mu_B(s',s)\left[\sum_{j=1}\overrightarrow{M_{mj}}(s_1',s_1)\frac{\partial}{\partial s_{j1}'}\right]f(s_1')\,\mathrm{d}[s_1'].\end{aligned} \tag{5.17}$$

Again, the proof is along the same lines as the proof of formula (4.7) and the proof of formula (5.9) in Ref. 1.

Thus, there is a family of rules to transform operators symmetric in s_{i1} $L_m(s),\tilde{L}_m(s)$ acting onto an integral into an operator acting under the integral. We need one more such transformation rule which tells us how the product $[L_m(s)\tilde{L}_l(s)]$ transforms into operators acting under the integral. This formula and further details are given in Appendix E. Collecting everything, we finally arrive at

$$\begin{aligned}\Phi_{44}(-is,r)=4\hat{G}_{44}\exp(-\mathrm{tr}\,(r_2s_2))\prod_{i,j}(r_{i1}-ir_{j2})\Bigg[&\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)\\&\times\left(8\prod_{i=1}^2(r_{i1}-ir_{12})\prod_{j=1}^4(s_{j1}-is_{12})+4\sum_{i=1}^4\prod_{j\neq i}^4(s_{j1}-is_{12})\left(r_{11}+r_{21}-ir_{12}-\frac{\partial^{\rightarrow}}{\partial s_{i1}}\right)\right)\\&\times\left(8\prod_{i=1}^2(r_{i1}-ir_{22})\prod_{j=1}^4(s_{j1}-is_{22})+4\sum_{i=1}^4\prod_{j\neq i}^4(s_{j1}-is_{22})\left(r_{11}+r_{21}-ir_{22}-\frac{\partial}{\partial s_{i1}}\right)\right)\\&-\frac{16}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\sum_{i=1}^4\prod_{j\neq i}^4(s_{j1}-is_{12})(s_{j1}-is_{22})\Big(r_{11}^2+r_{21}^2+r_{11}r_{21}-(ir_{12}+ir_{22})\end{aligned}$$

$$\times(r_{11}+r_{21})+ir_{12}ir_{22}-\frac{1}{2}\mathrm{trg}\,r\frac{\partial}{\partial s_{i1}}\Bigg)-\frac{8}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\sum_{\substack{i=1\\j=1}}^{4}\prod_{l\neq i}^{4}(s_{l1}-is_{12})$$

$$\times\prod_{l\neq j}^{4}(s_{l1}-is_{22})\left(\frac{\partial}{\partial s_{i1}}-\frac{\partial}{\partial s_{j1}}\right)\Bigg]\Phi_4^{(1)}(-is_1,r_1)+(ir_{12}\leftrightarrow ir_{22}). \tag{5.18}$$

We mention that in the derivation of this result we frequently used properties of the matrix Bessel functions $\Phi_3^{(1)}(s_1,r_1)$ and $\Phi_4^{(1)}(s_1,r_1)$ that only hold for the case that one matrix has an additional degeneracy.

VI. ASYMPTOTICS AND NORMALIZATION

The asymptotic behavior of the supermatrix Bessel functions calculated in the previous sections is a useful check which also allows us to fix the normalization constants. We find from the expressions in Eqs. (4.1), (4.8) and in Eqs. (5.2), (5.10), (5.12), and (5.18),

$$\lim_{\substack{s\to\infty\\r\to\infty}}\Phi_{k_1 2k_2}(-is,r)=2^{k_1k_2}\hat{G}_{k_1 2k_2}\frac{\Pi_{l=1}^{k_1}\Pi_{m=1}^{k_2}(s_{l1}-is_{m2})(r_{l1}-ir_{m2})}{\Delta_{k_2}^2(is_2)\Delta_{k_2}^2(ir_2)}$$

$$\times\det[\exp(2s_{i2}r_{j2})]_{i,j=1\cdots k_2}\lim_{\substack{s_1\to\infty\\r_1\to\infty}}\Phi_{k_1}^{(1)}(-is_1,r_1). \tag{6.1}$$

In the degenerate case, each degenerate eigenvalue contributes according to its multiplicity. The asymptotics of the matrix Bessel functions of the orthogonal group is given by[27,28]

$$\lim_{t\to 0}\Phi_{k_1}^{(1)}(-is_1/t,r_1)=\hat{C}^{(k_1)}t^{(k_1-1)k_1/4}\frac{\det[\exp(s_{n1}r_{m1}/t)]_{n,m=1,\ldots,k_1}}{|\Delta_{k_1}(s_1)\Delta_{k_1}(r_1)|^{1/2}}, \tag{6.2}$$

where the constant can be found in Muirhead's book,[28]

$$\hat{C}^{(k_1)}=\frac{\Gamma(k_1/2)}{k_1!}\pi^{k_1^2/2-k_1/4}. \tag{6.3}$$

Thus we find

$$\lim_{t\to 0}\Phi_{k_1 2k_2}(-is/t,r)=2^{k_1k_2}t^{((k_1-2k_2)^2+(k_1-2k_2))/4}\hat{C}^{(k_1)}\hat{G}_{k_1 2k_2}$$

$$\times\frac{\det[\exp(s_{n1}r_{m1}/t)]_{n,m=1,\ldots,k_1}\det[\exp(2s_{i2}r_{j2}/t)]_{i,j=1\cdots k_2}}{\sqrt{\tilde{B}_{k_1k_2}(s)\tilde{B}_{k_1k_2}(r)}} \tag{6.4}$$

for the asymptotic behavior.

On the other hand, the supermatrix Bessel function relates to the kernel of Dyson's Brownian motion in superspace.[22] Due to the normalization of the Gaussian integral,

$$\left(\frac{\pi}{2t}\right)^{-((k_1-2k_2)^2+(k_1-2k_2))/4}2^{k_2^2-k_2-k_1/2}\int\mathrm{d}[\sigma]\exp\left(-\frac{1}{t}(\sigma-\rho)\right)=1, \tag{6.5}$$

the kernel

$$\Gamma_{k_1k_2}(s,r,t)=\left(\frac{\pi}{2t}\right)^{-((k_1-2k_2)^2+(k_1-2k_2))/4}2^{k_2^2-k_2-k_1/2}\int_{u\in \mathrm{UOSp}(k_1/2k_2)}\mathrm{d}\mu(u)\exp\left(-\frac{1}{t}(\sigma-\rho)\right) \tag{6.6}$$

is also normalized. Since it is obviously connected with to the supermatrix Bessel function by

$$\Gamma_{k_1k_2}(s,r,t)=\left(\frac{\pi}{2t}\right)^{-((k_1-2k_2)^2+(k_1-2k_2))/4}2^{k_2^2-k_2-k_1/2}\exp\left(-\frac{1}{t}(\mathrm{trg}\,s^2+\mathrm{trg}\,r^2)\right)\Phi_{k_1 2k_2}(-is/t,r) \tag{6.7}$$

we can fix the normalization by using the asymptotic behavior

$$\lim_{t\to 0}\Gamma_{k_1k_2}(s,r,t)=\left(\frac{\pi}{2}\right)^{-((k_1-2k_2)^2+(k_1-2k_2))/4}\frac{2^{k_2^2-k_2-k_1/2}}{k_1!\,k_2!}\times\frac{\det[\,\delta(s_{i1}-r_{j1})]_{i,j=1\cdots k_1}\det[\,\delta(s_{i2}-r_{j2})]_{i,j=1\cdots k_2}}{\sqrt{\tilde{B}_{k_1k_2}(s)\tilde{B}_{k_1k_2}(r)}} \tag{6.8}$$

of the kernel. Comparing Eq. (6.4) with Eq. (6.8), we find

$$\hat{G}_{k_1 2k_2}=\frac{2^{3k_2(k_2-k_1)+k_1^2/4-5k_2/2-k_1/2}}{\pi^{((k_1-2k_2)^2+2k_1^2-2k_2)/4}k_2!\,\Gamma(k_1/2)}. \tag{6.9}$$

We mention that this calculation also shows that the diffusion kernels of the one-point function and of the two-point function of Dyson's Brownian motion,[22] i.e., the function $\Gamma_{(2k)k}(s,r,t)$ which was denoted by $\Gamma_k(s,r,t)$ in Ref. 22, indeed satisfy the proper initial condition.

VII. APPLICATIONS

Although we focus in this contribution on the mathematical aspects, we now briefly comment on a particular kind of application. As the reader will realize, our results derived in Sec. VI are, in some sense, more general than what we need in those applications on which we focus here. We take this as an indication that explicit results for even more complex supermatrix Bessel functions can also be obtained. The results of the previous sections yield the kernels of the supersymmetric analog of Dyson's Brownian Motion for the GOE and the GSE in the cases $k=1$ and $k=2$. We do not present the physics background here. The reader interested in these applications is asked to consult Refs. 19–21 for generalities and Ref. 22, in particular Sec. 4.2, for the issue discussed here. In the present contribution, we use the same notations and conventions. We restrict ourselves to the transition toward the GOE and suppress the index c. The corresponding formulas for the transition toward the GSE are derived accordingly. We treat the one- and two-point functions in Secs. VII A and VII B, respectively.

Forrester and Nagao[29] derived expressions for generalized one-point functions of Dyson's Brownian motion model with Poissonian initial conditions. They used an expansion of the Green function in terms of Jack polynomials. Datta and Kunz[30] employed a supersymmetric technique to address the two-level correlation function of the Poisson GOE transition. They arrive at a finite number of ordinary and Grassmannian integrals which are still to be performed. In our approach, we also arrive at a representation of the correlation function in terms of a finite number of integrals. However, since we managed to integrate over almost all angular integrals in the previous sections, our result contains considerably less integrals, in particular, no Grassmannian ones. It has a clear structure due to the fact that, apart from two integrals, all others are eigenvalue integrals, i.e., live in the curved eigenvalue space of Dyson's Brownian motion. Moreover, since our formulas for the kernel are valid on all scales, our result is also exact for finite level number.

A. Level density

We use the result (4.9), derived in Sec. IV, for the supermatrix Bessel function $\Phi_{22}(-is,r)$. Using the replacement $r\to(x+J)$ and $s\to s/t$ and the relation (6.7), we obtain the diffusion kernel for the level density

$$\Gamma_1(s,x+J,t)=(2\pi)^{-1/2}\frac{J_1}{2t}\exp\left(-\frac{1}{t}(s_{11}-x_1-J_1)^2-\frac{1}{t}(s_{21}-x_1-J_1)^2+\frac{2}{t}(is_{12}-x_1+J_1)^2\right)$$
$$\times\left(-2\frac{J_1}{t}\prod_{j=1}^{2}(is_{12}-s_{j1})+\sum_{q=1}^{2}(is_{12}-s_{q1})\right). \tag{7.1}$$

We take the derivative with respect to the source variable J_1 and arrive at the level density

$$\hat{R}_1(x_1,t)=\frac{1}{(2\pi)^{3/2}t}\int\exp\left(-\frac{1}{t}(s_{11}-x_1)^2-\frac{1}{t}(s_{21}-x_1)^2+\frac{2}{t}(is_{12}-x_1)^2\right)$$
$$\times((is_{12}-s_{11})+(is_{12}-s_{21}))\tilde{B}_{21}(s)\,Z_1^{(0)}(s)\,d[s], \tag{7.2}$$

where the Berezinian is given by Eq. (2.10) for $k_1=2$ and $k_2=1$. This result is exact for an arbitrary initial condition and for arbitrary N. In the case of a diagonal matrix $H^{(0)}$ as the initial condition, we have for arbitrary k,

$$Z_k^{(0)}(s)=\int \mathrm{d}[H^{(0)}]P(H^{(0)})\prod_{n=1}^{N}\frac{\Pi_{j=1}^{k}(is_{j2}-H_{nn}^{(0)})}{\Pi_{j=1}^{2k}(s_{j1}+i\varepsilon-H_{nn}^{(0)})^{1/2}} \tag{7.3}$$

and analogously for the GSE. This has to be used in Eq. (7.2) for $k=1$.

In the limit $t\to\infty$ the stationary distribution of classical Gaussian random matrix theory is recovered. This can be seen by rewriting Eq. (7.1) for the rescaled energy $\tilde{x}_1=x_1/t$ and the rescaled source variable $\tilde{J}_1=J_1/t$, see also Ref. 22. In this limit the initial condition yields unity and we arrive at an integral representation of the one-point correlation function of the pure GOE,

$$R_1(x_1)=\frac{1}{(2\pi)^{3/2}}\Im\int\exp(-(s_{11}-x_1)^2-(s_{21}-x_1)^2+(is_{12}-x_1)^2)$$
$$\times\frac{|s_{11}-s_{21}|}{(is_{12}-s_{11})(is_{12}-s_{21})}\left(\frac{1}{is_{12}-s_{11}}+\frac{1}{is_{12}-s_{21}}\right)\frac{(is_{12})^N}{(s_{11}+i\varepsilon)^{N/2}(s_{21}+i\varepsilon)^{N/2}}\mathrm{d}[s] \tag{7.4}$$

where the symbol $\Im$ denotes the imaginary part. Equation. (7.4) is equivalent to the classical expressions for the one-point functions as in Mehta's book.[19]

Finally, we state an integral expression for the one-point function for the case of Poissonian initial conditions, see Eq. (5.1) of Ref. 22. We have

$$Z_k^{(0)}(s)=\left(\int \mathrm{d}z\,p(z)\frac{\Pi_{j=1}^{k}(is_{j2}-z)}{\Pi_{j=1}^{2k}(s_{j1}+i\varepsilon-z)^{1/2}}\right)^N. \tag{7.5}$$

Inserting this initial condition for $k=1$ into Eq. (7.2) yields the level density of a transition ensemble between Poisson regularity and GOE in terms of a fourfold integral. A further analysis will be published elsewhere.

B. Two-point function

The result (5.18), derived in Sec. V, for the supermatrix Bessel function $\Phi_{44}(-is,r)$ gives, with the replacement $r\to(x+J)$ and $s\to s/t$ and according to Eq. (6.7), the diffusion kernel for the two-point function

$$\Gamma_k(s,x+J,t)=\exp\left(-\frac{1}{t}(\mathrm{trg}\,s^2+\mathrm{trg}\,(x+J)^2)\right)\Phi_{44}(-2is/t,x+J). \tag{7.6}$$

The derivative with respect to the source terms leaves us with the two-point correlation function

$$\begin{aligned}\hat{R}_2(x_1,x_2,t)=\frac{2^6\hat{G}_{44}}{t^2\pi^2}\Im\int\Bigg(&\sqrt{\tilde{B}_{42}(s)}\sqrt{|\Delta_4(s_1)|}Z_2^{(0)}(s)\exp\Bigg(-\frac{1}{t}(\mathrm{trs}_1^2+2x_1^2+2x_2^2-2(is_{12}-x_1)^2\\&-2(is_{22}-x_2)^2)\Bigg)\sum_{k,j}\Bigg[\frac{1}{(is_{12}-s_{k1})(is_{22}-s_{j1})}\left(\frac{2x_1}{t}-\frac{\partial}{\partial s_{j1}}\right)\left(\frac{2x_2}{t}-\frac{\partial}{\partial s_{k1}}\right)\\&+\frac{t}{2(x_1-x_2)(is_{12}-is_{22})(is_{12}-s_{k1})(is_{22}-s_{j1})}\left(\frac{2x_1}{t}-\frac{\partial}{\partial s_{j1}}\right)\left(\frac{2x_2}{t}-\frac{\partial}{\partial s_{k1}}\right)\\&\times-\frac{1}{4}\frac{t}{(x_1-x_2)(is_{12}-s_{k1})(is_{22}-s_{j1})(is_{12}-is_{22})^2}\left(\frac{\partial}{\partial s_{j1}}-\frac{\partial}{\partial s_{k1}}\right)\Bigg]\\&\times\Phi_4^{(1)}(-2is_1/t,x)\Bigg)\,\mathrm{d}[s]+(x_1\leftrightarrow x_2).\end{aligned} \tag{7.7}$$

The last line indicates that the integral with x_1 and x_2 interchanged has to be added. Since the terms antisymmetric in x_1 and x_2 are antisymmetric in s_{i2} and s_{22} as well this yields just a factor 2 in Eq. (7.7). The symbol $\Im$ denotes a certain linear combination of $\hat{R}_2(x_1,x_2,t)$ as explained in Ref. 22. The normalization constant obtains from Eq. (6.9) and is given by $\hat{G}_{44}=2(2\pi)^{-4}$. This result is an exact expression for the two-point function of Dyson's Brownian motion for every initial condition. Plugging in the initial condition of Eq. (7.5) for $k=2$, we find an integral representation of the two-point function for the transition toward the GOE. We notice that $\Phi_4^{(1)}(-2is_1/t,x)$ is, according to Eq. (5.15), given as a double integral.

In the previous discussion, we referred to properties of the kernels which can be seen from the explicit formulas. In Ref. 22, only the explicit form of the kernel for $\beta=2$ was available. However, some of the general properties of the kernels for $\beta=1$ and $\beta=4$ could be anticipated in Ref. 22 from scaling relations of the supersymmetric version of Dyson's Brownian motion. The explicit formulas derived in the present contribution allow one to derive the integral representations (7.2) and (7.7) for the one-point and for the two-point function. Moreover, we emphasize that the kernels for the supersymmetric version of Dyson's Brownian motion are the same on all energy scales.[22] Thus, the integral representation derived here for the two-level correlation function is, apart from the initial condition, the same on the so-called unfolded scale which is relevant for physics applications. The initial condition on the unfolded scale is found along the lines given in Ref. 22.

VIII. SUMMARY AND CONCLUSION

We extended the recursion formula of Ref. 1 to superspace. Due to the group structures in superspace, we could restrict ourselves to the unitary orthosymplectic supergroup. As in the ordinary case, the recursion formula is an exact map of a group integration onto an iteration in the radial space. We used it to calculate explicit expression for certain supermatrix Bessel functions.

In ordinary space, we saw that the matrix Bessel functions are only special cases of the radial functions.[1] We have not yet studied this further, but in our opinion a similar generalization is likely to also exist in superspace.

It is a major advantage of the radial Gelfand–Tzetlin coordinates in superspace that the Grassmann variables appear only as moduli squared. Thus, the number of Grassmann integrals is *a priori* reduced by half. As we showed in detail, this is a highly welcome feature for explicit calculations. As a remarkable consequence of this recursive way to proceed, the structure of the supermatrix Bessel functions is only very little influenced by the matrix dimension. We also saw that the basic structures of the supermatrix Bessel function for smaller matrix dimensions survive during the iteration to higher ones. The matrix Bessel functions in ordinary space show similar features. There, the structure of the matrix Bessel functions is much more influenced by the group parameter β than by the matrix dimension. However, as in ordinary space, it remains a challenge to find the structure of these functions for arbitrary matrix dimension.

An interesting feature occurred which sheds light on the general properties of the recursion. Total derivatives showed up in the integral over the commuting variables after having done the Grassmann integration. Since similar terms already occurred in ordinary space, they are likely to be an intrinsic property of the recursion formula. Here, we succeeded in constructing a series of operator identities to remove them. This was a crucial step for the application of the recursion formula. A deeper understanding of these identities is highly desired.

It should be emphasized that the total derivatives are no boundary terms in the sense of Rothstein. We showed in detail that such terms cannot occur because we always work in a compact space. Thus, according to a theorem due to Berezin,[2] the transformation of the invariant measure to our radial Gelfand–Tzetlin coordinates cannot yield Rothstein boundary terms. However, if further integration over the eigenvalues is required, such terms can emerge.

As an application, we worked out some kernels for the supersymmetric analog of Dyson's Brownian motion.

The radial Gelfand–Tzetlin coordinates are the natural coordinate system for the matrix Bessel functions in superspace. This parametrization represents the appropriate tool for the recursive integration of Grassmann variables. Once the particular features of this parametrization are better understood, they may allow for the evaluation of higher dimensional group integrals.

APPENDIX A: RADIAL GELFAND–TZETLIN COORDINATES FOR THE UNITARY ORTHOSYMPLECTIC GROUP UOSp($k_1/2k_2$)

We wish to express the moduli squared of the elements of an orthogonal $(k_1/2k_2)$ dimensional unit supervector in radial Gelfand–Tzetlin coordinates. To illustrate the mechanism, we start with the smallest nontrivial case, the group UOSp(2/4). We notice that there are at first sight minor, yet crucial, differences to the calculation in Ref. 11 where we also started with the smallest nontrivial case. The set of solutions of the Gelfand–Tzetlin equations (3.23) involves one bosonic and two fermionic eigenvalues. The eigenvalue equations read

$$1=\sum_{p=1}^{2}\left(|v_p^{(1)}|^2+|\alpha_p^{(1)}|^2\right), \tag{A1}$$

$$0=\sum_{q=1}^{2}\left(\frac{|v_q^{(1)}|^2}{s_{q1}-s_1^{(1)}}+\frac{|\alpha_q^{(1)}|^2}{is_{q2}-s_1^{(1)}}\right), \tag{A2}$$

$$z_1 = is_2^{(1)} \prod_{q=1}^{2} \frac{(s_{q1} - is_2^{(1)})}{(is_{q2} - is_2^{(1)})^2} \sum_{q=1}^{2} \left(\frac{|v_q^{(1)}|^2}{s_{q1} - is_2^{(1)}} + \frac{|\alpha_q^{(1)}|^2}{is_{q2} - is_2^{(1)}} \right), \tag{A3}$$

where the last equation has to be solved in the limit $z_1 \to \infty$. The bosonic equation (A2) has a unique solution $s_1^{(1)} = s'_{11}$. Taking s'_{11} as new parameter, Eqs. (A1) and (A2) can be solved,

$$|v_p^{(1)}|^2 = \frac{s_{p1} - s'_{11}}{s_{p1} - s_{q1}} \left(1 - \sum_{k=1}^{2} \frac{is_{k2} - s_{q1}}{is_{k2} - s'_{11}} |\alpha_k^{(1)}|^2 \right), \quad p = 1,2. \tag{A4}$$

We insert these relations in Eq. (A3) and obtain

$$z_1 = is_2^{(1)}(s'_{11} - is_2^{(1)}) \prod_{q=1}^{2} \frac{(s_{q1} - is_2^{(1)})}{(is_{q2} - is_2^{(1)})^2} \left(1 + \sum_{k=1}^{2} \frac{c_k}{is_{k2} - is_2^{(1)}} |\alpha_k^{(1)}|^2 \right) \tag{A5}$$

with $z_1 \to \infty$. Here, we have defined the commuting variables

$$c_k = \frac{\Pi_{q=1}^{2}(is_{k2} - s_{q1})}{is_{k2} - s'_{11}}, \quad k = 1,2. \tag{A6}$$

It remains to determine the set of solutions of the fermionic eigenvalue equation (A5). To this end, both sides are inverted

$$0 = \prod_{q=1}^{2} (is_{q2} - is_2^{(1)})^2 \left(1 - \sum_{k=1}^{2} \frac{c_k}{is_{k2} - is_2^{(1)}} |\alpha_k^{(1)}|^2 + 2 \prod_{k=1}^{2} \frac{c_k}{is_{k2} - is_2^{(1)}} |\alpha_k^{(1)}|^2 \right). \tag{A7}$$

We can now take the square root on both sides

$$0 = \prod_{q=1}^{2} (is_{q2} - is_2^{(1)}) \left(1 - \frac{1}{2} \sum_{k=1}^{2} \frac{c_k}{is_{k2} - is_2^{(1)}} |\alpha_k^{(1)}|^2 + \frac{3}{4} \prod_{k=1}^{2} \frac{c_k}{is_{k2} - is_2^{(1)}} |\alpha_k^{(1)}|^2 \right). \tag{A8}$$

The most general form of the fermionic eigenvalue is

$$is_2^{(1)} = a_0 + \sum_{k=1}^{2} a_k |\alpha_k^{(1)}|^2 + a_{12} \prod_{k=1}^{2} |\alpha_k^{(1)}|^2. \tag{A9}$$

After inserting this ansatz in Eq. (A8), we obtain two sets of solutions for the coefficients a_{i0}, a_{i12} and a_{ij} with $i = 1,2, j = 1,2$

$$\begin{aligned} is'_{12} &= is_{12} + \left(c_1 + \frac{c_1 c_2}{is_{12} - is_{22}} |\alpha_2^{(1)}|^2 \right) \frac{|\alpha_1^{(1)}|^2}{2}, \\ is'_{22} &= is_{22} + \left(c_2 + \frac{c_1 c_2}{is_{22} - is_{12}} |\alpha_1^{(1)}|^2 \right) \frac{|\alpha_2^{(1)}|^2}{2}. \end{aligned} \tag{A10}$$

Remarkably, we have $a_{12} = a_{21} = 0$. This allows us to write the nilpotent part of is'_{k2} as the modulus squared of a new anticommuting coordinate,

$$is'_{k2} = is_{k2} + |\xi'_k|^2. \tag{A11}$$

We solve Eq. (A10) for $|\alpha_p^{(1)}|^2$, insert the results in Eq. (A4) and arrive at

$$|v_p^{(1)}|^2=\frac{(s_{p1}-s'_{11})\Pi_{n=1}^{2}(s_{p1}-is_{n2})^2}{(s_{p1}-s_{q1})\Pi_{n=1}^{2}(s_{p1}-is'_{n2})^2},$$
$$|\alpha_p^{(1)}|^2=2(is'_{p2}-is_{p2})\frac{(is_{p2}-s'_{11})(is_{p2}-is_{q2})^2}{(is_{p2}-is'_{q2})^2\Pi_{n=1}^{2}(is_{p2}-s_{n1})},\quad p,q=1,2\ ,\quad q\neq p. \tag{A12}$$

The structure of Eq. (A12) indicates the form of the solutions for groups of higher order as they were stated in Eq. (3.24). They are checked by inserting them directly into the Gelfand–Tzetlin equations (3.23). The algebra needed is, although tedious, straightforward and similar to the one here.

APPENDIX B: DERIVATION OF FORMULA (4.7)

The technique we use is an extension of the one developed in Appendix D of Ref. 1. First, we rewrite the integral in terms of Θ functions. The left hand side reads

$$L_m(s)\int \mu_B(s',s)f(s'_1)\mathrm{d}[s'_1]\prod_{k\leqslant l}\Theta(s_{k1}-s'_{l1})\prod_{l<n}\Theta(s'_{l1}-s_{n1}). \tag{B1}$$

The integration domain is now the real axis for all variables. The action of $L_m(s)$ on the integral yields:

$$\int\left(\mu_B(s',s)\sum_{i=1}^{k_1}\sum_{j=1}^{k_1-1}\frac{1}{2}\frac{-1}{(is_{12}-s_{i1})(s_{i1}-s'_{j1})}f(s'_1)\prod_{k\leqslant l}\Theta(s_{k1}-s'_{l1})\prod_{l<n}\Theta(s'_{l1}-s_{n1})\right)\mathrm{d}[s'_1]$$
$$+\int\mu_B(s',s)\sum_{i=1}^{k_1}\frac{1}{is_{m2}-s_{i1}}\frac{\partial}{\partial s_{i1}}\prod_{k\leqslant l}\Theta(s_{k1}-s'_{l1})\prod_{l<n}\Theta(s'_{l1}-s_{n1})\mathrm{d}[s'_1]. \tag{B2}$$

We decompose the first term in partial fractions and find

$$\int\left(\mu_B(s',s)\sum_{i=1}^{k_1}\sum_{j=1}^{k_1-1}\frac{1}{2}\frac{-1}{(is_{12}-s_{i1})(is_{12}-s'_{j1})}\ f(s'_1)-\Delta_{k_1}(s'_1)\ f(s'_1)\right.$$
$$\times\sum_{j=1}^{k_1-1}\frac{1}{is_{12}-s'_{j1}}\frac{\partial}{\partial s'_{j1}}\frac{1}{\sqrt{-\Pi_{i=1}^{k_1}(s_{i1}-s'_{j1})}}\prod_{k\leqslant l}\Theta(s_{k1}-s'_{l1})\prod_{l<n}\Theta(s'_{l1}-s_{n1})\mathrm{d}[s'_1]$$
$$+\int\mu_B(s',s)\ f(s')\sum_{i=1}^{k_1}\frac{1}{is_{m2}-s_{i1}}\frac{\partial}{\partial s_{i1}}\prod_{k\leqslant l}\Theta(s_{k1}-s'_{l1})\prod_{l<n}\Theta(s'_{l1}-s_{n1})\mathrm{d}[s'_1]. \tag{B3}$$

An integration by parts yields

$$\int\mu_B(s',s)\sum_{j=1}^{k_1-1}(-M_{mj}(s'_1,s_1))\prod_{k\leqslant l}\Theta(s_{k1}-s'_{l1})\prod_{l<n}\Theta(s'_{l1}-s_{n1})\mathrm{d}[s'_1]+\int\mu_B(s',s)\,f(s')$$
$$\times\left(\sum_{i=1}^{k_1}\frac{1}{is_{m2}-s_{i1}}\frac{\partial}{\partial s_{i1}}+\sum_{j=1}^{k_1-1}\frac{1}{is_{m2}-s'_{j1}}\frac{\partial}{\partial s'_{j1}}\right)\prod_{k\leqslant l}\Theta(s_{k1}-s'_{l1})\prod_{l<n}\Theta(s'_{l1}-s_{n1})\mathrm{d}[s'_1]. \tag{B4}$$

The derivatives of the Θ functions yield δ distributions. Upon integration of the δ distribution the two terms in the last integral cancel each other. Hence the last term vanishes identically. This completes the proof.

APPENDIX C: ALTERNATIVE DERIVATIONS OF $\Phi_{22}(s,r)$

We present two different alternative derivations. We do this in some detail, because the calculations give helpful informations on the rôle played by the radial Gelfand–Tzetlin coordinates.

First, we use an angular parametrization of the coset UOSp(2/2)/UOSp(1/2) by writing the first column of $u \in \mathrm{UOSp}(2/2)$ as

$$u_1 = \begin{bmatrix} \sqrt{1-|\alpha|^2}\cos\vartheta \\ \sqrt{1-|\alpha|^2}\sin\vartheta \\ \frac{1}{\sqrt{2}}\alpha \\ \frac{1}{\sqrt{2}}\alpha^* \end{bmatrix}. \tag{C1}$$

This is a canonical way to parametrize the supersphere $S^{1|2}$ that is isomorphic to the coset UOSp(2/2)/UOSp(1/2), see Ref. 31. It coincides with a special choice of the *angular* Gelfand–Tzetlin coordinates. The invariant measure is in these coordinates simply $\mathrm{d}\mu(u_1)=\mathrm{d}\alpha^*\,\mathrm{d}\alpha\mathrm{d}\vartheta$. Thus, one directly obtains the the volume $V(S^{1|2})=0$, see Ref. 31. In the parametrization of the measure by *radial* Gelfand–Tzetlin coordinates (4.3), one has to perform the Grassmann integration and to apply formula (4.7) to achieve this result.

Although we use a different coordinate system, we still take advantage of the recursion formula (3.1). To use it in the parametrization (C1), one has to solve the Gelfand–Tzetlin equations (3.21)–(3.23) for the eigenvalues. The unique solution of the bosonic equation (3.22) is

$$s'_{11}=a_0+\frac{\Pi_{i=1}^2(s_{i1}-a_0)}{is_{12}-a_0}|\alpha|^2, \quad a_0=\frac{s_{11}+s_{21}}{2}-\frac{s_{11}-s_{12}}{2}\cos 2\vartheta. \tag{C2}$$

The fermionic equation yields

$$is'_{12}=is_{12}+\frac{\Pi_{i=1}^2(s_{i1}-is_{12})}{is_{12}-a_0}|\alpha|^2. \tag{C3}$$

After inserting Eqs. (C2) and (C3) and the measure $\mathrm{d}\mu(u_1)$ into the recursion formula (3.1), the Grassmann integration can be performed. Remarkably, we arrive at the denominator–free expression

$$\begin{aligned}\Phi_{22}(s,r)=\hat{G}_{22}\int_0^{2\pi}\mathrm{d}\vartheta\exp\left(\mathrm{trg}\,rs-\frac{z}{2}+\frac{z}{2}\cos 2\vartheta\right)\\ \times\Bigg[\left(\prod_{i=1}^{2}(r_{i1}-ir_{12})(s_{i1}-is_{12})+\frac{1}{2}\sum_{\substack{i=1\\ j=1}}^{2}(s_{j1}-is_{12})(r_{i1}-ir_{12})\right)\\ -\frac{1}{2}\left(ir_{12}-\frac{1}{2}(r_{11}+r_{21})\right)(s_{11}-s_{21})\cos 2\vartheta-\frac{z}{8}(ir_{12}-r_{21})(s_{11}-s_{21})\sin^2 2\vartheta\Bigg].\end{aligned} \tag{C4}$$

To make contact with Eq. (4.9) one has to realize that in Eq. (C4) an additional total derivative appears in the integrand. This becomes obvious if one adds and subtracts $z/4\cos 2\vartheta$ in the square bracket of Eq. (C4),

$$\Phi_{22}(s,r)=\hat{G}_{22}\int_0^{2\pi}\mathrm{d}\vartheta\,\exp\left(\mathrm{trg}\,rs-\frac{z}{2}+\frac{z}{2}\cos 2\vartheta\right)$$
$$\times\left(\prod_{i=1}^{2}(r_{i1}-ir_{12})(s_{i1}-is_{12})+\frac{1}{2}\sum_{\substack{i=1\\j=1}}^{2}(s_{j1}-is_{12})(r_{i1}-ir_{12})-\frac{z}{4}\cos 2\vartheta\right)$$
$$+\frac{ir_{12}-r_{21}}{r_{21}-r_{11}}\int_0^{2\pi}\mathrm{d}\vartheta\,\frac{\partial^2}{\partial(2\vartheta)^2}\exp\left(\mathrm{trg}\,rs-\frac{z}{2}(1-\cos 2\vartheta)\right). \tag{C5}$$

While the first integral reproduces Eq. (4.9), the second one vanishes identically. In general, in performing Grassmann integrations, one has to take care of boundary contributions.[2,24] These contributions can appear whenever even coordinates are shifted by nilpotents and the function one integrates does not have compact support.[2] However, in our case the basis space is always given by an n dimensional sphere, i.e., by a compact manifold *without boundary*. Thus in a properly chosen coordinate system, no boundary terms should appear. With regard to Eq. (C5) this means: the fact that the last term vanishes is a direct consequence of the compactness of the circle and of the analyticity of the function, that we integrate. However, in the radial Gelfand–Tzetlin coordinates, only the moduli squared of the vector u_1 are determined. Therefore, not the whole sphere, but only a (2^{n+1})th segment of it is covered by Eq. (3.24). In our case, not the circle but only a quarter of it is parametrized. This is allowed since the supermatrix Bessel functions depend only on the moduli squared $|u_{i1}|^2$. Nevertheless, one has to ensure that the introduction of these artificial boundaries does not alter the result. To this end we use the following integration formula.

Let $s_{11}<s'_{11}<s_{21}$ be real and let ξ',ξ'^* be anticommuting. Furthermore, define

$$f(s'_{11},\xi,\xi^*)=f_0(s'_{11})+f_1(s'_{11})|\xi|^2, \tag{C6}$$

with two analytic functions $f_0(s'_{11}),f_1(s'_{11})$. Then the integral

$$I=\int_{s_{11}}^{s_{21}}\mathrm{d}s'_{11}\,\mathrm{d}\xi^*\,\mathrm{d}\xi f(s'_{11},\xi,\xi^*) \tag{C7}$$

transforms under a shift of s'_{11} by nilpotents

$$s'_{11}=y+g(y)|\xi|^2 \tag{C8}$$

in the following way:

$$I=\int_{s_{11}}^{s_{21}}\mathrm{d}y\,\mathrm{d}\xi^*\mathrm{d}\xi\frac{\partial s'_{11}}{\partial y}f(y(s'_{11}),\xi,\xi^*)-[f_0(s_{21})g(s_{21})-f_0(s_{11})g(s_{11})]. \tag{C9}$$

The proof is by direct calculation. The second term in Eq. (C9) is often referred to as boundary term. It can be viewed as the integral of a total derivative, i.e., an exact one-form, that has to be added to the integration measure for functions with noncompact support.[24] For functions of an arbitrary number of commuting and anticommuting arguments, a similar integral formula holds with additional boundary terms.[2] In going from the canonical coordinates $(\vartheta,\alpha,\alpha^*)$ to the radial ones $(s'_{11},\xi'_1,\xi'^*_1)$, in principle boundary terms can arise, since the bosonic Gelfand–Tzetlin eigenvalue (C2) contains nilpotents. However, the crucial quantity is $g(y)$ in formula (C9) which, in our case, is given by

$$g(s'_{11})=\frac{\Pi_{i=1}^{2}(s_{i1}-s'_{11})}{is_{12}-s'_{11}}. \tag{C10}$$

Thus, $g(s'_{11})$ causes the boundary term to vanish at s_{11} and s_{21}. It is the product structure of the left-hand side of Eq. (3.24) which always guarantees the vanishing of the boundary terms, when one goes from the Cartesian set of coordinates to the radial Gelfand–Tzetlin coordinates.

Therefore, one may think of the denominators, arising in Eqs. (4.4) and (4.5), as belonging to total derivatives of functions, which vanish at the boundaries. Keeping this in mind we derive Eq. (4.9) in yet another way. We expand the product

$$\prod_{q=1}^{k_1}(is_{m2}-s_{q1})=\sum_{n=0}^{k_1}\frac{1}{n!}(is_{m2}-s'_{j1})^n\frac{\partial^n}{\partial(s'_{j1})^n}\prod_{q=1}^{k_1}(s'_{j1}-s_{q1}), \tag{C11}$$

and insert it into the integral

$$\begin{aligned}&\int_{s_{11}}^{s_{21}}\cdots\int_{s_{(k_1-1)1}}^{s_{k_1 1}}\mu_B(s'_1,s_1)K_{mj}(s'_1,s_1)f(s'_1)\mathrm{d}[s'_1]\\&\quad=\int_{s_{11}}^{s_{21}}\cdots\int_{s_{(k_1-1)1}}^{s_{k_1 1}}\mu_B(s'_1,s_1)\prod_{n=1}^{k_1}(is_{m2}-s_{n1})M_{mj}(s'_1,s_1)\,f(s'_1)\,\mathrm{d}[s'_1].\end{aligned} \tag{C12}$$

We can remove the term proportional to $(is_{m2}-s'_{j1})^{-2}$ in the integrand by an integration by parts. Through the expansion (C11), the vanishing of the boundary terms is assured. We arrive at

$$\begin{aligned}K_{mj}(s'_1,s_1)=&-\sum_{n=2}^{k_1}\frac{1}{n!}(is_{m2}-s'_{j1})^{n-2}\frac{\partial^n}{\partial(s'_{j1})^n}\prod_{q=1}^{k_1}(s'_{j1}-s_{q1})\\&+\frac{\Pi_{q=1}^{k_1}(is_{m2}-s_{q1})-\Pi_{q=1}^{k_1}(s'_{j1}-s_{q1})}{is_{m2}-s'_{j1}}\\&\times\left(\frac{1}{2}\sum_{q=1}^{k_1}\frac{1}{is_{m2}-s_{q1}}-\frac{1}{2}\sum_{q=1}^{k_1}\frac{1}{s'_{j1}-s_{q1}}-\sum_{\substack{q=1\\q\neq j}}^{k_1}\frac{1}{s'_{j1}-s'_{q1}}-\frac{\partial}{\partial s'_{j1}}\right).\end{aligned} \tag{C13}$$

We notice that in the new operator $K_{mj}(s'_1,s_1)$ all denominators of the type $(is_{m2}-s'_{j1})^{-1}$ have disappeared. For $k_1=2$, we calculate

$$K_{11}=-(is_{12}+s'_{11}-s_{11}-s_{21})\frac{\partial}{\partial s'_{q1}}, \tag{C14}$$

which can be inserted into Eq. (4.4) by using the definition (C12). Finally, the result (4.9) is reproduced by the substitution

$$s'_{11}=\frac{s_{11}+s_{21}}{2}-\frac{s_{11}-s_{12}}{2}\cos 2\vartheta, \tag{C15}$$

see Eq. (C2). In other words, we have seen that the result of this procedure is summarized in formula (4.7).

Finally, some remarks are in order: First, from this discussion, one might conclude that the radial Gelfand–Tzetlin coordinates are less adapted to the problem than the canonical parametrization (C1), because, in the latter, no denominators appear. We stress that this is not true. Certainly, the denominators appear due to the shift of the bosonic variable by nilpotents in Eq. (C2). However, the difficulty in deriving Eq. (4.9) is the identification of the different parts of the integrand after the Grassmann integration. Some of them belong to total derivatives and this problem exists in both parametrizations. Second, we emphasize that the appearance of total derivatives in the integrand is not a peculiarity of supersymmetry. Already in Ref. 1 where the matrix

Bessel functions in ordinary space were treated we had to solve a similar problem. The appearance of these total derivatives is an intrinsic property of the recursion formula. A geometrical interpretation of this phenomenon is highly desired.

APPENDIX D: DETAILS FOR THE DERIVATION OF $\Phi_{34}(-is,r)$

We always consider the case that one matrix has an additional degeneracy according to Eqs. (5.11) and (5.13). We introduce the notation

$$S_{ij}=(s_{i1}-is_{j2}),\quad R_{ij}=(r_{i1}-ir_{j2}). \tag{D1}$$

Due to the degeneracy, $\Phi_{24}(-is,\tilde{r})$ simplifies enormously as compared to the general result (5.10). We insert it into the recursion formula (3.1) and do the trivial integral over the O(2) subgroup. After performing the Grassmann integrals we arrive at an expression similar to Eq. (5.7),

$$\begin{aligned}
\Phi_{34}(-is,r)=4\hat{G}_{34}\exp(\mathrm{tr}\, r_2 s_2+r_{11}(s_{11}+s_{21}))\int \mathrm{d}\mu_B(s_1',s_1)\prod_{i=1}^{2} R_{1i}\prod_{j=1}^{3} S_{ji}\\
\times\Bigg[\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)\left(4\prod_{i=1}^{2} R_{i1}-2\sum_{k=1}^{3} R_{21}S_{k1}^{-1}\right.\\
\left.+2\sum_{j=1}^{2} M_{1j}(s_1',s_1)\right)\left(4\prod_{i=1}^{2} R_{i2}-2\sum_{k=1}^{3} R_{22}S_{k2}^{-1}+2\sum_{j=1}^{2} M_{2j}(s_1',s_1)\right)\\
+\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^3(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\right)\\
\times\sum_{j=1}^{2}\left(\frac{4}{is_{12}-s_{j1}'}M_{2j}(s_1',s_1)-\frac{4}{is_{22}-s_{j1}'}M_{1j}(s_1',s_1)\right)\\
-\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^3(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)\prod_{\substack{k=1\\ j=1}}^{2}\frac{2}{is_{k2}-s_{j1}'}+\frac{2}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\\
\times\left(\mathrm{trg}\, r+r_{11}-\sum_{i=1}^{2} S_{i2}^{-1}\right)\sum_{j=1}^{2} M_{1j}(s_1',s_1)-\frac{2}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\\
\times\left(\mathrm{trg}\, r+r_{11}-\sum_{i=1}^{2} S_{i1}^{-1}\right)\sum_{j=1}^{2} M_{2j}(s_1',s_1)\\
-\frac{4}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\sum_{k=1}^{3}\prod_{j=1}^{2} R_{2j}S_{kj}^{-1}\Bigg]\exp((s_{21}'+s_{11}')(r_{21}-r_{11}))+(ir_{12}\leftrightarrow ir_{22}).
\end{aligned} \tag{D2}$$

Formulas (5.9) and (4.7) are needed to remove the denominators, in a way similar as for $\Phi_{24}(s,r)$. A single sum $\Sigma_{j=1}^{2} M_{1j}(s_1',s_1)$ transforms according to formula (4.7). Moreover, we observe that parts of Eq. (D2) together with the product $\Sigma_{j=1}^{2} M_{1j}(s_1',s_1)\Sigma_{k=1}^{2} M_{2k}(s_1',s_1)$ yield exactly the integrand of formula (5.9). Thus, it can be transformed accordingly. After rearranging terms, we arrive at the result (5.12).

APPENDIX E: DETAILS FOR THE DERIVATION OF $\Phi_{44}(-is,r)$

For the recursion, we need $\Phi_{34}(s,r)$ with degenerate $\tilde{r}=\mathrm{diag}(r_{11},r_{21},r_{21})$ according to Eq. (5.11). Using the integral representation (5.14) for $\Phi_3^{(1)}(-is_1',\tilde{r}_1)$ we find the helpful identity

$$\frac{\partial}{\partial s_{i1}'}\frac{\partial}{\partial s_{j1}'}\exp(-r_{21}\,\mathrm{tr}\,s_1')\Phi_3^{(1)}(-is_1',\tilde{r}_1)=\frac{1}{2}\frac{1}{s_{i1}'-s_{j1}'}\left(\frac{\partial}{\partial s_{i1}'}-\frac{\partial}{\partial s_{j1}'}\right)\exp(-r_{21}\mathrm{trs}_1')\Phi_3^{(1)}(-is_1',\tilde{r}_1). \tag{E1}$$

We stress that this relation, which is crucial in the derivation, only holds, because of the degeneracy in the matrix $\tilde{r}_1$. Employing Eq. (5.14) and another identity,

$$\sum_{i=1}^{3}\frac{\partial}{\partial s_{i1}'}\exp(-r_{21}\mathrm{tr}\,s_1')\Phi_3^{(1)}(-is_1',\tilde{r}_1)=(r_{11}-r_{21})\exp(-r_{21}\,\mathrm{tr}\,s_1')\Phi_3^{(1)}(-is_1',\tilde{r}_1). \tag{E2}$$

We insert $\Phi_{34}(s',\tilde{r})$ into the recursion formula (3.1). We then can arrange the terms emerging from the Grassmann integration in a way similar to the former cases. We obtain

$$\begin{aligned}
\Phi_{44}(-is,r)=4\hat{G}_{44}\exp(\mathrm{tr}\,r_2s_2+r_{11}\,\mathrm{tr}\,s_1)\int \mathrm{d}\mu_B(s_1',s_1)\prod_{i=1}^{2}R_{2i}\prod_{j=1}^{4}S_{ji}\\
\times\Bigg[\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)\\
\times\left(8R_{21}R_{11}^2-4R_{11}R_{21}\sum_{k=1}^{4}S_{k1}^{-1}+4\sum_{j=1}^{3}\left(R_{21}-\frac{\partial^{\rightarrow}}{\partial s_{j1}'}\right)M_{1j}^{\rightarrow}(s_1',s_1)\right)\\
\times\left(8R_{22}R_{12}^2-4R_{12}R_{22}\sum_{k=1}^{4}S_{k2}^{-1}+4\sum_{j=1}^{3}\left(R_{22}-\frac{\partial^{\rightarrow}}{\partial s_{j1}'}\right)M_{2j}(s_1',s_1)\right)\\
+\frac{16}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\sum_{j=1}^{3}M_{1j}^{\rightarrow}(s_1',s_1)\Bigg(\frac{1}{2}R_{11}R_{12}\left(\mathrm{trg}\,r-\sum_{i=1}^{4}S_{i1}^{-1}\right)\\
+\left(r_{21}-r_{11}-\frac{\partial}{\partial s_{j1}'}\right)\left(R_{22}R_{12}+R_{11}R_{12}+R_{11}R_{21}+\frac{1}{2}(R_{12}+R_{22})\sum_{i=1}^{4}S_{i1}^{-1}\right)\Bigg)\\
-\frac{16}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\sum_{j=1}^{3}M_{2j}^{\rightarrow}(s_1',s_1)\Bigg(\frac{1}{2}R_{11}R_{12}\left(\mathrm{trg}\,r-\sum_{i=1}^{4}S_{i2}^{-1}\right)\\
+\left(r_{21}-r_{11}-\frac{\partial}{\partial s_{j1}'}\right)\left(R_{11}R_{21}+R_{11}R_{12}+R_{12}R_{22}+\frac{1}{2}(R_{12}+R_{22})\sum_{i=1}^{4}S_{i2}^{-1}\right)\Bigg)\\
-\frac{16}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\sum_{k=1}^{4}\prod_{i,j}^{2}R_{ij}S_{kj}^{-1}\exp(-r_{11}\,\mathrm{tr}\,s_1')\Phi_3^{(1)}(-is_1',\tilde{r}_1)+C(s,r)\\
+(ir_{12}\leftrightarrow ir_{22}).
\end{aligned} \tag{E3}$$

Again, all operators with an arrow are understood to act only onto the term outside the squared bracket, i.e., onto $\exp(-r_{11}\,\mathrm{tr}\,s_1')\Phi_3^{(1)}(-is_1',\tilde{r}_1)$. In the function $C(s,r)$, we summarized the terms that are expected to arise due to noncommutativity of some operators acting on the integral and some operators acting under the integral. The last two lines in formula (5.9) are examples of such terms

$$
\begin{aligned}
C(s,r) = 4\hat{G}_{44} \exp(\mathrm{tr}\, r_2 s_2 + r_{11}\mathrm{tr} s_1) \int \mathrm{d}\mu_B(s_1', s_1) \prod_{i=1}^{2} R_{2i} \prod_{j=1}^{4} S_{ji} \Bigg[\Bigg(& \frac{1}{\Delta_2^2(ir_2)\Delta_2^3(is_2)} \\
& + \frac{1}{\Delta_2^3(ir_2)\Delta_2^4(is_2)} \Bigg) \sum_{j=1}^{3} \left(R_{11}R_{12} + (R_{11}+R_{12})(r_{21}-r_{11}) - (R_{11}+R_{12}) \frac{\partial^{\rightarrow}}{\partial s_{j1}'} \right) \\
& \times \left(\frac{16}{is_{12}-s_{j1}'} M_{2j}(s_1', s_1) - \frac{16}{is_{22}-s_{j1}'} M_{1j}(s_1', s_1) \right) \\
& - \left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)} + \frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)} \right) \\
& \times \prod_{k=1}^{2} \prod_{j=1}^{3} \left(R_{11}R_{12} + (R_{11}+R_{12})(r_{21}-r_{11}) - (R_{11}+R_{12}) \frac{\partial^{\rightarrow}}{\partial s_{j1}'} \right) \\
& \times \frac{8}{is_{k2}-s_{j1}'} - \left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)} + \frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)} \right) \\
& \times \sum_{j,k}^{3} \left((r_{21}-r_{11}) - \frac{\partial^{\rightarrow}}{\partial s_{j1}'} \right) \left((r_{21}-r_{11}) - \frac{\partial^{\rightarrow}}{\partial s_{k1}'} \right) M_{1j}^{\rightarrow} M_{2k} - \frac{8}{\Delta_2^2(ir_2)\Delta_2^3(is_2)} \\
& \times \sum_{j=1}^{3} \left((r_{21}-r_{11}) - \frac{\partial^{\rightarrow}}{\partial s_{j1}'} \right) \left(\sum_{k=1}^{4} S_{k2}^{-1} M_{j1}^{\rightarrow} - \sum_{k=1}^{4} S_{k1}^{-1} M_{j2} \right) \\
& + \frac{8}{\Delta_2^2(ir_2)\Delta_2^3(is_2)} \left(\sum_{i \neq j} M_{j1} M_{j2}^{\rightarrow} \left(\frac{\partial^{\rightarrow}}{\partial s_{i1}'} - \frac{\partial^{\rightarrow}}{\partial s_{j1}'} \right) \right) \Bigg] \exp(-r_{11}\mathrm{tr} s_1') \Phi_3^{(1)}(-is_1', \tilde{r}_1).
\end{aligned}
\tag{E4}
$$

In order to evaluate Eqs. (E3) and (E4) we need some more properties of the matrix Bessel function $\Phi_4^{(1)}(-is_1, r_1)$. We investigate the action of $\tilde{L}_k$ on $\Phi_4^{(1)}(-is_1, r_1)$ using the integral representation (5.15).

After a straightforward calculation involving an integration by parts we find

$$
\begin{aligned}
& \tilde{L}_k \exp(-r_{11}\mathrm{tr}\, s_1) \Phi_4^{(1)}(-is_1, r_1) \\
& \quad = \sum_{i=1}^{4} \frac{1}{is_{k2}-s_{i1}} \left((r_{21}-r_{11})^2 + (r_{21}-r_{11}) \frac{\partial}{\partial s_{i1}} \right) \exp(-r_{11}\,\mathrm{tr}\, s_1) \Phi_4^{(1)}(-is_1, r_1).
\end{aligned}
\tag{E5}
$$

Now Eqs. (E3) and (E4) can be enormously simplified by the observation that

$$
((r_{21}-r_{11})L_k - \tilde{L}_k) \exp(-r_{11}\mathrm{tr} s_1) \Phi_4^{(1)}(-is_1, r_1) = 0, \tag{E6}
$$

which follows directly from Eq. (E5). We find for Eq. (E3)

$$\Phi_{44}(-is,r)=4\hat{G}_{44}\exp(\mathrm{tr}\, r_2 s_2+r_{11}\mathrm{tr} s_1)\int \mathrm{d}\mu_B(s_1',s_1)\prod_{i=1}^{2} R_{1i}\prod_{k=1}^{4} S_{ki}$$
$$\times\Bigg[\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)\left(R_{12}R_{11}\left(8R_{12}R_{22}-4R_{22}\sum_{k=1}^{4} S_{k2}^{-1}\right)\right.$$
$$\times\left(8R_{11}R_{21}-4R_{21}\sum_{k=1}^{4} S_{k1}^{-1}+4\sum_{j=1}^{3} M_{1j}^{\rightarrow}(s_1',s_1)\right)$$
$$+R_{12}R_{11}\left(8R_{11}R_{21}-4R_{21}\sum_{k=1}^{4} S_{k1}^{-1}\right)$$
$$\times\left(8R_{22}R_{12}-4R_{22}\sum_{k=1}^{4} S_{k2}^{-1}+4\sum_{j=1}^{3} M_{2j}(s_1',s_1)\right)$$
$$+\sum_{j,i} R_{11}\left(r_{21}-r_{11}-\frac{\partial^{\rightarrow}}{\partial s_{j1}'}\right)M_{1i}^{\rightarrow}(s_1',s_1)M_{2j}(s_1',s_1)$$
$$+\sum_{j,i} R_{12}\left(r_{21}-r_{11}-\frac{\partial^{\rightarrow}}{\partial s_{i1}'}\right)M_{1i}^{\rightarrow}(s_1',s_1)M_{2j}(s_1',s_1)$$
$$+\sum_{j,i} R_{21}R_{22}M_{1j}^{\rightarrow}(s_1',s_1)M_{2i}(s_1',s_1)+\frac{8}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}R_{11}R_{12}$$
$$\times\left(\mathrm{tr} g\, r-\sum_{i=1}^{4} S_{i1}^{-1}\right)\sum_{j=1}^{3}\left(M_{1j}(s_1',s_1)-M_{2j}(s_1',s_1)\right)$$
$$\left.-\frac{16}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\sum_{k=1}^{4}\prod_{i,j}^{2} R_{ij}S_{kj}^{-1}\right]$$
$$\times\exp(-r_{11}\mathrm{tr}\, s_1')\Phi_3^{(1)}(-is_1',\tilde{r}_1)+C(s,r)+(ir_{12}\leftrightarrow ir_{22}). \tag{E7}$$

The terms contained in Eq. (E4) simplify, too. We arrive at

$$C(s,r)=4\hat{G}_{44}\exp(\mathrm{tr}\, r_2 s_2+r_{11}\,\mathrm{tr}\, s_1)\int \mathrm{d}\mu_B(s_1',s_1)\prod_{i=1}^{2} R_{1i}\prod_{j=1}^{4} S_{ji}$$
$$\times\Bigg[\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^3(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\right)$$
$$\times\sum_{j=1}^{3}\left(R_{11}R_{12}+(R_{11}+R_{12})(r_{21}-r_{11})-(R_{11}+R_{12})\frac{\partial^{\rightarrow}}{\partial s_{j1}'}\right)$$
$$\times\left(\frac{16}{is_{12}-s_{j1}'}M_{2j}(s_1',s_1)-\frac{16}{is_{22}-s_{j1}'}M_{1j}(s_1',s_1)\right)$$
$$-\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)$$
$$\times\prod_{\substack{k=1\\ j=1}}^{2}\left(R_{11}R_{12}+(R_{11}+R_{12})(r_{21}-r_{11})-(R_{11}+R_{12})\frac{\partial^{\rightarrow}}{\partial s_{j1}'}\right)$$
$$\left.\times\frac{8}{is_{k2}-s_{j1}'}+\frac{8}{\Delta_2^2(ir_2)\Delta_2^3(is_2)}\left(\sum_{i\neq j} M_{j1}^{\rightarrow}(s_1',s_1)M_{j2}(s_1',s_1)\left(\frac{\partial^{\rightarrow}}{\partial s_{i1}'}-\frac{\partial^{\rightarrow}}{\partial s_{j1}'}\right)\right)\right]$$
$$\times\exp(-r_{11}\mathrm{tr}\, s_1')\Phi_3^{(1)}(-is_1',\tilde{r}_1). \tag{E8}$$

To further evaluate the expressions, we can now invoke a symmetry argument between the eigenvalues r_{11} and r_{21}, respectively. Since the product $R_{11}R_{12}$ appears as a prefactor in front of the integral (E7), $R_{21}R_{22}$ must also appear as a prefactor in the final result. Thus, all terms in Eqs. (E7) and (E8) which do not contain $R_{21}R_{22}$ as a factor must yield zero. The remaining terms which are proportional to $R_{21}R_{22}$ can again be treated using formulas (4.7) and (5.9). However, we want to show explicitly that this line of arguing is correct and that the other terms indeed vanish. To this end, we need an additional identity to treat the operator product

$$\sum_{j=1}^{2} \frac{\partial^{\rightarrow}}{\partial s'_{j1}} M_{1j}(s'_1,s_1) \sum_{k=1}^{2} M_{2k}(s'_1,s_1). \tag{E9}$$

The required identity is given by the following formula: The same conditions as for formula (4.7) apply, furthermore we define

$$L_m^{\rightarrow}(s)\tilde{L}_n(s) = \sum_{i,j} \frac{1}{(is_{m2}-s_{i1})(is_{n2}-s_{j1})} \frac{\partial^3}{\partial s_{i1}\partial s_{j1}^2} + \frac{1}{2}\sum_{i,j} \frac{1}{(is_{m2}-s_{i1})(is_{n2}-s_{j1})} \times \frac{\partial}{\partial s_{i1}} \sum_{k\neq j}^{k_1} \frac{1}{s_{j1}-s_{k1}} \left(\frac{\partial}{\partial s_{j1}} - \frac{\partial}{\partial s_{k1}} \right). \tag{E10}$$

Then we have

$$\begin{aligned} & L_m^{\rightarrow}(s)\tilde{L}_n(s) \int_{s_{11}}^{s_{21}} \cdots \int_{s_{(k_1-1)1}}^{s_{k_1 1}} \mu_B(s',s)\mathrm{d}[s'_1] f(s'_1) \\ &= \int_{s_{11}}^{s_{21}} \cdots \int_{s_{(k_1-1)1}}^{s_{k_1 1}} \Bigg[\sum_{j=1}^{k_1-1} \sum_{i=1}^{k_1-1} M_{mi}^{\rightarrow}(s'_1,s_1) \frac{\partial^{\rightarrow}}{\partial s'_{j1}} M_{nj}(s'_1,s_1) f(s'_1) - \frac{1}{is_{n2}-is_{m2}} \\ &\times \sum_{i=1}^{k_1-1} \left(\frac{1}{is_{m2}-s'_{i1}} \frac{\partial^{\rightarrow}}{\partial s'_{i1}} M_{ni}(s'_1,s_1) - \frac{1}{is_{n2}-s'_{i1}} \frac{\partial^{\rightarrow}}{\partial s'_{i1}} M_{mi}(s'_1,s_1) \right) \\ &- \frac{1}{2}\sum_{k\neq l} \frac{1}{(is_{m2}-s'_{k1})(is_{n2}-s'_{k1})(s'_{k1}-s'_{l1})^2} \frac{\partial^{\rightarrow}}{\partial s_{k1}} \\ &+ \frac{1}{2}\sum_{k\neq l} \frac{1}{(is_{m2}-s'_{k1})(is_{n2}-s'_{l1})(s'_{k1}-s'_{l1})^2} \frac{\partial^{\rightarrow}}{\partial s_{k1}} \Bigg] f(s'_1)\mu_B(s',s)\mathrm{d}[s'_1]. \end{aligned} \tag{E11}$$

The proof is similar to the one of formula (4.7). We notice that the arrow in Eq. (E10) is used slightly differently than previously. The operator $L_m^{\rightarrow}(s)$ acts also on a part of $\tilde{L}_n(s)$. This is not consistent with the definition in Eq. (5.6). However, since this is obvious where it occurs, we still use the same arrow. We can now translate the left-hand side of Eq. (E8) into an expression in terms of $\Phi_4^{(1)}(-is,r)$. After some further manipulations involving the identities in Eqs. (E6), (E1), and (E2) we arrive at

$$\Phi_{44}(-is,r)=\hat{G}_{44}\exp(\mathrm{tr}\, r_2 s_2+r_{11}\,\mathrm{tr}\, s_1)\prod_{i,j}^{2} R_{ji}\prod_{k=1}^{4} S_{ki}\Bigg[\left(\frac{1}{\Delta_2^2(ir_2)\Delta_2^2(is_2)}+\frac{1}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\right)$$
$$\times\left(8R_{12}R_{22}-4R_{22}\sum_{k=1}^{4} S_{k2}^{-1}-4L_2(s)\right)\left(8R_{11}R_{21}-4R_{21}\sum_{k=1}^{4} S_{k1}^{-1}-4L_1(s)\right)$$
$$-\frac{8}{\Delta_2^3(ir_2)\Delta_2^4(is_2)}\left(\mathrm{trg}\, r-\sum_{i=1}^{4} S_{i1}^{-1}\right)(L_1(s)-L_2(s))$$
$$-\frac{16}{\Delta_2^3(ir_2)\Delta_2^3(is_2)}\sum_{k=1}^{4}\prod_{j=1}^{2} R_{2j}S_{kj}^{-1}\Bigg]\exp(-r_{11}\mathrm{tr}\, s_1')\Phi_4^{(1)}(s_1',\tilde{r}_1)(ir_{12}\leftrightarrow ir_{22}). \tag{E12}$$

After rearranging terms this yields the result (5.18) for $\Phi_{44}(-is,r)$.

A second look at $U_q(Sl2)$ at third root of unity[a)]

Daniel Kastler[b)]
Centre de Physique Théorique du C.N.R.S. Marseille, Luminy, France

(Received 13 July 2001; accepted for publication 4 February 2002)

We revisit the 27-dimensional quotient of $\mathbf{U}_q(Sl2)$ at third roots of unity within a presentation adapted to a Hopf bar-operation. We describe in detail the regular representation and display the Hopf automorphisms and the Hopf bar-operations.
 [DOI: 10.1063/1.1463710]

I. INTRODUCTION

This paper offers a detailed description (regular representation, Hopf automorphisms, and Hopf bar-operations) of the 27-dimensional quotient (called $\mathbf{H}_1$ for brevity) of the archetypical quantum group $\mathbf{U}_q(Sl2)$.[1] Our interest in this object stems from the hope that it governs the basic structure of fermions as suggested by Alain Connes[2]—a fascinating proposal opening crucial perspectives in basic physics: first-principles construction of the Lagrangian of the standard model, computation of the fermion masses, improved supersymmetry—see Ref. 3 for a detailed comment, and Ref. 4 [**IIh**] for a possible scenario. In this perspective one wishes to gather detailed information on $\mathbf{H}_1$ (in the first place on its regular representation—which we computed amongst other features in Ref. 4 independently of Ref. 5. In Ref. 6 we displayed a ''Hopf bar-operation'' Γ making $\mathbf{H}_1$ the complexification of the real Hopf fixpoint-algebra $\mathbf{H}_1^\Gamma$ (or real dimension 27). This feature is congenial to the fact that the inner space real spectral triple of the standard model works with algebras over the reals. In the traditional presentation of $\mathbf{H}_1$—by generators $E,F,K=\exp G$ (E,F,G the quantum coordinates, E and F playing asymmetric roles)—Γ has the somewhat strange expression $\Gamma k=k$, $\Gamma E=-qKF$, $\Gamma F=-qK^{-1}E$ (perhaps responsible for its absence in the literature (see Ref. 7 where other examples are mentioned). However there is a presentation (Ref. 8) of $\mathbf{U}_q(Sl2)$ (or rather of its double-cover) which uses more symmetrical generators x, y, k (specifically $x=-ik^{-1}F$, $y=-iEk$, $k=k^{-2}=K=\exp\frac{1}{2}G$) making Γ the mere exchange of x and y. Our $\mathbf{H}_1$ is obtained by ''halving'' the object of Ref. 8 at sixth root of unity by taking instead the third root (whilst the whole object would give $\mathbf{H}_2$ of Ref. 4)—we also multiplied the two first coordinates by i to get the simple form of Γ. The present more symmetrical description was already signaled in Ref. 6 but not exploited there.

In Sec. II we rewrite the whole theory from scratch in this more limpid langage, displaying the underlying real Hopf algebra $\mathbf{H}_1^\Gamma$ and a still smaller (real 15-dimensional) bialgebra $\mathbf{H}_1^\Gamma\cap\mathbf{H}_1^\Omega$ obtained from a ''pseudo-Hopf bar-operation'' Ω stemming from the fact that the coproduct involves only real numbers in the ''**MNF** basis.''

In Sec. III we display the (scarce) Hopf automorphisms and Hopf bar-operations (unique up to scale), a rigidity result showing that the prospective role of $\mathbf{H}_1$ in physics is largely ''frozen.'' We bypass in the proofs a considerable amount of routine computations expounded in detail in the Marseille preprints[9] available on request.

II. THE 27-DIMENSIONAL HOPF ALGEBRA H_1. REGULAR REPRESENTATION. NILRADICAL AND SEMI-SIMPLE QUOTIENT. HOPF BAR-OPERATION

1. Definition—proposition: (the Hopf algebra $\mathbf{H}_1$ with generators x,y,k).

(i) The complex algebra $\mathbf{H}_1$, coherently defined by generators and relations

---

[a)]Dedicated to the memory of Daniel Testard.
[b)]Electronic mail: kastler.daniel@wanadoo.fr

$$\begin{cases} kk^{-1}=k^{-1}k=\mathbb{1}, \\ kx=vxk, \text{ i.e., } kxk^{-1}=vx, \\ ky=v^{-1}yk, \text{ i.e., } kyk^{-1}=v^{-1}y, \\ xy-yx=-\dfrac{k^2-k^{-2}}{v-v^{-1}}, \end{cases} \tag{1a}$$

$$\begin{cases} x^3=0, \\ y^3=0, \\ k^3=\mathbb{1}, \end{cases} \tag{1b}$$

where $v=e^{2\pi i/3}$ (whence $v^3=1$, $v^{-1}=v^2$, and $1+v+v^2=0$) becomes a Hopf algebra with coproduct Δ, antipode S, and counit ϵ such that

$$\begin{cases} \Delta k=k\otimes k, \\ \Delta k^{-1}=k^{-1}\otimes k^{-1}, \\ \Delta x=x\otimes k+k^{-1}\otimes x, \\ \Delta y=y\otimes k+k^{-1}\otimes v \end{cases} \tag{2a}$$

$$\begin{cases} Sk=k^{-1} \\ Sk^{-1}=k, \\ Sx=-vx, \\ Sy=-v^{-1}y, \end{cases} \tag{2b}$$

$$\begin{cases} \epsilon(k)=1, \\ \epsilon(x)=0, \\ \epsilon(y)=0, \end{cases} \tag{2c}$$

and with central Casimir operator.

$$C=-xy+\frac{vk^{-2}+v^{-1}k^2}{(v-v^{-1})^2}=-yx+\frac{v^{-1}k^{-2}+vk^2}{(q-q^{-1})^2}, \tag{3}$$

(ii) The ternary Hopf automorphism

$$S^{-2}=adk \tag{4}$$

yields a $\mathbb{Z}/3$-grading of $\mathbf{H}_1$:

$$\mathbf{H}_1=\mathbf{H}_1^{(0)}\oplus\mathbf{H}_1^{(1)}\oplus\mathbf{H}_1^{(2)},$$

where

$$\mathbf{H}_1^{(i)}=\{a\in\mathbf{H}_1;kak^{-1}=v^ia,\ \ i\in\mathbb{Z}/3\} \tag{5}$$

for which $\mathbf{H}_1$ is a $\mathbb{Z}/3$-graded Hopf algebra: one has $\mathbf{H}_1^{(i)}\cdot\mathbf{H}_1^{j}c\mathbf{H}_1^{(i+j)}, i,j\in\mathbb{Z}/3$.

Proof: The coherence of definitions (1a) and (1b) and (2a)–(2c) is classical. For the Casimir operator we refer to *3* below. The fact that S^{-2} is a $\mathbb{Z}/3$-grading of $\mathbf{H}_1$ follows from (2b) implying $S^{-2}k=k$, $S^{-2}k^{-1}=k^{-1}$, $S^{-2}x=vx$, $S^{-2}y=v^{-1}y$ implying (4) by (1a). Commutation with the coproduct is readily checked on generators.

2. Definitions-lemma: (*-operations, Hopf bar-, and pseudo-Hopf bar-operations.)

(i) Setting

$$\begin{cases} k^{*}=k^{-1}, \\ x^{*}=-y, \\ y^{*}=-x, \end{cases} \tag{6a}$$

$$\begin{cases} k^{\underline{*}}=k^{-1}, \\ x^{\underline{*}}=y, \\ y^{\underline{*}}=x \end{cases} \tag{6b}$$

specifies respective*-operations$^{*},^{\underline{*}}$ fulfilling

$$\begin{cases} \Delta\circ *=(*\otimes *)\circ\tau\circ\Delta, \\ S\circ *=*\circ S, \\ \epsilon\circ *=\bar{}\circ\epsilon, \end{cases} \tag{7a}$$

$$\begin{cases} \Delta\circ \underline{*}=(\underline{*}\otimes \underline{*})\circ\tau\circ\Delta, \\ S\circ \underline{*}=\underline{*}\circ S, \\ \epsilon\circ \underline{*}=\bar{}\circ\epsilon. \end{cases} \tag{7b}$$

One has $\underline{*}=*\circ\xi=\xi\circ *$ with $\xi\in \mathrm{Aut}\mathbf{H}_1$ specified by

$$\begin{cases} \xi k=k, \\ \xi x=-x, \\ \xi y=-y. \end{cases} \tag{8}$$

(ii) Setting

$$\begin{cases} \Gamma k=k, \\ \Gamma k^{-1}=k^{-1}, \\ \Gamma x=y, \\ \Gamma y=x, \end{cases} \tag{9a}$$

$$\begin{cases} \Omega k=k^{-1}, \\ \Omega k^{-1}=k, \\ \Omega x=x, \\ \Omega y=y \end{cases} \tag{9b}$$

specifies respective bar-operations (antilinear, multiplicative, involutory) Γ, Ω, Hopf and pseudo-Hopf in the sense

$$\begin{cases} \Delta\circ\Gamma=(\Gamma\otimes\Gamma)\circ\Delta, \\ S\circ\Gamma=\Gamma\circ S, \\ \epsilon\circ\Gamma=\bar{}\circ\epsilon, \end{cases} \tag{10a}$$

$$\begin{cases} \Delta\circ\Omega=(\Omega\otimes\Omega)\circ\Delta, \\ S\circ\Omega=\Omega\circ S^{-1}, \\ \epsilon\circ\Omega=\bar{}\circ\epsilon. \end{cases} \tag{10b}$$

(iii) The maps $*,^{\underline{*}}$, Γ, Ω, ξ all commute.

(iv) Let $\mathbf{H}_1^{\Gamma}$, respectively, $\mathbf{H}_1^{\Omega}$, be the sets of fix points of $\mathbf{H}_1$ under Γ, respectively Ω, and consider $\mathbf{H}_1$ as an algebra over the reals. Then $\mathbf{H}_1^{\Gamma}$ and $\mathbf{H}_1^{\Omega}$ (and thus $\mathbf{H}_1^{\Gamma}\cap\mathbf{H}_1^{\Omega}$) are real subalgebras of $\mathbf{H}_1$, all three mapped by Δ into their tensor squares. Furthermore one has the inclusion $S\mathbf{H}_1^{\Gamma}\subset\mathbf{H}_1^{\Gamma}$ (however $S\mathbf{H}_1^{\Omega}\not\subset\mathbf{H}_1^{\Omega}$, $S\mathbf{H}_1^{\Gamma}\cap\mathbf{H}_1^{\Omega}\not\subset\mathbf{H}_1^{\Gamma}\cap\mathbf{H}_1^{\Omega}$). Consequently $\mathbf{H}_1^{\Gamma}$ is a real Hopf algebra under Δ, ϵ, and S, and $\mathbf{H}_1^{\Omega}$ and $\mathbf{H}_1^{\Gamma}\cap\mathbf{H}_1^{\Omega}$ are real bialgebras under Δ and ϵ.

The real Hopf nature of $\mathbf{H}_1^{\Gamma}$ stemming from the existence of the Hopf bar-operation Γ is a basic feature of $\mathbf{H}_1$, thus obtained (as a complex Hopf algebra) by ''complexifying'' a real Hopf algebra of the same (now real) dimension. This fact has important consequences, amongst others a tendency of purely algebraically defined representations to become *-representations on appropriate Hilbert spaces. The bialgebra nature of both $\mathbf{H}_1^{\Omega}$ and $\mathbf{H}_1^{\Gamma}\cap\mathbf{H}_1^{\Omega}$ sheds light on the nature of the coproduct.

Proof: Straightforward verifications.

3 Proposition (generators x, y, e_0, e_1, e_2)*:* $\mathbf{H}_1$ has the alternative generators x, y, e_0, e_1, e_2 such that

$$\begin{cases} 3e_0=\mathbb{1}+k+k^2, \\ 3e_1=\mathbb{1}+vk+v^2k^2, \\ 3e_2=\mathbb{1}+v^2k+vk^2, \end{cases}$$

$$\text{i.e.,}\quad e_i=\Sigma_{m\in\mathbb{Z}/3}v^{im}k^m,\quad i\in\mathbb{Z}/3, \tag{11}$$

$$\begin{cases} \mathbb{1}=e_0+e_1+e_2, \\ k=e_0+v^2e_1+ve_2, \\ k^2=k^{-1}=e_0+ve_1+v^2e_2 \end{cases}$$

$$\text{i.e.,}\quad k^j=\Sigma_{n\in\mathbb{Z}/3}v^{-nj}e_n,\quad j\in\mathbb{Z}/3 \tag{12}$$

with the relations:

$$\begin{cases} e_ie_k=\delta_{ik}e_i, \\ \Sigma_{i=0,1,2}e_i=\mathbb{1}, \end{cases} \tag{13a}$$

$$\begin{cases} xe_i=e_{i-1}x, \\ ye_i=e_{i+1}y, \\ xy-yx=e_2-e_1, \end{cases} \tag{13b}$$

$$\begin{cases} x^3=0, \\ y^3=0, \end{cases} \tag{13c}$$

implying

$$\begin{cases} yx=xy+e_1-e_2, \\ yx^2=x^2y+(e_0-e_2)x, \\ y^2x=xy^2+(e_1-e_0)y, \\ y^2x^2=x^2y^2+(e_1-e_2)xy+e_1, \end{cases} \tag{14a}$$

$$\begin{cases} e_0k=ke_0=e_0, \\ e_1k=ke_1=v^2e_1 \\ e_2k=ke_2=ve_2. \end{cases} \tag{14b}$$

The Casimir operator reads

$$C=C^*=C^{\bar{*}}=\tfrac{1}{3}\mathbb{1}-xy-e_1=\tfrac{1}{3}\mathbb{1}-yx-e_2. \tag{15}$$

Δ, ϵ, S,*, $\bar{*}$, Γ are specified as follows on e_0, e_1, e_2:

$$\begin{cases} \Delta e_0=e_0\otimes e_0+e_1\otimes e_2+e_2\otimes e_1, \\ \Delta e_1=e_1\otimes e_0+e_0\otimes e_1+e_2\otimes e_2, \\ \Delta e_2=e_2\otimes e_0+e_0\otimes e_2+e_1\otimes e_1, \end{cases} \tag{16a}$$

$$\begin{cases} \epsilon e_0 = 1, \\ \epsilon e_1 = 0, \\ \epsilon e_2 = 0, \end{cases} \tag{16b}$$

$$\begin{cases} S e_0 = 0, \\ S e_1 = e_2, \\ S e_2 = e_1, \end{cases} \tag{16c}$$

$$e_i{}^* = e_i, \quad i = 0,1,2, \tag{17a}$$

$$e_i{}^{\underline{*}} = e_i, \quad i = 0,1,2, \tag{17b}$$

$$\begin{cases} \Gamma e_0 = e_0, \\ \Gamma e_1 = e_2, \\ \Gamma e_2 = e_1, \end{cases} \tag{18a}$$

$$\begin{cases} \Omega e_0 = e_0, \\ \Omega e_1 = e_1, \\ \Omega e_2 = e_2. \end{cases} \tag{18b}$$

We now turn to the decomposition of the regular representation of $\mathbf{H}_1$. The technique is based on the remark that projectors on different eigenspaces λ, μ of the central Casimir operator generate principal ideals $\mathbf{I}_\lambda$, $\mathbf{I}_\mu$ such that $\mathbf{I}_\lambda \mathbf{I}_\mu = \mathbf{I}_\mu \mathbf{I}_\lambda = 0$. The eigenvalues $-\frac{2}{3}$ and $\frac{1}{3}$ then generate, respectively, the principal ideal $\mathbf{M} \cong \mathbf{M}_3(\mathbb{C})$ and the radical $\mathbf{N}$ of respective dimensions 9 and 13. Since these eigenvalues of C do not exhaust the 27 dimensions of $\mathbf{H}_1$, there is a five-dimensional "residual space" $\mathbf{F} \cong \mathbf{M}_1(\mathbb{C}) \oplus \mathbf{M}_2(\mathbb{C})$. As a consequence the semisimple quotient $\mathbf{H}_1$ is $\mathbf{H}_1/\mathbf{N} \cong \mathbf{M}_1(\mathbb{C}) \oplus \mathbf{M}_2(\mathbb{C}) \oplus \mathbf{M}_3(\mathbb{C})$.

4 Proposition (ideal $\mathbf{M}$ eigenspace of C to the eigenvalue $-\frac{2}{3}$)*:*

(i) The elements of the eigenspace $\mathbf{M}$ of C to the eigenvalue $-\frac{2}{3}$ are related to each other as shown in the following diagram:

$$\begin{array}{ccccc}
0 & & 0 & & 0 \\
\uparrow y\cdot & & \uparrow y\cdot & & \uparrow y\cdot \\
0 \underset{\cdot x}{\leftarrow} m_{11} = e_1(\mathbb{1} + xy + x^2y^2)e_1 & \underset{\cdot x}{\overset{\cdot y}{\rightleftarrows}} & m_{10} = e_1(\mathbb{1} + xy)ye_0 & \underset{\cdot x}{\overset{\cdot y}{\rightleftarrows}} & m_{12} = e_1y^2e_2 \overset{\cdot y}{\rightarrow} 0 \\
x\cdot \downarrow \uparrow y\cdot & & x\cdot \downarrow \uparrow y\cdot & & x\cdot \downarrow \uparrow y\cdot \\
0 \underset{\cdot x}{\leftarrow} m_{01} = e_0x(\mathbb{1} + xy)e_1 & \underset{\cdot x}{\overset{\cdot y}{\rightleftarrows}} & m_{00} = e_0x(\mathbb{1} + xy)ye_0 & \underset{\cdot y}{\overset{\cdot x}{\rightleftarrows}} & m_{02} = e_0xy^2e_2 \overset{\cdot y}{\rightarrow} 0 \\
x\cdot \downarrow \uparrow y\cdot & & x\cdot \downarrow \uparrow y\cdot & & x\cdot \downarrow \uparrow y\cdot \\
0 \underset{\cdot x}{\leftarrow} m_{21} = e_2x^2e_1 & \underset{\cdot x}{\overset{\cdot y}{\rightleftarrows}} & m_{20} = e_2x^2ye_0 & \underset{\cdot x}{\overset{\cdot y}{\rightleftarrows}} & m_{22} = e_2x^2y^2e_2 \overset{\cdot y}{\rightarrow} 0 \\
x\cdot \downarrow & & x\cdot \downarrow & & x\cdot \downarrow \\
0 & & 0 & & 0
\end{array} \tag{19}$$

$\underline{*}$-symmetric with respect to its first diagonal (elements and arrows):

$$m_{mn}{}^{\underline{*}} = m_{nm}, \quad m,n = 0,1,2. \tag{20}$$

(ii) One has in $\mathbf{M}$ the matrix unit-relations:

$$m_{mn}m_{pq}=\delta_{np}m_{mq}, \quad m,n,p,q=0,1,2. \tag{21}$$

(iii) $\mathbf{M}$ is a principal ideal with central projection

$$e_{\mathbf{M}}=m_{00}+m_{11}+m_{22}, \tag{22}$$

thus with supplementary ideal $\mathbf{M}^{\perp}$.

Proof: Construction of the diagram (19) of the ideal $\mathbf{M}$: starting from the upper right element: $m_{12}=e_1{y^2}_2$, $y^3=0$, and ${e_1}^2=e_1$ implying $Cm_{12}=-\frac{2}{3}m_{12}$, deduce the other elements by means of the arrows.

Matrix units relations (21): $m_{ik}m_{jl}=0$ for $j\neq k$ follows from the orthogonality of the projections e_i. The other relations follow by applying x and y.

We notice the following consequence of the relations (21): the m_{ik}, $i,k=1,0,2$, are either all zero or linearly independent: indeed from (21) it follows $m_{ii}=0\Rightarrow m_{ik}=m_{ki}=0$ for all $k\Rightarrow m_{kk}=0$ for all $k\Rightarrow m_{ij}=0$ for all i and j, with in turn $m_{ik}=0\Rightarrow m_{ii}=0$ with the above vanishing. This remark goes along toward a direct proof of the PBW-theorem which could be accomplished for $\mathbf{H}_1$ in an explicit way without the Diamond Lemma.

5 Proposition (ideal $\mathbf{N}$ eigenspace of C to the eigenvalue $\frac{1}{3}$)*:*

(i) The elements of the eigenspace $\mathbf{N}$ of C to the eigenvalue $\frac{1}{3}$ are mutually related as shown in the following diagram:

$$\begin{array}{ccccccccc}
 & & \begin{matrix}0\\ \uparrow -y\cdot\end{matrix} & & \begin{matrix}0\\ \uparrow -y\cdot\end{matrix} & & & & \\

 & & \begin{matrix}x\cdot\downarrow\\ 0\end{matrix} & & \begin{matrix}x\cdot\downarrow\\ 0\end{matrix} & & \begin{matrix}-x\cdot\downarrow\uparrow y\cdot\\ 0\end{matrix} & &
\end{array} \tag{23}$$

This diagram is *-symmetric with respect to its first diagonal (elements and arrows).
(Note that this diagram lies on a cylinder rather than a plane, x_{00},*, and # in the left upper and in the right lower corners being the same).

(ii) The nonvanishing products in $\mathbf{N}$ are

$$\begin{cases} r_{0i}r_{i0}=s_{0i}s_{i0}=x_{00}, \\ r_{i0}r_{0k}=s_{i0}s_{0k}=x_{ik}, \end{cases} \quad i,k=1,2. \tag{24}$$

(iii) $\mathbf{N}$ is an ideal of $\mathbf{H}_1$ consisting of nilpotent elements (of vanishing square). Since $\mathbf{H}_1/\mathbf{N}$ is semisimple (see the following) $\mathbf{N}$ is the radical of $\mathbf{H}_1$.

Proof: (i) Construction of the diagram (23) of the ideal $\mathbf{N}$. Element s_{20}: (15) yields $y^2e_0C=\frac{1}{3}y^2e_0$. Element r_{01}: (15) yields $Ce_0y^2=\frac{1}{3}e_0y^2$. One then use the arrows.

(ii) Nonvanishing products (24) in **N**: Since all arrows starting from x_{00} point to 0 one has $x_{00}h=hx_{00}=0$ for any polynomial in x and y. The relations $r_{10}r_{02}=e_1x^2y=x_{12}$, $s_{20}r_{01}=0$, $s_{02}r_{20}=0$, $s_{02}x_{22}=0$, $s_{02}x_{21}=0$, $s_{02}s_{20}=x_{00}$, $r_{01}x_{12}=0$, $r_{10}s_{02}=0$, $r_{10}s_{01}=0$ are obvious. The others are then obtained using the arrows.

6 Proposition (residual five-dimensional subspace $\mathbf{F}\subset\mathbf{M}^{\perp}$. Modified **PWB** and **MNF** basis)*:* (i) $\mathbf{H}_1$ is linearly spanned by the elements in the diagrams (19) and (23), plus the elements: (diagram *-symmetric with respect to first diagonal) spanning the subspace **F** and yielding the central projection $e_{\mathbf{M}^{\perp}}=\phi_{00}+\phi_{11}+\phi_{22}$,

$$\begin{aligned}&\phi_{00}=e_0(\mathbb{1}-xy-x^2y^2)e_0, \quad \phi_{22}=e_2(\mathbb{1}-x^2y^2)e_2, \quad \phi_{21}=e_2(\mathbb{1}+\tfrac{1}{2}xy)ye_1,\\ &\qquad\qquad \phi_{12}=-e_1x(\mathbb{1}+\tfrac{1}{2}xy)e_2, \quad \phi_{11}=-e_1x(\mathbb{1}+xy)ye_1,\end{aligned} \tag{25}$$

Table displaying the system $\{m_{ik},\phi_{00},\phi_{mn},r_{0m},r_{m0},s_{0m},s_{m0},x_{mn}\}_{i,k=0,1,2;m,n=1,2}$ spanning $\mathbf{H}_1$ [in fact a basis, called the MNF-basis (see the following)]:

$$\begin{aligned}&m_{11}=e_1(\mathbb{1}+xy+x^2y^2)e_1, \quad m_{10}=e_1(y+xy^2)e_0, \quad m_{12}=e_1y^2e_2,\\ &x_{11}=e_1x^2y^2e_1, \quad s_{10}=-e_1xy^2e_0, \quad x_{12}=e_1x^2ye_2,\end{aligned}$$

$$\phi_{11}=-e_1(xy+x^2y^2)e_1, \quad r_{10}=e_1x^2e_0, \quad \phi_{12}=-e_1x(\mathbb{1}+\tfrac{1}{2}xy)e_2.$$

$$\begin{aligned}&m_{01}=e_0(x+x^2y)e_1, && m_{00}=e_0(xy+x^2y^2)e_0, && m_{02}=e_0xy^2e_2,\\ &s_{01}=e_0x^2ye_1, && x_{00}=e_0x^2y^2e_0, && s_{02}=-e_0x^2e_2,\\ &r_{01}=e_0y^2e_1, && \phi_{00}=e_0(\mathbb{1}-xy-x^2y^2), && r_{02}=e_0(y-xy^2)e_2,\\ &m_{21}=e_2x^2e_1, && m_{20}=e_2x^2ye_0, && m_{22}=e_2x^2y^2e_2,\\ &x_{21}=-e_2xy^2e_1, && s_{20}=e_2y^2e_0, && x_{22}=-e_2(xy-x^2y^2)e_2,\\ &\phi_{21}=e_2(\mathbb{1}+\tfrac{1}{2}xy)ye_1, && r_{20}=-e_2(x-x^2y)e_0, && \phi_{22}=e_2(\mathbb{1}-x^2y^2)e_2.\end{aligned} \tag{26}$$

The system $\{e_ix^py^q\}_{i,p,q=0,1,2}$ is given as follows in terms of the system (26):

$$\begin{cases}e_0=m_{00}+\phi_{00},\\ e_1=m_{11}+\phi_{11},\\ e_2=m_{22}+\phi_{22},\end{cases}$$

$$\begin{cases}e_0x=m_{01}-s_{01},\\ e_1x=-\phi_{12}-\tfrac{1}{2}x_{12},\\ e_2x=m_{20}-r_{20},\end{cases} \quad \begin{cases}e_0y=m_{02}+r_{02},\\ e_1y=m_{10}+s_{10},\\ e_2y=\phi_{21}+\tfrac{1}{2}x_{21},\end{cases}$$

$$\begin{cases}e_0x^2=s_{02},\\ e_1x^2=r_{10},\\ e_2x^2=m_{21},\end{cases} \quad \begin{cases}e_0xy=m_{00}-x_{00},\\ e_1xy=-\phi_{11}-x_{11},\\ e_2xy=m_{22}-x_{22},\end{cases} \quad \begin{cases}e_0y^2=r_{01},\\ e_1y^2=m_{12},\\ e_2y^2=s_{20},\end{cases} \tag{27}$$

$$\begin{cases}e_0x^2y=-s_{01},\\ e_1x^2y=x_{12},\\ e_2x^2y=m_{20},\end{cases} \quad \begin{cases}e_0xy^2=m_{02},\\ e_1xy^2=-s_{01},\\ e_2xy^2=-x_{21},\end{cases}$$

$$\begin{cases}e_0x^2y^2=x_{00},\\ e_1x^2y^2=x_{11},\\ e_2x^2y^2=m_{22}.\end{cases}$$

The tabulation (26) is arranged according to polynomial order: here is an alternative version arranged according to indices which reveals the splitting of the coordinate change:

$$\begin{array}{lll}
e_1\mathbb{1}=m_{11}+\phi_{11}, & e_1y=m_{10}+s_{10}, & e_1x=-\phi_{12}-\tfrac{1}{2}x_{12},\\
e_1xy=\phi_{11}-x_{11}, & e_1x^2=r_{10}, & e_1y^2=m_{12},\\
e_1x^2y^2=x_{11}, & e_1xy^2=-s_{10}, & e_1x^2y=x_{12},\\
e_0x=m_{01}-s_{01}, & e_0\mathbb{1}=m_{00}+\phi_{00}, & e_0y=m_{02}+r_{02},\\
e_0y^2=r_{01}, & e_0xy=m_{00}-x_{00}, & e_0x^2=s_{02},\\
e_0x^2y=s_{01}, & e_0x^2y^2=x_{00}, & e_0xy^2=m_{02},\\
e_2y=\phi_{21}+\tfrac{1}{2}x_{21}, & e_2x=m_{20}-r_{20}, & e_2\mathbb{1}=m_{22}+\phi_{22},\\
e_2x^2=m_{21}, & e_2y^2=s_{20}, & e_2xy=m_{22}-x_{22},\\
e_2xy^2=-x_{21}, & e_2x^2y=m_{20}, & e_2x^2y^2=m_{22}.
\end{array} \tag{28}$$

(ii) The nonvanishing products in **F** are as follows:

$$\begin{cases} \phi_{00}\phi_{00}=\phi_{00},\\ \phi_{mn}\phi_{nj}=\phi_{mj}, \end{cases} \quad m,\ j=1,2. \tag{29}$$

(iii) Additional nonvanishing products in $\mathbf{M}^{\perp}$ (products **MN** and **NM**):

$$\begin{cases} \phi_{ij}r_{jk}=r_{ik}\\ \phi_{ij}s_{jk}=s_{ik}\\ \phi_{ij}x_{jk}=x_{ik} \end{cases} \quad \begin{cases} r_{ij}\phi_{jk}=r_{ik}\\ s_{ij}\phi_{jk}=s_{ik}, \\ x_{ij}\phi_{jk}=x_{ik} \end{cases} \quad i,j,k=1,2,0, \text{ whenever these make sense.} \tag{30}$$

In particular ϕ_{00}, ϕ_{11}, and ϕ_{22} acting on the right (left) are the respective projections on $e_0\mathbf{M}^{\perp}$, $e_1\mathbf{M}^{\perp}$, and $e_2\mathbf{M}^{\perp}$ (on $\mathbf{M}^{\perp}e_0$, $\mathbf{M}^{\perp}e_1$, and $\mathbf{M}^{\perp}e_2$); we have

$$m_{22}+m_{00}+m_{11}+\phi_{22}+\phi_{00}+\phi_{11}=e_{\mathbf{M}}+e_{\mathbf{M}^{\perp}}=\mathbb{1}. \tag{31}$$

(iv) In fact both generating systems (25) and (26) are linearly independent: they thus yield basis of $\mathbf{H}_1$, the respective *MNF-basis* and *modified PBW-basis* (the *PBW-basis* is the system $\{k^px^my^n\}_{p,m,n=0,1,2}$). $\mathbf{H}_1$ is thus 27-dimensional.

Proofs (i) and (ii): Construction of the residual five-dimensional subspace **F**): we need additional $5=27-9-13$ elements (expected to span $\mathbf{M}_1\oplus\mathbf{M}_2$) to get a basis of $\mathbf{H}_1$ together with the above elements of **M** and **N**. The inventory of the latter is given by (26). Computation of the additional elements ϕ_{00}, ϕ_{22}, ϕ_{21}, ϕ_{12}, ϕ_{11}:

Diagonal $\phi_{ii}=\alpha e_i+\beta m_{ii}+\gamma x_{ii}$.

We want $0=e_{\mathbf{M}}\phi_{ii}=\alpha m_{ii}+\beta m_{ii}$, whence $\alpha+\beta=0$: we have $\phi_{ii}=\alpha(e_i-m_{ii})+\gamma x_{ii}$.

We want $0=\phi_{ii}{}^2-\phi_{ii}=\alpha^2(e_i-m_{ii})+2\alpha\gamma x_{ii}-\alpha(e_i-m_{ii})-\gamma x_{ii}=\alpha(\alpha-1)(e_i-m_{ii})+(2\alpha-1)\gamma x_{ii}$. Multiplying by x_{ii} shows that $\alpha(\alpha-1)=0$, $\alpha=0$ is excluded, thus $\alpha=1$, implying vanishing of $(2\alpha-1)\gamma=\gamma$: we end up with $\phi_{ii}=e_i-m_{ii}$: we find

$$\phi_{11}=e_1-m_{11}=-e_1(xy+x^2y^2)e_1,$$

$$\phi_{00}=e_0-m_{00}=e_0(\mathbb{1}-xy-x^2y^2)e_0,$$

$$\phi_{22}=e_2-m_{22}=e_2(\mathbb{1}-x^2y^2)e_2.$$

Off-diagonal $\phi_{12}=\lambda e_1x+\mu m_{12}+\nu x_{12}$, and $\phi_{21}=\lambda' e_2y+\mu' m_{21}+\nu' x_{21}$.

We want $0=e_{\mathbf{M}}\phi_{12}=\lambda m_{11}x+\mu m_{12}=0+\mu m_{12}$: this reads $\mu=0$,

$$0=e_{\mathbf{M}}\phi_{21}=\lambda' m_{22}y+\mu' m_{21}=0+\mu' m_{21}:\ \text{this reads}\ \ \mu'=0$$

where we used $m_{11}x=m_{22}y=0$ [cf. diagram (19)].

We have then on the one hand $\phi_{11}\phi_{12}=\phi_{12}\phi_{22}=\phi_{12}$, since, by (19):

$$m_{11}\phi_{12}=m_{11}(\lambda e_1 x+\nu x_{12})=\lambda m_{11}x=0,\ \text{and}\ \ \phi_{12}m_{22}=(\lambda e_1 x+\nu x_{12})m_{22}=\lambda x m_{22}=0$$

and on the other hand $\phi_{22}\phi_{21}=\phi_{21}\phi_{11}=\phi_{21}$, since by (18):

$$m_{22}\phi_{21}=m_{22}(\lambda' e_2 y+\nu' x_{21})=\lambda' m_{22}y=0,\ \text{and}\ \ \phi_{21}m_{11}=(\lambda' e_2 y+\nu' x_{21})m_{11}=\lambda' y m_{11}=0.$$

We want in addition $\phi_{12}\phi_{21}=\phi_{11}$, and $\phi_{12}\phi_{21}=\phi_{11}$: now, since, using (13b) and (23),

$$\begin{aligned}\phi_{12}\phi_{21}&=(\lambda e_1 x+\nu x_{12})(\lambda' e_2 y+\nu' x_{21})=\lambda\lambda' e_1 xy+\lambda\nu' e_1 x x_{21}+\lambda'\nu e_1 x_{12}y\\&=\lambda\lambda' e_1 xy-\lambda\nu' x_{11}+\lambda'\nu x_{11}=e_1[\lambda\lambda' xy-(\lambda\nu'-\lambda'\nu)x^2y^2].\end{aligned}$$

The first requirement leads to $\lambda\lambda'=-1$ and $\lambda\nu'-\lambda'\nu=1$; and since, using (14),

$$\begin{aligned}\phi_{21}\phi_{12}&=(\lambda' e_2 y+\nu' x_{21})(\lambda e_1 x+\nu x_{12})=\lambda\lambda' e_2 yx+\lambda'\nu e_2 y x_{12}+\lambda\nu' e_2 x_{21}x\\&=\lambda\lambda' e_2(xy+e_1-e_2)e_2+(\lambda'\nu-\lambda\nu')x_{22}=\lambda\lambda' e_2(xy-\mathbb{1})e_2-(\lambda'\nu-\lambda\nu')x_{22}\\&=\lambda\lambda' e_2(xy-\mathbb{1})e_2-(\lambda'\nu-\lambda\nu')e_2(x^2y^2-xy)e_2,\end{aligned}$$

the second leads to to the same relations $\lambda\lambda'=-1$, $\lambda\overline{\lambda'}=\lambda'\nu-\lambda\nu'$ and $\lambda\nu'-\lambda'\nu=1$. The symmetry $\phi_{21}{}^*=\phi_{12}$ is impossible [would require $\lambda\overline{\lambda}=-1$, cf. (17a) and (17b)]. We require *-symmetry, $\lambda'=1$, $\lambda=-1$ then yields (25), whence (26)–(28). (iii): ϕ_{ii} bilaterally acts on $\mathbf{M}^\perp$ e_i as follows from $\phi_{ii}=e_i-m_{ii}$. Further ϕ_{21}, respectively, ϕ_{12} act bilaterally on $\mathbf{M}$ like $e_2 y e_1$, respectively, $e_1 x e_2$, cf. (26), since by (22) $x_{21}\mathbf{N}=\mathbf{N}x_{21}=0$, and $x_{12}\mathbf{N}=\mathbf{N}x_{12}=0$: (28) for $i\neq j$ then proceeds from the arrows $\overset{y}{\rightarrow}$ and $\underset{-x}{\leftarrow}$.

(iv) By the PWB-theorem ordered monomials (we chose the order *kxy*) build the PWB-basis, the relations (11) and (12) yielding the *modified PWB*-basis. The mutual correspondence (26) and (27) then yield the MNF basis.

7 Additional features of $\mathbf{H}_1$. We state for completeness miscellaneous results which are established as in Ref. 4 [**IIb**] to which the reader is referred for proofs.

(i) (Center of $\mathbf{H}_1$). The center $\mathbf{Z}_1$ of $\mathbf{H}_1$ is

$$\mathbf{Z}_1=\mathbb{C}e_{\mathbf{M}}\oplus\mathbb{C}e_{\mathbf{M}^\perp}\oplus\mathbb{C}x_{00}\oplus\mathbb{C}W\quad(W=x_{22}+x_{11}).\tag{32}$$

In this context the Casimir operator C is written as

$$C=-\tfrac{2}{3}e_{\mathbf{M}}+\tfrac{1}{3}e_{\mathbf{M}^\perp}+x_{00}+x_{22}+x_{11}.\tag{33}$$

The cental idempotents of $\mathbf{H}_1$ are 0, $e_{\mathbf{M}}$, $e_{\mathbf{M}^\perp}$, and $e_{\mathbf{M}}+e_{\mathbf{M}^\perp}=\mathbb{1}$. Consequently the ideals $\mathbf{M}$ and $\mathbf{M}^\perp$ are left stable by all automorphisms of $\mathbf{H}_1$.

(ii) (The linear form Tr_λ and the semipositive scalar product $(\cdot,\cdot)$.) The trace Tr_λ of the left regular representation λ of $\mathbf{H}_1$ on itself: vanishes on $\mathbf{N}$, and passes to the semisimple quotient $\mathbf{H}_1/\mathbf{N}\cong\mathbf{M}_1(\mathbb{C})\oplus\mathbf{M}_2(\mathbb{C})\oplus\mathbf{M}_3(\mathbb{C})$ (or restricts to the isomorphic sub-algebra $\mathbf{A}=\mathbf{M}\oplus\mathbf{F}$) as $6\mathrm{tr}_{\mathbf{M}_1}\oplus 6\mathrm{tr}_{\mathbf{M}_2}\oplus 3\mathrm{tr}_{\mathbf{M}_3}$, where $\mathrm{tr}_{\mathbf{M}_n}$ denotes the usual trace of $n\times n$ matrices yielding the semi-positive scalar product $\langle\cdot,\cdot,\rangle$ in conjunction with the *-operation $\times$:

$$\langle a,b\rangle=\mathrm{Tr}_\lambda(a\times b),\quad a,b\in H_1,\tag{34}$$

$$\begin{cases} \times = \overset{*}{-} & \text{in restriction to } \mathbf{M}, \\ \times = * & \text{in restriction to } \mathbf{M}^{\perp}. \end{cases} \tag{35}$$

This scalar product has the nilradical **N** as his space of null-vectors and is positive-definite in restriction to $\mathbf{A}=\mathbf{M}\oplus\mathbf{F}$ which thereby acquires a Hilbert space structure. Here the trace of matrices is the sum of their diagonal elements with the traces of endomorphisms of finite-dimensional vector spaces the trace of their matrices. In spite of the apparently ad hoc definition (35) the Hilbert space topology of **M** is canonical: this topology indeed also stems from the adjoint representation of $\mathbf{H}_1$, cf. Ref. 4 [**IId**].

Note the fact that the nilradical consists of the nullvectors of a semipositive scalar product—a phenomenon which we also observed at fourth root of the unit[11] and which also shows up with the longitudinal photons of Lorentz-gauge electrodynamics. We propose this ''synonimy of positivity and semisimplicity as an axiom of the ''medusae'' (=generalized supermanifolds, which it would be interesting to define precisely and axiomatize as Alain Connes did for the spin manifolds.[2]

8 Proposition (antipode in *MNF*-basis) (i) (Antipode in *M*)*:* One has

$$\begin{gathered} Sm_{11}=m_{22}, \quad Sm_{10}=-v^{-1}m_{02}, \quad Sm_{12}=vm_{12}, \\ Sm_{01}=-vm_{20}, \quad Sm_{00}=m_{00}, \quad Sm_{02}=-v^{-1}m_{10}, \\ Sm_{21}=-v^{-1}m_{21}, \quad Sm_{20}=-vm_{01}, \quad Sm_{22}=m_{11}. \end{gathered} \tag{36}$$

(ii) (antipode in **N**). One has

$$\begin{array}{llll} Sx_{00}=x_{00}, & Sr_{02}=-v^{-1}s_{10}, & Sr_{01}=vs_{20}, & \\ Sr_{20}=-vs_{01}, & Sx_{22}=x_{11}, & Sx_{21}=v^{-1}x_{21}, & Ss_{20}=vr_{01}, \\ Sr_{10}=v^{-1}s_{02}, & Sx_{12}=-vx_{12}, & Sx_{11}=x_{22}, & Ss_{10}=v^{-1}r_{02}, \\ & Ss_{02}=v^{-1}r_{10}, & Ss_{01}=-vr_{20}, & Sx_{00}=x_{00}. \end{array} \tag{37}$$

(iii) (antipode in **F**). One has
$S\phi_{00}=\phi_{00}$

$$\begin{gathered} S\phi_{22}=\phi_{11}, \quad S\phi_{21}=-v^{-1}\phi_{21}, \\ S\phi_{12}=-v\phi_{12}, \quad S\phi_{11}=\phi_{22} \end{gathered} \tag{38}$$

(note that *S* maps $\mathbf{H}_1^{(0)}$ into itself and exchanges $\mathbf{H}_1^{(1)}$ and $\mathbf{H}_1^{(2)}$).

Proof: Straightforward verifications. Notice that one has $S\mathbf{H}_1^{\Gamma}\subset\mathbf{H}_1^{\Gamma}$.

9 Proposition (Hopf bar-operation in **MNF**-basis)*:* The Hopf bar-operation Γ leaves **M**, **N**, and **F** stable, acting there as follows:

(i) in (18) Γ is symmetry with respect to the diagram centrum:

$$\begin{gathered} \Gamma m_{11}=m_{22}, \quad \Gamma m_{10}=m_{20}, \quad \Gamma m_{12}=m_{21}, \\ \Gamma m_{01}=m_{02}, \quad \Gamma m_{00}=m_{00}, \quad \Gamma m_{02}=m_{01}, \\ \Gamma m_{21}=m_{12}, \quad \Gamma m_{20}=m_{10}, \quad \Gamma m_{22}=m_{11}. \end{gathered} \tag{39}$$

(ii) In (22) Γ is symmetry with respect to diagram centrum with a sign-change for the pairs (r_{02},s_{01}), (r_{20},s_{10}) *and* (x_{21},x_{12}):

$$\begin{array}{llll} \Gamma x_{00}=x_{00}, & \Gamma r_{02}=-s_{01}, & \Gamma r_{01}=s_{02}, & \\ \Gamma r_{20}=-s_{10}, & \Gamma x_{22}=x_{11}, & \Gamma x_{21}=-x_{12}, & \Gamma s_{20}=r_{10}, \\ \Gamma r_{10}=s_{20}, & \Gamma x_{12}=-x_{21}, & \Gamma x_{11}=x_{22}, & \Gamma s_{10}=-r_{20}, \\ & \Gamma s_{02}=r_{01}, & \Gamma s_{01}=-r_{02}, & \Gamma x_{00}=x_{00}. \end{array} \tag{40}$$

(iii) In (25) Γ is given by
$\Gamma\phi_{00}=\phi_{00}$,

$$\begin{array}{ll} \Gamma\phi_{22}=\phi_{11}, & \Gamma\phi_{21}=-\phi_{12}, \\ \Gamma\phi_{12}=-\phi_{21}, & \Gamma\phi_{11}=\phi_{22}. \end{array} \tag{41}$$

Proof: Straightforward verifications.

10 Remark (pseudo-Hopf bar-operation in the **MNF**-basis)*:* The pseudo-Hopf bar-operation Ω leaves unchanged each of the elements of the **MNF** basis because these are products of the e_i by polynomials in x and y with real coefficients, the multiplicative antilinear Ω leaving all these invariant, cf. (9) and (18b).

11 Proposition (the real Hopf algebra $\mathbf{H}_1^\Gamma$)*:* As an algebra over $\mathbb{R}$ $\mathbf{H}_1^\Gamma$ is the direct sum $\mathbf{F}^\Gamma \oplus \mathbf{M}^\Gamma \oplus \mathbf{N}^\Gamma$, where, as real algebras:

(i) $\mathbf{M}^\Gamma \cong \mathbf{M}_3(\mathbb{R})$ with the matrix units:

$$\begin{array}{lll} \mu_{11}=\frac{1}{2}(m_{11}+m_{22}-m_{12}-m_{21}), & \mu_{10}=\frac{1}{i\sqrt{2}}(m_{10}-m_{20}), & \mu_{12}=\frac{1}{2i}(m_{11}-m_{22}+m_{12}-m_{21}), \\ \mu_{01}=\frac{i}{\sqrt{2}}(m_{01}-m_{02}), & \mu_{00}=m_{00}, & \mu_{02}=\frac{1}{\sqrt{2}}(m_{01}+m_{02}), \\ \mu_{21}=\frac{i}{2}(m_{11}-m_{22}-m_{12}+m_{21}), & \mu_{20}=\frac{1}{\sqrt{2}}(m_{10}+m_{20}), & \mu_{22}=\frac{1}{2}(m_{11}+m_{22}+m_{12}+m_{21}), \end{array} \tag{42}$$

such that $\mu_{im}\mu_{nj}=\delta_{mn}\mu_{ij}$.

(ia) $\mathbf{M}^\Gamma \cap \mathbf{H}_1^\Omega$ is spanned by μ_{11}, μ_{00}, μ_{02}, μ_{20}, and μ_{22} [thus isomorphic to $\mathbb{R}\oplus\mathbf{M}_3(\mathbb{R})$ as a real algebra].

(ii) $\mathbf{F}^\Gamma \cong \mathbb{R}\oplus\mathbb{H}$, with $\mathbb{R}$ spanned by ϕ_{00} and $\mathbb{H}$ spanned by the

$$1_{\mathrm{H}}=\phi_{22}+\phi_{11}, \quad I=\frac{1}{i}(\phi_{21}+\phi_{12}), \quad J=\phi_{21}-\phi_{12}, \quad K=\frac{1}{i}(\phi_{22}-\phi_{11}) \tag{43}$$

fulfilling the quaternionic relations:

$$1_{\mathrm{H}}1_{\mathrm{H}}=1_{\mathrm{H}}, \tag{44a}$$

$$\begin{cases} 1_{\mathrm{H}}I=I1_{\mathrm{H}}=I, \\ 1_{\mathrm{H}}J=J1_{\mathrm{H}}=J, \\ 1_{\mathrm{H}}K=K1_{\mathrm{H}}=K, \end{cases} \tag{44b}$$

$$\begin{cases} IJ=-JI=-K, \\ JK=-KJ=-I, \\ KI=-IK=-J, \end{cases} \tag{44c}$$

$$\begin{cases} I^2=-1_{\mathrm{H}}, \\ J^2=-1_{\mathrm{H}}, \\ K^2=-1_{\mathrm{H}}. \end{cases} \tag{44d}$$

(iia) $\mathbf{F}^{\Gamma}\cap\mathbf{H}_1^{\Omega}$ is spanned by ϕ_{00}, 1_{H}, and J (thus isomorphic to $\mathbb{R}\oplus\mathbb{C}$ as a real algebra).
(iii) $\mathbf{N}^{\Gamma}$ is spanned by the

$$\begin{cases} x_{00}, \\ x'=x_{11}+x_{22}, \quad x''=\dfrac{1}{i}(x_{11}-x_{22}), \\ y'=x_{21}-x_{12}, \quad y''=\dfrac{1}{i}(x_{21}+x_{12}) \end{cases} \tag{45a}$$

$$\begin{cases} q'=r_{01}+s_{02}, \quad q''=\dfrac{1}{i}(r_{01}-s_{02}), \\ r'=r_{02}-s_{01}, \quad r''=\dfrac{1}{i}(r_{02}+s_{01}), \\ s'=s_{10}-r_{20}, \quad s''=\dfrac{1}{i}(s_{10}+r_{20}), \\ t'=s_{20}+r_{10}, \quad t''=\dfrac{1}{i}(s_{20}-r_{10}) \end{cases} \tag{45b}$$

with nonvanishing products:

$$r's'=-q''t''=r''s''=-2x_{00}, \tag{46a}$$

$$\begin{cases} t'q'=s'r'=t''q''=-s''r''=x', \\ t''q'=-s''r'=-t'q''=-s'r=-x'', \\ s'q'=t'r'=s''q''=t''r''=-y', \\ s''q'=t''r'=-s'q''=t'q''=y''. \end{cases} \tag{46b}$$

(iiia) $\mathbf{N}^{\Gamma}\cap\mathbf{H}_1^{\Omega}$ is spanned by x_{00}, x', y', q', r', s', t'.
(iv) The nonvanishing products between elements of $\mathbf{F}$ and $\mathbf{N}$ are

$$\begin{cases} \phi_{00}x_{00}=x_{00}, \\ \phi_{00}q'=q', \quad \phi_{00}q''=q'', \\ \phi_{00}r'=r', \quad \phi_{00}r''=r'', \end{cases} \tag{47a}$$

$$\begin{cases} x_{00}\phi_{00}=x_{00}, \\ s'\phi_{00}=s', \quad s''\phi_{00}=s'', \\ t'\phi_{00}=t', \quad t''\phi_{00}=t'', \end{cases} \tag{47b}$$

$$\begin{cases} 1_{\mathrm{H}}x'=x', \\ 1_{\mathrm{H}}x''=x'', \\ 1_{\mathrm{H}}y'=y', \\ 1_{\mathrm{H}}y''=y'', \end{cases} \tag{47c}$$

$$\begin{cases} 1_{\mathbb{H}}s' = s', \\ 1_{\mathbb{H}}s'' = s'', \\ 1_{\mathbb{H}}t' = t', \\ 1_{\mathbb{H}}t'' = t'', \end{cases} \tag{47d}$$

$$\begin{cases} x'1_{\mathbb{H}} = x', \\ x''1_{\mathbb{H}} = x'', \\ y'1_{\mathbb{H}} = y', \\ y''1_{\mathbb{H}} = y'', \end{cases} \tag{37e}$$

$$\begin{cases} q'1_{\mathbb{H}} = q', \\ q''1_{\mathbb{H}} = q'', \\ r'1_{\mathbb{H}} = r', \\ r''1_{\mathbb{H}} = r'', \end{cases} \tag{47f}$$

$$\begin{cases} Ix' = y'', & Iy'' = -x', \\ Ix'' = -y', & Iy' = x'', \\ Is' = t'', & It'' = -s', \\ Is'' = -t', & It' = s'', \end{cases} \tag{47g}$$

$$\begin{cases} x'I = y'', & y''I = -x', \\ x''I = -y', & y'I = x'', \\ q'I = r'', & r''I = -q', \\ r'I = q'', & q''I = -r', \end{cases} \tag{47h}$$

$$\begin{cases} Jx' = y', & Jy' = -x', \\ Jx'' = y'', & Jy'' = -x'', \\ Js' = t', & Jt' = -s', \\ Js'' = t'', & Jt'' = -s'', \end{cases} \tag{47i}$$

$$\begin{cases} x'J = y', & y'J = -x', \\ x''J = -y'', & y''J = x'', \\ q'J = -r', & r'J = q', \\ q''J = -r'', & r''J = q'', \end{cases} \tag{47j}$$

$$\begin{cases} Kx' = -x'', & Kx'' = x', \\ Ky' = y'', & Ky'' = -y', \\ Ks' = -s'', & Ks'' = s', \\ Kt' = t'', & Kt'' = -t', \end{cases} \tag{47k}$$

$$\begin{cases} x'K = x'', & x''K = -x', \\ y'K = -y'', & y''K = y', \\ q'K = -q'', & q''K = q', \\ r'K = r'', & r''K = -r'. \end{cases} \tag{47l}$$

Proof: Straightforward verifications.

III. HOPF AUTOMORPHISMS, AND HOPF BAR-OPERATIONS

We now investigate the Hopf automorphisms and the Hopf bar-operations. The Hopf automorphism-group is shown to be a complex one-parameter group—in fact the group of a (truncated) $\mathbb{Z}$-grading with degree the excess of powers of x over those of y in ordered PBW-monomials (with quotient through $3\mathbb{Z}$ the $\mathbb{Z}/3$-group of powers of the antipode). The Hopf bar-operation is unique up to scale. These (relative rigidity) results indicate the kind of freedom one expects in the prospective use of $\mathbf{H}_1$ for describing the basic structure of fermions.

The main technical problem is the classification of the Hopf automorphisms. Our method consists in first exploiting the commutation with the antipode, much simpler than commutation with the coproduct which we use only for passing from the commutant of S in Aut$\mathbf{H}_1$. Section 12 exhibits the (truncated) Hopf $\mathbb{Z}$-grading. Section 13 computes the commutant of S in Aut$\mathbf{H}_1$. Section 14 describes the passage from there to Aut$\mathbf{H}_1$ which turns out to be the group of the truncated $\mathbb{Z}$-grading of Sec. 12. This yields the description of the Hopf bar-operations in 15, found unique up to scale

12 Proposition (the truncated $\mathbb{Z}$-grading $\mathbf{H}_1=\oplus_{n\in\mathbb{Z}}\mathbf{H}_1^{[n]}$ of $\mathbf{H}_1$)*:*

(i) Let $a\in\mathbb{C}$, $a\neq 0$: setting

$$\begin{cases} \alpha_a k=k, \\ \alpha_a k^{-1}=k^{-1}, \\ \alpha_a x=ax, \\ \alpha_a y=a^{-1}y, \end{cases} \tag{48}$$

specifies on generators a Hopf automorphism α_a of $\mathbf{H}_1$ in such a way that $a\to\alpha_a$ is a complex one-parameter group $\mathcal{G}$ of automorphisms of $\mathbf{H}_1$. One has

$$\alpha_a(hh')=(\alpha_a h)(\alpha_a h'), \quad h,h'\in\mathbf{H}_1, \tag{49}$$

$$\alpha_a\alpha_b=\alpha_{ab}, \quad a,b\in\mathbb{C}, \quad ab\neq 0, \tag{50}$$

$$\alpha_1=id_{\mathbf{H}_1}. \tag{51}$$

(ii) Defining

$$\mathbf{H}_1^{[i]}=\{h\in\mathbf{H}_1;\ \ \alpha_a h=a^i h\}, \tag{52}$$

$\mathcal{G}$ is in fact the grading group of a Hopf $\mathbb{Z}$-grading $\mathbf{H}_1=\oplus_{n\in\mathbb{Z}}\mathbf{H}_1^{[n]}$ of $\mathbf{H}_1$ where the degree n measures the excess of powers of x over those of y in ordered polynomials (x written before y). For $h\in\mathbf{H}_1^{[i]}$: we write $\partial_{\mathbb{Z}}=i$ and call i the $\mathbb{Z}$*-degree of* h.

(iii) Division of the Hopf $\mathbb{Z}$-grading through $3\mathbb{Z}$ yields the $\mathbb{Z}/3$-grading $H_1=\oplus_{n\in\mathbb{Z}}H_1^{(n)}$ of H_1 described in *I* (cf. (8) in 1—observe the distinction in notation).

(iv) The Hopf $\mathbb{Z}$-grading of $\mathbf{H}_1$ induces on the subalgebras, $\mathbf{M}$, $\mathbf{F}$, $\mathbf{N}$, and $\mathbf{M}^{\perp}$ respective $\mathbb{Z}$-gradings $\mathbf{M}=\oplus_{n\in\mathbb{Z}}\mathbf{M}^{[n]}$, $\mathbf{F}=\oplus_{n\in\mathbb{Z}}\mathbf{F}^{[n]}$, $\mathbf{N}=\oplus_{n\in\mathbb{Z}}\mathbf{N}^{[n]}$ and $\mathbf{M}^{\perp}=\oplus_{n\in\mathbb{Z}}\mathbf{M}^{\perp[n]}$: one has $\mathbf{H}_1^{[n]}=\mathbf{M}^{[n]}\oplus\mathbf{F}^{[n]}\oplus\mathbf{N}^{[n]}$, $\mathbf{n}\in\mathbb{Z}$, where

$$\begin{cases} \mathbf{M}^{[2]}=\mathbb{C}m_{21}, \\ \mathbf{M}^{[1]}=\mathbb{C}m_{01}+\mathbb{C}m_{20}, \\ \mathbf{M}^{[0]}=\mathbb{C}m_{11}+\mathbb{C}m_{00}+\mathbb{C}m_{22}, \quad \mathbf{M}^{[i]}=\{0\} \ \text{ if } \ i>2 \ \text{ or } \ i<-2, \\ \mathbf{M}^{[-1]}=\mathbb{C}m_{10}+\mathbb{C}m_{02}, \\ \mathbf{M}^{[-2]}=\mathbb{C}m_{12}, \end{cases} \tag{53}$$

$$\begin{cases} \mathbf{F}^{[1]}=\mathbb{C}\phi_{21}, \\ \mathbf{F}^{[0]}=\mathbb{C}\phi_{00}+\mathbb{C}\phi_{22}+\mathbb{C}\phi_{11}, \quad \mathbf{F}^{[i]}=\{0\} \text{ if } i>1 \text{ or } i<-1, \\ \mathbf{F}^{[-1]}=\mathbb{C}\phi_{12}, \end{cases} \tag{54}$$

$$\begin{cases} \mathbf{N}^{[2]}=\mathbb{C}r_{10}+\mathbb{C}s_{02}, \\ \mathbf{N}^{[1]}=\mathbb{C}r_{20}+\mathbb{C}x_{12}+\mathbb{C}s_{01}, \\ \mathbf{N}^{[0]}=\mathbb{C}x_{00}+\mathbb{C}x_{22}+\mathbb{C}x_{11}, \quad \mathbf{N}^{[i]}=\{0\} \text{ if } i>2 \text{ or } i<-2. \\ \mathbf{M}^{[-1]}=\mathbb{C}r_{02}+\mathbb{C}x_{21}+\mathbb{C}s_{10}, \\ \mathbf{M}^{[-2]}=\mathbb{C}r_{01}+\mathbb{C}s_{20}. \end{cases} \tag{55}$$

Remarks: (i) For simplicity the $\mathbb{Z}$-graded algebra $\oplus_{n\in\mathbb{Z}}\mathbf{H}_1^{[n]}$ is denoted by $\mathbf{H}_1$ instead of $\mathbf{H}_1\oplus\{0\}$, and analogously for $\mathbf{M}$, $\mathbf{F}$, $\mathbf{N}$, and $\mathbf{M}^{\perp}$ (the $\mathbb{Z}$-grading is "truncated" in that all but a finite number of $\mathbf{H}_1^{[n]}$ vanish).

(ii) Looked at on the diagrams of $\mathbf{M}$, $\mathbf{N}$, and $\mathbf{F}$ in Sec. I (cf. 1, 2, 3) the $\mathbb{Z}$-grading exhibits the following features: the elements of the same degree are located on lines parallel to the first diagonal, with decreasing grading (from 2 to -2 for $\mathbf{M}$ and $\mathbf{N}$, from 1 to -1 for $\mathbf{F}$) on the second diagonal oriented SW–NE (see the following).

(iii) Replacing in diagrams $\mathbf{M}$ and $\mathbf{F}$ the index 2 by $-1=2\,\mathrm{mod}\,\mathbb{Z}/3$ the degree becomes $\partial_{\mathbb{Z}}m_{ij}=j-i$.

We reproduce those diagrams for the convenience of the reader, and indicate the nonvanishing products.

Diagram **M**			Diagram **N**				Diagram **F**			
			x_{00}	r_{02}	r_{01}					
m_{11}	m_{10}	m_{12}	r_{20}	x_{22}	x_{21}	s_{20}	ϕ_{00}			
m_{01}	m_{00}	m_{02}	r_{10}	x_{12}	x_{11}	s_{10}		ϕ_{11}	ϕ_{12}	
m_{21}	m_{20}	m_{22}		s_{02}	s_{01}	x_{00}		ϕ_{21}		ϕ_{22}

Products in $\mathbf{M}$: $m_{ij}m_{pq}=\delta_{jp}m_{iq}$, $i,j,p,q=1,0,-1$.
Products in $\mathbf{F}$: $\phi_{00}\phi_{00}=\phi_{00}$, $\phi_{00}\phi_{ij}=\phi_{ij}\phi_{00}=0$, $\phi_{pq}=\delta_{jp}\phi_{iq}$, $i,j,p,q=1,-1$.
Other nonvanishing products in: $\mathbf{M}^{\perp}$:

$$\begin{array}{llll} \phi_{00}r_{01}=r_{01}, & \phi_{00}r_{02}=r_{02}, & \phi_{00}s_{01}=s_{01}, & \phi_{00}s_{02}=s_{02}, \\ \phi_{11}r_{10}=r_{10}, & \phi_{11}x_{12}=x_{12}, & \phi_{11}x_{11}=x_{11}, & \phi_{11}s_{10}=s_{10}, \\ \phi_{22}r_{20}=r_{20}, & \phi_{22}x_{22}=x_{22}, & \phi_{22}x_{21}=x_{21}, & \phi_{22}s_{20}=s_{20}, \\ \phi_{12}r_{20}=r_{10}, & \phi_{12}x_{22}=x_{12}, & \phi_{12}x_{21}=x_{11}, & \phi_{12}s_{20}=s_{10}, \\ \phi_{21}r_{10}=r_{20}, & \phi_{21}x_{12}=x_{22}, & \phi_{21}x_{11}=x_{21}, & \phi_{21}s_{10}=s_{20}. \end{array}$$

Proof of 12: (i) The relations (48) obviously comply with the definition of $\mathbf{H}_1$ by symbols and relations (cf. *1*). Linearity and multiplicativity of α_a hold by definition. Properties (49)–(51) need only be checked on generators where they are obvious.

(ii) Definition (52) obviously defines a $\mathbb{Z}$-grading for which the degree is as indicated. Claims (iii) and (iv) are obvious. Check of the Hopf property: It suffices to show commutation of the α_a with Δ, which it is enough to check on generators owing to multiplicativity of Δ. Now:

$$\Delta(\alpha_a k)=\Delta k=k\otimes k \quad \text{whilst} \quad (\alpha_a\otimes\alpha_a)\Delta k=(\alpha_a\otimes\alpha_a)k\otimes k=k\otimes k,$$

$$\Delta(\alpha_a x)=\Delta(ax)=a\Delta x \quad \text{whilst} \quad (\alpha_a\otimes\alpha_a)\Delta x=(\alpha_a\otimes\alpha_a)(x\otimes k+k^{-1}\otimes x)=(ax\otimes k+k^{-1}\otimes ax),$$

$$\Delta(\alpha_a y)=\Delta(a^{-1}y)=a^{-1}\Delta y$$

$$\text{whilst } (\alpha_a\otimes\alpha_a)\Delta y=(\alpha_a\otimes\alpha_a)(y\otimes k+k^{-1}\otimes y)=(a^{-1}y\otimes k+k^{-1}\otimes a^{-1}y).$$

It is instructive to check the $\mathbb{Z}$-grading properties on the elements of the **MNF**-basis along the lines of (iv). for this we want to check that for homogeneous h, $h'\in\mathbf{H}_1$ one has $\delta_{\mathbb{Z}}h+\delta_{\mathbb{Z}}h'=\delta_{\mathbb{Z}}hh'$. For $hh'=0$ this is trivial because $0\in\mathbf{H}_1^{[n]}$ for all $n\in\mathbb{Z}$. Hence we need only look at the nonvanishing products listed previously. For the products in **M**, by the above remark (iii) we have $\partial_{\mathbb{Z}}(m_{ij}m_{jq})=\partial_{\mathbb{Z}}m_{iq}=q-i$ whilst $\partial_{\mathbb{Z}}m_{ij}+\partial_{\mathbb{Z}}m_{jq}=j-i+q-j=q-i$. The same reasoning settles the nonvanishing products between ϕ_{ij}, $i, j=1, -1$. Remain the other products for which one checks individually by inspection of the diagrams **N** and **F** that, for h in line i and h' in line j, hh' lies in line $i+j$.

We now embark upon the characterization of Hopf automorphisms. An $\alpha\in\mathrm{Aut}_{\mathrm{Hopf}}\mathbf{H}_1$ maps the ideals **M** and **N** into ideals of the same dimension, and thus preserves **M** and **N**. Hence $\alpha e_{\mathbf{M}}=e_{\mathbf{M}}$, and α thus preserves also $\mathbf{M}^{\perp}$. Moreover α commuting with S also commutes with $S^2=adh$, and thus leaves stable the subsets $\mathbf{H}_1^{(i)}$, $i=0,1,2$, hence the intersections $\mathbf{M}^{(i)}=\mathbf{M}\cap\mathbf{H}_1^{(i)}$, $\mathbf{N}^{(i)}=\mathbf{N}\cap\mathbf{H}_1^{(i)}$, $\mathbf{M}^{\perp(i)}=\mathbf{M}^{\perp}\cap\mathbf{H}_1^{(i)}$, which are also stable under S. By exploiting the multiplicativity of α and its commutativity with S, we first obtain Proposition 13. By the (less easily exploitable) commutativity of α with Δ we pass from 13 to the characterization 14 of the Hopf automorphisms. This then allows the description 15 of the Hopf bar-operations. We first state those results, and then sketch the proofs (the details of which are contained in the preprints[9]).

13 Proposition: (The group $\mathcal{A}$ of automorphisms of the complex algebra $\mathbf{H}_1$ commuting with S) With $a, \beta, \gamma, A, K, L, M, N$ complex constants such that

$$\begin{cases} a\beta AKN\neq 0 \\ \beta(KN-LM)=A, \end{cases} \tag{56}$$

we specify the $\mathbb{C}$-linear operator $\alpha=\alpha_{a\beta AKN}$ of $\mathbf{H}_1$ by requiring:
(1) on **M**:

$$\begin{cases} \alpha m_{11}=m_{11}, \\ \alpha m_{00}=m_{00}, \\ \alpha m_{22}=m_{22}, \end{cases} \quad \begin{cases} \alpha m_{01}=a m_{01}, \\ \alpha m_{12}=a^{-2}m_{12}, \\ \alpha m_{20}=a m_{20}, \end{cases} \quad \begin{cases} \alpha m_{10}=a^{-1}m_{10}, \\ \alpha m_{21}=a^{2}m_{21}, \\ \alpha m_{02}=a^{-1}m_{02}, \end{cases} \tag{57}$$

(2) on **F**:

$$\begin{cases} \alpha\phi_{11}=\phi_{11}, \\ \alpha\phi_{00}=\phi_{00}, \\ \alpha\phi_{22}=\phi_{22}, \end{cases} \quad \begin{cases} \alpha\phi_{12}=\beta\phi_{12}+\gamma x_{12}, \\ \alpha\phi_{21}=\beta^{-1}\phi_{21}-\beta^{-2}\gamma x_{21}, \end{cases} \tag{58}$$

(3)on **N**:

$$\begin{cases} \alpha x_{11}=A x_{11}, \\ \alpha x_{00}=A x_{00}, \\ \alpha x_{22}=A x_{22}, \end{cases} \quad \begin{cases} \alpha x_{12}=A\beta x_{12}, \\ \alpha x_{21}=A\beta^{-1}x_{21}, \end{cases} \tag{59}$$

$$\begin{cases} \alpha r_{01}=Kr_{01}+Ls_{01}, \\ \alpha s_{01}=Mr_{01}+Ns_{01}, \end{cases} \quad \begin{cases} \alpha r_{20}=Nr_{20}-Ms_{20}, \\ \alpha s_{20}=-Lr_{20}+Ks_{20}, \end{cases} \tag{60}$$

$$\begin{cases} \alpha r_{10}=\beta Nr_{10}-\beta Ms_{10}, \\ \alpha s_{10}=-\beta Lr_{10}+\beta Ks_{10}, \end{cases} \quad \begin{cases} \alpha r_{02}=\beta Kr_{02}+\beta Ls_{02}, \\ \alpha s_{02}=\beta Mr_{02}+\beta Ns_{02}. \end{cases}$$

The set of $\alpha_{a\beta AKN}$ is a subgroup of the automorphism group Aut$\mathbf{H}_1$ of the complex algebra $\mathbf{H}_1$, namely the subgroup of elements of Aut$\mathbf{H}_1$ commuting with S. One has
(1) *the product* $\alpha_{a\beta AKN}\alpha_{a'\beta'A'K'N'}=\alpha_{a''\beta''A''K''N''}$ with

$$\begin{cases} a''=aa', \\ \beta''=\beta\beta', \\ A''=AA', \\ K''=KK'+LM', \quad L''=KL'+LN', \\ M''=MK'+NM', \quad N''=ML'+NN', \end{cases}$$

(2) *the inverse* $(\alpha_{\beta AKN})^{-1}=\alpha_{\beta''' A''' K''' N'''}$ with

$$\begin{cases} a'''=a^{-1}, \\ \beta'''=\beta^{-1}, \\ A'''=A^{-1}, \\ K'''=\beta A^{-1}N, \quad L'''=-\beta A^{-1}L, \\ M'''=-\beta A^{-1}M, \quad N'''=\beta A^{-1}K. \end{cases}$$

Proof: Let $C_S\mathbf{X}$ be the requirement that α commute with S in restriction to $\mathbf{X}\subset\mathbf{H}_1$. The proof evolves in six steps (a) through (f):
(a) $C_S\mathbf{M}^{(0)}\Rightarrow\alpha$ acts on $\mathbf{M}^{(0)}$ either as the identity or as the exchange of m_{11} and m_{22}.
(b) $C_S\mathbf{M}^{(1)}$ (b)$\Rightarrow$(i): α acts on $\mathbf{M}^{(0)}$ as the identity
(ii) α acts on $\mathbf{M}^{(1)}$ as

$$\begin{cases} \alpha m_{01}=am_{01}, \\ \alpha m_{12}=a^{-2}m_{12}, \\ \alpha m_{20}=am_{20}, \end{cases}$$

respectively on $\mathbf{M}^{(2)}$ as

$$\begin{cases} \alpha m_{10}=a^{-1}m_{10}, \\ \alpha m_{21}=a^{2}m_{21}, \\ \alpha m_{02}=a^{-1}m_{02}. \end{cases}$$

(c) $C_S\mathbf{F}^{(0)}\Rightarrow\mathbf{F}^{(0)}$ is stable under α which acts on it as the identity.
(d) $C_S\mathbf{F}^{(1)}$ and $C_S\mathbf{F}^{(1)}\Rightarrow$one has

$$\begin{cases} \alpha\phi_{12}=\beta\phi_{12}+\gamma x_{12}, \\ \alpha\phi_{21}=\beta^{-1}\phi_{21}-\beta^{-1}\gamma\beta^{-1}x_{21}. \end{cases}$$

(e) $C_S\mathbf{N}^{(0)}\Rightarrow$(i): one has

$$\begin{cases} \alpha x_{11}=Ax_{11}, \\ \alpha x_{00}=Ex_{00}, \\ \alpha x_{22}=Ax_{22}. \end{cases}$$

(ii) One has anticipating on the next paragraph

$$\begin{cases} \alpha x_{12}=A\beta x_{12}, \\ \alpha x_{21}=A\beta' x_{21}. \end{cases}$$

(f) $C_S\mathbf{N}^{(1)}\Rightarrow$(i): one has

$$\begin{cases} \alpha r_{01}=Kr_{01}+Ls_{01}, \\ \alpha s_{01}=Mr_{01}+Ns_{01}, \end{cases} \quad \begin{cases} \alpha r_{20}=Nr_{20}-Ms_{20}, \\ \alpha s_{20}=-Lr_{20}+Ks_{20}, \end{cases}$$

$$\begin{cases} \alpha r_{10}=\beta Nr_{10}-\beta Ms_{10}, \\ \alpha s_{10}=-\beta Lr_{10}+\beta Ks_{10}, \end{cases} \quad \begin{cases} \alpha r_{02}=\beta Kr_{02}+\beta Ls_{02}, \\ \alpha s_{02}=\beta Mr_{02}+\beta Ns_{02}. \end{cases}$$

(ii) One has

$$\beta(KN-LM)=A=E.$$

14 Theorem: Let α be a Hopf automorphism of $\mathbf{H}_1$. We have the following action of α on the elements of the **MNF**-basis:

(1) in **M**: $\alpha m_{11}=m_{11}$, $\alpha m_{10}=a^{-1}m_{10}$, $\alpha m_{12}=a^{-2}m_{12}$,
$\alpha m_{01}=am_{01}$, $\alpha m_{00}=m_{00}$, $\alpha m_{02}=a^{-1}m_{02}$,
$\alpha m_{21}=a^2m_{21}$, $\alpha m_{20}=am_{20}$, $\alpha m_{22}=m_{22}$,

(2) in **F**: $\alpha\phi_{00}=\phi_{00}$,
$\alpha\phi_{22}=\phi_{22}$, $\alpha\phi_{21}=a^{-1}\phi_{21}$,
$\alpha\phi_{12}=a\phi_{12}$, $\alpha\phi_{11}=\phi_{11}$,

(3) in **N**: $\alpha x_{00}=x_{00}$, $\alpha r_{02}=a^{-1}r_{02}$, $\alpha r_{01}=a^{-2}r_{01}$,
$\alpha r_{20}=ar_{20}$, $\alpha x_{22}=x_{22}$, $\alpha x_{21}=a^{-1}x_{21}$, $\alpha s_{20}=a^{-2}s_{20}$,
$\alpha r_{10}=a^2r_{10}$, $\alpha x_{12}=ax_{12}$, $\alpha x_{11}=x_{11}$, $\alpha s_{10}=a^{-1}s_{10}$,
$\alpha s_{02}=a^2s_{02}$, $\alpha s_{01}=as_{01}$, $\alpha x_{00}=x_{00}$.

Conferring this with 12 Remarks (iii) this amounts to saying that α coincides with the automorphism α_a defined in (52). Hence $\mathrm{Aut}_{\mathrm{Hopf}}\mathbf{H}_1$ is the same as the group $\mathcal{G}$ of automorphisms of $\mathbf{H}_1$ furnished by the $\mathbb{Z}$-grading of $\mathbf{H}_1$.

Proof: We shall now exploit the rule $\Delta\circ\alpha=(\alpha\otimes\alpha)\circ\Delta$ (commutativity of α with the coproduct). Writing that the automorphism α commutes with Δ is trivial. What is not obvious is which elements one should adress to obtain the properties of α in 14.

Our proof relies on the tabulation[10] [4a] of the coproduct of $\mathbf{H}_1$. Although the latter was computed using the traditional version of $\mathbf{H}_1$, it works for our present purposes: indeed, as we shall see, we need only to know which elements of the **MNF**-basis figure in their coproduct: the precise knowledge of the numerical coefficients is immaterial for the coming proof.

Showing that $\beta=a$.

We read off p. 433 of Ref. 10 [4a] that the $\mathbf{F}\otimes\mathbf{N}$-component of Δm_{11} is of the form:

$$\Delta m_{11}=\lambda\phi_{22}\otimes x_{22}+\mu\phi_{21}\otimes r_{20}+\nu\phi_{12}\otimes r_{02}+\rho\phi_{11}\otimes x_{00} \tag{61}$$

with the constants λ, μ, ν, ρ all nonvanishing. Writing $(\alpha\otimes\alpha)\Delta m_{11}=\Delta(\alpha m_{11})$ and using relations (58)–(60) this equals

$$\begin{aligned}(\alpha\otimes\alpha)\Delta m_{11}=&\lambda\phi_{22}\otimes Ax_{22}+\mu(\beta^{-1}\phi_{21}-\beta^{-2}\gamma x_{21})\otimes(Nr_{20}-Ms_{20})\\&+\nu(\beta\phi_{12}+\gamma x_{12})\otimes(\beta Kr_{02}+\beta Ls_{02})+\rho\phi_{11}\otimes Ax_{00}.\end{aligned} \tag{62}$$

Equating coefficients yields after division through nonzero constants:
$1=A$, $1=\beta^{-1}N$, $1=\beta^2K$ whence $\beta=N$ $\beta^{-2}=K$,

$\beta^{-1}M=\beta^{-2}\gamma N=\beta^{-2}\gamma M=\gamma\beta K=\beta^2L=\gamma\beta L=0$ whence $M=L=\gamma=0$.
Corroboration of (56): we have $A=1=\beta KN=\beta\beta^{-2}\beta$.

We read off p. 440 of Ref. 4 [4a] that the $\mathbf{M}\otimes\mathbf{M}$-component of $\Delta\phi_{12}$ is of the form:

$$\Delta\phi_{12}=\lambda' m_{11}\otimes m_{01}+\mu' m_{01}\otimes m_{11}+\nu' m_{20}\otimes m_{22}+\rho' m_{22}\otimes m_{20} \tag{63}$$

with the constants γ',μ',ν',ρ' all nonvanishing. Writing $\beta\Delta(\phi_{12})=(\alpha\otimes\alpha)\Delta\phi_{12}$ (observe that $\alpha\phi_{12}=\beta\phi_{12}$ since we showed that $\gamma=0$) and furthermore using (57) we get

$$\begin{aligned}&\beta[\lambda' m_{11}\otimes m_{01}+\mu' m_{01}\otimes m_{11}+\nu' m_{20}\otimes m_{22}+\rho' m_{22}\otimes m_{20}]\\&\quad=\lambda' m_{11}\otimes am_{01}+\mu' am_{01}\otimes m_{11}+\nu' am_{20}\otimes m_{22}+\rho' m_{22}+\rho' m_{22}\otimes am_{20}.\end{aligned}$$

Equating coefficients yields after division through nonzero constants yields $\beta=a$. Collecting results yields our claim: $A=1$, $a=\beta=\mathrm{N}$, $a^2=K$, $M=L=\gamma=0$.

15 Theorem: The Hopf bar-operations of $\mathbf{H}_1$ are of the type $\Gamma_r=\alpha_r\Gamma$, $r\in\mathbb{R}^+$, thus specified as follows on generators:

$$\Gamma k=k,\quad \Gamma x=rx,\quad \Gamma y=r^{-1}x. \tag{64}$$

In other terms the Hopf bar-operation is unique up to a scaling factor.

Proof: We know (cf. Appendix B) that all Hopf bar-operations are of the type $w\Gamma=\Gamma w^{-1}$, w a Hopf automorphism of the type α_a, $0\neq a\in\mathbb{C}$. Now $\alpha_a\Gamma=\Gamma\alpha_a{}^{-1}$ iff Γ is real: indeed $\alpha_a\Gamma k=\Gamma\alpha_a{}^{-1}k=k$, $\alpha_a\Gamma x=\alpha_a y=a^{-1}y$ whilst $\Gamma\alpha_a{}^{-1}x=\Gamma a^{-1}x=\overline{a^{-1}}y$, and $\alpha_a\Gamma y=\alpha_a x=ax$ whilst, $\Gamma\alpha_a{}^{-1}y=\Gamma ay=\overline{a}x$.

APPENDIX A: BAR-OPERATIONS OF COMPLEX ALGEBRAS

[A1] Definitions: With $\mathbf{A}$ an algebra over $\mathbb{C}$ a *bar-operation of* $\mathbf{A}$ is a map $\Gamma:\mathbf{A}\to\mathbf{A}$ which is: (a) antilinear, (b) involutive, (c) multiplicative (in other terms the bar-operations of the complex algebra $\mathbf{A}$ are the $\mathbb{Z}/2$ gradings of the real algebra $\mathbf{A}$ which anticommute with i).

We denote by Bar $\mathbf{A}$ the set of bar-operations of $\mathbf{A}$. The elements of Bar $\mathbf{A}$ are so to speak the "mirror symmetries" of $\mathbf{A}$. They leave invariant the unit of $\mathbf{A}$ if $\mathbf{A}$ is unital.

[A2] Proposition (the groupoïd Bar $\mathbf{A}\times$Bar $\mathbf{A}$): With $\mathbf{A}$ and Bar $\mathbf{A}$ as in *[A1]*, the Cartesian product Bar $\mathbf{A}\times$Bar $\mathbf{A}$ is a bipoint-groupoïd (transitive and unicursal)*:*

(i) *Given* Γ_1, $\Gamma_2\in$Bar $\mathbf{A}$ there is a unique $w_{12}\in$Aut $\mathbf{A}$ s.t.$\Gamma_2=\Gamma_1 w_{12}$, namely $w_{12}=\Gamma_1\Gamma_2$ Γ_1, Γ_2 are groupoïd units and w_{12} is the only morphism: $\Gamma_1\to\Gamma_2$.

(ii) Given Γ_1, $\Gamma_2\in$Bar $\mathbf{A}$ there is a unique $w_{21}\in$Aut $\mathbf{A}$ s.t. $\Gamma_2=w_{21}\Gamma_1$, namely $w_{21}=\Gamma_2\Gamma_1$. Γ_1, Γ_2 are groupoïd units and w_{21} is the only morphism: $\Gamma_2\to\Gamma_1$.

(iii) w_{12} and w_{21} are inverse of each other. Given $\Gamma\in$Bar $\mathbf{A}$ and $w\in$Aut $\mathbf{A}$ one has $\Gamma w\in$Bar $\mathbf{A}$ iff $\Gamma w=w^{-1}\Gamma$ (respectively, $w\Gamma\in$Bar $\mathbf{A}$ iff $w\Gamma=\Gamma w^{-1}$).

(iv) One has the equivalences: $w_{21}=w_{12}\Leftrightarrow(w_{12})^2=\mathrm{id}\Leftrightarrow(w_{21})^2=\mathrm{id}\Leftrightarrow\Gamma_1$ and Γ_2 commute.

[A3] Proposition (the real fix-point algebra $\mathbf{A}^\Gamma$)*:* Let $\mathbf{A}$ be an algebra over $\mathbb{C}$ and let $\Gamma\in$Bar $\mathbf{A}$. Then:

(i) the set $\mathbf{A}^\Gamma=\{a\in\mathbf{A};\Gamma a=a\}$ is an algebra over $\mathbb{R}$.

(ii) $\frac{1}{2}(\mathrm{id}+\Gamma)$ and $\frac{1}{2}(\mathrm{id}-\Gamma)$ are complementary projections of $\mathbf{A}$. We have

$$\mathbf{A}^\Gamma=\mathrm{Ker}\,\tfrac{1}{2}(\mathrm{id}-\Gamma)=\mathrm{Im}\,\tfrac{1}{2}(\mathrm{id}+\Gamma), \tag{A1}$$

and

$$i\mathbf{A}^\Gamma=\mathrm{Ker}\,\tfrac{1}{2}(\mathrm{id}+\Gamma)=\mathrm{Im}\,\tfrac{1}{2}(\mathrm{id}-\Gamma), \tag{A2}$$

hence

$$\mathbf{A}=\mathbf{A}^\Gamma\oplus i\mathbf{A}^\Gamma. \tag{A3}$$

(iii) If $\mathbf{A}$ has a finite complex dimension n, $\mathbf{A}^\Gamma$ has the real dimension n.
Note that a general $\mathbb{Z}/2$ grading Γ of the algebra $\mathbf{A}$ over $\mathbb{R}$ does not need to have $\dim_{\mathbb{R}}\mathbf{A}^+ = \dim_{\mathbb{R}}\mathbf{A}^-$—but this is the case if Γ anticommutes with i, due to $\mathbf{A}^- = i\mathbf{A}^+$.

[A4] Proposition: With $\mathbf{A}$ an algebra over $\mathbb{C}$, the following objects are one-to-one:
(i) the *bar operations* of $\mathbf{A}$.
(ii) the subalgebras $\mathbf{A}^\Gamma$ of the real algebra $\mathbf{A}$ such moreover that $\mathbf{A}=\mathbf{A}^\Gamma\oplus i\mathbf{A}^\Gamma$ as complex algebras: we call those the *real spines of* $\mathbf{A}$.

The bijection is as follows:
(i) $\rightarrow$ (ii):

$$\mathbf{A}^\Gamma=\{a\in\mathbf{A};\Gamma a=a\} \tag{A4}$$

(ii) $\rightarrow$ (i):

$$\Gamma(a'+ia'')=a'-ia'',\quad a',a''\in\mathbf{A}^\Gamma. \tag{A5}$$

[A5] Remarks: (i) If $\mathbf{A}$ is n-dimensional each basis $\{a_i\}_{i=1,\ldots,n}$ of $\mathbf{A}$ giving rise to a real multiplication table yields a real spine of $\mathbf{A}$ $(\{ua_iu^{-1}\}_{i=1,\ldots,n}$, $u\in\mathbf{A}$ invertible, another.
(ii): Given a fixed real spine Γ_0 of $\mathbf{A}$ the real spines of $\mathbf{A}$ are one-to-one with the $\phi\Gamma_0$ for the $\phi\in\mathrm{Aut}\,\mathbf{A}$ such that $\phi\Gamma_0\phi\Gamma_0=\mathrm{id}$, or alternatively such that $\phi\Gamma_0\phi=\Gamma_0$.

APPENDIX B: HOPF BAR-OPERATIONS AND MODULAR *-OPERATIONS OF HOPF ALGEBRAS

In what follows $\mathbf{H}(m,\Delta,e,\epsilon,S)$ is a Hopf algebra over $\mathbb{C}$.

[B1] Definitions: (i) A Hopf bar-operation of $\mathbf{H}$ is a $\Gamma\in\mathrm{Bar}\,\mathbf{H}$ which is Hopf in the sense:

$$\begin{cases}\epsilon(\Gamma a)=\epsilon(\overline{a}),\\ \Delta\Gamma a=(\Gamma\otimes\Gamma)\Delta a,\quad a\in\mathbf{H}.\\ \Gamma S=S\Gamma.\end{cases} \tag{B1}$$

We denote by Hopf bar $\mathbf{H}$ the set of Hopf bar-operations of $\mathbf{H}$.
(ii) A modular *-operation of $\mathbf{H}$ is a map $\Sigma:\mathbf{H}\rightarrow\mathbf{H}$, which is
(a) antilinear,
(b) of square S^2,
(c) antimultiplicative,
(d) Hopf in the sense:

$$\begin{cases}\epsilon(\Sigma a)=\epsilon(\overline{a}),\\ \Delta\Sigma a=(\Sigma\otimes\Sigma)\Delta P_{12}a,\quad a\in\mathbf{H}.\\ \Sigma S=S\Sigma.\end{cases} \tag{B2}$$

[B2] Proposition: Let $\mathbf{H}$ be a Hopf algebra with invertible antipode. The following objects are one-to-one:
(i) the Hopf bar operations Γ of $\mathbf{H}$,
(ii) the modular*-operations Σ of $\mathbf{H}$,
with the bijection given by $\Sigma=\Gamma S=S\Gamma$, $\Gamma=S^{-1}\Sigma=\Sigma S^{-1}$.

[B3] Proposition: Let $\Gamma_1,\Gamma_2\in\mathrm{Hopf\ bar}\,\mathbf{H}$: $w_{12}=\Gamma_1\Gamma_2$ is a Hopf automorphism of $\mathbf{H}$.

[B4] Proposition: Assume the Hopf algebra $\mathbf{H}$ of finite complex dimension n.
(i): Let $\Gamma\in\mathrm{Hopf\ bar}\,\mathbf{H}$. The algebra $\mathbf{H}^\Gamma=\{a\in\mathbf{H};\Gamma a=a\}$ of fixpoints of Γ (cf. *[A3]*) is a real Hopf algebra of real dimension n. In particular one has
(a) $\Delta\mathbf{H}^\Gamma\in\mathbf{H}^\Gamma\otimes\mathbf{H}^\Gamma$
(a) $S\mathbf{H}^\Gamma\in\mathbf{H}^\Gamma$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 5 MAY 2002

On quasicrystal Lie algebras

Volodymyr Mazorchuk[a)]
Department of Mathematics, Uppsala University, Box 480, SE-751 06, Uppsala, Sweden

(Received 12 October 2001; accepted for publication 5 February 2002)

We realize the aperiodic Witt and Virasoro algebras as well as other quasicrystal Lie algebras as factor algebras of some subalgebras of the higher rank Virasoro algebras. This realization allows us to generalize the notion of quasicrystal Lie algebras. In the case when the constructed algebra admits a conjugation, we compute the Kac determinant for the Shapovalov form on the corresponding Verma modules. In the case of the aperiodic Virasoro algebra this proves the conjecture of R. Twarock. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1468255]

I. INTRODUCTION

This article has grown from my attempt to understand the recently introduced notion of quasicrystal Lie algebras and the aperiodic Witt and Virasoro algebras (Patera *et al.*, 1998; Twarock, 2000a). These algebras form a new family of infinite-dimensional Lie algebras, whose generators are indexed by points of an aperiodic set (which is in fact a one-dimensional cut-and-project quasicrystal, an object, intensively studied by many authors) (see, e.g., Katz, 1998; Kramer, 1999; Radin, 1999, and references therein).

Quasicrystal Lie algebras and their representations were studied by several authors, (see, for example, Patera and Twarock, 1999; Patera *et al.*, 1998; Twarock, 2000a), and in Twarock (2000b, c) some applications of these algebras to the construction of some integrable models in quantum mechanics were given. However, there are many important questions about quasicrystal Lie algebras, which are still open. For example, in Twarock (2000a) the author constructs a triangular decomposition for the aperiodic Virasoro algebra, hence constructing Verma modules, and conjectures a formula for the Kac determinant of the Shapovalov form on these modules. This formula is important both for the description of simple highest weight modules and for picking up those of them which can be unitarizable, which is the question of primary interest in physical applications.

It was clear from the very first definition of quasicrystal Lie algebras that this notion should be closely connected with the notion of the higher rank Virasoro algebras, defined in Patera and Zassenhaus (1991). The major difference between these algebras is that the indexing set for quasicrystal Lie algebras is a discrete subset of $\mathbb{R}$ while for the higher rank Virasoro algebras the corresponding set is everywhere dense. In the present article we establish this connection by realizing quasicrystal Lie algebras as factor algebras of some subalgebras of the higher rank Virasoro algebras. This realization allows us to generalize quasicrystal Lie algebras in several directions, preserving the property to have a discrete indexing set. Moreover, the notion and construction of a triangular decomposition for these algebras appears naturally in this framework. Further, we discuss the existence of conjugation on the constructed algebras, which pairs the components of the positive and negative parts. In the case when such pairing exists, the definition of the Shapovalov form on Verma modules (see Shapovalov, 1972; Moody and Pianzola, 1995) is straightforward and we compute the Kac determinant (see Shapovalov, 1972; Kac and Kazhdan, 1979); Moody and Pianzola, 1995; Kac and Raina, 1987 of this form. In the case of the aperiodic Virasoro algebras this proves Twarock, 2000a, Conjecture V.7.

The article is organized as follows: in Secs. II and III we recall the definitions of quasicrystal Lie algebras and higher rank Virasoro algebras. We give a realization of quasicrystal Lie algebras

a)Electronic mail: mazor@math.uu.se, web-page: http://www.math.uu.se/~mazor/

as factor algebras of certain subalgebras of the higher rank Virasoro algebras in Sec. IV and use it to construct parabolic and triangular decompositions of our algebras in Sec. V. In Sec. VI we study the Verma modules and, in particular, calculate the determinant of the Shapovalov form on them. We finish with discussing several generalizations of our construction in Secs. VII and VIII.

II. QUASICRYSTAL LIE ALGEBRAS

Denote by $(\cdot)^{\#}$ the unique nontrivial automorphism of the field $\mathbb{Q}(\sqrt{5})$ and let $\mathbb{F}$ be a field of characteristic 0, containing $\sqrt{5}$. Let Ω be a nonempty, connected and bounded real set, whose set of inner points does not contain 0. Set $\tau=\frac{1}{2}(1+\sqrt{5})$. Then the *cut-and-project quasicrystal* $\Sigma(\Omega)$ associated with Ω is the set of all $x\in\mathbb{Z}[\tau]$, such that $x^{\#}\in\Omega$ (see Duneau and Katz, 1985). The *quasicrystal Lie algebra* $L(\Omega)$, associated with Ω, is defined as follows (see Patera *et al.*, 1998): it is generated over $\mathbb{F}$ by L_x, $x\in\Sigma(\Omega)$, with the Lie bracket defined via

$$[L_x,L_y]=\begin{cases}(y-x)L_{x+y}, & x+y\in\Sigma(\Omega),\\ 0, & \text{otherwise.}\end{cases}$$

To define the aperiodic Witt and Virasoro algebras as it is done in Twarock (2000a), we introduce the map $\varphi:\mathbb{Z}[\tau]\to\mathbb{Z}$, which sends $x=a+b\tau$ to $\varphi(x)=b$. Then *the aperiodic Witt algebra* $AW([0,1],\mathbb{F})$ is generated over $\mathbb{F}$ by L_x, $x\in\Sigma([0,1])$, with the Lie bracket defined via

$$[L_x,L_y]=\begin{cases}(\varphi(y)-\varphi(x))L_{x+y}, & x+y\in\Sigma([0,1]),\\ 0, & \text{otherwise.}\end{cases}$$

By Twarock (2000a), Theorem III.4, the algebra $AW([0,1],\mathbb{F})$ admits the unique central extension $AV([0,1],\mathbb{F})$, called *the aperiodic Virasoro algebra*, which is generated over $\mathbb{F}$ by L_x, $x\in\Sigma([0,1])$, and $\mathfrak{c}$, with the Lie bracket defined via

$$[L_x,L_y]=\begin{cases}(\varphi(y)-\varphi(x))L_{x+y}+\delta_{\varphi(x),-\varphi(y)}\dfrac{\varphi(x)^3-\varphi(x)}{12}\mathfrak{c}, & x+y\in\Sigma([0,1]),\\ 0, & \text{otherwise.}\end{cases}$$

III. THE HIGHER RANK VIRASORO ALGEBRAS

Let P denote the free Abelian group $\mathbb{Z}^k$ of finite rank k and $\psi:P\to(\mathbb{F},+)$ a group monomorphism. The *rank k Virasoro* algebra $V(\psi,\mathbb{F})$, associated with ψ, is generated over $\mathbb{F}$ by elements e_x, $x\in P$, and central term $\mathfrak{c}$, with the Lie bracket defined via

$$[e_x,e_y]=(\psi(y)-\psi(x))e_{x+y}+\delta_{x,-y}\frac{\psi(x)^3-\psi(x)}{12}\mathfrak{c}.$$

The *rank k Witt* algebra $W(\psi,\mathbb{F})$ is the quotient of $V(\psi,\mathbb{F})$ modulo the central ideal $\mathbb{F}c$.

We will need the notion of a triangular decomposition for $V(\psi,\mathbb{F})$ and $W(\psi,\mathbb{F})$, introduced and studied in Mazorchuk (1999). The *standard triangular decomposition* of $\mathfrak{G}=W(\psi,\mathbb{F})$ [or $\mathfrak{G}=V(\psi,\mathbb{F})$] is associated with a linear order, $<$, on the Abelian group P, satisfying the Archimed law: for any $0<a<b\in T$ there exists $k\in\mathbb{N}$ such that $b<ka$. After fixing such $<$ we define $\mathfrak{G}_+$ (resp. $\mathfrak{G}_-$) as generated by e_x, $x>0$ (resp. $x<0$), and $\mathfrak{G}_0$ as the span of e_0 [and c in case of $V(\psi,\mathbb{F})$]. We get $\mathfrak{G}=\mathfrak{G}_-\oplus\mathfrak{G}_0\oplus\mathfrak{G}_+$. The disadvantage of this construction is that the Verma modules $U(\mathfrak{G})\otimes_{U(\mathfrak{G}_0\oplus\mathfrak{G}_+)}\mathbb{F}_\lambda$, $\lambda:\mathfrak{G}_0\to\mathbb{F}$, associated with this decomposition, have infinite-dimensional weight spaces. The reason why this is the case is explained by the fact that any injective additive real one-dimensional projection of the set, indexing $\mathfrak{G}_-$, is not discrete. The linear orders on P, satisfying the Archimed law, will be called *admissible*. For an admissible order, $<$, on P, we denote by P_+ the set $\{x\in P:0<x\}$ and by P_- the set $\{x\in P:x<0\}$. We also set $P_+^0=P_+\cup\{0\}$ and $P_-^0=P_-\cup\{0\}$.

The notions of the rank k Virasoro and Witt algebras have an immediate generalization if one forgets about the requirement on ψ to be a monomorphism. From now on we will not require this, but, however, will assume that ψ is nonzero. We will then understand the notions of the rank k Virasoro and Witt algebras in this more general sense.

IV. REALIZATION OF QUASICRYSTAL LIE ALGEBRAS

In this section we realize the quasicrystal Lie algebras as quotients of the positive part of a higher rank Virasoro algebra. Since the quasicrystal Lie algebras are defined in terms of $\mathbb{Z}[\tau]$, which is a free Abelian group of rank 2, we naturally reduce our consideration to the case of rank 2 Virasoro algebras. So, we assume that $P \simeq \mathbb{Z}^2$. If $<$ is an admissible order on P and I is a *non-negative ideal* of P, i.e., $I \subset P_+^0$ and $x \in I$, $x < y$, implies $y \in I$, then we denote by $L(\mathfrak{G}, <, I)$ the Lie subalgebra of $\mathfrak{G}$, generated by all e_x, $x \in I$. Our main statement about the realization of quasicrystal algebras is the following.

Theorem 1: *Let L be a quasicrystal Lie algebra. Then there exist a rank 2 Witt algebra, $\mathfrak{G} = W(\psi, \mathbb{F})$, an admissible order, $<$, on P, and two non-negative ideals $I \supset J$ of $\mathfrak{G}$, such that L is isomorphic to the quotient algebra $L(\mathfrak{G}, <, I)/L(\mathfrak{G}, <, J)$.*

Proof: Let $\psi: P \to \mathbb{F}$ be the monomorphism sending a fixed basis, $\{a, b\}$, of P to $\{1, \tau\}$. For a, $b \in P$ we define $a < b$ provided $0 < (\psi(b) - \psi(a))^{\#}$ and claim that this is an admissible order on P. Indeed, $<$ is obviously antisymmetric, antireflexive and transitive. So, it is a partial order. But from the definition it also follows immediately that $<$ is linear. Further, for any $a < b$ in P and $c \in P$ we have $(\psi(a+c) - \psi(b+c))^{\#} = (\psi(a+c-b-c))^{\#} = (\psi(a-b))^{\#} = (\psi(a) - \psi(b))^{\#} < 0$ and hence $a + c < b + c$, thus $<$ is compatible with the addition in P. Finally, if $0 < a < b$, then $0 < (\psi(a))^{\#}$ and hence there always exists $k \in \mathbb{N}$ such that $(\psi(b) - \psi(ka))^{\#} = (\psi(b))^{\#} - k(\psi(a))^{\#} < 0$, which shows that the order is admissible.

Consider the rank 2 Witt algebra $\mathfrak{G} = W(\psi, \mathbb{F})$. Without loss of generality we can assume that $\Omega \subset \mathbb{R}_{\geqslant 0}$, as otherwise we can work with the order opposite to $<$. As Ω is a connected bounded subset of $\mathbb{R}$, it has one of the following four forms: $[a,b]$, $(a,b]$, $[a,b)$, (a,b) for some non-negative real numbers a, b. We define I and J as follows: I is generated by all e_x such that $\psi(x)^{\#} > a$ [resp. $\psi(x)^{\#} \geqslant a$] if $a \notin \Omega$ (resp. $a \in \Omega$); and J is generated by all e_x such that $\psi(x)^{\#} > b$ [resp. $\psi(x)^{\#} \geqslant b$] if $b \in \Omega$ (resp. $b \notin \Omega$). From the definition it follows immediately that both I and J are non-negative ideals of P with respect to $<$. Hence, the algebras $L(\mathfrak{G}, <, I)$ and $L(\mathfrak{G}, <, J)$ are well-defined subalgebras of $\mathfrak{G}$ and $L(\mathfrak{G}, <, J) \subset L(\mathfrak{G}, <, I)$ by definition.

Now we show that $L(\mathfrak{G}, <, J)$ is actually an ideal of $L(\mathfrak{G}, <, I)$. Indeed, if $x \in I$ and $y \in J$, we get that $x + y \in J$ as J is an ideal of P and $x \in P_+^0$. Hence $[e_x, e_y] \in L(\mathfrak{G}, <, J)$ for any $e_x \in L(\mathfrak{G}, <, I)$ and $e_y \in L(\mathfrak{G}, <, J)$.

Finally, we consider the map $f: L(\mathfrak{G}, <, I) \to L(\Omega)$ defined by

$$f(e_x) = \begin{cases} L_x, & x^{\#} \in \Omega, \\ 0, & \text{otherwise.} \end{cases}$$

From the definition of the Lie brackets in $L(\Omega)$ (Sec. II) and in $\mathfrak{G}$ (Sec. III) we immediately get that f is a Lie algebra homomorphism. Moreover, it is also clear that its kernel coincides with $L(\mathfrak{G}, <, J)$. This completes the proof. □

Theorem 1 motivates the following definition: let $\mathfrak{G} = W(P, \psi)$ be a higher rank Witt algebra (it is important here that $k > 1$, i.e., that $\mathfrak{G}$ is not the classical Witt algebra), $<$ be an admissible order on P, and $I \supset J$ be two non-negative ideals of P with respect to the order $<$. Then we define the *Lie algebra $\mathfrak{A}(P, \psi, <, I, J)$ of quasicrystal type* as the quotient algebra $L(\mathfrak{G}, <, I)/L(\mathfrak{G}, <, J)$. In particular, all quasicrystal Lie algebras are Lie algebra of quasicrystal type. Now we can formulate some basic properties of Lie algebras of quasicrystal type and we see that these algebras share a lot of properties of classical quasicrystal Lie algebras. We start with the following easy observations.

Lemma 1: Let $<$ be an admissible order on $\mathbb{Z}^k$. Then there exists a homomorphism, $\sigma: P \to \mathbb{R}$, such that $\sigma(P_{\pm}) \subset \mathbb{R}_{\pm}$.

Proof: Identify P with $\mathbb{Z}^k \subset \mathbb{R}^k$. Using the description of admissible orders on an Abelian group from Zaytseva (1953), we find a hyperplane, H, of $\mathbb{R}^k$, such that P_+ coincides with the set of points from $\mathbb{Z}^k$, which are settled on the same side with respect to H. Then σ can be taken, e.g., as the projection onto $H^\perp$ with respect to H (here $\mathbb{R}^k$ is considered as an Euclidean space in a natural way).

For given $\mathfrak{G}=W(P,\psi)$ and $<$ we fix some σ, which exists by Lemma 1. We define $a=\inf_{x\in I}(\sigma(x))$ and $b=\inf_{x\in J}(\sigma(x))$ and will use this notation in the following statement.

Proposition 1: Let $\mathfrak{A}(P,\psi,<,I,J)$ be a Lie algebra of quasicrystal type.

(1) $\mathfrak{A}(P,\psi,<,I,J)$ is Abelian if and only if $2a\geqslant b$.
(2) $\mathfrak{A}(P,\psi,<,I,J)$ has a nontrivial center if and only if $a\neq 0$.
(3) $\mathfrak{A}(P,\psi,<,I,J)$ is nilpotent if and only if $a>0$ and $J\neq\varnothing$.
(4) The algebra *$\mathfrak{A}(P,\psi,<,I,J)$ is perfect if and only if $a=0$ and $0\notin I$.*
(5) If $J\neq\varnothing$, then the algebra $\mathfrak{A}(P,\psi,<,I,J)$ is locally finite, that is, any finite set of elements from $\mathfrak{A}(P,\psi,<,I,J)$ generates a finite-dimensional Lie subalgebra of $\mathfrak{A}(P,\psi,<,I,J)$. In particular, $\mathfrak{A}(P,\psi,<,I,J)$ has finite-dimensional subalgebras of arbitrary non-negative dimension.

Proof: All statements are easy corollaries of the fact that the indices of the generating elements are added under the Lie bracket. Indeed, with this remark the first statement reduces to the fact that $x\geqslant a$ and $y\geqslant a$ implies $x+y\geqslant 2a\geqslant b$; the second one reduces to the fact that for any $x\geqslant a$ and $y>b-a$ one has $x+y>b$; and the third one reduces to the fact that for $ka>b$ we have $kx>b$ for any $x\geqslant a$. If $a\neq 0$, the algebra $\mathfrak{A}(P,\psi,<,I,J)$ is nilpotent by statement 3 and hence not perfect. It is also clear that it is impossible to get 0 in the derived algebra. But if $a=0$ and $0\notin I$, then $L(\mathfrak{G},<,I)=\mathfrak{G}_+$, $\sigma(P_+)$ is dense in $\mathbb{R}_+$ and hence for any $x>0$ there exist y, $z\in P_+$ such that $y+z=x$. This implies that $\mathfrak{A}(P,\psi,<,I,J)$ is perfect in this case and hence property 4 holds.

The first part of the last statement is equivalent to the trivial statement that a finite subset of $\mathbb{R}_+$ generates an additive semigroup, whose intersection with any bounded set is finite. To prove the second part it is sufficient to consider the span of e_{ix}, $i=1,\ldots,n$, such that $nx<b$ and $(n+1)x>b$. This completes the proof. □

For example, to realize the aperiodic Witt algebra $AW([0,1])$, defined in Twarock (2000a), as a Lie algebra of quasicrystal type, one should take $P=\mathbb{Z}^2$, ψ being the projection onto the second coordinate; $<$ defined by $x<y$ if and only if the inner product of $y-x$ with $(1,\frac{1}{2}(1-\sqrt{5}))=(1,\tau^{\#})$ is greater than zero; $I=P_+^0$; $J=\{x\in P:(1,0)<x\}$.

V. STANDARD AND NONSTANDARD TRIANGULAR DECOMPOSITIONS

The realization of Lie algebras of quasicrystal type, obtained in the previous section, allows us to adopt the technique from Mazorchuk (1999) to construct various triangular and parabolic decompositions of these algebras. The general procedure will look as follows.

Let $\mathfrak{A}=\mathfrak{A}(P,\psi,<,I,J)$ be a Lie algebra of quasicrystal type. Abusing notation we will denote by e_x, $x\in I\backslash J$, the generators of $\mathfrak{A}$. Choose any linear pre-order, $\preccurlyeq$, on the Abelian group P, which is different from $<$ and its opposite. Define $\mathfrak{A}_\pm$ as the Lie subalgebras of $\mathfrak{A}$, generated by all e_x, $0\preccurlyeq\pm x$, and set $\mathfrak{A}_0$ to be the Lie subalgebra of $\mathfrak{A}$, generated by all e_x, $0\preccurlyeq x$ and $x\preccurlyeq 0$. We get the following obvious fact.

Lemma 2: $\mathfrak{A}=\mathfrak{A}_-\oplus\mathfrak{A}_0\oplus\mathfrak{A}_+$.

Proof: Clearly, $\mathfrak{A}=\mathfrak{A}_-+\mathfrak{A}_0+\mathfrak{A}_+$. The fact that this is actually a direct sum decomposition follows easily from the property $x\preccurlyeq y$ implies $x+z\preccurlyeq y+z$. □

It is natural to call the decomposition $\mathfrak{A}=\mathfrak{A}_-\oplus\mathfrak{A}_0\oplus\mathfrak{A}_+$ the *parabolic decomposition* of $\mathfrak{A}$ associated with $\preccurlyeq$. Given a parabolic decomposition and a simple $\mathfrak{A}_0$-module, V, one can extend V to a $\mathfrak{A}_0\oplus\mathfrak{A}_+$-module with the trivial action of $\mathfrak{A}_+$ and construct the associated *generalized Verma module* $M(V)$ as follows: $M(V)=U(\mathfrak{A})\otimes_{U(\mathfrak{A}_0\oplus\mathfrak{A}_+)}V$.

If $\mathfrak{A}_0$ happens to be rather special, it is natural to rename the corresponding parabolic decomposition into it *triangular decomposition*. However, this is a subtle question and the terminology

I give here represents only my point of view and is inspired by the corresponding notions for the higher rank Witt algebras (Mazorchuk, 1999).

We will say that the decomposition $\mathfrak{A}=\mathfrak{A}_-\oplus\mathfrak{A}_0\oplus\mathfrak{A}_+$ is a *standard triangular decomposition* provided that $\mathfrak{A}_0=\mathbb{F}e_x$ for some $x\in P$, which is not maximal in $I\backslash J$. We call $\mathfrak{A}=\mathfrak{A}_-\oplus\mathfrak{A}_0\oplus\mathfrak{A}_+$ a *nonstandard triangular decomposition* provided that $\mathfrak{A}_0$ is a commutative Lie algebra and the parabolic decomposition fails to be standard triangular. In the case of a triangular decomposition, generalized Verma modules become classical *Verma modules* as in this case $\dim(V)=1$.

The first case is natural and corresponds to triangular decompositions of the higher rank Witt algebras (Mazorchuk, 1999). Actually, here one has to be careful because, depending on whether $\preccurlyeq$ satisfies the Archimed law or not, one can further distinguish two cases of standard triangular decompositions. We will not do this, as we will not study the difference between the corresponding situations. But the second case has a striking difference from the first one and comes from the definition of triangular decompositions for the aperiodic Virasoro algebra in Twarock (2000a). This means that the triangular decomposition for the aperiodic Virasoro algebra, constructed in Twarock (2000a), is an example of a nonstandard triangular decomposition. We now will study analogous situations in more detail.

We retain the notation for σ, a,b from the previous section and further assume that $a=0$ and that there is an element, $e_u\in\mathfrak{A}$, such that $\sigma(u)=b$ and $\psi(u)=0$. Since $<$ is an admissible order, such an element is unique and we retain the notation e_u for it.

Lemma 3: Under the above assumptions we consider the vector space $\mathfrak{A}'=\mathfrak{A}\oplus\mathbb{F}\mathfrak{c}$. *Then the formula*

$$[e_x+a\mathfrak{c},e_y+b\mathfrak{c}]=[e_x,e_y]+\frac{\psi(x)^3-\psi(x)}{12}\delta_{x,u-y}\mathfrak{c}$$

defines on $\mathfrak{A}'$ *the structure of a Lie algebra, which is a central extension of* $\mathfrak{A}$. *Furthermore, if* $e_0\in\mathfrak{A}$, *the algebra* $\mathfrak{A}'$ *is the unique nontrivial central extension of* $\mathfrak{A}$.

Proof: Up to an automorphism we can assume that $u=(1,0)$. Let a now denote the unique element of $I\backslash J$, which can be written $a=(a_1,1)$. Then it is obvious that for any element $y\in I\backslash J$ either $y+a+in I\backslash J$ or $y+a-(1,0)\in I\backslash J$. Using this description of the minimal distances in $I\backslash J$, one can repeat the proof of Twarock (2000a, Theorem III.4) word by word. □

The algebra $\mathfrak{A}$, constructed in Lemma 3, is a natural generalization of the aperiodic Virasoro algebra from Twarock (2000a). In particular, the aperiodic Virasoro algebra coincides with $\mathfrak{A}'$ for those $\mathfrak{A}$ constructed at the end of the previous section. However, if, e.g., the rank of P is bigger than 2, we get an example of $\mathfrak{A}'$, which differs from the aperiodic Virasoro algebra. We will call such algebras $\mathfrak{A}'$ *Virasoro-like algebras of quasicrystal type*.

By assigning to the element $\mathfrak{c}$ the index u we easily transfer the notions of parabolic and both standard and nonstandard triangular decompositions to the algebra $\mathfrak{A}'$. If P has rank 2, then, up to taking the opposite order, the nonstandard triangular decomposition of $\mathfrak{A}$, for which $\mathfrak{A}_0'$ contains e_u, is unique, and in the case of the aperiodic Virasoro algebra this coincides with the triangular decomposition, constructed in Twarock (2000a Sec. V). For the rank 2 case one can easily construct an example of $\mathfrak{A}'$ such that with respect to the unique natural nonstandard triangular decomposition mentioned above, $\dim(\mathfrak{A}_0')$ is an arbitrary positive integer. Hence even in the rank 2 case one gets a lot of examples of $\mathfrak{A}'$, which are different from the aperiodic Virasoro algebras. All these algebras will have discrete aperiodic root systems, and, if considered as graded by the action of e_0, all roots will be multiples with multiplicity $\dim(\mathfrak{A}_0')-2$. In the case of the aperiodic Virasoro algebra we have $\dim(\mathfrak{A}_0')=3$ and hence all roots (with nonzero action of e_0) are multiplicity free. We will discuss this situation in more detail in the next section, when we will define the Shapovalov form on the Verma modules and compute its determinant.

VI. SHAPOVALOV FORM AND KAC DETERMINANT

In this section we present several results on the structure of Verma modules over Lie and Virasoro-like algebras of quasicrystal type. As in the case of the Witt and the Virasoro algebras,

their representation theory is more complicated, which, in particular, gives a bigger variety of simple highest weight modules. Our main tool in the case of the Virasoro-like algebras of quasicrystal type and the corresponding Lie algebras of quasicrystal type will be the Shapovalov form on Verma modules, first defined in Shapovalov (1972) for simple finite-dimensional Lie algebras. However, we start with the more elementary general case of Lie algebras of quasicrystal type, which happens to be really trivial. Before starting we just note that in this section we always assume that $\mathbb{F}$ is an algebraically closed field of characteristic zero.

We recall that, given a triangular decomposition, $\mathfrak{A}=\mathfrak{A}_-\oplus\mathfrak{A}_0\oplus\mathfrak{A}_+$, a $\mathfrak{A}$-module, M, is called a *highest weight module*, if there exists a generator, $v\in M$, such that $\mathfrak{A}_+v=0$.

Proposition 2: All simple highest weight modules over Lie algebras of quasicrystal type, which correspond to a standard triangular decompositions with $\mathfrak{A}_0=\mathbb{F}e_x\mathfrak{C}[\mathfrak{A},\mathfrak{A}]$, *are one-dimensional. In particular, the corresponding Verma modules are always reducible*.

Proof: This is a direct consequence of $\mathfrak{A}_0=\mathbb{F}e_x$ and $e_x\notin[\mathfrak{A},\mathfrak{A}]$. □

Proposition 3: All Verma modules over a Lie algebra of quasicrystal type, which correspond to a standard triangular decompositions with $\mathfrak{A}_0=\mathbb{F}e_x\subset[\mathfrak{A},\mathfrak{A}]$, *are reducible. The corresponding unique simple quotients are one-dimensional if and only if the eigenvalue of* e_x *on the primitive generator of the module is zero. Otherwise they are infinite-dimensional*.

Proof: Let v be the canonical generator of the Verma module in question. The reducibility follows from the fact that x is not maximal in $I\backslash J$, and hence there are infinitely many elements $y\in P_-$ satisfying $e_x\notin[e_y,\mathfrak{A}]$, which implies that $U(\mathfrak{A})e_yv$ is a proper submodule of the Verma module.

The second statement follows considering the set of elements e_y, $y\in P_-$, satisfying $e_x\in[e_y,\mathfrak{A}]$, which is obviously infinite. □

So, we can now move on to the case of nonstandard triangular decompositions. First, we reduce our consideration to the natural case of weight modules with finite-dimensional weight spaces, which corresponds to the situation when the root system of $\mathfrak{A}$ is discrete. This is only possible in the case when $P\simeq\mathbb{Z}^2$. Here our main tool will be the Shapovalov form and to be able to work with it we will also need the following assumptions from the previous section: $e_0\in\mathfrak{A}$; and there is $e_u\in\mathfrak{A}$, such that $\sigma(u)=b$ and $\psi(u)=0$. As it was mentioned above, this situation covers, for example, the case of the aperiodic Witt algebra. Since in the case of the algebra $\mathfrak{A}'$ the arguments will be absolutely the same, we consider both cases simultaneously with all the notation for the algebra $\mathfrak{A}'$. The case of $\mathfrak{A}$ is then easily obtained by factoring $\mathfrak{c}=0$ out.

We define conjugation on P via $\omega(x)=u-x$ and it follows immediately from our assumptions that $e_x\in\mathfrak{A}'$ implies $e_{\omega(x)}\in\mathfrak{A}'$. However, it is easy to see that ω does not extend to an (anti)involution on $\mathfrak{A}'$. We note that $\sigma(\omega(x))=b-\sigma(x)$.

We recall that the algebra $\mathfrak{A}'$ is graded by the adjoint action of e_0 (or, more generally, $\mathfrak{A}_0'$) and for $\mathbb{C}\ni\alpha\neq0$ the dimension of $\mathfrak{A}_\alpha'$ is either 0 or $\dim(\mathfrak{A}_0')-2$ [$(\dim(\mathfrak{A}_0)-1$ in the case of the algebra $\mathfrak{A}$]. We denote by Δ the set of all (nonzero) roots of $\mathfrak{A}'$ with respect to this action and by $\Delta_\pm$ the sets of all positive and negative roots corresponding to our triangular decomposition. Obviously, ω extends to a linear bijection $\mathfrak{A}_\alpha'\to\mathfrak{A}_{-\alpha}'$ for any $\alpha\in\Delta\cup\{0\}$.

As $\mathfrak{A}_0'$ is commutative, simple $\mathfrak{A}_0'$-modules are one-dimensional and have the form V^λ, where λ is an element from the dual space $(\mathfrak{A}_0')^*$, and the action is defined via $g(v)=\lambda(g)v$ for $v\in V^\lambda$ and $g\in\mathfrak{A}_0'$. Let v_λ denote a canonical generator of $M(V^\lambda)$.

Let Δ' (resp. $\Delta_\pm'$) denote the semigroup, generated by Δ (resp. $\Delta_\pm$). Then the module $M(V^\lambda)$ is a weight module with respect to $\mathfrak{A}_0'$ with the support $\lambda\cup\lambda-\Delta_+'$. All weight spaces of $M(V^\lambda)$ are finite dimensional. Moreover, $M(V^\lambda)$ is isomorphic to $U(\mathfrak{A}_-')v_\lambda$ as a vector space.

The $\Delta_\pm$-gradation of $\mathfrak{A}_\pm'$ extends to the $\Delta_\pm'$-gradation of $U(\mathfrak{A}_\pm')$ and, in the antinvolutive way, ω extends to a linear componentwise isomorphism from $U(\mathfrak{A}_+')$ to $U(\mathfrak{A}_-')$ and back, which matches $U(\mathfrak{A}_+')_\alpha$ with $U(\mathfrak{A}_-')_{-\alpha}$.

For $\mu\in\mathrm{supp}(M(V^\lambda))$, $\mu=\lambda-\nu$, $\nu\in\Delta_+'$, we define the it *Shapovalov form* $F_{\lambda,\nu}$ on $M(V^\lambda)_\mu$ by setting that $F_{\lambda,\nu}(fv_\lambda,gv_\lambda)$, $f,g\in U(\mathfrak{A}_-')_{-\nu}$, equals the coefficient of $\omega(f)gv_\lambda\in M(V^\lambda)_\lambda$, written in the basis $\{v_\lambda\}$. The following properties of $F_\lambda=\oplus_{\nu\in\Delta'}F_{\lambda,\nu}$ are standard and the reader can consult Kac and Kazhdan (1979) and Moody and Pianzola (1995) for the arguments.

Lemma 4: (1.) $M(V^\lambda)$ *is simple if and only if* F_λ is nondegenerate. *(2.) The kernel of* F_λ *coincides with the unique maximal submodule of* $M(V^\lambda)$.

Hence in order to study the reducibility of $M(V^\lambda)$ it is sufficient to compute the determinant of $F_{\lambda,\nu}$ for all λ and ν. To be able to do this we consider the following monomial generators of $U(\mathfrak{A}'_-)_{-\nu}$: $\mathcal{G}=\mathcal{G}(\nu)=\{g(x_1,\ldots,x_k)=e_{x_1}\ldots e_{x_k}: x_i\in\Delta_-;\ \Sigma_i x_i=-\nu;\sigma(x_i)\leqslant\sigma(x_{i+1})\}$. We define the linear order $\preccurlyeq$ on this set of generators as the lexicographical order with respect to the values of $\sigma(x_i)$. The key property of this construction is the following.

Lemma 5: If $g(x_1,\ldots,x_k)\in\mathcal{G}$ *and* $g(y_1,\ldots,y_m)\in\mathcal{G}$ *are such that* $g(x_1,\ldots,x_k)\preccurlyeq g(y_1,\ldots,y_m)$, *then* $F_{\lambda,\nu}(g(x_1,\ldots,x_k)v_\lambda, g(y_1,\ldots,y_m)v_\lambda)=0$.

Proof: Consider the smallest index i such that $\sigma(x_i)<\sigma(y_i)$. Then $\sigma(\omega(x_i))>b-\sigma(y_i)$ and hence $e_{\omega(x_i)}$ commutes with e_{y_i} and thus with all e_{y_j}, $j\geqslant i$, since for such j we have $\sigma(y_j)\geqslant\sigma(y_i)$ from the definition of $\mathcal{G}$. For $j<i$ we have $x_j=u_j$ and thus $[e_{\omega(x_j)},e_{y_j}]\in\mathfrak{A}'_0$. We can write

$$e_{\omega(x_i)}(\omega(e_{x_1}\cdots e_{x_{i-1}})e_{y_1}\cdots e_{y_{i-1}})e_{y_i}\cdots e_{y_m}v_\lambda=\varepsilon(\omega(e_{x_1}\cdots e_{x_{i-1}})e_{y_1}\cdots e_{y_{i-1}})e_{\omega(x_i)}e_{y_i}\cdots e_{y_m}v_\lambda + \text{further terms}$$

for some $\varepsilon\in\mathbb{F}$, where in the further terms of the expansion some $e_{\omega(x_j)}$, $j<i$, occur already after the corresponding e_{y_j}. As $e_{\omega(x_i)}$ commutes with all e_{y_j}, $j\geqslant i$, we get that the first summand equals zero.

Now consider one of the *other terms* and let $e_{\omega(x_j)}$ be the factor occurring most to the right in the monomial. This means, in particular, that for $s<j$ this monomial contains $[e_{\omega(x_s)},e_{y_s}]$, which are the elements of $\mathfrak{A}'_0$ and thus, up to a scalar factor, can be moved to the left. In particular, $\sigma(\omega(x_s))$ is the biggest value among all others occurring in this monomial. If the element e_y, standing next to $e_{\omega(x_j)}$ satisfies $y\neq x_j$, this means that $e_{\omega(x_j)}$ commutes with e_y and hence the monomial contributes 0 to the global sum. Otherwise the number of factors, standing to the right from $e_{\omega(x_j)}$, which equal x_j, is less than the same number before the last commutation. Hence induction in this number reduces the problem to the case $y\neq x_j$, thus proving that all monomials occurring in *other terms* contribute 0 to the global sum.

From this it follows directly that $F_{\lambda,\nu}(g(x_1,\ldots,x_k)v_\lambda, g(y_1,\ldots,y_m)v_\lambda)=0$, which completes the proof. □

From Lemma 5 we immediately get the following statement, which, in particular, proves Twarock (2000a, Conjecture V.7).

Corollary 1: The determinant of $F_{\lambda,\nu}$ *coincides with the product of diagonal elements* $F_{\lambda,\nu}(g(x_1,\ldots,x_k)v_\lambda, g(x_1,\ldots,x_k)v_\lambda)$.

Now we can formulate explicit results for the determinant of the Shapovalov form and the corresponding corollaries for the structure of $M(V^\lambda)$. Denote by P' the set of all nonzero $x\in P$ such that $e_x\in\mathfrak{A}'$ is nonzero. Then the decomposition $\Delta=\Delta_-\cup\Delta_+$ induces a decomposition $P'=P'_-\cup P'_+$. For $\nu\in\Delta'_+$ and $x\in P'_-$ we denote by $p_\nu(x)$ the number of occurrences of e_x as factors in the canonical decomposition of all monomials in $\mathcal{G}(\nu)$.

Theorem 2: *Up to a nonzero constant the determinant of* $F_{\lambda,\nu}$ *equals*

$$\prod_{x\in P'_-}\left(\lambda(e_u)-\frac{\psi(x)^2-1}{24}\lambda(\mathfrak{c})\right)^{p_\nu(x)}.$$

Proof: According to Lemma 4, the corresponding determinant is the product of

$$F_{\lambda,\mu}(g(x_1,\ldots,x_k)v_\lambda, g(x_1,\ldots,x_k)v_\lambda)$$

over all $g(x_1,\dots,x_k)\in\mathcal{G}(\nu)$. First, for $x\in P'_-$ we observe that $[e_{u-x},e_u]=\psi(2x)e_u-[\psi(x)^3-\psi(x)/12]\mathfrak{c}$, as $\psi(u)=0$. Moreover, $[e_{u-x},e_u]$ is in fact central in $\mathfrak{A}'$. Hence, we can move the nonzero factor $2\psi(x)$ out and get that, up to a nonzero constant factor, we have

$$F_{\lambda,\mu}(g(x_1,\dots,x_k)v_\lambda,g(x_1,\dots,x_k)v_\lambda)=\prod_{i=1}^{k}\left(\lambda(e_u)-\frac{\psi(x_i)^2-1}{24}\lambda(\mathfrak{c})\right).$$

The general formula is now obtained by multiplying these expressions for all $g(x_1,\dots,x_k)\in\mathcal{G}(\nu)$. □

This theorem immediately implies the following structural result for $M(V^\lambda)$.

Corollary 2: $M(V^\lambda)$ is irreducible if and only if $24\lambda(e_u)\neq(\alpha^2-1)\lambda(\mathfrak{c})$ for all $\alpha\in\Delta'_-$.

Proof: Follows from Theorem 2 and the fact that we have $\psi(x)=\alpha$ provided that $x\in\mathfrak{A}'_\alpha$. □

In particular, we see that the reducibility of $M(V^\lambda)$ depends only on $\lambda(e_u)$ and $\lambda(\mathfrak{c})$ and does not depend on the values of λ on other generators of $\mathfrak{A}'_0$.

Let $\mathbb{F}=\mathbb{C}$. Call a $\mathfrak{A}'$-module, M, *ω-unitarizable* provided that there exists an inner product, $(\cdot,\cdot)$, on M such that $(e_xv,w)=(v,e_{\omega(x)}w)$ [resp. $(\mathfrak{c}v,w)=(v,\mathfrak{c}w)$] for all $v,w\in M$. For the unique simple quotient of the Verma module $M(V^\lambda)$ this is equivalent to the fact that the Shapovalov form on $M(V^\lambda)$ is non-negative (Of course, the Shapovalov form, being symmetric, cannot be considered as an inner product; however, one can consider it on the real part and extend to the complexification in the Hermitian way.) Here our determinant formula immediately implies the following unitarizability result.

Corollary 3: Assume that $\psi(P)\subset\mathbb{R}$ and $\psi(x)\leqslant-1$ for all $x\in P'_-$, $\lambda(e_u)\leqslant0$, $\lambda(c)\geqslant0$. Then the unique simple quotient of $M(V^\lambda)$ is ω-unitarizable.

Proof: Under these conditions all factors of the diagonal elements of the matrix of the Shapovalov form are non-negative and hence all leading minors are non-negative as well. This implies the statement. □

Using these results we also get some information about highest weight modules, associated with standard triangular decompositions.

Corollary 4: The dimensions of the weight spaces of infinite-dimensional highest weight modules over Lie algebras of quasicrystal type, associated with standard triangular decompositions, are not uniformly bounded.

Proof: Let $\mathfrak{A}_0=\mathbb{F}e_x$ be the zero component of the given standard triangular decomposition. Then we can factor our an ideal of $\mathfrak{A}$ such that the factor algebra is still of quasicrystal type, but the element x is maximal in the corresponding $I\backslash J$, and hence the induced triangular decomposition is nonstandard. Now we have $\lambda(e_x)\neq0$ and hence the corresponding Verma module over this algebra is simple and the dimensions of its weight spaces are obviously unbounded. But this module naturally embeds (as a vector subspace) into the simple highest weight module which we started with. □

VII. FURTHER GENERALIZATIONS OF QUASICRYSTAL LIE ALGEBRAS

Geometrical realization of the algebra $\mathfrak{A}$, obtained in Sec. IV, motivates the following generalization of the class of Lie algebras of quasicrystal type.

We consider an arbitrary rank n Witt algebra $\mathfrak{G}=\mathfrak{G}(P,\psi)$ with $P\simeq\mathbb{Z}^n$ being realized in $\mathbb{R}^n$ in a natural way. Let Ω be a convex subset of $\mathbb{R}^n$, containing at least one nonzero point of P, and satisfying the following it 0-*star* condition: $v\in\Omega$ implies $\lambda v\in\Omega$ for all $\lambda>1$. In this case we will call Ω a 0-*star set*. Denote by $L(\Omega)$ the vector subspace in $\mathfrak{G}$, spanned by e_x, $x\in\Omega$.

Lemma 6: $L(\Omega)$ is a Lie subalgebra of $\mathfrak{G}$.

Proof: If $x,y\in P\cap\Omega$, then $x+y=2(\frac{1}{2}x+\frac{1}{2}y)$. $\frac{1}{2}x+\frac{1}{2}y$ belongs to Ω because of convexity and thus $x+y\in\Omega$ by the 0-star condition. □

Lemma 7: Let Ω be a 0-star set, $v\in\Omega$ and $\lambda>0$. Then, if the set $\Omega_{\lambda,v}=\lambda v+\Omega$ contains at least one nonzero point of P, it is a 0-star set. Moreover, $\Omega_{\lambda,v}\subset\Omega$.

Proof: Clearly, $\Omega_{\lambda,v}$ is convex. Further, if $w\in\Omega$ and $\gamma>1$, then $\gamma(w+\lambda v)=\gamma(\lambda+1)\times([1/(\lambda+1)]w+[\lambda/(\lambda+1)]v)$ belongs to Ω by the same arguments as in Lemma 6. This completes the proof. □

Lemma 8: Let Ω be a 0-star set, $v\in\Omega$ and $\lambda>0$. Then $L(\Omega_{\lambda,v})$ is an ideal of $L(\Omega)$.

Proof: If $w\in\Omega$ and $w'=w''+v\in\Omega_{\lambda,v}$ for some $w''\in\Omega$, then $w+w'=w+w''+v\in\Omega_{\lambda,v}$. This implies the statement. □

Hence, for arbitrary $\mathfrak{G}$, Ω and v as above we can form the algebra $\mathfrak{A}(P,\psi,\Omega,\lambda,v)=L(\Omega)/L(\Omega_{\lambda,v})$, which we will call a *Lie algebra of convex quasicrystal type*. To obtain the usual Lie algebra of quasicrystal type, one should take Ω to be a half-space (open or closed), which does not contain 0 as an inner point. The basic properties of Lie algebras of convex quasicrystal type are similar to those of Lie algebra of quasicrystal type, however, their formulation is more complicated because it usually depends on the structure of Ω. Here we list only some most straightforward ones.

Proposition 4: Let $\mathfrak{A}=\mathfrak{A}(P,\psi,\Omega,\lambda,v)$ be a Lie algebra of convex quasicrystal type and let a denote the infimum over the distances of the points in $\Omega\cap P$ to 0. Assume that $\dim(\mathfrak{A})>1$ *and that for any $x\in\Omega$ some neighborhood (in $\mathbb{R}^n$) of $2x$ belongs to Ω. Then*

(1) if $a>0$, then any element of $\mathfrak{A}$ is nilpotent.
(2) $\mathfrak{A}$ is locally finite.

Proof: If $x\in S=\Omega\backslash\Omega_{\lambda,v}$, then there always exists y such that $|x-y|\leqslant|v|$ and such that $y\notin\Omega$. Let $w\in\Omega$. If some ball of radius r about $2w$ belongs to Ω, then for $\lambda>1$ the point $2\lambda w$ belongs to Ω together with the ball of radius λr around it. Making $\lambda r>|v|$ we get that $2\lambda w\in\Omega_{\lambda,v}$. This implies the first statement.

If the set $\{w_1,\ldots,w_k\}\subset\Omega$ is finite, then we find some r such that $2w_i$ belongs to Ω together with its ball of radius r about $2w_i$. Then the same is true for all linear combinations of these elements with non-negative integer coefficients. By the same arguments as in the previous paragraph, there exists $N\in\mathbb{N}$ such that any linear combination of $\{Nw_1,\ldots,Nw_k\}$ with non-negative integer coefficients belongs to $\Omega_{\lambda,v}$. This implies the second statement. □

Let us study an example of such an algebra, which, as we will show, has some interesting properties. Take $P=\mathbb{Z}^2$, ψ the projection onto the second component, $\Omega=\{w\in\mathbb{R}^2:(w,(1,1))\geqslant 0$ and $(w,(1,-1))\geqslant 0\}$, $v=(n+\epsilon,0)$, $n\in\mathbb{N}$, $\epsilon\in(0,1)$. The corresponding algebra $\mathfrak{A}=\mathfrak{A}(P,\psi,\Omega,\lambda,v)$ is graded with respect to the e_0 action with graded components corresponding to all integers and having dimension n. In particular, one can define and study triangular (parabolic) decompositions of this algebra and corresponding (generalized) Verma modules. The set $P'=P\cap(\Omega\backslash\Omega_{\lambda,v})$ coincides with $\{(a,b):0\leqslant a-|b|\leqslant n\}$. Define the conjugation ω on this set via $\omega(a,b)=(2|b|+n-a,-b)$. Then we have the natural notions of Verma modules and the Shapovalov form on them. In our situation we have $\Delta_+=\mathbb{N}$.

Lemma 9: The Verma module $M(V^\lambda)$ is always reducible. However, the unique simple quotient of $M(V^\lambda)$ is infinite dimensional if and only if at least one of the numbers $\lambda(e_{(2,0)}),\ldots,\lambda(e_{(n,0)})$ is nonzero. Otherwise it is one-dimensional.

Proof: We note that the intersection of $[\mathfrak{A},\mathfrak{A}]$ with $\mathfrak{A}_0$ coincides with the linear span $\tilde{\mathfrak{A}}_0$ of elements $\{e_{(2,0)},\ldots,e_{(n,0)}\}$. Hence, if the restriction of λ to $\tilde{\mathfrak{A}}_0$ is zero, the Shapovalov form is identically zero on all $M(V^\lambda)_{\lambda-k}$, $k\in\mathbb{N}$.

Otherwise, assume that $\lambda(e_{(i,o)})\neq 0$ and take $e_x\in\mathfrak{A}_1$ and $e_y\in\mathfrak{A}_{-1}$ such that $[e_x,e_y]=e_{(i,0)}$. We get $F_{\lambda,k}(e^k_{\omega(y)},e^k_x)\neq 0$ and the statement is proved. □

From Lemma 9 it follows that there exists a large family of infinite-dimensional highest weight modules over $\mathfrak{A}$ with respect to this triangular decomposition. The study of the properties of these modules, e.g., their characters, multiplicities and unitarizability seems to be an interesting problem.

VIII. APPLICATION TO THE *q*-ANALOG OF THE VIRASORO ALGEBRAS

All constructions described above work perfectly also in the case of different quantum analogs of the Virasoro algebra [and, actually, in the case of arbitrary $\mathbb{Z}^n$-graded Lie algebra, in particular,

everything works smoothly for generalized Witt algebras in the sense of Kaplansky (see Ree, 1956)]. As we saw that the most interesting case is that of rank 2, we would like to finish this article with outlining some results related to the q-analog of the Virasoro algebra, defined in Kirkman *et al.* (1994). Let $\mathbb{F}=\mathbb{C}$ and $q\in\mathbb{C}$ be such that $q\neq 0$ and q is not a root of unity. We set $P=\mathbb{Z}^2$ and will write an element, $x\in P$, as $x=(x_1,x_2)$. Then the algebra $\mathcal{V}_q$ is generated by e_x, $x\in P\backslash\{(0,0)\}$, with the Lie brackets defined via $[e_x,e_y]=(q^{x_2y_1}-q^{x_1y_2})e_{x+y}$. For $<$, I and J as in Sec. IV, we define the algebra $\mathfrak{A}(\mathcal{V}_q,<,I,J)$ in the same way as for $\mathfrak{A}(P,<,I,J)$ but using the algebra $\mathcal{V}_q$ instead of the rank 2 Virasoro algebra. We extend the algebra $\mathfrak{A}(P,<,I,J)$ by a derivation, d, satisfying $[d,e_x]=x_1e_x$, and will denote the extended algebra also by $\mathfrak{A}(P,<,I,J)$. The element d will always belong to $\mathfrak{A}_0$ in any parabolic decomposition and the notions of standard triangular and triangular decompositions are transfered modulo d. We will also assume that $I=P_+$ and that $I\backslash J$ has the maximal element u.

Theorem 3:

(1) Any parabolic decomposition of $\mathfrak{A}(\mathcal{V}_q,\leqslant,I,J)$ is in fact a triangular decomposition.
(2) All Verma modules over $\mathfrak{A}(\mathcal{V}_q,\leqslant,I,J)$ associated with a triangular decomposition satisfying $e_u\notin\mathfrak{A}_0$ are reducible.
(3) The unique simple quotient of a Verma module, $M(V^\lambda)$, is one-dimensional if and only if $\lambda(e_x)=0$ for all $e_x\in\mathfrak{A}_0$. Otherwise it is infinite-dimensional.
(4) The Verma module $M(V^\lambda)$ associated with a triangular decomposition satisfying $e_u\in\mathfrak{A}_0$ is simple if and only if $\lambda(e_u)\neq 0$.
(5) If q is real and the dimension of the unique simple quotient of $M(V^\lambda)$ is greater that one, this module is not ω-unitarizable and the dimensions of its weight spaces are not bounded.

Proof: The first statement follows from the fact that $[e_x,e_y]=0$ in $\mathcal{V}_q$ provided that $x=\lambda y$. The second and the third ones are analogous to Proposition 3. For the fourth statement we can use the arguments of Lemma 5 and derive that the determinant of the Shapovalov form on $M(V^\lambda)_\mu$ is the product of factors of the form $q^{-x_2x_1}(q^{u_2x_1}-q^{u_1x_2})\lambda(e_u)$. Since $x\in P'_-$ and u cannot be proportional, we derive that this factor is nonzero if and only if $\lambda(e_u)\neq 0$, which implies the fourth statement. The first part of the last statement follows from the observation that for any real q we can always find $x\in P'$, arbitrary small with respect to $<$, such that $q^{u_2x_1}-q^{u_1x_2}$ is positive (resp. negative) and the second part is analogous to Corollary 4. □

Static Bloch sums for the square array

R. C. McPhedran[a] and N. A. Nicorovici
School of Physics, University of Sydney, New South Wales 2006, Australia

(Received 30 January 2002; accepted for publication 11 February 2002)

We consider sums arising in doubly quasiperiodic Green's functions for the Laplace equation, over the square array. The sums are represented as Fourier series, and it is shown that the coefficients in the series can be obtained as polynomials. We give expressions from which the first six array sums can be evaluated efficiently, and accurate to better than one part in 10^7, over most of the Brillouin zone. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1467968]

I. INTRODUCTION

Lattice sums for Laplace's equation have a long history, as discussed by Glasser and Zucker.[1] They were introduced into physics by Appell,[2] and important contributions to sums for arrays and lattices were made by Rayleigh in 1892.[3] Glasser and Zucker discuss the many investigations relating to Madelung sums in solid state physics, and numerical methods of summation related to Ewald's method.[4] They also stress the value of sums which can be evaluated in closed form.

Here, we wish to consider a class of sums for the square array, which can be developed in the form of rapidly convergent Fourier series, with coefficients which are polynomials in form. The sums in question appear not to have been considered in two dimensions before, but they are close in form to lattice sums studied by Born and Bradburn.[5] They differ from the multipole sums of Rayleigh and subsequent authors by the insertion of a Bloch factor, depending on a wave vector or crystal momentum $\mathbf{k}_0$. Such a factor would arise in a study of electrostatic problems, in the quasistatic limit, involving arrays of inclusions with dielectric constant modulated by a plane wave optical beam, for example. We analyze the sums in Fourier series according to the angle θ_0 specifying the direction of $\mathbf{k}_0$. The Fourier coefficients depend on the magnitude k_0 in a way we show is given by array sums calculated in closed form by Nicorovici *et al.*[6]

We show that these Fourier series converge rapidly, and exhibit formulas for the first seven, most slowly convergent of the sums. These formulas can be used to calculate the sums over most of the Brillouin zone to an accuracy better than one part in 10^7.

II. BLOCH SUMS AND FOURIER SERIES

We consider the following two-dimensional lattice sums:

$$\sigma_l(\mathbf{k}_0)=\sum_{p\neq 0}\frac{\exp(il\varphi_p)}{R_p^l}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}. \tag{1}$$

Here we sum over a two-dimensional array specified by points $\mathbf{R}_p=(R_p,\varphi_p)$, the latter being the polar representation. The exponential term containing $\mathbf{k}_0$ will be recognized as a Bloch factor, with $\mathbf{k}_0$ being the crystal momentum. We specify in polar form $\mathbf{k}_0=(k_0,\theta_0)$. We will be interested primarily in sums of order l in the range zero to six. The sums for orders $l>6$ can be easily evaluated by direct summation.

We relate the static sums (1) to corresponding dynamic forms arising for the Helmholtz equation:

[a]Electronic mail: ross@physics.usyd.edu.au

$$S_l^Y(k,\mathbf{k}_0)=\sum_{p\neq 0} Y_l(kR_p)\, e^{il\varphi_p}\, e^{i\mathbf{k}_0\cdot\mathbf{R}_p}, \tag{2}$$

for which we know that[7]

$$S_l^Y(k,\mathbf{k}_0)J_l(k\xi)=-Y_0(k\xi)\,\delta_{l,0}-\frac{4i^l}{A}\sum_h \frac{J_l(Q_h\xi)}{Q_h^2-k^2}e^{il\theta_h}. \tag{3}$$

Here the sum is carried out over the reciprocal array of vectors $\mathbf{K}_h$, and $\mathbf{Q}_h=\mathbf{K}_h+\mathbf{k}_0=(Q_h,\theta_h)$. Also, A denotes the area of the unit cell in the direct lattice.

If we take the limit as $k\to 0$ in (2), we find for $l\neq 0$,

$$\lim_{k\to 0}\left[\frac{-\pi}{(l-1)!}\left(\frac{k}{2}\right)^l S_l^Y(k,\mathbf{k}_0)\right]=\sum_{p\neq 0}\frac{\exp(il\varphi_p)}{R_p^l}e^{i\mathbf{k}_0\cdot\mathbf{R}_p}=\sigma_l(\mathbf{k}_0). \tag{4}$$

Then, by substituting (3) in (4), we obtain

$$\sigma_l(\mathbf{k}_0)=\frac{4\pi l i^l}{A\xi^l}\sum_h \frac{J_l(Q_h\xi)}{Q_h^2}e^{il\theta_h}, \tag{5}$$

where ξ is an arbitrary length, no longer than the distance from the origin to the nearest point on the unit cell boundary in direct space. This expression can be accelerated by successive integration,[7] and forms one method for evaluating the static Bloch sums.

We write the definition (1) in the form

$$\sigma_l(\mathbf{k}_0)=\sum_{p\neq 0}\frac{\exp(il\varphi_p)}{R_p^l}e^{ik_0R_p\cos(\theta_0-\varphi_p)}, \tag{6}$$

and expand the second exponential factor to give

$$\sigma_l(\mathbf{k}_0)=\sum_{p\neq 0}\frac{\exp(il\varphi_p)}{R_p^l}\sum_q i^q J_q(k_0R_p)e^{iq(\theta_0-\varphi_p)}. \tag{7}$$

Hence, if we write $\sigma_l(\mathbf{k}_0)$ in the form of an angular Fourier series

$$\sigma_l(\mathbf{k}_0)=\sum_q c_q^l(k_0)e^{iq\theta_0}, \tag{8}$$

we can identify the coefficients as

$$c_q^l(k_0)=i^q\sum_{p\neq 0}\frac{J_q(k_0R_p)}{R_p^l}\exp^{i(l-q)\varphi_p}. \tag{9}$$

We now specialize to the case of a square array of period d. Then the array sums in (9) are nonzero only if the integer $l-q$ is divisible by four. This is a direct consequence of the C_{4v} symmetry of the array: the sums (9) remain unchanged under rotations of $\pi/2$.

We compare the array sums with the dimensionless sums studied by Nicorovici *et al.*:[6]

$$\mathcal{S}_{l,4m,n}(\xi/D)=\frac{1}{D^n}\sum_{h\neq 0}\frac{J_l(K_h\xi)}{K_h^n}e^{i4m\psi_h}, \tag{10}$$

where $K_h=(2\pi/D)(h_1,h_2)$ runs over the reciprocal array (itself a square array) to a square array of period D. Given that $R_p=d(p_1,p_2)$, we see that

$$c_q^l(k_0) = i^q \left(\frac{2\pi}{d}\right)^l \mathcal{S}_{q,l-q,l}\left(\frac{k_0 d}{2\pi}\right), \tag{11}$$

where $l-q$ must be divisible by four for the sum to be nonzero.

Using (11) in (8), we obtain

$$\sigma_l(\mathbf{k}_0) = \left(\frac{2\pi i}{d}\right)^l \sum_{m=-\infty}^{\infty} \mathcal{S}_{l-4m,4m,l}\left(\frac{k_0 d}{2\pi}\right) e^{i(l-4m)\theta_0}. \tag{12}$$

III. THE LOWEST SUM AND ITS CONSEQUENCES

$$\sigma_0(\mathbf{k}_0) = \sum_{p\neq 0} e^{i\mathbf{k}_0\cdot\mathbf{R}_p} = \sum_m \mathcal{S}_{4m,4m,0}\left(\frac{k_0 d}{2\pi}\right) e^{-4im\theta_0}, \tag{13}$$

for the square array. Now,

$$\sum_{p\neq 0} e^{i\mathbf{k}_0\cdot\mathbf{R}_p} = \frac{4\pi^2}{A}\sum_h \delta(\mathbf{k}_0 - K_h) - 1 = \frac{4\pi^2}{A}\delta(\mathbf{k}_0) - 1, \tag{14}$$

for $\mathbf{k}_0$ in the Brillouin zone. Evaluating the Fourier coefficients of the delta function, we find

$$\mathcal{S}_{4m,4m,0}(\xi/D) = \left[\frac{1}{2\pi}\frac{\delta(\xi/D)}{\xi/D} - 1\right]\delta_{m,0}. \tag{15}$$

Hence, the Fourier series for σ_0 reduces to a single, distributive term:

$$\sigma_0(\mathbf{k}_0) = \frac{2\pi}{k_0 d^2}\delta(k_0) - 1, \tag{16}$$

for $\mathbf{k}_0$ in the first Brillouin zone.

We can use the result (15) to build up analytic formulas for those lattice sums $\mathcal{S}_{l,m,n}$ for which the index sum $l+m+n$ is even. We can increase the indices l and n using the following formula:[6]

$$\int_0^{\xi} \eta^{l+1}\mathcal{S}_{l,m,n}(\eta)\,\mathrm{d}\eta = \xi^{l+1}\mathcal{S}_{l+1,m,n+1}(\xi), \tag{17}$$

working in dimensionless variables (i.e., replacing ξ/D by ξ in working). This gives, used once,

$$\mathcal{S}_{4m+1,4m,1}(\xi/D) = \left[\frac{D}{2\pi\xi} - \frac{\xi}{2D}\right]\delta_{m,0}. \tag{18}$$

Continuing this process, for $l \geqslant 1$, we obtain

$$\mathcal{S}_{4m+l,4m,l}(\xi/D) = \frac{1}{(2l)!!}\left[\frac{l}{\pi}\left(\frac{\xi}{D}\right)^{l-2} - \left(\frac{\xi}{D}\right)^l\right]\delta_{m,0}, \tag{19}$$

where $(2l)!! = 2l(2l-2)(2l-4)\ldots 2$.

The result (19) is very useful. It guarantees that all negative m terms in the expansion (12) are zero, and also gives the term $m=0$:

$$\sigma_l(\mathbf{k}_0) = \left(\frac{2\pi i}{d}\right)^l \left\{\frac{1}{(2l)!!}\left[\frac{l}{\pi}\left(\frac{k_0 d}{2\pi}\right)^{l-2} - \left(\frac{k_0 d}{2\pi}\right)^l\right] + \sum_{m\geqslant 1}^{\infty} \mathcal{S}_{l-4m,4m,l}\left(\frac{k_0 d}{2\pi}\right) e^{-4im\theta_0}\right\} e^{il\theta_0}. \tag{20}$$

We can extend these results, using[6]

$$\mathcal{S}_{l+1,m,n-1}(\xi) = -\xi^l[\xi^{-l}\mathcal{S}_{l,m,n}(\xi)]', \tag{21}$$

with the prime denoting differentiation. Using this once with (19), we obtain for $l \geqslant 1$,

$$\mathcal{S}_{4m+l+1,4m,l-1}(\xi/D) = \frac{2}{2\pi(2l-2)!!}\left(\frac{\xi}{D}\right)^{l-3}\delta_{m,0}. \tag{22}$$

Thus, the sum for $m=0$ is singular at $\xi=0$ for $l=1,2$, and regular for $l>3$. Using (21) a second time, we have for $l \geqslant 2$

$$\mathcal{S}_{4m+l+2,4m,l-2}(\xi/D) = \frac{2\times 4}{2\pi(2l-2)!!}\left(\frac{\xi}{D}\right)^{l-4}\delta_{m,0}. \tag{23}$$

Generalizing, we find for an arbitrary positive integer p

$$\mathcal{S}_{4m+l+p,4m,l-p}(\xi/D) = \frac{(2p)!!}{2\pi(2l-2)!!}\left(\frac{\xi}{D}\right)^{l-p-2}\delta_{m,0}. \tag{24}$$

Three simple double sums which are particular cases of the above-given results are

$$\sum_h J_0(K_h\xi) = \sum_{h_1,h_2=-\infty}^{\infty} J_0[2\pi(\xi/D)\sqrt{h_1^2+h_2^2}] = \frac{\delta(\xi/D)}{2\pi\xi/D}, \tag{25}$$

$$\sum_h J_2(K_h\xi) = \frac{1}{\pi}\left(\frac{D}{\xi}\right)^2, \tag{26}$$

and

$$\sum_h J_4(K_h\xi) = \frac{2}{\pi}\left(\frac{D}{\xi}\right)^2. \tag{27}$$

The general form is

$$\sum_h J_{2l}(K_h\xi) = \frac{l}{\pi}\left(\frac{D}{\xi}\right)^2. \tag{28}$$

We give numerical confirmation of the results (26) and (27) in Fig. 1. Note that the averages of the numerical sums over the ranges shown are 1.2737 and 2.5483; the analytic values are $4/\pi \simeq 1.2732$ and $8/\pi \simeq 2.5465$, respectively. Thus, even though the raw sums in Fig. 1 oscillate rapidly, their average over a large ensemble of regions of summation can be used as a good indicator of the correct value.

IV. ANALYTIC FORMS FOR THE FOURIER SERIES

We will now assemble the series for the σ_l, with $l>0$. Note that, in this section, we will use the notations $\tau=\xi/D$ and $\kappa=k_0d/2\pi$ to simplify the formulas.

We first consider the case $l=1$. The sums we require are then of the form $\mathcal{S}_{1-4m,4m,1} = -\mathcal{S}_{4m-1,4m,1}$, and can be evaluated using the following general expression:[6]

$$\mathcal{S}_{l-4m,4m,l}(\tau) = \frac{(-1)^l(4m-l)!}{\pi 2^l(l-1)!}\sum_{s=0}^{l-1}\frac{(4m+1-l)_s(1-l)_s}{s!(s+4m-l)!}\sigma^{(4m)}_{2s+4m-2l+2}\,\tau^{2s+4m-l} - \frac{1}{l!}\left(\frac{\tau}{2}\right)^l\delta_{l,2m}. \tag{29}$$

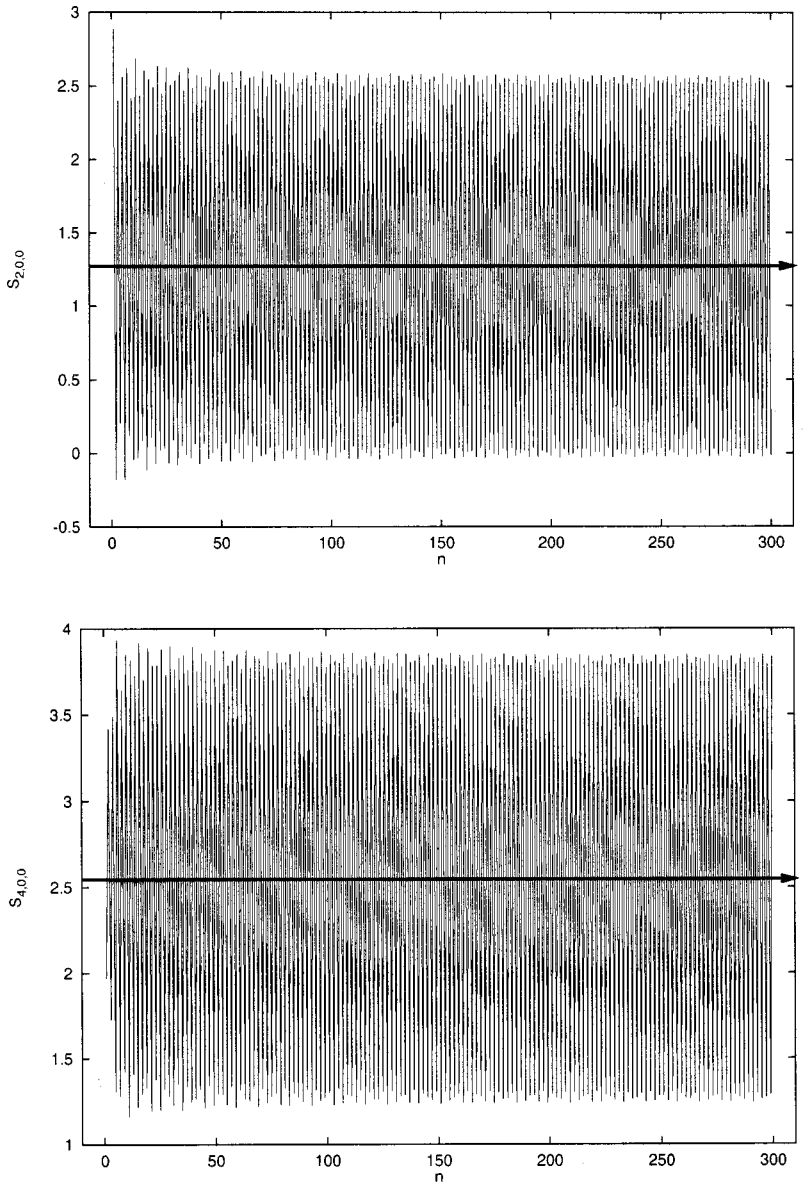

FIG. 1. The sums (26) (above) and (27) (below) as a function of the size of the square summation region. The analytic results are indicated by the arrows.

Here we have used the Pochhammer symbol: $(a)_0=1$, $(a)_s=a(a+1)\cdots(a+s-1)$, and the quantities $\sigma_n^{(m)}$ are lattice sums with no Bloch factor:

$$\sigma_n^{(m)}-\frac{2\pi}{m}\delta_{n,2}=\sum_{p\neq 0}\frac{\exp(im\varphi_p)}{R_p^n}. \tag{30}$$

They are nonzero unless m is a multiple of four, except for $n=2$, when they are conditionally convergent. If $n=2$, we denote the left-hand side of (30) by $\tilde{\sigma}_n^{(m)}$, which has the effect of combining together the Kronecker delta term in (29) with the term $s=0$ from the sum. The necessary sums for $l=1$ require only one term in (29):

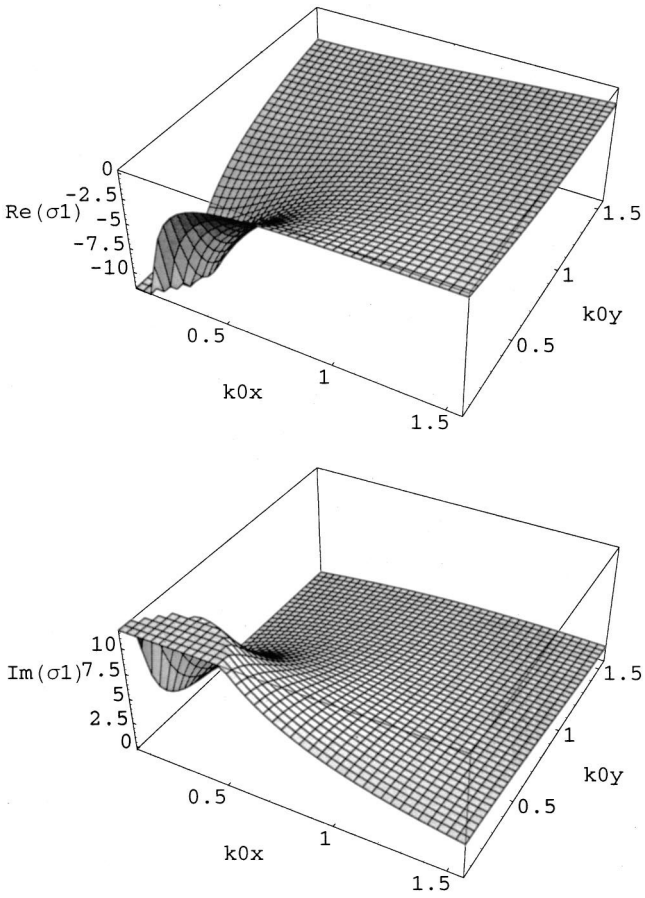

FIG. 2. Real part (above) and imaginary part (below) of σ_1 in the Brillouin zone.

$$\mathcal{S}_{1-4m,4m,1}(\tau)=-\frac{\sigma_{4m}^{(4m)}}{2\pi}\tau^{4m-1}. \tag{31}$$

The result (31) enables us to derive the desired series for σ_1:

$$\sigma_1(\mathbf{k}_0)=\frac{i}{d}\left(\frac{1}{\kappa}-\pi\kappa-\sum_{m=1}^{\infty}\sigma_{4m}^{(4m)}\kappa^{4m-1}e^{-4im\theta_0}\right)e^{i\theta_0}. \tag{32}$$

We have derived this expression in another way, using a result given by Glasser,[8] expressing

$$\Phi=\sum_{k\neq 0}\frac{\exp(i\mathbf{k}\cdot\mathbf{S})}{k^2}, \tag{33}$$

a two-dimensional sum over a square or rectangular array, in terms of the logarithm of the Jacobi theta function θ_1. From Glasser's result, we may obtain σ_1 by application of the complex gradient operator $\partial/\partial k_{0x}+i\partial/\partial k_{0y}$. Figure 2 shows the variation of σ_1 in the first quadrant of the Brillouin zone, with the singularity at the origin or Γ point the most prominent feature.

We next consider $l=2$. Here,

$$\mathcal{S}_{2-4m,4m,2}(\tau)=S_{4m-2,4m,2}(\tau), \tag{34}$$

and, using (29),

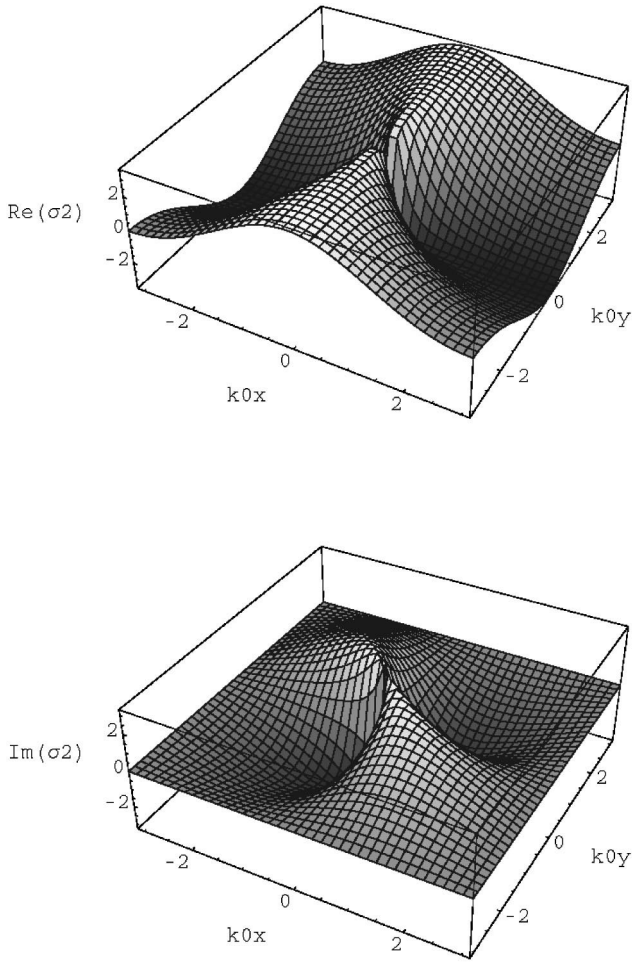

FIG. 3. Real part (above) and imaginary part (below) of σ_2 in the Brillouin zone.

$$\mathcal{S}_{2-4m,4m,2}(\tau)=\frac{1}{4\pi}(\sigma_{4m-2}^{(4m)}\tau^{4m-2}-\sigma_{4m}^{(4m)}\tau^{4m})-\frac{1}{2}\left(\frac{\tau}{2}\right)^2\delta_{m,1}. \tag{35}$$

Using (35) in (20), we obtain

$$\sigma_2(\mathbf{k}_0)=\frac{-\pi}{d^2}\left\{1-\frac{\pi}{2}\kappa^2+\sum_{m=1}^{\infty}\left[\left(\sigma_{4m-2}^{(4m)}-\frac{\pi}{2}\delta_{m,1}\right)\kappa^{4m-2}-\sigma_{4m}^{(4m)}\kappa^{4m}\right]e^{-4im\theta_0}\right\}e^{2i\theta_0}. \tag{36}$$

We have attempted to derive this expression from Glasser's results, but the algebra involved is considerably more involved than in the case $l=1$. Figure 3 shows the variation of σ_2 across the Brillouin zone; note the nonanalytic nature of the behavior near Γ, evident from the form of (36).

If $l\geqslant 3$, special sums occur in (20) which cannot be evaluated using the general form (29). For $l=3$, the only special sum is

$$\mathcal{S}_{-1,4,3}(\tau)=-\mathcal{S}_{1,4,3}(\tau)=-\left[\frac{1}{(2\pi)^2}\tilde{\sigma}_2^{(4)}\frac{\tau}{2}-\frac{1}{\pi}\tilde{\sigma}_2^{(4)}\left(\frac{\tau}{2}\right)^3+\frac{2}{\pi}\sigma_4^{(4)}\left(\frac{\tau}{2}\right)^5\right], \tag{37}$$

where $\tilde{\sigma}_2^{(4)}=\sigma_2^{(4)}-\pi/2$. The third order sum is

$$\sigma_3(\mathbf{k}_0)=\left(\frac{2\pi i}{d}\right)^3\left[\frac{1}{16\pi}\kappa-\frac{1}{48}\kappa^3-\mathcal{S}_{1,4,3}(\kappa)\,e^{-4i\theta_0}-\sum_{m=2}^{\infty}\mathcal{S}_{4m-3,4m,3}(\kappa)\,e^{-4im\theta_0}\right]e^{3i\theta_0}. \tag{38}$$

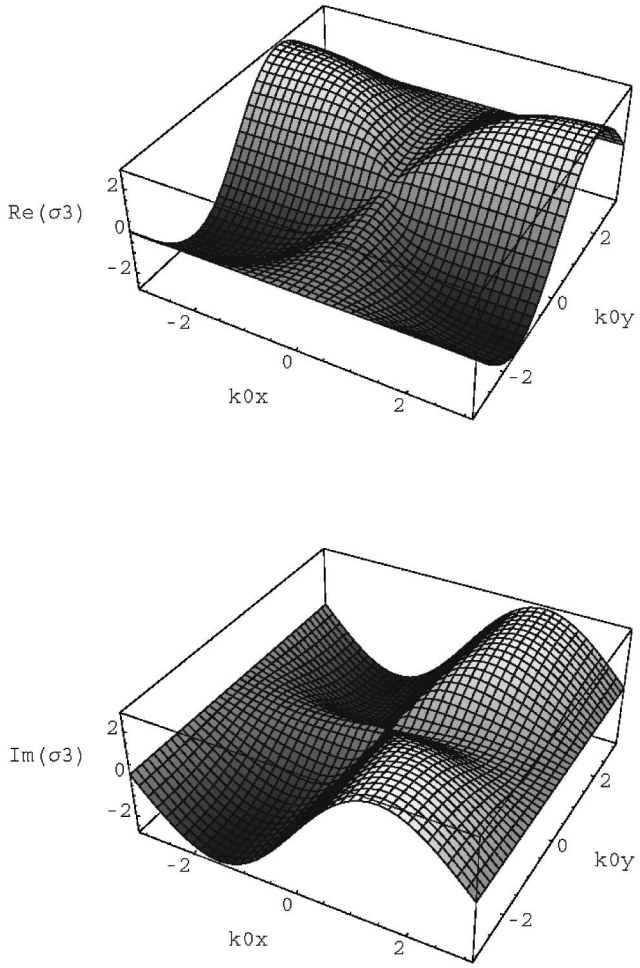

FIG. 4. Real part (above) and imaginary part (below) of σ_3 in the Brillouin zone.

We show the variation of σ_3 across the Brillouin zone in Fig. 4. The sum is now continuous at Γ.

For $l=4$, we require

$$\mathcal{S}_{0,4,4}(\tau)=\frac{1}{(2\pi)^4}\sigma_4^{(4)}-\frac{1}{(2\pi)^2}\tilde{\sigma}_2^{(4)}\left(\frac{\tau}{2}\right)^2+\frac{1}{2\pi}\tilde{\sigma}_2^{(4)}\left(\frac{\tau}{2}\right)^4-\frac{2}{3\pi}\sigma_4^{(4)}\left(\frac{\tau}{2}\right)^6. \tag{39}$$

The fourth-order sum consequently is

$$\sigma_4(\mathbf{k}_0)=\left(\frac{2\pi i}{d}\right)^4\left[\frac{1}{384}\left(\frac{4}{\pi}\kappa^3+\kappa^4\right)+\mathcal{S}_{0,4,4}(\kappa)\,e^{-4i\theta_0}+\sum_{m=2}^{\infty}\mathcal{S}_{4m-4,4m,4}(\kappa)\,e^{-4im\theta_0}\right]e^{4i\theta_0}. \tag{40}$$

We show the variation of σ_4 across the Brillouin zone in Fig. 5.

For $l=5$, the special sums are

$$\mathcal{S}_{1,4,5}(\tau)=\frac{1}{(2\pi)^4}\sigma_4^{(4)}\frac{\tau}{2}-\frac{1}{8\pi^2}\tilde{\sigma}_2^{(4)}\left(\frac{\tau}{2}\right)^3+\frac{1}{6\pi}\tilde{\sigma}_2^{(4)}\left(\frac{\tau}{2}\right)^5-\frac{1}{6\pi}\sigma_4^{(4)}\left(\frac{\tau}{2}\right)^7, \tag{41}$$

and

$$\mathcal{S}_{3,8,5}(\tau)=\frac{\tau^3}{768\,\pi^2}[\,\pi^2\,\tau^2+\pi\,\tau^2\,(-4\,\sigma_2^{(8)}+6\,\tau^2\,\sigma_4^{(8)}-4\,\tau^4\,\sigma_6^{(8)}+\tau^6\,\sigma_8^{(8)})+4\,\tilde{\sigma}_2^{(8)}], \tag{42}$$

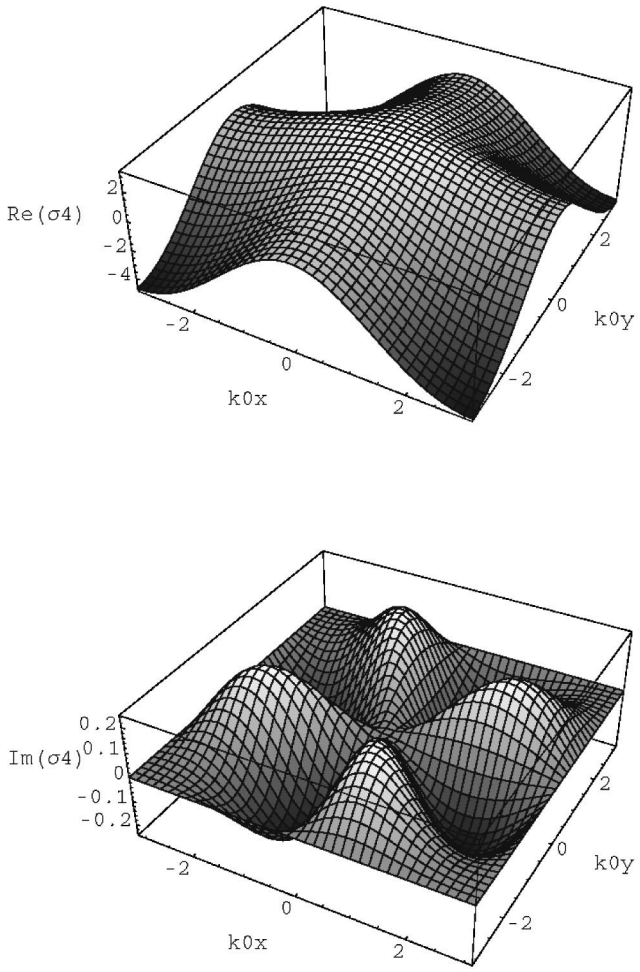

FIG. 5. Real part (above) and imaginary part (below) of σ_4 in the Brillouin zone.

where $\tilde{\sigma}_2^{(8)}=\sigma_2^{(8)}-\pi/4$. So, the fifth-order sum is

$$\sigma_5(\mathbf{k}_0)=\left(\frac{2\pi i}{d}\right)^5\left[\frac{1}{3840}\left(\frac{5}{\pi}\kappa^3-\kappa^5\right)+\mathcal{S}_{1,4,5}(\kappa)\,e^{-4i\theta_0}-\sum_{m=2}^{\infty}\mathcal{S}_{4m-5,4m,5}(\kappa)\,e^{-4im\theta_0}\right]e^{5i\theta_0}. \tag{43}$$

We show the variation of σ_5 across the Brillouin zone in Fig. 6.

Lastly, for $l=6$, we need

$$\mathcal{S}_{2,4,6}(\tau)=\frac{\tau^2}{7680\,\pi^4}[(60-\pi^3\,\tau^6)\,\sigma_4^{(4)}+5\,\pi^2\,\tau^2\,(-4+\pi\,\tau^2)\,\tilde{\sigma}_2^{(4)}], \tag{44}$$

and

$$\mathcal{S}_{2,8,6}(\tau)=\frac{-\tau^2}{15\,360\,\pi^4}[5\,\pi^4\,\tau^4-120\,\sigma_4^{(8)}+2\,\pi^3\,\tau^4\,(-10\,\sigma_2^{(8)}+10\,\tau^2\,\sigma_4^{(8)}-5\,\tau^4\,\sigma_6^{(8)}+\tau^6\,\sigma_8^{(8)})$$
$$+40\,\pi^2\,\tau^2\,\tilde{\sigma}_2^{(8)}]. \tag{45}$$

So, the sixth-order sum is

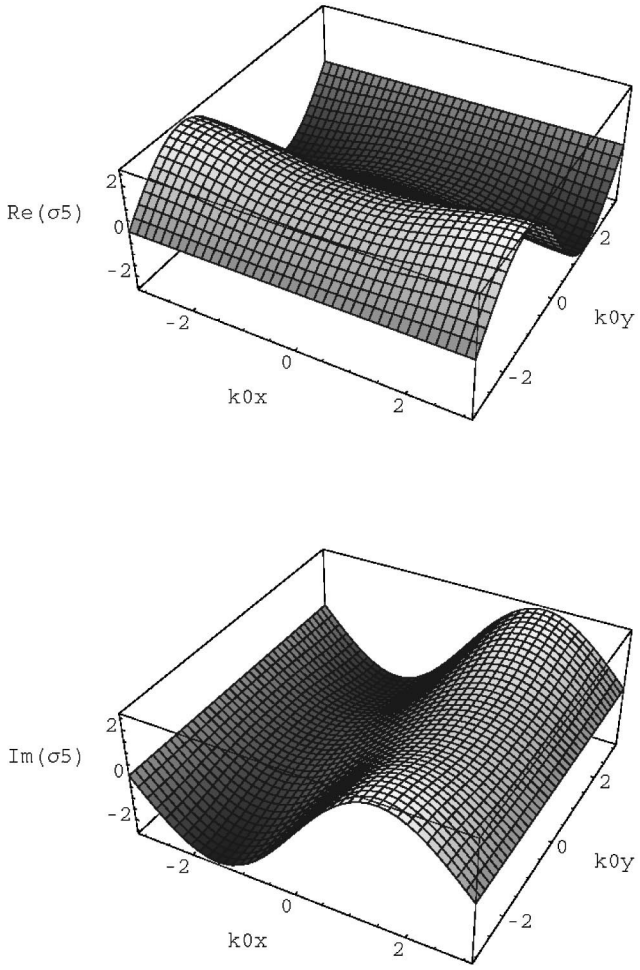

FIG. 6. Real part (above) and imaginary part (below) of σ_5 in the Brillouin zone.

$$\sigma_6(\mathbf{k}_0)=\left(\frac{2\pi i}{d}\right)^6\left[\frac{1}{46\,080}\left(\frac{6}{\pi}\kappa^4+\kappa^6\right)+\mathcal{S}_{2,8,6}(\kappa)e^{-4i\theta_0}+\sum_{m=2}^{\infty}\mathcal{S}_{4m-6,4m,6}(\kappa)e^{-4im\theta_0}\right]e^{6i\theta_0}. \tag{46}$$

We show the variation of σ_6 across the Brillouin zone in Fig. 7.

One interesting trend evident in Figs. 1–6 is that σ_l tends to become increasingly smooth in its angular variation with increasing l. The prefactor $\exp(il\theta_0)$ might suggest the contrary, but in fact the dominant contribution comes from $m=1$, not $m=0$, i.e., the angular variation goes as $\exp[i(l-4)\theta_0]$ for moderate l.

The figures in this section were calculated with expansions running up to $m=6$. The necessary static lattice sums $\sigma_n^{(m)}$ are given to ten figures accuracy in Table I; some of these have previously been tabulated by Movchan *et al.*,[9] Helsing,[10] and Berman and Greengard.[11] For $n\geqslant 4$, they can be evaluated readily by direct summation. For $n=2$, they are evaluated by the method described by Nicorovici *et al.*:[6] a rapidly convergent sum $\mathcal{S}$ is found in which the relevant σ occurs, and the former is evaluated, being used in an equation for the desired σ. Of course, direct summation is not possible for sums σ_2^{4m}, since the result obtained depends on the shape chosen for the summation region. Table II shows that $m=6$ gives relative precision of better than one part in 10^7 at a point halfway across the Brillouin zone; accuracy better than this can be expected at points further inside the Brillouin zone.

For general l, we exhibit the form:

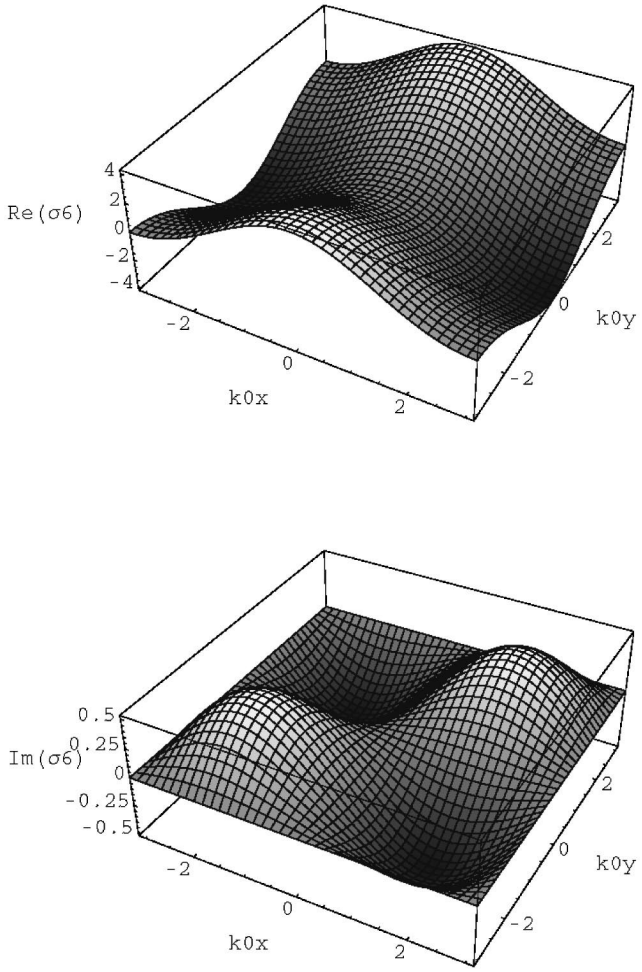

FIG. 7. Real part (above) and imaginary part (below) of σ_6 in the Brillouin zone.

$$\sigma_l(\mathbf{k}_0)=\left(\frac{2\pi i}{d}\right)^l\left[\frac{1}{(2l)!!}\left(\frac{l}{\pi}\kappa^{l-2}-\kappa^l\right)+\sum_{m\geqslant 1,l-4m>0}\mathcal{S}_{l-4m,4m,l}(\kappa)\,e^{-4im\theta_0}\right.$$
$$\left.+\sum_{4m\geqslant l}^{\infty}(-1)^l\mathcal{S}_{4m-l,4m,l}(\kappa)\,e^{-4im\theta_0}\right]e^{il\theta_0}. \tag{47}$$

Here, exceptional sums have $l<2m$; all other sums may be evaluated using (29). This expression

TABLE I. The lattice sums $\sigma_n^{(4m)}$ $(n=4m,4m-2,...)$ for the square array.

TABLE II. Convergence of σ_l at the point $(k_{0x},k_{0y})=(\pi/2,\pi/2)$. The value of σ shown is calculated with terms up to $m=6$; Δ gives the relative difference between sums (29) with terms up to $m=5$ and $m=6$ included.

l	σ_l	Δ
1	$1.311\,028\,777\times(-1+i)$	-8.88×10^{-11}
2	$-1.718\,796\,455\times i$	7.45×10^{-10}
3	$2.253\,391\,614\times(1+i)$	-1.56×10^{-9}
4	$-0.295\,426\,125$	4.38×10^{-8}
5	$1.936\,560\,760\times(-1+i)$	9.00×10^{-9}
6	$0.507\,777\,377\times i$	7.76×10^{-8}

may be regarded as complementary to expressions (1) and (5). As we have $\kappa=k_0d/2\pi\leqslant1/\sqrt{2}$ in the Brillouin zone of the square array, the series involved in (47) converge rapidly, but as l increases they become more and more cumbersome. On the other hand, as l increases, direct summation of (1) becomes more and more computationally viable. The expressions (5) can be used for all l, but the occurrence of Bessel functions in the summand means they can be slow to compute. Thus, we recommend use of (47) for small l, and (1) for l moderate to large.

Pseudo-Hermiticity versus *PT*-symmetry. II. A complete characterization of non-Hermitian Hamiltonians with a real spectrum

Ali Mostafazadeh[a)]
Department of Mathematics, Koç University, Rumelifeneri Yolu, 80910 Sariyer, Istanbul, Turkey

(Received 17 October 2001; accepted for publication 28 January 2002)

We give a necessary and sufficient condition for the reality of the spectrum of a non-Hermitian Hamiltonian admitting a complete set of biorthonormal eigenvectors. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1461427]

Recently, we have explored in Ref. 1 the basic mathematical structure underlying the spectral properties of PT-symmetric Hamiltonians.[2] In particular, we have shown that these properties are associated with a class of more general (not necessarily Hermitian) Hamiltonians H satisfying

$$H^\dagger = \eta H \eta^{-1}, \tag{1}$$

where a dagger denotes the adjoint of the corresponding operator and η is a Hermitian invertible linear operator. We have termed such a Hamiltonian "*η-pseudo-Hermitian.*" Hermitian and the PT-symmetric Hamiltonians that admit a complete set of biorthonormal eigenvectors constitute subsets of the set of pseudo-Hermitian Hamiltonians. For a PT-symmetric Hamiltonian, the exactness of PT-symmetry ensures the reality of the energy spectrum. The purpose of this article is to provide a complete characterization of the Hamiltonians that have a real spectrum assuming that they are endowed with a complete set of biorthonormal eigenvectors.

By definition, a PT-symmetric Hamiltonian has a symmetry given by an antilinear operator, namely PT. It is well-known that if a Hamiltonian satisfies

$$[H,A] = 0, \tag{2}$$

for an anti-linear operator A, then

(★) either the eigenvalues of H are real or they come in complex conjugate pairs.

Furthermore, an eigenvalue of H is real provided that a corresponding eigenvector is invariant under the action of A, i.e., Eq. (2), together with

$$H|E\rangle = E|E\rangle, \tag{3}$$

and

$$A|E\rangle = |E\rangle \tag{4}$$

imply $E \in \mathbb{R}$. Therefore, a Hamiltonian with an antilinear symmetry has a real spectrum if the symmetry is exact.

In Ref. 1, we have shown that every pseudo-Hermitian Hamiltonian has the property (★).

Furthermore, for Hamiltonians with a complete set of biorthonormal eigenvectors this property is the necessary and sufficient condition for pseudo-Hermiticity. This, in particular, means that pseudo-Hermiticity is a necessary condition for having a real spectrum, but it is not sufficient. In the following we give the necessary and sufficient condition for the reality of the spectrum of any

a)Electronic mail address: amostafazadeh@ku.edu.tr

Hamiltonian that admits a complete set of biorthonormal eigenvectors. We shall only consider the case of discrete spectra. The generalization to continuous spectra does not seem to involve major difficulties.

We first recall the defining properties of a Hamiltonian admitting a complete set of biorthonormal eigenvectors.[3] If a Hamiltonian H has a complete set of biorthonormal eigenvectors $\{|\psi_n\rangle,|\phi_n\rangle\}$, then

$$H|\psi_n\rangle=E_n|\psi_n\rangle, \quad H^\dagger|\phi_n\rangle=E_n^*|\phi_n\rangle, \tag{5}$$

$$\langle\phi_m|\psi_n\rangle=\delta_{mn}, \tag{6}$$

$$\sum_n |\psi_n\rangle\langle\phi_n|=1, \tag{7}$$

where n is the spectral label, δ_{mn} denotes the Kronecker delta function, and 1 is the identity operator.

Theorem: Let $H:\mathcal{H}\to\mathcal{H}$ be a Hamiltonian that acts in a Hilbert space $\mathcal{H}$, has a discrete spectrum, and admits a complete set of biorthonormal eigenvectors $\{|\psi_n\rangle,|\phi_n\rangle\}$. Then the spectrum of H is real if and only if there is an invertible linear operator $O:\mathcal{H}\to\mathcal{H}$ such that H is $OO^\dagger$-pseudo-Hermitian.

Proof: Let $\{|n\rangle\}$ be a complete orthonormal basis of $\mathcal{H}$, i.e.,

$$\langle m|n\rangle=\delta_{mn}, \quad \sum_n |n\rangle\langle n|=1, \tag{8}$$

and $O:\mathcal{H}\to\mathcal{H}$ and $H_0:\mathcal{H}\to\mathcal{H}$ be defined by

$$O:=\sum_n |\psi_n\rangle\langle n|, \quad H_0:=\sum_n E_n|n\rangle\langle n|. \tag{9}$$

Then, in view of (5)–(9), O is invertible with the inverse given by

$$O^{-1}=\sum_n |n\rangle\langle\phi_n|, \tag{10}$$

and

$$O^{-1}HO=H_0. \tag{11}$$

Now suppose that the spectrum of H is real. Then, H_0 is Hermitian, and taking the adjoint of both sides (11), we have

$$O^{-1}HO=O^\dagger H^\dagger O^{-1\dagger} \tag{12}$$

or alternatively

$$H=(OO^\dagger)H^\dagger(OO^\dagger)^{-1}. \tag{13}$$

This equation shows that H is $OO^\dagger$-pseudo-Hermitian. This completes the proof of necessity. Next we suppose that H is $OO^\dagger$-pseudo-Hermitian. Then (13) and consequently (12) hold. On the other hand, in view of (6) and (9), we have

$$H_0=O^{-1}HO, \quad H_0^\dagger=O^\dagger H^\dagger O^{-1\dagger}.$$

Therefore, (12) implies that H_0 is Hermitian, and the eigenvalues E_n are all real. □

It should be emphasized that the characterization of the non-Hermitian Hamiltonians with a real spectrum given by the preceding theorem applies to the Hamiltonians that admit a complete biorthonormal system of eigenvectors. A generalization of this result to the case of arbitrary Hamiltonians is not known.

The basic idea of the present work was originated from a comment made by Z. Ahmed about his checking the results the author had reported in Ref. 1 for a specific example of a non-Hermitian Hamiltonian with a real spectrum. This project was supported by the Young Researcher Award Program (GEBIP) of the Turkish Academy of Sciences.

Compatibility and decompositions of effects

Sylvia Pulmannová[a)]
Mathematical Institute, Slovak Academy of Sciences, Sk-814 73 Bratislava, Slovakia

(Received 4 November 2001; accepted for publication 31 January 2002)

Compatibility relations in effect algebras and their connections with refinements of the orthogonal partitions of unity are studied. Properties of blocks as maximal sets of compatible elements are discussed. Some special kinds of effect algebras are characterized using properties of compatibility. Using refinements, an additional structure on the effect test spaces is introduced and used to a characterization of different types of effect algebras. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1462857]

I. INTRODUCTION

Effect algebras (Foulis and Bennett, 1994), alternatively D-posets (Kôpka and Chovanec, 1994), have been introduced as an algebraic generalization of the set of Hilbert space effects, i.e., self-adjoint operators between 0 and I on a Hilbert space. These effects play an important role in the theory of unsharp quantum measurements and positive operator valued (POV) measures (Bush *et al.*, 1991).

Besides the Hilbert space effects, effect algebras include the most important structures used in quantum and classical logic: orthomodular lattices, orthomodular posets, Boolean algebras, and also MV-algebras, an algebraic base of multivalued logic (Chang, 1958). For basic properties of effect algebras and D-posets, see Dvurečenskij and Pulmannová (2000).

In the present article we study compatibility relations on effect algebras and their connections with refinements of the orthogonal partitions of unity. We use properties of compatibility to a characterization of some types of effect algebras and their blocks.

Using refinements, we introduce additional structures to effect test spaces and characterize test spaces of different types of effect algebras.

II. BASIC DEFINITIONS AND PROPERTIES OF EFFECT ALGEBRAS

An *effect algebra* is a partial algebra $(E;\oplus,0,1)$ with a binary partial operation $\oplus$ and two nullary operations 0, 1 satisfying the following conditions.

(E1) If $a\oplus b$ is defined, then $b\oplus a$ is defined and $a\oplus b=b\oplus a$.

(E2) If $a\oplus b$ and $(a\oplus b)\oplus c$ are defined, then $b\oplus c$ and $a\oplus(b\oplus c)$ are defined and $a\oplus(b\oplus c)=(a\oplus b)\oplus c$.

(E3) For every $a\in E$ there is a unique $a'\in E$ such that $a\oplus a'=1$.

(E4) If $a\oplus 1$ is defined, then $a=0$.

Effect algebras in this setting have been introduced in Foulis and Bennett (1994). Essentially equivalent structures, called D-posets, were introduced in Kôpka and Chovanec (1994). Another equivalent structure, called weak orthoalgebra, was introduced in Giuntini and Greuling (1989), and so-called quasilogics were introduced in Belavkin (1987).

For brevity we denote the effect algebra $(E;\oplus,0,1)$ by E. We write $a\leqslant b$ if there is a $c\in E$ with $a\oplus c=b$. It is easy to check that each effect algebra is cancellative, i.e., $a\oplus b=a\oplus c$ implies $b=c$, and positive, i.e., $a\oplus b=0$ implies $a=b=0$. We can derive from this that $\leqslant$ is a partial order with 0 as the least and 1 as the greatest element. Moreover, it is possible to introduce a new

a)Electronic mail: pulmann@mat.savba.sk

partial operation $\ominus$ such that $b\ominus a$ is defined iff $a\leqslant b$ and then $a\oplus(b\ominus a)=b$. We can also prove that $a\oplus b$ is defined iff $a\leqslant b'$, equivalently, iff $b\leqslant a'$. For convenience, we will write $a\perp b$ if $a\oplus b$ is defined, and say that a and b are *orthogonal*.

Let E_0 be a subset of E such that $a\in E_0$ implies $a'\in E_0$ and $a,b\in E_0$, $a\perp b$ implies $a\oplus b\in E_0$. Let $a,b\in E_0$ such that $a\leqslant b$. Then $b'\in E_0$ and $a\perp b'$ implies that $b\ominus a=(b'\oplus a)'\in E_0$, so that E_0 is closed under $\ominus$. Then E_0 is called the *subeffect algebra* of E. Another possibility to construct a substructure of E is to consider an element $a\in E$ and the interval $[0,a]$ of E, and to restrict the $\oplus$ operation letting a act as the unit element. We denote such effect algebra by $[0,a]_E$. Observe that for x, y in $[0,a]_E$, $x\perp_a y$ iff $x\oplus y$ exists in E and $x\oplus y\leqslant a$.

An effect algebra satisfying $a\perp a\Rightarrow a=0$ is called an *orthoalgebra*. An effect algebra E is an *orthomodular poset* (OMP, for short) if for a, b, $c\in E$, $a\perp b$, $b\perp c$, $c\perp a$ implies that $a\oplus b\oplus c$ exists (Foulis and Bennett, 1994). An orthoalgebra is an *orthomodular lattice* (OML, for short) if it is lattice ordered. An effect algebra E is said to have the *Riesz decomposition property* (RDP) (Ravindran, 1996) if for any a_1, a_2, b_1, $b_2\in E$ with $a_1\oplus a_2=b_1\oplus b_2$ there are elements $(w_{ij})_{i,j=1}^2$ such that $w_{11}\oplus w_{12}\oplus w_{21}\oplus w_{22}$ is defined and $a_i=\oplus_{j=1}^2 w_{ij}$, $b_j=\oplus_{i=1}^2 w_{ij}$. Alternatively, E has the Riesz decomposition property if $a\leqslant b\oplus c$ implies $a=b_1\oplus c_1$, $b_1\leqslant b$, $c_1\leqslant c$. If E is lattice ordered and has the RDP, then E can be organized into an MV-algebra (cf., e.g., Dvurečenskij and Pulmannová, 2000). An interesting weakening of the RDP was recently introduced in Jenča (2001): an effect algebra E is called *homogeneous* if $a\leqslant b\oplus c$, and $a\leqslant(b\oplus c)'$ implies $a=b_1\oplus c_1$, $b_1\leqslant b$, $c_1\leqslant c$. Finally, an MV-algebra which is an orthoalgebra is a Boolean algebra.

III. COMPATIBILITY IN EFFECT ALGEBRAS

Let E be an effect algebra. Let $C=(c_1,\ldots,c_n)$ be a finite sequence of elements of E. We say that C is *jointly orthogonal* (or simply *orthogonal*) if the sum $c_1\oplus\cdots\oplus c_n$ is defined. We then write $\oplus C=c_1\oplus\cdots\oplus c_n$. For $n=0$ we define $\oplus C=0$.

Let $\sigma:=(P_1,\ldots,P_k)$ be an ordered partition of the set $\{1,\ldots,n\}$. We put $\|\sigma\|:=k$. Then $\sigma(C)=(\oplus_{i\in P_1}c_i,\ldots,\oplus_{i\in P_k}c_i)$ is an orthogonal sequence and $\oplus\sigma(C)=\oplus_{l=1}^k\oplus_{i\in P_l}c_i=\oplus C$. We will say that C is a *refinement* of $\sigma(C)$. To every ordered partition σ of $\{1,\ldots,n\}$ we can define a function $f_\sigma:\{1,\ldots,n\}\to\{1,\ldots,k\}$ by $f_\sigma(i)=j$ iff $i\in P_j$. Conversely, every such surjection f defines a partition of $\{1,\ldots,n\}$. We will call f_σ the *refinement mapping*.

Observe that if $C=(c_1,\ldots,c_n)$ is an orthogonal sequence, then there may exist different partitions of $\{1,\ldots,n\}$ with different refinement mappings leading to the same orthogonal sequence $D=\{d_1,\ldots,d_k\}$ of which C is a refinement. This may happen only if there is $c\in C$ such that $c\perp c$.

Let E be an effect algebra. A finite family M of elements of E is said to be *jointly compatible* (or simply *compatible*) if there is an orthogonal sequence $C=(c_1,\ldots,c_n)$ such that for every $a\in M$ there is a set $I_a\subset\{1,\ldots,n\}$ such that $a=\oplus_{i\in I_a}c_i$. We say that C *covers* M, and call C a *cover* of M. If M is any subset of E, we say that M is compatible if every finite subset of M is compatible.

An ordered pair (a,b) of elements of M is said to be *Mackey compatible* if there is an orthogonal sequence (a_1,b_1,c) such that $a=a_1\oplus c$, $b=b_1\oplus c$. The sequence (a_1,b_1,c) is called a *Mackey decomposition* of (a,b). Clearly, if (a,b) is Mackey compatible, then (b,a) is Mackey compatible with the decomposition (b_1,a_1,c). We will write $a\leftrightarrow b$ if (a,b) are Mackey compatible.

Let F be a subset of E. We say that events $A=(a_1,\ldots,a_n)$ are *compatible in* F if A is compatible with a cover $C\subset F$. A subset M of E is called *compatible in* F if any finite subset of M is compatible with covers in F. We say that M is *internally compatible* if M is compatible in M. We say that elements (a,b) are *Mackey compatible in* F if there is a Mackey decomposition (a_1,b_1,c) of (a,b) with a_1, b_1, $c\in F$, and we write $a\leftrightarrow^F b$

In the following propositions we collect some basic properties of compatibility (Kôpka, 1995; Dvurečenskij and Pulmannová, 2000).

Proposition 1: Let a, b be elements of an effect algebra E.

(i) $a \leftrightarrow a,\ 0 \leftrightarrow a,\ 1 \leftrightarrow a,\ \forall a \in E.$
(ii) $a \leqslant b \Rightarrow a \leftrightarrow b,\ a \perp b \Rightarrow a \leftrightarrow b.$
(iii) $a \leftrightarrow b \Rightarrow a' \leftrightarrow b.$
(iv) *If elements* $a_1,\ldots,a_n$ *are jointly compatible, they are pairwise Mackey compatible. If* $n \geqslant 3$, *the converse need not hold even in OMP* (Pták and Pulmannová, 1991).

Proof of the above statement is straightforward.

Proposition 2: Let (a,b) *be an ordered pair of elements in* E. *The following statements are equivalent.*

(C1) $a \leftrightarrow b$.

(C2) a,b *are jointly compatible.*

(C3) $a = x \oplus y$ *with* $x \leqslant b,\ y \leqslant b'$.

(C4) *There are elements* u,v such that $u \leqslant a,\ b \leqslant v$ and $a \ominus u = v \ominus b$.

Proof: (C1)$\Rightarrow$(C2). Let (a_1,b_1,c) be a Mackey decomposition of (a,b). The orthogonal sequence (a_1,b_1,c) covers (a,b), so $a,\ b$ are jointly compatible.

(C2)$\Rightarrow$(C3): Let $(c_1,\ldots,c_n)$ be a cover of a,b. Then $a = \oplus_{i \in I_a} c_i,\ b = \oplus_{i \in I_b} c_i$, where $I_a,\ I_b$ are subsets of $\{1,\ldots,n\}$. Putting $P_1 = I_a \cap I_b,\ P_2 = I_a \cap I_b^c,\ P_3 = I_a^c \cap I_b,\ P_4 = I_a^c \cap I_b^c$, where $I_a^c,\ I_b^c$ are complements of $I_a,\ I_b$ in $\{1,\ldots,n\}$, respectively, we obtain a partition of $\{1,\ldots,n\}$. Clearly, $I_a = P_1 \cup P_2$, and $I_b = P_1 \cup P_3$. Then $a_1 = \oplus_{i \in P_2} c_i,\ b_1 = \oplus_{i \in P_3} c_i,\ c = \oplus_{i \in P_1} c_i$ is a Mackey decomposition of (a,b). Put $d = (c_1 \oplus \cdots \oplus c_n)'$. Then $b \oplus b' = \oplus_{i=1}^n c_i \oplus d = 1$, and by cancellativity, $b' = \oplus_{i \in I_b^c} c_i \oplus d$. Therefore $a_1 = \oplus_{i \in I_a \cap I_b^c} c_i \leqslant b'$, and $c \leqslant b$. Putting $x = c,\ y = a_1$ concludes the proof.

(C3)$\Rightarrow$(C4). Let $a = x \oplus y,\ x \leqslant b,\ y \leqslant b'$. Then $x \leqslant a,\ x \leqslant b$ and $a \leqslant b \oplus y,\ b \leqslant b \oplus y$. In addition, $a \ominus x = y = (b \oplus y) \ominus b$. Putting $u = x,\ v = b \oplus y$ yields the desired statement.

(C4)$\Rightarrow$(C1). Let $u \leqslant a,\ b \leqslant v$ and $a \ominus u = v \ominus b$. Then $a = u \oplus (a \ominus u),\ b = u \oplus (b \ominus u),\ v = b \oplus (v \ominus b) = u \oplus (b \ominus u) \oplus (a \ominus u)$, which shows that $(a \ominus u, b \ominus u, u)$ is a Mackey decomposition of (a,b). □

We will say that elements a,b in E are *strongly compatible* if there is a Mackey decomposition (a_1,b_1,c) of the ordered pair (a,b) such that $a_1 \wedge b_1 = 0$ (in the sense that $x \leqslant a_1,\ x \leqslant b_1$ implies $x = 0$). We will write $a \leftrightarrow^c b$. More generally, we say that a finite set $A = (a_1,\ldots,a_n)$ of elements are *jointly strongly compatible* if there is a cover $C = (c_1,\ldots,c_m)$ of A such that for every a_i,a_j in A,

$$\oplus_{k \in I_{a_i} \cap I_{a_j^c}} c_k \wedge \oplus_{k \in I_{a_i^c} \cap I_{a_j}} c_k = 0.$$

We then say that C *strongly covers* A (or that C is a strong cover of A).

Lemma 1: Let (a_1,b_1,c) *be a Mackey decomposition of* (a,b). *Let* $c \leqslant \overline{c} \leqslant a,b$. *Then* $(a \ominus \overline{c}, b \ominus \overline{c}, \overline{c})$ *is a Mackey decomposition of* (a,b).

Proof: We can write $a = \overline{c} \oplus (a \ominus \overline{c}),\ b = \overline{c} \oplus (b \ominus \overline{c})$. Then $a \oplus (b \ominus \overline{c}) \leqslant a \oplus (b \ominus c) = a_1 \oplus b_1 \oplus c$. It follows that $(a \ominus \overline{c}, b \ominus \overline{c}, \overline{c})$ is a Mackey decomposition of (a,b). □

Proposition 3: Let a,b *be elements of an effect algebra* E. *Let* (a_1,b_1,c) *be a Mackey decomposition of* (a,b). *The following statements are equivalent.*

(i) (a_1,b_1,c) *is a strong Mackey decomposition of* (a,b);
(ii) c *is a maximal lower bound of* a,b;
(iii) $d := a_1 \oplus b_1 \oplus c$ *is a minimal upper bound of* a,b.

Proof: $(i) \Rightarrow (ii)$: Let (a_1,b_1,c) be a strong Mackey decomposition of (a,b). Let $\overline{c} \in E$ be such that $c \leqslant \overline{c} \leqslant a,b$. There is an $x \in E$ such that $\overline{c} = c \oplus x$. We have

$$a = \overline{c} \oplus (a \ominus \overline{c}) = c \oplus x \oplus (a \ominus \overline{c}) = c \oplus a_1,$$

hence $a_1 = x \oplus (a \ominus c)$, and

$$b=\overline{c}\oplus(b\ominus\overline{c})=c\oplus x\oplus(b\ominus\overline{c})=c\oplus b_1,$$

hence $b_1=x\oplus(b\ominus\overline{c})$. It follows that $x\leqslant a_1,b_1$, so $x=0$. Therefore c is a maximal lower bound of a,b.

$(ii)\Rightarrow(i)$: Let c be a maximal lower bound of a,b and let (a_1,b_1,c) be a Mackey decomposition of (a,b). Assume that $x\leqslant a_1,b_1$. Then $a_1=x\oplus\overline{a_1}$, $b_1=x\oplus\overline{b_1}$, so that $a=x\oplus c\oplus\overline{a_1}$, $b=x\oplus c\oplus\overline{b_1}$. Hence $c\leqslant x\oplus c\leqslant a,b$. As c is a maximal lower bound of a,b then $x=0$, and (a_1,b_1,c) is a strong Mackey decomposition of (a,b).

$(ii)\Leftrightarrow(iii)$: Assume that (a_1,b_1,c) is a Mackey decomposition of (a,b). Put $d:=a_1\oplus b_1\oplus c$. Then $a\ominus c=d\ominus b$. Let there be a $\overline{d}$ with $a,b\leqslant\overline{d}\leqslant d$. There is $y\in E$ such that $d=\overline{d}\oplus y$. So we obtain $a\ominus c=(\overline{d}\oplus y)\ominus b=(\overline{d}\ominus b)\oplus y$, and hence $(a\ominus c)\ominus y=\overline{d}\ominus b$, which implies that $a\ominus(c\oplus y)=\overline{d}\ominus b$. Hence $c\oplus y\leqslant a$, and similarly we prove that $c\oplus y\leqslant b$. So if d is not a minimal upper bound of a,b, then c is not a maximal lower bound of a,b. By reversing the implications we obtain the converse. It follows that c is a maximal lower bound of a,b iff d is a minimal upper bound of a,b. □

Remark 1: Let E be an effect algebra.

(a) E is an orthoalgebra iff every Mackey decomposition is strong. Indeed, $(a,a',0)$ is a Mackey decomposition of (a,a') for every $a\in E$. If it is strong, then $a\wedge a'=0$. The converse is clear.

(b) E is an OMP iff for every Mackey decomposition (a_1,b_1,c) of (a,b), $a_1\oplus b_1\oplus c=a\vee b$. That is, every Mackey decomposition is strong and unique. The converse need not hold, there are orthoalgebras with unique Mackey decompositions which are not OMPs.

(c) E is an MV-algebra iff E is lattice ordered and $a\leftrightarrow b$ for every a,b in E (Chovanec and Kôpka, 1995; Pulmannová, 1997a; Dvurečenskij and Pulmannová, 2000). Indeed, according to Chovanec and Kôpka (1995), a lattice ordered effect algebra can be organized into an MV-algebra iff $a\ominus(a\wedge b)=(a\vee b)\ominus b$ holds for every $a,b\in E$. It is easy to see that $(a\ominus(a\wedge b),b\ominus(a\wedge b),a\wedge b)$ is a Mackey decomposition of (a,b). If E is a lattice and $a\leftrightarrow b$, then it can be derived from Lemma 1 and Proposition 3 that $(a\ominus(a\wedge b),b\ominus(a\wedge b),a\wedge b)$ is a strong Mackey decomposition of (a,b). It follows that $((a\ominus(a\wedge b))\oplus b$ is a minimal upper bound of a,b, which is $a\vee b$.

Recall that a partially ordered set P satisfies the *Riesz interpolation property* (RIP) if whenever $x,y\leqslant a,b$ there is an element c in P such that $x,y\leqslant c\leqslant a,b$. In partially ordered Abelian groups the Riesz interpolation property and the Riesz decomposition property are equivalent. In an effect algebra, the Riesz decomposition property implies the Riesz interpolation property, but the converse need not hold (Ravindran, 1996).

Proposition 4: Let E be an effect algebra with RIP. If the elements a,b in E are strongly compatible, there is a unique strong Mackey decomposition (a_1,b_1,c) of (a,b) and $c=a\wedge b$, $d=a_1\oplus b_1\oplus c=a\vee b$.

Proof: Let (a_1,b_1,c) be a strong Mackey decomposition of (a,b). Then $c\leqslant a,b$ and let $x\in E$ be any lower bound of a,b. By RIP, there is $y\in E$ such that $x,c\leqslant y\leqslant a,b$. Since c is maximal, we have $y=c$. Therefore $c=a\wedge b$. Similarly we prove that $d=a\vee b$. □

Corollary 1: An effect algebra E with RIP is an MV-algebra iff any two elements are strongly compatible.

Proof: If any two elements are strongly compatible, it follows by Proposition 4 that E is a lattice. Since any two elements are compatible, E is an MV-algebra. The converse statement is well known (see, e.g., Pulmannová, 1997a). □

Recall that for $u\in E$, $[0,u]_E$ denotes the interval $0\leqslant x\leqslant u$ in E with the operation $\oplus$ defined with respect u as the unit element. Two elements $a,b\in[0,u]_E$ are said to be compatible in $[0,u]_E$ if there is a Mackey decomposition (a_1,b_1,c) of (a,b) such that $a_1\oplus b_1\oplus c\in[0,u]_E$. In Cattaneo *et al.* (2000), the following characterization of different types of effect algebras has been given.

Theorem 1: *Let E be an effect algebra.*

(1) *E satisfies RDP if and only if every pair* (a,b) *of elements of* E *is compatible in every interval* $[0,x]_E$ *which contains* a,b.
(2) *E is an MV-algebra if and only if for every elements* (a,b) *there is a Mackey decomposition* (a_1,b_1,c) *such that* $a_1\oplus b_1\oplus c\in[0,x]_E$ *whenever* $a,b\leqslant x$.

The following characterization of effect algebras with the RDP has been proved in Jenča (2001), Theorem 3.5. It shows what we need to add to the joint compatibility of all finite subfamilies of elements of E to obtain the RDP.

Proposition 5: Let E be an effect algebra. The following statements are equivalent.

(a) *E satisfies the RDP.*
(b) *Every finite family of elements in E is jointly compatible and the following weakening of the RDP holds for any* $x,a,b\in E$: (*) *If* $x\leqslant a\oplus b$, *and* $x\leqslant(a\oplus b)'$, *then there are* $a_1\leqslant a$, $b_1\leqslant b$ *such that* $x=a_1\oplus b_1$.

Proof: (a)⇒(b): Let $a_1,\ldots,a_n$ be elements of E. We will proceed by induction on n. If $n=1$, there is nothing to prove. Now assume that an orthogonal cover exists for $n-1$, and consider elements $(a_1,\ldots,a_n)$. By induction hypothesis, there is an orthogonal cover of $(a_1,\ldots,a_{n-1})$, say $(c_1,\ldots,c_k)$. Put $c=\oplus_{i=1}^k c_i$. Then (c,a_n) have an orthogonal cover-Mackey decomposition (y_1,y_2,z). So $a_n=z\oplus y_2$, where $z\leqslant c$, $y_2\leqslant c'$. Since $z\leqslant c=\oplus_{i=1}^k c_i$, there are elements $d_i\leqslant c_i$, $i=1,\ldots,k$, such that $z=\oplus_{i=1}^k d_i$, and then $(d_1,\ldots,d_k,c_1\ominus d_1,\ldots,c_k\ominus d_k,y_2)$ is an orthogonal cover of $(a_1,\ldots,a_n)$. It is immediate that (*) is satisfied.

(b)⇒(a): Let a,b,x be elements of E such that $a,b\leqslant x$. We wish to prove that a,b are compatible in the interval $[0,x]_E$. First we prove that for any cover C of (a,x) with $a\leqslant x$ there exists a refinement D such that a cover of a in D is contained in a cover of x in D (see Jenča, 2001, Proposition 3.2). So let $C=(c_1,\ldots,c_n)$ be an orthogonal cover of (a,x). Then there are subsets $A\subset\{1,\ldots,n\}$, $X\subset\{1,\ldots,n\}$ such that $a=\oplus_A c_i$, $x=\oplus_X c_i$. Without any loss of generality, we may assume that $A\setminus X=\{1,\ldots,r\}$, $A\cap X=\{r+1,\ldots,s\}$, and $X\setminus A=\{s+1,\ldots,n\}$ with $r<s<n$. Define $a_1=\oplus_{i=1}^r c_i$, $d=\oplus_{i=r+1}^s c_i$, $x_1=\oplus_{i=s+1}^n c_i$. Then $a=a_1\oplus d$, $x=x_1\oplus d$. From $a\leqslant x$ and cancellativity we get $a_1\leqslant x_1$, and since C is an orthogonal family, we also have $a_1\leqslant x_1'$. Now for any c_i, $i=1,\ldots,r$, we have $c_i\leqslant x_1$ and $c_i\leqslant x_1'$. Using (*) we obtain that $c_i=\oplus_{j=s+1}^t d_j^i$, where $d_j^i\leqslant c_j$, $j=s+1,\ldots,n$. It is then easy to check that $(d_j^i)_{i=1,\ldots,r;j=s+1,\ldots,n}\cup(c_i)_{i=r+1,\ldots,s}\cup(c_i\ominus\oplus_{j=1}^r d_j^i)_{i=s+1,\ldots,n})$ is a refinement of C with the desired property.

Now we can find a cover $W=(w_1,\ldots,w_n)$ of a,b,x and subsets A,B,X of $\{1,\ldots,n\}$ with $A\subset X$, $B\subset X$ with $a=\oplus_A w_i$, $B=\oplus_B w_i$, $X=\oplus_X w_i$. Putting $a_1=\oplus_{A\setminus B}w_i$, $b_1=\oplus_{B\setminus A}w_i$, $c=\oplus_{A\cap B}w_i$ we obtain a Mackey decomposition of a,b in $[0,x]_E$. □

The following proposition collects some characterizations of MV-algebras among effect algebras with the RDP.

Proposition 6: Let E be an effect algebra with the RDP. The following statements are equivalent.

(i) *E is an MV-algebra.*
(ii) *Every two elements in E are strongly compatible.*
(iii) *E is lattice ordered.*
(iv) *The partial operation* $\oplus$ *can be extended uniquely to a total operation* $+$ *which is commutative, associative, monotone and such that* $a'=\wedge\{x:a+x=1\}$.

Proof: (*i*)⇒(*ii*): See Corollary 1.
(*ii*)⇒(*iii*): Follows by Proposition 4.
(*iii*)⇒(*iv*): Recall that the RDP implies that for any elements a,b,

$$b\leqslant a\oplus a'\Rightarrow b=c\oplus b_1,\ c\leqslant a \text{ and } b_1\leqslant a'.$$

Therefore any two elements a,b have a Mackey decomposition. Since E is lattice ordered, by Lemma 1, (a,b) have also a strong Mackey decomposition (a_1,b_1,c) with $c=a\wedge b$, $a_1\oplus b_1\oplus c=a\vee b$. It follows that $a\ominus(a\wedge b)=(a\vee b)\ominus b$.

Define $a+b:=a\oplus(a'\wedge b)$. Clearly, $+$ coincides with $\oplus$ if $a\perp b$, and is monotone in b. By the interplay between $\oplus$ and $\ominus$, we obtain

$$(a+b)'=a'\ominus(a'\wedge b)=(a'\vee b)\ominus b=(a\wedge b'\oplus b)'=(b+a)'.$$

Therefore $+$ is commutative. Further, using $a\ominus(a\wedge b)=(a\vee b)\ominus b$, and the fact that $a\oplus(b\wedge c)=(a\oplus b)\wedge(a\oplus c)$ if $a\perp b,a\perp c$, we have

$$\begin{aligned}(a+b)+c&=(a\oplus a'\wedge b)\oplus((a\oplus a'\wedge b))'\wedge c=(a\oplus a'\wedge b)\oplus(a'\ominus a'\wedge b)\wedge a'\wedge c\\&=(a\oplus(a'\ominus a'\wedge b)\wedge a'\wedge c)\oplus a'\wedge b=(a\oplus(a'\ominus a'\wedge b)\wedge(a\oplus a'\wedge c))\oplus a'\wedge b\\&=(a'\ominus(a'\ominus a'\wedge b)\vee(a'\ominus a'\wedge c))'\oplus a'\wedge b=(a'\wedge b\vee(a'\ominus a'\wedge c))'\oplus a'\wedge b\\&=((a'\wedge b\vee(a'\ominus a'\wedge c))\ominus a'\wedge b)'=((a'\ominus a'\wedge c)\ominus(a'\ominus a'\wedge c)\wedge a'\wedge b)'\\&=(a\oplus a'\wedge c)\oplus(a\oplus a'\wedge c)'\wedge b=(a+c)+b.\end{aligned}$$

This proves associativity of $+$.

If $a+x=1$, then $0=(a+x)'=(a\oplus a'\wedge x)'=a'\ominus a'\wedge x$, hence $a'=a'\wedge x$, so that $a'\leqslant x$. Since $a+a'=a\oplus a'=1$, the operation $+$ has the desired property.

$(iv)\Rightarrow(i)$: Let there exist an operation $+$ with the desired properties. First we prove that $(p'+q)'+q$ is an upper bound of both p and q in E. We have $1=(p'+q)+(p'+q)'=p'+(q+(p'+q)')$ assuming commutativity and associativity of $+$. Hence $p\leqslant(p'+q)'+q$ by the last property of $+$. By monotony of $+$, $q\leqslant(p'+q)'+q$. Put $s=(p'+q)'+q$. We have just proved that s is an upper bound of p,q. Suppose that there is x in E with $x\geqslant p$, $x\geqslant q$. We want to prove that $x\geqslant s$. We may write

$$x=(x\ominus q)\oplus q \tag{1}$$

$$=(x'\oplus q)'\oplus q=(x'+q)'+q, \tag{2}$$

since $+$ is an extension of $\oplus$. From $x\geqslant p$ we obtain $x'\leqslant p'$, and by monotony of $+$, we get $x'+q\leqslant p'+q$. Since $'$ is order reversing, by repeated application of the monotony of $+$ we obtain

$$(p'+q)'+q\leqslant(x'+q)'+q,$$

and so

$$x'=((x'+q)'+q)'\leqslant((p'+q)'+q)'=s';$$

i.e., $s\leqslant x$, as required. This proves that $p\vee q=(p'+q)'+q$.

It remains to prove the uniqueness of $+$. Let E be an effect algebra with the RDP. Assume that there are two total extensions of $\oplus$ with the desired properties and denote them by $+_1$ and $+_2$. We want to prove that $+_1=+_2$. Assume that there are $q,r\in E$ such that $q+_1r\neq q+_2r$. Putting $p=r'$, we get $q+_1p'\neq q+_2p'$ and hence $(p'+_1q)'\neq(p+_2q)'$. Put $z:=(p'+_1q)'$. Then $q\leqslant q+_1p'=z'$. Hence $q\perp z$, so $q\oplus z=q+_1z$. By the last part of the above proof, we have $p\vee q=(p+_1q)'+_1q=z+_1q=z\oplus q$. Similarly, letting $y:=(p'+_2q)'$, we prove that $y\perp q$, and we obtain $p\vee q=y\oplus q=y+_2q$. We conclude $y=z$, in contradiction with our suppositions. □

Remark 2: The equivalence $(i)\Leftrightarrow(iv)$ was proved in Mundici and Panti (1993) in relation with the K_0 theory for AF C^*-algebras. Our proof was based purely on the algebraic properties of E. Combining it with the result of Effross *et al.* (1980), which proves that Elliott's invariant is an interval in a partially ordered group with the RDP and so it has a RDP itself, the result of Mundici and Panti (1993) follows.

Remark 3: Let (a_1,b_1,c) be a strong Mackey decomposition of (a,b). Then (b_1,a_1,d') where $d=a_1\oplus b_1\oplus c$ is a strong Mackey decomposition of (a',b'). Indeed, by Proposition 3 c is a maximal lower bound of a,b and d is a minimal upper bound of a,b. Then d' is a maximal lower bound of a',b', and (b_1,a_1,d') is a Mackey decomposition of (a',b'). By Proposition 3 (ii), (b_1,a_1,d') is a strong Mackey decomposition of (a',b'). Strong compatibility of (a,b'), resp. (a',b), can be derived iff a_1 is a maximal lower bound of a,b', resp. b_1 is a maximal lower bound of a',b. In particular, if c is any lower bound of a,a', then $(a\ominus c,a'\ominus c,c)$ is a Mackey decomposition of a,a', but a,a' are strongly compatible iff they have a maximal lower bound.

Evidently, strong Mackey decompositions need not exist even for compatible elements, and if they exist, they may be not unique. In the following theorem we show that in any Hilbert space effect algebra $\mathcal{E}(H)$, there exist strong Mackey decompositions (not necessarily unique) for any two compatible elements. This follows from the existence of maximal lower bounds (Moreland and Gudder, 1999, Theorem 4.5).

Theorem 2: *In $\mathcal{E}(H)$, any two Mackey compatible effects have also a strong Mackey decomposition.*

Proof: If $a,b\in\mathcal{E}(H)$ are Mackey compatible, there are $c,d\in\mathcal{E}(H)$ such that $c\leqslant a$, $b\leqslant d$ and $a\ominus c=d\ominus b$. Put $S:=\{x\in\mathcal{E}(H):c\leqslant x\leqslant a,b\}$. Let $K\subset S$ be a chain. S is partially ordered and nonempty, since $c\in S$. K can be considered as an increasing net in $\mathcal{E}(H)$ and by Topping (1971), Lemma 1, $\lim_K\langle x\phi,\phi\rangle=\langle x_0\phi,\phi\rangle$ for some $x_0\in\mathcal{E}(H)$ and every $\phi\in H$. It follows that $x_0\in S$ and $c\leqslant x\leqslant x_0$ for every $x\in K$. By Zorn's lemma, S has a maximal element c_1, say, such that $c\leqslant c_1$. By Lemma 1, $(a\ominus c_1,b\ominus c_1,c_1)$ is a Mackey decomposition of (a,b), and by Proposition 3, it is a strong Mackey decomposition. □

IV. BLOCKS IN EFFECT ALGEBRAS

Recall than an *observable* on an effect algebra E is a morphism $\alpha:B\to E$ from a Boolean algebra B to E. Let $\mathrm{ran}(\alpha)=\{\alpha(b):b\in B\}$ denote the range of α. An observable α is finite if there is a finite set $\{a_1,\ldots,a_n\}$ of elements in B such that $(\alpha(a_1),\ldots,\alpha(a_n))$ is a finite partition of unity in E, and $\mathrm{ran}(\alpha)$ consists of all $\oplus$-sums of $(\alpha(a_1),\ldots,\alpha(a_n))$. Conversely, to every finite partition of unity in E, there corresponds a finite observable.

We say that two observables α and β are *coexistent* if there is an observable γ such that $\mathrm{ran}(\alpha)\cup\mathrm{ran}(\beta)\subseteq\mathrm{ran}(\gamma)$. Clearly, $\mathrm{ran}(\alpha)$ is a compatible set. A system $A=(\alpha_i)_{i\in I}$ will be called *coexistent* (in A) if every two observables α,β in A are coexistent with $\gamma\in A$, where $\mathrm{ran}(\alpha)\cup\mathrm{ran}(\beta)\subseteq\mathrm{ran}(\gamma)$. Clearly, the system A is coexistent iff $\cup_{i\in I}\mathrm{ran}(\alpha_i)$ is compatible with covers in itself.

By a *block* of E we mean a maximal subsystem A of E such that every finite subset of elements of A is compatible in A. Alternatively, a block is union of the ranges of a maximal coexistent system of finite observables on E. Using Zorn lemma, we can prove that every effect algebra E can be expressed as the union of its blocks. The structure of blocks in effect algebras is not known, in general. In fact, we can only say that the blocks bear a structure of a compatible quasi-effect algebra (see Cattaneo *et al.*, 2000). A *quasi-effect algebra* is a structure $(A;\leqslant,\oplus,',1,0)$ where $(A;\leqslant,',1,0)$ is a bounded involutive poset, and $\oplus$ is a partially defined binary operation such that

(1) $\exists(a\oplus b)$ implies $\exists(b\oplus a)$ and $a\oplus b=b\oplus a$.
(2) $a\oplus a'=1$.
(3) $\exists(a\oplus 1)$ implies $a=0$.
(4) $a\leqslant b$ and $\exists(a\oplus c)$ and $\exists(b\oplus c)$ implies $a\oplus c\leqslant b\oplus c$.

Let α be an observable on E. Then $A=\mathrm{ran}(\alpha)$ can be organized into a quasi-effect algebra $(A;\leqslant_A,\oplus_A,'_A,1_A,0_A)$ where $\leqslant_A$ is the restriction of $\leqslant$ in E to A, $'_A='$, $1_A=1$, $0_A=0$, and $\exists(a\oplus_A b)$ iff $\exists(a\oplus b)$ and $a\oplus b\in A$, and then $a\oplus_A b=a\oplus b$ (Cattaneo *et al.*, 2000, Lemma 1).

We say that a system $(\alpha_i)_{i\in I}$ of observables is directed if to every $i,j\in I$ there is $k\in I$ such that $\mathrm{ran}(\alpha_i)\cup\mathrm{ran}(\alpha_j)\subseteq\mathrm{ran}(\alpha_k)$. Let $(\alpha_i)_{i\in I}$ be a directed system of observables. Put A

$=\cup_{i\in I}\mathrm{ran}(\alpha_i)$. With partial order $\leqslant$ and orthosupplementation $'$ and 0,1 inherited from E, A is an involutive, bounded poset. Define $\oplus_A$ as follows: $a\oplus_A b$ is defined if there is $i\in I$ with $a,b,a\oplus b\in\mathrm{ran}(\alpha_i)$ and then put $a\oplus_A b=a\oplus b$. Clearly, $(A;\leqslant_A,\oplus_A,{}'_A,1,0)$ is a quasi-effect algebra. We may conclude that, in general, a block of an effect algebra is a compatible quasi effect algebra.

Theorem 3: *A block A of an effect algebra E is a subeffect algebra of E if and only if the following condition is satisfied: $\{a_1,a_2\ldots,a_n\}$ is a compatible set and $a_1\perp a_2$ implies that $\{a_1,a_2,\ldots,a_n,a_1\oplus a_2\}$ is a compatible set.*

Proof: If a block A is a subeffect algebra of E, then $a_1,a_2\in A$ and $a_1\perp a_2$ implies $a_1\oplus a_2\in A$. Since every finite subset of A is compatible, we have, for any finite set $\{b_1,\ldots,b_n\}$ in A that $\{a_1,a_2,b_1,\ldots,b_n,a_1\oplus a_2\}$ is a compatible set.

Conversely, if $a_1,a_2\in A$, $a_1\perp a_2$ and for any $b_1,\ldots,b_n$ in A the set $a_1,a_2,b_1,\ldots,b_n,a_1\oplus a_2$ is compatible, then the maximality of A implies that $a_1\oplus a_2\in A$. □

Observe that in the above theorem, the condition $a_1,a_2,\ldots,a_n$ compatible and $a_1\perp a_2$ implies $a_1,a_2,\ldots,a_n,a_1\oplus a_2$ compatible can be replaced by the condition $a_1,a_2,\ldots,a_n$ compatible and $a_1\leqslant a_2$ implies $a_1,a_2,\ldots,a_n,a_2\ominus a_1$ compatible.

In analogy with orthomodular posets, we say that an effect algebra E is *regular* if any pairwise compatible finite set is jointly compatible. In a regular effect algebra, a block is a maximal system of pairwise compatible elements.

The following special cases are known.

Case 1: Let E be an orthoalgebra. It is well known that the range of every observable α is a subeffect algebra of E which, endowed with ''local'' lattice operations $\vee_\alpha,\wedge_\alpha$ taken with respect to $\mathrm{ran}(\alpha)$, is a Boolean algebra. Moreover, the mapping $\alpha:B\to\mathrm{ran}(\alpha)$ is a Boolean algebra homomorphism. The corresponding ''global'' suprema and infima in E need not exist, and even if they exist, they need not belong to $\mathrm{ran}(\alpha)$.

Let $(\alpha_i)_{i\in I}$ be a maximal coexistent system of finite observables, so that $\cup_{i\in I}\mathrm{ran}(\alpha_i)$ is a block. Then $(\mathrm{ran}(\alpha_i))_{i\in I}$ form a directed system of Boolean algebras. Indeed, if $\mathrm{ran}(\alpha_i)\subseteq\mathrm{ran}(\alpha_j)$, then by well known theorems by Sikorski and Varadarajan (Varadarajan, 1985), there is a function $f:\Omega_j\to\Omega_i$ where Ω_i,Ω_j are finite sets such that $\alpha_i(\Omega_i)=1$, $\alpha_j(\Omega_j)=1$, such that for every $X\in 2^{\Omega_i}$, $\alpha_i(X)=\alpha_j(f^{-1}(X))$. Let $a,b\in\mathrm{ran}(\alpha_i)$, $a=\alpha_i(X)$, $b=\alpha_i(Y)$. Then

$$a\wedge_i b=\alpha_i(X\cap Y)=\alpha_j(f^{-1}(X\cap Y))=\alpha_j(f^{-1}(X)\cap f^{-1}(Y))=\alpha_j(f^{-1}(X))\wedge_j\alpha(f^{-1}(Y))=a\wedge_j b.$$

Let $A=\cup_{i\in I}\mathrm{ran}(\alpha_i)$ be a block. It is clear that A is a bounded orthocomplemented poset. For every $a,b,c\in A$ there is a $k\in I$ such that $a,b,c\in\mathrm{ran}(\alpha_k)$. It follows that A is a subeffect algebra of E and, with suprema and infima taken in A, it is a distributive lattice, hence a Boolean algebra. The lattice operations in a block coincide with those in E iff E is an orthomodular poset.

Case 2: Let E be a lattice ordered effect algebra. It has been proved in Riečanová (2000) that the maximal pairwise compatible subsets are subeffect algebras of E which are closed under the lattice operations and form MV-algebras. It follows that lattice ordered effect algebras are regular and blocks are MV-algebras with the lattice operations inherited from E.

Case 3: Homogeneous effect algebras introduced in Jenča (2001) have blocks that form subeffect algebras of E satisfying the Riesz decomposition property. Homogeneous effect algebras include orthoalgebras and lattice ordered effect algebras as special cases. In both these subcases, blocks form distributive lattices, but the nature of lattice operations may be different.

Case 4: According to Dvurečenskij (2002), if an effect algebra satisfies the Riesz interpolation property (RIP) and so-called difference meet property (DMP), that is, if $a,b,c\in E$, $a\leqslant b$, are such that $a\wedge c,b\wedge c$ exist in E, then $(b\ominus a)\wedge c$ exists in E, then E can be covered by MV-algebras, which are maximal sets of pairwise strongly compatible subsets of E. The lattice operations in the MV-algebras coincide with the lattice operations in E. Since every lattice ordered effect algebra satisfies RIP and DMP, and in a lattice ordered effect algebra any two compatible elements are also strongly compatible, this case generalizes the case of lattice ordered effect algebras. It is not known whether the maximal strongly compatible sets coincide with the maximal compatible sets.

Case 5: Let H be a Hilbert space (complex, separable). Consider a maximal subset A of the effect algebra $\mathcal{E}(H)$ consisting of pairwise commuting elements. Using well-known results of von Neumann (1955) and Varadarajan (1985), there is an observable (self-adjoint operator) u and Borel functions $f_a:\mathbb{R}\to[0,1]$ such that every $a\in A$ is a function of u, $a=f_a(u)$. Since A is maximal, the set $\{f_a:a\in A\}$ consists of all measurable functions. The functions $f_a:\mathbb{R}\to[0,1]$ can be endowed with a structure of an MV-algebra, if we define (Cattaneo *et al.*, 2000) $(f\oplus g)(x)=\min(1,f(x)+g(x)),x\in\mathbb{R}$.

Using the functional calculus, we can transfer the MV-algebra structure to the operators in A. In this way, $\mathcal{E}(H)$ can be covered by MV-algebras.

By the functional calculus, we have

$$\begin{aligned} a\wedge_A b&=\int_0^1 \min(f_a(\lambda),f_b(\lambda))u(d\lambda)\\ &=\int_a^b \frac{1}{2}(f_a+f_b-|f_a-f_b|)u(d\lambda)\\ &=\tfrac{1}{2}(a+b-|a-b|)=a\sqcap b. \end{aligned}$$

According to Gudder (1996), $a\sqcap b\geqslant 0$ and it is a maximal lower bound of a,b. Since, again by the functional calculus, $a+(b-a\sqcap b)=\frac{1}{2}(a+b+|a-b|)=a\sqcup b\leqslant 1$, a,b are strongly compatible. The infimum of a,b in A is then equal to $a\sqcap b$, which is equal to $a\wedge b$ iff $a\wedge b$ exists in $\mathcal{E}(H)$. We note that $a\wedge b$ need not exist in $\mathcal{E}(H)$ even if a and b commute. Let $a\in\mathcal{E}(H)$ be a regular effect such that 0,1 do not belong to the point spectrum of a (recall that a is regular if a and a' are incomparable). By Ando (1999), the infimum $a\wedge a'$ in $\mathcal{E}(H)$ exists iff

$$\int_{0+}^{1-}\lambda\,du(\lambda)\quad\text{and}\quad\int_{0+}^{1-}(1-\lambda)du(\lambda),$$

where $\lambda\to u(\lambda)$ is the spectral measure of a, are comparable, and then the infimum is the smaller of both. But if the point spectrum of a does not contain 0,1, then the above integrals coincide with a and $a'=1-a$, respectively, which are regular, hence incomparable. Therefore, $a\wedge a'$ does not exist.

We conclude that in the MV-algebras A corresponding to maximal sets of commuting effects, the lattice operations in A need not coincide with the lattice operations in $\mathcal{E}(H)$.

It can be shown that there are noncommuting effects a,b in $\mathcal{E}(H)$ such that (a,b) have a Mackey decomposition $(a\ominus a\sqcap b,b\ominus a\sqcap b,a\sqcap b)$. Let ϕ and ψ be different unit vectors in H. Put $a=\lambda\phi$, $b=\mu\psi$, $0<\lambda$, $\mu<1$. We can choose λ and μ such that $a+b\leqslant I$. Then $a\wedge b=0=a\sqcap b$ in $\mathcal{E}(H)$, and $(a,b,0)$ is a strong Mackey decomposition of (a,b).

We conclude that the above MV-algebras do not correspond to maximal compatible sets in $\mathcal{E}(H)$.

V. EFFECT TEST SPACES

In Dvurečenskij and Pulmannová (1994, 2000), Gudder (1997), and Foulis *et al.* (1996) close relations between effect algebras and so-called D-test spaces, resp. effect test spaces, were shown. D-test spaces and effect test spaces are essentially equivalent and they are a generalized form of test spaces introduced by Foulis and Randall (1972) and Randall and Foulis (1973). Let us recall some basic facts about effect test spaces.

Let X be a nonempty set; elements of X are called *outcomes*. Let I be a nonempty set. A function $F:I\to X$ is said to be of *finite multiplicity* if for every $x\in X$, $F^{-1}(x)$ is of finite cardinality. Observe that if $I=\emptyset$, then $X^I=\{\emptyset\}$. For arbitrary sets I,J and functions $F\in X^I$, $G\in X^J$ define $F\subset G$ if there is an injection $\sigma:I\to J$ such that $F=G\circ\sigma$, i.e., $F(i)=G(\sigma(i))$ for all $i\in I$. If $F\subset G$ and $\sigma:I\to J$ is a bijection, we say that F and G are *equivalent*, in symbols $F\sim G$.

Sometimes we will identify equivalent functions, and write $F=G$. Let $F\in X^I$, $G\in X^J$. We can now define unambiguously a function $F\dot\cup G$ as follows: Let $K=I'\cup J'$, $I'\cap J'=\emptyset$, and $\phi:I\to I'$, $\psi:J\to J'$ be bijections. Then $F\dot\cup G\in X^K$, and $F\dot\cup G(k)=F(i)$ if $k=\phi(i), i\in I$, and $F\dot\cup G(k)=G(j)$ if $k=\psi(j), j\in J$. Evidently, $\dot\cup$ is commutative and associative.

For $F\in X^I$, let $\mathcal{R}(F):=\{x\in X: x=F(i) \text{ for some } i\in I\}$, denote the range of F.

Definition 1: Let $\mathcal{J}$ be a nonvoid family of index sets, $X\neq\emptyset$, and let $\mathcal{T}\subseteq\{T\in X^I: I\in\mathcal{J}\}$. We say that $(X,\mathcal{T})$ is an **effect test space** *if the following conditions are satisfied*:

(i) *any $T\in\mathcal{T}$ is of finite multiplicity,*
(ii) *for every $x\in X$ there is a $T\in\mathcal{T}$ such that $x\in\mathcal{R}(T)$,*
(iii) *if $S,T\in\mathcal{T}$ and $S\subset T$, then $S\sim T$.*

An element $T\in\mathcal{T}$ is said to be a **test**.

Notice that if $T\in\mathcal{T}$ and $T\in X^I$, then $I\neq\emptyset$. For otherwise by (*iii*), $\emptyset\subset T\Rightarrow\emptyset=T$ for all tests T, contradicting (*ii*). A function $G\in X^J$ is called an *event* if there is a $T\in\mathcal{T}$ such that $G\subset T$. Denote the set of all events by $\mathcal{E}=\mathcal{E}(X,\mathcal{T})$.

Definition 2: Let F,G be events. We say that F and G are

(i) **orthogonal** (*written $F\perp G$*) *if there is a $T\in\mathcal{T}$ such that $F\dot\cup G\subset T$,*
(ii) **local complements** *of each other* (Floc$G$) *if there is a $T\in\mathcal{T}$ with $F\dot\cup G=T$,* or
(iii) **perspective with axis** H ($F\approx_H G$, *or simply $F\approx G$*) *if they share a common complement H.*

Observe that if $\emptyset\approx G$, then $G\sim\emptyset$. Moreover, two arbitrary tests R,S are perspective with axis $\emptyset$.

Definition 3: An effect test space $(X,\mathcal{T})$ is **algebraic** *if for $F,G,H\in\mathcal{E}$, $F\approx G$ and $F\perp H$ implies $G\perp H$.*

Equivalently, $(X,\mathcal{T})$ is algebraic iff $F,G,H\in\mathcal{E}$, F loc H and $F\approx G$ implies G loc H. If $(X,\mathcal{T})$ is algebraic, then the relation $\approx$ becomes an equivalence relation. Denote by $\Pi=\Pi(X,\mathcal{T})$ the set of all equivalence classes of events. For $F\in\mathcal{E}$, define $\Pi(F)'=\Pi(G)$, where G is any local complement of F. Then $\Pi(F)'$ is well defined. For $F,G\in\mathcal{E}$ define $\Pi(F)\oplus\Pi(G):=\Pi(H)$ iff $F\perp G$ and $H=F\dot\cup G$. Putting $0:=\Pi(\emptyset)$ and $1:=\Pi(T)$, for any $T\in\mathcal{T}$, it can be proved that $\Pi(X,\mathcal{T})$ becomes an effect algebra.

Conversely, let $(E,\oplus,0,1)$ be an effect algebra. Recall that a finite sequence $(a_1,a_2,\ldots,a_n)$ of nonzero elements of E is a finite partition of unity if $a_1\oplus a_2\cdots\oplus a_n$ is defined in $\mathcal{E}$ and equals 1. Put $X:=E\setminus\{0\}$ and let $\mathcal{F}$ be the family of all finite partitions of unity in E. Then $(X,\mathcal{F})$ is an algebraic effect test space, where two events $A=(a_i)_{i\leqslant n}$, $B=(b_j)_{j\leqslant m}$ are perspective iff $\oplus_{i\leqslant n}a_i=\oplus_{j\leqslant m}b_j$. The logic $\Pi(X,\mathcal{F})$ is isomorphic with E. Such a test space is called the *standard test space* for the effect algebra E.

In what follows, we consider an algebraic effect test space $(X,\mathcal{T})$. Let $T\in\mathcal{T}$ be a test. We may assume that $T\in X^{I_T}$, where I_T denotes the index set of T. Let $\sigma(I_T)$ be an ordered partition of I_T. Then there is a mapping $f_\sigma: I_T\to\sigma(I_T)$, such that $f_\sigma(i)=j$ iff $i\in P_j$ where $P_j\in\sigma(I_T)$. Let $\|\sigma\|$ denote the cardinality of $\sigma(I_T)$. We may consider $\{j: P_j\in\sigma(I_T)\}$ as a new index set and assume that there exists a test $\sigma(T)$ in $\mathcal{T}$ such that

$$\sigma(T)(j)\approx\dot\cup_{i\in f_\sigma^{-1}(j)}T(i)=\dot\cup_{i\in P_j}T(i).$$

We will say that $\sigma(T)$ is a *coarsening* of T, or that T is a *refinement* of $\sigma(T)$.

Consider the index set $I_{\sigma(T)}$ of $\sigma(T)$. Let τ be any ordered partition of $I_{\sigma(T)}$. We can build a function $\tau(\sigma(T))$ putting

$$\tau(\sigma(T))(j)\approx\dot\cup_{k\in f_\tau^{-1}(j)}\dot\cup_{i\in f_\sigma^{-1}(k)}T(i)=\dot\cup_{k\in Q_j}(\dot\cup_{i\in P_k}T(i)),$$

where $Q_j\in\tau(\sigma(T))$.

Using the refinement mappings $f_\sigma, f_\tau, f_\kappa$ we can show associativity of compositions. If σ is an ordered partition of I_T, τ is an ordered partition of $I_{\sigma(T)}$ and κ is an ordered partition of $I_{\tau(\sigma(T))}$, then we have

$$\kappa\cdot(\tau\cdot\sigma)(T)=(\kappa\cdot\tau)\cdot\sigma(T).$$

For every $n\in\mathbb{N}$ let σ_n denote the n-ary partition of I_T, so $\|\sigma_n\|=n$. Then $I_{\sigma_n(T)}=\{1,\ldots,n\}$, and we obtain an n-ary test

$$\sigma_n(T)=(\sigma_n(T)(1),\ldots,\sigma_n(T)(n)).$$

In what follows, we show examples of test spaces, where coarsenings and refinements make sense.

Example 1: Let $X=2^Y\setminus\{\varnothing\}$ be the set of all nonempty subsets of nonempty set Y, and consider a classical test space $(X,\mathcal{T})$, i.e., for every test $T\in\mathcal{T}$ the cardinality of $T^{-1}(x)$, $x\in X$, is at most 1. For any test $T\in X^{I_T}$ and any ordered partition $\sigma=\{P_j:j\in J\}$ of I_T, the sets $\cup\{T(i):i\in P_j\}$, $j\in J$ belong to X. Therefore it makes sense to define a function $F:J\to X$ putting $F(j)=\cup\{T(i):i\in P_j\}$. Instead of 2^Y we can consider a subfamily of it, e.g., a σ field of sets, and consider partitions with members in that family.

Example 2: Let $(X,+,0)$ be a positive cone. Let U be a subset of X such that $v\in X$, $u\leqslant v$ for some $u\in U$ implies $v\notin U$. Put $I_n=\{1,\ldots,n\}$ $n\in\mathbb{N}$, and define a function $f:I_n\to X$ to be a test if $\Sigma_{i=1}^n f(i)$ belongs to U. Let $\mathcal{T}$ denote the set of all tests. Then $(X\setminus\{0\},\mathcal{T})$ is an effect test space, and the structure of X enables us to take into account partitions of index sets and the corresponding coarsenings, resp. refinements.. If f is an event, we denote it by $\Sigma f:=\Sigma_{i\in I_f}f(i)$, where I_f is the index set of f. An event h is a local complement of f if $\Sigma_i f(i)+\Sigma_j h(j)\in U$. Events f and g are perspective if they share a common complement. The test space is algebraic iff whenever two events share one local complement, they share all local complements. In this case, the quotient with respect to the perspectivity relation is an effect algebra. For example, if $U=\{u\}$ is a one-element set, then by cancellativity of the positive cone, the test space is algebraic, and we obtain an interval effect algebra. More generally, a positive cone may be replaced by a partial Abelian monoid (cf. Wilce, 1998; Pulmannová and Wilce, 1995, Pulmannová, 1997b).

Example 3: Let $(E\setminus\{0\},\mathcal{T})$ be a standard effect test space of an effect algebra E. Tests in $\mathcal{T}$ are orthogonal subsets $(a_1,\ldots,a_n)$ of nonzero elements such that $\oplus_{i=1}^n a_i=1$. If $(P_1,\ldots,P_s)$ is any partition of the set $\{1,\ldots,n\}$, then $(b_1,\ldots,b_s)$, where $b_i=\oplus_{\{j\in P_i\}}a_j$, is also a test. This example is a special case of Example 2.

Example 4: Let $(X,\mathcal{T})$ be an effect test space, and $\mathcal{E}$ be the set of its events. Put $Z:=\mathcal{E}\setminus\{\varnothing\}$. Consider the set $\mathcal{F}$ of functions $\tilde{F}:I_n\to Z$, where I_n denotes the set $\{1,\ldots,n\}$, $n\in\mathbb{N}$, such that $\dot\cup_{i=1}^n\tilde{F}(i)\in\mathcal{T}$. We prove that $(Z,\mathcal{F})$ is an effect test space. Let $E\in\mathcal{E}-\{\varnothing\}$. Then for any local complement E' of E, the function $\tilde{F}:\{1\}\to Z$, $\tilde{F}(1)=E$ if E is a test, $\tilde{F}:\{1,2\}\to Z$, $\tilde{F}(1)=E$, $\tilde{F}(2)=E'$ otherwise, belongs to $\mathcal{F}$. Hence the union of ranges of functions in $\mathcal{F}$ covers Z. Assume that $\tilde{F}:I_m\to Z$, $\tilde{G}:I_n\to Z$ belong to $\mathcal{F}$, and $\tilde{F}\subset\tilde{G}$. Then there must be an injection $\sigma:I_m\to I_n$ such that $\tilde{F}(\sigma(i))=\tilde{G}(j)$ whenever $\sigma(i)=j$. Then

$$\dot\cup_{\{j\in I_n:j=\sigma(i)\}}\tilde{G}(j)=\dot\cup_{\{i\in I_m\}}\tilde{F}(i)\in\mathcal{T}$$

and hence $\tilde{G}(k)=0$ for $k\in I_n\setminus\sigma(I_m)$, so that $\tilde{F}=\tilde{G}$. This proves that $(Z,\mathcal{F})$ is an effect test space. Denote by $\tilde{\mathcal{E}}$ the set of events of $(Z,\mathcal{F})$. For every $\tilde{E}:I_n\to Z$ in $\tilde{\mathcal{E}}$, define $w(\tilde{E}):=\dot\cup_{i\in I_n}\tilde{E}(i)$. Clearly $w(\tilde{E})$ belongs to $\mathcal{E}$ and $w:\tilde{\mathcal{E}}\to\mathcal{E}$ is a surjective mapping. In addition, if $\tilde{E}\perp\tilde{F}$, then $w(E)\perp w(F)$ and $w(\tilde{E}\dot\cup\tilde{F})=w(\tilde{E})\dot\cup w(\tilde{F})$, and also $w(\tilde{E})\perp w(\tilde{F})$ implies $\tilde{E}\perp\tilde{F}$.

Assume that $(X,\mathcal{T})$ is an algebraic effect test space. We show that $(Z,\mathcal{F})$ is also an algebraic effect test space. Moreover, the corresponding effect algebras $\Pi(X)$ and $\Pi(Z)$ are isomorphic. To prove it, assume that $\tilde{E},\tilde{F},\tilde{G}\in\tilde{\mathcal{E}}$, and $\tilde{E}\approx_{\tilde{G}}\tilde{F}$. Then $w(\tilde{E})\dot{\cup}w(\tilde{G})\in\mathcal{T}$, $w(\tilde{F})\dot{\cup}w(\tilde{G})\in\mathcal{T}$, and hence $w((\tilde{E})\approx_{w(\tilde{G})}w(\tilde{F})$.

Conversely, let $w(\tilde{E})\approx_{w(\tilde{G})}w(\tilde{F})$. Then $w(\tilde{E})\dot{\cup}w(\tilde{G})\in\mathcal{T}$, $w(\tilde{F})\dot{\cup}w(\tilde{G})\in\mathcal{T}$, so that $\tilde{E}\dot{\cup}\tilde{G}\in\mathcal{F}$, $\tilde{F}\dot{\cup}\tilde{G}\in\mathcal{F}$, and hence $\tilde{E}\approx_{\tilde{G}}\tilde{F}$.

Define $\nu:\Pi(Z)\to\Pi(X)$ by $\nu(\Pi(\tilde{E}))=\Pi(w(\tilde{E}))$. If $\tilde{E}\perp\tilde{F}$, then

$$\begin{aligned}\nu(\Pi(\tilde{E})\oplus\Pi(\tilde{F}))&=\nu(\Pi(\tilde{E}\dot{\cup}\tilde{F}))\\&=\Pi(w(\tilde{E}\dot{\cup}\tilde{F}))\\&=\Pi(w(\tilde{E})\dot{\cup}w(\tilde{F}))=\Pi(w(\tilde{E}))\oplus\Pi(w(\tilde{F}))=\nu(\Pi(\tilde{E}))\oplus\nu(\Pi(\tilde{F})).\end{aligned}$$

Clearly, $\nu(\Pi(0))=0$, and $\nu(\Pi(\tilde{T}))=\Pi(w(\tilde{T})=1$ whenever $\tilde{T}\in\mathcal{F}$. Hence ν is a surjective morphism of effect algebras. Since

$$\nu(\Pi(\tilde{E})\perp\nu(\Pi(\tilde{F}))\Rightarrow\Pi(w(\tilde{E}))\perp\Pi(w(\tilde{F}))\Rightarrow w(\tilde{E})\perp w(\tilde{F})\Rightarrow\tilde{E}\perp\tilde{F},$$

ν is an isomorphism.

It is easy to see that if $\tilde{E}$ is any event in $(Z,\mathcal{F})$, $\tilde{E}:I_n\to Z$, and $\kappa(I_n)=(P_1,\ldots,P_{\|\kappa\|})$ is any partition of I_n, then $\tilde{F}:I_{\|\kappa\|}\to Z$, $\tilde{F}(i)=\dot{\cup}(\tilde{E}(j):j\in P_i)\}$ is an event in $(Z,\mathcal{F})$.

VI. TEST SPACES WITH REFINEMENTS

The following definition is inspired by Harding (2001).

Definition 4: Let $(X,\mathcal{T})$ be an effect test space. We will say that $(X,\mathcal{T})$ is a **leveled effect test space** *if for every test $T:I_T\to X$ in $\mathcal{T}$ and every finite partition $\sigma(I_T)=(P_1,\ldots,P_n)$, $\|\sigma\|=n$, $n\in\mathbb{N}$, of the set I_T, there is a test $\sigma(T):\{1,\ldots,n\}\to X$ such that $\sigma(T)(i)=\dot{\cup}_{j\in P_i}T(j)$.*

Let $(X,\mathcal{T})$ be a leveled algebraic effect test space and $\mathcal{E}$ be its set of events. We say that an event F is a *refinement* of an event E if there is a mapping $\kappa:I_F\to I_E$ such that for every $i\in I_E$, $E(i)\approx\dot{\cup}\{F(j):j\in\kappa^{-1}(i)\}$. Clearly, if F is a refinement of E, then $F\approx E$. We say that two events E and G have a *common refinement*, if there is an event F which is a refinement of both E and G. Clearly, if E and G have a common refinement, then $E\approx G$.

We say that events $E_1,\ldots,E_k$ *can be built* from an event F if there are subevents $F_1,\ldots,F_k$ of F which are refinements of $E_1,\ldots,E_k$, respectively.

Let $A,B:\{1,2\}\to X$ be binary events, and let $C:I_C\to X$ be their common refinement. Then there are partitions (I_1,I_2) and (J_1,J_2) of the set I_C such that $A(1)=\dot{\cup}_{i\in I_1}C(i)$, $A(2)=\dot{\cup}_{i\in I_2}C(i)$, $B(1)=\dot{\cup}_{j\in J_1}C(j)$, $B(2)=\dot{\cup}_{j\in J_2}C(j)$. We can construct a partition of I_C consisting of sets $I_1\cap J_1,I_1\cap J_2,I_2\cap J_1,I_2\cap J_2$ and define the events $W_{ij}=\dot{\cup}_{k\in I_i\cap J_j}C(k)$, $i,j=1,2$. The four-element event $(W_{ij})_{i,j=1}^2$ is a common refinement of A and B. Any two binary events A,B which have a common refinement also have a common refinement of the latter type. We say that the events A, B admit a *strong common refinement* if they have a common refinement $(W_{ij})_{i,j=1}^2$ such that $W_{12}\cap W_{21}=\varnothing$, that is, there is no nonempty event V under W_{12} and W_{21}.

Theorem 4: *Let $(X,\mathcal{T})$ be an algebraic leveled effect test space. Let $\mathbb{E}=\Pi(\mathcal{E})$ be the corresponding effect algebra. The following statements are equivalent.*

(i) *Elements $a_1,\ldots,a_n$ in $\mathbb{E}$ are compatible.*
(ii) *There are events $A_1,\ldots,A_n$ in $\mathcal{E}$, $\Pi(A_i)=a_i$, that can be built from a test T in $\mathcal{T}$.*
(iii) *There are binary tests B_i with $\Pi((B_i)(1))=a_i$, $i=1,\ldots,n$, which have a common refinement.*

Moreover, elements a,b in E are strongly compatible if and only if there are binary events A,B, such that $\Pi(A)=a,\Pi(B)=b$ and A,B admit a strong common refinement.

Proof: $(i)\Rightarrow(ii)$. By (i), there is an orthogonal set $(c_1,\ldots,c_k)$ such that $a_i=\oplus_{j\in I_i}c_j$, $I_i\subset\{1,\ldots,k\}$, $i=1,\ldots,n$. Hence there are orthogonal events $C_1,\ldots,C_k$ with $\Pi(C_i)=c_i$, $i=1,\ldots,k$, and a test $T\in\mathcal{T}$ to which $C_1,\ldots,C_k$ belong. We then have $a_i=\Pi(\dot{\cup}_{j\in I_i}C_j)$, $i=1,\ldots,n$, and $A_i=\dot{\cup}_{j\in I_i}C_j$, $i=1,\ldots,n$, can be built from T.

$(ii)\Rightarrow(iii)$. Let $a_i=\Pi(A_i)$, $i=1,\ldots,n$, and $A_1,\ldots,A_n$ can be built from a test T. We may assume, with no loss of generality, that $A_1,\ldots,A_n$ are subevents of T. Then there are subsets $I_1,\ldots,I_n$ of the index set I_T of T such that $A_k=\dot{\cup}_{j\in I_k}T(j)$, $k=1,\ldots,n$. Taking partitions $(I_k,I_T\setminus I_k)$ of I_T, we obtain binary tests B_k, $k=1,\ldots,n$, with $B_k(1)\approx A_k=\dot{\cup}_{i\in I_k}T(j)$, which can be built from T.

$(iii)\Rightarrow(i)$. Let B_i, $i=1,\ldots,n$, be binary tests with $\Pi(B_i(1))=a_i$ which can be built from a test T. Then there are subsets I_i of I_T with $B_i(1)\approx\dot{\cup}_{j\in I_i}T(i)$. Taking a suitable coarsening if necessary, we may assume that I_T is finite, $I_T=\{1,\ldots,k\}$. Then $c_j=\pi(T(j))$, $j=1,\ldots,k$, is an orthogonal sequence, and $a_i=\Pi(\dot{\cup}_{j\in I_i}T(j))=\oplus_{j\in I_i}c_j$.

To prove the remaining part, assume that (a,b) in E have a strong Mackey decomposition (a_1,b_1,c) and put $d=a_1\oplus b_1\oplus c$. Let A,B be any events such that $\Pi(A)=a$, $\Pi(B)=b$. Then there are orthogonal events A_1,B_1,C,D' belonging to a test T, such that $\Pi(A_1)=a_1,\Pi(B_1)=b_1,\Pi(C)=c$ and $\Pi(D')=d'$. We have $\Pi(A_1\dot{\cup}C)=a$, $\Pi(B_1\dot{\cup}C)=b$, hence $A\approx A_1\dot{\cup}C$, $B\approx B_1\dot{\cup}C$, and (A_1,B_1,C,D') is a common refinement of the binary tests (A,A') and (B,B'). From $a_1\wedge b_1=0$, we obtain that there is no event $V\neq\varnothing$ lying under A_1 and B_1.

The proof of the opposite statement is analogous. □

In the following theorem, we give a characterization of the most important types of effect algebras by properties of leveled effect test spaces. Notice that statements similar to (ii) and (iii) in terms of ordinary effect test spaces have been proved in Di Nola and Dvurečenskij (2001).

Theorem 5: *Let $(X,\mathcal{T})$ be a leveled algebraic effect test space, $\mathcal{E}$ its set of events and $\mathbb{E}=\Pi(\mathcal{E})$ the corresponding effect algebra. The following statements hold.*

(i) *$\mathbb{E}$ is an orthoalgebra if and only if every test is an injective function.*
(ii) *$\mathbb{E}$ is an OMP if and only if every pairwise orthogonal event E,F,G can be built from one test T.*
(iii) *$\mathbb{E}$ has the RDP if and only if every two perspective binary events have a common refinement.*
(iv) *$\mathbb{E}$ is an MV-algebra if and only if every two perspective binary events have a strong common refinement.*

Proof: (i) is well-known. (ii) easily follows from the fact that an effect algebra E is an OMP iff for any a,b,c in $\mathbb{E}$ which are pairwise orthogonal $a\oplus b\oplus c$ exists.

(iii) Let $\mathbb{E}$ have the RDP. Let $A:\{1,2\}\to X$, $B:\{1,2\}\to X$ be perspective binary events. Put $\pi(A(1))=a_1$, $\pi(A(2))=a_2$, $\pi(B(1))=b_1$, $\pi(B(2))=b_2$. By assumption $A\approx B$, which implies $A(1)\dot{\cup}A(2)\approx B(1)\dot{\cup}B(2)$, and this in turn implies $a_1\oplus a_2=b_1\oplus b_2$. By RDP, there are elements $w_{11},w_{12},w_{21},w_{22}$, jointly orthogonal and such that $a_1=w_{11}\oplus w_{12}$, $a_2=w_{21}\oplus w_{22}$, $b_1=w_{11}\oplus w_{21}$, $b_2=w_{12}\oplus w_{22}$. Then there are events W_{ij}, $i,j\in\{1,2\}$, such that $w_{ij}=\Pi(W_{ij})$, which all belong to one test. The event $W=(W_{11},W_{12},W_{21},W_{22})$ is a common refinement of A and B.

Conversely, assume that every two perspective binary events have a common refinement. Let $a_1\oplus a_2=b_1\oplus b_2$, where a_1,a_2,b_1,b_2 are elements in E. Then there are perspective binary events A,B such that $A(i)=a_i$, $i=1,2$, and $B(j)=b_j$, $j=1,2$. By supposition, they have a common refinement $W=(W_{11},W_{12},W_{21},W_{22})$, $A_i\approx\dot{\cup}_{j=1}^{2}W_{1j}$, $i=1,2$, $B_j=\dot{\cup}_{i=1}^{2}W_{ij}$, $j=1,2$. It follows that $a_1=\oplus_{j=1}^{2}\Pi(W_{ij})$, $i=1,2$, $b_j=\oplus_{i=1}^{2}\Pi(W_{ij})$, $j=1,2$, which yields the RDP.

(iv) Let $\mathbb{E}$ be an MV-algebra and let A, B be perspective binary events. Put $\Pi(A_i)=a_i$ and $\Pi(B_j)=b_j$, $i,j=1,2$. Then we have $a_1\oplus a_2=b_1\oplus b_2$, and since E is an MV-algebra, there are

jointly orthogonal elements $w_{ij}, i,j=1,2$, such that $a_i=\oplus_{j=1}^{2} w_{ij}$, $b_j=\oplus_{i=1}^{2} w_{ij}$ and $w_{12}\wedge w_{21}=0$ (Fuchs, 1963). Then there are orthogonal events W_{ij}, $i,j=1,2$, such that $\Pi(W_{ij})=w_{ij}$, so that $W_{12}\cap W_{21}=\varnothing$. It follows that A and B have a strong common refinement. By reversing the arguments, the converse statement is proved. □

On the complete solution of the Sturm–Liouville problem $(d^2X/dx^2)+\lambda^2X=0$ over a closed interval

Yuriy Sosov and Constantine E. Theodosiou[a)]
Department of Physics and Astronomy, The University of Toledo, Toledo, Ohio 43606-3390

(Received 4 June 2001; accepted for publication 24 January 2002)

We discuss the sets of orthogonal functions that form solutions to the Sturm–Liouville problem for the equation $d^2X/dx^2+\lambda^2X=0$ and for the general unmixed boundary conditions over a closed interval of the variable x. The conditions for the presence of the solutions with $\lambda^2\leqslant 0$ are specifically considered and their necessity for completeness of a set of eigenfunctions. Their implications are discussed for three examples from mathematical physics, showing that although for some problems the solutions, corresponding to the negative values of λ^2, may reflect physically unusual boundary conditions, their presence is necessary in the general solution for the drift diffusion equation where they may represent stationary or growing in time solutions. © *2002 American Institute of Physics.*

I. INTRODUCTION

Second-order partial differential equations are commonly solved in different domains of physics. In our case we need to solve the continuity equation of a fluid with specific boundary conditions, as part of our simulation of gaseous discharges in plasmas. In treating such systems we found that a careful study of the ''separation-of-variables'' constant parameters must be made to assure that we include all the correct physical solutions, analytic or numerical. We have found that the relevant literature does not always provide complete solutions and the choices of solutions are not carefully justified. In the following we make a careful analysis of the Sturm–Liouville problem, point out where problems with the identification of the solutions arise, and provide some characteristic examples.

II. THE STURM–LIOUVILLE PROBLEM

The method of separation-of-variables, when used in second-order partial differential equations with constant coefficients often lead to ordinary differential equations of the form

$$\frac{d^2X}{dx^2}+\lambda^2X=0 \tag{1}$$

for the space part, in an interval with general unmixed boundary conditions

$$\frac{dX}{dx}+h_1X=0 \quad \text{for } x=0, \tag{2a}$$

$$\frac{dX}{dx}+h_2X=0 \quad \text{for } x=1. \tag{2b}$$

Without loss of generality, x will be assumed to take values on the interval [0,1].

a)Electronic mail: cet@physics.utoledo.edu

Usually the partial solutions representing different values of parameter λ are then written in the form

$$X_\lambda = A_\lambda \sin(\lambda x) + B_\lambda \cos(\lambda x), \quad \lambda^2 > 0, \tag{3a}$$

$$X_\lambda = A_\lambda x + B_\lambda, \quad \lambda^2 = 0, \tag{3b}$$

$$X_\lambda = A_\lambda \sinh(\lambda x) + B_\lambda \cosh(\lambda x), \quad \lambda^2 < 0, \tag{3c}$$

and the three different cases of the ranges of the values of λ^2 are considered together with the boundary conditions.

The consistency requirement for the system of the two equations obtained after the substitution of (3) into (2) gives the different ranges of the values for λ^2, the eigenvalues, which determine the different types of functions that should be present in the set of solutions. The same equation determines the interdependence of A_λ and B_λ for a given λ.

A differential equation defined on the interval $a \leqslant x \leqslant b$ having the form of

$$\frac{\mathrm{d}}{\mathrm{d}x}\left[k(x)\frac{\mathrm{d}X}{\mathrm{d}x}\right] + [\lambda^2 r(x) - q(x)]X = 0$$

with the boundary conditions

$$a_1 X(a) + a_2 \frac{\mathrm{d}X}{\mathrm{d}x}(a) = 0,$$

$$b_1 X(b) + b_2 \frac{\mathrm{d}X}{\mathrm{d}x}(b) = 0$$

is called the *Sturm–Liouville boundary value problem*. In our case, $k(x)=1$, $q(x)=0$, $r(x)=1$, and $h_1 = a_1/a_2$, $h_2 = b_1/b_2$, limited to the real values of h_1 and h_2.

The set of eigenfunctions X_λ obtained as nontrivial solutions of the Sturm–Liouville boundary value problem corresponding to the eigenvalues λ, is used to construct a general solution

$$X = \sum_\lambda X_\lambda \tag{4}$$

as well as to decompose some given function (that represents the initial conditions) to determine the values of A_λ and B_λ, or to build the Green's function for a differential equation. In this case completeness of the set of functions in the set is critical. Orthogonality of the functions X_λ in the set of solutions for Eq. (1) with the boundary conditions (2) and ${\lambda^2}_1 \neq ({\lambda^2}_2)^*$, assuming that h_1 and h_2 are real, can be easily verified:

$$\begin{aligned}
({\lambda^2}_1 - {\lambda^2}_2{}^*) \int_0^1 X_{\lambda_1} X^*_{\lambda_2}\,\mathrm{d}x &= \int_0^1 [({\lambda^2}_1 X_{\lambda_1}) X^*_{\lambda_2} - ({\lambda^2}_2{}^* X^*_{\lambda_2}) X_{\lambda_1}]\mathrm{d}x \\
&= \int_0^1 \left[\frac{\mathrm{d}^2 X_{\lambda_1}}{\mathrm{d}x^2} X^*_{\lambda_2} - \frac{\mathrm{d}^2 X^*_{\lambda_2}}{\mathrm{d}x^2} X_{\lambda_1}\right]\mathrm{d}x \\
&= \left(X_{\lambda_1} \frac{\mathrm{d}X^*_{\lambda_2}}{\mathrm{d}x} - \frac{\mathrm{d}X_{\lambda_1}}{\mathrm{d}x} X^*_{\lambda_2} \right)\Bigg|_0^1 \\
&= X_{\lambda_1}(0) X^*_{\lambda_2}(0)(h_1 - h_1^*) - X_{\lambda_1}(1) X^*_{\lambda_2}(1)(h_2 - h_2{}^*) = 0.
\end{aligned} \tag{5}$$

These solutions are not orthogonal if h_1 and/or h_2 are complex. It should be noted that in the procedure of building the general solution, *all* possible values of λ^2 corresponding to an eigenfunction X_λ should be taken into account. The failure to include even one of the former will lead to an incomplete set of eigenfunctions unable to decompose the function representing the initial conditions in the general case. The question of completeness is further considered in the Appendix.

Solutions in the form (4) are routinely used today in computational applications. Examples are the computational procedures used to solve partial differential equations with constant coefficients. As can be seen from commonly used textbooks for mathematical physics,[1–4] the long-term teaching practice for treating the method of separation-of-variables is to give the solution of Sturm–Liouville problem for Eq. (1) in an interval for zero boundary conditions, namely $X=0$ for $x=0$ and for $x=1$. This leads only to the positive values of the separation parameter λ^2.[1–4] It may be due to this widespread practice that we can often find examples where only eigenfunctions corresponding to $\lambda^2>0$ are taken into account, whereas those for $\lambda^2\leqslant 0$ are omitted.[1,3] For example, Arfken and Weber[5] state in a footnote that λ^2 depends on the boundary conditions but make no further use of that fact. Whether representing physically existing cases (see example IV A in the following) or physically rare or unusual boundary conditions (see Example IV B in the following), the solutions representing negative values of λ^2 should be carefully taken into account. Furthermore, in the construction of a complete solution or in building a Green's function (see example IV C in the following) completeness is absolutely required. The goal of the present paper is to carefully consider the implications of the cases of the solutions for zero and negative values of λ^2.

III. EFFECT OF THE BOUNDARY CONDITIONS

It is useful then to address the question whether it is possible for certain values of h_1 and h_2, involved in the boundary conditions (2), to find an eigenfunction that corresponds to a certain value of the parameter λ^2. In order to answer this question, we will consider the Sturm–Liouville problem for Eq. (1) satisfying the general unmixed boundary conditions (2). It is convenient to write solutions of (1) in the form

$$X_\lambda(x)=\frac{A_\lambda}{\lambda}\sin(\lambda x)+B_\lambda\cos(\lambda x) \tag{6}$$

that can represent all possible values of the separation constant $\lambda^2\in R$. For $\lambda^2=0$ it is assumed that

$$X_0(x)=\lim_{\lambda\to 0}[X_\lambda(x)]=A_0x+B_0.$$

We should also remark that $X_\lambda(x)=X_{-\lambda}(x)$, so that, in this paper, whenever $\lambda^2\geqslant 0$ then $\lambda=+\sqrt{\lambda^2}$, and if $\lambda^2<0$ then $\lambda=+i\sqrt{|\lambda^2|}$.

When the solution (6) is substituted into the boundary conditions (2) it gives a homogeneous system of linear equations for A and B,

$$A_\lambda+B_\lambda h_1=0, \tag{7a}$$

$$A_\lambda\left(\frac{h_2}{\lambda}\sin\lambda+\cos\lambda\right)+B_\lambda(h_2\cos\lambda-\lambda\sin\lambda)=0, \tag{7b}$$

which must have a zero determinant to be consistent. This condition results in the following transcendental equation for the eigenvalues λ:

$$\frac{\sin\lambda}{\lambda}(\lambda^2+h_2h_1)=(h_2-h_1)\cos\lambda, \tag{8}$$

which should be carefully considered for the different values of h_1 and h_2.

(A) $h_1=h_2=0$. This condition represents the case when $dX/dx=0$ for both $x=0$ and $x=1$. It gives $\lambda\in\{0,\pi,2\pi,3\pi,\ldots\}$, $A_\lambda=0$, and the solution

$$X_\lambda(x)=B_\lambda\cos(\lambda x).$$

(B) $h_1\to\infty$, $h_2\to\infty$. This condition represents the situation when $X=0$ for both $x=0$ and $x=1$, giving $\lambda\in\{\pi,2\pi,3\pi,\ldots\}$, $B_\lambda=0$, and

$$X_\lambda(x)=\frac{A_\lambda}{\lambda}\sin(\lambda x)=A'_\lambda\sin(\lambda x).$$

(C) $h_1=h_2=h\neq 0$. Then $\lambda=\{ih\}\cup\{\pi,2\pi,3\pi,\ldots\}$, i.e., λ^2 has one negative root, $B_\lambda=-A_\lambda/h$, and

$$X_\lambda(x)=\frac{A_\lambda}{h}[\sinh(hx)-\cosh(hx)]=A_\lambda e^{-hx}\quad\text{for }\lambda\in\{ih\},$$

and

$$X_\lambda(x)=A_\lambda\left[\frac{\sin(\lambda x)}{\lambda}-\frac{\cos(\lambda x)}{h}\right]=A_\lambda\sin(\lambda x+\delta_\lambda),\quad \delta_\lambda=-\tan^{-1}(\lambda/h)$$

for $\lambda\in\{\pi,2\pi,3\pi,\ldots\}$. It is worth pointing out that the complete set of eigenfunctions in this case will contain not only sine's and cosine's but also an exponent.

(D) $h_1\neq h_2$. Then Eq. (8) can be rewritten for convenience as

$$\lambda\cot\lambda=\frac{\lambda^2+h_2h_1}{h_2-h_1}. \tag{9}$$

To further demonstrate the influence of the parameters h_1 and h_2 on the type of solution (6), we rewrite Eq. (9) as

$$\lambda\cot\lambda=a\lambda^2+b \tag{10a}$$

for $h_1\neq h_2$, with

$$a=\frac{1}{h_2-h_1},\quad b=\frac{h_2h_1}{h_2-h_1}. \tag{10b}$$

For $\lambda\to 0$, Eq. (10a) should be understood as its limit $1=a\lambda^2+b$. Form (10a) becomes amenable to a graphical illustration of finding its solutions by drawing its left- and right-hand sides separately, as seen in Fig. 1.

The general solution (4) of the Sturm–Liouville problem can be split into two parts, one for $\lambda^2>0$ and one for $\lambda^2\leqslant 0$:

$$X=\sum_\lambda X_\lambda=\sum_\lambda\left[\frac{A_\lambda}{\lambda}\sin(\lambda x)+B_\lambda\cos(\lambda x)\right]=\sum_{\lambda^2\leqslant 0}X_\lambda+\sum_{\lambda^2>0}X_\lambda \tag{11}$$

with the values of A_λ and B_λ restricted by either (7a) or (7b). As can be concluded now from Fig. 1, and depending on the values of h_1, h_2, a, and b [cf. Eq. (10)], the sum $\Sigma_{\lambda^2\leqslant 0}X_\lambda$ can contain two, one, or zero terms, corresponding to lines III, II, and I respectively, in contrast to the case of $\lambda^2>0$ when the sum has an infinite number of terms.

To investigate the possibility of appearance zero and negative eigenvalues we look into the values of function $\lambda\cot(\lambda)$ for $\lambda^2<\pi^2$, represented by curve C in Fig. 1. The slope of this curve

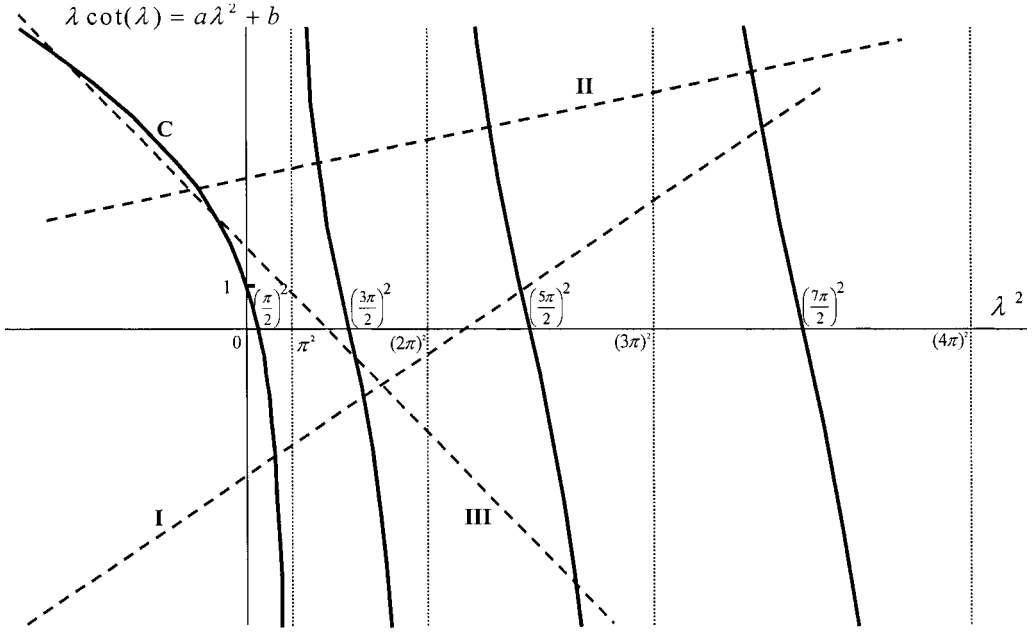

FIG. 1. Graphical solution of the transcendental equation $\lambda \cot\lambda = a\lambda^2 + b$. The numbers above the horizontal axis give the points of intersection of this axis with the displayed graph of the function.

varies from zero, when $\lambda^2 \to -\infty$, to $-\infty$, when $\lambda^2 \to \pi^2$. When $\lambda^2 \to 0$, it equals $-1/3$. Therefore, for any $a<0$ in (10a) it is possible to find the appropriate value $b_0>0$ so that the line $a\lambda^2+b_0$ becomes tangential to curve C. Let T be the point of contact.

(D1) For $\lambda^2<0$, the tangent of curve C (Fig. 2) has a slope varying from $-1/3$ to 0. Let us consider the lines $a\lambda^2+b$ with $-1/3<a<0$ and the following values of b:

(1) $b>b_0$, the region above $a\lambda^2+b_0$ (dashed line I in Fig. 3), gives no negative or zero roots for λ^2 in (10a),
(2) $b=b_0$, coincides with line I and renders one negative root,
(3) $1<b<b_0$, region in between line I and $a\lambda^2+1$ (dashed line II in Fig. 3), two negative roots,
(4) $b=1$, line II, one negative and one zero root,
(5) $b<1$, region below line II, one negative root.

(D2) For $0\leqslant\lambda^2<\pi^2$ the tangent of curve C (Fig. 3) has a slope varying from $-\infty$ to $-1/3$. Following the same geometrical construction as noted previously, for $a\leqslant -1/3$ and different values of b we obtain

(1) $1<b$, region to the right of line II, no negative or zero roots,
(2) $b=1$, line II, one negative and one zero root,
(3) $b<1$, region below line II, one negative root.

(D3) For $0\leqslant a$ line $a\lambda^2+b$ can have only one intersection with curve C. So for:

(1) $1<b$, the region below the dashed line in Fig. 4, the equation has one negative root,
(2) $b=1$, the dashed line, one negative and one zero root,
(3) $b<1$, the region above the dashed line, no negative or zero roots.

Using the parametric dependence of a and b_0 on λ, i.e.,

$$a=\frac{\cot\lambda-\lambda\csc^2\lambda}{2\lambda}, \quad b_0=\frac{\lambda}{2}(\lambda\csc^2\lambda+\cot\lambda), \tag{12}$$

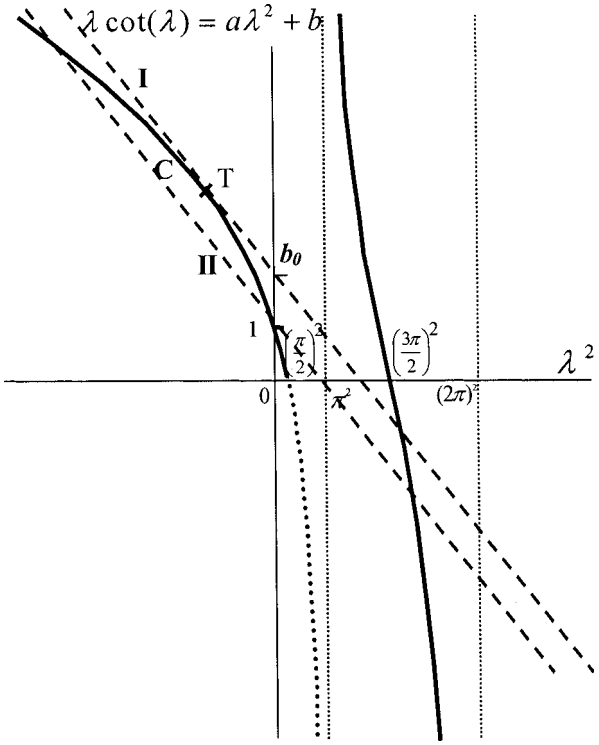

FIG. 2. Same as Fig. 1, highlighting the case of $-1/3 \leqslant a \leqslant 0$.

two useful formulas are easily derivable:

$$ab_0 = -\frac{1}{4}(\lambda^2 \csc^4 \lambda - \cot^2 \lambda), \quad \frac{db_0}{da} = -\lambda^2.$$

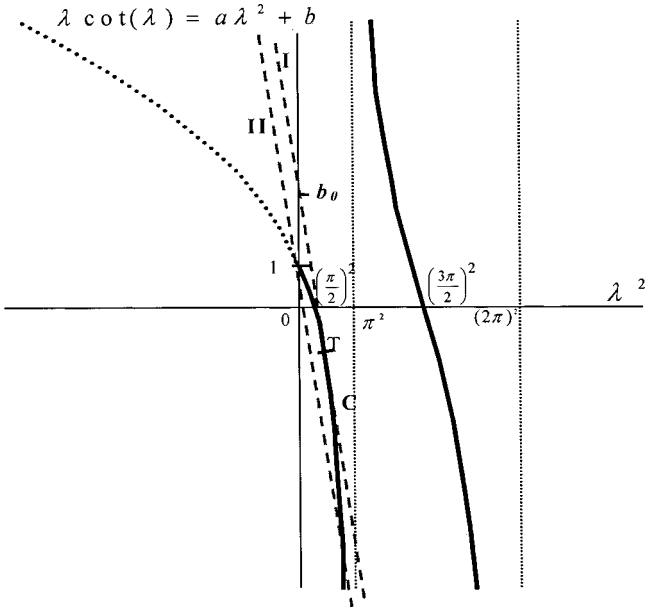

FIG. 3. Same as Fig. 2, highlighting the case of $a \leqslant -1/3$.

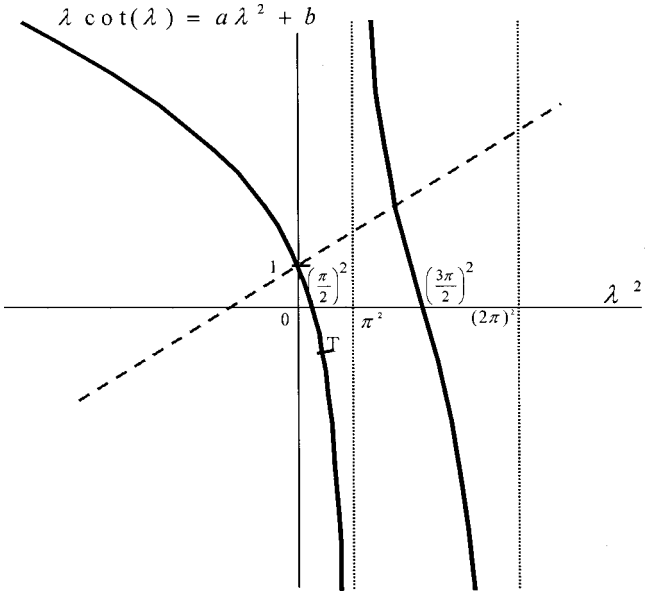

FIG. 4. Same as Fig. 2, highlighting the case of $0 \leqslant a$.

Some other useful expressions are $\lambda^2 \csc^4\lambda - \cot^2\lambda > 1$ for any value of λ^2 and $\lim_{\lambda^2 \to -\infty}(\lambda^2 \csc^4\lambda - \cot^2\lambda) = 1$. These allow us to plot $b_0(a)$ for $a \in (-\frac{1}{3}, 0)$.

Finally, Fig. 5 summarizes cases D1–D3 mentioned previously. Here the two dashed curves correspond to $ab_0 = -\frac{1}{4}$. The solid gray curve illustrates the graph for $b_0(a)$. The line $b = 1$ corresponds to one zero root. The regions $1 < b, 0 \leqslant a$ and $b < 1, 0 < a$, together with the curve $b_0(a)$ give the area where there is one negative root. Finally, the open region bordered by curves $b_0(a)$, $b = 1$, and $a = 0$, renders two negative roots. The arrows at the ends of corresponding curves denote that the end points are excluded. It is worth mentioning that a pair of a and b corresponds to two possible values of h,

$$h_1 = \frac{-1 \mp \sqrt{1+4ab}}{2a}, \quad h_2 = \frac{1 \mp \sqrt{1+4ab}}{2a},$$

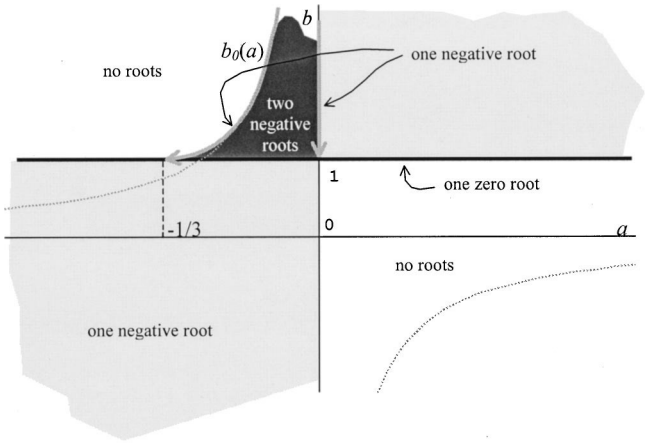

FIG. 5. Summary of the mapping of the zero and negative λ^2 roots as a function of the parameters a and b. Branches of the $ab = -\frac{1}{4}$ graph are shown as dotted lines. The values of the parameters a and b between the branches correspond to real vlaues of h_1 and h_2.

and only the values of a and b between two branches of $ab_0=-\frac{1}{4}$ correspond to the real values of h_1 and h_2.

Some specific examples are presented in the following that demonstrate the above-mentioned analysis for different cases of the values of λ^2.

IV. EXAMPLES

A. Drift-diffusion equation

In our study of gas discharges in plasma displays we use the drift-diffusion equation

$$\frac{\partial n}{\partial t}=\alpha^2\frac{\partial^2 n}{\partial x^2}+\beta\frac{\partial n}{\partial x}+\gamma n, \quad x\in[0,1], \tag{13}$$

to check the behavior of a finite-difference numerical scheme solution against the exact solution derived in the following. This equation can be interpreted as a system of two equations, the continuity equation with *a source*

$$\frac{\partial n}{\partial t}+\frac{\partial J}{\partial x}=\gamma n$$

and the equation determining the density flux

$$J=-\alpha^2\frac{\partial n}{\partial x}-\beta n.$$

By making the substitution

$$n=u\exp(\kappa x+\eta t) \quad \text{with} \quad \kappa=-\beta/2a^2, \quad \eta=\gamma-\beta^2/4a^2,$$

Eq. (13) takes the familiar form of the heat-flow equation

$$\frac{\partial u}{\partial t}=a^2\frac{\partial^2 u}{\partial x^2},$$

which can be solved by the separation of variables method. Assuming that $u(x,t)=\Sigma_i T_i X_i$, we obtain the equations for T_i and X_i: $\mathrm{d}T_\lambda/\mathrm{d}t=-a^2\lambda^2 T_\lambda$, with the solution $T_\lambda=\exp(-a^2\lambda^2 t)$, and $\mathrm{d}^2X/\mathrm{d}x^2+\lambda^2 X=0$.

We are interested in the case when both fluxes are zero at the boundaries. Recalculation of the flux at the boundaries

$$J=-e^{\kappa x+\eta t}\left[a^2\frac{\partial u}{\partial x}+(a^2\kappa+\beta)u\right]=0$$

in terms of u, gives values of constants with the boundary conditions $h_1=h_2=h=\kappa+\beta/\alpha^2=\beta/2\alpha^2$. This represents the previously mentioned case (C), so that $X_\lambda(x)=A_\lambda e^{-hx}$ for $\lambda\in\{ih\}$, and

$$u_\lambda(x)=A_\lambda\sin(\lambda x+\delta_\lambda), \quad \delta_\lambda=-\tan^{-1}(\lambda/h), \quad \lambda\in\{\pi,2\pi,3\pi,\ldots\}.$$

The general solution is then

$$n(x,t)=e^{\kappa x+\eta t}\sum_\lambda T_\lambda X_\lambda=\sum_\lambda \exp\left[\left(\gamma-\frac{\beta^2}{4a^2}-a^2\lambda^2\right)t\right]\exp\left(-\frac{\beta}{2a^2}x\right)X_\lambda.$$

After substitution of X_λ and splitting the sum in parts for $\lambda^2\geqslant 0$ and $\lambda^2<0$ it becomes

$$n(x,t)=A_{ih}e^{\gamma t}\exp\left(-\frac{\beta}{a^2}x\right)+\sum_{\lambda^2\geqslant 0}A_\lambda\exp\left[\left(\gamma-\frac{\beta^2}{4a^2}+a^2\lambda^2\right)t\right]\exp\left(-\frac{\beta}{2a^2}x\right)\sin(\lambda x+\delta_\lambda).$$

It is interesting to remark that in the case of $\gamma=0$, i.e., zero sources and $\int_0^1 n(x,t)\mathrm{d}x=\text{const}$, the term $A_\lambda\exp[-(\beta/a^2+h)x]$ represents the stationary solution which can also be found from a physical reasoning that the stationary solution makes the flux $J=-\alpha^2(\partial n/\partial x)-\beta n$ zero. A physical realization of this case would be the diffusion of particles suspended in the air under the influence of the gravitation field.

B. Oscillations of a fixed rod

To give an example where the eigenfunctions with $\lambda^2<0$ represent a physically impossible situation, let us consider the problem of finding the longitudinal oscillations of the elastically fixed rod over a space interval. This leads to[3]

$$\frac{\mathrm{d}^2u}{\mathrm{d}t^2}=a^2\frac{\mathrm{d}^2u}{\mathrm{d}x^2}$$

with the boundary conditions

$$\frac{\mathrm{d}u}{\mathrm{d}x}-hu=0 \quad \text{for } x=0,$$

$$\frac{\mathrm{d}u}{\mathrm{d}x}+hu=0 \quad \text{for } x=1$$

for all times t. Here h represents the coefficient of elasticity and should be positive to represent a physically meaningful case. Further separation of variables gives $u(x,t)=\Sigma_i T_iX_i$ as the general solution. Equation $\mathrm{d}^2X/\mathrm{d}x^2+\lambda^2X=0$ for the space part X is solved with the boundary conditions $\mathrm{d}X/\mathrm{d}x-hX=0$ for $x=0$ and $\mathrm{d}X/\mathrm{d}x+hX=0$ for $x=1$. This gives $h_1=-h$, $h_2=h$, so that $a=1/(2h)$ and $b=-h/2$ [cf. case (D)]. The possible values of a and b are represented by $ab=-1/4$, the dashed curve in Fig. 5. X_λ with negative and zero values of λ^2 are possible for $a\leqslant 0$ or $h<0$; however, they represent a physically unusual boundary condition since the negative value of h implies a negative sign of Hook's constant, i.e., stretching grows continuously with time.

C. Construction of Green's functions

Smirnov's *Course of Higher Mathematics*[1] considers the equation $\mathrm{d}^2X/\mathrm{d}x^2+\lambda^2X=0$ with boundary conditions $X=0$ for $x=0$ and $\mathrm{d}X/\mathrm{d}x+hX=0$ for $x=1$ in order to find a complete set of eigenfunctions. We should point out that a similar problem would appear in Sec. IV B assuming the rigid fixing of the rod's end at $x=0$ in the previous example, when constructing the general solution in the form (4) or when obtaining the Green's function in the form[1] (see Appendix)

$$G(x,\xi)=\sum_{\lambda_i}\frac{X_{\lambda_i}(x)X_{\lambda_i}(\xi)}{\lambda^2-\lambda^2{}_i}.$$

Obviously, an incomplete basis will not project the correct solution out of the inhomogeneous term.

Although Titchmarsh[6] in a similar case gives the example of negative λ^2, Smirnov[1] mentions the possibility but does not implement such values. For example, Smirnov[1] mentions that the complete set of solutions is (in our notation here) $X_\lambda(x)=A_\lambda\sin(\lambda x)$, where λ is to be found from equation $\tan\lambda+h\lambda=0$ giving all λ^2 to be positive. Since he uses this example several times throughout his multivolume work, but only mentions once (and that only in the Russian edition[7]) that he will limit his consideration to $h>0$, it makes it hard for the reader to consider that

limitation. Following the previously mentioned case (D), with $h_1=\infty$ and $h_2=h$, it is possible to see that here $a=0$ and $b=-h$, so that one zero or negative root of λ^2 is possible for $b\geqslant 1$ or $h\leqslant -1$, giving an additional eigenfunction

$$X_{i|\lambda|}(x)=\frac{B_{i|\lambda|}}{i|\lambda|}\sin[i|\lambda|x]=\frac{B_{i|\lambda|}}{|\lambda|}\sinh[|\lambda|x]$$

for $\lambda^2\leqslant 0$.

APPENDIX: OUTLINE OF THE COMPLETENESS PROOF

Here we want to briefly illustrate the necessity for taking into account all eigenfunctions corresponding to solutions of (1) with (2) when building a general solution. The argument takes its root in the proof of the expansion theorem. The most straightforward and useful way, for our purpose, is to use the method of contour integration. The application of this method to the boundary value problem of the ordinary linear differential equations of the nth order has been discussed in Ref. 8, and specifically to differential equations of the second order with boundary conditions (2) in Refs. 6 and 9 and we will follow their approach.

The resolvent for

$$\frac{d^2\Phi}{dx^2}+\lambda^2\Phi=f(x) \tag{A1}$$

is the function

$$\Phi(x,\lambda^2)=\frac{\chi(x,\lambda)}{\omega(\lambda)}\int_0^x\phi(y,\lambda)f(y)\mathrm{d}y+\frac{\phi(x,\lambda)}{\omega(\lambda)}\int_x^1\chi(y,\lambda)f(y)\mathrm{d}y, \tag{A2}$$

satisfying the boundary conditions (2). Here ϕ and χ are solutions of homogeneous equation (1) with ϕ satisfying (2a) and χ satisfying (2b), and $\omega(\lambda)=\phi(\mathrm{d}\chi/\mathrm{d}x)-\chi(\mathrm{d}\phi/\mathrm{d}x)$ is the Wronskian of the functions ϕ and χ. The zeroes of the Wronskian coincide with the roots of (9) confirming linear dependence of ϕ and χ at λ_i where $\omega(\lambda_i)=0$ so that $\chi(x,\lambda_i)=k(\lambda_i)\phi(x,\lambda_i)$.

Denoting $\lambda=\sigma+it$ and considering two segments $\sigma=R, -R\leqslant t\leqslant R$ and $t=R, -R\leqslant\sigma\leqslant R$, it is possible to see that they form the closed contour $C(R)$ on the λ^2 plane. Using the explicit form for

$$\phi(x,\lambda)=\frac{\cos(\lambda x)}{h_1}-\frac{\sin(\lambda x)}{\lambda},$$

$$\chi(x,\lambda)=\frac{\cos[\lambda(x-1)]}{h_2}+\frac{\sin[\lambda(x-1)]}{\lambda},$$

and

$$\omega(\lambda)=\frac{\sin(\lambda)(h_1h_2+\lambda^2)-\lambda\cos(\lambda)(h_2-h_1)}{h_1h_2\lambda},$$

the integration can be done over $C(R)$ on the λ^2 plane. Then if $f(x)\in L_1$ it is possible to show[6,9] that for $0<x<1$ and $R\to\infty$:

$$\frac{1}{2\pi i}\int_{C(R)}\Phi(x,\lambda^2)\mathrm{d}\lambda^2\to\frac{1}{2\pi i}\int_{C(R)}\frac{\mathrm{d}\lambda^2}{\lambda\sin(\lambda)}\Bigg\{\cos[\lambda(1-x)]\int_0^x f(y)\cos(\lambda y)\mathrm{d}y + \cos(\lambda x)\Bigg]\int_x^1 f(y)\cos[\lambda(1-y)]\mathrm{d}y\to\frac{1}{2}(f(x+0)+f(x-0)). \tag{A3}$$

On the other hand, $\Phi(x,\lambda^2)$ has residues at $\lambda=\lambda_i$ resulting in

$$\frac{1}{2\pi i}\int_{C(R)}\Phi(x,\lambda^2)d\lambda^2=\sum_{\lambda_i\text{being inside }C(R)}\frac{k(\lambda_i)}{\mathrm{d}\omega(\lambda)/d(\lambda^2)|_{\lambda=\lambda_i}}\phi(x,\lambda_i)\int_0^1\phi(y,\lambda_i)f(y)\mathrm{d}y, \tag{A4}$$

assuming that λ_i are the roots of $\omega(\lambda_i)=0$ with multiplicity one. When $R\to\infty$, this sum includes all of the λ_i.

We should mention that for any $\lambda^2{}_i$ such that $\omega(\lambda_i)=0$ it is possible to find a and b so that also

$$\left.\frac{\mathrm{d}\omega(\lambda)}{\mathrm{d}(\lambda^2)}\right|_{\lambda^2=\lambda^2{}_i}=0,$$

i.e., $\lambda^2{}_i$ is a root of multiplicity two for $\omega(\lambda^2{}_i)$. Line $a\lambda^2+b=0$ then becomes tangential to $\lambda\cot\lambda$ at $\lambda^2{}_i$, so that the values of a and b in this case will be given parametrically by (12). For some $\lambda^2{}_i$ it is possible to satisfy the additional condition

$$\left.\frac{\mathrm{d}^2\omega(\lambda)}{(\mathrm{d}(\lambda^2))^2}\right|_{\lambda^2=\lambda^2{}_i}=0,$$

so that $\lambda^2{}_i$ becomes a root of multiplicity three for $\omega(\lambda^2{}_i)$. As seen from Fig. 6, there are no roots of multiplicity higher than 3 and all of them lie in the region on the outside of the two branches of $ab=-\frac{1}{4}$ corresponding to the imaginary values of h_1 and h_2.

Comparing these two results (A4) and (A5) we see that

$$\frac{1}{2}(f(x+0)+f(x-0))=\lim_{R\to\infty}\frac{1}{2\pi i}\int_{C(R)}\Phi(x,\lambda^2)\mathrm{d}\lambda^2 = \sum_{\lambda_i:\omega(\lambda_i)=0}\frac{k(\lambda_i)}{\left.\frac{\mathrm{d}\omega(\lambda)}{\mathrm{d}(\lambda^2)}\right|_{\lambda=\lambda_i}}\phi(x,\lambda_i)\int_0^1\phi(x,\lambda_i)f(y)\mathrm{d}y \tag{A5}$$

completing the proof. We can see that each root of equation $\omega(\lambda_i)=0$ corresponds to a function used in the expansion (A5). Removing any function, e.g., $\phi(x,\lambda_r)$, from the set will result in the deficient set of functions on the interval $0<x<1$, so that setting $f(y)=\phi(x,\lambda_r)$ and using the expansion (A5) *always* gives $\frac{1}{2}[\phi(x+0,\lambda_r)+\phi(x-0,\lambda_r)]=0$ for $0<x<1$, due to orthogonality (5). This contradiction proves the deficiency.

Using the explicit form for

$$k(\lambda)=\frac{h_1}{h_1\cos(\lambda)+\lambda\sin(\lambda)},$$

$$\frac{\mathrm{d}\omega(\lambda)}{\mathrm{d}(\lambda^2)}=\frac{\lambda\cos(\lambda)-h_1\sin(\lambda)}{2\lambda^3h_1}+\frac{h_1(h_1-1)+\lambda^2}{2\lambda^2h_1[h_1\cos(\lambda)+\lambda\sin(\lambda)]},$$

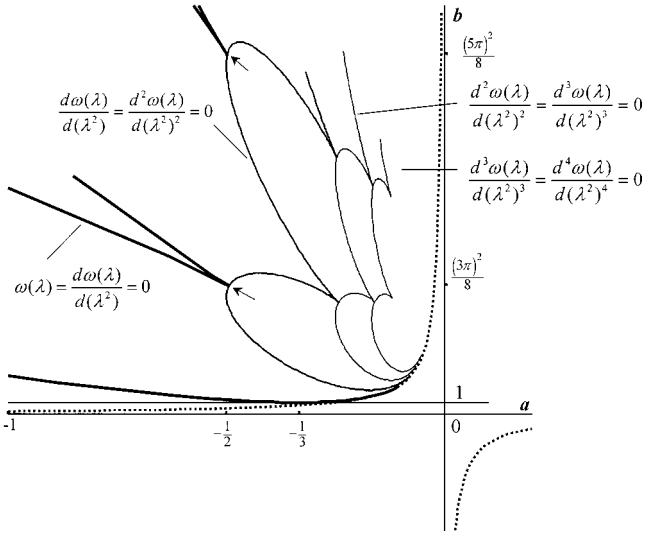

FIG. 6. Higher-multiplicity roots of the Wronskian. $ab=-\frac{1}{4}$ are shown as dotted lines. Solid curves show parameters a and b for which $\omega(\lambda)=0$ has roots of multiplicity two. Arrows indicate roots of multiplicity three.

and (A5) for $f(x)=\phi(x,\lambda_i)$, we can find the normalization constant

$$N_i=\int_0^1 \phi^2(x,\lambda_i)\mathrm{d}y$$

$$=\frac{k(\lambda_i)}{\left.\frac{\mathrm{d}\omega(\lambda)}{\mathrm{d}(\lambda^2)}\right|_{\lambda=\lambda_i}}=\frac{[\lambda\cos(\lambda)-h_1\sin(\lambda)][h_1\cos(\lambda)+\lambda\sin(\lambda)]+\lambda[h_1(h_1-1)+\lambda^2]}{2\lambda^3 {h_1}^2}.$$

Now (A5) takes a well-known form of orthogonal function expansion

$$f(x)=\sum_i c_i\psi_i(x) \tag{A6}$$

with

$$\psi_i=\phi(x,\lambda_i)/\sqrt{N_i}$$

and

$$c_i=\int_0^1 \psi_i(y)f(y)\mathrm{d}y.$$

For the boundary value problem (1) with (2) the resolvent (A2) can be rewritten in the form of the Green's function

$$\Phi(x,\lambda^2)=\int_0^1 G(x,y,\lambda)f(y)\mathrm{d}y$$

with

$$G(x,y,\lambda)=\frac{1}{\omega(\lambda)}\begin{cases}\chi(x,\lambda)\phi(y,\lambda), & y\leqslant x\\ \phi(x,\lambda)\chi(y,\lambda), & y\geqslant x.\end{cases}$$

Assuming that the resolvent itself can be expanded in the form

$$\Phi(x,\lambda^2)=\sum_i a_i(\lambda^2)\psi_i(x),$$

substituting it, together with (A6), into (A1), and using the orthogonality expression (5), it follows that

$$a_i(\lambda^2)=\frac{c_i}{\lambda^2-\lambda_i{}^2}.$$

This yields another form for the Green's function,

$$G(x,y,\lambda)=\sum_i \frac{\psi_i(x)\psi_i(y)}{\lambda^2-\lambda_i{}^2}.$$

I. INTRODUCTION

Let us consider the Schrödinger equation for the time evolution of a d-dimensional quantum particle:

$$\begin{cases} \dot{\psi} = -\dfrac{i}{\hbar} H\psi, \\ \psi(0, x) = \psi_0(x), \end{cases} \tag{1}$$

where $H = p^2/2m + V$ is the Hamiltonian of the system, $m > 0$ is the mass of the particle, $\hbar$ is the (reduced) Planck' constant, and p is the quantum mechanical momentum operator. Under suitable conditions on the potential V, in the position representation H is realized as the self-adjoint operator in the Hilbert space $\mathcal{H} = \mathcal{L}_2(\mathbb{R}^d)$, obtained by closure of the operator

$$H\psi(x) = -\frac{\hbar^2}{2m}\Delta\psi(x) + V(x)\psi(x), \quad \psi \in D(-\Delta) \cap D(V),$$

$$\psi \in \mathcal{H}, \quad \int_{\mathbb{R}^d} |\psi(x)|^2 \, \mathrm{d}x < +\infty,$$

where $D(A)$ denotes the domain of the operator A in $\mathcal{H}$ (see, e.g. Ref. 1). Let $G(t,x,y)$ be the Green function or propagator, namely the kernel of the unitary group $e^{-itH/\hbar}$,

$$\psi(t,x) = \int_{\mathbb{R}^d} G(t,x,y)\psi_0(y)\mathrm{d}y$$

(see, e.g., Ref. 1 for a discussion on sufficient conditions for the existence of G and for the properties of it). In 1942 Feynman gave a suggestive representation of the propagator and showed the connection between the classical Lagrangian description of the physical world and the quantum one. In fact the kernel of the unitary group can be heuristically computed by means of an infinite dimensional path integral of the following form:

$$G(t,x,y) = \text{const} \int e^{(i/\hbar)\, S(\gamma)} \mathrm{d}\gamma, \tag{2}$$

a)Electronic mail: mazzucch@science.unitn.it

where the integration is on the set of paths starting in y at time 0 and ending in x at time t and $S(\gamma)$ is the classical action of the system, evaluated on the path γ:

$$S(\gamma)=\int_0^t (\dot{\gamma}(s)^2/2m - V(\gamma(s))\mathrm{d}s.$$

Expression (2) lacks rigor, e.g., neither the constant in front of the integral nor the ''infinite dimensional Lebesgue measure'' $\mathrm{d}\gamma$ are well defined. Nevertheless a rigorous mathematical formulation of the *Feynman functional* can be given (see Refs. 2 and 3, and references therein; for other approches see also Refs. 4 and 5). Feynman himself (see Ref. 6) gave other heuristic representations of the integral, e.g., the heuristic integration over paths in phase space. For physical discussions of this concept see also Ref. 7.

The aim of the present paper is to give a mathematical definition of a ''phase space path integral:'' a Hamiltonian instead of a Lagrangian representation of the propagator. We want to give mathematical meaning to the Hamiltonian version of formula (2), namely to

$$G(t,x,y)=\text{const}\int e^{(i/\hbar)\,S(q,p)}\mathrm{d}q\,\mathrm{d}p, \tag{3}$$

where $q(s),p(s)$, $s\in[0,t]$ are paths in the phase space and S is the action in the Hamiltonian fomulation: $S(q,p)=\int_0^t(\dot{q}(s)p(s)-H(q(s),p(s)))ds$.

The Hamiltonian formulation is more convenient for two reasons:

(1) for many classical systems it is better than the Lagrangian one;
(2) the discussion of the approach from quantum mechanics to classical mechanics, i.e., the study of the behavior of physical quantities taking into account that $\hbar$ is small, is more natural in a Hamiltonian setting (see, e.g., Refs. 8 and 9 for a discussion of this behavior).

We note that an approach of phase space Feynman path integrals via analytic continuation of ''phase space Wiener integrals'' has been presented by Daubechies and Klauder.[10] Analytic continuation was also used in other ''path space'' approaches, see Refs. 11 and 4, and references therein. Our approach is more direct in the spirit of Ref. 2.

II. LIE–TROTTER PRODUCT FORMULA

We first recall an abstract version of the Lie–Trotter product formula.

Lemma 1: Let A and B be self-adjoint operators in a Hilbert space $\mathcal{H}$ and let $A+B$ be essentially self-adjoint on $D(A)\cap D(B)$. Then

$$s-\lim_{n\to\infty}(e^{ita/n}e^{itB/n})^n=e^{i(A+B)t},\quad t\in\mathbb{R}. \tag{4}$$

Here $s-\lim$ is the strong operator limit. For a proof and a discussion of this lemma see e.g., Refs. 12 and 1.

Let $\mathcal{H}=L^2(\mathbb{R}^d)$ and let us consider a potential V depending both on the position and on the momentum in the following way: $V=V_1(x)+V_2(p)$. V_1 is defined as a self-adjoint operator in $\mathcal{H}$, with its natural domain as a multiplication operator. V_2 is the operator in $\mathcal{H}$ with domain

$$D(V_2(p))=\{\psi\in\mathcal{H}\,|\,\alpha\to V_2(\alpha)\hat{\psi}(\alpha)\in\mathcal{H}\},$$

where $\hat{\psi}$ is the Fourier transform of ψ. It coincides with the operator defined by functional calculus as $V_2(p)$, with p the self-adjoint operator $-i\hbar\nabla$ in $\mathcal{H}$. V is then the sum, as a self-adjoint operator in $\mathcal{H}$, of the self-adjoint operators V_1 and V_2. We assume that the functions V_1 and V_2 are such that the corresponding operators have a common dense domain of essentially self-adjointness D. This is the case, e.g., when $V_1\in L^2(\mathbb{R}^d)+L^\infty(\mathbb{R}^d)$, V_2 is bounded measurable, and $D=C_0^\infty(\mathbb{R}^d)$ or $D=\mathcal{S}(\mathbb{R}^d)$. We assume, in order to apply lemma 1, that V_1, V_2 are such that $-(\hbar^2/2m)\,\Delta+V_2$ and $-(\hbar^2/2m)\,\Delta+V_1+V_2$ are essentially self-adjoint on D. We denote by H the closure of the

latter operator. H (which we also write simply as $-(\hbar^2/2m)\,\Delta+V_1+V_2$) is then the quantum Hamiltonian.

By lemma 1 we have then

$$\exp\left(-\frac{it(p^2/2m+V}{\hbar}\right)=s-\lim_{n\to\infty}\left(\exp\left(-\frac{i\epsilon(p^2/2m+V_2)}{\hbar}\right)\exp\left(-\frac{i\epsilon(V_1)}{\hbar}\right)\right)^n,\quad \epsilon\equiv\frac{t}{n},$$

$$\psi(t)=\exp\left(-\frac{it(p^2/2m+V}{\hbar}\right)\psi_0=\lim_{n\to\infty}\left(\exp\left(-\frac{i\epsilon(p^2/2m+V_2)}{\hbar}\right)\exp\left(-\frac{i\epsilon V_1}{\hbar}\right)\right)^n\psi_0,$$

$$\psi_0\in\mathbb{C}_0^\infty(\mathbb{R}^d),$$

(see, e.g., Refs. 12 and 13 for related uses of the Lie–Trotter formula).

By shifting from the position representation to the momentum representation and vice versa and assuming that V_1 and V_2 are continuous, we can write in the strong $L^2(\mathbb{R}^d)$-sense, for all $t>0$:

$$\begin{aligned}\psi(t,x)&=\lim_{n\to\infty}\int_{\mathbb{R}^d}\exp\left(-\frac{i\epsilon(p_{n-1}^2/2m+V_2(p_{n-1}))}{\hbar}\right)\cdot\left(\exp\left(-\frac{i\epsilon V_1}{\hbar}\right)\right.\\&\quad\left.\times\left(\exp\left(-\frac{i\epsilon(p^2/2m+V_2)}{\hbar}\right)\exp\left(-\frac{i\epsilon(V_1)}{\hbar}\right)\right)^{n-1}\psi_0\right)(p_1)\,\frac{\exp\left(i\,\frac{xp_{n-1}}{\hbar}\right)}{(2\pi\hbar)^{d/2}}\,\mathrm{d}p_{n-1}\\&=\lim_{n\to\infty}\int_{\mathbb{R}^{2d}}\exp\left(-\frac{i\epsilon(p_{n-1}^2/2m+V_2(p_{n-1}))}{\hbar}\right)\exp\left(-\frac{i\epsilon V_1(x_{n-1}}{\hbar}\right)\\&\quad\cdot\left(\left(\exp\left(-\frac{i\epsilon(p^2/2m+V_2)}{\hbar}\right)\exp\left(-\frac{i\epsilon(V_1)}{\hbar}\right)\right)^{n-1}\psi_0\right)(x_{n-1})\,\frac{\exp\left(i\,\frac{xp_{n-1}}{\hbar}\right)}{(2\pi\hbar)^{d/2}}\\&\quad\times\frac{\exp\left(-i\,\frac{x_{n-1}p_{n-1}}{\hbar}\right)}{(2\pi\hbar)^{d/2}}\,\mathrm{d}p_{n-1}\mathrm{d}x_{n-1}\\&=\lim_{n\to\infty}\left(\frac{1}{\sqrt{2\pi\hbar}}\right)^{2nd}\cdot\int_{\mathbb{R}^{2nd}}\exp\left(-\frac{i\epsilon}{\hbar}\sum_{j=0}^{n-1}\left(\frac{p_j^2}{2m}+V_1(x_j)+V_2(p_j)\right.\right.\\&\quad\left.\left.-p_j\,\frac{(x_{j+1}-x_j)}{\epsilon}\right)\right)\psi_0(x_0)\prod_{j=0}^{n-1}\mathrm{d}p_j\mathrm{d}x_j,\end{aligned}\tag{5}$$

where $x_n\equiv x$.

Remark: The integrals above are to be understood as limits as $\Lambda\uparrow\mathbb{R}^d$, $n\to\infty$ in the $L^2(\mathbb{R}^{2nd})$ sense of the corresponding integrals over Λ^{2nd}, with Λ bounded (see Ref. 11). Formula (5) holds first as a strong L^2-limit, but then (possibly by subsequences) also for Lebesgue a.e.x. It also follows from this that (5) gives the solution to the Cauchy problem (1).

The latter expression suggests the following formula for the limit:

$$\begin{aligned}\psi(t,x)&=\mathrm{const}\int_{q(t)=x}e^{(i/\hbar)\,S(q,p)}\psi(0,q(0))\mathrm{d}q\,\mathrm{d}p,\\S(q,p)&=\int_0^t p(s)\dot{q}(s)-H(q(s),p(s))\mathrm{d}s,\end{aligned}\tag{6}$$

which does not yet have a mathematical meaning. It will be rigorously defined in Secs. III and IV.

III. OSCILLATORY INTEGRALS AND THE CAMERON MARTIN FORMULA

In this section we recall for later use some known results, for more details we refer to Refs. 2, 3, and 8.

A. Finite dimensional oscillatory integrals

Let us consider the finite dimensional real Hilbert space $\mathbb{R}^n$, whose elements are denoted by $x,y\in\mathbb{R}^n$ and the scalar product with $\langle x,y\rangle$. Let $T:\mathbb{R}^n\to\mathbb{R}^n$ be a nondegenerate symmetric operator.

Definition 1: A function $f:\mathbb{R}^n\to\mathbb{C}$ is Fresnel integrable with respect to T if and only if for each $\phi\in\mathcal{S}(\mathbb{R}^n)$ such that $\phi(0)=1$ the limit

$$\lim_{\epsilon\to 0}\int e^{i\langle x,Tx\rangle}f(x)\phi(\epsilon x)\mathrm{d}x \tag{7}$$

exists and is independent of ϕ. In this case the limit is called the Fresnel integral of f with respect to T and denoted by

$$\int e^{i\langle x,Tx\rangle}f(x)\mathrm{d}x.$$

There is an important class $\mathcal{F}(\mathbb{R}^n)$ of Fresnel integrable functions: those which are Fourier transforms of complex bounded variation measures on $\mathbb{R}^n$, $\mathcal{M}(\mathbb{R}^n)$:

$$f\in\mathcal{F}(\mathbb{R}^n)\Leftrightarrow f(x)=\int e^{i\langle x,\alpha\rangle}\mu_f(d\alpha),\quad \mu_f\in\mathcal{M}(\mathbb{R}^n),\quad x\in\mathbb{R}^n.$$

$\mathcal{F}(\mathbb{R}^n)$ contains in particular $\mathcal{S}(\mathbb{R}^n)$, hence it is also dense in $L^2(\mathbb{R}^n)$. In this case the Parseval equality gives us the following expression for the limit (7):

$$(2\pi i)^{-n/2}\int e^{(i/2)\langle x,Tx\rangle}f(x)\mathrm{d}x=(\det T)^{-1/2}\int e^{(-i/2)\langle x,T^{-1}x\rangle}\mu_f(\mathrm{d}x).$$

Analogously one can define the normalized Fresnel integral by means of the following expression:

$$\widetilde{\int}\int e^{(i/2)\langle x,Tx\rangle}f(x)\mathrm{d}x:=(\det T)^{1/2}(2\pi)^{-n/2}\int e^{(i/2)\langle x,Tx\rangle}f(x)\mathrm{d}x=\int e^{(-i/2)\langle x,T^{-1}x\rangle}\mu_f(\mathrm{d}x).$$

Note that if we substitute into the latter definition the function $f=1$ we have $\tilde{\int}e^{(i/2)\langle x,Tx\rangle}f(x)\mathrm{d}x=1$.

B. Infinite dimensional oscillatory integrals

Let us consider an infinite dimensional real Hilbert space of paths $\mathcal{H}$ whose elements are denoted by $\gamma,\eta\in\mathcal{H}$ and the scalar product by $\langle\gamma,\eta\rangle$. Let P_n be a sequence of projectors on n-dimensional subspaces of $\mathcal{H}$ such that $P_n\leqslant P_{n+1}$ [i.e., $P_{n+1}=I$ on $P_n(\mathcal{H})$] and $P_n\to I$ strongly as $n\to\infty$; let $f:\mathcal{H}\to\mathbb{C}$ be a function on $\mathcal{H}$ and let $T:D(T)\subseteq\mathcal{H}\to\mathcal{H}$ be a self-adjoint invertible operator.

Definition 2: A function $f:\mathcal{H}\to\mathbb{C}$ is Fresnel integrable with respect to T if and only if for each n the following finite dimensional integral

$$\widetilde{\int}_{P_n\mathcal{H}}e^{i\langle P_n\gamma,TP_n\gamma\rangle}f(P_n\gamma)\mathrm{d}P_n\gamma \tag{8}$$

is well defined and the limit

$$\lim_{n\to\infty} \widetilde{\int}_{P_n\mathcal{H}} e^{i\langle P_n\gamma, TP_n\gamma\rangle} f(P_n\gamma)\mathrm{d}P_n\gamma \tag{9}$$

exists and is independent of the sequence $\{P_n\}$.

In this case the limit is called the Fresnel integral of f *with respect to* T *and is denoted by*

$$\widetilde{\int} e^{i\langle \gamma, T\gamma\rangle} f(\gamma)\mathrm{d}\gamma.$$

Equation (8) is called the normalized finite dimensional approximation of this Fresnel integral.

One can prove that if $f\in\mathcal{F}(\mathcal{H})$ then $f\circ P_n\in\mathcal{F}(P_n(\mathcal{H}))$. Moreover f is Fresnel integrable and the Cameron–Martin-type formula holds:

$$\widetilde{\int} e^{(i/2)\langle \gamma, T\gamma\rangle} f(\gamma)\mathrm{d}\gamma = \int_{\mathcal{H}} e^{-(i/2)\langle \gamma, T^{-1}\gamma\rangle}\mu_f(\mathrm{d}\gamma), \tag{10}$$

see Refs. 8 and 3.

IV. PHASE SPACE FEYNMAN FUNCTIONAL

Let us consider again the expression (6) in the particular case of the free particle, namely when the Hamiltonian is just the kinetic energy: $H=p^2/2m$. In this case we have heuristically

$$\psi(t,x) = \text{const} \int_{q(t)=x} \exp\left(\frac{i}{\hbar}\int_0^t (p(s)\dot{q}(s) - p(s)^2/2m)\mathrm{d}s\right)\psi(0,q(0))\mathrm{d}q\,\mathrm{d}p. \tag{11}$$

We can give a precise meaning to this expression: under suitable hypothesis on the initial wave function ψ_0, it is an infinite dimensional oscillatory integral.[14] In fact, following Ref. 15, let us introduce the Hilbert space $\mathcal{H}_t\times\mathcal{L}_t$, namely the space of paths in the d-dimensional phase space $(q(s),p(s))_{s\in[0,t]}$, such that the path $(q(s))_{s\in[0,t]}$ belongs to the Cameron–Martin space $\mathcal{H}_t$, namely to the space of the absolutely continuous functions q from $[0,t]$ to $\mathbb{R}^d$ such that $q(t)=0$ and $\dot{q}\in\mathcal{L}_2([0,t],\mathbb{R}^d)$, with inner product $\langle q_1,q_2\rangle = \int_0^t \dot{q}_1(s)\dot{q}_2(s)\mathrm{d}s$, while the path in the momentum space $(p(s))_{s\in[0,t]}$ belongs to $\mathcal{L}_t=\mathcal{L}_2([0,t],\mathbb{R}^d)$. $\mathcal{H}_t\times\mathcal{L}_t$ is an Hilbert space with the natural inner product

$$\langle q,p;Q,P\rangle = \int_0^t \dot{q}(s)\dot{Q}(s)\mathrm{d}s + \int_0^t p(s)P(s)\mathrm{d}s.$$

Let us introduce the following bilinear form:

$$[q,p;Q,P] = \int_0^t \dot{q}(s)P(s)\mathrm{d}s + \int_0^t p(s)\dot{Q}(s)\mathrm{d}s - \int_0^t p(s)P(s)\mathrm{d}s = \langle q,p;A(Q,P)\rangle,$$

where A is the following operator in $\mathcal{H}_t\times\mathcal{L}_t$:

$$A(Q,P)(s) = \left(\int_t^s P(u)\mathrm{d}u, \dot{Q}(s) - P(s)\right). \tag{12}$$

$A(Q,P)$ is densely defined, e.g., on $C^1([0,t];\mathbb{R}^d)\times C^1([0,t];\mathbb{R}^d)$. Moreover $A(Q,P)$ is invertible with inverse given by

$$A^{-1}(Q,P)(s) = \left(\int_t^s P(u)\mathrm{d}u + Q(s), \dot{Q}(s)\right) \tag{13}$$

(on the range of A).

Now expression (6) can be realized rigorously as

$$\widetilde{\int}_{\mathcal{H}_t\times\mathcal{L}_t} e^{(i/2\hbar)\langle q,p;A(q,p)\rangle}\psi(0,q(0)+x)\mathrm{d}q\,\mathrm{d}p,$$

where $q+x$ denotes the traslated path $q(s)\to q(s)+x$, and the normalized integral is defined by (10).

In this case the heuristic expression (6) is well defined through Lie–Trotter product formula, namely as the limit of a sequence of finite dimensional integrals, as we saw in Sec. II. We are now going to show that it is also the limit of a sequence of finite dimensional oscillatory integrals in the sense of definition 2.

Let us consider a sequence of partitions π_n of the interval $[0,t]$ into n subintervals of amplitude $\epsilon\equiv t/n$:

$$t_0=0,t_1=\epsilon,\ldots,t_i=i\epsilon,\ldots,t_n=n\epsilon=t.$$

To each π_n we associate a projector $P_n:\mathcal{H}_t\times L_t\to:\mathcal{H}_t\times L_t$ onto a finite dimensional subspace of $\mathcal{H}_t\times L_t$, namely the subspace of polygonal paths. In other words each projector P_n acts on a phase space path $(q,p)\in\mathcal{H}_t\times\mathcal{L}_t$ in the following way:

$$P_n(q,p)(s)=\left(\sum_{i=1}^{n}\chi_{[t_{i-1},t_i]}(s)\left(q(t_{i-1})+\frac{(q(t_i)-q(t_{i-1})}{t_i-t_{i-1}}(s-t_{i-1})\right),\sum_{i=1}^{n}\chi_{[t_{i-1},t_i]}(s)p_i\right),$$

where

$$p_i=\frac{\int_{t_{i-1}}^{t_i}p(s)\mathrm{d}s}{t_i-t_{i-1}}=\frac{1}{\epsilon}\int_{t_{i-1}}^{t_i}p(s)\mathrm{d}s.$$

Theorem 1: *For each $n\in\mathbb{N}$, P_n is a projector in $\mathcal{H}_t\times\mathcal{L}_t$. Moreover for $n\to\infty$ $P_n\to I$ as a bounded operator.*

Proof: P_n is symmetric, indeed for all $(Q,P)\in\mathcal{H}_t\times\mathcal{L}_t$ and all $(q,p)\in\mathcal{H}_t\times\mathcal{L}_t$,

$$\begin{aligned}\langle Q,P;P_n(q,p)\rangle&=\int_0^t\dot{Q}(s)\sum_{i=1}^{n}\chi_{[t_{i-1},t_i]}(s)\frac{(q(t_i)-q(t_{i-1})}{t_i-t_{i-1}}\mathrm{d}s+\int_0^t P(s)\sum_{i=1}^{n}\chi_{[t_{i-1},t_i]}(s)p_i\mathrm{d}s\\&=\sum_{i=1}^{n}\frac{(q(t_i)-q(t_{i-1})(Q(t_i)-Q(t_{i-1})}{t_i-t_{i-1}}+\sum_{i=1}^{n}\frac{\int_{t_{i-1}}^{t_i}p(s)\mathrm{d}s\int_{t_{i-1}}^{t_i}P(s)\mathrm{d}s}{t_i-t_{i-1}}\\&=\langle P_n(Q,P);q,p\rangle.\end{aligned}$$

$P_n^2=P_n$, indeed

$$\begin{aligned}P_n^2(q,p)(s)&=\left(\sum_{i=1}^{n}\chi_{[t_{i-1},t_i]}(s)\left(q(t_{i-1})+\frac{\big(q(t_i)-q(t_{i-1})}{t_i-t_{i-1}}(s-t_{i-1})\right),\sum_{i=1}^{n}\chi_{[t_{i-1},t_i]}(s)p_i\right)\\&=P_n(q,p)(s)\end{aligned}$$

$\forall(q,p)\in\mathcal{H}_t\times\mathcal{L}_t$, $\|P_n(q,p)-(q,p)\|\to 0$ as $n\to\infty$:

Let us consider the subset $\mathcal{K}\subseteq\mathcal{H}_t\times\mathcal{L}_t$, $\mathcal{K}=\{(q,p)\in\mathcal{H}_t\times\mathcal{L}_t:\|P_n(q,p)-(q,p)\|\to 0,n\to\infty\}$. It is enough to prove that the closure of $\mathcal{K}$ is $\mathcal{H}_t\times\mathcal{L}_t$. To prove this it is sufficient to show that $\mathcal{K}$

is a closed subspace of $\mathcal{H}_t \times \mathcal{L}_t$ and contains a dense subset of $\mathcal{H}_t \times \mathcal{L}_t$. This follows from the density of the piecewise linear paths in $\mathcal{H}_t$ and the density of the piecewise constant paths in $\mathcal{L}_t$ (see, e.g., Ref. 14).

Theorem 2: *Let the function* $(q,p) \to \psi_0(x+q(0))$, $\psi_0 \in \mathcal{S}(\mathbb{R}^d)$, *be Fresnel integrable with respect to A [with A defined by (12)]. Then the phase space Feynman path integral, namely the limit*

$$\lim_{n\to\infty} \widetilde{\int}_{P_n(\mathcal{H}_t \times \mathcal{L}_t)} e^{(i/2\hbar)\langle P_n(q,p), AP_n(q,p)\rangle} \psi_0(x+q(0)) \mathrm{d}P_n(q,p) \tag{14}$$

coincides with the limit (5), namely with the solution of the Schrödinger equation with a free Hamiltonian.

Proof: The result follows by direct computation, indeed:

$$\widetilde{\int}_{P_n(\mathcal{H}_t \times \mathcal{L}_t)} e^{(i/2\hbar)\langle P_n(q,p), AP_n(q,p)\rangle} \psi_0(x+q(0)) \mathrm{d}P_n(q,p)$$
$$= \left(\frac{1}{\sqrt{2\pi\hbar}} \right)^{2nd} \int_{\mathbb{R}^{2nd}} \exp\left(-\frac{i\epsilon}{\hbar} \sum_{j=0}^{n-1} \left(\frac{p_j^2}{2m} - p_j \frac{(x_{j+1}-x_j)}{\epsilon} \right) \right) \psi_0(x_0) \prod_{j=0}^{n-1} \mathrm{d}p_j \, \mathrm{d}x_j ,$$

and the two limits (5) and (14) coincide. Indeed (14) is a pointwise limit by hypothesis. On the other hand (5) is a limit in L_2 sense, hence, passing if necessary to a subsequence, it is also a pointwise limit.

Remark 1: The latter result is equivalent to the ''traditional'' formulation of the Feynman path integral in the configuration space. Indeed it can be obtained by means of Fubini theorem[2] and an integration with respect to the momentum variables:

$$\lim_{n\to\infty} \left(\frac{1}{\sqrt{2\pi\hbar}} \right)^{2nd} \int_{\mathbb{R}^{2nd}} \exp\left(-\frac{i\epsilon}{\hbar} \sum_{j=0}^{n-1} \left(\frac{p_j^2}{2m} - p_j \frac{(x_{j+1}-x_j)}{\epsilon} \right) \right) \psi_0(x_0) \prod_{j=0}^{n-1} \mathrm{d}p_j \, \mathrm{d}x_j$$
$$= \lim_{n\to\infty} \left(\frac{1}{\sqrt{2\pi i\hbar}} \right)^{nd} \int_{\mathbb{R}^{nd}} \exp\left(-\frac{i\epsilon}{\hbar} \sum_{j=0}^{n-1} m \frac{(x_{j+1}-x_j)^2}{2\epsilon^2} \right) \psi_0(x_0) \prod_{j=0}^{n-1} \mathrm{d}x_j .$$

The latter expression yields the Feynman functional on the configuration space, i.e., heuristically const $\int \exp(\int_0^t \mathcal{L}(q(s),\dot{q}(s))\mathrm{d}s)\mathrm{d}q$ ($\mathcal{L}$ being the classical Lagrangian density).

Remark 2: The integration with respect to the momentum variables might seem to be superfluous, but it is very useful when we introduce a potential depending on the momentum.

Theorem 3: *Let us consider a semibounded potential V depending explicitly on the momentum:* $V=V(p)$ *and the corresponding quantum mechanical Hamiltonian* $H=-(\hbar^2/2)\Delta+V(p)$. *Let us suppose H is an essentially self-adjoint operator on* $\mathcal{L}_2(\mathbb{R}^d)$. *Let the function* $(q,p) \to \exp(-(\mathrm{i}/\hbar)\int_0^t V(P_n(p(s)))\mathrm{d}s)\,\psi_0(x+q(0))$ *be Fresnel integrable with respect to the operator A, with A defined by* (12). *Then the solution to the Schrödinger equation*

$$\begin{cases} \dot{\psi} = -\dfrac{i}{\hbar} H\psi, \\ \psi(0,x) = \psi_0(x), \quad \psi_0 \in \mathcal{S}(\mathbb{R}^d) \end{cases} \tag{15}$$

is given by the phase space path integral

$$\lim_{n\to\infty}\widetilde{\int}_{P_n(\mathcal{H}_t\times\mathcal{L}_t)}\exp\left(\frac{i}{2\hbar}\langle P_n(q,p),AP_n(q,p)\rangle\right)\exp\left(-\frac{i}{\hbar}\int_0^t V(P_n(p(s)))\mathrm{d}s\right)$$
$$\times\psi_0(x+q(0))\mathrm{d}P_n(q,p).$$

Proof: We can proceed in a completely analogous way as in the proof of Theorem 2, therefore we shall omit the details. □

V. THE PHASE SPACE FEYNMAN–KAC FORMULA

Let us consider a classical potential V depending both on the position $Q\in\mathbb{R}^d$ and on the momentum $P\in\mathbb{R}^d$, but of the special form: $V=V(Q,P)=V_1(Q)+V_2(P)$ (The general case presents problems due to the noncommutativity of the quantized expression of Q and P), for a different approach with more general Hamiltonians see Ref. 16. Moreover let us suppose the function $f:\mathcal{H}_t\times\mathcal{L}_t\to\mathbb{C}$,

$$f(q,p)=\psi_0(x+q(0))\exp\left(-\frac{i}{\hbar}\int_0^t V(q(s)+x,p(s))\mathrm{d}s\right),\quad \psi_0\in\mathcal{S}(\mathbb{R}^d)$$

is the Fourier transform of a complex bounded variation measure μ_f on $\mathcal{H}_t\times\mathcal{L}_t$:[17]

$$f(q,p)=\int_{\mathcal{H}_t\times\mathcal{L}_t}e^{i\langle q,p;Q,P\rangle}\mathrm{d}\mu_f(Q,P).$$

Under additional assumptions on V_1 and V_2 we shall see that the phase space Feynman path integral of the function f can be computed and is given by

$$\widetilde{\int}_{\mathcal{H}_t\times\mathcal{L}_t}\exp\left(\frac{i}{2\hbar}\langle q,p;A(q,p)\rangle\right)\exp\left(-\frac{i}{\hbar}\int_0^t V(q(s)+x,p(s))\mathrm{d}s\right)\psi(0,q(0)+x)\mathrm{d}q\,\mathrm{d}p$$
$$=\int_{\mathcal{H}_t\times\mathcal{L}_t}\exp\left(\frac{-i\hbar}{2}\langle q,p;A^{-1}(q,p)\rangle\right)\mathrm{d}\mu_f(q,p).\tag{16}$$

This follows from Sec. III together with the following.

Lemma 2: Let us consider a potential $V(Q,P)=V_1(Q)+V_2(P)$ and an initial wave function ψ_0 such that V_1, $\psi_0\in\mathcal{F}(\mathbb{R}^d)$ and the function $p(s)_{s\in[0,t]}\to\int_0^t V_2(p(s))\mathrm{d}s\in\mathcal{F}(\mathcal{L}_t)$. Then the functional

$$f(q,p)=\psi_0(x+q(0))\exp\left(-\frac{i}{\hbar}\int_0^t V(q(s)+x,p(s))\mathrm{d}s\right)$$

belongs to $\mathcal{F}(\mathcal{H}_t\times\mathcal{L}_t)$.

Proof: $f(q,p)$ is the product of two functions: the first, say f_1, depends only on the first variable q, while the second f_2 depends only on the variable p, more precisely

$$f_1(q)=\psi_0(x+q(0))\exp\left(-\frac{i}{\hbar}\int_0^t V_1(q(s)+x)\mathrm{d}s\right),\quad f_2(p)=\exp\left(-\frac{i}{\hbar}\int_0^t V_2(p(s))\mathrm{d}s\right).$$

Under the given hypothesis on V_1 and ψ_0, f_1 belongs to $\mathcal{F}(\mathcal{H}_t)$. The proof is given for instance in Ref. 2. For f_2 one must pay more attention: indeed the same proof given for f_1 does not work, as f_2 is defined on a different Hilbert space and we have to require explicitly that $\int_0^t V_2(p(s))\mathrm{d}s\in\mathcal{F}(\mathcal{L}_t)$. Under this hypothesis one can easily prove that (see Ref. 2) $f_2\in\mathcal{F}(\mathcal{L}_t)$.

Now if $f_1=\hat{\mu}_{f_1}\in\mathcal{F}(\mathcal{H}_t)$, f_1 can be extended to a function, denoted again by f_1, in $\mathcal{F}(\mathcal{H}_t\times\mathcal{L}_t)$: it is the Fourier transform of the product measure on $\mathcal{H}_t\times\mathcal{L}_t$ of $\mu_{f_1}(\mathrm{d}q)$ and $\delta_0(\mathrm{d}p)$. The same holds for $f_2=\hat{\mu}_{f_2}$: $f_2=(\delta_0(\mathrm{d}q)\mu_{f_2}(\mathrm{d}p))$.

Finally, as $\mathcal{F}(\mathcal{H}_t\times\mathcal{L}_t)$ is a Banach algebra,[2] the product of two elements f_1f_2 is again an element of $\mathcal{F}(\mathcal{H}_t\times\mathcal{L}_t)$: more precisely it is the Fourier transform of the convolution of the two measures in $\mathcal{M}(\mathcal{H}_t\times\mathcal{L}_t)$ corresponding to f_1 and f_2, respectively., and the conclusion follows. The next theorem shows that the above oscillatory integral (16) gives the solution to the Schrödinger equation.

Theorem 4: *Let us consider the following Hamiltonian*

$$H(Q;P)=\frac{P^2}{2}+V_1(Q)+V_2(P)$$

in $L^2(\mathbb{R}^d)$ *and the corresponding Schrödinger equation*

$$\begin{cases}\dot{\psi}=-\dfrac{i}{\hbar}H\psi,\\ \psi(0,x)=\psi_0(x),\quad x\in\mathbb{R}^d.\end{cases}\tag{17}$$

Let us suppose that V_1, $\psi_0\in\mathcal{F}(\mathbb{R}^d)$ *and* $\int_0^t V_2(p(s))\mathrm{d}s\in\mathcal{F}(\mathcal{L}_t)$. *Then the solution to the Cauchy problem (17) is given by the phase space Feynman path integral:*

$$\widetilde{\int}_{\mathcal{H}_t\times\mathcal{L}_t}\exp\left(\frac{i}{2\hbar}\langle q,p;A(q,p)\rangle\right)\exp\left(-\frac{i}{\hbar}\int_0^t(V_1(q(s)+x)+V_2(p(s)))\mathrm{d}s\right)\psi(0,q(0)+x)\mathrm{d}q\,\mathrm{d}p.$$

Proof: We follow the proof given by Elworthy and Truman in Ref. 3.

For $0\leqslant u\leqslant t$ let $\mu_u(V_1,x)\equiv\mu_u$, $\nu_u^t(V_1,x)\equiv\nu_u^t$, $\eta_u^t(V_2)\equiv\eta_u^t$, and $\mu_0(\psi)$ be the measures on $\mathcal{H}_t\times\mathcal{L}_t$ whose Fourier transforms when evaluated at $(q,p)\in\mathcal{H}_t\times\mathcal{L}_t$ are

$$V_1(x+q(u)),\quad \exp\left(-i\int_u^t V_1(x+q(s))\mathrm{d}s\right),\quad \exp\left(-i\int_u^t V_2(p(s))\mathrm{d}s\right),\quad \psi_0(q(0)+x).$$

We set

$$U(t)\psi_0(x)=\widetilde{\int}_{\mathcal{H}_t\times\mathcal{L}_t}\exp\left(\frac{i}{2\hbar}\langle q,p;A(q,p)\rangle\right)\times\exp\left(-\frac{i}{\hbar}\int_0^t(V_1(q(s)+x)+V_2(p(s)))\mathrm{d}s\right)\psi(0,q(0)+x)\mathrm{d}q\,\mathrm{d}p$$

and

$$U_0(t)\psi_0(x)=\widetilde{\int}_{\mathcal{H}_t\times\mathcal{L}_t}\exp\left(\frac{i}{2\hbar}\langle q,p;A(q,p)\rangle\right)\times\exp\left(-\frac{i}{\hbar}\int_0^t V_2(p(s))\right)\mathrm{d}s\,\psi(0,q(0)+x)\mathrm{d}q\,\mathrm{d}p.$$

By Sec. III we have

$$U(t)\psi_0(x)=\int_{\mathcal{H}_t\times\mathcal{L}_t}e^{(-i\hbar/2)\langle q,p;A^{-1}(q,p)\rangle}(\eta_0^t*\nu_0^t*\mu_0(\psi))(\mathrm{d}q\,\mathrm{d}p).\tag{18}$$

Now, if $\{\mu_u:a\leqslant u\leqslant t\}$ is a family in $\mathcal{M}(\mathcal{H}_t\times\mathcal{L}_t)$, we shall let $\int_a^b\mu_u\,\mathrm{d}u$ denote the measure on $\mathcal{H}_t\times\mathcal{L}_t$ given by

$$f \to \int_a^b \int_{\mathcal{H}_t \times \mathcal{L}_t} f(q,p)\,\mathrm{d}\mu_u(q,p)\,\mathrm{d}u$$

whenever it exists.

Since for any continuous path q,

$$\exp\left(-i\int_0^t V_1(q(s))\mathrm{d}s\right) = 1 - i\int_0^t V_1(q(u))\exp\left(-i\int_u^t V_1(q(s))\mathrm{d}s\right)\mathrm{d}u,$$

the following relation holds:

$$\nu_0^t = \delta_0 - i\int_0^t (\mu_u * \nu_u^t)\mathrm{d}u, \tag{19}$$

where δ_0 is the Dirac measure at $0 \in \mathcal{H}_t$.

Applying this relation to (18) we obtain

$$\begin{aligned} U(t)\psi_0(x) &= \int_{\mathcal{H}_t \times \mathcal{L}_t} \exp\left(\frac{-i\hbar}{2}\langle q,p;A^{-1}(q,p)\rangle\right)(\eta_0^t * \mu_0(\psi))(\mathrm{d}q\,\mathrm{d}p) \\ &\quad - i\int_0^t \int_{\mathcal{H}_t \times \mathcal{L}_t} \exp\left(\frac{-i\hbar}{2}\langle q,p;A^{-1}(q,p)\rangle\right)(\eta_0^t * \mu_u(V_1,x) * \nu_u^t * \mu_0(\psi))(\mathrm{d}q\,\mathrm{d}p)\mathrm{d}u \\ &= U_0(t)\psi_0(x) - i\int_0^t \widetilde{\int}_{\mathcal{H}_t \times \mathcal{L}_t} \exp\left(\frac{i}{2\hbar}\langle q,p;A(q,p)\rangle\right)\exp\left(-\frac{i}{\hbar}\int_u^t V_1(q(s)+x)\mathrm{d}s\right) \\ &\quad \times \exp\left(-\frac{i}{\hbar}\int_0^t V_2(p(s))\right)\mathrm{d}s V_1(q(u)+x)\psi_0(q(0)+x)\mathrm{d}q\,\mathrm{d}p\,\mathrm{d}u. \end{aligned}$$

Now we have, by Fubini theorem for Fresnel integrals,[2]

$$\widetilde{\int}_{\mathcal{H}_t \times \mathcal{L}_t} \exp\left(\frac{i}{2\hbar}\langle q,p;A(q,p)\rangle\right)\exp\left(-\frac{i}{\hbar}\int_u^t V_1(q(s)+x)\mathrm{d}s\right)\exp\left(-\frac{i}{\hbar}\int_0^t V_2(p(s))\right)\mathrm{d}s.$$

$$\begin{aligned} &V_1(q(u)+x)\psi_0(q(0)+x)\mathrm{d}q\,\mathrm{d}p \\ &\quad = \widetilde{\int}_{\mathcal{H}_{t-u} \times \mathcal{L}_{t-u}} \exp\left(\frac{i}{2\hbar}\langle q,p;A(q,p)\rangle_{\mathcal{H}_{t-u} \times \mathcal{L}_{t-u}}\right) \\ &\qquad \times \exp\left(-\frac{i}{\hbar}\int_0^{t-u} V_1(q(s)+x)\mathrm{d}s\right)\left(\exp -\frac{i}{\hbar}\int_0^{t-u} V_2(p(s))\right) \\ &\qquad \times \mathrm{d}s V_1(q(0)+x)\widetilde{\int}_{\mathcal{H}_u \times \mathcal{L}_u} \exp\left(\frac{i}{2\hbar}\langle q_1,p_1;A(q_1,p_1)\rangle_{\mathcal{H}_u \times \mathcal{L}_u}\right) \\ &\qquad \times \exp\left(-\frac{i}{\hbar}\int_0^u V_2(p_1(s))\right)\mathrm{d}s\,\psi_0(q_1(0))\mathrm{d}q_1\mathrm{d}p_1\mathrm{d}q\,\mathrm{d}p p. \end{aligned}$$

Here $q \in \mathcal{H}_{t-u}$ and $q_1 \in \mathcal{H}_u$ are the integration variables, and $\mathcal{H}_s$ denotes the Cameron–Martin space of paths $\gamma:[0,s] \to \mathbb{R}^d$.

We have

$$U(t)\psi_0(x) = U_0(t)\psi_0(x) - i\int_0^t U(t-u)(V_1 U_0(u)\psi_0)(x)\mathrm{d}u$$

$$= U_0(t)\psi_0(x) - i\int_0^t U(u)(V_1 U_0(-u)U_0(t)\psi_0)(x)\mathrm{d}u.$$

The iterative solution of the latter integral equation is the convergent Dyson perturbation series for $U(t)$ with respect to $U_0(t)$, which proves the theorem. □

Remark: We have stated our results for $\psi_0 \in \mathcal{F}(\mathbb{R}^d)$. They can be extended by density to $L^2(\mathbb{R}^d)$.

We consider two- and three-dimensional complex Schrödinger equations with Abelian potentials and a fixed energy level. The potential, wave function, and the spectral Bloch variety are calculated in terms of the Kleinian hyperelliptic functions associated with a genus two hyperelliptic curve. In the special case in two dimensions when the curve covers two elliptic curves, exactly solvable Schrödinger equations are constructed in terms of the elliptic functions of these curves. The solutions obtained are illustrated by a number of plots. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1470708]

I. INTRODUCTION

Modern physical technologies have led to the manufacture of new materials—films, superlattices, two-dimensional (2D) quantum dots arrays, etc., whose mathematical models are based on the 2D and 3D (three-dimensional) Schrödinger equation with periodic and quasiperiodic potentials. The recent discoveries of soliton theory, which involve the theory of Abelian functions, make it possible to construct exactly solvable Schrödinger equations with Abelian potentials. Progress in this area has been made by Novikov and co-workers since the middle of the 1970s (see, e.g., Ref. 1). In Ref. 2, the multidimensional spectral problem for the Schrödinger equation under the action of an external magnetic field was considered, and the corresponding Bloch solutions were constructed at specific values of the energy. The case of a real *pure potential* was solved in Refs. 3 and 4 for some special hyperelliptic curves which permit involution with two stable points, leading to Prym varieties.

The complex theory of the 2D Schrödinger equation with an Abelian potential was developed by Buchstaber and Enolskii[5] by differentiating the addition theorem for the Baker function of genus two; in this approach, the 2D Schrödinger equation appeared as a compatibility condition for the ansatz introduced in Ref. 5. The key ingredient of this technique is the use of the Weierstrass–Klein realization of the hyperelliptic functions, which is treated in the classical literature[6,7] and more recently developed in Ref. 8.

The aim of the present paper is to develop the theory for 2D and 3D Schrödinger equations with an Abelian potential using, as the basic ingredient, the Baker function $\Phi(\mathbf{x};\boldsymbol{\alpha})$ of the hyperelliptic curve V of genus g,

$$\Phi_B(\mathbf{x};\boldsymbol{\alpha})=\frac{\sigma(\boldsymbol{\alpha}-\mathbf{x})}{\sigma(\boldsymbol{\alpha})\sigma(\mathbf{x})}\exp(\boldsymbol{\zeta}(\boldsymbol{\alpha})^T\mathbf{x}),$$

where the variable $\mathbf{x}$ and spectral variable $\boldsymbol{\alpha}$ belong to the Jacobi varieties of the underlying hyperelliptic curve, the σ-function is a generalization of the Weierstrass σ-function to higher genera, and $\zeta_i=\partial/\partial x_i \ln\sigma(\mathbf{x})$, $i=1,\ldots,g$ are hyperelliptic ζ-functions. We emphasize that the Baker function is defined on the product of Jacobians $\mathrm{Jac}(V)\times\mathrm{Jac}(V)$ in contrast to the Baker–Akhiezer function, which is defined on the product $V\times\mathrm{Jac}(V)$.

To explain the results, we first consider the n-dimensional Schrödinger equation

$$\left\{\sum_{k=1}^{n}\frac{\partial^2}{\partial x_k^2}-\mathcal{U}(\mathbf{x})\right\}\Psi(\mathbf{x};\boldsymbol{\alpha})=\lambda(\boldsymbol{\alpha})\Psi(\mathbf{x};\boldsymbol{\alpha}),\tag{1.1}$$

where *the potential* $\mathcal{U}(\mathbf{x})$ depends on the column vector $\mathbf{x}$ belonging to the n-dimensional complex space $\mathbb{C}^n$, $\Psi(\mathbf{x};\boldsymbol{\alpha})$ is *the wave function* depending both on $\mathbf{x}$ and *the spectral parameter*, which is a column vector $\boldsymbol{\alpha}\in\mathbb{C}^n$, and $\lambda(\boldsymbol{\alpha})$ is the *spectral function*. We assume that the functions introduced have the following periodicity properties with respect to the $2n$ n-dimensional vectors, which are columns of the $n\times 2n$ matrix $(2\omega,2\omega')$, where ω,ω' are $n\times n$-matrices given by

$$\mathcal{U}(\mathbf{x}+2\omega\mathbf{n}+2\omega'\mathbf{m})=\mathcal{U}(\mathbf{x}),\tag{1.2}$$

$$\Psi(\mathbf{x}+2\omega\mathbf{n}+2\omega'\mathbf{m};\boldsymbol{\alpha})=\xi_{\mathbf{n},\mathbf{m}}(\boldsymbol{\alpha})\Psi(\mathbf{x};\boldsymbol{\alpha}),\tag{1.3}$$

$$\Psi(\mathbf{x};\boldsymbol{\alpha}+2\omega\mathbf{n}+2\omega'\mathbf{m})=\Psi(\mathbf{x};\boldsymbol{\alpha}),\tag{1.4}$$

where $\mathbf{n}$, $\mathbf{m}$ are arbitrary integer column vectors, and the function $\xi_{\mathbf{n},\mathbf{m}}(\boldsymbol{\alpha})$ is *the Bloch factor*. The Bloch factor is assumed to be of the form

$$\xi_{\mathbf{n},\mathbf{m}}(\boldsymbol{\alpha})=\exp\{2\mathbf{k}^T(\boldsymbol{\alpha})(\omega\mathbf{n}+\omega'\mathbf{m})\},\tag{1.5}$$

and the *quasimomentum* $\mathbf{k}(\boldsymbol{\alpha})$ is identified with the eigenvalue of the translation operator on the lattice.

Equations (1.3) and (1.5) represent a natural generalization of the usual Bloch theorem to the case of Abelian potentials. Indeed, after expressing the spectral parameter in terms of the quasimomentum and considering translations in the crystal lattice by a vector of the form $2\omega\mathbf{n}$, with $2\omega=(2\omega_{i,j})_{i,j=1,\ldots,n}$ being the $n\times n$ period matrix, we have from (1.3)

$$\Psi(\mathbf{x}+2\omega\mathbf{n};\mathbf{k})=\mathrm{e}^{2\mathbf{k}^T\omega\mathbf{n}}\Psi(\mathbf{x};\mathbf{k}).\tag{1.6}$$

Similarly, with respect to points of the reciprocal lattice, (1.4) gives

$$\Psi(\mathbf{x};\mathbf{k}+2\tilde{\omega}\mathbf{n})=\Psi(\mathbf{x};\mathbf{k}),\tag{1.7}$$

where $2\tilde{\omega}\mathbf{n}$ is a *reciprocal period*, which is represented as a column of the $n\times n$ *reciprocal period matrix* $2\tilde{\omega}$, which will be shown later to be equal to $i\pi(\omega)^{-1}$.

These properties mean that the Schrödinger equation is considered on the product of tori $T\times T$, $T=\mathbb{C}^n/2\omega\oplus 2\omega'$, which we assume to be generated by a hyperelliptic curve V and therefore T is the Jacobian $\mathrm{Jac}(V)$ of the curve. Since the potential has the periodicity property (1.2), it is an *Abelian function*, as is the corresponding spectral function.

In this case, the periods 2ω and $2\omega'$ are generated by the holomorphic integrals over cycles of the curve V, and it is always possible to fix the parameters of the curve in such a way that the period matrix 2ω is real and the period matrix $2\omega'$ is pure imaginary.

From the physical viewpoint, it is natural to consider the potential and the wave functions as functions of the argument $\imath\mathbf{x}+\mathbf{\Omega}$, where $\mathbf{\Omega}$ is a real half period. Then the potential $\mathcal{U}(\imath\mathbf{x}+\mathbf{\Omega})$ is periodic with respect to the period lattice $2\imath\omega'$ and is smooth and real at real $\mathbf{x}$, and the wave function $\Psi(\imath\mathbf{x}+\mathbf{\Omega};\boldsymbol{\alpha}+\mathbf{\Omega}')$, where $\mathbf{\Omega}'$ is a pure imaginary period, satisfy the periodicity property (1.6)

$$\Psi(\imath\mathbf{x}+\mathbf{\Omega}+2\omega'\mathbf{n};\mathbf{k}(\boldsymbol{\alpha}))=\mathrm{e}^{2\imath\mathbf{k}^T(\boldsymbol{\alpha})\mathrm{Im}(\omega')\mathbf{n}}\Psi(\imath\mathbf{x}+\mathbf{\Omega};\mathbf{k}(\boldsymbol{\alpha})), \tag{1.8}$$

with real quasimomentum $\mathbf{k}(\boldsymbol{\alpha})$.

In this context, we shall call this periodicity property of the wave function the *Bloch property*. The subvariety $\mathcal{B}\subset\mathrm{Jac}(V)$ for which the spectral problem (1.1) can be solved is called the *Bloch variety*.

The Bloch variety, when parametrized in terms of the quasimomentum $\mathbf{k}$, and restricted to a fixed value of the *energy* $\mathcal{E}=\lambda(\boldsymbol{\alpha})=\mathrm{const}$, is called a *Fermi variety*, denoted by $\mathcal{F}$. If the Schrödinger equation permits solutions *only* at a fixed energy level, which is independent of the spectral parameter $\boldsymbol{\alpha}$, then the Bloch variety and the Fermi variety are isomorphic, but generally speaking $\dim\mathcal{B}\geqslant\dim\mathcal{F}$. The Fermi variety is a *Fermi surface* in the case $\dim\mathcal{F}=2$ (this situation is usually realized at $n=3$) and a *Fermi curve* in the case when $\dim\mathcal{F}=1$. In the theory of the electronic structure of metals, most interest lies in those exactly solvable Schrödinger equations which admit nontrivial Fermi varieties.

In what follows we shall interpret all these quantities for the case of 2D and three-dimensional (3D) Schrödinger equations in terms of Abelian functions of genus two and genus three hyperelliptic curves.

We would like to emphasize that the known methods of derivation of exact solutions of multidimensional Schrödinger equations suppose the separability of the potential, i.e., in 2D, $\mathcal{U}(\mathbf{x})=\alpha\wp(x_1)\wp(x_2)$, where the $\wp(x_i)$ are the Weierstrass elliptic functions, and $\alpha=$ const. In this case the lattice structure is necessarily rectangular(cubic) in 2D(3D). The nonseparable potentials which we are considering enable us to investigate more general lattice symmetries, with a greater range of physical applications.

The paper is organized as follows. In Sec. II we consider the well-known case of the one-dimensional (1D) Schrödinger equation with elliptic Lamé potentials. In Sec. III we introduce a suitable generalization of the Kleinian function to higher genera and present a natural extension of the theory of the one-gap Lamé potential to higher dimensions. The results of this section will not be restricted to two dimensions but will be valid also in the 3D case. In Sec. IV we apply the general results of Sec. III to the 2D case, by deriving the explicit form of a certain family of Abelian potentials for which the 2D Schrödinger equation is exactly solvable. A set of figures for the potential profiles, showing that they are periodic, real and nonsingular, and therefore suitable for physical applications, is also given. The corresponding eigenvalues and eigenfunctions are also explicitly displayed. Section V is devoted to the case of reduction of the 2D Abelian potential and associated eigenfunction to elliptic functions. To do this we use the general results of Sec. III together with the explicit formulas for the deformation of the two-gap Lamé potential under the action of the Korteweg–de Vries (KdV) flow and the three-particle dynamics over the locus, to derive exactly solvable 2D Schrödinger equations with elliptic potentials. Finally, in Sec. VI we will consider the extension of the theory to the 3D case.

II. THE 1D SCHRÖDINGER EQUATION WITH ELLIPTIC POTENTIALS

One of the main problems in condensed matter physics is the construction of solutions of the Schrödinger equation with real and nonsingular periodic or quasiperiodic potentials. Except in very few cases, this problem is in general not solvable without resorting to approximations.

One of the few cases for which exact solutions are known is provided by the remarkable example of the one-dimensional *Lamé equation* with an elliptic potential (here and in the following we follow the standard notation of the theory of elliptic functions fixed in Ref. 9),

$$\left\{\frac{d^2}{dx^2}-\mathcal{U}(x)\right\}\Psi(x;\alpha)=\wp(\alpha)\Psi(x;\alpha), \tag{2.1}$$

$$\mathcal{U}(x)=2\wp(x), \quad \Psi(x;\alpha)=\Phi_W(x;\alpha)=\frac{\sigma(\alpha-x)}{\sigma(\alpha)\sigma(x)}\exp\{\zeta(\alpha)x\}. \tag{2.2}$$

Since in the following sections we will consider the generalization of this classical case to higher dimensions, we shall briefly review it here.

We recall that the Weierstrass functions $\wp,\zeta$ are given as logarithmic derivatives of the σ-function,

$$\wp(x)=-\frac{d^2}{dx^2}\ln\sigma(x), \quad \zeta(x)=\frac{d}{dx}\ln\sigma(x).$$

The σ-function, which is the generating function for the whole theory, is constructed from the elliptic curve

$$w^2=4z^3-g_2z-g_3\equiv 4(z-e_1)(z-e_2)(z-e_3) \tag{2.3}$$

equipped with a canonical basis of cycles $\mathfrak{a}$, $\mathfrak{b}$ as follows. The holomorphic differential and the associated meromorphic differential of the second kind are given, respectively, by dz/w and $z\,dz/w$. Their $\mathfrak{a}$ and $\mathfrak{b}$ periods

$$2\omega=\oint_{\mathfrak{a}}\frac{dz}{w}, \quad 2\omega'=\oint_{\mathfrak{b}}\frac{dz}{w}, \tag{2.4}$$

$$2\eta=-\oint_{\mathfrak{a}}\frac{z\,dz}{w}, \quad 2\eta'=-\oint_{\mathfrak{b}}\frac{z\,dz}{w} \tag{2.5}$$

satisfy the *Legendre relation*

$$\eta\omega'-\omega\eta'=\frac{\imath\pi}{2}. \tag{2.6}$$

The Weierstrass σ-function has the form

$$\sigma(x)=\sqrt{\frac{\pi}{\omega}}\frac{1}{\sqrt[8]{\Delta}}\exp\left(\frac{\eta x^2}{2\omega}\right)\vartheta_1\left(\frac{x}{2\omega}\middle|\tau\right), \tag{2.7}$$

where ϑ_1 is the Jacobian θ-function, $\tau=\omega'/\omega$, and $\Delta=16(e_2-e_3)^2(e_3-e_1)^2(e_1-e_2)^2$. This σ-function can be also be represented as the power series

$$\sigma(x)=x-\frac{g_2x^5}{2^4\cdot 3\cdot 5}+\frac{g_3x^7}{2^3\cdot 3\cdot 5\cdot 7}+\cdots$$

with coefficients connected by a recursion relation first found by Weierstrass[10] and documented in Ref. 11 (see also Ref. 12). The Weierstrass σ-function has the periodicity property

$$\sigma(x+2n\omega+2m\omega)=(-1)^{n+m+mn}\exp\{2(n\eta+m\eta')(x+n\omega+m\omega')\}\sigma(x), \tag{2.8}$$

which leads to the following expression for the Bloch factor:

$$\xi_i(\alpha)=\exp(2\omega_i\zeta(\alpha)-2\alpha\eta_i),\quad i=1,2,3. \tag{2.9}$$

The functions $\xi_i(\alpha)$ are elliptic functions with periods $2\omega,2\omega'$, because of the Legendre relation.

To give the physical interpretation of the above-mentioned formulas we shall fix the potential and the wave function as follows:

$$\mathcal{U}(x)=2\wp(\imath x+\omega),\quad \Psi(x;\alpha)=\Phi_W(\imath x+\omega;\alpha+\omega'),\quad x,\alpha\in\mathbb{R}. \tag{2.10}$$

The potential has the real period $-2\imath\omega'$. The associated quasimomentum is given by

$$k(\alpha)=\zeta(\alpha+\omega')-\frac{\eta'}{\omega'}(\alpha+\omega'),\quad \alpha\in\mathbb{R}. \tag{2.11}$$

The wave function, considered as a function of k instead of α, has the periodicity property (1.7) with the reciprocal period

$$2\tilde{\omega}=\frac{\imath\pi}{\omega'}.$$

The Bloch variety $\mathcal{B}$ is the Jacobian of the elliptic curve, which is isomorphic in this case to the elliptic curve itself.

We remark here that the one-dimensional finite-gap potentials appear to be important in applications. For example, Belokolos proved in 1980[13] that the exact solution of the famous Peierls problem is a finite-gap potential.

The simplest generalization of (2.1) to the n-dimensional case can be obtained if we consider the separable potential

$$\mathcal{U}(\mathbf{x})=2\sum_{k=1}^{n}\wp(\imath x_k+\omega^{(k)};2\omega^{(k)},2\omega^{(k)'}),$$

where $\wp(\cdot;2\omega^{(k)},2\omega^{(k)'})$ are Weierstrass elliptic functions with periods $2\omega^{(k)}$ and $2\omega^{(k)'}$. The energy $\mathcal{E}$ and components of the quasimomenta $\mathbf{k}$ are then

$$\mathcal{E}=\sum_{k=1}^{n}\wp(\alpha_k+\omega^{(k)'};2\omega^{(k)},2\omega^{(k)'}),$$

$$k_j(\alpha_j)=\zeta(\alpha_j)-\frac{\eta^{(j)'}}{\omega^{(j)'}}\alpha_j,\quad j=1,\ldots,n.$$

The wave function is given in this case as a product of the functions Φ_W.

In the case $n=3$ such potentials lead to nontrivial and sometimes very interesting Fermi surfaces. For example, Baryakhtar *et al.*[14] have used separable potentials to successfully calculate the electron energy of metals and high-temperature superconductors, and Belokolos and Korostil[15] have studied the electron–phonon interaction function.

Moreover, a general theory for the Schrödinger equations with separable multidimensional Lamé potentials with an arbitrary number of gaps in the spectrum was recently developed in Ref. 16. This approach was shown to be effective for the exact computation of the energy bands and Fermi surfaces of 2D lattices with square or rectangular symmetry. The extension of these results, however, to lattices with more general spatial symmetries seems problematic in the context of separable multidimensional Lamé potentials.

We shall develop in the following another generalization, which leads to a nonseparable potential. Namely we shall show that the Lamé equation (2.1) can be generalized to higher dimensions within the Weierstrass–Klein generalization of Weierstrass elliptic function theory to higher genera, following Refs. 6 and 7 and also Refs. 17 and 8. This generalization enables us to treat more general symmetries than the separable case.

III. MULTIDIMENSIONAL SCHRÖDINGER EQUATIONS AS GENERALIZED LAMÉ EQUATIONS OF HIGHER GENERA

To develop the theory of the multidimensional Schrödinger equation we need a suitable generalization of the *fundamental σ-function* of the hyperelliptic curve $V=V(w,z)$ of genus g,

$$w^2=4\prod_{i=1}^{2g+1}(z-e_i)\equiv 4z^{2g+1}+\sum_{i=0}^{2g}\lambda_i z^i \tag{3.1}$$

by the following formula, which is analogous to that in the elliptic case

$$\sigma(\mathbf{x})=\sqrt{\frac{\pi^g}{\det 2\omega}}\frac{1}{\sqrt[4]{\Pi_{i\neq j}(e_i-e_j)}}\exp\{\mathbf{x}^T\varkappa\mathbf{x}\}\,\theta[\varepsilon]((2\omega)^{-1}\mathbf{x}|\tau). \tag{3.2}$$

The entries to (3.2) are as follows $\theta[\varepsilon](\mathbf{v}|\tau)$ is the standard multidimensional theta function with characteristic

$$\theta[\varepsilon](\mathbf{v}|\tau)=\sum_{\mathbf{m}\in\mathbb{Z}^g}\exp\{\pi\imath(\mathbf{m}+\boldsymbol{\varepsilon}')^T\tau(\mathbf{m}+\boldsymbol{\varepsilon}')+2\pi\imath(\mathbf{m}+\boldsymbol{\varepsilon}')^T(\mathbf{v}+\boldsymbol{\varepsilon})\}; \tag{3.3}$$

$$[\varepsilon]=\begin{bmatrix}\boldsymbol{\varepsilon}'^T\\ \boldsymbol{\varepsilon}^T\end{bmatrix}=\begin{bmatrix}\varepsilon_1' & \dots & \varepsilon_g'\\ \varepsilon_1 & \dots & \varepsilon_g\end{bmatrix}$$

is the necessarily half integer characteristic of the vector of Riemann constants whose base point is chosen as (∞,∞). The matrix

$$\varkappa=\eta(2\omega)^{-1} \tag{3.4}$$

is the symmetric matrix which generalizes the factor $\eta/2\omega$ in the exponential (2.7) to the higher genera. The $2g\times 2g$ period matrix, $\left(\begin{smallmatrix}\omega & \omega'\\ \eta & \eta'\end{smallmatrix}\right)$ satisfies the generalized Legendre relation

$$\begin{pmatrix}\omega & \omega'\\ \eta & \eta'\end{pmatrix}\begin{pmatrix}0 & -1_g\\ 1_g & 0\end{pmatrix}\begin{pmatrix}\omega & \omega'\\ \eta & \eta'\end{pmatrix}^T\begin{pmatrix}0 & -1_g\\ 1_g & 0\end{pmatrix}=-\frac{\imath\pi}{2}, \tag{3.5}$$

where the $g\times g$ period matrices $2\omega,2\omega',2\eta,2\eta'$ are

$$2\omega=\left(\oint_{\mathfrak{a}_i}\mathrm{d}u_j\right)_{i,j=1,\dots,g},\quad 2\omega'=\left(\oint_{\mathfrak{b}_i}\mathrm{d}u_j\right)_{i,j=1,\dots,g},$$

$$2\eta=\left(-\oint_{\mathfrak{a}_i}\mathrm{d}r_j\right)_{i,j=1,\dots,g},\quad 2\eta'=\left(-\oint_{\mathfrak{b}_i}\mathrm{d}r_j\right)_{i,j=1,\dots,g}.$$

Here the $\mathrm{d}u_i$ are the holomorphic differentials

$$\mathrm{d}\mathbf{u}^T=(\mathrm{d}u_1,\dots,\mathrm{d}u_g),\quad \mathrm{d}u_k=\frac{z^{k-1}\mathrm{d}z}{w}, \tag{3.6}$$

and the dr_i are the differentials of the second kind with a pole at infinity

$$\begin{gathered} d\mathbf{r}^T=(dr_1,\ldots,dr_g),\\ dr_j=\sum_{k=j}^{2g+1-j}(k+1-j)\lambda_{k+1+j}\frac{z^k dz}{4w},\quad j=1,\ldots,g. \end{gathered} \tag{3.7}$$

The Kleinian σ-function has the following periodicity property:

$$\sigma(\mathbf{x}+2\boldsymbol{\Omega}(\mathbf{n},\mathbf{m}))=\exp\{2\mathbf{E}^T(\mathbf{n},\mathbf{m})(\mathbf{x}+\boldsymbol{\Omega}(\mathbf{n},\mathbf{m}))\}\exp\{-\imath\pi\mathbf{n}^T\mathbf{m}-2\imath\pi\boldsymbol{\varepsilon}^T\mathbf{m}\}\sigma(\mathbf{x}), \tag{3.8}$$

where $\mathbf{E}(\mathbf{n},\mathbf{m})=\eta\mathbf{n}+\eta'\mathbf{m}$, $\boldsymbol{\Omega}(\mathbf{n},\mathbf{m})=\omega\mathbf{n}+\omega'\mathbf{m}$, $\mathbf{n},\mathbf{m}\in\mathbb{Z}^g$ and $\boldsymbol{\varepsilon}^T$ is the lower line of the characteristic of the vector of the Riemann constant. The Kleinian ζ- and $\wp$-functions are introduced through logarithmic derivatives of the Kleinian σ-function,

$$\zeta_i(\mathbf{x})=\frac{\partial\ln\sigma(\mathbf{x})}{\partial x_i},\quad \wp_{i,j}(\mathbf{x})=-\frac{\partial^2\ln\sigma(\mathbf{x})}{\partial x_i\partial x_j},$$

$$\wp_{i,j,k}(\mathbf{x})=-\frac{\partial^3\ln\sigma(\mathbf{x})}{\partial x_i\partial x_j\partial x_k},\quad i,j,k=1,\ldots,g,\ \text{etc.}$$

We will omit commas between indices when the resulting formula is unambiguous.

The Abel map $\mathfrak{A}:(V)^g\to\mathrm{Jac}(V)$ of the symmetrized product $V\times\cdots\times V$ to the Jacobi variety $\mathrm{Jac}(V)=\mathbb{C}^g/2\omega\oplus 2\omega'$ of the curve V is defined by

$$\sum_{k=1}^{g}\int_{(\infty,\infty)}^{(w_k,z_k)}d\mathbf{u}=\mathbf{x}. \tag{3.9}$$

The Kummer variety is defined as the factor $\mathrm{Kum}(V)=\mathrm{Jac}(V)/\mathbf{x}\to-\mathbf{x}$ by the involution $\mathbf{x}\to-\mathbf{x}$.

The principal results of the theory of the hyperelliptic Kleinian can be formulated using the $(g+2)\times(g+2)$-matrix

$$\begin{aligned} H=\{h_{i,k}\}_{i,k=1,\ldots,g+2},\quad h_{ik}&=4\wp_{i-1,k-1}-2\wp_{k,i-2}-2\wp_{i,k-2}+\tfrac{1}{2}(\delta_{i,k}(\lambda_{2i-2}+\lambda_{2k-2})\\ &+\delta_{k,i+1}\lambda_{2i-1}+\delta_{i,k+1}\lambda_{2k-1}). \end{aligned} \tag{3.10}$$

We denote the minors of the matrix H as follows:

$$H\left[\begin{smallmatrix}k_1&\cdots&k_n\\ j_1&\cdots&j_m\end{smallmatrix}\right]\{h_{i_k,j_l}\}_{k=1,\ldots,m;l=1,\ldots,n}.$$

Theorem 3.1 (Ref. 7): *The matrix H has the following properties*

(1) Let $(w_1,z_1),\ldots,(w_g,z_g)$ be a divisor and $\mathbf{Z}=(1,z,\ldots,z^{g+1})^T$, then for arbitrary vectors

$$w_r w_s=\mathbf{Z}_r^T H\mathbf{Z}_s,$$

and in particular

$$\mathbf{Z}^T H\mathbf{Z}=\sum_{i=0}^{2g+2}\lambda_i z^i.$$

(2) Let $(w_1,z_1),\ldots,(w_g,z_g)$ be the divisor, then the vectors $\mathbf{Z}=(1,z_r,\ldots,z_r^{g+1})^T$, $r=1,\ldots,g$ are orthogonal to the last column of the matrix H or equivalently the z_r are the roots of

$$z^g-\wp_{gg}(\mathbf{x})z^{g-1}-\ldots-\wp_{1g}(\mathbf{x})=0, \tag{3.11}$$

which yields the solution of the Jacobi inversion problem, where the second coordinate of the divisor is defined as follows:

$$w_k = -\sum_{j=1}^{g} \wp_{jgg}(\mathbf{x}) z_k^{g-j}. \tag{3.12}$$

(3) Rank $H=3$ *at generic points and*

$$-\frac{1}{4}\wp_{igg}\wp_{kgg} = \det H\begin{bmatrix} k & g+1 & g+2 \\ i & g+1 & g+2 \end{bmatrix}, \quad \forall i,k=1,\ldots,g. \tag{3.13}$$

The intersection of the $g(g+1)/2$ *cubics defines the Jacobi variety as an algebraic variety in* $\mathbb{C}^{g+(1/2)g(g+1)}$.

(4) The intersection of the $g(g-1)/2$ *quartics*

$$\det H\begin{bmatrix} k & l & g+1 & g+2 \\ i & j & g+1 & g+2 \end{bmatrix} = 0, \quad \forall i \neq j, k \neq l = 1,\ldots,g \tag{3.14}$$

defines the Kummer variety as an algebraic variety in $\mathbb{C}^{(1/2)g(g+1)}$.

(5) The following equality holds:

$$\mathbf{R}^T \boldsymbol{\pi}_{jl} \boldsymbol{\pi}_{ik}^T \mathbf{S} = \frac{1}{4}\det\begin{pmatrix} H\begin{bmatrix} i & k & g+1 & g+2 \\ j & l & g+1 & g+2 \end{bmatrix} & \mathbf{S} \\ \mathbf{R}^T & 0 \end{pmatrix}, \tag{3.15}$$

where $\mathbf{R}$, $\mathbf{S} \in \mathbb{C}^4$ *are arbitrary vectors and*

$$\boldsymbol{\pi}_{ik} = \begin{pmatrix} -\wp_{ggk} \\ \wp_{ggi} \\ \wp_{g,i,k-1} - \wp_{g,i-1,k} \\ \wp_{g-1,i,k-1} - \wp_{g-1,k,i-1} + \wp_{g,k,i-2} - \wp_{g,i,k-2} \end{pmatrix}.$$

On the basis of the above-mentioned relations, we shall construct the linear differential operators for which the spectral variety will be defined in $\mathrm{Jac}(V)$. Following Baker (see Ref. 6, p. 421) we define a function on $\mathrm{Jac}(V)\times\mathrm{Jac}(V)$.

Definition 3.1: The standard Baker function Φ_B of the curve V is the function on the product $\mathrm{Jac}(V)\times\mathrm{Jac}(V)$, and is defined as follows:

$$\Phi_B : \mathrm{Jac}(V)\times \mathrm{Jac}V \to \mathbb{C},$$

$$\Phi_B(\mathbf{x};\boldsymbol{\alpha}) = \frac{\sigma(\boldsymbol{\alpha}-\mathbf{x})}{\sigma(\boldsymbol{\alpha})\sigma(\mathbf{x})}\exp(\boldsymbol{\zeta}^T(\boldsymbol{\alpha})\mathbf{x}),$$

where $\boldsymbol{\zeta}^T(\boldsymbol{\alpha}) = (\zeta_1(\boldsymbol{\alpha}),\ldots,\zeta_g(\boldsymbol{\alpha}))$, and

$$\mathbf{x} = \sum_{k=1}^{g} \int_{(\infty,\infty)}^{(w_k,z_k)} \mathrm{d}\mathbf{u}, \quad \boldsymbol{\alpha} = \sum_{k=1}^{g} \int_{(\infty,\infty)}^{(\nu_k,\mu_k)} \mathrm{d}\mathbf{u} \in \mathrm{Jac}(V),$$

where $((w_1,z_1),\ldots,(w_g,z_g))$ and $((\nu_1,\mu_1),\ldots,(\nu_g,\mu_g))$ are nonspecial divisors on V. The Φ_B-function is meromorphic in $\mathbf{x}$ and has the periodicity property (1.3) with the Bloch factor

$$\xi_{\mathbf{n},\mathbf{m}}(\alpha) = \exp\{2\boldsymbol{\zeta}^T(\boldsymbol{\alpha})\boldsymbol{\Omega}(\mathbf{n},\mathbf{m}) - 2\mathbf{E}^T(\mathbf{n},\mathbf{m})\boldsymbol{\alpha}\}, \quad i=1,\ldots,g, \tag{3.16}$$

where $\mathbf{\Omega}(\mathbf{n},\mathbf{m})=\omega\mathbf{n}+\omega'\mathbf{m}$, $\mathbf{E}(\mathbf{n},\mathbf{m})=\eta\mathbf{n}+\eta'\mathbf{m}$, $\mathbf{n},\mathbf{m}\in\mathbb{Z}^g$ are arbitrary integer vectors. We shall call the Baker function any function which is meromorphic on $\mathrm{Jac}(V)\times\mathrm{Jac}(V)$ and has the periodicity property (1.3) with the Bloch factors (3.16). Evidently in the case of genus one $\Phi_W \equiv \Phi_B$.

We remark that the spectral variety of the standard Baker function is the Jacobi variety of the curve, in contrast with the *Baker–Akhiezer function*, whose spectral parameter is evaluated on the curve. In our notation, the Baker–Akhiezer function is $\Phi_{\mathrm{BA}}(\mathbf{u};(\mu,\nu))$, which is given by (see Ref. 18)

$$\Phi_{\mathrm{BA}}(\mathbf{x};(\mu,\nu))=\frac{\sigma(\int_{(\nu_0,\mu_0)}^{(\nu,\mu)}\mathrm{d}\mathbf{u}-\mathbf{x})}{\sigma(\mathbf{x})}\exp\left(\int_{(\nu_0,\mu_0)}^{(\nu,\mu)}\mathrm{d}\mathbf{r}^T\mathbf{x}\right),$$

where $(\nu,\mu)\in V$, and $\mathbf{x}\in\mathrm{Jac}(V)$. The function Φ_{BA} solves the one-dimensional Schrödinger equation with the potential $2\wp_{gg}$,

$$(\partial_g^2-2\wp_{gg})\Phi_{\mathrm{BA}}=\left(z+\frac{\lambda_{2g}}{4}\right)\Phi_{\mathrm{BA}}, \tag{3.17}$$

with respect to u_g for all $(\nu,\mu)\in V$.

Let us fix as the period lattice the matrix of real periods 2ω. In analogy with the case of genus one, the Bloch factor (3.16) of the standard Baker function can be written as

$$\begin{gathered}\xi_{\mathbf{n}}(\boldsymbol{\alpha})=\exp\{2\mathbf{k}^T(\boldsymbol{\alpha})\omega\mathbf{n}\},\\ \mathbf{k}(\boldsymbol{\alpha})=\boldsymbol{\zeta}(\boldsymbol{\alpha}+\mathbf{\Omega}')-2\varkappa(\boldsymbol{\alpha}+\mathbf{\Omega}'),\end{gathered} \tag{3.18}$$

where $\mathbf{\Omega}'$ is an imaginary half period.

To prove the last formula we take into account the definition and the symmetry property of the matrix $\varkappa$. We have

$$(\eta\mathbf{n})^T\boldsymbol{\beta}=(\varkappa(2\omega)\mathbf{n})^T\boldsymbol{\beta}=2\boldsymbol{\beta}^T\varkappa\omega\mathbf{n}.$$

The Bloch factor is an Abelian function, whose periodicity properties are provided by the periodicity property of the ζ-function and the generalized Legendre relation (3.5).

We shall prove the following

Proposition 3.2: Let V be a hyperelliptic curve of genus $g<4$. Then the $g+1+\frac{1}{2}g(g+1)$ Baker functions on $\mathrm{Jac(V)}\times\mathrm{Jac}(V)$ are

$$\begin{gathered}F_0(\mathbf{x};\boldsymbol{\alpha})=\Phi_B(\mathbf{x};\boldsymbol{\alpha}),\\ F_i(\mathbf{x};\boldsymbol{\alpha})=\frac{\partial}{\partial x_i}\Phi_B(\mathbf{x};\boldsymbol{\alpha}),\quad i=1,\ldots,g,\\ F_{ij}(\mathbf{x};\boldsymbol{\alpha})=\left\{\frac{\partial^2}{\partial x_i\partial x_j}-2\wp_{ij}(\mathbf{x})\right\}\Phi_B(\mathbf{x};\boldsymbol{\alpha}),\quad i\leqslant j=1,\ldots,g,\end{gathered} \tag{3.19}$$

where $\Phi_B(\mathbf{x};\boldsymbol{\alpha})$ is the standard Baker function of the curve. These functions, regarded as functions of $\mathbf{x}$, are linearly dependent, i.e., there exists at least one relation between them of the form

$$c_0(\boldsymbol{\alpha})F_0(\mathbf{x};\boldsymbol{\alpha})+\sum_{i=1}^{g}c_i(\boldsymbol{\alpha})F_i(\mathbf{x};\boldsymbol{\alpha})+\sum_{i\leqslant j=1,\ldots,g}c_{ij}(\boldsymbol{\alpha})F_{ij}(\mathbf{x};\boldsymbol{\alpha})=0, \tag{3.20}$$

where not all functions in $\boldsymbol{\alpha}$: $c_0(\boldsymbol{\alpha}),c_i(\boldsymbol{\alpha}),c_{ij}(\boldsymbol{\alpha})$ are equal to zero.

Proof: We shall prove the statement for $g=2$ and $g=3$. Let us write the standard addition theorem of the second-order θ-functions,

$$\theta\begin{bmatrix}\boldsymbol{\varepsilon}'^T\\ \boldsymbol{\varepsilon}^T+\boldsymbol{\gamma}^T\end{bmatrix}(\mathbf{v}+\mathbf{u}|\tau)\,\theta\begin{bmatrix}\boldsymbol{\varepsilon}'^T\\ \boldsymbol{\varepsilon}^T\end{bmatrix}(\mathbf{v}-\mathbf{u}|\tau)=\sum_{2\boldsymbol{\delta}\in(\mathbb{Z}/2\mathbb{Z})^g}(-1)^{4\boldsymbol{\varepsilon}^T\boldsymbol{\delta}}\theta\begin{bmatrix}\boldsymbol{\delta}^T\\ \boldsymbol{\gamma}^T\end{bmatrix}(2\mathbf{v}|2\tau)\,\theta\begin{bmatrix}\boldsymbol{\varepsilon}'^T+\boldsymbol{\delta}^T\\ \boldsymbol{\gamma}^T\end{bmatrix}(2\mathbf{u}|2\tau).$$

Now set $\mathbf{u}=0$ and $\boldsymbol{\gamma}=\mathbf{0}$,

$$\theta^2\begin{bmatrix}\boldsymbol{\varepsilon}'^T\\ \boldsymbol{\varepsilon}^T\end{bmatrix}(\mathbf{v}|\tau)=\sum_{2\boldsymbol{\delta}\in(\mathbb{Z}/2\mathbb{Z})^g}(-1)^{4\boldsymbol{\varepsilon}^T\boldsymbol{\delta}^T}\theta\begin{bmatrix}\boldsymbol{\delta}^T\\ \mathbf{0}^T\end{bmatrix}(2\mathbf{v}|2\tau)\,\theta\begin{bmatrix}\boldsymbol{\varepsilon}'^T+\boldsymbol{\delta}^T\\ \mathbf{0}^T\end{bmatrix}(\mathbf{0}|2\tau),\tag{3.21}$$

where $\boldsymbol{\delta}^T=(\delta_1,\ldots,\delta_g)$ with $2\delta_i=1$ or 0, $i=1,\ldots,g$. We multiply both sides of (3.21) by the factor $\exp\{2\mathbf{u}^T\varkappa\mathbf{u}\}$, where $\mathbf{v}=(2\omega)^{-1}\mathbf{u}$ and the matrix $\varkappa$ is given in the definition of the fundamental σ-function. One can see that the entire functions

$$\begin{aligned}\psi\begin{bmatrix}\boldsymbol{\varepsilon}'^T\\ \boldsymbol{\varepsilon}^T\end{bmatrix}(\mathbf{v}|\tau)&=\exp\{2\mathbf{u}^T\varkappa\mathbf{u}\}\,\theta^2\begin{bmatrix}\boldsymbol{\varepsilon}'^T\\ \boldsymbol{\varepsilon}^T\end{bmatrix}(\mathbf{v}|\tau),\\ \widetilde{\psi}\begin{bmatrix}\boldsymbol{\delta}^T\\ \mathbf{0}^T\end{bmatrix}(2\mathbf{v}|2\tau)&=\exp\{2\mathbf{u}^T\varkappa\mathbf{u}\}\,\theta\begin{bmatrix}\boldsymbol{\delta}^T\\ \mathbf{0}^T\end{bmatrix}(2\mathbf{v}|2\tau)\end{aligned}\tag{3.22}$$

have the same periodicity property

$$\psi\begin{bmatrix}\boldsymbol{\delta}^T\\ \mathbf{0}^T\end{bmatrix}(2\mathbf{v}+2\boldsymbol{\Omega}(\mathbf{m},\mathbf{m}')|\tau)=\exp\{2\mathbf{E}^T(\mathbf{m},\mathbf{m}')(\mathbf{x}+\boldsymbol{\Omega}(\mathbf{m},\mathbf{m}'))\}\psi\begin{bmatrix}\boldsymbol{\delta}^T\\ \mathbf{0}^T\end{bmatrix}(2\mathbf{v}|\tau),\tag{3.23}$$

with $\mathbf{E}(\mathbf{m},\mathbf{m}')=\eta\mathbf{m}+\eta'\mathbf{m}'$ as defined previously. Therefore any 2^g+1 entire functions which possess the periodicity property (3.23) are linearly dependent. Moreover this statement can be extended to the case of entire functions which have the periodicity property

$$\psi(\mathbf{v}+2\boldsymbol{\Omega}(\mathbf{m},\mathbf{m}'))=\exp\{2\mathbf{E}^T(\mathbf{m},\mathbf{m}')(\mathbf{x}+\boldsymbol{\Omega}(\mathbf{m},\mathbf{m}'))+\gamma(\mathbf{m},\mathbf{m}')\}\psi(\mathbf{v}),\tag{3.24}$$

where $\gamma(\mathbf{m},\mathbf{m}')$ is some constant. The proof given is valid for genera satisfying the inequality

$$2^g<g+\frac{g(g+1)}{2}.$$

These are the cases $g=2$ and $g=3$. □

We remark that in the case of $g=2$ the statement of Proposition 3.2 was derived in Ref. 5, see also Ref. 17, as the condition of the validity of the addition theorem for the Baker function

$$\boldsymbol{\Phi}_B(\mathbf{u}+\mathbf{v};\boldsymbol{\alpha})=\frac{\mathbf{Y}^T(\mathbf{u};\boldsymbol{\alpha})A\mathbf{Y}(\mathbf{v};\boldsymbol{\alpha})}{\mathbf{X}^T(\mathbf{u})A\mathbf{X}(\mathbf{v})}\tag{3.25}$$

with the integer 4×4-matrix A, where $\mathbf{X}(\mathbf{u})$ is a four-component meromorphic vector function and the four-component vector function $\mathbf{Y}(\mathbf{u};\boldsymbol{\alpha})$ has the periodicity properties (1.3) and (1.4).

The origin of the ansatz (3.25) is explained as follows. In the case $g=1$, (3.25) follows from the Weierstrass addition formula for the σ-functions,

$$\frac{\sigma(u+v)\sigma(u-v)}{\sigma^2(u)\sigma^2(v)}=\wp(v)-\wp(u),\tag{3.26}$$

which can be written in the equivalent form

$$\Phi_W(u+v;\alpha)=\frac{\Phi_W(u;\alpha)\Phi'_W(v;\alpha)-\Phi_W(v;\alpha)\Phi'_W(u;\alpha)}{\wp(u)-\wp(v)}. \tag{3.27}$$

This last equality can be rewritten in the form (3.25) with the vectors

$$\mathbf{Y}(u;\alpha)=\begin{pmatrix}\Phi(u;\alpha)\\ \Phi'(u;\alpha)\end{pmatrix},\quad \mathbf{X}(u)=\begin{pmatrix}\wp(u)\\ 1\end{pmatrix}, \tag{3.28}$$

and the 2×2-matrix

$$A=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}. \tag{3.29}$$

In the case of genus $g=2$, a solution of (3.25) was found in Ref. 5 with

$$\mathbf{X}^T(\mathbf{u})=(\wp_{22}(\mathbf{u}),\wp_{12}(\mathbf{u}),\wp_{11}(\mathbf{u}),1),$$

$$\mathbf{Y}^T(\mathbf{u};\boldsymbol{\alpha})=C(F_0(\mathbf{u};\boldsymbol{\alpha}),F_1(\mathbf{u};\boldsymbol{\alpha}),F_2(\mathbf{u};\boldsymbol{\alpha}),F_{12}(\mathbf{u};\boldsymbol{\alpha})),$$

where the functions F_0, F_1, F_2, and F_{12} are defined in (3.19) and the 4×4-matrices A and C are given as follows:

$$A=\begin{pmatrix}0 & -1 & 0 & 0\\ 1 & 0 & 0 & 0\\ 0 & 0 & 0 & 1\\ 0 & 0 & -1 & 0\end{pmatrix},\quad C=\begin{pmatrix}1 & 0 & 0 & 0\\ 0 & 1 & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & -1/\wp_{22}(\boldsymbol{\alpha})\end{pmatrix},$$

The Schrödinger equation (4.11) and the hyperbolic equation (4.16) in this approach are the compatibility condition of the validity of the ansatz (3.25).

We shall show in the following how Proposition 3.2 is used to derive 2D and 3D Schrödinger equations with a potential expressible in terms of Kleinian $\wp$-functions.

IV. THE TWO-DIMENSIONAL SCHRÖDINGER EQUATION WITH AN ABELIAN POTENTIAL

Consider the Riemann surface of a curve $V(x,y)$ of genus 2, in the form

$$w^2=4z^5+\lambda_4z^4+\lambda_3z^3+\lambda_2z^2+\lambda_1z+\lambda_0=4\Pi_{k=1}^5(z-e_k) \tag{4.1}$$

equipped with a homology basis $(\mathfrak{a}_1,\mathfrak{a}_2;\mathfrak{b}_1,\mathfrak{b}_2)\in H_1(V,\mathbb{Z})$. The canonical holomorphic differentials and the associated meromorphic differentials of the second kind have the form

$$\mathrm{d}u_1=\frac{\mathrm{d}z}{w},\quad \mathrm{d}u_2=\frac{z\,\mathrm{d}z}{w},$$

$$\mathrm{d}r_1=\frac{\lambda_3z+2\lambda_4z^2+12z^3}{4w}dz,\quad \mathrm{d}r_2=\frac{z^2}{w}dz.$$

The fundamental Kleinian σ-function is expanded near $\mathbf{x}=0$ as follows

$$\sigma(x_1,x_2)=x_1-\tfrac{1}{3}x_2^3+\tfrac{1}{24}\lambda_2x_1^3+o(\mathbf{x}^3). \tag{4.2}$$

Denote

$$\zeta_i(\mathbf{x})=\frac{\partial}{\partial x_i}\ln\sigma(\mathbf{x}),\quad i=1,2,$$

$$\wp_{ij}(\mathbf{x})=-\frac{\partial^2}{\partial x_i\partial x_j}\ln\sigma(\mathbf{x}),\quad i,j=1,2.$$

The equations of the Jacobi inversion problem

$$x_i=\int_{(\infty,\infty)}^{(w_1,z_1)}\mathrm{d}u_i+\int_{(\infty,\infty)}^{(w_2,z_2)}\mathrm{d}u_i,\quad i=1,2$$

are equivalent to an algebraic equation

$$\mathcal{P}(z,\mathbf{x})=z^2-\wp_{22}(\mathbf{x})z-\wp_{12}(\mathbf{x})=0, \tag{4.3}$$

i.e., the pair (z_1,z_2) is the pair of roots of (4.3). So we have

$$\wp_{22}(\mathbf{x})=z_1+z_2,\ \ \wp_{12}(\mathbf{x})=-z_1z_2. \tag{4.4}$$

The corresponding w_i is expressed as

$$w_i=\wp_{222}(\mathbf{x})z_i+\wp_{122}(\mathbf{x}),\quad i=1,2. \tag{4.5}$$

The function $\wp_{11}(\mathbf{x})$ is expressed in terms of symmetric functions of the divisor as

$$\wp_{11}(\mathbf{x})=\frac{\mathcal{F}(z_1,z_2)-2w_1w_2}{4(z_1-z_2)^2}, \tag{4.6}$$

where the polynomial $\mathcal{F}$ is the *Kleinian polar*

$$\mathcal{F}(z_1,z_2)=\sum_{k=0}^{2}z_1^kz_2^k(2\lambda_{2k}+\lambda_{2k+1}(z_1+z_2)).$$

The three functions $\wp_{11},\wp_{12},\wp_{22}$ are known to be algebraically dependent, being the coordinates of the quartic Kummer surface, which is given by

$$\det\begin{pmatrix}\lambda_0 & \frac{1}{2}\lambda_1 & -2\wp_{11} & -2\wp_{12}\\ \frac{1}{2}\lambda_1 & \lambda_2+4\wp_{11} & \frac{1}{2}\lambda_3+2\wp_{12} & -2\wp_{22}\\ -2\wp_{11} & \frac{1}{2}\lambda_3+2\wp_{12} & \lambda_4+4\wp_{22} & 2\\ -2\wp_{12} & -2\wp_{22} & 2 & 0\end{pmatrix}=0,$$

where the variables $\wp_{22}=X,\wp_{12}=Y,\wp_{11}=Z$ are regarded as coordinates of the surface in $\mathbb{C}^3$.

We are now in a position to formulate the following theorem.

Theorem 4.1: *The following equality is valid for the six Baker functions* $F_0(\mathbf{x};\alpha)$, $F_1(\mathbf{x};\boldsymbol{\alpha})$, $F_2(\mathbf{x};\boldsymbol{\alpha})$, $F_{11}(\mathbf{x};\boldsymbol{\alpha})$, $F_{12}(\mathbf{x};\boldsymbol{\alpha})$, *and* $F_{22}(\mathbf{x};\boldsymbol{\alpha})$ *in the case of genus two*

$$\begin{aligned}&[aF_{11}+bF_{12}+a\wp_{12}(\boldsymbol{\alpha})F_{22}+\tfrac{1}{2}b\wp_{22}(\boldsymbol{\alpha})F_{22}+(a\wp_{122}+\tfrac{1}{2}b\wp_{222}(\boldsymbol{\alpha}))F_2]\\ &\quad=[a(\wp_{11}(\boldsymbol{\alpha})-\wp_{12}(\boldsymbol{\alpha})\wp_{22}(\boldsymbol{\alpha})+\tfrac{1}{4}\lambda_2)-\tfrac{1}{2}b\wp_{22}^2(\boldsymbol{\alpha})]F_0,\end{aligned} \tag{4.7}$$

where a,b are arbitrary and the λ_i parameters of the curve (4.1).

Proof: Consider the six functions,

$$\sigma(\mathbf{x})^2 F(\mathbf{x};\boldsymbol{\alpha}), \quad \sigma(\mathbf{x})^2 F_i(\mathbf{x};\boldsymbol{\alpha}), \quad \sigma(\mathbf{x})^2 F_{ij}(\mathbf{x};\boldsymbol{\alpha}), \quad i,j=1,2. \tag{4.8}$$

These are linearly dependent second-order entire functions, satisfying (3.24) with $\gamma(\mathbf{m},\mathbf{m}') = \boldsymbol{\zeta}^T(\boldsymbol{\alpha})\boldsymbol{\Omega}(\mathbf{m},\mathbf{m}') - \mathbf{E}^T(\mathbf{m},\mathbf{m}')\boldsymbol{\alpha} \equiv \mathbf{k}(\boldsymbol{\alpha})$. Therefore there exist constants $c_0, c_1, c_2, c_{11}, c_{12}, c_{22} \neq 0$, such that

$$c_0 F_0(\mathbf{x};\boldsymbol{\alpha}) + \sum_{k=1,2} c_k F_k(\mathbf{x};\boldsymbol{\alpha}) + \sum_{i,j=1,2} c_{ij} F_{ij}(\mathbf{x};\boldsymbol{\alpha}) = 0. \tag{4.9}$$

Using the expansion (4.2) and the identity $\wp_{112} = \wp_{222}\wp_{12} - \wp_{122}\wp_{22}$, we arrive at

$$\begin{aligned}
c_1 &= 0,\\
c_0 + c_{11}\wp_{11}(\boldsymbol{\alpha}) + \tfrac{1}{4}c_{11}\lambda_2 - c_{22}\wp_{22}(\boldsymbol{\alpha}) &= 0,\\
2c_{11}\wp_{12}(\boldsymbol{\alpha}) + c_{12}\wp_{22}(\boldsymbol{\alpha}) - 2c_{22} &= 0,\\
-2c_2\wp_{12}(\boldsymbol{\alpha}) + c_{12}\wp_{122}(\boldsymbol{\alpha}) + 2c_{22}\wp_{122}(\boldsymbol{\alpha}) &= 0,\\
-c_2\wp_{22}(\boldsymbol{\alpha}) - c_{11}\wp_{112}(\boldsymbol{\alpha}) + c_{22}\wp_{222}(\boldsymbol{\alpha}) &= 0,\\
2c_2 - 2c_{11}\wp_{122}(\boldsymbol{\alpha}) - c_{12}\wp_{222}(\boldsymbol{\alpha}) &= 0,
\end{aligned}$$

whose solution reads

$$\begin{aligned}
c_{11} &= a, \quad c_{12} = b,\\
c_0 &= a(\wp_{11}(\boldsymbol{\alpha}) - \wp_{12}(\boldsymbol{\alpha})\wp_{22}(\boldsymbol{\alpha}) + \tfrac{1}{4}\lambda_2) - \tfrac{1}{2}b\wp_{22}^2(\boldsymbol{\alpha}),\\
c_{22} &= a\wp_{12}(\boldsymbol{\alpha}) + \tfrac{1}{2}b\wp_{22}(\boldsymbol{\alpha}),\\
c_2 &= a\wp_{122}(\boldsymbol{\alpha}) + \tfrac{1}{2}b\wp_{222}(\boldsymbol{\alpha}),
\end{aligned} \tag{4.10}$$

where a and b are arbitrary. The equality (4.7) then follows immediately. □

By choosing the parameters $a=1$, $b=0$ and then $a=0$, $b=1$ we get from the equality (4.7) the following equations on $\mathrm{Jac}(V)\times\mathrm{Jac}(V)$:

$$\begin{aligned}
&\left\{\left[\frac{\partial^2}{\partial x_1^2} - 2\wp_{11}(\mathbf{x})\right] + \wp_{12}(\boldsymbol{\alpha})\left[\frac{\partial^2}{\partial x_2^2} - 2\wp_{22}(\mathbf{x})\right]\right\}\Psi_1(\mathbf{x};\boldsymbol{\alpha})\\
&\quad = \frac{1}{4\wp_{12}(\boldsymbol{\alpha})}(\lambda_0 + \lambda_2\wp_{12}(\boldsymbol{\alpha}) + \lambda_4\wp_{12}^2(\boldsymbol{\alpha}))\Psi_1(\mathbf{x};\boldsymbol{\alpha}),
\end{aligned}$$

where

$$\Psi_1(\mathbf{x};\boldsymbol{\alpha}) = \Phi(\mathbf{x};\boldsymbol{\alpha})\exp\left\{\frac{1}{2}\frac{\wp_{122}(\boldsymbol{\alpha})}{\wp_{12}(\boldsymbol{\alpha})}x_2\right\},$$

and

$$\wp_{22}(\boldsymbol{\alpha})\left\{\left[\frac{\partial^2}{\partial x_1^2}-2\wp_{11}(\mathbf{x})\right]+2\wp_{12}(\boldsymbol{\alpha})\left[\frac{\partial^2}{\partial x_1\partial x_2}-2\wp_{12}(\mathbf{x})\right]\right\}\Psi_2(\mathbf{x};\boldsymbol{\alpha})=-\wp_{22}^2(\boldsymbol{\alpha})\Psi_2(\mathbf{x};\boldsymbol{\alpha}),$$

where

$$\Psi_2(\mathbf{x};\boldsymbol{\alpha})=\Phi(\mathbf{x};\boldsymbol{\alpha})\exp\{-\tfrac{1}{2}\wp_{122}(\boldsymbol{\alpha})x_1\}.$$

Therefore the following theorems are valid for the case of genus two:

Theorem 4.2: *Let V be nonsingular hyperelliptic curve of genus 2 given by Eq. (4.1). Let $\Phi_B(\mathbf{x};\boldsymbol{\alpha})$ be the standard Baker function on $\mathrm{Jac}(V)\times\mathrm{Jac}(V)$. Let $\boldsymbol{\Omega}=(\omega_{11},\omega_{21})^T$, $\boldsymbol{\Omega}'=(\omega_{11},\omega_{21})^T$ be the real and imaginary half periods.*

Then the following 2D Schrödinger equation at a fixed energy level is valid:

$$\left\{\frac{\partial^2}{\partial x_1^2}+\frac{\partial^2}{\partial x_2^2}-\mathcal{U}_1(\mathbf{x})\right\}\Psi_1(\mathbf{x};\boldsymbol{\alpha})=\tfrac{1}{4}(\lambda_0+\lambda_2+\lambda_4)\Psi_1(\mathbf{x};\boldsymbol{\alpha}), \tag{4.11}$$

where the smooth and real potential $\mathcal{U}_1(\mathbf{x})$ and wave function $\Psi_1(\mathbf{x};\boldsymbol{\alpha})$ have the form

$$\mathcal{U}_1(\mathbf{x})=2\wp_{11}(\imath\mathbf{x}+\boldsymbol{\Omega})+2\wp_{22}(\imath\mathbf{x}+\boldsymbol{\Omega}),\quad \mathbf{x}\in\mathbb{R}^2, \tag{4.12}$$

$$\Psi_1(\mathbf{x};\boldsymbol{\alpha})=\Phi_B(\imath\mathbf{x}+\boldsymbol{\Omega};\boldsymbol{\alpha}+\boldsymbol{\Omega}')\exp\{\tfrac{1}{2}\wp_{122}(\boldsymbol{\alpha}+\boldsymbol{\Omega}')(\imath x_2+\omega_{12}')\},\quad \mathbf{x},\boldsymbol{\alpha}\in\mathbb{R}^2, \tag{4.13}$$

and are restricted to the complex one-dimensional Bloch variety $\mathcal{B}_1$ given by

$$\mathcal{B}_1=\{(\boldsymbol{\alpha})\,|\,\wp_{12}(\boldsymbol{\alpha}+\boldsymbol{\Omega}')=1\}. \tag{4.14}$$

The vector of quasimomentum is real and is given by

$$\mathbf{k}(\boldsymbol{\alpha})=\boldsymbol{\zeta}(\boldsymbol{\alpha}+\boldsymbol{\Omega}')-2\varkappa(\boldsymbol{\alpha}+\boldsymbol{\Omega}')+\tfrac{1}{2}\wp_{122}(\boldsymbol{\alpha}+\boldsymbol{\Omega}')\begin{pmatrix}0\\1\end{pmatrix}. \tag{4.15}$$

Theorem 4.3: *For the conditions of Theorem 4.2, the following hyperbolic equation at the zero energy level is valid:*

$$\left\{\frac{\partial^2}{\partial x_1\partial x_2}-\mathcal{U}_2(\mathbf{x})\right\}\Psi_2(\mathbf{x};\boldsymbol{\alpha})=0, \tag{4.16}$$

where the smooth and real potential $\mathcal{U}_2(\mathbf{x})$ and the wave function have the form

$$\mathcal{U}_2(\mathbf{x})=2\wp_{12}(\imath\mathbf{x}+\boldsymbol{\Omega}),\quad \mathbf{x}\in\mathbb{R}^2, \tag{4.17}$$

$$\Psi_2(\mathbf{x};\boldsymbol{\alpha})=\Phi_B(\imath\mathbf{x}+\boldsymbol{\Omega};\boldsymbol{\alpha}+\boldsymbol{\Omega}')\times\exp\{\tfrac{1}{2}\wp_{122}(\boldsymbol{\alpha})(\imath x_1+\omega_{21}')\},\quad \mathbf{x},\boldsymbol{\alpha}\in\mathbb{R}^2, \tag{4.18}$$

and is restricted to the complex one-dimensional Bloch variety $\mathcal{B}_2$ given by

$$\mathcal{B}_2:\ \{(\boldsymbol{\alpha})\,|\,\wp_{22}(\boldsymbol{\alpha}+\boldsymbol{\Omega}')=0\}. \tag{4.19}$$

The vector of quasimomentum is real and given by

$$\mathbf{k}(\boldsymbol{\alpha})=\boldsymbol{\zeta}(\boldsymbol{\alpha}+\boldsymbol{\Omega}')-2\varkappa(\boldsymbol{\alpha}+\boldsymbol{\Omega}')+\frac{1}{2}\wp_{222}(\boldsymbol{\alpha}+\boldsymbol{\Omega}')\begin{pmatrix}1\\0\end{pmatrix}. \tag{4.20}$$

The Bloch varieties $\mathcal{B}_k\subset\mathrm{Jac}(V)$, $k=1,2$ are pull-backs of the varieties $\tilde{\mathcal{B}}_k\subset\mathrm{Kum}(V)$, $k=1,2$ under the projection $\mathrm{Jac}(V)\to\mathrm{Kum}(V)$, where the $\tilde{\mathcal{B}}_k$ are given by

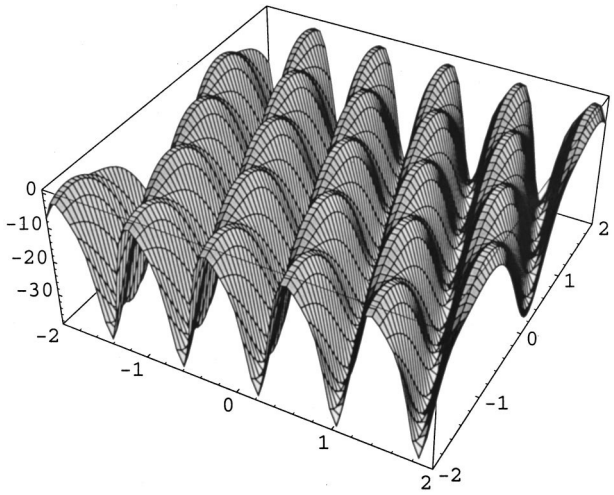

FIG. 1. Potential profile as function of x,y for the branching points $e_1=2\sqrt{3}$, $e_2=3$, $e_3=0$, $e_4=-e_2$, $e_5=-e_1$.

$$\mathcal{B}_1=(X,Z):\det\begin{pmatrix} \lambda_0 & \frac{1}{2}\lambda_1 & -2Z & -2 \\ \frac{1}{2}\lambda_1 & \lambda_2+4Z & \frac{1}{2}\lambda_3+2 & -2X \\ -2Z & \frac{1}{2}\lambda_3+2 & \lambda_4+4X & 2 \\ -2 & -2X & 2 & 0 \end{pmatrix}=0$$

in the case of the 2D Schrödinger equation, and

$$\mathcal{B}_2=(Y,Z):\det\begin{pmatrix} \lambda_0 & \frac{1}{2}\lambda_1 & -2Z & -2Y \\ \frac{1}{2}\lambda_1 & \lambda_2+4Z & \frac{1}{2}\lambda_3+2Y & 0 \\ -2Z & \frac{1}{2}\lambda_3+2Y & \lambda_4 & 2 \\ -2Y & 0 & 2 & 0 \end{pmatrix}=0$$

in the case of the hyperbolic equation.

The Bloch varieties $\mathcal{B}_{1,2}$ are algebraic curves, and it is straightforward to show that these curves are genus two hyperelliptic curves with a branching point at infinity. But in contrast with the case of genus one, these curves are not equivalent to the initial curve at generic $\lambda_0,\ldots,\lambda_4$.

We remark that the explicit description of the varieties $\mathcal{B}_k$, $k=1,2$, which can be realized as algebraic curve of genus 4 with involution, and its link with the results of Veselov and Novikov,[4,3] is given in Ref. 19.

As an application of the above-given theory we show in Figs. 1 and 2, the potential profiles as derived from (4.12), for two different sets of the parameter values (in Figs. 3 and 4 the corresponding level sets of these potentials are also shown). We see from these figures that the potentials are both real and smooth and have a spatial symmetry which is more general than the square or rectangular one considered in Ref. 16. The full choice of more general crystal symmetries which can be found by properly appropriate choices of the parameters $\{e_i\}$, one can arrange is still

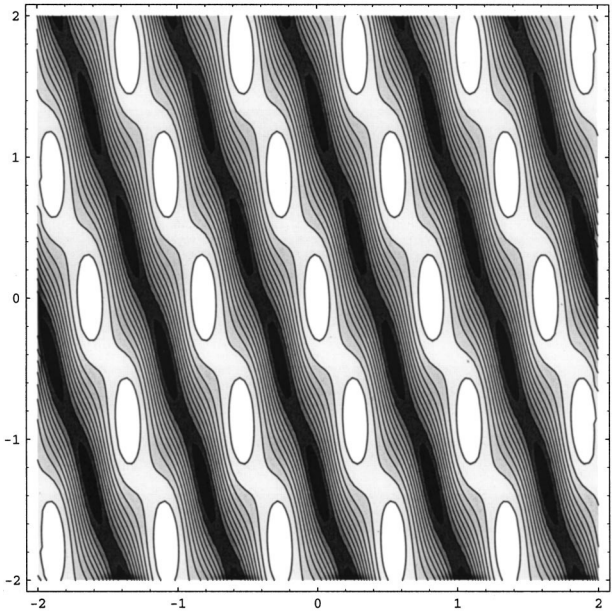

FIG. 2. The same as in Fig. 1 for $e_1=2$, $e_2=1$, $e_3=0$, $e_4=-1$, $e_5=-2$.

under investigation. These properties make the above-mentioned potentials suitable for physical applications. Similar results can be obtained for the potential (4.17) (for simplicity details are omitted).

V. THE TWO DIMENSIONAL SCHRÖDINGER EQUATION WITH AN ELLIPTIC POTENTIAL

In this section we shall construct an elliptic 2D Schrödinger equation with a potential which can be expressed in terms of an elliptic function by using the concept of elliptic solitons for the KdV equation. We shall show that the real and nonsingular potential in the (x,y) plane is provided

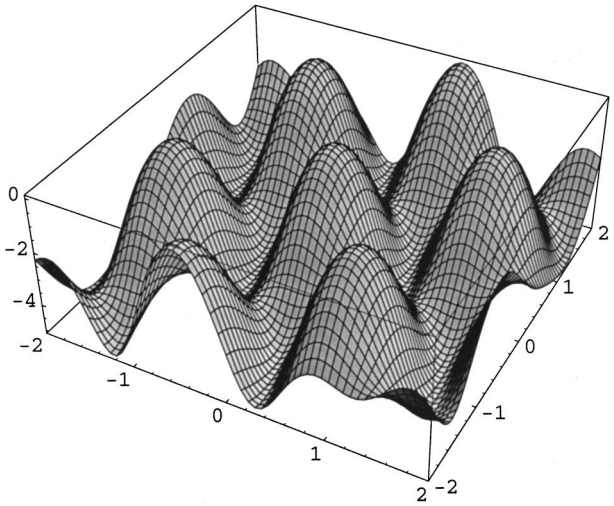

FIG. 3. Topographic map of the potential in the case: $e_1=2\sqrt{3}$, $e_2=3$, $e_3=0$, $e_4=-e_2$, $e_5=-e_1$. The regions between contours are shaded in such a way that the ones with higher values are lighter.

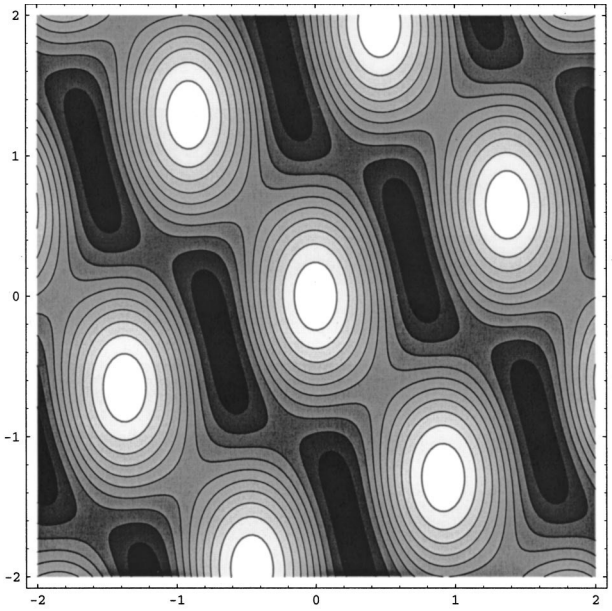

FIG. 4. The same as in Fig. 2 for $e_1=2$, $e_2=1$, $e_3=0$, $e_4=-1$, $e_5=-2$.

by the dynamics over the locus of the Calogero–Moser system. The particle dynamics of the system over locus is essentially complex and was traditionally considered as nonphysical. The equations for the Kleinian $\wp$-functions

$$\wp_{2222}=6\wp_{22}^2+4\wp_{12}+\lambda_4\wp_{22}+\tfrac{1}{2}\lambda_3, \tag{5.1}$$

$$\wp_{1222}=6\wp_{22}\wp_{12}-2\wp_{11}+\lambda_4\wp_{12}, \tag{5.2}$$

represent the KdV hierarchy for genus two curves with respect to the function

$$\mathcal{U}=2\wp_{22}(\mathbf{x})+\tfrac{1}{6}\lambda_4. \tag{5.3}$$

Equation (5.1) becomes, after differentiation by $u_2\equiv x$, the KdV equation,

$$\mathcal{U}_{x_1}=\tfrac{1}{2}(\mathcal{U}_{x_2x_2x_2}-6\mathcal{U}_{x_2}\mathcal{U}), \tag{5.4}$$

while the second equation (5.2) represents the second KdV flow which is stationary for the two-gap potential (5.3).

We further interpret the coordinates (x_1,x_2) as space coordinates $(\mathbf{x})$ and set $(x_1,x_2)=(y,x)$. Consider the elliptic solution of the KdV equation

$$\mathcal{U}(x,y)=2\wp(x-f_1(y))+2\wp(x-f_2(y))+2\wp(x-f_3(y)), \tag{5.5}$$

where $\wp(x)$ is the standard Weierstrass elliptic function, which represents the isospectral deformation of the two-gap Lamé potential $6\wp(x)$ under the action of the KdV flow. The solution of the form (5.5) was introduced for the first time by Dubrovin and Novikov;[20] the general case was investigated by Airault *et al.*[21] We use this elliptic KdV solution in the following to construct a special solution of the 2D problem.

The ansatz (5.5) implies the following structure of the hyperelliptic, genus two, σ-function in the reduction case:

$$\sigma(x,y)=\prod_{i=1}^{3}\sigma(x-f_i(y)), \tag{5.6}$$

where σ is the standard σ-function from the Weierstrass theory of elliptic functions. The associated algebraic curve is known to be of the form

$$w^2=4(z^2-3g_2)(z+3e_1)(z+3e_2)(z+3e_3). \tag{5.7}$$

The remaining Kleinian $\wp$-functions, $\wp_{12}(\mathbf{x})$ and $\wp_{11}(\mathbf{x})$, are expressible from (5.1) and (5.2) as differential polynomials of $\wp_{22}$, and have the form

$$\wp_{12}=-3\sum_{i<j=1,2,3}\wp(x-f_i(y))\wp(x-f_j(y))+\frac{9}{4}g_2, \tag{5.8}$$

$$\begin{aligned}\wp_{11}=&-27\wp(x-f_1(y))\wp(x-f_2(y))\wp(x-f_3(y))\\&+3\sum_{i<j=1,2,3}\wp'(x-f_i(y))\wp'(x-f_j(y))+\frac{21}{4}\sum_{i}^{3}\wp(x-f_i(y)),\end{aligned} \tag{5.9}$$

where $\wp$ is the standard Weierstrass $\wp$-function. This implies that the Abelian elliptic potential for the two-dimensional Schrödinger equation has the form

$$\begin{aligned}\mathcal{U}(x,y)=&-54\wp(x-f_1(y))\wp(x-f_2(y))\wp(x-f_3(y))\\&+6\sum_{i<j=1,2,3}\wp'(x-f_i(y))\wp'(x-f_j(y))+\frac{25}{4}\sum_{i}^{3}\wp(x-f_i(y)).\end{aligned} \tag{5.10}$$

For the proof we remark that the compatibility of the ansatz (5.5) with the KdV equation leads to

$$\frac{df_1}{dy}=-6\mathfrak{B}_{12}-6\mathfrak{B}_{13},$$

$$\frac{df_2}{dy}=-6\mathfrak{B}_{21}-6\mathfrak{B}_{23},$$

$$\frac{df_3}{dy}=-6\mathfrak{B}_{31}-6\mathfrak{B}_{33},$$

with

$$\mathfrak{B}'_{12}+\mathfrak{B}'_{13}=0,\quad \mathfrak{B}'_{21}+\mathfrak{B}'_{23}=0,\quad \mathfrak{B}'_{31}+\mathfrak{B}'_{33}=0. \tag{5.11}$$

Here we denote $\mathfrak{B}_{ij}=\wp(f_i(y)-f_j(y))$. These equations represent the well-known dynamics of the third flow of the integrable Calogero–Moser system, restricted to the stable points of the second flow. We remark that the addition theorem for the Weierstrass $\wp$-function and the equations of the *locus* (5.11) allow us to rewrite the first group of the equations for f_i in the form

$$\frac{df_1}{dy}=6\mathfrak{B}_{23},\quad \frac{df_2}{dy}=6\mathfrak{B}_{13},\quad \frac{df_3}{dy}=6\mathfrak{B}_{12} \tag{5.12}$$

and therefore the elliptic KdV solution is given in the form

$$\mathcal{U}(x,y)=2\sum_{i<j=1,2,3}\wp\left(ix+\omega-6\int_0^y\wp(f_i(y)-f_j(y))dy\right) \tag{5.13}$$

with ω being a constant of integration. We shall find in the following the explicit expressions for the functions $\wp(f_i(y)-f_j(y))$ and show that (5.13) represents an elliptic soliton, i.e., a real and smooth function which is doubly periodic in both x and y. With this aim we consider the equations of the Jacobi inversion problem associated with the curve (5.7):

$$\int_{(\infty,\infty)}^{(w_1,z_1)} \frac{dz}{w} + \int_{(\infty,\infty)}^{(w_2,z_2)} \frac{dz}{w} = x_1 \equiv y, \tag{5.14}$$

$$\int_{(\infty,\infty)}^{(w_1,z_1)} \frac{z\,dz}{w} + \int_{(\infty,\infty)}^{(w_2,z_2)} \frac{z\,dz}{w} = x_2 \equiv x. \tag{5.15}$$

The solution of the problem has the form

$$z_1+z_2=2\sum_{i=1}^{3} \wp(x-f_i(y)), \tag{5.16}$$

$$z_1 z_2 = 3 \sum_{i<j=1,2,3} \wp(x-f_i(y))\wp(x-f_j(y)) - \frac{9}{4} g_2, \tag{5.17}$$

where we use (5.1), (5.2) and (5.5) to derive (5.16) and (5.17). Let us take the limit $x \to f_1(y)$. Then it follows from (5.16) and (5.17)

$$z_2 \to \infty, \quad z_1 \to 3(\mathfrak{P}_{12}+\mathfrak{P}_{13}) \equiv -3\mathfrak{P}_{23},$$

and the equations of the Jacobi inversion problem will take the form

$$\int_{\infty}^{-3\mathfrak{B}_{23}} \frac{dz}{2\sqrt{(z^2-3g_2)(z-3e_1)(z-3e_2)(z-3e_3)}} = y, \tag{5.18}$$

$$\int_{\infty}^{-3\mathfrak{B}_{23}} \frac{z\,dz}{2\sqrt{(z^2-3g_2)(z-3e_1)(z-3e_2)(z-3e_3)}} = x. \tag{5.19}$$

Two other pairs of equations of the form (5.18) and (5.19) appear as the result of cyclic permutations of the indices 1,2,3. To proceed we shall use the reduction formulas of Hermite, under which the hyperelliptic integrals on the left-hand side of (5.14) and (5.15) are reduced to elliptic integrals associated with the elliptic curves:

$$\nu^2 = 4\mu^3 - g_2\mu - g_3, \quad \tilde{\nu}^2 = 4\tilde{\mu}^3 - \tilde{g}_2\tilde{\mu} - \tilde{g}_3, \tag{5.20}$$

whose moduli are linked by the relation

$$\tilde{g}_2 = \frac{4}{g_2^2}(3g_2^3+27g_3), \quad \tilde{g}_3 = \frac{72}{g_2^3}(g_3 g_2^3 - 3g_3^3). \tag{5.21}$$

The equations for the cover are

$$(\mu,\nu) = \left(\frac{w}{27} \frac{z^3-9g_2-54g_3}{z^2-3g_2}, \frac{z^3+27g_3}{9(z^2-3g_2)} \right), \tag{5.22}$$

$$(\tilde{\nu},\tilde{\mu}) = \left(\sqrt{\frac{2}{27g_2^3}} w(4z^2-3g_2), \frac{1}{3g_2}(4z^3-9g_2z+9g_3) \right). \tag{5.23}$$

The reduction of the holomorphic differentials has the form

$$\frac{dz}{w}=\frac{2}{3\sqrt{3g_2}}\frac{d\tilde{\mu}}{\tilde{\nu}},\quad \frac{zdz}{w}=\frac{1}{3}\frac{d\mu}{\nu}. \tag{5.24}$$

The application of the reduction formulas to Eq. (5.18) results in the following cubic equation with respect to $\mathfrak{P}_{23}$:

$$4\mathfrak{P}_{23}^3-g_2\mathfrak{P}_{23}-\tfrac{1}{3}g_3+\tfrac{1}{9}g_2\tilde{\wp}(\tfrac{3}{2}\sqrt{3g_2}y)=0. \tag{5.25}$$

Evidently the remaining two roots are exactly $\mathfrak{P}_{12}$ and $\mathfrak{P}_{13}$. Note that Eq. (5.25) displays the following properties of the functions $\mathfrak{P}_{ij}$ on the locus:

$$\mathfrak{P}_{12}+\mathfrak{P}_{13}+\mathfrak{P}_{23}=0, \tag{5.26}$$

$$\mathfrak{P}_{12}\mathfrak{P}_{13}+\mathfrak{P}_{23}\mathfrak{P}_{13}+\mathfrak{P}_{13}\mathfrak{P}_{23}=-\tfrac{1}{4}g_2. \tag{5.27}$$

Let us show that the application of the reduction formulas to Eq. (5.19) leads to the equivalence. Indeed the substitution of the reduction formula (5.22) into (5.18) implies

$$\wp(3f_1)=\frac{\mathfrak{P}_{23}^3-g_3}{g_2-3\mathfrak{P}_{23}^2}. \tag{5.28}$$

We transform the left-hand side:

$$\begin{aligned}\wp(3f_1)&=\wp(\{f_1-f_2\}+\{f_1-f_3\})\quad(\text{because of the equality}\quad f_1+f_2+f_3=0)\\&=-\mathfrak{P}_{12}-\mathfrak{P}_{13}+\frac{1}{4}\left[\frac{\mathfrak{P}'_{12}-\mathfrak{P}'_{13}}{\mathfrak{P}_{12}-\mathfrak{P}_{13}}\right]^2\\&\quad(\text{because of the addition theorem for the Weierstrass elliptic function})\\&=\mathfrak{P}_{23}+\frac{\mathfrak{P}'^{\,2}_{23}}{(2\mathfrak{P}_{12}+\mathfrak{P}_{23})^2}\\&\quad[\text{because(5.26)and locus equations, which imply}\\&\quad\mathfrak{P}'^{\,2}_{23}-\mathfrak{P}'^{\,2}_{12}=(\mathfrak{P}'_{23}+\mathfrak{P}'_{21})(\mathfrak{P}'_{23}+\mathfrak{P}'_{12})=0].\end{aligned}$$

Further, Eq. (5.27) leads to the relation

$$(2\mathfrak{P}_{12}+\mathfrak{P}_{23})^2=g_2-3\mathfrak{P}_{23}^2.$$

Collecting all these equalities together we transform (5.28) to the equality

$$\mathfrak{P}_{23}+\frac{\mathfrak{P}'^{\,2}_{23}}{g_2-3\mathfrak{P}_{23}^2}\equiv\frac{\mathfrak{P}_{23}^3-g_3}{g_2-3\mathfrak{P}_{23}^2},$$

whose validity can be checked directly.

Therefore we have proved the following proposition (a proof in compressed form was given in Ref. 22, see also Ref. 21, p. 144).

Proposition 5.1: Let (μ,ν) and $(\tilde{\nu},\tilde{\mu})$ be two elliptic curves in the Weierstrass form with the moduli g_2,g_3 and $\tilde{g}_2,\tilde{g}_3$ given in (5.12). Denote by $\wp$ and $\tilde{\wp}$ the corresponding Weierstrass elliptic functions. Then the formula (5.13) describes the elliptic solution of the KdV equation with the integrands

$$\wp(f_i(y)-f_j(y))=\mathfrak{P}_{i,j},\quad (i,j)=(1,2),(1,3),(2,3)$$

being the roots of the cubic equation with coefficients depending on the moduli of the elliptic curve g_2, g_3 and the Weierstrass function $\tilde{\wp}$,

$$4X^3 - g_2 X - \tfrac{1}{3} g_3 + \tfrac{1}{9} g_2 \tilde{\wp}(\tfrac{3}{2}\sqrt{3g_2}\, y) = 0. \tag{5.29}$$

We shall summarize the results as follows:

Theorem 5.2: *Let V be the Lamé curve*

$$w^2 = 4(z^2 - 3g_2)(z + 3e_1)(z + 3e_2)(z + 3e_3),$$

which covers three-sheetedly the two elliptic curves

$$\wp'^2 = 4\wp^3 - g_2\wp - g_3, \quad \tilde{\wp}'^2 = 4\tilde{\wp}^3 - \tilde{g}_2\tilde{\wp} - \tilde{g}_3, \tag{5.30}$$

whose moduli are linked by the relation

$$\tilde{g}_2 = \frac{4}{g_2^2}(3g_2^3 + 27g_3), \quad \tilde{g}_3 = \frac{72}{g_2^3}(g_3 g_2^3 - 3g_3^3). \tag{5.31}$$

Then the wave function

$$\Psi_E(\mathbf{x}; \alpha, \beta) = \prod_{i=1}^{3} \Phi_W(ix + \omega - f_i(y); \alpha - f_i(\beta)), \tag{5.32}$$

where the three functions f_i are given by

$$f_i(y) = -6 \int_0^y X_i(y)\mathrm{d}y,$$

and X_i are the three roots of the cubic equation

$$4X^3 - g_2 X - \tfrac{1}{3} g_3 + \tfrac{1}{9} g_2 \tilde{\wp}(\tfrac{3}{2}\sqrt{3g_2}\, y) = 0, \tag{5.33}$$

satisfy the 2D Schrödinger equation

$$\left\{ \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} - \mathcal{U}(x,y) \right\} \Psi_E = \Lambda \Psi_E,$$

with the elliptic smooth and nonseparable potential given by

$$\begin{aligned} \mathcal{U}(x,y) = &-54\wp(x - f_1(y))\wp(x - f_2(y))\wp(x - f_3(y)) \\ &+ 6 \sum_{i<j=1}^{3} \wp'(x - f_i(y))\wp'(x - f_j(y)) + \frac{25}{4} \sum_{i}^{3} \wp(x - f_i(y)), \end{aligned} \tag{5.34}$$

on the fixed energy level $\Lambda = -36 g_2 g_3 + 36 g_3$. The spectral variety is a one-dimensional variety given by

$$3 \sum_{i<j=1,2,3} \wp(\alpha - f_i(\beta))\wp(\alpha - f_j(\beta)) - \frac{9}{4} g_2 = 1. \tag{5.35}$$

We remark that the Bloch variety (5.35), which is given as a hyperelliptic curve, is uniformizable in this case by elliptic functions with moduli (5.31).

We note that we could consider other two-gap elliptic potentials in an analogous fashion.

VI. THE 3D SCHRÖDINGER EQUATION

We consider the case of the curve defined by

$$y^2=4x^7+\sum_0^6 \lambda_j x^j.$$

The principal matrix H is given by (3.10) and is a 5×5 matrix of the form

$$H=\begin{pmatrix} \lambda_0 & \frac{1}{2}\lambda_1 & -2\wp_{11} & -2\wp_{12} & -2\wp_{13} \\ \frac{1}{2}\lambda_1 & 4\wp_{11}+\lambda_2 & 2\wp_{12}+\frac{1}{2}\lambda_3 & 4\wp_{13}-2\wp_{22} & -2\wp_{23} \\ -2\wp_{11} & 2\wp_{12}+\frac{1}{2}\lambda_3 & 4\wp_{22}-4\wp_{13}+\lambda_4 & 2\wp_{23}+\frac{1}{2}\lambda_5 & -2\wp_{33} \\ -2\wp_{12} & 4\wp_{13}-2\wp_{22} & 2\wp_{23}+\frac{1}{2}\lambda_5 & 4\wp_{33}+\lambda_6 & 2 \\ -2\wp_{13} & -2\wp_{23} & -2\wp_{33} & 2 & 0 \end{pmatrix}.$$

The expansion of the σ-function of genus 3 in the vicinity of $\mathbf{u}=0$ (found for the first time in Ref. 8) has the form

$$\sigma(u_1,u_2,u_3)=u_1u_3-u_2^2-\tfrac{1}{24}(2\lambda_0u_1^4+2\lambda_1u_1^3u_2+\lambda_2u_1^2(3u_2^2-u_1u_3)+8u_2u_3^3+2\lambda_3u_1u_2^3+2\lambda_4u_2^4 +2\lambda_5u_2^3u_3+\lambda_6u_3^2(3u_2^2-u_1u_3))+\text{higher order terms}. \tag{6.1}$$

We are in position now to prove the following theorem.

Theorem 6.1: *Let $F_{i,j}(\mathbf{x};\boldsymbol{\alpha})$ be the functions (3.19). Then the following equalities are valid for all $\mathbf{x};\boldsymbol{\alpha}\in\mathbb{C}^3$,*

$$4(\wp_{113}(\boldsymbol{\alpha})-\wp_{122}(\boldsymbol{\alpha}))F_{33}(\mathbf{x};\boldsymbol{\alpha})-4(2F_{13}(\mathbf{x};\boldsymbol{\alpha})+F_{22}(\mathbf{x};\boldsymbol{\alpha}))\wp_{133}(\boldsymbol{\alpha})+8F_{23}(\mathbf{x};\boldsymbol{\alpha})\wp_{123}(\boldsymbol{\alpha}) +4F_{11}(\mathbf{x};\boldsymbol{\alpha})\wp_{333}(\boldsymbol{\alpha})=\Lambda F_0(\mathbf{x};\boldsymbol{\alpha}), \tag{6.2}$$

where

$$\Lambda=4(2\wp_{13}(\boldsymbol{\alpha})-\wp_{22}(\boldsymbol{\alpha}))\wp_{133}(\boldsymbol{\alpha})+\lambda_6\wp_{122}(\boldsymbol{\alpha})-4\wp_{33}(\boldsymbol{\alpha})\wp_{113}(\boldsymbol{\alpha})-\lambda_2\wp_{333}(\boldsymbol{\alpha}) +4\wp_{33}(\boldsymbol{\alpha})\wp_{122}(\boldsymbol{\alpha})-4\wp_{11}(\boldsymbol{\alpha})\wp_{333}(\boldsymbol{\alpha})-\lambda_6\wp_{113}(\boldsymbol{\alpha}),$$

and

$$4(2\wp_{123}(\boldsymbol{\alpha})-\wp_{222}(\boldsymbol{\alpha}))F_{33}(\mathbf{x};\boldsymbol{\alpha})+8(\wp_{223}(\boldsymbol{\alpha})-\wp_{133}(\boldsymbol{\alpha}))F_{23}(\mathbf{x};\boldsymbol{\alpha})-4(2F_{13}(\mathbf{x};\boldsymbol{\alpha}) +F_{22}(\mathbf{x};\boldsymbol{\alpha}))\wp_{233}(\boldsymbol{\alpha})+8F_{12}(\mathbf{x};\boldsymbol{\alpha})\wp_{3,3,3}(\boldsymbol{\alpha})=\Lambda F_0(\mathbf{x};\boldsymbol{\alpha}),$$

where

$$\Lambda=4(2\wp_{13}-\wp_{22})\wp_{233}-2\lambda_6\wp_{123}+\lambda_6\wp_{222}-8\wp_{33}\wp_{123}+4\wp_{33}\wp_{222}.$$

Proof: Let us take (3.20) in the case $g=3$ and assume $c_{13}=2c_{22}$. Then we have

$$c_0F_0+\sum_{i=1}^3 c_iF_i+\sum_{i\le j=1,\dots,3} C_{i+j}F_{i,j}=0, \tag{6.3}$$

where we denote $c_{ij}=C_{i+j}$. Let us multiply (6.3) by $\sigma^2(\boldsymbol{\alpha})$ and expand the resulting equality in a power series in u_1,u_2,u_3 by using (6.1). We find

$$c_1=c_2=c_3=0, \tag{6.4}$$

and six equations to define C_0,C_2,C_3,C_4,C_5,C_6:

$$-2C_5+2C_4\wp_{33}+2C_2\wp_{13}+2C_3\wp_{23}=0,$$

$$-4C_2\wp_{12}+(-4\wp_{22}+8\wp_{13})\,C_3+(\lambda_5+4\wp_{23})\,C_4+(8\wp_{33}+2\lambda_6)\,C_5+4C_6=0,$$

$$(\lambda_2-4\wp_{11})\,C_2+(2\lambda_3+8\wp_{12})C_3+(4\lambda_4+12\wp_{22}-8\wp_{13})\,C_4+(2\lambda_5+8\wp_{23})\,C_5+(\lambda_6-4\wp_{33})\,C_6+4C_0=0,$$

$$(\lambda_2+4\wp_{11})\,C_2+(8\wp_{13}-4\wp_{22})\,C_4+(\lambda_6+4\wp_{33})\,C_6+4C_0=0,$$

$$\lambda_1C_2+(8\wp_{11}+2\lambda_2)\,C_3+(\lambda_3+4\wp_{12})\,C_4+(8\wp_{13}-4\wp_{22})\,C_5-4C_6\wp_{23}=0,$$

$$4\lambda_0C_2+2\lambda_1C_3-8C_5\wp_{12}-8C_6\wp_{13}-8C_4\wp_{11}=0.$$

We find from the third equation

$$C_0=-(\wp_{11}-\tfrac{1}{4}\lambda_2)C_2+(\wp_{22}-2\wp_{13})C_4-(\wp_{33}+\tfrac{1}{4}\lambda-6)C_6. \tag{6.5}$$

To define the remaining parameters, add the third equation to the fourth and consider the remaining five equations. They are homogeneous equations with respect to the five variables C_2,C_3,C_4,C_5,C_6, whose matrix is exactly the matrix H. Because the matrix H has rank three, the general solution depends on two arbitrary variables $a=C_2$ and $b=C_3$. The remaining variables are computed by applying formula (3.15).

The matrix of the first equation (6.2) is

$$M_1=\begin{bmatrix} \wp_{333} & 0 & -\wp_{133} \\ 0 & -\wp_{133} & \wp_{123} \\ -\wp_{133} & \wp_{123} & \wp_{113}-\wp_{122} \end{bmatrix}$$

and the matrix of the second equation (6.3) is

$$M_2=\begin{bmatrix} 0 & \wp_{333} & -\wp_{233} \\ \wp_{333} & -\wp_{233} & -\wp_{133}+\wp_{223} \\ -\wp_{233} & -\wp_{133}+\wp_{223} & 2\,\wp_{123}-\wp_{222} \end{bmatrix}.$$

It can be checked by direct substitution that in the rational limit

$$\sigma(\alpha_1,\alpha_2,\alpha_3)=-\alpha_2^2+\alpha_1\alpha_3-\tfrac{1}{3}\alpha_2\alpha_3^3+\tfrac{1}{45}\alpha_3^6$$

there are regions in $(\alpha_1,\alpha_2,\alpha_3)$ space where the principal minors are all nonpositive. □

(Received 2 January 2002; accepted for publication 10 March 2002)

Quantum systems with adiabatic classical parameters are widely studied, e.g., in the modern holonomic quantum computation. We here provide complete geometric quantization of a Hamiltonian system with time-dependent parameters, without the adiabatic assumption. A Hamiltonian of such a system is affine in the temporal derivative of parameter functions. This leads to the geometric Berry factor phenomena. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1477262]

I. INTRODUCTION

At present, quantum systems with classical parameters attract special attention in connection with holonomic quantum computation.[1–3] This approach to quantum computing is based on the generalization of Berry's adiabatic phase to the non-Abelian case corresponding to adiabatically driving an n-fold degenerate eigenstate of a Hamiltonian over the parameter manifold.[4] In the framework of the holonomic quantum computation scheme, information is encoded in this degenerate state, while the parameter manifold plays the role of a control parameter space. The key point of this scheme is that the parallel transport along the curves in the parameter space is assumed to be adiabatic with respect to a dynamic Hamiltonian.

At the same time, the adiabatic condition of Berry's phase phenomena can be removed.[5,6] Moreover, one observes that the Berry factor is a standard ingredient in evolution of quantum systems with classical time-dependent parameters.[7,8] Here, we provide complete geometric quantization of a mechanical system depending on parameters, without adiabatic assumption.

The configuration space of such a system is a composite fiber bundle

$$Q \to \Sigma \to \mathbf{R}, \tag{1}$$

where $\mathbf{R}$ is the time axis and $\Sigma \to \mathbf{R}$ is a fiber bundle whose sections are parameter functions.[7–9] The configuration space (1) is coordinated by (t, σ^λ, q^k), where (t, σ^λ) are bundle coordinates on $\Sigma \to \mathbf{R}$ and t is a fixed Cartesian coordinate on $\mathbf{R}$. The corresponding momentum phase space is the vertical cotangent bundle V^*Q of $Q \to \Sigma$ equipped with holonomic coordinates $(t, \sigma^\lambda, q^k, p_k)$. It is provided with the following canonical Poisson structure. Let T^*Q be the cotangent bundle of Q endowed with the canonical Poisson bracket $\{,\}_T$. Given the canonical fibration

$$\zeta: T^*Q \to V^*Q, \tag{2}$$

the Poisson bracket $\{,\}_V$ on the space $C^\infty(V^*Q)$ of smooth real functions on V^*Q is defined by the relation

[a]Electronic mail: giovanni.giachetta@unicam.it
[b]Electronic mail: luigi.mangiarotti@unicam.it
[c]Electronic mail: sard@grav.phys.msu.su

$$\zeta^*\{f,f'\}_V=\{\zeta^*f,\zeta^*f'\}_T, \tag{3}$$

$$\{f,f'\}_V=\partial^k f\partial_k f'-\partial_k f\partial^k f', \quad f,f'\in C^\infty(V^*Q). \tag{4}$$

Its characteristic symplectic foliation coincides with the fibration $V^*Q\to\Sigma$.

It seems natural to quantize the Poisson manifold V^*Q in accordance with the well-known geometric quantization procedure.[10,11] However, one faces the problem that the mean values of quantum operators are defined via integration over the momentum phase space V^*Q, including integration over classical parameters. At the same time, quantization of a system with classical parameters should necessarily imply its quantization under fixed values of parameters. Its generic carrier space is a Hilbert module of sections of a smooth Hilbert bundle over the parameter space Σ,[7,8] i.e., a locally trivial smooth field of Hilbert spaces on Σ in the terminology of Ref. 12. In particular, the instantwise quantization of time-dependent mechanics (where $\Sigma=\mathbf{R}$) is of this type.[13,14] However, geometric quantization of a Poisson manifold need not yield quantization of its symplectic leaves.[15]

To dispose of these problems, we will apply to $V^*Q\to\Sigma$ the technique of leafwise geometric quantization of symplectic foliations.[16] There is one-to-one correspondence between Poisson structures on a smooth manifold and its symplectic foliations. The quantum algebra of a symplectic foliation is a particular quantum algebra of the associated Poisson manifold such that its restriction to each symplectic leaf is defined and quantized. We choose the canonical real polarization of $V^*Q\to\Sigma$ which is the vertical tangent bundle VV^*Q of the fiber bundle $V^*Q\to Q$. The corresponding quantum algebra $\mathcal{A}_\mathcal{F}$ consists of functions on V^*Q which are affine in momenta p_k. It is represented by Schrödinger operators in the pre-Hilbert $C^\infty(\Sigma)$-module E_Q of fiberwise complex half-forms on the fiber bundle $Q\to\Sigma$ whose restriction to each fiber is of compact support.

We show that a Hamiltonian of a quantum system with classical parameters is affine in the temporal derivative of parameter functions χ^λ, namely,

$$\hat{\mathcal{H}}=-i(\Lambda^k_\lambda\partial_k+\tfrac{1}{2}\partial_k\Lambda^k_\lambda)\partial_t\chi^\lambda+\hat{\mathcal{H}}'(\chi), \tag{5}$$

where Λ^k_λ are components of a connection on the fiber bundle $Q\to\Sigma$. The key point is that integration of the first term of this Hamiltonian over time through a parameter function $\chi(t)$ depends only on a trajectory of this function in a parameters space, but not on parametrization of this trajectory by time (i.e., the adiabatic assumption is not necessary). As a consequence, this term is responsible for the geometric Berry factor phenomena. It plays the role of a control operator in holonomic quantum computation.

II. THE LEAFWISE DIFFERENTIAL CALCULUS

Geometric quantization of symplectic foliations is phrased in terms of the leafwise differential calculus on a foliated manifold. Manifolds throughout are assumed to be smooth, Hausdorff, second-countable (i.e., paracompact), and connected.

Recall that a (regular) foliation $\mathcal{F}$ of a manifold Z consists of (maximal) integral manifolds of an involutive distribution $i_\mathcal{F}:T\mathcal{F}\to TZ$ on Z. A foliated manifold $(Z,\mathcal{F})$ admits an adapted coordinate atlas

$$\{(U_\xi;z^\lambda;z^i)\}, \quad \lambda=1,\ldots,\text{codim }\mathcal{F}, \quad i=\text{codim }\mathcal{F}+1,\ldots,\dim Z, \tag{6}$$

such that transition functions of coordinates z^λ are independent of the remaining coordinates z^i and, for each leaf $F\in\mathcal{F}$, the connected components of $F\cap U_\xi$ are given by the equations $z^\lambda=\text{const}$. These connected components coordinated by (z^i) make up a coordinate atlas of a leaf F.

Let $S_\mathcal{F}(Z)$ denote the subring of the ring $C^\infty(Z)$ of smooth real functions on Z which consists of functions constant on leaves of $\mathcal{F}$. Global sections of the distribution $T\mathcal{F}$ constitute the Lie

algebra $\mathcal{T}(\mathcal{F})$ of derivations of the ring $C^\infty(Z)$ regarded as a $S_{\mathcal{F}}(Z)$-ring. Therefore, one can introduce the leafwise differential calculus[17] as the Chevalley–Eilenberg differential calculus over the $S_{\mathcal{F}}(Z)$-ring $C^\infty(Z)$. It is the cochain complex

$$0\to S_{\mathcal{F}}(Z)\to C^\infty(Z)\stackrel{\tilde d}{\to}\mathfrak{F}^1(Z)\cdots\stackrel{\tilde d}{\to}\mathfrak{F}^{\dim\ \mathcal{F}}(Z)\to 0 \tag{7}$$

of global sections of exterior products $\wedge^r T\mathcal{F}^*$ of the dual $T\mathcal{F}^*\to Z$ of $T\mathcal{F}\to Z$.[8] These sections are called the leafwise forms on a foliated manifold $(Z,\mathcal{F})$, and read

$$\phi=\frac{1}{r!}\phi_{i_1\cdots i_r}\tilde{\mathrm{d}}z^{i_1}\wedge\cdots\wedge\tilde{\mathrm{d}}z^{i_r},$$

where $\{\tilde{\mathrm{d}}z^i\}$ are the duals of the holonomic fiber bases $\{\partial_i\}$ for $T\mathcal{F}$. Accordingly, the Chevalley–Eilenberg coboundary operator

$$\tilde{\mathrm{d}}\phi=\frac{1}{r!}\partial_j\phi_{i_1\cdots i_r}\tilde{\mathrm{d}}z^j\wedge\tilde{\mathrm{d}}z^{i_1}\wedge\cdots\wedge\tilde{\mathrm{d}}z^{i_r}$$

is the leafwise exterior differential. The complex (7) is said to be the leafwise de Rham complex (or the tangential de Rham complex in the terminology of Ref. 17). This is the complex $(\mathcal{A}^{0,*},d_f)$ in Ref. 18.

Let us consider the exact sequence

$$0\to\mathrm{Ann}\ \ T\mathcal{F}\to T^*Z\stackrel{i_{\mathcal{F}}^*}{\to}T\mathcal{F}^*\to 0 \tag{8}$$

of vector bundles over Z. The epimorphism $i_{\mathcal{F}}^*$ yields an epimorphism of the graded algebra $\mathcal{O}^*(Z)$ of exterior forms on Z to the algebra $\mathfrak{F}^*(Z)$ of leafwise forms. The relation $i_{\mathcal{F}}^*\circ d=\tilde d\circ i_{\mathcal{F}}^*$ holds and, thereby, we have the cochain morphism

$$i_{\mathcal{F}}^*:(\mathbf{R},\mathcal{O}^*(Z),d)\to(S_{\mathcal{F}}(Z),\mathfrak{F}^*(Z),\tilde d),\quad \mathrm{d}z^\lambda\mapsto 0,\quad \mathrm{d}z^i\mapsto\tilde{\mathrm{d}}z^i \tag{9}$$

of the de Rham complex of Z to the leafwise de Rham complex (7) and the corresponding homomorphism

$$[i_{\mathcal{F}}^*]^*:H^*(Z)\to H^*_{\mathcal{F}}(Z) \tag{10}$$

of the de Rham cohomology of Z to the leafwise de Rham cohomology $H^*_{\mathcal{F}}(Z)$ of the complex (7).

Given a leaf $i_F:F\to Z$ of a foliation $\mathcal{F}$, there is the pull-back homomorphism

$$(\mathbf{R},\mathcal{O}^*(Z),d)\to(\mathbf{R},\mathcal{O}^*(F),d) \tag{11}$$

of the de Rham complex of Z to that of F and the corresponding homomorphism of their cohomology groups

$$H^*(Z)\to H^*(F). \tag{12}$$

Proposition 1: The cohomology morphism (12) factorizes through the leafwise cohomology

$$H^*(Z)\stackrel{[i_{\mathcal{F}}^*]}{\to}H^*_{\mathcal{F}}(Z)\stackrel{[i_F^*]}{\to}H^*(F). \tag{13}$$

Proof: It is readily observed that the pull-back bundles $i_F^*T\mathcal{F}$ and $i_F^*T\mathcal{F}^*$ over F are isomorphic to the tangent and the cotangent bundles of F, respectively. Furthermore, a direct computation shows that $i_F^*(\tilde{d}\phi)=d(i_F^*\phi)$ for any leafwise form ϕ. It follows that the cochain morphism (11) factorizes through the cochain morphism (9) and the cochain morphism

$$i_F^*:(S_{\mathcal{F}}(Z),\mathfrak{F}^*(Z),\tilde{d})\to(\mathbf{R},\mathcal{O}^*(F),d),\quad \tilde{\mathrm{d}}z^i\mapsto \mathrm{d}z^i$$

of the leafwise de Rham complex of $(Z,\mathcal{F})$ to the de Rham complex of F. Then the cohomology sequence (13) takes place.

Turn now to (even) symplectic foliations $\mathcal{F}$. A $\tilde{d}$-closed nondegenerate leafwise two-form $\Omega_{\mathcal{F}}$ on a foliated manifold $(Z,\mathcal{F})$ is called symplectic. Its pull-back $i_F^*\Omega_{\mathcal{F}}$ onto each leaf F of $\mathcal{F}$ is a symplectic form on F. A leafwise symplectic form $\Omega_{\mathcal{F}}$ yields the bundle isomorphism

$$\Omega_{\mathcal{F}}^\flat:T\mathcal{F}\to T\mathcal{F}^*,\quad \Omega_{\mathcal{F}}^\flat:v\mapsto -v\rfloor\Omega_{\mathcal{F}}(z),\quad v\in T_z\mathcal{F}.$$

The inverse isomorphism $\Omega_{\mathcal{F}}^\sharp$ determines the Poisson bivector field

$$w_\Omega(\alpha,\beta)=\Omega_{\mathcal{F}}(\Omega_{\mathcal{F}}^\sharp(i_{\mathcal{F}}^*\alpha),\Omega_{\mathcal{F}}^\sharp(i_{\mathcal{F}}^*\beta)),\quad \forall\alpha,\beta\in T_z^*Z,\quad z\in Z, \tag{14}$$

on Z subordinate to $\overset{2}{\wedge}T\mathcal{F}$. The corresponding Poisson bracket reads

$$\{f,f'\}_{\mathcal{F}}=\vartheta_f\rfloor\tilde{\mathrm{d}}f',\quad \vartheta_f\rfloor\Omega_{\mathcal{F}}=-\tilde{\mathrm{d}}f,\quad f,f'\in C^\infty(Z). \tag{15}$$

Its kernel is $S_{\mathcal{F}}(Z)$. Conversely, let (Z,w) be a (regular) Poisson manifold and $\mathcal{F}$ its characteristic foliation. Since $\mathrm{Ann}\,T\mathcal{F}$ is the kernel of the Poisson bivector field w, the bundle homomorphism $w^\sharp:T^*Z\to TZ$ factorizes in a unique fashion

$$w^\sharp:T^*Z\xrightarrow{i_{\mathcal{F}}^*}T\mathcal{F}^*\xrightarrow{w_{\mathcal{F}}^\sharp}T\mathcal{F}\xrightarrow{i_{\mathcal{F}}}TZ$$

through the bundle isomorphism

$$w_{\mathcal{F}}^\sharp:T\mathcal{F}^*\to T\mathcal{F},\quad w_{\mathcal{F}}^\sharp:\alpha\mapsto -w(z)\rfloor\alpha,\quad \alpha\in T_z\mathcal{F}^*.$$

The inverse isomorphism $w_{\mathcal{F}}^\flat$ yields the symplectic leafwise form

$$\Omega_{\mathcal{F}}(v,v')=w(w_{\mathcal{F}}^\flat(v),w_{\mathcal{F}}^\flat(v')),\quad \forall v,v'\in T_z\mathcal{F},\quad z\in Z. \tag{16}$$

Formulas (14) and (16) establish the above-mentioned correspondence between the Poisson structures on a manifold Z and its symplectic foliations.

III. PREQUANTIZATION OF SYMPLECTIC FOLIATIONS

Prequantization of a symplectic foliation $(\mathcal{F},\Omega_{\mathcal{F}})$ of a manifold Z provides a representation

$$f\mapsto i\hat{f},\quad [\hat{f},\hat{f}']=-i\widehat{\{f,f'\}_{\mathcal{F}}} \tag{17}$$

of the Poisson algebra $(C^\infty(Z),\{f,f'\}_{\mathcal{F}})$ by first-order differential operators on the space $C(Z)$ of sections of the complex line bundle $\pi:C\to Z$. These operators are given by the Kostant–Souriau formula

$$\hat{f}=-i\nabla^{\mathcal{F}}_{\vartheta_f}+f, \tag{18}$$

where ϑ_f is the Hamiltonian vector field (15) and $\nabla^{\mathcal{F}}$ is the covariant differential with respect to a leafwise connection on $C\to Z$ whose curvature form obeys the prequantization condition

$$\widetilde{R}=i\Omega_{\mathcal{F}}. \tag{19}$$

In this section, we provide the cohomology analysis of this condition, and show that prequantization of a symplectic foliation yields prequantization of its symplectic leaves.

The inverse images $\pi^{-1}(F)$ of leaves F of the foliation $\mathcal{F}$ of Z make up a (regular) foliation $C_{\mathcal{F}}$ of the complex line bundle C. Given the tangent bundle $TC_{\mathcal{F}}$ of this foliation, we have the exact sequence of vector bundles

$$0\to VC\underset{C}{\to}TC_{\mathcal{F}}\underset{C}{\to}C\underset{Z}{\times}T\mathcal{F}\to 0, \tag{20}$$

where VC is the vertical tangent bundle of $C\to Z$. A linear leafwise connection on the complex line bundle $C\to Z$ is defined as a splitting of the exact sequence (20) which is linear over C.

One can choose an adapted coordinate atlas $\{(U_\xi;z^\lambda;z^i)\}$ (6) of a foliated manifold $(Z,\mathcal{F})$ such that U_ξ are trivialization domains of the complex line bundle $C\to Z$. Let $(z^\lambda;z^i;c)$, $c\in\mathbf{C}$ be the corresponding bundle coordinates on $C\to Z$. They are also adapted coordinates on the foliated manifold $(C,C_{\mathcal{F}})$. With respect to these coordinates, a leafwise connection is represented by a $TC_{\mathcal{F}}$-valued leafwise one-form

$$A_{\mathcal{F}}=\widetilde{\mathrm{d}}z^i\otimes(\partial_i+A_i c\partial_c), \tag{21}$$

where A_i are local complex functions on C. The covariant differential of sections of the line bundle $C\to Z$ with respect to the leafwise connection (21) reads

$$\nabla^{\mathcal{F}}s=\widetilde{\mathrm{d}}s-A_i s\ \ \widetilde{\mathrm{d}}z^i.\quad s\in C(Z).$$

The exact sequence (20) is obviously a subsequence of the exact sequence

$$0\to VC\underset{C}{\to}TC\underset{C}{\to}C\underset{Z}{\times}TZ\to 0.$$

Consequently, any connection

$$\Gamma=\mathrm{d}z^\lambda\otimes(\partial_\lambda+\Gamma_\lambda c\partial_c)+\mathrm{d}z^i\otimes(\partial_i+\Gamma_i c\partial_c) \tag{22}$$

on the complex line bundle $C\to Z$ yields a leafwise connection

$$\Gamma_{\mathcal{F}}=\widetilde{\mathrm{d}}z^i\otimes(\partial_i+\Gamma_i c\partial_c). \tag{23}$$

Conversely, one can show that any leafwise connection on the complex line bundle $C\to Z$ comes from a connection on it.[16]

The curvature form of the leafwise connection $A_{\mathcal{F}}$ (21) is

$$\widetilde{R}=\tfrac{1}{2}R_{ij}\widetilde{\mathrm{d}}z^i\wedge\widetilde{\mathrm{d}}z^j,\quad R_{ij}=\partial_i A_j-\partial_j A_i. \tag{24}$$

If a leafwise connection $A_{\mathcal{F}}$ comes from a connection A, its curvature form $\widetilde{R}$ (24) is the image $\widetilde{R}=i_{\mathcal{F}}^*R$ of the curvature form R of A with respect to the morphism $i_{\mathcal{F}}^*$ (9).

Let us return to the prequantization condition (19).

Lemma 2: Let us assume that there is a leafwise connection $\Gamma_{\mathcal{F}}$ on the complex line bundle $C\to Z$ which fulfills the prequantization condition (19). Then, for any Hermitian metric g on $C\to Z$, there exists a leafwise connection $A_{\mathcal{F}}^g$ on $C\to Z$ which (i) satisfies the condition (19), (ii) preserves g, and (iii) comes from a $U(1)$-principal connection on $C\to Z$.

Proof: For any Hermitian metric g on $C\to Z$, there exists an associated bundle atlas $\Psi^g=\{(z^\lambda;z^i,c)\}$ of C with $U(1)$-valued transition functions such that

$$g(c,c')=c\overline{c'}. \tag{25}$$

Let the leafwise connection $\Gamma_{\mathcal{F}}$ come from a linear connection Γ (22) on $C\to Z$ written with respect to the atlas Ψ^g. The connection $\Gamma_{\mathcal{F}}$ is split into the sum $A^g+\gamma$ where

$$A^g=dz^\lambda\otimes(\partial_\lambda+\mathrm{Im}(\Gamma_\lambda)c\partial_c)+dz^i\otimes(\partial_i+\mathrm{Im}(\Gamma_i)c\partial_c) \tag{26}$$

is a $U(1)$-principal connection, preserving the Hermitian metric g. The curvature forms R of Γ and R^g of A^g obey the relation $R^g=\mathrm{Im}(R)$. The connection A^g (26) defines the leafwise connection

$$A^g_{\mathcal{F}}=i^*_{\mathcal{F}}A^g=\tilde{d}z^i\otimes(\partial_i+iA^g_ic\partial_c), \quad iA^g_i=\mathrm{Im}(\Gamma_i), \tag{27}$$

preserving the Hermitian metric g (25). Its curvature fulfills the desired relation

$$\tilde{R}^g=i^*_{\mathcal{F}}R^g=\mathrm{Im}(i^*_{\mathcal{F}}R)=i\Omega_{\mathcal{F}}. \tag{28}$$

Since A^g (26) is a $U(1)$-principal connection, we have $R_g=-2\pi ic_1$ where c_1 is the first Chern form of integer de Rham cohomology class. If the prequantization condition (19) holds, the relation (28) shows that the leafwise cohomology class of the leafwise form $(2\pi)^{-1}\Omega_{\mathcal{F}}$ is the image of an integer de Rham cohomology class with respect to the cohomology morphism $[i^*_{\mathcal{F}}]$ (10). Conversely, if a leafwise symplectic form $\Omega_{\mathcal{F}}$ on a foliated manifold $(Z,\mathcal{F})$ is of this type, there exists a complex line bundle $C\to Z$ and a $U(1)$-principal connection A on $C\to Z$ such that the leafwise connection $i^*_{\mathcal{F}}A$ fulfils the relation (19). Thus, we have stated the following.

Proposition 3: A symplectic foliation $(\mathcal{F},\Omega_{\mathcal{F}})$ of a manifold Z admits prequantization (18) iff the leafwise cohomology class of $(2\pi)^{-1}\Omega_{\mathcal{F}}$ is the image of an integer de Rham cohomology class of Z.

Note that the leafwise connection $A^g_{\mathcal{F}}$ in Lemma 2 by no means is unique. Any connection $A^g+ic\phi\otimes\partial_c$ where ϕ is a closed leafwise one-form obeys the prequantization condition (24) and preserves the Hermitian metric (25).

Let F be a leaf of the symplectic foliation $(\mathcal{F},\Omega_{\mathcal{F}})$ provided with the symplectic form $\Omega_F=i^*_F\Omega_{\mathcal{F}}$. In accordance with Proposition 1, the symplectic form $(2\pi)^{-1}\Omega_F$ belongs to an integer de Rham cohomology class if the leafwise symplectic form $\Omega_{\mathcal{F}}$ fulfills the condition of Proposition 3. Thus, if a symplectic foliation admits prequantization, its symplectic leaves do as well. The corresponding prequantization bundle for F is the pull-back complex line bundle i^*_FC, coordinated by (z^i,c). Furthermore, let $A^g_{\mathcal{F}}$ (27) be a leafwise connection on the prequantization bundle $C\to Z$ which obeys Lemma 2, i.e., comes from a $U(1)$-principal connection A^g on $C\to Z$. Then the pull-back

$$A_F=i^*_FA^g=dz^i\otimes(\partial_i+ii^*_F(A^g_i)c\partial_c) \tag{29}$$

of the connection A^g onto $i^*_FC\to F$ satisfies the prequantization condition $R_F=i^*_FR=i\Omega_F$, and preserves the pull-back Hermitian metric i^*_Fg on $i^*_{\mathcal{F}}C\to F$.

IV. QUANTIZATION OF SYMPLECTIC FOLIATIONS

The next step is polarization of the symplectic foliation $(\mathcal{F},\Omega_{\mathcal{F}})$ of a manifold Z. It is defined as a maximal involutive distribution $\mathbf{T}\subset T\mathcal{F}$ on Z such that

$$\Omega_{\mathcal{F}}(u,v)=0, \quad \forall u,v\in\mathbf{T}_z, \quad z\in Z.$$

Given the Lie algebra $\mathbf{T}(Z)$ of vector fields on Z subordinate to $\mathbf{T}$, the quantum algebra of $(\mathcal{F},\Omega_{\mathcal{F}})$ is defined as the complexified subalgebra $\mathcal{A}_{\mathcal{F}}\subset C^\infty(Z)$ of functions f whose Hamiltonian vector fields ϑ_f (15) fulfill the condition $[\vartheta_f,\mathbf{T}(Z)]\subset\mathbf{T}(Z)$. This algebra obviously contains the ring $S_{\mathcal{F}}(Z)$, and is a Lie $S_{\mathcal{F}}(Z)$-algebra.

Let (F,Ω_F) be a symplectic leaf of the symplectic foliation $(\mathcal{F},\Omega_\mathcal{F})$. Given a polarization $\mathbf{T}\to Z$ of $(\mathcal{F},\Omega_\mathcal{F})$, its restriction $\mathbf{T}_F=i_F^*\mathbf{T}\subset i_F^*T\mathcal{F}=TF$ to F is an involutive distribution on F. It obeys the condition

$$i_F^*\Omega_\mathcal{F}(u,v)=0, \quad \forall u,v\in\mathbf{T}_{Fz}, \quad z\in F,$$

i.e., it is a polarization of the symplectic manifold (F,Ω_F). Thus, polarization of a symplectic foliation induces polarization of each symplectic leaf. Clearly, the quantum algebra $\mathcal{A}_F$ of a symplectic leaf F with respect to the polarization $\mathbf{T}_F$ contains all functions i_F^*f of the quantum algebra $\mathcal{A}_\mathcal{F}$ restricted to F.

Every polarization $\mathbf{T}$ of a symplectic foliation $(\mathcal{F},\Omega_\mathcal{F})$ yields polarization of the associated Poisson manifold. Indeed, let Φ be the sheaf of germs of local functions f on Z whose Hamiltonian vector fields ϑ_f (15) are subordinate to $\mathbf{T}$. The Poisson bracket of elements of Φ vanishes. Consequently, Φ is polarization the Poisson manifold $(Z,\{,\}_\mathcal{F})$. Furthermore, one can show that polarization $\mathbf{T}$ of a symplectic foliation $(\mathcal{F},\Omega_\mathcal{F})$ and the corresponding polarization Φ of the Poisson manifold $(Z,\{,\}_\mathcal{F})$ define the same quantum algebra $\mathcal{A}_\mathcal{F}$.[16] However, in order to provide the leafwise quantization of $\mathcal{A}_\mathcal{F}$, we modify the standard metaplectic correction technique[19,20] as follows.

Let us consider the exterior bundle $\overset{m}{\wedge}T\mathcal{F}^*$, $m=\dim\mathcal{F}$. Its structure group is $GL^+(m,\mathbf{R})$ since a symplectic foliation is oriented. One can regard this fiber bundle as being associated to a $GL(m,\mathbf{C})$-principal bundle $P\to Z$. Let us assume that $H^2(Z;\mathbf{Z}_2)=0$. Then the principal bundle P admits a twofold covering principal bundle with the structure metalinear group $ML(m,\mathbf{C})$.[20] As a consequence, there exists a complex line bundle $\mathcal{D}_\mathcal{F}\to Z$ characterized by an atlas $\Psi_\mathcal{F}=\{(U_\xi;z^\lambda;z^i;c)\}$ with the transition functions $c'=S_\mathcal{F}c$ such that $S_\mathcal{F}\overline{S_\mathcal{F}}=J^{-1}$ where J is the Jacobian of the transition functions of coordinates z^i. One can think of its sections as being leafwise half-forms on Z. The metalinear bundle $\mathcal{D}_\mathcal{F}\to Z$ admits the canonical lift of a vector field τ on Z. The corresponding Lie derivative of its sections reads

$$\mathbf{L}_\tau=\tau^i\partial_i+\tfrac{1}{2}\partial_i\tau^i. \tag{30}$$

We define the quantization bundle as the tensor product $Y=C\otimes\mathcal{D}_\mathcal{F}$. Given a leafwise connection $A_\mathcal{F}^q$ (27) and the Lie derivative $\mathbf{L}$ (30), let us associate the first-order differential operator

$$\hat{f}=-i[(\nabla^\mathcal{F}_{\vartheta_f}+if)\otimes\mathrm{Id}+\mathrm{Id}\otimes\mathbf{L}_{\vartheta_f}]=-i[\nabla^\mathcal{F}_{\vartheta_f}+if+\tfrac{1}{2}\partial_i\vartheta_f^i] \tag{31}$$

on sections ρ of Y to each element f of the quantum algebra $\mathcal{A}_\mathcal{F}$. A direct computation shows that the operators (31) obey the Dirac condition (17) and that, if a section ρ fulfills the relation

$$(\nabla^\mathcal{F}_\vartheta\otimes\mathrm{Id}+\mathrm{Id}\otimes\mathbf{L}_\vartheta)\rho=(\nabla^\mathcal{F}_\vartheta+\tfrac{1}{2}\partial_i\vartheta^i)\rho=0 \tag{32}$$

for all Hamiltonian vector field ϑ subordinate to $\mathbf{T}$, then $\hat{f}\rho$ possesses the same property for any $f\in\mathcal{A}_\mathcal{F}$.

Let us restrict the representation of the quantum algebra $\mathcal{A}_\mathcal{F}$ by the operators (31) to the subspace $E\subset Y(Z)$ of sections ρ which obey the condition (32) and whose restriction to each leaf of $\mathcal{F}$ is of compact support. The last condition is motivated by the following.

Since $i_F^*T\mathcal{F}^*=T^*F$, the pull-back $i_F^*\mathcal{D}_\mathcal{F}$ of $\mathcal{D}_\mathcal{F}$ onto a leaf F is a metalinear bundle of half-forms on F. Therefore, the pull-back i_F^*Y of the quantization bundle $Y\to Z$ onto F is a quantization bundle for the symplectic manifold $(F,i_F^*\Omega_\mathcal{F})$. Given the pull-back connection A_F (29) and the polarization $\mathbf{T}_F=i_F^*\mathbf{T}$, this symplectic manifold is subject to the standard geometric quantization by the first-order differential operators

$$\hat{f}=-i(i_F^*\nabla^\mathcal{F}_{\vartheta_f}+if+\tfrac{1}{2}\partial_i\vartheta_f^i), \quad f\in\mathcal{A}_F, \tag{33}$$

on sections ρ_F of $i_F^*Y \to F$ of compact support which obey the condition

$$(i_F^*\nabla_\vartheta^{\mathcal{F}} + \tfrac{1}{2}\partial_i\vartheta^i)\rho_F = 0$$

for all Hamiltonian vector fields ϑ on F subordinate to $\mathbf{T}_F$. These sections constitute a pre-Hilbert space E_F with respect to the Hermitian form

$$\langle \rho_F | \rho_F' \rangle = \left(\frac{1}{2\pi}\right)^{m/2} \int_F \rho_F \overline{\rho_F'}$$

so that $\hat{f}$ (33) are Hermitian operators in E_F. It is readily observed that $i_F^*E \subset E_F$. Moreover, the relation

$$i_F^*(\hat{f}\rho) = (\widehat{i_F^*f})(i_F^*\rho)$$

holds for all elements $f \in \mathcal{A}_{\mathcal{F}}$ and $\rho \in E$. This relation enables one to think of the operators $\hat{f}$ (31) in E as being the leafwise quantization of the $S_{\mathcal{F}}(Z)$-algebra $\mathcal{A}_{\mathcal{F}}$ by Hermitian operators in a pre-Hilbert $S_{\mathcal{F}}(Z)$-module E.

V. QUANTIZATION OF A MECHANICAL SYSTEM WITH PARAMETERS

Let Q (1) be the configuration space of a mechanical system with parameters such that $H^2(Q;\mathbf{Z}_2) = H^2(V^*Q;\mathbf{Z}_2) = 0$. The characteristic symplectic foliation $\mathcal{F}$ of the Poisson structure (4) on the momentum phase space V^*Q is the fibration $V^*Q \to \Sigma$ endowed with the leafwise symplectic form

$$\Omega_{\mathcal{F}} = \tilde{\mathrm{d}}p_k \wedge \tilde{\mathrm{d}}q^k.$$

Since this form is $\tilde{\mathrm{d}}$-exact, its leafwise de Rham cohomology class equals zero, and it is the image of the zero de Rham cohomology class with respect to the morphism $[i_{\mathcal{F}}^*]$ (10). Then, in accordance with Proposition 3, the symplectic foliation $(V^*Q \to \Sigma, \Omega_{\mathcal{F}})$ admits prequantization.

The prequantization bundle $C \to V^*Q$, associated to the zero Chern class, is trivial. Let its trivialization $C = V^*Q \times \mathbf{C}$ hold fixed, and let $(t, \sigma^\lambda, q^k, p_k, c)$ be the corresponding bundle coordinates. Unless Q is specified, we choose the leafwise connection

$$A_{\mathcal{F}} = \tilde{\mathrm{d}}p_k \otimes \partial^k + \tilde{\mathrm{d}}q^k \otimes (\partial_k + ip_k c\partial_c)$$

on $C \to V^*Q$. This connection preserves the Hermitian metric g (25) on C, and its curvature fulfills the prequantization condition $\tilde{R} = i\Omega_{\mathcal{F}}$. The corresponding prequantization operators (18) read

$$\hat{f} = -i\vartheta_f + (f - p_k\partial^k f), \quad \vartheta_f = \partial^k f \partial_k - \partial_k f \partial^k, \quad f \in C^\infty(V^*Q).$$

Let us choose the canonical vertical polarization of the symplectic foliation $(V^*Q \to \Sigma, \Omega_{\mathcal{F}})$ which is the vertical tangent bundle $\mathbf{T} = VV^*Q$ of the fiber bundle $\pi_{VQ}: V^*Q \to Q$. It is readily observed that the corresponding quantum algebra $\mathcal{A}_{\mathcal{F}}$ consists of functions which are affine in momenta p_k.

Following the quantization procedure in Sec. IV, one should define a representation of $\mathcal{A}_{\mathcal{F}}$ in the space E of sections ρ of the quantization bundle $C \otimes \mathcal{D}_{\mathcal{F}}$ which obey the condition (32) and whose restriction to each fiber of $V^*Q \to \Sigma$ is of compact support. The condition (32) reads

$$\partial_k f \partial^k \rho = 0, \quad \forall f \in C^\infty(Q),$$

i.e., elements of E are constant on fibers of $V^*Q \to Q$ and E reduces to $\{0\}$.

Therefore, we modify the quantization procedure as follows. Given a fibration $Q\to\Sigma$, let us consider the corresponding metalinear bundle $\mathcal{D}_Q\to Q$ and the tensor product $Y_Q=C_Q\otimes\mathcal{D}_Q$, where $C_Q=Q\times\mathbf{C}$ is the trivial complex line bundle over Q. It is readily observed that the Hamiltonian vector fields

$$\vartheta_f=a^k\partial_k-(p_r\partial_k a^r+\partial_k b)\partial^k,\quad f=a^k(t,\sigma^\lambda,q^r)p_k+b(t,\sigma^\lambda,q^r),$$

of elements $f\in\mathcal{A}_\mathcal{F}$ are projectable onto Q. Then one can associate to each element f of the quantum algebra $\mathcal{A}_\mathcal{F}$ the first-order differential operator

$$\hat{f}=(-i\nabla_{\pi_{VQ}(\vartheta_f)}+f)\otimes\mathrm{Id}+\mathrm{Id}\otimes\mathbf{L}_{\pi_{VQ}(\vartheta_f)}=-ia^k\partial_k-\frac{i}{2}\partial_k a^k+b \tag{34}$$

in the space E_Q of sections of the fiber bundle $Y_Q\to Q$ whose restriction to each fiber of $Q\to\Sigma$ is of compact support. Since the pull-back of $\mathcal{D}_Q$ onto each fiber Q_σ of $Q\to\Sigma$ is the metalinear bundle of half-forms on Q_σ, the restrictions ρ_σ of elements of $\rho_Q\in E_Q$ to Q_σ constitute a pre-Hilbert space with respect to the nondegenerate Hermitian form

$$\langle\rho_\sigma|\rho'_\sigma\rangle_\sigma=\int_{Q_\sigma}\rho_\sigma\overline{\rho'_\sigma}.$$

The Schrödinger operators (34) are Hermitian operators in the pre-Hilbert $C^\infty(\Sigma)$-module E_Q, and provide the desired geometric quantization of the symplectic foliation $(V^*Q\to\Sigma,\Omega_\mathcal{F})$.

VI. THE CLASSICAL EVOLUTION EQUATION

In order to quantize the evolution equation of a time-dependent mechanical system on the configuration space Q (1), one should bear in mind that this equation is not reduced to the Poisson bracket $\{,\}_V$ on V^*Q, but is expressed into the Poisson bracket $\{,\}_T$ on the cotangent bundle T^*Q.[14,21] Therefore, let us start from the classical evolution equation.

It is convenient to assume for a time that parameters are dynamic variables. The momentum phase space of such a system is the vertical cotangent bundle V^*_RQ of the configuration bundle $Q\to\mathbf{R}$ provided with holonomic coordinates $(t,\sigma^\lambda,q^k,p_\lambda,p_k)$.[8,9] A Hamiltonian on this momentum phase space is defined as a global section

$$h:V^*_RQ\to T^*Q,\quad p\circ h=-\mathcal{H}(t,\sigma^\lambda,q^k,p_\lambda,p_k), \tag{35}$$

of the affine bundle

$$\zeta_R:T^*Q\to V^*_RQ\quad(t,\sigma^\lambda,q^k,p,p_\lambda,p_k)\mapsto(t,\sigma^\lambda,q^k,p_\lambda,p_k).$$

Given the canonical Liouville form Ξ on T^*Q, every Hamiltonian h (35) yields the pull-back Hamiltonian form

$$H=h^*\Xi=p_\lambda\mathrm{d}\sigma^\lambda+p_k\mathrm{d}q^k-\mathcal{H}\,\mathrm{d}t \tag{36}$$

on V^*_RQ. For any Hamiltonian form H (36), there exists a unique vector field γ_H on V^*_RQ such that

$$\gamma_H\rfloor\mathrm{d}t=1,\quad \gamma_H\rfloor\mathrm{d}H=0.$$

This vector field defines the first-order Hamilton equations on V^*_RQ.[7–9,14,21,22] Accordingly,

$$\gamma_H\rfloor\mathrm{d}f=0,\quad f\in C^\infty(V^*_RQ) \tag{37}$$

is the evolution equation. In order to express it into a Poisson bracket, let us consider the pull-back $\zeta_R^* H$ of the Hamiltonian form H (36) onto T^*Q. It is readily observed that the difference $\Xi - \zeta_R^* h^* \Xi$ is a horizontal one-form on $T^*Q \to \mathbf{R}$ and that

$$\mathcal{H}^* = \partial_t \rfloor (\Xi - \zeta^* h^* \Xi)) = p + \mathcal{H} \tag{38}$$

is a function on T^*Q. Then the evolution equation (37) is brought into the form $\{\mathcal{H}^*, \zeta_R^* f\}_T = 0$ adapted for quantization.[14,21]

Let us return to a system where σ^λ are parameters. Its Hamiltonian $\mathcal{H}$ is affine in momenta p_λ, namely,

$$\mathcal{H} = p_\lambda \Gamma^\lambda + p_k(\Lambda^k + \Gamma^\lambda \Lambda_\lambda^k) + \mathcal{H}_\Lambda(t, \sigma^\lambda, q^r, p_r), \tag{39}$$

where $\mathcal{H}_\Lambda \in \zeta^* C^\infty(V^*Q)$ is the pull-back of a function on V^*Q and

$$\Lambda \circ \Gamma = dt \otimes (\partial_t + \Gamma^\lambda \partial_\lambda + (\Lambda^k + \Gamma^\lambda \Lambda_\lambda^k) \partial_k)$$

is a connection on $Q \to \mathbf{R}$ which is the composition of a connection

$$\Gamma = dt \otimes (\partial_t + \Gamma^\lambda \partial_\lambda) \tag{40}$$

on the parameter bundle $\Sigma \to \mathbf{R}$ and a connection

$$\Lambda = dt \otimes (\partial_t + \Lambda^k \partial_k) + d\sigma^\lambda \otimes (\partial_\lambda + \Lambda_\lambda^k \partial_k) \tag{41}$$

on $Q \to \Sigma$.[7–9] Note that the second term of the connection (41) provides the lift

$$\tau^\lambda \partial_\lambda \mapsto \tau^\lambda (\partial_\lambda + \Lambda_\lambda^k \partial_k)$$

onto Q of vertical vector fields on the parameter bundle $\Sigma \to \mathbf{R}$. It plays the role of a control operator in holonomic quantum computation. If a parameter function $\chi: \mathbf{R} \to \Sigma$ is given, the connection Γ (40) on $\Sigma \to \mathbf{R}$ is determined in such a way that

$$\nabla^\Gamma \chi = 0, \quad \Gamma^\lambda(t, \chi^\mu(t)) = \partial_t \chi^\lambda. \tag{42}$$

It is readily observed that, if a Hamiltonian $\mathcal{H}$ is affine in momenta p_λ and if f is a function on V^*Q, then the bracket $\{\mathcal{H}^*, \zeta^* f\}_T$ where ζ is the fibration (2) is the pull-back of a function on V^*Q. It provides a derivation of the $\mathbf{R}$-ring $C^\infty(V^*Q)$. Therefore, one can think of the equality

$$\{\mathcal{H}^*, \zeta^* f\}_T = 0, \quad f \in C^\infty(V^*Q), \tag{43}$$

as being a classical evolution equation on $C^\infty(V^*Q)$.

VII. THE QUANTUM EVOLUTION EQUATION

In order to quantize the evolution equation (43), one should quantize the Poisson manifold $(T^*Q, \{,\}_T)$ so that its quantum algebra $\mathcal{A}_T$ contains $\zeta^* \mathcal{A}_\mathcal{F}$. Let Φ be polarization of the Poisson manifold $(V^*Q, \{,\}_V)$ which determines $\mathcal{A}_\mathcal{F}$. Then, by virtue of the relation (3), $\zeta^* \Phi$ is a polarization of $(T^*Q, \{,\}_T)$. Clearly, $\mathcal{A}_\mathcal{F}$ is a subalgebra of the quantum algebra $\mathcal{A}_T$ of T^*Q determined by this polarization. The quantum algebra $\mathcal{A}_T$ consists of functions on T^*Q which are affine in momenta p, p_λ, p_k. Let us restrict our consideration to its subalgebra $\mathcal{A}_T'$ of functions

$$f = a(t, \sigma^\mu) p + a^\lambda(t, \sigma^\mu) p_\lambda + a^k(t, \sigma^\mu, q^r) p_k + b(t, \sigma^\mu, q^r),$$

where a and a^λ are the pull-back onto T^*Q of functions on the parameter space Σ. Of course, $\mathcal{A}_\mathcal{F} \subset \mathcal{A}_T'$. Moreover, $\mathcal{A}_T'$ admits a representation by the Hermitian operators

$$\hat{f}=-i(a\partial_t+a^\lambda\partial_\lambda+a^k\partial_k)-\frac{i}{2}\partial_k a^k+b$$

in the carrier space E_Q of the representation (34) of $\mathcal{A}_\mathcal{F}$. Then, if $\mathcal{H}^*\in\mathcal{A}'_T$, the evolution equation (43) is quantized as the Heisenberg equation

$$i[\hat{\mathcal{H}}^*,\hat{f}]=0, \quad f\in\mathcal{A}_\mathcal{F}. \tag{44}$$

The problem is that the function $\mathcal{H}^*$ (38) fails to belong to the algebra $\mathcal{A}'_T$, unless the Hamiltonian function $\mathcal{H}_\Lambda$ (39) is affine in momenta p_k. Let us assume that $\mathcal{H}_\Lambda$ is polynomial in momenta. This is the case of almost all physically relevant models.

Lemma 4: Any smooth function f on V^*Q which is a polynomial of momenta p_k is decomposed in a finite sum of products of elements of the algebra $\mathcal{A}_\mathcal{F}$.

The proof follows that of the similar statement in Sec. V of Ref. 14.

By virtue of Lemma 4, one can associate to a polynomial Hamiltonian function $\mathcal{H}_\Lambda$ an element of the enveloping algebra $\overline{\mathcal{A}}_\mathcal{F}$ of the Lie algebra $\mathcal{A}_\mathcal{F}$ (though it by no means is unique). Accordingly, $\mathcal{H}^*$ is represented by an element of the enveloping algebra $\overline{\mathcal{A}}'_T$ of the Lie algebra $\mathcal{A}'_T$. Then the Schrödinger representation of $\mathcal{A}'_T$ and $\mathcal{A}_\mathcal{F}$ is naturally extended to their enveloping algebras $\overline{\mathcal{A}}'_T$ and $\overline{\mathcal{A}}_\mathcal{F}$ that provides quantization $\hat{\mathcal{H}}^*$ of $\mathcal{H}^*$.

Given the operator $\hat{\mathcal{H}}^*$, the bracket

$$\nabla\hat{f}=i[\hat{\mathcal{H}}^*,\hat{f}] \tag{45}$$

defines a derivation of the quantum algebra $\overline{\mathcal{A}}_\mathcal{F}$. Since $\hat{p}=-i\partial_t$, the derivation (45) obeys the Leibniz rule

$$\nabla(r\hat{f})=\partial_t r\hat{f}+r\nabla\hat{f}, \quad r\in C^\infty(\mathbf{R}).$$

Therefore, it is a connection on the $C^\infty(\mathbf{R})$-algebra $\overline{\mathcal{A}}_\mathcal{F}$, which enables one to treat quantum evolution of $\overline{\mathcal{A}}_\mathcal{F}$ as a parallel transport along time.[7,8,14] In particular, $\hat{f}$ is parallel with respect to the connection (45) if it obeys the Heisenberg equation (44). Given a trivialization $Q\cong\mathbf{R}\times M$ and the corresponding (global) decomposition $\hat{\mathcal{H}}^*=-i\partial_t+\hat{\mathcal{H}}$, we can introduce the evolution operator U which obeys the equation

$$\hat{\mathcal{H}}^*\circ U=-iU\circ\partial_t,$$

and can be written as the formal time-ordered exponent

$$U=T\exp\left[-i\int_0^t\hat{\mathcal{H}}\,dt'\right].$$

Now let us consider a mechanical system depending on a given parameter function $\chi:\mathbf{R}\to\Sigma$. Its configuration space is the pull-back bundle $Q_\chi=\chi^*Q$ which is a subbundle $i_\chi:Q_\chi\to Q$ of the fiber bundle $Q\to\mathbf{R}$. The corresponding momentum phase space is the vertical cotangent bundle $V^*Q_\chi=i_\chi^*V^*Q$ of $Q_\chi\to\mathbf{R}$. The pull-back of the Hamiltonian form H (36) onto V^*Q_χ, where the connection Γ obeys the relation (42), reads

$$H_\chi=p_k\,dq^k-\mathcal{H}_\chi\,dt,$$

$$\mathcal{H}_\chi=p_k(\Lambda^k(t,\chi^\mu(t),q^r)+\Lambda^k_\lambda(t,\chi^\mu(t),q^r)\partial_t\chi^\lambda)+\mathcal{H}_\Lambda(t,\chi^\mu(t),q^r,p_r).$$

It characterizes the dynamics of a mechanical system with a given parameter function χ.[7–9]

In order to quantize this system, let us consider the pull-back bundle $\mathcal{D}_\chi = i_\chi^* \mathcal{D}_Q$ over Q_χ and its pull-back sections $\rho_\chi = i_\chi^* \rho_Q$, $\rho_Q \in E_Q$. It is easily justified that these are leafwise half-forms on the fiber bundle $Q_\chi \to \mathbf{R}$ whose restrictions to each fiber $i_t : Q_t \to Q_\chi$ are of compact support. These sections constitute a pre-Hilbert $C^\infty(\mathbf{R})$-module E_χ with respect to the Hermitian forms

$$\langle i_t^* \rho_\chi | i_t^* \rho'_\chi \rangle_t = \int_{Q_t} i_t^* \rho_\chi \overline{i_t^* \rho'_\chi}.$$

Then the pull-back operators

$$(\chi^* \hat{f}) \rho_\chi = (\hat{f} \rho)_\chi, \quad \chi^* \hat{f} = -ia^k(t, \chi^\lambda(t), q^r) \partial_k - \frac{i}{2} \partial_k a^k(t, \chi^\mu(t), q^r) + b(t, \chi^\mu(t), q^r),$$

in E_χ provide the representation of the pull-back functions

$$i_\chi^* f = a^k(t, \chi^\lambda(t), q^r) p_k + b(t, \chi^\lambda(t), q^r), \quad f \in \mathcal{A}_\mathcal{F}$$

on $V^* Q_\chi$. Accordingly, the quantum operator $\hat{\mathcal{H}}_\chi^* = \hat{p} + \hat{\mathcal{H}}_\chi$ coincides with pull-back operator $\chi^* \hat{\mathcal{H}}^*$. Then the Heisenberg equation of a quantum system with a parameter function χ takes the form

$$i[\hat{\mathcal{H}}_\chi^*, \chi^* \hat{f}] = 0,$$

and the corresponding evolution operator reads

$$U = T \exp\left[-i \int_0^t \hat{\mathcal{H}}_\chi \mathrm{d}t' \right]. \tag{46}$$

The Hamiltonian $\hat{\mathcal{H}}_\chi$ in the evolution operator U (46) takes the form (5). Its second term $\hat{\mathcal{H}}'$ can be regarded as a dynamic Hamiltonian of a quantum system, while the first term is responsible for the geometric Berry factor phenomena as follows.

Bearing in mind possible applications to holonomic quantum computations, let us simplify the quantum system in question. The above trivialization $Q \cong \mathbf{R} \times M$ implies a trivialization of the parameter bundle $\Sigma = \mathbf{R} \times S$ such that the fibration $Q \to \Sigma$ reads

$$\begin{array}{ccc} & {\scriptstyle \mathrm{Id} \times \pi_M} & \\ \mathbf{R} \times M & \to & \mathbf{R} \times S, \end{array}$$

where $\pi_M : M \to S$ is a fiber bundle. Let us suppose that the components Λ_λ^k of the connection Λ (41) are independent of time. Then one can regard the second term in this connection as a connection on the fiber bundle $M \to S$. It also follows that the first term in the Hamiltonian (5) depends on time only through parameter functions $\chi^\lambda(t)$. Furthermore, let the two terms in the Hamiltonian (5) mutually commute on $[0,t]$. Then the evolution operator U (46) takes the form

$$U = T \exp\left[-\int_{\chi([0,t])} \left(\Lambda_\lambda^k \partial_k + \frac{1}{2} \partial_k \Lambda_\lambda^k \right) \mathrm{d}\sigma^\lambda \right] \circ T \exp\left[-i \int_0^t \hat{\mathcal{H}}' \mathrm{d}t' \right].$$

One can think of the first factor in this evolution operator as being the parallel displacement operator along the curve $\chi([0,t]) \subset S$ with respect to the connection

$$\nabla^\Lambda \rho_Q = (\partial_\lambda + \Lambda_\lambda^k \partial_k + \tfrac{1}{2} \partial_k \Lambda_\lambda^k) \rho_Q \, \mathrm{d}\sigma^\lambda, \quad \rho_Q \in E_Q$$

on the $C^\infty(S)$-module E_Q. Its peculiarity in comparison with the remaining one lies in the fact that integration over time through a parameter function $\chi(t)$ depends only on a trajectory of this function in a parameter space, but not on parametrization of this trajectory by time. Therefore, one can think of it as being a geometric factor.

(Received 25 November 2001; accepted for publication 1 March 2002)

The independent eigenstates of the total orbital angular momentum operators for a three-body system in an arbitrary D-dimensional space are presented by the method of group theory. The Schrödinger equation is reduced to the generalized radial equations satisfied by the generalized radial functions with a given total orbital angular momentum denoted by a Young diagram $[\mu, \nu, 0,..., 0]$ for the SO(D) group. Only three internal variables are involved in the functions and equations. The number of both the functions and the equations for the given angular momentum is finite and equal to $(\mu-\nu+1)$. © *2002 American Institute of Physics.*

I. INTRODUCTION

From the very early stage of the progress in quantum mechanics in the real three-dimensional world, it has been pointed out that the essence of these theories would be easily understandable if their mathematics were constructed in the nonrelativistic hyperspace worlds.[1,2] The mathematical tools for generalization of the orbital angular momentum in an arbitrary D-dimensional space have been presented.[3–7] Recently, the D-dimensional Coulombic and the harmonic oscillator problems in a two-body system have been studied in some detail by many authors.[8–22]

Exact solutions played very important roles in the development of physics. The exact solutions of the Schrödinger equation in the real three-dimensional space for a hydrogen atom and for a harmonic oscillator were important technical achievements in quantum mechanics,[23] which provided strong evidence in favor of the theory being correct, at least as far as atomic physics is concerned. The next simplest atom is the helium atom, for which the Schrödinger equation cannot be solved analytically, but only numerically.[24–28] In the numerical calculation, one of the main difficulties is how to separate the global rotational degrees of freedom.

In our previous paper[29] we separated completely the global rotational degrees of freedom in the Schrödinger equation for an N-body system in the real three-dimensional space from the internal ones. We have determined a complete set of $(2l+1)$ independent base functions for a given total orbital angular momentum l, which are the homogeneous polynomials in the components of coordinate vectors and do not contain the Euler angles explicitly. Any function with the given angular momentum l in the system can be expanded with respect to the base functions, where the coefficients are the functions of the internal variables, called the generalized radial

a)Present address: Institute of High Energy Physics.
b)Electronic mail: guxy@mail.ihep.ac.cn

functions. The generalized radial equations satisfied by the functions are established explicitly.[29] For the typical three-body system in the real three-dimensional space,[30,31] such as a helium atom[32,33] and a positronium negative ion,[34] the generalized radial equations[35] have been solved numerically with high precision.

With the recent interest in higher dimensional field theory, we attempt to generalize the study of the D-dimensional two-body system to the D-dimensional three-body system. The purpose of this paper is, for a three-body system in an arbitrary D-dimensional space, to find a complete set of independent base functions with any given total orbital angular momentum and to reduce the Schrödinger equation with a spherically symmetric potential V to the generalized radial equations, where only three internal variables are involved. Any function with the given angular momentum in the system can be expanded with respect to the base functions. It provides a possibility to calculate numerically the energy levels of the three-body system in D-dimensions with high precision.

From the viewpoint of mathematics, the separation of the global rotational degrees of freedom from the internal ones is a typical application of group theory to physics. The properties of the independent base functions for a given total orbital angular momentum would be clearer if they were constructed in arbitrary D-dimensional space rather than in the real three-dimensional space. The total orbital angular momentum for a three-body system in a D-dimensional space is described by an irreducible representation denoted by a Young diagram with one or two rows. For the real three-dimensional space, the rotational symmetry group is SO(3) group, and its only irreducible representations denoted by the Young diagrams with two rows are $[l,1]$, which are equivalent to the representations denoted by the one-row Young diagrams $[l,0]$, respectively. This is the reason why the angular momentum can be described by only one quantum number l for the real three-dimensional space.

This paper is organized as follows. After separating the motion of the center of mass by the Jacobi coordinate vectors in Sec. II, we review in Sec. III the generalization of the orbital angular momentum operators and the properties of the spherical harmonics[4,6] and the harmonic polynomials[7] for a two-body system in D dimensions. In Sec. IV we will define the generalized harmonic polynomials for a three-body system in D dimensions and prove that they constitute a complete set of independent base functions for a given total orbital angular momentum in the system. The generalized radial functions are defined and the generalized radial equations are derived in Sec. V. Some conclusions will be given in Sec. VI.

II. SCHRÖDINGER EQUATION IN D DIMENSIONS

For a quantum N-body system in an arbitrary D-dimensional space, we denote the position vectors and the masses of N particles by $\mathbf{r}_k$ and by m_k, $k=1,2,\ldots,N$, respectively. $M=\Sigma_k m_k$ is the total mass. The Schrödinger equation for the N-body system with a pair potential V, depending upon the distance of each pair of particles, $|\mathbf{r}_j-\mathbf{r}_k|$, is

$$-\frac{1}{2}\sum_{k=1}^{N} m_k^{-1}\nabla_{\mathbf{r}_k}^2\Psi+V\Psi=E\Psi, \tag{1}$$

where $\nabla_{\mathbf{r}_k}^2$ is the Laplace operator with respect to the position vector $\mathbf{r}_k$. For simplicity, the natural units $\hbar=c=1$ are employed throughout this paper. The total orbital angular momentum operators L_{ab} in D dimensions are defined as[4,6]

$$L_{ab}=-L_{ba}=-i\sum_{k=1}^{N}\left\{r_{ka}\frac{\partial}{\partial r_{kb}}-r_{kb}\frac{\partial}{\partial r_{ka}}\right\}, \quad a,b=1,2,\ldots,D, \tag{2}$$

where r_{ka} denotes the ath component of the position vector $\mathbf{r}_k$.

Now, we replace the position vectors $\mathbf{r}_k$ by the Jacobi coordinate vectors $\mathbf{R}_j$:

$$\mathbf{R}_0 = M^{-1/2}\sum_{k=1}^{N} m_k \mathbf{r}_k, \quad \mathbf{R}_j = \left(\frac{m_{j+1}M_j}{M_{j+1}}\right)^{1/2}\left(\mathbf{r}_{j+1} - \sum_{k=1}^{j}\frac{m_k \mathbf{r}_k}{M_j}\right),$$
$$1 \leqslant j \leqslant (N-1), \quad M_j = \sum_{k=1}^{j} m_k, \quad M_N = M, \tag{3}$$

where $\mathbf{R}_0$ describes the position of the center of mass, $\mathbf{R}_1$ describes the mass-weighted separation from the second particle to the first particle. $\mathbf{R}_2$ describes the mass-weighted separation from the third particle to the center of mass of the first two particles, and so on. An additional factor $\sqrt{M}$ is included in $\mathbf{R}_j$ for convenience. The mass-weighted factors in front of the formulas for $\mathbf{R}_j$ are determined by the condition

$$\sum_{k=1}^{N} m_k \mathbf{r}_k^2 = \sum_{j=0}^{N-1} \mathbf{R}_j^2,$$

One may determine the factors one by one from the following schemes. In the center-of-mass frame, if the first j particles coincide with each other and the last $(N-j-1)$ particles are located at the origin, the factor in front of $\mathbf{R}_j$ is determined by

$$\mathbf{r}_1 = \mathbf{r}_2 = \cdots = \mathbf{r}_j = -m_{j+1}\mathbf{r}_{j+1}/M_j, \quad \sum_{k=1}^{j+1} m_k \mathbf{r}_k^2 = \mathbf{R}_j^2. \tag{4}$$

A straightforward calculation by replacement of variables shows that the Laplace operator in Eq. (1) and the total orbital angular momentum operator L_{ab} in Eq. (2) are directly expressed in $\mathbf{R}_j$:

$$\nabla^2 = \sum_{k=1}^{N} m_k^{-1}\nabla_{\mathbf{r}_k}^2 = \sum_{j=0}^{N-1} \nabla_{\mathbf{R}_j}^2,$$
$$L_{ab} = -i\sum_{j=0}^{N-1}\left\{R_{ja}\frac{\partial}{\partial R_{jb}} - R_{jb}\frac{\partial}{\partial R_{ja}}\right\}. \tag{5}$$

In the center-of-mass frame, $\mathbf{R}_0 = 0$. The Laplace operator (5) obviously has the symmetry of the $\mathrm{O}(ND-D)$ group with respect to $(N-1)D$ components of $(N-1)$ Jacobi coordinate vectors. The $\mathrm{O}(ND-D)$ group contains a subgroup $\mathrm{SO}(D)\times\mathrm{O}(N-1)$, where $\mathrm{SO}(D)$ is the rotation group in the D-dimensional space. The space inversion and the different definitions for the Jacobi coordinate vectors in the so-called Jacobi tree[24] can be obtained by $\mathrm{O}(N-1)$ transformations. For the system of identical particles, the permutation group among particles is also a subgroup of the $\mathrm{O}(N-1)$ group.[29]

It is easy to obtain the inverse transformation of Eq. (3):

$$\mathbf{r}_j = \left[\frac{M_{j-1}}{m_j M_j}\right]^{1/2}\mathbf{R}_{j-1} - \sum_{k=j}^{N-1}\left[\frac{m_{k+1}}{M_k M_{k+1}}\right]^{1/2}\mathbf{R}_k + M^{-1/2}\mathbf{R}_0,$$
$$\mathbf{r}_j - \mathbf{r}_k = \left[\frac{M_j}{m_j M_{j-1}}\right]^{1/2}\mathbf{R}_{j-1} + \sum_{i=k}^{j-2}\left[\frac{m_{i+1}}{M_i M_{i+1}}\right]^{1/2}\mathbf{R}_i - \left[\frac{M_{k-1}}{m_k M_k}\right]^{1/2}\mathbf{R}_{k-1}. \tag{6}$$

Thus, the potential V is a function of $\mathbf{R}_j\cdot\mathbf{R}_k$ and is rotationally invariant.

III. HARMONIC POLYNOMIALS IN *D* DIMENSIONS

In the center-of-mass frame, $\mathbf{R}_0=0$. Hence, for a two-body system there is only one Jacobi coordinate vector $\mathbf{R}_1$, which will be denoted by $\mathbf{x}$ for simplicity:

$$\mathbf{x}=\left(\frac{m_1m_2}{m_1+m_2}\right)^{1/2}\{\mathbf{r}_2-\mathbf{r}_1\},$$
$$\nabla^2=\nabla_{\mathbf{x}}^2,\quad L_{ab}=-i\left\{x_a\frac{\partial}{\partial x_b}-x_b\frac{\partial}{\partial x_a}\right\}. \tag{7}$$

Louck[4,6] introduced the hyperspherical coordinates

$$\begin{aligned}
x_1&=r\cos\theta_1\sin\theta_2\cdots\sin\theta_{D-1},\\
x_2&=r\sin\theta_1\sin\theta_2\cdots\sin\theta_{D-1},\\
x_k&=r\cos\theta_{k-1}\sin\theta_k\cdots\sin\theta_{D-1},\quad 3\leqslant k\leqslant D-1,\\
x_D&=r\cos\theta_{D-1}.
\end{aligned} \tag{8}$$

The spherical harmonics $Y^l_{l_{D-2},\ldots,l_1}$ in D dimensions[4,6] are the simultaneous eigenfunctions of the commutant operators $\mathbf{L}_k^2$:

$$\mathbf{L}_1^2=-\frac{\partial^2}{\partial\theta_1^2},\quad \mathbf{L}_k^2=-\left\{\frac{1}{\sin^{k-1}\theta_k}\frac{\partial}{\partial\theta_k}\sin^{k-1}\theta_k\frac{\partial}{\partial\theta_k}-\frac{\mathbf{L}_{k-1}^2}{\sin^2\theta_k}\right\}, \tag{9}$$

$$\mathbf{L}_1^2Y^l_{l_{D-2},\ldots,l_1}(\theta_1\cdots\theta_{D-1})=l_1^2Y^l_{l_{D-2},\ldots,l_1}(\theta_1\cdots\theta_{D-1}),$$
$$\mathbf{L}_k^2Y^l_{l_{D-2},\ldots,l_1}(\theta_1\cdots\theta_{D-1})=l_k(l_k+k-1)Y^l_{l_{D-2},\ldots,l_1}(\theta_1\cdots\theta_{D-1}), \tag{10}$$
$$l\equiv l_{D-1}=0,1,\ldots,\quad l_k=0,1,\ldots,l_{k+1},\quad l_1=-l_2,-l_2+1,\ldots,l_2-1,l_2,$$

where $\mathbf{L}^2\equiv\mathbf{L}_{D-1}^2$, $0\leqslant r<\infty$, $-\pi\leqslant\theta_1\leqslant\pi$, $0\leqslant\theta_k\leqslant\pi$, and $2\leqslant k\leqslant D-1$. The volume element of the configuration space is[4,14]

$$\prod_{j=1}^{D}\mathrm{d}x_j=r^{D-1}\mathrm{d}r\prod_{j=1}^{D-1}(\sin\theta_j)^{j-1}\mathrm{d}\theta_j. \tag{11}$$

Through a direct calculation by replacement of variables, one obtains[4,6]

$$\nabla_{\mathbf{x}}^2=\frac{1}{r^{D-1}}\frac{\partial}{\partial r}r^{D-1}\frac{\partial}{\partial r}-\frac{\mathbf{L}^2}{r^2}, \tag{12}$$

Due to the spherical symmetry, the wave function can be expressed as

$$\psi^l_{l_{D-2},\ldots,l_1}(\mathbf{x})=\phi_l(r)Y^l_{l_{D-2},\ldots,l_1}(\theta_1\cdots\theta_{D-1}), \tag{13}$$

and the D-dimensional Schrödinger equation (1) for a two-body system in the center-of-mass frame reduces to the radial equation

$$\frac{1}{r^{D-1}}\frac{\partial}{\partial r}r^{D-1}\frac{\partial}{\partial r}\phi_l(r)-\frac{l(l+D-2)}{r^2}\phi_l(r)=-2[E-V(r)]\phi_l(r). \tag{14}$$

Bander and Itzykson[7] introduced the harmonic polynomials in D dimensions

$$\mathcal{Y}^l_{l_{D-2},\ldots,l_1}(\mathbf{x}) = r^l Y^l_{l_{D-2},\ldots,l_1}(\theta_1\cdots\theta_{D-1}) \equiv r^l Y^l_{l_{D-2},\ldots,l_1}(\hat{\mathbf{x}}), \tag{15}$$

to avoid the angular functions $Y^l_{l_{D-2},\ldots,l_1}(\theta_1\cdots\theta_{D-1})$. $\mathcal{Y}^l_{l_{D-2},\ldots,l_1}(\mathbf{x})$ is a homogeneous polynomial of degree l in the components of $\mathbf{x}$ and satisfies the Laplace equation

$$\nabla^2_{\mathbf{x}} \mathcal{Y}^l_{l_{D-2},\ldots,l_1}(\mathbf{x}) = 0. \tag{16}$$

The number of linearly independent homogeneous polynomials of degree l in D components of $\mathbf{x}$ is $N(l) = (l+D-1)!/l!(D-1)!$. The Laplace equation (16) gives $N(l-2) = (l+D-3)!/(l-2)!(D-1)!$ constraints. Hence, the number of the harmonic polynomials $\mathcal{Y}^l_{l_{D-2},\ldots,l_1}(\mathbf{x})$ of degree l as well as the number of the spherical harmonics $Y^l_{l_{D-2},\ldots,l_1}(\hat{\mathbf{x}})$ in D dimensions is

$$N(l) - N(l-2) = \frac{(2l+D-2)(l+D-3)!}{l!(D-2)!} = d_D([l,0,\ldots,0]). \tag{17}$$

$d_D([l,0,\ldots,0])$ is the dimension of the irreducible representation of SO(D) denoted by the one-row Young diagram $[l,0,\ldots,0]$. $[l,0,\ldots,0]$ describes the symmetric traceless tensor representation. In fact, any polynomial in the components of one vector $\mathbf{x}$ has to belong to a symmetric representation.

Due to the spherical symmetry, one only needs to write the explicit form of the highest weight state[7]

$$\mathcal{Y}^l_{l,\ldots,l}(\mathbf{x}) = N_l (x_1 + i x_2)^l, \tag{18}$$

where N_l denotes the normalization factor. The partners of $\mathcal{Y}^l_{l,\ldots,l}(\mathbf{x})$ can be simply generated by rotation. Now, the solution to the Schrödinger equation in the center-of-mass frame can be reexpressed as

$$\psi^l_{l,\ldots,l}(\mathbf{x}) = R_l(r)\mathcal{Y}^l_{l,\ldots,l}(\mathbf{x}), \tag{19}$$

and the radial equation is easy to derive:

$$\frac{1}{r^{D-1}}\frac{\partial}{\partial r} r^{D-1}\frac{\partial}{\partial r} R_l(r) + \frac{2l}{r}\frac{\partial}{\partial r} R_l(r) = -2[E - V(r)]R_l(r). \tag{20}$$

Recall $R_l(r) = r^{-l}\phi_l(r)$. Equation (20) coincides with Eq. (14) but the angle variables do not appear explicitly in calculation.

The number (17) of the harmonic polynomials $\mathcal{Y}^l_{l_{D-2},\ldots,l_1}(\mathbf{x})$ of degree l can be understood from another viewpoint. After removing those homogeneous polynomials in the form $r^2 f(\mathbf{x})$, where $f(\mathbf{x})$ is a homogeneous polynomial of degree $(l-2)$, Eq. (17) shows the number of the remaining linearly independent homogeneous polynomials of degree l in the components of $\mathbf{x}$. Therefore, the harmonic polynomials $\mathcal{Y}^l_{l_{D-2},\ldots,l_1}(\mathbf{x})$ construct a complete set of linearly independent base functions for the homogeneous polynomials of degree l in the components of $\mathbf{x}$, excluding those in the form of $r^2 f(\mathbf{x})$.

IV. THREE-BODY SYSTEM IN D-DIMENSIONS

For a three-body system, in the center-of-mass frame there are two Jacobi coordinate vectors $\mathbf{R}_1$ and $\mathbf{R}_2$, which will be denoted by $\mathbf{x}$ and $\mathbf{y}$, respectively:

$$\mathbf{x}=\left[\frac{m_1m_2}{m_1+m_2}\right]^{1/2}\{\mathbf{r}_2-\mathbf{r}_1\},\quad \mathbf{y}=\left[\frac{(m_1+m_2)m_3}{m_1+m_2+m_3}\right]^{1/2}\left\{\mathbf{r}_3-\frac{m_1\mathbf{r}_1+m_2\mathbf{r}_2}{m_1+m_2}\right\},$$

$$\nabla^2=\nabla_{\mathbf{x}}^2+\nabla_{\mathbf{y}}^2, \tag{21}$$

$$L_{ab}=L_{ab}^{(x)}+L_{ab}^{(y)}=-i\left\{x_a\frac{\partial}{\partial x_b}-x_b\frac{\partial}{\partial x_a}\right\}-i\left\{y_a\frac{\partial}{\partial y_b}-y_b\frac{\partial}{\partial y_a}\right\},$$

The Schrödinger equation (1) reduces to

$$\{\nabla_{\mathbf{x}}^2+\nabla_{\mathbf{y}}^2\}\Psi(\mathbf{x},\mathbf{y})=-2\{E-V(\xi_1,\xi_2,\xi_3)\}\Psi(\mathbf{x},\mathbf{y}),$$
$$\xi_1=\mathbf{x}\cdot\mathbf{x},\quad \xi_2=\mathbf{y}\cdot\mathbf{y},\quad \xi_3=\mathbf{x}\cdot\mathbf{y}, \tag{22}$$

where ξ_j are the internal variables. Since Eq. (22) is rotational invariant, the total orbital angular momentum is conserved. The wave function $\Psi(\mathbf{x},\mathbf{y})$ with the given total angular momentum has to belong to an irreducible representation of SO(D). In the traditional method, one calculates the wave function by the Clebsch–Gordan coefficients:

$$\sum_{l_{D-2},\ldots,l_1 l'_{D-2},\ldots,l'_1}\mathcal{Y}^{l}_{l_{D-2},\ldots,l_1}(\mathbf{x})\mathcal{Y}^{l'}_{l'_{D-2},\ldots,l'_1}(\mathbf{y})\langle l,l_{D-2},\ldots,l_1;l',l'_{D-2},\ldots,l'_1|L,M\rangle. \tag{23}$$

As usual, $\mathcal{Y}^{l}_{l_{D-2},\ldots,l_1}(\mathbf{x})$ and $\mathcal{Y}^{l'}_{l'_{D-2},\ldots,l'_1}(\mathbf{y})$ are called the partial angular momentum states, and their combination is called the total angular momentum state, which is a homogeneous polynomial of degrees l and l' in the components of $\mathbf{x}$ and $\mathbf{y}$, respectively.

There are three problems. First, what kinds of representations (or total angular momentum L) appear in the Clebsch–Gordan series for decomposition of the direct product of two representations denoted by one-row Young diagrams $[l,0,\ldots,0]$ and $[l',0,\ldots,0]$? This problem has been solved in group theory by the Littlewood–Richardson rule and traceless conditions. A new character is that the representations denoted by two-row Young diagrams appear in the Clebsch–Gordan series for a three-body system when $D>3$. Those representations denoted by the Young diagrams with more than two rows could not appear because there are only two Jacobi coordinate vectors. For simplicity we denote a one-row or two-row Young diagram by $[\mu,\nu]\equiv[\mu,\nu,0,\ldots,0]$. Hence, we have the Clebsch–Gordan series:

$$[l,0]\otimes[l',0]\simeq\bigoplus_{s=0}^{n}\bigoplus_{t=0}^{n-s}[l+l'-s-2t,s], \tag{24}$$

where n is the minimum between l and l'. The representations with $t=0$ are calculated by the Littlewood–Richardson rule, and the remaining are calculated by the traceless conditions. The dimension of a representation denoted by a two-row Young diagram is

$$d_D([\mu,\nu])=(D+2\mu-2)(D+\mu+\nu-3)(D+2\nu-4)(\mu-\nu+1)$$
$$\times\frac{(D+\mu-4)!(D+\nu-5)!}{(\mu+1)!\,\nu!(D-2)!(D-4)!}. \tag{25}$$

When $D=4$, the representation denoted by a two-row Young diagram reduces to a direct sum of a self-dual representation $[(S)\mu,\nu]$ and an anti-self-dual one $[(A)\mu,\nu]$. Their dimensions are equal to half of $d_4([\mu,\nu])$ given in Eq. (25). When $D=3$, due to the traceless condition, the only representations with the two-row Young diagrams are representations $[\mu,1]$, which are equivalent to that with the one-row Young diagrams $[\mu,0]$, respectively. Equation (25) still holds for $D=3$. The second problem is how to calculate the Clebsch–Gordan coefficients. The calculation must be

very complicated. We will avoid the difficulty by the method of determining the highest weight states directly. The third problem is determining how many base functions are independent for a given total orbital angular momentum such that any wave function with the same angular momentum can be expanded with respect to the base functions where the coefficients are the functions of the internal variables. We are going to solve the last two problems by group theory.

Let us sketch some necessary knowledge of group theory. From the representation theory of Lie groups,[36–38] the Lie algebras of the SO$(2n+1)$ group and the SO$(2n)$ group are B_n and D_n, respectively. Their Chevalley bases with the subscript j, $1\leqslant j\leqslant n-1$, are the same:

$$H_j=L_{(2j-1)(2j)}-L_{(2j+1)(2j+2)},$$

$$E_j=(L_{(2j)(2j+1)}-iL_{(2j-1)(2j+1)}-iL_{(2j)(2j+2)}-L_{(2j-1)(2j+2)})/2, \tag{26a}$$

$$F_j=(L_{(2j)(2j+1)}+iL_{(2j-1)(2j+1)}+iL_{(2j)(2j+2)}-L_{(2j-1)(2j+2)})/2.$$

But, the bases with the subscript n are different:

$$H_n=2L_{(2n-1)(2n)},$$

$$E_n=L_{(2n)(2n+1)}-iL_{(2n-1)(2n+1)}, \tag{26b}$$

$$F_n=L_{(2n)(2n+1)}+iL_{(2n-1)(2n+1)}$$

for SO$(2n+1)$, and

$$H_n=L_{(2n-3)(2n-2)}+L_{(2n-1)(2n)},$$

$$E_n=(L_{(2n-2)(2n-1)}-iL_{(2n-3)(2n-1)}+iL_{(2n-2)(2n)}+L_{(2n-3)(2n)})/2, \tag{26c}$$

$$F_n=(L_{(2n-2)(2n-1)}+iL_{(2n-3)(2n-1)}-iL_{(2n-2)(2n)}+L_{(2n-3)(2n)})/2$$

for SO$(2n)$. H_k span the Cartan subalgebra, and their eigenvalues are the components of a weight vector $\mathbf{m}=(m_1,\ldots,m_n)$:

$$H_k|\mathbf{m}\rangle=m_k|\mathbf{m}\rangle, \quad 1\leqslant k\leqslant n. \tag{27}$$

If the eigenstates for a given weight $\mathbf{m}$ are degeneracy, this weight is called a multiple weight, otherwise a simple one. E_k are called the raising operators and F_k the lowering ones. For an irreducible representation denoted by a Young diagram $[\mu_1,\mu_2,\ldots]$ of SO(D), $\mu_j\geqslant\mu_{j+1}$, there is a highest weight $\mathbf{M}=(M_1,M_2,\ldots)$, which must be simple:

$$M_j=\mu_j-\mu_{j+1}, \quad 1\leqslant j\leqslant n-2,$$

$$M_{n-1}=\mu_{n-1}-\mu_n, \quad M_n=2\mu_n, \text{ for SO}(2n+1),$$

$$M_{n-1}=\mu_{n-1}-\mu_n, \quad M_n=\mu_{n-1}+\mu_n, \quad \text{for self-dual representation in SO}(2n),$$

$$M_{n-1}=\mu_{n-1}+\mu_n, \quad M_n=\mu_{n-1}-\mu_n, \quad \text{for anti-self-dual representation in SO}(2n). \tag{28}$$

Here we are not interested in the spinor representations where M_n is odd for SO$(2n+1)$ and $M_{n-1}+M_n$ is odd for SO$(2n)$. For a given irreducible representation $[\mu_1,\mu_2,\ldots]$ of SO(D), we only need to consider the highest weight state $|\mathbf{M}\rangle$, which satisfies

$$H_k|\mathbf{M}\rangle = M_k|\mathbf{M}\rangle, \quad E_k|\mathbf{M}\rangle = 0, \quad 1 \leqslant k \leqslant n, \tag{29}$$

because its partners can be calculated by the lowering operators F_k. In this paper the highest weight state will simply be called the wave functions with the given angular momentum $[\mu,\nu]$ for simplicity.

Now, we return to our problems. Recalling the Clebsch–Gordan series in Eq. (24), we can rewrite Eq. (23) for the highest weight state $\mathbf{M}$:

$$\mathcal{Y}^{l,l',s,t}_{\mathbf{M}}(\mathbf{x},\mathbf{y}) = \sum_{\mathbf{m}} \mathcal{Y}^{l}_{\mathbf{m}}(\mathbf{x})\mathcal{Y}^{l'}_{\mathbf{M}-\mathbf{m}}(\mathbf{y})\langle l,\mathbf{m},l',(\mathbf{M}-\mathbf{m})|[(l+l'-s-2t),s],\mathbf{M}\rangle, \tag{30}$$

where the subscripts of the harmonic polynomials are changed to the weights for simplicity. $\mathcal{Y}^{l,l',s,t}_{\mathbf{M}}(\mathbf{x},\mathbf{y})$ is the highest weight state of the representation $[(l+l'-s-2t),s]$. It is a homogeneous polynomial of degrees l and l' in the components of $\mathbf{x}$ and $\mathbf{y}$, respectively. Generally speaking, some $\mathcal{Y}^{l,l',s,t}_{\mathbf{M}}(\mathbf{x},\mathbf{y})$ may be expressed as a sum where each term is a product of an internal variable ξ_j and a homogeneous polynomial $f(\mathbf{x},\mathbf{y})$ of lower degree (see p. 042108-5 in Ref. 29). Since $\mathcal{Y}^{l,l',s,t}_{\mathbf{M}}(\mathbf{x},\mathbf{y})$ will be used as a base function for the wave function with a given angular momentum and the combinative coefficient is the function of the internal variables, in this meaning, the base function in the form of $\xi_j f(\mathbf{x},\mathbf{y})$ is not independent, and we should find out the independent and complete base functions for any given angular momentum $[\mu,\nu]$. In the following we are going to prove $\mathcal{Y}^{q,(\mu+\nu-q),\nu,0}_{\mathbf{M}}(\mathbf{x},\mathbf{y})$ and their partners, where $l=q$, $l'=\mu+\nu-q$, $s=\nu$, $t=0$, and $\nu \leqslant q \leqslant \mu$, constitute a complete set of independent base functions for the total orbital angular momentum $[\mu,\nu]$. In other words, those total angular momentum states $\mathcal{Y}^{l,l',s,t}_{\mathbf{M}}(\mathbf{x},\mathbf{y})$ with $t>0$ are not independent, where the sum of the partial angular momentum quantum number l and l' is larger than $\mu+\nu$ for the total angular momentum $[\mu,\nu]$.

The highest weight for the representation $[\mu,\nu]$ is $\mathbf{M}=(\mu-\nu,\nu,0,\ldots,0)$. Removing the normalization factor in $\mathcal{Y}^{q,(\mu+\nu-q),\nu,0}_{\mathbf{M}}(\mathbf{x},\mathbf{y})$, which is irrelevant here, we can determine the explicit form for $\mathcal{Y}^{q,(\mu+\nu-q),\nu,0}_{\mathbf{M}}(\mathbf{x},\mathbf{y})$ according to its orders in the components of $\mathbf{x}$ and $\mathbf{y}$ and the property of the highest weight state (29), and denote it by the generalized harmonic polynomial $Q^{\mu\nu}_q(\mathbf{x},\mathbf{y})$:

$$Q^{\mu\nu}_q(\mathbf{x},\mathbf{y}) = \frac{X_{12}^{q-\nu}Y_{12}^{\mu-q}}{(q-\nu)!(\mu-q)!}(X_{12}Y_{34}-Y_{12}X_{34})^{\nu} \sim \mathcal{Y}^{q,(\mu+\nu-q),\nu,0}_{\mathbf{M}}(\mathbf{x},\mathbf{y}), \quad 0 \leqslant \nu \leqslant q \leqslant \mu,$$
$$X_{12}=x_1+ix_2, \quad X_{34}=x_3+ix_4, \quad Y_{12}=y_1+iy_2, \quad Y_{34}=y_3+iy_4. \tag{31}$$

The formula for $Q^{\mu\nu}_q(\mathbf{x},\mathbf{y})$ holds for $D=3$ ($x_4=y_4=0$, $\nu=0$ or 1)[35,29] and $D>4$. When $D=4$ we denote the highest weight states by $Q^{(S)\mu\nu}_q(\mathbf{x},\mathbf{y})$ and $Q^{(A)\mu\nu}_q(\mathbf{x},\mathbf{y})$ for the self-dual representations and the anti-self-dual representations, respectively:

$$Q^{(S)\mu\nu}_q(\mathbf{x},\mathbf{y}) = \frac{X_{12}^{q-\nu}Y_{12}^{\mu-q}}{(q-\nu)!(\mu-q)!}(X_{12}Y_{34}-Y_{12}X_{34})^{\nu},$$

$$Q^{(A)\mu\nu}_q(\mathbf{x},\mathbf{y}) = \frac{X_{12}^{q-\nu}Y_{12}^{\mu-q}}{(q-\nu)!(\mu-q)!}(X_{12}Y'_{34}-Y_{12}X'_{34})^{\nu}, \tag{32}$$

$$X'_{34}=x_3-ix_4, \quad Y'_{34}=y_3-iy_4.$$

The generalized harmonic polynomial $Q^{\mu\nu}_q(\mathbf{x},\mathbf{y})$ is a homogeneous polynomial of degrees q and $(\mu+\nu-q)$ in the components of $\mathbf{x}$ and $\mathbf{y}$, respectively. It is a simultaneous eigenfunction of $\nabla^2_{\mathbf{x}}$, $\nabla^2_{\mathbf{y}}$, $\nabla_{\mathbf{x}}\cdot\nabla_{\mathbf{y}}$, and the total angular momentum operator $\mathbf{L}^2$ [see Eq. (9)],

$$\nabla_{\mathbf{x}}^2 Q_q^{\mu\nu}(\mathbf{x},\mathbf{y}) = \nabla_{\mathbf{y}}^2 Q_q^{\mu\nu}(\mathbf{x},\mathbf{y}) = \nabla_{\mathbf{x}} \cdot \nabla_{\mathbf{y}} Q_q^{\mu\nu}(\mathbf{x},\mathbf{y}) = 0,$$

$$\mathbf{L}^2 Q_q^{\mu\nu}(\mathbf{x},\mathbf{y}) = C_2([\mu,\nu]) Q_q^{\mu\nu}(\mathbf{x},\mathbf{y}), \tag{33}$$

$$C_2([\mu,\nu]) = \mu(\mu+D-2) + \nu(\nu+D-4),$$

where $C_2([\mu,\nu])$ is the Casimir calculated by a general formula [see (1.131) in Ref. 38]. The parity of $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ is obviously $(-1)^{\mu+\nu}$.

It is evident that $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ do not contain a function of the internal variables as a factor, nor do their partners due to the rotational symmetry. Therefore, $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ are independent base functions for the given angular momentum described by $[\mu,\nu]$. Now, we are going to prove that $(\mu-\nu+1)$ base functions $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ where $\nu \leqslant q \leqslant \mu$ are complete for the angular momentum $[\mu,\nu]$. That is, $Q_q^{\mu(l-\mu)}(\mathbf{x},\mathbf{y})$ with $0 \leqslant l-\mu \leqslant q \leqslant \mu$ and their partners construct a complete set of linearly independent base functions for the homogeneous polynomials of degree l in the components of $\mathbf{x}$ and $\mathbf{y}$, excluding those in the forms of $\xi_j f(\mathbf{x},\mathbf{y})$, where $f(\mathbf{x},\mathbf{y})$ is a homogeneous polynomial of degree $(l-2)$.

The number of linearly independent homogeneous polynomials of degree l in the components of $\mathbf{x}$ and $\mathbf{y}$ is

$$M_D(l) = \begin{pmatrix} l+2D-1 \\ 2D-1 \end{pmatrix}.$$

After removing those polynomials in the form $\xi_j f(\mathbf{x},\mathbf{y})$, the number $M(l)$ reduces to $K(l)$:

$$\begin{aligned} K_D(l) &= M_D(l) - 3M_D(l-2) + 3M_D(l-4) - M_D(l-6) \\ &= 4(l+D-3)[2l(l+2D-6) + (D-2)(2D-5)] \frac{(l+2D-7)!}{l!(2D-4)!}, \end{aligned} \tag{34}$$

when $l+2D \geqslant 7$, which only excludes one case of $l=0$ and $D=3$, where $K_3(0)=1$.

On the other hand, the number of $Q_q^{\mu(l-\mu)}(\mathbf{x},\mathbf{y})$ with $0 \leqslant l-\mu \leqslant q \leqslant \mu$ and their partners can be calculated directly from Eq. (25):

$$\sum_{l/2 \leqslant \mu \leqslant l} (2\mu - l + 1) d_D([\mu,(l-\mu)]) = K_D(l). \tag{35}$$

Equations (34) and (35) are checked by MATHEMATICA. Thus, we have proved that $(\mu-\nu+1)$ base functions $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ where $0 \leqslant \nu \leqslant q \leqslant \mu$ are independent and complete for the angular momentum $[\mu,\nu]$. Any function with the angular momentum $[\mu,\nu]$ in the system can be expanded with respect to the base functions $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$, where the coefficients are functions of internal variables.

From Eq. (30), for a given total orbital angular momentum $[\mu,\nu]$ there are infinite number of wave functions $\mathcal{Y}_{\mathbf{M}}^{(q+t),(\mu+\nu+t-q),\nu,t}(\mathbf{x},\mathbf{y})$ combined from different partial angular momentum states. Now, what we have proved is that only a finite number of partial angular momentum states $(t=0)$ are involved in the complete set of independent base functions $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ for a given total orbital angular momentum $[\mu,\nu]$.

V. GENERALIZED RADIAL EQUATIONS

In Sec. IV we proved that any function with angular momentum $[\mu,\nu]$ in the quantum three-body system of D dimensions can be expanded with respect to the base functions $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$,

$$\Psi_{\mathbf{M}}^{[\mu,\nu]}(\mathbf{x},\mathbf{y}) = \sum_{q=\nu}^{\mu} \psi_q^{\mu\nu}(\xi_1,\xi_2,\xi_3) Q_q^{\mu\nu}(\mathbf{x},\mathbf{y}), \tag{36}$$

where the coefficients $\psi_q^{\mu\nu}(\xi_1,\xi_2,\xi_3)$ are called the generalized radial functions. When substituting Eq. (36) into the Schrödinger equation (22), the main calculation in the derivation is to apply the Laplace operator (21) to the function $\Psi_{\mathbf{M}}^{[\mu,\nu]}(\mathbf{x},\mathbf{y})$. The calculation consists of three parts. The first is to apply the Laplace operator to the generalized radial functions $\psi_q^{\mu\nu}(\xi_1,\xi_2,\xi_3)$, which can be calculated by replacement of variables:

$$\nabla^2\psi_q^{\mu\nu}(\xi_1,\xi_2,\xi_3)=\{4\xi_1\partial_{\xi_1}^2+4\xi_2\partial_{\xi_2}^2+2D(\partial_{\xi_1}+\partial_{\xi_2})+(\xi_1+\xi_2)\partial_{\xi_3}^2 +4\xi_3(\partial_{\xi_1}+\partial_{\xi_2})\partial_{\xi_3}\}\psi_q^{\mu\nu}(\xi_1,\xi_2,\xi_3), \tag{37}$$

where ∂_ξ denotes $\partial/\partial\xi$ and so on. The second is to apply it to the generalized harmonic polynomials $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$. This part is vanishing because $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ satisfies the Laplace equation. The last part is the mixed application

$$2\{(\partial_{\xi_1}\psi_q^{\mu\nu})2\mathbf{x}+(\partial_{\xi_3}\psi_q^{\mu\nu})\mathbf{y}\}\cdot\nabla_{\mathbf{x}}Q_q^{\mu\nu}+2\{(\partial_{\xi_2}\psi_q^{\mu\nu})2\mathbf{y}+(\partial_{\xi_3}\psi_q^{\mu\nu})\mathbf{x}\}\cdot\nabla_{\mathbf{y}}Q_q^{\mu\nu}. \tag{38}$$

From the definition (31) for $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ we have

$$\begin{gathered}\mathbf{x}\cdot\nabla_{\mathbf{x}}Q_q^{\mu\nu}=qQ_q^{\mu\nu},\quad \mathbf{y}\cdot\nabla_{\mathbf{y}}Q_q^{\mu\nu}=(\mu+\nu-q)Q_q^{\mu\nu}\\ \mathbf{y}\cdot\nabla_{\mathbf{x}}Q_q^{\mu\nu}=(\mu-q+1)Q_{q-1}^{\mu\nu},\quad \mathbf{x}\cdot\nabla_{\mathbf{y}}Q_q^{\mu\nu}=(q-\nu+1)Q_{q+1}^{\mu\nu}.\end{gathered} \tag{39}$$

Hence, we obtain the generalized radial equation, satisfied by the $(\mu-\nu+1)$ functions $\psi_q^{\mu\nu}(\xi_1,\xi_2,\xi_3)$:

$$\begin{aligned}&\nabla^2\psi_q^{\mu\nu}+4q\partial_{\xi_1}\psi_q^{\mu\nu}+4(\mu+\nu-q)\partial_{\xi_2}\psi_q^{\mu\nu}+2(\mu-q)\partial_{\xi_3}\psi_{q+1}^{\mu\nu}+2(q-\nu)\partial_{\xi_3}\psi_{q-1}^{\mu\nu}\\ &\quad=-2(E-V)\psi_q^{\mu\nu},\end{aligned} \tag{40}$$

where $\nabla^2\psi_q^{\mu\nu}$ is given in Eq. (37). Only three invariant variables ξ_1, ξ_2, and ξ_3 are involved both in the equations and in the functions. When $D=4$, Eq. (40) holds for the generalized radial functions either in $[(S)\mu,\nu]$ or in $[(A)\mu,\nu]$, because two representations incorporate to one irreducible representation of the O(4) group when the space inversion is considered. When $D=3$, the equations for the functions in $[\mu,0]$ and in $[\mu,1]$ are different although two representations $[\mu,0]$ and $[\mu,1]$ are equivalent, because the functions have different parity.

At last, we discuss rotational variables and the volume element of the configuration space. We fix the body-fixed frame such that $\mathbf{x}$ is parallel with its Dth axis, and $\mathbf{y}$ is located in its $(D-1)D$ hyperplane with a non-negative $(D-1)$th component. That is, in the body-fixed frame, the nonvanishing components of two Jacobi coordinate vectors $\mathbf{x}'$ and $\mathbf{y}'$ are

$$x_D'=\xi_1^{1/2},\quad y_{D-1}'=(\xi_2-\xi_3^2/\xi_1)^{1/2},\quad y_D'=\xi_3\xi_1^{-1/2}. \tag{41}$$

Let $R=R^{(1)}R^{(2)}\in\mathrm{SO}(D)$ rotate the center-of-mass frame to the body-fixed frame:

$$\begin{gathered}R^{(1)}=R_{12}(\theta_1)R_{31}(\theta_2)R_{43}(\theta_3)R_{54}(\theta_4)\cdots R_{D(D-1)}(\theta_{D-1}),\\ R^{(2)}=R_{12}(\varphi_1)R_{31}(\varphi_2)R_{43}(\varphi_3)R_{54}(\varphi_4)\cdots R_{(D-1)(D-2)}(\varphi_{D-2}),\\ R\mathbf{x}'=\mathbf{x},\quad R\mathbf{y}'=\mathbf{y},\end{gathered} \tag{42}$$

where, for example, $R_{12}(\theta)$ is a rotation on the hyperplane with the first and the second axes through θ angle:

$$R_{12}(\theta)=\begin{pmatrix}\cos\theta & -\sin\theta & 0\\ \sin\theta & \cos\theta & 0\\ 0 & 0 & \mathbf{1}_{D-2}\end{pmatrix}.$$

$(D-1)\,\theta_j$ and $(D-2)\,\varphi_k$ are the rotational variables, called the generalized Euler angles. Through a straightforward calculation, we obtain

$$x_1+ix_2=\xi_1^{1/2}e^{i\theta_1}\prod_{a=2}^{D-1}\sin\theta_a,\quad x_3+ix_4=\xi_1^{1/2}(\cos\theta_2\sin\theta_3+i\cos\theta_3)\prod_{a=4}^{D-1}\sin\theta_a,$$

$$y_1+iy_2=\xi_3\xi_1^{-1/2}e^{i\theta_1}\prod_{a=2}^{D-1}\sin\theta_a+(\xi_2-\xi_3^2/\xi_1)^{1/2}e^{i\theta_1}\Bigg\{i\prod_{a=1}^{D-2}\sin\varphi_a+\sum_{a=1}^{D-2}\cos\theta_{a+1}\cos\varphi_a\Bigg(\prod_{b=2}^{a}\sin\theta_b\Bigg)\Bigg(\prod_{c=a+1}^{D-2}\sin\varphi_c\Bigg)\Bigg\},\tag{43}$$

$$y_3+iy_4=\xi_3\xi_1^{-1/2}(\cos\theta_2\sin\theta_3+i\cos\theta_3)\prod_{a=4}^{D-1}\sin\theta_a+(\xi_2-\xi_3^2/\xi_1)^{1/2}$$
$$\times\Bigg\{-\cos\varphi_1\sin\theta_2\prod_{a=2}^{D-2}\sin\varphi_a+(\cos\theta_2\cos\theta_3-i\sin\theta_3)\cos\varphi_2\prod_{a=3}^{D-2}\sin\varphi_a$$
$$+(\cos\theta_2\sin\theta_3+i\cos\theta_3)\sum_{a=3}^{D-2}\cos\theta_{a+1}\cos\varphi_a\Bigg(\prod_{b=4}^{a}\sin\theta_b\Bigg)\Bigg(\prod_{c=a+1}^{D-2}\sin\varphi_c\Bigg)\Bigg\},$$

where $\Pi_{a=b+1}^{b}F_a=1$. The volume element of the configuration space is

$$\prod_{j=1}^{D}\mathrm{d}x_j\mathrm{d}y_j=\frac{1}{4}(\xi_1\xi_2-\xi_3^2)^{(D-3)/2}\mathrm{d}\xi_1\mathrm{d}\xi_2\mathrm{d}\xi_3\prod_{j=1}^{D-1}(\sin\theta_j)^{j-1}\mathrm{d}\theta_j\prod_{k=1}^{D-2}(\sin\varphi_k)^{k-1}\mathrm{d}\varphi_k.\tag{44}$$

VI. CONCLUSIONS

After separating the motion of center of mass, we have defined the homogeneous polynomial $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ of degree q and $(\mu+\nu-q)$ in the components of the Jacobi coordinate vectors $\mathbf{x}$ and $\mathbf{y}$, respectively. $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ is a solution of the Laplace equation. We have proved that $(\mu-\nu+1)$ generalized harmonic polynomials $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$ constitute a complete set of independent base functions for the total orbital angular momentum $[\mu,\nu]$. Any wave function with the given angular momentum in the system can be expanded with respect to the base functions, where the coefficients are the functions of the internal variables, called the generalized radial functions. The three-body Schrödinger equation with a spherically symmetric potential V in D dimensions reduces to the generalized radial equations satisfied by the generalized radial functions. Only three internal variables are involved in the functions and equations. The number of both the functions and the equations for the given angular momentum $[\mu,\nu]$ is finite and equal to $(\mu-\nu+1)$. Only a finite number of partial angular momentum states are involved in constructing the generalized harmonic polynomials $Q_q^{\mu\nu}(\mathbf{x},\mathbf{y})$, and the contributions from the remaining partial angular momentum states have been incorporated into those from the generalized radial functions.

The generalization of this method to a quantum N-body system in D-dimensions is straightforward. The difficulty is how to obtain the unified forms for the generalized harmonic polynomials, because it needs $D-1$ vectors to determine the body-fixed frame and there are $N-1$ Jacobi coordinate vectors. The cases with $N<D$ are very different from the cases with $N\geqslant D$. We will study this problem elsewhere.

The reduction of a quantum system of three identical particles on a plane

Toshihiro Iwai[a] and Toru Hirose
Department of Applied Mathematics and Physics, Kyoto University, Kyoto 606-8501, Japan

(Received 12 October 2001; accepted for publication 25 February 2002)

Quantum systems of three identical particles on a plane are analyzed from the viewpoint of symmetry. Upon reduction by rotation, such systems are described in the space of sections of a line bundle over a three-dimensional shape space whose origin represents triple collision. It is shown that if the total angular momentum is nonzero, then the wave section must vanish at the origin, while if it is zero, then the wave section can be finite at the origin. Since the particles are assumed to be identical, the quantum system admits the action of the symmetric group S_3 as well, which stands for the group of particle exchanges and is commutative with rotation. Hence the reduced system still admits the S_3 action, so that Bose and Fermi states can be discussed in the space of sections of the line bundle. A detailed analysis of a system of three free particles on a plane is presented in the latter part of the article. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1473872]

I. INTRODUCTION

This article deals with quantum mechanics on the center-of-mass system of three identical particles on a plane, which has manifestly two kinds of symmetries: They are rotation of all particles about the origin and particle exchanges. As is well recognized, symmetry is closely associated with the reduction of dynamical systems. One of the authors (T.I.) has already studied the reduction of quantum planar three-body systems by the use of rotational symmetry.[1] As for the reduction of multiparticle systems with rotational symmetry, a point to make is the fact that the center-of-mass system is made into a principal fiber bundle with the rotation group as structure group, if the center-of-mass system is restricted to a subspace on which the rotation group acts freely. This fact was first proved by Guichardet.[2] On the basis of this bundle picture, a gauge theoretical treatment becomes feasible for multiparticle systems. After Ref. 2, a number of articles[3–8] were published by T.I. for analyzing multiparticle systems in a gauge theoretical manner. The reduction method for multiparticle systems with rotational symmetry has been extended in a rather abstract way by the use of the Peter–Weyl theorem on unitary irreducible representations of compact Lie groups.[9] From a physical point of view, an original article[10] and a review article[11] are of great help for the gauge theoretical treatment of multiparticle systems. The gauge theoretical treatment has been given to deformable bodies as well.[12–14]

As is already known,[1] if the triple collision of particles is excluded, the center-of-mass system for planar three bodies is diffeomorphic with $\dot{\mathrm{R}}^4$ and made into a principal fiber bundle $\dot{\mathrm{R}}^4 \to \dot{\mathrm{R}}^3$ with structure group SO(2), where SO(2) stands for the rotational symmetry whose action is to the left, and the dot symbol indicates that the origin is removed from the space in question. Further, if all the particles are identical, it will be found that the symmetric group S_3, which stands for the symmetry of three-particle exchanges, also acts on the center-of-mass system. This action is to the right and will be shown to be expressed in terms of matrices representing the group S_3. Since the right and left actions commute, the action of S_3 will project to the factor space $\dot{\mathrm{R}}^3 \cong \dot{\mathrm{R}}^4/\mathrm{SO}(2)$. In

[a]Electronic mail: iwai@amp.i.kyoto-u.ac.jp

what follows, when the whole center-of-mass system is considered, the triple collision is taken into account.

On the basis of the symmetry of rotation and particle exchanges, the space of wave functions on R^4 is broken up into a series of subspaces that are interpreted as eigenspaces associated with both SO(2) and S_3, and the time evolution of the original quantum system on R^4 induces respective time evolutions in the subspaces, accordingly. The reduction to subsystems is thus accomplished. These subsystems will be identified with reduced systems to be defined on $\dot{\mathrm{R}}^3 \cong \dot{\mathrm{R}}^4/\mathrm{SO}(2)$ along with boundary conditions at the origin. While the theory should apply to a system containing any number of particles, and of course can do in three dimensions, too, we have chosen $n=3$ for the number of particles to present the idea in a simple form.

The organization of this paper is as follows: Section II contains a review of the center-of-mass system and of Jacobi vectors. Section III is a review of the principal bundle $\dot{\mathrm{R}}^4 \to \dot{\mathrm{R}}^3$ with structure group SO(2). A connection form defined on $\dot{\mathrm{R}}^4$ and a metric defined on $\dot{\mathrm{R}}^3$ will also be reviewed, and thereby the distance function with respect to that metric on $\dot{\mathrm{R}}^3$ will be discussed. In Sec. IV, the action of the symmetric group S_3 on the center-of-mass system is represented explicitly in terms of matrices. Since the action of SO(2) and of S_3 commute, the action of S_3 on the center-of-mass system $\dot{\mathrm{R}}^4$ projects to $\dot{\mathrm{R}}^3$, which is given explicitly in Sec. V. In Sec. VI, the L^2 space of wave functions on the center-of-mass system R^4 is decomposed into the sum of spaces of ''equivariant'' functions with respect to the SO(2) action on R^4. If a quantum system is SO(2) invariant, the time evolution in the L^2 space is reduced to that in the space of equivariant functions, accordingly. In Sec. VII, interest will center on what will actually happen at the origin, the boundary of $\dot{\mathrm{R}}^4$, if the triple collision is taken into account. Boundary conditions for wave functions at the origin of R^4 are to be considered by the use of the equivariance condition. It will be shown that according to whether the total angular momentum is nonzero or zero, the wave function vanishes at the origin or takes a finite value there. In Sec. VIII, the symmetry of particle exchanges are discussed in the space of wave functions on the center-of-mass system. The Bose and Fermi states are characterized by the respective representations of the permutation group S_3 acting on the center-of-mass system. Since the action of SO(2) and of S_3 commute, both the Bose and Fermi states can be constructed in the space of equivariant functions. Thus the reduction to subsystems is accomplished by the use of the symmetry of rotation and particle exchanges. Section IX deals with complex line bundles associated with the principal bundle $\dot{\mathrm{R}}^4 \to \dot{\mathrm{R}}^3$. It is shown that the spaces of equivariant functions described in Sec. VI are in one-to-one correspondence with the spaces of ''sections'' in those complex line bundles with boundary conditions at the origin of R^3. Since the action of SO(2) and of S_3 commute, it further turns out that the subsystems studied in Sec. VIII are indeed equivalent to quantum systems defined in the space of sections with the boundary condition at the origin along with the restriction to the Bose or Fermi state. In Sec. X, the reduction procedure is applied to a system of free identical particles on a plane. The time evolution of the system reduces to the time evolution in the space of equivariant functions, which is expressed in the form of integral transform, and further Bose and Fermi states are formed according to the procedure developed in Sec. VIII. Section XI contains a local expression of the boundary conditions studied in Sec. VII, and also deals with a local expression of the integral transform obtained in Sec. X, to show explicitly how the reduction is accomplished indeed. Section XII contains remarks on applications to electrons on a plane.

II. THE CONFIGURATION SPACE

Suppose there are three particles on a plane, each with position vectors $\mathbf{x}_j$, $j=1,2,3$, and masses m_j, $j=1,2,3$, respectively. The set of all possible particle positions, X, is identified with $\mathrm{R}^{2\times 3}$, which consists of ordered triples of position vectors $(\mathbf{x}_1,\mathbf{x}_2,\mathbf{x}_3)$.

Given the space X, one can consider two fundamental motions traced by the particles, one of which is translation and the other rotation. The space X is endowed with the inner product $K:X \times X \to \mathrm{R}$ which is defined by

$$K(x,y)=\sum_{j=1}^{3} m_j(\mathbf{x}_j,\mathbf{y}_j), \quad x=(\mathbf{x}_1,\mathbf{x}_2,\mathbf{x}_3), \quad y=(\mathbf{y}_1,\mathbf{y}_2,\mathbf{y}_3)\in X, \tag{1}$$

where $(\mathbf{x},\mathbf{y})$ denotes the standard inner product on R^2.

Getting rid of translational degrees of freedom, we shall focus on the center-of-mass system, which is defined by

$$X_0=\left\{(\mathbf{x}_1,\mathbf{x}_2,\mathbf{x}_3)\in X\left|\sum_{j=1}^{3} m_j\mathbf{x}_j=0\right.\right\}. \tag{2}$$

From Ref. 1, we find that X_0 has the following orthonormal basis with respect to the metric K:

$$\begin{aligned} f_1&=N_1(-m_2\mathbf{e}_1,m_1\mathbf{e}_1,0),\\ f_2&=N_1(-m_2\mathbf{e}_2,m_1\mathbf{e}_2,0),\\ f_3&=N_2(-m_3\mathbf{e}_1,-m_3\mathbf{e}_1,(m_1+m_2)\mathbf{e}_1),\\ f_4&=N_2(-m_3\mathbf{e}_2,-m_3\mathbf{e}_2,(m_1+m_2)\mathbf{e}_2), \end{aligned} \tag{3}$$

where N_j are the normalizing factors explicitly given by

$$\begin{aligned} N_1&=(m_1m_2(m_1+m_2))^{-1/2},\\ N_2&=(m_3(m_1+m_2)(m_1+m_2+m_3))^{-1/2}. \end{aligned} \tag{4}$$

With respect to $f_j, j=1,\ldots,4$, any $x\in X_0$ is represented as

$$x=\sum_{j=1}^{4} q_jf_j, \quad q_j=K(x,f_j). \tag{5}$$

These coefficients q_j serve as the Cartesian coordinates in X_0.

The space X_0 is isomorphic to R^4 and also to $\mathrm{R}^2\times\mathrm{R}^2$, the set of pair of vectors in R^2. We define the pair of two vectors as follows:

$$\begin{aligned} \mathbf{r}_1&=q_1\mathbf{e}_1+q_2\mathbf{e}_2=\sqrt{\frac{m_1m_2}{m_1+m_2}}(\mathbf{x}_2-\mathbf{x}_1),\\ \mathbf{r}_2&=q_3\mathbf{e}_1+q_4\mathbf{e}_2=\sqrt{\frac{m_3(m_1+m_2)}{m_1+m_2+m_3}}\left(\mathbf{x}_3-\frac{m_1\mathbf{x}_1+m_2\mathbf{x}_2}{m_1+m_2}\right). \end{aligned} \tag{6}$$

The vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ are called the Jacobi vectors, which will be effectively used in dealing with particle exchanges. Figure 1 illustrates the visual view of the Jacobi vectors, but the arrow lengths are not drawn to scale.

Both the orthonormal basis $\{f_j\}_{j=1,\ldots,4}$ and the Jacobi vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ are easily generalized for a planar n-body system,[5] and for a spatial n-body system[3,9] as well.

III. THE INTERNAL SPACE

Having removed the translational degrees of freedom in Sec. II, we now consider in this section the symmetry due to the rotation,

$$x=(\mathbf{x}_1,\mathbf{x}_2,\mathbf{x}_3)\mapsto gx=(g\mathbf{x}_1,g\mathbf{x}_2,g\mathbf{x}_3), \quad g\in \mathrm{SO}(2), \quad x\in X_0. \tag{7}$$

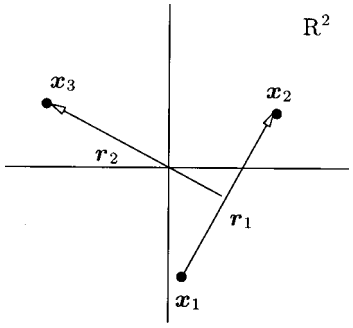

FIG. 1. Illustrating the Jacobi vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ as seen in Eq. (6). $\mathbf{r}_1$ points along the line joining particles 1 and 2, while $\mathbf{r}_2$ points along the line joining particles 3 and the center-of-mass of particles 1 and 2. Note that the arrow lengths are *not* drawn to scale.

For a while, we forget the case where all particles collide at the origin, and consider the configuration space $\dot{X}_0 := X_0 - \{0\}$. Then the SO(2) action becomes free. Further, the SO(2) action defines an equivalence relation on $\dot{X}_0$, and gives rise to a quotient space $\dot{X}/\mathrm{SO}(2)$. We denote by π the natural projection from $\dot{X}_0$ to the quotient space,

$$\pi: \dot{X}_0 \to M := \dot{X}_0/\mathrm{SO}(2), \quad \pi(x) = [x], \quad x \in \dot{X}_0, \tag{8}$$

where $[x]$ denotes the equivalence class of x. The space M turns out to be a manifold which we shall call the internal or the shape space. Thus $\dot{X}_0$ is made into a fiber bundle with structure group SO(2).[1]

To elaborate the discussion, we give the explicit form of the projection (8). Let $q = (q_1, q_2, q_3, q_4)$ denote points of space $\dot{X}_0$, just as was defined in (5). We notice that $X_0 \cong \mathrm{R}^4$ is identified with C^2 by introducing the complex variables z_1, z_2 through

$$z_1 = q_1 + iq_2, \quad z_2 = q_3 + iq_4, \quad i = \sqrt{-1}. \tag{9}$$

On account of $g = \left(\begin{smallmatrix} \cos t & -\sin t \\ \sin t & \cos t \end{smallmatrix}\right)$, the SO(2) action on C^2 turns out to be expressed as

$$z = (z_1, z_2) \mapsto (e^{it} z_1, e^{it} z_2) = e^{it} z. \tag{10}$$

With the identification $X_0 \cong \mathrm{C}^2$, the natural projection π is realized as

$$\pi: (z_1, z_2) \mapsto (\xi_1, \xi_2, \xi_3), \tag{11}$$

where

$$\xi_1 + i\xi_2 = 2z_1\overline{z_2}, \quad \xi_3 = |z_1|^2 - |z_2|^2. \tag{12}$$

Note here that

$$\sqrt{\sum_{k=1}^{3} \xi_k^2} = \sum_{j=1}^{4} q_j^2 . \tag{13}$$

It can be verified that the shape space M is diffeomorphic with $\dot{\mathrm{R}}^3 := \mathrm{R}^3 - \{0\}$;[1]

$$M := \dot{X}_0/\mathrm{SO}(2) \cong \dot{\mathrm{R}}^3. \tag{14}$$

Thus the rotational degree of freedom is removed to provide the shape space M.

In the remainder of this section, we make a review of the connection defined on the SO(2) bundle $\dot{X}_0 \to M$ and of the metric defined on M. A one-form ω defined to be

$$\omega = \frac{1}{\Sigma_{j=1}^{4} q_j^2}(-q_2 dq_1 + q_1 dq_2 - q_4 dq_3 + q_3 dq_4) \tag{15}$$

is called a connection form on the SO(2) bundle $\dot{X}_0 \to M$. The connection form gives rise to a direct sum decomposition of the tangent space $T_x(\dot{X}_0)$ at each point x of $\dot{X}_0$,

$$T_x(\dot{X}_0) = V_x \oplus H_x, \quad H_x := \ker \omega_x, \quad V_x := T_x(\mathcal{O}_x), \tag{16}$$

where ω_x is considered as a linear map from the tangent space $T_x(\dot{X}_0)$ to the Lie algebra $so(2) \cong \mathrm{R}$ of SO(2), and $T_x(\mathcal{O}_x)$ denotes the tangent space at x to the SO(2)-orbit $\mathcal{O}_x$ through $x \in \dot{X}_0$. Note here that the subspaces H_x and V_x are orthogonal to each other with respect to the Euclidean metric K_x on $\dot{X}_0$. Since the subspace H_x is isomorphic, as a vector space, to the tangent space $T_{\pi(x)}(M)$ to M at $\pi(x) = \xi$ through the differential π_* of the projection map π, and since the metric on the center-of-mass system $\dot{X}_0$ is invariant under the SO(2) action, a metric $\tilde{K}$ on M is defined through

$$K_x(U_1, U_2) = \tilde{K}_{\pi(x)}(\pi_* U_1, \pi_* U_2), \quad U_1, U_2 \in H_x. \tag{17}$$

A straightforward calculation shows that $\tilde{K}$ is expressed as

$$\tilde{K} = \frac{1}{4r} \sum_{k=1}^{3} d\xi_k^2, \quad r = \sqrt{\sum_{k=1}^{3} \xi_k^2}. \tag{18}$$

By using the metric $\tilde{K}$, we are to evaluate the distance $d_M(\xi, \xi')$ of two points ξ, ξ' of M, which will be used in Sec. XI. Since $d_M(\xi, \xi')$ is equal to the length of the geodesic joining ξ to ξ', we have to find that geodesic. To this end, we first consider horizontal geodesics in $\dot{X}_0$ with respect to the Euclidean metric, where a curve $c(t)$ in $\dot{X}_0$ is, in general, called horizontal if its tangent vector $\dot{c}(t)$ is horizontal, $\dot{c}(t) \in H_{c(t)}$. We now take $z \in \pi^{-1}(\xi)$ and $w \in \pi^{-1}(\xi')$. The horizontal geodesic in $\dot{X}_0$ which projects to the geodesic in M joining ξ to ξ' should be a horizontal straight line joining $e^{is}z$ to w for a certain real number s,

$$u(t) = w + t(e^{is}z - w), \quad 0 \leqslant t \leqslant 1, \tag{19}$$

where the parameter s is to be determined so that $u(t)$ may be horizontal. By definition, the curve $u(t)$ is horizontal if and only if $\omega(\dot{u}(t)) = 0$. A straightforward calculation along with (15) shows that $\omega(\dot{u}(t)) = 0$ is equivalent to

$$\sum_{k=1}^{2} \left(u_k \frac{d\overline{u_k}}{dt} - \overline{u_k} \frac{du_k}{dt} \right) = -2i \left| \sum_{k=1}^{2} z_k \overline{w_k} \right| \sin(s + \theta) = 0, \tag{20}$$

where θ is the argument of $\Sigma_{k=1}^{2} z_k \overline{w_k}$. Thus, $u(t)$ is horizontal if and only if s is determined so as to satisfy $\sin(s+\theta) = 0$ or $\cos(s+\theta) = \pm 1$. For s thus determined, the horizontal straight line $u(t)$ projects to the geodesic $\pi(u(t))$ joining ξ and ξ'. From the definition of the metric $\tilde{K}$, the length of $u(t)$, $0 \leqslant t \leqslant 1$, with respect to K, is equal to that of $\pi(u(t))$, $0 \leqslant t \leqslant 1$, with respect to $\tilde{K}$. The squared length of the $u(t)$, $0 \leqslant t \leqslant 1$ is now calculated as

$$\sum_{k=1}^{2}|e^{is}z_k-w_k|^2=\sum_{k=1}^{2}|z_k|^2+\sum_{k=1}^{2}|w_k|^2\pm 2\left|\sum_{k=1}^{2}z_k\overline{w_k}\right|. \tag{21}$$

On account of the minimum property of the distance, we must choose the minus sign in Eq. (21). The right-hand side of (21) can be expressed in terms of ξ and ξ', and then provides the squared distance between ξ and ξ',

$$d_M(\xi,\xi')^2=r+r'-\sqrt{2}\sqrt{rr'+\sum_{k=1}^{3}\xi_k\xi'_k}, \tag{22}$$

where

$$r=\sqrt{\sum_{k=1}^{3}\xi_k^2},\quad r'=\sqrt{\sum_{k=1}^{3}\xi_k'^2}. \tag{23}$$

IV. EXCHANGES OF PARTICLES

In Sec. III, we made use of the rotational symmetry to obtain the shape space M. We now turn to another symmetry, the symmetry of configurations arising from exchanges of identical particles. Thus, in this section, we assume that all particles are identical, and without loss of generality put $m_j=1$, $j=1,2,3$. Then the Jacobi vectors defined in Eq. (6) become

$$\begin{aligned}\mathbf{r}_1&=\frac{1}{\sqrt{2}}(\mathbf{x}_2-\mathbf{x}_1),\\ \mathbf{r}_2&=\sqrt{\frac{2}{3}}\left(\mathbf{x}_3-\frac{\mathbf{x}_1+\mathbf{x}_2}{2}\right).\end{aligned} \tag{24}$$

Let S_3 be a symmetric group, the group of permutations of three symbols. If a configuration undergoes the change

$$(\mathbf{x}_1,\mathbf{x}_2,\mathbf{x}_3)\mapsto(\mathbf{x}_{\sigma(1)},\mathbf{x}_{\sigma(2)},\mathbf{x}_{\sigma(3)}),\quad \sigma\in S_3, \tag{25}$$

the Jacobi vectors associated with the new configuration are given by

$$\begin{aligned}\mathbf{r}_1^{\sigma}&=\frac{1}{\sqrt{2}}(\mathbf{x}_{\sigma(2)}-\mathbf{x}_{\sigma(1)}),\\ \mathbf{r}_2^{\sigma}&=\sqrt{\frac{2}{3}}\left(\mathbf{x}_{\sigma(3)}-\frac{\mathbf{x}_{\sigma(1)}+\mathbf{x}_{\sigma(2)}}{2}\right).\end{aligned} \tag{26}$$

The graphical representation of particle exchanges is given in Fig. 2, indicating which transformation takes the reference Jacobi vectors to which pair of new Jacobi vectors. From (26), one soon realizes that any particle exchanges can be represented by a linear transformation of Jacobi vectors $\mathbf{r}_1$ and $\mathbf{r}_2$. This will imply that the center-of-mass system of three identical particles admits the action of S_3 to the right.

We have to note here that since we are dealing with the right action of matrices, the representation of S_3, $\rho:S_3\to GL(2,\mathrm{R})$, must act on X_0 in the following manner:

$$(\mathbf{r}_1,\mathbf{r}_2)\mapsto(\mathbf{r}_1^h,\mathbf{r}_2^h)=(\mathbf{r}_1,\mathbf{r}_2)\rho(h)^{-1},\quad h\in S_3. \tag{27}$$

A straightforward calculation then provides

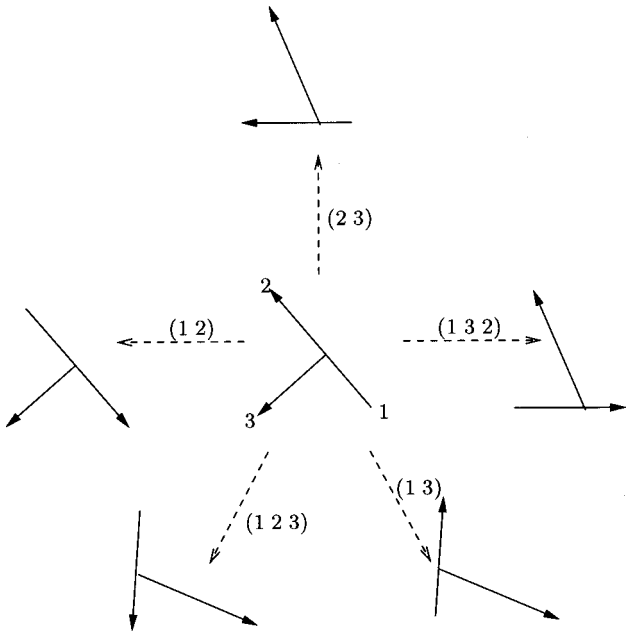

FIG. 2. This diagram represents the graphical view of all possible particle exchanges. Numbers in brackets are the elements of permutations from S_3. By the action of $\sigma \in S_3$, the site occupied by the particle k in the reference configuration gets occupied in turn by the particle $\sigma(k)$.

$$\rho(e)=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},\quad \rho(1\ 2)=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix},$$

$$\rho(1\ 2\ 3)=\begin{pmatrix}-1/2 & \sqrt{3}/2\\ -\sqrt{3}/2 & -1/2\end{pmatrix},\quad \rho(1\ 3\ 2)=\begin{pmatrix}-1/2 & -\sqrt{3}/2\\ \sqrt{3}/2 & -1/2\end{pmatrix}, \tag{28}$$

$$\rho(2\ 3)=\begin{pmatrix}1/2 & \sqrt{3}/2\\ \sqrt{3}/2 & -1/2\end{pmatrix},\quad \rho(1\ 3)=\begin{pmatrix}1/2 & -\sqrt{3}/2\\ -\sqrt{3}/2 & -1/2\end{pmatrix}.$$

It is an easy matter to verify that the matrices in (28) form a discrete subgroup of O(2) which is isomorphic to the symmetric group S_3. It is also well known that the set of the matrices given in (28) forms a unitary irreducible representation of S_3.[15]

So far we have not touched upon collision of particles, or excluded collision configurations from the center-of-mass system X_0. A remarkable point to make on the S_3 action on X_0 is that S_3 acts on the whole space X_0. This means that even if two or three particles collide, where the rank of the 2×2 matrix $(\mathbf{r}_1,\mathbf{r}_2)$ is less than two, Eq. (27) is applicable together with (28).

V. THE ACTION OF S_3 ON M

In Sec. IV, we have observed that the exchanges of identical particles give rise to the action of S_3 on X_0. With the identification $\dot{X}_0 \cong \dot{\mathrm{C}}^2$, the action of S_3 on $\dot{X}_0$ is expressed, like (27), as

$$(z_1,z_2)\mapsto(z_1,z_2)\rho(h)^{-1},\quad h\in S_3. \tag{29}$$

Since the action of SO(2) and of S_3 on X_0 commute, the action of S_3 on M can be defined through

$$[x]\tau(h)^{-1}:=[x\rho(h)^{-1}],\quad x\in\dot{X}_0\cong\dot{\mathrm{C}}^2,\quad h\in S_3, \tag{30}$$

where τ is a homomorphism: $S_3\to\mathrm{GL}(3,\mathrm{R})$, and represented as

$$(\xi_1,\xi_2,\xi_3)\mapsto(\xi_1,\xi_2,\xi_3)\tau(h)^{-1},\quad (\xi_1,\xi_2,\xi_3)\in M,\quad h\in S_3. \tag{31}$$

Note here that the definition (30) is independent of the choice of representatives. A straightforward calculation along with (12), (28), and (30) shows that $\tau(S_3)$ forms a discrete subgroup of SO(3), which is expressed as

$$\tau(e)=\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix},\quad \tau(1\ 2)=\begin{pmatrix}-1&0&0\\0&-1&0\\0&0&1\end{pmatrix},$$

$$\tau(1\ 2\ 3)=\begin{pmatrix}-1/2&0&-\sqrt{3}/2\\0&1&0\\\sqrt{3}/2&0&-1/2\end{pmatrix},\quad \tau(1\ 3\ 2)=\begin{pmatrix}-1/2&0&\sqrt{3}/2\\0&1&0\\-\sqrt{3}/2&0&-1/2\end{pmatrix}, \tag{32}$$

$$\tau(2\ 3)=\begin{pmatrix}1/2&0&\sqrt{3}/2\\0&-1&0\\\sqrt{3}/2&0&-1/2\end{pmatrix},\quad \tau(1\ 3)=\begin{pmatrix}1/2&0&-\sqrt{3}/2\\0&-1&0\\-\sqrt{3}/2&0&-1/2\end{pmatrix}.$$

At first sight, the dimension of matrices presented in (32) is 3×3, which is larger than those presented in (28), resulting in an increase in the number of dimension by one. This seems not to fit the fact that the dimension of M is less than that of $\dot{X}_0$. However, this is not a contradiction. While we have identified X_0 with $\mathrm{R}^{2\times2}$, the set of Jacobi vectors, we are allowed alternatively to identify X_0 with R^4, the set of row vectors of length 4, so that we would have seen a discrete subgroup of GL(4,R) acting on R^4, and would have been able to see an immediate reduction in the size of matrices. In fact, the O(2) action given in (27) proves to take the form

$$(q_1,q_2,q_3,q_4)\mapsto(q_1,q_2,q_3,q_4)\begin{pmatrix}aI_2&bI_2\\cI_2&dI_2\end{pmatrix}^{-1}\qquad\text{for}\quad\rho(h)=\begin{pmatrix}a&b\\c&d\end{pmatrix}, \tag{33}$$

where $h\in S_3$ and I_2 denotes the 2×2 unit matrix. We also see that the determinant of the 4×4 matrix $\left(\begin{smallmatrix}aI_2&bI_2\\cI_2&dI_2\end{smallmatrix}\right)$ is equal to the square of the determinant of the 2×2 matrix $\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)$, so that the S_3 action (33) is represented as a discrete subgroup of SO(4).

VI. REDUCTION BY ROTATIONAL SYMMETRY

In this section, we present the reduction of a quantum system on the center-of-mass system X_0 by rotational symmetry. The reduction procedure runs irrespectively of whether all particles are identical or not. We first need a decomposition of $L^2(\mathrm{C}^2)$ with respect to the SO(2) action. For $f\in L^2(\mathrm{C}^2)$ given, we consider a function $f(e^{is}z)$ with a parameter s, which can be expanded into the Fourier series

$$f(e^{is}z)=\sum_{m=-\infty}^{\infty}f_m(z)e^{ims},\quad f_m(z)=\frac{1}{2\pi}\int_{-\pi}^{\pi}f(e^{is}z)e^{-ims}\,\mathrm{d}s. \tag{34}$$

In particular, for $s=0$, one has

$$f(z)=\sum_{m=-\infty}^{\infty}f_m(z). \tag{35}$$

Note here that the function f_m defined in (34) satisfies $f_m(e^{is}z)=e^{ims}f_m(z)$. In general, a function F on C^2 satisfying the condition

$$F(e^{is}z)=e^{ims}F(z) \tag{36}$$

is called ρ_m-equivariant, where ρ_m denotes a unitary irreducible representation of SO(2) $\cong$U(1); $\rho_m(e^{is})=e^{ims}$ with $m\in\mathrm{Z}$. As is easily seen, the decomposition (35) has remarkable properties,

$$\|f\|^2=\sum_{m=-\infty}^{\infty}\|f_m\|^2, \quad \langle f_n,f_m\rangle=0 \qquad \text{if} \quad n\neq m. \tag{37}$$

Thus $L^2(\mathrm{C}^2)$ is decomposed into the orthogonal direct sum,

$$L^2(\mathrm{C}^2)=\bigoplus_{m=-\infty}^{\infty}L^2_m(\mathrm{C}^2), \tag{38}$$

where each $L^2_m(\mathrm{C}^2)$ is the space of equivariant functions,

$$L^2_m(\mathrm{C}^2)=\{f\in L^2(\mathrm{C}^2)\,|\,f(e^{is}z)=e^{ims}f(z)\}. \tag{39}$$

Suppose we are given a quantum dynamical system on $L^2(\mathrm{C}^2)$, of which the time evolution is expressed as a unitary transformation,

$$\psi_t(z)=\int_{\mathrm{C}^2}G_t(z,w)\psi_{t_0}(w)\mathrm{d}w, \tag{40}$$

where $G_t(z,w)$ is a Green's function. Moreover, we assume that this quantum system is U(1) invariant, so that $G_t(z,w)$ is required to be U(1) invariant,

$$G_t(e^{is}z,e^{is}w)=G_t(z,w). \tag{41}$$

Our task in the following is to decompose the time evolution (40) in $L^2(\mathrm{C}^2)$ into a series of those in respective subspaces $L^2_m(\mathrm{C}^2)$. This process will be called the reduction of the quantum system for simplicity. We will see later how the time evolution in $L^2_m(\mathrm{C}^2)$ is looked upon as the time evolution of a state on the internal space M. Since the Lebesgue measure $\mathrm{d}w$ on C^2 is invariant under the U(1) action, and since $\psi_{t_0}(e^{is}w)$ can be expanded into a Fourier series $\Sigma\psi^m_{t_0}(w)e^{ims}$, the time evolution (40) can be decomposed into the following series:

$$\begin{aligned}\psi_t(z)&=\frac{1}{2\pi}\int_{-\pi}^{\pi}\mathrm{d}s\int_{\mathrm{C}^2}G_t(z,w)\psi_{t_0}(w)\mathrm{d}w\\&=\frac{1}{2\pi}\int_{-\pi}^{\pi}\mathrm{d}s\int_{\mathrm{C}^2}G_t(z,e^{-is}w)\psi_{t_0}(e^{-is}w)\mathrm{d}w\\&=\sum_{m=-\infty}^{\infty}\int_{\mathrm{C}^2}G^m_t(z,w)\psi^m_{t_0}(w)\mathrm{d}w,\end{aligned} \tag{42}$$

where

$$G^m_t(z,w):=\frac{1}{2\pi}\int_{-\pi}^{\pi}G_t(e^{is}z,w)e^{-ims}\,\mathrm{d}s, \tag{43}$$

and we have assumed that the order of integration and summation can be interchanged safely, which is the case for $\psi_{t_0}\in\mathcal{S}(\mathrm{C}^2)$, rapidly decreasing C^∞ functions. At a glance of the definition of $G^m_t(z,w)$, we can observe that

$$G_t^m(e^{is}z,w)=e^{ims}G_t^m(z,w), \tag{44}$$

$$G_t^m(z,e^{is}w)=G_t^m(z,w)e^{-ims}. \tag{45}$$

On account of (44), the integral transform

$$\psi_t^m(z)=\int_{\mathrm{C}^2}G_t^m(z,w)\psi_{t_0}^m(w)\mathrm{d}w \tag{46}$$

proves to be in $L_m^2(\mathrm{C}^2)$, so that the map $\psi_{t_0}^m\mapsto\psi_t^m$ becomes also unitary. Thus we have decomposed the time evolution ψ_t of the original system in $L^2(\mathrm{C}^2)$ into a series of those ψ_t^m in $L_m^2(\mathrm{C}^2)$,

$$\psi_t(z)=\sum_{m=-\infty}^{\infty}\psi_t^m(z),\quad \psi_t^m\in L_m^2(\mathrm{C}^2). \tag{47}$$

VII. BOUNDARY CONDITIONS

In treating the shape space in Sec. III, we have started with the restricted center-of-mass system $\dot{X}_0$. In this section, we wish to take the whole space X_0 into account to consider what will happen when the three particles collide at a point. First we note that the quotient space of the whole space X_0 by the SO(2) action becomes homeomorphic to R^3,

$$X_0/\mathrm{SO}(2)\cong\dot{\mathrm{R}}^3\cup\{0\}=\mathrm{R}^3. \tag{48}$$

Let us be reminded of the fact that $M=\dot{X}_0/\mathrm{SO}(2)\cong\dot{\mathrm{R}}^3$ is made into a Riemannian manifold with metric $\tilde{K}$. Since the motion of the three free particles is associated with a geodesic in $\dot{X}_0$, and since the three particles may collide at a point simultaneously, we may expect that the geodesics in $\dot{X}_0$ that correspond to collision motion may project to geodesics in M which may get out of M within a finite time. This suggests that the Riemannian manifold $(M,\tilde{K})$ is not geodesically complete. To prove this, it suffices to show that there is a geodesics which gets to the origin of R^3, a point out of $M=\dot{\mathrm{R}}^3$, within a finite time. One can indeed find such a geodesic as follows: Let w, $z\in\dot{\mathrm{C}}^2=\dot{X}_0$ such that $w=\lambda z$ with $\lambda\neq1$ a real constant. Then the straight line $u(t)=w+t(z-w)$, a geodesic in $\dot{X}_0$, proves to be horizontal, since Eq. (20) is satisfied by this $u(t)$. Now, it is clear that $u(t)$ projects to a geodesic $\pi(u(t))$ approaching the origin of R^3. In fact, one has

$$2u_1(t)\overline{u_2(t)}=(\lambda+t(1-\lambda))^2(\xi_1+i\xi_2),\quad |u_1(t)|^2-|u_2(t)|^2=(\lambda+t(1-\lambda))^2\xi_3, \tag{49}$$

where $2z_1\overline{z_2}=\xi_1+i\xi_2$, $|z_1|^2-|z_2|^2=\xi_3$, so that $\pi(u(t))\to0$ as $t\to\lambda/(\lambda-1)$. We have to point out in addition that Eq. (49) allows of the interpretation that the geodesic $\pi(u(t))$ remains to exist after getting out of M for an instant. In fact, we may interpret that it traces backward the path it has printed before having reached the origin. This interpretation of the continuation of the geodesic comes from the mechanical fact that three particles on a plane may collide at a point, but they may continue to move after the collision.

We are to prove that if three particles collide at a point, the total angular momentum of them must vanish. Let $u(t)=w+tv$ be a geodesic in C^2, which stands for a motion of free particles. We assume here that $w\neq0$, $v\neq0$. We are to consider whether or not $u(t)$ passes through the origin of C^2. A necessary and sufficient condition for $|u(t)|^2=0$ for some real number t is given by $(\mathrm{Re}\langle v,w\rangle)^2=|v|^2|w|^2$. But, in general, one has $|\langle v,w\rangle|\leqslant|v||w|$, so that

$$\mathrm{Im}\langle v,w\rangle=0,\quad\text{and}\quad\lambda v+\mu w=0\quad\text{for}\quad(\lambda,\mu)\neq0,\lambda,\mu\in\mathrm{C}. \tag{50}$$

Since $v\neq 0$, $w\neq 0$ by assumption, Eq. (50) implies that v and w are related by $v=kw$ with k a nonzero real constant. Thus we have verified that if $|u(t)|=0$ for some t, v and w are related by $v=kw$, $k\in \mathrm{R}-\{0\}$. Moreover, the condition $\mathrm{Im}\langle v,w\rangle=0$ implies that

$$\mathrm{Im}\left\langle u(t),\frac{du}{dt}\right\rangle=\mathrm{Im}\langle u(t),v\rangle=\mathrm{Im}\langle w,v\rangle=0, \tag{51}$$

which means that the angular momentum of the orbit $u(t)$ must vanish [see (20)]. Thus we conclude that if three free particles collide at a point simultaneously, the total angular momentum of them must vanish. By contraposition, three free particles with nonvanishing total angular momentum do not collide simultaneously at a point.

This observation suggests that we consider what happens in wave functions at $z=0$ according to whether the total angular momentum vanishes or not. We have to note here that the $L^2_m(\mathrm{C}^2)$ is the space of wave functions with the total angular momentum m. In fact, the ρ_m-equivariance condition (36) for a smooth function F is differentiated with respect to s at $s=0$ to provide

$$\frac{1}{i}\left(-q_2\frac{\partial}{\partial q_1}+q_1\frac{\partial}{\partial q_2}-q_4\frac{\partial}{\partial q_3}+q_3\frac{\partial}{\partial q_4}\right)F(z)=mF(z), \tag{52}$$

where the operator on the left-hand side stands for the total angular momentum operator. Moreover, condition (36) implies that $F(0)=e^{ims}F(0)$ for $z=0$, and hence

$$F(0)=0 \quad \text{for} \quad m\neq 0, \tag{53}$$

which means that if the total angular momentum does not vanish ($m\neq 0$), the three particles do not collide at the origin. If $m=0$, then $F(0)$ should be a finite value.

If some of the wave functions are analytic at $z=0$, we can describe more of the behavior of them at $z=0$. Let $f(z)$ be a function analytic at $z=0$. Then it may be expanded into a power series such as $f(z)=\Sigma c_{j_1j_2k_1k_2}z_1^{j_1}z_2^{j_2}\bar{z}_1^{k_1}\bar{z}_2^{k_2}$. We can rewrite this series in the form

$$f(z)=\sum_{m=0}^{\infty}\sum_{n=m}^{\infty}\sum_{\substack{j_1+j_2-k_1-k_2=m\\ j_1+j_2+k_1+k_2=n}}c_{j_1j_2k_1k_2}z_1^{j_1}z_2^{j_2}\bar{z}_1^{k_1}\bar{z}_2^{k_2}+\sum_{m=-1}^{-\infty}\sum_{n=|m|}^{\infty}\sum_{\substack{j_1+j_2-k_1-k_2=m\\ j_1+j_2+k_1+k_2=n}}{}^{*}. \tag{54}$$

This expansion shows that $f(z)$ is broken up into a series of ρ_m-equivariant functions, each of which takes the form of power series starting with a term of order $|m|$ irrespective of whether m is non-negative or negative. Further, since $n=m+2(k_1+k_2)$, the power series starting with a term of order $|m|$ contains only terms of every other higher order. This fact was pointed out for planar two-body systems,[16] while Ref. 16 mainly studies the behavior of wave functions at the collinear configurations of spatial three-body systems.

In the rest of this section, we describe analytic ρ_m-equivariant functions in terms of the local coordinate system (R,θ,ϕ,ψ) introduced through

$$z_1=\mathrm{R}e^{i(\psi+\phi)/2}\cos\frac{\theta}{2},\quad z_2=\mathrm{R}e^{i(\psi-\phi)/2}\sin\frac{\theta}{2}, \tag{55}$$

$$R\geqslant 0,\quad 0\leqslant\theta\leqslant\pi,\quad 0\leqslant\psi\leqslant 4\pi,\quad 0\leqslant\phi\leqslant 2\pi. \tag{56}$$

A ρ_m-equivariant function F which is assumed to be analytic at $z=0$ is then expanded, on account of (54), into a power series of the form

$$F(z)=e^{im\psi/2}\sum_{\ell=0}^{\infty}R^{|m|+2\ell}\Phi_{m\ell}(\theta,\phi), \tag{57}$$

where

$$\Phi_{m\ell}(\theta,\phi)=\sum_{\substack{j_1+j_2=1/2(|m|+m)+\ell\\ k_1+k_2=1/2(|m|-m)+\ell}} c_{j_1j_2k_1k_2}e^{i\phi(j_1-j_2-k_1+k_2)/2}\left(\cos\frac{\theta}{2}\right)^{j_1+k_1}\left(\sin\frac{\theta}{2}\right)^{j_2+k_2}. \quad (58)$$

From this, we observe that the ρ_m-equivariant function F is expressed as $e^{im\psi/2}$ times a power series in R which starts with a term of the lowest order $|m|$ and contains only terms of every other order. Since R is a measure to describe how configurations of particles are distant from the triple collision, Eq. (57) implies that the more the total angular momentum $|m|$ grows, the less closely the particles get together.

VIII. REDUCTION BY PARTICLE EXCHANGES

This section deals with reduction due to exchanges of identical particles. According to whether particles are all bosons or fermions, the wave function must be symmetric or antisymmetric with respect to particle exchanges. From a wave function ψ on the center-of-mass system $X_0\cong\mathrm{C}^2$, we can construct such wave functions $\psi^{(s)}$ and $\psi^{(a)}$ by the following procedure;

$$\psi^{(s)}(x):=\sum_{h\in S_3}\psi(x\rho(h)^{-1}), \quad (59)$$

$$\psi^{(a)}(x):=\sum_{h\in S_3}\mathrm{sgn}(h)\psi(x\rho(h)^{-1}), \quad (60)$$

where ρ is the representation of S_3 in $\mathrm{O}(2)$, which is given in (28), and $\mathrm{sgn}(g)$ denotes the signum of g; $\mathrm{sgn}(g)$ equals 1 or -1, depending on whether $g\in S_3$ is an even or odd permutation. It is easy to see that the $\psi^{(s)}$ and $\psi^{(a)}$ are symmetric and antisymmetric, respectively, with respect to the S_3 action,

$$\psi^{(s)}(x\rho(g)^{-1})=\psi^{(s)}(x), \quad \psi^{(a)}(x\rho(g)^{-1})=\mathrm{sgn}(g)\psi^{(a)}(x). \quad (61)$$

In comparison with the ρ_m-equivariance with respect to the $\mathrm{SO}(2)\cong\mathrm{U}(1)$ action, Eq. (61) shows that bosonic and fermionic states are equivariant with respect to the trivial representation $\sigma\mapsto 1$ and to the signum representation $\sigma\mapsto\mathrm{sgn}(\sigma)$, respectively.

We assume here that our quantum system $(L^2(\mathrm{C}^2),\psi_t)$ is invariant under the particle exchanges, so that $G_t(z,w)$ is assumed to be invariant under the action of S_3,

$$G_t(z\rho(h)^{-1},w\rho(h)^{-1})=G_t(z,w), \quad h\in S_3. \quad (62)$$

We note further that the Lebesgue measure $\mathrm{d}w$ on $X_0\cong\mathrm{R}^4$ is also invariant under the action of S_3. This is because the S_3 action on X_0 is represented as a discrete subgroup of $\mathrm{SO}(4)$, as is seen from (33). The invariance of the Green's kernel and of the measure $\mathrm{d}w$ under the S_3 action are put together to imply that the time evolution preserves the statistics to which the particles are subject, that is, bosonic or fermionic state remains unchanged during the time evolution. This can be seen from the change that the time evolution (40) undergoes by the S_3 action,

$$\psi_t(z\rho(h)^{-1})=\int_{\mathrm{C}^2}G_t(z,w)\psi_{t_0}(w\rho(h)^{-1})\mathrm{d}w. \quad (63)$$

Since the action of $\mathrm{U}(1)$ and of S_3 commute, the time evolution (63) is decomposed into

$$\psi_t(z\rho(h)^{-1})=\sum_{m=-\infty}^{\infty}\psi_t^m(z\rho(h)^{-1})=\sum_{m=-\infty}^{\infty}\int_{\mathrm{C}^2}G_t^m(z,w)\psi_{t_0}^m(w\rho(h)^{-1})\mathrm{d}w, \quad (64)$$

where the Green's functions are invariant under the S_3 action,

$$G_t^m(z\rho(h)^{-1},w\rho(h)^{-1})=G_t^m(z,w),\quad h\in S_3. \tag{65}$$

Putting (64) together with (59) and (60), we obtain the time evolution of wave functions for Bose or Fermi particles, which are decomposed into

$$\psi_t^{(s)}(z)=\sum_{m=-\infty}^{\infty}\psi_t^{(s)m}(z),\quad \psi_t^{(s)m}(z):=\sum_{h\in S_3}\psi_t^m(z\rho(h)^{-1}), \tag{66}$$

$$\psi_t^{(a)}(z)=\sum_{m=-\infty}^{\infty}\psi_t^{(a)m}(z),\quad \psi_t^{(a)m}(z):=\sum_{h\in S_3}\mathrm{sgn}(h)\psi_t^m(z\rho(h)^{-1}), \tag{67}$$

respectively.

Proposition 1: A planar three-particle quantum system $(L^2(\mathrm{C}^2),\psi_t)$ with symmetry of rotation and particle exchanges is reduced to subsystems $(L_m^2(\mathrm{C}^2),\psi_t^{(s)m})$ or $(L_m^2(\mathrm{C}^2),\psi_t^{(a)m})$ according to whether the particles are bosons or fermions, where $\psi_t^{(s)m}$ and $\psi_t^{(a)m}$ are given by (66) and (67), respectively, along with (46).

IX. COMPLEX LINE BUNDLES

So far we have discussed the reduction to subsystems (see Proposition 1). In this section, we show that these subsystems indeed give rise to reduced quantum systems on the shape space, by introducing complex line bundles associated with the U(1) bundle $\dot{\mathrm{C}}^2\cong\dot{X}_0\to M$. To this end, we first recall that the time evolution ψ_t in $L^2(\mathrm{C}^2)$ was decomposed into the series of those in $L_m^2(\mathrm{C}^2)$,

$$\psi_t^m(z):=\int_{\mathrm{C}^2}G_t^m(z,w)\psi_{t_0}^m(w)\mathrm{d}w,\quad \psi_{t_0}^m\in L_m^2(\mathrm{C}^2). \tag{68}$$

Since the integrand in (68) is invariant under the U(1) action, the integration with respect to w over C^2 will reduce to that over the shape space M, if C^2 is restricted to $\dot{\mathrm{C}}^2$. Hence the time evolution $\psi_t^m(z)$ may define the time evolution of a quantum state on the shape space M. In what follows, we make a brief review of complex line bundles associated with $\dot{\mathrm{C}}^2\cong\dot{X}_0\to M=\dot{\mathrm{R}}^3$ along with boundary conditions at the origin of R^3.

For a unitary irreducible representation ρ_m, the complex line bundle E_m associated with the U(1) bundle $\dot{X}_0\cong\dot{\mathrm{C}}^2\to M$ is defined to be the quotient of the product space $\dot{X}_0\times\mathrm{C}$ by the equivalence relation defined through $(z,\zeta)\sim(e^{is}z,e^{ims}\zeta)$ for $(z,\zeta)\in\dot{\mathrm{C}}^2\times\mathrm{C}$. By $[(z,\zeta)]$ and by π_m we denote the equivalence class in $\dot{X}_0\times\mathrm{C}$ and the projection $E_m\to M$, respectively, so that one has $\pi_m([(z,\zeta)])=\pi(z)$. A section σ in E_m is a map $M\to E_m$ such that $\pi_m\circ\sigma=\mathrm{id}_M$, where id_M is the identity map of M. Then any ρ_m-equivariant function F on $\dot{X}_0$ determines a section σ in E_m by

$$\sigma(\pi(z))=[(z,F(z))]. \tag{69}$$

Sections in E_m and ρ_m-equivariant functions are in one-to-one correspondence. Furthermore, from (53), ρ_m-equivariant functions should be subject to the boundary condition that $F(z)\to 0$ as $z\to 0$ if $m\neq 0$ and that $F(z)$ is bounded as $z\to 0$ if $m=0$, so that the corresponding section $\sigma(\xi)$ should satisfy the corresponding boundary condition as $\xi\to 0$ in M.

For sections σ_1 and σ_2 corresponding to ρ_m-equivariant functions F_1 and F_2, respectively, the inner product $\langle\sigma_1,\sigma_2\rangle$ is defined to be

$$\langle\sigma_1,\sigma_2\rangle=\int_M(\sigma_1,\sigma_2)\mathrm{d}\mu_M=\int_{\mathrm{C}^2}\overline{F_1(z)}F_2(z)\mathrm{d}z, \tag{70}$$

where (σ_1,σ_2) denotes the inner product in each fiber $\pi_m^{-1}(\pi(z))\cong\mathrm{C}$, and $\mathrm{d}\mu_M$ is the measure on M defined for any function χ on M through

$$\int_M \chi(p)\mathrm{d}\mu_M=\int_{\mathrm{C}^2}\chi(\pi(z))\mathrm{d}z \quad \text{with} \quad \pi(z)=p\in M. \tag{71}$$

To put the measure $\mathrm{d}\mu_M$ in an explicit form, it is of great help to use the connection form ω given in (15). A straightforward calculation then shows that the standard volume form on X_0 is put in the form

$$dq_1\wedge dq_2\wedge dq_3\wedge dq_4=\frac{1}{8r}\omega\wedge d\xi_1\wedge d\xi_2\wedge d\xi_3, \quad r=\sqrt{\xi_1^2+\xi_2^2+\xi_3^2}, \tag{72}$$

where $\xi_k, k=1,2,3$, are defined in (12). To be precise, $d\xi_k$ on the right-hand side of (72) should be replaced by $\pi^* d\xi_k$, the pull-back of $d\xi_k$ through π, but we have used $d\xi_k$ for simplicity. From (71) and (72), we conclude after the integration over the fiber $S^1\cong\mathrm{U}(1)$ that

$$\mathrm{d}\mu_M=\frac{\pi}{4r}d\xi_1\wedge d\xi_2\wedge d\xi_3. \tag{73}$$

From (69) and (70), we see that any function $F\in L_m^2(\dot{\mathrm{C}}^2)$ determines a square integrable section in E_m. Taking into account the above-mentioned boundary condition for ρ_m-equivariant functions, we may regard $L_m^2(\mathrm{C}^2)$ as being in one-to-one correspondence to the space of square integrable sections in E_m together with the boundary condition.

For the ρ_m-equivariant function $\psi_t^m(z)$ given in (68), one has the time evolution of the corresponding section σ_t^m in E_m together with the boundary condition,

$$\sigma_t^m(\pi(z))=[(z,\psi_t^m(z))]. \tag{74}$$

Since the time evolution ψ_t^m is unitary, that is, $\|\psi_t^m\|=\|\psi_{t_0}^m\|$, the time evolution of the corresponding section σ_t^m is also unitary, that is, $\|\sigma_t^m\|=\|\sigma_{t_0}^m\|$ for all time t.

The S_3 action on $L_m^2(\mathrm{C}^2)$ can be transferred to that on the space of square integrable sections in E_m. From (66) and (67), we obtain corresponding time evolutions of sections in E_m, respectively,

$$\sigma_t^{(s)m}(\pi(z)):=\sum_{h\in S_3}\sigma_t^m(\pi(z)\tau(h)^{-1}), \tag{75}$$

$$\sigma_t^{(a)m}(\pi(z)):=\sum_{h\in S_3}\mathrm{sgn}(h)\sigma_t^m(\pi(z)\tau(h)^{-1}). \tag{76}$$

The reduction is thus completed for the time evolution of a $\mathrm{U}(1)\cong\mathrm{SO}(2)$ invariant quantum system of three identical particles on a plane.

Theorem 2: If a quantum system for three identical particles on a plane admits the symmetry of rotation and particle exchanges, the time evolution of the quantum system, which is defined in the L^2 space of wave functions on the center-of-mass system, is reduced to that on the L^2 space of sections in the complex line bundle E_m over the internal space M, where sections σ must satisfy the boundary condition that $\sigma(\xi)\to 0$ as $\xi\to 0$ if $m\neq 0$ or that $\sigma(\xi)$ is bounded as $\xi\mapsto 0$ if $m=0$. According to whether the quantum system is bosonic or fermionic, the time evolution is put in the form of (75) or (76).

X. APPLICATION TO FREE PARTICLES

Having set up the reduction method, we are to apply it to a system of free particles. The Schrödinger equation for three free particles on a plane is expressed, in terms of (q_i), as

$$i\hbar\frac{\partial\psi}{\partial t}=-\frac{\hbar^2}{2}\nabla^2\psi \quad \text{with} \quad \nabla^2=\sum_{j=1}^{4}\frac{\partial^2}{\partial q_j^2}. \tag{77}$$

In fact, since the operator $\Sigma_{k=1}^{3}(1/m_k)(\partial/\partial\mathbf{x}_k)^2$, a constant multiple of the kinetic energy operator, is the Laplacian ∇^2 with respect to the metric (1) on X, and since this metric is expressed as $\Sigma_{j=1}^{4}dq_j^2$ if restricted to the linear subspace X_0 of X, the Laplacian takes the form $\nabla^2=\Sigma_{j=1}^{4}\partial^2/\partial q_j^2$. As is well known, Eq. (77) can be solved by Fourier transform with little difficulty, to give a solution of the form

$$\psi_t(z)=\int_{\mathrm{C}^2}F_t(z,w)\psi_{t_0}(w)\mathrm{d}w, \tag{78}$$

where F_t is the Green's function given by

$$F_t(z,w)=\left[\frac{1}{2\pi i\hbar(t-t_0)}\right]^2\exp\left(\frac{i|z-w|^2}{2\hbar(t-t_0)}\right). \tag{79}$$

Since the Schrödinger equation (77) is invariant under the U(1) action (10), the free particle system can be reduced after the procedure in Sec. VI. As is easily seen from (79), the Green's kernel $F_t(z,w)$ satisfies the condition (41), so that we can compute explicitly Eq. (43) with F_t replaced for G_t to obtain

$$F_t^m(z,w)=\frac{e^{im(\theta(z,w)-\pi/2)}}{(2\pi i\hbar(t-t_0))^2}\exp\left(\frac{iB(z,w)}{2\hbar(t-t_0)}\right)J_m\left(\frac{A(z,w)}{\hbar(t-t_0)}\right), \tag{80}$$

where J_m is the Bessel function defined as

$$J_m(x)=\frac{1}{2\pi}\int_{-\pi}^{\pi}e^{ix\sin s}e^{-ims}\mathrm{d}s, \quad x\in\mathrm{C}, \tag{81}$$

and

$$B(z,w)=\sum_{j=1}^{2}(|z_j|^2+|w_j|^2), \tag{82}$$

$$A(z,w)=\left|\sum_{j=1}^{2}z_j\overline{w}_j\right|, \tag{83}$$

$$\theta(z,w)=\arg\sum_{j=1}^{2}z_j\overline{w}_j. \tag{84}$$

It is of great interest to observe that $A(z,w)$ and $B(z,w)$ are invariant under the U(1) action, $z\mapsto e^{is}z$ and/or $w\mapsto e^{is}w$, and hence can be expressed in the coordinates of the shape space M. In fact, we can verify that

$$B(z,w)=\tilde{B}(\xi,\xi')\coloneqq\sqrt{\sum_{k=1}^{3}\xi_k^2}+\sqrt{\sum_{k=1}^{3}\xi_k'^2}, \tag{85}$$

$$A(z,w)=\tilde{A}(\xi,\xi'):=\left[\frac{1}{2}\sqrt{\sum_{k=1}^{3}\xi_k^2}\sqrt{\sum_{k=1}^{3}\xi_k'^2}+\frac{1}{2}\sum_{k=1}^{3}\xi_k\xi_k'\right]^{1/2}, \tag{86}$$

where ξ_k' are given by the formula similar to (12). We notice further that under the U(1) action the factor $e^{im\theta(z,w)}$ is subject to the transformation

$$\begin{aligned}\exp(im\theta(e^{is}z,w))&=e^{ims}\exp(im\theta(z,w)),\\ \exp(im\theta(z,e^{is}w))&=\exp(im\theta(z,w))e^{-ims}.\end{aligned} \tag{87}$$

Properties (85)–(87) show that F_t^m is subject to the transformations (44) and (45). Thus the time evolution (78) is reduced to (46) with G_t^m replaced by F_t^m.

Furthermore, since F_t is invariant under the S_3 action, as is seen from (79), so is F_t^m. Thus the free particle system reduces to subsystems according to Proposition 1. Finally, application of Theorem 2 provides reduced systems defined on the complex line bundles E_m.

In conclusion, we note that the reduced Hamiltonian operator, which acts on sections of E_m and is denoted by $\hat{H}_m$, is given by

$$\hat{H}_m=-\frac{\hbar^2}{2}4r\sum_{k=1}^{3}\nabla_k^2+\frac{m^2}{2r}, \tag{88}$$

where ∇_k's are the covariant differential operators with respect to the vector fields $\partial/\partial\xi_k$. See Ref. 1 for details, in which the reduced Hamiltonian operator was studied for a generic Hamiltonian system of planar three particles.

XI. LOCAL EXPRESSION

The purpose of this section is to look into the boundary conditions and the Green's function discussed in previous sections, in terms of local coordinates.

We first consider the boundary condition at $z=0$ for ρ_m-equivariant functions in the coordinates (R,θ,ϕ,ψ) introduced in (55). As is easily seen from (12) and (55), one has

$$\xi_1+i\xi_2=re^{i\phi}\sin\theta,\quad \xi_3=r\cos\theta,\quad r=R^2, \tag{89}$$

which means that (r,θ,ϕ) serve as spherical polar coordinates in the shape space $M\cong\dot{\mathrm{R}}^3$. We take a local section, $s=(s_1,s_2)$, in the bundle $\dot{X}_0\cong\dot{\mathrm{C}}^2\to M$ as follows:

$$s_1(r,\theta,\phi)=\sqrt{r}e^{i\phi/2}\cos\frac{\theta}{2},\quad s_2(r,\theta,\phi)=\sqrt{r}e^{-i\phi/2}\sin\frac{\theta}{2}, \tag{90}$$

where

$$r>0,\quad 0<\theta<\pi,\quad 0<\phi<2\pi. \tag{91}$$

Then one has $z=e^{i\psi/2}s(r,\theta,\phi)$, so that the local section corresponding to a ρ_m-equivariant function F is expressed as $[(z,F(z))]=[s(r,\theta,\phi),F\circ s(r,\theta,\phi)]$. This implies that $F\circ s$ may be identified with a local section in E_m. If F is given by (57), we obtain

$$F\circ s(r,\theta,\phi)=r^{|m|/2}\sum_{\ell=0}^{\infty}r^{\ell}\Phi_{m\ell}(\theta,\phi). \tag{92}$$

This shows that if a ρ_m-equivariant function $F(z)$ is analytic in R at $R=0$, then the corresponding local section is expressed as $r^{|m|/2}$ times an analytic function in r. In particular, the local section associated with the kernel function F_t^m, as a function of z, given in (80) can be expanded in this form.

We turn to expressing the integral transform (68) with G_t^m replaced by F_t^m as the integral of a function on the shape space M explicitly. To this end, we use local sections σ_+ and σ_- in the bundle $\dot{X}_0 \to M$, which are defined to be

$$\sigma_+(\xi)=\left(\frac{\sqrt{r+\xi_3}}{\sqrt{2}},\frac{\xi_1-i\xi_2}{\sqrt{2(r+\xi_3)}}\right) \quad \text{for } \xi\in D_+, \tag{93}$$

$$\sigma_-(\xi)=\left(\frac{\xi_1+i\xi_2}{\sqrt{2(r-\xi_3)}},\frac{\sqrt{r-\xi_3}}{\sqrt{2}}\right) \quad \text{for } \xi\in D_-, \tag{94}$$

where $D_\pm$ are domains in M defined, respectively, to be

$$D_+=\{\xi\in \dot{\mathrm{R}}^3 | \xi_3+r\neq 0\}, \tag{95}$$

$$D_-=\{\xi\in \dot{\mathrm{R}}^3 | \xi_3-r\neq 0\}. \tag{96}$$

The sections σ_+ and σ_- are subject to the transformation in the intersection $D_+\cap D_-$,

$$\sigma_-(\xi)=\frac{\xi_1+i\xi_2}{\sqrt{\xi_1^2+\xi_2^2}}\sigma_+(\xi), \quad \xi\in D_+\cap D_-. \tag{97}$$

By using the section σ_+, points of $\pi^{-1}(D_+)$ are expressed as $z=e^{i\varphi}\sigma_+(\xi)$ with $\xi=\pi(z)$ and φ an angle variable. Thus local coordinates (ξ,φ) are introduced in $\pi^{-1}(D_+)$. Local coordinates are defined in $\pi^{-1}(D_-)$ as well. Then, a ρ_m-equivariant function F restricted on $\pi^{-1}(D_+)$ is put in the form $F(z)=e^{im\varphi}F(\sigma_+(\xi))$. A similar expression of F is available on $\pi^{-1}(D_+)$.

We first divide M into a union $M=M_+\cup M_-$, where $M_\pm$ are the upper and the lower half spaces of $M\cong \dot{\mathrm{R}}^3$; $M_+=\{\xi\in M|\xi_3\geqslant 0\}$, $M_-=\{\xi\in M|\xi_3\leqslant 0\}$, and hence we have the division of $\dot{\mathrm{C}}^2$ in the form $\dot{\mathrm{C}}^2=\pi^{-1}(M_+)\cup\pi^{-1}(M_-)$. Accordingly, the integral transform (68) with F_t^m replaced for G_t^m is broken up into

$$\psi_t^m(z)=\int_{\pi^{-1}(M_+)} F_t^m(z,w)\psi_{t_0}^m(w)\mathrm{d}w+\int_{\pi^{-1}(M_-)} *. \tag{98}$$

We now use the local sections σ_+ and σ_- restricted on M_+ and M_-, respectively, to rewrite the integrals (98) in terms of the variable $w=e^{i\varphi'}\sigma_+(\xi')\in\pi^{-1}(M_+)$, etc. In particular, for $z\in\pi^{-1}(D_+)$, Eq. (98) is put in the form

$$\begin{aligned}\psi_t^m(\sigma_+(\xi))=&\int_{M_+}\tilde{F}_t^m(\xi,\xi')e_{++}^m(\xi,\xi')\psi_{t_0}^m(\sigma_+(\xi'))\mathrm{d}\mu_M(\xi')\\&+\int_{M_-}\tilde{F}_t^m(\xi,\xi')e_{+-}^m(\xi,\xi')\psi_{t_0}^m(\sigma_-(\xi'))\mathrm{d}\mu_M(\xi'),\end{aligned} \tag{99}$$

where the angle variables φ has been canceled out from the both sides, and the definition (71) of $\mathrm{d}\mu_M$ has been used along with

$$\tilde{F}_t^m(\xi,\xi') := \frac{e^{-im\pi/2}}{(2\pi i\hbar(t-t_0))^2}\exp\left(\frac{\tilde{B}(\xi,\xi')}{2\hbar(t-t_0)}\right)J_m\left(\frac{\tilde{A}(\xi,\xi')}{\hbar(t-t_0)}\right), \tag{100}$$

$$e_{++}^m(\xi,\xi') := e^{im\theta(\sigma_+(\xi),\sigma_+(\xi'))}, \tag{101}$$

$$e_{+-}^m(\xi,\xi') := e^{im\theta(\sigma_+(\xi),\sigma_-(\xi'))}. \tag{102}$$

A similar expression for $\psi_t^m(\sigma_-(\xi)), \xi \in D_-$, can be obtained as well with due definition of $e_{-+}^m(\xi,\xi')$ and of $e_{--}^m(\xi,\xi')$. The functions $\psi_t^m(\sigma_-(\xi))$ and $\psi_t^m(\sigma_+(\xi))$ are related on $D_+ \cap D_-$ by

$$\psi_t^m(\sigma_-(\xi)) = \left(\frac{\xi_1 + i\xi_2}{\sqrt{\xi_1^2+\xi_2^2}}\right)^m \psi_t^m(\sigma_+(\xi)), \quad \xi \in D_+ \cup D_-, \tag{103}$$

which is observed from (97) and from the fact that ψ_t^m is ρ_m-equivariant.

In the rest of this section, we are to look into the function $\tilde{F}_t^m(\xi,\xi')$ in detail by using asymptotic expansion of Bessel functions. As is well known, a simple form of the asymptotic expansion of $J_n(x)$ for $|x| \gg 1$ is given by

$$\begin{aligned} J_m(x) &\sim \sqrt{\frac{2}{\pi x}}\cos\left(x - \frac{1}{2}m\pi - \frac{1}{4}\pi\right) \\ &= \frac{1}{2}\sqrt{\frac{2}{\pi x}}\left(\exp\left(i\left(x - \frac{1}{2}m\pi - \frac{1}{4}\pi\right)\right) + \exp\left(-i\left(x - \frac{1}{2}m\pi - \frac{1}{4}\pi\right)\right)\right). \end{aligned} \tag{104}$$

Then one has, for $0 < |t-t_0|\hbar \ll \tilde{A}(\xi,\xi')$,

$$\begin{aligned} J_m\left(\frac{\tilde{A}(\xi,\xi')}{(t-t_0)\hbar}\right) \sim \sqrt{\frac{(t-t_0)\hbar}{2\pi\tilde{A}(\xi,\xi')}}\Bigg(& e^{-\pi i/4}e^{-im\pi/2}\exp\left(i\frac{\tilde{A}(\xi,\xi')}{(t-t_0)\hbar}\right) + e^{\pi i/4}e^{im\pi/2} \\ &\times\exp\left(-i\frac{\tilde{A}(\xi,\xi')}{(t-t_0)\hbar}\right)\Bigg), \end{aligned} \tag{105}$$

where we have assumed that $\tilde{A}(\xi,\xi') \neq 0$. We note in addition that $\tilde{A}(\xi,\xi') = 0$ with $\xi \neq 0, \xi' \neq 0$, if and only if there exists a positive constant $\lambda > 0$ such that $\xi_k' = -\lambda\xi_k, k = 1,2,3$, as observed from (86). Inserting the asymptotic expansion (105) of $J_m(\tilde{A}(\xi,\xi')/(t-t_0)\hbar)$ in the right-hand side of (100), one obtains, for $0 < |t-t_0|\hbar \ll \tilde{A}(\xi,\xi')$,

$$\tilde{F}_t^m(\xi,\xi') \sim -\frac{(-1)^m e^{-\pi i/4}}{\tilde{A}(\xi,\xi')^{1/2}}\frac{1}{(2\pi(t-t_0)\hbar)^{3/2}}\exp\left(\frac{i}{2(t-t_0)\hbar}(r+r'+2\tilde{A}(\xi,\xi'))\right) \tag{106}$$

$$+\frac{1}{\tilde{A}(\xi,\xi')^{1/2}}\frac{1}{(2\pi i(t-t_0)\hbar)^{3/2}}\exp\left(\frac{i}{2(t-t_0)\hbar}(r+r'-2\tilde{A}(\xi,\xi'))\right). \tag{107}$$

We now consider the quantity appearing in the argument of the exponential function in (106). To this end, let

$$\alpha(\xi,\xi') := r + r' + 2\tilde{A}(\xi,\xi'). \tag{108}$$

Then, differentiation of α with respect to ξ' implies that for nonvanishing ξ', $\partial\alpha/\partial\xi'=0$ if and only if

$$\sqrt{2}\sqrt{rr'+\sum_{k=1}^{3}\xi_k\xi_k'}+r+r'\frac{\xi_k}{\xi_k'}=0, \quad k=1,2,3, \tag{109}$$

so that $\partial\alpha/\partial\xi_k'=0$ if and only if $\xi_k=-\nu\xi_k'$, $k=1,2,3$ for a positive constant $\nu>0$. Incidentally, for ξ and ξ' with $\xi=-\nu\xi'$, one obtains $\tilde{A}(\xi,\xi')=0$, which contradicts the assumption that $\tilde{A}(\xi,\xi')\neq 0$. From this it follows that if $\tilde{A}(\xi,\xi')\neq 0$ then $\alpha(\xi,\xi')$ does not attain its stationary values, i.e., $\partial\alpha/\partial\xi_k'\neq 0$, $k=1,2,3$, so that the function

$$\exp\left(\frac{i}{2(t-t_0)\hbar}\alpha(\xi,\xi')\right)$$

rapidly oscillates throughout the ξ'-space with $\xi\neq-\nu\xi'$. Hence, the first term (106) of the right-hand side of the asymptotic expansion (106) and (107) would make no contribution in the integral transform. As for the argument of the exponential function in the second term (107), we find that $r+r'-2\tilde{A}(\xi,\xi')$ is equal to $d_M(\xi,\xi')^2$, the squared distance defined in (22). The distance function takes a minimum if and only if $\xi=\xi'$, so that

$$\exp\left(\frac{i}{2(t-t_0)\hbar}d_M(\xi,\xi')^2\right)$$

makes a definite contribution as part of an integral kernel. Thus, for small $t-t_0$, one may conclude that the function $\tilde{F}_t^m(\xi,\xi')$ has an asymptotic expansion of the form

$$\tilde{F}_t^m(\xi,\xi')\sim\frac{1}{\tilde{A}(\xi,\xi')^{1/2}}\frac{1}{(2\pi i(t-t_0)\hbar)^{3/2}}\exp\left(\frac{i}{2(t-t_0)\hbar}d_M(\xi,\xi')^2\right). \tag{110}$$

XII. REMARKS ON ELECTRONS ON A PLANE

A system of electrons on a plane is of fundamental interest from the viewpoint of the quantum Hall effect. In his lecture[17] on the quantum Hall effect, Laughlin gives a trial wave function for planar three electrons on a plane, which is expressed as

$$\psi_{n,m}(z_1,z_2)=((z_2+iz_1)^{3m}-(z_2-iz_1)^{3m})(z_1^2+z_2^2)^n e^{-(1/4)(|z_1|^2+|z_2|^2)}, \tag{111}$$

up to a constant factor, where z_1 and z_2 are variables given in (9). It is easy to see that this function is equivariant under the U(1) action. We can also verify that the function $\psi_{n,m}$ satisfies the Pauli principle. To show this, we have only to see how z_2+iz_1 and z_2-iz_2 transform under the S_3 action. Writing out the transformation (29) for every element $h\in S_3$ results in the following transformation except for the identity:

$$\begin{gathered}
(z_2+iz_1)\rho(12)^{-1}=z_2-iz_1, \quad (z_2-iz_1)\rho(12)^{-1}=z_2+iz_1,\\
(z_2+iz_1)\rho(13)^{-1}=(z_2-iz_1)e^{-(2\pi/3)i}, \quad (z_2-iz_1)\rho(13)^{-1}=(z_2+iz_1)e^{(2\pi/3)i},\\
(z_2+iz_1)\rho(23)^{-1}=(z_2-iz_1)e^{(2\pi/3)i}, \quad (z_2-iz_1)\rho(23)^{-1}=(z_2+iz_1)e^{-(2\pi/3)i},\\
(z_2+iz_1)\rho(123)^{-1}=(z_2+iz_1)e^{(2\pi/3)i}, \quad (z_2-iz_1)\rho(123)^{-1}=(z_2-iz_1)e^{-(2\pi/3)i},\\
(z_2+iz_1)\rho(132)^{-1}=(z_2+iz_1)e^{-(2\pi/3)i}, \quad (z_2-iz_1)\rho(132)^{-1}=(z_2-iz_1)e^{(2\pi/3)i}.
\end{gathered} \tag{112}$$

From these transformations, it follows that $\psi_{m,n}$ indeed satisfies the Pauli principle under the S_3 action.

According to our procedure (60), we can form another function which satisfies the Pauli principle. For example, taking an equivariant function $(z_2+iz_1)^m$ as a seed, we can form a function

$$(z_2+iz_1)^m+(z_2+iz_1)^m e^{(2m\pi/3)\,i}+(z_2+iz_1)^m e^{-(2m\pi/3)\,i}-(z_2-iz_1)^m$$
$$-(z_2-iz_1)^m e^{(2m\pi/3)\,i}-(z_2-iz_1)^m e^{-(2m\pi/3)\,i}, \tag{113}$$

which is subject to the Pauli principle. We can multiply the function (113) by the factor $e^{-(1/4)(|z_1|^2+|z_2|^2)}$ to form a plausible wave function.

Reduction of quantum systems with symmetry, continuous and discrete

Toshihiro Iwai[a] and Toru Hirose
Department of Applied Mathematics and Physics, Kyoto University, Kyoto-606-8501, Japan

(Received 25 November 2001; accepted for publication 26 February 2002)

Reduction of dynamical systems is closely related with symmetry. The purpose of this article is to show that Fourier analysis both on compact Lie groups and on finite groups serves as a reduction procedure for quantum systems with symmetry on an equal footing. The reduction procedure is applied to systems of many identical particles lying in $\mathbf{R}^3$ which admit the action of a rotation group SO(3) and of a symmetric or permutation group. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1473873]

I. INTRODUCTION

As is widely recognized, reduction of dynamical systems is closely related with symmetry. A well-known example of reduction in ordinary quantum mechanics in $\mathbf{R}^3$ comes from rotational symmetry.[1] It gives rise to the conservation of the angular momentum, and thereby the quantum state of the system can be restricted to that with a fixed angular momentum eigenvalue. The restricted state is described by one of the spherical harmonics multiplied by a function of the radial variable. The original Schrödinger equation then reduces to provide a Schrödinger equation for the radial function. In this manner, the original quantum system reduces to a quantum system of lower degree(s) of freedom. This reduction procedure proves to be based upon Fourier analysis on the rotation group SO(3). The reason why Fourier analysis on SO(3) is referred to, instead of that on S^2 with spherical harmonics, is that Fourier analysis on SO(3) reduces to that on S^2 through the bundle structure $\mathrm{SO}(3)\to S^2$, when SO(3) acts on $\mathbf{R}^3$.

As for discrete symmetry, systems of many identical particles admit symmetry by the action of symmetric (or permutation) groups, that is, symmetry of particle exchanges. A point to make here is that the particles are not assumed to be placed at vertices of regular polyhedrons, but free to spread in the space. The center-of-mass system for N identical particles is actually shown to admit the action of the symmetric group S_N. Fourier analysis on finite groups will work well in reducing the quantum system of identical particles. However, the reduction by a finite group does not mean that of degrees of freedom, but a reduction to ''eigenstates'' for the symmetric group.

A key idea to reduction procedure is the Peter–Weyl theorem[2,3] on unitary irreducible representations of compact Lie groups and of finite groups, both of which are stated in the same manner. The Peter–Weyl theorem says that matrix elements of all the inequivalent irreducible unitary representations provide a basis of Fourier analysis on the group in question. The purpose of this article is to show that Fourier analysis both on compact Lie groups and on finite groups serves as a reduction procedure for quantum systems with symmetry, continuous and discrete, on an equal footing.

The fact that the Peter–Weyl theorem on compact Lie groups serves as a reduction procedure for quantum systems has been already stated and applied, in a previous paper,[4] to many-particle systems. To understand how the Peter–Weyl theorem comes to be associated with reduction procedure for many-particle systems, one has to review geometric method for many-particle systems. For a long period before a bundle picture was introduced in the study of many-particle

[a]Electronic mail: iwai@amp.i.kyoto-u.ac.jp

systems, a vain effort had been made to separate rotational and vibrational motions. However, the separation of them was shown to be impossible by A. Guichardet[5] by the use of the connection theory or gauge theory applied to the center-of-mass system which is viewed as a principal fiber bundle with structure group SO(3), if collinear configurations of particles are gotten rid of. With this constraint taken into account, reduction procedure was described in the bundle picture.[6] Since then, classical and quantum mechanics for many-particle systems have been studied in the bundle picture.[7–14]

A question has been kept unsettled as to how the collinear configurations should be treated in the study of reduction procedure. An answer to this question is brought about when the problem is put in a generic setting.[4] Since the center-of-mass system admits an SO(3) action, a geometric setting to start with is simply that a manifold M is given on which a compact Lie group G acts. The action of G is not assumed to be free, so that M is not made into a fiber bundle in general. Though the bundle picture fails to work, the theory of unitary representations of compact Lie groups works well on the space, $L^2(M)$, of square integrable functions on M. By an effective use of the Peter–Weyl theorem, $L^2(M)$ is decomposed into a series of subspaces, each of which is isomorphic with the space of equivariant functions taking values in a representation space, and may be viewed as the space of eigenstates assigned by the parameter, like an angular momentum eigenvalue, characterizing the representation chosen. If a given Hamiltonian is G-invariant, the original quantum system reduces to a system on the space of equivariant functions, which may be called a reduced system actually. The question mentioned above is now solved. In fact, the reduction procedure in this sense can be applied to many-particle systems without excluding collinear configurations. In this stage of reduction, we have not taken up a bundle picture, yet. If the action of G is free furthermore, the reduction procedure can be described in the bundle picture. In fact, M is then made into a principal bundle, $M \to M/G$, and the reduced system is brought into one-to-one correspondence with a quantum system defined on a complex vector bundle associated with the principal bundle $M \to M/G$.[10]

A review article by Littlejohn and Reinsch[15] is of great help in studying quantum mechanics of many-particle systems in the bundle picture. A lecture note by Ezra[16] is a unifying survey of rotation, reflection and identical particle symmetry in molecules before the introduction of the bundle theory in many-particle systems.

This article is organized as follows: Section II contains a brief review of the reduction of quantum systems by a compact Lie group on the basis of the study in Ref. 4. Section III is devoted to the study of the reduction by a finite group. The reduction procedure will run in parallel with that by a compact Lie group. Section IV contains examples. To a better comprehension, the reduction procedure is performed for quantum systems on $L^2(\mathbf{R}^3)$ with SO(3) symmetry. As is stated in the beginning of this section, Fourier analysis on SO(3) reduces to that on S^2 according to the bundle structure $\mathrm{SO}(3) \to S^2$, and thereby the quantum system on $L^2(\mathbf{R}^3)$ will reduce to a series of systems defined on the closed half line $\{r \in \mathbf{R} | r \geqslant 0\}$ with r the radial variable. Boundary conditions for wave functions at $r=0$ are also analyzed by the use of the group theory. Section V centers on the application of the reduction procedure to systems of N identical particles. The reduction procedures with both a compact Lie group SO(3) and a symmetric group S_N, a discrete finite group, are performed simultaneously. Matrix representations of S_3 and S_4 will be given explicitly, which act on the center-of-mass systems for three and four particles, respectively.

II. REDUCTION BY A COMPACT LIE GROUP

We put the problem of reduction of quantum systems with symmetry in a general setting. This section is a review from Ref. 4. Let M be a manifold on which a compact Lie group G acts. Let μ_M be a G-invariant measure on M. The space $L^2(M)$ of square integrable functions on M is the Hilbert space that we take as the space of wave functions. The inner product of functions on M is denoted, as usual, by

$$\langle f_1, f_2 \rangle_{L^2(M)} = \int_M \overline{f_1(x)} f_2(x) d\mu_M(x). \tag{1}$$

The group G is represented unitarily in $L^2(M)$ through

$$(U(g)f)(x) = f(g^{-1}x), \quad g \in G, x \in M. \tag{2}$$

By the use of the representation $g \mapsto U(g)$, one can decompose $L^2(M)$ into a direct sum of subspaces. Before describing the decomposition, we have to make a brief review of the Peter–Weyl theorem on unitary representations of compact Lie groups.

Let μ_G and $L^2(G)$ denote the normalized invariant measure on G and the space of square integrable functions on G with respect to μ_G, respectively. Let $(\mathcal{H}^\chi, \rho^\chi)$ be unitary irreducible representations of G, where χ ranges over all the inequivalent unitary irreducible representations. We denote by ρ^χ_{ij} the matrix elements of the representation ρ^χ with respect to some orthonormal basis of the representation space $\mathcal{H}^\chi$, where $i,j = 1,\ldots,d_\chi$, and $d_\chi = \dim \mathcal{H}^\chi$. The Peter–Weyl theorem[2] states that the set of all the matrix elements $\{\sqrt{d_\chi}\rho^\chi_{ij}\}_{\chi,i,j}$ form a complete orthonormal system in $L^2(G)$. Then any function φ in $L^2(G)$ is expanded into a Fourier series:

$$\varphi(h) = \sum_\chi d_\chi \sum_{i,j} \rho^\chi_{ij}(h) \int_G \overline{\rho^\chi_{ij}(g)} \varphi(g) d\mu_G(g) = \sum_\chi d_\chi \sum_i \int_G \rho^\chi_{ii}(g) \varphi(g^{-1}h) d\mu_G(g). \tag{3}$$

This theorem can be used to find a Fourier series expansion of a function on M. Given a function $f \in L^2(M)$, we may view $f(hx)$ as a function of $h \in G$, if $x \in M$ is fixed arbitrarily. We may write this function as f_x, so that $f_x(h) := f(hx)$ for $h \in G$. For $\varphi = f_x$, Eq. (3) provides

$$f(hx) = \sum_\chi d_\chi \sum_i \int_G \rho^\chi_{ii}(g) f(g^{-1}hx) d\mu_G(g). \tag{4}$$

In particular, for $h = e$, this formula gives a Fourier series expansion of f:

$$f(x) = \sum_\chi d_\chi \sum_i \int_G \rho^\chi_{ii}(g) f(g^{-1}x) d\mu_G(g). \tag{5}$$

This expansion suggests we define operators P^χ_i on $L^2(M)$ to be

$$P^\chi_i := d_\chi \int_G \rho^\chi_{ii}(g) U(g) d\mu_G(g). \tag{6}$$

Then, a straightforward calculation shows that

$$(P^\chi_i)^\dagger = P^\chi_i, \quad P^\chi_i P^{\chi'}_j = \delta^{\chi\chi'} \delta_{ij} P^\chi_i. \tag{7}$$

Further, the Fourier series expansion (5) means that

$$\sum_\chi \sum_i P^\chi_i = \mathrm{id}_{L^2(M)}, \tag{8}$$

where $\mathrm{id}_{L^2(M)}$ denotes the identity map of $L^2(M)$. Equations (7) and (8) implies that the set $\{P^\chi_i\}_{\chi,i}$ forms a family of orthogonal projection operators and provides a resolution of unity. Hence one has the orthogonal decomposition of $L^2(M)$,

$$L^2(M) = \bigoplus_\chi \bigoplus_{i=1}^{d_\chi} \mathrm{Im}\, P^\chi_i. \tag{9}$$

Moreover, we define the operators

$$P^{\chi}_{ij} := d_{\chi} \int_G \rho^{\chi}_{ij}(g) U(g) d\mu_G(g), \tag{10}$$

which prove to satisfy that

$$(P^{\chi}_{ij})^{\dagger} = P^{\chi}_{ji}, \quad P^{\chi}_{ij} P^{\chi'}_{k\ell} = \delta^{\chi\chi'} \delta_{jk} P^{\chi}_{i\ell}. \tag{11}$$

In particular, from $P^{\chi}_{ii} = P^{\chi}_{i}$ along with (11), one has

$$P^{\chi}_{ij} P^{\chi}_{j} = P^{\chi}_{i} P^{\chi}_{ij}, \quad (P^{\chi}_{ij})^{\dagger} P^{\chi}_{i} = P^{\chi}_{j} (P^{\chi}_{ij})^{\dagger}, \tag{12}$$

and further

$$(P^{\chi}_{ij})^{\dagger} P^{\chi}_{ij} = P^{\chi}_{j}, \quad P^{\chi}_{ij} (P^{\chi}_{ij})^{\dagger} = P^{\chi}_{i}. \tag{13}$$

From (12) and (13), it follows that when restricted to $\mathrm{Im}\, P^{\chi}_{j}$ the operator P^{χ}_{ij} provides a unitary isomorphism

$$P^{\chi}_{ij} : \ \mathrm{Im}\, P^{\chi}_{j} \tilde{\to} \mathrm{Im}\, P^{\chi}_{i}, \quad i,j = 1,\ldots,d_{\chi}. \tag{14}$$

Furthermore, we can show that the operators P^{χ}_{ij} and $U(g)$ are composed to give

$$P^{\chi}_{ij} U(g) = \sum_k \overline{\rho^{\chi}_{jk}(g)} P^{\chi}_{ik}, \quad U(g) P^{\chi}_{ij} = \sum_k \overline{\rho^{\chi}_{ki}(g)} P^{\chi}_{kj}. \tag{15}$$

We now denote by $\mathcal{H}^{\chi} \otimes L^2(M)$ the space of $\mathcal{H}^{\chi}$-valued square integrable functions on M. The inner product in $\mathcal{H}^{\chi} \otimes L^2(M)$ is defined by

$$\langle \psi, \phi \rangle_{\mathcal{H}^{\chi} \otimes L^2(M)} = \int_M (\psi(x), \phi(x)) d\mu_M(x), \quad \psi, \phi \in \mathcal{H}^{\chi} \otimes L^2(M), \tag{16}$$

where $(\psi(x), \phi(x))$ denotes the inner product of $\psi(x)$ and $\phi(x)$ in $\mathcal{H}^{\chi}$. The second equation of (15) then implies that the map $E^{\chi}_{j} : L^2(M) \to \mathcal{H}^{\chi} \otimes L^2(M)$ defined by

$$E^{\chi}_{j} = \frac{1}{\sqrt{d_{\chi}}} (P^{\chi}_{1j}, P^{\chi}_{2j}, \ldots, P^{\chi}_{d_{\chi} j})^{T}, \tag{17}$$

the superscript T denoting the transpose, satisfies

$$U(g^{-1}) E^{\chi}_{j} = \rho^{\chi}(g) E^{\chi}_{j}, \quad g \in G, \tag{18}$$

which implies that $\mathcal{H}^{\chi}$-valued functions $E^{\chi}_{j} f$ with $f \in L^2(M)$ are subject to the transformation

$$(E^{\chi}_{j} f)(gx) = \rho^{\chi}(g) (E^{\chi}_{j} f)(x), \quad g \in G. \tag{19}$$

Put another way, the $\mathcal{H}^{\chi}$-valued functions $E^{\chi}_{j} f$ are ρ^{χ}-equivariant functions. We here define the space of $\mathcal{H}^{\chi}$-valued ρ^{χ}-equivariant square integrable functions to be

$$L^2(M; \mathcal{H}^{\chi})^{G} = \{ \psi \in \mathcal{H}^{\chi} \otimes L^2(M) \,|\, \psi(gx) = \rho^{\chi}(g) \psi(x), \ g \in G, x \in M \}. \tag{20}$$

We then observe from (19) that the operator E^{χ}_{j} is a map $L^2(M) \to L^2(M; \mathcal{H}^{\chi})^{G}$. The adjoint operator $(E^{\chi}_{j})^{\dagger} : L^2(M; \mathcal{H}^{\chi})^{G} \to L^2(M)$ is defined, of course, through

$$\langle \psi, E_j^\chi f\rangle_{\mathcal{H}^\chi\otimes L^2(M)} = \langle (E_j^\chi)^\dagger \psi, f\rangle_{L^2(M)}, \quad \psi \in L^2(M;\mathcal{H}^\chi)^G, \quad f \in L^2(M). \tag{21}$$

We note here that components of ρ^χ-equivariant functions satisfy

$$P_{ij}^\chi \psi_j = \psi_i \quad \text{for} \quad \psi = (\psi_i) \in L^2(M;\mathcal{H}^\chi)^G. \tag{22}$$

Then, from the definition of $(E_j^\chi)^\dagger$, it follows that

$$(E_j^\chi)^\dagger \psi = \sqrt{d_\chi}\,\psi_j \quad \text{for} \quad \psi = (\psi_i) \in L^2(M;\mathcal{H}^\chi)^G. \tag{23}$$

Further, from (22) and (23), one can easily show that

$$(E_j^\chi)^\dagger E_j^\chi = P_j^\chi, \quad E_j^\chi (E_j^\chi)^\dagger = \mathrm{id}_{L^2(M;\mathcal{H}^\chi)^G}, \tag{24}$$

which implies that when restricted to $\mathrm{Im}\, P_j^\chi$ the map E_j^χ provides a unitary isomorphism

$$E_j^\chi : \ \mathrm{Im}\, P_j^\chi \xrightarrow{\sim} L^2(M;\mathcal{H}^\chi)^G, \quad j = 1,\ldots,d_\chi, \tag{25}$$

so that all $\mathrm{Im}\, P_j^\chi$, $j=1,\ldots,d_\chi$, are unitarily isomorphic to one another.

Forming the direct sum of d_χ copies of $L^2(M;\mathcal{H}^\chi)^G$, we obtain

$$\bigoplus_{j=1}^{d_\chi} \mathrm{Im}\, P_j^\chi \cong (\mathcal{H}^\chi)^* \otimes L^2(M;\mathcal{H}^\chi)^G. \tag{26}$$

From (9) and (26), $L^2(M)$ is decomposed, in conclusion, into

$$L^2(M) \cong \bigoplus_\chi ((\mathcal{H}^\chi)^* \otimes L^2(M;\mathcal{H}^\chi)^G). \tag{27}$$

We are now in a position to describe a method for reducing quantum systems with symmetry. Let $\hat{H}$ be a Hamiltonian operator acting on a dense domain in $L^2(M)$. We assume that $\hat{H}$ and $U(g)$ commute for any $g \in G$. Then $\hat{H}$ and P_i^χ also commute, so that the subspace $\mathrm{Im}\, P_i^\chi$ is invariant under $\hat{H}$. This implies that the quantum system $(L^2(M),\hat{H})$ reduces to a series of subsystems $(\mathrm{Im}\, P_i^\chi,\hat{H})$ or equivalently to $(L^2(M;\mathcal{H}^\chi)^G, \mathrm{id}_{\mathcal{H}^\chi}\otimes\hat{H})$, where $\mathrm{id}_{\mathcal{H}^\chi}\otimes\hat{H}$ means that $\mathcal{H}^\chi$-valued functions are operated componentwise with $\hat{H}$. The assumption we have used so far is that M carries the G-invariant measure μ_M. To give an example of $\hat{H}$ explicitly, we now assume that M is endowed with a Riemannian metric and that G acts on M by isometry. We take $d\mu_M$ as the volume element formed from the metric. As usual, we take $\hat{H} = -\frac{1}{2}\Delta_M + v$, where Δ_M is the Laplacian on M and v is a G-invariant function on M. Since this Hamiltonian is G-invariant, the quantum system $(L^2(M),\hat{H})$ reduces to $(L^2(M;\mathcal{H}^\chi)^G, \mathrm{id}_{\mathcal{H}^\chi}\otimes\hat{H})$.

If the action of the compact Lie group G is free furthermore, M is made into a fiber bundle $M \to M/G$ with structure group G. Then, as is well known, the space of the $\mathcal{H}^\chi$-valued ρ^χ-equivariant functions is in one-to-one correspondence with the space of sections in the complex vector bundle associated with the principal bundle $M \to M/G$. According to this, the Hamiltonian operator $\mathrm{id}_{\mathcal{H}^\chi}\otimes\hat{H}$ gives rise to a Hamiltonian operator $\hat{H}^\chi$ acting on the space of sections. Let $\Gamma_\chi^2(M/G)$ denote the space of square integrable sections in the complex vector bundle. The reduced quantum system $(L^2(M;\mathcal{H}^\chi)^G, \mathrm{id}_{\mathcal{H}^\chi}\otimes\hat{H})$ now determines a quantum system $(\Gamma_\chi^2(M/G),\hat{H}^\chi)$. To find $\hat{H}^\chi$ in an explicit manner, we need a further study, which we do not touch upon here (see Ref. 4 for details).

If the action of G is not free, the orbit space M/G is not a manifold, and hence the bundle picture of reduction procedure stated above fails to work. However, the reduction to

$(L^2(M;\mathcal{H}^\chi)^G, \mathrm{id}_{\mathcal{H}^\chi}\otimes\hat{H})$ remains to be the case. In some cases, orbit spaces become manifolds with boundary. For example, for $M=\mathbf{R}^3$ and $G=\mathrm{SO}(3)$, the orbit space M/G is a closed half line $\{r\in\mathbf{R}|r\geqslant 0\}$. This will be treated in Sec. IV.

III. REDUCTION BY A FINITE GROUP

We wish to show that the reduction procedure will work as well if we take finite groups in place of compact Lie groups. We start with a review of the Peter–Weyl theorem for finite groups. Let H be a finite group. Let π^χ_{ij} denote the matrix elements of the representation $(\mathcal{K}^\chi,\pi^\chi)$ of H, where $i,j=1,\ldots,d^\chi$ with $d^\chi=\dim\mathcal{K}^\chi$, and χ ranges all the inequivalent unitary irreducible representations. The Peter–Weyl theorem for finite groups[3] says that all the matrix elements $\{\pi^\chi_{ij}\}_{\chi,i,j}$ form a complete orthogonal set in $L^2(H)$. The inner product for $\varphi,\psi\in L^2(H)$ is defined, as usual, to be

$$\langle\varphi,\psi\rangle_{L^2(H)}=\sum_{g\in H}\overline{\varphi(g)}\psi(g). \tag{28}$$

The orthogonality of the matrix elements is expressed as

$$\frac{d^\chi}{|H|}\sum_{g\in H}\overline{\pi^\chi_{ij}(g)}\pi^{\chi'}_{i'j'}(g)=\delta_{\chi\chi'}\delta_{ii'}\delta_{jj'}, \tag{29}$$

where $|H|=\#H$, the order of H. The Fourier inversion formula then holds to provide

$$\varphi(g)=\frac{1}{|H|}\sum_\chi d^\chi\sum_{1\leqslant i,j\leqslant d^\chi}\pi^\chi_{ij}(g)\langle\pi^\chi_{ij},\varphi\rangle_{L^2(H)}=\frac{1}{|H|}\sum_\chi d^\chi\sum_{j=1}^{d^\chi}\sum_{k\in H}\overline{\pi^\chi_{jj}(k)}\varphi(gk). \tag{30}$$

Let M be a manifold which admits a right action of H, where the right action means that $x(gh)=(xg)h$ for $x\in M$ and $g,h\in H$. Let $L^2(M)$ denote the space of square integrable functions on M, where the measure μ_M on M is assumed to be invariant under H. The H is unitarily represented in $L^2(M)$ through

$$(V(g)f)(x)=f(xg),\quad x\in M,\ g\in H. \tag{31}$$

Applying the Peter–Weyl formula for $f(xg)$ with $x\in M$ arbitrarily fixed, one obtains

$$f(xg)=\frac{1}{|H|}\sum_\chi d^\chi\sum_{1\leqslant i,j\leqslant d^\chi}\pi^\chi_{ij}(g)\sum_{h\in H}\overline{\pi^\chi_{ij}(h)}f(xh)=\sum_\chi\sum_{j=1}^{d^\chi}\frac{d^\chi}{|H|}\sum_{k\in H}\overline{\pi^\chi_{jj}(k)}f(xgk). \tag{32}$$

In particular, for $g=e$, this formula gives a Fourier series expansion of f,

$$f(x)=\sum_\chi\sum_{j=1}^{d^\chi}\frac{d^\chi}{|H|}\sum_{k\in H}\overline{\pi^\chi_{jj}(k)}f(xk). \tag{33}$$

This suggests we define operators Q^χ_j on $L^2(M)$ by

$$Q^\chi_j=\frac{d^\chi}{|H|}\sum_{k\in H}\overline{\pi^\chi_{jj}(k)}V(k). \tag{34}$$

A straightforward calculation shows that

$$(Q^\chi_i)^\dagger=Q^\chi_i,\quad Q^\chi_iQ^{\chi'}_{i'}=\delta^{\chi\chi'}\delta_{ii'}Q^\chi_i, \tag{35}$$

which means that Q_j^χ's form a family of mutually orthogonal projection operators. The Fourier series expansion (33) is now put in the form

$$f(x)=\sum_\chi \sum_{j=1}^{d^\chi} (Q_j^\chi f)(x), \tag{36}$$

which implies that $L^2(M)$ is decomposed into

$$L^2(M)=\bigoplus_\chi \bigoplus_{j=1}^{d^\chi} \mathrm{Im}\, Q_j^\chi. \tag{37}$$

We now define operators Q_{ij}^χ on $L^2(M)$ to be

$$Q_{ij}^\chi=\frac{d^\chi}{|H|}\sum_{k\in H}\overline{\pi_{ij}^\chi(k)}V(k). \tag{38}$$

A straightforward calculation shows that these operators have the properties

$$(Q_{ij}^\chi)^\dagger=Q_{ji}^\chi, \quad Q_{ij}^\chi Q_{i'j'}^{\chi'}=\delta^{\chi\chi'}\delta_{ji'}Q_{ij'}^\chi. \tag{39}$$

In particular, from $Q_{ii}^\chi=Q_i^\chi$ together with (39), one verifies that

$$Q_{ij}^\chi Q_j^\chi=Q_i^\chi Q_{ij}^\chi=Q_{ij}^\chi, \tag{40}$$

and further that

$$(Q_{ij}^\chi)^\dagger Q_{ij}^\chi=Q_j^\chi, \quad Q_{ij}^\chi(Q_{ij}^\chi)^\dagger=Q_i^\chi. \tag{41}$$

From (40) and (41), it turns out that when restricted to $\mathrm{Im}\, Q_j^\chi$ the map Q_{ij}^χ provides a unitary isomorphism,

$$Q_{ij}^\chi:\ \mathrm{Im}\, Q_j^\chi \xrightarrow{\sim} \mathrm{Im}\, Q_i^\chi, \quad i,j=1,\ldots,d^\chi. \tag{42}$$

We can also verify that Q_{ij}^χ and $V(g)$ are composed to give

$$Q_{ij}^\chi V(g)=\sum_\ell \pi_{j\ell}^\chi(g)Q_{i\ell}^\chi, \quad V(g)Q_{ij}^\chi=\sum_\ell \pi_{\ell i}^\chi(g)Q_{\ell j}^\chi. \tag{43}$$

We here denote by $\mathcal{K}^\chi\otimes L^2(M)$ the space of $\mathcal{K}^\chi$-valued square integrable functions on M. Then the second equation of (43) implies that the operators $F_j^\chi: L^2(M)\to\mathcal{K}^\chi\otimes L^2(M)$ defined to be

$$F_j^\chi:=\frac{1}{\sqrt{d^\chi}}(Q_{1j}^\chi,\ldots,Q_{d^\chi j}^\chi)^T \tag{44}$$

have the property

$$V(g)F_j^\chi=\pi^\chi(g)^T F_j^\chi, \quad g\in H. \tag{45}$$

This implies that for $f\in L^2(M)$ the $\mathcal{K}^\chi$-valued function $F_j^\chi f$ is subject to the transformation

$$(F_j^\chi f)(xg)=\pi^\chi(g)^T(F_j^\chi f)(x), \quad g\in H. \tag{46}$$

We may say that the $\mathcal{K}^\chi$-valued function $F_j^\chi f$ is π^χ-equivariant. We here define the space of $\mathcal{K}^\chi$-valued square integrable π^χ-equivariant functions to be

$$L^2(M;\mathcal{K}^\chi)^H=\{\psi\in\mathcal{K}^\chi\otimes L^2(M)\,|\,\psi(xg)=\pi^\chi(g)^T\psi(x),\ \ g\in H, x\in M\}. \tag{47}$$

Then Eq. (46) shows that the operator F_j^χ is a map $L^2(M)\to L^2(M;\mathcal{K}^\chi)^H$. The adjoint operator $(F_j^\chi)^\dagger: L^2(M;\mathcal{K}^\chi)^H\to L^2(M)$ is defined through

$$\langle\psi,F_j^\chi f\rangle_{\mathcal{K}^\chi\otimes L^2(M)}=\langle(F_j^\chi)^\dagger\psi,f\rangle_{L^2(M)},\quad \psi\in L^2(M;\mathcal{K}^\chi)^H,\ \ f\in L^2(M). \tag{48}$$

We notice here that components ψ_i of $\psi\in L^2(M;\mathcal{K}^\chi)^H$ are related by Q_{ij}^χ:

$$Q_{ij}^\chi\psi_j=\psi_i,\quad i,j=1,\ldots,d^\chi. \tag{49}$$

Then, writing out the defining equation of $(F_j^\chi)^\dagger$, one obtains

$$(F_j^\chi)^\dagger\psi=\sqrt{d^\chi}\psi_j\quad\text{for}\quad\psi=(\psi_i)\in L^2(M;\mathcal{K}^\chi)^H. \tag{50}$$

Now it is easy to verify that

$$(F_j^\chi)^\dagger F_j^\chi=Q_j^\chi,\quad F_j^\chi(F_j^\chi)^\dagger=\mathrm{id}_{L^2(M;\mathcal{K}^\chi)^H}. \tag{51}$$

This implies that when restricted to $\mathrm{Im}\,Q_j^\chi$ the operator F_j^χ provides a unitary isomorphism

$$F_j^\chi:\ \mathrm{Im}\,Q_j^\chi\tilde{\to}L^2(M;\mathcal{K}^\chi)^H,\quad j=1,\ldots,d^\chi, \tag{52}$$

so that all $\mathrm{Im}\,Q_j^\chi, j=1,\ldots,d^\chi$, are unitarily isomorphic to one another.

Forming the direct sum of d^χ copies of $L^2(M;\mathcal{K}^\chi)^H$, we obtain the isomorphism

$$\bigoplus_j\ \mathrm{Im}\,Q_j^\chi\cong(\mathcal{K}^\chi)^*\otimes L^2(M;\mathcal{K}^\chi)^H, \tag{53}$$

and further, from (37),

$$L^2(M)\cong\bigoplus_\chi\ ((\mathcal{K}^\chi)^*\otimes L^2(M;\mathcal{K}^\chi)^H). \tag{54}$$

Reduction procedure for quantum systems with discrete symmetry is quite the same as that for those with compact Lie group symmetry. If the Hamiltonian $\hat{H}$ is invariant under the H action, the original system $(L^2(M),\hat{H})$ reduces to a series of subsystems $(\mathrm{Im}\,Q_j^\chi,\hat{H})$ and then equivalently to $(L^2(M;\mathcal{K}^\chi)^H,\mathrm{id}_{\mathcal{K}^\chi}\otimes\hat{H})$.

IV. EXAMPLES

In this section, we give examples of the reduction procedure discussed in Secs. II and III. As the group SO(3) is the most frequently used compact Lie group in ordinary quantum mechanics, we first perform the reduction procedure with $G=\mathrm{SO}(3)$ and $M=\mathbf{R}^3$. In this case, one has matrix elements $D_{mm'}^\ell$ for ρ_{ij}^χ, where $\ell=0,1,2,\ldots$, $|m|,|m'|\leqslant\ell$, and $d_\chi=2\ell+1$. Then the Fourier series expansion (5) is put in the form

$$f(\mathbf{x})=\sum_{\ell=0}^\infty\ \sum_{|m|\leqslant\ell}\ (2\ell+1)\int_{\mathrm{SO}(3)}\overline{D_{mm}^\ell(h)}f(h\mathbf{x})d\mu(h),\quad \mathbf{x}\in\mathbf{R}^3, \tag{55}$$

where $d\mu(h)$ is the invariant measure on SO(3) and expressed in terms of the Euler angles $h=e^{\phi\hat{\mathbf{e}}_3}e^{\theta\hat{\mathbf{e}}_2}e^{\psi\hat{\mathbf{e}}_3}$ as

$$d\mu(h)=\frac{1}{2\pi^2}\sin\theta\, d\theta d\phi d\psi \quad \text{with} \quad \int_{\mathrm{SO}(3)} d\mu(h)=1, \tag{56}$$

where $\mathbf{e}_k$, $k=1,2,3$, are the standard basis of $\mathbf{R}^3$ and $\hat{\mathbf{e}}_k$ denote the 3×3 matrices defined by $\hat{\mathbf{e}}_k\mathbf{a}=\mathbf{e}_k\times\mathbf{a}$ for $\mathbf{a}\in\mathbf{R}^3$. We wish to show that Eq. (55) provides actually a Fourier series expansion in terms of the spherical harmonics. To this end, we are to write out the integrals on the right-hand side of (55). Let $|\mathbf{x}|=r$ and set $\mathbf{x}=rg\mathbf{e}_3$, $g\in\mathrm{SO}(3)$. Then, introducing new variable $k=hg\in\mathrm{SO}(3)$, one obtains

$$\int_{\mathrm{SO}(3)}\overline{D^{\ell}_{mm}(h)}f(h\mathbf{x})d\mu(h)=\sum_{|n|\leqslant\ell}\int_{\mathrm{SO}(3)}\overline{D^{\ell}_{mn}(k)D^{\ell}_{nm}(g^{-1})}f(rk\mathbf{e}_3)d\mu(k). \tag{57}$$

We now set $k=e^{\phi'\hat{\mathbf{e}}_3}e^{\theta'\hat{\mathbf{e}}_2}e^{\psi'\hat{\mathbf{e}}_3}$, and use the fact that the D-functions[17] are expressed as

$$D^{\ell}_{mn}(k)=e^{-im\phi'}d^{\ell}_{mn}(\theta')e^{-in\psi'}, \tag{58}$$

where we do not need to give the explicit expression of $d^{\ell}_{mn}(\theta')$, but need only to note that the D-functions are factorized in accordance with the Euler variables. Then the integration with respect to $d\mu(k)$ in (57) is put in the form

$$\int_{\mathrm{SO}(3)}\overline{D^{\ell}_{mn}(k)}f(rk\mathbf{e}_3)d\mu(k)=\frac{1}{8\pi^2}\int_0^{2\pi}d\psi' e^{in\psi'}\int_{S^2}d^{\ell}_{mn}(\theta')e^{im\phi'}f(rk\mathbf{e}_3)\sin\theta'\,d\theta'\,d\phi'. \tag{59}$$

Since the right-hand side of (59) vanishes if $n\neq 0$, the Fourier series expansion (55) turns out to take the form

$$\begin{aligned} f(\mathbf{x})&=\sum_{\ell=0}^{\infty}\sum_{|m|\leqslant\ell}(2\ell+1)\int_{\mathrm{SO}(3)}\overline{D^{\ell}_{m0}(k)D^{\ell}_{0m}(g^{-1})}f(rk\mathbf{e}_3)d\mu(k)\\ &=\sum_{\ell=0}^{\infty}\sum_{|m|\leqslant\ell}\overline{Y}_{\ell m}(\theta,\phi)\int_{S^2}Y_{\ell m}(\theta',\phi')f(rk\mathbf{e}_3)\sin\theta'\,d\theta'\,d\phi', \end{aligned} \tag{60}$$

where we have also set $g=e^{\phi\hat{\mathbf{e}}_3}e^{\theta\hat{\mathbf{e}}_2}e^{\psi\hat{\mathbf{e}}_3}$ and used the formulas that relate D-functions to spherical harmonics:[16]

$$\overline{D^{\ell}_{m0}(k)}=\sqrt{\frac{4\pi}{2\ell+1}}Y_{\ell m}(\theta',\phi'),\quad \overline{D^{\ell}_{0m}(g^{-1})}=D^{\ell}_{m0}(g)=\sqrt{\frac{4\pi}{2\ell+1}}\overline{Y}_{\ell m}(\theta,\phi), \tag{61}$$

and $Y_{\ell m}(\theta,\phi)$ are given explicitly by

$$Y_{\ell m}(\theta,\phi)=(-1)^m\sqrt{\frac{(2\ell+1)(\ell-m)!}{4\pi(\ell-m)!}}P^m_{\ell}(\cos\theta)e^{im\phi}, \tag{62}$$

where P^m_{ℓ} are associated Legendre functions.[16] We notice here that $\overline{Y}_{\ell m}(\theta,\phi)=\overline{Y}_{\ell m}(g\mathbf{e}_3)$ may be considered as functions on S^2. If we introduce the notation

$$\langle\overline{Y}_{\ell m},f\rangle_{S^2}=:\int_{S^2}Y_{\ell m}(\theta',\phi')f(rk\mathbf{e}_3)\sin\theta'\,d\theta'\,d\phi', \tag{63}$$

which is a function of r, the Fourier series expansion (60) is put in the form

$$f(\mathbf{x})=\sum_{\ell=0}^{\infty}\sum_{|m|\leqslant\ell}\overline{Y}_{\ell m}(\theta,\phi)\langle\overline{Y}_{\ell m},f\rangle_{S^2},\quad \mathbf{x}=re^{\phi\hat{\mathbf{e}}_3}e^{\theta\hat{\mathbf{e}}_2}\mathbf{e}_3. \tag{64}$$

Thus we have obtained a Fourier series expansion in terms of spherical harmonics. It is of great interest to view the function $f(rk\mathbf{e}_3)$ in (63) as a function on $\mathbf{R}_+\times S^2$ which is reduced from a function on $\mathbf{R}_+\times\mathrm{SO}(3)$ through the bundle projection $\mathrm{SO}(3)\to S^2$ realized as $k\mapsto k\mathbf{e}_3$.

We proceed to the projection and "transition" operators, which are defined by (6) and (10) and denoted by P^{ℓ}_{m} and P^{ℓ}_{nm}, respectively, in the case of $G=\mathrm{SO}(3)$. Applied to a function $f(\mathbf{x})$ with $|\mathbf{x}|=r$ and $\mathbf{x}=rg\mathbf{e}_3$, the definition (10) gives rise to the function

$$(P^{\ell}_{nm}f)(\mathbf{x})=(2\ell+1)\int_{\mathrm{SO}(3)}D^{\ell}_{nm}(h)f(h^{-1}\mathbf{x})d\mu(h)=\overline{Y}_{\ell n}(\theta,\phi)\langle\overline{Y}_{\ell m},f\rangle_{S^2}, \tag{65}$$

which can be proved in a similar manner to that for bringing (55) into (60). Setting $m=n$ in the above equation results in

$$(P^{\ell}_{m}f)(\mathbf{x})=\overline{Y}_{\ell m}(\theta,\phi)\langle\overline{Y}_{\ell m},f\rangle_{S^2}, \tag{66}$$

which means that $\mathrm{Im}\,P^{\ell}_{m}$ is the space of functions which are expressed as $\overline{Y}_{\ell m}$ times functions of r. In particular, operating $\overline{Y}_{\ell m}$ with P^{ℓ}_{nm}, one obtains

$$(P^{\ell}_{nm}\overline{Y}_{\ell m})(\theta,\phi)=\overline{Y}_{\ell n}(\theta,\phi). \tag{67}$$

Then the unitary isomorphism $P^{\ell}_{nm}:\mathrm{Im}\,P^{\ell}_{m}\to\mathrm{Im}\,P^{\ell}_{n}$ [see (14)] implies that the spaces $\mathrm{Im}\,P^{\ell}_{n}$, $|n|\leqslant\ell$, are isomorphic to one another as spaces of functions of r. In the Dirac notation, we may describe P^{ℓ}_{nm} and P^{ℓ}_{m} as

$$P^{\ell}_{nm}=|\overline{Y}_{\ell n}\rangle\langle\overline{Y}_{\ell m}|,\quad P^{\ell}_{m}=|\overline{Y}_{\ell m}\rangle\langle\overline{Y}_{\ell m}|, \tag{68}$$

respectively. Here, integration must be performed not over $\mathbf{R}^3$ but over S^2, if one wishes to evaluate $P^{\ell}_{m}f$, for example.

We now proceed to the map E^{χ}_{j} defined by (17). From the definition along with (68), we see that $E^{\ell}_{m}:L^2(\mathbf{R}^3)\to\mathcal{H}^{\ell}\otimes L^2(\mathbf{R}^3)$ is given by

$$E^{\ell}_{m}f=\frac{1}{\sqrt{2\ell+1}}\begin{pmatrix}P^{\ell}_{\ell m}f\\ P^{\ell}_{\ell-1\,m}f\\ \vdots\\ P^{\ell}_{-\ell\,m}f\end{pmatrix}=\begin{pmatrix}\overline{Y}_{\ell\ell}\\ \overline{Y}_{\ell\,\ell-1}\\ \vdots\\ \overline{Y}_{\ell\,-\ell}\end{pmatrix}\frac{\langle\overline{Y}_{\ell m},f\rangle_{S^2}}{\sqrt{2\ell+1}}. \tag{69}$$

According to (19), $E^{\ell}_{m}f$ must be a D^{ℓ}-equivariant function, that is, it must satisfy the condition

$$(E^{\ell}_{m}f)(h\mathbf{x})=D^{\ell}(h)(E^{\ell}_{m}f)(\mathbf{x}),\quad h\in\mathrm{SO}(3). \tag{70}$$

However, this can also be shown to hold from the transformation rule for the spherical harmonics,

$$\overline{Y}_{\ell m}(hg\mathbf{e}_3)=\sum_{|n|\leqslant\ell}D^{\ell}_{mn}(h)\overline{Y}_{\ell n}(g\mathbf{e}_3),\quad h\in\mathrm{SO}(3), \tag{71}$$

and from the SO(3) invariance of $\langle\overline{Y}_{\ell m},f\rangle_{S^2}$.

We have to note here that if h is in $G_{\mathbf{x}}$, the isotropy subgroup of SO(3) at $\mathbf{x}=rg\mathbf{e}_3$, Eq. (70) reduces to

$$(E^{\ell}_{m}f)(\mathbf{x})=D^{\ell}(h)(E^{\ell}_{m}f)(\mathbf{x}),\quad h\in G_{\mathbf{x}}. \tag{72}$$

Since the left-hand side of the above equation is independent of h, so is the right-hand side which looks dependent on h. However, this is not a contradiction, but rather accounts for the fact that $P^{\ell}_{nm}f(=\overline{Y}_{\ell n}\langle\overline{Y}_{\ell m},f\rangle_{S^2})$ is expressed as $\overline{Y}_{\ell n}$ times a function of r. The proof runs as follows: Let $h\in G_{\mathbf{x}}$ with $\mathbf{x}\neq 0$. Then h must be a rotation about the $\mathbf{x}$-axis, and is expressed as

$$h=e^{t\hat{\mathbf{x}}/r}=ge^{t\hat{\mathbf{e}}_3}g^{-1},\quad \mathbf{x}=rg\mathbf{e}_3,\quad t\in\mathbf{R}. \tag{73}$$

Put together, Eqs. (72) and (73) give rise to

$$(E^{\ell}_m f)(r\mathbf{e}_3)=D^{\ell}(e^{t\hat{\mathbf{e}}_3})(E^{\ell}_m f)(r\mathbf{e}_3). \tag{74}$$

Since $D^{\ell}_{nm}(e^{t\hat{\mathbf{e}}_3})=e^{-int}\delta_{nm}$, the above equation implies that 2ℓ components of $(E^{\ell}_m f)(r\mathbf{e}_3)$ vanish:

$$(P^{\ell}_{nm}f)(r\mathbf{e}_3)=0\quad \text{if}\quad n\neq 0. \tag{75}$$

From (15) and (75), it follows that

$$(P^{\ell}_{nm}f)(\mathbf{x})=\sum_{|k|\leqslant\ell}D^{\ell}_{nk}(g)(P^{\ell}_{km}f)(r\mathbf{e}_3)=D^{\ell}_{n0}(g)(P^{\ell}_{0m}f)(r\mathbf{e}_3). \tag{76}$$

We observe from (61) and (76) that $(P^{\ell}_{nm}f)(\mathbf{x})$ takes the form of $\overline{Y}_{\ell n}(g\mathbf{e}_3)$ times a function of r, $\sqrt{4\pi/(2\ell+1)}(P^{\ell}_{0m}f)(r\mathbf{e}_3)$.

With $P^{\ell}_m f=\overline{Y}_{\ell m}\langle\overline{Y}_{\ell m},f\rangle_{S^2}$ instead of f, the right-hand side of (69) is unchanged:

$$E^{\ell}_m P^{\ell}_m f=\begin{pmatrix}\overline{Y}_{\ell\ell}\\ \overline{Y}_{\ell\,\ell-1}\\ \vdots\\ \overline{Y}_{\ell\,-\ell}\end{pmatrix}\frac{\langle\overline{Y}_{\ell m},f\rangle_{S^2}}{\sqrt{2\ell+1}}. \tag{77}$$

This equation must be a realization of the unitary isomorphism (25), which is denoted by E^{ℓ}_m: $\mathrm{Im}\,P^{\ell}_m\to L^2(\mathbf{R}^3;\mathcal{H}^{\ell})^{\mathrm{SO}(3)}$ in the present case, where $\mathcal{H}^{\ell}\cong\mathbf{C}^{2\ell+1}$. From (66) and (77), both $\mathrm{Im}\,P^{\ell}_m$ and $L^2(\mathbf{R}^3;\mathcal{H}^{\ell})^{\mathrm{SO}(3)}$ may be identified with the space of functions of the form $\langle\overline{Y}_{\ell m},f\rangle_{S^2}$. This space can be endowed with a suitable norm. We set $\varphi_{\ell m}(r)=\langle\overline{Y}_{\ell m},f\rangle_{S^2}$ for simplicity. Then, the squared norm of $P^{\ell}_m f=\overline{Y}_{\ell m}\varphi_{\ell m}$ is calculated as

$$\int_0^{\infty}dr\int_{S^2}\overline{\varphi_{\ell m}(r)}\varphi_{\ell m}(r)\overline{Y}_{\ell m}Y_{\ell m}\,r^2\sin\theta\,d\theta d\phi=\int_0^{\infty}|\varphi_{\ell m}(r)|^2r^2dr. \tag{78}$$

Thus $L^2(\mathbf{R}^3;\mathcal{H}^{\ell})^{\mathrm{SO}(3)}$ can be identified with the space of functions of r which are subject to the condition

$$\int_0^{\infty}|\varphi(r)|^2r^2dr<+\infty. \tag{79}$$

To consider boundary conditions for $\varphi(r)$ at $r=0$, we now take into account the D^{ℓ}-equivariance condition (70) at the origin. Since the isotropy subgroup at the origin is SO(3) itself, the D^{ℓ}-equivariance condition (70) at the origin is expressed as

$$\overline{Y}_{\ell n}(g\mathbf{e}_3)\varphi_{\ell m}(0)=\sum_{|m'|\leqslant\ell}D^{\ell}_{nm'}(h)\overline{Y}_{\ell m'}(g\mathbf{e}_3)\varphi_{\ell}(0)\quad\text{for}\quad\forall\,h\in\mathrm{SO}(3). \tag{80}$$

This implies that the vector $(\overline{Y}_{\ell n}\varphi_{\ell m}(0))_{|n|\leqslant\ell}\in\mathcal{H}^{\ell}$ is invariant under the action of all the matrices $D^{\ell}(h)$, $h\in\mathrm{SO}(3)$. Since the representation D^{ℓ} is irreducible, $\varphi_{\ell m}(0)$ must vanish if $\dim\mathcal{H}^{\ell}\geqslant 2$, i.e., $\ell\geqslant 1$. If $\ell=0$, then $\dim\mathcal{H}^{0}=1$, so that $\varphi_{\ell m}(0)$ does not need to vanish. It should be a finite value. Thus the space of square integrable functions on the closed half line $\{r\in\mathbf{R}|\ r\geqslant 0\}$, as a reduced space of quantum states, should be given by

$$\left\{\varphi\left|\int_0^{\infty}|\varphi(r)|^2r^2dr<+\infty,\quad \varphi(0)=0\right.\right\}\quad\text{for}\quad \ell\geqslant 1, \tag{81}$$

and

$$\left\{\varphi\left|\int_0^{\infty}|\varphi(r)|^2r^2dr<+\infty,\ \ \varphi(r)\text{is bounded as } r\to 0\right.\right\}\quad\text{for}\quad \ell=0. \tag{82}$$

The reduction procedure for quantum systems with symmetry proceeds as follows: Let $(L^2(\mathbf{R}^3),\hat{H})$ be a quantum system with a Hamiltonian operator $\hat{H}$. Assume that $\hat{H}$ is invariant under the action of SO(3). According to the procedure stated in Sec. II, one obtains a reduced quantum system $(\mathrm{Im}\,P_m^{\ell},\hat{H})$ or $(L^2(\mathbf{R}^3;\mathcal{H}^{\ell})^{\mathrm{SO}(3)},\mathrm{id}_{\mathcal{H}}^{\ell}\otimes\hat{H})$. The space $L^2(\mathbf{R}^3;\mathcal{H}^{\ell})^{\mathrm{SO}(3)}$ may be identified with the L^2-space on the half line which is defined by (81) for $\ell\geqslant 1$ and by (82) for $\ell=0$.

We show that the reduced quantum system $(\mathrm{Im}\,P_m^{\ell},\hat{H})$ gives rise to a quantum system to be defined on the closed half line $\{r\in\mathbf{R}|r\geqslant 0\}$. For simplicity, we assume that the Hamiltonian operator has the form

$$\hat{H}=-\tfrac{1}{2}\Delta+v(r), \tag{83}$$

where Δ and $v(r)$ are the standard Laplacian on $\mathbf{R}^3$ and a potential function depending on $r=|\mathbf{x}|$, respectively. The Δ is expressed, in terms of the spherical polar coordinates, as

$$\Delta=\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{1}{r^2}\Lambda, \tag{84}$$

where Λ is the spherical Laplacian on S^2,

$$\Lambda=\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2}. \tag{85}$$

Operating $P_m^{\ell}f=\overline{Y}_{\ell m}\varphi_{\ell m}$ with $\hat{H}$, one obtains

$$\hat{H}P_m^{\ell}f=\overline{Y}_{\ell m}\left(-\frac{1}{2}\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{\ell(\ell+1)}{2r^2}+v(r)\right)\varphi_{\ell m}, \tag{86}$$

where we have used the fact that

$$\Lambda\overline{Y}_{\ell m}=-\ell(\ell+1)\overline{Y}_{\ell m}. \tag{87}$$

Equation (86) shows that the Hamitonian $\hat{H}$ restricted to $\mathrm{Im}\,P_m^{\ell}$ gives rise to the operator

$$\hat{H}^{\ell}:=-\frac{1}{2}\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{\ell(\ell+1)}{2r^2}+v(r), \tag{88}$$

which acts on functions of r. Here we have denoted the restricted operator by $\hat{H}^{\ell}$ without referring to m, since it is independent of m, actually. Thus we have obtained reduced quantum systems which are defined on the space given by (81) or (82) together with the reduced Hamiltonian operator $\hat{H}^{\ell}$ given by (88).

In conclusion of this example, we consider what boundary conditions come out on wave functions if those wave functions are assumed to be analytic at the origin. Let f be analytic at the origin. Then f is expressed as

$$f(\mathbf{x})=\sum_{n=0}^{\infty}\sum_{\substack{i+j+k=n\\ i\geqslant 0,j\geqslant 0,k\geqslant 0}} c_{ijk}x_1^i x_2^j x_3^k=\sum_{n=0}^{\infty} r^n\left(Y_n^{(n)}+Y_{n-2}^{(n)}+\cdots+\begin{Bmatrix} Y_0^{(n)} & (\text{if } n \text{ is even})\\ Y_1^{(n)} & (\text{if } n \text{ is odd})\end{Bmatrix}\right), \tag{89}$$

where $Y_k^{(n)}$ are spherical harmonics of degree k, $k=0,2,\ldots,n$ or $k=1,3,\ldots,n$, depending on whether n is even or odd. Here, use has been made of the fact that the space, $P^n(\mathbf{R}^3)$, of homogeneous polynomials of degree n is decomposed into the direct sum[18]

$$P^n(\mathbf{R}^3)=H^n(\mathbf{R}^3)\oplus r^2H^{n-2}(\mathbf{R}^3)\oplus\cdots\oplus\begin{cases} r^nH^0(\mathbf{R}^3) & (\text{if } n \text{ is even}),\\ r^{n-1}H^1(\mathbf{R}^3) & (\text{if } n \text{ is odd}),\end{cases} \tag{90}$$

where $H^k(\mathbf{R}^3)$ denotes the space of solid harmonics of degree k, and each spherical harmonic $Y_k^{(n)}$ in (89) is expressed as a linear combination of the basis of spherical harmonics, Y_{km}, $|m|\leqslant k$, of degree k:

$$Y_k^{(n)}=\sum_{|m|\leqslant k} c_m^{(n)}Y_{km}. \tag{91}$$

If we rewrite the Taylor series (89) as a Fourier series with respect to spherical harmonics $Y_{\ell m}$, and put together the terms containing spherical harmonics of degree ℓ, then we obtain

$$r^{\ell}Y_{\ell}^{(\ell)}+r^{\ell+2}Y_{\ell}^{(\ell+2)}+\cdots=\sum_{|m|\leqslant \ell}(r^{\ell}c_m^{(\ell)}+r^{\ell+2}c_m^{(\ell+2)}+\cdots)Y_{\ell m}. \tag{92}$$

This implies that if a quantum state with the angular momentum eigenvalues $\mathbf{J}^2=\ell(\ell+1)$ and $J_3=m$ is analytic at the origin, it is $Y_{\ell m}$ times an analytic function of r which has the term of the lowest order ℓ and those of every other higher order. This fact was pointed out in Ref. 1 with the assumption that $v(r)$ is analytic at $r=0$. Our conclusion holds true if $v(r)$ is not analytic at $r=0$, as long as a wave function analytic at the origin is admitted as a quantum state.

We turn to an example of the reduction by a finite group. Since we shall deal with a nontrivial application of it in the next section, we give here a quite simple example. Let $M=\mathbf{R}^n$ and $H=\mathbf{Z}_2=\{\pm 1\}$. The group $\mathbf{Z}_2$ acts on $\mathbf{R}^n$ in the manner

$$x\mapsto\varepsilon x,\quad x\in\mathbf{R}^n,\quad \varepsilon\in\mathbf{Z}_2. \tag{93}$$

All the inequivalent unitary irreducible representations are the trivial representation, $\varepsilon\mapsto 1$, and the tautological representation, $\varepsilon\mapsto\varepsilon$. Then the Fourier series expansion (36) becomes simply

$$f(x)=\tfrac{1}{2}(f(x)+f(-x))+\tfrac{1}{2}(f(x)-f(-x)). \tag{94}$$

V. APPLICATION TO MANY-PARTICLE SYSTEMS

We consider a system of many particles lying in $\mathbf{R}^3$. Let $\mathbf{x}_1,\ldots,\mathbf{x}_N$ be position vectors of particles and $m_1,\ldots,m_N$ their masses. Let M be the center-of-mass system, which is defined to be

$$M=\left\{ x=(\mathbf{x}_1,\ldots,\mathbf{x}_N)\left|\sum_{i=1}^{N} m_i\mathbf{x}_i=0\right.\right\}, \tag{95}$$

and isomorphic to $\mathbf{R}^{3(N-1)}$ as a vector space. The rotation group SO(3) acts on M in such a manner that

$$(\mathbf{x}_1,\ldots,\mathbf{x}_N)\mapsto(g\mathbf{x}_1,\ldots,g\mathbf{x}_N),\quad g\in \mathrm{SO}(3). \tag{96}$$

The configurations of particles are characterized by the linear subspaces

$$F_x:=\mathrm{span}\{\mathbf{x}_1,\mathbf{x}_2,\ldots,\mathbf{x}_N\},\quad x\in M. \tag{97}$$

According to $\dim F_x=0,1,2,3$, the configurations x are pointlike, collinear, planar, and spatial, respectively. Let M_k, $k=0,1,2,3$, denote the space of respective configurations of particles. Then M is broken up into

$$M=\bigcup_{k=0}^{3} M_k,\quad M_k:=\{x\in M\,|\,\dim F_x=k\}. \tag{98}$$

One can show that SO(3) acts on $\dot{M}:=M_2\cup M_3$ freely, that is, if $gx=x$ for some $x\in M_2\cup M_3$, then $g=I$ (the 3×3 identity matrix). This means that the isotropy subgroup is trivial at every point of $\dot{M}$, that is, $G_x=\{e\}$ for $x\in\dot{M}$. However, the isotropy subgroups G_x at $x\in M_1$ and at $x\in M_0$ are isomorphic with SO(2) and with SO(3), respectively. On restricting M to $\dot{M}$, we can make $\dot{M}$ into a principal fiber bundle $\dot{M}\to\dot{M}/\mathrm{SO}(3)$. However, the total space M cannot be made into a fiber bundle. This is because one has ''singular'' orbits of SO(3) through points outside of $\dot{M}$; the orbits through each point of M_1 and of M_0 are diffeomorphic with $S^2=\mathrm{SO}(3)/\mathrm{SO}(2)$ and with a point, respectively, while generic orbits through $x\in\dot{M}$ are diffeomorphic with SO(3).

Since a Hamiltonian $\hat{H}$ for many-particle systems with internal interaction only is SO(3) invariant, the reduction procedure with compact Lie groups is applied to provide a reduced system $(L^2(M;\mathcal{H}^\ell)^G,\mathrm{id}_{\mathcal{H}^\ell}\otimes\hat{H})$ with $G=\mathrm{SO}(3)$ and $\ell=0,1,2,\ldots$. Note that at this level of reduction, M does not need to be restricted to $\dot{M}$. Equation (19) then takes the form

$$(E_m^\ell f)(gx)=D^\ell(g)(E_m^\ell f)(x),\quad g\in\mathrm{SO}(3),\ x\in M, \tag{99}$$

which implies that the $\mathcal{H}^\ell$-valued function $E_m^\ell f$ describes an eigenstate associated with the eigenvalue $\ell(\ell+1)$ of the total angular momentum operator.

Restricting M to $\dot{M}$, we obtain a principal bundle $\dot{M}\to\dot{M}/\mathrm{SO}(3)$ and can make up the vector bundle associated with $\dot{M}\to\dot{M}/\mathrm{SO}(3)$ by using a representation space $\mathcal{H}^\ell$. The reduced system $(L^2(\dot{M};\mathcal{H}^\ell)^{\mathrm{SO}(3)},\mathrm{id}_{\mathcal{H}^\ell}\otimes\hat{H})$ is then in one-to-one correspondence with $(\Gamma_\ell^2(\dot{M}/\mathrm{SO}(3)),\hat{H}^\ell)$. If we want to treat the whole of M, we must impose boundary conditions on wave functions at the boundary $\partial\dot{M}=M_0\cup M_1$.[4] Since the collinear configurations are in M_1, we have to consider boundary conditions on wave functions at collinear configurations. For a three-body system, Mitchell and Littlejohn[19] studied the behavior of wave functions at collinear configurations from the viewpoint of bundle theory. By a coordinate-based method, Watson[20] studied small vibrations in the neighborhood of collinear configurations.

We turn to the reduction of quantum systems with discrete symmetry. The center-of-mass system M is looked upon as the set of configurations of the Jacobi vectors $(\mathbf{r}_1,\ldots,\mathbf{r}_{N-1})$, where $\mathbf{r}_j$'s are defined to be

$$\mathbf{r}_j=\left(\frac{1}{\mu_j}+\frac{1}{m_{j+1}}\right)^{-1/2}\left(\mathbf{x}_{j+1}-\frac{1}{\mu_j}\sum_{i=1}^{j} m_i\mathbf{x}_i\right),\quad \mu_j=\sum_{i=1}^{j} m_i\,. \tag{100}$$

We here assume that all particles are identical and set the masses all equal to one. Then Eq. (100) becomes

$$\mathbf{r}_j=\sqrt{\frac{j}{j+1}}\left(\mathbf{x}_{j+1}-\frac{1}{j}\sum_{i=1}^{j}\mathbf{x}_i\right). \tag{101}$$

Since all particles are identical, the system is unchanged if particles are exchanged mutually. Put another way, the configurations of particles admits symmetry by the action of the symmetric group S_N;

$$(\mathbf{x}_1,\ldots,\mathbf{x}_N)\mapsto(\mathbf{x}_{\sigma(1)},\ldots,\mathbf{x}_{\sigma(N)}),\quad \sigma\in S_N\,. \tag{102}$$

Since new Jacobi vectors associated with a new configuration $(\mathbf{x}_{\sigma(1)},\ldots,\mathbf{x}_{\sigma(N)})$,

$$\mathbf{r}_j^{\sigma}=\sqrt{\frac{j}{j+1}}\left(\mathbf{x}_{\sigma(j+1)}-\frac{1}{j}\sum_{i=1}^{j}\mathbf{x}_{\sigma(i)}\right),\quad j=1,\ldots,N-1, \tag{103}$$

are linearly related with the old Jacobi vectors $\mathbf{r}_j$, there exists an $N\times N$ matrix A depending on $\sigma\in S_N$ such that $(\mathbf{r}_1^{\sigma},\ldots,\mathbf{r}_{N-1}^{\sigma})=(\mathbf{r}_1,\ldots,\mathbf{r}_{N-1})A$. Thus one can find a matrix representation π: $S_N\to GL(N-1,\mathbf{R})$ through $\pi(\sigma^{-1})=A$. Thus, S_N acts on M in the manner

$$(\mathbf{r}_1,\ldots,\mathbf{r}_{N-1})\mapsto(\mathbf{r}_1,\ldots,\mathbf{r}_{N-1})\pi(\sigma^{-1}),\quad \sigma\in S_N\,. \tag{104}$$

We have to note here that since we deal with S_N as acting on M to the right, the product $\sigma\tau$ of σ, $\tau\in S_N$ is interpreted as this: σ comes first and then τ follows, so that one has $(1\,2)(1\,2\,3)=(1\,3)$, for example. If we choose the left action of S_N, we shall obtain $(1\,2)(1\,2\,3)=(2\,3)$, of course.

For example, if $N=3$, one obtains the two-dimensional representation π^2 which has the matrix expression as follows:

$$\begin{gathered}\pi^2(\sigma_1)=\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad \pi^2(\sigma_4)=\begin{pmatrix}-1&0\\0&1\end{pmatrix},\\ \pi^2(\sigma_2)=\begin{pmatrix}-1/2&\sqrt{3}/2\\-\sqrt{3}/2&-1/2\end{pmatrix},\quad \pi^2(\sigma_5)=\begin{pmatrix}1/2&\sqrt{3}/2\\\sqrt{3}/2&-1/2\end{pmatrix},\\ \pi^2(\sigma_3)=\begin{pmatrix}-1/2&-\sqrt{3}/2\\\sqrt{3}/2&-1/2\end{pmatrix},\quad \pi^2(\sigma_6)=\begin{pmatrix}1/2&-\sqrt{3}/2\\-\sqrt{3}/2&-1/2\end{pmatrix},\end{gathered} \tag{105}$$

where

$$\begin{gathered}\sigma_1=(1),\quad \sigma_2=(1\ 2\ 3),\quad \sigma_3=(1\ 3\ 2),\\ \sigma_4=(1\ 2),\quad \sigma_5=(2\ 3),\quad \sigma_6=(1\ 3).\end{gathered} \tag{106}$$

Incidentally, it is well known that there are three inequivalent unitary irreducible representations of S_3. The π^2 is one of them, and the other two are the trivial representation: $\pi^0(\sigma)=1$, and the signum representation; $\pi^1(\sigma)=\mathrm{sgn}(\sigma)$, both of which are one-dimensional representations. According to the Fourier series expansion formula (36), $f\in L^2(M)$ is decomposed into

$$f(x)=(Q_1^0 f)(x)+(Q_1^1 f)(x)+\sum_{j=1}^{2}(Q_j^2 f)(x), \tag{107}$$

where $Q_j^\ell := Q_j^{\pi^\ell}$, $\ell=0,1,2$, $j=1,...,d^{\pi^\ell}$, are the projection operators defined by (34). Denoting $(\mathbf{r}_1,\mathbf{r}_2)\pi^2(\sigma_\alpha^{-1})$, $\alpha=1,\ldots,6$, simply by $x\sigma_\alpha$, we can show that

$$(Q_1^0 f)(x)=\tfrac{1}{6}(f(x\sigma_1)+f(x\sigma_2)+f(x\sigma_3)+f(x\sigma_4)+f(x\sigma_5)+f(x\sigma_6)), \tag{108}$$

$$(Q_1^1 f)(x)=\tfrac{1}{6}(f(x\sigma_1)+f(x\sigma_2)+f(x\sigma_3)-f(x\sigma_4)-f(x\sigma_5)-f(x\sigma_6)), \tag{109}$$

$$\begin{aligned}(Q_1^2 f)(x)&=\tfrac{1}{3}(f(x\sigma_1)-\tfrac{1}{2}f(x\sigma_2)-\tfrac{1}{2}f(x\sigma_3)-f(x\sigma_4)+\tfrac{1}{2}f(x\sigma_5)+\tfrac{1}{2}f(x\sigma_6)),\\ (Q_2^2 f)(x)&=\tfrac{1}{3}f(x\sigma_1)-\tfrac{1}{2}f(x\sigma_2)-\tfrac{1}{2}f(x\sigma_3)+f(x\sigma_4)-\tfrac{1}{2}f(x\sigma_5)-\tfrac{1}{2}f(x\sigma_6)).\end{aligned} \tag{110}$$

We proceed to the reduction of quantum systems of many identical particles by S_N. Since the Hamiltonian $\hat{H}$ should be permutation invariant, we can apply the reduction procedure with finite groups to obtain $(L^2(M;\mathcal{K}^\chi)^H, \mathrm{id}_{\mathcal{K}^\chi}\otimes\hat{H})$ with $H=S_N$. As for S_N, we have two representations frequently used in many-identical particle systems, one of which is a trivial representation, π^0: $g\mapsto 1$, and the other the signum representation, π^1: $g\mapsto \mathrm{sgn}(g)$, where $\mathrm{sgn}(\sigma)$ is equal to 1 or -1 according to whether σ is an even or odd permutation. For π^0 and π^1, the projection operators defined in (34) take the form

$$Q^0=\frac{1}{N!}\sum_{\sigma\in S_N}V(\sigma) \quad \text{and} \quad Q^1=\frac{1}{N!}\sum_{\sigma\in S_N}\mathrm{sgn}(\sigma)V(\sigma), \tag{111}$$

respectively, where we have denoted Q_1^0 and Q_1^1 simply by Q^0 and Q^1, respectively, as π^0 and π^1 are one-dimensional representations. The operators Q^0 and Q^1 provide a method for forming wave functions obeying Bose and Fermi statistics, respectively. In fact, from (46) with $H=S_N$, one obtains

$$(Q^0 f)(xg)=(Q^0 f)(x), \quad (Q^1 f)(xg)=\mathrm{sgn}(g)(Q^1 f)(x), \quad g\in S_N. \tag{112}$$

Note here that one has $F_1^0=Q^0$ and $F_1^1=Q^0$, since π^0 and π^1 are one-dimensional representations. Thus Bose and Fermi statistics are viewed as π^0-equivariant and π^1-equivariant states, respectively, so that they are considered as reduced states with respect to S_N.

To give another reduced state, we consider the system of three identical particles and the representation π^2 given by (105). Then we can form $\mathbf{C}^2$-valued π^2-equivariant functions $F_j^2 f$ which obey the transformation rule coming from (46):

$$(F_j^2 f)(xg)=\pi^2(g)^T(F_j^2 f)(x), \quad j=1,2, \quad x\in M. \tag{113}$$

Since (113) is a generalization of (112) with $N=3$, we may consider that $F_j^2 f$ obeys some kind of statistics, like Bose or Fermi statistics. The $\mathbf{C}^2$-valued equivariant functions are described explicitly as follows:

$$(F_1^2 f)(x)=\frac{1}{\sqrt{2}}\begin{pmatrix}(Q_{11}^2 f)(x)\\ (Q_{21}^2 f)(x)\end{pmatrix}, \quad (F_2^2 f)(x)=\frac{1}{\sqrt{2}}\begin{pmatrix}(Q_{12}^2 f)(x)\\ (Q_{22}^2 f)(x)\end{pmatrix}, \tag{114}$$

where

$$(Q_{21}^2 f)(x)=\frac{1}{3}\left(-\frac{\sqrt{3}}{2}f(x\sigma_2)+\frac{\sqrt{3}}{2}f(x\sigma_3)+\frac{\sqrt{3}}{2}f(x\sigma_5)-\frac{\sqrt{3}}{2}f(x\sigma_6)\right),$$
$$(Q_{12}^2 f)(x)=\frac{1}{3}\left(\frac{\sqrt{3}}{2}f(x\sigma_2)-\frac{\sqrt{3}}{2}f(x\sigma_3)+\frac{\sqrt{3}}{2}f(x\sigma_5)-\frac{\sqrt{3}}{2}f(x\sigma_6)\right), \tag{115}$$

and $Q_{11}^2=Q_1^2$ and $Q_{22}^2=Q_1^2$ are given in (110). We notice in addition that terms containing $f(x\sigma_1)$ and $f(x\sigma_4)$ disappear on the right-hand sides of (115) on account of vanishing coefficients $\pi_{21}^2(\sigma_1)=\pi_{21}^2(\sigma_4)=0$, etc.

In conclusion, we have to point out that the action (104) of S_N on the center-of-mass system M determines an $(N-1)$-dimensional unitary representation of S_N. For example, for $N=4$, we can show, by the help of computer algebra, that the representation determined by (104) has the matrix expression as follows:

$$\pi(1)^{-1}=\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix}, \tag{116}$$

$$\pi(123)^{-1}=\begin{pmatrix}-\frac{1}{2}&-\frac{1}{2}\sqrt{3}&0\\\frac{1}{2}\sqrt{3}&-\frac{1}{2}&0\\0&0&1\end{pmatrix}, \tag{117}$$

$$\pi(124)^{-1}=\begin{pmatrix}-\frac{1}{2}&-\frac{1}{6}\sqrt{3}&-\frac{1}{3}\sqrt{6}\\\frac{1}{6}\sqrt{3}&\frac{5}{6}&-\frac{1}{3}\sqrt{2}\\\frac{1}{3}\sqrt{6}&-\frac{1}{3}\sqrt{2}&-\frac{1}{3}\end{pmatrix}, \tag{118}$$

$$\pi(132)^{-1}=\begin{pmatrix}-\frac{1}{2}&\frac{1}{2}\sqrt{3}&0\\-\frac{1}{2}\sqrt{3}&-\frac{1}{2}&0\\0&0&1\end{pmatrix}, \tag{119}$$

$$\pi(134)^{-1}=\begin{pmatrix}\frac{1}{2}&-\frac{1}{6}\sqrt{3}&-\frac{1}{3}\sqrt{6}\\-\frac{1}{2}\sqrt{3}&-\frac{1}{6}&-\frac{1}{3}\sqrt{2}\\0&\frac{2}{3}\sqrt{2}&-\frac{1}{3}\end{pmatrix}, \tag{120}$$

$$\pi(142)^{-1}=\begin{pmatrix} -\frac{1}{2} & \frac{1}{6}\sqrt{3} & \frac{1}{3}\sqrt{6} \\ -\frac{1}{6}\sqrt{3} & \frac{5}{6} & -\frac{1}{3}\sqrt{2} \\ -\frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{121}$$

$$\pi(143)^{-1}=\begin{pmatrix} \frac{1}{2} & -\frac{1}{2}\sqrt{3} & 0 \\ -\frac{1}{6}\sqrt{3} & -\frac{1}{6} & \frac{2}{3}\sqrt{2} \\ -\frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{122}$$

$$\pi(234)^{-1}=\begin{pmatrix} \frac{1}{2} & \frac{1}{6}\sqrt{3} & \frac{1}{3}\sqrt{6} \\ \frac{1}{2}\sqrt{3} & -\frac{1}{6} & -\frac{1}{3}\sqrt{2} \\ 0 & \frac{2}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{123}$$

$$\pi(243)^{-1}=\begin{pmatrix} \frac{1}{2} & \frac{1}{2}\sqrt{3} & 0 \\ \frac{1}{6}\sqrt{3} & -\frac{1}{6} & \frac{2}{3}\sqrt{2} \\ \frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{124}$$

$$\pi((12)(34))^{-1}=\begin{pmatrix} -1 & 0 & 0 \\ 0 & \frac{1}{3} & \frac{2}{3}\sqrt{2} \\ 0 & \frac{2}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{125}$$

$$\pi((13)(24))^{-1}=\begin{pmatrix} 0 & -\frac{1}{3}\sqrt{3} & \frac{1}{3}\sqrt{6} \\ -\frac{1}{3}\sqrt{3} & -\frac{2}{3} & -\frac{1}{3}\sqrt{2} \\ \frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{126}$$

$$\pi((14)(23))^{-1}=\begin{pmatrix} 0 & \frac{1}{3}\sqrt{3} & -\frac{1}{3}\sqrt{6} \\ \frac{1}{3}\sqrt{3} & -\frac{2}{3} & -\frac{1}{3}\sqrt{2} \\ -\frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{127}$$

$$\pi(12)^{-1}=\begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \tag{128}$$

$$\pi(13)^{-1}=\begin{pmatrix} \frac{1}{2} & -\frac{1}{2}\sqrt{3} & 0 \\ -\frac{1}{2}\sqrt{3} & -\frac{1}{2} & 0 \\ 0 & 0 & 1 \end{pmatrix}, \tag{129}$$

$$\pi(14)^{-1}=\begin{pmatrix} \frac{1}{2} & -\frac{1}{6}\sqrt{3} & -\frac{1}{3}\sqrt{6} \\ -\frac{1}{6}\sqrt{3} & \frac{5}{6} & -\frac{1}{3}\sqrt{2} \\ -\frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{130}$$

$$\pi(23)^{-1}=\begin{pmatrix} \frac{1}{2} & \frac{1}{2}\sqrt{3} & 0 \\ \frac{1}{2}\sqrt{3} & -\frac{1}{2} & 0 \\ 0 & 0 & 1 \end{pmatrix}, \tag{131}$$

$$\pi(24)^{-1}=\begin{pmatrix} \frac{1}{2} & \frac{1}{6}\sqrt{3} & \frac{1}{3}\sqrt{6} \\ \frac{1}{6}\sqrt{3} & \frac{5}{6} & -\frac{1}{3}\sqrt{2} \\ \frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{132}$$

$$\pi(34)^{-1}=\begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{3} & \frac{2}{3}\sqrt{2} \\ 0 & \frac{2}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{133}$$

$$\pi(1234)^{-1}=\begin{pmatrix} -\frac{1}{2} & -\frac{1}{6}\sqrt{3} & -\frac{1}{3}\sqrt{6} \\ \frac{1}{2}\sqrt{3} & -\frac{1}{6} & -\frac{1}{3}\sqrt{2} \\ 0 & \frac{2}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{134}$$

$$\pi(1243)^{-1}=\begin{pmatrix} -\frac{1}{2} & -\frac{1}{2}\sqrt{3} & 0 \\ \frac{1}{6}\sqrt{3} & -\frac{1}{6} & \frac{2}{3}\sqrt{2} \\ \frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{135}$$

$$\pi(1324)^{-1}=\begin{pmatrix} 0 & \frac{1}{3}\sqrt{3} & -\frac{1}{3}\sqrt{6} \\ -\frac{1}{3}\sqrt{3} & -\frac{2}{3} & -\frac{1}{3}\sqrt{2} \\ \frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{136}$$

$$\pi(1342)^{-1}=\begin{pmatrix} -\frac{1}{2} & \frac{1}{6}\sqrt{3} & \frac{1}{3}\sqrt{6} \\ -\frac{1}{2}\sqrt{3} & -\frac{1}{6} & -\frac{1}{3}\sqrt{2} \\ 0 & \frac{2}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{137}$$

$$\pi(1423)^{-1}=\begin{pmatrix} 0 & -\frac{1}{3}\sqrt{3} & \frac{1}{3}\sqrt{6} \\ \frac{1}{3}\sqrt{3} & -\frac{2}{3} & -\frac{1}{3}\sqrt{2} \\ -\frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}, \tag{138}$$

$$\pi(1432)^{-1}=\begin{pmatrix} -\frac{1}{2} & \frac{1}{2}\sqrt{3} & 0 \\ -\frac{1}{6}\sqrt{3} & -\frac{1}{6} & \frac{2}{3}\sqrt{2} \\ -\frac{1}{3}\sqrt{6} & -\frac{1}{3}\sqrt{2} & -\frac{1}{3} \end{pmatrix}. \tag{139}$$

It is known that there are two three-dimensional inequivalent unitary representations of S_4, one of which is isomorphic with the group of symmetries of the tetrahedron, and the other with the group

of symmetries of the cube.[18] The former is a discrete subgroup of O(3) and the latter a discrete subgroup of SO(3). Since the group $\pi(S_4)$ given above includes matrices of determinant -1, it must be isomorphic with the group of symmetries of the tetrahedron.

In conclusion, we note that since the actions of SO(3) and S_N commute, one can perform the reduction procedure with SO(3) and further with S_N, so that one can talk about Bose and Fermi statistics for the reduced states in $(\Gamma^2_\ell(\dot{M}/\mathrm{SO}(3);\mathcal{H}^\ell)$.

Internal Lifshitz tails for Schrödinger operators with random potentials

Frédéric Klopp[a)]

(Received 10 October 2001; accepted for publication 30 January 2002)

In this short note, we prove that, for periodic Schrödinger operators perturbed by an Anderson-type random potential with long-range single site potential, the density of states always show a Lifshitz tail at a band edge. Thus, we correct a mistake made in an earlier paper [F. Klopp, Duke Math. J. **98**, 335–396 (1999)]. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1470706]

I. INTRODUCTION

The present note is devoted to the study of Lifshitz tails for periodic Schrödinger operators perturbed by a random potential of Anderson-type (or alloy-type) with long-range single site potentials. The existence of Lifshitz tails at any band edge is proven.

Lifshitz tails are a special behavior of the density of states at the edges of the spectrum; this behavior is typical for random operators. We refer to Ref. 1 for a more detailed presentation of Lifshitz tails.

Let us describe the model we study. Pick Γ a nondegenerate lattice in $\mathbb{R}^d$. $C(0,0)$ denotes the fundamental cell of the lattice Γ, i.e., if $\Gamma=f(\mathbb{Z}^d)$ where f is linear and invertible, then, we set $C(x,n)=f(\tilde{C}(x,n))$, where $\tilde{C}(x,n)=\{y\in\mathbb{R}^d;\ \text{for } j=1,\dots,d,\ -n-1/2<y_j-x_j\leqslant n+1/2\}$.

Let the potential W be real valued, Γ-periodic, and in $L^p_{\mathrm{loc}}(\mathbb{R}^d)$ (here, $p=2$ if $d\leqslant 3$, $p>2$ if $d=4$, and $p>d/2$ if $d\geqslant 5$) and, let $H=-\Delta+W$ be a periodic Schrödinger operator acting on $L^2(\mathbb{R}^d)$. Then, by Ref. 2, H is essentially self-adjoint on $\mathcal{C}_0^\infty(\mathbb{R}^d)$ with domain $H^2(\mathbb{R}^d)$. Its unique self-adjoint extension is also denoted by H.

It is well known that the spectrum of H is made of bands of purely absolutely continuous spectrum separated by gaps (see, e.g., Refs. 1, 2, 3). We assume that one of the gaps is open (that is nonempty) and that the band above this gap starts at energy 0 (this is not a restriction as W may be shifted by a constant); that is, we assume that $\sigma(H)$, the spectrum of H, has a gap below energy 0 of length at least δ that is:

(H.1) For some $a>0$ and $\delta>0$, $\sigma\cap[0,a]=[0,a]$ and $\sigma\cap[-\delta,0)=\varnothing$.

We now consider the random Schrödinger operator

$$H_\omega=H+V_\omega=H+\sum_{\gamma\in\Gamma}\omega_\gamma V(\cdot-\gamma), \tag{1.1}$$

where V is a real valued function on $\mathbb{R}^d$ satisfying:

(H.2) There exists $\nu\in(d,d+2]$ and $0\leqslant g_-\leqslant g_+$, $g_+\in L^p(C(0,0))$; here, $p=2$ if $d\leqslant 3$, $p>2$ if $d=4$, and $p>d/2$ if $d\geqslant 5$ (see Refs. 2 and 4) and $0<g_-$ on some open set, such that, for any $\gamma\in\Gamma$ and almost every $x\in C(0,0)$, one has

$$g_-(x)\leqslant V(x+\gamma)\cdot(1+|\gamma|)^\nu\leqslant g_+(x), \tag{1.2}$$

and the random variables $(\omega_\gamma)_{\gamma\in\Gamma}$ satisfy

a)Electronic mail: klopp@math.univ-paris13.fr

(H.3)

(1) They are independent, identically distributed, nontrivial and bounded.

(2) They are nonnegative and 0 is in their essential support.

(3) $\limsup_{\epsilon\to 0^+} \log|\log \mathbb{P}(\{\omega_0 \leqslant \epsilon\})|/|\log \epsilon| = 0$.

Remark 1.1: Assumption (H.2) is the correct *long-range condition* for the single site potentials.

The positivity assumption on the $(\omega_\gamma)_{\gamma\in\Gamma}$ is not necessary as using the boundedness of the random variables, we may always shift them to be positive. The price to pay for that is a change in the periodic background potential W.

The second point of the previous assumption ensures that the common probability measure of the i.i.d random variables $(\omega_\gamma)_{\gamma\in\Gamma}$ does not vanish too fast (actually exponentially fast) at 0.

Assumption (H.2) and the boundedness of the random variables guarantee that, for all $\omega = (\omega_\gamma)_{\gamma\in\Gamma}$, V_ω is locally uniformly L^p, i.e., there exists $M>0$ such that, for any $\gamma\in\Gamma$, $\int_{C(\gamma,0)} |V_\omega(x)|^p dx \leqslant M$ (see Refs. 2 and 4).

We define the main object of our study, the integrated density of states. For H_ω defined as above and $n>0$, we define $H^D_{\omega,n}$ to be the Dirichlet restriction of H_ω to the cube $C(0,n)$. $H^D_{\omega,n}$ has only discrete spectrum (Ref. 2). For $E\in\mathbb{R}$, we define

$$N^n_\omega(E) = \frac{\sharp\{\text{eigenvalues of } H^D_{\omega,n} \leqslant E\}}{\mathrm{Vol}(C(0,n))}, \tag{1.3}$$

where $\sharp\mathcal{E}$ denotes the number of points of the set $\mathcal{E}$ and $\mathrm{Vol}(C(0,n))$, the volume of $C(0,n)$.

Under assumptions (H.1)–(H.3), one shows that, ω-almost surely, $N^n_\omega(E)$ has a limit when $n\to+\infty$ (Refs. 4 and 5.) This limit is independent of the realization of ω. It is the *integrated density of states* of H_ω. We denote it by $N(E)$.

Assumptions (H.1)–(H.3) guarantee that Σ, the almost sure spectrum of H_ω, contains some interval of the form $[0,a)$ $(a>0)$ (see Ref. 6). We want to study Lifshitz tails near 0. Therefore, we need to know that 0 is the edge of a gap for Σ. More precisely, for $t\in[0,1]$, we define the random Schrödinger operator $H_\omega(t) = H + tV_\omega$ and its almost sure spectrum, $\Sigma(t)$; we assume that

(H.4) For some $\delta'>0$, for any $t\in[0,1]$, $\Sigma(t)\cap[-\delta',0) = \varnothing$.

Note that, if the random variables or the potential V are sufficiently small, then assumption (H.4) holds by standard perturbation theory.

Our main result is

Theorem 1.1: *Let H and H_ω be constructed as previously, and assume that (H.1), (H.2), (H.3), and (H.4) hold. Then,*

$$\lim_{E\to 0^+} \frac{\log|\log(N(E)-N(0))|}{\log E} = -\frac{d}{\nu-d}. \tag{1.4}$$

Let us comment on this result. First, it corrects a result given in Ref. 1 where it was stated that (1.4) holds if and only if the density of states of H is nondegenerate at 0. Here, we prove that (1.4) is obtained without any condition on the behavior of the integrated density of states of the underlying periodic operator.

The behavior (1.4) was already known at the bottom of the spectrum (see, e.g., Refs. 4, 5, and 7). Note that we stated Theorem 1.1 for lower band edges; under symmetric assumptions, the corresponding result is valid for upper band edge.

We note that Theorem 1.1 also explains the necessity of single sites potentials that decay sufficiently fast at infinity in the study done in Ref. 8.

II. PERIODIC APPROXIMATIONS

Though working in the framework of Ref. 1, we use a method different from the one developed in that paper; it is related to the method used in Refs. 9 and 10. The proof goes roughly as follows. First we prove that the periodic approximations introduced in Sec. 5.1 of Ref. 1 are

exponentially close to the true density of states. Then, for a given small energy, we pick a large enough cube so that the density of states of the periodic approximation is close enough to the density of states of the random operator, and we study the density of states of that approximation.

Let us first recall some facts from the Floquet theory for periodic Schrödinger operators. Basic references where this material may be found are Refs. 2, 11, and 3. Pick $\theta\in\mathbb{R}^d$. As H is Γ-periodic, we consider H_θ the operator defined by the differential expression $-\Delta+W$ acting on L^2_θ, the space of locally square integrable functions satisfying the quasiperiodic boundary conditions $u(\cdot+\gamma)=e^{i\gamma\theta}u(\cdot)$ for all $\gamma\in\Gamma$. As H is essentially self-adjoint with domain $H^2(\mathbb{R}^d)$, H_θ is essentially self-adjoint with domain H^2_θ (i.e., the functions in L^2_θ that are locally in H^2). Moreover, as H is elliptic, the spectrum of H_θ is discrete. Let $E_0(\theta)\leqslant E_1(\theta)\leqslant\cdots\leqslant E_k(\theta)\leqslant\cdots$ be its eigenvalues; they are called *Floquet eigenvalues* of H. It is well known that H admits the Floquet decomposition

$$H=\int_{\mathbb{T}^*}^{\oplus} H_\theta\,\mathrm{d}\theta, \tag{2.1}$$

where $\mathbb{T}^*:=\mathbb{R}^d/\Gamma^*$ where $\Gamma^*=\{\gamma^*\in\mathbb{R}^d;\ \forall\,\gamma\in\Gamma,\ \langle\gamma^*\gamma\rangle\in 2\pi\mathbb{Z}\}$.

Let $n\in\mathbb{N}\backslash\{0\}$ and define the following periodic Schrödinger operator:

$$H_{\omega,n}=H+\sum_{\gamma\in C(0,n)\cap\Gamma}\omega_\gamma\sum_{\beta\in(2n+1)\Gamma}V(x-\gamma-\beta)=H+V_{\omega,n}. \tag{2.2}$$

Then, for any $\omega\in\Omega$ and $n\in\mathbb{N}^*$, $H_{\omega,n}$ is a $(2n+1)$ Γ-periodic, essentially self-adjoint Schrödinger operator. It is an H-bounded perturbation of H with relative bound 0. We notice that the boundedness assumption on the (ω_γ) implies that the family $(H_{\omega,n})_{\omega,n}$ is uniformly H-bounded (see Remark 1.1). $H_{\omega,n}$ also denotes its self-adjoint extension.

The operator $H_{\omega,n}$ admits an integrated density of states denoted by $N_{\omega,n}$ and given by

$$N_{\omega,n}(E)=\frac{1}{\mathrm{Vol}(\mathbb{T}^*_n)}\sum_{k\in\mathbb{N}}\int_{\{\theta\in\mathbb{T}^*_n;\ E_{k,n}(\theta,\omega)\leqslant E\}}\mathrm{d}\theta,$$

where $\mathbb{T}^*_n:=\mathbb{R}^d/((2n+1)\Gamma)^*$ and $(E_{k,n}(\theta,\omega))_{k\geqslant 0}$ are the Floquet eigenvalues of $H_{\omega,n}$. In Ref. 1, we proved

Theorem 2.1 (Ref. 1): *For any $\varphi\in\mathcal{C}^\infty_0(\mathbb{R})$, we have*

$$\lim_{n\to+\infty}\mathbb{E}\left(\int_{\mathbb{R}}\varphi(\lambda)\mathrm{d}N_{\omega,n}\right)=\int_{\mathbb{R}}\varphi(\lambda)\mathrm{d}N. \tag{2.3}$$

Moreover, for $\lambda\in\mathbb{R}$, a continuity point of $N(\lambda)$, one has

$$\lim_{n\to+\infty}\mathbb{E}(N_{\omega,n}(\lambda))=N(\lambda). \tag{2.4}$$

We now give an estimate on the rate of convergence in (2.3) and (2.4). Let $H_{\omega,n}$ be the periodic approximation (2.2) and $N_{\omega,n}$ be its integrated density of state. Then, we prove

Theorem 2.2: *Assume (H.1), (H.2), and (H.3). Pick $\eta_0>0$ and $I\subset\mathbb{R}$, a compact interval. Then, there exists $\nu_0>0$ and $\epsilon_0>0$ such that, for $0<\epsilon<\epsilon_0$, $E\in I$, and $n\geqslant\epsilon^{-\nu_0}$, we have*

$$\begin{aligned}\mathbb{E}(N_{\omega,n}(E+\epsilon/2)-N_{\omega,n}(E-\epsilon/2))-e^{-\epsilon^{-\eta_0}}&\leqslant N(E+\epsilon)-N(E)\\&\leqslant\mathbb{E}(N_{\omega,n}(E+2\epsilon)-N_{\omega,n}(E-2\epsilon))+e^{-\epsilon^{-\eta_0}}.\end{aligned} \tag{2.5}$$

Theorem 2.2 states that the density of states of the random Hamiltonian H_ω is exponentially well approximated by the expectation of the densities of states of the periodic Hamiltonians $H_{\omega,n}$ even for n not very large (i.e., for n of size roughly a negative power of the approximation parameter ϵ).

Proof: Theorem 2.2 is a consequence of a similar result for random operators with compactly supported single site potentials. More precisely, define $V_\epsilon(x)=V(x)\mathbf{1}_{\epsilon\cdot|x|\leqslant 1}$ and the random operator

$$H_{\epsilon,\omega}=H+V_{\epsilon,\omega}=H+\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma V_\epsilon(\cdot-\gamma).$$

Let N_ϵ be the integrated density of states of $H_{\epsilon,\omega}$. We define $H_{\epsilon,\omega,n}$, the periodic approximations of $H_{\epsilon,\omega}$ in the same way as for H_ω [just replace V by V_ϵ in (2.2)]. Let $N_{\epsilon,\omega,n}$ be their integrated density of states.

We first notice that, using the decay assumption (H.2) and the fact that the random variables $(\omega_\gamma)_\gamma$ are bounded, uniformly in n and ω, we have

$$\|(1-\Delta)^{-1}(H_{\epsilon,\omega}-H_\omega)\|+\|(1-\Delta)^{-1}(H_{\epsilon,\omega,n}-H_{\omega,n})\|\leqslant C\epsilon^{\nu-d}.$$

This implies that, uniformly in n and ω, and locally uniformly in E, one has

$$\begin{aligned}N_\epsilon(E-C\epsilon^{\nu-d})\leqslant N(E)\leqslant N_\epsilon(E+C\epsilon^{\nu-d}),\\ N_{\epsilon,\omega,n}(E-C\epsilon^{\nu-d})\leqslant N_{\omega,n}(E)\leqslant N_{\epsilon,\omega,n}(E+C\epsilon^{\nu-d}).\end{aligned}\tag{2.6}$$

So to prove Theorem 2.2, we only need to prove it for $H_{\epsilon,\omega}$ and replace ϵ by $\epsilon^{1/(\nu-d)}$. The gain is that, for the new operators, the single site potential is compactly supported. The proof of Theorem 2.2 in this case relies upon the

Lemma 2.1: Assume that the single site potential V is compactly supported in a ball of radius R centered at 0. Pick I, a relatively compact open interval in $\mathbb{R}$. *For any* $\beta\in(0,1)$, *there exists* $C>1$ *and* $\rho>0$ [*depending only on d, the bound on* $(\omega_\gamma)_\gamma$ *and on* $\|V\|_{\ell^1(L^p)}:=\Sigma_{\gamma\in\Gamma}\|V\|_{L^p(C(\gamma,0))}$] *such that, for any* $\varphi\in\mathcal{C}_0^\infty(I)$, *for* $k\in\mathbb{N}^*$ *and* $n\in\mathbb{N}^*$, $n>R$, *we have*

$$|\mathbb{E}((\varphi,\mathrm{d}N_{\omega,n}))-(\varphi,\mathrm{d}N)|\leqslant C|n-R|^{-(1-\beta)k}\cdot k^k\cdot\sup_{\substack{x\in\mathbb{R}\\0\leqslant j\leqslant k+\rho}}\left|(|x|+C)^{\rho+k}\frac{d^j\varphi}{d^jx}(x)\right|.\tag{2.7}$$

Proof: This lemma was proved in Refs. 9, 10, and 12 in different settings but essentially the same arguments apply in the present case too. The proof relies upon two facts.

(1) For $\varphi\in\mathcal{C}_0^\infty(\mathbb{R})$, one has

$$\mathbb{E}((\varphi,\mathrm{d}N_{\omega,n}))=\frac{1}{\mathrm{Vol}(C(0,0))}\mathbb{E}(\mathrm{tr}(\mathbf{1}_{C(0,0)}\varphi(H_{\omega,n})\mathbf{1}_{C(0,0)})).\tag{2.8}$$

(2) The following estimate on the difference between the resolvents of $H_{\omega,n}$ and H_ω at an energy $z\in\mathbb{C}\backslash\mathbb{R}$:

$$\begin{aligned}\|\mathbf{1}_{C(0,0)}((z-H_{\omega,n})^{-1}-(z-H_\omega)^{-1})\mathbf{1}_{C(0,0)}\|&=\|\mathbf{1}_{C(0,0)}((z-H_{\omega,n})^{-1}(V_{\omega,n}-V_\omega)(z-H_\omega)^{-1})\mathbf{1}_{C(0,0)}\|\\&\leqslant C\exp\left(-\frac{|\mathrm{Im}\,z|}{C\cdot(1+|z|)}|n-R|\right).\end{aligned}\tag{2.9}$$

Equality (2.8) is proved in Ref. 1 [formula (5.7) on p. 357]. Estimate (2.9) is a consequence of the computation done to prove Theorem 5.1 in Ref. 1 (pp. 358–360) of the fact that, by construction, $(V_{\omega,n}-V_\omega)$ vanishes in the cube centered at 0 of side length $2(n-R)+1$ (as V is supported in a

ball of size R), and of the exponential decay of the resolvent kernels $(z-H_\omega)^{-1}$ and $(z-H_{\omega,n})^{-1}$ [this is a consequence of the Combes–Thomas estimates, see, e.g., (Refs. 13 and 14)]. To obtain Lemma 2.1 from (2.9), one then uses the representation formula (5.9) in Ref. 1 for $\varphi(H)$ in terms of almost analytic extensions of φ, and the standard estimates for almost analytic extension (5.8) in Ref. 1. □

Let us now derive Theorem 2.2 from Lemma 2.1. Let φ be a Gevrey class function of Gevrey exponent $\alpha>1$ (see Ref. 15); assume, moreover, that φ has compact support in $(-2,2)$, that $0\leqslant\varphi\leqslant 1$, and that $\varphi\equiv 1$ on $[-1,1]$. Let $E\in\mathbb{R}$ and set

$$\varphi_{E,\epsilon}(\cdot)=\varphi\left(\frac{\cdot-E}{\epsilon}\right).$$

Fix $I\subset\mathbb{R}$ compact. Then, by Lemma 2.1 and the Gevrey estimates on the derivatives of φ, we get that, there exist $C>1$ such that, for $E\in I$, $n>R$, $k\geqslant 1$ and $0<\epsilon<1$, we have

$$\left|\mathbb{E}((\varphi_{E,\epsilon},\mathrm{d}N_{\omega,n}))-(\varphi_{E,\epsilon},\mathrm{d}N)\right|\leqslant\epsilon^{-k-\rho}(k+\rho)^{2\alpha(k+\rho)}(n-R)^{-(1-\beta)k}.$$

We pick $k+\rho=(n-R)^{(1-\beta)/(4\alpha)}$ for $n-R$ large, and get that, there exist $C>1$ such that, for $E\in I$, $n>R+2$, $k\geqslant\rho$ and $0<\epsilon<1$, we have

$$\left|\mathbb{E}((\varphi_{E,\epsilon},\mathrm{d}N_{\omega,n}))-(\varphi_{E,\epsilon},\mathrm{d}N)\right|\leqslant((n-R)^{-(1-\beta)/4}\epsilon^{-\alpha})^{(n-R)^{(1-\beta)/(4\alpha)}}.$$

Now, in the case we are interested in, we have set $R=R_\epsilon\sim\epsilon^{1/(d-\nu)}$. Hence, we choose $\eta>1$, $n\geqslant\epsilon^{-\eta(4\alpha)/(1-\beta)}+R_\epsilon$; so, there exist $\epsilon_0>0$ such that, for $0<\epsilon<\epsilon_0$, we have

$$\left|\mathbb{E}((\varphi_{E,\epsilon},\mathrm{d}N_{\omega,n}))-(\varphi_{E,\epsilon},\mathrm{d}N)\right|\leqslant e^{-\epsilon^{-\eta}}. \tag{2.10}$$

By the definition of φ, as $dN_{\epsilon,\omega,n}$ and dN_ϵ are positive measures, we have

$$\mathbb{E}(N_{\epsilon,\omega,n}(E+\epsilon)-N_{\epsilon,\omega,n}(E-\epsilon))\leqslant\mathbb{E}((\varphi_{E,\epsilon},\mathrm{d}N_{\epsilon,\omega,n}))\leqslant\mathbb{E}(N_{\epsilon,\omega,n}(E+2\epsilon)-N_{\epsilon,\omega,n}(E-2\epsilon)),$$

$$N_\epsilon(E+\epsilon)-N_\epsilon(E-\epsilon)\leqslant(\varphi_{E,\epsilon},\mathrm{d}N)\leqslant N_\epsilon(E+2\epsilon)-N_\epsilon(E-2\epsilon).$$

This, Eqs. (2.6) and (2.10) complete the proof of Theorem 2.2 for $H_{\epsilon,\omega}$ and hence for H_ω. □

III. THE PROOF OF THE LOWER BOUND

We now turn to the proof of

$$\liminf_{\substack{\epsilon\to 0\\ \epsilon>0}}\frac{\log|\log(N(\epsilon)-N(0^-))|}{\log\epsilon}\geqslant-\frac{d}{\nu-d}. \tag{3.1}$$

In Sec. 6 of Ref. 1, it is proved that if 0 is a band edge of the spectrum of H and $\theta_0\in\mathbb{T}^*$ is a Floquet parameter such that, for some $n\geqslant 0$, one has $E_n(\theta_0)=0$, then, there exists V, a neighborhood of θ_0 in $\mathbb{T}^*$, and $f:\theta\in V\mapsto f(\cdot,\theta)$ a real analytic, H^2_θ-valued function such that, for some $C>0$, one has

$$\forall\,\theta\in V,\quad \|H_\theta f(\cdot,\theta)\|_{L^2(C(0,0))}\leqslant C|\theta|^2 \text{ and } \|f(\cdot,\theta)\|_{L^2(C(0,0))}=1. \tag{3.2}$$

Let $\alpha>0$ be a small constant. Pick $\epsilon>0$. Let $\chi\in\mathcal{C}_0^\infty(\{|\theta|<1\})$ be positive, and such that $\int_{\{|\theta|<1\}}\chi^2\,\mathrm{d}\theta=2$. Then, we define

$$w_\epsilon(\theta)=\epsilon^{-d(1+\alpha)/4}\chi(\epsilon^{-(1+\alpha)/2}(\theta-\theta_0))\in L^2(\mathbb{T}^*).$$

We also define

$$w_\epsilon^f(\cdot)=\int_{\mathbb{T}^*} w_\epsilon(\theta)\cdot f(\cdot,\theta)\mathrm{d}\theta.$$

Using (3.2), for ϵ sufficiently small, one checks that

$$\|w_\epsilon^f\|^2=\int_{\mathbb{T}^*}\|f(\cdot,\theta)\|^2_{L^2(C(0,0))}|w_\epsilon(\theta)|^2\mathrm{d}\theta=2 \tag{3.3}$$

and that, for some $C>0$, one has

$$\|Hw_\epsilon^f\|^2\leqslant C\epsilon^{2(1+\alpha)}. \tag{3.4}$$

Using the fact that $f(\cdot,\theta)$ satisfies quasiperiodic boundary conditions, the smoothness of the function $\theta\mapsto f(x,\theta)$ and the nonstationary phase, one proves that, for any $k\in\mathbb{N}$, there exists $C_k>0$ such that, for any $\gamma\in\Gamma$,

$$\begin{aligned}\int_{C(\gamma,0)}|w_\epsilon^f(x)|^2\mathrm{d}x&=\int_{C(0,0)}\left|\int_{\mathbb{T}^*}e^{-i\gamma\theta}w_\epsilon(\theta)f(x,\theta)\mathrm{d}\theta\right|^2\mathrm{d}x\\&=\int_{C(0,0)}\left|\epsilon^{d(1+\alpha)/4}\int_{\{|\theta|<1\}}e^{-i\epsilon^{1+\alpha/2}\gamma\theta}\chi(\theta)f(x,\theta_0+\epsilon^{(1+\alpha)/2}\theta)\mathrm{d}\theta\right|^2\mathrm{d}x\\&\leqslant C_k(1+|\epsilon^{(1+\alpha)/2}\gamma|^2)^{-k/2}.\end{aligned} \tag{3.5}$$

Similar estimates hold for $\int_{C(\gamma,0)}|\nabla w_\epsilon^f(x)|^2\mathrm{d}x$ and for $\int_{C(\gamma,0)}|Hw_\epsilon^f(x)|^2\mathrm{d}x$.

Pick $\tilde{\chi}$, a $\mathcal{C}_0^\infty$-function supported in $|x|\leqslant 2$ such that $\tilde{\chi}\equiv 1$ for $|x|\leqslant 1$; and set $\tilde{\chi}_\epsilon(x)=\tilde{\chi}(\epsilon^{(1+2\alpha)/2}x)$. Then, for ϵ sufficiently small, the function $w_\epsilon=\tilde{\chi}_\epsilon w_\epsilon^f$ satisfies

(1) w_ϵ is supported in a ball of center 0 and radius $2\epsilon^{-(1+2\alpha)/2}$,
(2) $1\leqslant\|w_\epsilon\|^2_{L^2}\leqslant 2$,
(3) $\|Hw_\epsilon\|^2_{L^2}\leqslant C\epsilon^{2(1+\alpha)}$ for some $C>0$.

Point (1) is obvious. Point (2) follows from (3.3) and (3.5). And point (3) follows from (3.4), (3.5) and its analog for ∇w_ϵ^f and Hw_ϵ^f as $\|\nabla\tilde{\chi}_\epsilon\|_\infty\leqslant C\epsilon^{(1+2\alpha)/2}$ and $\|\Delta\tilde{\chi}_\epsilon\|_\infty\leqslant C\epsilon^{1+2\alpha}$.

Pick $n\in\mathbb{N}^*$ such that $n\sim\epsilon^{-\eta}$ for $\eta>\max(\nu_0,1/(\nu-d)+\alpha)$; here, ν_0 is given in Theorem 2.2 for $\eta_0>d/(\nu-d)+\mathrm{d}\alpha$. As w_ϵ has compact support in the interior of $C(0,n)$, it can be "periodized" to satisfy quasiperiodic boundary conditions; for $\theta\in\mathbb{R}^d$, we set

$$w_{\epsilon,\theta}(\cdot)=\sum_{\beta\in(2n+1)\Gamma}e^{-i\beta\theta}w_\epsilon(\cdot+\beta).$$

Then, $w_{\epsilon,\theta}$ satisfies $w_{\epsilon,\theta}(x+\beta)=e^{i\beta\theta}w_{\epsilon,\theta}(x)$ for $x\in\mathbb{R}^d$ and $\beta\in(2n+1)\Gamma$. And, one has

$$\|w_{\epsilon,\theta}\|^2_{L^2(C(0,n))}\geqslant 1. \tag{3.6}$$

We define

$$\Lambda_\alpha(\epsilon)=\{\gamma\in\Gamma;\quad\text{for } 1\leqslant j\leqslant d,\ |\gamma_j|\leqslant\epsilon^{-(1+3\alpha)/(\nu-d)}\}.$$

Using assumption (H.1), one computes

$$V_{\omega,n}(x)=\sum_{\gamma\in\Gamma}\omega_{[\gamma]}V(x-\gamma)\text{where }[\gamma]=\gamma \bmod (2n+1)\Gamma$$

$$\leqslant\sum_{\gamma\in\Gamma}\omega_{[\gamma]}\sum_{\alpha\in\Gamma}g_+(x-\gamma-\alpha)\cdot(1+|\alpha|)^{-\nu}$$

$$=\sum_{\alpha\in\Gamma}A_\alpha(\omega)g_+(x-\alpha)\text{where }A_\alpha(\omega)=\sum_{\gamma\in\Gamma}\omega_{[\gamma]}(1+|\alpha-\gamma|)^{-\nu}. \tag{3.7}$$

If we assume that, for $\gamma\in\Lambda_\alpha(\epsilon)$, one has $\omega_\gamma\leqslant\epsilon^{1+\alpha}$, then (3.7) implies

$$\|V_{\omega,n}w_{\epsilon,\theta}\|\leqslant C\epsilon^{1+\alpha}\|w_{\epsilon,\theta}\|. \tag{3.8}$$

This, (3.6), and point (3) imply that, for some $C>0$ and ϵ sufficiently small, one has

$$\|H_{\omega,n,\theta}w_{\epsilon,\theta}\|\leqslant C\epsilon^{1+\alpha}\|w_{\epsilon,\theta}\|.$$

This proves that, for ϵ sufficiently small, if, for $\gamma\in\Lambda_\alpha(\epsilon)$, one has $\omega_\gamma\leqslant\epsilon^{1+\alpha}$, then for all $\theta\in\mathbb{T}_n^*$, $H_{\omega,n,\theta}$ has an eigenvalue in $[-\epsilon/2,\epsilon/2]$. Hence, we get that

$$\mathbb{E}(N_{\omega,n}(E+\epsilon/2)-N_{\omega,n}(E-\epsilon/2))\geqslant P(\epsilon,\alpha), \tag{3.9}$$

where $P(\epsilon,\alpha)$ is the probability of the event $\{\omega;\ \forall\gamma\in\Lambda_\alpha(\epsilon),\ \omega_\gamma\leqslant\epsilon^{1+\alpha}\}$. By assumption (H.3), one has

$$\liminf_{\substack{\epsilon\to0\\\epsilon>0}}\frac{\log|\log(P(\epsilon,\alpha))|}{\log\epsilon}\geqslant-\frac{d}{\nu-d}(1+3\alpha).$$

Combining this estimate with (3.9) and (2.5) [recall that we picked $\eta_0>d/(\nu-d)+d\alpha$], we obtain

$$\liminf_{\substack{\epsilon\to0\\\epsilon>0}}\frac{\log|\log(N(\epsilon)-N(0^-))|}{\log\epsilon}\geqslant-\frac{d}{\nu-d}(1+3\alpha).$$

As α is an arbitrary positive number, we get (3.1).

IV. THE PROOF OF THE UPPER BOUND

We pick $\eta_0>d/(\nu-d)$ in Theorem 2.2 and $n\sim\epsilon^{-\eta}$ for $\eta>\nu_0$ (ν_0 is given in Theorem 2.2). To complete the proof of (1.4), in view of (2.5), we only need to prove that

$$\limsup_{\epsilon\to0^+}\frac{\log|\log(\mathbb{E}(N_{\omega,n}(\epsilon)-N_{\omega,n}(0)))|}{\log\epsilon}\leqslant-\frac{d}{\nu-d}. \tag{4.1}$$

Indeed, by assumption (H.4), we know that, for ϵ sufficiently small, for all ω and n, one has $N_{\omega,n}(0)=N_{\omega,n}(-\epsilon)$ (see also Sec. 5.2 in Ref. 1).
We prove

Lemma 4.1: Define the potential G by $G(\cdot)=\Sigma_{\gamma\in\Gamma}g_-(\cdot-\gamma)$. Then, if $n\sim\epsilon^{-\rho}$ with $\rho>1/(\nu-d)$, the event $\{\omega;\ V_{\omega,n}\geqslant\epsilon G\}$ has probability at least $1-P_\epsilon$ where P_ϵ satisfies

$$\limsup_{\epsilon\to0^+}\frac{\log|\log(P_\epsilon)|}{\log\epsilon}\leqslant-\frac{d}{\nu-d}. \tag{4.2}$$

Lemma 4.2: There exists $C>0$ *and* $\epsilon_0>0$ *(independent of* n *and* ω*) such that, if* $0<\epsilon<\epsilon_0$ *and* ω *satisfies* $V_{\omega,n}\geqslant C\epsilon G$*, then for* $n\in\mathbb{N}$*, one has* $N_{\omega,n}(0)=N_{\omega,n}(\epsilon)$.

Lemma 4.2 just says that if $V_{\omega,n}\geqslant C\epsilon G$, then $H_{\omega,n}$ has no spectrum in the interval $(0,\epsilon)$.

Estimate (4.1) is now an immediate consequence of Lemmas 4.1 and 4.2. Indeed, picking C as in Lemma 4.2, one computes

$$\begin{aligned}\mathbb{E}(N_{\omega,n}(\epsilon)-N_{\omega,n}(0)) &= \mathbb{E}([N_{\omega,n}(\epsilon)-N_{\omega,n}(0)]\mathbf{1}_{\{\omega;\ V_{\omega,n}\geqslant C\epsilon G\}})\\ &\quad+\mathbb{E}([N_{\omega,n}(\epsilon)-N_{\omega,n}(0)]\mathbf{1}_{\{\omega;\ V_{\omega,n}\not\geqslant C\epsilon G\}})\\ &= \mathbb{E}([N_{\omega,n}(\epsilon)-N_{\omega,n}(0)]\mathbf{1}_{\{\omega;\ V_{\omega,n}\not\geqslant C\epsilon G\}})\leqslant C_0\mathbb{P}(\{\omega;\ V_{\omega,n}\not\geqslant C\epsilon G\})\\ &= C_0(1-\mathbb{P}(\{\omega;\ V_{\omega,n}\geqslant C\epsilon G\}))=C_0P_{C\epsilon}\end{aligned}$$

and we conclude using (4.2) as $(\nu-d)\eta_0>1$. Here, we have used the fact that the integrated density of states of $H_{\omega,n}$ is bounded locally uniformly in energy, uniformly in ω and n.

A. Proof of Lemma 4.2

The operator $H+\epsilon G$ is Γ-periodic. Hence, it is also $(2n+1)\Gamma$-periodic. When doing the Floquet reduction using this period, we call it $(H+\epsilon G)_n$, and $(H+\epsilon G)_{n,\theta}$ denotes this operator considered with quasiperiodic boundary conditions given by θ, i.e., as acting on $\{u\in L^2_{\mathrm{loc}};\ u(\cdot+\gamma)=e^{i\gamma\theta}u(\cdot),\ \forall\gamma\in(2n+1)\Gamma\}$.

Let $\vartheta((H+\epsilon G)_{n,\theta},E)$ denote the number of eigenvalues of $(H+\epsilon G)_{n,\theta}$ below energy E. Standard perturbation theory and the results of Sec. 5.2 in Ref. 1 [see in particular (5.24)] tell us that, for $\epsilon>0$ sufficiently small, one has

$$\vartheta((H+\epsilon G)_{n,\theta},0)=\vartheta((H)_{n,\theta},0)=\vartheta(H_{\omega,n,\theta},0^-). \tag{4.3}$$

Hence, if $V_{\omega,n}\geqslant\epsilon G$, this immediately implies that, for $E\geqslant 0$, one has

$$0\leqslant N_{\omega,n}(E)-N_{\omega,n}(0)\leqslant N_\epsilon(E)-N_\epsilon(0),$$

where N_ϵ is the density of states of the Γ-periodic operator $H+\epsilon G$. So Lemma 4.1 is proved if we prove that there exists $C>0$ (independent of ϵ) such that, for ϵ sufficiently small, one has $N_\epsilon(\epsilon/C)-N_\epsilon(0)=0$. This is a consequence of

Lemma 3.3: Let H *be a* Γ*-periodic Schrödinger operator, and* G *be a non-negative* Γ*-periodic potential in* $L^p_{\mathrm{loc}}(\mathbb{R}^d)$ *[where* p *is chosen as in assumption (H.2)] and such that* $G>0$ *on some open set. Assume that, for some* $\delta>0$, $(-\delta,0)$ *does not intersect the spectrum of* H.

Then, there exists $C>0$ *and* $\epsilon_0>0$ *such that, for* $0\leqslant\epsilon\leqslant\epsilon_0$, $(-\delta/2,\epsilon/C)$ *does not intersect the spectrum of* $H+\epsilon G$.

Proof: Let us first assume that 0 is not in the spectrum of H; then, there exists $\delta'>0$ such that $(-\delta,\delta')$ does not intersect the spectrum of H, and regular perturbation theory tells us that, for ϵ sufficiently small, $(-\delta/2,\delta'/2)$ does not intersect the spectrum of $H+\epsilon G$. This completes the proof of Lemma 4.3 in this case.

We now assume that 0 belongs to the spectrum of H. Let $(E_n(\epsilon,\theta))_{1\leqslant n}$ be the Floquet eigenvalues of $(H+\epsilon G)_\theta$ ordered increasingly; they are continuous in ϵ and θ. Hence, there exists $\epsilon_0>0$ and $n_0\geqslant 1$ such that, for $0\leqslant\epsilon\leqslant 0$, one has that $E_n(\epsilon,\theta)<0$ if and only if $n<n_0$. Then, to prove Lemma 4.3, we need to prove that there exists $C>0$ and $\epsilon_0>0$ such that, for $0\leqslant\epsilon\leqslant\epsilon_0$, one has

$$E_{n_0}(\epsilon,\theta)\geqslant\epsilon/C. \tag{4.4}$$

Define $\mathcal{S}=\{\theta\in\mathbb{T}^*;\ E_{n_0}(0,\theta)=0\}$; $\mathcal{S}$ is compact. Outside of a neighborhood of $\mathcal{S}$, (4.4) is certainly satisfied as, there, one has $E_{n_0}(\epsilon,\theta)\geqslant E_{n_0}(0,\theta)\geqslant\delta'$ (for some $\delta'>0$). So we need only to prove (4.4) in a neighborhood of $\mathcal{S}$.

Therefore, pick $\theta_0\in\mathcal{S}$. Let $p(\theta_0)$ be the multiplicity of 0 as an eigenvalue of $H_\theta=(H+\epsilon G)_{\theta|\epsilon=0}$; it is finite. For θ close to θ_0 and ϵ small, define the Riesz projector

$$\Pi_{\epsilon,\theta}=\frac{1}{2i\pi}\oint_{\mathcal{C}_0}((H+\epsilon G)_\theta-z)^{-1}\mathrm{d}z, \tag{4.5}$$

where $\mathcal{C}_0=\{|z|=\delta'\}$ is a small loop in the complex plane. $\Pi_{\epsilon,\theta}$ is the projector onto the spectral space associated with the interval $(-\delta',\delta')$ and the operator $(H+\epsilon G)_\theta$. It is real analytic in θ and ϵ, hence, of constant rank. Moreover, for some $C>0$, for any ϵ, ϵ' sufficiently small and θ, θ' sufficiently close to θ_0, one has

$$\|\Pi_{\epsilon,\theta}-\Pi_{\epsilon',\theta'}\|\leqslant C(|\epsilon-\epsilon'|+|\theta-\theta|). \tag{4.6}$$

This implies that, for any ϵ, ϵ' sufficiently small and θ, θ' sufficiently close to θ_0, one has

$$\Pi_{\epsilon,\theta}\Pi_{\epsilon',\theta'}\Pi_{\epsilon,\theta}\geqslant\tfrac{1}{2}\,\Pi_{\epsilon,\theta}. \tag{4.7}$$

$E_{n_0}(\epsilon,\theta)$ is the smallest eigenvalue of the finite rank operator $O_{\epsilon,\theta}=\Pi_{\epsilon,\theta}(H+\epsilon G)_\theta\Pi_{\epsilon,\theta}$ [acting on $\Pi_{\epsilon,\theta}L^2_\theta(\mathbb{R}^d)$]. The operator $O_{\epsilon,\theta}$ is real analytic in ϵ and θ. Consider the operator $\tilde{O}_{\epsilon,\theta}=\Pi_{\epsilon,\theta}\Pi_{0,\theta}(H+\epsilon G)_\theta\Pi_{0,\theta}\Pi_{\epsilon,\theta}$. Using $\Pi_{0,\theta}H=H$, one computes

$$\begin{aligned}
O_{\epsilon,\theta}-\tilde{O}_{\epsilon,\theta}&=\Pi_{\epsilon,\theta}(1-\Pi_{0,\theta})(H+\epsilon G)_\theta(1-\Pi_{0,\theta})\Pi_{\epsilon,\theta}+\epsilon\Pi_{\epsilon,\theta}(1-\Pi_{0,\theta})G\Pi_{0,\theta}\Pi_{\epsilon,\theta}\\
&\quad+\epsilon\Pi_{\epsilon,\theta}\Pi_{0,\theta}G(1-\Pi_{0,\theta})\Pi_{\epsilon,\theta}\\
&=\Pi_{\epsilon,\theta}(\Pi_{\epsilon,\theta}-\Pi_{0,\theta})(H+\epsilon G)_\theta(\Pi_{\epsilon,\theta}-\Pi_{0,\theta})\Pi_{\epsilon,\theta}+\epsilon\Pi_{\epsilon,\theta}(\Pi_{\epsilon,\theta}-\Pi_{0,\theta})G\Pi_{0,\theta}\Pi_{\epsilon,\theta}\\
&\quad+\epsilon\Pi_{\epsilon,\theta}\Pi_{0,\theta}G(\Pi_{\epsilon,\theta}-\Pi_{0,\theta})\Pi_{\epsilon,\theta}.
\end{aligned}$$

This implies that, for some $C>0$, for ϵ sufficiently small and θ close to θ_0, one has

$$\|O_{\epsilon,\theta}-\tilde{O}_{\epsilon,\theta}\|\leqslant C\epsilon^2.$$

So, for ϵ sufficiently small positive and θ close to θ_0, one has

$$O_{\epsilon,\theta}\geqslant\tilde{O}_{\epsilon,\theta}-C\epsilon^2\geqslant\epsilon\Pi_{\epsilon,\theta}\Pi_{0,\theta}G\Pi_{0,\theta}\Pi_{\epsilon,\theta}-C\epsilon^2. \tag{4.8}$$

One proves

Lemma 4.4: For some $C>0$ and θ close to θ_0, one has

$$\Pi_{0,\theta}G\Pi_{0,\theta}\geqslant 1/C\Pi_{0,\theta}. \tag{4.9}$$

This, (4.8) and (4.7) imply that, for ϵ positive, sufficiently small, one has

$$O_{\epsilon,\theta}\geqslant\frac{\epsilon}{2C}\,\Pi_{\epsilon,\theta}. \tag{4.10}$$

Equation (4.10) then immediately implies (4.4) for ϵ sufficiently small and θ sufficiently close to θ_0. We then obtain (4.4) for a neighborhood of $\mathcal{S}$ as $\mathcal{S}$ is compact. This completes the proof of Lemma 4.3. □

Proof of Lemma 4.4: First, we note that

$$\Pi_{0,\theta}G\Pi_{0,\theta}=\Pi_{0,\theta}\Pi_{0,\theta_0}G\Pi_{0,\theta_0}\Pi_{0,\theta}-\Pi_{0,\theta}(\Pi_{0,\theta_0}G\Pi_{0,\theta_0}-\Pi_{0,\theta}G\Pi_{0,\theta})\Pi_{0,\theta}.$$

Hence, as $\theta\mapsto\Pi_{0,\theta}G\Pi_{0,\theta}$ is continuous, by (4.7), we just need to prove (4.9) for $\theta=\theta_0$. Let $(\psi_j)_{1\leqslant j\leqslant p(\theta_0)}$ be a basis of eigenvector in the kernel of H_{θ_0}. Then $\Pi_{0,\theta_0}=\Sigma_{1\leqslant j\leqslant p(\theta_0)}\psi_j\otimes\psi_j$. Hence, (4.9) is satisfied if and only if the matrix $((\langle G\psi_i,\psi_j\rangle))_{i,j}$ is positive definite. It is nonnegative. If 0 were an eigenvalue of this matrix, there would exist $\psi\in\mathrm{Span}((\psi_j)_{1\leqslant j\leqslant p(\theta_0)})$ such that $\int_{C(0,0)}G(x)|\psi(x)|^2\mathrm{d}x=0$. Hence, as $G>0$ on some open set, ψ would vanish on this open set: this is not possible by the unique continuation principle as ψ satisfies $H\psi=0$ (see, e.g., Refs. 16 and 17). □

B. Proof of Lemma 3.1

Let us write out $V_{\omega,n}$ and use assumption (H.2). One computes

$$V_{\omega,n}(x)=\sum_{\gamma\in\Gamma}\omega_{[\gamma]}V(x-\gamma)\geqslant\sum_{\gamma\in\Gamma}\omega_{[\gamma]}\sum_{\alpha\in\Gamma}g_-(x-\gamma-\alpha)\cdot(1+|\alpha|)^{-\nu}$$

$$=\sum_{\alpha\in\Gamma}A_\alpha(\omega)g_-(x-\alpha)\text{where }A_\alpha(\omega)=\sum_{\gamma\in\Gamma}\omega_{[\gamma]}(1+|\alpha-\gamma|)^{-\nu}.$$

As $\omega_{[\gamma]}$ is $(2n+1)\Gamma$-periodic, so is $A_\alpha(\omega)$. Define $\Gamma_{2n+1}=\Gamma/(2n+1)\Gamma=\{\gamma\in\Gamma;|\gamma|\leqslant n\}$. Then, we have

$$\mathbb{P}(\{V_{\omega,n}\geqslant\epsilon G\})\geqslant\mathbb{P}(\{\forall\gamma\in\Gamma_{2n+1};\ A_\gamma(\omega)\geqslant\epsilon\})\geqslant1-\sum_{\gamma\in\Gamma_{2n+1}}\mathbb{P}(\{A_\gamma(\omega)\leqslant\epsilon\}).$$

Note that, as the $(\omega_\gamma)_\gamma$ are stationary, the distribution of the random variable $A_\gamma(\omega)$ is independent of γ. Hence

$$\mathbb{P}(\{V_{\omega,n}\geqslant\epsilon G\})\geqslant1-(2n+1)^d\mathbb{P}(\{A_0(\omega)\leqslant\epsilon\}). \tag{4.11}$$

So we only need to estimate $\mathbb{P}(\{A_0(\omega)\leqslant\epsilon\})$. Therefore, we compute

$$A_0(\omega)=\sum_{\beta\in(2n+1)\Gamma}\sum_{\gamma\in\Gamma_{2n+1}}\omega_\gamma(1+|\beta+\gamma|)^{-\nu}$$

$$=\sum_{\gamma\in\Gamma_{2n+1}}\omega_\gamma u_\gamma\text{ where }u_\gamma=\sum_{\beta\in(2n+1)\Gamma}(1+|\beta+\gamma|)^{-\nu}.$$

Using Markov's inequality, for any $\lambda>0$, one obtains

$$\mathbb{P}(A_0(\omega)\leqslant\epsilon)\leqslant\mathbb{E}\left(\exp\left(\lambda\left(\epsilon-\sum_{\gamma\in\Gamma_{2n+1}}\omega_\gamma u_\gamma\right)\right)\right)\leqslant e^{\lambda\epsilon}\prod_{\gamma\in\Gamma_{2n+1}}\mathbb{E}(e^{-\lambda\omega_\gamma u_\gamma}). \tag{4.12}$$

Using the Taylor expansion of $x\mapsto e^{-x}$ at 0, as the random variables $(\omega_\gamma)_\gamma$ are bounded, for $\lambda u_\gamma<\eta$, η sufficiently small, one obtains

$$\mathbb{E}(e^{-\lambda\omega_\gamma u_\gamma})\leqslant1-\mathbb{E}(\omega_\gamma)\lambda u_\gamma+C(\lambda u_\gamma)^2\leqslant1-\mathbb{E}(\omega_\gamma)\lambda u_\gamma(1-C\eta).$$

Hence, we have proved that, there exists $\eta>0$ such that, if $\lambda u_\gamma<\eta$, then

$$\mathbb{E}(e^{-\lambda\omega_\gamma u_\gamma})\leqslant e^{-\overline{\omega_0}\lambda u_\gamma/2}, \tag{4.13}$$

where $\overline{\omega_0}=\mathbb{E}(\omega_0)>0$ by assumption (H.3).
Plugging (4.13) into (4.12), we compute

$$\log(\mathbb{P}(A_0(\omega)\leqslant\epsilon))\leqslant\lambda\epsilon-\frac{\lambda\overline{\omega_0}}{2}\cdot\sum_{\substack{\gamma\in\Gamma_{2n+1}\\ \lambda u_\gamma<\eta}}u_\gamma. \tag{4.14}$$

Assume that $n\geqslant\lambda^{1/\nu}$; then, the definition of u_γ implies that, for some $C>0$, one has

$$\sum_{\substack{\gamma\in\Gamma_{2n+1}\\ \lambda u_\gamma<\eta}}u_\gamma\geqslant\sum_{\substack{\gamma\in\Gamma\\ C\lambda^{1/\nu}\leqslant|\gamma|\leqslant n-\lambda^{1/\nu}}}(1+|\gamma|)^{-\nu}\geqslant\frac{1}{C}\lambda^{(d-\nu)/\nu}.$$

Plugging this back into (4.14) and picking $\lambda=\rho\epsilon^{\nu/(d-\nu)}$, we obtain

$$\log(\mathbb{P}(A_0(\omega)\leqslant\epsilon))\leqslant-\rho(\overline{\omega_0}\rho^{d/\nu}/C-1)\epsilon^{-d/(\nu-d)}\leqslant-\frac{1}{C}\epsilon^{-d/(\nu-d)} \tag{4.15}$$

for ρ sufficiently large.

So that, if we pick, e.g., $n\sim\epsilon^{-p}$ with $p>1/(\nu-d)$, and, we exponentiate estimate (4.15) and plug into (4.11), we complete the proof of Lemma 4.1. □

Noncommutative tori and universal sets of nonbinary quantum gates

Alexander Yu. Vlasov[a)]
Federal Radiological Center (IRH), 197101, Mira Street 8, St. Petersburg, Russia

(Received 12 December 2000; accepted for publication 13 March 2002)

We address the problem of universality in simulation of evolution of quantum system and in theory of quantum computations related with the possibility of expression or approximation of arbitrary unitary transformation by composition of specific unitary transformations (quantum gates) from given set. In an earlier paper application of Clifford algebras to constructions of universal sets of binary quantum gates $U_k \in U(2^n)$ was shown. For application of a similar approach to nonbinary quantum gates $U_k \in U(l^n)$, in present work we used rational noncommutative torus $\mathbb{T}^{2n}_{1/l}$. A set of universal nonbinary two-gates is presented here as one example. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1476391]

I. INTRODUCTION

Let $\mathcal{H}_l$ be a Hilbert space of quantum systems with l states and $\mathcal{H}_l^n \equiv \mathcal{H}_l^{\otimes n}$ is an l^n-dimensional Hilbert space of n systems expressed as the nth tensor power. For $l=2$ an element of $\mathcal{H}_2$ ($\mathcal{H}_2^n$) is usually called a qubit(s). An algebra $\mathbb{C}(l^n \times l^n)$ of all complex $l^n \times l^n$ matrices corresponds to general linear transformations of $\mathcal{H}_l^n$ and a group of unitary matrices $U(l^n)$ corresponds to physically possible evolution. Because of the natural structure of tensor power it is possible to consider groups of transformations of subsystems $U(l^k) \cong U(l^n) \cap (\mathbb{C}(l^k \times l^k) \otimes \mathbb{1}_l^{\otimes n-k})$. Such transformations correspond to *quantum gates*. For $l=2$ they are usually called k-qubits gates.

The problem of universality in quantum simulation and computation is related to approximation with necessary precision (in some appropriate norm) of arbitrary unitary transformation $U \in U(l^n)$ of $\mathcal{H}_l^n$ as a product of matrices U_k from some fixed set called here the *universal set of quantum gates*. One origin of the task was the idea of generalization of the Church–Turing principle from computer science to physical systems in works by David Deutsch,[1,2] where it was suggested there be some universal set of matrices for "*binary*" quantum gates with $l=2$.

It was found also that it is possible to express necessary conditions of universality by using elegant framework with Lie algebra $\mathfrak{u}(2^n)$ of Lie group $\mathrm{U}(2^n)$.[3–5] In the approach it is necessary to find a set of elements $A_k \in \mathfrak{u}(2^n)$, $A_k^\dagger = -A_k$, which generate full algebra $\mathfrak{u}(2^n)$. It is possible to use $U_k^\tau = \exp(\tau A_k)$ with infinitesimal parameter $\tau \in \mathbb{R}$ as a universal set of quantum gates. In a more physical picture, $A_k \triangleq iH_k$, where H_k are Hamiltonians and Lie brackets also contain multipliers with imaginary unit.

Previous work[6] suggested construction of the universal set by inclusion $\mathfrak{u}(2^n)$ in Clifford algebra $\mathfrak{Cl}(2n,\mathbb{C}) \cong \mathbb{C}(2^n \times 2^n)$ with Lie algebra structure due to bracket operation $[a,b] \equiv ab - ba$ (cf. Ref. 7). Because commutation laws for basis elements of Clifford algebra are simple enough due to canonical relations between generators,

$$\Gamma_j \Gamma_k + \Gamma_k \Gamma_j = 2\delta_{kj}\mathbb{1}, \tag{1.1}$$

it was possible to represent useful constructions of universal sets with $2n+1$ elements (see Ref. 6).

a)Electronic mail: qubeat@mail.ru or alex@protection.spb.su

For generalization of the method for "nonbinary" quantum gates $U(l^n)$, $l>2$, it is useful to find some algebra with simple commutation rules, like Eq. (1.1), and use it to express elements of $\mathfrak{u}(l^n)$. In this article as such, generalization of $\mathfrak{Cl}(2n,\mathbb{C})\cong\mathbb{C}(2^n\times 2^n)$ used a *noncommutative torus* $\mathbb{T}^{2n}_{1/l}\cong\mathbb{C}(l^n\times l^n)$ with $2n$ generators:

$$(T_k)^l=\mathbb{1}, \tag{1.2a}$$

$$T_jT_k=\zeta T_kT_j \quad (j<k), \tag{1.2b}$$

$$\zeta=\exp(2\pi i/l). \tag{1.2c}$$

For $l=2$ Eq. (1.2) coincides with Eq. (1.1). For $l>2$, elements $T_k\notin\mathfrak{u}(l^n)$ for most or all k, but it is possible to use representation $\mathfrak{u}(N)\subset\mathfrak{R}(\mathfrak{gl}(N,\mathbb{C}))$. More concretely, it is enough to find a set of elements $M_k\in\mathfrak{gl}(N,\mathbb{C})$, which generate full algebra $\mathfrak{gl}(N,\mathbb{C})$. It is possible to use $G_k^\tau=\exp(i\tau(M_k+M_k^\dagger))$, $F_k^\tau=\exp(\tau(M_k-M_k^\dagger))$ with infinitesimal parameter $\tau\in\mathbb{R}$ as a universal set of quantum gates.

II. NONCOMMUTATIVE TORUS $\mathbb{T}^2_\theta$ AND QUANTUM ONE-GATES

Let us consider one-particle transformations. For two-dimensional case, $\mathcal{H}_2$, any two Pauli matrices, for example σ_x and σ_z, generate full four-dimensional basis of $\mathbb{C}(2\times 2)$, i.e., $\{\sigma_x^2=\sigma_y^2=\mathbb{1}_2,\sigma_x,\sigma_z,\sigma_y=i\sigma_x\sigma_z\}$.

Analogously, two generators U,V of noncommutative torus $\mathbb{T}^2_\theta$ defined as[8]

$$UV=\exp(2\pi i\theta)VU, \quad VV^\dagger=UU^\dagger=\mathbb{1}, \tag{2.1}$$

produce for rational $\theta=1/l$ an algebra isomorphic to $\mathbb{C}(l\times l)$. The bases of the algebra are l^2 elements U^mV^n, $m,n=0,\ldots,l-1$.

Let us use the Weyl representation of U and V as the right cyclic shift operator and its Fourier transform:

$$U_{kj}=\delta_{k+1(\mathrm{mod}\ l),j}, \quad V_{kj}=\exp(2\pi ik/l)\,\delta_{kj}. \tag{2.2}$$

The representation and U^mV^n basis are well known in quantum information science after application to the theory of quantum error correction.[9]

To find transformation between basis U^mV^n and canonical basis E^{ab} of $\mathbb{C}(l\times l)$, there $(E^{ab})_{jk}=\delta_{aj}\delta_{bk}$, it is enough to use $E^{00}=(1/l)\,\Sigma_{k=0}^{l-1}V^k$ together with $E^{ab}=U^{l-a}E^{00}U^b$.

Let us show that any U^mV^n (except $\mathbb{1}_l$ for $m=n=0$) can be generated from U and V using only commutators $[A,B]\equiv(\mathrm{ad}\ A)\,B\equiv AB-BA$. For U and V commutator is simply $[U,V]=(1-\zeta)\,UV\propto UV$, where $\zeta=\exp(2\pi i/l)$. It is convenient to use "ad" for consecutive commutators, for example, $(\mathrm{ad}\ A)^2B\equiv[A,[A,B]]$, and symbol "proportional," $A\propto B\Rightarrow A=\alpha B$, to avoid unessential nonzero complex multipliers α.

Direct expressions for l^2-1 elements U^mV^n are

$$U^mV^n\propto(\mathrm{ad}\ U)^{m-1(\mathrm{mod}\ l)}((\mathrm{ad}\ V)^{n-1(\mathrm{mod}\ l)}[U,V]), \tag{2.3}$$

where $0\leqslant m,n<l$ for any pair of numbers except $m=n=0$, $(\mathrm{ad}\ U)^0$ or $(\mathrm{ad}\ V)^0$ corresponds to the absence of the term, and $-1(\mathrm{mod}\ l)=l-1$.

Of course it is possible to suggest simpler expression for particular values of m and n, but Eq. (2.3) shows also application of a third element $W\propto UV$:

$$UW=\zeta WU, \quad WV=\zeta VW. \tag{2.4}$$

It is convenient to define

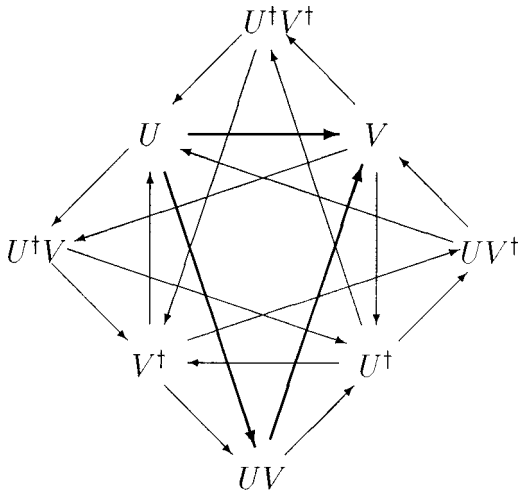
$$W=\zeta^{(l-1)/2}UV, \quad W^l=\mathbb{1}_l. \tag{2.5}$$

Similar with case $l=2$ with $(\sigma_x,\sigma_y,\sigma_z)$, any pair between (U,V,W) may be used for generation of a full algebra due to Eq. (2.3) and due to possibility to express initial pair (U,V) from (U,W) or (V,W):

$$V\propto(\text{ad } U)^{l-1}W, \quad U\propto(\text{ad } V)^{l-1}W, \tag{2.6}$$

but for $l\geqslant 3$ there is a special property that should be taken into account. Let us use notation $A\rightarrow_\zeta B$ for $AB=\zeta BA$. The definition of relation "$\rightarrow_\zeta$" is asymmetric for $l\geqslant 3$.

It is clear from the diagram:



For different sets with three operators the relation may be transitive or not.

For example, $U\rightarrow_\zeta V$ from Eq. (2.1), $U\rightarrow_\zeta W$ and $W\rightarrow_\zeta V$ from Eq. (2.4) and so we have transitive relation $U\rightarrow_\zeta W\rightarrow_\zeta V$, i.e., *ordering*. Let us call it *ζ-order* for certainty. On the other hand, it is simply to check $W^\dagger\rightarrow_\zeta U$ and $V\rightarrow_\zeta W^\dagger$ and here is some cyclic graph. The cyclic case is more symmetric, because all pairs are equivalent.

For the ordered case it is not so, because ζ-order produces a canonical map to a set of natural numbers, i.e., indexes, and it is convenient for construction of noncommutative torus $\mathbb{T}^{2n}_{1/l}$, ζ-ordered by definition: $\mathbb{T}_k\rightarrow_\zeta\mathbb{T}_j$ for $k<j$ [see Eq. (1.2)].

Because of the principle we use the following definition for generators of $\mathbb{T}^2_{1/l}$:

$$T_0\equiv U, \quad T_1\equiv W. \tag{2.7}$$

where U is defined in Eq. (2.2) and W in Eq. (2.5).

III. REPRESENTATIONS OF NONCOMMUTATIVE TORI $\mathbb{T}^{2n}_{1/l}$

Let us use notation $T_x\equiv U$, $T_y\equiv W$, $T_z=V$, where U, V, W are defined in Eqs. (2.2) and (2.5). There is ζ-order $T_x\rightarrow_\zeta T_y\rightarrow_\zeta T_z$, i.e.,

$$T_xT_y=\zeta T_yT_x, \quad T_yT_z=\zeta T_zT_y, \quad T_xT_z=\zeta T_zT_x. \tag{3.1}$$

It is possible to introduce $2n$ generators of $\mathbb{T}^{2n}_{1/l}$ as

$$T_{2k}=\underbrace{\mathbb{1}_l\otimes\cdots\otimes\mathbb{1}_l}_{n-k-1}\otimes T_x\otimes\underbrace{T_z\otimes\cdots\otimes T_z}_{k}, \tag{3.2a}$$

$$T_{2k+1}=\underbrace{\mathbb{1}_l\otimes\cdots\otimes\mathbb{1}_l}_{n-k-1}\otimes T_y\otimes\underbrace{T_z\otimes\cdots\otimes T_z}_{k}, \tag{3.2b}$$

in direct analogy with construction of Clifford algebras.[6,7]

It is clear that different products of T_k generate full matrix algebra $\mathbb{C}(l^n\times l^n)$, because T_x and T_y generate $\mathbb{C}(l\times l)$. Let us prove that generators Eq. (3.2) satisfy definition (1.2) of noncommutative torus $\mathbb{T}^{2n}_{1/l}$:

$T^l_k=\mathbb{1}$ because $T^l_x=T^l_y=T^l_y=\mathbb{1}_l$.

To prove that $T_k\rightarrow_\zeta T_j$ for any $k<j$, it is enough to consider a few cases (here "T" means "any element" and "$\downarrow_\zeta$" marks ζ-order of only a pair of noncommutative terms in the tensor products):

Case 1: $T_{2k}\rightarrow_\zeta T_{2k+1}$, $k\geqslant 0$

$$T_{2k}=\underbrace{\mathbb{1}_l\otimes\cdots\otimes\mathbb{1}_l}_{n-k-1}\otimes T_x\otimes\underbrace{T_z\otimes\cdots\otimes T_z}_{k}$$

$$\downarrow_\zeta$$

$$T_{2k+1}=\mathbb{1}_l\otimes\cdots\otimes\mathbb{1}_l\otimes T_y\otimes T_z\otimes\cdots\otimes T_z$$

Case 2: $T_{2k}\rightarrow_\zeta T_{2k+j+1}$, $k\geqslant 0$, $j>0$

$$T_{2k}=\underbrace{\mathbb{1}_l\otimes\cdots\otimes\mathbb{1}_l}_{n-k-1}\otimes T_x\otimes\underbrace{T_z\otimes\cdots\otimes T_z}_{k}$$

$$\downarrow_\zeta$$

$$T_{2k+1+j}=\mathbb{1}_l\otimes\cdots\otimes T\otimes T_z\otimes T_z\otimes\cdots\otimes T_z$$

Case 3: $T_{2k+1}\rightarrow_\zeta T_{2k+1+j}$, $k\geqslant 0$, $j>0$

$$T_{2k+1}=\underbrace{\mathbb{1}_l\otimes\cdots\otimes\mathbb{1}_l}_{n-k-1}\otimes T_y\otimes\underbrace{T_z\otimes\cdots\otimes T_z}_{k}$$

$$\downarrow_\zeta$$

$$T_{2k+1+j}=\mathbb{1}_l\otimes\cdots\otimes T\otimes T_z\otimes T_z\otimes\cdots\otimes T_z$$

IV. GENERATION OF $\mathbb{T}^{2n}_{1/l}$ BY COMMUTATORS

Let us prove that for $l>2$ it is possible to generate $\mathbb{T}^{2n}_{1/l}$ using only commutators of $2n$ elements T_k. The case with $l=2$, $\mathfrak{CL}(2n,\mathbb{C})\cong\mathbb{T}^{2n}_{1/2}$ was considered in earlier work,[6] and it was shown that $2n$ generators are not enough and it is necessary to add any element of third or fourth order.

We present proof that for $l>2$ $2n$ generators are enough. Let us instead of $T^{n_i}_i T^{n_j}_j\cdots T^{n_k}_k$ write simply $T(n_i,n_j,\ldots,n_k)$ if it is possible without lost of clarity. Sequences of indexes are always chosen ordered $0\leqslant i<j<\cdots<k<2n$. Let us use # for the number of different indexes in product $\#(n_0,\ldots,n_{k-1})\equiv k$ and Σ for total number of terms $\Sigma(n_0,\ldots,n_{k-1})\equiv\Sigma^{k-1}_{j=0}n_j$.

It is possible to prove proposition using recursion. The case with $\#=2$ may be expressed by generalization of Eq. (2.3):

$$T(n_i,n_j)\propto(\mathrm{ad}\ T_i)^{n_i-1(\mathrm{mod}\ l)}((\mathrm{ad}\ T_j)^{n_j-1(\mathrm{mod}\ l)}[T_i,T_j]). \tag{4.1}$$

Let all cases with $T(n_{i_1},\ldots,n_{i_k})$, $2\leqslant k<2n$, $i_1<i_2<\cdots<i_k$, be proved and it is necessary to generate all $T(n_{i_1},\ldots,n_{i_k},n_j)$ with $i_k<j\leqslant 2n$.

There are a few different cases:

Case 1: $\Sigma(n_{i_1},\ldots,n_{i_k})\ \mathrm{mod}\ l\neq 0$:

$$T(n_{i_1},\ldots,n_{i_k},n_j)\propto(\mathrm{ad}\ T_j)^{n_j}T(n_{i_1},\ldots,n_{i_k}). \tag{4.2}$$

Case 2: $\Sigma(n_{i_1},\ldots,n_{i_k})\ \mathrm{mod}\ l=0$ and Eq. (4.2) vanishes:

Case 2.1: $\exists n_i\in(n_{i_1},\ldots,n_i,\ldots,n_{i_k}),n_i\neq n_j$:

$$T(n_{i_1},\ldots,n_{i_k},n_j)\propto[T_i,(\mathrm{ad}\ T_j)^{n_j}T(n_{i_1},\ldots,n_i-1,\ldots,n_{i_k})]. \tag{4.3}$$

Case 2.2: $\nexists n_i\in(n_{i_1},\ldots,n_i,\ldots,n_{i_k}),n_i\neq n_j$, i.e., $n_{i_1}=\ldots=n_{i_k}=n_j$.

Case 2.2.1: $2n_j\neq l$:

$$T(n_{i_1},\ldots,n_{i_k},n_j)\propto[T(n_{i_1},\ldots,n_{i_{k-1}}),T(n_{i_k},n_j)]. \tag{4.4}$$

Case 2.2.2: $2n_j=l$; let $n_{k_i}=n'_{k_i}+n''_{k_i}$:

$$T(n_{i_1},\ldots,n_{i_k},n_j)\propto[T(n_{i_1},\ldots,n'_{k_i}),T(n''_{i_k},n_j)]. \tag{4.5}$$

The cases include all possible variants and so the suggestion is proved by recursion and all l^n-1 possible products of generators except of $\mathbb{1}$ can be represented using commutators.

V. UNIVERSAL SET OF QUANTUM TWO-GATES

Elements T_k have up to n non-unit terms in tensor product Eq. (3.2). Here is described construction with no more than two terms. It is used for description of a universal set of quantum two-gates and also has direct analog with two-qubit gates.[6]

Let us consider $B_0=T_0$, $B_j=T_jT_{j-1}^{\dagger}$, $1\leqslant j<2n$. It is possible to generate full $\mathbb{T}_{1/l}^{2n}$ using the $2n$ elements: $T_1\propto[T_0,B_1]$, $T_i\propto[B_i,T_{i-1}]$, $\forall i>1$, and so it is possible to generate recursively all T_i and use construction of $\mathbb{T}_{1/l}^{2n}$ described above.

With using Eq. (3.2) it is possible to write expressions for B_j:

$$B_0=T_0=\mathbb{1}^{\otimes(n-1)}\otimes T_x, \tag{5.1a}$$

$$B_{2k+1}=T_{2k+1}T_{2k}^{\dagger}\propto\mathbb{1}^{\otimes(n-k-1)}\otimes T_z\otimes\mathbb{1}^{\otimes k}, \tag{5.1b}$$

$$B_{2k+2}=T_{2k+2}T_{2k+1}^{\dagger}\propto\mathbb{1}^{\otimes(n-k-2)}\otimes T_x\otimes T_x^{\dagger}\otimes\mathbb{1}^{\otimes k}, \tag{5.1c}$$

with $k=0,\ldots,n-1$ (or $n-2$).

To produce a universal set of quantum one- and two-gates it is enough to use constructions of unitary matrices mentioned in the Introduction:

$$G_k^{\tau}=e^{i\tau(B_k+B_k^{\dagger})},\quad F_k^{\tau}=e^{\tau(B_k-B_k^{\dagger})}. \tag{5.2}$$

It is possible to choose τ to express an arbitrary matrix with given precision as product of matrices (5.2).

A note on the improvement ambiguity of the stress tensor and the critical limits of correlation functions

D. Anselmi
Dipartimento di Fisica, Università di Pisa, via F. Buonarroti 2, 56126 Pisa, Italia

(Received 6 November 2001; accepted for publication 26 February 2002)

I study various properties of the critical limits of correlators containing insertions of conserved and anomalous currents. In particular, I show that the improvement term of the stress tensor can be fixed unambiguously, studying the RG interpolation between the UV and IR limits. The removal of the improvement ambiguity is encoded in a variational principle, which makes use of sum rules for the trace anomalies a and a'. Compatible results follow from the analysis of the RG equations. I perform a number of self-consistency checks and discuss the issues in a large set of theories. © *2002 American Institute of Physics.*

I. INTRODUCTION

In a large set of models, the renormalization-group (RG) flow interpolates between well-defined ultraviolet (UV) and infrared (IR) fixed points, the zeros of the beta function. The RG interpolation can be studied comparing the UV and IR limits of a certain class of correlators. Finite operators play a special role in this context, since they define central charges in the conformal limits.

Among the finite operators, noticeable are the conserved currents, in particular the stress tensor $T_{\mu\nu}$. When the theory contains scalar fields φ, there exists an improvement operator

$$\Delta T_{\mu\nu}=(\partial_\mu\partial_\nu-\Box\delta_{\mu\nu})\varphi^2,$$

which mixes with $T_{\mu\nu}$ under renormalization. It is possible to diagonalize this mixing,[1,2] and this makes the improvement term finite as well. There exists a one-parameter family of finite, conserved, spin-2, dimension-4 operators $T_{\mu\nu}(\eta)=T_{\mu\nu}+\eta\Delta T_{\mu\nu}$. At the level of the Lorentz commutator algebra, the operators $T_{\mu\nu}(\eta)$ are equivalent. At the level of the correlation functions and operator-product expansions, they are not. For example, in a conformal field theory, the embedding in external gravity is fixed unambiguously by conformal invariance. This means that there is no improvement arbitrariness in the UV and IR limits. In most models, the RG equations for η extend the removal of the improvement arbitrariness from the critical points to the intermediate energies.

A universal principle for the removal of the improvement ambiguity can be formulated using the sum rules for the trace anomalies a and a'.[3] This is a sort of variational principle,[4] which fixes a privileged value $\overline{\eta}$ for η. We can distinguish two cases.

(i) When the improvement term survives in a critical limit (typically, the UV), the value $\overline{\eta}$ determined by the variational principle coincides with the value fixed by conformal invariance at criticality and the RG equations. Matching the stress tensor at intermediate energies with its UV limit removes the η-arbitrariness at all energies.

(ii) When the improvement term vanishes at the critical points, all operators $T_{\mu\nu}(\eta)$ are in principle equally acceptable, but the value $\overline{\eta}$ is still privileged. Specifically, the minimum of $\Delta a'(\overline{\eta})$ over the flow trajectories connecting the same pair of fixed points is equal to Δc

in a class of models. (This relation is empirically known to hold in massive Gaussian models, unitary and not unitary. Nevertheless, a satisfactory theoretical understanding of this relation is still lacking.)

There is a universal way to remove the η-arbitrariness and select a unique stress tensor, in accord with all present knowledge.

In this paper I study this issue and other properties of the critical limits of correlators. In Sec. II I discuss the properties of the improvement term and list the criteria for the removal of the η-ambiguity. In Sec. III I illustrate the statements in a set of Gaussian models where calculations can be carried over to the end. Then, I analyze the RG equations in IR-free and UV-free theories. In all cases the parameter η is fixed uniquely with the rules of Sec. II. In the appendix I discuss other aspects of the critical limits of correlators containing insertions of finite and nonfinite operators. In particular, I show that anomalous currents and the topological charge density are finite in various models.

II. REMOVAL OF THE η-AMBIGUITY

The UV and IR limits of correlators containing insertions of the trace of the stress-tensor have been studied systematically in Ref. 3. General sum rules for the central charges a and a' have been written. Particularly meaningful is the notion of flow invariant, that is to say, a flow integral, or combination of flow integrals, whose value depends only on the extrema of the flow.

I briefly summarize the derivation of the sum rules. The theory is embedded in external gravity. The central charges a and a' (and c) are defined by the trace anomaly at criticality, which reads

$$\Theta_* = \frac{1}{(4\pi)^2}\left[c\, W^2 - \frac{a}{4}\mathrm{G} + \frac{2}{3}a'\,\Box R\right], \tag{2.1}$$

where W is the Weyl tensor and $\mathrm{G} = 4R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} - 16R_{\mu\nu}R^{\mu\nu} + 4R^2$ is the Euler density. The induced action for the background metric is denoted with $\Gamma[g_{\mu\nu}]$. The Θ-correlators are related to the derivatives of $\Gamma[g_{\mu\nu}\mathrm{e}^{2\phi}]$ with respect to the conformal factor ϕ of the metric. In particular,

$$\Theta = -\left.\frac{\delta\Gamma[g_{\mu\nu}\mathrm{e}^{2\phi}]}{\delta\phi}\right|_{\phi=0}.$$

In general, the Θ-correlators have involved expressions, at intermediate energies, but their critical limits are universal and simple: they contain just two local structures, multiplied by a and a', which can be read from (2.1). The sum rules for $\Delta a = a_{\mathrm{UV}} - a_{\mathrm{IR}}$ and $\Delta a' = a'_{\mathrm{UV}} - a'_{\mathrm{IR}}$ are direct consequences of the property that the Θ-correlators tend to the universal critical limits parametrized by a and a'.

The derivation of the sum rules for Δa and $\Delta a'$ simplifies considerably if the metric is conformally flat, $g_{\mu\nu} = \delta_{\mu\nu}\mathrm{e}^{2\phi}$. More general metrics are necessary to derive sum rules for Δc, because Θ_* is insensitive to c on conformally flat spaces. In that case, it is not sufficient to study the critical limits of the correlators of Θ. Correlators with one insertion of Θ and at least two insertions of the full stress tensor $T_{\mu\nu}$ have to be considered.

From now on, I assume that the background metric is conformally flat.

Concretely, I study two sum rules for Δa, taken from Sec. 7 of Ref. 3. The first formula involves integrals of the two- and three-point functions:

$$\Delta a_1=\frac{\pi^2}{48}\int \mathrm{d}^4x\,|x|^4\,\langle\tilde\Theta(x)\,\tilde\Theta(0)\rangle+\frac{\pi^2}{48}\int \mathrm{d}^4x\,\mathrm{d}^4y\;x^2\,y^2\left\{\langle\tilde\Theta(x)\,\tilde\Theta(y)\,\tilde\Theta(0)\rangle\right.$$
$$\left.+\left\langle\frac{\tilde\delta\tilde\Theta(x)}{\tilde\delta\phi(y)}\tilde\Theta(0)\right\rangle+2\left\langle\frac{\tilde\delta\tilde\Theta(x)}{\tilde\delta\phi(0)}\tilde\Theta(y)\right\rangle\right\}. \tag{2.2}$$

The second formula involves integrals of the two-, three- and four-point functions:

$$\Delta a_2=\frac{\pi^2}{48}\int \mathrm{d}^4x\,|x|^4\,\langle\tilde\Theta(x)\,\tilde\Theta(0)\rangle+\frac{\pi^2}{48}\int \mathrm{d}^4x\,\mathrm{d}^4y\,\mathrm{d}^4z\,(x\cdot y)(x\cdot z)\left\langle\tilde\Theta(x)\,\tilde\Theta(y)\,\tilde\Theta(z)\,\tilde\Theta(0)\right.$$
$$+2\,\frac{\tilde\delta\tilde\Theta(x)}{\tilde\delta\phi(y)}\tilde\Theta(z)\,\tilde\Theta(0)+\frac{\tilde\delta\tilde\Theta(x)}{\tilde\delta\phi(0)}\tilde\Theta(y)\,\tilde\Theta(z)+\frac{\tilde\delta\tilde\Theta(y)}{\tilde\delta\phi(z)}\tilde\Theta(x)\,\tilde\Theta(0)+2\,\frac{\tilde\delta\tilde\Theta(y)}{\tilde\delta\phi(0)}\tilde\Theta(x)\,\tilde\Theta(z)$$
$$+\frac{\tilde\delta^2\tilde\Theta(x)}{\tilde\delta\phi(y)\,\tilde\delta\phi(z)}\tilde\Theta(0)+2\,\frac{\tilde\delta^2\tilde\Theta(x)}{\tilde\delta\phi(y)\,\tilde\delta\phi(0)}\tilde\Theta(z)+\frac{\tilde\delta^2\tilde\Theta(y)}{\tilde\delta\phi(z)\,\tilde\delta\phi(0)}\tilde\Theta(x)+2\,\frac{\tilde\delta\tilde\Theta(x)}{\tilde\delta\phi(y)}\,\frac{\tilde\delta\tilde\Theta(z)}{\tilde\delta\phi(0)}$$
$$\left.+\frac{\tilde\delta\tilde\Theta(x)}{\tilde\delta\phi(0)}\,\frac{\tilde\delta\tilde\Theta(y)}{\tilde\delta\phi(z)}\right\rangle. \tag{2.3}$$

The notation is as follows. If ϕ is the conformal factor of the metric and φ denotes generically the dynamical fields of the theory, with conformal weight h, then the $\tilde\delta/\tilde\delta\phi$-derivatives are the derivatives with respect to ϕ at constant $\tilde\varphi\equiv\varphi\,\mathrm{e}^{h\phi}$. We have $\tilde\Theta=-\tilde\delta S/\tilde\delta\phi$, where S denotes the action. It is understood that, after taking the ϕ-derivatives of $\tilde\Theta$, ϕ is set to zero.

I also study the $\Delta a'$-sum rule

$$\Delta a'=\frac{\pi^2}{48}\int \mathrm{d}^4x\,|x|^4\,\langle\tilde\Theta(x)\,\tilde\Theta(0)\rangle. \tag{2.4}$$

The central charge a is unambiguous at criticality, but a' is ambiguous. This ambiguity disappears in the difference $\Delta a'$, which is a physical quantity. These facts have important implications in the context of flow invariance and the dependence on the improvement ambiguity.

We can evaluate the above flow integrals using the one-parameter family of stress tensors $T_{\mu\nu}(\eta)$. Two situations can occur.

If the improvement term of the stress tensor does not vanish at both critical points, some nontrivial functions of η are generated, which depend also on the sum rule. This dependence is emphasized by the subscript i in the labels $\Delta_i a$. Formulas (2.2) and (2.3) define the functions $\Delta_1 a(\eta)$ and $\Delta_2 a(\eta)$, respectively. Formula (2.4) defines $\Delta a'(\eta)$. Since, however, a is unambiguous at criticality, there must be a privileged value of η which resolves the ambiguity and reproduces the correct Δa. This value can be found studying the RG equations for the parameter η, imposing conformal invariance at the critical points.

If the improvement term vanishes at both critical points, all values of η are in principle acceptable. The functions $\Delta_i a(\eta)$ do not depend on i and η and are identically equal to Δa. Instead, since a' has no unambiguous definition at criticality, the function $\Delta a'(\eta)$ can depend on η. We know from Ref. 4 that the value $\overline{\eta}$ at which $\Delta a'(\eta)$ is minimum has particularly interesting properties. Using this, we can remove the improvement ambiguity also in this case.

Both situations are resolved by a universal criterion for the removal of the improvement ambiguity, encoded in a variational principle studied in Ref. 4, which expresses the independence of the flat-space theory from the embedding in external gravity. When both this principle and the analysis of the RG equations fix η, the results agree.

A. Criterion for the removal of the improvement ambiguity

Determine the (unique) $\overline{\eta}$ which satisfies

$$\left.\frac{\mathrm{d}\Delta a'(\eta)}{\mathrm{d}\eta}\right|_{\eta=\overline{\eta}}=0, \quad \left.\frac{\mathrm{d}\Delta_i a(\eta)}{\mathrm{d}\eta}\right|_{\eta=\overline{\eta}}=0. \tag{2.5}$$

The functions $\Delta_i a(\eta)$ and $\Delta a'(\eta)$ are at most quadratic in η (this will be shown explicitly in the next section), so the condition (2.5) has one solution for every sum rule. (In even dimension greater than four, the η-polynomials can have a higher degree. I am grateful to G. Festuccia for this remark.) The solution $\overline{\eta}$ does not depend on the sum rule. The correct stress tensor is $T_{\mu\nu}(\overline{\eta})$ and the correct value of Δa is $\Delta_i a(\overline{\eta})$, independently of i. This criterion fixes also $\Delta a'$ unambiguously.

The integrals of (2.2) and (2.3) are assured to converge, when there is no improvement ambiguity. When the stress tensor admits improvement terms, instead, there can be a divergence in $\Delta a'(\eta)$. This divergence provides alternative criteria for the removal of the η-ambiguity (see Sec. II B). If, on the other hand, the Θ-correlators are expanded perturbatively, the convergence of the term-by-term integration is not assured. Observe that the resolution of the η-ambiguity is intrinsically nonperturbative. A useful perturbative expansion can be defined, although computations are not simple.

B. Shortcuts and other criteria to remove the η-ambiguity

The value $\overline{\eta}$ does not depend on the sum rule and so it can be determined from the simplest of those, i.e., $\Delta a'(\eta)$. The Δa-sum rules involve more complicated flow integrals. In various cases, $\overline{\eta}$ can be fixed by conformal invariance at the critical points. In the next sections I study the criteria for the removal of the improvement ambiguity in a variety of models. These cover essentially all cases. We can have the following behaviors:

(i) The RG equations imply that the improvement term of $T_{\mu\nu}(\eta)$ survives at one of the critical points, where, however, the stress tensor is uniquely fixed by conformal invariance.
(ii) The RG equations imply that the improvement term of $T_{\mu\nu}(\eta)$ diverges at one of the critical points and the divergence disappears if η is chosen appropriately.
(iii) The improvement term vanishes at the critical points, but not sufficiently quickly. The quantity $\Delta a'$ should be finite because it is physically meaningful (although it is not a flow invariant[4]). The finiteness of $\Delta a'(\eta)$ can fix η. This can also be seen as a consequence of (2.5).

In all cases, the $\overline{\eta}$ fixed with the criteria (i), (ii), and (iii) coincides with the $\overline{\eta}$ of (2.5). In the next section I present checks of this.

The fourth situation is when the improvement term disappears quickly enough at both critical points. When this happens, we have $\Delta_i a(\eta)=\Delta a$ for every i and η. The variational principle (2.5) applies also to this case, in the sense that it outlines a noticeable value $\overline{\eta}$, such that $\Delta a'(\overline{\eta})$ has the properties studied in Ref. 4. This behavior is studied in a higher-derivative model.

C. Modified, η-independent sum rules

Following Ref. 4, the criterion (2.5) is equivalent to the η-independence of more complicated sum rules. This illustrates that the removal of the $\overline{\eta}$-ambiguity fixed by (2.5) is compatible with the fact that the quantum field theory in flat space is independent of the nonminimal couplings to external gravity.

We proceed as follows. Using the fact that $\Delta_i a(\eta)$ is at most quadratic in η, we write

$$\Delta_i a(\eta)=\Delta_i a(\tilde{\eta})+(\eta-\tilde{\eta})\frac{\mathrm{d}\Delta_i a(\eta)}{\mathrm{d}\eta}\bigg|_{\tilde{\eta}}+\frac{1}{2}(\eta-\tilde{\eta})^2\frac{\mathrm{d}^2\Delta_i a(\eta)}{\mathrm{d}\eta^2}\bigg|_{\tilde{\eta}}. \tag{2.6}$$

The right-hand side is clearly independent of $\tilde{\eta}$.

Finding $\overline{\eta}$ according to (2.5), inserting it in (2.6) and renaming $\tilde{\eta}\to\eta$, we get

$$\Delta a=\Delta_i a(\overline{\eta})=\Delta_i a(\eta)-\frac{1}{2}\frac{(\mathrm{d}\Delta_i a(\eta)/\mathrm{d}\eta)^2}{\mathrm{d}^2\Delta_i a(\eta)/\mathrm{d}\eta^2}. \tag{2.7}$$

The final expression is an involved combination of flow integrals. It can be seen as a generalized sum rule for Δa, in the spirit of the formulas of Ref. 4. The result is clearly independent of η and gives the correct value of Δa. In the generalized sum rule, we can choose for $\Delta_i a(\eta)$ any equivalent Δa-formula from Ref. 3; for example, (2.2) and (2.3) of the present article. The i-independence of the result can be rephrased in terms of equivalence relations among the flow integrals. These involve correlators of Θ and the improvement operator.

III. CHECKS AND ILLUSTRATIVE EXAMPLES

In this section I study various examples, starting from simplest case, namely the massive free scalar. A richer structure is exhibited by Gaussian nonunitary theories, where the issue of flow invariance is more apparent. This model describes some qualitative features of physical theories with several independent masses or dimensioned parameters. Then, I consider the φ^4-theory and asymptotically free theories, supersymmetric and non-supersymmetric. Finally, I comment on the most general case.

A. Massive scalar field

The action in external gravity is

$$S=\frac{1}{2}\int \mathrm{d}^4x\,\sqrt{g}\,\{g^{\mu\nu}\partial_\mu\varphi\,\partial_\nu\varphi+\eta R\varphi^2+m^2\varphi^2\}.$$

Focusing on the conformal factor ϕ and eliminating a total derivative, we can simplify the action and write

$$S=\frac{1}{2}\int \mathrm{d}^4x\{(\partial_\mu\tilde{\varphi})^2+m^2\tilde{\varphi}^2\mathrm{e}^{2\phi}+(1-6\eta)\tilde{\varphi}^2(\Box\phi+(\partial_\mu\phi)^2)\}, \tag{3.1}$$

where $\tilde{\varphi}=\varphi\,\mathrm{e}^{\phi}$. We need

$$\tilde{\Theta}=-\frac{\tilde{\delta}S}{\tilde{\delta}\phi}=-m^2\tilde{\varphi}^2\mathrm{e}^{2\phi}+\frac{1}{2}(1-6\eta)[\Box(\tilde{\varphi}^2)-2\partial_\mu(\tilde{\varphi}^2\partial_\mu\phi)], \tag{3.2}$$

where $\tilde{\delta}$ is the ϕ-derivative at fixed $\tilde{\varphi}$ (check Ref. 3 for definitions), and the first two derivatives of $\tilde{\Theta}$ with respect to ϕ.

The calculations give

$$\Delta_1 a(\eta) = -\tfrac{89}{360} + 3\eta - 9\eta^2, \quad \Delta_2 a(\eta) = -\tfrac{37}{180} + \tfrac{5}{2}\eta - \tfrac{15}{2}\eta^2.$$

The condition (2.5) gives the (expected) value $\overline{\eta} = \frac{1}{6}$ in both cases and $\Delta_1 a(\overline{\eta}) = \Delta_2 a(\overline{\eta}) = \frac{1}{360} = \Delta a$. It is well-known that the value $\overline{\eta} = \frac{1}{6}$ is such that the action (3.1) is conformal at $m = 0$. The correct stress tensor can be fixed, more simply, by requiring that $\widetilde{\Theta}$ be zero in the UV limit. This is a check that the criterion (2.5) gives the same result as conformal invariance at the critical points, expressed by shortcut (i). On the other hand, $\Delta_1 a(\eta)$ and $\Delta_2 a(\eta)$ do not coincide for $\eta \neq \overline{\eta}$.

The coincidences of the values of $\overline{\eta}$ determined by $\Delta_{1,2} a(\eta)$ and the equality of $\Delta_{1,2} a(\overline{\eta})$ are nontrivial. They are due to identities among the flow integrals. An illustrative example is

$$m^2 \int \mathrm{d}^4x\, \mathrm{d}^4y\; x^2 \langle \varphi^2(x)\, \varphi^2(y)\, \varphi^2(0) \rangle = 2 \int \mathrm{d}^4x\; x^2 \langle \varphi^2(x)\, \varphi^2(0) \rangle,$$

which is relevant for the calculation of $\Delta_1 a(\eta)$. This identity can be verified directly or seen as a consequence of dimensional counting (each integral has the form const/m^2), combined with the property that an insertion of $\int \mathrm{d}^4x\, m^2 \varphi^2(x)$ is equivalent to the derivative $-m\partial/\partial m$. A similar cancellation takes place in $\Delta_2 a(\eta)$. The variational principle (2.5) ''knows'' about such relations.

Let us now study $\Delta a'$. The explicit calculation shows that a coefficient is infinite. Precisely,

$$\Delta a'(\eta) = -\tfrac{3}{40} + \tfrac{1}{2}\eta + (1 - 6\eta)^2 \infty.$$

In the Δa-sum rule (2.2), the infinite term is compensated by a contribution coming from the flow integral of $\langle \widetilde{\delta}\widetilde{\Theta}/\widetilde{\delta}\phi\, \Theta \rangle$ and the sum is finite for each value of η. An analogous compensation occurs in (2.3). Observe that (2.5), applied to $\Delta a'$, still fixes $\overline{\eta}$ to $\frac{1}{6}$, so that, correctly, $\Delta a'(\overline{\eta}) = \frac{1}{120}$.[5,4]

The quantity $\Delta a'$ is much less restricted than Δa. For example, it can depend on the flow connecting the two fixed points.[4] Still, it is a physically meaningful quantity and characterizes the flow. The infinity of $\Delta a'(\eta)$ is not a ''divergence'' to be removed. The correct value of $\Delta a'$ must be finite. In the theory at hand (but also in the φ^4-theory and other models discussed below), finiteness of $\Delta a'$ fixes $\overline{\eta}$. We have a check that the $\overline{\eta}$'s fixed with shortcut (iii) and any of the (2.5) coincide.

B. Flow invariance

Examples of flows interpolating between the same fixed points are easy to construct. As an illustration, take non-Abelian Yang–Mills theory with group $G = \mathrm{SU}(N_c)$, N_f massless quarks and M_f massive quarks in the fundamental representation. In the large N_c limit, with $N_f/N_c \lesssim \frac{11}{2}$ fixed, the theory is UV-free and has an interacting IR fixed point. Indeed, at low energies, the massive fermions decouple and the beta function

$$\beta = -\frac{1}{6\pi}(11N_c - 2N_f)\,\alpha^2 + \frac{25}{(4\pi)^2} N_c^2\, \alpha^3 + \mathcal{O}(\alpha^4)$$

has a second zero. The higher-loop terms can be neglected in the given large-N_c limit.

The UV and IR fixed points do not depend on the values of the masses of the M_f massive quarks. For each set of values of the masses we have a different flow interpolating between the same conformal field theories.

At the computational level, it is not easy to study the sum rules (2.2) and (2.3) in this model. A treatable perturbative expansion of the flow integrals of (2.2) and (2.3) has still to be developed. Gaussian higher-derivative theories, on the other hand, provide an interesting laboratory of flows interpolating between the same fixed points. Calculations are still lengthy, but doable.

C. Higher-derivative scalar field

The Lagrangian of the theory is

$$\mathcal{L}=\tfrac{1}{2}[(\Box\varphi)^2+\beta m^2(\partial_\mu\varphi)^2+m^4\varphi^2]. \tag{3.3}$$

The embedding in external gravity gives

$$\mathcal{L}=\tfrac{1}{2}\sqrt{g}(\varphi\Delta_4\varphi+\beta m^2(\partial_\mu\varphi)(\partial_\nu\varphi)g^{\mu\nu}+\eta R m^2\varphi^2+m^4\varphi^2), \tag{3.4}$$

where the differential operator

$$\Delta_4=\nabla^2\nabla^2+2\nabla_\mu[R^{\mu\nu}-\tfrac{1}{3}g^{\mu\nu}R]\nabla_\nu \tag{3.5}$$

is such that $\sqrt{g}\Delta_4$ is conformally invariant (see, for example, Ref. 6).

I do not consider nonminimal couplings of the form $R^2\varphi^2$. Their coefficients can be set to zero imposing $\Theta=0$ at criticality, as in the previous example. The nonminimal coupling $m^2R\varphi^2$, instead, disappears both in the UV limit ($m\to0$) and IR limit ($m\to\infty$ and $\varphi\to0$, keeping the mass term $m^4\varphi^2$ bounded).

I perform two calculations, with (2.2) and (2.3). The relevant operator is

$$\overline{\Theta}=-\frac{\delta S}{\delta\phi}=-\beta m^2(\partial_\mu\varphi)^2\mathrm{e}^{2\phi}-2m^4\varphi^2\mathrm{e}^{4\phi}+3\eta m^2[\mathrm{e}^{\phi}\Box(\varphi^2\mathrm{e}^{\phi})+\mathrm{e}^{\phi}\varphi^2\Box\mathrm{e}^{\phi}].$$

Tilded quantities are equal to untilded quantities in this model, since the canonical weight of the higher-derivative scalar field is zero.

Cubic and quartic terms in η do not contribute to (2.2) and (2.3). The improvement term (in $\widetilde{\Theta}$ and its ϕ-derivatives) carries a $\Box$. Using integrations by parts, the boxes can be moved and act on the degree-4 polynomials x^2y^2 or $(x\cdot y)(x\cdot z)$. Three boxes kill the polynomials and therefore the integral. This observation implies that the condition (2.5) always has a unique solution.

The sum rules (2.2) and (2.3) give

$$\Delta_1a(\eta)=\Delta_2a(\eta)=-\tfrac{7}{90}=\Delta a,$$

independently of η. I recall that in this model, $a_{\mathrm{UV}}=-7/90$ (Ref. 7) and $a_{\mathrm{IR}}=0$.

The calculations, lengthy and cumbersome, have been done with Mathematica. I do not report here intermediate results, because they do not seem to be particularly instructive.

The flow invariance of $\Delta_ia(\eta)$ and the cancellation of the $\mathcal{O}(\eta)$-terms and $\mathcal{O}(\eta^2)$-terms in (2.2) and (2.3) are consequences of nontrivial identities among flow integrals. Each term of (2.2) and (2.3) separately violates these properties. As for the quantity $\Delta a'$, we have

$$\Delta a'(\eta)=\frac{1+17r^2-17r^4-r^6+10(1+r^2+r^4+r^6)\ln r}{40(r^2-1)^3}+\eta U(r)+\eta^2V(r),$$

$$U(r)=-3r\frac{1-r^4+2(1+r^4)\ln r}{2(r^2-1)^3},\quad V(r)=9r^2\frac{1-r^2+(1+r^2)\ln r}{(r^2-1)^3},$$

where r is defined by $\beta=r+1/r$. r is the unique dimensionless parameter of the theory, besides the improvement coefficient η. Since $\Delta a'(\eta)$ is finite for every η, none of the shortcuts of the previous section applies. All values of η are in principle acceptable, but the value of η which minimizes $\Delta a'(\eta)$ is privileged, in the sense that it has various interesting properties, outlined in Ref. 4. We have

$$\overline{\eta}(r)=-\frac{U(r)}{2V(r)}=\frac{1-r^4+2(1+r^4)\ln r}{12r(1-r^2+(1+r^2)\ln r)}$$

and[4]

$$\Delta a'(\overline{\eta})=-\frac{(r^2-1)^2(3r^4-26r^2+3)+(r^8+18r^6-18r^2-1)\ln r^2-10r^2(r^4+1)\ln^2 r^2}{40(r^2-1)^3(r^2\ln r^2+\ln r^2-2r^2+2)}.$$

The value $\Delta a'(\overline{\eta})$ depends on r, which means that it not a flow invariant. Its minimum coincides with $\Delta c=-1/15$.[4]

In conclusion, the "good" stress tensor of the theory (3.3) is

$$\begin{aligned}T_{\mu\nu}=&-\partial_\nu\Box\varphi\,\partial_\mu\varphi-\partial_\mu\Box\varphi\,\partial_\nu\varphi+2\Box\varphi\,\partial_\mu\partial_\nu\varphi+\frac{2}{3}\partial_\mu\partial_\nu\partial_\alpha\varphi\,\partial_\alpha\varphi-\frac{4}{3}\partial_\mu\partial_\alpha\varphi\,\partial_\nu\partial_\alpha\varphi\\&+\delta_{\mu\nu}\left[\frac{1}{3}\partial_\alpha\Box\varphi\,\partial_\alpha\varphi+\frac{1}{3}(\partial_\alpha\partial_\beta\varphi)^2-\frac{1}{2}(\Box\varphi)^2-\frac{m^4}{2}\varphi^2\right]+\beta m^2\left(\partial_\mu\varphi\,\partial_\nu\varphi-\frac{\delta_{\mu\nu}}{2}(\partial_\alpha\varphi)^2\right)\\&-\overline{\eta}(r)m^2(\partial_\mu\partial_\nu-\Box\delta_{\mu\nu})\varphi^2,\end{aligned}$$

and does not contain more parameters than the flat-space action (3.3).

D. The φ^4-theory

The renormalization mixing between the stress tensor and its improvement term in the φ^4-theory has been studied in detail by Brown and Collins[1] and Hathrell.[2] In the formulas below, the dimensional regularization technique and the minimal subtraction scheme are understood.

The parameter η satisfies the inhomogeneous RG equation[2]

$$\mu\frac{\mathrm{d}\eta}{\mathrm{d}\mu}-\delta(\lambda)\,\eta=\beta_\eta(\lambda)\equiv-\delta(\lambda)d(\lambda). \tag{3.6}$$

Here $\delta(\lambda)$ is the anomalous dimension of the composite operator φ^2, while $d(\lambda)$ is determined by the simple pole in the φ^4-$\Box\varphi^2$ renormalization mixing. Precisely,

$$\frac{\mu^{4-n}[\varphi^4]}{4!}=\frac{(n-4)}{\hat{\beta}}\left\{\frac{\lambda_0\varphi_0^4}{4!}-\frac{\gamma}{n-4}[\mathrm{E}]-\frac{d+L_d}{n-4}\Box[\varphi^2]\right\},$$

where n is the space–time dimension, $[\mathrm{E}]$ is the φ-field equation, γ is the φ-anomalous dimension, $\hat{\beta}=(n-4)\lambda+\beta(\lambda)$, $\beta(\lambda)$ is the beta function, and L_d denotes the poles higher that the simple one. The subscript 0 denotes bare quantities, and the square brackets denote renormalized operators. The trace of the stress tensor reads in four dimensions

$$\widetilde{\Theta}=-\beta\frac{[\varphi^4]}{4!}-\gamma[\mathrm{E}]+(\eta-d)\Box[\varphi^2].$$

The equation (3.6) can be decomposed in the following way:

$$\eta=\widetilde{\eta}(\lambda)+\eta' v(\lambda),$$

where η' is finite ($\mu\mathrm{d}\eta'/\mathrm{d}\mu=0$), $\widetilde{\eta}$ is a particular solution of (3.6), fixed conventionally so that $\widetilde{\eta}(0)=0$, and v satisfies the homogeneous equation:

$$v(\lambda)=\exp\left(\int^\lambda\frac{\delta(\lambda')}{\beta(\lambda')}\mathrm{d}\lambda'\right). \tag{3.7}$$

It is not necessary to specify the second extremum of integration, which can be absorbed in the factor η'. The function $v(\lambda)$ is related to the renormalization constant of the operator φ^2.

The surviving finite constant η' parametrizes the stress-tensor ambiguity, which reads

$$T_{\mu\nu}(\eta') = T_{\mu\nu}(0) - \tfrac{1}{3}\eta' v(\lambda)(\partial_\mu\partial_\nu - \delta_{\mu\nu}\Box)[\varphi^2]. \tag{3.8}$$

It follows immediately from (3.7) that if $T_{\mu\nu}(0)$ is finite ($\mu\, dT_{\mu\nu}(0)/d\mu = 0$), then $T_{\mu\nu}(\eta')$ is also finite.

In Ref. 1 it was observed that η' can be consistently set to zero. In Ref. 2 it was remarked that η' should be fixed "by experiment," since it is the coefficient of the nonminimal coupling to external gravity. Here we want to see if there is a reason why η' should be set *a priori* to a particular value.

There is strong evidence that the φ^4-theory is nonperturbatively trivial. Even if we cannot view this theory as an RG interpolation between a UV and a IR fixed point, we can make a couple of general observations, which apply also to more general cases studied below.

To the lowest order, we have[2]

$$\delta(\lambda) = \frac{\lambda}{(4\pi)^2} + \mathcal{O}(\lambda^2), \quad \beta(\lambda) = 3\frac{\lambda^2}{(4\pi)^2} + \mathcal{O}(\lambda^3), \quad \beta_\eta(\lambda) = -\frac{1}{36}\frac{\lambda^4}{(4\pi)^8},$$

so that

$$\eta = -\frac{1}{288}\frac{\lambda^3}{(4\pi)^6} + \mathcal{O}(\lambda^4) + \eta'\lambda^{1/3}(1 + \mathcal{O}(\lambda)).$$

Let us consider the flow integral (2.4), which defines $\Delta a'(\eta)$. In the absence of information about the UV, we can study the convergence of this integral around the IR limit. Using the perturbative values given above and the Callan–Symanzik equations for the pair of operators $(\varphi^4, \Box\varphi^2)$, the behavior of the integral around the IR is

$$\Delta a'(\eta) \sim \int^\infty dt \left(\frac{a_1}{t^4} + \eta' \frac{a_2}{t^{10/3}} + \eta'^2 \frac{a_3}{t^{2/3}} \right),$$

where the a_i are numerical factors. We see that the $\mathcal{O}(\eta'^2)$-contribution diverges in the IR extremum of integration. Since the integrand is non-negative, this divergence cannot be cured by contributions from intermediate energies or by a hypothetical second fixed point (which exists in the models studied below, to which similar considerations apply). Therefore, the only value compatible with a finite $\Delta a'$ is $\eta' = 0$.

This case is different from the case of a free-massive scalar field. Here the improvement term of (3.8) does disappear at criticality [at a velocity $\lambda(t)^{1/3}$, where $\lambda(t) \sim 1/t$, $t = \ln|x|\mu$], but it does not disappear sufficiently quickly for the sum rule to converge. This forces η' to be zero, by shortcut (iii).

The φ^4-interaction can be nontrivial in several models, which may admit conformal windows. In particular, interesting cases are the supersymmetric models, with or without superpotential. Supersymmetry is not necessary to the logic of the arguments below, but it simplifies the examples.

E. $N=1$ supersymmetric QCD

I consider now $N=1$ supersymmetric QCD with gauge group $G = \mathrm{SU}(N_c)$ and N_f quark and antiquark superfields in the fundamental representation. The theory has no superpotential and a unique coupling constant g. For $N_f < 3N_c$ the theory is asymptotically free. The mass operator $\bar{\varphi}\varphi$, which is essential for the improvement term, is the lowest component of the Konishi

superfield.[8] Since the axial currents have no anomalous dimension at the one-loop order (see the appendix), this is true also of $\overline{\varphi}\varphi$. The two-loop contribution to the anomalous dimension δ can be found in Ref. 9:

$$\delta(g)=4(N_c^2-1)N_f\left(\frac{g^2}{16\pi^2}\right)^2+\mathcal{O}(g^6).$$

The structure of the RG equation for η and the η'-ambiguity of the stress tensor are the same as in (3.6) and (3.8). In particular, the function v is given by the analog of (3.7). The one-loop beta function is $\beta=-g^3(3N_c-N_f)/(16\pi^2)+\mathcal{O}(g^5)$, so that the function

$$v(g)=\exp\left(-\frac{g^2}{8\pi^2}\frac{N_f(N_c^2-1)}{(3N_c-N_f)}+\mathcal{O}(g^4)\right) \tag{3.9}$$

tends to unity at $g\to 0$. Instead, $\beta_\eta(g)$ goes to zero at least as fast as g^8. We conclude that $\eta\to\eta'$ in the UV limit, so that the improvement term of (3.8) survives at criticality. As in the case of the free massive scalar field, this forces η' to be set to zero, by shortcut (i).

F. Supersymmetric theories with a superpotential

The superpotential gives a one-loop contribution to the anomalous dimension of the Konishi operator. An example of UV-free supersymmetric theory with superpotential and a well-defined IR fixed point is the theory obtained adding mesonic fields M_i^j to the $N=1$ supersymmetric QCD. The meson superfields interact with the quarks q_i and $\overline{q}^j$ by means of a superpotential $fM_j^i q_i\overline{q}^j$.[10,11] In complete generality, denoting the superpotential couplings by Y_{ijk}, the one-loop anomalous dimension of the mass operator $\overline{\varphi}\varphi$ is

$$\delta(Y)=\frac{3}{16\pi^2}|Y|^2, \tag{3.10}$$

$|Y|$ being defined by $Y_{ijk}Y^{ijl}=|Y|^2\delta_k^l$. Solving the RG equations around the UV fixed point[10] and applying (3.7), we have

$$v\sim|t|^c, \tag{3.11}$$

for $t\to-\infty$, with c positive numerical constant. The situation is even worse than in the previous model, where the superpotential was absent: the improvement term of the stress tensor diverges in the free-field limit. This forces us again to set $\eta'=0$, by shortcut (ii).

G. Asymptotically free theories and flows with interacting UV fixed points

The arguments of the previous two cases apply to the most general asymptotically free theory with scalar fields, supersymmetric or not. The anomalous dimension of the improvement term can have a vanishing one-loop contribution or a nonvanishing one-loop contribution. In either case, its first radiative correction is positive. On the other hand, the first term of the beta function is negative. Then, $v(t)$ behaves as in (3.9) or (3.11). In the free-field limit, the improvement term of the stress tensor is finite and nonvanishing or divergent. This fixes η'.

The same can be said of flows with interacting UV fixed points, where $\delta_{\rm UV}$ can be nonvanishing. We can conclude, in full generality, that in unitary models the UV behavior of $T_{\mu\nu}(\eta')$ is unacceptable, unless the η'-term of (3.8) is suitably fixed, according to the rules of Sec. II.

IV. CONCLUSIONS

A proper RG interpolation between the UV and IR fixed points removes the improvement ambiguity of the stress tensor. The general criterion for this removal is encoded in the variational principle (2.5). In various cases suitable shortcuts can be more efficient. I have analyzed concrete

examples, one for each relevant situation. In particular, in asymptotically free theories, the RG equations imply that the improvement term survives at one critical point or diverges there, unless the improvement parameter is suitably fixed. In IR free theories, the improvement term does disappear at criticality, but not sufficiently quickly. The behavior of Gaussian higher-derivative theories shows that there are cases in which all improved stress tensors are in principle acceptable. Nevertheless, the criterion (2.5) outlines a privileged stress tensor also in this case. In conclusion, we can always consistently remove the improvement ambiguity with the rules of Sec. II.

APPENDIX: OTHER REMARKS ABOUT THE CRITICAL LIMITS OF CORRELATORS

In this appendix I consider other ambiguities in the critical limits of correlators. Let us assume that two observers study the same model using different renormalization schemes. We want to know what amount of information the observers can objectively compare and how many quantities they need to normalize before the comparison. I consider correlators of composite operators and distinguish the cases of finite and nonfinite operators.

Let $\mathcal{O}$ be a multiplicatively renormalized operator. The Callan–Symanzik equations imply that the two-point function can be written in the form

$$\langle \mathcal{O}(x)\,\mathcal{O}(0)\rangle = \frac{1}{|x|^{2d}} Z^2(\alpha(1/|x|),\alpha(\mu))G(\alpha(1/|x|)), \tag{A1}$$

where d is the canonical dimension of $\mathcal{O}$, Z is the renormalization constant and $\alpha(\lambda)$ is the running coupling constant at the energy scale λ. Now, in the UV (respectively, IR) limit, namely $|x|\to 0$ ($|x|\to\infty$), $\alpha(1/|x|)$ tends to the critical value $\alpha_{\mathrm{UV\,(IR)}}$. If $\mathcal{O}$ is not finite (i.e., $Z\neq 1$), then the limit depends on $\alpha(\mu)$ and the subtraction scheme. The values $\alpha_{\mathrm{UV\,(IR)}}$ are themselves scheme dependent.

Among the finite operators, we distinguish conserved currents, anomalous (classically conserved) currents and others. Suppressing the space–time indices, if $\mathcal{O}$ is a conserved current, the UV and IR limits of (A1) have the structure

$$\langle \mathcal{O}(x)\,\mathcal{O}(0)\rangle_{\mathrm{UV\,(IR)}} \sim \frac{G(\alpha_{\mathrm{UV\,(IR)}})}{(x^2)^d}. \tag{A2}$$

The quantities $G(\alpha_{\mathrm{UV\,(IR)}})$ (called primary central charges[12]) carry information about the conformal fixed points. The scheme dependence of $\alpha_{\mathrm{UV\,(IR)}}$ is compensated by an equal and opposite scheme dependence of G, so that $G(\alpha_{\mathrm{UV\,(IR)}})$ is scheme independent. Similar considerations extend to correlators with more insertions. When the two observers compare their results, they have to find the same answer.

Classically conserved anomalous currents can be finite. In an asymptotically free theory, for example, the renormalization constant Z_5 of the axial current J_5^μ resums nonperturbatively to a finite function $C(\alpha)$. Finiteness can be formally recovered multiplying J_5^μ by $C^{-1}(\alpha)$. Then, in (A1) the renormalization constant can be nonperturbatively replaced by unity. Scalar operators can be finite as well. An example is the topological-charge density. Details are given below. The function $G(\alpha(1/|x|))$ tends to a constant in the free-field limit and behaves like a power of $x^2\mu^2$ around the interacting critical limit. Formula (A2) is upgraded to the more general expression

$$\langle \mathcal{O}(x)\,\mathcal{O}(0)\rangle_{\mathrm{UV\,(IR)}} \sim \frac{G_{\mathrm{UV\,(IR)}}}{(x^2)^d(x^2\mu^2)^{h_{\mathrm{UV\,(IR)}}}}. \tag{A3}$$

Here the critical limits are unambiguous once the scale μ is normalized (μ plays the role of the RG invariant scale, e.g., $\Lambda_{\rm QCD}$). Two observers can compare their results, once they agree on the definition of the reference scale. It is possible to define "secondary" central charges,[12] where the μ-normalization is simplified away.

Finally, the critical limits of correlators containing insertions of nonfinite operators provide one piece of information less,[12] since a nonfinite operator needs to be normalized at some reference energy. In (A1) this is emphasized by the $\alpha(\mu)$-dependence surviving in the limits $|x|\to 0$ and $|x|\to\infty$.

These observations apply to operators whose correlators have power-behaved critical limits. Logarithmic behaviors are not infrequent, however. The improvement term of the stress tensor often exhibits a logarithmic behavior: check the $\overline{\varphi}\varphi$-two-point function in (a) the φ^4-theory around the IR and (b) supersymmetric theories with superpotential around the UV [see (3.11)].

1. Anomalous currents

Anomalous currents can be finite operators, and therefore have unambiguous critical limits, of the form (A3). This paragraph extends a discussion of Collins[13] to singlet currents and the topological-charge density.

I consider the axial current in an asymptotically free gauge theory. I assume that the current is conserved at the classical level. The inclusion of mass terms is straightforward. The anomaly equation

$$\partial_\mu J_5^\mu - \frac{g^2 N_f}{16\pi^2} F\widetilde{F} = \overline{\psi}\gamma_5 \frac{\delta_l S}{\delta\overline{\psi}} + \frac{\delta_r S}{\delta\psi}\gamma_5\psi = \text{finite} \tag{A4}$$

and the definition $[J_5^\mu] = Z_5 J_5^\mu$ imply the relations

$$[\partial_\mu J_5^\mu] = Z_5 \partial_\mu J_5^\mu, \quad \frac{g^2 N_f}{16\pi^2}[F\widetilde{F}] = (Z_5 - 1)\partial_\mu J_5^\mu + \frac{g_0^2 N_f}{16\pi^2} F\widetilde{F}.$$

Calling $\mathcal{O}_1 = \partial_\mu J_5^\mu$ and $\mathcal{O}_2 = g^2 F\widetilde{F}/(16\pi^2)$, we have

$$[\mathcal{O}_i] = Z_{ij}\mathcal{O}_j, \quad Z_{ij} = \begin{pmatrix} Z_5 & 0 \\ Z_5 - 1 & 1 \end{pmatrix}.$$

Consider the two-point function $\langle [J_5]^\mu(x)\,[J_5]^\nu(0)\rangle$. At the one-loop order it has a conformal-invariant form, namely,

$$\langle [J_5^\mu](x)\,[J_5^\nu](0)\rangle = A(g^2)\,\frac{\delta^{\mu\nu} - 2x^\mu x^\nu/x^2}{(x^2)^{3+\delta_5(g^2)}} + \mathcal{O}(g^4). \tag{A5}$$

The one-loop conformal invariance is assured by the Callan–Symanzik equations. Indeed, the conformal-violating term in

$$\mu\frac{\partial}{\partial\mu} + \beta(g)\frac{\partial}{\partial g} + 2\,\delta_5(g^2)$$

is $\beta\,\partial/\partial g$. Since $\beta = \mathcal{O}(g^3)$, this term is irrelevant at the one-loop order.

Taking two divergences of (A5), using the anomaly equation (A4) and excluding the coincident point, we get

$$\langle [\partial_\mu J_5^\mu](x)\ [\partial_\nu J_5^\nu](0)\rangle = \frac{g^4 N_f^2}{(4\pi)^4}\langle [F\widetilde{F}](x)\ [F\widetilde{F}](0)\rangle = -4A(g^2)\,\frac{\delta_5(g^2)(2+\delta_5(g^2))}{(x^2)^{4+\delta_5(g^2)}}.$$

Since $A(g^2)=\mathcal{O}(1)$, we conclude $\delta_5(g^2)=\mathcal{O}(g^4)$. This result is unaffected by the presence of masses or other super-renormalizable parameters, but does not hold when the conservation of J_5^μ is violated at the classical level by marginal operators, such as in supersymmetric theories with a superpotential: see (3.10).

Now, we observe that the renormalization constant Z_5 has a finite limit when the cut-off is sent to infinity. We can see this using the dimensional-regularization technique, but it is more explicit to write the limit in the familiar cut-off notation. Precisely,

$$\lim_{\Lambda\to\infty} Z_5(g(\Lambda),g(\mu))=\lim_{\Lambda\to\infty}\exp\left(-\int_{g(\mu)}^{g(\Lambda)}\frac{\delta_5(g')}{\beta(g')}\,dg'\right)=C(g^2)=\text{finite}.$$

This property holds because in an asymptotically free theory, $g(\Lambda)$ tends to zero when $\Lambda\to\infty$. The integral is convergent around zero, because $\delta_5(g^2)=\mathcal{O}(g^4)$ and $\beta(g)=\mathcal{O}(g^3)$.

The full matrix Z_{ij} has a finite limit $C_{ij}(g^2)$. Using the Callan–Symanzik equations, we conclude that the operators $J_5^{\mu R}\equiv C^{-1}(g^2)[J_5^\mu]$ and $\mathcal{O}_i^R\equiv C_{ij}^{-1}(g^2)[\mathcal{O}_j]$ have two-point functions of the form

$$\langle J_5^{\mu R}(x)\,J_5^{\nu R}(0)\rangle=\frac{A(g^2(1/|x|))\,\delta_{\mu\nu}+B(g^2(1/|x|))\,x^\mu x^\nu/x^2}{(x^2)^3},\quad \langle\mathcal{O}_i^R(x)\,\mathcal{O}_j^R(0)\rangle=\frac{A_{ij}(g^2(t))}{(x^2)^4},$$

and admit unambiguous critical limits, as in (A3).

(Received 1 August 2001; accepted for publication 11 February 2002)

The algebra of conserved observables of the SO(4,1) gauge-invariant theory of the Dirac fermions in the external field of the Kaluza–Klein monopole is investigated. It is shown that the Dirac conserved operators have physical parts associated with Pauli operators that are also conserved in the sense of the Klein–Gordon theory. In this way one gets simpler methods of analyzing the properties of the conserved Dirac operators and their main algebraic structures including the representations of dynamical algebras governing the Dirac quantum modes. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1469669]

I. INTRODUCTION

The relativistic quantum mechanics, seen as the one-particle restriction of the Lagrangian quantum field theory on curved space–times, give rise to interesting mathematical problems concerning the properties of the physical observables. It is known that one of the largest algebras of conserved operators is produced by the Euclidean Taub-NUT geometry since, beside usual isometries, this has a hidden symmetry of the Kepler type.[1,2] This is related to the existence of Stäckel–Killing tensors connected with the components of an analog to the Runge–Lenz vector of the Kepler-type problem which, in addition, can be expressed in terms of four Killing–Yano tensors.[2–4]

The theory of the Dirac equation in the Kaluza–Klein monopole field was studied in the mid-1980s.[5] An attempt to take into account the Runge–Lenz vector of this problem was done in Ref. 6. We have continued this study showing that the Dirac equation is analytically solvable[7] and determining the energy eigenspinors of the central modes. Moreover, we derived all the conserved observables of this theory, including those associated with the hidden symmetries of the Taub-NUT geometry. Thus we obtained the Runge–Lenz vector-operator of the Dirac theory, pointing out its specific properties.[8] The consequences of the existence of this operator were studied in Ref. 9 showing that the dynamical algebras of the Dirac theory corresponding to different spectral domains are the same as in the scalar case[2] but involving other irreducible representations. Thus for the discrete energy spectra we obtained two irreducible representations of the $o(4)$ algebra describing distinguish quantum modes for each energy level.[9]

This new phenomenon encourages us to continue the mathematical study of the whole algebra of conserved observables of the Dirac theory in Taub-NUT background. In our opinion, the operators related to the manifest or hidden symmetries of the Taub-NUT geometry are of a special interest since they reflect the effects of the geometry on the behavior of different quantum systems, with integer or half-integer spin. However, in the Dirac case there are several complicated operators whose manipulation can be sometime extremely difficult. We hope that a general study of their action on the Dirac spinors could lead to simpler calculation methods.

[b)]Electronic mail: mvisin@theor1.theory.nipne.ro

The present article is devoted to this problem. Our goal is to separate the active parts of the conserved Dirac operators, called here physical parts, which determine the effects on the Dirac energy eigenspinors. Obviously these are projections obtained with the help of the projection operator on the whole space of physical spinors. We show that these are of a specific diagonal (even) or off-diagonal (odd) form depending on Pauli operators that are also conserved in the sense of the Klein–Gordon theory. In this way we derive simpler calculation rules and identify associations among conserved Dirac and Pauli operators as those currently used in theories involving monopoles[10–12] or new others we write down here.

We start in the second section with a brief review of some previous results[7–9] we need. In the next section we study the algebra of the conserved Dirac operators and introduce a new type of even operators which help us to define the projection operator that separates the physical parts. Furthermore, we point out that the diagonal (even) physical parts of the Dirac observables can be associated with well-defined conserved Pauli operators obeying the same algebraic relations. In Sec. IV we discuss the physical parts of the main conserved Dirac operators[7–9] and we identify their associated Pauli conserved operators. Here, after presenting the simplest conserved Pauli operators, we derive those corresponding to isometries or hidden symmetries including the generators of the dynamical algebras. In this way we show that the results of Ref. 9 hold also in the case of continuous energy spectra, for $so(3,1)$ or $e(3)$ dynamical algebras. The conclusions and comments are presented in the last section and in a short Appendix some formulas involving an important Pauli operator studied in Refs. 11 and 12 are given.

We work in natural units with $\hbar = c = 1$.

II. PRELIMINARIES

The background of the gauge-invariant five-dimensional theory of the Dirac fermions in the external field of the Kaluza–Klein monopole[13] is the Taub-NUT space with the time coordinate trivially added. It is convenient to consider the static chart of Cartesian coordinates x^μ, $(\mu,\nu,\ldots=0,1,2,3,5)$, with the line element

$$ds^2 = g_{\mu\nu}dx^\mu dx^\nu = dt^2 - \frac{1}{V}dl^2 - V(dx^5 + A_i dx^i)^2, \tag{1}$$

where $dl^2 = (d\vec{x})^2 = (dx^1)^2 + (dx^2)^2 + (dx^3)^2$ is the usual Euclidean three-dimensional line element in Cartesian physical space coordinates x^i $(i,j,\ldots=1,2,3)$. The other coordinates are the time, $x^0 = t$, and the Cartesian Kaluza–Klein extra-coordinate, x^5. In (1) the function $1/V(r) = 1 + \mu/r$ depends on $r = |\vec{x}|$ and the real parameter μ while A_i are the potentials of the Dirac monopole.

This background has the isometry group $G_s = \mathrm{SO}(3) \otimes \mathrm{U}(1)_5 \otimes T_t(1)$ formed by the rotations of the Cartesian space coordinates and x^5 and t translations. The $\mathrm{U}(1)_5$ symmetry is important since this eliminates the so called NUT singularity if x^5 has the period $4\pi\mu$. The Killing vectors $k_{(i)}$ $(i=1,2,3)$ and $k_{(5)}$ are directly connected with the conserved operators which appear in the scalar case. They can be expressed in terms of momentum operators $P_i = -i(\partial_i - A_i\partial_5)$ and $P_5 = -i\partial_5$.[2] The last one, for negative mass models, can be interpreted as the "relative electric charge" and it is always conserved. Moreover, the Taub-NUT geometry possesses four Killing–Yano tensors, $f^{(i)}_{\mu\nu}$ $(i=1,2,3)$ and $f^{Y}_{\mu\nu}$, of valence 2, related to the hidden symmetries of the Taub-NUT geometry reflected by the existence of the nontrivial Stäckel–Killing tensors $k^{\mu\nu}_{(i)}$.[2,4,7,14]

In this Kaluza–Klein geometry there is a pentad gauge fixing[15] where the massless Dirac field, ψ, satisfies a simple gauge-covariant Dirac equation, $\not{D}\psi = 0$, where $\not{D} = i\gamma^0\partial_t - \not{D}_s$.[16,5,7,9] In the standard representation of the Dirac matrices [with diagonal γ^0 (Ref. 17)] the Hamiltonian operator[7,9]

$$H = \gamma^0 \not{D}_s = \begin{pmatrix} 0 & \alpha^* \\ \alpha & 0 \end{pmatrix} \tag{2}$$

has manifest supersymmetry. It is expressed in terms of Pauli operators,

$$\alpha=\sqrt{V}\pi=\sqrt{V}\left(\sigma_P-\frac{iP_5}{V}\right), \tag{3}$$

$$\alpha^*=V\pi^*\frac{1}{\sqrt{V}}=V\left(\sigma_P+\frac{iP_5}{V}\right)\frac{1}{\sqrt{V}}, \tag{4}$$

where $\sigma_P=\vec{\sigma}\cdot\vec{P}$ involves the Pauli matrices, σ_i. These operators give the space part of the Klein–Gordon operator as[7,9]

$$\Delta=\alpha^*\alpha=V\pi^*\pi=V\vec{P}^2+\frac{1}{V}P_5^2. \tag{5}$$

We specify that the star superscript is a mere notation that does not represent the Hermitian conjugation because here we use a nonunitary representation of the algebra of Dirac operators. Of course, this is equivalent with the unitary representation where all of these operators are self-adjoint.[7]

Since P_5 commutes with all the other conserved observables, we settle its eigenvalue, $\hat{q}$, such that $q\equiv-\mu\hat{q}=0,\pm1/2,\pm1,\ldots$.[1,2] We denote by $\mathfrak{G}$ the space of usual and generalized energy eigenspinors of the form $U_E=(u_E,E^{-1}\alpha u_E)^T$ which solve the eigenvalue problem $HU_E=EU_E$.[7] In Refs. 7 and 9 we showed that u_E is a solution of the static Klein–Gordon equation, $\Delta u_E=E^2u_E$, that may be square integrable with respect to the specific relativistic scalar product of the Dirac theory[7] or behave as tempered distributions. The Klein–Gordon equation is analytically solvable producing continuous energy spectra, $E\geqslant|\hat{q}|$, for any real μ and discrete energy levels, E_n with $n>|q|>0$, only for $\mu<0$. These are included in the domain $(0,\hat{q})$ such that $\lim_{n\to\infty}E_n=|\hat{q}|$. Hence, there are no zero modes and the operator Δ can be considered invertible on the space of of the spinors u_E. Therefore, we can conclude that the Dirac equation produces the *same* energy spectra as the Klein–Gordon one. Moreover, since there are no zero modes the Hamiltonian operator (2) is also invertible. The meaning of this operation will be discussed in the next section.

III. THE ALGEBRA OF CONSERVED DIRAC OPERATORS

Our aim is to study here the form and the action of the *conserved* operators of the Dirac theory which, by definition, are the Dirac operators that *commute* with the Hamiltonian (2). We denote by **D** the algebra of these operators. We say that a Pauli operator $\hat{X}$ acting on the space of the two-component Pauli spinors u_E is *conserved* if it commutes with Δ. We denote by **P** the algebra of the conserved Pauli operators, including the conserved observables of the Klein–Gordon theory, called here *orbital* operators. In this section we denote systematically by capitals the operators of **D** and by hatted ones the operators of **P** without using special notations for the identity operators of these algebras.

In general, the Pauli blocks, $\hat{X}^{(ab)}$ $(a,b=1,2)$, of any conserved Dirac operator

$$X=\begin{pmatrix}\hat{X}^{(11)} & \hat{X}^{(12)}\\ \hat{X}^{(21)} & \hat{X}^{(22)}\end{pmatrix}\in\mathbf{D} \tag{6}$$

satisfy the conditions

$$\hat{X}^{(22)}\alpha=\alpha\hat{X}^{(11)},\quad \alpha^*\hat{X}^{(22)}=\hat{X}^{(11)}\alpha^*, \tag{7}$$

$$\hat{X}^{(12)}\alpha=\alpha^*\hat{X}^{(21)},\quad \alpha\hat{X}^{(12)}=\hat{X}^{(21)}\alpha^*, \tag{8}$$

which are equivalent with $[X,H]=0$. Hereby it results that

$$\hat{X}^{(21)}=\alpha\hat{X}^{(12)}\alpha\Delta^{-1} \tag{9}$$

and

$$[\hat{X}^{(11)},\Delta]=[\hat{X}^{(12)}\alpha,\Delta]=[\alpha^*\hat{X}^{(21)},\Delta]=0, \tag{10}$$

which means that $\hat{X}^{(11)}$, $\hat{X}^{(12)}\alpha$, $\alpha^*\hat{X}^{(21)}\in\mathbf{P}$.

We observe that possible solutions of Eqs. (7) and (8) are the diagonal operators

$$\mathcal{D}(\hat{X})=\begin{pmatrix}\hat{X} & 0\\ 0 & \alpha\hat{X}\Delta^{-1}\alpha^*\end{pmatrix}, \tag{11}$$

where $\hat{X}\in\mathbf{P}$. Particularly, for $\hat{X}=1$ we obtain the projection operator

$$I=\mathcal{D}(1)=\begin{pmatrix}1 & 0\\ 0 & \alpha\Delta^{-1}\alpha^*\end{pmatrix} \tag{12}$$

on the space $\mathfrak{G}$. This split the algebra $\mathbf{D}=\mathbf{D}_0\oplus\mathbf{D}_1$ in two subspaces of the projections $XI\in\mathbf{D}_0$ and $X(1-I)\in\mathbf{D}_1$ of all $X\in\mathbf{D}$. According to Eqs. (7) and (8) we find that the projections of two arbitrary operators $X,Y\in\mathbf{D}$ satisfy $(XI)(YI)=(XY)I$ and $[X(1-I)](YI)=0$ which lead to the conclusion that $\mathbf{D}_0$ is a subalgebra while $\mathbf{D}_1$ is even an ideal in $\mathbf{D}$. Obviously, I is the identity operator of $\mathbf{D}_0$. On the other hand, in Ref. 7 we introduced the $\mathcal{Q}$-operators defined as

$$\mathcal{Q}(\hat{X})=\left\{H,\begin{pmatrix}\hat{X} & 0\\ 0 & 0\end{pmatrix}\right\}=\begin{pmatrix}0 & \hat{X}\alpha^*\\ \alpha\hat{X} & 0\end{pmatrix}, \tag{13}$$

where $\hat{X}$ may be any Pauli operator. However, if $\hat{X}\in\mathbf{P}$, then $\mathcal{Q}(\hat{X})\in\mathbf{D}_0$ since $[\mathcal{Q}(\hat{X}),H]=0$ and $\mathcal{Q}(\hat{X})I=\mathcal{Q}(\hat{X})$. If $\hat{X}=1$, we obtain just the Hamiltonian operator $H=\mathcal{Q}(1)\in\mathbf{D}_0$. Consequently, the inverse of H with respect to I can be represented as $H^{-1}=\mathcal{Q}(\Delta^{-1})$. The mappings $\mathcal{D}:\mathbf{P}\rightarrow\mathbf{D}_0$ and $\mathcal{Q}:\mathbf{P}\rightarrow\mathbf{D}_0$ are linear and have the following algebraic properties,

$$\mathcal{D}(\hat{X})\mathcal{D}(\hat{Y})=\mathcal{D}(\hat{X}\hat{Y}), \tag{14}$$

$$\mathcal{Q}(\hat{X})\mathcal{Q}(\hat{Y})=\mathcal{D}(\hat{X}\hat{Y}\Delta), \tag{15}$$

$$\mathcal{D}(\hat{X})\mathcal{Q}(\hat{Y})=\mathcal{Q}(\hat{X})\mathcal{D}(\hat{Y})=\mathcal{Q}(\hat{X}\hat{Y}), \tag{16}$$

for any $\hat{X},\hat{Y}\in\mathbf{P}$. Moreover, the relations

$$[\gamma^0,\mathcal{D}(\hat{X})]=0,\quad \{\gamma^0,\mathcal{Q}(\hat{X})\}=0 \tag{17}$$

indicate that, according to the usual terminology,[17] $\mathcal{D}$ and $\gamma^0\mathcal{D}$ are *even* Dirac operators while $\mathcal{Q}$ and $\gamma^0\mathcal{Q}$ are *odd* ones. We note that there are many other odd or even operators which do not have such forms.

In general, since I is the projection operator on the space of the Dirac energy eigenspinors $\mathfrak{G}$, we say that the projection IXI of any Dirac operator X, conserved or not, represents the *physical part* of X. We can convince ourselves that if $X\in\mathbf{D}$, then

$$IXI\equiv XI=\mathcal{D}(\hat{X}^{(11)})+\mathcal{Q}(\hat{X}^{(12)}\alpha\Delta^{-1}), \tag{18}$$

which means that all the operators from $\mathbf{D}_0$ can be written as $\mathcal{D}$ or $\mathcal{Q}$-operators. Thus the action of X reduces to that of the Pauli operators involved in (18), allowing us to rewrite the problems of the Dirac theory in terms of Pauli operators.[8,9] Indeed, it is easy to show that the action of any operator $X\in\mathbf{D}$ on $U_E\in\mathfrak{G}$ is

$$XU_E=XIU_E=\begin{pmatrix}\hat{\mathcal{P}}_E(X)u_E\\ E^{-1}\alpha\hat{\mathcal{P}}_E(X)u_E\end{pmatrix}, \tag{19}$$

where, by definition,

$$\hat{\mathcal{P}}_E(X)=\hat{X}^{(11)}+E^{-1}\hat{X}^{(12)}\alpha \tag{20}$$

is the *conserved* Pauli operator *associated* to X. Since the mapping $\hat{\mathcal{P}}_E:\mathbf{D}\to\mathbf{P}$ is linear and satisfies $\hat{\mathcal{P}}_E(X)=\hat{\mathcal{P}}_E(XI)$ it results that $\mathrm{Ker}\hat{\mathcal{P}}_E=\mathbf{D}_1$. In other respects, Eqs. (7) and (8) lead to the important property

$$\hat{\mathcal{P}}_E(XY)=\hat{\mathcal{P}}_E(X)\hat{\mathcal{P}}_E(Y),\quad \forall X,Y\in\mathbf{D}, \tag{21}$$

which guarantees that $\hat{\mathcal{P}}_E$ preserves the algebraic relations, mapping any algebra or superalgebra of $\mathbf{D}_0$ into an *isomorphic* algebra or superalgebra of $\mathbf{P}$, with the same commutation and anticommutation rules.

IV. CONSERVED OBSERVABLES

In what follows we focus on the physical parts of the main Dirac conserved observables, pointing out the technical advantages of using $\mathcal{D}$ and $\mathcal{Q}$-operators that help us to identify the associated Pauli operators defined by (20). The even physical parts, $\mathcal{D}$, are associated to Pauli operators independent on E which are, therefore, well-defined physical observables. For this reason it is useful to briefly review the most important conserved Pauli operators and then turn to the physical parts of the Dirac ones.

A. Conserved orbital and Pauli operators

In general, the Pauli operators are 2×2 matrix differential operators acting on two-component Pauli spinors. There are many nonconserved operators which do not commute with Δ as, for example, $\alpha,\alpha^*,\pi,\pi^*,\sigma_r=\vec{\sigma}\cdot\vec{x}/r$ or the operator $\lambda=\vec{\sigma}\cdot(\vec{x}\times\vec{P})+1$ proposed in Ref. 11 and discussed in Ref. 12. Some algebraic properties of these operators are given in the Appendix.

By definition, the conserved operators of $\mathbf{P}$ commute with Δ, which is the static part of the Klein–Gordon operator. As mentioned, these can be the usual conserved orbital operators of the scalar fields or more complicated ones involving, in addition, the Pauli matrices which also commute with Δ.

The main conserved orbital operators are the basis generators of the natural representation of the group G_s carried by the space of scalar fields. These generators are defined up to the factor $-i$ as the Killing vector fields corresponding to isometries or the operators given by the Killing tensors associated to the hidden symmetries. The $U_5(1)$ generator is P_5 and the Killing vectors $k^\mu_{(i)}$ give the SO(3) generators which are the components L_i of the orbital angular momentum operator[7,9]

$$\vec{L}=\vec{x}\times\vec{P}-\mu\frac{\vec{x}}{r}P_5. \tag{22}$$

These commute with Δ and satisfy the canonical commutation relations among themselves and with the components of all the other vector operators (e.g. coordinates, momenta, etc.). On the other hand, the specific Killing tensors $k^{\mu\nu}_{(i)}$ of the Taub-NUT geometry allow one to define the Runge–Lenz operator for scalar particles[2]

$$\vec{K}=\frac{1}{2}(\vec{P}\times\vec{L}-\vec{L}\times\vec{P})-\frac{\mu}{2}\frac{\vec{x}}{r}\Delta+\mu\frac{\vec{x}}{r}P_5^2, \tag{23}$$

which commute with Δ and its components satisfy the commutation relations

$$[L_i,K_j]=i\varepsilon_{ijk}K_k, \quad [K_i,K_j]=i\varepsilon_{ijk}L_kF^2, \tag{24}$$

where $F^2=P_5^2-\Delta$. For given values of E and $\hat{q}$ this operator can be rescaled in order to recover the dynamical algebras corresponding to different spectral domains of the Kepler-type problems.[2] The new operators

$$R_i=\begin{cases} F^{-1}K_i & \text{for } \mu<0 \text{ and } E<|\hat{q}|, \\ K_i & \text{for any } \mu \text{ and } E=|\hat{q}|, \\ \pm iF^{-1}K_i & \text{for any } \mu \text{ and } E>|\hat{q}|, \end{cases} \tag{25}$$

and L_i $(i=1,2,3)$ generate either a representation of the $o(4)$ algebra for the discrete energy spectrum in the domain $0<E<|\hat{q}|$ or a representation of the $o(3,1)$ algebra for continuous spectrum in the domain $E>|\hat{q}|$. A special case is that of the dynamical algebra $e(3)$ which corresponds only to the ground energy of the continuous spectrum, $E=|\hat{q}|$.

The operators of **P** involving Pauli matrices can be vector operators as the total angular momentum,

$$\vec{J}=\vec{L}+\frac{\vec{\sigma}}{2}, \tag{26}$$

or scalar operators of the form $\sigma_L=\vec{\sigma}\cdot\vec{L}$, $\sigma_K=\vec{\sigma}\cdot\vec{K}$ or $\sigma_R=\vec{\sigma}\cdot\vec{R}$, involved in superalgebras as

$$\{\sigma_K,\sigma_L+1\}=0. \tag{27}$$

Other conserved Pauli operators with more complicated structure have to be derived in association with the physical parts of the conserved Dirac observables.

B. Associated Dirac and Pauli operators

We have seen that the physical parts of the conserved Dirac observables can have diagonal or off-diagonal terms; among them only the diagonal ones can be correctly associated to conserved Pauli operators independent on E. However, the off-diagonal operators can be transformed at any time in diagonal ones using the multiplication with H or H^{-1}. For example, H itself which is off-diagonal is related to the diagonal operators $H^2=\mathcal{D}(\Delta)$ or I. Thus each conserved Dirac operator can be brought in a diagonal form associated with an operator from **P**.

Let us start with the generators of the representations of the group G_s carried by the space of the Dirac spinors. The $U(1)_5$ generator remains the former operator P_5 but the SO(3) generators get the usual spin terms, $S_i=\frac{1}{2}\mathrm{diag}(\sigma_i,\sigma_i)$ of the total angular momentum whose components, $\mathcal{J}_i=L_i+S_i$, commute with H even if neither L_i nor S_i do not have this property.[7,9] However, the effect on the spinors of $\mathfrak{G}$ is due only to the physical parts which read

$$\mathcal{J}_iI=\mathcal{D}(J_i)=\mathcal{D}(L_i)+\tfrac{1}{2}\mathcal{D}(\sigma_i), \tag{28}$$

where both the orbital and the spin terms are *separately* conserved since L_i and σ_i commute with Δ. Obviously, in this case the associated Pauli operators are just J_i defined by (26).

The simplest conserved off-diagonal operators are the so called Dirac-type operators generated by the first three Killing–Yano tensors, $f^{(i)}$. We have shown[7,8] that these can be written

simply in the form $Q_i=\mathcal{Q}(\sigma_i)$, which explains why their algebraic properties are close to those of the Pauli matrices. Now, we can prove that the diagonal operators $H^{-1}Q_i=\mathcal{D}(\sigma_i)$ form a representation of the algebra of Pauli matrices with values in $\mathbf{D}_0$ since

$$H^{-1}Q_iH^{-1}Q_j=\delta_{ij}I+i\varepsilon_{ijk}H^{-1}Q_k\,. \tag{29}$$

The corresponding Dirac-type operator of the last Killing–Yano tensor, f^Y, calculated according to the general rule of Ref. 18 has been obtained in Ref. 8. This has the form

$$Q^Y=-\mathcal{Q}(\sigma_r)+\frac{2i}{\mu\sqrt{V}}\begin{pmatrix}0 & \lambda\\ -\lambda & 0\end{pmatrix}. \tag{30}$$

Using the identities presented in the Appendix one finds the equivalent forms reported in Ref. 8 and verifies that Q^Y commutes with H and P_5 and anticommutes with $\not{D}_s$ and γ^0. Moreover, after a little calculation, we obtain the remarkable identity

$$\mu P_5[Q^Y+\mathcal{Q}(\sigma_r)]=\{H,\Lambda\} \tag{31}$$

involving the operator $\Lambda=\mathrm{diag}(\lambda,\lambda)$ that is a particular version of a Biedenharn operator.[19] This is not conserved but $\Lambda^2=\vec{\mathcal{J}}^2-\mu^2P_5^2+\frac{1}{4}$ has this property. Furthermore, we observe that, according to (A1) and (A3), the physical part of Q^Y can be put in the form

$$Q^YI=\mathcal{Q}\left(-\sigma_r+\frac{2i}{\mu}\lambda\pi\Delta^{-1}\right)=\mathcal{Q}(\sigma^Y\Delta^{-1})\,, \tag{32}$$

where

$$\sigma^Y=\frac{2}{\mu}[\sigma_K+(\sigma_L+1)P_5] \tag{33}$$

is a new conserved Pauli operator associated to $HQ^Y=HQ^YI=\mathcal{D}(\sigma^Y)$.

C. The Runge–Lenz operator and dynamical algebras

These results allow us to calculate directly the physical parts of the Runge–Lenz operator of the Dirac theory (related to the Killing tensor $\vec{k}^{\mu\nu}$), following the same procedure as in Ref. 8. We start with the equivalent definition of the physical parts of the auxiliary operators[8]

$$\mathcal{N}_iI=\frac{\mu}{4}\{HQ^Y,H^{-1}Q_i\}-\mathcal{J}_iP_5I, \tag{34}$$

which can be written as

$$\mathcal{N}_iI=\mathcal{D}\left(\frac{\mu}{4}\{\sigma^Y,\sigma_i\}-J_iP_5\right)=\mathcal{D}(\hat{N}_i), \tag{35}$$

in terms of their associated conserved Pauli operators,

$$\hat{N}_i=K_i+\frac{\sigma_i}{2}P_5\,. \tag{36}$$

Furthermore, we define the physical parts of the components of the conserved Runge–Lenz operator[8,9]

$$\mathcal{K}_i I = \mathcal{N}_i I + \tfrac{1}{2}(\mathcal{F} - P_5)H^{-1}Q_i, \tag{37}$$

where $\mathcal{F}^2 = P_5^2 - H^2$. Since $\mathcal{F}^2 I = \mathcal{D}(F^2)$, we can express $\mathcal{K}_i I = \mathcal{D}(\hat{K}_i)$, now the associated conserved Pauli operators being

$$\hat{K}_i = K_i + \frac{\sigma_i}{2}F. \tag{38}$$

All these associations help us to understand the significance of the isomorphism among the algebra of the Dirac operators,[8,9]

$$[\mathcal{J}_i, \mathcal{K}_j] = i\varepsilon_{ijk}\mathcal{K}_k, \quad [\mathcal{K}_i, \mathcal{K}_j] = i\varepsilon_{ijk}\mathcal{J}_k\mathcal{F}^2, \tag{39}$$

that of the Pauli operators,

$$[J_i, \hat{K}_j] = i\varepsilon_{ijk}\hat{K}_k, \quad [\hat{K}_i, \hat{K}_j] = i\varepsilon_{ijk}J_k F^2, \tag{40}$$

and (24).

Rescaling (37) as in the case of the orbital operators (25), but using $\mathcal{F}$ instead of F, one obtains the even operators $\mathcal{R}_i \in \mathbf{D}$ (Ref. 9) having simple physical parts, $\mathcal{R}_i I = \mathcal{D}(\hat{R}_i)$, associated with the conserved Pauli operators

$$\hat{R}_i = \begin{cases} R_i + \dfrac{\sigma_i}{2} & \text{for } E \neq \hat{q}, \\ K_i & \text{for } E = \hat{q}. \end{cases} \tag{41}$$

We specify that the orbital and spin terms of $\mathcal{N}_i I$, $\mathcal{K}_i I$ and $\mathcal{R}_i I$ (for $E \neq \hat{q}$) are also separately conserved, as in the case of the angular momentum, since K_i and F commute with Δ.

The representations of the dynamical algebras $o(4)$ or $o(3,1)$ that govern the Dirac modes for $E \neq \hat{q}$ are generated by $\mathcal{J}_i$ and $\mathcal{R}_i$ (Ref. 9) whose physical parts, $\mathcal{J}_i I$ and $\mathcal{R}_i I$, have the same spin terms, $\mathcal{D}(\sigma_i)/2$. Therefore, each of these representations is the direct product between the irreducible representation of scalar modes and a spin half two-dimensional (fundamental) representation of the dynamical algebra.[9] When $E = \hat{q}$, then $\mathcal{F}$ and F vanish such that the representation of the subalgebra $so(3) \subset e(3)$ remains generated by the operators (28) while the operators $\mathcal{K}_i I$ lose their spin terms, becoming the translation generators of $e(3)$. All these representations arising from direct products are reducible. We note that this phenomenon is new since in the scalar (Klein–Gordon) case the representations of the dynamical algebras of the Kepler-type problems are irreducible.[2] However, these results could be easily obtained analyzing the *equivalent* representations generated by the associated Pauli operators J_i and $\hat{R}_i$ as we did already in Ref. 9 for the discrete energy spectrum. We recall that therein we introduced the new conserved operator $\mathcal{C} = 2\vec{\mathcal{J}}\cdot\vec{\mathcal{R}} - \frac{1}{2}$ in order to distinguish between the irreducible representations of the $o(4)$ dynamical algebra. Now we see that $\mathcal{C}I = \mathcal{D}(\sigma_R + \sigma_L + 1)$ where, according to (27), we have $\{\sigma_R, \sigma_L + 1\} = 0$.

V. CONCLUSIONS

The first conclusion is that our approach allows one to associate the conserved Dirac operators of diagonal (even) form to conserved Pauli operators independent on E. Thus for each type of symmetry we have conserved operators at three levels: Dirac, Pauli and orbital (of the Klein–Gordon theory). The following table resumes this hierarchy (K is an abbreviation for Killing, K-Y for Killing–Yano; * denotes entries which involve issues too complex to be abbreviated in the table and some comments are given below).

Geometric object	Nature	Symmetry	Dirac operator	Pauli operator	Klein–Gordon operator
$f^{(i)}_{\mu\nu}$	K-Y tensor	*	$H^{-1}Q_i$	σ_i	$\cdots$
$f^{Y}_{\mu\nu}$	K-Y tensor	*	HQ^Y	σ^Y	$\cdots$
$k^{\mu}_{(5)}$	K vector	$U(1)_5$	P_5	P_5	P_5
$k^{\mu}_{(i)}$	K vector	SO(3)	$\mathcal{J}_i$	J_i	L_i
$k^{\mu\nu}_{(i)}$	K tensor	hidden	$\mathcal{K}_i, \mathcal{R}_i$	$\hat{K}_i, \hat{R}_i$	K_i, R_i

However, there are many other even or odd conserved Dirac operators [e.g., $\mathcal{D}(\sigma_K^2)$, $\mathcal{Q}(L_i)$, $\mathcal{Q}(\sigma^Y)$, etc.] which can be constructed with the help of the conserved Pauli or orbital ones. This large collection of conserved observables is in fact a rich algebra freely generated by those related to the manifest or hidden symmetries of the Taub-NUT geometry.

In $N=1$ supersymmetric quantum models with standard supersymmetry there is a single supercharge Q that closes $Q^2=H$ on the Hamiltonian. In many of these models, and that is the case of the Taub-NUT manifold, one can find additional or hidden, nonstandard supercharges involving Killing–Yano tensors. The Killing–Yano tensors $f^{(i)}_{\mu\nu}$ $(i=1,2,3)$ give a vector representation of SO(3) and their existence is connected with the complex structures of the hyper-Kähler Taub-NUT space. The forth Killing–Yano tensor $f^{Y}_{\mu\nu}$ is a singlet and exists by virtue of the metric being type D. All four Killing–Yano tensors are invariant under the action of $U(1)_5$ which physically represents the relative electric charge of two monopoles.

For spin-$\frac{1}{2}$ particles, the Killing–Yano tensors are essential in construction of Dirac-type operators and evaluation of the spin contributions to the conserved quantities from the scalar case. The antisymmetric features of these operators make them the natural object used in description of the Dirac fermion in a curved space–time. On the other hand, the fact that the Stäckel–Killing tensors involved in the Runge–Lenz vector (23) can be expressed as symmetrized products of Killing–Yano tensors seems to be useless for scalar particles described by Schrödinger or Klein–Gordon equations. Therefore the existence of a certain square root of the Stäckel–Killing tensors becomes relevant only in the presence of fermions.

In other respects, we can eliminate many difficulties due to the spin terms of the Dirac theory if we restrict ourselves only to the physical parts XI of the operators $X\in\mathbf{D}$ giving up the projections $X(1-I)\in\mathbf{D}_1$ which can give rise sometimes to very complicated calculations. Moreover, we get the advantage of reducing the algebraic operations among the physical parts from $\mathbf{D}_0$ to calculations involving only the associated Pauli operators from $\mathbf{P}$. For example, if instead of $[\vec{Q},Q^Y]$, we calculate only its physical part, $[\vec{Q},Q^Y]I=[H^{-1}\vec{Q},HQ^Y]=\mathcal{D}([\vec{\sigma},\sigma^Y])$, we avoid a tedious algebra, easily obtaining the interesting identity

$$\frac{\mu}{4}[\vec{Q},Q^YI]=i(\vec{\mathcal{K}}+\vec{\mathcal{J}}P_5)\times(H^{-1}\vec{Q})+(\mathcal{F}+P_5)\,H^{-1}\vec{Q} \tag{42}$$

which shows that this commutator does not produce new conserved observables.

Finally, we note that our method based on the separation of the physical parts expressed in terms of $\mathcal{D}$ and $\mathcal{Q}$-operators could be used in any problem where the Hamiltonian is invertible and has manifest supersymmetry.

APPENDIX: THE OPERATOR λ

The operator

$$\lambda=\vec{\sigma}\cdot(\vec{x}\times\vec{P})+1=\sigma_L+1+\mu\sigma_rP_5 \tag{A1}$$

has the properties

$$\{\sigma_r,\lambda\}=0, \quad [\sigma_r,\sigma_P]=\frac{2i}{r}\lambda, \tag{A2}$$

and

$$\sigma_P\lambda=-\lambda\sigma_P=\frac{i}{2}\vec{\sigma}\cdot(\vec{P}\times\vec{L}-\vec{L}\times\vec{P})-\frac{i\mu}{r}\lambda P_5, \tag{A3}$$

which lead to

$$\{\alpha^*,\lambda\}=\frac{2i}{\sqrt{V}}\lambda P_5, \quad \{\alpha,\lambda\}=-\frac{2i}{\sqrt{V}}\lambda P_5. \tag{A4}$$

(Received 19 July 2001; accepted for publication 18 February 2002)

We study a large N_c limit of a two-dimensional Yang–Mills theory coupled to bosons and fermions in the fundamental representation. Extending an approach due to Rajeev we show that the limiting theory can be described as a classical Hamiltonian system whose phase space is an infinite-dimensional super-Grassmannian. The linear approximation to the equations of motion and the constraint yields the 't Hooft equations for the mesonic spectrum. Two other approximation schemes to the exact equations are discussed. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1477936]

I. INTRODUCTION

To gain a better understanding of gauge theories, two-dimensional models are often used as a testing ground. In a by now classic paper, 't Hooft has shown that the large-N_c limit allows us to obtain an equation describing the meson spectrum of two-dimensional Quantum Chromodynamics (QCD).[1] The same model was analyzed using different approaches[2–5] and they confirmed the results obtained by 't Hooft.

In this article we study the large-N_c limit of certain two-dimensional (2D) theories following a general approach developed by Rajeev[6,7] (see also Refs. 8 and 9 for similar approaches). In the large N_c limit of various quantum field theories (e.g., QCD) the quantum fluctuations become small and the theories are well described by a classical limit. This classical limit however is different from the conventional one in that many of the essential nonperturbative features of the quantum theory survive the large N_c limit.[10,1,11] In the formulation of Ref. 7 the classical theory corresponding to large N_c limit of 2D QCD is described by a Hamiltonian system defined on an infinite-dimensional Grassmannian. The points of this infinite-dimensional manifold can be identified with subspaces in infinite-dimensional Hilbert space (see the main text for precise definitions). The Grassmannian is a topologically nontrivial manifold whose connected components are labeled by an integer which can be identified with the baryon number. The 't Hooft equation describing the meson mass spectrum can be obtained in the linear approximation to the equations of motion on the Grassmannian.[7] In addition to meson masses, this approach also allows one to estimate the baryon mass via a variational ansatz.[12,6] The overall scheme resembles the Skyrme model of baryons in four-dimensional QCD. However unlike the Skyrme model the Grassmannian system of Ref. 7 can be derived as a large N_c limit of an underlying gauge theory. The Grassmannian is a homogeneous manifold. It is equipped with an action of an infinite-dimensional group (which is unitary for the fermionic matter and pseudounitary in the case of bosonic matter). This fact is very important for the structure of the phase space. In particular, it can be used for

a)Electronic mail: konechny@thsrv.lbl.gov
b)Electronic mail: turgutte@boun.edu.tr

quantization of the classical system which would allow one to get a handle on $1/N_c$ corrections (including nonperturbative ones). We believe that besides the possibility of describing baryons, not captured by the original 't Hooft approach,[10] the present approach can be made mathematically more precise. We remark that when the matter fields are in the adjoint representation, the mathematical techniques required are also very elegant and interesting, involving the Cuntz algebra in various forms. For this approach, we refer the reader to the papers of Halpern and Schwartz[13] and Rajeev and Lee.[14]

The 2D QCD interacting with bosons in the fundamental representation was also worked out following 't Hooft, partly because bosonic theory resembles the four-dimensional QCD in certain respects more than the fermionic one.[15–17] The approach of Ref. 7 was extended to the bosonic case in Ref. 18 (see also Ref. 19 for a similar approach to the problem).

In this paper we study the case when both bosonic and fermionic matter are present. One motivation for this is the fact that a dimensional reduction of four-dimensional QCD produces two-dimensional fundamental fermions and bosons in the adjoint representation coupled to the fermions via gauge fields. We do not expect that the bosons in the fundamental representation capture completely the adjoint case, but it can be used again as a testing ground. We also explore a more general case that includes the Yukawa type interaction between bosons and fermions.

The model of fundamental bosons and fermions interacting via SU(N_c) gauge field was studied, following the same ideas in the original paper of 't Hooft, by Aoki.[20,21] The more general models in the large-N_c limit are presented in a paper by Cavicchi, where he uses a bilocal field approach in the path integral picture.[22] Some of the models discussed in Ref. 22 are more general containing more complicated interactions, some of which in fact require a coupling constant renormalization.

In Refs. 20–22 it is shown that there are 't Hooft-like spectral equations for various types of mesons. In our case we have boson–boson, fermion–fermion, and boson–fermion type mesons, and they all satisfy essentially the same equation. In each case the meson spectrum is discrete and these mesons are all stable in the large-N_c approximation. One cannot say much about the baryons using these methods.

In the present work we generalize the approach of Ref. 7 to QCD for the bosonic and fermionic matter fields coupled via gauge fields. We will see that the phase space of the theory corresponds to a certain superversion of the infinite-dimensional Grassmanian. Although the original system does not have any supersymmetry the main objects describing the large N_c limit, such as the phase space, group action, symplectic form, can be described in supergeometric terms. (A similar phenomenon was observed in another two-dimensional model in Ref. 23, and indeed this is a general feature of bosons and fermions coupled via gauge fields). We obtain the equations describing the meson spectrum of the model within the linear approximation. These equations agree with the ones found by Aoki.[20,21] The theory we will present is actually nonlinear and can accommodate solitonic solutions which should describe baryons. We identify the operator which gives us the baryon number. We also propose some approximations to the spectral equations going beyond the linear approximation and discuss some consequences.

The layout of the paper is as follows. In Sec. II we reformulate the model in terms of color invariant bilinears. We further derive the Poisson brackets and the constraints imposed on the bilinear variables in large N_c limit. In Sec. III we describe this Hamiltonian system in more precise terms using the language of supergeometry. The linear approximation to the equations of motion giving the meson mass spectrum is discussed in Sec. IV. In Sec. V we propose two approximation schemes that incorporate some nonlinear corrections and give a qualitative discussion of their influence on the spectrum.

II. THE ALGEBRA OF COLOR INVARIANT OPERATORS

We start by writing the action functionals of the two theories that we are interested in. Both theories have a gauge field that can be completely eliminated in favor of static 2D Coulomb potential. We will use the light cone coordinates $x^+=(1/\sqrt{2})(t+x)$, $x^-=(1/\sqrt{2})(t-x)$ and

choose the $A_+=0$ gauge. We first look at the gauge-coupled complex bosons with a quartic self-interaction term and Dirac fermions both in the fundamental representation of SU(N_c):

$$S=\int \mathrm{d}x^+\,\mathrm{d}x^-\Big[-\frac{1}{2}\mathrm{Tr}\,F_{+-}F^{+-}+i\sqrt{2}\psi_L^{*\alpha}(\partial_-+igA_-)^\beta_\alpha\psi_{L\beta}+i\sqrt{2}\psi_R^{*\alpha}\partial_+\psi_{R\alpha}$$
$$-m_F(\psi_L^{*\alpha}\psi_{R\alpha}+\psi_R^{*\alpha}\psi_{L\alpha})-2\phi^{*\alpha}\partial_-\partial_+\phi_\alpha+ig(\partial_+\phi^{*\alpha}A^\beta_{-\alpha}\phi_\beta-\phi^{*\alpha}A^\beta_{-\alpha}\partial_+\phi_\beta)$$
$$-m_B^2\phi^{*\alpha}\phi_\alpha-\frac{\lambda^2}{4}\phi^{*\alpha}\phi_\alpha\phi^{*\beta}\phi_\beta\Big]. \tag{1}$$

In the other model we will look at parity broken and a Yukawa-type interaction is added between fermions and bosons,

$$S_Y=\int \mathrm{d}x^+\,\mathrm{d}x^-\Big[-\frac{1}{2}\mathrm{Tr}\,F_{+-}F^{+-}+i\sqrt{2}\psi_L^{*\alpha}(\partial_-+igA_-)^\beta_\alpha\psi_{L\beta}+i\sqrt{2}\psi_R^{*}\partial_+\psi_R-2\phi^{*\alpha}\partial_-\partial_+\phi_\alpha$$
$$+ig(\partial_+\phi^{*\alpha}A^\beta_{-\alpha}\phi_\beta-\phi^{*\alpha}A^\beta_{-\alpha}\partial_+\phi_\beta)-m_B^2\phi^{*\alpha}\phi_\alpha-\frac{\lambda^2}{4}\phi^{*\alpha}\phi_\alpha\phi^{*\beta}\phi_\beta+\mu(\psi_R^*\psi_{L\alpha}\phi^{*\alpha}$$
$$+\psi_L^{*\alpha}\psi_R\phi_\alpha)\Big]. \tag{2}$$

In both cases we normalize the Lie algebra generators T^a as $\mathrm{Tr}\,T^aT^b=\delta^{ab}$, and we choose them to be Hermitian. This second model is anomalous because it is not a chiral gauge theory. There exist some ideas in the literature to treat an anomalous two-dimensional model,[24] but we will not follow this path. Instead we will take the above-mentioned model at the classical level and eliminate the gauge fields which are not dynamical, and subsequently quantize the effective theory. One can check that the resulting system has a global SU(N_c) symmetry and relativistic invariance. We regard this as a toy model which is *inspired from gauge theory*.

We can further use the Gauss constraint to eliminate the gauge field A_- and the fermionic equations of motion to eliminate the right moving fermion ψ_R ($\psi_{R\alpha}$). We will do these reductions in the quantized model for the first case, and classically for the second one. The resulting action is first order in the "time direction" x^- so we can pass to Hamiltonian formalism in a straightforward way.

The Fourier mode expansions read,

$$\phi_\alpha(x^+)=\int a_\alpha(p)e^{-ipx^+}\frac{dp}{2\pi(2|p|)^{1/2}},\quad \psi_{L\alpha}(x^+)=\int \chi_\alpha(p)e^{-ipx^+}\frac{dp}{2\pi 2^{1/4}}$$

(to simpify the notation instead of p_+ we write p). The normalization factors are chosen to give the correct classical limits. The commutation/anticommutation relations for the fields in the light cone gauge take the form,[6]

$$[\chi_\alpha(p),\chi^{\dagger\beta}(q)]_+=\delta^\beta_\alpha 2\pi\delta(p-q),\quad [a_\alpha(p),a^{\dagger\beta}(q)]=\mathrm{sgn}(p)\,\delta^\beta_\alpha 2\pi\delta(p-q). \tag{3}$$

We define $\delta[p-q]=2\pi\delta(p-q)$, and use $[\mathrm{d}p]=\mathrm{d}p/2\pi$ to keep track of factors of 2π.

One defines a Fock vacuum state $|0\rangle$ by the conditions,

$$a_\alpha(p)|0\rangle=\chi_\alpha(p)|0\rangle=0\quad \text{for}\quad p>0,\quad a^{\dagger\alpha}(p)|0\rangle=\chi^{\dagger\alpha}(p)|0\rangle=0\quad \text{for}\quad p<0. \tag{4}$$

The corresponding normal orderings are defined as

$$:\chi^{\dagger\alpha}(p)\chi_\beta(q):=\begin{cases}-\chi_\beta(q)\chi^{\dagger\alpha}(p) & \text{if } p<0, q<0,\\ \chi^{\dagger\alpha}(p)\chi_\beta(q) & \text{otherwise,}\end{cases} \tag{5}$$

$$:a^{\dagger\alpha}(p)a_\beta(q):=\begin{cases} a_\beta(q)a^{\dagger\alpha}(p) & \text{if } p<0, q<0, \\ a^{\dagger\alpha}(p)a_\beta(q) & \text{otherwise.} \end{cases} \tag{6}$$

(Later on we also use the extension of normal ordering to product of four operators, and it is the standard one.) For our purposes it is most convenient to remember the normal orderings of bilinears in the following form:

$$:\chi^{\alpha\dagger}(p)\chi_\beta(q):=\chi^{\alpha\dagger}(p)\chi_\beta(q)-\frac{\delta^\alpha_\beta}{2}[1-\mathrm{sgn}(p)]\delta[p-q],$$

$$:a^{\alpha\dagger}(p)a_\beta(q):=a^{\alpha\dagger}(p)a_\beta(q)-\frac{\delta^\alpha_\beta}{2}[1-\mathrm{sgn}(p)]\delta[p-q].$$

Written as quantum operators, we have in the first model,

$$\psi_{R\alpha}=\frac{m_F}{\sqrt{2}i\partial_+}\psi_{L\alpha} \tag{7}$$

and its Hermitian conjugate, and

$$\psi_R=-\frac{\mu}{\sqrt{2}i\partial_+}\phi^{*\alpha}\psi_{L\alpha} \tag{8}$$

and its Hermitian conjugate for the second model. In the first case, A_- is given in terms of the other fields as

$$A^a_-=-\frac{g}{\partial_+^2}:(\sqrt{2}\psi^{\dagger\alpha}_L(T^a)^\beta_\alpha\psi_{L\beta}+i[\phi^{\dagger\alpha}(T^a)^\beta_\alpha\partial_+\phi_\beta-\partial_+\phi^{\dagger\alpha}(T^a)^\beta_\alpha\phi_\beta]):. \tag{9}$$

In the second model we are using the same equation to eliminate A_- at the classical level (which means without the normal ordering).

By eliminating the redundant degrees of freedom we can express the action in terms of the bilinears of the fields $\psi_{L\alpha}$ and ϕ_α only. We introduce

$$\begin{aligned} \hat{M}(p,q)&=\frac{2}{N_c}:\chi^{\dagger\alpha}(p)\chi_\alpha(q):, \\ \hat{N}(p,q)&=\frac{2}{N_c}:a^{\dagger\alpha}(p)a_\alpha(q):, \end{aligned} \tag{10}$$

and their odd counterparts,

$$\hat{Q}(p,q)=\frac{2}{N_c}\chi^{\dagger\alpha}(p)a_\alpha(q), \quad \hat{\tilde{Q}}(r,s)=\frac{2}{N_c}a^{\dagger\alpha}(r)\chi_\alpha(s). \tag{11}$$

Once the redundancies are removed the resulting action is already first order in the ''time'' variable hence we can read off the Hamiltonian, and the resulting commutation relations are consistent with the ones obtained from the conventional canonical quantization. The reduction is straightforward in principle but requires a long and careful computation. Since the details are explained in Rajeev's lecture notes[6] we only give the result:

$$H=H_0+H_I, \tag{12}$$

$$H_0=\frac{1}{4}M_B^2\int\frac{[\mathrm{d}p]}{|p|}N(p,p)+\frac{1}{4}M_F^2\int\frac{[\mathrm{d}p]}{p}M(p,p), \tag{13}$$

where for the first model we use

$$M_F^2=m_F^2-\frac{g^2}{\pi},\quad M_B^2=m_{RB}^2-\frac{g^2}{\pi}. \tag{14}$$

We employ a logarithmic renormalization on the bare mass of the bosonic field,[19] and denote the renormalized mass as m_{RB}. For the second model, since we reduce it at the classical level there are no corrections coming to the boson mass term,

$$M_F^2=0,\quad M_B^2=\frac{m_B^2}{4}. \tag{15}$$

The interaction parts are given by

$$H_I=\int[\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t]G_1(p,q;s,t)M(p,q)M(s,t)+\int[\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t]G_2(p,q;s,t)N(p,q)N(s,t)$$
$$+\int[\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t]G_3(p,q;s,t)Q(p,q)\overline{Q}(s,t),$$

where for both the first and second models,

$$G_1(p,q;s,t)=-\frac{g^2}{16}\left(\frac{1}{(p-t)^2}+\frac{1}{(q-s)^2}\right)\delta[p+s-t-q], \tag{16}$$

$$G_2(p,q;s,t)=\frac{g^2}{64}\left(\frac{1}{(p-t)^2}+\frac{1}{(q-s)^2}\right)\delta[p+s-t-q]\frac{qt+ps+st+pq}{\sqrt{|pqst|}}+\frac{\lambda^2}{64}\frac{\delta[p+s-t-q]}{\sqrt{|pqst|}}. \tag{17}$$

In the first model we use

$$G_3(p,q;s,t)=\frac{g^2}{8}\frac{q+s}{(q-s)^2}\frac{\delta[p+s-t-q]}{\sqrt{|qs|}}, \tag{18}$$

and for the second model we only have an additional term,

$$G_3(p,q;s,t)=\frac{\mu^2}{16}\frac{1}{(p-q)}\frac{1}{\sqrt{|qs|}}\delta[p-t-q+s]+\frac{g^2}{8}\frac{q+s}{(q-s)^2}\frac{\delta[p+s-t-q]}{\sqrt{|qs|}}. \tag{19}$$

Above we rescaled our coupling constants by a factor of N_c and kept the same symbols for the couplings (so $g^2N_c\mapsto g^2$, $\mu^2N_c\mapsto\mu^2$, and $\lambda^2N_c\mapsto\lambda^2$) to simplify notation. For the precise meaning of these singular integral kernels we refer to the lecture notes of Rajeev:[6] we should interpret them as Hadamard principal value. We will continue to write the ordinary integrals but keep in mind that the integrals are evaluated with this prescription.

The theory we obtained still possesses a global SU(N_c) invariance. The corresponding generator of symmetry is

$$\hat{\mathcal{Q}}^{\alpha}_{\beta}=\int [\mathrm{d}p]\left(:\chi^{\dagger\alpha}(p)\chi_{\beta}(p):-\frac{1}{N_c}\delta^{\alpha}_{\beta}:\chi^{\dagger\gamma}(p)\chi_{\gamma}(p):\right)$$
$$+\int [\mathrm{d}p]\mathrm{sgn}(p)\left(:a^{\dagger\alpha}(p)a_{\beta}(p):-\frac{1}{N_c}\delta^{\alpha}_{\beta}:a^{\dagger\gamma}(p)a_{\gamma}(p):\right). \tag{20}$$

It is known (at least for the purely spinor and purely scalar QCD_2) that in the light-like axial gauge only the color singlet sector of the model can be quantized in a way that preserves Lorentz invariance (Refs. 5, and 4). In this paper we will therefore consider only the restrictions of our models to this sector. In general for a gauge theory it is expected that in the large N_c limit any gauge invariant correlator factorizes, i.e., $\langle AB\rangle=\langle A\rangle\langle B\rangle+O(1/N_c)$. So when the two-dimensional theory is restricted to the color invariant subspace in the large N_c limit any color invariant correlator should be expressible in terms of correlators of color invariant bilinear operators, $\hat{M}$, $\hat{N}$ and $\hat{Q}$, $\hat{\bar{Q}}$ given in (10) and (11). We compute the (anti)commutation relations between these bilinears:

$$[\hat{M}(p,q),\hat{M}(r,s)]=\frac{2}{N_c}[\hat{M}(p,s)\delta[q-r]-\hat{M}(r,q)\delta[p-s]-\delta[p-s]\delta[q-r](\mathrm{sgn}(p)$$
$$-\mathrm{sgn}(q))],$$

$$[\hat{N}(p,q),\hat{N}(r,s)]=\frac{2}{N_c}[\hat{N}(p,s)\mathrm{sgn}(q)\delta[q-r]-\hat{N}(r,q)\mathrm{sgn}(p)\delta[p-s]$$
$$-\delta[q-r]\delta[p-s](\mathrm{sgn}(p)-\mathrm{sgn}(q))],$$

$$[\hat{Q}(p,q),\hat{\bar{Q}}(r,s)]_{+}=\frac{2}{N_c}[\hat{M}(p,s)\mathrm{sgn}(q)\delta[q-r]+\hat{N}(r,q)\delta[p-s]$$
$$+\delta[p-s]\delta[q-r](1-\mathrm{sgn}(p)\mathrm{sgn}(q))],$$

$$[\hat{M}(p,q),\hat{Q}(r,s)]=\frac{2}{N_c}\delta[q-r]\hat{Q}(p,s), \tag{21}$$

$$[\hat{N}(p,q),\hat{Q}(r,s)]=-\frac{2}{N_c}\delta[p-s]\mathrm{sgn}(p)\hat{Q}(r,q),$$

$$[\hat{M}(p,q),\hat{\bar{Q}}(r,s)]=-\frac{2}{N_c}\delta[p-s]\hat{\bar{Q}}(r,q),$$

$$[\hat{N}(p,q),\hat{\bar{Q}}(r,s)]=\frac{2}{N_c}\delta[q-r]\mathrm{sgn}(q)\hat{\bar{Q}}(p,s).$$

All the other (anti)commutators vanish. The first two relations were used before in Refs. 7 and 18, respectively. These (anti)commutation relations define an infinite dimensional Lie superalgebra. Its even part is isomorphic to a direct sum of central extensions of infinite-dimensional unitary and pseudounitary groups each one generated by operators $\hat{M}(p,q)$ and $\hat{N}(p,q)$, respectively (see Ref. 18 for details). We will talk more about this Lie superalgebra and the corresponding supergroup in Sec. III. As the right-hand sides of (21) all contain a factor of $1/N_c$ in the large N_c limit all of the bilinears commute (or anticommute, respectively) and can be thought of as coordinates on a classical phase space. We denote the classical variables corresponding to $\hat{M}$, $\hat{N}$, $\hat{Q}$, $\hat{\bar{Q}}$ by the same letters with carets removed. This classical phase space is an infinite-dimensional supermanifold endowed with a super-Poisson structure inherited from the (anti)commutation relations (21).

The corresponding Poisson superbrackets are obtained from the (anti)commutators in (21) by substituting $-i$ instead of $1/N_c$ factors (note that this brings an extra factor of 2). There is no simple way to decide which multiple of $1/N_c$ should be the quantum parameter. If one attempts a geometric quantization of this model, the symplectic form should be an integer multiple of the Chern character of the line bundle; the symplectic form we have in Sec. III is in fact the basic two form. The other possibility is to write the symplectic form in the action and use single valuedness of the path integral as is done in Ref. 7. (We note in passing that there is a factor of 2 missing in Ref. 18, due to an error in the conventions, but we scale the Hamiltonian with the same parameter so the large-N_c results are the same. The geometric quantization parameter instead should have been $1/N_c$).

However the super-Poisson structure corresponding to (21) only gives a local structure of the classical phase space of the theory. In addition to that there are some global constraints on the classical variables assigned to the color invariant bilinears. The constraints emerge in the large N_c limit as consequences of the color invariance condition $\hat{\mathcal{Q}}^{\alpha}_{\beta}=0$.

To write down these constraints it is convenient to introduce the following operator product convention:

$$(AB)(p,q)=\int [\mathrm{d}r]A(p,r)B(r,q),$$

where A, B stand for any of the above-mentioned (classical) bilinears. We also introduce operators 1 and ϵ as the operators with the kernels $\delta[p-q]$ and $-\mathrm{sgn}(p)\delta[p-q]$, respectively. In this notation the constraints read as follows:

$$\begin{aligned}
(M+\epsilon)^2+Q\epsilon Q^{\dagger}&=1,\\
\epsilon Q^{\dagger}M+\epsilon Q^{\dagger}\epsilon+\epsilon N\epsilon Q^{\dagger}+Q^{\dagger}&=0,\\
MQ+\epsilon Q+Q\epsilon N+Q\epsilon&=0,\\
(\epsilon N+\epsilon)^2+\epsilon Q^{\dagger}Q&=1.
\end{aligned}\tag{22}$$

For brevity we will present here a derivation only of the first constraint in (22). The derivations of all the others are very similar. We will restrict ourselves to the zero subspace of the operator $\hat{\mathcal{Q}}^{\alpha}_{\beta}$ and we define the number operators

$$\hat{F}\equiv\frac{1}{N_c}\int [\mathrm{d}p]:\chi^{\dagger\alpha}(p)\chi_{\alpha}(p):,\quad \hat{B}\equiv\frac{1}{N_c}\int [\mathrm{d}p]\mathrm{sgn}(p):a^{\dagger\alpha}(p)a_{\alpha}(p):. \tag{23}$$

(Note that these operators are scaled by a factor of $1/N_c$ so taking the limit $N_c\to\infty$ gives us zero when these operators are acting on mesonic states. They are nonzero when we look at the baryonic states as we will see shortly.)

By writing out the product of operators at hand in terms of the variables a, $a^{\dagger}$, χ and $\chi^{\dagger}$ and moving the suitable combinations to the right one can prove the identity (that holds on the whole Fock space)

$$((\hat{M}+\epsilon)^2+\hat{Q}\epsilon\hat{Q}^{\dagger})(r,s)=\delta[r-s]+\frac{2}{N_c^2}\chi^{\dagger\alpha}(r)\chi_{\beta}(s)(\hat{\mathcal{Q}}^{\beta}_{\alpha}+\delta^{\beta}_{\alpha}(\hat{F}+\hat{B})).$$

On the subspace $\hat{\mathcal{Q}}^{\beta}_{\alpha}=0$, the operator $\hat{B}+\hat{F}$ will be equal to the baryon number operator $\hat{\mathbf{B}}$. Thus when we restrict ourselves to a fixed baryon number B, we get

$$((\hat{M}+\epsilon)^2+\hat{Q}\epsilon\hat{Q}^{\dagger})(r,s)=\delta[r-s]+(\hat{M}+1-\epsilon)(r,s)\frac{B}{N_c},$$

this in the large N_c limit produces the first constraint in (22).

When we look at a possible exotic baryon state:

$$\int \epsilon_{\alpha_1 \dots \alpha_s \alpha_{s+1} \cdots \alpha_{N_c}} Z(p_1, \dots, p_s; p_{s+1}, \dots, p_{N_c}) \chi^{\dagger \alpha_1}(p_1) \dots \chi^{\dagger \alpha_s}(p_s) a^{\dagger \alpha_{s+1}}(p_{s+1}) \dots a^{\dagger \alpha_{N_c}}(p_{N_c}) |0>, \tag{24}$$

where $p_1, p_2, \dots, p_{N_c}$ are all positive, and $Z(p_1, \dots, p_s, p_{s+1}, \dots, p_{N_c})$ is symmetric in $p_1, \dots, p_s$ and antisymmetric in $p_{s+1}, \dots, p_{N_c}$. The operator $\hat{\mathbf{B}}$ gives 1 acting on such a state. On mesonic states this operator has vanishing matrix elements in the large-N_c limit. One can prove more generally therefore that this operator is the baryon number operator. If we act by this operator on a product of such exotic baryons and finite number of mesons in the large-N_c limit we get the number of baryons, B. In this discussion we see the possibility of having exotic baryons, and we will come back to the geometric meaning of this in Sec. III (and show that it is indeed an integer in our model). We will also show that just as in the purely bosonic and purely fermionic cases the constraints (22) have an elegant geometric interpretation in terms of infinite dimensional disk and Grassmannian.

III. PHASE SPACE OF THE THEORY: SUPER-GRASSMANNIAN

In this section we present the geometry of the phase space without going into the mathematical intricacies. We believe the most proper treatment requires an infinite-dimensional extension of Berezin's **Z**-graded version of supergeometry. We do not give such a complete presentation, and develop a more formal approach (in many cases we provide parenthetical remarks on the general case). We plan to provide a more detailed discussion in a later publication when we discuss geometric quantization of this system. The proper treatment of second quantization with bosons and fermions, which fits to our point of view, can be found in Refs. 25, 26, and also in Ref. 27. In order to understand the geometry of the phase space, we define an operator in supermatrix form;

$$\Phi = \begin{pmatrix} \epsilon N + \epsilon & \epsilon Q^\dagger \\ Q & M + \epsilon \end{pmatrix}, \tag{25}$$

where $\Phi: \mathcal{H}^e | \mathcal{H}^o \to \mathcal{H}^e | \mathcal{H}^o$. We think of the direct sum $\mathcal{H}^e \oplus \mathcal{H}^o$ of one-particle Hilbert spaces of bosons and fermions, respectively, as even and odd graded and the notation $\mathcal{H}^e | \mathcal{H}^o$ is used to emphasize this grading. We use $\epsilon = \left(\begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ in both of these spaces. This matrix realization corresponds to the decomposition of the Hilbert spaces into positive and negative energy subspaces as $\mathcal{H}^e_+ \oplus \mathcal{H}^e_-$ for bosons and $\mathcal{H}^o_+ \oplus \mathcal{H}^o_-$ for fermions.

The constraints and the conditions that we found in Sec. II on the basic variables of our theory in terms of Φ become

$$\Phi^2 = 1, \quad E \Phi^\dagger E = \Phi, \tag{26}$$

where $E = \left(\begin{smallmatrix} \epsilon & 0 \\ 0 & 1 \end{smallmatrix}\right)$.

If we introduce a supergroup of operators acting on $\mathcal{H}^e | \mathcal{H}^o$, obeying the relations

$$g E g^\dagger = E, \quad g^\dagger E g = E, \tag{27}$$

we see that the action of this group on the variable Φ, $(g, \Phi) \mapsto g \Phi g^{-1}$ preserves the above-stated conditions on Φ. The orbit of $\hat{\epsilon} = \left(\begin{smallmatrix} \epsilon & 0 \\ 0 & \epsilon \end{smallmatrix}\right)$ under the action of this superunitary group can be parametrized by Φ.

The condition that the bilinears, originally defined on the Fock space of the quantum theory, create finite norm vectors implies that the off-diagonal components of M and N are Hilbert–Schmidt operators (see Refs. 7, 6, and 18 and for the ideals in the nonsuper case see Refs. 28 and

29). A similar computation shows that the off-diagonal components of the superoperators Q and $Q^\dagger$ also satisfy these conditions. These finite norm conditions in two dimensions can be written in an economical way as the Hilbert–Schmidt condition on the supermatrix Φ. To state these convergence conditions more properly we should decompose $\mathcal{H}^e|\mathcal{H}^o$ into negative and positive energy subspaces and think of Φ as an operator acting from $\mathcal{H}^e_+|\mathcal{H}^o_+ \oplus \mathcal{H}^e_-|\mathcal{H}^o_-$ to the same space. Thus we have the convergence conditions,

$$[\hat{\epsilon},\Phi] \in \mathcal{I}_2, \quad \hat{\epsilon}=\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{28}$$

where we write $\hat{\epsilon}$'s matrix realization with respect to this positive–negative energy decomposition. Here for the upper off-diagonal component the ideal of Hilbert–Schmidt operators $\mathcal{I}_2$ refers to the set of operators $B:\mathcal{H}^e_-|\mathcal{H}^o_- \to \mathcal{H}^e_+|\mathcal{H}^o_+$, such that $\mathrm{Tr}\, B^\dagger B$ is convergent. (This definition in the $\mathbf{Z}_2$ graded case is the usual one, since the operators have ordinary numbers as their matrix entries, in a fully $\mathbf{Z}$ graded case these questions are delicate and we have to give a precise meaning to the Hilbert–Schmidt condition. For this work we ignore this question but see Ref. 30 for further comments on it). The lower off-diagonal block will be a Hilbert–Schmidt operator $C:\mathcal{H}^e_+|\mathcal{H}^o_+ \to \mathcal{H}^e_-|\mathcal{H}^o_-$ as well. (Since the even and odd Hilbert spaces are isomorphic, it is convenient to drop the superscript when there is no confusion.) The above-mentioned considerations suggest that we should use as our symmetry group the restricted superunitary group:

$$U_1(\mathcal{H}_-,\mathcal{H}_+|\mathcal{H}) = \{g | gEg^\dagger = E, \quad g^\dagger E g = E \quad [\hat{\epsilon},g] \in \mathcal{I}_2\}, \tag{29}$$

where $\mathcal{I}_2$ denotes the ideal of Hilbert–Schmidt operators as in the above-mentioned positive–negative energy decomposition used for Φ's convergence conditions.

We look at the orbit of $\hat{\epsilon}=\left(\begin{smallmatrix} \epsilon & 0 \\ 0 & \epsilon \end{smallmatrix}\right)$, this time we write it with respect to the original decomposition $\mathcal{H}^e|\mathcal{H}^o$, under the restricted superunitary group. We notice that this orbit is in fact a homogeneous supersymplectic manifold:

$$SGr_1 = \frac{U_1(\mathcal{H}_-,\mathcal{H}_+|\mathcal{H})}{U(\mathcal{H}_-|\mathcal{H}_-)\times U(\mathcal{H}_+|\mathcal{H}_+)}. \tag{30}$$

The stability subgroup has a natural embedding into the full group. This physically means that we allow mixing of the positive energy states of bosons and fermions as well as the negative ones.

Notice that a tangent vector V_u at any point on this super-Grassmannian is given by its effect on Φ, $V_u(\Phi)=i[u,\Phi]_s$, where we use the super-Lie bracket which is defined by

$$\begin{aligned}\left[\begin{pmatrix} a_1 & \beta_1 \\ \gamma_1 & d_1 \end{pmatrix},\begin{pmatrix} a_2 & \beta_2 \\ \gamma_2 & d_2 \end{pmatrix}\right]_s &= \left[\begin{pmatrix} a_1 & 0 \\ 0 & d_1 \end{pmatrix},\begin{pmatrix} a_2 & 0 \\ 0 & d_2 \end{pmatrix}\right] + \left[\begin{pmatrix} a_1 & 0 \\ 0 & d_1 \end{pmatrix},\begin{pmatrix} 0 & \beta_2 \\ \gamma_2 & 0 \end{pmatrix}\right] \\ &\quad + \left[\begin{pmatrix} 0 & \beta_1 \\ \gamma_1 & 0 \end{pmatrix},\begin{pmatrix} a_2 & 0 \\ 0 & d_2 \end{pmatrix}\right] + \left[\begin{pmatrix} 0 & \beta_1 \\ \gamma_1 & 0 \end{pmatrix},\begin{pmatrix} 0 & \beta_2 \\ \gamma_2 & 0 \end{pmatrix}\right]_+\end{aligned}$$

for a decomposition of u into $\left(\begin{smallmatrix} a & \beta \\ \gamma & d \end{smallmatrix}\right)$, with respect to $\mathcal{H}^e|\mathcal{H}^o$. In general the super-Lie algebra element u will depend on the position Φ.

Our homogeneous manifold carries a natural two-form, this turns it into a phase space. We formally define a two-form;

$$\Omega = \frac{i}{4}\,\mathrm{Str}\,\Phi\, d\Phi \wedge d\Phi. \tag{31}$$

One can give the symplectic form explicitly via its action on vector fields, and this defines the above-mentioned two-form:

$$i_{V_u} i_{V_v} \Omega = \frac{i}{8} \mathrm{Str}\, \Phi [[u,\Phi]_s,[v,\Phi]_s]_s . \tag{32}$$

Using exactly the same methods as in Refs. 7 and 18 we can show that it is closed and nondegenerate.

In fact the above-mentioned form is also a homogeneous two-form invariant under the group action, as can be verified in a simple manner. We note that the super-Poisson brackets which we introduced in Sec. I as a result of the large-N_c limit, are precisely the ones given by this symplectic form. Therefore we may introduce a classical dynamical system defined on this super-Grassmannian with this symplectic form which gives us the same set of super-Poisson brackets. This shows that the large-N_c limit of our theory has an independent geometric formulation: the phase space is an infinite-dimensional homogeneous manifold with a natural symplectic structure on it.

The group action is generated by moment maps $F_u = -(i/2)\mathrm{Str}_\epsilon\, u(\Phi - \left(\begin{smallmatrix}\epsilon & 0\\ 0 & \epsilon\end{smallmatrix}\right))$, where we use the even–odd decomposition to write all the operators and conditional trace to be defined in the following. They satisfy the following super-Poisson realization of the super-unitary group:

$$\{F_u, F_v\} = F_{-i[u,v]_s} - \frac{i}{2} \mathrm{Str}_\epsilon \left[\begin{pmatrix} \epsilon & 0 \\ 0 & \epsilon \end{pmatrix}, u \right]_s v, \tag{33}$$

where $[.,.]_s$ again denotes the super-commutator(super-Lie bracket). To see this, one way is to compute both sides, the other is to use general principles and evaluate both sides at $\hat{\epsilon} = \left(\begin{smallmatrix}\epsilon & 0\\ 0 & \epsilon\end{smallmatrix}\right)$ (written with respect to the even–odd decomposition). The moment function on the right vanishes there and the central term is constant on the phase space, this gives us

$$\begin{aligned}
\Sigma_s(u,v) &= -\frac{i}{8} \mathrm{Str} \begin{pmatrix} \epsilon & 0 \\ 0 & \epsilon \end{pmatrix} \left[\left[\left[\begin{pmatrix} \epsilon & 0 \\ 0 & \epsilon \end{pmatrix}, u \right], \left[\begin{pmatrix} \epsilon & 0 \\ 0 & \epsilon \end{pmatrix}, v \right] \right] \right]_s \\
&= -\frac{i}{2} (\mathrm{Tr}_\epsilon [\epsilon, a(u)] a(v) - \mathrm{Tr}_\epsilon ([\epsilon, \beta(u)] \gamma(v) \\
&\quad + [\epsilon, \beta(v)] \gamma(u)) - \mathrm{Tr}_\epsilon [\epsilon, \mathrm{d}(u)] \mathrm{d}(v)) \\
&= -\frac{i}{2} \mathrm{Str}_\epsilon \left[\begin{pmatrix} \epsilon & 0 \\ 0 & \epsilon \end{pmatrix}, u \right] v .
\end{aligned}$$

The conditional supertrace is defined by $\mathrm{Str}_\epsilon \left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right) = \mathrm{Tr}_\epsilon A - \mathrm{Tr}_\epsilon D$, and $\mathrm{Tr}_\epsilon A = \frac{1}{2}\mathrm{Tr}(A + \epsilon A \epsilon)$. Notice that the convergence conditions on Φ guarantees that the conditional trace exists (in fact a better convergence is possible, see the following). This can be seen most easily by using, $\Phi - \hat{\epsilon} = g \hat{\epsilon} g^{-1} - \hat{\epsilon} = -[\hat{\epsilon}, g] g^{-1}$. It is more natural to compute this with respect to the positive–negative energy decomposition (we use the subscripts $\pm$ to denote the supermatrix elements acting between various subspaces),

$$[\hat{\epsilon}, g] g^{-1} = \begin{pmatrix} 0 & g_{+-} \\ g_{-+} & 0 \end{pmatrix} \begin{pmatrix} (g^{-1})_{++} & (g^{-1})_{+-} \\ (g^{-1})_{-+} & (g^{-1})_{--} \end{pmatrix} = \begin{pmatrix} \mathcal{I}_1 & \mathcal{I}_2 \\ \mathcal{I}_2 & \mathcal{I}_1 \end{pmatrix}, \tag{34}$$

where $\mathcal{I}_1$ denotes the ideal of trace class operators and $\mathcal{I}_2$ is the ideal of Hilbert–Schmidt operators. We used the fact that the off-diagonal elements are Hilbert–Schmidt and the others are bounded, and the analog of the well-known conditions $\mathcal{I}_2 \mathcal{I}_2 \in \mathcal{I}_1$ in the supercase. If we multiply this with an element of the Lie algebra we see that the conditional traces exist. It suggests a

slightly better way to write the moment maps, $F_u = -(i/2)\mathrm{Str}_{\hat{\epsilon}} u(\Phi - \hat{\epsilon})$, which shows that the conditional convergence could be actually defined with respect to the positive–negative energy decomposition.

The previous discussion further implies that $\mathrm{Str}_{\hat{\epsilon}}(\Phi - \hat{\epsilon})$ is convergent. This expression is in fact conserved by the equations of motion of a quadratic Hamiltonian. We may understand the meaning of this number, if we think of its action on color invariant states before we take the large-N_c limit. We can prove that in this case this operator gives us twice the baryon number. Recall that the baryons in this theory can be exotic, that is we may have color singlet combinations of the form,

$$\int \epsilon_{\alpha_1 \alpha_2 \cdots \alpha_{N_c}} Z(q_1, \ldots q_s; q_{s+1}, \ldots, q_{N_c}) \chi^{\dagger \alpha_1}(q_1) \cdots \chi^{\dagger \alpha_k}(q_k) a^{\dagger \alpha_{k+1}}(q_{k+1}) \cdots a^{\dagger \alpha_{N_c}}(q_{N_c})|0\rangle, \tag{35}$$

where all the momenta are positive, and Z is symmetric in $p_1, \ldots, p_s$ and antisymmetric in $p_{s+1}, \ldots, p_{N_c}$, as we have seen in Sec. II. The negative momenta case,

$$\int \epsilon^{\alpha_1 \alpha_2 \cdots \alpha_{N_c}} \overline{Z}(q_1, \ldots, q_k; q_{k+1}, \ldots, q_{N_c}) \chi_{\alpha_1}(q_1) \ldots \chi_{\alpha_k}(q_k) a_{\alpha_{k+1}}(q_{k+1}) \ldots a_{\alpha_{N_c}}(q_{N_c})|0\rangle, \tag{36}$$

where all the momenta are negative, and similar symmetry properties for $\overline{Z}$ correspond to an antibaryon and $\hat{\mathbf{B}}$ acting on such a state gives -1. So we identify the large-N_c limit of the baryon number operator as

$$\mathbf{B} = -\tfrac{1}{2}\mathrm{Str}_{\hat{\epsilon}}(\Phi - \hat{\epsilon}). \tag{37}$$

We show in Appendix A that the baryon number operator is indeed an integer using the geometry of our phase space. We will leave the discussion of the geometry of the phase space at this point and return to the dynamics.

IV. THE LINEAR APPROXIMATION

In this section we discuss the linear approximation to the above-mentioned theory. At present we do not have a simple physical interpretation of the full equations of motion. In principle they are straightforward to compute using the Hamiltonians we have and the defining Poisson brackets. Our phase space is defined by the Poisson brackets we get from the supercommutators for this system in the large-N_c limit and the constraints which define the global nature of the phase space. We note that part of the interactions of this theory are in these constraints. We give the super-Poisson brackets that define the kinematics of our theory:

$$\begin{aligned}
\{M(p,q), M(r,s)\} &= -2i[M(p,s)\delta[q-r] - M(r,q)\delta[p-s] \\
&\quad - \delta[p-s]\delta[q-r](\mathrm{sgn}(p) - \mathrm{sgn}(q))], \\
\{N(p,q), N(r,s)\} &= -2i[N(p,s)\mathrm{sgn}(q)\delta[q-r] - N(r,q)\mathrm{sgn}(p)\delta[p-s] \\
&\quad - \delta[q-r]\delta[p-s](\mathrm{sgn}(p) - \mathrm{sgn}(q))], \\
\{Q(p,q), \overline{Q}(r,s)\}_+ &= -2i[M(p,s)\mathrm{sgn}(q)\delta[q-r] + N(r,q)\delta[p-s] \\
&\quad + \delta[p-s]\delta[q-r](1 - \mathrm{sgn}(p)\mathrm{sgn}(q))], \\
\{M(p,q), Q(r,s)\} &= -2i\,\delta[q-r]Q(p,s),
\end{aligned} \tag{38}$$

$$\{N(p,q),Q(r,s)\}=2i\delta[p-s]\mathrm{sgn}(p)Q(r,q),$$

$$\{M(p,q),\overline{Q}(r,s)\}=2i\delta[p-s]\overline{Q}(r,q),$$

$$\{N(p,q),\overline{Q}(r,s)\}=-2i\delta[q-r]\mathrm{sgn}(q)\overline{Q}(p,s).$$

We have the constraints for the basic variables given in Eq. (21).

If we are given a Hamiltonian we can compute the equations of motion using the above-mentioned super-Poisson brackets. This is a complete description of a classical system. Of course since the theory is infinite dimensional there are various delicate questions, such as, is it possible to define trajectories for any given initial data, what is the dense domain on which the Hamiltonian is defined, etc. We will not attempt to answer these questions here. In the limit $N_c\to\infty$, we can rewrite the Hamiltonians of interest in terms of these classical variables, the answers are given in Sec. II,

$$H=H_0+H_I. \tag{39}$$

Here $H_0=\int[\mathrm{d}p]h_F(p)M(p,p)+\int[\mathrm{d}p]h_B(p)N(p,p)$, and we take $h_F(p)=(M_F^2/4)(1/p)$ and $h_B(p)=(M_B^2/4)(1/|p|)$ with the interpretation that these mass terms are given by the previous expressions. H_I, the interaction part, is given generally by

$$H_I=\int[\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t]G_1(p,q;s,t)M(p,q)M(s,t)+\int[\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t]G_2(p,q;s,t)N(p,q)N(s,t)$$
$$+\int[\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t]G_3(p,q;s,t)Q(p,q)\overline{Q}(s,t).$$

In Sec. V, it will be useful to keep this general form of the Hamiltonian, but their explicit forms are given in the discussion of the models in Sec. II in (16), (17), (19); we will use them directly (in the calculations we keep μ^2 always, for the first model we must set $\mu^2=0$).

It is straightforward to find the resulting nonlinear equations of motion simply by computing

$$\frac{\partial O(x^-)}{\partial x^-}=\{O(x^-),H\}_s, \tag{40}$$

for any observable O of the theory (we allow for an odd Hamiltonian in the above-mentioned form, but in our cases, the Hamiltonians are even). However, it is simpler to first look at the linearization where everything decouples (equations for M and N were analyzed in this approximation in previous publications[7,18,6]). We will see that we get the same equations for M,N as in Refs. 7 and 18 in our linearized theory.

Let us ignore all the quadratic terms in the equations of motion and all the quadratic terms in the constraints. First let us write down the resulting constraints in this approximation:

$$\epsilon M+M\epsilon=0,$$

$$\epsilon N\epsilon+N=0,$$

$$\epsilon Q^\dagger\epsilon+Q^\dagger=0,$$

$$\epsilon Q+Q\epsilon=0.$$

We note that the last two equations are identical and the constraints on these variables decouple, hence they can be solved independently. The solutions are

$$M(u,v)=0,\quad N(u,v)=0,\quad Q(u,v)=0\quad\text{for}\quad uv>0. \tag{41}$$

The other components, that is the ones which have opposite sign momenta, are not restricted. The equations of motion one gets for the variable M in the linear approximation are (for $u>0, v<0$):

$$\frac{\partial M(u,v;x^-)}{\partial x^-}=i\frac{M_F^2}{2}\left(\frac{1}{u}-\frac{1}{v}\right)M(u,v)-\frac{ig^2}{2\pi}\int_{-(u-v)/2}^{(u-v)/2}\mathrm{d}p\,\frac{M\left(p-\frac{u-v}{2},p+\frac{u-v}{2}\right)}{\left(p-\frac{u+v}{2}\right)^2}, \quad (42)$$

which is identical with the one in Refs. 7 and 6. If we make the ansatz (see Ref. 7) $M(u,v)=\xi_M(x)e^{iP_-x^-}$, where $x=u/(u-v)$, and define the invariant mass $\Lambda_M^2=2P_-(u-v)$—recall that $(u-v)=P_+$—we get

$$\Lambda_M^2\xi_M(x)=M_F^2\left(\frac{1}{x}+\frac{1}{1-x}\right)\xi_M(x)-\frac{g^2}{\pi}\int_0^1\frac{\mathrm{d}y}{(y-x)^2}\xi_M(y). \quad (43)$$

This is the well-known 't Hooft equation.[10] Similarly for $N(u,v)$ using the same type of ansatz, $N(u,v)=\xi_N(x)e^{iP_-x^-}$, and the invariant mass $\Lambda_N^2=2P_-(u-v)$, we get

$$\Lambda_N^2\xi_N(x)=M_B^2\left(\frac{1}{x}+\frac{1}{1-x}\right)\xi_N(x)-\frac{g^2}{4\pi}\int_0^1\frac{\mathrm{d}y}{(y-x)^2}\frac{(x+y)(2-x-y)}{\sqrt{x(1-x)y(1-y)}}\xi_N(y)$$
$$+\frac{\lambda^2}{8\pi}\int_0^1\frac{\mathrm{d}y}{\sqrt{x(1-x)y(1-y)}}\xi_N(y). \quad (44)$$

This is the bosonic analog of the 't Hooft equation.[15,16,17,19] The equations for $Q,\overline{Q}$ are given in Sec. V in a slightly more general context, so we will not repeat it here. If we again use an ansatz for the $Q(u,v)$ given by $Q(u,v;x^-)=c_Q(x)e^{iP_-x^-}$ and the same interpretation of the symbols, and an invariant mass, $\Lambda_Q^2=2P_-(u-v)$, we get

$$\Lambda_Q^2c_Q(x)=\left(\frac{M_F^2}{x}+\frac{M_B^2}{1-x}\right)c_Q(x)-\frac{g^2}{2\pi}\int_0^1\frac{\mathrm{d}y}{(y-x)^2}\frac{2-x-y}{\sqrt{(1-x)(1-y)}}c_Q(y)$$
$$+\frac{\mu^2}{4\pi}\int_0^1\frac{\mathrm{d}y}{\sqrt{(1-y)(1-x)}}c_Q(y). \quad (45)$$

Setting $\mu^2=0$ we recover the equations found by Aoki.[20,21] Similarly for the complex conjugate variable $\overline{Q}$, we get

$$\Lambda_{\overline{Q}}^2c_{\overline{Q}}(x)=\left(\frac{M_B^2}{x}+\frac{M_F^2}{1-x}\right)c_{\overline{Q}}(x)-\frac{g^2}{2\pi}\int_0^1\frac{\mathrm{d}y}{(y-x)^2}\frac{x+y}{\sqrt{xy}}c_{\overline{Q}}(y)+\frac{\mu^2}{4\pi}\int_0^1\frac{\mathrm{d}y}{\sqrt{yx}}c_{\overline{Q}}(y). \quad (46)$$

We remark that the equation for $c_{\overline{Q}}$ can be obtained from the equation for c_Q if we make the change of variable $x\mapsto 1-x$, and interchange M_B and M_F and use the principal value prescription (this ultimately comes from the charge conjugation invariance).

The properties of these equations have been discussed in the literature. The two kernels above differ from the ones given in Refs. 10, 15, 20, and 21 by a relatively compact perturbation so they behave in the same way. What is remarkable about them is that they only allow for discrete spectrum, they do not have scattering states. The corresponding eigenvectors form a basis.

We make a short digression and note an interesting limit: in the second model let us set $g^2=0$. There is no coupling to gauge fields thus there is no reason to assume that the observables

of the theory are color invariant. We can study this case along the same lines assuming *it is a sort of mean-field approximation only* and we search for bound states of a fermion and a boson in the linear approximation. The Hamiltonian is quite simple,

$$H=\frac{1}{4}m_B^2\int\frac{[\mathrm{d}p]}{|p|}N(p,p)+\frac{\mu^2}{16}\int\frac{[\mathrm{d}p\ \mathrm{d}q\ \mathrm{d}s\ \mathrm{d}t]}{\sqrt{|qs|}}\frac{\delta[p-q+s-t]}{t-s}Q(p,q)\overline{Q}(s,t). \tag{47}$$

The linearization is the same as before, for the bound state solution we obtain Eq. (44) with $g^2=0$. Unfortunately this equation will not have a solution for the bound state energy. We need the opposite sign in the Hamiltonian for the coupling of $Q\overline{Q}$. It is an amusing exercise to check that the seemingly different interaction $i\mu(\phi^{*\alpha}\psi_R^*\psi_{L\alpha}-\psi_L^{*\alpha}\psi_R\phi_\alpha)$ produces the same Hamiltonian, so we will still not find a bound state for fermion–boson pair. We hope to come back to some of these issues in a separate work.

V. BEYOND THE LINEAR APPROXIMATION

In this section we will discuss the equations of motion of our theory in a semilinear approximation. The exact equations of motion can of course be written, but it is hard to grasp their meaning at this point for the most general case. It will be interesting to look at other approximations to see what new information they contain.

Our first semilinear approach is this: We will keep everything linear in the variables M and N and terms second order in Q and $Q^\dagger$ only. We will drop terms of the form MQ, NQ and M^2,N^2. Even though we have not found a justification for why this should be a good approximation, we expect that it may give us a better feeling for the system. We first show that this is a consistent approximation, that is, if the equations of motion are also kept to the same approximation, the truncated constraints are preserved.

The constraints in this new approximation become

$$M\epsilon+\epsilon M+Q\epsilon Q^\dagger=0,$$

$$Q\epsilon+\epsilon Q=0,$$

$$\epsilon N\epsilon+N+\epsilon Q^\dagger Q=0.$$

We should also obtain semilinearized equations of motion for these variables. We now show that the linearized constraints are left invariant by the semilinearized equations of motion. We will present the proof for a general quadratic Hamiltonian. The solution of the constraint on Q is simple: $Q(u,v)=0$ when u and v have the same sign. We notice that the first constraint does not impose anything on $M(u,v)$ for $u>0,v<0$ or $u<0,v>0$, and the constraint is consistent since for this case we have $\int Q(u,q)[-\mathrm{sgn}(q)]\overline{Q}(q,v)[\mathrm{d}q]=0$. Thus we should look at $u>0,v>0$ or both negative case for M in the constraint:

$$-2M(u,v)+\int Q(u,q)[-\mathrm{sgn}(q)]\overline{Q}(q,v)[\mathrm{d}q]=-2M(u,v)+\int_{-\infty}^{0}[\mathrm{d}q]Q(u,q)\overline{Q}(q,v)=0. \tag{48}$$

Let us check that it is preserved by the linearized equations of motion,

$$\frac{\partial M(u,v)}{\partial x^-}=\{M(u,v),H\}=2i(h_F(u)-h_F(v))M(u,v)+\int [\mathrm{d}p\ \mathrm{d}r\ \mathrm{d}s\ \mathrm{d}t]G_1(p,r,s,t)$$

$$\times\{M(u,v),M(p,r)M(s,t)\}+\int [\mathrm{d}p\ \mathrm{d}r\ \mathrm{d}r\ \mathrm{d}t]G_3(p,r,s,t)\{M(u,v),Q(p,r)\overline{Q}(s,t)\})$$

$$=2i(h_F(u)-h_F(v))M(u,v)+4i\int [\mathrm{d}p\ \mathrm{d}r]G_1(p,r;v,u)M(p,r)[\mathrm{sgn}(u)-\mathrm{sgn}(v)]$$

$$-2i\int [\mathrm{d}r\ \mathrm{d}s\ \mathrm{d}t]G_3(v,r,s,t)Q(u,r)\overline{Q}(s,t)$$

$$+2i\int [\mathrm{d}p\ \mathrm{d}r\ \mathrm{d}s]G_3(p,r,s,u)Q(p,r)\overline{Q}(s,v).$$

The equations of motion for Q in this approximation become

$$\frac{\partial Q(u,q)}{\partial x^-}=2ih_F(u)Q(u,q)-2i\,\mathrm{sgn}(q)h_B(q)Q(u,q)$$

$$+2i\int G_3(p,r,q,u)Q(p,r)[1-\mathrm{sgn}(u)\mathrm{sgn}(q)]. \tag{49}$$

Similarly for $Q^\dagger$,

$$\frac{\partial \overline{Q}(q,v)}{\partial x^-}=-2ih_F(v)\overline{Q}(q,v)+2i\,\mathrm{sgn}(q)h_B(q)\overline{Q}(q,v)$$

$$-2i\int G_3(v,q;s,t)\overline{Q}(s,t)[1-\mathrm{sgn}(v)\mathrm{sgn}(q)]. \tag{50}$$

Combining these equations and using the constraint again we obtain

$$2\frac{\partial M(u,v)}{\partial x^-}-\int_{-\infty}^{0}\left[\frac{\partial Q(u,q)}{\partial x^-}\overline{Q}(q,v)+Q(u,q)\frac{\partial \overline{Q}(q,v)}{\partial x^-}\right][\mathrm{d}q]=0. \tag{51}$$

Using the same equations, we can check that the condition $Q(u,v)=0$ when u, v have the same sign, is also preserved by the equations of motion, hence also for $\overline{Q}(u,v)$.

We write down the equation of motion for $N(u,v)$,

$$\frac{\partial N(u,v)}{\partial x^-}=2i[h_B(u)\mathrm{sgn}(u)-h_B(v)\mathrm{sgn}(v)]N(u,v)$$

$$+4i\int [\mathrm{d}p\ \mathrm{d}q]G_2(p,q;v,u)[\mathrm{sgn}(u)-\mathrm{sgn}(v)]N(p,q)$$

$$+2i\int [\mathrm{d}p\ \mathrm{d}q\ \mathrm{d}t][G_3(p,u;q,t)Q(p,v)\overline{Q}(q,t)\mathrm{sgn}(u)$$

$$-G_3(p,q;v,t)Q(p,q)\overline{Q}(u,t)\mathrm{sgn}(v)].$$

Using the above-mentioned equations of motion we can check that the truncated constraint on N is preserved under time evolution:

$$(1+\mathrm{sgn}(u)\mathrm{sgn}(v))\frac{\partial N(u,v)}{\partial x^-}-\mathrm{sgn}(u)\int_{-\infty}^{0}[\mathrm{d}q]\left[\frac{\partial\overline{Q}(u,q)}{\partial x^-}Q(q,v)+\overline{Q}(u,q)\frac{\partial Q(q,v)}{\partial x^-}\right]=0. \tag{52}$$

Next we discuss the equations of motion for the unconstraint components. From the above-mentioned equations we see that the equations for Q and $Q^\dagger$ are independent of M and N, therefore they can be solved independently. Furthermore, the solution acts as a source term for the M and N equations. Let us write down the equation of motion for Q in the case of $u>0$ and $v<0$ for our model:

$$\begin{aligned}\frac{\partial Q(u,v)}{\partial x^-}&=2ih_F(u)Q(u,v)+2ih_B(v)Q(u,v)\\&\quad+i\frac{\mu^2}{8(u-v)}\int_{-(u-v)/2}^{(u-v)/2}[\mathrm{d}q]\frac{Q\left(q-\frac{u-v}{2},q+\frac{u-v}{2}\right)}{\sqrt{\left|q+\frac{u-v}{2}\right||v|}}\\&\quad-i\frac{g^2}{2}\int_{-(u-v)/2}^{(u-v)/2}[\mathrm{d}p]\frac{p-\frac{u}{2}+\frac{3v}{2}}{\left(p-\frac{u+v}{2}\right)^2}\frac{Q\left(p+\frac{u-v}{2},p-\frac{u-v}{2}\right)}{\sqrt{\left|p-\frac{u-v}{2}\right||v|}}.\end{aligned}$$

A similar equation for $\overline{Q}(u,v)$ holds [which can also be found by complex conjugation of the $Q(v,u)$].

Notice that the equations of motion for $M(u,v)$ (for $u>0,v<0$) become

$$\begin{aligned}\frac{\partial M(u,v)}{\partial x^-}&=2i(h_F(u)-h_F(v))M(u,v)-ig^2\int[\mathrm{d}s]\frac{M(s+(u-v)/2,s-(u-v)/2)}{[s-(u+v)/2]^2}\\&\quad+\frac{ig^2}{4}\int[\mathrm{d}q\,\mathrm{d}s]\frac{q+s}{(q-s)^2}\frac{1}{\sqrt{|qs|}}[Q(q+u-s,q)\overline{Q}(s,v)-Q(u,q)\overline{Q}(s,v+s-q)]\\&\quad-\frac{i\mu^2}{8}\int\frac{[\mathrm{d}q\,\mathrm{d}s]}{\sqrt{|qs|}}\left[\frac{Q(u,q)\overline{Q}(s,s-v+q)}{v-q}-\frac{Q(u+q-s,q)\overline{Q}(s,v)}{u-s}\right].\end{aligned}$$

We note that in the second term on the right we should separate the constrained variables of M from the unconstrained ones. At the same time we do some shift of integration variables, and obtain

$$\begin{aligned}\frac{\partial M(u,v;x^-)}{\partial x^-}&=i\frac{M_F^2}{2}\left[\frac{1}{u}-\frac{1}{v}\right]M(u,v)-ig^2\int_{-(u-v)/2}^{(u-v)/2}[\mathrm{d}s]\frac{M(s+(u-v)/2,s-(u-v)/2)}{[s-(u+v)/2]^2}\\&\quad+f_+(u,v;x^-)+f_-(u,v;x^-)+g_+(u,v;x^-)+g_-(u,v;x^-)+Y_+(u,v;x^-)\\&\quad+Y_-(u,v;x^-),\end{aligned}$$

where all the forcing terms are functions of $Q,\overline{Q}$ and their explicit expressions are given in Appendix B. Note that once we know the solution for Q and $Q^\dagger$, f's, g's, and Y's just become-

time dependent sources for the M and N equations. Therefore we can think of this as a forced linear equation. Let us also write down the resulting equation of motion for $N(u,v)$, for $u>0$, $v<0$,

$$\frac{\partial N(u,v;x^-)}{\partial x^-}=i\frac{M_B^2}{2}\left[\frac{1}{u}-\frac{1}{v}\right]N(u,v)+i\int_{-(u-v)/2}^{(u-v)/2}[\mathrm{ds}]$$
$$\times\frac{N(s+(u-v)/2,s-(u-v)/2)}{\sqrt{\left|s-\frac{u-v}{2}\right|\left|s+\frac{u-v}{2}\right||uv|}}\left[\frac{g^2}{4}\frac{\left(s+\frac{3u}{2}-\frac{v}{2}\right)\left(s+\frac{3v}{2}-\frac{u}{2}\right)}{\left[s-\frac{(u+v)}{2}\right]^2}-\frac{\lambda^2}{8}\right]$$
$$+\tilde{f}_+(u,v;x^-)+\tilde{f}_-(u,v;x^-)+\tilde{g}_+(u,v;x^-)+\tilde{g}_-(u,v;x^-)+\tilde{Y}_+(u,v;x^-)$$
$$+\tilde{Y}_-(u,v;x^-),$$

where we again have the forcing terms determined by the variables $Q,\overline{Q}$ (the explicit formulas are given in Appendix B).

We can give a rough argument of how these equations behave. If we look at the formulas given in Appendix B, we notice that the singular looking kernels are actually harmless, since the integration regions are outside of the singular points. This means that once we have the solutions for the $Q,\overline{Q}$ variables we can treat them as small perturbations to the equations. If we could find the Green's function for these linear operator equations given the sources we should be able to solve them. Let us assume that we have the linear equation $i(\partial M/\partial x^-)=\mathbf{L}M+S(x^-)$, where $\mathbf{L}$ is a linear Hermitian operator. If we know the eigenvectors $\mathbf{L}M_\lambda=\lambda M_\lambda$ then we can use a general ansatz as $M=\Sigma_\lambda a_\lambda(x^-)M_\lambda(x^-)$, and get $a_\lambda(x^-)=-i\int_0^{x^-}\mathrm{d}x^-<M_\lambda(x^-),S(x^-)>$. (In our case the leading singular integral operators are Hermitian and have only discrete spectrum, hence the expansion makes sense). This is the full solution and represents transition probabilities among the stationary states of the operator $\mathbf{L}$. Perhaps it is better to think of the ordinary forced harmonic oscillator problem. When we have a time-dependent forcing, this causes transitions between the stationary levels of the oscillator. So, without actually solving the above equation we see that the forcing terms will cause transition between the stationary levels. That physically means that the energy levels of the mesons will have a broadening due to possible transitions.

There is another possible approximation, for which we drop all MM, NN, and $Q\overline{Q}$ terms and allow for the cross terms MQ, NQ, etc., and neglect any higher orders. In some sense this is the complementary approximation to the previous one. This implies that we should write the constraint as

$$M\epsilon+\epsilon M=0,$$

$$MQ+Q\epsilon N+\epsilon Q+Q\epsilon=0,$$

$$\epsilon N\epsilon+N=0.$$

The first and the last equations are familiar conditions. The middle one has the following solution (in the given approximation): For $u,v>0$ [recall that $\epsilon(p)=-\mathrm{sgn}(p)$],

$$-2Q(u,v)+\int_{-\infty}^{0}[\mathrm{d}q]M(u,q)Q(q,v)+\int_{-\infty}^{0}[\mathrm{d}q]Q(u,q)(-\mathrm{sgn}(q))N(q,v)=0. \qquad (53)$$

For $u>0,v<0$ we have

$$\int_{-\infty}^{0}[\mathrm{d}q]M(u,q)Q(q,v)-\int_{0}^{\infty}[\mathrm{d}q]Q(u,q)N(q,v)=0. \tag{54}$$

We satisfy the lower equation by noting that the same momenta case for Q is given by the first constraint and the integrands then become of lower order in this case. The consistency of these approximations could be checked. In fact if we write down the time derivative of the above-mentioned constraint,

$$-2\frac{\partial Q(u,v)}{\partial x^-}+\int_{-\infty}^{0}[\mathrm{d}q]\left(\frac{\partial M(u,q)}{\partial x^-}Q(q,v)+M(u,q)\frac{\partial Q(q,v)}{\partial x^-}\right)$$
$$+\int_{-\infty}^{0}[\mathrm{d}q]\left(\frac{\partial Q(u,q)}{\partial x^-}N(q,v)+Q(u,q)\frac{\partial N(q,v)}{\partial x^-}\right)=0.$$

To see this we use

$$\frac{\partial Q(u,v;x^-)}{\partial x^-}=4i\int[\mathrm{d}p\ \mathrm{d}s\ \mathrm{d}t]G_1(p,u;s,t)Q(p,v)M(s,t)$$
$$-4i\int[\mathrm{d}q\ \mathrm{d}s\ \mathrm{d}t]G_2(v,q;s,t)Q(u,q)N(s,t)\mathrm{sgn}(v)+2i(h_F(u)$$
$$-\mathrm{sgn}(v)h_B(v))Q(u,v)+2i\int[\mathrm{d}p\ \mathrm{d}q\ \mathrm{d}t]G_3(p,q;v,t)Q(p,q)M(u,t)\mathrm{sgn}(v)$$
$$+2i\int[\mathrm{d}p\ \mathrm{d}q\ \mathrm{d}s]G_3(p,q;s,u)Q(p,q)N(s,v)$$
$$+2i\int[\mathrm{d}p\ \mathrm{d}q]G_3(p,q;v,u)Q(p,q)[1-\mathrm{sgn}(u)\mathrm{sgn}(v)].$$

For the first time derivative in the constraint we insert this expression, for the time derivatives of Q inside the integral we only retain the linear terms in Q, since other combinations are of lower order by assumption. We should also use the equations of motion of M and N for the opposite momenta case and only within the linear approximation as is given in the previous semilinear case, we do not repeat them, higher order terms get multiplied by Q and become small. Then we see that the constraint is preserved within the given approximation.

This time we have decoupled linear equations for M and N for the opposite momenta case, since we ignore $Q\overline{Q}$ type terms, and in principle they can be solved independently. When we look at the equations for Q, we should again be careful. The opposite momenta case is to be treated as independent dynamical variables: if we use the constraint equation, we may express the same sign momenta in terms of the solutions of M and N and the opposite momenta terms of Q. When we look at the opposite sign momenta equation for Q we may separate the same sign momenta contributions in the integral operators. But these same momenta terms in the integral equation become of higher order, since all these terms are multiplied by other variables, and the central part vanishes in this case, hence they can be dropped. Let us denote the resulting integral equation which only acts on the opposite momenta terms by **K**, this is the expression we have found before, and write the remaining parts as an abstract integral operator $\mathbf{F}(x^-)$. Notice that it has dependence on x^- via the solutions of M and N. The time dependence of M and N is rather simple for this case, since we have singular integral equations with discrete spectra. We can in principle substitute the solutions we picked into this equation. Hence we have an integral equation

$$\frac{\partial Q(u,v;x^-)}{\partial x^-}=[\mathbf{K}Q](u,v;x^-)+[\mathbf{F}(x^-)Q](u,v;x^-). \tag{55}$$

It is most natural to think of the last term as a time-dependent perturbation. We can write this perturbation term $\mathbf{F}(x^-)$:

$$
\begin{aligned}
[\mathbf{F}(x^-)Q](u,v;x^-) = &-\frac{ig^2}{2}\left[\int_0^u [\mathrm{d}s]\int_0^{u-s}[\mathrm{d}p]+\int_{-\infty}^0[\mathrm{d}s]\int_{u-s}^{\infty}[\mathrm{d}p]\right]\frac{M(s,s+p-u;x^-)}{(s-u)^2}Q(p,v)\\
&+i\left[\int_{-\infty}^v[\mathrm{d}q]\int_0^{v-q}[\mathrm{d}t]+\int_v^0[\mathrm{d}q]\int_{v-q}^0[\mathrm{d}t]\right]\\
&\times\left[\frac{g^2}{8}\frac{(t+q)^2+(q-v)^2-2q^2}{(v-t)^2}-\frac{\lambda^2}{16}\right]\frac{N(t+q-v,t;x^-)}{\sqrt{|vq(t+q-v)|}}Q(u,q)\\
&-i\left[\int_v^0[\mathrm{d}t]\int_0^{t-v}[\mathrm{d}p]+\int_{-\infty}^v[\mathrm{d}t]\int_{t-v}^0[\mathrm{d}p]\right]\\
&\times\left(\frac{\mu^2}{8(t-v)}+\frac{g^2}{4}\frac{p-t+2v}{(p-t)^2}\right)\frac{M(u,t;x^-)}{\sqrt{|(p-t+v)v|}}Q(p,p-t+v)\\
&+i\left[\int_0^u[\mathrm{d}s]\int_0^{u-s}[\mathrm{d}p]+\int_u^{\infty}[\mathrm{d}s]\int_{u-s}^0[\mathrm{d}p]\right]\\
&\times\left(\frac{\mu^2}{8(u-s)}+\frac{g^2}{4}\frac{p+2s-u}{(p-u)^2}\right)\frac{N(s,v;x^-)}{\sqrt{|(p+s-u)s|}}Q(p,p+s-u).
\end{aligned}
$$

The method of solving such equations is known in principle. We can treat the last term as a truly time-dependent perturbation, but this time it involves the unknown itself and thus cannot be solved in closed form. However, we can solve it perturbatively. The kernels again do not become singular within the given ranges of the integrals except at the boundaries. The singularities are not as severe and we expect that the perturbations are small, so that one can obtain a reasonable answer from this approach. We will not go into further details, but the basic result is again the possibility of transitions between the different levels of the boson–fermion mesons due to the interactions.

ACKNOWLEDGMENTS

First of all we would like to thank S. G. Rajeev for various useful discussions and suggestions. E. Langmann's efforts improved the presentation considerably. The revision was done while O.T. Turgut was in KTH, as a Gustafsson fellow. We thank K. Bardakci for useful discussions. A.K. thanks Feza Gursey Institute for hospitality during the summer of 99 where this work began. O.T.T. would like to acknowledge discussions with M. Arik, K. Gawedzki, J. Gracia-Bondia, J. Mickelsson, R. Nest, Y. Nutku, C. Saclioglu, and M. Walze. He also would like to thank E. Schrohe for an opportunity to present this work in Potsdam and for the hospitality, as well as W. Zakrzewski for the kind invitation to talk in Durham and for the hospitality of the theory group, and Lawrence Berkeley National Laboratory for the invitation to complete this work.

The work of A.K. was partially supported by the Director, Office of Energy Research, Office of High Energy and Nuclear Physics, Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC03-76SF00098 and partially by National Science Foundation Grant No. PHY-95-14797.

APPENDIX A: BARYON NUMBER

We define the Fredholm operators in a $\mathbf{Z}_2$ graded context as in the ordinary case (there is an extension to the $\mathbf{Z}$ grading which should fit to our model better: The definition of the Fredholm operator shows that the body is an ordinary Fredholm operator and the rest is compact. So in the

following use the body for all the formulas, and take the supertrace of $\Phi-\hat{\epsilon}$'s body part): a Fredholm operator is an invertible operator up to compact operators. This again implies the kernel and the cokernel are actually finite dimensional. Let us write down the kernel in a decomposition $V_e|V_o$, and define a superdimension, which is the dimension of the even part of the kernel minus the dimension of the odd part. $\mathrm{Sdim}(\mathrm{Ker}(A))=\dim(P_e\mathrm{Ker}(A)P_e)-\dim(P_o\mathrm{Ker}(A)P_o)$, where P_e and P_o denote projections onto the even and odd subspaces, respectively. Then the index should be

$$\mathrm{SInd}(A)=\mathrm{Sdim}(\mathrm{Ker}(A))-\mathrm{Sdim}(\mathrm{Coker}(A)). \tag{A1}$$

We can extend the Calderon theorem to our case (see Ref. 31 for a good introduction and the original result): If we have an operator A which is Fredholm, and assume we have an operator B such that $(I-AB)^m$ and $(I-BA)^m$ are trace class for an integer m, then we can compute the super-Fredholm index as $\mathrm{Str}(I-BA)^m-\mathrm{Str}(I-AB)^m$. Let us now see that in our problem the supertrace of Φ is indeed this index. It will be more convenient to decompose our operator with respect to the positive and negative subspaces, thus we write everything with respect to $\mathcal{H}_+|\mathcal{H}_+\oplus\mathcal{H}_-|\mathcal{H}_-$. We do not repeat odd and even superscripts, since the bar indicates this separation. In this decomposition our group conditions can be found from

$$g^\dagger Eg=E,\quad gEg^\dagger=E,\quad E=\begin{pmatrix}\epsilon & 0\\ 0 & 1\end{pmatrix}, \tag{A2}$$

so E is the same as before in this matrix representation, it is interpreted differently. The orbit is with respect to this decomposition,

$$\Phi=g\hat{\epsilon}g^{-1},\quad \hat{\epsilon}=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix}. \tag{A3}$$

So if we write $g:\mathcal{H}_+|\mathcal{H}_+\oplus\mathcal{H}_-|\mathcal{H}_-\to\mathcal{H}_+|\mathcal{H}_+\oplus\mathcal{H}_-|\mathcal{H}_-$, explicitly, we have

$$g=\begin{pmatrix}A & B\\ C & D\end{pmatrix}\quad B,\quad C\in\mathcal{I}_2(\mathcal{H}_\mp|\mathcal{H}_\mp,\mathcal{H}_\pm|\mathcal{H}_\pm). \tag{A4}$$

From the first group condition we get, $A^\dagger\epsilon A+C^\dagger C=\epsilon$ and $D^\dagger D+B^\dagger\epsilon B=1$ and from the second one we get $A\epsilon A^\dagger+BB^\dagger=\epsilon$ and $DD^\dagger+C\epsilon C^\dagger=1$. Since B,C are Hilbert–Schmidt in the more generalized sense, we have A,D super-Fredholm. Further we can use the above-mentioned theorem to compute the index of A,D, for example,

$$\mathrm{SInd}(D)=\mathrm{Str}(B^\dagger\epsilon B)-\mathrm{Str}(C\epsilon C^\dagger). \tag{A5}$$

Let us compute the conditional supertrace of $\Phi-\hat{\epsilon}$, (in fact we see that this is the correct way we should be computing it), first we write it explicitly with respect to the above-given decomposition,

$$g\hat{\epsilon}g^{-1}-\hat{\epsilon}=\begin{pmatrix}-A\epsilon A^\dagger\epsilon+BB^\dagger\epsilon+1 & *\\ * & -C\epsilon C^\dagger+D\epsilon D^\dagger-1\end{pmatrix}. \tag{A6}$$

If we use the above-mentioned group properties, we get

$$\Phi-\hat{\epsilon}=\begin{pmatrix}2BB^\dagger\epsilon & *\\ * & -2C\epsilon C^\dagger\end{pmatrix}. \tag{A7}$$

The conditional supertrace of this operator gives us, $\mathrm{Str}_\epsilon(\Phi-\hat{\epsilon})=2(\mathrm{Str}(BB^\dagger\epsilon)-\mathrm{Str}(C\epsilon C^\dagger))$, which is equal to $2\,\mathrm{SInd}(D)$ (using $\mathrm{Str}(BB^\dagger\epsilon)=\mathrm{Str}(B^\dagger\epsilon B)$). Thus we prove using only the geometry of the super-Grassmanian that this is an integer.

APPENDIX B: FORCING TERMS

Here we present the forcing functions for the inhomogeneous equations of Sec. V. The ones we obtained for M in the first semilinear approximation are given by

$$f_+(u,v;x^-)=-i\frac{g^2}{2}\int_{(u-v)/2}^{\infty}[\mathrm{d}p]\int_{-\infty}^{0}[\mathrm{d}q]\frac{Q\left(p-\frac{u-v}{2},q\right)\overline{Q}\left(q,p+\frac{u-v}{2}\right)}{\left[p-\frac{u+v}{2}\right]^2},$$

$$f_-(u,v;x^-)=-i\frac{g^2}{2}\int_{-\infty}^{-(u-v)/2}[\mathrm{d}p]\int_{0}^{\infty}[\mathrm{d}q]\frac{Q\left(p-\frac{u-v}{2},q\right)\overline{Q}\left(q,p+\frac{u-v}{2}\right)}{\left[p-\frac{u+v}{2}\right]^2},$$

$$g_+(u,v;x^-)=i\frac{g^2}{4}\Bigg[\int_0^u[\mathrm{d}s]\int_{-(u-s)/2}^{(u-s)/2}[\mathrm{d}q]+\int_u^{\infty}[\mathrm{d}s]\int_{-(s-u)/2}^{(s-u)/2}[\mathrm{d}q]\Bigg]\frac{q+\frac{3s}{2}-\frac{u}{2}}{\left[q-\frac{u+s}{2}\right]^2}\frac{Q\left(q+\frac{u-s}{2},q-\frac{u-s}{2}\right)\overline{Q}(s,v)}{\sqrt{\left|q-\frac{u-s}{2}\right||s|}},$$

$$g_-(u,v;x^-)=-i\frac{g^2}{4}\Bigg[\int_v^0[\mathrm{d}s]\int_{-(s-v)/2}^{(s-v)/2}[\mathrm{d}q]+\int_{-\infty}^{v}[\mathrm{d}s]\int_{-(v-s)/2}^{(v-s)/2}[\mathrm{d}q]\Bigg]\frac{q+\frac{3s}{2}-\frac{v}{2}}{\left[q-\frac{v+s}{2}\right]^2}\frac{Q(u,s)\overline{Q}\left(q-\frac{v-s}{2},q+\frac{v-s}{2}\right)}{\sqrt{\left|q-\frac{v-s}{2}\right||s|}},$$

$$Y_-(u,v;x^-)=+\frac{i\mu^2}{8}\Bigg[\int_0^u[\mathrm{d}s]\int_{-(u-s)/2}^{(u-s)/2}[\mathrm{d}q]+\int_u^{\infty}[\mathrm{d}s]\int_{-(s-u)/2}^{(s-u)/2}[\mathrm{d}q]\Bigg]\frac{Q\left(q+\frac{u-s}{2},q-\frac{u-s}{2}\right)\overline{Q}(s,v)}{(u-s)\sqrt{\left|q-\frac{u-s}{2}\right||s|}},$$

$$Y_+(u,v;x^-)=-\frac{i\mu^2}{8}\Bigg[\int_v^0[\mathrm{d}s]\int_{-(s-v)/2}^{(s-v)/2}[\mathrm{d}q]+\int_{-\infty}^{v}[\mathrm{d}s]\int_{-(v-s)/2}^{(v-s)/2}[\mathrm{d}q]\Bigg]\frac{Q(u,s)\overline{Q}\left(q-\frac{v-s}{2},q+\frac{v-s}{2}\right)}{(v-s)\sqrt{\left|q-\frac{v-s}{2}\right||s|}}.$$

The forcing terms for the first semilinear approximation for the N variable are

$$\tilde{f}_-(u,v;x^-) = -i\int_{(u-v)/2}^{\infty}[\mathrm{d}p]\int_{-\infty}^{0}[\mathrm{d}q]\frac{\overline{Q}\left(p+\frac{u-v}{2},q\right)Q\left(q,p-\frac{u-v}{2}\right)}{\sqrt{\left|p-\frac{u-v}{2}\right|\left|p+\frac{u-v}{2}\right||uv|}}$$
$$\times\left[\frac{g^2}{8}\frac{\left(p+\frac{3u}{2}-\frac{v}{2}\right)\left(p+\frac{3v}{2}-\frac{u}{2}\right)}{\left[p-\frac{u+v}{2}\right]^2}-\frac{\lambda^2}{4}\right],$$

$$\tilde{f}_+(u,v;x^-) = i\int_{-\infty}^{-(u-v)/2}[\mathrm{d}p]\int_{0}^{\infty}[\mathrm{d}q]\frac{\overline{Q}\left(p+\frac{u-v}{2},q\right)Q\left(q,p-\frac{u-v}{2}\right)}{\sqrt{\left|p-\frac{u-v}{2}\right|\left|p+\frac{u-v}{2}\right||uv|}}$$
$$\times\left[\frac{g^2}{8}\frac{\left(p+\frac{3u}{2}-\frac{v}{2}\right)\left(p+\frac{3v}{2}-\frac{u}{2}\right)}{\left[p-\frac{u+v}{2}\right]^2}-\frac{\lambda^2}{4}\right],$$

$$\tilde{g}_+(u,v;x^-) = i\frac{g^2}{4}\left[\int_0^u[\mathrm{d}p]\int_{-(u-p)/2}^{(u-p)/2}[\mathrm{d}s]\right.$$
$$\left.+\int_u^{\infty}[\mathrm{d}p]\int_{-(p-u)/2}^{(p-u)/2}[\mathrm{d}s]\right]\frac{s-\frac{p}{2}+\frac{3u}{2}}{\left[s-\frac{u+p}{2}\right]^2}\frac{Q(p,v)Q\left(s+\frac{u-p}{2},s-\frac{u-p}{2}\right)}{\sqrt{\left|s-\frac{p-u}{2}\right||u|}},$$

$$\tilde{g}_-(u,v;x^-) = i\frac{g^2}{4}\left[\int_v^0[\mathrm{d}p]\int_{-(p-v)/2}^{(p-v)/2}[\mathrm{d}s]\right.$$
$$\left.+\int_{-\infty}^{v}[\mathrm{d}p]\int_{-(v-p)/2}^{(v-p)/2}[\mathrm{d}s]\right]\frac{q+\frac{3s}{2}-\frac{v}{2}}{\left[q-\frac{v+s}{2}\right]^2}\frac{Q\left(s-\frac{v-p}{2},s+\frac{v-p}{2}\right)\overline{Q}(u,p)}{\sqrt{\left|s-\frac{p-v}{2}\right||v|}},$$

$$\tilde{Y}_+(u,v;x^-) = -\frac{i\mu^2}{8}\left[\int_0^u[\mathrm{d}p]\int_{-(u-p)/2}^{(u-p)/2}[\mathrm{d}s]\right.$$
$$\left.+\int_u^{\infty}[\mathrm{d}p]\int_{-(p-u)/2}^{(p-u)/2}[\mathrm{d}s]\right]\frac{Q(p,v)\overline{Q}\left(s+\frac{u-p}{2},s-\frac{u-p}{2}\right)}{(p-u)\sqrt{\left|s+\frac{u-p}{2}\right||u|}},$$

$$\widetilde{Y}_{-}(u,v;x^{-})=\frac{i\mu^{2}}{8}\Bigg[\int_{v}^{0}[\mathrm{d}p]\int_{-(p-v)/2}^{(p-v)2}[\mathrm{d}s]+\int_{-\infty}^{v}[\mathrm{d}p]\int_{-(v-p)/2}^{(v-p)/2}[\mathrm{d}s]\Bigg]\frac{Q\left(s-\frac{v-p}{2},s+\frac{v-p}{2}\right)\overline{Q}(u,p)}{(p-v)\sqrt{\left|s+\frac{p-v}{2}\right||v|}}.$$

Structure conserving parametrization of Feynman diagrams

E. Mendels
Schenkkade 221, 2595 AT The Hague, The Netherlands

(Received 1 December 2001; accepted for publication 4 March 2002)

Using **x**-space parameters instead of Feynman parameters, dimensionally regularized Feynman diagrams are expanded with respect to the external momenta, the internal masses, the logarithms of these masses and the regularization parameter $(\nu\text{-}\frac{1}{2}n)$. A general formula for an arbitrary Feynman diagram is obtained for any dimension n. All ultraviolet divergences appear in a direct and transparent way as poles. Their residues in the limit $(\nu\text{-}\frac{1}{2}n)\to 0$ are subseries that are recognized as subdiagrams. Relations between diagrams are transparent in all orders of perturbation theory. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1475767]

I. INTRODUCTION

In the usual formalism of quantum field theory, a Feynman diagram is represented by a momentum space integral of the type[1]

$$\prod_{\substack{1\leqslant i\leqslant f\\ 1\leqslant i'<i\\ 1\leqslant j\leqslant f-1\\ d}} \int d\mathbf{k}^d_{i',i}\,\frac{P^d_{i',i}(\boldsymbol{\gamma};\mathbf{k};m)}{(\mathbf{k}^{d\,2}_{i',i}+m^{d\,2}_{i',i})^{\alpha^d_{i',i}}}\,V_i(\boldsymbol{\gamma};\mathbf{k};m)\,\delta\left(\mathbf{p}_j-\sum_{\substack{1\leqslant a\leqslant f\\ d}}\mathbf{k}^d_{a,j}\right), \tag{1.1}$$

with

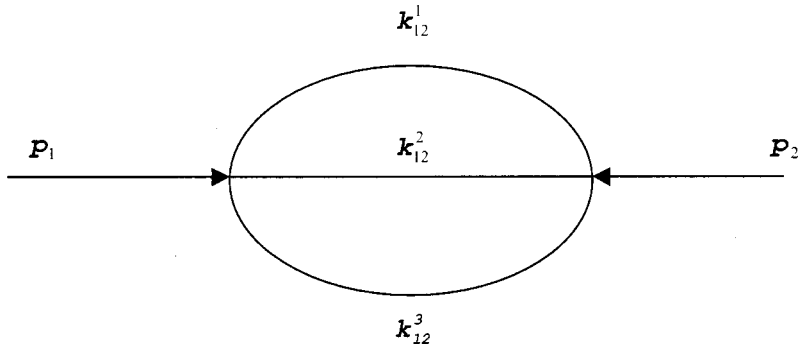
$$k^d_{a,j}=-k^d_{j,a}. \tag{1.2}$$

About the notation we remark the following points;

- Internal momenta and masses of propagators wear three indices. The two subscripts i',i indicate the vertices that they are connecting, the superscript d counts lines between these vertices.
- The exponents α in the denominator are introduced in order to clarify what happens throughout this article. In physics, they are equal to 1.
- The $i\varepsilon$-prescription of propagators has been transformed away by Wick rotations. The internal momenta, over which it is integrated, are n-dimensional Euclidean vectors.
- The numerators $P^d_{i',i}(\boldsymbol{\gamma};\mathbf{k};m)$ represent spin. They may be polynomials of matrices. In the scalar case
$$P^d_{i',i}(\boldsymbol{\gamma};\mathbf{k};m)=1, \tag{1.3}$$
and if the spin is 1/2,
$$P^d_{i',i}(\boldsymbol{\gamma};\mathbf{k};m)=\boldsymbol{\gamma}\cdot\mathbf{k}^d_{i',i}+m^d_{i',i}. \tag{1.4}$$
- The factors $V_i(\boldsymbol{\gamma};\mathbf{k};m)$ are vertex functions representing interaction. In the case of neutral scalar fields,
$$V_i(\boldsymbol{\gamma};\mathbf{k};m)=1. \tag{1.5}$$

- The number of vertices is denoted by f. The number of δ-functions, that guarantee momentum conservation in each vertex, is one less, because of overall momentum conservation:
$$\mathbf{p}_1+\mathbf{p}_2+\cdots+\mathbf{p}_f=0. \tag{1.6}$$
- Integrating away the δ-functions, the number of remaining integration vectors equals the number of independent loops.
- Remarks about notation are bulleted here and in the following sections, in order to promote legibility.

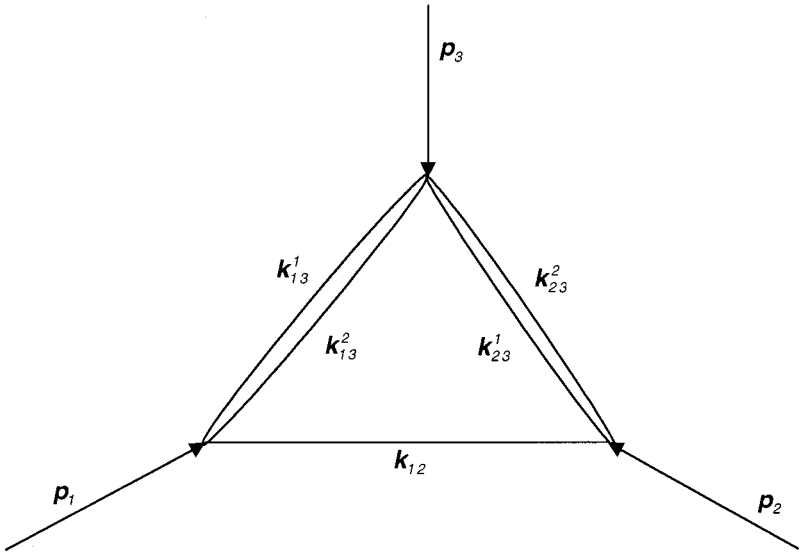
We give two diagrams as an ilustration.
The first example to be considered is the two vertice, three internal line, scalar diagram.



Its expression in momentum space is given by

$$\int d\mathbf{k}^1_{12}d\mathbf{k}^2_{12}d\mathbf{k}^3_{12}\frac{1}{(\mathbf{k}^{1\,2}_{12}+m^{1\,2}_{12})^{\alpha^1_{12}}(\mathbf{k}^{2\,2}_{12}+m^{2\,2}_{12})^{\alpha^2_{12}}(\mathbf{k}^{3\,2}_{12}+m^{3\,2}_{12})^{\alpha^3_{12}}}\,\delta(\mathbf{p}_1-\mathbf{k}^1_{12}-\mathbf{k}^2_{12}-\mathbf{k}^3_{12})$$
$$=\int d\mathbf{k}^1_{12}d\mathbf{k}^2_{12}\frac{1}{(\mathbf{k}^{1\,2}_{12}+m^{1\,2}_{12})^{\alpha^1_{12}}(\mathbf{k}^{2\,2}_{12}+m^{2\,2}_{12})^{\alpha^2_{12}}((\mathbf{p}_1-\mathbf{k}^1_{12}-\mathbf{k}^2_{12})^2+m^{3\,2}_{12})^{\alpha^3_{12}}}. \tag{1.1$'$}$$

The second example to be considered is the three vertice, five line diagram



Its momentum space representation is given by

$$\int d\mathbf{k}_{12}d\mathbf{k}_{13}^1d\mathbf{k}_{13}^2d\mathbf{k}_{23}^1d\mathbf{k}_{23}^2\delta(\mathbf{p}_1-\mathbf{k}_{12}-\mathbf{k}_{13}^1-\mathbf{k}_{13}^2)\,\delta(\mathbf{p}_2+\mathbf{k}_{12}-\mathbf{k}_{23}^1-\mathbf{k}_{23}^2)$$

$$\times\frac{1}{(\mathbf{k}_{12}{}^2+m_{12}{}^2)^{\alpha_{12}}(\mathbf{k}_{13}^1{}^2+m_{13}^1{}^2)^{\alpha_{13}^1}(\mathbf{k}_{13}^2{}^2+m_{13}^2{}^2)^{\alpha_{13}^2}(\mathbf{k}_{23}^1{}^2+m_{23}^1{}^2)^{\alpha_{23}^1}(\mathbf{k}_{23}^2{}^2+m_{23}^2{}^2)^{\alpha_{23}^2}}. \tag{1.1''}$$

In the case of charged fields, a vertex function $\mathbf{k}_a+\mathbf{k}_b$ may appear in the numerator and insertion of the identity

$$(\mathbf{k}_b-\mathbf{k}_a).\frac{(\mathbf{k}_a+\mathbf{k}_b)}{(\mathbf{k}_a{}^2+m^2)(\mathbf{k}_b{}^2+m^2)}=\frac{1}{\mathbf{k}_a{}^2+m^2}-\frac{1}{\mathbf{k}_b{}^2+m^2} \tag{1.7}$$

into (1.1) yields a relation between diagrams.

After introduction of integration parameters ρ,[2] all **k**-integrations—the ''easy integrations''—may be performed by means of Gauss integrals. Thus, (1.1′) is transformed into

$$(1.1')=\frac{(\pi^{1/2\,n})^3(4\pi)^{1/2\,n}}{(2\pi)^n}\,\frac{(m^1)^{2b^1}(m^2)^{2b^2}(m^3)^{2b^3}}{\Gamma(\alpha^1)\Gamma(\alpha^2)\Gamma(\alpha^3)}$$

$$\times\int_0^\infty d\rho^1d\rho^2d\rho^3(\rho^1)^{-b^1}(\rho^2)^{-b^2}(\rho^3)^{-b^3}\left(\frac{m^1{}^2}{\rho^1}+\frac{m^2{}^2}{\rho^2}+\frac{m^3{}^2}{\rho^3}\right)^{-(1/2)\,n}$$

$$\times\exp\left\{-\rho^1-\rho^2-\rho^3-\frac{\mathbf{p}_1^2}{m^1{}^2/\rho^1+m^2{}^2/\rho^2+m^3{}^2/\rho^3}\right\}. \tag{1.8'}$$

- The subscripts 1,2 are omitted for the sake of surveyability.

The parameter representation of (1.1′′) is

(1.1′′)

$$=\frac{(\pi^{1/2\,n})^5(4\pi)^n}{(2\pi)^{2n}}\,\frac{(m_{12})^{2b_{12}}(m'_{13})^{2b'_{13}}(m_{13}^2)^{2b_{13}^2}(m'_{23})^{2b'_{23}}(m_{23}^2)^{2b_{23}^a}}{\Gamma(\alpha_{12})\Gamma(\alpha'_{13})\Gamma(\alpha_{13}^2)\Gamma(\alpha'_{23})\Gamma(\alpha_{23}^2)}$$

$$\times\int d\rho_{12}d\rho_{13}^1d\rho_{13}^2d\rho_{23}^1d\rho_{23}^2(\rho_{12})^{-b_{12}}(\rho_{13}^1)^{-b_{13}^1}(\rho_{13}^2)^{-b_{13}^2}(\rho_{23}^1)^{-b_{23}^1}(\rho_{23}^2)^{-b_{23}^2}$$

$$\times\left\{\left(\frac{m_{13}^1{}^2}{\rho_{13}^1}+\frac{m_{13}^2{}^2}{\rho_{13}^2}\right)\left(\frac{m_{23}^1{}^2}{\rho_{23}^1}+\frac{m_{23}^2{}^2}{\rho_{23}^2}\right)+\left(\frac{m_{13}^1{}^2}{\rho_{13}^1}+\frac{m_{13}^2{}^2}{\rho_{13}^2}\right)\frac{m_{12}{}^2}{\rho_{12}}+\left(\frac{m_{23}^1{}^2}{\rho_{23}^1}+\frac{m_{23}^2{}^2}{\rho_{23}^2}\right)\frac{m_{12}{}^2}{\rho_{12}}\right\}^{-(1/2)\,n}$$

$$\times\exp\Bigg\{-\rho_{12}-\rho_{13}^1-\rho_{13}^2-\rho_{23}^1-\rho_{23}^2$$

$$-\frac{\mathbf{p}_1^2(m_{23}^1{}^2/\rho_{23}^1+m_{23}^2{}^2/\rho_{23}^2)+\mathbf{p}_2{}^2(m_{13}^1{}^2/\rho_{13}^1+m_{13}^2{}^2/\rho_{13}^2)+\mathbf{p}_3{}^2\,m_{12}{}^2/\rho_{12}}{(m_{13}^1{}^2/\rho_{13}^1+m_{13}^2{}^2/\rho_{13}^2)(m_{23}^1{}^2/\rho_{23}^1+m_{23}^2{}^2/\rho_{23}^2)+(m_{13}^1{}^2/\rho_{13}^1+m_{13}^2{}^2/\rho_{13}^2)\,m_{12}{}^2/\rho_{12}+(m_{23}^1{}^2/\rho_{23}^1+m_{23}^2{}^2/\rho_{23}^2)\,m_{12}{}^2/\rho_{12}}\Bigg\}. \tag{1.8''}$$

- The number of dimensions is denoted by n and the notation

$$b=\tfrac{1}{2}n-\alpha \tag{1.9}$$

has been used.

- The number of integration variables ρ equals the number of internal lines.

A parameter representation of the general Feynman diagram is derived in Ref. 2. A shorthand derivation is given in Appendix B.

The integrals (1.1′) and (1.1′′) are ultraviolet divergent in four dimensional space–time and so the integrals (1.8′) and (1.8′′) are divergent. They have to be regularized. Using dimensional regularization,[3] the n in (1.8′) and (1.8′′) is replaced by 2ν, which is considered to be a continuous variable.

Thus, the ultraviolet infinities in four dimensional momentum space are found back as poles at $\nu=2$ in the complex ν-plane. After a change of integration variables according to

$$\begin{aligned}\rho_1&=\rho\sigma_1,\\ \rho_2&=\rho(1-\sigma_1)\sigma_2,\\ \rho_3&=\rho(1-\sigma_1)(1-\sigma_2)\sigma_3,\\ &\text{etc.},\end{aligned}\tag{1.10}$$

the ρ-integration may be done. It yields a Γ-function being responsible for a pole at $\nu=2$. In the case of one-loop diagrams, this is the only divergence and the finite part is obtained by integration over the Feynman parameter σ.

In the case of multiple loops, integration over Feynman parameters—the ''difficult integrations''—itself may be divergent[3] and all kinds of infinities mix together. It is not easy to unravel them. It has been proposed to do it by partial integrations,[3] but even in the most simple two-loop integral (1.8′) we did not succeed. The little bit more complicated expression (1.8′′) does not look very inviting either. Anyway, there is no recipe for the general case.

The cause of this mixing of infinities is the fact that the structure of the original expression (1.1) is obscured by the Gauss integrations that were used at the derivation of (1.8′) and (1.8′′). This loss of structure is also illustrated by relation (1.7), which is not translated into a simple relation in the parameter language of (1.8′) and (1.8′′).

Dimensional regularization being introduced because the structure of the original momentum space expression is left unimpaired, it seems to be logical to combine it with a structure conserving parametrization. Because of this philosophy, it has been proposed[4] to use **x**-space parameters rather than Feynman parameters. Using these parameters, infinities were found easily in one- and two-loop diagrams.

In this article the method is extended to all orders of perturbation theory. The **x**-space parametrization is structure conserving so that relations between diagrams are transparent in all orders of perturbation theory. Moreover, all ultraviolet divergences are separated in a direct way. The **x**-parameters are a useful guide for this separation, rather than an obstacle.

Finally, the integrations over all **x**-space parameters may be done in a systematical way, partly analytically, partly numerically. In this way, a general formula, giving the expansion series with respect to external momenta, internal masses, the logarithms of these masses and the regularization parameter, is obtained in any dimension for an arbitrary Feynman diagram.

II. DIMENSIONAL REGULARIZATION IN x-SPACE

Representation (1.1) may be written by means of **x**-space integrals over polynomials, exponentials and k-functions as

$$\frac{1}{(2\pi)^{n(f-1)}}\sum_{s,t} S(s_c;s_{a,b};s^d_{a,b};t^d_{a,b})$$
$$\times\prod_{\substack{1\leqslant i\leqslant f-1\\ 1\leqslant i'<i\\ d}}\left\{\frac{2\pi^{(1/2)n}}{\Gamma(a^d_{i,f})}(m^d_{i,f})^{2b^d_{i,f}+2t^d_{i,f}}\right\}\left\{\frac{2\pi^{(1/2)n}}{\Gamma(a^d_{i',i})}(m^d_{i',i})^{2b^d_{i',i}+2t^d_{i',i}}\right\}$$
$$\times\int d\mathbf{x}_i e^{i\mathbf{p}_i\cdot\mathbf{x}_i}(x_i)^{2s_i}(\mathbf{x}_{i'}\cdot\mathbf{x}_i)^{s_{i',i}}k(b^d_{i,f}+s^d_{i,f};m^d_{i,f}x_i)k(b^d_{i',i}+s^d_{i',i};m^d_{i',i}|\mathbf{x}_i-\mathbf{x}_{i'}|). \tag{2.1}$$

- The number of **x**-space integration variables is $f-1$, one less than the number of vertices.

The functions $k(b;mx)$ differ by a factor $(mx/2)^b$ from the well known $K_b(mx)$ (Ref. 5)—the latter are named ''Bessel functions of the third kind'' or ''McDonald functions''—and are, up to another factor, the n-dimensional Fourier transform of the propagator $(\mathbf{k}^2+m^2)^{-\alpha}$:

$$\frac{2\pi^{(1/2)n}}{\Gamma(\alpha)}m^{2b}k(b;mx)=\int d\mathbf{k}e^{-i\mathbf{k}\cdot x}\frac{1}{(\mathbf{k}^2+m^2)^{\alpha}}. \tag{2.2}$$

If an internal line corresponds to mass zero, the $k(b;mx)$ has to be replaced according to

$$m^{2b}k(b;mx)\overset{m\to 0}{\to}\frac{1}{2}\Gamma(b)\left(\frac{x}{2}\right)^{-2b}. \tag{2.3}$$

Properties of the k-functions are summarized in Appendix A.

The momenta in the polynomials $P^d{}_{a,b}(\boldsymbol{\gamma};\mathbf{k};m)$ and $V_i(\boldsymbol{\gamma};\mathbf{k};m)$ become derivatives in **x**-language; the latter become, according to (A8), polynomials of $\mathbf{x}_c{}^2,\mathbf{x}_a\cdot\mathbf{x}_b$ and $(m^d{}_{a,b})^2$, in combination with higher order k-functions. The coefficients are matrices, denoted by $S(s_c;s_{a,b};s^d{}_{a,b};t^d{}_{a,b})$. In the scalar case, S is a c-number and the s_c, $s_{a,b}$, $s^d{}_{a,b}$ and $t^d{}_{a,b}$ assume only the value *0*.

If derivatives $\partial_\mu k(b;mx)$ appear, identity

$$\partial_\mu[k(b;m|\mathbf{x}-\mathbf{x}_1|)\{\partial^\mu k(b;m|\mathbf{x}-\mathbf{x}_2|)\}-\{\partial^\mu k(b;m|\mathbf{x}-\mathbf{x}_1|)\}k(b;m|\mathbf{x}-\mathbf{x}_2|)]$$
$$=(1-\alpha)m^2\{k(b;m|\mathbf{x}-\mathbf{x}_1|)k(b+1;m|\mathbf{x}-\mathbf{x}_2|)-k(b+1;m|\mathbf{x}-\mathbf{x}_1|)k(b;m|\mathbf{x}-\mathbf{x}_2|)\} \tag{2.4}$$

is obtained by using differential equation (A9). It is the translation into **x**-space language of the **p**-space relation (1.7). Equation (2.4) may be inserted into (2.1) and yields a relation between diagrams.

- The summation variables s and t of spin and complicated interaction do not impair the essence of our method and will be omitted from now on.
- The number of independent vectors $\mathbf{p}_i$ is g $(g\leqslant f-1)$ and we use the notation

$$c_{i',i}=\frac{\mathbf{x}_{i'}\cdot\mathbf{x}_i}{x_{i'}x_i},\qquad c_{i,f-1+j}=\frac{\mathbf{x}_i\cdot\mathbf{p}_j}{x_ip_j},\qquad c_{f-1+j',f-1+j}=\frac{\mathbf{p}_{j'}\cdot\mathbf{p}_j}{p_{j'}p_j} \tag{2.5}$$
$$(1\leqslant i'<i\leqslant f-1)\quad 1\leqslant i\leqslant f-1;1\leqslant j\leqslant g\qquad 1\leqslant j'<j\leqslant g$$

After introduction of appropriate coordinate systems and after calculation of the corresponding Jacobians, a number of integrations may be done and the regularized expression

$$(2.1)=\frac{1}{(2\pi)^{2\nu(f-1)}}\prod_{\substack{1\leqslant i\leqslant f-1\\ 1\leqslant i'<i\\ 1\leqslant j\leqslant g\\ d}}\left\{\frac{2\pi^{\nu}(m^d_{i,f})^{2\beta^d_{i,f}}}{\Gamma(a^d_{i,f})}\right\}\left\{\frac{2\pi^{\nu}(m^d_{i',i})^{2\beta^d_{i',i}}}{\Gamma(a^d_{i',i})}\right\}\frac{2^{f-1}\pi^{(2\nu-f-g+i+1)/2}}{\Gamma((2\nu-f-g+i+1)/2)}$$

$$\times\int_{I^2>0}dx_i dc_{i',i}dc_{i,f-1+j}x_i^{2\nu-1}e^{i\mathbf{p}_i\cdot\mathbf{x}_i}k^d_{i,f}(\beta;mx_i)$$

$$\times k^d_{i',i}(\beta;m|\mathbf{x}_i-\mathbf{x}_{i'}|)\frac{(I_{i,i+1,\ldots,f-1+g})^{2\nu-f-g+i-1}}{(I_{i+1,\ldots,f-1+g})^{2\nu-f-g+i}} \tag{2.6}$$

is obtained.

- The ν and β's are given by

$$\nu=\tfrac{1}{2}n,$$
$$\beta=\nu-\alpha, \tag{2.7}$$

  and are considered as continuous variables.

- We use the notation

$$k^d_{i,f}(\beta;mx_i)=k(\beta^d_{i,f};m^d_{i,f}x_i),$$
$$k^d_{i',i}(\beta+l+r;m\mathbf{x}_i)=k(\beta^d_{i',i}+l^d_{i',i}+r^d_{i',i};m^d_{i',i}\mathbf{x}_i). \tag{2.8}$$

- $I_{i,i+1,\ldots,f-1+g}$ is the content of an $f+g-i$ dimensional parallelopipidum formed by the unit vectors $\mathbf{x}_i/x_i,\ldots,\mathbf{x}_{f-1}/x_{f-1},\mathbf{p}_1/p_1,\ldots,\mathbf{p}_g/p_g$.

This content is the square root of a polynomial of cosines. Details are discussed in Appendix C. Integration is restricted to the area where the polynomials are positive.

We finish this section by clearing up (2.1) and (2.6) on the hand of the two example diagrams of Sec. I.

The diagram of Fig. 1 is in **x**-space given by

$$(1.1')=(1.8')$$
$$=\frac{(2\pi^{(1/2)n})^3}{(2\pi)^n}\frac{(m^1)^{2b^1}(m^2)^{2b^2}(m^3)^{2b^3}}{\Gamma(a^1)\Gamma(a^2)\Gamma(a^3)}\int d\mathbf{x}_1 e^{i\mathbf{p}_1\cdot\mathbf{x}_1}k^1(b;mx_1)k^2(b;mx_1)k^3(b;mx_1). \tag{2.1'}$$

After performance of most of the angle integrations, formula

$$(2.1')=\frac{(2\pi^{\nu})^3}{(2\pi)^{2\nu}}\frac{(m^1)^{2\beta^1}(m^2)^{2\beta^2}(m^3)^{2\beta^3}}{\Gamma(\alpha^1)\Gamma(\alpha^2)\Gamma(\alpha^3)}\frac{2\pi^{(2\nu-1)/2}}{\Gamma((2\nu-1)/2)}(ip_1)^{q_{12}}$$
$$\times\int dc_{12}(c_{12})^{q_{12}}(\sqrt{1-c_{12}{}^2})^{2\nu-3}\int dx x^{2\nu-1+q_{12}}k^1(\beta;mx)k^2(\beta;mx)k^3(\beta;mx) \tag{2.6'}$$

is obtained.

The diagram of Fig. 2 is given by

$$(1.1'')=(1.8'')$$

$$=\frac{(2\pi^{(1/2)n})^5}{(2\pi)^{2n}}\frac{(m_{13}^1)^{2b_{13}^1}(m_{13}^2)^{2b_{13}^2}(m_{23}^1)^{2b_{23}^1}(m_{23}^2)^{2b_{23}^2}(m_{12})^{2b_{12}}}{\Gamma(a_{13}^1)\Gamma(a_{13}^2)\Gamma(a_{23}^1)\Gamma(a_{23}^2)\Gamma(a_{12})}$$

$$\times\int d\mathbf{x}_1 d\mathbf{x}_2 e^{i\mathbf{p}_1\cdot\mathbf{x}_1}e^{i\mathbf{p}_2\cdot\mathbf{x}_2}k_{13}^1(b;mx_1)k_{13}^2(b;mx_1)k_{23}^1(b;mx_2)k_{23}^2(b;mx_2)k_{12}(b;m|\mathbf{x}_1-\mathbf{x}_2|), \tag{2.1''}$$

which becomes, after angle integrations,

$$(2.1'')=\frac{(2\pi^{\nu})^5}{(2\pi)^{4\nu}}\frac{(m_{12})^{2\beta_{12}}(m_{13}^1)^{2\beta_{13}^1}(m_{13}^2)^{2\beta_{13}^2}(m_{23}^1)^{2\beta_{23}^1}(m_{23}^2)^{2\beta_{23}^2}}{\Gamma(a_{12})\Gamma(a_{13}^1)\Gamma(a_{13}^2)\Gamma(a_{23}^1)\Gamma(a_{23}^2)}\frac{2^2\pi^{(2\nu-3)/2}\pi^{(2\nu-2)/2}}{\Gamma((2\nu-3)/2)\Gamma((2\nu-2)/2)}$$

$$\times\int_{I^2>0}dx_1dx_2dc_{12}dc_{13}dc_{14}dc_{23}dc_{24}{x_1}^{2\nu-1}{x_2}^{2\nu-1}e^{i\mathbf{p}_1\cdot\mathbf{x}_1}e^{i\mathbf{p}_2\cdot\mathbf{x}_2}k_{13}^1(\beta;mx_1)$$

$$\times k_{13}^2(\beta;mx_1)k_{23}^1(\beta;mx_2)k_{23}^2(\beta;mx_2)k_{12}(\beta;m|\mathbf{x}_1-\mathbf{x}_2|)\frac{(I_{1,2,3,4})^{2\nu-5}(I_{2,3,4})^{2\nu-4}}{(I_{2,3,4})^{2\nu-4}(I_{3,4})^{2\nu-3}}. \tag{2.6''}$$

- In the following sections, the notation

$$\varepsilon=\nu-\tfrac{1}{2}n=\beta_{a,b}^d-b_{a,b}^d \tag{2.9}$$

will be used and (2.6), (2.6′) and (2.6′′) will be considered in the limit $\varepsilon\to 0$.

III. SERIES EXPANSION; ANGULAR PART

The I-functions in (2.6) cancel, with the exception of the first I in the numerator and the last I in the denominator.

Furthermore, $f-1$ of the $1/2f(f-1)$ arguments of k-functions are "simple," i.e., of the form $|\mathbf{x}_i|$. The other $1/2(f-1)(f-2)$ arguments are "nonsimple:" they are absolute values of linear combinations of $\mathbf{x}_i$. The latter have to be split according to (A12). Because of condition (A13), the integration region is to be divided into $(f-1)!$ subregions:

$$(2.6)=\frac{1}{(2\pi)^{2\nu(f-1)}}\sum_{l,q,r}\prod_{\substack{1\le i\le f-1\\1\le i'<i\\1\le j\le g\\d}}(-)^{l_{i',i}^d}\left(\frac{1}{2}\right)^{2l_{i',i}^d+r_{i',i}^d}(ip_j)^{\sum_{1\le a\le f-1}q_{a,f-1+j}}$$

$$\times\frac{1}{l_{i',i}^d!q_{i,f-1+j}!r_{i',i}^d!}\left\{\frac{2\pi^{\nu}(m_{i,f}^d)^{2\beta_{i,f}^d}}{\Gamma(a_{i,f}^d)}\right\}$$

$$\times\left\{\frac{2\pi^{\nu}(m_{i',i}^d)^{2\beta_{i',i}^d+2l_{i',i}^d+2r_{i',i}^d}}{\Gamma(a_{i',i}^d)}\right\}\frac{2^{f-1}\pi^{(2\nu-f-g+i+1)/2}}{\Gamma((2\nu-f-g+i+1)/2)}$$

$$\times\int_{I^2>0}dc_{i',i}dc_{i,f-1+j}(c_{i',i})^{\sum_d r_{i',i}^d}(c_{i,f-1+j})^{q_{i,f-1+j}}\frac{(I_{1,2,\ldots,f-1+g})^{2\nu-f-g}}{(I_{f,\ldots,f-1+g})^{2\nu-g-1}}$$

$$\times\int_{0\le x_1\le x_2\le\ldots\le x_{f-1}\le\infty}dx_i{x_i}^{2\nu-1+\sum_a q_{i,f-1+a}+\sum_d^{1\le a<i}r_{a,i}^d+\sum_d^{i<a\le f-1}r_{i,a}^d+2\sum_d^{i<a\le f-1}l_{i,a}^d}$$

$$\times k_{i,f}^d(\beta;mx_i)k_{i',i}^d(\beta+l+r;mx_i)+(f-1)!-1\text{ permutations}. \tag{3.1}$$

- Multiplication is over indices $i,j,$ etc.; summation is over indices $a,b,c,$ etc., i.e.,

$$\sum_{i<a\leqslant f-1} = \sum_{a=i+1}^{f-1}, \text{ etc.} \tag{3.2}$$

If all external momenta are linearly independent,

$$g=f-1,$$
$$q_{i,f-1+j}=\delta_{i,j}q_{i,f-1+i}. \tag{3.3}$$

The angular part of (3.1) may be worked out after transformation according to Appendix C:

$$y_{i,j}=\frac{(I_{j+1,\ldots,f-1+g})^2 c_{i,j}-c_{i,j+1}c_{j,j+1}+\cdots}{I_{i,j+1,\ldots,f-1+g}I_{j,j+1,\ldots,f-1+g}}, \tag{3.4a}$$

the inverse of which is given by

$$\begin{aligned} c_{i,j}=&y_{i,j}(\sqrt{1-(y_{i,j+1})^2}\cdots\sqrt{1-(y_{i,f-1+g})^2})(\sqrt{1-(y_{j,j+1})^2}\cdots\sqrt{1-(y_{j,f-1+g})^2})\\ &+(y_{i,j+1}\sqrt{1-(y_{i,j+2})^2}\cdots\sqrt{1-(y_{i,f-1+g})^2})(y_{j,j+1}\sqrt{1-(y_{j,j+2})^2}\cdots\sqrt{1-(y_{j,f-1+g})^2})\\ &+\cdots+(y_{i,f-2+g}\sqrt{1-(y_{i,f-2+g})^2})(y_{j,f-2+g}\sqrt{1-(y_{j,f-2+g})^2})+y_{i,f-1+g}y_{j,f-1+g}. \end{aligned} \tag{3.4b}$$

It results in

$$\begin{aligned} &\prod_{\substack{1\leqslant i\leqslant f-1\\ 1\leqslant i'<i\\ 1\leqslant j<g}} \frac{2^{f-1}\pi^{(2\nu-f-g+i+1)/2}}{\Gamma((2\nu-f-g+i+1)/2)}\\ &\quad\times\int_{I^2>0} dc_{i',i}dc_{i,f-1+j}(c_{i',i})^{\Sigma_d r^d_{i',i}}(c_{i,f-1+j})^{q_{i,f-1+j}}\frac{(I_{1,2,\ldots,f-1+g})^{2\nu-f-g}}{(I_{f,\ldots,f-1+g})^{2\nu-g-1}}\\ &=\sum_q{}' \prod_{\substack{1\leqslant i'<i\\ 1\leqslant i\leqslant i''\leqslant f-1+g\\ 1\leqslant j'<j\leqslant j''\leqslant g}} \frac{(\Sigma_d r^d_{i',i})!}{q_{i',i}{}^{i''}!}\frac{q_{i,f-1+j}!}{q_{i,f-1+j}{}^{j''}!}\frac{2^{f-1}\pi^{(2\nu-f+1-g+i)/2}}{\Gamma((2\nu-f+1-g+i)/2)}\\ &\quad\times\int_{-1}^{1} dy_{i',i}(y_{i',i})^{\Sigma_{1\leqslant a<i'} q_{a,i'}{}^{i}+\Sigma_{i'<a\leqslant i}q_{i',a}{}^{i}}\\ &\quad\times(\sqrt{1-(y_{i',i})^2})^{2\nu-f-g+i-2+\Sigma_{1\leqslant a<i'\leqslant b\leqslant i-1}q_{a,i'}{}^{b}+\Sigma_{i'<a\leqslant b\leqslant i-1}q_{i',a}{}^{b}}\\ &\quad\times\int_{-1}^{1} dy_{i,f-1+j}(y_{i,f-1+j})^{\Sigma_{1\leqslant a<i}q_{a,i}{}^{f-1+j}+\Sigma_{i<a\leqslant f-1+j}q_{i,a}{}^{f-1+j}}\\ &\quad\times(\sqrt{1-(y_{i,f-1+j})^2})^{2\nu-g+j-3+\Sigma_{1\leqslant a<i\leqslant b\leqslant f-2+j}q_{a,i}{}^{b}+\Sigma_{i<a\leqslant b\leqslant f-2+j}q_{i,a}{}^{b}}\\ &\quad\times(y_{f-1+j',f-1+j})^{\Sigma_{1\leqslant a\leqslant f-1}q_{a,f-1+j'}{}^{f-1+j}}\sqrt{(1-(y_{f-1+j',f-1+j})^2}^{\Sigma^{1\leqslant a\leqslant f-1}_{f-1+j'\leqslant b\leqslant f-2+j}q_{a,f-1+j'}{}^{b}}. \end{aligned} \tag{3.5}$$

- The summation variables ${q_{a,b}}^c$ are defined in (C6). They run from 0 to ∞ under the conditions

$$\sum_{i\leqslant c\leqslant f-1+g} {q_{i',i}}^c = \sum_d r^d_{i',i},$$
$$\sum_{f-1+j\leqslant c\leqslant f-1+g} {q_{i,f-1+j}}^c = q_{i,f-1+j}, \tag{3.6}$$

  which has been indicated by the $'$ of Σ'.
- The superscript c of ${q_{a,b}}^c$ counts terms from b to $f-1+g$ in a polynomial expansion of (3.4b) to the power $q_{a,b}$.

Integrations over $y_{i',i}$ and $y_{i,f-1+j}$ yield B-functions and after a number of cancellations, the result is

(3.5)

$$\begin{aligned}
&= \sum_q{}'' \prod_{\substack{1\leqslant i'<i\\ 1\leqslant i\leqslant i''\leqslant f-1\\ 1\leqslant j'<j\leqslant j''\leqslant g}} \frac{(\Sigma_d r^d_{i',i})!\, q_{i,f-1+j}!}{{q_{i',i}}^{i''}!\, {q_{i,f-1+j}}^{j''}!} \\
&\quad\times \frac{2^{f-1}\pi^{(2\nu-f+1-g+i)/2}\Gamma((2\nu-f-g+i+1+\Sigma_{a<b\leqslant i}{q_{a,b}}^b)/2)}{\Gamma((2\nu-f-g+i+1)/2)} \\
&\quad\times \frac{\Gamma((1+\Sigma_{1\leqslant a<i'}{q_{a,i'}}^i+\Sigma_{i'<a\leqslant i}{q_{i',a}}^i)/2)\Gamma((1+\Sigma_{1\leqslant a<i}{q_{a,i}}^{f-1+j}+\Sigma_{i<a\leqslant f-1+j}{q_{i,a}}^{f-1+j})/2)}{\Gamma(2\nu+\Sigma_{1\leqslant a<i\leqslant b\leqslant f-1+g}{q_{a,i}}^b+\Sigma_{i<a\leqslant b\leqslant f-1+g}{q_{i,a}}^b/2)} \\
&\quad\times (y_{f-1+j',f-1+j})^{\Sigma_{1\leqslant a<f-1}{q_{a,f-1+j'}}^{f-1+j}} \left(\sqrt{(1-(y_{f-1+j',f-1+j})^2}\right)^{\Sigma^{1<a\leqslant f-1}_{f-1+j'<b\leqslant f-2+j}{q_{a,f-1+j'}}^b}.
\end{aligned} \tag{3.7}$$

- The summation variables in (3.7) obey both (3.6) and the subsidiary condition that the arguments of the Γ-functions in the numerator have to be half integer. This has been indicated by the $''$ of Σ''.

In order to get familiar with the notations, we shall repeat the derivation line (3.1)–(3.7) for the two example diagrams.

In the case of the example of Fig. 1, where $f-1=g=1$, (3.1) reduces to

$$\begin{aligned}
(2.6') &= \frac{(2\pi^\nu)^3}{(2\pi)^{2\nu}}(ip_1)^{q_{12}}\frac{2\pi^{(2\nu-1)/2}}{\Gamma((2\nu-1)/2)}\int dc_{12}(c_{12})^{q_{12}}\left(\sqrt{1-{c_{12}}^2}\right)^{2\nu-3} \\
&\quad\times\int_0^\infty dx x^{2\nu-1+q_{12}}k^1(\beta;mx)k^2(\beta;mx)k^3(\beta;mx),
\end{aligned} \tag{3.1'}$$

where the notation (2.5) means that

$$c_{12}=\frac{\mathbf{x}_1\cdot\mathbf{p}_1}{x_1p_1} \tag{2.5'}$$

and the transformation (3.4) becomes trivial:

$$y_{12}=c_{12}. \tag{3.4'}$$

The angular part of (3.1′) becomes

$$\frac{2\pi^{(2\nu-1)/2}}{\Gamma((2\nu-1)/2)}\int_{-1}^1 dy_{12}(y_{12})^{q_{12}}\left(\sqrt{1-{y_{12}}^2}\right)^{2\nu-3}=\frac{2\pi^{(2\nu-1)/2}\Gamma((q_{12}+1)/2)}{\Gamma((2\nu+q_{12})/2)}, \tag{3.7'}$$

if q_{12} is even. If q_{12} is odd, the integral of (3.7′) is zero.

In the case of the example of Fig. 2, where $f-1=g=2$, (3.1) reduces to

$$(2.6'')=\frac{(2\pi^{\nu})^5}{(2\pi)^{4\nu}}(ip_1)^{q_{13}}(ip_2)^{q_{24}}\frac{(m_{13}^1)^{2\beta_{13}^1}(m_{13}^2)^{2\beta_{13}^2}(m_{23}^1)^{2\beta_{23}^1}(m_{23}^2)^{2\beta_{23}^2}(m_{12})^{2\beta_{12}+2l_{12}+2r_{12}}}{l_{12}!q_{13}!q_{24}!r_{12}!\Gamma(\alpha_{13}^1)\Gamma(\alpha_{13}^2)\Gamma(\alpha_{23}^1)\Gamma(\alpha_{23}^2)\Gamma(\alpha_{12})}$$
$$\times\frac{2^2\pi^{(2\nu-3)/2}\pi^{(2\nu-2)/2}}{\Gamma((2\nu-3)/2)\Gamma((2\nu-2)/2)}(-)^{l_{12}}\left(\frac{1}{2}\right)^{2l_{12}+r_{12}}$$
$$\times\int dc_{12}dc_{13}dc_{14}dc_{23}dc_{24}(c_{12})^{r_{12}}(c_{13})^{q_{13}}(c_{24})^{q_{24}}\frac{(I_{1,2,3,4})^{2\nu-5}}{(I_{3,4})^{2\nu-3}}$$
$$\times\int_{0\leqslant x_1\leqslant x_2\leqslant\infty}dx_1dx_2{x_1}^{2\nu-1+q_{13}+r_{12}+2l_{12}}{x_2}^{2\nu-1+q_{24}+r_{12}}k_{13}^1(\beta;mx_1)k_{13}^2(\beta;mx_1)$$
$$\times k_{23}^1(\beta;mx_2)k_{23}^2(\beta;mx_2)k_{12}(\beta+l+r;mx_2)+1\text{permutation.}\qquad(3.1'')$$

- The notation (2.5) means

$$c_{12}=\frac{\mathbf{x}_1\cdot\mathbf{x}_2}{x_1x_2},\quad c_{13}=\frac{\mathbf{x}_1\cdot\mathbf{p}_1}{x_1p_1},\quad c_{14}=\frac{\mathbf{x}_1\cdot\mathbf{p}_2}{x_1p_2},$$
$$c_{23}=\frac{\mathbf{x}_2\cdot\mathbf{p}_1}{x_2p_1},\quad c_{24}=\frac{\mathbf{x}_2\cdot\mathbf{p}_2}{x_2p_2},\quad c_{34}=\frac{\mathbf{p}_1\cdot\mathbf{p}_2}{p_1p_2}\qquad(2.5'')$$

- The explicit form of $I_{1,2,3,4}$ and $I_{3,4}$ is given in (C1).

The $y\to c$ transformation (3.4) becomes in this case

$$y_{12}=\frac{(I_{3,4})^2c_{12}-c_{13}c_{32}-c_{14}c_{42}+c_{13}c_{34}c_{42}+c_{14}c_{43}c_{32}}{I_{1,3,4}I_{2,3,4}},\quad y_{13}=\frac{c_{13}-c_{14}c_{34}}{I_{1,4}I_{3,4}},$$
$$y_{14}=c_{14}\quad y_{23}=\frac{c_{23}-c_{24}c_{34}}{I_{2,4}I_{3,4}},\quad y_{24}=c_{24},\quad y_{34}=c_{34},\qquad(3.4a'')$$

and the inverse transformation $c\to y$ is, according to (C5c), given by

$$c_{12}=y_{12}\{\sqrt{1-(y_{13})^2}\sqrt{1-(y_{14})^2}\}\{\sqrt{1-(y_{23})^2}\sqrt{1-(y_{24})^2}\}$$
$$+\{y_{13}\sqrt{1-(y_{14})^2}\}\{y_{23}\sqrt{1-(y_{24})^2}\}+y_{14}y_{24},$$
$$c_{13}=y_{13}\sqrt{1-(y_{14})^2}\sqrt{1-(y_{34})^2}+y_{14}y_{34},\quad c_{14}=y_{14},$$
$$c_{23}=y_{23}\sqrt{1-(y_{24})^2}\sqrt{1-(y_{34})^2}+y_{24}y_{34},$$
$$c_{24}=y_{24},\quad c_{34}=y_{34}.\qquad(3.4b'')$$

The angular part of (3.1′′) now becomes

$$\frac{2^2\pi^{(2\nu-3)/2}\pi^{(2\nu-2)/2}}{\Gamma((2\nu-3)/2)\Gamma((2\nu-2)/2)}\int_{I^2>0}dc_{12}dc_{13}dc_{14}dc_{23}dc_{24}(c_{12})^{r_{12}}(c_{13})^{q_{13}}(c_{24})^{q_{24}}\frac{(I_{1,2,3,4})^{2\nu-5}}{(I_{3,4})^{2\nu-3}}$$
$$=\frac{2^2\pi^{(2\nu-3)/2}\pi^{(2\nu-2)/2}}{\Gamma((2\nu-3)/2)\Gamma((2\nu-2)/2)}\int_{-1}^{1}dy_{12}dy_{13}dy_{14}dy_{23}dy_{24}$$
$$\times\{\sqrt{1-(y_{12})^2}\sqrt{1-(y_{13})^2}(\sqrt{1-(y_{14})^2}\}^{2\nu-5}\{\sqrt{1-(y_{23})^2}\sqrt{1-(y_{24})^2}\}^{2\nu-4}$$

$$\times\{y_{12}\sqrt{1-(y_{13})^2}\sqrt{1-(y_{14})^2}\sqrt{1-(y_{23})^2}\sqrt{1-(y_{24})^2}+y_{13}\sqrt{1-(y_{14})^2}y_{23}\sqrt{1-(y_{24})^2}$$
$$+y_{14}y_{24}\}^{r_{12}}\{y_{13}\sqrt{1-(y_{14})^2}\sqrt{1-(y_{34})^2}+y_{14}y_{34}\}^{q_{13}}(y_{24})^{q_{24}}$$
$$=\frac{2^2\pi^{(2\nu-3)/2}\pi^{(2\nu-2)/2}}{\Gamma((2\nu-3)/2)\Gamma((2\nu-2)/2)}\sum_q{}'\frac{(r_{12})!}{q_{12}{}^2!q_{12}{}^3!q_{12}{}^4!}\frac{q_{13}!}{q_{13}{}^3!q_{13}{}^4!}\frac{q_{14}!}{q_{14}{}^4!}$$
$$\times\int_{-1}^{1}dy_{12}(y_{12})^{q_{12}{}^2}(\sqrt{1-(y_{12})^2})^{2\nu-5}\int_{-1}^{1}dy_{13}(y_{13})^{q_{12}{}^3+q_{13}{}^3}(\sqrt{1-(y_{13})^2})^{2\nu-4+q_{12}{}^2}$$
$$\times\int_{-1}^{1}dy_{14}(y_{14})^{q_{12}{}^4+q_{13}{}^4}(\sqrt{1-(y_{14})^2})^{2\nu-3+q_{12}{}^2+q_{12}{}^3+q_{13}{}^3}$$
$$\times\int_{-1}^{1}dy_{23}(y_{23})^{q_{12}{}^3}(\sqrt{1-(y_{23})^2})^{2\nu-4+q_{12}{}^2}$$
$$\times\int_{-1}^{1}dy_{24}(y_{24})^{q_{12}{}^4+q_{24}{}^4}(\sqrt{1-(y_{24})^2})^{2\nu-3+q_{12}{}^2+q_{12}{}^3}(y_{34})^{q_{13}{}^4}(\sqrt{(1-(y_{34})^2})^{q_{13}{}^3}. \tag{3.5''}$$

- The Σ' means that summation is under the subsidiary conditions

$$q_{12}{}^2+q_{12}{}^3+q_{12}{}^4=r_{12},$$
$$q_{13}{}^3+q_{13}{}^4=q_{13}, \tag{3.6''}$$
$$q_{14}{}^4=q_{14}.$$

Integration over y_{12}, y_{13}, y_{14}, y_{23}, and y_{24} yields Γ-functions, many of which cancel:

(3.5'')
$$=\frac{2^2\pi^{(2\nu-3)/2}\pi^{(2\nu-2)/2}\Gamma((2\nu-2+q_{12}{}^2)/2)}{\Gamma((2\nu-2)/2)}\sum_q{}''$$
$$\times\frac{\Gamma((1+q_{12}{}^2)/2)\Gamma((1+q_{12}{}^3+q_{13}{}^3/2)\Gamma((1+q_{12}{}^4+q_{13}{}^4)/2)\Gamma((1+q_{12}{}^3)/2)\Gamma((1+q_{12}{}^4+q_{24}{}^4)/2)}{\Gamma((2\nu+q_{12}{}^2+q_{12}{}^3+q_{13}{}^3+q_{12}{}^4+q_{13}{}^4)/2)\Gamma((2\nu+q_{12}{}^2+q_{12}{}^3+q_{12}{}^4+q_{24}{}^4)/2)}$$
$$\times(y_{34})^{q_{13}{}^4}(\sqrt{1-(y_{34})^2})^{q_{13}{}^3},$$

(3.7'')

if the arguments of all Γ-functions in the numerator are half integer, otherwise (3.5'')=0.

IV. SERIES EXPANSION; RADIAL PART

The radial part of (3.1) is transformed by insertion of expansion (A7) for k-functions with argument $x_1,x_2,\ldots,x_{f-2}$. Moreover, the integration variables x_i are transformed according to

$$\frac{x_i}{x_{i+1}}\to\xi_{i,i+1}(1\leqslant i\leqslant f-2),$$
$$x_{f-1}\to x. \tag{4.1}$$

The result is

$$\prod_{\substack{1\leqslant i\leqslant f-1\\ 1\leqslant i'<i\\ d}} \int_{0\leqslant x_1\leqslant x_2\leqslant\ldots\leqslant x_{f-1}\leqslant\infty} dx_i\; k^d_{i'i}(\beta+l+r;mx_i)k^d_{i,f}(\beta;mx_i)$$

$$\times x_i^{2\nu-1+\Sigma_{1\leqslant a\leqslant g}q_{i,f-1+a}+\sum_d{}^{1\leqslant a<i}r^d_{a,i}+\sum_d{}^{i<a\leqslant f-1}r^d_{i,a}+2\sum_d{}^{i<a\leqslant f-1}l^d_{i,a}}$$

$$=\sum_{k,u,w,\theta}\prod_{\substack{1\leqslant i\leqslant f-2\\ 1\leqslant i'<i\\ d}} K^{\theta^d}_{i',i}(b+l+r;k;u;w)K^{\theta^d}_{i,f}(b;k;u;w)\left(\frac{m^d_{i',i}}{2}\right)^{-2\theta^d_{i',i}(\beta^d_{i',i}+l^d_{i',i}+r^d_{i',i})+2k^d_{i',i}}\left(\frac{m^d_{i,f}}{2}\right)^{-2\theta^d_{i,f}\beta^d_{i,f}+2k^d_{i,f}}$$

$$\times\varepsilon^{w^d_{i',i}}\varepsilon^{w^d_{i,f}}\int_0^1 d\xi_{i,i+1}(\xi_{i,i+1})^{\Sigma_{1\leqslant a\leqslant i}N_a-1}\left\{2\ln\left(\frac{m^d_{i',i}\xi_{i,i+1}\xi_{i+1,i+2}\cdots\xi_{f-2,f-1}x}{2}\right)\right\}^{u^d_{i',i}}$$

$$\times\left\{2\ln\left(\frac{m^d_{i,f}\xi_{i,i+1}\xi_{i+1,i+2}\cdots\xi_{f-2,f-1}x}{2}\right)\right\}^{u^d_{i,f}}$$

$$\times\int_0^\infty dx\, x^{2\nu-1+\Sigma_{1\leqslant a\leqslant g}q_{f-1,f-1+a}+\sum_d{}^{1\leqslant a<f-1}r^d_{a,f-1}+\Sigma_{1\leqslant a\leqslant f-2}N_a}$$

$$\times k^d_{i,f-1}(\beta+l+r;mx)k^d_{f-1,f}(\beta;mx), \tag{4.2}$$

with the obvious notation of (2.8):

$$K^{\theta^d}_{i,f}(b;k;u;w)=K^{\theta}(b^d_{i,f};k^d_{i,f};u^d_{i,f};w^d_{i,f}),$$
$$K^{\theta^d}_{i',i}(b+l+r;k;u;w)=K^{\theta}(b^d_{i',i}+l^d_{i',i}+r^d_{i',i};k^d_{i',i};u^d_{i',i};w^d_{i',i}), \tag{4.3}$$

and with

$$N_i=2\nu+\sum_{1\leqslant a\leqslant g}q_{i,f-1+a}-2\sum_{\substack{1\leqslant a<i\\ d}}\theta^d_{a,i}(\beta^d_{a,i}+l^d_{a,i}+r^d_{a,i})-2\sum_d\theta^d_{i,f}\beta^d_{i,f}$$
$$+2\sum_{\substack{1\leqslant a<i\\ d}}k^d_{a,i}+2\sum_d k^d_{i,f}+2\sum_{\substack{i<a\leqslant f-1\\ d}}l^d_{i,a}+\sum_{\substack{1\leqslant a<i\\ d}}r^d_{a,i}+\sum_{\substack{i<a\leqslant f-1\\ d}}r^d_{i,a}. \tag{4.4}$$

The range of the summation variables is given in (A7): the θ's assume values $\theta=0$ and $\theta=1$; $k_{i',i}$ runs from 0 to ∞ if $\theta=0$ and from 0 to $b_{i',i}+l_{i',i}+r_{i',i}-1$ if $\theta=1$; $k_{i,f}$ runs from 0 to ∞ if $\theta=0$ and from 0 to $b-1$ if $\theta=1$; u runs from 0 to $w+1$ if $\theta=0$ and it takes only the value 0 if $\theta=1$; w runs from 0 to ∞.

The x-integral in (4.2) is split into two parts:

$$\int_0^\infty dx=\int_0^{1/M}dx+\int_{1/M}^\infty dx. \tag{4.5}$$

The ξ-integrations and the ${}_0\int^{1/M}dx$-integration are performed by (D2) and the result is

$$
\begin{aligned}
(4.2)=&\sum_{k,u,w,\theta}\left(\frac{1}{M}\right)^{2\nu(f-l)+\sum_{l\leqslant b\leqslant g}^{1\leqslant a\leqslant f-1}q_{a,f-1+b}+2\sum_{1\leqslant a'\leqslant a\leqslant f-1}l^d_{a',a}+2\sum_{1\leqslant a'<a\leqslant f-1}r^d_{a',a}}\\
&\times\prod_{\substack{1\leqslant i\leqslant i''\leqslant f-1\\ 1\leqslant i'<i\\ d}}K^{\theta^d}_{i',i}(b+l+r;k;u;w)K^{\theta^d}_{i,f}(b;k;u;w)\\
&\times\frac{(-)^{u^d_{i',i}\,i''+u^d_{i,f}\,i''}2^{u^d_{i',i}+u^d_{i,f}}u^d_{i',i}!u^d_{i,f}!(\sum_d{}^{1\leqslant a'<a\leqslant i}u^d_{a',a}{}^i+\sum_d{}^{1\leqslant a\leqslant i}u^d_{a,f}{}^i)!}{(u^d_{i',i}-\Sigma_{i\leqslant c\leqslant f-1}u^d_{i',i}{}^c)!(u^d_{i,f}-\Sigma_{i\leqslant c\leqslant f-1}u^d_{i,f}{}^c)!u^d_{i',i}{}^{i''}!u^d_{i,f}{}^{i''}!(\Sigma_{1\leqslant a\leqslant i}N_a)^{1+\Sigma_d^{1\leqslant a'<a\leqslant i}u^d_{a',a}{}^i+\Sigma_d^{1\leqslant a\leqslant i}u^d_{a,f}{}^i}}\\
&\times\left(\frac{m^d_{i',i}}{2M}\right)^{-2\theta^d_{i',i}(\beta^d_{i',i}+l^d_{i',i}+r^d_{i',i})+2k^d_{i',i}}\left(\frac{m^d_{i,f}}{2M}\right)^{-2\theta^d_{i,f}\beta^d_{i,f}+2k^d_{i,f}}\left\{\ln\left(\frac{m^d_{i',i}}{M}\right)\right\}^{u^d_{i',i}-\sum_{i\leqslant c\leqslant f-1}u^d_{i',i}{}^c}\left\{\ln\left(\frac{m^d_{i,f}}{M}\right)\right\}^{u^d_{i,f}-\sum_{i\leqslant c\leqslant f-1}u^d_{i,f}{}^c}\\
&\times\varepsilon^{w^d_{i',i}+w^d_{i,f}}+\sum_{k,u,w,\theta}\prod_{\substack{1\leqslant i\leqslant i''\leqslant f-2\\ 1\leqslant i'<i\\ d}}K^{\theta^d}_{i',i}(b+l+r;k;u;w)K^{\theta^d}_{i,f}(b;k;u;w)\\
&\times\frac{(-)^{u^d_{i',i}\,i''+u^d_{i,f}\,i''}2^{u^d_{i',i}+u^d_{i,f}}u^d_{i',i}!u^d_{i,f}!(\sum_d{}^{1\leqslant a'<a\leqslant i}u^d_{a',a}{}^i+\sum_d{}^{1\leqslant a\leqslant i}u^d_{a,f}{}^i)!}{(u^d_{i',i}-\Sigma_{i\leqslant c\leqslant f-2}u^d_{i',i}{}^c)!(u^d_{i,f}-\Sigma_{i\leqslant c\leqslant f-2}u^d_{i,f}{}^c)!u^d_{i',i}{}^{i''}!u^d_{i,f}{}^{i''}!(\Sigma_{1\leqslant a\leqslant i}N_a)^{1+\Sigma_d^{1\leqslant a'<a\leqslant i}u^d_{a',a}{}^i+\Sigma_d^{1\leqslant a\leqslant i}u^d_{a,f}{}^i}}\\
&\times\left(\frac{m^d_{i',i}}{2}\right)^{-2\theta^d_{i',i}(\beta^d_{i',i}+l^d_{i',i}+r^d_{i',i})+2k^d_{i',i}}\left(\frac{m^d_{i,f}}{2}\right)^{-2\theta^d_{i,f}\beta^d_{i,f}+2k^d_{i,f}}\varepsilon^{w^d_{i',i}+w^d_{i,f}}\\
&\times\int_{1/M}^{\infty}dx\,x^{2\nu-1+\Sigma_{1\leqslant a\leqslant g}q_{f-1,f-1+a}+\sum_d^{1\leqslant a\leqslant f-2}r^d_{a,f-1}+\Sigma_{1\leqslant a\leqslant f-2}N_a}\\
&\times\{\ln(m^d_{i',i}x)\}^{u^d_{i',i}-\Sigma_{i\leqslant c\leqslant f-2}u^d_{i',i}{}^c}\{\ln(m^d_{i,f}x)\}^{u^d_{i,f}-\Sigma_{i\leqslant c\leqslant f-2}u^d_{i,f}{}^c}k^d_{i,f-1}(\beta+l+r;mx)k^d_{f-1,f}(\beta;mx).
\end{aligned}
\tag{4.6}
$$

- The superscript c of $u^d_{a,b}{}^c$ appears because of a repeated integral (D2) over logarithms. It runs from b to $f-1$.
- In the ${}_0\int^{1/M}$-term of (4.6) the index f is treated differently from the other ones because of the special position of $\mathbf{x}_f$, right from the beginning.
- In the ${}_{1/M}\int^{\infty}$-term of (4.6), the index $f-1$ is treated differently as well, as the x_{f-1}-integration is the last one.

The general Feynman diagram is given by summation over all variables of a product of (3.7), (4.6) and some factors:

$$
\begin{aligned}
(3.1)=&\frac{1}{(2\pi)^{2\nu(f-1)}}\sum_{l,q,r}\prod_{\substack{1\leqslant i\leqslant f-1\\ 1\leqslant i'<i\\ 1\leqslant j\leqslant g\\ d}}(-)^{l^d_{i',i}}\left(\frac{1}{2}\right)^{2l^d_{i',i}+r^d_{i',i}}(ip_j)^{\Sigma_{1\leqslant a\leqslant f-1}q_{a,f-1+j}}\\
&\times\frac{1}{l^d_{i',i}!q_{i,f-1+j}!r^d_{i',i}!}\left\{\frac{2\pi^\nu(m^d_{i,f})^{2\beta^d_{i,f}}}{\Gamma(a^d_{i,f})}\right\}\left\{\frac{2\pi^\nu(m^d_{i',i})^{2\beta^d_{i',i}+2l^d_{i',i}+2r^d_{i',i}}}{\Gamma(a^d_{i',i})}\right\}\cdot(3.7)\cdot(4.6).
\end{aligned}
\tag{4.7}
$$

This formula may look frightening but it has to be compared with (B4), which is the general integration parameter expression. The latter might look nicer, but the integrations are mostly divergent.

On the other hand, the infinities are honestly visible in (4.6), as will be discussed in the next section. The price for it is summation variables with three or four indices. We think this price is worth paying.

The ${}_{1/M}\int^{\infty} dx$-integration may be computed numerically after insertion of the asymptotic series (A11). The splitting point $1/M$ is arbitrary and may be determined by the accuracy of the calculations.

If all u's are 0, which may happen in the limit $\varepsilon \to 0$, the logarithmic factors in the integrand disappear and the integral is recognized as the finite part of a two vertex diagram with a number of internal lines, like (3.1′). It is named ''sunset diagram,'' ''sunrise diagram'' or ''water melon diagram.'' Several authors[6–23] derived relations in order to simplify the numerical calculations in practice. Most of these authors make use of Feynman parameters which, according to the formalism of Appendix B, are correcting for a first approximation of the propagator by a Gaussian curve

$$\int d\mathbf{k} e^{i\mathbf{k}\cdot\mathbf{x}} \frac{1}{(\mathbf{k}^2+m^2)^{\alpha}} \to \frac{2\pi^{\nu}(4\pi)^{\nu} m^{2\beta}}{\Gamma(\alpha)} e^{-m^2\mathbf{x}^2}. \tag{4.8}$$

Our approach starts from the propagator

$$\int d\mathbf{k} e^{-i\mathbf{k}\cdot\mathbf{x}} \frac{1}{(\mathbf{k}^2+m^2)^{\alpha}} \to \frac{\pi^{\nu+1/2} 2^{\beta+1/2}}{\Gamma(\alpha)} m^{2\beta} \frac{e^{-mx}}{(mx)^{\beta+(1/2)}}, \tag{4.9}$$

which is a better first approximation at high mx. For this reason, we have good hope for better numerical results.

The formalism of this section will be elucidated by applying the derivation line (4.1)–(4.6) on our two examples.

No (4.1)-like transformation is needed for the radial part of (2.6′), the x-variable being the only one. It becomes

$$\begin{aligned}
&\int_0^{\infty} dx\, x^{2\nu-1+q_{12}} k^1(\beta;mx) k^2(\beta;mx) k^3(\beta;mx) \\
&\quad = \int_0^{1/M} dx\, x^{2\nu-1+q_{12}} k^1(\beta;mx) k^2(\beta;mx) k^3(\beta;mx) \\
&\qquad + \int_{1/M}^{\infty} dx\, x^{2\nu-1+q_{12}} k^1(\beta;mx) k^2(\beta;mx) k^3(\beta;mx).
\end{aligned} \tag{4.5′}$$

Since the θ's may assume two values, the first part of (4.5′) consists of eight subseries:

$$\begin{aligned}
&\int_0^{1/M} dx\, x^{2\nu-1+q_{12}} k^1(\beta;mx) k^2(\beta;mx) k^3(\beta;mx) \\
&\quad = \sum_{k,u,w,\theta} K^{\theta^1}(b;k;u;w) K^{\theta^2}(b;k;u;w) K^{\theta^3}(b;k;u;w) \\
&\qquad \times \left(\frac{m^1}{2}\right)^{-2\theta^1\beta^1+2k^1} \left(\frac{m^2}{2}\right)^{-2\theta^2\beta^2+2k^2} \left(\frac{m^3}{2}\right)^{-2\theta^3\beta^3+2k^2} \varepsilon^{w^1+w^2+w^3} \\
&\qquad \times \int_0^{1/M} dx\, x^{2\nu-1+q_{12}-2\theta^1\beta^1-2\theta^2\beta^2-2\theta^3\beta^3+2k^1+2k^2+2k^3} \\
&\qquad \times \left\{2\ln\left(\frac{m^1 x}{2}\right)\right\}^{u^1} \left\{2\ln\left(\frac{m^2 x}{2}\right)\right\}^{u^2} \left\{2\ln\left(\frac{m^3 x}{2}\right)\right\}^{u^3}.
\end{aligned}$$

Using (D1) we find

$$
\begin{aligned}
(4.5')=&\left(\frac{1}{M}\right)^{2\nu+q_{12}}\sum_{k,u,w}K^{0^1}(b;k;u;w)K^{0^2}(b;k;u;w)K^{0^3}(b;k;u;w)\\
&\times\frac{(-)^{u^{1,1}+u^{2,1}+u^{3,1}}2^{u^1+u^2+u^3}(u^{1,1}+u^{2,1}+u^{3,1})!}{(n+2\varepsilon+q_{12}+2k^1+2k^2+2k^3)^{1+u^{1,1}+u^{2,1}+u^{3,1}}}\\
&\times\frac{u^1!}{(u^1-u^{1,1})!u^{1,1}!}\,\frac{u^2!}{(u^2-u^{2,1})!u^{2,1}!}\,\frac{u^3!}{(u^3-u^{3,1})!u^{3,1}!}\\
&\times\left\{\ln\left(\frac{m_1}{M}\right)\right\}^{u^1-u^{1,1}}\left\{\ln\left(\frac{m_2}{M}\right)\right\}^{u^2-u^{2,1}}\left\{\ln\left(\frac{m_3}{M}\right)\right\}^{u^3-u^{3,1}}\left(\frac{m^1}{2M}\right)^{2k^1}\left(\frac{m^2}{2M}\right)^{2k^2}\left(\frac{m^3}{2M}\right)^{2k^3}\\
&\times\varepsilon^{w^1+w^2+w^3}+\left(\frac{1}{M}\right)^{2\nu+q_{12}}\sum_{k,u,w}K^{0^1}(b;k;u;w)K^{0^2}(b;k;u;w)K^{1^3}(b;k;0;w)\\
&\times\frac{(-)^{u^{1,1}+u^{2,1}}2^{u^1+u^2}(u^{1,1}+u^{2,1})!}{(2a^3+q_{12}+2k^1+2k^2+2k^3)^{1+u^{1,1}+u^{2,1}+u^{3,1}}}\,\frac{u^1!}{(u^1-u^{1,1})!u^{1,1}!}\,\frac{u^2!}{(u^2-u^{2,1})!u^{2,1}!}\\
&\times\left\{\ln\left(\frac{m_1}{M}\right)\right\}^{u^1-u^{1,1}}\left\{\ln\left(\frac{m_2}{M}\right)\right\}^{u^2-u^{2,1}}\left(\frac{m^1}{2M}\right)^{2k^1}\left(\frac{m^2}{2M}\right)^{2k^2}\left(\frac{m^3}{2M}\right)^{-2\beta^3+2k^2}\varepsilon^{w^1+w^2+w^3}\\
&+2\text{ permutations}+\left(\frac{1}{M}\right)^{2\nu+q_{12}}\sum_{k,u,w}K^{0^1}(b;k;u;w)K^{1^2}(b;k;0;w)K^{1^3}(b;k;0;w)\\
&\times\frac{(-)^{u^{1,1}}2^{u^1}(u^{1,1})!}{(2a^2+2a^3-n-2\varepsilon+q_{12}+2k^1+2k^2+2k^3)^{1+u^{1,1}}}\,\frac{u^1!}{(u^1-u^{1,1})!u^{1,1}!}\\
&\times\left\{\ln\left(\frac{m_1}{M}\right)\right\}^{u^1-u^{1,1}}\left(\frac{m^1}{2M}\right)^{2k^1}\left(\frac{m^2}{2M}\right)^{-2\beta^2+2k^2}\left(\frac{m^3}{2M}\right)^{-2\beta^3+2k^3}\varepsilon^{w^1+w^2+w^3}+2\text{ permutations}\\
&+\left(\frac{1}{M}\right)^{\nu+2q_{12}}\sum_{k,u,w}K^{1^1}(b;k;0;w)K^{1^2}(b;k;0;w)K^{1^3}(b;k;0;w)\\
&\times\frac{1}{(2a^1+2a^2+2a^3-2n-4\varepsilon+q_{12}+2k^1+2k^2+2k^3)}\left(\frac{m^1}{2M}\right)^{-2\beta^1+2k^1}\left(\frac{m^2}{2M}\right)^{-2\beta^2+2k^2}\\
&\times\left(\frac{m^3}{2M}\right)^{-2\beta^3+2k^3}\varepsilon^{w^1+w^2+w^3}+\int_{1/M}^{\infty}dx\,x^{2\nu-1+q_{12}}k^1(\beta;mx)k^2(\beta;mx)k^3(\beta;mx). \qquad (4.6')
\end{aligned}
$$

This formula, which still has to be multiplied by (3.7′), may be compared with the Feynman parameter representation (1.8′). The hidden divergences of (1.8′) are manifest via the ε's of (4.6′).

Indeed, it is seen from this formula that in four dimensional space–time ($n=4$) and in the limit $\varepsilon\to 0$

(i) the 0,0,0 subseries is finite;
(ii) the three 0,0,1 subseries too are finite;
(iii) the three 0,1,1 subseries have single poles and double poles for some values of the summation variables, as $u=0$ or $u=1$; and
(iv) the 1,1,1 subseries has a single pole for some values of the summation variables.

The radial part of our second example is obtained from (3.1′′). The radial integration variables are transformed according to

$$\frac{x_1}{x_2}\to\xi_{12},\qquad x_2\to x. \tag{4.1''}$$

After insertion of (A7)

$$\begin{aligned}&\int_{0\leqslant x_1\leqslant x_2\leqslant\infty} dx_1dx_2\,x_1^{2\nu-1+q_{13}+r_{12}+2l_{12}}x_2^{2\nu-1+q_{24}+r_{12}}\\&\quad\times k_{13}^1(\beta;x_1)k_{13}^2(\beta;mx_1)k_{23}^1(\beta;mx_2)k_{23}^2(\beta;mx_2)k_{12}(\beta+l+r;mx_2)\\&\quad=K_{13}^{\theta^1}(b;k;u;w)K_{13}^{\theta^2}(b;k;u;w)\\&\qquad\times\left(\frac{m_{13}^1}{2}\right)^{-2\theta'_{13}\beta'_{13}+2k_{13}^1}\left(\frac{m_{13}^2}{2}\right)^{-2\theta_{13}^2\beta_{13}^2+2k_{13}^2}\varepsilon^{w_{13}^1+w_{13}^2}\int_0^1 d\xi_{12}(\xi_{12})^{N_1-1}\left\{2\ln\left(\frac{m_{13}^1\xi_{12}}{2}\right)\right\}^{u_{13}^1}\\&\qquad\times\left\{2\ln\left(\frac{m_{13}^2\xi_{12}}{2}\right)\right\}^{u_{13}^2}\int_0^\infty dx\,x^{2\nu-1+q_{24}+r_{12}+N_1}k_{23}^1(\beta;mx)k_{23}^2(\beta;mx)k_{12}(\beta+l+r;mx),\end{aligned} \tag{4.2''}$$

with

$$N_1=2\nu+q_{13}-2\theta_{13}^1\beta_{13}^1-2\theta_{13}^2\beta_{13}^2+2k_{13}^1+2k_{13}^2+2l_{12}+r_{12} \tag{4.4''}$$

is obtained.

The x-integration has to be split as in (4.5′). The $\int d\xi_{12}$-integration and the ${}_0\int^{1/M}dx$-integration are done as in (4.6′) yielding 32 terms and a ${}_{1/M}\int^{\infty}dx$-integration which has to be done numerically after introduction of (A11).

Conclusion of this section and the previous one: (2.6) leads to the series expansion (3.1). Expansion with respect to external momenta, internal masses, their logarithms and the regularization parameter ε is obtained via an angular part given by (3.7) and a radial part given by (4.6) and (4.4).

V. DIVERGENCES AND THEIR UNRAVELMENT

The UV divergences of momentum space appear in **x**-space by integration in area's where the arguments of a number of the functions $k(\beta;mx)$ are zero.

Two or more of the θ's in (4.4) may assume the value 1 and, consequently, there are values of the summation variables for which

$$\sum_{1\leqslant a\leqslant i} N_a\approx\varepsilon. \tag{5.1}$$

Factor (5.1) appears after integration over x_i in the neighborhood of 0 as a factor

$$\left(\sum_{1\leqslant a\leqslant i} N_a\right)^{1+\sum\limits_{\substack{1\leqslant a'<a\leqslant i\\ d}} u_{a',a}^{d\ i}+\sum\limits_{\substack{1\leqslant a\leqslant i\\ d}} u_{a,f}^{d\ i}}$$

in the denominator and so it may lead to multiple poles at $\varepsilon=0$. The residue of such a pole at $\varepsilon=0$ is a series that is obtained by summation over the remaining variables. In the limit $\varepsilon\to0$, this subseries is recognized as a subdiagram.

All these are divergences caused by $k(\beta;m)$'s with a simple argument. If integration over nonsimple arguments does not produce infinities, the expressions of the previous sections are correct.

If $k(\beta;m)$'s with nonsimple argument do lead to infinity after integration, it will manifest by divergence of the summations over $l^d_{a,b}$ and $r^d_{a,b}$ in (3.1).

In (2.1), it is integrated over $f-1$ $\mathbf{x}$-variables and $f-1$ momenta appear in the integrand. The momentum $\mathbf{p}_f$ is not present manifestly, but is given by (1.6). Due to this momentum conservation, there is a freedom in the choice of the "dead integration variable" x_f. Translations of the kind

$$\mathbf{x}_i \to \mathbf{x}_i + \sum_{a<i} e_{a,i}\mathbf{x}_a + \sum_{b>i} e_{i,b}\mathbf{x}_b\,. \tag{5.2}$$

are allowed.

The elements of the matrix e may be chosen in such a way that any other set of $f-1$ independent arguments is made simple. The elements of e are 0 or 1 and the exponential part of (2.1) is transformed by (5.2) as

$$\sum_a \mathbf{p}_a\cdot\mathbf{x}_a \to \sum_{a,b} (e^T_{a,b}\mathbf{p}_b)\cdot\mathbf{x}_a\,, \tag{5.3}$$

where e^T is the transponed of matrix e.

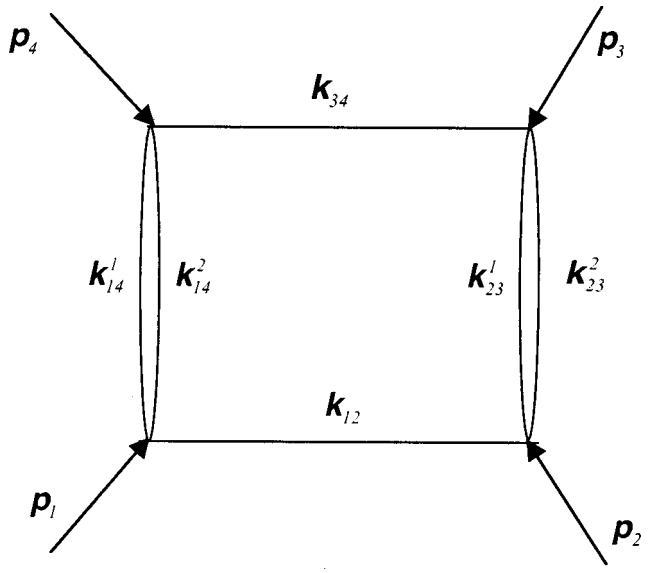
In the given examples, this freedom has been used in order to put all divergences into the integrations over simple arguments.

In the integral (2.1′) of the example of Fig. 1 there is nothing to be transformed, but the integral of (2.1′′) of the second example may be written in three forms:

$$\begin{aligned}
&\int d\mathbf{x}_1 d\mathbf{x}_2 e^{i\mathbf{p}_1\cdot\mathbf{x}_1} e^{i\mathbf{p}_2\cdot\mathbf{x}_2} k^1_{13}(b;mx_1)k^2_{13}(b;mx_1)k^1_{23}(b;mx_2)k^2_{23}(b;mx_2)k_{12}(b;m|\mathbf{x}_1-\mathbf{x}_2|)\\
&\quad=\int d\mathbf{x}_1 d\mathbf{x}_2 e^{i\mathbf{p}_1\cdot\mathbf{x}_1} e^{i(\mathbf{p}_1+\mathbf{p}_2)\cdot\mathbf{x}_2} k^1_{13}(b;m|\mathbf{x}_1+\mathbf{x}_2|)k^2_{13}(b;m|\mathbf{x}_1+\mathbf{x}_2|)\\
&\qquad\times k^1_{23}(b;mx_2)k^2_{23}(b;mx_2)k_{12}(b;mx_1)\\
&\quad=\int d\mathbf{x}_1 d\mathbf{x}_2 e^{i(\mathbf{p}_1+\mathbf{p}_2)\cdot\mathbf{x}_1} e^{i\mathbf{p}_2\cdot\mathbf{x}_2} k^1_{13}(b;mx_1)k^2_{13}(b;mx_1)k^1_{23}(b;m|\mathbf{x}_1+\mathbf{x}_2|)\\
&\qquad\times k^2_{23}(b;m|\mathbf{x}_1+\mathbf{x}_2|)k_{12}(b;mx_2).
\end{aligned} \tag{5.4}$$

Only the first integral of (5.4) satisfies the criterium that all multiple internal lines are represented

by a k-function with simple argument. In a diagram like



there are 16 integral representations where three independent internal lines are made simple. We give five of them:

$$
\begin{aligned}
&\int d\mathbf{x}_1 d\mathbf{x}_2 d\mathbf{x}_3 e^{i\mathbf{p}_1\cdot\mathbf{x}_1} e^{i\mathbf{p}_2\cdot\mathbf{x}_2} e^{i\mathbf{p}_3\cdot\mathbf{x}_3} k^1_{14}(\beta;mx_1) k^2_{14}(\beta;mx_1) k_{12}(\beta;m|\mathbf{x}_1-\mathbf{x}_2|)\\
&\quad\times k^1_{23}(\beta;m|\mathbf{x}_2-\mathbf{x}_3|) k^2_{23}(\beta;m|\mathbf{x}_2-\mathbf{x}_3|) k_{34}(\beta;mx_3)\\
&\quad= \int d\mathbf{x}_1 d\mathbf{x}_2 d\mathbf{x}_3 e^{i\mathbf{p}_1\cdot\mathbf{x}_1} e^{i\mathbf{p}_2\cdot\mathbf{x}_2} e^{i(\mathbf{p}_1+\mathbf{p}_2+\mathbf{p}_3)\cdot\mathbf{x}_3} k^1_{14}(\beta;m|\mathbf{x}_1+\mathbf{x}_3|) k^2_{14}(\beta;m|\mathbf{x}_1+\mathbf{x}_3|)\\
&\qquad\times k_{12}(\beta;m|\mathbf{x}_1-\mathbf{x}_2|) k^1_{23}(\beta;mx_2|) k^2_{23}(\beta;mx_2|) k_{34}(\beta;mx_3)\\
&\quad= \int d\mathbf{x}_1 d\mathbf{x}_2 d\mathbf{x}_3 e^{i\mathbf{p}_1\cdot\mathbf{x}_1} e^{i(\mathbf{p}_1+\mathbf{p}_2+\mathbf{p}_3)\cdot\mathbf{x}_2} e^{i\mathbf{p}_3\cdot\mathbf{x}_3} k^1_{14}(\beta;m|\mathbf{x}_1+\mathbf{x}_2|) k^2_{14}(\beta;m|\mathbf{x}_1+\mathbf{x}_2|)\\
&\qquad\times k_{12}(\beta;mx_1) k^1_{23}(\beta;mx_3|) k^2_{23}(\beta;mx_3) k_{34}(\beta;m|\mathbf{x}_2+\mathbf{x}_3|)\\
&\quad= \int d\mathbf{x}_1 d\mathbf{x}_2 d\mathbf{x}_3 e^{i(\mathbf{p}_2+\mathbf{p}_2+\mathbf{p}_3)\cdot\mathbf{x}_2} e^{i\mathbf{p}_2\cdot\mathbf{x}_2} e^{i\mathbf{p}_3\cdot\mathbf{x}_3} k^1_{14}(\beta;mx_1|) k^2_{14}(\beta;mx_1) k_{12}(\beta;mx_2)\\
&\qquad\times k^1_{23}(\beta;m|\mathbf{x}_2-\mathbf{x}_3|) k^2_{23}(\beta;m|\mathbf{x}_2-\mathbf{x}_3|) k_{34}(\beta;m|\mathbf{x}_1+\mathbf{x}_3|)\\
&\quad= \int d\mathbf{x}_1 d\mathbf{x}_2 d\mathbf{x}_3 e^{i\mathbf{p}_1\cdot\mathbf{x}_1} e^{i(\mathbf{p}_2+\mathbf{p}_3)\cdot\mathbf{x}_2} e^{i\mathbf{p}_3\cdot\mathbf{x}_3} k^1_{14}(\beta;mx_1) k^2_{14}(\beta;mx_1)\\
&\qquad\times k_{12}(\beta;m|\mathbf{x}_1-\mathbf{x}_2|) k^1_{23}(\beta;mx_3) k^2_{23}(\beta;mx_3|) k_{34}(\beta;m|\mathbf{x}_2+\mathbf{x}_3|). \qquad (5.5)
\end{aligned}
$$

Only the last integral satisfies the criterium that all double lines are represented by a k-function with simple argument.

However, at least in theory, there are diagrams where not all multiple lines can be made simple. For instance, if the vertices 1 and 2 of Fig. 2 would have been double connected as well, or Fig. 3 with all vertices double connected. In such cases a more delicate procedure is required.

In order to avoid zeroes of nonsimple arguments, the integration region in (3.1) is restricted to a subregion where simple arguments are smaller than the arguments that depend on them:

$$\begin{gathered} x_1 \leqslant x_2 \leqslant |\mathbf{x}_2 - \mathbf{x}_1|, \\ x_1 \leqslant x_3 \leqslant |\mathbf{x}_3 - \mathbf{x}_1|, \\ x_2 \leqslant x_3 \leqslant |\mathbf{x}_3 - \mathbf{x}_2| \\ \text{etc.} \end{gathered} \tag{5.6}$$

In terms of angles, (5.6) means that the integration is bounded by the conditions

$$\begin{gathered} x_1 \leqslant x_2 \leqslant x_3 \leqslant \cdots \leqslant x_{f-1}, \\ c_{12} \leqslant \tfrac{1}{2}\xi_{12}, \\ c_{13} \leqslant \tfrac{1}{2}\xi_{13}, \\ c_{23} \leqslant \tfrac{1}{2}\xi_{23}, \\ \text{etc.} \end{gathered} \tag{5.7}$$

with

$$\xi_{ij} = \frac{x_i}{x_j}. \tag{5.8}$$

In this way, the integration region is restricted to truncated parallelopipida. Since nonsimple arguments $|\mathbf{x}_a - \mathbf{x}_b|$ are zero only in the region where both $x_a = x_b$ and $c_{ab} = 1$, it is clear from (5.7) that dangerous regions are avoided.

Transformations like (3.4) are not useful anymore, because of the restriction conditions. Instead, the angular integrals of (3.1) in the region restricted by (5.7) are expanded directly with respect to $\xi_{a,b}$:

$$\begin{aligned} &\prod_{\substack{1 \leqslant i' < i \leqslant f=1 \\ 1 \leqslant j \leqslant g}} \int_{\substack{I^2>0 \\ c_{i',i} < 1/2\, \xi_{i',i}}} dc_{i',i} dc_{i,f-1+j} \{ (c_{i',i})^{\Sigma_d r^d_{i',i}} (c_{i,f-1+j})^{q_{i,f-1+j}} (I_{1,2,\ldots,f-1+g})^{2\nu-f-g} \} \\ &\quad = \sum_{i_{a,b}=0}^{\infty} I\left(\sum_d r^d_{a,b}; q_{a,f-1+b}; i_{a,b} \right) \frac{\left(\frac{1}{2}\xi_{1,2} \right)^{i_{1,2}}}{i_{1,2}!} \cdots \frac{\left(\frac{1}{2}\xi_{f-2,f-1} \right)^{i_{f-2,f-1}}}{i_{f-2,f-1}!}, \end{aligned} \tag{5.9}$$

where

$$\begin{aligned} &I\left(\sum_d r^d_{a,b}; q_{a,f-1+b}; i_{a,b} \right) \\ &\quad = \prod_{\substack{1 \leqslant i' < i \leqslant f-1 \\ 1 \leqslant j \leqslant g}} \int_{I^2>0} dc_{i,f-1+j} (c_{i,f-1+j})^{q_{i,f-1+j}} \\ &\qquad \times \left[(\partial_{c_{i',i}})^{i_{i',i}-1} \left\{ \prod_{1 \leqslant k' < k \leqslant f-1} (c_{k',k})^{\Sigma_d r^d_{k',k}} (I_{1,2,\ldots,f-1+g})^{2\nu-f-g} \right\} \right]_{c_{12}=c_{13}=\cdots=c_{f-2,f-1}=0}. \end{aligned} \tag{5.10}$$

The symbolical notations

$$[\partial^{-1}_{c_{i',i}} F(c_{i',i})]_{c_{i',i}=0} \equiv \int_{c_{i',i}\leqslant 0} dc_{i',i} F(c_{i',i})$$

and

$$[\partial^{0}_{c_{i',i}} F(c_{i',i})]_{c_{i',i}=0} \equiv F(0) \tag{5.11}$$

have been used. The coefficients $I(\Sigma_d {r^d}_{a,b}; q_{a,f-1+b}; i_{a,b})$ have to be computed numerically if at least one $i_{a,b}$ is zero; in all other cases they are obtained analytically.

According to (5.9), the angular integrations in the restricted area produce factors

$$(\xi_{a,b})^{i_{a,b}}.$$

These factors have to be joined to the radial part. This radial part in the truncated area now is given by (4.6) with additional summation variables $i_{i,a}$ in N_i:

$$N_i = 2\nu + \sum_{1\leqslant a\leqslant g} q_{i,f-1+a} - 2\sum_{\substack{1\leqslant a<i \\ d}} \theta^d_{a,i}(\beta^d_{a,i} + l^d_{a,i} + r^d_{a,i}) - 2\sum_d \theta^d_{i,f}\beta^d_{i,f} + 2\sum_{\substack{1\leqslant a<i \\ d}} k^d_{a,i}$$

$$+ 2\sum_d k^d_{i,f} + 2\sum_{\substack{i<a\leqslant f-1 \\ d}} l^d_{i,a} + \sum_{\substack{1\leqslant a<i \\ d}} r^d_{a,i} + \sum_{\substack{i<a\leqslant f-1 \\ d}} r^d_{i,a} + \sum_{i<a\leqslant f-1} i_{i,a}\,. \tag{5.12}$$

Conclusion of this section: Feynman diagrams in the area restricted by (5.7) may be written as an expansion (3.1); the angular part is given by (5.9)–(5.11) and the radial part is given by (4.6) and (5.12).

Finally, all possible translations (5.2) producing a set of $f-1$ independent simple arguments have to be carried out and corresponding series expansions similar to (3.1) have to be summed. In this way, integration over all space is obtained and all UV infinities are manifestly present through a factor

$$\prod_{1\leqslant i\leqslant f-1} \left(\sum_{1\leqslant a\leqslant i} N_a \right)^{1+\Sigma_d^{1\leqslant a'<a\leqslant i} u^d_{a',a} \; i \; + \Sigma_d^{1\leqslant a\leqslant i} u^d_{a,f} \; i}$$

in the denominator.

APPENDIX A

Most of the formulas of this appendix are found in the textbook by Watson[5] for the functions $K_\beta(mx)$. Because of practical reasons, functions $k(\beta;mx)$ have been introduced in this article. They differ by a factor $(mx/2)^\beta$:

$$k(\beta;mx) = \left(\frac{mx}{2}\right)^{-\beta} K_\beta(mx). \tag{A1}$$

Series expansion of $k(\beta;mx)$ is given by

$$k(\beta;mx) = \frac{1}{2}\sum_{k=0}^{\infty} \frac{(-)^k}{k!} \left\{ \Gamma(-\beta-k)\left(\frac{mx}{2}\right)^{2k} + \Gamma(\beta-k)\left(\frac{mx}{2}\right)^{-2\beta+2k} \right\}. \tag{A2}$$

The Γ-functions are infinite, when their argument is zero or a negative integer, but these infinities cancel, as may be seen after translation of the summation variable k in the second part of (A2). In this way, $k(\beta;mx)$ is split into two parts:

$$k(\beta;mx)=k^0(\beta;mx)+k^1(\beta;mx), \tag{A3}$$

where

$$k^0(\beta;mx)=\frac{(-)^b\pi}{2\sin(\pi\varepsilon)}\sum_{k=0}^{\infty}\left\{\frac{1}{\Gamma(1+k-\varepsilon)(b+k)!}\left(\frac{mx}{2}\right)^{2k-2\varepsilon}-\frac{1}{k!\Gamma(1+\varepsilon+b+k)}\left(\frac{mx}{2}\right)^{2k}\right\} \tag{A4a}$$

and

$$k^1(\beta;mx)=\frac{1}{2}\sum_{k=0}^{b-1}\frac{(-)^k}{k!}\Gamma(b+\varepsilon-k)\left(\frac{mx}{2}\right)^{-2\beta+2k}, \tag{A4b}$$

with

$$\varepsilon=\nu-\tfrac{1}{2}n=\beta-b. \tag{A5}$$

Expansion with respect to $(mx/2)$, $\ln(mx/2)$ and ε yields

$$k^0(\beta;mx)=\sum_{k=0}^{\infty}\sum_{w=0}^{\infty}\sum_{u=0}^{w+1}K^0(b;k;u;w)\left(\frac{mx}{2}\right)^{2k}\left\{2\ln\left(\frac{mx}{2}\right)\right\}^u\varepsilon^w, \tag{A6a}$$

$$k^1(\beta;mx)=\sum_{k=0}^{b-1}\sum_{w=0}^{\infty}K^1(b;k;w)\left(\frac{mx}{2}\right)^{-2\beta+2k}\varepsilon^w. \tag{A6b}$$

A combined notation of (A6a) and (A6b) is

$$k^\theta(\beta;mx)=\sum_{k,u,w,\theta}K^\theta(b;k;u;w)\left(\frac{mx}{2}\right)^{-2\theta\beta+2k}\left\{2\ln\left(\frac{mx}{2}\right)\right\}^u\varepsilon^w. \tag{A7}$$

The θ's assume values $\theta=0$ and $\theta=1$; k runs from 0 to ∞ if $\theta=0$ and from 0 to $b-1$ if $\theta=1$; u runs from 0 to $w+1$ if $\theta=0$ and it takes only the value 0 if $\theta=1$; w runs from 0 to ∞.

The $K^\theta(b;k;u;w)$ are finite coefficients that may be computed.

The functions $k(\beta;mx)$ satisfy the recursion relation

$$\frac{dk(\beta;mx)}{dx^\mu}=-\left(\frac{m^2x_\mu}{2}\right)k(\beta+1;mx) \tag{A8}$$

and the differential equations

$$\left(\partial_\mu\partial_\nu-m^2\frac{x_\mu x_\nu}{x^2}\right)k(\beta;mx)=m^2\left\{(\beta+1)\frac{x_\mu x_\nu}{x^2}-\frac{1}{2}g_{\mu\nu}\right\}k(\beta+1;mx), \tag{A9a}$$

$$(\partial_\mu\partial^\mu-m^2)k(\beta;mx)=(1-\alpha)m^2k(\beta+1;mx). \tag{A9b}$$

Their asymptotic behavior is given by

$$k(\beta;mx)=\sqrt{\pi}\sum_{h=0}^{H-1}2^{\beta-h-1/2}\frac{\Gamma(\beta+h+\frac{1}{2})}{h!\Gamma(\beta-h+\frac{1}{2})}(mx)^{-\beta-h-1/2}e^{-mx}+O(x^{-H-\beta-1/2}),\quad \text{if } x\to\infty \tag{A10}$$

from which the asymptotic expression

$$\prod_{1\leqslant d\leqslant D}\int_{1/M}^{\infty} dx\, x^{2\nu-1}\{\ln(m^d x)\}^{u^d} k(\beta^d; m^d x)$$

$$= \pi^{(1/2)\,D} \sum_{0\leqslant h^d\leqslant H^d-1} 2^{\Sigma_{1\leqslant a\leqslant D}^{(\beta_a-h_a)-(1/2)D}} \prod_{1\leqslant d\leqslant D} \frac{\Gamma(\beta^d+h^d+1/2)}{h^d!\,\Gamma(\beta^d-h^d+1/2)(m^d)^{\beta^d+h^d+1/2}}$$

$$\times \int_{1/M}^{\infty} dx\, x^{2\nu-1-\Sigma_{1\leqslant a\leqslant D}(\beta^a+h^a)-1/2D}\{\ln(m^d x)\}^{u^d} e^{-(\Sigma_{1\leqslant a\leqslant d}\, m^a)x}$$

$$+ O(M^{-2\nu+Min(H_i)+\Sigma_{1\leqslant a\leqslant D}\beta^a+1/2D}) \quad \text{if } M\to 0 \tag{A11}$$

is obtained.

The k-functions with a nonsimple argument may be split according to

$$k(\beta; m|\mathbf{x}_i-\mathbf{x}_{i'}|) = \sum_{l,r=0}^{\infty} \frac{(-)^l}{l!\,r!}\left(\frac{1}{2}\right)^{2l+r} (mx_{i'})^{2l+r}(mx_i)^r (c_{i',i})^r k(\beta+l+r; mx_i) \tag{A12}$$

if

$$x_{i'} < x_i\,. \tag{A13}$$

This formula may be obtained via the representation by Bessel functions and Gegenbauer polynomials, as shown in Ref. 4. It also is obtained by straight insertion of

$$\frac{(\mathbf{x}_i-\mathbf{x}_{i'})^{2k}}{k!} = \sum_{l,r} (-)^r \frac{(x_{i'})^{2l}(2c_{i',i}x_{i'}x_i)^r (x_i)^{2k-2l-2r}}{l!\,r!\,(k-l-r)!}$$

and

$$(\mathbf{x}_i-\mathbf{x}_{i'})^{-2\beta+2k}\Gamma(\beta-k) = \sum_{l,r} (-)^l \frac{(x_{i'})^{2l}(2c_{i',i}x_{i'}x_i)^r (x_i)^{-2\beta+2k-2l-2r}\Gamma(\beta+l+r-k)}{l!\,r!} \tag{A14}$$

into (A2).

Finally, the integral representation of $k(\beta; mx)$ is

$$k(\beta; mx) = \frac{1}{2}\int_0^{\infty} d\rho\;\; \rho^{-\beta} e^{-\rho} e^{-(mx)^2/4\rho}. \tag{A15}$$

APPENDIX B

By multiple application of the n-dimensional Gauss integral

$$G_1(\mathbf{p}^2; m^2) \equiv \int_{-\infty}^{+\infty} d\mathbf{x}\;\; e^{i\mathbf{p}\cdot\mathbf{x}} e^{-(1/4)\,m^2\mathbf{x}^2} = \frac{(4\pi)^\nu}{m^{2\nu}} e^{-\mathbf{p}^2/m^2}, \tag{B1}$$

formula

$$G_{f-1}((\Sigma_a \mathbf{p}_a)^2; m_{a,b}^2)$$
$$\equiv \prod_{1\leqslant i\leqslant f-1} \int d\mathbf{x}_i e^{i\mathbf{p}_i\cdot\mathbf{x}_i} e^{-(1/4)\sum_{1\leqslant a\leqslant i} m_{a,f}{}^2 \mathbf{x}_i^2 - 1/4 \sum_{1\leqslant a\leqslant i} m_{a,i}{}^2 (\mathbf{x}_i-\mathbf{x}_a)^2} = \frac{(4\pi)^{(f-1)\nu}}{(n_{1,2,\dots,f})^{\nu}}$$
$$\cdot \exp\left\{ - \frac{n_1 n_{2,3,\dots,f} \mathbf{p}_1{}^2 + n_2 n_{1,3,\dots,f} \mathbf{p}_2{}^2 + \cdots + n_{1,2} n_{3,4,\dots,f} (\mathbf{p}_1+\mathbf{p}_2)^2 + \cdots + n_{1,2,3} n_{4,5,\dots,f} (\mathbf{p}_1+\mathbf{p}_2+\mathbf{p}_3)^2 + \cdots}{n_{1,2,\dots,f}} \right\} \tag{B2}$$

is obtained.

The coefficients $n_{1,2,\dots,f}$ are sums of products of the square masses of $f-1$ independent internal lines between the vertices $1,2,\dots,f$:

$$n_1 = 1, \quad n_2 = 1, \quad n_3 = 1, \quad \text{etc.},$$
$$n_{1,2} = m_{1,2}{}^2, \quad n_{1,3} = m_{1,3}{}^2, \quad \text{etc.}$$
$$n_{1,2,3} = m_{1,2}{}^2 m_{1,3}{}^2 + m_{1,2}{}^2 m_{2,3}{}^2 + m_{1,3}{}^2 m_{2,3}{}^2, \quad \text{etc.}, \tag{B3}$$
$$\cdots.$$
$$n_{1,2,\cdots,f} = \sum m_{1,f}{}^2 m_{2,f}{}^2 \cdots, m_{f-1,f}{}^2 + \cdots.$$

Combination of (A15) and (B2) yields

$$\prod_{\substack{1\leqslant i\leqslant f-1 \\ 1\leqslant i'<i \\ d}} \int d\mathbf{x}_i e^{i\mathbf{p}_i\cdot\mathbf{x}_i} k_{i,f}^d(\beta; m x_i) k_{i',i}^d(\beta; m|\mathbf{x}_i - \mathbf{x}_{i'}|)\}$$
$$= \prod_{\substack{1\leqslant i'<i\leqslant f \\ d}} \left(\int_0^\infty d\left(\frac{1}{2}\rho_{i',i}^d\right) (\rho_{i',i}^d)^{-\beta_{i',i}^d} e^{-\sum_d^{1\leqslant a'<a\leqslant f} \rho_{a',a}^d} G_{f-1}\left\{ (\Sigma_a \mathbf{p}_a)^2; \sum_d \frac{m_{a,b}^d{}^2}{\rho_{a,b}^d} \right\} \right). \tag{B4}$$

The rhs is, up to a factor, the parameter representation of scalar Feynman diagrams. In the case of spin, polynomials of masses and derivatives with respect to the external momenta, combined with higher β's have to be added, as explained in Sec. II.

The integration parameters ρ come straight from the textbook of Watson. Hence, Feynman parameters were known in mathematical literature long before the discovery of quantum field theory.

APPENDIX C

The expressions for the content of a unit parallelopipidum in one, two, three, and four dimensions are

$$I_1 = 1,$$
$$I_{12} = \sqrt{1 - c_{12}{}^2},$$
$$I_{123} = \sqrt{1 - c_{12}{}^2 - c_{13}{}^2 - c_{23}{}^2 + 2c_{12}c_{23}c_{31}} = I_{13} I_{23} \sqrt{1 - \left(\frac{c_{12} - c_{13}c_{23}}{I_{13} I_{23}} \right)^2},$$

$$I_{1234}$$

$$= \sqrt{1-c_{12}{}^2-c_{13}{}^2-c_{14}{}^2-c_{23}{}^2-c_{24}{}^2-c_{34}{}^2+2c_{12}c_{23}c_{31}+2c_{12}c_{24}c_{41}+2c_{13}c_{34}c_{41}+2c_{23}c_{34}c_{41} \\ +c_{12}{}^2c_{34}{}^2+c_{13}{}^2c_{24}{}^2+c_{14}{}^2c_{23}{}^2-2c_{12}c_{23}c_{34}c_{41}-2c_{13}c_{32}c_{24}c_{41}-2c_{12}c_{24}c_{43}c_{31}}$$

$$= \frac{I_{134}I_{234}}{I_{34}}\sqrt{1-\left(\frac{I_{34}{}^2c_{12}-c_{13}c_{32}-c_{14}c_{42}+c_{13}c_{34}c_{42}+c_{14}c_{43}c_{32}}{I_{134}I_{234}}\right)^2}. \tag{C1}$$

For the general case, the recursion formula

$$I_{1,2,3,,\dots,f}=\frac{I_{1,3,\dots,f}I_{2,3,\dots,f}}{I_{3,\dots,f}}\sqrt{1-y_{12}{}^2} \tag{C2}$$

is valid, with

$$y_{12}=\frac{I_{3,4,\dots,f}{}^2c_{1,2}-b_{1,2(3,4,\dots,f)}}{I_{1,3,\dots,f}I_{2,3,\dots,f}}, \tag{C3}$$

where

$$b_{1,2(3,4,\dots,f)}=c_{13}c_{32}+\cdots+c_{1f}c_{f2}-c_{13}c_{34}c_{42}-\cdots+\cdots \tag{C4}$$

is the coefficient of $2c_{12}$ in $I_{1,2,\dots,f}{}^2$.

Application of these formulas yields

$$\frac{I_{1,2,\dots,f}}{I_{2,\dots,f}}=\sqrt{1-y_{12}{}^2}\sqrt{1-y_{13}{}^2}\cdots\sqrt{1-y_{1,f}{}^2}, \tag{C5a}$$

$$\frac{dc_{12}\cdots dc_{1,f}}{I_{2\dots f}}=dy_{12}\cdots dy_{1,f}\left(\frac{I_{1,3,\dots,f}}{I_{3,4,\dots,f}}\right)\left(\frac{I_{1,4,\dots,f}}{I_{4,5,\dots,f}}\right)\dots\left(\frac{I_{1,f-1,f}}{I_{f-1,f}}\right)I_{1,f}$$
$$=dy_{12}\cdots dy_{1,f}\sqrt{1-y_{13}{}^2}(\sqrt{1-y_{14}{}^2})^2\cdots(\sqrt{1-y_{1,f}{}^2})^{f-2} \tag{C5b}$$

and

$$c_{i,j}=\frac{b_{i,j(j+1,\dots,f)}+y_{i,j}I_{i,j+1,\dots,f}I_{j,j+1,\dots,f}}{I^2_{j+1\dots f-1}}=y_{i,j}(\sqrt{1-(y_{i,j+1})^2}\cdots\sqrt{1-(y_{i,f})^2})$$
$$\times(\sqrt{1-(y_{j,j+1})^2}\cdots\sqrt{1-(y_{j,f})^2})+(y_{i,j+1}\sqrt{1-(y_{i,j+2})^2}\cdots\sqrt{1-(y_{i,f})^2})$$
$$\times(y_{j,j+1}\sqrt{1-(y_{j,j+2})^2}\cdots\sqrt{1-(y_{j,f})^2})+\dots+(y_{i,f-1}\sqrt{1-(y_{i,f})^2})(y_{j,f-1}\sqrt{1-(y_{j,f})^2})$$
$$+y_{i,f}y_{j,f}. \tag{C5c}$$

The formula

$$\frac{c_{i,j}{}^{q_{i,j}}}{q_{i,j}!}=\sum_{\substack{f\\ \sum\\ b=j}}{}_{q_{i,j}{}^b=q_{i,j}}\frac{\{y_{i,j}(\sqrt{1-(y_{i,j+1})^2}\cdots\sqrt{1-(y_{i,f})^2})(\sqrt{1-(y_{j,j+1})^2}\cdots\sqrt{1-(y_{j,f})^2})\}^{q_{i,j}{}^j}}{q_{i,j}{}^j!}\cdots$$
$$\times\left(\frac{y_{i,f}y_{j,f}}{q_{i,j}{}^f!}\right)^{q_{i,j}{}^f}, \tag{C6}$$

has been used in Section III.

APPENDIX D

By multiple application of

$$\prod_{1\leqslant i\leqslant f-1}\int_0^{\eta} d\xi\,\xi^{N-1}\{\ln(m_i\xi)\}^{u_i}=\sum_{0\leqslant u_i^{\,i}\leqslant u_i}\frac{(-)^{\Sigma_{1\leqslant a\leqslant f-1}u_a{}^a}\left(\sum_{1\leqslant a\leqslant f-1}u_a{}^a\right)!}{(N)^{1+\Sigma_{1\leqslant a\leqslant f-1}u_a{}^a}}\times\prod_{i=1}^{f-1}\frac{u_i!}{(u_i-u_i{}^i)!\,u_i{}^i!}\,\eta^N\{\ln(m_i\eta)\}^{u_i-u_i{}^i},\tag{D1}$$

the formula

$$\prod_{1\leqslant i'<i\leqslant f-1}\int_0^{\eta_i} d\xi_i(\xi_i)^{N_i-1}\{\ln(m_{i',i}\xi_i\xi_{i+1}\cdots\xi_{f-1})\}^{u_{i',i}}$$

$$=\sum_{n_{a,b}{}^c}\prod_{1\leqslant i'<i\leqslant i''\leqslant f-1}\frac{(-)^{u_{i',i}{}^{i''}}\left(\Sigma_{1\leqslant a'<a\leqslant i}u_{a',a}{}^i\right)!\,u_{i',i}!}{\left(u_{i',i}-\Sigma_{i\leqslant c\leqslant f-1}u_{i',i}{}^c\right)!\,u_{i',i}{}^{i''}!\,N_i^{1+\Sigma_{1\leqslant a'<a\leqslant i}u_{a',a^i}}}\times\eta_i^{N_i}\{\ln(m_{i',i}\eta_i\eta_{i+1}\cdots\eta_{f-1})\}^{u_{i',i}-\sum_{i\leqslant c\leqslant f-1}u_{i',i}{}^c}\tag{D2}$$

is obtained.

These formulas are obtained after a number of partial integrations. As a matter of fact, these are the partial integrations discussed in the introduction and presumably meant in Ref 3.

Classical history theory of vector fields

Duncan Noltingk[a)]
Blackett Laboratory, Imperial College, Prince Consort Road, London SW7 2BZ, United Kingdom

(Received 19 July 2001; accepted for publication 13 November 2001)

We consider the extension of classical history theory to the massive vector field and electromagnetism. It is argued that the action of the two Poincaré groups introduced by Savvidou suggests that the history fields should have five components. The extra degrees of freedom introduced to make the fields five dimensional result in an extra pair of second class constraints in the case of the massive vector field, and in an extended gauge group in the case of electromagnetism. The total gauge transformations depend on two arbitrary parameters, and contain ''internal'' and ''external'' U(1) gauge transformations as subgroups. © *2002 American Institute of Physics.*

I. INTRODUCTION

A. Motivation

The Hamiltonian formalism provides a strong link between classical and quantum theories and is mathematically well-developed in both cases. However, a major drawback of the standard Hamiltonian approach to relativistic field theories is that it requires a splitting of space–time into space and time, thus breaking the manifest covariance of the theory. This problem becomes particularly acute when canonical methods are applied to generally covariant theories such as general relativity, and this is one aspect of the ''problem of time'' in canonical quantum gravity.

Recently a Hamiltonian formalism has been proposed by Isham and co-workers,[1–3] in which the fundamental physical entities are entire histories of the system under consideration, as opposed to Cauchy data at an instant of time. For a thorough introduction see Ref. 4. The histories formalism was originally developed in the quantum case, but there is a well-defined classical history formalism. The central object in a classical history theory is the space of histories, Π, which is defined to be a one-parameter family of single-time state spaces. An element of Π is called a history, and the space of histories carries a symplectic structure which provides the crucial link to the corresponding quantum history theory.

A particularly striking fact about history theories is that there are two notions of time evolution.[5] External time corresponds to the parameter labeling the copies of state space, and internal time is generated by Hamiltonian evolution. In this way the notion of time plays two different roles in a history theory, one corresponding to the causal ordering of logical propositions, and the second corresponding to dynamical evolution. The two times are linked together in the action principle.

The histories formalism has been applied to scalar field theory on flat[6] and curved[7,8] space–times, and in the following we discuss the extension of the classical theory to the case of vector fields. In particular we examine the massive vector field and the electromagnetic field from a histories perspective. We shall argue that, as a consequence of the two time directions, a history field should be regarded as a certain type of field on a five-dimensional space–time. We also give an analysis of the gauge transformations of histories electromagnetism.

These results are relevant to the ultimate goal of the histories program: the formulation of a histories version of general relativity.[9] First, they suggest the possibility that a covariant history

a)Electronic mail: d.noltingk@ic.ac.uk

theory of gravity should be concerned with the metric of a five-dimensional extended space–time. Second, gauge symmetry is an important feature of general relativity, particularly when formulated in terms of tetrad fields. The study of the extended gauge transformations of histories electromagnetism is relevant in this context.

B. Scalar field theory

In this section we give a brief account of the histories description of the classical scalar field on Minkowski space–time, $\mathcal{M}$, as given by Savvidou.[6] We define the Minkowski metric $\eta_{\mu\nu}$ to have signature $(+,-,-,-)$.

1. The history algebra

The canonical configuration space of the scalar field is $Q_{n,t}=C^\infty(\Sigma_{n,t})$ where $\Sigma_{n,t}$ is a Cauchy surface in $\mathcal{M}$, and $C^\infty(\Sigma_{n,t})$ denotes the set of all smooth, real-valued functions on $\Sigma_{n,t}$. The Cauchy surfaces are labeled by a future pointing timelike unit vector n normal to $\Sigma_{n,t}$, and a real number t. Each Cauchy surface represents an instant of time in a particular inertial frame. The state space $P_{n,t}$ is identified with $C^\infty(\Sigma_{n,t})\times C^\infty(\Sigma_{n,t})$ which is a dense subspace of the cotangent bundle of $Q_{n,t}$. The construction of the corresponding classical history theory begins by defining a trivial vector bundle $\xi_n : P\times\mathbb{R}\to\mathbb{R}$ such that $\xi_n^{-1}(t)=P_{n,t}$, where P is an abstract copy of the state space. The space of histories of the scalar field corresponds to the space of sections of this bundle, $\Pi_n=\Gamma(\xi_n)$. Note that Π_n could be defined directly as the space of paths $\mathbb{R}\to P_n$. However, the bundle picture is useful in more general situations (e.g., on curved space–times), and also gives a motivation for the ''internal'' / ''external'' nomenclature in history theory: internal transformations act internally to the fibers of ξ_n, while external transformations act across the fibers. The history fields satisfy the following Poisson algebra:

$$\{\phi_n(t;\mathbf{x}),\phi_n(t';\mathbf{x}')\}=0, \tag{1}$$

$$\{\pi_n(t;\mathbf{x}),\pi_n(t';\mathbf{x}')\}=0, \tag{2}$$

$$\{\phi_n(t;\mathbf{x}),\pi_n(t';\mathbf{x}')\}=\delta(t-t')\,\delta^{(3)}_{n,t}(\mathbf{x}-\mathbf{x}'), \tag{3}$$

where $\delta^{(3)}_{n,t}(\mathbf{x}-\mathbf{x}')$ is the delta function on $\Sigma_{n,t}$. The right-hand side of this equation is a space–time scalar density of weight one. In Minkowski space–time, there is no difference between a scalar density and a scalar (if we restrict attention to transformations under the connected part of the Poincaré group), which suggests that the fields can be thought of as space–time scalars. A pair $(t,\mathbf{x})\in\mathbb{R}\times\Sigma$ can be identified with a unique four-vector $X\in\mathcal{M}$ as $X=tn+x_n$, where the three-vector $\mathbf{x}$ has been associated with a corresponding four-vector x_n that is n-spatial (i.e., $n\cdot x_n := \eta_{\mu\nu}n^\mu x_n^\nu=0$). Hence we can write $\phi_n(t;\mathbf{x})$ as $\phi_n(X)$. The history algebra can then be written in the more covariant looking form

$$\{\phi_n(X),\phi_n(X')\}=0, \tag{4}$$

$$\{\pi_n(X),\pi_n(X')\}=0, \tag{5}$$

$$\{\phi_n(X),\pi_n(X')\}=\delta^{(4)}(X-X'). \tag{6}$$

Now it is tempting to drop the n label from the fields since the right-hand side of this algebra does not depend on n. However, this would be somewhat misleading in the sense that the field $\pi(X)$ has no physical meaning. This is because the conjugate momentum corresponds to the field momentum along a certain timelike *direction*, and so must be written as $\pi_n(X)$. Although the algebra (4)–(6) is independent of n, Savvidou[6] has shown that in the quantum theory n labels the physically relevant, inequivalent *representations* of the algebra on a particular Fock space. So in the analysis of the classical theory the n-labels remain on the fields under the understanding that

they are necessary for the physical interpretation of the theory and arise naturally in quantization. However, we note that it is rather unsatisfactory to have an n label on the ϕ field because, physically, the value of the field at a point in space–time *is* independent of the foliation. In this particular histories formulation of classical scalar field theory all propositions about the field are made in the context of a particular inertial reference frame.

2. Time translations

For each n, a ''Liouville'' functional can be constructed from the fields,

$$V_n := \int d^4X \pi_n n_\mu \partial^\mu \phi_n , \tag{7}$$

which generates external time translations in the n direction. In coordinates adapted to n these transformations take the form $\phi_n(t,\mathbf{x}) \mapsto \phi_n(t+\lambda,\mathbf{x})$, and similarly for $\pi_n(t,\mathbf{x})$.

There is another notion of time translation in the history theory. Intuitively the Hamiltonian at each instant of external time generates dynamical evolution *internal* to each fiber of ξ_n. More precisely, the time-averaged Hamiltonian,

$$H_n := \frac{1}{2} \int d^4X [\, \pi_n^2 + (\, \eta^{\mu\nu} - n^\mu n^\nu) \partial_\mu \phi_n \partial_\nu \phi_n + m^2 \phi_n^2], \tag{8}$$

generates transformations $\phi_n(X) \mapsto \phi_n(X,s)$.

The action operator is made up of the Liouville and Hamiltonian operators as follows:

$$S_n := V_n - H_n , \tag{9}$$

and the equations of motion can be written in the form

$$\{S_n , \phi_n(X)\} = 0, \tag{10}$$

$$\{S_n , \pi_n(X)\} = 0. \tag{11}$$

3. Poincaré covariance

Savvidou[6] has shown the existence of two Poincaré groups in the histories formulation of the scalar field. The n-spatial components of the two groups are identical, but the time translations of the internal Poincaré group are generated by the Hamiltonian while the time translations of the external Poincaré group are generated by the Liouville functional.

External boosts correspond to the following automorphism of the history algebra:

$$\phi_n(t,\mathbf{x},0) \mapsto \phi_{\Lambda n}(\Lambda(t,\mathbf{x}),0), \tag{12}$$

$$\pi_n(t,\mathbf{x},0) \mapsto \pi_{\Lambda n}(\Lambda(t,\mathbf{x}),0), \tag{13}$$

where we have used adapted coordinates to write $\phi_n(X,0) = \phi_n(t,\mathbf{x},0)$ and $\Lambda(t,\mathbf{x})$ denotes the usual Lorentz transformations acting on inertial coordinates $(t,\mathbf{x})$. We note that, in the classical case, these automorphisms cannot be generated by canonical transformations. This is because there is no momentum conjugate to the foliation vector n, and thus no way to generate changes in n. The ''multisymplectic'' approach[10] offers a solution to this problem in the classical theory, and in the quantum theory changes in n correspond to mapping between inequivalent representations of the history algebra.

Internal boosts act on the fields as follows:

$$\phi_n(0,\mathbf{x},s) \mapsto \phi_n(0,\Lambda(\mathbf{x},s)), \tag{14}$$

$$\pi_n(0,\mathbf{x},s)\mapsto\pi_n(0,\Lambda(\mathbf{x},s)). \tag{15}$$

The internal boosts leave the foliation vector fixed and can be implemented by canonical transformations. The generator of internal boosts on the hyperplane $s=\text{const}$ is

$$^{\text{int}}K_n(m)=m_\mu\int d^4X[\,\pi s\,\partial^\mu\phi-X^\mu H_n(X)], \tag{16}$$

where $H_n(X)$ is the Hamiltonian density and the integral is over the surface $s=\text{const}$.

The fields $\phi_n(X,s)$ are defined on an extended space–time $\mathcal{N}=\mathcal{M}\times\mathbb{R}$. However, the theory is not invariant under the full SO(2, 3) isometry group of this space–time. This is evident from the fact that the algebra (4)–(6) is defined on external space–time, that is the surface in $\mathcal{N}$ defined by $s=0$, and does not take the same form on internal space–time (defined by $n\cdot X=0$). This indicates that the fields are not true scalar fields on $\mathcal{N}$. However, the fields are covariant under the internal and external SO(1, 3) subgroups of SO(2, 3).

In the case of the scalar field these subtleties can be overlooked, but the construction of a history theory of vector fields acutely illustrates this issue. A particularly relevant question is whether the history vector field should have four indices, or five as it must to be a vector field on $\mathcal{N}$.

II. MASSIVE VECTOR FIELD

A. State space theory

In this section we give a brief overview of the standard state space theory of the massive vector field on $\mathcal{M}$.

We begin with the covariant theory. The covariant configuration space is $\mathcal{X}_0(\mathcal{M})$, the space of vector fields on $\mathcal{M}$ with appropriate boundary conditions. The massive vector field is described by the following Lagrangian:[11]

$$\mathcal{L}=-\tfrac{1}{4}\phi_{\mu\nu}\phi^{\mu\nu}+\tfrac{1}{2}m^2\phi_\mu\phi^\mu, \tag{17}$$

where $\phi^{\mu\nu}(X):=2\partial^{[\mu}\phi^{\nu]}(X)$ and $\phi\in\mathcal{X}_0(\mathcal{M})$. The resulting field equations are

$$(\Box+m^2)\phi^\mu(X)=0, \tag{18}$$

$$\partial_\mu\phi^\mu(X)=0. \tag{19}$$

The first of these equations shows that each component of the field behaves like a massive scalar field. The second equation is known as the Fierz–Pauli equation and it is the first indication of the presence of constraints in the theory.

To pass to the canonical theory we choose a Cauchy surface in $\mathcal{M}$ and consider the fields on this Cauchy surface. More precisely, we choose a spacelike embedding $\iota:\Sigma\to\mathcal{M}$, where $\Sigma\simeq\mathbb{R}^3$, and take the corresponding configuration space to be the space of fields $\phi^\mu_\iota(\mathbf{x})$ where $\mathbf{x}\in\Sigma$. However the fields $\phi^\mu_\iota(\mathbf{x})$ are not geometric objects on either Σ or $\mathcal{M}$. The geometrical interpretation of the fields is clarified by considering $\text{Emb}(\Sigma,\mathcal{M})$, the space of embeddings of Σ into $\mathcal{M}$. Then ϕ_ι can be thought of as an element of $T_\iota\text{Emb}(\Sigma,\mathcal{M})$ where the tangent space to $\text{Emb}(\Sigma,\mathcal{M})$ at the embedding ι is defined as

$$T_\iota\text{Emb}(\Sigma,\mathcal{M})=\{\psi:\Sigma\to T\mathcal{M}\,|\,\psi(\mathbf{x})\in T_{\iota(\mathbf{x})}\mathcal{M}\}. \tag{20}$$

The configuration space of the canonical theory is then defined as $Q_\iota:=T_\iota\text{Emb}(\Sigma,\mathcal{M})$ for some fixed ι. The cotangent space of $\text{Emb}(\Sigma,\mathcal{M})$ at ι is defined similarly:

$$T^*_\iota\text{Emb}(\Sigma,\mathcal{M})=\{l:\Sigma\to T^*\mathcal{M}\,|\,l(\mathbf{x})\in T^*_{\iota(\mathbf{x})}\mathcal{M}\} \tag{21}$$

and the pairing between these two spaces is given by

$$\langle l, \psi \rangle_\iota = \int_\Sigma \mathrm{d}\theta_{\mathbf{x}} l_\mu(\iota(\mathbf{x}))\psi^\mu(\iota(\mathbf{x})), \tag{22}$$

where $\mathrm{d}\theta_{\mathbf{x}}$ is an arbitrary volume element on Σ. The state space P_ι is defined as the Cartesian product $Q_\iota \times T^*_\iota \mathrm{Emb}(\Sigma, \mathcal{M})$.

As we are considering flat space–time, there exists a family of preferred embeddings; those which correspond to inertial frames. The space of preferred embeddings can be parametrized by pairs (n,t) where n is a future pointing unit vector in $\mathcal{M}$ and $t \in \mathbb{R}$. As we are considering a deterministic system, we choose $t=0$ without loss. We denote the configuration space and the state space corresponding to the embedding labeled by $(n,0)$ as Q_n and P_n, respectively. The state space P_n carries the following Poisson algebra:

$$\{\phi^\mu_n(\mathbf{x}), \phi^\nu_n(\mathbf{x}')\} = 0, \tag{23}$$

$$\{\pi^n_\mu(\mathbf{x}), \pi^n_\nu(\mathbf{x}')\} = 0, \tag{24}$$

$$\{\phi^\mu_n(\mathbf{x}), \pi^n_\nu(\mathbf{x}')\} = \delta^\mu_\nu \delta^{(3)}_n(\mathbf{x}-\mathbf{x}'), \tag{25}$$

where $\delta^{(3)}_n(\mathbf{x}-\mathbf{x}')$ is the delta function on Σ_n.

A field $\phi^\mu_n(\mathbf{x}) \in Q_n$ can be decomposed into the pair $(\phi^t_n(\mathbf{x}), {}^n\phi^\mu(\mathbf{x}))$ where

$$\phi^t_n(\mathbf{x}) := n_\mu \phi^\mu_n(\mathbf{x}), \tag{26}$$

$${}^n\phi^\mu(\mathbf{x}) := {}^nP^\mu_\nu \phi^\nu_n(\mathbf{x}), \tag{27}$$

and we have introduced the n-spatial projection tensor defined by

$${}^nP^\mu_\nu := \delta^\mu_\nu - n^\mu n_\nu. \tag{28}$$

It follows that $n_\mu {}^nP^\mu_\nu = 0$ and $n^\nu {}^nP^\mu_\nu = 0$. The fields $\phi^t_n(\mathbf{x})$ and ${}^n\phi^\mu(\mathbf{x})$ are defined on the space of embeddings, but $\phi^t_n(\mathbf{x})$ pulls back to give a "scalar field" on Σ_n. We can use the metric on $\mathcal{M}$ to lower the index on ${}^n\phi^\mu(\mathbf{x})$. The resulting one-form can be pulled back to Σ_n, and then the index can be raised using the metric on Σ_n to give a "vector field" on Σ_n. In a similar way, objects defined by ${}^n\pi_\mu(\mathbf{x}) := {}^nP^\nu_\mu \pi^n_\nu(\mathbf{x})$, and ${}^n\phi^{\mu\nu}(\mathbf{x}) := {}^nP^\mu_\sigma {}^nP^\nu_\rho \phi^{\sigma\rho}_n(\mathbf{x})$ can be thought of as a "one-form" and a "covariant tensor" on Σ_n.

The canonical momenta are computed from the Lagrangian and turn out to be[12]

$$\pi^n_t(\mathbf{x}) = 0, \quad {}^n\pi_\mu(\mathbf{x}) = {}^nP^\rho_\mu n^\nu \phi_{\nu\rho}(\mathbf{x}). \tag{29}$$

The first of these equations is a primary constraint. The canonical Hamiltonian is computed to be

$$H_n = \int_\Sigma \mathrm{d}\theta_{\mathbf{x}} \left[\frac{1}{2} {}^n\pi_\mu {}^n\pi^\mu + \frac{1}{4} {}^n\phi_{\mu\nu} {}^n\phi^{\mu\nu} - \frac{1}{2} m^2 (\phi^t_n)^2 + \frac{1}{2} m^2 {}^n\phi_\mu {}^n\phi^\mu - \phi^t_n {}^n\partial^\mu {}^n\pi_\mu \right], \tag{30}$$

where the n-spatial derivative is defined as ${}^n\partial^\mu = {}^nP^\mu_\nu \partial^\nu$. For the primary constraint $\pi^n_t(\mathbf{x}) = 0$ to be preserved by the dynamical evolution, it is necessary and sufficient that $\{H_n, \pi^n_t(\mathbf{x})\} = 0$. This implies the secondary constraint

$$m^2 \phi^t_n(\mathbf{x}) + {}^n\partial^\mu {}^n\pi_\mu(\mathbf{x}) = 0. \tag{31}$$

A point in the constraint surface C_n determines and is fully determined by the pair $({}^n\pi_\mu(\mathbf{x}), {}^n\phi^\nu(\mathbf{x}))$.

The constraints do not commute under the Poisson bracket and so they form a second class pair. This implies that the pull-back of the symplectic two-form on P_n to the constraint surface is nondegenerate. Therefore there is a well-defined Poisson algebra on the constraint surface which is given by the Dirac brackets:

$$\{{}^n\phi^\mu(\mathbf{x}), {}^n\pi_\nu(\mathbf{x}')\}_D = {}^nP^\mu_\nu \delta^{(3)}(\mathbf{x}-\mathbf{x}'), \tag{32}$$

with all other brackets vanishing.

B. Classical history theory

We begin with the abstract state space P, and follow the usual procedure of taking a one-parameter family of copies of P. This results in a trivial vector bundle $\xi_n : P\times\mathbb{R}\to\mathbb{R}$ where the fiber $\xi_n^{-1}(t) = P_{n,t}$ for each t. Sections of ξ_n correspond to histories of the vector field with respect to the foliation labeled by n. Thus a history is a map

$$h_n : t \mapsto (\phi^\mu_n(t;\mathbf{x}), \pi^n_\nu(t;\mathbf{x})). \tag{33}$$

If we choose a volume element on $\mathbb{R}$ then a symplectic structure is induced on the space of maps $\mathbb{R}\to P$ because P is a symplectic manifold. Using the Lebesgue measure, the symplectic structure defines the following algebra:

$$\{\phi^\mu_n(t;\mathbf{x}), \phi^\nu_n(t';\mathbf{x}')\} = 0, \tag{34}$$

$$\{\pi^n_\mu(t;\mathbf{x}), \pi^n_\nu(t';\mathbf{x}')\} = 0, \tag{35}$$

$$\{\phi^\mu_n(t;\mathbf{x}), \pi^n_\nu(t';\mathbf{x}')\} = \delta^\mu_\nu \delta(t-t')\,\delta^{(3)}_n(\mathbf{x}-\mathbf{x}'). \tag{36}$$

In the case of the scalar field a one-parameter family of functions on Σ_n:

$$t \mapsto \phi_n(t;\mathbf{x}) \tag{37}$$

was identified with a function $\phi_n(X)$ on $\mathcal{M}$. In a similar way, for a fixed foliation, a one-parameter family of elements of Q_n,

$$t \mapsto \phi^\mu_n(t;\mathbf{x}), \tag{38}$$

is equivalent to a unique vector field $\phi^\mu_n(X) \in \mathcal{X}(\mathcal{M})$. The one-parameter family $t\mapsto\pi^n_\mu(t;\mathbf{x})$ can be identified with a one-form $\pi^n_\mu(X) \in \Lambda^1(\mathcal{M})$ in the same way, and these fields satisfy the covariant looking algebra

$$\{\phi^\mu_n(X), \phi^\nu_n(X')\} = 0, \tag{39}$$

$$\{\pi^n_\mu(X), \pi^n_\nu(X')\} = 0, \tag{40}$$

$$\{\phi^\mu_n(X), \pi^n_\nu(X')\} = \delta^\mu_\nu \delta^{(4)}(X-X'). \tag{41}$$

In this way, the history space, Π_n, can be identified with the space $\mathcal{X}(\mathcal{M})\times\Lambda^1(\mathcal{M})$. We can decompose $\phi^\mu_n(X)$ into the pair $(\phi^t_n(X), {}^n\phi^\mu(X))$ defined by

$$\phi^t_n(X) := n_\mu \phi^\mu_n(X), \tag{42}$$

$${}^n\phi^\mu(X) := {}^nP^\mu_\nu \phi^\nu_n(X), \tag{43}$$

and we use these fields to define the generators of internal and external time translations. External time translations are generated by the ''Liouville'' functional,

$$V_n := \int d^4X \, [\, \pi_t^n n_\nu \partial^\nu \phi_n^t + {}^n\pi_\mu n_\nu \partial^\nu {}^n\phi^\mu]. \tag{44}$$

Internal time translations are generated by the time-averaged Hamiltonian

$$H_n = \int d^4X \Big[\frac{1}{2} {}^n\pi_\mu {}^n\pi^\mu + \frac{1}{4} {}^n\phi_{\mu\nu} {}^n\phi^{\mu\nu} - \frac{1}{2} m^2 (\phi_n^t)^2 \tag{45}$$

$$+ \frac{1}{2} m^2 {}^n\phi_\mu {}^n\phi^\mu - \phi_n^t {}^n\partial^\mu {}^n\pi_\mu \Big]. \tag{46}$$

The internal time translations generated by H_n take the form

$$\phi_n^\mu(X) \mapsto \phi_n^\mu(X,s). \tag{47}$$

In Sec. II C we will consider the geometric meaning of these curious objects which have four components, but depend on five space–time variables.

In the remainder of this section we discuss the history constraint surface $\mathcal{C}_n \subset \Pi_n$. An arbitrary element of Π_n will not be compatible with the constraints. The constraint submanifold, $\mathcal{C}_n$, contains all elements of Π which satisfy the constraints:

$$\pi_t^n(X) = 0, \quad m^2 \phi_n^t(X) + {}^n\partial^\mu {}^n\pi_\mu(X) = 0. \tag{48}$$

Thus a point in $\mathcal{C}_n$ is equivalent to a pair $({}^n\phi^\mu(X), {}^n\pi_\nu(X))$. The Poisson algebra induced on $\mathcal{C}_n$ by pulling back along the natural inclusion map $\mathcal{C}_n \hookrightarrow \Pi_n$ is given by

$$\{ {}^n\phi^\mu(X), {}^n\phi^\nu(X') \} = 0, \tag{49}$$

$$\{ {}^n\pi_\mu(X), {}^n\pi_\nu(X') \} = 0, \tag{50}$$

$$\{ {}^n\phi^\mu(X), {}^n\pi_\nu(X') \} = {}^nP^\mu_\nu \delta^{(4)}(X - X'), \tag{51}$$

and we note that $\mathcal{C}_n$ is symplectomorphic to the space of sections of the bundle $C_n \times \mathbb{R} \to \mathbb{R}$.

C. Poincaré covariance

As discussed in Sec. I. B. 3 for the case of the scalar field, the notion of two times leads naturally to the definition of two Poincaré groups. The external Poincaré group mixes the external time with the n-spatial variables $\mathbf{x}$ and the internal Poincaré group mixes internal time with $\mathbf{x}$. The crucial new feature of the generators for the vector field is the mixing of the time-like and space-like components of the field.

1. External Poincaré group

The generators of external space–time translations can be written in covariant looking form as

$${}^{\text{ext}}P^\mu_n = \int d^4X \, \pi^n_\nu(X) \partial^\mu \phi^\nu_n(X). \tag{52}$$

Next we define

$$M^{\mu\nu}_n = \int d^4X \, \pi^n_\rho(X) (X^\mu \partial^\nu - X^\nu \partial^\mu) \phi^\rho_n(X) + \sigma^{\mu\nu}_n, \tag{53}$$

where the "spin tensor" is

$$\sigma_n^{\mu\nu} = \int d^4X \pi_\rho^n(X)(\delta^{\rho\mu}\delta_\sigma^\nu - \delta^{\rho\nu}\delta_\sigma^\mu)\phi_n^\sigma(X). \tag{54}$$

By an "n-spatial rotation" we shall mean a rotation that leaves n fixed. n-spatial rotations can be parametrized by two vectors m^1 and m^2 satisfying $m^1 \cdot n = m^2 \cdot n = 0$ in the following way:

$$M_n(m^1, m^2) = m_\mu^1 m_\nu^2 M_n^{\mu\nu}. \tag{55}$$

As in the case of the scalar field, the external boosts cannot be implemented by canonical transformations because of the change in foliation. The natural definition of the automorphisms generated by the action of the external boosts is

$$\phi_n^\mu(t,\mathbf{x},0) \mapsto \Lambda_\nu^\mu \phi_{\Lambda n}^\nu(\Lambda(t,\mathbf{x}),0), \tag{56}$$

$$\pi_\mu^n(t,\mathbf{x},0) \mapsto \Lambda_\mu^\nu \pi_\nu^{\Lambda n}(\Lambda(t,\mathbf{x}),0). \tag{57}$$

So the external boosts mix t with $\mathbf{x}$, and the external time component $\phi_{\Lambda n}^t(t,\mathbf{x},0)$ with the space-like components ${}^{\Lambda n}\phi^\mu(t,\mathbf{x},0)$.

2. Internal Poincaré group

The n-spatial rotation and translation generators of the internal Poincaré group coincide with those for the external Poincaré group. However, internal time translations are generated by the Hamiltonian, and therefore act internally as $\phi_n^\mu(X) \mapsto \phi_n^\mu(X,s)$. We tentatively define the generator of internal Lorentz transformations on the $s = \text{const}$ hyperplane in the "obvious" way:

$${}^{\text{int}}K_n(m) := m_\mu \int d^4X[\pi_\nu^n s\partial^\mu \phi_n^\nu - X^\mu H_n(X)] + n_\mu m_\nu \sigma^{\mu\nu}, \tag{58}$$

where $H_n(X)$ is the Hamiltonian density, m is a vector satisfying $m \cdot n = 0$, and the integral is over the surface $s = \text{const}$. This functional generates the automorphisms

$$\phi_n^\mu(0,\mathbf{x},s) \mapsto \Lambda_\nu^\mu \phi_n^\nu(0,\Lambda(\mathbf{x},s)), \tag{59}$$

$$\pi_\mu^n(0,\mathbf{x},s) \mapsto \Lambda_\mu^\nu \pi_\nu^n(0,\Lambda(\mathbf{x},s)). \tag{60}$$

${}^{\text{int}}K_n(m)$ mixes s with $\mathbf{x}$, and $\phi_n^t(0,\mathbf{x},s)$ with ${}^n\phi_n^\mu(0,\mathbf{x},s)$. So in this transformation, the function $\phi_n^t(0,\mathbf{x},s)$ is associated with the *internal* time direction, whereas it was associated with the *external* time direction by the external boosts. These transformations are rather curious, and do not lead to a clear geometric interpretation of the history vector field.

D. Alternative interpretations of the history vector field

The above-presented discussion suggests that it is inappropriate to think of the history vector fields as a family of four-vectors on external space–time. We propose two alternative interpretations of the history vector fields.

1. Four-component fields

One way of thinking of the history fields is as a family of four-vectors, but with the temporal component in the $\partial_\tau := \partial_s + \partial_t$ direction,

$$\phi_n = \phi_n^\tau(X,s)\partial_\tau + \phi_n^i(X,s)\partial_i, \tag{61}$$

where $\phi_n^\tau(X,s) = \phi_n^t(X,s)$ and we have used coordinates adapted to n. From this perspective it is natural to look for a representation of the Poincaré group in which the boosts act in this direction. The internal boost generator on $s = 0$ would be

$$K_n(m) := \int d^4X[n\cdot X\pi^n_\mu(X)m_\nu\partial^\nu\phi^\mu_n(X) - m\cdot X(V_n(X)+H_n(X))], \tag{62}$$

where $V_n(X)$ is the ''Liouville'' density. However, it can be shown that

$$\{K_n(m^1),K_n(m^2)\} \neq m^1_\mu m^2_\nu M^{\mu\nu}_n, \tag{63}$$

even on the solutions to the equations of motion, and so the functionals $K_n(m)$ do not form a representation of the Poincaré group.

Thus it is not possible to eliminate the two times in favor of one ''physical'' time direction ∂_τ, in a covariant way. Nevertheless, τ does have a special significance in the theory. This is indicated by the equations of motion. Returning to the example of the scalar field for a moment, if $\phi_n(X)$ is a solution then $\{S_n,\phi_n(X)\}=0$ implies that

$$(\partial_s-\partial_t)\phi_n(X)|_{s=0}=0 \tag{64}$$

and so all the temporal change in such histories occurs in the τ direction.

2. Five-component fields

We can augment $\phi^\mu_n(X,s)$ with a new degree of freedom $\phi^s_n(X,s)$ to form $\tilde{\phi}^M_n(X,s)$, a five-component ''vector field'' on the extended space–time $\mathcal{N}=\mathcal{M}\times\mathbb{R}$. The extended fields are written

$$\tilde{\phi}_n=\tilde{\phi}^M_n(X,s)\partial_M, \quad \tilde{\pi}^n=\tilde{\pi}^n_M(X,s)\mathrm{d}x^M. \tag{65}$$

The label M runs over t, 1, 2, 3, s, where we define $M=t$ to refer to external time, $M=1,2,3$ to correspond to the spatial directions, and $M=s$ to refer to internal time.

The extended history space, $\tilde{\Pi}_n$, contains all ordered pairs $(\tilde{\phi}_n,\tilde{\pi}_n)$ that satisfy the internal field equations:

$$\partial_s\tilde{\phi}^M_n(X,s)=\{\tilde{H}_n,\tilde{\phi}^M_n(X,s)\}, \tag{66}$$

$$\partial_s\tilde{\pi}^n_M(X,s)=\{\tilde{H}_n,\tilde{\pi}^n_M(X,s)\}, \tag{67}$$

where $\tilde{H}_n$ is the Hamiltonian on extended history space, and is defined in Sec. II. E.

The history algebra can be extended to these fields in a natural way:

$$\{\tilde{\phi}^M_n(X),\tilde{\pi}^n_N(X')\}=\delta^M_N\delta^{(4)}(X-X'). \tag{68}$$

This defines the algebra of the fields on the surface $s=0$, which is a submanifold of $\mathcal{N}$. Hamiltonian evolution can be used to extend this definition to the rest of $\mathcal{N}$. The fact that the algebra is naturally defined on the hyperplane $s=0$ and not on the hyperplane $n\cdot X=0$ reflects the underlying asymmetry between the two ''modes'' of time. As a consequence of this asymmetry, the theory constructed from the fields $\tilde{\phi}_n$ will not be covariant under the full SO(2, 3) isometry group associated with $\mathcal{N}$. In particular it will not be covariant under the action of the SO(2) subgroup acting in the (s,t) plane.

In order to discuss the Poincaré transformations of the five-component fields, we make the definition:

$$\tilde{M}^{MN}_n=\int_{\mathcal{M}^{(e)}}d^4X\tilde{\pi}^n_R(X)(X^M\partial^N-X^N\partial^M)\tilde{\phi}^R_n(X)+\tilde{\sigma}^{MN}_n, \tag{69}$$

where $\mathcal{M}^{(e)} \subset \mathcal{N}$ is external space–time, defined as the surface $s=0$, and the extended spin tensor is defined as

$$\tilde{\sigma}_n^{MN} = \int_{\mathcal{M}^{(e)}} d^4X \tilde{\pi}_A^n(X)(\delta^{AM}\delta_B^N - \delta^{AN}\delta_B^M)\tilde{\phi}_n^B(X). \tag{70}$$

Using $\tilde{M}_n^{MN}$ we can write the rotation generators as

$$\tilde{M}_n(\tilde{m}^1,\tilde{m}^2) = \tilde{m}_M^1 \tilde{m}_N^2 \tilde{M}_n^{MN}, \tag{71}$$

where $\tilde{m}^1$ and $\tilde{m}^2$ are n-spatial in the sense that $\tilde{m}_M^1 \tilde{n}^M = \tilde{m}_M^1 \tilde{e}^M = 0$, and similarly for $\tilde{m}^2$.

The foliation vector n is an element of the external space–time which is a subspace of $\mathcal{N}$. Using the canonical embedding, n can be considered as a vector in $\mathcal{N}$, which we denote by $\tilde{n}$ and is given in coordinates (X,s) by $(n,0)$. Using this coordinate system the internal future pointing unit vector $\tilde{e}$ can be written as $(0,1)$. We can use these vectors to decompose an extended field $\tilde{\phi}_n^M(X,s)$ into its external and internal time components as follows:

$$\tilde{\phi}_n^t(X,s) = \tilde{n}_M \tilde{\phi}_n^M(X,s), \quad \tilde{\phi}_n^s(X,s) = \tilde{e}_M \tilde{\phi}_n^M(X,s). \tag{72}$$

Finally, given three orthogonal, n-spatial, unit vectors in $\mathcal{N}$, $\tilde{m}^i$, where $i=1,2,3$, the spatial components of $\tilde{\phi}_n^M(X,s)$ are

$$\tilde{\phi}_n^i(X,s) = \tilde{m}_M^i \tilde{\phi}_n^M(X,s). \tag{73}$$

Using this basis we write the action of the external boosts as

$$\tilde{\phi}_n^s(t,\mathbf{x},0) \mapsto \tilde{\phi}_{\Lambda n}^s(\Lambda(t,\mathbf{x}),0), \tag{74}$$

$$\tilde{\phi}_n^\mu(t,\mathbf{x},0) \mapsto \Lambda_\nu^\mu \tilde{\phi}_{\Lambda n}^\nu(\Lambda(t,\mathbf{x}),0), \tag{75}$$

$$\tilde{\pi}_s^n(t,\mathbf{x},0) \mapsto \tilde{\pi}_s^{\Lambda n}(\Lambda(t,\mathbf{x}),0), \tag{76}$$

$$\tilde{\pi}_\mu^n(t,\mathbf{x},0) \mapsto \Lambda_\mu^\nu \tilde{\pi}_\nu^{\Lambda n}(\Lambda(t,\mathbf{x}),0), \tag{77}$$

where μ takes the values t, 1, 2, 3.

Internal boosts are generated by

$${}^{\text{int}}\tilde{K}_n(\tilde{m}) := \tilde{m}_M \int_{\mathcal{M}_s^{(e)}} d^4X[\tilde{\pi}_N^n s\partial^M \tilde{\phi}_n^N - X^M \tilde{H}_n(X)] + \tilde{e}_M \tilde{m}_N \tilde{\sigma}_n^{MN}, \tag{78}$$

and the resultant automorphisms are

$$\tilde{\phi}_n^t(0,\mathbf{x},s) \mapsto \tilde{\phi}_n^t(0,\Lambda(\mathbf{x},s)), \tag{79}$$

$$\tilde{\phi}_n^{\bar{\mu}}(0,\mathbf{x},s) \mapsto \Lambda_{\bar{\nu}}^{\bar{\mu}} \tilde{\phi}_n^{\bar{\nu}}(0,\Lambda(\mathbf{x},s)), \tag{80}$$

$$\tilde{\pi}_t^n(0,\mathbf{x},s) \mapsto \tilde{\pi}_t^n(0,\Lambda(\mathbf{x},s)), \tag{81}$$

$$\tilde{\pi}_{\bar{\mu}}^n(0,\mathbf{x},s) \mapsto \Lambda_{\bar{\mu}}^{\bar{\nu}} \tilde{\pi}_{\bar{\nu}}^n(0,\Lambda(\mathbf{x},s)), \tag{82}$$

where $\bar{\mu}$ takes the values 1, 2, 3, s. Now the components of $\tilde{\phi}_n$ and $\tilde{\pi}^n$ are mixed in a way which is consistent with the mixing of the space–time variables. This indicates that the extended fields are an appropriate way of thinking about the history fields. However, it should be emphasized that

the extended fields are not covariant under SO(2, 3). Let V^M denote the vector defined by the field $\tilde{\phi}_n^M(X,s)$ at the point (X,s). Using the basis $(\tilde{n},\tilde{e},\tilde{m}^i)$, V^M can be decomposed into an "external" four-vector (V^t,V^i), or into an "internal" four-vector (V^s,V^i), and each of these four-vectors *is* a covariant object under the appropriate Poincaré group. This suggests a third interpretation of the history vector fields as *pairs* of four-component fields with identical n-spatial components. However, this identification is not preserved under the action of the boosts, so it seems that we are left with the five-vector interpretation as the only viable one.

It remains to be shown that the extra degrees of freedom can be included in the action in a way that is consistent with the symmetries and equations of motion of the theory.

E. The action

In the case of scalar field theory the physical action functional is written as $S_n = V_n - H_n$. The Liouville operator is associated with external time in the sense that it generates translations in the external time direction. In the same way, the Hamiltonian is associated with internal time, and the action functional mixes the two "modes" of time.

First we will need the following definition: The n-spatial part of $\tilde{\phi}_n^M(X,s)$ is defined as

$$ {}^n\tilde{\phi}^M(X,s) := {}^n\tilde{P}^M_N \tilde{\phi}^N(X,s), \tag{83}$$

where the extended n-spatial projection tensor is

$$ {}^n\tilde{P}^M_N := \delta^M_N - \tilde{n}^M\tilde{n}_N - \tilde{e}^M\tilde{e}_N. \tag{84}$$

Similarly we define ${}^n\partial^M := {}^n\tilde{P}^M_N\partial^N$.

Let $\tilde{V}_n$ denote the extension of the Liouville operator to the extended fields. $\tilde{V}_n$ is defined in the following natural way.

$$ \tilde{V}_n := \int_{\mathcal{M}^{(e)}} d^4X[\,\tilde{\pi}^n_s \partial^t_n \tilde{\phi}^s_n + \tilde{\pi}^n_t \partial^t_n \tilde{\phi}^t_n + {}^n\tilde{\pi}_M \partial^t_n {}^n\tilde{\phi}^M], \tag{85}$$

where $\partial^t_n := \tilde{n}_M\partial^M$ is the derivative in the external time direction defined by $\tilde{n}$. The extended Hamiltonian, $\tilde{H}_n$, is defined as

$$ \tilde{H}_n := \int_{\mathcal{M}^{(e)}} d^4X\left[\frac{1}{2}{}^n\tilde{\pi}_M\,{}^n\tilde{\pi}^M + \frac{1}{4}{}^n\tilde{\phi}_{MN}\,{}^n\tilde{\phi}^{MN} - \frac{1}{2}m^2(\tilde{\phi}^s_n)^2 \right.$$
$$ \left. - \frac{1}{2}m^2(\tilde{\phi}^t_n)^2 + \frac{1}{2}m^2\,{}^n\tilde{\phi}_M\,{}^n\tilde{\phi}^M - \tilde{\phi}^t_n\,{}^n\partial^M\,{}^n\tilde{\pi}_M\right]. \tag{86}$$

The important thing about this Hamiltonian is that $\tilde{\phi}^s_n$ and $\tilde{\phi}^t_n$ both appear in the mass term, but only $\tilde{\phi}^t_n$ appears as the coefficient of ${}^n\partial^M\,{}^n\tilde{\pi}_M$. Due to this asymmetry between $\tilde{\phi}^s_n$ and $\tilde{\phi}^t_n$, the Hamiltonian is not invariant under SO(2, 3). The action is defined to be $\tilde{S}_n := \tilde{V}_n - \tilde{H}_n$. The resulting field equations are

$$ \{\tilde{S}_n, \tilde{\phi}^s_n\} = 0 \Rightarrow \partial^t_n\tilde{\phi}^s_n = 0, \tag{87}$$

$$ \{\tilde{S}_n, \tilde{\pi}^n_s\} = 0 \Rightarrow \partial^t_n\tilde{\pi}^n_s + m^2\tilde{\phi}^s_n = 0, \tag{88}$$

$$ \{\tilde{S}_n, \tilde{\phi}^t_n\} = 0 \Rightarrow \partial^t_n\tilde{\phi}^t = 0, \tag{89}$$

$$ \{\tilde{S}_n, \tilde{\pi}^n_t\} = 0 \Rightarrow \partial^t_n\tilde{\pi}^n_t + m^2\tilde{\phi}^t_n + {}^n\partial^M\,{}^n\tilde{\pi}_M = 0, \tag{90}$$

$$\{\tilde{S}_n, {}^n\tilde{\phi}^M\}=0\Rightarrow\partial_n^t\,{}^n\tilde{\phi}^M-({}^n\tilde{\pi}^M+{}^n\partial^M\tilde{\phi}_n^t)=0, \tag{91}$$

$$\{\tilde{S}_n, {}^n\tilde{\pi}_M\}=0\Rightarrow\partial_n^t\,{}^n\tilde{\pi}_M-({}^n\partial^N\,{}^n\tilde{\phi}_{NM}+m^2\,{}^n\tilde{\phi}_M)=0. \tag{92}$$

The physical action has not been derived in the usual way from a Lagrangian, so we do not have the usual identification of primary constraints. The field equations do not determine the time-like components of the $\tilde{\pi}$ field, so we augment the equations of motion with the following equations which are interpreted as the primary constraints of the theory:

$$\tilde{\pi}_s^n(X)=0,\quad \tilde{\pi}_t^n(X)=0. \tag{93}$$

We require these constraints to be conserved in internal time which implies the following secondary constraints:

$$\tilde{\phi}_n^s(X)=0,\quad m^2\tilde{\phi}_n^t(X)+{}^n\partial^M\,{}^n\tilde{\pi}_M(X)=0, \tag{94}$$

so in the history theory of the massive vector field there are *two* pairs of second class constraints. In the state space theory a single pair of constraints allow the theory to be written in a Lorentz covariant way. In the five-component history theory where there are two SO(1, 3) symmetry groups, we have to introduce two pairs of constraints in order to have a covariant theory.

The three functionals, $\tilde{V}_n$, $\tilde{H}_n$, and $\tilde{S}_n$ are all invariant under the action of the internal Poincaré group. However, the external boosts change the foliation with respect to which $\tilde{V}_n$ and $\tilde{H}_n$ are defined, giving the transformations $\tilde{V}_n\mapsto\tilde{V}_{\Lambda n}$ and $\tilde{H}_n\mapsto\tilde{H}_{\Lambda n}$. These transformations imply $\tilde{S}_n\mapsto\tilde{S}_{\Lambda n}$, and the history theory is covariant under both Poincaré groups if we include the internal foliation dependence.

III. ELECTROMAGNETISM

A. State space theory

In this section we consider vacuum electromagnetism on $\mathcal{M}$. The covariant configuration space for electromagnetism is $Q=\Lambda^1(\mathcal{M})$, and the Lagrangian is

$$\mathcal{L}=-\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}, \tag{95}$$

where $F_{\mu\nu}(X):=2\partial_{[\mu}A_{\nu]}(X)$ for $A\in Q$. The covariant equations of motion which follow from this Lagrangian are

$$F^{\nu\mu}{}_{,\nu}(X)=0. \tag{96}$$

Given an embedding $\iota:\Sigma\to\mathcal{M}$, the canonical configuration space is $Q_\iota=T_\iota^*\mathrm{Emb}(\Sigma,\mathcal{M})$ and the state space, P_ι, can be identified with $Q_\iota\times T_\iota\mathrm{Emb}(\Sigma,\mathcal{M})$. The Poisson algebra on the state space associated with the embedding labeled by $(n,0)$ is

$$\{A_\mu^n(\mathbf{x}),A_\nu^n(\mathbf{x}')\}=0, \tag{97}$$

$$\{E_n^\mu(\mathbf{x}),E_n^\nu(\mathbf{x}')\}=0, \tag{98}$$

$$\{A_\mu^n(\mathbf{x}),E_n^\nu(\mathbf{x}')\}=\delta_\mu^\nu\delta_n^{(3)}(\mathbf{x}-\mathbf{x}'). \tag{99}$$

The canonical momenta are computed from the Lagrangian;

$$E_n^t(\mathbf{x})=0,\quad {}^nE^\mu(\mathbf{x})={}^nP_\rho^\mu n_\nu F^{\nu\rho}(\mathbf{x}), \tag{100}$$

where we again use the decomposition into time-like and space-like parts. The canonical Hamiltonian is

$$H_n = \int_\Sigma \mathrm{d}\theta_{\mathbf{x}} \left[\frac{1}{2} {}^nE^\mu {}^nE_\mu + \frac{1}{4} {}^nF_{\mu\nu} {}^nF^{\mu\nu} - A_t^n {}^n\partial_\mu {}^nE^\mu \right]. \tag{101}$$

The equation of motion for E_n^t implies the secondary constraint

$$ {}^n\partial_\mu {}^nE^\mu(\mathbf{x}) = 0, \tag{102}$$

which can be recognized as Gauss' law. The constraints form a first class pair. The corresponding gauge freedom is manifested in the fact that the equations of motion do not determine A_t^n or A_L^n where A_L^n is the longitudinal part of A^n. The pull back of the symplectic two-form on P_n to the constraint surface C_n is degenerate because of the first class nature of the constraints. The reduced state space is obtained after gauge fixing and contains only four of the original eight degrees of freedom.

B. History theory

We follow the same procedure as before and consider sections of the trivial vector bundle $P \times \mathbb{R} \to \mathbb{R}$. So a history is a map

$$t \mapsto (A_\mu^n(t;x), E_n^\nu(t;x)), \tag{103}$$

and again, there is a unique pair $(A_\mu^n(X), E_n^\nu(X))$ corresponding to such a history so we fix an n and identify Π_n with the abstract space $\Lambda^1(\mathcal{M}) \times \mathcal{X}(\mathcal{M})$. These history fields satisfy the covariant looking algebra,

$$\{A_\mu^n(X), A_\nu^n(X')\} = 0, \tag{104}$$

$$\{E_n^\mu(X), E_n^\nu(X')\} = 0, \tag{105}$$

$$\{A_\mu^n(X), E_n^\nu(X')\} = \delta_\nu^\mu \, \delta^{(4)}(X - X'), \tag{106}$$

and the Liouville, Hamiltonian, and action operators are defined as

$$V_n := \int d^4X [E_n^t \partial_n^t A_t^n + {}^nE^\mu \partial_n^t {}^nA_\mu], \tag{107}$$

$$H_n := \int d^4X \left[\frac{1}{2} {}^nE_\mu {}^nE^\mu + \frac{1}{4} {}^nF_{\mu\nu} {}^nF^{\mu\nu} - A_t^n {}^n\partial^\mu {}^nE_\mu \right], \tag{108}$$

$$S_n := V_n - H_n . \tag{109}$$

C. Constraints

We follow the procedure detailed for the vector field and work in the extended history space $\tilde{\Pi}_n$. The extended history fields are written in the form

$$\tilde{A}^n = \tilde{A}_M^n(X,s)\mathrm{d}x^M, \quad \tilde{E}_n = \tilde{E}_n^M(X,s)\partial_M , \tag{110}$$

and using a basis we have the decomposition of $\tilde{A}^n$ into time-like and space-like components $(\tilde{A}_s^n, \tilde{A}_t^n, \tilde{A}_i^n)$. The transformations of the history electromagnetic field under the action of the

Poincaré group are very similar to the transformations of the vector field. From now on we fix an n, and work in coordinates adapted to n, dropping the n-label for typographical convenience. The new feature of electromagnetism is, of course, gauge invariance.

We extend the Liouville, Hamiltonian, and action functionals to the extended history space as

$$\tilde{V} := \int_{\mathcal{M}^{(e)}} d^4X[\tilde{E}^s \partial_t \tilde{A}_s + \tilde{E}^t \partial_t \tilde{A}_t + \tilde{E}^i \partial_t \tilde{A}_i], \tag{111}$$

$$\tilde{H} := \int_{\mathcal{M}^{(e)}} d^4X\left[\frac{1}{2}\tilde{E}_i \tilde{E}^i + \frac{1}{4}\tilde{F}_{ij}\tilde{F}^{ij} - \tilde{A}_t \partial^i \tilde{E}_i\right], \tag{112}$$

$$\tilde{S} := \tilde{V} - \tilde{H}. \tag{113}$$

As before we regard the equations

$$\tilde{E}^s(X) = 0, \quad \tilde{E}^t(X) = 0 \tag{114}$$

as the primary constraints of the theory. The corresponding secondary constraints follow from the Hamilitionian evolution of $\tilde{E}^s$ and $\tilde{E}^t$. The equation $\{\tilde{H}, \tilde{E}^s(X)\} = 0$ is identically satisfied and $\{\tilde{H}, \tilde{E}^t(X)\} = 0$ implies Gauss' law,

$$\partial_i \tilde{E}^i(X) = 0. \tag{115}$$

Gauss' law is conserved in internal time, $\{\tilde{H}, \partial_i \tilde{E}^i(X)\} = 0$, as a consequence of the antisymmetry of $\tilde{F}_{ij}$. Equations (114) and (115) are the first class constraints of the theory.

D. External local symmetries

To investigate the external local symmetries we define the extended action,[13]

$$\tilde{S}^E := \tilde{S} - \int_{\mathcal{M}^{(e)}} d^4X[\lambda_0 \tilde{E}^s + \lambda_1 \tilde{E}^t + \lambda_2 \partial_i \tilde{E}^i]. \tag{116}$$

The transformations

$$\delta \tilde{A}_s(X) = \epsilon_0(X), \tag{117}$$

$$\delta \tilde{A}_t(X) = \epsilon_1(X), \tag{118}$$

$$\delta \tilde{A}_i(X) = \partial_i \epsilon_2(X), \tag{119}$$

are generated by the functional

$$\psi = \int_{\mathcal{M}^{(e)}} d^4X[\epsilon_0 \tilde{E}^s + \epsilon_1 \tilde{E}^t + \epsilon_2 \partial_i \tilde{E}^i]. \tag{120}$$

The extended action is invariant under these transformations if

$$\delta \lambda_0(X) = \partial^t \epsilon_0(X), \tag{121}$$

$$\delta \lambda_1(X) = \partial^t \epsilon_1(X), \tag{122}$$

$$\delta \lambda_2(X) = \epsilon_1(X) - \partial^t \epsilon_2(X). \tag{123}$$

The symmetry of the total action, and therefore of the underlying Lagrangian theory is found by setting $\lambda_2=0$ (and $\delta\lambda_2=0$), thus eliminating the secondary constraint. The resulting transformations are

$$\delta\tilde{A}_s(X)=\epsilon_0(X), \tag{124}$$

$$\delta\tilde{A}_\mu(X)=\partial_\mu\epsilon_2(X), \tag{125}$$

where $\mu=t$, 1, 2, 3. These transformations contain two arbitrary real functions on external space–time. Setting $\epsilon_0=0$ we obtain "external" U(1) gauge transformations:

$$\delta\tilde{A}_\mu(X)=\partial_\mu\epsilon_2(X), \tag{126}$$

which correspond to the symmetries of the external Maxwell tensor $\tilde{F}_{\mu\nu}=2\partial_{[\mu}\tilde{A}_{\nu]}$.

E. Internal local symmetries

The map $\tilde{A}_M(X)\mapsto\tilde{A}_M(X,s)$ is one-to-many for gauge systems. This introduces an extra ambiguity into the theory which is not contained in Eqs. (124) and (125). We make this extra ambiguity explicit by introducing Lagrange multipliers to make the map $\tilde{A}_M(X)\mapsto\tilde{A}_M(X,s)$ one-to-one. To accomplish this we define the extended Hamiltonian,

$$\tilde{H}^E_s[\lambda_0,\lambda_1,\lambda_2]:=\tilde{H}-\int_{\mathcal{M}^{(e)}_s}d^4X[\lambda_0\tilde{E}^s+\lambda_1\tilde{E}^t+\lambda_2\partial_i\tilde{E}^i]. \tag{127}$$

At each moment of internal time s, the integral is over $\mathcal{M}^{(e)}_s$ (the surface $s=\text{const}$), and the Lagrange multipliers are arbitrary real valued functions $\lambda(\cdot,s):\mathcal{M}^{(e)}_s\to\mathbb{R}$. The extended Hamiltonian generates canonical transformations of the potential field

$$\partial_s\tilde{A}_M(X,s)=\{H^E_s,\tilde{A}_M(X,s)\}, \tag{128}$$

and the map $\tilde{A}_M(X)\mapsto\tilde{A}_M(X,s)$ is given by the flow of the time-dependent vector field generated by H^E_s. Thus $\tilde{A}_M(X,s)$ is the solution of the following integral equation:

$$\tilde{A}_M(X,s)=\tilde{A}_M(X,0)+\exp\left(\int_0^s ds'\{\tilde{H}^E_{s'},\tilde{A}_M(X,s')\}\right). \tag{129}$$

Because the transformation $\tilde{A}_M(X)\mapsto\tilde{A}_M(X,s)$ is canonical, it preserves the Poisson bracket so

$$\{\tilde{A}_M(X,s),\tilde{E}^N(X',s)\}=\delta^N_M\delta^{(4)}(X-X'). \tag{130}$$

Gauge-equivalent histories correspond to different choices of the Lagrange multipliers in the extended Hamiltonian. The functional defined by

$$\psi_s=\int_{\mathcal{M}^{(e)}_s}d^4X[\epsilon_0\tilde{E}^s+\epsilon_1\tilde{E}^t+\epsilon_2\partial_i\tilde{E}^i], \tag{131}$$

generates transformations on the fields on $\mathcal{M}^{(e)}_s$ as follows:

$$\delta\tilde{A}_M(X,s)=\{\psi_s,\tilde{A}_M(X,s)\}, \tag{132}$$

and these transformations take the form

$$\delta\tilde{A}_s(X,s)=\epsilon_0(X,s), \tag{133}$$

$$\delta\tilde{A}_t(X,s)=\epsilon_1(X,s), \tag{134}$$

$$\delta\tilde{A}_i(X,s)=\partial_i\epsilon_2(X,s). \tag{135}$$

In order that Eq. (128) is preserved by these transformations up to a change in the Lagrange multipliers associated with the primary constraints, the transformations must satisfy

$$\delta\tilde{A}_s(X,s)=\epsilon_0(X,s), \tag{136}$$

$$\delta\tilde{A}_t(X,s)=\partial_s\epsilon_2(X,s), \tag{137}$$

$$\delta\tilde{A}_i(X,s)=\partial_i\epsilon_2(X,s). \tag{138}$$

These are the internal local symmetry transformations of histories electromagnetism. They contain two arbitrary real valued functions on extended space–time, but are not just a trivial extension of the external local transformations to each moment of internal time. The transformation of $\tilde{A}_t$ contains a derivative with respect to internal time rather than external time. This is because the internal gauge transformations correspond to the symmetries of the internal field equations rather than the symmetries of the external field equations.

If we set $\epsilon_0=\partial^s\epsilon_2$ and restrict to a surface $t=$const, we obtain "internal" U(1) gauge transformations:

$$\delta\tilde{A}_{\bar{\mu}}(X,s)=\partial_{\bar{\mu}}\epsilon_2(X,s), \tag{139}$$

where $\bar{\mu}$ runs over $1, 2, 3, s$. These are the symmetries of the internal Maxwell tensor $\tilde{F}_{\bar{\mu}\bar{\nu}}=2\partial_{[\bar{\mu}}\tilde{A}_{\bar{\nu}]}$.

F. Internal versus external

An arbitrary history satisfies the internal equations of motion. Therefore all histories that are related by internal gauge transformations should be regarded as physically equivalent. However, most histories will not satisfy the external equations of motion, and so need not respect the external symmetry transformations. Histories which are solutions to the external equations of motion are invariant under both internal and external symmetry transformations.

An internal local symmetry transformation is also an external local symmetry transformation if and only if

$$(\partial^t-\partial^s)\epsilon_2(X,s)=0, \tag{140}$$

so the equation of motion $(\partial^t-\partial^s)\tilde{A}_\mu=0$ is conserved by these transformations. It is interesting to note that if Eq. (140) holds and we set $\epsilon_0=\partial^s\epsilon_2$ then we obtain U(1) gauge transformations on $\mathcal{N}$:

$$\delta\tilde{A}_M(X,s)=\partial_M\epsilon_2(X,s) \tag{141}$$

which are the symmetries of the five-dimensional Maxwell tensor $\tilde{F}_{MN}=\partial_{[M}\tilde{A}_{N]}$.

IV. SUMMARY AND CONCLUSION

We have shown that the global symmetry transformations of geometric objects in a history theory suggests the introduction of an extra pair of fields. The extended history fields can then be interpreted as fields on $\mathcal{N}=\mathcal{M}\times\mathbb{R}$ that are covariant under the action of two Poincaré groups, but not the SO(2, 3) group associated with $\mathcal{N}$. The history fields can be decomposed into two SO(1, 3)-vectors at each point in the extended space–time, where the spatial components of these two vectors are the same.

In the case of the massive vector field, the theory contains two pairs of second class constraints, and in the case of electromagnetism, we obtain three first class constraints. In both these examples, the extra degrees of freedom can be set to zero, and eliminated from the theory by taking Dirac brackets. It seems reasonable to expect this pattern to continue in the extension to other constrained field theories as there is no physical information in the extra degrees of freedom. So although Lorentz covariance suggests that the fields should have five components, the extra constraints allow the extra variables to be eliminated.

In conclusion, the geometry of classical history theories is not fully understood. In the state space approach the solutions to the field equations are sections of tensor bundles associated to an $\mathrm{SO}(1,3)$ principal bundle over $\mathcal{M}$. This formulation elegantly characterizes the way that the fields transform under Lorentz transformations. If the history fields were covariant under $\mathrm{SO}(2,3)$ then we would have a description of history fields in terms of sections of bundles associated to an $\mathrm{SO}(2,3)$ principal bundle over $\mathcal{N}$. However the reality of the situation appears to be more complicated. There is an $\mathrm{SO}(1,3)$ group associated to each surface of constant t, and to each surface of constant s, but the action of these two groups is intertwined in a nontrivial way. Similar remarks apply to the local symmetries in a history theory: they cannot be interpreted as the transformations of a $\mathrm{U}(1)$ connection on a principal bundle over $\mathcal{N}$.

In a subsequent paper we will discuss the quantization of histories electromagnetism using the BRST formalism.

(Received 4 June 2001; accepted for publication 18 February 2002)

We show that the relativistic analog of the two types of time translation in a nonrelativistic history theory is the existence of two distinct *Poincaré groups*. The ''internal'' Poincaré group is analogous to the one that arises in the standard canonical quantization scheme; the ''external'' Poincaré group is similar to the group that arises in a *Lagrangian* description of the standard theory. In particular, it *performs explicit changes of the space–time foliation* that is implicitly assumed in standard canonical field theory. © *2002 American Institute of Physics.*

I. INTRODUCTION

The generalization of continuous-time history theory to include relativistic quantum fields raises some subtle issues that tend to be hidden in the normal canonical treatment of a quantum field.

The standard canonical quantization of a relativistic field requires the choice of a Lorentzian foliation on the background space–time: the Hamiltonian is then defined with respect to this foliation. There exist many unitarily inequivalent representations of the canonical commutation relations for this quantum field theory: the physically appropriate one is chosen by requiring that the Hamiltonian exists as a well-defined self-adjoint operator. In this sense—like the Hamiltonian itself—the physically appropriate representation is foliation dependent. Relativistic covariance is then implemented by seeking a representation of the Poincaré group on the resulting Hilbert space. However, the Poincaré group thus constructed does not explicitly perform a *change of the foliation*.

The HPO continuous-time histories approach to quantum theory[1–4] is particularly suited to deal with systems that have a nontrivial temporal structure, and therefore it should be able to provide a significant clarification of this point.

Specifically, we will show that the relativistic analog of the two types of time translation that arise in a nonrelativistic history theory is the existence of two distinct *Poincaré groups*. The ''internal'' Poincaré group is analogous to the one that arises in the standard canonical quantization scheme as sketched above.

However, the ''external'' one is a novel object: it is similar to the group that arises in the *Lagrangian* description of the field theory. In particular, it explicitly performs *changes* of the foliation. This arises from the striking property that HPO theories admit two distinct types of time transformation, each representing a distinct quality of time.[1] The first corresponds to time considered purely as a kinematical parameter of a physical system, with respect to which a history is defined as a succession of possible events. It is strongly connected with the temporal-logical structure of the theory and is related to the view of time as a parameter that determines the ordering of events. The second corresponds to the dynamical evolution generated by the Hamiltonian. For a detailed presentation of the HPO continuous-time program, see Ref. 1.

As we shall see, one of the important results of the formalism as applied to a field theory is that, even though the representations of the history algebra are foliation dependent, the physical quantities (probabilities) are *not*.

a)Electronic mail: ntina@ic.ac.uk

In Sec. II, we shall give a brief description of the underlying concepts of the continuous-histories program: this is necessary for establishing the framework of the ensuing work.

In Sec. III, we present the histories version of a classical scalar field theory: in particular, we show how two Poincaré groups arise as an analog of the two types of time transformation in the nonrelativistic history theory.

The free quantum scalar field theory is presented in Sec. IV. We show that due to the histories' temporal structure previously introduced in Ref. 1, manifest Poincaré invariance is possible. Specifically, we show how different representations of the history algebra—corresponding to different choices of foliation—are realized on the *same* Fock space (notwithstanding the fact that the different representations are unitarily inequivalent), and we show that they are related in a certain way with Poincaré transformations.

II. THE HISTORY PROJECTION OPERATOR APPROACH

The history projection operator (the, so-called, ''HPO'' approach) theory was a development[2] (emphasizing quantum *temporal* logic) of the consistent-histories approach to quantum theory inaugurated by Griffiths, Omnés, Gell-Mann and Hartle.[5] However, the novel temporal structure introduced in Ref. 1 led to a departure from the original ideas on decoherence. In particular, in our approach, emphasis is placed on the distinction between (i) the temporal logic structure of the theory and (ii) the dynamics.[3]

In consistent-histories theory, a history is defined as a sequence of time-ordered propositions about properties of a physical system, each of which can be represented, as usual, by a projection operator. In normal quantum theory, it is not possible to assign a probability measure to the set of all histories. However, when a certain ''decoherence condition'' is satisfied by a set of histories, the elements of this set *can* be given probabilities.

The probability information of the theory is encoded in the decoherence functional: a complex function of pairs of histories which—in the original approach of Griffiths *et al.*—can be written as

$$d(\alpha,\beta)=\mathrm{tr}(\tilde{C}_\alpha^\dagger \rho \tilde{C}_\beta), \tag{2.1}$$

where ρ is the initial density-matrix, and where the *class operator* $\tilde{C}_\alpha$ is defined in terms of the standard Schrödinger-picture projection operators α_{t_i} as

$$\tilde{C}_\alpha := U(t_0,t_1)\alpha_{t_1}U(t_1,t_2)\alpha_{t_2}\cdots U(t_{n-1},t_n)\alpha_{t_n}U(t_n,t_0), \tag{2.2}$$

where $U(t,t')=e^{-i(t-t')H/\hbar}$ is the unitary time-evolution operator from time t to t'. Each projection operator α_{t_i} represents a proposition about the system at time t_i, and the class operator $\tilde{C}_\alpha$ represents the composite history proposition ''α_{t_1} is true at time t_1, and then α_{t_2} is true at time t_2, and then ..., and then α_{t_n} is true at time t_n.''

Isham and Linden developed the consistent-histories formalism further, concentrating on its *temporal* quantum logic structure.[2] They showed that propositions about the histories of a system could be represented by *projection operators* on a new, ''history'' Hilbert space. In particular, the history proposition ''α_{t_1} is true at time t_1, and then α_{t_2} is true at time t_2, and then ..., and then α_{t_n} is true at time t_n'' is represented by the *tensor product* $\alpha_{t_1}\otimes\alpha_{t_2}\otimes\cdots\otimes\alpha_{t_n}$ which, unlike $\tilde{C}_\alpha$, *is* a genuine projection operator that is defined on the tensor product of copies of the standard Hilbert space $\mathcal{H}_{t_1}\otimes\mathcal{H}_{t_2}\otimes\cdots\otimes\mathcal{H}_{t_n}$. Hence the ''history projection operator'' formalism extends to multiple times, the quantum logic of single-time quantum theory.

The history space. An important way of understanding the history Hilbert space $\mathcal{F}$ is in terms of the representations of the ''history group''—in elementary systems this is the history analog of the canonical group.[2] For example, for the simple case of a point particle moving on a line, the Lie algebra of the history group for a *continuous* time parameter t is described by the history commutation relations

$$[x_t, x_{t'}] = 0, \tag{2.3}$$

$$[p_t, p_{t'}] = 0, \tag{2.4}$$

$$[x_t, p_{t'}] = i\hbar\,\delta(t-t'), \tag{2.5}$$

where $-\infty \leqslant t, t' \leqslant \infty$. It is important to note that these operators are in the *Schrödinger* picture, and that the history algebra is invariant under translations of the time index of these operators.

The choice of the Dirac delta-function on the right hand side of Eq. (2.5) is associated with the requirement that time be treated as a continuous variable. One important consequence is the fact that the observables cannot be defined at sharp moments of time, but rather appear naturally as *time-averaged*.

A unique representation of this algebra can be found by requiring the existence of an operator analog of a time-averaged Hamiltonian $H = \int_{-\infty}^{\infty} dt\, H_t$, where H_t is the standard Hamiltonian defined at a moment of time t.[6]

The action and Liouville operators. One of the original problems in the development of the HPO theory was the lack of a clear notion of time evolution, in the sense that there was no natural way to express the time translations from one time slot—that refers to one copy of the Hilbert space $\mathcal{H}_t$—to another one that refers to another copy $\mathcal{H}_{t'}$. The situation changed with the introduction of the "*action*" *operator* S.

Indeed, the crucial step for constructing the temporal structure of the theory was the definition in Ref. 1 of the action operator S—a quantum analog of the Hamilton–Jacobi functional,[7] written as

$$S_\kappa := \int_{-\infty}^{+\infty} dt (p_t \dot{x}_t - \kappa(t) H_t), \tag{2.6}$$

where $\kappa(t)$ is an appropriate test function.

The first term of the action operator S_κ in Eq. (2.6) is identical to the kinematical part of the classical phase space action functional. This "Liouville" operator is formally written as

$$V := \int_{-\infty}^{\infty} dt\, (p_t \dot{x}_t) \tag{2.7}$$

so that

$$S_\kappa = V - H_\kappa. \tag{2.8}$$

A. The temporal structure

A fundamental property of the HPO form of history theory is that the Liouville operator V and the Hamiltonian operator H_κ generate two distinct types of time transformation. The Liouville operator V relates the Schrödinger-picture operators associated with different time-t labels, whereas H_t is associated with internal dynamical changes at the fixed time t (with an analogous statement for the smeared operator H_κ). The action operator S_κ is thus the generator of both types of time translation.[1]

More precisely, it was shown that there exist *two* distinct types of time transformation. One—generated by the Liouville operator V—refers to time as it appears in temporal logic, and it is related to t-label in Eqs. (2.3)–(2.5). The other—generated by the Hamiltonian—refers to time as it appears in the implementation of dynamical laws, and it is related to the label s in the "history Heisenberg picture" operator, which is hence defined in accord to the novel conceptual issues introduced with the "two modes of time,"

$$x_t(s) := e^{isH/\hbar} x_t e^{-isH/\hbar}, \tag{2.9}$$

where H is defined to be H_κ with κ set equal to 1.

We will use the notation $x_f(s)$ for these history Heisenberg-picture operators smeared with respect to the time label t, and we notice from Eq. (2.9) that these quantities behave like standard Heisenberg-picture operators with a time parameter s.

For any specific physical system these two transformations are intertwined with the aid of the action operator S as

$$e^{i\tau S/\hbar} x_f(s) e^{-i\tau S/\hbar} = x_{f_\tau}(s+\tau), \tag{2.10}$$

where $f_\tau(t) := f(t+\tau)$, and where S means S_κ with $\kappa = 1$.

B. Classical histories theory

The continuous-time histories description has a natural analog for classical histories.[3] In this scheme, the basic mathematical entity is the space $\Pi = C(\mathbb{R}, \Gamma)$ of differentiable paths taking their value in the manifold Γ of classical states. Hence an element of Π is a smooth path $\gamma: \mathbb{R} \to \Gamma$. In effect, we associate a copy of the classical state space with each moment of time, and employ differentiable sections of the ensuing bundle over $\mathbb{R}$.

The key idea in this approach to classical histories is contained in the symplectic structure on this space of temporal paths Π. For example, for a particle moving in one dimension (with configuration coordinate x and momentum coordinate p), the history space Π is equipped with a symplectic form

$$\omega = \int dt\, dp_t \wedge dx_t, \tag{2.11}$$

which generates the history Poisson brackets

$$\{x_t, x_{t'}\} = 0, \tag{2.12}$$

$$\{p_t, p_{t'}\} = 0, \tag{2.13}$$

$$\{x_t, p_{t'}\} = \delta(t - t'). \tag{2.14}$$

In general, given a function f on Γ we can define an associated family $t \mapsto F_t$ of functions on Π as

$$F_t(\gamma) := f(\gamma(t)). \tag{2.15}$$

In this way, all transformations implemented through the Poisson bracket in the normal canonical theory correspond to transformations in the history theory that *preserve the time label* t. Indeed, for two families of functions $t \mapsto F_t$ and $t \mapsto G_t$ defined through (2.15) we have

$$\{F_t, G_{t'}\} = L_t \delta(t, t'), \tag{2.16}$$

where L_t corresponds to the function l on Γ:

$$l = \{f, g\}_\Gamma. \tag{2.17}$$

In this way all relevant structures of the canonical theory can be naturally transferred to the histories framework.[3]

The Liouville, Hamilton and action functionals on Π are defined respectively as

$$V(\gamma) := \int_{-\infty}^{\infty} dt\, [p_t \dot{x}_t](\gamma), \tag{2.18}$$

$$H(\gamma) := \int_{-\infty}^{\infty} dt\,[H_t(p_t, x_t)](\gamma), \tag{2.19}$$

$$S(\gamma) := V(\gamma) - H(\gamma), \tag{2.20}$$

where $\dot{x}_t(\gamma) = (\partial x_t/\partial t)(\gamma)$ is the velocity at the time point t of the path γ. These definitions are crucial for the dynamics of the theory. In particular, V and H are the classical analogs of the generators of the two types of time transformation in the history quantum theory.[1]

The crucial result of classical histories theory is that one may deduce the equations of motion in the following way:[1] a classical history γ_{cl} is the realized path of the system—i.e., a solution of the equations of motion of the system—if it satisfies the equations

$$\{x_t, V\}(\gamma_{cl}) = \{x_t, H\}(\gamma_{cl}), \tag{2.21}$$

$$\{p_t, V\}(\gamma_{cl}) = \{p_t, H\}(\gamma_{cl}), \tag{2.22}$$

where γ_{cl} is the path $t \mapsto (x_t(\gamma_{cl}), p_t(\gamma_{cl}))$, and $x_t(\gamma_{cl})$ is the position coordinate of the realized path γ_{cl} at the time point t.

The equations (2.21)–(2.22) are the history equivalent of the canonical equations of motion. In particular, the symplectic transformation generated by the history action functional $S(\gamma)$ leaves invariant the paths that are classical solutions of the system:

$$\{x_t, S\}(\gamma_{cl}) = 0, \tag{2.23}$$

$$\{p_t, S\}(\gamma_{cl}) = 0. \tag{2.24}$$

More generally, any function F on Π satisfies the equation

$$\{F, S\}(\gamma_{cl}) = 0. \tag{2.25}$$

This is the way in which equations of motion appear in the classical history theory. Notice that the role of the action as the generator of time transformations emerges naturally in this classical case. Furthermore, the condition (2.25) above emphasizes the role of the Hamiltonian and Liouville functionals in histories theory as generators of different types of time transformation. It also clarifies the new temporal structure that arises in history theory when compared with the standard classical theory.

This result is of particular importance in the case of parameterized systems, where the notion of time is recovered *after the phase space reduction*.[3]

III. CLASSICAL SCALAR FIELD THEORY

A. Background

1. Standard canonical treatment

In the Hamiltonian description of a free scalar field ϕ with mass $\tilde{m}$ on Minkowski space–time, the first step is to choose a spacelike foliation, which can be specified by its normal—a unit timelike vector n^μ. We shall take the signature of the Minkowski metric $\eta^{\mu\nu}$ to be $(+,-,-,-)$.

The first step is to select a specific foliation, and to choose a reference leaf $\Sigma \simeq \mathbb{R}^3$ that is characterized by $t=0$, where t is the natural time label associated with the foliation.

The corresponding configuration space is the space $C^\infty(\Sigma)$ of all smooth scalar functions $\phi(x)$ on Σ, while the phase space Γ is its cotangent bundle $T^*C^\infty(\Sigma)$ defined in an appropriate way. [To make these statements mathematically rigorous it would be necessary to invoke the differential geometry of infinite-dimensional spaces like $C^\infty(\Sigma)$. However, we do not need to

become involved in such complexities here: for our purposes it suffices to postulate the basic Poisson algebra relations (3.12)–(3.14) that follow.] The key point about this structure is that the state space of fields is equipped with the Poisson brackets

$$\{\phi(\underline{x}),\phi(\underline{x}')\}=0, \tag{3.1}$$

$$\{\pi(\underline{x}),\pi(\underline{x}')\}=0, \tag{3.2}$$

$$\{\phi(\underline{x}),\pi(\underline{x}')\}=\delta(\underline{x}-\underline{x}'). \tag{3.3}$$

Poincaré group symmetry. The relativistic scalar field theory is covariant under the action of the Poincaré group.[8] For a free massive scalar field, the generators of time translations P^0, space translations P^i, spatial rotations J^i and Lorentz boosts K^i are respectively (obtained by the use of Noether's theorem on the Lagrangian theory, and a Legendre transform)

$$H=P^0=\frac{1}{2}\int d^3\underline{x}\,[\pi^2+\partial_i\phi\partial_i\phi+\tilde{m}^2\phi^2], \tag{3.4}$$

$$P^i=\int d^3\underline{x}\;\pi\partial^i\phi, \tag{3.5}$$

$$J^i=\frac{1}{2}\epsilon^{ijk}\int d^3\underline{x}\;\pi x_j\partial_k\phi, \tag{3.6}$$

$$K^i=M^{0i}=\int d^3\underline{x}\left[t\pi\partial^i\phi-x^i\frac{1}{2}(\pi^2+\partial_j\phi\partial_j\phi+\tilde{m}^2\phi^2)\right], \tag{3.7}$$

where we note that the sub/superscripts i,j,k refer to coordinates in the surface Σ that is spatial with respect to the chosen foliation vector n. Similarly, the integrals above are all defined over Σ.

If we define the partial differential operator

$$(\Gamma f)(\underline{x}):=[(\eta^{\mu\nu}-n^\mu n^\nu)\partial_\mu\partial_\nu+\tilde{m}^2]f(\underline{x}), \tag{3.8}$$

we can write the convenient expressions for the Hamiltonian and the boosts generator as

$$H=\frac{1}{2}\int d^3\underline{x}\,[\pi^2+\phi\Gamma\phi], \tag{3.9}$$

$$K^i=\int d^3\underline{x}\left[t\pi\partial^i\phi-\frac{1}{2}x^i(\pi^2+\phi\Gamma\phi)\right]. \tag{3.10}$$

For the special case of hypersurface $t=0$ the boost generator is written as

$$K^i=\int d^3\underline{x}\left[-\frac{1}{2}x^i(\pi^2+\phi\Gamma\phi)\right]. \tag{3.11}$$

B. Histories description for the classical scalar field

In the histories formalism of a scalar field, the space of phase-space histories Π is an appropriate subset of the continuous Cartesian product $\times_t\Gamma_t$ of copies of the standard state space Γ, each labeled by the time parameter t. (One may write a history version of the Lagrangian treatment, however this description is not relevant to the immediate aims of this work.) The choice of Γ depends on the choice of a foliation vector n^μ, hence the space of histories also has an implicit

dependence on n^μ and should therefore be written as ${}^n\Pi$. Furthermore, we write $\Sigma_t=(n,t)$, the spacelike surface Σ defined with respect to its normal vector n, and labeled by the parameter t.

To be more precise, for each spacelike surface Σ_t we consider the state space $\Gamma_t = T^*C^\infty(\Sigma_t)$. Then we define the fiber bundle with basis $\mathbb{R}$ and fiber Γ_t, at each $t\in\mathbb{R}$. Histories are defined as the cross-sections of the ensuing bundle, and the history space ${}^n\Pi$ is the space of all smooth cross-sections of this bundle.

The Poisson algebra relations of the history theory are

$$\{\phi(X),\phi(X')\}=0, \tag{3.12}$$

$$\{\pi(X),\pi(X')\}=0, \tag{3.13}$$

$$\{\phi(X),\pi(X')\}=\delta^4(X-X'), \tag{3.14}$$

where X and X' are space–time points. The field $\phi(X)$ and its conjugate momentum $\pi(X')$ are implicitly defined with respect to the foliation vector n^μ.

The definitions of the action S, Liouville V and "Hamiltonian" H functionals are

$$S:=V-\frac{1}{2}\int d^4X\{\pi^2(X)+\phi(X)\,{}^n\Gamma\,\phi(X)\}, \tag{3.15}$$

$$V:=\int d^4X\,\pi(X)n^\mu\partial_\mu\,\phi(X), \tag{3.16}$$

$$H:=\frac{1}{2}\int d^4X\{\pi^2(X)+\phi(X)\,{}^n\Gamma\,\phi(X)\}, \tag{3.17}$$

respectively, where again there is an implicit n label on these three quantities, and where Γ is the differential operator

$$\Gamma:=[(\eta^{\mu\nu}-n^\mu n^\nu)\partial_\mu\partial_\nu+\tilde{m}^2] \tag{3.18}$$

introduced above.

As we explained earlier, the variation of $S[\gamma]$ leaves invariant the paths γ_{cl} that are classical solutions of the system:

$$\{\phi(X),S\}(\gamma_{cl})=0, \tag{3.19}$$

$$\{\pi(X),S\}(\gamma_{cl})=0. \tag{3.20}$$

As we shall now see, H is the generator to the time averaged internal Poincaré group.

C. Poincaré symmetry

The Poincaré group is the group of isometries of the Minkowski metric. Hence, any field theory in Minkowski space–time needs to be covariant under the action of the Poincaré group. As we shall now see, in a history theory—because of its augmented temporal structure—the associated group theory leads to a particular interesting result: namely, there are *two* distinct Poincaré groups that act on the history space.

1. The internal Poincaré group

One significant feature of histories theory is that it gives a representation of the temporal logic of the system that is *independent* of the dynamics involved. Hence, propositions about the state of the system at different times are represented by appropriate subsets of the space of paths. In the context of symmetries, however, the temporal logic structure entails the following.

For each copy Γ_t of the standard state space, there exists a Poincarè group symmetry of the type one would expect in a canonical treatment of relativistic field theory. On the other hand, in the history theory the state space is heuristically the Cartesian product of such copies, and all physical quantities in the standard treatment now appear as naturally time-averaged.[1] Hence one may write time-averaged generators of the *internal* Poincaré groups, in a covariantlike notation, as

$$H=\frac{1}{2}\int d^4X\,\{\pi(X)^2+\phi(X)\,{}^n\Gamma\,\phi(X)\}, \tag{3.21}$$

$$P(m)=m_\mu\int d^4X\,\pi(X)\,\partial^\mu\,\phi(X), \tag{3.22}$$

$$J(m)=\frac{1}{2}n_\mu m_\nu\epsilon^{\mu\nu\rho\sigma}\int d^4X\,\pi(X)\,X_\rho\,\partial_\sigma\,\phi(X), \tag{3.23}$$

$$K(m)=m_\mu\int d^4X\left\{-\frac{1}{2}X^\mu[\,\pi(X)^2+\phi(X)\,{}^n\Gamma\,\phi(X)]\right\}, \tag{3.24}$$

where m^μ is an "n-spacelike" vector, i.e., one such that $n\cdot m:=n^\mu m^\nu\eta_{\mu\nu}=0$ and $K(m)$ is written for the special case of hypersurface $s=0$.

Of special interest are the groups of canonical transformations generated by the Hamiltonian generator H and the boosts generator K. Note that a space–time point X can be associated with the pair $(t,\underline{x})\in\mathbb{R}\times\mathbb{R}^3$, as $X=tn+x_n$, where the three-vector $\underline{x}$ has been associated with a corresponding n-spatial four-vector x_n (i.e., $n\cdot x_n=0$); note that $t=n\cdot X$. Then we define the classical analog of the Heisenberg picture fields as

$$\phi(X)\underset{\longrightarrow}{H}\phi(X,s) \tag{3.25}$$

or

$$\phi(t,\underline{x})\underset{\longrightarrow}{H}\phi(t,\underline{x},s):=\cos({}^n\Gamma^{1/2}s)\,\phi(X)+\frac{1}{{}^n\Gamma^{1/2}}\sin({}^n\Gamma^{1/2}s)\,\pi(X), \tag{3.26}$$

where $\phi(X):=\phi(t,\underline{x})$ and $\phi(X,s):=\phi(t,\underline{x},s)$. The square-root operator ${}^n\Gamma^{1/2}$, and functions thereof, can be defined rigorously using the spectral theory of the self-adjoint, partial differential operator ${}^n\Gamma$ on the Hilbert space $L^2(\mathbb{R}^4,d^4X)$.

Notice also that the time label t is not affected by this transformation since $[\,n\cdot\partial,\,{}^n\Gamma\,]=0$. For a fixed value of time t, the field $\phi(t,\underline{x},s)$ is the "Heisenberg-picture" field of the standard canonical treatment.

The action of boost transformations is best shown upon objects $\phi(X,s)=\phi(t,\underline{x},s)$ as

$$\phi(t,\underline{x},s)\rightarrow\phi(t,\underline{x}',s'), \tag{3.27}$$

where $(\underline{x}',s')$ and $(\underline{x},s)$ are related by the Lorentz boost parametrized by m^μ as

$$s'=\cosh|m|s+\frac{\sinh|m|}{|m|}x^i m_i\,,$$

$$x^{i\prime}=\left(\delta_{ij}-\frac{m^i m_j}{|m|^2}\right)x^j+\frac{m^i m_j}{|m|^2}\cosh|m|x^j+\frac{\sinh|m|}{|m|}m^i s, \tag{3.28}$$

where, as above, x_i is the spatial part of X with respect to n, so that $X=tn+x_n$ and $i=1,2,3$.

Hence, for each copy of the standard classical state space, there exists an ''internal'' Poincarè group that acts on the copy of standard canonical field theory that is labeled by the same t-time label.

2. The external Poincaré group

For each fixed n, there also exists an ''*external*'' Poincaré group with generators

$$\tilde{P}^{\mu}=\int d^4X\,\pi(X)\partial^{\mu}\phi(X), \tag{3.29}$$

$$\tilde{M}^{\mu\nu}=\int d^4X\,\pi(X)(X^{\mu}\partial^{\nu}-X^{\nu}\partial^{\mu})\phi(X), \tag{3.30}$$

where $\mu,\nu=0,1,2,3$ and $\tilde{P}^{\mu}$ generate space–time translations. The n-spatial parts of the tensor $\tilde{M}^{\mu\nu}$ generate spatial rotations; the time parts generate boosts.

The space translations and rotations are identical to those of the *internal* Poincaré group. However, the time translation and the boosts differ. Indeed, under $V:=\tilde{P}^0$ we have

$$\phi(t,\underline{x}) \underset{\rightarrow}{V} \phi(t+\tau,\underline{x}), \tag{3.31}$$

$$\pi(t,\underline{x}) \underset{\rightarrow}{V} \pi(t+\tau,\underline{x}), \tag{3.32}$$

where τ is the time translation generated by V. Thus, what we have shown here is that the time-translation generator for the ''external'' Poincaré group is the Liouville functional V. On the other hand, the boost generator $\tilde{K}^i=\tilde{M}^{0i}$ generates Lorentz transformations of the type

$$\phi(X)\rightarrow\phi(\Lambda X), \tag{3.33}$$

$$\pi(X)\rightarrow\pi(\Lambda X), \tag{3.34}$$

where for future convenience we write as Λ the element of the Lorentz group obtained by exponentiation of the boost parameterized by m^i.

Furthermore, under the action of this external group, the generators of the *internal* Poincaré group transform as follows

$${}^nH \underset{\rightarrow}{\tilde{K}} {}^{\Lambda n}H, \tag{3.35}$$

$${}^nK(m) \underset{\rightarrow}{\tilde{K}} {}^{\Lambda n}K(\Lambda m), \tag{3.36}$$

where we have now attached the explicit n labels that were implicit in our previous notation for these quantities. The action functional transforms in the same way

$${}^nS\rightarrow{}^{\Lambda n}S. \tag{3.37}$$

Note that the action of the two groups coincides on classical solutions γ_{cl}:

$$\{\phi(X),K(m)\}(\gamma_{cl})=\{\phi(X),\tilde{K}(m)\}(\gamma_{cl}), \tag{3.38}$$

$$\{\pi(X),K(m)\}(\gamma_{cl})=\{\pi(X),\tilde{K}(m)\}(\gamma_{cl}). \tag{3.39}$$

We must emphasize again that the definition of Π depends on the foliation vector. Hence, so will the action of the Poincaré group. Here we deal with the scalar field, for which this dependence is not explicit. However, this dependence, and analog of the Poincaré group action, is a major feature in systems where there is an explicit foliation dependence. For example, this is the case of general relativity which is discussed in Ref. 9.

IV. HISTORIES QUANTUM SCALAR FIELD THEORY

A. Background

1. Canonical quantum field theory

Canonical quantization proceeds by looking for a representation of the *canonical commutation relations*

$$[\hat{\phi}(\underline{x}),\hat{\phi}(\underline{x}')]=0, \tag{4.1}$$

$$[\hat{\pi}(\underline{x}),\hat{\pi}(\underline{x}')]=0, \tag{4.2}$$

$$[\hat{\phi}(\underline{x}),\hat{\pi}(\underline{x}')]=i\hbar\,\delta^3(\underline{x}-\underline{x}') \tag{4.3}$$

on a Hilbert space which, in practice, is selected by requiring the existence of the Hamiltonian as a genuine (essentially) self-adjoint operator.

For a free field, such a representation can be found on the Fock space $\mathcal{F}=\exp L^2(\mathbb{R}^3, d^3\underline{x})$ on which the fields can be written in terms of the creation and annihilation operators b and $b^\dagger$ that define $\mathcal{F}$

$$\hat{\phi}(\underline{x})=\frac{1}{\sqrt{2}}{}^n\Gamma^{-1/4}(\hat{b}(\underline{x})+\hat{b}^\dagger(\underline{x})), \tag{4.4}$$

$$\hat{\pi}(\underline{x})=\frac{1}{\sqrt{2}}{}^n\Gamma^{1/4}(\hat{b}(\underline{x})-\hat{b}^\dagger(\underline{x})), \tag{4.5}$$

where

$$[b(\underline{x}),b^\dagger(\underline{x}')]=\delta^3(\underline{x}-\underline{x}'). \tag{4.6}$$

The (normal-ordered) Hamiltonian then reads

$$\hat{H}=\int d^3\underline{x}\hat{b}^\dagger(\underline{x})\,{}^n\Gamma^{1/2}\,\hat{b}(\underline{x})=\sum_{\mathbf{k}}\,\omega_{\mathbf{k}}\hat{b}^\dagger_{\mathbf{k}}\hat{b}_{\mathbf{k}}. \tag{4.7}$$

(In momentum space we write b and $b^\dagger$ from the well known relation $b_{\mathbf{k}}=\sqrt{\omega_{\mathbf{k}}/2}\phi_{\mathbf{k}}+i/\sqrt{2\omega_{\mathbf{k}}}\pi_{\mathbf{k}}$.)

Poincaré group symmetry. A representation of the full Poincaré group exists on this Hilbert space. The starting point is the generators of the classical theory, suitably normal-ordered to correspond to well-defined operators. Substituting the fields in terms of creation and annihilation operators, the generators can be written as

$$\hat{P}^i=i\int d^3\underline{x}\hat{b}^\dagger(\underline{x})\,\partial^i\,\hat{b}(\underline{x}), \tag{4.8}$$

$$\hat{J}^i=i\,\epsilon^{ijk}\int d^3\underline{x}\hat{b}^\dagger(\underline{x})\,x_j\,\partial_k\,\hat{b}(\underline{x}), \tag{4.9}$$

$$\hat{K}^i = \int d^3\underline{x}\,\hat{b}^\dagger(\underline{x})\,{}^n\Gamma^{1/4}\,x^i\,{}^n\Gamma^{1/4}\,\hat{b}(\underline{x}). \tag{4.10}$$

These generators, together with $\hat{H}$ defined in Eq. (4.7), satisfy the Lie algebra relations of the Poincaré group.

In the canonical picture, the covariant fields are obtained by the Heisenberg equations of motion:

$$\hat{\phi}(\underline{x},s) := e^{(i/\hbar)\,s\hat{H}}\hat{\phi}(\underline{x})e^{-(i/\hbar)\,s\hat{H}} = \cos({}^n\Gamma^{1/2}s)\,\hat{\phi}(\underline{x}) + {}^n\Gamma^{-1/2}\sin({}^n\Gamma^{1/2}s)\,\hat{\pi}(\underline{x}), \tag{4.11}$$

$$\hat{\pi}(\underline{x},s) := e^{(i/\hbar)\,s\hat{H}}\hat{\pi}(\underline{x})e^{-(i/\hbar)\,s\hat{H}} = -{}^n\Gamma^{1/2}\sin({}^n\Gamma^{1/2}s)\,\hat{\phi}(\underline{x}) + \cos({}^n\Gamma^{1/2}s)\,\hat{\pi}(\underline{x}). \tag{4.12}$$

The explicit automorphisms generated by the boosts may easily be calculated for the Heisenberg picture creation and annihilation operators,

$$\hat{b}(\underline{x},s) := e^{(i/\hbar)\,s\hat{H}}\hat{b}(\underline{x})e^{-(i/\hbar)\,s\hat{H}} = e^{-is\,{}^n\Gamma}\hat{b}(\underline{x}), \tag{4.13}$$

and they give

$$e^{im_i\hat{K}^i}\hat{b}(\underline{x},s)e^{-im_i\hat{K}^i} = \hat{b}(\underline{x}',s'), \tag{4.14}$$

where the transformation $(\underline{x},s)\mapsto(\underline{x}',s')$ is given by Eq. (3.28), so that we can write

$$e^{im_i\hat{K}^i}\quad\hat{b}(\underline{x},s)e^{-im_i\hat{K}^i} = \hat{b}(\Lambda(\underline{x},s)). \tag{4.15}$$

From this, one can write the explicit transformation laws for the Heisenberg fields $\hat{\phi}(\underline{x},s)$ and $\hat{\pi}(\underline{x},s)$.

Some questions that arise in the canonical treatment. The first question that arises in this standard treatment is whether the Poincaré transformations are associated with any changes of foliation. Working canonically *there is no trace of the foliation vector* on the Fock space defined by Eq. (4.6), so this question cannot readily be answered.

Being able to talk about foliations is a necessary step if we are to elucidate the space–time character of a quantum theory, in which the parameter s of the Heisenberg-picture objects corresponds to the foliation time parameter in space–time. For example, the physical meaning of the parameter s of the Heisenberg objects depends on the choice of foliation vector.

B. Histories quantum field theory

Quantum mechanics histories. As we have already mentioned in Sec. II, the introduction of the history group[2] as an analog of the canonical group relates the spectral projectors of the generators of its Lie algebra with propositions about history phase space quantities. This algebra is infinite-dimensional and therefore there exist infinitely many representations. However, the physically appropriate representation of the smeared history algebra can be uniquely selected by the requirement that the time-averaged energy exists as a proper self-adjoint operator.[2] The resulting Hilbert space has a natural interpretation as a continuous-tensor product: hence by this means we also gain a natural mathematical implementation of the concept of ''continuous'' temporal logic.

1. Histories Hamiltonian algebra

We shall now apply the histories ideas to relativistic quantum field theory on Minkowski space–time. The representation of the history algebra is to be selected by requiring that the time-averaged energy $H_\chi = \int d^4X\,\chi(t)H_t$ (which is associated with history propositions about

temporal averages of the energy) exists as a proper essentially self-adjoint operator.[2] In what follows, for the sake of typographical simplicity we will no longer use hats to indicate quantum operators.

We start with the abstract algebra

$$[\phi(X),\phi(X')]=0, \tag{4.16}$$

$$[\pi(X),\pi(X')]=0, \tag{4.17}$$

$$[\phi(X),\pi(X')]=i\hbar\,\delta^4(X-X'), \tag{4.18}$$

where X and X' are space–time points.

In order to find suitable representations of this algebra we start with the Fock space $\mathcal{F}:=\exp L^2(\mathbb{R}^4,d^4X)$ in which there is a natural definition of creation and annihilation operators $b(X)$ and $b^\dagger(X)$ that satisfy the commutation relations

$$[b(X),b(X')]=0, \tag{4.19}$$

$$[b^\dagger(X),b^\dagger(X')]=0, \tag{4.20}$$

$$[b(X),b^\dagger(X')]=\hbar\,\delta^4(X-X'). \tag{4.21}$$

An appropriate representation of the Poincaré group can be defined by requiring

$$U(\Lambda)b(X)U(\Lambda)^\dagger=b(\Lambda X), \tag{4.22}$$

$$U(\Lambda)|0\rangle=|0\rangle, \tag{4.23}$$

where $|0\rangle$ is the cyclic ''vacuum'' state for the theory. Then clearly history fields can be defined by

$$\phi(X):=\frac{1}{\sqrt{2}}(b(X)+b^\dagger(X)), \tag{4.24}$$

$$\pi(X):=\frac{1}{i\sqrt{2}}(b(X)-b^\dagger(X)), \tag{4.25}$$

and satisfy Eqs. (4.16)–(4.18). They also transform in the obvious covariant way under the operators $U(\Lambda)$ introduced above.

It should be emphasized that the fields $\phi(X)$ and $\pi(X)$ thus defined *do not* have any foliation vector dependence. However, an operator H_χ of the time-averaged energy of the system *cannot* be well defined so that it depends functionally on these fields in the usual way.

Hence we must seek a different, and more physically appropriate, representation for the history algebra on the history Hilbert space $\mathcal{F}$.

We start by making a *fixed* choice of a unit timelike vector n which we use to foliate the four-dimensional Minkowski space–time. It is clear that the average-energy operator is itself dependent upon the choice of foliation n, and therefore this must also be true for the elements of the history algebra. Hence to emphasize that the physically appropriate representation depends on n we rewrite the history commutation relations as

$$[{}^n\phi(X),{}^n\phi(X')]=0, \tag{4.26}$$

$$[{}^n\pi(X),{}^n\pi(X')]=0, \tag{4.27}$$

$$[{}^n\phi(X),{}^n\pi(X')]=i\hbar\,\delta^4(X-X'), \tag{4.28}$$

where X and X' are space–time points. The dependence of the representation of the history algebra on the choice of the timelike foliation vector n is indicated by the upper left symbol for the field ${}^n\phi(X)$ and its "conjugate" ${}^n\pi(X)$.

One may also write the canonical version of the history algebra. Notice that—as in the discussion above of classical history theory—in relating Eqs. (4.26)–(4.28) with the canonical version of the history algebra the three-vector $\underline{x}$ may be equated with a four-vector x_n that satisfies $n\cdot x_n=0$ (the dot product is taken with respect to the Minkowski metric $\eta_{\mu\nu}$) so that the pair $(t,\underline{x})\in\mathbb{R}\times\mathbb{R}^3$ is associated with the space–time point $X=tn+x_n$ (in particular, $t=n\cdot X$). The canonical history commutation relations can be written therefore as

$$[{}^n\phi(t,\underline{x}),{}^n\phi(t',\underline{x}')]=0, \tag{4.29}$$

$$[{}^n\pi(t,\underline{x}),{}^n\pi(t',\underline{x}')]=0, \tag{4.30}$$

$$[{}^n\phi(t,\underline{x}),{}^n\pi(t',\underline{x}')]=i\hbar\,\delta(t-t')\,\delta^3(\underline{x}-\underline{x}'), \tag{4.31}$$

where, for each $t\in\mathbb{R}$, the fields ${}^n\phi(t,\underline{x})$ and ${}^n\pi(t,\underline{x})$ are associated with the spacelike hypersurface $\Sigma_t=(n,t)$, characterized by the normal vector n and by the foliation parameter t. In particular, the three-vector $\underline{x}$ in ${}^n\phi(t,\underline{x})$ or in ${}^n\pi(t,\underline{x})$ denotes a vector in this space.

A central feature of the approach that is followed in this work for the histories quantum field theory is that, for all foliation vectors n, the corresponding foliation-dependent representations of the history algebra Eqs. (4.26)–(4.28) can all be realized on the *same* Fock space $\mathcal{F}=\exp L^2(\mathbb{R}^4,d^4X)$ that also carries the "covariant" fields $\phi(X)$ and $\pi(X)$ defined in Eqs. (4.24) and (4.25).

The foliation-dependent fields ${}^n\phi(X)$ and ${}^n\pi(X)$ are expressed in terms of the covariant creation and annihilation operators of $\exp L^2(\mathbb{R}^4,d^4X)$, and the related covariant fields $\phi(X)$ and $\pi(X)$ of Eqs. (4.26)–(4.28), as

$${}^n\phi(X)=\frac{1}{\sqrt{2}}\,{}^n\Gamma^{-1/4}(b(X)+b^\dagger(X))={}^n\Gamma^{-1/4}\phi(X), \tag{4.32}$$

$${}^n\pi(X)=\frac{1}{i\sqrt{2}}\,{}^n\Gamma^{1/4}(b(X)-b^\dagger(X))={}^n\Gamma^{1/4}\pi(X), \tag{4.33}$$

and, conversely,

$$b(X)=\frac{1}{\sqrt{2}}(\phi(X)+i\,\pi(X))=\frac{1}{\sqrt{2}}({}^n\Gamma^{1/4}\,{}^n\phi(X)+i\,{}^n\Gamma^{-1/4}\,{}^n\pi(X)) \tag{4.34}$$

$$b^\dagger(X)=\frac{1}{\sqrt{2}}(\phi(X)-i\,\pi(X))=\frac{1}{\sqrt{2}}({}^n\Gamma^{1/4n}\phi(X)-i\,{}^n\Gamma^{-1/4}\,{}^n\pi(X)), \tag{4.35}$$

where ${}^n\Gamma$ denotes the partial differential operator defined in Eq. (3.18) on the Hilbert space $L^2(\mathbb{R}^4,d^4X)$.

For a fixed foliation vector n, we seek a family of "internal" Hamiltonians ${}^nH_t$, $t\in\mathbb{R}$, whose explicit formal expression may be deduced from the standard quantum field theory expression to be

$${}^nH_t:=\frac{1}{2}\int d^4X\{{}^n\pi(X)^2+(n^\mu n^\nu-\eta^{\mu\nu})\partial_\mu\,{}^n\phi(X)\partial_\nu\,{}^n\phi(X)+\tilde{m}^2\,{}^n\phi(X)^2\}\delta(t-n\cdot X). \tag{4.36}$$

The corresponding smeared expression (which must be normal-ordered to be well defined) is

$$ {}^nH_\chi := \int_{-\infty}^{\infty} dt\chi(t)\, {}^nH_t = \frac{1}{2}{:}\int d^4X\{{}^n\pi(X)^2 + (n^\mu n^\nu - \eta^{\mu\nu})\partial_\mu {}^n\phi(X)\partial_\nu {}^n\phi(X) + \tilde{m}^2\, {}^n\phi(X)^2\}\chi(n\cdot X){:}, \tag{4.37} $$

where χ is a real-valued test function.

We next augment the history algebra with the following commutation relations that would be satisfied by the operators ${}^nH(\chi)$, if they existed:

$$ [{}^nH_\chi, {}^n\phi(X)] = -i\hbar\chi(n\cdot X)\, {}^n\pi(X), \tag{4.38} $$

$$ [{}^nH_\chi, {}^n\pi(X)] = i\hbar\chi(n\cdot X)\, {}^n\Gamma\, {}^n\phi(X), \tag{4.39} $$

$$ [{}^nH_\chi, {}^nH_{\chi'}] = 0. \tag{4.40} $$

If the operators ${}^nH$ existed, the above commutation relations would give rise to the transformations

$$ e^{(i/\hbar){}^nH_\chi}\, {}^n\phi(X)\, e^{(-i/\hbar){}^nH_\chi} = \cos[\chi(n\cdot X){}^n\Gamma^{1/2}]\, {}^n\phi(X) + {}^n\Gamma^{-1/2}\sin[\chi(n\cdot X){}^n\Gamma^{1/2}]\, {}^n\pi(X), \tag{4.41} $$

$$ e^{(i/\hbar){}^nH_\chi}\, {}^n\pi(X)\, e^{(-i/\hbar){}^nH_\chi} = -{}^n\Gamma^{1/2}\sin[\chi(n\cdot X){}^n\Gamma^{1/2}]\, {}^n\phi(X) + \cos[\chi(n\cdot X){}^n\Gamma^{1/2}]\, {}^n\pi(X). \tag{4.42} $$

Note that the expression $\chi(n\cdot X){}^n\Gamma^{\frac{1}{2}}$ is unambiguous since, viewed as an operator on $L^2(\mathbb{R}^4, d^4X)$, multiplication by $\chi(n\cdot X)$ commutes with ${}^n\Gamma^{\frac{1}{2}}$.

The right hand sides of Eqs. (4.41) and (4.42) define an automorphism of the history algebra Eqs. (4.26)–(4.28), and all that remains is to show that these automorphisms are unitarily implementable in this representation. To this end, we use Eqs. (4.34) and (4.35) to prove that

$$ e^{i\,{}^nH_\chi/\hbar}\, b(X)\, e^{-i\,{}^nH_\chi/\hbar} = e^{-i\,\chi(n\cdot X){}^n\Gamma^{1/2}} b(X). \tag{4.43} $$

However, the operator defined on $L^2(\mathbb{R}^4, d^X)$ by

$$ (O(\chi)\psi)(X) := e^{-i\chi(n\cdot X){}^n\Gamma^{1/2}}\psi(X) \tag{4.44} $$

is easily seen to be unitary, and hence we conclude[2] that the desired quantities ${}^nH_\chi$ exist as self-adjoint operators on the Fock space $\mathcal{F}$ associated with the creation and annihilation operators $b^\dagger(X)$ and $b(X)$. The spectral projectors of these operators ${}^nH_\chi$ represent propositions about the time-averaged value of the energy in the space–time foliation determined by n.

To conclude: for each *fixed* choice of a foliation vector n, we have a physically meaningful representation of the history algebra Eqs. (4.26)–(4.28) on the Hilbert space $\mathcal{F} = \exp L^2(\mathbb{R}^4, d^4X)$. Thus the same Hilbert space $\mathcal{F}$ carries *all* different representations—for different choices of n—of the quantum field theory history algebra.

2. The action operator

We now define the action ${}^nS_\chi$ and the Liouville ${}^nV$ operators as normal-ordered versions of their classical analogus

$$ {}^nS_\chi = {}^nV - \frac{1}{2}{:}\int d^4X\{{}^n\pi^2(X) + {}^n\phi(X){}^n\Gamma{}^n\phi(X)\}\chi(n\cdot X){:}, \tag{4.45} $$

$$ {}^{n}V =: \int_{-\infty}^{\infty} d^4X\, {}^{n}\pi(X)\, n^{\mu}\partial_{\mu}\, {}^{n}\phi(X) :. \tag{4.46} $$

The automorphisms of the history algebra that are generated by the action and Liouville operators are

$$ e^{is\,{}^{n}S_{\chi}/\hbar}\, b(X) e^{-is\,{}^{n}S_{\chi}/\hbar} = e^{-i\int_{s'-s}^{s'+s} ds'\ \chi(nX+s')\,{}^{n}\Gamma^{1/2} - s n^{\mu}\partial_{\mu}} b(X), \tag{4.47} $$

$$ e^{is\,{}^{n}V/\hbar} b(X)\, e^{-is\,{}^{n}V/\hbar} = e^{-s\, n^{\mu}\partial_{\mu}} b(X), \tag{4.48} $$

and are easily shown to be unitarily implementable. In what follows, the real-valued smearing function χ is set equal to $\chi(t)=1$ for every $t \in \mathbb{R}$.

C. Poincaré group covariance

A significant feature of the histories formalism is the temporal structure of the theory. It introduces a new approach to the concept of time, in which time is distinguished as an ordering parameter (logical structure), and as an evolution parameter (dynamics). In particular, as we have already shown in nonrelativistic quantum mechanics,[1] the Liouville operator ${}^{n}V$ generates time translations with respect to the ''external'' t-time parameter, and the Hamiltonian operator ${}^{n}H$ generates time translations with respect to the ''internal'' evolution s-time parameter. The action operator ${}^{n}S$ generates *both* types of time transformations; it is the time generator for the histories theory for solutions of the equations of motion. [In histories theory the physical time translation generator is the action operator ${}^{n}S$; both Liouville ${}^{n}V$ and Hamiltonian ${}^{n}H$ operators are time translation generators that correspond to two different aspects (two modes) of the notion of time. However, only ${}^{n}S$ is related to the actual physical time parameter, in analogy with the standard theory where the Hamiltonian ${}^{n}H$ is the time translation generator.] The same construction is true for a histories quantum field theory.

The invariance of standard quantum field theory under the Poincaré group has been a difficult issue to address for many years. In a canonical treatment of quantum field theory, the Schrödinger-picture fields depend on the reference frame (i.e., choice of foliation). In order to demonstrate manifest independence of this choice with the aid of Heisenberg-picture fields, one still has to contend with the foliation dependence of the Hamiltonian that generates the Heisenberg fields.

In histories theory, the enhanced temporal structure enables the study of a Poincaré group transformation between different foliations. In particular we will show that different representations corresponding to different foliation vectors n are related by Lorentz boosts of the ''external'' Poincaré group,

$$ U(\Lambda)\, {}^{n}\phi(X) U(\Lambda)^{-1} = {}^{\Lambda n}\phi(\Lambda X), \tag{4.49} $$

and where the time translations generator is closely related to the ''Liouville'' operator V.

The Heisenberg-picture operators. We first define the Heisenberg-picture analog of the scalar field to illustrate the different time translations associated with the two time labels. We use a similar notation to that in the classical case: i.e., the Heisenberg-picture field is written as ${}^{n}\phi(X,s) = {}^{n}\phi(t,\underline{x},s)$, where the space–time point $X=(t,\underline{x})$ is expressed in coordinates adapted to n. Thus

$$ \begin{aligned} {}^{n}\phi(X,s) = {}^{n}\phi(t,\underline{x},s) &:= e^{(i/\hbar)\, s\, {}^{n}H}\, {}^{n}\phi(t,\underline{x}) e^{-(i/\hbar)\, s\, {}^{n}H} \\ &= \cos(s\, {}^{n}\Gamma^{1/2})\, {}^{n}\phi(X) + {}^{n}\Gamma^{-1/2} \sin(s\, {}^{n}\Gamma^{1/2})\, {}^{n}\pi(X), \end{aligned} \tag{4.50} $$

$$ \begin{aligned} {}^{n}\pi(X,s) = {}^{n}\pi(t,\underline{x},s) &:= e^{(i/\hbar)\, s\, {}^{n}H}\, {}^{n}\pi(t,\underline{x}) e^{-(i/\hbar)\, s\, {}^{n}H} \\ &= -{}^{n}\Gamma^{1/2} \sin(s\, {}^{n}\Gamma^{1/2})\, {}^{n}\phi(X) + \cos(s\, {}^{n}\Gamma^{1/2})\, {}^{n}\pi(X). \end{aligned} \tag{4.51} $$

The different types of time translation are particularly easy to see by studying the action of the Liouville ${}^nV$ and action ${}^nS$ operators on the Heisenberg-picture fields $b(X,s)$:

$$e^{i\tau {}^nH} b(t,\underline{x},s) e^{-i\tau {}^nH} := b(t,\underline{x},s+\tau), \tag{4.52}$$

$$e^{i\tau {}^nV} b(t,\underline{x},s) e^{-i\tau {}^nV} := b(t+\tau,\underline{x},s), \tag{4.53}$$

$$e^{i\tau {}^nS} b(t,\underline{x},s) e^{-i\tau {}^nS} := b(t+\tau,\underline{x},s+\tau). \tag{4.54}$$

The label s corresponds to the ''internal'' time of the unitary Hamiltonian time evolution, while t corresponds to the ''external'' time that labels the time ordering of events in a history for the Shrödinger-picture operators.

1. The internal Poincaré group

As we showed previously, each fixed choice of foliation vector n corresponds to a it *different* representation of the history algebra on the *same* Fock space $\mathcal{F}=\exp L^2(\mathbb{R}^4,d^4X)$. Hence, we may heuristically say that, for a given vector n, and for each value of the associated time t, there will be a Hilbert space $\mathcal{H}_t$ that carries an independent copy of the standard quantum field theory. (The physical quantities in histories appear naturally[1] space–time averaged, therefore they are smeared with appropriate test functions. Strictly speaking, quantities labeled at moments of time are not well-defined mathematically.) In particular, there exists a representation of the Poincaré group associated with each spacelike slice (n,t), where $t\in\mathbb{R}$.

In what follows, a particularly important role will be assigned to the averaged ''internal'' Poincaré group. For example, we define the averaged energy ${}^nH := \int d^4X\, {}^nH_t$ that generates translations on the s-time parameter of the Heisenberg-picture fields ${}^n\phi(X,s)={}^n\phi(t,\underline{x},s)$, without affecting the ''external'' t-time parameter:

$$ {}^n\phi(X,s) = \underset{\rightarrow}{{}^nH}\, {}^n\phi(X,s+s'), \tag{4.55}$$

$$ {}^n\pi(X,s) = \underset{\rightarrow}{{}^nH}\, {}^n\pi(X,s+s'). \tag{4.56}$$

The expressions for the ''internal'' Poincaré generators of spatial translations P^i, and rotations J^i, can be written in direct analogy with the expressions (3.22)–(3.24) of the classical case. We use the normal-ordered expressions

$$P(m) = :\int d^4X \pi(X) m^\mu \partial_\mu \phi(X): = i\int d^4X b^\dagger(X) m^\mu \partial_\mu b(X), \tag{4.57}$$

$$J(m) = \frac{1}{2} n_\mu m_\nu \epsilon^{\mu\nu\rho\sigma} :\int d^4X \pi(X) X_\rho \partial_\sigma \phi(X): = i\frac{1}{2} n_\mu m_\nu \epsilon^{\mu\nu\rho\sigma} \int d^4X b^\dagger(X) X_\rho \partial_\sigma b(X). \tag{4.58}$$

We have used a ''pseudo-covariant'' notation by employing an n-spacelike vector m (i.e., such that $n_\mu m^\mu = 0$). Note that the terms involving a pair of creation operators, or a pair of annihilation operators, can be shown to vanish through integration by parts.

Of particular interest is the action of the boost generator ${}^nK(m)$ defined as

$$ {}^nK(m) = \int d^4X b^\dagger(X)\, {}^n\Gamma^{1/4} X^\mu m_\mu\, {}^n\Gamma^{1/4} b(X). \tag{4.59}$$

The key feature of the boost generator ${}^{n}K(m)$ is that it mixes the it s-time parameter with the three-vectors $\underline{x}$. The action of these boost transformations is most clearly seen on the Heisenberg objects $\phi(X,s)=\phi(t,\underline{x},s)$:

$$ {}^{\mathrm{int}}U(\Lambda)\,{}^{n}\phi(t,\underline{x},s)\,{}^{\mathrm{int}}U(\Lambda)^{-1}={}^{n}\phi(t,\Lambda(\underline{x},s)), \tag{4.60}$$

where ${}^{\mathrm{int}}U(\Lambda):=e^{iK(m)}$ is the unitary operator that generates Lorentz transformations, and Λ is the Lorentz transformation generated by m.

At this point we note the action of the internal Poincaré group on the action ${}^{n}S$, Hamiltonian ${}^{n}H$ and Liouville ${}^{n}V$ operators, respectively:

$$ {}^{\mathrm{int}}U(\Lambda)\,{}^{n}H\,{}^{\mathrm{int}}U(\Lambda)^{-1}={}^{n}H, \tag{4.61}$$

$$ {}^{\mathrm{int}}U(\Lambda)\,{}^{n}V\,{}^{\mathrm{int}}U(\Lambda)^{-1}={}^{n}V, \tag{4.62}$$

$$ {}^{\mathrm{int}}U(\Lambda)\,{}^{n}S\,{}^{\mathrm{int}}U(\Lambda)^{-1}={}^{n}S. \tag{4.63}$$

As we would expect from standard canonical quantum field theory, we see that the above operators remain invariant under the ''internal'' Lorentz transformations.

2. External Poincaré group

A key result in histories classical field theory is that there also exists a second—the ''external''—Poincaré group symmetry of the theory, with generators

$$ \tilde{P}^{\mu}=:8\int d^{4}X\,\pi(X)\partial^{\mu}\phi(X):, \tag{4.64}$$

$$ \tilde{M}^{\mu\nu}=:\int d^{4}X\,\pi(X)(X^{\mu}\partial^{\nu}-X^{\nu}\partial^{\mu})\phi(X):. \tag{4.65}$$

Note that these definitions use the covariant fields $\phi(X)$ and $\pi(X)$ that satisfy the algebra (4.16)–(4.18) rather than the foliation-dependent fields ${}^{n}\phi(X)$ and ${}^{n}\pi(X)$ of Eqs. (4.26)–(4.28). However, many of the generators of the external Poincaré group are exactly the same whether one uses covariant fields expressions or foliation-dependent ones: they differ only for the case of the boosts generators ${}^{n}K(m)$.

In particular, the Liouville operator $\tilde{P}^{0}=V$, given by the expression

$$ V=:\int d^{4}X\;\pi(X)n^{\mu}\partial_{\mu}\,\phi(X):=i\int d^{4}X\,b^{\dagger}(X)n^{\mu}\partial_{\mu}b(X), \tag{4.66}$$

generates translations on the time label t.

The space translations and rotation generators are identical to those of the internal Poincaré group (4.57) and (4.58). However, the external boost generator $\tilde{K}(m)$ differs from the internal one ${}^{n}K(m)$, and hence it is of particular interest to study the action of the former.

The generator of time-translations V acts on Schrödinger picture objects as

$$ {}^{n}\phi(X)={}^{n}\phi(t,\underline{x})\underset{\rightarrow}{\overset{V}{}}{}^{n}\phi(t+\tau,\underline{x}), \tag{4.67}$$

$$ {}^{n}\pi(X)={}^{n}\pi(t,\underline{x})\underset{\rightarrow}{\overset{V}{}}{}^{n}\pi(t+\tau,\underline{x}). \tag{4.68}$$

The ''external'' boost generator $\tilde{K}(m)$ is

$$\tilde{K}(m) =: \int_{-\infty}^{\infty} d^4X \ \pi(X)\, T_m\, \phi(X): \tag{4.69}$$

$$= i \int_{-\infty}^{\infty} d^4X \ b^{\dagger}(X)\, T_m\, b(X), \tag{4.70}$$

where we define the operator T_m as

$$(T_m f)(X) := n_{\mu} m_{\nu} (X^{\mu} \partial^{\nu} - X^{\nu} \partial^{\mu}) f(X) \tag{4.71}$$

and $n \cdot m = 0$. Then the boost generator $\tilde{K}(m)$ acts on the fields ${}^n\phi(X)$ as

$${}^{\text{ext}}U(\Lambda)\, {}^n\phi(X)\, {}^{\text{ext}}U(\Lambda)^{-1} = {}^{\Lambda n}\phi(\Lambda(X)), \tag{4.72}$$

and it mixes the t-time parameter with the three-vector $\underline{x}$. However, the crucial point is that $\tilde{K}(m)$ generates Lorentz transformations *on the foliation vector n* as well.

This can be viewed as a demonstration of explicit Poincaré covariance, as we can see from the action of the external Lorentz transformations on the Heisenberg-picture fields ${}^n\phi(X,s)$ as

$${}^{\text{ext}}U(\Lambda)\, {}^n\phi(X,s)\, {}^{\text{ext}}U(\Lambda)^{-1} = {}^{\Lambda n}\phi(\Lambda(X,s)). \tag{4.73}$$

The generators of the *internal* Poincaré group transform under the action of the *external* Poincaré group as

$${}^{\text{ext}}U(\Lambda)\, {}^nH\, {}^{\text{ext}}U(\Lambda)^{-1} = {}^{\Lambda n}H, \tag{4.74}$$

$${}^{\text{ext}}U(\Lambda)\, {}^n\tilde{K}(m)\, {}^{\text{ext}}U(\Lambda)^{-1} = {}^{\Lambda n}\tilde{K}(\Lambda m). \tag{4.75}$$

Of considerable importance is the fact that the action operator ${}^nS$ transforms in the same way:

$${}^{\text{ext}}U(\Lambda)\, {}^nS\, {}^{\text{ext}}U(\Lambda)^{-1} = {}^{\Lambda n}S. \tag{4.76}$$

Hence the action of the external Poincaré group *relates* representations of the theory that *differ* with respect to the foliation vector n. As we shall see in the following section, this is crucial when we discuss the Poincaré invariance of probabilities.

In summary, we have shown that the history version of quantum field theory carries representations of two Poincaré groups. The ''internal'' Poincaré group is defined in analogy to the one in the standard canonical treatment of the theory. It corresponds to time-translations with respect to the ''internal'' s-time parameter of histories theory. The Lorentz part of the ''external'' Poincaré group intertwines representations of the theory associated with different choices of foliation, all of which, however, are realized on the *same* Fock space $\mathcal{F}$. It corresponds to time-translations with respect to the ''external'' t-time parameter.

The translation parts of these two types of Poincaré transformation—corresponding to the relations between the t time parameter and kinematics, and the s time parameter and dynamics—have very significant analogs in the case of the histories version of general relativity.[9]

3. The decoherence functional

"Classical" coherent states. In Ref. 1, we showed how a classical quantum relation can be nicely described in histories theory by using the history analog of coherent states. In the histories formalism, a non-normalized coherent state vector is written as[2]

$$|\exp z\rangle = \bigoplus_{n=0}^{\infty} (n!)^{-1/2} (\otimes |z\rangle)^n. \tag{4.77}$$

The corresponding normalized coherent states can be obtained by unitary transformations of the vacuum state as

$$|z\rangle := \frac{1}{\sqrt{\langle \exp z | \exp z\rangle}} |\exp z\rangle = U[f,h]|0\rangle, \tag{4.78}$$

where $U[f,h]$ is the Weyl operator defined as

$$U[f,h] := e^{(i/\hbar)({}^n\phi(f) - {}^n\pi(h))}, \tag{4.79}$$

and f and h are smearing functions that belong to $L^2(\mathbb{R}^4, d^4X)$. We write the normalized coherent state $|z\rangle$ corresponding to the pair f,h as $|f,h\rangle$. In this context we know that f and h correspond to classical values and therefore correspond to a path on classical phase space. In this correspondence, the functions f and h are the classical values of the field $\phi(X)$ and its conjugate momenta $\pi(X)$, respectively.

The set of all coherent states is independent of the choice of foliation since these coherent states are eigenstates of the annihilation operator $b(X)$, which is foliation independent. However, the physical identification of the vector $|z\rangle$ with a phase space path *is* foliation dependent since it depends on the Weyl operator, which itself depends on the choice of the representation of the history algebra on the Fock space $\mathcal{F}$. [Given a complex path z, the classical phase space path (f,h) is defined by the foliation-dependent expression $z = {}^n\Gamma^{1/4} f + i\,{}^n\Gamma^{-1/4} h$.] One should recall that the space of classical histories Π is itself dependent on the choice of foliation.

So far our discussion of the histories version of quantum field theory has been at the level of field algebras and group transformations. However, in histories formalism physically crucial "probabilistic" information is contained in the decoherence functional.

In this HPO formalism, the most general form for the decoherence functional of a pair of history propositions α, β is

$$d(\alpha,\beta) = Tr_{\mathcal{F}\times\mathcal{F}}(\alpha\otimes\beta\Xi), \tag{4.80}$$

in terms of an operator Ξ on $\mathcal{F}\times\mathcal{F}$.[10]

In our case, the operator Ξ reads

$$\Xi := \langle 0|\rho_{-\infty}|0\rangle (\mathcal{S}_{cts}\mathcal{U})^\dagger \otimes (\mathcal{S}_{cts}\mathcal{U}), \tag{4.81}$$

in terms of the operator $\mathcal{S}_{cts}\mathcal{U}$ that we proved in Ref. 1 that it is an implicit function of the action operator: therefore there is an implicit dependence of Ξ on the foliation vector n. The matrix elements of $\mathcal{S}_{cts}\mathcal{U}$ in a coherent state basis can written in terms of the classical action functional $S[f,h]$ as

$$\langle f,h|\mathcal{S}_{cts}\mathcal{U}|f,h\rangle = e^{iS[f,h]}. \tag{4.82}$$

The explicit relation of $\mathcal{S}_{cts}\mathcal{U}$ with the action operator ${}^nS$ is as follows. For a general operator A on $L^2(\mathbb{R}^4, d^4X)$ one can define an operator $\Gamma(A)$ on $\mathcal{F}$ as

$$\Gamma(A)|\exp z\rangle = |Az\rangle. \tag{4.83}$$

In our case we have

$$e^{is\,{}^nS} = \Gamma(e^{is\,{}^n\sigma}), \tag{4.84}$$

$$\mathcal{S}_{cts}\mathcal{U} = \Gamma(1 + i\,{}^n\sigma), \tag{4.85}$$

in terms of the operator ${}^n\sigma = n^\mu\partial_\mu - {}^n\Gamma^{1/2}$. Hence, the decoherence functional depends on the representation through the phase space action ${}^nS$.

This raises the critical issue of the physical meaning of the fact that the formalism appears to depend on a specific choice of the foliation vector n. We have seen above that the representation of the phase space quantities by Hilbert space operators depends on n, and that there exist unitary intertwiners between different representations given by the boosts of the external Poincaré group. As has been discussed in Ref. 11, a transformation law for the observables by means of a unitary operator U,

$$\alpha \rightarrow \alpha' = U\alpha U^{\dagger}, \tag{4.86}$$

implies that the operator Ξ of the decoherence functional, carrying a label for the foliation dependence n, ought to transform as

$$^{n}\Xi \rightarrow {}^{\Lambda n}\Xi = (U \otimes U)\, {}^{n}\Xi\, (U^{\dagger} \otimes U^{\dagger}) \tag{4.87}$$

so that the values of the decoherence functional (corresponding to probabilities and correlation functions of the theory) *are representation independent*,

$$^{\Lambda n}d(^{\Lambda n}\alpha, {}^{\Lambda n}\beta) = {}^{n}d(^{n}\alpha, {}^{n}\beta), \tag{4.88}$$

where $^{\Lambda n}d$ is the decoherence functional defined with reference to the operator $^{\Lambda n}\Xi$.

In our case we have $U = e^{i\tilde{K}(m)} = {}^{ext}U(\Lambda)$. This changes the foliation dependence of the fundamental fields $^{n}\phi(X)$ and $^{n}\pi(X)$, and hence of any observable $^{n}\alpha$ that depends upon them

$$^{n}\alpha \rightarrow {}^{\Lambda n}\alpha := U(\Lambda)\, {}^{n}\alpha U(\Lambda)^{\dagger}. \tag{4.89}$$

Some physically interesting examples of observables, in this sense, are integrals $\int d^{X}\, {}^{n}\phi(X) f(X)$ of fields $^{n}\phi(X)$, smeared with appropriate test functions $f(X)$, that satisfy $f(X) = f(\Lambda(X))$; another example is any space–time average of the normal-ordered polynomial functions of these fields.

In order to see how the boosts generator acts on $^{n}\Xi$, it suffices to check its action on $\mathcal{S}_{cts}\mathcal{U}$. This is

$$U\, {}^{n}\mathcal{S}_{cts}\mathcal{U}\, U^{\dagger} = \Gamma(1 + ie^{-T_m}\, {}^{n}\sigma\, e^{T_m}) = \Gamma(1 + i\, {}^{\Lambda n}\sigma). \tag{4.90}$$

Consequently, the operator $^{n}\Xi$ transforms as $^{n}\Xi \rightarrow {}^{\Lambda n}\Xi$. Hence the values of the decoherence functional are foliation independent:

$$^{n}d(^{n}\alpha, {}^{n}\beta) = {}^{\Lambda n}d(^{\Lambda n}\alpha, {}^{\Lambda n}\beta). \tag{4.91}$$

V. CONCLUSIONS

We have studied both the classical and the quantum history versions of scalar field theory. We have showed that, in both cases, the crucial feature of the history field theory is the appearance of two Poincaré groups, in direct analogy to the two types of time transformation that characterizes the history formalism. The internal Poincaré group is related to time as an ordering parameter (the Hamiltonian H is the time translations generator), and it is in analogy to the Poincaré group of standard field theory. On the other hand, the external Poincaré group is related to time as a parameter of evolution (the Liouville V is the time translations generator), and it is of particular interest for the quantum case, as it relates representations of the quantum field theory, for different choices of foliation, with Poincaré transformations.

These results will be proved to be of great importance in the study of history general relativity theory in Ref. 9. In particular, the histories formalism is suitable to deal with issues that lie at the level of the interplay between quantum theory and the space–time structure. The present work focuses on quantum field theory in a fixed space–time, however the techniques involved and the concepts introduced have been able to precisely identify the relation between the quantum me-

chanical observables and the necessary notion of the space–time foliation. Many issues are raised at the level of the meaning of reference frames in quantum theory—a foliation corresponds to a reference frame—and more importantly at the level of quantum gravity.

The latter is eventually the aim of the histories program, and this involves a further elucidation of the meaning of space–time in a quantum theory. What strikes us as relevant at present is that one might have to disentangle between the two different views of space–time transformations: the *passive* and the *active* view. This is subtly hinted by the fact that the transformations generated by the external Poincaré group should be viewed in the passive sense, since the argument X cannot be identified with a fixed, absolute space–time point *in all representations*.

In order to successfully address the above issues we must first study the history version of general relativity; this is the context of the forthcoming paper.[9]

(Received 12 November 2001; accepted for publication 26 December 2001)

In this paper we study the large N_c limit of SO(N_c) gauge theory coupled to a Majorana field and a real scalar field in $1+1$ dimensions extending ideas of Rajeev [Int. J. Mod. Phys. A **9**, 5583 (1994)]. We show that the phase space of the resulting classical theory of bilinears, which are the mesonic operators of this theory, is $\mathrm{OSp}_1(\mathcal{H}|\mathcal{H})/U(\mathcal{H}_+|\mathcal{H}_+)$, where $\mathcal{H}|\mathcal{H}$ refers to the underlying complex graded space of combined one-particle states of fermions and bosons and $\mathcal{H}_+|\mathcal{H}_+$ corresponds to the positive frequency subspace. In the begining to simplify our presentation we discuss in detail the case with Majorana fermions only [the purely bosonic case is treated in Toprak and Turgut, J. Math. Phys. **43**, 1340 (2002)]. In the Majorana fermion case the phase space is given by $O_1(\mathcal{H})/U(\mathcal{H}_+)$, where $\mathcal{H}$ refers to the complex one-particle states and $\mathcal{H}_+$ to its positive frequency subspace. The meson spectrum in the linear approximation again obeys a variant of the 't Hooft equation. The linear approximation to the boson/fermion coupled case brings an additonal bound state equation for mesons, which consists of one fermion and one boson, again of the same form as the well-known 't Hooft equation.

I. INTRODUCTION

Gauge theories play a fundamental role in our description of nature. Nevertheless our understanding of confining phase of gauge theories is not so complete. In principle we should be able to calculate the hadronic spectrum starting from quantum chromodynamics (QCD), which is a gauge theory, yet this has not been possible up to now. It is believed that the hadrons are colorless excitations of the underlying gauge theory and we never see the constituent quarks as free particles. This suggests that in this case we should have an independent formulation of gauge theories in terms of color singlet operators of the original gauge theory. In general this is a very hard task.

Gauge theories in $1+1$ dimensions provide a great testing ground for many ideas about realistic theories. This is a great simplification, various difficult problems of higher dimensional theories will not be there, yet there are still interesting aspects of these theories which make them worth studying in depth. In Ref. 1, Rajeev constructed a theory of mesons in two dimensions in the limit N_c, the number of colors in SU(N_c) goes to infinity using only the color invariant variables (which correspond to the meson operators). The idea that QCD should simplify while keeping all its essential features in this limit goes back to 't Hooft[2,3] and that this limit should be a kind of classical mechanics to Migdal and Witten.[4] This is a very promising step in simplifying gauge theories, but the large-N_c theory is also quite complicated and it is not possible as yet to understand it in four dimensions.

[a)]Electronic mail: toprake@boun.edu.tr
[b)]Electronic mail: turgutte@boun.edu.tr

Originally 't Hooft studied two-dimensional QCD in the large-N_c limit to understand the meson spectrum and obtained his bound state equation in his seminal paper.[3] Soon after the scalar two-dimensional QCD was worked out by Shei and Tsao in Ref. 5 following 't Hooft, and later by Tomaras using Hamiltonian methods in Ref. 6. These works obtained the analog of the 't Hooft equation for this case. A natural extension of these would be to look at combined (fermionic) QCD and scalar QCD; this is done in a paper of Aoki,[7] where it is shown that three types of mesons are possible and they all obey a certain type of 't Hooft equation (see also Ref. 8). Cavicchi[9] using a path integral approach with bilocal fields, developed in Ref. 10, studied coupled fermions and bosons as well as some other models in two dimensions and he obtained some generalized versions of the 't Hooft equation.

To understand gauge theories better, we study the problem of bosons and fermions coupled to SO(N_c) gauge fields in $1+1$ dimensions. We will apply the methods developed by Rajeev to this toy model. We recommend his lectures for a more detailed exposition of the underlying ideas and various other directions.[11] In Ref. 1 it was shown that the phase space of the two-dimensional QCD is an infinite dimensional Grassmannian.[12] Using the same methods scalar version of QCD is worked out in Ref. 13, the phase space of the theory comes out to be an infinite dimensional disk. Recently Konechny and O.T.T. obtained the large-N_c phase space of bosons and fermions coupled to SU(N_c) gauge theory; a certain kind of super-Grassmannian.[14] The linearized equations agree with the ones found in Ref. 7. The correct equations are nonlinear and various approximation schemes are also discussed in Ref. 14. There are some ideas in the literature which suggest that gauge theories in two dimensions all behave in a very similar way,[15] therefore it will be interesting to see how much of this holds for SO(N_c) gauge theory.

The organization of our work is as follows, since we did not want to go into technical details of supergeometry immediately, we first study the purely fermionic case. The essential calculations are very similar to the ones in Rajeev's lectures[11] and for the geometry basic ideas are already in Refs. 16 and 12, we also recommend Ref. 17 for a good discussion. We show that one can formulate the large-N_c limit in terms of bilinears along the lines in Ref. 1. We obtain a variant of the 't Hooft equation in the linear approximation. We explain the geometry of the phase space and show that it is a homogeneous manifold, $O_1(\mathcal{H})/U(\mathcal{H}_+)$ (see explanations in Sec. IV), and the symplectic form is the natural one. In the second part, we study the combined system of bosons and fermions, this part is very brief—we mostly state the results. We obtain a super-Poisson structure of the bilinears in the large-N_c limit and the resulting Hamiltonian. The equations of motion in the linear approximation agree with the purely bosonic and purely fermionic ones with an additional one for the mesons made up of one fermion and one boson. This is again a variant of the well-known 't Hooft equation. The discussion on the geometry of the resulting infinite dimensional supersymplectic space requires some new ideas. This part is technically complicated; we use essentially Berezin's ideas,[18] but we do not claim that all the technicalities of the infinite dimensional case are understood. We show that the underlying phase space should be the super-homogeneous manifold $\mathrm{OSp}_1(\mathcal{H}|\mathcal{H})/U(\mathcal{H}_+|\mathcal{H}_+)$, and the supersymplectic form is the natural one on this space. We plan to come to the more mathematical aspects of this problem in a future publication.

II. THE SO(N_c) MAJORANA FERMIONS IN THE LIGHT-CONE

Since the basic philosophy was explained in Ref. 1 we can be brief and only state our conventions and define our theory. We will use the light cone coordinates $x^+=(1/\sqrt{2})(t+x)$, $x^-=(1/\sqrt{2})(t-x)$, (we recommend Ref. 19 for an introduction to light-cone quantization, and Ref. 20 for a more comprehensive review), the action functional is

$$S=\int\left[\frac{1}{2}\mathrm{Tr}\,F_{\mu\nu}F^{\mu\nu}+i\overline{\Psi}_M\gamma^\mu(\partial_\mu+gA_\mu)\Psi_M-m\overline{\Psi}_M\Psi_M\right], \tag{1}$$

where we have an SO(N_c) gauge theory for which the matter fields are in the fundamental representation and Tr denotes an invariant inner product in the Lie algebra. The Lie algebra condition for SO(N_c) implies that $A_\mu^T=-A_\mu$. To compute the variations of the action we need the

independent degress of freedom, we can expand $A_\mu = A_\mu^a T^a$, where T^a are the generators of the Lie algebra of SO(N_c), chosen such that $\mathrm{Tr}\, T^a T^b = -1/2\, \delta^{ab}$. Our conventions for the Majorana fermions are as follows: we choose the Majorana representation in which the fermions are real, i.e., $\Psi_M^\dagger = \Psi_M^T$ (transpose here also includes the color indices to simplify the notation). The gamma matrices now are given by,

$$\gamma^0 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \quad \gamma^1 = \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix} \quad \gamma^5 = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{2}$$

Note that γ^5 happens to be diagonal in $1+1$ dimensions and we set $\overline{\Psi}_M = \Psi_M^T \gamma^0$. We now rewrite the action in the light-cone coordinates and eliminate all nondynamical degrees of freedom. We write $\Psi_M = \binom{\psi_1}{\psi_2}$, and use $\gamma^+ = (1/\sqrt{2})(\gamma^0 + \gamma^1)$, $\gamma^- = (1/\sqrt{2})(\gamma^0 - \gamma^1)$. We further set $A_- = 0$ and choose x^+ as the evolution variable, which we call "time,"

$$S = \int \mathrm{d}x^+ \, \mathrm{d}x^- \left[\frac{1}{2} (\partial_- A_+^a)^2 + i\sqrt{2} \psi_1^T \partial_- \psi_1 + i\sqrt{2} \psi_2^T \partial_+ \psi_2 + i2m \psi_1^T \psi_2 + i\sqrt{2} g \psi_2^T A_+^a T^a \psi_2 \right] \tag{3}$$

(from now on T only means tranpose in the color space). We note also that we have a *real* two component fermion, they are Grassmann valued obeying $\psi_1 \psi_2 = -\psi_2 \psi_1$. We can check that the action is real if we use the following complex conjugation convention for spinors, $(\psi\xi)^* = \xi^* \psi^*$. We see that ψ_1^α is nondynamical, and hence can be eliminated using its equation of motion,

$$\psi_1^\alpha = -\frac{m}{\sqrt{2}\partial_-} \psi_2^\alpha. \tag{4}$$

Similarly we solve for the nondynamical A_+^a, and get

$$A_+^a = \frac{i\sqrt{2} g}{\partial_-^2} \psi_2^T T^a \psi_2. \tag{5}$$

A remark is in order here to clarify what we mean by "real fermions" while the action and the constraint equation for A_+^a have explicit factors of i. The resolution of this seeming paradox is that it is the equations of motion which are actually real. To see this note first that the symplectic form has a factor of i in it, and the ψ_1^α constraint only has real operators. The A_+^a constraint is also real if we choose complex conjugation of fermions to be $(\psi\xi)^* = \xi^* \psi^*$. This convention implies that the product of two real fermions is imaginary, and this is the reason for the extra factors of i in the action. The equation of motion for ψ_2^α reads

$$\partial_+ \psi_2^\alpha = \frac{m}{\sqrt{2}} \psi_1^\alpha, \tag{6}$$

which is manifestly real. This shows that the "time" evolution preserves the real valuedness condition imposed on the fermions.

If we insert the above-mentioned constraints into the action we arrive at

$$S = \int \mathrm{d}x^+ \, \mathrm{d}x^- \left[i\sqrt{2} \psi_2 \partial_+ \psi_2 - \frac{\sqrt{2} m^2}{2} \psi_2 \frac{1}{i\partial_-} \psi_2 - g^2 \psi_2^T T^a \psi_2 \frac{1}{\partial_-^2} \psi_2^T T^a \psi_2 \right]. \tag{7}$$

This defines our theory at the classical level with the redundant degrees of freedom eliminated. *Since it is written entirely in terms of ψ_2 we will refer to this field as ψ from now on.* The real fermions have a super-Poisson bracket, which can be read off from the action, given by

$$\{\psi^{\alpha}(x^{-},x^{+}),\psi^{\beta}(y^{-},x^{+})\}_{+}=\frac{-i}{2\sqrt{2}}\,\delta^{\alpha\beta}\delta(x^{-}-y^{-}). \tag{8}$$

Since our real fermions are Grassmann valued we use a symplectic structure which is i times a real symmetric operator, and the Hamiltonian is actually i times an antisymmetric one, as we will see in more detail in Sec. III. There is an ambiguity in the quantization, we follow Rajeev's original approach,[11,1] we will remove the nondynamical fields after quantizing the dynamical field, ψ^{α}. Using the Dirac rule we get an anticommutator for ψ,

$$[\psi^{\alpha}(x^{-}),\psi^{\beta}(y^{-})]_{+}=i\hbar\left(\frac{-i}{2\sqrt{2}}\,\delta^{\alpha\beta}\delta(x^{-}-y^{-})\right)=\frac{\hbar}{2\sqrt{2}}\,\delta^{\alpha\beta}\delta(x^{-}-y^{-}). \tag{9}$$

(Note that for the orthogonal group, the distinction of upper and lower indices is irrelevant, since the metric tensor is unity.) The reason for our convention of complex conjugation is to arrive at this more familiar form of the Clifford algebra. We could have chosen a convention in which the product of real fermions is real, then we would arrive at a Clifford algebra with a factor of i as in Ref. 16, but this usual form is preferable (it leads to a positive inner product, or the Hermitian conjugation is compatible with the inner product in the fermionic Fock space). Let us introduce the Fourier decomposition, which is done in a complex Hilbert space (to simplify notation we drop the subscript in p_{-}, set $\hbar=1$, and $[\mathrm{d}p]=\mathrm{d}p/2\pi$),

$$\psi^{\alpha}(x^{-})=\int_{-\infty}^{\infty}\frac{[\mathrm{d}p]}{2^{3/4}}\chi^{\alpha}(p)e^{-ipx^{-}}. \tag{10}$$

(To be precise, in the above-mentioned expansion, we should assume a cut-off ϵ_0 around zero momentum, to be taken to zero at the end of our calculations.) We see that $\chi^{\alpha}(p)$ satisfies the basic anticommutator,

$$[\chi^{\alpha}(p),\chi^{\beta}(q)]_{+}=\delta^{\alpha\beta}\delta[p+q], \tag{11}$$

where we write $\delta[p-q]=2\pi\delta(p-q)$. Real valuedness of the original field implies that $\chi^{\alpha\dagger}(p)=\chi^{\alpha}(-p)$. In standard physics notation the expansion would be written as

$$\psi^{\alpha}(x^{-})=\int_{0}^{\infty}[\chi^{\alpha}(p)e^{-ipx^{-}}+\chi^{\alpha\dagger}(p)e^{ipx^{-}}]\frac{[\mathrm{d}p]}{2^{3/4}}. \tag{12}$$

As is well known in the physics literature, to make the Hamiltonian bounded from below, we should choose a vacuum to be used to construct a fermion Fock space, and further impose a normal ordering prescription. This is done by simply requiring that $\chi^{\alpha}(p)|0>=0$ for $p>0$, and defining

$$:\chi^{\alpha}(p)\chi^{\beta}(q):=\begin{cases}-\chi^{\beta}(q)\chi^{\alpha}(p) & \text{if} \quad p>0,\ q<0,\\ \chi^{\alpha}(p)\chi^{\beta}(q) & \text{otherwise.}\end{cases} \tag{13}$$

This can be stated in one formula as

$$:\chi^{\alpha}(p)\chi^{\beta}(q):=\chi^{\alpha}(p)\chi^{\beta}(q)-\tfrac{1}{2}\,\delta^{\alpha\beta}\delta[p+q][1+\mathrm{sgn}(p)]. \tag{14}$$

For most of our calculations we need only the bilinears and the above-given expressions. (For the Hamiltonian we actually need the normal ordering of product of four such operators, and it is defined as usual all the annihilation operators are to be taken to the right of creation operators, it will be briefly explained later on.) We can reduce our Hamiltonian after this quantization process, and we get

$$H=\int \mathrm{d}x^{-}\left(\frac{m^2\sqrt{2}}{2}:\psi^{\alpha}\frac{1}{i\partial_{-}}\psi^{\alpha}:-\frac{g^2}{2}:\psi^{\alpha}(x^{-})\psi^{\beta}(x^{-}):|x^{-}-y^{-}|:\psi^{\beta}(y^{-})\psi^{\alpha}(y^{-}):\right). \quad (15)$$

Previously we used $(T^a)^{\alpha\beta}(T^a)^{\lambda\sigma}=-1/2(\delta^{\alpha\sigma}\delta^{\beta\lambda}-\delta^{\alpha\lambda}\delta^{\beta\sigma})$ and the Green function $1/2|x^{-}-y^{-}|=\partial_{-}^{-2}\delta(x^{-}-y^{-})$. The last normal orderings can be rearranged to act only on the color invariant combinations in the large-N_c limit, we will discuss this in Sec. III.

Next we introduce the algebra of color invariant bilinears and study the resulting system in the large-N_c limit following Refs. 1 and 11.

III. CLASSICAL MECHANICS OF COLOR INVARIANT OPERATORS

We define color invariant bilinears as in Refs. 1, 11, and 14 to be our dynamical variables and find the large-N_c limit by postulating Poisson algebra of these bilinears and defining the phase space to be a manifold where these Poisson brackets make sense. Since the theory is super-renormalizable we expect this to be related to the Hilbert–Schmidt ideal condition which is well-known in the literature on the Fock spaces.[12,21–23] We will see these aspects in more detail in Sec. IV when we talk about the geometry of the phase space. We define our basic dynamical variables, bilinears,

$$\hat{R}(p,q)=\frac{2}{N_c}\sum_{\alpha}:\chi^{\alpha}(p)\chi^{\alpha}(q):, \quad (16)$$

which are color invariant combinations of the fermion operators. We find it useful to define a related operator, $\hat{F}(p,q)=\hat{R}(-p,q)$, we will see that this is the correct variable for the geometry of the phase space. We assume that there are proper large-N_c limits of our operators, then they become classical variables when they are restricted to color invariant sector of the full Fock space. Following Ref. 1, we postulate the following Poisson brackets (we choose the quantization parameter to be $1/N_c$);

$$\{R(p,q),R(s,t)\}=-2i(R(p,t)\delta[q+s]-R(q,t)\delta[p+s]+R(s,p)\delta[q+t]-R(s,q)\delta[p+t]$$
$$+(\delta[q+t]\delta[p+s]-\delta[p+t]\delta[q+s])(\mathrm{sgn}(t)+\mathrm{sgn}(s))).$$

Our dynamical system is not defined completely yet, since there is still a left over global color invariance, generated by

$$\hat{Q}^{\alpha\beta}=\int[\mathrm{d}p]:\chi^{\alpha\dagger}(p)\chi^{\beta}(p):=\int_0^{\infty}[\mathrm{d}p]\chi^{\alpha\dagger}(p)\chi^{\beta}(p)-\int_0^{\infty}[\mathrm{d}p]\chi^{\beta\dagger}(p)\chi^{\alpha}(p). \quad (17)$$

The commutators of these generators satisfy the Lie algebra of SO(N_c).

If we restrict ourselves to the color invariant states, we find a constraint equation satisfied in the large-N_c limit, which can be best expressed in terms of $F(p,q)=R(-p,q)$,

$$\int[\mathrm{d}q]F(p,q)F(q,s)-\mathrm{sgn}(p)F(p,s)-F(p,s)\mathrm{sgn}(s)=0. \quad (18)$$

We define $\epsilon(p,q)=-\mathrm{sgn}(p)\delta[p-q]$, then we can rewrite this constraint as a simple quadratic operator equation,

$$(F+\epsilon)^2=1 \quad (19)$$

(we interpret F,ϵ as integral kernels acting on L_2 space of initial data). In Sec. IV we will analyze the geometric meaning of these constraints. The Hamiltonian and the above-mentioned Poisson brackets determine the evolution of our classical system; the Poisson brackets are consistent with the constraint equation.

The large-N_c Hamiltonian is obtained by dividing the original Hamiltonian by N_c and rewriting it in terms of our large-N_c variables. After certain manipulations which are sketched in the following, we obtain the following Hamiltonian,

$$H=\mathcal{P}\int \frac{1}{8}\left(m^2-\frac{g^2}{2\pi}\right)\frac{[\mathrm{d}p]}{p}R(-p,p)-\frac{g^2}{64}\mathcal{FP}\int \frac{[\mathrm{d}p\ \mathrm{d}q\ \mathrm{d}s\ \mathrm{d}t]}{(p+s)^2}R(p,q)R(s,t)\delta[p+q+s+t], \tag{20}$$

where $\mathcal{P}$ and $\mathcal{FP}$ refer to the principal value and finite part prescriptions, respectively. In the following we will often write $\int$ for $\mathcal{P}\int$ and $\mathcal{FP}\int$, but one should keep in mind that these regularization perscriptions are used to define the singular integrals. The main steps of the derivation of the above-mentioned Hamiltonian are very similar to the one in Ref. 11, although there are some small differences. Here we supply the basic ingredients to help the reader: for simplicity in many places we write x,y instead of x^-,y^-, we define $\epsilon(z)=\mathcal{P}\int_{-\infty}^{\infty}\mathrm{sgn}(p)e^{+ipz}$, note the sign of the exponent. We have the vacuum expectation value of our field product,

$$\langle 0|\psi^\alpha(x^-)\psi^\beta(y^-)|0\rangle=\frac{1}{4\sqrt{2}}[\delta(x^--y^-)-\epsilon(x^--y^-)]. \tag{21}$$

An important formula for the reduction is given in Ref. 11: If $f(x,y)=\int[\mathrm{d}p\ \mathrm{d}q]e^{ipx+iqy}\tilde{f}(p,q)$,

$$\int \epsilon(x-y)|x-y|f(x,y)=-\frac{1}{\pi}\mathcal{P}\int\frac{[\mathrm{d}p]}{p}\tilde{f}(-p,p). \tag{22}$$

We also have

$$|x-y|=\mathcal{FP}\int\frac{[\mathrm{d}p]}{p^2}e^{ip(x-y)}.$$

We use a form of Wick's theorem for normal ordered products,

$$\begin{aligned}:\psi^\alpha(x)\psi^\beta(x)::\psi^\beta(y)\psi^\alpha(y):=:\psi^\alpha(x)\psi^\beta(x)\psi^\beta(y)\psi^\alpha(y):&+\langle 0|\psi^\alpha(x)\psi^\alpha(y)|0\rangle:\psi^\beta(x)\psi^\beta(y):\\&+\langle 0|\psi^\beta(x)\psi^\beta(y)|0\rangle:\psi^\alpha(x)\psi^\alpha(y):\\&-\langle 0|\psi^\alpha(x)\psi^\beta(y)|0\rangle:\psi^\beta(x)\psi^\alpha(y):\\&-\langle 0|\psi^\beta(x)\psi^\alpha(y)|0\rangle:\psi^\alpha(x)\psi^\beta(y):+\langle 0|\psi^\alpha(x)\psi^\alpha(y)|0\rangle\\&\times\langle 0|\psi^\beta(x)\psi^\beta(y)|0\rangle-\langle 0|\psi^\beta(x)\psi^\alpha(y)|0\rangle\langle 0|\psi^\alpha(x)\psi^\beta(y)|0\rangle.\end{aligned}$$

Note that when we take the large-N_c limit we can expand the full normal ordering in the leading order to get $:\psi^\alpha(x)\psi^\alpha(y)::\psi^\beta(x)\psi^\beta(y):$. In the above-mentioned equality the fourth and fifth terms on the right are of smaller order in the large-N_c limit as well as the last term in the equality. The sixth term is an infinite vacuum expectation value, but that is a constant term which will not contribute to the equations of motion hence we can drop it. As a result,

$$\begin{aligned}:\psi^\alpha(x)\psi^\beta(x)::\psi^\beta(y)\psi^\alpha(y):=:\psi^\alpha(x)\psi^\alpha(y)::\psi^\beta(x)\psi^\beta(y):&+\langle 0|\psi^\alpha(x)\psi^\alpha(y)|0\rangle:\psi^\beta(x)\psi^\beta(y):\\&+\langle 0|\psi^\beta(x)\psi^\beta(y)|0\rangle:\psi^\alpha(x)\psi^\alpha(y):\end{aligned}$$

Using the above-given formulas we get a finite renormalization of the mass term.

Let us compute the equations of motion at the linear approximation. What we mean by this is to linearize the constraint as well as the equations of motion. The linearization of the constraint simply says that $R(u,v)=0$ if u,v have different signs. We thus restrict ourselves to $u,v>0$ and compute

$$\frac{\partial R(u,v;x^+)}{\partial x^+}=\{R(u,v;x^+);H\}. \tag{23}$$

We also put $P=u+v, x=u/P$ and make the ansatz $R(u,v;x^+)=\zeta_R(x)e^{-iP_+x^+}$. For further details we refer to Refs. 1 and 11, where similar calculations are done in more detail with the same type of ansatz; this yields an eigenvalue equation,

$$\mu^2\zeta_R(x)=\left(m^2-\frac{g^2}{2\pi}\right)\left[\frac{1}{x}+\frac{1}{1-x}\right]\zeta_R(x)-\frac{g^2}{8\pi}\int_0^1 dy\,\frac{\zeta_R(y)-\zeta_R(1-y)}{(y-x)^2}, \tag{24}$$

where $\mu^2=2P_+P$ is the invariant mass of the excitation. By looking at the behavior of this equation under $x\mapsto 1-x$, and $y\mapsto 1-y$, we see that we can choose our wave functions to be antisymmetric under $y\mapsto 1-y$, thus $\zeta(1-y)=-\zeta(y)$. This gives us

$$\mu^2\zeta_R(x)=\left(m^2-\frac{g^2}{2\pi}\right)\left[\frac{1}{x}+\frac{1}{1-x}\right]\zeta_R(x)-\frac{g^2}{4\pi}\int_0^1 dy\,\frac{\zeta_R(y)}{(y-x)^2}. \tag{25}$$

This equation is one of our main results and it is a variant of the well-known 't Hooft equation. Apart from the numerical factors this equation is the same as the original one, and this result fits to the ideas in Ref. 15. Its properties are well known, the most important one is that there are only bound state solutions.

An interesting question is the existence of ''baryon''-like excitations. These should correspond to operators of the form

$$\frac{1}{Z}\epsilon_{\alpha_1\alpha_2\ldots\alpha_{N_c}}\chi^{\alpha_1\dagger}(p_1)\chi^{\alpha_2\dagger}(p_2)\ldots\chi^{\alpha_{N_c}\dagger}(p_{N_c}), \tag{26}$$

but the meaning of these operators as $N_c\to\infty$ is not so obvious. Yet we can think about normalized states of this form when *all the momenta are positive* acting on the Fock vacuum, they should correspond to such baryon-like states. Perhaps our large-N_c theory can detect their presence. Indeed, one can check that the operator,

$$\hat{B}=\frac{1}{N_c}\int_0^\infty [dp]\chi^{\alpha\dagger}(p)\chi^{\alpha}(p), \tag{27}$$

measures the number of such excitations. This operator can be given a meaning in our theory: in the large-N_c limit therefore it is natural to expect that the operator, $B=1/2\int_0^\infty [dp]F(p,p)$ gives us this number and as we will see it is well-defined. In our classical limit we can ask if this number makes sense for our system, that is if it is a conserved quantity. The answer, not surprisingly, is no: the above-given baryon number *is not conserved* by our equations of motion. Thus there are really no baryons in this theory.

IV. GEOMETRY OF THE PHASE SPACE

To understand the geometry behind the classical system that we introduce in Sec. III, we must take a look at the finite dimensional orthogonal group. Our approach will be similar to the one in Ref. 24 where we discussed the bosonic version of this theory. The basic ideas of the quantization of free Weyl fermions and the underlying geometry is discussed in the paper of Bowick and Rajeev,[16] but we would like to expand on it and there are some differences in our conventions.

We recall that the real orthogonal group can be defined as the set of linear transformations which leave a quadratic form invariant.

$$Q(Au,Av)=Q(u,v) \tag{28}$$

[here $Q(u,v)=u^TQv$ represents this quadratic form, and superscript T denotes the ordinary transpose]. In our case the quadratic form is diagonal, so it is the standard inner product u^Tv. We work with the complexification of the original real Hilbert space, and if our Hilbert space is even dimensional, in this complex space we can use a different quadratic form, simply by using an invertible transformation S, $Q_2=S^TQS$. Assume now that we have a complex structure J acting on our original real Hilbert space, that is, a real antisymmetric matrix with respect to this form, which is also orthogonal, implying $J^2=-1$. If the quadratic form is the identity, we may think of such a matrix as $J=\left(\begin{smallmatrix}0 & 1\\ -1 & 0\end{smallmatrix}\right)$ in an appropriate basis of the *real Hilbert space*. Let us split our Hilbert space into two isomorphic pieces with respect to the above-mentioned decomposition of the complex structure, $W\oplus\tilde{W}$, and complexify the real Hilbert space, naturally we have $W\otimes\mathbf{C}\oplus\tilde{W}\otimes\mathbf{C}$. Choose with respect to this decomposition,

$$S=\begin{pmatrix} i1 & -i1 \\ 1 & 1 \end{pmatrix}. \tag{29}$$

This is the transform which we can use to diagonalize our complex structure. Of course our original quadratic form now changes as we described previously: we get

$$Q=\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \tag{30}$$

(In our problem we actually transform the inverse of this form, but one can see that as matrices these two forms are identical.) The complex orthogonal group is the set of transformations which leaves the form Q invariant. Thus a general complex matrix $g=\left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right)$ is orthogonal if

$$a^Tc=-c^Ta,\quad a^Td+c^Tb=1,\quad b^Td=-d^Tb. \tag{31}$$

In finite dimensions the quadratic form is $Q(z,z)=z_1z_{m+1}+z_2z_{m+2}+\cdots+z_mz_{2m}$. We see then that the original *real orthogonal group* is embedded into the complex orthogonal group defined by this quadratic form as a set of matrices

$$g=\begin{pmatrix} a & b \\ \overline{b} & \overline{a} \end{pmatrix}, \tag{32}$$

with now a,b satisfying, $a^T\overline{a}+b^\dagger b=1$ and $a^T\overline{b}=-b^\dagger a$ (where we decomposed the matrix in the obvious way). This explicitly shows that the complex structure, which is a real orthogonal matrix, becomes diagonal,

$$J=\left(\begin{smallmatrix}-i1 & 0\\ 0 & i1\end{smallmatrix}\right).$$

In our physical example these diagonalizations will be accomplished by the Fourier transform.

An immediate consequence of this way of looking at the real orthogonal group is that the real orthogonal group actually carries a copy of the unitary group in it, corresponding to the elements, $\left(\begin{smallmatrix}a & 0\\ 0 & \overline{a}\end{smallmatrix}\right)$. The quadratic form implies $a^T\overline{a}=1$, as well as $aa^\dagger=1$, this implies $aa^\dagger=a^\dagger a=1$. It is the unitary group of $\mathcal{H}_+$, where $\mathcal{H}_+$ refers to the subspace on which J acts as i.

For our purposes we should extend these discussions to the infinite dimensional case. In the infinite dimensional one we should not use the full orthogonal group but the one with a convergence condition.[16] This condition is the well-known Hilbert–Schmidt condition in the quasifree representations of canonical anticommutation algebra. We will comment further on the convergence conditions when we make contact with our system. We define the restricted orthogonal group on the complexified Hilbert space as follows:

$$O_1(\mathcal{H})=\left\{ g^TQg=Q \,\middle|\, g=\begin{pmatrix} a & b \\ \overline{b} & \overline{a} \end{pmatrix} \quad b\in\mathcal{I}_2 \right\}, \tag{33}$$

where $\mathcal{I}_2$ is the ideal of Hilbert–Schmidt operators.[25] We can state the convergence condition more economically as $[\epsilon,g]\in\mathcal{I}_2$, where $\epsilon=\left(\begin{smallmatrix}1&0\\0&-1\end{smallmatrix}\right)$ with respect to the above-mentioned decomposition. This is basically the complex structure we had, except that a factor of i has been removed. The Lie algebra of this group can be found from an infinitesimal group element,

$$g=1+i\Delta u=1+i\Delta\begin{pmatrix} S & R \\ -\overline{R} & -\overline{S}\end{pmatrix}, \tag{34}$$

with $R^T=-R$ and $S^\dagger=S$ and Δ represents an infinitesimal parameter. The reader can verify that $u^TQ+Qu=0$. We would like to define a classical phase space using this infinite dimensional orthogonal group. This will be our phase space for the large-N_c theory, but for the moment let us define it as a mathematical system. We introduce a variable Φ,

$$\Phi=g\epsilon g^{-1},\quad g\in O_1(\mathcal{H}). \tag{35}$$

The orbit of ϵ under the restriced orthogonal group is parametrized by this operator. It is easy to see that the orbit is diffeomorphic to

$$O_1(\mathcal{H})/U(\mathcal{H}_+). \tag{36}$$

The operator Φ satisfies

$$\Phi^2=1,\quad \Phi=-Q^{-1}\Phi^TQ,\quad \Phi-\epsilon=\begin{pmatrix}\mathcal{I}_1 & \mathcal{I}_2\\ \mathcal{I}_2 & \mathcal{I}_1\end{pmatrix}, \tag{37}$$

where $\mathcal{I}_1$ denotes the trace class operators in the appropriate space of operators (here Q^{-1} is identical to Q as a matrix, but transforms differently). The second condition really says that Φ is in the Lie algebra of this group (it is possible to think of this space as a real subset of the restricted Grassmanian, and there is an analogous construction of a line-bundle on this space, see Ref. 26). The tangent space of this orbit is given by the infinitesimal action of the group at any point, and in fact it is a copy of the Lie algebra of this group at every point. The action of a vector field on the basic variable Φ becomes $V_u(\Phi)=i[u(\Phi),\Phi]$, for a Lie algebra element $u(\Phi)$, which changes differentiably over the orbit. So a vector field at a point $\Phi=g\epsilon g^{-1}$ comes from a Lie algebra element $g^{-1}u(\Phi)g$.

It is well-known[27] that such orbits in finite dimensions typically carry a symplectic structure. If we formally define a two form,

$$\Omega=\frac{i}{4}\operatorname{Tr}\Phi\, d\Phi\wedge d\Phi, \tag{38}$$

following the methods in Ref. 1 we can check that it is closed and nondegenerate. The form evaluated at two vector fields V_u,V_v is given by

$$\Omega(V_u,V_v)=\frac{i}{8}\operatorname{Tr}\epsilon[[\epsilon,g^{-1}u(\Phi)g],[\epsilon,g^{-1}v(\Phi)g]], \tag{39}$$

which shows that it is well-defined, due to the Hilbert–Schmidt conditions, nondegenerate, homogeneous, and Kähler. The group action on this phase space $\Phi\mapsto g^{-1}\Phi g$ is actually Hamiltonian, that is there are moment maps which generate this action, given by a conditional trace, $F_u=-1/2\operatorname{Tr}_\epsilon(\Phi-\epsilon)u$, with $\operatorname{Tr}_\epsilon(A)=1/2\operatorname{Tr}(A+\epsilon A\epsilon)$. Just for completeness we record that

$$\{F_u,F_v\}=F_{-i[u,v]}-2\,\mathfrak{Im}\operatorname{Tr}(R_1R_2^\dagger), \tag{40}$$

if we decompose u,v as above. The last term represents a central part and cannot be removed in this classical theory.

How does this tie up with our system? Recall that we had a symplectic form which was i times a quadratic form Q, and a Hamiltonian for the free theory which is the mass part, i times an antisymmetric form ω, the combination of the two provides a natural operator: $\tilde{\omega}=Q^{-1}\omega$ is a type (1,1) tensor hence a proper linear transformation. Its polar decomposition will have all the basic pieces we need. Of course we have also $\omega^{-1}Q$, so which one we choose is determined by the equations of motion. If we look at this general system in the Hamiltonian formalism,

$$S_0=\int \mathrm{d}t\,\frac{1}{2}i\psi Q\partial_t\psi-\int \mathrm{d}t\,H=\int \mathrm{d}t\,\frac{1}{2}i\psi Q\partial_t\psi-\int \mathrm{d}t\,\frac{1}{2}i\psi\omega\psi, \tag{41}$$

the equations of motion will give us

$$\partial_t\psi=Q^{-1}\omega\psi. \tag{42}$$

Hence the operator $Q^{-1}\omega$ is the one we should use. We find the polar decomposition of this operator, $\tilde{\omega}=KJ$, where K is positive symmetric and $J^TJ=1$, orthogonal (we should be using the natural inner product defined by Q to define the transpose, and in the infinite dimensional case to define underlying real Hilbert space of initial data). However $\tilde{\omega}$ is antisymmetric with respect to our quadratic form, this means that $J^2=-1$ and orthogonal, thus a complex structure (the complex structure coming from the other choice differs from this by a minus sign). In our example we see that the quadratic form is $2\sqrt{2}\,\delta(x^--y^-)\delta_{\alpha\beta}$ (thus all the calculations can be done with the usual matrix transpose), and the antisymmetric form is $-\sqrt{2}m^2\partial_-^{-1}$, so we get from the polar decomposition, $K=(m^2/2)[-\partial_-^2]^{-1/2}$, $J=-[-\partial_-^2]^{1/2}\partial_-^{-1}$ (we omit the identity in the color space). When we use a basis which diagonalizes $\tilde{\omega}$ we get solutions which oscillate in time with a frequency given by the eigenvalues of K. In our example, if we decompose the field ψ^α using a Fourier mode decomposition,

$$\psi^\alpha(x^-)=\int_{-\infty}^{\infty}\frac{[\mathrm{d}p]}{2^{3/4}}w^\alpha(p)e^{-ipx^-}, \tag{43}$$

we have

$$\begin{aligned} w^\alpha(p,x^+)&=w^\alpha(p,0)\exp\left(-i\frac{m^2}{2|p|}x^+\right) \quad \text{for } p>0,\\ w^\alpha(p,x^+)&=w^\alpha(p,0)\exp\left(+i\frac{m^2}{2|p|}x^+\right) \quad \text{for } p<0. \end{aligned} \tag{44}$$

(Note that the above-given combinations on the exponents are relativistically invariant if we recall the mass-shell condition $p_+=m^2/2p_-$.) This suggests that the i subspace of J goes to creation operators, and $-i$ subspace goes to the annihilation operators, it is better therefore to represent our Fourier coefficients as $w^\alpha(p)=\xi^\alpha(p)$ and $w^\alpha(-p)=\overline{\xi}^\alpha(p)$ for $p>0$. If we act with J on our field variables,

$$(J\psi)^\alpha(x^-)=\int_0^\infty\frac{[\mathrm{d}p]}{2^{3/4}}(-i\overline{\xi}^\alpha(p)e^{-ipx^-}+i\xi^\alpha(p)e^{ipx^-}). \tag{45}$$

We see now that this Fourier transform diagonalizes our complex structure. If we look at the inverse of the quadratic form it transforms as $\int \mathrm{d}x^-\,\mathrm{d}y^-\,2^{3/4}e^{ipx^-}(2\sqrt{2})^{-1}\delta(x^--y^-)2^{3/4}e^{iqy^-}$, which gives us $\delta[p+q]$. This is the form of Q that we wanted to obtain.

From the Fourier decomposition, creation and annihilation operators therefore are assigned according to sgn(p), $\xi(p)\mapsto\chi^{\dagger\alpha}(p)$ and $\overline{\xi}(p)\mapsto\chi^{\alpha}(p)$. The ultimate reason for the choice of Fock vacuum is to make the Hamiltonian bounded from below, if we write our Hamiltonian in the Fourier space,

$$H_0=\mathcal{P}\int\frac{[dp]}{2^{3/2}}\frac{\sqrt{2}m^2}{2|p|}\mathrm{sgn}(p):\chi^{\alpha}(-p)\chi^{\alpha}(p)$$

$$:=\int_{0^+}^{\infty}\frac{[dp]}{2^{3/2}}\frac{\sqrt{2}m^2}{2|p|}[:\chi^{\alpha\dagger}(p)\chi^{\alpha}(p):-:\chi^{\alpha}(-p)\chi^{\alpha\dagger}(-p):].$$

Notice that sgn(p) appears in the Hamiltonian, which is basically the complex structure we have, and the normal ordering (according to our choice of creation and annihilation operators) now makes the Hamiltonian bounded from below:

$$H_0=\int_{0^+}^{\infty}\frac{m^2}{2|p|}\chi^{\alpha\dagger}(p)\chi^{\alpha}(p). \tag{46}$$

We could question the effect of the interactions since we have been describing everything in terms of the free part of the Hamiltonian. Here we see a clear advantage of our light-cone point of view, the complex structure we start with using the free Hamiltonian is independent of any of the parameters of the theory, *thus the choice of quasifree representation of the canonical anticommutation relations is not affected by the change of parameters due to interactions*. In our case we explicitly keep the change of mass due to the interactions with the gauge fields, so we are not taking advantage of this property. In the more general case this property may be helpful, in fact for the scalar theory it is essential. We thus conclude our discussion on the choice of Fock space and its relation to the natural complex structure in our system.

Next we show that $\Phi-\epsilon$ really represents our basic bilinears: let us decompose the complexification of our one-particle Hilbert space as $\mathcal{H}_+\oplus\mathcal{H}_-$ according to $-\mathrm{sgn}(p)$, we can write a general bilinear as an operator acting on the one-particle space and decomposed according to this direct sum, one checks that

$$F=\begin{pmatrix} S & R \\ -\overline{R} & -\overline{S}\end{pmatrix}, \tag{47}$$

with exactly $S^{\dagger}=S$ and $R^{T}=-R$. We also know that $(F+\epsilon)^2=1$. But these are exactly the properties satisfied by Φ. Our physical system has a one-particle Hilbert space given by the initial data on the light-cone $x^{+}=0$, we complexify this space and use Fourier transform to put our operators into the desired form. Then $\mathcal{H}_-$ corresponds to the negative frequency components in the physics language. The Poisson bracket relations can be meaningfully extended to the Hilbert–Schmidt type R, so we need the convergence conditions. The convergence conditions are also a natural consequence of the super-renormalizability of this system. The time evolution of the finite N_c system should keep us in the same free Fock space, and in the large-N_c limit this should be expressible as an operator like Φ. In fact the smeared out Poisson brackets are given by the Poisson bracket relations of the moment maps. Thus the symplectic structure we have on this homogeneous manifold is the one we have found for our bilinears.

It is useful to look at the same issue from the point of view of generalized coherent states: assume that we have a Lie group which is representable on a Hilbert space by unitary operators through a highest weight vector. If we look at the orbit of this vector under the action of the group, this orbit has a natural symplectic structure, and all the vectors on the orbit correspond to the generalized coherent states.[28,29,4] In our case the group of Bogoluibov automorphisms, which do not act on the color part of our fermions, are represented on the fermion Fock space by the color invariant bilinears. The highest weight vector is the vacuum and its orbit under this group there-

fore carries a natural symplectic structure. The corresponding group is the restricted orthogonal group $O_1(\mathcal{H})$ and the orbit is our phase space. [In fact physically we should be using the projective Fock space, since the phase does not change the physical content of a state. The bilinears provide a unitary representation of the central extension $\hat{O}_1(\mathcal{H})$ of the group $O_1(\mathcal{H})$, when we use the projective Fock space, the central part disappears and we descend to the restricted orthogonal group.] The convergence conditions are now a result of the implementability of these automorphism in the Fock space, which is defined by our choice of the vacuum.[22,21,12] The large-N_c limit allows us to restrict to the bilinears and the super-normalizability keeps us in the restricted class of implementable automorphisms. Thus taking the large-N_c limit provides a classical limit in this sense.

This shows that our large-N_c limit has a well-defined classical phase space with a natural symplectic structure. This opens up various possibilities, such as studying large fluctuations of the field in this limit. There are various delicate questions, such as the domain of the Hamiltonian, existence of finite time evolution, completeness of the trajectories which we plan to come back to in the future.

V. BOSONS AND FERMIONS

This is the begining of the second part of our paper. The second part has two themes again: the construction of the phase space via the large-N_c limits of the bilinears and the geometry of the ensuing phase space. Since the bosonic theory is developed in Ref. 24 and the fermionic version is explained in detail in the previous sections the construction of the phase space and finding the Hamiltonian will be very brief. We recommend that the reader look at Ref. 24 and we use the results of the previous sections freely. The geometry part, which is in Sec. VI, will require new methods and in some sense it is not as complete. It may be helpful if the reader also consults Ref. 14, where the SU(N_c) version is discussed. We will develop these aspects as much as we can and in some cases we indicate what the idea should be.

We start our first theme: we use the same conventions as in the previous sections and our previous paper. The action functional of the combined system of bosons and fermions can be written as

$$S=\int\left[\frac{1}{2}\mathrm{Tr}\,F_{\mu\nu}F^{\mu\nu}+i\overline{\Psi}_M\gamma^\mu D_\mu\Psi_M-m_F\overline{\Psi}_M\Psi_M+\frac{1}{2}(D^\mu\phi)^T(D_\mu\phi)-\frac{1}{2}m_B^2\phi^T\phi\right], \quad (48)$$

where we use the same conventions as in Sec. IV for the Majorana fermions. The transpose refers to the color indices for the scalar field. Again the covariant derivative is $D_\mu=\partial_\mu+gA_\mu$, where A_μ has values in the Lie algebra of SO(N_c). We choose x^+ as time and set $A_-=0$ as our gauge fixing condition. Then the action in the light-cone formalism reads

$$S=\int \mathrm{d}x^+\,\mathrm{d}x^-\Bigg[i\sqrt{2}\psi_1^T\partial_-\psi_1+i\sqrt{2}\psi_2^T\partial_+\psi_2+2im_F\psi_1^T\psi_2+\frac{1}{2}\phi^T(-2\partial_-)\partial_+\phi-\frac{m_B^2}{2}\phi^T\phi$$
$$+gA_+^a\left[i\sqrt{2}\psi_2^TT^a\psi_2+\frac{1}{2}(\partial_-\phi^TT^a\phi-\phi^TT^a\partial_-\phi)\right]+\frac{1}{2}(\partial_-A_+^a)^2\Bigg].$$

The advantage of the light-cone formalism is again clear, we are already in the Hamiltonian picture. We can read off the Poisson brackets satisfied by the dynamical fields. We also see that ψ_1 is not dynamical, as well as A_+^a, therefore they can be eliminated through their equations of motion. The dynamical fermion field ψ_2^α will be called ψ^α for simplicity as in the previous sections. We will assume that the field A_+^a is eliminated after the dynamical fields are quantized, this will give us the quantized Hamiltonian of the system,

$$H=\int \mathrm{d}x^{-}\left(\frac{1}{2}m_B^2:\phi^T\phi:+\frac{1}{2}\sqrt{2}m_F^2:\psi^T\frac{1}{i\partial_-}\psi:-\frac{g^2}{2}:J^a:\frac{1}{\partial_-^2}:J^a:\right), \tag{49}$$

where

$$J^a=[i\sqrt{2}\psi^T T^a\psi+\tfrac{1}{2}(\partial_-\phi^T T^a\phi-\phi^T T^a\partial_-\phi)]. \tag{50}$$

The quantization process is defined for the Fermionic sector in Sec. II and for bosons in Ref. 24. We expand fermions and bosons into Fourier modes in a *complex* space,

$$\psi^\alpha(x^-)=\int_{-\infty}^{\infty}\frac{[\mathrm{d}p]}{2^{3/4}}\chi^\alpha(p)e^{-ipx^-},\quad \phi^\alpha(x^-)=\int_{-\infty}^{\infty}\frac{[\mathrm{d}p]}{\sqrt{2|p|}}a^\alpha(p)e^{-ipx^-}, \tag{51}$$

with now $\chi^{\alpha(p)\dagger}=\chi^\alpha(-p)$ and $a^{\alpha\dagger}(p)=a^\alpha(-p)$. (We should again assume that there is an infinitesimal cutoff around the zero momentum to be taken to zero at a later stage.) The Poisson bracket relations go to

$$[\chi^\alpha(p),\chi^\beta(q)]_+=\delta[p+q]\delta^{\alpha\beta},\quad [a^\alpha(p),a^\beta(q)]=\mathrm{sgn}(p)\,\delta[p+q]\delta^{\alpha\beta}. \tag{52}$$

These are exactly the same as before, there is one more commutator now,

$$[\chi^\alpha(p),a^\beta(q)]=0. \tag{53}$$

As we will see in Sec. VI the definition of the Fock vacuum brings new features—a larger symmetry algebra appears. We introduce the vacuum state $|0>_s$, characterized by $\chi^\alpha(p)|0>_s=0, a^\alpha(p)|0>_s=0$ for $p>0$, where we put a subscript s to emphasize that the vacuum is for the full algebra of the boson/fermion system. We repeat for the convenience of the reader the normal ordering rules of the bilinears (rewritten to fit to our needs),

$$:\chi^\alpha(p)\chi^\beta(q):=\chi^\alpha(p)\chi^\beta(q)-\tfrac{1}{2}\delta^{\alpha\beta}(1+\mathrm{sgn}(p))\,\delta[p+q],$$

$$:a^\alpha(p)a^\beta(q):=a^\alpha(p)a^\beta(q)-\tfrac{1}{2}\delta^{\alpha\beta}(1+\mathrm{sgn}(p))\,\delta[p+q].$$

There is an obvious extension of the general definition of normal ordering to the product of more than two operators, which one needs for the reduction of the Hamiltonian: set all the annihilation operators to the right of creation operators in a recursive way.

We first introduce our bilinears for the large-N_c limit and work out their Poisson brackets. Then we express our Hamiltonian in the large-N_c limit in terms of these bilinears. We can see that the basic color invariant observables are

$$\hat{F}(p,q)=\frac{2}{N_c}:\chi^{\alpha\dagger}(p)\chi^\alpha(q):,\quad \hat{B}(p,q)=\frac{2}{N_c}:a^{\alpha\dagger}(p)a^\alpha(q):,$$

$$\hat{C}(p,q)=\frac{2}{N_c}\chi^{\alpha\dagger}(p)a^\alpha(q),\quad \hat{\bar{C}}(p,q)=\frac{2}{N_c}a^{\alpha\dagger}(p)\chi^\alpha(q).$$

Note that we have no need for normal ordering in the last two operators since they consist of commuting operators. In the large-N_c limit $\hat{C}$ and $\hat{\bar{C}}$ are related, $\overline{C}=C^\dagger$, and there are similar conditions on F,B (when we represent the resulting classical observables as integral kernels and think of them as now abstract operators). For our calculational purposes it is better to introduce the following variables as in Sec. III and Ref. 24,

$$\hat{T}(p,q)=\frac{2}{N_c}:a^\alpha(p)a^\alpha(q):=\hat{B}(-p,q)\quad \hat{R}(p,q)=\frac{2}{N_c}:\chi^\alpha(p)\chi^\alpha(q):=\hat{F}(-p,q), \tag{54}$$

and also the variable,

$$\hat{S}(p,q)=\frac{2}{N_c}\chi^{\alpha}(p)a^{\alpha}(q)=\hat{C}(-p,q). \tag{55}$$

These variables in the large-N_c limit satisfy the following (super)Poisson brackets,

$$\begin{aligned}\{T(p,q),T(s,t)\}=&-2i(\mathrm{sgn}(p)\,\delta[p+s]T(q,t)+\mathrm{sgn}(q)\,\delta[q+s]T(p,t)+\mathrm{sgn}(p)\,\delta[p+t]T(s,q)\\&+\mathrm{sgn}(q)\,\delta[q+t]T(s,p)+(\mathrm{sgn}(p)+\mathrm{sgn}(q))(\delta[p+s]\delta[q+t]\\&+\delta[p+t]\delta[s+q])),\end{aligned}$$

$$\begin{aligned}\{R(p,q),R(s,t)\}=&-2i(R(p,t)\,\delta[q+s]-R(q,t)\,\delta[p+s]+R(s,p)\,\delta[q+t]-R(s,q)\,\delta[p+t]\\&+(\delta[q+t]\delta[p+s]-\delta[p+t]\delta[q+s])(\mathrm{sgn}(t)+\mathrm{sgn}(s))),\end{aligned}$$

$$\{T(p,q),S(s,t)\}=-2i(S(s,q)\mathrm{sgn}(p)\,\delta[p+t]+S(s,p)\mathrm{sgn}(q)\,\delta[q+t]),$$

$$\{R(p,q),S(s,t)\}=-2i(S(p,t)\,\delta[q+s]-S(q,t)\,\delta[p+s]),$$

$$\begin{aligned}\{S(p,q),S(s,t)\}_{+}=&-2i(T(q,t)\,\delta[p+s]-R(s,p)\mathrm{sgn}(q)\,\delta[q+t]\\&+\delta[p+s]\delta[q+t](1+\mathrm{sgn}(p)\mathrm{sgn}(q))).\end{aligned}$$

We note that the last one is symmetric in the variables and the third and fourth ones show that S behaves as a module of the algebras defined by the Poisson brackets of T,R, thus it carries a representation of these two algebras. This is the general form of a superalgebra structure. We will denote the full set of these brackets as a super-Possion bracket $\{\ ,\ \}_s$.

The conversion of the normal ordered products of noncolor invariant combinations appearing in the above Hamiltonian to the full normal ordering in the large-N_c limit can be achieved as before resulting with the same changes in the masses $m_F^2\mapsto m_F^2-g^2/2\pi$ and $m_B^2\mapsto m_R^2-g^2/2\pi$, where $m_R^2=m_B^2-g^2/4\pi\ln(\Lambda_U/\Lambda_I)$ denotes the renormalized mass of the boson. We skip the details of this reduction, since they are the extensions of the details in Ref. 11 and we have given some essential steps in Sec. III. The resulting Hamiltonian of our system in the large-N_c can be expressed as a free part and an interacting part:

$$H_0=\frac{1}{8}\left(m_R^2-\frac{g^2}{2\pi}\right)\mathcal{P}\int\frac{[\mathrm{d}p]}{|p|}T(-p,p)+\frac{1}{8}\left(m_F^2-\frac{g^2}{2\pi}\right)\mathcal{P}\int\frac{[\mathrm{d}p]}{p}R(-p,p). \tag{56}$$

The interaction part is written as

$$\begin{aligned}H_I=&\mathcal{FP}\int[\mathrm{d}p\,\mathrm{d}q\,\mathrm{d}s\,\mathrm{d}t](G_1(p,q;s,t)T(p,q)T(s,t)+G_2(p,q;s,t)R(p,q)R(s,t)\\&+G_3(p,q;s,t)S(p,q)S(s,t)),\end{aligned}$$

where the kernels are given by

$$G_1(p,q;s,t)=\frac{g^2}{64}\frac{\delta[p+q+s+t]}{\sqrt{|pqst|}}\frac{sq-st+pt-pq}{(p+s)^2},$$

$$G_2(p,q;s,t)=-\frac{g^2}{64}\frac{\delta[p+q+s+t]}{(p+s)^2},$$

$$G_3(p,q;s,t)=\frac{g^2}{64}\,\frac{\delta[p+q+s+t]}{\sqrt{|tq|}(p+s)^2}.$$

We have not completed the definition of our large-N_c limit yet, there is a constraint. Recall that we still have a left over global color invariance, which is generated by the operator,

$$\hat{Q}^{\alpha\beta}=\int [\mathrm{d}p](:\chi^{\alpha\dagger}(p)\chi^{\beta}(p):+\mathrm{sgn}(p):a^{\alpha\dagger}(p)a^{\beta}(p):). \tag{57}$$

When we restrict our color invariant bilinears to the color invariant sector of the full Fock space, we find that

$$(F+\epsilon)^2+C\epsilon C^{\dagger}=1,$$

$$C\epsilon B+C\epsilon+FC+\epsilon C=0,$$

$$\epsilon B\epsilon C^{\dagger}+C^{\dagger}+\epsilon C^{\dagger}\epsilon+\epsilon C^{\dagger}F=0,$$

$$(\epsilon B+\epsilon)^2+\epsilon C^{\dagger}C=1,$$

where we define as in Sec. III, $\epsilon(p,q)=-\mathrm{sgn}(p)\delta[p-q]$ (here the minus sign is crucial, in our previous works that was not important, but in the super case there is a preferred choice) and we also employ the product convention as before for example $(FC)(p,s)=\int[dq]F(p,q)C(q,s)$. We warn the reader that above the two epsilons have the same matrix elements but they are acting on different spaces. The meaning of this constraint could best be understood if we introduce a superoperator,

$$\Phi=\begin{pmatrix}\epsilon B+\epsilon & \epsilon C^{\dagger}\\ C & F+\epsilon\end{pmatrix}. \tag{58}$$

The above-mentioned constraint is simply given by

$$\Phi^2=1. \tag{59}$$

It also satisfies a Lie algebra condition, it is better to write it in the following form: use a decomposition of our superspace into $\mathcal{H}_+|\mathcal{H}_+\oplus\mathcal{H}_-|\mathcal{H}_-$, according to the sign of ϵ in even and odd parts, respectively. Then we have $\hat{\epsilon}=\left(\begin{smallmatrix}1&0\\0&-1\end{smallmatrix}\right)$, and we introduce with respect to this decomposition

$$\hat{\omega}_s=\left(\begin{smallmatrix}0&-\overline{\epsilon}\\1&0\end{smallmatrix}\right),$$

where $-\overline{\epsilon}=\left(\begin{smallmatrix}1&0\\0&-1\end{smallmatrix}\right)$, and this is a supermatrix acting between positive and negative subspaces, then

$$\hat{\omega}_s\Phi^{\tau}+\Phi\hat{\omega}_s=0, \tag{60}$$

we invite the reader to verify this.

There are also convergence conditions, which come from the super-renormalizability of this system again. The time evolution should leave this system in the same Fock space. Another way to see this is to think about the smeared out operators, and see that the central terms make sense only for the restricted set of operators, for which the off-diagonal blocks are in the Hilbert–Schmidt class. We can write down these convergence conditions in an economical way as

$$[\hat{\epsilon},\Phi]\in\mathcal{I}_2, \tag{61}$$

where $\mathcal{I}_2$ refers to the ideal of Hilbert–Schmidt operators in this superspace. We have proposed elsewhere[30] a method of introducing such operators in the supercontext, and we assume this definition is used. Since these technical matters are not completely settled we are brief at this point—see also Sec. VI on the geometry. This completes the construction of our large-N_c limit: we

postulate the above-mentioned Hamiltonian, the super-Possion brackets with the constraint and this defines a classical system. The ''time'' evolution is given by the basic rule: for any observable O_s of the theory

$$\frac{\partial O_s}{\partial x^+} = \{O_s, H\}_s, \tag{62}$$

where the Hamiltonian is in general an even function of our bilinears—which we should consider as the coordinates of this phase space.

It is possible to carry out the analysis given in Ref. 14, but we will be content with describing only the linear approximation. We plan to report on these in a separate publication (they will appear in the Ph.D. thesis of E.T.).

We start with the linearization of the constraint $\Phi^2=1$, which gives us

$$F\epsilon+\epsilon F=0, \quad \epsilon B\epsilon+B=0, \quad \epsilon C+C\epsilon=0. \tag{63}$$

The first two are exactly the conditions we have found before, for mesons made up of only bosons in Ref. 24, the first one is in Sec. III, and the last one is the new condition on our odd variable. In terms of S that means we have $S(u,v)=0$ unless $u,v>0$ or $u,v<0$. If we assume $u,v>0$ and evaluate the equations of motion in the linear approximation for $S(u,v)$, $\partial_+ S(u,v;x^+) = \{S(u,v;x^+),H\}$ and furthermore we make the same type of ansatz as in Refs. 11, 24, and 14, $S(u,v;x^+)=\zeta_S(x)e^{-iP_+x^+}$, with $P=u+v, x=u/P$,

$$\mu_s^2\zeta_S(x)=\left[\frac{m_F^2-g^2/2\pi}{x}+\frac{m_R^2-g^2/2\pi}{1-x}\right]\zeta_S(x)-\frac{g^2}{8\pi}\int_0^1\frac{\mathrm{d}y}{\sqrt{xy}}\frac{x+y}{(x-y)^2}\zeta_S(1-y). \tag{64}$$

The other linearized equations are the same as before (see Sec. III and Ref. 24).

There are baryonic states that we can measure by the operator

$$\hat{\mathbf{B}}=\frac{1}{N_c}\int_0^\infty [\mathrm{d}p](\chi^{\alpha\dagger}(p)\chi^\alpha(p)+a^{\alpha\dagger}(p)a^\alpha(p)), \tag{65}$$

in the large-N_c limit this operator should go to $\mathbf{B}=1/2\int_0^\infty[\mathrm{d}p](F(p,p)+B(p,p))$. The *baryonic states* for finite N_c correspond to states of the form

$$\frac{1}{Z}\epsilon_{\alpha_1\alpha_2\cdots\ \alpha_{N_c}}\chi^{\alpha_1\dagger}(p_1)\cdots\ \chi^{\alpha_s\dagger}(p_s)a^{\alpha_{s+1}\dagger}(p_{s+1})\cdots\ a^{\alpha_{N_c}\dagger}(p_{N_c}), \tag{66}$$

where $p_1\cdots\ p_{N_c}>0$ and products of them acting on $|0>_s$.

Not surprisingly *the above-given baryon number is not a conserved quantity*, so it does not have the physical importance as it has in the case of Dirac fermions where it is a conserved number, in fact a topological number (see Ref. 11 for the discussion of this in the large-N_c limit and its extension in Ref. 14).

VI. THE GEOMETRY OF THE PHASE SPACE

Let us define a superspace $\mathcal{H}|\mathcal{H}$, where we use a splitting to even and odd according to the grading $+,-$ (we are using a $\mathbf{Z}_2$ graded *real Hilbert space*). We recall some of the conventions, following Berezin[18]: we work with the Grassmann envelope of this graded vector space (thus we acquire a $\mathbf{Z}$ grading). Its mathematical theory is delicate and we will comment on it later (some good examples of homogeneous supersymplectic manifolds are worked out in Ref. 31, this is a good reference to learn by examples). We decompose every linear transformation or tensor according to this grading, the standard matrix form of a linear transformation is

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} : \mathcal{H}|\mathcal{H} \to \mathcal{H}|\mathcal{H}, \tag{67}$$

where A,D are even and B,C are odd. This means that $A=A_B+A_S, D=D_B+D_S$ where the subscript B refers to the body that is the ordinary numbers, the subscript S refers to the soul, that is only the Grassmann part. B,C have no body, they are purely Grassmann valued.

We have the usual Hermitian conjugation of such block matrices, but the transpose has to be carefully defined. We introduce a supertranspose, τ,

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}^{\tau} = \begin{pmatrix} A^T & C^T \\ -B^T & D^T \end{pmatrix}, \tag{68}$$

where T denotes the ordinary matrix transpose. One can verify that this form satisfies $(AB)^{\tau} = B^{\tau}A^{\tau}$. It will be useful to record the following properties, $\mathrm{Str}(A^{\tau}) = \mathrm{Str}\, A$, if we decompose our graded space into a direct sum, for example in our case into $\mathcal{H}_+|\mathcal{H}_+ \oplus \mathcal{H}_-|\mathcal{H}_-$, the operators can also be decomposed into superoperators, say into $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, then

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^{\tau} = \begin{pmatrix} a^{\tau} & c^{\tau} \\ b^{\tau} & d^{\tau} \end{pmatrix}. \tag{69}$$

Realness is related to an involution in the Grassmann algebra, $\xi \mapsto \xi^*$ and we assume that this involution obeys $(\xi^i \xi^j)^* = (\xi^j)^*(\xi^i)^*$ and $(a\xi)^* = \overline{a}\xi^*$, where a is a complex number and the bar denotes the ordinary complex conjugation. The real Grassmann algebra is the part which is invariant under this involution. This means that there will be factors of i to make things invariant. This implies that *the real graded Hilbert space is defined residing inside a complex graded Hilbert space*.

On the space of linear transformations there is a complex conjugation operator, according to Berezin conventions it should be given by the following: write a linear transformation in its standard form, then

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^* = \begin{pmatrix} a^* & -b^* \\ c^* & d^* \end{pmatrix}. \tag{70}$$

We note that $A^{**}=A$, and $(A^{\tau})^* = \left(\begin{smallmatrix} a^{\dagger} & -c^{\dagger} \\ -b^{\dagger} & d^{\dagger} \end{smallmatrix}\right) = \tilde{E}A^{\dagger}\tilde{E}$, here $\tilde{E} = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$, whereas $(A^*)^{\tau} = A^{\dagger}$.

We have the set of *real linear transformations*, this set is invariant under the above conjugation, $M^*=M$, it remains so under the product of supermatrices, thanks to $(A_1A_2)^* = A_1A_2$. The set of real linear operators thus is an algebra.

Let us assume that the even part has a symplectic form ω and the odd part has a standard quadratic form 1. On the complexification of this space we introduce a supersymplectic form,

$$\omega_s = \begin{pmatrix} \omega & 0 \\ 0 & i1 \end{pmatrix}, \quad \omega = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}. \tag{71}$$

Note that multiplying the last part with an i does not really change anything as far as only the even transformations are concerned but for the full case we need this factor. We look at the space of *real transformations* which will leave this form invariant,

$$g^{\tau}\omega_s g = g\omega_s g^{\tau} = \omega_s, \tag{72}$$

this is a supergroup, and it is denoted by $\mathrm{OSp}(\mathcal{H}|\mathcal{H})$. Its even part has body isomorphic to $\mathrm{Sp}(\mathcal{H}) \oplus \mathrm{O}(\mathcal{H})$, the odd parts are modules over the Grassmann envelopes of these groups. If we write down the group conditions for an element $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) = \left(\begin{smallmatrix} a^* & -b^* \\ c^* & d^* \end{smallmatrix}\right)$, where a,d are real even, c real odd, and b imaginary odd operators,

$$a^T\omega a+ic^Tc=\omega,\quad a^T\omega b+ic^Td=0,\quad -b^T\omega a+id^Tc=0,\quad -b^T\omega b+id^Td=i1. \tag{73}$$

Since we have the complex conjugation convention $(\psi\xi)^*=-\psi^*\xi^*$, the complex conjugate of a product of odd operators become imaginary, this is why we have ic^Tc, then it becomes a real even element of the Grassmann envelope.

Decompose our spaces according to the matrix representation of ω_s, $W\oplus\tilde{W}|W\oplus\tilde{W}$. Let us assume that we also have a supercomplex structure, which is a type (1,1) tensor,

$$J_s=\begin{pmatrix} J & 0\\ 0 & J\end{pmatrix},\quad J=\begin{pmatrix} 0 & 1\\ -1 & 0\end{pmatrix}. \tag{74}$$

Assume that we extend everything to the complexification of our original Hilbert space. Then we can perform a transformation S that will put the above-mentioned complex structure into diagonal form in this complexified space. To accomplish this it is better to represent it in a slightly different way, use a decomposition $W|W\oplus\tilde{W}|\tilde{W}$, then

$$J_s=\begin{pmatrix} 0 & 1\\ -1 & 0\end{pmatrix},\quad S=\frac{1}{\sqrt{2}}\begin{pmatrix} i & -i\\ 1 & 1\end{pmatrix}. \tag{75}$$

Now compute $S^{-1}J_sS$ and see that we get $\hat{J}_s=i\hat{\epsilon}=\left(\begin{smallmatrix}-i & 0\\ 0 & i\end{smallmatrix}\right)$, which defines $\hat{\epsilon}$ in this decomposition. We use a decomposition according to the sign of i and the resulting graded Hilbert space becomes $\mathcal{H}_+|\mathcal{H}_+\oplus\mathcal{H}_-|\mathcal{H}_-$. If we compute the transformation of ω_s, it goes into $S^\tau\omega_sS$ since it is a two form, and we get

$$\hat{\omega}_s=\begin{pmatrix} 0 & -\overline{\epsilon}\\ 1 & 0\end{pmatrix},\quad \overline{\epsilon}=\begin{pmatrix} 1 & 0\\ 0 & -1\end{pmatrix}, \tag{76}$$

with respect to the above-given decomposition. Obviously our real group also transformed by the same rule as J_s, so a typical group element becomes according to the above-given decomposition,

$$g=\begin{pmatrix} A & B\\ B^* & A^*\end{pmatrix}. \tag{77}$$

Note that each of the blocks are superoperators with standard decompositions, and for each one we are using Berezin definition of the complex conjugate $\left(\begin{smallmatrix}a & b\\ c & d\end{smallmatrix}\right)^*=\left(\begin{smallmatrix}a^* & -b^*\\ c^* & d^*\end{smallmatrix}\right)$. We have a full complex group which leaves invariant the above transformed version of the two form, this is the complex OSp group,

$$g^\tau\hat{\omega}_sg=\hat{\omega}_s,\quad g=\begin{pmatrix} A & B\\ C & D\end{pmatrix}, \tag{78}$$

and the real group now sits inside this complex group. Thus a complex transformation satisfies

$$A^\tau\overline{\epsilon}C-C^\tau A=0,\quad A^\tau\overline{\epsilon}D-C^\tau B=\overline{\epsilon},\quad -B^\tau\overline{\epsilon}C+D^\tau A=1,\quad B^\tau\overline{\epsilon}D-D^\tau B=0. \tag{79}$$

The reader may question the consistency of these equations. We should remember that $(M^\tau)^\tau=\overline{\epsilon}M\overline{\epsilon}$, then we can see that they are consistent. There is an interesting subgroup, given by elements of the form $g=\left(\begin{smallmatrix}A & 0\\ 0 & A^*\end{smallmatrix}\right)$ and A satisfies

$$A^\tau\overline{\epsilon}A^*=\overline{\epsilon},\quad A^{*\tau}A=1; \tag{80}$$

recall that $A^{*\tau}=A^{\dagger}$ and $(A^{\tau})^{*}=\overline{\epsilon}A^{\dagger}\overline{\epsilon}$, this is the same as before except that we express it in the subspace, so we should use $\overline{\epsilon}$ instead of $\tilde{E}$, we get $A^{\dagger}A=AA^{\dagger}=1$. Let us see what it means when we expand $A=\left(\begin{smallmatrix}a & \beta\\ \gamma & d\end{smallmatrix}\right)$,

$$a^{\dagger}a=1+\gamma^{\dagger}\gamma,\quad a^{\dagger}\beta+\gamma^{\dagger}d=0,\quad \beta^{\dagger}a+d^{\dagger}\gamma=0,\quad d^{\dagger}d=1+\beta^{\dagger}\beta. \tag{81}$$

We see that the body parts satisfy $a_B^{\dagger}a_B=1$, $d_B^{\dagger}d_B=1$, these are the ordinary unitary groups inside. Therefore we have shown that this group's even part has body $U(\mathcal{H}_+)\oplus U(\mathcal{H}_+)$. This group is denoted by $U(\mathcal{H}_+|\mathcal{H}_+)$ and it is the superunitary group of $\mathcal{H}_+$.

Let us define the orbit of $\hat{\epsilon}$, this is really the complex structure if we remove the factors of i, under the real group OSp:

$$\Phi=g^{-1}\hat{\epsilon}g. \tag{82}$$

It is immediate that $\Phi^2=1$. We will now show that we also have

$$\hat{\omega}_s\Phi^{\tau}+\Phi\hat{\omega}_s=0, \tag{83}$$

so it is an element of the Lie algebra of OSp. Define $\hat{E}=\left(\begin{smallmatrix}\overline{\epsilon} & 0\\ 0 & \epsilon\end{smallmatrix}\right)$, this is really our $\tilde{E}$ written in this splitting of the Hilbert space, and note $(\hat{\omega}_s^{\tau})^{-1}=\hat{\omega}_s$, $\hat{\omega}_s^{\tau}=\hat{\omega}_s\hat{E}$, $\hat{\omega}_s^2=\hat{E}$ and $\hat{\epsilon}\hat{\omega}_s=-\hat{\omega}_s\hat{\epsilon}$, then,

$$\begin{aligned}\Phi^{\tau}\omega_s&=(\hat{\omega}_s^{-1}g^{\tau}\hat{\omega}_s\hat{\epsilon}g)^{\tau}\omega_s=g^{\tau}\hat{\epsilon}\hat{\omega}_s\hat{E}g^{\tau\tau}\hat{E}=g^{\tau}\hat{\epsilon}\hat{\omega}_sg=-g^{\tau}\hat{\omega}_s\hat{\epsilon}g=-\hat{\omega}_s\hat{\omega}_s^{-1}g^{\tau}\hat{\omega}_s\hat{\epsilon}g=-\hat{\omega}_sg^{-1}\hat{\epsilon}g\\ &=-\hat{\omega}_s\Phi,\end{aligned}$$

where we used $\hat{E}g^{\tau\tau}\hat{E}=g$. Let us look at the stability subgroup of $\hat{\epsilon}$, that is given by operators of the form $\left(\begin{smallmatrix}A & 0\\ 0 & A^{*}\end{smallmatrix}\right)$, and we have seen that this can be identified with the unitary operators on $\mathcal{H}_+|\mathcal{H}_+$, $U(\mathcal{H}_+|\mathcal{H}_+)$. Hence we conclude that our variable Φ is actually parametrizing the space

$$\mathrm{OSp}(\mathcal{H}|\mathcal{H})/U(\mathcal{H}_+|\mathcal{H}_+). \tag{84}$$

What is the advantage of this parametrization? The above supermanifold is actually a symplectic manifold with a supersymplectic structure most naturally written in terms of the variable Φ:

$$\Omega_s=\frac{i}{4}\,\mathrm{Str}\,\Phi\,d\Phi\wedge d\Phi. \tag{85}$$

This is formally defined, but we use the rules of super analysis to define our differential forms. Clearly it is closed, use

$$\begin{aligned}d\,\mathrm{Str}\Phi\,d\Phi\wedge d\Phi&=\mathrm{Str}\,d\Phi\wedge d\Phi\wedge d\Phi=\mathrm{Str}\,\Phi^2d\Phi\wedge d\Phi\wedge d\Phi=\mathrm{Str}\,\Phi\,d\Phi\wedge d\Phi\wedge d\Phi\Phi\\ &=-\mathrm{Str}\,\Phi^2\,d\Phi\wedge d\Phi\wedge d\Phi\wedge d\Phi.\end{aligned}$$

where we used $\mathrm{Str}\,AB=\mathrm{Str}\,BA$. It is also clear that this form is homogeneous. Its nondegenaracy can be proved at $\hat{\epsilon}$, and homogeneity proves it everywhere.

Up to now we have really used a finite dimensional approach, but to identify the large-N_c phase space of Sec. V, we need to extend these notions to the infinite dimensional case. The extension is formally simple, we assume that we have super-Hilbert spaces, that is even and odd spaces each one are coming from a separable Hilbert space and we use a proper extension of the Grassmann envelope to this case(this is not so obvious and we assume our proposal in Ref. 30, this may not be the only possibility, see Refs. 32 and 33). In this infinite dimensional setting we introduce a Hilbert–Schmidt condition, the group that we use should be the restricted *real* OSp group,

$$\mathrm{OSp}_1(\mathcal{H}|\mathcal{H})=\left\{ g=\begin{pmatrix} A & B \\ B^* & A^* \end{pmatrix} \middle| \, g^{-1}\text{exists}, \quad g^{\tau}\hat{\omega}_s g=\hat{\omega}_s \quad [\hat{\epsilon},g]\in\mathcal{I}_2 \right\}. \tag{86}$$

The variable Φ now satisfies some convergence conditions, indeed one can check that

$$\Phi-\hat{\epsilon}\in\begin{pmatrix} \mathcal{I}_1 & \mathcal{I}_2 \\ \mathcal{I}_2 & \mathcal{I}_1 \end{pmatrix}, \tag{87}$$

where each block refers to a superoperator in the appropriate class of operator ideal. These convergence conditions imply that the supersymplectic form Ω_s we defined in the finite dimensional setting makes sense. The trace class conditions are important to write down moment maps, but we will ignore it for this work. Hence we have an infinite dimensional phase space,

$$\mathrm{OSp}_1(\mathcal{H}|\mathcal{H})/U(\mathcal{H}_+|\mathcal{H}_+), \quad \Omega_s=\frac{i}{4}\,\mathrm{Str}\,\Phi\,\mathrm{d}\Phi\wedge\mathrm{d}\Phi. \tag{88}$$

The reader can now see how this is related to our system, from the experience we have in the previous cases. In our problem we have a free action which has bosons and fermions,

$$S_0=\int \mathrm{d}x^+\,\mathrm{d}x^-\left(\frac{1}{2}\phi^T(-2\partial_-)\partial_+\phi+\frac{1}{2}i2\sqrt{2}\psi^T\partial_+\psi-\frac{1}{2}m_B^2\phi^T\phi-\frac{1}{2}\sqrt{2}m_F^2\psi^T\frac{1}{i\partial_-}\psi\right). \tag{89}$$

This action is written in the standard light-cone frame and one of the components of the Majorana field has been eliminated in favor of the other. The transpose refers to the color indices for the gauge group SO(N_c). As it stands this does not require the full content of the supergeometry, but as we have seen the interaction terms, given by the proper bilinears of field operators, make the use of supergeometry most convenient: when we reformulate our theory in terms of bilinears, we need the combinations which can only be expressed in terms of odd operators. We will now see that the Poisson algebra of these bilinears can only be formulated as a super-two form. Moreover a simple iterative solution of the constraint equation reveals that the bosonic operators should be given as an infinite series of products of odd operators, this is why we think it is most natural to use the full content of the Berezin's superanalysis. (We hope to come back to the more mathematical aspects of our system in a future publication.)

In our theory we have a supersymplectic form and a superquadratic form which is in the standard representation given by

$$\omega_s=\begin{pmatrix} -2\partial_- & 0 \\ 0 & i2\sqrt{2} \end{pmatrix} I_c, \quad Q_s=\begin{pmatrix} m_B^2 & 0 \\ 0 & -\sqrt{2}m_F^2 i\partial_-^{-1} \end{pmatrix} I_c, \tag{90}$$

where we have the identity I_c in the color space. The relevant operator is

$$\omega_s^{-1}Q_s=\begin{pmatrix} -\dfrac{m_B^2}{2}\partial_-^{-1} & 0 \\ 0 & -\dfrac{m_F^2}{2}\partial_-^{-1} \end{pmatrix} I_c. \tag{91}$$

The complex structure becomes (we drop the identity in the color space)

$$J_s=[(-\omega_s^{-1}Q_s)^2]^{-1/2}\omega_s Q_s=\begin{pmatrix} -(-\partial_-^2)^{1/2}\partial_-^{-1} & 0 \\ 0 & -(-\partial_-^2)^{1/2}\partial_-^{-1} \end{pmatrix}. \tag{92}$$

Clearly we can use the Fourier decomposition of our fields to diagonalize this and the frequency operator K_s,

$$\phi^\alpha(x^-)=\int \frac{[\mathrm{d}p]}{\sqrt{2|p|}} w^\alpha(p) e^{-ipx^-}, \quad \psi^\alpha(x^-)=\int \frac{[\mathrm{d}p]}{2^{3/4}} \zeta^\alpha(p) e^{-ipx^-}, \tag{93}$$

here we should think of w^α as even and ζ^α odd elements of the Grassmann algebra defined by a series (an infinite one) of unspecified generators $\theta^\alpha(p)$, Apply the operator J_s to the vectors of this graded space,

$$J_s\Psi = J_s\begin{pmatrix}\phi^\alpha\\ \psi^\alpha\end{pmatrix} = \int [\mathrm{d}p] e^{-ipx^-}(-i\,\mathrm{sgn}(p))\begin{pmatrix}(\sqrt{2|p|})^{-1} w^\alpha(p)\\ 2^{-3/4}\zeta^\alpha(p)\end{pmatrix}, \tag{94}$$

which we should rewrite as

$$(J_s\Psi)(x^-)=\int_0^\infty [\mathrm{d}p] e^{-ipx^-}\left[(-i)\begin{pmatrix}(\sqrt{2p})^{-1}\overline{z^\alpha}(p)\\ 2^{-3/4}\overline{\xi^\alpha}(p)\end{pmatrix}+i\begin{pmatrix}(\sqrt{2p})^{-1} z^\alpha(p)\\ 2^{-3/4}\xi^\alpha(p)\end{pmatrix}\right], \tag{95}$$

defining the superholomorphic coordinates, $(z^\alpha(p),\xi^\alpha(p))$. If we assign now our creation and annihilation operators according to the sign of i,

$$\begin{pmatrix}z^\alpha(p)\\ \xi^\alpha(p)\end{pmatrix}\mapsto\begin{pmatrix}a^{\alpha\dagger}(p)\\ \chi^{\alpha\dagger}(p)\end{pmatrix}, \quad \begin{pmatrix}\overline{z^\alpha}(p)\\ \overline{\xi^\alpha}(p)\end{pmatrix}\mapsto\begin{pmatrix}a^\alpha(p)\\ \chi^\alpha(p)\end{pmatrix}, \tag{96}$$

we get the commutation/anticommutation relations for $a^{\alpha\dagger}(p), a^\beta(q)$ and $\chi^{\alpha\dagger}(p), \chi^\alpha(q)$ respectively, and the zero commutator between the two sets. These commutation/anticommutation relations have the operator $\hat{\omega}_s$ on the right-hand side, this is what determines the algebra. Hence we see that we are in the geometric setting we were describing. Our bilinears combined in the form of Φ satisfy all the Lie algebra properties. In fact it is instructive to write down the supersymplectic form Ω_s with Φ expressed in terms of the bilinears $B,F,C,C^\dagger$. Then the reader can see that we have the same Poisson brackets satisfied by these bilinears.

From the above-given discussion we again see the remarkable fact that the geometry which is defined by the complex structure J_s is independent of the parameters of the theory in this light-cone method. This means *even though the masses change due to the interactions this will not change the representation of canonical commutation/anticommutation relations we started with*, as a result the geometry stays the same.

Our bilinears will correspond to the generators of the automorphisms of this full algebra of commutation/anticommutation relations, and it is the restricted real OSp group (for finite dimensional automorphism groups see Ref. 34, for Bogoliubov automorphisms of qausifree representations see Refs. 35–38). We can check that the bilinears we have satisfy the Lie algebra conditions and the implementability of these automorphisms will imply the convergence conditions. Therefore the evolution of the system in the large-N_c limit realizes all automorphisms of the quasifree second quantization of this system when we think of it without the color part—the color part has been averaged out and reduced the system to the bilinears. We may give an argument using the supercoherent states,[39,40] similar to the ordinary cases: there is a central extension of the automorphism group $\widehat{\mathrm{OSp}_1}$ which is realized by these bilinears on the full Fock space. When we think about the projective Fock space this descends to the OSp_1 group. The orbit of the vacuum under this group gives us a classical phase space albeit a more general one, with a supersymplectic form. The large-N_c limit provides this reduction to the space of supercoherent states. This is a natural classical phase space and the large-N_c limit corresponds to this classical limit.

Before ending our discussions we would like to make a few comments of general nature. Let us write down a superdynamical system in the Hamiltonian form

$$S_0 = \int \mathrm{d}t \frac{1}{2} \Psi^\tau \omega_s \partial_t \Psi - \int \mathrm{d}t \frac{1}{2} \Psi^\tau Q_s \Psi. \tag{97}$$

We assume that the action is an element of the even part of the Grassmann algebra. If we want this to be real we demand $(\Psi^\tau Q_s \Psi)^* = \Psi^\tau \tilde{E} Q_s^* \Psi = \Psi^\tau Q_s \Psi$, that is $Q_s = \tilde{E} Q_s^*$, we are again using $\tilde{E} = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ in the standard decomposition. For the first term it implies the same $\tilde{E} \omega_s^* = \omega$. If we further note that it should be invariant under the transpose, we get for the first term using an integration by parts for the time derivative, $\Psi^\tau \omega_s \partial_t \Psi = -\Psi^\tau \omega_s^\tau \tilde{E} \partial_t \Psi$, which implies $\omega_s = -\omega_s^\tau \tilde{E}$ and the second term requires $\Psi^\tau Q_s \Psi = \Psi^\tau Q_s^\tau \tilde{E} \Psi$, which means we should have $Q_s = Q_s^\tau \tilde{E}$. The equations of motion will give us

$$\partial_t \Psi = \omega_s^{-1} Q_s \Psi. \tag{98}$$

This suggests that we should further investigate operator $\omega_s^{-1} Q_s$ which is a type (1,1) tensor, thus a true linear transformation. We note that $\omega_s^{-1} Q_s$ is real: $(\omega_s^{-1} Q_s)^* = (\omega_s^{-1})^* Q_s^* = \omega_s^{-1} \tilde{E} \tilde{E} Q_s = \omega_s^{-1} Q_s$, by using the conjugation properties of ω_s and Q. This operator is antisymmetric with respest to the form defined by Q_s:

$$Q_s^{-1} (\omega_s^{-1} Q_s)^\tau Q_s = Q_s^{-1} Q_s^\tau (\omega_s^\tau)^{-1} Q_s = -Q_s^{-1} Q_s \tilde{E} \tilde{E} \omega_s^{-1} Q_s = -\omega_s^{-1} Q_s, \tag{99}$$

as well as under ω_s. It would be most natural if we could use a generalization of the polar decomposition for $Q_s^{-1} \omega_s$, and write this operator as $\omega_s^{-1} Q_s = J_s K_s$, where $J_s^t J_s = 1$, and $K_s > 0$, $K_s^t = K_s$, with an appropriate transpose t and positivity is assumed to be given a meaning in this supercontext. Then we could claim that the basis in which J_s is diagonal, will tell us the separation of creation and annihilation operators in this full generality. This can be done in the simple case we looked at, when the operators involved only had body parts, and no Grassmann numbers. Unfortunately for the general case we do not have the proper mathematical machinery. If we could find a supertransformation S, such that $S^{-1} \omega_s^{-1} Q_s S$ is diagonal with each entry $(\pm i \lambda_k)$ for a pure number λ_k we could postulate the quantization by means of canonical commutation/anticommutation relations. To the best of our knowledge there is no such theorem. We think these questions deserve further investigations.

ACKNOWLEDGMENTS

This research is largely based on the ideas of S. G. Rajeev. The authors express their gratitude to him for his generosity and being such a unique source of inspiration and guidance. The research of O.T.T. in Stockholm has been supported by G. Gustafsson fellowship. O.T.T. would like to especially thank J. Mickelsson for such a great opportunity to be in KTH, and thank J. Mickelsson, E. Langmann for hospitality of the group and for discussions. E. Langmann made a critical reading of the paper and improved the presentation drastically. The embedding of space–times in five dimensions with nondegenerate Ricci tensor

F. Dahia and C. Romero
Departamento de Física, Universidade Federal da Paraíba, C. Postal 5008, João Pessoa, PB, 58059-970, Brazil

(Received 23 November 2001; accepted for publication 5 February 2002)

We discuss and prove a theorem which asserts that any n-dimensional semi-Riemannian manifold can be locally embedded in an $(n+1)$-dimensional space with a nondegenerate Ricci tensor which is equal, up to a local analytic diffeomorphism, to the Ricci tensor of an arbitrary specified space. This may be regarded as a further extension of the Campbell–Magaard theorem. We highlight the significance of embedding theorems of increasing degrees of generality in the context of higher dimensional space–times theories and illustrate the new theorem by establishing the embedding of a general class of Ricci-flat space–times. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1473680]

I. INTRODUCTION

Modern physical theories which regard our space–time as a hypersurface embedded in a five-dimensional manifold constitute nowadays a branch of theoretical physics undergoing quite an active research. On the other hand, the idea of an extra fifth dimension is not new and goes back to the works of Kaluza and Klein carried out around the first quarter of the 20th century.[1,2] Kaluza–Klein's seminal work has inspired theoretical physicists to generalize their conjecture in the construction of unified theories of the fundamental interactions of nature. Subsequent developments which assume that the universe contains extra hidden dimensions include among others 11-dimensional supergravity and superstring theories.[3,4] More recently much attention has been devoted to the so-called Randall–Sundrum braneworld scenario where the space–time is viewed as a four-dimensional hypersurface embedded in a five-dimensional Einstein space.[5] Noncompactified approaches to Kaluza–Klein gravity also make use of embedding mechanisms and have been largely discussed in the literature.[6–11]

In a sense one could say that all space–time embedding theories[12] assume, implicitly or explicitly, a mathematical framework which must provide consistency for the postulates and basic principles set forth by such theories. In this connection it is of interest to know whether the embedding theorems of differential geometry are properly taken into account when constructing higher dimensional models. The analysis of the geometrical structure underlying some modern embedding theories has recently attracted the interest of some authors.[13–18] It seems that there is now a quest for embedding theorems with increasing degrees of generality, i.e., theorems ensuring that arbitrary n-dimensional space–times can be embeddable in classes of $(n+1)$-dimensional spaces the most general as possible.

Two theorems of historical importance which have played a significant role in physical theories of higher dimensions should be mentioned. The first is the well-known Janet–Cartan theorem, which asserts that if the embedding space is flat, the minimum number of extra dimensions needed to analytically embed an n-dimensional Riemannian manifold is d, with $0 \leqslant d \leqslant n(n-1)/2$.[19] An important application of this theorem may be illustrated by the isometric embedding of the Schwarzschild solution in a six-dimensional flat space.[20] Other interesting examples of isometric embeddings with application to general relativity and strings may be found in Refs. 21 and 22.

The second theorem is a little known but powerful theorem due to Campbell,[23] the proof of which was outlined by Campbell and completed by Magaard.[24] The content of the Campbell–Magaard theorem is that any n-dimensional Riemannian manifold with analytic metric, locally,

can be isometrically embedded into a certain $(n+1)$-dimensional Ricci-flat manifold. How geometric properties of the embedding space, such as extrinsic curvature, can be related to the energy-momentum tensor is discussed in Ref. 25. It is interesting to note that both theorems specify a geometry property to be satisfied by the embedding space by imposing the restrictions $R_{\mu\nu\lambda\rho}=0$ in one case and $R_{\mu\nu}=0$ in the other. It is also worth noting that by relaxing the flatness condition, assumed in the Janet–Cartan theorem, and replacing it by the weaker Ricci-flatness condition, the Campbell–Magaard theorem drastically reduces the codimension of the embedding space to $d=1$. This seems to give support to the mathematical consistency of theories in which the dynamics of the embedding space is governed by the vacuum Einstein field equations.[6] However, the view adopted by Randall–Sundrum braneworld model[5] that the embedding space, i.e., the bulk, should correspond to an Einstein space sourced by a negative cosmological constant has naturally raised the question of whether the Campbell–Magaard theorem could be extended to include embeddings in arbitrary Einstein spaces. This conjecture was shown to be, in fact, a theorem, the proof of which is given in Ref. 18. Embeddings into spaces sourced by scalar fields also have been considered and a different extension of the Campbell–Magaard theorem has been proved.[17,26] In seeking higher levels of generalization one is led to consider the more general situation of embedding spaces whose Ricci tensor is arbitrary. In this paper we shall be concerned with this problem. In Sec. II we state and prove a theorem which considers embedding spaces with arbitrary nondegenerate Ricci tensor, and, in a way, would represent a further generalization of Campbell–Magaard's result. In Sec. III we illustrate the theorem by establishing the embedding of a general class of Ricci-flat space–times in a given collection of five-dimensional spaces whose Ricci tensor is equivalent to a specified nondegenerate and nonconstant Ricci tensor.

We believe that insofar as five-dimensional embedding theories are metric theories it appears to be of relevance to allow the embedding spaces to have different geometrical properties, which must ultimately be determined by the dynamics of the theory in question. Therefore generalizations of the known embedding theorems might be helpful in building new higher dimensional models.

II. EXTENSION OF CAMPBELL–MAGAARD THEOREM: EMBEDDING SPACES WITH ARBITRARY NONDEGENERATE RICCI TENSOR

In this section we want to investigate the existence of a local analytic embedding of an n-dimensional semi-Riemannian manifold (M^n,g) into a class of $(n+1)$-dimensional spaces whose Ricci tensor is *equivalent* to the Ricci tensor of a $(n+1)$-dimensional space arbitrarily specified.

Definition: Consider a $(n+1)$*-dimensional semi-Riemannian space* $(\tilde{M}_0^{n+1},\tilde{g}_0)$ *and let* $S_{\alpha\beta}$ *denote the components of the Ricci tensor in a coordinate system* $\{x'^{\alpha}\}$. *Let* $(\tilde{M}^{n+1},\tilde{g})$ *be another* $(n+1)$*-dimensional semi-Riemannian space with* $\tilde{R}_{\alpha\beta}$ *denoting the components of the Ricci tensor in a coordinate system* $\{x^{\alpha}\}$ *which covers a neighborhood of a point* $p\in\tilde{M}^{n+1}$ *whose coordinates are* $x_p^1=\cdots=x_p^{n+1}=0$. *Then, we shall say that* $S_{\alpha\beta}$ *and* $\tilde{R}_{\alpha\beta}$ *are equivalent if there exists an analytic local diffeomorphism* $\overline{f}:\tilde{M}_0^{n+1}\to\tilde{M}^{n+1}$ *at* p *such that*

$$\tilde{R}_{\alpha\beta}(x^{\gamma})=\frac{\partial\overline{f}^{\mu}}{\partial x^{\alpha}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\beta}}S_{\mu\nu}(x'^{\kappa}), \tag{1}$$

where $x'^{\kappa}=\overline{f}^{\kappa}(x^{\lambda})$. *In others words,* $S_{\alpha\beta}$ *and* $\tilde{R}_{\alpha\beta}$ *are said to be equivalent if there exists a analytic function* $\overline{f}^{\mu}=\overline{f}^{\mu}(x^{\alpha})$ *such that: (i)* $|\partial\overline{f}^{\mu}/\partial x^{\alpha}|\neq 0$ *at* $0\in\mathbb{R}^{n+1}$ *and (ii) the condition (1) holds in a neighborhood of* $0\in\mathbb{R}^{n+1}$. *In this case* $(\tilde{M}_0^{n+1},\tilde{g}_0)$ *and* $(\tilde{M}^{n+1},\tilde{g})$ *are said to be "Ricci-equivalent" spaces*. (Henceforth we shall follow the convention adopted in Ref. 18 where Latin and Greek indices run from 0 to n and $n+1$, respectively.)

Clearly, from the above, the collection $\mathcal{M}_{\tilde{g}_0}^{n+1}$ of all spaces which are Ricci-equivalent to a given space $(\tilde{M}_0^{n+1},\tilde{g}_0)$ is well defined. Therefore it makes sense to discuss the existence of the

embedding of a given arbitrary n-dimensional semi-Riemannian manifold $(\tilde{M}^n,\tilde{g})$ into the class $\mathcal{M}^{n+1}_{\tilde{g}_0}$. In what follows we shall show that if the Ricci tensor of $(\tilde{M}^{n+1}_0,\tilde{g}_0)$ is nondegenerate, i.e., the matrix formed by its components has inverse, then the existence of the embedding can be ensured.

We should note, however, that (1) defines a notion of equivalence between the covariant Ricci tensor $S_{\alpha\beta}$ and $\tilde{R}_{\alpha\beta}$. This equivalence does not imply that the contravariant Ricci tensor $S^{\alpha\beta}$ and $\tilde{R}^{\alpha\beta}$ are also equivalent. In general they are not, unless the diffeomorphism is an isometry, a condition which is more restrictive than (1).

Let us consider $(\tilde{M}^{n+1},\tilde{g})$ and choose a coordinate system in which the metric has the form

$$ds^2=\overline{g}_{ik}dx^i dx^k+\varepsilon\,\overline{\phi}^2 dy^2, \tag{2}$$

where $\varepsilon=\pm 1$. In these coordinates (1) may be written in the following equivalent form:

$$\tilde{R}_{ik}=\overline{R}_{ik}+\varepsilon\overline{g}^{jm}(\overline{\Omega}_{ik}\overline{\Omega}_{jm}-2\overline{\Omega}_{jk}\overline{\Omega}_{im})-\frac{\varepsilon}{\overline{\phi}}\frac{\partial\overline{\Omega}_{ik}}{\partial y}+\frac{1}{\overline{\phi}}\overline{\nabla_i\nabla_k\phi}=\frac{\partial\overline{f}^{\mu}}{\partial x^i}\frac{\partial\overline{f}^{\nu}}{\partial x^k}S_{\mu\nu}(\overline{f}^{\alpha}), \tag{3}$$

$$\tilde{R}^y_i=\frac{\varepsilon}{\overline{\phi}}\overline{g}^{jk}(\overline{\nabla_j\Omega_{ik}}-\overline{\nabla_i\Omega_{jk}})=\frac{\varepsilon}{\overline{\phi}^2}\frac{\partial\overline{f}^{\mu}}{\partial y}\frac{\partial\overline{f}^{\nu}}{\partial x^i}S_{\mu\nu}(\overline{f}^{\alpha}), \tag{4}$$

$$\tilde{G}^y_y=-\frac{1}{2}\overline{g}^{ik}\overline{g}^{jm}(\overline{R}_{ijkm}+\varepsilon(\overline{\Omega}_{ik}\overline{\Omega}_{jm}-\overline{\Omega}_{jk}\overline{\Omega}_{im}))=\frac{1}{2}\frac{\varepsilon}{\overline{\phi}^2}\frac{\partial\overline{f}^{\mu}}{\partial y}\frac{\partial\overline{f}^{\nu}}{\partial y}S_{\mu\nu}(\overline{f}^{\alpha})$$

$$-\frac{1}{2}\overline{g}^{jm}\frac{\partial\overline{f}^{\mu}}{\partial x^j}\frac{\partial\overline{f}^{\nu}}{\partial x^m}S_{\mu\nu}(\overline{f}^{\alpha}), \tag{5}$$

where

$$\overline{\Omega}_{ik}=-\frac{1}{2\overline{\phi}}\frac{\partial\overline{g}_{ik}}{\partial y}, \tag{6}$$

$G_{\alpha\beta}$ is the Einstein tensor and a bar is used to denote all the geometrical quantities calculated with the induced metric $\overline{g}_{ik}$ on a generic hypersurface Σ_c of the foliation $y=c=\text{const}$. Before we state the main theorem we need a few preliminaries.

We begin by defining the tensor

$$\tilde{F}^{\alpha}_{\beta}=\tilde{G}^{\alpha}_{\beta}-\left(\tilde{g}^{\alpha\gamma}\frac{\partial\overline{f}^{\mu}}{\partial x^{\gamma}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\beta}}S_{\mu\nu}-\frac{1}{2}\delta^{\alpha}_{\beta}\tilde{g}^{\gamma\lambda}\frac{\partial\overline{f}^{\mu}}{\partial x^{\gamma}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\lambda}}S_{\mu\nu}\right). \tag{7}$$

If we now impose that the functions $\overline{f}^{\alpha}$ satisfy the equation

$$\tilde{\nabla}_{\alpha}\left(\tilde{g}^{\alpha\gamma}\frac{\partial\overline{f}^{\mu}}{\partial x^{\gamma}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\beta}}S_{\mu\nu}-\frac{1}{2}\delta^{\alpha}_{\beta}\tilde{g}^{\gamma\lambda}\frac{\partial\overline{f}^{\mu}}{\partial x^{\gamma}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\lambda}}S_{\mu\nu}\right)=0, \tag{8}$$

then it is easily seen that, as the Einstein tensor G^{α}_{β} has vanishing divergence, the tensor $\tilde{F}^{\alpha}_{\beta}$ also is divergenceless for any metric $\tilde{g}_{\alpha\beta}$, even those which are not solutions of Eq. (1). Thus, we are ready to state the following lemma.

Lemma 1: Let the functions $\overline{g}_{ik}(x^1,\ldots,x^n,y),\overline{\phi}(x^1,\ldots,x^n,y)$ *and* $\overline{f}^{\alpha}(x^1,\ldots,x^n,y)$ *be analytical at* $(0,\ldots,0)\in\Sigma_0\subset\mathbb{R}^{n+1}$. *Assume that the following conditions hold:*

(i) $\overline{g}_{ik}=\overline{g}_{ki}$;
(ii) $\det(\overline{g}_{ik})\neq 0$;
(iii) $\overline{\phi}\neq 0$.

Suppose further that $\overline{g}_{ik}$ *and* $\overline{f}^{\alpha}$ *satisfy the equations (3) and (8) in an open set* $V\subset\mathbb{R}^{n+1}$ *which contains* $0\in\mathbb{R}^{n+1}$, *and (4) and (5) hold at* Σ_0. *Then,* $\overline{g}_{ik}$, $\overline{\phi}$ *and* $\overline{f}^{\alpha}$ *satisfy (4) and (5) in a neighborhood* $0\in\mathbb{R}^{n+1}$.

Proof: The key point of the proof is given by the equation $\tilde{\nabla}_{\alpha}\tilde{F}^{\alpha}_{\beta}=0$, which can be written as

$$\frac{\partial\tilde{F}^{y}_{\beta}}{\partial y}=-\frac{\partial\tilde{F}^{i}_{\beta}}{\partial x^{i}}-\tilde{\Gamma}^{\mu}_{\mu\lambda}\tilde{F}^{\lambda}_{\beta}+\tilde{\Gamma}^{\mu}_{\lambda\beta}\tilde{F}^{\lambda}_{\mu}. \tag{9}$$

On the other hand, by assumption (3) holds in $V\subset\mathbb{R}^{n+1}$. Then, it can be shown that in V we have $\tilde{F}^{i}_{k}=-\delta^{i}_{k}\tilde{F}^{y}_{y}$. After some algebra we can deduce that

$$\frac{\partial\tilde{F}^{y}_{y}}{\partial y}=-\varepsilon\overline{\phi}^{2}\overline{g}^{ij}\frac{\partial\tilde{F}^{y}_{i}}{\partial x^{j}}-2\tilde{\Gamma}^{i}_{iy}\tilde{F}^{y}_{y}+\left(-\varepsilon\frac{\partial(\overline{\phi}^{2}\overline{g}^{ij})}{\partial y^{j}}-\varepsilon\overline{\phi}^{2}\overline{g}^{ij}\tilde{\Gamma}^{k}_{kj}+\tilde{\Gamma}^{i}_{yy}\right)\tilde{F}^{y}_{i}, \tag{10}$$

$$\frac{\partial\tilde{F}^{y}_{i}}{\partial y}=\frac{\partial\tilde{F}^{y}_{y}}{\partial x^{i}}+2\tilde{\Gamma}^{y}_{yi}\tilde{F}^{y}_{y}+(\tilde{\Gamma}^{k}_{yi}+\varepsilon\overline{\phi}^{2}\overline{g}^{kj}\tilde{\Gamma}^{y}_{ij}-\tilde{\Gamma}^{\mu}_{y\mu}\delta^{k}_{i})\tilde{F}^{y}_{k}. \tag{11}$$

Since at the hypersurface Σ_0 the equations (4) and (5) also hold, it follows that $\tilde{F}^{y}_{\beta}=0$ at Σ_0 and hence $\partial\tilde{F}^{y}_{\beta}/\partial y\,|_{y=0}=0$. It is not difficult to show by mathematical induction that all the derivatives (to any order) of $\tilde{F}^{y}_{\beta}$ vanish at $y=0$. As $\tilde{F}^{y}_{\beta}$ is analytic we conclude that $\tilde{F}^{y}_{\beta}=0$ in an open set of $\mathbb{R}^{n+1}$. Hence, Eqs. (4) and (5), which are equivalent to $\tilde{F}^{y}_{\beta}=0$, also hold in an open set of $\mathbb{R}^{n+1}$ which includes the origin. This proves the lemma.

The question which now arises is: do Eqs. (3) and (8) admit solution? To answer this question we first note that (3) can be expressed in the following form:

$$\begin{aligned}\frac{\partial^{2}\overline{g}_{ik}}{\partial y^{2}}=&-2\varepsilon\overline{\phi}^{2}\left(\frac{\partial\overline{f}^{\mu}}{\partial x^{i}}\frac{\partial\overline{f}^{\nu}}{\partial x^{k}}S_{\mu\nu}(\overline{f}^{\alpha})\right)+\frac{1}{\overline{\phi}}\frac{\partial\overline{\phi}}{\partial y}\frac{\partial\overline{g}_{ik}}{\partial y}-\frac{1}{2}\overline{g}^{jm}\left(\frac{\partial\overline{g}_{ik}}{\partial y}\frac{\partial\overline{g}_{jm}}{\partial y}-2\frac{\partial\overline{g}_{im}}{\partial y}\frac{\partial\overline{g}_{jk}}{\partial y}\right)\\&-2\varepsilon\overline{\phi}\left(\frac{\partial^{2}\overline{\phi}}{\partial x^{i}\partial x^{k}}-\frac{\partial\overline{\phi}}{\partial x^{j}}\overline{\Gamma}^{j}_{ik}\right)-2\varepsilon\overline{\phi}^{2}\overline{R}_{ik}.\end{aligned} \tag{12}$$

Second, let us rewrite Eq. (8) in the form

$$\begin{aligned}&\frac{\partial}{\partial x^{\alpha}}\left(\tilde{g}^{\alpha\gamma}\frac{\partial\overline{f}^{\mu}}{\partial x^{\gamma}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\beta}}S_{\mu\nu}-\frac{1}{2}\delta^{\alpha}_{\beta}\tilde{g}^{\gamma\lambda}\frac{\partial\overline{f}^{\mu}}{\partial x^{\gamma}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\lambda}}S_{\mu\nu}\right)+\tilde{\Gamma}^{\alpha}_{\alpha_{\sigma}}\left(\tilde{g}^{\sigma\gamma}\frac{\partial\overline{f}^{\mu}}{\partial x^{\gamma}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\beta}}S_{\mu\nu}\right)\\&-\tilde{\Gamma}^{\sigma}_{\alpha_{\beta}}\left(\tilde{g}^{\alpha\gamma}\frac{\partial\overline{f}^{\mu}}{\partial x^{\gamma}}\frac{\partial\overline{f}^{\nu}}{\partial x^{\sigma}}S_{\mu\nu}\right)=0.\end{aligned} \tag{13}$$

We now isolate the terms which contain second-order derivatives of $\overline{f}^{\alpha}$ with respect to y in the equation above. Putting $\beta=n+1$ we obtain

$$\frac{\varepsilon}{\overline{\phi}^2}\frac{\partial^2\overline{f}^\mu}{\partial y^2}\frac{\partial\overline{f}^\nu}{\partial y}S_{\mu\nu}=-\frac{1}{2}\frac{\partial\overline{f}^\mu}{\partial y}\frac{\partial\overline{f}^\nu}{\partial y}\frac{\partial}{\partial y}\left(\frac{\varepsilon}{\overline{\phi}^2}S_{\mu\nu}\right)+\frac{1}{2}\frac{\partial}{\partial y}\left(\overline{g}^{jk}\frac{\partial\overline{f}^\mu}{\partial x^j}\frac{\partial\overline{f}^\nu}{\partial x^k}S_{\mu\nu}\right)$$
$$-\frac{\partial}{\partial x^j}\left(\overline{g}^{jk}\frac{\partial\overline{f}^\mu}{\partial x^k}\frac{\partial\overline{f}^\nu}{\partial y}S_{\mu\nu}\right)-\tilde{\Gamma}^\alpha_{\alpha_\sigma}\left(\tilde{g}^{\sigma\gamma}\frac{\partial\overline{f}^\mu}{\partial x^\gamma}\frac{\partial\overline{f}^\nu}{\partial x^\beta}S_{\mu\nu}\right)+\tilde{\Gamma}^\sigma_{\alpha_\beta}\left(\tilde{g}^{\alpha\gamma}\frac{\partial\overline{f}^\mu}{\partial x^\gamma}\frac{\partial\overline{f}^\nu}{\partial x^\sigma}S_{\mu\nu}\right). \tag{14}$$

For $\beta=i$ we have

$$\frac{\varepsilon}{\overline{\phi}^2}\frac{\partial^2\overline{f}^\mu}{\partial y^2}\frac{\partial\overline{f}^\nu}{\partial x^i}S_{\mu\nu}=-\frac{\partial\overline{f}^\mu}{\partial y}\frac{\partial}{\partial y}\left(\frac{\varepsilon}{\overline{\phi}^2}\frac{\partial\overline{f}^\nu}{\partial x^i}S_{\mu\nu}\right)-\frac{\partial}{\partial x^j}\left(\overline{g}^{jk}\frac{\partial\overline{f}^\mu}{\partial x^j}\frac{\partial\overline{f}^\nu}{\partial x^i}S_{\mu\nu}\right)$$
$$+\frac{1}{2}\frac{\partial}{\partial x^i}\left(\tilde{g}^{\sigma\gamma}\frac{\partial\overline{f}^\mu}{\partial x^\gamma}\frac{\partial\overline{f}^\nu}{\partial x^\beta}S_{\mu\nu}\right)-\tilde{\Gamma}^\alpha_{\alpha_\sigma}\left(\tilde{g}^{\sigma\gamma}\frac{\partial\overline{f}^\mu}{\partial x^\gamma}\frac{\partial\overline{f}^\nu}{\partial x^\beta}S_{\mu\nu}\right)$$
$$+\tilde{\Gamma}^\sigma_{\alpha_\beta}\left(\tilde{g}^{\alpha\gamma}\frac{\partial\overline{f}^\mu}{\partial x^\gamma}\frac{\partial\overline{f}^\nu}{\partial x^\sigma}S_{\mu\nu}\right). \tag{15}$$

Clearly, the right-hand side of (14) and (15) does not contain second-order derivatives of the functions $\overline{f}^\alpha$ and $\overline{g}_{ik}$ with respect to y. Therefore, they are of the form

$$\frac{\partial^2\overline{f}^\mu}{\partial y^2}\frac{\partial\overline{f}^\nu}{\partial x^\beta}S_{\mu\nu}=Q_\beta\left(\overline{f}^\lambda,\frac{\partial\overline{f}^\lambda}{\partial x^\sigma},\frac{\partial^2\overline{f}^\lambda}{\partial x^\sigma\partial x^i},\overline{g}_{ik},\frac{\partial\overline{g}_{ik}}{\partial x^\sigma}\right). \tag{16}$$

(Of course Q_β also depends on $\overline{\phi}$ and its derivatives, however this fact is not relevant for our present reasoning.) Thus, assuming that $|\partial\overline{f}^\mu/\partial x^\alpha|\neq 0$ (we shall see later on that this assumption can always be made) we can write

$$\frac{\partial^2\overline{f}^\mu}{\partial y^2}S_{\mu\nu}=\frac{\partial x^\beta}{\partial\overline{f}^\nu}Q_\beta\left(\overline{f}^\lambda,\frac{\partial\overline{f}^\lambda}{\partial x^\sigma},\frac{\partial^2\overline{f}^\lambda}{\partial x^\sigma\partial x^i},\overline{g}_{ik},\frac{\partial\overline{g}_{ik}}{\partial x^\sigma}\right). \tag{17}$$

If we suppose that $S_{\mu\nu}$ is invertible, i.e., there exists $(S^{-1})^{\nu\lambda}$ such that

$$S_{\mu\nu}(S^{-1})^{\nu\lambda}=\delta^\lambda_\mu, \tag{18}$$

then (8) can be put into the canonical form

$$\frac{\partial^2\overline{f}^\mu}{\partial y^2}=P^\mu\left(\overline{f}^\lambda,\frac{\partial\overline{f}^\lambda}{\partial x^\sigma},\frac{\partial^2\overline{f}^\lambda}{\partial x^\sigma\partial x^i},\overline{g}_{ik},\frac{\partial\overline{g}_{ik}}{\partial x^\sigma}\right), \tag{19}$$

where each P^μ is analytic with respect to its arguments provided that $|\partial\overline{f}^\mu/\partial x^\alpha|\neq 0$, $|\overline{g}_{ik}|\neq 0$ and $\overline{\phi}\neq 0$.

It easy to see that the Cauchy–Kowalewski theorem (see the Appendix) can be applied to the equations (19) and (12), which are equivalent to (3) and (8), respectively. According to the above-mentioned theorem, if an analytic function $\overline{\phi}\neq 0$ is chosen, then there exists a unique set of analytic functions $\overline{g}_{ik}$ and $\overline{f}^\alpha$ that are solutions of (3) and (8) satisfying the initial conditions

$$\overline{g}_{ik}(x^1,\ldots,x^n,0)=g_{ik}(x^1,\ldots,x^n), \tag{20}$$

$$\frac{\partial \overline{g}_{ik}}{\partial y}(x^1,\ldots,x^n,0) = -2\,\overline{\phi}(x^1,\ldots,x^n,0)\,\Omega_{ik}(x^1,\ldots,x^n), \tag{21}$$

$$\overline{f}^{\alpha}(x^1,\ldots,x^n,0) = \xi^{\alpha}(x^1,\ldots,x^n), \tag{22}$$

$$\frac{\partial \overline{f}^{\alpha}}{\partial y}(x^1,\ldots,x^n,0) = \eta^{\alpha}(x^1,\ldots,x^n), \tag{23}$$

where g_{ik}, Ω_{ik}, ξ^{α} and η^{α} are analytic functions at the origin $0 \in \mathbb{R}^n$, and the following conditions hold: (i) $|\partial \overline{f}^{\mu}/\partial x^{\alpha}|_0 \neq 0$ and (ii) $|g_{ik}| \neq 0$. [Incidentally, we can easily verify that the condition (i) is satisfied by simply choosing: $\xi^i = x^i$; $\xi^{n+1} = 0$; $\eta^i = 0$ and $\eta^{n+1} = 1$. With this choice, $|\partial \overline{f}^{\mu}/\partial x^{\alpha}|_0 = 1$.]

We now are ready to state the following theorem.

Theorem 1: *Let M^n be an n-dimensional semi-Riemannian manifold with metric given by*

$$ds^2 = g_{ik}dx^i dx^k,$$

in a coordinate system $\{x^i\}$ of M^n. Let $p \in M^n$ have coordinates $x^1_p = \cdots = x^n_p = 0$. Then, M^n has a local isometric and analytic embedding (at the point p) in an $(n+1)$-dimensional space $(\tilde{M}^{n+1}, \tilde{g})$ whose Ricci tensor is equivalent to the symmetric, analytic and nondegenerate tensor $S_{\mu\nu}$ if and only if there exist functions $\Omega_{ik}(x^1,\ldots,x^n)$ $(i,k = 1,...,n)$, $\xi^{\alpha}(x^1,\ldots,x^n)$, $\eta^{\alpha}(x^1,\ldots,x^n)$ $(\alpha = 1,\ldots,n+1)$ and $\phi(x^1,\ldots,x^n) \neq 0$ that are analytic at $0 \in \mathbb{R}^n$, such that

$$\Omega_{ik} = \Omega_{ki}, \tag{24}$$

$$g^{jk}(\nabla_j \Omega_{ik} - \nabla_i \Omega_{jk}) = \frac{1}{\phi}\,\eta^{\mu}\frac{\partial \xi^{\nu}}{\partial x^i} S_{\mu\nu}(\xi^{\alpha}), \tag{25}$$

$$g^{ik}g^{jm}(R_{ijkm} + \varepsilon(\Omega_{ik}\Omega_{jm} - \Omega_{jk}\Omega_{im})) = -\frac{\varepsilon}{\phi^2}\,\eta^{\mu}\eta^{v} S_{\mu\nu}(\xi^{\alpha}) + g^{jm}\frac{\partial \xi^{\mu}}{\partial x^j}\frac{\partial \xi^{\nu}}{\partial x^m} S_{\mu\nu}(\xi^{\alpha}), \tag{26}$$

$$\begin{vmatrix} \dfrac{\partial \xi^1}{\partial x^1} & \cdots & \dfrac{\partial \xi^{n+1}}{\partial x^1} \\ \vdots & & \vdots \\ \dfrac{\partial \xi^1}{\partial x^n} & \cdots & \dfrac{\partial \xi^{n+1}}{\partial x^n} \\ \eta^1 & \cdots & \eta^{n+1} \end{vmatrix} \neq 0. \tag{27}$$

Proof: Let us start with the necessary condition. If (M^n, g) has an embedding in $(\tilde{M}^{n+1}, \tilde{g})$, then it can be proved that there exists a coordinate system in which the metric of the embedding space has the form[18]

$$ds^2 = \overline{g}_{ik}dx^i dx^k + \varepsilon\,\overline{\phi}^2 dy^2, \tag{28}$$

where the analytic functions $\overline{g}_{ik}(x^1,\ldots,x^n,y)$ and $\overline{\phi}(x^1,\ldots,x^n,y)$ are such that $\overline{\phi}(x^1,\ldots,x^n,y) \neq 0$ and that $\overline{g}_{ik}(x^1,\ldots,x^n,0) = g_{ik}(x^1,\ldots,x^n)$ in an open set of $\mathbb{R}^n$ which contains the origin. Given that the Ricci tensor of the embedding space $(\tilde{M}^{n+1}, \tilde{g})$ is, by assumption, equivalent to $S_{\mu\nu}$, then the equations (3), (4), (5) and (8) are satisfied in a neighborhood of 0

$\in \mathbb{R}^{n+1}$ for some functions $\overline{f}^{\mu}$. In particular, the equations (4) and (5) hold for $y=0$. Therefore, if we define Ω_{ik}, ξ^{α}, η^{α} by the relations (21), (22) and (23), and take $\phi(x^1,\ldots,x^n) = \overline{\phi}(x^1,\ldots,x^n,0)$, then the Eqs. (24)–(27) are satisfied.

Let us turn to the sufficiency. Suppose there exist functions $\Omega_{ik}(x^1,\ldots,x^n)$, $\xi^{\alpha}(x^1,\ldots,x^n)$, $\eta^{\alpha}(x^1,\ldots,x^n)$ and $\phi(x^1,\ldots,x^n)\neq 0$ which satisfy (24)–(27). Choose an analytic function $\overline{\phi}(x^1,\ldots,x^n,y)\neq 0$ such that $\overline{\phi}(x^1,\ldots,x^n,0)=\phi(x^1,\ldots,x^n)$. By virtue of the Cauchy–Kowalewski theorem there exists a unique set of analytic functions $\overline{g}_{ik}(x^1,\ldots,x^n,y)$ and $\overline{f}^{\alpha}(x^1,\ldots,x^n,y)$ satisfying the equations (3) and (8) and the initial conditions (20)–(23). Since, by assumption, the initial conditions satisfy the equations (24)–(26), then $\overline{g}_{ik}, \overline{\phi}$ and $\overline{f}^{\alpha}$ satisfy (4) and (5) at $y=0$. It follows from Lemma 1 that $\overline{g}_{ik}, \overline{\phi}$ and $\overline{f}^{\alpha}$ satisfy (1) in an open set of $\mathbb{R}^{n+1}$ which contains the origin. Further, we can say that $\overline{f}^{\alpha}$ is a diffeomorphism since by virtue of (27) we have $\left|\partial \overline{f}^{\mu}/\partial x^{\alpha}\right|\neq 0$. Therefore, we conclude that the $(n+1)$-dimensional manifold whose line element (28) is formed with the solutions $\overline{g}_{ik}$ and $\overline{\phi}$ is a space whose Ricci tensor is equivalent to $S_{\mu\nu}$, and the embedding of the manifold (M^n,g) is given by $y=0$. This completes the proof.

We now need to show that once the functions g_{ik} are given the system of equations (24)–(27) always admits solution for Ω_{ik}. For simplicity we take $\xi^i=x^i$; $\xi^{n+1}=0$; $\eta^i=0$ e $\eta^{n+1}=1$. With this choice the condition (27) is readily satisfied. The equations (24)–(26) constitute a set of n partial differential equations (25) plus a constraint equation (26) for $n(n+1)/2$ independent functions Ω_{ik}. Except for $n=1$, the number of unknown functions is greater than [or equal to $(n=2)$] the number of equations. Then, out of the set of functions Ω_{ik} we pick n functions $\Omega_{1k}(k\geqslant 2)$ and $\Omega_{r'n}$ to be regarded as the unknown. (The r' index has the following meaning. We assume, for the sake of the argument, that we are using a coordinate system in which $g_{11}\neq 0$ and $g_{1k}=0$, $k=2,\ldots,n$. Hence, there exists at least an index $r'>1$ such that $g^{r'n}\neq 0$, since $|g_{ik}| \neq 0$.) The next step is to write (25) in a suitable form for application of the Cauchy–Kowalewski theorem (first-order derivative version) to ensure the existence of the solution. For the sake of brevity we shall omit the detailed proof and refer the reader to Refs. 18 and 24 where a similar procedure is carried out. Then it can be shown that after solving (25) for Ω_{1k} $(k\geqslant 2)$ and $\Omega_{r'n}$ we obtain

$$\frac{\partial \Omega_{r'n}}{\partial x^1} = \frac{1}{g^{r'n}(\delta_{r'n}-2)}\Bigg[-\sum_{r,s>1} g^{rs}\,\Omega_{1s,r} + 2\sum_{\substack{1<r<s\\ r,s\neq r',n}} g^{rs}\,\Omega_{rs,1} + \sum_{\substack{r>1\\ r\neq r'}} g^{rr}\Omega_{rr,1} + g^{r'r'}\Omega_{r'r',1}(1-\delta_{r'n})$$
$$- \sum_{r,s>1} g^{rs}\left(\sum_{t\leqslant r}\Omega_{tr}\Gamma^{t}_{s1} + \sum_{r<t}\Omega_{rt}\Gamma^{t}_{s1} - \Omega_{11}\Gamma^{1}_{sr} - \sum_{t<1}\Omega_{1t}\Gamma^{t}_{sr}\right) + \frac{1}{\phi}S_{1y}(x^i)\Bigg], \tag{29}$$

where no sum over r' is implied, and

$$\frac{\partial \Omega_{1k}}{\partial x^1} = g_{11}\Bigg[-\sum_{r,s>1} g^{rs}\left(\sum_{s\leqslant k}\Omega_{sk,r} + \sum_{k<s}\Omega_{ks,r} - 2\sum_{r<s}\Omega_{rs,k}\right) - g^{11}\Omega_{11,k} - \sum_{r>1} g^{rr}\Omega_{rr,k}$$
$$- g^{rs}\left(\sum_{t\leqslant r}\Omega_{tr}\Gamma^{t}_{sk} + \sum_{r<t}\Omega_{rt}\Gamma^{t}_{sk} - \sum_{t\leqslant k}\Omega_{tk}\Gamma^{t}_{sr} - \sum_{k<t}\Omega_{kt}\Gamma^{t}_{sr}\right) + \frac{1}{\phi}S_{ky}(x^i)\Bigg], \quad k\geqslant 2, \tag{30}$$

where Ω_{11} must be substituted by

$$\Omega_{11}=\frac{1}{2g^{11}\underset{r,s>1}{g^{rs}}\left(\underset{r\leqslant s}{\Omega_{rs}}+\underset{s<r}{\Omega_{sr}}\right)}\left[2g^{11}\underset{r,s>1}{g^{rs}}\,\Omega_{1r}\Omega_{1s}-\underset{r,s,t,u>1}{g^{rs}g^{tu}}\left[\left(\underset{r\leqslant s}{\Omega_{rs}}+\underset{s<r}{\Omega_{sr}}\right)\left(\underset{t\leqslant u}{\Omega_{tu}}+\underset{u<t}{\Omega_{ut}}\right)-\left(\underset{r\leqslant u}{\Omega_{ru}}+\underset{u<r}{\Omega_{ur}}\right)\right.\right.$$
$$\left.\left.\times\left(\underset{s\leqslant t}{Q_{st}}+\underset{t<s}{\Omega_{ts}}\right)\right]-\varepsilon\left(R-\frac{\varepsilon}{\phi^2}S_{yy}(x^i)+g^{jm}S_{jm}(x^i)\right)\right]. \tag{31}$$

Finally, if we choose the functions Ω_{ik} $[i\leqslant k, i>1, (i,k)\neq(r',n)]$, $\phi\neq 0$ as being analytic at the origin, and since $S_{\mu\nu}(x^i)$ are also analytic, then in view of the Cauchy–Kowalewski theorem the system of equations (29) and (30) admits a solution that is analytic at the origin. Therefore, given arbitrary analytic functions $g_{ik}(x^1,\ldots,x^n)$ the existence of the functions $\Omega_{ik}(x^1,\ldots,x^n)$ $\times(i,k=1,...,n)$, $\xi^\alpha(x^1,\ldots,x^n)$, $\eta^\alpha(x^1,\ldots,x^n)$ which satisfy (24)–(27) is ensured, so Theorem 1 applies.

It should be mentioned that in the case where $S_{\mu\nu}=0$, Eq. (8) holds for any functions $\overline{f^\alpha}(x^\beta)$; hence all the results derived above apply when the space $(\tilde{M}_0^{n+1},\tilde{g}_0)$ has a vanishing Ricci tensor. Therefore, we can state the following theorem:

Theorem 2: *Let M^n be an n-dimensional semi-Riemannian manifold with metric given by*

$$ds^2=g_{ik}dx^i dx^k,$$

in a coordinate system $\{x^i\}$ of M^n. Let $p\in M^n$, have coordinates $x_p^1=\cdots=x_p^n=0$. Consider an $(n+1)$-dimensional semi-Riemannian space $(\tilde{M}_0^{n+1},\tilde{g}_0)$ whose Ricci tensor is either nondegenerate or null. If g_{ik} are analytic functions at $0\in\mathbb{R}^n$, then (M^n,g) has a local isometric and analytic embedding (at the point p) in an $(n+1)$-dimensional space which is Ricci equivalent to $(\tilde{M}_0^{n+1},\tilde{g}_0)$.

Therefore, we conclude that if the space $(\tilde{M}_0^{n+1},\tilde{g}_0)$ is a solution of the Einstein equations for some source, then Theorem 2 guarantees that there exists a space which satisfies the ''same'' Einstein equations up to a coordinate transformation [see Eq. (1)], in which the space–time (M^n,g) can be embedded.

III. A SIMPLE APPLICATION OF THEOREM 2

Up to this point we have considered the Ricci tensor only through its covariant components $\tilde{R}_{\alpha\beta}$. However, it is not difficult to realize that all the previous results we have obtained are still valid if the mixed $\tilde{R}_\beta^\alpha$ or contravariant components $\tilde{R}^{\alpha\beta}$ are considered instead.

In what follows we illustrate Theorem 2 in its Ricci tensor mixed-components version.

Consider the five-dimensional semi-Riemannian space $(\tilde{M}_0^5,\tilde{g}_0)$ with a metric given by

$${}^5ds^2=(y+1)^{4/5}(-dt^2+dx^2+dy^2+dz^2)+\tfrac{24}{25}\varepsilon dy^2. \tag{32}$$

If we calculate the mixed components of the Ricci S_ν^μ tensor for this metric we obtain

$$S_\nu^\mu=\mathrm{diag}\left(\frac{1}{4},\frac{1}{4},\frac{1}{4},\frac{1}{4},-1\right)\frac{\varepsilon}{(y+1)^2}. \tag{33}$$

We can view (32) as a five-dimensional analog of the Friedmann–Robertson–Walker cosmological metric for radiation, with an energy density given by $\rho(y)=-\varepsilon/(y+1)^2$ (as measured by observers ∂_y).

Consider now a four-dimensional space (M^4,g) with a vanishing Ricci tensor, i.e., a vacuum solution of the Einstein field equations. Let us consider the question of embedding (M^4,g) into the collection $\mathcal{M}_{\tilde{g}_0}^5$ of five-dimensional spaces that are Ricci equivalent to $(\tilde{M}_0^5,\tilde{g}_0)$. In order to work with a mixed Ricci tensor we redefine the Ricci-equivalence property by the equation

$$\tilde{R}^{\mu}_{\nu}=\frac{\partial \overline{f}^{\mu}}{\partial x^{\alpha}}\frac{\partial x^{\beta}}{\partial \overline{f}^{v}}S^{\alpha}_{\beta}. \tag{34}$$

To find the embedding we begin with the ansatz

$$\overline{g}_{ik}(x^1,\ldots,x^4,y)=u(y)g_{ik}(x^1,\ldots,x^4), \tag{35}$$

$$\overline{\phi}(x^1,\ldots,x^4,y)=1, \tag{36}$$

$$\overline{f}^{\alpha}(x^1,\ldots,x^4,y)=x^{\alpha}, \tag{37}$$

where g_{ik} is the metric of (M^4,g) and $u(y)$ is a function such that $u(0)=1$.

From Lemma 1 we can show that (34) is equivalent to the ordinary differential equation

$$u'=\frac{4}{5}\frac{u}{(y+1)}. \tag{38}$$

Therefore, after integrating (38) we conclude that (M^4,g) has a local embedding in the space

$${}^5ds^2=(y+1)^{4/5}(g_{ik}dx^i dx^k)+\tfrac{24}{25}\varepsilon dy^2, \tag{39}$$

whose Ricci tensor is the same as S^{μ}_{ν}, given by (33). Finally, it is worth mentioning that although the spaces (32) and (39) are Ricci equivalent they are not isometric. This can simply be verified since the Weyl tensor $W_{\mu\nu\lambda\rho}$ calculated from (32) vanishes while (39) may have $W_{\mu\nu\lambda\rho}\neq 0$ for some g_{ik} (choose, for example, $g_{ik}dx^i dx^k$ to be the line element of Schwarzschild space–time).

IV. FINAL COMMENTS

The restriction of the Ricci tensor being nondegenerate, as required by Theorem 2, certainly imposes a limitation on the set of possible sources of the embedding space. For example, we would have to leave out of consideration solutions of the Einstein equations such as cosmological models sourced by dust-type perfect fluid. We feel that although a great number of solutions of physical interest have nondegenerate Ricci tensor, e.g., Friedman–Robertson–Walker models sourced by incoherent radiating perfect fluids, it seems indisputable that a theorem in which the condition of nondegeneracy is relaxed would be most welcome. We are currently investigating whether this limitation can be overcome by taking into account the divergenceless condition

$${}^0\tilde{\nabla}_{\alpha}(\tilde{g}_0^{\alpha\gamma}S_{\mu\nu}-\tfrac{1}{2}\delta^{\alpha}_{\beta}\tilde{g}_0^{\gamma\lambda}S_{\mu\nu})=0, \tag{40}$$

where ${}^0\tilde{\nabla}_{\alpha}$ denotes the covariant derivative compatible with the metric $\tilde{g}_0$.

APPENDIX: CAUCHY–KOWALEWSKI THEOREM

Theorem (Cauchy–Kowalewski): *Let us consider the set of partial differential equations:*

$$\frac{\partial^2 u^A}{\partial (y^{n+1})^2}=F^A\left(y^{\alpha},u^B,\frac{\partial u^B}{\partial y^{\alpha}},\frac{\partial^2 u^B}{\partial y^{\alpha}\partial y^{i}},\right),\quad A=1,\ldots,m, \tag{41}$$

where $u^1,\ldots,u^m$ *are* m *unknown functions of the* $n+1$ *variables* $y^1,\ldots,y^n,y^{n+1}$, $\alpha=1,\ldots,n+1$, $i=1,...,n$, $B=1,\ldots,m$. *Also, let* $v^1,\ldots,v^m,w^1,\ldots,w^m$, *functions of the variables* $y^1,\ldots,y^n$, *be analytic at* $0\in\mathbb{R}^n$. *If the functions* F^A *are analytic with respect to each of their arguments around the values evaluated at the point* $y^1=\cdots=y^n=0$, *then there exists a unique solution of Eqs. (41) which is analytic at* $0\in\mathbb{R}^{n+1}$ *and that satisfies the initial condition*

$$u^A(y^1,\ldots,y^n,0)=v^A(y^1,\ldots,y^n), \tag{42}$$

$$\frac{\partial u^A}{\partial y^{n+1}}(y^1,\ldots,y^n,0)=w^A(y^1,\ldots,y^n), \quad A=1,\ldots,m. \tag{43}$$

(Received 6 March 2001; accepted for publication 14 March 2002)

Liouville integrable noncanonical Hamiltonian systems with variable coefficient symplectic forms are generated from the AKNS 3×3 matrix Lax pairs by binary symmetry constraints of the AKNS hierarchy. These integrable systems provide new integrable factorization for every AKNS system in the hierarchy. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1478802]

I. INTRODUCTION

Symmetry constraints of soliton systems give us a systematic method of constructing Liouville integrable finite-dimensional Hamiltonian systems, as well as allow us to find an important class of solutions of related field systems. Moreover, most of the examples constructed so far (for example, see Refs. 1–20), both through mono nonlinearization[1] and through binary nonlinearization[13] of spectral problems of soliton systems, written down in natural coordinates, i.e., eigenfunctions of spectral problems, are Hamiltonian (or multi-Hamiltonian[5,7–12]) systems with constant coefficient symplectic forms. A natural question arises whether there are some symmetry constraints which nonlinearize spectral problems of soliton systems into Hamiltonian systems with variable coefficient symplectic forms.

In this article we give a positive answer on the basis of considering the symmetry constraints of the AKNS 2×2 matrix spectral problem as an illustrative example. The appropriate Poisson structure will be derived by the Dirac constraint method applied to the Poisson structure of binary constrained AKNS 3×3 matrix spectral problem.[18] Nevertheless, the method suggests the existence of Hamiltonian systems with variable coefficient symplectic forms by binary symmetry constraints for other spectral problems like multicomponent KdV or Kaup–Newell ones.

The article is organized as follows. In Sec. II we present a concept of factorization of a given soliton system into a pair of Hamiltonian systems with constant coefficient symplectic forms, derived through the so-called binary symmetry constraints.[13,21] Then, in Sec. III we illustrate the method by the example of binary symmetry constraints of the AKNS systems in the cases of the 2×2 matrix spectral problem and the 3×3 matrix spectral problem. In each case we obtain a respective factorization of every AKNS field system into a pair of finite-dimensional Liouville integrable Hamiltonian systems with constant coefficient symplectic forms. Finally, in Sec. IV we present a new factorization of the AKNS systems into a pair of finite-dimensional Liouville integrable Hamiltonian systems with variable coefficient symplectic forms. This new class of factorizations will be derived by using the Dirac constraint method applied to the binary symmetry constraints of the AKNS 3×3 matrix spectral problem.

II. BASIC FORMULATION OF BINARY SYMMETRY CONSTRAINTS

Let $\mathcal{B}$ denote the differential algebra of differential functions $u=u(x,t)$ and we write

$$\tilde{\mathcal{V}}^r=\mathcal{V}^r\otimes C[\lambda,\lambda^{-1}],\quad \mathcal{V}^r=\{(P^{ij})_{r\times r}|P^{ij}\in\mathcal{B}\}.$$

[a)]Electronic mail: blaszakm@main.amu.edu.pl
[b)]Electronic mail: mawx@math.usf.edu

A typical soliton system is related to a particular spectral problem

$$\phi_x = U\phi = U(u,\lambda)\phi, \quad U \in \tilde{\mathcal{V}}^r, \tag{1}$$

and its adjoint representation equation

$$V_x = [U,V], \quad V \in \tilde{\mathcal{V}}^r. \tag{2}$$

For an infinite set of Lax pairs

$$\phi_x = U\phi, \quad \phi_{t_n} = V^{(n)}\phi, \quad V^{(n)} = (\lambda^n V)_+ + \Delta_n, \quad n \geqslant 1, \tag{3}$$

where plus denotes the choice of the non-negative power of λ and Δ_n is some additional term which depends on a particular system under consideration, the compatibility conditions, i.e., the so-called zero-curvature equations, are equivalent to an infinite hierarchy of nonlinear partial differential equations (PDEs) in the evolutionary form under the condition that $\lambda_{t_n} = 0$:

$$U_{t_n} - V_x^{(n)} + [U,V^{(n)}] = 0 \Leftrightarrow u_{t_n} = K(u,u_x,\dots) = K[u], \quad n \geqslant 1. \tag{4}$$

Moreover, the property

$$V_{t_n}^{(m)} - V_{t_m}^{(n)} + [V^{(m)},V^{(n)}] = 0, \quad m,n \geqslant 1, \tag{5}$$

means[22] that all vector fields do commute in pairs, $[K_m,K_n] = 0$.

In fact, there is another natural set of Lax pairs related to the adjoint spectral problem

$$\psi_x = U^*\psi = -U^T\psi, \quad \psi_{t_n} = V^{*(n)}\psi = -(V^{(n)})^T\psi, \quad n \geqslant 1, \tag{6}$$

where T means the transpose of matrices. Obviously we have

$$U_{t_n} - V_x^{(n)} + [U,V^{(n)}] = 0 \Leftrightarrow U_{t_n}^* - V_x^{*(n)} + [U^*,V^{*(n)}] = 0. \tag{7}$$

There exists an additional object being very important in our theory, i.e., so-called recursion operator Φ. This second rank tensor, generally of integro-differential form, can be derived directly from the Lax representation (3) and (4), and has such a property that an action on one symmetry generator K_i produces another one K_{i+1}: $K_{i+1} = \Phi K_i$. So, the infinite hierarchy of PDEs (4) can be generated recursively: $u_{t_n} = \Phi^n K_0$. In generic cases, i.e., before different type of reductions, K_n are multi-Hamiltonian vector fields and the adjoint operator Φ^* produces a hierarchy of closed one-forms being differentials of conserved functionals (see, for example, Ref. 12).

It is well known that eigenfunctions of the recursion operator (or its adjoint) are closely related to particular solutions of systems of equations from the considered chain of PDEs. On the other hand, each eigenfunction of $\Phi(\Phi^*)$ is expressible through the respective components of eigenfunctions ϕ, ψ of isospectral problem (1) and its adjoint (6). The idea of symmetry constraints means the restriction of the kth symmetry (respectively, kth conserved one-form) to a finite number of eigenfunctions of Φ (respectively, Φ^*) and then to express each component of chosen eigenfunctions by related components of ϕ and ψ. This last step for binary symmetry constraints is carried out according to the following.

Lemma 1:[18] *Let $U(u,\lambda)$ be a square matrix of order r depending on $u,u_x,\dots$ and a parameter λ. Suppose that $\phi = (\phi_1,\phi_2,\dots,\phi_r)^T$, $\psi = (\psi_1,\psi_2,\dots,\psi_r)^T$ satisfy the spectral problem and the adjoint spectral problem*

$$\phi_x = U(u,\lambda)\phi, \quad \psi_x = -U^T(u,\lambda)\psi,$$

and set the matrix $\overline{V} = \phi\psi^T = (\phi_k\psi_l)_{r\times r}$. Then

(i) the variational derivative of the spectral parameter λ *with respect to the potential* u *can be expressed, up to a normalized constant, by*

$$\frac{\delta\lambda}{\delta u}=tr(\overline{V}\partial U/\partial u), \tag{8}$$

(ii) the matrix $\overline{V}$ *is a solution of the adjoint representation equation* $V_x=[U,V]$, *i.e.,* $\overline{V}_x=[U,\overline{V}]$.

Restriction of K_0, i.e., the simplest symmetry from the hierarchy, to a finite sum of eigenfunctions of the recursion operator allows us to express u through these eigenfunctions. Let $\tilde{u}(\phi,\psi)$ denote such a restricted potential u. Introducing N distinct eigenvalues $\lambda_1,\lambda_2,\ldots,\lambda_N$, the nth Lax pair (3) and its adjoint (6) become

$$\begin{aligned}\phi_{ix}&=U(\tilde{u},\lambda_i)\phi_i, \quad i=1,\ldots,N,\\ \psi_{ix}&=-U^T(\tilde{u},\lambda_i)\psi_i, \quad i=1,\ldots,N,\end{aligned} \tag{9}$$

$$\begin{aligned}\phi_{it_n}&=V^{(n)}(\tilde{u},\lambda_i)\phi_i, \quad i=1,\ldots,N,\\ \psi_{it_n}&=-(V^{(n)})^T(\tilde{u},\lambda_i)\psi_i, \quad i=1,\ldots,N.\end{aligned} \tag{10}$$

The compatibility condition of (9) and (10) is still the nth PDE system $\tilde{u}_{t_n}=K_n[\tilde{u}]$, but now systems (9) and (10) turn into finite-dimensional Hamiltonian systems with constant coefficient symplectic forms. Hence, such a procedure factorizes a given system of PDEs into two systems of ordinary differential equations (ODEs). Solving simultaneously both systems of ODEs, we get immediately a solution of the related PDE.

III. BINARY SYMMETRY CONSTRAINTS OF THE AKNS SYSTEMS

In the following section we illustrate the factorization procedure by binary symmetry constraints on the example of the AKNS hierarchy. These results will be important for our further considerations, when we present a factorization procedure by a new type of binary symmetry constraint which leads to noncanonical Hamiltonian systems with variable coefficient symplectic forms.

A. The case of 2×2 matrix spectral problem

Consider the AKNS 2×2 matrix spectral problem[23]

$$\phi_x=U\phi, \quad U=U(u,\lambda)=\begin{pmatrix}-\lambda & q\\ r & \lambda\end{pmatrix}, \quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}, \quad u=\begin{pmatrix}q\\ r\end{pmatrix}. \tag{11}$$

Take

$$V=\begin{pmatrix}a & b\\ c & -a\end{pmatrix}=\sum_{i=0}^{\infty}\begin{pmatrix}a_i & b_i\\ c_i & -a_i\end{pmatrix}\lambda^{-i} \tag{12}$$

and

$$\phi_{t_n}=V^{(n)}(u,\lambda)\phi, \quad V^{(n)}=\sum_{i=0}^{n}\begin{pmatrix}a_i & b_i\\ c_i & -a_i\end{pmatrix}\lambda^{n-i}. \tag{13}$$

The adjoint representation equation $V_x=[U,V]$ gives

$$a_0=-1,\quad b_0=c_0=0,\quad a_1=0,\quad b_1=q,\quad c_1=r,\quad a_2=\tfrac{1}{2}qr,\quad \ldots\begin{pmatrix}c_{k+1}\\ b_{k+1}\end{pmatrix}=\Phi^*\begin{pmatrix}c_k\\ b_k\end{pmatrix},$$

$$a_k=\partial^{-1}(qc_k-rb_k),\quad k=1,2,\ldots, \tag{14}$$

$$\Phi^*=\frac{1}{2}\begin{pmatrix}\partial-2r\partial^{-1}q & 2r\partial^{-1}r\\ -2q\partial^{-1}q & -\partial+2q\partial^{-1}r\end{pmatrix},\quad \partial=\frac{\partial}{\partial x},\quad \partial\partial^{-1}=\partial^{-1}\partial=1.$$

The AKNS hierarchy associated with (11) and (13) takes the form[24]

$$u_{t_n}=\begin{pmatrix}q\\ r\end{pmatrix}_{t_n}=\pi(\Phi^*)^n\begin{pmatrix}r\\ q\end{pmatrix}=\pi\frac{\delta\tilde{H}_n}{\delta u},\quad n\geqslant 0, \tag{15}$$

where

$$\pi=\begin{pmatrix}0 & -2\\ 2 & 0\end{pmatrix},\quad \tilde{H}_n=\int\frac{2}{n+1}a_{n+2}dx,\quad \begin{pmatrix}c_{n+1}\\ b_{n+1}\end{pmatrix}=\frac{\delta\tilde{H}_n}{\delta u},\quad n\geqslant 0.$$

For $n=2$ we have

$$V^{(1)}=\begin{pmatrix}-\lambda & q\\ r & \lambda\end{pmatrix}\equiv U,\quad V^{(2)}=\begin{pmatrix}-\lambda^2+\frac{1}{2}qr & q\lambda-\frac{1}{2}q_x\\ r\lambda+\frac{1}{2}r_x & \lambda^2-\frac{1}{2}qr\end{pmatrix}, \tag{16}$$

and zero curvature conditions (7) give $n=2$ AKNS systems (15):

$$\begin{aligned}q_{t_2}&=-\tfrac{1}{2}q_{xx}+q^2r,\\ r_{t_2}&=\tfrac{1}{2}r_{xx}-r^2q.\end{aligned} \tag{17}$$

According to Lemma 1, we have[13]

$$\frac{\delta\lambda}{\delta u}=\begin{pmatrix}\delta\lambda/\delta q\\ \delta\lambda/\delta r\end{pmatrix}=tr\left[\begin{pmatrix}\phi_1\psi_1 & \phi_1\psi_2\\ \phi_2\psi_1 & \phi_2\psi_2\end{pmatrix}\frac{\partial U(u,\lambda)}{\partial u}\right]=\begin{pmatrix}\phi_2\psi_1\\ \phi_1\psi_2\end{pmatrix}, \tag{18}$$

which should be read componentwise. Moreover, one can verify that under $\phi_x=U\phi$, $\psi_x=-U^T\psi$, we have

$$\Phi^*\begin{pmatrix}\phi_2\psi_1\\ \phi_1\psi_2\end{pmatrix}=\lambda\begin{pmatrix}\phi_2\psi_1\\ \phi_1\psi_2\end{pmatrix}+I\begin{pmatrix}\phi_2\psi_1\\ \phi_1\psi_2\end{pmatrix},\quad I=\frac{1}{2}\phi_1\psi_1-\frac{1}{2}\phi_2\psi_2, \tag{19}$$

where I is an integral of motion of $\phi_x=U\phi$, $\psi_x=-U^T\psi$.

Binary symmetry constraints are determined by[13,25]

$$\frac{\delta H_k}{\delta u}=\begin{pmatrix}c_{k+1}\\ b_{k+1}\end{pmatrix}=\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}=\begin{pmatrix}\langle Q_2,P_1\rangle\\ \langle Q_1,P_2\rangle\end{pmatrix}. \tag{20}$$

Hereafter we denote the inner product in R^N by $\langle .,.\rangle$ and

$$Q_i=(\phi_{i1},\ldots,\phi_{iN})^T,\quad P_i=(\psi_{i1},\ldots,\psi_{iN})^T,\quad i=1,2. \tag{21}$$

The simplest binary constraint for $k=0$ gives

$$\frac{\delta H_0}{\delta u}=\begin{pmatrix} c_1 \\ b_1 \end{pmatrix}=\begin{pmatrix} \langle Q_2,P_1\rangle \\ \langle Q_1,P_2\rangle \end{pmatrix}=\begin{pmatrix} r \\ q \end{pmatrix}. \tag{22}$$

Under constraint (22), for arbitrary n, and for N distinct eigenvalues $\lambda_1,\ldots,\lambda_N$, the nth Lax pair (9) and its adjoint (10),

$$\begin{aligned} &\begin{pmatrix} \phi_{1j} \\ \phi_{2j} \end{pmatrix}_x = U(\tilde{u},\lambda_j)\begin{pmatrix} \phi_{1j} \\ \phi_{2j} \end{pmatrix}, \quad j=1,\ldots,N, \\ &\begin{pmatrix} \psi_{1j} \\ \psi_{2j} \end{pmatrix}_x = -U^T(\tilde{u},\lambda_j)\begin{pmatrix} \psi_{1j} \\ \psi_{2j} \end{pmatrix}, \quad j=1,\ldots,N, \end{aligned} \tag{23}$$

$$\begin{aligned} &\begin{pmatrix} \phi_{1j} \\ \phi_{2j} \end{pmatrix}_{t_n} = V^{(n)}(\tilde{u},\lambda_j)\begin{pmatrix} \phi_{1j} \\ \phi_{2j} \end{pmatrix}, \quad j=1,\ldots,N, \\ &\begin{pmatrix} \psi_{1j} \\ \psi_{2j} \end{pmatrix}_{t_n} = -(V^{(n)})^T(\tilde{u},\lambda_j)\begin{pmatrix} \psi_{1j} \\ \psi_{2j} \end{pmatrix}, \quad j=1,\ldots,N, \end{aligned} \tag{24}$$

become two finite-dimensional Hamiltonian systems with constant coefficient symplectic forms, with evolution parameters $t_1=x$ and t_n, respectively. $2N$ pairs of canonical coordinates are given by $(\phi_{1j},\psi_{1j})_{j=1}^N$, $(\phi_{2j},\psi_{2j})_{j=1}^N$. For x-evolution we have

$$\begin{aligned} &Q_{1x}=\frac{\partial H_1}{\partial P_1}, \quad Q_{2x}=\frac{\partial H_1}{\partial P_2}, \quad P_{1x}=-\frac{\partial H_1}{\partial Q_1}, \quad P_{2x}=-\frac{\partial H_1}{\partial Q_2}, \quad x=t_1, \\ &H_1=\langle AP_2,Q_2\rangle-\langle AP_1,Q_1\rangle+\langle P_2,Q_1\rangle\langle P_1,Q_2\rangle, \end{aligned} \tag{25}$$

and for t_2-evolution

$$\begin{aligned} &Q_{1t_2}=\frac{\partial H_2}{\partial P_1}, \quad Q_{2t_2}=\frac{\partial H_2}{\partial P_2}, \quad P_{1t_2}=-\frac{\partial H_2}{\partial Q_1}, \quad P_{2t_2}=-\frac{\partial H_2}{\partial Q_2}, \\ &H_2=\langle A^2P_2,Q_2\rangle-\langle A^2P_1,Q_1\rangle+\langle P_2,Q_1\rangle\langle AP_1,Q_2\rangle+\langle AP_2,Q_1\rangle\langle P_1,Q_2\rangle-\tfrac{1}{2}(\langle P_2,Q_2\rangle \\ &\quad -\langle P_1,Q_1\rangle)\langle P_2,Q_1\rangle\langle P_1,Q_2\rangle. \end{aligned} \tag{26}$$

Hence, t_2-AKNS PDE (17) is factorized by two ODE systems (25) and (26). For $N=1$ one finds

$$\begin{aligned} \phi_{1x}&=-\lambda\phi_1+\phi_1\phi_2\psi_2, \\ \phi_{2x}&=\lambda\phi_2+\phi_1\phi_2\psi_1, \\ \psi_{1x}&=\lambda\psi_1-\phi_2\psi_1\psi_2, \\ \psi_{2x}&=-\lambda\psi_2-\phi_1\psi_1\psi_2, \end{aligned} \tag{27}$$

$$\begin{aligned} \phi_{1t_2}&=-\lambda^2\phi_1+2\lambda\phi_1\phi_2\psi_2+\phi_1^2\phi_2\psi_1\psi_2-\tfrac{1}{2}\phi_1\phi_2^2\psi_2^2, \\ \phi_{2t_2}&=\lambda^2\phi_2+2\lambda\phi_1\phi_2\psi_1-\phi_1\phi_2^2\psi_1\psi_2+\tfrac{1}{2}\phi_1^2\phi_2\psi_1^2, \end{aligned} \tag{28}$$

$$\psi_{1t_2}=\lambda^2\psi_1-2\lambda\phi_2\psi_1\psi_2-\phi_1\phi_2\psi_1^2\psi_2+\tfrac{1}{2}\phi_2^2\psi_1\psi_2^2,$$

$$\psi_{2t_2}=-\lambda^2\psi_2-2\lambda\phi_1\psi_1\psi_2+\phi_1\phi_2\psi_1\psi_2^2-\tfrac{1}{2}\phi_1^2\psi_1^2\psi_2,$$

and it is easy to verify that for any solution $(\phi_1,\phi_2,\psi_1,\psi_2)$ of two ODE systems (27) and (28) $\tilde{q}=\phi_1\psi_2$, $\tilde{r}=\phi_2\psi_1$ is a solution of the PDE system

$$\begin{aligned}\tilde{q}_{t_2}&=-\tfrac{1}{2}\tilde{q}_{xx}+\tilde{q}^2\tilde{r},\\ \tilde{r}_{t_2}&=\tfrac{1}{2}\tilde{r}_{xx}-\tilde{r}^2\tilde{q}.\end{aligned}\tag{29}$$

Both systems (25) and (26) belong to the same family of Liouville integrable systems.

As shown in Ref. 13, there is a natural set of integrals of motion generated by the relation

$$F_x=\left(\frac{1}{2}trV^2\right)_x=\frac{d}{dx}(a^2+bc)=0,\tag{30}$$

i.e., F is a generating function of integrals of motion for (25). After setting $F=\Sigma_{n\geqslant 0}F_n\lambda^{-n}$, we obtain the following expressions:

$$\begin{aligned}F_1&=-2a_1=\langle P_2,Q_2\rangle-\langle P_1,Q_1\rangle,\\ F_n&=\sum_{i=1}^{n-1}(a_ia_{n-i}+b_ic_{n-i})-2a_n\\ &=\langle A^{n-1}P_2,Q_2\rangle-\langle A^{n-1}P_1,Q_1\rangle\\ &\quad+\sum_{i=1}^{n-1}\left[\frac{1}{4}(\langle A^{i-1}P_1,Q_1\rangle-\langle A^{i-1}P_2,Q_2\rangle)(\langle A^{n-i-1}P_1,Q_1\rangle\right.\\ &\quad\left.-\langle A^{n-i-1}P_2,Q_2\rangle)+\langle A^{i-1}P_2,Q_1\rangle\langle A^{n-i-1}P_1,Q_2\rangle\right].\end{aligned}\tag{31}$$

Integrals of motion (31) are closely related to the zero boundary condition imposed on ϕ and ψ: $\lim_{|x|\to\infty}\phi_i=\lim_{|x|\to\infty}\psi_i=0$, $i=1,2$. Actually, one can then verify that

$$\Phi^*\begin{pmatrix}\phi_2\psi_1\\ \phi_1\psi_2\end{pmatrix}=\lambda\begin{pmatrix}\phi_2\psi_1\\ \phi_1\psi_2\end{pmatrix},\tag{32}$$

and under the constraint (22) we have

$$\begin{pmatrix}c_{n+1}\\ b_{n+1}\end{pmatrix}=(\Phi^*)^n\begin{pmatrix}c_1\\ b_1\end{pmatrix}=\begin{pmatrix}\langle A^nQ_2,P_1\rangle\\ \langle A^nQ_1,P_2\rangle\end{pmatrix},\tag{33}$$

where $A=\mathrm{diag}(\lambda_1,\ldots,\lambda_N)$, and thus

$$a_{n+1}=\partial^{-1}(qc_{n+1}-rb_{n+1})=\tfrac{1}{2}(\langle A^nP_1,Q_1\rangle-\langle A^nP_2,Q_2\rangle).\tag{34}$$

All Hamiltonian functions H_n are expressible through the F_k ones[13]

$$H_n=\sum_{m=0}^{n}\frac{d_m}{m+1}\sum_{i_1+\ldots+i_{m+1}=n+1}F_{i_1}\cdots F_{i_{m+1}},\quad i_1,\ldots,i_{m+1}\geqslant 1,\quad n\geqslant 0,\tag{35}$$

where constants d_m are defined by

$$d_0=1,\quad d_1=-\frac{1}{2},\quad d_2=\frac{3}{8},\quad d_m=-d_{m-1}-\frac{1}{2}\sum_{s=1}^{m-2} d_s d_{m-s-1}-\frac{1}{2}\sum_{s=1}^{m-1} d_s d_{m-s},\quad m\geqslant 3. \tag{36}$$

For example $H_1=F_2-\frac{1}{4}F_1^2$, $H_2=F_3-\frac{1}{2}F_1F_2+\frac{1}{8}F_1^3,\ldots$. Notice that $I=-\frac{1}{2}F_1$. The involutivity and functional independence of one of two sets $\{F_n\}_{n=1}^N$, $\{H_n\}_{n=1}^N$ results in the same properties of another one. Moreover, there exists an additional set of N integrals of motion

$$f_k=\phi_{1k}\psi_{1k}+\phi_{2k}\psi_{2k},\quad k=1,\ldots,N. \tag{37}$$

The set of $2N$ functions $(f_k,H_k)_{k=1}^N$ is functionally independent and all functions are in involution,[13] and hence all systems (23) and (24) are Liouville integrable. Moreover, as demonstrated in Refs. 26–28, they are also separable, so again integrable by quadratures, and give rise to explicit solutions to the related PDE systems.

B. The case of 3×3 matrix spectral problem

As was demonstrated in Ref. 18, the AKNS hierarchy can also be reconstructed from the following 3×3 matrix spectral problem:

$$\tilde{\phi}_x=\begin{pmatrix}\tilde{\phi}_1\\ \tilde{\phi}_2\\ \tilde{\phi}_3\end{pmatrix}_x=U(u\lambda)\begin{pmatrix}\tilde{\phi}_1\\ \tilde{\phi}_2\\ \tilde{\phi}_3\end{pmatrix}=\begin{pmatrix}-2\lambda & \sqrt{2}q & 0\\ \sqrt{2}r & 0 & \sqrt{2}q\\ 0 & \sqrt{2}r & 2\lambda\end{pmatrix}\begin{pmatrix}\tilde{\phi}_1\\ \tilde{\phi}_2\\ \tilde{\phi}_3\end{pmatrix}. \tag{38}$$

The standard procedure with

$$V=\begin{pmatrix}-2a & \sqrt{2}b & 0\\ \sqrt{2}c & 0 & \sqrt{2}b\\ 0 & \sqrt{2}c & 2a\end{pmatrix}=\sum_{i=0}^{\infty}\begin{pmatrix}-2a_i & \sqrt{2}b_i & 0\\ \sqrt{2}c_i & 0 & \sqrt{2}b_i\\ 0 & \sqrt{2}c_i & 2a_i\end{pmatrix}\lambda^{-i} \tag{39}$$

generates again the hierarchy (14) and (15), but binary symmetry constraints lead to another factorization, i.e., another Liouville integrable Hamiltonian system with constant coefficient symplectic forms, and, as a consequence, to a new class of solutions of the underlying AKNS systems.

Let us briefly sketch the results of Ref. 18. Following Lemma 1, for the zero boundary conditions imposed on $\tilde{\phi}$ and $\tilde{\psi}$ functions, we have the variational derivative of the spectral parameter for the spectral problem (38) and its adjoint given by

$$\frac{\delta\lambda}{\delta q}=\sqrt{2}(\tilde{\phi}_2\tilde{\psi}_1+\tilde{\phi}_3\tilde{\psi}_2),\quad \frac{\delta\lambda}{\delta r}=\sqrt{2}(\tilde{\phi}_1\tilde{\psi}_2+\tilde{\phi}_2\tilde{\psi}_3). \tag{40}$$

The simplest binary constraint (20) with $k=0$ takes the form

$$\begin{pmatrix}c_1\\ b_1\end{pmatrix}=\sqrt{2}\begin{pmatrix}\langle\tilde{P}_1,\tilde{Q}_2\rangle+\langle\tilde{P}_2,\tilde{Q}_3\rangle\\ \langle\tilde{P}_2,\tilde{Q}_1\rangle+\langle\tilde{P}_3,\tilde{Q}_2\rangle\end{pmatrix}=\begin{pmatrix}\tilde{r}\\ \tilde{q}\end{pmatrix}, \tag{41}$$

and, hence, using (38)

$$\Phi^*\begin{pmatrix}\sqrt{2}(\tilde{\phi}_2\tilde{\psi}_1+\tilde{\phi}_3\tilde{\psi}_2)\\ \sqrt{2}(\tilde{\phi}_1\tilde{\psi}_2+\tilde{\phi}_2\tilde{\psi}_3)\end{pmatrix}=\lambda\begin{pmatrix}\sqrt{2}(\tilde{\phi}_2\tilde{\psi}_1+\tilde{\phi}_3\tilde{\psi}_2)\\ \sqrt{2}(\tilde{\phi}_1\tilde{\psi}_2+\tilde{\phi}_2\tilde{\psi}_3)\end{pmatrix}+I\begin{pmatrix}\sqrt{2}(\tilde{\phi}_2\tilde{\psi}_1+\tilde{\phi}_3\tilde{\psi}_2)\\ \sqrt{2}(\tilde{\phi}_1\tilde{\psi}_2+\tilde{\phi}_2\tilde{\psi}_3)\end{pmatrix}, \tag{42}$$

$I=\tilde{\phi}_1\tilde{\psi}_1-\tilde{\phi}_3\tilde{\psi}_3$, where again $\langle .,.\rangle$ denotes the standard inner product of R^N and

$$\begin{pmatrix} \tilde{Q}_i \\ \tilde{P}_i \end{pmatrix} = \begin{pmatrix} (\tilde{\phi}_{i1}, \ldots, \tilde{\phi}_{iN})^T \\ (\tilde{\psi}_{i1}, \ldots, \tilde{\psi}_{iN})^T \end{pmatrix}, \quad i = 1,2,3. \tag{43}$$

The substitution of (41) and (38) into the corresponding Lax equations (9) and (10) yields a hierarchy of finite-dimensional Hamiltonian systems with constant coefficient symplectic forms for $n \geqslant 1$:

$$\begin{aligned} \begin{pmatrix} \tilde{\phi}_{1j} \\ \tilde{\phi}_{2j} \\ \tilde{\phi}_{3j} \end{pmatrix}_{t_n} &= V^{(n)}(\tilde{u}, \lambda_j) \begin{pmatrix} \tilde{\phi}_{1j} \\ \tilde{\phi}_{2j} \\ \tilde{\phi}_{3j} \end{pmatrix}, \quad j = 1, \ldots, N, \\ \begin{pmatrix} \tilde{\psi}_{1j} \\ \tilde{\psi}_{2j} \\ \tilde{\psi}_{3j} \end{pmatrix}_{t_n} &= -(V^{(n)})^T(\tilde{u}, \lambda_j) \begin{pmatrix} \tilde{\psi}_{1j} \\ \tilde{\psi}_{2j} \\ \tilde{\psi}_{3j} \end{pmatrix}, \quad j = 1, \ldots, N. \end{aligned} \tag{44}$$

For example, for $t_1 = x$,

$$\tilde{H}_1 = -2(\langle A\tilde{P}_1, \tilde{Q}_1\rangle - \langle A\tilde{P}_3, \tilde{Q}_3\rangle) + 2(\langle \tilde{P}_1, \tilde{Q}_2\rangle + \langle \tilde{P}_2, \tilde{Q}_3\rangle)(\langle \tilde{P}_2, \tilde{Q}_1\rangle + \langle \tilde{P}_3, \tilde{Q}_2\rangle), \tag{45}$$

and for t_2

$$\begin{aligned} H_2 = &-2(\langle A^2\tilde{P}_1, \tilde{Q}_1\rangle - \langle A^2\tilde{P}_3, \tilde{Q}_3\rangle) + 2(\langle A\tilde{P}_1, \tilde{Q}_2\rangle + \langle A\tilde{P}_2, \tilde{Q}_3\rangle)(\langle \tilde{P}_2, \tilde{Q}_1\rangle + \langle \tilde{P}_3, \tilde{Q}_2\rangle) \\ &+ 2(\langle \tilde{P}_1, \tilde{Q}_2\rangle + \langle \tilde{P}_2, \tilde{Q}_3\rangle)(\langle A\tilde{P}_2, \tilde{Q}_1\rangle + \langle A\tilde{P}_3, \tilde{Q}_2\rangle) + 2(\langle \tilde{P}_1, \tilde{Q}_2\rangle + \langle \tilde{P}_2, \tilde{Q}_3\rangle)(\langle \tilde{P}_2, \tilde{Q}_1\rangle \\ &+ \langle \tilde{P}_3, \tilde{Q}_2\rangle)(\langle \tilde{P}_1, \tilde{Q}_1\rangle - \langle \tilde{P}_3, \tilde{Q}_3\rangle). \end{aligned} \tag{46}$$

Hence, t_2-AKNS PDE system (17) is again factorized by two ODE systems (44)–(46).

For $N = 1$ one finds

$$\begin{aligned} \tilde{\phi}_{1x} &= -2\lambda\tilde{\phi}_1 + 2\tilde{\phi}_2(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3), \\ \tilde{\phi}_{2x} &= 2\tilde{\phi}_3(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3) + 2\tilde{\phi}_1(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2), \\ \tilde{\phi}_{3x} &= 2\lambda\tilde{\phi}_3 + 2\tilde{\phi}_2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2), \\ \tilde{\psi}_{1x} &= 2\lambda\tilde{\psi}_1 - 2\tilde{\psi}_2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2), \\ \tilde{\psi}_{2x} &= -2\tilde{\psi}_1(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3) - 2\tilde{\psi}_3(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2), \\ \tilde{\psi}_{3x} &= -2\lambda\tilde{\psi}_3 - 2\tilde{\psi}_2(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3), \end{aligned} \tag{47}$$

and

$$\begin{aligned} \tilde{\phi}_{1t_2} = &-2\lambda^2\tilde{\phi}_1 + 4\lambda(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)\tilde{\phi}_2 + 2(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)(\tilde{\phi}_1\tilde{\psi}_1 - \tilde{\phi}_3\tilde{\psi}_3)\tilde{\phi}_2 \\ &+ 2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)\tilde{\phi}_1, \\ \tilde{\phi}_{2t_2} = &\,4\lambda(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)\tilde{\phi}_1 + 4\lambda(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)\tilde{\phi}_3 + 2(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)(\tilde{\phi}_1\tilde{\psi}_1 - \tilde{\phi}_3\tilde{\psi}_3)\tilde{\phi}_3 \\ &+ 2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)(\tilde{\phi}_1\tilde{\psi}_1 - \tilde{\phi}_3\tilde{\psi}_3)\tilde{\phi}_1, \end{aligned}$$

$$
\begin{aligned}
\tilde{\phi}_{3t_2} &= 2\lambda^2\tilde{\phi}_3 + 4\lambda(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)\tilde{\phi}_2 + 2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)(\tilde{\phi}_1\tilde{\psi}_1 - \tilde{\phi}_3\tilde{\psi}_3)\tilde{\phi}_2 \\
&\quad - 2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)\tilde{\phi}_3, \\
\tilde{\psi}_{1t_2} &= 2\lambda^2\tilde{\psi}_1 - 4\lambda(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)\tilde{\psi}_2 - 2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)(\tilde{\phi}_1\tilde{\psi}_1 - \tilde{\phi}_3\tilde{\psi}_3)\tilde{\psi}_2 \\
&\quad - 2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)\tilde{\psi}_1, \\
\tilde{\psi}_{2t_2} &= -4\lambda(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)\tilde{\psi}_3 - 4\lambda(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)\tilde{\psi}_1 - 2(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)(\tilde{\phi}_1\tilde{\psi}_1 - \tilde{\phi}_3\tilde{\psi}_3)\tilde{\psi}_1 \\
&\quad - 2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)(\tilde{\phi}_1\tilde{\psi}_1 - \tilde{\phi}_3\tilde{\psi}_3)\tilde{\psi}_3, \\
\tilde{\psi}_{3t_2} &= -2\lambda^2\tilde{\psi}_3 - 4\lambda(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)\tilde{\psi}_2 - 2(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)(\tilde{\phi}_1\tilde{\psi}_1 - \tilde{\phi}_3\tilde{\psi}_3)\tilde{\psi}_2 \\
&\quad + 2(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)\tilde{\psi}_3,
\end{aligned}
\tag{48}
$$

and it is not difficult to verify that for an arbitrary solution $(\tilde{\phi}_1, \tilde{\phi}_2, \tilde{\phi}_3, \tilde{\psi}_1, \tilde{\psi}_2, \tilde{\psi}_3)$ of two ODE systems (47) and (48), $\tilde{q} = \sqrt{2}(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3)$, $\tilde{r} = \sqrt{2}(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2)$ is a solution of the PDE system (29). The integrals of motion (30), expressed by $\tilde{Q}, \tilde{P}$ coordinates, are

$$
\begin{aligned}
\tilde{F}_1 &= 2(\langle \tilde{P}_3, \tilde{Q}_3\rangle - \langle \tilde{P}_1, \tilde{Q}_1\rangle), \\
\tilde{F}_n &= 2(\langle A^{n-1}\tilde{P}_3, \tilde{Q}_3\rangle - \langle A^{n-1}\tilde{P}_1, \tilde{Q}_1\rangle) + \sum_{i=1}^{n-1} [(\langle A^{i-1}\tilde{P}_3, \tilde{Q}_3\rangle - \langle A^{i-1}\tilde{P}_1, \tilde{Q}_1\rangle)(\langle A^{n-i-1}\tilde{P}_3, \tilde{Q}_3\rangle \\
&\quad - \langle A^{n-i-1}\tilde{P}_1, \tilde{Q}_1\rangle) + 2(\langle A^{i-1}\tilde{P}_2, \tilde{Q}_1\rangle + \langle A^{i-1}\tilde{P}_3, \tilde{Q}_2\rangle)(\langle A^{n-i-1}\tilde{P}_1, \tilde{Q}_2\rangle \\
&\quad + \langle A^{n-i-1}\tilde{P}_2, \tilde{Q}_3\rangle)],
\end{aligned}
\tag{49}
$$

and again $I = -\frac{1}{2}\tilde{F}_1$. Integrals (49) are related to the zero boundary condition imposed on $\tilde{\phi}$ and $\tilde{\psi}$ which leads to the following relations:

$$
\Phi^* \begin{pmatrix} \sqrt{2}(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2) \\ \sqrt{2}(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3) \end{pmatrix} = \lambda \begin{pmatrix} \sqrt{2}(\tilde{\phi}_2\tilde{\psi}_1 + \tilde{\phi}_3\tilde{\psi}_2) \\ \sqrt{2}(\tilde{\phi}_1\tilde{\psi}_2 + \tilde{\phi}_2\tilde{\psi}_3) \end{pmatrix}, \tag{50}
$$

$$
\begin{aligned}
a_{i+1} &= \langle A^i\tilde{P}_1, \tilde{Q}_1\rangle - \langle A^i\tilde{P}_3, \tilde{Q}_3\rangle, \quad i \geq 0, \\
b_{i+1} &= \sqrt{2}(\langle A^i\tilde{P}_2, \tilde{Q}_1\rangle + \langle A^i\tilde{P}_3, \tilde{Q}_2\rangle), \quad i \geq 0, \\
c_{i+1} &= \sqrt{2}(\langle A^i\tilde{P}_1, \tilde{Q}_2\rangle + \langle A^i\tilde{P}_2, \tilde{Q}_3\rangle), \quad i \geq 0.
\end{aligned}
\tag{51}
$$

Again all Hamiltonian functions $\tilde{H}_n$ are expressible through the $\tilde{F}_k$ ones according to formulas (35) and (36). For example, $\tilde{H}_1 = \tilde{F}_2 - \frac{1}{4}\tilde{F}_1^2$, $\tilde{H}_2 = \frac{1}{4}\tilde{F}_3 - \frac{1}{2}\tilde{F}_1\tilde{F}_2 + \frac{1}{8}\tilde{F}_1^3, \ldots$. Moreover, there exists an additional set of N integrals of motion

$$
\tilde{f}_k = \tilde{\phi}_{1k}\tilde{\psi}_{1k} + \tilde{\phi}_{2k}\tilde{\psi}_{2k} + \tilde{\phi}_{3k}\tilde{\psi}_{3k}, \quad k = 1, \ldots, N. \tag{52}
$$

As was shown in Ref. 18, the set of $3N$ functions $(\tilde{f}_k)_{k=1}^N$, $(\tilde{H}_k)_{k=1}^{2N}$ is functionally independent and all functions are in involution, hence all systems (44) with $n \geq 1$ are Liouville integrable. Separability of these systems leads to a new class of solutions of the underlying PDEs.

IV. NEW LIOUVILLE INTEGRABLE NONCANONICAL HAMILTONIAN SYSTEMS

The importance of factorization of a given PDE system into two integrable Hamiltonian ODE systems makes the procedure of binary nonlinearization worth further investigation. A natural question arises, whether in the frames of the formalism presented one can find another factorization, different from those found till now. Of course one possibility is to search for a higher order matrix Lax representation and stay inside a binary symmetry constraint yielding integrable Hamiltonian systems with constant coefficient symplectic forms. Another one is to go beyond such a symmetry constraint. Let us come back again to the AKNS 2×2 matrix Lax representation. According to Lemma 1, we found that $(\phi_2\psi_1,\phi_1\psi_2)^T$ is an AKNS symmetry constraint. On the other hand, we also know that $f=\phi_1\psi_1+\phi_2\psi_2$ is an integral of motion $\phi_x=U\phi$, $\psi_x=-U^T\psi$, i.e., $f_x=0$. So, it is not difficult to verify that

$$\frac{\delta\lambda}{\delta u}=\begin{pmatrix}\delta\lambda/\delta q\\ \delta\lambda/\delta r\end{pmatrix}=\begin{pmatrix}2\phi_2\psi_1 f\\ 2\phi_1\psi_2 f\end{pmatrix}=\begin{pmatrix}2\phi_2\psi_1(\phi_1\psi_1+\phi_2\psi_2)\\ 2\phi_1\psi_2(\phi_1\psi_1+\phi_2\psi_2)\end{pmatrix} \tag{53}$$

is again an admissible symmetry constraint and for the zero boundary condition case it is also an eigenfunction of Φ^* with an eigenvalue λ. The constant 2 was chosen for further convenience. Let us factorize the AKNS hierarchy with respect to the constraint (53). Denoting

$$XY=(x_1y_1,\ldots,x_Ny_N)^T,\quad \text{if } X=(x_1,\ldots,x_N)^T,\quad Y=(y_1,\ldots,y_N)^T, \tag{54}$$

the simplest symmetry constraint takes the form

$$\frac{\delta H_0}{\delta u}=\begin{pmatrix}r\\ q\end{pmatrix}=\begin{pmatrix}c_1\\ b_1\end{pmatrix}=\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}=\begin{pmatrix}2(\langle Q_2^2,P_1P_2\rangle+\langle P_1^2,Q_1Q_2\rangle)\\ 2(\langle Q_1^2,P_1P_2\rangle+\langle P_2^2,Q_1Q_2\rangle)\end{pmatrix}. \tag{55}$$

Under the substitution (55), for N distinct eigenvalues $\lambda_1,\ldots,\lambda_N$, the $t_1=x$ spectral problem (11) and its adjoint take the form of finite-dimensional dynamical system (23), which is equivalent to the following one

$$\begin{aligned}
\phi_{1i,x}&=-\lambda_i\phi_{1i}+2\sum_{j=1}^{N}[\phi_{1j}\psi_{2j}(\phi_{1j}\psi_{1j}+\phi_{2j}\psi_{2j})]\phi_{2i},\quad i=1,\ldots,N,\\
\phi_{2i,x}&=\lambda_i\phi_{2i}+2\sum_{j=1}^{N}[\phi_{2j}\psi_{1j}(\phi_{1j}\psi_{1j}+\phi_{2j}\psi_{2j})]\phi_{1i},\quad i=1,\ldots,N,\\
\psi_{1i,x}&=\lambda_i\psi_{1i}-2\sum_{j=1}^{N}[\phi_{2j}\psi_{1j}(\phi_{1j}\psi_{1j}+\phi_{2j}\psi_{2j})]\psi_{2i},\quad i=1,\ldots,N,\\
\psi_{2i,x}&=-\lambda_i\psi_{2i}-2\sum_{j=1}^{N}[\phi_{1j}\psi_{2j}(\phi_{1j}\psi_{1j}+\phi_{2j}\psi_{2j})]\psi_{1i},\quad i=1,\ldots,N.
\end{aligned} \tag{56}$$

Contrary to the cases from the previous section, this system has no Hamiltonian structure with constant coefficient symplectic forms.[29] Actually, the system (56) was considered recently in Ref. 29, where the authors confirmed the nonexistence of some class of constant coefficient Poisson structures. As we will show later, this considered system has a coordinate dependent Poisson structure. In fact, such a Poisson structure can be attached to any finite-dimensional dynamical system (24) constructed from t_n spectral problem (13) and its adjoint, under the constraint (55).

For $N=1,t_n=t_1=x$ and $t_n=t_2$, one finds respectively

$$\begin{aligned}
\phi_{1x} &= -\lambda\phi_1 + 2\phi_1\phi_2\psi_2(\phi_1\psi_1 + \phi_2\psi_2),\\
\phi_{2x} &= \lambda\phi_2 + 2\phi_1\phi_2\psi_1(\phi_1\psi_1 + \phi_2\psi_2),\\
\psi_{1x} &= \lambda\psi_1 - 2\phi_2\psi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2),\\
\psi_{2x} &= -\lambda\psi_2 - 2\phi_1\psi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2),
\end{aligned} \tag{57}$$

and

$$\begin{aligned}
\phi_{1t} &= -\lambda^2\phi_1 + 4\lambda\phi_1\phi_2\psi_2(\phi_1\psi_1 + \phi_2\psi_2) + 4\phi_1^2\phi_2\psi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2)^2\\
&\quad - 2\phi_1\phi_2^2\psi_2^2(\phi_1\psi_1 + \phi_2\psi_2)^2,\\
\phi_{2t} &= \lambda^2\phi_2 + 4\lambda\phi_1\phi_2\psi_1(\phi_1\psi_1 + \phi_2\psi_2) - 4\phi_1\phi_2^2\psi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2)^2\\
&\quad + 2\phi_1^2\phi_2\psi_1^2(\phi_1\psi_1 + \phi_2\psi_2)^2,\\
\psi_{1t} &= \lambda^2\psi_1 - 4\lambda\phi_2\psi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2) - 4\phi_1\phi_2\psi_1^2\psi_2(\phi_1\psi_1 + \phi_2\psi_2)^2\\
&\quad + 2\phi_2^2\psi_1\psi_2^2(\phi_1\psi_1 + \phi_2\psi_2)^2,\\
\psi_{2t} &= -\lambda^2\psi_2 - 4\lambda\phi_1\psi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2) + 4\phi_1\phi_2\psi_1\psi_2^2(\phi_1\psi_1 + \phi_2\psi_2)^2\\
&\quad - 2\phi_1^2\psi_1^2\psi_2(\phi_1\psi_1 + \phi_2\psi_2)^2.
\end{aligned} \tag{58}$$

Again one can verify that when $(\phi_1, \phi_2, \psi_1, \psi_2)$ is a solution of two ODE systems (57) and (58), then

$$\tilde{q} = \phi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2), \quad \tilde{r} = \phi_2\psi_1(\phi_1\psi_1 + \phi_2\psi_2)$$

is a solution of a related PDE system (29). Moreover, one can verify that with the constraint (55) and x-evolution (57)

$$\Phi^*\begin{pmatrix} 2\phi_2\psi_1(\phi_1\psi_1 + \phi_2\psi_2) \\ 2\phi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2) \end{pmatrix} = \lambda\begin{pmatrix} 2\phi_2\psi_1(\phi_1\psi_1 + \phi_2\psi_2) \\ 2\phi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2) \end{pmatrix} + I\begin{pmatrix} 2\phi_2\psi_1(\phi_1\psi_1 + \phi_2\psi_2) \\ 2\phi_1\psi_2(\phi_1\psi_1 + \phi_2\psi_2) \end{pmatrix},$$

$$I = \phi_1^2\psi_1^2 - \phi_2^2\psi_2^2.$$

For the zero boundary condition we have

$$\begin{pmatrix} c_{n+1} \\ b_{n+1} \end{pmatrix} = (\Phi^*)^n\begin{pmatrix} c_1 \\ b_1 \end{pmatrix} = \begin{pmatrix} 2(\langle A^n Q_2^2, P_1P_2\rangle + \langle A^n P_1^2, Q_1Q_2\rangle) \\ 2(\langle A^n Q_1^2, P_1P_2\rangle + \langle A^n P_2^2, Q_1Q_2\rangle) \end{pmatrix}, \tag{59}$$

and thus

$$a_{n+1} = \partial^{-1}(qc_{n+1} - rb_{n+1}) = (\langle A^n P_1^2, Q_1^2\rangle - \langle A^n P_2^2, Q_2^2\rangle). \tag{60}$$

Formula (30) still guarantees the existence of integrals of motion for the system (56) which now, according to relations (59) and (60), takes the form

$$\overline{F}_1 = -2a_1 = -2(\langle P_1^2, Q_1^2\rangle - \langle P_2^2, Q_2^2\rangle),$$

$$\begin{aligned}\overline{F}_n = &\sum_{i=1}^{n-1}(a_i a_{n-i} + b_i c_{n-i}) - 2a_n = -2(\langle A^{n-1}P_1^2, Q_1^2\rangle - \langle A^{n-1}P_2^2, Q_2^2\rangle)\\ &+ \sum_{i=1}^{n-1}[(\langle A^{i-1}P_1^2, Q_1^2\rangle - \langle A^{i-1}P_2^2, Q_2^2\rangle)(\langle A^{n-i-1}P_1^2, Q_1^2\rangle - \langle A^{n-i-1}P_2^2, Q_2^2\rangle)\\ &+ 4(\langle A^{i-1}Q_1^2, P_1P_2\rangle + \langle A^{i-1}P_2^2, Q_1Q_2\rangle)(\langle A^{n-i-1}Q_2^2, P_1P_2\rangle + \langle A^{n-i-1}P_1^2, Q_1Q_2\rangle)].\end{aligned} \tag{61}$$

Notice that again $I = -\frac{1}{2}\overline{F}_1$ and one can construct the alternative set of integrals of motion $\{\overline{H}_n\}$ according to formulas (35) and (36).

The question is how to relate these integrals of motion to an appropriate Hamiltonian formulation for Eqs. (56). The key observation is that the two constraints

$$\tilde{\phi}_2^2 - 2\tilde{\phi}_1\tilde{\phi}_3 = 0, \quad \tilde{\psi}_2^2 - 2\tilde{\psi}_1\tilde{\psi}_3 = 0 \tag{62}$$

imposed on the eigenfunction components of the 3×3 matrix spectral problem (38) relate it to the 2×2 matrix spectral problem. Actually, the relation between $(\tilde{\phi}_1, \tilde{\phi}_2, \tilde{\phi}_3)$, $(\tilde{\psi}_1, \tilde{\psi}_2, \tilde{\psi}_3)$ and (ϕ_1, ϕ_2), (ψ_1, ψ_2) takes the form[29]

$$(\tilde{\phi}_1, \tilde{\phi}_2, \tilde{\phi}_3) = (\phi_1^2, \sqrt{2}\phi_1\phi_2, \phi_2^2), \quad (\tilde{\psi}_1, \tilde{\psi}_2, \tilde{\psi}_3) = (\psi_1^2, \sqrt{2}\psi_1\psi_2, \psi_2^2). \tag{63}$$

One can immediately notice that under constraints (63) binary symmetry constraint (40) transforms into the one (53) yielding integrable Hamiltonian systems with variable coefficient symplectic forms. It means that the dynamical system (56) can be reconstructed by the Dirac constraint procedure applied to the Hamiltonian system (25).

Actually, let us impose on the system (44), (45) $2N$ constraints of the following form:

$$\begin{aligned}\varphi_i &= \tilde{\phi}_{2i}^2 - 2\tilde{\phi}_{1i}\tilde{\phi}_{3i}, \quad i = 1, \ldots, N,\\ \varphi_{N+i} &= \tilde{\psi}_{2i}^2 - 2\tilde{\psi}_{1i}\tilde{\psi}_{3i}, \quad i = 1, \ldots, N.\end{aligned} \tag{64}$$

The general theory due to Dirac assures that the modified Poisson structure is defined by

$$\{A,B\}_D = \{A,B\} - \{A,\varphi_i\}G_{ij}^{-1}\{\varphi_j, B\}, \quad G_{ij} = \{\varphi_i, \varphi_j\}, \quad \det G \neq 0, \quad G = (G_{ij}). \tag{65}$$

In the case considered we have

$$\begin{aligned}&\varphi_{N+i} := \overline{\varphi_i}, \quad i = 1, \ldots, N, \quad G = \begin{pmatrix} G^{11} & G^{12} \\ -(G^{12})^T & G^{22}\end{pmatrix},\\ &(G^{11})_{ij} = \{\varphi_i, \varphi_j\} = 0, \quad (G^{22})_{ij} = \{\overline{\varphi_i}, \overline{\varphi_j}\} = 0,\\ &(G^{12})_{ij} = \{\varphi_i, \overline{\varphi_j}\} = \delta_{ij}(\tilde{\phi}_{1j}\tilde{\psi}_{1j} + \tilde{\phi}_{2j}\tilde{\psi}_{2j} + \tilde{\phi}_{3j}\tilde{\psi}_{3j}),\end{aligned} \tag{66}$$

so,

$$\{A,B\}_D = \{A,B\} + \sum_{i=1}^{N}\frac{\{A,\varphi_i\}\{B,\overline{\varphi_i}\} - \{A,\overline{\varphi_i}\}\{B,\varphi_i\}}{(\tilde{\phi}_{1i}\tilde{\psi}_{1i} + \tilde{\phi}_{2i}\tilde{\psi}_{2i} + \tilde{\phi}_{3i}\tilde{\psi}_{3i})}. \tag{67}$$

The Poisson bracket $\{.,.\}_D$ is degenerated, contrary to the canonical one $\{.,.\}$, and has $2N$ Casimir functions $\varphi_i, \overline{\varphi_i}$, $i=1,\ldots,N$. Substituting for A,B the coordinates ϕ, ψ, one gets appropriate matrix elements of the Dirac Poisson tensor D. All nonzero elements are as follows:

$$\{\tilde{\phi}_{1i},\tilde{\psi}_{1i}\}_D=\tilde{\phi}_{1i}\tilde{\psi}_{1i}+\tilde{\phi}_{2i}\tilde{\psi}_{2i},\quad \{\tilde{\phi}_{1i},\tilde{\psi}_{2i}\}_D=\tilde{\phi}_{2i}\tilde{\psi}_{3i},\quad \{\tilde{\phi}_{1i},\tilde{\psi}_{3i}\}_D=-\tilde{\phi}_{1i}\tilde{\psi}_{3i},$$

$$\{\tilde{\phi}_{2i},\tilde{\psi}_{1i}\}_D=\tilde{\phi}_{3i}\tilde{\psi}_{2i},\quad \{\tilde{\phi}_{2i},\tilde{\psi}_{2i}\}_D=\tilde{\phi}_{1i}\tilde{\psi}_{1i}+\tilde{\phi}_{3i}\tilde{\psi}_{3i},\quad \{\tilde{\phi}_{2i},\tilde{\psi}_{3i}\}_D=\tilde{\phi}_{1i}\tilde{\psi}_{2i}, \tag{68}$$

$$\{\tilde{\phi}_{3i},\tilde{\psi}_{1i}\}_D=-\tilde{\phi}_{3i}\tilde{\psi}_{1i},\quad \{\tilde{\phi}_{3i},\tilde{\psi}_{2i}\}_D=\tilde{\phi}_{2i}\tilde{\psi}_{1i},\quad \{\tilde{\phi}_{3i},\tilde{\psi}_{3i}\}_D=\tilde{\phi}_{2i}\tilde{\psi}_{2i}+\tilde{\phi}_{3i}\tilde{\psi}_{3i}.$$

Now, let us perform the following coordinate transformation:

$$\begin{gathered}\phi_{1i}^2=\tilde{\phi}_{1i},\\ \phi_{2i}^2=\tilde{\phi}_{3i},\\ \psi_{1i}^2=\tilde{\psi}_{1i},\\ \psi_{2i}^2=\tilde{\psi}_{3i},\\ c_{1i}=\varphi_i(\tilde{\phi})=\tilde{\phi}_{2i}^2-2\tilde{\phi}_{1i}\tilde{\phi}_{3i},\\ c_{2i}=\overline{\varphi_i}(\tilde{\psi})=\tilde{\psi}_{2i}^2-2\tilde{\psi}_{1i}\tilde{\psi}_{3i},\quad i=1,\ldots,N.\end{gathered} \tag{69}$$

Then, on the symplectic leaf $c_{1i}=c_{2i}=0$, $i=1,\ldots,N$, parametrized by a set of coordinates $(\phi_{1i},\phi_{2i},\psi_{1i},\psi_{2i})_{i=1}^N$, we get the following nonzero elements of a nondegenerated Poisson tensor $\overline{\pi}$:

$$\begin{aligned}\{\phi_{1i},\psi_{1i}\}&=\frac{\phi_{1i}\psi_{1i}+2\phi_{2i}\psi_{2i}}{4(\phi_{1i}\psi_{1i}+\phi_{2i}\psi_{2i})^2},\quad \{\phi_{1i},\psi_{2i}\}=\frac{-\phi_{1i}\psi_{2i}}{4(\phi_{1i}\psi_{1i}+\phi_{2i}\psi_{2i})^2},\\ \{\phi_{2i},\psi_{1i}\}&=\frac{-\phi_{2i}\psi_{1i}}{4(\phi_{1i}\psi_{1i}+\phi_{2i}\psi_{2i})^2},\quad \{\phi_{2i},\psi_{2i}\}=\frac{2\phi_{1i}\psi_{1i}+\phi_{2i}\psi_{2i}}{4(\phi_{1i}\psi_{1i}+\phi_{2i}\psi_{2i})^2}.\end{aligned} \tag{70}$$

Moreover, the transformation (69) with $c_{1i}=c_{2i}=0$ relates

$$\tilde{f}_k=\tilde{\phi}_{1k}\tilde{\psi}_{1k}+\tilde{\phi}_{2k}\tilde{\psi}_{2k}+\tilde{\phi}_{3k}\tilde{\psi}_{3k}\to\overline{f_k}=(\phi_{1k}\psi_{1k}+\phi_{2k}\psi k)^2,\quad k=1,\ldots,N, \tag{71}$$

$$\tilde{F}_n(\tilde{\phi},\tilde{\psi})(49)\to\overline{F}_n(\phi,\psi)(61),\quad n\geqslant 1$$

$$\tilde{H}_n(\tilde{\phi},\tilde{\psi})\to\overline{H}_n(\phi,\psi),\quad n\geqslant 1,$$

where $\tilde{H}_n$ and $\overline{H}_n$ are constructed according to recursion formulas (35) and (36). Hence, Hamiltonian function (45) reduces to the following one:

$$\begin{aligned}\overline{H}_1&=-2(\langle AP_1^2,Q_1^2\rangle-\langle AP_2^2,Q_2^2\rangle)+4(\langle P_1P_2,Q_1^2\rangle+\langle P_2^2,Q_1Q_2\rangle)(\langle P_1P_2,Q_2^2\rangle+\langle P_1^2,Q_1Q_2\rangle)\\ &=-2\sum_{i=1}^N\lambda_i(\phi_{1i}^2\psi_{1i}^2-\phi_{2i}^2\psi_{2i}^2)+4\sum_{i,j=1}^N(\phi_{1i}^2\psi_{1i}\psi_{2i}+\phi_{1i}\phi_{2i}\psi_{2i}^2)(\phi_{1j}\phi_{2j}\psi_{1j}^2+\phi_{2j}^2\psi_{1j}\psi_{2j}),\end{aligned} \tag{72}$$

which is an appropriate Hamiltonian function of the system (56). In the simplest case of $N=1$ (57), the Hamiltonian function and the Poisson tensor are

$$\overline{H}_1=-2\lambda(\phi_1^2\psi_1^2-\phi_2^2\psi_2^2)+4\phi_1\phi_2\psi_1\psi_2(\phi_1\psi_1+\phi_2\psi_2)^2,$$

and

$$\overline{\pi}=\frac{1}{4(\phi_1\psi_1+\phi_2\psi_2)^2}\times\begin{pmatrix}0&0&\phi_1\psi_1+2\phi_2\psi_2&-\phi_1\psi_2\\0&0&-\phi_2\psi_1&2\phi_1\psi_1+\phi_2\psi_2\\-\phi_1\psi_1-2\phi_2\psi_2&\phi_2\psi_1&0&0\\\phi_1\psi_2&-2\phi_1\psi_1-\phi_2\psi_2&0&0\end{pmatrix}. \tag{73}$$

Theorem 1: *The integrals of motion* $(\overline{f}_k,\overline{F}_n)$ *and* $(\overline{f}_k,\overline{H}_n)$ *are in involution with respect to the Poisson bracket (70).*

Proof: The relation $\{\overline{f}_i,\overline{f}_j\}=0$ is obvious as $\overline{\pi}$ does not relate coordinates to different i. Noticing that $\overline{\pi}\nabla\overline{f}_i=(0,\ldots,0,\phi_{1i},\phi_{2i},-\psi_{1i},-\psi_{2i},0,\ldots,0)^T$, one immediately gets

$$\{\overline{F}_n,\overline{f}_i\}=\frac{1}{2}\left(\frac{\partial\overline{F}_n}{\partial\phi_{1i}}\phi_{1i}+\frac{\partial\overline{F}_n}{\partial\phi_{2i}}\phi_{2i}-\frac{\partial\overline{F}_n}{\partial\psi_{1i}}\psi_{1i}-\frac{\partial\overline{F}_n}{\partial\psi_{2i}}\psi_{2i}\right)=0, \tag{74}$$

which follows from the form of $\overline{F}_n$ (61). Therefore, $\{\overline{H}_n,\overline{f}_i\}=0$. According to Noether's theorem, the relation $\{\overline{H}_n,\overline{H}_m\}=0$ is equivalent to commutativity of related vector fields

$$\begin{pmatrix}\vdots\\\phi_{1i}\\\phi_{2i}\\\vdots\\\psi_{1i}\\\psi_{2i}\\\vdots\end{pmatrix}_{t_n}=\overline{V}^{(n)}(\lambda_1,\ldots,\lambda_N;\tilde{u})\begin{pmatrix}\vdots\\\phi_{1i}\\\phi_{2i}\\\vdots\\\psi_{1i}\\\psi_{2i}\\\vdots\end{pmatrix}:=K_{(n)}(\lambda;\tilde{u})=\overline{\pi}\nabla\overline{H}_n, \tag{75}$$

where $\overline{V}^{(n)}(\lambda_1,\ldots,\lambda_N;\tilde{u})=\mathrm{diag}(V^{(n)}(\lambda_1,\tilde{u}),\ldots,V^{*(n)}(\lambda_N,\tilde{u}))$. After simple calculations one gets the following form of the commutator:

$$\begin{aligned}[K_{(n)}(\lambda;\tilde{u}),K_{(m)}(\lambda;\tilde{u})]&=K'_{(n)}(\lambda;\tilde{u})[K_{(m)}(\lambda;\tilde{u})]-K'_{(m)}(\lambda;\tilde{u})[K_{(n)}(\lambda;\tilde{u})]\\&=(\overline{V}^{(n)}_{t_m}-\overline{V}^{(m)}_{t_n}+[\overline{V}^{(n)},\overline{V}^{(m)}])\begin{pmatrix}\vdots\\\phi_{1i}\\\phi_{2i}\\\vdots\\\psi_{1i}\\\psi_{2i}\\\vdots\end{pmatrix},\end{aligned} \tag{76}$$

where $'$ means a Gateaux derivative with respect to the coordinates $(\phi_{1i},\ldots,\psi_{2N})$. The commutator (76) is equal to zero if $\overline{V}^{(n)}_{t_m}-\overline{V}^{(m)}_{t_n}+[\overline{V}^{(n)},\overline{V}^{(m)}]=0$. The last equality holds if

$$V^{(n)}_{t_m}(\lambda_i,\tilde{u})-V^{(m)}_{t_n}(\lambda_i,\tilde{u})+[V^{(n)}(\lambda_i,\tilde{u}),V^{(m)}(\lambda_i,\tilde{u})]=0, \tag{77}$$

$$V^{*(n)}_{t_m}(\lambda_i,\tilde{u})-V^{*(m)}_{t_n}(\lambda_i,\tilde{u})+[V^{*(n)}(\lambda_i,\tilde{u}),V^{*(m)}(\lambda_i,\tilde{u})]=0,$$

for $i=1,\ldots,N$. As the relations (77) are true for arbitrary λ and u, they are also true for particular $\lambda=\lambda_i, u=\tilde{u}(\phi,\psi)$. Finally, $\{\overline{H}_n,\overline{H}_m\}=0$ and thus $\{\overline{F}_n,\overline{F}_m\}=0$. The proof is finished.

Theorem 2: *The functions* $\overline{f}_i$, $i=1,\ldots,N$, *and* $\overline{F}_n, n=1,\ldots,N$, *are functionally independent over some region of* R^{4N}.

Proof: We use the method established in Ref. 20. Let P_0 be a point of R^{4N} satisfying

$$\psi_{ik}=\varepsilon,\quad k=1,\ldots,N,\quad i=1,2. \tag{78}$$

At P_0 we have

$$\begin{aligned}\frac{\partial\overline{f}_k}{\partial\phi_{ij}}&=2\varepsilon^2(\phi_{1j}+\phi_{2j})\phi_{ij}\delta_{kj},\\ \frac{\partial\overline{F}_k}{\partial\phi_{ij}}&=-4\varepsilon^2\lambda_j^{k-1}\phi_{ij}+O(\varepsilon^4),\quad i=1,2,\ k,j=1,\ldots,N.\end{aligned} \tag{79}$$

Then, at the point P_0, the Jacobian of the functions $\overline{f}_k$, $\overline{F}_k$, $k=1,\ldots,N$, with respect to ϕ_{ij} can be calculated as follows

$$\begin{aligned}&\left|\frac{\partial(\overline{f}_1,\ldots,\overline{f}_N,\overline{F}_1,\ldots,\overline{F}_N)}{\partial(\phi_{11},\phi_{21},\ldots,\phi_{1N},\phi_{2N})}\right|\\ &\quad=-4\varepsilon^{4N}\\ &\quad\times\begin{vmatrix}-\frac{1}{2}(\phi_{11}+\phi_{21}) & 0 & 0 & \ldots & \ldots & 0\\ 0 & -\frac{1}{2}(\phi_{12}+\phi_{22}) & 0 & \ldots & \ldots & 0\\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots\\ 0 & 0 & 0 & \ldots & 0 & -\frac{1}{2}(\phi_{1N}+\phi_{2N})\\ \phi_{11} & \phi_{21} & \ldots & \ldots & \phi_{1N} & \phi_{2N}\\ \lambda_1\phi_{11} & \lambda_1\phi_{21} & \ldots & \ldots & \lambda_N\phi_{1N} & \lambda_N\phi_{2N}\\ \ldots & \ldots & \ldots & \ldots & \ldots & \ldots\\ \lambda_1^{N-1}\phi_{11} & \lambda_1^{N-1}\phi_{21} & & & \lambda_N^{N-1}\phi_{1N} & \lambda_N^{N-1}\phi_{2N}\end{vmatrix}\\ &\quad+O(\varepsilon^{4N+2})=-4\varepsilon^{4N}\left(-\frac{1}{2}\right)^N\prod_{k,l=1,k>l}^{N}(\lambda_k-\lambda_l)\prod_{j=1}^{N}(\phi_{1j}^2-\phi_{2j}^2)+O(\varepsilon^{4N+2}).\end{aligned} \tag{80}$$

In the evaluation of the determinant we first subtracted from the $2r-1$ column the $2r$ one for $r=1,\ldots,N$. Hence we conclude that if the $\lambda_1,\ldots,\lambda_N$ are distinct, the above Jacobian is not identically equal to zero and additionally is a polynomial function of ϕ_{ij}, therefore, the functions $\overline{f}_k$, $\overline{F}_k$, $k=1,\ldots,N$, are functionally independent at least over some dense open subset of R^{4N}. The proof is finished.

So, finally, we can summarize our results in the following way.

Theorem 3: *The binary constrained spatial system (56) is a Liouville integrable Hamiltonian system*

$$\begin{pmatrix} Q_1 \\ Q_2 \\ P_1 \\ P_2 \end{pmatrix}_x = \overline{\pi}\nabla\overline{H}_1, \tag{81}$$

with a Poisson structure given by (70) and a Hamiltonian function

$$\begin{aligned}\overline{H}_1 &= -2(\langle AP_1^2, Q_1^2\rangle - \langle AP_2^2, Q_2^2\rangle) + 4(\langle P_1P_2, Q_1^2\rangle + \langle P_2^2, Q_1Q_2\rangle)(\langle P_1P_2, Q_2^2\rangle + \langle P_1^2, Q_1Q_2\rangle) \\ &= \overline{F}_2 - \frac{1}{4}\overline{F}_1^2.\end{aligned} \tag{82}$$

Moreover, the system (81) has $2N$ *functionally independent and involutive integrals of motion* $\overline{f}_i$, $i=1,\ldots,N$, *and* $\overline{F}_n$, $n=1,\ldots,N$, *defined by (61) and (71).*

Let us mention that all other binary constrained temporal systems

$$\begin{aligned}\begin{pmatrix} \phi_{1j} \\ \phi_{2j} \end{pmatrix}_{t_n} &= V^{(n)}(\tilde{u},\lambda_j)\begin{pmatrix} \phi_{1j} \\ \phi_{2j} \end{pmatrix}, \quad j=1,\ldots,N, \\ \begin{pmatrix} \psi_{1j} \\ \psi_{2j} \end{pmatrix}_{t_n} &= -(V^{(n)})^T(\tilde{u},\lambda_j)\begin{pmatrix} \psi_{1j} \\ \psi_{2j} \end{pmatrix}, \quad j=1,\ldots,N,\end{aligned} \tag{83}$$

form a family of Hamiltonian systems with the Poisson tensor (70) and the corresponding Hamiltonian functions $\overline{H}_n$ expressible through $\overline{F}_m$. For example, $\overline{H}_2 = \overline{F}_3 - \frac{1}{2}\overline{F}_1\overline{F}_2 + \frac{1}{8}\overline{F}_1^3$.

V. CONCLUDING REMARKS

In this article we have established the Liouville integrability of a factorization of the AKNS field systems of PDEs into pairs of systems of ODEs, presented in Ref. 29. In other words, it has been shown that in a natural set of coordinates, i.e., eigenfunctions of a spectral problem, the resulting binary constrained flows defined by (56) are Liouville integrable Hamiltonian systems with variable coefficient symplectic forms. The results also provide an amendment to the answer of the question posed in Ref. 29.

The method applied suggests the existence of similar factorizations for other soliton hierarchies. However, in order to find explicit solutions of the AKNS field systems, a transformation from the set of eigenfunctions to the set of separated coordinates has to be found. This work is in progress and it will be prepared for a separate paper.

Bruhat Poisson structure on $\mathbb{CP}^n$ and integrable systems

Philip Foth[a)]
Department of Mathematics, University of Arizona, Tucson, Arizona 85721-0089

(Received 18 December 2001; accepted for publication 5 March 2002)

In this note we present a simple formula for the Bruhat Poisson structure on complex projective spaces in terms of the momentum coordinates. We also give a simple description of a family of functions in involution on compact Hermitian symmetric spaces obtained via the bi-Hamiltonian approach using the Bruhat Poisson structure and an invariant symplectic structure. We compute these functions explicitly on $\mathbb{CP}^n$ and relate them to the Gelfand–Tsetlin coordinates. We also show how the Lenard scheme can be applied. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1477261]

I. INTRODUCTION

Let K be a compact real form of a complex semi-simple Lie group G and let $H\subset K$ be a subgroup of K defined by $H=K\cap P$, where P is a parabolic subgroup of G containing a Borel subgroup $B\subset G$. The Bruhat Poisson structure π_∞ on $X=K/H$ is constructed from a classical dynamical r-matrix and has its origin from quantum groups. It was first introduced by Lu–Weinstein[1] and Soibelman,[2] and has the property that its symplectic leaves are precisely the Bruhat cells in X. If $T=K\cap B$, a maximal torus of K, then π_∞ is T-invariant. When $X=\mathbb{CP}^n$, we use the momentum map coordinates $(x_1,\ldots,x_n)$ and the corresponding angular coordinates $(\phi_1,\ldots,\phi_n)$ to show that π_∞ is given by

$$\pi_\infty=\sum_{i=1}^{n}\Theta_i\wedge\partial_{\phi_i},$$

where

$$\Theta_i=(x_1+\cdots+x_i-1)\partial_{x_i}+\sum_{j=i+1}^{n}x_j\partial_{x_j}.$$

Let ω_s (respectively, π_s) stand for a K-invariant symplectic form (respectively, its dual bi-vector field) on X. When X is a Hermitian symmetric space, Khoroshkin, Radul, and Rubtsov[3] proved that the two Poisson structures, π_∞ and π_s form a Poisson pair, meaning that the Schouten bracket of π_∞ and π_s vanishes, $[\pi_\infty,\pi_s]=0$. In particular, any bi-vector field of the form $\alpha\pi_\infty+\beta\pi_s$, $(\alpha,\beta)\in\mathbb{R}^2$, is Poisson. In this situation, one can take $\alpha=\beta=1$ and introduce the following family $\{\sigma_k\}$ of functions:

$$\sigma_k:=((\pi_s+\pi_\infty)^{\wedge k},\omega_s^{\wedge k}),$$

obtained by the duality pairing of exterior powers of ω and $\pi_\infty+\pi_s$. If the (real) dimension of X is equal to $2n$, then we have n functions: $\sigma_1,\ldots,\sigma_n$, which may carry useful information about X. These functions are in involution with respect to either of the two Poisson structures and are related to the fundamental weights for the Lie algebra $\mathfrak{sl}(n+1,\mathbb{C})$. We show that on $\mathbb{CP}^n$ the functions that we have obtained are constant multiples of the elementary symmetric polynomials

a)Electronic mail: foth@math.arizona.edu

in the Gelfand–Tsetlin variables studied by Guillemin and Sternberg.[4] These variables define completely integrable systems on coadjoint orbits of the unitary group. In a subsequent publication we show that this statement extends to the complex Grassmannians as well as other Hermitian symmetric spaces. In the last part of the paper we make explicit computations using the Lenard scheme.[5]

II. BRUHAT POISSON STRUCTURE ON $\mathbb{CP}^n$

We recall the Bruhat Poisson structure and its properties.[1] Let K be a compact semi-simple Lie group with Lie algebra $\mathfrak{k}$, G a complexification of K with Lie algebra $\mathfrak{g}$, and $T\subset K$ a maximal torus with Lie algebra $\mathfrak{t}$. The complexification $\mathfrak{h}$ of $\mathfrak{t}$ is a Cartan in $\mathfrak{g}$. Let Δ be the set of all roots of $\mathfrak{g}$ with respect to $\mathfrak{h}$. We choose $\Delta^+\subset\Delta$ a subset of positive roots. Let $\langle,\rangle$ be the Killing form of $\mathfrak{g}$ and let H_α be the image of $\alpha\in\Delta$ under the isomorphism $\mathfrak{h}^*\to\mathfrak{h}$ which is defined by $\langle,\rangle$. For each $\alpha\in\Delta^+$ choose a root vector E_α such that $\langle E_\alpha,\theta E_\alpha\rangle=-1$, where θ is the complex conjugation on $\mathfrak{g}$ defined by $\mathfrak{k}$. Then $E_{-\alpha}:=-\theta E_\alpha$ is a root vector for $-\alpha$. Let $X_\alpha,Y_\alpha\in\mathfrak{k}$ be given by $X_\alpha=E_\alpha-E_{-\alpha}$ and $Y_\alpha=\sqrt{-1}(E_\alpha+E_{-\alpha})$. We set:

$$\Lambda=\sum_{\alpha>0}X_\alpha\wedge Y_\alpha\in\mathfrak{k}\wedge\mathfrak{k}.$$

Let Λ^l and Λ^r be the left and right invariant bivector fields on K with their value at identity equal to Λ. Then $\pi_K=\Lambda^l-\Lambda^r$ becomes a Poisson structure on K, making it into a Poisson Lie group. Let $H\subset K$ be a subgroup of K given by the intersection of K with a parabolic subgroup of G containing the Borel determined by Δ^+. There is a unique Poisson structure on $X=K/H$, denoted by π_∞ such that the natural projection $(K,\pi_K)\to(X,\pi_\infty)$ is a Poisson map. The space (X,π_∞) is a (K,π_K)-homogeneous Poisson manifold, and the symplectic leaves of π_∞ on X are precisely the Bruhat cells.

When $K=\mathrm{SU}(n+1)$, an obvious choice of H yields $X=\mathbb{CP}^n$, the complex projective space of (complex) dimension n. Let $[Z_0:Z_1:\cdots:Z_n]$ be a homogeneous coordinate system on X. We use the standard Fubini-Study form ω for the invariant symplectic form ω_s and the following description of π_∞ obtained by Lu.[6] First, we need Lu's coordinates on the largest Bruhat cell, where $Z_0\neq 0$ and we let $z_i=Z_i/Z_0$:

$$y_i:=\frac{z_i}{\sqrt{1+|z_{i+1}|^2+\cdots+|z_n|^2}},\quad 1\leqslant i\leqslant n.$$

Lu's coordinates are not holomorphic, but convenient for the Bruhat Poisson structure, which now assumes the following form:

$$\pi_\infty=\sqrt{-1}\sum_{i=1}^{n}(1+|y_i|^2)\partial_{y_i}\wedge\partial_{\overline{y_i}}.$$

In order to be able to compute with ω and π_∞, we need to move to the polar variables r_i,ϕ_j defined by $z_i=r_ie^{\sqrt{-1}\phi_i}$ and eventually to the momentum map variables x_i,ϕ_j, where x_i is defined by

$$x_i=\frac{r_i^2}{1+r_1^2+\cdots r_n^2}.$$

The functions x_i's are globally defined on $\mathbb{CP}^n$, and if one identifies $\mathbb{R}^n$ with $\mathfrak{t}^*$, then these functions define the momentum map associated with the T-action on $\mathbb{CP}^n$. One of the advantages of using the coordinates $\{x_1,\ldots,x_n\}$ is that the Fubini–Study symplectic structure and the corresponding bi-vector field have the following simple form:

$$\omega=\sum_{i=1}^{n} \mathrm{d}x_i\wedge \mathrm{d}\phi_i, \quad \pi_s=\sum_{i=1}^{n} \partial_{x_i}\wedge\partial_{\phi_i}.$$

In fact, the simplest form for the Bruhat Poisson structure is also achieved in this coordinate system.

Proposition 2.1: The Bruhat Poisson structure π_∞ on $\mathbb{CP}^n$ can be written in the coordinate system (x_j,ϕ_i) as follows:

$$\pi_\infty=\sum_{i=1}^{n} \Theta_i\wedge\partial_{\phi_i},$$

where

$$\Theta_i=(x_1+\cdots+x_i-1)\partial_{x_i}+\sum_{j=i+1}^{n} x_j\partial_{x_j}.$$

Proof: The proof of this statement is purely computational. One can introduce auxiliary variables $q_i=\log(1+|y_i|^2)$, and use these to write

$$\pi_\infty=-\sum_{i=1}^{n} \partial_{q_i}\wedge\partial_{\phi_i},$$

the action-angle form for π_∞. Eventually, one can establish the following relations: $x_1=1-e^{-q_1}$, and for $j>1$,

$$x_j=e^{-(q_1+\cdots+q_{j-1})}-e^{-(q_1+\cdots+q_j)}.$$

The rest is straightforward. □

Notice that if we take the sum $\pi_\infty+\pi_s$, the -1 in the above-given formula will disappear.

III. FAMILIES OF FUNCTIONS IN INVOLUTION

Multi-Hamiltonian structures are very important in the theory of integrable systems. Starting with the fundamental works of Magri,[5] they found many interesting and fundamental applications, as in Refs. 7–10, and references therein. We say that two Poisson structures π_0 and π_1 form a *Poisson pair* if their Schouten bracket equals zero: $[\pi_0,\pi_1]=0$. This is equivalent to the condition that for any $\alpha,\beta\in\mathbb{R}$ the bi-vector field $\alpha\pi_0+\beta\pi_1$ is also Poisson. We refer to such family $\alpha\pi_0+\beta\pi_1$ as a *Poisson pencil*.

Let M be a manifold and let π_b and π_s be two Poisson structures on M such that:

(1) The Poisson structure π_s is nondegenerate (so the subscript s stands for symplectic).
(2) The Poisson structures π_s and π_b form a Poisson pair.

If $\dim(M)=2n$, then we can define n functions $\sigma_1,\ \ldots,\ \sigma_n$ as follows:

$$\sigma_j=\frac{\pi_b^j\wedge\pi_s^{n-j}}{\pi_s^n}.$$

The operation of division by the top degree bi-vector field makes perfect sense, since π_s is nondegenerate, and thus in any local coordinate system $(x_1,\ \ldots\ x_{2n})$ the $2n$-vector field π_s^n looks like

$$\pi_s^n=h(x_1,\ldots,x_{2n})\partial_{x_1}\wedge\cdots\wedge\partial_{x_{2n}},$$

for a nonvanishing function $(hx_1, \ldots, x_{2n})$. For an equivalent definition, which only differs by a constant multiple, one can use the symplectic form ω_s dual to π_s, then one can define

$$\sigma_k=(\pi_b^{\wedge k},\omega_s^{\wedge k}),$$

where we use the duality pairing

$$\Gamma(M,\wedge^{2k}TM)\otimes\Gamma(M,\wedge^{2k}T^*M)\to C^\infty(M).$$

It turns out that this family of functions has the following property.

Proposition 3.1: The family of functions σ_i defined previously are in involution with respect to either Poisson structure, π_b or π_s.

Proof: (J.-H. Lu) Let $X_j=i_{d\sigma_j}\pi_b$ and let $Y_j=i_{d\sigma_j}\pi_s$. Then we have: $[X_j,\pi_s]=-[Y_j,\pi_b]$, $[X_j,\pi_b]=0$, and $[Y_j,\pi_s]=0$. Consider the equality $\sigma_k\pi_s^n=\pi_b^k\wedge\pi_s^{n-k}$ and compute L_{X_l} of both sides to arrive at the following identity:

$$\frac{n-k}{k+1}\{\sigma_{k+1},\sigma_l\}_s=-\{\sigma_k,\sigma_l\}_b+n\sigma_k\{\sigma_1,\sigma_l\}_s,$$

where the subscripts s and b indicate the Poisson structure with respect to which the Poisson bracket is taken. Finally, use the induction on l. □

Remark: The approach that we have followed here is intimately related to the Poisson–Nijenhuis structures, which were studied by Magri and Morosi,[11] Kosmann-Schwarzbach and Magri,[7] Vaisman,[8] and others. The set of our functions $\{\sigma_j\}$ can be expressed, polynomially, through the traces of powers of the intertwining operator corresponding to the Nijenhuis tensor.

Now let us take $M=X$ to be a coadjoint orbit in $\mathfrak{k}^*$, which we assume to be a compact Hermitian symmetric space. Let $\pi_s=\pi$ be the Kirillov–Kostant–Souriau symplectic structure and $\pi_b=\pi_\infty$ the Bruhat Poisson structure, which is obtained via an identification of X with $K/(P\cap K)$ as in Sec. I. Under this identification, π is K-invariant. The following was first proved in Ref. 3, and we offer a shorter proof due to Lu:

Proposition 3.2: If X is a Hermitian symmetric space as previously, then the Poisson structures π_s and π_∞ form a Poisson pair.

Proof: If (K,π_K) is a connected Poisson–Lie group, and (X,π_X) is a (K,π_K) Poisson homogeneous space, then for any $Y\in\mathfrak{k}$,

$$L_{\kappa(Y)}\pi_X=\kappa(\delta(Y)),$$

where $\kappa:\mathfrak{k}\to\Gamma(TX)$ is the infinitesimal action map, extended to $\kappa:\wedge^2\mathfrak{k}\to\Gamma(\wedge^2TX)$ and $\delta:\mathfrak{k}\to\wedge^2\mathfrak{k}$ is the cocycle defining π_K. Indeed, by definition of the Poisson homogeneous space,

$$\pi_X(kx)=k_*\pi_X(x)+x_*\pi_K(k),$$

where

$$k:X\to X,\ \ k(x)=k\cdot x,\quad \text{and } x:K\to X,\ \ x(k)=k\cdot x$$

are the action and the evaluation maps, respectively. Since K acts by diffeomorphisms, we can define

$$k^*(\pi_X)(x):=k_*\pi_X(k^{-1}(x)).$$

Then we see that

$$k^*(\pi_X)(x)=k_*(k_*^{-1}\pi_X(x)+x_*\pi_K(k^{-1}))=\pi_X(x)+x_*(l_{k*}\pi_K(k^{-1})),$$

where l_k is the left translation on K. Now we set $k=\exp(tY)$ and compute $\mathrm{d}/\mathrm{d}t_{|t=0}$ of both sides to conclude that

$$L_{\kappa(Y)}\pi_X(x)=\kappa(\delta(Y))(x),$$

where

$$\delta(Y)=\frac{\mathrm{d}}{\mathrm{d}t}_{|t=0} l_{\exp(tY)}\pi_K(\exp(-tY))\in\wedge^2\mathfrak{k}$$

is the Lie algebra cocycle which determines π_K.

Now since π_s is K-invariant, we can compute that for any $Y\in\mathfrak{k}$:

$$L_{\kappa(Y)}[\pi_\infty,\pi_s]=[L_{\kappa(Y)}\pi_\infty,\pi_s]+[\pi_\infty,L_{\kappa(Y)}\pi_s]=[\kappa(\delta(Y)),\pi_s]+[\pi_\infty,0]=0,$$

since $\kappa(\delta(Y))$ is the sum of wedges of generating vector fields for the K-action. This shows that $[\pi_\infty,\pi_s]$ is an invariant three-vector field.

Now we notice that in the case when $X=G/P$ is a Hermitian symmetric space, the nilradical of P is Abelian, and therefore each K-invariant nonzero differential form is closed and not exact. We also know that $H^3(X)=0$, and thus there is no nonzero K-invariant three-forms on X. Thus there is no nonzero K-invariant three-vector field on X, which implies that $[\pi_s,\pi_\infty]=0$.

Thus we have proven that π_∞ and π_s commute with respect to the Schouten bracket, and hence form a Poisson pair. □

Therefore, we have the following:

Proposition 3.3: Let X be a coadjoint orbit of K. Assume that X is a Hermitian symmetric space of complex dimension n. The above-mentioned recipe yields n functions $(\sigma_1,\ \ldots,\ \sigma_n)$ *on X, which are in involution with respect to either π_∞ or π_s.*

Now let us return to the case of $X=\mathbb{CP}^n$ with the commuting Poisson structures π_s and π_∞ introduced in Sec. II. Let us introduce the following linear change of variables on $\mathbb{R}^n$:

$$c_k=x_1+\cdots+x_k.$$

In these variables, we can easily compute the desired functions as follows:

Theorem 3.4: *The functions $\{\sigma_i\}$, $1\leqslant i\leqslant n$ on $\mathbb{CP}^n$ defined by*:

$$\sigma_i=(\omega^{\wedge i},(\pi_s+\pi_\infty)^{\wedge i}),$$

up to constant multiples, are equal to the elementary symmetric polynomials in $(c_1,\ \ldots,\ c_n)$:

$$\sigma_j=\sum_{i_1<\cdots<i_j} c_{i_1}\cdots c_{i_j}.$$

Proof: The simple linear and triagonal form of $\pi_\infty+\pi_s$ makes the computation of the functions $\{\sigma_i\}$ straightforward. □

The explicit nature of these integrals is essential in looking at the relation with the certain natural flows. So, in particular we see that

$$\sigma_1=c_1+\cdots+c_n$$

and that the Hamiltonian σ_1 in terms of the momentum map variables is given by

$$\sigma_1=nx_1+(n-1)x_2+\cdots+2x_{n-1}+x_n.$$

Then the gradient of this function in the momentum simplex has coordinates $\lambda_i=n+1-i$. If we treat these numbers as weights assigned to the vertices of the moment polytope, which correspond

to the centers of the Bruhat cells, we see the clear correspondence between these numbers and the complex dimensions of the corresponding cells. Besides, we see that the functions $\{c_i\}$ are linearly independent and satisfy $c_i - c_{i-1} = x_i$, so we conclude that:

Theorem 3.5: *The functions $\{\sigma_i\}$ are generically linearly independent on $\mathbb{CP}^n$. They Poisson commute with respect to either π_s or π_∞. The corresponding common level sets coincide with those for the standard torus action on $\mathbb{CP}^n$. The value of σ_1 at the center of a Bruhat cell equals n minus the complex dimension of that cell.*

Remark: For any compact semi-simple Lie algebra $\mathfrak{k}$ of rank l, there are l distinguished linear functions on $\mathfrak{k}^*$ defined by the fundamental weights for $\mathfrak{g} = \mathfrak{k} \otimes \mathbb{C}$. Namely, let $p: \mathfrak{k}^* \to \mathfrak{t}^*$ be the projection dual to the inclusion $\mathfrak{t} \hookrightarrow \mathfrak{k}$. The restriction of p to any co-adjoint orbit X in $\mathfrak{k}^*$ is a momentum map for the T-action on X. If we regard the l fundamental weights for $\mathfrak{g}$ as linear functions on $\mathfrak{t}^*$, then their pull-backs by p^* composed with the restriction to X define l functions on X. For $k = \mathfrak{su}(n+1)$ these functions are exactly $c_1, \ldots, c_n$.

Remark: The function σ_1 has another application. The gradient flow with respect to σ_1 on $\mathbb{CP}^n$ is just the Toda flow as explained, e.g., in Ref. 12.

The functions $(\sigma_1, \ldots, \sigma_n)$ that we have constructed turn out to be related to the Gelfan–Tsetlin coordinates in the case when $K = \mathrm{SU}(n)$, as we will see later on. In Sec. IV we will carry explicit computations of these functions on the projective spaces.

IV. RELATION WITH GELFAND–TSETLIN

When $X = \mathrm{Gr}(k)$—the Grassmannian of k-planes in $\mathbb{C}^{n+1}$, we have obtained $k(n-k+1)$ functions in involution on X. Let us recall the standard embedding

$$\Psi: F_n \hookrightarrow \mathrm{Gr}(1) \times \cdots \times \mathrm{Gr}(n),$$

where F_n is the manifold of full flags in $\mathbb{C}^{n+1}$, and the locus of the embedding is given by the incidence relations. This embedding respects the KKS Kähler structures on the manifolds involved, if we would like to view them as coadjoint orbits in $\mathfrak{k}^*$. Moreover, this embedding is equivariant with respect to the $K = \mathrm{SU}(n+1)$-action. For convenience we identify the dual of the unitary Lie algebra $\mathfrak{u}_k$ with the space of $k \times k$ complex Hermitian matrices using $-\sqrt{-1}\,\mathrm{Tr}(AB)$ as the pairing.

Recall the Gelfan–Tsetlin system on F_n. We fix the orbit type of F_n, i.e., we fix the eigenvalues λ_i of a complex Hermitian matrix A and order them, so $\lambda_1 > \lambda_2 > \cdots > \lambda_{n+1}$. For convenience and easier visualization, we will assume that $\lambda_{n+1} = 0$ (so all the eigenvalues are non-negative), which corresponds to taking $A \in \mathfrak{u}^*_{n+1}$ rather than in $\mathfrak{su}^*_{n+1}$. The Gelfand–Tsetlin system looks like:[4,13]

$$\begin{array}{c}
\lambda_1 > \lambda_2 > \cdots > \lambda_n > 0 \\
\mu_1^{(n)} \geqslant \mu_2^{(n)} \geqslant \cdots \geqslant \mu_n^{(n)} \\
\cdots \quad \cdots \quad \cdots \\
\mu_1^{(2)} \geqslant \mu_2^{(2)} \\
\mu_1^{(1)},
\end{array}$$

where in the ith row are the eigenvalues of the image $p_i(A)$ of the projection $p_i: \mathfrak{u}^*_{n+1} \to \mathfrak{u}^*_{n+2-i}$, which is dual to the embedding $U(n+2-i) \hookrightarrow U(n+1)$ as the left upper corner submatrix. The eigenvalues μ_i^j together with λ_i's satisfy the interlacing property:

$$\mu_i^{(j)} \geqslant \mu_i^{(j-1)} \geqslant \mu_{i+1}^{(j)}, \qquad \lambda_i \geqslant \mu_i^{(n)} \geqslant \lambda_{i+1}, \qquad \mu_n^{(n)} > 0.$$

The above-given picture can be adapted to any orbit, in particular to $\mathrm{Gr}(k)$, where we would take $\lambda_1=\cdots=\lambda_k>0$, and other λ's equal to zero. When k varies from 1 to n, the above-mentioned picture acquires more and more nonzero elements. At each step, while going from level k to $k+1$, we will get new integrals on $\mathrm{Gr}(k+1)$, which we can pull back to F_n using Ψ.

We also notice that if $\rho\in\sqrt{-1}\cdot\mathfrak{t}$ is given by $2\rho=\Sigma_{\alpha>0}\alpha$, then it is easy to see that the sum of all $\mu_i^{(j)}$'s is equal to the value of the momentum map for the diagonal torus action evaluated in the direction of ρ.

Our goal is to relate the integrals σ_j which we obtained in Sec. III using the bi-Hamiltonian approach on Hermitian symmetric spaces, and the Gelfand–Tsetlin coordinates for $X=\mathbb{CP}^n$.

Let B be the $(n+1)\times(n+1)$ matrix, representing an element of $\mathfrak{u}(n+1)^*$ such that the only nonzero element of B is λ, located in the very left upper place. The coadjoint orbit $\mathcal{O}_B$ of B is isomorphic to $\mathbb{CP}^n$, where the identification goes as follows. Any element in the coadjoint orbit of B can be viewed as ABA^{-1}, where $A\in U(n+1)$. Let (a_{ij}) be the entries of A. Then the identification

$$w:\ \mathcal{O}_B\to\mathbb{CP}^n$$

is given by

$$w(ABA^{-1})=[a_{11}:a_{21}:\cdots:a_{n+1,1}],$$

in terms of a homogeneous coordinate system $[Z_0:\cdots:Z_n]$ on $\mathbb{CP}^n$. We suspect that the following is well-known, and in any case, is not hard to compute, that the Gelfand–Tsetlin coordinates are:

$$\mu_r^{(k)}=0 \quad \text{for } r\neq 1,$$

$$\mu_1^{(k)}=\lambda(x_1+\cdots+x_k),$$

where $(x_1,\ldots,x_n)$ are the momentum map coordinates that we used in Sec. III. We arrive at the conclusion that the Gelfand–Tsetlin coordinates $\{\mu_1^{(k)}\}$ coincide (up to the multiple of λ, which we can assume equals one) with the coordinates $\{c_k\}$ introduced in Sec. III. Now, it remains to notice that our Theorem 3.4 from Sec. III immediately yields:

Theorem 4.1: *The complete family of integrals in involution $\{\sigma_i\}$ on $\mathbb{CP}^n$ obtained using the bi-Hamiltonian approach with respect to the Bruhat Poisson structure and an invariant symplectic structure are expressed by the elementary polynomials in the Gelfand–Tsetlin coordinates.*

We prove a similar result for other Hermitian symmetric spaces in a forthcoming paper.

V. COMPARISON TO THE LENARD SCHEME

Recall the following result.[5] If $\alpha\pi_0+\beta\pi_1$ is a Poisson pencil on a manifold M, and V a vector field, preserving this pencil, then there exists a sequence of smooth functions $\{g_i\}$ on M, such that g_1 is the Hamiltonian of V with respect to π_0 and the vector field of the π_0-Hamiltonian g_j is the same as the vector field of the π_1-Hamiltonian g_{j+1}:

$$i_{dg_j}\pi_0=i_{dg_{j+1}}\pi_1.$$

Moreover, the functions in the family $\{g_j\}$ are in involution with respect to both π_0 and π_1.

Our goal in this section is to show that if we start with $M=\mathbb{CP}^n$, and take the pencil (π_s,π_∞) as before, then there is a natural choice of V on $\mathbb{CP}^n$ leading to a completely integrable systems, and the integrals $\{g_j\}$ in question can be easily expressed in terms of the coordinates $(c_1,\ldots,c_n)$ that we introduced in Sec. III.

It is a matter of a simple computation that if we start with a Hamiltonian $g_1=a_1x_1+\cdots+a_nx_n$, where $(x_1,\ldots,x_n)$ are the momentum map coordinates as before, then on the big cell the corresponding initial vector field V is given by

$$V=i_{dg_1}\pi_\infty=\sum_j\ [a_j(x_1+\cdots x_j)+a_{j+1}x_{j+1}+\cdots+a_nx_n]\partial_{\phi_j}.$$

From this, one can compute

$$g_2=\sum_j\ \frac{a_j}{2}x_j^2+\sum_{l<k}\ a_kx_lx_k,$$

etc. An interesting choice for g_1 turns out to be

$$g_1=c_1+\cdots+c_n=nx_1+(n-1)x_2+\cdots+x_n,$$

which coincides with σ_1 from Sec. III. The reason for this choice is:

Proposition 5.1: The Lenard scheme associated with the Poisson pencil $(\pi_\infty,\ \pi_s)$ on $\mathbb{CP}^n$ *which starts with* $g_1=c_1+\cdots+c_n$ *and*

$$V=\sum_j\ [(n-j+1)(x_1+\cdots+x_j)+(n-j)x_{j+1}+\cdots+2x_{n-1}+x_n]\partial_{\phi_j},$$

yields

$$g_k=c_1^k+c_2^k+\cdots+c_n^k,$$

which determines a completely integrable bi-Hamiltonian system on $\mathbb{CP}^n$.

Proof: With all the explicit formulas that we have presented in this paper, the proof is a simple computation. □

We should remark that the constants $(a_1,\ldots,a_n)$ for the first Hamiltonian in the Lenard scheme have to be chosen with care for two reasons. First, the computations are not simple for an arbitrary choice. Second, as the next example shows, we do not always arrive at a completely integrable system.

Example. If one takes $g_1=x_1+\cdots+x_n$, and $V=\Sigma_j(x_1+\cdots+x_n)\partial_{\phi_j}$, then applying the above-mentioned scheme, one would obtain

$$g_k=(x_1+\cdots+x_n)^k=(g_1)^k.$$

The differentials of all functions in this family are clearly linearly dependent.

Remark: In fact, it was shown in Ref. 7 that in the Poisson–Nijenhuis situation the traces of the powers of the intertwining operator do satisfy the Lenard recursion relations. And, in fact, it is easy to see that in our situation for $X=\mathbb{CP}^n$, equipped with π_∞, and ω_s, the trace of the operator itself is a multiple of $c_1+\cdots+c_n$. However, the computations for the higher powers seem more complicated.

ACKNOWLEDGMENTS

I would like to thank Lu Jiang-Hua and Sam Evens for answering many questions regarding Bruhat Poisson structures. Lu Jiang-Hua also provided simple proofs of Propositions 3.1 and 3.2. I thank Hermann Flaschka for conversations about integrable systems. I thank Yan Soibelman for historical remarks, Ping Xu for discussions about Poisson–Nijenhuis manifolds, and Mikhail Gekhtman for useful comments. Research is partially supported by NSF Grant No. DMS-0072520.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 6 JUNE 2002

The coupled modified Korteweg–de Vries equations: Similarity reduction, Lie–Bäcklund symmetries and integrability

R. Sahadevan and N. Kannagi[a)]
Ramanujan Institute for Advanced Study in Mathematics, University of Madras, Chennai 600 005, Tamil Nadu, India

(Received 17 July 2001; accepted for publication 15 February 2002)

The Lie point symmetries of N-coupled modified Korteweg–de Vries equations (N-$cmKdV$) is derived and shown that the similarity reduction associated with symmetries passes the Painlevé property indicating its integrability. The nonclassical symmetry analysis of Bluman and Cole and the direct method of Clarkson and Kruskal to N-$cmKdV$ equations show that there exists no new similarity reductions. A sequence of Lie–Bäcklund symmetries for N-$cmKdV$ equations is derived explicitly, establishing its complete integrability. The question of constructing the recursion operator of N-$cmKdV$, a characteristic of integrable systems, is also discussed. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1473219]

I. INTRODUCTION

One of the most remarkable achievements in mathematics in the second half of the twentieth century is the discovery of solitons or integrable systems governed by nonlinear partial differential equations (PDEs).[1,2] The discovery of solitons exhibited by a particular class of wave equations has generated much interest to investigate different mathematical and physical aspects of nonlinear PDEs, both $(1+1)$ and higher dimensions, during the past few decades or so. It was found that these integrable nonlinear partial differential equations have rich mathematical structures with surprising features. For example, it possesses infinitely many Lie–Bäcklund (or nonpoint or generalized) symmetries, infinitely many integrals of motion (if the model is conservative), Bäcklund transformations, bilinear or trilinear structure equations, the Painlevé property (after perhaps a suitable change of variables), recursion operator, hereditary operator, master symmetries, etc.[1–7] Analytical techniques from Lie theory, group theory, differential geometry, etc., have been used in connection with these properties.[3,7–12] Among them, the Lie symmetry analysis originally advocated by Sophus Lie and later on developed by Ovsiannikov[13] and others[8,9,14] provides an effective and algorithmic technique to investigate mathematical aspects starting from finding an exact solution to deriving Kac–Moody algebras of nonlinear PDEs. The applicability of this algorithmic method has been widely illustrated to several nonlinear PDEs in different contexts.[15–17] It is well known that if a nonlinear PDE admits infinitely many Lie–Bäcklund or generalized symmetries, then it is expected to be integrable.[3] If the Lie–Bäcklund symmetries of a given nonlinear PDE are explicitly known, then it is quite often possible to construct the so called recursion and hereditary operator.[18] It is widely believed that the existence of recursion operator helps one to construct the Hamiltonian operators, if they exist, enabling one to check whether a given nonlinear PDE is a bi-Hamiltonian or tri-Hamiltonian system or not. Another systematic approach to investigate the integrability nature of nonlinear PDEs, using the symmetry consideration, is due to Shabat and his school.[11,12] In this approach, requiring the existence of a small number of symmetries (conservation laws) yields large classes of integrable nonlinear PDEs. It is well known that several scalar integrable nonlinear PDEs of $(1+1)$ dimension admit a sequence of Lie–Bäcklund symmetries.

a)On leave of absence from the Department of Mathematics, Queen Mary's College, Chennai-600 004, Tamil Nadu, India. Electronic mail: nkannagi@yahoo.com

However, the existence of a sequence of Lie–Bäcklund symmetries for the coupled or multicomponent integrable nonlinear PDEs has not been investigated so far, perhaps except for two coupled Korteweg–de Vries equations. In this article, we consider a system of N-coupled modified Korteweg–de Vries (N-$cmKdV$) equations

$$\frac{\partial U^i}{\partial t}+6\left(\sum_{j=1}^{N}(U^j)^2\right)\frac{\partial U^i}{\partial x}+\frac{\partial^3 U^i}{\partial x^3}=0, \quad i=1,2,\ldots,N, \tag{1.1}$$

and investigate different group theoretical properties including a sequence of Lie–Bäcklund symmetries and discuss its relation with the integrability of it. Tsuchida and Wadati[19] have shown that Eq. (1.1) is solvable by inverse scattering transform technique and also derive soliton solutions of it.

The plan of the article is as follows: In Sec. II, the Lie point symmetries of N-$cmKdV$, Eqs. (1.1), is derived and shown that the similarity reduction associated with symmetries passes the Painlevé property of ordinary differential equations. Also the existence of nonclassical symmetries and other reduction to be obtained from the direct method have been investigated in detail. In Sec. III, a sequence of Lie–Bäcklund symmetries for Eqs. (1.1) is explicitly derived, establishing its integrability. The question of constructing the recursion operator for Eqs. (1.1) has been discussed in Sec. IV. Section V contains brief details of our results.

II. SIMILARITY REDUCTION AND INTEGRABILITY

A. Classical Lie symmetry analysis

Consider a one parameter (ϵ) Lie group of continuous point transformations

$$\begin{aligned} x^*&=x+\epsilon\xi(x,t,U^1,U^2,\ldots,\ U^N)+O(\epsilon^2),\\ t^*&=t+\epsilon\tau(x,t,U^1,U^2,\ldots,\ U^N)+O(\epsilon^2),\\ (U^i)^*&=U^i+\epsilon\eta^i(x,t,U^1,U^2,\ldots,\ U^N)+O(\epsilon^2), \end{aligned} \tag{2.1}$$

where $\xi,\ \tau,\ \eta^i (i=1,2,\ldots,N)$ are infinitesimal symmetries and so the infinitesimal generator is

$$X=\xi\frac{\partial}{\partial x}+\tau\frac{\partial}{\partial t}+\eta\frac{\partial}{\partial U^1}+\eta^2\frac{\partial}{\partial U^2}+\cdots+\eta^N\frac{\partial}{\partial U^N}. \tag{2.2}$$

Hereafter, the index i varies from 1,2,…,N unless otherwise specified. Equations (1.1) are invariant under the above continuous point transformations Eq. (2.1) if

$$\frac{\partial U^{*i}}{\partial t^*}+6\left(\sum_{j=1}^{N}(U^{*j})^2\right)\frac{\partial U^{*i}}{\partial x^*}+\frac{\partial^3 U^{*i}}{\partial x^{*3}}=0, \tag{2.3}$$

provided U^i satisfy Eqs. (1.1). Substituting the expressions for various derivatives of $(U^i)^*$ in Eq. (2.3) along with Eq. (2.1) and then equating different coefficients of like derivative terms of U^i to zero, we obtain a system of overdetermined linear PDEs and, solving them successively, we determine the explicit form of infinitesimals

$$\xi=\frac{\alpha}{3}x+\delta, \quad \tau=\alpha t+\gamma, \tag{2.4}$$

$$\eta^1=\frac{-\alpha}{3}U^1, \quad \eta^2=\frac{-\alpha}{3}U^2, \quad \ldots, \quad \eta^N=\frac{-\alpha}{3}U^N, \tag{2.5}$$

where $\alpha,\ \gamma,\ \delta$ are constants and so the infinitesimal generator Eq. (2.2) takes the following form:

$$X=\left(\frac{\alpha}{3}x+\delta\right)\frac{\partial}{\partial x}+(\alpha t+\gamma)\frac{\partial}{\partial t}-\frac{\alpha}{3}\left[U^1\frac{\partial}{\partial U^1}+U^2\frac{\partial}{\partial U^2}+\ldots+U^N\frac{\partial}{\partial U^N}\right]. \tag{2.6}$$

Obviously the generators are

$$\begin{gathered}X_1=\frac{x}{3}\frac{\partial}{\partial x}+t\frac{\partial}{\partial t}-\frac{1}{3}\left(U^1\frac{\partial}{\partial U^1}+U^2\frac{\partial}{\partial U^2}+\ldots+U^N\frac{\partial}{\partial U^N}\right),\\ X_2=\frac{\partial}{\partial t},\quad X_3=\frac{\partial}{\partial x}.\end{gathered} \tag{2.7}$$

The commutator relations satisfy

$$[X_1,X_2]=-X_2,\quad [X_1,X_3]=\tfrac{1}{3}X_3,\quad [X_2,X_3]=0, \tag{2.8}$$

and so the underlying symmetry algebra is a finite dimensional one.

In order to find the similarity variable and similarity transformations associated with the infinitesimal symmetries given in Eqs. (2.4) and (2.5), we solve the characteristic equation,

$$\frac{dx}{\xi}=\frac{dt}{\tau}=\frac{dU^1}{\eta^1}=\frac{dU^2}{\eta^2}=\ldots=\frac{dU^N}{\eta^N}. \tag{2.9}$$

The similarity variable ζ and the similarity transformations $f_i(\zeta)$ are

$$\zeta=\left(x+\frac{3\delta}{\alpha}\right)\left(t+\frac{\gamma}{\alpha}\right)^{-1/3}, \tag{2.10}$$

$$f_1(\zeta)=\left(t+\frac{\gamma}{\alpha}\right)^{1/3}U^1,\quad f_2(\zeta)=\left(t+\frac{\gamma}{\alpha}\right)^{1/3}U^2,\quad \ldots,\quad f_N(\zeta)=\left(t+\frac{\gamma}{\alpha}\right)^{1/3}U^N. \tag{2.11}$$

Substituting the similarity transformations, Eq. (2.11), along with the similarity variable, Eq. (2.10), in Eqs. (1.1), we find that it reduces into a system of N-coupled nonautonomous third order ordinary differential equations

$$\begin{gathered}(\zeta f_1'+f_1)-18\left(\sum_{j=1}^{n}f_j^2\right)f_1'-3f_1'''=0,\\ (\zeta f_2'+f_2)-18\left(\sum_{j=1}^{N}f_j^2\right)f_2'-3f_2'''=0,\\ \ldots\\ \ldots\\ (\zeta f_N'+f_N)-18\left(\sum_{j=1}^{N}f_j^2\right)f_N'-3f_N'''=0,\end{gathered} \tag{2.12}$$

where $f'=df/d\zeta$. Obviously Eqs. (2.12) can be transformed into the well known second Painlevé transcendental equation for $N=1$. However, for $N\geqslant 2$ it is very difficult to transform the coupled third order Eqs. (2.12) into a known integrable equation. In order to investigate the nature of the system of Eqs. (2.12), whether integrable or not, we apply the Painlevé analysis of ordinary differential equations.[6] Also, it was demonstrated by Ablowitz, Ramani, and Segur (ARS) that there exists a deep connection between the nonlinear PDEs solvable by inverse scattering trans-

form (IST) and the Painlevé equations. In fact, they have conjectured that every ordinary differential equation obtained by an exact reduction of PDEs solvable by IST is of Painlevé type, perhaps after a transformation of variable. Exploiting the Painlevé analysis (also known as ARS algorithm), several new integrable systems have been identified in recent years[2,17,20–22] (see also Refs. 23 and 24). We present below brief details of the Painlevé analysis of the similarity reduction equations (2.12).

B. Painlevé analysis of the *N*-coupled similarity reduction

The Painlevé[6] analysis essentially consists of the following three steps:

(a) determination of the leading order of the Laurent series solution of the given ordinary differential equation in the neighborhood of a movable singular point;
(b) determination of powers (called resonances) at which arbitrary constants enter into the Laurent series expansion; and
(c) verification that a sufficient number of arbitrary constants exist as that of the order of the differential equation without the introduction of movable critical points.

To apply the Painlevé analysis, we consider a solution of Eqs. (2.12) expressed as a series expansion

$$f_i(\zeta)=(\zeta-\zeta_0)^{p_i}\sum_{m=0}^{\infty} a_{im}(\zeta-\zeta_0)^m,$$

where p_i are negative integers, $a_{i0}\neq 0$ in the neighborhood of arbitrary movable singularity ζ_0.

Substituting now

$$f_i(\zeta)\approx a_{i0}\lambda^{p_i},\quad \lambda=(\zeta-\zeta_0)\to 0 \tag{2.13}$$

in Eqs. (2.12), we find from the dominating terms that

$$p_i=-1, \tag{2.14}$$

and the N equations resulting from Eqs. (2.12) reduce into a single equation

$$\sum_{j=1}^{N} a_{j0}^2=-1. \tag{2.15}$$

To obtain the resonance values, we substitute

$$f_i(\zeta)\approx a_{i0}\lambda^{p_i}+\beta_i\lambda^{p_i+r},\ \ \lambda\to 0, \tag{2.16}$$

into the leading order terms of Eqs. (2.12) and obtain a system of N-coupled linear algebraic equations for the β_i. To have a nontrivial set of solutions, we require

$$\det M_N(r)=0, \tag{2.17}$$

where

$$M_N(r)=\begin{bmatrix} -12a_{10}^2+r' & -12a_{10}a_{20} & \dots & -12a_{10}a_{N0} \\ -12a_{20}a_{10} & -12a_{20}^2+r' & \dots & -12a_{20}a_{N0} \\ \vdots & \vdots & \vdots & \vdots \\ -12a_{N0}a_{10} & -12a_{N0}a_{20} & \dots & -12a_{N0}^2+r' \end{bmatrix},$$

where $r'=r(r-1)(r-5)$. Solving Eq. (2.17) we find the following resonance values: $r=-1,0,0,\ldots(N-1)$ times, $1,1,\ldots(N-1)$ times, $3,4,5,5,\ldots(N-1)$ times.
Next, in order to identify the arbitrary constants $a_{i\mu}$, we substitute the series expansion

$$f_i(\zeta)=\sum_{\mu=1}^{5} a_{i\mu}\lambda^{\mu-1} \tag{2.18}$$

into all the terms of Eqs. (2.12) and, by equating the like coefficients of λ at each μ, we obtain an equation of the form

$$[M_{N,\mu}][a_{i\mu}]=[S_\mu], \tag{2.19}$$

where $[M_{N,\mu}]$ is an $N\times N$ matrix, and $[a_{i\mu}]$ and $[S_\mu]$ are $N\times 1$ column matrices. The matrix $[S_\mu]$ depends only on the $a_{i\mu-1}$ coefficients. The application of Cramer's rule for determinants yields a unique solution to Eq. (2.19):

$$a_{i\mu}=\det \overline{M}_{N,\mu}/\det M_{N,\mu}, \quad \det M_{N,\mu}\neq 0, \tag{2.20}$$

where the $N\times N$ matrix $[\overline{M}_{N,\mu}]$ is obtained by replacing the ith column in $[M_{N,\mu}]$ by the column matrix $[S_\mu]$.

From Eq. (2.15) we conclude that $(N-1)$ of a_{i0}'s, $i=1,2,\ldots,N$'s, are arbitrary corresponding to the resonance values $0,0,0,\ldots,(N-1)$ times. Similarly, by equating the coefficients of λ^{-3} in all the equations of Eqs. (2.12) to zero, we find that the N-equations reduce to a single equation

$$\sum_{j=1}^{N} a_{i0}a_{j1}=0, \tag{2.21}$$

and so the $(N-1)$ coefficients of a_{j1}, $j=1,2,\ldots,N$, are arbitrary associated with the resonance values $1,1,1,\ldots,(N-1)$ times. Next, by solving a system of N-equations obtained by equating the coefficient of λ^{-2} of Eqs. (2.12) to zero, we obtain

$$a_{i2}=a_{i0}\left[\sum_{j=1}^{N} a_{j1}^2-\frac{\zeta_0}{18}\right], \tag{2.22}$$

uniquely. Similarly, by solving a system of N-equations obtained from the coefficients of λ^{-1} and λ^0 in Eqs. (2.12) we find that one of coefficients of a_{i3} and a_{i4} is arbitrary corresponding to the resonance values 3 and 4, respectively. Next by equating the coefficients of λ^1 in Eqs. (2.12) we find that the N-equations reduce into a single equation and therefore $(N-1)$ coefficients of a_{i5} are arbitrary corresponding to the resonance values $5,5,5,\ldots,(N-1)$ times.

Thus the Laurent series expansion solution (2.18) of the similarity reduction (2.12) possesses the required number, $3N$, of arbitrary constants, and is free from movable critical points. Thus the Painlevé property or ARS conjecture is satisfied. Hence the similarity reduction, Eqs. (2.12), of the N-$cmKdV$ equation (1.1) is expected to be integrable.

C. Nonclassical symmetry analysis

The nonclassical symmetry analysis which is also known as method of conditional symmetries was originally proposed by Bluman and Cole[25] and illustrated its applicability through the heat equation as an example. Later on this method was applied to several nonlinear evolution equations possessing solitons by different authors and they derived similarity reductions.[25–29] In the literature, there do exist nonlinear PDEs which possess similarity reductions that are not obtained through the classical Lie group method. For instance, new similarity reductions of the Boussinesq equation were derived through the nonclassical method which cannot be obtained through classical Lie method.[28] In this subsection we apply the nonclassical symmetry analysis to Eqs. (1.1) and

investigate whether there exist any new symmetry reductions or not. Since the methodology of nonclassical symmetry analysis is presented by different authors[25–28] in detail, we refrain from presenting detailed calculations.

In the nonclassical method, N coupled systems of Eqs. (1.1) are augmented with the invariant surface conditions

$$\xi\frac{\partial U^i}{\partial x}+\tau\frac{\partial U^i}{\partial t}-\eta^i=0, \tag{2.23}$$

where $\xi(x,t,U^i)$, $\tau(x,t,U^i)$ and $\eta^i(x,t,U^i)$ are unknowns to be determined. Now we apply the standard symmetry algorithm that provides the symmetry algebra. Then there are two cases, namely $(\tau\neq 0,\xi\neq 0)$ and $(\tau=0,\xi\neq 0)$, possible.

Let us first consider the case $\tau\neq 0,\xi\neq 0$. Without loss of generality we assume that $\tau=1$ and so the invariant surface conditions, Eqs. (2.23), become

$$\frac{\partial U^i}{\partial t}+\xi\frac{\partial U^i}{\partial x}-\eta^i=0. \tag{2.24}$$

Making use of the point transformations (2.1) we obtain a system of invariant equations for Eqs. (1.1) which involves $\partial U^i/\partial t$ and $\partial^3 U^i/\partial x^3$. Using Eq. (2.24) we replaced the derivative term $\partial U^i/\partial t$ in the above mentioned invariance equation and rearranging it yields a system of overdetermined nonlinear PDEs. By solving the obtained determining equations successively we explicitly determine ξ, η^i,

$$\tau=1,\quad \xi=\frac{x}{3t},\quad \eta^1=\frac{-U^1}{3t},\quad \eta^2=\frac{-U^2}{3t},\quad \ldots,\quad \eta^N=\frac{-U^N}{3t}, \tag{2.25}$$

and the associated infinitesimal generator takes the following form:

$$X=\frac{x}{3t}\frac{\partial}{\partial x}+\frac{\partial}{\partial t}-\frac{1}{3t}\left(U^1\frac{\partial}{\partial U^1}+U^2\frac{\partial}{\partial U^2}+\ldots+U^N\frac{\partial}{\partial U^N}\right). \tag{2.26}$$

Let us compare the nonclassical symmetries of Eqs. (1.1) with the classical ones. We now multiply the invariant surface conditions (2.24) and the corresponding vector field (2.26) by t gives the following vector field:

$$Y=t\frac{\partial}{\partial t}+\frac{x}{3}\frac{\partial}{\partial x}-\frac{1}{3}\left(U^1\frac{\partial}{\partial U^1}+U^2\frac{\partial}{\partial U^2}+\ldots+U^N\frac{\partial}{\partial U^N}\right). \tag{2.27}$$

Comparing the infinitesimal generator of Eq. (2.6) obtained from the classical symmetry analysis with that of Eq. (2.27) we find that there exist no nonclassical symmetries in this case. Similar conclusions for the case $\tau=0$ and $\xi\neq 0$ can also be arrived at. Thus we conclude that no nonclassical symmetries exist for the system of N-$cmKdV$, Eqs. (1.1).

D. Direct method

The direct method of deriving similarity reductions of PDEs was originally proposed by Clarkson and Kruskal[30] and was applied to a variety of nonlinear PDEs by different researchers[2,31–33] (see also Ref. 34). The unusual characteristic of this method in comparison with the other methods is that it involves no use of group theory or Lie symmetry analysis. The basic idea of this method is to seek a solution of a nonlinear PDEs involving two independent variables in the form

$$U(x,t)=F(x,t,w(z(x,t))). \tag{2.28}$$

Then, requiring that substitution of Eq. (2.28) into the given nonlinear PDE yields an ordinary differential equation for $w(z)$. This imposes a condition upon $F(x,t,w(z))$ and its derivatives which enables one to solve for $F(t,x,w(z))$, which yields the desired reduction.

In order to use the direct method as usual we substitute

$$U^i(x,t)=A_i(x,t)+B_i(x,t)w_i(z(x,t)), \tag{2.29}$$

where $A_i(x,t)$ and $B_i(x,t)$ are unknown functions in Eqs. (1.1). We then obtain the following third order nonlinear ordinary differential equation:

$$\begin{aligned} &B_i z_x^3 w_i''' + w''(3B_{i,x}z_x^2+3B_i z_x z_{xx}) + w_i'(B_i z_t+3B_{i,xx}z_x+3B_{i,x}z_{xx}+B_i z_{xxx}+\tilde{A}B_i z_x)\\ &\quad + w_i(B_{i,t}z_t+B_{i,xxx}+\tilde{A}B_{i,x})+\tilde{B}A_{i,x}+w_i\tilde{B}B_{i,x}+w_i\tilde{C}B_{i,x}+w_i'\tilde{C}B_i z_x\\ &\quad + w_i'\tilde{B}B_i z_x+\tilde{C}A_{i,x}+A_{i,t}+A_{i,xxx}+\tilde{A}A_{i,x}=0, \end{aligned} \tag{2.30}$$

where

$$\tilde{A}=6\sum_{j=1}^{N} A_j^2, \tilde{B}=6\sum_{j=1}^{N} w_j^2 B_j^2, \tilde{C}=12\sum_{j=1}^{N} w_j A_j B_j, w'=\frac{dw}{dz}.$$

Note that the coefficient of w_i''' is $B_i z_x^3$. Using this as the normalizing coefficient and taking the other coefficient of the form $B_i z_x^3 \Gamma(z)$, where $\Gamma(z)$ is an unknown function to be determined, we obtain the following equations:

$$w_i^2 w_i' : B_i^3 z_x = B_i z_x^3 \Gamma_1, \tag{i}$$

$$w_i^2 : B_i^2 A_{i,x} = B_i z_x^3 \Gamma_2, \tag{ii}$$

$$w_i w_i' : A_i B_i^2 z_x = B_i z_x^3 \Gamma_3, \tag{iii}$$

$$w_i^3 : B_i^2 B_{i,x} = B_i z_x^3 \Gamma_4, \tag{iv}$$

$$w_i'' : B_{i,x} z_x^2 + B_i z_x z_{xx} = B_i z_x^3 \Gamma_5, \tag{v}$$

$$w_i' : B_i z_t + 3B_{i,xx}z_x + 3B_{i,x}z_{xx} + B_i z_{xxx} + 6\left(\sum_{i=1}^{N} A_j^2\right) B_i z_x = B_i z_x^3 \Gamma_6, \tag{vi}$$

$$w_i : B_{i,t} + B_{i,xxx} + 12A_i B_i A_{i,x} + 6\left(\sum_{j=1}^{N} A_j^2\right) B_{i,x} = B_i z_x^3 \Gamma_7. \tag{vii}$$

Solving the above determining equations (i)–(vii) successively, we find that the consistency condition holds only if

$$U^i(x,t)=t^{-1/3}w_i(z), z=xt^{-1/3}. \tag{2.31}$$

Thus the similarity transformation and the similarity variable obtained through the direct method are exactly the same derived through the classical Lie method. Thus we conclude that the direct method also does not yield any new similarity reductions for the system of N-$cmKdV$, Eqs. (1.1).

III. LIE–BÄCKLUND SYMMETRIES OF N-cmKdV EQUATIONS

It is well known that the existence of infinitely many commuting Lie–Bäcklund symmetries is the defining feature of complete integrability of nonlinear PDEs. It was shown by different authors

that several scalar integrable nonlinear PDEs of $(1+1)$ dimension admit a sequence of Lie–Bäcklund symmetries.[3,14,35,36] However, the existence of a sequence of Lie–Bäcklund symmetries for the coupled or multicomponent integrable PDEs has not been investigated so far. In this subsection we show that the N-coupled modified Korteweg–de Vries equations (1.1) admits a sequence of Lie–Bäcklund symmetries.

Basically the Lie–Bäcklund transformations are the generalized Lie groups of point transformations that are defined by infinitesimals depending on a finite number of derivatives of the dependent variables. Now consider a one parameter (ϵ) infinitesimal Lie–Bäcklund transformation,

$$\begin{gathered}(U^i)^*=U^i+\epsilon\eta^i(x,t,U^i_k)+O(\epsilon^2),\\ x^*=x,t^*=t,\\ (U^i_t)^*=U^i_t+\epsilon[\eta^i_t]+O(\epsilon^2),\\ (U^i_k)^*=U^i_k=\epsilon[\eta^i_x]+O(\epsilon^2),k=0,1,2,\ldots,\infty,\end{gathered}\tag{3.1}$$

where

$$\begin{gathered}U^i_0=U^i,\quad U^i_k=\frac{\partial^k U^i}{\partial x^k},\quad U^i_{kt}=\frac{\partial U^i_k}{\partial t},\quad [\eta^i_t]=D_t\eta^i,\\ [\eta^i_x]=D_x\eta^i,\quad [\eta^i_{xx}]=D^2_x\eta^i,\quad [\eta^i_{xxx}]=D^3_x\eta^i.\end{gathered}\tag{3.2}$$

Define the total derivative operators

$$D_x=\sum_{i=0}^{N}\sum_{k=0}^{\infty}U^i_{k+1}\frac{\partial}{\partial U^i_k},\quad D_t=\sum_{i=0}^{N}\sum_{k=0}^{\infty}U^i_{kt}\frac{\partial}{\partial U^i_k},\tag{3.3}$$

and the Lie–Bäcklund (LB) operator

$$X(\eta^i)=\sum_{i=0}^{N}(D_t\eta^i)\frac{\partial}{\partial U^i_t}+\sum_{i=0}^{N}\sum_{k=0}^{\infty}(D^k_x\eta^i)\frac{\partial}{\partial U^i_k}.\tag{3.4}$$

Making use of the one parameter (ϵ) Lie–Bäcklund transformations (3.1) along with the different derivatives of U^i in Eqs. (1.1) we obtain the following system of coupled invariance equations:

$$[\eta^i_t]+6\left(\sum_{j=1}^{N}(U^j)^2\right)[\eta^i_x]+12\left(\sum_{j=1}^{N}U^j\eta^j\right)U^i_x+[\eta^i_{xxx}]=0.\tag{3.5}$$

The above coupled equations can be written as a polynomial in U^i and its derivatives with respect to the variables x and t. We further assume that η^i do not depend on the independent variables x and t. Then by equating the coefficients of different derivatives of U^i in Eq. (3.5) to zero and solving them successively we find the form of η^i's explicitly. Since the calculations of obtaining the Lie–Bäcklund symmetries η^i for Eqs. (1.1) are tedious and cumbersome for arbitrary N, for clarity, we present the details for the cases $N=2$ and $N=3$. Let

$$\begin{gathered}U^1=u,\quad U^2=v,\quad U^3=w,\quad \frac{\partial U^1}{\partial x}=u_1,\quad \frac{\partial U^2}{\partial x}=v_1,\quad \frac{\partial U^3}{\partial x}=w_1,\\ \frac{\partial^2U^1}{\partial x^2}=u_2,\quad \frac{\partial^2U^2}{\partial x^2}=v_2,\quad \frac{\partial^2U^3}{\partial x^2}=w_2,\quad \frac{\partial^3U^1}{\partial x^3}=u_3,\quad \frac{\partial^3U^2}{\partial x^3}=v_3,\quad \frac{\partial^3U^3}{\partial x^3}=w_3.\end{gathered}\tag{3.6}$$

Case (i): $N=2$. The two coupled $mKdV$ equations are

$$u_t+6(u^2+v^2)u_1+u_3=0, \quad v_t+6(u^2+v^2)v_1+v_3=0, \tag{3.7}$$

and so the invariance equations (3.5) become

$$[\eta_{1,t}]+6(u^2+v^2)[\eta_{1,x}]+12(u\eta_1+v\eta_2)u_1+[\eta_{1,xxx}]=0, \tag{3.8a}$$

$$[\eta_{2,t}]+6(u^2+v^2)[\eta_{2,x}]+12(u\eta_1+v\eta_2)v_1+[\eta_{2,xxx}]=0. \tag{3.8b}$$

The trivial symmetries of the two coupled modified Korteweg–de Vries equations (3.7) are

$$\eta_I^1=u_1, \quad \eta_I^2=v_1 \tag{3.9}$$

and

$$\eta_{II}^1=u_3+6(u^2+v^2)u_1, \quad \eta_{II}^2=v_3+6(u^2+v^2)v_1. \tag{3.10}$$

Detailed calculations show that the next higher order symmetries η_{III}^1 and η_{III}^2 to be of the form

$$\eta_{III}^1=u_5+F(u,u_1,u_2,u_3,u_4,v,v_1,v_2,v_3,v_4), \tag{3.11}$$

$$\eta_{III}^2=v_5+G(u,u_1,u_2,u_3,u_4,v,v_1,v_2,v_3,v_4), \tag{3.12}$$

where F, G are unknown functions to be determined. Substituting the above Eqs. (3.11) and (3.12) along with derivative terms with respect to x and t in the two coupled invariant equations (3.8a) and (3.8b) and first equating the coefficients of u_7,u_6,u_5,u_4 and v_7,v_6,v_5,v_4 to zero yields the following determining PDEs:

$$\frac{\partial\eta_{III}^1}{\partial u_4}=0, \quad \frac{\partial\eta_{III}^2}{\partial u_4}=0, \quad \frac{\partial\eta_{III}^1}{\partial v_4}=0, \quad \frac{\partial\eta_{III}^2}{\partial v_4}=0, \quad \frac{\partial\eta_{III}^1}{\partial v_3}=0, \quad \frac{\partial\eta_{III}^2}{\partial u_3}=0, \tag{3.13}$$

$$\frac{\partial\eta_{III}^1}{\partial u_3}=10(u^2+v^2), \quad \frac{\partial\eta_{III}^2}{\partial v_3}=10(u^2+v^2). \tag{3.14}$$

Solving Eqs. (3.13) and (3.14) we obtain

$$F=10(u^2+v^2)u_3+F_1(u,u_1,u_2,v,v_1,v_2) \tag{3.15}$$

and

$$G=10(u^2+v^2)v_3+G_1(u,u_1,u_2,v,v_1,v_2), \tag{3.16}$$

where F_1, G_1 are arbitrary functions to be determined. Proceeding further we obtain the explicit forms of F_1 and G_1 and so the next order Lie–Bäcklund symmetries η_{III}^1 and η_{III}^2 are

$$\begin{aligned}\eta_{III}^1=&u_5+10(u^2+v^2)u_3+30(u^2+v^2)^2u_1+10(u_1^2+v_1^2)u_1\\&+20(uu_2+vv_2)u_1+20(uu_1+vv_1)u_2,\end{aligned} \tag{3.17}$$

$$\begin{aligned}\eta_{III}^2=&v_5+10(u^2+v^2)v_3+30(u^2+v^2)^2v_1+10(u_1^2+v_1^2)v_1\\&+20(uu_2+vv_2)v_1+20(uu_1+vv_1)v_2.\end{aligned} \tag{3.18}$$

Continuing this algorithmic procedure, we find that the two coupled modified Korteweg–de Vries equations (3.7) admit a sequence of Lie–Bäcklund symmetries.

Case (ii): $N=3$. The three coupled $mKdV$ equations are

$$u_t+6\rho^2u_1+u_3=0,\quad v_t+6\rho^2v_1+v_3=0,\quad w_t+6\rho^2w_1+w_3=0, \tag{3.19}$$

and the associated invariance equations become

$$[\eta_{1,t}]+6\rho^2[\eta_{1,x}]+12(u\eta_1+v\eta_2+w\eta_3)u_1+[\eta_{1,xxx}]=0, \tag{3.20a}$$

$$[\eta_{2,t}]+6\rho^2[\eta_{2,x}]+12(u\eta_1+v\eta_2+w\eta_3)v_1+[\eta_{2,xxx}]=0, \tag{3.20b}$$

$$[\eta_{3,t}]+6\rho^2[\eta_{3,x}]+12(u\eta_1+v\eta_2+w\eta_3)w_1+[\eta_{3,xxx}]=0, \tag{3.20c}$$

where $\rho^2=u^2+v^2+w^2$. Proceeding as before, as that of two coupled modified Korteweg–de Vries equations we obtain following Lie–Bäcklund symmetries for the three-$cmKdV$ equations:

$$\eta_I^1=u_1,\eta_{II}^1=u_3+6\rho^2u_1,\eta_I^2=v_1,\quad \eta_{II}^2=v_3+6\rho^2v_1,\quad \eta_I^3=w_1,\eta_{II}^3=w_3+6\rho^2w_1, \tag{3.21}$$

$$\eta_{III}^1=u_5+10\rho^2u_3+30\rho^4u_1+10\rho_1^2u_1+20\rho_2u_2+20\rho_3u_1, \tag{3.22}$$

$$\eta_{III}^2=v_5+10\rho2v_3+30\rho^4v_1+10\rho_1^2v_1+20\rho_2v_2+20\rho_3v_1, \tag{3.23}$$

$$\eta_{III}^3=w_5+10\rho^2w_3+30\rho^4w_1+10\rho_1^2w_1+20\rho_2w_2+20\rho_3w_1, \tag{3.24}$$

where $\rho_1^2=u_1^2+v_1^2+w_1^2$, $\rho_2=uu_1+vv_1+ww_1$ and $\rho_3=uu_2+vv_2+ww_2$. Since the procedure is algorithmic we refrain from presenting the further details of the next order Lie–Bäcklund symmetries.

Case (iii): For N-$cmKdV$, Eqs. (1.1), the Lie–Bäcklund symmetries take the following forms:

$$\eta_I^1=U_x^1,\quad \eta_I^2=U_x^2,\quad \ldots,\quad \eta_I^N=U_x^N, \tag{3.25}$$

$$\eta_{II}^1=U_{xxx}^1+6V^2U_x^1,\quad \eta_{II}^2=U_{xxx}^2+6V^2U_x^2,\quad \ldots,\quad \eta_{II}^N=U_{xxx}^N+6V^2U_x^N, \tag{3.26}$$

$$\eta_{III}^1=U_{xxxxx}^1+10V^2U_{xxx}^1+30V^4U_x^1+10V_1^2U_x^1+20V_2U_{xx}^1+20V_3U_x^1, \tag{3.27}$$

$$\eta_{III}^2=U_{xxxxx}^2+10V^2U_{xxx}^2+30V^4U_x^2+10V_1^2U_x^2+20V_2U_{xx}^2+20V_3U_x^2, \tag{3.28}$$

$$\ldots$$

$$\ldots$$

$$\eta_{III}^N=U_{xxxxx}^N+10V^2U_{xxx}^N+30V^4U_x^N+10V_1^2U_x^N+20V_2U_{xx}^N+20V_3U_x^N, \tag{3.29}$$

where $V^2=\Sigma_{j=1}^N(U^j)^2$, $V_1^2=\Sigma_{j=1}^N(U_x^j)^2$, $V_2=\Sigma_{j=1}^NU^jU_x^j$, $V_3=\Sigma_{j=1}^NU^jU_{xx}^j$.

The next higher order Lie–Bäcklund symmetries N-$cmKdV$ of Eqs. (1.1) can be obtained in a straightforward manner.

IV. RECURSION OPERATOR

In the investigation of algebraic properties of integrable nonlinear PDEs such as infinitely many symmetries, integrals of motion, existence of a bi-Hamiltonian formulation, etc., recursion operators play a central role.[3,4] If a nonlinear PDE admits a sequence of Lie–Bäcklund symmetries, it is often possible to construct its recursion operator. If the recursion operator is hereditary, then the equation possesses infinitely many symmetries. It is widely believed that the existence of recursion operators helps one to construct the Hamiltonian operators, if they exist, enabling one to check whether a given nonlinear PDE is a bi-Hamiltonian or tri-Hamiltonian system or not. There

exist different analytical techniques to construct a recursion operator for a given integrable nonlinear PDE.[4,37–40] Among them the method proposed by Aiyer[37] provides an effective technique to construct a recursion operator through group theory techniques. The advantage of this approach is that it does not require the existence of Lax representation of the concerned equation. In this subsection we use this method to construct recursion operators for the *N-cmKdV* equations (1.1). For clarity, we present the details for $N=2$ and $N=3$, which are 2×2 and 3×3 matrices, respectively.

Case (i): $N=2$

Here $U^1=u$, $U^2=v$. Let $T(u,v)$ be a 2×2 recursion operator of the two-*cmKdV* equations (3.7), connecting $(u_x,v_x)=(u_1,v_1)$ to (u_t,v_t). Then $T(u,v)$ is given by

$$T(u,v)\begin{pmatrix} u_1 \\ v_1 \end{pmatrix}=\begin{pmatrix} T_{11} & T_{12} \\ T_{21} & T_{22} \end{pmatrix}=\begin{pmatrix} u_t \\ v_t \end{pmatrix}, \tag{3.30}$$

where

$$T_{11}=-D_x^2-4(u^2+v^2)-4u_1D_x^{-1}(u);\quad T_{12}=-4u_1D_x^{-1}(v),$$

$$T_{21}=-4v_1D_x^{-1}(u);\quad T_{22}=-D_x^2-4(u^2+v^2)-4v_1D_x^{-1}(v).$$

In order to find the Lie–Bäcklund or infinitesimal transformations of the next higher order, we look for a recursion operator such that

$$T^2(u,v)\begin{pmatrix} u_1 \\ v_1 \end{pmatrix}=\begin{pmatrix} \eta^1_{III} \\ \eta^2_{III} \end{pmatrix}. \tag{3.31}$$

Then $T^2(u,v)$ takes the following form:

$$T^2(u,v)=\begin{pmatrix} T_{11} & T_{12} \\ T_{21} & T_{22} \end{pmatrix},$$

where

$$\begin{aligned} T_{11}=&D_x^4+8(u^2+v^2)D_x^2+20uu_1D_x+10vv_1D_x+20(uu_2+vv_2)\\ &+10(u_1^2+v_1^2)+18(u^2+v^2)^2+4\{u_3+6(u^2+v^2)u_1\}D_x^{-1}(u),\\ T_{12}=&10u_2v+4\{u_3+6(u^2+v^2)u_1\}D_x^{-1}(v),\\ T_{21}=&10v_2u+4\{v_3+6(u^2+v^2)v_1\}D_x^{-1}(u),\\ T_{22}=&D_x^4+8(u^2+v^2)D_x^2+20vv_1D_x+10uu_1D_x+20(uu_2+vv_2)\\ &+10(u_1^2+v_1^2)+18(u^2+v^2)^2+4\{v_3+6(u^2+v^2)v_1\}D_x^{-1}(v). \end{aligned}$$

Thus $T(u,v)$, whose elements are given by Eq. (3.30), exists, and, acting repeatedly on $\binom{u_1}{v_1}$, generates two sets of infinitesimal transformations. Further, we get the following hierarchy of the two *cmKdV* equations (3.7):

$$\begin{pmatrix} u_t \\ v_t \end{pmatrix}=T^n(u,v)\begin{pmatrix} u_1 \\ v_1 \end{pmatrix}=\begin{pmatrix} \eta_1^{(n+1)} \\ \eta_2^{(n+1)} \end{pmatrix}, \tag{3.32}$$

where

$$\eta_1^{(1)}=\eta_{\rm I}^1=u_1,\quad \eta_2^{(1)}=\eta_{\rm I}^2=v_1,$$

$$\eta_1^{(2)}=\eta_{\rm II}^1=u_3+6(u^2+v^2)u_1,\quad \eta_2^{(2)}=\eta_{\rm II}^2=v_3+6(u^2+v^2)v_1,\ \text{etc.}$$

Case (ii): $N=3$

Here $U^1=u$, $U^2=v$, $U^3=w$. Let $T(u,v,w)$ be a 3×3 recursion operator of the three-*cmKdV* equations, connecting (u_1,v_1,w_1) to (u_t,v_t,w_t). Then $T(u,v,w)$ is given by

$$T(u,v,w)\begin{pmatrix}u_1\\v_1\\w_1\end{pmatrix}=\begin{pmatrix}T_{11}&T_{12}&T_{13}\\T_{21}&T_{22}&T_{23}\\T_{31}&T_{32}&T_{33}\end{pmatrix}=\begin{pmatrix}u_t\\v_t\\w_t\end{pmatrix}\tag{3.33}$$

with

$$T_{11}=-D_x^2-4\rho^2-4u_1D_x^{-1}(u);\ \ T_{12}=-4u_1D_x^{-1}(v);\ \ T_{13}=-4u_1D_x^{-1}(w);$$

$$T_{21}=-4v_1D_x^{-1}(u);\ \ T_{22}=-D_x^2-4\rho^2-4v_1D_x^{-1}(v)\ \ T_{23}=-4v_1D_x^{-1}(w);$$

$$T_{31}=-4w_1D_x^{-1}(u);\ \ T_{32}=-4w_1D_x^{-1}(v);$$

$$T_{33}=-D_x^2-4\rho^2-4w_1D_x^{-1}(w);$$

where $\rho^2=u^2+v^2+w^2$.

In order to find the Lie–Bäcklund or infinitesimal transformations of the next higher order, we look for a recursion operator $T(u,v,w)$ for the three-*cmKdV* Eqs. (3.19) such that

$$T^2(u,v,w)\begin{pmatrix}u_1\\v_1\\w_1\end{pmatrix}=\begin{pmatrix}\eta^1_{III}\\\eta^2_{III}\\\eta^3_{III}\end{pmatrix}.\tag{3.34}$$

Then $T(u,v,w)$ takes the following form:

$$T(u,v,w)=\begin{pmatrix}T_{11}&T_{12}&T_{13}\\T_{21}&T_{22}&T_{23}\\T_{31}&T_{32}&T_{33}\end{pmatrix},\tag{3.35}$$

where

$$\begin{aligned}T_{11}&=D_x^4+8\rho^2D_x^2+20uu_1D_x+10(vv_1+ww_1)D_x+20(uu_2+vv_2+ww_2)\\&\quad+10\rho_1^2+18\rho^4+4\{u_3+6\rho^2u_1\}D_x^{-1}(u),\\T_{12}&=10u_2v+4\{u_3+6\rho^2u_1\}D_x^{-1}(v),\\T_{13}&=10u_2w+4\{u_3+6\rho^2u_1\}D_x^{-1}(w),\\T_{21}&=10v_2u+4\{v_3+6\rho^2v_1\}D_x^{-1}(u),\\T_{22}&=D_x^4+8\rho^2D_x^2+20vv_1D_x+10(uu_1+ww_1)D_x+20(uu_2+vv_2\\&\quad+ww_2)+10\rho_1^2+18\rho^4+4\{v_3+6\rho^2v_1\}D_x^{-1}(v),\\T_{23}&=10v_2w+4\{v_3+6\rho^2v_1\}D_x^{-1}(w),\end{aligned}\tag{3.36}$$

$$T_{31}=10w_2u+4\{w_3+6\rho^2w_1\}D_x^{-1}(u),$$

$$T_{32}=10w_2v+4\{w_3+6\rho^2w_1\}D_x^{-1}(v),$$

$$T_{33}=D_x^4+8\rho^2D_x^2+20ww_1D_x+10(uu_1+vv_1)D_x+20(uu_2+vv_2+ww_2)$$
$$+10\rho_1^2+18\rho^4+4\{w_3+6\rho^2w_1\}D_x^{-1}(w),$$

where $\rho_1^2=u_1^2+v_1^2+w_1^2$.

Here also, we get the following hierarchy of the three-$cmKdV$ equations (3.19)

$$\begin{pmatrix} u_t \\ v_t \\ w_t \end{pmatrix}=T^n(u,v,w)\begin{pmatrix} u_1 \\ v_1 \\ w_1 \end{pmatrix}=\begin{pmatrix} \eta_1^{(n+1)} \\ \eta_2^{(n+1)} \\ \eta_3^{(n+1)} \end{pmatrix},$$

where

$$\eta_1^{(1)}=\eta_{\mathrm{I}}^1=u_1,\quad \eta_2^{(1)}=\eta_{\mathrm{I}}^2=v_1,\quad \eta_3^{(1)}=\eta_{\mathrm{I}}^3=w_1,$$

$$\eta_1^{(2)}=\eta_{\mathrm{II}}^1=u_3+6\rho^2u_1,\quad \eta_2^{(2)}=\eta_{\mathrm{II}}^2=v_3+6\rho^2v_1,\quad \eta_3^{(2)}=\eta_{\mathrm{II}}^3=w_3+6\rho^2w_1,\quad \text{etc.}$$

By applying the procedure described above to N-$cmKdV$ equations (1.1), one can derive its recursion operator.

V. CONCLUSIONS

Using the classical Lie symmetry approach we derive the Lie point symmetries of N-$cmKdV$ equations and show that the similarity reduction associated with symmetries passes the Painlevé property for ordinary differential equations. Also, detailed investigations through the nonclassical symmetry approach and the direct method show that no new similarity reductions exist. Further, a sequence of Lie–Bäcklund symmetries for N-$cmKdV$ equations is derived, explicitly establishing its integrability. We have made an attempt to derive the recursion operator, a characteristic of integrable systems, for N-$cmKdV$ equations. The question of factorization of the derived recursion operator and the derivation of the well known hereditary operator is under investigation.

Generalized symmetries in mechanics and field theories

L. Fatibene,[a] M. Ferraris, M. Francaviglia, and R. G. McLenaghan[b]

(Received 25 November 2001; accepted for publication 23 January 2002)

Generalized symmetries are introduced in a geometrical and global formalism. Such a framework applies naturally to field theories and specializes to mechanics. Generalized symmetries are characterized in a Lagrangian context by means of the transformation rules of the Poincaré–Cartan form and the (generalized) Nöther theorem is applied to obtain conserved quantities (first integrals in mechanics). In the particular case of mechanics it is shown how to use generalized symmetries to study the separation of variables of Hamilton–Jacobi equations recovering standard results by means of this new method. Supersymmetries (Wess–Zumino model) are considered as an intriguing example in field theory. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1469668]

I. INTRODUCTION

In a number of different applications, both in mechanics and in field theory, symmetries of a more general nature than the standard Lagrangian symmetries are often used (see Refs. 1–4). Ordinary Lagrangian symmetries are usually defined as transformations in the phase space which preserve the Lagrangian (or the Hamiltonian) form (see Refs. 5–8 and references quoted therein). To each one-parameter flow of Lagrangian symmetries a conserved quantity can then be associated via the so-called *Nöther theorem* (see, e.g., Refs. 6, 8, and 9). Such a theorem can be generalized in at least two physically relevant different directions.

First, one can consider transformations which do not preserve the Lagrangian form exactly, but modulo contact forms and exact differentials. Both contact forms and exact forms are, in fact, irrelevant to the Nöther theorem. Second, one can consider transformations acting on field configurations which are not induced by a transformation on the configuration space. Furthermore, since all quantities in the Nöther theorem are computed along a field configurations (and, in particular, usually along a solution) a one-parameter flow of transformations is enough to define Nöther currents by Lie dragging. In this perspective transformations on the configuration space are just a way of obtaining such a flow. More generally one can consider a transformation on the infinite jet prolongation of the configuration bundle; the infinitesimal generators of such transformations are *generalized vector fields* which will be introduced and discussed later (see Refs. 2 and 10). This approach turns out to be along the lines traced by Carter in the linear case (see Ref. 11). In the present article we develop the necessary notions and tools to deal with nonlinear systems and provide detailed examples which illustrate the relation between Lagrangian symmetries and Killing tensors.

Such a geometrical definition of generalized symmetries has been implicitly used in a number of contexts and applications. In mechanics, the first integrals of motion can often be related to separation of variables for the Hamilton–Jacobi equation and they may be generated via Nöther theorem starting from generalized symmetries. In field theory, BRST transformations, which are the most powerful tool for the quantization of gauge theories, are generalized symmetries (see Refs. 3, 4, and 12). Finally, also supersymmetries are interpretable as generalized symmetries (see Refs. 3 and 13).

[b]On the leave of absence from Department of Applied Mathematics, University of Waterloo, Ontario, Canada.

The main purpose of this article is to set these applications in the general and standard contexts of Lagrangian formalism and variational calculus. In fact, as we shall discuss in the sequel, most of the applications mentioned above in their original formulation strongly rely on Hamiltonian formalism, while we are going to set them in a purely Lagrangian context (which is certainly more standard, at least for field theories).

The plan of the article is as follows. In Sec. II we shall briefly recall the geometrical formulation of field theory which will be used extensively below. We use the geometric language of the Lagrangian framework on bundles together with the Poincaré–Cartan formulation since it is particularly suited to deal with mechanics and field theory at the same time and at any order of fields derivatives involved. In Sec. III generalized vector fields, generalized symmetries and generalized Nöther's theorem are defined. In Sec. IV we collect a number of worked out examples to mechanics and separation of variables for Hamilton–Jacobi equation. Finally, in Secs. V and VI we deal with BRST transformations and Wess–Zumino supersymmetric model as examples of application of generalized symmetries to field theory.

II. GEOMETRICAL FRAMEWORK FOR FIELD THEORY AND MECHANICS

We shall here briefly summarize the notations used in the geometrical formulation of field theory and mechanics. We assume the reader to be familiar with the basic ideas of bundle theory and classical differential geometry. Further details can be found in Refs. 6, 8, 10, and 14–17.

Let $\mathcal{C}=(C,M,\pi;F)$ be the *configuration bundle*; here C, M and F are manifolds called the *total space*, the *base* and the *standard fiber*, respectively. The map $\pi:C\to M$ is called the *projection* and it is a surjective map of maximal rank. Fiber bundles are the natural framework to deal with calculus of variations; in fact fibered coordinates on C are $(x^\mu;y^i)$ where the coordinates x^μ $[\mu=1,\ldots,\dim(M)]$ on M denote the *independent variables* while the coordinates y^i $[i=1,\ldots,\dim(F)]$ on F denote the *dependent variables*, i.e., the fields.

In mechanics one can choose $C=\mathbb{R}\times Q$ where Q is the configuration space of the system. The base manifold is $M=\mathbb{R}$ and the only independent variable is denoted by t. The fibered coordinates on $\mathbb{R}\times Q$ are (t,q^i) and q^i are the usual Lagrangian coordinates of the system.

A vector field Ξ over $\mathcal{C}$ is *projectable* if it projects over a vector field ξ of the base manifold M. Locally, projectable vector fields are hence of the form

$$\Xi=\xi^\mu(x)\partial_\mu+\xi^i(x,y)\partial_i. \tag{2.1}$$

The flow of such a projectable vector field is made of fiber preserving morphisms, i.e., a one-parameter subgroup of bundle morphisms

$$\begin{aligned} x'^\mu&=\phi_s^\mu(x),\\ y'^i&=Y_s^i(x,y). \end{aligned} \tag{2.2}$$

The vector field Ξ is the infinitesimal generator of the flow of bundle morphisms, i.e.,

$$\begin{aligned} \xi^\mu&=\frac{\mathrm{d}\phi_s^\mu}{\mathrm{d}s}(x)\bigg|_{s=0},\\ \xi^i&=\frac{\mathrm{d}Y_s^i}{\mathrm{d}s}(x,y)\bigg|_{s=0}. \end{aligned} \tag{2.3}$$

A *vertical vector field* is a vector field over $\mathcal{C}$ which projects over the zero vector field in M. Locally, a vertical vector field is in the form $\Xi=\xi^i(x,y)\partial_i$.

A *(field) configuration* is a section $\sigma:M\to C$ of the configuration bundle; locally it corresponds to a map $\sigma(x)=(x^\mu,y^i(x))$, which specifies the dependent variables as functions of the

independent variable [in mechanics $\sigma(t)=(t,q^i(t))$ represents a curve in the configuration space Q]. The transition functions of the bundle $\mathcal{C}$ encode the global topological properties of the system.

The *jet prolongation of order k* of the bundle $\mathcal{C}$ will be denoted by $J^k\mathcal{C}$, for each $k\geqslant 0$. We set $J^0\mathcal{C}\simeq\mathcal{C}$. It is a bundle over M (and over C as well as over each J^hC for $h\leqslant k$) which takes into account the fields with their derivatives up to order k included. The intermediate projections are $\pi^k_h: J^k\mathcal{C}\to J^h\mathcal{C}$, with $\pi^k_k=id$. Fibered coordinates on J^kC are denoted by $(x^\mu,y^i,y^i_\mu,y^i_{\mu\nu},\ldots,y^i_{\mu_1\ldots\mu_k})$. In mechanics the configuration bundle is isomorphic to $\mathbb{R}\times Q$ (the isomorphism being, by definition, the *observer*) and one has $J^kC\simeq\mathbb{R}\times T^kQ$ where T^kQ is the tangent bundle of order k (a point in T^kQ is an equivalence class of curves in Q having contact of order k at $t=0$). For $k=1$ the bundle T^kQ reduces to the ordinary tangent bundle TQ of the configuration space and the standard first order framework of mechanics is recovered.

The inverse limit of the inverse family $J^k\mathcal{C}$ is an infinite dimensional bundle which is denoted by $J^\infty\mathcal{C}$ and it is called the *infinite jet bundle* of $\mathcal{C}$ (see Ref. 18). All the constructions we make on finite jet bundles extend in a straighforward way to the infinite jet bundle.

If one considers a bundle morphism $\mathbf{\Phi}=(\Phi,\phi):\mathcal{C}\to\mathcal{C}'$, it can be prolonged at any order; the jet prolongation will be denoted by $J^k\mathbf{\Phi}=(j^k\Phi,\phi)$, and it makes the following diagram commutative

$$\begin{array}{ccc} J^kC & \xrightarrow{j^k\Phi} & J^kC' \\ \downarrow & & \downarrow \\ C & \xrightarrow{\Phi} & C' \\ \downarrow & & \downarrow \\ M & \xrightarrow{\phi} & M' \end{array} \tag{2.4}$$

One can also define the infinite jet prolongation $j^\infty\mathbf{\Phi}$ as the inverse limit of the family of bundle morphisms $j^k\mathbf{\Phi}$.

A section $\sigma:M\to C$ can be lifted to a section $j^k\sigma:M\to J^kC$ which is locally given by $j^k\sigma(x)=(x^\mu,y^i(x),\mathrm{d}_\mu y^i(x),\ldots,\mathrm{d}_{\mu_1\ldots\mu_k}y^i(x))$. The lift to the infinite jet bundles is obtained by the inverse limit and it is denoted by $j^\infty\sigma$.

Finally any (projectable) vector field $\Xi=\xi^\mu(x)\partial_\mu+\xi^i(x,y)\partial_i$ on $\mathcal{C}$ can be prolonged at any order to define a (projectable) vector field $j^k\Xi$ on $J^k\mathcal{C}$. The prolongation of a (projectable) vector field Ξ is the infinitesimal generator of the prolongation of the bundle morphisms (2.2). As an example, for $k=1$ the vector field $j^1\Xi=\xi^\mu\partial_\mu+\xi^i\partial_i+\xi^i_\mu\partial^\mu_i$ is locally expressed by

$$\xi^i_\mu=\mathrm{d}_\mu\xi^i-y^i_\nu\mathrm{d}_\mu\xi^\nu, \tag{2.5}$$

where the operator

$$\mathrm{d}_\mu=\partial_\mu+y^i_\mu\partial_i+y^i_{\nu\mu}\partial^\nu_i+\cdots \tag{2.6}$$

denotes (at any order k) the *formal total derivative* with respect to x^μ. Analogous but more complicated expressions hold for $k>1$ (see, e.g., Refs. 8, 17, and 18).

Contact one-forms over $J^k\mathcal{C}$ are the forms belonging to the ideal generated in $\Omega(J^k\mathcal{C})$ by

$$\begin{aligned} \omega^i&=\mathrm{d}y^i-y^i_\nu\mathrm{d}x^\nu, \\ \omega^i_\mu&=\mathrm{d}y^i_\mu-y^i_{\nu\mu}\mathrm{d}x^\nu, \\ &\cdots \end{aligned} \tag{2.7}$$

$$\omega^i_{\mu_1\dots\mu_{k-1}} = \mathrm{d}y^i_{\mu_1\dots\mu_{k-1}} - y^i_{\mu_1\dots\mu_{k-1}\nu}\mathrm{d}x^\nu.$$

Notice that all contact forms ω vanish when evaluated along the prolongation of any section, i.e., $(j^k\sigma)^*\omega = 0$.

Whenever we consider a form α over J^kC we can uniquely split its pull-back $(\pi^{k+1}_k)^*\alpha$ into the sum of a horizontal part $\mathrm{hor}(\alpha)$ and a contact part $\alpha_{(K)}$ so that $(\pi^{k+1}_k)^*\alpha = \mathrm{hor}\alpha \oplus \alpha_{(K)}$, where both $\mathrm{hor}(\alpha)$ and $\alpha_{(K)}$ are forms over $J^{k+1}C$. By an abuse of notation one identifies $(\pi^{k+1}_k)^*\alpha$ with α and simply writes $\alpha = \mathrm{hor}\alpha \oplus \alpha_{(K)}$. For example, if $\alpha = \alpha_\mu \mathrm{d}x^\mu + \alpha_i \mathrm{d}y^i + \alpha^\mu_i \mathrm{d}y^i_\mu$ is a one-form over J^1C, where all coefficients depend on (x^μ, y^i, y^i_μ), then we have the splitting

$$\alpha = (\alpha_\mu + \alpha_i y^i_\mu + \alpha^\nu_i y^i_{\mu\nu})\mathrm{d}x^\mu \oplus (\alpha_i \omega^i + \alpha^\mu_i \omega^i_\mu) = \mathrm{hor}\alpha \oplus \alpha_{(K)}. \tag{2.8}$$

We stress once again that both $\mathrm{hor}(\alpha) = (\alpha_\mu + \alpha_i y^i_\mu + \alpha^\nu_i y^i_{\mu\nu})\mathrm{d}x^\mu$ and $\alpha_{(K)} = \alpha_i \omega^i + \alpha^\mu_i \omega^i_\mu$ are one-forms over J^2C since they both involve $y^i_{\mu\nu}$. Such an example can be easily generalized to any form over any J^kC (see Ref. 19).

A *Lagrangian of order k* is a bundle morphism $L: J^kC \to A_m(M)$, where $A_m(M)$ is the bundle of m-forms over M $[\dim(M) = m]$. Locally the Lagrangian is expressed as

$$L = \mathcal{L}(x^\mu, y^i, y^i_\mu, y^i_{\mu\nu}, \dots, y^i_{\mu_1\dots\mu_k})\mathbf{ds} \tag{2.9}$$

with $\mathbf{ds} = \mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^m$. We will consider only first order Lagrangians $(k=1)$ even though most of the theory can be easily generalized to any order (see Refs. 20–23). The *Poincaré–Cartan form* of a first order Lagrangian is the m-form Θ_L over J^1C locally given by

$$\Theta_L = \mathcal{L}\mathbf{ds} + p^\mu_i \omega^i \wedge \mathbf{ds}_\mu, \quad p^\mu_i = \frac{\partial \mathcal{L}}{\partial y^i_\mu}, \tag{2.10}$$

where $\mathbf{ds}_\mu = i_{\partial_\mu}\mathbf{ds}$ and p^μ_i are the *Lagrangian momenta*.

The action functional can be recast in terms of the Poincaré–Cartan form as

$$A_D(\sigma) \equiv \int_D L \circ j^1\sigma = \int_D (j^1\sigma)^*\Theta_L, \tag{2.11}$$

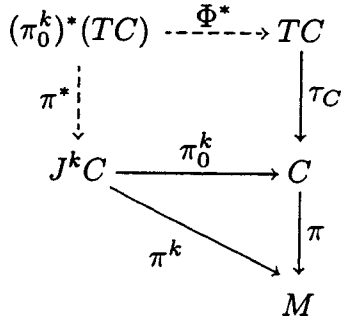
where $D \subseteq M$ is any compact domain with a regular boundary ∂D. If $X = \xi^i(x,y)\partial_i$ is any vertical vector field on C, together with its flow Φ_s and its lift j^1X to J^1C, we can drag the section σ along X by defining $\sigma_s = \Phi_s \circ \sigma$. The *variation of the action* along X is hence given by

$$\delta_X A_D(\sigma) = \frac{\mathrm{d}}{\mathrm{d}s} A_D(\sigma_s) = \int_D (j^1\sigma)^* \pounds_{j^1X}\Theta_L = \int_D (j^1\sigma)^* i_{j^1X}\mathrm{d}\Theta_L + \int_{\partial D} (j^1\sigma)^* i_{j^1X}\Theta_L, \tag{2.12}$$

where i_{j^1X} denotes contraction of forms along the vector field j^1X and $\mathrm{d}(\cdot)$ denotes the relevant exterior differential. If the vector X vanishes on the boundary ∂D of the region D, the second integral vanishes, too. By the Hamilton principle a section σ is then a *critical section* when $\delta_X A_D(\sigma) = 0$, for all regions D and any vertical vector field X which vanishes on ∂D. Equivalently, σ is a critical section if and only if $i_{j^1X}\mathrm{d}\Theta_L = 0$, for any vertical vector field X. This framework is completely equivalent to the ordinary Lagrangian framework (see Refs. 20 and 21). In fact, it can be easily shown that for X vanishing on the boundary one has $\delta_X A_D(\sigma) = \int_D (j^1\sigma)^* i_{j^1X} d\Theta_L = \int_D (j^2\sigma)^* \langle \mathbb{E}(L) | X \rangle$, where $\mathbb{E}(L)$ is the Euler–Lagrange morphism and $\langle | \rangle$ denotes the standard contraction. The Poincaré–Cartan formulation is well suited to deal with symmetries (as well as an introduction for Hamiltonian formalism and as a tool to unifying mechanics and field theory at any order). In mechanics all standard results are recovered.

III. GENERALIZED SYMMETRIES AND GENERALIZED NÖTHER THEOREM

Consider the following commutative diagram



(3.1)

The bundle $(\pi_0^k)^*(TC)$ is the pull-back of the bundle $\tau_C : TC \to C$ along the map $\pi_0^k : J^kC \to C$ and Φ^* is uniquely defined (see Refs. 10 and 19); a point in $(\pi_0^k)^*(TC)$ is a pair (p,v) where $p \in J^k\mathcal{C}$, $v \in TC$ and $\tau_C(v) = \pi_0^k(p)$, i.e., $v \in T_{\pi_0^k(p)}C$. Let Ξ be a section of the bundle $(\pi_0^k)^*(TC) \to J^k\mathcal{C}$ with local expression

$$\Xi : J^k\mathcal{C} \to (\pi_0^k)^*(TC) : p \mapsto (p, \xi^\mu(p)\partial_\mu + \xi^i(p)\partial_i). \tag{3.2}$$

The section Ξ is called a *generalized vector field* and by an abuse of notation is denoted simply by

$$\Xi = \xi^\mu(x^\mu, y^i, y^i_\mu, \ldots, y^i_{\mu_1 \ldots \mu_k})\partial_\mu + \xi^i(x^\mu, y^i, y^i_\mu, \ldots, y^i_{\mu_1 \ldots \mu_k})\partial_i . \tag{3.3}$$

Consider further a section $\sigma : M \to C$ together with its prolongation $j^k\sigma$; by composition we obtain a section $\Phi^* \circ \Xi \circ j^k\sigma$ of the bundle $TC \to M$ which is a *vector field over the section* σ. In principle, the section σ can be dragged along Ξ.

Notice that a generalized vector field Ξ is not a vector field on C (unless $k=0$) since its components depend on the derivatives of fields (see Ref. 2). Moreover, no jet prolongation $j^r\Xi$ of a generalized vector field Ξ is an ordinary vector field on any $J^s\mathcal{C}$. As an example, we can consider its prolongation to $J^1\mathcal{C}$

$$j^1\Xi = \xi^\mu\partial_\mu + \xi^i\partial_i + \xi^i_\mu\partial^\mu_i , \quad \xi^i_\mu = \mathrm{d}_\mu\xi^i - y^i_\nu \mathrm{d}_\mu\xi^\nu . \tag{3.4}$$

Clearly this is not a vector field on $J^1\mathcal{C}$ (since ξ^i_μ depends on the second order derivatives of fields) nor it is a vector field on $J^2\mathcal{C}$ [since no $\partial^{\mu\nu}_i$ is involved and the local expressions (3.4) do not glue together when changes of fibered coordinates on $\mathcal{C}$ are considered]. In other words, even if one can drag sections along a generalized vector field Ξ, such an object does not define a transformation on any finite jet bundle. Generalized vector fields can in fact be regarded as infinitesimal generators of transformations on $J^\infty C$ (see Refs. 2 and 18). We shall hereafter restrict to *projectable generalized vector fields* when the components $\xi^\mu(x)$ are independent on fields or *vertical generalized vector fields* which have $\xi^\mu = 0$.

Let σ_s be a family of sections of C and let Ξ be a projectable (generalized) vector field. The *vertical part* of $\Xi = \xi^\mu\partial_\mu + \xi^i\partial_i$ is defined by

$$\Xi_{(V)} = \xi^i - \xi^\mu y^i_\mu . \tag{3.5}$$

We remark that even when Ξ is an ordinary vector field the vertical part $\Xi_{(V)}$ is in any case a generalized (vertical) vector field. We say that σ_s is *dragged along* Ξ if and only if

$$\frac{\mathrm{d}}{\mathrm{d}s}\sigma_s = \Xi_{(V)} \circ \sigma_s . \tag{3.6}$$

A *generalized symmetry* of a Lagrangian L is a generalized vector field Ξ over C such that the Poincaré–Cartan form of L satisfies the following condition

$$\pounds_{j^1\Xi}\Theta_L = \omega + \mathrm{d}\alpha, \tag{3.7}$$

where ω is any contact form and α is any $(m-1)$-form (both possibly depending on the derivatives of fields).

Since the sum between horizontal and contact forms is direct, condition (3.7) is equivalent to

$$\mathrm{hor}(\pounds_{j^1\Xi}\Theta_L) = \mathrm{hor}\ \mathrm{d}\alpha, \tag{3.8}$$

which, since the Lie derivative of a contact form is again a contact form, is in turn equivalent to

$$\mathrm{hor}(\pounds_{j^1\Xi}(\mathrm{hor}\Theta_L)) = \mathrm{hor}(\pounds_{j^1\Xi}(\mathcal{L}\mathbf{ds})) = \mathrm{hor}\ \mathrm{d}\alpha. \tag{3.9}$$

By expanding this last equation in local fiber coordinates (x^μ, y^i, y^i_μ) over J^1C, for the jet prolongation of a (generalized) vector field $j^1\Xi = \xi^\mu\partial_\mu + \xi^i\partial_i + \xi^i_\mu\partial^\mu_i$ projecting onto $\xi = \xi^\mu\partial_\mu$, one obtains

$$[\mathrm{d}_\mu(\xi\mathcal{L}) - p_i(\xi^\mu y^i_\mu - \xi^i) - p^\mu_i(\xi^\nu y^i_{\mu\nu} - \xi^i_\mu)] = \mathrm{d}_\mu\alpha^\mu. \tag{3.10}$$

One can also regard this latter condition as a global condition expressed directly in terms of the Lagrangian (i.e., not involving the Poincaré–Cartan form); in the standard notation, see, e.g., Ref. 8, Eq. (3.10) can be in fact intrinsically expressed as

$$\pounds_\xi L - \langle \delta L | j^1\pounds_\Xi\sigma\rangle = \mathrm{Div}(\alpha). \tag{3.11}$$

In other words, a generalized symmetry leaves the Lagrangian form invariant modulo pure divergence terms plus terms which depend on the first variation δL. However, in the sequel we shall prefer to use the Poincaré–Cartan formalism which is more direct since it deals only with forms over J^kC.

If Ξ is a generalized symmetry, σ is a solution of field equations and σ_s is a dragging of σ along Ξ in the sense of (3.6), then σ_s is a solution for all s. In fact we have

$$\frac{\mathrm{d}}{\mathrm{ds}}A_D(\sigma_s) = \frac{\mathrm{d}}{\mathrm{ds}}\int_D (j^1\sigma_s)^*\Theta_L = \int_D (j^1\sigma)^*\pounds_{j^1\Xi}\Theta_L = \int_D (j^1\sigma)^*\omega + \int_D (j^1\sigma)^*\mathrm{d}\alpha. \tag{3.12}$$

The first integrand vanishes since ω is contact; by Stokes' theorem the second integral reduces to $\int_{\partial D}(j^1\sigma)^*\alpha$, which is constant with respect to deformations. In fact its variation along a vertical vector field X vanishes since $X=0$ on ∂D. Hence $(\mathrm{d}/\mathrm{ds})\,\delta_X A_D(\sigma_s) = 0$, which implies that the variation of the action is constant along the flow of the symmetry, which in turn preserves critical sections. The *generalized Nöther theorem* immediately follows. It is a constructive theorem associating to any symmetry generator Ξ a conserved current $\mathcal{E}$. In fact for any generalized symmetry generator Ξ (of order s) the following identity holds true:

$$\pounds_{j^1\Xi}\Theta_L = \omega + \mathrm{d}\alpha. \tag{3.13}$$

Expanding the Lie derivative and collecting terms it can immediately be recast as

$$\mathrm{d}(i_{j^1\Xi}\Theta_L - \alpha) = -i_{j^1\Xi}\mathrm{d}\Theta_L + \omega. \tag{3.14}$$

Define the quantities

$$\begin{cases} \mathcal{E} = (j^{2k-1}\sigma)^*(i_{j^1\Xi}\Theta_L - \alpha), \\ \mathcal{W} = -(j^{2k}\sigma)^* i_{j^1\Xi}\mathrm{d}\Theta_L. \end{cases} \tag{3.15}$$

Then the identity (3.14), pulled back on M along a section σ, can be expressed as

$$\mathrm{d}\mathcal{E}=\mathcal{W}. \tag{3.16}$$

This is the expression of Nöther's theorem; in fact, whenever σ is a solution of field equations, then $\mathcal{W}=0$ and hence the so-called *Nöther current* $\mathcal{E}$ is conserved, i.e., $\mathrm{d}\mathcal{E}=0$ which is equivalent to a continuity equation.

Equation, (3.16) is called a *weak conservation law* since it implies $\mathrm{d}\mathcal{E}=0$ on-shell (i.e., along critical sections).

For formal reasons it will be useful to define also the quantity

$$\overline{\mathcal{E}}=\mathrm{hor}(i_{j^1\Xi}\Theta_L-\alpha). \tag{3.17}$$

Because of the splitting into horizontal and contact part we have

$$(j^{2k}\sigma)^*\overline{\mathcal{E}}=\mathcal{E}. \tag{3.18}$$

IV. GENERALIZED SYMMETRIES IN MECHANICS AND SEPARATION OF VARIABLES

Let us consider a mechanical system described by a first order Lagrangian L (or, equivalently, by its Poincaré–Cartan form Θ_L) on the configuration bundle $C\simeq\mathbb{R}\times Q$ and a first order (projectable) generalized vector field

$$\Xi=\xi^\mu(t)\partial_t+\xi^i(t,q^i,\dot{q}^i)\partial_i. \tag{4.1}$$

The generator Ξ is a generalized symmetry if it leaves the Poincaré–Cartan form invariant modulo contact forms and exact forms, i.e., if

$$\pounds_{j^1\Xi}\Theta_L=\omega+\mathrm{d}\alpha, \tag{4.2}$$

where $\alpha(t,q,\dot{q})$ is a zero-form over $J^1C\simeq\mathbb{R}\times TQ$ and ω is a contact form. Then, in this case, we have for the horizontal part

$$\mathrm{hor}(\pounds_{j^1\Xi}\Theta_L)=\frac{\mathrm{d}\alpha}{\mathrm{d}t}\mathrm{d}t, \tag{4.3}$$

where $\mathrm{d}\alpha/\mathrm{d}t$ is the formal total derivative of α with respect of t and, consequently, the right hand side of Eq. (4.3) is an horizontal one-form over $J^2\mathcal{C}$. Hence Ξ is a generalized symmetry if and only if the horizontal part of the Lie derivative of the Poincaré–Cartan form is an exact differential.

Now one can consider $L'=\mathrm{hor}(\pounds_{j^1\Xi}\Theta_L)$ as an auxiliary Lagrangian. Whenever its equations of motion are identically satisfied, then L' is an exact differential. The equations of motion of the auxiliary Lagrangian L', considered as a system of partial differential equations for the components (ξ^μ,ξ^i) of the symmetry generator Ξ, are hence called the *covariance conditions for the original Lagrangian* L.

These partial differential equations are usually quite diffucult to solve, but one can try to solve them for the most general generalized symmetry and subsequently to apply the Nöther theorem with the aim of obtaining conserved quantities (i.e., first integrals in mechanics). As we shall see, such a computation leads to quite general results.

A. Free particle in the plane

Let us consider the free particle on the plane $\mathbb{R}^2$. Without loss of generality we can assume its mass to be unitary. The Lagrangian is hence

$$L=\tfrac{1}{2}(\dot{x}^2+\dot{y}^2)\mathrm{d}t. \tag{4.4}$$

The corresponding Poincaré–Cartan form reads

$$\Theta_L = -\tfrac{1}{2}(\dot{x}^2+\dot{y}^2)\mathrm{d}t+\dot{x}(\mathrm{d}x-\dot{x}\mathrm{d}t)+\dot{y}(\mathrm{d}y-\dot{y}\mathrm{d}t)=\tfrac{1}{2}(\dot{x}^2+\dot{y}^2)\mathrm{d}t+\dot{x}\mathrm{d}x+\dot{y}\mathrm{d}y. \tag{4.5}$$

Let us look for the general expression of the generators of generalized (first order) symmetries of L. A first order generalized vector field may be locally expressed as

$$\Xi = \xi(t)\partial_t+\Xi_x(t,x,y,\dot{x},\dot{y})\partial_x+\Xi_y(t,x,y,\dot{x},\dot{y})\partial_y. \tag{4.6}$$

Let us assume the components to be linear in the velocities, i.e., let us suppose that we have

$$\begin{aligned}\Xi_x(t,x,y,\dot{x},\dot{y})&=\alpha_x(t,x,y)+\xi_x(t,x,y)\dot{x}+\zeta_x(t,x,y)\dot{y},\\ \Xi_y(t,x,y,\dot{x},\dot{y})&=\alpha_y(t,x,y)+\zeta_y(t,x,y)\dot{x}+\xi_y(t,x,y)\dot{y}.\end{aligned} \tag{4.7}$$

The horizontal part of the Lie derivative of the Poincaré–Cartan form Θ_L with respect to the symmetry generator Ξ is hence

$$\begin{aligned}\mathrm{hor}(\pounds_{j^1\Xi}\Theta_L)=[&(\xi_x\dot{x}+\zeta_y\dot{y})\ddot{x}+(\zeta_x\dot{x}+\xi_y\dot{y})\ddot{y}+\dot{x}^2(\dot{x}\partial_x\xi_x+(\partial_y\xi_x+\partial_x\zeta_x+\partial_x\zeta_y)\dot{y}\\ &+\partial_t\xi_x+\partial_x\alpha_x-\tfrac{1}{2}\partial_t\xi)+\dot{y}^2(\dot{y}\partial_y\xi_y+(\partial_x\xi_y+\partial_y\zeta_y+\partial_y\zeta_x)\dot{x}+\partial_t\xi_y+\partial_y\alpha_y-\tfrac{1}{2}\partial_t\xi)\\ &+\dot{x}\dot{y}(\partial_y\alpha_x+\partial_y\alpha_x+\partial_t\zeta_x+\partial_t\zeta_y)+\dot{x}\partial_t\alpha_x+\dot{y}\partial_t\alpha_y.]\mathrm{d}t.\end{aligned} \tag{4.8}$$

To check whether (4.8) is a total derivative with respect to time we have to regard it as an auxiliary Lagrangian and see when its equations of motion identically vanish. In that way we obtain a system of partial differential equations which can be solved with respect to the symmetry generator Ξ. The result one obtains is the following general expression for the (generalized) symmetry generator:

$$\begin{aligned}\Xi=&a_0\xi(t)(\partial_t+\dot{x}\partial_x+\dot{y}\partial_y)\oplus a_1\partial_x\oplus b_1\partial_y\oplus a_2t\partial_x\oplus b_2t\partial_y\oplus a_3(xt-\dot{x}t^2)\partial_x\oplus b_3(yt+\dot{y}t^2)\partial_y\\ &\oplus a_4\dot{x}\partial_x\oplus b_4\dot{y}\partial_y\oplus a_5((tx\dot{x}-2ty\dot{x})\partial_x+(tx\dot{x}-x^2)\partial_y)\oplus b_5((ty\dot{y}-y^2)\partial_x+(ty\dot{y}-2tx\dot{y})\partial_y)\\ &\oplus a_6((y-\dot{y}t)\partial_x-t\dot{x}\partial_y)\oplus b_6(-t\dot{y}\partial_x+(x-\dot{x}t)\partial_y)\oplus a_7((x\dot{x}-2y\dot{y})\partial_x+x\dot{x}\partial_y)\\ &\oplus b_7(y\dot{y}\partial_x+(y\dot{y}-2x\dot{x})\partial_y)\oplus a_8(x-2t\dot{x})\partial_x\oplus b_8(y-2t\dot{y})\partial_y\oplus c_1(\dot{y}\partial_x+\dot{x}\partial_y)\\ &\oplus c_2((xy\dot{y}-y^2\dot{x})\partial_x+(xy\dot{x}-x^2\dot{y})\partial_y)\oplus c_3((yt-t^2\dot{y})\partial_x+(xt-t^2\dot{x})\partial_y),\end{aligned} \tag{4.9}$$

where a_1 $(i=0,1,\ldots,8)$, b_j $(j=1,2,\ldots,8)$ and c_l $(l=1,2,3)$ are 20 real constants.

Each of these generators yields a generalized symmetry for the Lagrangian L. We can now apply the Nöther theorem to obtain respectively the following 20 first integrals of motion (one of which is trivial) for the free particle in the plane:

$$\begin{aligned}E_0&=0,\\ E_1&=\dot{x},\quad E_2=\dot{y},\\ E_3&=t\dot{x}-x,\quad E_4=t\dot{y}-y,\\ E_5&=-\tfrac{1}{2}(x-t\dot{x})^2,\quad E_6=-\tfrac{1}{2}(y-t\dot{y})^2,\\ E_7&=\tfrac{1}{2}\dot{x}^2,\quad E_8=\tfrac{1}{2}\dot{y}^2,\\ E_9&=-(x-t\dot{x})(x\dot{y}-y\dot{x}),\quad E_{10}=(y-t\dot{y})(x\dot{y}-y\dot{x}),\\ E_{11}&=(x-t\dot{x})\dot{y},\quad E_{12}=(y-t\dot{y})\dot{x},\end{aligned} \tag{4.10}$$

$$E_{13}=(x\dot{y}-y\dot{x})\dot{x}, \quad E_{14}=(y\dot{x}-x\dot{y})\dot{y},$$

$$E_{15}=(x-t\dot{x})\dot{x}, \quad E_{16}=(y-t\dot{y})\dot{y},$$

$$E_{17}=\dot{x}\dot{y},$$

$$E_{18}=-\tfrac{1}{2}(x\dot{y}-y\dot{x})^2,$$

$$E_{19}=-(x-t\dot{x})(y-t\dot{y}).$$

One can easily check that all these quantities are conserved along solutions of the equations of motion of L. We should remark that the particular form of these first integrals of motion depends on the particular basis we have chosen for the symmetry generators, which in turn depends on the algorithm chosen to solve the covariance condition. One is free to change the basis, i.e., to perform any linear combination of the first integrals of motion. For example, one can consider $E_{11}-E_{12}=x\dot{y}-y\dot{x}$, and recover angular momentum.

It is known (see Refs. 1 and 24–26) that there are exactly four coordinate systems (independent on time) which lead to the separation of variables of the corresponding Hamilton–Jacobi equation in the plane; they are related to the following first integrals of motion (see Refs. 1 and 25):

$$\begin{gathered}\dot{x}^2=2E_7 \quad \text{(Cartesian coordinates)},\\ (x\dot{y}-y\dot{x})\dot{y}=-E_{14} \quad \text{(parabolic coordinates)},\\ (x\dot{y}-y\dot{x})^2=-2E_{18} \quad \text{(polar coordinates)},\\ -2E_{18}-c\dot{y}(x\dot{y}-y\dot{x})=-2E_{18}+2c^2E_7 \quad \text{(Elliptic coordinates)}.\end{gathered} \tag{4.11}$$

Consequently we can relate (modulo overall constant factors which are unessential) the four separation of variables in the plane with the following symmetry generators:

$$\begin{gathered}\Xi_1=\dot{x}\partial_x \quad \text{(Cartesian coordinates)},\\ \Xi_2=y\dot{y}\partial_x+(y\dot{y}-2x\dot{x})\partial_y \quad \text{(parabolic coordinates)},\\ \Xi_3=(x\dot{y}-y\dot{x})(y\partial_x-x\partial_y) \quad \text{(polar coordinates)}.\\ \Xi_4=\Xi_3\oplus c(y\dot{y}\partial_x+(y\dot{y}-2x\dot{x})\partial_y) \quad \text{(Elliptic coordinates)}.\end{gathered} \tag{4.12}$$

Notice that none of these is an ordinary vector field so that separation of variables is not related to ordinary vector fields and generalized symmetries are required. Explicit calculations have been carried out by using the MapleV tensor package (see Ref. 27).

B. Kepler problem

Let us consider a particle on the plane attracted to a fixed center by a Newtonian potential. We can assume its mass to be unitary. The Lagrangian is hence

$$L=\left[\frac{1}{2}(\dot{r}^2+r^2\dot{\theta}^2)+\frac{\kappa}{r}\right]\mathrm{d}t. \tag{4.13}$$

The corresponding Poincaré–Cartan form reads as

$$\Theta_L=\left[\frac{1}{2}(\dot r^2+r^2\dot\theta^2)+\frac{\kappa}{r}\right]\mathrm{d}t+\dot r(\mathrm{d}r-\dot r\,\mathrm{d}t)+r^2\dot\theta(\mathrm{d}\theta-\dot\theta\mathrm{d}t)=-\left[\frac{1}{2}(\dot r^2+r^2\dot\theta^2)-\frac{\kappa}{r}\right]\mathrm{d}t+\dot r\,\mathrm{d}r+r^2\dot\theta\,\mathrm{d}\theta. \tag{4.14}$$

Let us look for the general expression of the generators of generalized (first order) symmetries of L. A first order generalized vector field is locally expressed as

$$\Xi=\xi(t)\partial_t+\Xi_x(t,x,y,\dot x,\dot y)\partial_x+\Xi_y(t,x,y,\dot x,\dot y)\partial_y\,, \tag{4.15}$$

and the components are assumed to be linear in the velocities, i.e., we have

$$\begin{aligned}\Xi_x(t,x,y,\dot x,\dot y)&=\alpha_x(t,x,y)+\xi_x(t,x,y)\dot x+\zeta_x(t,x,y)\dot y,\\ \Xi_y(t,x,y,\dot x,\dot y)&=\alpha_y(t,x,y)+\zeta_y(t,x,y)\dot x+\xi_y(t,x,y)\dot y.\end{aligned} \tag{4.16}$$

The resulting generalized symmetry generators have the following general expression:

$$\begin{aligned}\Xi=a_0\partial_t\oplus a_1\partial_\theta\oplus a_2(r^2\dot\theta\sin\theta\partial_r+(-2r\cos\theta+\dot r\sin\theta)\partial_\theta)\\ \oplus a_3(r^2\dot\theta\cos\theta\partial_r+(-2r\sin\theta+\dot r\cos\theta)\partial_\theta)\oplus a_4r^2\dot\theta\partial_\theta\,,\end{aligned} \tag{4.17}$$

where a_i $(i=0,1,2,3,4)$ are five real constants.

All these generators can be directly checked to provide a generalized symmetry for the Lagrangian L. We can apply Nöther's theorem to obtain respectively the following five first integrals of motion

$$\begin{aligned}E_0&=\frac{1}{2}(\dot r^2+r^2\dot\theta^2)-\frac{\kappa}{r},\\ E_1&=r^2\dot\theta,\\ E_2&=r^3\dot\theta^2\cos\theta+r^2\dot r\,\dot\theta\sin\theta-\kappa\cos\theta,\\ E_3&=r^3\dot\theta^2\sin\theta+r^2\dot r\,\dot\theta\cos\theta-\kappa\sin\theta,\\ E_4&=-\tfrac{1}{2}r^4\dot\theta^2.\end{aligned} \tag{4.18}$$

The first one is total energy, the second the z-component of angular momentum; the vector $L=E_2\partial_x+E_3\partial_y=v\times(r\times v)-\kappa\partial_r$ is the so-called *Laplace vector*, also known as the *Runge–Lenz vector*, which is related to the perihelia precession.

One can easily check that all these quantities are conserved along solutions of the equations of motion. The integral E_4 leads to polar separation. The components of the Laplace vector E_2 lead to parabolic separation, while $-2E_4+2c^2E_2$ leads to elliptic separation (c is the distance between the center and the focuses) (see Refs. 1, 24 and 25).

Explicit calculations have been carried out by using the Maple V tensor package (see Ref. 27).

V. BRST TRANSFORMATIONS

As an example of generalized symmetries in field theories we shall hereafter consider BRST transformations, which are very relevant to the contemporary approach to quantum field theories (see Refs. 4, 12 and reference quoted therein).

Let us consider Minkowski space–time (M,η) on which we choose Cartesian coordinates x^μ and we define the dynamical field A^C_μ. The field A^C_μ is a Yang–Mills field, i.e., a principal

connection on a suitable (*a priori* fixed) principal bundle $\mathcal{P}$ with a semisimple gauge group G (see Ref. 28). The Cartan–Killing metric over G will be denoted by κ_{AB}. The curvature of A^C_μ is given by

$$F^A{}_{\mu\nu}=\mathrm{d}_\nu A^C_\mu-\mathrm{d}_\mu A^C_\nu+c^C{}_{AB}A^A_\mu A^B_\nu, \quad F^{\mu\nu}_A\equiv\kappa_{AB}F^B_{\rho\sigma}g^{\mu\rho}g^{\nu\sigma}. \tag{5.1}$$

The Yang–Mills Lagrangian,

$$L_{\mathrm{YM}}=-\tfrac{1}{4}F^A_{\mu\nu}F^{\mu\nu}_A\sqrt{g}\,\mathbf{ds}, \tag{5.2}$$

has very attractive symmetry properties related to gauge transformations.

From a quantum viewpoint, however, the situation does not appear so positive. The Yang–Mills Lagrangian is degenerate; as a direct consequence one cannot define the propagator of the Yang–Mills field. This is ultimately due to the fact that the gauge field A^A_μ contains both physical and unphysical degrees of freedom. One usually fixes a gauge, for example, the Lorentz gauge $g^{\mu\nu}\mathrm{d}_\mu A^A_\nu=0$. This solves the problem of propagators, but unfortunately the theory is no longer unitary, i.e. its dynamics does not conserve probability normalization (see 12). Fortunately enough unitarity can be restored by introducing a *ghost field* c^A together with its antighost field $\overline{c^A}$. In our case $(c^A,\overline{c^A})$ are scalar anticommuting fields. Another field B^A has to be introduced as a Lagrangian multiplier for the Lorentz gauge fixing.

Following Ref. 4, we consider the Lagrangian

$$L_{\mathrm{BRST}}=\left[-\frac{1}{4}F^A{}_{\mu\nu}F_A{}^{\mu\nu}+\mathrm{d}^\mu\overline{c}_A D_\mu c^A-\mathrm{d}^\mu B_A A^A_\mu+\frac{\alpha}{2}B_A B^A\right]\sqrt{g}\,\mathbf{ds}, \tag{5.3}$$

where α is a coupling constant and $D_\mu c^A=\mathrm{d}_\nu c^A+c^A{}_{BC}A^B_\mu c^A$, is the covariant derivative of the ghost field. Modulo a pure divergence term $-\mathrm{d}^\mu(B_A A^A_\mu)$, one can identify the Lagrange multiplier term $B_A\mathrm{d}^\mu A^A_\mu$ in order to introduce the Lorentz gauge and the ghost kinetic term $\mathrm{d}^\mu\overline{c}_A D_\mu c^A$. This Lagrangian is no longer gauge covariant but it yields a unitary quantum field theory and it defines good propagators which are nonetheless gauge dependent. However, propagators are not observable physical quantities. Only Green functions will be observable and one can prove that they are not affected by the gauge choice; gauge covariance is hence restored at an observational level.

The field equations are

$$\begin{gathered}
D_\nu F_C{}^{\nu\lambda}=\mathrm{d}^\lambda\overline{c}_A c^A{}_{BC}c^B+\mathrm{d}^\lambda B_C,\\
\Box\overline{c}_A+\overline{c}_C c^C{}_{AB}\mathrm{d}^\mu A^B_\mu=\mathrm{d}^\mu(\overline{c}_C c^C{}_{AB}A^B_\mu),\\
\Box c^A=\mathrm{d}^\mu(c^A{}_{BC}A^B_\mu c^C),\\
\alpha B^A+\mathrm{d}^\mu A^A_\mu=0,
\end{gathered} \tag{5.4}$$

where, as usual, we restrict to deformations which keep the background η fixed and where we denote by $\Box$ the box operator $\Box=\mathrm{d}^\mu\mathrm{d}_\mu$.

In the quantization of such a theory, which is beyond the scope of this article, it turns out to be useful to notice that the Lagrangian L_{BRST} is covariant with respect to the following generalized transformations:

$$\begin{gathered}
\delta A^A{}_\mu=\epsilon D_\mu c^A=\epsilon(\mathrm{d}_\mu c^A+c^A{}_{BC}A^B_\mu c^C),\\
\delta c^A=-\frac{\epsilon}{2}\{c,c\}^A,\\
\delta\overline{c^A}=\epsilon B^A,
\end{gathered} \tag{5.5}$$

$$\delta B^A = 0,$$

where $\{c,c\}^A = c^A{}_{BC} c^B c^C$ is the relevant (anti)-commutator. We remark that $\delta c^A \neq 0$, since c^A is an anticommuting field.

These are generalized symmetries, both since they depend on the derivatives of fields (thus they are generalized vector fields Ξ in the sense of our definition above)

$$\Xi = (D_\mu c^A) \frac{\partial}{\partial A^A{}_\mu} - \frac{1}{2}\{c,c\}^A \frac{\partial}{\partial c^A} + B^A \frac{\partial}{\partial \overline{c^A}}, \tag{5.6}$$

and since they do not leave the Poincaré–Cartan form invariant. In fact, one can easily check that the Poincaré–Cartan form is (see Ref. 4)

$$\begin{aligned}\Theta_L = \mathcal{L}\mathbf{ds} + [F_A{}^{\mu\nu}(\mathrm{d}A^A_\nu - \mathrm{d}_\lambda A^A_\nu \mathrm{d}x^\lambda) + \mathrm{d}^\mu \overline{c}_A (\mathrm{d}c^A - \mathrm{d}_\lambda c^A \mathrm{d}x^\lambda) \\ + (\mathrm{d}\overline{c}_A - \mathrm{d}_\lambda \overline{c}_A \mathrm{d}x^\lambda)(\mathrm{d}_\nu c^A + c^A{}_{BC} A^B_\nu c^C) g^{\mu\nu} - A^A_\nu g^{\mu\nu}(\mathrm{d}B^A - \mathrm{d}_\lambda B^A \mathrm{d}x^\lambda)] \wedge \mathbf{ds}_\mu .\end{aligned} \tag{5.7}$$

Its Lie derivative along Ξ is given by

$$\pounds_{j^1\Xi}\Theta = -F_A{}^{\mu\nu}(\mathrm{d}c^A_\mu - c^A_{\mu\lambda}\mathrm{d}x^\lambda) \wedge \mathbf{ds}_\nu + \mathrm{d}^\mu B_A (\mathrm{d}c^A - c^A_\lambda \mathrm{d}x^\lambda) \wedge \mathbf{ds}_\mu . \tag{5.8}$$

Hence the hypotheses of the generalized Nöther theorem are satisfied and the conserved currents are given by

$$\mathcal{E}(L,\Xi) = [F_A{}^{\mu\nu} D_\nu c^A - B_A D^\mu c^A + \tfrac{1}{2}\, \mathrm{d}^\mu \overline{c}_A \{c,c\}^A] \mathbf{ds}_\mu . \tag{5.9}$$

VI. WESS–ZUMINO MODEL

We consider finally another example of generalized symmetries in field theory (see Refs. 3, 13, 29). Let us fix a signature $\eta = (r,s)$ and a principal $\mathrm{Spin}(\eta)$-bundle Σ over the space–time M of dimension $m = r+s$. Consider the action

$$\lambda : \mathrm{Spin}(\eta) \times \mathrm{GL}(m) \to \mathrm{GL}(m), \quad \lambda(S,J) \cdot e^\mu_a = J^\mu_\nu \cdot e^\nu_b \not{\rho}^b_a (S^{-1}), \tag{6.1}$$

where $\not{\rho} : \mathrm{Spin}(\eta) \to \mathrm{SO}(\eta)$ is the covering map exhibiting the spin group as a double covering of the orthogonal group in the fixed signature. By means of the action λ we can define the associated bundle $\Sigma_\lambda = \Sigma \times_M L(M) \times_\lambda \mathrm{GL}(m)$ which admits fiber coordinates (x^μ, e^μ_a). The fields e^μ_a are called *spin frames on* Σ and they are in one-to-one correspondence with the spin structures defined on Σ (see Refs. 30 and 31 and references quoted therein). A spin frame e^μ_a induces a metric $g_{\mu\nu} = e^a_\mu \eta_{ab} e^b_\nu$ (e^b_ν being the inverse matrix of e^μ_a). Despite the fact that spin frames can be locally confused with local sections of $L(M)$, their behavior with respect to change of coordinates and their global properties differ from local frames (see Refs. 30–32). We have to warn the reader that in many cases in the literature of spinor physics when vielbein are mentioned spin frames in fact are what is meant. One can recognize this by comparing the expression for the covariant derivative of vielbein (which is there introduced as an *ad hoc* prescription) and the canonical covariant derivative for spin frames (see Refs. 33 and 34).

Let us then consider another representation of the spin group

$$\rho : \mathrm{Spin}(\eta) \times V \to V, \quad \rho(S) \cdot \psi^a = \rho^a_b(S) \psi^b, \tag{6.2}$$

induced by the choice of a set of $k \times k$ Dirac matrices γ_a such that $\{\gamma_a, \gamma_b\} = 2\eta_{ab}\mathbb{I}$, η_{ab} being the canonical diagonal matrix in signature $\eta = (r,s)$. As a further Hermitian requirement we assume that $\gamma_0 \gamma_a^\dagger \gamma_0 = \gamma_a$. The sections ψ of the associated bundle $\Sigma_\rho = \Sigma \times_\rho V$ are called *spinor fields*. The conjugation $\overline{\psi} = \psi^\dagger \gamma^0$ induces an inner product on spinors given by $\overline{\psi}\psi$. Hereafter (see also Refs. 10, 17, and 35) we shall consider $V = [\Lambda_-]^k$ modeled on the odd part of an exterior algebra

so that the local components $\psi^a: U \to \Lambda_-$ of spinors actually anticommute, i.e., $\psi^a \phi^b = -\phi^b \psi^a$. This is necessary for path integral quantization (see Refs. 3 and 36) in order to implement the Pauli principle. Hence we implement it from the very beginning also in the classical framework. For convenience we consider Majorana spinors. Recall that a spinor field ψ is called a *Majorana spinor* if it satisfies the condition $\psi = C\overline{\psi}^{\dagger}$, where C is the *charge conjugation operator*. In dimension $m=4$ and Lorentzian signature $\eta=(1,3)$ we choose a set of Dirac matrices

$$\gamma_0 = \begin{pmatrix} 0 & \mathbb{I} \\ \mathbb{I} & 0 \end{pmatrix}, \quad \gamma_i = \begin{pmatrix} 0 & -\sigma^i \\ \sigma^i & 0 \end{pmatrix}, \tag{6.3}$$

where the σ^i two-by-two matrices denote the standard Pauli matrices. We have

$$C = \begin{pmatrix} -i\sigma^2 & 0 \\ 0 & i\sigma^2 \end{pmatrix}, \quad \psi_{\mathrm{Maj}} = \begin{pmatrix} \alpha \\ i\sigma^2 {}^t\alpha^{\dagger} \end{pmatrix}, \tag{6.4}$$

where α is any two-component spinor. The action of the spin group Spin(1,3) is compatible with the Majorana condition, so that Majorana spinors are globally well-defined.

Let us consider the following fields: a Majorana (anticommuting) field ψ and four scalar (possibly densities) commuting fields (A,B,C,D) on a space–time manifold M with a spin frame e_a^{μ} fixed on it. We shall denote by e_{μ}^{a} the spin coframe which is represented by the inverse of the matrix e_a^{μ}. As a consequence of the spin frame fixing the manifold M is endowed with an induced metric structure g and a compatible spin structure. We further consider the Lagrangian

$$\begin{aligned} L_{\mathrm{WZ}} = {} & \frac{\lambda}{2}(\nabla_{\mu} A \nabla^{\mu} A + D^2 + 2mAD) e \mathbf{ds} - \overline{\psi}(i\gamma^a \nabla_a \psi + m\psi)) e \mathbf{ds} \\ & + \frac{\lambda}{2}(\nabla_{\mu} B \nabla^{\mu} B + C^2 - 2mBC) e^3 \, \mathbf{ds}. \end{aligned} \tag{6.5}$$

Here the covariant derivatives of scalar fields are considered with respect to the Levi-Civita connection induced by the metric, which is in turn induced by the spin frame. Analogously, the covariant derivatives of spinors are with respect to the spin connection induced by the spin frame, i.e.,

$$\nabla_a \psi = e_a^{\mu}(\mathrm{d}_{\mu}\psi + \tfrac{1}{8}\, \Gamma_{\mu}^{ab}[\gamma_a, \gamma_b]\psi), \quad \Gamma_{\mu}^{ab} = e_{\rho}^{a}(\Gamma_{\sigma\mu}^{\rho} e_c^{\sigma} + \mathrm{d}_{\mu} e_c^{\rho})\, \eta^{cb}. \tag{6.6}$$

This Lagrangian is kept invariant (modulo divergence terms) by the infinitesimal transformations

$$\begin{aligned} & \delta A = \frac{a}{2}(\overline{\epsilon}\psi), \quad \delta C = -\frac{a}{2}(\overline{\epsilon}\gamma^5 \gamma^a \nabla_a \psi) e^{-1}, \\ & \delta B = -i\frac{a}{2}(\overline{\epsilon}\gamma^5 \psi) e^{-1}, \quad \delta D = i\frac{a}{2}(\overline{\epsilon}\gamma^a \nabla_a \psi), \\ & \delta\psi = \frac{a}{2}[(\gamma^a \epsilon) i \nabla_a A + (\gamma^a \gamma^5 \epsilon) e \nabla_a B + (\gamma^5 \epsilon) ieC + (\epsilon) D], \\ & \delta\overline{\psi} = \frac{a}{2}[-i\nabla_a A(\overline{\epsilon}\gamma^a) - e\nabla_a B(\overline{\epsilon}\gamma^5 \gamma^a) + ieC(\overline{\epsilon}\gamma^5) + D(\overline{\epsilon})]. \end{aligned} \tag{6.7}$$

Here the transformation parameter ϵ is a Majorana (anticommuting) spinor which is assumed to be covariantly conserved, i.e., $\nabla_{\mu}\epsilon = 0$. Further comments about spinor transformation (anticommut-

ing) parameters will follow below. Notice that the relative coupling constants appear to be fixed by the requirement that the infinitesimal transformations (6.7) are symmetries of the Lagrangian L_{WZ}. On the contrary, one could replace the fields (A,B,C,D) with scalar densities of arbitrary weight. (Of course, in this case the Lagrangian has then to undergo a number of minor changes to manitain covariance.)

We stress that the condition for ϵ to be covariantly conserved is a very strong one. It corresponds more or less to the point independent transformation on which gauge theories are based. The model we present here is a first step towards a field theory which is covariant with respect to point-dependent transformations. Such a theory is called *supergravity* and one has to redefine the Lagrangian and to introduce auxiliary fields to obtain covariance with respect to this wider class of transformations (see Ref. 13). Here we are not interested in these generalizations for which we refer the interested reader to Refs. 3 and 13. Under these conditions the transformation (6.7) is global only when trivial structure bundles $\Sigma = M \times \mathrm{Spin}(\eta)$ are considered.

One can define the infinitesimal (vertical) generalized symmetry

$$\Xi = (\delta A)\frac{\partial}{\partial A} + (\delta B)\frac{\partial}{\partial B} + (\delta C)\frac{\partial}{\partial C} + (\delta D)\frac{\partial}{\partial D} + (\delta\psi)\frac{\partial}{\partial \psi} + (\delta\overline{\psi})\frac{\partial}{\partial \overline{\psi}}, \tag{6.8}$$

which is called the *supersymmetry generator* and which can be shown to leave the Lagrangian invariant modulo the following divergence term:

$$\delta L_{\mathrm{WZ}} = \mathrm{Div}(\alpha), \tag{6.9}$$

$$\alpha = \frac{a}{4}[(2imA(\overline{\epsilon}\gamma^{\mu}\psi) + 2\nabla^{\mu}A(\overline{\epsilon}\psi) - \nabla_{\nu}A(\overline{\epsilon}\gamma^{\nu}\gamma^{\mu}\psi) + iD(\overline{\epsilon}\gamma^{\mu}\psi))e + (2mB(\overline{\epsilon}\gamma^{5}\gamma^{\mu}\psi)$$
$$- 2i\nabla^{\mu}B(\overline{\epsilon}\gamma^{5}\psi) + i\nabla_{\nu}B(\overline{\epsilon}\gamma^{5}\gamma^{\nu}\gamma^{\mu}\psi) + C(\overline{\epsilon}\gamma^{\mu}\gamma^{5}\psi))e^{2}]\mathbf{ds}_{\mu}.$$

Notice that the supersymmetry generators are not closed with respect to the commutator. One can in fact check that, given two supersymmetries generated by ϵ_1 and ϵ_2, their commutator is the Lie derivative with respect to the vector field defined on the structure bundle Σ by

$$\hat{\xi} = \xi^{\mu}(\partial_{\mu} - \Gamma_{\mu}^{ab}\sigma_{ab}) \oplus (e_{\mu}^{a}\nabla_{\nu}\xi^{\mu}e^{b\nu})\sigma_{ab}, \quad \xi^{\mu} = i\frac{a^2}{2}(\epsilon_2\gamma^{\mu}\epsilon_1). \tag{6.10}$$

We remark that the vector field (6.10) is the so-called *Kosmann lift* of the space–time vector field $\xi = \xi^{\mu}\partial_{\mu}$ (see Ref. 34).

The vector fields (6.10) and the supersymmetry generators form an algebra with the following commutation rules.

$$[\delta_1, \delta_2] = \pounds_{\hat{\xi}}, \quad [\delta_1, \pounds_{\hat{\xi}}] = 0, \quad [\pounds_{\hat{\zeta}}, \pounds_{\hat{\xi}}] = 0. \tag{6.11}$$

Of course these vector fields do not span an ordinary Lie algebra, since some of the parameters are actually anticommuting, while the ordinary Lie algebra parameters are scalars. In fact, one should regard them as generators of a graded Lie algebra (also called *superalgebra*).

VII. CONCLUSION AND PERSPECTIVES

Nöther's theorem has been generalized to include a number of cases which play a prominent role in modern applications both in mechanics and field theory. As a first application of this generalized Nöther theorem we have shown how to recover the classical results for the separation of variables of the Hamilton–Jacobi equation in mechanics. This new perspective for separation of variables is particularly interesting. In fact Nöther's theorem is stated in a purely Lagrangian context. Though of course one needs the Hamiltonian formalism to obtain the Hamilton–Jacobi

equation, its separation of variables appears to be studied both in the Hamiltonian and in the Lagrangian framework.

This is of some interest for mechanics but may turn out to be very important in field theory. In field theory there are a number of examples of separation of variables which rely on operators which commute with field equations. The relation between separation of variables in mechanics and in field theory is still unclear. Although one has a fairly general theory on separation of variables in mechanics in field theory a general framework still needs to be developed. The generalized Nöther's theorem may provide such a framework for treating the problem of separation of variables in field theory. The advantage of this perspective is that it relies completely on the Lagrangian formalism which is quite important in field theory (where there is no general agreement on what is to be regarded as Hamiltonian framework). Further investigations will therefore be devoted to separation of variables in field theory.

Radiation of horizontal electric dipole on large dielectric sphere

Dionisios Margetis[a)]
Lyman Laboratory of Physics, Harvard University, Cambridge, Massachusetts 02138

(Received 27 June 2001; accepted for publication 29 January 2002)

The electromagnetic field in air of a radiating electric dipole located below and tangential to the surface of a homogeneous, isotropic and optically dense sphere is studied anew. The starting point is the eigenfunction expansion for the field in spherical harmonics, which is now converted into series of integrals via the Poisson summation formula. A creeping-wave structure for all six components along the boundary is revealed that consists of waves exponentially decreasing through air and rays bouncing and circulating inside the sphere. The character of individual modes of propagation and the interplay between ''electric'' and ''magnetic'' types of polarization are investigated. Connections with and differences from standard ray optics and the cases of the radiating vertical dipole and scalar plane-wave scattering are outlined. © *2002 American Institute of Physics.*

I. INTRODUCTION

The scattering and diffraction of electromagnetic waves have long been understood as boundary-value problems of Maxwell's equations. In principle, the field can be determined everywhere by specifying the source and the boundary conditions. In practice, even when closed-form solutions are then obtained, the chosen representations may not be amenable to quantitative understanding. This difficulty often plagues analyses where current sources lie too close to the boundary separating two media. Such a case arises in connection with the long-distance communication along the sea surface at very low frequencies.[1,2]

In the present article, a three-dimensional idealized model is studied in which the source is an electric dipole located below and tangential to the surface of a homogeneous and isotropic, electrically large sphere surrounded by air. Of course, none of the field components can be made to vanish identically in this case. A dipole vertical to the spherical boundary,[3,4] on the other hand, introduces an axis of symmetry, having only three nonzero spherical components; these admit eigenfunction expansions of simpler structure. In both problems, the formal solution is easily attainable in terms of spherical harmonics but is not directly amenable to computations and interpretation. One of the objectives of this work is to unveil the underlying physical picture by asymptotic methods for the case of the horizontal dipole, describing the interplay between two coexisting polarizations. The assumption of an optically dense sphere is thus imposed while attention is restricted to points lying in the spherical boundary. The analysis is also intended to reveal differences from the known case of plane-wave scattering in the context of the scalar wave and Schrödinger's equations. Because the emphasis is on the physical concepts and the tools needed to expose such concepts, actual numerical calculations are beyond the scope of this article.

There is a fairly long sequence of papers in connection with the present problem. Noteworthy is Mie's formal expansion[5] in partial waves for a plane wave incident on a homogeneous sphere. Another formulation found in a later paper by Debye[6] is related to his previous studies of high-frequency plane-wave scattering by an infinitely long cylinder.[7] An exposition and discussion of

[a)]On leave from the Department of Mathematics, Massachusetts Institute of Technology, Cambridge, MA 02139. Electronic mail: dio@math.mit.edu

these as well as of other works was given by van de Hulst.[8] Watson[9] appears to be the first to investigate systematically the radiation of a point source in the presence of a sphere with radius large compared to the wavelength. In his formulation the source was an electric dipole located above and vertical to the surface of a perfectly conducting sphere; his focus was on scalar potentials that furnish the electromagnetic field via successive differentiations. The merits of Watson's approach are unquestionable: the slowly converging expansion in partial waves was converted to an integral which in turn generated a rapidly converging series. This method was later invoked by other authors[10–12] in their efforts to treat the case of a finitely conducting sphere. Among these authors, Gray,[12] for example, identified a ''magnetic'' type of wave propagating and attenuating through air with an attenuation rate independent of the adjacent medium, when the source is a magnetic dipole vertical to the surface of a lossy sphere.

Being aware of these works, Norton[13] proposed simplified formulas and graphs for the field intensity of vertical and horizontal dipoles elevated over a spherical earth. Bremmer[14,15] compared the fields of the two configurations by considering the direct wave and the leading reflected wave in free space; his analysis pointed to a simple picture for wave propagation in air for distances exceeding the free-space wavelength. The radiation of a horizontal dipole above a finitely conducting sphere was investigated by Fock[16] by use of scalar potentials. He approximated the field through air in the ''shadow region'' in terms of exponentially decreasing waves, and gave the corresponding attenuation rates as solutions to two uncoupled transcendental equations. Fock started with an extension of Watson's method[9] by neglecting the field that travels through the sphere and not examining the transition to planar-earth formulas. In the same spirit, the problem was essentially revisited by Wait[17] in the 1950s; he concluded that at ''low radio frequencies'' the horizontal component of the electric field is negligibly small compared to the vertical one. On the basis of Watson's method,[9] geometrical-ray pictures were invoked in that same period of time in the study of elastic waves inside spherical cavities.[18,19] (See Refs. 20 and 21 for later developments in the theory of elastic-wave propagation.)

In a remarkable paper, Wu[22] invoked the concept of the creeping wave in order to study the high-frequency scattering of plane waves by impenetrable cylinders and spheres in the context of Schrödinger's and Maxwell's equations. He derived asymptotic expansions for the total scattering cross sections that went well beyond the standard geometrical optics, and pointed out that a mathematical tool leading to the creeping wave in the case of a sphere is the Poisson summation formula. Notably, Wu[22] extended the familiar concept of the creeping wave in two space dimensions[23–26] from high frequencies to all positive frequencies by arguments of algebraic topology.[27] The underlying physical idea was soon after generalized to other scatterers by Seshadri.[28] A similar analysis based on the Poisson summation formula was later used by Nussenzveig,[29] who referred to Ref. 22, for the study of high-frequency, plane-wave scattering by transparent spheres. Key points in his analysis were the imposition of a large index of refraction and the expansion of the total scattering amplitude in a series of the Debye type.[7] Nussenzveig provided a description in terms of waves that attenuate exponentially along the boundary and rays bouncing and circulating inside the sphere. The relevant Poisson summation formula can be written as[30]

$$\sum_{l=0}^{\infty} g(l) = \sum_{n=-\infty}^{\infty} e^{-in\pi} \int_0^{\infty} d\nu\, g\left(\nu - \frac{1}{2}\right) e^{i2\pi n\nu}, \tag{1.1}$$

where the left-hand side is the starting eigenfunction expansion. The right-hand side of this equation was interpreted in terms of ''classical paths'' by Berry and Mount.[31] This interpretation stems from noticing that for high frequencies each index n identifies a path that encircles the origin n times.[31,32] Accordingly, these authors invoked stationary-phase calculations and elaborate uniform approximations.

Recently, Houdzoumis[3,4,33] applied the Poisson summation formula in order to study the radiation of a vertical electric dipole over a sphere, by imposing the simplifying assumption of a large index of refraction. As mentioned earlier, the number of nonzero field components is reduced

to three in this case, with the corresponding polarization being termed as of the ''electric type.'' Houdzoumis placed equal emphasis on the wave that attenuates exponentially along the boundary in air and the rays that circulate around the origin inside the sphere. King *et al.*[1,2] made use of these results for the surface wave in order to calculate the field of an antenna on the sea surface in the range of very low frequencies (VLF).

In the spirit of Houdzoumis' analysis,[3,4,33] the present article has a threefold purpose. The first purpose is to give the complete solution for the field of an electric dipole located inside a sphere without recourse to scalar potentials. The dipole is taken to lie in the plane defined by a local tangent and the center of the sphere, and is parallel to the tangent. The second purpose is to evaluate all six components when the dipole approaches the boundary from below by converting the series of partial waves into integrals according to the Poisson summation formula. In this limit all series diverge in the usual sense and some care needs to be exercised. By use of asymptotics, it is found that, apart from waves that reach the observation point with the air and earth phase velocities, significant contributions may arise from rays bouncing and circulating inside the sphere. The third purpose is to compare these findings with other, known cases such as the plane-wave scattering and the radiation of a vertical electric dipole.

The remainder of the article is organized as follows. Section II starts with Maxwell's equations; the ordinary differential equations in the radial distance for the θ- and ϕ-components of the field in spherical coordinates are solved explicitly. The eigenfunction expansions in spherical harmonics are then converted into series of integrals, and both the source and the observation point are allowed to approach the boundary. In Sec. III, integral expressions are obtained with the inverse electrical radius used as the expansion parameter. The lowest-order terms are known Sommerfeld integrals.[34] Corrections to these integrals account for the finite curvature of the boundary, describing waves that travel through air and through the dense medium. Integrated expressions are given for these waves when $k_2^2 \ll |k_1^2|$, $k_2\rho \gg 1$ and the observation angle θ is sufficiently small, where k_2 is the wave number in air, assumed to be real throughout the paper, k_1 is the complex wave number in the sphere, and ρ is the cylindrical distance from the source. The expressions for the wave through the sphere are new to the author's knowledge. The accompanying zeroth-order integral terms have been evaluated via rapidly converging series elsewhere.[34,35] In Sec. IV, the aforementioned asymptotic formulas are modified to account for the transition of the planar-boundary formulas to waves decreasing exponentially through air, with the distinction of two modes of propagation pertaining to polarizations of an ''electric'' and a ''magnetic'' type. A description is also provided for the field with the phase velocity of the enclosed medium. The analysis in Sec. V shows that, for $\theta = O(1)$ and $\pi - \theta = O(1)$, the total field consists of waves that attenuate exponentially, and rays that circulate in the sphere and are multiply reflected at the boundary. The contributions of these rays are negligible for a finitely conducting sphere. A few limiting cases of the ray contributions are placed under scrutiny, an example being the case where the antipodal point at $\theta = \pi$ is approached along the boundary. The interplay between contributions of the two polarizations to the ray amplitudes as well as deviations from the ray character are discussed.

In some of the calculations presented in this article, such as those in Appendix A, the wave number in the sphere, k_1, is treated as real for the sake of simplicity. This poses no restriction on the final asymptotic formulas, however, which are usable for complex values of k_1 with $0 \leqslant \mathrm{Arg}\, k_1 \leqslant \pi/4$, and are therefore applicable to spheres of finite conductivity. The $e^{-i\omega t}$ time dependence is suppressed throughout the analysis.

II. FORMULATION

A. Formal representations

The geometry of the problem is depicted in Fig. 1. It consists of an x-directed electric dipole S of unit moment located inside a homogeneous, isotropic and nonmagnetic sphere (region 1, $r < a$) at a distance b from the origin. The sphere is surrounded by air (region 2, $r > a$). Maxwell's equations in each region j ($j = 1, 2$) read as follows:

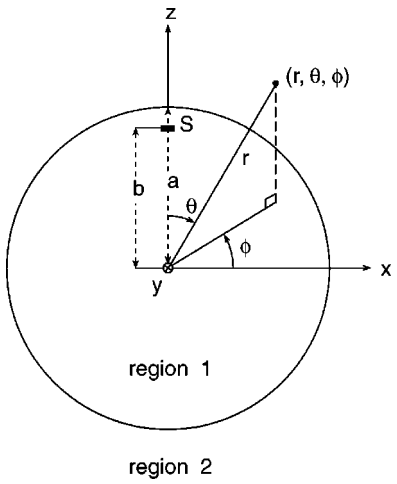

FIG. 1. Spherical coordinates and horizontal electric dipole S inside an isotropic and homogeneous sphere.

$$\frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}(\sin\theta E_{j\phi})-\frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}(E_{j\theta})=i\omega B_{jr}, \tag{2.1}$$

$$\frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}(E_{jr})-\frac{1}{r}\frac{\partial}{\partial r}(rE_{j\phi})=i\omega B_{j\theta}, \tag{2.2}$$

$$\frac{1}{r}\frac{\partial}{\partial r}(rE_{j\theta})-\frac{1}{r}\frac{\partial}{\partial\theta}(E_{jr})=i\omega B_{j\phi}, \tag{2.3}$$

$$\frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}(\sin\theta B_{j\phi})-\frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}(B_{j\theta})=-i\frac{k_j^2}{\omega}E_{jr}, \tag{2.4}$$

$$\frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}(B_{jr})-\frac{1}{r}\frac{\partial}{\partial r}(rB_{j\phi})=\mu_0 J_{j\theta}-i\frac{k_j^2}{\omega}E_{j\theta}, \tag{2.5}$$

$$\frac{1}{r}\frac{\partial}{\partial r}(rB_{j\theta})-\frac{1}{r}\frac{\partial}{\partial\theta}(B_{jr})=\mu_0 J_{j\phi}-i\frac{k_j^2}{\omega}E_{j\phi}, \tag{2.6}$$

where the current density is

$$\mathbf{J}(\mathbf{r})=\delta(x)\,\delta(y)\,\delta(z-b)\hat{\mathbf{x}}. \tag{2.7}$$

The field in region 1 is the superposition of a primary and a secondary field, viz.,

$$\mathbf{F}_1=\mathbf{F}_1^{(\mathrm{pr})}+\mathbf{F}_1^{(\mathrm{sc})},\quad \mathbf{F}=\mathbf{E},\,\mathbf{B}. \tag{2.8}$$

In order to calculate the primary field, introduce the vector potential $\mathbf{A}_1^{(\mathrm{pr})}=G(\mathbf{r};b)\hat{\mathbf{x}}$, where

$$G(\mathbf{r};b)=\frac{\mu_0}{4\pi}\frac{e^{ik_1R}}{R}=\frac{i\mu_0k_1}{4\pi}\sum_{l=0}^{\infty}(2l+1)j_l(k_1r_<)h_l^{(1)}(k_1r_>)\mathrm{P}_l(\cos\theta), \tag{2.9}$$

$R=\sqrt{r^2+b^2-2rb\cos\theta}$, $r_>$ is the larger of r and b, and $r_<$ is the smaller. j_l and $h_l^{(1)}$ denote the spherical Bessel and Hankel functions, and P_l^m is the Legendre function of the first kind.[36] Hence,

$$B_{1r}^{(\mathrm{pr})}=b_{1r}^{(\mathrm{pr})}(r,\theta)\sin\phi=-\frac{1}{r}\frac{\partial G}{\partial\theta}\sin\phi=-\frac{i\mu_0 k_1}{4\pi r}\sin\phi\sum_{l=0}^{\infty}(2l+1)j_l(k_1r_<)h_l^{(1)}(k_1r_>)\mathrm{P}_l^1(\cos\theta), \tag{2.10}$$

$$B_{1\theta}^{(\mathrm{pr})}=b_{1\theta}^{(\mathrm{pr})}(r,\theta)\sin\phi,\quad B_{1\phi}^{(\mathrm{pr})}=b_{1\phi}^{(\mathrm{pr})}(r,\theta)\cos\phi, \tag{2.11}$$

$$\begin{aligned}E_{1r}^{(\mathrm{pr})}=e_{1r}^{(\mathrm{pr})}(r,\theta)\cos\phi&=-\frac{i\omega}{k_1^2 r}\frac{\partial}{\partial\theta}\left(\frac{\partial G}{\partial b}+\frac{1}{b}G\right)\cos\phi\\&=\frac{\omega\mu_0}{4\pi b}\frac{1}{k_1 r}\cos\phi\sum_{l=0}^{\infty}(2l+1)\psi_l(k_1r)[\breve{\psi}_l(k_1b)+k_1b\,\breve{\psi}_l'(k_1b)]\mathrm{P}_l^1(\cos\theta),\end{aligned} \tag{2.12}$$

$$E_{1\theta}^{(\mathrm{pr})}=e_{1\theta}^{(\mathrm{pr})}(r,\theta)\cos\phi,\quad E_{1\phi}^{(\mathrm{pr})}=e_{1\phi}^{(\mathrm{pr})}(r,\theta)\sin\phi, \tag{2.13}$$

where $(\psi_l,\breve{\psi}_l)=(j_l,h_l^{(1)})$ if $r<b$, $(\psi_l,\breve{\psi}_l)=(h_l^{(1)},j_l)$ if $r>b$, and the prime denotes differentiation with respect to the argument. Let

$$B_{jr}=b_{jr}(r,\theta)\sin\phi,\quad B_{j\theta}=b_{j\theta}(r,\theta)\sin\phi,\quad B_{j\phi}=b_{j\phi}(r,\theta)\cos\phi, \tag{2.14}$$

$$E_{jr}=e_{jr}(r,\theta)\cos\phi,\quad E_{j\theta}=e_{j\theta}(r,\theta)\cos\phi,\quad E_{j\phi}=e_{j\phi}(r,\theta)\sin\phi. \tag{2.15}$$

It follows that

$$\frac{\partial^2}{\partial r^2}(rb_{j\phi})+k_j^2(rb_{j\phi})=\frac{1}{\sin\theta}\frac{\partial}{\partial r}(b_{jr})+\frac{ik_j^2}{\omega}\frac{\partial}{\partial\theta}(e_{jr}), \tag{2.16}$$

$$\frac{\partial^2}{\partial r^2}(re_{j\phi})+k_j^2(re_{j\phi})=-i\omega\frac{\partial}{\partial\theta}(b_{jr})-\frac{1}{\sin\theta}\frac{\partial}{\partial r}(e_{jr}), \tag{2.17}$$

$$b_{j\theta}=\frac{i}{\omega}\left[\frac{1}{r\sin\theta}e_{jr}+\frac{1}{r}\frac{\partial}{\partial r}(re_{j\phi})\right], \tag{2.18}$$

$$e_{j\theta}=\frac{i\omega}{k_j^2}\left[\frac{1}{r\sin\theta}b_{jr}-\frac{1}{r}\frac{\partial}{\partial r}(rb_{j\phi})\right]. \tag{2.19}$$

The total field must be bounded at the origin and satisfy the usual radiation conditions.[37] It is natural to set

$$e_{1r}^{(\mathrm{sc})}=-\frac{\mu_0\omega}{4\pi r}\frac{1}{k_1b}\sum_{l=0}^{\infty}(2l+1)\tilde{A}_l j_l(k_1r)[j_l(k_1b)+k_1bj_l'(k_1b)]\mathrm{P}_l^1(\cos\theta), \tag{2.20}$$

$$e_{2r}=\frac{\mu_0\omega}{4\pi r}\frac{1}{k_1b}\sum_{l=0}^{\infty}(2l+1)\tilde{B}_l h_l^{(1)}(k_2r)[j_l(k_1b)+k_1bj_l'(k_1b)]\mathrm{P}_l^1(\cos\theta), \tag{2.21}$$

$$b_{1r}^{(\mathrm{sc})}=\frac{i\mu_0 k_1}{4\pi r}\sum_{l=0}^{\infty}(2l+1)\tilde{C}_l j_l(k_1r)j_l(k_1b)\mathrm{P}_l^1(\cos\theta), \tag{2.22}$$

$$b_{2r}=-\frac{i\mu_0 k_1}{4\pi r}\sum_{l=0}^{\infty}(2l+1)\tilde{D}_l h_l^{(1)}(k_2r)j_l(k_1b)\mathrm{P}_l^1(\cos\theta), \tag{2.23}$$

where $\tilde{A}_l$, $\tilde{B}_l$, $\tilde{C}_l$, and $\tilde{D}_l$ are coefficients yet to be determined.

In region 1, Eqs. (2.16) and (2.17) split into two equations by virtue of Eq. (2.8). In compact notation, these equations are

$$\frac{\partial^2}{\partial r^2}(rw)+k^2(rw)=\frac{1}{\sin\theta}\frac{\partial g}{\partial r}, \tag{2.24a}$$

$$\frac{\partial^2}{\partial r^2}(rw)+k^2(rw)=\frac{\partial g}{\partial \theta}, \tag{2.24b}$$

where $g=g(r,\theta)$ ($g=b_{jr},e_{jr}$) is treated as known. Specifically,

$$g(r,\theta)=r^{-1}\sum_{l=0}^{\infty}(2l+1)c_l\psi_l(kr)\mathrm{P}_l^1(\cos\theta). \tag{2.25}$$

In the above, $\psi_l=j_l$ and $k=k_1$ if $r<a$, $\psi_l=h_l^{(1)}$ and $k=k_2$ if $r>a$.

A solution to Eq. (2.24a) is

$$rw(r,\theta)=\frac{1}{\sin\theta}\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}c_l w_l(r)\mathrm{P}_l^1(\cos\theta). \tag{2.26}$$

Each $w_l(r)$ ($l=0, 1, 2, \ldots$) should of course satisfy

$$\left(\frac{d^2}{dr^2}+k^2\right)w_l(r)=-\frac{l(l+1)}{r^2}[\psi_l(kr)-kr\psi_l'(kr)], \tag{2.27}$$

and therefore equals $w_l(r)=(d/dr)[r\psi_l(kr)]$. With regard to Eq. (2.24b),

$$rw(r,\theta)=\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}c_l w_l(r)\frac{\partial \mathrm{P}_l^1}{\partial\theta}, \tag{2.28}$$

where $w_l(r)$ is forced to satisfy

$$\left(\frac{d^2}{dr^2}+k^2\right)w_l(r)=\frac{l(l+1)}{r}\psi_l(kr), \tag{2.29}$$

with an admissible solution $w_l(r)=r\psi_l(kr)$. Once $b_{j\phi}$ and $e_{j\phi}$ are determined in this fashion, $b_{j\theta}$ and $e_{j\theta}$ follow from Eqs. (2.18) and (2.19).

The coefficients $\tilde{A}_l$, $\tilde{B}_l$, $\tilde{C}_l$, and $\tilde{D}_l$ in Eqs. (2.20)–(2.23) are calculated via imposition of the continuity of E_ϕ and B_θ at $r=a$. These conditions yield two independent systems of linear equations, namely, one for $\tilde{A}_l$, $\tilde{B}_l$ and one for $\tilde{C}_l$ and $\tilde{D}_l$. The former set describes a magnetic-type (H-) polarization ($B_r=0$, $E_r\neq 0$), while the latter one pertains to an electric-type (E-) polarization ($E_r=0$, $B_r\neq 0$), in correspondence to the case with a planar boundary. Explicitly,

$$\tilde{A}_l=\frac{h_l^{(1)}(k_1a)}{j_l(k_1a)}\left\{\frac{1}{k_2a}+\frac{h_l^{(1)\prime}(k_2a)}{h_l^{(1)}(k_2a)}-\frac{k_2}{k_1}\left[\frac{1}{k_1a}+\frac{h_l^{(1)\prime}(k_1a)}{h_l^{(1)}(k_1a)}\right]\right\}\frac{1}{K_l}, \tag{2.30}$$

$$\tilde{B}_l=\frac{i}{k_1k_2a^2\,j_l(k_1a)h_l^{(1)}(k_2a)\,K_l}, \tag{2.31}$$

$$\tilde{C}_l=\frac{h_l^{(1)}(k_1a)}{j_l(k_1a)}\left[\frac{h_l^{(1)'}(k_1a)}{h_l^{(1)}(k_1a)}-\frac{k_2}{k_1}\frac{h_l^{(1)'}(k_2a)}{h_l^{(1)}(k_2a)}\right]\frac{1}{M_l}, \tag{2.32}$$

$$\tilde{D}_l=-\frac{i}{(k_1a)^2 j_l(k_1a)h_l^{(1)}(k_2a)\,M_l}, \tag{2.33}$$

where the two principal denominators read as

$$K_l=\frac{h_l^{(1)'}(k_2a)}{h_l^{(1)}(k_2a)}+\frac{1}{k_2a}-\frac{k_2}{k_1}\left[\frac{1}{k_1a}+\frac{j_l'(k_1a)}{j_l(k_1a)}\right], \tag{2.34}$$

$$M_l=\frac{j_l'(k_1a)}{j_l(k_1a)}-\frac{k_2}{k_1}\frac{h_l^{(1)'}(k_2a)}{h_l^{(1)}(k_2a)}. \tag{2.35}$$

The terminology above primarily serves the purpose of distinguishing between contributions from these two denominators.

The field in region 2 is

$$E_{2r}=\frac{i\omega\mu_0}{4\pi k_1 r k_2 a^2}\cos\phi\sum_{l=0}^{\infty}(2l+1)\frac{j_l(k_1b)}{j_l(k_1a)}\frac{h_l^{(1)}(k_2r)}{h_l^{(1)}(k_2a)}\frac{1}{K_l}\left[\frac{1}{k_1b}+\frac{j_l'(k_1b)}{j_l(k_1b)}\right]\mathrm{P}_l^1(\cos\theta), \tag{2.36}$$

$$\begin{aligned}E_{2\theta}=&\frac{i\omega\mu_0}{4\pi k_1 a^2}\cos\phi\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}\frac{j_l(k_1b)}{j_l(k_1a)}\frac{h_l^{(1)}(k_2r)}{h_l^{(1)}(k_2a)}\frac{1}{K_l}\left[\frac{1}{k_1b}+\frac{j_l'(k_1b)}{j_l(k_1b)}\right]\\&\times\left[\frac{1}{k_2r}+\frac{h_l^{(1)'}(k_2r)}{h_l^{(1)}(k_2r)}\right]\frac{\partial\mathrm{P}_l^1}{\partial\theta}\\&-\frac{i\omega\mu_0}{4\pi k_1 a^2\sin\theta}\cos\phi\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}\frac{j_l(k_1b)}{j_l(k_1a)}\frac{h_l^{(1)}(k_2r)}{h_l^{(1)}(k_2a)}\frac{1}{M_l}\mathrm{P}_l^1(\cos\theta),\end{aligned} \tag{2.37}$$

$$\begin{aligned}E_{2\phi}=&-\frac{i\omega\mu_0}{4\pi k_1 a^2\sin\theta}\sin\phi\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}\frac{j_l(k_1b)}{j_l(k_1a)}\frac{h_l^{(1)}(k_2r)}{h_l^{(1)}(k_2a)}\frac{1}{K_l}\left[\frac{1}{k_1b}+\frac{j_l'(k_1b)}{j_l(k_1b)}\right]\\&\times\left[\frac{1}{k_2r}+\frac{h_l^{(1)'}(k_2r)}{h_l^{(1)}(k_2r)}\right]\mathrm{P}_l^1(\cos\theta)\\&+\frac{i\omega\mu_0}{4\pi k_1 a^2}\sin\phi\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}\frac{j_l(k_1b)}{j_l(k_1a)}\frac{h_l^{(1)}(k_2r)}{h_l^{(1)}(k_2a)}\frac{1}{M_l}\frac{\partial\mathrm{P}_l^1}{\partial\theta},\end{aligned} \tag{2.38}$$

$$B_{2r}=-\frac{\mu_0}{4\pi k_1 r a^2}\sin\phi\sum_{l=0}^{\infty}(2l+1)\frac{j_l(k_1b)}{j_l(k_1a)}\frac{h_l^{(1)}(k_2r)}{h_l^{(1)}(k_2a)}\frac{1}{M_l}\mathrm{P}_l^1(\cos\theta), \tag{2.39}$$

$$\begin{aligned}B_{2\theta}=&-\frac{\mu_0 k_2}{4\pi k_1 a^2}\sin\phi\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}\frac{j_l(k_1b)}{j_l(k_1a)}\frac{h_l^{(1)}(k_2r)}{h_l^{(1)}(k_2a)}\frac{1}{M_l}\left[\frac{1}{k_2r}+\frac{h_l^{(1)'}(k_2r)}{h_l^{(1)}(k_2r)}\right]\frac{\partial\mathrm{P}_l^1}{\partial\theta}\\&-\frac{\mu_0 k_2}{4\pi k_1 a^2\sin\theta}\sin\phi\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}\frac{j_l(k_1b)}{j_l(k_1a)}\frac{h_l^{(1)}(k_2r)}{h_l^{(1)}(k_2a)}\frac{1}{K_l}\left[\frac{1}{k_1b}+\frac{j_l'(k_1b)}{j_l(k_1b)}\right]\mathrm{P}_l^1(\cos\theta),\end{aligned} \tag{2.40}$$

$$B_{2\phi}=-\frac{\mu_0 k_2}{4\pi k_1 a^2 \sin\theta}\cos\phi\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}\frac{j_l(k_1 b)}{j_l(k_1 a)}\frac{h_l^{(1)}(k_2 r)}{h_l^{(1)}(k_2 a)}\frac{1}{M_l}\left[\frac{1}{k_2 r}+\frac{h_l^{(1)\prime}(k_2 r)}{h_l^{(1)}(k_2 r)}\right]\mathrm{P}_l^1(\cos\theta)$$
$$-\frac{\mu_0 k_2}{4\pi k_1 a^2}\cos\phi\sum_{l=0}^{\infty}\frac{2l+1}{l(l+1)}\frac{j_l(k_1 b)}{j_l(k_1 a)}\frac{h_l^{(1)}(k_2 r)}{h_l^{(1)}(k_2 a)}\frac{1}{K_l}\left[\frac{1}{k_1 b}+\frac{j_l'(k_1 b)}{j_l(k_1 b)}\right]\frac{\partial \mathrm{P}_l^1}{\partial\theta}. \tag{2.41}$$

Expansions (2.36)–(2.41) converge uniformly in all parameters if $r\neq a$ or $b\neq a$. For large l each series is majorized by a geometric series with expansion parameter $(b/a)\times(\min\{r,a\}/\max\{r,a\})$. For $k_2 a\gg 1$, the summands with $l\leqslant O(k_1 a)$ oscillate rapidly, hindering physical interpretation and rendering direct computations impractical.

B. Electromagnetic field on the surface

When the dipole and the observation point are allowed to approach the boundary ($b\to a^-$, $r\to a^+$), the series expansions for the field diverge.[38] Application of the Poisson summation formula (1.1) converts Eqs. (2.36)–(2.41) into the following series:

$$E_{2r}=\frac{i\omega\mu_0}{2\pi k_1 k_2 a^3}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\mathcal{K}(\nu)}\left[\frac{1}{2k_1 a}+\frac{J_\nu'(k_1 a)}{J_\nu(k_1 a)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta), \tag{2.42}$$

$$E_{2\theta}=\frac{i\omega\mu_0}{2\pi k_1 a^2}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{K}(\nu)}\left[\frac{1}{2k_2 a}+\frac{H_\nu^{(1)\prime}(k_2 a)}{H_\nu^{(1)}(k_2 a)}\right]$$
$$\times\left[\frac{1}{2k_1 a}+\frac{J_\nu'(k_1 a)}{J_\nu(k_1 a)}\right]\frac{\partial \mathrm{P}^1_{\nu-1/2}}{\partial\theta}-\frac{i\omega\mu_0}{2\pi k_1 a^2\sin\theta}\cos\phi$$
$$\times\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{M}(\nu)}\mathrm{P}^1_{\nu-1/2}(\cos\theta), \tag{2.43}$$

$$E_{2\phi}=-\frac{i\omega\mu_0}{2\pi k_1 a^2\sin\theta}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{K}(\nu)}\left[\frac{1}{2k_2 a}+\frac{H_\nu^{(1)\prime}(k_2 a)}{H_\nu^{(1)}(k_2 a)}\right]$$
$$\times\left[\frac{1}{2k_1 a}+\frac{J_\nu'(k_1 a)}{J_\nu(k_1 a)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta)$$
$$+\frac{i\omega\mu_0}{2\pi k_1 a^2}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{M}(\nu)}\frac{\partial \mathrm{P}^1_{\nu-1/2}}{\partial\theta}, \tag{2.44}$$

$$B_{2r}=-\frac{\mu_0}{2\pi k_1 a^3}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\mathcal{M}(\nu)}\mathrm{P}^1_{\nu-1/2}(\cos\theta), \tag{2.45}$$

$$B_{2\theta}=-\frac{\mu_0 k_2}{2\pi k_1 a^2}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{M}(\nu)}\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\frac{\partial \mathrm{P}^1_{\nu-1/2}}{\partial\theta}$$

$$-\frac{\mu_0 k_2}{2\pi k_1 a^2\sin\theta}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{K}(\nu)}$$

$$\times\left[\frac{1}{2k_1a}+\frac{J_\nu'(k_1a)}{J_\nu(k_1a)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta), \tag{2.46}$$

$$B_{2\phi}=-\frac{\mu_0 k_2}{2\pi k_1 a^2\sin\theta}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{M}(\nu)}$$

$$\times\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta)$$

$$-\frac{\mu_0 k_2}{2\pi k_1 a^2}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{K}(\nu)}\left[\frac{1}{2k_1a}+\frac{J_\nu'(k_1a)}{J_\nu(k_1a)}\right]\frac{\partial \mathrm{P}^1_{\nu-1/2}}{\partial\theta}, \tag{2.47}$$

where

$$\mathcal{K}(\nu)=\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}+\frac{1}{2k_2a}-\frac{k_2}{k_1}\left[\frac{1}{2k_1a}+\frac{J_\nu'(k_1a)}{J_\nu(k_1a)}\right], \tag{2.48}$$

$$\mathcal{M}(\nu)=\frac{J_\nu'(k_1a)}{J_\nu(k_1a)}-\frac{k_2}{k_1}\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}. \tag{2.49}$$

The integrands in Eqs. (2.42)–(2.47) are meromorphic functions of ν. The zeros of $\mathcal{K}(\nu)$ and $\mathcal{M}(\nu)$ are sometimes called Regge poles in the literature (for example, see Ref. 29). The study of the possible resonances associated with these poles, which are often believed to give rise to various effects of absorption and scattering from spheres and other scatterers, lies beyond the scope of this analysis. A discussion on the location of the zeros of $\mathcal{K}(\nu)$ and $\mathcal{M}(\nu)$ is provided in Appendix A. Each integral diverges in the usual sense, but is interpreted unambiguously as[38]

$$\int_0^\infty d\nu\,(\cdots)=\lim_{\nu\to 0^+}\int_0^\infty d\nu\,(\cdots)\,e^{-\nu\nu}. \tag{2.50}$$

III. SOMMERFELD INTEGRALS AND LOWEST-ORDER CORRECTIONS

A. Approximate integral formulas

As $\theta\to 0^+$, Eqs. (2.42)–(2.47) should reduce to known integral formulas.[34] The following steps are taken when $\theta\ll 1$: (i) Only the $n=0$ terms are retained, since the integrands with $n\neq 0$ are highly oscillatory. (ii) The Bessel functions are replaced by asymptotic formulas that are valid outside the transitional regions.[39] (iii) The Legendre functions are replaced by MacDonald's formulas[36] that involve Bessel functions. (iv) The integration path is properly deformed in the fourth quadrant of the ν-plane, as suggested by the analysis in Appendix A.

Accordingly, $\mathcal{K}^{-1}(\nu)$ and $\mathcal{M}^{-1}(\nu)$ from Eqs. (2.48) and (2.49) are approximated as follows:

$$\frac{1}{\mathcal{K}(\nu)} \sim -i\left[\sqrt{1-\left(\frac{\nu}{k_2 a}\right)^2}+\frac{k_2}{k_1}\sqrt{1-\left(\frac{\nu}{k_1 a}\right)^2}\right]^{-1} - \frac{1}{2k_2 a}\frac{(\nu/k_2 a)^2[1-(\nu/k_2 a)^2]^{-1}-(k_2^2/k_1^2)(\nu/k_1 a)^2[1-(\nu/k_1 a)^2]^{-1}}{[\sqrt{1-(\nu/k_2 a)^2}+(k_2/k_1)\sqrt{1-(\nu/k_1 a)^2}]^2}, \tag{3.1}$$

$$\frac{1}{\mathcal{M}(\nu)} \sim i\left[\sqrt{1-\left(\frac{\nu}{k_1 a}\right)^2}+\frac{k_2}{k_1}\sqrt{1-\left(\frac{\nu}{k_2 a}\right)^2}\right]^{-1} - \frac{1}{2k_1 a}\frac{[1-(\nu/k_1 a)^2]^{-1}-[1-(\nu/k_2 a)^2]^{-1}}{\left[\sqrt{1-(\nu/k_1 a)^2}+\frac{k_2}{k_1}\sqrt{1-(\nu/k_2 a)^2}\right]^2}. \tag{3.2}$$

Note that the simplified $\mathcal{K}^{-1}(\nu=\lambda a)$ exhibits a pair of poles at

$$\lambda = \pm k_S = \pm\frac{k_1 k_2}{\sqrt{k_1^2+k_2^2}} \sim \pm\left(k_2-\frac{k_2^3}{2k_1^2}\right), \quad k_2^2 \ll |k_1^2|. \tag{3.3}$$

No poles exist in the approximation for $\mathcal{M}^{-1}(\lambda a)$.

With $\lambda=\nu/a$ and $\rho=a\theta$, the field components reduce to

$$E_{2r}^{n=0} \sim i\frac{\omega\mu_0 k_2^2}{2\pi k_1}(I_{ez}-I_{ez}^c)\cos\phi, \tag{3.4}$$

$$E_{2\theta}^{n=0} \sim -\frac{\omega\mu_0 k_2^2}{4\pi k_1}(I_{e\rho}+I_{e\rho}^c)\cos\phi, \tag{3.5}$$

$$E_{2\phi}^{n=0} \sim \frac{\omega\mu_0 k_2^2}{4\pi k_1}(I_{e\phi}+I_{e\phi}^c)\sin\phi, \tag{3.6}$$

$$B_{2r}^{n=0} \sim i\frac{\mu_0 k_2^2}{2\pi}(I_{bz}+I_{bz}^c)\sin\phi, \tag{3.7}$$

$$B_{2\theta}^{n=0} \sim -\frac{\mu_0 k_2^3}{4\pi k_1}(I_{b\rho}+I_{b\rho}^c)\sin\phi, \tag{3.8}$$

$$B_{2\phi}^{n=0} \sim -\frac{\mu_0 k_2^3}{4\pi k_1}(I_{b\phi}+I_{b\phi}^c)\cos\phi. \tag{3.9}$$

In the above, $I_{f\kappa}$ $(f=e,\ b;\ \kappa=\rho,\ \phi,\ z)$ denote the Sommerfeld integrals,[34] viz.,

$$I_{ez} = k_2^{-3}\int_0^\infty d\lambda\,\frac{\sqrt{1-(\lambda/k_1)^2}}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}\lambda^2 J_1(\lambda\rho), \tag{3.10}$$

$$I_{e\rho} = k_2^{-2}\int_0^\infty d\lambda\,\lambda\left\{\frac{\sqrt{1-(\lambda/k_1)^2}\,\sqrt{1-(\lambda/k_2)^2}}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}[J_0(\lambda\rho)-J_2(\lambda\rho)] + \frac{1}{\sqrt{1-(\lambda/k_1)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}}[J_0(\lambda\rho)+J_2(\lambda\rho)]\right\}, \tag{3.11}$$

$$I_{e\phi}=k_2^{-2}\int_0^\infty d\lambda\,\lambda\left\{\frac{\sqrt{1-(\lambda/k_1)^2}\,\sqrt{1-(\lambda/k_2)^2}}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}[J_0(\lambda\rho)+J_2(\lambda\rho)]\right.$$
$$\left.+\frac{1}{\sqrt{1-(\lambda/k_1)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}}[J_0(\lambda\rho)-J_2(\lambda\rho)]\right\}, \tag{3.12}$$

$$I_{bz}=k_1^{-1}k_2^{-2}\int_0^\infty d\lambda\,\frac{1}{\sqrt{1-(\lambda/k_1)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}}\lambda^2 J_1(\lambda\rho), \tag{3.13}$$

$$I_{b\rho}=k_2^{-2}\int_0^\infty d\lambda\,\lambda\left\{\frac{\sqrt{1-(\lambda/k_2)^2}}{\sqrt{1-(\lambda/k_1)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}}[J_0(\lambda\rho)-J_2(\lambda\rho)]\right.$$
$$\left.+\frac{\sqrt{1-(\lambda/k_1)^2}}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}[J_0(\lambda\rho)+J_2(\lambda\rho)]\right\}, \tag{3.14}$$

$$I_{b\phi}=k_2^{-2}\int_0^\infty d\lambda\,\lambda\left\{\frac{\sqrt{1-(\lambda/k_2)^2}}{\sqrt{1-(\lambda/k_1)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}}[J_0(\lambda\rho)+J_2(\lambda\rho)]\right.$$
$$\left.+\frac{\sqrt{1-(\lambda/k_1)^2}}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}[J_0(\lambda\rho)-J_2(\lambda\rho)]\right\}. \tag{3.15}$$

The lowest-order corrections $I_{f\kappa}^{\mathrm{c}}$ read as

$$I_{ez}^{\mathrm{c}}=\frac{i}{2k_2^4 a}\int_0^\infty d\lambda\left\{\frac{k_2}{k_1}\frac{(\lambda/k_1)^2}{1-(\lambda/k_1)^2}\frac{1}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}\right.$$
$$\left.+\sqrt{1-(\lambda/k_1)^2}\frac{\dfrac{(\lambda/k_2)^2}{1-(\lambda/k_2)^2}-(k_2^2/k_1^2)\dfrac{(\lambda/k_1)^2}{1-(\lambda/k_1)^2}}{[\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}]^2}\right\}\lambda^2 J_1(\lambda\rho), \tag{3.16}$$

$$I_{e\rho}^{\mathrm{c}}=\frac{i}{2k_2^3 a}\int_0^\infty d\lambda\left\{\frac{\sqrt{1-(\lambda/k_1)^2}\dfrac{(\lambda/k_2)^2}{1-(\lambda/k_2)^2}-(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}\dfrac{(\lambda/k_1)^2}{1-(\lambda/k_1)^2}}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}\right.$$
$$\left.-\sqrt{1-(\lambda/k_2)^2}\sqrt{1-(\lambda/k_1)^2}\frac{\dfrac{(\lambda/k_2)^2}{1-(\lambda/k_2)^2}-(k_2^2/k_1^2)\dfrac{(\lambda/k_1)^2}{1-(\lambda/k_1)^2}}{[\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}]^2}\right\}\lambda[J_0(\lambda\rho)$$
$$-J_2(\lambda\rho)]+\frac{i}{2k_1k_2^2a}\int_0^\infty d\lambda\,\frac{[1-(\lambda/k_1)^2]^{-1}-[1-(\lambda/k_2)^2]^{-1}}{[\sqrt{1-(\lambda/k_1)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}]^2}\lambda[J_0(\lambda\rho)+J_2(\lambda\rho)], \tag{3.17}$$

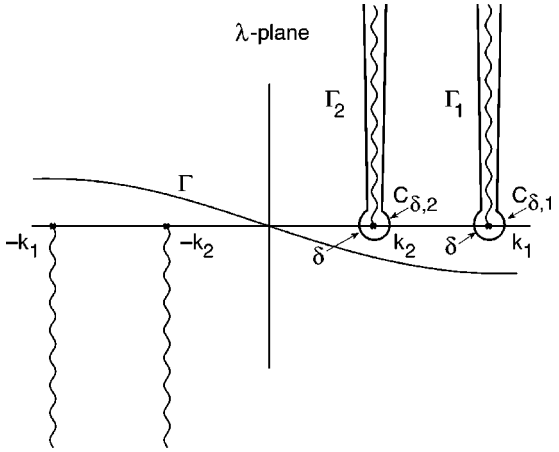

FIG. 2. Branch-cut configuration and integration paths Γ and Γ_j, $j=1,2$, pertaining to integrals (3.10)–(3.21); k_1 is taken to be real. The final formulas can be extended to complex k_1.

The first Riemann sheet is chosen so that all square roots are positive for $0<\lambda<k_2$, if k_1 is real, with the branch-cut configuration of Fig. 2; evidently, no pole lies in this sheet.

B. Integrated formulas, $k_2\rho\gg 1$, $k_2^2\ll|k_1^2|$

When $k_2\rho\gg 1$, the major contributions to integration in Eqs. (3.10)–(3.21) arise from the vicinities of branch points at $\lambda=k_j$ $(j=1,2)$. Explicit expressions for the integrals $I_{f\kappa}$ are given elsewhere.[34,35] It is noted in passing that $I_{e\rho}$, $I_{e\phi}$ and I_{bz} are evaluated exactly in terms of well-converging series that involve Fresnel and exponential integrals.[35]

Attention is now turned to $I^{c}_{f\kappa}$. By following the procedure in Appendix B of Ref. 35, let $I^{c}_{f\kappa,j}$ denote the contour integral over the path Γ_j of Fig. 2. Clearly, $I^{c}_{f,\kappa}=I^{c}_{f\kappa,2}+I^{c}_{f\kappa,1}$, since each $I^{c}_{f\kappa,j}$ follows from $I^{c}_{f\kappa}$ under

$$\int_0^\infty d\lambda\,(\cdots)J_s(\lambda\rho)\to\frac{1}{2}\int_{\Gamma_j}d\lambda\,(\cdots)H_s^{(1)}(\lambda\rho). \tag{3.22}$$

With $\lambda=k_j(1+it)$ in each side of the branch cuts in Fig. 2, it follows that

$$\sqrt{1-(\lambda/k_j)^2}=\pm e^{-i\pi/4}\sqrt{2t}\,\sqrt{1+it/2}\sim\pm e^{-i\pi/4}\sqrt{2t},\quad t\to 0^+,\quad \sqrt{t}\geqslant 0, \tag{3.23}$$

where the upper sign holds along the left-hand side and the lower sign along the right-hand side of each branch cut. Due to the factors $[1-(\lambda/k_j)^2]^{-1}$, the indentations $C_{\delta,j}$ contribute to the value of $I^{c}_{f\kappa,j}$ as δ approaches 0. For example, $I^{c}_{ez,2}$ requires the limit

$$\begin{aligned}
&\lim_{\delta\to 0^+}\int_{C_{\delta,2}}d\lambda\left\{\frac{(k_2/k_1)(\lambda/k_1)^2[1-(\lambda/k_1)^2]^{-1}}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}\right.\\
&\left.+\frac{\sqrt{1-(\lambda/k_1)^2}\{(\lambda/k_2)^2[1-(\lambda/k_2)^2]^{-1}-(k_2^2/k_1^2)(\lambda/k_1)^2[1-(\lambda/k_1)^2]^{-1}\}}{[\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}]^2}\right\}\\
&\times\lambda^2H_1^{(1)}(\lambda\rho)\\
&=2\pi i\left(\frac{-k_2}{2}\right)\sqrt{\frac{1-(k_2/k_1)^2}{[(k_2/k_1)\sqrt{1-(k_2/k_1)}]^2}}\,k_2^2H_1^{(1)}(k_2\rho)\sim-e^{i(k_2\rho-\pi/4)}k_1^2k_2\sqrt{\frac{2\pi}{k_2\rho}}.
\end{aligned} \tag{3.24}$$

Define

$$\wp = \frac{k_2^3 \rho}{2k_1^2} = \frac{k_2^2}{2k_1^2}(k_2 a)\,\theta, \tag{3.25}$$

$$F(\wp) = e^{-i\wp}\int_{\wp}^{\infty} dx\,\frac{e^{ix}}{\sqrt{2\pi x}} = e^{-i\wp}\left[\frac{1}{2}(1+i) - C(\wp) - iS(\wp)\right], \tag{3.26}$$

where $C(\wp)$ and $S(\wp)$ are the Fresnel integrals defined as[36]

$$C(\wp) = \int_0^{\wp} dx\,\frac{\cos x}{\sqrt{2\pi x}}, \quad S(\wp) = \int_0^{\wp} dx\,\frac{\sin x}{\sqrt{2\pi x}}. \tag{3.27}$$

The relevant calculations are illustrated by

$$\begin{aligned} I_{ez,2}^{c} \sim & -\frac{1}{4}e^{i(k_2\rho - 3\pi/4)}\frac{1}{k_2 a}\sqrt{\frac{2}{\pi k_2 \rho}}\int_0^{\infty} dt\left\{\frac{k_2^3}{k_1^3}\left[-\frac{1}{e^{-i\pi/4}\sqrt{2t}+k_2/k_1} + \frac{1}{-e^{-i\pi/4}\sqrt{2t}+k_2/k_1}\right]\right. \\ & \left. + \left(\frac{1}{-2it} - \frac{k_2^4}{k_1^4}\right)\left[-\frac{1}{(e^{-i\pi/4}\sqrt{2t}+k_2/k_1)^2} + \frac{1}{(-e^{-i\pi/4}\sqrt{2t}+k_2/k_1)^2}\right]\right\} e^{-k_2\rho t} \\ & + \frac{1}{2}e^{i(k_2\rho - 3\pi/4)}\frac{k_1^2}{k_2^3 a}\sqrt{\frac{\pi}{2k_2\rho}} \\ \sim & \frac{i}{2}e^{ik_2\rho}\frac{1}{k_2 a}\sqrt{\pi k_2 \rho}\left\{F(\wp) - i(2\pi\wp)^{-1/2} + (2i\wp)^{-1}\left[F(\wp) - \frac{1}{2}(1+i)\right]\right\} \end{aligned} \tag{3.28a}$$

$$\sim \begin{cases} \dfrac{1+i}{4}e^{ik_2\rho}\sqrt{\dfrac{\pi}{k_2\rho}}\,\dfrac{k_1^2}{k_2^3 a}, & |\wp| \gg 1, \\ \dfrac{1-i}{4}e^{ik_2\rho}\sqrt{\dfrac{\pi}{k_2\rho}}\,\dfrac{\rho}{a}, & |\wp| \ll 1, \end{cases} \tag{3.28b}$$

$$I_{ez,1}^{c} \sim -\frac{1}{2}e^{i(k_1\rho - \pi/4)}\frac{k_1}{k_2^2 a}\sqrt{\frac{\pi}{2k_1\rho}}. \tag{3.29}$$

From formulas (3.4)–(3.9), with $k_2 a \gg 1$, $k_2^2 \ll |k_1^2|$, $k_2 a\,\theta \gg 1$, and θ *sufficiently small*,

$$\begin{aligned} E_{2r}^{n=0} \sim & i\frac{\omega\mu_0 k_2^2}{2\pi k_1}\cos\phi\left\{-ie^{ik_2\rho}\frac{k_2}{k_1}\sqrt{\frac{\pi}{k_2\rho}}\left[F(\wp) - i(2\pi\wp)^{-1/2} + \frac{k_1\rho}{2k_2 a}\left\{F(\wp) - i(2\pi\wp)^{-1/2}\right.\right.\right. \\ & \left.\left.\left. + (2i\wp)^{-1}\left[F(\wp) - \frac{1}{2}(1+i)\right]\right\}\right] + \frac{e^{ik_1\rho}}{k_2^2\rho^2}\left(1 + \frac{1-i}{4}\sqrt{\pi k_1\rho}\frac{\rho}{a}\right)\right\}, \end{aligned} \tag{3.30}$$

$$B_{2\theta}^{n=0}\sim i\frac{\mu_0 k_2^3}{2\pi k_1}\sin\phi\Bigg\{\frac{e^{ik_2\rho}}{k_1\rho}\sqrt{\frac{\pi}{k_2\rho}}\Bigg[F(\wp)-2i(2\pi\wp)^{-1/2}+\frac{k_1\rho}{2k_2a}\Bigg\{F(\wp)-i(2\pi\wp)^{-1/2}$$
$$+(2i\wp)^{-1}\Bigg[F(\wp)-\frac{1}{2}(1+i)(1-2i\wp)\Bigg]\Bigg\}\Bigg]+e^{ik_1\rho}\frac{k_1}{k_2^3\rho^2}\Bigg(1+\frac{1-i}{4}\sqrt{\pi k_1\rho}\frac{\rho}{a}\Bigg)\Bigg\},\tag{3.34}$$

$$B_{2\phi}^{n=0}\sim-\frac{\mu_0 k_2^3}{2\pi k_1}\cos\phi\Bigg\{e^{ik_2\rho}\frac{k_2}{k_1}\sqrt{\frac{\pi}{k_2\rho}}\Bigg[F(\wp)-i(2\pi\wp)^{-1/2}+\frac{k_1\rho}{2k_2a}\Bigg\{F(\wp)-i(2\pi\wp)^{-1/2}$$
$$+(2i\wp)^{-1}\Bigg[F(\wp)-\frac{1}{2}(1+i)\Bigg]\Bigg\}\Bigg]+\frac{e^{ik_1\rho}}{k_2^2\rho^2}\Bigg(i\frac{k_2}{k_1}-\frac{1}{k_2\rho}\Bigg)\Bigg(1+\frac{1-i}{4}\sqrt{\pi k_1\rho}\frac{\rho}{a}\Bigg)\Bigg\}.\tag{3.35}$$

Consequently, $|I_{f\kappa,j}|\sim|I_{f\kappa,j}^{c}|$ provided that, for real k_1,

$$\rho\sim a(k_j a/2)^{-1/3}=\rho_{\mathrm{cr},j}=a\,\theta_{\mathrm{cr},j},\quad j=1,2,\tag{3.36}$$

where $\rho_{\mathrm{cr},2}$ is essentially Fock's "reduced distance."[16] Both $\rho_{\mathrm{cr},j}$, $j=1,2$, enter as parameters in the analysis for a vertical electric dipole.[3,4,33] Evidently, expressions (3.30)–(3.35) imply that

$$\theta\ll\theta_{\mathrm{cr},j}.\tag{3.37}$$

Of course, if k_1 is complex, one of these inequalities is replaced by $\theta\ll|\theta_{\mathrm{cr},1}|$.

When $1\ll k_2\rho\ll|k_1\rho|\ll|k_1\rho_{\mathrm{cr},2}|$, the maximum magnitudes in ϕ of the field components traveling with the air phase velocity satisfy

$$|E_{2r,2}^{n=0}|_m:|E_{2\theta,2}^{n=0}|_m:|E_{2\phi,2}^{n=0}|_m=O(1):O(k_2/k_1):O[(k_1\rho)^{-1}],\quad|\wp|\leqslant O(1),$$
$$=O(1):O(k_2/k_1):O(k_2^3/k_1^3),\quad|\wp|\gg 1,\tag{3.38a}$$

$$|B_{2r,2}^{n=0}|_m:|B_{2\theta,2}^{n=0}|_m:|B_{2\phi,2}^{n=0}|_m=O[(k_1\rho)^{-1}]:O[(k_2\rho)^{-1}]:O(1),\quad|\wp|\ll 1,$$
$$=O[(k_2\rho)^{-3/2}]:O[(k_2\rho)^{-1}]:O(1),\quad\wp=O(1),$$
$$=O(k_2^3/k_1^3):O(k_2^2/k_1^2):O(1),\quad|\wp|\gg 1.\tag{3.38b}$$

IV. WAVES IN THE CRITICAL RANGES, $\theta=O(\theta_{cr,j})$

When θ becomes of the order of $\theta_{\mathrm{cr},1}$ or $\theta_{\mathrm{cr},2}$ introduced in Eq. (3.36), approximations (3.4)–(3.9) break down. The approximation of Bessel functions by Airy integrals gives[39,40]

$$\mathcal{K}^{-1}(\nu)\sim-\frac{k_2}{k_1}\Bigg[1+\frac{k_2^2}{k_1^2}\Bigg(\frac{2}{k_1a}\Bigg)^{1/3}\mathcal{H}(\xi_1;0)\Bigg],\quad\xi_1=(k_1a/2)^{-1/3}(\nu-k_1a)=O(1),\tag{4.1a}$$

$$\mathcal{K}^{-1}(\nu)\sim-\left(\frac{k_2a}{2}\right)^{1/3}[\mathcal{H}(\xi_2;2\pi/3)-i\alpha]^{-1},\quad \xi_2=(k_2a/2)^{-1/3}(\nu-k_2a)=O(1), \tag{4.1b}$$

while

$$\mathcal{M}^{-1}(\nu)\sim 1+\left(\frac{2}{k_1a}\right)^{1/3}\mathcal{H}(\xi_1;0),\quad \xi_1=O(1), \tag{4.2a}$$

$$\mathcal{M}^{-1}(\nu)\sim i+\frac{k_2}{k_1}\left(\frac{2}{k_2a}\right)^{1/3}\mathcal{H}(\xi_2;2\pi/3),\quad \xi_2=O(1). \tag{4.2b}$$

In the above,

$$\mathcal{H}(\xi;\psi)=e^{i\psi}\frac{\mathrm{Ai}'(e^{i\psi}\xi)}{\mathrm{Ai}(e^{i\psi}\xi)}, \tag{4.3}$$

$$\alpha=\frac{k_2}{k_1}\left(\frac{k_2a}{2}\right)^{1/3}. \tag{4.4}$$

Notice the appearance of the Airy function $\mathrm{Ai}(z)$ and its derivative.[40] The Legendre functions are replaced by Bessel functions[36,39] of argument $\nu\theta$ where $\nu\theta\gg 1$.

By using the subscript j to denote the contribution from $\nu=k_ja$ $(j=1,2)$,

$$E_{2r,2}^{n=0}\sim-\frac{\omega\mu_0}{4\pi a}e^{i(k_2a\theta+\pi/4)}\frac{k_2}{k_1}\left(\frac{k_2a}{2}\right)^{2/3}\sqrt{\frac{2}{\pi k_2a\theta}}\mathcal{I}\cos\phi, \tag{4.5a}$$

$$E_{2r,1}^{n=0}\sim-\frac{\omega\mu_0}{4\pi a}e^{i(k_1a\theta-\pi/4)}\sqrt{\frac{2}{\pi k_1a\theta}}\mathcal{I}_1\cos\phi, \tag{4.5b}$$

$$E_{2\theta,2}^{n=0}\sim-\frac{\omega\mu_0}{4\pi a}e^{i(k_2a\theta+\pi/4)}\frac{k_2^2}{k_1^2}\left(\frac{k_2a}{2}\right)^{2/3}\sqrt{\frac{2}{\pi k_2a\theta}}\left[\mathcal{I}+\frac{i}{k_2a\theta}\left(\frac{k_2a}{2}\right)^{-2/3}\mathcal{I}_2\right]\cos\phi, \tag{4.6a}$$

$$E_{2\theta,1}^{n=0}\sim\frac{\omega\mu_0}{4\pi a}e^{i(k_1a\theta+\pi/4)}\sqrt{\frac{2}{\pi k_1a\theta}}\mathcal{I}_1\cos\phi, \tag{4.6b}$$

$$E_{2\phi,2}^{n=0}\sim-\frac{\omega\mu_0}{4\pi a}e^{i(k_2a\theta+\pi/4)}\frac{k_2^2}{k_1^2}\sqrt{\frac{2}{\pi k_2a\theta}}\left[\mathcal{I}_2+i\frac{\theta_{\mathrm{cr},2}}{2\theta}\mathcal{I}\right]\sin\phi, \tag{4.7a}$$

$$E_{2\phi,1}^{n=0}\sim-\frac{\omega\mu_0}{4\pi a}e^{i(k_1a\theta+\pi/4)}\sqrt{\frac{2}{\pi k_1a\theta}}\mathcal{I}_1\sin\phi, \tag{4.7b}$$

$$B_{2r,2}^{n=0}\sim-\frac{\mu_0k_2}{4\pi a}e^{i(k_2a\theta+\pi/4)}\frac{k_2^2}{k_1^2}\sqrt{\frac{2}{\pi k_2a\theta}}\mathcal{I}_2\sin\phi, \tag{4.8a}$$

$$B_{2r,1}^{n=0}\sim-\frac{\mu_0k_1}{4\pi a}e^{i(k_1a\theta+\pi/4)}\sqrt{\frac{2}{\pi k_1a\theta}}\mathcal{I}_1\sin\phi, \tag{4.8b}$$

$$B_{2\theta,2}^{n=0}\sim-\frac{\mu_0k_1}{4\pi a}e^{i(k_2a\theta+\pi/4)}\frac{k_2^2}{k_1^2}\sqrt{\frac{2}{\pi k_2a\theta}}\left[\mathcal{I}_2+i\frac{\theta_{\mathrm{cr},2}}{2\theta}\mathcal{I}\right]\sin\phi, \tag{4.9a}$$

$$B_{2\theta,1}^{n=0}\sim-\frac{\mu_0 k_1}{4\pi a}e^{i(k_1 a\theta-\pi/4)}\sqrt{\frac{2}{\pi k_1 a\theta}}\mathcal{I}_1\sin\phi, \tag{4.9b}$$

$$B_{2\phi,2}^{n=0}\sim\frac{\mu_0 k_2}{4\pi a}e^{i(k_2 a\theta+\pi/4)}\frac{k_2}{k_1}\left(\frac{k_2 a}{2}\right)^{2/3}\sqrt{\frac{2}{\pi k_2 a\theta}}\left[\mathcal{I}+\frac{i}{k_2 a\theta}\left(\frac{k_2 a}{2}\right)^{-2/3}\mathcal{I}_2\right]\cos\phi, \tag{4.10a}$$

$$B_{2\phi,1}^{n=0}\sim\frac{\mu_0 k_2}{4\pi a}e^{i(k_1 a\theta+\pi/4)}\left(\frac{1}{k_2 a\theta}-i\frac{k_2}{k_1}\right)\sqrt{\frac{2}{\pi k_1 a\theta}}\mathcal{I}_1\cos\phi, \tag{4.10b}$$

where

$$\mathcal{I}_1=\mathcal{I}_1(\theta)=\int_{-\infty-i\varsigma}^{\infty-i\varsigma}d\xi\, e^{i(\theta/\theta_{\mathrm{cr},1})\xi}\mathcal{H}(\xi;0), \tag{4.11}$$

$$\mathcal{I}_2=\mathcal{I}_2(\theta)=\int_{-\infty-i\varsigma}^{\infty-i\varsigma}d\xi\, e^{i(\theta/\theta_{\mathrm{cr},2})\xi}\mathcal{H}(\xi;2\pi/3), \tag{4.12}$$

$$\mathcal{I}=\mathcal{I}(\theta;\alpha)=\int_{-\infty-i\varsigma}^{\infty-i\varsigma}d\xi\frac{e^{i(\theta/\theta_{\mathrm{cr},2})\xi}}{\mathcal{H}(\xi;2\pi/3)-i\alpha},\quad \varsigma>0. \tag{4.13}$$

Because the sole singularities of the integrands are poles in the upper ξ-plane, including the real axis, terms with factors $e^{-i(\theta/\theta_{\mathrm{cr},j})\xi}$ are integrated out to zero. $\mathcal{I}$ and $\mathcal{I}_2$ describe propagation through region 2.

For $\theta\ll|\theta_{\mathrm{cr},1}|$, the leading contributions to integration in Eqs. (4.11)–(4.13) are determined by the large-ξ behavior of $\mathcal{H}(\xi;\psi)$. Accordingly,[40]

$$\mathcal{I}_1\sim-\int_{-\infty-i\varsigma}^{\infty-i\varsigma}d\xi\, e^{i(\theta/\theta_{\mathrm{cr},1})\xi}\left(\sqrt{\xi}+\frac{1}{4\xi}\right)=e^{-i\pi/4}\sqrt{\frac{2\pi}{k_1 a}}\left(\frac{\rho}{a}\right)^{-3/2}-\frac{i\pi}{2}, \tag{4.14}$$

while, for $\theta\ll\theta_{\mathrm{cr},2}$,

$$\mathcal{I}_2\sim\int_{-\infty-i\varsigma}^{\infty-i\varsigma}d\xi\, e^{i(\theta/\theta_{\mathrm{cr},2})\xi}\left(\sqrt{\xi}-\frac{1}{4\xi}\right)=-e^{-i\pi/4}\sqrt{\frac{2\pi}{k_2 a}}\left(\frac{\rho}{a}\right)^{-3/2}-\frac{i\pi}{2}, \tag{4.15}$$

$$\mathcal{I}\sim\int_{-\infty-i\varsigma}^{\infty-i\varsigma}d\xi\frac{e^{i(\theta/\theta_{\mathrm{cr},2})\xi}}{\sqrt{\xi}-1/4\xi-i\alpha}\sim i\pi e^{i\pi/4}2^{3/2}\frac{k_2}{k_1}\left(\frac{k_2 a}{2}\right)^{1/3}\left\{F(\wp)-i(2\pi\wp)^{-1/2}+\frac{k_1\rho}{2k_2 a}\left[F(\wp)\right.\right.$$
$$\left.\left.-i(2\pi\wp)^{-1/2}+(2i\wp)^{-1}\left\{F(\wp)-\frac{1}{2}(1+i)\right\}\right]\right\}, \tag{4.16}$$

in agreement with formulas (3.30)–(3.35).

A. Propagation through air

The integral $\mathcal{I}_2$ of Eq. (4.12) is expressed as a general Dirichlet series[41] over the residues associated with poles of $\mathcal{H}(\xi;2\pi/3)$. (See Appendix A for $\kappa=k_2/k_1$.) By closing the contour in the upper ξ-plane,

$$\mathcal{I}_2=2\pi i\sum_{s=1}^{\infty}e^{i(\theta/\theta_{\mathrm{cr},2})|a_s|e^{i\pi/3}}, \tag{4.17}$$

where a_s are the zeros of $\mathrm{Ai}(z)$ numbered in order of ascending magnitude.[40] Series (4.17) is approximated by its first term if $\theta \gg \theta_{\mathrm{cr},2}$.

The poles associated with $\mathcal{I}$ are obtained by solving

$$e^{i2\pi/3}\frac{\mathrm{Ai}'(\xi e^{i2\pi/3})}{\mathrm{Ai}(\xi e^{i2\pi/3})} = i\alpha, \quad \alpha = \frac{k_2}{k_1}\left(\frac{k_2 a}{2}\right)^{1/3}. \tag{4.18}$$

Let $\{\xi_s = \xi_s(\alpha)\}_{s=1,2,\ldots}$ be the sequence of these roots; $\xi_s(0)$ are numbered in order of increasing imaginary part. The integral $\mathcal{I}$ equals

$$\mathcal{I} = 2\pi i \sum_{s=1}^{\infty} \frac{e^{i(\theta/\theta_{\mathrm{cr},2})\xi_s}}{\xi_s + \alpha^2}. \tag{4.19}$$

Because $\{\xi_s\}$ do not have any finite limit, they should approach the Stokes line Arg $\xi = \pi/3$ as $s \to \infty$. Each $\xi_s(z)$ satisfies

$$\frac{d\xi_s}{dz} = \frac{i}{\xi_s + z^2}, \quad \xi_s(0) = |\check{a}_s| e^{i\pi/3}, \tag{4.20}$$

via differentiation of both sides of Eq. (4.18) in $\alpha \equiv z$. $\check{a}_s$ denote the zeros of $\mathrm{Ai}'(z)$.[40] Equation (4.20) was given by Fock[16] and has been studied numerically in the literature.[42] By integrating (4.20) along a path where $|\xi_s(z)| \gg |z^2|$,

$$\xi_s(\alpha) \sim \xi_s(0) + \frac{i\alpha}{\xi_s(0)}. \tag{4.21}$$

Clearly,

$$\mathcal{I} \sim 2\pi i \frac{e^{i(\theta/\theta_{\mathrm{cr},2})\bar{\xi}}}{\bar{\xi} + \alpha^2}, \quad \theta \gg \theta_{\mathrm{cr},2}, \tag{4.22}$$

where $\bar{\xi} = \bar{\xi}(\alpha)$ is the root of Eq. (4.18) with the smallest imaginary part. It is of interest to compare $\min_s \mathrm{Im}\, \xi_s(\alpha)$ with its limiting value for $\alpha \to \infty$. With $\alpha = te^{-i\vartheta}$ $(0 \leqslant t < \infty,\ 0 \leqslant \vartheta \leqslant \pi/4)$ and fixed ϑ, the trajectory of each $\xi_j(\alpha) = \beta_j(t) + i\gamma_j(t)$ can be described by the coupled equations

$$\frac{d\beta_j}{dt} = \frac{\gamma_j \cos\vartheta + (\beta_j - t^2)\sin\vartheta}{(\beta_j + t^2\cos 2\vartheta)^2 + (\gamma_j - t^2 \sin 2\vartheta)^2}, \tag{4.23a}$$

$$\frac{d\gamma_j}{dt} = \frac{(\beta_j + t^2)\cos\vartheta - \gamma_j \sin\vartheta}{(\beta_j + t^2\cos 2\vartheta)^2 + (\gamma_j - t^2 \sin 2\vartheta)^2}, \tag{4.23b}$$

where $\beta_j(0) = |\check{a}_j|/2$, $\gamma_j(0) = \sqrt{3}|\check{a}_j|/2$, and $|\check{a}_j| < |a_j| < |\check{a}_{j+1}|$. Of course, $\lim_{t\to\infty} \xi_j(\alpha(t)) = |a_j| e^{i\pi/3}$ uniformly in ϑ. For definiteness, consider $j = 1$. If $\vartheta = 0$, $\beta_1(t)$ and $\gamma_1(t)$ are monotonically increasing in t, and the slope of $\xi_1(\alpha(t))$ equals $\pi/6$ for $t = 0$ and approaches $\pi/2$ as $t \to \infty$. A close inspection of Eqs. (4.23) shows that $\gamma_1(t)$ remains monotonically increasing for fixed $\vartheta \in (0, \pi/6]$, while $\beta_1(t)$ reaches a maximum. For fixed $\vartheta \in (\pi/6, \pi/4]$, $\gamma_1(t)$ is monotonically decreasing and reaches a minimum, and then progresses monotonically to its limiting value. The lowest minimum of $\gamma_1(t)$ is reached for $\vartheta = \pi/4$, when the slope of $\xi_1(\alpha(t))$ is $-\pi/12$ for $t = 0$ and $3\pi/4$ as $t \to \infty$. By relaxing routine rigor, the assumed analyticity of $\xi_1(\alpha)$ in $\Delta_R = \{\alpha: 0 < |\alpha| < R,\ -\pi/4 < \mathrm{Arg}\ \alpha < 0\}$, where R is positive and arbitrarily large, entails that $\mathrm{Im}\, \xi_1(\alpha)$ is harmonic in Δ_R and hence cannot attain any maximum or minimum there. It follows from Fig. 3 that the maximum occurs along the boundary $\{\alpha: |\alpha| = R,\ \mathrm{Arg}\ \alpha = \pi/4\}$.

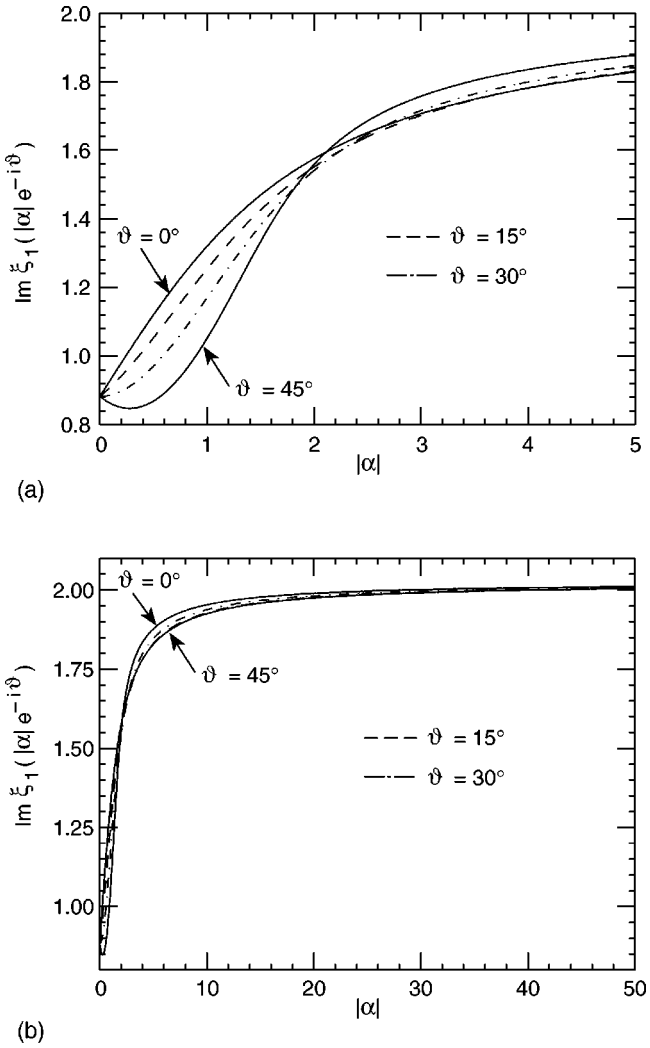

FIG. 3. Imaginary part of the root $\xi_1(\alpha)$ of (4.18) for fixed values of the phase $-\vartheta$ and varying magnitude $|\alpha|$, where $\alpha=|\alpha|e^{-i\vartheta}=(k_2/k_1)(k_2a/2)^{1/3}$, for (a) $0\leqslant|\alpha|\leqslant 5$, and (b) $0\leqslant|\alpha|\leqslant 50$.

It is therefore implied that, for $\alpha\leqslant O(1)$,

$$\mathcal{I}_2/\mathcal{I}=O[e^{-(\theta/\theta_{\mathrm{cr},2})\overline{h}}],\quad \overline{h}\equiv \tfrac{1}{2}\sqrt{3}\,|a_1|-\min_s \operatorname{Im}\xi_s(\alpha),\quad \theta\gg\theta_{\mathrm{cr},2}, \tag{4.24a}$$

while for $\alpha\to\infty$,

$$\mathcal{I}_2/\mathcal{I}=O(\alpha^2)\quad \text{as}\quad \alpha\to\infty. \tag{4.24b}$$

Formulas (4.6a) and (4.10a) are further simplified:

$$E^{n=0}_{2\theta,2}\sim -\frac{\omega\mu_0}{4\pi a}e^{i(k_2a\theta+\pi/4)}\frac{k_2^2}{k_1^2}\left(\frac{k_2a}{2}\right)^{2/3}\sqrt{\frac{2}{\pi k_2a\theta}}\,\mathcal{I}\cos\phi\sim\frac{k_2}{k_1}E^{n=0}_{2r,2}, \tag{4.25}$$

$$B^{n=0}_{2\phi,2}\sim \frac{\mu_0k_2}{4\pi a}e^{i(k_2a\theta+\pi/4)}\frac{k_2}{k_1}\left(\frac{k_2a}{2}\right)^{2/3}\sqrt{\frac{2}{\pi k_2a\theta}}\,\mathcal{I}\cos\phi\sim-\frac{1}{c}E^{n=0}_{2r,2}, \tag{4.26}$$

where c is the velocity of light in air.

From expressions (4.7a) and (4.9a),

$$E_{2\phi,2}^{n=0} \sim -i\frac{\omega\mu_0}{8\pi a}e^{i(k_2 a\theta+\pi/4)}\frac{k_2^2}{k_1^2}\sqrt{\frac{2}{\pi k_2 a\theta}}\,\frac{\theta_{\mathrm{cr},2}}{\theta}\mathcal{I}\sin\phi, \tag{4.27}$$

$$B_{2\theta,2}^{n=0} \sim -i\frac{\mu_0 k_1}{8\pi a}e^{i(k_2 a\theta+\pi/4)}\frac{k_2^2}{k_1^2}\sqrt{\frac{2}{\pi k_2 a\theta}}\,\frac{\theta_{\mathrm{cr},2}}{\theta}\mathcal{I}\sin\phi, \quad \theta \gg \theta_{\mathrm{cr},2},\ |\alpha| \leqslant O(1). \tag{4.28}$$

It is inferred that when $O(\theta_{\mathrm{cr},2}) \leqslant \theta \ll 1$, $|\alpha| \leqslant O(1)$,

$$|E_{2r,2}^{n=0}|_m : |E_{2\theta,2}^{n=0}|_m : |E_{2\phi,2}^{n=0}|_m = O(1) : O(k_2/k_1) : O[(k_1 a\theta)^{-1}], \tag{4.29a}$$

$$|B_{2r,2}^{n=0}|_m : |B_{2\theta,2}^{n=0}|_m : |B_{2\phi,2}^{n=0}|_m = O\left[\frac{\mathcal{I}_2}{\mathcal{I}}\frac{k_2}{k_1}\left(\frac{k_2 a}{2}\right)^{-2/3}\right] : O[(k_2 a\theta)^{-1}] : O(1). \tag{4.29b}$$

B. Propagation through region 1

Difficulties in the evaluation of $\mathcal{I}_1$ arise because of the presence of poles in the negative real axis. These poles stem from zeros of $\mathcal{K}(\nu)$ or $\mathcal{M}(\nu)$, as outlined in Appendix A. By use of the Wronskian of $\mathrm{Ai}(\zeta e^{-i\pi/3})$ and $\mathrm{Ai}(\zeta e^{i\pi/3})$,

$$\mathcal{I}_1 = \int_{\mathcal{L}} d\zeta\ [\mathcal{H}(-\zeta;0) - \mathcal{H}(-\zeta;-2\pi/3)]\, e^{-i(\theta/\theta_{\mathrm{cr},1})\zeta} = -\frac{e^{i\pi/6}}{2\pi}\int_{\mathcal{L}} d\zeta\,\frac{e^{-i(\theta/\theta_{\mathrm{cr},1})\zeta}}{\mathrm{Ai}(\zeta e^{i\pi/3})\,\mathrm{Ai}(-\zeta)}, \tag{4.30}$$

where $\mathcal{L}$ is a path that extends along the negative real axis, passes through zero and then extends slightly above the positive real axis. This integral can be cast in a form that is amenable to numerical computation.[33] Alternatively, rewrite $\mathcal{I}_1$ as

$$\begin{aligned}\mathcal{I}_1 &= -\frac{e^{i\pi/6}}{2\pi}\left[\int_0^\infty d\xi\,\frac{e^{i(\theta/\theta_{\mathrm{cr},1})\xi}}{\mathrm{Ai}(\xi e^{-i2\pi/3})\,\mathrm{Ai}(\xi)} + \int_0^{\infty+i\varsigma} d\zeta\,\frac{e^{-i(\theta/\theta_{\mathrm{cr},1})\zeta}}{\mathrm{Ai}(\zeta e^{i\pi/3})\,\mathrm{Ai}(-\zeta)}\right] \\ &= -\frac{i}{\pi}\left\{\int_0^\infty dy\,\frac{\exp[-(\theta/\theta_{\mathrm{cr},1})ye^{i\pi/6}] + 2\exp[(\theta/\theta_{\mathrm{cr},1})ye^{-i\pi/6}]}{\mathrm{Ai}(y)^2+\mathrm{Bi}(y)^2}\right. \\ &\quad \left. + i\int_0^\infty dy\,\frac{\exp[-(\theta/\theta_{\mathrm{cr},1})ye^{i\pi/6}]}{\mathrm{Ai}(y)^2+\mathrm{Bi}(y)^2}\,\frac{\mathrm{Bi}(y)}{\mathrm{Ai}(y)}\right\},\end{aligned} \tag{4.31}$$

by rotation of each integration path in the ξ- or ζ-plane by $2\pi/3$ or $\pi/3$ counterclockwise. The right-hand side of Eq. (4.31) involves exponentially converging integrals.

When $\theta \gg |\theta_{\mathrm{cr},1}|$, $\mathcal{I}_1$ is further simplified. By virtue of the equality

$$\mathrm{Ai}(-\zeta) + e^{i2\pi/3}\mathrm{Ai}(\zeta e^{-i\pi/3}) + e^{-i2\pi/3}\mathrm{Ai}(\zeta e^{i\pi/3}) = 0,$$

it is deduced that

$$\frac{1}{\mathrm{Ai}(\zeta e^{i\pi/3})\,\mathrm{Ai}(-\zeta)} = 2\pi e^{-i\pi/6}\frac{d}{d\zeta}\int_0^{\varpi(\zeta)}\frac{dy}{1+y}, \tag{4.32}$$

where

$$\varpi(\zeta) \equiv e^{-i2\pi/3}\,\frac{\mathrm{Ai}(\zeta e^{-i\pi/3})}{\mathrm{Ai}(\zeta e^{i\pi/3})}. \tag{4.33}$$

Note that $\varpi(\zeta)$ is bounded everywhere except near the zeros of $\mathrm{Ai}(\zeta e^{i\pi/3})$. Substitution of Eq. (4.32) into (4.30) and application of integration by parts furnish

$$\mathcal{I}_1 = -i\frac{\theta}{\theta_{\mathrm{cr},1}}\left[\sum_{p=0}^{P-1}\frac{(-1)^p}{p+1}\int_{\mathcal{L}} d\zeta\, e^{-i(\theta/\theta_{\mathrm{cr},1})\zeta}\,\varpi(\zeta)^{p+1} + \mathcal{R}_P(\theta/\theta_{\mathrm{cr},1})\right], \tag{4.34}$$

where

$$\mathcal{R}_P(x) = (-1)^P \int_{\mathcal{L}} d\zeta\, e^{-ix\zeta}\int_0^{\varpi(\zeta)} dy\,\frac{y^P}{1+y}, \quad P \gg 1, \tag{4.35}$$

$$\mathcal{R}_P(x) \sim \frac{(-1)^P}{P+1}\int_{\mathcal{L}} d\zeta\, e^{-ix\zeta}\frac{\varpi(\zeta)^{P+1}}{1+\varpi(\zeta)}, \quad P \gg 1. \tag{4.36}$$

For $\theta \gg |\theta_{\mathrm{cr},1}|$, the leading contributions in Eq. (4.34) come from points ζ_p that render the phase of $e^{-i(\theta/\theta_{\mathrm{cr},1})\zeta}\,\varpi(\zeta)^{p+1}$ stationary. Consequently, ζ_p obey

$$\frac{\varpi'(\zeta_p)}{\varpi(\zeta_p)} = i\frac{\theta}{\theta_{\mathrm{cr},1}(p+1)}, \tag{4.37}$$

or

$$\frac{1}{\pi}\frac{1}{\mathrm{Ai}(-\zeta_p)^2 + \mathrm{Bi}(-\zeta_p)^2} = \frac{\theta}{2\,\theta_{\mathrm{cr},1}(p+1)} = \chi_p\,. \tag{4.38}$$

When $p < O(\theta/\theta_{\mathrm{cr},1})$, ζ_p is positive and large,[40] viz.,

$$\zeta_p = \chi_p^2 + O(\chi_p^{-4}), \quad |\chi_p| \gg 1. \tag{4.39}$$

On the other hand, $\chi_p = O(1)$ implies $\zeta_p = O(1)$. In view of approximation (4.36), the remainder in Eq. (4.34) can be neglected if P is of the order of $\theta/\theta_{\mathrm{cr},1}$. With

$$\varpi(\zeta)^{p+1} \sim (-i)^{p+1}\exp\left[i\frac{4}{3}(p+1)\zeta^{3/2}\right], \tag{4.40}$$

an ordinary stationary-phase calculation leads to

$$\begin{aligned}\mathcal{I}_1 &\sim -i\frac{\theta}{\theta_{\mathrm{cr},1}}\sum_{p=0}^{O(\theta/\theta_{\mathrm{cr},1})}\frac{(-1)^p}{p+1}\exp\left[-\frac{i}{12}\frac{\theta^3}{\theta_{\mathrm{cr},1}^3(p+1)^2}\right](-i)^{p+1}\\ &\quad\times\int_{-\infty}^{\infty} d\zeta\exp\left\{i\frac{\theta}{\theta_{\mathrm{cr},1}}\left[\frac{\theta_{\mathrm{cr},1}(p+1)}{\theta}\right]^2(\zeta-\zeta_p)^2\right\}\\ &\sim -e^{i\pi/4}\left(\frac{\theta}{\theta_{\mathrm{cr},1}}\right)^{3/2}\sqrt{\pi}\,\mathcal{S}(k_1 a\,\theta^3),\end{aligned} \tag{4.41}$$

$$\mathcal{S}(z) = \sum_{p=0}^{\infty}\frac{i^p}{(p+1)^2}\exp\left[-\frac{i}{24}\frac{z}{(p+1)^2}\right]. \tag{4.42}$$

Finally, for $\theta \gg |\theta_{\mathrm{cr},1}|$, $k_2^2 \ll |k_1^2|$ and $k_2 a\,\theta \gg 1$,

$$E_{2r,1}^{n=0} \sim \frac{\omega\mu_0\theta}{4\pi a}e^{ik_1 a\,\theta}\,\mathcal{S}(k_1 a\,\theta^3)\cos\phi \sim iE_{2\theta,1}^{n=0}\,, \tag{4.43}$$

$$E_{2\phi,1}^{n=0}\sim\frac{i\omega\mu_0\theta}{4\pi a}e^{ik_1a\theta}\mathcal{S}(k_1a\theta^3)\sin\phi, \tag{4.44}$$

$$B_{2r,1}^{n=0}\sim\frac{i\mu_0k_1\theta}{4\pi a}e^{ik_1a\theta}\mathcal{S}(k_1a\theta^3)\sin\phi\sim iB_{2\theta,1}^{n=0}, \tag{4.45}$$

$$\begin{aligned}B_{2\phi,1}^{n=0}&\sim-\frac{i\mu_0k_2\theta}{4\pi a}e^{ik_1a\theta}\left(\frac{1}{k_2a\theta}-i\frac{k_2}{k_1}\right)\mathcal{S}(k_1a\theta^3)\cos\phi\\&\sim-\frac{\mu_0k_2^2\theta}{4\pi k_1a}e^{ik_1a\theta}\mathcal{S}(k_1a\theta^3)\cos\phi,\quad k_2a\theta\gg|k_1|/k_2.\end{aligned} \tag{4.46}$$

V. FIELD IN THE RANGE $O(\theta_{cr,j})<\theta\leqslant\pi$

A. Formulation

Consider the identity

$$\begin{aligned}\mathcal{M}(\nu)-\frac{H_\nu^{(2)'}(k_1a)}{H_\nu^{(2)}(k_1a)}&=-\frac{\mathrm{W}[H_\nu^{(1)}(k_1a),H_\nu^{(2)}(k_1a)]}{2H_\nu^{(2)}(k_1a)\,J_\nu(k_1a)}-\frac{k_2}{k_1}\frac{H_\nu^{(1)'}(k_2a)}{H_\nu^{(1)}(k_2a)}\\&=\frac{2i}{\pi k_1a\,H_\nu^{(2)}(k_1a)\,J_\nu(k_1a)}-\frac{k_2}{k_1}\frac{H_\nu^{(1)'}(k_2a)}{H_\nu^{(1)}(k_2a)},\end{aligned} \tag{5.1}$$

which is implied from Eq. (4.32) and leads to the decomposition

$$\frac{1}{\mathcal{M}(\nu)}=\frac{1}{\mathcal{D}(\nu)}-\mathcal{F}(\nu)\sum_{p=0}^{P-1}\mathcal{G}(\nu)^p-\mathcal{F}(\nu)\frac{\mathcal{G}(\nu)^P}{1-\mathcal{G}(\nu)}, \tag{5.2}$$

where

$$\mathcal{D}(\nu)=\frac{H_\nu^{(2)'}(k_1a)}{H_\nu^{(2)}(k_1a)}-\frac{k_2}{k_1}\frac{H_\nu^{(1)'}(k_2a)}{H_\nu^{(1)}(k_2a)}, \tag{5.3}$$

$$\mathcal{F}(\nu)=\frac{4i}{\pi k_1a}\frac{1}{\mathcal{D}(\nu)^2\,H_\nu^{(2)}(k_1a)^2}, \tag{5.4}$$

$$\mathcal{G}(\nu)=\frac{-H_\nu^{(1)}(k_1a)}{H_\nu^{(2)}(k_1a)}-\frac{4i}{\pi k_1a}\frac{1}{\mathcal{D}(\nu)\,H_\nu^{(2)}(k_1a)^2}. \tag{5.5}$$

When $P\to\infty$, Eq. (5.2) reduces to an expansion of the Debye type,[7] also employed by Nussenzveig.[29,32] In the lower ν-plane slightly below the positive real axis, the limit $P\to\infty$ in Eq. (5.2) is meaningful because $|\mathcal{G}(\nu)|<1$. However, care should be exercised in taking this limit under the integral sign.

A corresponding decomposition for $\mathcal{K}^{-1}(\nu)$ reads as

$$\frac{1}{\mathcal{K}(\nu)}=\frac{1}{\mathcal{A}(\nu)}+\mathcal{B}(\nu)\sum_{p=0}^{P-1}\mathcal{C}(\nu)^p+\mathcal{B}(\nu)\frac{\mathcal{C}(\nu)^P}{1-\mathcal{C}(\nu)}, \tag{5.6}$$

where

$$\mathcal{A}(\nu)=\frac{H_\nu^{(1)'}(k_2a)}{H_\nu^{(1)}(k_2a)}-\frac{k_2}{k_1}\frac{H_\nu^{(2)'}(k_1a)}{H_\nu^{(2)}(k_1a)}+\frac{1}{2k_2a}-\frac{k_2^2}{k_1^2}\frac{1}{2k_2a}, \tag{5.7}$$

$$\mathcal{B}(\nu)=\frac{4i}{\pi k_1 a}\frac{k_2}{k_1}\frac{1}{\mathcal{A}(\nu)^2 H_\nu^{(2)}(k_1 a)^2}, \tag{5.8}$$

$$\mathcal{C}(\nu)=\frac{-H_\nu^{(1)}(k_1 a)}{H_\nu^{(2)}(k_1 a)}+\frac{4i}{\pi k_1 a}\frac{k_2}{k_1}\frac{1}{\mathcal{A}(\nu) H_\nu^{(2)}(k_1 a)^2}. \tag{5.9}$$

Expressions (5.6)–(5.9) are also derived in Ref. 33 for the field of a vertical electric dipole over a spherical earth. $\mathcal{A}(\nu)$ and $\mathcal{D}(\nu)$ are entire functions of ν satisfying[39]

$$\mathcal{A}(-\nu)=\mathcal{A}(\nu), \quad \mathcal{D}(-\nu)=\mathcal{D}(\nu). \tag{5.10}$$

A brief discussion on the location of their zeros is given in Appendix B.

Residues that are associated with the poles ν_j of $\mathcal{A}^{-1}(\nu)$ and $\tilde{\nu}_j$ of $\mathcal{D}^{-1}(\nu)$ in the upper ν-plane give rise to exponentially decreasing waves that propagate through air. On the other hand, stationary-phase contributions from $\mathcal{B}(\nu)\mathcal{C}(\nu)^p$ and $\mathcal{F}(\nu)\mathcal{G}(\nu)^p$, combined with $e^{i2\pi n\nu}$ and the Legendre functions, give rise to rays that travel in region 1. Contributions from these rays become significant when $\mathrm{Im}\, k_1 a \ll 1$.

With Eqs. (C1) and (C5) of Appendix C,

$$\mathbf{E}_2=\mathbf{E}_2^{\mathrm{res}}+\mathbf{E}_2^{\mathrm{ray}}, \quad \mathbf{B}_2=\mathbf{B}_2^{\mathrm{res}}+\mathbf{B}_2^{\mathrm{ray}}, \tag{5.11}$$

where

$$E_{2r}^{\mathrm{res}}=\frac{i\omega\mu_0}{2\pi k_1 k_2 a^3}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\mathcal{A}(\nu)}\left[\frac{1}{2k_1 a}+\frac{H_\nu^{(2)\prime}(k_1 a)}{H_\nu^{(2)}(k_1 a)}\right]\mathrm{P}_{\nu-1/2}^1(\cos\theta), \tag{5.12}$$

$$\begin{aligned}E_{2\theta}^{\mathrm{res}}=&\frac{i\omega\mu_0}{2\pi k_1 a^2}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\\&\times\left\{\frac{H_\nu^{(2)\prime}(k_1 a)}{H_\nu^{(2)}(k_1 a)}+\frac{k_2}{k_1}\frac{1}{\mathcal{A}(\nu)}\left[\frac{1}{2k_1 a}+\frac{H_\nu^{(2)\prime}(k_1 a)}{H_\nu^{(2)}(k_1 a)}\right]^2\right\}\frac{\partial\mathrm{P}_{\nu-1/2}^1(\cos\theta)}{\partial\theta}\\&-\frac{i\omega\mu_0}{2\pi k_1 a^2\sin\theta}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{D}(\nu)}\mathrm{P}_{\nu-1/2}^1(\cos\theta),\end{aligned} \tag{5.13}$$

$$\begin{aligned}E_{2\phi}^{\mathrm{res}}=&-\frac{i\omega\mu_0}{2\pi k_1 a^2\sin\theta}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\\&\times\left\{\frac{H_\nu^{(2)\prime}(k_1 a)}{H_\nu^{(2)}(k_1 a)}+\frac{k_2}{k_1}\frac{1}{\mathcal{A}(\nu)}\left[\frac{1}{2k_1 a}+\frac{H_\nu^{(2)\prime}(k_1 a)}{H_\nu^{(2)}(k_1 a)}\right]^2\right\}\mathrm{P}_{\nu-1/2}^1(\cos\theta)\\&+\frac{i\omega\mu_0}{2\pi k_1 a^2}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{D}(\nu)}\frac{\partial\mathrm{P}_{\nu-1/2}^1}{\partial\theta},\end{aligned} \tag{5.14}$$

$$B_{2r}^{\mathrm{res}}=-\frac{\mu_0}{2\pi k_1 a^3}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\frac{\nu}{\mathcal{D}(\nu)}\mathrm{P}_{\nu-1/2}^1(\cos\theta), \tag{5.15}$$

$$B_{2\theta}^{\mathrm{res}}=-\frac{\mu_0}{2\pi a^2}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\,e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{D}(\nu)}\left[\frac{1}{2k_1a}+\frac{H_\nu^{(2)\prime}(k_1a)}{H_\nu^{(2)}(k_1a)}\right]$$
$$\times\frac{\partial \mathrm{P}_{\nu-1/2}^1}{\partial\theta}-\frac{\mu_0k_2}{2\pi k_1a^2\sin\theta}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\,e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{A}(\nu)}$$
$$\times\left[\frac{1}{2k_1a}+\frac{H_\nu^{(2)\prime}(k_1a)}{H_\nu^{(2)}(k_1a)}\right]\mathrm{P}_{\nu-1/2}^1(\cos\theta),\tag{5.16}$$

$$B_{2\phi}^{\mathrm{res}}=-\frac{\mu_0}{2\pi a^2\sin\theta}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\,e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\frac{1}{\mathcal{D}(\nu)}$$

$$\times\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]^2\mathrm{P}_{\nu-1/2}^1(\cos\theta)-\frac{i\omega\mu_0}{2\pi k_1a^2}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n$$
$$\times\sum_{p=0}^{\infty}\int_0^{\infty}d\nu\,e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{F}(\nu)\mathcal{G}(\nu)^p\frac{\partial \mathrm{P}_{\nu-1/2}^1}{\partial\theta},\tag{5.20}$$

$$B_{2r}^{\mathrm{ray}}=\frac{\mu_0}{2\pi k_1a^3}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\sum_{p=0}^{\infty}\int_0^{\infty}d\nu\,e^{i2\pi n\nu}\nu\mathcal{F}(\nu)\mathcal{G}(\nu)^p\,\mathrm{P}_{\nu-1/2}^1(\cos\theta),\tag{5.21}$$

$$B_{2\theta}^{\mathrm{ray}}=\frac{\mu_0 k_2}{2\pi k_1 a^2}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n\sum_{p=0}^{\infty}\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{F}(\nu)\mathcal{G}(\nu)^p$$
$$\times\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\frac{\partial \mathrm{P}^1_{\nu-1/2}}{\partial\theta}-\frac{\mu_0}{2\pi a^2\sin\theta}\sin\phi\sum_{n=-\infty}^{\infty}(-1)^n$$
$$\times\sum_{p=0}^{\infty}\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{B}(\nu)\mathcal{C}(\nu)^p\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\mathrm{P}^1_{\nu-1/2},\tag{5.22}$$

$$B_{2\phi}^{\mathrm{ray}}=\frac{\mu_0 k_2}{2\pi k_1 a^2\sin\theta}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\sum_{p=0}^{\infty}\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{F}(\nu)\mathcal{G}(\nu)^p$$
$$\times\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta)-\frac{\mu_0}{2\pi a^2}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n$$
$$\times\sum_{p=0}^{\infty}\int_0^{\infty}d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{B}(\nu)\mathcal{C}(\nu)^p\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\frac{\partial \mathrm{P}^1_{\nu-1/2}}{\partial\theta}.\tag{5.23}$$

B. Residue series

The residue contributions are illustrated by

$$E_{2r}^{\mathrm{res}}=-\frac{i\omega\mu_0}{k_1k_2a^3}\cos\phi\sum_{n=0}^{\infty}\sum_{j=1}^{\infty}\left\{e^{i(2n+1)\pi\nu}\,\nu\left[\frac{1}{2k_1a}+\frac{H_\nu^{(2)\prime}(k_1a)}{H_\nu^{(2)}(k_1a)}\right]\right.$$
$$\left.\times\mathrm{P}^1_{\nu-1/2}(-\cos\theta)\right\}_{\nu=\nu_j}\mathrm{Res}_{\nu=\nu_j}\{\mathcal{A}^{-1}(\nu)\},\tag{5.24}$$

$$B_{2r}^{\mathrm{res}}=\frac{\mu_0}{k_1a^3}\sin\phi\sum_{n=0}^{\infty}(-1)^n\sum_{j=1}^{\infty}\left[e^{i(2n+1)\pi\nu}\,\nu\,\mathrm{P}^1_{\nu-1/2}(-\cos\theta)\right]_{\nu=\tilde{\nu}_j}\mathrm{Res}_{\nu=\tilde{\nu}_j}\{\mathcal{D}^{-1}(\nu)\},\tag{5.25}$$

where the poles are numbered in order of ascending imaginary part.

If both θ and $\pi-\theta$ are $O(1)$,[36]

$$\mathrm{P}^1_{\nu-1/2}(-\cos\theta)\sim\sqrt{\frac{\nu}{2\pi\sin\theta}}\sum_{s=\pm}e^{-is[\nu(\pi-\theta)+\pi/4]}.\tag{5.26}$$

Hence, each n in Eqs. (5.24) and (5.25) represents the "winding number" of two wave paths in air, namely, one of length $\rho_n^+(\theta)=(2\pi n+\theta)a$ and another of length $\rho_n^-=\rho_n^+(2\pi-\theta)$. Both paths originate from the source and reach the observation point clockwise $(+)$ or counterclockwise $(-)$ in the plane determined by the point source, center of sphere and observation point. This plane is henceforth called the meridian plane. The configuration is shown in Fig. 4.

The approximations for the Hankel functions yield[39]

$$\mathcal{A}(\nu)\sim-\left(\frac{2}{k_2a}\right)^{1/3}[\mathcal{H}(\xi;2\pi/3)-i\alpha],\quad \alpha=(k_2/k_1)(k_2a/2)^{1/3},\tag{5.27}$$

$$\mathcal{D}(\nu)\sim\frac{k_2}{k_1}\left(\frac{2}{k_2a}\right)^{1/3}\mathcal{H}(\xi;2\pi/3)-i,\quad \xi=(\nu-k_2a)(k_2a/2)^{-1/3},\tag{5.28}$$

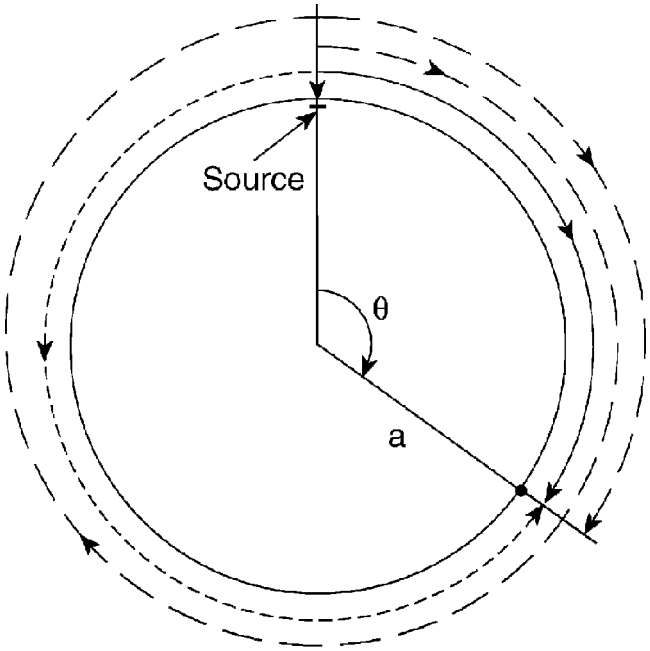

FIG. 4. Paths of lengths $\rho_n^{\pm}$ $(n\geqslant 0)$ traveled by exponentially decreasing waves that reach the observation point through the air.

where $\mathcal{H}(\xi;\psi)$ is defined by Eq. (4.3). Retainment of the $n=0$ terms in the residue series (5.24) and (5.25) and use of approximation (5.26) recover formulas (4.5a) and (4.8a), when $O(\theta_{\mathrm{cr},2})\leqslant\theta<\pi$ and $k_2a(\pi-\theta)\geqslant 1$. This procedure is also applied to the tangential field components. Care should be exercised when (i) $\theta<O(\theta_{\mathrm{cr},2})$, because the relevant residue series converge slowly, calling for the procedure of Sec. III, and (ii) $\pi-\theta\leqslant O[(k_2a)^{-1}]$, where the Legendre functions must be replaced by Bessel functions of argument $\nu(\pi-\theta)$.

By following point (ii) above and extending MacDonald's formulas[36] to the range $O(\theta_{\mathrm{cr},2})<\theta\leqslant\pi$, one gets[43]

$$E_{2r}^{\mathrm{res}}\sim-\frac{\omega\mu_0}{a}\frac{k_2}{k_1}\left(\frac{k_2a}{2}\right)^{2/3}\frac{1}{\overline{\xi}+\alpha^2}\sqrt{\frac{\pi-\theta}{\sin\theta}}e^{i\nu_1\pi}J_1(\nu_1(\pi-\theta))\cos\phi, \tag{5.29}$$

$$B_{2r}^{\mathrm{res}}\sim-\frac{\mu_0k_2}{a}\frac{k_2^2}{k_1^2}\sqrt{\frac{\pi-\theta}{\sin\theta}}e^{i\pi\tilde{\nu}_1}J_1(\tilde{\nu}_1(\pi-\theta))\sin\phi, \tag{5.30}$$

where

$$\nu_1\sim k_2a+(k_2a/2)^{1/3}\overline{\xi},\quad \tilde{\nu}_1\sim k_2a+(k_2a/2)^{1/3}|a_1|e^{i\pi/3}. \tag{5.31}$$

Bear in mind that $\overline{\xi}$ is introduced in Eq. (4.22) and a_1 is the first zero of $\mathrm{Ai}(z)$.

Evidently, for fixed $\alpha=(k_2/k_1)(k_2a/2)^{1/3}$ and $\theta\gg\theta_{\mathrm{cr},2}$, the H-type wave attenuates faster than the E-type one. Due to the factors of $\mathrm{P}^1_{\nu-1/2}(-\cos\theta)/\sin\theta$, the latter prevails for all $O(\theta_{\mathrm{cr},2})<\theta\leqslant\pi$. For example,

$$E_{2\phi}^{\mathrm{res}}\sim-\frac{i\omega\mu_0}{a}e^{ik_2a\pi}\frac{k_2^2}{k_1^2}\sqrt{\frac{\pi-\theta}{\sin\theta}}\left[\frac{1}{2\theta_{\mathrm{cr},2}}e^{i(\pi/\theta_{\mathrm{cr},2})\bar{\xi}}\frac{J_1(\nu_1(\pi-\theta))}{\sin\theta}\frac{1}{\bar{\xi}+\alpha^2}\right.$$
$$\left.+e^{i(\pi/\theta_{\mathrm{cr},2})|a_1|e^{i\pi/3}}J_1'(\tilde{\nu}_1(\pi-\theta))\right]\sin\phi$$
$$\sim-\frac{i\omega\mu_0}{2\rho_{\mathrm{cr},2}}e^{ik_2a\pi}\sqrt{\frac{\pi-\theta}{\sin\theta}}\frac{k_2^2}{k_1^2}\frac{J_1(\nu_1(\pi-\theta))}{\pi-\theta}\frac{e^{i(\pi/\theta_{\mathrm{cr},2})\bar{\xi}}}{\bar{\xi}+\alpha^2}\sin\phi. \tag{5.32}$$

C. Ray representations

1. Case $\theta=O(1)$, $\pi-\theta=O(1)$

Attention is now turned to Eqs. (5.18)–(5.23). Approximations of the Bessel functions outside the transitional regions for $k_2^2a/|k_1|\gg1$ yield[39]

$$\mathcal{A}(\nu)\sim i\sqrt{1-\left(\frac{\nu}{k_2a}\right)^2}+i\frac{k_2}{k_1}\sqrt{1-\left(\frac{\nu}{k_1a}\right)^2}, \tag{5.33}$$

$$\mathcal{B}(\nu)\sim-2i\frac{k_2}{k_1}\left[1-\left(\frac{\nu}{k_2a}\right)^2\right]^{-1/2}\mathcal{T}_E(\nu/a)\exp\left[2i\sqrt{(k_1a)^2-\nu^2}-2i\nu\arccos\left(\frac{\nu}{k_1a}\right)-i\frac{\pi}{2}\right], \tag{5.34}$$

$$\mathcal{C}(\nu)\sim R_E(\nu/a)\exp\left[2i\sqrt{(k_1a)^2-\nu^2}-2i\nu\arccos\left(\frac{\nu}{k_1a}\right)-i\frac{\pi}{2}\right], \tag{5.35}$$

$$\mathcal{D}(\nu)\sim-i\sqrt{1-\left(\frac{\nu}{k_1a}\right)^2}-i\frac{k_2}{k_1}\sqrt{1-\left(\frac{\nu}{k_2a}\right)^2}, \tag{5.36}$$

$$\mathcal{F}(\nu)\sim-2i\,\mathcal{T}_H(\nu/a)\exp\left[2i\sqrt{(k_1a)^2-\nu^2}-2i\nu\arccos\left(\frac{\nu}{k_1a}\right)-i\frac{\pi}{2}\right], \tag{5.37}$$

$$\mathcal{G}(\nu)\sim R_H(\nu/a)\exp\left[2i\sqrt{(k_1a)^2-\nu^2}-2i\nu\arccos\left(\frac{\nu}{k_1a}\right)-i\frac{\pi}{2}\right], \tag{5.38}$$

where

$$R_E(\lambda)=-\frac{\sqrt{1-(\lambda/k_2)^2}-(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}{\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}}, \tag{5.39}$$

$$R_H(\lambda)=\frac{\sqrt{1-(\lambda/k_1)^2}-(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}}{\sqrt{1-(\lambda/k_1)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}}, \tag{5.40}$$

$$\mathcal{T}_E(\lambda)=\frac{\sqrt{1-(\lambda/k_1)^2}\sqrt{1-(\lambda/k_2)^2}}{[\sqrt{1-(\lambda/k_2)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_1)^2}]^2}, \tag{5.41}$$

$$\mathcal{T}_H(\lambda)=\frac{\sqrt{1-(\lambda/k_1)^2}}{[\sqrt{1-(\lambda/k_1)^2}+(k_2/k_1)\sqrt{1-(\lambda/k_2)^2}]^2}. \tag{5.42}$$

R_E and R_H are the usual Fresnel reflection coefficients. The corresponding integrands are separated into two groups as follows.

(*i*) The first group contains terms of the radial components along with integrands proportional to $\partial \mathrm{P}^1_{\nu-1/2}/\partial\theta$. For instance,

$$\nu\mathcal{B}(\nu)\,\mathcal{C}(\nu)^p\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta)\,e^{i2\pi n\nu}$$
$$\sim\frac{k_2}{k_1}\,\nu\,\sqrt{\frac{2\nu}{\pi\sin\theta}}\,\mathcal{T}_E(\nu/a)\,R_E(\nu/a)^p\,(e^{i\Phi_{pn+}}+e^{i\Phi_{pn-}}), \tag{5.43}$$

$$\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{B}(\nu)\,\mathcal{C}(\nu)^p\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]^2\frac{\partial\mathrm{P}^1_{\nu-1/2}}{\partial\theta}\,e^{i2\pi n\nu}$$
$$\sim i\frac{k_2}{k_1}\sqrt{\frac{2\nu}{\pi\sin\theta}}\left[1-\left(\frac{\nu}{k_2a}\right)^2\right]^{1/2}\mathcal{T}_E(\nu/a)\,R_E(\nu/a)^p\,[e^{i(\Phi_{pn+}+\pi/2)}+e^{i(\Phi_{pn-}-\pi/2)}], \tag{5.44}$$

where

$$\Phi_{pn\pm}(\nu;\theta)=2(p+1)\sqrt{(k_1a)^2-\nu^2}-2(p+1)\,\nu\,\arccos\left(\frac{\nu}{k_1a}\right)-(p+1)\,\frac{\pi}{2}+2\pi n\nu\pm\left(\nu\theta+\frac{\pi}{4}\right). \tag{5.45}$$

The phase $\Phi_{pn\pm}(\nu;\theta)$ becomes stationary at

$$\nu=\nu_{pn\pm}=k_1a\cos\psi_{pn\pm},\quad \psi_{pn\pm}=\frac{2\pi n\pm\theta}{2(p+1)},\quad 0\leqslant\psi_{pn\pm}\leqslant\pi/2, \tag{5.46}$$

where the "+" sign holds if $0\leqslant 2n\leqslant p$ and the "−" sign holds if $0<2n\leqslant p+1$. The integrals are calculated by the stationary-phase method with

$$\left.\frac{d^2\Phi_{pn\pm}}{d\nu^2}\right|_{\nu=\nu_{pn\pm}}=\frac{2(p+1)}{k_1a\sin\psi_{pn\pm}}. \tag{5.47}$$

The radial components involve the integrals

$$\int_0^\infty d\nu\,e^{i2\pi n\nu}\,\nu\mathcal{B}(\nu)\,\mathcal{C}(\nu)^p\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta)$$
$$\sim e^{-i\pi/4}\frac{k_1k_2a^2}{\sqrt{\sin\theta}}\,\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\cos\psi_{pns}\sqrt{\sin 2\psi_{pns}}\,\mathcal{T}_E(k_1\cos\psi_{pns})\,R_E(k_1\cos\psi_{pns})^p$$
$$\times\exp[2i(p+1)k_1a\sin\psi_{pns}+is\pi/4], \tag{5.48}$$

$$\int_0^\infty d\nu\,e^{i2\pi n\nu}\,\nu\mathcal{F}(\nu)\,\mathcal{G}(\nu)^p\,\mathrm{P}^1_{\nu-1/2}(\cos\theta)$$
$$\sim -e^{i\pi/4}\frac{(k_1a)^2}{\sqrt{\sin\theta}}\,\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\cos\psi_{pns}\sqrt{\sin 2\psi_{pns}}\,\mathcal{T}_H(k_1\cos\psi_{pns})\,R_H(k_1\cos\psi_{pns})^p$$
$$\times\exp[2i(p+1)k_1a\sin\psi_{pns}+is\pi/4]. \tag{5.49}$$

(*ii*) Terms of the second group pertain to the tangential components containing the factor $\mathrm{P}^1_{\nu-1/2}(\cos\theta)$. The respective integrals are treated similarly, but the leading contributions stem from the endpoint $\nu=0$ with width $O(1)$ and from the stationary-phase points $\nu_{pn\pm}$ with width $O(\sqrt{k_1 a})$. The former contributions are cancelled. The surviving terms are corrections $O[(k_1 a)^{-1}]$ when $\psi_{pn\pm}=O(1)$ and $\pi/2-\psi_{pn\pm}=O(1)$. For instance,

$$\sum_{n=-\infty}^{\infty}\sum_{p=0}^{\infty}\int_0^{\infty} d\nu\, e^{i2\pi n\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{F}(\nu)\,\mathcal{G}(\nu)^p\,\mathrm{P}^1_{\nu-1/2}(\cos\theta)$$

$$\sim -e^{i\pi/4}\frac{1}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}\sqrt{2\tan\psi_{pns}}$$

$$\times\mathcal{T}_H(k_1\cos\psi_{pns})\,R_H(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}+is\pi/4], \quad (5.50)$$

where

$$S_{p+}=\{n:\ 0\leqslant 2n\leqslant p\},\quad S_{p-}=\{n:\quad 0<2n\leqslant p+1\}. \quad (5.51)$$

The preceding considerations lead to the rays

$$E^{\mathrm{ray}}_{2r}\sim e^{i\pi/4}\frac{\omega\mu_0 k_1}{2\pi k_2 a}\frac{\cos\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\cos\psi_{pns}\sqrt{\sin 2\psi_{pns}}$$

$$\times\mathcal{T}_E(k_1\cos\psi_{pns})\,R_E(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}+is\pi/4], \quad (5.52)$$

$$E^{\mathrm{ray}}_{2\theta}\sim e^{-i\pi/4}\frac{\omega\mu_0}{2\pi a}\frac{\cos\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\sqrt{\sin 2\psi_{pns}}$$

$$\times\overline{\mathcal{T}}_E(k_1\cos\psi_{pns})\,R_E(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}-is\pi/4]$$

$$+\frac{1}{k_1 a}e^{-i\pi/4}\frac{\omega\mu_0}{2\pi a\sin\theta}\frac{\cos\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\sqrt{2\tan\psi_{pns}}$$

$$\times\mathcal{T}_H(k_1\cos\psi_{pns})\,R_H(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}+is\pi/4], \quad (5.53)$$

$$E^{\mathrm{ray}}_{2\phi}\sim e^{-i\pi/4}\frac{\omega\mu_0}{2\pi a}\frac{\sin\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\sqrt{\sin 2\psi_{pns}}$$

$$\times\mathcal{T}_H(k_1\cos\psi_{pns})\,R_H(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}-is\pi/4]$$

$$+\frac{1}{k_1 a}e^{-i\pi/4}\frac{\omega\mu_0}{2\pi a\sin\theta}\frac{\sin\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\sqrt{2\tan\psi_{pns}}$$

$$\times\overline{\mathcal{T}}_E(k_1\cos\psi_{pns})\,R_E(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}+is\pi/4], \quad (5.54)$$

$$B^{\mathrm{ray}}_{2r}\sim -e^{i\pi/4}\frac{\mu_0 k_1}{2\pi a}\frac{\sin\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\cos\psi_{pns}\sqrt{\sin 2\psi_{pns}}$$

$$\times\mathcal{T}_H(k_1\cos\psi_{pns})\,R_H(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}+is\pi/4], \quad (5.55)$$

$$B_{2\theta}^{\text{ray}} \sim -e^{-i\pi/4}\frac{\mu_0 k_2}{2\pi a}\frac{\sin\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\sqrt{\sin 2\psi_{pns}}$$
$$\times\overline{\mathcal{T}}_H(k_1\cos\psi_{pns})\,R_H(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}-is\pi/4]$$
$$-\frac{1}{k_1 a}e^{-i\pi/4}\frac{\mu_0 k_2}{2\pi a\sin\theta}\frac{\sin\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\sqrt{2\tan\psi_{pns}}$$
$$\times\mathcal{T}_E(k_1\cos\psi_{pns})\,R_E(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}+is\pi/4], \qquad (5.56)$$

$$B_{2\phi}^{\text{ray}} \sim e^{-i\pi/4}\frac{\mu_0 k_2}{2\pi a}\frac{\cos\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\sqrt{\sin 2\psi_{pns}}$$
$$\times\mathcal{T}_E(k_1\cos\psi_{pns})\,R_E(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}-is\pi/4]$$
$$+\frac{1}{k_1 a}e^{-i\pi/4}\frac{\mu_0 k_2}{2\pi a\sin\theta}\frac{\cos\phi}{\sqrt{\sin\theta}}\sum_{p=0}^{\infty}\frac{e^{-ip\pi/2}}{\sqrt{p+1}}\sum_{s=\pm}\sum_{n\in S_{ps}}(-1)^n\sqrt{2\tan\psi_{pns}}$$
$$\times\overline{\mathcal{T}}_H(k_1\cos\psi_{pns})\,R_H(k_1\cos\psi_{pns})^p\exp[2i(p+1)k_1 a\sin\psi_{pns}+is\pi/4], \qquad (5.57)$$

where

$$\overline{\mathcal{T}}_F(\lambda)=\sqrt{1-(\lambda/k_2)^2}\,\mathcal{T}(\lambda),\quad F=E,H. \qquad (5.58)$$

Note that corrections to the leading terms of the first group introduced above are omitted.

An inspection of the summands for $p\gg 2n>1$, $\theta=O(1)$ and $\pi-\theta=O(1)$ shows that their magnitudes decrease as $|R|^p/p^2$ when medium 1 is lossless. Of course, convergence is improved when $\mathrm{Im}\,k_1$ is positive and $O(1)$. In general, $|R(\lambda)|\leqslant 1$ for complex λ while the condition $k_2^2 \ll |k_1^2|$ forces $|R(k_1\cos\psi_{pn\pm})|$ to be nearly 1.[44]

The rays described by formulas (5.52)–(5.57) circulate around the origin in the meridian plane while they are multiply reflected at the spherical boundary, as depicted in Fig. 5; p is the number of reflections, n is the number of circulations, the sign $s=\pm$ specifies the sense of circulation, and $\psi_{pn\pm}$ is the angle between the incident ray and the corresponding local tangent. The overall phase of each ray undergoes a change of $-\pi/2$ at each reflection (see also Ref. 33).

2. Reduction to a wave through region 1, $\theta\ll 1$

When $\theta=O[(k_1 a)^{-1/3}]$ and $n=0$, the width $O(\sqrt{k_1 a\,\theta})$ of the stationary-phase contribution above becomes comparable to the width $O[(k_1 a)^{1/3}]$ of the transitional region about $\nu=k_1 a$. This suggests the transition of rays to the wave propagating in region 1 according to the integral $\mathcal{I}_1$ in Sec. IV. The two asymptotic formulas connect smoothly if $O[(k_1 a)^{-1/3}]<\theta<O[(k_1 a)^{-1/5}]$. The approximation

$$\sin\psi_{p0+}\sim\psi_{p0+}-\psi_{p0+}^3/6,\quad |k_1|a\,\theta^5\ll 2^4\,5!,$$

in the phase, along with $k_2^2 a\,\theta/|k_1|\gg 1$, $\sin(2\psi_{p0+})\sim 2\psi_{p0+}$, and

$$R(k_1\sin\psi_{p0+})\sim -1,$$

$$\mathcal{T}_E(k_1\sin\psi_{p0+})\sim -i(k_2/k_1)\,\psi_{p0+},\quad \mathcal{T}_H(k_1\sin\psi_{p0+})\sim -\psi_{p0+}$$

in the amplitude reduce the $n=0$ terms in (5.52)–(5.57) to formulas (4.42)–(4.45).

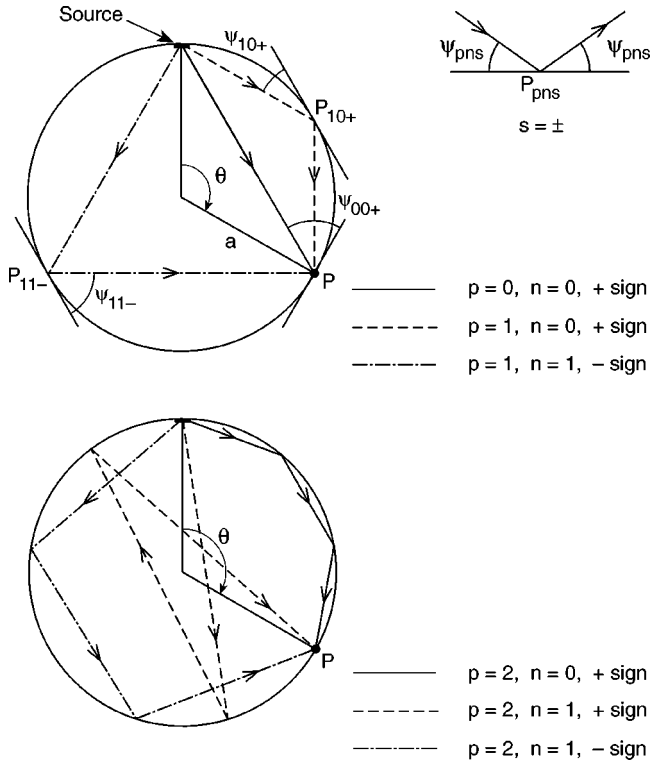

FIG. 5. Geometry of rays bouncing and circulating in the interior of the sphere. P is the observation point.

3. Field close to the antipodes, $\pi-\theta \ll 1$

Care should be exercised when $\theta \sim \pi$. This condition implies that a combination of exponentials may no longer be a reasonable approximation for the Legendre function.[36] In fact, in order to overcome this difficulty, one has to seek an alternative representation *a priori*. The identity $\mathrm{P}_l^1(\cos\theta)=(-1)^{l+1}\mathrm{P}_l^1(\cos(\pi-\theta))$ suggests the replacement

$$\mathrm{P}^1_{\nu-1/2}(\cos\theta)\to ie^{i\pi\nu}\mathrm{P}^1_{\nu-1/2}(\cos(\pi-\theta)). \tag{5.59}$$

The new representation is illustrated by

$$E^{\mathrm{ray}}_{2r}=-\frac{\omega\mu_0}{2\pi a}\frac{1}{(k_2a)^2}\cos\phi\sum_{n'=-\infty}^{\infty}(-1)^{n'}\sum_{p=0}^{\infty}\int_0^{\infty}d\nu\, e^{i\pi(2n'+1)\nu}\nu\mathcal{B}(\nu)\mathcal{C}(\nu)^p \times\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)\prime}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\mathrm{P}^1_{\nu-1/2}(-\cos\theta). \tag{5.60}$$

The ray $(n,p,s=\pm)$ of Sec. V C 1 is identified with the ray $(n'=n,p,s'=-)$ if $s=+$, or $(n'=n-1,p,s'=+)$ if $s=-$ in the present formalism. The stationary-phase points are given by

$$\tilde{\nu}_{pn'\pm}=k_1a\cos\overline{\psi}_{pn'\pm},\quad \overline{\psi}_{pn'\pm}=\frac{(2n'+1)\pi\pm\theta'}{2(p+1)},\quad 0\leqslant\overline{\psi}_{pn'\pm}\leqslant\pi/2, \tag{5.61a}$$

$$\theta'=\pi-\theta, \tag{5.61b}$$

with the sign convention $\{+:\ 0\leqslant 2n'\leqslant p-1\}$ and $\{-:\ 0\leqslant 2n'\leqslant p\}$.

An interesting case arises when $\pi-\theta \leqslant O[(k_1a)^{-1/2}]$ and $2n'=p$ $(s'=-)$, because the endpoint of integration, $\nu=0$, then falls inside the critical vicinity of a stationary-phase point. The requisite integrals for $2n'=p$ are evaluated through MacDonald's formulas[36] with $|\lambda|=|\nu/a| \ll 1$ in the radicals of expressions (5.33)–(5.42). The phase of $e^{i\pi(2n'+1)\nu}\mathcal{B}(\nu)\mathcal{C}(\nu)^p$ and $e^{i\pi(2n'+1)\nu}\mathcal{F}(\nu)\mathcal{G}(\nu)^p$ is expanded about $\nu=0$ up to $O(\nu^2)$. Let $\partial \mathrm{P}^1_{\nu-1/2}/\partial\theta' = -\partial \mathrm{P}^1_{\nu-1/2}(-\cos\theta)/\partial\theta$. The requisite integral for E_{2r} is

$$
\begin{aligned}
& i\int_0^\infty d\nu\, e^{i\pi(p+1)\nu}\,\nu\mathcal{B}(\nu)\mathcal{C}(\nu)^p\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)'}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta') \\
& \quad \sim -2\frac{k_2}{k_1}e^{2i(p+1)k_1a-ip\pi/2}\int_0^\infty d\nu\left(\nu^2-\frac{1}{4}\right)J_1(\nu\theta')\,e^{i(p+1)\nu^2/(k_1a)} \\
& \quad \sim \frac{k_1k_2a^2}{2}\,\frac{e^{-ip\pi/2}}{(p+1)^2}(\pi-\theta)\exp[2i(p+1)k_1a-(i/4)k_1a(\pi-\theta)^2/(p+1)], \qquad (5.62)
\end{aligned}
$$

provided that $|k_1a|(\pi-\theta)^2 \leqslant O(1)$. Comparison with formula (5.48) shows that the character of this ray is not modified as θ approaches π, in contradistinction to the case of a vertical dipole.[33] Indeed, the approximation

$$
\sin\psi_{(2n)n+} \sim 1-\frac{(\pi-\theta)^2}{8(p+1)^2}, \quad \frac{|k_1a|\,(\pi-\theta)^4}{(p+1)^4} \ll 1,
$$

in the phase of formula (5.48), along with

$$
\cos\psi_{(2n)n+} \sim \frac{\pi-\theta}{2(p+1)}, \quad \sin 2\psi_{(2n)n+} \sim \frac{\pi-\theta}{p+1}, \quad \mathcal{T}_E \sim 1, \quad R_E \sim 1,
$$

readily furnish formula (5.62). Similar considerations apply to B^{ray}_{2r}, with the requisite integral

$$
\begin{aligned}
& i\int_0^\infty d\nu\, e^{i\pi(p+1)\nu}\,\nu\mathcal{F}(\nu)\mathcal{G}(\nu)^p\,\mathrm{P}^1_{\nu-1/2}(\cos\theta') \\
& \quad \sim -i\frac{(k_1a)^2}{2}\,\frac{e^{-ip\pi/2}}{(p+1)^2}(\pi-\theta)\exp[2i(p+1)k_1a-(i/4)k_1a(\pi-\theta)^2/(p+1)].
\end{aligned} \qquad (5.63)
$$

For $E^{\mathrm{ray}}_{2\theta}$, it suffices to compare the following integrals:[39]

$$
\begin{aligned}
e_{\theta p} &= \frac{-i}{k_2a}\int_0^\infty d\nu\, e^{i\pi(p+1)\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{B}(\nu)\mathcal{C}(\nu)^p\left[\frac{1}{2k_2a}+\frac{H_\nu^{(1)'}(k_2a)}{H_\nu^{(1)}(k_2a)}\right]^2\frac{\partial \mathrm{P}^1_{\nu-1/2}}{\partial\theta'} \\
& \sim \frac{-2i}{k_1a}e^{2i(p+1)k_1a-ip\pi/2}\frac{\partial}{\partial\theta'}\int_0^\infty d\nu\, J_1(\nu\theta')\,e^{i(p+1)\nu^2/(k_1a)} \\
& = -\left[\frac{e^{-(i/4)k_1a(\pi-\theta)^2/(p+1)}}{p+1}+2i\,\frac{1-e^{-(i/4)k_1a(\pi-\theta)^2/(p+1)}}{k_1a(\pi-\theta)^2}\right]e^{2i(p+1)k_1a-ip\pi/2} \qquad (5.64)
\end{aligned}
$$

and

$$\tilde{e}_{\theta p}=\frac{i}{k_1 a(\pi-\theta)}\int_0^\infty d\nu\, e^{i\pi(p+1)\nu}\frac{\nu}{\nu^2-\frac{1}{4}}\mathcal{F}(\nu)\mathcal{G}(\nu)^p\,\mathrm{P}^1_{\nu-1/2}(\cos\theta')$$

$$\sim 2i\,\frac{1-e^{-(i/4)k_1(\pi-\theta)^2/(p+1)}}{k_1 a(\pi-\theta)^2}\,e^{2i(p+1)k_1 a-ip\pi/2}. \tag{5.65}$$

The three terms of formula (5.64) become of the same order in magnitude if $k_1 a(\pi-\theta)^2=O(1)$. The first term is dominant if $|k_1 a|(\pi-\theta)^2\gg 1$ and then recovers the corresponding geometrical ray with $2n=p$ and $s=+$. In contrast, in formula (5.65) all terms must be retained; the second term multiplied by $k_1 a(\pi-\theta)$ connects smoothly to the correction appearing in (5.53), while the first term is the contribution from the endpoint $\nu=0$. This contribution is cancelled by the corresponding term in (5.64), viz.,

$$e_{\theta p}+\tilde{e}_{\theta p}\sim -i\,\frac{e^{-ip\pi/2}}{p+1}\exp[2i(p+1)k_1 a-(i/4)k_1 a(\pi-\theta)^2/(p+1)]. \tag{5.66}$$

These considerations can be repeated for the integral of $E^{\mathrm{ray}}_{2\phi}$ with $\mathrm{P}^1_{\nu-1/2}(\cos\theta')/\theta'$ and $\partial\mathrm{P}^1_{\nu-1/2}/\partial\theta'$ interchanged. Along the same lines is the analysis for the components of the magnetic field, because the presence of the factor $[(2k_2a)^{-1}+H_\nu^{(1)\prime}(k_2a)/H_\nu^{(1)}(k_2a)]$ amounts to multiplication by i.

The amplitudes of other rays with $2n'\leqslant p-1$ are determined by noticing that the Bessel function varies slowly over the region of width $O(\sqrt{k_1 a})$ about each stationary-phase point, and can therefore be pulled out of the corresponding integrals. This program can be carried out straightforwardly; this case is not discussed further in this article.

VI. REMARKS AND DISCUSSION

Before closing this article, it is worthwhile making the following remarks.

(*i*) The order of magnitude of the critical distance $\rho_{\mathrm{cr},j}$ in Eq. (3.36) can be obtained by postulating that, when $\rho=O(\rho_{\mathrm{cr},j})$, the difference between the arc length $\rho=a\theta$ and its projection on the tangent at $\theta=0$ becomes comparable to the wavelength in air ($j=2$) or earth ($j=1$).[3,4]

(*ii*) It is tempting to compare the field of a horizontal dipole to that of the vertical dipole with equal moment, examined, for example, in Ref. 33. The dominant components of the former field are E_{2r}, $E_{2\theta}$ and $B_{2\phi}$. These are precisely the nonzero components of a vertical dipole. The corresponding maximum magnitudes in ϕ satisfy the relations

$$|E^{\mathrm{hor}}|_m\sim\frac{k_2}{|k_1|}|E^{\mathrm{ver}}|,\quad |B^{\mathrm{hor}}_\phi|_m\sim\frac{k_2}{|k_1|}|B^{\mathrm{ver}}_\phi|. \tag{6.1}$$

(*iii*) The present analysis offers some insight into the problem of a dipole elevated at a height h ($h=b-a\ll a$). A complication in this case stems from the additional transitional point in the integrands of the Poisson summation formula. For example,

$$E_{2r}=\frac{i\mu_0\omega}{2\pi a}\left(\frac{a}{b}\right)^{1/2}\frac{1}{(k_2a)^2}\cos\phi\sum_{n=-\infty}^{\infty}(-1)^n\int_0^\infty d\nu\, e^{i2\pi n\nu}\nu\,\frac{H_\nu^{(1)}(k_2b)}{H_\nu^{(1)}(k_2a)}\,\frac{1}{\mathcal{K}(\nu)}$$

$$\times\left[\frac{1}{2k_2b}+\frac{H_\nu^{(1)\prime}(k_2b)}{H_\nu^{(1)}(k_2b)}\right]\mathrm{P}^1_{\nu-1/2}(\cos\theta). \tag{6.2}$$

It is readily concluded that elevation of the dipole results in the increase of the critical angle $\theta_{\mathrm{cr},j}$ by $O(\sqrt{2h/a})$. The analysis is simplified when $k_2h\ll(k_2a)^{1/3}$ so that the points k_2a and k_2b can be treated, in some sense, as a single transitional point.

For arbitrary h, the residue series for E_{2r} when $\theta > O(\sqrt{2h/a})$ contains the factors

$$f_j(h) = \frac{H^{(1)}_{\nu_j}(k_2 b)}{H^{(1)}_{\nu_j}(k_2 a)}, \quad j = 1, 2, \ldots, \tag{6.3}$$

where ν_j are zeros of the $\mathcal{A}(\nu)$ defined by Eq. (5.7) that lie in the vicinity of $\nu = k_2 a$. $f_j(h)$ is the "height-gain factor" introduced by Bremmer.[14] In the corresponding factor $\tilde{f}_j(h)$ for B_{2r}, the ν_j need to be replaced by the zeros $\tilde{\nu}_j$ of the $\mathcal{D}(\nu)$ defined by Eq. (5.3). These factors express the dependence of the field beyond the horizon on the parameter $(k_2 a)^{1/3}\sqrt{2h/a}$. The height-gain factors for the θ- and ϕ-components are defined in a similar fashion. With regard to $E_{2\theta}$, one needs to consider the factor

$$\frac{H^{(1)}_{\nu_j}(k_2 b)}{H^{(1)}_{\nu_j}(k_2 a)} \frac{(1/k_2 b) + [H^{(1)\prime}_{\nu_j}(k_2 b)/H^{(1)}_{\nu_j}(k_2 b)]}{(1/k_2 a) + [H^{(1)\prime}_{\nu_j}(k_2 a)/H^{(1)}_{\nu_j}(k_2 a)]}.$$

(*iv*) The method of solution here needs to be modified when the medium in region 1 or 2 contains inhomogeneities, as is the case with ionospheric effects. The ionosphere can be modeled crudely via replacement of the air for $r > d$ $(d > a)$ by a perfect conductor.

A problem of interest arises when the index of refraction near the earth's surface exhibits variations due to high moisture. This phenomenon is called "ducting" and may cause superrefraction when rays emitted from the radiating source bend downwards.[14] A model for the dielectric permittivity gives[14]

$$\epsilon_2(r) = \epsilon_0 \frac{A + B(r - r_0)^2}{r^2}. \tag{6.4}$$

(*v*) The method of stationary phase for the rays employed in Sec. V becomes questionable when $\nu_{pn\pm}$ lies in a neighborhood of width $O(\sqrt{k_1 a})$ of any pole of $\mathcal{A}^{-1}(\nu)$ or $\mathcal{D}^{-1}(\nu)$ close to the positive real axis. The value $\nu_{pn\pm} \sim k_2 a$ corresponds to a ray that undergoes total internal reflection.[45] Such a case follows, for instance, from taking $2n = p$, $s = +$ and

$$\nu_{pn+} = k_2 a(1 - \overline{\epsilon}), \quad \overline{\epsilon} = 1 - \frac{k_1}{k_2}\frac{\pi - \theta}{2(p+1)}, \quad |\overline{\epsilon}| \ll 1. \tag{6.5}$$

A remedy to this anomaly is quite elaborate, in principle involving sums of Fresnel integrals, and is provided elsewhere.[33]

VII. SUMMARY AND CONCLUSIONS

The problem of the radiating electric dipole lying just below and tangential to the surface of an electrically large, homogeneous, isotropic and nonmagnetic sphere surrounded by air has been revisited. The present analysis, however, has a different perspective from previous works, since it was guided by the physical concept of the creeping wave.[22] The Poisson summation formula, employed over 40 years ago in the study of plane-wave scattering by impenetrable objects,[22] provided a useful starting point. In the present case the creeping wave, although evidently two-dimensional, has a more intricate structure being dependent on the nature and orientation of the source.

All six components of the electromagnetic field on the boundary were determined without recourse to scalar potentials. For an optically dense sphere, each component is decomposed into waves propagating through air and through the sphere. When the polar angle θ is sufficiently lower than a critical value given by Eq. (3.36), known planar-earth formulas are recovered[34] along with simplified corrections to account for the curved boundary. In particular, the electric-type wave in

the tangential components with the air phase velocity gives rise to Fresnel integrals and surface waves,[34] and therefore has a character distinctly different from solutions to plane-wave scattering within the scalar wave and Schrödinger's equations.[29]

As θ progresses to values that are comparable to or exceed $\theta_{\mathrm{cr},2}$, the electric-type wave through air is described by series of exponentials decreasing in θ. The attenuation rates were determined to the lowest order in $(k_2 a)^{-1}$ and k_2/k_1 by solving a transcendental equation, also encountered in the problem of the vertical radiating dipole;[42] its roots depend on the widely varying parameter $\alpha=(k_2 a/2)^{1/3} k_2/k_1$. On the other hand, lowest-order attenuation constants for the magnetic-type wave are fixed numbers, in agreement with early findings by Gray.[12] Higher-order corrections to these equations are easily obtained within this scheme. By starting with the zeroth-order equations, an argument was presented to show that the H-type wave attenuates faster than the E-type one when $|\alpha| \leqslant O(1)$; a conjecture made by Fock[16] was therefore placed on firmer grounds. The electric field was found to have a dominant component perpendicular to the boundary, while the magnetic field has a dominant component in the azimuthal direction. The ensuing polarization resembles that of a vertical electric dipole, but the maximum magnitude of the field in this case is multiplied by the factor $k_2/|k_1|$. When $\theta=O(\theta_{\mathrm{cr},1})$ the wave inside the sphere is described by a well-converging integral of Airy functions.

A physical picture of waves exponentially decreasing in air and rays circulating in the interior of the sphere via their multiple reflections at the boundary was exposed when $\theta=O(1)$ and $\pi-\theta=O(1)$. These ray contributions are significant when $\mathrm{Im}\, k_1 a \ll 1$. As expected from elementary geometrical optics, only one type of wave (electric or magnetic) prevails in each component, with the amplitude of the dominant ray being described by the corresponding Fresnel reflection coefficient. There are features of both the amplitude and phase of these rays, however, that are attributed to the nature of the source and are not fully predictable by standard geometrical optics. This ray picture breaks down at the antipodal point ($\theta \sim \pi$), or any point of total internal reflection.[45] In both cases, the modified analysis unveils characteristics due to the nature of the source. For instance, the two types of polarization in the tangential components can provide comparable ray contributions if $\theta \sim \pi$, when $2n=p$, $s=+$ in the notation of Sec. V; the total amplitude then recovers the Fresnel reflection coefficient of geometrical optics. This situation is to be contrasted with the case of a vertical dipole, where the ray amplitude changes drastically at the antipodes.

The author is grateful to Ronold W. P. King, Tai Tsun Wu, and Nicola Khuri for discussions. He is also indebted to Margaret Owens for her assistance throughout the preparation of the manuscript.

APPENDIX A: ON THE ZEROS OF $\mathcal{K}(\nu)$, $\mathcal{M}(\nu)$

To simplify the calculations in this appendix, consider k_1 to be real, unless it is stated otherwise. For $k_2 a \gg 1$, $k_2^2 \ll k_1^2$ and $k_2^2 a/k_1 \gg 1$, the terms $(2k_2 a)^{-1}$ and $k_2 k_1^{-1}(2k_1 a)^{-1}$ in $\mathcal{K}(\nu)$ are neglected. Following Refs. 29 and 33, define

$$\mathcal{P}(\nu;\kappa)=\frac{J_\nu'(k_1 a)}{J_\nu(k_1 a)}-\kappa\frac{H_\nu^{(1)\prime}(k_2 a)}{H_\nu^{(1)}(k_2 a)}, \tag{A1}$$

where $\kappa=k_1/k_2$ corresponds to $\mathcal{K}(\nu)$ and $\kappa=k_2/k_1$ corresponds to $\mathcal{M}(\nu)$. In this appendix, the task is to locate those ν that satisfy

$$\mathcal{P}(\nu;\kappa)=0. \tag{A2}$$

For $0<\nu<k_1 a$ and $|\nu-k_{1,2}a| \gg (k_{1,2}a)^{1/3}$,

$$\frac{J_\nu'(k_1a)}{J_\nu(k_1a)}\sim-\sqrt{1-\left(\frac{\nu}{k_1a}\right)^2}\tan\left[\sqrt{(k_1a)^2-\nu^2}-\nu\arccos\left(\frac{\nu}{k_1a}\right)-\frac{\pi}{4}\right], \tag{A3}$$

$$\frac{H_\nu^{(1)'}(k_2a)}{H_\nu^{(1)}(k_2a)}\sim i\sqrt{1-\left(\frac{\nu}{k_2a}\right)^2}, \tag{A4}$$

and the branch cut emanating from $\nu=k_2a$ lies in the upper ν-plane. Accordingly,

$$\mathcal{P}(\nu;\kappa)\sim-\sqrt{1-\left(\frac{\nu}{k_1a}\right)^2}\tan\left[\sqrt{(k_1a)^2-\nu^2}-\nu\arccos\left(\frac{\nu}{k_1a}\right)-\frac{\pi}{4}\right]$$
$$-i\kappa\sqrt{1-\left(\frac{\nu}{k_2a}\right)^2}. \tag{A5}$$

No zeros of the right-hand side lie in $(0,k_2a)$. The analytic continuation to (k_2a,k_1a) through the lower ν-plane does not exhibit any zeros either. More precisely,

$$\frac{H_\nu^{(1)'}(k_2a)}{H_\nu^{(1)}(k_2a)}\sim\frac{Y_\nu'(k_2a)}{Y_\nu(k_2a)}\left\{1+i\frac{\mathrm{W}[J_\nu,Y_\nu]}{Y_\nu(k_2a)\,Y_\nu'(k_2a)}\right\}, \tag{A6}$$

where $\mathrm{W}[J_\nu,Y_\nu]=(2/\pi)(k_2a)^{-1}$ denotes the Wronskian of $J_\nu(k_2a)$ and $Y_\nu(k_2a)$. This approximation produces a recessive imaginary term for $\nu>k_2a$. Hence, (A2) reads as

$$\tan\left[\sqrt{(k_1a)^2-\nu^2}-\nu\arccos\left(\frac{\nu}{k_1a}\right)-\frac{\pi}{4}\right]$$
$$\sim\kappa\sqrt{\frac{[\nu/(k_2a)]^2-1}{1-[\nu/(k_1a)]^2}}\left\{1-i\exp\left[-2\nu\cosh^{-1}\left(\frac{\nu}{k_2a}\right)+2\sqrt{\nu^2-(k_2a)^2}\right]\right\}. \tag{A7}$$

This equation cannot be satisfied by any real ν. In fact, it is satisfied only in the upper ν-plane. Let $\nu=\nu_r+i\nu_i$, where ν_r and ν_i are real, $|\nu_i|\ll\nu_r$, and $k_2a<\nu_r<k_1a$. Then,

$$\tan\left[\sqrt{(k_1a)^2-\nu_r^2}-\nu_r\arccos\left(\frac{\nu_r}{k_1a}\right)-i\nu_i\arccos\left(\frac{\nu_r}{k_1a}\right)-\frac{\pi}{4}\right]$$
$$\sim\kappa\sqrt{\frac{[\nu_r/(k_2a)]^2-1}{1-[\nu_r/(k_1a)]^2}}\left\{1-i\exp\left[-2\nu_r\cosh^{-1}\left(\frac{\nu_r}{k_2a}\right)+2\sqrt{\nu_r^2-(k_2a)^2}\right]\right\}. \tag{A8}$$

For $\kappa=k_1/k_2$,

$$\sqrt{(k_1a)^2-\nu_r^2}-\nu_r\arccos\left(\frac{\nu_r}{k_1a}\right)\sim\arctan\left\{\frac{k_1}{k_2}\sqrt{\frac{[\nu_r/(k_2a)]^2-1}{1-[\nu_r/(k_1a)]^2}}\right\}+m\pi+\frac{\pi}{4}, \tag{A9}$$

$$\nu_i\arccos\left(\frac{\nu_r}{k_1a}\right)\sim\frac{k_2}{k_1}\sqrt{\frac{1-[\nu_r/(k_1a)]^2}{[\nu_r/(k_2a)]^2-1}}\exp\left[-2\nu_r\cosh^{-1}\left(\frac{\nu_r}{k_2a}\right)+2\sqrt{\nu_r^2-(k_2a)^2}\right], \tag{A10}$$

where m is any integer. In particular, if $k_2a\ll\nu_r\ll k_1a$,

$$\nu_r\sim\frac{2k_1a}{\pi}-\left(2m+\frac{3}{2}\right),\quad \nu_i\sim\frac{4k_2}{\pi k_1}\left(\frac{k_2a}{2\nu_r}\right)^{2\nu_r+1}e^{2\nu_r}. \tag{A11}$$

For $\kappa=k_2/k_1$,

$$\sqrt{(k_1a)^2-\nu_r^2}-\nu_r\arccos\left(\frac{\nu_r}{k_1a}\right)\sim\arctan\left\{\frac{k_2}{k_1}\sqrt{\frac{[\nu_r/(k_2a)]^2-1}{1-[\nu_r/(k_1a)]^2}}\right\}+m\pi+\frac{\pi}{4}, \tag{A12}$$

$$\nu_i\arccos\left(\frac{\nu_r}{k_1a}\right)\sim\frac{k_2}{k_1}\sqrt{[\nu_r/(k_2a)]^2-1}\,\sqrt{1-[\nu_r/(k_1a)]^2}\times\exp\left[-2\nu_r\cosh^{-1}\left(\frac{\nu_r}{k_2a}\right)+2\sqrt{\nu_r^2-(k_2a)^2}\right]. \tag{A13}$$

These expressions are trivially simplified if $k_2a\ll\nu_r\ll k_1a$, i.e.,

$$\nu_r\sim\frac{2k_1a}{\pi}-\left(2m+\frac{1}{2}\right),\quad \nu_i\sim\frac{2\nu_r}{\pi k_1a}\left(\frac{k_2a}{2\nu_r}\right)^{2\nu_r}e^{2\nu_r}. \tag{A14}$$

Consider $0<\mathrm{Re}\,\nu<k_2a$. Setting the right-hand side of (A5) equal to zero in the upper ν-plane yields

$$k_1a-\frac{\nu\pi}{2}\sim m\pi+\frac{\pi}{4}-i\arctan\left[\frac{k_1}{k_2}\sqrt{1-\left(\frac{\nu}{k_2a}\right)^2}\right] \tag{A15}$$

for $\kappa=k_1/k_2$, or

$$k_1a-\frac{\nu\pi}{2}\sim m\pi+\frac{\pi}{4}-i\frac{k_2}{k_1}\sqrt{1-\left(\frac{\nu}{k_2a}\right)^2} \tag{A16}$$

for $\kappa=k_2/k_1$. With $0<|\nu|\ll k_2a$,

$$\nu\sim\frac{2k_1a}{\pi}-\left(2m+\frac{1}{2}\right)+i, \tag{A17}$$

or

$$\nu\sim\frac{2k_1a}{\pi}-\left(2m+\frac{1}{2}\right)+i\frac{2k_2}{\pi k_1}. \tag{A18}$$

In consideration of the transitional region of $H_\nu^{(1)}(k_2a)$,[39] (A2) becomes

$$\tan\left[\sqrt{(k_1a)^2-\nu^2}-\nu\arccos\left(\frac{\nu}{k_1a}\right)-\frac{\pi}{4}\right]=\kappa\left(\frac{2}{k_2a}\right)^{1/3}e^{i2\pi/3}\frac{\mathrm{Ai}'(e^{i2\pi/3}\xi)}{\mathrm{Ai}(e^{i2\pi/3}\xi)}. \tag{A19}$$

This is not satisfied by any real ν. In the lower ν-plane,

$$e^{i2\pi/3}\frac{\mathrm{Ai}'(e^{i2\pi/3}\xi)}{\mathrm{Ai}(e^{i2\pi/3}\xi)}=i\overline{\kappa}, \tag{A20}$$

where

$$\overline{\kappa}=\kappa^{-1}\left(\frac{k_2a}{2}\right)^{1/3}. \tag{A21}$$

Use of the large-argument approximation for the Airy function when $|\overline{\kappa}|\gg1$ evinces that no zeros exist for $-\pi<\mathrm{Arg}\,\xi<0$. In the upper ξ-plane, Eq. (A20) is satisfied at points ξ_s lying in the neighborhoods of zeros of the denominator:

$$\xi_s \sim (-a_s) e^{i\pi/3} [1 + e^{i\pi/6} a_s^{-1} \overline{\kappa}^{-1}], \quad |\overline{\kappa}| \gg 1, \quad s = 1, 2, \ldots, \tag{A22}$$

where a_s are the zeros of $\mathrm{Ai}(z)$ $(a_s < 0)$ numbered in order of ascending magnitude.[40] On the other hand,

$$\xi_s \sim (-\check{a}_s) e^{i\pi/3} [1 + e^{i\pi/6} \check{a}_s^{-2} \overline{\kappa}], \quad |\overline{\kappa}| \ll 1, \quad s = 1, 2, \ldots, \tag{A23}$$

where $\check{a}_s$ are zeros of $\mathrm{Ai}'(z)$.[40] A function can be constructed which is holomorphic in the sector $\{\overline{\kappa}: -\pi/4 < \mathrm{Arg}\ \overline{\kappa} < \pi/4\}$ and whose values are determined by the zeros in the lower ξ-plane given by Eq. (A20). By starting with expression (A22), it can be shown via analytic continuation that no such zeros exist. Such a construction is given in Ref. 33.

APPENDIX B: ON THE ZEROS OF $\mathcal{A}(\nu)$ AND $\mathcal{D}(\nu)$

In the spirit of Appendix A, consider the equation

$$\frac{H_\nu^{(2)'}(k_1 a)}{H_\nu^{(2)}(k_1 a)} - \kappa \frac{H_\nu^{(1)'}(k_2 a)}{H_\nu^{(1)}(k_2 a)} = 0, \tag{B1}$$

where $\kappa = k_1/k_2$ for $\mathcal{A}(\nu)$ and $\kappa = k_2/k_1$ for $\mathcal{D}(\nu)$. The following conclusions are reached.

(i) $\mathcal{A}(\nu)$ and $\mathcal{D}(\nu)$ exhibit no zeros for $0 \leqslant \mathrm{Re}\ \nu < k_2 a$ and $k_2 a < \mathrm{Re}\ \nu < k_1 a$ outside the transitional regions associated with $\nu = k_1 a$ or $\nu = k_2 a$.

(ii) The zeros inside the transitional region of $H_\nu^{(1)}(k_2 a)$ are approximated by those of the corresponding $\mathcal{K}(\nu)$ and $\mathcal{M}(\nu)$ in the upper ν-plane according to (A20) of Appendix A.

(iii) $\mathcal{A}(\nu)$ and $\mathcal{D}(\nu)$ have zeros inside the transitional region of $H_\nu^{(2)}(k_1 a)$ in the lower ν-plane. In view of Eq. (4.3), the equation there is

$$\mathcal{H}(\xi; -2\pi/3) = \kappa \frac{k_1}{k_2} \left(\frac{k_1 a}{2} \right)^{1/3}, \quad \xi = (\nu - k_1 a)(k_1 a/2)^{-1/3}, \tag{B2}$$

which is in turn approximated by

$$\mathrm{Ai}(e^{-i2\pi/3} \xi) = 0. \tag{B3}$$

APPENDIX C: AN INTEGRAL IDENTITY

In this appendix, it is shown that

$$\sum_{n=-\infty}^{\infty} (-1)^n \int_0^\infty d\nu\, e^{i2\pi n\nu} f(\nu)\, \mathrm{P}^1_{\nu-1/2}(\cos\theta)$$

$$= -2\pi \sum_{n=0}^{\infty} (-1)^n \sum_{s=\pm} \sum_{j=1}^{\infty} s\, e^{is(2n+1)\pi\nu_j^s}\, \mathrm{P}^1_{\nu_j^s - 1/2}(-\cos\theta)\, \mathrm{Res}\{f(\nu)\}\big|_{\nu=\nu_j^s}, \tag{C1}$$

where $f(\nu)$ is a meromorphic function with simple poles $\{\nu_j^s\}$ in the first $(s = +)$ and fourth $(s = -)$ quadrant $(j = 1, 2, \ldots,$ in order of ascending imaginary part), and with no singularities in the imaginary and real axes other than poles that coincide with zeros of $\mathrm{P}^1_{\nu-1/2}(\cos\theta)$. $f(\nu)$ is assumed to satisfy

$$f(-\nu) = -f(\nu) \quad \forall\ \nu, \quad f(\nu) = O(\nu^d) \quad \text{as} \quad \nu \to \infty, \ \mathrm{Re}\ \nu > 0, \tag{C2}$$

where d is a real number that may depend on Arg ν.

In the spirit of Ref. 9, the left-hand side of (C1) is written as an integral over a contour C encircling the positive real axis clockwise, as shown in Fig. 6. Then,

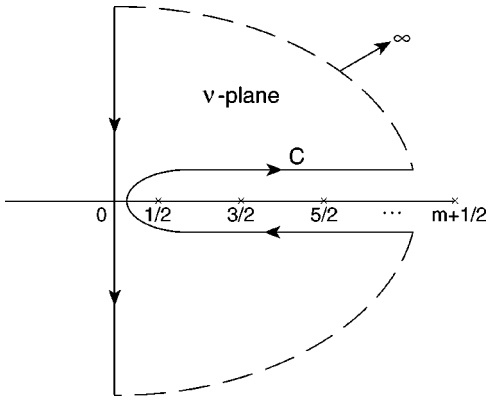

FIG. 6. Contour C that serves the derivation of identity (C1) of Appendix C; m is a non-negative integer.

$$\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\,e^{i2\pi n\nu}f(\nu)\,\mathrm{P}^1_{\nu-1/2}(\cos\theta)$$

$$=i\sum_{l=0}^{\infty}e^{i(l+1/2)\pi}f\left(l+\frac{1}{2}\right)\mathrm{P}^1_l(-\cos\theta)$$

$$=-\frac{1}{2i}\int_C\frac{d\nu}{\cos\pi\nu}f(\nu)\mathrm{P}^1_{\nu-1/2}(-\cos\theta)$$

$$=-\pi\sum_{s=\pm}\sum_{j=1}^{\infty}\frac{\mathrm{P}^1_{\nu_j^s-1/2}(-\cos\theta)}{\cos\pi\nu_j^s}\mathrm{Res}\{f(\nu)\}\big|_{\nu=\nu_j^s}-\frac{1}{2i}\int_{-i\infty}^{i\infty}\frac{d\nu}{\cos\pi\nu}f(\nu)\,\mathrm{P}^1_{\nu-1/2}(-\cos\theta), \tag{C3}$$

by employing $\mathrm{P}^1_l(\cos\theta)=(-1)^{l+1}\mathrm{P}^1_l(\cos(\pi-\theta))$ and properly closing C at infinity. By virtue of (C2) and the identity $\mathrm{P}_{-\nu-1/2}(x)=\mathrm{P}_{\nu-1/2}(x)$, the integral in the right-hand side of (C3) is identically zero. The expansion

$$\frac{1}{\cos\pi\nu}=2e^{\pm i\pi\nu}\sum_{n=0}^{\infty}(-1)^n e^{\pm i2\pi n\nu}, \tag{C4}$$

where $\mathrm{Im}\,\nu>0$ $(+)$ or $\mathrm{Im}\,\nu<0$ $(-)$, immediately yields (C1). As a corollary,

$$\sum_{n=-\infty}^{\infty}(-1)^n\int_0^{\infty}d\nu\,e^{i2\pi n\nu}f(\nu)\,\mathrm{P}^1_{\nu-1/2}(\cos\theta)=0, \tag{C5}$$

if $f(\nu)$ is holomorphic for $\mathrm{Re}\,\nu>0$.

Plasma velocity in hydromagnetic dynamos

Manuel Núñez[a)]
Departamento de Análisis Matemático, Universidad de Valladolid, 47005 Valladolid, Spain

(Received 12 February 2002; accepted for publication 25 February 2002)

Hydromagnetic dynamos are plasma configurations generating for some time an exponentially increasing magnetic field. By using a number of functional inequalities, we estimate the rate of increase of magnetic energy in terms of the plasma resistivity and diferent norms on the plasma velocity. Our bounds are proved to be optimal as far as the powers of the relevant magnitudes are concerned. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1473679]

I. INTRODUCTION

A hydromagnetic dynamo in a plasma is a configuration allowing for a finite time an exponential growth of the magnetic field. The behavior of the main magnitudes in an incompressible plasma is governed by the magnetohydrodynamic (MHD) system: the velocity **u**, magnetic field **B**, kinetic pressure p, viscosity ν and resistivity η satisfy, after the usual normalizations,

$$\frac{\partial \mathbf{u}}{\partial t} = \nu \Delta \mathbf{u} - \mathbf{u} \cdot \nabla \mathbf{u} + \mathbf{B} \cdot \nabla \mathbf{B} - \nabla p - \nabla \left(\frac{B^2}{2} \right), \tag{1}$$

$$\frac{\partial \mathbf{B}}{\partial t} = \eta \Delta \mathbf{B} - \mathbf{u} \cdot \nabla \mathbf{B} + \mathbf{B} \cdot \nabla \mathbf{u}, \tag{2}$$

$$\nabla \cdot \mathbf{u} = \nabla \cdot \mathbf{B} = 0. \tag{3}$$

The MHD system, for any boundary conditions allowing no input of energy from the outside, is dissipative (see e.g. Ref. 1). Therefore, any growth of magnetic energy must ultimately be done at the expense of the kinetic one, i.e., of the plasma velocity. Once this velocity is taken for granted, the magnetic field is governed by the induction equation (2), and the magnetic energy by the integral identity obtained making the scalar product of (2) and **B**:

$$\frac{1}{2} \frac{\partial}{\partial t} \int_\Omega B^2 dV = \eta \int_\Omega \Delta \mathbf{B} \cdot \mathbf{B} dV + \int_\Omega \mathbf{B} \cdot \nabla \mathbf{u} \cdot \mathbf{B} \, dV - \int_\Omega \mathbf{u} \cdot \nabla \mathbf{B} \cdot \mathbf{B} dV. \tag{4}$$

If we assume $\mathbf{u} \cdot \mathbf{n}|_{\partial\Omega} = 0$ (i.e., the fluid does not cross the boundary), the last integral vanishes. As for the term

$$\eta \int_\Omega \Delta \mathbf{B} \cdot \mathbf{B} dV = -\eta \int_\Omega |\nabla \mathbf{B}|^2 dV + \frac{\eta}{2} \int_{\partial\Omega} \frac{\partial B^2}{\partial n} d\sigma,$$

provided there is no input of magnetic energy from the outside,

$$\int_{\partial\Omega} \frac{\partial B^2}{\partial n} d\sigma \leqslant 0, \tag{5}$$

yields the fundamental energy inequality

a)Electronic mail: mnjmhd@am.uva.es

$$\frac{1}{2}\frac{\partial}{\partial t}\int_\Omega B^2 dV \leqslant -\eta\int_\Omega |\nabla \mathbf{B}|^2 dV + \int_\Omega \mathbf{B}\cdot\nabla\mathbf{u}\cdot\mathbf{B}dV. \tag{6}$$

Condition (5) holds (with an equality) for Dirichlet ($\mathbf{B}|_{\partial\Omega}=\mathbf{0}$) or perfect conductor ($\mathbf{B}\cdot\mathbf{n}|_{\partial\Omega}=0$; $(\nabla\times\mathbf{B})\times\mathbf{n}|_{\partial\Omega}=\mathbf{0}$) conditions. We will assume either periodic boundary conditions in a box Ω with

$$\int_\Omega \mathbf{u}\,dV = \int_\Omega \mathbf{B}\,dV = \mathbf{0}, \tag{7}$$

or

$$\mathbf{u}\cdot\mathbf{n}|_{\partial\Omega} = \mathbf{B}\cdot\mathbf{n}|_{\partial\Omega} = 0, \tag{8}$$

in a smooth N-dimensional domain Ω. Thus we will take (6) as the starting inequality. The first term on the right-hand side of (6) accounts for the diffusive effects of the resistivity, while the second is an advective term showing the transport of the magnetic field by the flow. In fact, in ideal plasmas ($\eta=0$) the magnetic field lines are transported by the plasma as material points and the field strength may be enhanced by this process.

From here one may ignore the diffusive term and bound the advective one by

$$\left|\int_\Omega \mathbf{B}\cdot\nabla\mathbf{u}\cdot\mathbf{B}dV\right| \leqslant \frac{1}{2}\|\nabla\mathbf{u}+(\nabla\mathbf{u})^t\|_\infty \int_\Omega B^2 dV, \tag{9}$$

where $\|\ \|_\infty$ means the maximum norm and $(\ )^t$ the transposed matrix (see, e.g., Ref. 2). Therefore, the growth parameter γ satisfies

$$\gamma \leqslant \tfrac{1}{2}\|\nabla\mathbf{u}+(\nabla\mathbf{u})^t\|_\infty. \tag{10}$$

This estimate goes back to Backus.[3] Thus the maximal exponential growth rate does not exceed the largest eigenvalue of the strain matrix $\frac{1}{2}(\nabla\mathbf{u}+(\nabla\mathbf{u})^t)$. This elementary inequality has some merits: the main one is that it does not depend on the resistivity and therefore it holds even when $\eta\to 0$. A velocity configuration yielding a dynamo even when $\eta\to 0$ [$\inf_{\eta\to 0}\gamma(\eta)>0$] is called a fast dynamo;[4] this is an extensively studied subject. On the minus side, we first note that anything involving the gradient of the velocity is somewhat unsatisfactory. This is so because in many turbulent flows there exist sharp changes in the velocity vector, whereas the velocity size remains moderate. Indeed, on general principles one may reject an extremely large plasma velocity, but there is no physical reason to exclude rapid variations of the flow: thus any norm on the velocity itself may be much smaller than the norm of the gradient. Moreover, the maximum norm is the worst possible: it could happen that the plasma remains almost quiescent except for a tiny portion which alone ensures that the maximum of the strain matrix is large. One does not expect the magnetic energy of the whole domain to be governed by a minute portion of the plasma. We will see that (9) may be significantly improved.

II. THE MAIN ESTIMATES

Certain subspaces of the Sobolev space $H^1(\Omega)$ possess the property that

$$\|f\|_{H^1} \leqslant k\|\nabla f\|_2,$$

i.e., the L^2-norm of f is dominated by the norm of its gradient. These are the so-called Poincaré inequalities. One of the most general descriptions of spaces where one of these inequalities holds is as follows (see Refs. 1 and 5): let p be a continuous seminorm [i.e., a continuous norm, except for the fact that $p(f)=0$ does not imply $f=0$] on $H^1(\Omega)$ such that for every *constant* function

$g\neq 0$, $p(g)\neq 0$. Then any subspace H of $H^1(\Omega)$, such that $p(f)=0$ for all $f\in H$, satisfies a Poincaré inequality. Among the many examples of such seminorms, we will use the following ones:

$$p(\mathbf{f})=\left|\int_\Omega \mathbf{f}dV\right|, \tag{11}$$

$$p(\mathbf{f})=\int_{\partial\Omega}|\mathbf{f}\cdot\mathbf{n}|\,d\sigma. \tag{12}$$

Equation (11) covers periodic problems because of the zero mean condition (7), while (12) covers the remaining cases, since (8) holds. That the seminorm p of (12) is continuous follows from the fact that the trace of any function $f\in H^1(\Omega)$ at the boundary belongs to $L^1(\partial\Omega)$ [and even to $L^2(\partial\Omega)$].

Our main tool will be a weak version of the Gagliardo–Nirenberg inequality (Ref. 6, pp. 65–68): denoting as usual by $\|\quad\|_p$ the norm in $L^p(\Omega)$,

$$\|f\|_p\leqslant C\|f\|_{H^1}^{\tau}\|f\|_2^{1-\tau}, \tag{13}$$

where C is a constant depending only on the domain, $\tau=(N/2)-(N/p)$. This holds provided $p\geqslant 2$, $(N/2)-(N/p)<1$, i.e., $p<2N/(N-2)$. Thus, for $N=3$, $2\leqslant p<6$; for $N=2$, any $p\geqslant 2$ is admissible.

Since

$$\int_\Omega \mathbf{B}\cdot\nabla\mathbf{u}\cdot\mathbf{B}dV=-\int_\Omega \mathbf{B}\cdot\nabla\mathbf{B}\cdot\mathbf{u}dV, \tag{14}$$

by the inequality of Cauchy–Schwarz

$$\left|\int_\Omega \mathbf{B}\cdot\nabla\mathbf{u}\cdot\mathbf{B}dV\right|\leqslant\int_\Omega|\mathbf{B}||\nabla\mathbf{B}||\mathbf{u}|dV\leqslant\|\mathbf{B}\|_p\|\nabla\mathbf{B}\|_2\|\mathbf{u}\|_q, \tag{15}$$

for any positive p, q such that $1/p+1/q=\frac{1}{2}$; hence $p,q\geqslant 2$. By (13),

$$\|\mathbf{B}\|_p\leqslant C\|\mathbf{B}\|_{H^1}^{(N/2)-(N/p)}\|\mathbf{B}\|_2^{1-(N/2)+(N/p)}=C\|\mathbf{B}\|_{H^1}^{N/q}\|\mathbf{B}\|_2^{1-(N/q)}, \tag{16}$$

provided $p<2N/(N-2)$, i.e., $q>N$. Thus,

$$\left|\int_\Omega \mathbf{B}\cdot\nabla\mathbf{u}\cdot\mathbf{B}dV\right|\leqslant C\|\mathbf{B}\|_{H^1}^{N/q}\|\mathbf{B}\|_2^{1-(N/q)}\|\nabla\mathbf{B}\|_2\|\mathbf{u}\|_q. \tag{17}$$

Let us use now the Poincaré inequality, written as

$$\|\mathbf{B}\|_{H^1}\leqslant k\|\nabla\mathbf{B}\|_2.$$

We have

$$\left|\int_\Omega \mathbf{B}\cdot\nabla\mathbf{u}\cdot\mathbf{B}dV\right|\leqslant Ck^{N/q}\|\nabla\mathbf{B}\|_2^{1+(N/q)}\|\mathbf{B}\|_2^{1-(N/q)}\|\mathbf{u}\|_q. \tag{18}$$

Let us denote

$$r=\frac{1}{2}-\frac{N}{2q}. \tag{19}$$

We may write the right-hand term as

$$Ck^{N/q}(\|\nabla\mathbf{B}\|_2^2)^{1-r}(\|\mathbf{B}\|_2^2)^r\|\mathbf{u}\|_q=(\alpha\|\nabla\mathbf{B}\|_2^2)^{1-r}((Ck^{N/q}\|\mathbf{u}\|_q)^{1/r}\alpha^{-(1-r)/r}\|\mathbf{B}\|_2^2)^r, \tag{20}$$

where α is a positive constant to be determined later. By using the classical inequality

$$x^r y^{1-r}\leqslant rx+(1-r)y,$$

for $x,y>0$ (which amounts to the convexity of the exponential function), we find

$$\left|\int_\Omega \mathbf{B}\cdot\nabla\mathbf{u}\cdot\mathbf{B}dV\right|\leqslant(1-r)\alpha\|\nabla\mathbf{B}\|_2^2+rC^{1/r}k^{N/qr}\alpha^{-(1-r)/r}\|\mathbf{u}\|_q^{1/r}\|\mathbf{B}\|_2^2. \tag{21}$$

Take now $\alpha=\eta/(1-r)$. Then the term in $\nabla\mathbf{B}$ cancels with the dissipative term in (6), and we are left with

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{B}\|_2^2\leqslant r(1-r)^{(1-r)/r}(Ck^{N/q}\eta^{-(1-r)}\|\mathbf{u}\|_q)^{1/r}\|\mathbf{B}\|_2^2. \tag{22}$$

Therefore, if there exists a magnetic dynamo of exponential growth rate γ, for any $q>N$,

$$\gamma\leqslant 2r(1-r)^{(1-r)/r}(Ck^{N/q}\eta^{-(1-r)}\|\mathbf{u}\|_q)^{1/r}, \tag{23}$$

where r is given by (19). C and k are universal constants. The estimate improves with large q and η, and becomes singular as $\eta\to 0$ or $r\to 0$ (i.e., $q\to N$). For $q\to\infty$ it becomes

$$\gamma\leqslant \tfrac{1}{2}C\eta^{-1}\|\mathbf{u}\|_\infty^2, \tag{24}$$

which improves the Backus bound (10) in the sense that it does not need the velocity gradient, although the resistivity occurs. The estimate (23) is satisfactory in the sense that it involves an integral norm of the velocity and therefore it is a measure of its mean size: it shows that the dynamo cannot be governed by what happens in small regions of the plasma, although these may be relevant in the process of stretching which is basic in the dynamo process. However, the physically most important norm of the velocity is the kinetic energy $\|\mathbf{u}\|_2$, which is not reached by (23). For $N=2$ it lies at the lower limit and the constants blow there; for $N=3$ it is well beyond reach. To see that this is a physical fact and not merely the result of poor bounds, we will prove that (23) is a sharp inequality as concerns the order of the magnitudes.

III. COUNTEREXAMPLES FOR LOWER ORDER NORMS

We will consider an initial condition formed by velocity and field depending only on the radius, and radially directed. Then $\mathbf{B}\cdot\nabla\mathbf{u}$ is also radially directed and the term $\mathbf{B}\cdot\nabla\mathbf{u}\cdot\mathbf{B}$ is precisely $|\mathbf{B}|^2|\nabla\mathbf{u}|$. Specifically, assume $\mathbf{B}=B(R)\mathbf{e}_r$, $\mathbf{e}_r$ the unit radial vector, B decreasing linearly from $B=h$ at $r=0$ to $B=0$ at $r=L$: $B(r)=h-hr/L$ for $r\in[0,L]$, $B(r)=0$ for $r>L$. Take $\mathbf{u}=\mathbf{B}$. These magnitudes are not really smooth, as they fail to be differentiable at $r=0$ and $r=L$, but they can be uniformly approximated by smooth functions such that the values of all the integrals tend to the respective values for our chosen functions.

First, since the Jacobian in dimension N depends on r like r^{N-1}, the norm $\|\mathbf{u}\|_q$ behaves like $hL^{N/q}$, and $\|\mathbf{B}\|_2$ like $hL^{N/2}$. $|\nabla\mathbf{u}|$ is identical to h/L for $r\in[0,L]$, and zero otherwise; thus

$$\int_\Omega|\mathbf{B}|^2|\nabla\mathbf{u}|dV=hL^{-1}\int_\Omega|\mathbf{B}|^2dV\sim hL^{-1}h^2L^N=h^3L^{N-1}. \tag{25}$$

On the other hand,

$$\eta \int_{\Omega} |\nabla \mathbf{B}|^2 dV \sim \eta h^2 L^{N-2}, \tag{26}$$

so that the behavior of the right-hand side of Eq. (6), as a function of h and L, is

$$-\eta h^2 L^{N-2} + h^3 L^{N-1}. \tag{27}$$

Therefore, any exponential growth rate γ should be of the order of (27) divided by $h^2 L^N$, i.e.,

$$\gamma \sim -\eta L^{-2} + hL^{-1}, \tag{28}$$

while $\|\mathbf{u}\|_q \sim hL^{N/q}$.

Assume $q<N$, and take s such that $1<s<N/q$. Choose $h=L^{-s}$. Then, for L small,

$$\gamma \sim -\eta L^{-2} + L^{-1-s} \sim L^{-1-s}. \tag{29}$$

While $\|\mathbf{u}\|_q \sim L^{N/q-s}$ tends to zero with L, $\gamma \to \infty$. Thus there is no possible bound of γ in terms of $\|\mathbf{u}\|_q$.

For $q=N$, we must avoid the possible indetermination in (29) occurring for $h=L^{-1}$. Therefore, we take $h=L^{-1}\log L^{-1}$. For L small enough,

$$-\eta L^{-2} + L^{-2}\log L^{-1} \sim L^{-2}\log L^{-1}, \tag{30}$$

whereas $\|\mathbf{u}\|_q \sim \log L^{-1}$. Since obviously, for any power n,

$$(\log L^{-1})^n \ll L^{-2}\log L^{-1}, \tag{31}$$

when $L \to 0$, there cannot be any bound of γ in terms of any power of $\|\mathbf{u}\|_q$.

Logically the method fails for $q>N$, because any attempt of setting $h=L^{-s}$ would yield a negative power of L at both sides; we could choose an adequate power on the right-hand side to make the magnitudes comparable. Notice that our test functions are localized in a neigborhood of **0** and therefore satisfy our boundary conditions.

IV. CONCLUSIONS

Defining hydromagnetic dynamos as plasma configurations producing an exponential growth of the magnetic field for some time, it is desirable to bound the possible growth rates in terms of the size of the plasma velocity. Classical inequalities involve the maximum norms of the velocity gradient, which are unsuitable for several reasons. We prove a bound of the growth rate by a power of the L^q-norm of the velocity and the conductivity, for any q strictly larger than the space dimension N. The estimate blows up in the limit $q=N$ as well as in the ideal limit of zero resistivity. It is shown by examples that there cannot be analogous bounds for $q \leqslant N$.

Symmetric periodic solutions of the anisotropic Manev problem

(Received 7 January 2002; accepted for publication 12 February 2002)

We consider the Manev potential in an anisotropic space, i.e., such that the force acts differently in each direction. Using a generalization of the Poincaré continuation method we study the existence of periodic solutions for weak anisotropy. In particular we find that the symmetric periodic orbits of the Manev system are perturbed to periodic orbits in the anisotropic problem. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1469670]

I. INTRODUCTION

In this article we consider the anisotropic Manev problem (AMP) that was introduced by Diacu[1] in the early 1990s. The work on the AMP was inspired by the anisotropic Kepler problem introduced by Gutzwiller in the early 1970s. Gutzwiller aimed to find connections between classical and quantum mechanics. His interest was stimulated by an old unsolved quantum mechanical problem formulated in a paper written by Einstein:[2] even if the Born–Sommerfeld–Einstein condition (e.g., see Ref. 2) were appropriate to describe the semi-classical limit of quantum theory, it was unclear how to find a classical approximation for nonintegrable systems.

Similarly the main reason for considering the AMP is to further analyze similarities between classical mechanics and quantum theory. Moreover, as it was remarked in Ref. 1, the AMP also brings general relativity into the game, since the Manev potential explains the perihelion advance of the inner planets with the same accuracy as general relativity.[3] It should be remarked that bringing general relativity into the game is of particular importance since a satisfactory quantum theory of gravitation does not exist.

Some of the qualitative features of the anisotropic Manev problem have already been studied. In Ref. 1, a large class of capture-collision and ejection-escape solutions is studied by means of the collision and infinity manifold techniques. In particular that paper also brought arguments favoring the chaoticity and nonintegrability of the system by showing the existence of heteroclinic orbits within the zero energy manifold. In Ref. 4 the occurrence of chaos on the zero energy manifold and the nonintegrability are finally proved, putting into evidence that the AMP is a very complex problem.

In this work, to gain a better understanding of the complicated dynamics of the AMP, we find the symmetric periodic orbits. Analyzing those orbits is especially important since, by now, it is well known that studying periodic orbits is a valuable general approach to tackle complex problems in classical mechanics. The existence of periodic orbits for small values of the anisotropy is proved using generalizations of the Poincaré continuation method developed in Refs. 5–8 (see also Refs. 9–11).

The (planar) anisotropic Manev problem is described by the Hamiltonian

$$H=\frac{1}{2}\mathbf{p}^2-\frac{1}{\sqrt{x^2+\mu y^2}}-\frac{b}{x^2+\mu y^2}, \tag{1}$$

where $\mu>1$ is a constant and $\mathbf{q}=(x,y)$ is the position of one body with respect to the other

a)Electronic mail: msantopr@math.uvic.ca

considered fixed at the origin of the coordinate system, and $\mathbf{p}=(p_x,p_y)$ is the momentum of the moving particle. The constant μ measures the strength of the anisotropy and for $\mu=1$ we recover the classical Manev problem. Furthermore, the equation of motion can be expressed as

$$\begin{aligned}\dot{\mathbf{q}}&=\mathbf{p},\\ \dot{\mathbf{p}}&=-\frac{\partial H}{\partial \mathbf{q}}.\end{aligned} \tag{2}$$

Now consider weak anisotropies, i.e., choose the parameter $\mu>1$ close to 1. Introducing polar coordinates $x=r\cos\theta$, $y=r\sin\theta$ and the notation $\epsilon=\mu-1$ with $\epsilon\ll 1$ we can expand the Hamiltonian (1) in powers of ϵ and obtain

$$H=\frac{1}{2}\mathbf{p}^2-\frac{1}{r}-\frac{b}{r^2}+\epsilon\left(\frac{1}{2r}+\frac{b}{r^2}\right)\cos^2\theta\equiv H_0+\epsilon W(r,\theta). \tag{3}$$

It should be pointed out that the term $W(r,\theta)$ becomes unbounded as $r\to 0$ so that a perturbation analysis is not correct on the ejection-collision orbits. This means that the global dynamics of the AMP cannot be completely described by perturbations to the Manev problem even at the limit $\epsilon\to 0$. However, many interesting results concerning the Hamiltonian (1) for weak anisotropies (i.e., $\epsilon\ll 1$) can be found studying the Hamiltonian (3), some of which are presented in this article.

In the next section we describe the symmetries of the AMP and we find some properties that will be useful to find symmetric periodic orbits. In Sec. III we prove a continuation theorem for the symmetric periodic orbits of ''second kind,'' i.e., the noncircular ones. In Sec. IV we prove a continuation theorem for the orbits of ''first kind,'' i.e., the circular ones, following the method developed in Ref. 8.

II. SYMMETRIES OF THE ANISOTROPIC MANEV PROBLEM

To find periodic orbits in the anisotropic problem it is peculiarly important to know the symmetries of the system, as it was, for example observed in Refs. 5 and 6. The symmetries of the problem under discussion have been examined in Ref. 1 and they are the same as the ones found in Ref. 7 for the anisotropic Kepler problem:

$$\begin{aligned}
E &: (x,y,p_x,p_y,t)\to(x,y,p_x,p_y,t),\\
S_0 &: (x,y,p_x,p_y,t)\to(x,y,-p_x,-p_y,-t),\\
S_1 &: (x,y,p_x,p_y,t)\to(x,-y,-p_x,p_y,-t),\\
S_2 &: (x,y,p_x,p_y,t)\to(-x,y,p_x,-p_y,-t),\\
S_3 &: (x,y,p_x,p_y,t)\to(-x,-y,-p_x,-p_y,t),\\
S_4 &: (x,y,p_x,p_y,t)\to(-x,y,-p_x,p_y,t),\\
S_5 &: (x,y,p_x,p_y,t)\to(x,-y,p_x,-p_y,t),\\
S_6 &: (x,y,p_x,p_y,t)\to(-x,-y,p_x,p_y,-t),
\end{aligned} \tag{4}$$

where E is the identity.

The symmetries above can be interpreted in the following way: Let $\gamma(t)$ be a solution of (2). Then $S_i(\gamma(t))$ is another solution for $i\in\{0,1,2,3,4,5,6\}$. For $i\in\{0,1,2,3,4,5,6\}$ the orbit $\gamma(t)$ will be called symmetric if and only if $S_i(\gamma(t))=\gamma(t)$.

Let us remark that the symmetries in (4), together with the composition of functions, denoted by $\bigcirc$, form an Abelian group in which the operation acts according to the table below.

$\circ$	E	S_0	S_1	S_2	S_3	S_4	S_5	S_6
E	E	S_0	S_1	S_2	S_3	S_4	S_5	S_6
S_0	S_0	E	S_5	S_4	S_6	S_2	S_1	S_3
S_1	S_1	S_5	E	S_3	S_2	S_6	S_0	S_4
S_2	S_2	S_4	S_3	E	S_1	S_0	S_6	S_5
S_3	S_3	S_6	S_2	S_1	E	S_5	S_4	S_0
S_4	S_4	S_2	S_6	S_0	S_5	E	S_3	S_1
S_5	S_5	S_1	S_0	S_6	S_4	S_3	E	S_2
S_6	S_6	S_3	S_4	S_5	S_0	S_1	S_2	E

From the table above it is easy to deduce the following.

Proposition 1: The symmetries of the anisotropic Manev problem form an elementary Abelian group of order eight, i.e., a group isomorphic to $\mathbf{Z}_2\times\mathbf{Z}_2\times\mathbf{Z}_2$.

The symmetries in (4), (except E and S_6) are very useful to find symmetric periodic orbits, especially by means of the continuation method, as we show in the next two sections. Some important properties of the symmetric orbit, summarized in Ref. 7, are expressed in the following lemma:

Lemma 1: (i) For $i=1$ *(resp.* $i=2$*) we have that an orbit* $\gamma(t)$ *is* S_i*-symmetric if and only if it crosses the x axis (resp. y axis) orthogonally.*

(ii) An orbit $\gamma(t)$ *is* S_0*-symmetric if and only if it has a point on the zero velocity curve.*

(iii) For $i=4,5$ *an orbit* $\gamma(t)$ *is* S_i*-symmetric if and only if it is* S_0*-symmetric.*

(iv) All the S_3*-symmetric orbits are periodic.*

The properties of the S_i-symmetric orbits were first studied by Birkhoff[9] for the restricted three body problem and later by many other authors. In particular Casasayas and Llibre[7] state a proposition that gives a technique useful to obtain symmetric periodic orbits with respect to S_0, S_1, S_2 for the anisotropic Kepler problem that are verified also for the problem under discussion in this article:

Proposition 2: (i) For $i=1$ *(resp.* $i=2$*) we have that an orbit* $\gamma(t)$ *is an* S_i*-symmetric periodic orbit if and only if it crosses the x axis (resp. y axis) orthogonally at two distinct points.*

(ii) An orbit $\gamma(t)$ *is an-*S_0 *symmetric periodic orbit if and only if it meets the zero velocity curves at two distinct points.*

(iii) An orbit $\gamma(t)$ *is an-*S_1 *and* S_2*-symmetric periodic orbit if and only if it crosses the x axis and the y axis orthogonally.*

(iv) For $i=1,2$ *an orbit* $\gamma(t)$ *is a* S_0*- and* S_i*-symmetric periodic orbit if and only if it meets the zero velocity curve and crosses the x, respectively y axis, orthogonally.*

(v) For $i=4,5$*, if an orbit* $\gamma(t)$ *is* S_i*-symmetric, then it is* S_0*-symmetric and periodic.*

Now we want to find the symmetric periodic orbit for the unperturbed problem ($\epsilon=0$ or $\mu=1$) and continue them to periodic solutions of the anisotropic system (for $\epsilon\ll 1$). First we observe that, by Proposition 2, the S_i-symmetric orbits with $i=0,4,5$ must meet the zero velocity curve at two points, i.e., there must be a point where the angular momentum $K=xp_y-yp_x$ is zero, but since K is a constant of motion it must be zero along the orbit. Therefore such orbits are ejection-collision orbits, are not periodic and cannot be studied by means of the continuation method. Hence we are going to consider the symmetric periodic orbits with $i=1,2$, and also the

ones with $i=3$ that are the circular orbits of the unperturbed problem. To exploit those properties of the symmetric periodic orbits it is convenient to write the equation of motion in different coordinates.

For the S_i symmetric orbits with $i=1,2$, as it was noted in Ref. 5, it is convenient to write the canonical equations of the restricted three body problem using the Delaunay variables in the rotating frame.[5] Also the Poincaré synodic variables can be used to find symmetric periodic orbits of the restricted three body problem.[6] The anisotropic Manev problem is different since the Hamiltonian that describes it is time independent, hence the idea of using rotating coordinates in the present case cannot be applied. Moreover, our problem is nondegenerate; however, even in our case it is advantageous to perform a change of variables and apply a variation of the action angle variables used in Refs. 4 and 12. Here the nondegeneracy of the problem plays a role similar to the rotating coordinate system in the restricted three body problem.

For the S_3-symmetric orbits we can instead consider the equations in the rotating frame, and prove a theorem similar to the one proved in Ref. 8 for the anisotropic Kepler problem (in Ref. 8 the author remarks that the analysis of the Kepler problem can be redone in the Manev case, but he does not provide a proof).

III. THE S_i-SYMMETRIC ORBITS WITH $i=1,2$

We recall that the action variables introduced in Refs. 4 and 12 are given by

$$I=\frac{1}{2\pi}\oint p_r dr=-\sqrt{K^2-2b}+\frac{1}{2}\sqrt{\frac{2}{|h|}},$$
$$K=xp_y-yp_x, \tag{5}$$

where h is the energy constant and K is the angular momentum. These variables are defined for $h<0$ and $K^2>2b$, $I>0$, to avoid collision orbits as well as circular orbits. The related frequencies are

$$\omega_I=\frac{1}{(I+\sqrt{K^2-2b})^3},$$

$$\omega_K=\frac{K}{\sqrt{K^2-2b}(I+\sqrt{K^2-2b})^3},$$

and θ and ϕ are the angle variables associated to K and I, respectively.

The unperturbed Hamiltonian in the new variables can be written as

$$H_0=-\frac{1}{2(I+\sqrt{K^2-2b})^2}.$$

Now we can consider new variables that are linear combination of the previous ones. They are defined by the following canonical transformation

$$L=K+I,$$
$$G=-I,$$
$$l=\theta,$$
$$g=\theta-\phi. \tag{6}$$

Where l is the mean anomaly [where $l(t)=\omega_L(t-t_0)$ and t_0 is the time of pericenter passage], g is the longitude of pericenter as they are defined for the Manev problem in Ref. 13. Moreover, also the action variables can be written in terms of the orbital elements of the Manev problem. If we set

$$a=\frac{1}{2|h|} \quad \text{and} \quad e=\sqrt{1-2(K^2-2b)|h|}$$

as in Refs. 4 and 13, then

$$G=-a^{1/2}[1-(1-e^2)^{1/2}] \quad \text{and} \quad L=-G\pm\sqrt{a(1-e^2)+2b},$$

where a is the pseudo-semimajor axis, e is the pseudo-eccentricity, and the sign $+$ (resp. $-$) holds for $K>0$ (resp. <0). The conditions to avoid collision orbits and circular orbits, on which g becomes meaningless, can be written in terms of the orbital elements as $a>0$ and $0<e<1$. The new unperturbed Hamiltonian is

$$H_0=-\frac{1}{2(-G+\sqrt{(G+L)^2-2b})^2}, \tag{7}$$

so the perturbed equations of motion become

$$\begin{aligned}
\dot{L}&=-\frac{\partial(H_0+\epsilon W)}{\partial l}=-\epsilon\frac{\partial W}{\partial l},\\
\dot{G}&=-\frac{\partial(H_0+\epsilon W)}{\partial g}=-\epsilon\frac{\partial W}{\partial g},\\
\dot{l}&=\frac{\partial(H_0+\epsilon W)}{\partial L}=\omega_L+\epsilon\frac{\partial W}{\partial L},\\
\dot{g}&=\frac{\partial(H_0+\epsilon W)}{\partial G}=\omega_G+\epsilon\frac{\partial W}{\partial G},
\end{aligned} \tag{8}$$

where W is expressed in the new variables and

$$\omega_L=\omega_K=\frac{G+L}{(-G+\sqrt{(G+L)^2-2b})^3\sqrt{(G+L)^2-2b}}$$

$$\omega_G=\omega_K-\omega_I=\frac{G+L-\sqrt{(G+L)^2-2b}}{(-G+\sqrt{(G+L)^2-2b})^3\sqrt{(G+L)^2-2b}}$$

With these preparations, i.e., the introduction of the action angle variables (6), we are well on our way to establishing the following result:

Theorem 1: *Let $\gamma(t)$ be an S_i-symmetric periodic orbit of the Manev problem with $i=1,2$. Let the period be τ and set $\epsilon=\mu-1$ with $\epsilon\ll 1$. Then there exists a τ-periodic solution of the anisotropic Manev problem $\gamma_\epsilon(t)$ such that $\gamma_\epsilon(t)=\gamma(t)+O(\epsilon)$.*

Proof: Let us consider an S_1-symmetric orbit of period $\tau=2\pi m/k$ (m, k relatively prime integers). We remark that, since the equations of motion are autonomous, we can reduce to study the symmetric orbits that have either the pericenter or the apocenter on the positive x axis at $t=0$.

If at $t=0$, $\epsilon=0$, the pericenter of this orbit is on the positive x axis, and it is crossing the x axis perpendicularly, we have

$$g(0)=0 \quad \text{and} \quad l(0)=0. \tag{9}$$

Since the periodic orbit is S_1-symmetric, by Proposition 2, at the half period one has

$$g\left(\frac{\tau}{2}\right)=m\pi, \quad l\left(\frac{\tau}{2}\right)=k\pi, \tag{10}$$

which follows from the solution of (8) for $\epsilon=0$:

$$\begin{gathered} L=\text{const}, \quad G=\text{const} \\ l=\omega_L t, \quad g=\omega_G t. \end{gathered} \tag{11}$$

Now if, for $\epsilon\neq 0$, we consider only S_1-symmetric solutions of (8), it follows from the implicit function theorem that if the functional determinant

$$D=\det\begin{pmatrix} \dfrac{\partial l}{\partial L} & \dfrac{\partial l}{\partial G} \\ \dfrac{\partial g}{\partial L} & \dfrac{\partial g}{\partial G} \end{pmatrix} \neq 0 \tag{12}$$

at

$$t=\frac{\tau}{2}, \quad \epsilon=0, \tag{13}$$

then (10) would be satisfied for $\epsilon>0$. To compute the determinant we can by analyticity substitute (10) into (11) to find out at the time $t=\tau/2$ that

$$D=\frac{6b(\tau/2)^2}{(-G+\sqrt{(G+L)^2-2b})^7((G+L)^2-2b)^{3/2}}\neq 0. \tag{14}$$

Thus the existence of S_1-symmetric periodic orbits of period τ obtained from the τ periodic S_1-symmetric solutions of the unperturbed problem, that at $t=0$ have the pericenter on the positive x axis, is readily established.

On the other hand, if at $t=0$, $\epsilon=0$, the apocenter is on the positive x axis, and it is crossing the x axis perpendicularly, we have

$$g(0)=\frac{\pi}{\lambda} \quad \text{and} \quad l(0)=-\frac{\pi}{\lambda}, \tag{15}$$

where $\lambda=(\omega_L-\omega_G)/\omega_L$. By Proposition 1, at the half period we have

$$g\left(\frac{\tau}{2}\right)=\left(m+\frac{1}{\lambda}\right)\pi, \quad l\left(\frac{\tau}{2}\right)=\left(-\frac{1}{\lambda}+k\right)\pi. \tag{16}$$

Instead of computing the functional determinant directly, in this case, it is easier to consider the new variables given by the relations

$$\begin{gathered} \tilde{L}=L, \\ \tilde{G}=G, \\ \tilde{l}=l+\frac{\pi}{\lambda_0}, \\ \tilde{g}=g-\frac{\pi}{\lambda_0}, \end{gathered} \tag{17}$$

which define a family of canonical transformations parametrized by $\lambda_0(L_0,G_0)$. For each orbit choose a different transformation from the family (17), where $\lambda_0=\lambda$ is a fixed quantity defined by the value of the action variables along the periodic orbit under consideration.

The equations (16), expressed in the new variables, are of the same form as in (10). Thus the functional determinant, in the new variables, is exactly D, and the existence of the remaining S_1-symmetric τ-periodic orbits follows.

Now the proof for the S_2-symmetric orbits can be done along the same lines. Consider an S_2-symmetric periodic orbit of period $\tau=2\pi m/k$. If at $t=0$, $\epsilon=0$ the pericenter of the orbit is on the positive y axis and it is crossing the y axis perpendicularly, we have

$$g(0)=\frac{\pi}{2} \quad \text{and} \quad l(0)=0. \tag{18}$$

Since the periodic orbit is S_2-symmetric one has, at the half period,

$$g\left(\frac{\tau}{2}\right)=m\pi+\frac{\pi}{2}, \quad l\left(\frac{\tau}{2}\right)=k\pi. \tag{19}$$

Now we consider only S_2-symmetric solutions of (8) for $\epsilon\neq 0$. Again it follows from the implicit function theorem that if the determinant D computed at $t=\tau/2$ for $\epsilon=0$ is nonzero, then (19) would be satisfied for $\epsilon>0$. It is trivial to see from (14) that $D\neq 0$, and hence we found S_2-symmetric periodic orbits for the perturbed problem.

For the S_2-symmetric orbits having the apocenter on the positive x axis at $t=0$ the canonical transformation (17) can be used. Again we find the same expression for the functional determinant and, hence, by the implicit function theorem, the existence of the remaining S_2-symmetric periodic orbits is proved.

It is interesting to remark that Theorem 1 and its proof can be easily extended to consider any S_i-symmetric perturbation with $i=1,2$ and a very general class of nondegenerate integrable Hamiltonians, however such a generalization is trivial and not strictly related to the problem under consideration and hence it will not be discussed any further.

We can also observe that for $b=0$, i.e., for the Kepler problem, the determinant in (14) is zero. Thus in the case of the anisotropic Kepler problem, the continuation theorem proved above cannot be applied, and the existence of symmetric periodic orbits of the ''second kind'' (for weak anisotropies) remains unclear. On the other hand, the continuation theorem that we prove in the next section (for the circular orbits) can be applied to the anisotropic Kepler problem[8] and hence at least the existence of symmetric periodic orbits of the first kind is a well established fact.

IV. THE S_3-SYMMETRIC ORBITS

Again we can consider the anisotropic Manev problem taking the parameter μ close to 1. Let $\Phi(t,(\mathbf{r},\dot{\mathbf{r}}),\mu)$ be the flow of the equation of motion (1). In this section we prove the following theorem:

Theorem 2: *Let* $\mathbf{r}^0(t)$ *be an* S_3*-symmetric periodic orbit of the Manev problem, i.e., a circular one. Set* $\epsilon=\mu-1$, *and let* τ *be the period of* $\mathbf{r}^0(t)$. *Then there exists a* τ*-periodic solution* $\Phi(t,(\mathbf{r}(\epsilon),\dot{\mathbf{r}}(\epsilon)),\epsilon)$ *of the anisotropic Manev problem such that* $\Phi(t,(\mathbf{r}(0),\dot{\mathbf{r}}(0)),0)=(\mathbf{r}^0(t),\dot{\mathbf{r}}^0(t))$.

A. The equation of motion

Now using the same notation as in Ref. 8 let $\mathbf{r}^0(t)$ be a circular solution of the Manev problem which corresponds to $\mu=1$ in the xy-plane, ω its angular speed and a its radius. For $\epsilon=\mu-1\neq 0$ we set

$$\mathbf{r}(t,\epsilon)=\mathbf{r}^0(t)+\epsilon\mathbf{s}(t,\epsilon). \tag{20}$$

Expanding ∇H in powers of $\mu-1$ sufficiently small, after substituting the expression for $\mathbf{r}$ given above, considering the notation $\mathbf{r}^0(t)=x_0(t)+iy_0(t)$ and $\mathbf{s}=u+iv$ we have that $\mathbf{r}(t,\epsilon)$ is a solution of equation of motion defined by (1) if, and only if, $\mathbf{s}(t,\epsilon)$ is a solution of the equations

$$\begin{aligned}\ddot{u}&=-\left(\frac{1}{a^3}-\frac{3x_0^2}{a^5}-\frac{8bx_0^2}{a^6}+\frac{2b}{a^4}\right)u+\left(\frac{3x_0y_0}{a^5}+\frac{8bx_0y_0}{a^6}\right)v+\eta(t)+O(\epsilon),\\ \ddot{v}&=\left(\frac{3x_0y_0}{a^5}+\frac{8bx_0y_0}{a^6}\right)u-\left(\frac{1}{a^3}-\frac{8by_0^2}{a^6}-\frac{3y_0^2}{a^5}+\frac{2b}{a^4}\right)v+\xi(t)+O(\epsilon)\end{aligned} \tag{21}$$

where

$$\eta(t)=\frac{3x_0y_0^2}{a^5}+\frac{4bx_0y_0^2}{a^6}$$

$$\xi(t)=\frac{3y_0^2}{2a^5}-\frac{y_0}{a^3}+\frac{4by_0^3}{a^6}-\frac{2by_0}{a^4}.$$

Consider the orthonormal frame in $\mathbf{R}^2$, $\mathbf{e}_1(t)$ and $\mathbf{e}_2(t)$ defined by

$$\mathbf{e}_1=\frac{\mathbf{r}^0}{|\mathbf{r}^0|}=e^{i\omega t}=\cos\omega t+i\sin\omega t,\quad \mathbf{e}_2=i\mathbf{e}_1,$$

and, using the same notation as in Ref. 8 where

$$\mathbf{s}=x_1\mathbf{e}_1+x_2\mathbf{e}_2,\quad \dot{\mathbf{s}}=y_1\mathbf{e}_1+y_2\mathbf{e}_2,$$

Eq. (21) can be written in an equivalent form as

$$\dot{\mathbf{z}}=A_0(t)+A\mathbf{z}+O(\epsilon), \tag{22}$$

where $\mathbf{z}=(x_1,x_2,y_1,y_2)^T$, and

$$A_0=\begin{pmatrix}0\\0\\\alpha(t)\\\beta(t)\end{pmatrix},\quad A=\begin{pmatrix}0 & \omega & 1 & 0\\ -\omega & 0 & 0 & 1\\ 2\omega^2+2\dfrac{b}{a^4} & 0 & 0 & \omega\\ 0 & -\omega^2 & -\omega & 0\end{pmatrix},$$

where

$$\alpha(t)\cos\omega t-\beta(t)\sin\omega t=\eta(t),$$

$$\alpha(t)\sin\omega t+\beta(t)\cos\omega t=\xi(t),$$

or, equivalently,

$$\alpha(t)=\sin^2\omega t\left(\frac{1}{2a^2}+\frac{2b}{a^3}\right), \tag{23}$$

$$\beta(t) = -\sin \omega t \cos \omega t \left(\frac{1}{a^2} + \frac{2b}{a^3} \right).$$

The eigenvalues of A are 0, with multiplicity two, $i/a^{3/2}$ and $-i/a^{3/2}$. One of the two eigenvalues vanishes because the system is autonomous, and the second due to the presence of the first integral H.

Now consider the real Jordan form J of A. The matrix J is defined by the relation $J = \mathcal{T}^{-1} A \mathcal{T}$ where $\mathcal{T}$ is

$$\mathcal{T} = \begin{pmatrix} 2\,\omega^2 a^3 & 0 & \dfrac{\omega^2 a^4 + 2\,b}{a} & 0 \\ 0 & -\dfrac{\omega(3\,\omega^2 a^4 + 2\,b)}{a} & 0 & -2\,\dfrac{\omega a^2(\omega^2 a^4 + 2\,b)}{(a)^{3/2}} \\ 0 & \dfrac{1}{2}\,\dfrac{4\,a(\omega^2 a^4 + b) + 2\,(\omega^2 a^4 + 2\,b)^2}{a^5} & 0 & \dfrac{(\omega^2 a^4 + 2\,b)^2}{a^{7/2}} \\ -\dfrac{\omega(\omega^2 a^4 + 2\,b)}{a} & 0 & -\dfrac{\omega(\omega^2 a^4 + 2\,b)}{a} & 0 \end{pmatrix}$$

and the columns of $\mathcal{T}$ are the generalized eigenvectors of A.

The vector $J_0 = \mathcal{T}^{-1} A_0$ and the matrix J are

$$J_0 = \begin{pmatrix} j_1(t) \\ j_2(t) \\ j_3(t) \\ j_4(t) \end{pmatrix}, \quad J = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \dfrac{\sqrt{a}}{a^2} \\ 0 & 0 & -\dfrac{\sqrt{a}}{a^2} & 0 \end{pmatrix},$$

where the fact that $j_1(t) = (2\omega^3 a^2 - \omega(\omega^2 a^4 + 2b)/a^2)^{-1} \beta(t)$ is the only information about J_0 that we need to retain. Furthermore, we remark that $\omega^2 a^4 - a - 2b = 0$ gives the relation between a and ω and solving this equations gives only one positive solution (for $b > 0$).

Letting $\mathbf{z} = \mathcal{T}\zeta$, the equation of motion becomes

$$\dot{\zeta} = J_0(t) + J\zeta + O(\epsilon), \tag{24}$$

and its flow is given by

$$\psi(t, \zeta, \epsilon) = \gamma(t) + e^{Jt} + O(\epsilon), \tag{25}$$

where by the variation of constants

$$\gamma(t) = e^{Jt} \int_0^t e^{-Js} J_0(s)\, ds. \tag{26}$$

Therefore, we have

$$e^{Jt}=\begin{pmatrix} 1 & 0 & 0 & 0 \\ t & 1 & 0 & 0 \\ 0 & 0 & \cos\frac{\sqrt{a}}{a^2}t & \sin\frac{\sqrt{a}}{a^2}t \\ 0 & 0 & -\sin\frac{\sqrt{a}}{a^2}t & \cos\frac{\sqrt{a}}{a^2}t \end{pmatrix},$$

and from (26) we obtain

$$\gamma(t)=\begin{pmatrix} \gamma_1(t) \\ \gamma_2(t) \\ \gamma_3(t) \\ \gamma_4(t) \end{pmatrix}, \tag{27}$$

where we retain only the information that

$$\gamma_1(t)=\left(2\omega^3a^2-\frac{\omega(\omega^2a^4+2b)}{a^2}\right)^{-1}\int_0^t\beta(s)ds. \tag{28}$$

B. The periodicity equation

Since the Hamiltonian H of the anisotropic Manev problem is S_3-symmetric, as we have shown, we can write the periodicity equation as in[8]

$$\Phi\left(\frac{\tau}{2},(\mathbf{r},\dot{\mathbf{r}}),\epsilon\right)=-(\mathbf{r},\dot{\mathbf{r}}). \tag{29}$$

Then it easy to check that $\Phi(t,(\mathbf{r},\dot{\mathbf{r}}),\epsilon)$ is a periodic solution of the equation of motion with period τ. To find periodic solutions we have to verify that (29) is satisfied for a family of initial conditions. Equation (29) in ζ coordinates is

$$\psi\left(\frac{\tau}{2},\zeta,\epsilon\right)-\zeta=0, \tag{30}$$

where $\psi(t,\zeta,\epsilon)$ is the flow of (24). Let us denote by $\mathcal{P}(\zeta,\epsilon)$ the left hand side of the periodicity equation (29), that is, let

$$\mathcal{P}(\zeta,\epsilon)=\psi\left(\frac{\tau}{2},\zeta,\epsilon\right)-\zeta=\gamma\left(\frac{\tau}{2}\right)+(e^{J\tau/2}-I)=0. \tag{31}$$

Using (25) we notice that the requirement

$$\mathcal{P}(\zeta^*,0)=\gamma\left(\frac{\tau}{2}\right)+(e^{J\tau/2}-I)\zeta^*=0 \tag{32}$$

imposes the restrictions

$$\gamma_1\left(\frac{\tau}{2}\right)=0,\quad \zeta_1^*=-\frac{2}{\tau}\gamma_2\left(\frac{\tau}{2}\right),\quad \zeta_2^*=\text{arbitrary}, \tag{33}$$

and

$$\zeta_3^*=\frac{1}{2(1-\cos\alpha^*)}\left(-\gamma_3\left(\frac{\tau}{2}\right)(\cos\alpha^*-1)+\gamma_4\left(\frac{\tau}{2}\right)\sin\alpha^*\right)$$
$$\zeta_4^*=\frac{-1}{2(1-\cos\alpha^*)}\left(\gamma_3\left(\frac{\tau}{2}\right)\sin\alpha^*+\gamma_4\left(\frac{\tau}{2}\right)(\cos\alpha^*-1)\right), \tag{34}$$

where $\alpha^*=\pi(1+2b/a)^{-1/2}$. It easy to see from (23) and (28) that $\gamma_1(\tau/2)=0$, therefore, we take

$$\zeta^*=(\zeta_1^*,\zeta_2^*,\zeta_3^*,\zeta_4^*)^T, \tag{35}$$

with ζ_2^* arbitrary, for the moment. Now using the flow (25), we determine that the Jacobian matrix of $\mathcal{P}$ with respect to the variables ζ evaluated at the point $(\zeta^*,0)$ is given by

$$\begin{pmatrix} 0 & 0 & 0 & 0 \\ \tau/2 & 0 & 0 & 0 \\ 0 & 0 & \cos\alpha^*-1 & \sin\alpha^* \\ 0 & 0 & -\sin\alpha^* & \cos\alpha^*-1 \end{pmatrix}. \tag{36}$$

Consider the system of three equations formed by those in (31) corresponding to the indices $i=2,3,4$, and fix the variable $\zeta_2=\zeta_2^*$. Its Jacobian matrix has determinant $\tau(1-\cos\alpha^*)$ that is always positive since $0<\pi(1+2b/a)^{-1/2}\leqslant\pi$. Therefore, the implicit function theorem guarantees the existence of analytic functions $\zeta_i=\zeta_i(\epsilon)$, $i=1,3,4$, in a neighborhood of $\epsilon=0$, satisfying the equations

$$\mathcal{P}_i(\zeta,\epsilon)=0 \quad (i=2,3,4), \tag{37}$$

where

$$\zeta(\epsilon)=(\zeta_1(\epsilon),\zeta_2^*,\zeta_3(\epsilon),\zeta_4(\epsilon)) \tag{38}$$

and such that

$$\zeta_i(0)=\zeta_i^* \quad (i=1,2,3,4). \tag{39}$$

It remains to show, in order to have periodicity, that also the remaining equation

$$\mathcal{P}_1(\zeta(\epsilon),\nu(\epsilon),\epsilon)=0 \tag{40}$$

is satisfied in a possibly smaller, neighborhood of $\epsilon=0$. That will be done employing a first integral of the system under discussion, i.e., the Hamiltonian.

C. Integral of motion

Since the Hamiltonian is an integral of motion of the problem under discussion we can apply the same analysis as in Refs. 8 and 14. In particular, using the same notations as in Ref. 8 we can define

$$H_\epsilon(\mathbf{z},t)=H(\mathbf{r},\dot{\mathbf{r}},\epsilon),$$

where $H_\epsilon(\mathbf{z},t)$ is a time-dependent, τ-periodic first integral for system (22). The above integral satisfies the following relation,

$$H_\epsilon\left(\mathbf{z},t+\frac{\tau}{2}\right)=H_\epsilon(\mathbf{z},t) \tag{41}$$

for all t, since $H(-\mathbf{r},-\dot{\mathbf{r}})=H(\mathbf{r},\dot{\mathbf{r}})$, $\mathbf{r}(t)=\mathbf{r}^0(t)+\epsilon\ \mathbf{s}(t)$ and

$$\mathbf{r}^0\left(t+\frac{\tau}{2}\right)=-\mathbf{r}^0(t),\quad \mathbf{s}\left(\mathbf{z},t+\frac{\tau}{2}\right)=-\mathbf{s}(\mathbf{z},t).$$

Performing a change of coordinates we can define $\mathcal{H}_\epsilon(\zeta,t)=H_\epsilon(\mathcal{T}\zeta,t)$, hence (41) can be written as

$$\mathcal{H}_\epsilon(\zeta,t+\tau/2)=\mathcal{H}_\epsilon(\zeta,t). \tag{42}$$

Moreover, since $\mathcal{H}_\epsilon$ is an integral of motion it verifies that

$$\mathcal{H}_\epsilon(\phi(\zeta,\epsilon,t))=H_\epsilon(\zeta,0). \tag{43}$$

Thus applying Eqs. (42) and (43) it follows that

$$\mathcal{H}_\epsilon(\psi(\tau/2,\zeta,\epsilon),0)=\mathcal{H}_\epsilon(\zeta,0),$$

and by means of the mean value theorem we obtain

$$\nabla_\zeta\mathcal{H}_\epsilon(\tilde{\zeta},0)\cdot\mathcal{P}(\zeta,\epsilon)=0, \tag{44}$$

where $\nabla_\zeta\mathcal{H}_\epsilon$ is the gradient of $\mathcal{H}_\epsilon$ with respect to ζ, and $\tilde{\zeta}$ is a point on the segment joining ζ to $\psi(\tau/2,\zeta,\epsilon)$.

Expanding $\Psi(\epsilon)=\psi(\tau/2,\zeta,\epsilon)$ in power of ϵ sufficiently small it is easy to show (see Ref. 8) that $\Psi(\epsilon)=\zeta^*+O(\epsilon)$ and consequently

$$\tilde{\zeta}=s\zeta(\epsilon)+(1-s)\Psi(\epsilon)=\zeta^*+O(\epsilon)$$

for some $s\in(0,1)$. Moreover, if we also expand the Hamiltonian $H_\epsilon(\mathbf{z},0)$ in powers of ϵ we get

$$H_\epsilon(\mathbf{z},0)=H_0+\epsilon(H_1+H_2\cdot\mathbf{z})+O(\epsilon^2)$$

or, in ζ coordinates

$$\mathcal{H}_\epsilon(\zeta,0)=\mathcal{H}_0+\epsilon(\mathcal{H}_1+\mathcal{H}_2\cdot\zeta)+O(\epsilon^2), \tag{45}$$

where $\mathcal{H}_0=H_0=(1/2\,\omega^2a^2-1/a-b/a^2)$, $\mathcal{H}_1=H_1$ and $\mathcal{H}_2=\mathcal{T}^TH_2=\mathcal{T}^T(a^{-2}+2ba^{-3},0,0,a\omega)$ $=(a\omega^2\zeta_1,0,0,0)$. Hence we obtain

$$\frac{1}{\epsilon}\nabla_\zeta\mathcal{H}_\epsilon(\tilde{\zeta},0)=\mathcal{H}_2+O(\epsilon). \tag{46}$$

With these preparations Eq. (44) reduces to the equation in the unknown $\mathcal{P}_1$

$$[a\omega^2+O(\epsilon)]\mathcal{P}_1=0, \tag{47}$$

since, for small ϵ, we already found in Sec. IV B that $\mathcal{P}_i=0$ for $i=2,3,4$. It is easy to see that for $\epsilon=0$ the equation above has solution $\mathcal{P}_1=0$. Thus, by continuity, $[a\omega^2+O(\epsilon)]$ is different from zero for ϵ sufficiently small. Therefore, for such values of ϵ, this equation has a unique solution that is the trivial one. Consequently, the remaining equation,

$$\mathcal{P}_1(\zeta(\epsilon),\epsilon)=0,$$

is also satisfied in a possibly smaller neighborhood of $\epsilon=0$. Hence all the equations of the periodicity system (31) are satisfied when $\zeta=\zeta(\epsilon)$, as long as ϵ is sufficiently small. This completes the proof of Theorem 2.

Metric-independent analysis of the stress-energy tensor

Reuven Segev[a)]
Ben-Gurion University, Department of Mechanical Engineering, P.O. Box 653, Beer-Sheva 84105, Israel

(Received 5 January 2001; accepted for publication 26 February 2002)

The stress-energy tensor of field theory is defined and analyzed in a geometric setting where a metric is not available. The stress is a linear mapping that transforms the three-form representing the flux of any given property, e.g., charge-current density, to the three-form representing the flux of energy. The example of the electromagnetic stress-energy tensor is given with the additional structure of a volume element. © *2002 American Institute of Physics.*

I. INTRODUCTION

The introduction of the stress-energy tensor in field theory and the related analysis of conservation laws utilize the metric properties of space–time afforded by relativity theory (see, for example, Refs. 1–5). Since one cannot assume that the metric tensor is known in advance, it would be preferable, at least from the theoretical point of view, to have a formulation of the theory that does not rely on the metric structure. Such a presentation of the stress-energy tensor and conservation laws is the subject of this article.

For the electromagnetic field as a concrete example, the construction may be described simply as follows: the value of a stress-energy tensor at any event is a linear mapping that transforms the charge-current density three-form to the corresponding energy flux three-form.

The basic geometric setting is that of an m-dimensional space–time manifold $\mathcal{U}$. Space–time is assumed to be orientable and a specific orientation is assumed to be chosen. In particular, we do not use a metric or a connection in the analysis. The first part of the article, containing Secs. II and III, is concerned with the fibration of space–time induced by a conservation law for an extensive property p, for example, the electric charge. Assuming that the flux of the property p out of any region $\mathcal{R}$ in space–time is given as an integral of a flux density $(m-1)$-form $\tau_{\mathcal{R}}$, and using a generalization of the traditional Cauchy assumptions regarding the dependence of the form $\tau_{\mathcal{R}}$ on $\mathcal{R}$, there is a unique flux $(m-1)$-form J (see Ref. 6), the analog of the charge-current density three-form in electromagnetism, such that for any region $\mathcal{R}$, $\tau_{\mathcal{R}}=\imath^*(J)$, where $\imath^*$ is the restriction of forms defined on space–time to the boundary of $\mathcal{R}$. The flux density form induces a one-dimensional subbundle of the tangent bundle $T\mathcal{U}$ whose integral manifolds are the worldlines associated with the property. Thus, even in this general setting, the conservation of the property induces enough structure so the analogs of particles and velocities—worldlines and flux $(m-1)$-forms—may be defined. If a volume element θ is given on $\mathcal{U}$, the flux form induces a vector field v, the analog of the four-velocity, by the condition $J=v\lrcorner\theta$.

The next part of the article, consisting of Secs. IV–VI, presents stress theory on manifolds (see also previous works, Refs. 7 and 8). Consider a vector bundle $W\to\mathcal{U}$, whose elements are interpreted as values of generalized velocities. For a region $\mathcal{R}$ in space–time, Sec. IV is concerned with a linear functional on sections w of W that contain a ''volume'' term and a boundary term. The boundary term for a region $\mathcal{R}\subset\mathcal{U}$ is given as $\mathbf{t}_{\mathcal{R}}(w)$ where $\mathbf{t}_{\mathcal{R}}$ is a section of the bundle of linear mappings $L(W,\Lambda^{m-1}(T^*\partial\mathcal{R}))$. Again, with the Cauchy postulates for the dependence of $\mathbf{t}_{\mathcal{R}}$ on $\mathcal{R}$, there is a unique section σ of $L(W,\Lambda^{m-1}(T^*\mathcal{U}))$, the Cauchy stress, that induces by restriction of forms the vector valued forms $\mathbf{t}_{\mathcal{R}}$ for the various regions.

[a)]Electronic mail: rsegev@bgumail.bgu.ac.il

Section V considers a linear functional on sections of W that may be represented as follows. Let $J^1(W)$ be the jet bundle associated with W. Then, there is a section of $L(J^1(W),\Lambda^m(T^*\mathcal{U}))$, the variational stress density, such that the value of the functional for a section w is $\int_{\mathcal{R}} S(j^1(w))$, where $j^1(w)$ is the first jet of the section w. The divergences of variational stress densities are defined and the relation between Cauchy stresses and variational stresses is presented in Sec. VI.

The values of the functionals described above are interpreted in Sec. VII as the energy variation associated with the motion of the property p as represented by the flux form J. Accordingly, $\Lambda^{m-1}(T^*\mathcal{U})$ is used for the vector bundle W over space–time. In this case, the Cauchy stress is a section of $L(\Lambda^{m-1}(T^*\mathcal{U}),\Lambda^{m-1}(T^*\mathcal{U}))$— the stress-energy tensor. It is shown in Sec. VIII that stress-energy tensors can be represented naturally by sections of the bundle of linear mappings $L(T\mathcal{U},T\mathcal{U})$.

Finally, Sec. IX presents the example of the stress-energy tensor for electromagnetism. No particular relation is used for the constitutive relation between the Maxwell and Faraday two-forms and the only additional geometric structure used is that of a volume element. Mathematically, this enables us to obtain the four-velocity vector field from the flux form. The expression for the Lorentz force we obtain is analogous to that of Ref. 2, p. 91, where a metric is used.

In Ref. 9, Gotay and Marsden present a derivation of a metric independent stress-energy tensor using a different approach. In comparison with the present article, the authors assume additional structure of a Lagrangian and a gauge group. Accordingly, the results they obtain are more comprehensive. The stress object derived in Ref. 9 is a (1,1)-tensor density, i.e., a section of $L(L(T\mathcal{U},T\mathcal{U}),\Lambda^m(T^*\mathcal{U}))$ that may be identified with a section of $L(T\mathcal{U},\Lambda^{m-1}(T^*\mathcal{U}))$. Here, allowing a slight generalization where a stress is an element of $L(L(W,T\mathcal{U}),\Lambda^m(T^*\mathcal{U}))$ for some vector bundle W, and then putting $W=\Lambda^{m-1}(T^*\mathcal{U})$ (see Sec. VII for the motivation), we arrive at a stress object that is a (1,1) tensor, i.e., a section of $L(T\mathcal{U},T\mathcal{U})$.

II. SCALAR VALUED EXTENSIVE PROPERTIES ON SPACE–TIME

We consider the conservation of an extensive property p in space–time $\mathcal{U}$. It is assumed that $\mathcal{U}$ is an m-dimensional orientable manifold with a definite orientation chosen. An m-dimensional submanifold with boundary $\mathcal{R}$ of $\mathcal{U}$ will be referred to as a *control region*.

Specifically, it is assumed that for each control region $\mathcal{R}$ there is an $(m-1)$-form $\tau_{\mathcal{R}}$ on $\partial\mathcal{R}$, the *flux density*. The integral $\int_{\partial\mathcal{R}}\tau_{\mathcal{R}}$ is interpreted as the flux of the property out of the control region in space–time relative to the positive orientation induced on $\partial\mathcal{R}$ by the orientation on $\mathcal{U}$ and the outwards pointing vectors. In case a frame is given, the flux density through a spacelike slice is interpreted as the density of the property p in space and the flux through a hyperplane containing the $\partial/\partial t$ tangent vector is interpreted as the classical flux density of p into the corresponding slice consisting of simultaneous events.

Regarding $\tau_{\mathcal{R}}$ as the value of a set function defined on the collection of control regions, Cauchy's postulates of continuum mechanics can be generalized to differentiable manifolds as follows (see Refs. 6 and 8).

GC1 There is a volume element θ on $\mathcal{U}$ such that

$$\left|\int_{\partial\mathcal{R}}\tau_{\mathcal{R}}\right|\leqslant\int_{\mathcal{R}}\theta.$$

GC2 Consider the Grassmann bundle of hyperplanes $\pi_G: G_{m-1}(T\mathcal{U})\to\mathcal{U}$ whose fiber $G_{m-1}(T_x\mathcal{U})$ at any event $x\in\mathcal{U}$ is the Grassmann manifold of hyperplanes, i.e., $(m-1)$-dimensional subspaces of the tangent space $T_x\mathcal{U}$. Let $\Lambda^{m-1}(G_{m-1}(T\mathcal{U}))^*\to G_{m-1}(T\mathcal{U})$ be the vector bundle over $G_{m-1}(T\mathcal{U})$ whose fiber over a hyperplane H is the vector space of $(m-1)$-forms on H. Then, the dependence of $\tau_{\mathcal{R}}$ on $\mathcal{R}$ is via a smooth section

$$\tau: G_{m-1}(T\mathcal{U})\to\overset{m-1}{\Lambda}(G_{m-1}(T\mathcal{U}))^*,$$

such that $\tau_{\mathcal{R}}=\tau(T_x\partial\mathcal{R})$.

Cauchy's theorem, generalized in Refs. 6 and 8 to manifolds, states that there is a unique $(m-1)$-form J on $\mathcal{U}$ such that for any control region $\mathcal{R}$,

$$\tau_{\mathcal{R}}=\tau(T_x\partial\mathcal{R})=\iota^*(J).$$

Here, $\iota:\partial\mathcal{R}\to\mathcal{U}$ is the natural inclusion and ι^* is the pull-back of forms it induces. We will refer to J as the *flux form* associated with the property p.

Usually, it is assumed that there is a source density term s for the property, an m-form on $\mathcal{U}$, so that the conservation equation of the property is

$$\int_{\partial\mathcal{R}}\tau_{\mathcal{R}}=\int_{\mathcal{R}}s.$$

In this case, Stokes' theorem implies that the conservation equation may be written in a differential form as $dJ=s$. Again, if a frame is given on space–time, then the time component of J is the density in space of the property p and the term in dJ containing it is the time derivative of that density. The spacelike components of J describe the three-dimensional flux and the terms in dJ involving the spacelike components make its $(m-1)$-dimensional divergence. In a particular frame, for every time t, the classical conservation law has the integral form

$$\int_{\mathcal{R}}\beta_{\mathcal{R}}+\int_{\partial\mathcal{R}}\tau_{\mathcal{R}}=\int_{\mathcal{R}}s,$$

where here $\mathcal{R}$ is interpreted as a region in space (a slice of space–time) and $\beta_{\mathcal{R}}$ is the rate of change of the density of the property—a three-form. In order that the previous Cauchy assumptions apply, it is usually assumed that $\beta_{\mathcal{R}}$ is actually independent of $\mathcal{R}$.

Remark 2.1: Assume the manifold $\mathcal{U}$ is given a particular volume element θ. Then, there is a vector bundle isomorphism

$$i_\theta:\ \overset{m-1}{\Lambda}\ (T_x^*\mathcal{U})\to T_x\mathcal{U}$$

such that $(i_\theta\circ J)\lrcorner\theta=J$, where $\lrcorner$ denotes the contraction (interior product) of forms by vectors. If θ is represented locally by

$$r(x^i)\,dx^1\wedge\ \cdots\wedge dx^m,$$

then $v=i_\theta\circ J$, which we will also write as $i_\theta(J)$, is represented by

$$v^i=\frac{(-1)^{i+1}J_i}{r}.$$

If J is a flux form of an extensive property p and a volume element is given, we will refer to $v=i_\theta(J)$ as the *kinematic flux* associated with p. The kinematic flux is the analog of the four-velocity field. If $\mathcal{L}$ denotes the Lie derivative, then the differential conservation equation can now be written in the form $\mathcal{L}_v\theta=s$.

III. WORLDLINES AND GENERALIZED BODY POINTS

A flux form J induces a one-dimensional distribution over the open submanifold of $\mathcal{U}$ where it does not vanish. Let $E(J)$ be the minimal enveloping subbundle associated with J, i.e., the minimal subbundle Z of $T^*\mathcal{U}$ such that $J(x)\in\Lambda^{m-1}Z_x$. We will refer to the annihilator $E(J)^\perp\subset T\mathcal{U}$ of the minimal enveloping subbundle as the *flux bundle*, that is,

$$E(J)_x^{\perp}=\{v\in T_x\mathcal{U};\phi(v)=0,\ \text{for all}\ \ \phi\in E(J)_x\}.$$

The flux bundle is one-dimensional and a tangent vector v is in the flux bundle if and only if $v\lrcorner J=0$. The flux bundle is also the one-dimensional bundle obtained by the relation $v=i_\theta(J)$ when the flux form J is kept fixed and the volume element θ is allowed to vary. Being one-dimensional, the flux bundle is integrable, and its one-dimensional integral manifolds will be referred to as (local) *worldlines*. Consider the equivalence relation $x\sim x'$ if x and x' are on the same worldline. We will refer to the collection of worldlines $\mathcal{B}=\mathcal{U}/\sim$ as the *material universe*.

The worldlines form a foliation of $\mathcal{U}$. (See Ref. 10 for a detailed treatment.) In case the foliation is regular, so $\mathcal{B}$ is an $(m-1)$-dimensional submanifold of $\mathcal{U}$ and the natural projection $\mathcal{U}\to\mathcal{B}=\mathcal{U}/\sim$ is a submersion, an element of $\mathcal{B}$ is a *material point* and a compact $(m-1)$-dimensional submanifold with boundary of $\mathcal{B}$ is a *material body*. A necessary and sufficient condition for the foliation to be regular is the existence of local slices, i.e., at every event x there exists a local $(m-1)$-dimensional submanifold P of $\mathcal{U}$ such that P intersects every worldline at one point at most and $T_x\mathcal{U}=T_xP\times T_xY$, where Y is the worldline through x.

Thus, in case the foliation by worldlines is regular, the construction we described generates a material structure in space even though the velocity field is not defined uniquely. In addition, the flux form J is an object that generalizes the velocity field even if a volume element is not given and even if the foliation it generates is not regular.

Clearly, foliated charts and slices generate frames that assign to events unique material points and ''time'' coordinates. If a volume element is given, the kinematic flux induces a unique time coordinate in the neighborhood of every event (independently of a chart). Thus, a flux form and a volume element induce together a local frame.

IV. CAUCHY'S STRESS THEORY FOR MANIFOLDS

Let $\pi:W\to\mathcal{U}$ be a vector bundle over the m-dimensional orientable manifold $\mathcal{U}$. The vector bundle is interpreted as the bundle of generalized velocities over $\mathcal{U}$. In classical continuum mechanics, if $\mathcal{U}$ is interpreted as the physical space (a slice of space–time), then in many cases W is the tangent bundle $T\mathcal{U}$. If $\mathcal{U}$ is interpreted as the material body, then W is usually the pull-back of the tangent bundle of the space manifold under the configuration mapping that embeds the material universe in space. This is the interpretation used in previous works (e.g., Refs. 7 and 8). In either case, a section of the bundle π is interpreted as a generalized velocity field from either the Eulerian or the Lagrangian points of view.

Cauchy's stress theory for manifolds, presented in Ref. 8, considers for each compact m-dimensional submanifold with boundary $\mathcal{R}$ of $\mathcal{U}$ a linear functional of the generalized velocity fields containing a volume term and a boundary term of the form

$$F_{\mathcal{R}}(w)=\int_{\mathcal{R}}\mathbf{b}_{\mathcal{R}}(w)+\int_{\partial\mathcal{R}}\mathbf{t}_{\mathcal{R}}(w).$$

Here, w is a section of W, $\mathbf{b}_{\mathcal{R}}$, the *body force*, is a section of $L(W,\Lambda^m(T^*\mathcal{R}))$ and $\mathbf{t}_{\mathcal{R}}$ the *boundary force* is a section of $L(W,\Lambda^{m-1}(T^*\partial\mathcal{R}))$ so the integrals make sense. The functional $F_{\mathcal{R}}$ is interpreted as the force, or power, functional and the value $F_{\mathcal{R}}(w)$ is classically interpreted as the power of the force for the generalized velocity field w.

We note that body forces and surface forces may be regarded as covector valued forms. For example, a surface force $\mathbf{t}_{\mathcal{R}}$ may be identified with a section $\hat{\mathbf{t}}_{\mathcal{R}}$ of $\Lambda^{m-1}(T(\partial\mathcal{R}),W^*)$ by

$$\hat{\mathbf{t}}_{\mathcal{R}}(v_1,\ldots,v_{m-1})(w)=\mathbf{t}_{\mathcal{R}}(w)(v_1,\ldots,v_{m-1}),$$

so we have an isomorphism of $\Lambda^{m-1}(T\partial\mathcal{R},W^*)$ with $L(W,\Lambda^{m-1}(T^*\partial\mathcal{R}))$.

The Cauchy postulates for forces are analogous to those pertaining to the scalar valued properties. The body term, $\mathbf{b}_{\mathcal{R}}$, is assumed to be independent of $\mathcal{R}$ (and is omitted in the space–time formulation anyhow). The local dependence on the tangent hyperplane is now provided by a section

$$\Sigma: G_{m-1}(T\mathcal{U}) \to L(\pi_G^*(W), \overset{m-1}{\Lambda}(G_{m-1}(T\mathcal{U}))^*),$$

where $\pi_G^*(W)$ is the pull-back of the vector bundle W by the projection of the Grassmann bundle onto $G_{m-1}(T\mathcal{U})$ (see diagram):

$$\begin{array}{ccccc} \pi_G^*(W) & \xrightarrow{\pi_G^*(\pi)} & G_{m-1}(T\mathcal{U}) & \longleftarrow & \Lambda^{m-1}(G_{m-1}(T\mathcal{U}))^* \\ \uparrow & & \downarrow{\scriptstyle \pi_G} & & \\ W & \xrightarrow{\pi} & \mathcal{U} & & \end{array} .$$

The boundedness postulate, the analog of GC1, requires that there is a section S of the bundle of linear mappings $L(J^1(W), \Lambda^m(T^*\mathcal{U}))$ such that

$$|F_{\mathcal{R}}(w)| = \left| \int_{\mathcal{R}} \mathbf{b}(w) + \int_{\partial\mathcal{R}} \mathbf{t}_{\mathcal{R}}(w) \right| \leqslant \int_{\mathcal{R}} |S(j^1(w))|.$$

Here, $J^1(W)$ is the first jet bundle of W, $j^1(w)$ is the first jet of the section w, and the absolute value of an m-form θ, $S(j^1(w))$, in this case, is given as

$$|\theta(x)| = \begin{cases} \theta(x) & \text{if } \theta(x) \text{ is positively oriented,} \\ -\theta(x) & \text{if } \theta(x) \text{ is negatively oriented,} \end{cases}$$

relatively to the orientation chosen on $\mathcal{U}$.

The resulting generalized version of Cauchy's theorem states that there is a unique section σ of $\Lambda^{m-1}(T\mathcal{U}, W^*) \cong L(W, \Lambda^{m-1}(T^*\mathcal{U}))$, called the *Cauchy stress*, such that $\mathbf{t}_{\mathcal{R}}(w) = \iota^*(\sigma \circ w)$. We will write $\sigma(w)$ for $\sigma \circ w$ and $\iota^*(\sigma)$ for $\iota^* \circ \sigma$ so we have the *Cauchy formula* $\mathbf{t}_{\mathcal{R}} = \iota^*(\sigma)$ in analogy with the scalar case (with the difference that the forms are vector valued now).

Using Stokes' theorem, the action of $F_{\mathcal{R}}$ may now be rewritten using an integral over $\mathcal{R}$ of $\mathcal{R}$-independent forms and without a boundary term as

$$F_{\mathcal{R}}(w) = \int_{\mathcal{R}} (d\sigma(w) + \mathbf{b}(w)).$$

Assume that (x^i, w^α) are local vector bundle coordinates in a neighborhood $\pi^{-1}(U) \subset W$, $U \subset \mathcal{U}$ with local basis elements $\{e_\alpha\}$ so a section of W is represented locally by $w^\alpha e_\alpha$. Then, denoting the dual base vectors by $\{e^\alpha\}$ a stress σ is represented locally by

$$\sigma_{\alpha 1 \ldots \hat{k} \ldots m} e^\alpha \otimes dx^1 \wedge \cdots \wedge \widehat{dx^k} \wedge \cdots \wedge dx^m,$$

where a "hat" indicates the omission of an item (an index or a factor). The value of $\sigma(w)$ is represented locally by

$$\sigma_{\alpha 1 \ldots \hat{k} \ldots m} w^\alpha dx^1 \wedge \cdots \wedge \widehat{dx^k} \wedge \cdots \wedge dx^m.$$

V. VARIATIONAL STRESSES

Let $\pi: W \to \mathcal{U}$ be a vector bundle as in the previous section. A *variational stress density* is a section of $L(J^1(W), \Lambda^m(T^*\mathcal{U}))$.

For the vector bundle coordinates $(x^i,w^\alpha), i=1,\ldots,m,\ \alpha=1,\ldots,\dim(W_x)$, the jet of a section is represented locally by the functions $\{w^\alpha(x^i),w^\beta_{,j}(x^k)\}$, where a subscript following a comma indicates partial differentiation. A variational stress density will be represented locally by the functions $\{S_{\alpha 1\ldots m},S^j_{\beta 1\ldots m}\}$ so that the single component of the m-form $S(j^1(w))$ in this coordinate system is

$$S(j^1(w))_{1\ldots m}=S_{\alpha 1\ldots m}w^\alpha+S^j_{\beta 1\ldots m}w^\beta_{,j}.$$

Note that the notation distinguishes between the components of S that are dual to the values of the section and those dual to the derivatives by the number of indices only. The next few paragraphs motivate the introduction of variational stress densities.

Variational stress theory is formulated usually in a particular frame where the space $(m-1)$-dimensional manifold $\mathcal{M}$ is a global slice of space–time and $\mathcal{U}$ is interpreted as the $(m-1)$-dimensional material universe manifold. In such a situation, for any body $\mathcal{R}$—an $(m-1)$-dimensional compact submanifold with boundary of $\mathcal{U}$—one may consider *configurations* of the body in space defined as embeddings of $\mathcal{R}$ in $\mathcal{M}$.

The rationale behind the variational formulation of stress theory is the framework for mechanical theories where a configuration manifold is constructed for the system under consideration, generalized velocities are defined as elements of the tangent bundle to the configuration manifold, and generalized forces are defined as elements of the cotangent bundle of the configuration space. For the mechanics of continuous bodies in space, the natural topology for the collection of embeddings is the C^1 topology for which the collection of embeddings is open in the collection of all C^1 mappings of the body into space. Using this topology, the tangent space to the configuration manifold at the configuration $\kappa:\mathcal{R}\to\mathcal{M}$ is $C^1(\kappa^*(T\mathcal{M}))$, the Banachable space of C^1 sections of the pull-back $\kappa^*(T\mathcal{M})$. Thus, forces in continuum mechanics are elements of $C^1(\kappa^*(T\mathcal{M}))^*$—continuous, linear functionals on the space of differentiable vector fields equipped with the C^1 topology.

The basic representation theorem (see Ref. 7) states that a force functional $F\in C^1(\kappa^*(T\mathcal{M}))^*$ may be represented by a measure on $\mathcal{U}$—the *variational stress measure*—valued in $J^1(\kappa^*(T\mathcal{M}))^*$, the dual of the first jet bundle $J^1(\kappa^*(T\mathcal{M}))\to\mathcal{U}$. The evaluation of a force $F_\mathcal{R}$ on the generalized velocity w is

$$F_\mathcal{R}(w)=\int_\mathcal{R} d\boldsymbol{\mu}(j^1(w)),$$

where $\boldsymbol{\mu}$ is the $J^1(\kappa^*T\mathcal{M})^*$-valued measure—a section Schwartz distribution.

Assuming that κ is defined on all the material universe $\mathcal{U}$, we use the notation W for $\kappa^*(T\mathcal{M})$. This vector bundle can be restricted to the individual bodies, and, with some abuse of notation, we use the same notation for both the bundle and its restrictions to the individual bodies.

In the smooth case, a variational stress measure is given in terms of a section S of $L(J^1(W),\Lambda^{m-1}(T^*\mathcal{U}))$ (recalling the $\mathcal{U}$ is now the material manifold with dimension $m-1$) so

$$F_\mathcal{R}(w)=\int_\mathcal{R} S(j^1(w)).$$

Since in the sequel we consider only the smooth case, we will use ''variational stresses'' to refer to the densities.

VI. THE RELATION BETWEEN THE CAUCHY APPROACH AND THE VARIATIONAL APPROACH

In Ref. 11 we define a canonical mapping

$$p_\sigma : L(J^1(W), \overset{m}{\Lambda}(T^*\mathcal{U})) \to L(W, \overset{m-1}{\Lambda}(T^*\mathcal{U}))$$

that assigns to a variational stress density S a Cauchy stress σ satisfying the following relation. At every $x \in \mathcal{U}$ (we suppress the evaluation at x in the notation)

$$\phi \wedge \sigma(w) = S(j_{\phi \otimes w}),$$

for any one-form ϕ. Here, $j_{\phi\otimes w}$ is roughly the jet at x of a section whose value is $0 \in W_x$ and its derivative is $\phi \otimes w$. More precisely, if $u : \mathcal{U} \to W$ is the section whose first jet at x is $j_{\phi\otimes w}$, then u satisfies the following conditions: $u(x)=0$; denoting the zero section of W by 0, $T_x u - T_x 0 \in L(T_x\mathcal{U}, T_{0(x)}W_x)$ induces the linear mapping $\phi \otimes w$ through the isomorphism of $T_{0(x)}W_x$ with W_x. The local representation of p_σ is as follows. If $\sigma = p_\sigma(S)$, then, using the local representatives of σ and S as in the previous sections,

$$\sigma_{\beta 1 \ldots \hat{\imath} \ldots m} = (-1)^{i-1} S^{+i}{}_{\beta 1 \ldots m}, \quad \text{(no sum over } i\text{)}.$$

The mapping p_σ is clearly linear and surjective.

Given a variational stress density S, its generalized divergence Div S is the section of $L(W, \Lambda^m(T^*\mathcal{U}))$ defined by

$$\mathrm{Div}\, S(w) = d(p_\sigma(S)(w)) - S(J^1(w)).$$

The local expression for $\mathrm{Div}\, S(w)$ is

$$(S^i_{\alpha 1 \ldots m, i} - S_{\alpha 1 \ldots m}) w^\alpha dx^1 \wedge \cdots \wedge dx^m,$$

which shows that Div S depends only on the values of w and not its derivative. With these definitions one obtains that

$$\int_{\mathcal{R}} S(j^1(w)) = \int_{\mathcal{R}} \mathbf{b}_{\mathcal{R}}(w) + \int_{\partial\mathcal{R}} \mathbf{t}_{\mathcal{R}}(w),$$

where $\mathbf{t}_{\mathcal{R}}(w) = \iota^*_{\mathcal{R}}(p_\sigma(S)(w))$ and $\mathrm{Div}\, S + \mathbf{b}_{\mathcal{R}} = 0$. We conclude that every variational stress induces a unique force system $\{(\mathbf{b}_{\mathcal{R}}, \mathbf{t}_{\mathcal{R}})\}$ through the Cauchy stress it induces and its divergence. Actually, we obtained a decomposition of $S(j^1(w))$ into an exact differential and a term that is linear in the values of w.

The converse is also true. If we have a force system that satisfies Cauchy's postulates, then the induced Cauchy stress enables us to define a section S of $L(J^1(W), \Lambda^m(T^*\mathcal{U}))$ by $S(j^1(w)) = \mathbf{b}(w) + d\sigma(w)$. Clearly, writing the local expression for S, it is linear in the jet of w. Hence,

$$F_{\mathcal{R}}(w) = \int_{\mathcal{R}} \mathbf{b}(w) + \int_{\mathcal{R}} d\sigma(w) = \int_{\mathcal{R}} S(j^1(w)).$$

If for a given variational stress $\mathbf{b} = \mathrm{Div}\, S = 0$, then, $S(j^1(w)) = dp_\sigma(S)(w)$.

Thus, we have a complete correspondence between the Cauchy approach and the variational approach to stress theory.

VII. STRESS-ENERGY TENSORS

Following the interpretation of the flux form J as an object generalizing the velocity vector field, we may consider stress theory on space–time $\mathcal{U}$ where we set $W=\Lambda^{m-1}(T^*\mathcal{U})$. To emphasize this we may write

$$F_{\mathcal{R}}(J)=\int_{\partial\mathcal{R}}\mathbf{t}_{\mathcal{R}}(J).$$

Here, the boundary term $\mathbf{t}_{\mathcal{R}}$ is a section of $L(\Lambda^{m-1}(T^*\mathcal{U}),\Lambda^{m-1}(T^*\partial\mathcal{R}))$. Note that for the space–time formulation the term involving $\mathbf{b}_{\mathcal{R}}$ is omitted. Assuming that the generalized Cauchy postulates hold for $\mathbf{t}_{\mathcal{R}}$, the Cauchy stress σ is a section of $L(\Lambda^{m-1}(T^*\mathcal{U}),\Lambda^{m-1}(T^*\mathcal{U}))$. Finally, $\mathrm{Div}\,S=0$ and $d\sigma(J)=S(j^1(J))$.

The situation may be described generally as follows. We started with an extensive property p, given in terms of the flux densities $\tau_{\mathcal{R}}$ for the various control regions $\mathcal{R}$ in space–time. The source term for property p is s and, assuming the Cauchy postulates are satisfied, the property p has a flux form J. We now consider a second property, the q property, whose flux densities $\tau_{\mathcal{R}}^{(q)}$ for the various control regions and source term $s^{(q)}$ satisfy the conservation equation

$$\int_{\partial\mathcal{R}}\tau_{\mathcal{R}}^{(q)}=\int_{\mathcal{R}}s^{(q)}.$$

Again, assuming the Cauchy postulates hold for the property q, we have the corresponding flux form $J^{(q)}$ satisfying $\tau_{\mathcal{R}}^{(q)}=\iota^*(J^{(q)})$ and the conservation equation has the differential representation $dJ^{(q)}=s^{(q)}$.

We will say that the property q is a *resource* for the property p if the flux density $\tau_{\mathcal{R}}^{(q)}$ depends pointwise linearly on the flux form J of the property p. Thus, there is a section $\mathbf{t}_{\mathcal{R}}$ as above such that $\tau_{\mathcal{R}}^{(q)}=\mathbf{t}_{\mathcal{R}}(J)$.

In this framework, the Cauchy theorem implies that

$$\iota^*(J^{(q)})=\tau_{\mathcal{R}}^{(q)}=\mathbf{t}_{\mathcal{R}}(J)=\iota^*(\sigma(J)),$$

for the inclusion ι of an arbitrary region, so $J^{(q)}=\sigma(J)$. In other words, the Cauchy stress transforms the flux of the property p to the flux of the resource that p uses—the property q. The source term for the property q is now given by $s^{(q)}=d\sigma(J)$.

Naturally, in the sequel we will be concerned primarily with the energy resource.

VIII. REPRESENTATIONS OF FORCE DENSITIES AND STRESS-ENERGY TENSORS

For the situation under consideration a force density (the analog of $\mathbf{b}_{\mathcal{R}}$ if considered) is given in terms of a section of $L(\Lambda^{m-1}W^*,\Lambda^mW^*)$. Such sections have simple representations as follows.

For a vector space $\mathbf{W}$ with dimension m, consider the space of linear mappings $(\Lambda^p\mathbf{W}^*)^{\mathrm{T}}=L(\Lambda^p\mathbf{W}^*,\Lambda^m\mathbf{W}^*)$. Define the mapping $\wedge^p:\Lambda^{m-p}\mathbf{W}^*\to(\Lambda^p\mathbf{W}^*)^{\mathrm{T}}$ by $\wedge^p(\alpha)(\beta)=\alpha\wedge\beta$.

Clearly $\wedge^p$ is a linear mapping between the two spaces. In addition, as $\Lambda^m\mathbf{W}^*$ is one-dimensional, $\dim(\Lambda^p\mathbf{W}^*)^{\mathrm{T}}=\dim(\Lambda^p\mathbf{W}^*)=\dim(\Lambda^{m-p}\mathbf{W}^*)$. Thus, $\wedge^p$ is an isomorphism if $\mathrm{Kernel}(\wedge^p)=\{0\}$. It is clear, however, that if $\wedge^p(\alpha)(\beta)=\alpha\wedge\beta=0$ for all β, then $\alpha=0$.

We may conclude, for example, that a body force density is of the form $A\wedge J$ for a one-form A.

As the stress-energy tensor is now a section of $L(\Lambda^{m-1}(T^*\mathcal{U}),\Lambda^{m-1}(T^*\mathcal{U}))$, it is locally represented by a matrix with respect to a local basis of $\Lambda^{m-1}(T^*\mathcal{U})$. We will make below some further observations regarding the representations of stresses.

Assume that a volume element θ is given on $\mathcal{U}$. Then, we may use the vector bundle isomorphism

$$i_\theta\colon \overset{m-1}{\Lambda}(T^*\mathcal{U})\to T\mathcal{U}$$

to represent the section σ of $L(\Lambda^{m-1}(T^*\mathcal{U}),\Lambda^{m-1}(T^*\mathcal{U}))$ by a section $\tilde{\sigma}$ of $L(T\mathcal{U},T\mathcal{U})$ satisfying $\tilde{\sigma}\circ i_\theta = i_\theta\circ\sigma$.

Let us consider the relation between the local representation of σ and the local representation $\tilde{\sigma}_i^j dx^i\otimes \partial/\partial x^j$ of $\tilde{\sigma}$. To represent σ locally, we will use the notation $\hat{e}^i$ for the basis element $dx^1\wedge\cdots\wedge\widehat{dx^i}\wedge\cdots\wedge dx^m$ of $\Lambda^{m-1}(T^*\mathcal{U})$. Thus, the flux form J is represented locally by $\hat{J}_i\hat{e}^i$, and the stress is represented locally in the form $\hat{\sigma}_i^j\hat{e}_j\otimes\hat{e}^i$, where $\{\hat{e}_j\}$ is the dual basis to $\{\hat{e}^i\}$.

If the volume element θ is represented locally by $r dx^1\wedge\cdots\wedge dx^m$, the action of i_θ is given locally by

$$\hat{J}_i\hat{e}^i \mapsto \sum_i (-1)^{i+1}\frac{1}{r}\hat{J}_i\frac{\partial}{\partial x^i}$$

(we use the summation symbol as the summation convention cannot be used on the right). Thus, $i_\theta(\sigma(J))$ is represented by

$$\sum_j (-1)^{j+1}\frac{1}{r}\hat{\sigma}_j^i\hat{J}_i\frac{\partial}{\partial x^j},$$

and $\tilde{\sigma}(i_\theta(J))$ is represented by

$$\sum_i (-1)^{i+1}\frac{1}{r}\tilde{\sigma}_i^j\hat{J}_i\frac{\partial}{\partial x^j}.$$

Hence, the relation between σ and $\tilde{\sigma}$ is represented locally as

$$\tilde{\sigma}_k^j = (-1)^{j+k}\hat{\sigma}_j^k.$$

It is interesting to note that the volume element does not enter the last relation and one may attempt to arrive at a natural isomorphism between the bundles $L(\Lambda^{m-1}(T^*\mathcal{U}),\Lambda^{m-1}(T^*\mathcal{U}))$ and $L(T\mathcal{U},T\mathcal{U})$. Such a natural isomorphism can be constructed as follows. Consider the tensor product $T^*\mathcal{U}\otimes_{\mathcal{U}}T\mathcal{U}$. This tensor product is naturally isomorphic to $L(T\mathcal{U},T\mathcal{U})$. For an element $\tilde{\sigma}=\tilde{\sigma}_i^j\phi^i\otimes v_j$ in $T^*\mathcal{U}\otimes_{\mathcal{U}}T\mathcal{U}$, $v_j\in T_x\mathcal{U}$, $\phi^i\in T_x^*\mathcal{U}$, set

$$\sigma\colon \overset{m-1}{\Lambda}(T^*\mathcal{U})\to \overset{m-1}{\Lambda}(T^*\mathcal{U})$$

by

$$(*)\qquad \sigma(J)=\tilde{\sigma}_i^j v_j\lrcorner(\phi^i\wedge J)=\tilde{\sigma}_i^j(\phi^i(v_j)J-\phi^i\wedge(v_j\lrcorner J)).$$

We note that σ is indeed linear in J. Since σ depends linearly on the v^i and on the ϕ^j, it depends linearly on the elements of the tensor product.

For the local coordinates $\{x^i\}$, let us determine the stress σ induced by the linear mapping $\tilde{\sigma}\in L(T\mathcal{U},T\mathcal{U})$ represented locally by the tensor $\tilde{\sigma}_i^j dx^i\otimes\partial/\partial x^j$. By definition, $\sigma(J)$ is represented by (the sum on i is explicitly written)

$$\sum_i \tilde{\sigma}_i^j \frac{\partial}{\partial x^j} \lrcorner (dx^i \wedge J) = \sum_i \tilde{\sigma}_i^j \frac{\partial}{\partial x^j} \lrcorner (dx^i \wedge (\hat{J}_k dx^1 \wedge \cdots \wedge \widehat{dx^k} \wedge \cdots \wedge dx^m))$$

$$= \sum_i \tilde{\sigma}_i^j \frac{\partial}{\partial x^j} \lrcorner ((-1)^{i+1} \hat{J}_i dx^1 \wedge \cdots \wedge dx^m)$$

$$= \sum_i \tilde{\sigma}_i^j (-1)^{i+j} \hat{J}_i dx^1 \wedge \cdots \wedge \widehat{dx^j} \wedge \cdots \wedge dx^m$$

$$= \sum_i \tilde{\sigma}_i^j (-1)^{i+j} \hat{J}_i \hat{e}^j = \sum_i \hat{\sigma}_j^i \hat{J}_i \hat{e}^j.$$

Hence, the matrix representing σ is $\hat{\sigma}_j^i = (-1)^{i+j} \tilde{\sigma}_i^j$. We conclude that $(*)$ is indeed the natural, invariant representation of the isomorphism between the bundles $L(\Lambda^{m-1}(T^*\mathcal{U}), \Lambda^{m-1}(T^*\mathcal{U}))$ and $L(T\mathcal{U}, T\mathcal{U})$. This motivates even further the interpretation of the Cauchy stress as a transformation operating on the flux or velocity field of the property p to give the flux form for the energy or velocity of the generalized energy points.

IX. EXAMPLE: THE MAXWELL STRESS-ENERGY TENSOR WITHOUT A METRIC

As an example for the foregoing analysis, we consider a generalization of the stress-energy tensor of classical electromagnetism to the setting where a metric is not available. We assume that there is a volume element on the four-dimensional $\mathcal{U}$. The following setting is also independent of any relation between the Maxwell two-form and the Faraday two-form such as the relations between the fields (**E**, **B**) and (**D**, **H**) in vacuum. The extensive property under consideration is of course the electric charge and J is the charge-current density—a three-form. The conservation of charge implies that $dJ = 0$ and the Maxwell two-form $\mathfrak{g}$ is a flow potential for the flux form so $J = d\mathfrak{g}$. For a one-form A, the vector potential, the energy source density is $A \wedge J$. It follows that the Faraday two-form $\mathfrak{f} = dA$ satisfies $d\mathfrak{f} = 0$.

Thus, assuming that a volume element θ is given on $\mathcal{U}$, we set $w = i_\theta(J)$ and define the stress-energy tensor as the section σ of $L(\Lambda^{m-1}(T^*\mathcal{U}), \Lambda^{m-1}(T^*\mathcal{U}))$ by (cf. Ref. 12, p. 36 for the closest expression we found)

$$\sigma(J) = (i_\theta(J) \lrcorner \mathfrak{g}) \wedge \mathfrak{f} - (i_\theta(J) \lrcorner \mathfrak{f}) \wedge \mathfrak{g}.$$

Alternatively, using

$$w \lrcorner (\mathfrak{g} \wedge \mathfrak{f}) = (w \lrcorner \mathfrak{g}) \wedge \mathfrak{f} + \mathfrak{g} \wedge (w \lrcorner \mathfrak{f}),$$

the definition of the electromagnetic stress-energy tensor may also be written as

$$\sigma(J) = i_\theta(J) \lrcorner (\mathfrak{g} \wedge \mathfrak{f}) - 2(i_\theta(J) \lrcorner \mathfrak{f}) \wedge \mathfrak{g}.$$

Note that the matrix of the Cauchy stress with respect to the natural basis of the space of $(m-1)$-forms is related to the usual matrix of the stress-energy-momentum tensor as discussed in the previous section.

We now consider the energy source term $d\sigma(J)$. Using $w = i_\theta(J)$ one obtains

$$d\sigma(J) = d((i_\theta(J) \lrcorner \mathfrak{g}) \wedge \mathfrak{f} - (i_\theta(J) \lrcorner \mathfrak{f}) \wedge \mathfrak{g})$$

$$= d(w \lrcorner \mathfrak{g}) \wedge \mathfrak{f} - (w \lrcorner \mathfrak{g}) \wedge d\mathfrak{f} + (w \lrcorner \mathfrak{f}) \wedge d\mathfrak{g} - d(w \lrcorner \mathfrak{f}) \wedge \mathfrak{g}$$

$$= d(w \lrcorner \mathfrak{g}) \wedge \mathfrak{f} + (w \lrcorner \mathfrak{f}) \wedge J - d(w \lrcorner \mathfrak{f}) \wedge \mathfrak{g},$$

where Maxwell's equations were used to arrive at the last line. Using the identity $d(w \lrcorner \alpha) = \mathcal{L}_w \alpha - w \lrcorner d\alpha$, for any differential form α, we have

$$d\sigma(J)=(w\lrcorner\mathfrak{f})\wedge J+(\mathcal{L}_w\mathfrak{g}-u\lrcorner d\mathfrak{g})\wedge\mathfrak{f}-(\mathcal{L}_w\mathfrak{f}-w\lrcorner d\mathfrak{f})\wedge\mathfrak{g}.$$

Finally, as $w\lrcorner J=0$, Maxwell's equations give

$$d\sigma(J)=(w\lrcorner\mathfrak{f})\wedge J+(\mathcal{L}_w\mathfrak{g})\wedge\mathfrak{f}-(\mathcal{L}_w\mathfrak{f})\wedge\mathfrak{g}.$$

It is noted that the term $(w\lrcorner\mathfrak{f})\wedge J$ represents the power of the Lorentz force. In addition, in the classical formulation where a metric is available and $\mathfrak{g}=*\mathfrak{f}$ ($*$ denotes the Hodge operator), the terms $(\mathcal{L}_w\mathfrak{g})\wedge\mathfrak{f}$ and $(\mathcal{L}_w\mathfrak{f})\wedge\mathfrak{g}$ are equal and the energy source density contains the power of the Lorentz force (and energy conservation) only. For an analogous expression where the constitutive relation between $\mathfrak{g}$ and $\mathfrak{f}$ is not specified but a metric is used, see Ref. 2, p. 91.

ACKNOWLEDGMENT

The author would like to thank Professor R. Tucker for the useful discussions.

APPENDIX: LOCAL REPRESENTATION OF THE MAXWELL STRESS-ENERGY TENSOR

We write the local representation $\hat{\mathfrak{f}}_{ij}dx^i\wedge dx^j$ of the Faraday two-form $\mathfrak{f}$ in the form

$$\{\hat{\mathfrak{f}}_{ij}\}=\begin{pmatrix}0&-E_1&-E_2&-E_3\\E_1&0&B_3&-B_2\\E_2&-B_3&0&B_1\\E_3&B_2&-B_1&0\end{pmatrix},$$

and the corresponding representation $\hat{\mathfrak{g}}_{ij}dx^i\wedge dx^j$ for the Maxwell two-form as

$$\{\hat{\mathfrak{g}}_{ij}\}=\begin{pmatrix}0&H_1&H_2&H_3\\-H_1&0&D_3&-D_2\\-H_2&-D_3&0&D_1\\-H_3&D_2&-D_1&0\end{pmatrix}.$$

For simplicity of the notation we assume that locally the volume element θ is of the form $dx^1\wedge\ \cdots\wedge dx^4$. Then, $w=i_\theta(J)$ is represented by $w^i=(-1)^{i+1}\hat{J}_i$. With this notation, the matrix $\{\hat{\sigma}_i^j\}$ representing the stress-energy tensor is

$$\{\hat{\sigma}_i^j\}=\begin{pmatrix}\{\hat{\sigma}_i^1\}&\{\hat{\sigma}_i^2\}&\{\hat{\sigma}_i^3\}&\{\hat{\sigma}_i^4\}\end{pmatrix},$$

where

$$\hat{\sigma}_i^1=\begin{Bmatrix}H_1B_1+H_2B_2+H_3B_3+D_1E_1+D_2E_2+E_3D_3\\2(E_3H_2-E_2H_3)\\2(E_3H_1-E_1H_3)\\2(E_2H_1-E_1H_2)\end{Bmatrix},$$

$$\hat{\sigma}_i^2=\begin{Bmatrix}2(B_3D_2-B_2D_3)\\H_1B_1-H_2B_2-H_3B_3+E_1D_1-E_2D_2-E_3D_3\\2(E_1D_2-B_2H_1)\\2(E_1D_3+B_3H_1)\end{Bmatrix},$$

$$\hat{\sigma}_i^3=\begin{Bmatrix} 2(B_3D_1-B_1D_3) \\ 2(B_1H_2-E_2D_1) \\ -H_1B_1+H_2B_2-H_3B_3-E_1D_1+E_2D_2-E_3D_3 \\ 2(-E_2D_3-B_3H_2) \end{Bmatrix},$$

$$\hat{\sigma}_i^4=\begin{Bmatrix} 2(B_2D_1-B_1D_2) \\ 2(B_1H_3-E_3D_1) \\ 2(-E_3D_2-B_2H_3) \\ -H_1B_1-H_2B_2+H_3B_3-E_1D_1-E_2D_2+E_3D_3 \end{Bmatrix}.$$

I. INTRODUCTION

Production of nuclear energy relies on the disintegration of atoms (uranium or plutonium), when subjected to collisions with neutrons. Therefore, reactor design requires an accurate description of the motion of the population of neutrons. The motion of neutrons is described through the evolution of the density $f(t,x,v)$ of neutrons occupying at time $t \geqslant 0$ the position $x \in \mathbb{R}^N$ and having velocity $v \in \mathbb{R}^N$. It will be convenient in what follows to see this last variable as $v = \sqrt{2e/m}\ \omega$, $m>0$ being the mass of the neutron, $e \geqslant 0$ its energy, and $\omega \in S^{N-1}$ the direction of the flight. The unknown f verifies a transport equation

$$\partial_t f + v \cdot \nabla_x f = Q(f) \tag{1}$$

that relates the free transport (left-hand side) to the various interaction processes undergone by the neutrons and described through the operator $Q(f)$. The latter are essentially collisions. Furthermore, the number of neutrons in any volume, at any time, remains smaller than the number of atomic nuclei (10^{11} is a typical ratio) so that it is reasonable to assume that the most probable event is an elastic collision with the surrounding medium. Consequently, the right-hand side of (1) is usually given by a Boltzmann linear operator

$$Q(f) = \int \sigma(x,v,v')\ \ f(t,x,v')\, \mathrm{d}v' - \Sigma(x,v)\ \ f(t,x,v). \tag{2}$$

The transfer function $\sigma(x,v,v') \geqslant 0$ is such that $\sigma(x,v,v')\mathrm{d}v$ represents the probability that a neutron impinging with velocity v' will have velocity in the volume $\mathrm{d}v$ around v after the collision; while $\Sigma(x,v) \geqslant 0$ is the so-called removal cross section. If the operator is conservative, i.e., $\int Q(f)\, \mathrm{d}v = 0$, which means that $\Sigma(x,v) = \int \sigma(x,v',v)\, \mathrm{d}v'$, then absorption/fission events are neglected or compensated with scattering. One also says that the reactor is critical in this case. It is worth remarking that, since the ratio of the mass of the nuclei to the mass of the neutrons is very large, then, during an elastic collision, the energy of the neutron is practically unchanged; the main effect of such a collision is only to modify the direction of the flight. Notice also that inelastic scattering, with loss of energy, remains possible, but it can only occur for highly energetic neutrons.

[b)]Electronic mail: mellet@mip.ups-tlse.fr

On the other hand, nuclear engineers are motivated in the derivation of simplified models that describe the physics accurately enough but remain of moderate computational cost. In these applications, one encounters a very large range of energies, from 1/40 eV to some MeV; and a first simplification arises by breaking the energy range into several disjoint energy groups: $[e_{\min},e_{\max}]=\cup_{i=1}^{I}[e_i,e_{i+1}]$. In most of the situations, the total number of groups I is finite. One assumes that the cross sections do not vary too much on the energy groups and neutrons evolve according to averaged quantities, such as average scattering cross sections. Consequently, one is led to semidiscrete versions of Eqs. (1) and (2). This will be detailed in Sec. II.

Next, a commonly used strategy consists in neglecting the angular variable ω and writing a diffusion equation for a macroscopic energy distribution function $\rho(t,x,e)$, e being the energy variable (discrete or continuous). Actually, one deals in this context with systems of equations, coupled by the energy variable, which usually have the following form:

$$\partial_t\rho(t,x,e)-\mathrm{div}_x(D(x,e)\nabla_x\rho(t,x,e))=\int \tilde{\sigma}(x,e,e')\rho(t,x,e')\,de'-\tilde{\Sigma}(x,e)\rho(t,x,e), \qquad (3)$$

where the coefficients D, $\tilde{\sigma}$, $\tilde{\Sigma}$ are non-negative. Of course, one obtains similar systems in the (energy-)discretized context. These equations can be derived directly from a balance relation on the population of neutrons, through a phenomenological analysis of the scattering events. The diffusion coefficients are due to elastic scattering when neutrons do not lose energy during the collision process. Zeroth-order terms are due to absorption, inelastic scattering (i.e., collisions with loss of energy), or fission. Furthermore, system (3) can be generalized by postulating that the diffusion operator couples the energy levels as follows:

$$\mathrm{div}_x\left(\int k(x,e,e')\ \nabla_x\rho(t,x,e')\,de'\right).$$

Indeed, gradients of the density ρ at a given energy e' can have some effect on the diffusion on another energy level e.

However, it is also tempting to obtain systems like (3) from the kinetic modeling, Eqs. (1) and (2), and to identify the coefficients through an asymptotic analysis. Then, starting from the continuity equation

$$\partial_t\rho+\mathrm{div}_x j=\int_{S^{N-1}}Q(f)\,d\omega \qquad (4)$$

satisfied by the macroscopic density

$$\rho(t,x,e)=\int_{S^{N-1}}f(t,x,\sqrt{2e/m}\,\omega)\,d\omega,$$

and the macroscopic current

$$j(t,x,e)=\int_{S^{N-1}}\sqrt{2e/m}\,\omega\,f(t,x,\sqrt{2e/m}\omega)\,d\omega,$$

we search for a diffusion equation by postulating a relation between ρ and j that takes the form of a generalized Fick's law

$$j(t,x,e)=-\int k(x,e,e')\,\nabla_x\rho(t,x,e')\,de'.$$

Such an approximation is intended to apply in the limit of small mean free paths, which is related to the probability of collisions by unit length and decreases when the density of the medium increases. It leads to singular perturbation problems and this work is devoted to such a question.

For details on the physics of nuclear reactors we refer to the classical books of B. Davison,[17] E. Wigner,[41] E. Wachspress,[40] J. Bussac and P. Reuss,[12] J. Planchard,[37] and C. Cercignani.[15] The mathematical study of the vanishing mean free path limit and of the diffusion approximation is by now a classical problem with applications in various fields of physics; we refer among others to E. Larsen and J. Keller,[32] A. Bensoussan, J.-L. Lions, and G. Papanicolaou,[10] C. Bardos, R. Santos, and R. Sentis,[8] and, for recent progresses, to R. Dautray and J. L. Lions,[16] F. Malvagi, D. Levermore, and G. Pomraning,[35] F. Poupaud,[38] F. Golse,[26] C. Bardos, F. Golse, and B. Perthame,[6] C. Bardos, F. Golse, B. Perthame, and R. Sentis,[7] F. Golse and F. Poupaud,[27] P. L. Lions and G. Toscani,[34] P. Degond, T. Goudon, and F. Poupaud,[20] etc. Another difficulty in reactor physics is related to the high heterogeneity of the surrounding medium. Accordingly, the cross sections depend on the space variable and present very large oscillations. This leads to homogenization questions. Depending on the ordering, the homogenization procedure can be performed at the kinetic level, see F. Golse,[24,25] L. Dumas and F. Golse,[22] P. Gérard and F. Golse[23] or directly on the diffusion approximation as in J. Dorning, R. Uddin, and H. Zhang,[21] Y. Capdeboscq,[13,14] G. Allaire and Y. Capdeboscq,[2] and G. Allaire and F. Malige.[3] We can also combine altogether these effects as in E. Larsen,[30,31] E. Larsen and M. Williams,[33] C. Bardos, L. Dumas, P. Gérard, and F. Golse,[5] G. Allaire and G. Bal,[1] G. Bal,[4] T. Goudon and F. Poupaud,[29] and T. Goudon and A. Mellet.[28]

However, it is a well-known fact that different (formal) methods of approximation can give rise to difference on the limit coefficients, see Ref. 31 or Refs. 37, 1, and 13 for some examples. Furthermore, when starting from multigroup equations and performing the diffusion approximation limit, one usually obtains a single diffusion equation in the space variable only, see Refs. 2 and 13: the limit procedure forgets the multigroup aspect. This is because the system is considered to relax toward an equilibrium under both elastic and inelastic collisions at the same scale. However, it could be interesting to derive more complex models, which retain the energy as a variable and where the diffusion as well as the inelastic collisions couple the various energy levels. This is the goal of the present paper. To that purpose, our analysis is inspired by reasonings developed in the modeling of semiconductor devices where, instead of obtaining a drift-diffusion equation, we are led to an intermediate system, by keeping the energy as a variable, see Ben Abdallah and P. Degond,[9] and P. Degond.[18,19] We also mention the recent application to the phonons dynamics by J. P. Bourgade.[11] These so-called SHE-models have been shown to be very accurate, in particular for numerical simulations. It is worth noticing at the moment that the energy coupling can be obtained either through the zeroth-order terms when the inelastic collisions are treated as perturbations, or through the diffusion operator when inelastic processes are treated in a more intricate way, as it has been done by P. Degond,[19] in the framework of semiconductor theory, for continuous energy levels. However, the analysis developed in the present paper, though largely inspired from Ref. 19, requires less restrictive hypotheses (see in particular Sec. III and Proposition 5). Note that this work is only concerned with the diffusion approximation problem; the homogenization question will be addressed elsewhere. Note also that we have chosen to treat the evolution problem but, of course, our analysis can be applied to eigenvalue problems as well.

The paper is organized as follows. In Sec. II, we will set up precisely the multigroup aspect on the Boltzmann equation. Section III is devoted to a discussion of some properties of the collision operator. In particular, we aim at splitting the Boltzmann operator into an elastic part, which leaves the number of neutrons in a given energy level unchanged, and an inelastic part. This can be done either locally or not as far as the energy variable is concerned. In some sense, the latter retains some relevant information on the energy exchange during the collisions with the medium. In Sec. IV we formally discuss the small mean free path asymptotic limit with the requirement that elastic, or quasielastic, processes dominate. Actually, our method can be viewed as a heuristic procedure to derive macroscopic models, which are intermediate between a full kinetic description and a simple diffusion equation. Finally, Sec. V is concerned with a rigorous proof of convergence.

II. MULTIGROUP EQUATIONS

The evolution of the population of neutrons is described through an equation relating transport to interaction processes as follows:

$$\begin{gathered}(\partial_t + v\cdot\nabla_x)f = Q(f),\\ Q(f) = \frac{1}{|S^{N-1}|}\int_{\mathbb{R}^N}\sigma(x,v,v')f(v')\,\mathrm{d}v' - \Sigma(x,v)f(v),\\ \Sigma(x,v) = \frac{1}{|S^{N-1}|}\int_{\mathbb{R}^N}\sigma(x,v',v)\,\mathrm{d}v'.\end{gathered} \tag{5}$$

The third relation means that the operator Q is conservative, or critical, in the sense that, neglecting integrability questions for the time being, we have

$$\int_{\mathbb{R}^N} Q(f)\,\mathrm{d}v = 0.$$

Compared to Sec. I, we have changed the cross sections by introducing the normalization by $1/|S^{N-1}|$ for pure convenience; it will allow us to work with normalized measure and will simplify some forthcoming computations.

We write the velocity of the particles as follows:

$$\begin{gathered}v = |v|\omega = \sqrt{2e/m}\,\omega,\\ \omega = v/|v| = \text{angular variable} \in S^{N-1},\\ e = mv^2/2 = \text{energy variable} \in \mathbb{R}^+.\end{gathered}$$

Denoting by $\mathrm{d}\omega$ the normalized Euclidian measure on S^{N-1}, we have $\mathrm{d}v = |S^{N-1}|r^{N-1}\mathrm{d}r\,\mathrm{d}\omega$, with $r = |v| = \sqrt{2e/m}$, and therefore $\mathrm{d}r = \mathrm{d}e/\sqrt{2me}$. We deduce the following change of variable formula:

$$\int_{\mathbb{R}^N}\varphi(v)\,\mathrm{d}v = \int_0^\infty |S^{N-1}|\int_{S^{N-1}}\varphi(\sqrt{2e/m}\,\omega)\,(2e/m)^{N/2}\frac{\mathrm{d}e}{2e}\,\mathrm{d}\omega,$$

which applies to any integrable function φ.

Let us discretize the energy levels by introducing the energy step $\varepsilon > 0$ (we point out that ε will remain fixed throughout the paper, and will not tend to zero). We set $E_i = [i\varepsilon,(i+1)\varepsilon[$ and then we consider

$$f_i(t,x,\omega) = \frac{1}{2\varepsilon}\int_{E_i} f(t,x,\sqrt{2e/m}\,\omega)\,(2e/m)^{N/2}\frac{\mathrm{d}e}{2e},$$

which will be a new unknown. Equations for the f_i's are obtained by averaging (5). On the left-hand side, we approach v by $v_i = \sqrt{2i\varepsilon/m}\,\omega$ and the transport term is approximately $(\partial_t + v_i\cdot\nabla_x)f_i$. For the collision term, one has

$$\begin{aligned}&\frac{1}{2\varepsilon}\int_{E_i} Q(f)(t,x,|v|\omega)\,|v|^N\frac{\mathrm{d}e}{2e}\\ &\quad= \frac{1}{2\varepsilon}\int_{E_i}\Bigg(\int_0^\infty\int_{S^{N-1}}\sigma(\sqrt{2e/m}\,\omega,\sqrt{2e'/m}\,\omega')f(\sqrt{2e'/m}\omega')\,(2e'/m)^{N/2}\frac{\mathrm{d}e'}{2e'}\,\mathrm{d}\omega'\\ &\qquad-\int_0^\infty\int_{S^{N-1}}\sigma(\sqrt{2e'/m}\,\omega',\sqrt{2e/m}\,\omega)\,(2e'/m)^{N/2}\frac{\mathrm{d}e'}{2e'}\,\mathrm{d}\omega'\,f(\sqrt{2e/m}\,\omega)\Bigg)\,(2e/m)^{N/2}\frac{\mathrm{d}e}{2e}\end{aligned}$$

$$= \frac{1}{2\varepsilon} \sum_j \int_{E_j} \int_{S^{N-1}} \left(\int_{E_i} \sigma(\sqrt{2e/m}\,\omega, \sqrt{2e'/m}\,\omega') \right.$$
$$\left. \times (2e/m)^{N/2} \frac{de}{2e} \right) f(\sqrt{2e'/m}\,\omega')\,(2e'/m)^{N/2} \frac{de'}{2e'}\,d\omega' - \frac{1}{2\varepsilon} \int_{E_i} f(\sqrt{2e/m}\,\omega)$$
$$\times \left(\sum_j \int_{E_j} \int_{S^{N-1}} \sigma(\sqrt{2e'/m}\,\omega', \sqrt{2e/m}\,\omega)(2e'/m)^{N/2} \frac{de'}{2e'}\,d\omega' \right) (2e/m)^{N/2} \frac{de}{2e}.$$

Then, we suppose that σ does not vary too much as the energy variables (e,e') belong to the set $E_i \times E_j$ and we make the following approximation:

For $e' \in E_j$,

$$\sigma_{ij}(\omega,\omega') \sim \int_{E_i} \sigma(\sqrt{2e/m}\,\omega, \sqrt{2e'/m}\,\omega')(2e/m)^{N/2} \frac{de}{2e},$$

so that $Q(f)$ is replaced by

$$Q(f)_i(\omega) = \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega,\omega') f_j(\omega')\,d\omega' - \Sigma_i(\omega)\, f_i(\omega), \tag{6}$$

where

$$\Sigma_i(\omega) = \sum_j \int_{S^{N-1}} \sigma_{ji}(\omega',\omega)\,d\omega'.$$

These notations lead to the following multigroup kinetic equation:

$$(\partial_t + v_i \cdot \nabla_x) f_i = Q(f)_i. \tag{7}$$

Remark 1: Of course, the subdomains E_i can be defined by using another discretization rule. For instance, one often discretizes the energy range by means of the lethargy $\lambda(e) = \ln(e_{\mathrm{ref}}/e)$ and $E_i = \{e \geqslant 0, \lambda(e) \in [\lambda_i, \lambda_{i+1}[\}$, see Ref. 41.

III. SPLITTING OF THE COLLISION OPERATOR

In this section, we introduce two different splittings of the collision operator into elastic and inelastic parts. Here and in the following "elastic" means that the operator leaves invariant the total number of neutrons on a given energy level. As in Ref. 19, we will see that it is relevant to use a convex combination of these splittings. For convenience, we skip the space dependence, having in mind that the estimates discussed in the following are uniform with respect to x. Besides, we shall only state precisely the assumptions on the cross-sections σ_{ij} and the properties of the collision operators that will be necessary later on; proofs are postponed to the Appendix.

A. First splitting

Let us split the collision operator (6) as follows:

$$Q(f)_i(\omega) = \sum_j \int_{S^{N-1}} (\sigma_{ij}(\omega,\omega') f_j(\omega') - \sigma_{ji}(\omega',\omega) f_i(\omega'))\,d\omega'$$
$$+ \int_{S^{N-1}} \left(\sum_j \sigma_{ji}(\omega',\omega) \right) (f_i(\omega') - f_i(\omega))\,d\omega'. \tag{8}$$

The first operator modifies energy while angle remains unchanged, thus, we refer to it as the inelastic part, denoted by Q_0^{inel}; the second operator modifies the velocity direction while energy is conserved, thus, we call it the elastic part, denoted by Q_0^{el}. Let us set

$$\Gamma_i(\omega',\omega)=\sum_j \sigma_{ji}(\omega',\omega), \quad \Sigma_i(\omega)=\int_{S^{N-1}}\Gamma_i(\omega',\omega)\,\mathrm{d}\omega'$$

then we have

$$Q_0^{\text{el}}(f)_i=\int_{S^{N-1}}\Gamma_i(\omega',\omega)(f_i(\omega')-f_i(\omega))\,\mathrm{d}\omega'=K(f)_i-\Sigma_i f_i.$$

Let us now state the first assumptions concerning the kernel $\sigma_{ij}(\omega,\omega')$:
$(h1)$ First symmetry assumption: $\Sigma_i(\omega)=\int_{S^{N-1}}\Gamma_i(\omega',\omega)\,\mathrm{d}\omega'=\int_{S^{N-1}}\Gamma_i(\omega,\omega')\,\mathrm{d}\omega'$.
In order to derive the coercivity properties of the operator Q_0^{el}, we also require the following hypothesis:

$$(h2)\quad \begin{cases} \text{There exists a sequence of positive reals } (\gamma_i)_{i\in\mathbb{N}} \\ \text{and a constant } M_0 \text{ such that } \gamma_i\leqslant\Gamma_i(\omega',\omega)\leqslant M_0\gamma_i. \end{cases}$$

For technical purposes now, we introduce a sequence $(B_i)_{i\in\mathbb{N}}$ of positive numbers, satisfying:
$(h3)$ Weight assumption: $(B_i)_{i\in\mathbb{N}}$ is such that $\Sigma_i B_i\gamma_i=M_1<\infty$
(it is easy to check that such a sequence always exists). Note that $(h2)$ and $(h3)$ yield

$$\sum_i B_i\int_{S^{N-1}}\Sigma_i(\omega)\mathrm{d}\omega\leqslant M_0M_1.$$

It is worth having in mind the following simple example of the isotropic Boltzmann equation, with typically $B_i=e^{-i}$:

$$\sigma_{ij}(\omega,\omega')=c_ic_jB_i, \quad c_iB_i\in\ell^1. \tag{9}$$

This leads to $\Gamma_i(\omega,\omega')=\|cB\|_{\ell^1}c_i$ and (h2) is fulfilled with $M_0=\|cB\|_{\ell^1}^2$, and $\gamma_i=c_i$.

We now introduce the following functional spaces:

$$\mathbb{E}=\left\{f:\mathbb{N}\times S^{N-1}\to\mathbb{R} \text{ such that } \|f\|_{\mathbb{E}}^2=\sum_i \int_{S^{N-1}}|f_i(\omega)|^2\frac{\Sigma_i(\omega)}{B_i}\mathrm{d}\omega<\infty\right\},$$

$$\mathbb{F}=\left\{f:\mathbb{N}\times S^{N-1}\to\mathbb{R} \text{ such that } \|f\|_{\mathbb{F}}^2=\sum_i \int_{S^{N-1}}|f_i(\omega)|^2\frac{1}{\Sigma_i(\omega)B_i}\mathrm{d}\omega<\infty\right\}.$$

We shall identify the space

$$\mathbb{L}=\left\{f:\mathbb{N}\times S^{N-1}\to\mathbb{R} \text{ such that } \|f\|_{\mathbb{L}}^2=\sum_i \int_{S^{N-1}}|f_i(\omega)|^2\frac{1}{B_i}\,\mathrm{d}\omega<\infty\right\}$$

with its dual when equipped with the inner product

$$(f,g)_{\mathbb{L}}=\sum_i \int_{S^{N-1}}f_i(\omega)g_i(\omega)\frac{1}{B_i}\,\mathrm{d}\omega.$$

Consequently, we note that

$$\left|\sum_i \int_{S^{N-1}} f_i(\omega) g_i(\omega) \frac{1}{B_i} \mathrm{d}\omega\right| \leqslant \|f\|_{\mathbb{E}} \|g\|_{\mathbb{F}}$$

for any $f \in \mathbb{E}$, $g \in \mathbb{F}$ and we can identify $\mathbb{F}$ with the dual $\mathbb{E}'$. We are now ready to establish the main properties of the elastic operator Q_0^{el}.

Proposition 1: Assume that $(h1)$ *holds. Then,* $Q_0^{\mathrm{el}} \in \mathcal{L}(\mathbb{E},\mathbb{F})$ *with* $\|Q_0^{\mathrm{el}}(f)\|_{\mathbb{F}} \leqslant 2\|f\|_E$, *and we have*

(i) Conservation property: $\int_{S^{N-1}} Q_0^{\mathrm{el}}(f)_i \mathrm{d}\omega = 0$ *(at least formally; see Remark 3),*

(ii) Dissipativity property: for all f, g *in* $\mathbb{E}$, *we set* $\mathcal{B}_0(f,g) = -\Sigma_i \int_{S_{N-1}} Q_0^{\mathrm{el}}(f)_i g_i B_i^{-1} \mathrm{d}\omega$. *Then,* $\mathcal{B}_0$ *is bilinear continuous on* $\mathbb{E}$ *and satisfies*

$$\mathcal{B}_0(f,f) = 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega',\omega) |f_i(\omega) - f_i(\omega')|^2 \, B_i^{-1} \, \mathrm{d}\omega' \, \mathrm{d}\omega \geqslant 1/2 \|Q_0^{\mathrm{el}}(f)\|_{\mathbb{F}}^2.$$

(iii) The eigenspace $\mathrm{Ker}(Q_0^{\mathrm{el}})$ *is the space* $\mathcal{E}_0$ *of functions in* $\mathbb{E}$ *which do not depend on the angular variable.*

Remark 2: Under Hypothesis $(h2)$, *one remarks that* $\mathcal{E}_0 = \{f : \mathbb{N} \to \mathbb{R}, \ \Sigma_i f_i^2 \gamma_i B_i^{-1} < \infty\}$ *does not reduce to* $\{0\}$. *For instance, with* $(h2)$–$(h3)$ *it contains* $\{f_i = B_i g_i, \ g \in \mathscr{C}^\infty\} \subset \mathcal{E}_0$. *Indeed, for such as* f, *we get*

$$0 \leqslant \sum_i \int_{S^{N-1}} \Sigma_i \, f_i^2 / B_i \, \mathrm{d}\omega = \sum_i \left(g_i^2 \, B_i \int_{S^{N-1}} \Sigma_i \, \mathrm{d}\omega \right) \leqslant M_1 M_0 \|g\|_{\mathscr{C}^\infty}^2 < \infty.$$

When taking into account time and space variable we will work with sequences of functions $f_i(t,x)$ *that satisfy the corresponding integrability condition.*

Remark 3: Assumption $(h3)$ *also implies that* $\mathbb{F}$ *is a subset of integrable functions, for the measure* $\mathrm{d}\omega \otimes \mathrm{d}i$, *where* $\mathrm{d}i$ *is the counting measure on* $\mathbb{N}$, *since one has*

$$\sum_i \int_{S^{N-1}} |g_i| \mathrm{d}\omega \leqslant \left(\sum_i \int_{S^{N-1}} g_i^2 / (B_i \Sigma_i) \mathrm{d}\omega \right)^{1/2} \left(\sum_i \int_{S^{N-1}} B_i \Sigma_i \, \mathrm{d}\omega \right)^{1/2} \leqslant \|g\|_{\mathbb{F}} (M_0 M_1)^{1/2}.$$

A similar conclusion holds for $f \in \mathbb{E}$ *if one assumes*

$$\sum_i \int_{S^{N-1}} B_i / \Sigma_i \, \mathrm{d}\omega < \infty.$$

For (9), this means that $B/c \in \mathscr{C}^1$.

In order to state a coercivity property in a useful setting, we introduce the following norm:

$$N(f) = \sum_i \int_{S^{N-1}} |f_i(\omega)|^2 \, \frac{\gamma_i}{B_i} \, \mathrm{d}\omega.$$

In view of Hypothesis (h2), it is readily seen that $N(f)$ defines an equivalent norm on $\mathbb{E}$. Actually we have

$$N(f)^2 \leqslant \|f\|_{\mathbb{E}}^2 \leqslant M_0 N(f)^2.$$

Corollary 1: Under Hypotheses $(h1)$–$(h3)$, *the following coercivity estimate*

$$\mathcal{B}_0(f,f) \geqslant N^2(f - \langle f \rangle)$$

holds for any $f \in \mathbb{E}$, *where one denotes* $\langle f \rangle_i = \int_{S^{N-1}} f_i(\omega) \mathrm{d}\omega$.

Remark 4: The adjoint operator of Q_0^{el} *reads*

$$Q_0^{\mathrm{el},*}(g)_i=\int_{S^{N-1}}\Gamma_i(\omega,\omega')g_i(\omega')\mathrm{d}\omega'-\Sigma_i(\omega)g_i(\omega)=\int_{S^{N-1}}\Gamma_i(\omega,\omega')(g_i(\omega')-g_i(\omega))\mathrm{d}\omega.$$

B. Second splitting

On the other hand, we can also introduce the following splitting into elastic and inelastic operators:

$$Q(f)_i=Q_1^{\mathrm{el}}(f)_i+Q_1^{\mathrm{inel}}(f)_i$$

with

$$\begin{aligned}Q_1^{\mathrm{el}}(f)_i&=\sum_j\ \int_{S^{N-1}}\sigma_{ij}(\omega,\omega')(f_j(\omega')-f_j(\omega))\mathrm{d}\omega',\\ Q_1^{\mathrm{inel}}(f)_i&=\sum_j\ \left(\int_{S^{N-1}}\sigma_{ij}(\omega,\omega')\mathrm{d}\omega'\,f_j(\omega)\right)-f_i(\omega)\sum_j\ \int_{S^{N-1}}\sigma_{ji}(\omega',\omega)\mathrm{d}\omega'.\end{aligned}\tag{10}$$

The boundedness of Q_1^{el} relies on the following assumption:

$$(h4)\quad\begin{cases}\text{There exists a constant } M_2 \text{ such that}\\ \displaystyle\sum_j\ \int_{S^{N-1}}\sigma_{ij}(\omega,\omega')B_j\,\mathrm{d}\omega'\leqslant M_2\gamma_iB_i\,.\end{cases}$$

It is worth pointing out that this assumption is a straightforward consequence of $(h2)$–$(h3)$, if we assume the following relation, known as the detailed balance principle,

$$\sigma_{ij}(\omega,\omega')B_j=\sigma_{ji}(\omega',\omega)B_i\,.\tag{11}$$

We also need the

$$(h1')\quad\text{Second symmetry condition: }\int_{S^{N-1}}\sigma_{ij}(\omega',\omega)\mathrm{d}\omega'=\int_{S^{N-1}}\sigma_{ij}(\omega,\omega')\mathrm{d}\omega'.$$

Remark that $(\mathrm{h}1')$ is stronger than $(h1)$, and that $(h4)$ as well as $(h2)$ are fulfilled if we assume $\sigma_{ij}\leqslant M\gamma_iB_i\gamma_j$.

Proposition 2: Assume that $(h1')$, $(h2)$, $(h3)$, $(h4)$ *hold. Then,* $Q_1^{\mathrm{el}}\in\mathcal{L}(\mathbb{E},\mathbb{F})$ *with* $\|Q_1^{\mathrm{el}}(f)\|_{\mathbb{F}}\leqslant 2M_2^{1/2}\|f\|_{\mathbb{E}}$, *and we have*

(i) Conservation property: $\int_{S^{N-1}}Q_1^{\mathrm{el}}(f)_i\,\mathrm{d}\omega=0$,

(ii) For all f, g *we set* $\mathcal{B}_1(f,g)=-\Sigma_i\int_{S^{N-1}}Q_1^{\mathrm{el}}(f)_ig_iB_i^{-1}\,\mathrm{d}\omega$. *Then,* $\mathcal{B}_1$ *is bilinear continuous on* $\mathbb{E}$ *and it satisfies*

$$\begin{aligned}\mathcal{B}_1(f,g)=\frac{1}{2}\sum_{i,j}\ &\int_{S^{N-1}}\int_{S^{N-1}}(f_j(\omega')-f_j(\omega))(\sigma_{ij}(\omega',\omega)g_i(\omega')\\ &-\sigma_{ij}(\omega,\omega')g_i(\omega))B_i^{-1}\mathrm{d}\omega'\,\mathrm{d}\omega.\end{aligned}$$

(iii) $\mathcal{E}_0\subset\mathrm{Ker}(Q_1^{\mathrm{el}})$, *and the following estimate holds:*

$$|\mathcal{B}_1(f,f)|\leqslant M_0\sqrt{2M_2}N(f-\langle f\rangle)^2.$$

Of course functions depending only on the energy variable belong to $\mathrm{Ker}(Q_1^{\mathrm{el}})$; however, the kernel of Q_1^{el} contains much more functions. Note that (iii) is slightly sharper than the estimate obtained by using the norm of Q_1^{el}; it can be improved under more restrictive assumptions on the kernels.

Corollary 2: Under the

$$(h1'') \quad \textit{Strong symmetry assumption: } \sigma_{ij}(\omega,\omega') = \sigma_{ij}(\omega',\omega)$$

and

$$(h2'') \quad \sigma_{ij}(\omega,\omega') \leqslant M\gamma_i B_i \gamma_j \quad \textit{with } \sum_i B_i\gamma_i = M_1 < \infty,$$

the operator Q_0^{el} is self-adjoint and, concerning Q_1^{el}, we have

$$\mathcal{B}_1(f,g) = 1/2 \sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} \sigma_{ij}(\omega,\omega')(f_j(\omega') - f_j(\omega))(g_i(\omega') - g_i(\omega)) B_i^{-1} \mathrm{d}\omega' \, \mathrm{d}\omega.$$

As a consequence, if $\langle f \rangle = 0$, then (iii) becomes

$$|\mathcal{B}_1(f,f)| \leqslant M M_1 \, N(f)^2.$$

Remark 5: Notice that $(h1'')$ implies $(h1')$ while $(h2'')$ implies both $(h2)$ and $(h3)$ with $M_0 = M M_1$, and $(h4)$ with $M_2 = M_1$. The bound from below in $(h2)$ is fulfilled if one assumes a similar estimate from below on the σ_{ij}'s.

Remark 6: The previous symmetry conditions are included in

$$\sigma_{ij}(\omega,\omega')B_j = \sigma_{ij}(\omega',\omega)B_j = \sigma_{ji}(\omega',\omega)B_i = \sigma_{ji}(\omega,\omega')B_i, \tag{12}$$

which also implies that Q_1^{el} is self-adjoint. This corresponds to the symmetry assumption used in Ref. 19; *but here we aim at dealing with a larger class of collision kernels.*

Let us go back to the fundamental example (9). Denote $C = \Sigma_i c_i B_i < \infty$. One has in this simple case

$$Q_0^{\mathrm{el}}(f)_i = C c_i (\langle f_i \rangle - f_i),$$
$$Q_1^{\mathrm{el}}(f)_i = c_i B_i \sum_j c_j (\langle f_j \rangle - f_j).$$

Therefore, we get

$$\mathcal{B}_0(f,g) = \sum_{i,j} c_i B_i^{-1} c_j B_j (\langle f_i \rangle \langle g_i \rangle - \langle f_i g_i \rangle),$$
$$\mathcal{B}_1(f,g) = \sum_{i,j} c_i c_j (\langle f_j \rangle \langle g_i \rangle - \langle f_j g_i \rangle).$$

We write $g_i = \langle g_i \rangle + r_i$ where $\langle r_i \rangle = 0$. It yields

$$\mathcal{B}_1(f,g)=\sum_{i,j} c_i c_j(\langle f_j\rangle\langle g_i\rangle-\langle f_j\langle g_i\rangle\rangle-\langle f_j r_i\rangle)$$

$$=-\sum_{i,j} c_i c_j\langle f_j r_i\rangle$$

$$=-\sum_{i,j} c_i c_j\int_{S^{N-1}} f_j r_i\,\mathrm{d}\omega$$

$$=-\int_{S^{N-1}}\left(\sum_j c_j f_j\right)\left(\sum_i c_i r_i\right)\mathrm{d}\omega.$$

If g lies in the orthogonal set of $\mathrm{Ran}(Q_1^{\mathrm{el}})$, we deduce that $\Sigma_i c_i r_i(\omega)$ vanishes for almost all $\omega\in S^{N-1}$.

Remark 7: The adjoint operator of Q_1^{el} is given by

$$Q_1^{\mathrm{el},*}(g)_i=\sum_j \int_{S^{N-1}}\sigma_{ji}(\omega',\omega)(g_j(\omega')-g_j(\omega))\frac{B_i}{B_j}\mathrm{d}\omega'.$$

In particular, we note that, if relation (11) holds, then Q_1^{el} is a self-adjoint operator.

C. Combination of the splitting

From now on, we assume that $(h1')$, $(h2)$, $(h3)$, $(h4)$ hold and we denote by (H) this set of hypotheses. The idea will be to combine Q_1^{el} with Q_0^{el} so that the coercivity of the latter compensates the lack of positivity of the former; we are thus able to preserve the crucial dissipation properties. Let us consider the following elastic operator, obtained as a convex combination of Q_0^{el} and Q_1^{el}; for $\theta\in[0,1]$, we set

$$Q_\theta=\theta Q_1^{\mathrm{el}}+(1-\theta)Q_0^{\mathrm{el}}.$$

One deduces from Corollary 1 and Proposition 2 that

$$\mathcal{B}_\theta(f,f)=-\sum_i \int_{S^{N-1}} Q_\theta(f)_i f_i B_i^{-1}\,\mathrm{d}\omega\geqslant(1-\theta(1+M_0\sqrt{2M_2}))N(f-\langle f\rangle)^2$$

holds for any $f\in\mathbb{E}$. We are thus led to the following statement.

Proposition 3: Let $\theta\in[0,(1+M_0\sqrt{2M_2})^{-1}[$. Then, there exists a constant $\kappa_\theta>0$ such that, for any $f\in\mathbb{E}$, we have

$$\mathcal{B}_\theta(f,f)\geqslant\kappa_\theta N(f-\langle f\rangle)^2.$$

Consequently, the set of equilibria $\mathcal{E}_\theta=\mathrm{Ker}(Q_\theta)$ coincides with $\mathcal{E}_0$ (the set of functions depending only on the energy level). If one assumes $(h1'')$ and $(h2'')$, the domain for θ enlarges to $[0,(1+M_0)^{-1}[$.

One may also establish the following Fredholm alternative.

Proposition 4: For any $h\in\mathbb{F}$ the problem to find $f\in\mathbb{E}$ such that $Q_\theta(f)=h$ has a solution if and only if $\langle h\rangle=0$. The solution is unique in $\mathbb{E}_0=\{f\in\mathbb{E}$ such that $\langle f\rangle=0\}$ and satisfies

$$N(f)\leqslant(1/\sqrt{\kappa_\theta})\|h\|_{\mathbb{F}}.$$

Proof: Since the operator Q_θ is clearly conservative, the condition of null average on the data h is necessary. The problem recasts into the following variational formulation:

$$\forall \varphi \in \mathbb{E}_0, \quad \mathcal{B}_\theta(f,\varphi)=\sum_i \int_{S^{N-1}} h_i \varphi_i B_i^{-1}\, \mathrm{d}\omega = (h,\varphi)_{\mathrm{L}}$$

and we conclude by applying the Lax–Milgram theorem. □

Of course, one has a similar statement for the adjoint operator: Q_θ^* is defined by

$$Q_\theta^* = \theta Q_1^{\mathrm{el},*} + (1-\theta) Q_0^{\mathrm{el},*},$$

and fulfills the same coercivity property as Q_θ with the same constant of coercivity, since

$$\mathcal{B}_\theta(f,f) = -\sum_i \int_{S^{N-1}} Q_\theta^*(f)_i f_i B_i^{-1}\, \mathrm{d}\omega.$$

Therefore we have

Corollary 3: For any $h \in \mathbb{F}$ there exists $f \in \mathbb{E}$ such that $Q_\theta^*(f)=h$ if and only if $\langle h \rangle = 0$. Moreover, there exists a unique such function in $\mathbb{E}_0=\{f \in \mathbb{E}$ such that $\langle f \rangle = 0\}$, and this solution satisfies

$$N(f) \leqslant (1/\sqrt{\kappa_\theta}) \|h\|_{\mathbb{F}}.$$

IV. FORMAL APPROACH

The starting point of the asymptotic study is the following rescaled equation:

$$\partial_t f_i^\eta + \frac{1}{\eta} v_i \cdot \nabla_x f_i^\eta = \frac{1}{\eta^2} (Q^\eta(f^\eta))_i. \tag{13}$$

Precisely, we consider the situation where the mean free path $\eta > 0$ is small at time scale of order $1/\eta$. On the other hand, we assume that the collision operator Q^η splits as follows:

$$Q^\eta(f) = Q_\theta(f) + \eta^2 Q_\theta^{\mathrm{inel}}(f),$$

which means that inelastic collisions are of order η^2 compared to the elastic ones. This agrees with the fact that dominant scattering events are elastic. Of course, in this splitting θ is fixed and cannot be too small compared to η. In particular, it is also required that θ belongs to the range which guarantees the coercivity of the operator Q_θ, see Proposition 3. Our aim is to describe the asymptotic behavior of the solutions of (13) as $\eta \to 0$. We will obtain a set of diffusion equations, which can be viewed as a semidiscrete (with respect to the energy) version of the SHE-system of Ref. 19 for the limit macroscopic density with a coupling of the energy levels due to the action of the operator Q_1^{el} and/or the inelastic terms.

A. Formal Hilbert expansion

We can guess the limit behavior by inserting the formal ansatz

$$f^\eta = f^0 + \eta f^1 + \eta^2 f^2 + \cdots$$

into (13) and then we identify the terms that arise with the same power of η. As usual, the η^{-2} terms lead to

$$Q_\theta(f^0) = 0,$$

which means, by Proposition 3, that $(f^0)_i(\omega) = \rho_i \in \mathcal{E}_0$ does not depend on the angular variable. Hence, one expects that the asymptotic limit is entirely determined in terms of ''macroscopic'' quantities. Next, the η^{-1} equation reads

$$Q_\theta(f^1) = v \cdot \nabla_x \rho,$$

while the η^0 equation is

$$Q_\theta(f^2)+Q_\theta^{\text{inel}}(\rho)=v\cdot\nabla_x f^1+\partial_t\rho.$$

Integrating with respect to ω, we are led to the following relation:

$$\partial_t\rho_i+\operatorname{div}_x\left(\int_{S^{N-1}}\sqrt{2e_i/m}\,\omega f_i^1(\omega)\mathrm{d}\omega\right)=\int_{S^{N-1}}Q_\theta^{\text{inel}}(\rho)\mathrm{d}\omega. \tag{14}$$

The usual strategy consists in inverting the η^{-1} equation; one expects in this way to determine the current $\int_{S^{N-1}}\sqrt{2e_i/m}\,\omega f_i^1(\omega)\mathrm{d}\omega$ in the previous equation as a linear function of $\nabla_x\rho$, i.e., a Fick's relation. The difficulty of this method here comes from the action of the operator Q_1^{el} which mixes the energy levels. In particular, if ρ_i depends only on the energy and $f_i(\omega)$ depends on the two variables, in general one has

$$\begin{aligned}Q_1(\rho f)_i&=\sum_j\int_{S^{N-1}}\sigma_{ij}(\omega,\omega')\rho_j(f_j(\omega')-f_j(\omega))\mathrm{d}\omega'\\&\neq\rho_i Q_1(f)_i\\&=\rho_i\sum_j\int_{S^{N-1}}\sigma_{ij}(\omega,\omega')(f_j(\omega')-f_j(\omega))\mathrm{d}\omega'\end{aligned}$$

[while $Q_0(\rho f)_i=\rho_i Q_0(f)_i$]. However, we can solve the problem as follows. Let us define $\overrightarrow{\chi^i}\in(\mathbb{E}_0)^N$ solution of

$$Q_\theta(\overrightarrow{\chi^i})_{i_0}=-v_{i_0}\delta_{i_0 i},$$

where $\delta_{i_0 i}=1$ if $i=i_0$, and 0 if $i\neq i_0$. The equation has to be understood componentwise, and this definition makes sense thanks to Proposition 4 (since $\int_{S^{N-1}}\omega\,\mathrm{d}\omega=0$). Then one checks that

$$f_{i_0}^1=\sum_i\overrightarrow{\chi}_{i_0}^i\cdot\nabla_x\rho_i$$

provides a solution to the η^{-1} equation. Plugging this expression into (14) gives

$$\begin{aligned}\partial_t\rho_{i_0}-\nabla_x\left(\sum_i D_{i_0 i}\nabla_x\rho_i\right)&=q(\rho)_{i_0},\\q(\rho)_{i_0}&=\int_{S^{N-1}}[Q_\theta^{\text{inel}}(\rho)]_{i_0}\mathrm{d}\omega,\\D_{i_0 i}&=-\int_{S^{N-1}}v_{i_0}\otimes\overrightarrow{\chi}_{i_0}^i\mathrm{d}\omega,\end{aligned}$$

where $\otimes$ stands for the tensor product in $\mathbb{R}^N$: for $(a_1,\ldots,a_N)$ and $(b_1,\ldots,b_N)$ in $\mathbb{R}^N$, $a\otimes b$ is the $N\times N$ matrix with components $a_\alpha b_\beta$. We observe in the limit equation a coupling between the energy levels, both from the diffusion matrix and from the right-hand side.

A possible strategy to justify these computations would be to start from a solution ρ of the expected limit equation (which has to be studied independently), and to define successively f^1, f^2 in terms of ρ as solutions of the η^{-1} and η^0 equations, respectively. It remains to estimate the remainder $r^\eta=f^\eta-(\rho+\eta f^1+\eta^2 f^2)$. The drawback of this method is that it is known to require some regularity on ρ, thus on the coefficients. Such an assumption can be unrealistic for neutron transport since the physical properties of the media interacting with the neutrons are usually highly

heterogeneous. On the other hand, it could be quite delicate to carry out this strategy in the full generality considered here. Therefore, let us instead develop a duality approach, which will be close to our actual method of proof.

B. Duality interpretation

Let us assume that f^η converges to some f^0 in a suitable sense. Multiplying by η^2 and taking the limit $\eta\to 0$ in (13), we recover

$$Q_\theta(f^0)_i=0, \quad \forall i\in\mathbb{N},$$

and thus $f_i^0(t,x,\omega)=\rho_i(t,x)$.

We introduce the following macroscopic quantities

$$\begin{aligned} &\text{density of } i\text{th energy level:} \quad \rho_i^\eta(t,x)=\int_{S^{N-1}} f_i^\eta(t,x,\omega)\mathrm{d}\omega,\\ &\text{current of } i\text{th energy level:} \quad J_i^\eta(t,x)=\frac{1}{\eta}\int_{S^{N-1}}|v_i|\omega f_i^\eta(t,x,\omega)\mathrm{d}\omega. \end{aligned} \tag{15}$$

In view of the penalization of the collision term, one expects that f^η tends to belong to the kernel of Q_θ, therefore it is mainly given by its macroscopic part ρ^η, up to a formally small remainder. Hence, let us write a first-order expansion of f^η as follows:

$$f_i^\eta(t,x,\omega)=\rho_i^\eta(t,x)+\eta g_i^\eta(t,x,\omega)$$

so that $\rho^\eta\in\mathrm{Ker}(Q_\theta)$ and

$$J_i^\eta(t,x)=\int_{S^{N-1}}|v_i|\omega g_i^\eta(t,x,\omega)\mathrm{d}\omega.$$

Integrate Eq. (13) with respect to ω. Since the operator Q_θ has null average on S^{N-1}, we get for all $i\in\mathbb{N}$:

$$\partial_t\rho_i^\eta+\nabla_x\cdot J_i^\eta=\int_{S^{N-1}} Q_\theta^{\mathrm{inel}}(f^\eta)_i\mathrm{d}\omega,$$

which is the η-dependent version of the integrated η^0 equation in the above-mentioned formal expansion. As η goes to 0, we are formally led to the continuity equation

$$\partial_t\rho_i+\nabla_x\cdot J_i=\int_{S^{N-1}} Q_\theta^{\mathrm{inel}}(\rho)_i\mathrm{d}\omega.$$

It remains to find the relation between the limit current J and ρ.

Multiply (13) by some $\eta\varphi_i(\omega)$. We get

$$\sum_i \frac{1}{\eta}\int_{S^{N-1}} Q_\theta(f^\eta)_i\varphi_i\mathrm{d}\omega=\sum_i \int_{S^{N-1}}(v\cdot\nabla_x f^\eta)_i\varphi_i\mathrm{d}\omega+\eta\sum_i \int_{S^{N-1}}\partial_t f_i^\eta\varphi_i\mathrm{d}\omega,$$

and therefore

$$\sum_i \int_{S^{N-1}} Q_\theta(g^\eta)_i\varphi_i\mathrm{d}\omega=\sum_i\left(\int_{S^{N-1}}|v_i|\omega\varphi_i\mathrm{d}\omega\right)\cdot\nabla_x\rho_i^\eta+R^\eta, \tag{16}$$

where R^η is formally of order $\mathcal{O}(\eta)$.

Suppose that, for i_0 fixed in $\mathbb{N}$, we are able to find the auxiliary function $B_i\chi_i^{i_0}(\omega)\in(\mathbb{E}_0)^N$, that solves

$$Q_\theta^*(B_\cdot\chi_\cdot^{i_0})_i=v_{i_0}B_{i_0}\delta_{i_0 i}=\sqrt{2e_{i_0}/m}B_{i_0}\omega\delta_{i_0 i}. \tag{17}$$

Since v_{i_0} lies in $\mathbb{R}^N$, Eq. (17) holds for the N scalar equations with right-hand sides ω_α for $\alpha\in\{1,\ldots,N\}$. Remarking that

$$\int_{S^{N-1}}\omega\,\mathrm{d}\omega=0,$$

the existence of χ^{i_0} is given by Corollary 3.

Hence, for the test function $\varphi_i(\omega)$, we choose the components of $\chi_i^{i_0}(\omega)$ and (16) becomes

$$\sum_i\int_{S^{N-1}}g_i^\eta Q_\theta^*(B\chi^{i_0})_iB_i^{-1}\,\mathrm{d}\omega=\sum_i\left(\int_{S^{N-1}}|v_i|\chi_i^{i_0}\otimes\omega\,\mathrm{d}\omega\right)\cdot\nabla_x\rho_i^\eta+\mathcal{O}(\eta), \tag{18}$$

with

$$\sum_i\int_{S^{N-1}}g_i^\eta Q_\theta^*(B\chi^{i_0})_iB_i^{-1}\,\mathrm{d}\omega=\sum_i\int_{S^{N-1}}g_i^\eta\sqrt{2e_{i_0}/m}\,\omega\delta_{i_0 i}\,\mathrm{d}\omega=\sqrt{2e_{i_0}/m}\int_{S^{N-1}}\omega g_{i_0}^\eta\,\mathrm{d}\omega=J_{i_0}^\eta.$$

Here, we used the following fact:

$$\begin{aligned}\sum_i\int_{S^{N-1}}Q_\theta(g^\eta)_i\chi_i^{i_0}\,\mathrm{d}\omega&=(Q_\theta(g^\eta),B\chi^{i_0})_{\mathbb{L}}\\&=\sum_i\int_{S^{N-1}}g_i^\eta Q_\theta^*(B\chi^{i_0})_iB_i^{-1}\,\mathrm{d}\omega.\end{aligned}$$

Thus, passing to the limit $\eta\to0$ in (18), we are led to

$$J_{i_0}(t,x)=-\sum_i D_{i_0 i}\nabla_x\rho_i(t,x), \tag{19}$$

where the matrix D is defined through the auxiliary function χ by

$$D_{i_0 i}=-|v_i|\int_{S^{N-1}}\chi_i^{i_0}\otimes\omega\,\mathrm{d}\omega\in\mathcal{M}_{N\times N}, \tag{20}$$

where $\mathcal{M}_{N\times N}$ stands for the space of $N\times N$ matrices.

The formal limit of (13) is therefore the following macroscopic equation:

$$\partial_t\rho-\nabla_x\cdot(D(x)\nabla_x\rho)=q(\rho), \tag{21}$$

where the unknown is the sequence $\rho(t,x)=\{\rho_i(t,x),i\in\mathbb{N}\}$, D is given by (17), (20) and the right-hand side by

$$q(\rho)_i=\int_{S^{N-1}}Q_\theta^{\mathrm{inel}}(\rho)_i\,\mathrm{d}\omega=\sum_j\Lambda_{ij}\rho_j-\tilde{\Sigma}_i\rho_i, \tag{22}$$

with

$$\Lambda_{ij}=\int_{S^{N-1}}\int_{S^{N-1}}\sigma_{ij}(\omega,\omega')\mathrm{d}\omega\,\mathrm{d}\omega',$$

$$\tilde{\Sigma}_i=\sum_j\int_{S^{N-1}}\int_{S^{N-1}}\sigma_{ji}(\omega',\omega)\mathrm{d}\omega\,\mathrm{d}\omega'=\sum_j\Lambda_{ji}.$$

It is also worth splitting the matrix D as follows. The properties discussed on Q_0^{el} allow us to define a unique $\varphi^{i_0}(\omega)\in\mathbb{R}^N$ verifying

$$(1-\theta)Q_0^*(B_\cdot\varphi^{i_0}\delta_{i_0\cdot})_i=v_{i_0}B_{i_0}\delta_{i_0 i},$$

with $\int_{S^{N-1}}\varphi^{i_0}(\omega)\mathrm{d}\omega=0$. Then, we split $\chi_i^{i_0}=\varphi^{i_0}\delta_{i_0 i}+\overline{\chi}_i^{i_0}$, where

$$Q_\theta^*(B_\cdot\overline{\chi}_\cdot^{i_0})_i=-\theta Q_1^*(B_\cdot\varphi^{i_0}\delta_{i_0\cdot})_i.$$

In this way, we can rewrite

$$D_{i_0 i}=d_{i_0}\delta_{i_0 i}+\Delta_{i_0 i},$$
$$d_{i_0}=-|v_{i_0}|\int_{S^{N-1}}\varphi^{i_0}\otimes\omega\,\mathrm{d}\omega,$$
$$\Delta_{i_0 i}=-|v_i|\int_{S^{N-1}}\overline{\chi}_i^{i_0}\otimes\omega\,\mathrm{d}\omega.$$

Hence, one gets $[D\nabla_x\rho]_{i_0}=d_{i_0}\nabla_x\rho_{i_0}+\Sigma_i\Delta_{i_0 i}\nabla_x\rho_i$. Of course, we can verify readily that this definition of the diffusion matrix coincides with the one obtained in the previous section.

This limit equation (21) appears as a semidiscrete (in energy) SHE-model with a coupling of the energy levels. Actually, one obtains a hierarchy of possible limit systems:

(1) A system of uncoupled diffusion equations with respect to the space variable, energy being only a parameter. This arises when inelastic terms are negligible and $\theta=0$.

(2) A system of diffusion equations with a coupling of the energy levels through zeroth-order terms. This arises with $\theta=0$ and treating inelastic processes as a perturbation. Diffusivity remains locally defined (with respect to energy) and the coupling describes gain/loss at a given energy level due to inelastic collisions.

(3) A system of diffusion equations with a strong coupling, from both zeroth-order terms and diffusion currents which are now nonlocal: energy exchanges during the collisions induce diffusive effects.

C. Fundamental properties of the diffusivity

We are naturally led to discuss some properties of the diffusivity D. To this end, one introduces the following Hilbert space of vector-valued sequences:

$$\mathbb{H}=\left\{\Phi:\mathbb{N}\to\mathbb{R}^N;\sum_i|\Phi_i|^2\frac{2\varepsilon i}{m\gamma_i B_i}<+\infty\right\}.$$

We shall identify $\mathscr{\ell}=\{\Phi:\mathbb{N}\to\mathbb{R}^N,\Sigma_i|\Phi_i|^2B_i^{-1}<\infty\}$ with its dual; accordingly, the dual of $\mathbb{H}$ reads

$$\mathbb{H}'=\left\{J:\mathbb{N}\to\mathbb{R}^N;\sum_i|J_i|^2\frac{m\gamma_i}{2\varepsilon i B_i}<+\infty\right\},$$

with the duality relation

$$\langle J,\Phi\rangle_{\mathbb{H}',\mathbb{H}}=\left(J\sqrt{\frac{mc_i}{2\varepsilon i}},\Phi\sqrt{\frac{2\varepsilon i}{mc_i}}\right)_{\ell^2}=\sum_i J_i\Phi_i B_i^{-1}.$$

Lemma 1: Assume (H). *Let us set*

$$\mathcal{D}(\Psi,\Phi)=\sum_{i,j} D_{ij}\Psi_j\cdot\Phi_i B_i^{-1}\quad\forall\Phi,\Psi\in\mathbb{H}.$$

Then,
(i) $\mathcal{D}$ *is a bilinear continuous form on* $\mathbb{H}$;
(ii) $\mathcal{D}$ *is positive-definite (symmetric as soon as* Q_θ *is a self-adjoint operator). Furthermore, there exists a constant* $c>0$ *such that for all* $\Phi\in\mathbb{H}$,

$$\mathcal{D}(\Phi,\Phi)\geqslant c\|\Phi\|_{\mathbb{H}}^2.$$

Proof: Assuming (H), one associates to Φ in the weighted ℓ^2 space $\mathbb{H}$, the function

$$\phi:\mathbb{N}\times S^{N-1}\to\mathbb{R}$$

$$(i,\omega)\mapsto\phi_i(\omega)=v_i\cdot\Phi_i=\omega\cdot\sqrt{2\varepsilon i/m}\Phi_i.$$

One remarks that ϕ lies in $\mathbb{F}_0$, and $\|\phi\|_{\mathbb{F}}$ provides a norm equivalent to the natural norm on $\mathbb{H}$ (by using $(h2)$). Therefore, Proposition 4 allows us to define the mapping

$$K:\mathbb{H}\to\mathbb{E}_0$$

$$\Phi\mapsto K^\Phi,$$

with $Q^*(K^\Phi)_i(\omega)=v_i\cdot\Phi_i=\phi_i(\omega)$, i.e., $K^\Phi=Q^{*-1}(\phi)$. Clearly, K is a bounded linear operator from $\mathbb{H}$ to $\mathbb{E}$.

With these notations, we have the following relation, which will be proved later on,

$$B_j^{-1}K_j^\Phi(\omega)=\sum_i \chi_j^i(\omega)\cdot\Phi_i B_i^{-1}. \tag{23}$$

From the definition of D_{ij}, and (23), we can rewrite $\mathcal{D}$ as follows:

$$\begin{aligned}\mathcal{D}(\Psi,\Phi)&=\sum_{ij} D_{ij}\Psi_j\cdot\Phi_i B_i^{-1}\\&=-\sum_{ij}\int_{S^{N-1}}\chi_j^i(\omega)\cdot\Phi_i B_i^{-1}v_j\cdot\Psi_j\,d\omega\\&=-\sum_j\int_{S^{N-1}}\left(\sum_i\chi_j^i(\omega)\cdot\Phi_i B_i^{-1}\right)v_j\cdot\Psi_j\,d\omega\\&=-\sum_j\int_{S^{N-1}}B_j^{-1}K_j^\Phi(\omega)\psi_j(\omega)d\omega.\end{aligned}$$

Hence we have

$$\mathcal{D}(\Psi,\Phi)=-\sum_i\int_{S^{N-1}}\psi_i(\omega)Q^{*-1}(\phi)_i(\omega)B_i^{-1}\,d\omega=-\sum_i\left(\Psi_i\cdot\left(\int_{S^{N-1}}v_iK_i^\Phi\,d\omega\right)B_i^{-1}\right). \tag{24}$$

The lemma follows, since the first expression recasts as

$$-\sum_i \int_{S^{N-1}} Q^*(K^\Psi)_i(\omega) K_i^\Phi(\omega) B_i^{-1}\, d\omega = \mathcal{B}_\theta(K^\Phi, K^\Psi),$$

which easily leads to the conclusion by using Corollary 3.

We are thus left with the task of proving (23). However, this is a simple consequence of the linearity of Q^*, which implies that summation over i commutes with the action of this operator. We are thus able to show that Q^* acts on the right-hand side of (23) as follows:

$$Q^*\left(\sum_i B_\cdot \chi^i_\cdot \cdot \Phi_i B_i^{-1}\right)_j = \sum_i Q^*(B_\cdot \chi^i_\cdot)_j \cdot \Phi_i B_i^{-1} = \sum_i v_i B_i \delta_{ij} \cdot \Phi_i B_i^{-1} = v_j \cdot \Phi_j = \phi_j = Q^*(K^\Phi)_j .$$

□

From Lemma 1, we can deduce the following claim which will give a precise meaning to the current relation (19). It will play a key role in our rigorous analysis.

Corollary 4: We can define a linear, continuous and invertible mapping $\mathcal{J}:\mathbb{H}\to\mathbb{H}'$ *such that, for any* Φ *and* Ψ *in* $\mathbb{H}$ *one has*

$$\mathcal{D}(\Phi,\Psi) = -(\mathcal{J}(\Phi),\Psi)_{\mathcal{E}} = -\sum_i \mathcal{J}(\Phi)_i \Psi_i B_i^{-1}.$$

Proof: For any $\Phi\in\mathbb{H}$, the Riesz theorem defines a unique $\mathcal{J}(\Phi)\in\mathbb{H}'$, such that $\mathcal{D}(\Phi,\Psi) = -(\mathcal{J}(\Phi),\Psi)_{\mathcal{E}}$ for any $\Psi\in\mathbb{H}$. The corresponding mapping $\mathcal{J}:\mathbb{H}\to\mathbb{H}'$ is of course linear and continuous. Conversely, let $J\in\mathbb{H}'$. The Lax–Milgram theorem applies to solve the variational problem

find $\Phi\in\mathbb{H}$ *such that, for all* $\Psi\in\mathbb{H}$ *one has* $\mathcal{D}(\Phi,\Psi) = -(J,\Psi)_{\mathcal{E}}$.

By Proposition 4, this problem admits a unique solution $\Phi\in\mathbb{H}$ which satisfies, by its definition, $\mathcal{J}(\Phi) = J$. □

This statement will allow us to interpret the current equation (19) in a duality sense by $J = \mathcal{J}(\nabla_x\rho)$. Accordingly, one expects that J lies in $L^2(\mathbb{R}_t^+\times\mathbb{R}_x^N;\mathbb{H}')$ and $\nabla_x\rho\in L^2(\mathbb{R}_t^+\times\mathbb{R}_x^N;\mathbb{H})$. It is worth noting this gain in "regularity," both in the space and energy variables on the density, since this property is not guaranteed in general for ρ^η, for $\eta>0$. This is a usual fact when dealing with diffusion approximation, see for instance Refs. 29 and 20; the noticeable point here is that this effect also applies to the energy variable.

V. RIGOROUS DERIVATION

This section is devoted to the rigorous study of the asymptotic behavior as η goes to 0 of the solution f^η of the kinetic equation

$$\begin{aligned} &\partial_t f_i^\eta + \frac{1}{\eta} v_i \cdot \nabla_x f_i^\eta = \frac{1}{\eta^2}(Q_\theta(f^\eta))_i \quad \text{in } \mathbb{R}_t^+\times\mathbb{R}_x^N\times\mathbb{N}_i\times S_\omega^{N-1}, \\ &f^\eta(t=0) = F_I^\eta . \end{aligned} \tag{25}$$

In order to take into account time and space variables, one needs to define again some functional spaces, based on the previous ones. We set

$$\mathcal{L}^2 = \left\{ f:\mathbb{R}_x^N\times\mathbb{N}_i\times S_\omega^{N-1}\to\mathbb{R},\ \sum_i \int_{\mathbb{R}^N}\int_{S^{N-1}} f_i^2\ B_i^{-1}\, d\omega\, dx < \infty \right\}.$$

It is nothing but the L^2 space on $\mathbb{R}^N\times\mathbb{N}\times S^{N-1}$ endowed with the measure $\mathrm{d}x\otimes(B_i^{-1}\,\mathrm{d}i)\otimes\mathrm{d}\omega$, where $\mathrm{d}i$ stands for the counting measure on $\mathbb{N}$. Accordingly, we also set

$$\mathcal{E}=\left\{f:\mathbb{R}^N_x\times\mathbb{N}_i\times S^{N-1}_\omega\to\mathbb{R},\quad \sum_i\int_{\mathbb{R}^N}\int_{S^{N-1}} f_i^2\ \frac{\gamma_i}{B_i}\mathrm{d}\omega\,\mathrm{d}x<\infty\right\}=L^2(\mathbb{R}^N;\mathbb{E})$$

and

$$\mathcal{F}=\left\{f:\mathbb{R}^N_x\times\mathbb{N}_i\times S^{N-1}_\omega\to\mathbb{R},\quad \sum_i\int_{\mathbb{R}^N}\int_{S^{N-1}} f_i^2\ \frac{1}{\gamma_i B_i}\mathrm{d}\omega\,\mathrm{d}x<\infty\right\}=L^2(\mathbb{R}^N;\mathbb{F}).$$

Similarly, for vector-valued macroscopic quantities, independent on the angular variable, we set

$$\mathcal{H}=\left\{\Phi:\mathbb{R}^N_x\times\mathbb{N}_i\to\mathbb{R}^N,\quad \sum_i\int_{\mathbb{R}^N}|\Phi_i|^2\ \frac{2\varepsilon i}{m\gamma_i B_i}\mathrm{d}x<\infty\right\}=L^2(\mathbb{R}^N;\mathbb{H})$$

and

$$\mathcal{H}'=\left\{J:\mathbb{R}^N_x\times\mathbb{N}_i\to\mathbb{R},\quad \sum_i\int_{\mathbb{R}^N}|J_i|^2\ \frac{m\gamma_i}{2\varepsilon i B_i}dx<\infty\right\}=L^2(\mathbb{R}^N;\mathbb{H}'),$$

which is the dual of $\mathcal{H}$ when one identifies $L^2(\mathbb{R}^N,\not{\ell})=L^2(\mathbb{R}^N\times\mathbb{N},\mathrm{d}x\otimes B_i^{-1}\mathrm{d}i)$ with its dual, namely

$$\langle J,\Phi\rangle_{\mathcal{H}',\mathcal{H}}=\sum_i\int_{\mathbb{R}^N}\Phi_i\cdot J_i B_i^{-1}\,\mathrm{d}x.$$

We shall not detail the existence theory for the transport equation (25). With some maybe stronger assumptions on the cross sections, this can be done by means of semigroups theory. We can also use some monotonicity argument, following Petterson.[36] Instead, we shall assume from now on that there exists a function $f^\eta\in C^0(\mathbb{R}^+;\mathcal{L}^2)\cap L^\infty(\mathbb{R}^+;\mathcal{E})$ satisfying the following weak formulation of (25)

$$-\int f^\eta\partial_t\varphi\ \ B^{-1}\,\mathrm{d}\mu-\frac{1}{\eta}\int f^\eta v\cdot\nabla_x\varphi\ \ B^{-1}\,\mathrm{d}\mu+\left[\int f^\eta\varphi\ \ B^{-1}\,\mathrm{d}\nu\right]_0^T=\frac{1}{\eta^2}\int Q_\theta(f^\eta)\varphi\ \ B^{-1}\,\mathrm{d}\mu. \tag{26}$$

Here, $\mathrm{d}\mu$ indicates integration over $(0,T)\times\mathbb{R}^N\times\mathbb{N}\times S^{N-1}$ with the measure $\mathrm{d}t\otimes\mathrm{d}x\otimes\mathrm{d}i\otimes\mathrm{d}\omega$ while $\mathrm{d}\nu$ has the same meaning on $\mathbb{R}^N\times\mathbb{N}\times S^{N-1}$ with the measure $\mathrm{d}x\otimes\mathrm{d}i\otimes\mathrm{d}\omega$. Relation (26) holds for any φ in an appropriate space of admissible test functions $\mathfrak{D}$. In particular, it makes sense for $\varphi\in L^1_{\mathrm{loc}}(\mathbb{R}^+;\mathcal{E})$ such that $\partial_t\varphi$ and $\nabla_x\cdot(v\varphi)$ belong to $L^1_{\mathrm{loc}}(\mathbb{R}^+;\mathcal{L}^2)$. It is worth remarking that a sequence defined by a finite number of non zero functions $\varphi_i(t,x,\omega)$ lying in $C^1_0([0,T]\times\mathbb{R}^N;L^\infty(S^{N-1}))$ is admissible.

Remark 8: If one assumes that $0<\gamma_i\leqslant C<+\infty$, we obtain the inclusions $\mathbb{F}\subset\mathbb{L}\subset\mathbb{E}$, and therefore Q_θ can be viewed as a bounded operator on $\mathcal{L}^2$, with values in $\mathcal{L}^2$, and existence-uniqueness is easy to be established. Of course, the problem for $\eta>0$ fixed and most of our convergence analysis become easier if one deals with a finite number of energy groups.

Then, we can now state our main result.

Theorem 1: *Suppose (H) and let F_I^η be bounded in $\mathcal{L}^2$. Then, $\rho^\eta=\int_{S^{N-1}}f^\eta\,\mathrm{d}\omega$ converges weakly-$*$ in $L^\infty(0,T;L^2(\mathbb{R}^N\times\mathbb{N};B^{-1}\,\mathrm{d}i\otimes\mathrm{d}x))$ (and in $C^0([0,T],L^2(\mathbb{R}^N\times\mathbb{N};B^{-1}\,\mathrm{d}i\otimes\mathrm{d}x))$-weak) to ρ and $J^\eta=\int_{S^{N-1}}\sqrt{2\varepsilon i/m}\,\omega\ \ f^\eta\,\mathrm{d}\omega$ converges weakly-$*$ in $L^2(0,T;\mathcal{H}')$ to J (see (27) in the following). These limits satisfy*

$$\partial_t \rho + \mathrm{div}_x J = 0,$$
$$\nabla_x \rho \in L^2(0,T;\mathcal{H}), \text{ and } \mathcal{J}(\nabla_x \rho) = J.$$

The proof naturally falls into four steps.

Step 1: A priori estimates and weak convergences.

The main estimates on f^η are obtained by formally multiplying Eq. (25) by f^η/B and integrating. It yields

$$\|f^\eta(t)\|^2_{\mathcal{L}^2} + \frac{2}{\eta^2}\int_0^t \int_{\mathbb{R}^N} \mathcal{B}_\theta(f^\eta, f^\eta)\,\mathrm{d}x\,\mathrm{d}s = \|F_I^\eta\|^2_{\mathcal{L}^2}.$$

Therefore, the coercivity of $\mathcal{B}_\theta$ allows us to estimate $\|f^\eta\|_{\mathcal{L}^2}$ and $(1/\eta)\,N(f^\eta - \rho^\eta) = N(g^\eta)$ and thus leads to the following statement.

Lemma 2: Suppose that (H) *holds and let* F_I^η *be bounded in* $\mathcal{L}^2$. *Then,*

(i) f^η *is bounded in* $L^\infty(\mathbb{R}_t^+;\mathcal{L}^2)$, *with* $\|f^\eta(t)\|^2_{\mathcal{L}^2} \leqslant \|F_I^\eta\|^2_{\mathcal{L}^2} \leqslant C$.

(ii) $g^\eta = (f^\eta - \rho^\eta)/\eta$ *is bounded in* $L^2(\mathbb{R}_t^+;\mathcal{E})$,

(iii) $\rho_i^\eta(t,x) = \int_{S^{N-1}} f_i^\eta(t,x,\omega)\,\mathrm{d}\omega$ *is bounded in* $L^\infty(\mathbb{R}_t^+;L^2(\mathbb{R}^N\times\mathbb{N},\mathrm{d}x\otimes B_i^{-1}\,\mathrm{d}i))$,

(iv) $J_i^\eta(t,x) = 1/\eta \int_{S^{N-1}} v_i f^\eta(t,x,\omega)\,\mathrm{d}\omega = \int_{S^{N-1}} (2\varepsilon i)/m\ \ \omega g^\eta(t,x,\omega)\,\mathrm{d}\omega$ *is bounded in* $L^\infty(\mathbb{R}_t^+;\mathcal{H}')$.

Proof: It remains to establish the bounds on the macroscopic quantities. Clearly, one has

$$\sum_i \int_{\mathbb{R}^N} |\rho_i^\eta|^2\ \ B_i^{-1}\,\mathrm{d}x = \sum_i \int_{\mathbb{R}^N} \left|\int_{S^{N-1}} f_i^\eta\,\mathrm{d}\omega\right|^2\ \ B_i^{-1}\,\mathrm{d}x \leqslant \|f^\eta\|_{\mathcal{L}^2}.$$

Next, the current satisfies

$$\sum_i \int_{\mathbb{R}^+}\int_{\mathbb{R}^N} |J_i^\eta|^2 \frac{m\gamma_i}{2\varepsilon i B_i}\,\mathrm{d}x\,\mathrm{d}t = \sum_i \int_{\mathbb{R}^+}\int_{\mathbb{R}^N} \left|\int_{S^{N-1}} \sqrt{\frac{2\varepsilon i}{m}}\ \ \omega g_i^\eta\,\mathrm{d}\omega\right|^2 \frac{m\gamma_i}{2\varepsilon i B_i}\,\mathrm{d}x\,\mathrm{d}t$$
$$\leqslant \sum_i \int_{\mathbb{R}^+}\int_{\mathbb{R}^N}\int_{S^{N-1}} |g_i^\eta|^2 \frac{\gamma_i}{B_i}\,\mathrm{d}\omega\,\mathrm{d}x\,\mathrm{d}t \leqslant \int_{\mathbb{R}^+}\int_{\mathbb{R}^N} N(g^\eta)^2\,\mathrm{d}x\,\mathrm{d}t$$

and the boundedness of J^η is a consequence of (ii). □

Possibly at the cost of extracting subsequences, we can assume that

$$\begin{aligned} &f^\eta \rightharpoonup_* f \quad \text{weakly } * \text{ in } L^\infty(\mathbb{R}_t^+;\mathcal{L}^2),\\ &g^\eta \rightharpoonup_* g \quad \text{weakly } * \text{ in } L^2(\mathbb{R}_t^+;\mathcal{E}),\\ &\rho^\eta \rightharpoonup_* \rho \quad \text{weakly } * \text{ in } L^\infty(\mathbb{R}_t^+;L^2(\mathbb{R}^N\times\mathbb{N},\mathrm{d}x\otimes B_i^{-1}\,\mathrm{d}i)),\\ &J^\eta \rightharpoonup_* J \quad \text{weakly } * \text{ in } L^2(\mathbb{R}_t^+;\mathcal{H}'). \end{aligned} \tag{27}$$

This means, respectively,

$$\lim_{\eta\to 0}\int f^{\eta}\varphi\ \ B_i^{-1}\,\mathrm{d}\mu=\int f\varphi\ \ B^{-1}\,\mathrm{d}\mu,$$

$$\text{where}\ \ \int_{\mathbb{R}^+}\left(\int_{\mathbb{R}^N\times\mathbb{N}\times S^{N-1}}\varphi_i(t,x,\omega)^2 B_i^{-1}\,\mathrm{d}\omega\,\mathrm{d}i\,\mathrm{d}x\right)^{1/2}\mathrm{d}t<\infty,$$

$$\lim_{\eta\to 0}\int g^{\eta}\psi\ \ B_i^{-1}\,\mathrm{d}\mu=\int g\psi\ \ B^{-1}\,\mathrm{d}\mu,$$

$$\text{where}\ \ \int \psi_i(t,x,\omega)^2\ \ (\gamma_i B_i)^{-1}\,\mathrm{d}\mu<\infty,$$

$$\lim_{\eta\to 0}\int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}\rho^{\eta}\kappa\ \ B_i^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t=\int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}\rho\kappa\ \ B^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t,$$

$$\text{where}\ \ \int_{\mathbb{R}^+}\left(\int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}\kappa_i(t,x)^2\ \ B_i^{-1}\,\mathrm{d}i\,\mathrm{d}x\right)^{1/2}\mathrm{d}t<\infty,$$

$$\lim_{\eta\to 0}\int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}J^{\eta}\cdot\Phi\ \ B^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t=\int_{\mathbb{R}^N\times\mathbb{N}}J\cdot\Phi\ \ B^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t,$$

$$\text{where}\ \ \int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}|\Phi_i(t,x)|^2\ \ \frac{2\varepsilon i}{m\gamma_i B_i}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t<\infty.$$

Choosing, with the above-mentioned properties, $\varphi_i(t,x,\omega)=\kappa_i(t,x)$ and $\psi_i(t,x,\omega)=(2\varepsilon i/m)^{1/2}\ \ \omega\cdot\Phi_i(t,x)$, we realize that

$$\rho=\int_{S^{N-1}} f\,\mathrm{d}\omega,\ \ J=\int_{S^{N-1}}\sqrt{\frac{2\varepsilon i}{m}}\ \ \omega g\,\mathrm{d}\omega$$

holds. In fact, we obviously have $f=\rho$ by taking the limit in the distributional sense in $f^{\eta}=\rho^{\eta}+\eta g^{\eta}$.

Step 2: Continuity equation.

We wish to establish the following claim.

Lemma 3: For any i the continuity relation

$$\partial_t\rho_i+\mathrm{div}_x J_i=0$$

holds in $\mathcal{D}'((0,T)\times\mathbb{R}^N)$.

Proof: We use in (26) the test function $\kappa_i B_i\zeta(t,x)$ with $\kappa_i\in\mathscr{C}^{\infty}$ (precisely $\kappa_i=\delta_{ij}$), and $\zeta\in C_0^{\infty}((0,T)\times\mathbb{R}^N)$; then we take the limit $\eta\to 0$. □

Remark 9: Under suitable hypotheses, one could also rigorously derive the inelastic term (22). Actually, if $\sigma_{ij}(\omega,\omega')$ is such that $Q_{\theta}^{\mathrm{inel}}$ is bounded in $\mathbb{L}$, a priori estimate can still be derived by means of an application of Gronwall's lemma when $Q_{\theta}=Q_{\theta}^{\mathrm{el}}+\eta^2 Q_{\theta}^{\mathrm{inel}}$.

Step 3: Current equation.

According to our discussion in the previous section, the expected current equation $J=-\Sigma_j D_{ij}\nabla_x\rho_j$ has to be understood in the dual sense $\mathcal{J}(\nabla_x\rho)=J$, which means that

$$\mathcal{D}(\nabla_x\rho,\Phi)=-\langle J,\Phi\rangle \tag{28}$$

holds for any $\Phi\in L^2(\mathbb{R}^+,\mathcal{H})$. Of course, the notation now takes into account the time and space variables. Precisely, the right-hand side reads

$$\int\ J\cdot\Phi\ \ B^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t=\int gv\cdot\Phi\ \ B^{-1}\,\mathrm{d}\mu.$$

Since we can associate to $\Phi \in L^2(\mathbb{R}^+,\mathcal{H})$ a unique $K^\Phi \in L^2(\mathbb{R}^+,\mathcal{E})$ (with null average) such that $Q^*(K^\Phi)=v\cdot\Phi$, we get

$$(J,\Phi)=\int g Q^*(K^\Phi)\ \ B^{-1}\,\mathrm{d}\mu.$$

On the other hand, the left-hand side in (28) is

$$-\int \nabla_x\rho\cdot v K^\Phi\ \ B^{-1}\,\mathrm{d}\mu=-\int_{\mathbb{R}\times\mathbb{N}\times\mathbb{R}^N}\nabla_x\rho\left(\int_{S^{N-1}} v K^\Phi\,\mathrm{d}\omega\right)\ \ B_i^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t$$

by using (23). Then, (28) reduces to

$$\int\ g Q^*(K^\Phi)\ \ B^{-1}\,\mathrm{d}\mu=\int_{\mathbb{R}\times\mathbb{N}\times\mathbb{R}^N}\nabla_x\rho\left(\int_{S^{N-1}} v K^\Phi\,\mathrm{d}\omega\right)\ \ B^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t. \tag{29}$$

In order to justify equality (28), it thus would be tempting to use $\varphi=K^\Phi$ as a test function in (26). However, difficulties arise when we ask for such a function to belong to the admissible set $\mathfrak{D}$. We note that, for $\Phi\in L^2(0,T;\mathcal{H})$, we naturally have $K^\Phi\in L^2(0,T;\mathcal{E})$ and $\int_{S^{N-1}} vK^\Phi\,\mathrm{d}\omega \in L^2(0,T;\mathcal{H}')$. However we recall that it is required that $\nabla_x\cdot(v\varphi)\in L^2(0,T;\mathcal{L}^2)$ for φ to be an admissible test function. Space regularity is not a real difficulty, but it is not clear how it can be guaranteed that vK^Φ belongs to $L^2(0,T;\mathcal{L}^2)$. Except in some very particular cases (for instance if $2\varepsilon i\leqslant C\gamma_i$ which implies that $\mathcal{H}'$ embeds to $\not\subset$ or in some isotropic case as in Ref. 19), since Q_θ^{-1} mixes all the energy levels, it seems that a truncation of Φ on the high levels does not give such a control and it is not clear at all that the set $\{\Phi\in L^2(0,T;\mathcal{H}),\ \nabla_x\cdot vK^\Phi\in L^2(0,T;\mathcal{L}^2)\}$ is not empty in the general case. This difficulty leads to some technical restrictions on the cross sections in Ref. 19.

On the other hand, if we are able to prove that $\nabla_x\rho\in L^2(0,T;\mathcal{H})$, then, the relation (29) makes sense provided $\Phi\in L^2(0,T;\mathcal{H})$ and does not require further property on Φ. This motivates our strategy of proof: First, we establish an approximate current equation, from which we will be able to deduce that $\nabla_x\rho\in L^2(0,T;\mathcal{H})$; and then we derive the current equation (29). We are thus led to the main statement of the step.

Proposition 5: We have $\nabla_x\rho\in L^2(0,T;\mathcal{H})$, and the limit J of J^η satisfies (29).

Proof: Let Φ be a test function in $L^2(0,T;\mathcal{H})$ compactly supported with respect to time in $(0,T)$. Moreover, one assumes that $\partial_t\Phi\in L^2(0,T;\not\subset)$ and $\nabla_x\Phi\in L^2(0,T;\mathcal{H})$. This can be obtained by regularizing in time and space and eventually truncating in energy a function in $L^2(0,T;\mathcal{H})$. Then, $Q_\theta^{*-1}(v\cdot\Phi)=K^\Phi\in L^2(0,T;\mathcal{E})$ (recall that K^Φ depends on ω, though Φ does not). We introduce the function $\mu^{(n)}$ defined on $\mathbb{N}$ by

$$\mu_i^{(n)}=\begin{cases}1 & \text{if}\quad i\leqslant n\\ 0 & \text{if}\quad i>n.\end{cases}$$

The parameter n will help us in approximating (29). Then, we consider the admissible test function $\varphi_i(t,x,\omega)=\mu_i^{(n)}\ \ K_i^\Phi(t,x,\omega)\in L^2(0,T;\mathcal{E})$. We obtain from (26)

$$-\int f^\eta v\cdot\nabla_x(\mu^{(n)}K^\Phi)\ \ B^{-1}\,\mathrm{d}\mu-\eta\int f^\eta\partial_t(\mu^{(n)}K^\Phi)\ \ B^{-1}\,\mathrm{d}\mu=\frac{1}{\eta}\int Q_\theta(f^\eta)\mu^{(n)}K^\Phi\ \ B^{-1}\,\mathrm{d}\mu. \tag{30}$$

The right-hand side gives

$$\int\ Q_\theta(g^\eta)\mu^{(n)}K^\Phi\ \ B^{-1}\,\mathrm{d}\mu=\int g^\eta\ \ Q_\theta^*(\mu^{(n)}K^\Phi)\ \ B^{-1}\,\mathrm{d}\mu,$$

while the left-hand side is rewritten

$$-\int \rho^{\eta}\ \mu^{(n)} v\cdot\nabla_x K^{\Phi}\ B^{-1}\,\mathrm{d}\mu-\eta\left(\int f^{\eta}\partial_t(\mu^{(n)}K^{\Phi})\ B^{-1}\,\mathrm{d}\mu+\int g^{\eta}\ \mu^{(n)} v\cdot\nabla_x K^{\Phi}\ B^{-1}\,\mathrm{d}\mu\right).$$

Since all the sums are actually finite, there is no trouble in applying convergences (27), n being fixed. The left-hand side in (30) tends, as η goes to 0, toward

$$-\int \rho\nabla_x\cdot(v_j\mu^{(n)}vK^{\Phi})\ B^{-1}\,\mathrm{d}\mu=-\int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}(\mu^{(n)}\rho)\nabla_x\cdot\left(\int_{S^{N-1}}vK^{\Phi}\,\mathrm{d}\omega\right)\ B^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t.$$

Moreover, the right-hand side in (30) becomes

$$\int\ g^{\eta}Q_{\theta}^{*}(\mu^{(n)}K^{\Phi})\ B^{-1}\,\mathrm{d}\mu\to\int gQ_{\theta}^{*}(\mu^{(n)}K^{\Phi})\ B^{-1}\,\mathrm{d}\mu.$$

Thus, we are led to the equality

$$-\int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}(\mu^{(n)}\rho)\nabla_x\cdot\left(\int_{S^{N-1}}vK^{\Phi}\,\mathrm{d}\omega\right)B^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t=\int gQ_{\theta}^{*}(\mu^{(n)}K^{\Phi})\ B^{-1}\,\mathrm{d}\mu,\quad(31)$$

which appears as an approximate form of (28). We wish to conclude by letting n go to ∞. Let us introduce the linear mapping $J^{(n)}$ defined on the set

$$\left\{\Phi\in L^2(0,T;\mathcal{H}),\nabla_x\cdot\left(\int_{S^{N-1}}vK^{\Phi}\,\mathrm{d}\omega\right)\in L^2(0,T;\mathcal{H}')\right\}$$

by

$$J^{(n)}(\Phi)=-\int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}(\mu^{(n)}\rho)\nabla_x\cdot\left(\int_{S^{N-1}}vK^{\Phi}\,\mathrm{d}\omega\right)B^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t,$$

which corresponds to a weak definition of $-\mathcal{D}(\mu^{(n)}\nabla_x\rho,\Phi)$. Note that this set is obviously dense in $L^2(0,T;\mathcal{H})$ (it is only concerned with space regularization since $\int_{S^{N-1}}vK^{\Phi}\,\mathrm{d}\omega$ naturally lies in $L^2(0,T;\mathcal{H}')$). Furthermore, (31) says that one actually has

$$J^{(n)}(\Phi)=\int\ gQ_{\theta}^{*}(\mu^{(n)}K^{\Phi})\ B^{-1}\,\mathrm{d}\mu.$$

One deduces that

$$|J^{(n)}(\Phi)|\leqslant C\|g\|_{L^2(0,T;\mathcal{E})}\ \|\Phi\|_{L^2(0,T;\mathcal{H})}$$

and $J^{(n)}$ is a bounded sequence of continuous linear forms defined on the whole space $L^2(0,T;\mathcal{H})$. According to Corollary 4, we can associate a sequence $\Theta^{(n)}$ satisfying

$$\|\Theta^{(n)}\|_{L^2(0,T;\mathcal{H})}\leqslant C\|g\|_{L^2(0,T;\mathcal{E})},$$

and

$$J^{(n)}(\Phi)=-\mathcal{D}(\Theta^{(n)},\Phi)=\int_{\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{N}}\Theta_i^{(n)}(t,x)\left(\int_{S^{N-1}}v_iK_i^{\Phi}(t,x,\omega)\,\mathrm{d}\omega\right)\ B_i^{-1}\,\mathrm{d}i\,\mathrm{d}x\,\mathrm{d}t,$$

for any $\Phi\in L^2(0,T;\mathcal{H})$ [where we used (24)]. Then, coming back to (31), $\Theta^{(n)}$ is a bounded sequence in $L^2(0,T;\mathcal{H})$ which coincides with $\mu^{(n)}\nabla_x\rho$ as a linear form on the subset

$\{\int_{S^{N-1}} v K^{\Phi}\, d\omega,\ \Phi \in L^2(0,T;\mathcal{H})\} \subset L^2(0,T;\mathcal{H}')$. Hence, we will conclude that the limit of $\Theta^{(n)}$ defines $\nabla_x \rho$ as element of $L^2(0,T;\mathcal{H})$ if we are able to prove the following claim.

Lemma 4: The set $\mathbb{K} = \{\int_{S^{N-1}} v K^{\Phi} d\omega,\ \Phi \in \mathbb{H}\}$ *is dense in* $\mathbb{H}'$.

Lemma 4 yields $\mu^{(n)} \nabla_x \rho = \Theta^{(n)}$ in $L^2(0,T;\mathcal{H})$, and therefore $\mu^{(n)} \nabla_x \rho$ is bounded in this space, uniformly with respect to n. Since the sequence converges toward $\nabla_x \rho$ as $n \to \infty$ in a distributional sense, we deduce that $\mu^{(n)} \nabla_x \rho$ converges weakly toward $\nabla_x \rho$ in $L^2(0,T,\mathcal{H})$.

We end the proof by taking the limit $n \to \infty$ in the equality (31); we finally get

$$-\mathcal{D}(\nabla_x \rho, \Phi) = \int g v \cdot \Phi \ \ B^{-1}\, d\mu = \int_{\mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{N}} J \cdot \Phi \ \ B^{-1}\, di\, dx\, dt.$$

Now, it remains to justify Lemma 4. □

Proof of Lemma 4: It is equivalent to prove that the orthogonal set of $\mathbb{K}$ is reduced to 0 in $\mathbb{H}$. Let $\Theta \in \mathbb{H}$ satisfy

$$\left(\Theta, \int_{S^{N-1}} v K^{\Phi}\, d\omega \right)_{\mathbb{L}} = 0, \quad \forall\, \Phi \in \mathbb{H}.$$

Then, by (24), this reads $\mathcal{D}(\Theta, \Phi) = 0$ for all $\Phi \in \mathbb{H}$, which yields $\Theta = 0$ thanks to the coercivity of the bilinear form $\mathcal{D}$. □

Step 4: Compactness in time.

We would like to recover as initial data ρ_I for the limit problem a function depending on the behavior of the sequence of data F_I^{η} for the kinetic equation. Of course this relies on a compactness in time property, at least for some weak topology. On the other hand, it can be shown a uniqueness result for the limit equation in the class of continuous functions with value in $L^2(\mathbb{R}^N \times \mathbb{N}; B^{-1}\, di \otimes dx)$ and having the gradient in $L^2(0,T;\mathcal{H})$. In turn, of course, the whole sequence ρ^{η} will converge to this ρ.

Lemma 5: The sequence $(\rho^{\eta})_{\eta > 0}$ *is sequentially compact in* $C^0([0,T]; L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1}\, di \otimes dx)$*-weak). In particular, there exists a sequence* $(\rho^{\eta_n})_{n \in \mathbb{N}}$ *such that for any* $\phi \in L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1}\, di \otimes dx)$

$$\int_{\mathbb{R}^N} \rho^{\eta_n} \phi \ \ B^{-1}\, di\, dx \to \int_{\mathbb{R}^N} \rho \phi \ \ B^{-1}\, di\, dx$$

as $n \to \infty$ *in* $C^0([0,T])$.

Proof: First, let $\psi \in L^2(\mathbb{R}^N \times \mathbb{N}, (1 + i/\gamma_i) B_i^{-1}\, di \otimes dx)$ with $\nabla_x \psi \in \mathcal{H}$. Looking at the continuity equation, one gets

$$\int_{\mathbb{R}^N} \rho^{\eta}(t) \psi \ \ B^{-1}\, di\, dx - \int_{\mathbb{R}^N} \rho^{\eta}(s) \psi B^{-1}\, di\, dx = \int_0^t (J^{\eta}, \nabla_x \psi)_{\mathcal{H}', \mathcal{H}}\, d\sigma$$

$$\leq C \|J^{\eta}\|_{L^2(0,T;\mathcal{H}')} \ \ \sqrt{|t-s|} \ \ \|\nabla_x \psi\|_{\mathcal{H}}.$$

The bound (iv) in Proposition 2 combined with the Arzela–Ascoli theorem allows us to deduce that $(\int \rho^{\eta}(t) \psi \ \ B^{-1}\, di\, dx)_{\eta > 0}$ lies in a compact set in $C^0([0,T])$. By considering finite series and space regularization, one sees that the above-used set of ψ's is dense into $L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$. Then, let $\phi \in L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$. We deduce that, for any $\varepsilon > 0$,

$$\left(\int_{\mathbb{R}^N} \rho^{\eta}(t) \phi \ \ B^{-1}\, di\, dx \right)_{\eta > 0} \subset B(0,\varepsilon) + \text{Compact Set} \quad \text{in} \ \ C^0([0,T]).$$

Hence, $(\int \rho^{\eta}(t) \phi \ \ B^{-1}\, di\, dx)_{\eta > 0}$ also lies in a compact set in $C^0([0,T])$. We conclude by using the separability of $L^2(\mathbb{R}^N \times \mathbb{N}, B_i^{-1} di \otimes dx)$ and a Cantor argument. □

Lemma 5 says that we recover as initial data for the limit equation the limit, in the weak $L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x)$ sense, of $\rho_I^\eta=\int_{S^{N-1}}F_I^\eta\,\mathrm{d}\omega$. Moreover, classical reasoning gives the continuity in time for the limit problem, see for instance Ref. 16.

Lemma 6: The limit ρ is a continuous function on $[0,T]$ with values in $L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x)$; and it satisfies

$$\frac{\mathrm{d}}{\mathrm{d}t}\|\rho\|_{L^2}^2=-2\int_{\mathbb{R}^N}\mathcal{D}(\nabla_x\rho,\nabla_x\rho)\,\mathrm{d}x \tag{32}$$

in $\mathcal{D}'(]0,T[)$.

Proof: The point relies on the following facts:

$$\rho\in L^\infty(\mathbb{R}^+;L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x)),$$
$$\rho\in C^0([0,T];L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x)-weak),$$
$$\nabla_x\rho\in L^2(\mathbb{R}^+;\mathcal{H}).$$

In turn, Eq. (21) implies that $\partial_t\rho$ reads as the space derivative of an element of $L^2(\mathbb{R}^+;\mathcal{H}')$. This legitimates the product with ρ. Indeed, by regularization (in time) and truncation (in energy), we can construct a sequence $\rho^{(n)}$ which lies in $C^\infty([0,T];\mathcal{H}\cap L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x))$, with $\partial_t\rho^{(n)}\in C^\infty([0,T];\mathcal{H}'\cap L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x))$ and satisfying

$$\rho^{(n)}\to\rho \ \text{ in } \ L^2(0,T;L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x)),$$
$$\partial_t\rho^{(n)}\to\partial_t\rho \ \text{ in } \ L^2(0,T;\nabla_x\cdot(\mathcal{H}'))$$

as n goes to ∞. When dealing with regular functions, one has clearly

$$\frac{\mathrm{d}}{\mathrm{d}t}\|\rho^{(n)}\|_{L^2}^2=2(\partial_t\rho^{(n)},\rho^{(n)})_{L^2}=2\langle\partial_t\rho^{(n)},\rho^{(n)}\rangle,$$

where the brackets stand for the duality product between $\{\rho$ such that $\nabla_x\rho\in\mathcal{H}\}$ and $\{\Sigma_{|\alpha|=1}\partial_x^\alpha J,J\in\mathcal{H}'\}$. Passing to the limit $n\to\infty$ justifies that

$$\frac{\mathrm{d}}{\mathrm{d}t}\|\rho\|_{L^2}=2\langle\partial_t\rho,\rho\rangle$$

holds in $\mathcal{D}'(]0,T[)$, which gives (32). Therefore, one deduces that $(\mathrm{d}/\mathrm{d}t)\,\|\rho\|_{L^2}\in L^1(0,T)$ and

$$\|\rho(t)\|_{L^2}^2=\|\rho_I\|_{L^2}^2+\int_0^t 2\langle\partial_t\rho,\rho\rangle\mathrm{d}s$$

defines a continuous function on $[0,T]$. Furthermore,

$$\|\rho(t)-\rho(t_0)\|_{L^2}^2=\|\rho(t)\|_{L^2}^2+\|\rho(t_0)\|_{L^2}^2-2(\rho(t),\rho(t_0))_{L^2}$$

tends to 0 as t goes to t_0 since $\rho\in C^0([0,T],L^2-weak)$. □

In turn, one deduces the following uniqueness statement which proves that the whole sequence ρ^η converges.

Corollary 5: There exists a unique solution ρ of (21) with $\rho\in L^\infty(\mathbb{R}^+;L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x))$ and $\nabla_x\rho\in L^2(\mathbb{R}^+;\mathcal{H})$.

Proof: The previous lemma guarantees that ρ is continuous with values in $L^2(\mathbb{R}^N\times\mathbb{N},B_i^{-1}\mathrm{d}i\otimes\mathrm{d}x)$. By linearity, it suffices to consider the solution ρ corresponding to data $\rho_I=0$. Then, (32) combined to the positivity of $\mathcal{D}$ implies that $\|\rho(t)\|_{L^2}=0$. □

As a concluding remark, let us notice that we can improve the convergence of ρ^η to ρ. Indeed, using $\omega\delta_{ij}$ as test function in (26), we obtain that $\nabla_x\rho_i$ reads as a bounded term in $L^2((0,T)$

$\times\mathbb{R}^N$) plus $\eta\times$(first derivatives of bounded terms in $L^2((0,T)\times\mathbb{R}^N)$), hence it is compact in $H^{-1}((0,T)\times B(0,R))$ for any $0<T,R<\infty$. Combining this information with the continuity equation in Lemma 3, we can apply the Div-Curl argument of L. Tartar,[39] as in Refs. 34, 29, 20, and 28 and we deduce that for any $i\in\mathbb{N}$, ρ_i^η lies in a compact set of $L^2_{\rm loc}((0,T)\times\mathbb{R}^N)$. If further the B_i's tend to 0, one easily concludes that ρ^η converges to ρ strongly in $L^2((0,T)\times B(0,R)\times\mathbb{N})$, for any $0<T,R<\infty$.

APPENDIX: PROPERTIES OF THE COLLISION OPERATORS

1. Proof of Proposition 1

We write $Q_0^{\rm el}(f)_i=K(f)_i-\Sigma_i f_i$. Of course, one has $\|\Sigma f\|_{\mathbb{F}}=\|f\|_{\mathbb{E}}$. Next, using $(h1)$, we get

$$\begin{aligned}
&\sum_i \int_{S^{N-1}}|K(f)_i|^2\frac{1}{\Sigma_i B_i}\,{\rm d}\omega\\
&\quad=\sum_i \int_{S^{N-1}}\left|\int_{S^{N-1}}\Gamma_i(\omega',\omega)f_i(\omega')\,{\rm d}\omega'\right|^2\frac{1}{\Sigma_i B_i}\,{\rm d}\omega\\
&\quad\leqslant\sum_i \int_{S^{N-1}}\left\{\left(\int_{S^{N-1}}\Gamma_i(\omega',\omega)\,{\rm d}\omega\right)|f_i(\omega')|^2\,{\rm d}\omega'\int_{S^{N-1}}\Gamma_i(\omega,\omega')\,{\rm d}\omega'\frac{1}{\Sigma_i B_i}\right\}{\rm d}\omega\\
&\quad\leqslant\sum_i \int_{S^{N-1}}\Sigma_i\,(\omega')|f_i(\omega')|^2B_i^{-1}\,{\rm d}\omega'=\|f\|_{\mathbb{E}}^2. \qquad\text{(A1)}
\end{aligned}$$

It follows that $Q_0^{\rm el}\in\mathcal{L}(\mathbb{E},\mathbb{F})$, with $\|Q_0^{\rm el}(f)\|_{\mathbb{F}}\leqslant 2\|f\|_{\mathbb{E}}$.

According to Hypothesis (h1), we easily get (i)

$$\int_{S^{N-1}}Q_0^{\rm el}(f)_i\,{\rm d}\omega=\int_{S^{N-1}}f_i(\omega)\left(\int_{S^{N-1}}(\Gamma_i(\omega,\omega')-\Gamma_i(\omega',\omega))\,{\rm d}\omega'\right){\rm d}\omega=0.$$

Now, $\mathcal{B}_0$ is clearly bilinear and continuous on $\mathbb{E}\times\mathbb{E}$ and we compute

$$\begin{aligned}
\mathcal{B}_0(f,f)&=-\sum_i\int_{S^{N-1}}\int_{S^{N-1}}\Gamma_i(\omega',\omega)[f_i(\omega')-f_i(\omega)]f_i(\omega)B_i^{-1}\,{\rm d}\omega'\,{\rm d}\omega\\
&=-\sum_i\int_{S^{N-1}}\int_{S^{N-1}}\Gamma_i(\omega',\omega)f_i(\omega)f_i(\omega')B_i^{-1}\,{\rm d}\omega'\,{\rm d}\omega\\
&\quad+\frac{1}{2}\sum_i\int_{S^{N-1}}\int_{S^{N-1}}\Gamma_i(\omega',\omega)|f_i(\omega)|^2{\rm d}\omega'\,{\rm d}\omega\\
&\quad+\frac{1}{2}\sum_i\int_{S^{N-1}}\int_{S^{N-1}}\Gamma_i(\omega,\omega')|f_i(\omega')|^2{\rm d}\omega'\,{\rm d}\omega\\
&=1/2\sum_i\int_{S^{N-1}}\int_{S^{N-1}}\Gamma_i(\omega',\omega)(|f_i(\omega)|^2\\
&\quad+|f_i(\omega')|^2-2\,f_i(\omega)f_i(\omega'))B_i^{-1}\,{\rm d}\omega'\,{\rm d}\omega\\
&=1/2\sum_i\int_{S^{N-1}}\int_{S^{N-1}}\Gamma_i(\omega',\omega)|f_i(\omega)-f_i(\omega')|^2B_i^{-1}\,{\rm d}\omega'\,{\rm d}\omega.
\end{aligned}$$

This obviously leads to the characterization of the kernel of $Q_0^{\rm el}$ in (iii).

Moreover, we have

$$\sum_i \int_{S^{N-1}} |Q_0^{\mathrm{el}}(f)_i|^2 \frac{1}{\Sigma_i B_i} \mathrm{d}\omega \leqslant \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega', \omega) |f_i(\omega) - f_i(\omega')|^2 \frac{\Sigma_i}{\Sigma_i B_i} \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$\leqslant 2\mathcal{B}_0(f,f),$$

which implies the last inequality in assertion (ii). □

2. Proof of Corollary 1

Set $f = \langle f \rangle - r$. Since r has null average, assumption $(h2)$ yields

$$\mathcal{B}_0(f,f) = 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_i(\omega' \omega) |f_i(\omega') - f_i(\omega)|^2 B_i^{-1} \, \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$\geqslant 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} |f_i(\omega') - f_i(\omega)|^2 \gamma_i B_i^{-1} \, \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$\geqslant 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} |r_i(\omega') - r_i(\omega)|^2 \gamma_i B_i^{-1} \, \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$\geqslant 1/2 \sum_i \int_{S^{N-1}} \int_{S^{N-1}} (r_i^2(\omega') + r_i^2(\omega) - 2 r_i(\omega) r_i(\omega')) \gamma_i B_i^{-1} \, \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$\geqslant \sum_i \int_{S^{N-1}} r_i^2(\omega) \gamma_i B_i^{-1} \, \mathrm{d}\omega = N^2(r).$$

□

3. Proof of Proposition 2

First, let us estimate

$$\|Q_1^{\mathrm{el}}(f)\|_{\mathbb{F}}^2 = \sum_i \int_{S^{N-1}} \left| \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') (f_j(\omega') - f_j(\omega)) \mathrm{d}\omega' \right|^2 (\Sigma_i(\omega) B_i)^{-1} \mathrm{d}\omega$$
$$\leqslant \sum_i \int_{S^{N-1}} \left(\sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') B_j \, \mathrm{d}\omega' \right.$$
$$\left. \times \sum_j \int_{S^{N-1}} \sigma_{ij}(\omega, \omega') |f_j(\omega') - f_j(\omega)|^2 B_j^{-1} \, \mathrm{d}\omega' \right) (\Sigma_i B_i)^{-1} \mathrm{d}\omega$$
$$\leqslant M_2 \sum_j \int_{S^{N-1}} \int_{S^{N-1}} \left(\sum_i \sigma_{ij}(\omega, \omega') \right) |f_j(\omega') - f_j(\omega)|^2 B_j^{-1} \, \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$\leqslant M_2 \sum_j \int_{S^{N-1}} \int_{S^{N-1}} \Gamma_j(\omega, \omega') |f_j(\omega') - f_j(\omega)|^2 B_j^{-1} \, \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$\leqslant 2 M_2 \mathcal{B}_0(f,f) \leqslant 2 M_2 \|Q_0^{\mathrm{el}}(f)\|_{\mathbb{F}} \|f\|_{\mathbb{F}} \leqslant 4 M_2 \|f\|_{\mathbb{E}}^2, \tag{A2}$$

where we used the Cauchy–Schwarz inequality and the results in Proposition 1. This proves that $Q_1^{\mathrm{el}} \in \mathcal{L}(\mathbb{E}, \mathbb{F})$.

In view of Remark 2, we can integrate Q_1^{el} with respect to ω and we get

$$\int_{S^{N-1}} Q_1^{\mathrm{el}}(f)_i \mathrm{d}\omega = \sum_j \int_{S^{N-1}} f_j(\omega') \left(\int_{S^{N-1}} \sigma_{ij}(\omega,\omega') \mathrm{d}\omega \right) \mathrm{d}\omega' - \sum_j \int_{S^{N-1}} f_j(\omega) \times \left(\int_{S^{N-1}} \sigma_{ij}(\omega,\omega') \mathrm{d}\omega' \right) \mathrm{d}\omega$$
$$= \sum_j \int_{S^{N-1}} f_j(\omega) \left(\int_{S^{N-1}} (\sigma_{ij}(\omega',\omega) - \sigma_{ij}(\omega,\omega')) \mathrm{d}\omega' \right) \mathrm{d}\omega = 0,$$

by using the symmetry assumption $(h1')$.

Then, $\mathcal{B}_1$ is obviously a bilinear continuous form on $\mathbb{E}$, and a straightforward computation yields

$$\mathcal{B}_1(f,g) = -\sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} \sigma_{ij}(\omega,\omega')(f_j(\omega') - f_j(\omega)) g_i(\omega) B_i^{-1} \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$= \sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} \sigma_{ij}(\omega',\omega)(f_j(\omega') - f_j(\omega)) g_i(\omega') B_i^{-1} \mathrm{d}\omega \, \mathrm{d}\omega'$$
$$= 1/2 \sum_{i,j} \int_{S^{N-1}} \int_{S^{N-1}} (f_j(\omega') - f_j(\omega))(\sigma_{ij}(\omega',\omega) g_i(\omega') - \sigma_{ij}(\omega,\omega') g_i(\omega)) B_i^{-1} \mathrm{d}\omega' \, \mathrm{d}\omega.$$

Finally, in view of (10), it is easy to check that $\mathcal{E}_0 \subset \mathrm{Ker}(Q_1^{\mathrm{el}})$, and writing $f = \langle f \rangle + r$, we immediately get

$$|\mathcal{B}_1(f,f)| = |(Q_1^{\mathrm{el}}(f), f)_{\mathbb{L}}| = |(Q_1^{\mathrm{el}}(r), r)_{\mathbb{L}}| \leq \|r\|_{\mathbb{E}} \|Q_1^{\mathrm{el}}(r)\|_{\mathbb{F}} \leq 2\sqrt{M_2} \|r\|_{\mathbb{E}}^2 \leq 2M_0 \sqrt{M_2} N(f - \langle f \rangle)^2.$$

We can improve this bound, by noticing that, since the average of r vanishes, (A2) and (h3) yield

$$\|Q_1^{\mathrm{el}}(r)\|_{\mathbb{F}}^2 \leq M_0 M_2 \sum_j \gamma_j B_j^{-1} \int_{S^{N-1}} \int_{S^{N-1}} |r_j(\omega') - r_j(\omega)|^2 \mathrm{d}\omega' \, \mathrm{d}\omega$$
$$\leq M_0 M_2 \sum_j \gamma_j B_j^{-1} (2\langle r_j^2 \rangle - 2\langle r_j \rangle^2)$$
$$\leq 2M_0 M_2 \sum_j \gamma_j B_j^{-1} \langle r_j^2 \rangle = 2M_0 M_2 N(r)^2,$$

and therefore

$$\mathcal{B}_1(f,f) \leq \sqrt{2M_0 M_2} \|r\|_{\mathbb{E}} N(r) \leq M_0 \sqrt{2M_2} N(f - \langle f \rangle)^2.$$

□

4. Proof of Corollary 2

By combining the symmetry condition $(h1'')$ with estimate $(h2'')$, we can dominate $|\mathcal{B}_1(f,f)|$, as given in Proposition 2(ii) by

$$M/2\sum_{ij}\ \int_{S^{N-1}}\int_{S^{N-1}}\gamma_i\gamma_j|f_j(\omega')-f_j(\omega)||f_i(\omega')-f_i(\omega)|\mathrm{d}\omega\,\mathrm{d}\omega'$$

$$\leqslant M/2\sum_{ij}\ \gamma_i\gamma_j\left(\int_{S^{N-1}}\int_{S^{N-1}}|f_j(\omega')-f_j(\omega)|^2\mathrm{d}\omega\,\mathrm{d}\omega'\right)^{1/2}$$

$$\times\left(\int_{S^{N-1}}\int_{S^{N-1}}|f_i(\omega')-f_i(\omega)|^2\mathrm{d}\omega\,\mathrm{d}\omega'\right)^{1/2}.$$

Since one assumes $\langle f\rangle=0$, the integral becomes

$$\int_{S^{N-1}}\int_{S^{N-1}}|f_i(\omega')-f_i(\omega)|^2\mathrm{d}\omega\,\mathrm{d}\omega'=2\langle f_i^2\rangle.$$

Hence, we get

$$|\mathcal{B}_1(f,f)|\leqslant M\sum_{ij}\ \gamma_i\gamma_j\langle f_j^2\rangle^{1/2}\langle f_i^2\rangle^{1/2}$$

$$\leqslant M\left(\sum_{ij}\ \gamma_i B_i^{-1}\langle f_i^2\rangle\gamma_j B_j^{-1}\langle f_j^2\rangle\right)^{1/2}\left(\sum_{ij}\ \gamma_i B_i\gamma_j B_j\right)^{1/2}$$

$$\leqslant MM_1\sum_{i}\ \gamma_i B_i^{-1}\langle f_i^2\rangle=MM_1N(f)^2.$$

(Received 29 August 2000; accepted for publication 14 September 2001)

In this note, we consider the six-vertex model with domain wall boundary conditions, defined on an $M\times M$ lattice, in the inhomogeneous case where the partition function depends on $2M$ inhomogeneities λ_j and μ_k. For a particular choice of the set of λ_j we find a new determinant representation for the partition function, which allows evaluation of the bulk free energy in the thermodynamic limit. This provides a new connection between two types of determinant formulas. We also show in a special case that spin correlations on the horizontal line going through the center coincide with the ones for periodic boundary conditions. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1415430]

I. INTRODUCTION

The six-vertex model was first introduced in Ref. 1. It was solved exactly by Lieb[2] and Sutherland[3] in 1967 by means of Bethe ansatz for periodic boundary conditions (PBC). Later the six-vertex model was studied for different boundary conditions.[4–6] Domain wall boundary conditions were introduced in 1982.[7] These boundary conditions are interesting because they allow one to derive determinant representations for correlation functions[8] and the same boundary conditions help to enumerate alternating sign matrices.[9,10] Recently the bulk free energy was calculated for these boundary conditions.[11]

In this paper we show that for special choices of inhomogeneities, one can compute the free energy and some correlation functions of the system. This observation might be useful because we expect some properties of the model to be independent of the inhomogeneities, i.e., to depend only on the anisotropy parameter. In the simplest situation, the correlation functions coincide with the ones for periodic boundary conditions.

II. INHOMOGENEITIES AND BETHE ANSATZ

In this section we define the inhomogeneous six-vertex model with domain wall boundary conditions and choose the spectral parameters (inhomogeneities) to satisfy Bethe ansatz equations; this will imply special properties of the partition function.

We now introduce the notations. Given an $M\times M$ square lattice with spectral parameters λ_i and μ_k attached to the lines and columns, one defines the usual Boltzmann weights *a*, *b*, *c* to be

$$a(\lambda,\mu)=\sinh(\gamma(\lambda-\mu+i/2)),$$

$$b(\lambda,\mu)=\sinh(\gamma(\lambda-\mu-i/2)), \tag{2.1}$$

$$c(\lambda,\mu)=\sinh(i\gamma),$$

a)Electronic mail: pzinn@insti.physics.sunysb.edu

where γ is the anisotropy. We have fixed boundary conditions for the external edges: horizontal (respectively, vertical) external edges are outgoing (respectively, incoming). The partition function is denoted by $Z_M(\{\lambda_j\},\{\mu_k\})$. Using recursion relations satisfied by the Z_M, one can show that the following determinant formula holds:[12,13]

$$Z_M(\{\lambda_j\},\{\mu_k\})=\frac{\Pi_{1\leqslant j,k\leqslant M}\sinh(\gamma(\lambda_j-\mu_k+i/2))\sinh(\gamma(\lambda_j-\mu_k-i/2))}{\Pi_{1\leqslant j\leqslant j'\leqslant M}\sinh(\gamma(\lambda_j-\lambda_{j'}))\Pi_{1\leqslant k<k'\leqslant M}\sinh(\gamma(\mu_k-\mu_{k'}))}$$
$$\times\det_{1\leqslant j,k\leqslant M}\left[\frac{\sinh(i\gamma)}{\sinh(\gamma(\lambda_j-\mu_k+i/2))\sinh(\gamma(\lambda_j-\mu_k-i/2))}\right]. \tag{2.2}$$

In the homogeneous case this representation was used in order to evaluate the bulk free energy in the thermodynamic limit.[11] In a special inhomogeneous case we shall use another determinant represention to evaluate the bulk free energy in the thermodynamic limit. Let us define our special case. We choose the spectral parameters in relation to the Bethe ansatz. In order to do that it is convenient to introduce the formalism of the algebraic Bethe ansatz. The Boltzmann weights are encoded into the L-matrix

$$L(\lambda)=\begin{pmatrix} a(\lambda) & 0 & 0 & 0\\ 0 & b(\lambda) & c(\lambda) & 0\\ 0 & c(\lambda) & b(\lambda) & 0\\ 0 & 0 & 0 & a(\lambda)\end{pmatrix}. \tag{2.3}$$

We next introduce the *monodromy matrix* $T(\lambda)$ which is an operator acting on $\mathbb{C}^{2^M}\otimes\mathbb{C}^2$ (physical space times auxiliary space) defined by

$$T(\lambda;\mu_1,\ldots,\mu_M)=L(\lambda-\mu_M)L(\lambda-\mu_{M-1})\ldots L(\lambda-\mu_1), \tag{2.4}$$

where $L(\lambda-\mu_k)$ acts on the kth factor of the tensor product in the physical space, and the auxiliary space. As an operator on the two-dimensional auxiliary space, $T(\lambda)$ can be written as

$$T(\lambda)=\begin{pmatrix}\mathbf{A}(\lambda) & \mathbf{B}(\lambda)\\ \mathbf{C}(\lambda) & \mathbf{D}(\lambda)\end{pmatrix}, \tag{2.5}$$

where **A**, **B**, **C**, **D** are operators on the physical space $\mathbb{C}^{2^M}$. The usual *transfer matrix* corresponding to periodic boundary conditions is defined as

$$\mathbf{T}(\lambda)=\mathbf{A}(\lambda)+\mathbf{D}(\lambda). \tag{2.6}$$

We shall make use of this operator later. Here, our fixed boundary conditions imply the following formal expression for the partition function:[7]

$$Z_M(\{\lambda_j\},\{\mu_k\})=\langle\downarrow|\mathbf{B}(\lambda_1;\mu_1,\ldots,\mu_M)\ldots\mathbf{B}(\lambda_M;\mu_1,\ldots,\mu_M)|\uparrow\rangle, \tag{2.7}$$

where

$$|\uparrow\rangle\equiv\begin{pmatrix}1\\0\end{pmatrix}^{\otimes M}\quad\left(\text{respectively }\ |\downarrow\rangle\equiv\begin{pmatrix}0\\1\end{pmatrix}^{\otimes M}\right)$$

is the state with all spins up (respectively, down).

Let us specify inhomogeneities. We choose the $\{\lambda_j\}$ to be divided into two sets $\{\lambda_j^1=\lambda_j,\ j=1,\ldots,m^1\}$ and $\{\lambda_j^2=\lambda_{j+m^1},\ j=1,\ldots,m^2\}$ which each satisfy the *Bethe ansatz equations:*

$$\prod_{\substack{j'=1\\ j'\neq j}}^{m^\alpha} \frac{\sinh(\gamma(\lambda_j^\alpha-\lambda_{j'}^\alpha+i))}{\sinh(\gamma(\lambda_j^\alpha-\lambda_{j'}^\alpha-i))}=\prod_{k=1}^{M}\frac{\sinh(\gamma(\lambda_j^\alpha-\mu_k+i/2))}{\sinh(\gamma(\lambda_j^\alpha-\mu_k-i/2))} \tag{2.8}$$

with $\alpha=1,2$. We define the left and right states

$$\begin{aligned}\langle 1|&=\langle\uparrow|\mathbf{C}(\lambda_1^1)\ldots\mathbf{C}(\lambda_{m^1}^1),\\ |2\rangle&=\mathbf{B}(\lambda_1^2)\ldots\mathbf{B}(\lambda_{m^2}^2)|\uparrow\rangle,\end{aligned} \tag{2.9}$$

and the *flip operator* $\mathbf{R}$ to be the operator on the physical space that flips all arrows: in terms of the usual Pauli matrices, $\mathbf{R}=\Pi_{k=1}^{M}\sigma_k^x$. Now using the overall invariance of the monodromy matrix under flip: $[T(\lambda),\mathbf{R}\sigma^x]=0$ (where the additional σ^x acts on the auxiliary space), one finds that $\mathbf{RB}(\lambda)\mathbf{R}=\mathbf{C}(\lambda)$ and therefore we can rewrite formula (2.7) in terms of the states we have defined:

$$Z_M(\{\lambda_j\},\{\mu_k\})=\langle 1|\mathbf{R}|2\rangle. \tag{2.10}$$

We now consider the situation where M is even and $m^1=m^2=M/2$. As proven in (A3), the Bethe state $|2\rangle$ is an eigenstate of $\mathbf{R}$ (with eigenvalue ±1). At this point we use orthogonality of Bethe states (A2) to conclude that

$$Z_M(\{\lambda_j\},\{\mu_k\})=\pm\,\delta_{\{\lambda_j^1\},\{\lambda_j^2\}}\langle 1|2\rangle. \tag{2.11}$$

The nonzero scalar product (square of the norm) is given by the following formula,[7] dropping the superscripts:

$$\langle 1|1\rangle=(\sin\gamma)^{M/2}\left[\prod_{j=1}^{M/2}a(\lambda_j)d(\lambda_j)\right]\left[\prod_{\substack{j,j'=1\\ j\neq j'}}^{M/2}\frac{\sinh(\gamma(\lambda_j-\lambda_{j'}+i))}{\sinh(\gamma(\lambda_j-\lambda_{j'}))}\right]\det_{1\leq j,j'\leq M/2}\left[\frac{\partial\varphi_j}{\partial\lambda_{j'}}\right] \tag{2.12}$$

with the following definitions: $a(\lambda)$ and $d(\lambda)$ are the eigenvalues of $\mathbf{A}(\lambda)$ and $\mathbf{D}(\lambda)$ acting on $|\uparrow\rangle$:

$$\begin{aligned}a(\lambda)&=\prod_{k=1}^{M}\sinh(\gamma(\lambda-\mu_k+i/2)),\\ d(\lambda)&=\prod_{k=1}^{M}\sinh(\gamma(\lambda-\mu_k-i/2)),\end{aligned} \tag{2.13}$$

and the φ_j are the logarithms of the B.A.E. (2.8):

$$\varphi_j=i\log(a(\lambda_j)/d(\lambda_j))+i\sum_{\substack{j'=1\\ j'\neq j}}^{M/2}\log\frac{\sinh(\gamma(\lambda_j-\lambda_{j'}+i))}{\sinh(\gamma(\lambda_j-\lambda_{j'}-i))}. \tag{2.14}$$

Note that the general determinant formula (2.2), in the case of two identical sets $\{\lambda_j^1\}=\{\lambda_j^2\}$, becomes

$$\begin{aligned}Z_M(\{\lambda_j\},\{\mu_k\})=&\frac{\Pi_{\substack{1\leq j\leq M/2\\ 1\leq k\leq M}}\sinh^2(\gamma(\lambda_k-\mu_k+i/2))\sinh^2(\gamma(\lambda_j-\mu_k-i/2))}{\Pi_{1\leq j<j'\leq M/2}\sinh^2(\gamma(\lambda_j-\lambda_{j'}))\Pi_{1\leq k\leq k'\leq M}\sinh(\gamma(\mu_k-\mu_{k'}))}\\ &\times\det_{\substack{1\leq j\leq M/2\\ 1\leq k\leq M}}[\phi(\lambda_j-\mu_k),\psi(\lambda_j-\mu_k)]\end{aligned} \tag{2.15}$$

with $\phi(\lambda)\equiv\sinh(i\gamma)/(\sinh(\gamma(\lambda+i/2))\sinh(\gamma(\lambda-i/2)))$ and

$$\psi(\lambda)=\frac{1}{\gamma}\frac{\mathrm{d}}{\mathrm{d}\lambda}\phi(\lambda).$$

Our new determinant representation (2.12) is quite different from Eq. (2.15); it is in particular much easier to study its thermodynamic limit.

III. CORRELATION FUNCTIONS

So far we have studied the function partition of the system; what about correlation functions?

Unfortunately it is not possible to find such a simple expression for an arbitrary correlation function; however, if we restrict ourselves to the case of special correlations which lie on a fixed horizontal line, then one can again derive determinant formulas for them.

To be specific, let us assume again that the $\{\lambda_j\}$ consist of two identical sets $\{\lambda_j, j=1\cdots M/2\}$. Then the probability that all arrows located at columns $k_1,\ldots,k_n$ and between lines $M/2$ and $M/2+1$ are up, is given by

$$\langle \pi_{k_1}\cdots\pi_{k_n}\rangle\equiv\frac{\langle\downarrow|\mathbf{B}(\lambda_1)\cdots\mathbf{B}(\lambda_{M/2})\pi_{k_1}\cdots\pi_{k_n}\mathbf{B}(\lambda_1)\cdots\mathbf{B}(\lambda_{M/2})|\uparrow\rangle}{\langle\downarrow|\mathbf{B}(\lambda_1)\cdots\mathbf{B}(\lambda_{M/2})\mathbf{B}(\lambda_1)\cdots\mathbf{B}(\lambda_{M/2})|\uparrow\rangle},\tag{3.1}$$

where $\pi_k\equiv\frac{1}{2}(1+\sigma_k^z)=\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)$ acts on the kth space.

Similarly to what was done for the partition function, one can transform Eq. (3.1) using the flip operator $\mathbf{R}$ and find:

$$\langle \pi_{k_1}\cdots\pi_{k_n}\rangle=\frac{\langle 1|\pi_{k_1}\cdots\pi_{k_2}|1\rangle}{\langle 1|1\rangle}.\tag{3.2}$$

In other words this is simply the usual correlation functions of the spin operators $\frac{1}{2}(1+\sigma^z)$ for the corresponding spin chain. The computation of these averages is a well-known problem, and the general strategy to perform it is by now well understood.[14] One must use the solution of the quantum inverse scattering problem for these operators:[15,16]

$$\pi_k=\prod_{l=1}^{k-1}\mathbf{T}(\mu_l+i/2)\mathbf{A}(\mu_k+i/2)\prod_{l=k+1}^{M}\mathbf{T}(\mu_l+i/2)\tag{3.3}$$

and then use the fact that our state $|1\rangle$ is an eigenstate of the $\mathbf{T}(\lambda)$, as well as the commutation relations satisfied by the $\mathbf{A}(\lambda)$ and $\mathbf{B}(\lambda)$. In this way we can reduce Eq. (3.1) [respectively, Eq. (3.2)] to a sum of expressions of the type $\langle\downarrow|\mathbf{B}(\tilde{\lambda}_1)\cdots\mathbf{B}(\tilde{\lambda}_{M/2})\mathbf{B}(\lambda_1)\cdots\mathbf{B}(\lambda_{M/2})|\uparrow\rangle$ (respectively $\langle\uparrow|\mathbf{C}(\tilde{\lambda}_1)\cdots\mathbf{C}(\tilde{\lambda}_{M/2})\mathbf{B}(\lambda_1)\cdots\mathbf{B}(\lambda_{M/2})|\uparrow\rangle$). These can finally be expressed as determinants either using Eq. (2.2), or according to the general formula for scalar products (p. 237 of Ref. 8).

The case $n=1$ is trivial: $|1\rangle$ is an eigenstate of $\mathbf{R}$, and therefore $\langle\pi_k\rangle=1/2$. The simplest higher correlation function is the emptiness formation probability where all k_i are nearest neighbors, in which case we obtain immediately

$$\langle \pi_{k+1}\cdots\pi_{k+n}\rangle=\prod_{l=k+1}^{k+n}\left[a(\mu_l+i/2)\prod_{j=1}^{M/2}\frac{\sinh(\gamma(\mu_l-\lambda_j+i/2))}{\sinh(\gamma(\mu_l-\lambda_j-i/2))}\right]\langle 1|\prod_{l=k+1}^{k+n}\mathbf{A}(\mu_l+i/2)|1\rangle.\tag{3.4}$$

We shall give the thermodynamic limit of this expression in a particular case.

IV. THERMODYNAMIC LIMIT

We shall show in a particular example how to take the thermodynamic limit in formulas (2.12) and (3.4). We set all μ_k to 0 and consider the critical regime, i.e., γ real. We specify the state $|1\rangle$ to be the ground state of the transfer matrices $\mathbf{T}(\lambda)$ (or of the Hamiltonian of the corresponding XXZ spin chain). In the limit $M\to\infty$ the λ_j form a continuous distribution on the real axis determined by its density $\rho(\lambda)=1/(2\cosh(\pi\lambda))$.

Let us first consider the free energy. One can show that the undetermined sign in Eq. (2.11) is $+$, and therefore we have $F=-\log\langle 1|1\rangle$. We now analyze Eq. (2.12) in the large M limit. We see that we have

$$-F\approx M^2\left[\frac{1}{2}\int d\lambda\,\rho(\lambda)\log[\sinh(\gamma(\lambda-i/2))\sinh(\gamma(\lambda+i/2))]\right.$$
$$\left.+\frac{1}{4}\int d\lambda\,\rho(\lambda)d\lambda'\rho(\lambda')\log\frac{\sinh(\gamma(\lambda-\lambda'+i))}{\sinh(\gamma(\lambda-\lambda'))}\right]+M\frac{1}{2}\log\sin\gamma+\log\det D. \quad (4.1)$$

The terms of order M^2 form the bulk free energy. In order to go further we have to analyze the behavior of the determinant. It is easy to see that the determinant of the matrix $D\equiv[\partial\varphi_j/\partial\lambda_{j'}]$ is dominated by its diagonal elements; the latter are, by definition of $\rho(\lambda)$,

$$\frac{\partial\varphi_j}{\partial\lambda_j}=2\pi\frac{M}{2}\rho(\lambda_j) \quad (4.2)$$

and therefore

$$\log\det D\approx\frac{M}{2}\log(\pi M)+\frac{M}{2}\int d\lambda\,\rho(\lambda)\log\rho(\lambda). \quad (4.3)$$

This gives us the expansion of the free energy up to linear terms in the size M. Note that similar expressions [with different densities $\rho(\lambda)$] can be found for other states, as long as they have a proper $M\to\infty$ limit.

As to the correlation functions, it is known that there is a general multiple integral representation for correlation functions in the thermodynamic limit[17] (see also Refs. 18 and 19). We shall not repeat the derivation here; let us simply mention that starting for example from (3.4), one can prove the following formula:[15,20]

$$\langle\pi_{k+1}\cdots\pi_{k+n}\rangle=2^{-n}\left(\frac{\pi}{\zeta}\right)^{n(n-1)/2}\int_{-\infty}^{+\infty}d\rho_1\cdots d\rho_n\prod_{j<k}\frac{\sinh\pi(\rho_j-\rho_k)}{\sinh\gamma(\rho_j-\rho_k-i)}$$
$$\times\prod_{j=1}^{n}\frac{\sinh^{j-1}\gamma(\rho_j-i/2)\sinh^{m-j}\gamma(\rho_j+i/2)}{\cosh^m\pi\rho_j}. \quad (4.4)$$

This result is identical to the correlation functions of the six-vertex model with periodic boundary conditions.

APPENDIX: A NONDEGENERACY PROPERTY

We assume in this appendix that $q\equiv e^{i\gamma}$ is generic (i.e., not a root of unity, except the isotropic case $q=-1$). We also assume that the spectral parameters $\{\mu_k\}$ do not form any "strings" [i.e., $\mathrm{Im}(\mu_k-\mu_l)\neq 1\ \forall k,l$]. We consider two Bethe states $|1\rangle$ and $|2\rangle$ characterized by two sets $\{\lambda_j^1, j=1,\ldots,m^1\}$ and $\{\lambda_j^2, j=1,\ldots,m^2\}$. Bethe states are eigenstates of the set of commuting transfer matrices $\mathbf{T}(\lambda)$, with corresponding eigenvalue

$$\mathbf{T}(\lambda)|\alpha\rangle=\left[\frac{Q^{\alpha}(\lambda-i)}{Q^{\alpha}(\lambda)}a(\lambda)+\frac{Q^{\alpha}(\lambda+i)}{Q^{\alpha}(\lambda)}d(\lambda)\right]|\alpha\rangle, \tag{A1}$$

where $a(\lambda)$ and $d(\lambda)$ are given by Eq. (2.13) and are independent of the state, whereas Q^{α} characterizes the $\{\lambda_j^{\alpha}\}$:

$$Q^{\alpha}(\lambda)=\prod_{j=1}^{m^{\alpha}}\sinh(\gamma(\lambda-\lambda_j^{\alpha})). \tag{A2}$$

Note that the Bethe ansatz equations are simply the equations which ensure pole cancellation in the eigenvalue of $\mathbf{T}(\lambda)$: Res $\mathbf{T}(\lambda)|\alpha\rangle_{|\lambda=\lambda_j^{\alpha}}=0$.

Because of the symmetry of the transfer matrices $\mathbf{T}(\lambda)$ under the flip operator $\mathbf{R}$, we are only considering states with $m^{\alpha}\leqslant M/2$.

We now assume that $|1\rangle$ and $|2\rangle$ have the same eigenvalue, that is

$$\frac{Q^1(\lambda+i)}{Q^1(\lambda)}a(\lambda)+\frac{Q^1(\lambda-i)}{Q^1(\lambda)}d(\lambda)=\frac{Q^2(\lambda+i)}{Q^2(\lambda)}a(\lambda)+\frac{Q^2(\lambda-i)}{Q^2(\lambda)}d(\lambda)\quad\forall\lambda. \tag{A3}$$

We rewrite this as

$$a(\lambda)[Q^1(\lambda+i)Q^2(\lambda)-Q^2(\lambda+i)Q^1(\lambda)]=d(\lambda)[Q^2(\lambda-i)Q^1(\lambda)-Q^1(\lambda-i)Q^2(\lambda)]. \tag{A4}$$

Up to an overall prefactor $e^{-2(M+m^1+m^2)\gamma\lambda}$, both the left- and right-hand sides are polynomials in $e^{2\gamma\lambda}$ of degree at most $M+m^1+m^2$. Furthermore they have the following $2M$ known zeroes: $\lambda=\mu_k\pm i/2$, $k=1,...,M$. If some μ_k coincide the zeroes have a multiplicity; however note that a $\mu_k+i/2$ cannot coincide with a $\mu_l-i/2$ (since the μ_k are not allowed to form strings). There are now two situations:

(1) $m^1+m^2<M$. In this case we conclude directly that both sides of Eq. (A4) are zero.
(2) $m^1+m^2=M$. Since $m^1\leqslant M/2$ and $m^2\leqslant M/2$, this can only happen if $m^1=m^2=M/2$. However in this case direct computation of the highest degree terms of the polynomials in Eq. (A4) shows that they are zero, and therefore they are in fact of degree at most $2M-1$. Again this means that both sides of the equation are zero.

In either case, we finally find

$$\frac{Q^1(\lambda+i)}{Q^1(\lambda)}=\frac{Q^2(\lambda+i)}{Q^2(\lambda)}\quad\forall\lambda. \tag{A5}$$

If q is not a root of unity, this implies immediately that $\{\lambda_j^1\}=\{\lambda_j^2\}$. What we have proven is the following result:

(A.1) Two Bethe states with $m\leqslant M/2$ (i.e., $S^z\geqslant 0$) correspond to the same eigenvalues of the $\mathbf{T}(\lambda)$ (for all λ) if and only if they are identical.

This has the following two immediate corollaries:

(A.2) Two distinct Bethe states are orthogonal to each other.

(A.3) A Bethe state with $m=M/2$ (i.e., $S^z=0$) is an eigenstate of the flip operator $\mathbf{R}$.

Remark: the situation is much more subtle if q is a root of unity. One way to see this is to consider Eq. (A5), and assume now that $q^{2N}=1$. One can add an extra "full string" of the form $\lambda_i=\lambda_0+ij$, $j=1,...,N$ to one of the sets without modifying the corresponding Q function. This suggests extra degeneracy can appear when q is a root of unity between states with $\Delta S^z=N$, which is precisely the phenomenon observed in Ref. 21.

In Isaev *et al.* [J. Phys. A **34**, 5815–5834 (2001)] diffusion algebras were introduced in the context of one-dimensional stochastic processes with exclusion in statistical mechanics. While Isaev *et al.* is based on the needs of the physicist reader and thus states results without proofs and focuses on the discussion of lower-dimensional examples, it is the purpose of this paper to present a construction formalism for diffusion algebras and to use the latter to prove the results in Isaev *et al.* © *2002 American Institute of Physics.* [DOI: 10.1063/1.1473220]

I. INTRODUCTION

Diffusion algebras play a key role in the understanding of one-dimensional stochastic processes. In the case of N species of particles with only nearest-neighbor interactions with exclusion on a one-dimensional lattice, diffusion algebras are useful tools in finding expressions for the probability distribution of the stationary state of these processes. Following the idea of matrix product states,[1,2] the latter are given in terms of monomials built from the generators of a quadratic algebra. Depending on whether the system is closed, i.e., the stochastic process is defined on a ring, or open, in which case boundary conditions at the end of the lattice come into play, this expression varies; Ref. 3 presents an exposition of these facts and the reader is referred to this reference and references within for more details about the application of diffusion algebras in physics.

It is the purpose of this work to treat diffusion algebras from the mathematician's point of view and to prove a construction theorem for diffusion algebras. We consider the following setting.

Let $\alpha<\beta\in I_N:=\{1,\ldots,N\}$ and consider quadratic relations of the form

$$g_{\alpha\beta}D_\alpha D_\beta - g_{\beta\alpha}D_\beta D_\alpha = x_\beta D_\alpha - x_\alpha D_\beta \tag{1}$$

with $g_{\alpha\beta}\in\mathbb{R}\backslash\{0\}$, $g_{\beta\alpha}\in\mathbb{R}$, and $x_\alpha\in\mathbb{C}$. [Note that dependence on all the nonvanishing coefficients x_α in (1) is easily suppressed by rescaling the elements D_α as $x_\alpha D_\alpha$. We choose to display the dependence on these coefficients here, because they are important in applications to stochastic models, which is the physical motivation for the study of this type of algebra.] Then one has

Definition 1.1: An algebra with generators $\{D_\alpha|\alpha\in I_N\}$ and relations of type (1) is called diffusion algebra, if it admits a linear PBW-basis of ordered monomials of the form

$$D_{\alpha_1}^{k_1}D_{\alpha_2}^{k_2}\cdots D_{\alpha_n}^{k_n},\quad k_j\in\mathbb{N}^0 \tag{2}$$

with $\alpha_1>\alpha_2>\cdots>\alpha_n$.

We remark that although we formulate the mathematical setting for coefficients in $\mathbb{R}$ in relation (1), for physical reasons only relations with positive coefficients $g_{\alpha\beta}\in\mathbb{R}^{>0}$ and $g_{\beta\alpha}$

a)Electronic mail: r.twarock@city.ac.uk

$\in \mathbb{R}^{\geqslant 0}(\alpha<\beta)$ are relevant, because they are interpreted as hopping rates in stochastic models. Since we are treating diffusion algebras from the mathematical point of view here, we will not impose this restriction, but comment on the implications of this restriction on our results after the main theorem.

The requirement of having a PBW basis (2) implies conditions on the coefficients $g_{\alpha\beta}$ and x_α in (1) according to the diamond lemma in ring theory.[4] In particular, the latter gives a criterion to check under which conditions the relations in (1) are of PBW type: it is the case if each subset of three generators $\{D_\alpha, D_\beta, D_\gamma\}$ with ordering $\alpha<\beta<\gamma$ is reduction unique with respect to the ordering, that is if the two ways of reducing the monomial $D_\alpha D_\beta D_\gamma$ to the monomial $D_\gamma D_\beta D_\alpha$ lead to the same result when expressed in the PBW basis (2).

The task of deriving all diffusion algebras with N generators thus reduces to the following two steps:

(1) Find all diffusion algebras with three generators.
(2) Find all algebras with N generators such that each subset of three generators coincides with one of the cases listed before.

The first is a trivial exercise, which amounts to finding those coefficients $g_{\alpha\beta}$ and x_α in (1) for which a set $\{D_\gamma, D_\beta, D_\alpha\}$ of three generators is reduction unique in the above-mentioned sense. The corresponding list of algebras is given in Ref. 3, and we review it here in order to set up notation and render this paper self-contained. The second is a combinatorial problem, and requires one to combine in a consistent way the three generator algebras listed before to algebras with N generators for general $N>3$.

A construction method for diffusion algebras, and thus a constructive method to approach the second point, is the so-called blending procedure in Ref. 3, which is an inductive procedure for the construction of diffusion algebras. It uses the three generator cases and augments them to larger units by attaching further generators in accordance with the requirements of the diamond lemma, then giving a prescription of how these larger building blocks may be glued (or in the terminology of Ref. 3 ''blended'') together in order to obtain a general diffusion algebra of N generators. The advantage of the inductive procedure is that it facilitates the construction of representations, which are crucial for applications in physics. The main purpose of this paper is to provide a different construction method, which is more suitable for mathematical purposes, in particular, to deliver a proof for the fact that the set of algebras obtained via the blending procedure corresponds exactly to the set of diffusion algebras in Definition 1.1.

After recalling the three-generator case in Sec. II, we present in Sec. III a derivation of diffusion algebras from first principles. Furthermore, we present in Sec. III a compact formulation for the blending procedure, and obtain the exhaustiveness of the inductive approach in Ref. 3 as a corollary to our main theorem.

II. REVIEW OF DIFFUSION ALGEBRAS WITH THREE GENERATORS

As mentioned in Sec. I, the three-generator case provides the building blocks for the derivation of diffusion algebras according to the diamond lemma and we therefore briefly recall the results of Ref. 3 for this case.

Consider a set $\{D_\alpha, D_\beta, D_\gamma\}$ of three generators with an ordering induced by the ordering of the index set $\alpha<\beta<\gamma$ and relations as in (1). Since $g_{\alpha\beta}\neq 0$ for all $\alpha<\beta\in I_N$ by assumption, we can cast the relations into the following form:

$$\begin{aligned} D_\alpha D_\beta &= q_{\beta\alpha} D_\beta D_\alpha + x_\beta^{\alpha\beta} D_\alpha - x_\alpha^{\alpha\beta} D_\beta, \\ D_\alpha D_\gamma &= q_{\gamma\alpha} D_\gamma D_\alpha + x_\gamma^{\alpha\gamma} D_\alpha - x_\alpha^{\alpha\gamma} D_\gamma, \\ D_\beta D_\gamma &= q_{\gamma\beta} D_\gamma D_\beta + x_\gamma^{\beta\gamma} D_\beta - x_\beta^{\beta\gamma} D_\gamma, \end{aligned} \tag{3}$$

where $q_{ji}:=g_{ji}/g_{ij}$, $x_k^{ij}:=x_k/g_{ij}$ for $k,\ i<j\in\{\alpha,\beta,\gamma\}$. Then, using (3), any monomial can be expressed in terms of the PBW basis (2). This is well defined, if applying (3) in different orders leads to the same result, that is if the reductions

$$D_\alpha D_\beta D_\gamma \to D_\beta D_\alpha D_\gamma \to D_\beta D_\gamma D_\alpha \to D_\gamma D_\beta D_\alpha \tag{4}$$

and

$$D_\alpha D_\beta D_\gamma \to D_\alpha D_\gamma D_\beta \to D_\gamma D_\alpha D_\beta \to D_\gamma D_\beta D_\alpha \tag{5}$$

using (3) coincide when expressed in the PBW basis (2).[4] This leads to restrictions on the coefficients $g_{\alpha\beta}$ and x_α in (1). In particular, they are constrained by a set of six equations [see (2.5)–(2.10) in Ref. 3] and their solutions determine all diffusion algebras of three generators. The latter are listed here for future convenience and in order to set up notations. Throughout this section, we assume $\alpha<\beta<\gamma$ and $x_j\neq 0$ for $j\in\{\alpha,\beta,\gamma\}$.

(1) *The case of A_I:*

$$\begin{aligned} g[D_\alpha,D_\beta]&=x_\beta D_\alpha - x_\alpha D_\beta,\\ g[D_\alpha,D_\gamma]&=x_\gamma D_\alpha - x_\alpha D_\gamma,\\ g[D_\beta,D_\gamma]&=x_\gamma D_\beta - x_\beta D_\gamma, \end{aligned} \tag{6}$$

where $g\neq 0$.

(2) *The case of A_{II}:*

$$\begin{aligned} g_{\alpha\beta}D_\alpha D_\beta&=x_\beta D_\alpha - x_\alpha D_\beta,\\ g_{\alpha\gamma}D_\alpha D_\gamma&=x_\gamma D_\alpha - x_\alpha D_\gamma,\\ g_{\beta\gamma}D_\beta D_\gamma&=x_\gamma D_\beta - x_\beta D_\gamma, \end{aligned} \tag{7}$$

where $g_{ij}:=g_i-g_j$ with $g_i\neq g_j$ for all $i<j\in\{\alpha,\beta,\gamma\}$.

(3) *The case of $B^{(1)}$:*

$$\begin{aligned} g_\beta D_\alpha D_\beta-(g_\beta-\Lambda)D_\beta D_\alpha&=-x_\alpha D_\beta,\\ gD_\alpha D_\gamma-(g-\Lambda)D_\gamma D_\alpha&=x_\gamma D_\alpha - x_\alpha D_\gamma,\\ g_\beta D_\beta D_\gamma-(g_\beta-\Lambda)D_\gamma D_\beta&=x_\gamma D_\beta, \end{aligned} \tag{8}$$

where $g\neq 0$ and $g_\beta\neq 0$. For the same ordering, we also find relations of type $B^{(1)}$ which are relations (8) with an exchange $\alpha\leftrightarrow\beta$ or $\gamma\leftrightarrow\beta$ and restrictions $g\neq 0$ and $g_\alpha\notin\{0,\Lambda\}$ or, respectively, $g\neq 0$ and $g_\gamma\notin\{0,\Lambda\}$ on the parameters.

(4) *The case of $B^{(2)}$:*

$$\begin{aligned} g_{\alpha\beta}D_\alpha D_\beta&=-x_\alpha D_\beta,\\ g_{\alpha\gamma}D_\alpha D_\gamma-g_{\gamma\alpha}D_\gamma D_\alpha&=x_\gamma D_\alpha - x_\alpha D_\gamma,\\ g_{\beta\gamma}D_\beta D_\gamma&=x_\gamma D_\beta, \end{aligned} \tag{9}$$

where $g_{\alpha\beta}$, $g_{\alpha\gamma}$ and $g_{\beta\gamma}\neq 0$.

(5) *The case of $B^{(3)}$:*

$$gD_\alpha D_\beta-(g-\Lambda)D_\beta D_\alpha=x_\beta D_\alpha - x_\alpha D_\beta,$$

$$g_\gamma D_\alpha D_\gamma = -x_\alpha D_\gamma, \tag{10}$$

$$(g_\gamma - \Lambda) D_\beta D_\gamma = -x_\beta D_\gamma,$$

where $g \neq 0$ and $g_\gamma \notin \{0, \Lambda\}$.

(6) *The case of* $B^{(4)}$*:*

$$(g_\alpha - \Lambda) D_\alpha D_\beta = x_\beta D_\alpha,$$

$$g_\alpha D_\alpha D_\gamma = x_\gamma D_\alpha, \tag{11}$$

$$g D_\beta D_\gamma - (g - \Lambda) D_\gamma D_\beta = x_\gamma D_\beta - x_\beta D_\gamma,$$

where $g \neq 0$ and $g_\alpha \notin \{0, \Lambda\}$.

(7) *The case of* $C^{(1)}$*:*

$$g_\beta D_\alpha D_\beta - (g_\beta - \Lambda) D_\beta D_\alpha = -x_\alpha D_\beta,$$

$$g_\gamma D_\alpha D_\gamma - (g_\gamma - \Lambda) D_\gamma D_\alpha = -x_\alpha D_\gamma, \tag{12}$$

$$g_{\beta\gamma} D_\beta D_\gamma - g_{\gamma\beta} D_\gamma D_\beta = 0,$$

where g_β, g_γ and $g_{\beta\gamma} \neq 0$. For the same ordering, we also find relations of type $C^{(1)}$ which are relations (12) with an exchange $\alpha \leftrightarrow \beta$ or $\alpha \to \gamma \to \beta \to \alpha$ and restrictions $g_\alpha \neq \Lambda$ and $g_\gamma, g_{\alpha\gamma} \neq 0$ or, respectively, $g_\alpha, g_\beta \neq \Lambda$ and $g_{\alpha\beta} \neq 0$ on the parameters.

(8) *The case of* $C^{(2)}$*:*

$$g_{\alpha\beta} D_\alpha D_\beta - g_{\beta\alpha} D_\beta D_\alpha = -x_\alpha D_\beta,$$

$$g_{\alpha\gamma} D_\alpha D_\gamma - g_{\gamma\alpha} D_\gamma D_\alpha = -x_\alpha D_\gamma, \tag{13}$$

$$D_\beta D_\gamma = 0,$$

where $g_{\alpha\beta}$ and $g_{\alpha\gamma} \neq 0$. For the same ordering, we also find relations of type $C^{(2)}$ which are relations (13) with an exchange $\alpha \leftrightarrow \beta$ or $\alpha \to \gamma \to \beta \to \alpha$ and restrictions $g_{\alpha\beta}, g_{\beta\gamma} \neq 0$ or, respectively, $g_{\alpha\gamma}, g_{\beta\gamma} \neq 0$ on the parameters.

(9) *The case of D:* With $q_{ji} := g_{ji}/g_{ij}$, $i, j \in \{\alpha, \beta, \gamma\}$ (recall that $g_{ij} \neq 0$ for $i < j$) we have

$$D_\alpha D_\beta - q_{\beta\alpha} D_\beta D_\alpha = 0,$$

$$D_\alpha D_\gamma - q_{\gamma\alpha} D_\gamma D_\alpha = 0, \tag{14}$$

$$D_\beta D_\gamma - q_{\gamma\beta} D_\gamma D_\beta = 0.$$

We remark that the division into algebras of type A, B, C, and D reflects the number of coefficients x_j, $j \in \{\alpha, \beta, \gamma\}$, being zero in comparison with the general form (1): for algebras of type A, B, C, and D, respectively, none, one, two, or all three of the coefficients x_i vanish. The subdivision for each type then corresponds to the different choices for the coefficients $g_{\alpha\beta}$, which are compatible with the diamond lemma.

III. THE CASE OF GENERAL *N*

This section consists of four parts: we start by providing a decomposition of the index set which later facilitates the presentation of the algebras. In other words, we decompose the whole family of algebras, which depends on the ordered set of parameters $\{g_{\alpha\beta}, x_\alpha | \alpha, \beta \in I\}$ in the

relations (1), into several subfamilies. Each subfamily is determined by a specific subset of the parameters x_α and $g_{\alpha\beta}$, which are subject to a set of conditions formulated in the following [see conditions (16), (20)–(23), (24) and (26)].

As a next step, we list some general properties specific to diffusion algebras in each of the subfamilies. They are later used in the proof of the main result. This is followed by the list of diffusion algebras and a theorem which proves the exhaustiveness of the approach. We finally comment on the counting of diffusion algebras.

A. Decomposition of the index set

The structure of the algebras in (6)–(14) suggests the following decomposition of the index set $I_N=\{1,\ldots,N\}$:

$$I_N = I \cup R, \tag{15}$$

where

$$\begin{aligned} I &:= \{\alpha \in I_N | x_\alpha \neq 0\}, \\ R &:= \{\alpha \in I_N | x_\alpha = 0\}. \end{aligned} \tag{16}$$

In the following we will use the notation $N_I := |I|$ and $N_R := |R|$ for the cardinalities of these sets.

We introduce the following terminology and notations:

Definition 3.1: Normal ordering of two generators D_α and D_β is defined as

$$:D_\alpha D_\beta: := \begin{cases} D_\alpha D_\beta & if\ \alpha < \beta \\ D_\beta D_\alpha & if\ \beta < \alpha. \end{cases} \tag{17}$$

Definition 3.2: For $\alpha<\beta$ we introduce the following short-hand notation:

$$[D_\alpha, D_\beta]_{q_{\beta\alpha}} := D_\alpha D_\beta - q_{\beta\alpha} D_\beta D_\alpha, \tag{18}$$

where the index at the commutator is referring to the coefficients $q_{\beta\alpha}$ in terms of which the commutator is defined.

Using these notations, we subdivide the set R into nonintersecting and nonempty subsets

$$R := R_1 \cup R_2 \cup \cdots \cup R_{M_R} \tag{19}$$

according to the following requirements.

(1) Relations between generators from the sets R_a and R_b for $a \neq b$ are given by

$$:D_{r_1} D_{r_2}: = 0, \quad \forall r_1 \in R_a \ \text{ and } \ \forall r_2 \in R_b. \tag{20}$$

(2) Relations within a set R_a such that $|R_a| \geqslant 2$ are given by

$$[D_{r_1}, D_{r_2}]_{q_{r_2 r_1}} = 0, \quad \forall r_1 < r_2 \in R_a, \tag{21}$$

where the coefficients in (21) are subject to the condition opposite to (20), that is: for any subdivision $R_a = R' \cup R''$ into two nonintersecting and nonempty parts R' and R'',

$$\exists r_1 \in R' \ \text{ and } \ r_2 \in R'' : g_{r_1 r_2} g_{r_2 r_1} \neq 0. \tag{22}$$

In other words, this means that for any pair of indices $r, s \in R_a$ there exists a finite sequence $\{r_k \in R_a | k = 1, \ldots, n\}$ such that $r_1 = r$, $r_n = s$ and

$$\prod_{k=1}^{n-1} g_{r_k r_{k+1}} g_{r_{k+1} r_k} \neq 0. \tag{23}$$

Thus, relations (22) and (23) may be represented graphically via a *connectivity condition* on an ordered graph the vertices of which are labeled by the indices $r \in R_a$ and the edges connect only those vertices $r_1 < r_2$ for which the condition $q_{r_2 r_1} \neq 0$ is satisfied.

Furthermore, for $N_I \geqslant 2$ we split the set R into two sets S and T as follows:

For any $R_a \subset R$ we define

$$R_a := \begin{cases} S_a & \text{if } \exists r \in R_a \text{ and } i \in I: g_{ir} g_{ri} \neq 0, \\ T_a & \text{otherwise.} \end{cases} \tag{24}$$

Suppose that the M_R sets R_a in (19) split into M_S sets S_a and M_T sets T_a in this way, thus $M_R = M_S + M_T$. We number these sets as S_a, $a = 1,\ldots,M_S$, and T_a, $a = 1,\ldots,M_T$, and introduce

$$S := \cup_{a=1}^{M_S} S_a, \quad T := \cup_{a=1}^{M_T} T_a. \tag{25}$$

Although the decomposition of the set S into subsets S_a has been used in the definition of the set S, it will not be of practical importance in what follows. Contrary to that, the structure of the set T is crucial and needs further refinement.

For any $T_a \subset T$ define

$$T_a := \begin{cases} T_a^{\bullet} & \text{if } \exists i < j \in I: \quad T_a \subset \{i+1, i+2 \ldots, j-1\} \text{ and} \\ & \qquad\qquad I \cap \{i+1, i+2, \ldots, j-1\} = \varnothing \\ T_a^{\circ} & \text{otherwise.} \end{cases} \tag{26}$$

Thus in short-hand notation $T = \{T_a^{\bullet} | a = 1,\ldots,M_T^{\bullet}\} \cup \{T_a^{\circ} | a = 1,\ldots,M_T^{\circ}\}$ with $M_T = M_T^{\bullet} + M_T^{\circ}$.

B. General structural remarks about *N*-generator diffusion algebras

Until now we have primarily discussed index sets. By an abuse of terminology, we will from now on also refer to "generators of a set I, S, T, or R," meaning the generators indexed by elements from the corresponding set.

Definition 3.3: A set of three generators $\{D_x, D_y, D_z\}$ with x, y, and $z \in X$, Y, Z, respectively, where X, Y, and Z are any of the sets I, R, S, and T or any set in their decomposition will be called a triplet (of type) $\{X,Y,Z\}$.

Note that any triplet of type $\{I,I,I\}$ in a diffusion algebra of $N \geqslant 3$ generators gives rise to a diffusion algebra of type A_I or A_{II}, any triplet of type $\{I,I,R\}$ to a diffusion algebra of type $B^{(1)}$, $B^{(2)}$, $B^{(3)}$, or $B^{(4)}$, any triplet of type $\{I,R,R\}$ to a diffusion algebra of type $C^{(1)}$ or $C^{(2)}$, and any triplet of type $\{R,R,R\}$ to a diffusion algebra of type D.

Then we have:

Lemma 3.4: For any Diffusion algebra (1) with $N \geqslant 3$ generators the following statements hold

(1) If $N_I \geqslant 3$, then all subalgebras corresponding to triplets of type $\{I,I,I\}$ are of the same type, which is either A_I (that is, $g_{ij} = g$ $\forall i,j \in I$) or A_{II} (that is, $g_{ji} = 0$, $g_{ij} = g_i - g_j$, $g_i \neq g_j$, $\forall i < j \in I$).

(2) If $N_I \geqslant 3$ and all subalgebras corresponding to triplets $\{I,I,I\}$ are of type A_I then for any $s \in S$ and for all $i \in I$ one has

$$g_{is} = g_{si} = g_s. \tag{27}$$

(3) If $N_I \geqslant 3$ and all subalgebras corresponding to triplets $\{I,I,I\}$ are of type A_{II} then $S = \varnothing$.

(4) Let $N_I \geqslant 2$.

For any $i \in I$ *and for all* $t,t' \in T_a$ *(here* T_a *means both* $T_a^{\bigcirc}$ *and* $T_a^{\bullet}$*) with* $t<i$ *and* $t'>i$ *the coefficients* g_{ti} *and* $g_{it'}$ *depend only on the index* a *of the set* T_a *and not on the individual indices* t *or* t'. *If* $t,t' \in T_a^{\bigcirc}$ *one furthermore has* $g_{ti}=-g_{it'}$.

For any $i<j \in I$ *and for all* $t,t' \in T_a : t<i$ *and* $t'>j$,

$$g_{ti}+\Lambda_{ij}=g_{tj}, \tag{28}$$

$$g_{it'}=g_{jt'}+\Lambda_{ij}, \tag{29}$$

where $\Lambda_{ij} := g_{ij}-g_{ji}$.

(5) Let $N_I=1$. *Denote the only index in* I *as* $\mathbf{i}$ *in order to stress that it is not a running index. For all* $r \in R_a$ *one has*

$$g_{\mathbf{i}r}-g_{r\mathbf{i}}=\Lambda_a. \tag{30}$$

Note that both the left- and the right-hand sides of relation (30) depend only on the index a *of the set* R_a *and not on the individual index* r.

Proof of (1): It follows from the fact that in each set $\{D_i,D_j,D_k | i,j,k \in I\}$ one has either $g_{\beta\alpha} \neq 0$ for all $\alpha<\beta \in \{i,j,k\}$, or, $g_{\beta\alpha}=0$, for all $\alpha<\beta \in \{i,j,k\}$, but no mixture thereof, which contradicts a mixing of A_I and A_{II} type algebras.

Proof of (2): Let $N_I \geqslant 3$ and $g_{ij}=g \ \forall i,j \in I$. By (25) it is enough to check (27) for any $S_a \subset S$. Consider an index $r \in S_a$ which satisfies the condition $g_{rj}g_{jr} \neq 0$ for some $j \in I$. Then, for any $i \in I$, the triplets $\{D_r,D_i,D_j\}$ are all of type $B^{(1)}$ with $\Lambda=0$ and, hence, $g_{ir}=g_{ri}=g_r$.

Next, take any $s \in S_a$. By definition, there exists a sequence $r_k \in S_a$, $k=1,\ldots,n$, such that $r_1=r$, $r_n=s$ and such that the connectivity condition (23) is satisfied. Then, for any $i \in I$, starting with the triplet $\{D_{r_1},D_{r_2},D_i\}$ one inductively proves that all the triplets $\{D_{r_k},D_{r_{k+1}},D_i\}$ are of type $C^{(1)}$ with $\Lambda=0$, and hence (27) follows.

Proof of (3): Let $N_I \geqslant 3$ and $g_{ji}=0$, $g_{ij}=g_i-g_j$, $g_i \neq g_j$, $\forall i<j \in I$ and suppose $S \neq \varnothing$. Consider some $S_a \subset S$ and take those indices $r \in S_a$ and $i_0 \in I$ for which condition $g_{i_0r}g_{ri_0} \neq 0$ is satisfied. For any $j,k \in I$ the triplets $\{D_{i_0},D_j,D_r\}$ and $\{D_{i_0},D_k,D_r\}$ are both of type $B^{(1)}$, which also implies that the triplets $\{D_j,D_k,D_r\}$, $\forall j,k \in I$, are all of type $B^{(1)}$. Now, there is no mutual ordering of any arbitrarily chosen indices $i<j<k \in I$ and the index $r \in S_p$ for which the existence of any $B^{(1)}$-type triplet $\{D_i,D_j,D_r\}$, $\{D_i,D_k,D_r\}$, and $\{D_j,D_k,D_r\}$ is compatible with the condition that $g_{ik}=g_{ij}+g_{jk}$—a contradiction.

Proof of (4): Let $N_I \geqslant 2$ and consider any three indices $i \in I$ and $t<t' \in T_a$. Exploiting the connectivity property (23) of the set T_a one can find a sequence $\{t_k | k=1,\ldots,n\}$ such that $t_1=t$, $t_n=t'$ and such that all the C-type triplets $\{D_i,D_{t_k},D_{t_{k+1}}\}$ are not of type $C^{(2)}$. Hence, their corresponding nonzero coefficients g_{it_k} (for $i<t_k$) or g_{t_ki} (for $t_k<i$) are subject to the conditions for triplets of type $C^{(1)}$ [see (12)] which together with the definition (24) of the set T_a implies $g_{it}=g_{it'}$ in the case $i<t<t'$, $g_{ti}=g_{t'i}$ in the case $t<t'<i$, and $g_{ti}=-g_{it'}$ in the case $t<i<t'$, thus proving the first part of the fourth statement in the lemma.

To prove the second part notice that for any four indices $i,j \in I$ and $t,t' \in T_a$ which are ordered as $t<i<j<t'$ their corresponding triplets $\{D_t,D_i,D_j\}$ and $\{D_i,D_j,D_{t'}\}$ are of type $B^{(4)}$ and, $B^{(3)}$, respectively. Conditions (28) and (29) then reproduce the relations between the coefficients in those triplets [see Eqs. (10) and (11)].

Proof of (5): Let $N_I=1$ and consider any pair of indices $r,r' \in R_a$. As before, for every connective set R_a there exists a chain of C-type triplets $\{D_{\mathbf{i}},D_{r_k},D_{r_{k+1}}\}$, $k=1,\ldots,n-1$, with $r_1=r$ and $r_n=r'$ which are not of type $C^{(2)}$. Hence one obtains (30) with one and the same coefficient Λ_a for all $C^{(1)}$ type triplets $\{I,R_a,R_a\}$. □

Lemma 3.4 suggests listing diffusion algebras in families according to the number of generators in the set I and provides information about the structure of relations among generators from the sets I, S, T, and R in each case.

C. List of diffusion algebras with *N* generators

In this section, we list all N-generator diffusion algebras and provide a theorem which proves the exhaustiveness of the formalism.

Diffusion algebras with N generators are listed as five families of algebras: A_I, A_{II}, B, C, and D. As in the case of $N=3$ the number of nonzero coefficients x_α or, in other words, the cardinality of the set I is used as a criterion for separating diffusion algebras into families of the types $A(N_I\geqslant 3)$, $B(N_I=2)$, $C(N_I=1)$ or $D(N_I=0)$. Type A algebras are separated further into two families A_I and A_{II} depending on the number of nonzero coefficients g_{ij} with indices i,j in the set I.

Different algebras in the families are obtained in dependence on the choice of the decomposition of the set $I_N=\{1,2,\ldots,N\}$ into *ordered subsets* I, S, T_a°, $a=1,\ldots,M_T^{\circ}$, $T_b^{\bullet}$, $b=1,\ldots,M_T^{\bullet}$ (or R_a, $a=1,\ldots,M_R$ for $N_I=1$) as well as on the choice of coefficients in their defining relations. In the following we adopt a notation for diffusion algebras where the corresponding decomposition of the set I_N is given explicitly as argument to the family symbol. To avoid any confusion let us stress that the subscript indices a and b in our notation are treated as running ones so that, e.g.,

$$A_I(I,S,T_a^{\circ},T_b^{\bullet})\equiv A_I(I,S,T_1^{\circ},\ldots,T_{M_T^{\circ}}^{\circ},T_1^{\bullet},\ldots,T_{M_T^{\bullet}}^{\bullet}),$$

where we imply $I_N=I\cup S\cup(\cup_{a=1}^{M_T^{\circ}}T_a^{\circ})\cup(\cup_{b=1}^{M_T^{\bullet}}T_b^{\bullet})$, and I, S, T_a°, and $T_b^{\bullet}$ are mutually nonintersecting ordered subsets in I_N. The values of the coefficients $g_{\alpha\beta}$ are not shown explicitly in these notations so that in fact our notation displays connnective components in a variety of diffusion algebras rather than the particular algebras.

All relations in (31)–(35) below are to be complemented by relations (20), (21) for the elements of the subset R together with the conditions (22) or (23) on the coefficients involved.

(1) *Diffusion algebras of type* $A_I(I,S,T_a^{\circ},T_b^{\bullet})$, $N_I\geqslant 3$*:*

$$\begin{aligned}
&g[D_i,D_j]=x_jD_i-x_iD_j, \quad \forall i,j\in I,\\
&g_s[D_s,D_i]=x_iD_s, \quad \forall s\in S, i\in I,\\
&g_a^{\circ}:D_iD_t:=-x_iD_t, \quad \forall a,t\in T_a^{\circ}, i\in I,\\
&g_b^{+}D_iD_t=-x_iD_t, \quad \forall b,t\in T_b^{\bullet}, i\in I: i<t,\\
&g_b^{-}D_tD_i=x_iD_t, \quad \forall b,t\in T_b^{\bullet}, i\in I: i>t,
\end{aligned} \tag{31}$$

where g, g_s, g_a°, $g_b^{\pm}\neq 0$.

(2) *Diffusion algebras of type* $A_{II}(I,T_a^{\circ},T_b^{\bullet})$, $N_I\geqslant 3$*:*

$$\begin{aligned}
&(g_i-g_j)D_iD_j=x_jD_i-x_iD_j, \quad \forall i<j\in I,\\
&(g_i+g_a^{\circ}):D_iD_t:=-x_iD_t, \quad \forall a,t\in T_a^{\circ}, i\in I,\\
&(g_i+g_b^{+})D_iD_t=-x_iD_t, \quad \forall b,t\in T_b^{\bullet}, i\in I: i<t,\\
&(g_b^{-}-g_i)D_tD_i=x_iD_t, \quad \forall b,t\in T_b^{\bullet}, i\in I: i>t,
\end{aligned} \tag{32}$$

where $g_i\neq g_j$ for $i\neq j$ and $g_i\notin\{g_a^{\circ},\mp g_b^{\pm}\}$.

(3) *Diffusion algebras of type* $B(I=\{\mathbf{i},\mathbf{j}\},S,T_a^{\circ},T_b^{\bullet})$*:*

We use the notation $\mathbf{i}$ and $\mathbf{j}$ with $\mathbf{i}<\mathbf{j}$ for the two elements of the set I to emphasize that they are not running indices. Note also that $\mathbf{i}<t<\mathbf{j}$ for all $t\in T_b^{\bullet}$ in this case.

$$
\begin{gathered}
gD_{\mathbf{i}}D_{\mathbf{j}}-(g-\Lambda)D_{\mathbf{j}}D_{\mathbf{i}}=x_{\mathbf{j}}D_{\mathbf{i}}-x_{\mathbf{i}}D_{\mathbf{j}},\\
g_sD_{\mathbf{i}}D_s-(g_s-\Lambda)D_sD_{\mathbf{i}}=-x_{\mathbf{i}}D_s,\quad \forall s\in S,\\
g_sD_sD_{\mathbf{j}}-(g_s-\Lambda)D_{\mathbf{j}}D_s=x_{\mathbf{j}}D_s,\quad \forall s\in S,\\
g_a^{\bigcirc}:D_{\mathbf{i}}D_t:=-x_{\mathbf{i}}D_t,\quad \forall t\in T_a^{\bigcirc},\\
(g_a^{\bigcirc}-\Lambda):D_{\mathbf{j}}D_t:=-x_{\mathbf{j}}D_t,\quad \forall t\in T_a^{\bigcirc},\\
g_b^{+}D_{\mathbf{i}}D_t=-x_{\mathbf{i}}D_t,\quad \forall t\in T_b^{\bullet},\\
g_b^{-}D_tD_{\mathbf{j}}=x_{\mathbf{j}}D_t,\quad \forall t\in T_b^{\bullet},
\end{gathered}
\tag{33}
$$

where $g\neq 0$, $g_s\neq 0$ for all s and $g_s\neq\Lambda$ for s such that either $s<\mathbf{i}$ or $s>\mathbf{j}$, $g_a^{\bigcirc}\notin\{0,\Lambda\}$ and $g_b^{\pm}\neq 0$.

(4) *Diffusion algebras of type* $C(I=\{\mathbf{i}\},R_a)$*:*

As in Lemma 3.4 the only element of I is denoted here as $\mathbf{i}$,

$$
g_rD_{\mathbf{i}}D_r-(g_r-\Lambda_a)D_rD_{\mathbf{i}}=-x_{\mathbf{i}}D_r,\quad \forall r\in R_a,
\tag{34}
$$

where $g_r\neq 0$ for $r<\mathbf{i}$ and $g_r\neq\Lambda_a$ for $r>\mathbf{i}$.

(5) *Diffusion algebras of type* $D(R)$*:*

$$
D_rD_s-q_{sr}D_sD_r=0,\quad \forall r<s\in R.
\tag{35}
$$

Theorem 3.5: *The previously given list of algebras is exhaustive and contains all possible diffusion algebras with N generators.*

Proof: According to the diamond lemma, an algebra of N generators with relations of type (1) is a diffusion algebra if each of its triplets $\{D_\alpha,D_\beta,D_\gamma\}$ generates a subalgebra coinciding with one of the cases listed in Sec. II. Lemma 3.4 provides information about possibile consistent combinations of several such triplets and we thus have to demonstrate that the families of algebras (31)–(35) exhaust the list of diffusion algebras which are allowed by this lemma.

Let us start with the case $N_I\geqslant 3$. According to the first statement of Lemma 3.4 there are two possible types of relations between generators from the set I. This gives rise to two families of diffusion algebras—A_I and A_{II}. Statement (2) of Lemma 3.4 describes the relations between the generators from the sets I and S in the case of the family A_I, and the third statement of Lemma 3.4 excludes the presence of a nonempty set S in the case of the family A_{II}. The coefficients in the relations between the generators from the set I and the sets $T_a^{\bigcirc}$ and $T_b^{\bullet}$ are subject to the conditions given in the fourth statement of Lemma 3.4, where $\Lambda_{ij}=0$ for the A_I family and $\Lambda_{ij}=(g_i-g_j)$ for the A_{II} family. These conditions fix the relations between the generators in the families of type A_I and A_{II} to the expressions in (31) and (32). Since the triplets of the form $\{I,S,T\}$ (occurring only for the A_I family) and $\{I,T_a,T_b\}$ for $a\neq b$ are of type $C^{(2)}$, no further conditions arise from these relations. This exhausts all possibilities, and thus no further conditions occur.

Let $N_I=2$. For each subset $S_a\subset S$ the connectivity property (23) implies relations of type $B^{(1)}$ for all triplets $\{I,I,S_a\}$, and thus for any triplet $\{I,I,S\}$. The corresponding relations are listed in the first three lines of (33). The compatibility conditions within the triplets $\{I,T_a,T_a\}$ and $\{I,I,T_a\}$ are given in the fourth statement of Lemma 3.4, where we now have $\Lambda_{\mathbf{ij}}\equiv\Lambda$. These conditions fix the form of the last four lines in (33). Since $C^{(2)}$ type relations for $\{I,S,T\}$ and $\{I,T_a,T_b\}$ $(a\neq b)$ triplets do not imply further restrictions, no further constraints arise.

In the case $N_I=1$ a decomposition of the set R into S and T is not necessary, and we thus work with the whole set R. Then the form of the relations (34) is implied by the fifth statement of Lemma 3.4, which describes the compatibility conditions for the $\{I,R_a,R_a\}$ triplets. The relations in the $C^{(2)}$ triplets $\{I,R_a,R_b\}$ for $a\neq b$ give no further constraints.

In the case $N_I=0$ all the triplets are of type D, which are compatible without any restrictions on the coefficients. □

Note that while mathematically possible, not all algebras in the families are relevant from the physicist's point of view. Due to the fact that the structure constants of diffusion algebras are interpreted as hopping rates, that is probabilities, in the framework of stochastic processes on linear lattices, only non-negative structure constants are relevant. This not only implies restrictions on the structure constants themselves, but also on the decompositions of the set I_N, because some configurations are not compatible with non-negative structure constants. In particular, due to Lemma 3.4, statement (4), part 1, non-negative structure constants throughout are possible only if the subsets $T_a^{\bigcirc}$ fulfill one of the following two requirements:

$$(1)\ \forall t \in T_a^{\bigcirc}\ \text{ and }\ \forall i \in I: t<i\ \text{ or }\ (2)\ \forall t \in T_a^{\bigcirc}\ \text{ and }\ \forall i \in I: t>i. \tag{36}$$

We conclude this section with some comments on the classification problem for diffusion algebras. To deal with the problem one should first establish criteria of equivalence, and we discuss two natural ones here.

(1) One can consider linear transformations on the set of generators $\{D_\alpha | \alpha \in I_N\}$. However, there is the difficulty that not all linear transformations respect the ansatz (1). There are two special cases: rescaling transformations $D_\alpha \to \kappa_\alpha D_\alpha$ and substitution transformations $D_\alpha \to D_{\sigma(\alpha)}$, where σ is an element of the symmetric group $\mathcal{S}_N$.

As has already been mentioned in Sec. I, rescalings may be used to fix (depending on the context of the physical application) some special values for the nonzero coefficients x_α. In particular, this implies that the values of the nonzero coefficients x_α are not relevant.

The substitution transformations clearly respect the form of the relations (1), but may contradict the requirement on the mutual ordering of the generators, that is $g_{\alpha\beta}\neq 0$ for $\alpha<\beta$. In particular, a permutation of the elements from different subsets T_a and between the subsets T and S, or T and I is strictly forbidden. In addition, one cannot permute two elements $r<s$ in the same subset R_a unless $q_{sr}\neq 0$. On the other hand, permutations inside the subset I and (in most cases) between the subsets I and S are allowed unless they contradict the above-described requirements. Thus, substitution transformations establish certain equivalence classes inside each of the families $A_I(I,S,T_a^{\bigcirc},T_b^{\bullet})$, $A_{II}(I,T_a^{\bigcirc},T_b^{\bullet})$, $B(\{\mathbf{i},\mathbf{j}\},S,T_a^{\bigcirc},T_b^{\bullet})$, $C(\{\mathbf{i}\},R_a)$, and $D(R)$. These equivalence classes can be calculated in concrete cases, but one hardly expects their complete description in the case of general N.

Note that besides the rescalings and the substitutions which always exist there may occur other types of linear transformations which relate different types of diffusion algebras. For instance, in the case of $N=3$ the $C^{(1)}$ type algebras in (12) with $\Lambda\neq 0$ can be reduced to (a subclass of) D type algebras by the transformation $D_\alpha \to D_\alpha - x_\alpha/\Lambda$. For general N, such transformations allow one to reduce the number of nonzero parameters Λ_a in the family of C type diffusion algebras in (34) by 1.

(2) One can use the algebra antihomomorphism which simultaneously inverts multiplication in the algebra, that is $D_\alpha D_\beta \to D_\beta D_\alpha$, and the order of indices, that is $\alpha<\beta \to \alpha>\beta$. This transformation amounts to a mirror reflection of the corresponding stochastic processes. For example, in the list of diffusion algebras with $N=3$ the families $B^{(3)}$ and $B^{(4)}$ are mirror symmetric. Further examples of mirror symmetry for the case $N=4$ can be found in Ref. 3 in Appendix B.

D. Description of the blending procedure

The blending procedure is a constructive method to generate diffusion algebras. The corresponding construction theorem states that any diffusion algebra can be obtained from a set of building blocks [Eqs. (4.1)–(4.7) in Ref. 3] via blending. In the following table we describe the correspondence between the building blocks from Ref. 1 (left-hand column below) and the specific subclasses of the families in Theorem 3.5 (right-hand column below):

$$
\begin{aligned}
A_I^{(1)} &: A_I(I,S), \quad T=\varnothing, \\
A_I^{(2)} &: A_I(I,T^{\bigcirc}), \text{ and } A_{II}(I,T^{\bullet}), \quad S=\varnothing, \\
A_{II} &: A_{II}(I,T^{\bigcirc}), \text{ and } A_{II}(I,T^{\bullet}), \\
B^{(1)} &: B(I=\{\mathbf{i},\mathbf{j}\},S), \quad T=\varnothing, \\
B^{(2)} &: B(I=\{\mathbf{i},\mathbf{j}\},T^{\bigcirc}), \text{ and } B(I=\{\mathbf{i},\mathbf{j}\},T^{\bullet}), \quad S=\varnothing, \\
C &: C(I=\{\mathbf{i}\},R), \\
D &: D(R).
\end{aligned}
\tag{37}
$$

Here it is understood that the sets $T^{\bigcirc}$ and $T^{\bullet}$ whenever they appear in the right-hand column are the only connective components in the decomposition (25) of the subset $T \in I_N$. The connectivity condition may be also imposed on the subsets S and R in the right-hand column of (37). We remark that the mathematical setting adopted in the present paper allow us to extract elementary building blocks for the blending procedure. They are shown in the right-hand column of (37) and the blocks listed in the left-hand column and used in Ref. 3 can be constructed by blending of an arbitrary number of the corresponding blocks from the right-hand column. Note that in the settings of Ref. 3 extracting the elementary blocks would only amount to imposing additional connectivity conditions (23) on the coefficients $g_{\alpha\beta}$ in relations (4.1)–(4.7) there and so would not suit the purposes of Ref. 3.

Furthermore we remark that in contrast to Ref. 3 we do not fix the order between $D_{\mathbf{i}}$, $D_{\mathbf{j}}$ and D_s to $\mathbf{i}<s<\mathbf{j}$ for all $s \in S$ in $B(I=\{\mathbf{i},\mathbf{j}\},S)$, because the other orders are needed when blending with $B(I=\{\mathbf{i},\mathbf{j}\},T^{\bigcirc})$ and $B(I=\{\mathbf{i},\mathbf{j}\},T^{\bullet})$ in order to obtain all diffusion algebras. This is an inaccurracy in the formulation of the construction theorem in Ref. 3. Despite that in the list of $N=4$ diffusion algebras given in Appendix B of Ref. 3 the blending of such blocks is treated correctly (see example 13 there).

Let $X_l(I,U_l)$, $l=1,\ldots,K$ denote K building blocks in the list (37), where U_l refers to the set R, S, $T^{\bigcirc}$, or $T^{\bullet}$ corresponding to the building block, and which are such that they have the same number of elements N_I in I with generators D_i, $i \in I$ satisfying in all blocks X_l the same relations among themselves.

Consider an ordered set $\mathcal{I}$ whose elements are labeled by the indices from the sets I, $U_1,\ldots,U_K$ and such that for any $l=1,\ldots,K$ the order of the elements of $\mathcal{I}$ with their labels form I and U_l is the same as the order of the indices in the block $X_l(I,U_l)$. In this situation we say that the order on $\mathcal{I}$ is *compatible* with the orders in the blocks X_l.

Let us denote as $X_{\mathcal{I}}(I,U_1,\ldots,U_K)$ the algebra with generators labeled by the elements in the set $\mathcal{I}$ and which satisfies the following conditions.

(1) For any $l=1,\ldots,K$ the generators of $X_{\mathcal{I}}$ with indices from the subsets I, $U_l \subset \mathcal{I}$ satisfy the same relations as their corresponding generators in the blocks $X_l(I,U_l)$.

(2) For any $l_1 \neq l_2 \in \{1,\ldots,K\}$ and for all $a \in U_{l_1} \subset \mathcal{I}$ and $b \in U_{l_2} \subset \mathcal{I}$ the corresponding generators D_a, $D_b \in X_{\mathcal{I}}$ satisfy the relation

$$
:D_aD_b:=0. \tag{38}
$$

The procedure of constructing the algebras $X_{\mathcal{I}}$ from their building blocks $X_l(I,U_l)$ is called *blending*. Clearly the number of different algebras $X_{\mathcal{I}}$ which are associated with the set of building blocks $\{X_l(I,U_l)\}_{l=1,\ldots,K}$, coincides with the number of different ordered sets $\mathcal{I}$ whose order is compatible with the orders in all blocks X_l.[5]

The following statement made in Ref. 1 is a corollary to the construction theorem 3.5:

Theorem 3.6: *Every diffusion algebra can be obtained via a blending of building blocks in (37).*

IV. CONCLUSION

We have presented a derivation of diffusion algebras, which has led to five different families of algebras: A_I, A_{II} B, C, and D and it has been shown that the approach is exhaustive. Since these families of algebras correspond to the algebras obtained via the blending procedure in Ref. 3, this also proves the construction theorem in Ref. 3.

(Received 27 August 2001; accepted for publication 30 January 2002)

In this paper the problem of recovering an algebraic dynamics in a perturbative approach is discussed. The mathematical environment in which the physical problem is considered is that of algebras of unbounded operators endowed with the quasiuniform topology. After some remarks on the domain of the perturbation, conditions are given for the dynamics to exist as the limit of a net of regularized linear maps. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1467609]

I. INTRODUCTION

In the so-called algebraic approach to quantum systems, one of the basic problems to solve consists of the rigorous definition of the algebraic dynamics, i.e., the time evolution of observables and/or states. For instance, in quantum statistical mechanics or in quantum field theory one tries to recover the dynamics by performing a certain limit of the strictly *local* dynamics. However, this can be successfully done only for few models and under quite strong topological assumptions (see, for instance, Ref. 1, and references therein). In many physical models the use of local observables corresponds, roughly speaking, to the introduction of some *cutoff* (and to its successive removal) and this is in a sense a general and frequently used procedure, see Refs. 2–4 for conservative and Refs. 5 and 6 for dissipative systems.

Introducing a cutoff means that in the description of some physical system, we know a *regularized* Hamiltonian H_L, where L is a certain parameter closely depending on the nature of the system under consideration. We assume that H_L is a bounded self-adjoint operator in the Hilbert space $\mathcal{H}$ of the physical system.

There are several possible situations of some interest. Among these we will consider the following ones:

a. H_L *converges to an operator* H. This is apparently the simplest situation. Of course we should specify the sense in which the convergence is understood. But for the moment, we want only to focus on the possible problems that arise.

For each fixed L, we know the solution of the dynamical problem, i.e., we know the solution of the Heisenberg equation

$$i\frac{\mathrm{d}\alpha_L^t(A)}{\mathrm{d}t}=[H_L,\alpha_L^t(A)]. \tag{1}$$

This solution, $\alpha_L^t(A)=e^{iH_Lt}Ae^{-iH_Lt}$, would give the *cutoff* dynamics of the system. Then it makes sense to ask the question as to whether $\alpha_L^t(A)$ converges, possibly in the same sense as H_L converges to H, to the solution $\alpha^t(A)$ of the Heisenberg equation

a)Electronic mail: bagarell@unipa.it
b)Electronic mail: trapani@unipa.it

$$i\frac{d\alpha^t(A)}{dt}=[H,\alpha^t(A)]. \tag{2}$$

It is worth stressing that even though H is a well-defined self-adjoint operator, it is in general, unbounded. For this reason, while the right-hand side of Eq. (1) is perfectly meaningful, the need for clarifying the right-hand side of Eq. (2) is always in order since H is certainly not everywhere defined in $\mathcal{H}$.

Of course, the analysis of the convergence of $\alpha_L^t(A)$ to $\alpha^t(A)$ [in this case where $\alpha^t(A)$ is explictly known] is significant only for deciding the accuracy of the approximation of $\alpha^t(A)$ with $\alpha_L^t(A)$.

b. H_L *does not converge*. In this case, the situation becomes more difficult and a series of questions arise whose answer is highly nontrivial.

As a first step, one could begin by considering the derivations

$$\delta_L(A)=i[H_L,A]$$

that give, at infinitesimal level, the dynamics of the system.

The first issue, of course, is if these derivations converge, in a certain sense, to a derivation δ and which properties this derivation δ enjoys. For instance, is it a spatial derivation? (i.e, is there a symmetric operator H that *implements*, at least in a generalized sense, the derivation?[7])

Further, can this derivation be integrated to some automorphisms group of the operator algebra we are dealing with? Or, conversely, since δ_L can be integrated without any problem, $\alpha_L^t(A)=e^{iH_Lt}Ae^{-iH_Lt}$, what can be said about the limit of α_L^t? And how are these two problems related? These questions are well-known not to admit an easy general solution.

In this paper we will be mainly concerned with situation (a) above, while we will only make a few comments on the more difficult situation (b), which will be considered in more detail in a future paper.

Our basic assumptions is that the Hamiltonian H of the system can be expressed in the form

$$H=H_0+B;$$

in other words, our approach is tentatively *perturbative*: indeed, we suppose that we have full knowledge of the *unperturbed system* whose Hamiltonian is H_0. In other words, given H we can extract what we call a free Hamiltonian H_0, which we know in all details, and consider $B:=H-H_0$ as a perturbation of H_0 itself.

As we have already said, handling with unbounded operators poses a problem of domain for the algebra generated by the powers of the Hamiltonian H_0. The natural choice is to take the set of C^∞-vectors of H_0. Once a perturbation B is introduced, it is natural to ask ourselves in which sense the corresponding domain for H is related to that of H_0.

This is the main subject of Sec. II, where we start with the assumption that $\mathcal{D}^\infty(H)=\mathcal{D}^\infty(H_0)$ and derive some properties of the corresponding *quasiuniform* topologies that the two operators define.

Then we give, in a quite general way, conditions on two self-adjoint operators H_0 and H for $\mathcal{D}^\infty(H)$ and $\mathcal{D}^\infty(H_0)$ to coincide.

In Sec. III, we come back to the problem of describing the dynamics of the perturbed system as limit of a cutoff dynamics. In other words, we introduce a regularized Hamiltonian $H_L=Q_L^0HQ_L^0$ where the Q_L^0's are certain spectral projections of the unperturbed Hamiltonian H_0 and we look for conditions under which the unitary group generated by H_L converges to that generated by H. A class of examples fitting our hypotheses is also given.

The main scope of the paper is to try and construct a mathematical environment where this kind of problem can be successfully treated and also to develop techniques that could be adapted for the study of the more relevant case (b) outlined previously. It is worth stressing that this is a rather common situation in physics (think of mean-field models or systems with ultraviolet

cutoff[2,3]) and a perturbative approach should also be considered for the derivations that describe the system at infinitesimal level. A short discussion on this point is made in Sec. IV.

II. THE MATHEMATICAL FRAMEWORK

We begin this section by summarizing some known facts on unbounded operator algebras and their topological properties. We refer to Refs. 4, 8–10 for full details.

Let $\mathcal{D}$ be a dense domain in Hilbert space $\mathcal{H}$; with $\mathcal{L}^\dagger(\mathcal{D})$ we denote the set of all weakly continuous endomorphisms of $\mathcal{D}$. Then to each operator $A\in\mathcal{L}^\dagger(\mathcal{D})$ we can associate an operator $A^\dagger\in\mathcal{L}^\dagger(\mathcal{D})$ with $A^\dagger=A^*_{\restriction\mathcal{D}}$ where A^* is the usual Hilbert adjoint of A. Then $\mathcal{L}^\dagger(\mathcal{D})$, under the usual operations and the involution †, is a*-algebra of unbounded operators or, simply, an O^*-algebra.

Now let S be a self-adjoint operator in $\mathcal{H}$ and

$$\mathcal{D}:=\mathcal{D}^\infty(S)=\cap_{n\geqslant 1}D(S^n).$$

Then $\mathcal{D}$ endowed with the topology t_S of $\mathcal{D}^\infty(S)$ defined by the set of seminorms

$$f\mapsto\|S^n f\|,\quad n=0,1,\ldots$$

or, equivalently

$$f\mapsto\|(1+S^{2n})^{1/2}f\|,\quad n=0,1,\ldots$$

is a reflexive Fréchet space and the topology t_S is equivalent to the topology $t_{\mathcal{L}^\dagger(\mathcal{D})}$ defined on $\mathcal{D}$ by the set of seminorms

$$f\mapsto\|Af\|,\quad A\in\mathcal{L}^\dagger(\mathcal{D}).$$

In the *-algebra $\mathcal{L}^\dagger(\mathcal{D})$ several topologies can be defined. For the purposes of this paper we will only need the *quasiuniform topology* defined on $\mathcal{L}^\dagger(\mathcal{D})$ in the following way. Put

$$\|A\|^{\mathcal{N},B}=\sup_{\phi\in\mathcal{N}}\|BA\phi\|,\quad B\in\mathcal{L}^\dagger(\mathcal{D}),\ \mathcal{N}\ \text{bounded in}\ \mathcal{D}[t_{\mathcal{L}^\dagger(\mathcal{D})}].$$

Then, the quasiuniform topology, $\tau^{\mathcal{D}}_*$ on $\mathcal{L}^\dagger(\mathcal{D})$ is defined by the set of seminorms:

$$A\in\mathcal{L}^\dagger(\mathcal{D})\to\max\{\|A\|^{\mathcal{N},B},\|A^\dagger\|^{\mathcal{N},B}\}.$$

In the case where $\mathcal{D}=\mathcal{D}^\infty(S)$, the quasiuniform topology on $\mathcal{L}^\dagger(\mathcal{D})$ can be described in an easier way.

Indeed, let $\mathcal{F}$ denote the class of all positive, bounded and continuous functions $f(x)$ on $\mathbb{R}_+$, which are decreasing faster than any inverse power of x, i.e., $\sup_{x\in\mathbb{R}_+}x^k f(x)<\infty$, $k=0,1,\ldots$.

Then, if we put

$$\mathcal{S}_f=\{f(S)\phi;\phi\in\mathcal{D},\|\phi\|=1\}$$

for $f\in\mathcal{F}$, the family $\{\mathcal{S}_f\}_{f\in\mathcal{F}}$ is a basis for the bounded sets of $\mathcal{D}[t_S]$.
In practice this means that, for each t_S-bounded set $\mathcal{N}$ in $\mathcal{D}$, there exists an $\mathcal{S}_f$ such that $\mathcal{N}\subset\mathcal{S}_f$.

This fact easily implies that the quasiuniform topology, $\tau^{\mathcal{D}}_*$ on $\mathcal{L}^\dagger(\mathcal{D})$ can be, equivalently, defined by the set of seminorms:

$$\mathcal{L}^\dagger(\mathcal{D})\ni A\mapsto\|A\|^{f,k}_*=\max\{\|S^kAf(S)\|,\|f(S)AS^k\|\}\quad f\in\mathcal{F},k\in\mathbb{N}\cup\{0\},\tag{3}$$

where the norm on the right-hand side of (3) is the usual norm in $\mathcal{B}(\mathcal{H})$. The *-algebra $\mathcal{L}^\dagger(\mathcal{D})[\tau^{\mathcal{D}}_*]$ is, in this case, a complete locally convex*-algebra, i.e., the involution and the right- and left-multiplications are continuous.

Remark: When estimating seminorms of type (3) we will often consider only the term $\|f(S)AS^k\|$; this is exactly what is needed when $A=A^\dagger$. In the general case, any $A\in\mathcal{L}^\dagger(\mathcal{D})$ is a linear combination of symmetric elements and so, as far as only estimates are concerned, the arguments go usually through.

We can now consider more concrete situations. To begin with, we consider the simplest possible example in which a physical system is described by a Hamiltonian H_0 that mathematically is a self-adjoint operator; we assume $H_0\geqslant 1$; then H_0 has a spectral decomposition

$$H_0=\int_1^\infty \lambda\, dE(\lambda).$$

We put, for $L\geqslant 1$,

$$Q_L^0=\int_1^L dE(\lambda) \tag{4}$$

and define the regularized Hamiltonian by

$$H_L=Q_L^0 H_0 Q_L^0.$$

Then if $\mathcal{D}=\mathcal{D}^\infty(H_0)$ it turns out that the operators Q_L^0 and H_L are bounded operators in $\mathcal{B}(\mathcal{H})$ which belong to $\mathcal{L}^\dagger(\mathcal{D})$ (the Q_L^0's are indeed projectors) and they commute with each other and with H_0.

This makes it quite easy to prove the following convergence properties [in what follows the topology $\tau_*^{\mathcal{D}}$ is that defined in Eq. (3) with S replaced by H_0]:

(c1) $H_L\to H_0$ with respect to the topology $\tau_*^{\mathcal{D}}$,
(c2) $e^{itH_L}\to e^{itH_0}$ with respect to the topology $\tau_*^{\mathcal{D}}$,
(c3) for each $A\in\mathcal{L}^\dagger(\mathcal{D})$, $e^{itH_L}Ae^{-itH_L}\overset{\tau_*^{\mathcal{D}}}{\to} e^{itH_0}Ae^{-itH_0}$.

All these statements can be derived from Lemma 2.2.

The next step consists in considering a Hamiltonian

$$H=H_0+B, \tag{5}$$

where B is regarded as a *perturbation* of the operator H_0. We suppose that the cutoff is determined by H_0, i.e., we assume that

$$H_L=Q_L^0(H_0+B)Q_L^0=H_0Q_L^0+Q_L^0BQ_L^0, \tag{6}$$

where Q_L^0 is defined as in Eq. (4) by the spectral family $E(\cdot)$ of H_0. The right-hand side is well defined since $Q_L^0AQ_L^0$ is bounded for any $A\in\mathcal{L}^\dagger(\mathcal{D})$.

Clearly (6) must be read as a formal expression unless the domains of the involved operators are specified. To be more definite, we make the following assumptions:

(a) $\mathcal{D}=\mathcal{D}^\infty(H_0)$,
(b) $D(H_0)\subseteq D(B)$ and $H=H_0+B$ is self-adjoint on $D(H_0)$,
(c) $\mathcal{D}^\infty(H_0)=\mathcal{D}^\infty(H)$.

Under these assumptions, we have:

Lemma 2.1: (1) The topologies t_{H_0} and t_H are equivalent on $\mathcal{D}$; (2) the topologies on $\mathcal{L}^\dagger(\mathcal{D})$ defined, respectively, by the set of seminorms

$$\mathcal{L}^\dagger(\mathcal{D})\ni A\mapsto \max\{\|H_0^kAf(H_0)\|,\|f(H_0)AH_0^k\|\}\quad f\in\mathcal{F},k\in\mathbb{N}$$

and

$$\mathcal{L}^\dagger(\mathcal{D}) \in A \mapsto \max\{\|H^k A f(H)\|, \|f(H) A H^k\|\} \quad f \in \mathcal{F}, k \in \mathbb{N}$$

are equivalent.

Proof: The statement (1) follows by taking into account that H is continuous with respect to t_{H_0} and H_0 is continuous with respect to t_H, according to the fact that the domain is reflexive.

The statement (2) follows from (1), since the family of t_H-bounded subsets of $\mathcal{D}$ and the family of t_{H_0}-bounded subsets coincide. □

By the previous Lemma, the topology $\tau_*^{\mathcal{D}}$, can be described, following the convenience, via the seminorms in H or by those in H_0. Now, we can prove the following

Lemma 2.2: For each $X \in \mathcal{L}^\dagger(\mathcal{D})$, $X = \tau_*^{\mathcal{D}} - \lim_{L\to\infty} Q_L^0 X Q_L^0$.

Proof: First, notice that, for $\ell \in \mathbb{N}^+$, we have

$$\|H_0^{-\ell}(I - Q_L^0)\phi\|^2 = \int_L^\infty \frac{1}{\lambda^{2\ell}} \mathrm{d}(E(\lambda)\phi, \phi) \leqslant \frac{1}{L^{2\ell}} \|\phi\|^2, \quad \forall \phi \in \mathcal{D}$$

and so

$$\|H_0^{-\ell}(I - Q_L^0)\| \to 0 \quad \text{as} \quad L \to \infty.$$

Now let $f \in \mathcal{F}$ and $k \in \mathbb{N}$; then we have

$$\begin{aligned}
\|f(H_0)(B - Q_L^0 B Q_L^0) H_0^k\| &\leqslant \|f(H_0) B H_0^k (I - Q_L^0)\| + \|f(H_0)(1 - Q_L^0) B H_0^k Q_L^0\| = \sup_{\|\phi\| = \|\psi\| = 1} | \\
&< H_0^{-\ell}(1 - Q_L^0)\phi, H_0^{k+\ell} B^+ f(H_0)\psi > | + \sup_{\|\phi\| = \|\psi\| = 1} | \\
&< f(H_0) H_0^\ell B H_0^k Q_L^0 \phi, H_0^{-\ell}(1 - Q_L^0)\psi > | \\
&\leqslant \|H_0^{-\ell}(1 - Q_L^0)\| \|H_0^{k+\ell} B^+ f(H_0)\| + \|H_0^\ell f(H_0) B H_0^k\| \|H_0^{-\ell}(1 - Q_L^0)\| \to 0
\end{aligned}$$

for $L \to \infty$. □

Incidentally, this lemma gives a proof of (c1) and (c2) above. The proof of (c3) requires the use of a triangular inequality of (c2) and of the commutation rule $[H_0, H_L] = 0$.

Taking into account the separate continuity of the multiplication and the previous lemma, we have:

Corollary 2.3: $\delta_L(A) := i[A, H_L]$ *converges to* $\delta(A) := i[A, H]$ *with respect to the topology* $\tau_*^{\mathcal{D}}$.

Going back to our assumptions on the domains, it is apparent that conditions (b) and (c) given previously are quite strong. It is natural to ask the question under which conditions on B they are indeed satisfied.

The domain. Our starting point is an operator

$$H = H_0 + B$$

under the assumption that the *perturbation* B is a symmetric operator and $D(B) \supseteq D(H_0)$. In general H may fail to be self-adjoint, unless B is H_0-bounded in the sense that there exist two real numbers a, b such that

$$\|B\phi\| \leqslant a\|H_0\phi\| + b\|\phi\|, \quad \forall \phi \in D(H_0). \tag{7}$$

If the inf of the numbers a for which 7 holds (the so-called *relative bound*) is smaller than 1, then the Kato–Rellich theorem[11] states that H is self-adjoint and essentially self-adjoint on any core of H_0.

This is clearly always true if B is bounded: in this case the relative bound is 0. In conclusion, the Kato–Rellich theorem gives a sufficient condition for (b) to be satisfied.

Let us now focus our attention on condition (c). We first discuss some examples.

Example 1: To begin with, we stress the fact that the conditions of the Kato–Rellich theorem are not sufficient to imply that $\mathcal{D}^\infty(H)=\mathcal{D}^\infty(H_0)$. This can be seen explicitly with a simple example. Indeed, let us consider the case where $B=P_f$ with $f\in\mathcal{H}\backslash D(H_0)$ and P_f the projection onto the one-dimensional subspace generated by f. It is quite simple to prove that, in this case:

$$D((H_0+P_f)^2)\cap D(H_0^2)=D(H_0)\cap\{f\}^\perp.$$

This equality implies that neither $\mathcal{D}^\infty(H_0+P_f)$ is a subset of $\mathcal{D}^\infty(H_0)$ nor the contrary. So, in this example, $\mathcal{D}^\infty(H)$ and $\mathcal{D}^\infty(H_0)$ do not compare.

Example 2: Let p and q be the operators in $L^2(\mathbb{R})$ defined by

$$(pf)(x)=if'(x),\quad f\in W^{1,2}(\mathbb{R}),$$

$$(qf)(x)=xf(x),\quad f\in\mathcal{F}W^{1,2}(\mathbb{R}),$$

where $\mathcal{F}$ denotes the Fourier transform. Let us consider

$$H_0=p^2+q^2,$$

then, as is known, H_0 is an essentially self-adjoint operator on $\mathcal{S}(\mathbb{R})$ and this domain is exactly $\mathcal{D}^\infty(H_0)$.

Let us now take as B the operator $-q^2$, then

$$\mathcal{D}^\infty(H)=\{f\in C^\infty(\mathbb{R})):f^{(k)}\in L^2(\mathbb{R}),\forall k\in\mathbb{N}\}.$$

Thus, in this case $\mathcal{D}^\infty(H)\supset\mathcal{D}^\infty(H_0)$.

In order to construct an example where the opposite inclusion holds, we start by taking $H_0=p^2$ and $B=q^2$. In this case,

$$\mathcal{D}^\infty(H)=\mathcal{S}(\mathbb{R})\subset\{f\in C^\infty(\mathbb{R})):f^{(k)}\in L^2(\mathbb{R}),\forall k\in\mathbb{N}\}=\mathcal{D}^\infty(H_0).$$

These examples show that all situations are possible, when comparing $\mathcal{D}^\infty(H)$ and $\mathcal{D}^\infty(H_0)$.

For shortness, we will call B a KR-perturbation if it satisfies the assumption of the Kato–Rellich theorem. Before going forth, we give the following

Proposition 2.4: Let A and B be two self-adjoint operators in Hilbert space $\mathcal{H}$. Then

$$\mathcal{D}^\infty(A)=\mathcal{D}^\infty(B)$$

if, and only if, the following two conditions hold:

(i) for each $k\in\mathbb{N}$ there exists $\ell\in\mathbb{N}$ such that $D(B^\ell)\subseteq D(A^k)$,
(ii) for each $h\in\mathbb{N}$ there exists $m\in\mathbb{N}$ such that $D(A^m)\subseteq D(B^h)$.

Proof: We put $\mathcal{D}=\mathcal{D}^\infty(A)=\mathcal{D}^\infty(B)$. Because of Lemma 2.1, the topologies t_A and t_B are equivalent. Without loss of generality we assume that $A\geqslant 0$, $B\geqslant 0$; this makes the usual families of seminorms defining the two topologies directed. This implies that for each $k\in\mathbb{N}$ there exist $\ell\in\mathbb{N}$ and $C_k>0$:

$$\|A^k\phi\|\leqslant C_k\|B^\ell\phi\|,\quad \phi\in\mathcal{D}.$$

But $\mathcal{D}$ is a core for any power of B, therefore for each $f\in D(B^\ell)$ there exists a sequence (f_n) of elements of $\mathcal{D}$ such that $f_n\to f$ and $(B^\ell f_n)$ is convergent. Then we get

$$\|A^k(f_n-f_m)\|\leqslant C_k\|B^\ell(f_n-f_m)\|\to 0$$

and therefore $f \in D(\overline{A^k_{\restriction D}}) = D(A^k)$. The proof of (ii) is similar.

Let us now assume that (i) and (ii) hold. For any $k \in \mathbb{N}$ we put

$$\ell_k = \min\{\ell \in \mathbb{N} : D(B^\ell) \subset D(A^k)\}.$$

Then we have

$$\mathcal{D}^\infty(B) \subseteq \bigcap_{k=1}^{\infty} D(B^{l_k}) \subset \bigcap_{k=1}^{\infty} D(A^k) = \mathcal{D}^\infty(A).$$

In similar way the converse inclusion can be proven. □

Example: The previous proposition easily implies the following well-known fact:

$$\mathcal{D}^\infty(A^k) = \mathcal{D}^\infty(A), \quad \forall k \in \mathbb{N}$$

since (i) and (ii) hold, as is readily seen.

Proposition 2.5: Let $A \geqslant 1$ and $B \geqslant 1$. Then if

$$\mathcal{D}^\infty(A) = \mathcal{D}^\infty(B)$$

the following two conditions hold:

(i) for each $k \in \mathbb{N}$ there exist $\ell \in \mathbb{N}$ such that $A^k B^{-\ell}$ is bounded;
(ii) for each $h \in \mathbb{N}$ there exist $m \in \mathbb{N}$ such that $B^h A^{-m}$ is bounded.

Conversely, if $D^\infty(A) \cap D^\infty(B)$ contains a common core $\mathcal{D}_0$ for all powers of A and B and both (i) and (ii) hold, then

$$\mathcal{D}^\infty(A) = \mathcal{D}^\infty(B).$$

Proof: Assume that $\mathcal{D}^\infty(A) = \mathcal{D}^\infty(B) =: \mathcal{D}$. As seen in the proof of Proposition 2.4, the equivalence of the topologies implies that for each $k \in \mathbb{N}$ there exist $\ell \in \mathbb{N}$ and $C_k > 0$:

$$\|A^k \phi\| \leqslant C_k \|B^\ell \phi\|, \quad \phi \in \mathcal{D},$$

which can be written as

$$\|A^k B^{-\ell} \phi\| \leqslant C_k \|\phi\|, \quad \phi \in \mathcal{D}.$$

The second condition can be proved in similar way.

Now, suppose that $\mathcal{D}_0$ is a common core for all powers of A and B and that (i) and (ii) hold. Then from (i) one gets that for each $k \in \mathbb{N}$ there exist $\ell \in \mathbb{N}$ and $C_k > 0$:

$$\|A^k \phi\| \leqslant C_k \|B^\ell \phi\|, \quad \phi \in \mathcal{D}_0.$$

Proceeding as in the proof of Proposition 2.4 one proves that for these k and ℓ, $D(B^\ell) \subseteq D(A^k)$. Analogously, condition (ii) implies (ii) of Proposition 2.4.

□

Proposition 2.6: Let B be a KR-perturbation and assume $B : \mathcal{D}^\infty(H_0) \to \mathcal{D}^\infty(H_0)$. Then $\mathcal{D}^\infty(H_0) \subseteq \mathcal{D}^\infty(H)$. Moreover, if the families of seminorms are directed,

$$\forall k, s \in \mathbb{N} \exists \ell \in \mathbb{N}, C_k > 0 : \|H_0^s H^k \phi\| \leqslant C_k \|H_0^\ell \phi\|, \quad \forall \phi \in \mathcal{D}^\infty(H_0).$$

Proof: In this case, $\mathcal{D}^\infty(H_0)$ is left invariant by H; but $\mathcal{D}^\infty(H)$ is the largest domain with this property. Therefore $\mathcal{D}^\infty(H_0) \subseteq \mathcal{D}^\infty(H)$.

The given inequality follows easily from the continuity of H^k in $\mathcal{D}^\infty(H_0)$. □

Remark: The above inequality also says that t_{H_0} is, in general, finer than t_H.

In order to get the equality of the two domains some stronger condition on B must be added. We have, indeed:

Proposition 2.7: Let B be a perturbation of H_0 such that $H:=H_0+B$ is self-adjoint on $D(H)=D(H_0)$. In order that

$$\mathcal{D}^\infty(H)=\mathcal{D}^\infty(H_0)$$

it is necessary and sufficient that the following conditions hold:

(i) $B:\mathcal{D}^\infty(H_0)\to\mathcal{D}^\infty(H_0)$,
(ii) *H is essentially self-adjoint in $\mathcal{D}^\infty(H_0)$,*
(iii) *the topologies t_{H_0} and t_H are equivalent on $\mathcal{D}^\infty(H_0)$.*

Proof: The necessity of (i) is obvious. As for (ii), it is well-known that $\mathcal{D}^\infty(H)$ is a core for H (and for all its powers). The necessity of (iii) follows from (1) in Lemma 2.1.

We now prove the sufficiency.

First, by Proposition 2.6 and (i) it follows that $\mathcal{D}^\infty(H_0)\subseteq\mathcal{D}^\infty(H)$ and since H is essentially self-adjoint in $\mathcal{D}^\infty(H_0)$,

$$\mathcal{D}^\infty(\overline{H_{\restriction\mathcal{D}^\infty(H_0)}})=\mathcal{D}^\infty(H).$$

But as is well known, the domain on the left-hand side is the completion of $\mathcal{D}^\infty(H_0)$ in the topology t_H. The equivalence of t_H and t_{H_0}, in turn implies that $\mathcal{D}^\infty(H_0)$ is complete under t_H and so the statement is proved. □

Remark: If B is bounded, then $H=H_0+B$ is automatically essentially self-adjoint in $\mathcal{D}^\infty(H_0)$.

Example: Let $H_0=p^2+q^2$; then $\mathcal{D}^\infty(H_0)=\mathcal{S}(\mathbb{R})$. Let $B=\alpha q$ with $\alpha\in\mathbb{R}$.
Then it is easily seen that $H=p^2+q^2+\alpha q$ leaves $\mathcal{S}(\mathbb{R})$ invariant.

Since $H=p^2+(q-\beta)^2+\beta^2$ with $\beta=\alpha/2$, it is clear that $\mathcal{S}(\mathbb{R})$ is a domain of essential self-adjointness for H.
The equivalence of the topologies t_{H_0} and t_H can be proven with easy estimates of the respective seminorms. Thus Proposition 2.7 leads us to conclude that $\mathcal{D}^\infty(H_0)=\mathcal{D}^\infty(H)$.

As a consequence of Proposition 2.7, we now consider the special case of a perturbation *weakly* commuting with H_0.

Let $\mathcal{L}^\dagger(\mathcal{D},\mathcal{H})$ denote the space of all closable operators A in $\mathcal{H}$ such that $D(A)=\mathcal{D}$, $D(A^*)\subset\mathcal{D}$. As for $\mathcal{L}^\dagger(\mathcal{D})$, we put $A^\dagger=A^*_{\restriction\mathcal{D}}$.

Now, if $\mathcal{A}$ is a $\dagger$-invariant subset of $\mathcal{L}^\dagger(\mathcal{D},\mathcal{H})$, the *weak unbounded commutant* $\mathcal{A}'_\sigma$ of $\mathcal{A}$ is defined as

$$\mathcal{A}'_\sigma=\{Y\in\mathcal{L}^\dagger(\mathcal{D},\mathcal{H}):\langle Xf,Y^\dagger g\rangle=\langle Yf,X^\dagger g\rangle,\forall f,g\in D;\forall X\in\mathcal{A}\}.$$

If T is a self-adjoint operator in $\mathcal{H}$, we can consider the O^*-algebra $\mathcal{P}(T)$ generated by T on $\mathcal{D}^\infty(T)$. It is well-known[10] that $\mathcal{P}(T)'_\sigma=\{T\}'_\sigma$. Furthermore, any $Y\in\{T\}'_\sigma$ leaves $\mathcal{D}^\infty(T)$ invariant. We now apply these facts to our situation:

Corollary 2.8: Let B be a perturbation of H_0. Assume that B satisfies the conditions:
(i) $\langle H_0f,Bg\rangle=\langle Bf,H_0g\rangle,\forall f,g\in\mathcal{D}^\infty(H_0)$,
(ii) *H is essentially self-adjoint in $\mathcal{D}^\infty(H_0)$,*
(iii) $\|H_0f\|\leqslant\|Hf\|,\forall f\in\mathcal{D}^\infty(H_0)$,

then $\mathcal{D}^\infty(H_0)=\mathcal{D}^\infty(H)$.

Proof: Condition (i) implies that B leaves $\mathcal{D}^\infty(H_0)$ invariant; therefore H is t_{H_0}-continuous (together with all its powers). So it remains to check that t_H is finer than t_{H_0} in order to apply Proposition 2.7.

We will prove by induction that

$$\|H_0^n f\| \leqslant \|H^n f\|, \quad \forall f \in \mathcal{D}^\infty(H_0).$$

The case $n=1$ is exactly condition (iii). Now we assume the statement true for $n-1$. Then we get

$$\|H_0^n f\| = \|H_0(H_0^{n-1} f)\| \leqslant \|H(H_0^{n-1} f)\| = \|H_0^{n-1} H f\| \leqslant \|H^n f\|, \quad \forall f \in \mathcal{D}^\infty(H_0).$$

since, by (i), H_0 and H commute (algebraically) on $\mathcal{D}^\infty(H_0)$. □

III. DYNAMICAL ASPECTS

We now come back to the dynamical problem posed at beginning of the paper concerning the perturbative situation and again we will consider the case where H exists. So far, we were able to prove the convergence of the dynamics only at infinitesimal level (Corollary 2.3). The problem of the convergence of $\alpha_L^t(A)$ to $\alpha^t(A)$ is not completely solved in the simple case we are dealing with. Of course, given H and its spectral projections Q_L as seen in Sec. II, we can always prove, setting $\hat{H}_L = Q_L H Q_L$, that $e^{i\hat{H}_L t} A e^{-i\hat{H}_L t}$ converges to $e^{iHt} A e^{-iHt}$ for any A in $\mathcal{L}^\dagger(\mathcal{D})$. What makes the difference here (and this is the spirit of the whole paper) is that we are defining the cut off Hamiltonian $H_L = Q_L^0 H Q_L^0$ via the spectral projections of the unperturbed Hamiltonian H_0. This is of practical interest since only in very few instances (finite discrete systems, harmonic oscillators, hydrogen atoms, etc.) the spectral projections of H are known. On the other hand, H_0 can be chosen with a sufficient freedom to guarantee the knowledge of the Q_L^0.

With this in mind, we consider the problem of finding conditions under which $e^{iH_L t}$ converges, with respect to the topology $\tau_*^{\mathcal{D}}$, to e^{iHt}.

To this aim, we define the operator function

$$g_L(t) = e^{iH_L t} - e^{iHt} = i \int_0^t e^{iH_L(t-t')} (H_L - H) e^{iHt'} \mathrm{d}t',$$

the latter equality being obtained by solving

$$\dot{g}_L(t) = iH_L g_L(t) + i(H_L - H) e^{iHt},$$

which comes directly from the definition of $g_L(t)$. Easy estimates allow one to state the following

Lemma 3.1: For each $k \in \mathbb{N}$ there exists $s \in \mathbb{N}$ such that

$$\lim_{L \to \infty} \|H_0^{-s} (H_L - H) H_0^k\| = 0,$$

then we have

Proposition 3.2: If there exists $T>0$ such that, for each $f \in \mathcal{F}$, $s \in \mathbb{N} \cup \{0\}$ there exists $M = M(T,f,s)$ such that

$$\int_0^t \|f(H_0) e^{iH_L(t-t')} H_0^s\| \mathrm{d}t' < M, \quad t \in [0,T]$$

then

$$\tau_*^{\mathcal{D}} - \lim_{L \to \infty} g_L(t) = 0.$$

Proof: We have indeed

$$\|g_L(t)\|^{f,k} \leqslant \int_0^t \|f(H)e^{iH_L(t-t')}(H_L-H)e^{-iHt'}H^k\|\mathrm{d}t'$$

$$= \int_0^t \|f(H)e^{iH_L(t-t')}(H_L-H)H^k\|\mathrm{d}t'$$

$$\leqslant C\int_0^t \|f_1(H_0)e^{iH_L(t-t')}(H_L-H)H_0^{k_1}\|\mathrm{d}t'$$

$$\leqslant C\int_0^t \|f_1(H_0)e^{iH_L(t-t')}H_0^s\|\mathrm{d}t'\cdot\|H_0^{-s}(H_L-H)H_0^{k_1}\|$$

for suitable $C>0$, $f_1\in\mathcal{F}$ and $k_1\in\mathbb{N}$ and with s chosen, correspondingly to k_1 so that Lemma 3.1 can be used. □

This proposition implies that the Schrödinger dynamics can be defined. The analysis of the Heisenberg dynamics is more complicated and will not be considered here.

The assumptions of Proposition 3.1 are indeed quite strong. They are, of course, verified if the perturbation B commutes with H_0. But this is, clearly, a trivial situation. We will now discuss a nontrivial example where they are satisfied.

Example: Let $H_0=a^\dagger a$ and $B=a^n$, n being an integer larger than 1. The conditions on the domains of the operators discussed in Sec. II are satisfied, as it is more easily seen working in the configuration space, so that our procedure can be applied. Here $Q_L^0=\Pi_0^0+\Pi_1^0+\Pi_2^0+\cdots+\Pi_L^0$, where Π_i^0 is the projection operator of H_0, $H_0=\Sigma_{l=0}^{\infty} l\Pi_l^0$. Using the algebraic rules discussed in Ref. 12, and, in particular the commutation rules $Q_L^0 a=aQ_{L+1}^0$ and $\Pi_l^0 a=a\Pi_{l+1}^0$, we find that $H_l=Q_L^0HQ_L^0=HQ_L^0$.

It is a straightforward computation now to check that for any $f\in\mathcal{F}$ and for any natural s, $\|f(H)e^{iH_L\tau}H^s\|=\|f(H)(H+(e^{iH\tau}-1)a^nP_{L,n}^0)^s\|$, where we have defined the following orthogonal projection operator

$$P_{L,n}^0=\Pi_{L+1}^0+\Pi_{L+2}^0+\cdots+\Pi_{L+n}^0=Q_{L+n}^0-Q_L^0.$$

These seminorms can be estimated for each value of s and it is not difficult to check that they are bounded by a constant which depends on f, s, and n (obviously) but not on L and τ. Therefore the main hypothesis of Proposition 3.1 is verified and so the Schrödinger dynamics can be defined. We give the estimate of the above seminorm here only in the easiest nontrivial case, $s=1$. The extension to $s>1$ only increases the length of the computation but does not affect the result,

$$\|f(H)(H+(e^{iH\tau}-1)a^nP_{L,n}^0)\|\leqslant\|f(H)H\|+\|f(H)(e^{iH\tau}-1)a^n\|\|P_{L,n}^0\|\leqslant\|f(H)H\|+2\|f(H)a^n\|,$$

which is bounded and independent of both L and τ.

The same strategy can also be applied to the more general situation when B is any given polynomial in a and $a^\dagger$.

In order to find more cases in which Proposition 3.2 can be applied, we begin with the following

Lemma 3.3: For each $f\in\mathcal{F}$ and for each $k,\ell\in\mathbb{N}$ we have

$$\lim_{L\to\infty}\|f(H)(H_L^\ell-H^\ell)H^k\|=0.$$

Proof: We proceed by induction on ℓ.

For $\ell=1$ the statement follows immediately by the equivalence of the topologies and from Lemma 2.2.

Now,

$$\|f(H)(H_L^{\ell+1}-H^{\ell+1})H^k\| \leq \|f(H)H_L(H_L^{\ell}-H^{\ell})H^k\| + \|f(H)(H_L-H)H^{\ell+k}\|$$

and the second term on the right-hand side goes to 0 because we have just proved the induction for $\ell=1$.

The first term of the right-hand side can easily be estimated, once more making use of the equivalence of the topologies, by a term of the kind

$$C'\|f_1(H_0)(H_L^{\ell}-H^{\ell})H^{k_1}\|,$$

which goes to zero again because of the induction. □

Proposition 3.4: If there exists $m \in \mathbb{N}$ *such that* $[H_L, H]_{m+1}=0$ *then*

$$\int_0^t \|f(H_0)e^{iH_L(t-t')}H_0^s\|\mathrm{d}t' < \infty, \quad t \in \mathbb{R}^+$$

for each $f \in \mathcal{F}$ *and for each* $s \in \mathbb{N}\cup\{0\}$.

Proof: By the assumption, we have

$$e^{iH_L(t-t')}He^{-iH_L(t-t')} = H + i(t-t')[H_L, H] + \cdots \frac{i^m}{m!}[H_L, H]_m. \tag{8}$$

Now, using the equivalence between the topologies produced by H_0 and H, it is easy to see that

$$\|f(H_0)e^{iH_L(t-t')}H_0^s\| \leq C\|f_1(H)(e^{iH_L(t-t')}He^{-iH_L(t-t')})^{s_1}\|.$$

Inserting (8) on the right-hand side and making use of Lemma 3.3, we finally get the estimate:

$$\|f(H_0)e^{iH_L(t-t')}H_0^s\| \leq C\|f_1(H)H^{s_1}\|,$$

and this easily implies the statement. □

Clearly, even if the conditions given previously for the $\tau_*^{\mathcal{D}}$-convergence of e^{iH_Lt} to e^{iHt} occur, the convergence of $\alpha_L^t(A)$ to $\alpha^t(A)$ is not guaranteed. For this reason we conclude this section by outlining a different possible approach.

Assume that, for each $L \in \mathbb{R}$ there exists a one-parameter family $\beta_L^t(A)$ of linear maps of $\mathcal{L}^\dagger(\mathcal{D})$ (not necessarily an automorphisms group) such that, for each $f \in \mathcal{F}$ and $k \in \mathbb{N}$,

$$\|f(H)(\beta_L^t(A)-\alpha_L^t(A))H^k\| \to 0 \quad \text{as} \quad L \to \infty. \tag{9}$$

Clearly the convergence of $\beta_L^t(A)$ to $\alpha^t(A)$ would directly lead to the solution of the dynamical problem. We want to stress that β_L^t could be rather *unusual* and, therefore, it should be only considered as a technical tool.

In general, however, the possibility of finding a good definition for the β_L^t's that allows (9) to hold is quite difficult and the lesson of the previous discussion on the convergence of e^{iH_Lt} is that strong assumptions must be imposed in order to get it.

A weaker condition on the β_L^t's, whose content of information is, nevertheless, nonempty, would consist in requiring, instead of (9), that

(a) $\beta_L^t(A)$ converges to $\alpha^t(A)$, for each $A \in \mathcal{L}^\dagger(\mathcal{D})$ together with all time derivatives. This means that an Heisenberg dynamics $e^{iHt}(\cdot)e^{-iHt}$ can be recovered.
(b) As for the Schrödinger dynamics, that is for the dynamics in the space of vectors, we ask β_L^t of being in some way (to be specified further) *generated* by a family of bounded operators which, when applied to any $\Psi \in \mathcal{D}$, is t_H-convergent together with all time derivatives.

This happens, for instance, in the case where H exists, if we define

$$\beta_L^t(A) = V_L^t A V_L^{-t},$$

where $V_L^t := Q_L^0 e^{iHt} Q_L^0$ and the Q_L^0's are the projection of H_0. (4).

Under these assumptions, V_L is a well-defined bounded operator of $\mathcal{L}^\dagger(\mathcal{D})$, and the following Proposition holds:

Proposition 3.5: In the above given conditions, the following statements hold:

(i) $t_H - \lim_{L\to\infty} V_L^t \psi = \psi(t) := e^{iHt}\psi, \quad \forall \psi \in \mathcal{D},$

(ii) $\tau_*^{\mathcal{D}} - \lim_{L\to\infty} V_L^t = e^{iHt},$

(iii) $\tau_*^{\mathcal{D}} - \lim_{L\to\infty} \beta_L^t(A) = \alpha^t(A) := e^{iHt} A e^{-iHt}, \quad \forall A \in \mathcal{L}^\dagger(\mathcal{D})$

and, more generally:

(i') $t_H - \lim_{L\to\infty} (\mathrm{d}^n/\mathrm{d}t^n)\, V_L^t \psi = (\mathrm{d}^n/\mathrm{d}t^n)\, \psi(t), \quad \forall \psi \in \mathcal{D}, n \in \mathbb{N}\cup\{0\},$

(iii') $\tau_*^{\mathcal{D}} - \lim_{L\to\infty} (\mathrm{d}^n/\mathrm{d}t^n)\, \beta_L^t(A) = (\mathrm{d}^n/\mathrm{d}t^n)\, \alpha^t(A), \quad \forall A \in \mathcal{L}^\dagger(\mathcal{D}), n \in \mathbb{N}\cup\{0\}.$

The proof of this Proposition follows from the equivalence between the topologies generated by H and H_0, proved in Lemma 2.1.

This approach, which is only one of the possible strategies when H exists, could be of a certain interest for situations when the dynamics can only be obtained via a net of operators $H_L = H_0 + B_L$, H_0 being the free Hamiltonian and B_L being a regularized perturbation. In this case the approach to the thermodynamical limit could involve the family of bounded operators $V_{L,M}^t := Q_L^0 e^{iH_M t} Q_L^0$, and one can try to extend the above results. A further analysis on this subject is currently *work in progress*.

IV. OUTCOME AND POSSIBLE DEVELOPMENTS

In this paper we have analyzed a possible approach to define an algebraic dynamics when a free Hamiltonian H_0 is perturbed by an operator B which essentially leaves the domain of all the powers of H_0 invariant.

What is still missing, as discussed in Sec. I, is the analysis of the situation where the definition of the dynamics is not straightforward since it should follow from a net of operators $\{H_L\}$ whose limit does not exist in any physical topology.[2,3] In this case a possible approach can be made in terms of derivations, for instance, in the way explained in the following.

Let us suppose that to a free spatial derivation $\delta_0(.) = i[H_0, .]$ a perturbation term δ_P is added, so that

$$\delta(A) = \delta_0(A) + \delta_P(A), \quad A \in \mathcal{L}^\dagger(\mathcal{D}).$$

In this case we define $\eta_L(A) = Q_L^0 \delta(A) Q_L^0$, with $A \in \mathcal{L}^\dagger(\mathcal{D})$ and Q_L^0 as in the previous sections. It is easy to see that η_L is not in general a derivation because the Leibniz rule may fail. Let Δ_L be a map on $\mathcal{L}^\dagger(\mathcal{D})$ which has the property that $\delta_L = \eta_L + \Delta_L$ satisfies the Leibniz rule together with the other properties of a derivation. Of course, this map is not unique since, for instance, we can always add a commutator $i[H', .]$ to Δ_L, with any self-adjoint operator H', without affecting the properties of a derivation (we should only care about domain problems in choosing H'!). From a physical point of view it is reasonable to expect that Δ_L can be chosen in such a way that $\|\Delta_L(A)\|^{f,k} \to 0$ with L since we would like to recover the original derivation δ after removing of the cutoff and we know from Corollary 2.3 that $\|(\eta_L(A) - \delta(A))\|^{f,k} \to 0$. If also δ_P is spatial, then it is not difficult to give an explicit expression for Δ_L and to check that the requirements above are satisfied. In this case in fact

$$\Delta_L(A) = \{Q_L^0 H_0, [Q_L^0, A]\} + Q_L^0 B [Q_L^0, A] + [Q_L^0, A] B Q_L^0,$$

where $\{X, Y\} = XY + YX$.

Once we have introduced δ_L the next step is to find conditions for this map to be spatial. The related operator H_L, which we expect to be of the form $Q_L^0(H_0 + B)Q_L^0$ for a suitable self-adjoint operator B, can be used to perform the same analysis as that discussed in Sec. III.

Of course this is by no means the only possibility of approaching this problem, but is the one which is closer to our previous analysis, and in this perspective, is particularly relevant for us. We hope to discuss this problem in full detail in a future paper.

Arnol'd and Thom's beautiful classification of caustics (shockwaves) for the Burgers equation suggests a similar one for the wavefronts of the corresponding heat equation. We give here a general theorem for Hamiltonian systems characterizing how the level surfaces of Hamilton's principal function (wavefronts) meet the caustic surface in both the deterministic and stochastic cases. We further show how these results can be applied to the stochastic Burgers equation by using earlier results of Truman and Zhao. The generic example of a caustic, appearing in the two-dimensional case, is the semicubical parabolic cusp with the corresponding zero level surface being a combination of a generalized hypocycloid and a line pair. We refer to these as the cusp and tricorn. The analogous butterfly caustic, in the three-dimensional case, has a cusped zero level surface, the fish, which meets the butterfly caustic in three cusped curves and touches it along a straight line. Our results explain in terms of classical mechanics the properties of the caustic and wavefront for these two archetypal examples and characterize the caustic-wavefront intersection for the general stochastic case. We discuss the application of these results to turbulence for the Burgers velocity field. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1471925]

I. INTRODUCTION

Stochastic Burgers equations have attracted a considerable amount of attention in recent years, e.g., Refs. 1–14. See also Refs. 15–20 for related works. They have been used to give models of turbulence (see especially Ref. 4) and to model the large scale structure of the universe.[21] Here we shall be interested in what has come to be called Burgulence.

Consider the stochastic viscous Burgers equation for the velocity field

$$v^{\mu}=v^{\mu}(x,t), x\in\mathbb{R}^{d}, t>0,$$

$$\frac{\partial v^{\mu}}{\partial t}+(v^{\mu}\cdot\nabla)v^{\mu}=\frac{\mu^{2}}{2}\Delta v^{\mu}-\nabla c(x)-\epsilon\nabla k(x,t)\dot{W}_{t}, \tag{1.1}$$

with initial velocity $v^{\mu}(x,0)=\nabla S_{0}(x)$ where μ^{2} is the coefficient of viscosity. Here c and k are C^{2} functions and W_{t} is a Wiener process on the probability space $\{\Omega, \mathcal{F}, P\}$. We shall be interested in the "blow-up" of $v^{0}(x,t)$ where

$$v^0(x,t)=\lim_{\mu\to 0} v^\mu(x,t),$$

i.e., the advent of discontinuities in v^0.

The corresponding heat equation for $u^\mu=u^\mu(x,t)$ is the Stratonovich equation

$$\frac{\partial u^\mu}{\partial t}=\frac{\mu^2}{2}\Delta u^\mu+\frac{1}{\mu^2}c(x)u^\mu+\frac{\epsilon}{\mu^2}k(x,t)u^\mu\circ\dot{W}_t,$$
$$u^\mu(x,0)=\exp(-S_0(x)/\mu^2), \tag{1.2}$$

the connection between u^μ and v^μ being the Hopf–Cole logarithmic transformation $v^\mu=-\mu^2\nabla\ln u^\mu$.

Following Donsker and Freidlin *et al.*[22,23] we expect, as $\mu\to 0$,

$$-\mu^2\ln u^\mu(x,t)\to\inf_{X(0)}[A(X(0),x,t)+S_0(X(0))]=S(x,t), \tag{1.3}$$

with

$$A(X(0),x,t)=\inf_{\substack{X(s)\\X(t)=x}} A[X], \tag{1.4}$$

where $A[X]$ is the stochastic action,

$$A(X(0),x,t)=\frac{1}{2}\int_0^t\dot{X}^2(s)\,ds-\int_0^t c(X(s))\,ds-\epsilon\int_0^t k(X(s),s)\,dW_s. \tag{1.5}$$

$S(x,t)$ is the solution of the stochastic Hamilton–Jacobi equation,

$$dS_t+\frac{|\nabla S|^2}{2}dt+c(x)dt+\epsilon k(x,t)dW_t=0,\quad S(x,0)=S_0(x), \tag{1.6}$$

and so $S(x,t)$ is Hamilton's principal function for a stochastic mechanical path. To see this observe that if $\dot{X}(s)$ is a continuous process with the integration by parts property (ibp^2): for all (deterministic) $u\in C^1(0,t)$,

$$\int_0^t\dot{u}(s)\dot{X}(s)\,ds=u(t)\dot{X}(t)-u(0)\dot{X}(0)-\int_0^t u(s)\,d\dot{X}(s),$$

setting $u(t)=0$, $\mathcal{A}[X]=A[X]+S_0(X(0))$, we easily obtain for $S_0\in C^1$, $c\in C^1$, $k\in C^{1,0}$

$$-\frac{d}{d\eta}\bigg|_{\eta=0}\mathcal{A}[X+\eta u]=\int_0^t u(s)[d\dot{X}(s)+\nabla c(X(s))ds+\epsilon\nabla k(X(s),s)dW_s]$$
$$+u(0)(\dot{X}(0)-\nabla S_0(X(0))).$$

Hence necessary conditions for the extremizer are, for $s\in[0,t]$,

$$d\dot{X}(s)+\nabla c(X(s))ds+\epsilon\nabla k(X(s),s)dW_s=0,\quad \dot{X}(0)=\nabla S_0(X(0)). \tag{1.7}$$

From Eq. (1.3), as $\mu\to 0$, we expect that u^μ switches from being exponentially large to exponentially small across the level surface

$$S(x,t)=0\quad\text{(zero level surface)}.$$

If we demand that $X(t)=x$, for fixed t and x, $X(s)$ satisfying Eq. (1.7) may not be unique. Hence, we expect that shockwaves for v arise from precaustics [in (x_0,t) variables] when infinitely many of these classical mechanical paths from x_0 and a neighborhood focus in a set of zero volume centered on $X(t)$. The condition for paths starting from x_0 focusing at a point X at time t is

$$\mathrm{Det}\left(\frac{\partial X(t)}{\partial x_0}\right)=0 \quad \text{(precaustic)}. \tag{1.8}$$

Define the random map $\Phi_s:\mathbb{R}^d\to\mathbb{R}^d$ corresponding to the classical flow by the second-order stochastic differential equation

$$d_s\dot{\Phi}_s=-\nabla c(\Phi_s)ds-\epsilon\nabla k(\Phi_s,s)dW_s, \tag{1.9}$$

with $\Phi_0=I$ and $\dot{\Phi}_0=\nabla S_0$ so that $X(s)=\Phi_s\Phi_t^{-1}x$, where we accept that $x_0(x,t)=\Phi_t^{-1}x$ is not necessarily unique. Given some regularity, the global inverse function theorem gives a caustic time $T(\omega)$ such that, for $s<T(\omega)$, Φ_s is a random diffeomorphism.[24] Therefore, as we shall see,

$$v^0(x,t)=\dot{\Phi}_t\Phi_t^{-1}x=\nabla S(x,t) \tag{1.10}$$

is a formal solution of the Burgers equation with $\mu=0$, which is well defined up to the caustic time because $x_0(x,t)$ is unique.

After the caustic time, for polynomial S_0, $x_0(x,t)$ will usually have finite multiplicity. As long as the minimizing $x_0(x,t)$ is unique, Eq. (1.10) can be assumed to be true beyond the caustic time if we work with that part of the level surface of Hamilton's principal function corresponding to the minimizing $x_0(x,t)$. This is equivalent to taking the minimum entropy solution of the Burgers equation.[25] As expected, the main contribution to $\lim_{\mu\to 0}v^\mu$ will come from the minimizing $x_0(x,t)$, which we shall assume is unique. When there are a finite number (>1) of minimizing x_0's the limiting solution, v^0, is more complicated,[26] but can still be written down.

We expect the nonuniqueness of $x_0(x,t)$ to be associated with the appearance of discontinuities in $v^0(x,t)$ and $u^0(x,t)$. An obvious way for these to arise is if (as above) infinitely many paths $X(s)$ focus in zero volume centered at x. Eliminating x_0 by using $x=\Phi_t(x_0)$ gives the equation of the caustic C_t:

$$\mathrm{Det}\left(\frac{\partial X(t)}{\partial x_0}\right)\Bigg|_{x_0=\Phi_t^{-1}x}=0 \quad \text{(caustic)}. \tag{1.11}$$

The precaustic $\Phi_t^{-1}C_t$ has defining equation (1.8). Starting with the level surfaces of Hamilton's principal function H_t one can define the prelevel surfaces $\Phi_t^{-1}H_t$ in a similar way by setting $x=\Phi_t(x_0)$. The prelevel surfaces and the precaustic are just the preimages of the level surfaces and the caustic under the classical flow map Φ_t. The wavefront is the zero level set of the minimizing Hamilton function which, as we shall see, is part of H_t.

For a nondegenerate critical point, when the multiplicity of $x_0(x,t)$, $n=n(x,t)$, is finite so that $\Phi_t^{-1}\{x\}=\{x_0^1(x,t),x_0^2(x,t),\ldots,x_0^n(x,t)\}$, from Refs. 26–30 we can deduce that

$$u^\mu(x,t)\sim\sum_{i=1}^{n}\theta_i\exp\{-S_0^i(x,t)/\mu^2\}, \tag{1.12}$$

where

$$S_0^i(x,t)=S_0(x_0^i(x,t))+A(x_0^i(x,t),x,t),$$

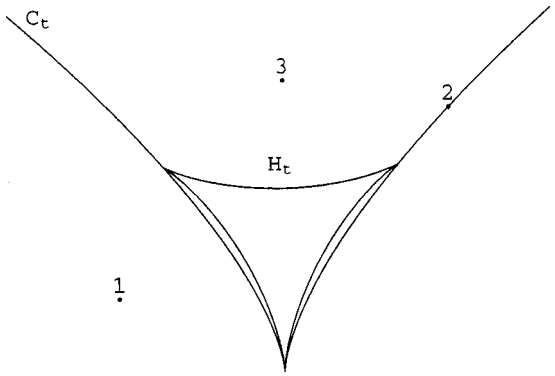

FIG. 1. Cusp and tricorn.

for $i=1,2,...,n$, and θ_i is an asymptotic series in μ^2 whose detailed structure is discussed later in this work. Here $H_t=\{x:S_0^i(x,t)=0,\ \text{some}\ i\}$ so it includes the wavefront where u^0 switches smoothly from being exponentially large to exponentially small. Needless to say, the dominant term in Eq. (1.12) comes from the minimizing $x_0(x,t)$ so that

$$S(x,t)=\min_{i=1,2,...,n} S_0^i(x,t)$$

in line with the results of Freidlin *et al.* Of course $u^0(x,t)$ can switch discontinuously from being exponentially large to exponentially small as we cross parts of the caustic since the minimizing S_0^i can disappear.

Example 1.1: The paradigm for $c=k\equiv 0$ is when $S_0(x,y)=x^2y/2$ in the two-dimensional case. This gives us the generic cusp catastrophe as shown in Fig. 1.

The caustic (shockwave), C_t, *with Eq. (4.2) is the classical semicubical parabola (cusp). This gives the surface of discontinuity of $v^0(x,t)$ with $v^0(x,0)=\nabla S_0=(xy,x^2/2)$. The corresponding zero level surface of Hamilton's principal function, H_t, is a generalized hypocycloid (tricorn) with Eq. (4.1) and line pair $x^2=0$. Only the top part of this tricorn forms the wavefront. The other two curves come from spurious zeros of S_0^i where S_0^i is not minimizing. This top part of the tricorn defines the region where u^μ switches from being exponentially large to exponentially small. We suppress the line pair in Fig. 1 to highlight how the caustic splits $\mathbb{R}^2$. The important result here is that u^0 has a sharp discontinuity on the caustic itself. Note that within the cusp there are three preimages for each point, on the cusp there are two preimages for each point, and outwith the cusp there is only one preimage for each point.*

If we fix the time t and let the point a be inside the semicubical parabolic cusp so that the multiplicity of the x_0's is three, there are three level surfaces $S_0^i(x,t)=c$, one for each $x_0^i(a,t)$, $i=1,2,3$, only one of which corresponds to the minimizer. The prelevel surfaces and their corresponding x_0's are shown in Figs. 2 and 3 with the cusp included for reference in the case of Fig. 2.

We now display all the level surfaces passing through the point a in relation to the cusp as shown in Figs. 4 and 5.

In the case when the point a is on the cusp, Fig. 6, there are only two preimage points and correspondingly only two level surfaces passing through a, one of which has a cusp at a.

The final case, Fig. 7, is where the point a lies outwith the cusp and there is only one level surface.

In Figs. 8 and 9 we see how the cusped level surfaces coalesce as the point a approaches the caustic. *The first of these figures corresponds to the two cusped level surfaces having positive S_0 and the second corresponds to the two cusped level surfaces having negative S_0. In both cases the*

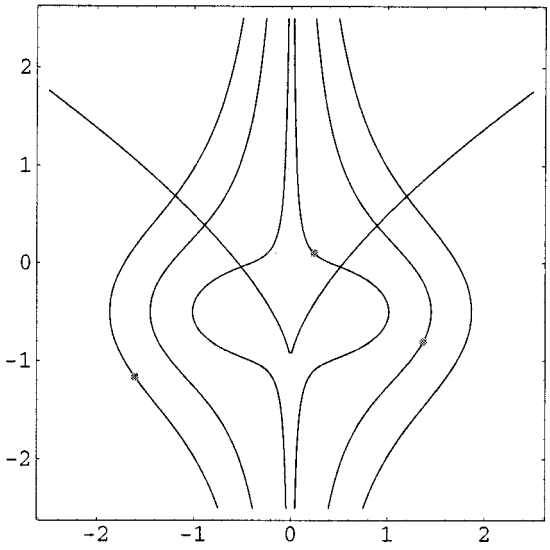

FIG. 2. Three prelevel surfaces—positive.

appearance of the cusp means that the corresponding S_0^i cannot be continued across the caustic. This is what makes u^0 discontinuous across the cusp caustic, because the cusped part of the level surface corresponds to the minimizer $x_0(x,t)$.

In the above example we see that the multiplicity of $x_0(x,t)$, n, changes by a multiple of 2 as we cross the caustic surface. We shall see that this is associated with level surfaces of Hamilton's principal function having cusps on the caustic, caused by different $x_0(x,t)$'s coalescing. Moreover, the cusp on the level surface (if it corresponds to the minimizing x_0) means that we have to take a different minimizer S_0^i on different sides of the caustic. This makes u^0 discontinuous. Thus, it is important to know when the point of intersection of a level surface and caustic is a genuine cusp, generalized cusp, or a crossover point.

In more than one dimension for $S_0 \in C^2$ there is a robust geometrical relationship between level surfaces and caustics even in the presence of noise. This is because, as we shall prove, the

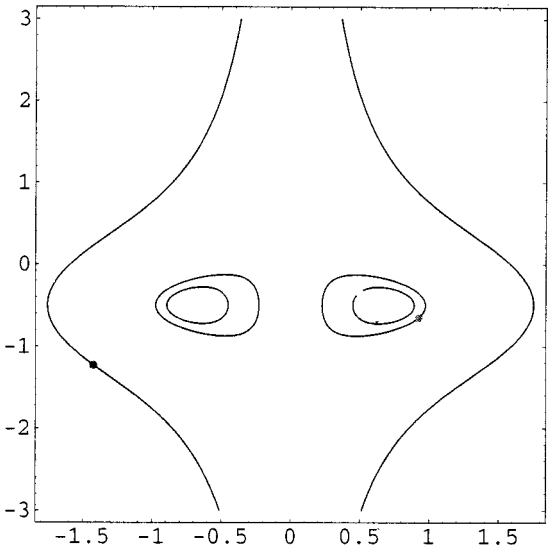

FIG. 3. Three prelevel surfaces—two negative and one positive.

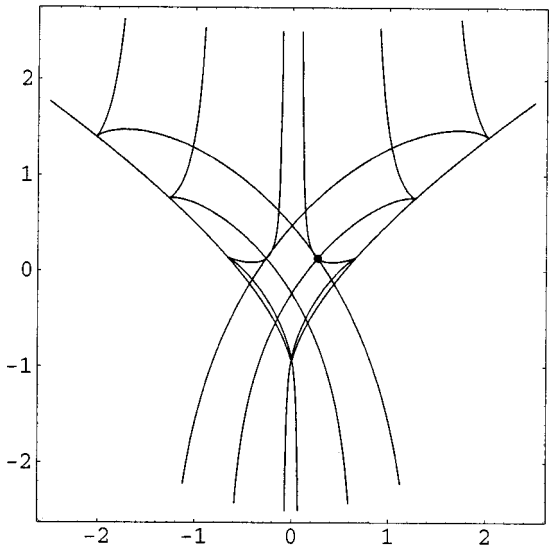

FIG. 4. Three level surfaces—positive.

tangent plane to the level surface H_t at a point x on the caustic C_t is spanned by the image of the tangent plane to the prelevel surface, where this prelevel surface tangent plane necessarily contains the kernel of the derivative of the Φ_t map if $x \in \Phi_t(\Phi_t^{-1}C_t \cap \Phi_t^{-1}H_t)$. In understanding Burgers turbulence this switches attention from C_t and H_t to their unfoldings $\Phi_t^{-1}C_t$ and $\Phi_t^{-1}H_t$. In two dimensions, at a point on the precaustic, it follows that this kernel spans the tangent plane to the prelevel surface. In three dimensions the dimension of the tangent plane to the level surface drops from two to one as we approach points on the caustic in $\Phi_t[\Phi_t^{-1}H_t \cap \Phi_t^{-1}C_t]$, which is essentially the cusped part of the level surface, $\mathrm{Cusp}(H_t)$. This manifests itself in the tangent plane to the level surface on the caustic folding back on itself—the fold being the one-dimensional tangent plane at the point of intersection. In two dimensions this is quite elementary to prove, but in three dimensions it depends on a careful analysis of the geometry of the level surface and its preimage.

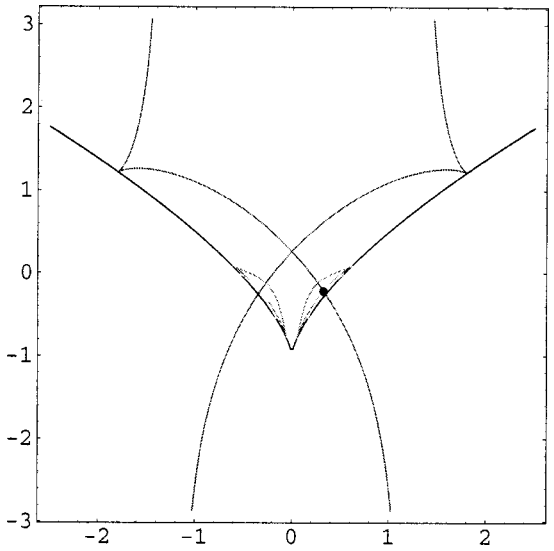

FIG. 5. Three level surfaces—two negative and one positive.

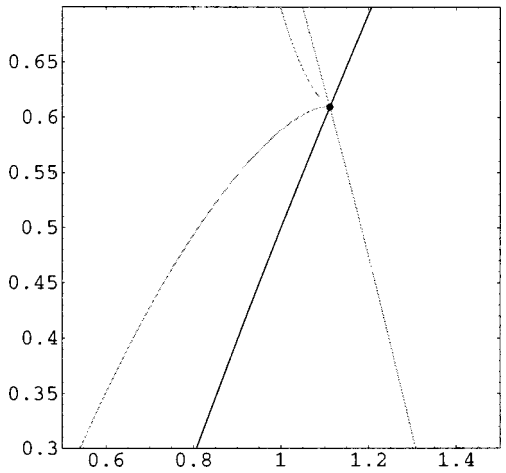

FIG. 6. Two level surfaces.

Our main theorem (in Sec. V) concerning this geometric relationship for the above stochastic Hamiltonian system, given some mild restrictions, is for fixed t:

Theorem: *Any point x on the level surface H_t, $x=\Phi_t(x_0)$ with $x_0=\Phi_t^{-1}(x)$ on the prelevel surface, can only be a generalized cusp of a curve on H_t if x_0 is a generalized cusp of the precurve on the prelevel surface or if $x_0 \in \Phi_t^{-1} C_t$ the precaustic. In three dimensions the planar cross section $y=const$ (with normal e_y) of the level surface H_t through a point x where it meets C_t, the caustic surface, will have a genuine cusp at x if $x \in \mathrm{Cusp}(H_t)$ and there is a nonzero solution δx of Eqs. (C_1), (C_2), and (C_3). The direction of the axis of the cusp will be $\widehat{\delta x}$.*

This result explains the bizarre pictures of the fish and the butterfly (Figs. 19–22) in Sec. IV and similar phenomena. In Sec. II we recapitulate our main results for the Burgers equation. This can be skipped if the reader is primarily interested in the geometrical result. An outline proof of our main geometrical result is given in Sec. III where the free case is considered in detail and proved. Section IV contains simple archetypal examples in both two and three dimensions. Section V treats the general stochastic case. In Secs. III–V we give a brief discussion of the ramifications

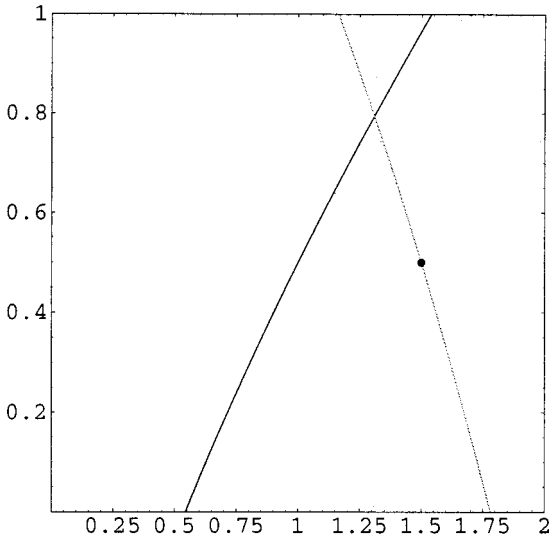

FIG. 7. One level surface.

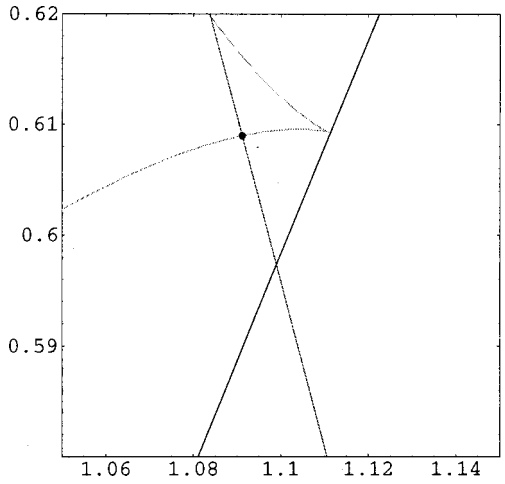

FIG. 8. Coalescing level surfaces—positive S_0.

of our results for Burgers turbulence. In particular we explain how our results give a simple model for the intermittence of turbulence for the stochastic Burgers equation at the end of Sec. V.

II. SOLUTIONS OF INVISCID BURGERS AND HEAT EQUATIONS AND ASYMPTOTIC SERIES θ

Here let $v^\mu = v^\mu(x,t)$ satisfy for $t>0$, $x \in \mathbb{R}^d$,

$$dv^\mu + (v^\mu \cdot \nabla)v^\mu dt + \nabla c dt + \epsilon \nabla k dW_t = \frac{\mu^2}{2}\Delta v^\mu dt,$$

with $v^\mu(x,0) = \nabla S_0(x)$, where $c = c(x)$, $k = k(x,t)$.

Since the convected derivative

$$\frac{D}{Dt} = \frac{\partial}{\partial t} + v \cdot \nabla,$$

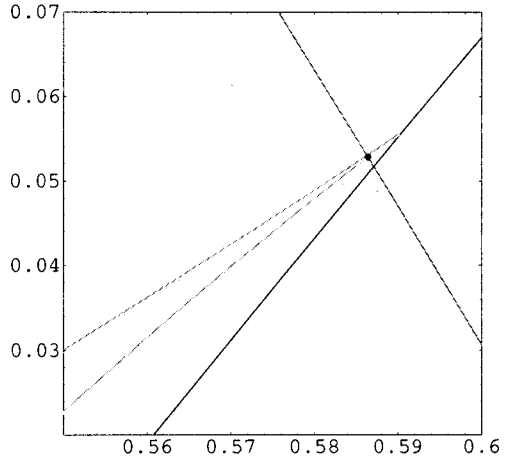

FIG. 9. Coalescing level surfaces—negative S_0.

the above Burgers equation describes a fluid where particles pass through each other with no interaction, the particles being subject to a force $(-\nabla c(x)-\epsilon\nabla k(x,t)\dot{W}_t)$ with $\dot{W}_t$ being white noise. (In fact, infinitely many pass through each other at points on the caustic and to this extent our continuation of the solution may be considered unphysical. Nevertheless, the Burgers equation has been used successfully in modeling the large-scale structure of the universe[21,31] and in studying related equations.)

Let $v^\mu=\nabla S^\mu$. Then S^μ satisfies the stochastic Hamilton–Jacobi equation

$$dS^\mu+\tfrac{1}{2}|\nabla S^\mu|^2dt+c\,dt+\epsilon k\,dW_t=\tfrac{1}{2}\mu^2\Delta S^\mu dt.$$

Formally, if $S^\mu\sim\sum_{j=0}^{\infty}\mu^{2j}S_j$, we obtain from the last equation the stochastic Hamilton–Jacobi continuity equations

$$\frac{\partial S_j}{\partial t}+\frac{1}{2}\sum_{\substack{i_1,i_2\geqslant 0\\ i_1+i_2=j}}\nabla S_{i_1}\cdot\nabla S_{i_2}=\frac{1}{2}\Delta S_{j-1},$$

for $j=0,1,2,...$, with the convention $1/2\Delta S_{-1}=-c-\epsilon k\dot{W}_t$, $\dot{W}_t$ being white noise.

The corresponding stochastic mechanical flow Φ_s satisfies

$$d\dot{\Phi}_s=-\nabla c(\Phi_s)ds-\epsilon\nabla k(\Phi_s,s)dW_s,$$

with $\Phi_0(x)=x$, $\dot{\Phi}_0(x)=\nabla S(x,0)=\nabla S_0(x)$. Now assume $\Phi_s(\omega):\mathbb{R}^d\to\mathbb{R}^d$ is a diffeomorphism for $0\leqslant s<T(\omega)$. Define

$$\tilde{S}_0(y,t)=\frac{1}{2}\int_0^t|\dot{\Phi}_s(y)|^2\,ds+S(y,0)-\int_0^t c(\Phi_s y)\,ds-\epsilon\int_0^t k(\Phi_s y,s)\,dW_s$$

and

$$S_0(x,t)=\tilde{S}_0(\Phi_t^{-1}x,t).$$

The main result of stochastic Hamilton–Jacobi theory[13,32] is the following.

Proposition 2.1: Assume $c\in C^2(\mathbb{R}^d)$, $k\in C^2(\mathbb{R}^d\times\mathbb{R})$ *and* $S_0(\cdot,0)\in C^2(\mathbb{R}^d)$. *Then*

(i) for a.e. $\omega\in\Omega$, $0\leqslant t<T(\omega)$,

$$\dot{\Phi}_t=\nabla S_0(\Phi_t,t),$$

and S_0 *satisfies the stochastic Hamilton–Jacobi equation*

$$dS_0(x,t)+\tfrac{1}{2}|\nabla S_0(x,t)|^2dt+c(x)dt+\epsilon k(x,t)dW_t=0.$$

(ii) Define $\rho(x,t)=|\mathrm{Det}((\partial/\partial x)\Phi_t^{-1}(x))|$. *Then for a.e.* $\omega\in\Omega$, *any* $x\in\mathbb{R}^d$, $0\leqslant t<T(\omega)$, ρ *satisfies the continuity equation*

$$\frac{\partial\rho}{\partial t}+\nabla\cdot(\rho\nabla S_0)=0.$$

Suppose now that $T_0:\mathbb{R}^d\to\mathbb{R}$ is a smooth positive function whose physical role is explained later. (Eventually we will set $T_0\equiv 1$ for the applications discussed here.) Define

$$T_0(y,t)=T_0(y)$$

and, for $j=1,2,...,$

$$T_j(y,t)=\int_0^t \rho^{-1/2}(\cdot,s)\Delta_{\cdot}(\rho^{1/2}(\cdot,s)T_{j-1}(\Phi_s^{-1}\cdot,s))|_{\Phi_s y}\,ds.$$

Then for $j=0,1,2,...,$ define

$$\psi_j(x,t)=T_j(\Phi_t^{-1}x,t)\rho^{1/2}(x,t).$$

Then we have the following lemma.

Lemma 2.1:

$$\frac{\partial\psi_j}{\partial t}+\nabla\psi_j\cdot\nabla S_0=-\frac{1}{2}\psi_j\Delta S_0+\Delta\psi_{j-1}$$

for $j=0,1,2,...,$ with the convention $\psi_{-1}\equiv 0$.

We have now assembled the main tools we need. We now explain how to solve the stochastic Hamilton–Jacobi continuity equations.

Proposition 2.2: Assume that $c\in C^2(\mathbb{R}^d)$, $k\in C^2(\mathbb{R}^d\times\mathbb{R})$, $S_0\in C^2(\mathbb{R}^d)$ and Φ_t satisfies a no-caustic condition. Then for a.e. $\omega\in\Omega$ solutions of the Hamilton–Jacobi continuity equations

$$\frac{\partial S_j}{\partial t}+\frac{1}{2}\sum_{\substack{i_1,i_2\geqslant 0\\ i_1+i_2=j}}\nabla S_{i_1}\cdot\nabla S_{i_2}=\frac{1}{2}\Delta S_{j-1},\quad j\geqslant 0,$$

(with the convention $1/2\Delta S_{-1}=-c-\epsilon k\dot{W}_t$) are given by

$$S_1(x,t)=-\ln\psi_0(x,t)$$

and for $j\geqslant 2$

$$S_j(x,t)=2^{1-j}\left(-\frac{\psi_{j-1}}{\psi_0}+\sum_{\substack{i_1,i_2\geqslant 1\\ i_1+i_2=j-1}}\frac{\psi_{i_1}\psi_{i_2}}{2\psi_0^2}-\sum_{\substack{i_1,i_2,i_3\geqslant 1\\ i_1+i_2+i_3=j-1}}\frac{\psi_{i_1}\psi_{i_2}\psi_{i_3}}{3\psi_0^3}+\cdots+\frac{(-1)^{j-1}\psi_1^{j-1}}{(j-1)\psi_0^{j-1}}\right)(x,t).$$

There is an important Corollary:

Corollary 2.1:

$$\frac{\partial}{\partial t}\left(\sum_{j=0}^m\mu^{2j}S_j\right)+\frac{1}{2}\sum_{j=0}^m\mu^{2j}\left(\sum_{\substack{i_1,i_2\geqslant 0\\ i_1+i_2=j}}\nabla S_{i_1}\cdot\nabla S_{i_2}\right)+c+\epsilon k\dot{W}_t=\frac{\mu^2}{2}\Delta\sum_{j=0}^{m-1}\mu^{2j}S_j.$$

An all important role is played by the Nelson diffusion process y_s^μ with drift given by $-\nabla(\Sigma_{j=0}^m\mu^{2j}S_j(y_s^\mu,t-s))$:

$$dy_s^\mu=\mu dB(s)-\nabla\sum_{j=0}^m\mu^{2j}S_j(y_s^\mu,t-s)ds,$$

$$y_0^\mu=(x).$$

Consider the stochastic heat equation of Stratonovich type:

$$du_t^\mu(x)=\left[\frac{\mu^2}{2}\Delta u_t^\mu(x)+\mu^{-2}c(x)u_t^\mu(x)\right]dt+\epsilon\mu^{-2}k(x,t)u_t^\mu(x)\circ dW_t,$$

$$u_0^\mu(x)=T_0(x)\exp(-S_0(x)/\mu^2).$$

Proposition 2.3: For each $m\geqslant 0$,

$$u_t^\mu(x)=\exp\left\{-\mu^{-2}\sum_{j=0}^{m}\mu^{2j}S_j(x,t)\right\}\mathbb{E}\exp\left\{-\frac{\mu^{2m}}{2}\int_0^t\Delta S_m(y_s^\mu,t-s)\,ds\right.$$

$$\left.+\frac{1}{2}\sum_{j=m+1}^{2m}\mu^{2(j-1)}\sum_{\substack{0\leqslant i_1,i_2\leqslant m\\ i_1+i_2=j}}\int_0^t\nabla S_{i_1}\cdot\nabla S_{i_2}(y_s^\mu,t-s)\,ds\right\}.$$

Note that the second factor is of the form $(1+O(\mu^{2m}))$ *and the first factor gives the expansion up to* μ^{2m-2} *for each m.*

Our main result is the following.

Proposition 2.4: The solution of the viscous stochastic Burgers equation is for each $m\geqslant 0$

$$v^\mu(x,t)=\sum_{j=0}^{m}+\mu^{2j}v_j(x,t)-\mu^2\nabla\ln\mathbb{E}\left\{\exp\left\{-\frac{\mu^{2m}}{2}\int_0^t\nabla\cdot v_m(y_s^\mu,t-s)\,ds\right.\right.$$

$$\left.\left.+\frac{1}{2}\sum_{j=m+1}^{2m}\mu^{2(j-1)}\sum_{\substack{0\leqslant i_1,i_2\leqslant m\\ i_1+i_2=j}}\int_0^t v_{i_1}\cdot v_{i_2}(y_s^\mu,t-s)\,ds\right\}\right\},$$

where $v_j(x,t)=\nabla S_j(x,t)$.

Remark 2.1: When $T_0=1$, *the fluid density* ρ *is simply given by*

$$\rho^{1/2}(x,t)=e^{-S_1(x,t)}. \tag{2.1}$$

In the case $T_0\neq 1$, *we note that initially* ρ *is* T_0^2 *explaining its physical significance. Also, observe that up to the caustic time*

$$\int_{\mathbb{R}^d}\rho(x,t)\,dx=\int_{\mathbb{R}^d}T_0^2(\Phi_t^{-1}(x))|\mathrm{Det}\,(\nabla_x\Phi_t^{-1}(x))|\,dx=\int_{\mathbb{R}^d}T_0^2(y)\,dy=\int_{\mathbb{R}^d}\rho(y,0)\,dy.$$

So, mass is conserved.

In this section we have recapitulated some of the key results of Refs. 12 and 14 on stochastic Burgers equations. We have elucidated the detailed structure of the asymptotic series θ in Eq. (1.12) when Φ_s is a diffeomorphism, $0\leqslant s\leqslant t$, so that $x_0(x,t)$ is unique. If we now combine the above results with those of Davies and Truman[26,27] and Ellis and Rosen,[28–30] we can see that even when $x_0(x,t)$ is not unique, for nondegenerate critical points, θ_i has exactly the same structure as above save that we work with the ith branch of Φ_t^{-1} defined by $x_0^i(x,t)$. What breaks down here is the closed form expansion for the remainder term as a functional integral. We hope to address this in a future paper,[33] but we will not need those results here.

III. SINGULARITIES OF THE FREE BURGERS EQUATION AND HEAT EQUATION

We investigate the geometrical relationship between the level surfaces of the heat equation and the shock waves (caustics) of the Burgers equation. We find a robust geometrical relationship between curves on level surfaces and the caustics which (when suitably modified) carries over to

the general stochastic setup. In two dimensions the curves on the level surfaces are the level surfaces themselves. In three dimensions we think of these curves as arising from planar cross sections.

Definition 3.1: A curve $x=x(\gamma)$, $\gamma\in N(\gamma_0,\delta)$, *is said to have a generalized cusp at* $\gamma=\gamma_0$, γ *being arc length if*

$$\left.\frac{dx(\gamma)}{d\gamma}\right|_{\gamma=\gamma_0}=0.$$

A. A simple geometrical relationship

In this section and Sec. V we were inspired by V. I. Arnol'd's beautiful treatment of classical mechanics in Ref. 34.

Let $\mathcal{A}=\mathcal{A}(x_0,x,t)$ be the classical action for the initial momentum ∇S_0,

$$\mathcal{A}(x_0,x,t)=A(x_0,x,t)+S_0(x_0), \tag{3.1}$$

where in the deterministic case

$$A(x_0,x,t)=\inf_{\substack{X(s)\\X(t)=x\\X(0)=x_0}}\left\{\frac{1}{2}\int_0^t\dot{X}^2(s)\,ds-\int_0^t c(X(s))ds\right\},$$

c being the deterministic potential energy. The Euler–Lagrange equation for the above action reduces to

$$\ddot{X}(s)=-\nabla c(X(s)),\quad s\in[0,t],$$

and $X(t)=x$, $X(0)=x_0$. The free case corresponds to setting $c\equiv 0$ and

$$A(x_0,x,t)=\frac{(x-x_0)^2}{2t},$$

$$\mathcal{A}(x_0,x,t)=\frac{(x-x_0)^2}{2t}+S_0(x_0).$$

We assume that $\mathcal{A}(x_0,x,t)$ is at least C^4 in space variables for $t>0$. Defining the corresponding classical flow now reduces to

$$\nabla_{x_0}\mathcal{A}(x_0,x,t)=0,$$

i.e.,

$$(x_0-x)/t+\nabla S_0(x_0)=0\quad\text{or}\quad x=\Phi_t(x_0)=x_0+t\nabla S_0(x_0).$$

We sometimes write $x_0=\Phi_t^{-1}x=x_0(x,t)$ as the (possibly nonunique) solution of

$$x_0+t\nabla S_0(x_0)=x.$$

Consider the level surface equations obtained by eliminating x_0 between

$$\mathcal{A}(x_0,x,t)=0\quad\text{and}\quad\frac{\partial\mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0,\quad\alpha=1,2,...,d. \tag{3.2}$$

We obtain the prelevel surface by eliminating x in the above equations. Considering for any real constant c, the equation obtained by eliminating x_0 between

$$\mathcal{A}(x_0,x,t)=c \quad \text{and} \quad \frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0, \quad \alpha=1,2,...,d, \tag{3.3}$$

gives the level surface of Hamilton's principal function $S(x,t)=c$ with $S(x,0)=S_0(x)$. We denote this level surface by H_t and the prelevel surface by $\Phi_t^{-1}H_t$.

Imitating the above, the precaustic equation and caustic equation can be obtained in a similar way by considering

$$\mathrm{Det}\left(\frac{\partial^2 \mathcal{A}}{\partial x_0{}^2}(x_0,x,t)\right)=0, \quad \frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0, \quad \alpha=1,2,...,d. \tag{3.4}$$

We denote these surfaces by $\Phi_t^{-1}C_t$ and C_t, respectively.

Let $x\to\alpha$, a point on the caustic. Then, since we expect the multiplicity of the $x_0^i\in\Phi_t^{-1}\{x\}$ to change as we cross the caustic, we anticipate that $x_0^j(x,t)\to x_0^k(x,t)$ as $x\to\alpha$. Since different parts of the level surface correspond to different x_0^i, if $S_j(\alpha,t)=S_k(\alpha,t)=c$, then the parts $S_j(x,t)=c$ and $S_k(x,t)=c$ meeting at α could have a cusp. It is cusps like this which give rise to turbulent behavior of the Burgers velocity field. We therefore investigate in the free case the conditions under which we get cusps.

In the free case the equation of the zero prelevel surface is the eikonal equation

$$\frac{t}{2}|\nabla S_0(x_0)|^2+S_0(x_0)=0,$$

and the derivative map $D\Phi_t(x_0):T_{x_0}\to T_x$, mapping tangent spaces, is the linear map

$$D\Phi_t(x_0)=(I+t\nabla^2 S_0(x_0)),$$

where $\nabla^2 S_0$ is the Hessian of S_0. The following elementary identity is crucial in what follows:

$$\nabla_{x_0}\left\{\frac{t}{2}|\nabla S_0(x_0)|^2+S_0(x_0)\right\}=(I+t\nabla^2 S_0(x_0))\nabla S_0(x_0). \tag{3.5}$$

Since $D\Phi_t(x_0)$ is in this case a real symmetric matrix, we can analyse what happens very easily, especially for two dimensions.

B. Results in two dimensions

Lemma 3.1: Assume that the prelevel surface meets the precaustic at the point x_0, *where* $|(I+t\nabla^2 S_0(x_0))\nabla S_0(x_0)|\neq 0$ *and* $\dim(\mathrm{Ker}(I+t\nabla^2 S_0(x_0)))=1$. *Then the tangent plane to the prelevel surface* T_{x_0} *is spanned by* $\mathrm{Ker}(I+t\nabla^2 S_0(x_0))$.

Proof: The last displayed formula shows that where the prelevel surface meets the precaustic the nonzero normal to the prelevel surface is a linear combination of eigenvectors corresponding to the nonzero eigenvalues of $(I+t\nabla^2 S_0(x_0))$. The eigenvector of $(I+t\nabla^2 S_0(x_0))$ corresponding to eigenvalue zero, e_0, is orthogonal to these eigenvectors, so because T_{x_0} is only one dimensional, we have $T_{x_0}=\langle e_0\rangle$. □

When $\nabla S_0(x_0)=0$ at x_0 a point of the prelevel surface, the above argument shows that x_0 is a singular point of the prelevel surface, typically a node with two different directions of the tangent plane. Because the partial derivatives

$$\frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0, \quad \alpha=1,2,$$

we have for $x_0 = \Phi_t^{-1} x$

$$\nabla_x \mathcal{A}(x_0, x, t) = \frac{(x - x_0)}{t} = \nabla S_0(x_0),$$

independent of dimension. (In point of fact the last result is true merely because in the free case the momentum is constant.) Hence, at the image point $x = \Phi_t(x_0)$ (independent of the dimensions of the space and independent of whether or not $x_0 \in \Phi_t^{-1} C_t$) $|\nabla_x \mathcal{A}| = 0$ so x is also a singular point. Typically then, even if we are not on the precaustic, we expect that in the free case x_0 and $\Phi_t(x_0)$ are both nodes with two or more different directions of the tangent plane. This eventuality is easy to investigate with the derivative map $D\Phi_t(x_0)$. When $x_0 \in \Phi_t^{-1} C_t$ [because $D\Phi_t(x_0)$ annihilates the zero eigenvector e_0 on the precaustic] we have only one direction for the tangent plane at $\Phi_t(x_0)$ even though there were two distinct directions for the tangent plane to the prelevel surface at x_0. This happens, for example, where the prelevel surface consists of an ellipse and a line pair crossing at x_0 where the ellipse is tangential to the parabolic precaustic. It also occurs in the three-dimensional fish and butterfly example along the straight line of intersection of the caustic and zero level surface. Both of these examples are elucidated in Sec. IV.

Lemma 3.2: Assume that the prelevel surface meets the precaustic at the point x_0 where $|\nabla S_0(x_0)| = 0$, x_0 being a node, and dim $(\mathrm{Ker}(I + t\nabla^2 S_0(x_0))) = 1$. *Then the image point $\Phi_t(x_0)$ where the level surface meets the caustic is a singular point which cannot be a node but can be a cusp. If x_0 is a node of the prelevel surface, $x_0 \notin \Phi_t^{-1} C_t$, then $x = \Phi_t(x_0)$ is a node of the level surface.*

Proof: In the first case, the two different directions t_1 and t_2 at x_0 of the tangent plane to the prelevel surface where it meets the precaustic are both mapped into $(I + t\nabla^2 S_0(x_0)) e_0^{\perp}$, $e_0^{\perp}$ being the nonzero eigenvector of $(I + t\nabla^2 S_0(x_0))$. So both t_1 and t_2 get mapped into the same direction as $e_0^{\perp}$. Moreover, $|\nabla \mathcal{A}| = 0$, so $\Phi_t(x_0)$ is a singular point so it has to be a cusp. The second case follows because the two different directions t_i get mapped into the two different directions $(I + t\nabla^2 S_0(x_0)) t_i$ for $i = 1,2$. □

Remark 3.1: Needless to say there is an analog of this lemma in d dimensions. The condition $|\nabla S_0(x_0)| = 0$ should be seen as a zero speed condition.

When $(I + t\nabla^2 S_0(x_0)) \nabla S_0(x_0)$ is nonzero, there is a simple result concerning the appearance of cusps on the level surface. We use the intrinsic equation of the prelevel surface $x_0 = x_0(\gamma)$, $\gamma \in N(\gamma_0, \delta)$, where $x_0(\gamma_0)$ is the point of intersection of the prelevel surface and precaustic. We write $x(\gamma) = \Phi_t(x_0(\gamma))$ and assume that x_0 and x are differentiable in γ.

Proposition 3.1: Assume that $|(I + t\nabla^2 S_0(x_0)) \nabla S_0(x_0)| \neq 0$, so x_0 is not a singular point of the prelevel surface. Then $\Phi_t(x_0)$ can only be a generalized cusp of the level surface if $\Phi_t(x_0) \in C_t$, the caustic. Moreover, if $x = \Phi_t(x_0) \in \Phi_t(\Phi_t^{-1} C_t \cap \Phi_t^{-1} H_t)$, x will indeed be a generalized cusp of the level surface.

Proof: We have the normal $n(x_0) = (I + t\nabla^2 S_0(x_0)) \nabla S_0(x_0) \neq 0$, $dx_0(\gamma)/d\gamma|_{\gamma = \gamma_0} \neq 0$ and from above

$$\left.\frac{dx(\gamma)}{d\gamma}\right|_{\gamma = \gamma_0} = (D\Phi_t(x_0)) \left.\frac{dx_0(\gamma)}{d\gamma}\right|_{\gamma = \gamma_0} = (I + t\nabla^2 S_0(x_0)) \left.\frac{dx_0(\gamma)}{d\gamma}\right|_{\gamma = \gamma_0}.$$

For this to be zero it is necessary that $\mathrm{Det}(I + t\nabla^2 S_0(x_0)) = 0$, so $x_0 \in \Phi_t^{-1} C_t$ i.e., it is necessary that $\Phi_t(x_0) \in C_t$. Trivially from Lemma 3.1 it follows that if $x_0 \in \Phi_t^{-1} C_t$, then $dx(\gamma)/d\gamma|_{\gamma = \gamma_0} = 0$. □

C. Results in three dimensions

Consider the above setup in three dimensions so that the wavefront H_t has the equation in x obtained by eliminating x_0 between

$$\mathcal{A}(x_0,x,t)=c \quad \text{and} \quad \frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0, \quad \alpha=1,2,3,$$

and the caustic C_t by eliminating x_0 between

$$\mathrm{Det}\left(\frac{\partial^2 \mathcal{A}}{\partial x_0{}^2}(x_0,x,t)\right)=0 \quad \text{and} \quad \frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0, \quad \alpha=1,2,3.$$

We define the cusped part of H_t by

$$\mathrm{Cusp}(H_t)=\{x\in H_t : x\in \Phi_t(\Phi_t^{-1}C_t\cap \Phi_t^{-1}H_t), x=\Phi_t(x_0),$$
$$x_0\in \Phi_t^{-1}C_t\cap \Phi_t^{-1}H_t, n(x_0)=(I+t\nabla^2 S_0(x_0))\nabla S_0(x_0)\neq 0\}.$$

Typical of what happens in three dimensions for which $d=3$ is the following:

Theorem 3.1: *Let $x\in \mathrm{Cusp}(H_t)$. Then T_x, the tangent plane to the level surface H_t at x, is at most one dimensional.*

Remark 3.2: The tangent plane T_x folds over onto itself at points $x\in \mathrm{Cusp}(H_t)$, the direction of the fold being the direction of the one-dimensional tangent space at x.

Proof: Let n be the unit normal to the tangent plane T_{x_0}, $x_0\in \Phi_t^{-1}C_t\cap \Phi_t^{-1}H_t$. This is the well-defined vector

$$n=|(I+t\nabla^2 S_0(x_0))\nabla S_0(x_0)|^{-1}(I+t\nabla^2 S_0(x_0))\nabla S_0(x_0),$$

which is clearly a linear combination of the nonzero eigenvectors of $(I+t\nabla^2 S_0(x_0))$. Let e_0 be an eigenvector corresponding to eigenvector zero which is orthogonal to n. Since $n\neq 0$, T_{x_0} is a well-defined two-dimensional space spanned by e_0 and $n\wedge e_0=e_0^\perp$. Because $D\Phi_t(x_0)=(I+t\nabla^2 S_0(x_0))$, T_x is spanned by $(I+t\nabla^2 S_0(x_0))e_0^\perp$. □

We now see what it takes for us to observe cusps on planar cross sections of the level surface where it meets the caustic. We shall assume, without loss of generality, that the planar cross sections are on a plane $y=\mathrm{const}$ with normal e_y. We write $x=\Phi_t(x_0)$ and

$$\nabla S_0(x_0)=\alpha_0 e_0+\alpha_1 e_1+\alpha_2 e_2=\nabla_x \mathcal{A},$$

where

$$(I+t\nabla^2 S_0(x_0))e_0=0,$$

$$(I+t\nabla^2 S_0(x_0))e_i=\lambda_i e_i, \quad i=1,2,$$

$x_0\in \Phi_t^{-1}C_t\cap \Phi_t^{-1}H_t$.

Then, from above, the unit normal

$$n=(\alpha_1\lambda_1 e_1+\alpha_2\lambda_2 e_2)\theta$$

and

$$e_0^\perp=(\alpha_2\lambda_2 e_1-\alpha_1\lambda_1 e_2)\theta,$$

where $\theta=(\alpha_1^2\lambda_1^2+\alpha_2^2\lambda_2^2)^{-1/2}$. At a point $x\in \mathrm{Cusp}(H_t)$, the axis system $\{e_0,e_0^\perp,n\}$ is well defined and intrinsically related to the geometry of the prelevel surface at $x_0\in \Phi_t^{-1}C_t\cap \Phi_t^{-1}H_t$. This is our preferred axis system for discussing cusps.

We assume that S_0 is at least C^4 and write

$$x=x_0+t\nabla S_0(x_0).$$

We work to second order

$$x+\delta x = x_0+\delta x_0 + t\nabla S_0(x_0+\delta x_0)$$
$$= x_0+\delta x_0 + t\nabla S_0(x_0) + t(\delta x_0\cdot\nabla)\nabla S_0(x_0) + \frac{t}{2}(\delta x_0\cdot\nabla)^2\nabla S_0(x_0) + O((\delta x_0)^3).$$

Hence, correct to second order,

$$\delta x = (I + t\nabla^2 S_0(x_0))\delta x_0 + \frac{t}{2}(\delta x_0\cdot\nabla)^2\nabla S_0(x_0).$$

We now set

$$\delta x_0 = \varepsilon(\lambda e_0 + \mu e_0^{\perp}) + \varepsilon^2(\xi e_0 + \eta e_0^{\perp} + \zeta n).$$

The first term gives the direction of $dx_0/d\gamma$ and the second $d^2x_0/d\gamma^2$ evaluated at $\gamma=\gamma_0$, where $x_0(\gamma_0)$ is the point of intersection. Then we obtain

$$\delta x = \varepsilon\mu\lambda_1\lambda_2(\alpha_2 e_1 - \alpha_1 e_2)\theta$$
$$+\varepsilon^2\left(\eta\lambda_1\lambda_2(\alpha_2 e_1-\alpha_1 e_2)\theta + \zeta(\alpha_1\lambda_1^2 e_1 + \alpha_2\lambda_2^2 e_2)\theta + \frac{t}{2}(\lambda\partial_0+\mu\partial_0^{\perp})^2\nabla S_0(x_0)\right),$$

∂_0 and $\partial_0^{\perp}$ being directional derivatives parallel to e_0 and $e_0^{\perp}$.

For a genuine cusp we clearly have to set $\mu=0$, for which

$$\delta x_0 = \varepsilon\lambda e_0 + \varepsilon^2(\xi e_0 + \eta e_0^{\perp} + \zeta n), \tag{C_0}$$

$$\delta x = \varepsilon^2\left(\eta\lambda_1\lambda_2(\alpha_2 e_1-\alpha_1 e_2)\theta + \zeta(\alpha_1\lambda_1^2 e_1 + \alpha_2\lambda_2^2 e_2)\theta + \frac{t}{2}\lambda^2\partial_0^2\nabla S_0(x_0)\right). \tag{C_1}$$

We now have to satisfy two further conditions:

$$\delta x\cdot e_y = 0, \tag{C_2}$$

$$\delta x\cdot\frac{\partial\mathcal{A}}{\partial x} = \delta x\cdot\nabla S_0(x_0) = \delta x\cdot(\alpha_0 e_0+\alpha_1 e_1+\alpha_2 e_2) = 0. \tag{C_3}$$

If we can choose λ, η, and ζ to satisfy the above two equations for nonzero δx, the planar cross section of the level surface H_t, $y=\text{const}$, will have a genuine cusp at $x\in\text{Cusp}(H_t)$. The axis of the cusp will be $\widehat{\delta x}$. This explains why genuine cusps are so numerous on planar cross sections.

Theorem 3.2: *Any point x on the level surface H_t, $x=\Phi_t(x_0)$ with $x_0=\Phi_t^{-1}(x)$ on the prelevel surface, can only be a generalized cusp of a curve on H_t if x_0 is a generalized cusp of the precurve on the prelevel surface or if $x_0\in\Phi_t^{-1}C_t$ the precaustic. In three dimensions, the planar cross section $y=\text{const}$ (with normal e_y) of the level surface H_t through a point x where it meets C_t will have a genuine cusp at x if $x\in\text{Cusp}(H_t)$ and there is a nonzero solution δx of Eqs. (C_0), (C_1), (C_2) and (C_3). The direction of the axis of the cusp is $\widehat{\delta x}$.*

Proof: The first part of the theorem is obvious.

Equations (C_1), (C_2) and (C_3) uniquely fix the direction of $\widehat{\delta x}$, if nonzero λ, η and ζ exist satisfying these equations. It is easy to see that Eqs. (C_0), (C_1), (C_2), and (C_3) are sufficient to solve

$$\mathcal{A}(x_0,x,t)=c,$$

$$\mathcal{A}(x_0+\delta x_0,x+\delta x,t)=c,$$

$$\frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0, \quad \alpha=1,2,3,$$

$$\frac{\partial \mathcal{A}}{\partial x_0^\alpha}((x_0+\delta x_0,x+\delta x,t)=0, \quad \alpha=1,2,3,$$

correct to second order, if

$$\mathrm{Det}\left(\frac{\partial^2 \mathcal{A}}{\partial x_0^2}(x_0,x,t)\bigg|_{x=\Phi_t(x_0)}\right)=0,$$

$x_0\in\Phi_t^{-1}C_t\cap\Phi_t^{-1}H_t$, $x=\Phi_t(x_0)$, and $n(x_0)$ nonzero. □

This analysis explains the plethora of cusps which we observe in the free case. Moreover, as we shall see, the argument above can be generalized to include random and deterministic external forces i.e., nonzero c and k terms in the Burgers equation.

Remark 3.3: We make the point that

$$\Phi_t^{-1}C_t\cap\Phi_t^{-1}H_t\subset\Phi_t^{-1}(C_t\cap H_t), \tag{3.6}$$

but the opposite inclusion does not hold and so images of points in $\Phi_t^{-1}(C_t\cap H_t)\backslash(\Phi_t^{-1}C_t\cap\Phi_t^{-1}H_t)$ *give rise to cross-over points.*

D. Consequences for the Burgers fluid

Here we recapitulate a result of Truman and Zhao.[12] See Ref. 31 for more recent related results.

Theorem 3.3: *Let* $\tau(a)$ *be the first time such that there exist minimizers* $y_1\neq y_2$, y_1, $y_2\in\mathbb{R}^d$, *such that* $\Phi_\tau(y_1)=\Phi_\tau(y_2)=a$ *and* $\dot\Phi_\tau(y_1)\neq\dot\Phi_\tau(y_2)$, *i.e.,* τ *is a caustic time at point a. Then* $v^0(x,t)$ *is discontinuous at* (τ,a).

We now give a simple application of the above results to the Burgers fluid in two dimensions. For smooth S_0, in two dimensions, we can divide one side of the caustic into *hot* and *cool* parts. We consider points of intersection α with the level surface $S(x,t)=S(\alpha,t)$ cusped at α: if the part of the level surface cusped at α corresponds to the minimizing $x_0(\alpha,t)$, then the Burgers velocity field $v^0(x,t)=\nabla S(x,t)\to\nabla S(\alpha,t)=0$ as $x\to\alpha$ from the cusped side of the caustic. This is merely because the condition for $S(x,t)=S(\alpha,t)$ to have a cusp at $x=\alpha$ is $\nabla S(\alpha,t)=0$. Moreover, this entails the minimizing surface changing as we cross the caustic. Indeed the cusp occurs because the minimizing surface on the cusped side of the caustic cannot be continued across the caustic. So $u^0(x,t)$ is necessarily exponentially discontinuous as we cross such parts of the caustic. This is because here two $x_0(x,t)$'s coalesce as the minimizer at the cusp and then disappear. We call such points α cool because the Burgers fluid has zero velocity on one side of the caustic at α. The whole of one side of the generic semi-cubical parabolic cusp is cool. Not all of one side of the two-dimensional swallowtail is cool. This is discussed in the next section, where we give numerical confirmation of this result. The exponential discontinuity in u^0 can be seen by inspecting Fig. 10 which shows the number of negative S_0^i's in the different regions. Similar results apply in three dimensions.

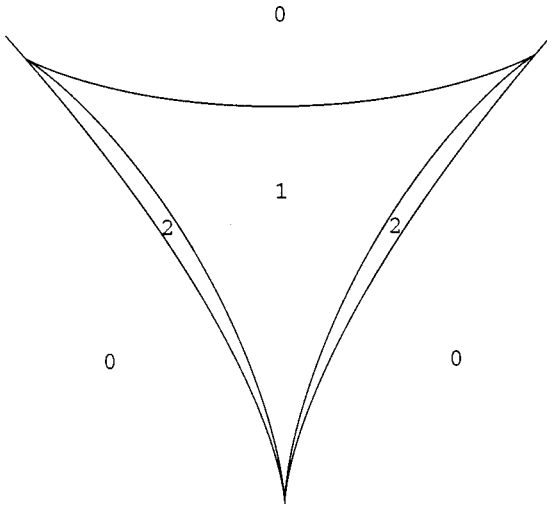

FIG. 10. Number of negative S_0.

IV. DETERMINISTIC AND ARCHETYPAL EXAMPLES

Consider S_0 given in the following table for two and three dimensions, respectively,

Shockwave	Zero Level Surface	S_0
Cusp	Tricorn	$x_0^2 y_0/2$
Swallowtail	Plough	$x_0^5+\lvert x_0\rvert^{3/2} y_0$
Butterfly	Fish	$x_0^3 y_0/3+x_0^2 z_0/2$
Swallowtail	Seagull	$\lvert x_0\rvert^5+\lvert x_0\rvert^{1+c} y_0+\lvert x_0\rvert^c z_0$

where $1/2<c<1$. The nature of the caustic (shockwave) is given in the first column and the corresponding zero level surfaces in the second. The zero level surface corresponding to the semicubical parabolic cusp is the tricorn, which has three cusps on the semi-cubical parabola, one of which coincides with the original cusp of the shockwave, and a line-pair. The zero level surface corresponding to the butterfly is the fish, which meets the butterfly in four curves (three of which are cusped and one of which is a straight line on which they touch). See Refs. 35 and 36 for further and more surprising examples.

A. A two-dimensional example

For $S_0(x_0,y_0)=x_0^2 y_0/2$ the zero prelevel surface has equation

$$x_0^2\left(\frac{(y_0+1/2t)^2}{(1/2t)^2}+\frac{x_0^2}{(1/t)^2}-1\right)=0,$$

and the precaustic has equation

$$1+ty_0=t^2x_0^2.$$

Note also that $\nabla S_0(x_0,y_0)=0$ at the point $(0,-1/t)$, so the zero speed condition is satisfied here and this point is a node of the zero prelevel surface. We now map $(x,y)=\Phi_t(x_0,y_0)$ to obtain the hypocycloid tricorn

$$x=\frac{\cos\theta(1+\sin\theta)}{2t},\quad y=\frac{\sin\theta(1-\sin\theta)}{2t}, \tag{4.1}$$

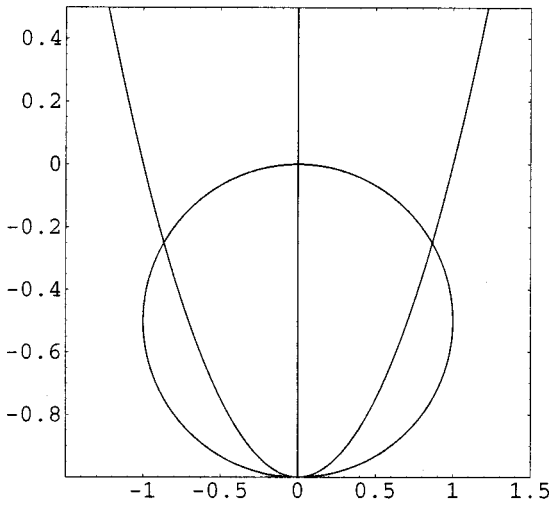

FIG. 11. Precaustic and prelevel surface.

for $0 \leqslant \theta < 2\pi$, as the zero level surface at time t for the heat equation and semi-cubical parabolic cusp

$$8(yt+1)^3 = 27t^2x^2, \tag{4.2}$$

as shockwave at time t for the corresponding Burgers velocity field.

Figures 11 and 12 illustrate the level surface $S_t(x,y)=0$. Figures 13 and 14 illustrate the level surface $S_t(x,y)=2$. Figures 15 and 16 illustrate the level surface $S_t(x,y)=-2^{-7}$.

We have verified numerically that the caustic surfaces are indeed discontinuities for the Burgers velocity field as shown in Fig. 17. Further, it is not difficult to see that the whole of one side of this cusp surface is cool. One has to note, and it is not too onerous to check, that for each point of the cusp the minimizing S_0^i corresponds to a cusp and not a crossover. The agreement with the cusp catastrophe is shown in Fig. 18.

Finally we add that in two dimensions the tricorn will be a common feature of the level surfaces of Hamilton's principal function when the corresponding prelevel surface touches the precaustic. Here the point is that the unfolding of the tricorn under the inverse classical flow map

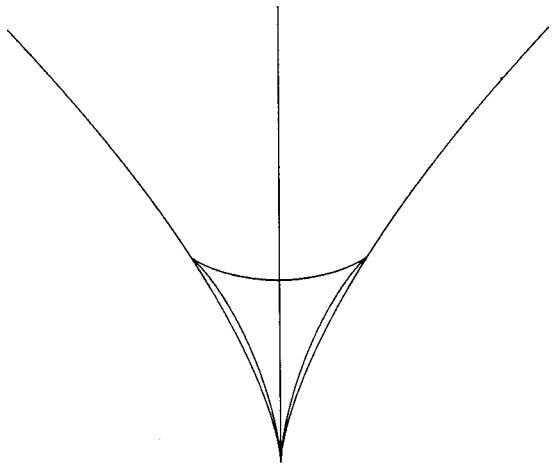

FIG. 12. Cusp and tricorn.

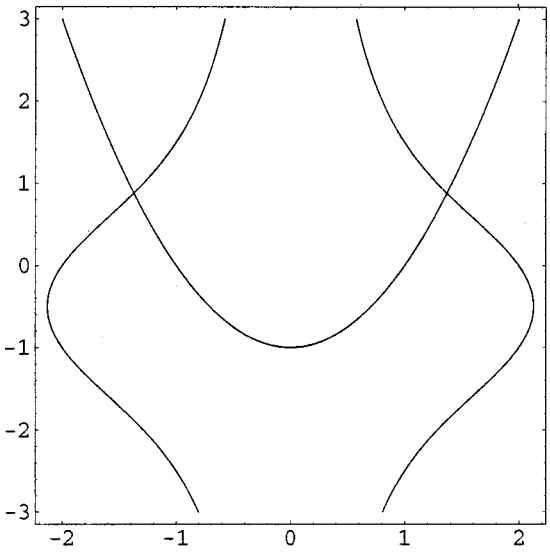

FIG. 13. Precaustic (parabola) and prelevel surface (kneecap).

Φ_t is the "halo" shown in Fig. 11. The point of contact is denoted by x_0^0 and the direction of the unit tangent vector by e_0. To see this from above we know that $\Phi_t(x_0^0 \pm \varepsilon e_0) = \Phi_t(x_0^0) + o(\varepsilon)$. If the slightly stronger result holds, namely, $\Phi_t(x_0^0 \pm \varepsilon e_0) = \Phi_t(x_0^0) + \varepsilon^2 w_0 + o(\varepsilon^2)$, then necessarily we have a tricorn with axis w_0 since both halves of the common tangent get mapped onto the half axis parallel to w_0, the other two points of intersection being mapped onto cusps.

B. A three-dimensional example

For $S_0(x_0, y_0, z_0) = x_0^3 y_0/3 + x_0^2 z_0/2$ we can quickly see the close relationship with the previous example by means of the cross sections $y = \text{const}$ shown in Figs. 19 and 20.

To see where the butterfly (Fig. 21) and fish (Fig. 22) meet, consider the classical mechanics:

$$x = x_0 + t(x_0^2 y_0 + x_0 z_0),$$

$$y = y_0 + \frac{t}{3} x_0^3,$$

$$z = z_0 + \frac{t}{2} x_0^2.$$

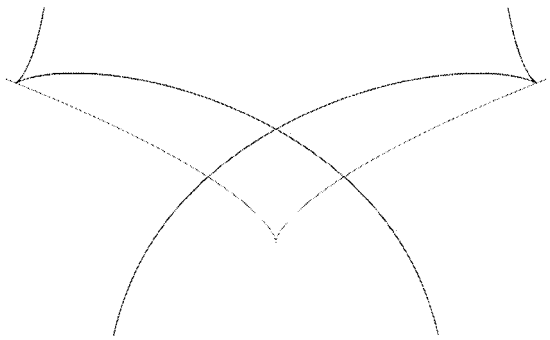

FIG. 14. Caustic (cusp) and level surface (neckline).

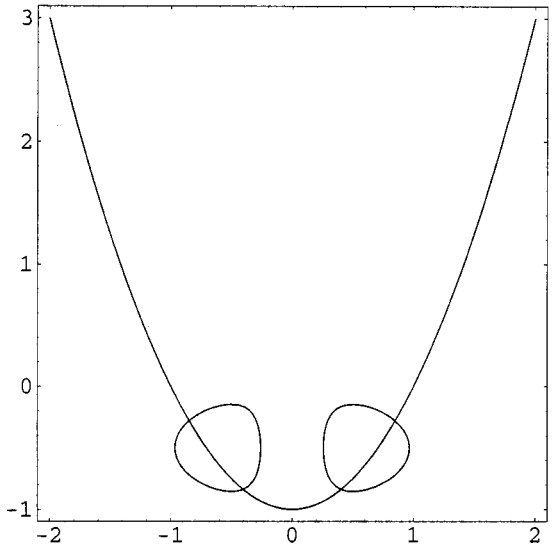

FIG. 15. Precaustic (parabola) and prelevel surface (pebble pair).

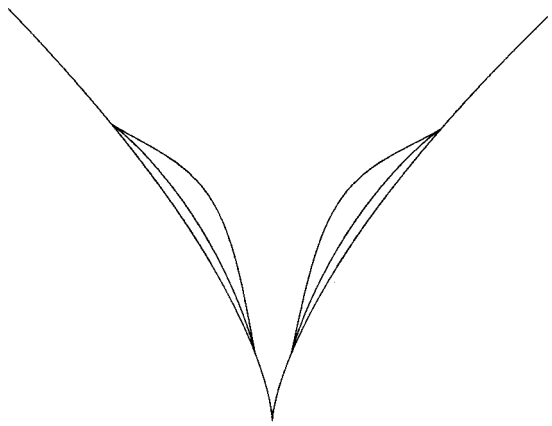

FIG. 16. Caustic (cusp) and level surface (lapel pair).

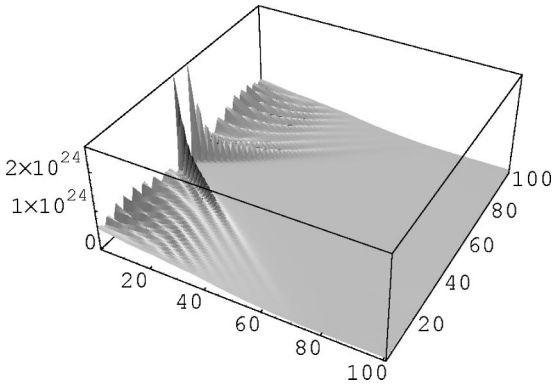

FIG. 17. $|v^{\mu}|^2$ for small μ.

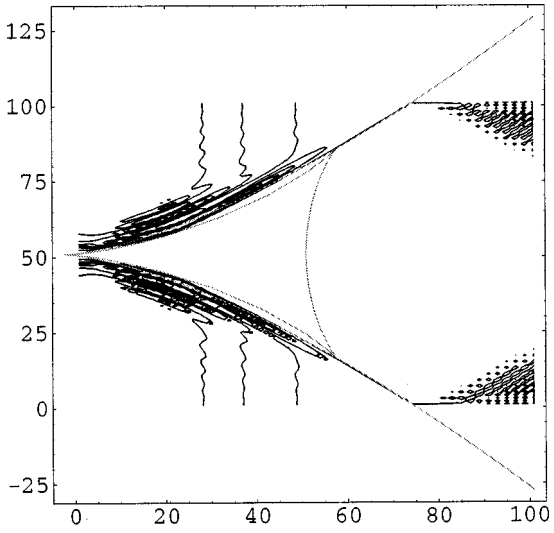

FIG. 18. Contour plot of $|v^{\mu}|^2$ with cusp and tricorn.

Solving the precaustic equation leads to

$$z_0 = -\frac{1-t^2x_0^2-t^2x_0^4+2tx_0y_0}{t},$$

and with this we simplify the zero prelevel surface equation, one solution of which is $x_0=0$ leaving a quadratic equation for y_0 with roots,

$$y_0=\frac{-2+6t^2x_0^2-6t^2x_0^4+\sqrt{4+3t^2x_0^2+8t^2x_0^4}}{6tx_0},$$

and

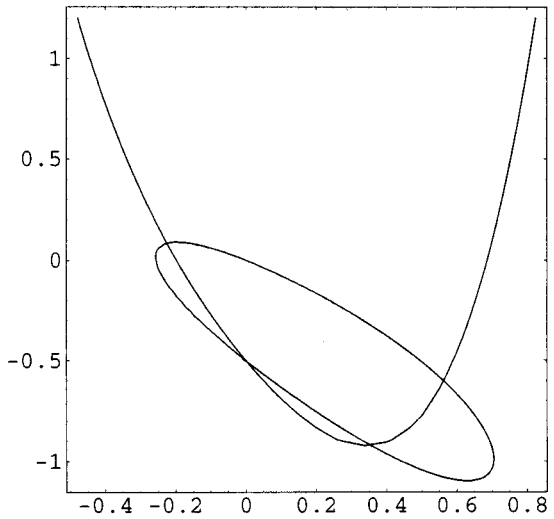

FIG. 19. Prebutterfly and fish.

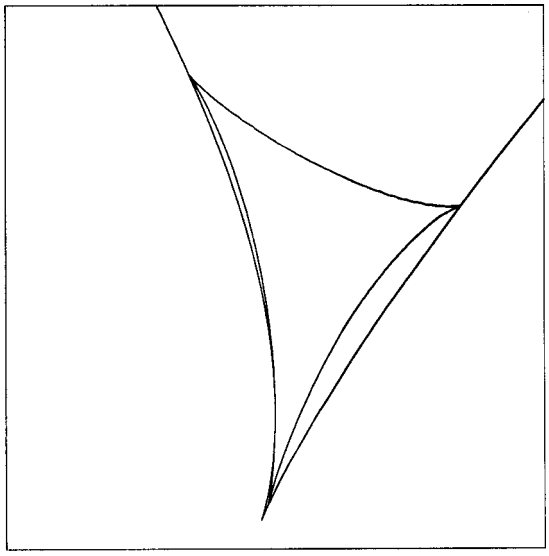

FIG. 20. Butterfly and fish.

$$y_0=\frac{-2+6t^2x_0^2+6t^2x_0^4+\sqrt{4+3t^2x_0^2+8t^2x_0^4}}{6tx_0}.$$

When $x_0=0$, we have $z_0=-1/t$ and $\nabla S_0(x_0,y_0,z_0)=0$ on this line. Hence on this line the zero speed condition is satisfied and the tangent plane to the zero prelevel surface here has two possible directions. Therefore the zero level surface and caustic meet on a straight line at

$$x=0, \quad z=-1/t, \quad y\in\mathbb{R}.$$

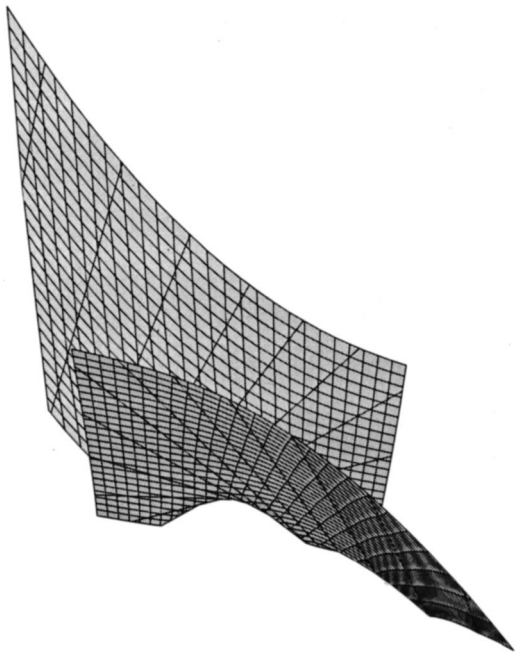

FIG. 21. The butterfly singularity for Burgers equation.

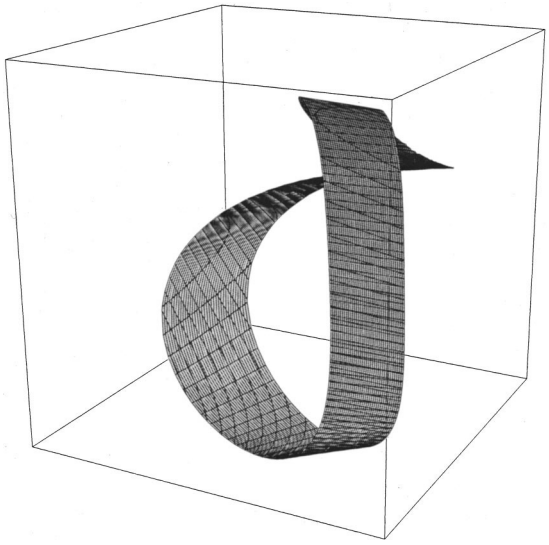

FIG. 22. The fish level surface for heat equation (a section).

It is easy to see that the two surfaces actually touch on this line because this line is on the precaustic. For one value of y_0, we obtain the parametric equations of the two curves of intersection ($x_0>0$ and $x_0<0$)

$$x=\tfrac{1}{6}x_0(2+\sqrt{4+t^2x_0^2(3+8x_0^2)}),$$

$$y=-\frac{2-2t^2x_0^2(3+4x_0^2)+\sqrt{4+t^2x_0^2(3+8t^2)}}{6tx_0},$$

$$z=\frac{-3t^2x_0^2(1+2x_0^2)+2(-1+\sqrt{4+t^2x_0^2(3+8t^2)})}{6t}.$$

For the other value of y_0 we obtain the parametric equation of one additional curve:

$$x=-\tfrac{1}{6}x_0(-2+\sqrt{4+t^2x_0^2(3+8x_0^2)}),$$

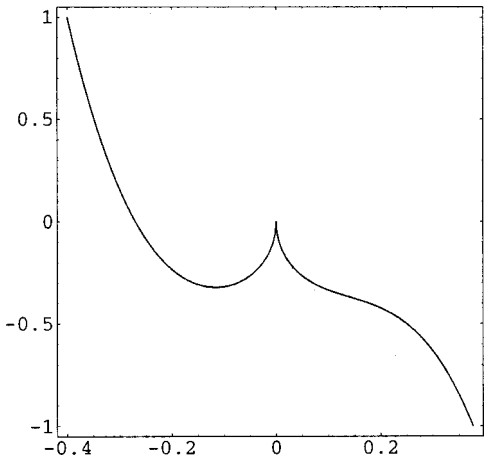

FIG. 23. Precaustic.

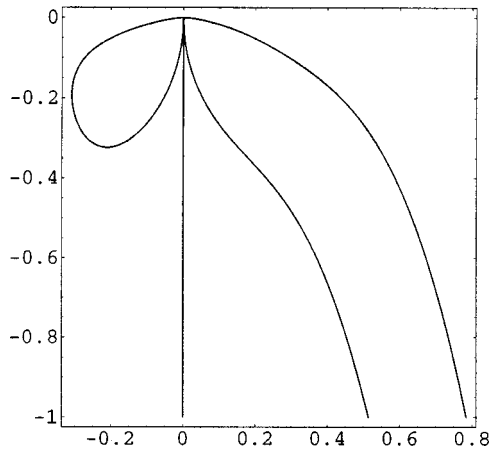

FIG. 24. Prelevel surface.

$$y=\frac{-2+2t^2x_0^2(3+4x_0^2)+\sqrt{4+t^2x_0^2(3+8t^2)}}{6tx_0},$$

$$z=-\frac{3t^2x_0^2(1+2x_0^2)+2(1+\sqrt{4+t^2x_0^2(3+8t^2)})}{6t}.$$

C. A cautionary two-dimensional example

We briefly consider the nongeneric two-dimensional swallowtail, where $S_0(x_0,y_0)=x_0^5+|x_0|^{3/2}y_0$. Here the zero level surface crosses the caustic because $\Phi_t^{-1}(C_t\cap H_t)\not\subset\Phi_t^{-1}C_t\cap\Phi_t^{-1}H_t$. This example also shows (Fig. 24) that we can have $dx_0(\gamma_0)/d\gamma=0$ occurring on the zero prelevel surface, although we should point out that S_0 is nonpolynomial in this case. We have many other cases of polynomial S_0 giving rise to two-dimensional swallowtail singularities.

Note the alignment of the generalized cusps on the zero prelevel surface and precaustic, Figs. 23 and 24, respectively. Figures 25 and 26 are the corresponding caustic and zero level surface.

We also illustrate in Fig. 27 the case where the zero level surface crosses the caustic, at the points P and Q, when Φ_t^{-1} gives distinct points on the zero prelevel surface and precaustic.

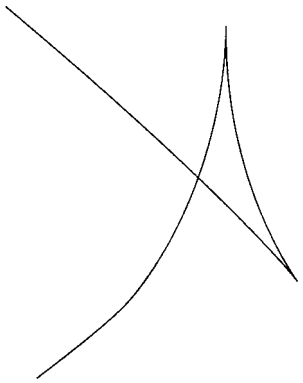

FIG. 25. Swallowtail caustic.

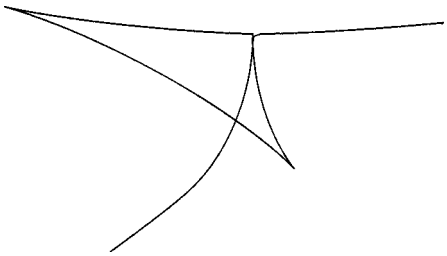

FIG. 26. Plough level surface.

D. Swallowtail

We briefly illustrate (Figs. 28 and 29), the caustic for $S_0(x_0,y_0,z_0)=|x_0|^5+|x_0|^{5/3}y_0+|x_0|^{2/3}z_0$. This was the first such S_0 found to generate the swallowtail, but we also have examples of strictly polynomial S_0 which generate the same archetypal caustic in three dimensions in analogy to the examples of the previous section.

V. THE STOCHASTIC AND GENERAL CASES

A. The stochastic action

Let $A(x_0,p_0,t)$ be defined by

$$A(x_0,p_0,t)=\frac{1}{2}\int_0^t \dot{X}^2(s)\,ds-\int_0^t [c(X(s))\,ds+\epsilon k(X(s),s)\,dW_s],$$

almost surely, where $X(s)=X_s=X(s,x_0,p_0)$ satisfies

$$d\dot{X}(s)=-\nabla c(X(s))ds-\epsilon\nabla k(X(s),s)dW_s, \quad s\in[0,t],$$

with $X(0)=x_0$ and $\dot{X}(0)=p_0,x_0,p_0\in\mathbb{R}^d$. We shall assume that X_s is unique and as usual is $\mathcal{F}_s$ measurable. We also allow for p_0 to be an as yet unspecified function of x_0.

Recall the integration by parts property (ibp^2) for the continuous process $\dot{X}(s)=\dot{X}(s,x_0,p_0)$,

$$\int_0^t u(s)\,d\dot{X}(s)=u(t)\dot{X}(t)-u(0)\dot{X}(0)-\int_0^t \dot{u}(s)\dot{X}(s)\,ds,$$

for deterministic $u\in C^1(0,t)$. This integration by parts property is also valid for random u, if the stochastic integral is of Itô's form and, $du_s d\dot{X}_s$, the corresponding Itô correction, is zero. An important case in point is when

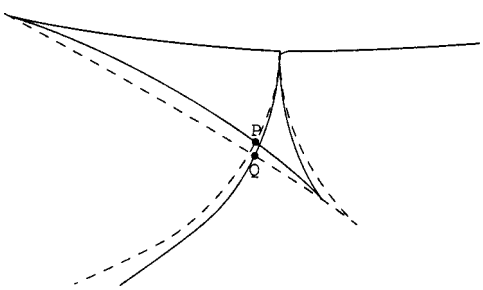

FIG. 27. Swallowtail and plough.

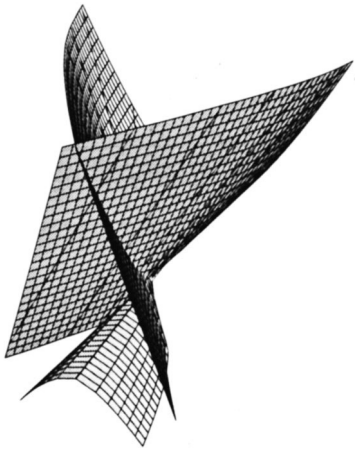

FIG. 28. The swallowtail singularity for Burgers equation.

$$u_s = \frac{\partial X_s}{\partial x_0^\alpha},$$

for $s \in [0,t]$ and $\alpha = 1,2,...,d$. Then, if we assume ∇c, ∇k are Lipschitz, with Hessians $\nabla^2 c$, $\nabla^2 k$ and all second derivatives with respect to space variables of c and k bounded, according to Kunita,[37] $\partial X_s / \partial x_0^\alpha$ satisfies

$$\frac{d}{ds}\left(\frac{\partial X_s}{\partial x_0^\alpha}\right) = \frac{\partial \dot{X}_0}{\partial x_0^\alpha} - \int_0^s \left[\nabla^2 c(X(r)) \frac{\partial X(r)}{\partial x_0^\alpha}\, dr + \epsilon \nabla^2 k(X(r),r) \frac{\partial X(r)}{\partial x_0^\alpha}\, dW_r \right].$$

So the Itô correction is zero. Hence for $u_s = \partial X_s / \partial x_0^\alpha$ we can use the ibp[2]. Moreover,

$$\dot{X}_s = \dot{X}_0 - \int_0^s [\nabla c(X(r))\, dr + \epsilon \nabla k(X(r),r)\, dW_r]. \tag{5.1}$$

Therefore, using Kunita[37] again, we obtain

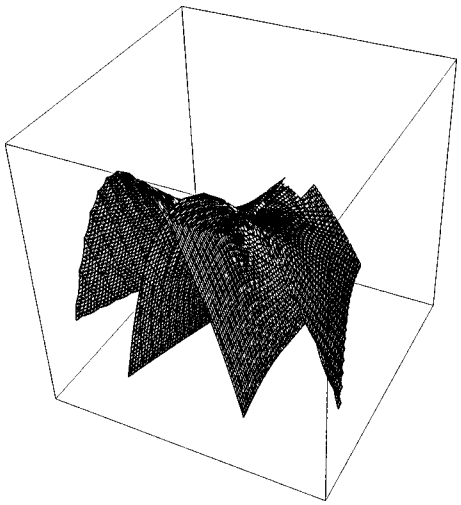

FIG. 29. The seagull level surface for heat equation.

$$\frac{d}{ds}\left(\frac{\partial X_s}{\partial x_0^\alpha}\right)=\frac{\partial \dot{X}_s}{\partial x_0^\alpha},\quad \alpha=1,2,...,d.$$

This gives the following lemma.

Lemma 5.1: Assume S_0, $c\in C^2$ and $k\in C^{2,0}$, ∇c, ∇k are Lipschitz, with Hessians $\nabla^2 c$, $\nabla^2 k$ and all second derivatives with respect to space variables of c and k bounded. If $\dot{X}_s$ satisfies Eq. (5.1) and p_0, possibly x_0 dependent, then almost surely

$$\frac{\partial A}{\partial x_0^\alpha}(x_0,p_0,t)=\dot{X}(t)\cdot\frac{\partial X(t)}{\partial x_0^\alpha}-\dot{X}_\alpha(0).$$

Proof: Arguing as above, for $\alpha=1,2,...,d$, we obtain

$$\frac{\partial A}{\partial x_0^\alpha}(x_0,p_0,t)=\int_0^t\left(\dot{X}(s)\cdot\frac{\partial \dot{X}(s)}{\partial x_0^\alpha}-\nabla c(X(s))\cdot\frac{\partial X(s)}{\partial x_0^\alpha}\right)ds-\epsilon\int_0^t\nabla k(X(s),s)\cdot\frac{\partial X(s)}{\partial x_0^\alpha}\,dW_s.$$

So using the key identity and the ibp^2 formula gives

$$\frac{\partial A}{\partial x_0^\alpha}(x_0,p_0,t)=-\int_0^t\frac{\partial X(s)}{\partial x_0^\alpha}\cdot[d\dot{X}(s)+\nabla c(X(s))\,ds+\epsilon\nabla k(X(s),s)\,dW_s]+\left[\dot{X}(s)\cdot\frac{\partial X(s)}{\partial x_0^\alpha}\right]_0^t,$$

proving the desired result. □

Remark 5.1: Observe that, if we fix $X(t)$, we obtain almost surely

$$\frac{\partial A}{\partial x_0^\alpha}(x_0,p_0,t)=-\dot{X}_\alpha(0),$$

for $\alpha=1,2,...,d$.

Let

$$X(s,x_0,x)=X(s,x_0,p_0)|_{p_0=p(x_0,x,t)},$$

where $p_0=p(x_0,x,t)$ is the (random) minimizer (assumed unique) of $A(x_0,p_0,t)$ with $X(t,x_0,p_0)=x$. Set

$$A(x_0,x,t)=A(x_0,p_0,t)|_{p_0=p(x_0,x,t)}.$$

Theorem 5.1: *Defining $A(x_0,x,t)$ as above,*

$$\left.\frac{\partial}{\partial x_0^\alpha}\right|_{\text{fixed}(x,t)}A(x_0,x,t)=-\dot{X}_\alpha(0),\quad \alpha=1,2,...d,$$

and so

$$\left.\frac{\partial}{\partial x_0^\alpha}\right|_{\text{fixed}(x,t)}[A(x_0,x,t)+S_0(x_0)]=0,\quad \alpha=1,2,...d,$$

defines the classical stochastic mechanical flow map Φ_t with $x=\Phi_t(x_0)$.

Proof: A trivial consequence of the last lemma. □

We now define the stochastic action corresponding to the initial momentum $\nabla S_0(x_0)$ by

$$\mathcal{A}(x_0,x,t)=A(x_0,x,t)+S_0(x_0).$$

B. The level surface geometry

We assume that $\mathcal{A}(x_0,x,t)$ is C^4 in space variables and that t is such that

$$\mathrm{Det}\left(\frac{\partial^2\mathcal{A}}{\partial x_0\partial x}(x_0,x,t)\right)\neq 0,\quad x_0,x\in\mathbb{R}^d.$$

The last assumption can be considerably weakened but with this last assumption the proofs are simpler. In the free case, considered previously, this assumption is valid for all $t>0$.

We now imitate the free case. We define the prelevel surface of Hamilton's principal function by eliminating x between the equations

$$\mathcal{A}(x_0,x,t)=c\quad\text{and}\quad\frac{\partial\mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0,\quad\alpha=1,2,...,d,$$

and the level surface by eliminating x_0. So the prelevel surface is $\Phi_t^{-1}H_t$. Similarly we define the caustic C_t and the precaustic $\Phi_t^{-1}C_t$ by eliminating x_0 or x between

$$\mathrm{Det}\left(\frac{\partial^2\mathcal{A}}{\partial {x_0}^2}(x_0,x,t)\right)=0\quad\text{and}\quad\frac{\partial\mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0,\quad\alpha=1,2,...,d.$$

Lemma 5.2: The classical flow map $x=\Phi_t(x_0)$ is a differentiable map from $\Phi_t^{-1}H_t$ to H_t with Frechet derivative

$$D\Phi_t(x_0)=\left(-\frac{\partial^2\mathcal{A}}{\partial x\partial x_0}(x_0,x,t)\right)^{-1}\left(\frac{\partial^2\mathcal{A}}{\partial {x_0}^2}(x_0,x,t)\right),$$

if $\mathcal{A}$ is C^3 in space derivatives.

Proof: We assume $x=\Phi_t(x_0)$, $x_0\in\Phi_t^{-1}H_t$, $x\in H_t$, so

$$\mathcal{A}(x_0,x,t)=c\quad\text{and}\quad\frac{\partial\mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0,\quad\alpha=1,2,...,d.$$

We move to a neighboring point $(x_0+\delta x_0,x+\delta x,t)$ on $\Phi_t^{-1}H_t$ and H_t, respectively. Then we obtain

$$\mathcal{A}(x_0+\delta x_0,x+\delta x,t)=c\quad\text{and}\quad\frac{\partial\mathcal{A}}{\partial x_0^\alpha}(x_0+\delta x_0,x+\delta x,t)=0,\quad\alpha=1,2,...,d,$$

i.e., correct to first order

$$\left(\frac{\partial^2\mathcal{A}}{\partial {x_0}^2}\right)\delta x_0+\left(\frac{\partial^2\mathcal{A}}{\partial x\partial x_0}\right)\delta x=0,$$

and

$$\delta x\cdot\frac{\partial\mathcal{A}}{\partial x}(x_0,x,t)=0,$$

proving the desired result. □

We can now prove the following proposition in d dimensions.

Proposition 5.1: We consider the random prelevel surface obtained by eliminating x between the equations

$$\mathcal{A}(x_0,x,t)=c \quad \text{and} \quad \frac{\partial \mathcal{A}}{\partial x_0^{\alpha}}(x_0,x,t)=0, \quad \alpha=1,2,...,d.$$

Then the normal to the prelevel surface at the point x_0 is to within a scalar multiplier given by

$$n(x_0)=-\left(\frac{\partial^2 \mathcal{A}}{\partial {x_0}^2}\right)\left(\frac{\partial^2 \mathcal{A}}{\partial x_0 \partial x}\right)^{-1}\dot{X}(t,x_0,\nabla S_0(x_0)).$$

Proof: Evidently $n(x_0)=\nabla_{x_0}\mathcal{A}(x_0,x,t)$, where $x=\Phi_t(x_0)$, the map Φ_t being defined by

$$\frac{\partial \mathcal{A}}{\partial x_0^{\alpha}}(x_0,x,t)=0, \quad \alpha=1,2,...,d.$$

Hence only the partial derivatives with respect to x contribute to $n(x_0)$, giving

$$n=(D\Phi_t(x_0))^T\frac{\partial A}{\partial x}(x_0,x,t)\bigg|_{x=\Phi_t(x_0)},$$

^{T} denoting transpose. However, following the method of Lemma 5.1, we obtain

$$\frac{\partial A}{\partial x^{\alpha}}(x_0,x,t)\bigg|_{x=\Phi_t(x_0)}=\dot{X}_{\alpha}(t,x_0,\nabla S_0(x_0)),$$

almost surely, for $\alpha=1,2,...,d$, proving the proposition. □

Corollary 5.1: In three dimensions at any point $x_0 \in \Phi_t^{-1}C_t \cap \Phi_t^{-1}H_t$ where $n(x_0)\neq 0$ and

$$\mathrm{Ker}\left(\frac{\partial^2 \mathcal{A}}{\partial {x_0}^2}(x_0,x,t)\right)\bigg|_{x=\Phi_t(x_0)}=\langle e_0\rangle,$$

e_0 being the zero eigenvector, T_{x_0} the tangent plane to the prelevel surface is spanned by e_0 and $(n(x_0)\wedge e_0)$.

Proof: We obtain by symmetry of $(\partial^2\mathcal{A}/\partial {x_0}^2)$

$$e_0\cdot n=-\left(\frac{\partial^2 \mathcal{A}}{\partial {x_0}^2}\right)e_0\cdot\left(\frac{\partial^2 \mathcal{A}}{\partial x_0 \partial x}\right)^{-1}\dot{X}(t,x_0,\nabla S_0(x_0))=0.$$

So e_0 is in the tangent plane T_{x_0}, setting $e_0^{\perp}=n\wedge e_0 \in T_{x_0}$ by definition. □

Remark 5.2: When the speed $|\dot{X}(t,x_0,\nabla S_0(x_0))|=0$, $n(x_0)=0$ and so x_0 is a singular point of the prelevel surface, either a node with two distinct directions for the tangent plane or a cusped singularity. Because $\partial\mathcal{A}/\partial x=\dot{X}$ necessarily $x=\Phi_t(x_0)$ is a singular point of the level surface even if $x_0 \notin \Phi_t^{-1}C_t$. In the case $x_0 \notin \Phi_t^{-1}C_t$ and $\dot{X}=0$ we know that this singularity can only be a node because the tangent space is fully two dimensional at this point.

Corollary 5.2: In two dimensions let the prelevel surface meet the precaustic at a point x_0 where $n(x_0)\neq 0$ and $\mathrm{Ker}(\partial^2\mathcal{A}/\partial {x_0}^2(x_0,\Phi_t(x_0),t))=\langle e_0\rangle$, e_0 being the zero eigenvector. Then the tangent plane to the prelevel surface at x_0, T_{x_0} is spanned by e_0.

Proof: This is a trivial consequence of the proposition above. □

Proposition 5.2: Assume that in two dimensions at $x_0 \in \Phi_t^{-1}H_t$ the above normal $n(x_0)\neq 0$, so that the prelevel surface does not have a generalized cusp at x_0. Then the level surface can only have a generalized cusp at $\Phi_t(x_0)$ if $\Phi_t(x_0)\in C_t$, the caustic surface. Moreover, if $x=\Phi_t(x_0) \in \Phi_t\{\Phi_t^{-1}C_t\cap\Phi_t^{-1}H_t\}$, the level surface will have a generalized cusp at x.

Proof: Because $n(x_0)$ is nonzero, the direction of the tangent to the prelevel surface curve is well defined at x_0. Hence, if the intrinsic parameterization of the curve is $x_0=x_0(\gamma)$, $\gamma \in N(\gamma_0,\delta)$ in a neighborhood of $x_0=x_0(\gamma_0)$, the tangent to the level surface

$$\left.\frac{dx(\gamma)}{d\gamma}\right|_{\gamma=\gamma_0}=\left(D\Phi_t(x_0)\left.\frac{dx_0(\gamma)}{d\gamma}\right|_{\gamma=\gamma_0}\right)=\left(-\frac{\partial^2\mathcal{A}}{\partial x\partial x_0}\right)^{-1}\left(\frac{\partial^2\mathcal{A}}{\partial {x_0}^2}\right)\frac{dx_0(\gamma_0)}{d\gamma}=0,$$

because T_{x_0} is spanned by e_0, $x_0\in\Phi_t^{-1}H_t\cap\Phi_t^{-1}C_t$. What is more $dx(\gamma_0)/d\gamma=0$ implies that necessarily $\mathrm{Det}(\partial^2\mathcal{A}/\partial {x_0}^2)=0$ if $x_0(\gamma_0)$ is not a generalized cusp. □

Needless to say, if $dx_0(\gamma_0)/d\gamma=0$, it follows from the above that $dx(\gamma_0)/d\gamma=0$. So generalized cusps map into generalized cusps regardless of whether or not $x_0\in\Phi_t^{-1}C_t$, cf. Figs. 23 and 24 for the two-dimensional swallowtail. This is true independent of the dimension of the space. We now return to the three-dimensional setup.

Definition 5.1: We define the cusped part of the level surface H_t in three dimensions by

$$\mathrm{Cusp}(H_t)=\{x\in H_t : x\in\Phi_t(\Phi_t^{-1}C_t\cap\Phi_t^{-1}H_t), x=\Phi_t(x_0), n(x_0)\neq 0\}.$$

Proposition 5.3: Let $x\in\mathrm{Cusp}(H_t)$. Then in three dimensions, T_x, the tangent space to the level surface at x, is one dimensional at most.

Proof: We know that $x=\Phi_t(x_0)$, $x_0\in\Phi_t^{-1}C_t\cap\Phi_t^{-1}H_t$ with $n(x_0)\neq 0$. It follows that there is a well-defined two-dimensional tangent plane to the prelevel surface at x_0, T_{x_0} spanned by e_0 and $(n\wedge e_0)$. However, the derivative map is given by

$$D\Phi_t(x_0)=\left(-\frac{\partial^2\mathcal{A}}{\partial x\partial x_0}\right)^{-1}\left(\frac{\partial^2\mathcal{A}}{\partial {x_0}^2}\right).$$

So $D\Phi_t(x_0)e_0=0$ and $T_x=\langle D\Phi_t(x_0)(n\wedge e_0)\rangle$ is at most one dimensional. □

Of course a similar result holds in higher dimensions.

C. A plethora of cusps

We conclude by explaining why we expect to see generalized cusps on planar cross sections of level surfaces in three dimensions. We first of all observe that, if δx is of second order of small quantities, solving

$$\frac{\partial\mathcal{A}}{\partial x_0^\alpha}(x_0,x,t)=0,\quad \alpha=1,2,3,$$

and

$$\frac{\partial\mathcal{A}}{\partial x_0^\alpha}(x_0+\delta x_0,x+\delta x,t)=0,\quad \alpha=1,2,3,$$

to second order reduces in our case to

$$\delta x=\left(-\frac{\partial^2\mathcal{A}}{\partial x\partial x_0}\right)^{-1}\left\{\left(\frac{\partial^2\mathcal{A}}{\partial {x_0}^2}\right)\delta x_0+\frac{1}{2}(\delta x_0\cdot\nabla_{x_0})^2\frac{\partial\mathcal{A}}{\partial x_0}\right\}.$$

Write

$$\left(\frac{\partial^2\mathcal{A}}{\partial x_0\partial x}\right)^{-1}\dot{X}(t,x_0,\nabla S_0(x_0))=-(\alpha_0e_0+\alpha_1e_1+\alpha_2e_2),$$

where e_0 is the zero eigenvector of $(\partial^2\mathcal{A}/\partial {x_0}^2)$ and

$$\frac{\partial^2 \mathcal{A}}{\partial x_0{}^2} e_i = \lambda_i e_i, \quad i=1,2,$$

are the remaining eigenvector equations, $\{e_0, e_1, e_2\}$ an orthonormal system. Then, from above, unit normal

$$n = (\alpha_1 \lambda_1 e_1 + \alpha_2 \lambda_2 e_2)(\alpha_1^2 \lambda_1^2 + \alpha_2^2 \lambda_2^2)^{-1/2}$$

and

$$e_0^{\perp} = n \wedge e_0 = (\alpha_2 \lambda_2 e_1 - \alpha_1 \lambda_1 e_2)(\alpha_1^2 \lambda_1^2 + \alpha_2^2 \lambda_2^2)^{-1/2}.$$

We now set

$$\delta x_0 = \varepsilon(\lambda e_0 + \mu e_0^{\perp}) + \varepsilon^2(\xi e_0 + \eta e_0^{\perp} + \zeta n).$$

The first term gives the direction of $dx_0(\gamma_0)/d\gamma$, the second term $d^2x_0(\gamma_0)/d\gamma^2$. Then

$$\delta x = \left(-\frac{\partial^2 \mathcal{A}}{\partial x \partial x_0} \right)^{-1} \left\{ [\varepsilon \mu \lambda_1 \lambda_2 (\alpha_2 e_1 - \alpha_1 e_2) + \varepsilon^2 (\eta \lambda_1 \lambda_2 (\alpha_2 e_1 - \alpha_1 e_2) + \zeta(\alpha_1 \lambda_1^2 e_1 + \alpha_2 \lambda_2^2 e_2))] \theta \right.$$
$$\left. + \frac{1}{2} (\delta x_0 \cdot \nabla_{x_0})^2 \frac{\partial \mathcal{A}}{\partial x_0} \right\},$$

where $\theta = (\alpha_1^2 \lambda_1^2 + \alpha_2^2 \lambda_2^2)^{-1/2}$. Note that there is an ε^2 term hidden within the last term of the above.

Clearly for a genuine cusp we have to set $\mu = 0$, giving

$$\delta x_0 = \varepsilon \lambda e_0 + \varepsilon^2(\xi e_0 + \eta e_0^{\perp} + \zeta n) \tag{C_0}$$

$$\delta x = \left(-\frac{\partial^2 \mathcal{A}}{\partial x \partial x_0} \right)^{-1} \left\{ \varepsilon^2 \theta (\eta \lambda_1 \lambda_2 (\alpha_2 e_1 - \alpha_1 e_2) + \zeta(\alpha_1 \lambda_1^2 e_1 + \alpha_2 \lambda_2^2 e_2)) + \frac{\varepsilon^2}{2} \lambda^2 \partial_0^2 \frac{\partial \mathcal{A}}{\partial x_0} \right\}. \tag{C_1}$$

We now have to satisfy two further conditions:

$$\delta x \cdot e_y = 0, \tag{C_2}$$

$$\delta x \cdot \frac{\partial \mathcal{A}}{\partial x} = (\alpha_0 e_0 + \alpha_1 e_1 + \alpha_2 e_2) \cdot \left(\theta (\eta \lambda_1 \lambda_2 (\alpha_2 e_1 - \alpha_1 e_2) + \zeta(\alpha_1 \lambda_1^2 e_1 + \alpha_2 \lambda_2^2 e_2)) + \frac{\lambda^2}{2} \partial_0^2 \frac{\partial \mathcal{A}}{\partial x_0} \right)$$
$$= 0. \tag{C_3}$$

Surprisingly the last condition does not depend upon η. It simplifies to give

$$(\zeta(\alpha_1^2 \lambda_1^2 + \alpha_2^2 \lambda_2^2))^{1/2} + \frac{\lambda^2}{2} (\alpha_0 e_0 + \alpha_1 e_1 + \alpha_2 e_2) \cdot \partial_0^2 \frac{\partial \mathcal{A}}{\partial x_0} = 0. \tag{C_3'}$$

The equation (C_3') determines the ratio $\zeta : \lambda^2$ and equation (C_2) determines the ratio $\eta : \lambda^2$.

Theorem 5.2: *Any point x on the level surface H_t, $x = \Phi_t(x_0)$ with $x_0 = \Phi_t^{-1}(x)$ on the prelevel surface can only be a generalized cusp of a curve on H_t if x_0 is a generalized cusp of the*

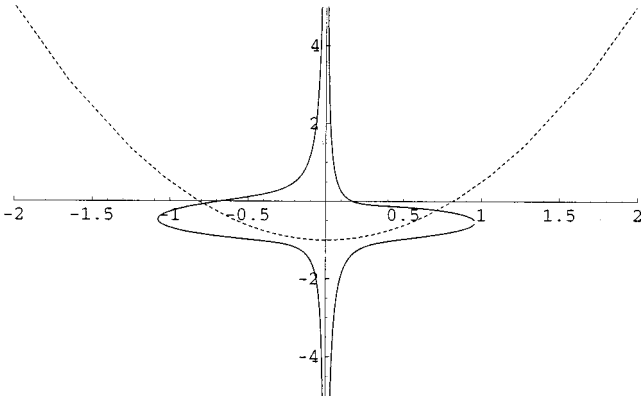

FIG. 30. Stochastic precaustic and prelevel surface.

precurve on the prelevel surface or if $x_0 \in \Phi_t^{-1} C_t$ *the precaustic. In three dimensions the planar cross section* $y = \text{const}$ *(with normal* e_y*) of the level surface* H_t *through a point x where it meets* C_t*, the caustic surface, will have a genuine cusp at x if* $x \in \text{Cusp}(H_t)$ *and there is a nonzero solution* δx *of Eqs.* (C_1)*,* (C_2)*, and* (C_3)*. The direction of the axis of the cusp will be* $\widehat{\delta x}$*.*

Proof: Similar to that of Theorem 3.2 using the generalizations expounded above. □

D. A random example

Example 5.1: Here we illustrate the random caustic and level surface for the case $S_0(x_0, y_0) = x_0^2 y_0/2$*,* $c(x) = 0$ *and* $k(x,t) = x$ *for* $\epsilon = 1/10$*. Figures 30 and 31 correspond to* $S_t(x, y, \omega) = 0$*.*

We now display Figs. 32 and 33 corresponding to $S_t(x, y, \omega) = -1/64$*.*

E. Consequences for the Burgers fluid

We now recast the comments made at the end of Sec. III in the more general setting of c and k nonzero. We emphasize that the above results hold for any finite ϵ (the strength of the white noise) as long as $\text{Det}(\partial^2 \mathcal{A}/\partial x_0 \partial x) \neq 0$. In a future paper[38] we will expound on the small ϵ case in some detail, explaining why the caustics (shockwaves) are stable and the level surfaces are unstable under noisy perturbations.

Recall that our random map $\Phi_s(\omega): \mathbb{R}^d \to \mathbb{R}^d$ satisfies

$$d_s \dot{\Phi}_s = -\nabla C(\Phi_s) ds - \epsilon \nabla k(\Phi_s, s) dW_s,$$

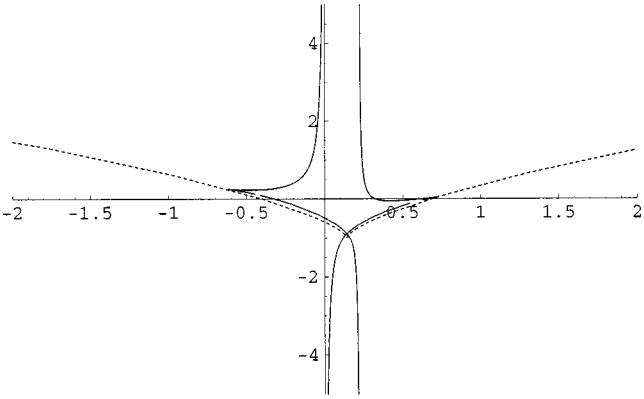

FIG. 31. Stochastic caustic and level surface.

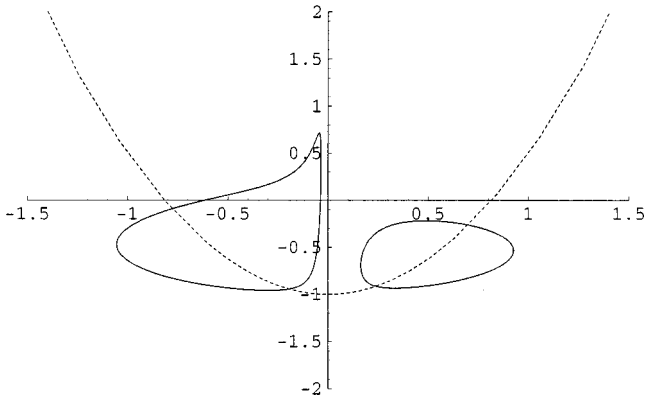

FIG. 32. Stochastic precaustic and prelevel surface.

with $\Phi_0 = I$ and $\dot{\Phi}_0 = \nabla S_0$. The global inverse function theorem[23] gives the following.

Proposition 5.4: If c, k and S_0 are smooth with bounded second order partial derivatives, there exists $T(\omega) > 0$ such that $\Phi_s(\omega): \mathbb{R}^d \to \mathbb{R}^d$ is a random diffeomorphism $0 \leqslant s \leqslant T(\omega)$.

We then have the following.

Proposition 5.5: The random Burgers velocity field in the limit of zero viscosity is

$$v^0(x,t) = v^0(\Phi_t^{-1}x,0) - \int_0^t \nabla C(\Phi_s \Phi_t^{-1}x)\, ds - \int_0^t \epsilon \nabla k(\Phi_s \Phi_t^{-1}x, s)\, dW_s,$$

with $v^0(x,0) = \nabla S_0(x)$. This v^0 is almost surely $0 \leqslant t \leqslant T(\omega)$, a classical solution of the Burgers equation. The corresponding solution of the continuity equation, the random density $\rho(x,t) = |\mathrm{Det}(\nabla \Phi_t^{-1}x)|$, is continuous almost surely for $0 \leqslant t \leqslant T(\omega)$, but v^0 has jump discontinuities on the random caustics. Evidently $\nabla \wedge v^0 \equiv 0$, almost surely.

Remark 5.3: More detailed information on the behavior of v^0 and ρ on the caustic is given in Ref. 31.

After the caustic time $T(\omega)$, we have seen how to characterize in terms of the stochastic action when the level surface meets the caustic in cusps. In two dimensions, this enables one to divide the caustic into hot and cool parts depending on whether or not the speed of the Burgers fluid is zero on one side of the caustic. We have also seen how a zero speed condition on the precaustic and prelevel surface leads to turbulent like behavior of the Burgers fluid at the corresponding points of the caustic. For instance, the large jump discontinuity in the speed of the Burgers fluid which we see in crossing the semicubical parabolic shockwave at the cusp is caused

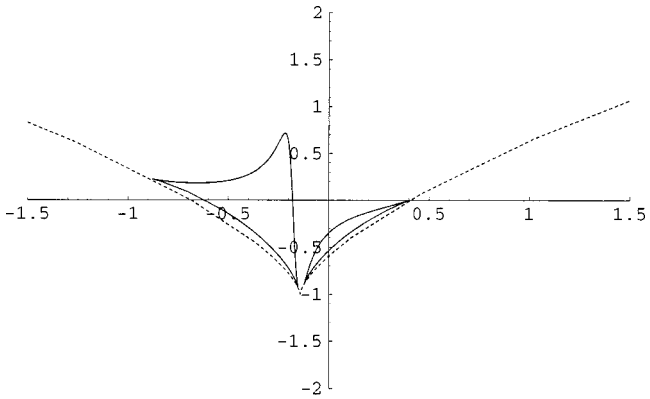

FIG. 33. Stochastic caustic and level surface.

by this zero speed condition. Here we should emphasize that the stochastic and deterministic behaviors are very similar if we take snapshots of the Burgers fluid fixed in time.

We now emphasize that new features emerge if one tries to use the above ideas to analyze the ''intermittence'' of stochastic turbulence as opposed to deterministic turbulence. We shall discuss this in detail in a future paper. The reason for the sharp contrast between stochastic and deterministic turbulence can already be seen here if we associate turbulent behavior with a change in the number of cusped curves on the level surface. According to Proposition 5.3 and Theorem 5.2, the times t when this occurs are just the times when the prelevel surfaces *touch* the precaustic. The times t when this number of curves changes in the deterministic case are simply the zeros of a deterministic function ζ, usually isolated zeros. In the stochastic case ζ is a stochastic process whose zeros usually form a perfect set, i.e., an infinite set containing no isolated points. At these times the number of cusped curves changes with infinite frequency because of the infinitely rapid oscillation of the stochastic process ζ. This is in line with what one would expect for turbulent behavior. When the stochastic process ζ is *recurrent* this turbulent behavior is ''intermittent'' so that the scale of turbulent fluctuations varies in a random periodic way.

VI. CONCLUSION

We have seen how generally the level surfaces of Hamilton's principal function meet the caustic surface in cusped curves and discussed some of the ramifications of this for Burgers turbulence. In particular, the cool part of the caustic is associated with jump discontinuities in both u^0 and v^0. The results in this article should be compared with results for Euler's equation, which is identical to the above save for the constraint that the fluid density ρ is unity. In a future paper we hope to relax the assumption that the Burgers velocity field is irrotational, when more realistic comparisons with Euler's equation can be made. Needless to say, the detailed nature of the geometry of the caustic surface and the level surface will affect the value of $v^\mu(x,t)$ on the caustic. Geometrical and analytical results are clearly relevant here for small noise in the way they relate the stochastic and deterministic situations. We will discuss some more analytical results in our future papers.[33,38]

The main object lesson of the present study is that the number of cusped curves on the wavefront will change infinitely rapidly in the stochastic case when the presurfaces touch and that this behavior will recur in a random periodic way if a certain stochastic process is recurrent. This is the ''intermittence'' of turbulence in our model. There is no analog of this for the deterministic Burgers equation. We shall discuss this in more detail in a future publication.

Regular obstructed categories and topological quantum field theory

Steven Duplij[a] and Wladyslaw Marcinek[b]
Institute of Theoretical Physics, University of Wroclaw, Pl. Maxa Borna 9, 50-204 Wroclaw, Poland

(Received 13 December 2001; accepted for publication 18 February 2002)

A proposal of the concept of *n*-regular obstructed categories is given. The corresponding regularity conditions for mappings, morphisms, and related structures are considered. An *n*-regular topological quantum field theory is introduced. The connection of time nonivertibility with the regularity is shown. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1473681]

I. INTRODUCTION

In the generalized histories approach[1] to quantum theory the whole universe is represented by a class of ''histories.'' In this approach the standard Hamiltonian time evolution is replaced by a partial semigroup called a ''temporal support.'' A possible realization of such program can be described in terms of cobordism manifolds and corresponding categories.[2] The temporal support arises naturally as a cobordism M, where the boundary ∂M of M is a disjoint sum of the ''incoming'' boundary manifold Σ_0 and the ''outgoing'' one Σ_1. This means that the cobordism M represents certain quantum process transforming Σ_0 into Σ_1. In other words, Σ_1 is a time consequence of Σ_0. Obviously, we have two opposite possibilities to declare which boundary is the initial one.

Let N be a cobordism with the ''outgoing'' boundary of M as its ''incoming boundary'' and Σ_2 as the ''outgoing boundary.'' Then there is a cobordism $N \circ M$ whose incoming boundary is Σ_0, and the outgoing one is Σ_3. In this case we say that these two cobordisms are glued along Σ_1. Such gluing of cobordisms up to diffeomorphisms define a partial semigroup operation. One can consider cobordism with several incoming and outgoing boundary manifolds. The class of possible histories can be represented by gluing of cobordisms in several different ways. Hence there is the corresponding coherence problem for such description.

Let Cob be a category of cobordisms, where the boundary ∂M of $M \in \mathrm{Cob}$ is a disjoint sum of the incoming boundary manifold Σ_0 and the outgoing one Σ_1. There is also the cylinder cobordism $\Sigma \times [0,1]$ such that $\partial(\Sigma \times [0,1]) = \Sigma \amalg \Sigma^*$. The class of boundary components is denoted by Cob_0. According to Atiyah,[3] Baez and Dolan,[4] the topological quantum field theory (TQFT) is a functor $\mathcal{F}$ from the category Cob to the category Vect of finite-dimensional vector spaces. This means that $\mathcal{F}$ sends every manifold $\Sigma \in \mathrm{Cob}_0$ into vector space $\mathcal{F}(\Sigma)$ such that

$$\mathcal{F}(\Sigma^*) = (\mathcal{F}(\Sigma))^*, \quad \mathcal{F}(\Sigma_0 \amalg \Sigma_1) = (\mathcal{F}\Sigma_0) \otimes (\mathcal{F}\Sigma_1), \quad \mathcal{F}(\varnothing) = I, \tag{1}$$

and a cobordism $M(\Sigma_0, \Sigma_1)$ to a mapping $\Phi(M) \in \mathrm{lin}_I(\mathcal{F}\Sigma_0, \mathcal{F}\Sigma_1)$ such that $\mathcal{F}(\Sigma \times [0,1]) = id_{\mathcal{F}\Sigma}$, where I is a field, and Σ^* is the same manifold Σ but with the opposite orientation. Kerler[5] found examples of categories formed by some classes of cobordism manifolds preserving some operations like the disjoint sum or surgery. It was discussed by Baez and Dolan[4] that it is not easy to describe such categories in a coherent way. Crane[6,7] applied the category theory to an algebraic structure of the quantum gravity.

The idea of regularity as generalized invertibility was first introduced by von Neumann[8] and applied by Penrose for matrices.[9] Let $\mathbb{R}$ be a ring. If for an element $a\in\mathbb{R}$ there is an element $a^\star$ such that

$$aa^\star a=a,\quad a^\star aa^\star=a^\star, \tag{2}$$

then a is said to be regular and $a^\star$ is called a generalized inverse inverse of a. Generalizing transition from invertibility to regularity is a widely used method of abstract extension of various algebraic structures. The intensive study of such regularity and related directions was developed in many different fields, e.g., generalized inverses theory,[10–12] semigroup theory,[13–19] supermanifold theory,[20–22] Yang–Baxter equation in endomorphism semigroup and braided almost bialgebras,[23–25] weak bialgebras, week Hopf algebras,[26] and category theory.[27]

In this paper we are going to study certain class of categories which can be useful for the study of quantum histories with noninvertible time, quantum, gravity, and field theory. The regularity concept for linear mappings and morphisms in categories are studied. Higher order regularity conditions are described. Commutative diagrams are replaced by ''semicommutative'' ones. The distinction between commutative and semicommutative cases is measured by a nonzero obstruction proportional to the difference of some self-mappings $e^{(n)}$ from the identity. This allows one to regularize the notion of categories, functions, and related algebraic structures. It is interesting that this procedure is unique up to an equivalence defined by invertible morphisms. Our regularity concept is nontrivial for equivalence classes of nonivertible morphisms. The regular version of TQFT is a natural application of the formalism presented here. In this case the n-regularity means that a time evolution is noninvertible, although repeated after n steps, but up to a classes of obstructions. Our considerations are based on the concepts of generalized inverse,[12,27] and semisupermanifolds.[20]

The paper is organized as follows. In Sec. II we consider linear mappings without requirement of ''invertibility.'' If $f:X\to Y$ is a linear mapping, then instead of the inverse mapping $f^{-1}:Y\to X$ we use less restricted ''regular'' $f^\star$ one by extending ''invertibility'' to ''regularity'' according to

$$f\circ f^\star\circ f=f,\quad f^\star\circ f\circ f^\star=f^\star. \tag{3}$$

We also propose some higher regularity conditions. In Sec. III the higher regularity notion is extended to morphisms of categories. Commutative diagrams are replaced by semicommutative ones. The concept of regular cocycles of morphisms in a category is described. An existence theorem for these cocycles is given. The corresponding generalization of certain categorical structures as tensor operation, algebras and coalgebras, etc., to our higher regularity case is given in Sec. IV. Regular equivalence classes of cobordism manifolds and the corresponding structures are considered in Sec. V. An n-regular TQFT is introduced as an n-regular obstructed category represented by some special classes of cobordisms called ''interactions.'' Our study is not complete, it is only a proposal for new algebraic structures related to topological quantum theories.

II. GENERALIZED INVERTIBILITY AND REGULARITY

Let X and Y be two linear spaces over a field k. We use the following notation. Denote by Id_X and Id_Y the identity mappings $\mathrm{Id}_X:X\to X$ and $\mathrm{Id}_Y:Y\to Y$. If $f:X\to Y$ is a linear mapping, then the image of f is denoted by $\mathrm{Im}\,f$, and the kernel by $\mathrm{Ker}\,f$.

Here we are going to study some generalizations of the standard concept of invertibility properties of mappings. Our considerations are based on the article of Nashed.[12] Let $f:X\to Y$ be a linear mapping. If $f\circ f_r^{-1}=\mathrm{Id}_Y$ for some $f_r^{-1}:Y\to X$, then f is called a *retraction*, and f_r^{-1} is the right inverse. Similarly, if $f_l^{-1}\circ f=\mathrm{Id}_X$, then it is called a *coretraction*, f_l^{-1} is the left inverse of f. A mapping f^{-1} is called an inverse of f if and only if it is both right and left inverse of f.

This standard concept of invertibility is in many cases too strong to be fulfilled. To obtain more weak conditions one has to introduce the following ''regularity'' conditions

$$f\circ f^{\star}_{\text{in}}\circ f=f, \tag{4}$$

where $f^{\star}_{\text{in}}:Y\to X$ is called an *inner inverse*, and such f is called *regular*. Similar ''reflexive regularity'' conditions

$$f^{\star}_{\text{out}}\circ f\circ f^{\star}_{\text{out}}=f^{\star}_{\text{out}} \tag{5}$$

define an *outer inverse* $f^{\star}_{\text{out}}$. Notice that in general $f^{\star}_{\text{in}}\neq f^{\star}_{\text{out}}\neq f^{-1}$ or it can be that f^{-1} does not exist at all.

Definition 1: A mapping f satisfying one of the conditions (4) or (5) is said to be regular or three-regular. A generalized inverse of a mapping f is a mapping $f^{\star}$, which is both inner and outer inverse $f^{\star}=f^{\star}_{\text{in}}=f^{\star}_{\text{out}}$.

Lemma 2: If $f^{\star}_{\text{in}}$ is an inner inverse of f, then a generalized inverse $f^{\star}$ exists, but need not be unique.

Proof: If $f^{\star}_{\text{in}}$ is an inner inverse, then

$$f^{\star}=f^{\star}_{\text{in}}\circ f\circ f^{\star}_{\text{in}} \tag{6}$$

is always both inner and outer inverse i.e., generalized inverse. It follows from (6) that both regularity conditions (4) and (5) hold. □

Definition 3: Let us define two operators $\mathcal{P}_f:Y\to Y$ and $\mathcal{P}_{f^{\star}}:X\to X$ by

$$\mathcal{P}_f:=f\circ f^{\star},\quad \mathcal{P}_{f^{\star}}:=f^{\star}\circ f. \tag{7}$$

Lemma 4: These operators satisfy

$$\begin{gathered}\mathcal{P}_f\circ\mathcal{P}_f=\mathcal{P}_f,\quad \mathcal{P}_f\circ f=f\circ\mathcal{P}_{f^{\star}}=f\\ \mathcal{P}_{f^{\star}}\circ\mathcal{P}_{f^{\star}}=\mathcal{P}_{f^{\star}},\quad \mathcal{P}_{f^{\star}}\circ f^{\star}=f^{\star}\circ\mathcal{P}_f=f^{\star}.\end{gathered} \tag{8}$$

□

Lemma 5: If $f^{\star}$ is the generalized inverse of the mapping f, then the following properties are obvious:

$$\begin{gathered}\operatorname{Im} f=\operatorname{Im}(f\circ f^{\star}),\quad \operatorname{Ker}(f\circ f^{\star})=\operatorname{Ker} f^{\star},\\ \operatorname{Im}(f^{\star}\circ f)=\operatorname{Im} f^{\star},\quad \operatorname{Ker}(f^{\star}\circ f)=\operatorname{Ker} f.\end{gathered} \tag{9}$$

In addition there are two decompositions

$$X=\operatorname{Im} f^{\star}\oplus\operatorname{Ker} f,\quad Y=\operatorname{Im} f\oplus\operatorname{Ker} f^{\star}. \tag{10}$$

The restriction $f|_{\operatorname{Im} f^{\star}}:\operatorname{Im} f^{\star}\to\operatorname{Im} f$ is one to one mapping, and operators P_f, $P_{f^{\star}}$ are projectors of Y, X onto $\operatorname{Im} f$, $\operatorname{Im} f^{\star}$, *respectively.*

Theorem 6: *Let $f:X\to Y$ be a linear mapping. If P and Q are projectors corresponding to the following two decompositions*

$$X=M\oplus\operatorname{Ker} f,\quad Y=\operatorname{Im} f\oplus N, \tag{11}$$

respectively, then there exist unique generalized inverse of f, and

$$f^{\star}:=i\circ\tilde{f}^{-1}\circ Q, \tag{12}$$

where $\tilde{f}:=f|_M$, and $i:M\hookrightarrow X$.

Here we try to construct higher analogs of generalized invertibility and regularity conditions (4) and (5). Let us consider two mappings $f:X\to Y$ and $f^{\star}:Y\to X$ and introduce two additional mappings $f^{\star\star}:X\to Y$ and $f^{\star\star\star}:Y\to X$. We propose here the following higher regularity condition:

$$f\circ f^{\star}\circ f^{\star\star}\circ f^{\star\star\star}\circ f=f. \tag{13}$$

This equation defines a four-regularity condition. By cyclic permutations we obtain

$$\begin{aligned} f^{\star}\circ f^{\star\star}\circ f^{\star\star\star}\circ f\circ f^{\star}&=f^{\star},\\ f^{\star\star}\circ f^{\star\star\star}\circ f\circ f^{\star}\circ f^{\star\star}&=f^{\star\star},\\ f^{\star\star\star}\circ f\circ f^{\star}\circ f^{\star\star}\circ f^{\star\star\star}&=f^{\star\star\star}. \end{aligned} \tag{14}$$

By recursive considerations we can propose the following formula of n-regularity:

$$\underbrace{f\circ f^{\star}\circ f^{\star\star}\ldots\circ f^{\overbrace{\star\star\ldots\star}^{n=2k+1}}\circ f}_{n+1}=f, \tag{15}$$

where $n=2k$, $k=1,2,\ldots$ and their cyclic permutations.

For the $\overbrace{\star\star\ldots\star}^{2k+1}$-operation we have the following formula:

$$(g\circ f)^{\overbrace{\star\star\ldots\star}^{2k+1}}=f^{\overbrace{\star\star\ldots\star}^{2k+1}}\circ g^{\overbrace{\star\star\ldots\star}^{2k+1}}. \tag{16}$$

We can introduce ''higher projector'' by

$$\mathcal{P}_f^{(n)}=f\circ f^{\star}\circ f^{\star\star}\cdots\circ f^{\overbrace{\star\star\ldots\star}^{2k+1}}. \tag{17}$$

It is easy to check the following properties:

$$\mathcal{P}_f^{(2k)}\circ f=f \tag{18}$$

and idempotence $\mathcal{P}_f^{(2k)}\circ\mathcal{P}_f^{(2k)}=\mathcal{P}_f^{(2k)}$.

In general case for a given $n=2k$ all $f^{\star}$, $f^{\star\star}$,$\ldots f^{\overbrace{\star\star\ldots\star}^{n}}$ are different, and, for instance, $(f^{\star})^{\star}\neq f^{\star\star}$. The existence of analogous conditions for n odd is a problem.

Theorem 7: *Let $f:X\to Y$ be a linear mapping. If P and Q are projectors corresponding to the following two decompositions*

$$X=M\oplus\operatorname{Ker} f,\quad `Y=\operatorname{Im} f\oplus N, \tag{19}$$

respectively, and

$$f^{\star}|\operatorname{Im} f=f^{\star\star\star}|_{\operatorname{Im} f}, \tag{20}$$

then the five-regularity condition of f can be reduced to the two three-regularity conditions

$$f\circ f^{\star}\circ f=f,\quad f^{\star}\circ f^{\star\star}\circ f^{\star}=f^{\star}. \tag{21}$$

III. SEMICOMMUTATIVE DIAGRAMS AND REGULAR OBSTRUCTED CATEGORIES

In Sec. II we considered mappings and regularity properties for two given spaces X and Y, because we studied various types of inverses. Now we will extend these considerations to any number of spaces and introduce semicommutative diagrams (first introduced in Ref. 20).

A *directed graph* $\mathfrak{C}$ is a pair $\{\mathfrak{C}_0,\mathfrak{C}_1\}$ and a pair of functions

$$\mathfrak{C}_0 \underset{t}{\overset{s}{\leftleftarrows}} \mathfrak{C}_1, \tag{22}$$

where elements of $\mathfrak{C}_0$ are said to be *objects*, elements of $\mathfrak{C}_1$ are said to be *arrows* or *morphisms*, sf is said to be a *domain (or source)* of f, and tf is a *codomain (or target)* of $f\in\mathfrak{C}_1$. If $sf=X\in\mathfrak{C}_0$, and $tf=Y\in\mathfrak{C}_0$, then we use the following notation $X\overset{f}{\to}Y$ and

$$\mathfrak{C}(X,Y):=\{f\in\mathfrak{C}_1: sf=X, tf=Y\}. \tag{23}$$

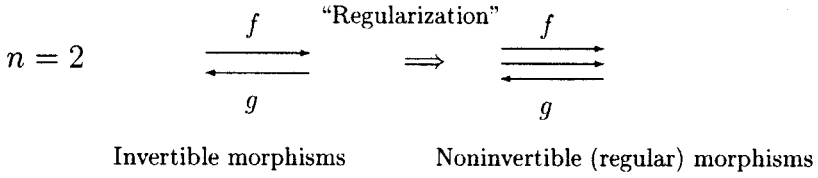
We denote by $\mathrm{End}(X)$ the collection of all morphisms defined on X into itself, i.e., $\mathrm{End}(X):=\mathfrak{C}(X,X), X\in\mathfrak{C}_0$.

Two arrows $f,g\in\mathfrak{C}_1$ such that $tf=sg$ are said to be composable. If in addition $sf=X$, $sg=tf=Y$, and $tg=Z$, then we use the notation $X\overset{f}{\to}Y\overset{g}{\to}Z$. In this case a composition $f\circ g$ of two arrows $f:X\to Y$ and $g:Y\to Z$ can be defined as an arrow $f:X\to Y$. The associativity means that $h\circ(g\circ f)=(h\circ g)\circ f=h\circ g\circ f$. An identity id in $\mathfrak{C}$ is an inclusion $X\in\mathfrak{C}_0\rightarrowtail \mathrm{id}_X\in\mathrm{End}(X)$ such that

$$f\circ \mathrm{id}_X=\mathrm{id}_Y\circ f=f \tag{24}$$

for every X, $Y\in\mathfrak{C}_1$, and $X\overset{f}{\to}Y$.

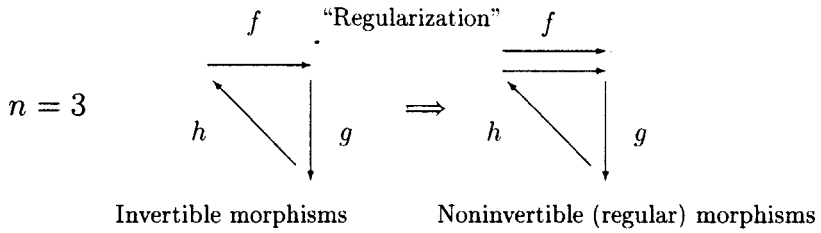
A directed graph $\mathfrak{C}$ equipped with associative composition of composable arrows and identity satisfying some natural axioms is said to be a *category*.[28,29] If $\mathfrak{C}$ is a category, then right cancellative morphisms are *epimorphisms* which satisfy $g_1\circ f=g_2\circ f\Rightarrow g_1=g_2$, where $g_{1,2}:Y\to Z$ and left cancellative morphisms are *monomorphisms* which satisfy $f\circ h_1=f\circ h_2\Rightarrow h_1=h_2$, where $h_{1,2}:Z\to X$. A morphism $X\overset{f}{\to}Y$ is invertible means that there is a morphism $Y\overset{g}{\to}X$ such that $f\circ g=\mathrm{id}_Y$ and $g\circ f=\mathrm{id}_X$. Instead of such invertibility we can use the regularity condition (4), i.e., $f\circ g\circ f=f$, where g plays the role of an inner inverse.[12]



Usually, for three objects X, Y, Z and three morphisms $f:X\to Y$ and $g:Y\to Z$ and $h:Z\to X$ one can have the "invertible" triangle commutative diagram $h\circ g\circ f=\mathrm{Id}_X$. Its regular extension has the form

$$f\circ h\circ g\circ f=f. \tag{25}$$

Such a diagram



can be called a *semicommutative diagram*. By cyclic permutations of (25) we obtain

$$h\circ g\circ f\circ h=h,$$
$$g\circ f\circ h\circ g=g. \tag{26}$$

These formulas define the concept of three-regularity.

Definition 8: A mapping $f:X\to Y$ satisfying conditions (25) and (26) is said to be three-regular. The mapping $h:Z\to X$ is called the first three-inversion and the mapping $g:Y\to Z$ the second one.

The above-given concept can be expanded to any number of objects and morphisms.

Definition 9: Let $\mathfrak{C}=(\mathfrak{C}_0,\mathfrak{C}_1)$ be a directed graph. An *n-regular cocycle* (X,f) in $\mathfrak{C}$, $n=1,2,...,$ is a sequence of composable arrows in $\mathfrak{C}$,

$$X_1\overset{f_1}{\to}X_2\overset{f_2}{\to}\cdots\overset{f_{n-1}}{\to}X_n\overset{f_n}{\to}X_1, \tag{27}$$

such that

$$f_1\circ f_n\circ\cdots\circ f_2\circ f_1=f_1,$$
$$f_2\circ f_1\circ\cdots\circ f_3\circ f_2=f_2, \tag{28}$$
$$f_n\circ f_{n-1}\circ\cdots\circ f_1\circ f_n=f_n,$$

and

$$e^{(n)}_{X_1}:=f_n\circ\cdots\circ f_2\circ f_1\in\mathrm{End}(X_1),$$
$$e^{(n)}_{X_2}:=f_1\circ\cdots\circ f_3\circ f_2\in\mathrm{End}(X_2), \tag{29}$$
$$e^{(n)}_{X_n}:=f_{n-1}\circ\cdots\circ f_1\circ f_n\in\mathrm{End}(X_n).$$

Definition 10: Let (X,f) be an n-regular cocycle in $\mathfrak{C}$, then the correspondence $e^{(n)}_X:X_i\in\mathfrak{C}_0\mapsto e^{(n)}_{X_i}\in\mathrm{End}(X_i)$, $i=1,2,...,n$, is called an n-regular cocycle obstruction structure on (X,f) in $\mathfrak{C}$.

Lemma 11: We have the following relations

$$f_i\circ e^{(n)}_{X_i}=f_i,\quad e^{(i)}_{X_{i+1}}\circ f_i=f_i,\quad e^{(n)}_{X_i}\circ e^{(n)}_{X_i}=e^{(n)}_{X_i} \tag{30}$$

for $i=1,2,...,n(\mathrm{mod}\,n)$.

Proof: The lemma simply follows from relations (28) and (29). □

Definition 12: An n-regular obstructed category is a directed graph $\mathfrak{C}$ with an associative composition and such that every object is a component of an n-regular cocycle.

Example 1: If all obstructions are equal to the identity $e^{(n)}_{X_i}=\mathrm{id}_{X_i}$, and

$$f_n\circ\cdots\circ f_2\circ f_1=\mathrm{id}_{X_1},$$

$$f_1\circ\cdots\circ f_3\circ f_2=\mathrm{id}_{X_2},\tag{31}$$

$$f_{n-1}\circ\cdots\circ f_1\circ f_n=\mathrm{id}_{X_n},$$

then the sequence (27) is trivially *n*-regular. Observe that the trivial two-regularity is just the usual invertibility, hence every grupoid *G* is a trivially two-regular obstructed category. We are interested with obstructed categories equipped with some obstruction different from the identity.

Definition 13: The minimum number $n=n_{\mathrm{obstr}}$ such that $e_X^{(n)}\neq \mathrm{id}_X$ is called the obstruction degree.

Example 2: Every inverse semigroup *S* is a nontrivial two-regular obstructed category. It has only one object, morphisms are the elements of *S*.

Theorem 14: *Let* $\mathfrak{C}$ *be a category, and*

$$X_1\xrightarrow{f_1}X_2\xrightarrow{f_2}\cdots\xrightarrow{f_{m-1}}X_n\xrightarrow{f_n}X_1\tag{32}$$

be a sequence of morphisms of category $\mathfrak{C}$*. Assume that there is a sequence*

$$Y_1\xrightarrow{\tilde f_1}Y_2\xrightarrow{\tilde f_2}\cdots\xrightarrow{\tilde f_{n-1}}Y_n\xrightarrow{\tilde f_n}Y_1,\tag{33}$$

where Y_i *is a subobject of* X_i *such that there is a collection of mappings* $\pi_i:X_i\to Y_i$ *and* $\iota:Y_i\to X_i$ *satisfying the condition* $\pi_i\circ\iota_i=\mathrm{id}_{Y_i}$ *for* $i=1,2,...,n$*. If in addition*

$$\tilde f_n\circ\cdots\tilde f_2\circ\tilde f_1=\mathrm{id}_{Y_1},$$

$$\tilde f_1\circ\cdots\tilde f_3\circ\tilde f_2=\mathrm{id}_{Y_2},$$

$$\cdots\tag{34}$$

$$\tilde f_{n-1}\circ\cdots\tilde f_1\circ\tilde f_n=\mathrm{id}_{Y_n},$$

and

$$f_i:=t_{i+1}\circ\tilde f_i\circ\pi_i\tag{35}$$

then the sequence (62) *is an n-regular cocycle.*

Proof: The corresponding obstruction structure is given by

$$e_{X_i}^{(n)}=\iota_i\circ\pi_i.\tag{36}$$

If $x\in\mathrm{Ker}\,f_1$, then the theorem is trivial, if $x\in X_i\backslash\mathrm{Ker}\,f_1$, then we obtain

$$(f_1\circ f_n\circ\cdots\circ f_2\circ f_1)(x)=\iota_2\circ\tilde f_1\circ\pi_1\circ\iota_1\circ\tilde f_n\circ\cdots\circ\tilde f_2\circ\tilde f_1\circ\pi_1(x)=\iota_2\circ\tilde f_1\circ\pi_1=f_1(x),$$

where conditions (34) and (35) have been used. We can calculate all cyclic permutations in a similar way. □

Example 3: There is an *n*-regular obstructed category $\mathfrak{C}=(\mathfrak{C}_0,\mathfrak{C}_1)$, where $\mathfrak{C}_0=\{X_i:i=1,...,n(\mathrm{mod}\,n+1)\}$ and $\mathfrak{C}_1=\{f_i:i=1,...,n(\mathrm{mod}\,n+1)\}$ are described in the above-mentioned theorem.

Definition 15: Let (X,f), (Y,g) be two *n*-regular cocycles in $\mathfrak{C}$. An *n*-regular cocycle morphism α: $(X,f)\to(Y,g)$ is a sequence of morphisms $\alpha:=(\alpha_1,\ldots,\alpha_n)$ such that the diagram

$$\begin{array}{ccccccc} X_1 & \overset{f_1}{\rightarrow} & X_2 & \overset{f_2}{\rightarrow}\cdots\overset{f_{n-1}}{\rightarrow} & X_n & \overset{f_n}{\rightarrow} & X_1 \\ \downarrow\alpha_1 & & \downarrow\alpha_2 & & \downarrow\alpha_n & & \downarrow\alpha_1 \\ Y_1 & \overset{g_1}{\rightarrow} & Y_2 & \overset{g_2}{\rightarrow}\cdots\overset{g_{n-1}}{\rightarrow} & Y_n & \overset{g_n}{\rightarrow} & Y_1 \end{array} \tag{37}$$

is commutative. If every component α_i of α is invertible, then α is said to be an n-regular cocycle equivalence.

It is obvious that the n-regular cocycle equivalence is an equivalence relation.

Definition 16: Let $\mathfrak{C}$ be an n-regular obstructed category. A collection of all equivalence classes of n-regular cocycles in $\mathfrak{C}$ and corresponding n-regular cocycle morphisms is denoted by $\mathrm{Reg}^{(n)}(\mathfrak{C})$ and is said to be an n-regularization of $\mathfrak{C}$.

Comment 17: It is obvious that the n-regular cocycle equivalence is an equivalence relation. Equivalence classes of this relation are just elements of $\mathrm{Reg}^{(n)}(\mathfrak{C})$. Our n-regular cocycles and obstruction structures are unique up to an invertible n-regular cocycle morphism. If $[(X,f)]$ is an equivalence class of n-regular cocycles, then there is the corresponding class of n-regular obstruction structures $e_X^{(n)}$ on it. The correspondence is a one to one.

IV. REGULARIZATION OF FUNCTORS AND RELATED STRUCTURES

We are going to introduce the concepts of n-regular functors, natural transformations, involution, duality, and so on. All of our definitions are in the general case the same as in the usual category theory,[29] but the preservation of the identity id_X is replaced by the requirement of preservation of obstructions $e_X^{(n)}$ up to the n-regular cocycle equivalence.

It is known that for two usual categories $\mathfrak{C}$ and $\mathfrak{D}$ a functor $\mathcal{F}:\mathfrak{C}\rightarrow\mathfrak{D}$ is defined as a pair of mappings $(\mathcal{F}_0,\mathcal{F}_1)$, where $\mathcal{F}_0$ sends objects of $\mathfrak{C}$ into objects of $\mathfrak{D}$, and $\mathcal{F}_1$ sends morphisms of $\mathfrak{C}$ into morphisms of $\mathfrak{D}$

$$\mathcal{F}_1(f\circ g)=\mathcal{F}_1(f)\circ\mathcal{F}_1(g),\quad \mathcal{F}_1\mathrm{id}_X=\mathrm{id}_{F_0X}, \tag{38}$$

for $X\in\mathfrak{C}_0$, $\mathcal{F}X\in\mathcal{D}_0$.

Let $\mathfrak{C}$ and $\mathfrak{D}$ be two n-regular obstructed categories. We postulate that all definitions are formulated on every n-regular cocycle (X,f) in $\mathfrak{C}$ up to the n-regular cocycle equivalence, and $i=1,2,\ldots \pmod n$.

Definition 18: An or n-regular cocycle functor $\mathcal{F}^{(n)}:\mathfrak{C}\rightarrow\mathfrak{D}$ is a pair of mappings $(\mathcal{F}_0^{(n)},\mathcal{F}_1^{(n)})$, where $\mathcal{F}_0^{(n)}$ sends objects of $\mathfrak{C}$ into objects of $\mathfrak{D}$, and $\mathcal{F}_1^{(n)}$ sends morphisms of $\mathfrak{C}$ into morphisms of $\mathfrak{D}$ such that

$$\mathcal{F}_1^{(n)}(f_i\circ f_{i+1})=\mathcal{F}_1^{(n)}(f_i)\circ\mathcal{F}_1^{(n)}(f_{i+1}),\quad \mathcal{F}_1^{(n)}(e_{X_i}^{(n)})=e_{\mathcal{F}_0(X_i)}^{(n)}, \tag{39}$$

where $X\in\mathfrak{C}_0$.

Lemma 19: Let $\mathfrak{C}$ and $\mathfrak{D}$ be n-regular obstructed categories, and let

$$X_1\overset{f_1}{\rightarrow}X_2\overset{f_2}{\rightarrow}\cdots\overset{f_{n-1}}{\rightarrow}X_n\overset{f_n}{\rightarrow}X_1 \tag{40}$$

be an n-regular cocycle in $\mathfrak{C}$. If $\mathcal{F}^{(n)}:\mathfrak{C}\rightarrow\mathfrak{D}$ is n-regular cocycle functor, then

$$\mathcal{F}^{(n)}(f_i)\circ e_{X_i}^{(n)}=\mathcal{F}^{(n)}(f_i). \tag{41}$$

Proof: It is a simple calculation

$$\mathcal{F}^{(n)}(f_i)=\mathcal{F}^{(n)}(f\circ e_{X_i}^{(n)})=\mathcal{F}^{(n)}(f)\circ\mathcal{F}^{(n)}(e_{X_i}^{(n)})=\mathcal{F}(f_i)\circ e_{\mathcal{F}_0X_i}^{(n)}. \tag{42}$$

□

Multifunctors can be regularized in a similar way.

Let $\mathcal{F}^{(n)}$ and $\mathcal{G}^{(n)}$ be two n-regular cocycle morphisms of the category $\mathfrak{C}$ into the category $\mathfrak{D}$.

Definition 20: An n-regular natural transformation $s:\mathcal{F}^{(n)}\to\mathcal{G}^{(n)}$ of $\mathcal{F}^{(n)}$ into $\mathcal{G}^{(n)}$ is a collection of functors $s=\{s_{X_i}:\mathcal{F}_0(X_i)\to\mathcal{G}_0(X_i)\}$ such that

$$s_{X_{i+1}}\circ\mathcal{F}_1^{(n)}(f_i)=\mathcal{G}_1^{(n)}(f_i)\circ s_{X_i}, \tag{43}$$

for $f_i:X_i\to X_{i+1}$.

Definition 21: An n-regular obstructed monoidal category $\mathfrak{C}\equiv\mathfrak{C}(\otimes,I)$ can be defined as usual, but we must remember that instead of the identity $\mathrm{id}_X\otimes\mathrm{id}_Y=\mathrm{id}_{X\otimes Y}$ we have an obstruction structure $e_X^{(n)}=\{e_{X_i}^{(n)}\in\mathrm{End}(X_i);n=1,2,...\}$ satisfying the condition

$$e_{X_i\otimes Y_i}^{(n)}=e_{X_i}^{(n)}\otimes e_{Y_i}^{(n)} \tag{44}$$

for every two n-regular cocycles (X,f) and (Y,f').

Let $\mathfrak{C}$ be an n-regular obstructed monoidal category. We introduce an *-operation in $\mathfrak{C}$ as a function which sends every object X_i into object X_i^* called the dual of X,

$$X_i^{**}=X_i,\quad (X_i\otimes Y_i)^*=X_i^*\otimes Y_i^*, \tag{45}$$

reverse all arrows

$$(f\circ g)^*=g^*\circ f^*. \tag{46}$$

The category $\mathfrak{C}$ equipped with such $*$-operation is called an *n-regular obstructed monoidal category with duals*.

Lemma 22: Let $\mathfrak{C}$ be an n-regular obstructed monoidal category with duals. If (X,f) is an n-regular cocycle in $\mathfrak{C}$, then there is a corresponding n-regular cocycle (X^*,f^*) in $\mathfrak{C}^*$, called the dual of (X,f).

Proof: If we reverse all arrows in (X,f) and replace all objects by the corresponding duals, then we obtain (X^*,f^*), where

$$X_1^*\xrightarrow{f_n^*}X_n^*\xrightarrow{f_{n-1}^*}\cdots\xrightarrow{f_2^*}X_2^*\xrightarrow{f_1^*}X_1^* \tag{47}$$

is a sequence such that

$$f_1^*\circ f_n^*\circ\cdots\circ f_2^*\circ f_1^*=f_1^*,\quad e_{X_1^*}^{(n)}:=f_n^*\circ\cdots\circ f_2^*\circ f_1^*, \tag{48}$$

where $f_i^*:X_{i+1}^*\to X_i^*$, $i=1,...,n$, and $X_{n+1}^*\equiv X_1^*$ is the dual. We have corresponding relations for all cyclic permutations. □

Definition 23: An n-regular pairing $g_{\mathfrak{C}}$ in an n-regular obstructed monoidal category $\mathfrak{C}$ can be defined in an analogy to the usual case as a collection of mappings

$$g_{\mathfrak{C}}=\{g_{X_i}\equiv\langle-|-\rangle_{X_i}:X_i^*\otimes X_i\to I\} \tag{49}$$

satisfying some natural consistency conditions and in addition the following regularity relations:

$$g_{X_{i+1}}\circ(f_i^*\otimes f_i)=g_{X_i}, \tag{50}$$

and

$$\langle e_{X_i^*}^{(n)}X_i^*|X_i\rangle_{X_i}=\langle X_i^*|e_{X_i}^{(n)}X_i\rangle_{X_i}, \tag{51}$$

where (X,f) is a regular n-cocycle in $\mathfrak{C}$, and let (X^*,f^*) be the corresponding duals.

It is known that an associative algebra in an ordinary category is an object $\mathcal{A}$ of this category such that there is a multiplication $m:\mathcal{A}\otimes\mathcal{A}\to\mathcal{A}$ which is also a morphism of this category satisfying some axioms like the associativity, the existence of the unity.

Definition 24: Let $\mathfrak{C}$ be an n-regular obstructed monoidal category. An n-regular cocycle algebra $\mathcal{A}$ in the category $\mathfrak{C}$ is an object of this category equipped with an associative multiplication $m:\mathcal{A}\otimes\mathcal{A}\to\mathcal{A}$ such that

$$m\circ(e_A^{(n)}\otimes e_A^{(n)})=e_A^{(n)}\circ m. \tag{52}$$

Obviously such multiplication does not need to be unique.

One can define an n-regular cocycle coalgebra or bialgebra in a similar way. A comultiplication $\Delta:\mathcal{A}\to\mathcal{A}\otimes\mathcal{A}$ can be regularized according to the relation

$$\Delta\circ e_{\mathcal{A}}^{(n)}=(e_{\mathcal{A}}^{(n)}\otimes e_{\mathcal{A}}^{(n)})\circ\Delta. \tag{53}$$

Definition 25: Let $\mathcal{A}$ be an n-regular cocycle algebra. If $\mathcal{A}$ is also regular coalgebra such that $\Delta(ab)=\Delta(a)\Delta(b)$, then it is said to be an n-regular cocycle almost bialgebra.

If $\mathcal{A}$ is an n-regular cocycle algebra, then we denote by $hom_m(\mathcal{A},\mathcal{A})$ the set of morphisms $s\in hom_C(\mathcal{A},\mathcal{A})$ satisfying the condition

$$s\circ m=m\circ(s\otimes s). \tag{54}$$

Let $\mathcal{A}$ be an n-regular cocycle almost bialgebra. We define the convolution product

$$s\star t:=m\circ(s\otimes t)\circ\Delta, \tag{55}$$

where $s,t\in hom_m(\mathcal{A},\mathcal{A})$. If $\mathcal{A}$ is a regular n-cocycle almost bialgebra, then the convolution product is regular.

Definition 26: A two-regular cocycle almost bialgebra $\mathcal{H}$ equipped with an element $S\in hom_m(\mathcal{H},\mathcal{H})$ such that

$$S\star\mathrm{id}_{\mathcal{H}}\star S=S,\quad \mathrm{id}_{\mathcal{H}}\star\mathrm{id}_{\mathcal{H}}=\mathrm{id}_{\mathcal{H}} \tag{56}$$

is said to be a two-regular cocycle almost Hopf algebra $\mathcal{H}$.

The above-given definition is a regular analogy of week Hopf algebras considered in Ref. 26. Similar algebras has been also considered in Ref. 30 and 31.

Lemma 27: If $\mathcal{A}$ is an n-regular cocycle algebra, then there is an n-regular cocycle coalgebra $\mathcal{A}^*$ such that[31]

$$\langle\Delta(\xi),x_1\otimes x_2\rangle=\langle\xi,m(x_1\otimes x_2)\rangle, \tag{57}$$

where $x_1,\ x_2\in\mathcal{A},\ \xi\in\mathcal{A}^*$.

Proof: Let us apply the regularity condition (52) to the above-given duality condition (57). Then the lemma follows from relations (44), (53), and (51). □

Lemma 28: Let $\mathcal{A}$ be an n-regular cocycle almost bialgebra. Then the dual $\mathcal{A}^*$ is also n-regular cocycle almost bialgebra

$$\begin{aligned}\langle\Delta(\xi),x_1\otimes x_2\rangle&=\langle\xi,m(x_1\otimes x_2)\rangle,\\ \langle\hat{m}(\xi\otimes\zeta),x_1\otimes x_2\rangle&=\langle\xi\otimes\zeta,\hat{\Delta}x\rangle.\end{aligned} \tag{58}$$

Let $\mathcal{A}$ be an n-regular cocycle algebra. Then we can define a left n-regular cocycle $\mathcal{A}$-module as an object equipped with an $\mathcal{A}$-module action $\rho_M:\mathcal{A}\otimes M\to M$ such that

$$\rho_M\circ(m\otimes \mathrm{id}_M)=\rho_M\circ(\mathrm{id}_{\mathcal{A}}\otimes\rho_M),$$
$$\rho_M\circ(e_{\mathcal{A}}^{(n)}\otimes e_M^{(n)})=e_M^{(n)}\circ\rho_M. \tag{59}$$

If $\mathcal{A}$ is an n-regular cocycle coalgebra, then one can define an n-regular cocycle comodule M in a similar way. For a coaction $\delta_M:\mathcal{A}\to\mathcal{A}\otimes M$ of $\mathcal{A}$ on M we have the following regularity condition:

$$\delta_M\circ(e_{\mathcal{A}}^{(n)}\otimes e_M^{(n)})=e_M^{(n)}\circ\varrho_M. \tag{60}$$

Remark 1: Observe that we have the following duality between $\mathcal{A}$-module action $\rho_M:\mathcal{A}\otimes M\to M$ and $\mathcal{A}^*$-comodule coactions $\delta_{M^*}:\mathcal{A}^*\to M^*\otimes\mathcal{A}^*$,

$$\langle\delta_{M^*}(\xi),a\otimes x\rangle=\langle\xi\varrho_M(a\otimes x)\rangle, \tag{61}$$

where $a\in\mathcal{A}$, $x\in M$, $\xi\in\mathcal{A}^*$.

V. REGULAR COBORDISMS AND TQFT

Let Cob be a directed graph of cobordisms whose objects Cob_0 are d-dimensional compact smooth and oriented manifolds without boundary and whose arrows are classes of cobordism manifolds with boundaries. We would like to discuss the corresponding n-regular cocycles and their meaning. For this goal we use here a parametrization such that the boundary ∂M is a multiconnected space, a disjoint sum of the ''incoming'' boundary manifold Σ_{in} and the ''outgoing'' one Σ_{out}. We call them ''physical.'' The empty boundary component is also admissible. Let Σ_0, $\Sigma_1\in\mathrm{Cob}_0$, then the disjoint sum is denoted by $\Sigma_0\amalg\Sigma_1$. For a manifold $\Sigma\in\mathrm{Cob}_0$ there is the corresponding manifold Σ^* with the opposite orientation.

We wish to represent quantum processes of certain physical system by cobordism manifolds M with the incoming boundary manifold Σ_0 (an ''input''), and the outgoing one Σ_0 (an ''output''). The incoming boundary manifold Σ_0 represents an initial condition of the system, the outgoing boundary represents the final configuration, and the cobordism manifolds represent possible interaction of the system. Note that the same cobordism manifold M but with different boundary parametrization represent different physical processes!

Definition 29: An ''interaction'' is a triple ${}_{\Sigma_0}\mathcal{M}_{\Sigma_1}$, where the incoming boundary manifold Σ_0 is multiconnected space with m components and the outgoing one Σ_1 is equipped with n components, and $\mathcal{M}$ is a class of cobordism manifolds up to parametrization preserving diffeomorfisms, Σ_0, $\Sigma_1\in\mathrm{Cob}_0$, $\mathcal{M}\in\mathrm{Cob}_1$.

Definition 30: The ''opposite interaction'' of ${}_{\Sigma_0}\mathcal{M}_{\Sigma_1}$ is the ''interaction'' ${}_{\Sigma_1}\mathcal{M}^{\mathrm{op}}_{\Sigma_0}$ with reversed boundary parametrization, i.e., the incoming boundary of $\mathcal{M}$ is the outgoing boundary of $\mathcal{M}^{\mathrm{op}}$ and vice versa.

Example 4: A ''collapsion'' of $\Sigma\in\mathrm{Cob}_0$ is an arbitrary ''interaction'' of the forms ${}_{\Sigma}\mathcal{M}_{\varnothing}$, this means the incoming boundary is Σ and the outgoing boundary is empty. The corresponding ''expansion'' of Σ is the opposite of the collapsion.

Definition 31: Let us denote by $\mathfrak{C}ob=(\mathfrak{C}ob_0,\mathfrak{C}ob_1)$ a directed graph whose objects are $\mathfrak{C}ob_0\equiv\mathrm{Cob}_0$ and arrows $\mathfrak{C}ob_1$ are ''interactions.'' A composition of two interactions ${}_{\Sigma_1}\mathcal{M}_{1\Sigma_2}$ and ${}_{\Sigma_2}\mathcal{M}_{2\Sigma_3}$ is an interaction ${}_{\Sigma_1}(\mathcal{M}_{1\Sigma_2}\mathcal{M}_2)_{\Sigma_3}$, where $\mathcal{M}_{1\Sigma_2}\mathcal{M}_2$ is a result of gluing $\mathcal{M}_1$ and $\mathcal{M}_2$ along Σ_2.

The trivial gluing along the empty boundary component is also admissible. For instance we can glue a ''collapsion'' of Σ and the corresponding ''expansion'' in the trivial way. In this way we obtain an interaction ${}_{\Sigma}(\mathcal{M}\mathcal{M}^{\mathrm{op}})_{\Sigma}$. If we glue the expansion of Σ and the collapsion of Σ along Σ, then we obtain a class of manifolds with empty boundaries.

Example 5: Classes of two-dimensional surfaces with holes provide examples of string interactions.

We wish to build the temporal support semigroup as an arbitrary sequence

$$X_1 \overset{f_1}{\to} X_2 \overset{f_2}{\to} \cdots \overset{f_{n-1}}{\to} X_n \tag{62}$$

of objects and arrows of a directed graph $\mathfrak{C}$ indexed by a discrete time. We wish to represent an interaction ${}_{\Sigma_1}\mathcal{M}_{\Sigma_2}$ as an arrow $X_1 \overset{f}{\to} X_2$ of $\mathfrak{C}$. Obviously composable arrows $X_1 \overset{f_1}{\to} X_2 \overset{f_2}{\to} X_3$ should represent the gluing ${}_{\Sigma_1}(\mathcal{M}_{1\Sigma_2}\mathcal{M}_2)_{\Sigma_3}$. Two interactions ${}_{\Sigma_1}\mathcal{M}_{\Sigma_2}$ and ${}_{\Sigma_1'}\mathcal{M}'_{\Sigma_2'}$ should be represented by the same arrow $X_1 \overset{f}{\to} X_2$ if and only if both interactions are "parallel (simultaneous) in the time."

Let us assume that the directed graph $\mathfrak{C}$ is an n-regular monoidal category with duals. Let $X_1 \overset{f_1}{\to} X_2 \overset{f_2}{\to} \cdots \overset{f_{n-1}}{\to} X_n$ be an n-regular cocycle. If there is an equivalence $\cong$ in $\mathfrak{C}$ob such that objects of the n-regular cocycle represent equivalence classes of $\cong$ and arrows represent time consequences, then we say that we have an n-regular TQFT.

What does n-regularity mean here? It is natural to assume that the opposite ${}_{\Sigma_2}\mathcal{M}^{\mathrm{op}}_{\Sigma_1}$ of ${}_{\Sigma_1}\mathcal{M}_{\Sigma_2}$ should be represented by a reversed arrow $X_1 \overset{f}{\leftarrow} X_2$. The trivial two-regularity is clear, it means that the time is invertible. We postulate that the time is directed and always runs further, never back, never stops. In other words, "our time" is not invertible in general, but it can be n-regular, where the regularity is nontrivial.

Example 6: Let us consider for instance the two-regular "interactions." Let

$${}_{\Sigma_1}\mathcal{M}_{1\Sigma_2} \text{ and } {}_{\Sigma_2}\mathcal{M}_{2\Sigma_1}$$

be two interactions, then ${}_{\Sigma_1}(\mathcal{M}_{1\Sigma_2}\mathcal{M}_2)_{\Sigma_1}$ and ${}_{\Sigma_2}(\mathcal{M}_{2\Sigma_1}\mathcal{M}_1)_{\Sigma_2}$ can be represented as arrows $X_1 \overset{f_1}{\to} X_2 \overset{f_2}{\to} X_1$, and $X_2 \overset{f_2}{\to} X_1 \overset{f_1}{\to} X_2$, respectively. Interactions ${}_{\Sigma_1}\mathcal{M}_{1\Sigma_2}\mathcal{M}_{2\Sigma_1}\mathcal{M}_{1\Sigma_2}$ and ${}_{\Sigma_2}\mathcal{M}_{2\Sigma_1}\mathcal{M}_{1\Sigma_2}\mathcal{M}_{2\Sigma_1}$ should be represented by $X_1 \overset{f_1}{\to} X_2 \overset{f_2}{\to} X_1 \overset{f_1}{\to} X_2$, and $X_2 \overset{f_2}{\to} X_1 \overset{f_1}{\to} X_2 \overset{f_2}{\to} X_1$, respectively. Now the two-regularity conditions are clear.

Observe that the regularity concept can be useful for the construction of quantum theory of the whole universe with nonivertible time evolution. In fact the nontrivial n-regularity conditions mean that all processes always go further, never back, never stop, but are cyclically repeating after n-steps up to an equivalence.

and Theoretische Quantendynamik, Fakultät für Physik, Universität Freiburg, Hermann-Herder-Strasse 3, D-79104 Freiburg, Germany

(Received 10 December 2001; accepted for publication 20 February 2002)

A recursion formula is derived which allows one to evaluate invariant integrals over the orthogonal group $O(N)$, where the integrand is an arbitrary finite monomial in the matrix elements of the group. The value of such an integral is expressible as a finite sum of partial fractions in N. The recursion formula largely extends presently available integration formulas for the orthogonal group. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1471367]

I. INTRODUCTION

Integrals over the classical compact groups[1,2] are of interest in various fields, such as harmonic analysis[3] or random matrix theory.[4] In these applications the integrand is often a polynomial in the matrix elements of the group itself (i.e., of the true matrix representation of the group). Thus we have to integrate an arbitrary monomial of these matrix elements. Closed formulas are available only for very special cases[3,5–7] and even a new method by Prosen *et al.*[8] using computer algebras is practically limited to low degrees. For arbitrary monomials there is strong evidence that the results in Ref. 8 are exact at least up to the next leading order in N^{-1} with respect to the approximation of the group integral by independent Gaussian distributed matrix elements.[9]

In the present paper we shall address the case of the orthogonal group $O(N)$. First we rederive the well-known one-vector formula.[4,6] In this context, the terms ''R-vector formula'' or ''R-vector integral'' refer to the case where the monomial in question contains only powers of matrix elements from R rows or R columns, respectively. Next we derive a recursion formula that relates an R-vector integral to a linear combination of $(R-1)$-vector integrals. This is the central result of the present paper. Together with the one-vector formula, it allows one to calculate any integral over a monomial of finite degree in a finite number of steps. This result is then used to obtain a closed expression for general two-vector integrals that is much simpler than the one known before.[6] Besides, the older formula contains mistakes which (to the best of my knowledge) had never been corrected in the literature.

The paper is organized as follows: In Sec. II we describe the current approach to the problem. In addition, we introduce some compact nonstandard notations, which help to keep the mathematical expressions manageable. Then the one-vector result of Ullah[6] is rederived, as it is the base for the recursion formula developed later on. In passing we obtain an equally simple formula for the corresponding one-vector integral over the unitary group. In Sec. III we derive the general recursion formula. In Sec. IV some applications are presented. As an immediate consequence, we obtain a closed expression for the two-vector integral, which is then compared to the corrected old result.[6] We also illustrate the use of our general formula for $R>2$, calculating a particular three-vector integral. Section V contains the conclusions.

II. GENERAL CONSIDERATIONS

To be specific, let us consider the orthogonal matrix $w \in O(N)$ as a point in Euclidean N^2-dimensional space. Then we are interested in integrals of monomials in the coordinates of w. These are denoted by

$$\langle M \rangle = \int \mathrm{d}\sigma(w) \quad \prod_{i,\xi=1}^{N,R} w_{i\xi}^{M_{i\xi}}. \tag{1}$$

Here σ is the normalized Haar measure[10] of $O(N)$, i.e., $\int \mathrm{d}\sigma(w) = 1$, and M is an $N \times R$ matrix of non-negative integers, with $R \leqslant N$. M is called the power matrix. In the recursion formula to be developed, R is used as the recursion parameter. Hence it is important, that R, the number of columns of M, is as small as possible.

The integral over the orthogonal group is invariant under any permutation of columns or rows of the integration variable $w \in O(N)$. It is also invariant under taking the transpose. Therefore it is sufficient to consider such monomials which contain matrix elements from the first $R \leqslant N$ columns of w only. According to Ullah[6] one may then write

$$\langle M \rangle = \frac{\mathcal{N}(M)}{\mathcal{N}(o)}, \quad \mathcal{N}(M) = \int \prod_{\xi=1}^{R} \left\{ \mathrm{d}\Omega(\vec{w}_\xi) \prod_{i=1}^{N} w_{i\xi}^{M_{i\xi}} \right\} \quad \prod_{\mu<\nu} \delta(\langle \vec{w}_\mu | \vec{w}_\nu \rangle), \tag{2}$$

where o is an $N \times R$ matrix of zeros. The integration region is the Cartesian product of R unit spheres with constant measures $\mathrm{d}\Omega(\vec{w}_\xi)$, and $\{\vec{w}_1, \ldots, \vec{w}_R\}$ are the corresponding unit vectors. The orthogonality of the unit vectors is implemented with the help of appropriately chosen δ-functions. $\langle \vec{w}_\mu | \vec{w}_\nu \rangle$ denotes the scalar product between the two vectors $\vec{w}_\mu$ and $\vec{w}_\nu$.

A. Compact notations for certain products of multinomials

In the calculations to follow, we will frequently deal with certain products of binomial and multinomial coefficients. For better legibility we use two special notations: In what follows, $\vec{x}$ and $\vec{y}$ are N-dimensional real vectors, and $\vec{m}$ and $\vec{n}$ are N-dimensional vector-indices of non-negative integers. There are two typical cases in which products of multinomials appear:

(1) Consider the expression $E = \Pi_{i=1}^{N} (x_i + y_i)^{n_i}$. Its expansion gives

$$E = \sum_{\vec{k}} \prod_{i=1}^{N} \binom{n_i}{k_i} x_i^{k_i} y_i^{n_i - k_i}, \tag{3}$$

where the sum runs over all $\vec{k}$ for which $\forall i : k_i \leqslant n_i$. In this case, the product of binomials is denoted by the following symbol:

$$\prod_{i=1}^{N} \binom{n_i}{k_i} = \binom{\vec{n}}{\vec{k}}. \tag{4}$$

(2) On other occasions, we encounter expressions of the type: $E' = \Pi_{i=1}^{N} \langle \vec{\tau} | \vec{w}_i' \rangle^{n_i}$, where $\langle \vec{\tau} | \vec{w}_i' \rangle$ is the scalar product of the two $(R-1)$-dimensional vectors $\vec{\tau}$ and $\vec{w}_i'$. In this case the expansion reads

$$E' = \sum_{K} \left\{ \prod_{i=1}^{N} (n_i | K_{i1}, \ldots, K_{i,R-1}) \right\} \quad \prod_{\xi=1}^{R-1} \bar{\tau}_\xi^{\bar{k}_\xi} \prod_{i=1}^{N} w_{i\xi}^{K_{i\xi}}. \tag{5}$$

Here we have to use the $N \times (R-1)$ matrix K as an index. The elements of K are non-negative integers. $\vec{k}_\xi$ is the ξth column vector of K, and $\bar{k}_\xi$ is the sum of its components: $\bar{k}_\xi = \Sigma_{i=1}^{N} K_{i\xi}$. The sum in Eq. (5) runs over all K for which $\forall i : \Sigma_{\xi=1}^{R-1} K_{i\xi} = n_i$. In this case, we use the following notation:

$$\prod_{i=1}^{N}(n_i|K_{i1},\ldots,K_{i,R-1})=(\vec{n}|K). \tag{6}$$

B. The one-vector integral

In the one-vector case, $R=1$, there are no orthogonality relations to respect. The power matrix M consists of one single column vector, here denoted by $\vec{m}$. According to Eq. (2) we may write

$$\langle\vec{m}\rangle=\frac{\mathcal{N}(\vec{m})}{\mathcal{N}(\vec{o})},\quad \mathcal{N}(\vec{m})=\int \mathrm{d}\Omega(\vec{w})\prod_{i=1}^{N} w_i^{m_i}, \tag{7}$$

where $\vec{o}$ is an N-dimensional vector of zeros. Following the original calculation of Ullah,[4,6] we integrate over the full vector space $\mathbb{R}^N$ and implement the normalization of the column vector with the help of a δ-function. This introduces the integration constant c_N:

$$\mathcal{N}(\vec{m})=c_N^{-1}\left\{\prod_{i=1}^{N}\int_{-\infty}^{\infty}\mathrm{d}x_i\, x_i^{m_i}\right\}\quad \delta(\|\vec{x}\|^2-1). \tag{8}$$

The next step is to remove the δ-function. Setting $x_i=u_i/\sqrt{r}$, we obtain

$$\mathcal{N}(\vec{m})r^{(N+\overline{m})/2-1}=c_N^{-1}\left\{\prod_{i=1}^{N}\int_{-\infty}^{\infty}\mathrm{d}u_i\, u_i^{m_i}\right\}\quad \delta(\|\vec{u}\|^2-r), \tag{9}$$

where $\overline{m}=\Sigma_{i=1}^{N} m_i$. The δ-function can now be removed by multiplying the *left-hand side* and the *right-hand side* with e^{-r} and integrating on r from 0 to ∞:

$$\mathcal{N}(\vec{m})\Gamma\left(\frac{N+\overline{m}}{2}\right)\quad c_N=\prod_{i=1}^{N}\int_{-\infty}^{\infty}\mathrm{d}u_i\, u_i^{m_i}e^{-u_i^2}=\prod_{i=1}^{N}\Gamma\left(\frac{1+m_i}{2}\right). \tag{10}$$

Solving this equation for $\mathcal{N}(\vec{m})$, the ratio $\mathcal{N}(\vec{m})/\mathcal{N}(\vec{o})$ can be calculated, which leads to the desired result:

$$\langle\vec{m}\rangle=\left(\frac{N}{2}\right)_{\overline{m}/2}^{-1}\prod_{i=1}^{N}\left(\frac{1}{2}\right)_{m_i/2}. \tag{11}$$

Here it is convenient to use the Pochhammer symbol $(z)_n=\Gamma(z+n)/\Gamma(z)$.[11] Note that Eq. (10) implies that the integral $\langle\vec{m}\rangle$ vanishes if at least one component of $\vec{m}$ is odd.

C. The one-vector integral over the unitary group

It is natural to consider also integrals over the unitary group $U(N)$. This is much more complicated because in general the monomials to integrate contain powers of the matrix elements and their complex conjugated counterparts. In the one-vector case, however, the integral over the unitary group can be mapped on a corresponding integral over the orthogonal group, which leads again to a simple result (it seems that such a formula has never been published elsewhere). If more vectors are involved, $R>1$, the orthogonality conditions destroy this simple correspondence.

To obtain the desired expression for one-vector integrals, it is convenient to consider monomials in the real and imaginary parts of the complex unit vector $\vec{w}$. They can be identified with the coordinates in a $2N$-dimensional Euclidean space, where the Haar measure reduces to the constant measure Ω_2 on the unit hypersphere. Denoting the one-vector integral of an arbitrary monomial by $\langle\vec{m}:\vec{n}\rangle=\langle\Pi_{i=1}^{N}x_i^{m_i}y_i^{n_i}\rangle$, where $w_i=x_i+\mathrm{i}y_i$, we may write

$$\langle \vec{m}:\vec{n}\rangle = \frac{\mathcal{M}(\vec{m},\vec{n})}{\mathcal{M}(\vec{o},\vec{o})}, \quad \mathcal{M}(\vec{m},\vec{n}) = \int \mathrm{d}\Omega_2(\vec{w}) \prod_{i=1}^{N} x_i^{m_i} y_i^{n_i}, \quad w_i = x_i + \mathrm{i}y_i . \tag{12}$$

Note the different notations: $\langle \vec{m}:\vec{n}\rangle$ stands for the one-vector integral over the unitary group, while $\langle \vec{m},\vec{n}\rangle$, used in Sec. IV, stands for the two-vector integral over the orthogonal group. As Eq. (12) shows, we may express $\langle \vec{m}:\vec{n}\rangle$ as a one-vector integral over the orthogonal group $O(2N)$: $\langle \vec{m}:\vec{n}\rangle = \langle \vec{p},\rangle$ where $\vec{p}$ is the $2N$-dimensional concatenation of $\vec{m}$ and $\vec{n}$. Then we may apply Eq. (11). This leads to

$$\langle \vec{m}:\vec{n}\rangle = (N)^{-1}_{(\overline{m}+\overline{n})/2} \prod_{i=1}^{N} \left(\frac{1}{2}\right)_{m_i/2} \left(\frac{1}{2}\right)_{n_i/2} . \tag{13}$$

Again the integral $\langle \vec{m}:\vec{n}\rangle$ vanishes, if at least one component of $\vec{m}$ or $\vec{n}$ is odd.

III. THE RECURSION FORMULA

The desired recursion formula shall express an arbitrary integral $\langle M\rangle$, where M is a power matrix with R columns, as a linear combination of simpler integrals $\langle M'\rangle$, where M' has only $R-1$ columns. Starting from Eq. (2) one may attack this problem head on, and separate the integration on the last unit vector $\vec{w}_R$ from the remaining integral:

$$\mathcal{N}(M) = \int \left\{ \prod_{\xi=1}^{R-1} \mathrm{d}\Omega(\vec{w}_\xi) \prod_{i=1}^{N} w_{i\xi}^{M_{i\xi}} \right\} \left\{ \prod_{\mu<\nu}^{R-1} \delta(\langle \vec{w}_\mu | \vec{w}_\nu \rangle) \right\} J(\vec{w}_1,\ldots,\vec{w}_{R-1};\vec{m}_R). \tag{14}$$

Here $\vec{m}_R$ is the last column vector of the power matrix M, and

$$J(\vec{w}_1,\ldots,\vec{w}_{R-1};\vec{m}_R) = \int \mathrm{d}\Omega(\vec{w}) \left\{ \prod_{i=1}^{R} w_i^{M_{iR}} \right\} \prod_{\xi=1}^{R-1} \delta(\langle \vec{w}_\xi | \vec{w} \rangle). \tag{15}$$

As shown in the following, the value of this integral can be expressed as a linear combination of monomials in the integration variables $\{w_{i\xi} | \xi \leqslant R-1\}$. If this is inserted back into Eq. (14), it obviously leads to the desired recursion formula.

To evaluate the integral (15), we replace the integration over the unit sphere by an integration over the full space $\mathbb{R}^N$, implementing the normalization condition with the help of a δ-function. This introduces the normalization constant c_N as before in Eq. (8). Then we remove the δ-function again, using the same trick as in Sec. II B. After that, we replace the remaining δ-functions (responsible for the orthogonality relations) by their respective Fourier representations. All this leads to

$$\begin{aligned} J(\vec{w}_1,\ldots,\vec{w}_{R-1};\vec{m}_R) &= c_N^{-1} \left\{ \prod_{i=1}^{N} \int \mathrm{d}x_i\, x_i^{M_{iR}} \right\} \delta(\|\vec{x}\|^2 - 1) \prod_{\xi=1}^{R-1} \delta(\langle \vec{w}_\xi | \vec{x} \rangle) \\ &= c_N^{-1} \Gamma\left(\frac{N-R+\overline{m}_R+1}{2} \right)^{-1} \left\{ \prod_{i=1}^{N} \int \mathrm{d}x_i\, x_i^{M_{iR}} e^{-x_i^2} \right\} \prod_{\xi=1}^{R-1} \delta(\langle \vec{w}_\xi | \vec{x} \rangle) \\ &= c_N^{-1} \Gamma\left(\frac{N-R+\overline{m}_R+1}{2} \right)^{-1} \int \frac{\mathrm{d}^{R-1}\vec{\tau}}{\pi^{R-1}} \prod_{i=1}^{N} \int \mathrm{d}x_i\, x_i^{M_{iR}} e^{-x_i^2 + 2i\langle \vec{\tau} | \vec{w}_i' \rangle x_i}, \end{aligned} \tag{16}$$

where $\vec{w}_i'$ stands for the row-vector $(w_{i1},\ldots,w_{i,R-1})^T$. The integrals on x_i are easily evaluated:

$$J(\cdots)\Gamma\left(\frac{N-R+\overline{m}_R+1}{2}\right)c_N=\int\frac{\mathrm{d}^{R-1}\vec{\tau}}{\pi^{R-1}}\exp^{-\Sigma_{i=1}^N\langle\vec{\tau}|\vec{w}_i'\rangle^2}\prod_{i=1}^N\left[\sum_{\kappa_i=0}^{M_{iR}}\kappa_i:\text{even}\binom{M_{iR}}{\kappa_i}\right.$$
$$\left.\times(\mathrm{i}\langle\vec{\tau}|\vec{w}_i'\rangle)^{M_{iR}-\kappa_i}\Gamma\left(\frac{1+\kappa_i}{2}\right)\right]. \tag{17}$$

Expanding the N-fold product in the second line, we obtain for the left-hand side

$$\text{l.h.s.}=\sum_{\vec{\kappa}}\binom{\vec{m}_R}{\vec{\kappa}}\mathrm{i}^{\overline{m}_R-\overline{\kappa}}\left\{\prod_{i=1}^N\Gamma\left(\frac{1+\kappa_i}{2}\right)\right\}\int\frac{\mathrm{d}^{R-1}\vec{\tau}}{\pi^{R-1}}\left\{\prod_{i=1}^N\langle\vec{\tau}|\vec{w}_i'\rangle^{M_{iR}-\kappa_i}\right\}e^{-\langle\vec{\tau}|A\vec{\tau}\rangle}, \tag{18}$$

where $\vec{\kappa}=(\kappa_1,\ldots,\kappa_N)^T$. Note that the sum runs only over such $\vec{\kappa}$, for which all components are even, and that for the product of binomials the abbreviation from Eq. (4) is used. A bar over vector quantities such as $\overline{m}_R$ and $\overline{\kappa}$ denotes the sum of all their components. The quadratic matrix A, with elements $A_{\mu\nu}=\langle\vec{w}_\mu|\vec{w}_\nu\rangle$, has dimension $R-1$.

Now, the key observation is the following: The orthogonality conditions implemented in the form of δ-functions in Eq. (14) select from the total integration region only a submanifold. There it holds that $\langle\vec{w}_\mu|\vec{w}_\nu\rangle=\delta_{\mu\nu}$, so that the matrix A may be replaced by the unit matrix. Then it is possible to evaluate the $\vec{\tau}$-integral. The expansion of the product of scalar products leads to

$$\text{l.h.s.}=\sum_{\vec{\kappa}}\binom{\vec{m}_R}{\vec{\kappa}}\mathrm{i}^{\overline{m}_R-\overline{\kappa}}\left\{\prod_{i=1}^N\Gamma\left(\frac{1+\kappa_i}{2}\right)\right\}\sum_K(\vec{m}_R-\vec{\kappa}|K)\left\{\prod_{\xi=1}^{R-1}\int\frac{\mathrm{d}\tau_\xi}{\pi}\tau_\xi^{\overline{k}_\xi}e^{-\tau_\xi^2}\prod_{i=1}^N w_{i\xi}^{K_{i\xi}}\right\}, \tag{19}$$

where K is a matrix index with $R-1$ columns, as introduced in Eq. (6) together with the abbreviation for the product of multinomials. The $\overline{k}_\xi$'s are the sums over the components of the column vectors of K. The remaining integrals are easily evaluated, which results in

$$J()=\frac{\pi^{1-R}}{c_N\Gamma\left(\frac{N-R+\overline{m}_R+1}{2}\right)}\sum_{\vec{\kappa}}\binom{\vec{m}_R}{\vec{\kappa}}(-1)^{(\overline{m}_R-\overline{\kappa})/2}\left\{\prod_{i=1}^N\Gamma\left(\frac{1+\kappa_i}{2}\right)\right\}$$
$$\times\sum_K(\vec{m}_R-\vec{\kappa}|K)\prod_{\xi=1}^{R-1}\Gamma\left(\frac{1+\overline{k}_\xi}{2}\right)\prod_{i=1}^N w_{i\xi}^{K_{i\xi}}. \tag{20}$$

Note that, as a consequence of the τ_ξ-integrals, the sum in the second line runs over such K only, for which all $\overline{k}_1,\ldots,\overline{k}_{R-1}$ are even. Inserting this expression into the initial Eq. (14) we obtain

$$\mathcal{N}(M)=\frac{\pi^{1-R}}{c_N\Gamma\left(\frac{N-R+\overline{m}_R+1}{2}\right)}\sum_{\vec{\kappa}}\binom{\vec{m}_R}{\vec{\kappa}}(-1)^{(\overline{m}_R-\overline{\kappa})/2}\left\{\prod_{i=1}^N\Gamma\left(\frac{1+\kappa_i}{2}\right)\right\}\sum_K(\vec{m}_R-\vec{\kappa}|K)$$
$$\times\left\{\prod_{\xi=1}^{R-1}\Gamma\left(\frac{1+\overline{k}_\xi}{2}\right)\right\}\left\{\prod_{\xi=1}^{R-1}\int\mathrm{d}\Omega(\vec{w}_\xi)\prod_{i=1}^N w_{i\xi}^{M_{i\xi}+K_{i\xi}}\right\}\left\{\prod_{\mu<\nu}^{R-1}\delta(\langle\vec{w}_\mu|\vec{w}_\nu\rangle)\right\}. \tag{21}$$

The integral over the normalized vectors $\vec{w}_1,\ldots,\vec{w}_{R-1}$ can be identified with $\mathcal{N}(M^{(R-1)}+K)$ which is a $(R-1)$-vector integral. In this way, we obtain a recursion formula for $\mathcal{N}(M)$. For the normalization constant, we find

$$\mathcal{N}(o)=\frac{\pi^{1-R}}{c_N\Gamma\left(\frac{N-R+1}{2}\right)}\left\{\prod_{i=1}^{N}\Gamma\left(\frac{1}{2}\right)\right\}\left\{\prod_{\xi=1}^{R-1}\Gamma\left(\frac{1}{2}\right)\right\}\mathcal{N}(o^{(R-1)}). \tag{22}$$

Thus we obtain for the R-vector integral $\langle M\rangle$, defined in Eq. (2):

$$\langle M\rangle=\left(\frac{N-R+1}{2}\right)^{-1}_{\overline{m}_R/2}\sum_{\vec{\kappa}}\binom{\vec{m}_R}{\vec{\kappa}}(-1)^{(\overline{m}_R-\overline{\kappa})/2}\left\{\prod_{i=1}^{N}\left(\frac{1}{2}\right)_{\kappa_i/2}\right\}$$
$$\times\sum_{K}(\vec{m}_R-\vec{\kappa}|K)\left\{\prod_{\xi=1}^{R-1}\left(\frac{1}{2}\right)_{\overline{k}_\xi/2}\right\}\langle M^{(R-1)}+K\rangle. \tag{23}$$

This is the desired recursion formula and the main result of the present paper. As mentioned before it is understood that the first sum runs over such $\vec{\kappa}$ only for which all components are even, while the second runs over such K only for which all $\overline{k}_\xi=\Sigma_{i=1}^{N}K_{i\xi}$ are even. Furthermore $\overline{m}_R=\Sigma_{i=1}^{N}M_{iR}$, $\overline{\kappa}=\Sigma_{i=1}^{N}\kappa_i$, and $M^{(R-1)}$ stands for the matrix consisting of the first $R-1$ columns of the matrix M.

In principle Eq. (23) allows one to evaluate integrals of arbitrary monomials of finite degree. The result is always expressible as a rational function of the dimension N, because the repeated expansion of Eq. (23) leads to nested sums of partial fractions in N. In this context it is useful to note that only the prefactor of the r.h.s. depends explicitly on N. The formula (23) can be used conveniently if either R or the degree of the monomial to be integrated is small. Otherwise Eq. (23) may lead to very lengthy expressions. However, such expressions should still be manageable with an appropriate computer algebra system. This would allow for further systematic studies of this class of integrals.

In contrast to what one might expect, the integral $\langle M\rangle$ does not necessarily vanish if the power matrix M has odd elements. It rather holds the following: If any sum over a row or column of M is odd, then $\langle M\rangle=0$. Though this is in fact well known,[12] it is still instructive to see that it follows almost immediately from the recursion relation (23).

To this end, permute columns and rows, and take the transpose if necessary, to transform M in such a way that its last column contains the row or column whose sum of components is odd. Then apply Eq. (23): The sum over $\vec{\kappa}$ is restricted to such $\vec{\kappa}$ which have only even components. Hence $\overline{\kappa}$ is even. As $\overline{m}_R$ is odd, and $\Sigma_{\xi=1}^{R-1}\overline{k}_\xi=\overline{m}_R-\overline{\kappa}$, at least one of the sums $\overline{k}_1,\ldots,\overline{k}_{R-1}$ must be odd as well. Such a term vanishes, because of what is said below Eq. (20). This implies that all terms of the sum over K vanish likewise, so that the complete integral gives zero.

IV. APPLICATIONS

In random matrix theory, many matrix ensembles are based on the concept of orthogonal invariance. Physically this corresponds to a situation where the Hamiltonian for a spinless quantum particle possesses an antiunitary symmetry, e.g., time reversal invariance. The Gaussian and circular orthogonal ensembles[4,13,14] are well-known examples based on this concept. Other examples are the Poisson orthogonal ensemble,[15] or the recently introduced matrix ensembles for semiseparable systems.[8] In those cases the orthogonal group acts directly on the Hamiltonian, and the statistical properties of the eigenvectors are uniquely determined by the orthogonal group and its invariant measure. In fact, the ensemble of eigenvectors is simply given by the orthogonal group itself. Therefore any correlators between the eigenvectors can be expressed and calculated in terms of R-vector integrals.

In what follows, we first apply our integration formula (23) to the two-vector case. In this way we obtain a closed expression for arbitrary two-vector integrals. Then we compare this result with

the corrected formula of Ref. 6. For illustration, we finally compute a simple three-vector integral, which can be evaluated with an independent method also. As it should be, we find the same answer with both methods.

A. The two-vector integral

Consider the arbitrary two-vector integral $\langle M\rangle=\langle\vec{m},\vec{n}\rangle$, where the first column vector of M is denoted by $\vec{m}$ and the second by $\vec{n}$. In this case, Eq. (23) leads directly to

$$\langle\vec{m},\vec{n}\rangle=\left(\frac{N-1}{2}\right)_{\overline{n}/2}^{-1}\sum_{\vec{\kappa}}\binom{\vec{n}}{\vec{\kappa}}(-1)^{(\overline{n}-\overline{\kappa})/2}\left\{\prod_{i=1}^{N}\left(\frac{1}{2}\right)_{\kappa_i/2}\right\}\left(\frac{1}{2}\right)_{(\overline{n}-\overline{\kappa})/2}\langle\vec{m}+\vec{n}-\vec{\kappa}\rangle. \tag{24}$$

The sum runs over such $\vec{\kappa}$ only, for which all components are even. A bar over a vector quantity denotes, as before, the sum of all its components. This formula has already been used in Ref. 16 to calculate various two-vector integrals, and numerical tests performed therein have confirmed its validity. For later purpose we use Eq. (24) to evaluate the following simple integral:

$$\left\langle\begin{pmatrix}1&1\\1&1\\0&0\\\vdots&\vdots\end{pmatrix}\right\rangle=\frac{2}{N-1}(-1)\frac{1}{2}\left\langle\begin{pmatrix}2\\2\\0\\\vdots\end{pmatrix}\right\rangle=\frac{-1}{(N-1)N(N+2)}. \tag{25}$$

Note that the same result can be obtained by an indirect method[12] also.

In principle, an integration formula for general two-vector integrals has already been published some time ago.[6] After the correction of two misprints, it reads

$$\begin{aligned}\overline{\prod_i u_i^{2m_i}v_i^{2n_i}}=\pi^{-N+1}2^{-2N+4-2\Sigma(m_i+n_i)}&\frac{\Gamma(N-1)\Gamma[N-1+\Sigma_i(m_i+n_i)]}{\Gamma[\Sigma_i m_i+(N-1)/2]\Gamma[\Sigma_i n_i+(N-1)/2]}\\&\times\sum_{k_1,\ldots,k_N,l_1,\ldots,l_N=0,\ldots,0}^{2m_1,\ldots,2m_N,2n_1,\ldots,2n_N}(-1)^{\Sigma_i l_i}\\&\times\frac{\Pi_i\binom{2m_i}{k_i}\binom{2n_i}{l_i}\Gamma[(k_i+l_i+1)/2]\Gamma[m_i+n_i-(k_i+l_i-1)/2]}{\Gamma[N/2+\Sigma_i(k_i+l_i)/2]\Gamma[N/2+\Sigma_i(m_i+n_i)-\Sigma_i(k_i+l_i)/2]},\end{aligned} \tag{26}$$

where $\forall i: k_i+l_i$ must be even. Here the original notation of Ref. 6 is used. The corrections concern the first line, where the nominator has been multiplied with $\Gamma[N-1+\Sigma_i(m_i+n_i)]$, and the sum over $k_1,\ldots,k_N,l_1,\ldots,l_N$, where the indices must start with zeros instead of ones. Finally the notation is quite unfortunate, as it seems to prohibit monomials with odd powers, though there is no reason for it. Indeed, Eq. (26) holds in those cases as well. This can be checked, for instance, by computing the integral (25) with the help of Eq. (26), setting $m_1=m_2=n_1=n_2=1/2$.

Using the notation adopted in the present work, Eq. (26) reads

$$\langle\vec{m},\vec{n}\rangle=\frac{(N-1)_{(\overline{m}+\overline{n})/2}}{2^{\overline{m}+\overline{n}}\left(\frac{N-1}{2}\right)_{\overline{m}/2}\left(\frac{N-1}{2}\right)_{\overline{n}/2}}\sum_{\vec{k},\vec{l}}\binom{\vec{m}}{\vec{k}}\binom{\vec{n}}{\vec{l}}(-1)^{\overline{l}}\langle\vec{k}+\vec{l}\rangle\langle\vec{m}-\vec{k}+\vec{n}-\vec{l}\rangle. \tag{27}$$

If we compare the integration formulas (24) and (27), they differ considerably. It seems rather difficult to prove their equivalence directly. Note moreover, that our result is much simpler, because there the sum runs over a single vector-index only.

B. A simple three-vector integral

The three-vector integral considered here is chosen because of its simplicity and because it may be evaluated using an indirect method, which allows to crosscheck the result. We will compute the integral $\langle M\rangle$ with

$$M=\begin{pmatrix} 2 & 0 & 0\\ 0 & 2 & 0\\ 0 & 0 & 2\\ 0 & 0 & 0\\ \vdots & \vdots & \vdots \end{pmatrix}. \tag{28}$$

Henceforth we will skip those parts of the column vectors which are zero anyway. Using our recursion formula (23) the three-vector integral $\langle M\rangle$ can be reduced to a linear combination of two-vector integrals, for which we already have a closed expression, i.e., Eq. (24). Thus, the evaluation of $\langle M\rangle$ needs only a few steps:

$$\begin{aligned}
&\left\langle \begin{pmatrix} 2 & 0 & 0\\ 0 & 2 & 0\\ 0 & 0 & 2 \end{pmatrix} \right\rangle \\
&\quad=\frac{2}{N-2}\left\{ -\sum_K \left(\begin{pmatrix} 0\\ 0\\ 2 \end{pmatrix} \middle| K \right) \left(\frac{1}{2}\right)_{\overline{k_1/2}} \left(\frac{1}{2}\right)_{\overline{k_2/2}} \left\langle \begin{pmatrix} 2 & 0\\ 0 & 2\\ 0 & 0 \end{pmatrix} + K \right\rangle + \frac{1}{2}\left\langle \begin{pmatrix} 2 & 0\\ 0 & 2 \end{pmatrix} \right\rangle \right\} \\
&\quad=\frac{2}{N-2}\left\{ -\frac{1}{2}\left[\left\langle \begin{pmatrix} 2 & 0\\ 0 & 2\\ 2 & 0 \end{pmatrix} \right\rangle + \left\langle \begin{pmatrix} 2 & 0\\ 0 & 2\\ 0 & 2 \end{pmatrix} \right\rangle \right] + \frac{1}{2}\,\frac{N+1}{(N-1)N(N+2)} \right\} \\
&\quad=\frac{1}{N-2}\left\{ \frac{N+1}{(N-1)N(N+2)} - 2\,\frac{N+3}{(N-1)N(N+2)(N+4)} \right\} \\
&\quad=\frac{N^2+3N-2}{(N-2)(N-1)N(N+2)(N+4)}.
\end{aligned} \tag{29}$$

The result is expressed as a rational function, where care has been taken that nominator and denominator have no more common factors.

Alternatively we may compute $\langle M\rangle$ with M as defined in Eq. (28), starting from the following identity:

$$\left(\sum_i w_{i1}^2\right)\left(\sum_j w_{j2}^2\right)\left(\sum_k w_{k3}^2\right)=1, \tag{30}$$

which holds for an arbitrary $w\in O(N)$. To this end we expand the products on the l.h.s. and integrate on both sides over the group. This gives

$$N(N-1)(N-2)\left\langle \begin{pmatrix} 2 & 0 & 0\\ 0 & 2 & 0\\ 0 & 0 & 2 \end{pmatrix} \right\rangle + 3N(N-1)\left\langle \begin{pmatrix} 2 & 0\\ 2 & 0\\ 0 & 2 \end{pmatrix} \right\rangle + N\left\langle \begin{pmatrix} 2\\ 2\\ 2 \end{pmatrix} \right\rangle = 1. \tag{31}$$

It allows one to express the three-vector integral $\langle M\rangle$ as a linear combination of a one-vector and a two-vector integral. According to Eqs. (11) and (24), these integrals are given by

$$\left\langle \begin{pmatrix} 2 \\ 2 \\ 2 \end{pmatrix} \right\rangle = \frac{1}{N(N+2)(N+4)}, \quad \left\langle \begin{pmatrix} 2 & 0 \\ 2 & 0 \\ 0 & 2 \end{pmatrix} \right\rangle = \frac{N+3}{(N-1)N(N+2)(N+4)}. \tag{32}$$

Thus we obtain

$$\left\langle \begin{pmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{pmatrix} \right\rangle = \frac{(N+2)(N+4)-3(N+3)+1}{(N-2)(N-1)N(N+2)(N+4)}$$

$$= \frac{N^2+3N-2}{(N-2)(N-1)N(N+2)(N+4)}. \tag{33}$$

As expected, the result coincides with that in Eq. (29). Here the indirect method worked so well because we first wrote down the identities (30) and (31), and then chose our particular example $\langle M \rangle$. However, if the value of a certain integral is needed, one would have to guess useful identities which allow one to express the integral by a linear combination of simpler ones, a procedure which is very difficult. In contrast to that, the recursion formula (23) always provides a well-defined finite procedure, for the computation of any integral.

V. CONCLUSIONS

To summarize, we have derived a recursion formula, which expresses an arbitrary R-vector integral over the orthogonal group as a linear combination of $(R-1)$-vector integrals. It allows one to successively evaluate the group integral of any finite monomial in the matrix elements of the group. The simplicity of the result depends primarily on R, the number of column or row vectors involved, and only secondarily on the degree of the monomial in question. The result is always given as a finite sum of partial fractions in N.

As an immediate consequence of the general result, we obtained a closed integration formula for arbitrary two-vector integrals, which is quite different and much simpler than the corrected, previously known result.

In principle a similar recursion formula can be obtained for integrals over the unitary group also. To that end one should consider monomials in the real and imaginary parts of the matrix elements. Though the derivation along the lines of the orthogonal case is rather straightforward, the resulting expressions are much more involved. It seems that the simple result for the case $R=1$ is only an exception. More work is clearly necessary to clarify the situation in this case.

(Received 21 December 2001; accepted for publication 26 February 2002)

A generalization of the Weierstrass system of equations corresponding to CP^2 harmonic maps is presented. This generalization allows us to study two-dimensional surfaces immersed in a flat space R^8 with Euclidean metric. We use this system to suggest a possible geometrical interpretation of CP^2 harmonic maps.
 [DOI: 10.1063/1.1473874]

I. INTRODUCTION

Sigma models in two spatial dimensions are integrable and have been studied for a variety of reasons. They are low dimensional analogs of four-dimensional Yang–Mills theories which play a pivotal role in particle physics, they arise in some areas of condensed-matter physics, etc., and they are also interesting from a purely mathematical point of view. Moreover, they arise naturally in differential geometry in the investigation of immersion and deformations of surfaces.

Of course, there are many classes of σ models; particularly important amongst them are the so-called CP^{N-1} σ models. These models, all, possess topological properties and, as such, lead to the appearance of ''topological solitons.''

The models are a generalization of the, perhaps simplest, σ model, namely the S^2 model—also called the vector $SO(3)$ model. The CP^{N-1} models involve maps from R^2, or S^2 if one wants to have nontrivial topology, to CP^{N-1}. It is easiest to define them in terms of the Lagrangian density[1]

$$L=\tfrac{1}{4}(D_\mu z)^\dagger \cdot D_\mu z, \tag{1.1}$$

where z is a vector field of N components, $z=(z^1,\ldots,z^N)$, which satisfies

$$z^\dagger \cdot z=1. \tag{1.2}$$

The covariant derivative D_μ acts on $z:S^2\to CP^{N-1}$ according to

$$D_\mu z=\partial_\mu z-z(z^\dagger \cdot \partial_\mu z). \tag{1.3}$$

Here $\mu=1,2$, of course, and denotes the space coordinates x and y.

The total Lagrangian is given by

$$\mathcal{L}=\int L\, \mathrm{d}x\, \mathrm{d}y \tag{1.4}$$

and, if the model is defined over S^2, we require that $\mathcal{L}$ is finite.

[b)]Electronic mail: W.J.Zakrzewski@durham.ac.uk

As is well known, the CP^1 sigma model ($N=2$) can be equivalently described in terms of a three-component real vector field $\vec{\phi}$ defined by

$$\vec{\phi}=z^{\dagger}\vec{\sigma}z, \tag{1.5}$$

where $\vec{\sigma}$ is a vector of Pauli's σ matrices.

Then the Lagrangian density of the CP^1 model (1) becomes

$$L=\partial_{\mu}\vec{\phi}\cdot\partial_{\mu}\vec{\phi} \tag{1.6}$$

together with the constraint

$$\vec{\phi}\cdot\vec{\phi}=1, \tag{1.7}$$

i.e., $\vec{\phi}$ lies on a unit sphere S^2.

For a model defined over S^2 all harmonic maps, i.e., solutions of the Euler Lagrange equations which follow from (1.4) are well known.[1] They come in three separate classes: those which are holomorphic, those which are antiholomorphic, and the mixed ones. The CP^1 model has only holomorphic and antiholomorphic harmonic maps but for CP^N $N\geqslant 2$ there are also mixed maps. These solutions have very different properties, e.g., holomorphic solutions are stable, as they are minima of the total Lagrangian, while the mixed solutions are not, as they are only saddle points.

Recently, there has been a lot of interest in relating CP^1 maps to the solutions of the Weierstrass problem.[2–4]

In this case, according to Ref. 4 one considers a set of first-order equations for complex fields ϕ and ψ of ζ and $\overline{\zeta}$, given by

$$\partial\psi=p\phi, \quad \overline{\partial}\phi=-p\psi, \quad p=|\phi|^2+|\psi|^2 \tag{1.8}$$

where

$$\partial=\frac{\partial}{\partial(x+iy)}=\frac{\partial}{\partial\zeta}, \quad \overline{\partial}=\frac{\partial}{\partial\overline{\zeta}}. \tag{1.9}$$

From the Weierstrass system (1.8) one constructs a geometric coordinate system of three real variables X_i, $i=1,2,3$ and, treating $X_i(x,y)$ as a map of R^2 into R^3 discusses the geometry of these surfaces.

In this paper we address the question of the generalization of these ideas to higher CP^N. Thus we consider the case of CP^2. What is the corresponding Weierstrass system and how does one construct the corresponding real quantities X_i? In Sec. II we collect together various results on the CP^1 system. We then discuss various formulations of the CP^2 model and recall some of its solutions. Next we present our generalized Weierstrass system and discuss some of its properties. We then present our ideas on how to construct a set of real-valued functions $X_i(x,y)$ and show how they describe the geometry of surfaces.

II. CP^1 MODEL

A. General properties

For the CP^1 sigma model it is convenient to introduce

$$W=\frac{z_2}{z_1}=\frac{\phi^1+i\phi^2}{1+\phi^3}. \tag{2.1}$$

In terms of W the Lagrangian becomes

$$\mathcal{L}=\int \frac{|\partial W|^2+|\partial \overline{W}|^2}{(1+|W|^2)^2}\,\mathrm{d}\zeta\,\mathrm{d}\overline{\zeta} \tag{2.2}$$

and its Euler Lagrange equations take the form

$$\partial\overline{\partial} W-2\overline{W}\frac{\partial W\overline{\partial} W}{|W|^2+1}=0. \tag{2.3}$$

In Ref. 3 it was shown that the relation between CP^1 maps W and the ϕ, ψ fields of the Weierstrass problem is given by (up to an overall multiplication of ϕ and ψ by a factor -1)

$$\psi=W\frac{(\overline{\partial W})^{1/2}}{1+|W|^2},\quad \phi=\frac{(\partial W)^{1/2}}{1+|W|^2}, \tag{2.4}$$

where

$$W=\frac{\psi}{\overline{\phi}}. \tag{2.5}$$

As is well known[5] the CP^1 equations can be written as a compatibility condition for a set of two linear spectral equations for a two component auxiliary vector Ψ,

$$\partial\Psi=\frac{2}{1+\lambda}[\partial P,P]\Psi,\quad \overline{\partial}\Psi=\frac{2}{1-\lambda}[\overline{\partial}P,P]\Psi, \tag{2.6}$$

where the 2 by 2 matrix P is a projector given by

$$P=\frac{1}{A}\begin{pmatrix}1 & \overline{W}\\ W & |W|^2\end{pmatrix},\quad A=1+|W|^2. \tag{2.7}$$

The compatibility conditions for (2.6) are, clearly,

$$[\partial\overline{\partial}P,\ P]=0 \tag{2.8}$$

which, as can be easily checked, are equivalent to (2.3).

Note that (2.8) can be written in the form of a conservation law

$$\partial[\overline{\partial}P,P]+\overline{\partial}[\partial P,P]=0 \tag{2.9}$$

or, equivalently, using the traceless matrices K and M,

$$\partial K+\overline{\partial}M=0, \tag{2.10}$$

where the matrices K and M are given by

$$K=\frac{1}{A^2}\begin{pmatrix}\overline{W\partial W}-W\overline{\partial W} & \overline{\partial W}+\overline{W}^2\overline{\partial}W\\ -\overline{\partial}W-W^2\overline{\partial W} & W\overline{\partial W}-\overline{W\partial W}\end{pmatrix} \tag{2.11}$$

and

$$M=\frac{1}{A^2}\begin{pmatrix}\overline{W}\partial W-W\partial\overline{W} & \partial\overline{W}+\overline{W}^2\partial W\\ -\partial W-W^2\partial\overline{W} & W\partial\overline{W}-\overline{W}\partial W\end{pmatrix}. \tag{2.12}$$

To proceed further it is worth recalling the existence of various quantities of the CP^{N-1} model which are holomorphic.[1] One of them is

$$T=(\overline{D}z)^{\dagger}\cdot Dz, \tag{2.13}$$

where $D=\frac{1}{2}(D_1-iD_2)$ and $\overline{D}=\frac{1}{2}(D_1+iD_2)$ denote the covariant derivative (1.3) with respect to $\zeta=x+iy$. As is easy to check, T satisfies

$$\overline{\partial}T=0 \tag{2.14}$$

and so is a function of $\zeta=x+iy$ only.

In the CP^1 case, the function T expressed in terms of W is given by

$$T=2\frac{\partial W\partial\overline{W}}{(1+|W|^2)^2}. \tag{2.15}$$

In fact, for the solutions of (2.3) which describe fields defined on S^2, W is any holomorphic or antiholomorphic function and so $T=0$.

B. Weierstrass system

Let us introduce the complex fields ϕ and ψ by (2.4) and (2.5). In Refs. 3 and 4 it was shown that

$$\partial\psi=p\phi,\quad \overline{\partial}\phi=-p\psi, \tag{2.16}$$

where

$$p=|\phi|^2+|\psi|^2=\frac{(\partial W\overline{\partial W})^{1/2}}{1+|W|^2}. \tag{2.17}$$

Now we reexpress the quantity T in terms of them using (2.4) we get

$$T=\overline{\psi}\partial\phi-\phi\partial\overline{\psi}. \tag{2.18}$$

Moreover, we also have

$$p=A|\phi|^2,\quad A=1+|W|^2 \tag{2.19}$$

and we can express the first derivatives of W in terms of ψ and ϕ:

$$\partial W=A^2\phi^2,\quad \overline{\partial}W=-\overline{T}(\overline{\phi})^{-2}. \tag{2.20}$$

This allows us to derive the explicit form of matrices K and M in terms of ϕ and ψ. So, we have

$$K=\begin{pmatrix} -(\psi\overline{\phi}+\overline{R\psi}\phi) & \overline{\phi}^2-\overline{R\psi}^2 \\ -\psi^2+\overline{R}\phi^2 & \psi\overline{\phi}+\overline{R\psi}\phi \end{pmatrix} \tag{2.21}$$

and

$$M=\begin{pmatrix} (\overline{\psi}\phi+R\psi\overline{\phi}) & \overline{\psi}^2-R\overline{\phi}^2 \\ -\phi^2+R\psi^2 & -(\overline{\psi}\phi+R\psi\overline{\phi}), \end{pmatrix} \tag{2.22}$$

where we have introduced the following notation:

$$R=\frac{T}{p^2}.$$

As a consequence of (2.9) we find that the system (2.16) possesses, at least, three further conservation laws

$$\begin{aligned}
&-\partial(\psi\overline{\phi}+\overline{R\psi}\phi)+\overline{\partial}(\overline{\psi}\phi+R\psi\overline{\phi})=0,\\
&\partial(-\psi^2+\overline{R}\phi^2)+\overline{\partial}(-\phi^2+R\psi^2)=0,\\
&\partial(\overline{\phi}^2-\overline{R\psi^2})+\overline{\partial}(\overline{\psi}^2-R\overline{\phi}^2)=0.
\end{aligned} \tag{2.23}$$

These formulas differ slightly from the conservation laws given in Ref. 4, as they contain additional terms involving R. However, if we put $R=0$ in (2.23) we recover the expressions of Ref. 4.

As a result of conservation laws (2.23) we can introduce three real-valued functions $X_i(\zeta,\overline{\zeta})$, $i=1,2,3$ given by

$$\begin{aligned}
X_1&=i\int_\gamma [\overline{\psi}^2+\phi^2-R(\psi^2+\overline{\phi}^2)]\mathrm{d}\zeta-[\psi^2+\overline{\phi}^2-\overline{R}(\overline{\psi}^2+\phi^2)]\mathrm{d}\overline{\zeta},\\
X_2&=\int_\gamma [\overline{\psi}^2-\phi^2+R(\psi^2-\overline{\phi}^2)]\mathrm{d}\zeta+[\psi^2-\overline{\phi}^2+\overline{R}(\overline{\psi}^2-\phi^2)]\mathrm{d}\overline{\zeta},\\
X_3&=-2\int_\gamma [\overline{\psi}\phi+R\psi\overline{\phi}]\mathrm{d}\zeta+[\psi\overline{\phi}+\overline{R\psi}\phi]\mathrm{d}\overline{\zeta},
\end{aligned} \tag{2.24}$$

where γ is any curve from a fixed point to ζ.

The conservation laws (2.23) guarantee that quantities X_i do not depend on the choice of the curve γ in the complex plane C (but only its end points). This is because X_i can be rewritten as

$$X_i=\int_\gamma F_i(\zeta,\overline{\zeta})\mathrm{d}\zeta+\overline{F}_i(\zeta,\overline{\zeta})\mathrm{d}\overline{\zeta},\quad i=1,2,3, \tag{2.25}$$

where F_i satisfy the following conditions:

$$\overline{\partial}F_i=\partial\overline{F}_i, \tag{2.26}$$

which shows that the integrands are total derivatives.

The functions $X_i(\zeta,\overline{\zeta})$ can be considered as components of a radius vector

$$\vec{r}(\zeta,\overline{\zeta})=(X_1(\zeta,\overline{\zeta}),X_2(\zeta,\overline{\zeta}),X_3(\zeta,\overline{\zeta})) \tag{2.27}$$

of an orientable, simply connected, surface (locally parametrized by ζ and $\overline{\zeta}$ immersed in R^3).

This allows us to calculate the tangent vectors to the surface, i.e.,

$$\partial\vec{r}=(i[\overline{\psi}^2+\phi^2-R(\psi^2+\overline{\phi}^2)],[\overline{\psi}^2-\phi^2+R(\psi^2-\overline{\phi}^2)],-2(\overline{\psi}\phi+R\psi\overline{\phi})) \tag{2.28}$$

and

$$\overline{\partial}\vec{r}=(-i[\psi^2+\overline{\phi}^2-\overline{R}(\overline{\psi}^2+\phi^2)],[\psi^2-\overline{\phi}^2+\overline{R}(\overline{\psi}^2-\phi^2)],-2(\psi\overline{\phi}+\overline{R\psi}\phi)). \tag{2.29}$$

These expressions allow us to calculate the induced metric. We find the following expressions for the components of the induced metric (written in holomorphic components):

$$g_{\zeta\zeta}=(\partial\vec{r},\partial\vec{r})=4Rp^2, \quad g_{\bar{\zeta}\bar{\zeta}}=(\bar{\partial}\vec{r},\bar{\partial}\vec{r})=4\bar{R}p^2 \tag{2.30}$$

and

$$g_{\zeta\bar{\zeta}}=(\partial\vec{r},\bar{\partial}\vec{r})=2(p^2+|R|^2p^2). \tag{2.31}$$

Hence, for the harmonic maps, $R=0$ and the only nonvanishing component of the metric is $g_{\zeta\bar{\zeta}}=2p^2$. In this case solutions of the system (2.16) are represented by expression (2.4), where $W(\zeta)$ is an arbitrary holomorphic function. As is well known[1] finiteness of the energy restricts $W(\zeta)$ to being a rational function. Geometrically, such functions parametrize an immersed sphere $S^2\in R^3$.

III. CP^2 MODEL

A. General properties

Now we consider a more general situation when the Lagrangian is given by (1.1) with a three-component vector $z=(z_1,z_2,z_3)$ (z_i, which satisfies $\bar{z}\cdot z=\Sigma_i \bar{z}_i z_i=1$). We can define two complex fields W_i, $i=1,2$ through

$$W_1=\frac{z_1}{z_3}, \quad W_2=\frac{z_2}{z_3} \tag{3.1}$$

and find that the Euler Lagrange equations take the form[6]

$$\begin{aligned}
&\bar{\partial}\partial W_1-\frac{2\bar{W}_1}{A}\partial W_1\bar{\partial}W_1-\frac{\bar{W}_2}{A}(\partial W_1\bar{\partial}W_2+\bar{\partial}W_1\partial W_2)=0,\\
&\bar{\partial}\partial W_2-\frac{2\bar{W}_2}{A}\partial W_2\bar{\partial}W_2-\frac{\bar{W}_1}{A}(\partial W_1\bar{\partial}W_2+\bar{\partial}W_1\partial W_2)=0,
\end{aligned} \tag{3.2}$$

and their respective complex conjugate equations and where

$$A=1+|W_1|^2+|W_2|^2.$$

Clearly, when, say, $W_2=0$ (i.e., $z_2=0$) the model, and its equations, reduce to the CP^1 case.

Like in the CP^1 case we still have an auxiliary spectral problem given by (2.6) but this time the auxiliary vector Φ has three components and the 3×3 projector P is given by

$$P=\frac{1}{A}\begin{pmatrix} 1 & \bar{W}_1 & \bar{W}_2 \\ W_1 & |W_1|^2 & W_1\bar{W}_2 \\ W_2 & \bar{W}_1W_2 & |W_2|^2 \end{pmatrix}. \tag{3.3}$$

As in the CP^1 case the compatibility condition for the two equations in (2.6) gives the equations of motion (2.8) which are equivalent to (3.2). Similarly as in the previous case the system (3.2) possesses a conservation law

$$\partial K+\bar{\partial}M=0 \tag{3.4}$$

with

$$K=[\bar{\partial}P,P], \quad M=[\partial P,P]. \tag{3.5}$$

The explicit forms of 3×3 traceless matrices K and M are rather complicated expressions so we shall not write them explicitly here.

In the CP^2 case the quantity T can be written in terms of W_1 and W_2 as

$$T=\frac{\partial W_1\partial\bar{W}_1+\partial W_2\partial\bar{W}_2+(\bar{W}_1\partial\bar{W}_2-\bar{W}_2\partial\bar{W}_1)(W_1\partial W_2-W_2\partial W_1)}{(1+|W_1|^2+|W_2|^2)^2}. \tag{3.6}$$

All solutions of the CP^2 model are well known. They fall into three classes; those described by analytic fields, i.e., $W_i=W_i(\zeta)$, antianalytic $[W_i=W_i(\bar{\zeta})]$, and mixed ones.

Mixed solutions can be determined from either the holomorphic or the antiholomorphic fields by the following procedure. Take arbitrary holomorphic functions $f_i=f_i(\zeta)$ and define

$$F_{ij}=f_i\partial f_j-f_j\partial f_i, \quad i,j=1,2,3. \tag{3.7}$$

Next, introduce new complex valued functions:

$$g_i=\sum_{k\neq i}\bar{f}_kF_{ki}. \tag{3.8}$$

Then we can determine W_i as ratios of the components of g_i, i.e.,

$$W_1=\frac{g_2}{g_1}, \quad W_2=\frac{g_3}{g_1}. \tag{3.9}$$

Then it can be shown[1] that all mixed solutions correspond to W_i constructed in this way from some $f_i(\zeta)$. An alternative approach starts with antiholomorphic f_i i.e., $f_i=f(\bar{\zeta})$ and constructs g_i in the same way but using $\bar{\partial}$ instead of ∂ in the definition of F_{ij}.

B. Generalized Weierstrass system

Now, according to the discussion of the previous section we can introduce two pairs of complex functions ψ_i,ϕ_i $i=1,2$, which have to satisfy

$$W_i=\frac{\psi_i}{\bar{\phi}_i}, \quad i=1,2. \tag{3.10}$$

The aim of this section is to find a system of first-order equations which is a generalization of (2.16) and which are in a one-to-one correspondence with the equations of the CP^2 sigma model (3.2).

Let us note that a possible set of equations for functions ψ_i and ϕ_i is given by

$$\bar{\partial}\phi_1=-\frac{1}{2}\left[(A+|W_1|^2)\phi_1\bar{\phi}_2\psi_2+(A+1+|W_1|^2)|\phi_1|^2\psi_1+\frac{\phi_2}{\phi_1}\bar{\psi}_2\psi_1^2+(1+|W_2|^2)\frac{|\phi_2|^4}{|\phi_1|^2}\psi_1\right], \tag{3.11}$$

$$\bar{\partial}\phi_2=-\frac{1}{2}\left[(A+|W_2|^2)\phi_2\bar{\phi}_1\psi_1+(A+1+|W_2|^2)|\phi_2|^2\psi_2+\frac{\phi_1}{\phi_2}\bar{\psi}_1\psi_2^2+(1+|W_1|^2)\frac{|\phi_1|^4}{|\phi_2|^2}\psi_2\right], \tag{3.12}$$

$$\partial\psi_1=-\frac{1}{2}\left[(A+|W_1|^2)\phi_2\overline{\psi}_2\psi_1+(A+1+|W_1|^2)|\psi_1|^2\phi_1+\frac{\overline{\phi}_2}{\overline{\phi}_1^2}\overline{\psi}_1\psi_2|\psi_1|^2\right]$$
$$-\frac{1}{2}(1+|W_2|^2)\frac{|\phi_2|^4}{\overline{\phi}_1|\phi_1|^2}|\psi_1|^2+A(1+|W_1|^2)|\phi_1|^2\phi_1+A\phi_2\psi_1\overline{\psi}_2, \tag{3.13}$$

$$\partial\psi_2=-\frac{1}{2}\left[(A+|W_2|^2)\phi_1\overline{\psi}_1\psi_2+(A+1+|W_2|^2)|\psi_2|^2\phi_2+\frac{\overline{\phi}_1}{\overline{\phi}_2^2}\overline{\psi}_2\psi_1|\psi_2|^2\right]$$
$$-\frac{1}{2}(1+|W_1|^2)\frac{|\phi_1|^4}{\overline{\phi}_2|\phi_2|^2}|\psi_2|^2+A(1+|W_2|^2)|\phi_2|^2\phi_2+A\phi_1\psi_2\overline{\psi}_1, \tag{3.14}$$

$$A=1+|W_1|^2+|W_2|^2,$$

and their respective complex conjugate equations, where we can use Eq. (3.10) to express the above-given expressions in terms of ψ_i and ϕ_i's.

It is easy to check that if we put $\phi_2=W_2=0$ then the system of equations (3.11)–(3.14) reduces to Eq. (2.16) and the system (3.2) reduces to the CP^1 model (2.3). These limits characterize some properties of solutions of the system of first-order equations (3.11)–(3.14).

Moreover, it is possible, although somewhat tedious, to show that Eqs. (3.11)–(3.14) are equivalent to (3.2). Thus Eqs. (3.11)–(3.14) can be thought of as being CP^2 analogs of (2.16); [like (2.16) they involve only first derivatives and only $\overline{\partial}\phi_i$ and $\partial\psi_i$ are given].

Here we can use the fact [the generalization of (2.4)] that

$$A^2\phi_1^2=(1+|W_2|^2)\partial W_1-W_1\overline{W}_2\partial W_2,$$
$$A^2\phi_2^2=(1+|W_1|^2)\partial W_2-W_2\overline{W}_1\partial W_1. \tag{3.15}$$

Next we address the question of the existence of real valued functions X_i's. To construct them we note that we can exploit the matrices K and M given by (3.4) and (3.5). Then the CP^2 analog of matrices (2.21) and (2.22) becomes

$$K=K_1-\frac{1}{A^2}K_2, \tag{3.16}$$

where

$$K_1=\begin{pmatrix} -(\psi_1\overline{\phi}_1+\psi_2\overline{\phi}_2) & \overline{\phi}_1^2 & \overline{\phi}_2^2 \\ -W_1(\psi_1\overline{\phi}_1+\psi_2\overline{\phi}_2) & \psi_1\overline{\phi}_1 & \dfrac{\psi_1}{\overline{\phi}_1}\overline{\phi}_2^2 \\ -W_2(\psi_1\overline{\phi}_1+\psi_2\overline{\phi}_2) & \dfrac{\psi_2}{\overline{\phi}_2}\overline{\phi}_1^2 & \psi_2\overline{\phi}_2 \end{pmatrix} \tag{3.17}$$

and

$$K_2=\begin{pmatrix} -(\overline{W}_1\overline{\partial}W_1+\overline{W}_2\overline{\partial}W_2) & -\overline{W}_1(\overline{W}_1\overline{\partial}W_1+\overline{W}_2\overline{\partial}W_2) & -\overline{W}_2(\overline{W}_1\overline{\partial}W_1+\overline{W}_2\overline{\partial}W_2) \\ \Phi_1 & \overline{W}_1\Phi_1 & \overline{W}_2\Phi_1 \\ \Phi_2 & \overline{W}_1\Phi_2 & \overline{W}_2\Phi_2 \end{pmatrix}, \tag{3.18}$$

where we have defined the following expressions:

$$\begin{aligned} \Phi_1&=(1+|W_2|^2)\overline{\partial}W_1-W_1\overline{W}_2\overline{\partial}W_2, \\ \Phi_2&=(1+|W_1|^2)\overline{\partial}W_2-W_2\overline{W}_1\overline{\partial}W_1 \end{aligned} \tag{3.19}$$

in order to abbreviate expressions (3.16) and (3.18).

Similarily, matrix M is given by

$$M=M_1-\frac{1}{A^2}M_2, \tag{3.20}$$

where

$$M_1=\begin{pmatrix} (\overline{\psi}_1\phi_1+\overline{\psi}_2\phi_2) & \overline{W}_1(\overline{\psi}_1\phi_1+\overline{\psi}_2\phi_2) & +\overline{W}_2(\overline{\psi}_1\phi_1+\overline{\psi}_2\phi_2) \\ -\phi_1^2 & -\overline{\psi}_1\phi_1 & -\dfrac{\overline{\psi}_2}{\phi_2}\phi_1^2 \\ -\phi_2^2 & -\dfrac{\overline{\psi}_1}{\phi_1}\phi_2^2 & -\overline{\psi}_2\phi_2 \end{pmatrix} \tag{3.21}$$

and

$$M_2=\begin{pmatrix} -(\overline{W}_1\overline{\partial}W_1+\overline{W}_2\overline{\partial}W_2) & \overline{\Phi}_1 & \overline{\Phi}_2 \\ -W_1(W_1\partial\overline{W}_1+W_2\partial\overline{W}_2) & W_1\overline{\Phi}_1 & W_1\overline{\Phi}_2 \\ -W_2(W_1\partial\overline{W}_1+W_2\partial\overline{W}_2) & W_2\overline{\Phi}_1 & W_2\overline{\Phi}_2 \end{pmatrix}. \tag{3.22}$$

Note that matrices K_2 and M_2 involve expressions which involve $\overline{\partial}W_i$ which are not known. In the holomorphic case $W=W_i(\zeta)$ and so $K_2=M_2=0$. In fact, this is also true in general; when the equations of motion are satisfied we can set $M_2=K_2=0$ and the conservation laws are still satisfied. Hence, in our search of real-valued functions X_i we can restrict our attention to only K_1 and M_1.

As both matrices (K_1 and M_1) are traceless we can use them to define eight new conservation laws. These in turn allow us to define nine real quantities $X_i(\zeta,\overline{\zeta})$, eight of which are linearly independent. X_i $i=1,2,3$ are constructed by taking diagonal entries of matrices M and K:

$$\begin{aligned} X_1&=-\int_\gamma[\overline{\psi}_1\phi_1+\overline{\psi}_2\phi_2]\mathrm{d}\zeta+[\psi_1\overline{\phi}_1+\psi_2\overline{\phi}_2]\mathrm{d}\overline{\zeta}, \\ X_2&=\int_\gamma\overline{\psi}_1\phi_1\mathrm{d}\zeta+\psi_1\overline{\phi}_1\,\mathrm{d}\overline{\zeta}, \\ X_3&=\int_\gamma\overline{\psi}_2\phi_2\,\mathrm{d}\zeta+\psi_2\overline{\phi}_2\,\mathrm{d}\overline{\zeta}, \end{aligned} \tag{3.23}$$

which satisfy

$$X_1+X_2+X_3=0. \tag{3.24}$$

The off-diagonal entries of matrices K and M when combined with the property that $K^{\dagger}=-M$ give us a further six real quantities X_i, $i=4,...,9$ i.e.,

$$X_4+iX_5=\int_\gamma\left[-\mu\phi_1^2+\overline{\mu}\left(\overline{\psi_1^2}+\overline{\psi_1}\,\overline{\psi_2}\,\frac{\phi_2}{\phi_1}\right)\right]d\zeta+\left[-\overline{\mu}\,\overline{\phi_1^2}+\mu\left(\psi_1^2+\psi_1\psi_2\frac{\overline{\phi_2}}{\overline{\phi_1}}\right)\right]d\overline{\zeta},$$

$$X_6+iX_7=\int_\gamma\left[-\nu\phi_2^2+\overline{\nu}\left(\overline{\psi_2^2}+\overline{\psi_1}\,\overline{\psi_2}\,\frac{\phi_1}{\phi_2}\right)\right]d\zeta+\left[-\overline{\nu}\,\overline{\phi_2^2}+\nu\left(\psi_2^2+\psi_1\psi_2\frac{\overline{\phi_1}}{\overline{\phi_2}}\right)\right]d\overline{\zeta}, \tag{3.25}$$

$$X_8+iX_9=-\int_\gamma\left[\alpha\phi_2^2\frac{\overline{\psi_1}}{\phi_1}+\overline{\alpha}\phi_1^2\frac{\overline{\psi_2}}{\phi_2}\right]d\zeta+\left[\overline{\alpha}\,\overline{\phi_2^2}\frac{\psi_1}{\overline{\phi_1}}+\alpha\,\overline{\phi_1^2}\frac{\psi_2}{\overline{\phi_2}}\right]d\overline{\zeta}.$$

Here μ, ν, and α are arbitrary constants. As in the CP^1 case the integrals in the definition of X_i do not depend on the trajectory of the curve γ (but are only on its end point ζ) in C since conditions (2.26) hold. So we can then consider function X_i as components of an eight-dimensional vector $\vec{r}$ and use it to construct and investigate two-dimensional surfaces immersed in R^8. Thus, putting it all together, we see that if the complex functions ψ_i and ϕ_i, $i=1,2$ are solutions of the system of first-order equations (3.11)–(3.14), the generalized Weierstrass formulas given by (3.23)–(3.25) determine the conformal immersion of a surface into R^8.

To see this we take $\mu=\nu=\alpha=(1+i)/2$ and consider X_i, $i=2,...,9$ as components of a radius vector in R^8,

$$\vec{r}(\xi,\overline{\xi})=(X_2,X_3,\ldots,X_9). \tag{3.26}$$

This allows us to define the induced metric [by expressions like (2.30) and (2.31)]. We find that only $g_{\xi\overline{\xi}}\neq 0$ and, in fact, is given by

$$g_{\xi\overline{\xi}}=\frac{|\partial W_1|^2+|\partial W_2|^2+|W_2\partial W_1-W_1\partial W_2|^2}{(1+|W_1|^2+|W_2|^2)^2}. \tag{3.27}$$

Having found the metric we can now study various geometrical aspects of our surfaces. This will be discussed in more detail in future work.

IV. CONCLUSIONS AND FURTHER COMMENTS

In this paper we have shown how to generalize the old ideas of Weierstrass from the CP^1 to the CP^2 case. We have found that the corresponding first-order equations have much more complicated form. We have also started discussing the geometry of the associated surfaces leaving details to a future publication. We are currently looking at the generalization of our results to CP^N.

ACKNOWLEDGMENTS

This work was started when one of the authors (W.J.Z.) visited the CRM, Université de Montréal in March 2000. W.J.Z. thanks the LMS and P. Winternitz for the support of his stay at the CRM. The work was continued when W.J.Z. spent a sabbatical term at the Center for Theoretical Physics, MIT and when A.M.G. visited the University of Durham. W.J.Z. would like to

thank theCenter for the support of his stay at MIT and its hospitality. A.M.G. would like to thank the University of Durham for the award of Alan Richards fellowship to him that allowed him to spend a term in Durham. Partial support for A.M.G.'s work was also provided by a grant from NSERC of Canada.

(Received 17 October 2001; accepted for publication 19 February 2002)

Expansion of higher transcendental functions in a small parameter are needed in many areas of science. For certain classes of functions this can be achieved by algebraic means. These algebraic tools are based on nested sums and can be formulated as algorithms suitable for an implementation on a computer. Examples such as expansions of generalized hypergeometric functions or Appell functions are discussed. As a further application, we give the general solution of a two-loop integral, the so-called C-topology, in terms of multiple nested sums. In addition, we discuss some important properties of nested sums, in particular we show that they satisfy a Hopf algebra. © *2002 American Institute of Physics.*

I. INTRODUCTION

The expansion of higher transcendental functions[1,2] is a common problem occurring in many areas of science. It is of particular interest in particle physics in the calculation of higher order radiative corrections to scattering amplitudes. There, higher transcendental functions occur frequently in formal solutions for specific loop integrals. The necessary expansions of these functions are in general a highly nontrivial task. This is particularly true if the expansions are required to a very high order.

In calculations of higher order radiative corrections, classical polylogarithms,[3] as well as Nielsen's generalized polylogarithms[4] appear. However, this set of functions will not suffice, if the number of loops grows, or if several different scales are involved in the problem. Several extensions of this class of functions to multiple polylogarithms have been discussed recently.[5–8]

It is the aim of this paper to perform a systematic study of multiple nested sums appearing in the expansion of higher transcendental functions around integer values of their indices. To that end, we define so-called Z-sums, study their algebraic properties, and discuss their relation to the multiple polylogarithms introduced in the literature.[5–8] We give algorithms to solve these multiple nested sums to any order in the expansion parameter ϵ in terms of a given basis in Z-sums. All algorithms can be readily implemented on a computer. The Z-sums can be considered as certain generalizations of Euler–Zagier sums[9,10] or of harmonic sums[11–13] involving multiple ratios of scales. The latter are known in physics since the calculation of higher order Mellin moments of the deep-inelastic structure functions.[11,14–16]

At the same time, our results allow us to investigate higher loop multiscale integrals occuring for instance in pertubative corrections to four-particle scattering amplitudes. These integrals have received great attention in recent years, mainly motivated by calculations of the next-to-next-to-leading order corrections to amplitudes for Bhabha scattering,[17] for $pp \to 2$ jets[18–20] for $pp \to \gamma\gamma$,[21] and for light-by-light scattering.[22]

The relevant master integrals at two loops with four external legs have been calculated using a variety of techniques. Analytic results were obtained either with the help of Mellin–Barnes representations[23,24] or with differential equations.[8,25] Numerical results were obtained by a numerical evaluation of the coefficients of the ϵ-expansion.[26,27] Here, we want to advocate a different point of view based on multiple nested sums. As a new result and to illustrate our approach, we discuss a specific two-loop integral, the so-called C-topology with one leg offshell, which can be reduced for arbitrary powers of the propagators and arbitrary dimensions to the aforementioned sums. This is useful for the calculation of the two-loop amplitude for $e^+e^- \to 3$ jets. Some of the techniques presented here have already been used in a recent calculation with massive fermions.[28] In addition, there exists a wide variety of related literature on higher transcendental functions occurring in loop integrals and we can only mention a few of them here.[29–35]

This paper is organized as follows. In Sec. II we introduce nested sums, show that they satisfy an algebra and summarize some important special cases of our definitions. Section III contains the main results of this paper, in particular the algorithms for solving certain classes of nested sums. In Sec. IV we give some examples for expansions of generalized hypergeometric functions, Appell functions, and the Kampé de Fériet function. As an application to higher loop multiscale integrals, we discuss the C-topology in Sec. IV D. In Appendix A we show that the algebraic structure of nested sums forms a Hopf algebra.[36,37] In Appendix B we briefly review the multiple polylogarithms of Goncharov.[5]

II. DEFINITION AND PROPERTIES OF NESTED SUMS

We define the Z-sums by

$$\begin{aligned} Z(n) &= \begin{cases} 1, & n \geqslant 0 \\ 0, & n < 0, \end{cases} \\ Z(n;m_1,\ldots,m_k;x_1,\ldots,x_k) &= \sum_{i=1}^{n} \frac{x_1^i}{i^{m_1}} Z(i-1;m_2,\ldots,m_k;x_2,\ldots,x_k), \end{aligned} \tag{1}$$

k is called the depth, $w = m_1 + \ldots + m_k$ the weight. An equivalent definition is given by

$$Z(n;m_1,\ldots,m_k;x_1,\ldots,x_k) = \sum_{n \geqslant i_1 > i_2 > \cdots > i_k > 0} \frac{x_1^{i_1}}{i_1^{m_1}} \cdots \frac{x_k^{i_k}}{i_k^{m_k}}. \tag{2}$$

In a similar way we define the S-sums by

$$\begin{aligned} S(n) &= \begin{cases} 1, & n > 0 \\ 0, & n \leqslant 0, \end{cases} \\ S(n;m_1,\ldots,m_k;x_1,\ldots,x_k) &= \sum_{i=1}^{n} \frac{x_1^i}{i^{m_1}} S(i;m_2,\ldots,m_k;x_2,\ldots,x_k). \end{aligned} \tag{3}$$

Once again an equivalent representation is given by

$$S(n;m_1,\ldots,m_k;x_1,\ldots,x_k) = \sum_{n \geqslant i_1 \geqslant i_2 \geqslant \cdots \geqslant i_k \geqslant 1} \frac{x_1^{i_1}}{i_1^{m_1}} \cdots \frac{x_k^{i_k}}{i_k^{m_k}}. \tag{4}$$

The S-sums are closely related to the Z-sums, the difference being the upper summation boundary for the nested sums: $(i-1)$ for Z-sums, i for S-sums. We introduce both Z-sums and S-sums, since some properties are more naturally expressed in terms of Z-sums while others are more naturally expressed in terms of S-sums. We can easily convert from the notation with Z-sums to the notation with S-sums and vice versa:

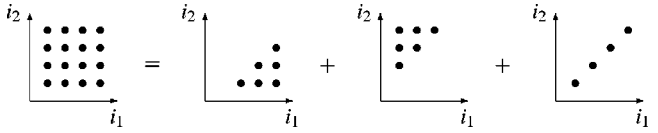

FIG. 1. Sketch of the proof for the multiplication of Z-sums. The sum over the square is replaced by the sum over the three regions on the right-hand side.

$$
\begin{aligned}
S(n;m_1,\ldots;x_1,\ldots)&=\sum_{i_1=1}^{n}\frac{x_1^{i_1}}{i_1^{m_1}}\sum_{i_2=1}^{i_1-1}\frac{x_2^{i_2}}{i_2^{m_2}}S(i_2;m_3,\ldots;x_3,\ldots)\\
&\quad+S(n;m_1+m_2,m_3,\ldots;x_1x_2,x_3,\ldots),\\
Z(n;m_1,\ldots;x_1,\ldots)&=\sum_{i_1=1}^{n}\frac{x_1^{i_1}}{i_1^{m_1}}\sum_{i_2=1}^{i_1}\frac{x_2^{i_2}}{i_2^{m_2}}Z(i_2-1;m_3,\ldots;x_3,\ldots)\\
&\quad-Z(n;m_1+m_2,m_3,\ldots;x_1x_2,x_3,\ldots).
\end{aligned}
\tag{5}
$$

The first formula allows to convert recursively an S-sum into a Z-sum. The second formula yields the conversion from a Z-sum to a S-sum. For example in terms of S-sums the Z-sum $Z(n;m_1,m_2,m_3,x_1,x_2,x_3)$ reads

$$
\begin{aligned}
Z(n;m_1,m_2,m_3,x_1,x_2,x_3)&=S(n;m_1,m_2,m_3,x_1,x_2,x_3)-S(n;m_1+m_2,m_3,x_1x_2,x_3)\\
&\quad-S(n;m_1,m_2+m_3,x_1,x_2x_3)+S(n;m_1+m_2+m_3,x_1x_2x_3).
\end{aligned}
\tag{6}
$$

Furthermore the Z-sums and the S-sums obey an algebra. A product of two Z-sums with the same upper summation limit can be written in terms of single Z-sums. A straightforward generalization of the results given by Vermaseren on the multiplication of harmonic sums yields[12]

$$
\begin{aligned}
&Z(n;m_1,\ldots,m_k;x_1,\ldots,x_k)Z(n;m_1',\ldots,m_l';x_1',\ldots,x_l')\\
&\quad=\sum_{i_1=1}^{n}\frac{x_1^{i_1}}{i_1^{m_1}}Z(i_1-1;m_2,\ldots,m_k;x_2,\ldots,x_k)Z(i_1-1;m_1',\ldots,m_l';x_1',\ldots,x_l')\\
&\quad+\sum_{i_2=1}^{n}\frac{x_1'^{i_2}}{i_2^{m_1'}}Z(i_2-1;m_1,\ldots,m_k;x_1,\ldots,x_k)Z(i_2-1;m_2',\ldots,m_l';x_2',\ldots,x_l')\\
&\quad+\sum_{i=1}^{n}\frac{(x_1x_1')^i}{i^{m_1+m_1'}}Z(i-1;m_2,\ldots,m_k;x_2,\ldots,x_k)Z(i-1;m_2',\ldots,m_l';x_2',\ldots,x_l').
\end{aligned}
\tag{7}
$$

Recursive application of Eq. (7) leads to single Z-sums. The proof of Eq. (7) follows immediately from

$$
\sum_{i=1}^{n}\sum_{j=1}^{n}a_{ij}=\sum_{i=1}^{n}\sum_{j=1}^{i-1}a_{ij}+\sum_{j=1}^{n}\sum_{i=1}^{j-1}a_{ij}+\sum_{i=1}^{n}a_{ii},
\tag{8}
$$

which is sketched in Fig. 1. Note that Eq. (7) directly translates into an algorithm for the multiplication of two Z-sums. Details on the implementation of this algorithm on a computer can be found for example in Ref. 12. We give an example for the product of two Z-sums:

$$Z(n;m_1,m_2;x_1,x_2)\times Z(n;m_3;x_3)=Z(n;m_1,m_2,m_3;x_1,x_2,x_3)+Z(n;m_1,m_3,m_2;x_1,x_3,x_2)$$
$$+Z(n;m_3,m_1,m_2;x_3,x_1,x_2)+Z(n;m_1,m_2+m_3;x_1,x_2x_3)$$
$$+Z(n;m_1+m_3,m_2;x_1x_3,x_2). \tag{9}$$

Note that the product conserves the weight. The Z-sums form actually a Hopf algebra. More details can be found in Appendix A.

The S-sums also obey an algebra. The basic formula reads

$$S(n;m_1,\ldots,m_k;x_1,\ldots,x_k)\times S(n;m_1',\ldots,m_l';x_1',\ldots,x_l')$$
$$=\sum_{i_1=1}^{n}\frac{x_1^{i_1}}{i_1^{m_1}}S(i_1;m_2,\ldots,m_k;x_2,\ldots,x_k)S(i_1;m_1',\ldots,m_l';x_1',\ldots,x_l')$$
$$+\sum_{i_2=1}^{n}\frac{x_1'^{i_2}}{i_2^{m_1'}}S(i_2;m_1,\ldots,m_k;x_1,\ldots,x_k)S(i_2;m_2',\ldots,m_l';x_2',\ldots,x_l')$$
$$-\sum_{i=1}^{n}\frac{(x_1x_1')^i}{i^{m_1+m_1'}}S(i;m_2,\ldots,m_k;x_2,\ldots,x_k)S(i;m_2',\ldots,m_l';x_2',\ldots,x_l'). \tag{10}$$

Note the minus sign in front of the last term compared to the corresponding formula for Z-sums.

Special cases. Z-sums and S-sums are generalizations of more known objects. We give here an overview of the most important special cases.

For $n=\infty$ the Z-sums are the multiple polylogarithms of Goncharov:[5]

$$Z(\infty;m_1,\ldots,m_k;x_1,\ldots,x_k)=\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1). \tag{11}$$

For $x_1=\cdots=x_k=1$ the definition reduces to the Euler–Zagier sums:[9,10]

$$Z(n;m_1,\ldots,m_k;1,\ldots,1)=Z_{m_1,\ldots,m_k}(n). \tag{12}$$

For $n=\infty$ and $x_1=\cdots=x_k=1$ the sum is a multiple ζ-value:[6]

$$Z(\infty;m_1,\ldots,m_k;1,\ldots,1)=\zeta(m_k,\ldots,m_1). \tag{13}$$

The S-sums reduce for $x_1=\cdots=x_k=1$ (and positive m_i) to harmonic sums:[12]

$$S(n;m_1,\ldots,m_k;1,\ldots,1)=S_{m_1,\ldots,m_k}(n). \tag{14}$$

The multiple polylogarithms of Goncharov contain as the notation already suggests as subsets the classical polylogarithms $\mathrm{Li}_n(x)$,[3] as well as Nielsen's generalized polylogarithms[4]

$$S_{n,p}(x)=\mathrm{Li}_{1,\ldots,1,n+1}(\underbrace{1,\ldots,1}_{p-1},x), \tag{15}$$

the harmonic polylogarithms of Remiddi and Vermaseren[7]

$$H_{m_1,\ldots,m_k}(x)=\mathrm{Li}_{m_k,\ldots,m_1}(\underbrace{1,\ldots,1}_{k-1},x) \tag{16}$$

and the two-dimensional harmonic polylogarithms introduced recently by Gehrmann and Remiddi.[8] The exact connection to the two-dimensional harmonic polylogarithms is shown in

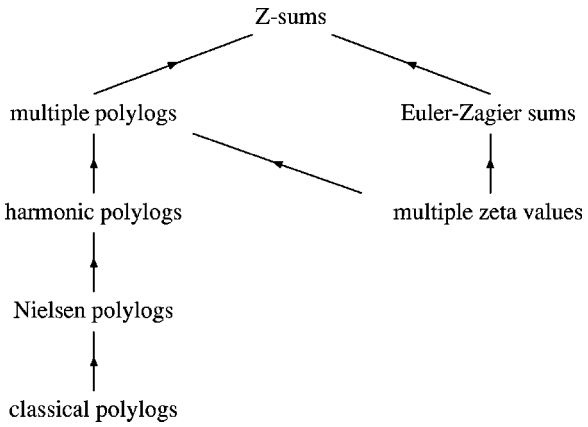

FIG. 2. The inheritance diagram for Z-sums shows the relations between the various special cases.

Appendix B together with a brief review of the multiple polylogarithms of Goncharov. Euler–Zagier sums and harmonic sums occur in the expansion of gamma functions: For positive integers n we have on the positive side

$$\Gamma(n+\epsilon)=\Gamma(1+\epsilon)\Gamma(n)(1+\epsilon Z_1(n-1)+\epsilon^2 Z_{11}(n-1)+\epsilon^3 Z_{111}(n-1) + \cdots +\epsilon^{n-1}Z_{11\ldots1}(n-1)). \tag{17}$$

On the negative side (again $n>0$) we have

$$\Gamma(-n+1+\epsilon)=\frac{\Gamma(1+\epsilon)}{\epsilon}\frac{(-1)^{n-1}}{\Gamma(n)}(1+\epsilon S_1(n-1)+\epsilon^2 S_{11}(n-1)+\epsilon^3 S_{111}(n-1)+\ldots). \tag{18}$$

The usefulness of the Z-sums lies in the fact that they interpolate between Goncharov's multiple polylogarithms and Euler–Zagier sums. In addition, the interpolation is compatible with the algebra structure. Figure 2 summarizes the relations between the various special cases.

III. ALGORITHMS

In this section we give the detailed algorithms which allow one to solve the ϵ-expansion of nested transcendental sums in terms of Z-sums or S-sums defined in Eqs. (1) and (3), respectively. By a transcendental sum we mean a sum over i of finite or infinite summation range involving the following objects.

(1) Fractions of the form

$$\frac{x^i}{(i+c)^m}, \tag{19}$$

where m is an integer, c a non-negative integer, and x a real number.

(2) Ratios of two gamma functions

$$\frac{\Gamma(i+a_1+b_1\epsilon)}{\Gamma(i+a_2+b_2\epsilon)}, \tag{20}$$

where a_1 and a_2 are integers.

(3) Z- and S-sums are also allowed to appear as subsums:

$$Z(i+c-1;m_1,\ldots;x_1,\ldots) \quad \text{or} \quad S(i+c';m_1,\ldots;x_1,\ldots). \tag{21}$$

The offsets c and c' are integers.

(4) We further allow these building blocks to occur also with index $(n-i)$, for example as in

$$S(n-i;m_1',\ldots;x_1',\ldots). \tag{22}$$

Here n denotes the upper summation limit.

(5) In addition binomials

$$\binom{n}{i} = \frac{n!}{i!(n-i)!} \tag{23}$$

may occur.

Some examples of sums which can be constructed from these building blocks are

$$\sum_{i=1}^{n} \frac{x^i}{(i+4)^3} \frac{y^i}{(i+2)^8} \frac{\Gamma(i+1+\epsilon)}{\Gamma(i+2+3\epsilon)}, \quad \sum_{i=1}^{\infty} x^i \frac{\Gamma(i+a\epsilon)}{\Gamma(i+1-c\epsilon)} \frac{\Gamma(i+b\epsilon)}{\Gamma(i+1)}. \tag{24}$$

There are some simplifications, which can be done immediately: Partial fractioning is used to reduce a product for $c_1 \neq c_2$,

$$\frac{x_1^i}{(i+c_1)^{m_1}} \frac{x_2^i}{(i+c_2)^{m_2}} = \frac{1}{c_2-c_1}\left[\frac{x_1^i}{(i+c_1)^{m_1}} \frac{x_2^i}{(i+c_2)^{m_2-1}} - \frac{x_1^i}{(i+c_1)^{m_1-1}} \frac{x_2^i}{(i+c_2)^{m_2}}\right], \tag{25}$$

to terms which involve only the first factor or only the second one, but not both.

Ratios of two gamma functions as in Eq. (20) are first reduced to the form $\Gamma(i+b_1\epsilon)/\Gamma(i+b_2\epsilon)$ with the help of the identity $\Gamma(x+1)=x\Gamma(x)$. They are then expanded in ϵ using Eq. (17). To invert the power series which is obtained in the denominator the formula

$$\begin{aligned}&(1+\epsilon Z_1(n-1)+\epsilon^2 Z_{11}(n-1)+\epsilon^3 Z_{111}(n-1)+\cdots+\epsilon^{n-1} Z_{11\ldots1}(n-1))^{-1}\\ &\quad = 1-\epsilon S_1(n-1)+\epsilon^2 S_{11}(n-1)-\epsilon^3 S_{111}(n-1)+\cdots\end{aligned} \tag{26}$$

is useful to speed up the computation on a computer.

There are also some basic operations involving Z- or S-sums. First of all we can easily convert between the two notations, using Eq. (5). Furthermore we would like to be able to relate the Z-sum $Z(n+c-1,\ldots)$ to $Z(n-1,\ldots)$ or the S-sum $S(n+c,\ldots)$ to $S(n,\ldots)$, where $c>0$ is a fixed number. This can easily be done with the help of the following formulas:

$$\begin{aligned}Z(n+c-1;m_1,\ldots;x_1,\ldots) &= Z(n-1;m_1,\ldots;x_1,\ldots)+\sum_{j=0}^{c-1} x_1^j \frac{x_1^n}{(n+j)^{m_1}}\\ &\quad \times Z(n-1+j;m_2,\ldots;x_2,\ldots),\\ S(n+c;m_1,\ldots;x_1,\ldots) &= S(n;m_1,\ldots;x_1,\ldots)+\sum_{j=1}^{c} x_1^j \frac{x_1^n}{(n+j)^{m_1}} S(n+j;m_2,\ldots;x_2,\ldots).\end{aligned} \tag{27}$$

The Z- or S-sums appearing in the last term have a reduced depth and the problem can be solved recursively.

Another situation which appears quite often is the product of two sums. If the upper summation limits of the two sums differ by some integer c we first synchronize them with the help of Eq. (27). For sums with equal upper summation limit one may use the algebra Eq. (7) or Eq. (10) to convert the product into single sums of higher weight.

Furthermore we can bring Z-sums and S-sums to a standard form by eliminating letters with negative degrees, that is positive powers of i. In general, these cases are easy to handle. We illustrate this for S-sums. We consider $S(n;-m_1,m_2,\ldots;x_1,x_2,\ldots)$, write out the outermost sum of the S-function, and then interchange the order of summation:

$$S(n;-m_1,m_2,\ldots;x_1,x_2,\ldots)=\sum_{i_2=1}^{n}\frac{x_2^{i_2}}{i_2^{m_2}}S(i_2;m_3,\ldots)\sum_{i_1=i_2}^{n}i_1^{m_1}x_1^{i_1}. \tag{28}$$

The inner sum can be evaluated for any given weight analytically. Subsequently the outer sum can be done with Eq. (3). If a negative weight occurs inside a sum, Eq. (28) is applied to the subsum starting from the negative weight.

If a binomial appears in the sum, this sum may be written as a conjugation. To any function $f(n)$ of an integer variable n one defines the conjugated function $C\circ f(n)$ as the following sum:[12]

$$C\circ f(n)=-\sum_{i=1}^{n}\binom{n}{i}(-1)^i f(i). \tag{29}$$

Conjugation satisfies the following two properties:

$$C\circ 1=1, \tag{30}$$

$$C\circ C\circ f(n)=f(n), \tag{31}$$

which can be easily verified.

We classify four types of transcendental sums, which are dealt with in the algorithms A–D.

(1) Sum over i involving only $Z(i-1;\ldots)$ (type A).
(2) Sum over i involving both $Z(i-1;\ldots)$ and $Z(n-i-1;\ldots)$ (type B).
(3) Sum over i involving $S(i;\ldots)$ and a binomial (type C).
(4) Sum over i involving both $S(i;\ldots)$, $S(n-i;\ldots)$ and a binomial (type D).

Many of the algorithms use a recursion. They relate a given problem to a simpler one, either with a reduced depth or weight of the Z-sums or S-sums involved. In these cases we only give one step in the recursion.

The algorithms presented in this paper are all suited for programming in a computer algebra system like GINAC,[38] FORM,[39] or the commercial ones like MATHEMATICA or MAPLE. Implementations within the GINAC framework and in FORM along the lines of Ref. 12 are in preparation or have been published elsewhere.[40]

A. Algorithm A

Here we consider sums of the form

$$\sum_{i=1}^{n}\frac{x^i}{(i+c)^m}\frac{\Gamma(i+a_1+b_1\epsilon)}{\Gamma(i+c_1+d_1\epsilon)}\cdots\frac{\Gamma(i+a_k+b_k\epsilon)}{\Gamma(i+c_k+d_k\epsilon)}Z(i+o-1,m_1,\ldots,m_l,x_1,\ldots,x_l) \tag{32}$$

and show how to reduce them to Z-sums. We assume that all a_j and c_j are integers, c is assumed to be a non-negative integer and o should be an integer. The upper summation limit is allowed to be infinity.

After expanding the gamma functions and synchronizing the subsum $Z(i+o-1,m_1,\ldots)$ the problem is reduced to sums of the form

$$\sum_{i=1}^{n}\frac{x^i}{(i+c)^m}Z(i-1,\ldots) \tag{33}$$

with $c \geqslant 0$. It remains to reduce the offset c to zero. If the depth of the subsum is zero, we have

$$\sum_{i=1}^{n} \frac{x^i}{(i+c)^m} = \frac{1}{x} \sum_{i=1}^{n} \frac{x^i}{(i+c-1)^m} - \frac{1}{c^m} + \frac{x^n}{(n+c)^m}. \tag{34}$$

The last term contributes only if n is not equal to infinity. If the depth of the subsum is not equal to zero, we have

$$\sum_{i=1}^{n} \frac{x^i}{(i+c)^m} Z(i-1,\ldots) = \frac{1}{x} \sum_{i=1}^{n} \frac{x^i}{(i+c-1)^m} Z(i-1,\ldots) - \sum_{i=1}^{n-1} \frac{x^i}{(i+c)^m} \frac{x_1^i}{i^{m_1}} Z(i-1,m_2,\ldots) + \frac{x^n}{(n+c)^m} Z(n-1,\ldots). \tag{35}$$

Note that the third term only contributes if n is not equal to infinity. Finally we arrive at

$$\sum_{i=1}^{n} \frac{x^i}{i^m} Z(i-1,\ldots), \tag{36}$$

which is again a Z-sum. If the upper summation limit n equals infinity this sum yields immediately a multiple polylogarithm according to Eq. (11). In the special case where n equals infinity and the subsum is an Euler–Zagier sum we obtain a harmonic polylogarithm according to Eq. (16).

B. Algorithm B

Here we consider sums of the form

$$\begin{aligned} &\sum_{i=1}^{n-1} \frac{x^i}{(i+c)^m} \frac{\Gamma(i+a_1+b_1\epsilon)}{\Gamma(i+c_1+d_1\epsilon)} \cdots \frac{\Gamma(i+a_k+b_k\epsilon)}{\Gamma(i+c_k+d_k\epsilon)} Z(i+o-1,m_1,\ldots,m_l,x_1,\ldots,x_l) \\ &\quad \times \frac{y^{n-i}}{(n-i+c')^{m'}} \frac{\Gamma(n-i+a_1'+b_1'\epsilon)}{\Gamma(n-i+c_1'+d_1'\epsilon)} \cdots \frac{\Gamma(n-i+a_{k'}'+b_{k'}'\epsilon)}{\Gamma(n-i+c_{k'}'+d_{k'}'\epsilon)} \\ &\quad \times Z(n-i+o'-1,m_1',\ldots,m_{l'}',x_1',\ldots,x_{l'}') \end{aligned} \tag{37}$$

and show how to reduce them to Z-sums. Here, all a_j, a_j', c_j and c_j' should be integers, c, c' should be non-negative integers and o, o' should be integers. Note that the upper summation limit is $(n-1)$. The upper summation limit should not be infinity.

Using the expansion of the gamma functions and the synchronization of the subsums, we immediately obtain sums of the form

$$\sum_{i=1}^{n-1} \frac{x^i}{(i+c)^m} Z(i-1,m_1,\ldots) \frac{y^{n-i}}{(n-i+c')^{m'}} Z(n-i-1,m_1',\ldots). \tag{38}$$

Partial fractioning [and a change of the summation index $i \to n-i$ in sums involving the fraction with $(n-i+c')$] reduces these sums further to sums of the type

$$\sum_{i=1}^{n-1} \frac{x^i}{(i+c)^m} Z(i-1,m_1,\ldots) Z(n-i-1,m_1',\ldots). \tag{39}$$

If the depth of $Z(n-i-1,m_1',\ldots)$ is zero, we have a sum of type A with upper summation index $(n-1)$:

$$\sum_{i=1}^{n-1} \frac{x^i}{(i+c)^m} Z(i-1,m_1,\dots). \tag{40}$$

Otherwise we can rewrite Eq. (39) as

$$\sum_{j=1}^{n-1} \left[\sum_{i=1}^{j-1} \frac{x^i}{(i+c)^m} Z(i-1,m_1,\dots) \frac{x_1'^{j-i}}{(j-i)^{m_1'}} Z(j-i-1,m_2',\dots) \right] \tag{41}$$

and use recursion. The inner sum is again of type B, but with a reduced depth, such that the recursion will finally terminate.

C. Algorithm C

Here we consider sums of the form

$$-\sum_{i=1}^{n} \binom{n}{i} (-1)^i \frac{x^i}{(i+c)^m} \frac{\Gamma(i+a_1+b_1\epsilon)}{\Gamma(i+c_1+d_1\epsilon)} \cdots \frac{\Gamma(i+a_k+b_k\epsilon)}{\Gamma(i+c_k+d_k\epsilon)} S(i+o,m_1,\dots,m_l,x_1,\dots,x_l), \tag{42}$$

where a_j and c_j are integers, c is a non-negative integer, and o is an integer. The upper summation limit should not be infinity. These sums cannot be reduced to Z-sums with upper summation limit n alone. However, they can be reduced to Z-sums with upper summation limit n and multiple polylogarithms (which are Z-sums to infinity).

Again, we expand the gamma functions and synchronize the subsum. It is therefore sufficient to consider sums of the form

$$-\sum_{i=1}^{n} \binom{n}{i} (-1)^i \frac{x^i}{(i+c)^m} S(i,\dots) \tag{43}$$

with $c \geqslant 0$. To reduce the offset c to zero we rewrite the sum as

$$\left(-\frac{1}{x}\right) \frac{1}{n+1} (-1) \sum_{i=1}^{n+1} \binom{n+1}{i} (-1)^i \frac{x^i}{(i+c-1)^m} iS(i-1,\dots). \tag{44}$$

Repeated application of the above-given relation yields sums of the form

$$-\sum_{i=1}^{n} \binom{n}{i} (-1)^i \frac{x^i}{i^m} S(i,\dots). \tag{45}$$

If m is negative we rewrite Eq. (45) as

$$-nx(-1) \sum_{i=1}^{n-1} \binom{n-1}{i} (-1)^i \frac{x^i}{(i+1)^{m+1}} S(i+1,\dots) + nxS(1,\dots). \tag{46}$$

We can therefore assume that m is a non-negative number. Furthermore, due to Eq. (28) we may assume that in the S-sum $S(i;m_1,\dots;x_1,\dots)$ no m_j is negative and that if some m_j is zero, then the corresponding x_j is not equal to 1. The sum $S(i,\dots)$ is then rewritten as

$$
\begin{aligned}
S(i;m_1,\ldots,m_k;x_1,\ldots,x_k) = {} & S(N;m_1,\ldots,m_k;x_1,\ldots,x_k) \\
& - S(N;m_2,\ldots,m_k;x_2,\ldots,x_k)\times\left(\sum_{i_1=i+1}^{N}\frac{x_1^{i_1}}{i_1^{m_1}}\right) \\
& + S(N;m_3,\ldots,m_k;x_3,\ldots,x_k)\times\left(\sum_{i_1=i+1}^{N}\sum_{i_2=i_1+1}^{N}\frac{x_1^{i_1}}{i_1^{m_1}}\frac{x_2^{i_2}}{i_2^{m_2}}\right) \\
& - \ldots + (-1)^k\left(\sum_{i_1=i+1}^{N}\sum_{i_2=i_1+1}^{N}\cdots\sum_{i_k=i_{k-1}+1}^{N}\frac{x_1^{i_1}}{i_1^{m_1}}\frac{x_2^{i_2}}{i_2^{m_2}}\cdots\frac{x_k^{i_k}}{i_k^{m_k}}\right).
\end{aligned}
\tag{47}
$$

The proof of Eq. (47) is not too complicated and consists in repeated application of the identity

$$
\sum_{i=1}^{n}\sum_{j=1}^{i}a_{ij} = \sum_{i=1}^{N}\sum_{j=1}^{i}a_{ij} - \sum_{i=n+1}^{N}\sum_{j=1}^{N}a_{ij} + \sum_{i=n+1}^{N}\sum_{j=i+1}^{N}a_{ij}. \tag{48}
$$

Equation (47) holds for any N and in particular we may take $N=\infty$ in the end. Each term is then a product of an S-sum at infinity and a sum of a new type. The S-sum at infinity is converted to a Z-sum at infinity and expressed in terms of multiple polylogarithms. We now deal with sums of the form

$$
-\sum_{i=1}^{n}\binom{n}{i}(-1)^i\frac{x_0^i}{i^{m_0}}\sum_{i_1=i+1}^{N}\sum_{i_2=i_1+1}^{N}\cdots\sum_{i_k=i_{k-1}+1}^{N}\frac{x_1^{i_1}}{i_1^{m_1}}\frac{x_2^{i_2}}{i_2^{m_2}}\cdots\frac{x_k^{i_k}}{i_k^{m_k}}. \tag{49}
$$

We introduce raising and lowering operators as follows:

$$
\begin{aligned}
(\mathbf{x}^+)^m\cdot 1 &= \frac{1}{m!}\ln^m(x), \\
\mathbf{x}^+\cdot f(x) &= \int_0^x\frac{dx'}{x'}f(x'), \\
\mathbf{x}^-\cdot f(x) &= x\frac{d}{dx}f(x).
\end{aligned}
\tag{50}
$$

It is understood that in the second line only functions which are integrable at $x=0$ are considered. We see that $\mathbf{x}^-$ is the inverse to $\mathbf{x}^+$, e.g. $\mathbf{x}^-\mathbf{x}^+=\mathrm{id}$. However $\mathbf{x}^+\mathbf{x}^-=\mathrm{id}$ holds only if applied to nontrivial sums. For the trivial sum we have $\mathbf{x}^+\mathbf{x}^-Z(n)=0$.

With the help of the raising operators Eq. (49) may be rewritten as

$$
\begin{aligned}
& (\mathbf{x_k}^+)^{m_k}(\mathbf{x_{k-1}}^+)^{m_{k-1}}\cdots(\mathbf{x_1}^+)^{m_1}(\mathbf{x_0}^+)^{m_0}(-1)\sum_{i=1}^{n}\binom{n}{i}(-x_0)^i \\
& \quad\times\sum_{i_1=i+1}^{N}\sum_{i_2=i_1+1}^{N}\cdots\sum_{i_k=i_{k-1}+1}^{N}x_1^{i_1}x_2^{i_2}\ldots x_k^{i_k}.
\end{aligned}
\tag{51}
$$

It may happen that some x_i's are equal to one. In this case we first calculate the sum for arbitrary x_i's and then take the limit $x_i\to 1$. Some care has to be taken for the double limit $x\to 1$ and $N\to\infty$. The order is as follows: First all limits $x\to 1$ are taken, then the limit $N\to\infty$ in Eq. (47) is performed.

The sums in Eq. (51) can be performed with the help of the geometric series

$$\sum_{i=n+1}^{N} x^i = \frac{x}{1-x}x^n - \frac{x}{1-x}x^N. \tag{52}$$

It is evident that if we do not have to take the limit $x\to 1$ we can immediately neglect the second term. Also in the case $x=1$ the second term can be neglected. It gives rise to terms of the form

$$(\mathbf{x}^+)^m \frac{x}{1-x}x^N = \sum_{i=N+1}^{\infty} \frac{x^i}{i^m}. \tag{53}$$

On the right-hand side the limit $x\to 1$ may safely be performed and the resulting sum gives a vanishing contribution in the limit $N\to\infty$.

Performing the sums in Eq. (51) we therefore only have to consider expressions of the form

$$(\mathbf{x_k}^+)^{m_k}(\mathbf{x_{k-1}}^+)^{m_{k-1}}\cdots(\mathbf{x_1}^+)^{m_1}(\mathbf{x_0}^+)^{m_0}\frac{x_k}{1-x_k}\frac{x_{k-1}x_k}{1-x_{k-1}x_k}\cdots\frac{x_1\cdots x_k}{1-x_1\cdots . x_k}$$
$$\times[1-(1-x_0x_1\cdots x_k)^n]. \tag{54}$$

We then perform succesively the integrations corresponding to the raising operators. The basic formulas are

$$\mathbf{x_1}^+[1-(1-x_1x_2)^n] = \sum_{i=1}^{n}\frac{1}{i}[1-(1-x_1x_2)^i],$$

$$\mathbf{x_1}^+\frac{x_1x_2}{1-x_1x_2}[1-(1-x_0x_1x_2)^n] = -(1-x_0)^n\sum_{i=1}^{n}\frac{1}{i}\left(\frac{1}{1-x_0}\right)^i[1-(1-x_0x_1x_2)^i]$$
$$+(1-(1-x_0)^n)\sum_{i=1}^{N}\frac{(x_1x_2)^i}{i}$$
$$+\mathbf{x_1}^+\frac{x_1x_2}{1-x_1x_2}(x_1x_2)^N(1-(1-x_0)^n), \tag{55}$$

$$\mathbf{x_1}^+\frac{x_1x_2}{1-x_1x_2}[1-(1-x_1x_2)^n] = -\frac{1}{n}[1-(1-x_1x_2)^n]+\sum_{i=1}^{N}\frac{(x_1x_2)^i}{i}+(\mathbf{x_1}^+)\frac{x_1x_2}{1-x_1x_2}(x_1x_2)^N.$$

We use the first formula to reduce m_0 in Eq. (54) to zero:

$$\sum_{i=1}^{n}\frac{1}{i}(x_k^+)^{m_k}\cdots(x_1^+)^{m_1}(x_0^+)^{m_0-1}\frac{x_k}{1-x_k}\frac{x_{k-1}x_k}{1-x_{k-1}x_k}\cdots\frac{x_1\cdots x_k}{1-x_1\cdots x_k}[1-(1-x_0x_1\cdots x_k)^i]. \tag{56}$$

In the following we may therefore assume $m_0=0$ in Eq. (54). If $m_0=0$, $m_1>0$ and $x_0\neq 1$ we obtain for Eq. (54)

$$-(1-x_0)^n\sum_{i=1}^{\infty}\frac{1}{i}\left(\frac{1}{1-x_0}\right)^i(x_k^+)^{m_k}\cdots((x_0x_1)^+)^{m_1-1}\frac{x_k}{1-x_k}\frac{x_{k-1}x_k}{1-x_{k-1}x_k}\cdots\frac{x_2\cdots x_k}{1-x_2\cdots x_k}$$
$$\times[1-(1-(x_0x_1)\cdots x_k)^i]+(1-(1-x_0)^n)\sum_{i=1}^{N}\frac{x_1^i}{i^{m_1}}\sum_{i_2=i+1}^{N}\cdots\sum_{i_k=i_{k-1}+1}^{N}\frac{x_2^{i_2}}{i_2^{m_2}}\cdots\frac{x_k^{i_k}}{i_k^{m_k}}. \tag{57}$$

Here we neglected terms of the form (53). In the case $m_0=0$, $m_1>0$, and $x_0=1$ we use the third formula of Eq. (55). Again we may neglect contributions of the form (53). Doing so we obtain

$$-\frac{1}{n}(x_k^+)^{m_k}\cdots(x_1^+)^{m_1-1}\frac{x_k}{1-x_k}\frac{x_{k-1}x_k}{1-x_{k-1}x_k}\cdots\frac{x_2\cdots x_k}{1-x_2\cdots x_k}[1-(1-x_1\cdots x_k)^n]$$
$$+\sum_{i=1}^{N}\frac{x_1^i}{i^{m_1}}\sum_{i_2=i+1}^{N}\cdots\sum_{i_k=i_{k-1}+1}^{N}\frac{x_2^{i_2}}{i_2^{m_2}}\cdots\frac{x_k^{i_k}}{i_k^{m_k}}. \tag{58}$$

It remains to treat the last term to complete the recursion. The last term introduces a sum of the type

$$\sum_{i_1=n+1}^{N}\cdots\sum_{i_k=i_{k-1}+1}^{N}\frac{x_1^{i_1}}{i_1^{m_1}}\cdots\frac{x_k^{i_k}}{i_k^{m_k}}. \tag{59}$$

Using the inverse formula to Eq. (47)

$$\sum_{i_1=n+1}^{N}\cdots\sum_{i_k=i_{k-1}+1}^{N}\frac{x_1^{i_1}}{i_1^{m_1}}\cdots\frac{x_k^{i_k}}{i_k^{m_k}}$$
$$=(-1)^k S(n;m_1,\ldots,m_k;x_1,\ldots,x_k)$$
$$-(-1)^k S(N;m_1,\ldots,m_k;x_1,\ldots,x_k)+(-1)^k S(N;m_2,\ldots,m_k;x_2,\ldots,x_k)$$
$$\times\sum_{i_1=n+1}^{N}\frac{x_1^{i_1}}{i_1^{m_1}}-\cdots+(-1)^k S(N;m_k;x_k)\sum_{i_1=n+1}^{N}\cdots\sum_{i_{k-1}=i_{k-2}+1}^{N}\frac{x_1^{i_1}}{i_1^{m_1}}\cdots\frac{x_{k-1}^{i_{k-1}}}{i_{k-1}^{m_{k-1}}}, \tag{60}$$

this sum is easily related to S-sums with upper summation limit n and (after taking the limit $N\to\infty$) to multiple polylogarithms.

If $m_0=0$, $m_1=0$, and $x_1\neq 1$ we rewrite Eq. (54) as

$$-\frac{1}{1-x_1}(x_k^+)^{m_k}\cdots(x_3^+)^{m_3}((x_2x_1)^+)^{m_2}\frac{x_k}{1-x_k}\cdots\frac{x_3\cdots x_k}{1-x_3\cdots x_k}\frac{(x_1x_2)x_3\cdots x_k}{1-(x_1x_2)x_3\cdots x_k}$$
$$\times[1-(1-x_0(x_1x_2)x_3\cdots x_k)^i]+\frac{x_1}{1-x_1}(x_k^+)^{m_k}\cdots(x_2^+)^{m_2}\frac{x_k}{1-x_k}\cdots\frac{x_2x_3\cdots x_k}{1-x_2x_3\cdots x_k}$$
$$\times[1-(1-(x_0x_1)x_2x_3\cdots x_k)^i]. \tag{61}$$

The case $m_0=0$, $m_1=0$, and $x_1=1$ has to be excluded. However, with an appropriate choice of the standard form for S-sums [cf. Eq. (28)] this case never occurs.

D. Algorithm D

Here we consider sums of the form

$$-\sum_{i=1}^{n-1}\binom{n}{i}(-1)^i\frac{x^i}{(i+c)^m}\frac{\Gamma(i+a_1+b_1\epsilon)}{\Gamma(i+c_1+d_1\epsilon)}\cdots\frac{\Gamma(i+a_k+b_k\epsilon)}{\Gamma(i+c_k+d_k\epsilon)}\times S(i+o,m_1,\ldots,m_l,x_1,\ldots,x_l)$$
$$\times\frac{y^{n-i}}{(n-i+c')^{m'}}\frac{\Gamma(n-i+a_1'+b_1'\epsilon)}{\Gamma(n-i+c_1'+d_1'\epsilon)}\cdots\frac{\Gamma(n-i+a_{k'}'+b_{k'}'\epsilon)}{\Gamma(n-i+c_{k'}'+d_{k'}'\epsilon)}$$
$$\times S(n-i+o',m_1',\ldots,m_{l'}',x_1',\ldots,x_{l'}'). \tag{62}$$

Here, all a_j, a_j', c_j, and c_j' are integers, c, c', are nonnegative integers, and o, o' are integers. Note that the upper summation limit is $(n-1)$. The upper summation limit should not be infinity. As in the case of sums of type C, we cannot relate these sums to Z-sums with upper summation limit $(n-1)$ alone, but we can reduce them to Z-sums with upper summation limit $(n-1)$ and multiple polylogarithms (which are Z-sums to infinity).

After the expansion of the gamma functions and the synchronization of the subsums we have sums of the form

$$-\sum_{i=1}^{n-1}\binom{n}{i}(-1)^i\frac{x^i}{(i+c)^m}S(i,m_1,\dots)\frac{y^{n-i}}{(n-i+c')^{m'}}S(n-i,m_1',\dots). \tag{63}$$

Partial fractioning leads to

$$-\sum_{i=1}^{n-1}\binom{n}{i}(-1)^i\frac{x^i}{(i+c)^m}S(i,m_1,\dots)S(n-i,m_1',\dots) \tag{64}$$

with $c\geqslant 0$. In order to reduce the offset c to zero one rewrites Eq. (64) as

$$\left(-\frac{1}{x}\right)\frac{1}{n+1}(-1)\sum_{i=1}^{n+1-1}\binom{n+1}{i}(-1)^i\frac{x^i}{(i+c-1)^m}iS(i-1,\dots)S(n+1-i,m_1',\dots). \tag{65}$$

We arrive at sums of the form

$$-\sum_{i=1}^{n-1}\binom{n}{i}(-1)^i\frac{x^i}{i^m}S(i,m_1,\dots)S(n-i,m_1',\dots). \tag{66}$$

If the depth of $S(n-i,m_1',\dots)$ is zero, we have a sum of type C:

$$-\sum_{i=1}^{n-1}\binom{n}{i}(-1)^i\frac{x^i}{i^m}S(i,m_1,\dots)=-\sum_{i=1}^{n}\binom{n}{i}(-1)^i\frac{x^i}{i^m}S(i,m_1,\dots)+\frac{(-x)^n}{n^m}S(n,m_1,\dots). \tag{67}$$

Otherwise, we first reduce m to zero. For $m>0$ we rewrite Eq. (66) as

$$\sum_{j=1}^{n}\frac{1}{j}\left[(-1)\sum_{i=1}^{j-1}\binom{j}{i}(-1)^i\frac{x^i}{i^{m-1}}S(i,m_1,\dots)S(j-i,m_1',\dots)\right]$$
$$+\sum_{j=1}^{n}\frac{1}{j}\left[(-1)\sum_{i=1}^{j-1}\binom{j}{i}(-1)^i\frac{x^i}{i^m}S(i,m_1,\dots)\frac{x_1'^{j-i}}{(j-i)^{m_1'-1}}S(j-i,m_2',\dots)\right]. \tag{68}$$

For $m<0$ we rewrite Eq. (66) as

$$-nx(-1)\sum_{i=1}^{n-2}\binom{n-1}{i}(-1)^i\frac{x^i}{(i+1)^{m+1}}S(i+1,m_1,\dots)S(n-1-i,m_1',\dots)$$
$$+nxS(1,m_1,\dots)S(n-1,m_1',\dots). \tag{69}$$

Having reduced m to zero we arrive at sums of the form

$$-\sum_{i=1}^{n-1}\binom{n}{i}(-1)^ix^iS(i,m_1,\dots)S(n-i,m_1',\dots). \tag{70}$$

For $x\neq 1$ we obtain after some algebra

$$-\sum_{i=1}^{n-1}\binom{n}{i}(-1)^i x^i S(i,m_1,\ldots)S(n-i,m_1',\ldots)=(1-x)^n\sum_{j=1}^{n}\frac{1}{j}\left(\frac{1}{1-x}\right)^j(-1)\sum_{i=1}^{j-1}\binom{j}{i}$$
$$\times(-1)^i\frac{(xx_1)^i}{i^{m_1-1}}S(i,m_2,\ldots)S(j-i,m_1',\ldots)+(1-x)^n\sum_{j=1}^{n}\frac{1}{j}\left(\frac{1}{1-x}\right)^j(-1)\sum_{i=1}^{j-1}\binom{j}{i}$$
$$\times(-1)^i x^i S(i,m_1,\ldots)\frac{x_1'^{j-i}}{(n-i)^{m_1'-1}}S(j-i,m_2',\ldots), \tag{71}$$

where the original problem is reduced to one of the same type but with lower weight. In the case $x=1$ the right-hand side of Eq. (71) reduces to

$$\frac{1}{n}(-1)\sum_{i=1}^{n-1}\binom{n}{i}(-1)^i\frac{x_1^i}{i^{m_1-1}}S(i,m_2,\ldots)S(n-i,m_1',\ldots)+\frac{1}{n}(-1)\sum_{i=1}^{n-1}\binom{n}{i}$$
$$\times(-1)^i S(i,m_1,\ldots)\frac{x_1'^{n-i}}{(n-i)^{m_1'-1}}S(n-i,m_2',\ldots). \tag{72}$$

Again, the original problem is reduced to one of the same type but with lower weight. The above-mentioned algorithm thus yields a recursion to treat sums of type D.

IV. APPLICATIONS

The algorithms given in this paper can be used for the expansion of higher transcendental functions around integer values of their indices, where the expansion parameter occurs in the Pochhammer symbols. In this section we give a few examples. Additionally, we illustrate the applicability of the algorithms for nested sums to the calculation of loop integrals, in particular to integrals with several scales. As an example, we discuss the C-topology and show that the integral can be written as a nested sum of the type previously discussed.

A. Generalized hypergeometric functions

The generalized hypergeometric functions are defined by[1,2]

$${}_{J+1}F_J(a_1,\ldots,a_{J+1};b_1,\ldots,b_J;x)=\sum_{n=0}^{\infty}\frac{(a_1)_n\cdots(a_{J+1})_n}{(b_1)_n\cdots(b_J)_n}\frac{x^n}{n!}, \tag{73}$$

where $(a)_n=\Gamma(n+a)/\Gamma(a)$ denotes a Pochhammer symbol. These functions can be rewritten as

$${}_{J+1}F_J(a_1,\ldots,a_{J+1};b_1,\ldots,b_J;x)$$
$$=1+\frac{\Gamma(b_1)\cdots\Gamma(b_J)}{\Gamma(a_1)\cdots\Gamma(a_{J+1})}\sum_{i=1}^{\infty}x^i\frac{\Gamma(i+a_1)}{\Gamma(i+b_1)}\cdots\frac{\Gamma(i+a_J)}{\Gamma(i+b_J)}\frac{\Gamma(i+a_{J+1})}{\Gamma(i+1)} \tag{74}$$

and fall therefore into the category of transcendental sums of type A. We give a few examples obtained using the algorithms given in Sec. III A:

$${}_2F_1(a\epsilon,b\epsilon;1-c\epsilon;x)=1+ab\,\mathrm{Li}_2(x)\epsilon^2+ab(c\,\mathrm{Li}_3(x)+(a+b+c)\,\mathrm{S}_{1,2}(x))\epsilon^3+O(\epsilon^4),$$
$${}_2F_1(1,-\epsilon;1-\epsilon;x)=1+\ln(1-x)\epsilon-\mathrm{Li}_2(x)\epsilon^2-\mathrm{Li}_3(x)\epsilon^3-\mathrm{Li}_4(x)\epsilon^4$$
$$-\mathrm{Li}_5(x)\epsilon^5-\mathrm{Li}_6(x)\epsilon^6-\mathrm{Li}_7(x)\epsilon^7+O(\epsilon^8), \tag{75}$$

$$
\begin{aligned}
&{}_3F_2(-2\epsilon,-2\epsilon,1-\epsilon;1-2\epsilon,1-2\epsilon;x)\\
&\quad=1+4\,\mathrm{Li}_2(x)\epsilon^2+(12\,\mathrm{Li}_3(x)-4S_{1,2}(x))\epsilon^3+(32\,\mathrm{Li}_4(x)\\
&\quad\quad+4S_{1,3}(x)-12S_{2,2}(x))\epsilon^4+(80\,\mathrm{Li}_5(x)-4S_{1,4}(x)\\
&\quad\quad+12S_{2,3}(x)-32S_{3,2}(x))\epsilon^5+O(\epsilon^6),
\end{aligned}
\tag{76}
$$

which all agree with known results in the literature.[41,42]

B. Appell functions

The first Appell function is defined by[43,2]

$$
F_1(a,b_1,b_2;c;x_1,x_2)=\sum_{m_1=0}^{\infty}\sum_{m_2=0}^{\infty}\frac{(a)_{m_1+m_2}(b_1)_{m_1}(b_2)_{m_2}}{(c)_{m_1+m_2}}\frac{x_1^{m_1}}{m_1!}\frac{x_2^{m_2}}{m_2!}.
\tag{77}
$$

It can be rewritten as

$$
\begin{aligned}
F_1(a,b_1,b_2;c;x_1,x_2)=1&+\frac{\Gamma(c)}{\Gamma(a)\Gamma(b_1)}\sum_{i=1}^{\infty}x_1^i\frac{\Gamma(i+a)\Gamma(i+b_1)}{\Gamma(i+c)\Gamma(i+1)}\\
&+\frac{\Gamma(c)}{\Gamma(a)\Gamma(b_2)}\sum_{i=1}^{\infty}x_2^i\frac{\Gamma(i+a)\Gamma(i+b_2)}{\Gamma(i+c)\Gamma(i+1)}\\
&+\frac{\Gamma(c)}{\Gamma(a)\Gamma(b_1)\Gamma(b_2)}\sum_{n=1}^{\infty}\frac{\Gamma(n+a)}{\Gamma(n+c)}\sum_{i=1}^{n-1}x_1^i\frac{\Gamma(i+b_1)}{\Gamma(i+1)}x_2^{n-i}\frac{\Gamma(n-i+b_2)}{\Gamma(n-i+1)}.
\end{aligned}
\tag{78}
$$

The inner sum of the last term is of type B. The first Appell function can therefore be expanded with the help of algorithms A and B.

The second Appell function is defined by[43,2]

$$
F_2(a,b_1,b_2;c_1,c_2;x_1,x_2)=\sum_{m_1=0}^{\infty}\sum_{m_2=0}^{\infty}\frac{(a)_{m_1+m_2}(b_1)_{m_1}(b_2)_{m_2}}{(c_1)_{m_1}(c_2)_{m_2}}\frac{x_1^{m_1}}{m_1!}\frac{x_2^{m_2}}{m_2!}.
\tag{79}
$$

It can be rewritten as

$$
\begin{aligned}
&F_2(a,b_1,b_2;c_1,c_2;x_1,x_2)\\
&\quad=1+\frac{\Gamma(c_1)}{\Gamma(a)\Gamma(b_1)}\sum_{i=1}^{\infty}x_1^i\frac{\Gamma(i+a)\Gamma(i+b_1)}{\Gamma(i+c_1)\Gamma(i+1)}+\frac{\Gamma(c_2)}{\Gamma(a)\Gamma(b_2)}\sum_{i=1}^{\infty}x_2^i\frac{\Gamma(i+a)\Gamma(i+b_2)}{\Gamma(i+c_2)\Gamma(i+1)}\\
&\quad\quad-\frac{\Gamma(c_1)\Gamma(c_2)}{\Gamma(a)\Gamma(b_1)\Gamma(b_2)}\sum_{n=1}^{\infty}\frac{\Gamma(n+a)}{\Gamma(n+1)}(-1)\sum_{i=1}^{n-1}\binom{n}{i}\\
&\quad\quad\times(-1)^i(-x_1)^i\frac{\Gamma(i+b_1)}{\Gamma(i+c_1)}x_2^{n-i}\frac{\Gamma(n-i+b_2)}{\Gamma(n-i+c_2)}.
\end{aligned}
\tag{80}
$$

The inner sum of the last term is of type D. The second Appell function can therefore be expanded with the help of algorithms A–D. As an example we give

$$
\begin{aligned}
F_2(1,1,\epsilon;1+\epsilon,1-\epsilon;x,y) = {} & \frac{1}{1-x} + \frac{1}{1-x}(2\ln(1-x) - \ln(1-x-y))\epsilon + \frac{1}{1-x}\Bigg[2\,\mathrm{Li}_2(x) \\
& + 2\,\mathrm{Li}_2(y) - \mathrm{Li}_2(x+y) + 4S_{0,2}(x) + S_{0,2}(x+y) + \mathrm{Li}_{1,1}\left(\frac{y}{x+y}, x+y\right) \\
& - 2\,\mathrm{Li}_{1,1}\left(\frac{x}{x+y}, x+y\right) - 2\,\mathrm{Li}_{1,1}\left(\frac{x+y}{x}, x\right)\Bigg]\epsilon^2 + \frac{1}{1-x}\Bigg[\mathrm{Li}_3(x+y) \\
& - 2\,\mathrm{Li}_3(x) + S_{0,3}(x+y) - 8S_{0,3}(x) - S_{1,2}(x+y) - 4S_{1,2}(x) + 4S_{1,2}(y) \\
& - H_{1,2}(x+y) - 4H_{1,2}(x) + 2\,\mathrm{Li}_{1,2}\left(\frac{x}{x+y}, x+y\right) - \mathrm{Li}_{1,2}\left(\frac{y}{x+y}, x+y\right) \\
& + 2\,\mathrm{Li}_{1,2}\left(\frac{x+y}{x}, x\right) + 2\,\mathrm{Li}_{2,1}\left(\frac{x}{x+y}, x+y\right) + 3\,\mathrm{Li}_{2,1}\left(\frac{y}{x+y}, x+y\right) \\
& + 2\,\mathrm{Li}_{2,1}\left(\frac{x+y}{x}, x\right) - 4\,\mathrm{Li}_{2,1}\left(\frac{y}{x}, x\right) + 4\,\mathrm{Li}_{1,1,1}\left(\frac{x}{x+y}, \frac{x+y}{x}, x\right) \\
& + 4\,\mathrm{Li}_{1,1,1}\left(\frac{x+y}{x}, 1, x\right) + 4\,\mathrm{Li}_{1,1,1}\left(1, \frac{x}{x+y}, x+y\right) + 2\,\mathrm{Li}_{1,1,1} \\
& \times\left(1, \frac{y}{x+y}, x+y\right) - 2\,\mathrm{Li}_{1,1,1}\left(\frac{y}{x+y}, \frac{x+y}{x}, x\right) + \mathrm{Li}_{1,1,1}\left(\frac{y}{x+y}, 1, x+y\right) \\
& - 2\,\mathrm{Li}_{1,1,1}\left(\frac{x}{x+y}, 1, x+y\right) - 2\,\mathrm{Li}_{1,1,1}\left(1, \frac{x+y}{x}, x\right) \\
& - 2\,\mathrm{Li}_{1,1,1}\left(\frac{x+y}{x}, \frac{x}{x+y}, x+y\right)\Bigg]\epsilon^3 + O(\epsilon^4). \qquad (81)
\end{aligned}
$$

After taking into account a typo in Eq. (A.47) of Ref. 44 this result agrees up to order ϵ with the one obtained along the lines of Ref. 44. Multiple polylogarithms of low weight can be expressed as products of classical polylogarithms and the result of the expansion in Eq. (81) can be simplified. However, we present here the output of our algorithm. Our algorithm gives the result as a linear combination of polylogarithms and does not generate products of polylogarithms.

C. Kampé de Fériet function

The Kampé de Fériet function is defined by[43]

$$
S_1(a_1,a_2,b_1;c,c_1;x_1,x_2) = \sum_{m_1=0}^{\infty}\sum_{m_2=0}^{\infty} \frac{(a_1)_{m_1+m_2}(a_2)_{m_1+m_2}(b_1)_{m_1}}{(c)_{m_1+m_2}(c_1)_{m_1}} \frac{x_1^{m_1}}{m_1!}\frac{x_2^{m_2}}{m_2!}. \qquad (82)
$$

It can be rewritten as

$$
\begin{aligned}
S_1(a_1,a_2,b_1;c,c_1;x_1,x_2) = {} & 1 + \frac{\Gamma(c)\Gamma(c_1)}{\Gamma(a_1)\Gamma(a_2)\Gamma(b_1)}\sum_{i=1}^{\infty} x_1^i \frac{\Gamma(i+a_1)\Gamma(i+a_2)\Gamma(i+b_1)}{\Gamma(i+c)\Gamma(i+c_1)\Gamma(i+1)} \\
& + \frac{\Gamma(c)}{\Gamma(a_1)\Gamma(a_2)}\sum_{i=1}^{\infty} x_2^i \frac{\Gamma(i+a_1)\Gamma(i+a_2)}{\Gamma(i+c)\Gamma(i+1)} \\
& - \frac{\Gamma(c)\Gamma(c_1)}{\Gamma(a_1)\Gamma(a_2)\Gamma(b_1)}\sum_{n=1}^{\infty} x_2^n \frac{\Gamma(n+a_1)\Gamma(n+a_2)}{\Gamma(n+c)\Gamma(n+1)}
\end{aligned}
$$

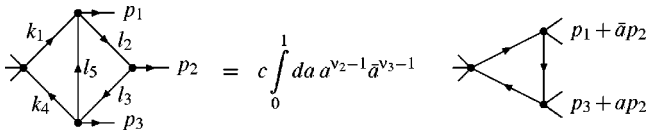

FIG. 3. The C-topology reduces to a triangle with three external masses and an additional integration over the Feynman parameter a.

$$\times(-1)\sum_{i=1}^{n-1}\binom{n}{i}(-1)^i\left(-\frac{x_1}{x_2}\right)^i\frac{\Gamma(i+b_1)}{\Gamma(i+c_1)}. \tag{83}$$

The inner sum of the last term is of type C. The Kampé de Fériet function can therefore be expanded with the help of the algorithms A and C.

D. The C-topology

Here we study the C-topology with one massive external leg and arbitrary powers of the propagators and arbitray dimensions, which can be solved using the algorithms given in this paper. The importance of this result lies in the fact that one avoids having to solve a system of equations obtained from partial integration or Lorentz invariance. Solving such a system becomes quite difficult if one external leg is massive. The result obtained here is thus a useful ingredient for the calculation of the two-loop amplitudes with one massive external leg, such as $e^+e^-\to 3$ jets.
The second C-topology, where the massive leg is attached to the other corner, as well as all simpler topologies, can be obtained along the same lines. The two-loop C-topology with one massive external leg is defined by

$$I=\int\frac{d^Dk_1}{i\pi^{D/2}}\int\frac{d^Dl_5}{i\pi^{D/2}}\frac{1}{(-k_1^2)^{\nu_1}}\frac{1}{(-l_2^2)^{\nu_2}}\frac{1}{(-l_3^2)^{\nu_3}}\frac{1}{(-k_4^2)^{\nu_4}}\frac{1}{(-l_5^2)^{\nu_5}} \tag{84}$$

with

$$\begin{aligned} l_2&=k_1+l_5-p_1,\\ l_3&=l_2-p_2,\\ k_4&=k_1-p_{123}. \end{aligned} \tag{85}$$

Figure 3 shows the corresponding Feynman diagram. We first perform the l_5-integration. Combining with Feynman parameters first l_2^2 and l_3^2 and then the resulting propagator with l_5^2 we obtain

$$\begin{aligned} I=&\frac{\Gamma(\nu_{235}-m+\epsilon)}{\Gamma(\nu_2)\Gamma(\nu_3)\Gamma(\nu_5)}\frac{\Gamma(-\nu_{23}+m-\epsilon)\Gamma(-\nu_5+m-\epsilon)}{\Gamma(-\nu_{235}+2m-2\epsilon)}\int_0^1 da\, a^{\nu_2-1}\bar{a}^{\nu_3-1}\\ &\times\int\frac{d^Dk_1}{i\pi^{D/2}}\frac{1}{(-k_1^2)^{\nu_1}}\frac{1}{(-(k_1-p_1-\bar{a}p_2)^2)^{\nu_{235}-m+\epsilon}}\frac{1}{(-k_4^2)^{\nu_4}}. \end{aligned} \tag{86}$$

As a short-hand notation we used $D=2m-2\epsilon$, $\bar{a}=1-a$, and $\nu_{235}=\nu_2+\nu_3+\nu_5$. The second line is a one-loop triangle with three external masses. The solution for this one-loop integral with arbitrary powers of the propagators and arbitrary dimensions is known.[45] We use the solution given in Ref. 44 and perform the remaining integration. We obtain

$$
\begin{aligned}
I=&\frac{\Gamma(2m-2\epsilon-\nu_{1235})\Gamma(1+\nu_{1235}-2m+2\epsilon)\Gamma(2m-2\epsilon-\nu_{2345})\Gamma(1+\nu_{2345}-2m+2\epsilon)}{\Gamma(\nu_1)\Gamma(\nu_2)\Gamma(\nu_3)\Gamma(\nu_4)\Gamma(\nu_5)\Gamma(3m-3\epsilon-\nu_{12345})}\\
&\times\frac{\Gamma(m-\epsilon-\nu_5)\Gamma(m-\epsilon-\nu_{23})}{\Gamma(2m-2\epsilon-\nu_{235})}(-s_{123})^{2m-2\epsilon-\nu_{12345}}\sum_{i_1=0}^{\infty}\sum_{i_2=0}^{\infty}\frac{x_1^{i_1}}{i_1!}\frac{x_2^{i_2}}{i_2!}\\
&\times\Bigg[\frac{\Gamma(i_1+\nu_3)\Gamma(i_2+\nu_2)\Gamma(i_1+i_2-2m+2\epsilon+\nu_{12345})\Gamma(i_1+i_2-m+\epsilon+\nu_{235})}{\Gamma(i_1+1-2m+2\epsilon+\nu_{1235})\Gamma(i_2+1-2m+2\epsilon+\nu_{2345})\Gamma(i_1+i_2+\nu_{23})}-x_1^{2m-2\epsilon-\nu_{1235}}\\
&\times\frac{\Gamma(i_1+2m-2\epsilon-\nu_{125})\Gamma(i_2+\nu_2)\Gamma(i_1+i_2+\nu_4)\Gamma(i_1+i_2+m-\epsilon-\nu_1)}{\Gamma(i_1+1+2m-2\epsilon-\nu_{1235})\Gamma(i_2+1-2m+2\epsilon+\nu_{2345})\Gamma(i_1+i_2+2m-2\epsilon-\nu_{15})}\\
&-x_2^{2m-2\epsilon-\nu_{2345}}\\
&\times\frac{\Gamma(i_1+\nu_3)\Gamma(i_2+2m-2\epsilon-\nu_{345})\Gamma(i_1+i_2+\nu_1)\Gamma(i_1+i_2+m-\epsilon-\nu_4)}{\Gamma(i_1+1-2m+2\epsilon+\nu_{1235})\Gamma(i_2+1+2m-2\epsilon-\nu_{2345})\Gamma(i_1+i_2+2m-2\epsilon-\nu_{45})}\\
&+x_1^{2m-2\epsilon-\nu_{1235}}x_2^{2m-2\epsilon-\nu_{2345}}\frac{\Gamma(i_1+2m-2\epsilon-\nu_{125})\Gamma(i_2+2m-2\epsilon-\nu_{345})}{\Gamma(i_1+1+2m-2\epsilon-\nu_{1235})\Gamma(i_2+1+2m-2\epsilon-\nu_{2345})}\\
&\times\frac{\Gamma(i_1+i_2+2m-2\epsilon-\nu_{235})\Gamma(i_1+i_2+3m-3\epsilon-\nu_{12345})}{\Gamma(i_1+i_2+4m-4\epsilon-\nu_{12345}-\nu_5)}\Bigg],
\end{aligned}
\tag{87}
$$

where we set $x_1=(-s_{12})/(-s_{123})$ and $x_2=(-s_{23})/(-s_{123})$. Changing the summation indices as in the case of the second Appell function yields a sum of type D. For specific (integer) values of ν_i and m this expression can be expanded in ϵ with the algorithm given in Sec. III. This is a new and useful result. Up to now this integral has only been known for $m=2$ and the sets (1,1,1,1,1) and (1,1,1,1,2) for $(\nu_1,\nu_2,\nu_3,\nu_4,\nu_5)$. We have verified that our result agrees in these two specific cases with the ones given by Gehrmann and Remiddi.[8]

V. CONCLUSIONS

In this paper we studied some algebraic properties of nested sums. Based on these properties we developed a number of algorithms which can be used to expand a certain class of mathematical functions. All presented algorithms are suitable for the implementation on a computer. These algorithms allow the evaluation of integrals occurring in high-energy physics. As an application we have shown how the two-loop C-topology can be evaluated for arbitrary powers of the propagators and arbitrary dimensions. Furthermore we have shown that the nested sums satisfy a Hopf algebra and established the connection with the Hopf algebra of Kreimer.

ACKNOWLEDGMENT

The authors would like to thank Jos Vermaseren for useful discussions.

APPENDIX A: THE HOPF ALGEBRA OF *Z*-SUMS

In this section we show that the Z-sums form a Hopf algebra.[36,37] It is sufficient to demonstrate that the Z-sums form a quasishuffle algebra. A general theorem[46] guarantees then, that they also form a Hopf algebra. We also discuss the connection with the Hopf algebra of Kreimer.[47]

Before we start, we have to introduce some notation. We call a pair $(m_j;x_j)$ a letter and the set of all letters the alphabet A. We further call m_j the degree of the letter (m_j,x_j). On the alphabet A we define a multiplication

$$
\begin{aligned}
&\cdot:A\times A\to A,\\
&(m_1,x_1)\cdot(m_2,x_2)=(m_1+m_2,x_1x_2),
\end{aligned}
\tag{A1}
$$

e.g., the x_j's are multiplied and the degrees are added. As a short-hand notation we will in the following denote a letter just by $X_j=(m_j;x_j)$. A word is an ordered sequence of letters, e.g.,

$$W=X_1,X_2,\ldots,X_k. \tag{A2}$$

We denote the word of length zero by e. The sums defined in (1) are therefore completely specified by the upper summation limit n and a word W. In particular for any positive n the sum corresponding to the empty word e equals 1. A quasishuffle algebra $\mathcal{A}$ on the vector space of words is defined by[46]

$$\begin{aligned} &e\circ W=W\circ e=W,\\ &(X_1,W_1)\circ(X_2,W_2)=X_1,(W_1\circ(X_2,W_2))+X_2,((X_1,W_1)\circ W_2)+(X_1\cdot X_2),(W_1\circ W_2). \end{aligned} \tag{A3}$$

Note that "$\cdot$" denotes multiplication of letters as defined in Eq. (A1), whereas "$\circ$" denotes the product in the algebra $\mathcal{A}$, recursively defined in Eq. (A3). We observe that the formula for the multiplication of Z-sums Eq. (7) is identical to Eq. (A3). The Z-sums therefore form a quasishuffle algebra.

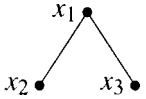
We now discuss the connection with the Hopf algebra of Kreimer.[47] Kreimer showed that the process of renormalization of UV-divergences occurring in quantum field theories can be formulated in terms of a Hopf algebra structure. We first recall the properties of an algebra and a coalgebra: An algebra has a unit and a multiplication, whereas a coalgebra has a counit and a comultiplication. A Hopf algebra is an algebra and a coalgebra at the same time, such that the two structures are compatible with each other. In addition there is an antipode. We show that the coalgebra structure of Z-sums is identical to the coalgebra structure of the Hopf algebra of Kreimer. To this aim we introduce the explicit definitions of the counit, the coproduct, and the antipode. It is convenient to phrase the coalgebra structure in terms of rooted trees. A Z-sums can be represented as rooted trees without any sidebranchings. As a concrete example we write down the pictorial representation of a sum of depth three:

$$Z(n;m_1,m_2,m_3;x_1,x_2,x_3)=\sum_{i_1=1}^{n}\sum_{i_2=1}^{i_1-1}\sum_{i_3=1}^{i_2-1}\frac{x_1^{i_1}}{i_1^{m_1}}\frac{x_2^{i_2}}{i_2^{m_2}}\frac{x_3^{i_3}}{i_3^{m_3}}= \tag{A4}$$

The pictorial representation views a Z-sum as a rooted tree without any sidebranchings. The outermost sum corresponds to the root. By convention, the root is always drawn on the top.

Trees with sidebranchings are given by nested sums with more than one subsum, e.g.,

$$\sum_{i=1}^{n}\frac{x_1^i}{i^{m_1}}Z(i-1;m_2,x_2)Z(i-1;m_3;x_3) \quad = \tag{A5}$$



Of course, due to the multiplication formula, trees with sidebranchings can always be reduced to trees without any sidebranchings:

$$\begin{aligned} \sum_{i=1}^{n}\frac{x_1^i}{i^{m_1}}Z(i-1;m_2,x_2)Z(i-1;m_3;x_3)&=Z(n;m_1,m_2,m_3;x_1,x_2,x_3)+Z(n;m_1,m_3,m_2;x_1,x_3,x_2)\\ &\quad+Z(n;m_1,m_2+m_3;x_1,x_2x_3). \end{aligned} \tag{A6}$$

The coalgebra structure is formulated in terms of rooted trees (e.g., there is no need to convert rooted trees to a basis of rooted trees without sidebranchings). We first introduce some notation how to manipulate rooted trees. We adopt the notation of Kreimer and Connes.[47,48] An elementary cut of a rooted tree is a cut at a single chosen edge. An admissible cut is any assignment of elementary cuts to a rooted tree such that any path from any vertex of the tree to the root has at most one elementary cut. An admissible cut maps a tree t to a monomial in trees $t_1\circ\cdots\circ t_{k+1}$.

Note that precisely one of these subtrees t_j will contain the root of t. We denote this distinguished tree by $R^C(t)$, and the monomial delivered by the k other factors by $P^C(t)$. The counit $\overline{e}$ is given by

$$\begin{aligned} \overline{e}(e) &= 1, \\ \overline{e}(t) &= 0, \quad t \neq e. \end{aligned} \tag{A7}$$

The coproduct Δ is defined by

$$\begin{aligned} \Delta(e) &= e \otimes e, \\ \Delta(t) &= e \otimes t + t \otimes e + \sum_{\text{adm. cuts } C \text{of } t} P^C(t) \otimes R^C(t), \\ \Delta(t_1 \circ \cdots \circ t_k) &= \Delta(t_1)(\circ \otimes \circ) \cdots (\circ \otimes \circ)\Delta(t_k). \end{aligned} \tag{A8}$$

The antipode $\mathcal{S}$ is given by

$$\begin{aligned} \mathcal{S}(e) &= e, \\ \mathcal{S}(t) &= -t - \sum_{\text{adm. cuts } C \text{ of } t} \mathcal{S}(P^C(t)) \circ R^C(t), \\ \mathcal{S}(t_1 \circ \cdots \circ t_k) &= \mathcal{S}(t_1) \circ \cdots \circ \mathcal{S}(t_k). \end{aligned} \tag{A9}$$

The proof that these definitions yield a Hopf algebra can be found in Ref. 46 and is not repeated here. The Hopf algebra of Kreimer and Connes,[47,48] which emerged in the context of renormalization of UV-divergences, has a slightly different algebra structure. There the algebra is generated by rooted trees. In this algebra a product of two rooted trees is not necessarily a rooted tree again. However, the coalgebra structures are identical, which is a remarkable observation.

Let us give some examples for the coproduct and the antipode for Z-sums:

$$\begin{aligned} \Delta Z(n;m_1;x_1) &= e \otimes Z(n;m_1;x_1) + Z(n;m_1;x_1) \otimes e, \\ \Delta Z(n;m_1,m_2;x_1,x_2) &= e \otimes Z(n;m_1,m_2;x_1,x_2) + Z(n;m_1,m_2;x_1,x_2) \otimes e + Z(n;m_2;x_2) \\ &\quad \otimes Z(n;m_1;x_1), \end{aligned} \tag{A10}$$

$$\begin{aligned} \mathcal{S}Z(n;m_1;x_1) &= -Z(n;m_1;x_1), \\ \mathcal{S}Z(n;m_1,m_2;x_1,x_2) &= Z(n;m_2,m_1;x_2,x_1) + Z(n;m_1+m_2;x_1x_2). \end{aligned} \tag{A11}$$

APPENDIX B: REVIEW OF GONCHAROV'S MULTIPLE POLYLOGARITHMS

At the end of the day we express our results in terms of Goncharov's multiple polylogarithms. They therefore form an important specialization of nested sums and we therefore review some of their properties. After the introduction by Gonacharov[5] they have been extensively studied by Borwein *et al.*[6] They use a different notation which is related to the one of Goncharov by

$$\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1) = \lambda\begin{pmatrix} m_1,\ldots,m_k \\ b_1,\ldots,b_k \end{pmatrix}, \quad b_j = \frac{1}{x_1 x_2 \cdots x_j}. \tag{B1}$$

Most of the material reviewed in this section is based on the work of Borwein *et al.*[6]

1. Integral representations

We first define the notation for iterated integrals

$$\int_0^\Lambda \frac{\mathrm{d}t}{a_n-t}\circ\cdots\circ\frac{\mathrm{d}t}{a_1-t}=\int_0^\Lambda \frac{\mathrm{d}t_n}{a_n-t_n}\int_0^{t_n}\frac{\mathrm{d}t_n-1}{a_{n-1}-t_{n-1}}\times\cdots\times\int_0^{t_2}\frac{\mathrm{d}t_1}{a_1-t_1}. \tag{B2}$$

We further use the following short-hand notation:

$$\int_0^\Lambda\left(\frac{\mathrm{d}t}{t}\circ\right)^m\frac{\mathrm{d}t}{a-t}=\int_0^\Lambda\underbrace{\frac{\mathrm{d}t}{t}\circ\cdots\frac{\mathrm{d}t}{t}}_{m\ \text{times}}\circ\frac{\mathrm{d}t}{a-t}. \tag{B3}$$

The integral representation for $\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1)$ reads

$$\begin{aligned}\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1)=&\int_0^{x_1x_2\cdots x_k}\left(\frac{\mathrm{d}t}{t}\circ\right)^{m_1-1}\frac{\mathrm{d}t}{x_2x_3\cdots x_k-t}\circ\left(\frac{\mathrm{d}t}{t}\circ\right)^{m_2-1}\\&\times\frac{\mathrm{d}t}{x_3\ldots x_k-t}\circ\cdots\circ\left(\frac{\mathrm{d}t}{t}\circ\right)^{m_k-1}\frac{\mathrm{d}t}{1-t}.\end{aligned} \tag{B4}$$

In the notation of Borwein *et al.* this representation reads

$$\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1)=(-1)^k\int_0^1\left(\frac{\mathrm{d}t}{t}\circ\right)^{m_1-1}\frac{\mathrm{d}t}{t-b_1}\circ\left(\frac{\mathrm{d}t}{t}\circ\right)^{m_2-1}\frac{\mathrm{d}t}{t-b_2}\circ\cdots\circ\left(\frac{\mathrm{d}t}{t}\circ\right)^{m_k-1}\frac{\mathrm{d}t}{t-b_k}, \tag{B5}$$

where the b_j's are related to the x_j's as in Eq. (B1). Changing the integration variables according to $t\to1-t$ yields the dual integral representation:

$$\begin{aligned}\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1)=&(-1)^k\int_0^1\frac{\mathrm{d}t}{1-b_k-t}\circ\left(\frac{\mathrm{d}t}{1-t}\circ\right)^{m_k-1}\\&\times\frac{\mathrm{d}t}{1-b_{k-1}-t}\circ\left(\frac{\mathrm{d}t}{1-t}\circ\right)^{m_{k-1}-1}\circ\cdots\circ\frac{\mathrm{d}t}{1-b_1-t}\circ\left(\frac{\mathrm{d}t}{1-t}\circ\right)^{m_1-1}.\end{aligned} \tag{B6}$$

In addition to these weight-dimensional integral representations there is also a depth-dimensional integral representation:

$$\begin{aligned}\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1)=&\frac{1}{\Gamma(m_1)\cdots\Gamma(m_k)}\int_1^\infty\frac{\mathrm{d}t_1}{t_1}\frac{(\ln t_1)^{m_1-1}}{\frac{t_1}{x_1}-1}\times\int_1^\infty\frac{\mathrm{d}t_2}{t_2}\frac{(\ln t_2)^{m_2-1}}{\frac{t_1t_2}{x_1x_2}-1}\times\cdots\\&\times\int_1^\infty\frac{\mathrm{d}t_k}{t_k}\frac{(\ln t_k)^{m_k-1}}{\frac{t_1\cdots t_k}{x_1\cdots x_k}-1}.\end{aligned} \tag{B7}$$

2. The shuffle algebra

Instead of specifying a multiple polylogarithm by the x_j's and m_j's, we may denote the function by a single string

$$(\alpha_1,\alpha_2,\ldots,\alpha_w)=(0,\ldots,0,b_1,0,\ldots,0,b_2,\ldots,0,\ldots,0,b_k), \tag{B8}$$

where (m_j-1) zeros preceed b_j. Defining further

$$\Omega(\alpha_i)=\frac{dt}{t-\alpha_i} \tag{B9}$$

allows us to rewrite the integral representation Eq. (B5) as

$$\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1)=(-1)^k\int_0^1\Omega(\alpha_1)\circ\cdots\circ\Omega(\alpha_w). \tag{B10}$$

From the iterated integral representation one deduces a second algebra structure with multiplication given by

$$\begin{aligned}&\mathrm{Li}_{m_k,\ldots,m_1}(x_k,\ldots,x_1)\times\mathrm{Li}_{m_{k+l},\ldots,m_{k+1}}(x_{k+l},\ldots,x_{k+1})\\&\quad=(-1)^{k+l}\int_0^1\Omega(\alpha_1)\circ\cdots\circ\Omega(\alpha_{w_k})\int_0^1\Omega(\alpha_{w_k+1})\circ\cdots\circ\Omega(\alpha_{w_k+w_l})\\&\quad=(-1)^{k+l}\sum_{\text{shuffle}}\int_0^1\Omega(\alpha_{\sigma(1)})\circ\cdots\circ\Omega(\alpha_{\sigma(w_k+w_l)}),\end{aligned} \tag{B11}$$

where $w_k=m_1+\cdots+m_k$, $w_l=m_{k+1}+\cdots+m_{k+l}$ and the sum is over all permutations, which preserve the relative order of the strings $\Omega(\alpha_1)\cdots\Omega(\alpha_{w_k})$ and $\Omega(\alpha_{w_k+1})\cdots\Omega(\alpha_{w_k+w_l})$.

3. Reduction to simpler functions

The multiple polylogarithms contain a variety of other functions as a subset. We start with depth one. As the notation already suggests, the multiple polylogarithms are in this case identical to the classical polylogarithms, e.g.,

$$\mathrm{Li}_0(x)=\frac{x}{1-x},\quad \mathrm{Li}_1(x)=-\ln(1-x) \tag{B12}$$

and

$$\mathrm{Li}_n(x)=\int_0^x dt\,\frac{\mathrm{Li}_{n-1}(t)}{t}. \tag{B13}$$

Nielsen's generalized polylogarithms,[4] defined through

$$S_{n,p}(x)=\frac{(-1)^{n-1+p}}{(n-1)!p!}\int_0^1 dt\,\frac{\ln^{n-1}(t)\ln^p(1-tx)}{t}, \tag{B14}$$

are related to the multiple polylogarithms by

$$S_{n,p}(x)=\mathrm{Li}_{1,\ldots,1,n+1}(\underbrace{1,\ldots,1}_{p-1},x), \tag{B15}$$

where $(p-1)$ one's occur before $n+1$ and x. The harmonic polylogarithms of Remiddi and Vermaseren[7] are related to the multiple polylogarithms for positive indices as

$$H_{m_1,\ldots,m_k}(x)=\mathrm{Li}_{m_k,\ldots,m_1}(\underbrace{1,\ldots,1}_{k-1},x). \tag{B16}$$

The harmonic polylogarithms are defined recursively through

$$H_0(x)=\ln(x),\quad H_1(x)=-\ln(1-x),\quad H_{-1}(x)=\ln(1+x), \tag{B17}$$

and

$$\begin{aligned} H_{m_1+1,m_2,\ldots,m_k}&=\int_0^x \mathrm{d}t\, f_0(t)H_{m_1,m_2,\ldots,m_k}(t),\\ H_{\pm 1,m_2,\ldots,m_k}&=\int_0^x \mathrm{d}t\, f_{\pm 1}(t)H_{m_2,\ldots,m_k}(t), \end{aligned} \tag{B18}$$

where the fractions $f_0(x)$, $f_1(x)$, and $f_{-1}(x)$ are given by

$$f_0(x)=\frac{1}{x},\quad f_1(x)=\frac{1}{1-x},\quad f_{-1}(x)=\frac{1}{1+x}. \tag{B19}$$

Recently Gehrmann and Remiddi[8] extended the harmonic polylogarithms to two-dimensional harmonic polylogarithms (2dHPL) by extending the fractions to

$$f(z,x)=\frac{1}{z+x},\quad f(1-z,x)=\frac{1}{1-z-x}. \tag{B20}$$

From the integral representation Eq. (B4) it is clear that the 2dHPL are a subset of Goncharov's multiple polylogarithms. If we identitfy $x=x_1x_2\times\cdots\times x_k$ we have

$$\int_0^x \mathrm{d}t\, f(z,t)\mathrm{Li}_{m_k,\ldots,m_1}\left(x_k,\ldots,x_2,\frac{t}{x_2\ldots x_k}\right)=-\mathrm{Li}_{m_k,\ldots,m_1,1}\left(x_k,\ldots,x_2,-\frac{z}{x_2\cdots x_k},-\frac{x}{z}\right), \tag{B21}$$

$$\int_0^x \mathrm{d}t\, f(1-z,t)\mathrm{Li}_{m_k,\ldots,m_1}\left(x_k,\ldots,x_2,\frac{t}{x_2\cdots x_k}\right)=\mathrm{Li}_{m_k,\ldots,m_1,1}\left(x_k,\ldots,x_2,\frac{1-z}{x_2\cdots x_k},\frac{x}{1-z}\right).$$
