and choose the volume element $\mathrm{d}x\wedge\mathrm{d}y\wedge\mathrm{d}u\wedge\mathrm{d}v$. Let $A\in T^*\mathbb{R}^4\otimes\mathbf{sl}(3,\mathbb{R})$ be a connection one-form on a real rank-three vector bundle, and let F be its curvature two-form. In a local trivalization $A=A_a\mathrm{d}x^a$ and $F=F_{ab}\mathrm{d}x^a\wedge\mathrm{d}x^b$, where $F_{ab}=[D_a,D_b]$ takes its values in $\mathbf{sl}(3,\mathbb{R})$. Here $D_a=\partial_a-A_a$ is the covariant derivative. The connection is defined up to gauge transformations $A\to h^{-1}Ah-h^{-1}\mathrm{d}h$, where $h\in\mathrm{Map}(\mathbb{R}^4,\mathrm{SL}(3,\mathbb{R}))$. The ASDYM equations on A_a are $F=-*F$, or

$$F_{xu}=0, \quad F_{xy}-F_{uv}=0, \quad F_{yv}=0.$$

These equations are equivalent to the commutativity of the Lax pair

$$L_0 = D_x - \lambda D_v, \quad L_1 = D_u - \lambda D_y \tag{9}$$

for every value of the parameter λ.

We shall require that the connection possess two commuting translational symmetries X_1, X_2, which in our coordinates are in $X_1 = \partial_u$ and $X_2 = \partial_v$ directions. The direct calculation shows that the ASDYM equations are solved by the following ansatze for Higgs fields A_u and A_v, and gauge fields A_x and A_y

$$\begin{aligned} A_u &= -\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ e^{\omega} & 0 & 0 \end{pmatrix}, \quad A_v = -\begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \\ A_x &= -\begin{pmatrix} -\omega_x & 0 & 0 \\ 1 & \omega_x & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad A_y = -\begin{pmatrix} 0 & e^{-2\omega} & 0 \\ 0 & 0 & e^{\omega} \\ 0 & 0 & 0 \end{pmatrix}, \end{aligned} \tag{10}$$

iff $\omega(x,y)$ satisfies the Tzitzéica equation (1). We note that the reduced Lax pair (9) could be obtained directly from (2) multiplying the second equation by λ.

We connect the ASDYM equations and those on a pseudo-hyper-complex four-dimensional metric (5) by considering gauge potentials that take values in a Lie algebra of vector fields on some manifold. Proposition 1 reveals one such connection: We make the identification: $X = D_x$, $Y = D_y$, $U = D_u$, $V = D_v$. By comparing (9) with (4), we see that the pseudo-hyper-complex equation is a reduction of the ASDYM with the infinite-dimensional gauge group Diff($\mathcal{M}$) by translations along the four coordinate vectors ∂_x, ∂_y, ∂_u, ∂_v.

To reveal the connection with the Tzitzéica equation we shall proceed in a slightly different way: Consider the ASDYM equations with the gauge group G, being a sup-group of Diff(Σ), where Σ is some two-dimensional real manifold. We can represent the components of the connection form of A by vector fields on Σ depending also on the coordinates on $\mathbb{R}^4$. Now we suppose that A is invariant under two translations. The reduced Lax pair will then descend to $\mathcal{M} = \mathbb{R}^2 \times \Sigma$ and give rise to a pseudo-hyper-complex metric. A similar idea has been used in Refs. 11 and 12 to construct new classes of hyper-Kähler four-manifolds out of solutions to some integrable ODEs and PDEs.

Because we are interested in the case $G = \mathrm{SL}(3,\mathbb{R})$, we take Σ to be a real projective plane $\mathbb{RP}^2$ with a natural $\mathrm{PSL}(3,\mathbb{R})$ group action. The relevant vector fields will be constructed in the next subsection.

A. sl(3,$\mathbb{R}$) as a subalgebra of diff($\mathbb{RP}^2$)

To construct a null tetrad for a pseudo-hyper-complex metric we will need an explicit embedding $\mathbf{sl}(3,\mathbb{R}) \to \mathbf{diff}(\mathbb{RP}^2)$. Let

$$\begin{pmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{pmatrix} \in \mathrm{SL}(3,\mathbb{R}).$$

Consider the projective transformations of a plane with local coordinates (p,q):

$$p \to \frac{A_{11}p + A_{12}q + A_{13}}{A_{31}p + A_{32}q + A_{33}}, \quad q \to \frac{A_{21}p + A_{22}q + A_{23}}{A_{31}p + A_{32}q + A_{33}}.$$

This gives rise to a representation of the Lie algebra $\mathbf{sl}(3,\mathbb{R})$ of $\mathrm{SL}(3,\mathbb{R})$ by vector fields on $\mathbb{RP}^2$. The easiest way to obtain this representation is to consider the infinitesimal linear left action of $\mathrm{SL}(3,\mathbb{R})$ on $\mathbb{R}^3$. The generators of this action pushed down to the projective plane are

$$\partial_p, \quad \partial_q, \quad p\partial_q, \quad q\partial_p, \quad -p^2\partial_p - pq\partial_q, \quad -pq\partial_p - q^2\partial_q,$$
$$p\partial_p - q\partial_q, \quad p\partial_p + 2q\partial_q.$$

More precisely, a vector field corresponding to an element

$$M = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & -a_{11}-a_{33} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} \in \mathbf{sl}(3,\mathbb{R})$$

is

$$\begin{aligned} X_M = {} & [a_{13} + (a_{11} - a_{33})p + a_{12}q - a_{31}p^2 - a_{32}pq]\partial_p \\ & + [a_{23} + a_{21}p - (a_{11} + 2a_{33})q - a_{31}pq - a_{32}q^2]\partial_q. \end{aligned} \tag{11}$$

IV. CURVED METRICS FROM THE TZITZÉICA EQUATION

Consider the reduced ASDYM Lax pair (9),

$$L_0 = \partial_x - A_x - \lambda A_v, \quad L_1 = -A_u - \lambda(\partial_y - A_y),$$

such that $[L_0, L_1] = 0$ yields (1) and use (11) to replace the matrices (10) by vector fields. Now compare the resulting Lax pair with (4), and read off the null tetrad for a hyper-complex metric (some care needs to be taken with signs because $[X_M, X_N] = -X_{[M,N]}$). This yields

$$\begin{gathered} X = \partial_x + (-\omega_x p + pq)\partial_p + (\omega_x q - p + q^2)\partial_q, \quad U = -e^{\omega}p^2\partial_p - e^{\omega}pq\partial_q, \\ Y = \partial_y - e^{-2\omega}q\partial_p - e^{\omega}\partial_q, \quad V = \partial_p. \end{gathered} \tag{12}$$

The first two equations in (6) are satisfied trivially, and the third one yields

$$[X,Y] - [U,V] = (\omega_{xy} + e^{-2\omega} - e^{\omega})(p\partial_p - q\partial_q),$$

which is 0 if $\omega(x,y)$ satisfies Eq. (1). Let $p = \exp(P), q = \exp(Q)$. The frame of dual one-forms is

$$\begin{aligned} & e_X = \mathrm{d}x, \quad e_U = (\omega_x e^{-\omega-P} + e^{-\omega-P+Q} - e^{-\omega-Q})\mathrm{d}x - e^{-P-Q}\mathrm{d}y - e^{-\omega-P}\mathrm{d}Q, \\ & e_Y = \mathrm{d}y, \quad e_V = (2\omega_x e^{P} - e^{2P-Q})\mathrm{d}x + (e^{Q-2\omega} - e^{\omega+P-Q})\mathrm{d}y - e^{P}\mathrm{d}Q + e^{P}\mathrm{d}P. \end{aligned} \tag{13}$$

Finally, the metric is given by

$$g = 2(e_X e_Y - e_U e_V). \tag{14}$$

It is instructive to verify our calculation by considering the dual formulation of Boyer. Using the identification between the two-forms, and endomorphisms given by g, define a basis $(\Omega_I, \Omega_S, \Omega_T)$ of Λ^2_+ by

$$\Omega_I(X_1,X_2) = -g(IX_1,X_2), \quad \Omega_S(X_1,X_2) = -g(SX_1,X_2), \quad \Omega_T(X_1,X_2) = -g(TX_1,X_2),$$

so that

$$\Omega_S = e_X \wedge e_U - e_Y \wedge e_V, \quad \Omega_T = e_X \wedge e_Y - e_U \wedge e_V, \quad \Omega_I = e_X \wedge e_U + e_Y \wedge e_V.$$

The Lee form $\mathcal{A}$ can be found, such that Eqs. (8) reduce down to (1). Indeed, taking

$$\mathcal{A} = (3e^{P-Q} - 4\omega_x)\mathrm{d}x + (3e^{\omega-Q} - \omega_y)\mathrm{d}y - \mathrm{d}P + 2\mathrm{d}Q$$

yields

$$d\Omega_I - \mathcal{A}\wedge\Omega_I = 0, \quad d\Omega_S - \mathcal{A}\wedge\Omega_S = 0,$$

$$d\Omega_T - \mathcal{A}\wedge\Omega_T = e^{\omega}[\omega_{xy} + e^{-2\omega} - e^{\omega}]dx\wedge dy\wedge d(P+Q) = 0.$$

The metric (14) is therefore never conformal to pseudo-hyper-Kähler because $d\mathcal{A}\neq 0$. Even the simplest solution $\omega = 0$ yields a nontrivial hyper-complex structure

$$g = (e^{P} - e^{2P-2Q})dx^2 + (3 - 2e^{P-2Q} - e^{2Q-P})dxdy + (e^{-P} - e^{2Q})dy^2 - 2dQ^2 + 2dQdP$$
$$+ (e^{P-Q} - e^{Q})dxdP + e^{-Q}dydP + (e^{Q} - 2e^{P-Q})dxdQ + (e^{Q-P} - 2e^{Q})dydQ.$$

[It is worth remarking that a Tzitzéica surface corresponding to $\omega = 0$ (so called Jonas Hexenhut) is also nontrivial.] The Backlund transformations for the Tzitzéica equation[2,13,14] may now be used to generate more complicated metrics.

V. THE TWISTOR CORRESPONDENCE

From the point of view of the Yang–Mills equations, the solutions (14) that we have obtained are metrics on the total space of $\mathcal{E}$, the $\mathbb{RP}^2$-bundle associated to the Yang–Mills bundle. In this section we explain how our construction ties in with the twistor correspondences.

Consider the manifold $\mathcal{Z} = \mathbb{R}^{2,2}\times\mathbb{CP}^1$ [$\mathbb{R}^{2,2}$ denotes $\mathbb{R}^4$ with a flat metric of signature (2,2)]. It decomposes into two open sets

$$\mathcal{Z}_+ = \{(x^a,\lambda)\in\mathcal{Z};\ \mathrm{Im}(\lambda) > 0\} = \mathbb{R}^{2,2}\times D_+,$$

$$\mathcal{Z}_- = \{(x^a,\lambda)\in\mathcal{Z};\ \mathrm{Im}(\lambda) < 0\} = \mathbb{R}^{2,2}\times D_-,$$

where $D_\pm$ are two copies of a Poincare disc. These submanifolds are separated by

$$\mathcal{F}_0 = \{(x^a,\lambda)\in\mathcal{Z};\ \mathrm{Im}(\lambda) = 0\} = \mathbb{R}^{2,2}\times\mathbb{RP}^1.$$

The complex structures on $\mathcal{Z}_\pm$ are specified by a distribution $\mathcal{D}$ of anti-holomorphic vector fields

$$\mathcal{D} = \{\partial_x - \lambda\partial_v,\ \partial_u - \lambda\partial_y,\ \partial_{\bar\lambda}\}.$$

The above distribution with $\lambda\in\mathbb{RP}^1$ defines a foliation of $\mathcal{F}_0$ with a quotient $\mathcal{Z}_0$ which leads to a double fibration:

$$\mathcal{M} \overset{r}{\leftarrow} \mathcal{F}_0 \overset{s}{\rightarrow} \mathcal{Z}_0. \tag{15}$$

The *twistor space* $\mathcal{Z}$ is a three complex dimensional union of two open subsets $\mathcal{Z}_\pm$ separated by a three-dimensional real boundary (*real twistor space*) $\mathcal{Z}_0 := s(\mathcal{F}_0)$.

Each point $\mathbf{x}\in\mathbb{R}^{2,2}$ determines a holomorphic curve $L_{\mathbf{x}}$ made up of two sheets $D_\pm$ of complex structures (3) compactified by adding S^1:

$$\mathbf{x} = (x,y,u,v) \rightarrow L_{\mathbf{x}} = \{(\omega^0,\omega^1,\lambda):\omega^0(\lambda) = v + \lambda x,\ \omega^1(\lambda) = u + \lambda y,\ \lambda\in\mathbb{CP}^1\}.$$

The normal bundle $N = T\mathcal{Z}|_{L_x}/TL_x$ of L_x in $\mathcal{Z}$ is a direct sum of two line bundles with a Chern class equal to one $\mathcal{O}(1)\oplus\mathcal{O}(1)$. If $\mathbf{x}$ and $\mathbf{x}'$ both lie on a self-dual null plane in $\mathbb{R}^{2,2}$ then $L_{\mathbf{x}}$ and $L_{\mathbf{x}}{}'$ intersect in $\mathcal{Z}$ at one point for which $\lambda\in\mathbb{RP}^1$.

Now we turn to the SL(3,$\mathbb{R}$) ASDYM equations on $\mathbb{R}^{2,2}$ with two commuting symmetries X_1, X_2. Let $\mathcal{E} = \mathbb{R}^{2,2}\times\mathbb{RP}^2$ be the bundle associated to the Yang–Mills bundle by the representation of SL(3,$\mathbb{R}$) as projective transformations of $\mathbb{RP}^2$. The SL(3,$\mathbb{R}$) ASDYM connection defines, by a $(++--)$ version of a Ward construction,[15] two holomorphic vector bundles $E_{W_\pm}\rightarrow\mathcal{Z}_\pm$.

The following construction describes also the general case of $G=\mathrm{Diff}(\mathbb{RP}^2)$. For this it is convenient to use the bundles $\mathcal{E}_{W_\pm}$ associated to $E_{W_\pm}$ by the G action on $\mathbb{RP}^2$ (the Ward bundles have infinite-dimensional fibers).

On the other hand, any pseudo-hyper-complex four-metric corresponds to a deformed twistor space $\mathcal{Z}_\mathcal{M}$.[7,9]

Proposition 2: Let $\mathcal{Z}_\mathcal{M}$ be a three-dimensional complex manifold with

(i) *a four parameter family of rational curves with normal bundle $\mathcal{O}(1)\oplus\mathcal{O}(1)$,*
(ii) *a holomorphic projection $\mu:\mathcal{Z}_\mathcal{M}\to\mathbb{CP}^1$, and*
(iii) *an anti-holomorphic involution $\rho:\mathcal{Z}_\mathcal{M}\to\mathcal{Z}_\mathcal{M}$ fixing a real equator of each rational curve.*

Then the real moduli space $\mathcal{M}$ of the ρ-invariant curves is equipped with conformal class $[g]$ of pseudo-hyper-Hermitian metrics. Conversely, given a real analytic pseudo-hyper-Hermitian metrics, there exists a corresponding twistor space with the above structures.

The existence of the holomorphic projection μ reflects the fact that the Lax pair (4) for the pseudo-hyper-complex equations does not contain vector fields ∂_λ.

In this article we have explained how the quotient q of $\mathcal{E}$ by lifts of X_1,X_2 is, by Proposition 4, equipped with a pseudo-hyper-complex metric. To give a more complete picture we can construct the deformed twistor space directly from $\mathcal{E}_{W_\pm}$ and show that this is the twistor space of $\mathcal{M}$.

Given an analytic solution to (1) one can obtain the corresponding twistor space by equipping $\mathcal{M}\times\mathbb{CP}^1$ with a structure of a complex manifold $\mathcal{Z}$: The basis of [0,1] vectors is given by the distribution $\mathcal{D}_\mathcal{M}$ consisting of the Lax pair for the Tzitzéica equation together with the standard complex structure on the $\mathbb{CP}^1$. The point is that this distribution can be obtained directly from $\mathcal{D}$. To see it consider the following chain of correspondences:

$$\begin{array}{ccccc}
\mathcal{Z}_\mathcal{M}=\mathcal{Z}_{\mathcal{M}_-}\cup\mathcal{Z}_{\mathcal{M}_0}\cup\mathcal{Z}_{\mathcal{M}_+} & \overset{\tilde\kappa}{\leftarrow} & \mathcal{E}_W=\mathbb{R}^{2,2}\times\mathbb{RP}^2\times\mathbb{CP}^1 & \overset{\pi}{\to} & \{\mathcal{Z},\mathcal{D}\}\\
\downarrow & & \uparrow & & \downarrow\\
\mathcal{M} & \overset{\kappa}{\leftarrow} & \mathcal{E}=\mathbb{R}^{2,2}\times\mathbb{RP}^2 & \to & \mathbb{R}^{2,2}.
\end{array}$$

Here $\mathcal{Z}$ and $\mathcal{Z}_\mathcal{M}$ are the twistor spaces of $\mathbb{R}^{2,2}$ and $\mathcal{M}$, respectively. The twistor space $\mathcal{Z}_\mathcal{M}$ is defined as the quotient $\tilde\kappa$ of $\mathcal{E}_W$ by lifts of symmetries X_1,X_2. The complex structures on $\mathcal{Z}_{\mathcal{M}_\pm}$ are given a subbundle

$$\mathcal{D}_M=\tilde\kappa(\pi^*\mathcal{D})=\{L_0,L_1,\partial_\lambda^-\}\subset T\mathcal{Z}_\mathcal{M},$$

where

$$L_0=\partial_x+(-\omega_x p+pq)\partial_p+(\omega_x q-p+q^2)\partial_q-\lambda\partial_p,$$

$$L_1=-e^\omega p^2\partial_p-e^\omega pq\partial_q-\lambda(\partial_y-e^{-2\omega}q\partial_p-e^\omega\partial_q).$$

Here π is a holomorphic fibration of the associated Ward bundle. The real three-dimensional surface $\mathcal{Z}_{\mathcal{M}_0}\subset\mathcal{Z}_\mathcal{M}$ is a quotient of $\mathbb{R}^{2,2}\times\mathbb{RP}^2\times\mathbb{RP}^1$ by the four-dimensional real distribution $\{L_0,L_1,X_1,X_2\}$. Moreover, $\mathcal{Z}_\mathcal{M}$ is holomorphically fibered over $\mathbb{CP}^1$ and it has a $\mathcal{O}(1)\oplus\mathcal{O}(1)$ rational curve embedded in it. Both structures are pulled back from $\mathcal{Z}$ and projected by $\tilde\kappa$. The compatibility of these projections is a consequence of the commutativity of the the above diagram, which follows from the integrability the the distribution spanned by (lifts of)

$$X_1,\ X_2,\ L_0,\ L_1,\ \partial_\lambda^-$$

and from the fact that (X_1,X_2) commute with (L_0,L_1).

ACKNOWLEDGMENTS

The author thanks Eugene Ferapontov for drawing attention to the role of the Tzitzéica equation in the theory of surfaces in affine geometry. Ian Strachan is acknowledged for having read the manuscript carefully.

Dimensionally dependent tensor identities by double antisymmetrization

S. Brian Edgar[a] and A. Höglund[b]

(Received 21 June 2001; accepted for publication 17 October 2001)

Some years ago, Lovelock showed that a number of apparently unrelated familiar tensor identities had a common structure, and could all be considered consequences in n-dimensional space of a pair of fundamental identities involving trace-free (p,p)-forms where $2p \geqslant n$. We generalize Lovelock's results, and by using the fact that associated with *any* tensor in n-dimensional space there is associated a fundamental tensor identity obtained by antisymmetrizing over $n+1$ indices, we establish a very general ''master'' identity for *all* trace-free (k,l)-forms. We then show how various other special identities are direct and simple consequences of this master identity; in particular we give direct application to Maxwell, Lanczos, Ricci, Bel, and Bel-Robinson tensors, and also demonstrate how relationships between scalar invariants of the Riemann tensor can be investigated in a systematic manner. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1425428]

I. INTRODUCTION

In an n-dimensional space any tensor expression $T_{a_1 a_2 \ldots a_k}$ with $k > n$ indices satisfies a tensor identity

$$T_{[a_1 a_2 \ldots a_k]} = 0. \tag{1}$$

Such mathematically obvious identities can be very useful in practical calculations. However, the antisymmetrization process may not be so explicit since it need not be applied only on free indices; it could also involve dummy indices, some of which could be absorbed into traces, as we shall demonstrate in the following example. (Here, and in the rest of this paper, we use the abstract index notation.[1] However, any index notation would probably work well as long as the above-mentioned property holds.)

Example I.1: Dianyan Xu[2] constructed the following two scalar identities for the Riemann tensor in *four dimensional* spaces,

$$R^a{}_b R^{bcde} R_{acde} = \tfrac{1}{4} R R^{abcd} R_{abcd} + 2 R^{ac} R^{bd} R_{abcd} + 2 R^a{}_b R^b{}_c R^c{}_a - 2 R R^a{}_b R^b{}_a + \tfrac{1}{4} R^3 \tag{2}$$

and

$$R^a{}_c{}^b{}_d R^c{}_e{}^d{}_f R^e{}_a{}^f{}_b = \tfrac{1}{2} R^{ab}{}_{cd} R^{cd}{}_{ef} R^{ef}{}_{ab} - \tfrac{3}{8} R R^{ab}{}_{cd} R^{cd}{}_{ab} - 3 R^{ac} R^{bd} R_{abcd} - 4 R^a{}_b R^b{}_c R^c{}_a + \tfrac{9}{2} R R^a{}_b R^b{}_a - \tfrac{5}{8} R^3. \tag{3}$$

These were obtained after a lengthy calculation by decomposing the Riemann tensor R_{abcd} into its Weyl and Ricci components, and then *using spinor methods*; in fact Dianyan Xu claimed that it was not possible to obtain these identities from the algebraic properties of the Riemann tensor alone.

[a]Electronic mail: bredg@mai.liu.se
[b]Electronic mail: anhog@mai.liu.se

However, it was pointed out by Harvey[3] that the first identity could be obtained directly by expanding

$$R^{ab}{}_{[ab}R^{cd}{}_{cd}R^{e}{}_{e]}=0 \tag{4}$$

and the second identity by expanding

$$R^{ab}{}_{[ab}R^{cd}{}_{cd}R^{ef}{}_{ef]}=0 \tag{5}$$

and combining the result with the first identity.

So it is now clear that identities of the type of (2) and (3) exist not only for Riemann tensors, nor even just for Riemann candidates (any four-tensors with the index symmetries of a Riemann tensor); they are in fact valid for any tensors which permit the antisymmetrization constructions (4) and (5). However it should be noted that to get the precise forms of (2) and (3) some of the symmetries of the Riemann tensor must be used.

Harvey's approach also confirmed that both identities were valid in four and lower dimensions—irrespective of the signature of the space (a fact that was missing from Dianyan Xu's spinor derivation). So this insight into the structure of the two identities not only led to a better appreciation of the relevance of these identities in the original context (concerning counterterms in Lagrangians[3–5]), but also highlights the importance of identities built from the antisymmetrization property (1) in the study of Riemann scalar invariants.

Of course the pattern and discussion above suggest how to obtain many more analogous identities for other tensors, for higher dimensions, and for higher order. In fact the identities (2) and (3) can be obtained more directly and compactly by instead using the Weyl tensor C_{abcd} (the trace-free part of the Riemann tensor), e.g., (3) can be obtained from the identity $C^{ab}{}_{[ab}C^{cd}{}_{cd}C^{ef}{}_{ef]}=0$.[3,5–7]

It is also interesting to note that it is not just scalar identities which can be constructed in this manner; for example, similar tensor identities can be considered to underlie the familiar Cayley–Hamilton theorem:

Example I.2: Antisymmetrizing over $n+1$ indices for matrices $M^{a}{}_{b}$ in n dimensions gives the Cayley–Hamilton theorem

$$M^{c_1}{}_{[c_1}M^{c_2}{}_{c_2}\ldots M^{c_n}{}_{c_n}\delta^{b}_{a]}=0. \tag{6}$$

Considering the Cayley–Hamilton theorem from this viewpoint suggests generalizations involving more than one matrix,

$$M^{c_1}{}_{[c_1}N^{c_2}{}_{c_2}\ldots P^{c_n}{}_{c_n}\delta^{b}_{a]}=0. \tag{7}$$

This generalized Cayley–Hamilton theorem has been used to find relations, (syzygies), between scalar invariants of matrices involving more than one matrix.[7–9]

An important question is whether this technique of antisymmetrizing is just a useful ''trick'' in very special circumstances, or whether there is deeper structure to be better understood and more fully exploited.

Some time ago Lovelock[10] noted the significance of certain types of identities—which he called *dimensionally dependent identities*—and demonstrated their existence and importance in quite a wide context (Lovelock[10] has defined a dimensionally dependent identity as an identity which is a direct consequence of the dimension of the space taking on a particular value, and which therefore is not valid for arbitrary dimension n in general). By showing precisely how and where dimensionality plays its role in familiar identities, Lovelock revealed a technique which could be generalized to arbitrary dimension. In fact Lovelock's technique simply involved the antisymmetrizing process being applied in n dimensions, to tensors with *two* sets of indices (upper and lower, in practice) and specialized in two theorems to trace-free tensors with an equal number p of upper and lower indices where $2p\geqslant n$.

Lovelock's investigations were motivated mostly by familiar four-dimensional identities satisfied by Weyl tensors (and Weyl candidates, i.e., tensors with the algebraic symmetries of the Weyl tensor); however, there are other identities which appear to be of a similar nature, but which cannot be confirmed by Lovelock's two theorems. It is the purpose of this paper to investigate dimensionally dependent identities in a systematic manner and obtain a more complete picture; in doing so we develop results more general than Lovelock's, and demonstrate that these new results can be used to confirm identities which cannot be obtained from Lovelock's results, and also to confirm other identities which can only be confirmed indirectly from Lovelock's results.

In Sec. II we make some general observations and present some examples as further motivation for the subsequent sections. We summarize and illustrate Lovelock's results[10] in Sec. III. Lovelock's theorems applied only to trace-free (p,p)-forms in n dimensions where $2p \geqslant n$. However, in Sec. IV, we shall develop more general results in the form of a "master" identity which will be applicable to any tensor in any dimension, and in particular to trace-free (k,l)-forms in any dimension. In Sec. V we will then show that a number of important identities are consequences of this master identity. In particular, we show that the simplification of the gravity–matter coupling terms in the Weyl wave equation and in the Bel tensor, and the complete symmetry of the super-energy tensor for the Lanczos potential of the Weyl tensor are all trivial consequences when the master identity is specialized to four dimensions; in a similar manner we confirm the complete symmetry of the Bel–Robinson tensor in four and five dimensions. In addition, we demonstrate how the results permit a systematic study of relationships between scalar invariants of the Riemann tensor. We also illustrate how the importance of dimensionally dependent identities have been overlooked by reducing the algebraic Rainich condition, and point out the potential usefulness of these results in more general situations.

II. IDENTITIES BY DOUBLE ANTISYMMETRIZATION

We consider the tensor $T^{\mathcal{A}}{}_{a_1}$ where we have adopted the convention that $\mathcal{A}$ denotes an arbitrary number of additional lower and/or upper indices.[1]

Associated with this tensor $T^{\mathcal{A}}{}_{a_1}$, in n-dimensional space, there will always be an identity

$$T^{\mathcal{A}}{}_{[a_1}\delta^{b_2}_{a_2}\delta^{b_3}_{a_3}\ldots\delta^{b_{n+1}}_{a_{n+1}]}=0. \tag{8}$$

For future reference we should note that such identities cannot be made "simpler," in the sense that taking the trace of (8) (on explicit indices, i.e., indices which are not implicit in $\mathcal{A}$) simply gives zero on the left-hand side also.

An alternative approach would be to assume the presence of a volume element $\eta_{a_1a_2\ldots a_n}$, and formulate analogous results in the η notation making use of duals; but we shall concentrate on developing results using the δ notation.

There will of course be one such identity associated with each separate index on T. We could obtain other identities, with less deltas, by taking more than one index of T explicitly into the antisymmetrization operation, but these new identities would involve only the antisymmetrized part of T with respect to the explicit indices.

However, when the tensor T is in fact antisymmetric in a group of k indices, then we can get an identity involving less deltas than the original identity

$$T^{\mathcal{A}}{}_{[a_1\ldots a_k}\delta^{b_{k+1}}_{a_{k+1}}\delta^{b_{k+2}}_{a_{k+2}}\ldots\delta^{b_{n+1}}_{a_{n+1}]}=0, \tag{9}$$

but without losing any part of T. Again, it is important to note that taking the trace of (9), on explicit indices, simply gives zero on the left-hand side also.

We next consider a tensor with both upper and lower indices, each of which contain groups of antisymmetric indices, i.e., $T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_l}=T^{\mathcal{A}}{}_{[a_1\ldots a_k]}{}^{[b_1\ldots b_l]}$ is a (k,l)-*form* with respect to its explicit indices; then we have the associated identity

$$T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta^{b_{k+1}}_{a_{k+1}}\ldots\delta^{b_{n+1}]}_{a_{n+1}}=0 \tag{10}$$

when $l\geqslant k$. (The analogous case obtained by antisymmetrizing on the lower indices for $k\leqslant l$ is obvious.)

Such classes of tensors include many familiar tensors (Riemann, Weyl, Ricci, Maxwell, Lanczos, torsion) and they shall be the main focus of our investigation in this paper.

It is important to note that, although some traces of (10) yield the trivial identity, *there are some traces of* (10) *which yield a nontrivial identity involving the trace of* T. It is these nontrivial traces which yield Lovelock's identities, and our generalizations of them. We illustrate this with the following example.

Example II.1: We consider the (2,2)-form $R_{ab}{}^{cd}$.

In three dimensions: $R_{ef}{}^{[gh}\delta^c_a\delta^{d]}_b=0$.

Contracting once over e and g gives

$$R_{f[a}{}^{[hc}\delta^{d]}_{b]}-R_{ef}{}^{e[h}\delta^c_a\delta^{d]}_b=0, \tag{11}$$

and then over h and f gives,

$$R_{ab}{}^{cd}-4R_{e[a}{}^{e[c}\delta^{d]}_{b]}+R_{ef}{}^{ef}\delta^{[c}_a\delta^{d]}_b=0. \tag{12}$$

From this last result follows the well-known fact that the trace-free part of a Riemann tensor is identically zero in three dimensions.

In four dimensions: $R_{gh}{}^{[ij}\delta^d_a\delta^e_b\delta^{f]}_c=0$.

Contracting once over g and i gives

$$3R_{h[a}{}^{[jd}\delta^e_b\delta^{f]}_{c]}-2R_{gh}{}^{g[j}\delta^d_a\delta^e_b\delta^{f]}_c=0, \tag{13}$$

and then over h and j gives

$$3R_{[ab}{}^{[de}\delta^{f]}_{c]}-6R_{g[a}{}^{g[d}\delta^e_b\delta^{f]}_{c]}+R_{gh}{}^{gh}\delta^{[d}_a\delta^e_b\delta^{f]}_c=0. \tag{14}$$

A third contraction gives zero on the left-hand side also.

All of the above-mentioned identities can be expressed in a more concise form if R_{abcd} is decomposed into trace-free and trace parts.

We note that certain of these contractions yield identities which, if we were to encounter them not knowing their source, would seem (to our surprise) to come from antisymmetrizing over n or $n-1$ explicit indices in n dimensions; on the other hand, when one takes into account *all* the terms in each identity and also notes that these contractions involve antisymmetrizing over upper and lower indices, of course, we would realize that our first judgment was superficial, and we have a disguised antisymmetrization over $n+1$ indices. However, we have noted previously that the identities exist in their most concise form when presented in terms of the trace free part of R_{abcd}; so such identities can be even more deceptive especially when constructed explicitly in terms of a trace-free tensor.

So we now specialize to the important special situation where the (k,l)-form $T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_l}=T^{\mathcal{A}}{}_{[a_1\ldots a_k]}{}^{[b_1\ldots b_l]}$ is *trace-free*, i.e., $T^{\mathcal{A}}{}_{a_1a_2\ldots a_k}{}^{a_1b_2\ldots b_l}=0$, and the underlying structure of the resulting identities become less transparent. To illustrate this we will give three simple examples involving, respectively, a trace-free (2,2)-form $W_{ab}{}^{cd}$ [of which the Weyl conformal curvature tensor $C_{ab}{}^{cd}$ is a special example being a symmetric trace-free (2,2)-form since $C_{abcd}=C_{cdab}$, with the additional property $C_{[abc]d}=0$], a trace-free (2,1)-form $L_{ab}{}^c$ [of which the torsion and Lanczos potential with the additional property $L_{[abc]}=0$ (Ref. 11) are special examples], and a trace-free (1,1)-form $S^a{}_b$ (of which the trace-free symmetric Ricci tensor $\tilde{R}^a{}_b$, the trace-free symmetric energy tensor $\tilde{T}^a{}_b$ and the antisymmetric Maxwell tensor $F^a{}_b$, are special examples).

Example II.2: We now apply the above-presented arguments to the trace-free (2,2)-form $W_{ab}{}^{cd}$.

In three dimensions: $W_{ef}{}^{[gh}\delta_a^c\delta_b^{d]}=0$.

Contracting over f and h gives

$$W_{e[a}{}^{[gc}\delta_{b]}^{d]}=0, \tag{15}$$

and then over e and g gives

$$W_{ab}{}^{cd}=0. \tag{16}$$

In four dimensions: $W_{gh}{}^{[ij}\delta_a^d\delta_b^e\delta_c^{f]}=0$.

Contracting over h and j gives

$$W_{g[a}{}^{[id}\delta_b^e\delta_{c]}^{f]}=0, \tag{17}$$

and then over g and i gives

$$W_{[ab}{}^{[de}\delta_{c]}^{f]}=0. \tag{18}$$

A third contraction gives zero on the left-hand side also.

In five dimensions: $W_{ij}{}^{[kl}\delta_a^e\delta_b^f\delta_c^g\delta_d^{h]}=0$.

Contracting over j and l gives

$$W_{i[a}{}^{[ke}\delta_b^f\delta_c^g\delta_{d]}^{h]}=0, \tag{19}$$

and then over i and k gives

$$W_{[ab}{}^{[ef}\delta_c^g\delta_{d]}^{h]}=0. \tag{20}$$

A third contraction gives zero on the left-hand side also.

So, in each of the three cases, the first identity is obvious in the sense that it is an explicit antisymmetrization over $n+1$ indices in n dimensions. What is particularly interesting, and at first sight perhaps surprising in these situations, is the existence of simple identities in n dimensions which involve explicit antisymmetrization over only $n-1$ indices. But of course, in addition, there is antisymmetrization on both lower and upper indices and the comparatively simple versions are due to the vanishing of the trace of W.

Example II.3: Consider the trace-free (2,1)-form $L_{ab}{}^{c}$.

When we apply the above-mentioned arguments we obtain,

In three dimensions: $L_{[fa}{}^{g}\delta_b^d\delta_{c]}^{e}=0$.

Contracting once on the upper index on L gives

$$L_{[ab}{}^{[d}\delta_{c]}^{e]}=0, \tag{21}$$

and contracting once more gives zero on the left-hand side also.

In four dimensions: $L_{[ha}{}^{i}\delta_b^e\delta_c^f\delta_{d]}^{g}=0$.

Contracting once on the upper index on L gives

$$L_{[ab}{}^{[e}\delta_c^f\delta_{d]}^{g]}=0, \tag{22}$$

and once more gives zero on the left-hand side also.

So, once again, we obtain identities in n dimensions involving explicit antisymmetrization over less than $n+1$ indices; although in this case it involves n indices.

Example II.4: Consider the trace-free (1,1)-form $S_a{}^{b}$.

When we apply the above-mentioned arguments we obtain,

In three dimensions: $S_{[g}{}^{h}\delta_a^d\delta_b^e\delta_{c]}^{f}=0$.

Contracting once on the upper index on S gives

$$S_{[a}{}^{[d}\delta^{e}_{b}\delta^{f]}_{c]}=0, \tag{23}$$

and contracting once more gives zero on the left-hand side also.

In four dimensions: $S_{[i}{}^{j}\delta^{e}_{a}\delta^{f}_{b}\delta^{g}_{c}\delta^{h}_{d]}=0$.

Contracting once on the upper index on S gives

$$S_{[a}{}^{[e}\delta^{f}_{b}\delta^{g}_{c}\delta^{h]}_{d]}=0, \tag{24}$$

and once more gives zero on the left-hand side also.

So, once again, we obtain identities in n dimensions involving explicit antisymmetrization over only n indices.

In the above-given examples we have obtained obvious identities by antisymmetrization over $n+1$ indices in n dimensions; but in addition, as a result of taking traces, we have obtained less obvious identities containing *less* deltas and explicit antisymmetrization over *less than* $n+1$ indices. The existence of these additional identities, which contain less deltas than the obvious ones, are very important for building up more complicated identities. For example, consideration of the obvious four-dimensional identity for the Weyl tensor $C_{[ab}{}^{fg}\delta^{h}_{c}\delta^{i}_{d}\delta^{j}_{e]}=0$ (with 10 free indices), would not suggest the possibility of any third-order *scalar* identities for C; on the other hand, the less obvious one formed from the double trace, $C_{[ab}{}^{[fg}\delta^{h]}_{c]}=0$ (with 6 free indices), certainly permits the constructions of third-order Weyl scalar identities by multiplication with a pair of C tensors.

For each case considered we have gone as far as we could, in the sense that taking an additional trace simply reduces the left-hand side to zero. Nevertheless, this does not in itself mean that there could not exist additional identities with even less deltas than those given previously; however, for each of the cases it can be shown directly that removing further deltas gives a restriction rather than an identity, e.g., *in four dimensions*, when the trace is calculated for $L_{[ab}{}^{[c}\delta^{g]}_{f]}=0$ we find that $L_{ab}{}^{c}=0$.

In Sec. III we shall give results due to Lovelock[10] and show that the results for three and four dimensions of Example II.2 follow directly as a special case; it will also be shown that the result for five dimensions can be deduced, more subtly, from Lovelock's results. In Sec. IV we will derive even more general results of which Lovelock's and the above-mentioned three examples will be seen to be special cases.

III. LOVELOCK'S DIMENSIONALLY DEPENDENT IDENTITIES

Some years ago, Lovelock[10] noted that familiar tensors, (such as the Weyl and Maxwell tensors), with antisymmetry and trace-free properties, obeyed assorted—apparently unrelated—identities. However, although there was no common structural link in the original derivations of these assorted identities, Lovelock[10] showed that they could all be considered to be consequences of two underlying basic tensor identities. These underlying identities had a very simple structure and were a mathematically trivial consequence of dimension alone. We will now quote Lovelock's two theorems, each of which he proved in two different ways; our proofs are essentially more concise presentations of one of his versions.

Theorem III.1: *In an n-dimensional space let* $T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_k}=T^{\mathcal{A}}{}_{[a_1\ldots a_k]}{}^{[b_1\ldots b_k]}$ *be trace-free on its explicit indices. If* $2k>n$ *then*

$$T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_k}=0. \tag{25}$$

Proof: Since $2k>n$, antisymmetrizing over $2k$ indices gives an identity

$$0=T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{i_1\ldots i_k}\delta^{b_1}_{i_1}\ldots\delta^{b_k}_{i_k]}. \tag{26}$$

Since the tensor T is trace-free, we get

$$0 = T^{\mathcal{A}}{}_{a_1 \ldots a_k}{}^{i_1 \ldots i_k} \delta^{b_1}_{i_1} \ldots \delta^{b_k}_{i_k}. \tag{27}$$

Absorbing the deltas gives the theorem. □

Theorem III.2: *In an n-dimensional space let* $T^{\mathcal{A}}{}_{a_1 \ldots a_k}{}^{b_1 \ldots b_k} = T^{\mathcal{A}}{}_{[a_1 \ldots a_k]}{}^{[b_1 \ldots b_k]}$ *be trace-free on its explicit indices. If* $2k = n$ *then*

$$T^{\mathcal{A}}{}_{[a_1 \ldots a_k}{}^{[b_1 \ldots b_k} \delta^{b_{k+1}]}_{a_{k+1}]} = 0. \tag{28}$$

Proof: The proof is analogous to the proof of Theorem II.1 but this time the antisymmetrization is over $2k+1$ indices. Starting with

$$0 = T^{\mathcal{A}}{}_{[a_1 \ldots a_k}{}^{i_1 \ldots i_k} \delta^{b_{k+1}}_{a_{k+1}} \delta^{b_1}_{i_1} \ldots \delta^{b_k}_{i_k]} = T^{\mathcal{A}}{}_{[a_1 \ldots a_k}{}^{i_1 \ldots i_k} \delta^{[b_{k+1}}_{a_{k+1}} \delta^{b_1}_{i_1} \ldots \delta^{b_k]}_{i_k}, \tag{29}$$

since the tensor is trace-free, we get

$$0 = T^{\mathcal{A}}{}_{[a_1 \ldots a_k}{}^{i_1 \ldots i_k} \delta^{[b_{k+1}}_{a_{k+1}]} \delta^{b_1}_{i_1} \ldots \delta^{b_k]}_{i_k}. \tag{30}$$

Absorbing the deltas gives the theorem. □

(This proof shows that this second theorem is actually true for the weaker condition, $2k \geqslant n$; but the validity of the second theorem when $2k > n$ also follows from the first theorem, which has the more fundamental condition.)

The theorems immediately yield the familiar results in Example II.2:

Example III.3: Theorem III.1 with $k=2$ applied to the trace-free (2,2)-form W_{abcd} gives $W_{abcd}=0$ when $n \leqslant 3$.

From Theorem III.2 we find directly $W^{[cd}{}_{[ef} \delta^{a]}_{b]} = 0$ when $n \leqslant 4$.

An additional well-known result is found by multiplying this with $W^{ef}{}_{cd}$ to get

$$W^{ac}{}_{de} W^{de}{}_{bc} = \tfrac{1}{4} \delta^a_b W^{cd}{}_{ef} W^{ef}{}_{cd}. \tag{31}$$

Multiplying with $W^{ef}{}_{ga} W^{bg}{}_{cd}$ instead yields the scalar identity cubic in $W^{ab}{}_{cd}$,

$$W^{ab}{}_{ce} W^{cd}{}_{af} W^{ef}{}_{bd} = \tfrac{1}{4} W^{ab}{}_{cd} W^{cd}{}_{ef} W^{ef}{}_{ab}. \tag{32}$$

The third result in Example II.2 may also be obtained—but in a more indirect manner; we consider the tensor $T^{abef}{}_{cdkl} = W^{[ab}{}_{[cd} \delta^e_k \delta^{f]}_{l]}$ and *by a direct calculation* we can confirm its trace to be zero in five dimensions. Hence, from Theorem III.1, it follows immediately that $T^{abef}{}_{cdkl}$ is identically zero in five dimensions.

The results in Example II.4 can also be obtained in the same way.

As well as showing how familiar identities were direct consequences of his theorems, Lovelock[10] also deduced some new interesting identities. More recently, additional important, and sometimes unexpected, identities have been shown to follow from Lovelock's theorems.[12–15]

However, we emphasize again that the results in Examples II.3 and II.4 cannot be deduced *directly* from Lovelock's theorems.

IV. GENERAL THEOREMS ON DIMENSIONALLY DEPENDENT IDENTITIES

The natural generalization of Lovelock's theorems is the following theorem.

Theorem IV.1: *In an n-dimensional space let* $T^{\mathcal{A}}{}_{a_1 \ldots a_k}{}^{b_1 \ldots b_l} = T^{\mathcal{A}}{}_{[a_1 \ldots a_k]}{}^{[b_1 \ldots b_l]}$ *be trace-free on its explicit indices. Then*

$$T^{\mathcal{A}}{}_{[a_1 \ldots a_k}{}^{[b_1 \ldots b_l} \delta^{b_{l+1}}_{a_{k+1}} \ldots \delta^{b_{l+d}]}_{a_{k+d}]} = 0, \tag{33}$$

where $n+1\leqslant d+k+l$ *and* $d\geqslant 0$.

Proof: The proof is analogous to the proof of Theorem III.2. This time we antisymmetrize over $k+l+d\geqslant n+1$ indices to get the identity.

$$0=T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{i_1\ldots i_l}\delta^{b_{l+1}}_{a_{k+1}}\ldots\delta^{b_{l+d}}_{a_{k+d}}\delta^{b_1}_{i_1}\ldots\delta^{b_l}_{i_l]}=T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{i_1\ldots i_l}\delta^{[b_{l+1}}_{a_{k+1}}\ldots\delta^{b_{l+d}}_{a_{k+d}}\delta^{b_1}_{i_1}\ldots\delta^{b_l]}_{i_l}. \tag{34}$$

Since the tensor T is trace-free, we get

$$0=T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{i_1\ldots i_l}\delta^{[b_{l+1}}_{a_{k+1}}\ldots\delta^{b_{l+d}}_{a_{k+d}]}\delta^{b_1}_{i_1}\ldots\delta^{b_l]}_{i_l}. \tag{35}$$

Absorbing the deltas gives the result. □

Remarks:

(1) For completeness, we add that if we adopt the convention that tensors with only lower or only upper indices are considered ''trace-free,'' then the above-mentioned results also hold for the two classes of tensors where $k=0$ or $l=0$. In addition, for the case $k=0$ and $l=0$, i.e., T a scalar, we simply get the trivial result of the vanishing of the Kronecker delta symbol with $n+1$ index pairs in n-dimensional space.

(2) The theorem generalizes Lovelock's results by associating, in n-dimensional space, an identity with *any* tensor, since—no matter what its index configuration—part of it can be considered as a (k,l)-form, with the above-mentioned conventions when $k=0$ or $l=0$. But it is for trace-free double forms with $k\neq 0\neq l$ that it will be most useful. So when $l=0$ or $k=0$ and $d=0$ we have identity (9); when $k=l\neq 0$ and $d=0$ this is Theorem III.1 and when $k=l\neq 0$ and $d=1$ this is Theorem III.2. Had we wished only to generalize to the case $k=l$ for any d, we could have used Theorem III.1 directly in our proof, as in Example II.2.

(3) No stronger result on T can be obtained by taking the trace of (33), since then the left-hand side just collapses to zero. In addition, the discussion at the end of Sec. II would strongly suggest that the conditions on d cannot be relaxed for nonzero T; we shall confirm later in Theorem IV.5 that this is indeed so.

(4) Of course this theorem does not mean that we cannot construct results beginning with double forms which are not trace-free. Rather, what will happen is that if we begin with such a tensor we will get an apparently more complicated identity with explicit trace terms; if the double form is then decomposed into trace-free and trace parts, the resulting simplification will leave us with the identity which would be obtained by beginning with the trace-free part of the double form.

We shall now illustrate the relevance of the new results in Theorem IV.1 to familiar tensors as follows,

Example IV.2: Applying Theorem IV.1 to the trace-free (2,1)-form $L_{ab}{}^{c}$ $(l=1,k=2)$ in dimensions $n=3$ with $d=1$ gives the identity

$$L_{[ab}{}^{[d}\delta^{e]}_{c]}=0 \tag{36}$$

and in dimensions $n=4$, with $d=2$,

$$L_{[ab}{}^{[e}\delta^{f}_{c}\delta^{g]}_{d]}=0. \tag{37}$$

For trace-free (2,2)-forms $(l=k=2)$ in dimensions $n=5$ with $d=2$ gives the identity

$$W_{[ab}{}^{[ef}\delta^{g}_{c}\delta^{h]}_{d]}=0. \tag{38}$$

For trace-free (1,1)-forms $S^{a}{}_{b}$ $(l=k=1)$, in dimensions $n=4$ with $d=3$ gives the identity

$$S_{[a}{}^{[e}\delta^{f}_{b}\delta^{g}_{c}\delta^{h]}_{d]}=0. \tag{39}$$

Analogous basic identities can be found in other dimensions, and all such identities can then be exploited to build up other useful important identities, as we shall demonstrate in Sec. V.

We now consider whether we can generalize these results in another manner, by asking whether any kind of converses exist. First, by way of example, we consider the identity (38) obtained from Theorem IV.1 for the trace-free (2,2)-forms when $n\leqslant 5$. As mentioned in the third remark above, we would like to confirm explicitly that the stronger condition $W_{[ab}{}^{[de}\delta_{c]}^{f]}=0$, which holds in four dimensions, does not hold in dimensions $n=5$. A related task would be to confirm explicitly that the same identity (38) as holds in $n\leqslant 5$ dimensions does not hold in higher dimensions. We shall see from Theorem IV.5 that we can confirm explicitly an even stronger version of these results.

Second, with respect to the same example, a natural question to ask is whether the trace-free condition is also a necessary condition, i.e., whether any forms with *nonzero trace* can satisfy this identity $W_{[ab}{}^{[ef}\delta_{c}^{g}\delta_{d]}^{h]}=0$ in dimensions $n\leqslant 5$. Whether an alternative (2,2)-form—lacking the trace-free properties but perhaps with different symmetry properties—can satisfy the basic identity is not obviously ruled out. As an example, we could ask whether a (2,2)-form like the Riemann tensor $R_{ab}{}^{cd}$—lacking the trace-free properties of $W_{ab}{}^{cd}$, but having the additional properties $R_{a[bcd]}=0$ and $R_{abcd}=R_{cdab}$—can satisfy the identities. However, we shall see from Theorem IV.6 that *only trace-free* (2,2)-forms satisfy the identity (38) in dimensions $n\leqslant 5$.

We first present a lemma which is then used in the proof of the two theorems. We emphasize that this lemma is also useful in its own right, and we shall demonstrate how it can be viewed as a generalization of a familiar result for the Kronecker delta.

Lemma IV.3: In n-dimensional space let $T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_l}=T^{\mathcal{A}}{}_{[a_1\ldots a_k]}{}^{[b_1\ldots b_l]}$, k, l *and* $d\geqslant 0$ *and* $(k+d)(l+d)>0$. *Then*

$$T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta_{a_{k+1}}^{b_{l+1}}\ldots\delta_{a_{k+d}}^{b_{l+d}]}\delta_{b_{l+d}}^{a_{k+d}}=\frac{d(n-(d+k+l-1))}{(k+d)(l+d)}T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta_{a_{k+1}}^{b_{l+1}}\ldots\delta_{a_{k+d-1}}^{b_{l+d-1}]}+\frac{(-1)^{k+l}kl}{(k+d)(l+d)}T^{\mathcal{A}}{}_{c[a_1\ldots a_{k-1}}{}^{c[b_1\ldots b_{l-1}}\delta_{a_k}^{b_l}\ldots\delta_{a_{k+d-1}}^{b_{l+d-1}]}. \tag{40}$$

Proof: If k, l, or d is zero the lemma is trivial. Assume they are nonzero.

On the left-hand side the last two deltas combine to give

$$T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta_{a_{k+1}}^{b_{l+1}}\ldots\delta_{a_{k+d-1}}^{b_{l+d-1}}\delta_{c]}^{c]}. \tag{41}$$

By summing over all possible positions of the dummy indices c we get

$$\frac{(k+d-1)!(l+d-1)!}{(k+d)!(l+d)!}\sum_{i,j}c_{ij}T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta_{a_{k+1}}^{b_{l+1}}\ldots\delta_{|c|}^{b_{k_i}}\ldots\delta_{a_{l_j}}^{|c|}\ldots\delta_{a_{k+d-1}}^{b_{l+d-1}]}, \tag{42}$$

where $c_{ij}=\pm 1$ depending on whether the index configuration is an even or an odd permutation.

It is now clear that we get only the two types of terms that are on the right-hand side of the theorem; the last type when both dummy indices are on T and the other type when at least one of them is on a δ. What remains is to confirm the coefficients, which essentially means counting how many of each kind occurs and what sign they have.

When both dummy indices are on T they can be moved to the first position. That means that they have moved a total of $(k+d-1)+(l+d-1)$ positions and changed sign equally many times. That gives a factor $(-1)^{k+l}$. There are a total of kl such terms.

When both dummy indices are on the same δ they have moved equally many positions; thus such terms are added. There are d such terms and we also get a factor n since $\delta_i^i=n$.

When both dummy indices are on different δ one of them can be absorbed thereby distorting the order of the other indices. Once that order is restored we have overall an odd permutation; thus such terms are subtracted. There is a total of $d(d-1)$ such terms.

The same situation occurs when one of the dummy indices is on a δ and the other one is on T. There are ld such terms with the upper index on T and kd with the lower index on T.

Taking all this together gives the identity in the lemma. □

When we consider $k=0$ and $l=0$, with T a nonzero constant, in Lemma IV.3 we get a familiar identity for the Kronecker delta,

Corollary IV.4: In n-dimensional space

$$\delta^{[b_1}_{[a_1}\cdots\delta^{b_d]}_{a_d]}\delta^{a_d}_{b_d}=\frac{(n-d+1)}{d}\,\delta^{[b_1}_{[a_1}\cdots\delta^{b_{d-1}]}_{a_{d-1}]}. \tag{43}$$

We now use Lemma IV.3 to establish the two theorems.

Theorem IV.5: *In an n-dimensional space let* $T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_l}=T^{\mathcal{A}}{}_{[a_1\ldots a_k]}{}^{[b_1\ldots b_l]}$. *If*

$$T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta^{b_{l+1}}_{a_{k+1}}\cdots\delta^{b_{l+d}]}_{a_{k+d}]}=0 \tag{44}$$

then

$$n+1>d+k+l\Rightarrow T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_l}=0. \tag{45}$$

Proof: The basic idea is to repeatedly take traces of Eq. (44) getting a sequence of equations; in the last of these no δ remains. The result follows from substituting equations at the end of this sequence into earlier ones. However, care must be taken so that no unwanted canceling of terms occur which forces this process to stop prematurely.

To make the proof easier to overview we define the following notation. Let $(d,k,l)=T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta^{b_{l+1}}_{a_{k+1}}\cdots\delta^{b_{l+d}]}_{a_{k+d}]}$ and if k and l are less than the actual number of indices on T then we contract over the remaining ones. Thus Lemma IV.3 can be written as

$$\text{trace }(d,k,l)=\frac{d(n-(d+k+l-1))}{(k+d)(l+d)}(d-1,k,l)+\frac{(-1)^{k+l}kl}{(k+d)(l+d)}(d,k-1,l-1)$$

and T itself as $(0,k,l)$ and the trace of T as $(0,k-1,l-1)$.

We observe that the coefficients in Lemma IV.3 are nonzero if d is nonzero and k and l are nonzero, respectively.

First assume that $k+l$ is even, then the coefficients in Lemma IV.3 are non-negative. Start with Eq. (44) and multiply with $\delta^{a_{k+d}}_{b_{l+d}}$ and use Lemma IV.3. Then we get $0=(d-1,k,l)+(d,k-1,l-1)$ where we have omitted the coefficients.

Doing that once more gives us $0=(d-2,k,l)+(d-1,k-1,l-1)+(d,k-2,l-2)$. Repeating this process gives a sequence of equations as illustrated in Fig. 1 where each row corresponds to one equation.

The last equation is $0=(0,k-l,0)$ (assuming $k\geqslant l$). Putting this into the second to last equation gives $0=(0,k-l+1,1)$ by using that $0=(j,k,l)\Rightarrow 0=(j+1,k,l)$. Feeding the new information into earlier equations gives the desired conclusion $0=(0,k,l)$.

If $k+l$ is odd then there is a minus sign in Lemma IV.3, which means that there is a risk of cancellation in the above-mentioned process. However, checking how the signs propagate gives us Fig. 2 where the sign at a node is the sign of the term and the sign at the edge is the sign of the coefficient in the identity in Lemma IV.3.

It is now clear that there will be no cancellations since each term originates as the difference between two terms with different sign. □

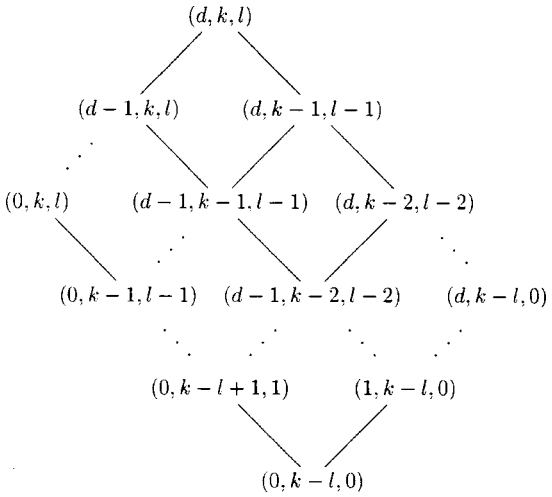

FIG. 1. Sequence of equations.

Theorem IV.6: *In an n-dimensional space let* $T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_l}=T^{\mathcal{A}}{}_{[a_1\ldots a_k]}{}^{[b_1\ldots b_l]}$ *where* $n+1\geqslant k+l$ *and let* $d=n-k-l+1$. *Then*

$$T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta^{b_{l+1}}_{a_{k+1}}\ldots\delta^{b_{l+d}]}_{a_{k+d}]}=0\Leftrightarrow T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{b_1\ldots b_l}\ \textit{is trace-free on its explicit indices.} \tag{46}$$

Proof: $\Leftarrow$: Follows directly from Theorem IV.1

$\Rightarrow$: The case $d=0$ is trivial. Assume $d>0$. Contracting

$$0=T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l}\delta^{b_{l+1}}_{a_{k+1}}\ldots\delta^{b_{l+d}]}_{a_{k+d}]} \tag{47}$$

once and using Lemma IV.3 gives

$$0=T^{\mathcal{A}}{}_{i[a_1\ldots a_{k-1}}{}^{i[b_1\ldots b_{l-1}}\delta^{b_l}_{a_k}\ldots\delta^{b_{l+d-1}]}_{a_{k+d-1}]}. \tag{48}$$

The theorem now follows from Theorem IV.5 applied to the tensor

$$\tilde{T}^{\mathcal{A}}{}_{a_1\ldots a_{k-1}}{}^{b_1\ldots b_{l-1}}=T^{\mathcal{A}}{}_{ia_1\ldots a_{k-1}}{}^{ib_1\ldots b_{l-1}}. \tag{49}$$

□

Example IV.7: We know that for the Weyl curvature tensor C_{abcd} [a trace-free symmetric (2,2)-form], $C_{[ab}{}^{[ef}\delta^g_c\delta^{h]}_{d]}=0$ in dimensions $n\leqslant 5$. From Theorem IV.5 we can conclude that this

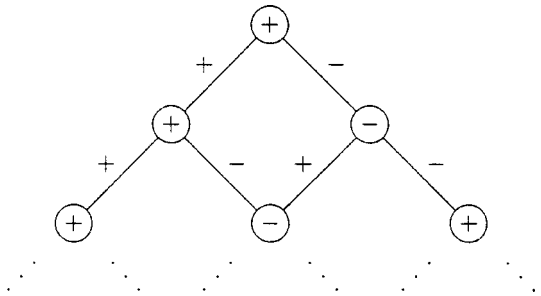

FIG. 2. Signs.

tensor [or indeed *any* nonzero (2,2)-form] cannot satisfy the stronger condition $C_{[ab}{}^{[de}\delta_{c]}^{f]}=0$ in dimensions $n\geqslant 5$; in addition we can conclude that there are absolutely no nonzero (2,2)-forms $T_{ab}{}^{cd}$ satisfying $T_{[ab}{}^{[ef}\delta_{c}^{g}\delta_{d]}^{h]}=0$ *in dimensions greater than five*.

From Theorem IV.6 we can conclude that there are no (2,2)-forms $R_{ab}{}^{cd}$ *with nonzero trace* (e.g., a Riemann tensor) satisfying the identity $R_{[ab}{}^{[ef}\delta_{c}^{g}\delta_{d]}^{h]}=0$ in dimensions $n=5$.

The trace in Lemma IV.3 is not the only trace that is possible for expressions of the type we are investigating. For completeness we here present the other possibility.

Lemma IV.8: Let $T^{\mathcal{A}}{}_{a_1\ldots a_k}{}^{cb_1\ldots b_l}=T^{\mathcal{A}}{}_{[a_1\ldots a_k]}{}^{c[b_1\ldots b_l]}$, k *and* $d\geqslant 0$ *and* $k+d>0$. *Then*

$$T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{c[b_1\ldots b_l}\delta_{a_{k+1}}^{b_{l+1}}\ldots\delta_{a_{k+d}}^{b_{l+d}]}\delta_{c}^{a_{k+d}}=\frac{d(-1)^{l+d-1}}{k+d}T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{[b_1\ldots b_l b_{l+1}}\delta_{a_{k+1}}^{b_{l+2}}\ldots\delta_{a_{k+d-1}}^{b_{l+d}]}+\frac{k(-1)^{k+d-1}}{k+d}T^{\mathcal{A}}{}_{c[a_1\ldots a_{k-1}}{}^{c[b_1\ldots b_l}\delta_{a_k}^{b_{l+1}}\ldots\delta_{a_{k+d-1}}^{b_{l+d}]}. \tag{50}$$

Proof: If k or d is zero the lemma is trivial. Assume they are nonzero.

Absorbing the last delta on the left-hand side gives

$$T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{c[b_1\ldots b_l}\delta_{a_{k+1}}^{b_{l+1}}\ldots\delta_{c]}^{b_{l+d}]}. \tag{51}$$

By summing over all possible positions of the lower dummy index c we get

$$\frac{(k+d-1)!}{(k+d)!}\sum_i c_i T^{\mathcal{A}}{}_{[a_1\ldots a_k}{}^{c[b_1\ldots b_l}\delta_{a_{k+1}}^{b_{l+1}}\ldots\delta_{|c|}^{b_i}\ldots\delta_{a_{k+d-1}}^{b_{l+d}]}, \tag{52}$$

where $c_i=\pm 1$ depending on whether the index configuration is an even or an odd permutaion.

When the c is on a delta it can be absorbed giving terms of the same type as the first term on the right-hand side of (50) There are d such terms and on each of them the indices have been moved a total of $l+d-1$ steps.

When the c is on T it can be moved to the first position of the lower indices giving terms of the same type as the second term on the right-hand side of (50). There are k such terms and on each of them the index has been moved a total of $k+d-1$ steps. □

V. APPLICATIONS

In the previous sections we have noted that, associated with each tensor are a number of fundamental identities; and it is from such identities that more involved and more subtle identities can be constructed, which in turn yield familiar identities. So, we shall now exploit our results in two particular types of applications.

A. Identities involving scalar invariants of Riemann tensors

Relationships between scalar invariants of tensors [such as (2), (3), and (32)] play a very important role in classical invariant theory, as well as in many practical applications. For instance, the study of the scalar invariants of the Riemann tensor in four dimensions has posed many interesting problems, which have not all been resolved.[3,5–9,16,17] The theorems given in this paper provide important tools for a systematic study of invariants of the Weyl, trace-free Ricci, and Lanczos tensors. However, now we shall just apply our results to some representative examples.

Example V.1: Although we can form different scalars from two (2,2)-forms $W_{ab}{}^{cd}$, in *four dimensions*, the simplest basic identity is $W^{[cd}{}_{[ef}\delta_{b]}^{a]}=0$ (with 6 free indices), and so we can immediately see that it cannot yield relationships between scalar invariants involving only two (2,2)-forms.

However, we already know that multiplying this identity by $W^{ef}{}_{ga}W^{bg}{}_{cd}$ gives us the scalar identity (32), which yields a relationship between some cubic scalar invariants; while multiplying by other quadratic terms will give different relationships between different cubic scalar invariants. Clearly we can also choose various suitable expressions involving three (2,2)-forms, which will yield scalar identities of fourth order when multiplied with $W^{[cd}{}_{[ef}\delta^{a]}_{b]}=0$. Hence, it is possible to investigate, for each order, all such possible relationships between all scalar invariants of that order.

When we consider higher dimensions we have analogous basic identities. In *five dimensions* the simplest basic identity is $W_{[ab}{}^{[ef}\delta^{g}_{c}\delta^{h]}_{d]}=0$ (with eight free indices), and hence the lowest order where we can get relationships between scalar invariants from this identity is also at third order; while in *six dimensions* with the simplest basic identity having 10 free indices there can exist no relationships between scalar invariants at third order coming from this identity. These results can be applied to the Weyl tensor, where they may simplify a little because of its extra symmetries.

It is interesting to note that Dianyan Xu's work[2] was motivated by a concern that nontrivial relationships might exist between counterterms in the Lagrangian (essentially invariant scalars constructed from products of the Riemann tensor) of a renormalizable quantum field theory; in particular, if his identities (2), (3), or any other cubic scalar identities, are true in six dimensions then work by Jack and Parker[4] would need to be reevaluated. However, Jack and Parker[5] have subsequently shown explicitly that no such third-order identities can exist in six dimensions; our result in the above-mentioned example agrees with this. Jack and Parker[5] have conjectured that in $2n$ dimensions there do not exist any identities between Riemann scalars of order n; we shall show how our results relate to this conjecture in a subsequent paper.

Example V.2: In order to confirm that the second identity found in Ref. 2 was a four-dimensional one, Harvey first established the intermediate third-order identity (5) by antisymmetrizing over *six* indices and this intermediate identity is therefore valid in five as well as in four dimensions; in our previous example we noted that five dimensions was the lowest dimension where such third-order identities could be constructed for the Weyl tensor. However, one would suspect that the second four-dimensional identity (3) could be obtained directly; this is confirmed by using the four-dimensional identity $C^{[cd}{}_{[ef}\delta^{a]}_{b]}=0$ and expanding $C^{ef}{}_{ai}C^{ib}{}_{cd}C^{[cd}{}_{[ef}\delta^{a]}_{b]}=0$. It can also be obtained, in the manner of Harvey, by antisymmetrizing over 5 indices and expanding

$$R^{ab}{}_{[ab}R^{ef}{}_{cd}R^{cd}{}_{e]f}=0. \tag{53}$$

Example V.3: An important application of the identity in Example IV.2 is to find relationships between scalar invariants of the Lanczos potential[11] in four dimensions. Since the identity $L_{[ab}{}^{[e}\delta^{f}_{c}\delta^{g]}_{d]}=0$ has seven free indices, the lowest order relationship between scalar invariants that we can obtain from it is of order four. For example, by expanding

$$0=L_{[ab}{}^{[e}\delta^{f}_{c}\delta^{g]}_{d]}L^{ab}{}_{e}L_{fg}{}^{h}L^{cd}{}_{h}, \tag{54}$$

we obtain the relationship

$$\begin{aligned}0=&L_{abc}L^{abc}L_{def}L^{def}+L_{abc}L^{abf}L_{def}L^{dec}-4L_{afc}L^{aec}L_{deh}L^{dfh}-2L_{abc}L^{abd}L_{def}L^{cef}\\&-4L_{abc}L^{ad}{}_{f}L^{bfh}L^{c}{}_{dh}.\end{aligned} \tag{55}$$

This of course will not be the only relationship; we could instead multiply the original identity by $L^{ab}{}_{e}L_{fh}{}^{c}L_{g}{}^{hd}$. Therefore, we can investigate all possible contractions of the original identity with three Lanczos tensors and find the corresponding relationship between all possible quartic Lanczos scalars in a systematic manner.

There is an important caveat in the above-given examples. By a systematic study we are able to obtain all relationships between scalar invariants of a particular order *which arise from our dimensionally dependent identities*. Of course, we would like to be able to conclude that we have obtained *all* such possible relationships. Recent work on invariant theory by Gover[18] links rela-

tionships involving scalar invariants of tensors in n dimensions to antisymmetrizing over $n+1$ indices. Although this does not, at this stage, enable us to conclude that all relationships between scalar invariants originate from our dimensionally dependent identities, it would lead us to believe that the results in this paper will be useful in such difficult tasks as determining complete and independent sets of scalar invariants, and their syzygies.

B. Simplifying complicated expressions in four dimensions

There have recently been situations[12–15] where rather complicated tensor expressions in n dimensions have been shown, unexpectedly, to be identically zero when specialized to four dimensions via Lovelock's theorems. So we would anticipate that the more general results obtained in this paper should also be useful in simplifying such expressions, and we now give some examples.

Example V.4: In Ref. 13 Lovelock's identities were used to show that, when the wave equation for the Weyl tensor is constructed from the Bianchi identities, the sum of terms which involve products of Weyl and trace-free Ricci tensors disappeared in *four, and only four, dimensions*, because from the four-dimensional identity $C_{[ab}{}^{[de}\delta_{c]}^{f]}=0$ we can obtain $C_{[ab}{}^{[de}\delta_{c]}^{f]}\tilde{R}_f{}^c=0$ whose left-hand side, when expanded, is precisely this sum of terms.

We shall now show that the analogous component of the Bel tensor[19] disappears in four dimensions by virtue of the same identity. The Bel tensor is given in n dimensions by

$$B_{abcd}=R_{aecf}R_b{}^e{}_d{}^f+R_{aedf}R_b{}^e{}_c{}^f-\tfrac{1}{2}g_{ab}R_{efcg}R^{ef}{}_d{}^g-\tfrac{1}{2}g_{cd}R_{aefg}R_b{}^{efg}+\tfrac{1}{8}g_{ab}g_{cd}R_{efgh}R^{efgh}. \tag{56}$$

When the standard decomposition is substituted we obtain[20]

$$B_{abcd}=\mathcal{T}_{abcd}+\mathcal{Q}_{abcd}+\mathcal{M}_{abcd}, \tag{57}$$

where $\mathcal{T}_{abcd}$ is the Bel–Robinson tensor consisting of quadratic terms in the Weyl tensor, $\mathcal{M}_{abcd}$ consists of quadratic terms in the Ricci tensor R_{ab}, and $\mathcal{Q}_{abcd}$ consists of products of Weyl and Ricci components (gravity-matter coupling term),[21]

$$\begin{aligned}\mathcal{Q}_{abcd}=\frac{1}{n-2}(&-4C^i{}_{(cd)(a}\tilde{R}_{b)i}-4C^i{}_{(ab)(c}\tilde{R}_{d)i}\\&+2\tilde{R}_{ij}(C_a{}^i{}_{(c}{}^j g_{d)b}-C_c{}^i{}_d{}^j g_{ab}+C_b{}^i{}_{(c}{}^j g_{d)a}-C_a{}^i{}_b{}^j g_{cd}))+\frac{2}{n(n-1)}R(C_{acbd}+C_{adbc}).\end{aligned} \tag{58}$$

The structure of $\mathcal{Q}$ (maximum of one delta, or equivalently as presented here with some indices lowered, maximum of one g) suggests that we investigate the *four-dimensional* identity $C_{[ac}{}^{[bd}\delta_{e]}^{f]}=0$; when we multiply this identity by $\tilde{R}^f{}_e$ we obtain the identity

$$C_{dij[a}g_{c]b}\tilde{R}^{ij}-C_{bij[a}g_{c]d}\tilde{R}^{ij}+C_{aci[b}\tilde{R}_{b]}{}^i+C_{bdi[a}\tilde{R}_{c]}{}^i=0. \tag{59}$$

By symmetrizing over the index pair (cd) we get precisely the identity

$$4C^i{}_{(cd)(a}\tilde{R}_{b)i}+4C^i{}_{(ab)(c}\tilde{R}_{d)i}-2\tilde{R}_{ij}(C_a{}^i{}_{(c}{}^j g_{d)b}-C_c{}^i{}_d{}^j g_{ab}+C_b{}^i{}_{(c}{}^j g_{d)a}-C_a{}^i{}_b{}^j g_{cd})=0 \tag{60}$$

and so the gravity–matter coupling term (58) simplifies, *in four dimensions*, to

$$\mathcal{Q}_{abcd}=R(C_{acbd}+C_{adbc})/6. \tag{61}$$

Bonilla and Senovilla[20] have obtained this result, but since they were working with duals, they did not encounter the four-dimensional identity explicitly; Zund[22] has also found the remarkably simple gravity–matter coupling term, using spinors.

The possibility of the *five-dimensional* identity $C_{[ab}{}^{[cd}\delta_e^f\delta_{h]}^{g]}=0$ supplying significant simplification is obviously ruled out since, after multiplication with one trace-free Ricci tensor, there will still be at least one term with two deltas.

Example V.5: The four-dimensional identity for the Lanczos potential $L_{ab}{}^c$,

$$2L^{def}g_{[a|c|}C_{b]def}-2L_{[a}{}^{de}C_{b]edc}-\tfrac{1}{2}L^{de}{}_cC_{deab}=0 \tag{62}$$

plays an important role in the derivation of the wave equation of the Lanczos potential.[23] Its existence was first noted because the spinor equivalence of the left-hand side collapsed; subsequently, it was proven by Edgar[12] by using four-dimensional duals, and also by using Lovelock's four-dimensional identity $C_{[ab}{}^{[cd}\delta_{e]}^{f]}=0$. We can also deduce it by using the four-dimensional identity in Example IV.2, and then expanding

$$L_{[ab}{}^{[c}\delta_d^f\delta_{e]}^{g]}C^{de}{}_{fg}=0. \tag{63}$$

The remaining examples involve identitities which cannot be deduced *directly* from Lovelock's identities.

Example V.6: In Ref. 16, Bonanos demonstrated that a complicated tensor

$$\begin{aligned}\chi'_{abcd}=&\tilde{R}_{ac}\tilde{R}_b{}^m\tilde{R}_{md}+\tilde{R}_{bd}\tilde{R}_a{}^m\tilde{R}_{mc}-\tilde{R}_{ad}\tilde{R}_b{}^m\tilde{R}_{mc}-\tilde{R}_{bc}\tilde{R}_a{}^m\tilde{R}_{md}+\tilde{R}_a{}^m\tilde{R}_m{}^n\tilde{R}_{nc}g_{bd}+\tilde{R}_b{}^m\tilde{R}_m{}^n\tilde{R}_{nd}g_{ac}\\&-\tilde{R}_a{}^m\tilde{R}_m{}^n\tilde{R}_{nd}g_{bc}-\tilde{R}_b{}^m\tilde{R}_m{}^n\tilde{R}_{nc}g_{ad}-\tfrac{1}{2}(\tilde{R}_{mn}\tilde{R}^{mn})(\tilde{R}_{ac}g_{bd}+\tilde{R}_{bd}g_{ac}-\tilde{R}_{ad}g_{bc}-\tilde{R}_{bc}g_{ad})\\&-\tfrac{1}{3}(\tilde{R}_{mn}\tilde{R}^{mr}\tilde{R}^n{}_r)(g_{ac}g_{bd}-g_{ad}g_{bc})\end{aligned} \tag{64}$$

of third order in the trace-free Ricci tensor $\tilde{R}_{ab}$, which had been used in the study of Riemann invariants in four dimensions,[17] was in fact, surprisingly, identically zero.

In Ref. 14 it was demonstrated how this result could be seen as an *indirect* consequence of Lovelock's results.[10] By applying Theorem III.2 to the trace-free Plebanski tensor $P_{ab}{}^{cd}$ which is the ''square'' of the Ricci tensor given by

$$P_{ab}{}^{cd}=2\tilde{R}_{[a}{}^{[c}\tilde{R}_{b]}{}^{d]}+2\tilde{R}_{[a}{}^i\tilde{R}_{|i|}{}^{[c}\delta_{b]}^{d]}-\tfrac{1}{3}\tilde{R}_j{}^i\tilde{R}_i{}^j\delta_{[a}^c\delta_{b]}^d, \tag{65}$$

the following identity of second order in the trace-free Ricci tensor was obtained:

$$2\tilde{R}_{[a}{}^{[c}\tilde{R}_b{}^d\delta_{e]}^{f]}+2\tilde{R}_{[a}{}^i\tilde{R}_{|i|}{}^{[c}\delta_b^d\delta_{e]}^{f]}-\tfrac{1}{3}\tilde{R}_j{}^i\tilde{R}_i{}^j\delta_{[a}^c\delta_b^d\delta_{e]}^f=0. \tag{66}$$

It was then shown in Ref. 14 that the identically zero tensor χ'_{abcd} found by Bonanos was just a direct consequence of multiplying the identity (66) by $\tilde{R}_f{}^e$.

But we now have the complete picture. The basic identity in four dimensions for the trace-free Ricci tensor is the first-order identity (39),

$$\tilde{R}_{[a}{}^{[c}\delta_b^d\delta_e^f\delta_{g]}^{h]}=0. \tag{67}$$

By successive multiplications by the trace-free Ricci tensor we obtain, first of all, the identity (66) which is second order in the trace-free Ricci tensor; subsequently by multiplying the left-hand side of (67) by $\tilde{R}_f{}^e\tilde{R}_h{}^g$ we obtain the third-order identity which is χ'_{abcd} identically zero, and finally the fourth-order identity, which is the Cayley–Hamilton theorem for the matrix representation of $\tilde{R}_a{}^b$ in four dimensions, as shown in Ref. 14.

Example V.7: The Bel–Robinson tensor[24] is given in n dimensions by

$$\mathcal{T}_{abcd}=C_{aecf}C_b{}^e{}_d{}^f+C_{aedf}C_b{}^e{}_c{}^f-\tfrac{1}{2}g_{ab}C_{efcg}C^{ef}{}_d{}^g-\tfrac{1}{2}g_{cd}C_{aefg}C_b{}^{efg}+\tfrac{1}{8}g_{ab}g_{cd}C_{efgh}C^{efgh}. \tag{68}$$

It is obviously symmetric over the first and last pair of indices, but in order to investigate its symmetry over *all* indices we need to examine,

$$\mathcal{T}_{a[bc]d}=\tfrac{1}{4}C_{adef}C_{bc}{}^{ef}-C_{eaf[b}C_{c]}{}^e{}_d{}^f-C_{fge[a}g_{d][b}C_{c]}{}^{efg}+\tfrac{1}{8}g_{a[b}g_{c]d}C_{efgh}C^{efgh}. \tag{69}$$

Its structure (maximum of two deltas) suggests that we investigate the five-dimensional identity $C_{[bc}{}^{[ad}\delta_e^g\delta_{f]}^{h]}=0$; by multiplying with $C_{gh}{}^{ef}$ we obtain precisely the right-hand side of (69). So the Bel–Robinson tensor is completely symmetric in both four and five dimensions, but of course this calculation does not give us any information about higher dimension. [Although we know that $C_{[ab}{}^{[cd}\delta_g^e\delta_{h]}^{f]}=0$ is *not* an identity in higher dimensions, we are considering the more complicated expression (69).] However, by taking the nontrivial double trace on (69) we obtain

$$\mathcal{T}^a{}_{[ab]}{}^b=\frac{(n-4)(n-5)}{16}C_{abcd}C^{abcd}, \tag{70}$$

which shows that the dimensions four and five are both necessary and sufficient conditions for the Bel–Robinson tensor to be completely symmetric.

The fact that $\mathcal{T}_{abcd}$ is completely symmetric, in, and only in, dimensions four and five was originally given by Senovilla[21] from its definition in terms of duals, but in a less direct manner, where each dimension was considered separately.

Example V.8: The Bel–Robinson tensor (constructed from the Weyl tensor), discussed in the last example, has the wrong dimension for energy, so Roberts[25] has proposed instead using an analogous construction with the Lanczos potential of the Weyl tensor which has the correct dimensions for energy. He has suggested looking at the most general expression quadratic in the Lanczos potential, but if instead we use Senovilla's definition of **super-energy tensor**[21] we find the super-energy tensor associated with the Lanczos potential $L_{ab}{}^c$ [a trace-free (2,1)-form] is given in n dimensions by

$$\mathcal{T}^L_{abcd}=L_{aec}L_b{}^e{}_d+L_{aed}L_b{}^e{}_c-\tfrac{1}{2}g_{ab}L_{efc}L^{ef}{}_d-g_{cd}L_{aef}L_b{}^{ef}+\tfrac{1}{4}g_{ab}g_{cd}L_{efg}L^{efg}. \tag{71}$$

It is obviously symmetric over the first and last pair of indices, respectively. It is not symmetric over all indices which can be shown by choosing a local orthonormalized basis and $L_{131}=-L_{311}=-L_{232}=L_{322}=1$, all others zero in n dimensions. Then $\mathcal{T}^L_{1[12]2}=\pm\frac{1}{2}$ (the sign depends on the signature).

The Bel–Robinson tensor in the previous example had the pairwise symmetry $\mathcal{T}_{abcd}=\mathcal{T}_{cdab}$. That symmetry can be imposed on the super-energy tensor for the Lanczos potential by examining

$$T^L{}_{abcd}=\tfrac{1}{2}\mathcal{T}^L_{abcd}+\tfrac{1}{2}\mathcal{T}^L_{cdab} \tag{72}$$

instead. In order to investigate whether this makes it symmetric over *all* indices we examine

$$T^{La}{}_{[bc]}{}^d=T^{L[a}{}_{[bc]}{}^{d]}=\tfrac{1}{4}L_{bce}L^{ade}-L^{[a}{}_{e[b}L_{c]}{}^{|e|d]}-\tfrac{1}{2}\delta^{[a}_{[b}L_{|ef|c]}L^{|ef|d]}-\delta^{[a}_{[b}L_{c]ef}L^{d]ef}$$
$$+\tfrac{1}{4}\delta^a_{[b}\delta^d_{c]}L_{efg}L^{efg}. \tag{73}$$

Its structure (maximum of two deltas) suggests that we investigate the four-dimensional identity $L_{[ef}{}^{[g}\delta_b^a\delta_{c]}^{d]}=0$. By multiplying with $L^{ef}{}_g$ we obtain the right-hand side of (73), so $T^L{}_{abcd}$ is completely symmetric in four dimensions and lower. It is, however, necessary to use the additional symmetry of the Lanczos potential $L_{[abc]}=0$ so this result does not hold for any (2,1)-form.

By taking the nontrivial double trace of (73) we obtain (by using $L_{[abc]}=0$ again)

$$T^{La}{}_{[ab]}{}^{b}=\frac{(n-4)(n-3)}{8}L_{abc}L^{abc}, \tag{74}$$

which shows that the dimension being four or less is both a necessary and sufficient condition for the symmetrized super-energy tensor $T^{L}{}_{abcd}$ for the Lanczos potential to be completely symmetric.

Although we can follow Senovilla's construction for the super-energy tensor from any (2,1)-form $L_{ab}{}^{c}$ in n dimensions, we should point out that the Lanczos potential for the Weyl tensor is unlikely to exist generally in dimensions above four.[15]

Example V.9: The four-dimensional algebraic Rainich identity associated with the energy momentum tensor $T^{a}{}_{b}=F^{a}{}_{c}F^{c}{}_{b}-\frac{1}{4}\delta^{a}_{b}F^{c}{}_{d}F^{d}{}_{c}$ of an electromagnetic field F_{ab} is given by

$$T^{a}{}_{c}T^{c}{}_{b}=\tfrac{1}{4}\,\delta^{a}_{b}T^{c}{}_{d}T^{d}{}_{c}\,. \tag{75}$$

When written out in full this identity is

$$F^{a}{}_{c}F^{c}{}_{d}F^{d}{}_{e}F^{e}{}_{b}-\tfrac{1}{2}F^{a}{}_{c}F^{c}{}_{b}F^{d}{}_{e}F^{e}{}_{d}-\tfrac{1}{4}\delta^{a}_{b}F^{c}{}_{d}F^{d}{}_{e}F^{e}{}_{f}F^{f}{}_{c}+\tfrac{1}{8}\delta^{a}_{b}F^{c}{}_{d}F^{d}{}_{c}F^{e}{}_{f}F^{f}{}_{e}=0. \tag{76}$$

But this is simply the Cayley–Hamilton theorem for $F^{a}{}_{b}$ as given in Example I.2,

$$F^{c}{}_{[c}F^{d}{}_{d}F^{e}{}_{e}F^{f}{}_{f}\delta^{a}_{b]}=0 \tag{77}$$

when specialized to antisymmetric F_{ab}. Equivalently the structure immmediately suggests specializing the four-dimensional identity for trace-free (1,1)-forms $F^{[f}{}_{[c}\delta^{g}_{d}\delta^{h}_{e}\delta^{a]}_{b]}=0$ given in (39) to antisymmetric forms, from which we obtain the identity

$$F^{[f}{}_{[c}\delta^{g}_{d}\delta^{h}_{e}\delta^{a]}_{b]}F^{c}{}_{f}F^{d}{}_{g}F^{e}{}_{h}=0 \tag{78}$$

which, when expanded and specialized to antisymmetric F_{ab}, is identical to (76)

A more direct way to obtain (76) is to expand

$$F^{cd}F^{ef}F_{[cd}F_{ef}\delta^{a}_{b]}=0. \tag{79}$$

VI. SUMMARY AND DISCUSSION

Of course, Lovelock's identities and our generalizations found in this paper are not really ''new'' since they are just simple and direct specializations of those fundamental identities found by antisymmetrizing over $n+1$ indices in n dimensions. Rather, the significance of these identities is that they highlight the fact that there exist heavily disguised versions of these fundamental identities when trace-free and antisymmetry properties are also introduced; and since we often are dealing with tensors with these explicit properties it is often the specializations of the fundamental identities which are relevant in practical applications.

The use of dimensionally dependent identities is a powerful method which has been largely overlooked, perhaps because of its simplicity. A very striking example of this is to be seen in the algebraic Rainich condition for the electromagnetic energy tensor in four dimensions. Over the past 75 years this condition has been obtained by a variety of very different methods: Rainich[26] used invariant planes, while others have used duality rotations,[27] complex duals,[28,29] and complicated matrix manipulation based on the Cayley–Hamilton theorem;[30] in spinors, a simple direct calculation has been given.[1] In fact Rainich's result was one of the motivations for Lovelock's work[10] and although he rederived the result using an explicit four-dimensional identity,[10,31] it is still a somewhat roundabout and contrived calculation. We have shown in example V.9 that the result can be viewed as simply the four-dimensional Cayley–Hamilton theorem when considered as a dimensionally dependent identity, or equivalently a trivial application of our basic result.

In this particular example, as in the others in Sec. V, we have been able to focus directly on the fundamental dimensionally dependent identity underlying the result. By identifying this un-

derlying identity in our various applications to four dimensions in this paper, we are in a position to explore directly the possibility of generalizations to other dimensions and to other forms. We shall present such generalizations in a subsequent paper.

Of course, it is possible to establish results peculiar to four dimensions without having to deal explicitly with dimensionally dependent identities; this is most easily done by using spinors, where the dimension is built into the formalism. Indeed, it was the apparent discrepency between results in spinors and tensors which originally gave the clue to the existence of a number of these four-dimensional identities. If we were only dealing with four-dimensional spaces with Lorentz signature, then spinors would be the more efficient formalism to use; on the other hand, the advantage of the tensor formalism is that once we have identified the underlying four-dimensional tensor identity, generalizations to other dimensions can be sought.

In a similar way, when explicit four-dimensional duals are used, then the dimension can also be built in by some of the identities satisfied by duals. For instance, the key identities associated with duals in work on super-energy tensors by Senovilla [Eqs. (2) and (3) in Ref. 21] have dimension n built in explicitly; so these are dimensionally dependent identities constructed from identities of the form

$$T^{A}_{[a_1}\eta_{a_2a_3\ldots a_{n+1}]}=0. \tag{80}$$

In this context, it is significant that the four-dimensional identity (31) is obtained in Ref. 21 essentially by taking double duals.

As emphasized in Sec. V, important applications of these results will be to Riemann tensors. Of course the Riemann tensor has additional symmetries to those of a (2,2)-form; these additional symmetries have not been explicitly considered in this paper, but would need to be considered explicitly in an exhaustive treatment of invariants of the Riemann tensor.

In conclusion, we emphasize that when examining what actually was required in the proofs of the theorems in Sec. IV one discovers that very little structure was needed. First, the results hold pointwise so the manifold structure is not needed. Second, there was no raising or lowering of indices so no assumption on what to use for that is needed; indeed not even the existence of such operations is needed. Third, no metric was used. This means that those theorems can be applied to objects other than tensors, e.g., spinors when $n=2$; matrices when the number of indices on the objects are appropriate; or other indexed objects such as Christoffel symbols or tensors in coordinate index notation or tetrad index notation.

We present numerical evidence that singularities form in finite time during the evolution of $2+1$ wave maps from spherically equivariant initial data of sufficient energy. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1418717]

I. INTRODUCTION

While it has been shown that wave maps on a $1+1$-dimensional Minkowski spacetime base evolved from smooth initial data exist for all time,[1,2] and that those on an $m+1$ $(m\geqslant 3)$ Minkowski spacetime base can blow up in finite time,[3] the global existence for the $2+1$ case remains as yet unresolved. Scaling considerations identify $2+1$ as the critical dimension for wave maps, and so there is considerable interest in determining if indeed $2+1$ wave maps developed from smooth initial data can become singular in finite time or not. Here, we describe numerical work that strongly supports the contention that, at least for some sets of smooth initial data, they can.

There are special classes of $2+1$ wave maps for which global existence has been shown to hold: (a) spherically equivariant wave maps with convex,[4] or slightly more general targets,[5] (b) spherically symmetric wave maps with compact targets (plus a further technical condition on the target),[6] (c) general wave maps (general target) with sufficiently small energy.

Not included in any of these three classes are spherically equivariant wave maps from $2+1$ Minkowski spacetime into the round two-sphere with initial data of arbitrary energy. Shatah and Struwe[7] have conjectured that singular behavior should be found in this class. Our numerical results reported here strongly support the validity of this conjecture.

We examine one-parameter families of data, with small values of the parameter corresponding to small energy data and therefore global existence, and with large values of the parameter corresponding to data possibly leading to singularity formation. One might hope to find especially interesting wave map development for data at or near the transition between small and large values. While this sort of ''critical'' behavior has been seen and studied in $3+1$ wave maps,[8,9] we have not found nearly as clear an indication of universal critical behavior for the present $2+1$ case. This criticality issue needs further study, and is not treated in this paper. Here, our focus is on numerical evidence for singular wave map evolution from regular initial data.

We note that our studies of singularity formation in $2+1$ wave maps have been carried out independently of the work of Bizoń, Chmaj, and Tabor[10] using numerical algorithms that differ from theirs. However, their results and ours agree substantially.

II. THE EQUATIONS

Generally a wave map is defined to be a map ϕ^A from a spacetime (the ''base'') into a Riemannian geometry (the ''target''), with ϕ^A a critical point for the action

[a)]Electronic mail: jim@newton.uoregon.edu
[b)]Electronic mail: steve@mozart.liu.edu

$$S[\phi]=\int_{M^{m+1}}\eta^{\mu\nu}g_{AB}(\phi)(\partial_\mu\phi^A\,\partial_\nu\phi^B), \tag{1}$$

where g_{AB} is the Riemannian metric on the target manifold N^n, and $\eta^{\mu\nu}$ is the (inverse) Lorentz-signature metric on the spacetime M^{m+1}. The Euler–Lagrange equations for this action take the form

$$\partial^\mu\partial_\mu\phi^A+\Gamma^A_{BC}\,\partial_\mu\phi^B\,\partial^\mu\phi^C=0, \tag{2}$$

where Γ^A_{BC} represents the Christoffel symbols corresponding to the target metric g_{AB}. This is a semilinear hyperbolic PDE system for ϕ^A. We note that for certain targets, wave maps are known to physicists as ''nonlinear sigma models.''

As noted above, the case of primary interest here is $2+1$ Minkowski spacetime for the base and the round two sphere for the target. In this case, the wave map PDE system (2) may be rewritten in the following form:

$$\Box\phi^a+(\partial_\mu\phi^b\,\partial^\mu\phi^c)\,\delta_{bc}\phi^a=0, \tag{3}$$

where the indices a,b,c take the values $\{1,2,3\}$ (indexing the ambient Euclidean 3-space for the target two sphere), and δ_{bc} is the metric for this ambient space. If we now impose the condition that the maps ϕ^a be spherically equivariant with angular wrapping number k, and write $\phi^a(r,\theta,t)$ in the ''hedgehog'' form

$$\phi^a=\begin{pmatrix}\sin\chi(r,t)\sin k\theta\\ \sin\chi(r,t)\cos k\theta\\ \cos\chi(r,t)\end{pmatrix}, \tag{4}$$

where r is the radial distance from the origin and θ is the azimuthal angle; then the wave map PDE system (2) reduces to the single equation,

$$\ddot{\chi}=\frac{1}{r}(r\chi')'-\frac{k^2\sin 2\chi}{2r^2} \tag{5}$$

where a prime and an overdot denote partial derivatives with respect to r and t, respectively. Thus, the study of the Cauchy problem for $2+1$ spherically equivariant (k-wrapped) wave maps into the round two sphere focuses on finding solutions $\chi(r,t)$ to Eq. (5) with regular initial data $\chi(r,0),\dot{\chi}(r,0)$. Note that regularity at $r=0$ requires that we set $\chi(0,t)=0$ for all t.

While it may be interesting to examine if there is any variation of the behavior of solutions for wrapping numbers k greater than one, we restrict our attention here to the single angular wrapping case $k=1$.

As for any field theory on Minkowski space, there is a divergence-free stress–energy tensor $T_{\mu\nu}$ associated with wave maps. From $T_{\mu\nu}$, we obtain the energy density function for spherically equivariant wave maps,

$$\rho(r,t)=\frac{1}{2}[\dot{\chi}^2+(\chi')^2]+\frac{\sin^2\chi}{2r^2}, \tag{6}$$

whose integral

$$E(t)=\int_r\rho(r,t)r\,dr \tag{7}$$

is conserved [i.e., $E(t)=E(0)$ for all t]. The energy is a useful monitor of numerical accuracy, as discussed below.

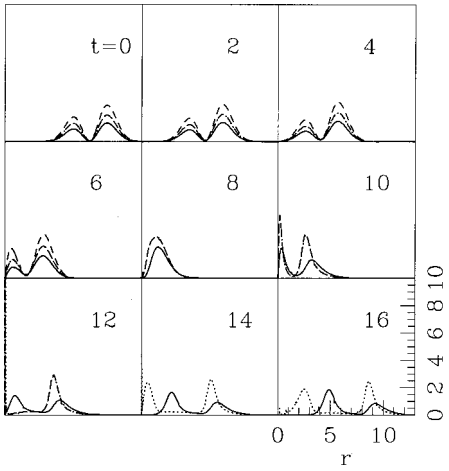

FIG. 1. Snapshots of the energy densities (times r) for a single family of initial data with varying amplitude. At $t=0$ the initial energy densities corresponding to ingoing Gaussian initial data ($R_0=8,\delta=2.3$) are shown. Supercritical ($A=1.4$) is shown as long-dashed line that exists only until $t=6$. Subcritical ($A=1.0$) is shown as a solid line. Two near-critical evolutions are also shown: slightly subcritical ($A=1.19$) is shown as a dotted line and slightly supercritical ($A=1.195$) is shown as a short-dashed line. The two near-critical evolutions coincide at the scale of this graph until $t=12$ after which we cannot compute the apparently singular supercritical solution. The energy densities reached by the supercritical solutions extend significantly off the scale of this graph.

III. NUMERICAL STUDIES OF SINGULARITY FORMATION

Our numerical experiments consist of specifying parametrized families of initial data $\{\chi_\lambda(r,0),\dot{\chi}_\lambda(r,0)\}$ and numerically evolving a number of sets of such data in each family. A typical family—one of the simplest—is the approximately ingoing Gaussian pulse,

$$\chi(r,0)=Ae^{-(r-R_0)^2/\delta^2}, \quad \dot{\chi}(r,0)=\chi'(r,0). \tag{8}$$

This family has three parameters A, R_0, and δ, with the most important one for our discussion being the scale parameter A. Note that the ingoing character of these solutions, which results from the choice of $\dot{\chi}(r,0)$, minimizes outer boundary effects. Note also that while, analytically, $\chi(0,0)$ is not zero, for the choices of R_0 and δ that we make, we can force $\chi(0,0)$ to be zero and retain smoothness to within numerical accuracy.

We evolve using a second-order finite difference approximation to Eq. (5). We use an iterative Crank–Nicholson scheme implemented with RNPL,[11] and also make use of the adaptive mesh framework developed by Choptuik.[12] We have verified that the code generates solutions that converge quadratically in the grid spacing and conserve energy. In arguing that we are indeed generating singularities, we will discuss the convergence and energy conservation tests in more detail below.

For a general set of ingoing Gaussian pulse data, regardless of amplitude, the wave map evolution has the pulse maximum and energy density maximum initially moving inward (decreasing r). For small (subcritical) values of A, this inward motion of the maximum proceeds for a finite time, after which the maximum ''bounces'' away from the origin and begins to move outward (see Fig. 1). There is a general dispersal of the energy density; and for large t, there is very little energy density remaining near the origin.

For large (supercritical) values of A, the behavior of the evolving wave map is qualitatively the same initially. However, rather than bouncing away from the origin, the maxima for supercritical data continue to approach the origin (Fig. 1), with the concentration of energy around the origin appearing to grow without bound. As the energy density and the gradient of the function χ grow very large at the origin, the numerical evolution inevitably becomes unable to resolve the gradient, and the solution becomes sufficiently nonsmooth to cause the numerical evolution to

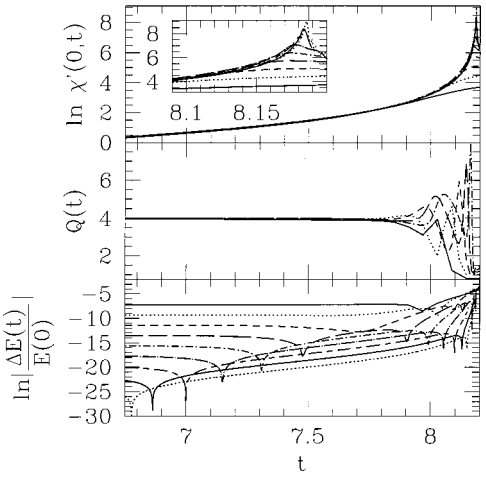

FIG. 2. Results of a supercritical evolution for an initially ingoing Gaussian pulse ($A=2, R_0=10, \delta=2.3, R_{\max}=30$). The results are shown for increasing resolutions $n=2^8$ (solid), $n=2^9$ (dot), $n=2^{10}$ (short dash), $n=2^{11}$ (long dash), $n=2^{12}$ (dot–short dash), $n=2^{13}$ (dot–long dash), $n=2^{14}$ (short dash–long dash), $n=2^{15}$ (solid), and $n=2^{16}$ (dot), where $h=R_{\max}/n$. The top frame shows the rapid growth of $\chi'(0,t)$ near the time of the blowup ($t\approx 8$). The middle frame shows the convergence factor [defined in Eq. (9)]. Factors greater than one indicate convergence. The bottom frame shows the change in energy with respect to the initial energy. As the resolution increases, so does the level of energy conservation.

stop. If this accumulation is indeed a singularity forming, there is no hope for the numerical evolution to resolve it, being itself of finite resolution. The task then is to examine the behavior of the numerical solution up to this point.

Before doing so, we first discuss a couple of standard tests of a numerical solution. We let $\chi(r,t)$ be some solution to the (continuum) partial differential equation (5) and let $\tilde{\chi}_h(r,t)$ be the solution to a discrete form of that equation, for corresponding initial data, on a grid spacing $h \equiv \Delta r$. The hope is that, as the grid spacing Δr gets smaller, the solutions to the discrete equation generated by the evolution code converge to the solutions of the PDE, $\tilde{\chi}(r,t)\to\chi(r,t)$. Because in general the explicit solutions to the PDE are unknown, we instead consider a series of numerical solutions on grids of increasing resolution, say $\tilde{\chi}_{4h}, \tilde{\chi}_{2h}, \tilde{\chi}_h$. If these are to converge to the PDE solution, then they must converge themselves. To examine this convergence, we define a convergence factor (Q) as follows:

$$Q \equiv \frac{|\tilde{\chi}_{4h}-\tilde{\chi}_{2h}|_2}{|\tilde{\chi}_{2h}-\tilde{\chi}_h|_2}, \tag{9}$$

where the norms are the l_2 norm. For these solutions to converge, the difference between solutions for increasing resolution must decrease and hence Q must be greater than one. For second-order schemes, Q is expected to be 4.

Another common test of numerical accuracy focuses on the degree to which energy is conserved by the numerical evolution. The evolution governed by the PDE (5) does conserve energy; the question is whether this remains true for the numerical evolution. Letting $E_{\rm num}(t)$ denote the energy calculated from the numerical solution at time t (on the finite grid), and setting $\Delta(t) \equiv \ln|(E_{\rm num}(t)-E_{\rm num}(0))/E_{\rm num}(0)|$, we monitor $\Delta(t)$ for different choices of grid spacing. The expectation is that $\Delta(t)$ should decrease with increasing resolution; if we observe this, our confidence in the accuracy of our numerical solution is enhanced.

In Fig. 2, we show the evolution in time of three quantities—$\ln\chi'(0,t)$, $Q(t)$, and $\Delta(t)$—for numerical runs of supercritical ingoing Gaussian pulse data, done with nine different grid spacings. In the top frame, we show the behavior of the derivative of χ at the origin as a function of time. The figure shows that as the pulse travels inward, the derivative increases. Until just before $t=8$, all the resolutions show the same behavior as would be expected for a convergent evolution.

However, near the blow-up time, the solutions diverge with higher resolutions providing a larger derivative. The convergence factor $Q(t)$ is shown in the middle frame; it likewise shows second-order convergence up to times close to the blow-up time. In the bottom frame, the change in energy $\Delta(t)$ is shown. We see that as the resolution is increased, energy conservation improves.

What does this tell us about singularity formulation in wave maps evolved from (supercritical) ingoing Gaussian pulse data? We first argue that these results are consistent with what would be expected for such a formation. As the singularity forms, higher- and higher-frequency components become important, and they are represented numerically only if one uses higher and higher grid resolutions. Hence, the behavior of the derivative of χ as the resolution improves would be expected to show larger and larger gradients, as seen in Fig. 2(a). Next, we note that the formation of a singularity should not hinder convergence except quite near the formation time, as is seen in Fig. 2(b). Finally, energy conservation should be fine until the high-frequency components play their role, as we see in Fig. 2(c). Hence, the results observed appear to be consistent with a singularity forming near $t=8$.

This does not guarantee that a singularity forms in these wave maps. There are other effects that might produce the apparently unbounded growth of the derivative of χ and of the energy density near the origin in these numerical simulations. For example, perhaps some unphysical, unstable mode grows because of the particulars of our chosen evolution scheme. We believe that this is not the case, for a number of reasons. First, the presence of such a mode would likely cause much larger growth in $\Delta(t)$ than we see. Second, such modes would have to be excited only after some time (roughly independent of resolution) and only for families of sufficiently large energy. This is not consistent with our observations. Third, the excitation of this sort of instability would almost certainly depend critically on the precise finite difference scheme. Because Bizoń and his collaborators[10] observe similar behavior, using a different numerical evolution scheme, this does not appear to be the case. Thus, we believe it very unlikely that the effects we are seeing are the result of a numerically unstable nonsingular mode.

Another situation in which one might numerically observe the formation of singularities that do not, in fact, evolve analytically from the corresponding data is if the continuum PDE solution is regularized by high-frequency components which cannot be seen by the finite grid resolutions we use. The rather strong convergence behavior we see in our numerical solutions leads us to believe that this is not happening. We note in particular that such unresolved components would have to be separated in frequency space from the nontrivial low-frequency components by a substantial margin, with a large range of dynamically irrelevant frequencies separating the two regimes. This seems to be very unlikely.

IV. CONCLUSION

The numerical studies we present here very strongly support the contention, previously conjectured by Shatah and Struwe,[7] that smooth initial data for wave maps from $2+1$ Minkowski spacetime into the round two sphere can develop singularities (with unbounded derivatives) in finite time. As we note, there are many ways in which the numerical exploration of possible singularity formation might produce misleading indications. However, we believe that as a consequence of the numerical tests we have carried out, together with those done independently by Bizoń and his collaborators,[10] the formation of singularities is the most likely conclusion.

There is much more one would like to know about these spatially equivariant wave maps, as well as about those without such symmetry. One would like to know, for example, if the solutions assume any universal form as one approaches the singularity. Our work (see Fig. 3) supports the results of Bizoń *et al.*,[10] which indicate that indeed the family of static spherically equivariant wave maps,

$$\chi(r)=\pm 2\arctan(\lambda r), \tag{10}$$

does serve as a sort of universal model for singularity formation. This needs to be studied further. One would also very much like to understand the behavior of the wave maps that evolve from

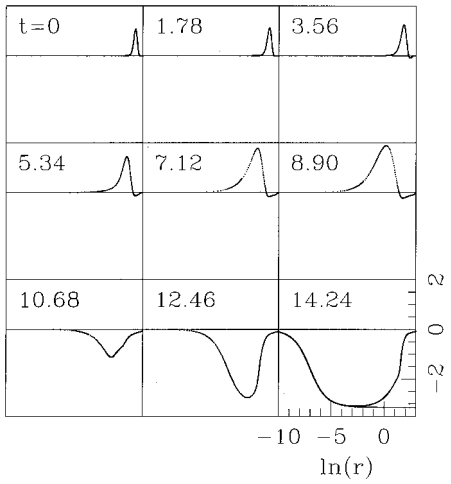

FIG. 3. Near-critical evolutions approach the static solution, Eq. (10). Nine frames equally spaced in time are shown for both *sub*- and *super*critical evolutions. The solutions are indistinguishable in the graph at these times and are shown with dots. After $t=14.24$, the two solutions have quite different fates, but both approach the form of the static solution. In the final frame, the static solution $\chi(r)=-2\arctan(1116r)$ is shown.

initial data near the transition from subcritical to supercritical data. The recent numerical work of Bizoń *et al.*[10] suggests that the static solutions (10) play a central role in the evolution of the transitional wave maps as well in that of supercritical ones; however, this issue needs further investigation. (Note the absence of any self-similar solutions to the $2+1$ wave map equations; for $3+1$ wave maps, such solutions play a key role in the behavior of solutions evolving from critical or near critical data).

(Received 9 July 2001; accepted for publication 11 October 2001)

Relative to a given factoring of the Hilbert space, the decomposition of an operator into a convex sum of correlated products of pairs of distinct 1-projectors, one set of projectors linearly independent, is unique. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1423764]

I. INTRODUCTION

Utilizing the Tridecompositional Uniqueness Theorem of Elby and Bub,[1] I establish the uniqueness, relative to a given factoring of the Hilbert space, of a decomposition of a state operator into a convex sum of correlated products of pairs of distinct 1-projectors,

$$\boldsymbol{\rho}=\sum_j w_j|a_j\rangle\langle a_j|\otimes|b_j\rangle\langle b_j|, \tag{1}$$

one set of projectors linearly independent.

In the Appendix, I present a slightly strengthened version and simplified proof of the Tridecompositional Uniqueness Theorem.

For the remainder of this paper I use the notation $|a_jb_k\rangle$ for the direct product $|a_j\rangle\otimes|b_k\rangle$.

II. PRELIMINARIES

All vectors are normalized.

Definition 1: $|a\rangle$ and $|b\rangle$ are collinear iff $|a\rangle=e^{i\alpha}|b\rangle$, $\alpha\in\mathcal{R}$; we denote this $|a\rangle\|b\rangle$.

Definition 2: The set $\{|a_j\rangle\}$ is noncollinear iff no pair of the set is collinear.

Definition 3: $\boldsymbol{\rho}$ is an operator on $\mathcal{H}_1\otimes\mathcal{H}_2$. The null space of $\boldsymbol{\rho}$ on $\mathcal{H}_\alpha$ is $\mathcal{N}_\alpha\doteq\{|\phi\rangle\in\mathcal{H}_\alpha|\rho|\phi\rangle=0\}$ $(\alpha\in\{1,2\})$.

Lemma 1: *With sets* $\{|a_j\rangle\in\mathcal{H}_1\}$, $\{|b_j\rangle\in\mathcal{H}_2\}$, *and* $\{w_j>0\}$, $j\in\{1\cdots N\}$, *and the operator* $\boldsymbol{\rho}=\Sigma w_j|a_jb_j\rangle\langle a_jb_j|$, *the set* $\{|a_j\rangle\}$ *spans* $\mathcal{G}_1\doteq(\mathcal{N}_1)^\perp$ *and the set* $\{|b_j\rangle\}$ *spans* $\mathcal{G}_2\doteq(\mathcal{N}_2)^\perp$.

Proof: For $|\phi\rangle\in\mathcal{N}_1$ and any $|\beta\rangle\in\mathcal{H}_2$, $\langle\phi\beta|\boldsymbol{\rho}|\phi\beta\rangle=0=\Sigma w_j|\langle a_j|\phi\rangle|^2|\langle b_j|\beta\rangle|^2$; thus $\langle a_j|\phi\rangle=0\forall|\phi\rangle\in\mathcal{N}_1$, so $|a_j\rangle\in(\mathcal{N}_1)^\perp=\mathcal{G}_1$. If $\{|a_j\rangle\}$ does not span $\mathcal{G}_1$, there is a vector in $\mathcal{G}_1$ orthogonal to $\{|a_j\rangle\}$; but any such vector is annihilated by ρ and is thus in $\mathcal{N}_1$, a contradiction.□

The following result appears in Ref. 2, in the midst of the proof of another theorem:

Lemma 2: $|\Psi\rangle$ *and* $|\Phi\rangle$ *are vectors in* $\mathcal{H}_1\otimes\mathcal{H}_2$. *If* $\mathrm{Tr}_2\{|\Psi\rangle\langle\Psi|\}=\mathrm{Tr}_2\{|\Phi\rangle\langle\Phi|\}$, *then there exists a unitary transformation* $\mathbf{U}$ *on* $\mathcal{H}_2$ *such that* $|\Psi\rangle=(1\otimes\mathbf{U})|\Phi\rangle$.

III. THE UNIQUENESS THEOREM

Theorem 1: *With noncollinear sets* $\{|a_j\rangle\in\mathcal{H}_1\}$ *and* $\{|b_j\rangle\in\mathcal{H}_2\}$, $j\in\{1\cdots n\}$, *one set linearly independent, and with noncollinear sets* $\{|A_k\rangle\in\mathcal{H}_1\}$ *and* $\{|B_k\rangle\in\mathcal{H}_2\}$, $k\in\{1\cdots N\}$, *one set linearly independent, and with sets* $\{w_j>0\}$ *and* $\{W_k>0\}$, *if*

$$\sum_{j=1}^{n} w_j|a_jb_j\rangle\langle a_jb_j|=\sum_{k=1}^{N} W_k|A_kB_k\rangle\langle A_kB_k|,$$

a)Electronic mail: kirkpatrick@physics.nmhu.edu

then $N=n$, *and, for all* $j\in\{1\cdots n\}$,

$$|A_j\rangle\|\,|a_{\pi(j)}\rangle,\quad |B_j\rangle\|\,|b_{\pi(j)}\rangle,\quad \textit{and}\quad W_j=w_{\pi(j)},$$

with $\pi(\cdot)$ *a permutation function on* $\{1\cdots n\}$.

Proof: Call the operator $\boldsymbol{\rho}$. Apply Lemma 1, with $d_1\doteq\dim\mathcal{G}_1$ and $d_2\doteq\dim\mathcal{G}_2$, and recall: A set of m vectors spans a space of dimension $d\leqslant m$; $d=m$ iff the vectors are linearly independent. Without loss of generality we take the set $\{|a_j\rangle\}$, which spans $\mathcal{G}_1$, to be linearly independent; thus $n=d_1$. Either $\{|A_k\rangle\}$ or $\{|B_k\rangle\}$ must be linearly independent; in either case, $N=n$: If $\{|A_k\rangle\}$ is linearly independent, then $N=d_1=n$. On the other hand, if $\{|B_k\rangle\}$ is linearly independent, then $N=d_2$; the n vectors $\{|b_j\rangle\}$ must span $\mathcal{G}_2$, hence $n\geqslant d_2=N$. Similarly, the N vectors $\{|A_k\rangle\}$ must span $\mathcal{G}_1$, hence $N\geqslant d_1=n$, thus $N=n$.

Introduce a third Hilbert space $\mathcal{H}_3$, with $\dim\mathcal{H}_3\geqslant n$; $\{|c_j\rangle\}$ and $\{|C_j\rangle\}$ are orthonormal bases of $\mathcal{H}_3$. Construct the two vectors,

$$|\psi\rangle=\sum_{j=1}^{n}\sqrt{w_j}|a_jb_jc_j\rangle\ \text{ and }\ |\Psi\rangle=\sum_{j=1}^{n}\sqrt{W_j}|A_jB_jC_j\rangle;$$

clearly, $\boldsymbol{\rho}=\mathrm{Tr}_3\{|\psi\rangle\langle\psi|\}=\mathrm{Tr}_3\{|\Psi\rangle\langle\Psi|\}$. By Lemma 2, there exists a unitary transformation $\mathbf{U}$ on $\mathcal{H}_3$ such that $|\psi\rangle=(1\otimes1\otimes\mathbf{U})|\Psi\rangle$; defining $|D_j\rangle\doteq\mathbf{U}|C_j\rangle$, we have

$$\sum_{j=1}^{n}\sqrt{w_j}|a_jb_jc_j\rangle=\sum_{j=1}^{n}\sqrt{W_j}|A_jB_jD_j\rangle,$$

to which we apply Theorem A. □

IV. DISCUSSION

"Uniqueness" is relative to the identification of system and apparatus. Elby and Bub claim that Eq. (1) "suffers from a version of the basis degeneracy problem." For example, with $\langle a_1|a_2\rangle=\langle b_1|b_2\rangle=0$, the sum-of-products expression

$$\boldsymbol{\rho}=\tfrac{1}{2}|a_1b_1\rangle\langle a_1b_1|+\tfrac{1}{2}|a_2b_2\rangle\langle a_2b_2| \tag{2}$$

(which, according to Theorem 1, is unique) is the diagonalization of a degenerate Hermitian operator (with eigenvalues 1/2 twice, and 0 twice). The eigenvectors may be taken to be $|a_1b_1\rangle$, $|a_2b_2\rangle$, $|a_1b_2\rangle$ and $|a_2b_1\rangle$—products of vectors taken pairwise from $\mathcal{H}_1$ and $\mathcal{H}_2$. Because of this degeneracy, we can rotate the eigenvectors into $|q_{1,2}\rangle=2^{-1/2}(|a_1b_1\rangle\pm|a_2b_2\rangle)$, $|q_3\rangle=|a_1b_2\rangle$, and $|q_4\rangle=|a_2b_1\rangle$. Then Eq. (2) may be written

$$\boldsymbol{\rho}=\tfrac{1}{2}|q_1\rangle\langle q_1|+\tfrac{1}{2}|q_2\rangle\langle q_2|; \tag{3}$$

"the pointer reading loses its 'special' status."

This argument is flawed—after all, the same claim may be made against the tridecompositional uniqueness theorem itself:

$$|\Psi\rangle=\frac{1}{\sqrt{2}}(|a_1b_1c_1\rangle+|a_2b_2c_2\rangle)=\frac{1}{\sqrt{2}}(|q_1d_1\rangle+|q_2d_2\rangle), \tag{4}$$

with $|d_{1,2}\rangle=2^{-1/2}(|c_1\rangle\pm|c_2\rangle)$. Equation (4) is no more a counterexample to the tridecompositional uniqueness theorem than Eq. (3) is a counterexample to Theorem 1, and for the same reason: the "special" nature of a pointer basis is based on the uniqueness of the form of the

decomposition in Eq. (1), which in turn is based on a particular identification of system and apparatus. One cannot speak of the ''pointer basis'' without having settled on the ''pointer''—the apparatus—thus having already specified the factor spaces.

Only having chosen a fixed identification of the subsystems (and the associated factoring of the space) may either of these uniqueness theorems then be applied.

APPENDIX: THE TRIDECOMPOSITIONAL UNIQUENESS THEOREM

This version of the Tridecompositional Uniqueness Theorem[1] avoids two assumptions of the original: that the linearly dependent set is in the same space in each expansion, and that the expansions each have the same number of terms. The proof here is similar to that of Ref. 1, but is considerably shorter and, perhaps, clearer.

Definition A: $|\Psi\rangle$ is factorable in $\mathcal{H}_1\otimes\mathcal{H}_2$ iff there exist $|\alpha\rangle\in\mathcal{H}_1$ and $|\beta\rangle\in\mathcal{H}_2$ such that $|\Psi\rangle=|\alpha\beta\rangle$.

Lemma A (Similar to Lemma 1 of Ref. 1): *With the set* $\{|a_j\rangle\in\mathcal{H}_1\}$ *linearly independent and the set* $\{|b_j\rangle\in\mathcal{H}_2\}$ *noncollinear,* $|\Psi\rangle=\Sigma_j s_j|a_j b_j\rangle$ *is factorable in* $\mathcal{H}_1\otimes\mathcal{H}_2$ *iff the set* $\{s_j\in\mathcal{C}\}$ *contains exactly one nonzero element.*

Proof: Let $|\Psi\rangle=|\alpha\beta\rangle$, with $|\alpha\rangle\in\mathcal{H}_1$ and $|\beta\rangle\in\mathcal{H}_2$. Expand $|\alpha\rangle=\Sigma_j a_j|a_j\rangle$, so $|\Psi\rangle=\Sigma_j a_j|a_j\beta\rangle$; the set $\{|a_j\rangle\}$ is linear independent, so, for each j, $a_j|\beta\rangle=s_j|b_j\rangle$. For every $s_j\neq 0$, $|b_j\rangle\|\,|\beta\rangle$. If more than one $s_j\neq 0$, $\{|b_j\rangle\}$ is not noncollinear, contrary to hypothesis, contradicting the assumption of factorability. The converse is obvious. □

Theorem A (Tridecompositional uniqueness): *With noncollinear sets* $\{|a_j\rangle\in\mathcal{H}_1\}$, $\{|b_j\rangle\in\mathcal{H}_2\}$, *and* $\{|c_j\rangle\in\mathcal{H}_3\}$, $j\in\{1\cdots n\}$, *two sets linearly independent, and noncollinear sets* $\{|A_k\rangle\in\mathcal{H}_1\}$, $\{|B_k\rangle\in\mathcal{H}_2\}$, *and* $\{|C_k\rangle\in\mathcal{H}_3\}$, $k\in\{1\cdots N\}$, *two sets linearly independent, and sets* $\{\phi_j\in\mathcal{C}|\,\phi_j\neq 0\}$ *and* $\{\varphi_k\in\mathcal{C}|\varphi_k\neq 0\}$, *if*

$$\sum_{j=1}^{n}\phi_j|a_j b_j c_j\rangle=\sum_{k=1}^{N}\varphi_k|A_k B_k C_k\rangle,$$

then $N=n$, *and, for all* $j\in\{1\cdots n\}$,

$$|A_j\rangle\|\,|a_{\pi(j)}\rangle,|B_j\rangle\|\,|b_{\pi(j)}\rangle,\quad |C_j\rangle\|\,|c_{\pi(j)}\rangle,\ \text{and}\ |\varphi_j|=|\phi_{\pi(j)}|,$$

with $\pi(\cdot)$ *a permutation function on* $\{1\cdots n\}$.

Proof: Take $\{|C_k\rangle\}$ and $\{|c_j\rangle\}$ to be linearly independent (with no loss of generality: in each expansion, two of the three sets are linearly independent, requiring coincidence in at least one space). These sets must span the same subspace of $\mathcal{H}_3$; thus $N=n$. Expand $|c_j\rangle=\Sigma_k\gamma_{jk}|C_k\rangle$; then $\varphi_k|A_k B_k\rangle=\Sigma_j\phi_j\gamma_{jk}|a_j b_j\rangle$. For each k, Lemma A requires $\gamma_{jk}=0$ for all but one j; define the function π: $\{1\cdots n\}\to\{1\cdots n\}$ by the relation $\gamma_{\pi(k)k}\neq 0$. We have $|c_{\pi(k)}\rangle=\gamma_{\pi(k)k}|C_k\rangle$, so $|c_{\pi(k)}\rangle\|\,|C_k\rangle$ (and normalization requires $|\gamma_{\pi(k)k}|=1$). Because the set $\{|C_k\rangle\}$ is noncollinear, $\pi(\cdot)$ must be 1:1, i.e., a permutation function on $\{1\cdots n\}$. We also have $\varphi_k|A_k B_k\rangle=\phi_{\pi(k)}\gamma_{\pi(k)k}|a_{\pi(k)}b_{\pi(k)}\rangle$, so $|a_{\pi(k)}\rangle\|\,|A_k\rangle$ and $|b_{\pi(k)}\rangle\|\,|B_k\rangle$; normalization requires $|\varphi_k|=|\phi_{\pi(k)}|$. □

(Received 31 January 2001; accepted for publication 20 September 2001)

In this paper the concept of pesudodifferential forms on supermanifolds is extended and a new complex is introduced. At last it is shown that the corresponding cohomology ring is sensitive to ''super'' structure. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1416888]

I. INTRODUCTION

Supermanifolds, in local view, are spaces with commuting and anticommuting variables. Supermanifolds provide a framework for quantum field theory. In this regard, one can consider fermion fields as anticommuting fields.

In order to understand the geometry and topology of supermanifolds, different concepts of differential geometry have been extended to supermanifolds. However, some concepts have not found any satisfactory generalization. Characteristic classes is an example. In conventional differential geometry, there is a duality between characteristic classes and Schubert cells.[1] Although the superanalog of Schubert cells defined,[2] it is not clear in what homology theory these supercells are closed.[3] It seems that homology classes corresponding to supercells are in cyclic cohomology of a proper algebra. Since there is a correspondence between cyclic cohomology classes and cycles $(\Omega,d,\int)$ where (Ω,d) is a differential graded algebra and $\int$ is a closed trace on Ω,[4] thus proper generalization of differential forms, exterior differential operator and integration lead to find cyclic cohomology classes, different from the ones associated with underlying manifold. One cycle is defined by Monge in Refs. 5, 6. In Ref. 5 a $\mathbf{Z}^2$-graded de Rham like cohomology developed which is not determined by cohomology of its underlying manifold and has a functorial definition within the category of supermanifolds. An integration theory is extended for these $\mathbf{Z}_2$-forms in Ref. 6. Establishing Stokes theorem shows that the integral is a closed trace. But projection which is used in the definition of an integral causes the fast elimination of odd variables. So its cycle does not seem to define a new invariant for supermanifolds.

In this paper we extend $\mathcal{P}$, the algebra of pseudodifferential forms, to an algebra of matrices over $\mathcal{P}$, in rough statement. This idea comes from the point which Connes made in Ref. 4. There, he proves the Gauss–Bonnet theorem for Σ, smooth closed surface in $\mathbf{R}^3$, by considering the algebra of 2×2 matrices with entries in $C^\infty(\Sigma)$.

At last we show that the corresponding cohomology ring is sensitive to a ''super'' structure. This provides a counterexample for the conjecture of Voronov.[5]

Integration theory is introduced in the coming paper.

II. PRELIMINARIES

Let M be a topological space and $\mathcal{A}$ be a sheaf of $\mathbf{Z}_2$-graded commutative real algebras on M. By a real supermanifold with dimension (m,n) we mean a pair $(M,\mathcal{A})$ with the following conditions.

(i) M is a second countable Hausdorff space.

a)Electronic mail: varsaie@iasbs.ac.ir

(ii) For every point $m \in M$ there exists a neighborhood U in which $\mathcal{A}|_U$ is isomorphic to $C^\infty(U)\otimes\wedge\mathbf{R}^n$ as the sheaves of $\mathbf{Z}_2$-graded commutative algebras. U is called a splitting neighborhood. Let $z^1,\ldots,z^m$ be a coordinate function on U and $e^1,\ldots,e^n$ be a basis for $\mathbf{R}^n$. Then z^i's are called even coordinates and e^j's are called odd coordinates.

Let $T_{\mathcal{A}}$ be the sheaf of derivations of $\mathcal{A}$. A $\mathbf{R}$-linear map $X:\mathcal{A}\to\mathcal{A}$ is called a derivation if $X(ab)=X(a)b+(-1)^{\tilde{a}\tilde{X}}aX(b)$ where $\tilde{a}$ and $\tilde{X}$ are degrees (or parities) of a and X according to $\mathbf{Z}_2$-graded structures of $\mathcal{A}$ and $\mathrm{Hom}(\mathcal{A},\mathcal{A})$, respectively.[7]

This sheaf is locally free and is generated by $\{\partial/\partial z^j, \partial/\partial e^i\}$. These derivations have the same parity as the coordinates $\{z^i,e^j\}$. The cotangent sheaf Ω^1_M can be defined as $\mathrm{Hom}_{\mathcal{A}}(T_{\mathcal{A}},\Pi\mathcal{A})$. Here Π can be considered as a formal factor of degree 1 and $\Pi\mathcal{A}$ is an $\mathcal{A}$-module such that

$$\Pi a+\Pi b=\Pi(a+b),$$

$$a(\Pi b)=(-1)^{\tilde{a}}\Pi(ab).$$

Locally, Ω^1_M is generated by $\{dz^i,de^j\}$. Obviously these differentials are of a parity opposite to the parity of coordinates $\{z^i,e^j\}$. Thus the elements $\partial/\partial z^j, de^i$ are commutative and $\partial/\partial e^j, dz^i$ are anticommutative. It is natural to consider functions $\omega(z^i,e^j,\partial/\partial z^i,de^j,dz^i,\partial/\partial e^j)$ which depend on commuting differentials as infinitely differentiable functions.[8] Berezine calls them pseudodifferential forms.

The sheaf of such forms, denoted by $\mathcal{P}$, is Grassmann algebra with generators $\partial/\partial e^j, dz^i$, and a coefficient in $\mathcal{P}_0$, the sheaf of smooth functions of $z^i,e^j,\partial/\partial z^i,de^j$.

III. EXTENDED BEREZIN PESUDODIFFERENTIAL FORMS

On pseudodifferential forms, Berezine introduced the differential

$$d=\sum_i dz^i\frac{\partial}{\partial z^i}+\sum_j de^j\frac{\partial}{\partial e^j}+\sum_i dw^i\frac{\partial}{\partial w^i}+\sum_j dt^j\frac{\partial}{\partial t^j},$$

where $w^i=\partial/\partial z^i$ and $t^j=de^j$.

Obviously the action of d does not produce integral forms. Thus in order to make a complete analogy with a de Rham complex we extend d. For this, it is necessary to have a proper extension of $\mathcal{A}$.

The sheaf of $T_{\mathcal{A}}$ is a locally free sheaf of $\mathcal{A}$-modules. It is locally generated by $\{\partial/\partial z^i, \partial/\partial e^j\}$. The parities of $\partial/\partial z^i$ and $\partial/\partial z^j$ are 0 and 1, respectively. Denote by τ_M the sheaf of algebras which is generated by $T_{\mathcal{A}}$ over $\mathcal{A}$. Obviously τ_M has a structure of a real supermanifold with dimension $(2m,2n)$ and is called a supermanifold that corresponds to $T_{\mathcal{A}}$. For this consider the homomorphism of algebras induced by transition maps due to the splitting representation of $T_{\mathcal{A}}$.

Denote by δ_M the supermanifold corresponding to ΠT_{τ_M}.

Now consider the sheaf $\mathcal{E}_M$ of all endomorphism φ on ΠT_{τ_M}.

Definition 3.1: By the extended pesudodfferential forms we mean the elements of $\mathcal{P}\otimes\mathcal{E}_M$.

There is a structure of algebra on $\mathcal{P}\otimes\mathcal{E}_M$ which is defined by

$$(a\otimes\varphi)\cdot(b\otimes\psi)=ab\otimes\varphi\psi;$$

let $\Omega^{p,q}(U)$ be a $\mathcal{A}(U)$-module with generators

$$\left\{dz^{i_1}\ldots dz^{i_k}\frac{\partial}{\partial e^{j_1}}\ldots\frac{\partial}{\partial e^{j_l}},\frac{\partial}{\partial z^{t_1}}\ldots\frac{\partial}{\partial z^{t_s}}de^{r_1}\ldots de^{r_u},k+l=p\ s+u=q\right\};$$

any element of algebra on $\Omega^{p,q}(U)\otimes\mathcal{E}_M$ is called a (p,q) form. There is also a differential on the algebra of all extended pesudodifferential forms defined as follows:

$$\tilde{d}(a\otimes\varphi)=\sum_{z^i} dz^i\left(\frac{\partial}{\partial z^i}a\right)\otimes\varphi+\sum_{z^i} de^i\left(\frac{\partial}{\partial e^i}a\right)\otimes\varphi+(-1)^{\tilde{a}}\sum_{e^j} a\otimes\frac{\partial}{\partial e^j}L_{\Pi\,\partial/\partial\,(\partial/\partial e^j)}\varphi$$
$$+(-1)^{\tilde{a}}\sum_{z^i} a\otimes\frac{\partial}{\partial z^i}L_{\Pi\,\partial/\partial\,(\partial/\partial z^i)}\varphi. \tag{1}$$

By $L_{\Pi[\partial/\partial(\partial/\partial e^j)]}\varphi$ we mean the Lie derivation along $\Pi[\partial/\partial(\partial/\partial e^j)]$. For this, consider φ as a 1.1 tensor on τ_M. Then the Lie derivative of the covariant component, say ω, is just $(d\bigcirc i(\Pi[\partial/\partial(\partial/\partial e^j)])+i(\Pi[\partial/\partial(\partial/\partial e^j)])\bigcirc d)(\omega)$ and the Lie derivative of contravariant component, say X, is $[X,\Pi[\partial/\partial(\partial/\partial e^j)]]$. A straightforward computation shows the following.

Proposition 3.2: $\tilde{d}$ does note depend upon the choice of coordinates.

Proof: The first two summations on the left-hand side of the equality in (1) obviously make an invariant statement under the change of coordinates. Now consider the last two summations. Let $y^k=y(z^i,e^j), f^l=f(z^i,e^j)$ be a new coordinate; we have

$$\frac{\partial}{\partial e^j}=\frac{\partial y^k}{\partial e^j}\frac{\partial}{\partial y^k}+\frac{\partial f^l}{\partial e^j}\frac{\partial}{\partial f^l},$$

$$\frac{\partial}{\partial z^i}=\frac{\partial y^k}{\partial z^i}\frac{\partial}{\partial y^k}+\frac{\partial f^l}{\partial z^i}\frac{\partial}{\partial f^l},$$

$$\frac{\partial}{\partial\dfrac{\partial}{\partial e^j}}=\frac{\partial e^j}{\partial y^k}\frac{\partial}{\partial\dfrac{\partial}{\partial y^k}}+\frac{\partial e^j}{\partial f^l}\frac{\partial}{\partial\dfrac{\partial}{\partial f^l}},$$

$$\frac{\partial}{\partial\dfrac{\partial}{\partial z^i}}=\frac{\partial z^i}{\partial y^k}\frac{\partial}{\partial\dfrac{\partial}{\partial y^k}}+\frac{\partial z^i}{\partial f^l}\frac{\partial}{\partial\dfrac{\partial}{\partial f^l}}.$$

By substitution we get

$$\sum a\otimes\left(\frac{\partial y^k}{\partial e^j}\frac{\partial}{\partial y^k}+\frac{\partial f^l}{\partial e^j}\frac{\partial}{\partial f^l}\right)L_{\Pi((\partial e^j/\partial y^t)[\partial/\partial(\partial/\partial y^t)]\,+\,(\partial e^j/\partial f^r)[\partial/\partial(\partial/\partial f^r)])}\varphi$$
$$+\sum a\otimes\left(\frac{\partial y^k}{\partial z^i}\frac{\partial}{\partial y^k}+\frac{\partial f^l}{\partial z^i}\frac{\partial}{\partial f^l}\right)L_{\Pi(\partial z^i/\partial y^t)[\partial/\partial(\partial/\partial y^t)]\,+\,(\partial z^i/\partial f^r)[\partial/\partial(\partial/\partial f^r)])}\varphi$$
$$=\sum a\otimes\left(\frac{\partial}{\partial y^k}L_{\Pi[\partial/\partial(\partial/\partial y^k)]}\varphi+\frac{\partial}{\partial f^l}L_{\Pi[\partial/\partial(\partial/\partial f^l)]}\varphi\right).$$

Thus the last two summations are also invariant under a change of coordinates.

Theorem 3.3: $(\mathcal{P}\otimes\mathcal{E}_M,\tilde{d})$ is a complex of differential graded algebra.

Proof: It is sufficient to prove $\tilde{d}^2=0$. It can be checked by direct computation. Let us use L_i, L_j instead of $L_{\Pi[\partial/\partial(\partial/\partial z^i)]}$ and $L_{\Pi[\partial/\partial(\partial/\partial e^j)]}$ respectively, then

$$\tilde{d}(a\otimes\varphi)=dz^i\left(\frac{\partial}{\partial z^i}a\right)\otimes\varphi+de^j\left(\frac{\partial}{\partial e^j}a\right)\otimes\varphi+(-1)^{\tilde{a}}a\otimes\frac{\partial}{\partial e^j}L_j\varphi+(-1)^{\tilde{a}}a\otimes\frac{\partial}{\partial z^i}L_i\varphi,$$

$$\begin{aligned}\tilde{d}(\tilde{d}(a\otimes\varphi)) &= dz^k\,dz^i\left(\frac{\partial}{\partial z^k}\frac{\partial}{\partial z^i}\right)a\otimes\varphi - de^l\,dz^j\left(\frac{\partial}{\partial e^l}\frac{\partial}{\partial z^j}a\right)\otimes\varphi + (-1)^{\tilde{a}}\,dz^i\left(\frac{\partial}{\partial z^i}a\right)\otimes\frac{\partial}{\partial e^l}L_l\varphi \\ &+ (-1)^{\tilde{a}+1}\,dz^i\left(\frac{\partial}{\partial z^i}a\right)\otimes\frac{\partial}{\partial z^k}L_k\varphi + dz^k\,de^j\left(\frac{\partial}{\partial z^k}\frac{\partial}{\partial e^j}a\right)\otimes\varphi + de^l\,de^j\left(\frac{\partial}{\partial e^l}\frac{\partial}{\partial e^j}a\right) \\ &\otimes\varphi + (-1)^{\tilde{a}-1}\,de^j\left(\frac{\partial}{\partial e^j}a\right)\otimes\frac{\partial}{\partial e^l}L_l\varphi + (-1)^{\tilde{a}-1}\,de^j\left(\frac{\partial}{\partial e^j}a\right)\otimes\frac{\partial}{\partial z^k}L_k\varphi \\ &+ (-1)^{\tilde{a}}\Big[dz^k\frac{\partial}{\partial z^k}a\otimes\frac{\partial}{\partial e^j}L_j\varphi + de^l\frac{\partial}{\partial e^l}a\otimes\frac{\partial}{\partial e^j}L_j\varphi + (-1)^{\tilde{a}+1}a\otimes\frac{\partial}{\partial e^l}\frac{\partial}{\partial e^j}\underline{L_l}\,\underline{L_j}\varphi \\ &+ (-1)^{\tilde{a}+1}a\otimes\frac{\partial}{\partial z^k}\frac{\partial}{\partial e^j}L_kL_j\varphi\Big] + (-1)^{\tilde{a}}\Big[dz^k\frac{\partial}{\partial z^k}a\otimes\frac{\partial}{\partial z^i}L_i\varphi + de^l\frac{\partial}{\partial e^l}a\otimes\frac{\partial}{\partial z^i}L_i\varphi \\ &+ (-1)^{\tilde{a}}a\otimes\frac{\partial}{\partial e^l}\frac{\partial}{\partial z^i}L_lL_i\varphi + (-1)^{\tilde{a}}a\otimes\frac{\partial}{\partial z^k}\frac{\partial}{\partial z^i}\underline{L_k}\,\underline{L_i}\varphi\Big].\end{aligned}$$

Since $\partial/\partial e^l$'s are odd and $L_lL_j - L_jL_l = 0$ thus the first underlined term is zero. Equality $L_kL_i = -L_iL_k$ implies that the second underlined term is zero too. Other terms are cancelled by their inverses.

To establish a correspondence with cyclic cohomology classes, we need $\varphi = \tilde{d}f_1\wedge\cdots\wedge\tilde{d}f_{m+n}$ to be an integral form for every $f_i\in\mathcal{A}$ (Ref. 4, p. 186). So φ must contain a section of Berezinian of M (Ref. 7, p. 213). Obviously, $\tilde{d}$ satisfies this condition. As far as we know, it is not true for other presented complexes on supermanifolds.

IV. COHOMOLOGY

A $\mathbf{Z}^2$-graded cohomology groups corresponding to complex of extended pesudodifferential forms can be defined as follows:

$$H_{\tilde{d}}^{(p,q)}(\mathcal{M},\mathcal{A}) = \frac{\operatorname{Ker}\tilde{d}|_{\Omega^{p,q}\otimes\mathcal{E}_M}}{\operatorname{Im} g\tilde{d}|_{(\Omega^{p-1,q}\oplus\Omega^{p,q-1})\otimes\mathcal{E}_M}}.$$

Now we show that these groups are sensitive to the ''super'' structure. For this, it is sufficient to compute them for a purely odd supermanifold $\mathbf{R}^{(0,1)}$.

Proposition 4.1:

$$H_{\tilde{d}}^{(1,1)}(\mathbf{R}^{(0,1)}) = \mathbf{R}^2.$$

Proof: On $\mathcal{E}_{\mathbf{R}^{(0,1)}}$ there are two endomorphism with nonvanishing differentials. Call them $E_1 = ed(\partial/\partial e)\otimes\partial/\partial e$, $E_2 = ed(\partial/\partial e)\otimes\partial/\partial(\partial/\partial e)$. We have $\tilde{d}(1\otimes E_1) = 2de\otimes\partial/\partial e$ and $\tilde{d}(1\otimes E_2) = 2de\otimes\partial/\partial(\partial/\partial e)$. Thus $H_{\tilde{d}}^{(1,1)}(\mathbf{R}^{(0,1)})$ as an $\mathbf{R}$-vector space is generated by the classes of two 1–1 forms $de\otimes(\partial/\partial e)E_1$ and $de\otimes(\partial/\partial e)E_2$.

We describe all the localization observables of a quantum particle in a one-dimensional box in terms of sequences of unit vectors in a Hilbert space. An alternative representation in terms of positive semidefinite complex matrices is furnished and the commutative localizations are singled out. As a consequence, we also get a vector sequence characterization of the covariant phase observables. [DOI: 10.1063/1.1425958]

I. INTRODUCTION

We investigate the problem of the localization of a free quantum particle moving in a one-dimensional box with periodic boundary conditions, adopting the point of view that observables are represented as appropriate normalized positive operator measures. (For that approach, see, e.g., Refs. 1–4.) Therefore, if one chooses the one-dimensional torus $\mathbb{T}$ as the configuration space of the system, then a localization observable E is a map that defines for any (Borel) subset $X \subset \mathbb{T}$ a bounded operator $E(X)$ such that, if ψ is the (vector) state of the system, the number $\langle \psi | E(X)\psi \rangle$ is the probability that a localization measurement of the particle in that state leads to a result in X. For example, the group of motions of the system is the torus itself that acts on the vector states by means of the *geometric* representation. The basic requirement for E to represent a localization observable is, therefore, that E is covariant with respect to this action. Hence a localization observable is a normalized positive operator measure covariant under the geometric action of the torus $\mathbb{T}$.

In the following we call such observables $\mathbb{T}$-covariant localization observables and we show that they are characterized in terms of sequences of unit vectors in an infinite dimensional Hilbert space. In this framework we select the measures that are projection valued or commutative, and we discuss the problem of the equivalence of such operator measures. As a by-product, we also get a representation of the phase observables, that is, the normalized positive operator measures which are covariant under the shifts generated by the number observable. Our proof is based on a direct application of a theorem due to Cattaneo,[5] which generalizes Mackey's imprimitivity theorem for positive operator measures. Instead, one could use the results of Holevo,[6,7] based also on group theoretical arguments, to obtain a classification in terms of measurable fields of sesquilinear forms, which in the present context can be described as infinite-dimensional positive semidefinite complex matrices with diagonal elements equal to one. For the sake of comparison, we also derive the

matrix characterization by direct methods, using only basic analysis and measure theory. This approach has been used in Ref. 8 to work out all the phase observables in terms of *phase matrices*.

II. $\mathbb{T}$-COVARIANT LOCALIZATION OBSERVABLES

Let $\mathbb{T}=\{z\in\mathbb{C}:|z|=1\}$ denote the one-dimensional torus, regarded as a compact (second countable) Abelian group. Let $\mathcal{B}(\mathbb{T})$ be the Borel σ-algebra of $\mathbb{T}$, μ the Haar measure on $\mathbb{T}$, $L_2(\mathbb{T},\mu)$ the Hilbert space of square integrable Borel functions $f:\mathbb{T}\to\mathbb{C}$, and $\mathcal{L}(L_2(\mathbb{T},\mu))$ the set of bounded operators on $L_2(\mathbb{T},\mu)$.

The group $\mathbb{T}$ acts on $L_2(\mathbb{T},\mu)$ via the geometric action

$$[U(a)f](z)=f(az),\quad a\in\mathbb{T},\ \ f\in L_2(\mathbb{T},\mu),\ \ z\in\mathbb{T},$$

which is unitary and continuous with respect to the strong operator topology.

A $\mathbb{T}$-covariant localization observable is a positive normalized operator measure on $\mathbb{T}$, $E:\mathcal{B}(\mathbb{T})\to\mathcal{L}(L_2(\mathbb{T},\mu))$, such that, for all $X\in\mathcal{B}(\mathbb{T})$, $a\in\mathbb{T}$,

$$U(a)E(X)U(a)^*=E(aX). \tag{1}$$

Since the action of $\mathbb{T}$ on itself is transitive, Eq. (1) means that (U,E) is a transitive system of $\mathbb{T}$-covariance based on $\mathbb{T}$ and, hence, (U,E) is described by Ref. 5, Proposition 2.

In order to apply the cited result, let us notice the following facts. The stability subgroup of any point of $\mathbb{T}$ is the trivial subgroup $\{1\}$. The trivial representation σ of $\{1\}$ acting on $L_2(\mathbb{T},\mu)$ contains all the (trivial) representations of $\{1\}$ and the corresponding imprimitivity system (R,P) for $\mathbb{T}$ based on $\mathbb{T}$ induced by σ acts on $L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)\simeq L^2(\mathbb{T},\mu,L_2(\mathbb{T},\mu))$ as

$$(R(a)\varphi)(z_1,z_2)=\varphi(az_1,z_2),$$

$$(P(X)\varphi)(z_1,z_2)=\chi_X(z_1)\varphi(z_1,z_2),$$

where $\varphi\in L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$, $a\in\mathbb{T}$, $X\in\mathcal{B}(\mathbb{T})$, and z_1, $z_2\in\mathbb{T}$.

Proposition 2 of Ref. 5 shows that, given a $\mathbb{T}$-covariant localization observable E, there exists an isometry

$$V:L_2(\mathbb{T},\mu)\to L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu),$$

which intertwines the action U with R and such that

$$E(X)=V^*P(X)V,\quad X\in\mathcal{B}(\mathbb{T}). \tag{2}$$

Conversely, given an intertwining isometry V from $L_2(\mathbb{T},\mu)$ to $L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$, Eq. (2) defines a positive normalized operator measure E satisfying Eq. (1).

Hence, to classify all the $\mathbb{T}$-covariant localization observables, one has to determine all the isometric mappings V such that

$$VU(a)=R(a)V,\quad a\in\mathbb{T}. \tag{3}$$

To perform this task, observe that the monomials e_n, $n\in\mathbb{Z}$, $e_n(z)=z^n$, $z\in\mathbb{T}$, form an orthonormal basis of $L_2(\mathbb{T},\mu)$ and the action of U on them is diagonal, that is,

$$U(a)e_n=a^ne_n.$$

Moreover, the vectors

$$(e_ne_j)(z_1,z_2)=e_n(z_1)e_j(z_2)=z_1^nz_2^j,$$

where n, $j \in \mathbb{Z}$, form an orthonormal basis of $L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$, and the action of R on them is simply

$$R(a)e_n e_j = a^n e_n e_j .$$

It follows that, for any $n \in \mathbb{Z}$, the subspace of $L_2(\mathbb{T},\mu)$ generated by e_n and the subspace of $L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$ generated by $\{e_n e_j\}_{j\in\mathbb{Z}}$ carry the representation of $\mathbb{T}$, $z \mapsto z^n$.

Hence, if $V: L_2(\mathbb{T},\mu) \to L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$ is an isometry intertwining U and R, for any $n \in \mathbb{Z}$, Ve_n must be in the vector space $\mathrm{span}\{(e_n e_j)\}_{j\in\mathbb{Z}} \simeq L_2(\mathbb{T},\mu)$, that is, $Ve_n = e_n h_n$ for some unit vector h_n in $L_2(\mathbb{T},\mu)$.

Conversely, if $(h_n)_{n\in\mathbb{Z}}$ is a sequence of unit vectors in $L_2(\mathbb{T},\mu)$, then the mapping $e_n \mapsto e_n h_n$ extends to a unique linear isometry $V: L_2(\mathbb{T},\mu) \to L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$ which intertwines the actions U and R and, by means of Eq. (2), the corresponding operator measure E is explicitly given by

$$\begin{aligned}\langle e_n | E(X) e_m\rangle &= \langle e_n | V^* P(X) V e_m\rangle \\ &= \langle Ve_n | P(X) V e_m\rangle \\ &= \langle e_n h_n | P(X) e_m h_m\rangle = \langle h_n | h_m\rangle \int_X z^{m-n} \mathrm{d}\mu(z),\end{aligned}$$

where n, $m \in \mathbb{Z}$. Then, if $|e_n\rangle\langle e_m|$ denotes the rank one operator $L_2(\mathbb{T},\mu) \ni f \mapsto \langle e_m | f\rangle e_n \in L_2(\mathbb{T},\mu)$, we may thus write, for all $X \in \mathcal{B}(\mathbb{T})$,

$$E(X) = \sum_{n,m\in\mathbb{Z}} \langle h_n | h_m\rangle \int_X z^{m-n}\, \mathrm{d}\mu(z) |e_n\rangle\langle e_m|, \tag{4}$$

where the double series converges in the weak operator topology. We observe that two sequences of unit vectors $(h_n)_{n\in\mathbb{Z}}$ and $(k_n)_{n\in\mathbb{Z}}$ define the same $\mathbb{T}$-covariant localization observable if and only if $\langle h_n | h_m\rangle = \langle k_n | k_m\rangle$ for all n, $m \in \mathbb{Z}$.

For the sake of completeness we also compute the adjoint map $V^*: L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu) \to L_2(\mathbb{T},\mu)$. We get

$$\begin{aligned}\langle V^* e_n e_j | e_p\rangle &= \langle e_n e_j | V e_p\rangle \\ &= \langle e_n e_j | e_p h_p\rangle = \begin{cases} 0, & \text{when } n \neq p, \\ \langle e_j | h_n\rangle, & \text{when } n = p, \end{cases}\end{aligned} \tag{5}$$

showing that for any n, $j \in \mathbb{Z}$,

$$V^* e_n e_j = \langle h_n | e_j\rangle e_n . \tag{6}$$

We now discuss the problem of the equivalence. Two $\mathbb{T}$-covariant localization observables E and E' are equivalent if there is a unitary operator $W: L_2(\mathbb{T},\mu) \to L_2(\mathbb{T},\mu)$ such that, for all $a \in \mathbb{T}$, $X \in \mathcal{B}(\mathbb{T})$,

$$WU(a) = U(a)W, \quad WE(X) = E'(X)W.$$

Clearly, this definition is the requirement that (U,E) and (U,E') are equivalent as $\mathbb{T}$-covariant systems.

The first condition implies now that for each $n \in \mathbb{Z}$, $We_n = z_n e_n$, for some $z_n \in \mathbb{T}$. Therefore, the equivalence of (U,E) and (U,E') equals the fact that for each n, $m \in \mathbb{Z}$ and $X \in \mathcal{B}(\mathbb{T})$,

$$\langle e_n | E'(X) e_m\rangle = z_n \overline{z_m} \langle e_n | E(X) e_m\rangle,$$

for some z_n, $z_m \in \mathbb{T}$. Then, taking into account Eq. (4), two sequences of unit vectors $(h'_n)_{n\in\mathbb{Z}}$ and $(h_n)_{n\in\mathbb{Z}}$ define equivalent $\mathbb{T}$-covariant localization observables if and only if for each n, $m \in \mathbb{Z}$,

$$\langle h'_n | h'_m \rangle = \langle z_n h_n | z_m h_m \rangle.$$

Finally, we consider the problem of projection-valued measures. Let $\mathcal{K}$ be the closed subspace of $L_2(\mathbb{T}\times\mathbb{T}, \mu\times\mu)$ generated by $\{P(X)e_n h_n : X \in \mathcal{B}(\mathbb{T}), n \in \mathbb{Z}\}$. The space $\mathcal{K}$ is stable under the action of the imprimitivity system (R,P). Since the projection measure P acts only on the vector e_n and $\{\chi_X e_n : X \in \mathcal{B}(\mathbb{T})\}$ generates $L_2(\mathbb{T}, \mu)$, one has

$$\mathcal{K} \simeq L_2(\mathbb{T}, \mu) \otimes L,$$

where L is the closed subspace generated by the vectors h_n, $n \in \mathbb{Z}$. According to Ref. 5, Proposition 1, E is projection valued if and only if $V(L_2(\mathbb{T}, \mu)) = \mathcal{K}$, that is, L is one-dimensional.

We summarize the above construction in the form of a theorem.

Theorem 1: *Any $\mathbb{T}$-covariant localization observable $E: \mathcal{B}(\mathbb{T}) \to L_2(\mathbb{T}, \mu)$ is of the form*

$$E(X) = \sum_{n,m\in\mathbb{Z}} \langle h_n | h_m \rangle \int_X z^{m-n} \, d\mu(z) |e_n\rangle\langle e_m|, \quad X \in \mathcal{B}(\mathbb{T}),$$

for some sequence of unit vectors $(h_n)_{n\in\mathbb{Z}}$ in $L_2(\mathbb{T}, \mu)$. Two sequences of unit vectors $(h_n)_{n\in\mathbb{Z}}$ and $(k_n)_{n\in\mathbb{Z}}$ in $L_2(\mathbb{T}, \mu)$ determine the same $\mathbb{T}$-covariant localization observable if and only if $\langle h_n | h_m \rangle = \langle k_n | k_m \rangle$ for all n, $m \in \mathbb{Z}$.

Two such operator measures E and E' are equivalent if and only if

$$\langle h'_n | h'_m \rangle = \langle z_n h_n | z_m h_m \rangle,$$

for some sequence $(z_n)_{n\in\mathbb{Z}}$ in $\mathbb{T}$.

The operator measure E is projection valued exactly when the vectors h_n, $n \in \mathbb{Z}$, are of the form $h_n = z_n h$ for some unit vector h and phase factors $z_n \in \mathbb{T}$.

A. Commutative localizations

By means of the above theorem, we are now in position to characterize the commutative $\mathbb{T}$-covariant localization observables. We recall that such an observable E is commutative if $E(X)E(Y) = E(Y)E(X)$, for all X, $Y \in \mathcal{B}(\mathbb{T})$, that is, if E is a commutative operator measure.

Let $(h_n)_{n\in\mathbb{Z}}$ be a sequence of unit vectors in $L_2(\mathbb{T}, \mu)$, E the corresponding operator measure given by Theorem 1, and define, for all n, $m \in \mathbb{Z}$, $c_{n,m} = \langle h_n | h_m \rangle$.

Proposition 1: The $\mathbb{T}$-covariant localization observable E is commutative if and only if

$$c_{n,n+k} c_{n+k,m} = c_{n,m-k} c_{m-k,m} \tag{7}$$

for all, n, m, $k \in \mathbb{Z}$.

Proof: Define $\mu_{n,m,Y}(X) := \langle n | [E(X)E(Y) - E(Y)E(X)] | m \rangle$ for all n, $m \in \mathbb{Z}$ and X, $Y \in \mathcal{B}(\mathbb{T})$. Let $k \in \mathbb{Z}$, and calculate

$$\int_{\mathbb{T}} z^k \, d\mu_{n,m,Y}(z) = [c_{n,n+k} c_{n+k,m} - c_{n,m-k} c_{m-k,m}] \int_Y z^{n+k-m} \, d\mu(z).$$

If $E(X)E(Y) = E(Y)E(X)$ for all X, $Y \in \mathcal{B}(\mathbb{T})$, then $\mu_{n,m,Y}(X) = 0$ and, thus, $c_{n,n+k} c_{n+k,m} = c_{n,m-k} c_{m-k,m}$ for all n, m, $k \in \mathbb{Z}$.

Conversely, if $c_{n,n+k} c_{n+k,m} = c_{n,m-k} c_{m-k,m}$, n, m, $k \in \mathbb{Z}$, holds, then

$$\mu_{n,m,Y}(X) = \sum_{k=-\infty}^{\infty} (c_{n,n+k} c_{n+k,m} - c_{n,m-k} c_{m-k,m}) \int_X z^{-k} \, d\mu(z) \int_Y z^{k+n-m} \, d\mu(z) = 0$$

for all $n, m \in \mathbb{Z}$ and $X, Y \in \mathcal{B}(\mathbb{T})$. Therefore, $E(X)E(Y)=E(Y)E(X)$ for all $X, Y \in \mathcal{B}(\mathbb{T})$. □

An example of a commutative $\mathbb{T}$-covariant localization observable is the following one. Let $\xi \in [-1,1]$ and $\phi, \psi \in L_2(\mathbb{T},\mu)$ be two-unit vectors such that

$$\langle \psi | \phi \rangle = \xi.$$

Consider the sequence of unit vectors $(h_n)_{n\in\mathbb{Z}}$, with

$$h_n = \psi, \quad \text{for even } n \text{ (including 0)},$$

$$h_n = \phi, \quad \text{for odd } n.$$

The coefficients $c_{n,m}=\langle h_n|h_m\rangle$, $n, m \in \mathbb{Z}$, satisfy condition (7) so that the corresponding $\mathbb{T}$-covariant localization observable E^ξ is commutative. Notice that E^ξ is projection valued if and only if $\xi = \pm 1$.

B. Matrix characterization

To end this section, we discuss an alternative characterization of the $\mathbb{T}$-covariant localization observables. If follows from Theorem 1 that the operator measure E is uniquely defined in terms of the complex matrix elements $c_{n,m}=\langle h_n|h_m\rangle$, $n, m \in \mathbb{Z}$. It is clear that they satisfy the following two conditions:

(a) $c_{n,n}=1$, for all $n \in \mathbb{Z}$,
(b) $\Sigma_{n,m=-k}^{k} c_{n,m}|e_n\rangle\langle e_m| \geqslant O$, for all $k \in \mathbb{N}$.

Conversely, it is known, (see, for example, Ref. 9, Chap. 3), that given a family of complex numbers $\{c_{n,m} \in \mathbb{C} | n,m \in \mathbb{Z}\}$ which has the properties (a) and (b), there exists a sequence of unit vectors $(h_n)_{n\in\mathbb{Z}}$ such that $c_{n,m}=\langle h_n|h_m\rangle$ and, hence, a $\mathbb{T}$-covariant localization observable E defined by

$$E(X) = \sum_{n,m\in\mathbb{Z}} c_{n,m} \int_X z^{m-n}\, \mathrm{d}\mu(z) |e_n\rangle\langle e_m|,$$

for all $X \in \mathcal{B}(\mathbb{T})$.

For completeness, we give a simple construction of a sequence of unit vectors which generates the matrix. The construction is slightly more general than actually needed here.

Let $J \subseteq \mathbb{Z}$ (especially $J=\mathbb{Z}$ or $J=\mathbb{N}$). A matrix $(b_{n,m})_{n,m\in J}$ is *positive semidefinite* if for all sequences $(d_n)_{n\in J} \subset \mathbb{C}$, for which $d_n \neq 0$ for only finitely many $n \in J$,

$$\sum_{n,m\in J} \overline{d_n} b_{n,m} d_m \geqslant 0.$$

For $J=\mathbb{Z}$ this is equivalent to the above condition (b). [Condition (a) is equivalent to the fact that $\|h_n\|=1$ for all $n \in \mathbb{Z}$.]

Proposition 2: Fix $J \subseteq \mathbb{Z}$. Let $l_2(J)$ be a sequence space with the basis $(\chi_{\{n\}})_{n\in J}$. A matrix $(b_{n,m})_{n,m\in J}$ is positive semidefinite if and only if there is a sequence $(h_n)_{n\in J}$ of vectors of $l_2(J)$ such that $b_{n,m}=\langle h_n|h_m\rangle$ for all $n, m \in J$.

Proof: Consider a sequence $(h_n)_{n\in J}$ of vectors of $l_2(J)$ and put $b_{n,m}=\langle h_n|h_m\rangle$. If $(d_n)_{n\in J} \subset \mathbb{C}$ is a sequence for which $d_n \neq 0$ for only finitely many $n \in J$, then

$$\sum_{n,m\in J} \overline{d_n} b_{n,m} d_m = \left\langle \left(\sum_{n\in J} d_n h_n \right) \middle| \left(\sum_{m\in J} d_m h_m \right) \right\rangle \geqslant O,$$

the sums being finite.

Suppose then that $(b_{n,m})_{n,m\in J}$ is positive semidefinite. It follows that $b_{n,n}\geqslant 0$, $b_{n,m}=\overline{b_{m,n}}$, and

$$\begin{vmatrix} b_{n,n} & b_{n,m} \\ b_{m,n} & b_{m,m} \end{vmatrix} = b_{n,n}b_{m,m} - |b_{n,m}|^2 \geqslant 0 \tag{8}$$

for all $n<m$. Especially, if $b_{n,n}b_{m,m}=0$, then $b_{n,m}=0$. Then the doubles series

$$\sum_{\substack{n,m\in J \\ b_{n,n}\neq 0\neq b_{m,m}}} \frac{b_{n,m}}{\sqrt{b_{n,n}b_{m,m}}(|n|+1)(|m|+1)} |\chi_{\{n\}}\rangle\langle\chi_{\{m\}}|$$

converges in the weak operator topology to a bounded and positive operator S. Let A be its square root and, for all $n\in J$,

$$h_n := \sqrt{b_{n,n}}(|n|+1)A\chi_{\{n\}}.$$

Then, taking into account that $S=A^2$, one gets, for all n, $m\in J$ such that $b_{n,n}b_{m,m}\neq 0$,

$$\langle h_n|h_m\rangle = \sqrt{b_{n,n}}(|n|+1)\sqrt{b_{m,m}}(|m|+1)\langle\chi_{\{n\}}|A^2\chi_{\{m\}}\rangle = b_{n,m}.$$

If $b_{n,n}b_{m,m}=0$, for example, $b_{n,n}=0$, then $h_n=0$ and, for all $m\in J$, $b_{n,m}=0=\langle h_n|h_m\rangle$. □

The above proposition, when applied together with the natural isomorphism $l_2(\mathbb{Z}) \ni \chi_{\{n\}}\mapsto e_n\in L_2(\mathbb{T},\mu)$, gives then a vector sequence representation of the matrix $(c_{n,m})_{n,m\in\mathbb{Z}}$ of a $\mathbb{T}$-covariant localization observable E. In Sec. IV we prove by direct methods a characterization of $\mathbb{T}$-covariant localization observables in terms of the matrix $(c_{n,m})_{n,m\in\mathbb{Z}}$. The same result can also be obtained from a theorem of Holevo (Ref. 7, Theorem 1), whose proof is also based on group theoretical arguments.

III. COVARIANT PHASE OBSERVABLES

Theorem 1 leads also to a characterization of the covariant phase observables. To describe them, let $\mathcal{H}$ be a complex separable Hilbert space, and let $(|n\rangle)_{n\in\mathbb{N}}$ be an orthonormal basis of $\mathcal{H}$. We call it the number basis. We define the number operator

$$N := \sum_{n\in\mathbb{N}} n|n\rangle\langle n|$$

with the domain $\mathcal{D}(N) := \{\psi\in\mathcal{H}: \Sigma_{n\in\mathbb{N}} n^2|\langle n|\psi\rangle|^2<\infty\}$, and the unitary "phase shifter" as

$$U^N(a) := \sum_{n\in\mathbb{N}} a^n|n\rangle\langle n|,$$

for all $a\in\mathbb{T}$. We say that a positive normalized operator measure $\tilde{E}:\mathcal{B}(\mathbb{T})\to\mathcal{L}(\mathcal{H})$ is a *phase observable* if it is covariant under the phase shifts, that is, if for any $X\in\mathcal{B}(\mathbb{T})$, $a\in\mathbb{T}$,

$$U^N(a)\tilde{E}(X)U^N(a)^* = \tilde{E}(aX). \tag{9}$$

To determine all the phase observables, let $T:\mathcal{H}\to L_2(\mathbb{T},\mu)$ be the linear isometry with the property

$$T|n\rangle = e_n, \quad \text{for all } n\in\mathbb{N}.$$

Clearly, T intertwines the unitary actions U^N and U, $TU^N=UT$, and $X\mapsto T\tilde{E}(X)T^*$ is a $\mathbb{T}$-covariant localization observable acting in $L_2(\mathbb{T},\mu)$. Using Theorem 1, and the fact that $T^*T=I$, one has the following result.

Corollary 1: A normalized positive operator measure $\tilde{E}:\mathcal{B}(\mathbb{T})\to\mathcal{L}(\mathcal{H})$ is a phase observable if and only if it is of the form

$$\tilde{E}(X)=T^*E(X)T,\quad X\in\mathcal{B}(\mathbb{T}),$$

for some $\mathbb{T}$-covariant localization observable E.

Equivalently, $\tilde{E}:\mathcal{B}(\mathbb{T})\to\mathcal{L}(\mathcal{H})$ is a phase observable if and only if

$$\tilde{E}(X)=\sum_{n,m\in\mathbb{N}}\langle\xi_n|\xi_m\rangle\int_X z^{m-n}\,\mathrm{d}\mu(z)|n\rangle\langle m|,\quad X\in\mathcal{B}(\mathbb{T}),$$

for some sequence of unit vectors $(\xi_n)_{n\in\mathbb{N}}$ of $\mathcal{H}$. Two sequences of unit vectors $(\xi_n)_{n\in\mathbb{N}}$ and $(\eta_n)_{n\in\mathbb{N}}$ define the same phase observable exactly when $\langle\xi_n|\xi_m\rangle=\langle\eta_n|\eta_m\rangle$ for all n, $m\in\mathbb{N}$.

Two phase observables $\tilde{E}$ and $\tilde{E}'$ are equivalent (in the sense of covariance systems) if and only if any of their generating vector sequences (ξ_n) and (ξ_n') are such that, for each n, $m\in\mathbb{N}$, $\langle\xi_n'|\xi_m'\rangle=\langle z_n\xi_n|z_m\xi_m\rangle$ for some z_n, $z_m\in\mathbb{T}$.

Since $T:\mathcal{H}\to L_2(\mathbb{T},\mu)$ is not surjective, there is no projection-valued phase observable.

We note, in addition, that Proposition 1, when applied to phase observables, gives Eq. (7) for all n, m, $k\in\mathbb{N}$ with $m\geqslant k$. For $n=m$ this gives $|c_{n,n+k}|=|c_{n-k,n}|$ for all $n\geqslant k$, which implies that $c_{n,m}=0$ for all $n\neq m$ (for details, see Ref. 11). This means that the only commutative phase observable is the trivial one

$$\mathcal{B}(\mathbb{T})\ni X\mapsto\mu(X)I\in\mathcal{L}(\mathcal{H}).$$

Following Ref. 8 we say that a positive semidefinite complex matrix $(c_{n,m})_{n,m\in\mathbb{N}}$ is a *phase matrix* if $c_{n,n}=1$ for all $n\in\mathbb{N}$. According to Ref. 8, Phase Theorem 2.2, any phase observable $\tilde{E}:\mathcal{B}(\mathbb{T})\to\mathcal{L}(\mathcal{H})$ is of the form

$$\tilde{E}(X)=\sum_{n,m\in\mathbb{N}}c_{n,m}\int_X z^{m-n}\,\mathrm{d}\mu(z)|n\rangle\langle m|$$

for a unique phase matrix $(c_{n,m})$, and any phase matrix determines a phase observable in this way. The equivalence of the two characterizations of the phase observables is again a consequence of Proposition 2.

IV. COVARIANT LOCALIZATIONS IN A BOX: A DIRECT METHOD

We determine next the covariant localizations by direct methods, using only basic analysis and measure theory. Actually, we determine all the normalized (not necessarily positive nor self-adjoint) operator measures which are translation covariant on the interval $[0,2\pi)$. In the rest of this article, we use the interval $[0,2\pi)$ instead of $\mathbb{T}$ when it simplifies the calculations. Note that the Haar measure μ is the normalized Lebesgue measure on $\mathcal{B}([0,2\pi))$, the Borel σ-algebra of $[0,2\pi)$ transferred by the map $\theta\mapsto e^{i\theta}$.

Let, again, $\mathcal{H}$ be a complex separable Hilbert space, but choose now an orthonormal basis $(|n\rangle)_{n\in\mathbb{Z}}\subset\mathcal{H}$ labeled by the integers. Define the "extended number operator" as follows: $\hat{N}:=\Sigma_{n\in\mathbb{Z}}n|n\rangle\langle n|$ with its domain $\mathcal{D}(\hat{N}):=\{\psi\in\mathcal{H}:\Sigma_{n\in\mathbb{Z}}n^2|\langle n|\psi\rangle|^2<\infty\}$, and define the corresponding unitary shift operators as

$$R(\theta):=e^{i\theta\hat{N}}=\sum_{n\in\mathbb{Z}}e^{in\theta}|n\rangle\langle n|$$

for all $\theta\in\mathbb{R}$.

We say that $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ is an operator measure if it is σ-additive with respect to the weak operator topology. If $E(X)^*=E(X)$, or $E(X)\geqslant O$, for all $X\in\mathcal{B}([0,2\pi))$, we say that E is self-adjoint, or positive. If $E([0,2\pi))=I$, we say that the operator measure E is normalized. Finally, E is covariant if $R(\theta)E(X)R(\theta)^*=E(X\oplus\theta)$ for all $X\in\mathcal{B}([0,2\pi))$ and $\theta\in\mathbb{R}$, where the symbol $\oplus$ means addition modulo 2π.

Before characterizing covariant normalized operator measures we prove the following lemma:

Lemma 1: Fix $q\in\mathbb{Z}$, and let $\nu_q:\mathcal{B}([0,2\pi))\to\mathbb{C}$ be a σ-additive set function such that $\nu_q(X\oplus\theta)=e^{iq\theta}\nu_q(X)$ for all $X\in\mathcal{B}([0,2\pi))$ and $\theta\in[0,2\pi)$, and for which $\nu_q([0,2\pi))=\delta_{0,q}$. Then $\nu_q(X)=c_q(2\pi)^{-1}\int_X e^{iq\theta}\,\mathrm{d}\theta$ for all $X\in\mathcal{B}([0,2\pi))$, where $c_q\in\mathbb{C}$ and $c_0=1$.

Proof: Fix $q\in\mathbb{Z}$, and let $k\in\mathbb{Z}^+$. Now

$$\begin{aligned}\delta_{0,q}=\nu_q([0,2\pi))&=\nu_q\left(\bigcup_{l=0}^{k-1}[l2\pi k^{-1},(l+1)2\pi k^{-1})\right)\\&=\sum_{l=0}^{k-1}\nu_q([0,2\pi k^{-1})+l2\pi k^{-1})\\&=\left[\sum_{l=0}^{k-1}e^{i2\pi qk^{-1}l}\right]\nu_q[0,2\pi k^{-1})=\begin{cases}k\nu_q[0,2\pi k^{-1}), & \text{when } qk^{-1}\in\mathbb{Z},\\0, & \text{when } qk^{-1}\notin\mathbb{Z}.\end{cases}\end{aligned}\tag{10}$$

Suppose that $q\in\mathbb{Z}$ and $k\in\mathbb{Z}^+$ are such that $qk^{-1}\notin\mathbb{Z}$. Then $\int_0^{2\pi k^{-1}}e^{iq\theta}\,\mathrm{d}\theta\neq0$, and we can define

$$c_q(k):=\frac{\nu_q([0,2\pi k^{-1}))}{(2\pi)^{-1}\int_0^{2\pi k^{-1}}e^{iq\theta}\,\mathrm{d}\theta},$$

so that

$$\nu_q([0,2\pi k^{-1}))=c_q(k)\frac{1}{2\pi}\int_0^{2\pi k^{-1}}e^{iq\theta}\,\mathrm{d}\theta=c_q(k)\frac{e^{iq2\pi k^{-1}}-1}{iq2\pi}.$$

On the other hand, for all $r\in\mathbb{Z}^+$, $q(rk)^{-1}\notin\mathbb{Z}$, and

$$\nu_q([0,2\pi k^{-1}))=\nu_q\left(\bigcup_{l=0}^{r-1}[l2\pi(rk)^{-1},(l+1)2\pi(rk)^{-1})\right)=\left[\sum_{l=0}^{r-1}e^{i2\pi q(rk)^{-1}l}\right]\nu_q([0,2\pi(rk)^{-1}))$$

$$=c_q(rk)\frac{e^{iq2\pi k^{-1}}-1}{iq2\pi}.$$

This shows that $c_q(k)=c_q(rk)$, $r\in\mathbb{Z}^+$. Since $q(|q|+1)^{-1}\notin\mathbb{Z}$, one has $c_q(k)=c_q((|q|+1)k)=c_q(|q|+1)$. Thus, for all $k\in\mathbb{Z}^+$, for which $qk^{-1}\notin\mathbb{Z}$, the number $c_q(k)$ is the same, and we may define $c_q:=c_q(|q|+1)$ for all $q\in\mathbb{Z}$ and $q\neq0$.

If $qk^{-1}\in\mathbb{Z}$, $q\in\mathbb{Z}$, $k\in\mathbb{Z}^+$, Eq. (10) gives

$$\nu_q([0,2\pi k^{-1}))=\frac{\delta_{0,q}}{k}=\frac{1}{2\pi}\int_0^{2\pi k^{-1}}e^{iq\theta}\,\mathrm{d}\theta.\tag{11}$$

Thus, if we define $c_0:=1$ we get

$$\nu_q([0,2\pi k^{-1}))=c_q\frac{1}{2\pi}\int_0^{2\pi k^{-1}}e^{iq\theta}\,\mathrm{d}\theta, \tag{12}$$

for all $k\in\mathbb{Z}^+$ and $q\in\mathbb{Z}$.

Let $q\in\mathbb{Z}$. Now one gets

$$\nu_q\left(\bigcup_{p=1}^{\infty}\{p^{-1}\}\right)=\nu_q(\{0\})\sum_{p=1}^{\infty}e^{iqp^{-1}},$$

which implies that $\nu_q(\{0\})=0$. Thus the measure ν_q is nonatomic, that is, $\nu_q(\{x\})=e^{ixq}\nu_q(\{0\})=0$, $x\in[0,2\pi)$, which implies that its distribution function $x\mapsto\nu_q([0,x))$ is continuous. From Eq. (12) it follows that for all $k\in\mathbb{Z}^+$, $p\in\{1,2,...,k\}$,

$$\nu_q([0,2\pi pk^{-1}))=\nu_q\left(\bigcup_{l=0}^{p-1}[l2\pi k^{-1},(l+1)2\pi k^{-1})\right)=c_q\,\frac{1}{2\pi}\int_0^{2\pi pk^{-1}}e^{iq\theta}\,\mathrm{d}\theta. \tag{13}$$

Since $x\mapsto\nu_q([0,x))$ is continuous, and the set $\{2\pi pk^{-1}\in[0,2\pi)|k\in\mathbb{Z}^+,p\in\{1,2,...,k\}\}$, is dense in $[0,2\pi)$, it follows that for all $x\in(0,2\pi]$

$$\nu_q([0,x))=c_q\,\frac{1}{2\pi}\int_0^{x}e^{iq\theta}\,\mathrm{d}\theta.$$

By the Hahn extension theorem

$$\nu_q(X)=c_q\,\frac{1}{2\pi}\int_X e^{iq\theta}\,\mathrm{d}\theta \tag{14}$$

for all $X\in\mathcal{B}([0,2\pi))$ and $q\in\mathbb{Z}$. □

Theorem 2: *Let $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ be a covariant normalized operator measure. For any $X\in\mathcal{B}([0,2\pi))$,*

$$E(X)=\sum_{n,m\in\mathbb{Z}}c_{n,m}\,\frac{1}{2\pi}\int_X e^{i(n-m)\theta}\,\mathrm{d}\theta|n\rangle\langle m|, \tag{15}$$

where $c_{n,m}\in\mathbb{C}$ and $c_{n,n}=1$ for all $n,m\in\mathbb{Z}$. If E is self-adjoint, then $\overline{c_{n,m}}=c_{m,n}$ for all $n,m\in\mathbb{Z}$, and if E is positive, then

$$\sum_{n,m=-k}^{k}c_{n,m}|n\rangle\langle m|\geqslant O, \tag{16}$$

for all $k\in\mathbb{N}$.

Proof: Denoting, in Lemma 1, $q=n-m$ and $\nu_q(X)=\langle n|E(X)|m\rangle$, Eq. (15) follows. If E is self-adjoint, then from (15) one gets

$$\overline{c_{n,m}}=2\pi\lim_{\epsilon\to0+}\frac{\overline{\langle n|E([0,\epsilon))|m\rangle}}{\epsilon}=c_{m,n}$$

for all n, $m\in\mathbb{Z}$.

Suppose that E is positive and, thus, self-adjoint. Hence, if (16) does not hold, one may choose a $\varphi\in\mathcal{H}$ and an $l\in\mathbb{N}$ such that $\Sigma_{n,m=-l}^{l}c_{n,m}\langle\varphi|n\rangle\langle m|\varphi\rangle<0$, and define a function

$$g:[0,2\pi)\to\mathbb{R},\quad \theta\mapsto g(\theta):=\sum_{n,m=-l}^{l} c_{n,m}e^{i(n-m)\theta}\langle\varphi|n\rangle\langle m|\varphi\rangle.$$

Due to the continuity of g one can choose an $\epsilon\in(0,2\pi)$ such that $\int_0^\epsilon g(\theta)\mathrm{d}\theta<0$. Thus, denoting $I_l:=\Sigma_{n=-l}^{l}|n\rangle\langle n|$,

$$\langle I_l\varphi|E([0,\epsilon))I_l\varphi\rangle=\frac{1}{2\pi}\int_0^\epsilon g(\theta)\,\mathrm{d}\theta<0,$$

which contradicts the positivity of E. □

For later use we note that the positive semi-definiteness condition (16) of the matrix $(c_{n,m})_{n,m\in\mathbb{Z}}$ can be written equivalently as the following determinant condition (see, e.g., Ref. 9, Chap. 3.1)

$$\begin{vmatrix} c_{k_1,k_1} & c_{k_1,k_2} & \cdots & c_{k_1,k_s} \\ c_{k_2,k_1} & c_{k_2,k_2} & \cdots & c_{k_2,k_s} \\ \vdots & \vdots & \ddots & \vdots \\ c_{k_s,k_1} & c_{k_s,k_2} & \cdots & c_{k_s,k_s} \end{vmatrix}\geqslant 0 \tag{17}$$

for all $s\in\mathbb{Z}^+$, $\{k_1,k_2,\ldots,k_s\}\subset\mathbb{Z}$, and $k_1<k_2<\cdots<k_s$. Note that in this case $c_{n,m}=\overline{c_{m,n}}$ and $|c_{n,m}|\leqslant 1$ for all n, $m\in\mathbb{Z}$.

Remark 1: One may ask if the converse statement of Theorem 2 is also true. Let $(c_{n,m})_{n,m\in\mathbb{Z}}$ be an infinite-dimensional complex matrix, and suppose that $c_{n,n}=1$ for all $n\in\mathbb{Z}$. Let $\mathcal{M}:=\mathrm{lin}\{|n\rangle|n\in\mathbb{Z}\}$, and define the following function for all φ, $\psi\in\mathcal{M}$:

$$\mathbb{R}\ni\theta\mapsto C_{\varphi,\psi}(\theta):=\sum_{n,m=-\infty}^{\infty} c_{n,m}e^{i(n-m)\theta}\langle\varphi|n\rangle\langle m|\psi\rangle\in\mathbb{C}.$$

For φ, $\psi\in\mathcal{M}$, define

$$E_{\varphi,\psi}([0,2\pi)):=\frac{1}{2\pi}\int_0^{2\pi} C_{\varphi,\psi}(\theta)\,\mathrm{d}\theta=\langle\varphi|\psi\rangle.$$

Clearly, $E_{\varphi,\psi}([0,2\pi))=\langle\varphi|\psi\rangle$, and $(\varphi,\psi)\mapsto E_{\varphi,\psi}([0,2\pi))$ is a bounded sesquilinear form defined on the dense subspace $\mathcal{M}$ of $\mathcal{H}$. Hence the mapping $(\varphi,\psi)\mapsto E_{\varphi,\psi}([0,2\pi))$ has a unique bounded extension to $\mathcal{H}$ which is $(\varphi,\psi)\mapsto\langle\varphi|\psi\rangle$. We let $E([0,2\pi))$ denote the unique bounded operator, which, actually, is the identity operator I.

Consider the following sesquilinear form defined for all $X\in\mathcal{B}([0,2\pi))$:

$$\mathcal{M}\times\mathcal{M}\ni(\varphi,\psi)\mapsto E_{\varphi,\psi}(X):=\frac{1}{2\pi}\int_X C_{\varphi,\psi}(\theta)\,\mathrm{d}\theta\in\mathbb{C}.$$

This form need not be bounded, so that it does not necessarily define a bounded operator on $\mathcal{H}$. Thus, the formal notation

$$E(X)=\sum_{n,m\in\mathbb{Z}} c_{n,m}\frac{1}{2\pi}\int_X e^{i(n-m)\theta}\,\mathrm{d}\theta|n\rangle\langle m|,\quad X\in\mathcal{B}([0,2\pi)), \tag{18}$$

must be understood as the sesquilinear form $(\varphi,\psi)\mapsto E_{\varphi,\psi}(X)$ defined on $\mathcal{M}$.

Since $R(\theta)\mathcal{M}=\mathcal{M}$, it follows that $X\to E(X)$ is covariant in the sense that

$$E_{R(\theta)*\varphi,R(\theta)*\psi}(X)=E_{\varphi,\psi}(X\oplus\theta)$$

for all $\varphi,\ \psi\in\mathcal{M},\ \theta\in[0,2\pi)$, and $X\in\mathcal{B}([0,2\pi))$.

Finally, if $E_{\varphi,\psi}(X)\geqslant 0$ for all $X\in\mathcal{B}([0,2\pi))$ and $\varphi\in\mathcal{M}$, we say that E is positive. If E is positive, then the matrix $(c_{n,m})_{n,m\in\mathbb{Z}}$ is positive semidefinite (see the proof of Theorem 2). Hence, $0\leqslant E_{\varphi,\varphi}(X)\leqslant E_{\varphi,\varphi}([0,2\pi))=\|\varphi\|^2$, $\varphi\in\mathcal{M}$, $X\in\mathcal{B}([0,2\pi))$, and $(\varphi,\psi)\mapsto E_{\varphi,\psi}(X)$ is bounded on $\mathcal{M}$. In this case, the sesquilinear form $E(X)$, for all $X\in\mathcal{B}([0,2\pi))$, can be regarded as a bounded operator with the unique matrix elements $E_{|n\rangle,|m\rangle}(X)=c_{n,m}(2\pi)^{-1}\int_X e^{i(n-m)\theta}\,\mathrm{d}\theta$, $n,\ m\in\mathbb{Z}$. The mapping $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ is σ-additive (see the proof of Phase Theorem 2.2 of Ref. 8). Thus, Eq. (18) defines weakly a covariant normalized positive operator measure $X\mapsto E(X)$.

A. Projection-valued covariant normalized positive operator measures

The application of Ref. 5, Proposition 1, in Sec. II gave, in Theorem 1, also a characterization of the $\mathbb{T}$-covariant projection measures. In the present approach one has to determine separately which of the solutions of Theorem 2 are projection valued. We shall do that next.

Proposition 3: Let $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ be a covariant normalized positive operator measure with the associated structure matrix $(c_{n,m})_{n,m\in\mathbb{Z}}$. E is projection valued, that is, $E(X)^2=E(X)$ for all $X\in\mathcal{B}([0,2\pi))$, if and only if $|c_{n,m}|=1$ for all $n,m\in\mathbb{Z}$.

Proof: Let $x\in(0,1)$ and $n\in\mathbb{Z}$. Using the equations $\Sigma_{k=1}^{\infty}k^{-2}=\pi^2/6$ and $y^2=\pi^2/3+4\Sigma_{k=1}^{\infty}k^{-2}\cos(k(y+\pi))$, $y\in(-\pi,\pi)$, one gets

$$\begin{aligned}\langle n|E([0,2\pi x))^2|n\rangle&=\sum_{s=-\infty}^{\infty}|c_{n,s}|^2\left|\frac{1}{2\pi}\int_0^{2\pi x}e^{i(s-n)\theta}\,\mathrm{d}\theta\right|^2\ (\text{put}\ \ k:=s-n)\\&\leqslant x^2+\frac{1}{2\pi^2}\sum_{k=1}^{\infty}\frac{|e^{2\pi ikx}-1|^2}{k^2}\\&=x^2+\frac{1}{\pi^2}\sum_{k=1}^{\infty}\frac{1}{k^2}-\frac{1}{\pi^2}\sum_{k=1}^{\infty}\frac{\cos(2\pi xk)}{k^2}=x=\langle n|E([0,2\pi x))|n\rangle,\end{aligned}$$

where the equality sign holds only when $|c_{n,m}|=1$ for all $n,m\in\mathbb{Z}$.

On the other hand, if $|c_{n,m}|=1$, then $c_{n,m}=e^{i(v_n-v_m)}$, $v_n\in[0,2\pi)$, for all $n,\ m\in\mathbb{Z}$, since $(c_{n,m})_{n,m\in\mathbb{Z}}$ is the structure matrix of E.[10] Define the following unitary transformations: $W:\mathcal{H}\to\mathcal{H}$, $|n\rangle\mapsto e^{-iv_n}|n\rangle$ and $T:\mathcal{H}\to L^2[0,2\pi)$, $|n\rangle\mapsto f_n$, where $f_n(x)=1/\sqrt{2\pi}e^{-inx}$, $x\in[0,2\pi)$. Now E is unitarily equivalent to the canonical spectral measure E^Q, $E^Q(X)f=\chi_X f$, $X\in\mathcal{B}([0,2\pi))$, $f\in L^2[0,2\pi)$, that is, $E(X)=W^*T^*E^Q(X)TW$, and, thus, E is projection valued.□

Remark 2: The $\mathbb{T}$-covariant localization observables $E:\mathcal{B}(\mathbb{T})\to\mathcal{L}(\mathcal{H})$ are compactly supported, supp $E=\mathbb{T}$. Therefore, all their moment operators

$$V^{(k)}=\int_{\mathbb{T}}z^k\,\mathrm{d}E(z),\quad E^{(k)}=\int_{\mathbb{T}}\arg(z)^k\,\mathrm{d}E(z),$$

with $k\in\mathbb{Z}$, are bounded operators. The cyclic moments $V^{(k)}$ are contractions whereas the phase moments $E^{(k)}$ are self-adjoint. The operator measure E is uniquely determined by both of its moment operator sequences $(V^{(k)})_{k\in\mathbb{Z}}$ and $(E^{(k)})_{k\in\mathbb{Z}}$.

The operator measure E is projection valued if and only if all its cyclic moment operators $V^{(k)}$, $k\in\mathbb{Z}$, are unitary. If E is not projection valued, then, at least, some of the moment operators $V^{(k)}$ are nonunitary. However, if the first cyclic moment operator $V^{(1)}$ of E is unitary, then E is projection measure. Indeed,

$$V^{(1)}=\sum_{n\in\mathbb{Z}}c_{n,n+1}|n\rangle\langle n+1|,$$

so that $V^{(1)}(V^{(1)})^*=I$ implies that $|c_{n,n+1}|=1$ for all $n\in\mathbb{Z}$. By induction, using (17), one then quickly computes that $|c_{n,n+k}|=1$ for all $n\in\mathbb{Z}$ and $k\in\mathbb{Z}^+$, which confirms that E is a projection measure (and hence all $V^{(k)}$ are unitary).

We recall further that $E^{(2)}=(E^{(1)})^2$ exactly when E is projection valued (Ref. 12, Appendix, Sec. 3). In view of that, it is interesting to observe that, due to the covariance condition, the operator measure E (projection valued or not) is uniquely determined already by its first phase moment operator

$$E^{(1)}=\int_{\mathrm{T}}\arg(z)\,\mathrm{d}E(z)=\int_0^{2\pi}\theta\,\mathrm{d}E(\theta)=\pi I+\sum_{n\neq m=-\infty}^{\infty}\frac{c_{n,m}}{i(n-m)}|n\rangle\langle m|$$

since $c_{n,m}=i(n-m)\langle n|E^{(1)}|m\rangle$ for all $n\neq m$. Clearly, the spectral measure $E^{E^{(1)}}$ of the bounded self-adjoint operator $E^{(1)}$ is shift covariant if and only if it is unitarily equivalent to E^Q.

(Received 12 January 2001; accepted for publication 4 October 2001)

When $t \to \infty$ any wave packet in the Liouvillian representation of the density matrices becomes a Hardy class function from below. This fact, in the global frame of the Reichenbach diagram, is used to explain the observed global time asymmetry of the universe. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421061]

I. INTRODUCTION

Many authors consider time asymmetry as having a *global* origin.[1] In the last few years, we have shared this position following Davies's reinterpretation of a remarkable idea conceived by Reichenbach.[2] Reichenbach's original idea concerning the arrow of time was that it appears in quasi-isolated systems with nonmaximum entropy at a certain time $t=0$, and he used a ''branched diagram'' originating out of an unstable state to explain this *local* phenomenon. Even if this unstable state can be—at least, theoretically—produced by a fluctuation, in practice it is actually due to the noncomplete isolation of the system before $t=0$. In fact, the truth is that it was interacting with a wider system containing it, in such a way that the energy flowing from this environment results in the production of the unstable initial state of the smaller or *branched* system. This idea was afterwards put in a cosmological scenario by Davies: ''In daily life the arrow of time manifiests itself in the way of quasi-isolated branch systems separated off from the main environment in uncorrelated, less-than-maximum entropy state. Such an explanation suppose, of course, that the wider environment is a less-than-maximum entropy state itself. So long as we confine our attention to subsystems, the question of why their initial state are able to possess less-than-maximum entropy can always be explained by appealing to the wider environment. An examination of realistic branch systems usually shows that they emerge as a result a chain, or hierarchy of branching which, if traced back, expand out into wider and wider regions of the universe. Thus, most of the important time-asymmetric phenomena on Earth are driven by the thermodynamics disequilibrium that exists in the vicinity of the sun, while the sun's own disequilibrium can be traced back to its nuclear constitution, which in turns takes back to the big bang. Eventually, the origin of the arrow of time always refers back to the initial cosmological condition. There exists an arrow of time only because the universe originated in a less-than-maximum entropy state'' (see also the coincident opinion of Feynman in Ref. 1).

We have developed this idea in great detail in several papers.[1] Its obvious simplest graphical representation is the Reichenbach diagram (Fig. 1), where each box represents a physical process, and the lines in the interior of some boxes represent unstable states. The arrow incoming from the left of each box represents the energy that produces the unstable state originating the process of the branch system, while the outgoing arrows emerging from the right of the box represent the energy produced by the process. The big box at the far left-hand side is the initial instability that originates all the branch systems of the diagram: the big-bang (the existence of the unstable initial state was explained in previous papers[3]). Originally, this figure can be considered as a macro-

[a)]Electronic mail: ordoniez@fceia.unr.edu.ar

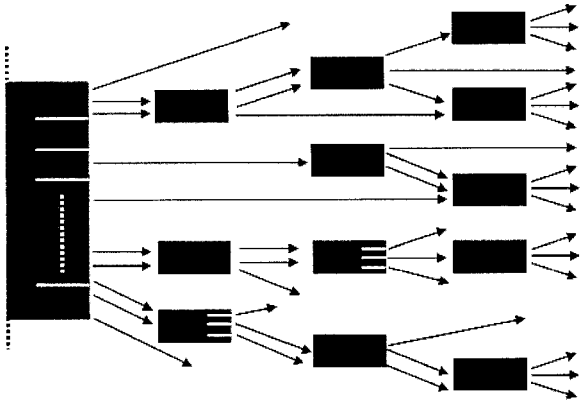

FIG. 1.

scopic process diagram, but as the deep essence of the phenomena is just nonequilibrium, it can be also considered as a microscopic-quantum one, using the quantum mechanics of an unstable system.[4] Then, the Reichenbach diagram is the combination of all the scattering processes within the evolution of the universe, beginning at the initial global instability or big-bang, which is considered as the source of all energy that subsequently flows through all the lines of the diagram. In each scattering process, the incoming energy is used to produce unstable forming states that decay, thus originating the outgoing ones. So, the set of outgoing lines of the diagram can be considered as evolutions from an unstable state toward equilibrium. Essentially, the whole diagram can be considered as only having outgoing lines. In fact, the incoming lines in each scattering "*S*" are just outgoing lines of a previous process. Moreover, the incoming lines (with their associated forming states), cannot be considered as *spontaneous evolutions*, since they just show the pumping of energy from a precedent process, which is really coupled with the scattering system "*S*," making these incoming lines representatives of *nonspontaneous* or forced evolutions. On the contrary, spontaneity clearly characterizes outgoing lines. Considered as a whole, the Reichenbach diagram symbolizes the asymmetrical flow of all the energy within the universe from its initial instability toward a final equilibrium state, resolving this flow as a sum of scattering processes.

Then, time asymmetry (which cannot be explained as a consequence of the local time-symmetric physical *laws*), can be easily explained as a consequence of the time asymmetry of the *universe* (as Fig. 1 shows), which must be considered—in cosmology, at least—as a really existent *physical object* and, as such, endowed with symmetries and asymmetries. Furthermore, the states corresponding to outgoing spontaneous states belong to some space Ψ_- while the incoming nonspontaneous ones belong to another space Ψ_+. These spaces are related by: $\Psi_+ = K\Psi_- \neq \Psi_-$, where K is Wigner time-reversal operator,[5] and time asymmetry—as well as other interesting phenomena—can be considered as a consequence of the existence of such a time-asymmetric space of physical admissible states.[6] *The aim of this paper is to mathematically characterize these spaces.*

For causality reasons, the space Ψ_- was associated with the space of Hardy class functions from below,[7] but this is not completely satisfactory, because it means to postulate causality *before* defining past and future. If all the lines in the Reichenbach diagram would be electromagnetic waves, this choice would be natural, since the outgoing waves of electromagnetic scattering *can* be represented as states belonging to the just mentioned Hardy space.[8] This conclusion can be extended to all hyperbolic scatterings, but not to the parabolic equation of nonrelativistic quantum mechanics. Nevertheless, we are going to show that *far from the scatterer, the outgoing lines belong to a Hardy space if the physical admissible states are wave packets of density matrices.* Thus, eventually all the spontaneously evolving states of the universe would belong to such a type of space, that we will call Ψ_-. On the other hand, the unphysical nonspontaneous time-inverted states would belong to a space Ψ_+. (In the usual popularization language, Ψ_- would be the space

of the spontaneous evolutions: the sugar lump dissolving in the coffee, or the elephant breaking the crystal shop. While Ψ_+ will be the space of impossible—or better, nonspontaneous—evolutions: the sugar lump concentrating in the coffee, or the elephant reconstructing the crystal shop.) The arrow of time would be the consequence of this asymmetry.

II. THE BAKER'S TRANSFORMATION

As a didactical introduction to the subject we will show how spaces Ψ_- and Ψ_+ appear in the famous Baker transformation.

Let us consider the unit square $S=[0,1]\times[0,1]$ with its restricted Lebesgue measure μ and the Baker's transformation:

$$B(x,y)=\begin{cases}(2x,\frac{1}{2}y) & \text{if } 0\leqslant x\leqslant\frac{1}{2}\\ (2x-1,\frac{1}{2}y+\frac{1}{2}) & \text{if } \frac{1}{2}\leqslant x\leqslant 1\end{cases}. \tag{1}$$

Let us consider the *independent and generating partition* of B,[9] i.e., the partition of the unit square into its left and right halves or ''vertical'' rectangles, $P=\{\Delta_1,\Delta_2\}$. ''Independence'' of the partition P with respect to B means that

$$\mu\left(\bigcap_{n=-m_1}^{m_2} B^n(\Delta_{i_n})\right)=\prod_{n=-m_1}^{m_2}\mu(\Delta_{i_n}), \tag{2}$$

where $\Delta_{i_n}\in P$. The ''generating'' character of the partition P with respect to B means that any Borel measurable set of the unit square can be obtained by forming *countable* unions and intersections of sets of the form

$$\bigcap_{n=-m_1}^{m_2} B^n(\Delta_{i_n}) \quad \text{with} \quad \Delta_{i_n}\in P.$$

Let $U:L^2(S,\mu)\to L^2(S,\mu)$ be the unitary map

$$(U^n\rho)(w)=\rho(B^{-n}(w)), \tag{3}$$

where $\rho\in L^2(S,\mu)$, $w\in S$. As is well known, U has a countable uniform Lebesgue spectrum, and therefore[10] there is a *system of imprimitivity* in $L^2(S,\mu)$ based on $\mathbb{Z}$ for the group $\{U^n:n\in\mathbb{Z}\}$. In other words, there is a spectral measure E defined on $\mathbb{Z}$ and taking its values in the set of the orthogonal projection operators of $L^2(S,\mu)$, such that

$$\forall n,m\in\mathbb{Z}:\ U^{-n}E_mU=E_{m+n}, \tag{4}$$

where $E_m=E(\{m\})$ and $E_{m+n}=E(\{m+n\})$. Then, we can define the *age operator*[9] by

$$A=\int_{\mathbb{Z}} n\,\mathrm{d}E=\sum_{n=-\infty}^{+\infty} nE_n. \tag{5}$$

As a consequence of Eqs. (4) and (5), and taking into account the properties of E, we have

$$\forall n\in\mathbb{Z}:\ U^{-n}AU=A+nI. \tag{6}$$

The age operator A has $\mathbb{Z}$ as uniform spectrum with countable multiplicity. In fact, the functions

$$\alpha_0(w)=\begin{cases}+1 & \text{if } w\in\Delta_1\\ -1 & \text{if } w\in\Delta_2\end{cases},$$

together with its transformed by U^n: $\alpha_n=U^n(\alpha_0)$, and all their finite products

$$\alpha_F=\alpha_{n_1}\cdots\alpha_{n_r}$$

$[F=\{n_1,\ldots,n_r\}\ n_j\in\mathbb{Z}]$ constitute an orthonormal eigenbasis $\{\alpha_F:F\subset\mathbb{Z}\}$ of A, each α_F being a "state" of age $n=\max\{n_1,\ldots,n_r\}$, in the sense that

$$A\alpha_F=n\alpha_F. \tag{7}$$

(Clearly, there are countably many states corresponding to each eigenvalue or age n, showing its multiplicity.) Because of Eq. (4), U acts as a *right bilateral shift*[10] on this basis:

$$U\alpha_F=\alpha_{F+1} \tag{8}$$

(where $F+1:=\{n_1+1,\ldots,n_r+1\}$). Equations (6) and (8) show how the age brought about by the dynamical evolution and growing with it matches with the progress of external (or observer's) time labeling the dynamical group.

Now, we can decompose $L^2(S,\mu)$ as a direct sum of two Hardy functions spaces[10] H^2_+ and H^2_- such that

$$H^2_+=\left\{\rho:\rho\in L^2(S,\mu)\wedge\rho=\sum_{F\subset\mathbb{Z}^+}a_F\alpha_F\right\} \tag{9}$$

having only non-null Fourier coefficients $a_F\in\mathbb{C}$ for positive indices, and

$$H^2_-=\left\{\rho:\rho\in L^2(S,\mu)\wedge\rho=\sum_{F\subset\mathbb{Z}^-_0}a_F\alpha_F\right\} \tag{10}$$

having only nonvanishing Fourier coefficients for negative (or zero) indices.

Then, it is obvious that

$$UH^2_+\subset H^2_+,UH^2_-\subset H^2_+\oplus H^2_-=L^2(S,\mu)\neq H^2_- \tag{11}$$

and that

$$\lim_{n\to+\infty}U^n(H^2_+\oplus H^2_-)=H^2_+. \tag{12}$$

We will describe this fact by saying that the states belonging to H^2_+ are "stable toward the future" under the induced evolution U, while those belonging to H^2_- are "unstable." In this way, when acted on by U^n, any function belonging to $L^2(S,\mu)$ will end in space H^2_+ in the "far future" (precisely when $n\to+\infty$). Of course, with respect to the inverse evolution U^{-1} "toward the past"—a *left bilateral shift*—we must reverse these terms, and also change Eq. (12) into

$$\lim_{n\to+\infty}U^{-n}(H^2_+\oplus H^2_-)=H^2_-. \tag{13}$$

In Sec. III we will consider the "quantum version" of what we have said previously.

III. PURE STATES AND THE HAMILTONIAN

Let us begin considering just pure states $|\psi\rangle$, belonging to a Hilbert space $\mathcal{H}$, of a quantum system with Hamiltonian H, such that

$$H|\omega,n\rangle=\omega|\omega,n\rangle, \tag{14}$$

where $0\leqslant\omega<\infty$ or $\omega\in\mathbb{R}^+$ and n belongs to a set of indices N, which is the same for any ω (for didactical reasons we will assume that this set is numerable, and therefore the index n will be discrete). Thus, H can be considered as a typical scattering Hamiltonian just endowed with an absolutely continuous and uniform energy spectrum. Precisely, there is a nuclear space Φ and a rigging of it with $\mathcal{H}$,

$$\Phi\subset\mathcal{H}\subset\Phi^{\times},$$

such that

$$\{|\omega,n\rangle:\omega\in\mathbb{R}^+\wedge n\in N\}\subset\Phi^{\times}$$

(we wil denote by $\Phi^{\times}$ the antidual space of Φ, composed of all continuous antilinear functionals on Φ, and by Φ' its dual) is a generalized eigenbasis of H[11,12] in the sense that

$$\forall\varphi,\psi\in\Phi:\langle\varphi|\psi\rangle=\sum_n\int_0^{\infty}\mathrm{d}\omega\langle\varphi|\omega,n\rangle\langle\omega,n|\psi\rangle, \tag{15}$$

where the left-hand side means the scalar product in $\mathcal{H}$ (antilinear in its left factor), while on the right-hand side $\langle\varphi|\omega,n\rangle$ means the evaluation of the antilinear functional $|\omega,n\rangle$ on φ, and $\langle\omega,n|\psi\rangle$ is the evaluation of the linear functional $\langle\omega,n|$ on ψ. This justifies Dirac's notation:

$$|\psi\rangle=\sum_n\int_0^{\infty}\mathrm{d}\omega|\omega,n\rangle\langle\omega,n|\psi\rangle. \tag{16}$$

Moreover, let us consider that real physical states are wave packets, mathematically modeled by Schwarz functions of $\omega\in\mathbb{R}^+$, for each value of n, so,

$$f(\omega)=\langle\omega,n|\psi\rangle\in\mathcal{S}^+=\mathcal{S}(\mathbb{R}^+). \tag{17}$$

($\mathcal{S}^+$ is the space of all infinite differentiable complex-valued functions defined on $[0,+\infty)$, such that converge to zero for $\omega\to+\infty$ faster than the inverse of any polynomial.)

Taking into account all the values of n we can say that

$$f(\omega)=\langle\omega,n|\psi\rangle\in\bigoplus_n\mathcal{S}_n^+. \tag{18}$$

This mathematical model is adopted for the following reasons:

(1) It is clear that we do not find infinite energies in nature, and so $\langle\omega,n|\psi\rangle$ must somehow go to zero when $\omega\to+\infty$.
(2) In order to use derivatives in our calculations it is not enough to postulate that the states belong to a Hilbert space. They must be representable by differentiable functions. We postulate that they are infinitely differentiable. After all, we cannot find an experimental contradiction to this assumption.
(3) But since these functions must also be square integrable, we can take for granted that they go to zero when $\omega\to+\infty$. We postulate that they go to zero faster than the inverse of any polynomial.

Of course, we are free to choose other spaces instead of $\mathcal{S}^+$, but it is evident that $\mathcal{S}^+$ is the simplest model endowed with all the usual properties of wave packets (that is why the same choice is made in Ref. 13).

IV. MIXED STATES AND THE LIOUVILLIAN

We will use the notation of Ref. 14. Then, the Liouville operator reads

$$L=[H,.]=H\times I-I\times H. \tag{19}$$

Let us consider the space of "density matrices" $\mathcal{L}=\mathcal{H}\otimes\mathcal{H}$, the rigged Hilbert space

$$\Phi\otimes\Phi\subset\mathcal{H}\otimes\mathcal{H}\subset\Phi^{\times}\otimes\Phi',$$

and the generalized basis

$$\{|\omega,n\rangle\langle\omega',n'|:\omega,\omega'\in\mathbb{R}^{+}\wedge n,n'\in N\} \tag{20}$$

(where $|\omega,n\rangle\langle\omega',n'|=|\omega,n\rangle\otimes\langle\omega',n'|\in\Phi^{\times}\otimes\Phi'$).

Let us define the Riezs indices:[14]

$$\begin{gathered}\nu=\omega-\omega', \quad -\infty<\nu<\infty,\\ \sigma=\frac{1}{2}(\omega+\omega'), \quad \frac{|\nu|}{2}\leqslant\sigma<\infty.\end{gathered} \tag{21}$$

It will be convenient to label the basis (20) as

$$|\omega,n\rangle\langle\omega',n'|=|\nu,\sigma,n,n'). \tag{22}$$

Then:

$$L|\nu,\sigma,n,n')=\nu|\nu,\sigma,n,n'). \tag{23}$$

So

$$\left\{|\nu,\sigma,n,n'):\nu\in\mathbb{R}\wedge\frac{|\nu|}{2}\leqslant\sigma<\infty\wedge n,n'\in N\right\} \tag{24}$$

is a generalized eigenbasis of the Liouvillian, ν being the corresponding generalized eigenvalue and σ, n, n', the "degeneration indices." From (21) we see that $\nu\in\mathbb{R}$, while n and $n'\in\mathbb{N}$, and $\sigma\in\mathbb{R}^{+}$, and these spaces have the same cardinality for any ν. So L has uniform Lebesgue spectrum $\mathbb{R}$.

In the basis (24) "the ν-wave function" reads

$$\rho(\nu)=(\rho|\nu,\sigma,n,n'). \tag{25}$$

Following the ideas of Sec. III (and taking into account that we are considering mixed states as "density matrices," identified with *tensor products* of pure states), it is physically justified to suppose that these functions are sums of products of functions $f(\omega)\in\mathcal{S}(\mathbb{R}^{+})$, namely:

$$f(\omega)g(\omega')=f\left(\sigma+\frac{\nu}{2}\right)g\left(\sigma-\frac{\nu}{2}\right). \tag{26}$$

They will have infinite derivatives with respect to ν, since f and g are infinitely differentiable. Moreover, $\rho(\nu)$ goes to zero when $\nu\to\pm\infty$ faster than the inverse of any polynomial since this is a property of f and g. Thus, for any σ, n, n':

$$\rho(\nu)=(\rho|\nu,\sigma,n,n')\in\mathcal{S}(\mathbb{R}). \tag{27}$$

V. THE AGE OPERATOR

Since L has uniform Lebesgue spectrum $\mathbb{R}$, there is a system of imprimitivity in $\mathcal{L}$ based on $\mathbb{R}$ for the group $\{U_t : t \in \mathbb{R}\}$. In other words, there is a spectral measure E defined on $\mathbb{R}$ and taking its values in the set of the orthogonal projection operators of $\mathcal{L}$,[10] such that

$$\forall t,s \in \mathbb{R}: U_t^{-1} E_s U_t = E_{t+s}, \tag{28}$$

where $E_s = E((-\infty, s])$, and $E_{t+s} = E((-\infty, t+s])$. Then we can define the *age operator*[15] by

$$A = \int_{\mathbb{R}} t \, \mathrm{d}E. \tag{29}$$

As a consequence of Eqs. (28) and (29), and taking into account the properties of E, we have

$$\forall t \in \mathbb{R}: U_t^{-1} A U_t = A + tI. \tag{30}$$

The age operator A has $\mathbb{R}$ as a uniform Lebesgue spectrum. In fact, for the physical states we have

$$A\rho(\nu,\sigma,n,n') \doteq i \frac{\partial}{\partial \nu} \rho(\nu,\sigma,n,n')|_{\sigma,n,n'=\text{const}}, \tag{31}$$

that is equivalent to the commutation relation

$$[A,L] = i. \tag{32}$$

(A and L have essentially the same commutation relation as position and momentum operators q and p.) Then $\hat{\rho}(a,\sigma,n,n')$, the Fourier transform in variables $\nu \leftrightarrow a$ of $\rho(\nu,\sigma,n,n')$, is an eigenvector of A, precisely:

$$A\hat{\rho}(a,\sigma,n,n') = a\hat{\rho}(a,\sigma,n,n'). \tag{33}$$

Moreover $\hat{\rho}(a,\sigma,n,n') \in \mathcal{S}(\mathbb{R})$ in the variable a since it is the Fourier transform of $\rho(\nu,\sigma,n,n')$. Then, the time evolution of $\hat{\rho}(a,\sigma,n,n')$ reads:

$$\begin{aligned}(\widehat{e^{-iLt}\rho})(a,\sigma,n,n') &= (\widehat{e^{-i\nu t}\rho})(a,\sigma,n,n') \\ &= \int_{-\infty}^{+\infty} e^{-i\nu t} \rho(\nu,\sigma,n,n') e^{-iat} \mathrm{d}\nu \\ &= \int_{-\infty}^{+\infty} e^{-i(a+t)\nu} \rho(\nu,\sigma,n,n') \mathrm{d}\nu = \hat{\rho}(a+t,\sigma,n,n').\end{aligned} \tag{34}$$

Thus, L is the generator of the time translations, and $\hat{\rho}(a,\sigma,n,n')$ increase its age as $a \to a + t$ becoming $\hat{\rho}(a+t,\sigma,n,n')$. This fact justifies the name given to A. But Eq. (34) tells us that during its time evolution, the wave packet $\hat{\rho}(a,\sigma,n,n') \in \mathcal{S}(\mathbb{R})$ does not change its shape, being merely shifted to the left. So, in the basis (24) all physical states are wave packets at any time, and we have

$$\lim_{t \to +\infty} \hat{\rho}(a+t,\sigma,n,n') = 0 \tag{35}$$

(in the pointwise convergence sense) because functions in Schwarz space go to zero when its variable goes toward the infinite.

VI. THE THEOREM

The quantum version of the Baker's transformation example would be as follows. Let us consider a quantum system whose states ρ are ''density matrices'' belonging to a Hilbert–Liouville space $\mathcal{L}$. Let L be the Liouville superoperator in $\mathcal{L}$, assumed as having $\mathbb{R}$ as uniform Lebesgue spectrum. This amounts to saying that the evolution superoperator $\exp[-iLt]$ is a bilateral shift, closely related with Hardy classes.[16,10]

We can decompose the space of physical states $\Psi=\Phi\otimes\Phi$ as $\Psi_+\oplus\Psi_-$, where

$$\Psi_+=\{\rho\in\Psi:[\forall a<0:\hat{\rho}(a,\sigma,n,n')=0]\}=\{\rho\in\Psi:\hat{\rho}(a,\sigma,n,n')\in L^2(\mathbb{R}^+)\}, \tag{36}$$

$$\Psi_-=\{\rho\in\Psi:[\forall a>0:\hat{\rho}(a,\sigma,n,n')=0]\}=\{\rho\in\Psi:\hat{\rho}(a,\sigma,n,n')\in L^2(\mathbb{R}^-)\} \tag{37}$$

are spaces of wave packets that are also Hardy class functions in the ν variable from above (Ψ_+), or below (Ψ_-), because of a Paley–Wiener Theorem (Ref. 12, Theorem II, p. 47). Then our theorem states that:

Theorem: *The limit of any physical state, when $t\to+\infty$, belongs to Ψ_-.*

Proof: Because of the fact that $L^2(\mathbb{R})=L^2(\mathbb{R}^-)\oplus L^2(\mathbb{R}^+)$, we can decompose any $\hat{\rho}(a)$ [abbreviation for $\hat{\rho}(a,\sigma,n,n')$] as

$$\hat{\rho}(a)=\hat{\rho}_-(a)+\hat{\rho}_+(a), \tag{38}$$

where

$$\begin{aligned}&\hat{\rho}_-(a)=\hat{\rho}(a)\quad\text{for}\quad a<0,\quad \hat{\rho}_-(a)=0\quad\text{for}\quad a>0,\\ &\hat{\rho}_+(a)=\hat{\rho}(a)\quad\text{for}\quad a>0,\quad \hat{\rho}_+(a)=0\quad\text{for}\quad a<0.\end{aligned} \tag{39}$$

In particular

$$\hat{\rho}(a+t)=\hat{\rho}_-(a+t)+\hat{\rho}_+(a+t) \tag{40}$$

(first the shift to the left, and then the decomposition into the negative and positive parts with respect to $a=0$, not with respect to $a+t=0$).

From Eqs. (40) and (35) we see that $\hat{\rho}_+(a+t)\to0$ in $L^2(\mathbb{R}^+)$, when $t\to+\infty$, and therefore $\hat{\rho}(a+t)-\hat{\rho}_-(a+t)\to0$ in $L^2(\mathbb{R}^+)$. So, when $t\to+\infty$ the function $\hat{\rho}(a+t)$ belongs to $L^2(\mathbb{R}^-)$, and thus its inverse Fourier transform, namely $(e^{-iLt}\rho)(\nu)$, belongs to Ψ_-. □

So, we have proved

$$\lim_{t\to+\infty} e^{-iLt}\Psi=\Psi_- \tag{41}$$

the wave packets analog of Eq. (13) for the left shift, as announced.

VII. CONCLUSION

As the typical distance among the scatterers is much bigger than the characteristic dimension of the scatterers itself, most of the states can be considered far from these scatterers. Therefore, most of the physical states *do* belong to space Ψ_-, thus explaining time-asymmetry (see Sec. I). Moreover, using the space of physical admissible states Ψ_-, most of the irreversible phenomena of nature can be foreseen, obtaining the same results as those of other formalisms (such as ''coarse-graining,'' Lindblad, etc.[17]).

(Received 13 June 2001; accepted for publication 1 November 2001)

The so-called Gazeau–Klauder and Perelomov coherent states are introduced for an arbitrary quantum system. We give also the general framework to construct the generalized intelligent states which minimize the Robertson–Schrödinger uncertainty relation. As illustration, the Pöschl–Teller potentials of trigonometric type will be chosen. We show the advantage of the analytical representations of Gazeau–Klauder and Perelomov coherent states in obtaining the generalized intelligent states in analytical way. © *2002 American Institute of Physics.*

I. INTRODUCTION

Coherent states, known as the closest states to classical ones, play an important role in many different contexts of theoretical and experimental physics, especially quantum optics.[1–3] Schrödinger first discovered the coherent states for the harmonic oscillator potential in 1926[4] and much work has been done since then on their properties and applications.[5,6] The coherent states have also been found in systems with the Lie group symmetry.[7,8] Recently, coherent states have been found in special Hamiltonians.[9] These coherent states are called minimum uncertainty coherent states. In coherent states the standard deviation of X (coordinate) and P (momentum) are equal and their product is minimum over states. There are also quantum states where, though we have minimum uncertainty for the standard deviation of coordinate and momentum, they are not equal any more; those states are called squeezed states. These states are as important as coherent ones. Their generation plays an important role in many different branches of physics.

There exist three definitions of coherent states. The first one defines the usual coherent states as eigenstates of the annihilation operator a^- for each individual oscillator mode of the electromagnetic field

$$a^-|z\rangle = z|z\rangle. \tag{1}$$

Here $[a^-,a^+]=1$ $((a^-)^\dagger = a^+)$ and z is a complex constant with conjugate $\overline{z}$. The resulting unit normalized states $|z\rangle$ are given by

$$|z\rangle = e^{-|z|^2/2}\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{n!}}|n\rangle, \tag{2}$$

where $|n\rangle$ is an element of the Fock space $\mathcal{H}\equiv\{|n\rangle, n\geqslant 0\}$. A second definition of coherent states for oscillators assumes the existence of a unitary "displacement" operator $D(z)$ defined as

$$D(z) = \exp(za^+ - \overline{z}a^-). \tag{3}$$

The coherent states parametrized by z are given by the action of $D(z)$ on the ground state $|0\rangle$. The unitarity of $D(z)$ ensures the correct normalization of $|z\rangle$. The Baker–Campbell–Hausdorff relation (BCH)

$$e^A e^B = e^{A+B+(1/2)[A,B]}, \tag{4}$$

valid only for any two operators A and B that both commute with the commutator $[A,B]$, implies the equivalence of this definition with the one above.

A third definition is based on the uncertainty relation, with the position X and momentum P given, as usual, by

$$X = \frac{1}{\sqrt{2}}(a^- + a^+), \quad P = \frac{i}{\sqrt{2}}(a^+ - a^-). \tag{5}$$

The coherent states defined above have the minimum-uncertainty value $2\Delta X \Delta P = 1$ and maintain this relation in time (temporal stability of coherent states). Coherent states have two important properties. First, they are not orthogonal to each other. Second, they provide a resolution of the identity, i.e., they form an over-complete set states.

A central goal of this article is to extend the above three definitions for an arbitrary quantum system (exactly solvable) and compare the equivalence between them. Note that an attempt in this sense was considered by Nieto *et al.*[9] concluding that the three definition are generally inequivalents. Our analysis is different from the Nieto *et al.* ones for several reasons which will be clear in the sequel of this article.

The method we adopt is an extension of the group-theoretical approach to coherent states which generalizes the displacement operator definition. We call the obtained coherent states: coherent states of Perelomov type. The latter will be compared with Gazeau–Klauder coherent states constructed using the approach adopted by Barut–Girardello[10,11] (see also Refs. 12–14) for an arbitrary quantum system. To extend to third definition, we solve the eigenvalue equation of states minimizing the Robertson–Schrödinger uncertainty relation which extends the Heisenberg one. These states are called generalized intelligent states (GIS).[15,16] We show that the set of GIS includes the Gazeau–Klauder coherent states in a particular situation.

This article is organized as follows: Creation and annihilation operators for an arbitrary quantum system (exactly solvable) are introduced in Sec. II. These operators are used to define Gazeau–Klauder coherent states in Sec. III. Section IV is devoted to giving a general algorithm leading to the Perelomov coherent states. States minimizing the Robertson–Schrödinger uncertainty relation are constructed in Sec. V. The results of Secs. III–V are applied to a quantum system evolving in Pöschl–Teller potentials. In particular, using the analytical representations of Gazeau–Klauder coherent states and Perelomov ones, we give the generalized intelligent states under analytical forms (Sec. VI). The last section concerns a summary of the main results of this work.

II. CREATION AND ANNIHILATION OPERATORS FOR AN ARBITRARY QUANTUM SYSTEM

We start with general consideration on the creation and annihilation operators from the factorization of a given Hamiltonian admitting a nondegenerate discrete infinite energy spectrum. Let us assume that the Hamiltonian H of a quantum system admits infinite spectrum of energy $\{E_n, n=0,1,2,\dots\}$ such that the fundamental energy $E_0=0$ and the others are in increasing order, i.e.,

$$E_0 = 0 < E_1 < E_2 < \cdots < E_{n-1} < E_n < \cdots. \tag{6}$$

For such a system, we know that the fundamental state $\psi_0(x)$ and the potential $V(x)$ are closely related so that the factorization is possible. Indeed, the time independent Schrödinger equation for $\psi_0(x)$ reads

$$H\psi_0(x)=\left(-\frac{1}{2}\frac{d^2}{dx^2}+V(x)\right)\psi_0(x)=0, \tag{7}$$

and we have

$$V(x)=\frac{1}{2}\frac{\psi_0''(x)}{\psi_0(x)}, \tag{8}$$

where the prime means the derivation with respect to x.

The usual factorization of H is then given by

$$H=A^+A^- \tag{9}$$

with

$$A^+=\frac{1}{\sqrt{2}}\left(-\frac{d}{dx}+W(x)\right), \quad A^-=\frac{1}{\sqrt{2}}\left(\frac{d}{dx}+W(x)\right), \tag{10}$$

where the superpotential $W(x)$ satisfies the Riccati equation

$$V(x)=\tfrac{1}{2}(W^2(x)-W'(x)). \tag{11}$$

It is clear, from Eqs. (8) and (11), that $W(x)$ takes the form

$$W(x)=-\frac{\psi_0'(x)}{\psi_0(x)}. \tag{12}$$

From Eq. (10), we have

$$[A^-,A^+]=W'(x), \tag{13}$$

which generalizes the usual one for the harmonic oscillator ($W(x)=x$). The operators A^+ and A^- are not the creation and annihilation operators of H. Then, we are interested now in identifying the operators creating and annihilating the quantum states of the system under consideration. The key ingredients in constructing them is to define the operator $H_+=A^-A^+$ obtained from $H=H_-=A^+A^-$ by reversing the order of A^- and A^+. The operator H_+ is in fact a Hamiltonian corresponding to a new potential $V_+(x)$:

$$H_+=-\frac{1}{2}\frac{d^2}{dx^2}+V_+(x), \quad V_+(x)=\frac{1}{2}(W^2(x)+W'(x)). \tag{14}$$

The potentials $V_-(x)=V(x)$ and $V_+(x)$ are known as supersymmetric partner potentials and $H_-\equiv H$ and H_+ are isospectrals (H_+ is also exactly solvable). Indeed, the Schrödinger equation for H_-,

$$H_-|\psi_n\rangle=E_n|\psi_n\rangle, \tag{15}$$

implies

$$H_+(A^-|\psi_n\rangle)=E_n(A^-|\psi_n\rangle). \tag{16}$$

Similarly, the Schrödinger equation for H_+,

$$H_+|\theta_n\rangle = e_n|\theta_n\rangle, \tag{17}$$

implies

$$H_-(A^+|\theta_n\rangle) = e_n(A^+|\theta_n\rangle), \tag{18}$$

where e_n are the eigenvalues and $|\theta_n\rangle$ are eigenstates of H_+. From the latter equations and the fact that $E_0=0$, it is clear that the energies and eigenstates of H_- and H_+ are related by

$$e_n = E_{n+1},$$

$$A^-|\psi_{n+1}\rangle = \sqrt{E_{n+1}}e^{i(E_{n+1}-E_n)\alpha}|\theta_n\rangle, \tag{19}$$

$$A^+|\theta_n\rangle = \sqrt{e_n}e^{-i(E_{n+1}-E_n)\alpha}|\psi_{n+1}\rangle, \tag{20}$$

where $\alpha \in \mathbf{R}$. Notice that if the eigenstates $|\psi_{n+1}\rangle$ ($|\theta_n\rangle$) of H_- (H_+) are normalized, then the wavefunctions $|\theta_n\rangle$ ($|\psi_{n+1}\rangle$) in Eqs. (19) and (20) are also normalized. Further, the operator A^- (A^+) converts an eigenfunction of H_- (H_+) into an eigenfunction of H_+ (H_-) with the same energy. Thus, the operators A^- and A^+ connect the states $|\psi_n\rangle$ and $|\theta_n\rangle$ and cannot be considered as creation and annihilation operators for $H \equiv H_-$. To define the ladder operators for the quantum system described by H, we consider the unitary transformation U connecting the basis $\{|\psi_n\rangle\}$ and $\{|\theta_n\rangle\}$ as follows:

$$|\theta_n\rangle = U|\psi_n\rangle \tag{21}$$

with

$$UU^+ = U^+U = I. \tag{22}$$

The explicit structure of the unitary operator U is given by

$$U = \sum_{n,m} U_{nm}|\psi_n\rangle\langle\psi_m|, \tag{23}$$

where the elements U_{nm} are evaluated by

$$U_{nm} = \langle\psi_n|\theta_m\rangle = \int \psi_n^*(x)\,\theta_m(x)\,dx. \tag{24}$$

Note that in the harmonic oscillator case $U=I$.

At this stage, we can introduce the creation and annihilation operators of H by

$$a^+ = A^+U, \quad a^- = U^+A^-. \tag{25}$$

The actions of the operators a^+ and a^- on the states $\{|\psi_n\rangle\}$ are given by

$$a^+|\psi_n\rangle = \sqrt{E_{n+1}}e^{-i(E_{n+1}-E_n)\alpha}|\psi_{n+1}\rangle, \tag{26}$$

$$a^-|\psi_n\rangle = \sqrt{E_n}e^{i(E_n-E_{n-1})\alpha}|\psi_{n-1}\rangle. \tag{27}$$

Note that $a^+a^- = A^+A^- = H$. It is easy to show that

$$|\psi_n\rangle = \frac{(a^+)^n}{\sqrt{E(n)}}e^{iE_n\alpha}|\psi_0\rangle, \quad n>0, \tag{28}$$

where we have defined

$$E(n)=E_1E_2\cdots E_n \tag{29}$$

and, for $n=0$, $E(0)=1$.

The exponential factor appearing in all these expressions produces only a phase factor and will be significant for the temporal stability of the coherent states we will construct in the following. From Eqs. (26) and (27), we have also

$$[a^-,a^+]|\psi_n\rangle=(E_{n+1}-E_n)|\psi_n\rangle. \tag{30}$$

Let us now introduce the operator N such that

$$N|\psi_n\rangle=n|\psi_n\rangle, \tag{31}$$

which is, in general (for an arbitrary quantum system), different from the product a^+a^- $(=H)$. We can see that it satisfies the following properties:

$$a^-N=(N+1)a^-, \quad a^+(N+1)=Na^+. \tag{32}$$

We are then able to define an operator G such that

$$[a^-,a^+]=G(N), \tag{33}$$

which acts in the states $|\psi_n\rangle$ as

$$G(N)|\psi_n\rangle=(E_{n+1}-E_n)|\psi_n\rangle. \tag{34}$$

The operator G is Hermitian.

III. GAZEAU–KLAUDER COHERENT STATES

A. Eigenstates of annihilation operator

The Gazeau–Klauder coherent states are eigenstates of the annihilation operator of the system under consideration. For the system governed by the Hamiltonian H $(=A^+A^-=a^+a^-)$, such states are labeled by $|z,\alpha\rangle$, $z\in\mathbf{C}$ and $\alpha\in\mathbf{R}$ (α is the parameter entering in Eqs. (26) and (27)), and they are assumed to be the solution of the eigenvalue equation

$$a^-|z,\alpha\rangle=z|z,\alpha\rangle. \tag{35}$$

To have their explicit form we decompose it in the basis $\{|\psi_n\rangle\}$ such that

$$|z,\alpha\rangle=\sum_{n=0}^{+\infty} a_n|\psi_n\rangle \tag{36}$$

and insert this equation in (35). Using Eq. (27), we find

$$a_n=\frac{z^n}{\sqrt{E(n)}}e^{-iE_n\alpha}a_0, \quad n>0, \tag{37}$$

with $E(n)$ is given by (29). For $n=0$, the state $|\psi_0\rangle$ is an eigenstate of a^- with eigenvalue 0. Finally, the coherent states $|z,\alpha\rangle$ take the form

$$|z,\alpha\rangle=a_0\sum_{n=0}^{+\infty}\frac{z^n}{\sqrt{E(n)}}e^{-iE_n\alpha}|\psi_n\rangle. \tag{38}$$

The constant a_0 will be fixed by imposing the normalization to unity. We get

$$|a_0|^{-2}=\sum_{n=0}^{+\infty}\frac{|z|^{2n}}{E(n)}. \tag{39}$$

The coherent states (38) are continuous in $z\in\mathbf{C}$ and $\alpha\in\mathbf{R}$. Moreover, the presence of the phase factor in the definition equations (26) and (27) of the a^- and a^+ actions leads to temporal stability of the coherent states. Indeed, we have

$$e^{iHt}|z,\alpha\rangle=|z,\alpha+t\rangle. \tag{40}$$

The analysis of completeness (in fact, the overcompleteness) requires us to compute the identity resolution, that is,

$$\int |z,\alpha\rangle\langle z,\alpha|d\mu(z)=I_{\mathcal{H}}. \tag{41}$$

Note that the integral is over the disk $\{z\in\mathbf{C},|z|<\mathcal{R}\}$, where the radius of convergence $\mathcal{R}$ is

$$\mathcal{R}=\lim_{n\to+\infty}\sqrt[n]{E(n)} \tag{42}$$

and the measure $d\mu(z)$ has to be determined. To determine it, we suppose that $d\mu(z)$ depends only on $|z|$ (isotropy condition). We take

$$d\mu(z)=[a_0]^{-2}h(r^2)rdrd\varphi;\quad z=re^{i\varphi}. \tag{43}$$

Hence, the identity resolution can be written in the following form:

$$I_{\mathcal{H}}=\sum_{n=0}^{+\infty}|\psi_n\rangle\langle\psi_n|\left[\frac{\pi}{E(n)}\int_0^{\mathcal{R}^2}h(u)u^n du\right]. \tag{44}$$

The last equation is satisfied when we have

$$\int_0^{\mathcal{R}^2}h(u)u^n du=\frac{E(n)}{\pi}. \tag{45}$$

It is clear that the identity resolution is then equivalent to the determination of the function $h(u)$ satisfying Eq. (45). For $\mathcal{R}\to\infty$, the function $h(u)$ is the inverse Mellin transform of $\pi^{-1}E(s-1)$,

$$h(u)=\frac{1}{2\pi^2 i}\int_{c-i\infty}^{c+i\infty}E(s-1)u^{-s}ds;\quad c\in\mathbf{R}. \tag{46}$$

Note that explicit computation of the function $h(u)$ requires the knowledge of the spectrum of the quantum mechanical system under consideration.

Using Eq. (35), one can obtain the mean value of the Hamiltonian H in the states $|z,\alpha\rangle$:

$$\langle z,\alpha|H|z,\alpha\rangle=|z|^2. \tag{47}$$

This relation in known as the action identity.

Finally, we remark that the coherent states $|z,\alpha\rangle$ can be written as an operator $U(z)$ acting in the ground state $|\psi_0\rangle$

$$U(z)=a_0\exp\left(z\frac{N}{g(N)}a^+\right) \tag{48}$$

such that we have

$$|z,\alpha\rangle=U(z)|\psi_0\rangle. \tag{49}$$

In (48), $g(N)\equiv H=a^+a^-$. The operator $U(z)$ is not unitary and cannot be interpreted as the displacement operator in the Perelomov's sense.

A final comment can be made in connection with the work of Gazeau and Klauder.[11] In fact, the coherent states (38) satisfy all the requirements (continuity, temporal stability, identity resolution, action identity) given in their approach but they are more general since we are working with $z\in\mathbf{C}$ and $\alpha\in\mathbf{R}$. They are eigenstates of the annihilation operator a^-. Additional properties of this set of states will be considered in Sec. V.

B. Fock–Bargmann representation

It is well known that the Fock–Bargmann representation enables one to find simple solutions to a number of problems, exploiting the theory of analytical entire functions. In this subsection, generalizing the pioneering work of Bargmann[17] for the usual harmonic oscillator, we give the Bargmann representation of an arbitrary quantum mechanical system. We recall that in the Fock–Bargmann representation for the standard harmonic oscillator, the creation operator a^+ is the multiplication by z while the annihilation operator a^- is the differentiation with respect to z.

For an arbitrary quantum system, we define the Fock–Bargmann space as a space of functions which are holomorphic on a ring D of the complex plane. The scalar product is written with an integral of the form

$$\langle f|g\rangle=\int\overline{f(z)}g(z)d\mu(z), \tag{50}$$

where $d\mu(z)$ is the measure defined above (see Eq. (43)). Let $|f\rangle$ be an arbitrary quantum state of the system under study,

$$|f\rangle=\sum_{n=0}^{+\infty}f_n|\psi_n\rangle,\quad\text{with}\quad\sum_{n=0}^{+\infty}|f_n|^2<\infty. \tag{51}$$

Any state $|f\rangle$ is represented, in the Fock–Bargmann representation, as a function of the complex variable z (using the so-called coherent states associated with the quantum system under consideration):

$$f(z)\equiv\langle\overline{z},\alpha|f\rangle=\sum_{n=0}^{+\infty}\frac{z^n}{\sqrt{E(n)}}e^{iE_n\alpha}f_n. \tag{52}$$

In particular, to the vectors $|\psi_n\rangle$ there correspond the monomials

$$\langle\overline{z},\alpha|\psi_n\rangle=\frac{z^n}{\sqrt{E(n)}}e^{iE_n\alpha}. \tag{53}$$

Using Eqs. (52) and (53), we can prove the following result: In the Fock–Bargmann representation, we realize the annihilation operator a^- by

$$a^-=z^{-1}g\left(z\frac{d}{dz}\right), \tag{54}$$

the creation operator a^+ by

$$a^+ = z, \tag{55}$$

and the operator number by

$$N = z\frac{d}{dz}. \tag{56}$$

The Fock–Bargmann representation exists if we have a measure such that

$$\int |z,\alpha\rangle\langle z,\alpha| d\mu(z) = I_{\mathcal{H}}. \tag{57}$$

The existence of the measure, discussed previously for the so-called Gazeau–Klauder coherent states, ensures that the scalar product takes the form (50). We note that in the case where

$$g\left(z\frac{d}{dz}\right) = z\frac{d}{dz}, \quad \text{i.e.,} \quad g(N) = N, \tag{58}$$

we recover the well-known Fock–Bargmann representation of the harmonic oscillator. The Fock–Bargmann realization discussed here will be the main tool to construct the generalized intelligent states (see Sec. VI).

IV. COHERENT STATES OF PERELOMOV'S TYPE

In view of the second definition of coherent states for the standard harmonic oscillator (group-theoretical approach), we define, for an arbitrary quantum system, the states

$$|z,\alpha\rangle = \exp(za^+ - \bar{z}a^-)|\psi_0\rangle, \quad \text{for} \quad z \in \mathbf{C}, \tag{59}$$

which we call of Perelomov's type. We have to compute the action of the displacement operator

$$D(z) = \exp(za^+ - \bar{z}a^-) \tag{60}$$

on the ground state $|\psi_0\rangle$ of the quantum system under study. We will give the result of this action in a closed form. An illustration is treated for the Pöschl–Teller and square-well potentials (in Sec. VI).

Using the actions of the annihilation and creation operators on the Hilbert space $\{|\psi_n\rangle, n = 0,1,2,\ldots\}$ (Eqs. (26) and (27)), one can, after more or less complicated computations, show that the states $|z,\alpha\rangle$ can be written as follows:

$$|z,\alpha\rangle = \sum_{n=0}^{+\infty} \frac{z^n}{\sqrt{F_n(|z|)}} e^{-iE_n\alpha}|\psi_n\rangle. \tag{61}$$

The quantities $F_n(|z|)$ satisfy

$$F_n(|z|)E(n)(c_n(|z|))^2 = 1, \tag{62}$$

where the coefficients $c_n(|z|)$ are given by

$$c_n(|z|) = \sum_{j=0}^{+\infty} \frac{(-|z|^2)^j}{(n+2j)!}\left(\sum_{i_1=1}^{n+1} E_{i_1}\sum_{i_2=1}^{i_1+1} E_{i_2}\cdots\sum_{i_j=1}^{i_{j-1}+1} E_{i_j}\right). \tag{63}$$

Setting

$$\pi(n+1,j)=\sum_{i_1=1}^{n+1} E_{i_1}\sum_{i_2=1}^{i_1+1} E_{i_2}\cdots\sum_{i_j=1}^{i_{j-1}+1} E_{i_j} \quad \text{and} \quad \pi(n+1,0)=1, \tag{64}$$

one can verify that the π's satisfy the following relation:

$$\frac{\pi(n+1,j)-\pi(n,j)}{E_{n+1}}=\pi(n+2,j-1). \tag{65}$$

Using this recurrence formula, one can show that the coefficients $c_n(|z|=r)$ satisfy the following differential equation:

$$\frac{dc_n(r)}{dr}=\frac{1}{r}c_{n-1}(r)-\frac{n}{r}c_n(r)-E_{n+1}c_{n+1}(r)r. \tag{66}$$

Hence, solving this equation, we can obtain explicitly the coherent states $|z,\alpha\rangle$ of Perelomov's type. Of course, to solve this equation for an arbitrary quantum system is, in general, not an easy task. However, solutions in some particular (and interesting physical system) will be given in Sec. VI. Here, as a first illustration of the approach leading to coherent states of Perelomov's type, we give the standard harmonic oscillator coherent states using the above considerations. In this case we show that (61) coincides with (2). For the harmonic oscillator $E_n=n$ and $E(n)=n!$.

To solve Eq. (66), we set

$$c_n(r)=\frac{1}{n!}\sum_{m=0}^{+\infty} a_m r^m. \tag{67}$$

Substituting this expression in (66), we get the coefficients a_m,

$$a_{2p}=\frac{(-1)^p}{2^p p!}a_0 \quad \text{and} \quad a_{2p+1}=0, \tag{68}$$

where $a_0=1$ because $c_0(r=0)=1$. Finally, we have

$$F_n(|z|)=n!\exp(|z|^2) \tag{69}$$

and

$$|z,\alpha\rangle=\exp\left(-\frac{|z|^2}{2}\right)\sum_{n=0}^{+\infty}\frac{z^n}{\sqrt{n!}}e^{-i\alpha n}|n\rangle. \tag{70}$$

We recover a well-known result.

V. GENERALIZED INTELLIGENT STATES

These states minimize the Robertson–Schrödinger uncertainty relation,[18,19] and generalize the Gazeau–Klauder coherent states.

Using the creation a^+ and annihilation a^- operators, we introduce the Hermitian operators

$$X=\frac{1}{\sqrt{2}}(a^+ + a^-), \quad P=\frac{i}{\sqrt{2}}(a^+ - a^-), \tag{71}$$

which satisfy the commutation relation

$$[X,P]=iG(N)\equiv iG. \tag{72}$$

The operator $G(N)$, defined by (34) is not necessarily a multiple of the unit operator (for an arbitrary quantum system). It is well known that for two Hermitian operators X and P satisfying the noncanonical commutation relation (72), the variances $(\Delta X)^2$ and $(\Delta P)^2$ satisfy the Robertson–Schrödinger uncertainty relation

$$(\Delta X)^2(\Delta P)^2 \geqslant \tfrac{1}{4}(\langle G\rangle^2+\langle F\rangle^2), \tag{73}$$

where the operator F is defined by

$$F=\{X-\langle X\rangle, P-\langle P\rangle\} \tag{74}$$

or by

$$F=i[(2a^- -\langle a^-\rangle)\langle a^-\rangle+(-2a^+ +\langle a^+\rangle)\langle a^+\rangle - a^{-2}+a^{+2}] \tag{75}$$

in terms of the operators a^- and a^+. The symbol $\{,\}$ in (74) stands for the anticommutator. When there is a correlation between X and P, i.e., $\langle F\rangle \neq 0$, the relation (73) is a generalization of the usual one (the Heisenberg uncertainty condition),

$$(\Delta X)^2(\Delta P)^2 \geqslant \tfrac{1}{4}\langle G\rangle^2. \tag{76}$$

The special form (76) is identical to the general form (73) if X and P are uncorrelated, i.e., $\langle F\rangle = 0$. The general uncertainty relation (73) is better suited to determine the lower bound on the product of variances in the measurement of observables corresponding to the noncanonical operators. The so-called generalized intelligent states are obtained when the equality in the Robertson–Schrödinger uncertainty relation is realized.[20] The inequality in (73) becomes equality for the states satisfying the equation (see also Refs. 20–23)

$$(X+i\lambda P)|\psi\rangle = z\sqrt{2}|\psi\rangle, \quad \lambda, z\in \mathbf{C}. \tag{77}$$

As a consequence, we have the following relations

$$(\Delta X)^2=|\lambda|\Delta, \quad (\Delta P)^2=\frac{1}{|\lambda|}\Delta, \tag{78}$$

with

$$\Delta=\tfrac{1}{2}\sqrt{\langle G\rangle^2+\langle F\rangle^2}. \tag{79}$$

The average values $\langle G\rangle$ and $\langle F\rangle$, in the states satisfying the eigenvalue equation (77) can be expressed in terms of the variances as follows:

$$\langle G\rangle = 2\,\mathrm{Re}(\lambda)\langle\Delta P\rangle^2, \quad \langle F\rangle = 2\,\mathrm{Im}(\lambda)\langle\Delta P\rangle^2. \tag{80}$$

It is clear, from (78) that if $|\lambda|=1$, we have

$$(\Delta X)^2=(\Delta P)^2. \tag{81}$$

We call the states satisfying (81) with $|\lambda|=1$ the generalized coherent states. For $|\lambda|\neq 1$, the states are called generalized squeezed states.

Using Eq. (77) one can obtain some general relations for the average values and dispersions of X and P in the states which minimize the Robertson–Schrödinger uncertainty relation (73). We have

$$(\Delta X)^2=\tfrac{1}{2}(\mathrm{Re}(\lambda)\langle G\rangle+\mathrm{Im}(\lambda)\langle F\rangle), \tag{82}$$

$$(\Delta P)^2=\frac{1}{2|\lambda|^2}(\mathrm{Re}(\lambda)\langle G\rangle+\mathrm{Im}(\lambda)\langle F\rangle), \tag{83}$$

$$\mathrm{Im}(\lambda)\langle G\rangle=\mathrm{Re}(\lambda)\langle F\rangle. \tag{84}$$

In order to give a complete classification of the so-called generalized intelligent states for an arbitrary quantum system, we have to solve the eigenvalue equation (77). Such computation was considered previously by the authors in Refs. 15 and 16. The states minimizing the Robertson–Schrödinger uncertainty relation are given by

$$|\psi\rangle\equiv|z,\lambda,\alpha\rangle=\sum_{n=0}^{+\infty} d_n|\psi_n\rangle, \quad d_n\equiv d_n(z,\alpha,\lambda). \tag{85}$$

For the case where $\lambda\neq -1$, the coefficients d_n are given by the following expression:

$$d_n=d_0\frac{(2z)^n}{(1+\lambda)^n\sqrt{E(n)}}\left[\sum_{h=0(1)[n/2]}(-1)^h\frac{(1-\lambda^2)^h}{(2z)^{2h}}\Delta(n,h)\right]e^{-i\alpha E_n}, \tag{86}$$

where the symbol $[n/2]$ stands for the integer part of $n/2$ and the function $\Delta(n,h)$ is defined by

$$\Delta(n,h)=\sum_{j_1=1}^{n-(2h-1)} E_{j_1}\left[\sum_{j_2=j_1+2}^{n-(2h-3)} E_{j_2}\cdots\left[\cdots\left[\sum_{j_h=j_{h-1}+2}^{n-1} E_{j_h}\right]\right]\cdots\right]. \tag{87}$$

We note that the case $\lambda=-1$, leading to the unnormalized solution, is not of interest.

The states $|z,\lambda,\alpha\rangle$ can be also given as the action of some operator on the ground state $|\psi_0\rangle$ of H. A more or less complicated manipulation gives the following result:

$$|z,\lambda,\alpha\rangle=U(\lambda,z)|\psi_0\rangle, \tag{88}$$

where

$$U(\lambda,z)=d_0\sum_{n=0}^{\infty}\left(\left(\frac{2z}{\lambda+1}\right)\frac{a^+}{g(N)}+\left(\frac{\lambda-1}{\lambda+1}\right)\frac{1}{g(N)}(a^+)^2\right)^n. \tag{89}$$

Note that the states $|z,\lambda,\alpha\rangle$ are stable temporally. As a first illustration of this construction, we can obtain the generalized intelligent states for the standard harmonic oscillator ($g(N)=N$). We have (up to normalization constant)

$$|z,\lambda,\alpha\rangle=\exp\left[\left(\frac{\lambda-1}{\lambda+1}\right)\frac{(a^+)^2}{2}\right]\exp\left[\left(\frac{2z}{\lambda+1}\right)a^+\right]|0\rangle, \tag{90}$$

where $|0\rangle$ is the ground states for the harmonic oscillator.

The Gazeau–Klauder coherent states correspond to the situation $\lambda=1$. In this case, the coefficients d_n are given by

$$d_n=d_0\frac{z^n}{\sqrt{E(n)}}e^{-i\alpha E_n}, \tag{91}$$

and the coherent states $|z,\lambda=1,\alpha\rangle$ coincide with Gazeau–Klauder ones $|z,\alpha\rangle$ given by Eq. (38). The normalization factor d_0 is given by Eq. (39). The states $|z,\lambda=1,\alpha\rangle\equiv|z,\alpha\rangle$ minimize the Heisenberg uncertainty relation (76) and are eigenvectors of the annihilation operator a^-. We have

$$(\Delta X)^2=(\Delta P)^2=\tfrac{1}{2}\langle G\rangle, \tag{92}$$

where

$$\langle G\rangle=d_0^2\sum_{n=0}^{+\infty}\frac{|z|^{2n}}{E(n)}E_{n+1}-|z|^2 \quad \text{and} \quad \langle F\rangle=0. \tag{93}$$

The latter equation traduces the fact that there is no correlation between X and P. For the harmonic oscillator, it is easy to see that $\langle G\rangle=1$ and 2 $(\Delta X)^2=2(\Delta P)^2=1$.

As we mentioned above, the coherent states minimizing Robertson–Schrödinger uncertainty relation correspond to the case $|\lambda|=1$. The case $\lambda=1$ corresponds to the Gazeau–Klauder coherent states and $\lambda=-1$ is not allowed by our construction. Setting $\lambda=e^{i\theta}$ ($\theta\neq k\pi;k\in\mathbf{N}$), the states $|z,\lambda,\alpha\rangle$ are coherent and dispersions are given by

$$(\Delta X)^2=(\Delta P)^2=\frac{1}{2|\cos\theta|}\langle G\rangle. \tag{94}$$

The main value of the operator F is nonvanishing (vanishes only in the Gazeau–Klauder coherent states, i.e., $\lambda=1$) and it is given by

$$\langle F\rangle=\mathrm{tg}\theta\langle G\rangle. \tag{95}$$

From the latter equation, we conclude that the presence of the correlation ($\langle F\rangle\neq 0$) does not forbid the system to be prepared in coherent states. This result is true for any quantum system. The properties of the states $|z,\lambda,\alpha\rangle$ turned out to be sensitive about the spectral properties of the commutator $[a^-,a^+]=G(N)$.

To close this section, we note that the minimization of the Robertson–Schrödinger uncertainty relation leads to more general expressions of coherent states associated to an arbitrary quantum system. The Gazeau–Klauder coherent states ($\lambda=1$) (eigenvectors of the annihilation operator) constitute a particular case of such coherent state classess ($|\lambda|=1$).

VI. APPLICATION: PÖSCHL–TELLER POTENTIALS

We start by recalling the eigenvalues and eigenstates of infinite square well and Pöschl–Teller potentials[24] (see also Ref. 25 and references therein). We consider the Hamiltonian

$$H=-\frac{d^2}{dx^2}+V_{\kappa,\kappa'}(x) \tag{96}$$

describing a particle on the line, and submitted to the potential

$$V_{\kappa,\kappa'}(x)=\begin{cases}\dfrac{1}{4a^2}\left[\dfrac{\kappa(\kappa-1)}{\sin^2(x/2a)}+\dfrac{\kappa'(\kappa'-1)}{\cos^2(x/2a)}\right]-\dfrac{(\kappa+\kappa')^2}{4a^2}, & 0<x<\pi a\\ \infty \quad x\leqslant 0, \quad x\geqslant \pi a,\end{cases} \tag{97}$$

for $\kappa>1$ and $\kappa'>1$. It is well known that the Pöschl–Teller potentials interpolate between the harmonic oscillator and infinite square well. The infinite square well takes place in the limit $\kappa=\kappa'=1$.

The Hamiltonian H can be written in the factorized form

$$H=A^+_{\kappa,\kappa'}A^-_{\kappa,\kappa'}, \tag{98}$$

where the operators $A^-_{\kappa,\kappa'}$ and $A^+_{\kappa,\kappa'}$ are given by

$$A^{\pm}_{\kappa,\kappa'} = \mp \frac{d}{dx} + W_{\kappa,\kappa'}(x) \tag{99}$$

in terms of the superpotentials $W_{\kappa,\kappa'}(x)$,

$$W_{\kappa,\kappa'}(x) = \frac{1}{2a}\left[\kappa \mathrm{cotg}\left(\frac{x}{2a}\right) - \kappa' \tan\left(\frac{x}{2a}\right)\right]. \tag{100}$$

The eigenvectors are given by

$$\psi_n(x) = [c_n(\kappa,\kappa')]^{-1/2}\left(\cos\frac{x}{2a}\right)^{\kappa'}\left(\sin\frac{x}{2a}\right)^{\kappa} P_n^{(\kappa-1/2,\kappa'-1/2)}\left(\cos\left(\frac{x}{a}\right)\right) \tag{101}$$

with $c_n(\kappa,\kappa')$ the normalization constant which takes the form

$$c_n(\kappa,\kappa') = a\frac{\Gamma(n+\kappa+1/2)\Gamma(n+\kappa'+1/2)}{\Gamma(n+1)\Gamma(n+\kappa+\kappa')\Gamma(2n+\kappa+\kappa')} \tag{102}$$

and $P_n^{(\alpha,\beta)}$'s stands for the Jacobi polynomials.

The eigenvalues of H are given by

$$H|\psi_n\rangle = n(n+\kappa+\kappa')|\psi_n\rangle. \tag{103}$$

To find the annihilation and creation operators for the Pöschl–Teller system, we follow the strategy given in Sec. II. So, we denote H by H_- and $V_{\kappa,\kappa'}(x)$ by $V^-_{\kappa,\kappa'}(x)$. The Hamiltonian $H_+ = A^-_{\kappa,\kappa'}A^+_{\kappa,\kappa'}$ (supersymmetric partner of $H \equiv H_-$),

$$H_+ = -\frac{1}{2}\frac{d^2}{dx^2} + V^+_{\kappa,\kappa'}(x), \tag{104}$$

describes a quantum system trapped in the potentials

$$V_{\kappa,\kappa'}(x) = \begin{cases} \dfrac{1}{8a^2}\left[\dfrac{\kappa(\kappa-1)}{\sin^2(x/2a)} + \dfrac{\kappa'(\kappa'-1)}{\cos^2(x/2a)}\right] - \dfrac{(\kappa+\kappa')^2}{8a^2}, & 0 < x < \pi a, \\ 0, \quad x \leqslant 0, \quad x \geqslant \pi a. \end{cases} \tag{105}$$

The eigenstates of H_+ are given by

$$\theta_n(x) = [c_n(\kappa+1,\kappa'+1)]^{-1/2}\left(\cos\frac{x}{2a}\right)^{\kappa'+1}\left(\sin\frac{x}{2a}\right)^{\kappa+1} P_n^{(\kappa+1/2,\kappa'+1/2)}\left(\cos\left(\frac{x}{a}\right)\right), \tag{106}$$

where the $c_n(\kappa,\kappa')$ are defined by (102).

The eigenvalues are $e_n = (n+1)(n+\kappa+\kappa'+1)$. Using the operators $A^-_{\kappa,\kappa'}$ and $A^+_{\kappa,\kappa'}$ and the unitary transformation U connecting $\psi_n(x)$ and $\theta_n(x)$ (see Sec. II), we define the creation and annihilation operators by

$$a^+_{\kappa,\kappa'} = A^+_{\kappa,\kappa'}U \quad \text{and} \quad a^-_{\kappa,\kappa'} = U^+A^-_{\kappa,\kappa'}. \tag{107}$$

The creation and annihilation operators $a^+_{\kappa,\kappa'}$ and $a^-_{\kappa,\kappa'}$ act on $|\psi_n\rangle$ as follows,

$$\begin{aligned} a^+_{\kappa,\kappa'}|\psi_n\rangle &= \sqrt{(n+1)(n+1+\kappa+\kappa')}e^{-i\alpha(2n+1+\kappa+\kappa')}|\psi_{n+1}\rangle, \\ a^-_{\kappa,\kappa'}|\psi_n\rangle &= \sqrt{n(n+\kappa+\kappa')}e^{i\alpha(2n-1+\kappa+\kappa')}|\psi_{n-1}\rangle, \end{aligned} \tag{108}$$

and satisfy the following commutation relation,

$$[a^{-}_{\kappa,\kappa'}, a^{+}_{\kappa,\kappa'}] = G_{\kappa,\kappa'}(N), \tag{109}$$

where

$$G_{\kappa,\kappa'}(N) \equiv G(N) = 2N + (1 + \kappa + \kappa'). \tag{110}$$

We note that $N \neq a^{+}_{\kappa,\kappa'} a^{-}_{\kappa,\kappa'} = H$.

A. Gazeau–Klauder coherent states

Using the result of Sec. III, the so-called Gazeau–Klauder coherent states (eigenstates of the annihilation operator $a^{-}_{\kappa,\kappa'}$) read as

$$|z,\alpha\rangle = \mathcal{N}(|z|) \sum_{n=0}^{+\infty} \frac{z^n e^{-i\alpha n(n+\kappa+\kappa')}}{\sqrt{\Gamma(n+1)\Gamma(n+\kappa+\kappa'+1)}} |\psi_n\rangle, \tag{111}$$

with $\mathcal{N}(|z|)$ the normalization constant which takes the form

$$[\mathcal{N}(|z|)]^2 = \frac{|z|^{\kappa+\kappa'}}{I_{\kappa+\kappa'}(2|z|)}, \tag{112}$$

where $I_{\kappa+\kappa'}(2|z|)$ is the modified Bessel function of the first kind.

The identity resolution is given explicitly by

$$\int |z,\alpha\rangle\langle z,\alpha| d\mu(z) = I_{\mathcal{H}}, \tag{113}$$

where the measure can be computed by the inverse Mellin transform[26]

$$d\mu(z) = \frac{2}{\pi} I_{\kappa+\kappa'}(2r) K_{(\kappa+\kappa)'/2}(2r) r dr d\phi, \quad z = r^{i\phi}. \tag{114}$$

The Gazeau–Klauder coherent states of the infinite square well are obtained from the Pöschl–Teller ones simply by putting $\kappa + \kappa' = 2$.

The Gazeau–Klauder coherent states form an overcomplete family of states (resolving the unity by integration with respect to the measure given by (114)), and provide a representation of any state $|f\rangle$ by an entire function

$$f(z,\alpha) = \sqrt{\frac{I_{\kappa+\kappa'}(2|z|)}{|z|^{\kappa+\kappa'}}} \langle \overline{z},\alpha | f\rangle = \sum_{n=0}^{+\infty} \langle \psi_n | f\rangle \frac{z^n e^{i\alpha n(n+\kappa+\kappa')}}{\sqrt{\Gamma(n+1)\Gamma(n+\kappa+\kappa'+1)}}. \tag{115}$$

In particular, the analytic functions corresponding to the vectors $|\psi_n\rangle$ are

$$\mathcal{F}_n(z,\alpha) = \frac{z^n e^{i\alpha n(n+\kappa+\kappa')}}{\sqrt{\Gamma(n+1)\Gamma(n+\kappa+\kappa'+1)}}. \tag{116}$$

Using the Fock–Bargmann representation discussed in Sec. III B, the creation and annihilation operators, for a quantum system evolving in Pöschl–Teller (or in the infinite square well) potentials, are realized by

$$a^{+}_{\kappa,\kappa'} = z, \quad a^{-}_{\kappa,\kappa'} = z \frac{d^2}{dz^2} + (\kappa + \kappa' + 1) \frac{d}{dz}, \tag{117}$$

and the operator $G_{\kappa,\kappa'}(N)$, in this representation, acts as

$$G=2z\frac{d}{dz}+(\kappa+\kappa'+1). \tag{118}$$

In fact, one can verify that

$$a^{+}_{\kappa,\kappa'}\mathcal{F}_n(z,\alpha)=\sqrt{(n+1)(n+1+\kappa+\kappa')}e^{-i\alpha(2n+1+\kappa+\kappa')}\mathcal{F}_{n+1}(z,\alpha), \tag{119}$$

$$a^{-}_{\kappa,\kappa'}\mathcal{F}_n(z,\alpha)=\sqrt{n(n+\kappa+\kappa')}e^{i\alpha(2n-1+\kappa+\kappa')}\mathcal{F}_{n-1}(z,\alpha), \tag{120}$$

$$G_{\kappa,\kappa'}(N)\mathcal{F}_n(z,\alpha)=(2n+1+\kappa+\kappa')\mathcal{F}_n(z,\alpha). \tag{121}$$

This realization will be useful, as we will see, to construct the Pöschl–Teller generalized intelligent states which minimize the Robertson–Schrödinger uncertainty relation.

B. Pöschl–Teller coherent states of Perelomov's type

In Sec. IV, we defined coherent states of Perelomov's type for an arbitrary quantum system. The expressions of these states are given by infinite series (more or less complicated). As a first illustration, we discussed the harmonic oscillator system. Here, we construct the Pöschl–Teller coherent states à la Perelomov. In this order, we have to solve the differential equation (66) for the Pöschl–Teller potentials ($E_n=n(n+\kappa+\kappa')$). In this case, the solutions are

$$c_n(r)=\frac{1}{n!r^n}ß^{-(1/2)(\kappa+\kappa'+1)}_{m,n+(1/2)(\kappa+\kappa'+1)}(\cosh(2r)), \tag{122}$$

because the Jacobi functions ß satisfy the following differential equation.[27]

$$\frac{d}{dr}ß^{l}_{m,n-l}(\cosh(2r))=nß^{l}_{m,n-1-l}(\cosh(2r))-(n-2l)ß^{l}_{m,n+1-l}(\cosh(2r)), \tag{123}$$

where $l=-\frac{1}{2}(\kappa+\kappa'+1)$ and m is a free integer parameter which will be fixed after. These functions play an important role in the representation theory of the $QU(2)$ group of unimodular quasi-unitary matrices.

The differential equation (123) admits several solutions. However, an admissible solution is obtained by noting that $D(z=0)=\mathbf{1}$. Using the definition of the Jacobi functions,[27] the unique solution, compatible with the condition $D(z=0)=\mathbf{1}$, is given by

$$c_n(r)=\frac{1}{n!r^n}ß^{-(1/2)(\kappa+\kappa'+1)}_{(1/2)(\kappa+\kappa'+1),n+(1/2)(\kappa+\kappa'+1)}(\cosh(2r)), \tag{124}$$

which can be written also as

$$c_n(r)=\frac{1}{n!}(\cosh(r))^{-(\kappa+\kappa'+1)}\left(\frac{\tanh r}{r}\right)^n. \tag{125}$$

The coherent states of Perelomov's type take the form

$$|z,\alpha\rangle=(1-\tanh^2|z|)^{(1/2)(\kappa+\kappa'+1)}\sum_{n=0}^{+\infty}\left(\frac{z\tanh|z|}{|z|}\right)^n \times\left[\frac{\Gamma(n+\kappa+\kappa'+1)}{\Gamma(n+1)\Gamma(\kappa+\kappa'+1)}\right]^{1/2}e^{-i\alpha n(n+\kappa+\kappa')}|\psi_n\rangle. \tag{126}$$

Finally, setting $\zeta = z\tanh|z|/|z|$, we obtain

$$|\zeta,\alpha\rangle \equiv (1-|\zeta|^2)^{(1/2)(\kappa+\kappa'+1)} \sum_{n=0}^{+\infty} \zeta^n \left[\frac{\Gamma(n+\kappa+\kappa'+1)}{\Gamma(n+1)\Gamma(\kappa+\kappa'+1)}\right]^{1/2} e^{-i\alpha n(n+\kappa+\kappa')}|\psi_n\rangle. \quad (127)$$

We note that the parameter ζ belongs to the unit disk $D=\{\zeta\in\mathbf{C}, |\zeta|<1\}$.

The states are stable temporally. Indeed,

$$e^{-iHt}|\zeta,\alpha\rangle = |\zeta,\alpha+t\rangle. \quad (128)$$

The identity resolution is given by

$$\int |\zeta,\alpha\rangle\langle\zeta,\alpha| d\mu(\zeta) = I_{\mathcal{H}}, \quad (129)$$

where the measure is

$$d\mu(\zeta) = \frac{\kappa+\kappa'}{\pi}\frac{d^2\zeta}{(1-|\zeta|^2)^2}. \quad (130)$$

There are two main consequences arising from the former result. First, we can express any coherent state $|\zeta',\alpha'\rangle$ in terms of the others:

$$|\zeta',\alpha'\rangle = \int |\zeta,\alpha\rangle\langle\zeta,\alpha|\zeta',\alpha'\rangle d\mu(\zeta). \quad (131)$$

The kernel $\langle\zeta,\alpha|\zeta',\alpha'\rangle$ is easy to evaluate from (127):

$$\langle\zeta,\alpha|\zeta',\alpha'\rangle = \sqrt{(1-|\zeta|^2)^{(\kappa+\kappa'+1)}(1-|\zeta'|^2)^{(\kappa+\kappa'+1)}} \times \sum_{n=0}^{+\infty} \overline{\zeta}^n \zeta'^n \frac{\Gamma(n+\kappa+\kappa'+1)}{\Gamma(n+1)\Gamma(\kappa+\kappa'++1)} e^{-i(\alpha'-\alpha)n(n+\kappa+\kappa')}. \quad (132)$$

The coherent states are normalized ($\langle\zeta,\alpha|\zeta,\alpha\rangle=1$), but they are not orthogonal to each other.

Second, an arbitrary element state of the Hilbert space $\mathcal{H}$, let us call it $|f\rangle$, can be written in terms of the coherent states,

$$|f\rangle = \int (1-|\zeta|^2)^{(1/2)(\kappa+\kappa'+1)} f(\overline{\zeta},\alpha)|\zeta,\alpha\rangle d\mu(\zeta), \quad (133)$$

where the analytic function

$$f(\overline{\zeta},\alpha) = (1-|\zeta|^2)^{-(1/2)(\kappa+\kappa'+1)}\langle\overline{\zeta},\alpha|f\rangle \sum_{n=0}^{+\infty} \zeta^n \left[\frac{\Gamma(n+\kappa+\kappa'+1)}{\Gamma(n+1)\Gamma(\kappa+\kappa'+1)}\right]^{1/2} e^{i\alpha n(n+\kappa+\kappa')}\langle\psi_n|f\rangle \quad (134)$$

determines in a complete way the state $|f\rangle\in\mathcal{H}$. The state $|\psi_n\rangle$ is represented by the function

$$\mathcal{F}'_n(\zeta,\alpha) = \zeta^n \left[\frac{\Gamma(n+\kappa+\kappa'+1)}{\Gamma(n+1)\Gamma(\kappa+\kappa'+1)}\right]^{1/2} e^{i\alpha n(n+\kappa+\kappa')}. \quad (135)$$

The creation $a^+_{\kappa,\kappa'}$, annihilation $a^-_{\kappa,\kappa'}$, and $G_{\kappa,\kappa'}(N)$ operators act in the Hilbert space of analytic functions $f(\zeta,\alpha)$ as first-order differential operators:

$$a^{+}_{\kappa,\kappa'}=\zeta^2\frac{d}{d\zeta}+(\kappa+\kappa'+1)\zeta,\quad a^{-}_{\kappa,\kappa'}=\frac{d}{d\zeta},$$
$$G_{\kappa,\kappa'}(N)\equiv G=2\zeta\frac{d}{d\zeta}+(\kappa+\kappa'+1). \tag{136}$$

One can verify that

$$a^{+}_{\kappa,\kappa'}\mathcal{F}'_n(\zeta,\alpha)=\sqrt{(n+1)(n+1+\kappa+\kappa')}e^{-i\alpha(2n+1+\kappa+\kappa')}\mathcal{F}'_{n+1}(\zeta,\alpha), \tag{137}$$

$$a^{-}_{\kappa,\kappa'}\mathcal{F}'_n(\zeta,\alpha)=\sqrt{n(n+\kappa+\kappa')}e^{i\alpha(2n-1+\kappa+\kappa')}\mathcal{F}'_{n-1}(\zeta,\alpha), \tag{138}$$

$$G_{\kappa,\kappa'}(N)\mathcal{F}'_n(\zeta,\alpha)=(2n+1+\kappa+\kappa')\mathcal{F}'_n(\zeta,\alpha). \tag{139}$$

The analytic representation of the Gazeau–Klauder coherent states and the analytical realization of the Perelomov ones in the unit disk are related through a Laplace transform. Indeed, one can verify easily that

$$\mathcal{F}'_n(\zeta,\alpha)=\frac{\zeta^{-(\kappa+\kappa'+1)}}{\sqrt{\Gamma(\kappa+\kappa'+1)}}\int_0^{+\infty}z^{\kappa+\kappa'}\mathcal{F}_n(z,\alpha)e^{-z/\zeta}dz, \tag{140}$$

which means that the function $\mathcal{F}'_n(1/\zeta,\alpha)$ is the Laplace transform of $z^{\kappa+\kappa'}\mathcal{F}_n(z,\alpha)$. A similar result was obtained in Ref. 28 showing that the representation in the unit disk and Barut–Girardello one, based on the su(1,1) coherent states, are related through a Laplace transform.

C. Pöschl–Teller generalized intelligent states

The generalized intelligent states can be determined by using two analytic representation, one based on the so-called Gazeau–Klauder coherent states (Sec. III) and the other one on the Perelomov's coherent states (Sec. IV).

1. The Gazeau–Klauder analytic representation

We introduce the analytic function

$$\Phi_{(z',\lambda,\alpha)}(z)=\sqrt{\frac{I_{\kappa+\kappa'}(2|z|)}{|z|^{\kappa+\kappa'}}}\langle\overline{z},\alpha|z',\lambda,\alpha\rangle \tag{141}$$

by means of which one converts the eigenvalues equation

$$[(1+\lambda)a^{-}_{\kappa,\kappa'}+(1-\lambda)a^{+}_{\kappa,\kappa'}]|z',\lambda,\alpha\rangle=2z'|z',\lambda,\alpha\rangle \tag{142}$$

into the second-order linear homogeneous differential equation

$$\left[(1+\lambda)\left(z\frac{d^2}{dz^2}+(\kappa+\kappa'+1)\frac{d}{dz}\right)+(1-\lambda)z-2z'\right]\Phi_{(z',\lambda)}(z)=0. \tag{143}$$

We first consider the general case $\lambda\neq\pm1$. Setting

$$\Phi_{(z',\lambda)}(z)=\exp\left(\pm\sqrt{\frac{\lambda-1}{\lambda+1}}z\right)F_{(z',\lambda)}(z), \tag{144}$$

the equation can be transformed in the Kummer equation

$$\left[Z\frac{d^2}{dZ^2}+(\kappa+\kappa'+1-Z)\frac{d}{dZ}-\left(\frac{\kappa+\kappa'+1}{2}\mp\frac{z'}{\sqrt{\lambda^2-1}}\right)\right]F_{(z',\lambda)}(z)=0, \tag{145}$$

where $Z=\mp 2\sqrt{(\lambda-1)/(\lambda+1)}z$.

Then the solutions of Eq. (143) are given by

$$\Phi_{(z',\lambda)}(z)=\exp\left(\pm\sqrt{\frac{\lambda-1}{\lambda+1}}z\right)\,{}_1F_1\left(\frac{\kappa+\kappa'+1}{2}\mp\frac{z'}{\sqrt{\lambda^2-1}},\kappa+\kappa'+1;\mp 2\sqrt{\frac{\lambda-1}{\lambda+1}}z\right) \tag{146}$$

or

$$\Phi_{(z',\lambda)}(z)=\exp\left(\pm\sqrt{\frac{\lambda-1}{\lambda+1}}z\right)z^{-(\kappa+\kappa')}{}_1F_1\left(\frac{1-(\kappa+\kappa')}{2}\mp\frac{z'}{\sqrt{\lambda^2-1}},1-(\kappa+\kappa');\mp 2\sqrt{\frac{\lambda-1}{\lambda+1}}z\right). \tag{147}$$

The first solution (146) is always analytic, but the solution (147) is not. (Remember that $\kappa>1$ and $\kappa'>1$.) The upper and lower signs in Eq. (146) are equivalent, because the confluent hypergeometric function ${}_1F_1(\alpha,\gamma;z)$ can be written in two equivalents forms which are related by Kummer's transformation:

$${}_1F_1(\alpha,\gamma;z)=e^z{}_1F_1(\gamma-\alpha,\gamma,-z). \tag{148}$$

Using the properties of this hypergeometric functions, we conclude that the squeezing parameter λ obeys the condition

$$\sqrt{\left|\frac{\lambda-1}{\lambda+1}\right|}<1\Leftrightarrow \mathrm{Re}(\lambda)>0, \tag{149}$$

which is exactly the restriction on λ imposed by the positivity of the commutator $[a^-_{\kappa,\kappa'},a^+_{\kappa,\kappa'}]=G_{\kappa,\kappa'}(N)$ [see Eqs. (109) and (110)].

We consider now the degenerate cases $\lambda=-1$ and $\lambda=1$. For the $\lambda=-1$ Eq. (143) does not have any normalized analytic solution (the operator $a^+_{\kappa,\kappa'}$ does not have any eigenstate). For $\lambda=1$, using the power series of ${}_1F_1(a,b;z)$, we get

$$\Phi_{(z',\lambda=1)}(z)={}_0F_1(\kappa+\kappa'+1;zz'). \tag{150}$$

The result (150) coincides with the solution (111) (up to normalization constant) for $\lambda=1$, and we recover the Pöschl–Teller coherent states defined as the $a^-_{\kappa,\kappa'}$ eigenstates.

2. The Perelomov coherent state basis and analytic representation in the unit disk

To solve the eigenvalues equation (142), using the analytic representation of Perelomov coherent states in the unit disk, we introduce the analytic function

$$\Phi_{(\zeta',\lambda)}(\zeta)=(1-|\zeta|^2)^{-(1/2)(\kappa+\kappa'+1)}\langle\overline{\zeta},\alpha|\zeta',\lambda,\alpha\rangle. \tag{151}$$

Equation (142) is then converted to the following differential equation:

$$\left[[(1-\lambda)\zeta^2+(1+\lambda)]\frac{d}{d\zeta}+(1-\lambda)(\kappa'+\kappa+1)\zeta-2\zeta'\right]\Phi_{(\zeta',\lambda)}(\zeta)=0. \tag{152}$$

Admissible values of λ and ζ' are determined by the requirements that the functions $\Phi_{(\zeta',\lambda)}(\zeta)$ must be analytic in the unit disk. We consider the general case. The solution of Eq. (152) is

$$\Phi_{(\zeta',\lambda)}(\zeta)=\mathcal{N}^{-1/2}\prod_{l=\pm 1}\left(1+l\left(\frac{\lambda-1}{\lambda+1}\right)^{1/2}\zeta\right)^{-(1/2)(\kappa+\kappa'+1)+l\,\zeta'/\sqrt{\lambda^2-1}}, \tag{153}$$

where $\mathcal{N}$ is a normalization constant. The condition of analyticity requires

$$\left|\frac{\lambda-1}{\lambda+1}\right|<1\Leftrightarrow \mathrm{Re}\,\lambda>0. \tag{154}$$

If $\mathrm{Re}\,\lambda<0$, the function $\Phi_{(\zeta',\lambda)}(\zeta)$ cannot be analytic in the unit disk.

The decomposition of the generalized intelligent states $|\zeta',\lambda,\alpha\rangle$ over the Hilbert orthonormal basis $\{|\psi_n\rangle\}$ can be obtained by expanding the function $\Phi_{(\zeta',\alpha)}(\zeta)$ into a power series in ζ. This can be done using the following relations:

$$\left(1+\left(\frac{\lambda-1}{\lambda+1}\right)^{1/2}\zeta\right)^{\alpha_+}\left(1-\left(\frac{\lambda-1}{\lambda+1}\right)^{1/2}\zeta\right)^{\alpha_-}=\sum_{n=0}^{+\infty}\zeta^n\left(2\sqrt{\frac{\lambda-1}{\lambda+1}}\right)^n P_n^{(\alpha_+-n,\alpha_--n)}(0), \tag{155}$$

where

$$\alpha_\pm=-\frac{1}{2}(\kappa+\kappa'+1)\pm\frac{\zeta'}{\sqrt{\lambda^2-1}}. \tag{156}$$

Then, the function $\Phi_{(\zeta',\alpha)}(\zeta)$ can be expanded in terms of the Jacobi polynomials $P_n^{(\alpha,\beta)}(x)$. Using the relation between the hypergeometric function and Jacobi polynomials,[27] one can show

$$|\zeta',\lambda,\alpha\rangle=\mathcal{N}^{-1/2}\sum_{n=0}^{+\infty}\left[\frac{\Gamma(\kappa+\kappa'+1)}{n!\Gamma(\kappa+\kappa'+1+n)}\right]^{1/2}\left[\frac{\Gamma(\alpha_++1)}{\Gamma(\alpha_+-n+1)}\right]\left(2\sqrt{\frac{\lambda-1}{\lambda+1}}\right)^n$$
$$\times{}_2F_1(-n,-n-(\kappa+\kappa'),\alpha_+-n+1;\tfrac{1}{2})e^{-i\alpha E_n}|\psi_n\rangle \tag{157}$$

or

$$|\zeta',\lambda,\alpha\rangle=\mathcal{N}^{-1/2}\sum_{n=0}^{+\infty}\left[\frac{n!\Gamma(\kappa+\kappa'+1)}{\Gamma(\kappa+\kappa'+1+n)}\right]^{1/2}\left(2\sqrt{\frac{\lambda-1}{\lambda+1}}\right)^n P_n^{(\alpha_+-n,\alpha_--n)}(0)e^{-i\alpha E_n}|\psi_n\rangle. \tag{158}$$

The generalized intelligent states $\Phi_{(\zeta',\lambda)}(\zeta)$ and $\Phi_{(z',\lambda)}(z)$ are related through a Laplace transform. In fact, Eq. (152) can be written as

$$\left[[(1+\lambda)\zeta^2+(1-\lambda)]\frac{d}{d\zeta}-\frac{(1-\lambda)(\kappa'+\kappa+1)}{\zeta}+2\zeta'\right]\Phi_{(\zeta',\lambda)}\left(\frac{1}{\zeta}\right)=0. \tag{159}$$

Using

$$\Phi_{(\zeta',\lambda)}\left(\frac{1}{\zeta}\right)=\frac{\zeta^{-(\kappa+\kappa'+1)}}{\sqrt{\Gamma(\kappa+\kappa'+1)}}\int_0^{+\infty}z^{\kappa+\kappa'}\Phi_{(\zeta',\lambda)}(z)e^{-z/\zeta}dz. \tag{160}$$

It is easy to see that the eigenvalue equation (159) becomes

$$\left[(1+\lambda)\left(z\frac{d^2}{dz^2}+(\kappa+\kappa'+1)\frac{d}{dz}\right)+(1-\lambda)z-2\zeta'\right]\Phi_{(\zeta',\lambda)}(z)=0, \tag{161}$$

which coincides with those in (143) ($\zeta'=z'$) that gives the generalized intelligent states (146).

VII. SUMMARY

In this work, we have explicitly constructed the Gazeau–Klauder and Perelomov coherent states for an arbitrary quantum system. As an application of this construction, we considered the system trapped in the Pöschl–Teller potential type. We showed that the analytical representations of Gazeau–Klauder and Perelomov coherent states (which are related through a Laplace transform) enable us to compute the generalized intelligent states for the Pöschl–Teller potentials. Finally, it should be interesting to investigate further applications of the results obtained on this work. Indeed, it is interesting, in our opinion, to construct the coherent states and generalized intelligent states for the shape invariant potentials.[29] This matter will be considered in a forthcoming work.

(Received 27 February 2001; accepted for publication 3 October 2001)

We study the chaotic behavior and the quantum-classical correspondence for the Baker's map. Correspondence between quantum and classical expectation values is investigated and it is numerically shown that it is lost at the logarithmic timescale. The quantum chaos degree is computed and it is demonstrated that it describes the chaotic features of the model. The correspondence between classical and quantum chaos degrees is considered. © *2002 American Institute of Physics.*

I. INTRODUCTION

The study of chaotic behavior in classical dynamical systems dates back to Lobachevsky and Hadamard, who have studied the exponential instability property of geodesics on manifolds of negative curvature, and to Poincare, who initiated the inquiry into the stability of the solar system. One believes now that the main features of chaotic behavior in the classical dynamical systems are rather well understood (see, for example, Refs. 1 and 2). However, the status of ''quantum chaos'' is much less clear although significant progress has been made on this front.

Sometimes one says that an approach to quantum chaos, which attempts to generalize the classical notion of sensitivity to initial conditions, fails for two reasons: first, there is no quantum analog of the classical phase space trajectories and, second, the unitarity of linear Schrödinger equations precludes sensitivity to initial conditions in the quantum dynamics of state vector. Let us remind, however, that in fact there exists a quantum analog of the classical phase space trajectories. It is quantum evolution of expectation values of appropriate observables in suitable states. Also, let us remind that the dynamics of a classical system can be described either by the Hamilton equations or by the linear Liouville equations. In quantum theory the linear Schrödinger equation is the counterpart of the Liouville equation while the quantum counterpart of the classical Hamilton equation is the Heisenberg equation. Therefore, the study of quantum expectation values should reveal the chaotic behavior of quantum systems. In this article we demonstrate this fact for the quantum Baker's map.

If one has the classical Hamilton equations

$$dq/dt=p, \quad dp/dt=-V'(q),$$

then the corresponding quantum Heisenberg equations have the same form

$$dq_h/dt=p_h, \quad dp_h/dt=-V'(q_h),$$

where q_h and p_h are quantum canonical operators of position and momentum. For the expectation values one gets the Ehrenfest equations

a)Electronic mail: volovich@mi.ras.ru

$$d\langle q_h\rangle/dt=\langle p_h\rangle, \quad d\langle p_h\rangle/dt=-\langle V'(q_h)\rangle.$$

Note that the Ehrenfest equations are classical equations but for nonlinear $V'(q_h)$ they are neither Hamilton equations nor even differential equations because one can not write $\langle V'(q_h)\rangle$ as a function of $\langle q_h\rangle$ and $\langle p_h\rangle$. However, these equations are very convenient for the consideration of the semiclassical properties of quantum system. The expectation values $\langle q_h\rangle$ and $\langle p_h\rangle$ are functions of time and initial data. They also depend on the quantum states. One of important problems is to study the dependence of expectation values from the initial data. In this article we will study this problem for the quantum Baker's map.

The main objective of ''quantum chaos'' is to study the correspondence between classical chaotic systems and their quantum counterparts in the semiclassical limit.[3,4] The quantum-classical correspondence for dynamical systems has been studied for many years (see for example Refs. 5–10 and reference therein). A significant progress in understanding this correspondence has been achieved in the Wentzel–Kromers–Brillouin (WKB) approach when one considers the Planck constant h as a small variable parameter. Then it is well known that in the limit $h\to 0$ quantum theory is reduced to the classical one.[11] However, in physics the Planck constant is a fixed constant although it is very small. Therefore, it is important to study the relation between classical and quantum evolutions when the Planck constant is fixed. There is a conjecture[12–14,8] that a characteristic timescale τ appears in the quantal evolution of chaotic dynamical systems. For time less than τ there is a correspondence between quantum and classical expectation values, while for times greater that τ the predictions of the classical and quantum dynamics no longer coincide. The important problem is to estimate the dependence τ on the Planck constant h. Probably a universal formula expressing τ in terms of h does not exist and every model should be studied case by case. It is expected that certain quantum and classical expectation values diverge on a timescale inversely proportional to some power of h.[15] Other authors suggest that a breakdown may be anticipated on a much smaller logarithmic timescale.[16–23] The characteristic time τ associated with the hyperbolic fixed points of the classical motion is expected to be of the logarithmic form $\tau=(1/\lambda)\ln(C/h)$, where λ is the Lyapunov exponent and C is a constant which can be taken to be the classical action. Such a logarithmic timescale has been found in the numerical simulations of some dynamical models.[7] It was shown also that the discrepancy between quantum and classical evolutions is decreased by even a small coupling with the environment, which in the quantum case leads to decoherence.[7]

The chaotic behavior of the classical dynamical systems is often investigated by computing the Lyapunov exponents. An alternative quantity measuring chaos in dynamical systems, which is called the chaos degree, has been suggested in Ref. 24 in the general framework of information dynamics.[25] The chaos degree was applied to various models in Ref. 26. An advantage of the chaos degree is that it can be applied not only to classical systems but also to quantum systems as well.

In this work we study the chaotic behavior and the quantum-classical correspondence for the Baker's map.[15,27] The quantum Baker's map is a simple model invented for the theoretical study of quantum chaos. Its mathematical properties have been studied in numerical works. In particular its semiclassical properties have been considered,[16–23] quantum computing and optical realizations have been proposed,[28–30] various quantization procedures have been discussed,[18,31–33] and a symbolic dynamics representation has been given.[33]

It is well known that for the consideration of the semiclassical limit in quantum mechanics it is very useful to use coherent states. We define an analog of the coherent states for the quantum Baker's map. We study the quantum Baker's map by using the correlation functions of the special form which corresponds to the expectation values, translated in time by the unitary evolution operator and taken in the coherent states.

To explain our formalism we first discuss the classical limit for correlation functions in ordinary quantum mechanics. Correspondence between quantum and classical expectation values for the Baker's map is investigated and it is numerically shown that it is lost at the logarithmic timescale. The chaos degree for the quantum Baker's map is computed and it is demonstrated that

it describes the chaotic features of the model. The dependence of the chaos degree on the Planck constant is studied and the correspondence between classical and quantum chaos degrees is established.

II. QUANTUM VERSUS CLASSICAL DYNAMICS

In this section we discuss an approach to the semiclassical limit in quantum mechanics by using the coherent states (see Ref. 6). Then in the next section an extension of this approach to the quantum Baker's map will be given. Consider the canonical system with the Hamilton function

$$H=\frac{p^2}{2}+V(x) \tag{1}$$

in the plane $(p,x)\in\mathbf{R}^2$. We assume that the canonical equations

$$\dot{x}(t)=p(t), \quad \dot{p}(t)=-V'(x(t)) \tag{2}$$

have a unique solution $(x(t),p(t))$ for times $|t|<T$ with the initial data

$$x(0)=x_0, \quad p(0)=v_0. \tag{3}$$

This is equivalent to the solution of the Newton equation

$$\ddot{x}(t)=-V'(x(t)), \tag{4}$$

with the initial data

$$x(0)=x_0, \quad \dot{x}(0)=v_0. \tag{5}$$

We denote

$$\alpha=\frac{1}{\sqrt{2}}(x_0+iv_0). \tag{6}$$

The quantum Hamilton operator has the form

$$H_h=\frac{p_h^2}{2}+V(q_h),$$

where p_h and q_h satisfy the commutation relations

$$[p_h,q_h]=-ih.$$

The Heisenberg evolution of the canonical variables is defined as

$$p_h(t)=U(t)p_hU(t)^*, \quad q_h(t)=U(t)q_hU(t)^*,$$

where

$$U(t)=\exp(-itH_h/h).$$

For the consideration of the classical limit we take the following representation,

$$p_h=-ih^{1/2}\partial/\partial x, \quad q_h=h^{1/2}x,$$

acting to functions of the variable $x\in\mathbf{R}$. We also set

$$a=\frac{1}{\sqrt{2}h^{1/2}}(q_h+ip_h)=\frac{1}{\sqrt{2}}\left(x+\frac{\partial}{\partial x}\right),\quad a^*=\frac{1}{\sqrt{2}h^{1/2}}(q_h-ip_h)=\frac{1}{\sqrt{2}}\left(x-\frac{\partial}{\partial x}\right).$$

Then,

$$[a,a^*]=1.$$

The coherent state $|\alpha\rangle$ is defined as

$$|\alpha\rangle=W(\alpha)|0\rangle, \tag{7}$$

where α is a complex number, $W(\alpha)=\exp(\alpha a^*-a\alpha^*)$ and $|0\rangle$ is the vacuum vector, $a|0\rangle=0$. The vacuum vector is the solution of the equation

$$(q_h+ip_h)|0\rangle=0. \tag{8}$$

In the x-representation one has

$$|0\rangle=\exp(-x^2/2)/\sqrt{2\pi}. \tag{9}$$

The operator $W(\alpha)$ one can write also in the form

$$W(\alpha)=Ce^{iq_hv_0/h^{1/2}}e^{-ip_hx_0/h^{1/2}}, \tag{10}$$

where $C=\exp(-v_0x_0/2h)$.

The mean value of the position operator with respect to the coherent vectors is the real valued function

$$q(t,\alpha,h)=\langle h^{-1/2}\alpha|q_h(t)|h^{-1/2}\alpha\rangle. \tag{11}$$

Now one can present the following basic formula describing the semiclassical limit

$$\lim_{h\to 0}q(t,\alpha,h)=x(t,\alpha). \tag{12}$$

Here $x(t,\alpha)$ is the solution of (4) with the initial data (5) and α is given by (6).

Let us notice that for time $t=0$ the quantum expectation value $q(t,\alpha,h)$ is equal to the classical one:

$$q(0,\alpha,h)=x(0,\alpha)=x_0 \tag{13}$$

for any h. We are going to compare the time dependence of two real functions $q(t,\alpha,h)$ and $x(t,\alpha)$; these functions are approximately equal. The important problem is to estimate for which t the large difference between them will appear. It is expected that certain quantum and classical expectation values diverge on a timescale inversely proportional to some power of h.[15] Other authors suggest that a breakdown may be anticipated on a much smaller logarithmic timescale.[16–23] One of very interesting examples[5] of classical systems with chaotic behavior is described by the Hamilton function

$$H=\frac{p_1^2}{2}+\frac{p_2^2}{2}+\lambda x_1^2x_2^2.$$

The consideration of this classical and quantum model within the described framework will be presented in another publication.

III. COHERENT STATES FOR THE QUANTUM BAKER'S MAP

The classical Baker's transformation maps the unit square $0 \leqslant q,\ p \leqslant 1$ onto itself according to

$$(q,p) \to \begin{cases} (2q, p/2), & \text{if} \quad 0 \leqslant q \leqslant \frac{1}{2}, \\ (2q-1, (p+1)/2), & \text{if} \quad \frac{1}{2} < q \leqslant 1. \end{cases}$$

This corresponds to compressing the unit square in the p direction and stretching it in the q direction, while preserving the area, then cutting it vertically and stacking the right part on top of the left part.

The classical Baker's map has a simple description in terms of its symbolic dynamics.[34] Each point (q,p) is represented by a symbolic string

$$\xi = \cdots \xi_{-2} \xi_{-1} \xi_0 . \xi_1 \xi_2 \cdots, \tag{14}$$

where $\xi_k \in \{0,1\}$, and

$$q = \sum_{k=1}^{\infty} \xi_k 2^{-k}, \quad p = \sum_{k=0}^{\infty} \xi_{-k} 2^{-k-1}.$$

The action of the Baker's map on a symbolic string ξ is given by the shift map (Bernoulli shift) U defined by $U\xi = \xi'$, where $\xi'_k = \xi_{k+1}$. This means that, at each time step, the dot is shifted one place to the right while the entire string remains fixed. After n steps the q coordinate becomes

$$q_n = \sum_{k=1}^{\infty} \xi_{n+k} 2^{-k}. \tag{15}$$

This relation defines the classical trajectory with the initial data

$$q = q_0 = \sum_{k=1}^{\infty} \xi_k 2^{-k}. \tag{16}$$

Quantum Baker's maps are defined on the D-dimensional Hilbert space of the quantized unit square. To quantize the unit square one defines the Weyl unitary displacement operators $\hat{U}$ and $\hat{V}$ in D—dimensional Hilbert space, which produces displacements in the momentum and position directions, respectively, and the following commutation relation is obeyed,

$$\hat{U}\hat{V} = \epsilon \hat{V}\hat{U},$$

where $\epsilon = \exp(2\pi i/D)$. We choose $D = 2^N$, so that our Hilbert space will be the N qubit space $\mathbb{C}^{\otimes N}$. The constant $h = 1/D = 2^{-N}$ can be regarded as the Plank constant. The space $\mathbb{C}^2$ has a basis

$$|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad |1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

The basis in $\mathbb{C}^{\otimes N}$ is

$$|\xi_1\rangle \otimes |\xi_2\rangle \otimes \cdots \otimes |\xi_N\rangle, \quad \xi_k = 0,1.$$

We write

$$\xi = \sum_{k=1}^{N} \xi_k 2^{N-k}.$$

Then $\xi=0,1,\ldots,2^N-1$ and we denote

$$|\xi\rangle=|\xi_1\xi_2\cdots\xi_N\rangle=|\xi_1\rangle\otimes|\xi_2\rangle\otimes\cdots\otimes|\xi_N\rangle.$$

We will also use for this basis notations $\{|\eta\rangle=|\eta_1\eta_2\cdots\eta_N\rangle,\quad \eta_k=0,1\}$ and $\{|j\rangle=|j_1j_2\cdots j_N\rangle, j_k=0,1\}$.

The operators $\hat{U}$ and $\hat{V}$ can be written as

$$\hat{U}=e^{2\pi i\hat{q}},\quad \hat{V}=e^{2\pi i\hat{p}},$$

where the position and momentum operators $\hat{q}$ and $\hat{p}$ are operators in $\mathbb{C}^{\otimes N}$ which are defined as follows. The position operator is

$$\hat{q}=\sum_{j=0}^{2^N-1} q_j|j\rangle\langle j|=\sum_{j_1,\ldots,j_N} q_j|j_N\ldots j_1\rangle\langle j_1\ldots j_N|,$$

where

$$|j\rangle=|j_1j_2\cdots j_N\rangle,\quad j_k=0,1,$$

is the basis in $\mathbb{C}^{\otimes N}$,

$$j=\sum_{k=1}^{N} j_k2^{N-k},$$

and

$$q_j=\frac{j+\frac{1}{2}}{2^N},\quad j=0,1,\ldots,2^N-1.$$

The momentum operator is defined as

$$\hat{p}=F_N\hat{q}F_N^*,$$

where F_N is the quantum Fourier transform acting to the basis vectors as

$$F_N|j\rangle=\frac{1}{\sqrt{D}}\sum_{\xi=0}^{D-1} e^{2\pi i\xi j/D}|\xi\rangle,$$

where $D=2^N$.

The symbolic representation of quantum Baker's map T was introduced by Schack and Caves[33] and studied in Refs. 35 and 36. Let us explain the symbolic representation of the quantum Baker's map as a special case:[33] By applying a partial quantum Fourier transform

$$G_m=\overbrace{I\otimes\cdots\otimes I}^{m}\otimes F_{N-m}$$

to the position eigenstates, one obtains the following quantum Baker's map T:

$$T|.\xi_1\cdots\xi_N\rangle\equiv|\xi_1.\xi_2\cdots\xi_N\rangle,$$

where

$$T=G_{N-1}\circ G_N^{-1}$$

and

$$|\xi_1\cdots\xi_{N-m}.\xi_{N-m+1}\cdots\xi_N\rangle \equiv G_m|\xi_{N-m+1}\cdots\xi_N\xi_{N-m}\cdots\xi_1\rangle$$
$$= |\xi_{N-m+1}\rangle\otimes\cdots\otimes|\xi_N\rangle\otimes F_{N-m}|\xi_{N-m}\rangle\otimes\cdots\otimes|\xi_1\rangle.$$

The quantum Baker's map T is the unitary operator in $\mathbb{C}^{\otimes N}$ with the following matrix elements,

$$\langle\xi|T|\eta\rangle = \frac{1-i}{2}\exp\left(\frac{\pi}{2}i|\xi_1-\eta_N|\right)\prod_{k=2}^{N}\delta(\xi_k-\eta_{k-1}), \tag{17}$$

where $|\xi\rangle=|\xi_1\xi_2\cdots\xi_N\rangle$, $|\eta\rangle=|\eta_1\eta_2\cdots\eta_N\rangle$ and $\delta(x)$ is the Kronecker symbol, $\delta(0)=1$; $\delta(x)=0$, $x\neq 0$.

We define the coherent states by

$$|\alpha\rangle = Ce^{2\pi i\hat{q}v}e^{-2\pi i\hat{p}x}|\psi_0\rangle. \tag{18}$$

Here $\alpha=x+iv$, x and v are integers, C is the normalization constant and $|\psi_0\rangle$ is the vacuum vector. This definition should be compared with (10). The vacuum vector can be defined as the solution of the equation

$$(q_h+ip_h)|\psi_0\rangle=0$$

[compare with (8)]. We will use the simpler definition which in the position representation is

$$\langle q_j|\psi_0\rangle = C\exp(-q_j^2/2)$$

[compare with (9)]. Here C is a normalization constant.

IV. CHAOS DEGREE

Let us review the entropic chaos degree defined in Ref. 24. This entropic chaos degree is given by a probability distribution φ and a dynamics (channel) Λ^* sending a state to a state; $\varphi=\Sigma_k p_k\delta_k$, where δ_k is the delta measure such as

$$\delta_k(j)\equiv\begin{cases}1 & (k=j),\\ 0 & (k\neq j).\end{cases}$$

Then the entropic chaos degree is defined as

$$D(\varphi;\Lambda^*)=\sum_k p_k S(\Lambda^*\delta_k) \tag{19}$$

with the von Neumann entropy S, equivalent to the Shannon entropy because the probability distribution φ is a classical object.

A dynamics $\mathcal{F}$ of the orbit produces the above channel Λ^*, so let $\{x_n\}$ be the orbit and $\mathcal{F}$ be a map from x_n to x_{n+1}.

Take a finite partition $\{B_k\}$ of $I=[a,b]^l$ $(a,b\in\mathbf{R})\subset\mathbf{R}^l$ such as

$$I=\bigcup_k B_k \quad (B_i\bigcap B_j=\varnothing, i\neq j)$$

for a map $\mathcal{F}$ on I with $x_{n+1}=\mathcal{F}(x_n)$ (a difference equation). The state $\varphi^{(n)}$ of the orbit determined by the difference equation is defined by the probability distribution $(p_i^{(n)})$, that is, $\varphi^{(n)}=p^{(n)}=\Sigma_i p_i^{(n)}\delta_i$, where for an initial value $x\in I$ and the characteristic function 1_A

$$p_i^{(n)} \equiv \frac{1}{m+1} \sum_{k=n}^{m+n} 1_{B_i}(\mathcal{F}^k x).$$

When the initial value x is distributed due to a measure ν on I, the above $p_i^{(n)}$ is given as

$$p_i^{(n)} \equiv \frac{1}{m+1} \int_I \sum_{k=n}^{m+n} 1_{B_i}(\mathcal{F}^k x) d\nu.$$

In the case that $\mathcal{F}$ is a classical Baker's transformation, if the orbit is not stable and periodic, then it is shown that the $m \to \infty$ limit of $p_i^{(n)}$ exists and equals a natural invariant measure for a fixed $n \in \mathbf{N}$.[37]

The joint distribution $(p_{ij}^{(n,n+1)})$ between the time n and $n+1$ is defined by

$$p_{ij}^{(n,n+1)} \equiv \frac{1}{m+1} \sum_{k=n}^{m+n} 1_{B_i}(\mathcal{F}^k x) 1_{B_j}(\mathcal{F}^{k+1} x)$$

or

$$p_{ij}^{(n,n+1)} \equiv \frac{1}{m+1} \int_I \sum_{k=n}^{m+n} 1_{B_i}(\mathcal{F}^k x) 1_{B_j}(\mathcal{F}^{k+1} x) d\nu.$$

Then the channel Λ_n^* at n is determined by

$$\Lambda_n^* \equiv \left(\frac{p_{ij}^{(n,n+1)}}{p_i^{(n)}} \right) \Rightarrow p^{(n+1)} = \Lambda_n^* p^{(n)},$$

and the chaos degree is given by

$$D_c(p^{(n)}; \Lambda_n^*) = sup_{\{B_k\}} \left\{ \sum_i p_i^{(n)} S(\Lambda_n^* \delta_i) = \sum_{i,j} p_{ij}^{(n,n+1)} \log \frac{p_i^{(n)}}{p_{ij}^{(n,n+1)}}; \{B_k\} \right\}. \tag{20}$$

We can judge whether the dynamics causes a chaos or not by the value of D as

$$D > 0 \Leftrightarrow \text{chaotic}, \quad D = 0 \Leftrightarrow \text{stable}.$$

Therefore, it is enough to find a partition $\{B_k\}$ such that D is positive when the dynamics produces chaos.

This classical chaos degree was applied to several dynamical maps, such as a logistic map, a Baker's transformation and a Tinkerbel map, and it could explain their chaotic characters.[24,26] Our chaos degree has several merits compared with usual measures such as the Lyapunov exponent.

V. EXPECTATION VALUES AND CHAOS DEGREE

In this section, we show a general representation of the mean value of the position operator $\hat{q}$ for the time evolution, which is constructed by the quantum Baker's map. Then we give the algorithm to compute the chaos degree for the quantum Baker's map.

To study the time evolution and the classical limit $h \to 0$ which corresponds to $N \to \infty$ of the quantum Baker's map T, we introduce the following the mean value of the position operator $\hat{q}$ for time $n \in \mathbf{N}$ with respect to a single basis $|\xi\rangle$:

$$r_n^{(N)} = \langle \xi | T^n \hat{q} T^{-n} | \xi \rangle, \tag{21}$$

where $|\xi\rangle = |\xi_1 \xi_2 \cdots \xi_N\rangle$.

From (17), the following formula of the matrix elements of T^n for any $n \in \mathbf{N}$ is easily obtained:

$$\langle \xi | T^n | \zeta \rangle = \begin{cases} \left(\frac{1-i}{2}\right)^n \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - \zeta_k)\right) \left(\prod_{l=1}^{n} A_{\xi_l \zeta_{N-n+l}}\right) & \text{if } n < N, \\ \left(\frac{1-i}{2}\right)^n \left(\prod_{k=1}^{n} A_{\xi_k \zeta_k}\right) & \text{if } n = N, \\ \left(\frac{1-i}{2}\right)^n \left(\prod_{k=1}^{p} (A^{m+1})_{\xi_k \zeta_{N-p+k}}\right) \left(\prod_{l=1}^{N-p} (A^m)_{\xi_{p+l} \zeta_l}\right) & \text{if } n = mN + p, \\ \left(\frac{1-i}{2}\right)^n \prod_{k=1}^{N} (A^m)_{\xi_k \zeta_k} & \text{if } n = mN, \end{cases} \tag{22}$$

where A is the 2×2 matrix with the element $A_{x_1 x_2} = \exp((\pi/2)\, i |x_1 - x_2|)$ for $x_1, x_2 = 0,\ 1,\ p = 1, \ldots, N-1$ and $m \in \mathbf{N}$.

Using these formulas, the following theorems are obtained and their proofs are given in the Appendix.

Theorem 5.1:

$$r_n^{(N)} = \begin{cases} \sum_{k=1}^{N-n} \xi_{n+k} 2^{-k} + \frac{2^n}{2^{N+1}} & \text{if } n < N, \\ \frac{1}{2} & \text{if } n = N, \\ \frac{1}{2^n} \sum_{j=0}^{2^N - 1} \frac{j + \frac{1}{2}}{2^N} \prod_{k=1}^{p} |(A^{m+1})_{\xi_k j_{N-p+k}}|^2 \prod_{l=1}^{N-p} |(A^m)_{\xi_{p+l} j_l}|^2 & \text{if } n = mN + p, \\ \frac{1}{2^n} \sum_{j=0}^{2^N - 1} \frac{j + \frac{1}{2}}{2^N} \prod_{k=1}^{N} |(A^m)_{\xi_k j_k}|^2 & \text{if } n = mN, \end{cases} \tag{23}$$

where A is the 2×2 matrix with the element $A_{x_1 x_2} = \exp((\pi/2)\, i |x_1 - x_2|)$ for $x_1, x_2 = 0,\ 1,\ p = 1, \ldots, N-1$ and $m \in \mathbf{N}$.

By diagonalizing the matrix A, we obtain the following formula of the absolute square of the matrix elements of A^n for any $n \in \mathbf{N}$.

Lemma 5.2: For any $n \in \mathbf{N}$, we have

$$|(A^n)_{kj}|^2 = \begin{cases} 2^n \cos^2\left(\frac{n\pi}{4}\right) & \text{if } k = j \\ 2^n \sin^2\left(\frac{n\pi}{4}\right) & \text{if } k \neq j \end{cases}.$$

Combining Theorem 5.1 and Lemma 5.2, we obtain the following two theorems with respect to the mean value $r_n^{(N)}$ of the position operator.

Theorem 5.3: *For the case $n = mN + p$, $p = 1, 2, \ldots, N-1$ and $m \in \mathbf{N}$, we have*

$$r_n^{(N)}=\begin{cases}\sum_{k=1}^{N-p}\xi_{p+k}2^{-k}+\dfrac{2^p}{2^{N+1}} & \text{if } m=0(\mathrm{mod}\,4),\\ \sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{-k}+\dfrac{2^N-2^p+1}{2^{N+1}} & \text{if } m=1(\mathrm{mod}\,4),\\ \sum_{k=1}^{N-p}\eta_{p+k}2^{-k}+\dfrac{2^p}{2^{N+1}} & \text{if } m=2(\mathrm{mod}\,4),\\ \sum_{k=N-p+1}^{N}\xi_{k-(N-p)}2^{-k}+\dfrac{2^N-2^p+1}{2^{N+1}} & \text{if } m=3(\mathrm{mod}\,4),\end{cases} \tag{24}$$

where $\eta_k=\xi_k+1(\mathrm{mod}2)$, $k=1,\ldots,N$.

Theorem 5.4: *For the case* $n=mN$, $m\in\mathbf{N}$, *we have*

$$r_N^{(n)}=\begin{cases}\sum_{k=1}^{N}\xi_k2^{-k}+\dfrac{1}{2^{N+1}} & \text{if } m=0(\mathrm{mod}\ 4),\\ \dfrac{1}{2} & \text{if } m=1,3(\mathrm{mod}\ 4),\\ \sum_{k=1}^{N}\eta_k2^{-k}+\dfrac{1}{2^{N+1}} & \text{if } m=2(\mathrm{mod}\ 4).\end{cases} \tag{25}$$

Using formulas (23)–(25), the probability distribution $(p_i^{(n)})$ of the orbit of mean value $r_n^{(N)}$ of the position operator $\hat{q}$ for the time evolution, which is constructed by the quantum Baker's map, is given by

$$p_i^{(n)}\equiv\frac{1}{m+1}\sum_{k=n}^{m+n}1_{B_i}(r_n^{(N)})$$

for an initial value $r_0^{(N)}\in[0,1]$ and the characteristic function 1_A. The joint distribution $(p_{ij}^{(n,n+1)})$ between the time n and $n+1$ is given by

$$p_{ij}^{(n,n+1)}\equiv\frac{1}{m+1}\sum_{k=n}^{m+n}1_{B_i}(r_k^{(N)})1_{B_j}(r_{k+1}^{(N)}).$$

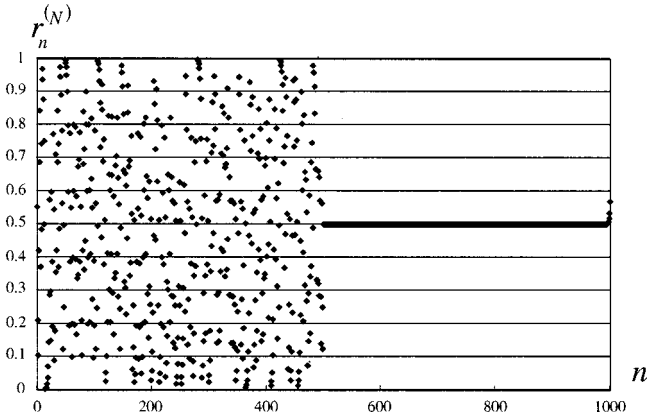

FIG. 1. The distribution of $r_N^{(n)}$ for the case $N=500$.

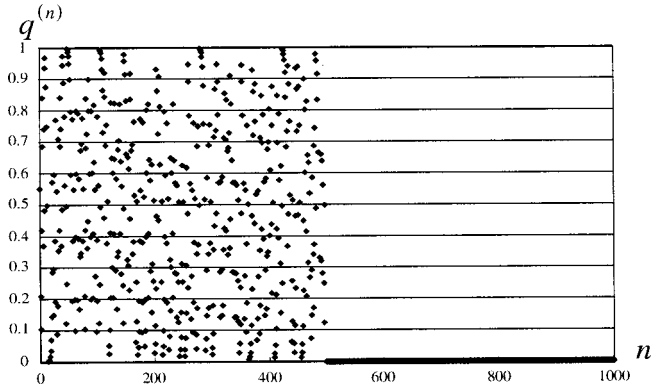

FIG. 2. The distribution of the classical value $q^{(n)}$ for the case $N=500$.

Thus the chaos degree for the quantum Baker's map is calculated by

$$D_q(p^{(n)};\Lambda_n^*)=\sum_{i,j} p_{ij}^{(n,n+1)}\log\frac{p_i^{(n)}}{p_{ij}^{(n,n+1)}}, \tag{26}$$

whose numerical value is shown in the next section.

VI. NUMERICAL SIMULATION OF THE CHAOS DEGREE AND CLASSICAL-QUANTUM CORRESPONDENCE

We compare the dynamics of the mean value $r_n^{(N)}$ of position operator $\hat{q}$ with that of the classical value q_n in the q direction. We take an initial value of the mean value as

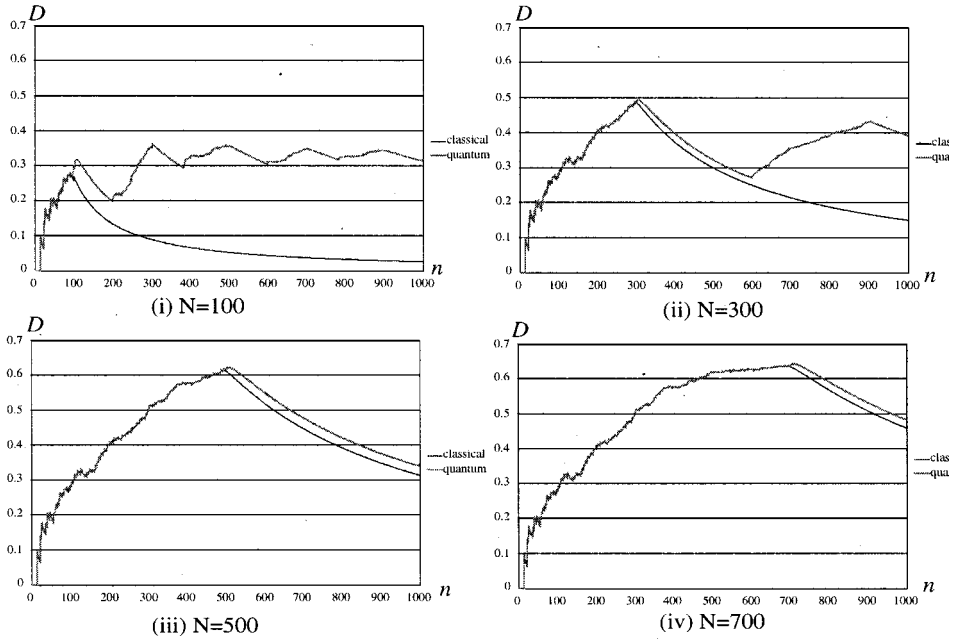

FIG. 3. The change of the chaos degree for several N's up to time $n=1000$.

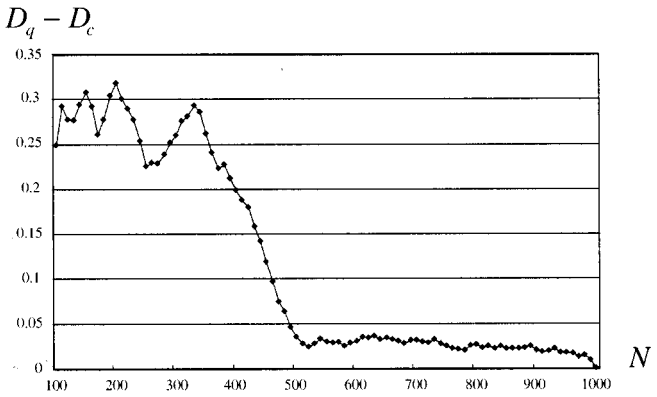

FIG. 4. The difference of the chaos degree between quantum and classical for the case $n=1000$.

$$r_0^{(N)}=\sum_{l=1}^{N}\xi_l 2^{-l}+\frac{1}{2^{N+1}}=0\cdot\xi_1\xi_2\cdots\xi_N 1,$$

where ξ_i is a pseudo-random number valued with 0 or 1. At the time zero we assume that the classical value q_0 in the q direction takes the same value as the mean value $r_0^{(N)}$ of position operator $\hat{q}$. The distribution of $r_n^{(N)}$ for the case $N=500$ is shown in Fig. 1 up to the time $n=1000$. The distribution of the classical value q_n for the case $N=500$ in the q direction is shown in Fig. 2 up to the time $n=1000$.

Figure 3 represents the change of the chaos degree for the case $N=100,300,500,700$ up to the time $n=1000$.

The correspondence between the chaos degree D_q for the quantum Baker's map and the chaos degree D_c for the classical Baker's map for some fixed N's (100,300,500,700 here) is shown for the time less than $T=\log_2(1/h)=\log_2 2^N=N$, and it is lost at the logarithtic time scale T. Here we took a finite partition $\{B_k\}$ of $I=[0,1]$ such as $B_k=[k/100,(k+1)/100))(k=0,1,\ldots,98)$ and $B_{99}=[99/100,1]$ to compute the chaos degree numerically.

The difference of the chaos degrees between the chaos degree D_q for the quantum Baker's map and the chaos degree D_c for the classical Baker's map for a fixed time n (1000, here) is displayed w.r.t. N in Fig. 4.

Thus we conclude that the dynamics of the mean value $r_n{}^{(N)}$ reduces the classical dynamics q_n in the q direction in the classical limit $N\to\infty(h\to 0)$.

The appearance of the logarithmic timescale have been proved rigorously in our recent paper.[38]

APPENDIX A:

Proof of Theorem 5.1: By a direct calculation, we obtain

$$
\begin{aligned}
r_n^{(N)} &= \langle \xi | T^n \hat{q} T^{-n} | \xi \rangle \\
&= \langle \xi | T^n \left(\sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} |j\rangle\langle j| \right) T^{-n} | \xi \rangle \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \langle \xi | T^n | j \rangle \langle j | T^{-n} | \xi \rangle \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \langle \xi | T^n | j \rangle \langle j | T^{*n} | \xi \rangle \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \langle \xi | T^n | j \rangle \overline{\langle \xi | T^n | j \rangle} \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} |\langle \xi | T^n | j \rangle|^2 .
\end{aligned}
$$

Using (22), the mean value $r_n^{(N)}$ in the case $n<N$ can be expressed as

$$
\begin{aligned}
r_n^{(N)} &= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} |\langle \xi | T^n | j \rangle|^2 \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \left| \left(\frac{1-i}{2} \right)^n \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - j_k) \right) \left(\prod_{l=1}^{n} A_{\xi_l j_{N-n+l}} \right) \right|^2 \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \left(\frac{1-i}{2} \right)^n \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - j_k) \right) \left(\prod_{l=1}^{n} A_{\xi_l j_{N-n+l}} \right) \\
&\quad \times \overline{\left(\frac{1-i}{2} \right)^n \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - j_k) \right) \left(\prod_{l-1}^{n} A_{\xi_l j_{N-n+l}} \right)} \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \left(\frac{1-i}{2} \right)^n \left(\frac{1+i}{2} \right)^n \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - j_k) \right) \left(\prod_{l=1}^{n} |A_{\xi_l j_{N-n+l}}|^2 \right) \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \left(\frac{1-i}{2} \right)^n \left(\frac{1+i}{2} \right)^n \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - j_k) \right) \\
&= \frac{1}{2^{N+n}} \sum_{j_1, \cdots j_N} \left\{ \left(\sum_{k=1}^{N} j_k 2^{N-k} \right) + \frac{1}{2} \right\} \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - j_k) \right) \\
&= \frac{1}{2^{N+n}} \sum_{j_1, \cdots j_N} \left(\sum_{k=1}^{N} j_k 2^{N-k} \right) \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - j_k) \right) + \frac{1}{2^{N+n+1}} \sum_{j_1, \cdots j_N} \left(\prod_{k=1}^{N-n} \delta(\xi_{n+k} - j_k) \right) \\
&= \frac{1}{2^{N+n}} \sum_{j_{N-n+1}, \cdots j_N} \left(\sum_{l=1}^{N-n} \xi_{n+l} 2^{N-l} + \sum_{l=N-n+1}^{N} j_l 2^{N-l} \right) + \frac{1}{2^{N+n+1}} \left(\sum_{j_{N-n+1}, \cdots j_N} 1 \right)
\end{aligned}
$$

$$
\begin{aligned}
&= \frac{1}{2^{N+n}}\left(\sum_{l=1}^{N-n} \xi_{n+l}2^{N-l}\right)\left(\sum_{j_{N-n+1},\cdots j_N} 1\right) + \frac{1}{2^{N+n}}\sum_{j_{N-n+1},\cdots j_N}\left(\sum_{l=N-n+1}^{N} j_l 2^{N-l}\right) \\
&\quad + \frac{1}{2^{N+n+1}}\left(\sum_{j_{N-n+1},\cdots j_N} 1\right) \\
&= \frac{2^n}{2^{N+n}}\left(\sum_{l=1}^{N-n} \xi_{n+l}2^{N-l}\right) + \frac{1}{2^{N+n}}\sum_{j_{N-n+1},\cdots j_N}\left(\sum_{l=N-n+1}^{N} j_l 2^{N-l}\right) + \frac{2^n}{2^{N+n+1}} \\
&= \frac{1}{2^N}\left(\sum_{l=1}^{N-n} \xi_{n+l}2^{N-l}\right) + \frac{1}{2^{N+n}}\sum_{j_{N-n+1},\cdots j_N}\left(\sum_{l=1}^{n} j_{N-n+l}2^{n-l}\right) + \frac{1}{2^{N+1}} \\
&= \frac{1}{2^N}\left(\sum_{l=1}^{N-n} \xi_{n+l}2^{N-l}\right) + \frac{1}{2^{N+n}}\frac{1}{2}(2^n-1)2^n + \frac{1}{2^{N+1}} \\
&= \frac{1}{2^N}\left(\sum_{l=1}^{N-n} \xi_{n+l}2^{N-l}\right) + \frac{2^n}{2^{N+1}}.
\end{aligned}
$$

For the case $n=N$, we similarly obtain

$$
\begin{aligned}
r_n^{(N)} &= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N}|\langle\xi|T^n|j\rangle|^2 \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N}\left|\left(\frac{1-i}{2}\right)^N\left(\prod_{k=1}^{N} A_{\xi_k j_k}\right)\right|^2 \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N}\left|\left(\frac{1-i}{2}\right)^N\right|^2\prod_{k=1}^{N}|A_{\xi_k j_k}|^2 \\
&= \frac{1}{2^{2N}}\sum_{j=0}^{2^N-1}\left(j+\frac{1}{2}\right) \\
&= \frac{1}{2^{2N}}\frac{1}{2}(2^N-1)2^N + \frac{1}{2^{N+1}} = \frac{1}{2}.
\end{aligned}
$$

For $n=mN+p,\ p=1,2,\ldots,N-1,\ m\in\mathbf{N}$,

$$
\begin{aligned}
r_n^{(N)} &= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N}|\langle\xi|T^n|j\rangle|^2 \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{/2}}{2^N}\left|\left(\frac{1-i}{2}\right)^n\left(\prod_{k=1}^{p}(A^{m+1})_{\xi_k j_{N-p+k}}\right)\left(\prod_{l=1}^{N-p}(A^m)_{\xi_{p+l}j_l}\right)\right|^2 \\
&= \frac{1}{2^n}\sum_{j=0}^{2^N-1}\frac{j+\frac{1}{2}}{2^N}\prod_{k=1}^{p}|(A^{m+1})_{\xi_k j_{N-p+k}}|^2\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2,
\end{aligned}
$$

and for $n=mN,\ m\in\mathbf{N}$,

$$
\begin{aligned}
r_N^{(n)} &= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} |\langle \xi | T^n | j \rangle|^2 \\
&= \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \left| \left(\frac{1-i}{2} \right)^n \prod_{k=1}^{N} (A^m)_{\xi_k j_k} \right|^2 \\
&= \frac{1}{2^n} \sum_{j=0}^{2^N-1} \frac{j+\frac{1}{2}}{2^N} \prod_{k=1}^{N} |(A^m)_{\xi_k j_k}|^2 .
\end{aligned}
$$

■

Proof of Lemma 5.2: By a direct calculation, the matrix A is diagonalized as follows:

$$A = FDF^*, \tag{A1}$$

where

$$F = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}, \quad D = \begin{pmatrix} 1+i & 0 \\ 0 & 1-i \end{pmatrix}.$$

From (A1), we have

$$
\begin{aligned}
A^n &= FD^nF^* \\
&= \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} (1+i)^n & 0 \\ 0 & (1-i)^n \end{pmatrix} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix} \\
&= \frac{1}{2} \begin{pmatrix} (1+i)^n + (1-i)^n & (1+i)^n - (1-i)^n \\ (1+i)^n - (1-i)^n & (1+i)^n + (1-i)^n \end{pmatrix}.
\end{aligned} \tag{A2}
$$

Using (A2), it follows that for any $k=j$, $k=1,2$,

$$
\begin{aligned}
|(A^n)_{kj}|^2 &= \tfrac{1}{2}\{(1+i)^n + (1-i)^n\} \overline{\tfrac{1}{2}\{(1+i)^n + (1-i)^n\}} \\
&= \tfrac{1}{4}\{(1+i)^n + (1-i)^n\}\{(1-i)^n + (1+i)^n\} \\
&= \tfrac{1}{4}\{(1+i)^n + (1-i)^n\}^2 \\
&= \frac{1}{4}\left\{ \left(\sqrt{2}\frac{1+i}{\sqrt{2}} \right)^n + \left(\sqrt{2}\frac{1-i}{\sqrt{2}} \right)^n \right\}^2 \\
&= \frac{1}{4}\left\{ (\sqrt{2})^n \left(\frac{1+i}{\sqrt{2}} \right)^n + (\sqrt{2})^n \left(\frac{1-i}{\sqrt{2}} \right)^n \right\}^2 \\
&= \frac{2^n}{4}\left\{ \left(\exp\left(\frac{\pi}{4} i \right) \right)^n + \left(\exp\left(-\frac{\pi}{4} i \right) \right)^n \right\}^2 \\
&= \frac{2^n}{4}\left\{ \exp\left(\frac{n\pi}{4} i \right) + \exp\left(-\frac{n\pi}{4} i \right) \right\}^2 \\
&= \frac{2^n}{4}\left[\left\{ \cos\left(\frac{n\pi}{4} \right) + i \sin\left(\frac{n\pi}{4} \right) \right\} + \left\{ \cos\left(\frac{n\pi}{4} \right) - i \sin\left(\frac{n\pi}{4} \right) \right\} \right]^2 \\
&= \frac{2^n}{4}\left\{ 2 \cos\left(\frac{n\pi}{4} \right) \right\}^2 = 2^n \cos^2\left(\frac{n\pi}{4} \right)
\end{aligned}
$$

and for any $k \neq j$, $k=1,2$,

$$
\begin{aligned}
|(A^n)_{kj}|^2 &= \tfrac{1}{2}\{(1+i)^n-(1-i)^n\}\overline{\tfrac{1}{2}\{(1+i)^n-(1-i)^n\}} \\
&= \tfrac{1}{4}\{(1+i)^n-(1-i)^n\}\{(1-i)^n-(1+i)^n\} \\
&= -\tfrac{1}{4}\{(1+i)^n-(1-i)^n\}^2 \\
&= -\frac{1}{4}\left\{\left(\sqrt{2}\frac{1+i}{\sqrt{2}}\right)^n-\left(\sqrt{2}\frac{1-i}{\sqrt{2}}\right)^n\right\}^2 \\
&= -\frac{1}{4}\left\{(\sqrt{2})^n\left(\frac{1+i}{\sqrt{2}}\right)^n-(\sqrt{2})^n\left(\frac{1-i}{\sqrt{2}}\right)^n\right\}^2 \\
&= -\frac{2^n}{4}\left\{\left(\exp\left(\frac{\pi}{4}i\right)\right)^n-\left(\exp\left(-\frac{\pi}{4}i\right)\right)^n\right\}^2 \\
&= -\frac{2^n}{4}\left[\left\{\cos\left(\frac{n\pi}{4}\right)+i\sin\left(\frac{n\pi}{4}\right)\right\}-\left\{\cos\left(\frac{n\pi}{4}\right)-i\sin\left(\frac{n\pi}{4}\right)\right\}\right]^2 \\
&= -\frac{2^n}{4}\left\{2i\sin\left(\frac{n\pi}{4}\right)\right\}^2 \\
&= 2^n\sin^2\left(\frac{n\pi}{4}\right).
\end{aligned}
$$

■

Proof of Theorem 5.3: For the case $n=mN+p$, $p=1,\ldots,N-1$ and $m\in\mathbf{N}$,

$$
r_n^{(N)}=\frac{1}{2^n}\sum_{j=0}^{2^N-1}\frac{j+\frac{1}{2}}{2^N}\prod_{k=1}^{p}|(A^{m+1})_{\xi_k j_{N-p+k}}|^2\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2.
$$

By a direct calculation, we obtain

$$
\begin{aligned}
r_n^{(N)} &= \frac{1}{2^n}\sum_{j=0}^{2^N-1}\frac{j+\frac{1}{2}}{2^N}\prod_{k=1}^{p}|(A^{m+1})_{\xi_k j_{N-p+k}}|^2\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2 \\
&= \frac{1}{2^n}\sum_{j=0}^{2^N-1}\frac{j+\frac{1}{2}}{2^N}\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=1}^{p}|(A^{m+1})_{\xi_k j_{N-p+k}}|^2 \\
&= \frac{1}{2^{n+N}}\sum_{j=0}^{2^N-1}\left(j+\frac{1}{2}\right)\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=1}^{p}|(A^{m+1})_{\xi_k j_{N-p+k}}|^2 \\
&= \frac{1}{2^{n+N}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N}j_k2^{N-k}\right)+\frac{1}{2}\right\}\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=1}^{p}|(A^{m+1})_{\xi_k j_{N-p+k}}|^2 \\
&= \frac{1}{2^{n+N}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2}\right\} \\
&\quad\times\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=1}^{p}|(A^{m+1})_{\xi_k j_{N-p+k}}|^2 \\
&= \frac{1}{2^{(m+1)N+p}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2}\right\} \\
&\quad\times\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2. \qquad \text{(A3)}
\end{aligned}
$$

(i) $m=0(\mathrm{mod}\,4)$

From the above lemma, we have

$$|(A^m)_{\xi_{p+l}j_l}|^2=\begin{cases}2^m & \text{if } j_l=\xi_{p+l},\\ 0 & \text{if } j_l\neq\xi_{p+l},\end{cases}\qquad |(A^{m+1})_{\xi_{k-(N-p)j_k}}|^2=2^m$$

for any $l=1,\cdots,N-p$ and $k=N-p+1,\cdots,N$. Using this formula the product of absolute squares can be expressed as

$$\begin{aligned}&\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2\\ &\quad=\begin{cases}(2^m)^{N-p}(2^m)^p & \text{if } j_l=\xi_{p+l} \text{ for all } l=1,\cdots,N-p,\\ 0 & \text{otherwise,}\end{cases}\\ &\quad=\begin{cases}2^{mN} & \text{if } j_l=\xi_{p+l} \text{ for all } l=1,\cdots,N-p,\\ 0 & \text{otherwise.}\end{cases}\end{aligned}$$

Equation (A3) can be rewritten as

$$\begin{aligned}r_n^{(N)}&=\frac{1}{2^{(m+1)N+p}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2}\right\}\\ &\quad\times\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2\\ &=\frac{2^{mN}}{2^{(m+1)N+p}}\sum_{j_{N-p+1},\cdots,j_N}\left\{\left(\sum_{k=1}^{N-p}\xi_{p+k}2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2}\right\} \qquad \text{(A4)}\\ &=\frac{1}{2^{N+p}}\left(\sum_{k=1}^{N-p}\xi_{p+k}2^{N-k}\right)\left(\sum_{j_{N-p+1},\cdots,j_N}1\right)\\ &\quad+\frac{1}{2^{N+p}}\sum_{j_{N-p+1},\cdots,j_N}\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2^{N+p}}\frac{1}{2}\left(\sum_{j_{N-p+1},\cdots,j_N}1\right)\\ &=\frac{1}{2^N}\sum_{k=1}^{N-p}\xi_{p+k}2^{N-k}+\frac{1}{2^{N+p}}\sum_{j_{N-p+1},\cdots,j_N}\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2^{N+1}}\\ &=\frac{1}{2^N}\sum_{k=1}^{N-p}\xi_{p+k}2^{N-k}+\frac{1}{2^{N+p}}\sum_{j_{N-p+1},\cdots,j_N}\left(\sum_{k=1}^{p}j_{N-p+k}2^{p-k}\right)+\frac{1}{2^{N+1}}\\ &=\frac{1}{2^N}\sum_{k=1}^{N-p}\xi_{p+k}2^{N-k}+\frac{1}{2^{N+p}}\sum_{k=0}^{2^p-1}k+\frac{1}{2^{N+1}}\\ &=\frac{1}{2^N}\sum_{k=1}^{N-p}\xi_{p+k}2^{N-k}+\frac{1}{2^{N+p}}\frac{1}{2}(2^p-1)2^p+\frac{1}{2^{N+1}}\\ &=\sum_{k=1}^{N-p}\xi_{p+k}2^{-k}+\frac{2^p}{2^{N+1}}.\end{aligned}$$

(ii) $m=1(\mathrm{mod}\,4)$

From the above lemma, we have

$$|(A^m)_{\xi_{p+l}j_l}|^2=2^{m-1},\quad |(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2=\begin{cases}2^{m+1} & \text{if } j_k\neq\xi_{k-(N-p)},\\ 0 & \text{if } j_k=\xi_{k-(N-p)},\end{cases}$$

for any $l=1,\cdots,N-p$ and $k=N-p+1,\cdots,N$. Using this formula the product of absolute squares can be expressed as

$$\begin{aligned}&\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|\\ &\quad=\begin{cases}(2^{m-1})^{N-p}(2^{m+1})^p & \text{if } j_k\neq\xi_{k-(N-p)} \text{ for all } k=N-p+1,\cdots,N,\\ 0 & \text{otherwise}\end{cases}\\ &\quad=\begin{cases}2^{(m-1)N+2p} & \text{if } j_k\neq\xi_{k-(N-p)} \text{ for all } k=N-p+1,\cdots,N,\\ 0 & \text{otherwise.}\end{cases}\end{aligned}$$

Let $\eta_{k-(N-p)}=\xi_{k-(N-p)}+1(\mathrm{mod}2), k=N-p+1,\ldots,N$. It follows that

$$\begin{aligned}r_n^{(N)}&=\frac{1}{2^{(m+1)N+p}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2}\right\}\\ &\quad\times\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2\\ &=\frac{2^{(m-1)N+2p}}{2^{(m+1)N+p}}\sum_{j_1,\cdots,j_{N-p}}\left\{\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{N-k}\right)+\frac{1}{2}\right\} \qquad \text{(A5)}\\ &=\frac{1}{2^{2N-p}}\sum_{j_1,\cdots,j_{N-p}}\left\{\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{N-k}\right)+\frac{1}{2}\right\}\\ &=\frac{1}{2^{2N-p}}\sum_{j_1,\cdots,j_{N-p}}\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\frac{1}{2^{2N-p}}\left(\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{N-k}\right)\left(\sum_{j_1,\cdots,j_{N-p}}1\right)\\ &\quad+\frac{1}{2^{2N-p}}\frac{1}{2}\left(\sum_{j_1,\cdots,j_{N-p}}1\right)\\ &=\frac{1}{2^{2N-p}}\sum_{j_1,\cdots,j_{N-p}}\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\frac{2^{N-p}}{2^{2N-p}}\left(\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{N-k}\right)+\frac{2^{N-p}}{2^{2N-p}}\frac{1}{2}\\ &=\frac{1}{2^{2N-p}}\sum_{j_1,\cdots,j_{N-p}}\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{-k}+\frac{1}{2^{N+1}}\\ &=\frac{2^p}{2^{2N-p}}\sum_{j_1,\cdots,j_{N-p}}\left(\sum_{k=1}^{N-p}j_k2^{N-p-k}\right)+\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{-k}+\frac{1}{2^{N+1}}\\ &=\frac{2^p}{2^{2N-p}}\sum_{k=0}^{2^{N-p}-1}k+\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{-k}+\frac{1}{2^{N+1}}\\ &=\frac{2^p}{2^{2N-p}}\frac{1}{2}(2^{N-p}-1)2^{N-p}+\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{-k}+\frac{1}{2^{N+1}}\\ &=\sum_{k=N-p+1}^{N}\eta_{k-(N-p)}2^{-k}+\frac{2^N-2^p+1}{2^{N+1}}.\end{aligned}$$

(iii) $m=2(\mathrm{mod}\,4)$

From the above lemma, we have

$$|(A^m)_{\xi_{p+l}j_l}|^2=\begin{cases}2^m & \text{if } j_l\neq\xi_{p+l}\\ 0 & \text{if } j_l=j_{p+l}\end{cases},\quad |(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2=2^m$$

for any $l=1,\cdots,N-p$ and $k=N-p+1,\cdots,N$. Using this formula the product of absolute squares can be expressed as

$$\begin{aligned}&\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|\\&=\begin{cases}(2^m)^{N-p}(2^m)^p & \text{if } j_l\neq\xi_{p+l} \text{ for all } l=1,\ldots,N-p,\\ 0 & \text{otherwise,}\end{cases}\\&=\begin{cases}2^{mN} & \text{if } j_l\neq\xi_{p+l} \text{ for all } l=1,\ldots,N-p,\\ 0 & \text{otherwise.}\end{cases}\end{aligned}$$

Let $\eta_{p+l}=\xi_{p+l}+1(\mathrm{mod}\,2)$, $l=1,\ldots,N-p$. It follows that

$$\begin{aligned}r_n^{(N)}&=\frac{1}{2^{(m+1)N+p}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N-p}j_k2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2}\right\}\\&\quad\times\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2\\&=\frac{2^{mN}}{2^{(m+1)N+p}}\sum_{j_{N-p+1},\cdots,j_N}\left\{\left(\sum_{k=1}^{N-p}\eta_{p+k}2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}j_k2^{N-k}\right)+\frac{1}{2}\right\}.\end{aligned}$$

Substituting η_{p+k} for ξ_{p+k} in (A4), we get

$$r_n^{(N)}=\sum_{k=1}^{N-p}\eta_{p+k}2^{-k}+\frac{2^p}{2^{N+1}}.$$

(iv) $m=3(\mathrm{mod}\,4)$

From the above lemma, we have

$$|(A^m)_{\xi_{p+l}j_l}|^2=2^{m-1},|(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2=\begin{cases}2^{m+1} & \text{if } j_k=\xi_{k-(N-p)},\\ 0 & \text{if } j_k\neq\xi_{k-(N-p)},\end{cases}$$

for any $l=1,\ldots,N-p$ and $k=N-p+1,\ldots,N$. Using this formula the product of absolute squares can be expressed as

$$\begin{aligned}&\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2\\&=\begin{cases}(2^{m-1})^{N-p}(2^{m+1})^p & \text{if } j_k=\xi_{k-(N-p)} \text{ for all } k=N-p+1,\ldots,N,\\ 0 & \text{otherwise,}\end{cases}\\&=\begin{cases}2^{(m-1)N+2p} & \text{if } j_k=\xi_{k-(N-p)} \text{ for all } k=N-p+1,\cdots,N,\\ 0 & \text{otherwise.}\end{cases}\end{aligned}$$

Equation (A3) can be rewritten as

$$r_n^{(N)}=\frac{1}{2^{(m+1)N+p}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N-p} j_k 2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N} j_k 2^{N-k}\right)+\frac{1}{2}\right\}$$
$$\times\prod_{l=1}^{N-p}|(A^m)_{\xi_{p+l}j_l}|^2\prod_{k=N-p+1}^{N}|(A^{m+1})_{\xi_{k-(N-p)}j_k}|^2$$
$$=\frac{2^{(m-1)N+2p}}{2^{(m+1)N+p}}\sum_{j_1,\cdots,j_{N-p}}\left\{\left(\sum_{k=1}^{N-p} j_k 2^{N-k}\right)+\left(\sum_{k=N-p+1}^{N}\xi_{k-(N-p)}2^{N-k}\right)+\frac{1}{2}\right\}.$$

Substituting $\xi_{k-(N-p)}$ for $\eta_{k-(N-p)}$ in (A5), we get

$$r_n^{(N)}=\sum_{k=N-p-1}^{N-p}\xi_{k-(N-p)}2^{-k}+\frac{2^N-2^p+1}{2^{N+1}}.$$

■

Proof of Theorem 5.4: For any $n=mN$, $m\in\mathbf{N}$,

$$r_n^{(N)}=\frac{1}{2^n}\sum_{j=0}^{2^N-1}\frac{j+\frac{1}{2}}{2^N}\prod_{k=1}^{N}|(A^m)_{\xi_k j_k}|^2.$$

By a direct calculation, we obtain

$$r_n^{(N)}=\frac{1}{2^n}\sum_{j=0}^{2^N-1}\frac{j+\frac{1}{2}}{2^N}\prod_{k=1}^{N}|(A^m)_{\xi_k j_k}|^2$$
$$=\frac{1}{2^{n+N}}\sum_{j=0}^{2^N-1}(j+\tfrac{1}{2})\prod_{k=1}^{N}|(A^m)_{\xi_k j_k}|^2$$
$$=\frac{1}{2^{(m+1)N}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N} j_k 2^{N-k}\right)+\frac{1}{2}\right\}\prod_{k=1}^{N}|(A^m)_{\xi_k j_k}|^2.$$

(i) $m=0(\mathrm{mod}\,4)$

From the above lemma, we have

$$|(A^m)_{\xi_k j_k}|^2=\begin{cases}2^m & \text{if } j_k=\xi_k,\\ 0 & \text{if } j_k\neq\xi_k,\end{cases}$$

for any $k=1,\ldots,N$. Using this formula the product of absolute squares can be expressed as

$$\prod_{l=1}^{N}|(A^m)_{\xi_k j_k}|^2=\begin{cases}2^{mN} & \text{if } j_k=\xi_k \quad \text{for all } k=1,\ldots,N,\\ 0 & \text{otherwise.}\end{cases}$$

Using this formula the mean value $r_n^{(N)}$ of the position operator can be expressed as

$$r_n^{(N)}=\frac{1}{2^{(m+1)N}}\sum_{j_1,\cdots,j_N}\left\{\left(\sum_{k=1}^{N} j_k 2^{N-k}\right)+\frac{1}{2}\right\}\prod_{k=1}^{N}|(A^m)_{\xi_k j_k}|^2$$
$$=\frac{2^{mN}}{2^{(m+1)N}}\left\{\left(\sum_{k=1}^{N}\xi_k 2^{N-k}\right)+\frac{1}{2}\right\}=\sum_{k=1}^{N}\xi_k 2^{-k}+\frac{1}{2^{N+1}}.$$

(ii) $m=1,3(\mathrm{mod}\,4)$

From the above lemma, we have

$$|(A^m)_{\xi_k j_k}|^2 = 2^{m-1}$$

for any $k=1,\ldots,N$. Note that

$$\prod_{l=1}^{N} |(A^m)_{\xi_k j_k}|^2 = 2^{(m-1)N}.$$

Using this formula the mean value $r_n^{(N)}$ of the position operator can be expressed as

$$\begin{aligned} r_n^{(N)} &= \frac{1}{2^{(m+1)N}} \sum_{j_1,\cdots,j_N} \left\{ \left(\sum_{k=1}^{N} j_k 2^{N-k} \right) + \frac{1}{2} \right\} \prod_{k=1}^{N} |(A^m)_{\xi_k j_k}|^2 \\ &= \frac{2^{(m-1)N}}{2^{(m+1)N}} \sum_{j_1,\cdots,j_N} \left\{ \left(\sum_{k=1}^{N} j_k 2^{N-k} \right) + \frac{1}{2} \right\} \\ &= \frac{1}{2^{2N}} \cdot \left\{ \sum_{j_1,\cdots,j_N} \left(\sum_{k=1}^{N} j_k 2^{N-k} \right) + \frac{1}{2} \left(\sum_{j_1,\cdots,j_N} 1 \right) \right\} \\ &= \frac{1}{2^{2N}} \sum_{k=0}^{2^N-1} k + \frac{1}{2^{N+1}} = \frac{1}{2^{2N}} 2^{N-1}(2^N-1) + \frac{1}{2^{N+1}} = \frac{1}{2}. \end{aligned}$$

(iii) $m=2 \pmod 4$

From the above lemma, we have

$$|(A^m)_{\xi_k j_k}|^2 = \begin{cases} 2^m & \text{if } j_k \neq \xi_k, \\ 0 & \text{if } j_k = \xi_k, \end{cases}$$

for any $k=1,\ldots,N$. Using this formula the product of absolute squares can be expressed as

$$\prod_{l=1}^{N} |(A^m)_{\xi_k j_k}|^2 = \begin{cases} 2^{mN} & \text{if } j_k \neq \xi_k \text{ for all } k=1,\ldots,N \\ 0 & \text{otherwise.} \end{cases}$$

Let $\eta_k = \xi_k + 1 \pmod 2$, $k=1,\ldots,N$. It follows that

$$\begin{aligned} r_n^{(N)} &= \frac{1}{2^{(m+1)N}} \sum_{j_1,\cdots,j_N} \left\{ \left(\sum_{k=1}^{N} j_k 2^{N-k} \right) + \frac{1}{2} \right\} \prod_{k=1}^{N} |(A^m)_{\xi_k j_k}|^2 \\ &= \frac{2^{mN}}{2^{(m+1)N}} \left\{ \left(\sum_{k=1}^{N} \eta_k 2^{N-k} \right) + \frac{1}{2} \right\} = \sum_{k=1}^{N} \eta_k 2^{-k} + \frac{1}{2^{N+1}}. \end{aligned}$$

(Received 22 February 2000; accepted for publication 22 October 2001)

A gauge invariant quantization in a closed integral form is developed over a linear phase space endowed with an inhomogeneous Faraday electromagnetic tensor. An analog of the Groenewold product formula (corresponding to Weyl ordering) is obtained via a membrane magnetic area, and extended to the product of N symbols. The problem of ordering in quantization is related to different configurations of membranes: A choice of configuration determines a phase factor that fixes the ordering and controls a symplectic groupoid structure on the secondary phase space. A gauge invariant solution of the quantum evolution problem for a charged particle in an electromagnetic field is represented in an exact continual form and in the semiclassical approximation via the area of dynamical membranes. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1426688]

I. INTRODUCTION AND OVERVIEW

The works by Berezin,[1] Berry,[2] as well as by Marinov[3] have introduced and focused attention on several geometrical formulas representing the phases of three primary quantum objects (the noncommutative product, semiclassical Wigner eigenfunctions, and the evolution Wigner functions) in terms of symplectic area of simple two-dimensional membranes whose boundary consists of line segments and pieces of Hamiltonian trajectories in phase space. The area of these membranes is determined with respect to the canonical 2-form

$$\omega_0=\tfrac{1}{2}J_{jk}dx^k\wedge dx^j,\quad x=(q,p)\in\mathbb{R}^{2n},\quad J=\begin{bmatrix}0 & I\\ -I & 0\end{bmatrix}.$$

Attempts to generalize some of these formulas to phase spaces with a generic symplectic form have been undertaken. For spaces with flat symplectic connection, a product of membrane type was constructed in Ref. 4. For curved symmetric spaces (see Ref. 5) the opportunity to represent the quantum product via the area of triangle membranes was mentioned by Berezin, and it was actually proved by Weinstein,[6] that the semiclassical phase of the product-generating kernel is given by such an area in this case. Over Kählerian manifolds formulas for the noncommutative product and for the solutions of stationary or evolution problems via the area of membranes in the complexification of phase space were obtained in Refs. 7–9 (see also Ref. 10). However, formulas which use only the usual symplectic area are still unavailable for the general case.

In the present paper we analyze three problems related to this topic.

A first and trivial remark, which one can make regarding generalization of the original approach of the works,[1,2,3] is that the specific matrix J in the definition of the symplectic form ω_0

a)Electronic mail: tosborn@cc.umanitoba.ca

can be replaced by an arbitrary skew-symmetric matrix without any changes in the geometrical picture. In particular, one can take J to be the matrix $\left[\begin{smallmatrix} F & I \\ -I & 0 \end{smallmatrix}\right]$, where the constant block F represents a homogenous electromagnetic field. But the next and more interesting generalization to consider is that of inhomogeneous (not constant) tensors F.

The second natural question is about ordering. All treatments of the geometrical picture of works[1,2,3] were made for one specific ordering choice: For the Weyl symmetrization of the noncommutative coordinates (operators). What happens with other possible orderings?

The third question which our paper addresses is the application of such Weyl and non–Weyl symbolic calculus, in the presence of an inhomogeneous field, to solving the Cauchy problem and developing a semiclassical representation.

We begin with the first question and consider the linear phase space $\mathbb{R}^{2n}$ with the following inhomogeneous symplectic form

$$\omega_F=\omega_0+F, \quad F=\tfrac{1}{2}F_{jk}(q)\,dq^k\wedge dq^j. \tag{1.1}$$

In cases $n=3$, $n=4$ the form (1.1) describes the structure of the phase space for charged particles in an electromagnetic field;[11,12] the additional summand F is the Faraday 2-form multiplied by the charge coupling constant e/c. For simplicity of notation we include this constant in F_{jk}; also note that the order of indices j,k in (1.1) is opposite to that used in some textbooks.[13]

In detail one has the following. In the three-dimensional case with $q=(q^1,q^2,q^3)$ then

$$F_{jk}=\frac{e}{c}\epsilon_{kjl}B^l \quad (j,k=1,2,3),$$
$$F=\frac{e}{c}(B^1(q)dq^2\wedge dq^3+B^2(q)dq^3\wedge dq^1+B^3(q)dq^1\wedge dq^2). \tag{1.2a}$$

Here B is the magnetic field, and $dF=0$ is equivalent to $\operatorname{div}B=0$. In the four-dimensional case with $q=(q^0,q^1,q^2,q^3)$, $q^0\equiv ct$ one has

$$F_{jk}=\frac{e}{c}\epsilon_{kjl}B^l, \quad (j,k=1,2,3), \quad F_{0j}=\frac{e}{c}E_j \quad (j=1,2,3),$$
$$F=\frac{e}{c}(B^1(t,q)\,dq^2\wedge dq^3+B^2(t,q)\,dq^3\wedge dq^1+B^3(t,q)\,dq^1\wedge dq^2)+eE_j(t,q)dq^j\wedge dt. \tag{1.2b}$$

The electric field is denoted by E, and $dF=0$ is equivalent to the pair of Maxwell equations $c^{-1}\partial B/\partial t+\operatorname{curl}E=0$, $\operatorname{div}B=0$; see Refs. 13 and 14.

The form ω_F is called the *magnetic symplectic form*. We show how this form generates the Weyl–symmetrized associative product $\star_F$ of functions over the phase space.

The general mathematical framework for such products was established by Bayen, Flato, Fronsdal, Lichnerowicz, and Sternheimer,[15] by Berezin,[1] Rieffel,[16] Fedosov[17] and intensively developed in many other works. The specific ''magnetic'' product $\star_F$ we construct and investigate is just a particular example of these quantization schemes. The method which we use to determine $\star_F$ follows Ref. 18 and is based on the creation of the left (right) regular representation for the magnetic commutation relations between the quantum position and the kinetic momentum.

The q^j,p_k are coordinates corresponding to the position of the charged particle and its gauge invariant kinetic momentum. The commutation relations between the corresponding quantum operators $\hat{q}^j,\hat{p}_k$ are the following:

$$[\hat{q}^j,\hat{q}^k]=0, \quad [\hat{q}^j,\hat{p}_k]=i\hbar\,\delta^j_k, \quad [\hat{p}_j,\hat{p}_k]=i\hbar F_{kj}(\hat{q}). \tag{1.3}$$

The usual realization of these operators in the Hilbert space $L^2(\mathbb{R}^n_q)$ is $\hat{q}=q$, $\hat{p}=-i\hbar\partial/\partial q - (e/c)\Phi(q)$, where $(e/c)d(\Phi dq)=F$, and Φ is the gauge potential. Specifically, for $n=3$:

$$\Phi=(\mathcal{A}_1,\mathcal{A}_2,\mathcal{A}_3), \quad \mathrm{curl}\mathcal{A}=B, \quad \hat{p}_j=-i\hbar\frac{\partial}{\partial q_j}-\frac{e}{c}\mathcal{A}_j(q) \quad (j=1,2,3), \tag{1.4a}$$

for $n=4$

$$\Phi=(-a,\mathcal{A}_1,\mathcal{A}_2,\mathcal{A}_3), \quad \mathrm{curl}\mathcal{A}=B, \quad -\left(\frac{1}{c}\frac{\partial\mathcal{A}}{\partial t}+\frac{\partial a}{\partial q}\right)=E,$$

$$\hat{p}_0=-\frac{i\hbar}{c}\frac{\partial}{\partial t}+\frac{e}{c}a(t,q), \quad \hat{p}_j=-i\hbar\frac{\partial}{\partial q_j}-\frac{e}{c}\mathcal{A}_j(t,q) \quad (j=1,2,3). \tag{1.4b}$$

All the formulas obtained in the paper depend on the symplectic form (1.1) only, but not on the choice of potentials, and so, all results are gauge independent.

The noncommutative product $\star_F$ which we construct necessarily reproduces the commutation relations (1.3) on coordinate functions

$$q^j\underset{F}{\star}q^k-q^k\underset{F}{\star}q^j=0, \quad q^j\underset{F}{\star}p_k-p_k\underset{F}{\star}q^j=i\hbar\delta^j_k, \quad p_j\underset{F}{\star}p_k-p_k\underset{F}{\star}p_j=i\hbar F_{kj}(q).$$

The operators of left multiplication $q\star_F$ and $p\star_F$, as well as right multiplication, are derived without difficulty from these relations, using the noncommutative calculus;[18,19] the result incorporates Valatin's[20] primitive of the closed 2-form F (see Sec. II). We note that the problem of a finding a gauge invariant symbol product in a convenient closed form was first addressed by Stratonovich.[21]

In Sec. III we derive explicit formulas for $\star_F$ in two equivalent forms, both valid when $F=0$ and when $F\neq 0$. The first is analogous to the exponential Janus derivative representation[22–24] due to Groenewold. The second is a modification of the $(F=0)$ Berezin's integral for the noncommutative product. In both versions there appears an additional electromagnetic action, or flux, over triangles in phase space. Moreover, the Groenewold-type product formula admits generalization for N multipliers via the magnetic area of polygon membranes.

Our exact formulas for the $\star_F$ product can be easily expanded to obtain formal $\hbar\to 0$ power series. Higher-order terms beyond the Poisson bracket contribution are functions of derivatives of F_{jk}. This series coincides structurally with that obtained by Müller.[25]

Our integral formula for $\star_F$ is similar to that found in Ref. 26 and is also related to constructions[27–29] of the Wigner function in the presence of electromagnetic fields, but the method and the geometric interpretation is our case are completely different. In Sec. IV we show that the $\star_F$ product can be produced by a convolution over $T\mathbb{R}^n$. This convolution is generated by a version of the Connes' tangential groupoid[30–32] but with an additional rapidly oscillating factor represented by the electromagnetic flux.

In Sec. V we analyze, following the general approach of Ref. 33, the structure of the symplectic groupoid corresponding to $\star_F$. This structure is given on the secondary cotangent bundle $T^*(T^*\mathbb{R}^n)=T^*\mathbb{R}^n\oplus\mathbb{R}^{2n}$. The first cotangent bundle, $T^*\mathbb{R}^n=\mathbb{R}^n_q\otimes\mathbb{R}^n_p$, is the primary phase space, over which we construct the product $\star_F$. We show how the symplectic groupoid structure on $T^*(T^*\mathbb{R}^n)$ senses the magnetic correction F in the symplectic form, and how the space $\mathbb{R}^{2n}$, dual to $T^*\mathbb{R}^n$, is equipped with a pseudogroup structure controlled by a hidden magnetic momentum of membranes.

From this point of view, we claim that in the formula for $\star_F$ it would be more natural to consider not the usual geodesic triangle, but the triangle with three additional ''wings'' directed vertically (i.e., parallel to the p-direction) in the phase space. The shape of wings is determined by the symplectic groupoid structure.

Then in Sec. VI we investigate what happens if the Weyl ordering of noncommuting coordinates is changed to some other ordering. The wide (matrix) family of orderings introduced in Ref. 34 we relate to phases in the exponential representation of the $*$-product. These phases can be again presented as symplectic areas of membranes. The membranes are combinations of the basic triangle with additional wings that are now not necessarily vertical. The shape and direction of the wings exactly control the choice of the ordering in quantization, and again it is related to the symplectic groupoid structure over the secondary phase space $T^*(T^*\mathbb{R}^n)$.

The symplectic area of the wings give three additional contributions to the phase. The transform from the original Berezin phase (the Weyl case) to the new one, generated by the wings, can be considered as a type of gauge transformation of the ''symplectic potential.'' On the level of $*$-products this is the transformation from the distinguished Weyl choice to other ordering choices. In a sense this is the ''gauge'' of quantization.

The special features of the Weyl quantization which have made it the preferred choice[2,23,24,35,36] for physical applications are: (1) It treats $\hat{q}$ and $\hat{p}$ symmetrically; (2) self-adjoint operators have real symbols; and, (3) the Groenewold–Moyal bracket is an even function of $\hbar$, in particular its leading semiclassical correction is $O(\hbar^2)$, not $O(\hbar)$. From the symplectic point of view, the Weyl ordering seems distinguished since the corresponding membranes are of the simplest shape (having no wings).

The Wick normal and anti-normal orderings $\hat{z}^{*}_{2},\hat{z}_{1}$ and $\hat{z}^{*}_{1},\hat{z}_{2}$ (where $z=q+ip$) correspond to pure imaginary wings of membranes in the product formulas.

Other convenient orderings—the standard $\hat{q}_{2},\hat{p}_{1}$ and anti-standard $\hat{q}_{1},\hat{p}_{2}$—correspond to the case when the wings are parallel to the basic triangle and the total membrane becomes a plane rectangle. These standard and anti-standard cases correspond to the push- and pull-groupoid structure on $T\mathbb{R}^n$ (see Sec. IV). From the symplectic point of view these cases are singular because of the totally caustic character of the graph of symplectic groupoid multiplication corresponding to these cases.

In Secs. VII and VIII we apply these ideas to the quantum dynamical problem: A charged particle in an electromagnetic field. The basic results for this system were found by Dirac, Fock, Peierls, and Schwinger. Gauge invariant versions of the WKB approximation were developed[37–42] mostly in terms of integral kernels (Green functions). In the context of the present paper we can use the $\star_F$ symbol calculus to obtain a phase space gauge invariant treatment of this problem.

We first study, in Sec. VII, the pure magnetic situation without electric field. We represent the gauge invariant version of the quantum evolution equation over phase space and show how the Berry and Marinov geometrical representation for the solution of the Hamilton–Jacobi equation, as well the geometrical phase summation rule are generalized in the presence of the magnetic field.

At the end of Sec. VII, using the membrane generalization of the Groenewold formula, we represent the symbol of the evolution operator exactly in a continual form. This continual membrane formula is dual to the Feynman path integral representation.

Then, in Sec. VIII, we consider a time-dependent electromagnetic field and represent the gauge invariant quantum equations over phase space in both the nonrelativistic and relativistic cases. Here we use dynamical quantum products which are time-dependent. The evolution of commutation relations in time is controlled by the electric field.

We describe the semiclassical solution of the Cauchy problem using membranes in seven-dimensional contact space $\mathbb{R}_t\times\mathbb{R}^3_q\times\mathbb{R}^3_p$. The boundary of these dynamic membranes are given by

the solution of two classical systems: one for the given particle and an additional one for a "virtual" particle of infinite mass.

The first draft of this paper appeared in the electronic archive: quant-ph/0002041.

II. MAGNETIC PRODUCT FOR WEYL ORDERING

We begin with the definition of magnetic product on a function space over $\mathbb{R}^{2n}$. The logic is the following: We transform relations (1.3) to the standard Heisenberg relations, apply the standard operators of regular representation, and then transform back to the magnetic variables. As the result, we obtain a formula for magnetic product in terms of left and right regular representation of the algebra (1.3).

First we recall the properties of closed forms on $\mathbb{R}^n$.

Lemma 1: Let $F=\frac{1}{2}F_{jk}(q)dq^k\wedge dq^j$ be a closed two-form on $\mathbb{R}^n$. Consider the vector-valued 1-form Fdq with components $(F(q)\,dq)_j=F_{jk}(q)\,dq^k$ and define the two point vector potential

$$A(q,q')=\frac{1}{|q-q'|}\int_{q'}^{q}|\tilde{q}-q'|F(\tilde{q})d\tilde{q}, \tag{2.1}$$

where the integral is taken along the straight line path from q' to q, and $|\cdot|$ denotes the Euclidean norm on $\mathbb{R}^n$. Then for an arbitrary fixed $q'\in\mathbb{R}^n$ the 1-form $A(q,q')dq$ is a primitive of F

$$d(A\,dq)=F.$$

The choice of a primitive (2.1) *(gauge choice) is uniquely characterized by the orthogonality condition*

$$A(q,q')\cdot(q-q')=0. \tag{2.2}$$

Note that construction (2.1) is different from that usually used in proofs of the known Poincaré lemma in the theory of differential forms. On the other hand, (2.1) is just a simple particular case of the solution of Lie system related to a general Poisson bracket; (see Ref. 18, p. 81, and references therein). Formula (2.1) was obtained by Valatin[20] for electromagnetic tensors. The characteristic condition (2.2) was stressed by Dirac (see Ref. 20, p. 101).

We need several other properties of Valatin's primitive.

Lemma 2: The following formulas hold:

$$d_{q'}(A(q,q')\,dq)=d_q(A(q',q)\,dq'),$$

$$A(q,q')-A(q',q)=\int_{q'}^{q}F(\tilde{q})\,d\tilde{q},$$

$$A(q,q')+A(q',q)=\frac{1}{|q-q'|}\int_{q_m}^{q}|\tilde{q}-\tilde{q}^*|(F(\tilde{q})-F(\tilde{q}^*))\,d\tilde{q},$$

where the integrals are taken along the straight line paths, and $\tilde{q}^*=2q_m-\tilde{q}$ is the point symmetric to $\tilde{q}$ with respect to the middle point $q_m=\frac{1}{2}(q+q')$.

Let Δ be the triangle in $\mathbb{R}^n$ with vertices q, q', q''. Consider the integral (flux) of the form F:

$$\mathrm{Flux}_{q''}(q,q')\equiv\int_{\Delta}F. \tag{2.3}$$

Note that here and everywhere in the sequel the orientation of a membrane corresponds to the sequence of its vertices (or sides) read from right to left; so the orientation of Δ corresponds to the sequence $q\leftarrow q'\leftarrow q''$.

Lemma 3: The following formulas hold:

$$\mathrm{Flux}_{q''}(q,q')=\int_{q'}^{q}A(\tilde{q},q'')d\tilde{q},$$
$$\frac{\partial}{\partial q}\mathrm{Flux}_{q''}(q,q')=A(q,q'')-A(q,q'), \tag{2.4}$$

where the integral in (2.4) *is taken along the straight line path.*

Now let us fix the second argument of $A(q,q')$ at some point, say, $q'=0$ and introduce the operators

$$\hat{p}'=\hat{p}+A(\hat{q},0).$$

Since $\hat{q}$, $\hat{p}$ satisfy relations (1.3), the new set of operators $\hat{q}$, $\hat{p}'$ satisfy the standard Heisenberg commutation relations

$$[\hat{q}^j,\hat{p}'_k]=i\hbar\delta^j_k, \quad [\hat{q}^j,\hat{q}^k]=[\hat{p}'_j,\hat{p}'_k]=0. \tag{2.5}$$

Any Weyl-symmetrized function of operators $\hat{q},\hat{p}$ can be transformed to a function of operators $\hat{q}$, $\hat{p}'$ by the formula

$$f(\hat{q},\hat{p})=f\left(\frac{\overset{3}{\hat{q}}+\overset{1}{\hat{q}}}{2},\overset{2}{\hat{p}'}-\overset{3}{\tilde{A}}(\overset{1}{\hat{q}},\hat{q})\right), \tag{2.6}$$

where

$$\tilde{A}(q,q')\equiv\int_0^1 A(q\mu+q'(1-\mu),0)d\mu.$$

We have used here formulas of noncommutative analysis[19] and Ref. 18, pp. 277–295; the superscripts on top of operators denote the order of application.

Throughout the paper we will not give a characterization of the spaces the symbols must belong to in order that (2.6) and the subsequent product formulas are well defined. This is a separate technical (and often not simple) question which has been extensively investigated in the pseudodifferential operator literature.[18,34,43,44] The reader can consider all formulas as formally algebraic or, depending on the formula, assume an appropriate simple symbol class such as polynomials, smooth rapidly decreasing functions, etc.

For the Heisenberg algebra (2.5) the operators of left and right regular representation are well known. Namely, consider arbitrary Weyl-symmetrized function g' with operator arguments $\hat{q},\hat{p}'$:

$$\hat{g}'\equiv g'(\hat{q},\hat{p}')=g'\left(\frac{\overset{3}{\hat{q}}+\overset{1}{\hat{q}}}{2},\overset{2}{\hat{p}'}\right). \tag{2.7}$$

Then the following left and right multiplication formulas hold:[18,34,43,45]

$$\begin{aligned}
&\hat{q}\hat{g}'=\widehat{L'_q g'}, \quad L'_q=q+\tfrac{1}{2}i\hbar\partial_{p'};\\
&\hat{p}'\hat{g}'=\widehat{L'_p g'}, \quad L'_p=p'-\tfrac{1}{2}i\hbar\partial_q;\\
&\hat{g}'\hat{q}=\widehat{R'_q g'}, \quad R'_q=q-\tfrac{1}{2}i\hbar\partial_{p'};\\
&\hat{g}'\hat{p}'=\widehat{R'_p g'}, \quad R'_p=p'+\tfrac{1}{2}i\hbar\partial_q.
\end{aligned} \tag{2.8}$$

Here we denote $\partial_q \equiv \partial/\partial q$ and $\partial_{p'} = \partial/\partial p'$. Operators L', R' satisfying multiplication formulas (2.8) are called the left and right regular representation of the given algebra, in our case, the algebra (2.5).

On the right-hand side of the formula (2.6) operators $\overset{1}{\hat{q}}$ and $\overset{3}{\hat{q}}$ in arguments of $\tilde{A}$ can be considered as multiplication by $\hat{q}$ from the left and from the right, and so they can be replaced by L'_q and R'_q acting on arguments of f. Thus we obtain from (2.6)

$$f(\hat{q},\hat{p}) = f'\left(\frac{\overset{3}{\hat{q}}+\overset{1}{\hat{q}}}{2}, \overset{2}{\hat{p}'}\right) = f'(\hat{q},\hat{p}'),$$

where

$$f'(q,p') = f(q,p' - \tilde{A}(\overleftarrow{L'_q},\overleftarrow{R'_q})) = \exp\{-\tilde{A}(L'_q,R'_q)\partial_{p'}\}f(q,p'),$$

and the left arrows mean that operators act on arguments standing to their left. After substitution of explicit formulas for L'_q, R'_q from (2.8) we conclude

$$f'(q,p') = \exp\{-\tilde{A}(q+\tfrac{1}{2}i\hbar\partial_{p'}, q-\tfrac{1}{2}i\hbar\partial_{p'})\partial_{p'}\}f(q,p').$$

Note that by Lemma 2

$$\tilde{A}(q+u/2,q-u/2)u = \int_{q-u/2}^{q+u/2} A(\tilde{q},0)\,d\tilde{q} = \mathrm{Flux}_0(q+u/2,q-u/2).$$

So we obtain the transformation formula

Proposition 1: Any Weyl-symmetrized function f in operators $\hat{q}$, $\hat{p}$, satisfying commutation relations (1.3), *can be transformed to the Weyl-symmetrized function f' in operators $\hat{q}$, $\hat{p}'$ satisfying Heisenberg relations* (2.5). *This transform is given by formula*

$$f' = U_F f, \quad U_F = \exp\left\{\frac{i}{\hbar}\mathrm{Flux}_0\left(q+\frac{1}{2}i\hbar\partial_p, q-\frac{1}{2}i\hbar\partial_p\right)\right\}, \tag{2.9}$$

where the Flux_0 *was defined in* (2.3).

Using this transform one easily obtains all objects which are needed for the algebra (1.3). For instance, the operators of left and right regular representation for (1.3) are the following

$$L_q = U_F^{-1}\cdot L'_q\cdot U_F, \quad R_q = U_F^{-1}\cdot R'_q\cdot U_F,$$

$$L_p = U_F^{-1}\cdot L'_p\cdot U_F - A(L_q,0), \quad R_p = U_F^{-1}\cdot R'_p\cdot U_F - A(R_q,0).$$

Applying explicit formulas (2.8) for L', R', (2.9) for U_F and using Lemma 3 we get

$$\begin{aligned} L_q &= q+\tfrac{1}{2}i\hbar\partial_p, \quad R_q = q-\tfrac{1}{2}i\hbar\partial_p, \\ L_p &= p-\tfrac{1}{2}i\hbar\partial_q - A(L_q,R_q), \quad R_p = p+\tfrac{1}{2}i\hbar\partial_q - A(R_q,L_q). \end{aligned} \tag{2.10}$$

Lemma 4: Operators L_q, L_p satisfy commutation relations (1.3), *and operators R_q, R_p satisfy the conjugate relations (with opposite signs). Operators L commute with R.*

If we know the regular representation of commutation relations, we know the product of symbols (see Ref. 18 Appendix 2).

Theorem 1: *The product of Weyl-symmetrized functions in operators satisfying relations* (1.3) *is given by*

$$f(\hat{q},\hat{p})\cdot g(\hat{q},\hat{p})=(f\underset{F}{\star}g)(\hat{q},\hat{p}), \tag{2.11}$$

where $\star_F$ *is the associative product of functions over* $\mathbb{R}^{2n}$ *defined by*

$$f\underset{F}{\star}g=f(L_q,L_p)g=g(R_q,R_p)f.$$

We call $\star_F$ the *magnetic product* of Weyl-symmetrized type. In particular, we have $L_q=q\star_F$, $L_p=p\star_F$, and $R_q=\star_F q$, $R_p=\star_F p$. These multiplication operators satisfy relations (1.3) and their conjugate companions; left and right multiplications commute with each other.

Note that the magnetic product, $\star_F$, since it one-to-one corresponds, by (2.11), to the operator product in the Hilbert space $L^2(\mathbb{R}^n)$, is an example of Rieffel's ''strict deformation quantization.'' [16] Moreover, the operator realization $f\to f(\hat{q},\hat{p})$ possesses the usual trace property

$$trf(\hat{q},\hat{p})=\frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^{2n}}f(x)dx.$$

In particular, this means that the space of symbols $L^2(\mathbb{R}^{2n})$ is invariant with respect to the $\star_F$ product (and isomorphic to the algebra of Hilbert–Schmidt operators on $L^2(\mathbb{R}^n)$). Also note the following useful identity:

$$\int_{\mathbb{R}^{2n}}(f\underset{F}{\star}g)(x)\,dx=\int_{\mathbb{R}^{2n}}f(x)g(x)\,dx,$$

which implies that the product $\star_F$ is ''closed'' in the sense of Connes, Flato, and Sternheimer.[46]

III. EXPONENTIAL FORMULA FOR MAGNETIC PRODUCT

The next useful stage in evaluation of the $\star_F$-product is to bring it into an exponential form. First, we apply Proposition 1 and the usual Groenewold formula[22,43] known for Weyl-symmetrized product of symbols over the Heisenberg algebra, namely

$$f'\star g'=f'\exp\left\{-\frac{i\hbar}{2}\overleftarrow{\partial}J^{-1}\overrightarrow{\partial}\right\}g'=f'(q+\vec{u}/2,p)\,g'(q-\tilde{u}/2,p), \tag{3.1}$$

where

$$\tilde{u}=i\hbar\overleftarrow{\partial}_p,\quad \vec{u}=i\hbar\overrightarrow{\partial}_p,\quad \partial=(\partial_q,\partial_p).$$

From (2.9) we calculate

$$U_Ff\star U_Fg=f\exp\left\{\frac{i}{\hbar}\mathrm{Flux}_0(q+(\tilde{u}+\vec{u})/2,q+(\vec{u}-\tilde{u})/2)\right.$$
$$\left.+\frac{i}{\hbar}\mathrm{Flux}_0(q+(\vec{u}-\tilde{u})/2,q-(\tilde{u}+\vec{u})/2)-\frac{i\hbar}{2}\overleftarrow{\partial}J^{-1}\overrightarrow{\partial}\right\}g.$$

Applying the inverse transformation U_F^{-1} we obtain

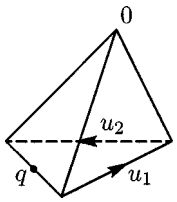

FIG. 1. Membrane $\Delta_q(u_2,u_1)$ is the base plane.

$$U_F^{-1}(U_F f\star U_F g)=f\exp\Big\{-\frac{i}{\hbar}\mathrm{Flux}_0(q+(\tilde{u}+\vec{u})/2,q-(\tilde{u}+\vec{u})/2)+\frac{i}{\hbar}\mathrm{Flux}_0(q+(\tilde{u}+\vec{u})/2,$$
$$q+(\vec{u}-\tilde{u})/2)+\frac{i}{\hbar}\mathrm{Flux}_0(q+(\vec{u}-\tilde{u})/2,q-(\tilde{u}+\vec{u})/2)-\frac{i\hbar}{2}\overleftarrow{\partial}J^{-1}\vec{\partial}\Big\}g.$$

The sum of three fluxes which appeared at last exponent can be simplified if we look at the geometrical picture. Indeed, the three fluxes represent integrals of the form F over three triangles with common vertex 0. They are sides of the tetrahedron. By the Stokes theorem these three fluxes together are equal to the flux over the bottom triangle; see Fig. 1, in which the vectors u_1 and u_2 represent the operators $\vec{u}$ and $\tilde{u}$, respectively.

The relation

$$f\underset{F}{\star}g=U_F^{-1}(U_F f\star U_F g),$$

and the representation of its right-hand side which we have derived above generate the following statement.

Proposition 2: The magnetic product $\star_F$, *corresponding to commutation relations* (1.3), *can be calculated by the formula*

$$(f\underset{F}{\star}g)(q,p)=f(q,p)\exp\Big\{\frac{i}{\hbar}\phi(q,i\hbar\overleftarrow{\partial}_p,i\hbar\vec{\partial}_p)+\frac{i\hbar}{2}(\overleftarrow{\partial}_q\vec{\partial}_p-\overleftarrow{\partial}_p\vec{\partial}_q)\Big\}g(q,p). \tag{3.2}$$

Here

$$\phi(q,u_2,u_1)=\int_{\Delta_q(u_2,u_1)}F, \tag{3.3}$$

and $\Delta_q(u_2,u_1)$ *is a membrane in* $\mathbb{R}^n$ *whose boundary is the triangle constructed by the middle point* q *of one side and by the two other sides* u_2, u_1. *The magnetic flux* (3.3) *can also be represented in the form*

$$\phi=\int_0^1 d\mu\int_0^\mu d\nu\, u_2 F(q+(\mu-\tfrac{1}{2})u_1+(\nu-\tfrac{1}{2})u_2)u_1.$$

Note the differential operators in the exponent (3.2) act only on the arguments of target functions f and g, but not on the argument q in the flux ϕ.

Also note that operators $i\hbar\partial_p$, which we substitute into the flux ϕ in the exponent (3.2), are of order $O(\hbar)$ over the space of non-oscillating functions as $\hbar\to 0$. So the flux ϕ actually is of order $O(\hbar^2)$, and the right-hand side of (3.2) can be easily expanded as a power series in $\hbar$. Thus for nonoscillating (as $\hbar\to 0$) functions f,g

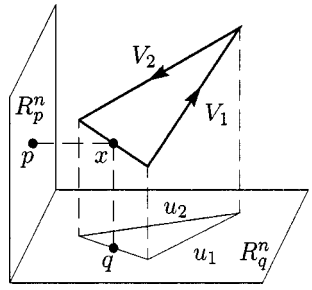

FIG. 2. Membrane $\Sigma_x(V_2,V_1)$.

$$f\underset{F}{\star}g\simeq\sum_{|\gamma|,|\varepsilon|=0}^{\infty}\frac{(-1)^{|\varepsilon|}}{\gamma!\varepsilon!}\left(-\frac{i\hbar}{2}\right)^{|\gamma|+|\varepsilon|}\partial_q^{\varepsilon}\partial_p^{\gamma}f\exp\left\{-\frac{i\hbar}{2}\sum_{|\alpha|,|\beta|=0}^{\infty}\frac{c_{|\alpha|,|\beta|}}{\alpha!\beta!}\right.$$
$$\left.\times\left(-\frac{i\hbar}{2}\right)^{|\alpha|+|\beta|}(\vec{\partial}_p)^{\alpha}\langle\vec{\partial}_p,\partial^{\alpha+\beta}F(q)\vec{\partial}_p\rangle(\vec{\partial}_p)^{\beta}\right\}\partial_q^{\gamma}\partial_p^{\varepsilon}g,$$

where

$$c_{s,m}=\frac{e[m+1]}{(s+1)(m+1)}-\frac{e[s+m]}{(s+1)(s+m+2)},$$

and $e[l]=0$ if l is even, and $e[l]=1$ if l is odd. Here $\langle\cdot,\cdot\rangle$ is the Euclidean scalar product in $\mathbb{R}^n$ and the Greek letters are multi-indices. Of course, the first two terms of this expansion are

$$f\underset{F}{\star}g=fg-\frac{i\hbar}{2}\{f,g\}_F+O(\hbar^2),$$

where $\{,\}_F$ is the Poisson bracket on $\mathbb{R}^{2n}$ corresponding to the symplectic form ω_F, i.e.,

$$\{f,g\}_F=\partial_p f\partial_q g-\partial_q f\partial_p g+\langle\partial_p f,F(q)\partial_p g\rangle. \tag{3.4}$$

In the case where F is restricted to be the pure magnetic form (1.2a), then the $\hbar$ series above is equivalent to the one derived in Ref. 25.

Now we return to the formula (3.2) and observe that it is still not presented in a completely symplectic manner. We have there the flux ϕ, which is the integral of the form F over the triangle in q-space. The other part of the exponent in (3.2) can also be related to the area of a triangle, but in the (q,p)-space; see Fig. 2.

This triangle $\Sigma_x(V_2,V_1)$ is constructed by the middle point x of one side, and by the two opposite sides V_2, V_1. Its projection onto $\mathbb{R}_q^n$ coincides with the triangle $\Delta_q(u_2,u_1)$.

Theorem 2: *The magnetic product can be represented in the form*

$$(f\underset{F}{\star}g)(x)=\exp\left\{\frac{i}{\hbar}\int_{\Sigma_x(\hat{V}_2,\hat{V}_1)}\omega_F\right\}f(x_2)g(x_1)\Big|_{x_1=x_2=x}, \tag{3.5}$$

where ω_F is the magnetic symplectic form (1.1), $\hat{V}=(i\hbar\partial_p,i\hbar\partial_q)$, *and* $x=(q,p)\in\mathbb{R}^{2n}$.

In (3.5) one has to evaluate first the symplectic ω_F-area of the membrane $\Sigma_x(V_2,V_1)$, and then substitute the operators $\hat{V}_1,\hat{V}_2$ for the vectors V_1,V_2; the operator $\hat{V}_1$ is applied to the argument x_1 and $\hat{V}_2$ to the argument x_2.

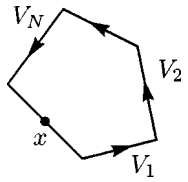

FIG. 3. Membrane $\Sigma_x(V_N,\dots,V_1)$.

Actually, formula (3.5) may be immediately generalized to the case of several multipliers. Consider a membrane in $\mathbb{R}^{2n}$ whose boundary is formed by N vectors $V_1,V_2,\dots,V_N$ as sides of a polygon, and by additional point x as a middle point of the $(N+1)$th side. Denote this membrane by $\Sigma_x(V_N,\dots,V_1)$; see Fig. 3.

Corollary 1: The following formula holds:

$$(f_N \underset{F}{\star} \cdots \underset{F}{\star} f_1)(x) = \exp\left\{\frac{i}{\hbar}\int_{\Sigma_x(\hat{V}_N,\dots,\hat{V}_1)} \omega_F\right\} f_N(x_N)\cdots f_1(x_1)\Big|_{x_1=\cdots=x_N=x}. \tag{3.6}$$

An immediate consequence of (3.5) is an integral formula for $f\star_F g$. Indeed, in (3.5) we have a pseudodifferential operator acting on f and g. By the usual formulas via Fourier and inverse Fourier transform we easily calculate this action and obtain an integral representation for $f\star_F g$. The triangle $\Sigma_x(V_2,V_1)$ in this new formula will be described not by the sides V_2,V_1, but by the middle points x_2,x_1 of those sides. Such a triangle in $\mathbb{R}^{2n}$, constructed by three middle points x,x_2,x_1, we denote by $\Sigma(x,x_2,x_1)$.

Proposition 3: The magnetic product is given by the integral formula

$$(f\underset{F}{\star}g)(x) = \frac{1}{(\pi\hbar)^{2n}}\int_{\mathbb{R}^{2n}}\int_{\mathbb{R}^{2n}} \exp\left\{\frac{i}{\hbar}\int_{\Sigma(x,x_2,x_1)}\omega_F\right\} f(x_2)g(x_1)\,dx_2\,dx_1. \tag{3.7}$$

Actually, the magnetic part F of the form ω_F is integrated in (3.5) and (3.7) over the projection of $\Sigma(x,x_2,x_1)$ onto q-space.

In the case $F=0$, (3.7) becomes the Berezin formula for the Weyl-symmetrized product, and (3.6) becomes equivalent to the N-factor products obtained in Refs. 23 and 24.

IV. TANGENTIAL GROUPOID AND MAGNETIC COCYCLE

Formula (3.7) for magnetic noncommutative product over $\mathbb{R}^{2n}=T^*\mathbb{R}^n$ can also be derived from the Connes type tangential groupoid structure on $T\mathbb{R}^n$,[30–32] equipped with an additional magnetic phase factor (cocycle).

The space $T\mathbb{R}^n$ consists of pairs (q,u), where $q\in\mathbb{R}^n$ and $u\in T_q\mathbb{R}^n$. Vector u is interpreted as a "displacement" at point q. The first and simplest groupoid structure on $T\mathbb{R}^n$ is given by formula $(q_2,u_2)\circ(q_1,u_1)=(q_1,u_2+u_1)$ iff $q_1=q_2$. This groupoid is commutative; it is called the *Galileo groupoid*. This structure is shown in Fig. 4. The set of units of this groupoid consists of all pairs $(q,0)$; so, the set of units is the configuration space $\mathbb{R}^n_q$ considered as the zero-section in $T\mathbb{R}^n$.

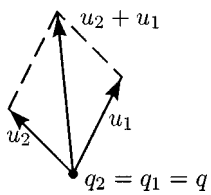

FIG. 4. Galileo groupoid.

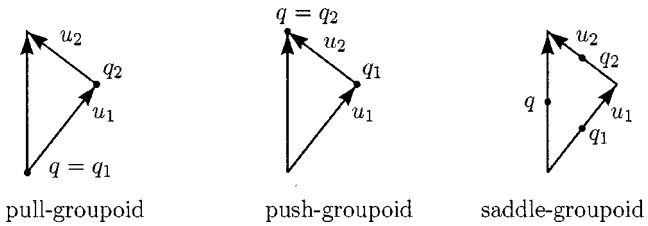

FIG. 5. Pull-groupoid; push-groupoid; saddle-groupoid.

Other geometric combinations of the vectors u_1, u_2 and the points q_1, q_2 may be assembled to give noncommutative groupoids. Three simple possibilities are shown in Fig. 5. The multiplication rule, for instance, in the *pull-groupoid* is $(q_2,u_2)\circ(q_1,u_1)=(q_1,u_2+u_1)$ iff $q_1+u_1=q_2$. For the *saddle-groupoid* one has

$$(q_2,u_2)\circ(q_1,u_1)=(q,u_2+u_1) \quad \text{iff} \quad q_1+u_1/2=q_2-u_2/2.$$

In this case, q is the middle point of the third side of the triangle: $q=q_1+u_2/2=q_2-u_1/2$.

All these groupoids are specific cases of a general *τ-groupoid*, where $0\leqslant\tau\leqslant 1$. Pull-, push-, and saddle-cases correspond to $\tau=1$, $\tau=0$, and $\tau=1/2$, respectively. In Fig. 6 one can see the generic case corresponding to some $\tau \quad (1/2<\tau<1)$; in this case $q_2=q_1+\tau u_1+(1-\tau)u_2$ and $q=q_1+(1-\tau)u_2$. The set of units for all of these groupoids is $\mathbb{R}^n_q\subset T\mathbb{R}^n$.

On any (measurable) groupoid there is a convolution of distributions[30,47]

$$(\phi_2\odot\phi_1)(a)=\int_{a=b\circ c}\phi_2(b)\phi_1(c)\,d\mu_b(c), \tag{4.1}$$

where $d\mu_b$ is the Haar measure on fibres of the left groupoid mapping $c\to c\circ c^{-1}$. For example, in the case of saddle-groupoid we have

$$(\phi_2\odot\phi_1)(q,u)=\int_{\mathbb{R}^n}\phi_2(q+u_1/2,u-u_1)\phi_1(q-(u-u_1)/2,u_1)du_1. \tag{4.2}$$

Each convolution over $T\mathbb{R}^n$ generates a noncommutative product over $T^*\mathbb{R}^n$ just by Fourier transform between u and p coordinates

$$f^{\sim}(q,u)\equiv\frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^n}e^{iup/\hbar}f(q,p)\,dp=\frac{1}{(2\pi)^n}\int_{\mathbb{R}^n}e^{iuk}f(q,\hbar k)\,dk. \tag{4.3}$$

For example, if one takes the saddle-groupoid convolution $\odot$ (4.2) then the corresponding product over $T^*\mathbb{R}^n$ is the usual Groenewold–Moyal product $\star$ (3.1), i.e.,

$$(f\star g)^{\sim}=f^{\sim}\odot g^{\sim}. \tag{4.4}$$

Remark 1: In this approach the quantum convolution $\odot$ is not an $\hbar$-deformation of a commutative one. The deformation parameter $\hbar$ appears only in the Fourier transform (4.3); this is

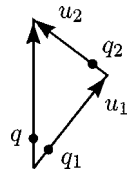

FIG. 6. τ-groupoid.

what makes it possible to include into the quantization scheme functions over $T^*\mathbb{R}^n$ that oscillate rapidly as $\hbar \to 0$. For nonoscillating functions $f(q,p)$ the transform (4.3) admits the classical limit $\hbar = 0$. With this limit one obtains the correspondence $f(q,p) \rightsquigarrow f(q,0)\,\delta(u)$ between the classical commutative algebra of functions over the phase space $T^*\mathbb{R}^n$ and the commutative subalgebra of distributions over $T\mathbb{R}^n$ of the type $\varphi(q)\,\delta(u)$ concentrated at the zero "displacement" $u=0$. Displacement by a nonzero vector u_0, represented over $T\mathbb{R}^n$ as the distribution $\delta(u-u_0)$, after the transform inverse to (4.3) generates the phase space observable $f(q,p)=\exp\{-iu_0 p/\hbar\}$. The corresponding operator $\hat{f}$ (if the magnetic tensor $F=0$) is just the Heisenberg translation operator $\hat{f}\psi(q)=\psi(q-u_0)$. This is the simplest example of rapidly oscillating functions f which one has to include into algebra of observables over $T^*\mathbb{R}^n$, but which lie outside the formal deformation quantization approach;[15,17] see also Refs. 31 and 48.

Now let us return to the relation (4.4) between star-product and convolution. The question arises: how to get the magnetic product $\star_F$ (3.7) via the groupoid structure on $T\mathbb{R}^n$? Let us slightly generalize (4.1) by introducing an exponential phase factor

$$(\phi_2 \odot \phi_1)(a) = \int_{a=b\circ c} e^{i\Phi(b,c)}\phi_2(b)\,\phi_1(c)\,d\mu_b(c). \tag{4.5}$$

Here Φ is a groupoid cocycle, i.e.,

$$\Phi(d,b\circ c)-\Phi(d\circ b,c)+\Phi(b,c)-\Phi(d,b)=0, \quad \Phi(b,c)=-\Phi(c^{-1},b^{-1}),$$

for any multiplicable $b,c,d \in T\mathbb{R}^n$. The cocycle Φ is called the coboundary iff

$$\Phi(b,c)=\psi(b)+\psi(c)-\psi(b\circ c), \quad \psi(b^{-1})=-\psi(b).$$

If Φ in (4.5) is a coboundary, then convolutions (4.5) and (4.1) are actually equivalent.

In the case of saddle-groupoid we can take the following magnetic cocycle (coboundary):

$$\Phi=\frac{1}{\hbar}\int_{\Delta(q,q_2,q_1)} F, \tag{4.6}$$

where F is the Faraday 2-form over $\mathbb{R}^n$, and $\Delta(q,q_2,q_1)$ is the triangle with middle points q, q_2, q_1. In this case the coboundary function ψ at the point $b=(q,u)$ is given by the integral $\psi(b) = 1/\hbar \int A(\tilde{q},0)\,d\tilde{q}$ along the chord $[q-\frac{1}{2}u, q+\frac{1}{2}u]$. Note that ψ controls the additional phase factor in the gauge invariant version of the Wigner function.[21,28,29]

Proposition 4: Let $\odot_F$ be the saddle-groupoid convolution, equipped with the magnetic cocycle (4.6). *Then the Fourier transform* (4.3) *relates this convolution to the magnetic product $\star_F$ via*

$$\underset{F}{(f\star g)}\tilde{} = \underset{F}{\tilde{f}\odot \tilde{g}}.$$

Note that other types of groupoids (like pull-, push-) will also generate some magnetic products over $\mathbb{R}^{2n}=T^*\mathbb{R}^n$. In Sec. VI we will consider a variety of such products. On the other hand, we will show that not all of products over $T^*\mathbb{R}^n$ are generated from the convolution over $T\mathbb{R}^n$ in this fashion.

In Sec. V we analyze the magnetic product (3.7) from the view point of symplectic groupoid structure of the secondary phase space (on the secondary cotangent) $T^*(T^*\mathbb{R}^n)$. Regarding this we mention the following.

Proposition 5: Each groupoid structure on $T\mathbb{R}^n$ whose set of units is $\mathbb{R}^n_q$, uniquely determines a symplectic groupoid structure on $T^*(T^*\mathbb{R}^n)$. Here $T^*\mathbb{R}^n$ is equipped with the symplectic form

$\omega_0 = dp \wedge dq$. If, in addition, on $T\mathbb{R}^n$ a cocycle of type (4.6) *is given, then on $T^*(T^*\mathbb{R}^n)$ we have a symplectic groupoid structure corresponding to the magnetic form ω_F.*

V. SYMPLECTIC GROUPOID AND MEMBRANES WITH WINGS

Formula (3.7) represents the exact magnetic product. On the other hand, it is known,[18] in a very general context, how to construct quantum products of functions over an arbitrary Poisson manifold $\mathcal{N}$ in the semiclassical approximation, to all orders in $\hbar \to 0$. This approximate product takes the form

$$(f*g)(x) \simeq \int \int K_\hbar(x,x_2,x_1) f(x_2) g(x_1)\, dx_1\, dx_2. \tag{5.1}$$

Here $x, x_2, x_1 \in \mathcal{N}$, and $K_\hbar$ is a "wave function" corresponding to some Lagrangian submanifold Λ_* in the "phase space" $\mathcal{E} \times \mathcal{E} \times \mathcal{E}$, where $\mathcal{E}$ is the symplectic groupoid over $\mathcal{N}$. In our case $\mathcal{N} = \mathbb{R}^{2n} = T^*\mathbb{R}^n$ with Poisson bracket (3.4). The Lagrangian submanifold Λ_* is the graph of groupoid multiplication in $\mathcal{E}$. If this graph is one-to-one projected onto the "configuration" space $\mathcal{N} \times \mathcal{N} \times \mathcal{N}$ along the polarization then the function $K_\hbar$ is just a Wentzel–Kramers–Brillouin (WKB) function

$$K_\hbar = \exp\{iS/\hbar\}\varphi + O(\hbar), \tag{5.2}$$

whose phase S is the Poincaré–Cartan action on Λ_* and φ is the solution of the corresponding transport equation.

In specific cases, for instance, in our case $\mathcal{N} = \mathbb{R}^{2n}$ with bracket (3.4), the asymptotic formula (5.1) becomes exact and the remainder $O(\hbar)$ in (5.2) is absent. Indeed, let us compare (5.1), (5.2) with formula (3.7) for the magnetic product $\star_F$. First, one can describe the symplectic groupoid $\mathcal{E}$ in our specific case. Let us set $\mathcal{E} = T^*\mathbb{R}^{2n} = \mathbb{R}^{2n}_x \oplus \mathbb{R}^{2n}_y$, and denote by (x,y) points in $\mathcal{E}$. The space $\mathbb{R}^{2n}_x$ is imbedded into $\mathcal{E}$ as a zero section $\{y=0\}$. The symplectic form on $\mathcal{E}$ is $dy \wedge dx$. The operators L, R (2.10) of left and right regular representation of algebra (1.3) generate two mappings

$$l: \mathcal{E} \to \mathbb{R}^{2n}, \quad r: \mathcal{E} \to \mathbb{R}^{2n}. \tag{5.3}$$

Here $l = (l_q, l_p)$ and $r = (r_q, r_p)$ are just symbols of $L = (L_q, L_p)$ and $R = (R_q, R_p)$, i.e.,

$$L = l(x, -i\hbar\partial_x), \quad R = r(x, -i\hbar\partial_x).$$

In our case formula (2.10) reads

$$\begin{aligned} l_q(x,y) &= x_q - y_p/2, \quad l_p(x,y) = x_p + y_q/2 - A(l_q, r_q), \\ r_q(x,y) &= x_q + y_p/2, \quad r_p(x,y) = x_p - y_q/2 - A(r_q, l_q). \end{aligned} \tag{5.4}$$

Mappings (5.3) are Poisson and anti-Poisson, i.e., l preserves brackets, r changes the sign of brackets [recall that on $\mathbb{R}^{2n}$ we have the bracket (3.4), and the bracket on $\mathcal{E}$ corresponds to the symplectic form $dy \wedge dx$].

The groupoid structure on $\mathcal{E}$ is defined as follows: points $m_2, m_1 \in \mathcal{E}$ are called *multiplicable* iff $r(m_2) = l(m_1)$; the product $m = m_2 \circ m_1$, by definition, is a point in $\mathcal{E}$ such that $l(m) = l(m_2)$, $r(m) = r(m_1)$. The subspace $\mathbb{R}^{2n}_x \subset \mathcal{E}$ is the set of units of this groupoid, and mappings (5.3) are left and right reduction mappings:

$$l(m) = m \circ m^{-1}, \quad r(m) = m^{-1} \circ m.$$

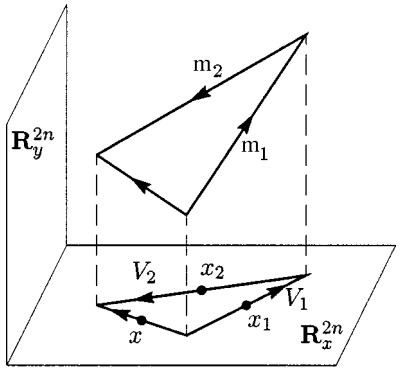

FIG. 7. Groupoid structure on $T^*\mathbb{R}^{2n}$.

The graph $\Lambda_* \subset \mathcal{E}\times\mathcal{E}\times\mathcal{E}$ of this groupoid multiplication consists of all multiplicable points and their products

$$\Lambda_* = \{(m, m_2, m_1) \mid m = m_2 \circ m_1\}. \tag{5.5}$$

If on $\mathcal{E}\times\mathcal{E}\times\mathcal{E}$ we introduce the symplectic form $dy\wedge dx - dy_2\wedge dx_2 - dy_1\wedge dx_1$, then the submanifold Λ_* is Lagrangian (see details in Refs. 33 and 49).

In the case $F=0$ (i.e., A=0) formulas (5.4) are interpreted as "middle point of chord" relations: $x=\frac{1}{2}(l+r)$, $y=JV$, where $V=l-r\in T\mathbb{R}^{2n}$. So, the groupoid structure on $\mathbb{R}^{4n} = T^*\mathbb{R}^{2n}$ is given by the triangle rule (see Fig. 7)

$$\begin{gathered} m = m_2 \circ m_1, \quad m=(x,y), \quad m_1=(x_1,y_1), \quad m_2=(x_2,y_2), \\ y = y_1 + y_2, \quad x = x_1 + \tfrac{1}{2}J^{-1}y_2 = x_2 - \tfrac{1}{2}J^{-1}y_1. \end{gathered} \tag{5.6}$$

For arbitrary given triple of points $x, x_2, x_1 \in \mathbb{R}^{2n}$ we uniquely construct the triangle for which these points are the middle points of its sides, and so reconstruct elements $m, m_2, m_1 \in \mathcal{E}$ such that $m = m_2 \circ m_1$. This means that the graph Λ_* is one-to-one projected onto $\mathbb{R}^{2n}\times\mathbb{R}^{2n}\times\mathbb{R}^{2n}$ along the "vertical" y-polarization. Hence, the kernel $K_\hbar$ has the WKB form (5.2), and its phase is

$$S(x, x_2, x_1) = \int_{(0,0,0)}^{(x,x_2,x_1)} (y\,dx - y_2\,dx_2 - y_1\,dx_1). \tag{5.7}$$

Here y, y_2, y_1 are determined via x, x_2, x_1 following the triangle multiplication rule; the initial point (0,0,0) corresponds to triple of elements $m_0 = m_0 \circ m_0$, where $m_0 = (0,0) \in \mathcal{E}$.

The integral (5.7) is taken over an arbitrary path on Λ_* connecting the triple (0,0,0) (i.e., the degenerate triangle) with the triple (x, x_2, x_1) (i.e., the given triangle). This path is actually a family of triangles in $\mathbb{R}^{2n}$; see Fig. 8. The phase (5.7) in the case $F=0$ (for more general "symmetric" cases see in Ref. 6) is just equal to the area of the final triangle

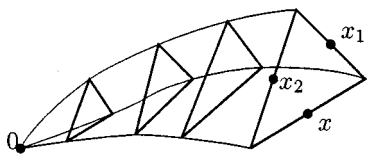

FIG. 8. Path on graph Λ_*.

$$S(x,x_2,x_1)=\int_{\Delta(x,x_2,x_1)}\omega_0.$$

Now let us see what happens in the general magnetic case $F\neq 0$. From (5.4) it follows that the groupoid structure now is given by formulas:

$$x=\tfrac{1}{2}(l+r)+V_F,\quad y=JV+Y_F,\quad \text{where}\quad V=l-r. \tag{5.8}$$

Here we have introduced notations

$$\begin{gathered}V_F=(0;A^s)\in\mathbb{R}^n_q\oplus\mathbb{R}^n_p,\quad Y_F=(A^a;0)\in\mathbb{R}^n_{y_q}\oplus\mathbb{R}^n_{y_p},\\ A^s=\tfrac{1}{2}(A(l_q,r_q)+A(r_q,l_q)),\quad A^a=A(l_q,r_q)-A(r_q,l_q).\end{gathered} \tag{5.9}$$

Comparing with the multiplication rule (5.6) in the case $F=0$ we see that points x, x_2, x_1 are no longer the middle points of sides of the basic triangle and do not even belong to those sides. They are shifted in the p-direction by the vectors V_F.

Another difference from the case $F=0$ is that the usual multiplication rule $y=y_1+y_2$ [see (5.6)] fails to hold for inhomogeneous magnetic case. New magnetic rule is

$$y=y_1+y_2+\left(\int_\Delta \nabla F;0\right), \tag{5.10}$$

where the vector-valued closed two-form ∇F is defined by $\nabla F=\frac{1}{2}\nabla F_{jk}dq^k\wedge dq^j$, and $\Delta=\Delta(q,q_2,q_1)$ is the triangle in q-space with middle points (q,q_2,q_1), which are projections of $x,x_2,x_1\in\mathbb{R}^{2n}$ onto $\mathbb{R}^n_q$. We have obtained the interesting physical quantity:

$$-\int_\Delta \nabla F=\oint_{\partial\Delta}F dq\sim\text{hidden momentum.}$$

The vector 2-form ∇F is a measure of *magnetic inhomogeneity*. So, this form controls the modification of the usual $(F=0)$ multiplication rule. The space $\mathbb{R}^{2n}_y$ (dual to $\mathbb{R}^{2n}_x$) now is not even a group, it is a pseudogroup over the Poisson manifold $\mathbb{R}^{2n}_x$ [see details in general case in Ref. 18, the word ''pseudo''—reflects the fact that the product (5.10) in the y-space depends on x-coordinates as additional parameters, and the condition of ''associativity'' of the product (5.10) senses this dependence]. The nontrivial part of the pseudogroup structure (5.10) is determined by the hidden momentum of the membrane Δ in the magnetic field.

Formula (5.7) in the case $F\neq 0$ still represents the phase in the product (3.7) if we put there the corrected values $y=JV+Y_F$. But now the triangle no longer represents the groupoid multiplication rule, and from this point of view, it seems unnatural to keep this triangle in the formula for the phase.

Actually, we have another configuration (see Fig. 9) related to the triple (x,x_2,x_1). This

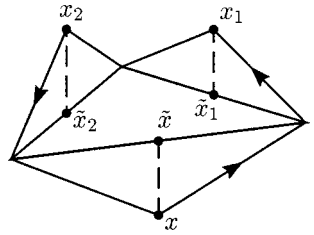

FIG. 9. Membrane $\Sigma_F(x,x_2,x_1)$.

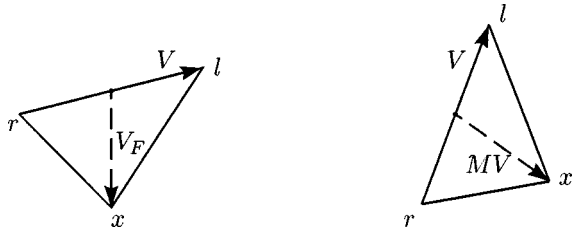

FIG. 10. Magnetic wing and *M*-wing.

configuration consists of triangle $\Sigma(\tilde{x},\tilde{x}_2,\tilde{x}_1)$, where $\tilde{x}=x-V_F$, and also of three additional triangles directed "vertically" (parallel to p) with "top" vertices x, x_2, x_1. We call them *magnetic wings*.

A magnetic wing is characterized by a sequence of its vertices $[l,x,r]$ related to each other by (5.8) (see Fig. 10, left picture). The configuration of membrane with wings, as we see, exactly corresponds to the new groupoid multiplication rule for $F\neq 0$.

Lemma 5:

$$\int_{\Sigma(\tilde{x},\tilde{x}_2,\tilde{x}_1)}\omega_F=\int_{\Sigma(x,x_2,x_1)}\omega_F,\quad \int_{\text{vertical wing}}\omega_F=0.$$

Both statements of the Lemma follow from the orthogonality condition (2.2).

Denote by $\Sigma_F(x,x_2,x_1)$ the triangle $\Sigma(\tilde{x},\tilde{x}_2,\tilde{x}_1)$ together with three magnetic wings described above; see Fig. 9. The boundary of this figure consists of six straight line segments. The figure itself looks like inflected hexagon. More generally, Σ_F could be any membrane in the phase space $\mathbb{R}^{2n}$ with that six segment boundary. In view of Lemma 5 we have

$$\int_{\Sigma(x,x_2,x_1)}\omega_F=\int_{\Sigma_F(x,x_2,x_1)}\omega_F.$$

Theorem 3: *The magnetic product over $T^*\mathbb{R}^n$ is given by*

$$(f\underset{F}{\star}g)(x)=\frac{1}{(\pi\hbar)^{2n}}\int\int\exp\left\{\frac{i}{\hbar}\int_{\Sigma_F(x,x_2,x_1)}\omega_F\right\}f(x_2)g(x_1)dx_2dx_1, \tag{5.11}$$

where Σ_F is the wing membrane corresponding to the magnetic groupoid structure (5.8) *on* $T^*(T^*\mathbb{R}^n)$.

VI. ORDERING IN QUANTIZATION

Now we demonstrate that membrane wings introduced in previous section are actually very natural objects in the quantization framework. We show how different configurations of wings relate to different choices in the ordering problem. In particular, we'll see why the Weyl ordering choice (Weyl symmetrization) looks like an optimal choice.

Let us take a constant real $2n\times 2n$ matrix M (actually, a linear operator in the space tangent to $T^*\mathbb{R}^n$) which obeys the condition

$$M^TJ+JM=0, \tag{6.1}$$

where M^T is the transposed matrix. One can represent M by its $n\times n$ blocks as follows:

$$M=\begin{pmatrix}N & K\\ S & -N^T\end{pmatrix}.$$

Now let us take an arbitrary function $f=f(q,p)$ (say, a polynomial) and determine the following general ordering of operators $\hat{q},\hat{p}'$ (generators of the Heisenberg algebra):

$$\hat{f}^M \equiv f(\tfrac{1}{2}N(\overset{4}{\hat{q}}-\overset{2}{\hat{q}})+\tfrac{1}{2}(\overset{2}{\hat{q}}+\overset{4}{\hat{q}})-\tfrac{1}{2}K(\overset{5}{\hat{p}'}-\overset{1}{\hat{p}'}),\quad \overset{3}{\hat{p}'}-\tfrac{1}{2}S(\overset{4}{\hat{q}}-\overset{2}{\hat{q}})-\tfrac{1}{2}N^T(\overset{5}{\hat{p}'}-\overset{1}{\hat{p}'})). \tag{6.2}$$

We would like to obtain the product formula

$$\hat{f}^M\cdot\hat{g}^M=\hat{k}^M,\quad k=\overset{M}{f*g}. \tag{6.3}$$

To derive the product $*^M$ we first note that the M-ordering (6.2) is related to the Weyl ordering via

$$\hat{f}^M=(U^M f)(\hat{q},\hat{p}'), \tag{6.4}$$

where

$$U^M=\exp\left\{\frac{i}{\hbar}S^M(\hat{V})\right\},\quad \hat{V}=(i\hbar\partial_p,i\hbar\partial_q),$$

and the function S^M is defined by the matrix M as follows

$$S^M(V)=\tfrac{1}{2}\langle JMV,V\rangle=\int_{\Delta^M(V)}\omega_0.$$

Here $\Delta^M(V)$ is the triangle, called the *M-wing*, generated by vector V and by vector MV applied at the middle point of V (see Fig. 10), right picture.

Using U^M we can calculate the product (6.3) by the formula

$$\overset{M}{f*g}\equiv U^{-M}(U^M f\star U^M g),$$

where $\star$ is the Weyl-symmetrized product (without magnetic correction, at first). Looking at exponential representation of the Weyl product, one concludes that

$$\overset{M}{f*g}=\exp\left\{\frac{i}{\hbar}\Phi^M(\hat{V}_2,\hat{V}_1)\right\}f(x_2)g(x_1)|_{x_1=x_2=x},$$

where $\hat{V}=(i\hbar\partial_p,i\hbar\partial_q)$. In this formula we use the notation

$$\Phi^M(V_2,V_1)=\int_{\Sigma(V_2,V_1)}\omega_0+S^M(V_1)+S^M(V_2)-S^M(V_1+V_2),$$

where $\Sigma(V_2,V_1)$ is the triangle generated by vectors V_1, V_2.

The phase function Φ^M can be written as the symplectic area of the *wing membrane* $\Sigma_x^M(V_2,V_1)$ generated by four triangles:

$$\Sigma_x^M(V_2,V_1)=\Delta(V_2,V_1)\cup\Delta^M(V_1)\cup\Delta^M(V_2)\cup\Delta^M(V_1+V_2).$$

Its boundary consists of six line segments. For reasons of uniformity in notation the point x is shown; actually, the ω_0-area of $\Sigma_x^M(V_2,V_1)$ is independent of x.

The picture for Σ_x^M is the same as in Fig. 9, but wings now are M-wings as in Fig. 10 (right picture).

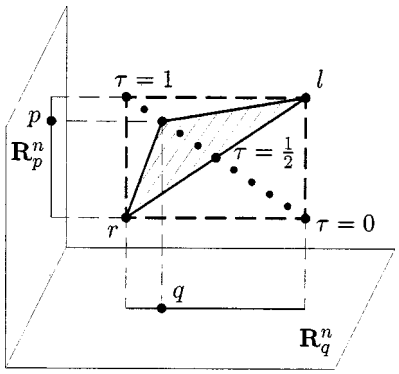

FIG. 11. τ—wings.

Theorem 4: *For an arbitrary real* $2n\times 2n$ *matrix* M*, satisfying* (6.1)*, there is a star-product over* $\mathbb{R}^{2n}$ *given by the wing membranes:*

$$(f\overset{M}{*}g)(x)=\exp\left\{\frac{i}{\hbar}\int_{\Sigma_x^M(\hat{V}_2,\hat{V}_1)}\omega_0\right\}f(x_2)g(x_1)|_{x_1=x_2=x}. \tag{6.5}$$

This product corresponds to the M-ordering rule (6.2) *of noncommutative operators* $\hat{q}$, $\hat{p}'$ (*generators of the Heisenberg algebra*)*, so that formula* (6.3) *holds.*

The family of orderings (6.2) was introduced and studied in detail in Ref. 34, where the following pseudodifferential formulas for M-product were obtained:

$$(f\overset{M}{\star}g)(x)=\overset{2}{f}(x-i\hbar(\tfrac{1}{2}-M)J^{-1}\overset{1}{\partial}_x)g(x)=\overset{2}{g}(x+i\hbar(\tfrac{1}{2}+M)J^{-1}\overset{1}{\partial}_x)f(x).$$

In the particular case

$$M=(\tfrac{1}{2}-\tau)\begin{pmatrix} I & 0\\ 0 & -I\end{pmatrix}, \tag{6.6}$$

the ordering (6.2) simplifies to

$$\hat{f}^\tau=f(\tau\overset{1}{\hat{q}}+(1-\tau)\overset{3}{\hat{q}},\overset{2}{\hat{p}'}). \tag{6.7}$$

The family of τ-wings corresponding to this family of orderings is represented in Fig. 11. The whole membrane Σ_x^M for the specific case $\tau=0$ is shown in Fig. 12.

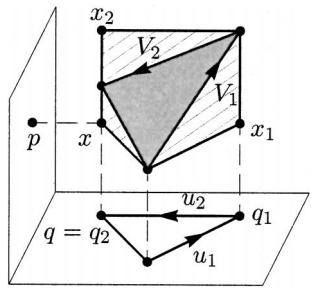

FIG. 12. Membrane Σ_x^M for $\tau=0$.

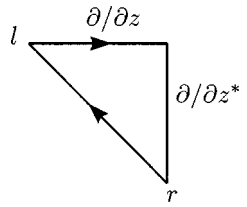

FIG. 13. Pure imaginary wing.

The cases $\tau=0$ and $\tau=1$ are called the standard and anti-standard ordering choices (they correspond to push- and pull- groupoid structures on $T\mathbb{R}^n$, see Sec. IV), and the case $\tau=1/2$ is the Weyl ordering (corresponding to the saddle-groupoid structure on $T\mathbb{R}^n$). In the later case $M=0$ and wings in membranes Σ^M are absent.

Matrix M is assumed to be real, but if we formally take $M=iJ/2$ (i.e., $N=0$, $S=-i/2$, $K=i/2$), then the transform $U^M=\exp\{-\hbar(\partial_q^2+\partial_p^2)/4\}$ relates Weyl ordering to the Wick normal ordering choice. In this case wings are pure imaginary (see Fig. 13), and the membrane Σ^M coincides with hexagon membrane introduced in Refs. 7 and 8.

Remark 2: In the general case, block N of the matrix M controls the position of the point $q\in\mathbb{R}^n$ with respect to the middle point of the vector u in the $T\mathbb{R}^n$-groupoid interpretation. The block S controls an additional $T\mathbb{R}^n$-groupoid cocycle (in u-coordinates) which appears in the convolution formula (see Sec. IV). In contrast to that, the block K in the matrix M generates the transformation of distributions over $T\mathbb{R}^n_q$ of the following type: $\exp\{-i\hbar K\partial_q\cdot\partial_q/2\}$. This is not a point transformation. Thus the product $*^M$ corresponding to matrix M with $K\neq 0$ can not be obtained from the groupoid convolution over $T\mathbb{R}^n$ by construction of Sec. 4. In particular, the Wick product is of such type.

Now let us consider the symplectic groupoid structure on the secondary phase space $T^*(T^*\mathbb{R}^n)$ corresponding to the $*^M$ product (6.3). In the same way as in Sec. II we calculate for the Heisenberg algebra (2.5) operators of left and right representations corresponding to the ordering choice (6.2). We know the transformation from (6.2) to the Weyl ordering; it is given by operator (6.4). Thus the left operators $L^M_q=q*^M$, $L^M_{p'}=p'*^M$ and right operators $R^M_q=*^Mq$, $\mathbb{R}^M_{p'}=*^Mp'$ are given by

$$L^M=U^{-M}\cdot L'\cdot U^M,\quad R^M=U^{-M}\cdot R'\cdot U^M, \tag{6.8}$$

where L', R' are determined in (2.8). We represent L^M,R^M via their symbols l,r:

$$L^M=l(x,-i\hbar\partial_x),\quad R^M=r(x,-i\hbar\partial_x),$$

and easily calculate l, r by (6.8) and by the definition of U^M. The result is

$$l(x,y)=x+(\tfrac{1}{2}-M)J^{-1}y,\quad r(x,y)=x-(\tfrac{1}{2}+M)J^{-1}y.$$

The inverse mapping $(l,r)\to(x,y)$ is given by

$$x=\tfrac{1}{2}(l+r)+MV,\quad V\equiv l-r=J^{-1}y. \tag{6.9}$$

For example, for the ordering cases (6.7), formulas (6.9) are represented in Fig. 11.

The corresponding symplectic groupoid structure on $T^*(T^*\mathbb{R}^n)=\mathbb{R}^{2n}_x\oplus\mathbb{R}^{2n}_y$ is given by the rule represented in Fig. 14. We observe that this structure is exactly given by the membrane with wings Σ^M which we described at the beginning of this section. What is new now is that we have identified the positions of points x,x_2,x_1 exactly as vertices of wings of the membrane Σ^M.

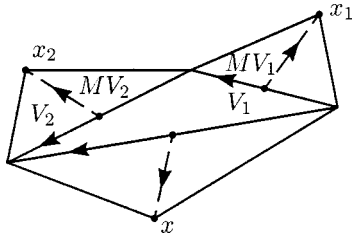

FIG. 14. M-groupoid.

Corollary 2: Let $\det(\frac{1}{2}-M)\neq 0$, *then the integral version of the product formula* (6.5) *reads*

$$(f\overset{M}{*}g)(x)=\frac{1}{(2\pi\hbar)^{2n}|\det(\frac{1}{2}-M)|}\int\int \exp\left\{\frac{i}{\hbar}\int_{\Sigma^M(x,x_2,x_1)}\omega_0\right\}f(x_2)g(x_1)dx_2dx_1, \quad (6.10)$$

where $\Sigma^M(x,x_2,x_1)$ *is the membrane with three* M*-wings having vertices* x, x_2, x_1.

Note that for the τ-ordering case (6.6) the denominator in formula (6.10) $\det(\frac{1}{2}-M)=\tau^n(1-\tau)^n$ is zero if $\tau=0$ or $\tau=1$. We see that the cases $\tau=0$ (standard ordering) and $\tau=1$ (anti-standard ordering) are special. In these cases the graph Λ_* of the groupoid multiplication (see Sec. V) is not one-to-one projected onto the "configuration space" $\mathbb{R}^{2n}_x\times\mathbb{R}^{2n}_{x_2}\times\mathbb{R}^{2n}_{x_1}$, i.e., the graph is totally caustic and the integral kernel $K_\hbar(x,x_2,x_1)$ (5.1) is not of WKB-type (5.2). This is one of essential differences between representations (6.5) and (6.10) for the $*$-product.

Corollary 3: For several multipliers there is the following product formula

$$(f_N\overset{M}{*}\cdots\overset{M}{*}f_1)(x)=\exp\left\{\frac{i}{\hbar}\int_{\Sigma^M_x(\hat{V}_N,\ldots,\hat{V}_1)}\omega_0\right\}f_N(x_N)\cdots f_1(x_1)\Big|_{x_1=\cdots=x_N=x}, \quad (6.11)$$

where $\Sigma^M_x(V_N,\ldots,V_1)$ *is the membrane with* $N+1$ *wings.*

These formulas are naturally generalized for products of differently quantized multipliers, i.e., for the case when each multiplier has its own ordering choice

$$\begin{gathered}\hat{f}_N^{M_N}\cdot\cdots\ \hat{f}_1^{M_1}=\hat{k}^{M_{N+1}},\\ k(x)=\exp\left\{\frac{i}{\hbar}\int_{\Sigma_x^{M_{N+1},\ldots,M_1}(\hat{V}_N,\ldots,\hat{V}_1)}\omega_0\right\}f_N(x_N)\cdots f_1(x_1)\Big|_{x_1=\cdots=x_N=x}.\end{gathered} \quad (6.12)$$

Here the membrane $\Sigma_x^{M_{N+1},\ldots,M_1}$ is constructed by $N+1$ wings each of different configuration determined by different matrices $M_{N+1},\ldots,M_1$.

In conclusion of this section we consider the magnetic case $F\neq 0$. For simplicity, we concentrate on the τ-ordering choice

$$\hat{f}^\tau=f(\overset{1}{\tau}\hat{q}+\overset{3}{(1-\tau)}\hat{q},\overset{2}{\hat{p}}), \quad (6.13)$$

where $\hat{q}$, $\hat{p}$ satisfy the magnetic commutation relations (1.3).

We first transform the magnetic τ-ordering to the magnetic Weyl ordering:

$$\hat{f}^\tau=(U^\tau f)(\hat{q},\hat{p}),\quad U^\tau=\exp\{(\tfrac{1}{2}-\tau)\hat{u}\partial_q\}, \quad (6.14)$$

where $\hat{u}=i\hbar\partial_p$. Then for product of two τ-ordered observables we have from (2.11)

$$\hat{f}^{\tau}\cdot\hat{g}^{\tau}=(U^{\tau}f)(\hat{q},\hat{p})\cdot(U^{\tau}g)(\hat{q},\hat{p})=(U^{\tau}f\underset{F}{\star}U^{\tau}g)(\hat{q},\hat{p}),$$

where $\star_F$ is the magnetic product (3.2), (3.5), corresponding to the Weyl ordering. Transforming back the Weyl symbol to τ-symbol by the transform $(U^{\tau})^{-1}$, we obtain the product formula

$$\hat{f}^{\tau}\cdot\hat{g}^{\tau}=\hat{k}^{\tau},$$

where

$$k\equiv f\overset{\tau}{\underset{F}{\star}}g=(U^{\tau})^{-1}(U^{\tau}f\underset{F}{\star}U^{\tau}g).$$

By formula (3.2) we calculate the new τ-magnetic product as follows

$$\begin{aligned}(f\overset{\tau}{\underset{F}{\star}}g)(q,p)=&\exp\left\{\left(\tau-\frac{1}{2}\right)\hat{u}\partial_q\right\}\left(\exp\left\{\frac{i}{\hbar}\phi(q,\hat{u}_2,\hat{u}_1)+\frac{1}{2}(\hat{u}_1\partial_{q_2}-\hat{u}_2\partial_{q_1})\right\}\right.\\&\left.\times\exp\left\{\left(\frac{1}{2}-\tau\right)(\hat{u}_1\partial_{q_1}+\hat{u}_2\partial_{q_2})\right\}f(q_2,p_2)g(q_1,p_1)\right)\Big|_{q_1=q_2=q,\ p_1=p_2=p}\\=&\exp\left\{\frac{i}{\hbar}\phi\left(q+\left(\tau-\frac{1}{2}\right)(\hat{u}_1+\hat{u}_2),\hat{u}_2,\hat{u}_1\right)+\frac{1}{2}(\hat{u}_1\partial_{q_2}-\hat{u}_2\partial_{q_1})+\left(\tau-\frac{1}{2}\right)\right.\\&\left.\times((\hat{u}_1+\hat{u}_2)(\partial_{q_1}+\partial_{q_2})-\hat{u}_1\partial_{q_1}-\hat{u}_2\partial_{q_2})\right\}f(q_2,p_2)g(q_1,p_1)\Big|_{q_1=q_2=q,\ p_1=p_2=p}.\end{aligned}\tag{6.15}$$

Note that the flux $\phi(q,u_2,u_1)$ was defined by (3.3) via the triangle $\Delta_q(u_2,u_1)$ in $\mathbb{R}^n$ with the middle point q of one of sides. Now we see that the position of the middle point $\tilde{q}$ differs from q by an additional vector $(\tau-\frac{1}{2})(u_1+u_2)$. So,

$$q=\tilde{q}+(\tfrac{1}{2}-\tau)(u_1+u_2)=\tilde{q}+(MV)_q,$$

where M is matrix (6.6) corresponding to τ-ordering, and $V=V_1+V_2$ is a vector in $\mathbb{R}^{2n}$ whose q-component is $u=u_1+u_2$.

The total phase in (6.14) is equal to the magnetic area of the membrane in $\mathbb{R}^{2n}$ constructed by the triangle with sides V_1,V_2,V_1+V_2 and by three additional wings generated by matrix M of special type (6.6). The configuration of the wings in this special case is shown in Fig. 11.

The position of the vertex of the wing is $x^{\tau}=\tilde{x}+MV$, where $\tilde{x}=(l+r)/2$. But actually this position should be changed to match the symplectic groupoid multiplication rule. To find this rule we have to calculate the operators of left and right regular representation in our τ-case. In view of (6.14) these operators are given by formulas

$$L^{\tau}=(U^{\tau})^{-1}\cdot L\cdot U^{\tau},\quad R^{\tau}=(U^{\tau})^{-1}\cdot R\cdot U^{\tau},$$

where L, R are operators (2.10), corresponding to the magnetic Weyl ordering. From (6.14) and (2.10) we obtain

$$L_q^{\tau}=q+\tau i\hbar\partial_p,\quad R_q^{\tau}=q-(1-\tau)i\hbar\partial_p,$$

$$L_p^{\tau}=p-(1-\tau)i\hbar\partial_q-A(L_q^{\tau},R_q^{\tau}),\quad R_p^{\tau}=p+\tau i\hbar\partial_q-A(R_q^{\tau},L_q^{\tau}).$$

So, if we represent these operators by symbols $L^{\tau}=l(x,-i\hbar\partial_x)$, $R^{\tau}=r(x,-i\hbar\partial_x)$, then two groupoid mappings appear

$$l:T^*\mathbb{R}^{2n}\to\mathbb{R}^{2n},\quad r:T^*\mathbb{R}^{2n}\to\mathbb{R}^{2n},$$

where

$$\begin{aligned} l(x,y)&=x+(\tfrac{1}{2}-M)J^{-1}y-(0;A(l_q,r_q)),\\ r(x,y)&=x-(\tfrac{1}{2}+M)J^{-1}y-(0;A(r_q,l_q)). \end{aligned} \tag{6.16}$$

From (6.16) we reconstruct x and y via l,r

$$x=\tfrac{1}{2}(l+r)+V_F+MV,\quad y=JV+Y_F, \tag{6.17}$$

where $V=l-r$, and vectors V_F,Y_F are given by the same formulas as in (5.9) (i.e., the same as in the case $\tau=1/2$ or $M=0$).

Relations (6.17) determine the final configuration of the *magnetic τ-wing*. Position of the vertex x of this magnetic wing is shifted by vector V_F with respect to position x^τ.

Lemma 6: The magnetic area of the magnetic τ-wing with the vertex x is equal to the magnetic area of the wing with vertex x^τ.

In view of this lemma the phase (6.15) can be represented by the area of a membrane $\Sigma_x^\tau(V_2,V_1)$ constructed by the triangle of vectors V_1,V_2,V_1+V_2, and by three magnetic τ-wings over each of these vectors. The point x is the vertex of the magnetic τ-wing over V_1+V_2.

Theorem 5: *The magnetic product corresponding to τ-ordering* (6.13) *of noncommutative coordinates $\hat q,\hat p$ is given by formula*

$$(f\underset{F}{\overset{\tau}{\star}}g)(x)=\exp\left\{\frac{i}{\hbar}\int_{\Sigma_x^\tau(\hat V_2,\hat V_1)}\omega_F\right\}f(x_2)g(x_1)\Big|_{x_1=x_2=x},$$

where Σ_x^τ is a membrane with magnetic τ-wings.

The immediate corollaries from this statement are formulas for several multipliers and also the integral formula for $\star_F^\tau$ via the magnetic area of membranes $\Sigma^\tau(x,x_2,x_1)$ supplied with magnetic τ-wings. These corollaries are formulated by the same way as (6.10)–(6.12), but with magnetic form ω_F in the exponent.

VII. DYNAMICS VIA MEMBRANE AREA

Quantum dynamics of a charged (spinless) particle in electromagnetic field can be described:

(i) in the nonrelativistic case by the Schrödinger equation

$$i\hbar\frac{\partial\psi}{\partial t}=\left[\frac{1}{2m}\left(-i\hbar\frac{\partial}{\partial q}-\frac{e}{c}\mathcal{A}\right)^2+ea\right]\psi, \tag{7.1}$$

(ii) in the relativistic case by the Klein–Gordon equation

$$\left(i\hbar\frac{\partial}{\partial t}-ea\right)^2\psi=c^2\left[\left(-i\hbar\frac{\partial}{\partial q}-\frac{e}{c}\mathcal{A}\right)^2+m^2c^2\right]\psi, \tag{7.2}$$

where $\mathcal{A}$ and a are magnetic and electric potentials of the field, and metric is assumed to be Euclidean.

First, we consider the pure magnetic time-independent situation $a=0$, $\mathcal{A}=\mathcal{A}(q)$. Let us introduce operators $\hat p=-i\hbar\partial/\partial q-(e/c)\mathcal{A}(q)$. Then the dynamical equations can be reduced to studying the evolution operator $\exp\{-itH(\hat p)/\hbar\}$, where $H(p)=p^2/2m$ in the nonrelativistic case, and $H(p)=\pm c\sqrt{p^2+m^2c^2}$ in the relativistic case.

More generally, in a presence of an additional non-Euclidean metric (gravitational field) the Hamiltonian will depend on the q-coordinate as well: $H=H(q,p)$. Say, $H\simeq g^{jk}(q)p_jp_k/2m$ in the nonrelativistic case.

So, the general problem is to study the operator

$$U^t=\exp\left\{-\frac{it}{\hbar}\hat{H}\right\},\quad \hat{H}=H(\hat{q},\hat{p}). \tag{7.3}$$

In particular, we are interested in its asymptotic behavior as $\hbar\to 0$.

Note that the symbol H and the permutation relations between quantum coordinates $\hat{q}$, $\hat{p}$ (1.3) are independent of the gauge choice of the magnetic potential $\mathcal{A}$. Thus the semiclassical approximation for U^t as $\hbar\to 0$, written in terms of the phase space symbol $H(q,p)$ and the phase space noncommutative structure (1.3), is automatically gauge invariant.

Let us represent the operator U^t in the Weyl-symmetrized form

$$U^t=\mathcal{U}^t(\hat{q},\hat{p}),$$

then for symbol $\mathcal{U}^t$ one obtains the following equations

$$i\hbar\frac{\partial\mathcal{U}^t}{\partial t}=H\underset{F}{\star}\mathcal{U}^t,\quad \mathcal{U}^0=1. \tag{7.4}$$

Using Theorem 1 we transform (7.4) to a pseudodifferential form

$$i\hbar\frac{\partial\mathcal{U}^t(x)}{\partial t}=\mathcal{H}_\hbar(x,-i\hbar\partial_x)\,\mathcal{U}^t(x),\quad \mathcal{U}^0=1. \tag{7.5}$$

Here $\mathcal{H}_\hbar(x,y)$ is the Weyl symbol of the operator $H(L_q,L_p)$, and L_q, L_p are given by (2.10). Obviously,

$$\mathcal{H}_\hbar=\mathcal{H}_0+O(\hbar^2),\quad \mathcal{H}_0\equiv H(l), \tag{7.6}$$

where l is the Weyl symbol of L, i.e., $L=l(x,-i\hbar\partial_x)$. The explicit formulas for $l=(l_q,l_p)$ are found in (5.4).

In view of (7.6) the principal term of the semiclassical solution of the Cauchy problem (7.5) is determined by the Hamilton function $\mathcal{H}_0$. For small enough time interval $t\in[0,T]$ the approximate solution has the simplest WKB-form

$$\mathcal{U}^t(x)=\exp\left\{\frac{i}{\hbar}S(t,x)\right\}u^t(x)+O(\hbar), \tag{7.7}$$

where the phase S is the solution of the Hamilton–Jacobi equation

$$\frac{\partial S}{\partial t}+\mathcal{H}_0\left(x,\frac{\partial S}{\partial x}\right)=0,\quad S|_{t=0}=0, \tag{7.8}$$

and the nonoscillatory amplitude u^t is the solution of the ''transport'' equation

$$\frac{\partial u^t}{\partial t}+\frac{\partial}{\partial x}\left(\frac{\partial\mathcal{H}_0}{\partial y}\left(x,\frac{\partial S}{\partial x}\right)u^t\right)=0,\quad u^0=1. \tag{7.9}$$

In order to solve (7.8) and (7.9) one has to consider the Hamiltonian system

$$\dot{X}=\frac{\partial\mathcal{H}_0}{\partial Y},\quad \dot{Y}=-\frac{\partial\mathcal{H}_0}{\partial X},\quad X|_{t=0}=x^0,\quad Y|_{t=0}=0, \tag{7.10}$$

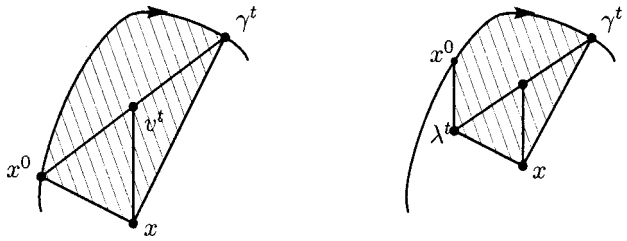

FIG. 15. Membrane Σ_x^t and trajectory of virtual particle.

and determine

$$S=\int_0^t (Y\dot{X}-\mathcal{H}_0)\,d\tilde{t},\quad u^t=\det\left(\frac{\partial X}{\partial x^0}\right)^{-1/2}, \tag{7.11}$$

where $x^0=(q^0,p^0)$ is taken from the equation

$$X(x^0,t)=x.$$

The time interval $t\in[0,T]$ over which the Jacobian $\mathcal{D}X/\mathcal{D}x^0\geqslant\delta>0$ (for any $x^0\in\mathbb{R}^{2n}$) is exactly the interval where the solution $\mathcal{U}^t$ can be represented in the WKB form (7.7).

Lemma 7: Trajectories of (7.10) *are given by formulas*

$$\begin{aligned} X(x^0,t)&=\tfrac{1}{2}(\gamma^t(x^0)+x^0)+v^t(x^0),\\ Y(x^0,t)&=J(\gamma^t(x^0)-x^0)+y^t(x^0), \end{aligned} \tag{7.12}$$

where

$$v^t=(0;\tfrac{1}{2}(A(\gamma_q^t,q^0)+A(q^0,\gamma_q^t))),\quad y^t=(A(\gamma_q^t,q^0)-A(q^0,\gamma_q^t);0),$$

and $\gamma^t=(\gamma_q^t,\gamma_p^t)$ *is the trajectory of the Hamiltonian system corresponding to the function* H *and the magnetic Poisson bracket* (3.4)

$$\begin{aligned} &\dot{\gamma}_q=\frac{\partial H}{\partial p}(\gamma_q,\gamma_p),\quad \dot{\gamma}_p=-\frac{\partial H}{\partial q}(\gamma_q,\gamma_p)-F(\gamma_q)\frac{\partial H}{\partial p}(\gamma_q,\gamma_p),\\ &\gamma|_{t=0}=x^0=(q^0,p^0). \end{aligned} \tag{7.13}$$

The proof of this lemma follows from (5.8) and from the fact that $\mathcal{H}_0=H(l)$, and so components of the mapping $r:\mathbb{R}_x^{2n}\oplus\mathbb{R}_y^{2n}\to\mathbb{R}^{2n}$ (5.4) are integrals of motion for system (7.10), i.e., $r(X,Y)=r(x^0,0)=x^0$ is constant in time.

After substitution of (7.12) into (7.11) one obtains the following result.

Theorem 6: *Let* $\hat{q}$, $\hat{p}$ *satisfy commutation relations* (1.3) *with magnetic tensor* F_{kj}, *and* $\hat{H}=H(\hat{q},\hat{p})$. *Then for small enough time* t *the semiclassical approximation for the magnetic Weyl symbol of the evolution operator* $\exp\{-(it/\hbar)\hat{H}\}=\mathcal{U}^t(\hat{q},\hat{p})$ *is given by the formula*

$$\mathcal{U}^t=\mathcal{J}^{-1/2}\exp\left\{\frac{i}{\hbar}\int_\Sigma\omega_F-\frac{it}{\hbar}H\right\}+O(\hbar). \tag{7.14}$$

Here the membrane $\Sigma=\Sigma_x^t$ (*see Fig.* 15, *left picture*) *is constructed from the piece of the Hamilton trajectory* (7.13), *which connects points* x^0 *and* $\gamma^t(x^0)$, *and from the magnetic wing with vertices* $[\gamma^t(x^0),x,x^0]$, *where*

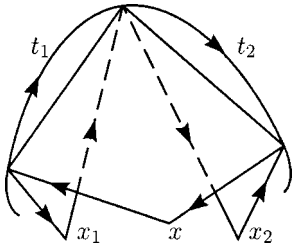

FIG. 16. Group property for membranes with wings.

$$x=\tfrac{1}{2}(\gamma^t(x^0)+x^0)+v^t(x^0). \tag{7.15}$$

Here

$$v^t(x^0)=(0;\tfrac{1}{2}(A(\gamma^t(x^0)_q,q^0)+A(q^0,\gamma^t(x^0)_q))),\quad x^0\equiv(q^0,p^0),$$

and A is the Valatin primitive (2.1). *The Jacobian* $\mathcal{J}$ *in* (7.14) *is given by*

$$\mathcal{J}(x^0,t)=\det[\tfrac{1}{2}(I+d\gamma^t(x^0))+dv^t(x^0)],\quad \mathcal{J}\geqslant\delta>0\quad for\quad t\in[0,T],$$

the Hamilton function H in (7.14) *is evaluated on the trajectory, i.e.,* $H=H(x^0)$, *and* x^0 *is assumed to be expressed in terms of* x,t *via Eq.* (7.15).

Remark 3: The group property of the family of symbols $\mathcal{U}^t$ over $\mathbb{R}^{2n}$ reads

$$\mathcal{U}^{t_2}\underset{F}{\star}\mathcal{U}^{t_1}=\mathcal{U}^{t_2+t_1}. \tag{7.16}$$

In terms of WKB-phase functions (7.14), the identity (7.16) requires that

$$\int_{\Sigma^{t_2}_{x_2}}\omega_F+\int_{\Sigma^{t_1}_{x_1}}\omega_F+\int_{\Sigma_F(x,x_2,x_1)}\omega_F=\int_{\Sigma^{t_2+t_1}_{x}}\omega_F, \tag{7.17}$$

(see Fig. 16), where $\Sigma_F(x,x_2,x_1)$ is the hexagon membrane with magnetic wings, defined at the end of Sec. V. Note that in the case $F=0$ formula (7.17) coincides with the phase addition rule obtained by Marinov.[3] In that particular case the magnetic "anomaly" v^t in (7.15) is absent and the magnetic wings of the membranes disappear.

Also note that the Hamilton function H could be time-dependent. In this case the first membrane phase factor in formula (7.14) is the same, but the second phase factor becomes $\exp\{-(i/\hbar)\int_0^t H(\tilde{\gamma}^{\tilde{t}}(x^0),\tilde{t})d\tilde{t}\}$; the trajectory γ^t is now the solution of system (7.13) with time-dependent Hamiltonian H.

Remark 4: One can use not only Weyl but any other ordering choice to represent the evolution operator as a function in coordinates $\hat{q},\hat{p}$. Then formula (7.14) still holds with membrane Σ constructed by wings corresponding to the given ordering choice (see Sec. VI); Eq. (7.15) and the Jacobian $\mathcal{J}$ are changed following (6.17). Moreover, in Ref. 34 it was proved that using and combining different orderings it is possible to avoid the difficulty with time limitations $t\in[0,T]$ where the WKB-approximation works.

For the Wick ordering choice the wings are pure imaginary (see Fig. 13) and the membrane representation (7.14) coincides with those obtained in Ref. 9. In this case the Jacobian $\mathcal{J}$ is never zero and representation (7.14) is global in t.

In conclusion of this section we apply formula (3.6) to derive the symbol $\mathcal{U}^t$ not asymptotically but in an exact continual form. Namely, one can use the approximation $\mathcal{U}^{t/N}=\exp\{-(it/\hbar N)H\}+O(N^{-2})$ and obtain the Trotter type formula

$$\mathcal{U}^t = \lim_{N\to\infty} \exp\left\{ -\frac{it}{\hbar N} H \right\} \underset{F}{\star} \cdots \underset{F}{\star} \exp\left\{ -\frac{it}{\hbar N} H \right\},$$

(N multipliers). Applying (3.6), one derives

$$\mathcal{U}^t(x) = \lim_{N\to\infty} \exp\left\{ \frac{i}{\hbar} \int_{\Sigma_x(\hat{V}_N,\ldots,\hat{V}_1)} \omega_F \right\} \exp\left\{ -\frac{it}{\hbar N} \sum_{j=1}^{N} H(x_j) \right\} \Bigg|_{x_1=\cdots=x_N=x}. \tag{7.18}$$

Now the question is how to represent this formula in a continual form.

Note that each vector field v on $\mathbb{R}^{2n}$ and any point $x\in\mathbb{R}^{2n}$, $t\in\mathbb{R}$ determines a membrane $\Sigma_x^t(v)\subset\mathbb{R}^{2n}$ whose boundary is constructed from a piece $\{\Gamma^\mu | 0\leqslant\mu\leqslant t\}$ of the trajectory of the field v in $\mathbb{R}^{2n}$ and from the magnetic wing with vertices $[\Gamma^t, x, \Gamma^0]$ (or, the magnetic τ-wing if one wants to use the general τ-ordering). The integral over the membrane in (7.18) is an approximation of the integral over $\Sigma_x^t(v)$ with a convenient choice of v.

Theorem 7: *The following continual formula for the symbol of the evolution operator* (7.3) *holds:*

$$\mathcal{U}^t(x) = \exp\left\{ \frac{i}{\hbar} \int_{\Sigma_x^t(\hat{v})} \omega_F \right\} \exp\left\{ -\frac{i}{\hbar} \int_0^t H(x(\mu))\, d\mu \right\} \Bigg|_{x(\mu)\equiv x}. \tag{7.19}$$

Here $\{x(\mu)=(q(\mu),p(\mu)) | 0\leqslant\mu\leqslant t\}$ *are continuous paths in* $\mathbb{R}^{2n}$ *and* $\hat{v}=(i\hbar\,\delta/\delta p(\mu), i\hbar\,\delta/\delta q(\mu))$ *is the variational derivative operator acting on the path functional.*

Formula (7.19) is dual to the Feynman path-integral formula.[24,50–53] The difference between (7.19) and the path integral is the same as between (3.5) and (3.7). The known Wick and Hori derivations[54,55] for the symbol of the evolution operator (see also generalizations in Ref. 56) are structurally close to (7.19), but use a different first exponential factor. The membrane exponential factor in (7.19) clearly demonstrates the influence of the magnetic form ω_F to the quantum dynamics.

VIII. ELECTROMAGNETIC FIELDS AND SPACE–TIME MEMBRANES

Let us now consider general time-dependent case, i.e., $\mathcal{A}=\mathcal{A}(t,q)$, $a=a(t,q)$ in (7.1), (7.2). We again study the Cauchy problem for the Schrödinger or Klein–Gordon equations.

As a first step one can remove the electric potential a from equations by introducing the new wave function $\psi\exp\{(ie/\hbar)\int_0^t a\,dt\}$. After such a transform the magnetic potential $\mathcal{A}$ is replaced by $\mathcal{A}+c\int_0^t(\partial a/\partial q)\,dt$, but the electromagnetic tensor F_{jk} (1.2b) remains unchanged. So, without loss of generality one can assume that

$$a\equiv 0, \quad E=-c^{-1}\partial\mathcal{A}/\partial t, \quad B=\operatorname{curl}\mathcal{A}.$$

The quantum dynamical equations have the following form:

(i) in the nonrelativistic case

$$i\hbar\frac{\partial\psi}{\partial t} = H(\hat{q},\hat{p}(t))\psi, \quad \text{where} \quad H \simeq \frac{1}{2m} g^{jk}(q) p_j p_k, \tag{8.1a}$$

(ii) in the relativistic case

$$\hbar^2\frac{\partial^2\psi}{\partial t^2} + H^2(\hat{q},\hat{p}(t))\psi = 0, \quad \text{where} \quad H^2 \simeq c^2(g^{jk}(q)p_j p_k + m^2c^2). \tag{8.1b}$$

In the latter case the metric g^{jk} is assumed to be non-negative definite; the symbols $\simeq$ in (8.1a) and (8.1b) mean that some terms of order $\hbar$, $\hbar^2$ could be added to the Hamilton function.[23,29,38,57,58]

In Eqs. (8.1) for each fixed time t the operators $\hat{p}(t)=-i\hbar\partial/\partial q-(e/c)\mathcal{A}(t,q)$ and $\hat{q}=q$ satisfy relations (1.3) with time-dependent tensor

$$F_{jk}(t,q)=\frac{e}{c}\epsilon_{kjl}B^l(t,q),\quad q\in\mathbb{R}^3,\quad j,k=1,2,3.$$

The time derivative of the operators $\hat{p}(t)$ in (8.1) is the following:

$$\frac{d}{dt}\hat{p}_j(t)=eE_j(t,q),\quad j=1,2,3. \tag{8.2}$$

So we see that the electric field is responsible for ''dynamical evolution'' of the quantum magnetic algebra (1.3).

Let us introduce two-point electric potential

$$\beta(t,q,q')\equiv\int_q^{q'}E(t,\tilde{q})d\tilde{q} \tag{8.3}$$

(the integral is taken along the straight line segment), and also the two-point magnetic potential

$$\alpha(t,q,q')\equiv\frac{1}{|q-q'|}\int_{q'}^{q}|\tilde{q}-q'|B(t,\tilde{q})\times d\tilde{q}. \tag{8.4}$$

We stress that these potentials are different from those used by Valatin[20] in the time dependent case, since in our present definitions there is no integration over the time variable. Time and space are separated because we study the Cauchy problem in time.

Lemma 8: The relation holds:

$$-\frac{\partial\beta}{\partial q}-\frac{1}{c}\frac{\partial\alpha}{\partial t}=E(t,q).$$

Now from (8.2) and from composition formulas (2.11) we obtain the following statement.

Proposition 6:

(i) *The time derivative of any Weyl-symmetrized function in quantum coordinates $\hat{q}$, $\hat{p}(t)$ is given by*

$$-i\hbar\frac{d}{dt}f(\hat{q},\hat{p}(t))=f^e(\hat{q},\hat{p}(t),t),$$

where

$$f^e(q,p,t)=e\beta(t,L_q,R_q)f(q,p),$$

and $L_q=q+\frac{1}{2}i\hbar\partial_p$, $R_q=q-\frac{1}{2}i\hbar\partial_p$ are operators of the regular representation (2.10);

(ii) *the composition of two Weyl-symmetrized functions is given by*

$$[f_2(\hat{q},\hat{p}(t))]\cdot[f_1(\hat{q},\hat{p}(t))]=k(\hat{q},\hat{p}(t)),\quad k=f_2(L_q,L_p(t))f_1,$$

where $L_p(t)=p-\frac{1}{2}i\hbar\partial_q-(e/c)\,\alpha(t,L_q,R_q)$.

The solution of the evolution problem (8.1a) has the general form

$$\psi(t,q)=\mathcal{U}^t(\hat{q},\hat{p}(t))(\psi|_{t=0}). \tag{8.5}$$

In view of Proposition 6 equations for symbol $\mathcal{U}^t$ are the following:

$$\left[-i\hbar\frac{\partial}{\partial t}+e\beta(t,L_q,R_q)+H(L_q,L_p(t))\right]\mathcal{U}^t(x)=0,\quad \mathcal{U}^0=1. \tag{8.6}$$

The operator acting on $\mathcal{U}^t$ can be represented [as in (7.5)] via a symbol $\mathcal{H}_\hbar$ over $\mathbb{R}_t\times\mathbb{R}^6_x\times\mathbb{R}^6_y$. In the same way as in (7.6) we have

$$\mathcal{H}_\hbar=\mathcal{H}_0+O(\hbar^2),\quad \mathcal{H}_0(t,x,y)=e\beta(t,l_q(x,y),r_q(x,y))+H(l_q(x,y),l_p(t,x,y)), \tag{8.7}$$

where $x=(q,p)$, $y=(y_q,y_p)$, and

$$l_q=q-\frac{1}{2}y_p,\quad r_q=q+\frac{1}{2}y_p,\quad l_p=p+\frac{1}{2}y_q-\frac{e}{c}\alpha(t,l_q,r_q).$$

[Of course, here we just re-state identities (5.4) in a new notation.] As in Sec. VII, the WKB-solution of (8.6) has the form (7.7), (7.11), where (X,Y) is now the trajectory of the Hamiltonian system

$$\dot X=\frac{\partial\mathcal{H}_0}{\partial y}(t,X,Y),\quad \dot Y=-\frac{\partial\mathcal{H}_0}{\partial x}(t,X,Y),\quad X|_{t=0}=x^0,\quad Y|_{t=0}=0. \tag{8.8}$$

The solution of problem (8.1b) with additional Cauchy data $\partial\psi/\partial t|_{t=0}=0$ can also be constructed in the form (8.5), where $\mathcal{U}^t$ satisfies the equations

$$\left[i\hbar\frac{\partial}{\partial t}-e\beta(t,L_q,R_q)\right]^2\mathcal{U}^t=H^2(L_q,L_p(t))\mathcal{U}^t,\quad \mathcal{U}^0=1,\quad \frac{\partial}{\partial t}\mathcal{U}^t|_{t=0}=0.$$

The WKB-approximation has the form

$$\mathcal{U}^t=\frac{1}{2}\sum_{\pm}\ \exp\left\{\frac{i}{\hbar}S_\pm\right\}u^t_\pm+O(\hbar), \tag{8.9}$$

where the phases $S_\pm$ and amplitudes $u^t_\pm$ correspond [by formulas (7.11)] to the Hamilton function $\mathcal{H}_0$ of type (8.7) with $\pm$ signs in the definition of H. The Hamiltonian system (8.8) again plays the basic role.

The difference in Hamiltonian system (8.8) from the earlier (7.10) is that function $\mathcal{H}_0$ in (8.8) now depends on l_q, l_p and on r_q as well. So, r_p is not an integral of motion for (8.8). Thus instead of dynamical system (7.13) we get now two systems: one for $\gamma=l(t,X,Y)$ and another for $\lambda=r(t,X,Y)$. They are the following:

$$\dot\gamma_q=\frac{\partial H}{\partial p}(\gamma_q,\gamma_p),\quad \dot\gamma_p=-\frac{\partial H}{\partial q}(\gamma_q,\gamma_p)-\frac{e}{c}B(t,\gamma_q)\times\dot\gamma_q+eE(t,\gamma_q) \tag{8.10}$$

and

$$\dot\lambda_q=0,\quad \dot\lambda_p=eE(t,\lambda_q), \tag{8.11}$$

with one and the same initial condition $\gamma|_{t=0}=\lambda|_{t=0}=x^0$.

The function $H(q,p)$ has the following form: $H(q,p)=g^{jk}(q)p_jp_k/2m$ in the nonrelativistic case and $H(q,p)=\pm c\sqrt{g^{jk}(q)p_jp_k+m^2c^2}$ in the relativistic case.

Note that (8.10) is the standard dynamical system for charged massive particle in the electromagnetic field. The additional system (8.11) can be interpreted as the dynamical system for a particle of charge e and mass $m=\infty$. The appearance of this additional ''virtual particle'' is due to the presence of the electric field E.

The phase S of the WKB-solution is given by (7.11); hence

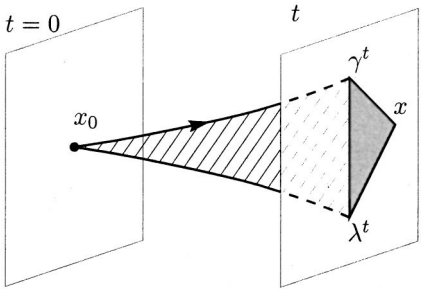

FIG. 17. Dynamical membrane $\Sigma_{t,x}$.

$$S(t,x)=\int_0^t Y\dot{X}\,d\tilde{t}-e\int_0^t \beta(\tilde{t},\gamma_q^{\tilde{t}},\lambda_q^{\tilde{t}})\,d\tilde{t}-\int_0^t H(\gamma^{\tilde{t}})\,d\tilde{t}. \tag{8.12}$$

Lemma 9: The following identity holds:

$$\int_0^t Y\dot{X}\,d\tilde{t}=\int_{\Sigma_x^t}\omega_F=\int_{\Sigma_x^t}\omega_0+\frac{e}{c}\int_{\tilde{\Sigma}_q^t}B(t,\tilde{q})\,d\tilde{q}\wedge d\tilde{q}, \tag{8.13}$$

where the membrane $\Sigma_x^t\subset\mathbb{R}^6=T^*\mathbb{R}^3$ *is constructed from the two trajectories* $\gamma=\gamma^t$ (8.10) *and* $\lambda=\lambda^t$ (8.11) *and from the magnetic wing with vertices* $[\gamma^t,x,\lambda^t]$, *where* $x=(q,p)$ (*see Fig.* 15, *right picture*). *The projection of* Σ_x^t *onto* $\mathbb{R}^3$ *is the membrane* $\tilde{\Sigma}_q^t$ *constructed by a piece of the trajectory* $\{\gamma_q^{\tilde{t}}\,|\,0\leqslant\tilde{t}\leqslant t\}$ *and by the chord* $[q^0,\gamma_q^t]$ *with middle point* q.

This is the membrane area interpretation of the first term in (8.12). The second term in view of definition (8.3) can also be written as two-dimensional area, but in extended space-time:

$$-e\int_0^t\beta\,d\tilde{t}=e\int_0^t d\tilde{t}\int_{q^0}^{\gamma_q^{\tilde{t}}}E(\tilde{t},\tilde{q})\,d\tilde{q}=e\int_{\tilde{\Sigma}_{t,q^0}}E\,dq\wedge dt. \tag{8.14}$$

Here $\tilde{\Sigma}_{t,q^0}$ is a membrane in $\mathbb{R}_t\times\mathbb{R}_q^3$ whose boundary consists of the trajectory (the world line) $\{(\tilde{t},\gamma^{\tilde{t}})\,|\,0\leqslant\tilde{t}\leqslant t\}+$ the chord $[\gamma^t,q^0]+$ the straight time-segment $\{(\tilde{t},q^0)\,|\,0\leqslant\tilde{t}\leqslant t\}$.

Now one can combine (8.13) and (8.14) and apply the Stokes theorem to transform the integration area to be of the most elegant geometry. Let us denote by $\Sigma_{t,x}$ the membrane in $\mathbb{R}_t\times\mathbb{R}_x^6$ whose boundary is constructed by the world line of the given particle $\{(\tilde{t},\gamma^{\tilde{t}})\,|\,0\leqslant\tilde{t}\leqslant t\}$, the world line of the virtual infinitely heavy particle $\{(\tilde{t},\lambda^{\tilde{t}})|0\leqslant\tilde{t}\leqslant t\}$, and also by the magnetic wing with vertices $[\lambda^t,x,\gamma^t]$ (see Fig. 17). We refer to $\Sigma_{t,x}$ as a *dynamical membrane*.

Proposition 7: The WKB-phase of symbol $\mathcal{U}^t$ *in* (8.5) *can be represented as*

$$S(t,x)=\int_{\Sigma_{t,x}}(\omega_0+F)-\int_0^t H(\gamma^{\tilde{t}})\,d\tilde{t}, \tag{8.15}$$

where $\omega_0=\frac{1}{2}Jdx\wedge dx$, *the two-form* F *is given by* (1.2b), $\Sigma_{t,x}$ *is the dynamical membrane in* $\mathbb{R}^7=\mathbb{R}_t\times\mathbb{R}_x^6$, *and* γ^t *is the solution of classical dynamical system* (8.10).

Remark 5: The closed two-form $\tilde{\omega}_F=\omega_0+F$, which appeared in (8.15), generates a contact structure on $\mathbb{R}^7=\mathbb{R}_t\times\mathbb{R}_x^6$.[59,60] The "virtual" system (8.11) is the characteristic system for $\tilde{\omega}_F$. More precisely, the vector field on $\mathbb{R}^7$ corresponding to (8.11) is

$$v_0=\frac{\partial}{\partial t}+eE(t,q)\frac{\partial}{\partial p},\quad x=(q,p).$$

This is the null-field for $\tilde{\omega}_F$

$$v_0 \rfloor \tilde{\omega}_F = 0,$$

and the flow of v_0 preserves $\tilde{\omega}_F$

$$\mathcal{L}_{v_0} \tilde{\omega}_F = 0.$$

Here we denote by $\mathcal{L}$ the Lie derivative and use the sign $\rfloor$ for the contraction of a vector field and a form: $v \rfloor \omega(u) \equiv \omega(u,v)$ for all u. If one denotes by v_H the vector field on $\mathbb{R}^7$ corresponding to (8.10)

$$v_H = \frac{\partial}{\partial t} + \frac{\partial H}{\partial p}(q,p)\frac{\partial}{\partial q} + \left(eE(t,q) - \frac{e}{c} B(t,q) \times \frac{\partial H}{\partial p}(q,p) - \frac{\partial H}{\partial q}(q,p) \right) \frac{\partial}{\partial p},$$

then

$$v_H \rfloor \tilde{\omega}_F = dH - v_0(H)\, dt, \quad \mathcal{L}_{v_H} \tilde{\omega}_F = d(v_0(H)) \wedge dt.$$

Here $v_0(H) = eE\, \partial H / \partial p$; so we see how the electric field E determines the "nonconservation" properties of the charged particle dynamics in the contact space $\mathbb{R}^7 = \mathbb{R}_t \times \mathbb{R}^6_x$.

Now let us return to the WKB-representation (7.7), (7.11) of symbol $\mathcal{U}^t$ and calculate the Jacobian $\mathcal{J} = \mathcal{D}X / \mathcal{D}x^0$. The trajectory X of system (8.9) is given now by a modification of (7.12): $X(x^0,t) = \frac{1}{2}(\gamma^t(x^0) + \lambda^t(x^0)) + v^t(x^0)$, where v^t is the same as in (7.12). Since the solution $\lambda = \lambda^t$ of (8.11) is easily calculated: $\lambda^t_q = q^0$, $\lambda^t_p = p^0 + e\int_0^t E(\tilde{t}, q^0)\, d\tilde{t}$, we derive

$$\mathcal{J} = \det\left[\frac{1}{2}(I + d\gamma^t) + \begin{pmatrix} 0 & 0 \\ C^t & D^t \end{pmatrix} \right]. \tag{8.16}$$

Here

$$C^t \equiv \frac{e}{c} \frac{\partial}{\partial q^0}(\alpha^s(t, \gamma^t_q(x^0), q^0)) + e\int_0^t \frac{\partial E(\tilde{t}, q^0)}{\partial q^0} d\tilde{t}, \quad D^t \equiv \frac{e}{c} \frac{\partial}{\partial p^0}(\alpha^s(t, \gamma^t_q(x^0), q^0)).$$

The function α^s is determined by $\alpha^s(t,q,q') \equiv \frac{1}{2}(\alpha(t,q,q') + \alpha(t,q',q))$, where the two-point magnetic potential α is given by (8.4). The point x^0 everywhere in these formulas has to be expressed via t,x by means of the equation

$$x = \tfrac{1}{2}(\gamma^t(x^0) + \lambda^t(x^0)) + v^t(x^0). \tag{8.17}$$

This equation is uniquely solvable while the Jacobian is positive

$$\mathcal{J} \geqslant \delta > 0, \quad t \in [0,T]. \tag{8.18}$$

So, we conclude with the following result.

Theorem 8: *The symbol $\mathcal{U}^t$ of the evolution operator* (8.5) *solving the equation of motion* (8.1a) *or* (8.1b) *can be represented* [*for sufficiently small time* (8.18)] *in the WKB-form* (7.7) *or* (8.9) *over the contact space $\mathbb{R}^7 = \mathbb{R}_t \times \mathbb{R}^6_x$. The phases S are given by membrane formula* (8.15) *and amplitudes $u^t = \mathcal{J}^{-1/2}$ by* (8.16).

Remark 6: Of course, the contact space $\mathbb{R}^7$ can be symplectified (see Refs. 59 and 60) up to $\mathbb{R}^8 = (\mathbb{R}_{p_0} \oplus \mathbb{R}_t) \times \mathbb{R}^6_x$ with symplectic form $\omega'_F = dp_0 \wedge dt + \tilde{\omega}_F$. The dynamical membrane $\Sigma_{t,x}$ in (8.15) can be blown up to a membrane $\Sigma'_{t,x}$ in such a way that the path γ^t is put on the level $p_0 = -H$, and the path λ^t is put on the level $p_0 = 0$; so, the summand $\int_0^t H\, d\tilde{t}$ in (8.15) is included into the membrane area, and altogether one obtains

$$S(t,x)=\int_{\Sigma'_{t,x}}\omega'_F\,.$$

ACKNOWLEDGMENTS

Ensemble fluctuations and the origin of quantum probabilistic rule

Andrei Khrennikov[a)]
International Center for Mathematical Modeling in Physics and Cognitive Sciences, MSI, University of Växjö, S-35195, Sweden

(Received 17 October 2000; accepted for publication 14 November 2001)

We demonstrate that the origin of the so-called quantum probabilistic rule (which differs from the classical Bayes' formula by the presence of cos θ-factor) might be explained in the framework of ensemble fluctuations which are induced by preparation procedures. In particular, quantum rule for probabilities (with nontrivial cos θ-factor) could be simulated for macroscopic physical systems via preparation procedures producing ensemble fluctuations of a special form. We discuss preparation and measurement procedures which may produce probabilistic rules which are neither classical nor quantum; in particular, hyperbolic ''quantum theory.''
 [DOI: 10.1063/1.1432485]

I. INTRODUCTION

It is well known that the classical probabilistic rule based on the Bayes' formula for conditional probabilities cannot be applied to quantum formalism, see, e.g., Refs. 1–3 for extended discussions. In fact, all special features of quantum systems are just consequences of violations of the classical probability rule, Bayes' theorem.[1] In this paper we restrict our investigations to the two-dimensional case. Here Bayes' formula (the formula of total probability) has the form ($i=1,2$):

$$\mathbf{p}(A=a_i)=\mathbf{p}(C=c_1)\mathbf{p}(A=a_i/C=c_1)+\mathbf{p}(C=c_2)\mathbf{p}(A=a_i/C=c_2), \tag{1}$$

where A and C are physical variables which take, respectively, values a_1, a_2 and c_1, c_2. Symbols $\mathbf{p}(A=a_i/C=c_j)$ denote conditional probabilities. There is a large diversity of opinions on the origin of violations of (1) in quantum mechanics. The common opinion is that violations of (1) are induced by special (quite mysterious) features of quantum systems.

Let ϕ be a quantum state. Let $\{\phi_i\}_{i=1}^2$ be an orthogonal basis consisting of eigenvectors of the operator $\hat{C}$ corresponding to the physical observable C.

The quantum theoretical rule (derived in the Hilbert space formalism) has the form ($i=1,2$):

$$q_i=\mathbf{p}_1\mathbf{p}_{1i}+\mathbf{p}_2\mathbf{p}_{2i}\pm 2\sqrt{\mathbf{p}_1\mathbf{p}_{1i}\mathbf{p}_2\mathbf{p}_{2i}}\cos\theta, \tag{2}$$

where $q_i=\mathbf{p}_\phi(A=a_i)$, $\mathbf{p}_j=\mathbf{p}_\phi(C=c_j)$, $\mathbf{p}_{ij}=\mathbf{p}_{\phi_i}(A=a_j)$, $i,j=1,2$. Here probabilities have indexes corresponding to quantum states. The common opinion is that this quantum probabilistic rule must be considered as a peculiarity of nature. However, there exists an opposition to this general opinion, namely the probabilistic opposition. The main domain of activity of this probabilistic opposition is Bell's inequality and the EPR paradox,[4] see, e.g., Refs. 1, 5–11. The general idea supported by the probabilistic opposition is that special quantum behavior can be understood on the basis of local realism, if we are careful with the probabilistic description of physical phenomena. It seems that the origin of all ''quantum troubles'' is probabilistic rule (2). It seems that the violation of Bell's inequality is just a new representation of the old contradiction between

a)Electronic mail: andrei.khrennikov@msi.vxu.se

rules (1) and (2) (the papers of Accardi[1] and De Muynck, De Baere, and Martens[7] contain extended discussions on this problem). Therefore, the main problem of the probabilistic justification of quantum mechanics is to find the clear probabilistic explanation of the origin of quantum probabilistic rule (2) and the violation of classical probabilistic rule (1) and explain why (2) is sometimes reduced to (1).

Accardi[5] introduced a notion of the *statistical invariant* to investigate the relation between classical Kolmogorovean and quantum probabilistic models, see also Gudder and Zanghi in Ref. 6. He was also the first who mentioned that Bayes' postulate is a ''hidden axiom of the Kolmogorovean model... which limits its applicability to the statistical description of the natural phenomena.'' [5] In fact, this investigation plays a crucial role in our analysis of classical and quantum probabilistic rules.

An interesting investigation on this problem is contained in the paper of Shummhammer.[11] He supports the idea that quantum probabilistic rule (2) is not a peculiarity of nature, but just a consequence of one special method of the probabilistic description of nature, the so-called method of *maximum predictive power*. We do not directly support the idea of Shummhammer. It seems that the origin of (2) is not only a consequence of the use of one special method for the description of nature, but merely a consequence of our manipulations with nature, ensembles of physical systems, in quantum preparation/measurement procedures.

In this paper we provide probabilistic analysis of quantum rule (2). In our analysis ''probability'' has the meaning of the *frequency probability*, namely the limit of frequencies in a long sequence of trials (or for a large statistical ensemble). Hence, in fact, we follow von Mises' approach to probability.[12] It seems that it would be impossible to find the roots of quantum rule (2) in the conventional probability framework, A. N. Kolmorogov, 1933.[13] In the conventional measure-theoretical framework probabilities are defined as sets of real numbers having some special mathematical properties. Classical rule (1) is merely a consequence of the definition of conditional probabilities. In the Kolmogorov framework to analyze the transition from (1) to (2) is to analyze the transition from one definition to another. In the frequency framework we can analyze behavior of trails which induce one or another property of probability. Our analysis shows that quantum probabilistic rule (2) can be explained on the basis of ensemble fluctuations (one of the possible sources of ensemble fluctuations is the so-called ensemble nonreproducibility, see De Baere;[7] see also Ref. 10 for the statistical variant of nonreproducibility). Such fluctuations can generate (under special conditions) the $\cos\theta$-factor in (2). Thus trigonometric fluctuations of quantum probabilities can be explained without using the wave arguments.

An unexpected consequence of our analysis is that quantum probability rule (2) is just one of the possible perturbations (by ensemble fluctuations) of classical probability rule (1). In principle, there might exist experiments which would produce perturbations of classical probabilistic rule (1) which differ from quantum probabilistic rule (2).

II. QUANTUM FORMALISM AND ENSEMBLE FLUCTUATIONS

A. Frequency probability theory

The frequency definition of probability is more or less standard in quantum theory; especially in the approach based on preparation and measurement procedures.[14,3]

Let us consider a sequence of physical systems $\pi=(\pi_1,\pi_2,\dots,\pi_N,\dots)$. Suppose that elements of π have some property, e.g., position, and this property can be described by natural numbers: $L=\{1,2,\dots,m\}$, the set of labels. Thus, for each $\pi_j\in\pi$, we have a number $x_j\in L$. So π induces a sequence

$$x=(x_1,x_2,\dots,x_N,\dots),\quad x_j\in L. \tag{3}$$

For each fixed $\alpha\in L$, we have the relative frequency $\nu_N(\alpha)=n_N(\alpha)/N$ of the appearance of α in $(x_1,x_2,\dots,x_N)$. Here $n_N(\alpha)$ is the number of elements in $(x_1,x_2,\dots,x_N)$ with $x_j=\alpha$. von Mises[12] said that x satisfies the principle of the *statistical stabilization* of relative frequencies, if, for each fixed $\alpha\in L$, there exists the limit

$$\mathbf{p}(\alpha)=\lim_{N\to\infty}\nu_N(\alpha). \tag{4}$$

This limit is said to be a probability of α.

We shall not consider the so-called principle of *randomness*, see Ref. 12 for details. This principle, despite its importance for the foundations of probability theory, is not related to our frequency analysis. We shall be interested only in the statistical stabilization of relative frequencies.

Remark 2.1 (randomness): The second von Mises' principle, randomness, was introduced to exclude from consideration deterministic sequences that satisfy the principle of statistical stabilization. For example, $x=(010101\ldots0101\ldots)$ satisfies the principle of the statistical stabilization, but, of course, it could not be considered as a random sequence. By the principle of randomness limits in (4) must be invariant with respect to selections of subsequences in (3) by using some class of so-called place selections. The notion of place selection induces numerous difficulties in von Mises theory, see, e.g., Ref. 10. In fact, the problem—to define randomness by using place selections—was not solved. Mathematicians escape this problem by using other approaches, e.g., Kolmogorov complexity or Marti–Löf tests for randomness, see, e.g., Ref. 10.

B. Preparation and measurement procedures and quantum formalism

We consider a statistical ensemble S of quantum particles described by a quantum state ϕ. This ensemble is produced by some preparation procedure $\mathcal{E}$, see, e.g., Refs. 14 and 3 for details. There are two discrete physical observables $C=c_1,c_2$ and $A=a_1,a_2$.

The total number of particles in S is equal to N. Suppose that n_i^c, $i=1,2$, particles in S would give the result $C=c_i$ and n_i^a, $i=1,2$, particles in S would give the result $A=a_i$. Suppose that, among those particles which would produce $C=c_i$, there are n_{ij}, $i,j=1,2$, particles which would give the result $A=a_j$. So

$$n_i^c=n_{i1}+n_{i2},\quad n_j^a=n_{1j}+n_{2j},\quad i,j=1,2.$$

We use the objective realist model in that both C and A are *objective properties* of a quantum particle, see Refs. 2, 3, and 10 for details. Such a viewpoint to quantum observables could be called Einstein's viewpoint. In such a model we can consider in the ensemble S subensembles $S_j(C)$ and $S_j(A),j=1,2$, of particles having properties $C=c_j$ and $A=a_j$, respectively. Set

$$S_{ij}(A,C)=S_i(C)\cap S_j(A).$$

Then n_{ij} is the number of elements in the ensemble $S_{ij}(A,C)$ (subensemble of S). We remark that the "existence" of the objective property ($C=c_i$ and $A=a_j$) need not imply the possibility to measure this property. For example, such a measurement is impossible in the case of incompatible observables. So in general ($C=c_i$ and $A=a_j$) is a kind of hidden property.

The quantum experience says that the following frequency probabilities are well defined for all observables C, A:

$$\mathbf{p}_i=\mathbf{p}_\phi(C=c_i)=\lim_{N\to\infty}\mathbf{p}_i^{(N)},\quad \mathbf{p}_i^{(N)}=\frac{n_i^c}{N}; \tag{5}$$

$$q_i=\mathbf{p}_\phi(A=a_i)=\lim_{N\to\infty}q_i^{(N)},\quad q_i^{(N)}=\frac{n_i^a}{N}. \tag{6}$$

Can we say something about the behavior of frequencies $\tilde{\mathbf{p}}_{ij}^{(N)}=n_{ij}/N$, $N\to\infty$?

In fact, not so much. Suppose that they stabilize, when $N\to\infty$. This implies that probabilities $\tilde{\mathbf{p}}_{ij}=\mathbf{p}_\phi(C=c_i,A=a_j)=\lim_{N\to\infty}\tilde{\mathbf{p}}_{ij}^{(N)}$ would be well defined. The quantum experience says that

(in general) this probability distribution could not be measured. Thus it may be the frequencies $\tilde{\mathbf{p}}_{ij}^{(N)}$ fluctuate, when $N\to\infty$. Such fluctuations can, nevertheless, produce the statistical stabilization (5), (6), see Ref. 10 for details.

Remark 2.2: The common interpretation of experimental violations of Bell's inequality is that realism cannot be used in quantum theory (at least in the local framework). However, Bell's considerations only imply that we cannot use realist models under the assumption that $\tilde{\mathbf{p}}_{ij}^{(N)}$ stabilize. The realist models with fluctuating frequencies $\tilde{\mathbf{p}}_{ij}^{(N)}$ can coexist with violations of Bell's inequality, see Ref. 10.

Let us now consider statistical ensembles T_i, $i=1,2$, of quantum particles described by the quantum states ϕ_i which are eigenstates of the operator $\hat{C}$: $\hat{C}\phi_i=c_i\phi_i$. These ensembles are produced by some preparation procedures $\mathcal{E}_i$. For instance, we can suppose that particles produced by a preparation procedure $\mathcal{E}$ for the quantum state ϕ pass through additional filters F_i, $i=1,2$. In quantum formalism we have

$$\phi=\sqrt{\mathbf{p}_1}\phi_1+\sqrt{\mathbf{p}_2}e^{i\theta}\phi_2. \tag{7}$$

In the objective realist model this representation may induce the illusion that ensembles T_i, $i=1,2$, for states ϕ_i must be identified with subensembles $S_i(C)$ of the ensemble S for the state ϕ. However, there are no physical reasons for such an identification. There are two main sources of troubles with this identification.

(a) The additional filter F_1 (and F_2) changes the properties of quantum particles. The probability distribution of the property A for the ensemble $S_1(C)=\{\pi\in S: C(\pi)=c_1\}$ [and $S_2(C)$] may differ from the corresponding probability distribution for the ensemble T_1 (and T_2) obtained by filtration. So different preparation procedures produce different distributions of properties.

(b) As we have already mentioned, frequencies $\tilde{\mathbf{p}}_{ij}^{(N)}=n_{ij}/N$ may fluctuate. Even if additional filters do not change properties of quantum particles, nonreproducibility implies that the distribution of the property A may be essentially different for statistical ensembles $S_1(C)$ and $S_2(C)$ (subensembles of S) and T_1 and T_2. Moreover, distributions may be different even for subensembles $S_1(C)$ and $S_1'(C)$ [or $S_2(C)$ and $S_2'(C)$, of two different ensembles S and S' of quantum particles prepared in the same quantum state ϕ, see Ref. 10].

Fluctuations of physical properties which could be induced by (a) or (b) will be called *ensemble fluctuations*.

Of course, principle (a) looks more attractive from the experimentalist (instrumentalists) point of view. This is the original viewpoint of Heisenberg, who paid much attention to the role of perturbations in quantum measurements. Similar ideas were presented by Bohr, who paid much attention to the role of experimental arrangement. Principle (a) implies that the transition from one context (complex of physical conditions) given by the preparation procedure $\mathcal{E}$ to other contexts given by the preparation procedures $\mathcal{E}_j$, $j=1,2$, produces statistical perturbations of properties of physical systems. Principle (a) has some relation to von Mises' principle of randomness. Filters F_j can be considered as place selections in the original ensemble S. Principle (a) is the hypothesis that we could not perform such place selection without changing properties of the physical systems.

Principle (b) looks more exotic, since we always observe the statistical stabilization of frequencies in our experiments. However, we shall also keep in mind this possibility.

Suppose that m_{ij} is the number of particles in the ensemble T_i having the objective property $A=a_j$.

The quantum experience says that the following frequency probabilities are well defined:

$$\mathbf{p}_{ij}=\mathbf{p}_{\phi_i}(A=a_j)=\lim_{N\to\infty}\mathbf{p}_{ij}^{(N)},\quad \mathbf{p}_{ij}^{(N)}=m_{ij}/n_i^c.$$

Here it is assumed that an ensemble T_i consists of n_i^c particles, $i=1,2$. It is also assumed that $n_i^c = n_i^c(N) \to \infty$, $N \to \infty$. In fact, the latter assumption holds true if both probabilities $\mathbf{p}_i$, $i=1,2$, are nonzero.

We remark that probabilities $\mathbf{p}_{ij} = \mathbf{p}_{\phi_i}(A=a_j)$ cannot be (in general) identified with conditional probabilities $\mathbf{p}_{\phi}(A=a_j/C=c_i) = \tilde{\mathbf{p}}_{ij}/\mathbf{p}_i$. As we have remarked, these probabilities are related to statistical ensembles prepared by different preparation procedures, namely by $\mathcal{E}_i$, $i=1,2$, and $\mathcal{E}$. The latter probabilities may be not exist at all, see principle (b).

Let $\{\psi_j\}_{j=1}^2$ be an orthonormal basis consisting of eigenvectors of the operator A. We can restrict our consideration to the case:

$$\phi_1 = \sqrt{\mathbf{p}_{11}}\psi_1 + e^{i\gamma_1}\sqrt{\mathbf{p}_{12}}\psi_2, \quad \phi_2 = \sqrt{\mathbf{p}_{21}}\psi_1 + e^{i\gamma_2}\sqrt{\mathbf{p}_{22}}\psi_2. \tag{8}$$

As $(\phi_1, \phi_2) = 0$, we obtain

$$\sqrt{\mathbf{p}_{11}\mathbf{p}_{21}} + e^{i(\gamma_1 - \gamma_2)}\sqrt{\mathbf{p}_{12}\mathbf{p}_{22}} = 0.$$

Hence, $\sin(\gamma_1 - \gamma_2) = 0$ (we suppose that all probabilities $\mathbf{p}_{ij} > 0$) and $\gamma_2 = \gamma_1 + \pi k$. We also have

$$\sqrt{\mathbf{p}_{11}\mathbf{p}_{21}} + \cos(\gamma_1 - \gamma_2)\sqrt{\mathbf{p}_{12}\mathbf{p}_{22}} = 0.$$

This implies that $k = 2l+1$ and $\sqrt{\mathbf{p}_{11}\mathbf{p}_{21}} = \sqrt{\mathbf{p}_{12}\mathbf{p}_{22}}$. As $\mathbf{p}_{12} = 1 - \mathbf{p}_{11}$ and $\mathbf{p}_{21} = 1 - \mathbf{p}_{22}$, we obtain that

$$\mathbf{p}_{11} = \mathbf{p}_{22}, \quad \mathbf{p}_{12} = \mathbf{p}_{21}. \tag{9}$$

These equalities are equivalent to the condition: $\mathbf{p}_{11} + \mathbf{p}_{21} = 1, \mathbf{p}_{12} + \mathbf{p}_{22} = 1$. So the matrix of probabilities $(\mathbf{p}_{ij})_{i,j=1}^2$ is the so-called *double stochastic matrix*, see, e.g., Ref. 3 for general considerations.

Thus, in fact,

$$\phi_1 = \sqrt{\mathbf{p}_{11}}\psi_1 + e^{i\gamma_1}\sqrt{\mathbf{p}_{12}}\psi_2, \quad \phi_2 = \sqrt{\mathbf{p}_{21}}\psi_1 - e^{i\gamma_1}\sqrt{\mathbf{p}_{22}}\psi_2. \tag{10}$$

So $\varphi = d_1\psi_1 + d_2\psi_2$, where

$$d_1 = \sqrt{\mathbf{p}_1\mathbf{p}_{11}} + e^{i\theta}\sqrt{\mathbf{p}_2\mathbf{p}_{21}}, \quad d_2 = e^{i\gamma_1}\sqrt{\mathbf{p}_1\mathbf{p}_{12}} - e^{i(\gamma_1+\theta)}\sqrt{\mathbf{p}_2\mathbf{p}_{22}}.$$

Thus

$$q_1 = \mathbf{p}_{\phi}(A=a_1) = |d_1|^2 = \mathbf{p}_1\mathbf{p}_{11} + \mathbf{p}_2\mathbf{p}_{21} + 2\sqrt{\mathbf{p}_1\mathbf{p}_{11}\mathbf{p}_2\mathbf{p}_{21}}\cos\theta; \tag{11}$$

$$q_2 = \mathbf{p}_{\phi}(A=a_2) = |d_2|^2 = \mathbf{p}_1\mathbf{p}_{12} + \mathbf{p}_2\mathbf{p}_{22} - 2\sqrt{\mathbf{p}_1\mathbf{p}_{12}\mathbf{p}_2\mathbf{p}_{22}}\cos\theta. \tag{12}$$

C. Probability relations connecting preparation procedures

Let us forget at the moment about the quantum theory. We consider an arbitrary preparation procedure $\mathcal{E}$ for microsystems or macrosystems. Suppose that $\mathcal{E}$ produced an ensemble S of physical systems. Let $C(=c_1, c_2)$ and $A(=a_1, a_2)$ be physical quantities which can be measured for elements $\pi \in S$. Let $\mathcal{E}_1$ and $\mathcal{E}_2$ be preparation procedures which are based on filters F_1 and F_2 corresponding, respectively, to values c_1 and c_2 of C. Denote statistical ensembles produced by these preparation procedures by symbols T_1 and T_2, respectively. Symbols N, n_i^c, n_i^a, n_{ij}, m_{ij} have the same meaning as in the previous considerations. Probabilities $\mathbf{p}_i$, $\mathbf{p}_{ij}$, q_i are defined in the same way as in the previous considerations. The only difference is that, instead of indexes corresponding to quantum states, we use indexes corresponding to statistical ensembles: $\mathbf{p}_i = \mathbf{P}_S(C=c_i)$, $q_i = \mathbf{P}_S(A=a_i)$, $\mathbf{p}_{ij} = \mathbf{P}_{T_i}(A=a_i)$.

In the classical frequency framework we obtain:

$$q_1^{(N)}=\frac{n_1^a}{N}=\frac{n_{11}}{N}+\frac{n_{21}}{N}=\frac{m_{11}}{N}+\frac{m_{21}}{N}+\frac{(n_{11}-m_{11})}{N}+\frac{(n_{21}-m_{21})}{N}.$$

But, for $i=1,2,$ we have

$$\frac{m_{1i}}{N}=\frac{m_{1i}}{n_1^c}\cdot\frac{n_1^c}{N}=\mathbf{p}_{1i}^{(N)}\mathbf{p}_1^{(N)},\quad \frac{m_{2i}}{N}=\frac{m_{2i}}{n_2^c}\cdot\frac{n_2^c}{N}=\mathbf{p}_{2i}^{(N)}\mathbf{p}_2^{(N)}.$$

Hence

$$q_i^{(N)}=\mathbf{p}_1^{(N)}\mathbf{p}_{1i}^{(N)}+\mathbf{p}_2^{(N)}\mathbf{p}_{2i}^{(N)}+\delta_i^{(N)}, \tag{13}$$

where

$$\delta_i^{(N)}=\frac{1}{N}[(n_{1i}-m_{1i})+(n_{2i}-m_{2i})],\quad i=1,2.$$

In fact, this rest term depends on the statistical ensembles $S,\ T_1,\ T_2,\ \delta_i^{(N)}=\delta_i^{(N)}(S,T_1,T_2)$.

D. Behavior of fluctuations

First we remark that $\lim_{N\to\infty}\delta_i^{(N)}$ exists for all physical measurements. This is a consequence of the property of statistical stabilization of relative frequencies for physical observables (in classical as well as in quantum physics). It may be that this property is a peculiarity of nature. It may be that this is just a property of our measurement and preparation procedures, see Ref. 10 for an extended discussion. In any case we always observe that

$$q_i^{(N)}\to q_i,\quad \mathbf{p}_i^{(N)}\to\mathbf{p}_i,\quad \mathbf{p}_{ij}^{(N)}\to\mathbf{p}_{ij},\quad N\to\infty.$$

Thus there exist limits

$$\delta_i=\lim_{N\to\infty}\delta_i^{(N)}=q_i-\mathbf{p}_1\mathbf{p}_{1i}-\mathbf{p}_2\mathbf{p}_{2i}.$$

Suppose that ensemble fluctuations produce negligibly small (with respect to N) changes in properties of particles. Then

$$\delta_i^{(N)}\to 0,\quad N\to\infty. \tag{14}$$

This asymptotic implies classical probabilistic rule (1). In particular, this rule appears in all experiments of classical physics. Hence, preparation and measurement procedures of classical physics produce ensemble fluctuations with asymptotic (14). We also have such a behavior in the case of compatible observables in quantum physics. Moreover, we can obtain the same classical probabilistic rule for incompatible observables C and A if the phase factor $\theta=\pi/2+\pi k$. Therefore classical probabilistic rule (1) is not directly related to commutativity of corresponding operators in quantum theory. It is a consequence of asymptotic (14) for ensemble fluctuations.

Suppose now that filters $F_i,\ i=1,2,$ produce relatively large (with respect to N) changes in properties of particles. Then

$$\lim_{N\to\infty}\delta_i^{(N)}=\delta_i\neq 0. \tag{15}$$

Here we obtain probabilistic rules which differ from the classical one—(1). In particular, this implies that behavior of ensemble fluctuations (15) cannot be produced in experiments of classical

physics. A rather special class of ensemble fluctuations (15) is produced in experiments of quantum physics. However, ensemble fluctuations of form (15) are not reduced to quantum fluctuations (see further considerations).

To carefully study behavior of fluctuations $\delta_i^{(N)}$, we represent them as

$$\delta_i^{(N)}=2\sqrt{\mathbf{p}_1^{(N)}\mathbf{p}_{1i}^{(N)}\mathbf{p}_2^{(N)}\mathbf{p}_{2i}^{(N)}}\lambda_i^{(N)},$$

where

$$\lambda_i^{(N)}=\frac{1}{2\sqrt{m_{1i}m_{2i}}}[(n_{1i}-m_{1i})+(n_{2i}-m_{2i})].$$

We have used the fact:

$$\mathbf{p}_1^{(N)}\mathbf{p}_{1i}^{(N)}\mathbf{p}_2^{(N)}\mathbf{p}_{2i}^{(N)}=\frac{n_1^c}{N}\cdot\frac{m_{1i}}{n_1^c}\cdot\frac{n_2^c}{N}\cdot\frac{m_{2i}}{n_2^c}=\frac{m_{1i}m_{2i}}{N^2}.$$

We have: $\delta_i=2\sqrt{\mathbf{p}_1\mathbf{p}_{1i}\mathbf{p}_2\mathbf{p}_{2i}}\lambda_i$, where the coefficients $\lambda_i=\lim_{N\to\infty}\lambda_i^{(N)}$, $i=1,2$.

In classical physics the coefficients $\lambda_i=0$. We have the same situation in quantum physics for all compatible observables as well as for some incompatible observables. In the general case in quantum physics we can only say that

$$|\lambda_i|\leqslant 1. \tag{16}$$

Hence, for quantum fluctuations, we always have

$$\left|\frac{(n_{1i}-m_{1i})+(n_{2i}-m_{2i})}{2\sqrt{m_{1i}m_{2i}}}\right|\leqslant 1,\quad N\to\infty.$$

Thus quantum ensemble fluctuations induce a relatively small (but in general nonzero!) variations of properties.

E. Fluctuations which induce the quantum probabilistic rule

Let us consider preparation procedures $\mathcal{E}$, $\mathcal{E}_j$, $j=1,2$, which have the deviations, when $N\to\infty$, of the following form ($i=1,2$):

$$\epsilon_{1i}^{(N)}=n_{1i}-m_{1i}=2\xi_{1i}^{(N)}\sqrt{m_{1i}m_{2i}}, \tag{17}$$

$$\epsilon_{2i}^{(N)}=n_{2i}-m_{2j}=2\xi_{2i}^{(N)}\sqrt{m_{1i}m_{2i}}, \tag{18}$$

where the coefficients ξ_{ij} satisfy the inequality

$$|\xi_{1i}^{(N)}+\xi_{2i}^{(N)}|\leqslant 1,\quad N\to\infty. \tag{19}$$

Suppose that $\lambda_i^{(N)}=\xi_{1i}^{(N)}+\xi_{2i}^{(N)}\to\lambda_i$, $N\to\infty$, where $|\lambda_i|\leqslant 1$. We can represent $\lambda_i^{(N)}=\cos\theta_i^{(N)}$. Then $\theta_i^{(N)}\to\theta_i, \mathrm{mod}\, 2\pi$, when $N\to\infty$. Thus $\lambda_i=\cos\theta_i$.

We obtained that

$$\delta_i=2\sqrt{\mathbf{p}_1\mathbf{p}_{1i}\mathbf{p}_2\mathbf{p}_{2i}}\cos\theta_i,\quad i=1,2. \tag{20}$$

Thus fluctuations of the form (17), (18) produce the probability rule ($i=1,2$):

$$q_i=\mathbf{p}_1\mathbf{p}_{1i}+\mathbf{p}_2\mathbf{p}_{2i}+2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{1i}\mathbf{p}_{2i}}\cos\theta_i. \tag{21}$$

The usual probabilistic calculations give us

$$1=q_1+q_2=\mathbf{p}_1\mathbf{p}_{11}+\mathbf{p}_2\mathbf{p}_{21}+ +\mathbf{p}_1\mathbf{p}_{12}+\mathbf{p}_2\mathbf{p}_{22}+2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{11}\mathbf{p}_{21}}\cos\theta_1+2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{12}\mathbf{p}_{22}}\cos\theta_2$$
$$=1+2\sqrt{\mathbf{p}_1\mathbf{p}_2}[\sqrt{\mathbf{p}_{11}\mathbf{p}_{21}}\cos\theta_1+\sqrt{\mathbf{p}_{12}\mathbf{p}_{22}}\cos\theta_2].$$

Thus we obtain the relation

$$\sqrt{\mathbf{p}_{11}\mathbf{p}_{21}}\cos\theta_1+\sqrt{\mathbf{p}_{12}\mathbf{p}_{22}}\cos\theta_2=0. \tag{22}$$

Suppose that ensemble fluctuations (17) and (18) satisfy the additional condition

$$\lim_{N\to\infty}\mathbf{p}_{11}^{(N)}=\lim_{N\to\infty}\mathbf{p}_{22}^{(N)}. \tag{23}$$

This condition implies that the matrix of probabilities is a double stochastic matrix. Hence, we get

$$\cos\theta_1=-\cos\theta_2. \tag{24}$$

So we demonstrated that ensemble fluctuations (17) and (18) in combination with the double stochastic condition (23) produce quantum probabilistic relations (11) and (12).

It must be noticed that the existence of the limits $\lambda_i=\lim_{N\to\infty}\lambda_i^{(N)}$ does not imply the existence of limits $\xi_{1i}=\lim_{N\to\infty}\xi_{1i}^{(N)}$ and $\xi_{2i}=\lim_{N\to\infty}\xi_{2i}^{(N)}$. For example, let $\xi_{1i}^{(N)}=\lambda_i\cos^2\alpha_i^{(N)}$ and $\xi_{2i}^{(N)}=\lambda_i\sin^2\alpha_i^{(N)}$, where "phases" $\alpha_i^{(N)}$ fluctuate $\mathrm{mod}\,2\pi$. Then numbers ξ_{1i} and ξ_{2i} are not defined, but $\lim_{N\to\infty}[\xi_{1i}^{(N)}+\xi_{2i}^{(N)}]=\lambda_i$, $i=1,2$, exist.

If $\xi_{ij}^{(N)}$ stabilize, then probabilities for the simultaneous measurement of incompatible observables would be well defined:

$$\mathbf{p}(A=a_1,C=c_1)=\lim_{N\to\infty}\frac{n_{11}}{N}=\mathbf{p}_1\mathbf{p}_{11}+2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{11}\mathbf{p}_{21}}\xi_{11},\ldots.$$

The quantum formalism implies that in general such probabilities do not exist.

Remark 2.3: The magnitude of fluctuations can be found experimentally. Let C and A be two physical observables. We prepare free statistical ensembles S, T_1, T_2 corresponding to states ϕ, ϕ_1, ϕ_2. By measurements of C and A for $\pi\in S$ we obtain frequencies $\mathbf{p}_1^{(N)}$, $\mathbf{p}_2^{(N)}$, $q_1^{(N)}$, $q_2^{(N)}$, by measurements of A for $\pi\in T_1$ and for $\pi\in T_2$ we obtain frequencies $\mathbf{p}_{1i}^{(N)}$. We have

$$f_i(N)=\lambda_i^{(N)}=\frac{q_i^{(N)}-\mathbf{p}_1^{(N)}\mathbf{p}_{1i}^{(N)}-\mathbf{p}_2^{(N)}\mathbf{p}_{2i}^{(N)}}{2\sqrt{\mathbf{p}_1^{(N)}\mathbf{p}_{1i}^{(N)}\mathbf{p}_2^{(N)}\mathbf{p}_{2i}^{(N)}}}.$$

It would be interesting to obtain graphs of functions $f_i(N)$ for different pairs of physical observables. Of course, we know that $\lim_{N\to\infty}f_i(N)=\pm\cos\theta$. However, it may be that such graphs can present a finer structure of quantum states.

III. ON THE MAGNITUDE OF FLUCTUATIONS WHICH PRODUCE THE CLASSICAL PROBABILISTIC RULE

We remark that the classical probabilistic rule (which is induced by ensemble fluctuations with $\xi_i^{(N)}\to 0$) can be observed for fluctuations having relatively large absolute magnitudes. For instance, let

$$\epsilon_{1i}^{(N)}=2\xi_{1i}^{(N)}\sqrt{m_{1i}},\quad \epsilon_{2i}^{(N)}=2\xi_{2i}^{(N)}\sqrt{m_{2i}},\quad i=1,2, \tag{25}$$

where sequences of coefficients $\{\xi_{1i}^{(N)}\}$ and $\{\xi_{2i}^{(N)}\}$ are bounded ($N\to\infty$). Here

$$\lambda_i^{(N)}=\frac{\xi_{1i}^{(N)}}{\sqrt{m_{2i}}}+\frac{\xi_{2i}^{(N)}}{m_{1i}}\to 0, \quad N\to\infty$$

(as usual, we assume that $\mathbf{p}_{ij}>0$).

Example 3.1: Let $N\approx 10^6$, $n_1^c\approx n_2^c\approx 5\times 10^5$, $m_{11}\approx m_{12}\approx m_{21}\approx m_{22}\approx 25\times 10^4$. So $\mathbf{p}_1=\mathbf{p}_2=1/2$; $\mathbf{p}_{11}=\mathbf{p}_{12}=\mathbf{p}_{21}=\mathbf{p}_{22}=1/2$ (symmetric state). Suppose we have fluctuations (25) with $\xi_{1i}^{(N)}\approx\xi_{2i}^{(N)}\approx 1/2$. Then $\epsilon_{1i}^{(N)}\approx\epsilon_{2i}^{(N)}\approx 500$. So $n_{ij}=24\times 10^4\pm 500$. Hence, the relative deviation $\epsilon_{ji}^{(N)}/m_{ji}=500/25\times 10^4\approx 0.002$.

Thus fluctuations of the relative magnitude $\approx 0{,}002$ produce the classical probabilistic rule.

It is evident that fluctuations of essentially larger magnitude

$$\epsilon_{1i}^{(N)}=2\xi_{1i}^{(N)}(m_{1i})^{1/2}(m_{21})^{1/\alpha}, \quad \epsilon_{2i}^{(N)}=2\xi_{2i}^{(N)}(m_{2i})^{1/2}(m_{1i})^{1/\beta}, \quad \alpha,\beta>2, \tag{26}$$

where $\{\xi_{1i}^{(N)}\}$ and $\{\xi_{2i}^{(N)}\}$ are bounded sequences ($N\to\infty$), also produce (for $\mathbf{p}_{ij}\neq 0$) the classical probability rule.

Example 3.2: Let all numbers $N,\ldots,m_{ij}$ be the same as in Example 3.1 and let deviations have behavior (26) with $\alpha=\beta=4$. Here the relative deviation $\xi_{ij}^{(N)}/mij\approx 0.045$.

IV. CLASSICAL, QUANTUM, AND "SUPERQUANTUM" PHYSICS

In this section we find relations between different classes of physical experiments. First we consider the so-called classical and quantum experiments. Classical experiments produce the classical probabilistic rule (Bayes' formula). Therefore the corresponding ensemble fluctuations have the asymptotic $\delta_i^{(N)}\to 0$, $N\to\infty$.

Nevertheless, we cannot say that classical measurements give just a subclass of quantum measurements. In the classical domain we have no symmetric relations $\mathbf{p}_{11}=\mathbf{p}_{22}$ and $\mathbf{p}_{12}=\mathbf{p}_{21}$. This is the special condition which connects the preparation procedures $\mathcal{E}_1$ and $\mathcal{E}_2$. This relation is a peculiarity of quantum preparation/measurement procedures.

Experiments with nonclassical probabilistic rules are characterized by the condition $\delta_i^{(N)}\to 0$, $N\to\infty$. Quantum experiments give only a particular class of nonclassical experiments. Quantum experiments produce ensemble fluctuations of form (17) and (18), where coefficients $\xi_{1i}^{(N)}$ and $\xi_{20}^{(N)}$ satisfy (19) and the orthogonality relation

$$\lim_{N\to\infty}(\xi_{11}^{(N)}+\xi_{21}^{(N)})+\lim_{N\to\infty}(\xi_{12}^{(N)}+\xi_{22}^{(N)})=0. \tag{27}$$

In particular, nonclassical domain contains (nonquantum) experiments which satisfy condition of boundedness (19), but do not satisfy orthogonality relation (27). Here we have only the relation of quasiorthogonality (22). In this case the matrix of probabilities is not double stochastic. The corresponding probabilistic rule has the form:

$$q_i=\mathbf{p}_1\mathbf{p}_{1i}+\mathbf{p}_2\mathbf{p}_{2i}+2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{1i}\mathbf{p}_{2i}}\cos\theta_i. \tag{28}$$

Here in general $\mathbf{p}_{11}+\mathbf{p}_{21}\neq 1$, $\mathbf{p}_{12}+\mathbf{p}_{22}\neq 1$.

We remark that, in fact, (28) and (22) imply that

$$q_1=\mathbf{p}_1\mathbf{p}_{11}+\mathbf{p}_2\mathbf{p}_{21}+2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{11}\mathbf{p}_{21}}\cos\theta_1;$$

$$q_2=\mathbf{p}_1\mathbf{p}_{12}+\mathbf{p}_2\mathbf{p}_{22}-2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{11}\mathbf{p}_{21}}\cos\theta_1.$$

V. HYPERBOLIC "QUANTUM" FORMALISM

Let us consider ensembles S, T_1, T_2 such that ensemble fluctuations have magnitudes (17) and (18) where

$$|\xi_{1i}^{(N)}+\xi_{2i}^{(N)}|\geqslant 1+c, c>0, \quad N\to\infty. \tag{29}$$

Here the coefficients $\lambda_i=\lim_{N\to\infty}(\xi_{1i}^{(N)}+\xi_{2i}^{(N)})$ can be represented in the form $\lambda_i=\mathrm{ch}\,\theta_i$, $i=1,2$. The corresponding probability rule is the following:

$$q_i=\mathbf{p}_1\mathbf{p}_{1i}+\mathbf{p}_2\mathbf{p}_{2i}+2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{1i}\mathbf{p}_{2i}}\,\mathrm{ch}\,\theta_i, \quad i=1,2.$$

The normalization $q_1+q_2=1$ gives the orthogonality relation:

$$\sqrt{\mathbf{p}_{11}\mathbf{p}_{21}}\,\mathrm{ch}\,\theta_1+\sqrt{\mathbf{p}_{12}\mathbf{p}_{22}}\,\mathrm{ch}\,\theta_2=0. \tag{30}$$

Thus

$$\mathrm{ch}\,\theta_2=-\,\mathrm{ch}\,\theta_1\sqrt{\frac{\mathbf{p}_{11}\mathbf{p}_{21}}{\mathbf{p}_{12}\mathbf{p}_{22}}}$$

and, hence,

$$q_2=\mathbf{p}_1\mathbf{p}_{12}+\mathbf{p}_2\mathbf{p}_{22}-2\sqrt{\mathbf{p}_1\mathbf{p}_2\mathbf{p}_{11}\mathbf{p}_{21}}\,\mathrm{ch}\,\theta_1.$$

Such a formalism can be called a *hyperbolic quantum formalism*. It describes a part of nonclassical reality which is not described by ''trigonometric quantum formalism.'' Experiments (and preparation procedures $\mathcal{E}$, $\mathcal{E}_1$, $\mathcal{E}_2$) which produce hyperbolic quantum behavior could be simulated on computer. On the other hand, at the moment we have no ''natural'' physical phenomena which are described by the hyperbolic quantum formalism. ''Trigonometric quantum behavior'' corresponds to essentially better control of properties in the process of preparation than ''hyperbolic quantum behavior.'' Of course, the aim of any experimenter is to approach ''trigonometric behavior.'' However, in principle there might exist such natural phenomena that ''trigonometric quantum behavior'' could not be achieved. In any case even the possibility of computer simulation demonstrates that quantum mechanics (trigonometric) is not complete (in the sense that not all physical reality is described by the standard quantum formalism). (We can compare the hyperbolic quantum formalism with the hyperbolic geometry.)

Example 6.1: Let $\mathbf{p}_1=\alpha$, $\mathbf{p}_2=1-\alpha$, $\mathbf{p}_{11}=\cdots=\mathbf{p}_{22}=1/2$. Then

$$q_1=\tfrac{1}{2}+\sqrt{\alpha(1-\alpha)}\lambda_1, \quad q_2=\tfrac{1}{2}-\sqrt{\alpha(1-\alpha)}\lambda_1.$$

If α is sufficiently small, then λ_1 can be, in principle, larger than 1: $\lambda_1=\mathrm{ch}\,\theta$.

A kind of Hilbert space representation of the hyperbolic transformations of probabilities was proposed in Ref. 15.

VI. QUANTUM BEHAVIOR FOR MACROSCOPIC SYSTEMS

Our analysis shows that ''quantum statistical behavior'' can be demonstrated by ensembles consisting of macroscopic systems, e.g., balls having colors $C=c_1$, red, or c_2, blue, and weights $A=a_1=1$ or $a_2=2$. Suppose that additional filters F_i, $i=1,2$, produce fluctuations (17), (18), and (27). Then, instead of classical Bayes' formula (1), we obtain quantum probability rule (2).

In the context of the statistical simulation of quantum statistical behavior via fluctuations (17) and (18) [with (27)] it would be useful to note that, in fact, we can choose constant coefficients $\xi_{ij}^{(N)}=\xi_{ij}$. Moreover, we have $\xi_{11}=-\xi_{12}$ and $\xi_{21}=-\xi_{22}$. The latter is a consequence of the general relations:

$$\frac{\xi_{11}^{(N)}}{\xi_{12}^{(N)}}\to-1, \quad \frac{\xi_{22}^{(N)}}{\xi_{21}^{(N)}}\to-1, \quad N\to\infty. \tag{31}$$

Asymptotic (31) can be obtained from (17) and (18):

Proof: By (17) we have

$$(n_{11}-m_{11})+(n_{12}-m_{12})=2\xi_{11}\sqrt{m_{11}m_{21}}+2\xi_{12}\sqrt{m_{12}m_{22}}. \tag{32}$$

The left-hand side is equal to zero: $(n_{11}+n_{12})-(m_{11}+m_{12})=n_1^c-n_1^c=0$ (as the ensemble T_1 has n_1^c elements). Hence, by (23) we get

$$\xi_{11}=-\xi_{12}\sqrt{\frac{m_{12}}{m_{21}}\frac{m_{22}}{m_{11}}}\to-\xi_{12},\quad N\to\infty$$

(as $\mathbf{p}_{11}=\mathbf{p}_{22}$ and $\mathbf{p}_{12}=\mathbf{p}_{21}$). In the same way we obtain that

$$\xi_{21}=-\xi_{22}\sqrt{\frac{m_{12}}{m_{21}}\frac{m_{22}}{m_{11}}}\to-\xi_{22},\quad N\to\infty.$$

VII. CORRELATIONS BETWEEN PREPARATION PROCEDURES

In this section we study the frequency meaning of the fact that in the quantum formalism the matrix of probabilities is double stochastic. We remark that this is a consequence of orthogonality of quantum states ϕ_1 and ϕ_2 corresponding to distinct values of a physical observable C. We have

$$\frac{\mathbf{p}_{11}}{\mathbf{p}_{12}}=\frac{\mathbf{p}_{22}}{\mathbf{p}_{21}}. \tag{33}$$

Suppose that (a), see Sec. II, is the origin of quantum behavior. Hence, all quantum features are induced by the impossibility to create new ensembles T_1 and T_2 without changing properties of quantum particles. Suppose that, for example, the preparation procedure $\mathcal{E}_1$ practically destroys the property $A=a_1$ (transforms this property into the property $A=a_2$). So $\mathbf{p}_{11}=0$. As a consequence, the $\mathcal{E}_1$ makes the property $A=a_2$ dominating. So $\mathbf{p}_{12}\approx 1$. Then the preparation procedure $\mathcal{E}_2$ *must* practically destroy the property $A=a_2$ (transforms this property into the property $A=a_1$). So $\mathbf{p}_{22}\approx 0$. As a consequence, the $\mathcal{E}_2$ makes the property $A=a_1$ dominating. So $\mathbf{p}_{21}\approx 1$.

Frequency relation (23) can be represented in the following form:

$$\frac{m_{11}}{n_1^c}-\frac{m_{22}}{n_2^c}\approx 0,\quad N\to\infty. \tag{34}$$

We recall that the number of elements in the ensemble T_i is equal to n_i^c.

Thus

$$\left(\frac{n_{11}-m_{11}}{n_1^c}\right)-\left(\frac{n_{22}-m_{22}}{n_2^c}\right)\approx\frac{n_{11}}{n_1^c}-\frac{n_{22}}{n_2^c}. \tag{35}$$

This is nothing than the relation between fluctuations of property A under the transition from the ensemble S to ensembles T_1, T_2 and distribution of this property in the ensemble S.

VIII. PHYSICAL CONSEQUENCES

By using frequency probabilistic analysis of transitions from one context (complex of physical conditions, preparation procedure) to other contexts we derived general transformation of probabilities induced by such transitions. In particular, quantum interference rule (2) was obtained as a particular case of our general transformation of probabilities.

The following consequences of our investigation might be interesting for physicists.

A. Contextualism

The crucial role of context (complex of physical conditions, experimental arrangement) in experiments with elementary particles was many times (at many occasions) underlined by ''fathers'' of quantum theory (especially, Heisenberg, Bohr, Dirac, see, e.g., Refs. 16 and 17); see also later investigations of Accardi, Ballentine, De Baere, De Muynck, Gudder, Khrennikov, Pitowsky.[1,5–10,15] In particular, Heisenberg mentioned that perturbations of quantum systems induced by context transitions are responsible for the violation of the classical rule of addition of probabilities (the formula of total probability) and the appearance of the quantum rule (interference), see Ref. 16. In fact, Bohr's complementarity principle is nothing other than the philosophy of contextualism. In this paper we present quantative probabilistic measure of statistical perturbations induced by context transitions. This gives the possibility to formulate contextual ideas in the mathematical framework.

B. Wave–particle dualism

It is well known, see, e.g., the historical introduction in Dirac's book[17] or see Feynman in Ref. 18, that the wave–particle dualism was proposed to solve the contradiction between the ''classical'' and ''quantum'' rules for the addition of probabilistic alternatives. The violation of the classical rule was observed in the well-known two slit experiment (by comparing results of measurements for three different complexes of physical conditions: both slits are open, only one of the slits is open). By using the frequency probabilistic framework we obtained ''quantum interference'' without applying wave arguments. Of course, as we have mentioned in this article, we can introduce complex amplitudes of probabilities, see Ref. 15. However, this wave description is just a mathematical description, complex linearization of nonlinear transformation of probabilities. So, in principle, we could use purely corpuscular phemenology.

C. Quantumlike behavior for macrosystems

Our derivation of ''quantum interference'' was purely mathematical. The only physical constraint is that context transitions induce statistical perturbations of relatively small magnitude. In principle, such perturbations could be produced in experiments with macroscopic systems. Thus we predict the possibility to observe quantumlike interference for macroscopic objects. In particular, recent experiments of the group of Zeilinger[19] and the Boulder-group[20] can be interpreted as successful steps in this direction.

By using contextual probabilistic calculus developed in this paper we can associate complex ''wave-amplitudes'' with macroscopic objects. This approach eliminates the gap between micro- and macroworlds. In particular, well-known experiments with Bose–Einstein condensate can be interpreted as the successful step in this direction.

D. Macroscopic quantum computers

The above arguments give the possibility to create experimental situations in that macrosystems would exhibit wave behavior. This implies the possibility to create computing devices based on quantumlike calculus of probabilities and composed of macrosystems.

E. Macroscopic quantum cryptography

The same arguments imply that, in principle, there could be created quantumlike cryptographic schemes based on macrosystems.

F. Hyperbolic interference

One of the unexpected consequences of our frequency probabilistic analysis of experimental statistical data is the possibility to produce not only usual trigonometric, but also hyperbolic interference. This is the concrete experimental prediction. We hope that in the future there will be performed experiments to observe hyperbolic interference.

G. Superquantum scale

We obtained hyperbolic interference for complexes of physical conditions that produce statistical perturbations of relatively large magnitude. Here physical systems are ''supersensitive'' to perturbations produced by measurement devices. Such a behavior would be natural for physical systems having essentially higher sensitivity (to perturbations induced by our macroscopic devices) than ordinary quantum systems (elementary particles). We can talk about ''superquantum'' scale of sizes and energies. In particular, on this scale there must exist a new *hyperbolic Planck constant*. Formally such a parameter appears in the hyperbolic analogue of Schrödinger equation in hyperbolic quantum mechanics, see Ref. 15. Of course, in accordance with our general ideology, hyperbolic interference also could be produced in some experiments with macrosystems.

H. Hyperbolic quantum computing and cryptography

Hyperbolic interference could be used (in a similar way as trigonometric) to realize hyperbolic quantumlike computing and cryptographic schemes. On one hand, hyperbolic quantumlike computing and cryptographic schemes might be realized for super quantum scales. On the other hand, they might be realized for macrosystems.

I. Cognitive quantumlike models

Our probabilistic derivation of interference rules was performed in the general framework. In principle, we can use quantumlike probabilistic calculus to investigate statistical data obtained in cognitive experiments, see Ref. 21.

IX. CONCLUSION

We demonstrated that the so-called quantum probabilistic rule has a natural explanation in the framework of ensemble fluctuations induced by preparation procedures. In particular, the quantum rule for probabilities (with nontrivial $\cos\theta$-factor) could be simulated for macroscopic physical systems via preparation procedures producing the special ensemble fluctuations.

(Received 22 May 2001; accepted for publication 31 October 2001)

In this paper, we prove that the global minimizer of the Ginzburg-Landau functional of an inhomogeneous superconductor in an external magnetic field below the first critical field H_{c_1} is the vortexless solution. Here, H_{c_1} is defined as the value of h_{ex}, the applied field, for which the minimal energy among vortexless configurations is equal to the minimal energy among single-vortex configurations. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1428808]

I. INTRODUCTION

We are interested in describing the global minimizers of the Ginzburg-Landau functional

$$J(u,A)=\frac{1}{2}\int_{\Omega}|\nabla_A u|^2+|h-h_{ex}|^2-h_{ex}^2+\frac{\kappa^2}{2}(a(x)-|u|^2)^2 \tag{1.1}$$

that corresponds to the free energy of a superconductor in a prescribed, constant magnetic field h_{ex}. Here $\Omega\subset\mathbb{R}^2$ is the smooth, bounded, simply connected section of the superconductor and $a(x):\Omega\to\mathbb{R}$ is a given function satisfying $0<\min_{\bar{\Omega}}a(x)\leqslant a(x)\leqslant 1$ in Ω. The unknowns in Eq. (1.1) are the complex-valued order parameter $u\in H^1(\Omega,\mathbb{C})$ and the $U(1)$ connection $A\in H^1(\Omega,\mathbb{R}^2)$. Here $h=\operatorname{curl}A$ is the induced magnetic field and $\nabla_A u=\nabla u-iAu$. The order parameter u indicates the local state of the material: $|u|$ is the density of superconducting electron pairs, so that, when $|u|\simeq 1$, the material is in its superconducting state, whereas when $|u|\simeq 0$, it is in its normal state. $\kappa=1/\varepsilon>0$ is the Ginzburg-Landau parameter depending on the material.

Minimizers of $J(u,A)$ in $H^1(\Omega,\mathbb{C})\times H^1(\Omega,\mathbb{R}^2)$ solve the Euler equations

$$(G.L.)\begin{cases}-\nabla_A^2 u=\kappa^2 u(a(x)-|u|^2) & \text{in } \Omega\\ -\nabla^{\perp}h=(iu,\nabla_A u) & \text{in } \Omega\end{cases},$$

with the boundary conditions

$$\begin{aligned}h&=h_{ex} \quad \text{on } \partial\Omega\\ (\nabla u-iAu)\cdot n&=0 \quad \text{on } \partial\Omega.\end{aligned} \tag{1.2}$$

Here $\nabla^{\perp}$ denotes $(-\partial_{x_2},\partial_{x_1})$, n is the unit outer normal vector to $\partial\Omega$ and $(z,w)=Re(z\bar{w})$, where z and w are in $\mathbb{C}$.

The mathematical and physical importance of solutions is to determine the zeros of the solutions for a certain range of value of h_{ex}. The points where the the zeros of u appear, with their

a)Author to whom correspondence should be addressed. Electronic mail: zuhanl@yahoo.com

topological degrees, are called the vortices of the map u. Understanding the vortex structures in the solutions and describing the vortices as h_{ex} varies are of significance both in mathematics and in physics.

There have been many works toward dealing with such problems. The first work is due to F. Bethuel, H. Brezis, and F. Helein.[1] They discuss the functional

$$F(u)=\frac{1}{2}\int_{\Omega}|\nabla u|^2+\frac{1}{2\epsilon^2}(1-|u|^2)^2 \tag{1.3}$$

with Dirichlet boundary condition $u=g:\partial\Omega\to S^1$. They proved that minimizes of $F(u)$ in $H^1_g(\Omega,\mathbb{R}^2)$ have $|\deg(g,\partial\Omega)|$ isolated vortices of degree one and they located them by minimizing a renomalized energy. The extensions to the functional

$$F_a(u,\Omega)=\frac{1}{2}\int_{\Omega}|\nabla u|^2+\frac{1}{2\epsilon^2}(a(x)-|u|^2)^2 \tag{1.4}$$

with Dirichlet boundary conditions were made by Ding and Liu.[2] They showed that the vortices of the minimizers are located at the points where $a(x)$ takes its minimum value. Bethuel, Brezis, and Helein[3] studied the functional (1.1) with $h_{ex}=0$, $a(x)\equiv 1$ and replaced by a gauge invariant variant of the Dirichlet condition. Results similar to those in Ref. 1 are obtained. However, all the above discussions are assumed that there is a nonzero topological degree in the Dirichlet boundary conditions which implies the existence of vortices in the minimizers.

Recently numbers of works on the minimizers of $J(u,A)$ with applied fields (without imposing boundary conditions) were done by Aftalion, Sandier, and Serfaty.[4–9] As we may see, there is no *a priori* bound on the numbers of the vortices for the minimizers in $H^1\times H^1$ at this time. To overcome this difficulty, i.e., to have *a priori* control on the numbers of the vortices, Serfaty studied in Refs. 5 and 6 the local minimizers in some open subdomain of functional space of the functional

$$G(u,A)=\frac{1}{2}\int_{\Omega}|\nabla_A u|^2+|h-h_{ex}|^2-h_{ex}^2+\frac{1}{2\varepsilon^2}(1-|u|^2)^2.$$

By constructing the local minimizer, Serfaty obtained the first critical magnetic field H_{c_1} and the location of vortices. In Ref. 8, Sandier and Serfaty concluded that if $h_{ex}\leqslant H_{c_1}$, then global minimizer of $G(u,A)$ in $H^1\times H^1$ is the vortexless solution. For other discussions, refer to Refs. 7 and 9 and references therein.

We studied the local minimizers of $J(u,A)$ in D^a_M where D^a_M is defined with some suitable $M>0$ as

$$D^a_M=\{(u,A):F_a(u,\Omega)<M|\ln\varepsilon|\} \tag{1.5}$$

and the following Theorem was obtained.[10]

Theorem A: *There exist* $k_1=1/2\max_{\bar{\Omega}}|\xi_0(x)/a(x)|$, $k_2^\varepsilon=O_\varepsilon(1)$, $k_3^\varepsilon=o_\varepsilon(1)$ *and* $\varepsilon_0=\varepsilon_0(M)>0$ *such that*

$$H_{c_1}=k_1|\ln\varepsilon|+k_2^\varepsilon \tag{1.6}$$

and for $\epsilon<\epsilon_0$, *the following holds:*

(*i*) *If* $h_{ex}\leqslant H_{c_1}$, *a solution of* (*G.L.*), *that is minimizing* $J(u,A)$ *in* D^a_M *exists, and satisfies* $\frac{1}{2}\min_\Omega a(x)\leqslant|u|\leqslant 1$.

(*ii*) *If* $H_{c_1}+k_3^\varepsilon\leqslant h_{ex}\leqslant H_{c_1}+O(1)$, *a solution of* (*G.L.*) *that is minimizing* $J(u,A)$ *in* D^a_M *exists. It has a bounded positive number of vortices* a_i^ε *of degree one such that* $\mathrm{dist}(a_i^\varepsilon,\Lambda)\to 0$ *as*

$\varepsilon \to 0$, *where* $\Lambda = \{x \in \Omega : |\xi_0(x)/a(x)| = \max_\Omega |\xi_0/a|\}$, $-\mathrm{div}(1/a\,\nabla\xi_0) + \xi_0 = -1$ *in* Ω, $\xi_0 = 0$ *on* $\partial\Omega$ *and there exists a constant* $C > 0$ *such that* $\mathrm{dist}(a_i^\varepsilon, a_j^\varepsilon) \geqslant C$ *for* $i \neq j$.

In this paper, we will study the global minimizers of $J(u,A)$ in $H^1 \times H^1$ and our main result is the following theorem.

Theorem 1.1: *Let* Ω *be a smooth, bounded, simply connected domain in* $\mathbb{R}^2$. *Assume that* $a(x) \in C^2(\overline{\Omega})$ *and* $0 < b_0 = \min_{\overline{\Omega}} a(x) \leqslant a(x) \leqslant 1$ *in* Ω. *Then there exists a value* $H'_{c_1} = H_{c_1} - O(|\ln|\ln\varepsilon||)$ *such that, for any sufficiently small* ε, *if* $h_{ex} \leqslant H'_{c_1}$, *a globally minimizing solution of the functional* $J(u,A)$ *in* $H^1 \times H^1$ *satisfies* $|u| \geqslant \frac{3}{4} b_0$ on $\overline{\Omega}$ *and coincides with the solution found in (i) of Theorem A*.

The energy J that we are going to study in this paper is slightly different from the classical Ginzburg-Landau energy in the sense that there is a term penalizing the variation of the order parameter u. We denote this function by $a(x)$. The minima of $a(x)$ corresponds to the impurities in the material. In the original study by Ginzburg and Landau, $a(x) \equiv 1$. The modified functional (1.1) was first written down by Likharev.[11] Then this model has been used and developed in Refs. 4 and 12.

This paper is organized as follows. In the next section, we shall give some basic estimates. In Sec. III, we shall split the energy J. In Sec. IV, we shall prove Theorem 1.1. In Sec. V, we shall prove Lemma 2.2 which is given in Sec. II.

II. PRELIMINARY RESULTS

Consider (u,A) such that

$$J(u,A) = \min_{(v,B) \in H^1(\Omega,\mathbb{C}) \times H^1(\Omega,\mathbb{R}^2)} J(v,B),$$

then (u,A) satisfies $(G.L.)$. Recall that $J(u,A)$ is invariant under $\mathbb{U}(1)$-gauge transformations, i.e., of the type

$$v = e^{i\phi}u, \quad B = A + \nabla\phi \quad \text{for any} \quad \phi \in H^2(\Omega,\mathbb{R})$$

which make the problem non-compact. Therefore, we shall impose the gauge condition

$$\mathrm{div}(aA) = 0 \ \text{ in } \ \Omega, \quad A \cdot n = 0 \ \text{ on } \ \partial\Omega. \tag{2.1}$$

Since we assumed that Ω is simply connected, there is a function $\xi \in H^2(\Omega,\mathbb{R})$ such that

$$aA = \nabla^\perp \xi = (-\xi_{x_2}, \xi_{x_1}) \ \text{ in } \ \Omega, \quad \xi = 0 \ \text{ on } \ \partial\Omega. \tag{2.2}$$

Hence

$$h = \mathrm{curl} A = \mathrm{div}\left(\frac{1}{a}\nabla\xi\right) \quad \text{in } \ \Omega, \tag{2.3}$$

$$h = h_{ex} \quad \text{on } \ \partial\Omega, \tag{2.4}$$

$$\frac{\partial u}{\partial n} = 0 \quad \text{on } \ \partial\Omega. \tag{2.5}$$

Now, let ξ_0 be the unique solution of the following equation:

$$-\mathrm{div}\left(\frac{1}{a}\nabla\left(\mathrm{div}\left(\frac{1}{a}\nabla\xi_0\right)\right)\right) + \mathrm{div}\left(\frac{1}{a}\nabla\xi_0\right) = 0 \quad \text{in } \ \Omega, \tag{2.6}$$

$$\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)=0 \quad \text{on } \partial\Omega, \tag{2.7}$$

$$\xi_0=0 \quad \text{on } \partial\Omega. \tag{2.8}$$

Then, by Lemma 4.4 in Ref. 10, ξ_0 satisfies

$$-\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)+\xi_0=-1 \quad \text{in } \Omega, \tag{2.9}$$

$$\xi_0=0 \quad \text{on } \partial\Omega. \tag{2.10}$$

Denote

$$J_0=-\frac{1}{2}h_{ex}^2\int_\Omega\left|\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)\right|^2+\frac{1}{a}|\nabla\xi_0|^2, \tag{2.11}$$

and decompose ξ as in Ref. 10 such that

$$\xi=h_{ex}\xi_0+\zeta. \tag{2.12}$$

Then $\zeta=0$ and $\operatorname{div}((1/a)\nabla\zeta)=0$ on $\partial\Omega$. From now on, we shall assume that

$$h_{ex}\leqslant C|\ln\varepsilon|. \tag{2.13}$$

Lemma 2.1: Let (u,A) *be a solution of* $(G.L.)$ *with gauge condition* (2.1). *Then the following holds:*

$$\|\nabla u\|_{L^\infty(\Omega)}\leqslant\frac{C}{\varepsilon}, \quad \|u\|_{L^\infty(\Omega)}\leqslant 1, \tag{2.14}$$

$$\|\nabla\xi\|_{L^\infty(\Omega)}\leqslant Ch_{ex}. \tag{2.15}$$

Moreover, if (u,A) *is a minimizer of the energy* J, *then*

$$J(u,A)\leqslant J_0+\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2\leqslant Ch_{ex}^2, \tag{2.16}$$

$$\|\nabla u\|_{L^2(\Omega)}\leqslant Ch_{ex}. \tag{2.17}$$

Proof: Equations (2.14)–(2.16) have been proven in Ref. 10. Now, we shall show Eq. (2.17). By using Eq. (2.16), we have

$$\int_\Omega|\nabla_A u|^2\leqslant Ch_{ex}^2.$$

Noting

$$\int_\Omega|\nabla_A u|^2=\int_\Omega|\nabla u|^2-\frac{1}{a}(iu,\xi_{x_2}u_{x_1}-\xi_{x_1}u_{x_2})+|u|^2|A|^2\leqslant Ch_{ex}^2,$$

we see that

$$\int_\Omega |\nabla u|^2 \leqslant Ch_{ex}^2 + C\|\nabla \xi\|_{L^\infty(\Omega)} \cdot \|\nabla u\|_{L^2(\Omega)} \leqslant Ch_{ex}^2 + C\|\nabla \xi\|_{L^\infty(\Omega)}^2 + \frac{1}{2}\int_\Omega |\nabla u|^2. \quad (2.18)$$

Then, by using Eq. (2.15) in Eq. (2.18), we get

$$\int_\Omega |\nabla u|^2 \leqslant Ch_{ex}^2, \quad (2.19)$$

which is the relation (2.17). □

Lemma 2.2: Let $u \in H^1(\Omega,\mathbb{C})$ be such that $\|\nabla u\|_{L^\infty(\Omega)} \leqslant C/\varepsilon$, and $F_a(u,\Omega) \leqslant Ch_{ex}^2$. Then, for any $\alpha > 2$, there is an $\varepsilon_0 > 0$ such that $\forall\, \varepsilon < \varepsilon_0$ there exists a finite family of disjoint balls $\{B_i\}_{i\in I} = \{B(a_i, r_i)\}_{i\in I}$ such that

$$\{x : |u(x)| < \tfrac{3}{4} b_0\} \subset \cup_{i\in I} B_i, \quad (2.20)$$

$$F_a(u, B_i) \geqslant \pi a(a_i)|d_i|(|\ln \varepsilon| - O(|\ln|\ln \varepsilon||)), \quad (2.21)$$

where $d_i = deg(u, \partial B_i)$ if $\overline{B_i} \subset \Omega$, and $d_i = 0$ otherwise. Moreover

$$r_i \leqslant C|\ln \varepsilon|^{-\alpha}, \quad (2.22)$$

$$\text{Card } I \leqslant Ch_{ex}^2. \quad (2.23)$$

Proof: The proof of this Lemma is postponed to Sec. V. □

III. SPLITTING OF THE ENERGY $J(u,A)$

Denote $\tilde{\Omega} = \Omega \backslash \cup_{i\in I} B_i$, where $\{B_i\}_{i\in I}$ is the family of balls defined in Lemma 2.2 with $\alpha > 5$, then we have the following Lemmas.

Lemma 3.1: We have

$$\frac{1}{2}\int_\Omega |\nabla_A u|^2 = \frac{1}{2}\int_\Omega \left|\nabla u - \frac{i}{a}\nabla^\perp \zeta\ u\right|^2 + \frac{1}{2}h_{ex}^2 \int_\Omega \frac{1}{a}|\nabla \xi_0|^2 + h_{ex}\int_\Omega \frac{1}{a}\nabla \xi_0 \nabla \zeta + 2\pi h_{ex}\sum_{i\in I} d_i \xi_0(a_i) + o(1). \quad (3.1)$$

Proof: We divide the proof into three steps.

Step 1: In this step, we show that

$$\begin{aligned} |\nabla u - iAu|^2 &= \left|\nabla u - \frac{i}{a}h_{ex}\nabla^\perp \xi_0 u - \frac{i}{a}\nabla^\perp \zeta\ u\right|^2 \\ &= \left|\nabla u - \frac{i}{a}\nabla^\perp \zeta\ u\right|^2 + \frac{1}{a^2}h_{ex}^2|u|^2|\nabla \xi_0|^2 + 2\left(\nabla u - \frac{i}{a}\nabla^\perp \zeta u, -\frac{i}{a}h_{ex}\nabla^\perp \xi_0 u\right) \\ &= \left|\nabla u - \frac{i}{a}\nabla^\perp \zeta u\right|^2 + \frac{1}{a^2}h_{ex}^2|u|^2|\nabla \xi_0|^2 + 2h_{ex}\left(\nabla u,\ -\frac{i}{a}\nabla^\perp \xi_0 u\right) \\ &\quad + \frac{2}{a^2}h_{ex}|u|^2 \nabla \xi_0 \nabla \zeta. \end{aligned} \quad (3.2)$$

Step 2: If $\alpha > 5$, we claim that

$$\int_\Omega \left(\nabla u, -\frac{i}{a} h_{ex} \nabla^\perp \xi_0 u \right) = 2\pi h_{ex} \sum_{i \in I} d_i \xi_0(a_i) + o(1). \tag{3.3}$$

In order to prove Eq. (3.3), by using Eqs. (2.13), (2.17), (2.22), and (2.23), we first have

$$\left| \int_{\cup B_i} \left(\nabla u, -\frac{i}{a} h_{ex} \nabla^\perp \xi_0 u \right) \right| \leqslant C(\mathrm{Card} I) h_{ex} \|\nabla u\|_{L^2(\Omega)} \max_{i \in I} r_i \leqslant C |\ln \varepsilon|^{4-\alpha}. \tag{3.4}$$

On the other hand,

$$\int_{\tilde{\Omega}} \left(\nabla u, -\frac{i}{a} h_{ex} \nabla^\perp \xi_0 u \right) = h_{ex} \int_{\tilde{\Omega}} \frac{1}{a} (iu, (\xi_0)_{x_2} u_{x_1} - (\xi_0)_{x_1} u_{x_2}). \tag{3.5}$$

By the change of variables $v = u/|u|$, $\eta = |u|$ and integrating by parts of the integral term on the right-hand side of Eq. (3.5), we obtain

$$\begin{aligned} \int_{\tilde{\Omega}} \frac{1}{a} (iu, (\xi_0)_{x_2} u_{x_1} - (\xi_0)_{x_1} u_{x_2}) &= \int_{\tilde{\Omega}} \frac{1}{a} \eta^2 (iv, dv \wedge d\xi_0) + \int_{\tilde{\Omega}} \frac{1}{a} \eta ((\xi_0)_{x_2} \eta_{x_1} - (\xi_0)_{x_1} \eta_{x_2}) (iv, v) \\ &= \int_{\tilde{\Omega}} (iv, (\xi_0)_{x_2} v_{x_1} - (\xi_0)_{x_1} v_{x_2}) + \int_{\tilde{\Omega}} \frac{1}{a} (\eta^2 - a)(iv, (\xi_0)_{x_2} v_{x_1} \\ &\quad - (\xi_0)_{x_1} v_{x_2}) = C + D. \end{aligned} \tag{3.6}$$

But since

$$C = \int_{\tilde{\Omega}} (iv, (\xi_0)_{x_2} v_{x_1} - (\xi_0)_{x_1} v_{x_2}) = \int_{\tilde{\Omega}} (iv, dv \wedge d\xi_0) = \sum_{i \in I} \int_{\partial B_i} \xi_0 \left(iv, \frac{\partial v}{\partial \tau} \right), \tag{3.7}$$

$$D \leqslant C \left(\int_\Omega (a - \eta^2)^2 \right)^{1/2} \|\nabla v\|_{L^2(\tilde{\Omega})} \|\nabla \xi_0\|_{L^\infty} = o(|\ln \varepsilon|^{-1}), \tag{3.8}$$

we can rewrite Eq. (3.6) as

$$\int_{\tilde{\Omega}} \frac{1}{a} (iu, (\xi_0)_{x_2} u_{x_1} - (\xi_0)_{x_1} u_{x_2}) = \sum_{i \in I} \int_{\partial B_i} \xi_0 \left(iv, \frac{\partial v}{\partial \tau} \right) + o(|\ln \varepsilon|^{-1}). \tag{3.9}$$

Now, denote $\mathcal{J} = \{i \in I : \overline{B_i} \subset \Omega\}$ and let $U_i = \{x \in B_i : |u| \leqslant \frac{1}{2} b_0\}$ $\forall\, i \in \mathcal{J}$. Then, by noting U_i does not intersect ∂B_i and by using Stokes' theorem, we get

$$\begin{aligned} &\left| \int_{\partial B_i} (\xi_0 - \xi_0(a_i)) \left(iv, \frac{\partial v}{\partial \tau} \right) - \int_{\partial U_i} (\xi_0 - \xi_0(a_i)) \left(iv, \frac{\partial v}{\partial \tau} \right) \right| \\ &\quad = \left| \int_{B_i \setminus U_i} d\xi_0 \wedge (iv, dv) \right| \leqslant C \|\nabla \xi_0\|_{L^\infty} r_i \left(\int_{B_i \setminus U_i} |\nabla v|^2 \right)^{1/2} \leqslant C |\ln \varepsilon|^{-\alpha}. \end{aligned} \tag{3.10}$$

Hence,

$$h_{ex} \int_{\partial B_i} (\xi_0 - \xi_0(a_i))(iv, dv) = h_{ex} \int_{\partial U_i} (\xi_0 - \xi_0(a_i))(iv, dv) + o(|\ln \varepsilon|^{-2}). \tag{3.11}$$

On the other hand, in the case that $\alpha \geqslant 5$, we have

$$h_{ex}\left|\int_{\partial U_i}(\xi_0-\xi_0(a_i))(iv,dv)\right|=h_{ex}\left|\int_{\partial U_i}(\xi_0-\xi_0(a_i))\frac{(iu,du)}{|u|^2}\right|$$
$$=\frac{4}{b_0^2}\left|\int_{\partial U_i}(\xi_0-\xi_0(a_i))(iu,du)\right|$$
$$=\frac{4}{b_0^2}\left|\int_{U_i}d\xi_0\wedge(iu,du)+(\xi_0-\xi_0(a_i))(idu,du)\right|$$
$$\leqslant Ch_{ex}r_i\|\nabla u\|_{L^2}+Ch_{ex}r_i\|\nabla\xi_0\|_{L^\infty}\int_\Omega|\nabla u|^2$$
$$\leqslant C|\ln\varepsilon|^{3-\alpha}\leqslant o(|\ln\varepsilon|^{-2}). \tag{3.12}$$

Thus, from Eqs. (3.10)–(3.12), we get

$$h_{ex}\int_{\partial B_i}\xi_0\left(iv,\frac{\partial v}{\partial\tau}\right)=2\pi h_{ex}d_i\xi_0(a_i)+o(|\ln\varepsilon|^{-2}). \tag{3.13}$$

Now, $\forall\, i\in I\backslash\mathcal{J}$, letting $U_i=B_i\cap\{|u|\leqslant\frac{1}{2}b_0\}$ and noting that $\xi_0=0$ on $\partial\Omega$, we have

$$h_{ex}\int_{\partial B_i\cap\Omega}\xi_0(iv,dv)=h_{ex}\int_{\partial U_i\cap\Omega}\xi_0(iv,dv)+o(|\ln\varepsilon|^{-2})$$
$$=\frac{4}{b_0^2}\left|\int_{U_i\cap\Omega}d\xi_0\wedge(iu,du)+\xi_0(idu,du)\right|+o(|\ln\varepsilon|^{-2})=o(|\ln\varepsilon|^{-2}). \tag{3.14}$$

Therefore, combining Eqs. (3.4), (3.5), (3.9), (3.13), and (3.14) and noting Card $I\leqslant Ch_{ex}^2$, the claim (3.3) is proved.

Step 3: From Eqs. (3.2) and (3.3), we obtain

$$\frac{1}{2}\int_\Omega|\nabla_A u|^2=\frac{1}{2}\int_\Omega\left|\nabla u-\frac{i}{a}\nabla^\perp\zeta\ \ u\right|^2+\frac{1}{2}h_{ex}^2\int_\Omega\frac{1}{a^2}|u|^2|\nabla\xi_0|^2+h_{ex}\int_\Omega\frac{1}{a^2}|u|^2\nabla\xi_0\nabla\zeta$$
$$+2\pi h_{ex}\sum_{i\in I}d_i\xi_0(a_i)+o(1). \tag{3.15}$$

But we know that

$$\frac{1}{\varepsilon^2}\int_\Omega(a(x)-|u|^2)^2\leqslant Ch_{ex}^2,$$

and thus we get

$$h_{ex}^2\int_\Omega\frac{1}{a^2}|a-|u|^2||\nabla\xi_0|^2\leqslant Ch_{ex}^2\left(\int_\Omega(a-|u|^2)^2\right)^{1/2}\leqslant C\varepsilon h_{ex}^3\leqslant o(1). \tag{3.16}$$

With the same manipulations, we also have

$$h_{ex}\left|\int_\Omega(a-|u|^2)\nabla\xi_0\nabla\zeta\right|\leqslant C\varepsilon h_{ex}^3\leqslant o(1). \tag{3.17}$$

Hence, combining Eqs. (3.15) with (3.16) and (3.17), we obtain Eqs. (3.1) and thus the proof of Lemma 3.1 is completed. □

Lemma 3.2: We have

$$\frac{1}{2}\int_\Omega (|h-h_{ex}|^2-h_{ex}^2)+\frac{1}{2}h_{ex}^2\int_\Omega \frac{1}{a}|\nabla\xi_0|^2+h_{ex}\int_\Omega \frac{1}{a}\nabla\xi_0\nabla\zeta = J_0+\int_\Omega \left|\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\right|^2. \tag{3.18}$$

Proof: First, consider

$$\begin{aligned}\int_\Omega |h-h_{ex}|^2-h_{ex}^2 &= \int_\Omega h^2-2hh_{ex}\\ &= \int_\Omega \left|h_{ex}\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)+\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\right|^2-2h_{ex}\left(h_{ex}\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)+\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\right)\\ &= h_{ex}^2\int_\Omega \left|\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)\right|^2+\int_\Omega \left|\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\right|^2-2h_{ex}^2\int_\Omega \operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)\\ &\quad +2h_{ex}\int_\Omega \operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)-2h_{ex}\int_\Omega \operatorname{div}\left(\frac{1}{a}\nabla\zeta\right).\end{aligned} \tag{3.19}$$

But we know that

$$\int_\Omega \frac{1}{a}|\nabla\xi_0|^2+\left|\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)\right|^2=\int_\Omega \operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)$$

and

$$\int_\Omega \frac{1}{a}\nabla\zeta\nabla\xi_0+\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)=\int_\Omega \left(\operatorname{div}\frac{1}{a}\nabla\zeta\right).$$

Therefore

$$\begin{aligned}&\frac{1}{2}\int_\Omega (|h-h_{ex}|^2-h_{ex}^2)+\frac{1}{2}h_{ex}^2\int_\Omega \frac{1}{a}|\nabla\xi_0|^2+h_{ex}\int_\Omega \frac{1}{a}\nabla\xi_0\nabla\zeta\\ &\quad =-\frac{1}{2}h_{ex}^2\int_\Omega \frac{1}{a}|\nabla\xi_0|^2+\left|\operatorname{div}\left(\frac{1}{a}\nabla\xi_0\right)\right|^2+\left|\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\right|^2\\ &\quad =J_0+\int_\Omega \left|\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\right|^2.\end{aligned}$$

Thus the proof of Lemma 3.2 is completed. □

Lemma 3.3: We have

$$\frac{1}{2}\int_\Omega \left|\nabla u-\frac{i}{a}u\nabla^\perp\zeta\right|^2+\frac{1}{2\varepsilon^2}(a-|u|^2)^2\geqslant\sum_{i\in I} F_a(u,B_i)+o(1). \tag{3.20}$$

Proof: We know the fact that

$$\frac{1}{2}\int_\Omega \left|\nabla u-\frac{i}{a}u\nabla^\perp\zeta\right|^2\geqslant\int_{\cup_{i\in I}B_i}\left|\nabla u-\frac{i}{a}u\nabla^\perp\zeta\right|^2=\int_{\cup_{i\in I}B_i}|\nabla u|^2+\frac{1}{a^2}|u\nabla^\perp\zeta|^2-\frac{2}{a}(\nabla u,\ iu\nabla^\perp\zeta).$$

But when $\alpha>5$,

$$\left|\int_{\cup_{i\in I}B_i}\left(\nabla u,\ \frac{i}{a}u\nabla^{\perp}\zeta\right)\right|\leqslant C(\mathrm{Card}I)\|\nabla\zeta\|_{L^{\infty}}\|\nabla u\|_{L^2}\max_{i\in I}r_i\leqslant C|\ln\varepsilon|^{4-\alpha}=o(1).$$

Hence,

$$\frac{1}{2}\int_{\Omega}\left|\nabla u-\frac{i}{a}u\nabla^{\perp}\zeta\right|^2\geqslant\frac{1}{2}\sum_{i\in I}\int_{B_i}|\nabla u|^2+o(1).$$

Now, if we add the term $1/\varepsilon^2(a-|u|^2)^2$ to both sides of the above inequality, we have

$$\frac{1}{2}\int_{\Omega}\left|\nabla u-\frac{i}{a}u\nabla^{\perp}\zeta\right|^2+\frac{1}{\varepsilon^2}(a-|u|^2)^2\geqslant\sum_{i\in I}F_a(u,B_i).$$

This completes the proof of Lemma 3.3. □

IV. PROOF OF THEOREM 1.1

Let $(u_\varepsilon,A_\varepsilon)$ be the minimizing solution, then it follows from Lemmas 3.1 and 3.2 that

$$J(u_\varepsilon,A_\varepsilon)=\frac{1}{2}\int_{\Omega}\left|\nabla u_\varepsilon-\frac{i}{a}u_\varepsilon\nabla^{\perp}\zeta\right|^2+\frac{1}{2\varepsilon^2}(a-|u_\varepsilon|^2)^2+\int_{\Omega}\left|\mathrm{div}\left(\frac{1}{a}\nabla\zeta\right)\right|^2+J_0$$

$$+2\pi h_{ex}\sum_{i\in I}d_i\xi_0(a_i)+o(1) \tag{4.1}$$

Then, by using Lemma 3.3 and Eq. (2.21), we get from Eq. (4.1)

$$J(u_\varepsilon,A_\varepsilon)\geqslant J_0+2\pi h_{ex}\sum_{i\in I}d_i\xi_0(a_i)+\pi\sum_{i\in I}a(a_i)|d_i|(|\ln\varepsilon|-O(|\ln|\ln\varepsilon\|)). \tag{4.2}$$

On the other hand, we have by minimality

$$J(u_\varepsilon,A_\varepsilon)\leqslant J\left(\sqrt{a},\frac{1}{a}\nabla^{\perp}\xi_0\right)=J_0+\frac{1}{2}\int_{\Omega}|\nabla\sqrt{a}|^2. \tag{4.3}$$

Thus, combining Eqs. (4.2) and (4.3) and noting $\xi_0<0$, we obtain

$$\begin{aligned}\pi\sum_{i\in I}a(a_i)|d_i|(|\ln\varepsilon|-O(|\ln|\ln\varepsilon||))&\leqslant 2\pi h_{ex}\sum_{i\in I}|d_i||\xi_0(a_i)|\\&\leqslant 2\pi h_{ex}\sum_{i\in I}|d_i|a(a_i)\left|\frac{\xi_0(a_i)}{a(a_i)}\right|\\&\leqslant 2\pi h_{ex}\left(\sum_{i\in I}|d_i|a(a_i)\right)\max\left|\frac{\xi_0(a_i)}{a(a_i)}\right|.\end{aligned}$$

Now, if $\Sigma_{i\in I}|d_i|\neq 0$, then $\Sigma_{i\in I}|d_i|a(a_i)\neq 0$ and thus

$$h_{ex}\geqslant\frac{1}{2\max|\xi_0/a|}(|\ln\varepsilon|-O(|\ln|\ln\varepsilon\|))=H'_{c_1}.$$

But since $H_{c_1}=1/2\max|\xi_0/a|\,|\ln\varepsilon|+O(1)$, we see that

$$H'_{c_1}=H_{c_1}-O(|\ln|\ln\varepsilon||). \tag{4.4}$$

Moreover, we deduce that $d_i=0$, $\forall\, i\in I$ if $h_{ex}<H'_{c_1}$ and hence we can reduce Eq. (4.1) to

$$J(u_\varepsilon,A_\varepsilon)=\frac{1}{2}\int_\Omega\left|\nabla u_\varepsilon-\frac{i}{a}u_\varepsilon\nabla^\perp\zeta\right|^2+\frac{1}{2\varepsilon^2}(a-|u_\varepsilon|^2)^2+\int_\Omega\left|\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\right|^2+J_0+o(1). \tag{4.5}$$

Here, noting that

$$\int_\Omega\left|\nabla u_\varepsilon-\frac{i}{a}u_\varepsilon\nabla^\perp\zeta\right|^2=\int_\Omega|\nabla u_\varepsilon|^2+\frac{1}{a^2}|u_\varepsilon|^2|\nabla^\perp\zeta|^2+\frac{1}{a}(iu_\varepsilon,\zeta_{x_2}(u_\varepsilon)_{x_1}-\zeta_{x_1}(u_\varepsilon)_{x_2}), \tag{4.6}$$

and with the same manipulations as in Step 2 of the Lemma 3.1, the third term on the right-hand side of Eq. (4.6) becomes

$$\int_\Omega\frac{1}{a}(iu_\varepsilon,\zeta_{x_2}(u_\varepsilon)_{x_1}-\zeta_{x_1}(u_\varepsilon)_{x_2})=2\pi\sum_{i\in I}d_i\zeta(a_i)+o(1)=o(1), \tag{4.7}$$

we obtain from Eq. (4.5)

$$\begin{aligned}J(u_\varepsilon,A_\varepsilon)&=\frac{1}{2}\int_\Omega|\nabla u_\varepsilon|^2+\frac{1}{2\varepsilon^2}(a-|u_\varepsilon|^2)^2+\frac{1}{a}|u_\varepsilon|^2|\nabla^\perp\zeta|^2+\int_\Omega\left|\operatorname{div}\left(\frac{1}{a}\nabla\zeta\right)\right|^2+J_0+o(1)\\&\geqslant F_a(u_\varepsilon,\Omega)+J_0+o(1).\end{aligned} \tag{4.8}$$

On the other hand, we also have by minimality that

$$J(u_\varepsilon,A_\varepsilon)\leqslant J_0+\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2,$$

and thus

$$F_a(u_\varepsilon,\Omega)\leqslant\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2+o(1). \tag{4.9}$$

Now, we claim that

$$\frac{1}{2}\int_\Omega|\nabla u_\varepsilon|^2\to\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2\quad\text{as}\quad\varepsilon\to0. \tag{4.10}$$

In fact, for any given sequence $\varepsilon_n\to0$ as $n\to\infty$, we see by Eq. (4.9) that there exists a subsequence (still denote $\{\varepsilon_n\}_{n=1}^\infty$) $\varepsilon_n\to0$ as $n\to\infty$, and $u_0\in H^1(\Omega,\mathbb{C})$ such that $u_{\varepsilon_n}\to u_0$ weakly in $H^1(\Omega,\mathbb{C})$. Thus, we have from Eq. (4.9) that

$$\int_\Omega(a-|u_{\varepsilon_n}|^2)^2\leqslant C\varepsilon_n,$$

and hence $|u_0|=\sqrt{a}$ a.e. in Ω. On the one hand, we have

$$\int_\Omega|\nabla u_0|^2\leqslant\liminf_{n\to\infty}\int_\Omega|\nabla u_{\varepsilon_n}|^2\leqslant\int_\Omega|\nabla\sqrt{a}|^2,$$

and on the other hand, we get by direct calculation,

$$\int_\Omega |\nabla u_0|^2 \geqslant \int_\Omega |\nabla |u_0||^2 = \int_\Omega |\nabla \sqrt{a}|^2,$$

so that the following equality holds:

$$\int_\Omega |\nabla u_0|^2 = \int_\Omega |\nabla \sqrt{a}|^2. \tag{4.11}$$

Combining Eqs. (4.9) and (4.11), we have

$$\int_\Omega |\nabla u_{\varepsilon_n}|^2 \leqslant \int_\Omega |\nabla u_0|^2 + o(1).$$

Hence, as $n \to \infty$,

$$\begin{aligned}\int_\Omega |\nabla u_{\varepsilon_n} - \nabla u_0|^2 &= \int_\Omega |\nabla u_{\varepsilon_n}|^2 + |\nabla u_0|^2 - \nabla \overline{u}_{\varepsilon_n} \nabla u_0 - \nabla u_{\varepsilon_n} \nabla \overline{u_0} \\ &\leqslant 2 \int_\Omega |\nabla u_0|^2 - \nabla \overline{u}_{\varepsilon_n} \nabla u_0 - \nabla u_{\varepsilon_n} \nabla \overline{u}_0 + o(1) = o(1). \end{aligned} \tag{4.12}$$

Therefore, $u_{\varepsilon_n} \to u_0$ strongly in $H^1(\Omega, \mathbb{C})$ and thus

$$\int_\Omega |\nabla u_{\varepsilon_n}|^2 \to \int_\Omega |\nabla \sqrt{a}|^2, \tag{4.13}$$

which is the proof of our claim (4.10). Combining now Eqs. (4.9) with (4.10), we also have

$$\frac{1}{2\varepsilon^2} \int_\Omega (a - |u_\varepsilon|^2)^2 \to 0 \quad \text{as} \quad \varepsilon \to 0, \tag{4.14}$$

from which we conclude that $|u_\varepsilon(x)| \geqslant \frac{3}{4} b_0$ in Ω. In fact, as $|\nabla u_\varepsilon| \leqslant C/\varepsilon$, if $|u_\varepsilon(x_0)| < \frac{3}{4} b_0$, then there exist constants λ, $\mu > 0$ such that $\forall\, \varepsilon > 0$,

$$\frac{1}{\varepsilon^2} \int_{B(x_0, \lambda\varepsilon)} (a - |u_\varepsilon|^2)^2 \geqslant \mu > 0, \tag{4.15}$$

which contradicts Eq. (4.14). Hence, u is the vortexless solution. Since u is the vortexless solution, we may re-use the computation of Ref. 10 to find that

$$J(u, A) = J_0 + F_a(u, \Omega) + \tilde{V}(\zeta) + o(1),$$

where $\tilde{V}(\zeta) \geqslant 0$. Hence $F_a(u, \Omega) \leqslant \frac{1}{2} \int_\Omega |\nabla \sqrt{a}|^2 + o(1)$, and by the definition of D_M^a, we have $(u, A) \in D_M^a$. This proves that for $h_{ex} < H'_{c_1}$, a globally minimizing solution $(u_\varepsilon, A_\varepsilon)$ for the functional $J(u, A)$ coincides with the solution found in (i) of Theorem A. Hence, the Theorem 1.1 is proved.

V. PROOF OF LEMMA 2.2

In this section, the methods in Refs. 13 and 5 are used to prove Lemma 2.2. We also need the Lemmas 5.3, 5.4, and 5.5. In order to prove those Lemmas, we need the following two lemmas.[8]

Lemma 5.1: Let $u : S_t \to \mathbb{C}$, *where* S_t *is a circle of radius* t *in* $\mathbb{R}^2$ *such that* $t > \varepsilon$. *Let* $m = \min\{\min_{S_t} |u|, 1\}$. *If* $m \neq 0$, $d = \deg(u, S_t)$. *If* $m = 0$, *let* $d = 0$. *Then*

$$\int_{S_t}\frac{1}{2}|\nabla u|^2+\frac{a(x)}{4\varepsilon^2}(1-|u|^2)^2\geqslant m^2\frac{\pi d^2}{t}+\frac{C_1(1-m)^{C_1}}{\varepsilon}, \tag{5.1}$$

where C_1 is an absolute constant.

Lemma 5.2: If $u:\Omega\to\mathbb{C}$, there exist $\rho(\Omega)$ and $C(\Omega)>0$ such that $\forall\, x\in\Omega$, $\forall\varepsilon<r<\rho$, letting $m=\min_{S_r\cap\Omega}|u|$,

$$\int_{S_r}\frac{1}{2}|\nabla u|^2+\frac{1}{4\varepsilon^2}(1-|u|^2)^2\geqslant\frac{(1-m)^C}{C\varepsilon}. \tag{5.2}$$

Lemma 5.3: Let $u:\Omega\to\mathbb{C}$ be such that $|\nabla u|<C/\varepsilon$. Then there exist disjoint balls $B_1,\cdots,B_k$ with radii r_i such that $\forall\, 1\leqslant i\leqslant k$,

$$(i)\quad r_i>\varepsilon,$$

$$(ii)\quad \left\{|u|<\frac{3b_0}{4}\right\}\subset\cup_i B_i \ \text{ and } B_i\cap\left\{|u|<\frac{3b_0}{4}\right\}\neq\varnothing,$$

$$(iii)\quad F_a(u,B_i\cap\Omega)\geqslant\frac{C_2 r_i}{\varepsilon}, \tag{5.3}$$

where C_2 is a constant.

Proof: We divide this proof into four steps.

Step 1: Let $S_1,\cdots,S_k$ be the connected components of $\{|u|<4b_0/5\}$ that intersect $\{|u|<3b_0/4\}$ and $x_1\in S_1,\cdots,x_k\in S_k$ be points such that $|u(x_i)|<3b_0/4$. For every i, define $r_i=\sup\{r>0:\partial B(x_i,r)\cap\{|u|<4b_0/5\}\neq\varnothing\}$, then

$$F_a(u,B(x_i,r_i)\cap\Omega)\geqslant\frac{C_2 r_i}{\varepsilon}. \tag{5.4}$$

Indeed, if $r_i\leqslant 2\varepsilon$, since $|\nabla u|\leqslant C/\varepsilon$, we have

$$F_a(u,B(x_i,r_i)\cap\Omega)\geqslant\frac{1}{\varepsilon^2}\int_{B(x_i,r_i)\cap\Omega}(a(x)-|u|^2)^2\geqslant C\geqslant\frac{C}{2}\,\frac{r_i}{\varepsilon},$$

and the conclusion (5.4) is true. If $r_i>2\varepsilon$, by the definition of r_i, we have that $\forall\, t\in[\varepsilon,t_i]$, $\min_{\partial B(x_i,t)}|u|<4b_0/5$. Now, let $v=\sqrt{u}/\sqrt{a}$, then by Lemma 5.2, $\forall\, t\in[\varepsilon,r_i]$, we have

$$\int_{\partial B(x_i,t)\cap\Omega}\frac{1}{2}|\nabla v|^2+\frac{1}{4\varepsilon^2}(1-|v|^2)^2\geqslant\frac{C}{\varepsilon}.$$

Thus, if $\varepsilon\leqslant\varepsilon_0$ as long as ε_0 is small enough, we get from the above equation that

$$\begin{aligned}F_a(u,\partial B(x_i,t)\cap\Omega)&=\int_{\Omega\cap\partial B(x_i,t)}\frac{1}{2}|\sqrt{a}\nabla v+v\nabla\sqrt{a}|^2+\frac{a^2}{4\varepsilon^2}(1-|v|^2)^2\\&\geqslant\frac{1}{2}\int_{\Omega\cap\partial B(x_i,t)}a\left[|\nabla v|^2+\frac{a}{2\varepsilon^2}(1-|v|^2)^2\right]-C|v||\nabla v|\\&\geqslant\frac{1}{2}b_0\int_{\Omega\cap\partial B(x_i,t)}|\nabla v|^2+\frac{b_0}{2\varepsilon^2}(1-|v|^2)^2-C-\frac{b_0}{4}\int_{\Omega\cap\partial B(x_i,t)}|\nabla v|^2\end{aligned}$$

$$\geqslant \frac{1}{4} b_0 \int_{\Omega \cap \partial B(x_i,t)} |\nabla v|^2 + \frac{b_0}{2\varepsilon^2}(1-|v|^2)^2 - C \geqslant \frac{C}{\varepsilon} - C \geqslant \frac{C}{\varepsilon}$$

Hence

$$F_a(u,\Omega \cap B(x_i,r_i)) \geqslant \int_{\varepsilon}^{r_i} F_a(u,\partial B(x_i,t)\cap\Omega)\,\mathrm{d}t \geqslant \frac{C}{\varepsilon}(r_i-\varepsilon) \geqslant \frac{Cr_i}{\varepsilon}.$$

The conclusion (5.4) is true in this case.

Step 2: We write B_i for $B(x_i,r_i)$ for the simplicity of our notation. Then, we claim that $\forall\, i \neq j$, either $B_j \subset B_i$ (in this case, we drop B_j) or $x_j \notin B_i$. In fact, assume that $x_j \in B_i$. By the definition of balls B_i, $\partial B_i \cap \cup_l S_l = \varnothing$, thus

$$S_j = (S_j \cap \overline{B_i^C}) \cup (S_l \cap B_i).$$

Since $x_j \in B_i$, $S_j \cap B_i \neq \varnothing$, using the connectedness of S_j, $S_j \subset B_i$, and we can drop B_j. The claim is proved.

Step 3: Dropping the unnecessary balls, we reduce to balls B_i such that $\cup_i S_i \subset \cup_k B_k$ and $\forall\, i \neq j$, $x_j \notin B_i$. It follows from the Besicovitch covering Lemma, any $x \in \cup B_i$ belongs to at most N of the balls, where N is an absolute constant.

Step 4: The rest of the proof of Lemma 5.3 is the same argument as the Lemma III.4 in Ref. 8. The proof of Lemma 5.3 is completed. □

Lemma 5.4: $\forall\, \alpha > 2$, $|\ln\varepsilon|^{-\alpha} > r > s > \varepsilon$, *if* $B_r(b)$ *and* $B_s(b)$ *are two concentric balls with respective radii* r *and* s, *and if* $u: B_r \backslash \overline{B}_s \to \mathbb{C}$ *is such that* $F_a(u, B_r \backslash \overline{B}_s) \leqslant C|\ln\varepsilon|^2$, $|u| > \frac{3}{4} b_0$, $d = \deg(u, \partial B_r)$, *then*

$$F_a(u, B_r \backslash \overline{B}_s) \geqslant a(b)|d| \left(\Lambda_\varepsilon\left(\frac{r}{|d|}\right) - \Lambda_\varepsilon\left(\frac{s}{|d|}\right)\right) + o(1), \tag{5.5}$$

where Λ_ε *is a function that satisfies the following properties:*

(*i*) $\Lambda_\varepsilon(s)/s$ *is decreasing on* $\mathbb{R}^+$,

(*ii*) $\sup_{s\in\mathbb{R}^+} \Lambda_\varepsilon(s)/s \leqslant C_2/\varepsilon$,

(*iii*) *there exist* $\varepsilon_0, t_0 > 0$ *such that if* $\varepsilon < \varepsilon_0$ *and* $\varepsilon < t < t_0$ *then* $|\Lambda_\varepsilon(t) - \pi \ln t/\varepsilon| \leqslant C$.

Proof: Let $v: S_t \to \mathbb{C}$ and $m = \min\{\min_{s_t}|u|, 1\}$ then by Lemma 5.1, we have

$$\begin{aligned}
\int_{S_t} \frac{1}{2}|\nabla v|^2 + \frac{a(x)}{4\varepsilon^2}(1-|v|^2)^2 &\geqslant m^2 \frac{\pi d^2}{t} + \frac{C_1(1-m)^{C_1}}{\varepsilon} \\
&\geqslant (m^{C'}) \frac{\pi|d|}{t} + \frac{C_1(1-m)^{C'}}{\varepsilon} \\
&\geqslant \min_{m\in[0,1]} \left\{ (m^{C'}) \frac{\pi|d|}{t} + \frac{C_1(1-m)^{C'}}{\varepsilon} \right\} = \frac{\tilde{a}\tilde{b}}{(\tilde{a}^q + \tilde{b}^q)^{1/q}},
\end{aligned}$$

where $C' = \max(2, C_1) \geqslant 2$, $\tilde{a} = \pi|d|/t$ and $\tilde{b} = C_1/\varepsilon$. Denote $f_\varepsilon(s) = \tilde{a}\tilde{b}/(\tilde{a}^q + \tilde{b}^q)^{1/q}$, $\tilde{a}(s) = \pi/s$, $\tilde{b}(s) = C_1/\varepsilon$, $\lambda_\varepsilon(s) = \min\{f_\varepsilon(s), C_1/\varepsilon\}$ and $\Lambda_\varepsilon(t) = \int_0^t \lambda_\varepsilon(s)\mathrm{d}s$, respectively. Here C_1 is defined in Lemma 5.1. Then Λ_ε satisfies properties (i), (ii) and (iii) of this lemma.

Now we prove (5.5). Let $\alpha > 2$, $|\ln\varepsilon|^{-\alpha} > r > s > \varepsilon$ and $u = \sqrt{a}v$, then

$$F_a(u,B_r)-F_a(u,B_s)\geqslant\int_r^s F_a(u,S_t)\mathrm{d}t=\frac{1}{2}\int_r^s\int_{S_t}\left[|\nabla u|^2+\frac{1}{2\varepsilon^2}(a-|u|^2)^2\right]\mathrm{d}\omega_t\ \mathrm{d}t$$
$$\geqslant\frac{1}{2}\int_r^s\int_{S_t}a\left[|\nabla v|^2+\frac{1}{2\varepsilon^2}(1-|v|^2)^2\right]-C|\nabla v|.$$

Noting that

$$\int_r^s\int_{S_t}|\nabla v|\leqslant|B_r\setminus B_s|\left(\int_{B_r\setminus B_s}|\nabla v|^2\right)^{1/2}\leqslant C|\ln\varepsilon|^{-2\alpha}|\ln\varepsilon|=o(1),$$

we have

$$F_a(u,B_r)-F_a(u,B_s)\geqslant\frac{1}{2}a(b)\int_r^s\int_{S_t}|\nabla v|^2+\frac{a}{2\varepsilon^2}(1-|v|^2)^2-C\int_r^s\int_{S_t}t\left[|\nabla v|^2+\frac{a}{2\varepsilon^2}(1-|v|^2)^2\right]$$
$$+o(1)\geqslant\frac{1}{2}a(b)\int_r^s\int_{S_t}|\nabla v|^2+\frac{a}{2\varepsilon^2}(1-|v|^2)^2-C|\ln\varepsilon|^{-\alpha+2}+o(1)$$
$$\geqslant\frac{1}{2}a(b)\int_r^s\int_{S_t}|\nabla v|^2+\frac{a}{2\varepsilon^2}(1-|v|^2)^2+o(1).$$

Hence,

$$F_a(u,B_r)-F_a(u,B_s)\geqslant\frac{1}{2}a(b)\int_r^s\int_{S_t}|\nabla v|^2+\frac{a}{2\varepsilon^2}(1-|v|^2)^2+o(1)$$
$$\geqslant a(b)\int_r^s\lambda_\varepsilon\left(\frac{t}{|d|}\right)\mathrm{d}t\geqslant a(b)\ \ |d|\left(\Lambda_\varepsilon\left(\frac{r}{|d|}\right)-\Lambda_\varepsilon\left(\frac{s}{|d|}\right)\right)+o(1),$$

and the proof of Lemma 5.4 is completed. □

Lemma 5.5: Let $u:\Omega\to\mathbb{C}$ *be such that* $|\nabla u|\leqslant C/\varepsilon$; *and* $\{B_i\}_i$ *be a family of balls of radii* r_i *satisfying the results of Lemma 5.3. Define*

$$d_i=\begin{cases}\deg(u,\partial B_i) & \text{if } \overline{B_i}\subset\Omega\\ 0 \quad \text{otherwise}\end{cases}. \tag{5.6}$$

Denote $s_0=\min_{\{i:d_i\neq0\}}r_i/|d_i|$. *Then, for every* $|\ln\varepsilon|^3\geqslant s\geqslant s_0$, *there exists a family* $B(s)$ *of disjoint balls* $B_1(s),\cdots,B_{k(s)}(s)$ *of radii* $r_i(s)$ *such that*

(*i*) *the family of balls is monotone, i.e., if* $s<t$ *then* $\cup_iB_i(s)\subset\cup_iB_i(t)$,

(*ii*) *for every* i, $F_a(u,B_i(s))\geqslant a(a_i)r_i(s)\,(\Lambda_\varepsilon(s)/s)$, *where* Λ_ε *is defined in Lemma 5.4,* $B_i(s)=B_i(a_i,r_i(s))$,

(*iii*) *if* $\overline{B_i}(s)\subset\Omega$ *and* $d_i(s)=\deg(u,\partial B_i(s))$, *then* $r_i(s)\geqslant s|d_i(s)|$.

Proof: This proof is exactly the same as Proposition III.1 in Ref. 8. □

Proof of Lemma 2.2: In order to apply Lemma 5.5 we first need to check s_0. From the assertion (iii) of Lemma 5.3, we have $C_1r_i<\varepsilon F_a(u,B_i\cap\Omega)\leqslant C\varepsilon|\ln\varepsilon|^2$, note that $s_0=\min_{\{i:d_i\neq0\}}r_i/|d_i|$. So, $s_0\leqslant C\varepsilon|\ln\varepsilon|^2$. We can apply Lemma 5.5 for all $s\geqslant C\varepsilon|\ln\varepsilon|^2$. We choose

$$s_1=\frac{1}{|\ln\varepsilon|^{\alpha+1}}. \tag{5.7}$$

It follows from Lemma 5.5 that final family of balls $B(s_1)$ such that if $\overline{B_i}(s_1)\subset\Omega$ for every i,

$$F_a(u,B_i(s_1)) \geqslant a(a_i)\frac{\Lambda_\varepsilon(s_1)}{s_1} r_i(s_i) \tag{5.8}$$

with $r_i(s_1) \geqslant s_1|d_i(s_1)|$. Therefore $F_a(u,B_i(s_1)) \geqslant a(a_i)\Lambda_\varepsilon(s_1)|d_i(s_1)|$, where $B_i(s_1) = B_i(a_i, r_i(s_1))$, and by Lemma 5.4

$$F_a(u,B_i(s_1)) \geqslant a(a_i)|d_i(s_1)|\left(\pi \ln\frac{s_1}{\varepsilon} - C\right) \geqslant \pi a(a_i)|d_i(s_1)|(|\ln\varepsilon| - O(|\ln|\ln\varepsilon||),$$

thus Eq. (2.21) is proved. By Eq. (5.8), we have

$$r_i(s_1)\frac{\Lambda_\varepsilon(s_1)}{s_1} \leqslant C|\ln\varepsilon|^2.$$

From Lemma 5.4, we know that $\Lambda_\varepsilon(s) \simeq \pi \ln s/\varepsilon$, note that Eq. (5.5),

$$\Lambda_\varepsilon(s_1) \geqslant \pi|\ln\varepsilon| - O(|\ln|\ln\varepsilon||).$$

Hence

$$r_i(s_1) \leqslant C\frac{s_1}{\Lambda_\varepsilon(s_1)}|\ln\varepsilon|^2 \leqslant \frac{C}{|\ln\varepsilon|^{\alpha+1}} \cdot \frac{|\ln\varepsilon|^2}{|\ln\varepsilon|} \leqslant \frac{C}{|\ln\varepsilon|^{\alpha}}$$

which is conclusion (2.22). From Lemma 5.3, $F_a(u,B_i \cap \Omega) \geqslant C_2 r_i/\varepsilon$ with $r_i > \varepsilon$, so, $F_a(u,B_i \cap \Omega) \geqslant C_2$. Since $F_a(u,\Omega) \leqslant C|\ln\varepsilon|^2$, we see that the number of balls there has to be bounded by $C|\ln\varepsilon|^2$. Thus, we have shown (2.23) and the proof of Lemma 2.2 is completed. □

(Received 18 January 2001; accepted for publication 3 October 2001)

A set of data supposed to give possible axioms for spacetimes with a sufficient number of isometries in spectral geometry is given. These data are shown to be sufficient to obtain $1+1$ dimensional de Sitter spacetime. The data rely at the moment somewhat on the guidance given by a required symmetry, in part to allow explicit calculations in a specific model. The framework applies also to the noncommutative case. Finite spectral triples are discussed as an example. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1420744]

I. INTRODUCTION

Spacetime is the fairy tale of a classical manifold. It is irreconcilable with quantum effects in gravity and most likely, in a strict sense, it does not exist. But to dismiss a mythical being that has inspired generations just because it does not really exist is foolish. Rather it should be understood together with the story tellers through whom and in whom the being exists.

The story tellers of spacetime are the physical fields. It is the interaction with fields that lets one believe that there was a spacetime in which particles of a field have propagated.

Here, the fairy tale of classical spacetime will be uncritically retold again: no quantum effects will be considered and the result will be an ordinary manifold of Lorentzian signature. And yet it is not at all the same old story: the story tellers, the fields are put into the place they deserve—at the center of the matter.

The right framework to allow the fields to play their distinguished role is noncommutative geometry, in particular the notion of a spectral triple.[1–3] A spectral triple $(A,\mathcal{H},D,J,\gamma)$ consists of a pre-C^*-algebra A represented (faithfully) on a Hilbert space $\mathcal{H}$, an unbounded self-adjoint operator D on $\mathcal{H}$, an antiunitary operator J and of a grading operator γ on $\mathcal{H}$. These structures satisfy a set of seven conditions given in Ref. 3.

(1) **Classical dimension.** The inverse D^{-1} of D is an infinitesimal of order $1/n$. Here, n is the dimension of the space.
(2) **First order condition.** For any a in the algebra A and b in the opposite algebra (represented with the help of J),
$$[[D,a],b^{\mathrm{op}}]=0. \tag{1}$$
(3) **Regularity.** The elements a of the algebra A as well as their commutators $[D,a]$ with D are smooth vectors of the derivation $[|D|,\bullet]$.
(4) **Orientability.** There exists the image γ of a Hochschild cycle in degree n such that for n even
$$\gamma=\gamma^*, \quad \gamma^2=\mathbf{1}, \quad \gamma D=-D\gamma, \tag{2}$$
and for n odd
$$\gamma=\mathbf{1}. \tag{3}$$
(5) **Finiteness.** The subspace of smooth Hilbert space vectors $\mathcal{H}_\infty$ is a finite projective module over A with a local Hermitean structure.
(6) **Poincaré duality.** The intersection form $K_\bullet\times K_\bullet\to\mathbb{Z}$ on the K-theory $K_\bullet$ is invertible.

(7) **Reality.** J satisfies

$$J^2=(-1)^{[(n-1)n(n+1)(n+2)]/8}, \quad JD=(-1)^{[n(n+1)(n+2)]/12}DJ, \tag{4}$$

and for n even

$$J\gamma=(-1)^{n/2}\gamma J. \tag{5}$$

If the algebra A is commutative then in a rather deep sense the spectral triple is more or less the same as a spin manifold M with positive definite metric[3] that can be recovered (for a proof see Refs. 4 and 5) in the following way: the algebra A is the algebra of functions on the spin manifold, $\mathcal{H}$ is the Hilbert space of square-integrable sections of the spinor bundle over M, D is the Dirac operator, C is the charge conjugation, and γ is the volume element. All spin manifolds with positive definite metric can be obtained in this way. A generalization covering the orientable Riemannian case without a spin structure was recently given by Lord.[6]

The possibility of choosing a noncommutative algebra A even allows to go beyond ordinary manifolds.

However, this description is not directly applicable to spin manifolds with Lorentzian signature. One problem seems to be that in this case the canonical inner product on spinor fields is not positive definite.

A way to deal with this is to foliate spacetime with spacelike leaves and to describe the Euclidean geometry of the leaves as above. Under the assumption that the spinor fields satisfy the Dirac equation, spinor fields on different leaves belonging to the same solution can be identified.[7] Then the algebras $A(t)$ for different leaves are represented on the same Hilbert space and their causal relationships may be tested by examination of their commutators. This can be exploited to obtain considerable information on the geometry and render further structures typical for Hamiltonian approaches, e.g., the lapse and the shift superfluous.[8]

The Hilbert space $\mathcal{H}$ has in this picture a clear physical interpretation as the phase space of a spinor field. An interpretation of the algebras $A(t)$ was suggested in Ref. 9 and will be scrutinized in future work.

However, previous results did not show how to obtain meaningful spectral information nor what axioms to start with in order to get interesting spacetime geometries. As a first step in this direction, the definition of a spectral quadruple, a set of data that aspires to take the place of such axioms is given. The spectral quadruple is called so because, compared to the spectral triple, a key structure (the time vector) is added. The spectral quadruple is to be understood as a working hypothesis rather than as a fixed concept. Nevertheless, in specific examples, the data of the spectral quadruple are strongly suggested and turn out to be sufficient to reconstruct spacetime. In particular, $1+1$-dimensional de Sitter space is worked out in great detail, based on the realization that postulated symmetries allow to completely carry out explicit calculations. Such an undertaking is not easy even in the Riemannian case[10] where a set of conditions as reviewed above is available. The example of de Sitter space provides at the same time a model against which any set of axioms may be tested.

This paper is structured as follows: Practical calculations to extract the spacetime geometry of a globally hyperbolic spin manifold out of commutators[11] and the generators of evolution (Hamiltonians) are reviewed in Sec. II. These motivate the definition of a spectral quadruple in Sec. III. This definition is to provide definiteness rather than definitiveness and is to be understood as a working hypothesis. In Sec. IV, the representation theory of the relevant symmetry group, $\mathrm{SL}_2(\mathbb{R})$ is reviewed. The spacetime of the postulated spectral quadruple is calculated in Sec. V. A discrete spectral quadruple is discussed as a further example in Sec. VI. The Conclusion contains a discussion of the obtained results and of possibilities for further investigations. A collection of calculations and formulas for $1+1$ de Sitter spacetime, that might be useful for other purposes also, is contained in the Appendix.

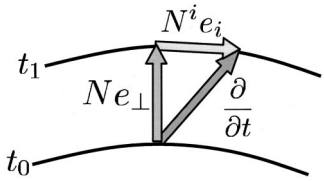

FIG. 1. The $n+1$ splitting of spacetime in the ADM formalism. The time vector $\partial/\partial t$ giving the evolution from a Cauchy hypersurface at time t_0 to the infinitesimally later Cauchy hypersurface at time t_1 can be decomposed into its part $N^i e_i$ parallel to the hypersurfaces and into its orthogonal part $Ne_\perp$. Here e_i, $e_\perp$ are unit vectors adapted to the hypersurfaces and N^i, N are the shift and the lapse.

II. THE RECONSTRUCTION OF SPACETIME FROM COMMUTATORS

In this section, a globally hyperbolic n-dimensional spacetime M with a given foliation Σ_t, $t \in \mathbb{R}$ by spacelike Cauchy hypersurfaces is preassumed. This is sufficient to define a family A_t of commutative algebras, the algebras of smooth functions on the hypersurfaces Σ_t,

$$A_t = C^\infty(\Sigma_t), \tag{6}$$

and to consider their action on the classical phase space (the space of solutions) $\mathcal{H}$ of a Dirac spinor field satisfying the Dirac equation

$$(\not{D} - m)\psi = 0, \quad \text{for } \psi \in \mathcal{H}. \tag{7}$$

This action is just the pointwise multiplication of the initial data of the spinor field by functions on the corresponding Cauchy space slice,

$$(a_t \psi)(x) = a_t(x)\psi(x) \quad \text{for } a_t \in A_t,\ \psi \in \mathcal{H}, \text{ and } x \in \Sigma_t. \tag{8}$$

It is well defined, since a solution is uniquely given by its initial values on any Cauchy hypersurface.

While the algebras A_t are themselves commutative, they do not commute with each other. We proceed now, following Ref. 11, to express this noncommutativity in terms of commutators and then show that the knowledge of the calculated commutators is sufficient to recover the preassumed spacetime manifold including its metric structure and spin structure.

The commutators of interest will be those of functions taken at different times and of functions with the (generically time-dependent) Hamiltonian H of the family A_t of algebras. In the calculations, we will assume to be given the standard data of the Hamiltonian description of gravity, the ADM (Arnowitt–Deser–Misner) formalism.[12] A time flow identifying the Cauchy surfaces in the family and the metric tensor g_{ij} on the hypersurfaces describe the leaves. Also needed is a lapse function N describing the infinitesimal distance between hypersurfaces and the shift function N^i expressing, how much the identification of neighboring hypersurfaces (the time vector field $\partial/\partial t$) is shifted from the normal direction $e_\perp$ along the spatial directions e_i (see Fig. 1),

$$\frac{\partial}{\partial t} = Ne_\perp + N^i e_i. \tag{9}$$

In addition, the Dirac generators $\not{e}_\perp$, $\not{e}_i$ corresponding to the vectors $e_\perp$, e_i and the canonical spin connection ω will appear in the calculations. (Here, the common slash notation is used. The natural insertion γ^μ of covectors a_μ into the Clifford algebra generated by covectors is just indicated by a slash, $\not{a} := \gamma^\mu a_\mu$.)

With this, the Hamiltonian of the spinor field can be written as

$$iH = -N(\omega_\perp^S + \not{e}_\perp \not{e}_i g^{ij} D_j - m\not{e}_\perp) + N^i \partial_i . \tag{10}$$

It is obtained by $n+1$ splitting of the Dirac equation (7)

$$\left(-\gamma_\perp \left(\frac{1}{N} D_t - \frac{N^i}{N} D_i \right) + \gamma_i g^{ij} D_j - m \right) \psi = 0, \tag{11}$$

multiplying from the right by $\not{e}_\perp$ and then extracting the time derivative term. The form (10) is then obtained using the splitting of the spin connection form in the time direction,

$$\omega_t^S = N\omega_\perp^S + N^i \omega_i^S . \tag{12}$$

The commutator of the Hamiltonian with a function $f = f(t_0)$ belonging to a particular algebra A_{t_0} is easily computed,

$$[f, iH] = N \not{e}_\perp \not{e}_i g^{ij} (\partial_j f) - N^i \partial_i f. \tag{13}$$

The commutator of two functions $g \in \Sigma_{t_0}$, $f \in \Sigma_{t_1}$ is a more subtle issue. A not so short calculation, taking into account the possible time dependence of the Hamiltonian, gives the following expansion in time $t_1 - t_0$:

$$[f(t_1), g(t_0)] = (t_1 - t_0)^0 0 \tag{14}$$

$$+ (t_1 - t_0)^1 0 \tag{15}$$

$$- (t_1 - t_0)^2 (N^2 g^{ij} g^{kl} (\partial_i f)[\not{e}_j, \not{e}_k] \partial_l g) \tag{16}$$

$$+ (t_1 - t_0)^3 4 \not{e}_\perp m N^3 g^{ij} (\partial_i f)(\partial_j g) + \begin{pmatrix} \text{terms vanishing} \\ \text{in } 1+1 \text{ dimensions} \end{pmatrix} \tag{17}$$

$$+ O((t_1 - t_0)^4). \tag{18}$$

Note 1. All functions on the right-hand side are taken at the time t_0. It is understood that $f(t_0) \in A_{t_0}$ is the element corresponding to $f(t_1) \in A_{t_1}$ under the identification of A_{t_0}, A_{t_1} induced from the identification of Σ_{t_0}, Σ_{t_1}.

The formulas (10)–(17) contain a wealth of information. They are interpreted in the following remarks.

Remark 1. Commutativity. The vanishing of the zeroth order (14) just expresses the commutativity of the algebra of functions. This is a particularity typical of classical geometry and is, of course, not to be expected to hold in generalizations to noncommutative geometry.

Remark 2. First order condition. The vanishing of the first order (15) can be traced back to the fact that the spinor field obeys a first order differential equation. It can be restated in the following formula valid for any Hamiltonian originating from an arbitrary choice of slicing and time:

$$[[f(t_0), iH], g(t_0)] = 0. \tag{19}$$

Remark 3. Conformal structure. The second order (16) provides the generators $[\not{e}_i, \not{e}_k]$ of spatial orthonormal rotations, also called Coriolis fields. Thus, while it does not provide a length scale, it allows to compare ratios of lengths in different spatial directions. This means that the second order fixes the conformal structure. This term is absent in $1+1$ dimensions as there is no conformal information to talk about.

Remark 4. Time vector and scale. In $1+1$ dimensions, the third order provides the time vector $\not{e}_\perp$. This is uniquely extractable by requiring that it be normalized,

$$\not{e}_\perp^2 = -1. \tag{20}$$

Moreover, the term sets a scale for the metric, the inverse mass $1/m$ of the Dirac field. This scale could not be extracted, e.g., from the spectrum of the Hamiltonian, since an arbitrary rescaling of time by a constant factor will give a rescaling of the Hamiltonian. In this sense the Hamiltonian alone is not sufficient to set a scale.

However, in the general case of $n+1$ dimensions, it is more useful to abandon the expansion to orders higher than one in time (for high energy and low energy expansions, see Ref. 13) and rather *postulate* the existence of a suitable time vector $\not{e}_\perp$ with the correct properties. This allows to avoid a complicated extraction procedure for $\not{e}_\perp$ and m. The ADM data for spacetime can then be extracted from

$$[[iH,\not{e}_\perp],f] \to N g^{ij} \not{e}_j, \tag{21}$$

$$tr(iH\not{e}_\perp) \to Nm, \tag{22}$$

$$tr([iH,f]) \to N^i. \tag{23}$$

This is the approach taken in the next section.

Remark 5. Gauge and spatial Clifford generators. The use of the commutator (13) is the following: Given the time vector, it is easy to recognize the commutator's two terms in an operational way and to extract thus the shift N^i, the spatial Clifford generators $\not{e}_\perp$ together with their correspondence with spatial codirections. The lapse N is obtained by checking the prefactor of the first term against (17). Thus the commutator (13) expresses the arbitrary choices (gauge freedom) of the ADM formalism, including the choice of a spinor basis and is in this sense a somewhat supplementary structure.

The following corollary and remark show that in $1+1$ dimensions the idea of reconstructing spacetime from commutators of the algebras A_t meets complete fulfillment (massive case) as well as complete failure (massless case). Both are due to special properties of the dimension.

Corollary 1. In $1+1$ *dimensions and under the assumption that* $m \neq 0$, *the geometric structure of spacetime can be recovered from the knowledge of the commutators* (*13*) *and* (*15*)–(*17*).

Remark 6. If $m=0$ in $1+1$ dimensions then the commutator $[f(t_1),g(t_0)]$ vanishes at all times. Any (generalized) eigenspaces of an algebra A_{t_0} can be split into a right-moving eigenvector and a left-moving eigenvector. These form a common eigenbasis for all algebras $A_\cdot$.

III. THE SPECTRAL QUADRUPLE

In this section, the structures and properties that were found useful in Sec. II to recover a spacetime manifold from spectral data are pronounced to be first principles, whose collection is called a spectral quadruple. At the same time, they are fused with an imposed symmetry, though it is hoped that the general suggestions are still visible. The imposition of symmetry is done for two reasons: First, it provides a computationally manageable example and in direct generalization the possibility of a large set of important analogous examples. Second, the imposed symmetries provide automatic smoothness which allows to leave this further difficulty for this work on the side lines. (For a physically motivated principle of smoothness see Ref. 9.)

Given a category (a collection of objects and morphisms between objects that can be composed, satisfying a certain set of axioms), a subset of morphisms such that each of its elements has an inverse morphism forms a groupoid.

The following Definition 1 is to be understood as a conceptual step and does not attempt to be free of any redundance. Note that, in the notation of the definition, the dependence of the operators $\not{e}_\perp = \not{e}_\perp(\bullet)$, $\gamma = \gamma(\bullet)$ on the symbolically written index $\bullet$ is present but mostly suppressed.

Definition 1. *The* **spectral quadruple** $(A_\bullet,\mathcal{H},G,C,\gamma(\bullet),\not{e}_\perp(\bullet))$ *consists of a collection of algebras* $A_\bullet$ *represented on the Hilbert space* $\mathcal{H}$*, of a groupoid* G *and of an antilinear operator* C*. In addition, for each of the algebras* $A_\bullet$ *two operators* $\not{e}_\perp$, γ *are given. These structures satisfy the following conditions.*

(1) **Evolution.** *Any two algebras* A_0, A_1 *of the collection* $A_\bullet$ *are required to be mutually unitarily equivalent through a (not necessarily unique) unitary* $U(A_0,A_1)$ *and not mutually commutative,* $[A_{t_1},A_{t_2\neq t_1}]\neq 0$*. The groupoid* G *consists of a subset of all possible unitary equivalences between the algebras in the collection* $A_\bullet$*. It is assumed that for each algebra* A_0 *in the collection there exists an evolution, a (not necessarily unique) differentiable path* $\alpha_t: t\in\mathbb{R}\rightarrow\mathbb{U}_t(\mathbb{A}_0,\mathbb{A}_t)$ *with* $\alpha_0=1$ *such that the generator (derivative) at* $t=0$*, denoted by* iH *is compatible with the further requirements.*

(2) **Charge conjugation.** *The antilinear operator* C *commutes with* G *and satisfies*

$$C^2=(-1)^{s(n)} \tag{24}$$

for the spacetime dimension n *and with*

$$s(n):=\tfrac{1}{8}(n-1)(n-2)(n-3)(n-4). \tag{25}$$

(3) **First order condition (dynamics)**

$$[[f,iH],g^{\mathrm{op}}]=0 \quad \text{for any } f,g\in A_0 \text{ and any generator } iH, \tag{26}$$

with $g^{\mathrm{op}}=Cg^*C$.

(4) **The time vector.** *For each algebra* A_0 *in the collection* $A_\bullet$ *there exists an operator* $\not{e}_\perp$ *called the time vector satisfying*

$$\not{e}_\perp^2=-1, \tag{27}$$

$$\not{e}_\perp^*=-\not{e}_\perp, \tag{28}$$

and the compatibility conditions in (5) and (6) of this definition.

(5) **The volume element.** *For any* A_t *there exists an operator* γ *such that*

$$\gamma^2=\pm 1, \tag{29}$$

$$\{\not{e}_\perp,\gamma\}=0 \quad \text{for even spacetime dimension,} \tag{30}$$

$$[\not{e}_\perp,\gamma]=0 \quad \text{for odd spacetime dimension,} \tag{31}$$

and

$$\gamma=\not{e}_\perp\sum_{f_\bullet\in A_t} f_{i_0}[D,f_{i_1}]\cdots[D,f_{i_n}] \quad \text{for even spacetime dimension } n+1, \tag{32}$$

$$\gamma=\sum_{f_\bullet\in A_t} f_{i_0}[D,f_{i_1}]\cdots[D,f_{i_n}] \quad \text{for odd spacetime dimension } n+1, \tag{33}$$

and for suitable functions $f_\bullet$ *where* D *is given by*

$$D=\begin{cases}\gamma[iH,\gamma] & \text{for even spacetime dimension,}\\ iH & \text{for odd spacetime dimension.}\end{cases} \tag{34}$$

(6) **Geometry of space.** *For any algebra* A_t *of the collection* $(A_t,\mathcal{H},\not{e}_\perp[H,\not{e}_\perp],\gamma,C)$ *is*

(i) *a* spectral triple for odd spacetime dimension,
(ii) *a spectral triple for even spacetime dimension, if restricted to each of the two eigenspaces of* $\not{\epsilon}_\perp$.

Remark 7. The right-hand sides of Eqs. (32) and (33) are to be understood as (images of) Hochschild cycles. The principal part of the operator D [compare with (10)] is the same as the principal part of the spatial Dirac operator but multiplied from the left by $\not{\epsilon}_\perp$. Since $\not{\epsilon}_\perp^2 = -1$, this has no effect on the form of (33) but requires the appearance of $\not{\epsilon}_\perp$ in (33), to cancel one superfluous $\not{\epsilon}_\perp$ coming from the commutators. Note that, together with the requirements in parts 5, 6 of the definition, it follows that

$$D\gamma = (-1)^{n+1}\gamma D. \tag{35}$$

Remark 8. A minimal version of G would be $G=\mathbb{R}$.

An interesting model in this respect would be the classical evolution induced from the modular automorphism group determined by a quasifree state on the Dirac-quantized phase space H. This would make contact with the work of Connes and Rovelli.[14]

However, G may be much larger and it is in this context that the concept of many-fingered time of general relativity comes to its full expression.

For a large G, the definition does not exclude the possibility that, along with generators iH satisfying the definition, there may be some that may not satisfy the definition. These are to be thought of as in some sense singular and are to be avoided (see Remark 11).

Remark 9. The last requirement in the definition of a spectral quadruple puts things on the safe side in order to be sure that reasonable spacetime geometries deserving to be called manifolds will be obtained. It is to be noted though that $\not{\epsilon}_\perp[H,\not{\epsilon}_\perp]$ is in general not the spatial Dirac operator, though it can be used as such for making sure the corresponding spatial section is a manifold, since only the principal symbol of the Dirac operator matters and is in this way obtained correctly.

Remark 10. **Spacetime points.** Compared with the situation in the preceding section, the definition of the spectral quadruple provides for more general situations, in particular for a many-fingered time. This leads to an additional difficulty: Assume, that the algebras in the collection are commutative. Then it is fine to take the characters of an algebra as being points of spacetimes. However, some characters of different algebras in the collection describe the same point. In order to compare characters, one has to extend them as functionals on a larger algebra encompassing all of the collection $A_\bullet$. But since the characters are distributions, they cannot be extended to all bounded operators on $\mathcal{H}$. It is natural to expect that this algebra should be determined by a smoothness principle common to the whole collection $A_\bullet$.

Two types of spectral quadruples are of particular interest.

Definition 2. *A* general spectral quadruple *is a spectral quadruple where G is given by all smooth unitary equivalences* $U(A_\bullet, A_\bullet)$.

A symmetric spectral quadruple *is a spectral quadruple distinguished by the following conditions*:

(1) G is *a finite dimensional Lie group (and iH is then in the Lie algebra of G).*
(2) *For any algebra* A_{t_0}, *the subgroup K preserving the algebra coincides with a maximal compact subgroup of* G.
(3) *The operators* $\not{\epsilon}_\perp$, γ *commute with the group* K,

$$[k, \not{\epsilon}_\perp] = 0, \tag{36}$$

$$[k, \gamma] = 0, \tag{37}$$

for any $k \in K$.

Remark 11. Specializing Remark 8 to a symmetric spectral quadruple, the generator iH for an algebra A_0 is not to be chosen as a compact generator in the Lie algebra of G preserving A_0 as it may not fulfill the geometry-of-space requirement in Definition 1 of a spectral quadruple.

Following these general consideration, we will choose a particular class of symmetric spectral quadruples which we will call de Sitter spectral quadruples.

The group G is chosen to be $\mathrm{SL}_2(\mathbb{R})$.

The set of algebras is generated from one algebra by the action of G. This algebra in turn is generated from one unitary generator u,

$$u^* = u^{-1}. \tag{38}$$

The mutual position of G and u on the representation space $\mathcal{H}$ is partially determined by the commutation relation of u, $\not{e}_\perp$, and γ with a compact generator T_{21} of the Lie algebra of G,

$$[T_{21}, u] = iu, \tag{39}$$

$$[T_{21}, \not{e}_\perp] = 0, \tag{40}$$

$$[T_{21}, \gamma] = 0. \tag{41}$$

The above set of structures is irreducibly represented. This requirement is to avoid dealing with multiple copies.

Note 2. The compact generators of a Lie group generate the maximal compact subgroup of a Lie group.[15] In the case of $\mathrm{SL}_2(\mathbb{R})$ a compact subalgebra of the Lie algebra is just one-dimensional and thus spanned by one element T_{21}. This indicates how to proceed in higher dimensional cases.

As is clear from the definitions, the Hilbert space $\mathcal{H}$ of a de Sitter spectral quadruple is in particular the representation space of a unitary representation of $G = \mathrm{SL}_2(\mathbb{R})$. Therefore, in the next section, the representation theory of $G = \mathrm{SL}_2(\mathbb{R})$ will be reviewed.

IV. $\mathrm{SL}_2(\mathbb{R})$ AND ITS REPRESENTATION THEORY

The group $\mathrm{SL}_2(\mathbb{R})$ is treated in a number of sources. The present review is based on Refs. 15–19.

Definition 3. *The group $SL_2(\mathbb{R})$ is the Lie group of 2×2-matrices of real numbers with unit determinant. $sl_2(\mathbb{R})$ is the Lie algebra of traceless 2×2-matrices of real numbers.*

Remark 12 (see Ref. 15). The Lie group $\mathrm{SL}_2(\mathbb{R})$ and the Lie algebra $\mathrm{sl}_2(\mathbb{R})$ have the following decomposition (Iwasawa decomposition):

$$\mathrm{SL}_2(\mathbb{R}) = K\times A\times N = \underbrace{\begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix}}_{\text{maximal compact}} \underbrace{\begin{pmatrix} a & 0 \\ 0 & a^{-1} \end{pmatrix}\begin{pmatrix} 1 & b \\ 0 & 1 \end{pmatrix}}_{\text{solvable}},$$

$$\mathrm{sl}_2(\mathbb{R}) = k\times a\times n = \underbrace{\begin{pmatrix} 0 & c \\ -c & 0 \end{pmatrix}}_{\text{antisymmetric}} \underbrace{\begin{pmatrix} d & 0 \\ 0 & -d \end{pmatrix}\begin{pmatrix} 0 & n \\ 0 & 0 \end{pmatrix}}_{\text{solvable}},$$

for $\phi, a, b, c, d, n \in \mathbb{R}$.

$\mathrm{SL}_2(\mathbb{R})$ is a simple Lie group and has thus a nondegenerate Killing metric on its Lie algebra with signature $(-,+,+)$.

$\mathrm{SL}_2(\mathbb{R})$ is a double cover for SO(1,2).

The Lie algebra $\mathrm{sl}_2(\mathbb{R})$ can be given by three generators T_{01}, T_{02}, and T_{21} satisfying the following commutation relations:

$$[T_{01}, T_{21}] = -T_{02}, \quad [T_{02}, T_{21}] = +T_{01}, \quad [T_{01}, T_{02}] = -T_{21}. \tag{42}$$

In a complex representation, raising and lowering operators may be defined

$$T_{\pm} = T_{01} \mp i T_{02}. \tag{43}$$

Together with T_{21}, these operators generate the complexification of $\mathrm{sl}_2(\mathbb{R})$. Their commutation relations are

$$[T_{21}, T_{\pm}] = \pm i T_{\pm}, \tag{44}$$

$$[T_{+}, T_{-}] = -2i T_{21}. \tag{45}$$

In addition, the following holds in unitary representations:

$$T_{21}^{*} = -T_{21}, \tag{46}$$

$$T_{01}^{*} = -T_{01}, \tag{47}$$

$$T_{02}^{*} = -T_{02}, \tag{48}$$

$$T_{\pm}^{*} = -T_{\mp}. \tag{49}$$

Representations. The group $\mathrm{SL}_2(\mathbb{R})$ is a noncompact group. Its unitary representations are thus bound to be infinite dimensional while there are nonunitary finite dimensional representations, e.g., the defining representation.

Any representation can be decomposed into irreducible representations of the maximal compact subgroup K which is just the circle group U_1. The irreducible representations of U_1 are one dimensional and given by $\pi_n : \phi \to e^{in\phi}$ with $n \in \mathbb{Z}$. The maximal compact subgroup can be taken to be generated by T_{21}. That the eigenvalues of T_{21} are to be integers or half-integers is a global requirement of the group representation and can in this case not be seen on the level of the generator T_{21} alone but comes from the requirement that the representation of $K = U_1$ should be single valued.

We will consider only admissible unitary representations[16] in which all eigenspaces of T_{21} are only finite dimensional.

The eigenvectors of T_{21} will be labeled by $|n\rangle$:

$$T_{21}|n\rangle = in|n\rangle \quad \text{for } n \text{ integer or half-integer} \tag{50}$$

and will be assumed to be normalized

$$\langle n|n\rangle = 1. \tag{51}$$

For any eigenvector in such an irreducible representation, the vectors $T_{-}T_{+}|n\rangle$, $T_{-}T_{+}|n\rangle$ are proportional to $|n\rangle$.

Define

$$T_{+}|n\rangle = c_n |n+1\rangle. \tag{52}$$

It follows from unitarity (49),

$$T_{-}|n+1\rangle = -\overline{c_n}|n\rangle. \tag{53}$$

From (49) and (45), it follows that

$$\langle n|[T_{+}, T_{-}]n\rangle = -2i\langle n|T_{21}n\rangle, \tag{54}$$

$$-\langle T_{-}n|T_{-}n\rangle + \langle T_{+}n|T_{+}n\rangle = 2n, \tag{55}$$

$$|c_n|^2-|c_{n-1}|^2=2n, \tag{56}$$

and solving the recursion relation gives

$$|c_n|^2=(n+\tfrac{1}{2})^2+R^2m^2, \tag{57}$$

with R^2m^2 being a real number (possibly negative; writing for this number the expression R^2m^2 is convenient for latter interpretation and has no importance here). Since $|c_n|^2$ is positive, R^2m^2 has to satisfy the following condition:

$$(n+\tfrac{1}{2})^2+R^2m^2\geqslant 0 \tag{58}$$

for all half-integers n appearing in the representation. This condition allows us to get insight into the classification of the unitary irreducible representations of $\mathrm{SL}_2(\mathbb{R})$:

(i) As long as $R^2m^2>0$, the condition (58) is always satisfied and c_n never vanishes. Given one eigenvector $|n\rangle$ of the Hermitean operator $-iT_{21}$ and for some half-integer n, one obtains eigenvectors $|n+k\rangle$, for all $k\in\mathbb{R}$. These then span the representation space of the irreducible representation. These representations, labeled by the number R^2m^2 and by whether the eigenvalues are integers or true half integers (i.e., integers$+\frac{1}{2}$), are referred to as the *principal series.*

(ii) If $0\geqslant R^2m^2>\frac{1}{4}$ then the condition (58) is always satisfied and c_n never vanishes under the assumption that the eigenvalues are integers. These representations are called the *complementary series.*

(iii) If the condition (58) cannot be satisfied for eigenvalues shifted by an arbitrary amount, then some c_n have to vanish in order not to run into contradictions with (58) while applying raising and lowering operators. This bounds the eigenvalues of $-iT_{21}$ in the unitary irreducible representation from above or from below. The number R^2m^2 has then to satisfy

$$R^2m^2=-(n_0+\tfrac{1}{2})^2 \tag{59}$$

for some half integer n_0. These unitary irreducible representations are thus discretely indexed by n_0 and by whether the eigenvalues of $-iT_{21}$ are bound from above or from below. This set of unitary irreducible representations is the *discrete series.*

V. THE SYMMETRIC SPECTRAL QUADRUPLES OF DE SITTER SPACE

The Hilbert space of the spectral quadruple is required to carry a representation of the group $\mathrm{SL}_2(\mathbb{R})$ and has in addition to accommodate the operators u, $\not{e}_\perp$, and γ. Since $\not{e}_\perp$ and γ commute with T_{21}, they can be considered separately on each eigenspace of T_{21}. Mutually, $\not{e}_\perp$ and γ anticommute and do not vanish, as follows from the definition of the spectral quadruple. Thus they force the eigenspaces $\mathcal{H}_n$ of T_{21} to be at least two dimensional. In addition, u is an invertible raising operator and its inverse u^* an invertible lowering operator, as follows from Eq. (39). Thus all the eigenspaces $\mathcal{H}_n$ of T_{21} are bound to have the same dimension. From the requirement of irreducibility and from the invertibility of the operator u we obtain that this dimension has to be 2 and that the discrete series can therefore not be a candidate.

We will further assume that the eigenvalues are true half-integers, as we are interested in interpreting the representation space as the phase space of a spinor field. This excludes the complementary series of representations as well as the part of the principal series with integer eigenvalues of $-iT_{21}$.

A common orthonormal eigenbasis $|n,\pm\rangle$ for the mutually commuting anti-Hermitean operators T_{21}, $\not{e}_0$ can be given as

$$T_{21}|n,\pm\rangle=in|n,\pm\rangle, \tag{60}$$

$$\not{e}_0|n,\pm\rangle = \pm i|n,\pm\rangle, \tag{61}$$

$$\langle n',\mathrm{sign}'|n,\mathrm{sign}\rangle = \delta_{n'n}\delta_{\mathrm{sign}'\mathrm{sign}}. \tag{62}$$

The eigenvectors are then unique, up to phases. The relative phases are fixed by requiring further

$$u|n,\pm\rangle = |n+1,\pm\rangle. \tag{63}$$

This leaves only two phases free, one of them an overall phase.

The order-one condition. The only unspecified operators of the spectral quadruple are now T_+ and T_-, the raising and lowering operators.

They are given by their restrictions

$$T_\pm(n):\mathcal{H}_n \to \mathcal{H}_{n\pm1}. \tag{64}$$

The eigenspaces $\mathcal{H}_n$ can be identified using the unitary bijections given by restrictions of u. Then the operators $T_\pm(n)$ can all be understood to operate on a common, two-dimensional Hilbert space.

The order-one condition for the raising and lowering operators can then be written as

$$T_\pm(n+1) - 2T_\pm(n) + T_\pm(n-1) = 0. \tag{65}$$

Note that

$$T_+(n)^* = -T_-(n+1), \tag{66}$$

$$T_-(n)^* = -T_+(n-1), \tag{67}$$

so that both equations (65) can be solved recursively, if two restrictions $T_\pm(\bullet)$ are known.

In order to keep the symmetric way in which the raising and lowering operators appear in the calculations, we choose the two required restrictions to be $T_+(+\frac{1}{2})$, $T_-(-\frac{1}{2})$.

From the preceding section, it is clear that the $T_\pm(n)$ have to be unitaries times the factor $\sqrt{(n+\frac{1}{2})^2+R^2m^2}$.

We set

$$T_+(+\tfrac{1}{2}) = \sqrt{1+R^2m^2}\,u_+, \quad u_+^* u_+ = u_+ u_+^* = \mathbf{1}, \tag{68}$$

$$T_-(-\tfrac{1}{2}) = \sqrt{1+R^2m^2}\,u_-, \quad u_-^* u_- = u_- u_-^* = \mathbf{1}. \tag{69}$$

Solving the order-one recursion condition, one obtains

$$T_+(n) = \sqrt{1+R^2m^2}\left(\left(+\frac{n}{2}-\frac{1}{4}\right)(u_+ + u_-^*) + u_+\right), \tag{70}$$

$$T_-(n) = \sqrt{1+R^2m^2}\left(\left(-\frac{n}{2}-\frac{1}{4}\right)(u_- + u_+^*) + u_-\right). \tag{71}$$

Charge conjugation. It remains to determine the 2×2-matrices u_+, u_-.

For that purpose we use a general parametrization of unitary 2×2 matrices,

$$u_+ = e^{i\rho_+}\frac{1}{\sqrt{1+x_+^2+y_+^2}}\begin{pmatrix} -ix_+ + \tanh\theta_+ & \dfrac{1}{\cosh\theta_+} + iy_+ \\ -\dfrac{1}{\cosh\theta_+} + iy_+ & ix_+ + \tanh\theta_+ \end{pmatrix}, \tag{72}$$

$$u_- = e^{i\rho_-}\frac{1}{\sqrt{1+x_-^2+y_-^2}}\begin{pmatrix} -ix_- + \tanh\theta_- & \dfrac{1}{\cosh\theta_-} + iy_- \\ -\dfrac{1}{\cosh\theta_-} + iy_- & ix_- + \tanh\theta_- \end{pmatrix}. \tag{73}$$

As a consequence of the commutation of the charge conjugation C with G in the definition of a spectral quadruple, one obtains

$$e^{i\rho} := e^{i\rho_+} = -e^{i\rho_-}, \tag{74}$$

$$x := x_+ = -x_-, \tag{75}$$

$$\theta := \theta_+ = \theta_-, \tag{76}$$

$$y := y_+ = y_-. \tag{77}$$

Out of the remaining four parameters, two of them, ρ and y can be set to zero, since they exactly correspond to the two remaining phases in the above choice of basis. ρ is the overall phase and y is connected with a phase freedom in the spinor basis as will become apparent once the geometric interpretation of the de Sitter quadruple is reached.

Thus the de Sitter spectral quadruples form a two-parametric family. Comparing with the representation theory of $\mathrm{SL}_2(\mathbb{R})$, one finds that x can be identified with the parameter Rm while there are no further restrictions on θ. Thus the two matrices u_+ and u_- can be written as

$$u_+ = \begin{pmatrix} -iRm + \tanh\theta & \dfrac{1}{\cosh\theta} \\ -\dfrac{1}{\cosh\theta} & iRm + \tanh\theta \end{pmatrix}, \tag{78}$$

$$u_- = \begin{pmatrix} -iRm + \tanh\theta & -\dfrac{1}{\cosh\theta} \\ \dfrac{1}{\cosh\theta} & iRm + \tanh\theta \end{pmatrix}. \tag{79}$$

Following Remark 4 and Remark 10 (or Corollary 1 and Remark 10, since this is the special, $1+1$-dimensional case), the corresponding spacetime geometry can be directly calculated.

The result is $1+1$ dimensional de Sitter space of radius R containing a Dirac spinor field of mass m. The mass m and the radius R may be reinterpreted at will, as long as Rm is kept constant. In that sense, the mass of the Dirac field becomes the meter stick. The parameter does not change the geometry: The algebra generated by u, from which all other algebras are obtained by symmetry group actions describes a spacelike circle invariant under the action of T_{21}. There is a one parameter set of such circles. θ can be chosen as that parameter.

Instead of carrying out the detailed calculations, one can get these results by checking that the de Sitter spectral quadruples obtained here are identical with the spectral data of $1+1$ de Sitter space calculated in the Appendix, see (A122)–(A127).

Remark 13. The fact that different symmetric spectral quadruples describe the same geometry is not surprizing. It is a consequence of G having been chosen too small to provide for all unitary equivalences that take any smooth spacelike circle into any other smooth spacelike circle on de Sitter. A one-to-one correspondence between spacetimes and spectral quadruples should be searched for with a sufficiently large choice of G only.

Remark 14. Going through a direct calculation, one cannot avoid the problem of extending characters of one algebra in the collection to generalized vectors, on which other algebras may act.

This requires to see the characters as distributions (functionals) on a dense subspace of the Hilbert space.[20] But suitable subspaces of test vectors are in this case obtained for free from the action of the group G: They can be chosen to consist of vectors with rapidly decaying coordinates in the eigenbasis of T_{21}. In this point, the employed Lie symmetry provides substantial help with matters of smoothness.

VI. FINITE SPECTRAL QUADRUPLES

A finite spectral quadruple is based on a collection of finite dimensional algebras with the necessary additional structures.

Here, we will build a spectral quadruple out of a spectral triple $(A_0,\mathcal{H},D,\gamma,J)$. This allows us to take advantage of the fact that the relevant spectral triples have already been fully characterized:[21,22] Finite spectral triples are classified by their algebra A which is a finite direct sum of matrix algebras, $A=\oplus_{i=1}^{k} M_{n_i}(\mathbb{C})$ and a symmetric and invertible $k\times k$ matrix with integer entries, the intersection form $q_{ij}:K_\bullet(A)\times K_\bullet(A)\to\mathbb{Z}$, from which the remaining data of the spectral quadruple can be read off. In particular, the Hilbert space $\mathcal{H}$ is given by

$$\mathcal{H}=\bigoplus_{i,j}^{k}\mathcal{H}_{ij}:=\bigoplus_{i,j}^{k}(\mathbb{C}^{n_i}\otimes\mathbb{C}^{|q_{ij}|}\otimes\mathbb{C}^{n_j}), \tag{80}$$

on which the algebra A acts by left multiplication as $a\otimes\mathbf{1}\otimes\mathbf{1}$ for $a\in A$ while the opposite algebra JA^*J, with $J:H_{ij}\to H_{ji}$, $J(v_i\otimes v_{ij}\otimes v_j)=\overline{v_j}\otimes\overline{v_{ij}}\otimes\overline{v_i}$ antilinear, acts by right matrix multiplication as $\mathbf{1}\otimes\mathbf{1}\otimes\mathbf{a}^{\mathbf{T}}$ for $a\in A$. Furthermore,

$$\gamma\mathcal{H}_{ij}=\mathcal{H}_{ij},\quad \gamma|_{\mathcal{H}_{ij}}=\mathrm{sign}(q_{ij})\mathbf{1}_{\mathcal{H}_{ij}}, \tag{81}$$

and the Dirac operator $D:\mathcal{H}_{kl}\to\mathcal{H}_{ij}$ satisfies the equations

$$D_{ij\,kl}=D^{+}_{ij\,kl},\quad D_{ij\,kl}=\overline{D_{ji\,lk}}, \tag{82}$$

following from the requirements

$$D=D^*, \tag{83}$$

$$JD=DJ. \tag{84}$$

The Dirac operator is further restricted by the order-one condition of a spectral triple.

Example 1. *Let a finite spectral triple be given by the algebra*

$$A=\mathbb{C}\oplus\mathbb{C} \tag{85}$$

and by the intersection form

$$q=\begin{pmatrix}1 & -1\\ -1 & 0\end{pmatrix}. \tag{86}$$

Then

$$\mathcal{H}=\mathbb{C}^3, \tag{87}$$

$$\gamma=\begin{pmatrix}1 & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & -1\end{pmatrix}, \tag{88}$$

$$J = \text{complex conjugation} \times \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}. \tag{89}$$

The representations π, π^{op} of the algebra A and of the opposite algebra A^{op} are given by

$$\pi(z_1 \oplus z_2) = \begin{pmatrix} z_1 & 0 & 0 \\ 0 & z_1 & 0 \\ 0 & 0 & z_2 \end{pmatrix}, \tag{90}$$

$$\pi^{\mathrm{op}}(z_1 \oplus z_2) = \begin{pmatrix} z_1 & 0 & 0 \\ 0 & z_2 & 0 \\ 0 & 0 & z_2 \end{pmatrix}, \tag{91}$$

and

$$D = \begin{pmatrix} 0 & m & \overline{m} \\ \overline{m} & 0 & 0 \\ m & 0 & 0 \end{pmatrix} \quad \text{for} \quad m \in \mathbb{C}. \tag{92}$$

In order to construct a spectral quadruple, it is now sufficient to find in addition to the spectral triple data an operator $\not{\epsilon}_\perp$:

$$\not{\epsilon}_\perp^2 = -\mathbf{1}, \tag{93}$$

$$\not{\epsilon}_\perp^* = -\not{\epsilon}_\perp, \tag{94}$$

$$[\not{\epsilon}_\perp, \gamma] = 0, \tag{95}$$

as required by the definition of a $1+0$-dimensional spectral quadruple, and to supply a Hamiltonian H as a function of time.

The operator $\not{\epsilon}_\perp$ and the Hamiltonian H can be chosen as

$$\not{\epsilon}_\perp := i\gamma(t), \tag{96}$$

$$H(t) := \not{\epsilon}_\perp(t) D(t). \tag{97}$$

Denoting the evolution operator by $U(t)$, one can write the time dependent operator $D(t)$ as $U^{-1}(t) D_0(t) U(t)$ with respect to a comoving basis in which the representation of the algebra remains diagonal. Here $D_0(t)$ has the same form for all times t as the Dirac operator D just with its entries replaced by smooth functions.

In particular, $D_0(t)$ has the form (92), if the spectral triple of Example 1 is taken. The equal time distance of the two points x_t, y_t of this discrete spectral geometry can be calculated via Connes' distance formula:[1]

$$d(x_t, y_t) = \sup_{a_t \in A_t, \|[D(t), a_t]\| \leq 1} \{|x_t(a_t) - y_t(a_t)|\} \tag{98}$$

$$= \sup_{a_0 \in A_0, \|[D_0(t), a_0]\| \leq 1} \{|x_0(a_0) - y_0(a_0)|\} \tag{99}$$

$$= \frac{1}{|m(t)|}. \tag{100}$$

Thus this spectral quadruple describes two points with varying spatial distance $1/|m(t)|$.

To determine the distance between the points, rather than to prescribe it, one would have to provide the corresponding theory of gravity given by an action functional. For example, one could use a spectral action for the Wick rotated system, thus avoiding problems of nondefiniteness of a Lorentzian action. Alternatively, one could try to write down an action directly, in terms of H and its time derivative $\dot{H}$. However, H is noninvertible and it becomes difficult to write a term invariant under time parametrization. For instance, typical terms like $\dot{H}^2/H^3$, $\sqrt[4]{\dot{H}}$ are pested with singularities while $\dot{H}/H$ leads to the solution $H=0$. But this is beyond the scope of the present work.

Remark 15. The here presented type of a discrete spectral quadruple is built in a rather naive way on the basis of a discrete spectral triple, just by adding time. Its value is in showing how the Lorentzian signature is taken up in the discrete case [see especially (96)] rather than in examining all possibilities of the discrete case.

VII. CONCLUSION

In this work, we have arrived at a spectral characterization of spin manifolds with Lorentzian metric through a spectral quadruple. While the spectral geometry of Riemannian spin manifolds as given by the spectral triple has motivated and was incorporated into the spectral quadruple, the spectral quadruple is not just a stack of spectral triples with time vectors $\not{e}_\perp$ and some sign changes added on. The results are derived from the Hamiltonian rather than from the Dirac operator, allowing thus for the many-fingered time typical of general relativity. The requirements of the order-one condition and of charge conjugation are significantly generalized with the first of the two containing the main information on dynamics: These requirements are not to hold for one algebra but instantly for all algebras in the collection $A\!\!\!\bullet$ at once.

Note also that the axioms do not presuppose global hyperbolicity. The lack of global hyperbolicity and the eventual occurrence of closed timelike curves leaves one still with a meaningful structure. For example, closed timelike curves will not allow an arbitrary choice of initial data on spatial sections and will thus severely restrict the size of the phase space but still a fuzzy description of spacetime is eventually left. This should not be seen as a failure. It simply means that certain details of geometry, though possibly existent in mathematical imagination, are automatically dropped, if there is no field to resolve them. This is not unrelated to the features of the Euclidean spectral quadruple presented in Joke 1 at the end of this section.

On the practical side, the notion of a spectral quadruple is backed up by the nontrivial example of de Sitter spectral quadruples which successfully describe $1+1$-dimensional de Sitter space. This is an achievement in itself as it is not so easy, despite the generality of spectral geometry, to produce examples. (This does not mean that there are no examples available in the Riemannian case, as the collection has been built up for some time. But still this is an area in need of substantial further work.) While the requirements of the spectral quadruple are in a preliminary form and confrontation with further examples is definitely needed, a number of important examples is under firm control: It is clear, how to deal with generalizations to higher dimensional de Sitter spaces and other cosmologies of high symmetries. Situations of such high symmetries are not just toy examples but have claim to be directly interpreted: the Friedmann–Robertson–Walker class of models is the one used as the background of realistic cosmology.

With this in hand it is now only natural to have a second look at the standard model of elementary particle physics along the lines of Ref. 23. Judging from the results of Sec. VI, in particular Eq. (97), no fermion doubling is to be expected.

Joke 1. It is amusing to note that the machinery of the spectral quadruple which was designed to deal with Lorentzian manifolds can be turned onto Euclidean situations. To give an example, we define a class of symmetric spectral quadruples which we will call ''spherical spectral almost quadruples.'' The word *almost* refers to one necessary adaptation of the definition of a spectral quadruple to the Euclidean signature: instead of $\not{e}_\perp^2=-\mathbf{1}$ we require $\not{e}_\perp^2=+\mathbf{1}$.

The group G is chosen to be SU_2.

The set of algebras is generated from one algebra by the action of G. This algebra in turn is generated from one unitary generator u:

$$u^* = u^{-1}. \tag{101}$$

The mutual position of G and u on the representation space $\mathcal{H}$ is partially determined by the commutation relation of u, $\not{e}_\perp$, and γ with a compact generator T_{21} of the Lie algebra of G:

$$[T_{21}, u] = iu, \tag{102}$$

$$[T_{21}, \not{e}_\perp] = 0, \tag{103}$$

$$[T_{21}, \gamma] = 0. \tag{104}$$

The above set of structures is irreducibly represented. This requirement is to avoid dealing with multiple copies.

The resulting space should be thought of as being a sphere S^2 with an axis of rotational symmetry determined by the chosen generator T_{21}. The algebra generated by u describes a circle preserved under the rotational symmetry generated by T_{21}. This circle may or may not be chosen at the equator of the sphere and is moved over the sphere by the action of the group SU_2. In this way any point of the sphere is reached by some circles. However, points of the sphere can be resolved only in a limit for the following reason: In analogy with the de Sitter example, the algebras are represented on the space of solutions of the counterpart of the Dirac equation

$$\not{D}\psi = (l + \tfrac{1}{2})\psi \tag{105}$$

for a fixed angular momentum l of the spherical harmonics. Since SU_2 is a compact group, the Hilbert space of any unitary irreducible representation is finite dimensional and so is the Hilbert space of the spectral quadruple. As seen from the point of view of a true sphere only maximally localized vectors in the Hilbert space rather than points of the sphere may be found and the representation of the algebras generates the matrix algebra on the Hilbert space. Thus the spherical spectral almost quadruples describe the fuzzy spheres.

ACKNOWLEDGMENTS

The authors would like to thank José M. Gracia-Bondía and Florian Scheck for their encouragement and for a number of useful discussions and remarks and Andrzej Sitarz and Joseph C. Várilly for a number of comments on earlier drafts. T.K. most thankfully acknowledges support from the Alexander von Humboldt Foundation.

APPENDIX: SPINORS ON de SITTER SPACE

In this appendix, a self-contained exposition of de Sitter space and of spinor fields on de Sitter space is given. The main purpose is to collect formulas and facts on this model for use as a testing case for Lorentzian spectral geometry. We will concentrate on two-dimensional de Sitter space. However, at instances where this restriction does not bring any simplification, the general n-dimensional case is dealt with directly.

In the course of this, an important particularity is obtained: There is a set of spectral data that can be compared with the spectral quadruples of Sec. V to provide for one of the main results of this paper: The de Sitter spectral quadruples describe de Sitter space.

The first three subsections deal with the differential geometry, with the symmetries and with the spin geometry of de Sitter space from both the point of view of an imbedding into Minkowski space as well as from the intrinsic point of view. In the following two sections, the Dirac operator

of de Sitter space is discussed and employed to construct the action of the symmetries on the space of solutions of the Dirac equation. There, the spectral data in a form comparable to the de Sitter spectral quadruples are obtained.

The geometry of de Sitter space

Definition 4. *The n-dimensional de Sitter geometry is a submanifold of $n+1$ dimensional Minkowski space given in a fixed Lorentz frame by the equation*

$$-(x^0)^2+(x^1)^2+\cdots+(x^n)^2=R^2 \tag{A1}$$

with the metric induced from the metric of the Minkowski imbedding space,

$$ds^2=-(dx^0)^2+(dx^1)^2+\cdots+(dx^n)^2. \tag{A2}$$

The induced metric has signature

$$(-,\underbrace{+,+,\ldots,+,+}_{n-1}).$$

Remark 16. The intrinsic de Sitter geometry may be defined without any reference to an imbedding space. This is not done here as the imbedding space proves to be a very useful technical tool for doing calculations. But for the sake of clarity, some calculations are done or redone in an entirely intrinsic way.

Following Definition 4, the two-dimensional de Sitter geometry can be embedded into the three-dimensional Minkowski space as the hyperboloid

$$-(x^0)^2+(x^1)^2+(x^2)^2=R^2, \tag{A3}$$

and can be parametrized by generalized spherical coordinates

$$x^0=R\sinh\theta, \qquad \theta\in(-\infty,\infty), \tag{A4}$$

$$x^1=R\cosh\theta\cos\phi, \qquad \phi\in[0,2\pi), \tag{A5}$$

$$x^2=R\cosh\theta\sin\phi, \tag{A6}$$

The coordinate vectors of the spherical coordinates $(\partial/\partial\theta)$ $(\partial/\partial\phi)$ are expressed in terms of the Cartesian basis $(\partial/\partial x^0)$, $(\partial/\partial x^1)$, $(\partial/\partial x^2)$ of Minkowski space by

$$\frac{\partial}{\partial\theta}=\frac{\partial x^i}{\partial\theta}\frac{\partial}{\partial x^1}=R\cosh\theta\frac{\partial}{\partial x^0}+R\sinh\theta\cos\phi\frac{\partial}{\partial x^1}+R\sinh\theta\sin\phi\frac{\partial}{\partial x^2}, \tag{A7}$$

$$\frac{\partial}{\partial\phi}=\frac{\partial x^i}{\partial\phi}\frac{\partial}{\partial x^1}=R\cosh\theta\left(-\sin\phi\frac{\partial}{\partial x^1}+\cos\phi\frac{\partial}{\partial x^2}\right). \tag{A8}$$

The induced metric is then

$$g_{\theta\theta}=-R^2, \quad g_{\theta\phi}=g_{\phi\theta}=0, \quad g_{\phi\phi}=R^2\cosh^2\theta, \tag{A9}$$

$$g_{\cdot\cdot}=\begin{matrix}\\ \theta\\ \phi\end{matrix}\overset{\begin{matrix}\theta & \phi\end{matrix}}{\begin{pmatrix}-R^2 & 0\\ 0 & R^2\cosh^2\phi\end{pmatrix}}, \quad g^{\cdot\cdot}=\begin{matrix}\\ \theta\\ \phi\end{matrix}\overset{\begin{matrix}\theta & \phi\end{matrix}}{\begin{pmatrix}-\frac{1}{R^2} & 0\\ 0 & \frac{1}{R^2\cosh^2 0}\end{pmatrix}}. \tag{A10}$$

The symbol • is used to indicate various types of indices without giving them names.

The Christoffel symbols of the unique torsion-free metric connection $\nabla_\bullet$ can be calculated as

$$\Gamma^A{}_{BC} = \tfrac{1}{2} g^{AD}(g_{BD,C} + g_{DC,B} - g_{BC,D}) \tag{A11}$$

with the nonzero components

$$\Gamma^\theta{}_{\phi\phi} = \cosh\theta \sinh\theta, \tag{A12}$$

$$\Gamma^\phi{}_{\theta\phi} = \Gamma^\phi{}_{\phi\theta} = \frac{\sinh\theta}{\cosh\theta}. \tag{A13}$$

The wave operator (Laplace–Beltrami) is then

$$\Box f = g^{AB}\nabla_A\nabla_B f = g^{AB}\left(\frac{\partial}{\partial\xi^A}\frac{\partial}{\partial\xi^B} - \Gamma^C{}_{AB}\frac{\partial}{\partial\xi^C}\right) f \tag{A14}$$

$$= -\frac{1}{R^2}\left(\frac{1}{\cosh\theta}\frac{\partial}{\partial\theta}\theta\frac{\partial}{\partial\theta} - \frac{1}{\cosh^2\theta}\frac{\partial^2}{\partial\phi^2}\right) f, \tag{A15}$$

Apart from the above intrinsic structures, the extrinsic curvature $K_A{}^B$ of the imbedding of de Sitter space into Minkowski space may be calculated, see Lemma 3.

Symmetries

The de Sitter spacetime is a homogeneous space with respect to the Lorentz group of the embedding space. The Lorentz group is generated by boosts and rotations. The generators can be given explicitly, decorated for convenience by a double index: rotation with axis x^0,

$$L_{21} = x^1\frac{\partial}{\partial x^2} - x^2\frac{\partial}{\partial x^1} = \frac{\partial}{\partial\phi}; \tag{A16}$$

boost with axis x^1,

$$L_{02} = x^0\frac{\partial}{\partial x^2} + x^2\frac{\partial}{\partial x^0} = \sin\phi\frac{\partial}{\partial\theta} + \cos\phi\tanh\theta\frac{\partial}{\partial\phi}; \tag{A17}$$

boost with axis x^2,

$$L_{01} = x^0\frac{\partial}{\partial x^1} + x^1\frac{\partial}{\partial x^0} = \cos\phi\frac{\partial}{\partial\theta} - \sin\phi\tanh\theta\frac{\partial}{\partial\phi}. \tag{A18}$$

The generators satisfy the commutation relations

$$[L_{01}, L_{21}] = L_{02}, \tag{A19}$$

$$[L_{02}, L_{21}] = -L_{01}, \tag{A20}$$

$$[L_{01}, L_{02}] = L_{21}. \tag{A21}$$

The Casimir operator is

$$L^\bullet L_\bullet = -R^2\nabla^A\nabla_A. \tag{A22}$$

The action of (the double cover of) these symmetries on spinors and spinor fields is given in the next section, after a description of spinors.

Spinors on de Sitter space

It is possible to construct spinors either intrinsically or as seen from the Minkowski space into which the de Sitter geometry is embedded.

In both cases it is useful to fix a frame (triad).

For the extrinsic description we chose

$$b_i = \frac{\partial}{\partial x^i}. \tag{A23}$$

For the intrinsic description, only two vector fields e_0, e_2 are needed but for further calculations it is useful to add a third vector field e_1, normal to the manifold in embedding space. The resulting triad is then

$$e_0 = \frac{1}{R}\frac{\partial}{\partial \theta} = \frac{1}{R}\frac{\partial x^i}{\partial \theta}\frac{\partial}{\partial x^i}, \tag{A24}$$

$$e_1 = \frac{\partial}{\partial R} = \frac{1}{R}x^i\frac{\partial}{\partial x^i}, \tag{A25}$$

$$e_2 = \frac{1}{R\cosh\theta}\frac{\partial}{\partial \phi} = \frac{1}{R\cosh\theta}\frac{\partial x^i}{\partial \phi}\frac{\partial}{\partial x^i}, \tag{A26}$$

$$e_0 = \cosh\theta\frac{\partial}{\partial x^0} + \sinh\theta\cos\phi\frac{\partial}{\partial x^1} + \sinh\theta\sin\phi\frac{\partial}{\partial x^2}, \tag{A27}$$

$$e_1 = \sinh\theta\frac{\partial}{\partial x^0} + \cosh\theta\cos\phi\frac{\partial}{\partial x^1} + \cosh\theta\sin\phi\frac{\partial}{\partial x^2}, \tag{A28}$$

$$e_2 = -\sin\phi\frac{\partial}{\partial x^1} + \cos\phi\frac{\partial}{\partial x^2}. \tag{A29}$$

The two frames coincide for

$$\theta = 0, \quad \phi = 0. \tag{A30}$$

The triad can then be chosen to generate the corresponding Clifford algebra for the Clifford generators $\not{e}_\bullet$ by the anticommutation relations

$$\not{e}_i\not{e}_j + \not{e}_j\not{e}_i = g_{ij}\mathbf{1}. \tag{A31}$$

The same anticommutation relations are satisfied by the Clifford generators corresponding to $b_\bullet$ but usually denoted by $\gamma_\bullet$ rather than by $\not{b}_\bullet$. One is free to choose a basis in the spinor space and this freedom will be used here to get the following representation of the Clifford generators $\gamma_\bullet$ (and similarly for $\not{e}_\bullet$):

$$\gamma_0 = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad \gamma_1 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \gamma_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \tag{A32}$$

The choice was made in such a way as to make γ_0 diagonal which seems to be useful in later computations.

Intrinsic description

The vectors e_0, e_2 are inside the de Sitter space and e_1 is orthogonal to it. e_1 can of course not be part of an intrinsic description but is useful for matters of comparison with extrinsic calculations.

The intrinsic spin connection D_A can be calculated from the connection form

$$\omega^b_{Ac} = e^b_B \nabla_A e^B_c = e^b_B \partial_A e^B_c + e^b_C \Gamma^{CB}{}_A e^B_c . \tag{A33}$$

The forms

$$e^0 = R\, d\theta, \tag{A34}$$

$$e^2 = R \cosh\theta\, d\phi \tag{A35}$$

are a basis dual to e_0, e_2,

$$\omega^0_{A2} = e^0_B \nabla_A e^B_2 = \underbrace{e^0_B \partial_A e^B_2}_{0} + e^0_C \Gamma^C{}_{AB} e^B_2 = \frac{1}{\cosh\theta} \Gamma^\theta{}_{A\phi} = \frac{1}{\cosh\theta} d\phi\, \Gamma^\theta{}_{\phi\phi} = \sinh\theta\, d\phi, \tag{A36}$$

$$\nabla_0 e_0 = 0, \quad \nabla_0 e_2 = 0, \tag{A37}$$

$$\nabla_2 e_0 = \frac{1}{R} \tanh\theta e_2, \quad \nabla_2 e_2 = \frac{1}{R} \tanh\theta e_0 . \tag{A38}$$

From the (tangent space) connection form ω_A, the spin connection form ω^S_A can be obtained as

$$\omega^S_A = \frac{1}{4} \omega^b_{Ac} \not{e}_b \not{e}^c = \frac{1}{2} \not{e}_0 \not{e}^2 \sinh\theta d\phi = \frac{1}{2} \not{e}_0 \not{e}^2 \sinh\theta \frac{e^2}{R\cosh\theta}. \tag{A39}$$

The intrinsic Dirac operator is then

$$\not{D} = \not{e}^a D_a = \not{e}^0 \frac{1}{R} \frac{\partial}{\partial\theta} + \not{e}^2 \frac{1}{R\cosh\theta} \frac{\partial}{\partial\phi} + \frac{1}{2R} \not{e}^0 \tanh\theta. \tag{A40}$$

Extrinsic description

Definition 5. *Let M be given as a submanifold in $\mathbb{R}^{n+1}$ of codimension 1, equipped with the metric induced from a global (translation invariant) metric on $\mathbb{R}^{n+1}$. The* **Levi-Civita covariant spin derivative** *(in an extrinsic basis) along a line parametrized by λ is given by*

$$\nabla_{d/d\lambda} \psi = \frac{d\psi}{d\lambda} + \frac{1}{2} \not{n} \frac{d\not{n}}{d\lambda}. \tag{A41}$$

This may be used to define an extrinsic Dirac operator, as discussed in the next section.

Comparison of extrinsic and intrinsic calculations

The intrinsic calculations proceed from the extrinsic point of view in a moving frame $e_\bullet$, related to the global frame $b_\bullet$ by orthogonal transformations. It is thus useful to know the spin matrices implementing those orthonormal transformations on spinor space.

The generators of rotations and boosts in spinor space can be constructed out of the Clifford generators γ_i by

$$\omega_{ij} = \tfrac{1}{4}[\gamma_i, \gamma_j]. \tag{A42}$$

The Clifford generators γ_i satisfy

$$[\gamma_0,\gamma_1]=2\gamma_2, \tag{A43}$$

$$[\gamma_0,\gamma_2]=-2\gamma_1, \tag{A44}$$

$$[\gamma_1,\gamma_2]=-2\gamma_0. \tag{A45}$$

It follows for the generators of rotations and boosts on the spinor space

$$[\omega_{01},\omega_{21}]=-\omega_{02}, \tag{A46}$$

$$[\omega_{02},\omega_{21}]=\omega_{01}, \tag{A47}$$

$$[\omega_{01},\omega_{02}]=-\omega_{21}. \tag{A48}$$

These are the commutation relations of the Lie algebra $\mathrm{sl}_2(\mathbb{R})$ [see Sec. IV for additional facts on $\mathrm{sl}_2(\mathbb{R})$ and on the corresponding Lie group $\mathrm{Sl}_2(\mathbb{R})$], the generators of (the double cover of) the group of Lorentz transformations.

The boost and rotation spin matrices are

$$S_{01-\mathrm{boost}}=\begin{pmatrix} e^{\theta/2} & 0 \\ 0 & e^{-\theta/2}\end{pmatrix},\quad S^{-1}_{01-\mathrm{boost}}=\begin{pmatrix} e^{-\theta/2} & 0 \\ 0 & e^{\theta/2}\end{pmatrix}, \tag{A49}$$

$$S_{02-\mathrm{boost}}=\begin{pmatrix} \cosh\left(\frac{\theta}{2}\right) & \sinh\left(\frac{\theta}{2}\right) \\ \sinh\left(\frac{\theta}{2}\right) & \cosh\left(\frac{\theta}{2}\right)\end{pmatrix},\quad S^{-1}_{02-\mathrm{boost}}=\begin{pmatrix} \cosh\left(\frac{\theta}{2}\right) & -\sinh\left(\frac{\theta}{2}\right) \\ -\sinh\left(\frac{\theta}{2}\right) & \cosh\left(\frac{\theta}{2}\right)\end{pmatrix}, \tag{A50}$$

$$S_{12-\mathrm{rotation}}=\begin{pmatrix} \cos\left(\frac{\phi}{2}\right) & \sin\left(\frac{\phi}{2}\right) \\ -\sin\left(\frac{\phi}{2}\right) & \cos\left(\frac{\phi}{2}\right)\end{pmatrix},\quad S^{-1}_{12-\mathrm{rotation}}=\begin{pmatrix} \cos\left(\frac{\phi}{2}\right) & -\sin\left(\frac{\phi}{2}\right) \\ \sin\left(\frac{\phi}{2}\right) & \cos\left(\frac{\phi}{2}\right)\end{pmatrix}. \tag{A51}$$

As the fact that the frames $b_\bullet$, $e_\bullet$ agree in a point [see (A30)] and from the knowledge of the spin matrices, the the transformation from $b_\bullet$ the global frame of Minkowski space to a local frame $e_\bullet$ can be calculated as $S_{\theta,\phi}=S_{12-\mathrm{rotation}}S_{01-\mathrm{boost}}$,

$$S_{\theta,\phi}=\begin{pmatrix} e^{\theta/2}\cos\left(\frac{\phi}{2}\right) & \frac{\sin(\phi/2)}{e^{\theta/2}} \\ -\left(e^{\theta/2}\sin\left(\frac{\phi}{2}\right)\right) & \frac{\cos(\phi/2)}{e^{\theta/2}}\end{pmatrix},\quad S^{-1}_{\theta,\phi}=\begin{pmatrix} \frac{\cos(\phi/2)}{e^{\theta/2}} & -\left(\frac{\sin(\phi/2)}{e^{\theta/2}}\right) \\ e^{\theta/2}\sin\left(\frac{\phi}{2}\right) & e^{\theta/2}\cos\left(\frac{\phi}{2}\right)\end{pmatrix}. \tag{A52}$$

This is the spin matrix that allows an explicit comparison of extrinsic and intrinsic calculations.

At times, it is also useful to know the spin matrix implementing the reflection exchanging b_1 and b_2:

$$S_{1\leftrightarrow 2}=S^{-1}_{1\leftrightarrow 2}=\begin{pmatrix} -1 & 1 \\ 1 & 1\end{pmatrix}. \tag{A53}$$

The full action of the symmetry group $\mathrm{Sl}_2(\mathbb{R})$ on spinor fields is given by the simultaneous action on the spinor space and on the spacetime manifold. The full symmetry generators are

$$T_{ij} = -L_{ij} + \omega_{ij} \tag{A54}$$

and satisfy the commutation relations

$$[T_{01}, T_{21}] = -T_{02}, \tag{A55}$$

$$[T_{02}, T_{21}] = T_{01}, \tag{A56}$$

$$[T_{01}, T_{02}] = -T_{21} \tag{A57}$$

analogous to (A19)–(A21) and (A46)–(A48). From the point of view of representation theory, it is useful to work with the rising and lowering operators

$$T_{\pm} = T_{01} \mp i T_{02}, \tag{A58}$$

satisfying

$$[T_{\pm}, T_{21}] = -T_{02} \mp i T_{01} = \mp T_{\pm}, \tag{A59}$$

$$[T_{+}, T_{-}] = -2i T_{21}. \tag{A60}$$

The Dirac operator on de Sitter space

In the following, it is shown that the Dirac operator on Minkowski space commutes with the generators of the Lorentz group action on Minkowski space spinors. Then the Dirac operator on a surface of codimension 1 in flat space is defined and re-expressed in terms of the intrinsic curvature of the surface and calculated for spacelike hyperboloids in Minkowski space. It is further shown that the Dirac operators on the hyperboloids also commute with the generators of the Lorentz group.

Lemma 2. *The Dirac operator* $\not{D}_M = \gamma^i \partial_i$ *commutes with the symmetry generators* $T_{ij} = -L_{ij} + \omega_{ij}$.

Proof. By definition

$$L_{ij} = x^k g_{k[i} \partial_{j]} \quad \text{with } g_{k[i} \partial_{j]} = g_{ki} \partial_j - g_{kj} \partial_i, \tag{A61}$$

$$\omega_{ij} = \tfrac{1}{4}[\gamma_i, \gamma_j]. \tag{A62}$$

A direct calculation gives then

$$[\not{D}_M, T_{ij}] = -\gamma^l (\partial_l L^k_{ij}) \partial_k - [\omega_{ij}, \gamma^k] \partial_k = \underbrace{(\gamma_i \delta^k_j - \gamma_j \delta^k_i - \tfrac{1}{4}[[\gamma_i, \gamma_j], \gamma^k])}_{\text{vanishes}} \partial_k. \tag{A63}$$

The coordinates of the commutator vanish for the following reasons.

If $i = j$ then it vanishes due to antisymmetry in i, j.

If i, j, k are all different then the Kronecker δs vanish and $[\gamma_i, \gamma_j]$ commutes with γ_k, thus everything vanishes.

If $k = i \neq j$ then δ^k_j vanishes and

$$[[\gamma_i, \gamma_j], \gamma^k] = 2[\gamma_i \gamma_j, \gamma^k] = -2\{\gamma_i, \gamma^k\} \gamma_j = -4 \delta^k_i \gamma_j,$$

and the resulting term cancels with $-\gamma_j \delta^k_i$.

If $k = j \neq i$ then use antisymmetry in i, j to transform it into the previous case.

Definition 6. (*The Dirac operator on a surface of codimension 1.*) *Let e_A be a Vielbein on the $n-1$-dimensional surface in n-dimensional flat space and let $\gamma^\bullet$ be global generators of the global Clifford algebra. Then the Dirac operator on the surface is given by*

$$\not{D} = \gamma^A e_A^B \nabla_B , \tag{A64}$$

where $\nabla_\bullet$ is the extrinsic connection of Definition 5.

A direct calculation, using the definition $K_A{}^B := e_A^C \partial_C n^B$ of the extrinsic curvature $K_A{}^B$ gives

$$\not{D}\psi = \gamma^A e_A^B \partial_B \psi + \tfrac{1}{2}\gamma^A e_A^B \not{n} \partial_B \not{n} \psi \tag{A65}$$

$$= \not{e}^B \partial_B \psi + \tfrac{1}{2} \underbrace{\not{e}^B \not{n}}_{\text{anticommute}} \partial_B \not{n} \psi \tag{A66}$$

$$= \not{e}^B \partial_B \psi - \tfrac{1}{2} \not{n} \underbrace{\not{e}^B \partial_B \not{n}}_{\not{e}^A K_{AB} \not{e}^B} \tag{A67}$$

$$= \not{e}^B \partial_B \psi - \tfrac{1}{2} K_A{}^A \not{n} . \tag{A68}$$

In the following lemma, the needed extrinsic curvature is calculated.

Lemma 3. *The extrinsic curvature tensor $K_A{}^B$ and its trace $K_A{}^A$ of the hyperboloid $-(x^0)^2 + \Sigma_i (x^i)^2 = R^2$ in n-dimensional Minkowski space are given by*

$$K_A{}^B = \frac{1}{R} \delta_A^B , \tag{A69}$$

$$K_A{}^A = \frac{n-1}{R} . \tag{A70}$$

Proof. Due to the transitive action of the symmetries on the hyperboloid, it is sufficient to calculate the formulas in one point only which may conveniently be chosen to be

$$x^\alpha = (0, R, 0, 0, \ldots, 0)$$

with normalized coordinates around this point,

$$x^A = \frac{1}{R}(x^0, x^2, x^3, \ldots, x^{n-1}),$$

and with the normal vector

$$n^\alpha = \frac{1}{R}(x^0, x^1 x^2, x^3, \ldots, x^{n-1}).$$

Then a simple calculation gives

$$K_A{}^B = \frac{dn^B}{dx^A} = \frac{1}{R} \delta_A^B . \tag{A71}$$

Corollary 4. On the hyperboloid $-(x^0)^2 + \Sigma_i (x^i)^2 = R^2$ in n-dimensional Minkowski space, the Dirac operator $\not{D}$ is given by

$$\not{D} = \not{e}^B \partial_B - \frac{n-1}{2R} \not{n}. \tag{A72}$$

Corollary 5. On the hyperboloid $-(x^0)^2+(x^i)^2=R^2$ *in n-dimensional Minkowski space, the Dirac operator* $\not{D}$ *can be induced from the Dirac operator* $\not{D}_M$ *on Minkowski space by extending the spinors outside the hyperboloid by (value on hyperboloid)*$\times e^{-n-1/2R(r-R)}$ *along the rays* λx^α, *with r being the spacetime interval as measured form the origin.*

Corollary 6. The Dirac operator $\not{D}$ *on the hyperboloid commutes with the symmetry generators* T_{ij}.

Proof. Note first that the symmetry generators T_{ij} preserve the hyperboloid $-(x^0)^2+(x^i)^2=R^2$ in n-dimensional Minkowski space. The Minkowski space Dirac operator $\not{D}_M$ commutes with the symmetry generators T_{ij}. From the previous corollary, $\not{D}$ can be understood to be a restriction of $\not{D}_M$ to a subset of functions behaving radially as $e^{-(n-1)/2R(r-R)}$.

The implementation of symmetries on the spinor field on de Sitter

The de Sitter hyperboloid embedded in Minkowski space is left invariant under the action of the Lorentz group and thus an an action of the Lorentz group can be given on spinor fields on this hyperboloid.

A representation of the Lorentz group can be given by restricting to the spinor fields ψ which are solutions of the Dirac equation:

$$(\not{D} - m)\psi = 0. \tag{A73}$$

This is reasonable, since the Dirac operator commutes with the generators of the Lorentz group and since the space of solutions of the Dirac equation is equipped with an invariant sesquilinear positive definite inner product:

$$(\psi_1, \psi_2) = \int_\Sigma \overline{\psi_1 \gamma^A} \psi_2 \, d_A\Sigma, \tag{A74}$$

with Σ being an arbitrary spacelike Cauchy surface on the hyperboloid.

The Hilbert space of the representation is then the classical phase space of spinor fields, the space of initial values of the spinor field on a Cauchy surface satisfying the Dirac equation. In order to give the action of the Lorentz group on the initial values, the Dirac equation has to be used.

The Cauchy hypersurface will be taken a sphere S^{n-2} on the hyperboloid at $x^0=$constant. It has a normal vector $\vec{n}=1/R\,(x^0,x^1,\ldots,x^{n-1})$ and an (unnormalized) spatial normal vector $\vec{r}=(0,x^1,\ldots,x^{n-1})$. The time evolution vector will be taken as

$$\frac{\partial}{\partial t} := e_0 = \frac{1}{R}\frac{\partial}{\partial \theta} = \cosh\theta \frac{\partial}{\partial x^0} + \sinh\theta \frac{\vec{r}}{|\vec{r}|} \tag{A75}$$

$$= \frac{1}{\cosh\theta}\left(\frac{\partial}{\partial x^0} + \sinh\theta \vec{n}\right). \tag{A76}$$

The Dirac operator can then be written as

$$\not{D} = \not{e}^0 \partial_t + \not{e}^I \partial_I - \frac{n-1}{2R}\not{n}, \tag{A77}$$

and using the Dirac equation

$$(\not{D} - m)\psi = 0, \tag{A78}$$

the infinitesimal time evolution can be given as

$$\partial_t = [\not{e}_J, \not{e}_0] g^{JI} \partial_I + \frac{n-1}{2R} \not{e}_0 \not{n} + m \not{e}_0 \tag{A79}$$

$$= \underbrace{\frac{\not{n}}{R \cosh\theta} L_{21} + \frac{1}{R} \not{e}_0 \not{n} + m \not{e}_0}_{\text{for 2-dim. de Sitter space}}. \tag{A80}$$

The generators T_{ij} of the Lorentz transformations in three-dimensional Minkowski space acting on spinor fields on the de Sitter space of radius R can now be expressed in terms of ∂_t, ∂_ϕ which in turn can be expressed in terms of the Cartan subalgebra generator T_{21}, eliminating all derivatives in the following formulas:

$$\frac{\partial}{\partial t} = \frac{\not{n}}{R \cosh\theta} (L_{21} - \not{e}_0 \cosh\theta) + m \not{e}_0 \tag{A81}$$

$$= \frac{\not{n}}{R \cosh\theta} \left(- T_{21} + \frac{1}{2} \gamma_0 - \not{e}_0 \cosh\theta \right) + m \not{e}_0, \tag{A82}$$

$$\frac{\partial}{\partial \phi} = - T_{21} + \frac{1}{2} \gamma_0, \tag{A83}$$

$$\omega_{21} = \tfrac{1}{2} \gamma_0, \tag{A84}$$

$$\omega_{02} = - \tfrac{1}{2} \gamma_1, \tag{A85}$$

$$\omega_{01} = \tfrac{1}{2} \gamma_2, \tag{A86}$$

$$L_{21} = \frac{\partial}{\partial \phi}, \tag{A87}$$

$$L_{02} = R \sin\phi \frac{\partial}{\partial t} + \cos\phi \tanh\theta \frac{\partial}{\partial \phi}, \tag{A88}$$

$$L_{01} = \cos\phi \frac{\partial}{\partial \theta} - \sin\phi \tanh\theta \frac{\partial}{\partial \phi}, \tag{A89}$$

$$T_{21} = - \frac{\partial}{\partial \phi} + \frac{1}{2} \gamma_0, \tag{A90}$$

$$T_{02} = - R \sin\phi \frac{\partial}{\partial t} - \cos\phi \tanh\theta \frac{\partial}{\partial \phi} - \frac{1}{2} \gamma_1, \tag{A91}$$

$$T_{01} = - R \cos\phi \frac{\partial}{\partial t} + \sin\phi \tanh\theta \frac{\partial}{\partial \phi} + \frac{1}{2} \gamma_2. \tag{A92}$$

There are now two natural bases in the space of spinors on $S^{n-2}(x^0) = S^1(x^0)$, namely the eigenbasis $|L{:}n, \pm\rangle$ of L_{21} and the eigenbasis $|T{:}n, \pm\rangle$ of T_{21}. The first choice looks to be simpler, if written in the local basis of eigenvectors of γ_0:

$$|L{:}n,+\rangle=\begin{pmatrix} e^{in\phi} \\ 0 \end{pmatrix}, \tag{A93}$$

$$|L{:}n,-\rangle=\begin{pmatrix} 0 \\ e^{-in\phi} \end{pmatrix}. \tag{A94}$$

with n being integers $\dots,-2,-1,0,+1,+2,\dots$ and is maybe somewhat easier to visualize. Compare it with the second basis

$$|T{:}n,+\rangle=\begin{pmatrix} e^{-i(n-1/2)\phi} \\ 0 \end{pmatrix}, \quad |T{:}n,-\rangle=\begin{pmatrix} 0 \\ e^{-i(n+1/2)\phi} \end{pmatrix}, \tag{A95}$$

with n being half-integers $\dots,-\frac{5}{2},-\frac{3}{2},-\frac{1}{2},+\frac{1}{2},+\frac{3}{2},+\frac{5}{2},\dots$.

However it is more appropriate to use the second one since it is the full symmetry generators T_{ij} that are to play the key role in the representation theory of the symmetry group; the generators L_{ij} may not exist on the spinor bundle of a higher dimensional example, due to its nontriviality and is thus not the right concept to be used. To give a meaning to L_{ij} one would have to enlarge the spinor bundle, e.g., by adding to it an inverse bundle.

Note 3. For the reasons given above, the calculations of the action of the symmetry generators $T_{\bullet}$ will be continued in the basis $|T{:}n,\pm\rangle$. But for completeness, analogous results in the basis $|L{:}n,\pm\rangle$ are stated here, in advance,

$$T_{21}|L{:}n,+\rangle=\frac{i}{2}(1-2n)|L{:}n,+\rangle,$$

$$T_{21}|L{:}n,-\rangle=\frac{i}{2}(-1-2n)|L{:}n,-\rangle,$$

$$T_{01}|L{:}n,+\rangle=\tfrac{1}{2}[n|L{:}n,-\rangle+(n-1)|L{:}n-2,-\rangle-is|L{:}n+1,+\rangle-is|L{:}n-1,+\rangle],$$

$$T_{01}|L{:}n,-\rangle=\tfrac{1}{2}[-n|L{:}n,+\rangle-(n+1)|L{:}n+2,+\rangle+is|L{:}n+1,-\rangle+is|L{:}n-1,-\rangle],$$

$$T_{02}|L{:}n,+\rangle=\frac{i}{2}[-n|L{:}n,-\rangle+(n-1)|L{:}n-2,-\rangle+is|L{:}n+1,+\rangle-is|L{:}n-1,+\rangle],$$

$$T_{02}|L{:}n,-\rangle=\frac{i}{2}[-n|L{:}n,+\rangle+(n+1)|L{:}n+2,+\rangle-is|L{:}n+1,-\rangle+is|L{:}n-1,-\rangle],$$

$$T_{+}|L{:}n,+\rangle=(n-1)|L{:}n-2,-\rangle-is|L{:}n-1,+\rangle, \tag{A96}$$

$$T_{+}|L{:}n,-\rangle=-n|L{:}n,+\rangle+is|L{:}n-1,-\rangle, \tag{A97}$$

$$T_{-}|L{:}n,+\rangle=n|L{:}n,-\rangle-is|L{:}n+1,+\rangle, \tag{A98}$$

$$T_{-}|L{:}n,-\rangle=-(n+1)|L{:}n+2,+\rangle+is|L{:}n+1,-\rangle. \tag{A99}$$

We now proceed with the calculation of the action of the $\mathrm{sl}_2(\mathbb{R})$-symmetries (Lorentz symmetries) on the space of solutions of the Dirac equation in the basis $|T{:}n,\bullet\rangle$.

By definition,

$$T_{21}|T{:}n,\pm\rangle=in|T{:}n,\pm\rangle, \tag{A100}$$

$$\not{e}_0 = \cosh\theta \underbrace{\not{b}^0}_{=\gamma^0} + \sinh\theta \frac{\vec{\not{r}}}{R}, \tag{A101}$$

$$\not{n} = \sinh\theta \not{b}^0 + \cosh\theta \frac{\vec{\not{r}}}{R}, \tag{A102}$$

$$\frac{\vec{\not{r}}}{R} := \frac{x^1}{R}\gamma_1 + \frac{x^2}{R}\gamma_2 = e^{i\phi}(\gamma_1 - i\gamma_2) + e^{-i\phi}(\gamma_1 + i\gamma_2) \tag{A103}$$

$$= -ie^{i\phi}\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} + ie^{-i\phi}\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}. \tag{A104}$$

The actions on the basis are

$$\frac{\vec{\not{r}}}{R}|T{:}n,\pm\rangle := \pm i|T{:}n,\mp\rangle, \tag{A105}$$

$$\not{e}_0|T{:}n,\pm\rangle := \pm i\cosh\theta|T{:}n,\pm\rangle \pm i\sinh\theta|T{:}n,\mp\rangle, \tag{A106}$$

$$\not{n}|T{:}n,\pm\rangle := \pm i\sinh\theta|T{:}n,\pm\rangle \pm i\cosh\theta|n,\mp\rangle. \tag{A107}$$

A direct calculation of $\partial/\partial\theta = R\,(\partial/\partial t)$ from (A82) using (A104)–(A106) gives

$$\frac{\partial}{\partial\theta}|T{:}n,\pm\rangle = \left(\left(\pm n - \frac{1}{2}\right)\tanh\theta \pm iRm\cosh\theta\right)|T{:}n,\pm\rangle \tag{A108}$$

$$+\left(\left(\pm n + \frac{1}{2}\right) \pm iRm\sinh\theta\right)|T{:}n,\mp\rangle, \tag{A109}$$

$$T_+|T{:}n,\pm\rangle = [(n+\tfrac{1}{2})\tanh\theta(1\mp 1) \mp iRm\cosh\theta]|T{:}n+1,\pm\rangle \tag{A110}$$

$$\mp[n+\tfrac{1}{2}+iRm\sinh\theta]|T{:}n+1,\mp\rangle, \tag{A111}$$

$$T_-|T{:}n,\pm\rangle = [-(n-\tfrac{1}{2})\tanh\theta(1\pm 1) \mp iRm\cosh\theta]|T{:}n-1,\pm\rangle \tag{A112}$$

$$\mp[n-\tfrac{1}{2}+iRm\sinh\theta]|T{:}n-1,\mp\rangle. \tag{A113}$$

In matrix notation, on the subspace $|T{:}n,\bullet\rangle$, one gets

$$T_+(n) = \begin{pmatrix} -iRm\cosh\theta & n+\frac{1}{2}+iRm\sinh\theta \\ -(n+\frac{1}{2}+iRm\sinh\theta) & 2(n+\frac{1}{2})\tanh\theta + iRm\cosh\theta \end{pmatrix} u, \tag{A114}$$

$$T_-(n) = \begin{pmatrix} -2(n-\frac{1}{2})\tanh\theta - iRm\cosh\theta & n-\frac{1}{2}+iRm\sinh\theta \\ -(n-\frac{1}{2}+iRm\sinh\theta) & iRm\cosh\theta \end{pmatrix} u^*, \tag{A115}$$

and the time vector $\not{e}_0$ is given by

$$\not{e}_0 = i\begin{pmatrix} \cosh\theta & -\sinh\theta \\ \sinh\theta & -\cosh\theta \end{pmatrix}. \tag{A116}$$

These matrices are understood to be given with respect to the basis $|T{:}n,\pm\rangle$. This basis is however not orthonormal. In order to find an orthogonal basis which would be suitable for comparison with representation–theoretic calculations, the structure of the inner product on the space of spinor fields has to be clarified.

Spacetime spinor fields are equipped with a Hermitean inner product, the Dirac product $B(\bullet,\bullet)$ which is given as the intertwiner B

$$\gamma_\mu^+ B = -B\gamma_\mu, \tag{A117}$$

$$B = \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix}, \tag{A118}$$

so that the inner product can be calculated as

$$B(\psi,\varphi) = (\overline{\psi}_1 \quad \overline{\psi}_2)\begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix}\begin{pmatrix} \varphi_1 \\ \varphi_2 \end{pmatrix}. \tag{A119}$$

Note 4. There is a second possibility to choose a Hermitean inner product A by taking the opposite sign in the intertwining relation:

$$\gamma_\mu^+ A = +A\gamma_\mu. \tag{A120}$$

But this is irreconcilable with other choices already made or to be required, in particular, the Dirac operator was defined to be $\not{D} = \gamma^\mu \partial_\mu$ rather than $i\gamma^\mu\partial_\mu$; the Dirac equation was chosen to be $(\not{D} - m)\psi = 0$; the Dirac operator is required to be formally self-adjoint,

$$B(\psi, \not{D}\varphi) - B(\not{D}\psi, \varphi) = \partial_\mu B(\psi, \gamma^\mu \varphi);$$

The physical time directions given by the metric are negative definite (rather than positive definite), i.e., $p_\mu p^\mu = -m^2$ for an approximate plane wave (rather than $p_\mu p^\mu = +m^2$)

It follows from the global hyperbolicity of the spacetime and the formal self-adjointness of the Dirac operator that the following is a well-defined Hermitean inner product on the space of solutions of the Dirac equation, independent of the spacelike Cauchy surface Σ, see (A74):

$$(\psi,\varphi) = \int_{S^1(\theta = \text{constant})} B(\psi(\phi), e^0 \varphi(\phi))\, d\phi. \tag{A121}$$

With respect to this inner product, the normalized eigenvectors $e_{\pm i}$ of $\not{e}_0$ for the eigenvalues $\pm i$ are

$$e_{\pm i} = \frac{1}{\sqrt{2\cosh\theta \pm 2}}\begin{pmatrix} \cosh\theta \pm 1 \\ \sinh\theta \end{pmatrix}, \tag{A122}$$

and in this orthogonal eigenbasis of $\not{e}_0$ we have

$$\not{e}_0 = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \tag{A123}$$

$$\not{e}_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \tag{A124}$$

$$T_+(n)=\begin{pmatrix} -iRm+(n+\frac{1}{2})\tanh\theta & \frac{1}{\cosh\theta}(n+\frac{1}{2}) \\ -\frac{1}{\cosh\theta}(n+\frac{1}{2}) & iRm+(n+\frac{1}{2})\tanh\theta \end{pmatrix}, \tag{A125}$$

$$T_-(n)=\begin{pmatrix} -iRm-(n-\frac{1}{2})\tanh\theta & \frac{1}{\cosh\theta}(n-\frac{1}{2}) \\ -\frac{1}{\cosh\theta}(n-\frac{1}{2}) & iRm-(n-\frac{1}{2})\tanh\theta \end{pmatrix}, \tag{A126}$$

and in particular

$$u_+=T_+(+\tfrac{1}{2})=\begin{pmatrix} -iRm+\tanh\theta & \frac{1}{\cosh\theta} \\ -\frac{1}{\cosh\theta} & iRm+\tanh\theta \end{pmatrix}, \tag{A127}$$

$$u_-=T_-(-\tfrac{1}{2})=\begin{pmatrix} -iRm+\tanh\theta & -\frac{1}{\cosh\theta} \\ \frac{1}{\cosh\theta} & iRm+\tanh\theta \end{pmatrix}. \tag{A128}$$

These data may be compared with the data of the de Sitter spectral quadruples obtained in Sec. V.

(Received 14 November 2000; accepted for publication 22 October 2001)

The Darboux transformation applied recurrently on a Schrödinger operator generates what is called a *dressing chain*, or from a different point of view, a set of supersymmetric shape invariant potentials. The finite-gap potential theory is a special case of the chain. For the finite-gap case, the equations of the chain can be expressed as a time evolution of a Hamiltonian system. We apply Sklyanin's method of separation of variables to the chain. We show that the classical equation of the separation of variables is the Baxter T-Q relation after quantization. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1426689]

I. INTRODUCTION

What is the most universal method of solving completely integrable models? From Sklyanin's point of view[1] it is the separation of variables in its most general form. Therefore, it is desirable to understand old methods of integration in the light of the modern approach to the separation of variables. One of the most important ''old'' techniques applied with success to many physical and mathematical problems is the Darboux transformation. In short, the two main themes of this paper can be best described by two keywords: The Darboux transformation and the Sklyanin method of separation of variables. The Darboux transformation is a fundamental tool in the supersymmetric approach to quantum mechanics and in the theory of dressing chains.[2,3] Though our example is different from the DST model studied in Ref. 4, this paper and Ref. 4 are closely related. The Sklyanin method aims to connect the separation of variables as we know it from the Hamiltonian mechanics with the new techniques of exactly solving mathematical physics problem, namely the Inverse Scattering Method and its quantum version.[5] The worked example in this paper is the dressing chain representation of the finite-gap potential theory. We review the main ideas from the Darboux transformations with an emphasis on the Hamiltonian view-point on the finite-gap theory, following Veselov and Shabat.[2] We then work the Sklyanin method[1,6,7] on the finite-gap theory. We find the canonical separated variables for the dressing chain representation of the finite-gap potential theory. From the Quantum Inverse Scattering Theory point of view, the equation for the separated variables is the classical version of the Baxter T-Q equation. Then the quantum version of the finite-gap theory is presented, together with the corresponding R-matrix and the Baxter Q-operator. The conclusions and outlook will close the paper.

II. THE DARBOUX TRANSFORMATION AND THE HAMILTONIAN APPROACH FOR THE FINITE-GAP THEORY

Consider the Schrödinger operator for a potential $u(x)$, $\mathcal{H}=-D^2+u(x)$ where $D\equiv d/dx$. Factorize it as a product of two first order operators

$$\mathcal{H}=A^*A, \tag{2.1}$$

[a)]Electronic mail: olipan@hsph.harvard.edu
[b)]Electronic mail: crasinariu@popmail.colum.edu

where $A=D-f(x)$ and $A^*=-D-f(x)$. The Darboux transformation sends $\mathcal{H}_1=A^*A$ into $\mathcal{H}_2=AA^*+\alpha\mathbf{1}$ where $\mathbf{1}$ is the identity operator and α is a constant. The functions f_1 and f_2 obtained from the factorization

$$\mathcal{H}_i=-(D+f_i)(D-f_i), \tag{2.2}$$

are related by the equation

$$(f_1+f_2)'=f_1^2-f_2^2+\alpha, \tag{2.3}$$

where the prime means differentiation with respect to x. From the supersymmetric quantum-mechanics point of view, Eq. (2.3) is exactly the shape invariance condition,[3] written in terms of the superpotentials $W_i=-f_i$.

We can continue this process of factorization and Darboux transformation and obtain a chain of equations

$$(f_i+f_{i+1})'=f_i^2-f_{i+1}^2+\alpha_i \quad i=1,2,\ldots. \tag{2.4}$$

This chain is called a *dressing chain*. In what follows we will consider only periodic chains

$$f_i=f_{i+N}, \quad \alpha_i=\alpha_{i+N}, \tag{2.5}$$

where the period N is a positive integer. Supersymmetrically speaking, periodic chains correspond to the cyclic shape invariant potentials.[8] The properties of the dressing chain depend drastically on the period N and the sum $\alpha=\alpha_1+\cdots+\alpha_N$. There are four cases to be considered depending if N is even or odd and α is equal to zero or not. The finite-gap theory, to be studied in this paper, corresponds to the case N odd and $\alpha=0$. In this case the chain is a completely integrable Hamiltonian system. We will use for the case $\alpha=0$ instead of the constant α_i, the constants β_i related with α by $\beta_i-\beta_{i+1}=\alpha_i$. If we regard the variable x in $f_i(x)$ as a *time* variable, then the dressing chain expresses the time evolution of the variables $f_i(x)$, $i=1,\ldots,N$. Their evolution is generated by the Hamiltonian

$$H=\sum_{i=1}^{N}\left(\tfrac{1}{3}f_i^3+\beta_i f_i\right), \tag{2.6}$$

with the Poisson bracket

$$\{f_i,f_j\}=(-1)^{(j-i)\mathrm{mod}N}, \tag{2.7}$$

$$\{f_i,f_i\}=0. \tag{2.8}$$

This Poisson bracket is not canonical. To obtain canonical variables, first let us denote by g_i a set of variables defined by

$$g_i=f_i+f_{i+1}, \tag{2.9}$$

with the Poisson structure

$$\{g_i,g_{i-1}\}=1, \tag{2.10}$$

all other brackets being zero. Though the variables g_i seem to be redundant at this point, later on they will prove to be useful. Now, the canonical variables (X_i,x_i)

$$\{X_i,X_j\}=\{x_i,x_j\}=0, \quad \{X_i,x_j\}=\delta_{ij}, \tag{2.11}$$

will generate the Poisson structure for the variables g_i if

$$g_i = X_i + x_{i+1}. \tag{2.12}$$

As we mentioned before, the finite-gap case ($N=2n+1=$odd) is completely integrable. Therefore, the Hamiltonian responsible for the time evolution belongs to a set of n-independent involutive Hamiltonians. To show this, we use the method of inverse scattering theory. The Lax matrix build on canonical variables (X_i, x_i) is

$$L_i^{(x)}(u) = \begin{pmatrix} x_i & 1 \\ x_i X_i + \beta_i + u & X_i \end{pmatrix}, \tag{2.13}$$

where $(x) \equiv (X_i, x_i)$ and u is a complex parameter. Then we construct the monodromy matrix

$$L^{(x)}(u) = \prod_{i=N}^{1} L_i^{(x)}(u) = L_N^{(x)}(u) L_{N-1}^{(x)}(u) \cdots L_1^{(x)}(u) \tag{2.14}$$

and take its trace

$$\tau_N(u) = TrL(u). \tag{2.15}$$

The trace $\tau_N(u)$ generates the set of involutive Hamiltonians

$$\tau_N(u) = H_1 u^n + H_3 u^{n-1} + \cdots + H_{2N+1}. \tag{2.16}$$

The Hamiltonian H_3 is just the Hamiltonian for the chain. The fact that the set of the Hamiltonians is involutive, is a consequence of the classical r-matrix identity. Denoting by id_2 the unit 2×2 matrix and introducing the notations for the tensor products $l^{(1)} = l \otimes id_2$, $l^{(2)} = id_2 \otimes l$, the r-matrix identity for the Lax matrices $l_i(u) = L_i^{(x)}(u)$

$$\{l_i^{(1)}(u_1), l_j^{(2)}(u_2)\} = [r_{12}(u_1 - u_2), l_i^{(1)}(u_1) l_i^{(2)}(u_2)]\delta_{ij}, \tag{2.17}$$

where

$$r_{12}(u) = -\frac{1}{u}\mathcal{P}_{12}, \tag{2.18}$$

and $\mathcal{P}_{12}$ is the permutation operator in $\mathbf{C}^2 \otimes \mathbf{C}^2$. It is important to notice that although the Lax matrix is written in terms of the variable (X,x), the Hamiltonians H_i (2.16) depend only on the variables g_i, $i=1,2,\ldots,N$. Moreover, it is possible to generate the Hamiltonians H_i as a trace of a monodromy matrix written directly in terms of the chain variables f_i

$$F(u) = \prod_{i=1}^{N} \begin{pmatrix} f_i & 1 \\ f_i^2 + \beta_i + u & f_i \end{pmatrix}, \tag{2.19}$$

$$\tau_N(u) = TrF(u). \tag{2.20}$$

The connection of the dressing chain with the finite-gap theory for the Schrödinger operators is described in Ref. 2. For the finite-gap theory see also[9,10] and the references therein. Here we will emphasize only those notions which will be important later on. To each solution $f_i(x)$ of the dressing chain, or in other words, to each solution of the time evolution of the Hamiltonian system, corresponds a sequence of N finite-gap Schrödinger operators

$$\mathcal{H}_i = -D^2 + u_i(x), \tag{2.21}$$

where the potentials $u_i(x)$ are given by

$$u_i = f_i' + f_i^2. \tag{2.22}$$

The spectral curve of these operators is the spectral curve of the monodromy matrix $F(u)$

$$\det(F(\lambda)-\mu\,\mathbf{1})=0, \tag{2.23}$$

where **1** is the unit matrix, and it can be written as

$$\mu^2-\tau_N(\lambda)\,\mu-\prod_{i=1}^{N}(\lambda+\beta_i)=0. \tag{2.24}$$

From the Darboux transformation we can obtain a recurrence relation between the logarithmic derivatives of the Bloch eigenfunctions. The Bloch eigenfunctions ψ_i of the operator $\mathcal{H}_i$ are given by

$$\mathcal{H}_i\psi_i=(\lambda+\beta_i)\psi_i\,. \tag{2.25}$$

Due to the Darboux transformation, two successive Bloch eigenfunctions are connected through

$$\psi_{i+1}=(D-f_i)\psi_i\,. \tag{2.26}$$

This implies that for the logarithmic derivatives $\chi_i=D\ln\psi_i$ we have the recurrence

$$\chi_i=f_i+\frac{\beta_i+\lambda}{f_i+\chi_{i+1}}. \tag{2.27}$$

III. SKLYANIN METHOD OF SEPARATION OF VARIABLES

To understand the Sklyanin method,[1,5–7] let us start with an old example. For a Hamiltonian of the form

$$H=\tfrac{1}{2}(p_1^2+\cdots+p_n^2)+\tfrac{1}{2}(\omega_1q_1^2+\cdots+\omega_nq_n^2), \tag{3.1}$$

we notice that the variables are not only *canonical*, $\{p_i,q_j\}=\delta_{ij}$ but also *separated*, i.e., each pair $(p_i(t),q_i(t))$ lies on the curve

$$p_i^2+\omega_iq_i^2=\text{const.} \tag{3.2}$$

In general, let us consider a Hamiltonian system having d degrees of freedom and integrable in Liouville's sense. This means that it is given a $2d$-dimensional symplectic manifold and d independent Hamiltonians H_i in involution

$$\{H_i,H_j\}=0,\quad i,j=1\cdots d. \tag{3.3}$$

A system of canonical variables $\lambda\equiv\{\lambda_i\}_{i=1}^d$ and $\mu\equiv\{\mu_i\}_{i=1}^d$ satisfying

$$\{\lambda_i,\lambda_j\}=\{\mu_i,\mu_j\}=0,\quad \{\lambda_i,\mu_j\}=\delta_{ij}\,, \tag{3.4}$$

will be called *separated* if there exists d relations of the form

$$W_j(\lambda_j,\mu_j,H_1,\ldots,H_d)=0. \tag{3.5}$$

For the dressing chain the variables (X,x) are canonical but not separated. We can raise then the question of how to find *canonical separated* variables for the dressing chain. If the integrable system is solvable via the Inverse Scattering Method then we can use a method proposed by Sklyanin to find the transformation from the canonical variables (X,x) to the canonical separated variables (λ,μ). The desired transformation will be obtained as a composition of Bäcklund transformations. The next section is devoted to the Bäcklund transformation for the dressing chain.

IV. BÄCKLUND TRANSFORMATIONS

Following Sklyanin, we need to find a canonical transformation (we will use also the name Bäcklund transformation) from the variables (X,x) to (Y,y). The important property is that the canonical transformation will depend on the spectral parameter λ. This parameter λ will allow us to find at the end the canonical separated variables. Being a canonical transformation, the Poisson structure and the set of Hamiltonians H_i must remain unchanged when expressed in the variable (Y,y). Since Lax matrix $L(u)$ is a monodromy matrix

$$L^{(x)}(u)=L_N^{(x)}(u)\cdots L_2^{(x)}(u)L_1^{(x)}(u), \tag{4.1}$$

we can transform the Lax matrices at each site $L_i^{(x)}(u)$

$$M_i(u-\lambda)L_i^{(x)}(u)=L_i^{(y)}(u)M_{i-1}(u-\lambda), \tag{4.2}$$

because the trace $\tau_N(u)$ is invariant due to $M_N(u-\lambda)L^{(x)}(u)=L^{(y)}(u)M_N(u-\lambda)$. To keep the same Poisson structure we ask that the matrices $M_i(u)$ should obey the same Poisson bracket (2.17) as $L_i(u)$ obeys. Practically, we first have to choose one out of many matrices which obeys the r-matrix Poisson bracket (2.17) and then be lucky enough to find that (4.2) has a solution $Y(X,x)$, $y(X,x)$ for every spectral parameter u. The solution will depend on the parameter λ which is exactly what we want. The technical way to solve (4.2) is quite interesting. The idea is to use, besides the phase spaces (X,x) and (Y,y), two more spaces: (S,s) and (T,t). The phase spaces (S,s) and (T,t) are auxiliary spaces, the Bäcklund transformation being between (X,x) and (Y,y). With the help of these auxiliary spaces, we can write a version of (4.2) as

$$M_i^{(s)}(u-\lambda)L_i^{(x)}(u)=L_i^{(y)}(u)M_i^{(t)}(u-\lambda). \tag{4.3}$$

To go back to (4.2) we simply need to impose the constraints

$$t_i=s_{i-1}, \quad T_i=S_{i-1}. \tag{4.4}$$

We apply now the above method to the dressing chain. The Lax matrix is

$$L_i^{(x)}(u)=\begin{pmatrix} x_i & 1 \\ x_iX_i+\beta_i+\lambda & X_i \end{pmatrix}. \tag{4.5}$$

Here (x) stands for the pair of variables (X,x) and u is the spectral parameter. We choose the matrix M to be identical with L. Because in (4.3) the index i is the same on both sides, we can drop it and write the matrix equation as

$$\begin{pmatrix} s & 1 \\ u-\lambda+sS & S \end{pmatrix}\begin{pmatrix} x & 1 \\ u+\beta+xX & X \end{pmatrix}=\begin{pmatrix} y & 1 \\ u+\beta+yY & Y \end{pmatrix}\begin{pmatrix} t & 1 \\ u-\lambda+tT & T \end{pmatrix}. \tag{4.6}$$

The solution to the system is

$$S=-x+\xi, \tag{4.7}$$

$$X=-s+\frac{\lambda+\beta}{t-x}, \tag{4.8}$$

$$T=-y+\frac{\lambda+\beta}{t-x}, \tag{4.9}$$

$$Y=-t+\xi. \tag{4.10}$$

We remark that ξ is a free variable. This is a consequence of the fact that the conserved Hamiltonians depend only on the combination X_i+x_{i+1}. The generating function $F_\lambda(y,t|x,s)$ is

$$F_\lambda(y,t|x,s)=y(t-\xi)-(x-\xi)s-(\lambda+\beta)\ln(t-x), \tag{4.11}$$

from which we get

$$X=\frac{\partial F_\lambda}{\partial x}, \quad S=\frac{\partial F_\lambda}{\partial s}, \tag{4.12}$$

$$Y=-\frac{\partial F_\lambda}{\partial y}, \quad T=-\frac{\partial F_\lambda}{\partial t}. \tag{4.13}$$

To simplify the formulas we choose the $\xi=x$. The generating function becomes

$$F_\lambda=y(t-x)-(\lambda+\beta)\ln(t-x). \tag{4.14}$$

The constrains $t_i=s_{i-1}$, $T_i=S_{i-1}$ give

$$X_i=-s_i+\frac{\lambda+\beta_i}{s_{i-1}-x_i}, \tag{4.15}$$

which can be solved, in principle, for s_i. Then

$$Y_i+y_{i+1}=X_{i+1}+x_i+s_{i+1}-s_{i-1}. \tag{4.16}$$

In terms of the old variables $g_i=X_i+x_{i+1}$ the transformation reads

$$g_i=z_i-\frac{\lambda+\beta_i}{z_{i-1}}, \tag{4.17}$$

$$\tilde{g}_i=g_{i+1}+z_{i-1}-z_{i+1}, \tag{4.18}$$

where $\tilde{g}_i$ are the transformed variables and

$$z_i=x_{i+1}-s_i. \tag{4.19}$$

Note that (4.17) and (4.18) are just the canonical transformations we were looking for. To obtain the concrete form of these transformations we need to solve (4.17) for z_i, and then to use these values to find $\tilde{g}_i$. Because for an arbitrary λ equation (4.17) cannot be explicitly solved, we leave the canonical transformation in an implicit form. However, for special values of λ, the canonical transformation can be explicitly solved, as we are going to exemplify in Sec. X, Eqs. (10.2)–(10.4).

The first equation in (4.17) is the discrete Riccati equation. It can be linearized with the help of the following change of variables:

$$z_i=\frac{\psi_{i+1}}{\psi_i}. \tag{4.20}$$

We obtain

$$\psi_{i+1}=\psi_i g_i+(\lambda+\beta_i)\psi_{i-1}, \quad i=0,\ldots,N. \tag{4.21}$$

The periodic boundary condition $z_0=z_N$ implies

$$\psi_1\psi_{N-1}=\psi_0\psi_N. \tag{4.22}$$

From (4.14), the generating function for the canonical transformation is

$$X_i=\frac{\partial\Phi_\lambda}{\partial x_i}, \tag{4.23}$$

$$Y_i=-\frac{\partial\Phi_\lambda}{\partial y_i}, \tag{4.24}$$

$$\Phi_\lambda(\boldsymbol{y},\boldsymbol{x})=\sum_{i=1}^{N} F_\lambda(y_i s_{i-1}|x_i s_i)=\sum_{i=1}^{N} y_i(s_{i-1}-x_i)-(\lambda+\beta_i)\ln(s_{i-1}-x_i). \tag{4.25}$$

Here we denote by $\boldsymbol{x}=(x_1,\ldots,x_N)$. Finally in terms of z_i the generating function can be written as

$$\Phi_\lambda(\boldsymbol{y},\boldsymbol{x})=\sum_{i=1}^{N} y_i(-z_{i-1})-(\lambda+\beta_i)\ln(-z_{i-1}). \tag{4.26}$$

V. CANONICAL TRANSFORMATIONS AND DARBOUX FACTORIZATION

To decipher the meaning of the variables z_i present in the canonical transformation (4.17) we will use the knowledge obtained from the Darboux method of factorization. First, from (4.17), find z_{i-1}

$$-z_{i-1}=\frac{\lambda+\beta_i}{g_i-z_i}. \tag{5.1}$$

Then, compare this result with formula (2.27) that gives the recurrence relation between two logarithmic derivatives of the Bloch eigenfunctions

$$\chi_i=f_i+\frac{\lambda+\beta_i}{f_i+\chi_{i+1}}. \tag{5.2}$$

We obtain thus

$$z_{i-1}=f_i-\chi_i, \tag{5.3}$$

which in terms of the superpotentials $W_i=-f_i$ reads as

$$-z_i=W_i+\chi_i.$$

Therefore the variable z_i taken with a minus sign, is the sum between the superpotential W_i and the logarithmic derivative of the Bloch eigenfunction. It is interesting to obtain the time evolution of the variables z_i. From

$$-\psi_i''+u_i\psi_i=(\lambda+\beta_i)\psi_i, \tag{5.4}$$

$$u_i=f_i'+f_i^2, \tag{5.5}$$

$$z_{i-1}'=f_i'-(\psi_i'/\psi_i)', \tag{5.6}$$

we get

$$z_{i-1}'=\chi_i^2-f_i^2+\lambda+\beta_i. \tag{5.7}$$

VI. SEPARATED CANONICAL VARIABLES

At this point we have the canonical Bäcklund transformations (4.17). Let us use the symbol B_λ for this transformation. Our goal is to find separated canonical variables. Following Sklyanin, we consider the composition $B_{\lambda_1\cdots\lambda_N}=B_{\lambda_1}\circ\cdots\circ B_{\lambda_N}$ of Bäcklund transformations and the corresponding generating function $F_{\lambda_1\cdots\lambda_N}(y,x)$. If we treat λ's as dynamical variables and y's as parameters then $F_{\lambda_1\cdots\lambda_N}(y,x)$ becomes the generating function of the N-parametric canonical transformation from (X,x) to (μ,λ) given by

$$X_i=\frac{\partial F_{\lambda_1\cdots\lambda_N}}{\partial x_i},\quad \mu_i=-\frac{\partial F_{\lambda_1\cdots\lambda_N}}{\partial \lambda_i}. \tag{6.1}$$

This transformation is not only canonical but also separates the variables. See Ref. 5 for details.

Each pair (λ_i,μ_i) lie on a curve given implicitly by

$$W(\lambda_i,\mu_i)=0. \tag{6.2}$$

To find the curve W we use the parameter μ which is the variable conjugated to λ

$$\mu=-\frac{\partial F_\lambda}{\partial\lambda}, \tag{6.3}$$

and search for a function $f(\mu)$ such that

$$\det(f(\mu)-L(\lambda))=0. \tag{6.4}$$

Then the spectral curve W is

$$W(\lambda_i,f(\mu_i);H_i)\equiv\det(f(\mu_i)-L(\lambda_i))=0. \tag{6.5}$$

For the dressing chain

$$f(\mu)=-e^\mu. \tag{6.6}$$

To prove this, we will show that $-e^\mu$ is an *eigenvalue* for $L(\lambda)$ so the property $\det(f(\mu)-L(\lambda))=0$ is immediate.

From the definition of μ (6.3) and from the generating function (4.26) we get

$$z_1\cdots z_N=-e^\mu. \tag{6.7}$$

Now, by a simple computation

$$L_i^{(x)}(\lambda)\begin{pmatrix}1\\-s_{i-1}\end{pmatrix}=z_{i-1}\begin{pmatrix}1\\-s_i\end{pmatrix}. \tag{6.8}$$

This proves that for $L=L_N\cdots L_1$ the eigenvalue is $z_1\cdots z_N$.

The spectral curve $W(\lambda,\mu)$ can be expressed in terms of the trace τ_N and β_i

$$\det(v-L(\lambda))=v^2-\tau_N(\lambda)\,v+\prod_{i=1}^{N}(\lambda+\beta_i), \tag{6.9}$$

so

$$e^{2\mu}+\tau_N(\lambda)\,e^\mu-\prod_{i=1}^{N}(\lambda+\beta_i)=0. \tag{6.10}$$

Here

$$\tau_N(\lambda)=H_1\lambda^n+H_3\lambda^{n-1}+\cdots+H_{2N+1}, \tag{6.11}$$

where $N=2n+1$ and $H_1,H_3,\ldots,H_{2N+1}$ are integrals of the chain.

VII. QUANTUM CASE

To get the quantum version of the theory described so far we will use the R-matrix approach. This will ensure the commutativity of the Hamiltonians H_i after quantization. From classical variables (x,X) we move to the quantum variables (x,∂_x). The local quantum Lax matrix

$$L(u|x,\partial_x)=\begin{pmatrix} x & 1 \\ u+x\partial_x & \partial_x \end{pmatrix}, \tag{7.1}$$

verifies the quantum commutation relation

$$R_{12}(u_1-u_2)L^{(1)}(u_1)L^{(2)}(u_2)=L^{(2)}(u_2)L^{(1)}(u_1)R_{12}(u_1-u_2), \tag{7.2}$$

where

$$R_{12}(u)=u+\mathcal{P}_{12}, \tag{7.3}$$

is the $SL(2)$-invariant solution to the quantum Yang–Baxter equation.[11] The monodromy operator and its trace are defined like in the classical case. The commutativity of the Hamiltonians H_i

$$[H_i,H_j]=0, \tag{7.4}$$

is a consequence of (7.2). The whole machinery of the Quantum Inverse Scattering Method can be put to work at this stage. We will limit to study only the Baxter Q-operator and the Baxter T-Q relation. The Q-operator will depend upon the spectral parameter λ. Let us denote it by $Q(\lambda)$. The interesting aspect is that the classical Bäcklund transformation B_λ is the classical limit of the similarity transformation

$$\mathcal{O}\rightarrow Q(\lambda)\mathcal{O}Q^{-1}(\lambda). \tag{7.5}$$

For details see Ref. 5. In the next section we will explicitly construct $Q(\lambda)$ as an integral operator.

VIII. *Q*-OPERATOR

For the Baxter Q-operator we require the three usual properties. First, it has to commute with the trace of the monodromy matrix $\tau_N(u)=\Pi_{i=N}^{1}L(u|x_i,\partial_{x_i})$

$$[\tau_N(u),Q(\lambda)]=0, \tag{8.1}$$

second, it has to commute with itself

$$[Q(\lambda_1),Q(\lambda_2)]=0, \tag{8.2}$$

and the last important property imposed is the Baxter T-Q equation, i.e., the Q-operator should satisfy a finite difference equation

$$\tau_N(\lambda)Q(\lambda)=A(\lambda)Q(\lambda-1)+B(\lambda)Q(\lambda+1), \tag{8.3}$$

where $A(\lambda)$ and $B(\lambda)$ are two functions (not operators) of the spectral parameter λ.

We will follow Ref. 4 and construct $Q(\lambda)$ as an integral operator

$$(Q(\lambda)\psi)(\boldsymbol{x})=\int d\boldsymbol{t}\int d\boldsymbol{y}\prod_{i=1}^{N}R_{\lambda+\beta_i-1}(t_i,x_i|t_{i-1}y_i)\psi(\boldsymbol{y}). \tag{8.4}$$

Here $d\boldsymbol{t}=dt_N\cdots dt_1$ and similar for alike symbols. If we introduce the $\mathcal{R}$-operator as

$$(\mathcal{R}_\lambda\psi)(s,x)=\int dy\int dtR_\lambda(s,x|t,y)\psi(y), \tag{8.5}$$

the formula (8.4) can be understand in the general sense of the trace of a monodromy matrix

$$Q(\lambda)=Tr_{t_N}\mathcal{R}^1_{\lambda+\beta_N-1}\cdots\ \mathcal{R}^N_{\lambda+\beta_1-1}. \tag{8.6}$$

In the notation $R_\lambda(t,y|s,x)$ we recognize the *auxiliary* indexes *s*, *t*, and the *quantum* indexes *x*, *y*. The *Q*-operator can be expressed as an integral operator

$$(Q(\lambda)\psi)(\boldsymbol{x})=\int dy_1\cdots\ \int dy_N\mathcal{Q}_\lambda(\boldsymbol{x}|\boldsymbol{y})\psi(\boldsymbol{y}), \tag{8.7}$$

with the kernel

$$\mathcal{Q}_\lambda(\boldsymbol{x}|\boldsymbol{y})=\int dt_N\cdots\ \int dt_1\prod_{i=N}^{1}R_{\lambda+\beta_i-1}(t_{i-1},x_i|t_i,y_i). \tag{8.8}$$

After this general introduction, we move forward to find the concrete form of the operator $\mathcal{R}_\lambda$. The first property of the Baxter Q-operator, namely the commutation $[\tau_N(u),Q(\lambda)]=0$ is fulfilled if $\mathcal{R}_\lambda$ is a solution of an equation similar to (7.2)

$$M(u-\lambda|s,\partial_s)L(u|x,\partial_x)\mathcal{R}_\lambda=\mathcal{R}_\lambda L(u|y,\partial_y)M(u-\lambda|t,\partial_t), \tag{8.9}$$

where $L(u|x,\partial_x)$ is the local quantum Lax matrix (7.1) and $M(u-\lambda)$ is another matrix which obeys the quantum commutation (7.2.) The main difficulty is how to choose the matrix $M(u-\lambda)$ so that, Eq. (8.9) for $\mathcal{R}(\lambda)$ has a solution for every complex parameter u and by the other hand the Q-operator thus obtained has the required properties. The second property of the Q-operator comes from the Yang–Baxter equation which can be obtained from (8.9) by a standard technique, see Ref. 11. Returning to Eq. (8.9) we take M to be of the same form as the Lax matrix (7.1). We obtain

$$\begin{pmatrix} s & 1\\ u-\lambda+s\partial_s & \partial_s\end{pmatrix}\begin{pmatrix} x & 1\\ u+x\partial_x & \partial_x\end{pmatrix}R_\lambda(t,y|s,x)=R_\lambda(t,y|s,x)\begin{pmatrix} y & 1\\ u+y\partial_y & \partial_y\end{pmatrix}\begin{pmatrix} t & 1\\ u-\lambda+t\partial_t & \partial_t\end{pmatrix}. \tag{8.10}$$

On the right-hand side of the above equation, move $R_\lambda(ty,sy)$ from the left side of the matrices product, to the right side. We have to change $\partial_x\to-\partial_x$ and $x\partial_x\to-1-x\partial_x$. Then the equation becomes

$$\begin{aligned}&\begin{pmatrix} s & 1\\ u-\lambda+s\partial_s & \partial_s\end{pmatrix}\begin{pmatrix} x & 1\\ u+x\partial_x & \partial_x\end{pmatrix}R_\lambda(t,y|s,x)\\ &\quad=\begin{pmatrix} y & 1\\ u-1-y\partial_y & -\partial_y\end{pmatrix}\begin{pmatrix} t & 1\\ u-\lambda-1-t\partial_t & -\partial_t\end{pmatrix}R_\lambda(t,y|s,x).\end{aligned} \tag{8.11}$$

The solution is:

$$R_\lambda(t,y|s,x)=\rho_\lambda\delta(s-y)e^{y(t-x)}(t-x)^{-\lambda-1}. \tag{8.12}$$

We notice that $R\sim\exp(F_\lambda)$ for $\beta=1$. Due to the Dirac function, the solution is gauge independent, i.e., the solution does not depend on the free variable ξ from (4.11). The $\mathcal{R}$-operator (8.5) becomes, after integration over y and changing the variable $t-x=\xi$

$$(\mathcal{R}\psi)(s,x)=\rho_\lambda\int d\xi e^{s\xi}\,\xi^{-\lambda-1}\psi(x+\xi,s), \tag{8.13}$$

or

$$(\mathcal{R}\psi)(s,x)=\rho_\lambda s^\lambda\int d\xi e^{\xi}\,\xi^{-\lambda-1}\psi(x+s^{-1}\xi,s). \tag{8.14}$$

The branch for the many valued function s^λ from (8.14) is fixed by making a cut along $(-\infty,0)$ and taking $\arg(s)\in[-\pi,\pi]$. We have to specify the factor ρ_λ and the integration contour (in the complex ξ pane) in (8.14). The integration contour is the Hankel contour for the Gamma function[12]

$$\int_{-\infty}^{(0+)} e^{\xi}\xi^{-z}d\xi=\frac{2\pi i}{\Gamma(z)}. \tag{8.15}$$

The previous formula inspired us to choose

$$\rho_\lambda=\frac{1}{2\pi i}\Gamma(\lambda+1). \tag{8.16}$$

Then

$$(\mathcal{R}_\lambda(\psi))(s,x)=\frac{1}{2\pi i}\Gamma(\lambda+1)s^\lambda\int d\xi e^{\xi}\xi^{-\lambda-1}\psi(x+s^{-1}\xi,s). \tag{8.17}$$

We are ready now to write the kernel of the Q-operator (8.8). From (8.12) and (8.6) we obtain

$$\mathcal{Q}_\lambda(\boldsymbol{x}|\boldsymbol{y})=\prod_{i=1}^{N} w_i(\lambda;y_{i-1},y_i,x_i), \tag{8.18}$$

where

$$w_i(\lambda;y_{i-1},y_i,x_i)=\frac{1}{2\pi i}\Gamma(\lambda+\beta_i)e^{y_i(y_{i-1}-x_i)}(y_{i-1}-x_i)^{-\lambda-\beta_i}. \tag{8.19}$$

Therefore we have found an explicit form for the Baxter Q-operator (8.18). Next we are going to investigate the third property of the Q-operator, namely the Baxter T-Q equation.

IX. BAXTER T-Q EQUATION

This last paragraph aims to show that the Baxter T-Q equation is the quantum version of the classical separation of variables (6.1). The computation parallels the one in Ref. 4. Start from the left side of the Baxter T-Q equation (8.3)

$$[\tau(\lambda)Q(\lambda)\psi](\boldsymbol{x})=Tr\left[\int d\boldsymbol{t}d\boldsymbol{y}\left(\prod_{i=N}^{1} L(\lambda|x_i,\partial_{x_i})R_{\lambda+\beta_i-1}(t_i,x_i|t_{i-1},y_i)\right)\psi(\boldsymbol{y})\right]. \tag{9.1}$$

We can integrate over t_i and get

$$[\tau(\lambda)Q(\lambda)\psi](\boldsymbol{x})=Tr\left[\int d\boldsymbol{y}\left(\prod_{i=N}^{1}L(\lambda|x_i,\partial_{x_i})w_i\right)\psi(\boldsymbol{y})\right], \tag{9.2}$$

where w_i are given by (8.19).

Move all w_i to the left using

$$L(\lambda|x_i,\partial_{x_i})w_i=w_i\widetilde{L}(\lambda|x_i,\partial_{x_i}), \tag{9.3}$$

with

$$\widetilde{L}(\lambda|x_i,\partial_{x_i})=\begin{pmatrix} x_i & 1 \\ \lambda+\beta_i+x_i\partial_{x_i}\ln w_i & \partial_{x_i}\ln w_i\end{pmatrix}, \tag{9.4}$$

or

$$\widetilde{L}(\lambda|x_i,\partial_{x_i})=\begin{pmatrix} x_i & 1 \\ -x_iy_i+\dfrac{(\lambda+\beta_i)y_{i-1}}{y_{i-1}-x_i} & -y_i+\dfrac{(\lambda+\beta_i)}{y_{i-1}-x_i}\end{pmatrix}. \tag{9.5}$$

At this point we can write

$$[\tau(\lambda)Q(\lambda)\psi](\boldsymbol{x})=\int d\boldsymbol{y}\prod_{i=N}^{1}w_iTr(\widetilde{L}(\lambda|x_N,\partial_{x_N})\cdots\widetilde{L}(\lambda|x_1,\partial_{x_1}))\psi(\boldsymbol{y}). \tag{9.6}$$

The last step is to perform a gauge transformation which leaves the trace invariant and make the matrices $\widetilde{L}(\lambda|x_i,\partial_{x_i})$ triangular, so the trace will be easy to compute

$$\widetilde{L}(\lambda|x_i,\partial_{x_i})\to N_i^{-1}\widetilde{L}(\lambda|x_i,\partial_{x_i})N_{i-1}. \tag{9.7}$$

With the help of the following gauge matrix:

$$N_i=\begin{pmatrix}1 & 0\\ y_i & 1\end{pmatrix}, \tag{9.8}$$

the triangular form for $\widetilde{L}(\lambda|x_i,\partial_{x_i})$ is

$$N_i^{-1}\widetilde{L}(\lambda|x_i,\partial_{x_i})N_{i-1}=\begin{pmatrix}-(y_{i-1}-x_i) & 1\\ 0 & \dfrac{\lambda+\beta_i}{y_{i-1}-x_i}\end{pmatrix}. \tag{9.9}$$

The entries of the previous matrix can be expressed in terms of the w_i (8.19)

$$-(y_{i-1}-x_i)=-(\lambda+\beta_i)\frac{w_i(\lambda-1)}{w_i(\lambda)}, \tag{9.10}$$

$$\frac{\lambda+\beta_i}{y_{i-1}-x_i}=\frac{w_i(\lambda+1)}{w_i(\lambda)}, \tag{9.11}$$

so we get for the trace

$$Tr(\tilde{L}(\lambda|x_N,\partial_{x_N})\cdots\tilde{L}(\lambda|x_1,\partial_{x_1}))=\prod_{i=1}^{N}-(\lambda+\beta_i)\frac{w_i(\lambda-1)}{w_i(\lambda)}+\prod_{i=1}^{N}\frac{w_i(\lambda+1)}{w_i(\lambda)}. \tag{9.12}$$

The last result implies the Baxter T-Q equation

$$\tau(\lambda)Q(\lambda)=-\prod_{i=1}^{N}(\lambda+\beta_i)Q(\lambda-1)+Q(\lambda+1). \tag{9.13}$$

Compare (9.13) with the classical result (6.10) written in the form

$$e^{\mu}+\tau_N-\prod_{i=1}^{N}(\lambda+b_i)e^{-\mu}=0. \tag{9.14}$$

The connection is obvious if we quantify the canonical pair (μ,λ) as

$$\mu\to\frac{d}{d\lambda},\quad \lambda\to\lambda. \tag{9.15}$$

Then (9.14) becomes an operator acting on the Q-operator

$$\left(e^{\mu}+\tau_N-\prod_{i=1}^{N}(\lambda+\beta_i)e^{-\mu}\right)Q(\lambda)=0, \tag{9.16}$$

which is the T-Q equation up to a minus sign. To obtain a T-Q equation which exactly matches the classical formula, we have to choose for ρ_λ the one in (8.16) multiplied with $(-1)^\lambda$.

X. THE CASE $N=3$

It is instructive to study the case $N=3$ which corresponds to the one-gap potentials. The trace (2.15) of the monodromy matrix (2.14) for $N=3$ is

$$\tau_3(u)=(g_1+g_2+g_3)u+g_1g_2g_3+g_1\beta_3+g_2\beta_1+g_3\beta_2. \tag{10.1}$$

The variables g_i, $i=1,2,3$ are (2.12): $g_1=X_1+x_2$, $g_2=X_2+x_3$, and $g_3=X_3+x_1$. The transformation $B(\lambda)$ [(4.17), (4.18)] can be explicitly found for $\lambda=-\beta_i$, $i=1,2,3$. For example, for $\lambda=-\beta_2$ we get

$$\tilde{g}_1=g_3+\frac{\beta_3-\beta_2}{g_2}, \tag{10.2}$$

$$\tilde{g}_2=g_1-\frac{\beta_3-\beta_2}{g_2}+\frac{\beta_1-\beta_2}{g_3+\dfrac{\beta_3-\beta_2}{g_2}}, \tag{10.3}$$

$$\tilde{g}_3=g_2-\frac{\beta_1-\beta_2}{g_3+\dfrac{\beta_3-\beta_2}{g_2}}. \tag{10.4}$$

This transformation can be recovered from the Bäcklund transformations T_k, $k=1,2,3$ from.[2,13] Recall that T_k is given by

$$T_k(g_{k\pm1})=g_{k\pm1}\pm\frac{\beta_{k+1}-\beta_k}{g_k}, \tag{10.5}$$

$$T_k(\beta_k)=\beta_{k+1}, \tag{10.6}$$

$$T_k(\beta_{k+1})=\beta_k, \tag{10.7}$$

the remaining β_j and g_j being not changed. We also need to introduce the shift S acting as

$$S(\beta_i)=\beta_{i-1}, \tag{10.8}$$

$$S(g_i)=g_{i-1}. \tag{10.9}$$

In terms of these last transformations, we can write

$$B(-\beta_2)=T_2ST_1. \tag{10.10}$$

We cannot recover T_k from $B(\lambda)$ because of the difference in nature between these transformations. T_k transforms the parameters β_j so it changes solutions of one system of equations (2.4) to solutions of another system of the same type (2.4). The transformations $B(\lambda)$ change the solutions of the same system (2.4) among themselves. In this respect $B(\lambda)$ is an auto-Bäcklund transformation.

We can try to solve the discrete Riccati equation (4.20) for ψ_i. In this case, we will get $\psi_1,\ldots,\psi_3$ in terms of ψ_0 and ψ_4

$$\psi_1=\frac{1}{Z}[\psi_4-\psi_0(g_2g_3+\lambda+\beta_3)(\lambda+\beta_1)], \tag{10.11}$$

$$\psi_2=\frac{1}{Z}[\psi_4g_1+\psi_0g_3(\lambda+\beta_2)(\lambda+\beta_1)], \tag{10.12}$$

$$\psi_3=\frac{1}{Z}[\psi_4(g_1g_2+\lambda+\beta_2)-\psi_0(\lambda+\beta_1)(\lambda+\beta_2)(\lambda+\beta_3)], \tag{10.13}$$

with $Z=g_1g_2g_3+g_1(\lambda+\beta_3)+g_3(\lambda+\beta_2)$. It obvious that $z_i=\psi_{i+1}/\psi_i$ will depend on ψ_4 and ψ_0 only through their ratio ψ_4/ψ_0. This ratio is not a free parameter because the periodic boundary condition $z_0=z_3$ imposes a restriction on it.

Though the τ-functions are not one of the major players of this paper, it is worthwhile to mention the connection it has with canonical transformations.

The τ-functions for the dressing chain were reported in Ref. 14 for $N=3$. For $N=3$ case, the dressing chain (2.4) written in variables g_i, (2.9), is

$$\begin{aligned} g_0'&=-g_0(g_1-g_2)+\beta_0-\beta_1,\\ g_1'&=-g_1(g_2-g_0)+\beta_1-\beta_2,\\ g_2'&=-g_2(g_0-g_1)+\beta_2-\beta_0. \end{aligned} \tag{10.14}$$

With the change of variables

$$g_0=F_1'-F_2'+c,\quad g_1=F_2'-F_0'+c,\quad g_2=F_0'-F_1'+c, \tag{10.15}$$

where the constant c is given by $3c=g_0+g_1+g_2$, the system of equations (10.14) transforms into

$$\begin{aligned} &F_0''+F_1''+(F_0'-F_1')^2-c\,(F_0'-F_1')+\beta_1=0,\\ &F_1''+F_2''+(F_1'-F_2')^2-c\,(F_1'-F_2')+\beta_2=0, \end{aligned} \tag{10.16}$$

$$F_2''+F_0''+(F_2'-F_0')^2-c\,(F_2'-F_0')+\beta_0=0.$$

The τ-functions $\tau_0,\ \tau_1,\ \tau_2$ are now given by

$$F_0=\log\tau_0,\quad F_1=\log\tau_1,\quad F_2=\log\tau_2. \tag{10.17}$$

In terms of the τ-functions, the dressing chain becomes a Hirota type system of equations

$$(D_x^2-cD_x+\beta_1)\,\tau_0\cdot\tau_1=0,\quad (D_x^2-cD_x+\beta_2)\,\tau_1\cdot\tau_2=0,\quad (D_x^2-cD_x+\beta_0)\,\tau_2\cdot\tau_0=0, \tag{10.18}$$

where for a polynomial P, the operator $P(D_x)$ is defined as

$$P(D_x)\,F(x)\cdot G(x)=P(\partial_y)\,F(x+y)G(x-y)\big|_{y=0}. \tag{10.19}$$

At this point the goal is to work the canonical transformation (4.17) and (4.18) in terms of the τ-functions. The canonical transformation (4.17), (4.18) namely

$$g_i=z_i-\frac{\lambda+\beta_i}{z_{i-1}} \tag{10.20}$$

and

$$\tilde{g}_i=g_{i+1}+z_{i-1}-z_{i+1}, \tag{10.21}$$

cannot be written explicitly as a formula which comprise only $\tilde{g}_i$ and g_i. Therefore, we use the following strategy: Given g_i, we have to solve for z_i in (10.20), and then obtain the transformed variables $\tilde{g}_i$ with the aid of (10.21). As a result, the canonical transformation for the τ-functions will be written in terms of the variables z_i.

First, by simple manipulations of (10.14) and (10.15) we get

$$F_0''=g_1g_2-c^2-\frac{\beta_0+\beta_1-\beta_2}{2}, \tag{10.22}$$

and similarly for F_1'' and F_2''. Using (10.17) we get

$$(\log e^{-\gamma_0x^2}\tau_0)''=g_1g_2, \tag{10.23}$$

and similarly for τ_1 and τ_2. Here $\gamma_0=-\frac{1}{2}(c^2+(\beta_0+\beta_1-\beta_2)/3)$.

After we apply the canonical transformation we obtain the function $\tilde{\tau}_0$ given by

$$(\log e^{-\gamma_0x^2}\tilde{\tau}_0)''=\tilde{g}_1\tilde{g}_2. \tag{10.24}$$

Now it is easy to write the canonical transformation for $\tau_0,\ \tau_1,\ \tau_2$ in terms of the variable z_i. Use (10.20) and (10.21) in (10.23) and (10.24) and get

$$\begin{aligned}
(\log e^{-\gamma_0x^2}\tau_0)''&=\left(z_1-\frac{\lambda+\beta_1}{z_0}\right)\left(z_2-\frac{\lambda+\beta_2}{z_1}\right),\\
(\log e^{-\gamma_1x^2}\tau_1)''&=\left(z_2-\frac{\lambda+\beta_2}{z_1}\right)\left(z_0-\frac{\lambda+\beta_0}{z_2}\right),\\
(\log e^{-\gamma_2x^2}\tau_2)''&=\left(z_0-\frac{\lambda+\beta_0}{z_2}\right)\left(z_1-\frac{\lambda+\beta_1}{z_0}\right)
\end{aligned} \tag{10.25}$$

and

$$(\log e^{-\gamma_0 x^2}\tilde{\tau}_0)''=\left(z_0-\frac{\lambda+\beta_2}{z_1}\right)\left(z_1-\frac{\lambda+\beta_0}{z_2}\right),$$

$$(\log e^{-\gamma_1 x^2}\tilde{\tau}_1)''=\left(z_1-\frac{\lambda+\beta_0}{z_2}\right)\left(z_0-\frac{\lambda+\beta_1}{z_0}\right), \tag{10.26}$$

$$(\log e^{-\gamma_2 x^2}\tilde{\tau}_2)''=\left(z_2-\frac{\lambda+\beta_1}{z_0}\right)\left(z_0-\frac{\lambda+\beta_2}{z_1}\right),$$

with

$$\gamma_0=-\frac{1}{2}\left(c^2+\frac{\beta_0+\beta_1-\beta_2}{3}\right),\quad \gamma_1=-\frac{1}{2}\left(c^2+\frac{\beta_1+\beta_2-\beta_0}{3}\right),\quad \gamma_2=-\frac{1}{2}\left(c^2+\frac{\beta_2+\beta_0-\beta_1}{3}\right).$$

The meaning of the transformations as presented in (10.25) and (10.26) is that first we must factorize like in (10.25) and then use the factorization variables z_i to obtain the transformed τ-functions, like in (10.26).

For the case $N=3$, the canonical transformation must be carried on three times, each time with another λ in order to obtain separated canonical variables, see (6.1). In variables g_i, these transformations read as

$$\tilde{g}_i=g_{i+1}+z_{i-1}-z_{i+1},\quad g_i=z_i-\frac{\lambda_1+\beta_i}{z_{i-1}},$$

$$\tilde{\tilde{g}}_i=\tilde{g}_{i+1}+\tilde{z}_{i-1}-\tilde{z}_{i+1},\quad \tilde{g}_i=\tilde{z}_i-\frac{\lambda_2+\beta_i}{\tilde{z}_{i-1}}, \tag{10.27}$$

$$\tilde{\tilde{\tilde{g}}}_i=\tilde{\tilde{g}}_{i+1}+\tilde{\tilde{z}}_{i-1}-\tilde{\tilde{z}}_{i+1},\quad \tilde{\tilde{g}}_i=\tilde{\tilde{z}}_i-\frac{\lambda_3+\beta_i}{\tilde{\tilde{z}}_{i-1}}.$$

If we add μ_1, μ_2, μ_3 given by (6.7)

$$e^{\mu_1}=-z_1z_2z_3,\quad e^{\mu_1}=-\tilde{z}_1\tilde{z}_2\tilde{z}_3,\quad e^{\mu_1}=-\tilde{\tilde{z}}_1\tilde{\tilde{z}}_2\tilde{\tilde{z}}_3, \tag{10.28}$$

the variables $(\lambda_1,\lambda_2,\lambda_3,\mu_1,\mu_2,\mu_3)$ are separated canonical variables. The time evolution of these variables, inherited from the dressing chain (10.14) is such that, (6.10),

$$e^{2\mu_1}+e^{\mu_1}-(\lambda_1+\beta_1)(\lambda_1+\beta_2)(\lambda_1+\beta_3)=0, \tag{10.29}$$

and similarly for the pairs (λ_2,μ_2) and (λ_3,μ_3). Here $\tau_N(\lambda_1)$ is given by (10.1) with λ_1 instead of u.

If we use the notation $\tau^{(1)}=\tau$, $\tau^{(2)}=\tilde{\tau}$, $\tau^{(3)}=\tilde{\tilde{\tau}}$ and similarly for z_i, the transformations (10.27) for the τ-functions, can be compactly expressed as follows:

factorization:

$$(\log e^{-\gamma_i x^2}\tau_i^{(k)})''=\left(z_{i+1}^{(k)}-\frac{\lambda_k+\beta_{i+1}}{z_i^{(k)}}\right)\left(z_{i+2}^{(k)}-\frac{\lambda_k+\beta_{i+2}}{z_{i+1}^{(k)}}\right),$$

transformation

$$(\log e^{-\gamma_i x^2}\tau_i^{(k+1)})''=\left(z_i^{(k)}-\frac{\lambda_k+\beta_{i+2}}{z_{i+1}^{(k)}}\right)\left(z_{i+1}^{(k)}-\frac{\lambda_k+\beta_i}{z_{i+2}^{(k)}}\right).$$

Here $i=0,1,2$, modulo 3, and $k=1,2,3$. The variables μ are given by (10.28) as before.

XI. HAMILTONIAN FLOW FOR THE CASE $N=3$

Here we discuss the time dependence of the canonical variables (X_i,x_i). We regard the variable x (i.e., the *space* variable) in the system of Eqs. (2.4) as being a time t for the Hamiltonian flow. The Hamiltonian that governs the motion in time is in variables f_i (2.9) given by

$$H=\tfrac{1}{3}(f_1^3+f_2^3+f_3^3+\beta_1 f_1+\beta_2 f_2+\beta_3 f_3). \tag{11.1}$$

It is useful to list all the variables which appeared so far

$$g_1=f_1+f_2, \quad f_1=\tfrac{1}{2}(g_1-g_2+g_3), \quad g_1=X_1+x_2, \tag{11.2}$$

$$g_2=f_2+f_3, \quad f_2=\tfrac{1}{2}(g_2-g_3+g_1), \quad g_2=X_2+x_3, \tag{11.3}$$

$$g_3=f_3+f_1, \quad f_3=\tfrac{1}{2}(g_3-g_1+g_2), \quad g_3=X_3+x_1. \tag{11.4}$$

The evolution of the variable x_1 in time is given by

$$\frac{dx_1}{dt}=\{x_1,H\}. \tag{11.5}$$

The Poisson bracket can be computed for two arbitrary functions f and g from

$$\{f,g\}=\sum_{\alpha,\beta}\frac{\partial f}{\partial y_\alpha}\frac{\partial g}{\partial y_\beta}\{y_\alpha,y_\beta\}, \tag{11.6}$$

where $(y_1,\ldots,y_{2N})=(X_1,\ldots,X_N,x_1,\ldots,x_N)$. In this way we arrive at

$$2\frac{dx_1}{dt}=(f_1^2+f_2^2-f_3^2+\beta_1+\beta_2-\beta_3)\{x_1,X_1\}, \tag{11.7}$$

which gives the evolution for x_1 knowing that the variables (X_1,x_1) are canonical, i.e.,

$$\{x_1,X_1\}=1. \tag{11.8}$$

From the paper of Veselov and Shabat[2] we even know the solutions for the dressing chain in terms of the elliptic Weierstrass $\mathcal{P}$-functions

$$f_i(t)=\frac{1}{2}\frac{\mathcal{P}'(t+a_i)-\mathcal{P}'(b_i)}{\mathcal{P}(t+a_i)-\mathcal{P}(b_i)}. \tag{11.9}$$

We can integrate (11.7) to

$$\begin{aligned}2x_1(t)=&\xi(t+a_3+b_3)+\xi(t+a_3)+\xi(b_3)-\xi(t+a_1+b_1)-\xi(t+a_1)-\xi(b_1)\\&-\xi(t+a_2+b_2)-\xi(t+a_2)-\xi(b_2)+\beta_1+\beta_2-\beta_3.\end{aligned} \tag{11.10}$$

Here $\xi'=-\mathcal{P}, b_i=\mathcal{P}(\beta_i)$ and $a_{i+1}-a_i=b_i$.

In the quantum case the Hamiltonians are generated from the Lax matrix (7.1). The trace of the monodromy matrix is

$$\tau_3(u)=H_1u+H_3, \tag{11.11}$$

where

$$H_1 = x_1 + x_2 + x_3 + \partial_{x_1} + \partial_{x_2} + \partial_{x_3}, \tag{11.12}$$

$$H_3 = \partial_{x_1}\partial_{x_2}\partial_{x_3} + x_1\,\partial_{x_1}\partial_{x_3} + x_2\,\partial_{x_2}\partial_{x_1} + x_3\,\partial_{x_3}\partial_{x_2} + x_2x_1\,\partial_{x_1} + x_3x_2\,\partial_{x_2} + x_1x_3\,\partial_{x_3} + x_1x_2x_3. \tag{11.13}$$

An interesting feature of the quantum case is the absence of evolution of the variables $g_i = \partial_{x_i} + x_{i+1}$ due to

$$[g_i, H_3] = 0. \tag{11.14}$$

This means that there is no quantum analog of the dressing chain in terms of the variables g_i. The only surviving variables are $X_i = \partial_{x_i}$ and x_i which each separately evolve in time under the Hamiltonian H_3.

XII. CONCLUSIONS

For the finite-gap potentials we have shown that the Darboux transformations can be viewed as canonical transformations if we apply the method of separation of variables proposed by Sklyanin. Not only the finite-gap case ($N=$ odd, $\alpha=0$) is interesting but also the other cases. For example, the spectrum of the potentials which are solution of the chain in the case $\alpha\neq 0$ and arbitrary N is described as following. The ground state is at zero energy; the next $(p-1)$ eigenvalues are $E_l = \Sigma_{k=0}^{l}\alpha_k$, $l=0,1,\ldots,(p-2)$, and all other eigenvalues are obtained by adding arbitrary multiples of the quantity $\alpha \equiv \alpha_0 + \alpha_1 + \cdots + \alpha_{p-1}$. The general formula for the excited energy levels is[8]

$$n\alpha + \sum_{k=0}^{l} \alpha_k;\ \{n=0,1,2,\ldots,\infty;\ l=0,1,\ldots,(p-1)\}. \tag{12.1}$$

The above potentials (also called *cyclic shape invariant potentials*) are a direct generalization of the harmonic oscillator. For $N=3$ the potentials are Painlevé transcendents.[2]

In this work we have also shown that there exists a quantum version of the dressing chain, namely the time evolution of the variables (X,x) under the Hamiltonian H_1. From here there are many ways to proceed. One way is along Bethe–Ansatz procedure. It will be interesting to find the spectrum of the quantum Hamiltonians. Also, each Hamiltonian H_i has its own time t_i for evolution, so there must be a τ-function which depends on all time variables $\tau(t_1,t_2,\ldots,t_N)$. The τ-function for the dressing chain was reported in Ref. 14 for $N=3$ in connection with the Painlevé equations. See also Refs. 15, 18, and 19.

We have analyzed the role of τ-functions in connection with the factorization method and canonical transformation. The τ-functions are an important tool in understanding integrable systems and we believe that the connections between the τ-functions and the Darboux transformations is worth to be studied further.

Finally, a word about KdV. The finite-gap potential theory provides solutions of the periodic boundary problems for KdV equation. The KdV equation

$$u_{xt} = u_{xxx} - 6uu_{xx}, \tag{12.2}$$

is a partial differential equation in two variables. One variable x we interpreted as a time variable associated with the Hamiltonian H_1. To what Hamiltonian is the second variable, i.e., t, associated? For $\beta_i=0$ the Hamiltonian is $H_5^2 - H_1H_3$. This result is buried in the paper.[16] What is the meaning of the Sklyanin separation of variables for KdV equation, both classical and quantum? From the conformal field point of view, the quantum KdV and the T-Q relation was already studied in the paper of Ref. 17.

In conclusion, the Darboux transformation together with the new approach of the separation of variables is a promising research direction.

Regularizing divergences in the von Neumann entropy

Juan C. Retamal and Lautaro Vergara
Departamento de Física, Universidad de Santiago de Chile, Casilla 307 Correo 2, Santiago, Chile

(Received 25 May 2001; accepted for publication 31 October 2001)

We study the decoherence process of a harmonic oscillator in a dissipative environment by considering the von Neumann entropy. Derivatives of the von Neumann entropy around the initial time exhibit divergences when the system is initially in a pure state. A regularization procedure based on the zeta function technique is considered in order to extract information about decoherence. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1428809]

Quantum-mechanical coherence is of central importance in quantum mechanics. Fundamental implications were pointed out in the early days of the quantum theory.[1,2] Presently, a problem which has received considerable attention is the irreversible loss of quantum coherence, namely quantum decoherence.[3,4] The unavoidable presence of the environment makes a quantum system experience a dissipative dynamics,[5–8] which is mainly responsible for destroying quantum coherence.[4]

Great effort has been devoted to the generation of pure quantum states in a variety of quantum optical devices.[9–13] Recently, great importance has been given to the study of those quantum-mechanical systems which are capable of preserving quantum-mechanical coherence,[14,15] One important issue closely related to this problem is the characterization of the time scales of the decoherence process.[16–19] Presently, the understanding of these ideas is very important because of their potential applications in quantum computing, the challenge to provide us with faster computing machines.

A pure state is defined as $\rho(t)=|\psi(t)\rangle\langle\psi(t)|$, in such a way that $\rho^2(t)=\rho(t)$ and Tr $\rho^2(t)=1$. A mixed state instead is defined by the class of states which satisfies the inequality Tr $\rho^2 \leqslant 1$; this simple relation leads to the definition of the linear entropy of a quantum state $S_l(t)=1-\mathrm{Tr}\ \rho^2(t)$, a quantity which is positive $S_l(t)\geqslant 0$ and bounded $S_l(t)\leqslant 1$.

In a recent paper,[19] fundamental questions such as which are the states that remain pure under the time evolution of an open system were addressed. To that end, the dissipative process described by a Lindblad form[20]

$$\partial_t\rho=\frac{\gamma}{2}(2\,f\rho f^\dagger-f^\dagger f\rho-\rho f^\dagger f\,), \tag{1}$$

was considered and time derivatives of $S_l(t)$ were used both to find whether the eigenstates of f are the only states that remain pure under Eq. (1) and the time scale for the onset of instabilities. In particular, it was found that the instabilities of $S_l(t)$ are at least of third order in time if the initial state is an eigenstate of f. That is, when considering an initial pure state which is an eigenstate of the operator f, i.e., $f|\psi_0\rangle\langle\psi_0|=\beta|\psi_0\rangle\langle\psi_0|$, it is found that

$$S_{l1}(0)=S_{l2}(0)=0,\quad S_{l3}(0)=\gamma^3|\beta|^2(\langle A^2\rangle-\langle A\rangle^2), \tag{2}$$

where $A=[f,f^\dagger]$ and

$$S_{ln}(0)=\left.\frac{d^nS_l(t)}{dt^n}\right|_{t=0}. \tag{3}$$

If A is a constant, then fluctuations of A are zero in an eigenstate of f. However, this can occur only for either $f=a$ or $f=\mu a+\nu a^{\dagger}$, that is, the initial state being either a coherent state or a squeezed state; they remain pure for all times. This result establishes that the linear entropy is unstable at third order in time for any other kind of states associated to other classes of restricted Lindblad dynamics given by Eq. (1). This result does not contradict that found in Refs. 21 and 22 because, as is known, the condition for the Lindblad theory is that the time scale considered for the open system should be very long compared to the relaxation time of the reservoir.

Since in general any nonlinear invariant of the density matrix is a good measure of quantum coherence, it is natural to ask how those results look if one uses an alternative and widely known functional of ρ: the von Neumann entropy $S(t)=-\mathrm{Tr}\,\rho(t)\ln\rho(t)$, which is an ideal parameter with which to characterize the decoherence, and is in fact the key to understanding the connection between decoherence and fluctuations.

In this work we address this problem, our main result being related to the appearance of divergences of the derivatives of the von Neumann entropy around an initial pure state of the system. We show here how to solve the problem of their presence by using the zeta function technique, well known in both spectral and quantum field theory.

We know that the von Neumann entropy can be written in terms of the eigenvalues of ρ as

$$S=-\sum_{i}\lambda_i\ln\lambda_i\,. \tag{4}$$

For a pure state there exists only the eigenvalues 0 and 1 of ρ; and then, S can be conveniently expressed as

$$S=-\lim_{\lambda_i\to 1}\lambda_i\ln\lambda_i+\sum_{i'\neq i}\lim_{\epsilon_{i'}\to 0}\epsilon_{i'}\ln\epsilon_{i'}\,. \tag{5}$$

It is clear that $S\to 0$, when we consider the limit $\epsilon_{i'}\ln\epsilon_{i'}\to 0$ when $\epsilon_{i'}\to 0$. A different situation arises when we calculate the derivatives of the von Neumann entropy around the initial time for the system initially in a pure state. In this case we have

$$S_1(0)=-\lim_{\lambda_i(0)\to 1}\dot{\lambda}_i(0)\ln\lambda_i(0)-\lim_{\lambda_i(0)\to 1}\dot{\lambda}_i(0)-\sum_{i'}\lim_{\epsilon_{i'}(0)\to 0}\dot{\epsilon}_{i'}(0)\ln\epsilon_{i'}(0)-\sum_{i'}\lim_{\epsilon_{i'}(0)\to 0}\dot{\epsilon}_{i'}(0). \tag{6}$$

We observe that in the decoherence process $\dot{\lambda}_i(0)<0$, $\dot{\epsilon}_{i'}(0)>0$ for some $\epsilon_{i'}$, such that $S_1(0)$ is divergent because of the presence of the $\ln\epsilon_{i'}(0)$. This simple calculation raises the question of whether one can consider the derivatives of the von Neumann entropy as giving physical information about the decoherence process. In this work we consider this question and show, by comparing with previous results using the linear entropy, that the von Neumann entropy contains the correct information, and in order to extract it unambiguously from the calculation we must consider a procedure to regularize the von Neumann entropy and separate from its derivatives, in a consistent way, the finite and infinite parts.

A first step to analyze the problem is to characterize which kinds of divergence appear when we consider the derivatives of the entropy evaluated in a pure state. In order to do this we expand the logarithm as

$$\ln(1+(\rho-1))=\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}(\rho-1)^n. \tag{7}$$

In a pure state we have $(\rho-1)^n=(-1)^n(1-\rho)$, so that $\ln(1+(\rho-1))=-(1-\rho)\zeta(1)$, where $\zeta(1)$ is the Riemann zeta function $\zeta(s)=\Sigma_{n=1}^{\infty}n^{-s}$ evaluated at $s=1$. From here, it follows that the entropy is $S=\mathrm{Tr}\rho(1-\rho)\zeta(1)$, a result that in principle is not well defined because $\rho(1-\rho)=0$

and $\zeta(1)$ diverges logarithmically. However, if we consider the series term by term, it is evident that the entropy vanishes in agreement with Eq. (5). Moreover, when calculating derivatives of $S(t)$, derivatives of the $\ln\rho$ appear and we can use the formal expansion (7). In this case, $S_1(t)$ is given by

$$S_1 = -\frac{d}{dt}\mathrm{Tr}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}\rho(\rho-1)^n = -\mathrm{Tr}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}\left[\rho_1(\rho-1)^n+\rho\frac{d}{dt}(\rho-1)^n\right]$$

$$= \mathrm{Tr}\,\rho_1(1-\rho)\zeta(1)+\mathrm{Tr}\sum_{n=1}^{\infty}\frac{1}{n}\rho(1-\rho)^{n-1}\rho_1, \qquad (8)$$

where $\rho_n = d^n\rho(t)/dt^n$. By taking into account that $\rho(1-\rho)^{n-1}=0$ for $n>1$, we have

$$S_1 = -[1+\zeta(1)]\mathrm{Tr}\,\rho\rho_1. \qquad (9)$$

A similar calculation shows that

$$S_2 = -[1+\zeta(1)]\mathrm{Tr}(2\rho\rho_1^2+\rho\rho_2)+2\zeta(0)\mathrm{Tr}(2\rho\rho_1^2-\rho_1^2), \qquad (10)$$

where $\zeta(0)=-1/2$.

It must be stressed that expressions in Eqs. (9) and (10) are completely general because they are calculated assuming only that the initial state is pure for any dissipative dynamics and therefore are applicable to the exact dynamics. These results contain the divergence $\zeta(1)$, the presence of which cannot be an accident as could be implied from the previous calculation for S. For example, in Eq. (9) the precise value of $\mathrm{Tr}\,\rho\rho_1$ depends on the particular dynamics and the initial conditions. In the particular case outlined in Eq. (2), for an eigenstate of f evolving according to Eq. (1), we obtain that $\mathrm{Tr}\,\rho\rho_1=0$, but S_1 is not well defined because of $\zeta(1)$. In addition, in the case of the second derivative of S, it is not difficult to prove that for the particular case of an eigenstate of f evolving according to Eq. (1), $\mathrm{Tr}\,2\rho\rho_1^2=\mathrm{Tr}\,\rho_1^2$, and

$$S_2 = -[1+\zeta(1)]\mathrm{Tr}(\rho_1^2+\rho\rho_2). \qquad (11)$$

The finite factor in S_2 is similar to that found in the case of the linear entropy[19]

$$S_{l2}(t) = -2\,\mathrm{Tr}(\rho_1^2+\rho_0\rho_2), \qquad (12)$$

which vanishes according to Eq. (2) for an eigenstate of f, so that the second derivative of the von Neumann entropy is still $S_2=0\cdot\infty$, which is not well defined.

From this analysis we realize that divergences in the derivatives of the von Neumann entropy around a pure state are independent of the particular kind of dissipative dynamics. A way out of the problem is simply to discard any divergent term appearing in the calculations, but this will only give a correct result after one manage to define, without ambiguity, the finite part of the von Neumann entropy and its derivatives. This is the essence of a regularization procedure. It is important to keep in mind that the divergences in the derivatives of the von Neumann entropy are related to the existence of zero eigenvalues of the density matrix.

In order to solve the problem, we can benefit from well-established regularization techniques widely used in field theory. It is well known that the calculation of functional determinants of some Hermitian operators involves the evaluation of the logarithm of the operator which contains zero modes (zero eigenvalues). The technique used in this case to regularize the expressions (remove divergent parts arising from zero modes) is the zeta function regularization.[23–26] We show in what follows that the von Neumann entropy can be defined in terms of the zeta function in a similar way.

The zeta function associated with a Hermitian operator, the density matrix $\rho(t)$ in our case, is defined as

$$\zeta_\rho(s,t)=\mathrm{Tr}\,\rho(t)^{-s}=\sum_n \lambda_n^{-s}(t), \tag{13}$$

where $\lambda_n(t)$ are the eigenvalues of $\rho(t)$. We included here a time dependence of the zeta function which comes from the temporal dependence of the density matrix. It is easy to see from this definition that the von Neumann entropy reads

$$S(t)=\frac{d}{ds}\zeta_\rho(s,t)\big|_{s=-1}=-\mathrm{Tr}\,\rho(t)\ln\rho(t). \tag{14}$$

The usefulness of this definition resides in the fact that one can represent the zeta function as an integral

$$\zeta_\rho(s,t)=\frac{1}{\Gamma(s)}\int_0^\infty d\tau\,\tau^{s-1}\,\mathrm{Tr}\,e^{-\tau\rho(t)}, \tag{15}$$

where $\mathrm{Tr}\,e^{-\tau\rho(t)}=\Sigma_i e^{-\tau\lambda_i(t)}$. When the operator involved has zero modes, the integral above leads to a divergent part associated with each zero modes. The procedure to remove the divergences is to redefine the integrand in the equation above, such that

$$\zeta_\rho(s,t)=\frac{1}{\Gamma(s)}\int_0^\infty d\tau\,\tau^{s-1}\mathrm{Tr}[e^{-\tau\rho(t)}-P_0(\rho(t))], \tag{16}$$

where $P_0(\rho(t))$ is the projector onto the zero modes of $\rho(t)$.[24,25] In this way the remnant part in the integral is associated only with the nonzero modes, which is the convergent part. We should stress that in this way the expression

$$S(t)=\lim_{s\to-1}\frac{d}{ds}\zeta_\rho(s,t) \tag{17}$$

is an analytic function of time.

Now, let us apply this technique to the problem at hand. It is clear that if we take as the initial condition that the system is in a pure state, we have

$$e^{-\tau\rho}=1-\rho+\rho e^{-\tau}, \tag{18}$$

such that at $t=0$ we have

$$\zeta_\rho(s,0)=\frac{1}{\Gamma(s)}\int_0^\infty d\tau\,\tau^{s-1}\,\mathrm{Tr}[1-\rho+\rho e^{-\tau}-P_0(\rho)]=1+\frac{1}{\Gamma(s)}\int_0^\infty d\tau\,\tau^{s-1}\,\mathrm{Tr}[1-\rho-P_0(\rho)]. \tag{19}$$

This expression clearly shows the existence of a divergence of the zeta function when evaluating in a pure state. In this way, in a pure state the projector onto zero modes is $P_0=1-\rho$, so that $\zeta_\rho(s,0)=1$, and hence the entropy in a pure state vanishes, as it should. This procedure is actually giving us a way to recognize, without ambiguity, the finite part of the $\zeta_\rho(s,0)$, which can be identified with the term in the integrand containing the exponential factor $e^{-\tau}$. Clearly, any other term inside gives rise to a divergence with no physical interpretation. This is precisely the idea we want to extend to solve the problem with the derivatives of the von Neumann entropy.

We are interested in evaluating temporal derivatives of the entropy using Eq. (14). To that end, we must know the temporal derivatives of $\zeta_\rho(s,t)$. In general, we have that

$$\frac{d}{dt}\mathrm{Tr}[e^{-\tau\rho(t)}]=-\tau\sum_{n=2}\frac{(-\tau)^{n-1}}{(n-1)!}\mathrm{Tr}\,\rho^{n-1}\rho_1=-\tau\sum_{n=1}\frac{(-\tau)^n}{n!}\mathrm{Tr}\,\rho^n\rho_1. \tag{20}$$

Assuming an initial pure state, we have

$$\frac{d}{dt}\mathrm{Tr}[e^{-\tau\rho(t)}]\big|_{t=0} = -\tau\sum_{n=1}\frac{(-\tau)^n}{n!}\mathrm{Tr}\,\rho\rho_1 = \tau\,\mathrm{Tr}\,\rho\rho_1 - \tau\sum_{n=0}\frac{(-\tau)^n}{n!}\mathrm{Tr}\,\rho\rho_1$$
$$= \tau\,\mathrm{Tr}\,\rho\rho_1 - \tau e^{-\tau}\mathrm{Tr}\,\rho\rho_1; \tag{21}$$

then, the derivative of $\zeta_\rho(s,t)$ is

$$\frac{d}{dt}\zeta_\rho(s,t)\bigg|_{t=0} = \frac{1}{\Gamma(s)}\int_0^\infty d\tau\,\tau^{s-1}\,\mathrm{Tr}\left\{\tau(1-e^{-\tau})\rho\rho_1 - \frac{d}{dt}P_0\bigg|_{t=0}\right\}. \tag{22}$$

According to the argument given above, we recognize in this expression the existence of a (logarithmic) divergence; this may be assumed to be removed by a counterterm given by the derivative of P_0.

$$\mathrm{Tr}\frac{d}{dt}P_0\bigg|_{t=0} = \tau\,\mathrm{Tr}\,\rho\rho_1. \tag{23}$$

Then, the convergent part is given by

$$\frac{d}{dt}\zeta_\rho(s,t)\bigg|_{t=0} = -\frac{\Gamma(s+1)}{\Gamma(s)}\mathrm{Tr}\,\rho\rho_1, \tag{24}$$

and therefore the first derivative of the entropy at $t=0$ for an initial pure state is obtained by deriving with respect to s according to Eq. (17)

$$S_1(0) = \frac{d}{ds}\frac{d}{dt}\zeta_\rho(s,0)\big|_{s=-1} = -\mathrm{Tr}\,\rho\rho_1. \tag{25}$$

Notice that this result coincides with that of Eq. (9) once the divergent $\zeta(1)$ is discarded.

The second derivative of the von Neumann entropy can be calculated in a similar way. In this case, in order to subtract the divergence we assume this is removed with

$$\mathrm{Tr}\frac{d^2}{dt^2}P_0 = \tau\,\mathrm{Tr}(\rho_1^2 - 2\rho\rho_1^2) + \tau\,\mathrm{Tr}(2\rho\rho_1^2 + \rho\rho_2) + (-3\tau^2 + 2\tau^3 + 2\tau)\mathrm{Tr}\,\rho\rho_1\rho\rho_1, \tag{26}$$

and then the finite part of the $\zeta_\rho(s,t)$ at $t=0$ is

$$\frac{d}{dt}\zeta_\rho(s,t)\big|_{t=0} = -s\,\mathrm{Tr}\,(2\rho\rho_1^2 + \rho\rho_2) + (s^2 - s)\,\mathrm{Tr}\,\rho\rho_1\rho\rho_1; \tag{27}$$

therefore, the second time derivative of S is

$$S_2(0) = \frac{d}{ds}\frac{d^2}{dt^2}\zeta_\rho(s,0)\big|_{s=-1} = -\mathrm{Tr}(2\rho\rho_1^2 + \rho\rho_2) - 3\,\mathrm{Tr}\rho\rho_1\rho\rho_1. \tag{28}$$

This expression is similar to that found in Eq. (11) once the divergent $\zeta(1)$ is discarded. The particular case of an eigenstate of f, $S_2(0)$, gives a similar result to Eq. (12), because in that case $\mathrm{Tr}\,2\rho\rho_1^2 = \mathrm{Tr}\,\rho_1^2$ and because the term $\mathrm{Tr}\,\rho\rho_1\rho\rho_1 = 0$.

Of course, in some cases it is not necessary to calculate higher-order derivatives because the first-order derivative is nonzero, and this derivative gives enough information about the decoher-

ence process.[19] However, for the case in Eq. (1) we have to calculate higher-order derivatives. In this case, applying the same procedure and discarding the divergent part, we find that the finite part of the third derivative of the von Neumann entropy is

$$S_3(0)=\frac{d}{ds}\frac{d^3}{dt^3}\zeta_\rho(s,0)\big|_{s=-1}=-\mathrm{Tr}(\rho\rho_3+3\rho_1\rho_2).$$

This can be compared with the corresponding derivative of the linear entropy

$$S_{l3}(t)=-2\,\mathrm{Tr}(3\rho_1\rho_2+\rho_0\rho_3), \tag{29}$$

showing that upon a factor we get essentially the same information.

These calculations show that the regularized expression for the von Neumann entropy in Eq. (17) allows us to distinguish, without ambiguity, the divergent part of its derivatives. The information that these derivatives give about the decoherence process is similar to that found by the linear entropy upon a factor. In addition, we have found a new application of the zeta function technique, unknown in the literature, to the best of our knowledge.

Since the completion of this work, we have been informed of a recent reference,[27] where some remote connection of the zeta function techniques to information theory has been discussed. This is a subject that warrants further investigation.

(Received 25 July 2001; accepted for publication 26 September 2001)

We show that it is possible to construct a quantum field theory that is invariant under the translation of the noncommutative parameter $\theta_{\mu\nu}$. This is realized in a noncommutative cohomological field theory. As an example, a noncommutative cohomological scalar field theory is constructed, and its partition function is calculated. The partition function is the Euler number of Gopakumar, Minwalla, and Strominger (GMS) soliton space. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1418428]

I. INTRODUCTION

Recently noncommutative geometry and noncommutative field theory revived in the string theory.[1] There are some correspondences between commutative and noncommutative geometry.[26] For example, in the gauge theory, it was shown that the commutative theory with some background field is equivalent to the noncommutative theory.[2] After that, a few kinds of nontrivial solitons in the noncommutative space are discovered. In the gauge theory, U(1) instanton solution was discovered by Nekrasov and Schwartz,[3] and in the scalar theory a nontrivial solution was discovered by Gopakumar, Minwalla, and Strominger,[4] which is called the GMS soliton. There is no corresponding solution in the commutative space, i.e., the GMS soliton is a specific solution in the noncommutative space.

In the noncommutative space, it is difficult to define the length or metric. There are few examples, like a noncommutative torus case, derived the differential geometry, e.g., connection and curvature.[5] But in general noncommutative space, to define the Riemannian geometry is difficult. What we can do is to classify the geometry to the extent of the algebric K-theory. However, it is not enough to classify the noncommutative space from a point of view of differential topology. If there are some characteristic classes that do not vary under the shift from commutative to noncommutative space, then they are useful for the classification of spaces. For instance, in the noncommutative torus the Euler number is independent of the noncommutative parameter θ.[6] We expect that some other topological invariants would be extended to noncommutative space and independent of θ.

The aim of this article is to construct a quantum field theory that is invariant under the transformation of the noncommutative parameter $\theta^{\mu\nu}$. This parameter characterizes the noncommutativity of spaces as

$$[x^{\mu},x^{\nu}]=\frac{\theta^{\mu\nu}}{2\pi i}, \tag{1.1}$$

where x^{μ} are the coordinates of the noncommutative space. Noncommutative parameter independence of the theory means that the partition function of the theory is independent of $\theta^{\mu\nu}$. Cohomological field theory is nominated as such a theory. We construct a cohomological field theory

[a]Electronic mail: sako@math.sci.hiroshima-u.ac.jp
[b]Electronic mail: kuroki@theo.phys.sci.hiroshima-u.ac.jp
[c]Electronic mail: tomomi@theo.phys.sci.hiroshima-u.ac.jp

on the noncommutative space, and we show that it is actually a usual cohomological field theory in the $\theta^{\mu\nu}=0$ limit. This fact means that noncommutative space succeed to some geometric or topological information of commutative space.

Another purpose of this article is to construct a concrete example of the invariants under the transformation of noncommutative parameter $\theta^{\mu\nu}$. The discovery of the GMS solution is one of the most important developments in recent work on noncommutative field theory. Therefore, we calculate the Euler number of the GMS soliton space as the example of $\theta^{\mu\nu}$ independent partition function. We will see the relation between the GMS soliton and commutative cohomological field theory.

Our example of the noncommutative cohomological field theory is a balanced scalar model that has two multiplets, the scalar and the vector. We consider the case that the potential is a general degree polynomial of the scalar field. In the commutative space, the degree of the potential determines the structure of the vacuum. We will show that in the noncommutative space there is similar picture of vacuum structure. As a result of investigation, the correspondence between the commutative limit $\theta\to 0$ and the noncommutative limit $\theta\to\infty$ is obtained. Especially in the large θ limit, the potential term plays a dominant role, and there are the specific GMS solutions. A point of this article is how we deal with the GMS solitons in quantum field theory.

This article is organized as follows. In Sec. II, we will construct the $\theta^{\mu\nu}$ invariant quantum field theory in general. In Sec. III, we construct a scalar model as a simple example. Balanced topological theory will be used there. It is necessary to introduce potential in topological scalar field theory. The partition function is calculated in both limits, commutative and noncommutative. In Sec. IV, we introduce the Morse theory on the noncommutative field theory, and show that the Euler number of the GMS soliton space is well-defined. In the last section, we summarize and discuss our result.

II. GENERAL FORMALISM

The aim of this section is to make a theory that is invariant under the shift of the noncommutative parameter $\theta_{\mu\nu}$. We discuss how we construct the cohomological field theory on the noncommutative space.

A. Cohomological field theory on noncommutative space

The noncommutative parameter is defined in the commutation relation Eq. (1.1). We introduce the infinitesimal rescaling operator δ_s as follows:

$$(1-\delta_s)[x^\mu,x^\nu]\equiv[x'^\mu,x'^\nu]=\frac{\theta^{\mu\nu}-\delta\theta^{\mu\nu}}{2\pi i}. \tag{2.1}$$

This commutation relation is given by defining δ_s as

$$x'^\mu=x^\mu-\delta_s x^\mu, \tag{2.2}$$

$$\delta_s x^\mu=(\tfrac{1}{2}\delta\theta^{\mu\nu}(\theta^{-1})_{\nu\rho})x^\rho. \tag{2.3}$$

This transformation corresponds to $x'^\mu=\sqrt{\theta}x^\mu$ in Ref. 4. We denote the inverse matrix of the transformation (2.2) by

$$J^\mu_\rho\equiv\delta^\mu{}_\rho+\tfrac{1}{2}\delta\theta^{\mu\nu}(\theta^{-1})_{\nu\rho}. \tag{2.4}$$

Then, the integration measure and the differential operator are transformed into

$$dx^D=\det\mathbf{J}dx'^D,\quad \frac{\partial}{\partial x^\mu}=(J^{-1})_{\mu\nu}\frac{\partial}{\partial x'^\nu}, \tag{2.5}$$

where det$\mathbf{J}$ is the Jacobian. By (2.5) the Moyal product(see, e.g., Ref. 7) is shifted as

$$(1-\delta_s)(*_\theta)=\delta_s(\exp(2\pi i\overleftarrow{\partial}_\mu(\theta-\delta\theta)^{\mu\nu}\vec{\partial}_\nu))=*_{\theta-\delta\theta}, \tag{2.6}$$

because $\delta_s(\overleftarrow{\partial}_\mu\theta^{\mu\nu}\vec{\partial}_\nu)=\overleftarrow{\partial}_\mu\delta\theta^{\mu\nu}\vec{\partial}_\nu$. Note that this transformation is just a rescaling of the coordinate, so that any action and its partition function are not changed under this transformation,

$$S_\theta=\int dx^D\mathcal{L}(*_\theta,\partial_\mu)=\int \det\mathbf{J}dx'^D\mathcal{L}\left(*_{\theta-\delta\theta},(J^{-1})^{\mu\nu}\frac{\partial}{\partial x'^\nu}\right), \tag{2.7}$$

where $\mathcal{L}(*_\theta,\partial_\mu)$ is an explicit description to emphasize that the products of fields are the Moyal product and it contains derivative terms in the Lagrangian. For convenience, we will often omit $*_\theta$ when we do not misunderstand. In the next step, we shift the noncommutative parameter:

$$\theta\rightarrow\theta'=\theta+\delta\theta. \tag{2.8}$$

This shift changes the action and the partition function in general, as follows:

$$S_{\theta'}=\int \det\mathbf{J}dx'^D\mathcal{L}\left(*_\theta,(J^{-1})^{\mu\nu}\frac{\partial}{\partial x'^\nu}\right). \tag{2.9}$$

Compared with (2.7), the shift is regarded as a rescaling without the Moyal product.

On the contrary, our purpose is to construct a field theory invariant under this shift. Immediately we expect the cohomological field theory would be an example since it is scale invariant theory.[8–10] Cohomological field theory is understood through several ways. Twisted SUSY is one of them, but noncommutative SUSY is not adverted here.[11–13] Meanwhile, a geometrical point of view is closely studied in Sec. IV. The Lagrangian of cohomological field theory is BRST-exact. We denote the BRST operator by $\hat{\delta}$, and generic bosonic fields by ϕ_i, which are sections of some vector bundle $s_a(*_\theta\phi_i)$. The BRST operator is defined as

$$\begin{aligned}&\hat{\delta}\phi_i=\psi_i, \quad \hat{\delta}\psi_i=0,\\ &\hat{\delta}\chi^a=H^a, \quad \hat{\delta}H^a=0,\end{aligned} \tag{2.10}$$

where ϕ_i and H^a are bosonic and ψ_i and χ^a are fermionic fields. Following the Mathai–Quillen formalism, the action of the cohomological field theory is written as

$$V=\chi^a(is_a+H_a), \tag{2.11}$$

$$S_\theta=\int dx^D\mathcal{L}(*_\theta,\partial_\mu)=\int dx^D\hat{\delta}V. \tag{2.12}$$

The partition function is defined by

$$Z_\theta=\int \mathcal{D}\phi\mathcal{D}\psi\mathcal{D}\chi\mathcal{D}H\exp(-S_\theta). \tag{2.13}$$

In the commutative space, the Mathai–Quillen formalism tells us that the partition function gives a representation of the Euler number of the space $\mathcal{M}=\{s_a^{-1}(0)\}$.

This partition function is invariant under an infinitesimal transformation which commutes with the BRST transformation (2.10).

$$\hat{\delta}\delta'=\pm\delta'\hat{\delta}, \tag{2.14}$$

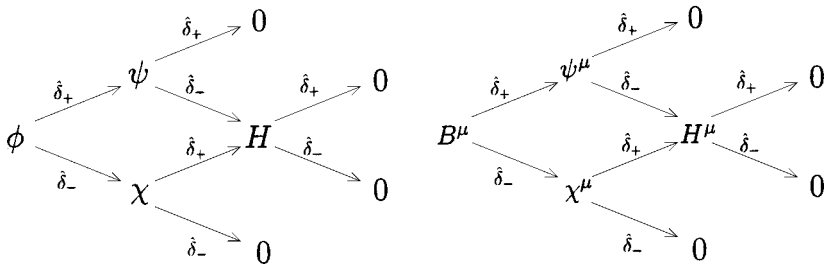

FIG. 1. BRST multiplets in the balanced scalar model. $\delta_+(\delta_-)$ carries ghost number $+1(-1)$.

$$\delta' Z_\theta = \int \mathcal{D}\phi\mathcal{D}\psi\mathcal{D}\chi\mathcal{D}H\,\delta'\left(-\int dx^D \hat{\delta}V\right)\exp(-S_\theta)$$
$$= \int \mathcal{D}\phi\mathcal{D}\psi\mathcal{D}\chi\mathcal{D}H\,\hat{\delta}\left(-\int \delta' V\right)\exp(-S_\theta) = 0.$$

The vacuum expectation value (VEV) of any BRST-exact observable is zero. Note that the path integral measure is invariant under δ' transformation since every field has only one supersymmetric partner and the Jacobian is totally canceled.

We introduce the θ-shift operator as

$$\delta_s x_\mu = -\delta_s x_\mu, \delta_\theta \theta_{\mu\nu} = \theta_{\mu\nu} + \delta\theta_{\mu\nu}. \tag{2.15}$$

Generally, it is possible to define δ_θ to commute with the BRST operator. Following (2.14), the partition function is invariant under this θ-shift and it means that the Euler number of the space $\mathcal{M}$ is independent of the noncommutative parameter θ.

In the end of this section, we list some general nature of this partition function. First, the Gaussian integral is formally defined and an exact result can be given by one-loop calculation. Second, naively the commutative limit ($\theta\to 0$) is given by removing potential terms without constant field, and the $\theta\to\infty$ limit is given by omitting kinetic terms in the action, because the limit $\theta\to 0$ ($\theta\to\infty$) means $\mathbf{J}\to 0$ ($\mathbf{J}\to\infty$) in Eq. (2.9).

In the next section, as an example of noncommutative cohomological field theory, we investigate the balanced scalar model.

III. BALANCED SCALAR MODEL

In this section, we study a concrete example of noncommutative cohomological field theory as θ-shift invariant field theory. For simplicity, we use a real scalar model to construct a cohomological field theory. However, there is no nontrivial example under usual construction of cohomological field theory. Therefore, we introduce the balanced topological field theory.[14,15] This theory is used in the investigation of the Vafa–Witten theory whose partition function is the sum of Euler number of the zero section space $\mathcal{M}$ without a sign, in general.[16–18] When we calculate the Vafa–Witten theory, zero mode integration is not essential because there is no ghost number anomaly. On the contrary, in this article, we carefully calculate the zero mode integration to compare the commutative limit with the large θ limit.

A. The action

We construct the balanced scalar model. The theory is composed of bosonic scalar fields ϕ and H, fermionic scalar fields ψ and χ, bosonic vector fields B_μ and H_μ, fermionic vector fields ψ_μ and χ_μ, and every field is Hermitian field. We give the BRST transformations (Fig. 1) as

$$\hat{\delta}_+\phi = \psi, \quad \hat{\delta}_-\phi = \chi,$$

$$
\begin{aligned}
-\hat{\delta}_-\psi &= \hat{\delta}_+\chi = H,\\
\hat{\delta}_+\psi &= \hat{\delta}_-\chi = \hat{\delta}_+H = \hat{\delta}_-H = 0,\\
\hat{\delta}_+B^\mu &= \psi^\mu,\ \hat{\delta}_-B^\mu = \chi^\mu,\\
-\hat{\delta}_-\psi^\mu &= \hat{\delta}_+\chi^\mu = H^\mu,\\
\hat{\delta}_+\psi^\mu &= \hat{\delta}_-\chi^\mu = \hat{\delta}_+H^\mu = \hat{\delta}_-H^\mu = 0,
\end{aligned}
\tag{3.1}
$$

where $\hat{\delta}_+$ and $\hat{\delta}_-$ satisfy the following relations,

$$
\hat{\delta}_+^2 = \hat{\delta}_-^2 = 0, \quad \hat{\delta}_+\hat{\delta}_- + \hat{\delta}_-\hat{\delta}_+ = 0. \tag{3.2}
$$

The action of the balanced scalar model is

$$
S = \int dx^D \sqrt{g}\mathcal{L}, \tag{3.3}
$$

where the Lagrangian $\mathcal{L}$ is given by an exact form with a ghost-number zero functional $\mathcal{F}$ as

$$
\mathcal{L} = i\hat{\delta}_+\hat{\delta}_-\mathcal{F}. \tag{3.4}
$$

In our case, the functional $\mathcal{F}$ is chosen as

$$
\mathcal{F} = B^\mu\partial_\mu\phi - i\chi^\mu\psi_\mu - i\chi\psi + V(\phi,B^\rho), \tag{3.5}
$$

where $V(\phi,B^\rho)$ is a potential. Therefore the Lagrangian $\mathcal{L}$ becomes

$$
\begin{aligned}
\mathcal{L} &= i\hat{\delta}_+\hat{\delta}_-\mathcal{F} = i\hat{\delta}_+\left\{\chi^\mu\partial_\mu\phi + B^\mu\partial_\mu\chi - i\chi^\mu H_\mu - i\chi H + \left(\chi\frac{\delta}{\delta\phi}\right)V(\phi,B^\rho) + \left(\chi^\mu\frac{\delta}{\delta B^\mu}\right)V(\phi,B^\rho)\right\}\\
&= i\hat{\delta}_+\left[\chi\left\{-\partial_\mu B^\mu + \frac{\delta}{\delta\phi}V(\phi,B^\rho) - iH\right\} + \chi^\mu\left\{\partial_\mu\phi + \frac{\delta}{\delta B^\mu}V(\phi,B^\rho) - iH_\mu\right\}\right] = \mathcal{L}_B + \mathcal{L}_F,
\end{aligned}
\tag{3.6}
$$

where $\mathcal{L}_B(\mathcal{L}_F)$ is the bosonic (fermionic) part of the Lagrangian,

$$
\mathcal{L}_B = iH\left\{-\partial_\mu B^\mu + \frac{\delta}{\delta\phi}V(\phi,B^\rho) - iH\right\} + iH^\mu\left\{\partial_\mu\phi + \frac{\delta}{\delta B^\mu}V(\phi,B^\rho) - iH_\mu\right\}, \tag{3.7}
$$

$$
\begin{aligned}
\mathcal{L}_F &= i\chi\left\{\partial_\mu\psi^\mu - \left(\psi\frac{\delta}{\delta\phi}\right)\frac{\delta}{\delta\phi}V(\phi,B^\rho) - \left(\psi^\mu\frac{\delta}{\delta B^\mu}\right)\frac{\delta}{\delta\phi}V(\phi,B^\rho)\right\}\\
&\quad - i\chi^\mu\left\{\partial_\mu\psi + \left(\psi\frac{\delta}{\delta\phi}\right)\frac{\delta}{\delta B^\mu}V(\phi,B^\rho) + \left(\psi^\nu\frac{\delta}{\delta B^\nu}\right)\frac{\delta}{\delta B^\mu}V(\phi,B^\rho)\right\}.
\end{aligned}
\tag{3.8}
$$

Here we consider the only case that the potential has separated form as

$$
V(\phi,B^\rho) = V(\phi) + \tfrac{1}{2}B_\mu B^\mu. \tag{3.9}
$$

As a result of taking this potential, B^μ has only zero solution in the large θ limit, and this is a necessary condition to investigate the GMS soliton space. If there is a nontrivial B^μ solution, then the moduli space is changed from GMS soliton moduli space and we are not interested in such a case. $\mathcal{L}_B$ and $\mathcal{L}_F$, therefore, become

$$\mathcal{L}_B = iH\left\{ -\partial_\mu B^\mu + \frac{\delta V(\phi)}{\delta\phi} - iH \right\} + iH^\mu(\partial_\mu\phi + B_\mu - iH_\mu), \tag{3.10}$$

$$\mathcal{L}_F = i\chi\left\{ \partial_\mu\psi^\mu - \psi\frac{\delta^2 V(\phi)}{\delta\phi^2} \right\} - i\chi^\mu(\partial_\mu\psi + \psi_\mu). \tag{3.11}$$

Note that every product of fields should be defined by replacing the normal product by the Moyal product when we consider the noncommutative field theory.

B. Commutative limit $\theta\to 0$

We consider the balanced scalar model in two-dimensional flat noncommutative space. One can get the theory on noncommutative space by changing the ordinary product into the star (Moyal) product $*_\theta$. Although noncommutativity is represented by the noncommutative parameter θ in the star product, this parameter is absorbed by the rescaling,

$$x^\mu \to \sqrt{\theta}x^\mu,$$

$$*_\theta \to *_{\theta=1}. \tag{3.12}$$

However, the action is changed as follows:

$$S_B = \int d^2x\,\theta\left[iH*\left\{ -\frac{\partial_\mu B^\mu}{\sqrt{\theta}} + \frac{\delta V(*\phi)}{\delta\phi} - iH \right\} + iH^\mu *\left(\frac{\partial_\mu\phi}{\sqrt{\theta}} + B_\mu - iH_\mu \right) \right], \tag{3.13}$$

$$S_F = \int d^2x\,\theta\left[i\chi*\left\{ \frac{\partial_\mu\psi^\mu}{\sqrt{\theta}} - \psi\frac{\delta^2 V(*\phi)}{\delta\phi^2} \right\} - i\chi^\mu *\left(\frac{\partial_\mu\psi}{\sqrt{\theta}} + \psi_\mu \right) \right], \tag{3.14}$$

where $S_B(S_F)$ is the bosonic (fermionic) part of the action and $*$ means $*_{\theta=1}$ implicitly.

Let us consider the $\theta\to 0$ limit and calculate its partition function, which is compared with the $\theta\to\infty$ limit in the next subsection. The partition function is calculated as

$$\mathcal{Z} = \int \mathcal{D}\phi\mathcal{D}\chi\mathcal{D}\psi\mathcal{D}\chi^\mu\mathcal{D}\psi^\mu\mathcal{D}B^\mu\mathcal{D}H\mathcal{D}H^\mu \exp(-S_B - S_F). \tag{3.15}$$

The part of the action which contributes to the nonzero modes of ϕ and H is

$$\int d^2x\sqrt{\theta}i(H^\mu * \partial_\mu\phi - H*\partial_\mu B^\mu). \tag{3.16}$$

We perform the integration of the nonzero modes of H^μ and B^μ, and it yields delta functionals,

$$\delta(\sqrt{2\pi\theta}\partial_\mu\phi)\,\delta(\sqrt{2\pi\theta}\partial_\mu H). \tag{3.17}$$

Therefore, for ϕ and H, only zero mode integrals remains. Next, the part of the action which contributes to the nonzero modes of χ and ψ is

$$\int d^2x\sqrt{\theta}i(\chi*\partial_\mu\psi^\mu - \chi^\mu*\partial_\mu\psi). \tag{3.18}$$

Integration of nonzero modes of χ,ψ and χ^μ,ψ^μ yields the factor

$$[\det(i\sqrt{\theta}\partial_\mu)]_{\chi_\varnothing\psi^\mu}[\det(i\sqrt{\theta}\partial_\mu)]_{\chi^\mu\psi_\varnothing}, \tag{3.19}$$

where the fields with the subscript $_\varnothing$ denote nonzero modes. Therefore, for χ and ψ, only zero modes remain and the partition function $\mathcal{Z}$ becomes

$$\mathcal{Z}=\frac{[\det(i\sqrt{\theta}\partial_\mu)]_{\chi^\mu\psi_\varnothing}}{[\det(\sqrt{2\pi\theta}\partial_\mu)]_{H^\mu\phi_\varnothing}}\frac{[\det(i\sqrt{\theta}\partial_\mu)]_{\chi_\varnothing\psi^\mu}}{[\det(\sqrt{2\pi\theta}\partial_\mu)]_{H_\varnothing B^\mu}}\int dy\,d\chi_0 d\psi_0\mathcal{D}\chi^\mu\mathcal{D}\psi^\mu\mathcal{D}B^\mu dH_0\mathcal{D}H^\mu \times\exp(-S_B'-S_F'), \tag{3.20}$$

where the fields with the subscript $_0$ denote zero modes and the variable y denotes the zero mode of ϕ (this is just a real constant number) and

$$S_B'=\int d^2x\,\theta\left[H_0\left\{H_0+i\frac{\delta V(y)}{\delta y}\right\}+H^\mu*(H_\mu+iB_\mu)\right], \tag{3.21}$$

$$S_F'=\int d^2x\,\theta i\left[-\chi_0\psi_0\frac{\delta^2V(y)}{\delta y^2}-\chi^\mu*\psi_\mu\right]. \tag{3.22}$$

The factors in front of the integral in Eq. (3.20) cancel each other and only $[\det(2\pi)]^{-1}_{H^\mu\phi_\varnothing}$ remains. H^μ, B^μ and the zero mode of H can be integrated out, and it yields the factor

$$\frac{1}{[v\,\theta/\pi]^{1/2}_{H_0}}\frac{1}{[\det(\theta/\pi)]^{1/2}_{H^\mu\phi_0}}\frac{1}{[\det(\theta/4\pi)]^{1/2}_{H_0B^\mu}}, \tag{3.23}$$

where v is the volume of space–time. This volume is infinity but this will be canceled out by ϕ, χ and ψ zero mode integration, later. Integration of χ^μ,ψ^μ yields the factor $[\det(i\theta)]_{\chi^\mu\psi^\mu}$, and the partition function $\mathcal{Z}$ becomes

$$\mathcal{Z}=\sqrt{\frac{\pi}{v\,\theta}}\det(-1)\int dy\,d\chi_0 d\psi_0\exp(-S_B''-S_F''), \tag{3.24}$$

where

$$S_B''=\int d^2x\frac{\theta}{4}\left\{\frac{\delta V(y)}{\delta y}\right\}^2, \tag{3.25}$$

$$S_F''=-\int d^2x\,\theta i\chi_0\psi_0\frac{\delta^2V(y)}{\delta y^2}. \tag{3.26}$$

Before integrating y, we expand $\delta V(y)/\delta y$ as

$$\frac{\delta V(y)}{\delta y}=y\frac{\delta^2V(y)}{\delta y^2}\bigg|_{y=y_c}+\mathcal{O}(y^2), \tag{3.27}$$

where y_c is a point of the extrema of the potential,

$$\frac{\delta V(y)}{\delta y}\bigg|_{y=y_c}=0, \tag{3.28}$$

and we should sum up all y_c in the calculation of $\mathcal{Z}$:

$$\mathcal{Z}=\sqrt{\frac{\pi}{v\,\theta}}\det(-1)\sum_{y_c}\int dy\,d\chi_0 d\psi_0\exp(-S'), \tag{3.29}$$

where

$$S' = v\,\theta\left[\frac{1}{4}\left\{ y\,\frac{\delta^2 V(y)}{\delta y^2}\bigg|_{y=y_c}\right\}^2 - i\chi\psi\frac{\delta^2 V(y)}{\delta y^2}\bigg|_{y=y_c}\right]. \tag{3.30}$$

Note that these zero modes do not depend on x^μ; then the volume v is factorized out. By integrating the zero modes of ϕ,χ and ψ, we get the partition function,

$$\mathcal{Z} = \sqrt{\frac{\pi}{v\,\theta}}\det(-1)\sum_{y_c}\frac{iv\,\theta\,\delta^2 V(y)/\delta y^2\,|_{y=y_c}}{\{(v\,\theta/4\pi)\;\delta^2 V(y)/\delta y^2\,|^2_{y=y_c}\}^{1/2}}$$

$$= 2\pi i\,\det(-1)\sum_{y_c}\;\mathrm{sgn}\left[\frac{\delta^2 V(y)}{\delta y^2}\bigg|_{y=y_c}\right]. \tag{3.31}$$

The factor in front of Σ_{y_c} is removable as a normalizing factor.

Generally, the potential $V(\phi)$ is a polynomial of the scalar field ϕ:

$$V(\phi) = b_0 + b_1\phi + \frac{b_2}{2!}\phi^2 + \cdots + \frac{b_m}{m!}\phi^m (m \geqslant 2), \tag{3.32}$$

and so the result Eq. (3.31) becomes

$$\mathcal{Z} = \begin{cases} \mathrm{sgn}[b_m]: & m \text{ is even number,} \\ 0: & m \text{ is odd number.} \end{cases} \tag{3.33}$$

In the limit $\theta \to 0$, it seems that the kinetic term plays a dominant role, but the effect of the potential term survives. By this effect, the degree of the polynomial completely determines the partition function as a cyclic form of Eq. (3.33).

C. Noncommutative limit $\theta \to \infty$

In the strong noncommutative limit $\theta \to \infty$, the terms that have derivatives are effectively ignored, and the remaining terms which are potential and mass terms in the balanced scalar model determine the field configuration. In the noncommutative space, there is a specific field configuration, that is, a GMS soliton.[4] This soliton is the solution of the field equation, and there are infinite solutions. Hence, the partition function is the sum of contributions from infinite vacuum states.

In the large θ limit, the balanced scalar model, Eqs. (3.10) and (3.11), is written as

$$S = S_B + S_F, \tag{3.34}$$

where

$$S_B = \int d^2x\,\theta\left[H * \left\{\frac{\delta V(*\phi)}{\delta\phi} - H\right\} + H^\mu * (B_\mu - H_\mu)\right], \tag{3.35}$$

$$S_F = \int d^2x\,\theta\left[-i\chi * \left(\psi\frac{\delta}{\delta\phi}\right)\frac{\delta V(*\phi)}{\delta\phi} + i\chi^\mu * \psi_\mu\right]. \tag{3.36}$$

After integrating over the fields H, H^μ, the action is

$$S = \int d^2x\,\theta\left[\frac{1}{4}\,\frac{\delta V(*\phi)}{\delta\phi}\,\frac{\delta V(*\phi)}{\delta\phi} - i\chi * \left(\psi\frac{\delta}{\delta\phi}\right)\frac{\delta V(*\phi)}{\delta\phi} + \frac{1}{4}B^\mu * B_\mu + i\chi^\mu * \psi_\mu\right]. \tag{3.37}$$

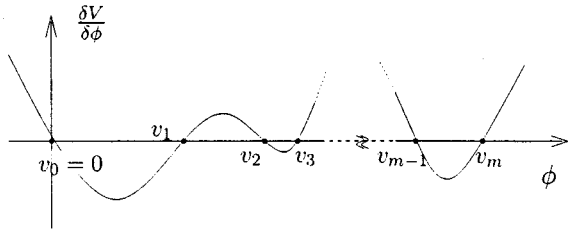

FIG. 2. $\delta V/\delta\phi$, $b_m>0$ and m is odd.

Integration of the fields B^μ, χ^μ and ψ_μ is simply performed, and the partition function is written as

$$\mathcal{Z}=\int \mathcal{D}\phi\mathcal{D}\chi\mathcal{D}\psi e^{-S}, \tag{3.38}$$

where the action is

$$S=\int d^2x\theta\left[\frac{1}{4}\frac{\delta V(*\phi)}{\delta\phi}\frac{\delta V(*\phi)}{\delta\phi}-i\chi*\left(\psi\frac{\delta}{\delta\phi}\right)\frac{\delta V(*\phi)}{\delta\phi}\right]. \tag{3.39}$$

In the large θ limit, the derivative terms are irrelevant, and the potential terms dominate. (Actually the kinetic term integral is survived for next order integral but it yields nothing because of the BRST symmetry.) The field configuration is determined by the form of the potential. In particular the stationary field configuration is obtained by solving the field equation:

$$\frac{\delta V(*\phi)}{\delta\phi}=0. \tag{3.40}$$

In the calculation of the partition function, we should treat these GMS solitons as the stationary points, and the quantum fluctuation is a perturbation from the GMS soliton. In the following section, we discuss the treatment of the GMS soliton in the partition function, and understand the GMS soliton from a topological view point.

We consider the ϕ^{m+2} potential,

$$V(\phi)=\{\phi\text{-polynomial of}(m+2)\text{degree}\}, \tag{3.41}$$

and the field equation takes the following factorized form

$$\frac{\delta V}{\delta\phi}=b_m\phi*(\phi-v_1)*(\phi-v_2)*\cdots*(\phi-v_m), \tag{3.42}$$

where we assume the v_i are real constant numbers with $v_1<v_2<\cdots<v_{m-1}<v_m$ (see Fig. 2). The GMS soliton is given by

$$\phi_{\mathrm{GMS}}=\lambda_i\mathbf{P}_i, \tag{3.43}$$

where $\mathbf{P}_i$ is a projection, and satisfies the idempotent relation $\mathbf{P}_i*\mathbf{P}_j=\delta_{ij}\mathbf{P}_i$. The coefficient λ_i is determined by Eq. (3.42). In the Moyal plane, this projection is given by the Laguerre polynomial $2(-1)^i e^{-x^2}\mathrm{L}_i(2x^2)$.[4] It is possible to choose concrete representation of a corresponding Weyl mapped projection operator, for example,

$$\hat{\mathbf{P}}_i=|i\rangle\langle i|, \tag{3.44}$$

where $|i\rangle$ is the number representation base.[19,20] The Weyl mapped GMS soliton is written as

$$\hat{\phi}_{GMS}=\lambda_i\hat{\mathbf{P}}_i. \tag{3.45}$$

We substitute the GMS solution to ϕ of Eq. (3.42):

$$\left.\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\right|_{GMS}=b_m\lambda_i(\lambda_i-v_1)(\lambda_i-v_2)\cdots(\lambda_i-v_m)\mathbf{P}_i=0. \tag{3.46}$$

The solutions of Eq. (3.46) are given by

$$\lambda_i=0,v_1,v_2,\ldots,v_m. \tag{3.47}$$

These solutions are coefficients of the GMS soliton. The general GMS solution is a linear combination of the projections,

$$\hat{\phi}_{\mathrm{GMS}}=\sum_i\lambda_i\hat{\mathbf{P}}_i=v_1\sum_{i\in\mathbf{S}_1}\hat{\mathbf{P}}_i+v_2\sum_{i\in\mathbf{S}_2}\hat{\mathbf{P}}_i+\cdots+v_m\sum_{i\in\mathbf{S}_m}\hat{\mathbf{P}}_i=v_1\hat{\mathbf{P}}_{\mathbf{S}_1}+v_2\hat{\mathbf{P}}_{\mathbf{S}_2}+\cdots+v_m\hat{\mathbf{P}}_{\mathbf{S}_m}, \tag{3.48}$$

where $\mathbf{S}_A(A\in\{1,2,\ldots,m\})$ is a set of the indices of the projections, and it is defined that if the coefficient of a projection $\hat{\mathbf{P}}_i$ is v_A in (3.48), then the index "i" belongs to $\mathbf{S}_A$. For example, if a GMS soliton takes the form $\hat{\phi}_{\mathrm{GMS}}=v_1(\hat{\mathbf{P}}_1+\hat{\mathbf{P}}_2)+v_2(\hat{\mathbf{P}}_0)$, then $\mathbf{S}_1=\{1,2\}$ and $\mathbf{S}_2=\{0\}$. We define $\hat{\mathbf{P}}_{\mathbf{S}_A}\equiv\Sigma_{i\in\hat{\mathbf{S}}_A}\mathbf{P}_i$. For $A\neq B(A,B\in\{1,2,\ldots,m\})$ the sets $\mathbf{S}_A$ and $\mathbf{S}_B$ are disjoint to each other $\mathbf{S}_A\cap\mathbf{S}_B=\varnothing$, and the projections are orthogonal, $\hat{\mathbf{P}}_{\mathbf{S}_A}\cdot\hat{\mathbf{P}}_{\mathbf{S}_B}=0$. In the commutative space, the field equation (3.42) has only constant solutions. On the contrary, in the noncommutative space, there exist GMS solitons that are operators for the Hilbert space of quantized coordinate, and this fact make new solutions with linear combinations of projections. The indices of the projection are not bound above; then the number of the element of $\mathbf{S}_A$ (rank $\mathbf{S}_A$) is allowed to be infinite. In the following, we introduce a cut-off N of total number of the rank $\mathbf{S}_A$, and then there are N projections $\{\hat{\mathbf{P}}_0,\hat{\mathbf{P}}_1,\hat{\mathbf{P}}_2,\ldots,\hat{\mathbf{P}}_{N-1}\}$. After the calculation we take the limit $N\to\infty$.

Next step, we perform a Gaussian integral around each vacuum. Note that, in the commutative space, the number of the solution is $(m+1)$, On the contrary, in the noncommutative space there are $(m+1)^N$ solutions. In the commutative space, we can take the quantum fluctuation from the vacua of the finite number of simply constant solutions of Eq. (3.42). On the contrary, there are infinite GMS solitons in noncommutative space. Let us take the quantum fluctuation around each of the GMS solitons as $\phi=\phi|_{\mathrm{GMS}}+\phi_q$. We expand the Lagrangian around the specific GMS soliton,

$$\mathcal{L}_{\mathbf{S}}=\frac{1}{4}\left(\phi_q\frac{\delta}{\delta\phi}\right)\frac{\delta V(*\phi)}{\delta\phi}\bigg|_{\mathrm{GMS}}*\left(\phi_q\frac{\delta}{\delta\phi}\right)\frac{\delta V(*\phi)}{\delta\phi}\bigg|_{\mathrm{GMS}}-i\chi*\left(\psi\frac{\delta}{\delta\phi}\right)\frac{\delta V(*\phi)}{\delta\phi}\bigg|_{\mathrm{GMS}}. \tag{3.49}$$

The subscript $\mathbf{S}$ of $\mathcal{L}$ means that the Lagrangian is expanded around the GMS soliton specified by $\mathbf{S}$ that is the family of $\{\mathbf{S}_1,\mathbf{S}_2,\ldots,\mathbf{S}_m\}$. (The rank k single GMS soliton space is an infinite dimensional moduli space of solution and it is concretely described as the coset space $U(N)/U(k)U(N-k)$.[21] In our case, the GMS solution space contains not only a single soliton but also multi-solitons that have any rank solutions. The moduli space specified by $\mathbf{S}$ is $U(N)/U(n_0)U(n_1)\cdots U(N-1)$, where n_i is the rank of $\mathbf{S}_i$.) On the Moyal plane, the field operators $\hat{\phi}_q$, $\hat{\chi}$ and $\hat{\psi}$ are expanded as

$$\hat{\phi}_q=\sum_{i,j=0}^{\infty}\phi_{ij}|i\rangle\langle j|,$$

$$\hat{\chi}=\sum_{i,j=0}^{\infty}\chi_{ij}|i\rangle\langle j|, \tag{3.50}$$

$$\hat{\psi}=\sum_{i,j=0}^{\infty}\psi_{ij}|i\rangle\langle j|.$$

The field operators $\hat{\phi}_q$, $\hat{\chi}$ and $\hat{\psi}$ are Hermitian operators,

$$\phi_q^{\dagger}=\phi_q, \quad \chi^{\dagger}=\chi, \quad \psi^{\dagger}=\psi. \tag{3.51}$$

We rewrite the field such as $\phi_{ij}=\phi_{ij}^R+i\phi_{ij}^I$ ($\phi_{ij}^R,\phi_{ij}^I\in\mathbf{R}$). Then the Hermitian conditions need that real (imaginary) parts are symmetric (anti-symmetric):

$$\begin{aligned}&\phi_{ij}^R=\phi_{ji}^R,\phi_{ij}^I=-\phi_{ji}^I,\\ &\chi_{ij}^R=\chi_{ji}^R, \quad \chi_{ij}^I=-\chi_{ji}^I,\\ &\psi_{ij}^R=\psi_{ji}^R, \quad \psi_{ij}^I=-\psi_{ji}^I.\end{aligned} \tag{3.52}$$

In the operator picture, the integration in the action is replaced by the trace over the field operators. The Lagrangian is always described as the Weyl mapped Lagrangian

$$S_{\mathbf{S}}=\mathrm{Tr}\hat{\mathcal{L}}_{\mathbf{S}}=S_B^{\mathbf{S}}+S_F^{\mathbf{S}}, \tag{3.53}$$

where $S_B^{\mathbf{S}}$ and $S_F^{\mathbf{S}}$ are given by

$$S_B^{\mathbf{S}}=\frac{1}{4}\theta\mathrm{Tr}\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}, \tag{3.54}$$

$$S_F^{\mathbf{S}}=-i\theta\mathrm{Tr}\hat{\chi}\left(\hat{\psi}\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}. \tag{3.55}$$

First, we consider the bosonic part of the action. The second derivative of the potential is

$$\begin{aligned}\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}&=\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\{b_m\hat{\phi}(\hat{\phi}-v_1)(\hat{\phi}-v_2)\cdots(\hat{\phi}-v_m)\}\bigg|_{\mathrm{GMS}}\\ &=b_m[\hat{\phi}_q(\hat{\phi}-v_1)(\hat{\phi}-v_2)\cdots(\hat{\phi}-v_m)\\ &\quad+\hat{\phi}\hat{\phi}_q(\hat{\phi}-v_2)\cdots(\hat{\phi}-v_m)+\hat{\phi}(\hat{\phi}-v_1)\phi_q\cdots(\hat{\phi}-v_m)\\ &\quad\vdots\\ &\quad+\hat{\phi}(\hat{\phi}-v_1)(\hat{\phi}-v_2)\cdots\hat{\phi}_q]_{\hat{\phi}=\hat{\phi}_{\mathrm{GMS}}}.\end{aligned} \tag{3.56}$$

We put the GMS soliton into Eq. (3.56), and we get

$$\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}$$

$$= b_m \sum_{A=0}^{m} \sum_{B=A}^{m} \prod_{i=0}^{A-1} (v_B - v_i) \sum_{C=0}^{A} \prod_{j=A+1}^{m} (v_C - v_j) \hat{\mathbf{P}}_{\mathbf{S}_B} \hat{\phi} \hat{\mathbf{P}}_{\mathbf{S}_C}$$

$$= b_m \sum_{A=0}^{m} \prod_{i=0}^{A-1} (v_A - v_i) \prod_{j=A+1}^{m} (v_A - v_j) \hat{\mathbf{P}}_{\mathbf{S}_A} \hat{\phi}_q \hat{\mathbf{P}}_{\mathbf{S}_A}$$

$$+ b_m \sum_{\substack{A>B \\ A,B \in \{0,\cdots,r\}}} \sum_{k=B}^{A} \prod_{i=0}^{k-1} (v_A - v_i) \prod_{j=k+1}^{m} (v_B - v_j) \hat{\mathbf{P}}_{\mathbf{S}_A} \hat{\phi}_q \hat{\mathbf{P}}_{\mathbf{S}_B}, \tag{3.57}$$

where we define the zeroth solution and the zeroth projection by

$$v_0 \equiv 0, \hat{\mathbf{P}}_{\mathbf{S}_0} \equiv \hat{\mathbf{1}} - \hat{\mathbf{P}}_{\mathbf{S}_1} - \hat{\mathbf{P}}_{\mathbf{S}_2} - \cdots - \hat{\mathbf{P}}_{\mathbf{S}_r}, \tag{3.58}$$

and we introduce the following symbols for convenience:

$$\prod_{i=0}^{-1} (v_0 - v_i) \equiv 1, \quad \prod_{j=m+1}^{m} (v_m - v_j) \equiv 1. \tag{3.59}$$

The coefficient of the cross term $\hat{\mathbf{P}}_{\mathbf{S}_A} \hat{\phi}_q \mathbf{P}_{\mathbf{S}_B} (A > B)$ in Eq. (3.57) is

$$\sum_{k=B}^{A} \prod_{i=0}^{k-1} (v_A - v_i) \prod_{j=k+1}^{m} (v_B - v_j). \tag{3.60}$$

Equation (3.60) is written as

$$\sum_{k=B}^{A} \prod_{i=0}^{k-1} (v_A - v_i) \prod_{j=k+1}^{m} (v_B - v_j) = (v_A - v_0)(v_A - v_1) \cdots (v_A - v_{B-1})(v_{A+1} - v_B) \times (v_{A+2} - v_B) \cdots (v_{m-1} - v_B)(v_m - v_B) \$_{A-B}, \tag{3.61}$$

where $\$_{A-B}$ is defined as

$$\begin{aligned} \$_{A-B} \equiv & (v_B - v_{B+1})(v_B - v_{B+2}) \cdots (v_B - v_A) \\ & + (v_A - v_B)(v_B - v_{B+2}) \cdots (v_B - v_A) \\ & \vdots \\ & + (v_A - v_B)(v_{B+1} - v_A) \cdots (v_{A-1} - v_A). \end{aligned} \tag{3.62}$$

We can see $\$_{A-B}$ always vanishes for any set of v_i (see Appendix D). Then the cross term does not appear. Finally, the remaining terms are closed in each set $\mathbf{S}_A$ such as

$$\left(\hat{\phi}_q \frac{\delta}{\delta \hat{\phi}} \right) \frac{\delta V(\hat{\phi})}{\delta \hat{\phi}} \bigg|_{\mathrm{GMS}} = b_m \sum_{A=0}^{m} \prod_{i=0}^{A-1} (v_A - v_i) \prod_{j=A+1}^{m} (v_A - v_j) \hat{\mathbf{P}}_{\mathbf{S}_A} \hat{\phi}_q \hat{\mathbf{P}}_{\mathbf{S}_A}. \tag{3.63}$$

Then the bosonic part of the action is written as

$$S_B^{\mathbf{S}} = \frac{1}{4} \theta \sum_{A=0}^{m} \left(b_m \prod_{i=0}^{A-1} (v_A - v_i) \prod_{j=A+1}^{m} (v_A - v_j) \right)^2 \mathrm{Tr}[\hat{\mathbf{P}}_{\mathbf{S}_A} \hat{\phi}_q \hat{\mathbf{P}}_{\mathbf{S}_A} \hat{\phi}_q]. \tag{3.64}$$

For the fermionic part, the calculation is the same as the bosonic part. Here $(\hat{\psi}(\delta/\delta\hat{\phi}) \times(\delta V(\hat{\phi})/\delta\hat{\phi})$ is given as

$$\left(\hat{\psi}\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}} = b_m \sum_{A=0}^{m}\prod_{i=0}^{A-1}(v_A - v_i)\prod_{j=A+1}^{m}(v_A - v_j)\hat{\mathbf{P}}_{\mathbf{S}_A}\hat{\psi}\hat{\mathbf{P}}_{\mathbf{S}_A}. \tag{3.65}$$

Then the fermionic part of the action is written as

$$S_F^{\mathbf{S}} = -i\theta b_m \sum_{A=0}^{m}\prod_{i=0}^{A-1}(v_A - v_i)\prod_{j=A+1}^{m}(v_A - v_j)\mathrm{Tr}[\hat{\chi}\hat{\mathbf{P}}_{\mathbf{S}_A}\hat{\psi}\hat{\mathbf{P}}_{\mathbf{S}_A}]. \tag{3.66}$$

We substitute $\mathbf{P}_{\mathbf{S}_A} = \Sigma_{i\in\mathbf{S}_A}\mathbf{P}_i$ into Eqs. (3.64) and (3.66), and use Eq. (3.50), Then we get the action,

$$S_{\mathbf{S}} = S_B^{\mathbf{S}} + S_F^{\mathbf{S}} = \sum_{A=0}^{m}\left\{\frac{1}{4}\theta\sum_{i,j\in\mathbf{S}_A}(b_m\zeta_A)^2\phi_{ij}\phi_{ji} - i\theta\sum_{i,j\in\mathbf{S}_A}b_m\zeta_A\chi_{ij}\psi_{ji}\right\}, \tag{3.67}$$

where we define

$$\zeta_A \equiv \prod_{k=0}^{A-1}(v_A - v_k)\prod_{l=A+1}^{m}(v_A - v_l), A\in\{0,1,2,\ldots,m\}. \tag{3.68}$$

Note that the ϕ_{ij}, χ_{ij} and ψ_{ij} are the c-numbers. Using the result in Appendix C, we can estimate both the partition function in the operator representation and in the commutative field representation with the Moyal product, but the results have no difference. Here, we perform the integral in the operator representation. Then the pathintegral becomes simply an integral of real number (real Grassmann number):

$$\begin{aligned}\mathcal{Z}_{\mathbf{S}} &= \int \mathcal{D}\chi\mathcal{D}\psi\mathcal{D}\phi e^{-S_{\mathbf{S}}} \\ &= \int \prod_{A=0}^{m}\prod_{\substack{m>n \\ i,j\in\mathbf{S}_A}}\left(\frac{d\phi_{ij}}{\sqrt{4\pi\theta}}\right)d\chi_{ij}d\psi_{ij}\exp\{-S_B^{\mathbf{S}} - S_F^{\mathbf{S}}\} \\ &= \prod_{A=0}^{m}[\sqrt{b_m\zeta_A}]^{-n_A^2}[b_m\zeta_A]^{n_A^2},\end{aligned} \tag{3.69}$$

and we get

$$\mathcal{Z}_{\mathbf{S}} = \prod_{A=0}^{m}[\mathrm{sgn}(b_m\zeta_A)]^{n_A}. \tag{3.70}$$

Here n_A is the number of the elements belonging to the set $\mathbf{S}_A$, and we call this number the ''rank'' of $\mathbf{S}_A$; $n_A = \mathrm{rank}\,\mathbf{S}_A$. The noncommutative parameter θ contained under integral measure $d\phi$ in the second line of (3.69) comes from the integral of H. The path integral of the fields ϕ_{ij}, χ_{ij} and ψ_{ij} with indices $(i\in\mathbf{S}_A, j\in\mathbf{S}_B, A\neq B)$ is done with the weight of the kinetic terms, which contributes ''1'' in the partition function. The number of the GMS solitons specified by $\mathbf{S} = \{\mathbf{S_1}, \mathbf{S_2}, \ldots, \mathbf{S_m}\}$ is $N!/n_0!n_1!\cdots n_m!$, where $n_i = \mathrm{rank}\,\mathbf{S_i}$. Therefore, the total partition function that includes all the GMS solitons is given by

$$\mathcal{Z}_{\text{Total}} = \lim_{N\to\infty} \sum_{\mathbf{S}} \mathcal{Z}_{\mathbf{S}}$$

$$= \lim_{N\to\infty} \sum_{\substack{n_0,\cdots,n_m=0 \\ n_0+\cdots+n_m=N}}^{N} \frac{N!}{n_0!n_1!\cdots n_m!} \prod_{A=0}^{m} [\text{sgn}(b_m\zeta_A)]^{n_A} \tag{3.71}$$

$$= \lim_{N\to\infty} (\text{sgn}[b_m])^N (\text{sgn}\,\zeta_0 + \text{sgn}\,\zeta_1 + \cdots + \text{sgn}\,\zeta_m)^N. \tag{3.72}$$

Under the same condition of $v_0 < v_1 < \cdots < v_m$ as in the previous section (see Fig. 2, too), the sign of ζ_A is a simple form,

$$\text{sgn}(\zeta_A) = (-1)^{m-A}, A \in \{0,1,2,\ldots,m\}. \tag{3.73}$$

Then the partition function is

$$\mathcal{Z}_{\text{Total}} = \lim_{N\to\infty} (\text{sgn}[b_m])^N (-1)^m (\underbrace{1-1+1-1+\cdots}_{m+1})^N$$

$$= \begin{cases} \lim_{N\to\infty} (\text{sgn}[b_m])^N & : m \text{ is even number,} \\ 0 & : m \text{ is odd number.} \end{cases} \tag{3.74}$$

Note that through a simple calculation, the partition function Eq. (3.71) is rewritten as

$$\mathcal{Z}_{\text{Total}} = \lim_{N\to\infty} [\text{sgn}(b_m)]^N (-1)^m \sum_{n_p=0}^{N} (-1)^{n_p} \frac{N!}{(N-n_p)!n_p!} [(m+1)/2]^{n_p} ([m/2]+1)^{N-n_p}, \tag{3.75}$$

where the bracket $[\cdots]$ is the Gauss notation. The integer n_p is the number of negative solutions, and it is the sum of n_{2i+1}. This number n_p is related to the Morse theory. This is discussed in the next section.

IV. EULER NUMBER OF GMS SOLITON SPACE

In this section we discuss the properties of the partition function from the point of view of quantum geometry.

A. Noncommutative Mathai–Quillen formalism

In the beginning, we study the partition function with Mathai–Quillen formalism.

As in the usual cohomological field theory, ψ is a tangent vector to the zero section, i.e., the tangent vector to the solution space, $\{\phi, B_\mu | s^a(\phi, B_\mu, \theta) = 0\} = \mathcal{M}$. Note that the vanishing theorem asserts that the zero section space is identified with the GMS solution space. In our theory, since $B^\mu B_\mu = 0$ has only a trivial solution, the zero section space is identified with $\{\phi |\ \delta V/\delta\phi = 0\}$. A condition like the vanishing theorem appears in general in the balanced topological field theory.

In the commutative limit ($\theta \to 0$), the relevant terms of the bosonic action are

$$|\partial_\mu \phi|^2 + \left|\frac{\delta V}{\delta \phi}\right|^2. \tag{4.1}$$

So the lowest energy solutions (true vacua) are constant that satisfy $\delta V/\delta\phi=0$. The number of solutions is $m+1$, that is, the exponent of $\delta V/\delta\phi$ in the commutative limit. Hence, there is no problem in defining the Euler number of the space $\mathcal{M}$ which consists of $m+1$ isolated points as $\pm\Sigma_{k=0}^{m}(-1)^k$. On the contrary, in the large θ limit, the number of GMS soliton solutions is infinite, that is, rank of K_0. Generally, it is a difficult case to define the Euler number of $\mathcal{M}$. However, as we saw in the previous sections, the partition function is invariant under the shift of θ. Finally, the Euler number of the moduli space is invariant under the noncommutative deformation of $\delta V/\delta\phi=0$.

The Gaussian integral in the noncommutative field theories is not familiar in general. But in this case, it is well-defined by the supersymmetry. As we see at first, the result of the path integral in the strong noncommutative limit does not contradict the commutative limit. This is evidence of the validity of the Gaussian integral of the noncommutative field theory. Note that the large θ limit is not the strong coupling limit. We have to consider two parameters, the noncommutative parameter θ and the coupling constant g multiplying overall. In order to get exact results by perturbative calculations, it is necessary for g to approach zero.

In the cohomological field theory, the partition function does not depend on an overall parameter like this g.

We summarize the previous sections by taking account of the fact that the partition function of cohomological field theory can be regarded as the Euler number of $\mathcal{M}$ by Mathai–Quillen formalism.[22]

Theorem IV.1 (θ-shift invariants): *The partition functions Z_θ of the noncommutative cohomological field theories are invariant under the shift of the noncommutative parameter θ:*

$$\frac{\delta}{\delta\theta}Z_\theta=0. \tag{4.2}$$

■

Theorem IV.2 (Euler number of GMS solution space): *On the Moyal plane, when the GMS solution space for real scalar field ϕ is*

$$\mathcal{M}_m=\{\,\phi\,|\,b_m(\cdots\underbrace{(\phi*_\theta(\phi-v_1))*_\theta(\phi-v_2))\cdots*_\theta(\phi-v_m)}_{m+1})=0,\ b_m>0\,\}, \tag{4.3}$$

and any two of v_i are different ($v_i\neq v_j$ for $i\neq j$), then the Euler number of the space $\mathcal{M}_m$ is given by

$$\chi_m=\begin{cases}1 & :\text{m is even number,}\\ 0 & :\text{m is odd number.}\end{cases} \tag{4.4}$$

■

B. Noncommutative Morse theory

In this subsection, we see that the noncommutative cohomological field theory can be regarded as the noncommutative Morse theory.[23,27]

In the commutative limit, the partition function of our theory is given by the Hessian of $\delta^2V/\delta\phi^2$ as we saw in Sec. III. Especially, the zero mode of $\partial_\mu\phi=0$ is just a real constant number. Then the determinant of the Hessian at the critical point p is determined by the sign of the second derivative of the real function at p, where the critical point p is the solution of $dV(x)/dx\,|_p=0 (x\in\mathbf{R})$. We denote the number of negative eigenvalues of the Hessian as n_p. In the commutative limit n_p is either 0 or 1, so the partition function is written by

$$Z=\sum_p \frac{\det \delta^2 V(p)/\delta p^2}{|\det \delta^2 V(p)/\delta p^2|}=\sum_p (-1)^{n_p}=\begin{cases}1: & m \text{ is even number},\\ 0: & m \text{ is odd number}.\end{cases} \tag{4.5}$$

By the fundamental theorem of Morse theory, this is the Euler number of the isolated points $\{p\}$ and this result is consistent with the result of applying Mathai–Quillen formalism to cohomological field theory.

On the other hand, the partition function is determined by the determinant of the operator valued Hessian $\delta^2 V(\phi)/\delta\phi^2$ in the large θ limit. The critical points are operators, too, i.e. GMS solitons are critical points and they exist infinitely at each p. But for each critical point, we can estimate $\det(\delta^2 V(\phi)/\delta\phi^2)$. Now we introduce the Morse index M_{n_p}. M_{n_p} is defined as the number of GMS solitons satisfying the condition that the Hessian consisting of the GMS solitons has n_p negative eigenvalues. As we saw in Sec. III and the Appendix, the n_p is the number of projection operators $\mathbf{P}_i$ whose coefficients belong to p_- in the GMS solution. Here we define p_- and p_+ as the set of critical points that satisfy

$$\begin{aligned}\left.\frac{\delta^2 V(p)}{\delta p^2}\right|_{p_-} &< 0,\\ \left.\frac{\delta^2 V(p)}{\delta p^2}\right|_{p_+} &> 0.\end{aligned} \tag{4.6}$$

In the case of positive b_m, the critical points are $p_-=\{v_0,v_2,\ldots,v_m\}$, and $p_+=\{v_1,v_3,\ldots,v_{m-1}\}$ (see Fig. 2). The number of p_- elements is $[(m+1)/2]$, and the number of p_+ is $[m/2]+1$. Then the number of combinations that n_p projections is combined with $[(m+1)/2]$ points of p_- in the soliton is $[(m+1)/2]^{n_p}$. When the total number of projections is fixed by N, then the remaining $(N-n_p)$ projections are combined with p_+ and its number of combinations is $([m/2]+1)^{(N-n_p)}$. Then the Morse index is given by

$$M_{n_p}(m,N)=[(m+1)/2]^{n_p}([m/2]+1)^{(N-n_p)}\cdot\frac{N!}{(N-n_p)!n_p!}. \tag{4.7}$$

M_{n_p} is divergent in the limit of $N\to\infty$. But we can define the Euler number of the isolated GMS soliton solutions as the fundamental theorem of Morse theory,

$$\chi_m=\sum_{\mathrm{GMS}}(-1)^{n_p}=\sum_{n_p}(-1)^{n_p}M_{n_p} \tag{4.8}$$

$$=(-[(m+1)/2]+[m/2]+1)^N=\begin{cases}1: & m \text{ is even number},\\ 0: & m \text{ is odd number}.\end{cases} \tag{4.9}$$

This is a result consistent with Sec. III and the Mathai–Quillen formalism. Therefore we can conclude that the noncommutative cohomological field theory makes it possible to generalize the Morse theory for the noncommutative field theory.

V. CONCLUSION AND DISCUSSION

We have studied the noncommutative cohomological field theory. Especially, the balanced scalar model is investigated carefully. A couple of theorems are provided. First, the partition function is invariant under the shift of the noncommutative parameter. Second, the Euler number of the GMS soliton space on the Moyal plane is calculated and it is ''1'' for the scalar potential with even degree and ''0'' for odd degree. (Note that the potential in the original GMS paper corresponds to $\delta V(\phi)/\delta\phi$ in our theory. So, the degree of potential is shifted from m to $m+1$.) In

general, Mathai–Quillen formalism tells us that the partition function of cohomological field theory is the Euler number of solution space $\mathcal{M}$ when the space is commutative. We expect that the noncommutative case is the same as the commutative case. Indeed, as we saw in the previous section, it is possible to identify the partition function of the noncommutative cohomological field theory with the Euler number as a result of the fundamental theorem of Morse theory, that is extended to the noncommutative field theory. In this article, we saw this relation in a scalar model, but it is expected that there is no obstacle to applying general cases.

It is possible to use our method for more complex models. For example, we can estimate the Euler number of the moduli space of instantons on noncommutative $\mathbf{R}^4$. In that case, the partition function is the Euler number of the instanton moduli space, and there is some new moduli space of the new instanton like Nekrasov–Schwarz.[3,24] For another example, we can change the base manifold to noncommutative torus. In that case, we will have to use the Powers–Rieffel projection for calculation in the strong noncommutative limit.[20,25] From another point of view, we should study other types of noncommutativity. For example, the noncommutative parameter is a locally defined type, a fuzzy sphere type and so on. To study such various cases it is important to construct the local geometry of noncommutative spaces. They are left as future works.

Most of the geometric nature of the noncommutative space is still unknown. But, as we saw, it is likely that some kinds of commutative space are succeeded by noncommutative space. We will have to study a huge number of them to throw light on the noncommutative geometry.

APPENDIX A: LARGE θ LIMIT: ϕ^3 POTENTIAL

In this appendix, we show calculations in the large θ limit for simple examples of the balanced scalar model. One example is the ϕ^3 potential, and another is the ϕ^4 potential that is discussed in Appendix B.

We consider the cubic potential,

$$V(\phi)=b_0+b_1\hat{\phi}+\frac{1}{2}b_2\phi*\phi+\frac{1}{3!}b_3\phi*\phi*\phi. \tag{A1}$$

The field equation is written as

$$\frac{\delta V}{\delta\phi}=b_1+b_2\phi+\frac{1}{2}b_3\phi*\phi=\frac{1}{2}b_3(\phi-\alpha)*(\phi-\beta), \tag{A2}$$

where we put

$$\alpha,\beta=-(b_2/b_3)\pm\sqrt{(b_2/b_3)^2-2(b_1/b_3)}. \tag{A3}$$

We consider the case where both α and β are real numbers. By the redefinition of the field ϕ by a translation,

$$\phi'\equiv\phi-\alpha, \tag{A4}$$

the field equation is written as

$$\frac{\delta V}{\delta\phi}=\frac{1}{2}b_3\phi'*(\phi'-(\beta-\alpha))=0. \tag{A5}$$

The GMS solution is given by

$$\hat{\phi}'_{\mathrm{GMS}}=\lambda_i\hat{\mathbf{P}}_i\,, \tag{A6}$$

where the projection operator is $\hat{P}_i=|i\rangle\langle i|$. We put the GMS solution to the field equation,

$$\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}=\frac{1}{2}b_3\lambda_i(\lambda_i-(\beta-\alpha))\hat{\mathbf{P}}_i=0. \tag{A7}$$

The solution is

$$\lambda_i=0,\quad \lambda_i=\beta-\alpha\equiv v\,. \tag{A8}$$

The general GMS solution is a linear combination of projections with coefficients λ_i,

$$\hat{\phi}_{\mathrm{GMS}}=v\sum_{i\in\mathbf{S}}\hat{\mathbf{P}}_i=v\hat{\mathbf{P}}_S\,. \tag{A9}$$

The bosonic part of the action is

$$S_B^{\mathbf{S}}=-\frac{1}{4}\theta\,\mathrm{Tr}\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}. \tag{A10}$$

The linear terms of expansion of $V(\hat{\phi})$ around the GMS soliton are

$$\begin{aligned}\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}&=\left(\hat{\phi}_q\frac{\delta}{\delta\hat{\phi}}\right)\left[\frac{b_3}{2}\hat{\phi}(\hat{\phi}-v)\right]_{\phi=\phi_{\mathrm{GMS}}}\\&=\frac{b_3}{2}\{\hat{\phi}_q(\hat{\phi}_{\mathrm{GMS}}-v)+\hat{\phi}_{\mathrm{GMS}}\hat{\phi}_q\}\\&=\frac{b_3v}{2}\{-\hat{\phi}_q(\hat{\mathbf{1}}-\hat{\mathbf{P}}_S)+\hat{\mathbf{P}}_S\hat{\phi}_q\}.\end{aligned} \tag{A11}$$

Hence, we get

$$S_B^{\mathbf{S}}=-\frac{1}{4}\theta\left(\frac{b_3v}{2}\right)^2\mathrm{Tr}[\,\hat{\phi}_q(\hat{\mathbf{1}}-\hat{\mathbf{P}}_S)\hat{\phi}_q(\hat{\mathbf{1}}-\hat{\mathbf{P}}_S)+\hat{\mathbf{P}}_S\hat{\phi}_q\hat{\mathbf{P}}_S\hat{\phi}_q]. \tag{A12}$$

The fermionic part of the action is

$$S_F^{\mathbf{S}}=-i\theta\mathrm{Tr}\hat{\chi}\left(\hat{\psi}\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}. \tag{A13}$$

As is the same as the bosonic part, the leading terms of quantum field are given by

$$\left(\hat{\psi}\frac{\delta}{\delta\hat{\phi}}\right)\frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}=\frac{b_3v}{2}\{-\hat{\psi}(\hat{\mathbf{1}}-\hat{\mathbf{P}}_{\mathbf{S}})+\hat{\mathbf{P}}_{\mathbf{S}}\hat{\psi}\}. \tag{A14}$$

Then the fermionic part of the action is written as

$$S_F^{\mathbf{S}}=-\frac{\theta b_3v}{2}\mathrm{Tr}[-\hat{\chi}(\hat{\mathbf{1}}-\hat{\mathbf{P}}_S)\hat{\psi}(\hat{\mathbf{1}}-\hat{\mathbf{P}}_S)+\hat{\chi}\hat{\mathbf{P}}_S\hat{\psi}\hat{\mathbf{P}}_S]. \tag{A15}$$

The partition function is given by

$$\begin{aligned}\mathcal{Z}_{\mathrm{S}} &= \int \mathcal{D}\chi\mathcal{D}\psi\mathcal{D}\phi e^{-S} \\ &= \int \prod_{\substack{i>j \\ i,j\neq\in S}} \frac{d\phi_{ij}}{\sqrt{4\pi\theta}} d\chi_{ij} d\psi_{ij} \prod_{\substack{i>j \\ i,j\in S}} \frac{d\phi_{ij}}{\sqrt{4\pi\theta}} d\chi_{ij} d\psi_{ij} e^{-S_B^{\mathrm{S}} - S_F^{\mathrm{S}}} \\ &= \left[\sqrt{\left(\frac{b_3 v}{2}\right)^2}\right]^{-(N-n)^2} \left[\sqrt{\left(\frac{b_3 v}{2}\right)^2}\right]^{-n^2} \left[-\frac{b_3 v}{2}\right]^{(N-n)^2} \left[\frac{b_3 v}{2}\right]^{n^2}, \end{aligned} \tag{A16}$$

and we get

$$\mathcal{Z}_{\mathrm{S}} = [-\mathrm{sgn}(b_3)]^{(N-n)^2} [\mathrm{sgn}(b_3)]^{n^2} = [-\mathrm{sgn}(b_3)]^{N-n} [\mathrm{sgn}(b_3)]^n, \tag{A17}$$

where $n = \mathrm{rank}\, S$. There are $N!/(N-n)!n!$ sets of the GMS solution which has the rank n. Then the total partition function is the sum over $\mathcal{Z}_{\mathrm{S}}$ with the weight $N!/(N-n)!n!$,

$$\begin{aligned}\mathcal{Z}_{\mathrm{Total}} &= \sum_{\mathrm{S}} \mathcal{Z}_{\mathrm{S}} \\ &= \lim_{N\to\infty} \sum_{n=0}^{N} {}_N C_n [-\mathrm{sgn}(b_3)]^{N-n} [\mathrm{sgn}(b_3)]^n. \end{aligned} \tag{A18}$$

From the binomial theorem, we find that

$$\mathcal{Z}_{\mathrm{Total}} = 0. \tag{A19}$$

In the ϕ^3 potential, the partition function is zero.

APPENDIX B: LARGE θ LIMIT: ϕ^4 POTENTIAL

Here we consider another simple example which has ϕ^4 potential,

$$V(\phi) = b_0 + b_1\phi + \frac{1}{2} b_2 \phi * \phi + \frac{1}{3!} b_3 \phi * \phi * \phi + \frac{1}{4!} b_4 \phi * \phi * \phi * \phi. \tag{B1}$$

The field equation is always written as a factorization form

$$\frac{\delta V}{\delta \phi} = \frac{1}{3!} b_4 (\phi - \alpha) * (\phi - \beta) * (\phi - \gamma). \tag{B2}$$

As is the same as the ϕ^3, we translate the scalar field

$$\phi' \equiv \phi - \alpha. \tag{B3}$$

Then the field equation is rewritten as

$$\frac{\delta V}{\delta \phi} = \frac{1}{3!} b_4 \phi' * (\phi' - (\beta - \alpha)) * (\phi' - (\gamma - \alpha)) = \frac{1}{3!} b_4 \phi' * (\phi' - v_1) * (\phi' - v_2), \tag{B4}$$

where we define

$$v_1 \equiv (\beta - \alpha), v_2 \equiv (\gamma - \alpha). \tag{B5}$$

For simplicity we take α, β and γ are real numbers. We put the GMS solution $\phi'_{\mathrm{GMS}} = \lambda_i \mathbf{P}_i$ into the field equation; then

$$\frac{\delta V}{\delta \phi} = \frac{1}{3!} b_4 \lambda_i (\lambda_i - v_1)(\lambda_i - v_2)\mathbf{P}_i = 0. \tag{B6}$$

The solution is

$$\lambda_i = 0, v_1, v_2. \tag{B7}$$

The general GMS solution is a linear combination of projections with coefficients λ_i,

$$\phi_{\mathrm{GMS}} = v_1 \sum_{i \in \mathbf{S_1}} \mathbf{P}_i + v_2 \sum_{i \in \mathbf{S_2}} \mathbf{P}_i \tag{B8}$$

$$= v_1 \mathbf{P}_{\mathbf{S_1}} + v_2 \mathbf{P}_{\mathbf{S_2}}. \tag{B9}$$

The bosonic part of the action is given by

$$S_B^{\mathbf{S}} = -\frac{1}{4} \mathrm{Tr} \left[\left(\hat{\phi}_q \frac{\delta}{\delta \hat{\phi}} \right) \frac{\delta V(\hat{\phi})}{\delta \hat{\phi}} \bigg|_{\mathrm{GMS}} \left(\hat{\phi}_q \frac{\delta}{\delta \hat{\phi}} \right) \frac{\delta V(\hat{\phi})}{\delta \hat{\phi}} \bigg|_{\mathrm{GMS}} \right]. \tag{B10}$$

The linear terms of expansion of $V(\hat{\phi})$ around the GMS soliton are

$$\begin{aligned}
\left(\hat{\phi}_q \frac{\delta}{\delta \hat{\phi}} \right) \frac{\delta V(\hat{\phi})}{\delta \hat{\phi}} \bigg|_{\mathrm{GMS}} &= \left(\phi_q \frac{\delta}{\delta \hat{\phi}} \right) \left[\frac{b_4}{3!} \hat{\phi}(\hat{\phi} - v_1)(\hat{\phi} - v_2) \right]_{\hat{\phi} = \hat{\phi}_{\mathrm{GMS}}} \\
&= \frac{b_4}{3!} \{ \hat{\phi}_q (\hat{\phi}_{\mathrm{GMS}} - v_1)(\hat{\phi}_{\mathrm{GMS}} - v_2) + \hat{\phi}_{\mathrm{GMS}} \hat{\phi}_q (\hat{\phi}_{\mathrm{GMS}} - v_2) \\
&\quad + \hat{\phi}_{\mathrm{GMS}} (\hat{\phi}_{\mathrm{GMS}} - v_2) \hat{\phi}_q \} \\
&= \frac{b_4}{3!} \{ (v_1 v_2) \hat{\phi}_q (\hat{\mathbf{1}} - \hat{\mathbf{P}}_{\mathbf{S_1}} - \hat{\mathbf{P}}_{\mathbf{S_2}}) + (v_1 \hat{\mathbf{P}}_{\mathbf{S_1}} v_2 \hat{\mathbf{P}}_{\mathbf{S_2}}) \hat{\phi}_q [- v_2 (\hat{\mathbf{1}} - \hat{\mathbf{P}}_{\mathbf{S_1}} - \hat{\mathbf{P}}_{\mathbf{S_2}}) \\
&\quad + (v_1 - v_2) \hat{\mathbf{P}}_{\mathbf{S_1}}] + v_2 (v_2 - v_1) \hat{\mathbf{P}}_{\mathbf{S_2}} \hat{\phi}_q \}.
\end{aligned} \tag{B11}$$

The bosonic part of the action is

$$\begin{aligned}
S_B^{\mathbf{S}} = -\frac{1}{4} \theta \mathrm{Tr} [& (b_4 \zeta_0)^2 \hat{\phi}_q (\hat{\mathbf{1}} - \hat{\mathbf{P}}_{\mathbf{S_1}} - \hat{\mathbf{P}}_{\mathbf{S_2}}) \hat{\phi}_q (\hat{\mathbf{1}} - \hat{\mathbf{P}}_{\mathbf{S_1}} - \hat{\mathbf{P}}_{\mathbf{S_2}}) \\
& + (b_4 \zeta_1)^2 \hat{\mathbf{P}}_{\mathbf{S_1}} \hat{\phi}_q \hat{\mathbf{P}}_{\mathbf{S_1}} \hat{\phi}_q + (b_4 \zeta_2) \hat{\mathbf{P}}_{\mathbf{S_2}} \hat{\phi}_q \hat{\mathbf{P}}_{\mathbf{S_2}} \hat{\phi}_q],
\end{aligned} \tag{B12}$$

where we define

$$\zeta_0 \equiv \frac{1}{3!} v_1 v_2, \quad \zeta_1 \equiv \frac{1}{3!} v_1 (v_1 - v_2), \quad \zeta_2 \equiv \frac{1}{3!} v_2 (v_2 - v_1). \tag{B13}$$

The fermionic part of the Lagrangian is written as

$$S_F^{\mathbf{S}} = -i\theta \mathrm{Tr}\hat{\chi}\left(\hat{\psi}\frac{\delta}{\delta\hat{\phi}} \right) \frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}}. \tag{B14}$$

The BRST operation is given by

$$\left(\hat{\psi}\frac{\delta}{\delta\hat{\phi}} \right) \frac{\delta V(\hat{\phi})}{\delta\hat{\phi}}\bigg|_{\mathrm{GMS}} = \frac{b_4}{3!}\{(v_1v_2)\hat{\psi}(\hat{\mathbf{1}}-\hat{\mathbf{P}}_{\mathbf{S}_1}-\hat{\mathbf{P}}_{\mathbf{S}_2}) + (v_1\hat{\mathbf{P}}_{\mathbf{S}_1}+v_2\hat{\mathbf{P}}_{\mathbf{S}_2})\hat{\psi}$$
$$\times[-v_2(\hat{\mathbf{1}}-\hat{\mathbf{P}}_{\mathbf{S}_1}-\hat{\mathbf{P}}_{\mathbf{S}_2}) + (v_1-v_2)\hat{\mathbf{P}}_{\mathbf{S}_1}] + v_2(v_2-v_1)\hat{\mathbf{P}}_{\mathbf{S}_2}\hat{\psi}\}. \tag{B15}$$

Then the fermionic part is

$$S_F^{\mathbf{S}} = -i\theta \mathrm{Tr}[b_4\zeta_0\hat{\chi}(\hat{\mathbf{1}}-\hat{\mathbf{P}}_{\mathbf{S}_1}-\hat{\mathbf{P}}_{\mathbf{S}_2})\hat{\psi}(\hat{\mathbf{1}}-\hat{\mathbf{P}}_{\mathbf{S}_1}-\hat{\mathbf{P}}_{\mathbf{S}_2}) + b_4\zeta_1\hat{\chi}\hat{\mathbf{P}}_{\mathbf{S}_1}\hat{\psi}\hat{\mathbf{P}}_{\mathbf{S}_1} + b_4\zeta_2\hat{\chi}\hat{\mathbf{P}}_{\mathbf{S}_2}\hat{\psi}\hat{\mathbf{P}}_{\mathbf{S}_2}]. \tag{B16}$$

The partition function is given by

$$\mathcal{Z}_{\mathbf{S}} = \int \mathcal{D}\chi\mathcal{D}\psi\mathcal{D}\phi e^{-S} \tag{B17}$$

$$= \int \prod_{\mathbf{S}=\mathbf{S}_0}^{S_2} \left[\prod_{\substack{m>n \\ i,j\in\mathbf{S}}} \frac{d\phi_{ij}}{\sqrt{4\pi\theta}} d\chi_{ij} d\psi_{ij} e^{-S_B^{\mathbf{S}}-S_F^{\mathbf{S}}} \right.$$
$$= [\sqrt{(b_4\zeta_0)^2}]^{-(N-n_1-n_2)^2}[\sqrt{(b_4\zeta_1)^2}]^{-n_1^2}[\sqrt{(b_4\zeta_2)^2}]^{-n_2^2}$$
$$\times [b_4\zeta_0]^{(N-n_1-n_2)^2}[b_4\zeta_1]^{n_1^2}[b_4\zeta_2]^{n_2^2}. \tag{B18}$$

Hence, we get

$$\mathcal{Z}_{\mathbf{S}} = [\mathrm{sgn}(b_4\zeta_0)]^{(N-n_1-n_2)^2}[\mathrm{sgn}(b_4\zeta_1)]^{n_1^2}[\mathrm{sgn}(b_4\zeta_2)]^{n_2^2}, \tag{B19}$$

where $n_1 = \mathrm{rank}\, S_1$, and $n_2 = \mathrm{rank}\, S_2$. From the definition of ζ_i's, one of $\mathrm{sgn}(\zeta_i)$ is always negative, and the others are positive. Then the partition function is always written as

$$\mathcal{Z}_{\mathbf{S}} = [\mathrm{sgn}(b_4)]^{(N-n_1-n_2)^2}[-\mathrm{sgn}(b_4)]^{n_1^2}[\mathrm{sgn}(b_4)]^{n_2^2} \tag{B20}$$

$$= [\mathrm{sgn}(b_4)]^{N-n_1-n_2}[-\mathrm{sgn}(b_4)]^{n_1}[\mathrm{sgn}(b_4)]^{n_2}. \tag{B21}$$

There are $N!/(N-n_1-n_2)!n_1!n_2!$ sets of the GMS solution when the ranks of $\mathbf{S}_1$ and $\mathbf{S}_2$ are n_1 and n_2. Then the total partition function is the sum over $\mathcal{Z}_{\mathbf{S}}$ with the weight $N!/(N-n_1-n_2)!n_1!n_2!$:

$$\mathcal{Z}_{\mathrm{Total}} = \sum_{\mathbf{S}} \mathcal{Z}_{\mathbf{S}}$$
$$= \lim_{N\to\infty} \sum_{n_1,n_2=0}^{N} \frac{N!}{(N-n_1-n)!n_1!n_2!}[\mathrm{sgn}(b_4)]^{N-n_1-n_2}[-\mathrm{sgn}(b_4)]^{n_1}[\mathrm{sgn}(b_4)]^{n_2}$$
$$= \lim_{N\to\infty} (\mathrm{sgn}(b_4) - \mathrm{sgn}(b_4) + \mathrm{sgn}(b_4))^N = \lim_{N\to\infty} (\mathrm{sgn}(b_4))^N. \tag{B22}$$

In the ϕ^4 potential, the partition function takes a nonvanishing value $\lim_{N\to\infty}(\mathrm{sgn}(b_4))^N$.

APPENDIX C: GAUSSIAN INTEGRAL IN THE NONCOMMUTATIVE SPACE

In our calculations, the Gaussian functional integral appears, whose form is

$$\int \mathcal{D}\phi \exp\left\{ -\int d^2x \phi(x) * V(\phi(x))\Big|_{\mathrm{GMS}} * \phi(x) \right\}, \tag{C1}$$

and we convert it into the number representation. Generally, the difference of the operator ordering may yield some difference of the result. Therefore we must show that our prescription is correct.

Generally operators can be represented in the number representation as

$$\hat{O} = \sum_{m,n} O_{mn} |m\rangle\langle n|, \tag{C2}$$

where $\hat{O}$ is any operator and $|m\rangle\langle n|$ is the basis of the number representation. Any operator can be represented as the Weyl ordered operator, so the basis $|m\rangle\langle n|$ can be written as

and its Weyl ordered symbol corresponding to the basis $|m\rangle\langle n|$ is

$$|m\rangle\langle n| = \underbrace{\int \frac{d^2k}{(2\pi)^2} \tilde{f}_{mn}(k) e^{i(k_1\hat{x}^1 + k_2\hat{x}^2)}}_{\text{Weyl ordered operator}}, \tag{C3}$$

$$f_{mn}(x) = \int \frac{d^2k}{(2\pi)^2} \tilde{f}_{mn}(k) e^{i(k_1x^1 + k_2x^2)}. \tag{C4}$$

Here, we consider the following integral,

$$\begin{aligned} \int d\hat{x}_1 d\hat{x}_2 |m\rangle\langle n|p\rangle\langle q| &= \int d\hat{x}_1 d\hat{x}_2 \int \frac{d^2k}{(2\pi)^2} \frac{d^2k'}{(2\pi)^2} \tilde{f}_{mn}(k) \tilde{f}_{pq}(k') e^{i(k_1\hat{x}^1 + k_2\hat{x}^2)} e^{i(k_1'\hat{x}^1 + k_2'\hat{x}^2)} \\ &= \int \frac{d^2k}{(2\pi)^2} \tilde{f}_{mn}(k) \tilde{f}_{pq}(-k), \end{aligned} \tag{C5}$$

where we set $[x^1, x^2] = 1$ for simplicity and use the Baker–Campbell–Hausdorff formula. On the other hand, since $|m\rangle\langle n|p\rangle\langle q| = |m\rangle \delta_{np} \langle q|$,

$$\int d\hat{x}_1 d\hat{x}_2 |m\rangle \delta_{np} \langle q| = \int d\hat{x}_1 d\hat{x}_2 \int \frac{d^2k}{(2\pi)^2} \tilde{f}_{mq}(k) \delta_{np} e^{i(k_1\hat{x}^1 + k_2\hat{x}^2)} = \int d^2k \tilde{f}_{mq}(k) \delta^2(k) \delta_{np}. \tag{C6}$$

Therefore, we can derive a relation:

$$\int \frac{d^2k}{(2\pi)^2} \tilde{f}_{mn}(k) \tilde{f}_{pq}(-k) = \int d^2k \tilde{f}_{mq}(k) \delta^2(k) \delta_{np}. \tag{C7}$$

Using Eq. (C7), we get the following relation:

$$\int d^2x f_{mn}(x) * f_{pq}(x) = \int d^2x f_{mq}(x) \delta_{np}. \tag{C8}$$

A similar calculation gives

$$\int d^2x f_{p_1q_1}(x)*f_{p_2q_2}(x)*\cdots*f_{p_nq_n}(x)=\int d^2x f_{p_1q_n}(x)\delta_{q_1p_2}\delta_{q_2p_3}\cdots\delta_{q_{n-1}p_n}. \tag{C9}$$

It is possible to expand any function in terms of $f_{mn}(x)$, so $\phi(x)$ and $V(\phi)|_{\mathrm{GMS}}$ in Eq. (C1) are expanded as

$$\phi(x)=\sum_{mn}\phi_{mn}f_{mn}(x), \tag{C10}$$

$$V(\phi)|_{\mathrm{GMS}}=\sum_{l}V_l f_{ll}(x). \tag{C11}$$

Therefore we perform the functional integral (C1) using Eqs. (C8) and (C9) as follows:

$$\int \mathcal{D}\phi\exp\left\{-\int d^2x\phi_{mn}V_l\phi_{pq}(f_{mn}(x)*f_{ll}(x)*f_{pq})\right\}=[\det|V_l|^{1/2}]^{-1}. \tag{C12}$$

On the other hand, a calculation in the number representation gives

$$\int \mathcal{D}\hat{\phi}\exp\{-\mathrm{Tr}\phi_{mn}V_l\phi_{pq}(|m\rangle\langle n|l\rangle\langle l|p\rangle\langle q|)\}=\int \mathcal{D}\phi\exp(-\phi_{ml}V_l\phi_{lm})=[\det|V_l|^{1/2}]^{-1}, \tag{C13}$$

which is the same result as Eq. (C12) without normalizing constant which is canceled out. Therefore, we can perform integration in both representations, and the number operator is used in our calculations.

APPENDIX D: $\$_n=0$

We prove a theorem here.

The theorem which we will prove here is

$$\sum_{i=B}^{A}\prod_{\alpha=0}^{i-1}(v_A-v_\alpha)\prod_{\beta=i+1}^{r}(v_B-v_\beta)=0, \tag{D1}$$

where integers A,B satisfy $0\leqslant B<A\leqslant r$, and v_i is any real number. We defined the following notation formally for convenience:

$$\prod_{\alpha=0}^{-1}(v_A-v_\alpha)=\prod_{\alpha=r+1}^{r}(v_A-v_\alpha)=1. \tag{D2}$$

Its proof is as follows.

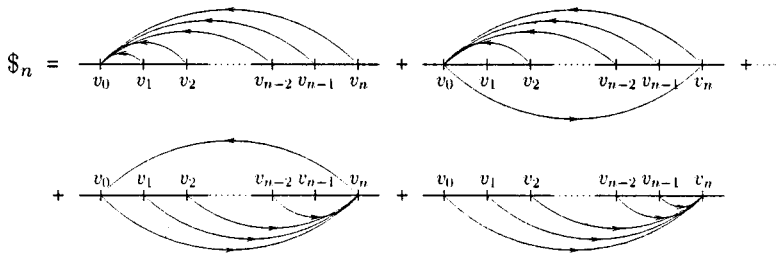

FIG. 3. Graphical representation of $\$_n$. The arrow $v_i \leftarrow v_j$ means $(v_j - v_i)$, and all arrows in one figure should be multiplied.

Proof:

$$\sum_{i=B}^{A}\prod_{\alpha=0}^{i-1}(v_A-v_\alpha)\prod_{\beta=i+1}^{r}(v_B-v_\beta)$$

$$=\sum_{i=B}^{A}(v_A-v_0)(v_A-v_1)\cdots(v_A-v_{i-1})^{\vee}(v_B-v_{i+1})(v_B-v_{i+2})(v_B-v_m)$$

$$=\underbrace{(v_A-v_0)(v_A-v_1)\cdots(v_A-v_{B-1})}_{B}\ \underbrace{(v_B-v_{B+1})(v_B-v_{B+2})\cdots(v_B-v_m)}_{r-B}$$

$$+\underbrace{(v_A-v_0)(v_A-v_1)\cdots(v_A-v_B)}_{B+1}\ \underbrace{(v_B-v_{B+2})(v_B-v_{B+3})\cdots(v_B-v_m)}_{r-B-1}$$

$$+\cdots$$

$$+\underbrace{(v_A-v_0)(v_A-v_1)\cdots(v_A-v_{A-1})}_{A}\ \underbrace{(v_B-v_{A+1})(v_B-v_{A+2})\cdots(v_B-v_m)}_{r-A}$$

$$=(v_A-v_0)(v_A-v_1)\cdots(v_A-v_{B-1})\cdot(v_B-v_{A+1})(v_B-v_{A+2})\cdots(v_B-v_m)$$
$$\times\{1\cdot(v_B-v_{B+1})(v_B-v_{B+2})\cdots(v_B-v_A)+(v_A-v_B)\cdot(v_B-v_{B+2})$$
$$\times(v_B-v_{B+3})\cdots(v_B-v_A)+\cdots$$
$$+(v_A-v_B)(v_A-v_{B+1})\cdots(v_A-v_{A-1})\cdot 1\}. \tag{D3}$$

To show that $\{\cdots\}$ in Eq. (D3) equals zero, we define $\$_n$ as (Fig. 3)

$$\$_n=(v_0-v_1)(v_0-v_2)(v_0-v_3)\cdots(v_0-v_n)+(v_n-v_0)\cdot(v_0-v_2)(v_0-v_3)\cdots(v_0-v_n)$$
$$+(v_n-v_0)(v_n-v_1)\cdot(v_0-v_3)\cdots(v_0-v_n)+\cdots+(v_n-v_0)\cdots(v_n-v_{n-3})\cdot(v_0-v_{n-1})$$
$$\times(v_0-v_n)+(v_n-v_0)\cdots(v_n-v_{n-3})(v_n-v_{n-2})\cdot(v_0-v_n)+(v_n-v_0)\cdots(v_n-v_{n-3})$$
$$\times(v_n-v_{n-2})(v_n-v_{n-1}). \tag{D4}$$

We prove $\$_n=0$ using mathematical induction as follows. First, for $n=1$,

$$\$_1=(v_0-v_1)+(v_1-v_0)=0. \tag{D5}$$

Next, we suppose $\$_n=0$.

And we consider $\$_{n+1}$ as (Fig. 4)

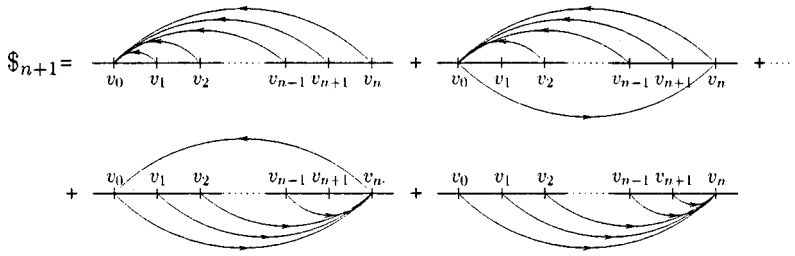

FIG. 4. Graphical representation of $\$_{n+1}$. We put v_{n+1} between v_{n-1} and v_n in the proof.

$$
\begin{aligned}
\$_{n+1} &= (v_0-v_1)(v_0-v_2)(v_0-v_3)\cdots(v_0-v_{n-1})(v_0-v_{n+1})(v_0-v_n)+(v_n-v_0)\cdot(v_0-v_2)\\
&\quad\times(v_0-v_3)\cdots(v_0-v_{n-1})(v_0-v_{n+1})(v_0-v_n)+(v_n-v_0)(v_n-v_1)\cdot(v_0-v_3)\cdots(v_0\\
&\quad-v_{n-1})(v_0-v_{n+1})(v_0-v_n)+\cdots+(v_n-v_0)\cdots(v_n-v_{n-2})\cdot(v_0-v_{n+1})(v_0-v_n)\\
&\quad+(v_n-v_0)\cdots(v_n-v_{n-2})(v_n-v_{n-1})\cdot(v_0-v_n)+(v_n-v_0)\cdots(v_n-v_{n-2})(v_n-v_{n-1})\\
&\quad\times(v_n-v_{n+1})\\
&=\{\$_n-(v_n-v_0)(v_n-v_1)\cdots(v_n-v_{n-1})\}(v_0-v_{n+1})+(v_n-v_0)(v_n-v_1)\cdots(v_n-v_{n-1})\\
&\quad\times\{(v_0-v_n)+(v_n-v_{n+1})\}\\
&=(v_n-v_0)(v_n-v_1)\cdots(v_n-v_{n-1})\{-(v_0-v_{n+1})+(v_0-v_n)+(v_n-v_{n+1})\}=0. \qquad \text{(D6)}
\end{aligned}
$$

Therefore $\$_n=0$ is valid for any n. Using it, $\{\cdots\}$ in Eq. (D3) equals zero, so the proof is completed.

(Received 23 April 2001; accepted for publication 8 November 2001)

It is shown that for any central potential $V(r)$ there exist a series of conserved aphelion and perihelion vectors $\tilde{\mathbf{R}}=\mathbf{p}\times\mathbf{L}-g(r)\mathbf{r}$, $g(r)=rV'(r)$. However, if and only if $V(r)$ is a pure or screened Coulomb potential, $\tilde{\mathbf{R}}$ and $\mathbf{L}$ constitute an SO_4 algebra in the subspace spanned by the degenerate states with a given energy eigenvalue $E<0$ at the aphelia and perihelia ($\dot{r}=0$). For a pure Coulomb potential, $\tilde{\mathbf{R}}$ is reduced to the Pauli–Runge–Lenz (PRL) vector $\mathbf{R}$ and for a screened Coulomb potential $\tilde{\mathbf{R}}$ is reduced to the extended PRL vector $\mathbf{R}'$. While $d\mathbf{R}/dt=0$ always holds, $d\mathbf{R}'/dt=0$ holds only at the aphelia and perihelia. Moreover, the space spanning the SO_4 algebra for a screened Coulomb potential is smaller than that for a pure Coulomb potential. The relation of closed orbits for a screened Coulomb potential with that for a pure Coulomb potential is clarified. The ratio of the radial frequency ω_r and angular frequency ω_ϕ, $\omega_r/\omega_\phi=\kappa=1$ for a pure Coulomb potential irrespective of the angular momentum L and energy $E(<0)$. For a screened Coulomb potential κ is determined by the angular momentum L, and when κ is any rational number ($\kappa<1$), the orbit is closed. The situation for a pure or screened isotropic harmonic oscillator is similar. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1430900]

I. INTRODUCTION

The orbits of a classical particle in an arbitrary central potential, due to the angular momentum conservation, always lie in a plane perpendicular to the angular momentum. However, the orbits are in general not closed. In classical mechanics, there is a celebrated Bertrand's theorem,[1,2] which says that the only central forces that result in closed orbits for all bound particles are the inverse square law and Hooke's law. The closure of orbits is guaranteed by an additional conserved quantity (apart from the energy and angular momentum)—the Runge–Lenz vector for Kepler's problem[3,4] and a quadrupole tensor for the isotropic harmonic oscillator,[5,6] which implies a higher dynamical symmetry than the geometric symmetry (space isotropy).[7–9]

In a previous paper, Bertrand's theorem was extended. It was shown[10,11] that for a screened Coulomb potential (in natural units)

$$V(r)=-1/r-\lambda/r^2 \quad (0<\lambda\ll 1) \tag{1}$$

there may exist an infinite number of closed orbits (rather than ellipses) characterized by a series of conserved aphelion and perihelion vectors, i.e., extended Runge–Lenz vector ($m=1$)

$$\mathbf{R}'=\mathbf{p}\times\mathbf{L}-(1+2\lambda/r)\mathbf{r}/r, \tag{2}$$

a)Electronic mail: zengbei@yahoo.com

$d\mathbf{R}'/dt=0$ at the aphelia and perihelia ($\dot{r}=0$), and each closed orbit corresponds to a discrete angular momentum

$$L=\sqrt{2\lambda/(1-\kappa^2)} \tag{3}$$

(κ being a rational number). It was also shown[12] that $\mathbf{L}$ and $\mathbf{R}'$ constitute an SO_4 algebra in the subspace spanned by the degenerate states belonging to a given bound energy eigenvalue $E<0$ at the aphelia and perihelia ($\dot{r}=0$). However, in this case only the energy (but not angular momentum) raising and lowering operators can be constructed from the factorization of radial Schrödinger equation.[10,12] A similar situation exists for the isotropic harmonic oscillator.

In this paper we will show that for an arbitrary central potential $V(r)$, there always exist a series of conserved aphelion and perihelion vectors,

$$\tilde{\mathbf{R}}=\mathbf{p}\times\mathbf{L}-g(r)\mathbf{r}, \tag{4}$$

where $g(r)=rV'(r)$, and $d\tilde{\mathbf{R}}/dt=0$ at $\dot{r}=0$. However, it is found that in general $\mathbf{L}$ and $\tilde{\mathbf{R}}$ do not constitute an SO_4 algebra at the aphelia and perihelia ($\dot{r}=0$). Therefore, the existence of $\tilde{\mathbf{R}}$ does not imply the closure of an orbit. In Sec. II we will show a theorem concerning the restriction on the form of $V(r)$ that $\mathbf{L}$ and $\tilde{\mathbf{R}}$ constitute an SO_4 algebra. A similar theorem concerning the extended quadrupole tensor for the screened isotropic harmonic oscillator will be presented in Sec. III. However, whether these restrictions imply the closure of orbits needs further investigation. Finally, the closure of orbits for a bound particle in the screened Coulomb potential and isotropic harmonic oscillator will be discussed in Sec. IV from another perspective.

II. DYNAMICAL SYMMETRY OF A SCREENED COULOMB POTENTIAL

Using the angular momentum conservation, it is easy to show that for an arbitrary central potential $V(r)$, there always exist a series of conserved aphelion and perihelion vectors $\tilde{\mathbf{R}}=\mathbf{p}\times\mathbf{L}-g(r)\mathbf{r}$, $g(r)=rV'(r)$. However, not all $\tilde{\mathbf{R}}$ can constitute an SO_4 algebra with $\mathbf{L}$ in a subspace spanned by the degenerate states belonging to a given bound energy eigenvalue $E<0$ at the aphelia and perihelia ($\dot{r}=0$). In fact, we have the following theorem.

Theorem 1: If and only if $V(r)$ is a pure or screened Coulomb potential, $\mathbf{L}$ and $\tilde{\mathbf{R}}$ constitute a closed SO_4 algebra in a subspace spanned by the degenerate states belonging to a given bound energy eigenvalue $E<0$ at the aphelia and perihelia ($\dot{r}=0$).

Proof: The quantum counterpart of $\tilde{\mathbf{R}}$ [see Eq. (4)] is

$$\tilde{\mathbf{R}}=\tfrac{1}{2}(\mathbf{p}\times\mathbf{L}-\mathbf{L}\times\mathbf{p})-g(r)\mathbf{r}. \tag{5}$$

In addition to the well-known commutation relations

$$[L_\alpha,L_\beta]=i\epsilon_{\alpha\beta\gamma}L_\gamma, \tag{6}$$

$$[L_\alpha,\tilde{R}_\beta]=i\epsilon_{\alpha\beta\gamma}\tilde{R}_\gamma, \tag{7}$$

it can be shown for the operator $\tilde{\mathbf{R}}$ (5),

$$\tilde{\mathbf{R}}\times\tilde{\mathbf{R}}=-2i\left[\frac{p^2}{2}-\frac{3g(r)+rg'(r)}{2}\right]\mathbf{L}. \tag{8}$$

Therefore, only when

$$\frac{p^2}{2}-\frac{3g(r)+rg'(r)}{2}=H, \tag{9}$$

where H is the Hamiltonian, do $\mathbf{L}$ and $\tilde{\mathbf{R}}$ constitute an SO_4 algebra in a subspace spanned by the degenerate states belonging to a given bound energy eigenvalue $E<0$ at the aphelia and perihelia ($\dot{r}=0$), i.e., $-[3g(r)+rg'(r)]/2=V(r)$. Thus, $V(r)$ must satisfy the following differential equation of Euler type;

$$r^2\frac{d^2V}{dr^2}+4r\frac{dV}{dr}+2V=0. \tag{10}$$

Solving the equation, we get

$$V(r)=\frac{C_1}{r}+\frac{C_2}{r^2}, \tag{11}$$

where C_1 and C_2 are two integral constants. To ensure the existence of bound states, $C_1<0$. Thus, we have two cases:

(1) $C_2=0$.

$V(r)$ is a pure Coulomb potential and $\tilde{\mathbf{R}}$ is reduced to the well-known Pauli–Runge–Lenz vector $\mathbf{R}=\frac{1}{2}(\mathbf{p}\times\mathbf{L}-\mathbf{L}\times\mathbf{p})-\mathbf{r}/r$.

(2) $C_2\neq=0$.

$V(r)$ is just the screened Coulomb potential (in natural units) $V(r)=-1/r-\lambda/r^2(0<\lambda\ll 1)$ and $\tilde{\mathbf{R}}$ is reduced to $\mathbf{R}'=\frac{1}{2}(\mathbf{p}\times\mathbf{L}-\mathbf{L}\times\mathbf{p})-(1+2\lambda/r)\mathbf{r}/r$, i.e., the extended Pauli–Runge–Lenz vector introduced in Refs. 11 and 12.

It is noted that for the pure Coulomb potential, $rg(r)-1=0$, and for the screened Coulomb potential, $rg(r)-1=2\lambda/r$. $rg(r)-1$ may be considered as a deviation from a pure Coulomb potential. From the above-given discussions, only when the deviation from the Coulomb potential $rg(r)-1\propto 1/r$, $\tilde{\mathbf{R}}$ and $\mathbf{L}$ constitute an SO_4 algebra in a subspace spanned by the states belonging to a given bound energy eigenvalue $E<0$ at the aphelia and perihelia ($\dot{r}=0$). However, even in this case there exist two distinct features between the two algebras. (a) While $d\mathbf{R}/dt=0$ always holds for a pure Coulomb potential, $d\mathbf{R}'/dt=0$ holds only at the aphelia and perihelia. (b) For the screened Coulomb potential, the L degeneracy of the energy eigenstates is removed. Therefore, the dimension of the subspace spanning the SO_4 algebra for the screened Coulomb potential is smaller than that for the pure Coulomb potential.

The two-dimensional (2D) case is similar. For any 2D central potential $V(\rho)$, one also can construct a conserved aphelion and perihelion vector,

$$\tilde{\mathbf{R}}=\mathbf{p}\times\mathbf{L}-g(\rho)\rho, \tag{12}$$

where $g(\rho)=\rho V'(\rho)$, $d\tilde{\mathbf{R}}/\mathbf{dt}=\mathbf{0}$ at $\dot{\rho}=0$. The quantum counterpart of $\tilde{\mathbf{R}}$ is

$$\tilde{\mathbf{R}}=\tfrac{1}{2}(\mathbf{p}\times\mathbf{L}-\mathbf{L}\times\mathbf{p})-g(\rho)\rho. \tag{13}$$

Also, it can be shown that, if and only if $V(\rho)$ is a pure or screened Coulomb potential,

$$[L_z,\tilde{R}_x]=i\tilde{R}_y, \tag{14}$$

$$[L_z,\tilde{R}_y]=-i\tilde{R}_x, \tag{15}$$

$$[\tilde{R}_x,\tilde{R}_y]=-2iHL_z, \tag{16}$$

i.e. $(L_z=xp_y-yp_x,\tilde{R}_x,\tilde{R}_y)$ constitute an SO_3 algebra in the subspace spanned by the states belonging to a given bound energy eigenvalue $E<0$ at the aphelia and perihelia ($\dot{\rho}=0$).

III. DYNAMICAL SYMMETRY OF A SCREENED ISOTROPIC HARMONIC OSCILLATOR

Now we address the isotropic harmonic oscillator. First we consider the 2D case. It can be shown that for an arbitrary 2D central field $V(\rho)$, there always exist two conserved aphelion and perihelion quantities,

$$\tilde{Q}_{xy}=h(\rho)xy+p_xp_y, \tag{17}$$

$$\tilde{Q}_1=\tfrac{1}{2}[h(\rho)(x^2-y^2)+(p_x^2-p_y^2)], \tag{18}$$

where $h(\rho)=V'(\rho)/\rho$, and $\mathrm{d}\tilde{Q}_{xy}/\mathrm{d}t=0$ and $\mathrm{d}\tilde{Q}_1/\mathrm{d}t=0$ at the aphelia and perihelia ($\dot{\rho}=0$). Similar to theorem 1, we have

Theorem 2: If and only if $V(\rho)$ is a pure or screened isotropic harmonic oscillator, do the operators $(L_z,\tilde{Q}_{xy},\tilde{Q}_1)$ constitute an SU_2 algebra.

Proof: For any $h(\rho)$, we have the following commutation relations:

$$[L_z,\tilde{Q}_{xy}]=-2i\tilde{Q}_1, \tag{19}$$

$$[L_z,\tilde{Q}_1]=2i\tilde{Q}_{xy}, \tag{20}$$

$$[\tilde{Q}_{xy},\tilde{Q}_1]=-2i[h(\rho)+\tfrac{1}{4}\rho h'(\rho)]L_z. \tag{21}$$

Therefore, only when

$$h(\rho)+\tfrac{1}{4}\rho h'(\rho)=C, \quad C>0 \tag{22}$$

do $(L_z,\tilde{Q}_{xy},\tilde{Q}_1)$ constitute an SU_2 algebra, i.e.,

$$\rho V''(\rho)+3V'(\rho)-4C\rho=0. \tag{23}$$

Solving the equation, we obtain

$$V(\rho)=C_1+C_2/\rho^2+\frac{C}{2}\rho^2, \tag{24}$$

where C_1 and C_2 are two integral constants. Neglecting a trivial additional constant of $V(\rho)$, i.e., letting $C_1=0$, we have two cases:

(1) $C_2=0$.

$V(\rho)$ is a pure isotropic harmonic oscillator and $\tilde{Q}_{xy}$ and $\tilde{Q}_1$ (in natural units $C=1$) are reduced to the well-known conserved quantities[8,9]

$$Q_{xy}=xy+p_xp_y, \tag{25}$$

$$Q_1=\tfrac{1}{2}[(x^2-y^2)+(p_x^2-p_y^2)]. \tag{26}$$

(2) $C_2\neq 0$.

$V(\rho)$ is just the screened isotropic harmonic oscillator (in natural units)

$$V(\rho)=\tfrac{1}{2}\rho^2-\lambda/\rho^2 \quad (0<\lambda\ll 1), \tag{27}$$

and

$$Q'_{xy}=(1+2\lambda/\rho^4)xy+p_xp_y, \tag{28}$$

$$Q_1' = \tfrac{1}{2}[(1+2\lambda/\rho^4)(x^2-y^2)+(p_x^2-p_y^2)], \tag{29}$$

which was introduced in Ref. 12.

It is noted that for a pure isotropic harmonic oscillator, $h(\rho)-1=0$, and for a screened isotropic harmonic oscillator, $h(\rho)-1=2\lambda/\rho$. $h(\rho)-1$ may be considered as a deviation from a pure isotropic harmonic oscillator. From the above discussions, only when the deviation from the isotropic harmonic oscillator $h(\rho)-1\propto 1/\rho$ do $(L_z,\tilde{Q}_{xy},\tilde{Q}_1)$ constitute an SU_2 algebra. However, while $\mathrm{d}Q_{xy}/\mathrm{d}t=0$ and $\mathrm{d}Q_1/\mathrm{d}t=0$ always hold for a pure isotropic harmonic oscillator, for a screened isotropic harmonic oscillator $\mathrm{d}Q_{xy}'/\mathrm{d}t=0$ and $\mathrm{d}Q_1'/\mathrm{d}t=0$ hold only at the aphelia and perihelia.

Now we turn to the three-dimensional case. Similarly, we can construct a conserved aphelion and perihelion quadrupole tensor for any central field $V(r)$,

$$\tilde{Q}_{xy}=h(r)xy+p_xp_y, \tag{30}$$

$$\tilde{Q}_{yz}=h(r)yz+p_yp_z, \tag{31}$$

$$\tilde{Q}_{zx}=h(r)zx+p_zp_x, \tag{32}$$

$$\tilde{Q}_1=\tfrac{1}{2}[h(r)(x^2-y^2)+(p_x^2-p_y^2)]=\tfrac{1}{2}(\tilde{Q}_{xx}-\tilde{Q}_{yy}), \tag{33}$$

$$\tilde{Q}_0=\frac{1}{2\sqrt{3}}[h(r)(x^2+y^2-2z^2)+(p_x^2+p_y^2-2p_z^2)]=\frac{1}{2\sqrt{3}}(\tilde{Q}_{xx}+\tilde{Q}_{yy}-2\tilde{Q}_{zz}), \tag{34}$$

where $h(r)=V'(r)/r$. It can be shown that at the points $\dot{r}=0$, $\mathrm{d}\tilde{Q}_{xy}/\mathrm{d}t=\mathrm{d}\tilde{Q}_{yz}/\mathrm{d}t=\mathrm{d}\tilde{Q}_{zx}/\mathrm{d}t=\mathrm{d}\tilde{Q}_1/\mathrm{d}t=\mathrm{d}\tilde{Q}_0/\mathrm{d}t=0$.

In a similar way as in the 2D case, it can be shown that if and only if $V(r)$ is a pure or screened isotropic harmonic oscillator in the eigen-coordinates[8,12] do $(L_\xi,\tilde{Q}_{\xi\eta},\tilde{Q}_1)$ constitute an SU_2 algebra.

IV. CLOSURE OF ORBITS

From the above-mentioned text, it has been shown that on the one hand the screened Coulomb potential and isotropic harmonic oscillator have higher dynamical symmetry than the geometric symmetry (space isotropy), and on the other hand there may exist profound relations between a pure Coulomb potential (isotropic harmonic oscillator) and a screened Coulomb potential (isotropic harmonic oscillator). To display this point of view, let us investigate further the condition of closure of classical orbits ($L=\sqrt{2\lambda/(1-\kappa^2)}$, $\kappa<1$ being any rational number) for a particle in a screened Coulomb potential or screened isotropic harmonic oscillator.

Consider the bound states. Let Φ be the angle between the rays leading from the center to the successive aphelion and perihelion, then Φ is given by the integral[13]

$$\Phi=\int_{r_p}^{r_a}\frac{L/r^2}{\sqrt{2(E-V(r)-L'^2/2r^2)}}\mathrm{d}r, \tag{35}$$

where $r_p(r_a)$ is the distance between the center and the perihelion (aphelion). It was shown[13] that the orbit is closed only when Φ is commensurable with 2π. It is easy to verify that for a Coulomb potential, $\Phi\equiv\pi$, and for an isotropic harmonic oscillator, $\Phi\equiv\pi/2$, which result in closed orbits for *all* bound particles. This may be considered as an alternative argument for the Bertrand's theorem.

Now we discuss the screened Coulomb potential. For a particle in this field, the equations of motion are

$$\dot{r}=\sqrt{2(E+1/r-L^2/2r^2)}, \tag{36}$$

$$\dot{\phi}=L/r^2, \tag{37}$$

and

$$\Phi_{\mathrm{sc}}=\int_{r_p}^{r_a}\frac{L/r^2}{\sqrt{2(E+1/r-L'^2/2r^2)}}\mathrm{d}r, \tag{38}$$

where

$$L'=\sqrt{L^2-2\lambda}. \tag{39}$$

By contrast, let us consider another particle in a pure Coulomb potential with energy E and angular momentum L'; the equations of motion are

$$\dot{r}=\sqrt{2(E+1/r-L'^2/2r^2)}, \tag{40}$$

$$\dot{\phi}=L'/r^2, \tag{41}$$

and

$$\Phi_c=\int_{r_p'}^{r_a'}\frac{L'/r^2}{\sqrt{2(E+1/r-L'^2/2r^2)}}\mathrm{d}r. \tag{42}$$

Comparing (36) and (40), it is seen that the radial motions of the two particles are the same. Therefore, we get $r_p'=r_p$, $r_a'=r_a$. Let

$$L'/L=\kappa, \tag{43}$$

$\kappa\leqslant 1$ for $\lambda\geqslant 0$. From (38) and (42), we have

$$\Phi_{\mathrm{sc}}=\Phi_c/\kappa=\pi/\kappa. \tag{44}$$

Obviously, if and only if κ is a rational number, the orbit of a particle in the screened Coulomb potential is closed. In this case, the radial frequency ω_r and angular frequency ω_ϕ are commensurable, and $\omega_r/\omega_\phi=\kappa$. For a pure Coulomb potential, $\kappa=1$, and for a screened Coulomb potential when κ is a rational number ($\kappa<1$), the orbit is closed. Equations (43) and (39) imply that κ is determined by the angular momentum, or inversely,

$$L=\sqrt{2\lambda/(1-\kappa^2)}\quad(\kappa<1,\ \text{rational}), \tag{45}$$

which is just Eq. (3). The above-presented discussion intuitively clarifies the relation of the closure of orbits for a pure and a screened Coulomb potential, and why there exist an infinite number of closed orbits for a particle in the screened Coulomb potential with suitable discrete angular momenta and any negative energy ($E<0$).

In quantum mechanics, it is well known that for a pure Coulomb potential, $\omega_r/\omega_\phi=(\partial E/\partial n_r)/(\partial E/\partial l)=1$. Similarly, it can be shown that in the large quantum number limit, for a screened Coulomb potential $\omega_r/\omega_\phi=(\partial E/\partial n_r)/(\partial E/\partial l)=\kappa$.

A similar situation exists for the isotropic harmonic oscillator, but $\omega_r/\omega_\phi=2\kappa$. For a pure isotropic harmonic oscillator, $\kappa=1$, and for a screened isotropic harmonic oscillator when κ is a rational number ($\kappa<1$), the orbit is closed.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 43, NUMBER 2 FEBRUARY 2002

On the Kolmogorov-like generalization of Tsallis entropy, correlation entropies and multifractal analysis

Alejandro M. Mesón and Fernando Vericat[a)]
Grupo de Aplicaciones Matemáticas y Estadísticas de la Facultad de Ingeniería (GAMEFI), Universidad Nacional de La Plata, Argentina and Instituto de Física de Líquidos y Sistemas Biológicos (IFLYSIB) UNLP-CONICET, cc. 565–(1900) La Plata, Argentina

(Received 30 April 2001; accepted for publication 1 November 2001)

The generalization à la Kolmogorov of Tsallis entropy, introduced by the authors in a previous work [J. Math. Phys. **37**, 4480 (1996)], is revisited. Invariance properties are pointed out under weaker conditions than before. This result leads us to wonder if Tsallis entropy at the Kolmogorov abstraction level brings new information with respect to the generalization that Kolmogorov did of Shannon entropy. The negative answer motivates us to look for other generalizations of Tsallis entropy in order to avoid the lack of new information. Correlation entropies seem to be good candidates for this purpose. The relationship of this kind of entropy with the multifractal analysis is studied with the help of the thermodynamic formalism. We also outline its usefulness to generalize properties of Tsallis entropy. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1429323]

I. INTRODUCTION

The concept of entropy, first introduced in classical thermodynamics, was reinterpreted by Shannon in his Mathematical Theory of Communications[1] as a measure of uncertainty. Shannon did his formulation at a level which involves just probabilistic vectors. He defines entropy as the positive number

$$H_1 = -\sum_{i=0}^{k-1} p_i \log p_i , \tag{1}$$

where $(p_0, p_1, \ldots, p_{k-1})$ is a probability vector, i.e., $\Sigma p_i = 1$.

After Gibbs gave his formulation of the statistical mechanics, it was posed the fundamental problem of relating temporal and ensembles averages (ergodic problem of the classical statistical mechanics). It was evident that the simple structure considered in Shannon theory was not enough to treat a problem of this nature, therefore a more elaborated one was necessary. In particular, dynamical aspects should be considered. It is the context in which Kolmogorov[2] generalizes Shannon entropy. He did it by using structures including measure preserving transformations that allow one to codify in a discrete way the temporal evolution of the systems. For a given partition of phase space, the quantity of information is calculated by replacing in Eq. (1) probabilities by the measure of the partition members. Then, Kolmogorov–Shannon entropy involves the average of the quantity of information of successive partitions.

One parameter families of entropies that contain Shannon entropy as a particular member have been introduced. Among these, we mention Renyi[3] and Tsallis[4] entropies. This last one appeared motivated by problems that require a nonextensive formalism.[5] It has been applied to study, e.g., gravitational systems[6,7] and phenomena like anomalous diffusion[8] and turbulence.[9]

For a probability vector $(p_0, p_1, \ldots, p_{k-1})$ Tsallis entropy reads

[a)]Author to whom correspondence should be addressed. Electronic mail: vericat@iflysib.unlp.edu.ar

$$H_q = \frac{1 - \sum_{i=0}^{k-1} p_i^q}{q-1}, \tag{2}$$

where q is any real number. Notice that for $q \to 1$, Shannon entropy is recovered.

In a previous work,[10] hereafter denoted I, we have generalized Tsallis entropy in the same sense that Kolmogorov did for Shannon's. There we have shown that, for any q, the Kolmogorov–Tsallis family of entropies is invariant under isomorphisms and that invariance is complete for Bernoulli schemes. This last result says to us that two Bernoulli schemes with the same entropy are ''finitarilly'' isomorphic.

The main goal of this article is to point out the true role played by the members of the Kolmogorov–Tsallis family of entropies about their ability to bring new information with respect to that contained in Kolmogorov–Shannon entropy. The invariance of the Kolmogorov-Tsallis entropies and a theorem by Ya Sinai[11] lead us to conclude that, under certain conditions, mainly the ergodicity, there is no substantial contribution of new information. Nevertheless, we do not believe that this claim invalidates the many results in several fields, especially in physics, deduced from Tsallis entropy [Eq. (2)] because in these cases what is actually considered is a particular quantity of information. In fact, in I it was shown that, for Bernoulli schemes, Tsallis entropy is obtained from one step in the definition of the Kolmogorov–Tsallis entropy if the quantity of information is calculated for a particular partition (the canonical generator).

The cause of the lack of new information may be due to the use of partitions. This is implicit in the statement of Sinai's theorem.[11] A way to introduce a family of entropies without using partitions is to consider correlation entropies.[12] These entropies are associated to a structure that involves, besides a measure, a metric. They are not only invariants under isomorphisms, in a measure theoretic sense, but also under other conditions which are not taken into account in Sinai's theorem. These additional conditions are related to the metric and are imposed on the function that determines the isomorphism. The family of correlation entropies that we shall introduce directly conducts to Tsallis entropy in the particular case of Bernoulli schemes (endowed with a metric). Also it contains, as a particular member, Kolmogorov–Shannon entropy, as it can be shown from the Brin–Katok theorem.[13] The correlation approach allows us to extend, in a relatively direct way, some properties of the Tsallis entropy to the level of abstract dynamical systems.

The article is organized as follows. In the next section, the main definitions and results of I are briefly reviewed and one of the isomorphism theorems thereof is reformulated under weaker conditions. In Sec. III we analyze the possibility that Kolmogorov–Tsallis entropy gives new information with respect to Kolmogorov–Shannon's. Section IV is devoted to introducing the correlation entropies in the above mentioned sense and also to establish invariant conditions for them. Then, a multifractal analysis is discussed for correlation entropies.

II. KOLMOGOROV–TSALLIS ENTROPY

The mathematical idea of measure preserving transformations generalizes, in some sense, the physical concept of dynamical system. Let recall that, physically, a dynamical system is understood as a collection of particles or states which obey a law that determines their temporal evolution and in such a way that the Liouville theorem is satisfied besides. Recall that the equilibrium condition are mathematically interpreted as the existence of an invariant measure which is the probability that a state belongs to a certain subspace of the phase space in a given instant.

From a mathematical point of view a dynamical system or, more precisely, a measure preserving dynamical system is a quadruple $\mathcal{S}=(X,\mathcal{B},\mu,T)$, where X is a set (phase space), $\mathcal{B}$ is a σ-algebra, μ is a probability measure on $\mathcal{B}$ and T is an invertible map $T:X\to X$ which is measurable and preserves μ, i.e., *for any* $B\in\mathcal{B}$, $T^{-1}B\in\mathcal{B}$ *and* $\mu(T^{-1}B)=\mu(B)$.

A particular structure that we shall frequently mention is the so called *Bernoulli schemes*. In this case the phase space is

$$BS(p)=\{x=(x_i)_{i\in\mathbf{Z}}:x_i\in\Omega,\forall i\in\mathbf{Z}\}\equiv\prod_{-\infty}^{\infty}\{0,1,2,\ldots,k-1\},\tag{3}$$

where p is a probability vector and $\Omega=\{0,1,\ldots,k-1\}$.

The σ-algebra $\mathcal{B}$ is that generated by the semi-algebra of the cylinders $C^{-m,\ldots,m}_{\alpha_{-m},\ldots,\alpha_m}=\{x\in\Sigma_A:x_i=\alpha_i:i=-m,\ldots,m\}$. The measure is defined in the following way: to each point $\{x_i\}$ is assigned a probability $P(\{x_i\})=p_{x_i}$ and the measure of the cylinder $C^{-m,\ldots,m}_{\alpha_{-m},\ldots,\alpha_m}$ is the product measure

$$\mu(C)=P(\{\alpha_{-m}\})\cdots P(\{\alpha_m\})=p_{\alpha_{-m}}\cdots p_{\alpha_m}.\tag{4}$$

These measures can be extended to the whole σ-algebra $\mathcal{B}$ by the extension Kolmogorov theorem.[14,15]

The measure preserving transformation is, finally, the Bernoulli shift $\sigma:BS(p)\to BS(p)$ given by $\sigma x=x'$, where $x'_i=x_{i+1}$.

The generalization à la Kolmogorov of Shannon entropy (1) is defined, first, by measuring the available quantity of information H_1 which is associated to a partition of the phase space X. If $\mathcal{A}=\{A_0,A_1,\ldots,A_{k-1}\}$ is such that $\cup_{i=0}^{k-1}A_i=X$; $A_i\cap A_j=\phi\ \forall i\neq j$, then

$$H_1(\mathcal{A})=-\sum_{i=0}^{k-1}\mu(A_i)\log\mu(A_i).\tag{5}$$

Here $\mu(A_i)$ is interpreted as the probability that a random point lies in A_i. Further, the average of this information quantity, when the experiment repeats infinitely, is calculated. Finally, all the available information is involved by taking the supreme over all the partitions by measurable sets.

Next we review the generalization presented in I. In order to generalize Tsallis entropy Eq. (2) according to the previous procedure, we begin by replacing "probabilities p_i by measures $\mu(A_i)$:"

$$H_q(\mathcal{A})=(q-1)^{-1}\left(1-\sum_{i=0}^{k-1}[\mu(A_i)]^q\right),\tag{6}$$

where q is any real number. The case $q=1$ will be imposed by continuity, and so Eq. (6) yields expression (5).

Given $x\in X$, we consider the following points of its orbit: x, Tx, $T^2x,\ldots,T^{n-1}x$. Since $\mathcal{A}$ is a partition, for each one of these points there is only one member of $\mathcal{A}$ to which it belongs. Then we can associate to each point x a string $\ell=(\ell_0,\ell_1,\ldots,\ell_{n-1})$, which will be called the name of x *of length* n. The assignation is done according to $T^ix\in A_{\ell_i}$, $i=0,1,\ldots,n-1$. Consequently, a new partition can be obtained from $\mathcal{A}$:

$$\mathcal{A}^n=\{A^n(\ell):A^n(\ell)\text{ is the set of points with same name }\ell\text{ of length }n\}.\tag{7}$$

Definition 2.1: The *mean generalized entropy*, associated to a transformation T that preserves a measure μ, is

$$h_q(T)=(q-1)^{-1}[1-\exp(\tilde{h}_q(T))]\tag{8}$$

with

$$\tilde{h}_q(T)=\sup_{\mathcal{A}}\tilde{h}_q(\mathcal{A},T)\tag{9}$$

and

$$\tilde{h}_q(\mathcal{A},T)=\overline{\lim_{n\to\infty}}\frac{1}{n}\{\log[1+(1-q)H_q(\mathcal{A}^n)]\},\tag{10}$$

where, for $H_q(\mathcal{A}^n)$, the sum in Eq. (6) must be taken over all the names of length n.

Remark: For the particular case of Bernoulli schemes $BS(p_0,p_1,\ldots,p_{k-1})$, as partition is considered the "canonical generator" $\mathcal{G}=\{G_i\}$, with $G_i=\{x=(x_l)_{l\in\mathbf{Z}}: x_0=i\}=C_i^0$ for $0\leqslant i\leqslant k-1$. Then $\mu(\mathcal{G}^n)=p_{\alpha_{-m}}\cdots p_{\alpha_m}$ and

$$[\tilde{h}_q(\mathcal{G},\sigma)]_{BS(p_0,p_1,\ldots,p_{k-1})}=\log\sum_{i=0}^{k-1}p_i^q,\tag{11}$$

which leads to Tsallis entropy for arbitrary q [Eq. (2)]:

$$[h_q(\mathcal{G},\sigma)]_{BS(p)}\equiv H_q(p)=(q-1)^{-1}\left[1-\sum_{i=0}^{k-1}p_i^q\right],\tag{12}$$

and the Shannon expression [Eq. (1)] is recovered for $q\to 1$.

Remark: We have (by the Kolmogorov–Sinai theorem) $H_1(p)\equiv h_1(\mathcal{G},\sigma)=h_1(\sigma)$. However, for arbitrary q, $H_q(p)$ does not necessarily agree with $h_q(\sigma)$.

A. Isomorphism theorems and other properties

In I we have proved the following isomorphism theorem:

Theorem I.1: Let $\mathcal{S}=(X,\mathcal{B},\mu,T)$ and $\mathcal{S}'=(X',\mathcal{B}',\mu',T')$ be a two isomorphic dynamical system. Then $h_q(T)=h_q(T')$.

Actually, it can be reformulated under a weaker hypothesis. Before doing this we recall the definition of *factor*.

Definition: A dynamical system $\mathcal{S}'=(X',\mathcal{B}',\mu',T')$ is a factor of the dynamical system $\mathcal{S}=(X,\mathcal{B},\mu,T)$ if there exists a measurable subjective map $f:X\to X'$, such that

(i) For every $B'\in\mathcal{B}$, $\mu(f^{-1}B')=\mu'(B')$.
(ii) For every x, $f(Tx)=T'(fx)$.

Two systems $\mathcal{S}$ and $\mathcal{S}'$ are *weakly isomorphic* if $\mathcal{S}$ is a factor of $\mathcal{S}'$ and $\mathcal{S}'$ is a factor of $\mathcal{S}$. When f is bijective the systems are *isomorphic*.

Theorem 2.2: Let $\mathcal{S}'=(X',\mathcal{B}',\mu',T')$ be a factor of the dynamical system $\mathcal{S}=(X,\mathcal{B},\mu,T)$. Then $h_q(T)\leqslant h_q(T')$ for $q>1$ and $h_q(T)\geqslant h_q(T')$ for $q<1$.

The proof is similar to that given for Theorem I.1, so we omit the details.

The equality holds when the systems are weakly isomorphic. In this case the generalized entropy becomes an invariant under weak isomorphisms.

The generalization in the spirit of Kolmogorov for the Renyi entropy was done in Ref. 12. There the analogous invariant result was proved.

Proposition 2.3: For any integer $m\geqslant 2$ it holds

$h_q(T^m)=(q-1)^{-1}[1-\exp(m\tilde{h}_q(T))]$ for every q.

Proof: We write $\tilde{H}_q(\mathcal{A})=1+(1-q)H_q(\mathcal{A})$. We recall that a partition $\mathcal{A}$ is a refinement of a partition $\mathcal{C}$, if any element of $\mathcal{C}$ can be expressed as union of elements of $\mathcal{A}$. If $q<1$, then $\tilde{H}_q(\mathcal{A})\geqslant\tilde{H}_q(\mathcal{C})$, whereas for $q>1$ is $\tilde{H}_q(\mathcal{A})\leqslant\tilde{H}_q(\mathcal{C})$.

Let $q<1$. We consider a partition $\mathcal{A}$, and let $\mathcal{A}^m$ be the partition by names of length m obtained from $\mathcal{A}$ and T. We have $\tilde{H}_q((\mathcal{A}^m)^n)=1+(1-q)H_q((\mathcal{A}^m)^n)$ where now $(\mathcal{A}^m)^n$ is the partition with names of length n obtained from $\mathcal{A}^m$ and T^m. Then

$$\tilde{h}_q(\mathcal{A}^m,T^m)=\overline{\lim_{n\to\infty}}\frac{1}{n}\{\log[\tilde{H}_q((\mathcal{A}^m)^n)]\}=\overline{\lim_{n\to\infty}}\frac{m}{mn}\{\log[\tilde{H}_q(\mathcal{A}^{mn})]\}$$

$$\geqslant m\overline{\lim_{s\to\infty}}\frac{1}{s}\tilde{H}_q(\mathcal{A}^s)=m\tilde{h}_q(\mathcal{A},T), \tag{13}$$

where $\mathcal{A}^{mn}$ is the partition with names of length mn built from the partition first given and T.

Thus, by taking the supreme over the finite partitions, we have

$$\tilde{h}_q(T^m)\geqslant m\tilde{h}_q(T). \tag{14}$$

For the other inequality, we have the following.

If $l\in\mathbf{N}$, then a partition by names of length l, with respect to $(\mathcal{A},T)$, involves the orbits $x,Tx,\ldots,T^{l-1}x$, for any point x. A partition by names of length n, with respect to $(\mathcal{A}^m,T^m)$ involves the orbits $x,T^mx,\ldots,(T^m)^{n-1}x$. Further, if $l=mn,mn+1,\ldots,mn+m$, then $\mathcal{A}^l$ is a refinement of $(\mathcal{A}^m)^n$. Then

$$\frac{1}{n}\{\log[\tilde{H}_q((\mathcal{A}^m)^n)]\}\leqslant\frac{1}{n}\{\log[\tilde{H}_q(\mathcal{A}^l)]\}=\frac{l}{n}\frac{1}{l}\{\log[\tilde{H}_q(\mathcal{A}^l)]\}\leqslant\frac{mn+m}{n}\frac{1}{l}\{\log[\tilde{H}_q(\mathcal{A}^l)]\}.$$

Consequently,

$$\frac{1}{n}\{\log[\tilde{H}_q(\mathcal{A}^{mn})]\}\leqslant m\left(1+\frac{1}{n}\right)\frac{1}{l}\{\log[\tilde{H}_q(\mathcal{A}^l)]\},$$

and thus

$$\sup_{j\geqslant n}\frac{1}{j}\{\log[\tilde{H}_q(\mathcal{A}^{mj})]\}\leqslant m\sup_{j\geqslant n}\left(1+\frac{1}{j}\right)\sup_{l=mj,mj+1,\ldots,mj+n}\frac{1}{l}\{\log[\tilde{H}_q(\mathcal{A}^l)]\}.$$

Therefore,

$$\tilde{h}_q(T^m)=\overline{\lim_{n\to\infty}}\frac{1}{n}\{\log[\tilde{H}_q((\mathcal{A}^m)^n)]\}=\lim_{j\to\infty}\sup_{j\geqslant n}\frac{1}{j}\{\log[\tilde{H}_q(\mathcal{A}^m)^j]\}\leqslant m\overline{\lim_{n\to\infty}}\frac{1}{l}\{\log[\tilde{H}_q(\mathcal{A}^l)]\}.$$

Finally,

$$\tilde{h}_q(\mathcal{A},T^m)\leqslant m\tilde{h}_q(\mathcal{A},T), \tag{15}$$

for every finite partition $\mathcal{A}$.

For $q>1$ the demonstration is similar, taking into account the inversion of the above inequalities. ■

Proposition 2.4: $h_q(T_1\times T_2)=(q-1)^{-1}[1-\exp(\tilde{h}_q(T_1))\exp(\tilde{h}_q(T_2))]$, where the product of transformation is defined in the usual form.

Proof: We consider two dynamical systems, $S_1=(X_1,\mathcal{B}_1,\mu_1,T_1)$ and $S_2=(X_2,\mathcal{B}_2,\mu_2,T_2)$, and define their ''product:''

$$S_1\times S_2=(X_1\times X_2,\mathcal{B},\mu,T_1\times T_2),$$

where $\mathcal{B}$ is the σ-algebra generated by rectangles $A_{1i}\times A_{2j}$ with $A_{\alpha k}\in\mathcal{B}_\alpha(\alpha=1,2)$ and μ is the product measure $\mu(A_{1i}\times A_{2j})=\mu_1(A_{1i})\cdot\mu_2(A_{2j})$. Let $\mathcal{A}'$ and $\mathcal{A}''$ be partitions of X_1 and X_2, respectively, and let $\mathcal{A}$ be a product partition of $\mathcal{A}'$ and $\mathcal{A}''$.

Since the σ-algebra considered is generated by the rectangles, we have

$$\tilde{h}_q(T_1\times T_2)=\sup\{\tilde{h}_q(\mathcal{A}'\times\mathcal{A}'',T_1\times T_2):\mathcal{A}' \text{ partition of } X_1\ \mathcal{A}'' \text{ partition of } X_2\}.$$

$$\tilde{h}_q(\mathcal{A}'\times\mathcal{A}'',T_1\times T_2)=\overline{\lim_{n\to\infty}}\frac{1}{n}\tilde{H}_q((\mathcal{A}'\times\mathcal{A}'')^n)=\overline{\lim_{n\to\infty}}\frac{1}{n}\log\left(\sum_{\mathscr{C}}[\mu_1((\mathcal{A}')^n)]^q\right)$$
$$+\overline{\lim_{m\to\infty}}\frac{1}{n}\log\left(\sum_{\mathscr{C}}[\mu_2((\mathcal{A}'')^n)]^q\right),$$

where both sums are extended over the names $\mathscr{C}$, of length n for T_1 and T_2. Then,

$$\tilde{h}_q(\mathcal{A}'\times\mathcal{A}'',T_1\times T_2)=\tilde{h}_q(\mathcal{A}',T_1)+\tilde{h}_q(\mathcal{A}'',T_2).$$

Because this is valid for any partition by rectangles, it results in

$$\tilde{h}_q(T_1\times T_2)=\tilde{h}_q(T_1)+\tilde{h}_q(T_2),$$

and so

$$h_q(T_1\times T_2)=(q-1)^{-1}[1-\exp(\tilde{h}_q(T_1))\exp(\tilde{h}_q(T_2))]. \tag{16}$$

■

III. LACK OF NEW INFORMATION IN THE ERGODIC CASE

In view of the previous results, it is natural to ask if the statement of Theorem I.1 (or its stronger version Theorem 2.2) could actually be due to the lack of new information, with respect to that involved in $h_1(T,\mu)$, of the members of the entropy family. We have an answer in the case that the systems are ergodic. For definition of ergodicity and related topics, see, for example, Refs. 16 and 14.

Herein we consider as an additional hypothesis that the space (X,μ) be "countable," i.e., $L^2(X,\mu)$ have a dense countable subset. We recall the following basic result.

Theorem (Ya Sinai):[11] Let $\mathcal{S}=(X,\mathcal{B},\mu,T)$ be an ergodic Lebesgue space and a $BS(p)$ Bernoulli scheme such that $h_1(T)\geqslant[h_1]_{BS(p)}$, then $BS(p)$ is a factor of T.

This theorem, together with Theorem I.1 (or Theorem 2.2) and Proposition 2.6 will serve as a basis to answer the question about the lack of new information.

Proposition 2.6: Let $\mathcal{S}=(X,\mathcal{A},\mu,T)$ be an ergodic Lebesgue space such that $h_1(T)\geqslant\log K$, for some integer $K>1$. Then, for $q>1$,

$$h_q(T)\leqslant\frac{1-K^{1-q}}{q-1}. \tag{17}$$

Proof: Let T be ergodic with $h_1(T)\geqslant\log K$, for some integer $K>1$. The right hand side of the inequality is the classical entropy of the Bernoulli scheme $BS(p)$, with $p=(1/K,\ldots,1/K)$.

By Sinai theorem $BS(1/K,\ldots,1/K)$ is a factor of T. Then by Theorem I.1 (or Theorem 2.2),

$$\tilde{h}_q(T)\geqslant[\tilde{h}_q]_{BS(p)}\geqslant[\tilde{h}_q,\mathcal{G}]_{BS(p)}=\log K^{1-q}, \tag{18}$$

where the last equality follows by taking in Eq. (12) $p_i=1/K$. Thus

$$h_q(T)\leqslant\frac{1-K^{1-q}}{q-1}, \quad \text{for} \quad q>1. \tag{19}$$

■

Definition: A dynamical system is a *Bernoulli automorphism* if it is isomorphic to a Bernoulli scheme.

We are now in conditions of demonstrating that the family h_q does not contain new information with respect to h_1.

Theorem 2.7: Let $\mathcal{S}=(X,\mathcal{A},\mu,T)$ be a Lebesgue space with T ergodic and $h_1(T)>0$. Then

$$h_q(T)=\begin{cases}\Psi_q(h_1) & \text{if } q>1,\\ \infty & \text{if } q<1,\end{cases} \tag{20}$$

where Ψ_q is a certain function.

Proof: (I) Case $q<1$. We will use the following result.[12]

Lemma (Takens and Verbistki): Let h be a real number such that $0\leqslant -t\log t<h<\infty$, with $t\in[0,1]$. Then there exists a natural number m and a vector $p=(p_0,\ldots,p_{m-1})$ such that

(i) $\Sigma_{i=0}^{m-1}p_i=t$, (ii) $-\Sigma_{i=0}^{m-1}p_i\log p_i=h$.

Then let us consider $0<q<1$, $n\in\mathbf{N}$ and define $p_i=n^{-(1+q)/2q}$, $i=0,1,2,\ldots,n-1$. We have

$$\sum_{i=0}^{n-1}p_i=n\times n^{-(1+q)/2q}=n^{(q-1)/2q}\to 0,\quad \text{with } n\to\infty \tag{21}$$

and

$$-\sum_{i=0}^{n-1}p_i\log p_i=\frac{1+q}{2q}n^{(q-1)/2q}\log n\to 0,\quad \text{with } n\to\infty. \tag{22}$$

Let $t=1-\Sigma_{i=0}^{n-1}p_i=1-n^{(q-1)/2q}$,

$\overline{h}=h_1(T)+\Sigma_{i=0}^{n-1}p_i\log p_i=h_1(T)-\dfrac{1+q}{2q}n^{(q-1)/2q}$.

Now by the above lemma (notice that $\overline{h}>-t\log t$, for n large enough), there is a natural number m and a vector $(w_{0,\ldots,}w_{m-1})$ with $\Sigma w_i=t$ and $-\Sigma w_i\log w_i=\overline{h}$. Let us define

$p=(p_0,\ldots,p_{n-1},p_n,\ldots,p_{n+m-1})$, where $p_i=n^{-(1+q)/2q}$, $i=0,1,2,\ldots,n-1$, $p_n=w_0,\ldots,p_{n+m-1}=w_{m-1}$.

Then

$$\sum_{i=0}^{n+m-1}p_i=1 \quad\text{and}\quad -\sum_{i=0}^{n+m-1}p_i\log p_i=h_1(T).$$

We have determined a Bernoulli scheme $BS(p)$ with classical entropy equal to $h_1(T)$. Therefore by the Sinai theorem $BS(p)$ is a factor of T and so by Theorem I.1 (or Theorem 2.2) we have $h_q(T)\geqslant[h_q]_{BS(p)}$. On the other hand, since $\Sigma_{i=0}^{m-1}p_i^q\geqslant\Sigma_{i=0}^{n-1}p_i^q=n^{(q-1)/2q}$, and with $\mathcal{G}$ the canonical generator we get

$$[\tilde{h}_q(\mathcal{G})]_{BS(p_0,\ldots,p_{n-1})}=\log\left(\sum p_i^q\right)=\log(n^{(q-1)/2q}). \tag{23}$$

Therefore,

$$h_q(T)\geqslant[h_q]_{BS(p)}\geqslant\frac{1-\Sigma_{i=0}^{n-1}p_i^q}{q-1}=\frac{1-n^{(q-1)/2q}}{q-1}. \tag{24}$$

Because n can be taken arbitrarily large, we have $h_q(T)=\infty$, for $q<1$.

For q negative, we have $q<q_0$ with $0<q_0<1$, and, since $h_q>h_{q_0}$, the theorem also holds in this case.

(II) Case $q>1$. We shall consider first the particular situation in which T^m is ergodic, for any $m\geqslant 2$ and $h_1(T^m)>0$. For each $x>0$, we choose a negative number $M_q = M_q(x)$ with the following property: for any $y>0$, $x\geqslant y$ if and only if $M_q x\geqslant(1-q)y$.

If, in particular, $x=h_1(T)>0$, and K is an integer such that $K>1$, it holds that $h_1(T)\geqslant\log K$ if and only if $M_q h_1(T)\geqslant(1-q)\log K$. Besides $h_1(T)\geqslant\log K$ implies $BS(1/K,\ldots,1/K)$ is a factor of T (by Sinai theorem), and consequently $\tilde{h}_q(T)\geqslant(1-q)\log K$ (cf. Proposition 2.6).

Also we have $h_1(T)\geqslant \tilde{h}_q(T)/(1-q)$; if $q>1$, this deduces directly from the corresponding definitions. Therefore $M_q h_1(T)\geqslant\tilde{h}_q(T)$, and so

$$\frac{M_q h_1(T)}{1-q}\leqslant\frac{\tilde{h}_q(T)}{1-q}. \tag{25}$$

If it were

$$\frac{M_q h_1(T)}{1-q}<\frac{\tilde{h}_q(T)}{1-q}, \tag{26}$$

then, by applying Proposition 2.6 in particular to T^m, we have

$$\frac{\tilde{h}_q(T^m)}{1-q}-\frac{M_q h_1(T^m)}{1-q}=m\left(\frac{\tilde{h}_q(T)}{1-q}-\frac{M_q h_1(T)}{1-q}\right)\to+\infty,\quad \text{with } m\to+\infty. \tag{27}$$

Then for an m large enough there will an integer $K>1$ such that

$$\frac{M_q h_1(T^m)}{1-q}<\log K<\frac{\tilde{h}_q(T)}{1-q}. \tag{28}$$

Now we have a contradiction with Proposition 2.6 applied to T^m. Let recall that we are assuming that all the positive iterations of T are ergodic.

Therefore, if T is ergodic and T^m is ergodic, $m\geqslant 2$, it holds $M_q h_1(T)=\tilde{h}_q(T)$.

Next we consider the general situation in which it is required that just T be ergodic. For a given ergodic transformation T with $h_1(T)>0$, there exists a Bernoulli scheme with classical entropy equal to $h_1(T)$.[16,17] This also will be valid for dynamical systems isomorphic to Bernoulli schemes, which are called *Bernoulli automorphisms*. Thus if T is ergodic with $h_1(T)>0$, there exists Bernoulli automorphism S with $h_1(T)= h_1(S)$. Then by the Sinai theorem S is a factor of T, so that $\tilde{h}_q(T)\geqslant\tilde{h}_q(S)$. For any transformation T there is associated an operator $\mathcal{L}_T: L^2(X,\mu)\to L^2(X,\mu)$, defined by $\mathcal{L}_T[f](x)=f(Tx)$. It says that this operator has discrete spectrum if there is an orthonormal basis of eigenfunctions. By a theorem of Rohlin, if $T:X\to X$ is a Bernoulli automorphism with X countable, the associated operator $\mathcal{L}_T$ has discrete spectrum (see e.g., Ref. 16, p. 109). It can be proved (Ref. 16, p. 66) that if $\mathcal{L}_T$ has discrete spectrum, then T is strong-mixing. What is actually proved is

$$\lim_{n\to\infty}(\mathcal{L}_T^n f,g)=(f,1)(1,g),$$

where $(.,.)$ denotes the usual product in the Hilbert space $L^2(X,\mu)$.

Thus the Bernoulli automorphism S is mixing and so S^m is ergodic for any $m\geqslant 1$.[18]

Recall that $h_1(T)\geqslant\tilde{h}_q(T)/(1-q)$, if $q>1$. Consequently,

$$M_q h_1(T)\geqslant\tilde{h}_q(T)\geqslant\tilde{h}_q(S)=M_q h_1(S)=M_q h_1(T). \tag{29}$$

Now $\Psi_q(h_1)=(q-1)^{-1}[1-\exp(M_q h_1)]$, and the theorem is proved. ■

Remarks: A similar theorem for Renyi entropy was proved in Ref. 12.

According to Theorem 2.7, the ergodicity implies a functional relationship between $h_1(T)$ and $h_q(T)$ (for $q>1$). If this relationship does not occur, then the dynamical system (X,T,μ) cannot be ergodic. In this way the generalization of the Tsallis entropy may be useful to detect ergodicity.

It would be interesting to relax the condition of ergodicity in Theorem 2.7. It is a matter for future investigation. So far we could anticipate that for $q>1$ the dependence is not directly with $h_1(T)$, but with a quantity which involves it. For $q<1$ the result would be the same, i.e., $h_q(T)=\infty$. If $T^n x=x$, for some n, the last assertion could not be true. This is clear from Proposition 2.3 and the fact of $h_q(id)=0$. Therefore, it must be required that the set $\{x:T^n x=x,$ for some $n\}$ have zero measure. The hypothesis $h_1(T)>0$ might be also relaxed.

IV. CORRELATION ENTROPIES

Let (X,d) be a compact metric space in which are also given a probability measure μ and a continuous map $T:X\to X$. Let consider the metric $d_n(x,y)=\max\{d(T^i(x)),T^i(y)):i=0,1,\ldots,n-1\}$ and let denote with $B_{\varepsilon,n}(x)$ the ball of radius ε in the metric d_n.

Definition 3.1: The *generalized correlation entropy is*

$$h_q^{\mathrm{corr}}(T)=\frac{1-e^{\tilde{h}_q^{\mathrm{corr}}(T)}}{q-1}, \tag{30}$$

where

$$\tilde{h}_q^{\mathrm{corr}}(T)=\lim_{\varepsilon\to 0}\tilde{h}_{q,\varepsilon}^{\mathrm{corr}}(T) \tag{31}$$

and the average of the information quantity is given by

$$\tilde{h}_{q,\varepsilon}^{\mathrm{corr}}(T)=\overline{\lim_{n\to\infty}}\frac{1}{n}\log\left[\int_X \mu(B_{\varepsilon,n}(x))^{q-1}d\mu\right]. \tag{32}$$

It can see that this entropy generalizes $h_1(T)$. For this the following result is used.

Theorem (Brin-Katok[13]): Let $T:X\to X$ be a continuous map in a compact metric space (X,d) and let μ be a T-invariant Borel measure in X. The following functions are defined in X:

$$\overline{h_1}(x,T)=\lim_{\varepsilon\to 0}\overline{\lim_{n\to\infty}}-\frac{1}{n}\log\mu(B_{\varepsilon,n}(x)) \tag{33}$$

$$\underline{h_1}(x,T)=\lim_{\varepsilon\to 0}\underline{\lim_{n\to\infty}}-\frac{1}{n}\log\mu(B_{\varepsilon,n}(x)) \tag{34}$$

($\overline{h_1}(x,T)$, $\underline{h_1}(x,T)$ are called the *upper and lower local entropies*, respectively). Then

(i) the local entropy does exist, i.e., $\overline{h_1}(x,T)=\underline{h_1}(x,T)=h_1(x,T)$, for every $x\in X$, and
(ii) $h_1(x)$ is a T-invariant function and $\int h_1(x)d\overline{\mu}=h_1(T)$.

Corollary 3.2: $\lim_{q\to 1}\tilde{h}_q^{\mathrm{corr}}(T)=h_1(T)$.

Proof: This corollary follows immediately by using standard results in measure theory (Fatou lemma, Monotone convergence theorem) and the Brin–Katok theorem. ■

The invariance is established in the following terms:

Proposition 3.3: Let (X_1,d_1) and (X_2,d_2) be compact metrizable spaces, and let us consider maps $T_1: X_1\to X_1$, $T_2: X_2\to X_2$ and T_i invariant measures μ_1, μ_2. Let $f:X_1\to X_2$ be a measurable bijection such that $f\circ T_1=T_2\circ f$ and $\mu_1(f^{-1}(A)) = \mu_2(A)$, for every measurable set A. If the condition

$$\frac{1}{K}d_1(x,y)\leqslant d_2(f(x),f(y))\leqslant Kd_1(x,y), \quad \text{for some } K>1, \tag{35}$$

holds for $x,y\in X_1$, then $h_q^{\mathrm{corr}}(T_1) = h_q^{\mathrm{corr}}(T_2)$.

A map f which verifies the above condition is called of *bounded distortion*.

Proof: Let $x,y\in X_1$. We have

$$\frac{1}{K}d_1(T_1^i x,T_1^i y)\leqslant d_2(f(T_1^i x),f(T_1^i y))\leqslant Kd_1(T_1^i x,T_1^i y); \quad i=0,1,\ldots,n-1. \tag{36}$$

Let us call

$$B^1_{\varepsilon,n}(x)=\{y:\max\{d_1(T_1^i x,T_1^i y):i=0,1,\ldots,n-1\}<\varepsilon\},$$

$$B^2_{\varepsilon,n}(x')=\{y':\max\{d_2(T_2^i x',T_2^i y'),i=0,1,\ldots,n-1\}<\varepsilon\}.$$

The condition of bounded distortion is equivalent to

$$\frac{1}{K}d_1(T_1^i x,T_1^i y)\leqslant d_2(T_2^i(f(x)),T_2^i(f(y)))\leqslant Kd_1(T_1^i x,T_1^i y), \quad i=0,1,\ldots,n-1. \tag{37}$$

Then we have $B^1_{\varepsilon,n}(x)\subset f^{-1}(B^2_{K\varepsilon,n}(f(x)))$, or

$$\mu_1(B^1_{\varepsilon,n}(x))\leqslant \mu_1(f^{-1}(B^2_{K\varepsilon,n}(f(x))))=\mu_2(B^2_{K\varepsilon,n}(f(x))). \tag{38}$$

Analogously

$$\mu_2(B^2_{\varepsilon,n}(f(x)))\leqslant \mu_1(B^1_{K\varepsilon,n}(x)). \tag{39}$$

Thus, for $q>1$,

$$\overline{\lim_{n\to\infty}}\frac{1}{n}\log\left[\int_{X_1}\mu_1(B^1_{\varepsilon,n}(x))^{q-1}d\mu_1\right]\leqslant\overline{\lim_{n\to\infty}}\frac{1}{n}\log\left[\int_{X_2}\mu_2(B^2_{K\varepsilon,n}(z))^{q-1}d\mu_2\right],$$

and

$$\overline{\lim_{n\to\infty}}\frac{1}{n}\log\left[\int_{X_2}\mu_2(B^2_{\varepsilon,n}(z))^{q-1}d\mu_2\right]\leqslant\overline{\lim_{n\to\infty}}\frac{1}{n}\log\left[\int_{X_1}\mu_1(B^1_{K\varepsilon,n}(x))^{q-1}d\mu_1\right].$$

For $q<1$, we proceed in a similar way but invert the inequalities.

Therefore, with $\varepsilon\to 0$ we have $\tilde{h}_q^{\mathrm{corr}}(T_1)=\tilde{h}_q^{\mathrm{corr}}(T_2)$ and, finally, $h_q^{\mathrm{corr}}(T_1) = h_q^{\mathrm{corr}}(T_2)$. ■

The invariance conditions related with the metric impose a restriction not taken into account in Sinai theorem. So, to have new information it should work in spaces with "more structure."

A. Bernoulli schemes

We shall see that the correlation entropies generalize Tsallis entropy, i.e., for Bernoulli schemes $BS(p_0,p_1,\ldots,p_{k-1})$, we have $h_q^{\mathrm{corr}}=H_q=(1-\Sigma_{i=0}^{k-1}p_i^q/(q-1)$. The metric considered is

$$d^{BS}(x,y)=2^{-|n|},$$

where $n=\min\{|i|:x_i=y_i\}$.

For each m, the ball $B_{2^{-m},n}(x)$, in the metric d_n^{BS}, with respect to the shift σ, is the cylinder

$$\{y:x_i=y_i:i=-n,\ldots,m-n+1\}.$$

Thus $\mu(B_{2^{-m},n}(x))=\Pi_{i=-m}^{n-m+1}p_{x_i}$, so that

$$[\tilde{h}_q^{\mathrm{corr}}]_{BS}=\overline{\lim_{n,m\to\infty}}\frac{1}{n}\log\left[\int_X\mu(B_{2^{-m},n}(x))^{q-1}d\mu\right]=\log\left(\sum p_i^q\right), \tag{40}$$

where the last equality is obtained by direct calculus. Then

$$[h_q^{\mathrm{corr}}]_{BS}=\frac{1-\Sigma p_i^q}{q-1}=H_q(p_0,p_1,\ldots,p_{k-1}). \tag{41}$$

V. RELATIONSHIP WITH MULTIFRACTAL ANALYSIS

The concept of ''multifractal analysis'' was suggested in relation to the scaling behavior of physical measures on strange attractors.[19] In the study of chaotic behaviors one is frequently faced with invariant sets with a complex mathematical structure and the multifractal analysis treats the so-called *fractal decomposition* of these sets. The aim of this procedure is to encode information about very complex structures by means of a sufficiently well behaved real function.

Here we will relate (Proposition 4.1) the correlation entropies introduced earlier to the function

$$\tau(q):=P(q\varphi)-qP(\varphi), \tag{42}$$

where $P(\varphi)$ is the *topological pressure* associated to a given potential φ.

More precisely, let $T:X\to X$ be a homeomorphism with X a compact metric space. A map $\varphi:X\to\mathbf{R}$ will be called a ''potential'' and the topological pressure associated to it is the number[17,16]

$$P(\varphi)=\sup_{\mu}\left\{h_1(T,\mu)+\int\varphi d\mu\right\}, \tag{43}$$

where the supreme is taken over all the Borel measures μ, T-invariant on X.

The function $\tau(q)$ has been used to describe completely the multifractal spectrum for local entropies and its properties, e.g., the convexity, have been studied.[20,21]

Now we give some definitions and declare the main hypothesis under which the relationship between the correlation entropy and the function $\tau(q)$ holds. These conditions are much weaker than those used in the multifractal analysis done by other authors.[20]

An *equilibrium state* for the potential φ is a measure μ_φ which satisfies

$$P(\varphi)=h_1(T,\mu_\varphi)+\int\varphi\,d\mu_\varphi. \tag{44}$$

Under certain conditions imposed on the map T and the potential φ an equilibrium state can be constructed.[17] The *specification property* for a map $T:X\to X$, introduced by R. Bowen in Ref. 22, reads as follows.

A homeomorphism $T:X\to X$ has the *specification property* if, given a finite disjoint collection of integer intervals $I_1,\ldots,I_k$, then, for $\varepsilon>0$, there is an integer $M(\varepsilon)$ and a function $\Phi:I=\cup I_i\to X$ such that

(i) $\mathrm{dist}(I_i, I_j) > M(\varepsilon)$ (Euclidean distance),
(ii) $T^{n_1-n_2}(\Phi(n_1)) = \Phi(n_2)$, and
(iii) $d(T^n(x), \Phi(n)) < \varepsilon$, for some $x: T^m(x) = x$, with $m \geqslant M(\varepsilon) + \mathrm{length}(I)$ and for every $n \in I$.

A homeomorphism $T: X \to X$ is called *expansive* if there is a constant $\delta > 0$, such that $d(T^n(x), T^n(y)) < \delta$, for any integer n, implies $x = y$.

For a potential φ we put

$$S_n(\varphi)(x) = \sum_{i=0}^{n-1} \varphi(T^i(x)). \tag{45}$$

Following Ref. 17, we say that a potential φ belongs to the class $\nu_T(X)$ if the following condition is fulfilled:

There are constants $\varepsilon, K > 0$ in a such way that

$$d_n(x,y) < \varepsilon \Rightarrow |S_n(\varphi)(x) - S_n(\varphi)(y)| < K. \tag{46}$$

A measure μ on X is called a *Gibbs state* if, for sufficiently small $\varepsilon > 0$, there are constants A_ε, $B_\varepsilon > 0$, such that, for any $x \in X$ and for any positive integer n, there is

$$A_\varepsilon \{\exp[S_n(\varphi)(x)] - nP(\varphi)\} \leqslant \mu(B_{n,\varepsilon}(x)) \leqslant B_\varepsilon \{\exp[S_n(\varphi)(x)] - nP(\varphi)\}. \tag{47}$$

Theorem:[17–23] Let T be an expansive homeomorphism which has the specification property and φ be a potential belonging to the class $\nu_T(X)$, Then μ_φ is an equilibrium state associated to φ, which is a Gibbs state. Besides, it is ergodic.

Proposition 4.1: Under the same hypothesis of the previous theorem it holds that

$$h_q^{\mathrm{corr}}(T) = \frac{1 - \exp[\tau(q)]}{q-1}. \tag{48}$$

Proof: Let μ be the equilibrium state μ_φ associated to the potential φ, which exists. It is a Gibbs state by the theorem above. For $E \subset X$, an (n,ε)-separate set[16,17] we have

$$\int_X \mu(B_{n,\varepsilon}(x))^{q-1} d\mu \geqslant \sum_{x_i \in B_{n,\varepsilon/2}} \int_{B_{n,\varepsilon/2}} \mu(B_{n,\varepsilon}(x))^{q-1} d\mu \geqslant \sum_{x_i \in E} \mu(B_{n,\varepsilon}(x_i))^q. \tag{49}$$

This is because $x \in B_{n,\varepsilon}(x_i) \Rightarrow B_{n,\varepsilon}(x_i) \subset B_{n,\varepsilon}(x)$. Denote

$$Z_n(\varphi, E) = \sum_{x \in E} \exp[S_n(\varphi)(x)].$$

We shall need the following estimations.[17]

(i) Let $E \subset X$ be a finite set. If E_n are (n,ε)-separate, then the topological pressure can be calculated by

$$P(\varphi) = \lim_{n \to \infty} \frac{1}{n} \log Z_n(\varphi, E_n). \tag{50}$$

(ii) If δ is the constant of the expansiveness and $\varepsilon < \delta/2$, then there exists a constant $C = C(\varphi, \varepsilon)$ such that

$$|\log Z_n(\varphi, E_n) - nP(\varphi)| < C \quad \text{for all } n \text{ and all maximal } (n,\varepsilon)\text{-separated sets.} \tag{51}$$

We consider first $q>1$. By using that E is (n,ε)-separated and that μ is a Gibbs state, we obtain

$$\int_X \mu(B_{n,\varepsilon}(x))^{q-1}d\mu \geqslant \sup_E\left\{\sum_{x_i\in E} A_{\varepsilon/2}^q \exp\left[-qnP(\varphi)+\sum_{j=0}^{n-1} q\varphi(T^j(x_i))\right]\right\}. \tag{52}$$

Therefore, using estimations and taking corresponding limits, we have

$$\tilde{h}_q^{\mathrm{corr}}(T)=\lim_{\varepsilon\to 0}\overline{\lim_{n\to\infty}}\frac{1}{n}\log\left[\int_X \mu(B_{\varepsilon,n}(x))^{q-1}d\mu\right]\geqslant P(q\varphi)-qP(\varphi)=\tau(q). \tag{53}$$

For the other inequality, let E be $(n,\varepsilon/2)$-separated,

$$\int_X \mu(B_{n,\varepsilon/2}(x))^{q-1}d\mu \leqslant \sum_{x_i\in E}\int_{B_{n,\varepsilon/2}(x_i)} \mu(B_{n,\varepsilon/2}(x))^{q-1}d\mu \leqslant \sum_{x_i\in E}\mu(B_{n,\varepsilon}(x_i))^{q-1}d\mu, \tag{54}$$

since $x\in B_{n,\varepsilon/2}(x_i)\Rightarrow B_{n,\varepsilon/2}(x)\subset B_{n,\varepsilon}(x_i)$. Thus by using again the estimations and that μ is a Gibbs state,

$$\int_X \mu(B_{n,\varepsilon/2}(x))^{q-1}d\mu \leqslant \sup_E\left\{\sum_{x_i\in E} B_\varepsilon^q \exp\left[-qnP(\varphi)+\sum_{j=0}^{n-1} q\varphi(T^j(x_i))\right]\right\}, \tag{55}$$

so that

$$\tilde{h}_q^{\mathrm{corr}}(T)\leqslant P(q\varphi)-qP(\varphi)=\tau(q). \tag{56}$$

The case $q<1$ is proved similarly by inverting inequalities. Finally,

$$h_q^{\mathrm{corr}}(T)=\frac{1-\exp[\tau(q)]}{q-1}. \tag{57}$$

■

The facts that $\tau(q)$ is strictly convex and its derivative is

$$\frac{d\tau}{dq}=\int_X \varphi d\mu_q - P(\varphi), \tag{58}$$

where μ_q is the equilibrium state for the potential $\varphi_q=q\varphi-qP(\varphi)$, were demonstrated first in Ref. 20 and, under the weaker hypothesis considered in the above results, in Ref. 21.

We finish by outlining the usefulness of this correlation approach to extend properties of the Tsallis entropies to general dynamical systems. We show as a sample two of them, say the properties (i) and (ii) of Lemma 1 in Ref. 24.

$$(i)\quad \tilde{h}_q^{\mathrm{corr}}(\lambda T_1+(1-\lambda)T_2)\overset{\leqslant}{\geqslant}\lambda^{q-1}\int_X(\mu_1(B_{n,\varepsilon}(x)))^{q-1}+(1-\lambda)^{q-1}\int_X \mu_2(B_{n,\varepsilon}(x))^{q-1}. \tag{59}$$

We have $\int_X(\mu_1(B_{n,\varepsilon}(x))+\mu_2(B_{n,\varepsilon}(x)))^{q-1}d\mu \overset{\leqslant}{\geqslant}\int_X(\mu_1(B_{n,\varepsilon}(x)))^{q-1}+\int_X\mu_2(B_{n,\varepsilon}(x))^{q-1}$, $\leqslant$ or $\geqslant$ accordingly to $q<1$ or $q>1$. The result follows immediately.

For the special case of Bernoulli schemes, (i) of Lemma 1 in Ref. 24 is obtained.

$$(ii)\quad h_q^{\mathrm{corr}}(T)\leqslant\frac{1-\exp[(1-q)h_{\mathrm{top}}]}{q-1},\quad \text{for } 0<q<1, \tag{60}$$

where h_{top} is the topological entropy of T. To prove it we use that, for $0<q<1$, it holds that

$$\frac{\tilde{h}_q^{\text{corr}}(T)}{1-q} \leqslant \tilde{h}_0^{\text{corr}}(T) = \tau(0) = P(0), \tag{61}$$

and, since $P(0)=h_{\text{top}}$,[16,17] we get

$$\tilde{h}_q^{\text{corr}}(T) \leqslant (1-q)h_{\text{top}}, \tag{62}$$

given Eq. (60) which generalizes property (ii) of Lemma 1 in Ref. 24.

(Received 21 August 2001; accepted for publication 18 October 2001)

We prove that the short distance asymptotics for the even Ising model scaling functions from below T_c is given by the Luther–Peschel formula. Generalizations to the odd scaling functions and holonomic fields are given. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1425960]

I. INTRODUCTION

In this paper we will use the Sato–Miwa–Jimbo (SMJ) characterization of the scaling functions for the two-dimensional Ising model to show that the short distance asymptotics of the even scaling functions below the critical point are given by the Luther–Peschel formula[1] (see Theorem 1). We will then present results for the odd correlations below T_c and also for holonomic quantum fields which are a consequence of the same technique used to prove Theorem 1.

This paper is a sequel to Ref. 2 and the reader is referred to that paper for a more detailed explanation of the Ising model scaling limits than we will give here. Continuum limits for the two-dimensional Ising correlations on a lattice were first considered in Ref. 3, where, in addition, a connection with Painlevé transcendents was discovered. In a series of papers Sato, Miwa, and Jimbo showed that the continuum correlations (the scaling functions) were associated with monodromy preserving deformations of the Euclidean Dirac equation and that this connection sufficed to account for the appearance of the Painlevé transcendents.[4–8] Here we exploit the fact that the SMJ formula for the log derivative of the scaling function (a τ function in their terminology) can be expressed in terms of the Fourier coefficients of a solution to the *linear* Dirac equation. We analyze the linear problem in order to control the short distance asymptotics. This analysis was suggested by the success of Riemann–Hilbert techniques in obtaining asymptotics for nonlinear integrable systems,[9] where a similar connection with a linear problem is a central feature.

We would like to point out that the two point function both for the Ising model and for holonomic fields in general has been analyzed in more detail than the result we obtain here, see Refs. 10–12. In particular, the constant term in the short distance asymptotics is obtained—our result for the log derivative has nothing to say about this.

We will begin by recalling some of the results of Ref. 2, where a sketch of the the proof was presented. The SMJ characterization involves certain solutions to the Dirac equation in two dimensions so we will start with a description of the situation of interest to us. The Euclidean Dirac operator in $\mathbf{R}^2$ (with a mass perturbation) is given by

$$mI-\not{\partial}=\begin{bmatrix} m & -2\partial \\ -2\bar{\partial} & m \end{bmatrix},$$

where

$$\partial := \frac{1}{2}\left(\frac{\partial}{\partial x_1}-i\frac{\partial}{\partial x_2}\right),$$

a)Electronic mail: palmer@math.arizona.edu

$$\overline{\partial} := \frac{1}{2}\left(\frac{\partial}{\partial x_1} + i\frac{\partial}{\partial x_2}\right).$$

Although we will *not* be working exclusively with holomorphic functions, the presence of ∂ and $\overline{\partial}$ in the Dirac operator makes it very convenient to introduce the complex variable $z = x_1 + ix_2$ with $\overline{z} = x_1 - ix_2$; we thus identify $\mathbf{R}^2$ with $\mathbf{C}$ in the usual fashion. For brevity we will write $f(z)$ for a function of two real variables even though it is customary to use a notation like $f(z,\overline{z})$ to avoid the temptation to regard $f(z)$ as a holomorphic function of z.

Let $\mathbf{a} = \{a_1, a_2, \ldots, a_N\}$ denote a collection of N distinct points in $\mathbf{C}$. The solutions of the Dirac equation that we are interested in are smooth sections of a rank 2 vector bundle over the punctured plane $\mathbf{C}\backslash\mathbf{a}$.

For the purpose of allowing some later remarks we will begin by defining a slightly more general family of *line* bundles, $\mathcal{E}_\lambda$, than is relevant for the Ising model. For $j = 1,2,\ldots,N$ suppose *real* numbers λ_j are given with $|\lambda_j| \leqslant \frac{1}{2}$. Define

$$\Lambda_j = e^{2\pi i \lambda_j}$$

and write

$$\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_N).$$

Roughly speaking the smooth sections of the bundle $\mathcal{E}_\lambda \to \mathbf{C}\backslash\mathbf{a}$ will be multivalued functions on $\mathbf{C}\backslash\mathbf{a}$ with values in $\mathbf{C}$ which have multiplier Λ_j when continued about a loop that circles a_j counterclockwise. This can be made precise in an elegant fashion by working on the simply connected covering space of $\mathbf{C}\backslash\mathbf{a}$ and then restricting attention to smooth sections that transform appropriately under the action of $\pi_1(\mathbf{C}\backslash\mathbf{a})$ by deck transformations. However, some later developments will be clearer for us if we can use functions with specific branching behavior as multipliers taking sections of $\mathcal{E}_\lambda$ to sections of the trivial bundle over $\mathbf{C}\backslash\mathbf{a}$. It will be easiest to be precise about this multiplier action if we define the bundles $\mathcal{E}_\lambda$ by giving transition functions, in spite of the fact that this is a little clumsy.

To begin, note that there are only a finite number of lines each of which consists of all multiples of $a_i - a_j$ for i and j distinct. Thus it is possible to choose a vector $\mathbf{r} \neq 0$ which is not contained in any of these lines. Then the rays, $\mathbf{r}_j$, defined by

$$\mathbf{r}_j = \{z : z = a_j + t\mathbf{r}, t > 0\},$$

do not intersect. Choose an argument $\theta_{\mathbf{r}}$ for $\mathbf{r}$ so that $\mathbf{r} = |\mathbf{r}| e^{i\theta_{\mathbf{r}}}$ with $|\theta_{\mathbf{r}}| \leqslant \pi$ and let $\theta(z)$ denote the polar angle with

$$\theta_{\mathbf{r}} - \pi < \theta(z) < \theta_{\mathbf{r}} + \pi, \quad z = |z| e^{i\theta(z)}.$$

This angle is branched along the ray $-\mathbf{r}$. For $\epsilon > 0$ define a tubular neighborhood, $\mathbf{t}_j(\epsilon)$, of $\mathbf{r}_j$ by

$$\mathbf{t}_j(\epsilon) = \{z : \mathrm{dist}(z, \mathbf{r}_j) < \epsilon\} \cap \left\{z : |\theta(z_j) - \theta_{\mathbf{r}}| < \frac{\pi}{4}\right\}.$$

Now choose $\epsilon > 0$ small enough so that the tubular neighborhoods $\mathbf{t}_j(\epsilon)$ are mutually disjoint *and* so that the disks,

$$D_j(2\epsilon) := \{z : |z - a_j| < 2\epsilon\},$$

are also mutually disjoint (this will be useful later on).

We now introduce a covering of $\mathbf{C}\backslash\mathbf{a}$ over each element of which the bundle $\mathcal{E}_\lambda$ is trivial. Let

$$\mathcal{U}_0 := \{z \in \mathbf{C}\backslash\mathbf{a} : z \notin r_j \text{ for } j = 1,2,\ldots,N\}.$$

Let

$$\mathcal{U}_j := \mathbf{t}_j(\epsilon) \quad \text{for } j=1,2,...,N.$$

Now we glue together the trivial bundles,

$$\mathcal{U}_k \times \mathbf{C} \to \mathcal{U}_k \quad \text{for } k=0,1,...,N,$$

by giving the transition functions s_j that define the bundle $\mathcal{E}_\lambda$. For $j=1,...,N$ define

$$s_j(z)=\begin{cases}\Lambda_j & \text{for } \theta(z_j)<0\\ 1 & \text{for } \theta(z_j)>0.\end{cases}$$

Then the bundle $\mathcal{E}_\lambda$ is defined by the following transition maps between vectors $(z,v)_0 \in \mathcal{U}_0 \times \mathbf{C}$ in the trivial bundle over $\mathcal{U}_0$ and vectors $(z,v)_j \in \mathcal{U}_j \times \mathbf{C}$ in the trivial bundle over $\mathcal{U}_j$ (for $k=1,2,...,N$),

$$(z,v)_0=(z,s_j(z)v)_j \quad \text{for } z \in \mathcal{U}_0 \cap \mathcal{U}_j.$$

The function $s_j(z)$ is smooth since it is constant on each of the two components of $\mathcal{U}_0 \cap \mathcal{U}_j$. The bundle that is relevant for the Ising model is the one with the choice $\Lambda_j=-1$ for all $j=1,2,...,N$. For simplicity we will denote this bundle by $\mathcal{E}$ with no subscript.

The rank 2 *vector* bundles that are more directly of interest to us are $\mathcal{E}_\lambda \otimes \mathbf{C}^2$ and $\mathcal{E} \otimes \mathbf{C}^2$, the direct sum of two copies of $\mathcal{E}_\lambda$ and $\mathcal{E}$, respectively. For simplicity we will use the same notation, $\mathcal{E}_\lambda$ and $\mathcal{E}$, to denote these vector bundles and when necessary make distinctions by referring to the *line bundles* $\mathcal{E}_\lambda$ and $\mathcal{E}$.

The differential operator $mI-\not\partial$ acts on $C^\infty(\mathcal{E}_\lambda)$, the space of smooth sections of the vector bundle $\mathcal{E}_\lambda$, since it commutes with multiplication by constants. We will now define a family of *local* smooth sections of $C^\infty(\mathcal{E}_\lambda)$ which are simultaneously solutions of the Dirac equation, $(mI-\not\partial)w=0$ and eigenfunctions for the infinitesimal rotation about a_j,

$$R_j=z_j\partial_j-\overline{z_j}\overline{\partial_j}+\frac{1}{2}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},$$

which commutes with $mI-\not\partial$. We write $z_j=z-a_j$ and $\partial_j=\partial_{z_j}$. Note that this infinitesimal rotation has eigenvalues which are translated by $\pm\frac{1}{2}$ compared to the infinitesimal monodromy. Following SMJ we will parametrize our local wave functions by the R_j eigenvalue rather than the infinitesimal monodromy.

Let $\Theta(z)$ denote the angular coordinate at 0 defined so that for $z \notin \{t\mathbf{r}: t>0\}$ we have,

$$z=|z|e^{i\Theta(z)} \quad \text{with } \theta_{\mathbf{r}}<\Theta(z)<\theta_{\mathbf{r}}+2\pi.$$

For l a real number we define a function $w_l(z)$ for $z \in \mathbf{C}\backslash\mathbf{r}$ by

$$w_l^0(z)=\begin{pmatrix}e^{i(l-1/2)\Theta(z)} & I_{l-1/2}(m|z|)\\ e^{i(l+1/2)\Theta(z)} & I_{l+1/2}(m|z|)\end{pmatrix},$$

where I_k is the modified Bessel function of order k. For $z \in \mathbf{C}\backslash(-\mathbf{r})$ we define

$$w_l^\pi(z)=\begin{pmatrix}e^{i(l-1/2)\theta(z)} & I_{l-1/2}(m|z|)\\ e^{i(l+1/2)\theta(z)} & I_{l+1/2}(m|z|)\end{pmatrix}.$$

The only difference being, of course, the choice of angle. Where defined these are solutions to the Dirac equation $(mI-\not\partial)w=0$ and are eigenfunctions of the infinitesimal rotation $Rw_l=lw_l$ about 0.[6] Now let l denote a real number and define (for $|z_j|<2\epsilon$ say)

$$w_l(z_j) = w_l^0(z_j) \text{ in the } \mathcal{U}_0 \text{ trivialization,}$$

$$w_l(z_j) = w_l^{\pi}(z_j) \text{ in the } \mathcal{U}_j \text{ trivialization.}$$

Then it is easy to check that $w_l(z_j)$ is a *local* section of $C^\infty(\mathcal{E}_\lambda)$ provided $l \equiv \frac{1}{2} + \lambda_j \bmod \mathbf{Z}$. Now define a conjugation on $\mathbf{C}^2$ by

$$\begin{pmatrix} a \\ b \end{pmatrix}^* = \begin{pmatrix} \overline{b} \\ \overline{a} \end{pmatrix}.$$

This conjugation commutes with the Dirac operator $\not{\partial}$ and we define

$$w_l^*(z) = \begin{pmatrix} \overline{w}_{l,2}(z) \\ \overline{w}_{l,1}(z) \end{pmatrix}.$$

One can check that $w_l^*(z_j)$ is a local smooth section of $C^\infty(\mathcal{E}_\lambda)$ if and only if $l \equiv \frac{1}{2} - \lambda_j \bmod \mathbf{Z}$. It is a result of SMJ that every solution to $(mI - \not{\partial})w = 0$ in $C^\infty(\mathcal{E}_\lambda)$ has local expansions,

$$w(z) = \sum_{k \in \mathbf{Z}+1/2} a_k^j(w) w_{k+\lambda_j}(z_j) + b_k^j(w) u^*_{k-\lambda_j}(z_j), \tag{1}$$

valid for $0 < |z_j| < 2\epsilon$.[6,13] As the reader may check the coefficients $a_k^j(w)$ and $b_k^j(w)$ are simply related to Fourier coefficients in the expansion of the restriction of w to say the circle $|z_j| = \epsilon$. We will refer to these coefficients as local expansion coefficients.

For the Ising case $\lambda_j = \pm \frac{1}{2}$ and it is better not to use this form of the expansion (which would require a somewhat arbitrary choice of $\pm \frac{1}{2}$ at each a_j); instead we will just write

$$w(z) = \sum_{n \in \mathbf{Z}} \epsilon_n^j(w) w_n(z_j) + c_n^{j*}(w) w_n^*(z_j). \tag{2}$$

Note that we have changed the names of the local expansion coefficients in (2) to $c_n^j(w)$ and $c_n^{j*}(w)$ so that it coincides with the terminology in Ref. 6. Our way of writing (1) is different than the corresponding local expansions in Ref. 6 and so we have given different names to the local expansion coefficients.

Before we move on we will make one further observation about local expansions in a neighborhood of ∞. Suppose that $R > 0$ is big enough so that all the points a_j for $j = 1,2,...,N$ are inside the circle of radius R. Then $\{z : |z| > R\} \setminus \cup_j \mathbf{r}_j$ splits into N distinct components and the $\mathcal{U}_0$ trivialization is not very convenient for the description of sections of $\mathcal{E}$ over this set. In particular suppose that N is even. Then we can alternately flip the signs of sections supported in adjacent components of the $\mathcal{U}_0$ trivialization to produce a trivialization $\mathcal{U}_\infty$ for $\mathcal{E}$ over $\{z : |z| > R\}$. Actually the $\mathcal{U}_0$ trivialization is not defined over the rays $\mathbf{r}_j$ but because of the sign flips on adjacent components it is easy to see that $\mathcal{U}_\infty$ extends to a trivialization of $\mathcal{E}$ over the exterior of the disk of radius R. It is also clear that $\mathcal{U}_\infty$ is only determined itself up to an overall sign which we fix by declaring the $\mathcal{U}_\infty$ trivialization of the $\mathcal{U}_0$ section $\Pi_j (z - a_j)^{\epsilon_j}$ for $|\epsilon| = 0$ to be

$$\prod_j \left(1 - \frac{a_j}{z}\right)^{\epsilon_j} \quad \text{for } |z| > R,$$

where the fractional powers in this last product are the holomorphic functions of z normalized to be 1 at $z = \infty$.

It can be shown (Refs. 6 and 13) that sections $w \in L^2(\mathcal{E})$ which are solutions to the Dirac equation in the exterior of the disk of radius R have convergent expansions (in the $\mathcal{U}_\infty$ trivialization),

$$w(z)=\sum_{n\in\mathbf{Z}} c_n^{\infty}(w)\hat{w}_n(z), \tag{3}$$

where,

$$\hat{w}_u(z):=\begin{bmatrix} -e^{in\theta}K_n(m|z|) \\ e^{-i(n-1)\theta}K_{n-1}(m|z|)\end{bmatrix}.$$

The functions K_n are the modified Bessel functions that tend to zero at ∞. The reader should note that there is more than one definition of these functions (differing by a factor $e^{in\pi}$). We are using the version defined in Ref. 14. Also note that because n is an integer the choice of angle θ is irrelevant.

Now write $x\cdot y=x_1y_1+x_2y_2$ for the standard bilinear form on $\mathbf{C}^2$, so that $\overline{x}\cdot y$ is the standard Hermitian form. For $w, v\in C_0^{\infty}(\mathcal{E}_\lambda)$ define an inner product,

$$(w,v)=\frac{i}{2}\int_C \overline{w}\cdot v\ \mathrm{d}z\ \mathrm{d}\overline{z},$$

which is well defined since $\overline{w}(z)\cdot v(z)$ descends to a compactly supported function on $\mathbf{C}\backslash\mathbf{a}$. We will write $L^2(\mathcal{E}_\lambda)$ for the Hilbert space completion of $C_0^{\infty}(\mathcal{E}_\lambda)$ with respect to the norm induced by this inner product.

For the rest of this introduction we will specialize our considerations to the situation relevant to the Ising model. For n an integer we write,

$$w_n^R=\tfrac{1}{2}(w_n+w_n^*),\quad w_n^I=\frac{1}{2i}(w_n-w_n^*),$$

for the real and imaginary parts of w_n with respect to the conjugation $*$. Since $\Lambda_j=-1$ is real for all j it follows that $w_n^R(z_j)$ and $w_n^I(z_j)$ are local sections of $C^{\infty}(\mathcal{E})$. In Ref. 2 it is shown that for $j=1,2,...,N$ there exists a real solution $\mathcal{W}_j(\mathcal{W}_j^*=\mathcal{W}_j)$ to the Dirac equation,

$$(mI-\not{\partial})\mathcal{W}_j=0,$$

which is in $L^2(\mathcal{E})$ and which has leading order local expansions given by

$$\mathcal{W}_j(z)=\delta_{ij}w_0^I(z_i)+T_{ij}w_0^R(z_i)+\cdots \quad \text{for } i=1,2,...,N. \tag{4}$$

Note that the coefficients $w_n(z)$ are less and less locally singular at $z=0$ as n increases. The $+\cdots$ in (4) refer to terms with w_n and w_n^* for $n>0$. Also note that in (4) it is not necessary to specify what the coefficients T_{ij} are—they are already uniquely determined by the other conditions on $\mathcal{W}_j$.[2]

We are now ready to present the SMJ characterization of the Ising model scaling function from below T_c, $\tau_-(ma)=\tau_-(ma_1,ma_2,\ldots,ma_N)$. It is,

$$\mathrm{d}_a\log\tau_-(ma)=\frac{m}{2i}\sum_j c_1^j(\mathcal{W}_j)\mathrm{d}a_j-\overline{c_1^j(\mathcal{W}_i)}\mathrm{d}\overline{a_j}. \tag{5}$$

The reader might want to consult Ref. 15 or 2 for an explanation of what exactly τ_- is and how it is related to two-dimensional Ising correlations. Most of the rest of this paper will be devoted to understanding the solution $\mathcal{W}_j$ well enough in the limit $m\to 0$ so that we can compute the limiting values of the coefficients $mc_1^j(\mathcal{W}_j)$ which appear in (5). Our principal result is

Theorem 1 (Luther–Peschel Asymptotics): *Suppose that N is even. Then*

$$\lim_{m\to 0} \mathrm{d}_a \log \tau_-(ma) = \frac{1}{2}\mathrm{d}_a \log \sum_{|\epsilon|=0} \prod_{i<j} |a_i - a_j|^{2\epsilon_i\epsilon_j} \tag{6}$$

where the sum is over all choices of $\epsilon_k = \pm\frac{1}{2}$ *with*

$$|\epsilon| := \epsilon_1 + \epsilon_2 + \cdots + \epsilon_N = 0.$$

After the proof of this result we will indicate the changes that are needed to adapt the proof to the case where N is odd. We find for N odd,

$$\lim_{m\to 0} \mathrm{d}_a \log \tau_-(ma) = \frac{1}{2}\mathrm{d}_a \log \sum_{|\epsilon|=\pm 1/2} \prod_{i<j} |a_i - a_j|^{2\epsilon_i\epsilon_j}.$$

We will also indicate how to derive the short distance behavior of the correlations for holonomic fields.

Very briefly the rest of the paper is organized as follows. In Sec. II we characterize $\mathcal{W}_j$ as the solution to a boundary value problem on a finite domain. In Sec. III we introduce the Green function for the $m\to 0$ limit of this boundary value problem. In Sec. IV we introduce the associated boundary value projection. In Sec. V we discuss the inversion of a suitable restriction of this projection. In Sec. VI we discuss how to put these results together to give the perturbation scheme which we use to approximate $\mathcal{W}_j$ in the limit $m\to 0$. In Sec. VII we examine the application of the same technique to other problems.

II. AN EQUIVALENT BOUNDARY VALUE PROBLEM

The tool we will use in dealing with the $m\to 0$ limit of $\mathcal{W}_j$ is a characterization of $\mathcal{W}_j$ as the solution to an inhomogeneous boundary value problem. We will now describe this characterization. It is a result of SMJ[6] that the space of solutions $w \in C^\infty(\mathcal{E})$ to the Dirac equation,

$$(mI - \not{\partial})w = 0,$$

which are also in $L^2(\mathcal{E})$ is N dimensional. We write $\mathbf{N}$ for this space of solutions. For $w \in \mathbf{N}$ define

$$c_0(w) = (c_0^1(w), c_0^2(w), \ldots, c_0^N(w)) \in \mathbf{C}^N,$$

with a similar definition for $c_0^*(w)$. Now let $\mathcal{N}$ denote the image of $\mathbf{N}$ in $\mathbf{C}^N \oplus \mathbf{C}^N$ under the map,

$$\mathbf{N} \ni w \to (c_0(w), c_0^*(w)).$$

Suppose now that $\mathcal{I}$ is any subspace of $\mathbf{C}^N \oplus \mathbf{C}^N$ which is *transverse* to $\mathcal{N}$. If $f \in C_0^\infty(\mathcal{E})$ then in Ref. 2 it was proved that there exists a unique solution $w \in L^2(\mathcal{E})$ to

$$(mI - \not{\partial})w = f,$$

which satisfies the boundary condition $(c_0(w), c_0^*(w)) \in \mathcal{I}$. It was also shown there that the subspace $\mathcal{I}$ given by the set of vectors (v, v) for $v \in \mathbf{C}^N$ (the diagonal subspace) is transverse to $\mathcal{N}$. Henceforth we will work with the subspace $\mathcal{I}$ which corresponds to the boundary condition,

$$c_0(w) = c_0^*(w). \tag{7}$$

Now we will make a subtraction from $\mathcal{W}_j$ which will put the result in the subspace of sections of $\mathcal{E}$ satisfying (7). Let $\varphi(z)$ denote a non-negative function in $C_0^\infty(\mathbf{R}^2)$ which is identically 1 for $|z| < 1$ and identically 0 outside the ball of radius 2. Define,

$$\varphi_{j,\epsilon}(z)=\varphi\left(\frac{z-a_j}{\epsilon}\right).$$

Then since ϵ has been chosen small enough we know that $\varphi_{j,\epsilon}$ is one in a neighborhood of a_j and vanishes near a_i for all $i\neq j$. Now define

$$\delta\mathcal{W}_j(z)=m^{1/2}(\mathcal{W}_j(z)-\varphi_{j,\epsilon}(z)w_0^I(z-a_j)). \tag{8}$$

Then consulting (4) we see that if we look at the local expansion for $\delta\mathcal{W}_j$ in an ϵ neighborhood of a_j then the local expansion coefficients satisfy condition (7). The scale factor $m^{1/2}$ has been introduced so that the following limit exists:

$$\lim_{m\to 0} m^{1/2}w_0^I(z_j)=\frac{1}{\sqrt{2\pi i}}\begin{bmatrix} z_j^{-1/2} \\ -\overline{z_j}^{-1/2}\end{bmatrix}.$$

Here we used $\Gamma(\frac{1}{2})=\sqrt{\pi}$, the fractional powers of z_j and $\overline{z_j}$ that occur are branched along $z=\mathbf{r}_j$ and we employ the convention that the section w_0^I can be identified with its $\mathcal{U}_0$ trivialization (which appears on the right-hand side). Using the fact that both $\mathcal{W}_j$ and $w_0^I(z_j)$ satisfy the massive Dirac equation we find that

$$(m-\not{\partial})\,\delta\mathcal{W}_j=\begin{bmatrix} 0 & -2\partial\varphi_j \\ -2\overline{\partial}\varphi_j & 0\end{bmatrix}m^{1/2}w_0^I(z_j):=f_j. \tag{9}$$

We are now prepared to give an alternative characterization of $\delta\mathcal{W}_j$. Choose $R>0$ big enough so that $D_i(2\epsilon)$ is contained inside $|z|=R$ for $i=1,2,...,N$. Let $D_\infty=\{z:|z|\geqslant R\}$ and define the bounded domain, Ω, by

$$\Omega=\mathbf{C}\backslash\{\cup_{i=1}^n D_i(\epsilon)\cup D_\infty\}.$$

We write $H^k(\mathcal{E}_\Omega)$ for the Sobolev space of sections of $\mathcal{E}$ over Ω which are in $L^2(\Omega)$ together with all their weak derivatives up to and including those of order k.

Lemma 1: The smooth section $\delta\mathcal{W}_j$ of $\mathcal{E}_\Omega$ (the restriction of $\mathcal{E}$ to Ω) is uniquely characterized by the following three properties:

(1) *$\delta W_j\in H^1(\mathcal{E}_\Omega)$ satisfies the inhomogeneous Dirac equation (9) in Ω.*
(2) *For $i=1,2,...,N$ the local Fourier expansions (2) for $\delta\mathcal{W}_j$ restricted to $C_\epsilon(a_i)$ have coefficients $c_k^i(\delta\mathcal{W}_j)$ and $c_k^{i*}(\delta\mathcal{W}_j)$ that vanish for $k<0$ and are equal for $k=0$.*
(3) *The section $\delta\mathcal{W}_j$ has a Fourier expansion $\delta\mathcal{W}_j=\Sigma_{n\in\mathbf{Z}}c_n^\infty(\delta\mathcal{W}_j)\hat{w}_n(z)$, on the circle of radius R.*

Remark: Henceforth we interpret the local expansions (2) as the Fourier expansions of the restrictions of the $\mathcal{U}_0$ trivialization of $\delta\mathcal{W}_j$ to $|z_i|=\epsilon$ in powers $e^{i(n+1/2)\Theta_i}$ for $n\in\mathbf{Z}$. In a similar fashion we interpret (3) as the Fourier expansions of the $\mathcal{U}_\infty$ trivialization of $\delta\mathcal{W}_j$ restricted to the circle of radius R.

Proof of Lemma 1: Because the solution, $\delta\mathcal{W}_j$, of condition (1) of the Lemma is assumed to be in $H^1(\mathcal{E}_\Omega)$ it follows from local elliptic regularity that the solution is actually in $C^\infty(\mathcal{E}_\Omega)$. The support properties of the inhomogeneous term f_j makes it possible to enlarge each circle $C_\epsilon(a_i)$ to an annular region in which $\delta\mathcal{W}_j$ satisfies the homogeneous Dirac equation. In this region it will have a convergent local expansion of type (2). Since the Fourier coefficients $c_k^i(\delta\mathcal{W}_j)$ and $c_k^{i*}(\delta\mathcal{W}_j)$ [for the restriction of $\delta\mathcal{W}_j$ to $C_\epsilon(a_i)$] vanish for $k<0$ and are equal for $k=0$ it follows (by the uniqueness of Fourier expansions) that the same is true for the local expansion coefficients in the annulus. Since the Bessel functions $I_l(r)$ are monotone increasing functions of r for $l\geqslant 0$ this restriction on the local expansions implies that they converge in a domain $0<|z_i|<\epsilon'$, where

ϵ' is slightly bigger than ϵ (only a finite number of Fourier coefficients will get larger for smaller values of $|z_j|$). This shows that a solution, $\delta\mathcal{W}_j$, to (1) and (2) of the Lemma extends to a solution of the Dirac equation which is in L^2 near a_i and has appropriate restrictions on its local expansion coefficients. The same sort of argument shows that restriction (3) allows one to extend $\delta\mathcal{W}_j$ to an L^2 solution to the Dirac equation in a neighborhood of ∞. Q.E.D.

Without much difficulty the reader should be able to verify the following formula for the local expansion coefficients $mc_1^j(\mathcal{W}_j)$ that appear in the SMJ formula for the log derivative of the τ function:

$$mc_1^j(\mathcal{W}_j)=\frac{\sqrt{m}}{2\pi I_{1/2}(m\epsilon)}\int_{\theta_{\mathbf{r}}}^{\theta_{\mathbf{r}}+2\pi}(\delta\mathcal{W}_j)_1(\epsilon e^{i\Theta_j})\exp\left(-i\frac{\Theta_j}{2}\right)\mathrm{d}\Theta_j. \tag{10}$$

In this formula $(\delta\mathcal{W}_j)_1$ is the first component of $\delta\mathcal{W}_j$ in the $\mathcal{U}_0$ trivialization. The formula follows easily from the standard formula for Fourier coefficients and the fact that the subtraction of $\varphi_j w_0(z_j)$ does not alter the local expansion coefficients at level 1, so that $c_1^j(\delta\mathcal{W}_j)=\sqrt{m}c_1^j(\mathcal{W}_j)$.

Our strategy in controlling the $m\to 0$ limit of the coefficients $mc_1^j(\mathcal{W}_j)$ will be to use the characterization of Lemma 1 in conjunction with formula (10). Since

$$\lim_{m\to 0}\frac{\sqrt{m}}{I_{1/2}(m\epsilon)}=\sqrt{\frac{2}{\epsilon}}\Gamma\left(\frac{3}{2}\right)=\sqrt{\frac{\pi}{2\epsilon}},$$

it will suffice for our purposes to control the $m\to 0$ convergence of $\delta\mathcal{W}_j$ in $L^p(C_\epsilon(a_i))$ for any $p\geqslant 1$ and all i. Here $C_\epsilon(a_i)$ is the circle of radius ϵ about a_i.

Next we introduce convenient orthornormal bases for the subspaces that are of interest to us. Define

$$e_n^{(m)}(r,\Theta)=\begin{bmatrix}e^{i(n-1/2)\Theta}\alpha_n^{(m)}(mr)\\ e^{i(n+1/2)\Theta}\beta_n^{(m)}(mr)\end{bmatrix},$$

where

$$\alpha_n^{(m)}(mr)=\frac{I_{n-1/2}(mr)}{\sqrt{I_{n-1/2}^2(mr)+I_{n+1/2}^2(mr)}},\quad \beta_n^{(m)}(mr)=\frac{I_{n+1/2}(mr)}{\sqrt{I_{n-1/2}^2(mr)+I_{n+1/2}^2(mr)}}.$$

Also define $e_n^{(m)*}(r,\Theta)=\left[\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right]\overline{e_n^{(m)}}(r,\Theta)$. The collection

$$\{e_n^{(m)}(\epsilon,\Theta_j),e_n^{(m)*}(\epsilon,\Theta_j)\},$$

as n ranges over the integers is an orthonormal basis for $L^2(C_\epsilon(a_j))$ (with values in $\mathbf{C}^2$). Here we write

$$\Theta_j(z):=\Theta(z-a_j).$$

Definition 1: Let $W_j^{(m)}$ denote the subspace of $L^2(C_\epsilon(a_j))$ which is the L^2 closure of the span of $e_n^{(m)}(\epsilon,\Theta_j)$, and $e_n^{(m)*}(\epsilon,\Theta_j)$ for $n>0$ and the vector $e_0^{(m)}(\epsilon,\Theta_j)+e_0^{(m)*}(\epsilon,\Theta_j)$.

Define

$$\hat{e}_n^{(m)}(r,\theta)=\begin{bmatrix}e^{-in\theta}\alpha_n^{\infty}(mr)\\ e^{-i(n-1)\theta}\beta_n^{\infty}(mr)\end{bmatrix}$$

with

$$\alpha_n^{\infty}(mr)=\frac{-K_n(mr)}{\sqrt{K_{n-1}^2(mr)+K_n^2(mr)}},\quad \beta_n^{\infty}(mr)=\frac{K_{n-1}(mr)}{\sqrt{K_{n-1}^2(mr)+K_n^2(mr)}}.$$

Then $\{\hat{e}_n^{(m)}(R,\theta)\}$, where n ranges over the integers, is an orthonormal set in $L^2(C_R)$.

Definition 2: Let $W_{\infty}^{(m)}$ be the L^2 closure of the span of the $\hat{e}_n^{(m)}(R,\theta)$ for $n\in\mathbf{Z}$.

The boundary conditions (2) and (3) in Lemma 1 become

$$\delta\mathcal{W}_j|_{C_{\epsilon}(a_i)}\in W_i^{(m)},\quad \delta\mathcal{W}_j|_{C_R}\in W_{\infty}^{(m)}.$$

As a first step toward controlling the $m\to 0$ limit of the solution of the boundary value problem described in Lemma 1 we will now record some elementary estimates for the convergence of $e_n^{(m)}(r,\Theta)$ and $\hat{e}_n^{(m)}(r,\theta)$ to their limits as $m\to 0$. For $l>0$ the Bessel function $I_l(r)$ behaves like a constant times r^l as $r\to 0$. It immediately follows that (for $n\geqslant 1$),

$$\lim_{m\to 0}\alpha_n^{(m)}(mr)=1,\quad \lim_{m\to 0}\beta_n^{(m)}(mr)=0,$$

and hence that

$$\lim_{m\to 0}e_n^{(m)}(r,\Theta)=e_n(\Theta):=\begin{bmatrix}e^{i(n-1/2)\Theta}\\0\end{bmatrix}\quad \text{for } n\geqslant 1.$$

For similar reasons we find that

$$\lim_{m\to 0}\hat{e}_n^{(m)}(r,\theta)=\hat{e}_n(\theta):=\begin{bmatrix}-e^{-in\theta}\\0\end{bmatrix}\quad \text{for } n\geqslant 1,$$

and recalling that $K_n(r)=K_{-n}(r)$ we find

$$\lim_{m\to 0}\hat{e}_n^{(m)}(r,\theta)=\hat{e}_n(\theta):=\begin{bmatrix}0\\e^{-i(n-1)\theta}\end{bmatrix}\quad \text{for } n\geqslant 0.$$

For $l>0$, $I_l(r)$ is an increasing function of r and since $I_l'(r)=-(l/r)I_l(r)+I_{l-1}(r)$ the right-hand side is non-negative and hence

$$\frac{I_l(r)}{I_{l-1}}\leqslant\frac{r}{l}\quad \text{for } l>0. \tag{11}$$

For $n>0$, $K_n(r)$ is a decreasing function of r and since $K_n'(r)=(n/r)K_n(r)-K_{n+1}(r)$ the right-hand side is nonpositive and hence

$$\frac{K_n(r)}{K_{n+1}(r)}\leqslant\frac{r}{n}\quad \text{for } n>0. \tag{12}$$

Now suppose that $0<a<b$, then we have,

$$\frac{a}{\sqrt{a^2+b^2}}\leqslant\frac{a}{b}, \tag{13}$$

and

$$1\geqslant\frac{b}{\sqrt{b^2+a^2}}=\frac{1}{\sqrt{1+(a/b)^2}}\geqslant 1-\frac{1}{2}\left(\frac{a}{b}\right)^2. \tag{14}$$

Using Eqs. (11), (12), (13), and (14), we obtain the following estimates:

$$|\alpha_n^{(m)}(mr)-1| \leqslant \frac{1}{2}\left(\frac{I_{n+1/2}(mr)}{I_{n-1/2}(mr)}\right)^2 \leqslant \frac{1}{2}\left(\frac{mr}{n+1/2}\right)^2 \quad \text{for } n \geqslant 1, \tag{15}$$

$$|\beta_n^{(m)}(mr)| \leqslant \frac{I_{n+1/2}(mr)}{I_{n-1/2}(mr)} \leqslant \frac{mr}{n+1/2} \quad \text{for } n \geqslant 1, \tag{16}$$

and

$$|\alpha_n^{\infty}(mr)+1| \leqslant \frac{1}{2}\left(\frac{K_{n-1}(mr)}{K_n(mr)}\right)^2 \leqslant \frac{1}{2}\left(\frac{mr}{n-1}\right)^2 \quad \text{for } n \geqslant 2, \tag{17}$$

$$|\beta_n^{\infty}(mr)| \leqslant \frac{K_{n-1}(mr)}{K_n(mr)} \leqslant \frac{mr}{n-1} \quad \text{for } n \geqslant 2. \tag{18}$$

For $n \leqslant -1$ we also have

$$|\alpha_n^{\infty}(mr)| \leqslant \frac{K_{|n|}(mr)}{K_{|n|+1}(mr)} \leqslant \frac{mr}{|n|}, \tag{19}$$

and

$$|\beta_n^{\infty}(mr)-1| \leqslant \frac{1}{2}\left(\frac{K_{|n|}(mr)}{K_{|n|+1}(mr)}\right)^2 \leqslant \frac{1}{2}\left(\frac{mr}{|n|}\right)^2. \tag{20}$$

We will use these bounds in Sec. V to estimate the norm of a graph operator for the inversion of a certain projection. The n dependence in these bounds will be of use to us there. Note that estimates (17) and (18) obviously fail for $n=1$. However, the first part of those estimates still holds for $n=1$ and since

$$\frac{K_0(mr)}{K_1(mr)} \xrightarrow{m\to 0} 0,$$

it follows that $|\alpha_1^{\infty}(mr)+1|$ and $|\beta_1^{\infty}(mr)|$ both tend to 0 as $m\to 0$. For the same reason even though (19) and (20) are not valid for $n=0$ we still find that $|\alpha_0^{\infty}(mr)|$ and $|\beta_0^{\infty}(mr)-1|$ both tend to 0 as $m\to 0$.

We write

$$W^{(m)} := W_{\infty}^{(m)} \oplus W_1^{(m)} \oplus \cdots \oplus W_N^{(m)},$$

and $W^{(0)}$ for the $m\to 0$ limit of $W^{(m)}$. The estimates we have just given allow us to calculate the limiting behavior of the basis elements of $W^{(m)}$. This makes it natural to define

$$W_j^{(0)} = \mathrm{span}_{n\geqslant 1}\left\{\begin{bmatrix} e^{i(n-1/2)\Theta_j} \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ e^{-i(n-1/2)\Theta_j} \end{bmatrix}\right\} \oplus C\begin{bmatrix} e^{-i\Theta_j/2} \\ e^{i\Theta_j/2} \end{bmatrix}, \tag{21}$$

for $j=1,\ldots,N$ and

$$W_{\infty}^{(0)} = \mathrm{span}_{n\geqslant 1}\left\{\begin{bmatrix} e^{-in\theta} \\ 0 \end{bmatrix}\right\} \oplus \mathrm{span}_{n\geqslant 1}\left\{\begin{bmatrix} 0 \\ e^{in\theta} \end{bmatrix}\right\}, \tag{22}$$

with

$$W^{(0)} := W_\infty^{(0)} \oplus W_1^{(0)} \oplus W_2^{(0)} \cdots \oplus W_N^{(0)}.$$

To be a little more precise we will write $W^{(0)}$ for the L^2 closure of the span of the basis vectors given previously [recall that $W^{(m)}$ was also a closed subspace of L^2].

We will always regard

$$W_j^{(0)} \subset L^2(\mathcal{E}_{C_\epsilon(a_j)}), \quad W_\infty^{(0)} \subset L^2(\mathcal{E}_{C_R}),$$

so that $W^{(0)} \subset L^2(\mathcal{E}_{\partial\Omega})$. Notice that the basis elements of the subspaces $W_j^{(0)}$ can be regarded as *smooth* sections of $\mathcal{E}_{C_\epsilon(a_j)}$ in the $\mathcal{U}_0$ trivialization. Similarly the basis elements of $W_\infty^{(0)}$ can be regarded as *smooth* sections of $\mathcal{E}_{C_R}$ in the $\mathcal{U}_\infty$ trivialization. We will do this henceforth and it will make a difference for us when we look at the subspaces of $W^{(0)}$ obtained by taking the closure of the span of the same basis elements in the Sobolev spaces $W^{1/2,p}(\mathcal{E}_{\partial\Omega})$.

III. THE $m=0$ GREEN FUNCTION

The Green function we want to understand has the following matrix kernel:

$$G_0(z,z') = -\frac{1}{4\pi i}\begin{bmatrix} \Sigma_j u_j(z)\overline{v_j(z')} & g(z,z') \\ \overline{g(z,z')} & \Sigma_j \overline{u_j(z)} v_j(z') \end{bmatrix}, \tag{23}$$

where

$$u_j(z) := (z-a_j)^{-1/2} \prod_{k\neq j} \frac{(z-a_k)^{1/2}}{(a_j-a_k)^{1/2}}, \tag{24}$$

$$g(z,z') := \sum_{|\epsilon|=0} c(\epsilon) \frac{\Pi_j (z-a_j)^{\epsilon_j} (z'-a_j)^{-\epsilon_j}}{z'-z}, \tag{25}$$

with $\epsilon = (\epsilon_1, \ldots, \epsilon_n)$ and each $\epsilon_j = \pm \frac{1}{2}$. Also

$$|\epsilon| := \sum_{j=1}^{N} \epsilon_j, \quad c(\epsilon) := \frac{\Pi_{j<k} |a_j - a_k|^{2\epsilon_j \epsilon_k}}{\Sigma_{|\epsilon|=0} \Pi_{j<k} |a_j - a_k|^{2\epsilon_j \epsilon_k}}, \tag{26}$$

and

$$v_j(z) = (z-a_j)^{-1/2} \sum_{|\epsilon|=0, \epsilon_j = 1/2} c(\epsilon) \prod_{k\neq j} \frac{(z-a_k)^{\epsilon_k}}{(a_j-a_k)^{\epsilon_k}}. \tag{27}$$

The multivalued functions $(z-a_j)^{\epsilon_j}$ are all defined using the argument Θ_j and are consequently branched along $z \in \mathbf{r}_j$. We regard $G_0(z,z')$ as defining an operator, G_0, acting on sections of $\mathcal{E}_\Omega$ in the following manner:

$$G_0 f(z) := \int_\Omega G_0(z,z') f(z') \mathrm{d}z' \, \mathrm{d}\overline{z'}, \tag{28}$$

where the section $f(z')$ is identified with its $\mathcal{U}_0$ trivialization. We also regard $G_0 f$ as a section of $\mathcal{E}_\Omega$ given in the $\mathcal{U}_0$ trivialization.

When working with $G_0 f(z)$ for $|z| > R$ it is useful to rewrite $v_j(z)$ and $g(z,z')$ in terms appropriate for the $\mathcal{U}_\infty$ trivialization. The conversion from the $\mathcal{U}_0$ to the $\mathcal{U}_\infty$ trivialization is given as follows:

$$\prod_k (z-a_k)^{\epsilon_k} \to \prod_k \left(1-\frac{a_k}{z}\right)^{\epsilon_k} \quad \text{for } |\epsilon|=0 \text{ and } |z|>R,$$

where the fractional powers on the right are holomorphic functions of z normalized to be 1 at $z=\infty$. In a similar fashion,

$$v_j(z) \to z^{-1}\left(1-\frac{a_j}{z}\right)^{-1/2} \sum_{|\epsilon|=0,\epsilon_j=1/2} c(\epsilon) \prod_{k\neq j} \frac{\left(1-\frac{a_k}{z}\right)^{\epsilon_k}}{(a_j-a_k)^{\epsilon_k}} \quad \text{for } |z|>R. \tag{29}$$

Our goal in this section is to show that G_0 inverts $-\not{\partial}$ with $W^{(0)}$ boundary conditions. It is precisely this property that determines our interest in G_0. We will at the same time establish some elementary but useful estimates.

It is helpful to recall some well-known results for the kernel $1/(z'-z)$. Let $f \in C^1(\overline{\Omega})$ (the continuously differentiable functions on Ω which are continuous together with their derivative on the closure of Ω) and define

$$Tf(z) := \frac{1}{2\pi i} \int_\Omega \frac{f(z')}{z'-z} \mathrm{d}z' \, \mathrm{d}\overline{z'}. \tag{30}$$

Then

Theorem 2: *The distribution derivative of Tf is*

$$\mathrm{d}T\, f = T(\partial_z f)\mathrm{d}z + f\, \mathrm{d}\overline{z}. \tag{31}$$

For $p>2$ one has the estimate,

$$\|Tf\|_{W^{1,p}(\Omega)} \leqslant C_p \|f\|_{W^{1,p}(\Omega)}, \tag{32}$$

for a constant C_p that depends only on p and Ω, and $W^{k,p}(\Omega)$ is the subspace of $L^p(\Omega)$ which consists of functions whose first k weak derivatives are in $L^p(\Omega)$.

Proof: Suppose $f \in C^1(\overline{\Omega})$ and $\phi \in C_0^\infty(\Omega)$. To compute the distribution derivative $\partial_z Tf(z)$ we wish to ''integrate by parts'' in

$$-\int_\Omega Tf(z)\partial_z \phi(z) \mathrm{d}z \, \mathrm{d}\overline{z}.$$

To stay away from the singularity in the kernel we introduce

$$T_\epsilon f(z) := \frac{1}{2\pi i} \int_{\Omega \setminus D_\epsilon(z)} \frac{f(z')}{z'-z} \mathrm{d}z' \, \mathrm{d}\overline{z'},$$

where $D_\epsilon(z)=\{z' : |z'-z|<\epsilon\}$. Also suppose for simplicity that ϵ is chosen small enough so that the distance from the support of ϕ to the boundary of Ω is greater than ϵ. For ϵ this small it follows that for all z in the support of ϕ the set of z' with $|z-z'|=\epsilon$ is completely contained in Ω.

In order to do the ''integration by parts'' efficiently we calculate the exterior derivative of a particular three form on the domain $\Omega \times \Omega \setminus \{z=z'\}$,

$$\mathrm{d}\left(\frac{f(z')\phi(z)-f(z)\phi(z')}{z'-z}\right)\mathrm{d}\overline{z}\,\mathrm{d}z'\,\mathrm{d}\overline{z'}$$
$$=\left(\frac{f(z')\partial\phi(z)-\partial f(z)\phi(z')}{z'-z}+\frac{f(z')\phi(z)-f(z)\phi(z')}{(z'-z)^2}\right)\mathrm{d}z\,\mathrm{d}\overline{z}\,\mathrm{d}z'\,\mathrm{d}\overline{z'}.$$

Now integrate this last identity over

$$(\Omega\times\Omega)_\epsilon:=\Omega\times\Omega\backslash\{(z,z'):|z'-z|<\epsilon\},$$

and use Stokes' theorem. Then make use of

$$\int_{(\Omega\times\Omega)_\epsilon}\frac{f(z')\phi(z)-f(z)\phi(z')}{(z'-z)^2}\mathrm{d}z\,\mathrm{d}\overline{z}\,\mathrm{d}z'\,\mathrm{d}\overline{z'}=0,$$

which follows from the fact that the integrand is odd under the transformation $(z,z')\to(z',z)$ and the domain $(\Omega\times\Omega)_\epsilon$ is invariant under this map. After multiplication by $1/2\pi i$ the resulting identity simplifies directly to,

$$-\int_\Omega T_\epsilon f(z)\partial_z\phi(z)\mathrm{d}z\,\mathrm{d}\overline{z}=\int_\Omega T_\epsilon(\partial f)(z)\phi(z)\mathrm{d}z\,\mathrm{d}\overline{z}$$
$$+\frac{1}{2\pi i}\int_\Omega \mathrm{d}z'\,\mathrm{d}\overline{z'}\int_{|z-z'|=\epsilon}\frac{f(z')\phi(z)-f(z)\phi(z')}{z'-z}\mathrm{d}\overline{z}.$$

Since both f and ϕ are $C^1(\Omega)$ it is easy to see that the second term on the right-hand side of this last equation tends to 0 in the limit $\epsilon\to0$. Because $1/(z'-z)$ is in $L^1_{\mathrm{loc}}(\mathbf{C}^2)$ it follows that $T_\epsilon f\to Tf$ in the sense of distributions as $\epsilon\to0$. Hence,

$$\partial Tf=T\partial f,$$

which is the first part of (31). To obtain the second part consider the exterior derivative,

$$\mathrm{d}\left(\frac{f(z')\phi(z)}{z'-z}\right)\mathrm{d}z\,\mathrm{d}z'\,\mathrm{d}\overline{z'}=-\overline{\partial}_z\left(\frac{f(z')\phi(z)}{z'-z}\right)\mathrm{d}z\,\mathrm{d}\overline{z}\,\mathrm{d}z'\,\mathrm{d}\overline{z'}=-\left(\frac{f(z')\overline{\partial}\phi(z)}{z'-z}\right)\mathrm{d}z\,\mathrm{d}\overline{z}\,\mathrm{d}z'\mathrm{d}\overline{z'}.$$

Integrate this over $(\Omega\times\Omega)_\epsilon$ and multiply the result by $1/2\pi i$. Using Stokes' theorem again, one finds that

$$-\int_\Omega T_\epsilon f(z)\overline{\partial}\phi(z)\mathrm{d}z\,\mathrm{d}\overline{z}=-\frac{1}{2\pi i}\int_\Omega \mathrm{d}z'\,\mathrm{d}\overline{z'}\int_{|z-z'|=\epsilon}\frac{f(z')\phi(z)}{z'-z}\mathrm{d}z.$$

As $\epsilon\to0$ the right-hand side tends to

$$\int_\Omega \mathrm{d}z'\,\mathrm{d}\overline{z'}\,f(z')\phi(z').$$

Hence,

$$\overline{\partial}Tf=f,$$

which is the second part of (31).

To prove the second part of the theorem we first observe that since Ω is a bounded domain it is straightforward to show that T defines a bounded operator on $L^p(\Omega)$ for $p>2$. Hölder's inequality implies that

$$\left| \int_\Omega \frac{f(z')}{z'-z} i\, dz'\, d\overline{z'} \right| \leqslant \|f\|_{L^p(\Omega)} \left(\int_\Omega |z'-z|^{-q} i\, dz'\, d\overline{z'} \right)^{1/q},$$

where $1/p+1/q=1$. However since $p>2$ it follows that $1<q<2$ and hence that

$$z \to \int_\Omega |z'-z|^{-q} i dz'\, d\overline{z'}$$

is a bounded function on Ω. It follows at once that T is bounded on $L^p(\Omega)$ since Ω is a finite domain and bounded functions are in $L^p(\Omega)$ [note: the analogue of T on $\Omega=\mathbf{C}$ is also bounded on $L^p(\mathbf{C})$ for $p>2$ (see Ref. 16)].

To see that it defines a bounded operator on $W^{1,p}(\Omega)$ for $p>2$ it is enough to use (31), which implies that for $f \in C^1(\overline{\Omega})$,

$$\|dT\, f\|_{D^p(\Omega)} \leqslant \|T\partial f\|_{L^p(\Omega)} + \|f\|_{L^p(\Omega)} \leqslant C\|f\|_{W^{1,p}(\Omega)} \quad \text{for } p>2,$$

where we used the fact that T is bounded on L^p $(p>2)$. Since the boundary of Ω is smooth, $C^1(\overline{\Omega})$ is dense in $W^{1,p}(\Omega)$, and the second part of the theorem is proved. QED

We will now use theorem 2 to establish that G_0 is a Green function for $-\not\partial$ on $W^{1,p}(\mathcal{E}_\Omega)$ for $p>2$. Incidentally, we work in the space $W^{1,p}(\mathcal{E}_\Omega)$ only in order to simplify some boundary estimates by using the Sobolev trace theorems; we could work in $L^p(\mathcal{E}_\Omega)$ at the cost of using more complicated global ellipticity estimates (see Ref. 17).

Theorem 3: *Suppose $p>2$ and suppose that $f \in W^{1,p}(\mathcal{E}_\Omega)$ and that f is compactly supported in Ω. Then $G_0 f \in W^{1,p}(\mathcal{E}_\Omega)$ and*

(1) $\|G_0 f\|_{W^{1,p}} \leqslant C_p \|f\|_{W^{1,p}}$,
(2) $-\not\partial G_0 f = f$,
(3) $G_0 f|_{\partial\Omega} \in W^{(0)}$.

Proof: Let $z_j^\epsilon = (z-a_j)^\epsilon$ be defined using the argument Θ_j so that these functions are branched along $\mathbf{r}_j$. For any choice $\boldsymbol{\epsilon}_j = \pm 1/2$ the function,

$$\mathbf{z}^{\boldsymbol{\epsilon}} := \prod_{j=1}^{N} z_j^{\boldsymbol{\epsilon}_j},$$

defines a map,

$$C^\infty(\mathcal{E}_\Omega) \ni f(z) \to \mathbf{z}^{\boldsymbol{\epsilon}} f(z) \in C^\infty(\Omega),$$

which has an inverse,

$$C^\infty(\Omega) \ni f(z) \to \mathbf{z}^{-\boldsymbol{\epsilon}} f(z) \in C^\infty(\mathcal{E}_\Omega),$$

where in each case sections of $C^\infty(\mathcal{E}_\Omega)$ are identified with their $\mathcal{U}_0$ trivializations. Since the derivatives of $\mathbf{z}^{\pm\boldsymbol{\epsilon}}$ are bounded on Ω it follows that these maps induce bounded maps,

$$W^{1,p}(\mathcal{E}_\Omega) \ni f(z) \to \mathbf{z}^{\boldsymbol{\epsilon}} f(z) \in W^{1,p}(\Omega)$$

and

$$W_{1,p}(\Omega) \ni f(z) \to \mathbf{z}^{-\boldsymbol{\epsilon}} f(z) \in W^{1,p}(\mathcal{E}_\Omega).$$

The upper right matrix element of the kernel $G_0(z',z)$ is a linear combination of terms,

$$\frac{\mathbf{z}^{\epsilon}(\mathbf{z}')^{-\epsilon}}{z'-z},$$

each of which is the kernel of an operator we can interpret as a composition,

$$W^{1,p}(\mathcal{E}_\Omega) \xrightarrow{\mathbf{z}^{-\epsilon}} W^{1,p}(\Omega)^{1/(z'-z)} W^{1,p}(\Omega) \xrightarrow{\mathbf{z}^{\epsilon}} W^{1,p}(\mathcal{E}_\Omega),$$

which is bounded for $p>2$ as a consequence of Theorem 2. To be more precise we note that it is the *line bundle* $\mathcal{E}_\Omega$ which appears in this composition. The same argument for $\overline{\mathbf{z}}^{\pm c}$ and $1/(\overline{z'}-\overline{z})$ coupled with the complex conjugate version of Theorem 2 shows that the lower left kernel in $G_0(z,z')$ determines a bounded linear transformation on $W^{1,p}(\mathcal{E}_\Omega)$. The diagonal elements of $G_0(z,z')$ are finite rank L^2 kernels with a range that consists of smooth sections of $\mathcal{E}_\Omega$. Consequently, they determine bounded operators on $W^{1,p}(\mathcal{E}_\Omega)$ as well and this finishes the proof of part (1) of the theorem.

The proof of part (2) of the theorem is a straightforward computation using (1) of Theorem 2 (and its complex conjugate), the fact that $\overline{\partial}_z \mathbf{z}^{\epsilon}=0$, $\partial \overline{\mathbf{z}}^{\epsilon}=0$, $\overline{\partial}_z u_j(z)=0$, $\partial_z \overline{u}_j(z)=0$, and finally,

$$\sum_{|\epsilon|=0} c(\epsilon)=1.$$

Note that both $\overline{\partial}$ and ∂ act on $C^\infty(\mathcal{E}_\Omega)$ since the transition functions that define the bundle are piecewise constant.

To establish part (3) of the theorem it is useful to observe that the subspace $W_j^{(0)}$ consists of L^2 boundary values on $C_\epsilon(a_j)$, of functions,

$$\begin{bmatrix} z_j^{1/2} h_1(z) \\ z_j^{1/2} \overline{h_2}(z) \end{bmatrix} + c_0 \begin{bmatrix} z_j^{-1/2} \\ \overline{z_j}^{1/2} \end{bmatrix},$$

where h_1 and h_2 are holomorphic functions on the disk $D_\epsilon(a_j)$ and c_0 is a complex constant (technically, h_1 and h_2 should be in the appropriate Hardy space). We wish to show that

$$\int_\Omega G_0(z,z') f(z') \mathrm{d}z' \, \mathrm{d}\overline{z'},$$

restricted to $z \in C_\epsilon(a_j)$, lies in $W_j^{(0)}$. Because we have assumed that the support of f is contained inside Ω it follows that for z' in the support of f we have $|z'-a_j|>|z-a_j|$ and so

$$\frac{1}{z'-z} = \frac{1}{z_j'-z_j} = \sum_{n=0}^{\infty} \frac{1}{z_j'} \left(\frac{z_j}{z_j'} \right)^n$$

will converge uniformly for $z \in D_\epsilon(a_j)$ and z' in the support of f. Substituting this expansion in the formula for $G_0 f(z)$ (and the analogue obtained by taking complex conjugates) one sees easily that the boundary value of $G_0 f(z)$ has the form,

$$\begin{bmatrix} z_j^{-1/2} h_1(z) \\ \overline{z_j}^{-1/2} \overline{h_2}(z) \end{bmatrix},$$

where h_1 and h_2 are holomorphic in $D_\epsilon(a_j)$. The only issue is whether the coefficient of $z_j^{-1/2}$ in the first component is the same as the coefficient of $\overline{z_j}^{-1/2}$ in the second component. A computation shows that the coefficient of $z_j^{-1/2}$ in the Fourier expansion on $C_\epsilon(a_j)$ of the first component of $G_0 f$ is

$$-\frac{1}{4\pi i}\int_\Omega dz'\,d\overline{z}'\left\{\overline{v_j}(z')f_1(z')+\sum_{|\epsilon|=0,\epsilon_j=1/2}c(\epsilon)z_j'^{-1/2}\prod_{k\neq j}\frac{(z'-a_k)^{\epsilon_k}}{(a_j-a_k)^{\epsilon_k}}f_2(z')\right\},$$

where we used the fact that

$$\sum_{|\epsilon|=0,\epsilon_j=-1/2}S(\epsilon)=\sum_{|\epsilon|=0,\epsilon_j=1/2}S(-\epsilon).$$

Computing the coefficient of $\overline{z}_j^{-1/2}$ in the Fourier expansion of the second component of G_0f we find

$$-\frac{1}{4\pi i}\int_\Omega dz'\,d\overline{z}'\left\{v_j(z')f_2(z')+\sum_{|\epsilon|=0,\epsilon_j=1/2}c(\epsilon)\overline{z}_j'^{-1/2}\prod_{k\neq j}\frac{\overline{(z'-a_k)^{\epsilon_k}}}{\overline{(a_j-a_k)^{\epsilon_k}}}f_1(z')\right\}.$$

Comparing these two coefficients using the definition of $v_j(z)$ we see that they are the same. Thus $G_0f|_{C_\epsilon(a_j)}\in W_j^{(0)}$.

To finish the proof we need to show that

$$G_0f|_{C_R}\in W_\infty^{(0)}.$$

Recalling the definition of $W_\infty^{(0)}$ we see that it consists of boundary values on C_R of functions,

$$\begin{bmatrix}h_1(z)\\ \overline{h_2}(z)\end{bmatrix},$$

where $h_1(z)$ and $h_2(z)$ are holomorphic functions on D_∞ which vanish at $z=\infty$. The condition $|\epsilon|=0$ in the sum that defines $g(z,z')$ makes it easy to see that

$$\int_\Omega g(z,z')f_2(z')dz'\,d\overline{z}'$$

is holomorphic for $z\in D_\infty$ and tends to 0 at ∞. For precisely the same reason,

$$\int_\Omega \overline{g(z,z')}f_1(z')dz'\,d\overline{z}'$$

is antiholomorphic in D_∞ and vanishes at ∞. The diagonal contributions,

$$-\frac{1}{4\pi i}\int_\Omega\sum_j u_j(z)\overline{v_j}(z')f_1(z')dz'\,d\overline{z}',$$

and

$$-\frac{1}{4\pi i}\int_\Omega\sum_j \overline{u_j}(z)v_j(z')f_2(z')dz'\,d\overline{z}',$$

do not at first appear to vanish at infinity since $u_j(z)$ does not tend to 0 at ∞. However in the lemma which follows this theorem we will prove the homogeneous function identity,

$$\sum_j u_j(z)\overline{v_j}(z')=\sum_j v_j(z)\overline{u_j}(z'). \tag{33}$$

Since $v_j(z)$ is holomorphic for $|z|>R$ and does tend to 0 at ∞ [see (29)] this identity finishes the proof of the theorem. Q.E.D.

We turn to the proof of the identity (33).

Lemma 2: The following identity is true for the functions u_j and v_j defined in (24) *and* (27),

$$\sum_j u_j(z)\overline{v_j}(z')=\sum_j v_j(z)\overline{u_j}(z').$$

Proof: Suppose that $v(z)$ is a holomorphic function branched along the rays $\mathbf{r}_j$ such that

$$V(z)=v(z)\prod_k z_k^{-1/2}$$

is holomorphic in the punctured plane, $\mathbf{C}\backslash\mathbf{a}$, with simple poles at each a_j and which tends to 0 as $z\to\infty$ (this will be the case for each of the functions v_j). Then $V(z)$ has the partial fraction decomposition,

$$V(z)=\sum_k \frac{V_k}{z-a_k},$$

where $V_k=\mathrm{Res}_{z=a_k}V(z)$. Rewriting this in terms of $v(z)$ one finds

$$v(z)=\sum_k V_k z_k^{-1/2}\prod_{l\neq k} z_l^{1/2}=\sum_k V_k\prod_{l\neq k}(a_k-a_l)^{1/2}u_k(z).$$

Thus we have,

$$v_j(z)=\sum_k v_{kj}u_k(z),$$

where the coefficients v_{kj} are found by residue calculation to be

$$v_{jj}=\sum_{|\epsilon|=0,\epsilon_j=1/2} c(\epsilon),$$

and for $k\neq j$,

$$v_{kj}=\frac{(a_k-a_j)^{1/2}}{(a_j-a_k)^{1/2}}\sum_{\substack{|\epsilon|=0\\ \epsilon_j=1/2,\epsilon_k=-1/2}} c(\epsilon)\prod_{l\neq j,k}\frac{(a_k-a_l)^{\epsilon_l}}{(a_j-a_l)^{\epsilon_l}}. \tag{34}$$

We will now show that $v_{kj}=\overline{v_{jk}}$, which will have (33) as a simple consequence. Since v_{jj} is real it is clear that $v_{jj}=\overline{v_{jj}}$. Now suppose that $k\neq j$ and note that

$$\frac{(a_k-a_j)^{1/2}}{(a_j-a_k)^{1/2}}=\frac{\overline{(a_j-a_k)^{1/2}}}{\overline{(a_k-a_j)^{1/2}}},$$

since cross multiplication produces the identity

$$|a_k-a_j|=|a_j-a_k|.$$

Thus the first factor in (34) is Hermitian symmetric and it remains only to check that the second factor is also. First we rewrite $c(\epsilon)$ for $\epsilon_j=\frac{1}{2}$ and $\epsilon_k=-\frac{1}{2}$ in the following manner:

$$c(\epsilon)_{\epsilon_k=-1/2}^{\epsilon_j=1/2}=\frac{|a_j-a_k|^{-1/2}}{\mathbf{c}}\prod_{\substack{\alpha<\beta\\ \alpha,\beta\notin\{j,k\}}}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta}\prod_{l\neq j,k}\frac{|a_j-a_l|^{\epsilon_l}}{|a_k-a_l|^{\epsilon_l}},$$

where $\mathbf{c}:=\sum_{\alpha<\beta}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta}$. Now define,

$$s_{kj}(\epsilon)=\frac{|a_j-a_k|^{-1/2}}{\mathbf{c}}\prod_{\substack{\alpha<\beta\\ \alpha,\beta\notin\{j,k\}}}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta}.$$

The second factor in (34) becomes

$$\sum_{\substack{|\epsilon|=0\\ \epsilon_j=1/2,\epsilon_k=-1/2}} s_{kj}(\epsilon)\prod_{l\neq j,k}\frac{|a_j-a_l|^{\epsilon_l}(a_k-a_l)^{\epsilon_l}}{|a_k-a_l|^{\epsilon_l}(a_j-a_l)^{\epsilon_l}}.$$

Since $s_{kj}(\epsilon)$ is real and obviously equal to $s_{jk}(\epsilon)$ this last expression will be Hermitian symmetric provided that

$$\prod_{l\neq j,k}\frac{|a_j-a_l|^{\epsilon_l}}{|a_k-a_l|^{\epsilon_l}}\frac{(a_k-a_l)^{\epsilon_l}}{(a_j-a_l)^{\epsilon_l}}=\prod_{l\neq j,k}\frac{|a_k-a_l|^{\epsilon_l}}{|a_j-a_l|^{\epsilon_l}}\frac{\overline{(a_j-a_l)^{\epsilon_l}}}{\overline{(a_k-a_l)^{\epsilon_l}}}.$$

But this follows directly from cross multiplication as before. We have shown that $v_{kj}=\overline{v}_{jk}$ and the following simple calculation now proves the identity (33):

$$\sum_j u_j(z)\overline{v}_j(z')=\sum_{j,k}u_j(z)\overline{v}_{kj}\overline{u}_k(z')=\sum_{j,k}v_{jk}u_j(z)\overline{u}_k(z')=\sum_k v_k(z)\overline{u}_k(z').$$

Q.E.D.

IV. THE PROJECTION ON $W^{(0)}$

In this section we will introduce the projection P_0 from $L^2(\mathcal{E}_{\partial\Omega})$ onto $W^{(0)}$ which is naturally associated with the Green function G_0. Another goal is a description of the complementary subspace for P_0 acting on $H^{1/2}(\mathcal{E}_{\partial\Omega})$. We will show that the complementary projection $I-P_0$ projects $H^{1/2}(\mathcal{E}_{\partial\Omega})$ onto the boundary values of sections $\Psi\in H^1(\mathcal{E}_\Omega)$ which are solutions to the Dirac equation, $\not{\partial}\Psi=0$ in Ω.

It is useful to start with a calculation. Write

$$G_0(z,z')=\begin{bmatrix}G_{11}(z,z') & G_{12}(z,z')\\ G_{21}(z,z') & G_{22}(z,z')\end{bmatrix},$$

for the matrix elements of G_0.

Now suppose that $f\in C^1(\mathcal{E}_{\overline{\Omega}})$ and choose $z\in\mathbf{C}\backslash\overline{\Omega}$. Then,

$$\begin{aligned}-G_0(\not{\partial}f)(z)&=-2\int_\Omega\begin{bmatrix}G_{11}(z,z')\partial_{z'}f_2(z')+G_{12}(z,z')\overline{\partial}_{z'}f_1(z')\\ G_{21}(z,z')\partial_{z'}f_2(z')+G_{22}(z,z')\overline{\partial}_{z'}f_1(z')\end{bmatrix}\mathrm{d}z'\,\mathrm{d}\overline{z}'\\ &=-2\int_\Omega d_{z'}\begin{bmatrix}G_{11}(z,z')f_2(z')\mathrm{d}\overline{z}'-G_{12}(z,z')f_1(z')\mathrm{d}z'\\ G_{21}(z,z')f_2(z')\mathrm{d}\overline{z}'-G_{22}(z,z')f_1(z')\mathrm{d}z'\end{bmatrix},\end{aligned}$$

which Stokes' theorem transforms into

$$-G_0(\not{\partial}f)(z)=-2\int_{\partial\Omega}\begin{bmatrix}G_{11}(z,z')f_2(z')\mathrm{d}\overline{z}'-G_{12}(z,z')f_1(z')\mathrm{d}z'\\ G_{21}(z,z')f_2(z')\mathrm{d}\overline{z}'-G_{22}(z,z')f_1(z')\mathrm{d}z'\end{bmatrix}.$$

The first equality follows from the fact that $G_{k2}(z,z')$ is holomorphic for $z' \in \Omega$ and $G_{k1}(z,z')$ is antiholomorphic in $z' \in \Omega$ (remember z is outside of Ω). Of course, this is not precisely accurate since these functions are branched along the rays $\mathbf{r}_j$. However, it is not hard to argue that the application of Stokes' theorem is still correct using the fact that $G_{k2}(z,z')f_1(z')$ and $G_{k1}(z,z')f_2(z')$ are continuous for z' on the rays $\mathbf{r}_j$. Also note that the orientation of $\partial\Omega$ appropriate for this Stokes' calculation is that C_R has the usual counterclockwise orientation and the circles $C_\epsilon(a_j)$ are all *clockwise oriented*. With this as our motivation, we define, for $f \in L^2(\mathcal{E}_{\partial\Omega})$,

$$P_0 f(z) := -2\int_{\partial\Omega}\begin{bmatrix} G_{11}(z,z')f_2(z')d\overline{z}' - G_{12}(z,z')f_1(z')dz' \\ G_{21}(z,z')f_2(z')d\overline{z}' - G_{22}(z,z')f_1(z')dz' \end{bmatrix}, \tag{35}$$

where we understand this as a section of $\mathcal{E}_{\partial\Omega}$ by letting $z \to \partial\Omega$ from outside of Ω. As usual sections of $\mathcal{E}$ are identified with their $\mathcal{U}_0$ or $\mathcal{U}_\infty$ trivializations. If $-\partial f$ is compactly supported in Ω we saw in the last section that the restriction of $-G_0\partial f$ to $\partial\Omega$ is in $W^{(0)}$. Thus (35) suggests that if $f|_{\partial\Omega} \in W^{(0)}$, we should have $P_0 f = f$. Our first result in this section is,

Theorem 4: *The map P_0 defined by* (35) *is a projection from $L^2(\mathcal{E}_{\partial\Omega})$ onto $W^{(0)}$. P_0 restricts to a continuous map,*

$$P_0 : H^{1/2}(\mathcal{E}_{\partial\Omega}) \to H^{1/2}(\mathcal{E}_{\partial\Omega}).$$

Proof: We will show that P_0 maps $L^2(\mathcal{E}_{\partial\Omega})$ into $W^{(0)}$. Observe first that the functions, f, in $L^2(\mathcal{E}_{C_\epsilon(a_j)})$, which are restrictions to $z \in C_\epsilon(a_j)$ of the type

$$f(z) = \sum_{n=-L}^{L}\begin{bmatrix} f_{1n} z_j^{n+1/2} \\ f_{2n}\overline{z}_j^{n+1/2} \end{bmatrix}, \tag{36}$$

for L finite, are dense in $L^2(\mathcal{E}_{C_\epsilon(a_j)})$, and have extensions to $\mathbf{C}\backslash\mathbf{r}_j$ which are solutions to $\partial f = 0$. If φ is a C_0^∞ function which is 1 for $|z| \leqslant 1.5\epsilon$ and 0 for $|z| > 2\epsilon$ and f is a function of type (36) then it is easy to see that $\varphi_j f(z) := \varphi(z_j) f(z)$ is a section of $\mathcal{E}_\Omega$ and $\partial(\varphi_j f)$ is compactly supported inside Ω. For such a function the calculation that we began this section with shows that

$$-G_0\partial(\varphi_j f)|_{\partial\Omega} = P_0 f,$$

and it follows from Theorem 3 that $P_0 f \in W^{(0)}$. The first part of the theorem now follows from the fact that $W^{(0)}$ is closed in $L^2(\mathcal{E}_{\partial\Omega})$ and P_0 is continuous on L^2. We won't bother to give the proof that P_0 is continuous on L^2 since the argument we now present to show that P_0 is continuous on $H^{1/2}(\mathcal{E}_{\partial\Omega})$ adapts directly to show L^2 continuity.

Observe first that the finite rank part of P_0 associated with the kernels G_{11} and G_{22} has a range which is a subset of $C^\infty(\mathcal{E}_{\partial\Omega}) \subset H^{1/2}(\mathcal{E}_{\partial\Omega})$ and is clearly continuous in L^2 and hence also in $H^{1/2}$. Next consider the part of P_0 associated with G_{12}. The component of this operator which maps $H^{1/2}(\mathcal{E}_{C_\epsilon(a_j)})$ into $H^{1/2}(\mathcal{E}_{C_\epsilon(a_k)})$ can be written as a sum of operators each of which has a factorization of the following sort:

$$H^{1/2}(\mathcal{E}_{C_\epsilon(a_j)}) \xrightarrow{z_j^{1/2}} H^{1/2}(C_\epsilon(a_j)) \xrightarrow{\phi(z)} H^{1/2}(C_\epsilon(a_j))$$

$$\xrightarrow{1/(z'-z)} H^{1/2}(C_\epsilon(a_k)) \xrightarrow{\psi(z)} H^{1/2}(C_\epsilon(a_k)) \xrightarrow{z_k^{1/2}} H^{1/2}(\mathcal{E}_{C_\epsilon(a_k)})),$$

where the first, second, fourth, and fifth maps are multiplication operators and the third map is

$$f(z)\to\frac{1}{2\pi i}\int_{C_\epsilon(a_j)}\frac{f(z')}{z'-z}\,dz', \tag{37}$$

which must be interpreted as a suitable boundary value when $j=k$. In this factorization $\phi(z)$ and $\psi(z)$ are smooth functions and hence determine bounded maps on $H^{1/2}$. The Cauchy projection (37) is easily seen to be continuous from $H^{1/2}(C_\epsilon(a_j))$ to $H^{1/2}(C_\epsilon(a_k))$ even when $j=k$. Nothing changes if C_R is one or both of the two components of $\partial\Omega$ that are involved and it follows that the part of P_0 associated with G_{12} is bounded on $H^{1/2}(\mathcal{E}_{\partial\Omega})$. The kernel G_{21} is just the complex conjugate of G_{12} and so it too defines a bounded operator on $H^{1/2}(\mathcal{E}_{\partial\Omega})$. This completes the proof that P_0 is continuous on $H^{1/2}(\mathcal{E}_{\partial\Omega})$.

To finish the proof of the theorem we need to show that if $f\in W^{(0)}$ then $P_0 f=f$. Clearly it is enough to show this for the basis elements (21) and (22). For the calculation on $W_j^{(0)}$ it is preferable to use the alternate forms for G_{11} and G_{22} found in Lemma 2. Thus (35) becomes

$$P_0 f(z)=\frac{1}{2\pi i}\int_{\partial\Omega}\left[\begin{array}{c}\Sigma_k\, v_k(z)\overline{u_k}(z')f_2(z')d\overline{z'}-g(z,z')f_1(z')dz' \\ g(z,z')f_2(z')d\overline{z'}-\Sigma_k\overline{v_k}(z)u_k(z')f_1(z')dz'\end{array}\right]. \tag{38}$$

The following residue calculations suffice to evaluate P_0 on the basis elements of $W_j^{(0)}$ [note that in these results $C_\epsilon(a_j)$ is counterclockwise oriented, as usual],

$$\frac{1}{2\pi i}\int_{C_\epsilon(a_j)}u_k(z)z_j^{n-1/2}dz=\delta_{jk}\delta_{n0}\quad\text{for } n=0,1,2,\ldots.$$

And for $n=0,1,2,\ldots$,

$$\frac{1}{2\pi i}\int_{C_\epsilon(a_j)}\sum_{|\epsilon|=0}c(\epsilon)\frac{\Pi_k z_k^{\epsilon_k}(z_k')^{-\epsilon_k}}{z'-z}(z')^{n-1/2}dz'=\begin{cases}z_j^{n-1/2}-\delta_{n0}v_j(z) & \text{for } z\in C_\epsilon(a_j)\\ -\delta_{n0}v_j(z) & \text{for } z\in\partial\Omega\backslash C_\epsilon(a_j).\end{cases}$$

One finds [being careful to recall the orientation of the $C_\epsilon(a_j)$ component of $\partial\Omega$ is clockwise] that P_0 fixes the elements of the basis for $W_j^{(0)}$. The reader might find the cancellation of the $v_j(z)$ terms that appear in the calculation of the action of P_0 on $\left[\begin{smallmatrix}z_j^{-1/2}\\ z_j^{-1/2}\end{smallmatrix}\right]$ instructive.

To compute the action of P_0 on the basis elements for $W_\infty^{(0)}$ the original form for the kernel of the Green function G_0 is preferable and one can do the needed calculation with the following residues:

$$\frac{1}{2\pi i}\int_{C_R}v_k(z)z^{-n}\,dz=0\quad\text{for } n=1,2,3,\ldots,$$

which follows from the fact that $v_k(z)$ is holomorphic in the exterior of C_R and vanishes at ∞ in the $\mathcal{U}_\infty$ trivialization. And for $n=1,2,3,\ldots$,

$$\frac{1}{2\pi i}\int_{C_R}\sum_{|\epsilon|=0}c(\epsilon)\frac{\Pi_k z_k^{\epsilon_k}(z_k')^{-\epsilon_k}}{z'-z}(z')^{-n}\,dz'=\begin{cases}z^{-n} & \text{for } z\in C_R\\ 0 & \text{for } z\in\partial\Omega\backslash C_R.\end{cases}$$

Again one finds that P_0 fixes the basis (22) and this finishes the proof of the theorem. Q.E.D.

Next we turn to a characterization of the complementary projection $I-P_0$.

Theorem 5: *The projection $I-P_0$ maps $H^{1/2}(\mathcal{E}_{\partial\Omega})$ into the subspace of $H^{1/2}(\mathcal{E}_{\partial\Omega})$ which consists of boundary values of functions $\Psi\in H^1(\mathcal{E}_\Omega)$ which satisfy the Dirac equation*

$$\not{\partial}\Psi=0$$

in Ω. *Furthermore, there exists a constant C so that for all* $f \in H^{1/2}(\mathcal{E}_{\partial\Omega})$ *we have*

$$\|(I-P_0)f\|_{H^1(\mathcal{E}_\Omega)} \leqslant C\|f\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})}. \tag{39}$$

Proof: Using (38) and the well-known identity,

$$(z'-z_{\text{int}})^{-1}-(z'-z_{\text{ext}})^{-1}=2\pi i\,\delta(z'-z),$$

for the difference of the interior and exterior boundary values of the Cauchy kernel on a circle we find the following formula for $P_0^c := I-P_0$,

$$P_0^c f(z) = -\frac{1}{2\pi i}\int_{\partial\Omega}\left[\frac{\Sigma_k v_k(z)\tilde{u}_k(z')f_2(z')\mathrm{d}\overline{z'}-g(z,z')f_1(z')\mathrm{d}z'}{g(z,z')f_2(z')\mathrm{d}\overline{z'}-\Sigma_k\ \overline{v_k}(z)u_k(z')f_1(z')\mathrm{d}z'}\right], \tag{40}$$

with the difference compared to (38) being that in this formula z tends to $\partial\Omega$ from the interior of Ω. It is clear from this formula that $(I-P_0)f(z)$ extends to a section of $\mathcal{E}_\Omega$ which is in the null space of $\not{\partial}$. We need only establish the estimate (39) to finish the proof. The finite rank operator,

$$f \to \frac{1}{2\pi i}\int_{\partial\Omega}\sum_k\ v_k(z)\overline{u_k}(zx')f(z')\mathrm{d}\overline{z'},$$

is obviously continuous on $H^{1/2}(\mathcal{E}_{\partial\Omega})$ since each u_k is in L^2 and the functions $v_k \in C^\infty(\mathcal{E}_\Omega)\subset H^1(\mathcal{E}_\Omega)$. The other finite rank operator that occurs in (40) is continuous from $H^{1/2}(\mathcal{E}_{\partial\Omega})$ into $H^1(\mathcal{E}_\Omega)$ for the same reason. Next we turn to the operator,

$$f \to \frac{1}{2\pi i}\int_{\partial\Omega} g(z,z')f(z')\mathrm{d}z'.$$

This operator is a linear combination of operators each of which we wish to interpret as a composition,

$$H^{1/2}(\mathcal{E}_{\partial\Omega}) \xrightarrow{\mathbf{z}^{-\epsilon}} H^{1/2}(\partial\Omega) \xrightarrow{1/(z'-z)} H^1(\Omega) \xrightarrow{\mathbf{z}^{\epsilon}} H^1(\mathcal{E}_\Omega).$$

The first and third maps are multiplication operators which are obviously continuous. The middle map is shorthand for the operator,

$$f \to \frac{1}{2\pi i}\int_{\partial\Omega}\frac{f(z')}{z'-z}\mathrm{d}z',$$

which is well known to be continuous from $H^{1/2}(\partial\Omega)$ to $H^1(\Omega)$. For the reader's convenience we recall a simple argument for this continuity.

Write $z_j = z-a_j$ and consider a function, f, defined on $\partial\Omega$ by

$$f(z)=\begin{cases}\Sigma_{n=-L}^{L} f_n z_j^n & \text{for } z\in C_c(a_j)\\ 0 & \text{for } z\in\partial\Omega\backslash C_\epsilon(a_j)\end{cases}. \tag{41}$$

Define $P_{\text{int}}f(z)$ for z in Ω by

$$P_{\text{int}}f(z)=\frac{1}{2\pi i}\int_\Omega\frac{f(z')}{z'-z}\mathrm{d}z'.$$

Then

$$P_{\text{int}}f(z)=\sum_{n=-L}^{-1} f_n z_j^n .$$

Since Ω is bounded the Poincaré inequality[18] implies that the $H^1(\Omega)$ norm of $P_{\text{int}}f$ is bounded by the $L^2(\Omega)$ norm of

$$\partial P_{\text{int}}f(z)=\sum_{n=-L}^{-1} n f_n z_j^{n-1}.$$

The $L^2(\Omega)$ norm of $\partial P_{\text{int}}f$ is in turn dominated by the L^2 norm of $\partial P_{\text{int}}f$ on $|z_j|\geqslant\epsilon$. To compute this norm it suffices to observe that (for n, $m=-1,-2,...$),

$$\int_{|z_j|\geqslant\epsilon} z_j^{n-1}\overline{z_j}^{m-1} i\,dz\,d\overline{z}=\int_{|z_j|\geqslant\epsilon} d\left(\frac{z_j^n\overline{z_j}^{m-1}}{n} i\,d\overline{z}\right)=-\frac{1}{n}\int_{C_\epsilon(a_j)} z_j^n\overline{z_j}^{m-1} i\,d\overline{z}=\frac{2\pi}{|n|}\epsilon^{2n}\delta_{nm}.$$

We then see that

$$\|P_{\text{int}}f\|^2_{H^1(\Omega)}\leqslant C\sum_{n=-L}^{-1}\epsilon^{2n}|n|f_n\overline{f_n}\leqslant C\|f\|^2_{H^{-1/2}(C_\epsilon(a_j))}.$$

Now suppose that

$$f(z)=\begin{cases}\displaystyle\sum_{n=-L}^{L} f_n z^n & \text{for } z\in C_R\\ 0 & \text{for } z\in\partial\Omega\backslash C_R .\end{cases} \tag{42}$$

Then the argument we just gave is easily modified to show that

$$\|P_{\text{int}}f\|_{H^1(\Omega)}\leqslant C\|f\|_{H^{1/2}(C_R)}.$$

Sums of functions of type (41) for $j=1,2,...,N$ and type (42) are dense in $H^{1/2}(\partial\Omega)$ and it follows that P_{int} extends to a continuous map from $H^{1/2}(\partial\Omega)$ to $H^1(\Omega)$.[19]

Taking complex conjugates the result we just proved also shows that the map,

$$f\to-\frac{1}{2\pi i}\int_{\partial\Omega}\overline{g(z,z')}f(z')d\overline{z}',$$

is bounded from $H^{1/2}(\mathcal{E}_{\partial\Omega})$ to $H^1(\mathcal{E}_\Omega)$. This finishes the proof of the theorem. QED

V. INVERTING THE PROJECTION $P_0: W^{(m)}\to W^{(0)}$

Remark: In this section we will write $W^{(m)}$ for $W^{(m)}\cap H^{1/2}(\mathcal{E}_{\partial\Omega})$ and $W^{(0)}$ for $W^{(0)}\cap H^{1/2}(\mathcal{E}_{\partial\Omega})$. We will prove the following theorem.

Theorem 6: *For all sufficiently small values of m the projection*

$$P_0: W^{(m)}\to W^{(0)}$$

is an isomorphism. Furthermore, there is a linear map δ from $W^{(0)}$ into $(I-P_0)H^{1/2}(\mathcal{E}_{\partial\Omega})$ and a constant C which is independent of f and m so that for all $f\in W^{(0)}$,

(1) $f+\delta f\in W^{(m)}$,

(2) $\|\delta f\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})} \leqslant Cm\|f\|_{H^{1/2}_{(\mathcal{E}_{\partial\Omega})}}$.

Remark: The map δ gives $W^{(m)}$ as a graph over $W^{(0)}$.

Proof: Suppose first that $f \in W^{(m)}$ and let f_j denote the restriction of f to $C_\epsilon(a_j)$ and let f_∞ denote the restriction of f to C_R. Write $e^{(m)}_{n,j}$ for $e^{(m)}_n(\epsilon,\Theta_j)$ and $\hat{e}^{(m)}_{n,\infty}$ for $\hat{e}^{(m)}_n(R,\theta)$. Then the Fourier expansions of f on $C_\epsilon(a_j)$ and C_R can be written,

$$f_j = a_{0,j}(e^{(m)}_{0,j} + e^{(m)}_{0,j}*) + \sum_{n=1}^{\infty} \{a_{n,j}e^{(m)}_{n,j} + b_{n,j}e^{(m)}_{n,j}*\} \tag{43}$$

and

$$f_\infty = \sum_{n=-\infty}^{\infty} a_{n,\infty}\hat{e}^{(m)}_{n,\infty}. \tag{44}$$

Now let $p_0 f$ denote the element of $W^{(0)}$ which has the same "Fourier coefficients" in the $m \to 0$ limiting basis. That is,

$$p_0 f_j = a_{0,j}(e_{0,j} + e^*_{0,j}) + \sum_{n=1}^{\infty} \{a_{n,j}e_{n,j} + b_{n,j}e^*_{n,j}\} \tag{45}$$

and

$$p_0 f_\infty = \sum_{n=-\infty}^{\infty} a_{n,\infty}\hat{e}_{n,\infty}, \tag{46}$$

where $e_{n,j}$ denotes the basis vector $e_n(\Theta_j)$ and $\hat{e}_{n,\infty}$ denotes the vector $\hat{e}_n(\theta)$. It is easy to check that

$$\langle e^{(m)}_{k,j} - e_{k,j}, e^{(m)}_{l,j} - e_{l,j}\rangle_{H^{1/2}(\mathcal{E}_{\partial\Omega})} = \delta_{kl}\|e^{(m)}_{k,j} - e_{k,j}\|^2_{H^{1/2}(\mathcal{E}_{\partial\Omega})},$$

and from (15) and (16) it follows that

$$\|e^{(m)}_{k,j} - e_{k,j}\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})} \leqslant Cm.$$

Analogous results for $e^{(m)}_{k,j}*$ and for $\hat{e}^{(m)}_k$ [which follow from (17) and (18)] imply the inequality

$$\|p_0 f - f\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})} \leqslant Cm\|f\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})}, \tag{47}$$

for some constant C and all $f \in W^{(m)}$. Now write $\Delta p_0 = p_0 - I$. Then for $f \in W^{(m)}$ we have

$$f + \Delta p_0 f \in W^{(0)}.$$

It follows from this that

$$(I - P_0)(f + \Delta p_0 f) = 0,$$

or

$$(I - P_0)f = -(1 - P_0)\Delta p_0 f.$$

From this, (47), and the fact that P_0 is bounded on $H^{1/2}(\mathcal{E}_{\partial\Omega})$ it follows that

$$\|f - P_0 f\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})} \leqslant Cm\|f\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})},$$

for some constant C and all $f \in W^{(m)}$. When m is small enough so that $Cm<1$ this last inequality implies that $P_0: W^{(m)} \to W^{(0)}$ is injective since $P_0 f = 0$ gives $\|f\| \leqslant Cm\|f\|$ with $Cm<1$, which in turn forces $\|f\|=0$.

Now start with $f_0 \in W^{(0)}$ with Fourier expansion given by (45) and (46) and define $p_m f_0 \in W^{(m)}$ to be the element of $W^{(m)}$ with the Fourier expansion (43) and (44). Then the same estimates we gave previously imply that for $f_0 \in W^{(0)}$ we have

$$\|\Delta p_m f_0\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})} \leqslant Cm\|f_0\|_{H^{1/2}(\mathcal{E}_{\partial\Omega})},$$

for $\Delta p_m := p_m - I$ and some constant C. Now choose m small enough so that the map,

$$P_0 + P_0 \Delta p_m : W^{(0)} \to W^{(0)},$$

is invertible. Define

$$g_0 := (P_0 + P_0 \Delta p_m)^{-1} f_0.$$

Then one can easily check that

$$g_0 + \Delta p_m g_0 \in W^{(m)}$$

and

$$P_0(g_0 + \Delta p_m g_0) = f_0.$$

This shows that $P_0: W^{(m)} \to W^{(0)}$ is subjective. Furthermore if we define

$$\delta = (I - P_0)\Delta p_m (P_0 + P_0 \Delta p_m)^{-1}$$

as a map from $W^{(0)}$ to $(I-P_0)H^{1/2}(\mathcal{E}_{\partial\Omega})$, then it is easy to check that $f_0 + \delta f_0 \in W^{(m)}$ and δ satisfies the estimate (2) of the theorem. Q.E.D.

VI. CONVERGENCE RESULTS

In this section we provide the details for the approximation scheme for $\delta \mathcal{W}_j$ that was outlined in Ref. 2. Let f_j denote the section of $\mathcal{E}_\Omega$ defined in (9). As a first approximation to $\delta \mathcal{W}_j$ we define

$$\delta_1 \mathcal{W}_j = G_0(1 + mG_0)^{-1} f_j. \tag{48}$$

We will show that for all sufficiently small m, $\delta_1 \mathcal{W}_j$ is well defined and

$$(m - \not{\partial})\, \delta_1 \mathcal{W}_j = f_j, \tag{49}$$

with $\delta_1 \mathcal{W}_{j|_{\partial\Omega}} \in W^{(0)}$. Thus $\delta_1 \mathcal{W}_j$ satisfies the same differential equation as $\delta \mathcal{W}_j$ but has boundary values in $W^{(0)}$ instead of $W^{(m)}$. Next we define

$$\delta_2 \mathcal{W}_j = \delta(\delta_1 \mathcal{W}_1). \tag{50}$$

Then the boundary values of $\delta_1 \mathcal{W}_j + \delta_2 \mathcal{W}_j$ are in $W^{(m)}$ but since $\not{\partial}\delta_2 \mathcal{W}_j = 0$ on Ω we find that

$$(m - \not{\partial})(\delta_1 \mathcal{W}_j + \delta_2 \mathcal{W}_j) = f_j + m\delta_2 \mathcal{W}_j.$$

Now let $\delta_3 \mathcal{W}_j$ denote the solution of

$$(m - \not{\partial})\, \delta_3 \mathcal{W}_j = -m\delta_2 \mathcal{W}_j, \tag{51}$$

such that $\delta_3 \mathcal{W}_{j|_{\partial\Omega}} \in W^{(m)}$. The solution we are interested in is then

$$\delta\mathcal{W}_j=\delta_1\mathcal{W}_j+\delta_2\mathcal{W}_j+\delta_3\mathcal{W}_j\,.$$

The following theorem gives convergence results that will allow us to calculate (10) in the limit $m\to 0$. We write f_{0j} for the $m\to 0$ limit of f_j,

$$f_{0j}(z)=i\sqrt{\frac{2}{\pi}}\begin{bmatrix}-\overline{z_j}^{1/2}\partial\varphi_j(z)\\ z_j^{-1/2}\overline{\partial}\varphi_j(z)\end{bmatrix}. \tag{52}$$

Theorem 7: *For $\delta_k\mathcal{W}_j$ defined previously $(k=1,2,3)$ we have,*
(1) *As $m\to 0$, $\delta_1\mathcal{W}_j$ converges to G_0f_{0j} in $W^{1,p}(\mathcal{E}_\Omega)$ for all $p>2$.*
(2) *$\|\delta_2\mathcal{W}_j\|_{H^1(\mathcal{E}_\Omega)}\leqslant Cm$ for some constant C independent of m.*
(3) *The Fourier coefficient,*

$$\int_{\theta_{\mathbf{r}}}^{\theta_{\mathbf{r}}+2\pi}(\delta_3\mathcal{W}_j)_1(\epsilon e^{i\Theta_j})\exp\left(-i\frac{\Theta_j}{2}\right)\mathrm{d}\Theta_j\,, \tag{53}$$

tends to 0 *as* $m\to 0$.

Remark: As we shall see in the following, the upshot of these estimates is that we can compute the $m\to 0$ limit of $mc_1^j(\mathcal{W}_j)$ by calculating the appropriate Fourier coefficient of G_0f_{0j}. Also in the course of proving (1)–(3) of theorem 7 we will confirm the properties asserted for $\delta_k\mathcal{W}_j$, $k=1,2,3$, when they were introduced above.

Proof: Estimate 1 of theorem 3 shows that for $p>2$, G_0 is bounded on $W^{1,p}(\mathcal{E}_\Omega)$. Thus for small enough m, the map $I+mG_0$ is invertible on $W^{1,p}(\mathcal{E}_\Omega)$. Since it is clear that $f_j\in C_0^\infty(\mathcal{E}_\Omega)\subset W^{1,p}(\mathcal{E}_\Omega)$ it follows that $\delta_1\mathcal{W}_j\in W^{1,p}(\mathcal{E}_\Omega)$ for $p>2$. Since $\delta_1\mathcal{W}_j$ is in the image of G_0, part (3) of theorem 3 implies that the boundary value of $\delta_1\mathcal{W}_j$ on $\partial\Omega$ is in $W^{(0)}$. We use part (2) of theorem 3 to do the following calculation:

$$\begin{aligned}(m-\not{\partial})G_0(I+mG_0)^{-1}f_j&=mG_0(I+mG_0)^{-1}f_j+(I+mG_0)^{-1}f_j\\&=(mG_0+I)(I+mG_0)^{-1}f_j=f_j\,,\end{aligned}$$

which confirms (49). Since G_0 is bounded on $W^{1,p}(\mathcal{E}_\Omega)$ the operator $(I+mG_0)^{-1}$ converges uniformly to I on $W^{1,p}(\mathcal{E}_\Omega)$ as $m\to 0$. Thus to finish the proof of 1 we need only show that for all $p>2$ the section f_j converges in $W^{1,p}(\mathcal{E}_\Omega)$ to f_{0j}. Using (9) one finds

$$f_j=i\sqrt{m}\begin{bmatrix}\exp\left(i\frac{\Theta_j}{2}\right)(I_{1/2}(mr)-I_{-1/2}(mr))\partial\varphi_j(z)\\ \exp\left(-i\frac{\theta_j}{2}\right)(I_{-1/2}(mr)-I_{1/2}(mr))\overline{\partial}\varphi_j(z)\end{bmatrix}. \tag{54}$$

The simple estimate,

$$I_{\pm 1/2}(mr)=\left(\frac{mr}{2}\right)^{\pm 1/2}\sum_{n=0}^{\infty}\frac{(mr)^{2n}}{2^{2n}n!\Gamma(n\mp 1/2)}\leqslant\left(\frac{mr}{2}\right)^{\pm 1/2}\frac{\exp\left(\frac{2m\epsilon}{2}\right)^2}{\Gamma(3/2)},$$

which is valid for $r<2\epsilon$ (which contains the support of $\partial\varphi_j$ and $\overline{\partial}\varphi_j$) shows that dominated convergence applies to

$$\lim_{m\to 0}\int_\Omega|f_j-f_{0j}|^p i\,\mathrm{d}z\,\mathrm{d}\overline{z}=0,$$

for all $p \geqslant 1$. The same estimate shows that dominated convergence applies to the $m \to 0$ limit of the integral,

$$\int_\Omega |\mathrm{d}f_j - \mathrm{d}f_{0j}|^p i \, \mathrm{dz} \, \mathrm{d}\bar{z}$$

and this proves that f_j converges to f_{0j} in $W^{1,p}(\mathcal{E}_\Omega)$. Now fix $p > 2$. Since f_j converges in $W^{1,p}(\mathcal{E}_\Omega)$ as $m \to 0$ it follows that its norm in this space is uniformly bounded. Hence the $W^{1,p}$ norm of $\delta_1 \mathcal{W}_j$ is also uniformly bounded. However since the domain Ω is bounded the $W^{1,p}(\mathcal{E}_\Omega)$ norm for $p > 2$ dominates (a constant times) the $H^1(\mathcal{E}_\Omega)$ norm. This shows that $\delta_1 \mathcal{W}_j$ is uniformly bounded in $H^1(\mathcal{E}_\Omega)$ as $m \to 0$. The Sobolev trace theorem[18] implies that the boundary value of $\delta_1 \mathcal{W}_j$ is uniformly bounded in $H^{1/2}(\mathcal{E}_{\partial\Omega})$ and estimate 2 of theorem 6 then shows that $\delta_2 \mathcal{W}_j = \delta(\delta_1 \mathcal{W}_j)$ has norm in $H^{1/2}(\mathcal{E}_\Omega)$ bounded by Cm. Finally estimate (39) shows that the extension of $\delta_2 \mathcal{W}_j$ to Ω has $H^1(\mathcal{E}_\Omega)$ norm dominated by Cm, which is estimate (2) of theorem 7.

Before we turn to the proof of part (3) of theorem 7 it will be useful to establish the following estimates for solutions to the massive Dirac equation.

Theorem 8: *Suppose that $\Psi \in L^2(\mathcal{E}_\Omega)$ is a weak solution to the Dirac equation,*

$$(m - \not{\partial})\Psi = f,$$

in Ω, where $f \in C_0^\infty(\mathcal{E}_\Omega)$. Suppose that $\Psi|_{\partial\Omega} \in W^{(m)}$ so that for $z \in C_\epsilon(a_j)$ the section Ψ has the local expansion

$$\Psi(z) = \sum_{n \geqslant 0} c_n^j(\Psi) w_n(z_j) + c_n^j(\Psi) w_n^*(z_j),$$

with $c_0^j(\Psi) = c_0^{j*}(\Psi)$, and for $z \in C_R$ the section Ψ has the local expansion

$$\Psi(z) = \sum_{n \in \mathbf{Z}} c_n^\infty(\Psi) \hat{w}_n(z).$$

Then,

$$\|\Psi\|_{L^2(\mathcal{E}_\Omega)} \leqslant \frac{1}{m} \|f\|_{L^2(\mathcal{E}_\Omega)}, \tag{55}$$

$$\sum_j |c_0^j(\Psi)|^2 \leqslant \frac{1}{8} \|f\|^2_{L^2(\mathcal{E}_\Omega)}, \tag{56}$$

$$4\pi \sum_{n \geqslant 0} \{|c_n^j(\Psi)|^2 + |c_n^{j*}(\Psi)|^2\} I_{n+1/2}(m\epsilon) I_{n-1/2}(m\epsilon) \epsilon \leqslant \frac{1}{m} \|f\|^2_{L^2(\mathcal{E}_\Omega)}, \tag{57}$$

$$4\pi \sum_{n \in \mathbf{Z}} |c_n^\infty(\Psi)|^2 K_n(mR) K_{n-1}(mR) R \leqslant \frac{1}{m} \|f\|^2_{L^2(\mathcal{E}_\Omega)}. \tag{58}$$

Proof: Since $f \in C_0^\infty(\mathcal{E}_\Omega)$, the existence theorem in Ref. 2 then gives us a weak solution $\Psi \in L^2(\mathcal{E}_\Omega)$ of

$$(m - \not{\partial})\Psi = f,$$

which is smooth as a consequence of local elliptic regularity. Next we calculate the exterior derivative of $2i\bar{\Psi}_1 \Psi_2 \mathrm{d}\bar{z}$ using the fact that Ψ satisfies the Dirac equation,

$$d(2i\overline{\Psi}_1\Psi_2\,d\overline{z}) = m|\Psi|^2 i\,dz\,d\overline{z} - (\overline{\Psi}_1 f_1 + \Psi_2 \overline{f}_2) i\,dz\,d\overline{z}.$$

Integrating this equality over Ω and using Stokes' theorem we find

$$m\|\Psi\|^2_{L^2(\mathcal{E}_\Omega)} - 2i\int_{\partial\Omega}\overline{\Psi}_1\Psi_2\,d\overline{z} = \int_\Omega (\overline{\Psi}_1 f_1 + \Psi_2\overline{f}_2) i\,dz\,d\overline{z}. \tag{59}$$

From this we deduce the inequality

$$m\|\Psi\|^2_{L^2(\mathcal{E}_\Omega)} - 2i\int_{\partial\Omega}\overline{\Psi}_1\Psi_2\,d\overline{z} \leqslant \|\Psi\|_{L^2(\mathcal{E}_\Omega)}\|f\|_{L^2(\mathcal{E}_\Omega)}. \tag{60}$$

Next we compute the boundary term in (60) using the local expansions for Ψ. We find

$$-2i\int_{C_R}\overline{\Psi}_1\Psi_2\,d\overline{z} = 4\pi\sum_n |c_n^\infty(\Psi)|^2 K_n(mR)K_{n-1}(mR)R, \tag{61}$$

and recalling the appropriate orientation of $\partial\Omega$,

$$2i\int_{C_\epsilon(a_j)}\overline{\Psi}_1\Psi_2\,d\overline{z} = 4\pi\sum_{n\geqslant 0}(|c_n^j(\Psi)|^2 + |c_n^{j*}(\Psi)|^2) I_{n+1/2}(m\epsilon)I_{n-1/2}(m\epsilon)\epsilon$$
$$+ 4\pi\overline{c}_0^j(\Psi)c_0^{j*}(\Psi)I^2_{-1/2}(m\epsilon)\epsilon + 4\pi\overline{c}_0^{j*}(\Psi)c_0^j(\Psi)I^2_{1/2}(m\epsilon)\epsilon.$$

The boundary condition $c_0^j(\Psi) = c_0^{j*}(\Psi)$ implies that the right-hand side of this last equation is positive definite. Thus the boundary term on the left-hand side of (60) is positive and we immediately deduce

$$m\|\Psi\|^2_{L^2(\mathcal{E}_\Omega)} \leqslant \|\Psi\|_{L^2(\mathcal{E}_\Omega)}\|f\|_{L^2(\mathcal{E}_\Omega)},$$

which is (55). Now (61) and (60) coupled with the positivity of all the boundary contributions and (55) together imply (57) and (58). For the same reasons we can pick out just one term from each of the $C_\epsilon(a_j)$ boundary terms to find the inequality

$$4\pi\sum_j |c_0^j(\Psi)|^2 I^2_{-1/2}(m\epsilon)\epsilon \leqslant \frac{1}{m}\|f\|^2_{L^2(\mathcal{E}_\Omega)}.$$

This must be true for all ϵ and since

$$\lim_{\epsilon\to 0} I^2_{-1/2}(m\epsilon)\epsilon = \frac{2}{m\pi},$$

we have proved (56). (Theorem 8.) QED

Now suppose as in the preceeding theorem that Ψ is an $L^2(\mathcal{E}_\Omega)$ solution to,

$$(m - \not{\partial})\Psi = f,$$

where $f \in C_0^\infty(\mathcal{E}_\Omega)$. To finish the proof of (3) of Theorem 7 we want to estimate $c_1^j(\Psi)$ in terms of f. To do this we first introduce the function

$$V_j(z) = (z - a_j)^{-3/2}\prod_{k\neq j}(a_j - a_k)^{1/2}(z - a_k)^{-1/2},$$

which we take to be branched along the rays $\mathbf{r}_j$. Next observe that if Ψ is identified with its $\mathcal{U}_0$ trivialization then $V_j\Psi$ is differentiable on Ω and

$$\mathrm{d}(2V_j\Psi_1\,\mathrm{d}z) = -\overline{\partial}(2V_j\Psi_1)\mathrm{d}z\,\mathrm{d}\overline{z} = -2V_j\overline{\partial}\Psi_1\,\mathrm{d}z\,\mathrm{d}\overline{z} = mV_j\Psi_2\,\mathrm{d}z\,\mathrm{d}\overline{z} - V_j f_2\,\mathrm{d}z\,\mathrm{d}\overline{z}.$$

Stokes' theorem implies

$$\int_{\partial\Omega} 2V_j\Psi_1\,\mathrm{d}z = \int_\Omega mV_j\Psi_2\,\mathrm{d}z\,\mathrm{d}\overline{z} - \int_\Omega V_j f_2\,\mathrm{d}z\,\mathrm{d}\overline{z},$$

from which, together with (55), we deduce the inequality

$$\left|\int_{\partial\Omega} V_j\Psi_1\,\mathrm{d}z\right| \leqslant \|V_j\|_{L^2(\Omega)}\|f\|_{L^2(\mathcal{E}_\Omega)}. \tag{62}$$

Next we wish to estimate the boundary integrals over $C_\epsilon(a_k)$. First observe that in a neighborhood of a_k the function V_j has a "Laurent" expansion in powers of $z_k = z - a_k$,

$$V_j(z) = \sum_{n\geqslant -1} c_n^k(V_j) z_k^{n-1/2},$$

and z is restricted to an annulus about $|z_k| = \epsilon$. One finds

$$\frac{1}{2\pi\epsilon i}\int_{C_\epsilon(a_k)} V_j\Psi_1\,\mathrm{d}z = c_1^k(\Psi)c_{-1}^k(V_j)I_{1/2}(m\epsilon)\epsilon^{-3/2} + c_0^k(\Psi)c_0^k(V_j)I_{-1/2}(m\epsilon)\epsilon^{-1/2}$$

$$+ \sum_{n\geqslant 0} c_n^{k*}(\Psi)c_n^k(V_j)I_{n+1/2}(m\epsilon)\epsilon^{n-1/2}.$$

Observe that the term with $c_1^k(\Psi)$ is present only for $k = j$ since one can easily check that

$$c_{-1}^k(V_j) = \delta_{jk}.$$

Next we use the fact that the Taylor expansion of V_j for $|z| \geqslant R$ has the form

$$V_j(z) = \sum_{n<-1} c_n^\infty(V_j) z^n$$

to calculate

$$\frac{1}{2\pi R i}\int_{C_R} V_j\Psi_1(z)\mathrm{d}z = -\sum_{n<-1} c_n^\infty(V_j)R^n c_{n+1}^\infty(\Psi)K_{n+1}(mR).$$

Note: The coefficients $c_n^\infty(V_j)$ are zero for $n > -(N/2) - 1$, where N is the number of branch points, but we will not need this.

Next we use (57) and Cauchy's inequality for the l^2 norm with weight,

$$I_{n+1/2}(m\epsilon)I_{n-1/2}(m\epsilon)\epsilon,$$

to estimate

$$\sum_{n\geqslant 0} |c_n^{k*}(\Psi)\|c_n^k(V_j)|I_{n+1/2}(m\epsilon)\epsilon\epsilon^{n-1/2} \leqslant A_k B_k, \tag{63}$$

where

$$A_k^2 = \sum_{n \geqslant 0} |c_k^{k*}(\Psi)|^2 I_{n+1/2}(m\epsilon) I_{n-1/2}(m\epsilon)\epsilon$$

and

$$B_k^2 = \sum_{n \geqslant 0} \left| \frac{c_k^k(V_j)\epsilon^{n-1/2}}{I_{n-1/2}(m\epsilon)} \right|^2 I_{n+1/2}(m\epsilon) I_{n-1/2}(m\epsilon)\epsilon.$$

Combining this with (11) we see that

$$B_k^2 \leqslant \sum_{n \geqslant 0} |c_n^k(V_j)\epsilon^{n-1/2}|^2 \frac{m\epsilon^2}{n+1/2} \leqslant \epsilon m \|V_j\|^2_{L^2(C_\epsilon a_k))},$$

since $c_n^k(V_j)\epsilon^{n-1/2}$ are Fourier coefficients for V_j on the circle $C_\epsilon(a_k)$. The norm of V_j that appears here is actually the $H^{-1/2}$ norm, but this won't matter for us. This last estimate for B_k combined with (57) for A_k give us

$$A_k B_k \leqslant \sqrt{\frac{\epsilon}{4\pi}} \|V_j\|_{L^2(C_\epsilon(a_k))} \|f\|_{L^2(\mathcal{E}_\Omega)}. \tag{64}$$

In a similar fashion we estimate

$$\sum_{n<-1} |c_n^\infty(V_j) R^n\|_{n+1}^\infty(\Psi)| K_{n+1}(mR) R \leqslant A_\infty B_\infty, \tag{65}$$

where

$$A_\infty^2 = \sum_{n<-1} |c_{n+1}^\infty(\Psi)|^2 K_{n+1}(mR) K_n(mR) R \leqslant \frac{1}{4\pi m} \|f\|^2_{L^2(\mathcal{E}_\Omega)},$$

and

$$B_\infty^2 = \sum_{n<-1} |c_n^\infty(V_j) R^n|^2 \frac{K_{n+1}(mR)}{K_n(mR)} R.$$

In this equation it is important for us that $n<-1$. For $n<-1$ we have

$$\frac{K_{n+1}(mR)}{K_n(mR)} = \frac{K_{|n|-1}(mR)}{K_{|n|}(mR)} \leqslant \frac{mR}{|n|-1},$$

so that

$$B_\infty^2 \leqslant mR \|V_j\|^2_{L^2(C_R)},$$

and

$$A_\infty B_\infty \leqslant \sqrt{\frac{R}{4\pi}} \|V_j\|_{L^2(C_R)} \|f\|_{L^2(\mathcal{E}_\Omega)}. \tag{66}$$

Combining the expressions for the boundary integrals with the estimates that follow from (63) to (66) we find the following lower bound;

$$\frac{1}{2\pi}\left|\int_{\partial\Omega} V_j \Psi_1 \, dz\right| \geq |c_1^j(\Psi)| I_{1/2}(m\epsilon)\epsilon^{-1/2} - \sum_k |c_0^k(V_j)||c_0^k(\Psi) I_{-1/2}(m\epsilon)\epsilon^{1/2}$$
$$- C\|V_j\|_{L^2(\partial\Omega)}\|f\|_{L^2(\mathcal{E}_\Omega)},$$

for a constant C which is independent of m. Now we put together this lower bound with (62) to find

$$I_{1/2}(m\epsilon)|c_1^j(\Psi)| \leq C(I_{-1/2}(m\epsilon)\sum_k |c_0^k(\Psi)| + \|f\|_{L^2(\mathcal{E}_\Omega)}, \tag{67}$$

where the constant C is independent of m but incorporates all the dependence on V_j. The form of this estimate that we will use is now obtained by combining (56) with (67). We find

$$I_{1/2}(m\epsilon)|c_1^j(\Psi)| \leq C(I_{-1/2}(m\epsilon)+1)\|f\|_{L^2(\mathcal{E}_\Omega)} \tag{68}$$

for a different constant C.

We are now prepared to finish the proof of part (3) of Theorem 7. Recall that $\delta_3\mathcal{W}_j$ is defined as the solution to

$$(m-\not\partial)\,\delta_3\mathcal{W}_j = -m\,\delta_2\mathcal{W}_j, \tag{69}$$

with boundary values in $W^{(m)}$. We could make this description technically precise and prove the existence of such a solution using H^1 estimates along the lines of the L^2 estimate (55). The relevant estimates can be obtained via a Stokes' theorem calculation involving the exterior derivative,

$$2id((\overline{\Psi}_1\overline{\partial}\Psi_1 + \overline{\Psi}_2\overline{\partial}\Psi_2)d\overline{z} - (\overline{\Psi}_1\partial\Psi_1 + \overline{\Psi}_2\partial\Psi_2)dz)$$

for a solution Ψ to

$$(M-\not\partial)\Psi = f.$$

However it will be simpler to proceed differently. The solution of (69) which is relevant to us is the one constructed via functional analysis in Ref. 2. This solution is a weak L^2 solution to (69) inside Ω which extends to a solution of the homogeneous equation $(m-\not\partial)\,\delta_3\mathcal{W}_j = 0$ outside Ω and is globally in $L^2(\mathcal{E})$. We can obtain such a solution by approximating the right-hand side $\delta_2\mathcal{W}_j$ in $L^2(\mathcal{E}_\Omega)$ by a sequence of functions $f_n \in C_0^\infty(\mathcal{E}_\Omega)$. Theorem 8 shows that the resulting sequence of solutions to the approximate equations tends strongly in $L^2(\mathcal{E}_\Omega)$ to a weak solution to (69). The norms on the left-hand sides of (57) and (58) are equivalent to the L^2 norms of limiting solution in the components of the exterior of Ω and so the resulting solution is globally in $L^2(\mathcal{E})$ (this is a consequence of the same Stokes' theorem calculation that went into the proof of Theorem 8 but done in the components of the exterior of Ω). We may thus identify the limiting solution with $\delta_3\mathcal{W}_j$ and by obtaining the solution $\delta_3\mathcal{W}_j$ in this fashion we see that estimate (68) remains valid, so that

$$I_{1/2}(m\epsilon)|c_1^j(\delta_3\mathcal{W}_j)| \leq C(I_{-1/2}(m\epsilon)+1)m\|\delta_2\mathcal{W}_j\|_{L^2(\Omega)}.$$

The left-hand side of this last inequality is the Fourier coefficient (53) and the right-hand side tends to 0 using estimate (2) of Theorem 7. This finishes the proof of Theorem 7. Q.E.D.

Remark: The norms on the left-hand side of (57) and (58) which are the appropriate norms for boundary values of L^2 solutions also appear to be equivalent to the $H^{-1/2}$ norms on the corresponding circles. The loss of one half derivative for boundary values of solutions to $(m=0)$ Dirac equations is a general property.[17] In our case, this would follow from the following Bessel function estimate:

$$\frac{K_n(r)}{K_{n-1}(r)} \leqslant 2(n-1)\left(1+\frac{1}{r}\right)$$

for $r>0$ and $n \geqslant 2$ which seems to be true.

We now substitute $\delta\mathcal{W}_j = \delta_1\mathcal{W}_j + \delta_2\mathcal{W}_j + \delta_3\mathcal{W}_j$ into (10) and use Theorem 7 to determine the limit as $m \to 0$. According to part (1) of Theorem 7, $\delta_1\mathcal{W}_j$ converges to $G_0 f_{0j}$ in $W^{1,p}(\mathcal{E}_\Omega)$ for $p>2$. The Sobolev trace theorem implies that it converges in $W^{1/2,p}(\mathcal{E}_{\partial\Omega})$ and this is enough to show that the Fourier coefficient of $\delta_1\mathcal{W}_j$ which appears in (10) converges to

$$\sqrt{\frac{\pi}{2\epsilon}}\frac{1}{2\pi}\int_{\theta_{\mathbf{r}}}^{\theta_{\mathbf{r}}+2\pi}(G_0 f_{0,j})_1(\epsilon e^{i\Theta_j})\exp\left(-i\frac{\Theta_j}{2}\right)\mathrm{d}\Theta_j. \tag{70}$$

Estimate (2) of Theorem 7 implies that the $H^1(\mathcal{E}_\Omega)$ norm of $\delta_2\mathcal{W}_j$ tends to 0 as $m \to 0$ and again the Sobolev trace theorem implies that the boundary value tends to 0 in $H^{1/2}(\mathcal{E}_{\partial\Omega})$, which is enough to show that the contribution made by $\delta_2\mathcal{W}_j$ to (10) is 0 in this limit. Finally part (3) of Theorem 7 shows that $\delta_3\mathcal{W}_j$ makes no contribution to the $m \to 0$ limit of (10). Thus to finish the proof of Theorem 1 we need only calculate (70).

We turn now to the calculation of (70). Using the definition of $f_{0,j}$ found in (52) we see that

$$(G_0 f_{0,j})_1(z) = i\sqrt{\frac{2}{\pi}}\int_\Omega(-G_{11}(z,z')\overline{z}_j'^{-1/2}\partial\varphi(z') + G_{12}(z,z')z_j'^{-1/2}\overline{\partial}\varphi)\mathrm{d}z'\,\mathrm{d}\overline{z}'.$$

Using the fact that $G_{11}(z,z')$ is antiholomorphic in z' and $G_{12}(z,z')$ is holomorphic in z we can rewrite this last integral as the integral of an exact form,

$$i\sqrt{\frac{2}{\pi}}\int_\Omega \mathrm{d}(-G_{11}(z,z')\overline{z}_j'^{-1/2}\varphi(z')\mathrm{d}\overline{z}' - G_{12}(z,z')z_j'^{-1/2}\varphi(z')\mathrm{d}z').$$

Since $\varphi(z)=1$ on $C_\epsilon(a_j)$ and vanishes on the rest of $\partial\Omega$, Stokes' theorem implies that the last integral is

$$i\sqrt{\frac{2}{\pi}}\int_{C_\epsilon(a_j)} G_{11}(z,z')\overline{z}_j'^{-1/2}\,\mathrm{d}\overline{z}' + G_{12}(z,z')z_j'^{-1/2}\,\mathrm{d}z'.$$

Now substitute

$$G_{11}(z,z') - \frac{1}{4\pi i}\sum_k v_k(z)\overline{u}_k(z)$$

and (25) for $G_{12}(z,z')$ in this last integral and use the residue calculations that are found in the results that follow (38) to find

$$(G_0 f_{0,j})_1(z) = -i\frac{z_j^{-1/2}}{\sqrt{2\pi}} + i\sqrt{\frac{2}{\pi}}v_j(z).$$

Using this result it is now a simple matter to convert the Fourier integral (70) into the following residue calculation:

$$\frac{1}{2\pi}\int_{C_\epsilon(a_j)} z_j^{-2}\sum_{|\epsilon|=0,\epsilon_j=1/2} c(\epsilon)\prod_{\neq j}\frac{(z-a_k)^{\epsilon_k}}{(a_j-a_k)^{\epsilon_k}}\mathrm{d}z,$$

which in turn gives

$$i\frac{\partial}{\partial z}\sum_{|\epsilon|=0,\epsilon=1/2} c(\epsilon)\prod_{k\neq j}\frac{(z-a_k)^{\epsilon_k}}{(a_j-a_k)^{\epsilon_k}}\bigg|_{z=a_j} = i\sum_{|\epsilon|=0,\epsilon_j=1/2} c(\epsilon)\sum_{k\neq j}\frac{\epsilon_k}{a_j-a_k}.$$

Dividing by $2i$ to get the limiting value of the coefficient that appears in the $m\to 0$ of the log derivative of the tau function we find

$$\lim_{m\to 0}\frac{mc_1^j(\mathcal{W}_j)}{2i} = \frac{1}{2}\sum_{|\epsilon|=0,\epsilon_j=1/2} c(\epsilon)\sum_{k\neq j}\frac{\epsilon_k}{a_j-a_k}. \tag{71}$$

To finish the proof of Theorem 1 we compare this result with

$$\frac{\partial}{\partial a_j}\sum_{|\epsilon|=0}\prod_{\alpha<\beta}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta} = \sum_{|\epsilon|=0}\sum_{k\neq j}\frac{\epsilon_j\epsilon_k}{a_j-a_k}\prod_{\alpha<\beta}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta}, \tag{72}$$

which we obtained using

$$\frac{\partial}{\partial a_j}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta} = \frac{\epsilon_\alpha\epsilon_\beta}{a_\alpha-a_\beta}(\delta_{\alpha j}-\delta_{\beta j})|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta}.$$

In (71) observe that the $|\epsilon|=0$ sum has two different possible values for ϵ_j, either $\epsilon_j=\frac{1}{2}$ or $\epsilon_j=-\frac{1}{2}$. However since the summand on the right-hand side of (71) is clearly invariant under the complete sign reversal $\epsilon_\alpha\to-\epsilon_\alpha$ it follows that the whole sum is just twice the result for $\epsilon_j=\frac{1}{2}$. That is,

$$\frac{\partial}{\partial a_j}\sum_{|\epsilon|=0}\prod_{\alpha<\beta}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta} = \sum_{|\epsilon|=0,\epsilon_j=1/2}\sum_{k\neq j}\frac{\epsilon_k}{a_j-a_k}\prod_{\alpha<\beta}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta}.$$

Comparing this with (71) and recalling the definition of $c(\epsilon)$ we have finished the proof of Theorem 1.

VII. ODD CORRELATIONS AND HOLONOMIC FIELDS

In this section we make some observations about the application of the technique used to prove Theorem 1 to work out the asymptotics of the odd Ising scaling functions from below T_c and also the short distance behavior of the correlations for holonomic quantum fields.

First we treat the case where N is odd. The one difference in the analogue of Lemma 1 for N odd is that the subspace $W_\infty^{(m)}$ is now the L^2 closure of the span of

$$\hat{w}_n(z) = \begin{bmatrix} -e^{-i(n+1/2)\theta} & K_{n+1/2}(m|z|) \\ -e^{-i(n-1/2)\theta} & K_{n-1/2}(m|z|)\end{bmatrix},$$

for $n\in\mathbf{Z}$. For definiteness we make the choice $0<\theta<2\pi$ and choose the $\mathcal{U}_\infty$ trivialization (in the complement of $\theta=0$) so that finite linear combinations of the $\hat{w}_n(z)$ are smooth sections of $\mathcal{E}$ in the $\mathcal{U}_\infty$ trivialization. Without difficulty one can compute the $m\to 0$ limit of the normalized versions of these vectors and as a consequence we define $W_\infty^{(0)}$ as the L^2 closure of the span of

$$\left\{\begin{bmatrix} e^{-i(n+1/2)\theta}\\ 0\end{bmatrix}\right\}_{n\geq 1}, \begin{bmatrix} -e^{-i(\theta/2)}\\ e^{i(\theta/2)}\end{bmatrix}, \left\{\begin{bmatrix} 0\\ e^{i(n+1/2)\theta}\end{bmatrix}\right\}_{n\geq 1}.$$

Next we introduce a Green function $-\not{\partial}$ with $W^{(0)}$ boundary conditions in the following manner:

$$G_0(z,z')=-\frac{1}{4\pi i}\begin{bmatrix}\sum_j u_j(z)\overline{v_j(z')} & g(z,z')\\ g(z,z') & \sum_j \overline{u_j(z)}v_j(z')\end{bmatrix}, \tag{73}$$

where

$$u_j(z):=(z-a_j)^{-1/2}\prod_{k\neq j}\frac{(z-a_k)^{1/2}}{(a_j-a_k)^{1/2}}, \tag{74}$$

$$g(z,z'):=\sum_{|\epsilon|=\pm 1/2} c(\epsilon)\frac{\Pi_j(z-a_j)^{\epsilon_j}(z'-a_j)^{-\epsilon_j}}{z'-z}, \tag{75}$$

with $\epsilon=(\epsilon_1,\ldots,\epsilon_N)$ and each $\epsilon_j=\pm\frac{1}{2}$. Also

$$|\epsilon|:=\sum_{j=1}^{N}\epsilon_j,\quad c(\epsilon):=\frac{\Pi_{j<k}|a_j-a_k|^{2\epsilon_j\epsilon_k}}{\sum_{|\epsilon|=\pm 1/2}\Pi_{j<k}|a_j-a_k|^{2\epsilon_j\epsilon_k}}, \tag{76}$$

and

$$v_j(z)=(z-a_j)^{-1/2}\sum_{|\epsilon|=\pm 1/2,\epsilon_j=1/2} c(\epsilon)\prod_{k\neq j}\frac{(z-a_k)^{\epsilon_k}}{(a_j-a_k)^{\epsilon_k}}. \tag{77}$$

The multivalued functions $(z-a_j)^{\epsilon_j}$ are all defined using the argument Θ_j and are consequently branched along $z\in\mathbf{r}_j$. We regard $G_0(z,z')$ as defining an operator, G_0, acting on sections of $\mathcal{E}_\Omega$ in the following manner:

$$G_0 f(z):=\int_\Omega G_0(z,z')f(z')\mathrm{d}z'\,\mathrm{d}\overline{z'}, \tag{78}$$

where the section $f(z')$ is identified with its $\mathcal{U}_0$ trivialization. We also regard $G_0 f$ as a section of $\mathcal{E}_\Omega$ given in the $\mathcal{U}_0$ trivialization.

The homogeneous function identity,

$$\sum_k \overline{u_k}(z)v_k(z')=\sum_k \overline{v_k}(z)u_k(z'),$$

can be proved along the lines of Lemma 2 and this makes it possible to establish the desired results concerning the Green function and the projection P_0. One matter that requires a little further analysis is the proof that $G_0 f$ has boundary values on C_R which are in $W_\infty^{(0)}$. For this purpose it is useful to introduce a $\mathcal{U}_\infty$ trivialization for $\mathcal{E}$ over $\{z:|z|>R\}\backslash\{t\in\mathbf{R}:t>0\}$ by introducing square root $z^{1/2}=|z|^{1/2}e^{i\theta/2}$ for $0<\theta<2\pi$, which is branched along the positive real axis. Smooth sections of $\mathcal{E}$ over $\{z:|z|>R\}\backslash\{t\in\mathbf{R}:t>0\}$ can then be represented in the $\mathcal{U}_\infty$ trivialization as products $z^{1/2}\phi(z)$ for a smooth map ϕ from $D_\infty:=\{z:|z|>R\}$ into $\mathbf{C}^2$. For the purpose of analyzing the behavior of the Green function $G_0(z,z')$ for $|z|>R$ it is useful to note that $v_j(z)$ has a representation in this domain given by

$$v_j(z)=z^{-1/2}\left(1-\frac{a_j}{z}\right)^{-1/2}\sum_{|\epsilon|=1/2,\epsilon_j=1/2}c(\epsilon)\prod_{k\neq j}\frac{\left(1-\frac{a_k}{z}\right)^{\epsilon_k}}{(a_j-a_k)^{\epsilon_k}}$$

$$+z^{-3/2}\left(1-\frac{a_j}{z}\right)^{-1/2}\sum_{|\epsilon|=-1/2,\epsilon_j=1/2}c(\epsilon)\prod_{k\neq j}\frac{\left(1-\frac{a_k}{z}\right)^{\epsilon_k}}{(a_j-a_k)^{\epsilon_k}}.$$

Using this one can check that for $\varphi\in C_0^\infty(\mathcal{E}_\Omega)$ we have $G_0\varphi|_{C_R}\in W_\infty^{(0)}$ provided the following reality conditions are satisfied:

$$\sum_{|\epsilon|=1/2,\epsilon_j=1/2}c(\epsilon)\prod_{k\neq j}(a_j-a_k)^{-\epsilon_k}=\sum_{|\epsilon|=1/2,\epsilon_j=1/2}\overline{c(\epsilon)}\prod_{k\neq j}\overline{(a_j-a_k)}^{\epsilon_k}.$$

This will be true for our choice of $c(\epsilon)$ provided that

$$\sum_{|\epsilon|=1/2,\epsilon_j=1/2}\prod_{\substack{\alpha<\beta\\ \alpha,\beta\neq j}}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta}\prod_{k\neq j}|a_j-a_k|^{\epsilon_k}(a_j-a_k)^{-\epsilon_k},$$

is real. However, under the transformation $\epsilon_k\to-\epsilon_k$ for $k\neq j$ the product

$$\prod_{k\neq j}|a_j-a_k|^{\epsilon_k}(a_j-a_k)^{-\epsilon_k},$$

maps into its complex conjugate while in the preceeding sum the coefficient of this product is real and invariant. This implies reality for the sum.

The rest of the analysis closely follows that in the even case and so we will only quote the final result. For N odd we have

$$\lim_{m\to0}\mathrm{d}_a\log\tau_-(ma)=\frac{1}{2}\mathrm{d}_a\log\sum_{|\epsilon|=\pm1/2}\prod_{\alpha<\beta}|a_\alpha-a_\beta|^{2\epsilon_\alpha\epsilon_\beta}.$$

Finally we describe the situation for the tau functions for holonomic fields in the formalism of Ref. 13. Suppose that for $j=1,...,N$ we have

$$-\tfrac{1}{2}<\lambda_j<\tfrac{1}{2},$$

and for simplicity we also suppose that

$$\sum_j\lambda_j=0.$$

The restricted local expansion that determines the subspace $W_j^{(m)}$ is

$$w(z)=\sum_{\substack{k\in\mathbf{z}+1/2\\ k>0}}a_k^j(w)w_{k-\lambda_j}(z_j)+b_k^j(w)w^*_{k+\lambda_j}(z_j).$$

At infinity the restricted expansion that determines $W_\infty^{(m)}$ is

$$w(z)=\sum_{k\in\mathbf{z}+1/2}c_k(w)\hat{w}_k(z).$$

Without difficulty one can check that the limiting subspaces, $W_j^{(0)}$, are spanned by

$$\begin{bmatrix} z_j^{k-\lambda_j} \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ \overline{z}_j^{k+\lambda_j} \end{bmatrix} \quad \text{for} \quad k=\frac{1}{2},\frac{3}{2},\ldots$$

and $W_\infty^{(0)}$ is spanned by

$$\begin{bmatrix} z^{-n} \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ \overline{z}^{-n} \end{bmatrix} \quad \text{for} \quad n=1,2,3,\ldots .$$

The mass 0 Green function for the Dirac operator of interest is clearly (see Proposition 1.1 in Ref. 13),

$$G_0(z,z')=-\frac{1}{4\pi}\begin{bmatrix} 0 & g(z,z') \\ \overline{g(z,z')} & 0 \end{bmatrix},$$

where

$$g(z,z')=\frac{\Pi_j z_j^{-\lambda_j}(z_j')^{\lambda_j}}{z'-z}.$$

There are no ''chiral symmetry breaking'' terms. In the notation of (4.3) of Ref. 13 we have

$$\mathrm{d}_a \log \tau(ma,\lambda)=\frac{m}{2}\sum_j \{a^j_{1/2,j}(-\lambda)\mathrm{d}a_j+\overrightarrow{a}^j_{1/2,j}(\lambda)\mathrm{d}\overline{a}_j\},$$

and we find for the $m\to 0$ limit,

$$\lim_{m\to 0}\mathrm{d}_a \log \tau(ma,\lambda)=\sum_{j=1}^{N}\left\{\sum_{k\neq j}\frac{\lambda_j\lambda_k}{a_j-a_k}\mathrm{d}a_j+\sum_{k\neq j}\frac{\lambda_j\lambda_k}{\overline{a}_j-\overline{a}_k}\mathrm{d}\overline{a}_j\right\},$$

which is also just

$$\mathrm{d}_a \log \prod_{j<k}|a_j-a_k|^{\lambda_j\lambda_k}.$$

(Received 17 January 2001; accepted for publication 31 October 2001)

Several families of classical integrable systems with two degrees of freedom are derived from phase-space realizations of $sl(2)$ Poisson coalgebras. As a remarkable fact, the existence of the N-dimensional integrable generalization of all these systems is always ensured (by construction) due to their underlying dynamical coalgebra symmetry. By following the same approach, different integrable deformations for such systems are obtained from the q-deformed analogues of $sl(2)$. The well-known Jordan-Schwinger realization is also proven to be related to a (non-coassociative) coalgebra structure on $sl(2)$ and the $2N$ dimensional integrable Hamiltonian generated by such Jordan-Schwinger representation is obtained. Finally, the relation between complete integrability and the properties of the initial phase-space realization is elucidated through two more examples based on the Heisenberg-Weyl and $so(3,2)$ Poisson coalgebras. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1428810]

I. INTRODUCTION

A Poisson coalgebra (A,Δ) is a Poisson algebra A endowed with a Poisson map Δ between A and $A\otimes A$ that defines a way to construct tensor product representations of A. In the case where A is the dynamical algebra for a one-particle problem, the coproduct Δ provides a two-particle realization of the same dynamical symmetry. In fact, under certain conditions the coproduct Δ can be generalized to a Poisson map between A and $A\otimes A\otimes \ldots {}^{N)}\otimes A$, and the N-particle realization of the symmetry arises. By following this approach, a systematic construction of completely integrable (classical and quantum) Hamiltonians from coalgebras has been introduced in Ref. 1 and several applications of this formalism have been proposed (see, for instance, Refs. 2–4).

It is worth stressing that, in order to obtain the complete integrability from the coalgebra structure, the phase-space realization of the symmetry coalgebra has to fulfill some ''non-degeneracy'' conditions. Actually, classical complete integrability is guaranteed provided that the coalgebra comes from a simple Lie algebra of rank r endowed with a symplectic realization on a $2r$-dimensional phase space and the coproducts $\Delta(C_i)$ of the r Casimirs are non-trivial and functionally independent (note that this was the case for all the examples presented within the previous references). Under these conditions the very role of the coproduct map is to provide the explicit form of all the integrals of motion. By construction, such integrals are organized in a hierarchical way: the k-th integral is defined on the k-th order tensor product of the initial representation. From this perspective, the coproduct can be also seen as the vehicle that ''propagates'' the integrability from the initial (trivial) Hamiltonian system to a new non-trivial family of systems with an arbitrary number of degrees of freedom. Moreover, since quantum deformations (see, for instance, Refs. 5–8) can be understood in a classical mechanical context as deformations of Poisson algebras preserving a coalgebra structure, such construction can be applied for them and leads to a systematic derivation of integrable deformations of Hamiltonian systems.

The aim of the present paper is two-fold. On one hand, we use the $sl(2)$ Poisson coalgebra and its deformations to provide new families of completely integrable systems through the previous construction. On the other hand, we would like to clarify the limitations imposed on this formalism by the choice of the phase-space representation of the dynamical Poisson coalgebra. In particular, we shall analyze the systems coming from a four-dimensional phase space realization of a rank one algebra, showing why, in this case, the complete integrability can also be explicitly proven. On the contrary, we also present some particular examples for which a specific choice of the representation gives rise to either trivial or functionally dependent integrals of the motion.

In Sec. II we recall both classical and quantum Poisson $sl(2)$ coalgebras. In Sec. III the general construction is reviewed through an example based on the Gelfan'd-Dyson realization[9] of $sl(2)$, and in Sec. IV new families of $N=2$ integrable systems are given, together with their standard and non-standard integrable deformations. Among them, we find as (canonically equivalent) examples of two-dimensional coalgebra symmetry the well-known Smorodinsky-Winternitz Hamiltonian[10,11] and the rational Calogero system,[12] as a consequence, two new integrable deformations for them can be constructed. In general, it is interesting to mention that quantum deformations introduce hyperbolic functions of the canonical variables in the Hamiltonian, and the associated integrals of the motion have also such kind of hyperbolic terms depending on positions and/or momenta. Note also that the existence of the N-dimensional generalization of all these systems is, by construction, ensured (although we will not describe their explicit form here).

In Sec. V we present the generalization of this construction to $sl(2)$ systems for which the phase-space realization of $sl(2)$ is defined in terms of two pairs of canonical variables. By using the classical Jordan-Schwinger (JS) realization[13,14] as an outstanding example of this kind of situation, we show how complete integrability is also preserved for the corresponding system, now with $2N$ degrees of freedom. Consequently, the deformation of such systems poses the interesting problem of deforming the JS map. It turns out that coalgebra symmetry is also essential at this point, since we show that the Jordan-Schwinger (JS) realization of $sl(2)$ is canonically equivalent to a reducible representation of $sl(2)$ given by a non-coassociative coproduct. From it, a standard deformation of the JS realization is given and related $2N$ dimensional integrable systems can be defined.

Finally, in Sec. VI we turn to Poisson coalgebras other than $sl(2)$ in order to illustrate the above-mentioned limitations of the formalism for certain phase-space realizations of the symmetry coalgebra. First, we consider an example of non-simple algebra, namely the Heisenberg-Weyl one. In this case, for the usual phase space realization the coalgebra method does not allow to prove the complete integrability of the non-deformed system. Remarkably enough on the contrary, the complete integrability of the systems obtained through one of its q-deformations (compatible with the same phase-space realization) can be explicitly demonstrated through the deformed coproduct. Second, a particular two-particle representation of the Poisson $so(3,2)$ algebra is used as a rank-two benchmark for the coalgebra formalism. In this example, the functional dependence of the coproduct of the two Casimir functions implies that only half of the integrals of the motion can be explicitly derived from the coproduct.

II. $sl(2)$ POISSON COALGEBRAS

Let us consider classical angular momentum variables J_3, $J_\pm$ and the associated $sl(2)$ Poisson-Lie algebra

$$\{J_3,J_\pm\}=\pm 2J_\pm, \quad \{J_+,J_-\}=J_3 \tag{2.1}$$

with Casimir function

$$C(J_3,J_+,J_-)=\tfrac{1}{4}J_3^2+J_+J_-. \tag{2.2}$$

The Poisson algebra (2.1) is endowed with a coalgebra structure by the usual ''primitive'' coproduct defined between $sl(2)$ and $sl(2)\otimes sl(2)$

$$\Delta(J_3)=1\otimes J_3+J_3\otimes 1,\quad \Delta(J_\pm)=1\otimes J_\pm+J_\pm\otimes 1. \tag{2.3}$$

Compatibility between Eqs. (2.3) and (2.1) means that Δ is a Poisson map: the three functions defined through Eq. (2.3) close also a Poisson $sl(2)$ algebra.

There are few deformations of the $sl(2)$ algebra for which there exist compatible deformations of the coproduct [Eq. (2.3)]. In fact, two relevant and distinct structures appeared in quantum group literature during last years, and they can be realized as Poisson algebras as follows:

• The "*standard*" deformation $sl_q(2)$ $(q=e^z)$[5,6,15] given by the following deformed Poisson brackets

$$\{\tilde J_3,\tilde J_+\}=2\,\tilde J_+,\quad \{\tilde J_3,\tilde J_-\}=-2\,\tilde J_-,\quad \{\tilde J_+,\tilde J_-\}=\frac{\sinh(z\tilde J_3)}{z}, \tag{2.4}$$

which are compatible with the deformed coproduct

$$\begin{aligned}
&\Delta_z(\tilde J_3)=1\otimes\tilde J_3+\tilde J_3\otimes 1,\\
&\Delta_z(\tilde J_+)=e^{-(z/2)\tilde J_3}\otimes\tilde J_++\tilde J_+\otimes e^{(z/2)\tilde J_3};\\
&\Delta_z(\tilde J_-)=e^{-(z/2)\tilde J_3}\otimes\tilde J_-+\tilde J_-\otimes e^{(z/2)\tilde J_3};
\end{aligned} \tag{2.5}$$

in the sense that Eq. (2.5) is a Poisson algebra homomorphism with respect to (2.4). The function

$$C_z(\tilde J_3,\tilde J_\pm)=\left(\frac{\sinh((z/2)\tilde J_3)}{z}\right)^2+\tilde J_+\tilde J_-, \tag{2.6}$$

is the deformed Casimir for this Poisson coalgebra.

• The "*non-standard*" deformation $sl_h(2)$[16–18] whose defining relations are

$$\{\tilde J_3,\tilde J_+\}=2\,\frac{\sinh(h\tilde J_+)}{h},\quad \{\tilde J_3,\tilde J_-\}=-2\,\tilde J_-\cosh(h\tilde J_+),\quad \{\tilde J_+,\tilde J_-\}=\tilde J_3. \tag{2.7}$$

$$\begin{aligned}
&\Delta_h(\tilde J_+)=1\otimes\tilde J_++\tilde J_+\otimes 1,\\
&\Delta_h(\tilde J_-)=e^{-h\tilde J_+}\otimes\tilde J_-+\tilde J_-\otimes e^{h\tilde J_+},\\
&\Delta_h(\tilde J_3)=e^{-h\tilde J_+}\otimes\tilde J_3+\tilde J_3\otimes e^{h\tilde J_+}.
\end{aligned} \tag{2.8}$$

The non-standard deformed Casimir is now

$$C_h(\tilde J_3,\tilde J_+,\tilde J_-)=\frac{1}{4}\,\tilde J_3^2+\frac{\sinh(h\tilde J_+)}{h}\tilde J_-. \tag{2.9}$$

Equivalently, an isomorphic non-standard Poisson deformation is obtained by choosing $\tilde J_-$ as the primitive generator. We then find that

$$\{\tilde{J}_3,\tilde{J}_+\}=2\,\tilde{J}_+\cosh(h\tilde{J}_-),\quad \{\tilde{J}_3,\tilde{J}_-\}=-2\,\frac{\sinh(h\tilde{J}_-)}{h},\quad \{\tilde{J}_+,\tilde{J}_-\}=\tilde{J}_3. \tag{2.10}$$

$$\begin{aligned}\Delta_h(\tilde{J}_-)&=1\otimes\tilde{J}_-+\tilde{J}_-\otimes 1,\\ \Delta_h(\tilde{J}_+)&=e^{-h\tilde{J}_-}\otimes\tilde{J}_++\tilde{J}_+\otimes e^{h\tilde{J}_-},\\ \Delta_h(\tilde{J}_3)&=e^{-h\tilde{J}_-}\otimes\tilde{J}_3+\tilde{J}_3\otimes e^{h\tilde{J}_-}.\end{aligned} \tag{2.11}$$

The non-standard deformed Casimir is now

$$C_h(\tilde{J}_3,\tilde{J}_+,\tilde{J}_-)=\frac{1}{4}\,\tilde{J}_3^2+\tilde{J}_+\frac{\sinh(h\tilde{J}_-)}{h}. \tag{2.12}$$

In what follows we shall make use of these coalgebra symmetries in order to construct new integrable systems. Note that the undeformed $sl(2)$ structure is smoothly recovered when deformation parameters vanish. Jacobi identity can be also easily checked for Eqs. (2.4), (2.7), and (2.10).

III. GELFAN'D-DYSON MAP, GAUDIN MAGNET, AND DEFORMATIONS

Let us now recall the general construction[1] through an example provided by the classical phase space analogue of the one-boson (polynomial) Gelfan'd-Dyson (GD) realization of $sl(2)$:

$$J_3=2\,p\,q-b,\quad J_+=p,\quad J_-=-p\,q^2+b\,q, \tag{3.1}$$

where b is a real constant that labels the representation through the Casimir [Eq. (2.2)], which turns out to be $b^2/4$ under Eq. (3.1).

Let us now consider an *arbitrary* function $\mathcal{H}(J_3,J_\pm)$. Since the coproduct [Eq. (2.3)] is an algebra homomorphism, it is immediate to prove that the two-particle Hamiltonian that can be defined through the coproduct of H in the form

$$H^{(2)}=\Delta(\mathcal{H}(J_3,J_\pm))=\mathcal{H}(\Delta(J_3),\Delta(J_\pm)) \tag{3.2}$$

will commute with the coproduct $C^{(2)}$ of the Casimir element:

$$\{H^{(2)},C^{(2)}\}=\{\Delta(\mathcal{H}),\Delta(C)\}=\Delta(\{\mathcal{H},C\})=0. \tag{3.3}$$

Therefore, in this case *any* function of the generators defines a two-site integrable Hamiltonian with $sl(2)$ coalgebra symmetry. In particular, the Casimir itself can be taken as the function $\mathcal{H}$ itself. In that case, the constant of motion will be given by the coproduct of any of the generators of the algebra. Explicitly, in the $sl(2)$ case we have

$$\begin{aligned}H_C^{(2)}&:=C(\Delta(J),\Delta(J_+),\Delta(J_-))=\tfrac{1}{4}(1\otimes J_3+J_3\otimes 1)^2+(1\otimes J_++J_+\otimes 1)(1\otimes J_-+J_-\otimes 1)\\ &=1\otimes C+C\otimes 1+\tfrac{1}{2}J_3\otimes J_3+J_-\otimes J_++J_+\otimes J_-,\end{aligned} \tag{3.4}$$

which is just the two-site hyperbolic Gaudin magnet.[19–21] Once Eq. (3.4) is realized in terms of two copies of Eqs. (3.1) we shall obtain an integrable two-particle Hamiltonian

$$H_C^{(2)}(q_1,q_2,p_1,p_2) := \frac{b^2}{4}+\frac{b^2}{4}+\frac{1}{2}(2\,p_1\,q_1-b)(2\,p_2\,q_2-b)$$
$$+(-p_1\,q_1^2+b\,q_1)\,p_2+p_1\,(-p_2\,q_2^2+b\,q_2)$$
$$=-\,p_1\,p_2\,(q_1-q_2)^2-b\,(p_1-p_2)\,(q_1-q_2)+b^2. \tag{3.5}$$

Since $H_C^{(2)}$ is the coproduct of C, it will commute, for instance, with $\Delta(J_+)$, which is just the total momentum p_1+p_2 and gives us the integral of the motion. The generalization of this result to an N-site Gaudin magnet is straightforward by taking into account the appropriate N-th generalization of the coproduct. By following Ref. 1, we obtain that

$$H^{(N)}=\sum_{i=1}^{N} C_i+\sum_{i<j}^{N}\,(\tfrac{1}{2}J_3^i\,J_3^j+J_-^i\,J_+^j+J_+^i\,J_-^j) \tag{3.6}$$

$$=\sum_{i<j}^{N}\{-\,p_i\,p_j\,(q_i-q_j)^2-b\,(p_i-p_j)\,(q_i-q_j)\}+\frac{b^2}{4}N^2. \tag{3.7}$$

The $m=2,\ldots,N$ Hamiltonians $H^{(m)}$, together with the total momentum $\Delta^{(N)}(J_+)=p_1+p_2+\ldots+p_N$ are again the functionally independent N constants of the motion in involution. Note also that we could have taken a different realization on each lattice site through different b_i constants in Eq. (3.1), and the formalism will guarantee the integrability in the same manner (this kind of realizations will be relevant when the coalgebra symmetry of the Calogero system is analyzed in Sec. IV).

Now, the same construction can be applied to deformed $sl(2)$ coalgebras. We shall consider the non-standard one [Eqs. (2.7)–(2.9)]. The following deformed phase-space realization of Eq. (2.7) can be found

$$\tilde{J}_+=p,\quad \tilde{J}=2\,\frac{\sinh(h\,p)}{h}\,q-b\,\cosh(h\,p),$$
$$\tilde{J}_-=-\,\frac{\sinh(h\,p)}{h}\,q^2+b\,\cosh(h\,p)\,q-b^2\frac{h}{4}\sinh(h\,p), \tag{3.8}$$

which leads again the same $b^2/4$ constant when substituted in the deformed Casimir function [Eq. (2.9)]. Therefore, an integrable deformation of the system [Eq. (3.5)] will be given by the deformed coproduct of the (also deformed) Casimir [Eq. (2.9)]. In terms of two phase-space realizations of the type [Eq. (3.8)], the coproduct [Eq. (2.8)] defines the two-particle functions

$$\tilde{f}_+=\Delta_h(\tilde{J}_+)=p_1+p_2,$$
$$\tilde{f}_-=\Delta_h(\tilde{J}_-)=e^{-h\,p_1}\left\{-\,\frac{\sinh(h\,p_2)}{h}\,q_2^2+b\,\cosh(h\,p_2)\,q_2-b^2\frac{h}{4}\sinh(h\,p_2)\right\}$$
$$+\left\{-\,\frac{\sinh(h\,p_1)}{h}\,q_1^2+b\,\cosh(h\,p_1)\,q_1-b^2\frac{h}{4}\sinh(h\,p_1)\right\}e^{h\,p_2}; \tag{3.9}$$
$$\tilde{f}_3=\Delta_h(\tilde{J}_3)=e^{-h\,p_1}\left\{2\,\frac{\sinh(h\,p_2)}{h}\,q_2-b\,\cosh(h\,p_2)\right\}+\left\{2\,\frac{\sinh(h\,p_1)}{h}\,q_1-b\,\cosh(h\,p_1)\right\}e^{h\,p_2}.$$

The corresponding Hamiltonian is obtained as

$$H_h^{(2)}(q_1,q_2,p_1,p_2)=\Delta_h\left(\frac{1}{4}\,\tilde{J}_3^2+\frac{\sinh(h\tilde{J}_+)}{h}\tilde{J}_-\right)$$

$$=\frac{1}{4}\,(\tilde{f}_3)^2+\frac{\sinh(h\tilde{f}_+)}{h}\tilde{f}_-$$

$$=-\frac{\sinh hp_1}{h}e^{-h(p_1-p_2)}\frac{\sinh hp_2}{h}(q_1-q_2)^2-b\,\frac{1-e^{-2h(p_1-p_2)}}{2h}(q_1-q_2)$$

$$+\frac{b^2}{4}(1+e^{-2h\,p_1}+e^{2h\,p_2}+e^{-2h(p_1-p_2)}). \tag{3.10}$$

This Hamiltonian will commute, by construction, with the coproduct of $\tilde{J}_+$ (i.e., the total momentum p_1+p_2 again) and the limit $h\to 0$ of this expression leads to Eq. (3.5). The N-th dimensional integrable generalization of this system is given by the N-th deformed coproduct of the deformed Casimir, and the integrals of motion will be the lower degree coproducts of such Casimir and the N-th total momenta. Apart from the GD realization [Eq. (3.1)], the essential ingredients for the explicit formulation of such system can be extracted from Ref. 1. We stress that, although the next section will be devoted to systems with two degrees of freedom, their corresponding N-dimensional integrable generalizations will be—by construction—completely defined.

IV. $N=2$ SYSTEMS AND THEIR INTEGRABLE DEFORMATIONS

Let us now use realizations of $sl(2)$ linked to well-known dynamical symmetries of physically relevant potentials like the Morse and the harmonic oscillator with centrifugal term in order to obtain new systems with $sl(2)$ coalgebra symmetry.

A. Morse potential realization

If we consider the following $sl(2)$ phase-space realization

$$J_3=2\,p_1,\quad J_+=\tfrac{1}{2}e^{-q_1},\quad J_-=-2\,p_1^2\,e^{q_1}-a_1\,e^{q_1}. \tag{4.1}$$

The dynamical Hamiltonian

$$H_m=\tfrac{1}{8}J_3^2-4\,s\,J_++4\,s\,J_+^2 \tag{4.2}$$

leads to the Morse one:

$$H_m=\tfrac{1}{2}p_1^2+s\,(e^{-2\,q_1}-2\,e^{-q_1}). \tag{4.3}$$

The corresponding Casimir is

$$C_m=\frac{1}{2}\,J_3^2+J_+\,J_-=-\frac{a_1}{2}. \tag{4.4}$$

The two-body system is obtained by applying the method described previously. The coproduct of the Hamiltonian [Eq. (4.2)] in the realization [Eq. (4.1)] is

$$H_m^{(2)}=\tfrac{1}{2}(p_1+p_2)^2+s\,(e^{-2\,q_1}-2\,e^{-q_1})+s\,(e^{-2\,q_2}-2\,e^{-q_2})+2\,s\,e^{-(\,q_1+q_2)}. \tag{4.5}$$

Note that, in general, we could have performed another coalgebra construction by taking different symplectic realizations on each copy of the algebra [for instance [Eq. (4.1)] and [Eq. (3.1)]. Of course, in order to have a Morse-type Hamiltonian, two realizations [Eq. (4.1)] are needed, though with possibly different Casimir values a_1 and a_2. In this way, the coproduct of the Casimir providess a two-parametric family of constants of the motion in the form:

$$C_m^{(2)} = -\tfrac{1}{2}(a_1+a_2) - (\tfrac{1}{2}a_1 + p_1^2)\, e^{\,q_1-q_2} - (\tfrac{1}{2}a_2 + p_2^2) e^{-(q_1-q_2)} + 2\, p_1\, p_2 . \tag{4.6}$$

The Hamiltonian [Eq. (4.5)] can be diagonalized if we consider a canonical transformation

$$P_1 = p_1 + p_2, \quad P_2 = p_2, \quad Q_1 = q_1 \quad Q_2 = q_2 - q_1 . \tag{4.7}$$

This leads to a Hamiltonian in which P_2 does not appear, and consequently the relative position between the particles $Q_2 = q_2 - q_1$ is a constant of the motion. Namely

$$H_{Q_2}^{(2)} = \tfrac{1}{2}P_1^2 + s(e^{-2\,Q_1}(1+e^{-Q_2})^2 - 2\, e^{-Q_1}(1+e^{-Q_2})). \tag{4.8}$$

Note that Eq. (4.8) is a Morse-type problem depending on the constant parameter Q_2. Actually, in the limit $Q_2 \to \infty$ we recover the original Morse potential. It is worth recalling that this kind of parameter-dependent dynamics was already observed in Ref. 22, where the classical motion on the Poisson-Lie $sl(2)$ group was considered. On the other hand, it is immediate to check that the N-dimensional generalization of the system [Eq. (4.5)] can be reduced to the same type of one-dimensional Morse-type problem (now with $N-2$ parameters) through a canonical transformation containing the new total momenta $P_1 = \Sigma_{i=1}^{N} p_i$.

B. Deformed Morse systems

- The *standard* case. The phase space realization

$$\tilde{J}_3 = 2p_1, \quad \tilde{J}_+ = \tfrac{1}{2}e^{-q_1}, \quad \tilde{J}_- = -2\left(\frac{\sinh(z\,p_1)}{z}\right)^2 e^{q_1} - a\, e^{q_1}, \tag{4.9}$$

leads to the $sl_q(2)$ Poisson algebra [Eq. (2.4)]. Therefore, the one-particle Hamiltonian

$$\mathcal{H}_z = \tfrac{1}{8}\tilde{J}_3^2 - 4\, s\, \tilde{J}_+ + 4\, s\, \tilde{J}_+^2 , \tag{4.10}$$

does not change under deformation:

$$H_z = \tfrac{1}{2}p_1^2 + s\,(e^{-2\,q_1} - 2\, e^{-q_1}), \tag{4.11}$$

and the deformed Casimir element [Eq. (2.6)] is just $-a_1/2$.

Let us now construct the associated two-body integrable deformation. By applying the deformed coproduct onto Eq. (4.10) and with the aid of two copies of the realization [Eq. (4.9)] we get

$$H_z^{(2)} = \tfrac{1}{2}(p_1+p_2)^2 + s\,(e^{-2\,(q_1 - z\,p_2)} - 2\, e^{-(q_1 - z\,p_2)}) + s\,(e^{-2(q_2+zp_1)} - 2\, e^{-(q_2+zp_1)}) + 2\, s\, e^{-\{(q_1 - z\,p_2)+(q_2+zp_1)\}}. \tag{4.12}$$

If we substitute again in terms of P_1, we see that P_2 does appear within the Hamiltonian, and the deformation would imply that Q_2 is no longer a constant of motion (however, note the persistent coupling of the type $q_1 - z\,p_2$ and $q_2 + z\,p_1$). The constant of motion for [Eq. (4.12)] would be just the result of taking the phase-space realization of

$$C_z^{(2)} = \Delta_z(C_z) = \left(\frac{\sinh((z/2)\Delta_z(\tilde{J}_3))}{z}\right)^2 + \Delta_z(\tilde{J}_+)\,\Delta_z(\tilde{J}_-). \tag{4.13}$$

Explicitly, Eq. (4.13) gives the following two-particle function:

$$C_z^{(2)}=\left(\frac{\sinh(z(p_1+p_2))}{z}\right)^2-\left(\left(\frac{\sinh z\,p_2}{z}\right)^2+\frac{a_2}{2}\right)(e^{-2zp_1}+e^{-(q_1-q_2)-z\,(p_1-p_2)})$$
$$-\left(\left(\frac{\sinh z\,p_1}{z}\right)^2+\frac{a_1}{2}\right)(e^{2zp_2}+e^{(q_1-q_2)-z\,(p_1-p_2)}). \tag{4.14}$$

Note that the limit $z\to 0$ of Eq. (4.14) leads to Eq. (4.6).

• The *non-standard* case. The deformed phase-space realization corresponding to the $-a/2$ value of the deformed Casimir is now

$$\tilde{J}_3=2\,\frac{\sinh(h\,e^{-q_1}/2)}{(h\,e^{-q_1}/2)}p_1,\quad \tilde{J}_+=\frac{1}{2}\,e^{-q_1},$$
$$\tilde{J}_-=-2e^{q_1}\frac{\sinh(h\,e^{-q_1}/2)}{(h\,e^{-q_1}/2)}p_1^2-h\,\frac{a_1}{\sinh(h\,e^{-q_1}/2)}. \tag{4.15}$$

Therefore, the one-particle Hamiltonian

$$\mathcal{H}=\tfrac{1}{8}\tilde{J}_3^2-4\,s\,\tilde{J}_++4\,s\,\tilde{J}_+^2, \tag{4.16}$$

leads to:

$$H_h^{(2)}=\frac{1}{2}\left(\frac{\sinh(h\,e^{-q_1}/2)}{(h\,e^{-q_1}/2)}\right)^2p_1^2+s\,(e^{-2\,q_1}-2\,e^{-q_1}). \tag{4.17}$$

The two-particle Hamiltonian is obtained from the deformed coproduct [Eq. (2.8)] of Eq. (4.16):

$$H_h^{(2)}=\frac{1}{4}\left(e^{-\,(h/2)\,e^{-q_1}}2\,\frac{\sinh(h\,e^{-q_2}/2)}{(h\,e^{-q_2}/2)}p_2+2\,\frac{\sinh(h\,e^{-q_1}/2)}{(h\,e^{-q_1}/2)}e^{(h/2)\,e^{-q_2}}p_1\right)^2$$
$$+s\,(e^{-2\,q_1}-2\,e^{-q_1})+s\,(e^{-2\,q_2}-2\,e^{-q_2})+2\,s\,e^{-(\,q_1+q_2)}. \tag{4.18}$$

Again, the role of the p_1+p_2 dynamical variable is no longer relevant under deformation. The two-particle Casimir would be obtained as the phase-space realization of

$$\Delta_h(C_h)=\frac{1}{4}\,(\Delta_h(\tilde{J}_3))^2+\frac{\sinh(h\,\Delta_h(\tilde{J}_+))}{h}\Delta_h(\tilde{J}_-) \tag{4.19}$$

in terms of two copies of the non-standard deformation [Eq. (4.15)].

C. The Smorodinsky-Winternitz system

The following realization of $sl(2)$

$$J_3=p_1\,q_1,\quad J_+=\frac{1}{2}\,p_1^2+\frac{c_1}{q_1^2};\quad J_-=-\frac{1}{2}\,q_1^2 \tag{4.20}$$

underlies the $sl(2)$ dynamical symmetry of the harmonic oscillator potential with centrifugal term ($c_1>0$), since by defining

$$\mathcal{H}_c=J_+-\omega^2\,J_- \tag{4.21}$$

we obtain that

$$H=\frac{1}{2}\,(p_1^2+\omega^2\,q_1^2)+\frac{c_1}{q_1^2}. \tag{4.22}$$

Note that the Casimir function is related to the centrifugal term, since

$$C_c=\frac{1}{4}\,J_3^2+J_+\,J_-=\frac{-c_1}{2}. \tag{4.23}$$

The realization [Eq. (4.20)] exhibits a singularity at $J_-=0$: hence, even if the Poisson vector fields associated with Eq. (4.21) are of course complete, such completeness may not be guaranteed at the level of phase-space dynamics. In this particular example, a finite-time divergence arises when $c_1<0$. Actually, for each concrete symplectic realization, a careful analysis of the relation between the Poisson dynamics and the corresponding description(s) in terms of canonical variables is needed.

A two-particle Hamiltonian with coalgebra symmetry can be immediately derived by computing the coproduct of Eq. (4.21). Since this dynamical Hamiltonian is linear in the generators, we have that

$$H^{(2)}=\frac{1}{2}\,(p_1^2+p_2^2)+\frac{1}{2}\;\omega^2(q_1^2+q_2^2)+\frac{c_1}{q_1^2}+\frac{c_2}{q_2^2}, \tag{4.24}$$

in case we assume both phase-space representations not to be the same ($c_1\neq c_2$). This system is the well-known Smorodinsky-Winternitz Hamiltonian (SW),[10,11] and its Casimir function can be straightforwardly obtained through the coproduct of C_c in the actual representation, which reads

$$\Delta(C_c)=C^{(2)}(q_1,q_2,p_1,p_2)=-\frac{1}{4}\,(p_1q_2-p_2q_1)^2-\frac{(q_1^2+q_2^2)}{2}\left(\frac{c_1}{q_1^2}+\frac{c_2}{q_2^2}\right). \tag{4.25}$$

1. Integrable deformations of the SW system

The very same deformation machinery can be now used provided suitable deformed realizations generalizing Eq. (4.20) are found. Hereafter it will be useful to consider the function

$$I_{(1/2)}[t,x]:=\frac{\sinh(t\,x/2)}{t\,x}. \tag{4.26}$$

Note that $\lim_{t\to 0} I_{(1/2)}[t,x]=1/2$.

• The *standard* case. The deformed realization is

$$\begin{gathered}\tilde{J}_3=p_1\,q_1,\quad \tilde{J}_+=I_{(1/2)}[z,p_1\,q_1]\,p_1^2+\frac{1}{2\,I_{(1/2)}[z,p_1\,q_1]}\,\frac{c_1}{q_1^2},\\ \tilde{J}_-=-I_{(1/2)}[z,p_1\,q_1]\,q_1^2.\end{gathered} \tag{4.27}$$

The one-particle Hamiltonian derived from

$$\mathcal{H}_z=\tilde{J}_+-\omega^2\tilde{J}_- \tag{4.28}$$

that in this realization becomes:

$$H_z=I_{(1/2)}[z,p_1\,q_1](p_1^2+\omega^2q_1^2)+\frac{1}{2\,I_{(1/2)}[z,p_1\,q_1]}\,\frac{c_1}{q_1^2}. \tag{4.29}$$

The deformed Casimir function is again

$$C_z=\left(\frac{\sinh(z\,\tilde{J}_3/2)}{z}\right)^2+\tilde{J}_+\,\tilde{J}_-=\frac{-c_1}{2}. \tag{4.30}$$

When the deformed coproduct of Eq. (4.28) is realized in terms of two-phase space realizations of the type [Eq. (4.27)] it leads to the following integrable two-particle Hamiltonian:

$$\begin{aligned}H_z^{(2)}=&\left(I_{(1/2)}[z,p_1\,q_1](p_1^2+\omega^2q_1^2)+\frac{1}{2\,I_{(1/2)}[z,p_1\,q_1]}\,\frac{c_1}{q_1^2}\right)e^{z\,p_2q_2/2}\\&+\left(I_{(1/2)}[z,p_2\,q_2](p_2^2+\omega^2q_2^2)+\frac{1}{2\,I_{(1/2)}[z,p_2\,q_2]}\,\frac{c_2}{q_2^2}\right)e^{-z\,p_1q_1/2}\\=&H^{(2)}+z\left\{p_2\,q_2\left(\frac{1}{2}\,p_1^2+\frac{1}{2}\;\omega^2q_1^2+\frac{c_1}{q_1^2}\right)-p_1\,q_1\left(\frac{1}{2}\,p_2^2+\frac{1}{2}\;\omega^2q_2^2+\frac{c_2}{q_2^2}\right)\right\}+o[z^2].\end{aligned} \tag{4.31}$$

Note that this power series expansion shows how the undeformed one-particle Hamiltonians arises in the first order of the perturbation. As usual, the constant of the motion wil be given by Eq. (4.13) where we should use two copies of the proper realization Eq. (4.27). As a result, we obtain

$$\begin{aligned}C_z^{(2)}=&\left(\frac{\sinh(z(p_1+p_2)/2)}{z}\right)^2-\left\{e^{-z\,p_1\,q_1}\left(I_{(1/2)}[z,p_2\,q_2]^2\,p_2^2\,q_2^2+\frac{c_2}{2}\right)\right.\\&\left.+e^{z\,p_2\,q_2}\left(I_{(1/2)}[z,p_1\,q_1]^2\,p_1^2\,q_1^2+\frac{c_1}{2}\right)\right\}-I_{(1/2)}[z,p_1\,q_1]\,I_{(1/2)}[z,p_2\,q_2]\\&\times\left\{(\,p_1^2\,q_2^2+\,p_2^2\,q_1^2)+\frac{1}{2}\left(\frac{c_1}{I_{(1/2)}[z,p_1\,q_1]^2}\,\frac{q_2^2}{q_1^2}+\frac{c_2}{I_{(1/2)}[z,p_2\,q_2]^2}\,\frac{q_1^2}{q_2^2}\right)\right\}.\end{aligned} \tag{4.32}$$

A straightforward computation shows that the limit $z\to 0$ of this integral gives the undeformed one [Eq. (4.25)].

• The *non-standard* case. The deformed realization for the non-standard $sl_h(2)$ Poisson algebra with $\tilde{J}_-$ as primitive generator [Eq. (2.10)] is:

$$\tilde{J}_3=2\,I_{(1/2)}[h,q_1^2]\,q_1\,p_1,\quad \tilde{J}_+=I_{(1/2)}[h,q_1^2]\,p_1^2+\frac{c_1}{2\,I_{(1/2)}[h,q_1^2]\,q_1^2},\quad \tilde{J}_-=-\frac{1}{2}\;q_1^2. \tag{4.33}$$

If we consider again the dynamical one-particle Hamiltonian as

$$\mathcal{H}_h=\tilde{J}_+-\omega^2\tilde{J}_-, \tag{4.34}$$

we obtain the following deformation of Eq. (4.22):

$$H_h=p_1^2\,I_{(1/2)}[h,q_1^2]+\frac{1}{2}\;\omega^2\,q_1^2+\frac{c_1}{2\,I_{(1/2)}[h,q_1^2]\,q_1^2}. \tag{4.35}$$

The corresponding two-body system is, as usual, provided by the non-standard coproduct of the dynamical Hamiltonian [Eq. (4.34)], that reads

$$H_h^{(2)}=\left(I_{(1/2)}[h,q_1^2]p_1^2+\frac{c_1}{2\,I_{(1/2)}[h,q_1^2]\,q_1^2}\right)e^{-h\,q_2^2/2}+\left(I_{(1/2)}[h,q_2^2]p_2^2+\frac{c_2}{2\,I_{(1/2)}[h,q_2^2]\,q_2^2}\right)e^{h\,q_1^2/2}$$
$$+\frac{1}{2}\,\omega^2\,(q_1^2+q_2^2)=H^{(2)}+\frac{h}{2}\left\{q_1^2\left(\frac{1}{2}\,p_2^2+\frac{c_2}{q_2^2}\right)-q_2^2\left(\frac{1}{2}\,p_1^2+\frac{c_1}{q_1^2}\right)\right\}+o[h^2]. \tag{4.36}$$

Note that this power series expansion shows the presence of ''crossed'' oscillator and centrifugal terms coming from the deformation. Finally, the associated constant of the motion can be deduced from the coproduct of the non-standard Casimir equation (2.12) under two realizations of the type [Eq. (4.33)]. We recall that that the N-dimensional generalization of this non-standard deformation has been explicitly obtained in Ref. 4.

2. Coalgebra symmetry of the N=2 rational Calogero system

Let us now consider the $N=2$ rational Calogero Hamiltonian[12]

$$H_{\alpha,\beta}^{(2)}(Q,P)=\tfrac{1}{2}(P_1^2+P_2^2)+\Omega^2(Q_1^2+Q_2^2)+\frac{\alpha}{(Q_1-Q_2)^2}+\frac{\beta}{(Q_1+Q_2)^2}. \tag{4.37}$$

It turns out that the canonical transformation

$$Q_1:=(q_1+q_2)/2,\quad Q_2:=(q_2-q_1)/2,\quad P_1:=p_1+p_2,\quad P_2:=p_2-p_1 \tag{4.38}$$

leads to the identification

$$H_{\alpha,\beta}^{(2)}(Q,P)=2\,H^{(2)}(q,p), \tag{4.39}$$

where $H^{(2)}(q,p)$ is given by Eq. (4.24) with $\Omega^2=\omega^2/2$, $\alpha=2\,c_1$, and $\beta=2\,c_2$.

Therefore, the Calogero Hamiltonian [Eq. (4.37)] does have $sl(2)$ coalgebra symmetry, being canonically equivalent to the (non-deformed) coproduct of $\mathcal{H}:=2\,(J_+-\omega^2\,J_-)$ and provided that two appropriate (and in general, different) phase-space realizations of $sl(2)$ are considered. Moreover, an integral of the motion for Eq. (4.37) is immediately deduced from the coalgebra symmetry, since it will be given by the (canonically transformed) coproduct of the $sl(2)$ Casimir given by Eq. (4.25), namely:

$$C_{\alpha,\beta}^{(2)}(Q,P)=-\tfrac{1}{4}(P_1Q_2-P_2Q_1)^2-(Q_1^2+Q_2^2)\left(\frac{\alpha/2}{(Q_1-Q_2)^2}+\frac{\beta/2}{(Q_1+Q_2)^2}\right). \tag{4.40}$$

As a further consequence, the coalgebra symmetry provides a systematic procedure to get integrable deformations of the $N=2$ Calogero system. In particular, a factor two times the deformed Hamiltonians [Eqs. (4.31) and (4.36)] will give rise [respectively, and by using the inverse of the canonical transformation of Eq. (4.38)] to the standard and non-standard deformations of $H_{\alpha,\beta}^{(2)}(Q,P)$. Once again, corresponding deformed integrals would be given by the inverse canonical transformation of the coproduct of the deformed Casimirs in the original (q,p) variables.

V. TWO-PARTICLE REALIZATIONS AND 2 *N* DIMENSIONAL SYSTEMS

So far we have considered one-particle phase-space realizations of coalgebras, but this is not the most general possibility. For instance, the classical analogue of the so-called Jordan-Schwinger (JS) realization of $sl(2)$ would be

$$J_3=a_1^+\,a_1-b_1^+\,b_1=\mathcal{N}_1^a-\mathcal{N}_1^b,\quad J_+=b_1\,a_1^+,\quad J_-=a_1\,b_1^+, \tag{5.1}$$

where $\{a_1,a_1^+\}=\{b_1,b_1^+\}=1$. This realization can be used to construct integrable systems by using the coalgebra approach, but now each $sl(2)$ copy will have two degrees of freedom.

Therefore, Eq. (5.1) would give rise to a $2N$ dimensional system, whose complete integrability will be linked to the existence of $2N$ quantities in involution. N of them are provided from the previous formalism (the m-th coproducts of the Casimir and the N-th coproduct of the dynamical Hamiltonian). However, N more integrals are also available if we take into account that, under Eq. (5.1), the Casimir of $sl(2)$ is no longer a numerical constant, but a two-particle function. Namely,

$$C_i=\tfrac{1}{4}(J_3^i)^2+J_+^i\,J_-^i=\tfrac{1}{4}(a_i^+\,a_i+b_i^+\,b_i)^2=\tfrac{1}{4}(\mathcal{N}_i^a+\mathcal{N}_i^b)^2. \tag{5.2}$$

And we have N of this quantities (in terms of classical number operators) that, by construction, will commute with the N integrals coming from the coproduct. For instance, from Eq. (3.6) we find that the JS classical Gaudin magnet is

$$\begin{aligned}H_{\mathrm{JS}}^{(N)}&=\sum_{i=1}^{N}C_i+\sum_{i<j}^{N}\left(\tfrac{1}{2}J_3^iJ_3^j+J_-^iJ_+^j+J_+^iJ_-^j\right)\\&=\frac{1}{4}\sum_{i=1}^{N}(\mathcal{N}_i^a+\mathcal{N}_i^b)^2+\frac{1}{2}\sum_{i<j}^{N}(\mathcal{N}_i^a-\mathcal{N}_i^b)(\mathcal{N}_j^a-\mathcal{N}_j^b)+\sum_{i<j}^{N}(a_i^+\,b_j^+\,a_j\,b_i+b_i^+\,a_j^+\,b_j\,a_i).\end{aligned} \tag{5.3}$$

Therefore, this Hamiltonian is completely integrable, since it is in involution with both the C_i functions [Eq. (5.2)] and the ''lower dimensional'' Hamiltonians $H_{JS}^{(m)}$. Finally, we remark that the last term in Eq. (5.3) is just the classical counterpart of a long-range interacting system with a four-wave interaction Hamiltonian mixing each pair of sites (see Ref. 23 for related quantum optical integrable systems).

A. Jordan-Schwinger map and coalgebra structure

At this point, it becomes clear that a suitable deformation of the classical JS map [Eq. (5.1)] would give rise to a new class of $2N$ dimensional $sl_q(2)$ invariant Hamiltonians. The answer to this question can be directly related to the study of the reducibility properties of the classical JS map, and it will lead us to a new interesting type of coalgebra structures.

A straightforward computation shows that the $\overline{J_i}$ functions

$$\begin{aligned}\overline{J_3}&=\overline{\Delta}(J_3)=1\otimes J_3+J_3\otimes 1,\\ \overline{J_+}&=\overline{\Delta}(J_+)=1\otimes J_+-J_+\otimes 1,\\ \overline{J_-}&=\overline{\Delta}(J_-)=1\otimes J_--J_-\otimes 1\end{aligned} \tag{5.4}$$

close a $sl(2)$ algebra. We could now consider a pair of ''harmonic oscillator'' realizations-given by Eq. (4.20) with $c=0$-and obtain a realization of Eq. (5.4) on the two-particle phase space in the form

$$\overline{J_3}=p_1\,q_1+p_2\,q_2,\quad \overline{J_+}=\tfrac{1}{2}(p_1^2-p_2^2),\quad \overline{J_-}=-\tfrac{1}{2}(q_1^2-q_2^2). \tag{5.5}$$

Now, the following canonical transformation can be defined

$$p_1 = b_1 + \tfrac{1}{2}a_1^+, \quad q_1 = a_1 - \tfrac{1}{2}b_1^+,$$
$$p_2 = b_1 - \tfrac{1}{2}a_1^+, \quad q_2 = -a_1 - \tfrac{1}{2}b_1^+. \tag{5.6}$$

By substituting Eq. (5.6) into Eq. (5.5) we recover Eq. (5.1). Therefore, the JS realization is canonically equivalent to a ''fermionic coproduct'' [Eq. (5.4)] of two irreps of $sl(2)$. Note that the map $\overline{\Delta}$ defined by Eq. (5.4) is not coassociative since

$$(id \otimes \overline{\Delta}) \circ \Delta \neq (\overline{\Delta} \otimes id) \circ \overline{\Delta}. \tag{5.7}$$

The coalgebra structure allows us to perform the same trick in the deformed case, where we can obtain the deformed realization by setting

$$\overline{\Delta}_z(\tilde{J}_3) = 1 \otimes \tilde{J}_3 + \tilde{J}_3 \otimes 1,$$
$$\overline{\Delta}_z(\tilde{J}_+) = e^{-(z/2)\tilde{J}_3} \otimes \tilde{J}_+ - \tilde{J}_+ \otimes e^{(z/2)\tilde{J}_3}, \tag{5.8}$$
$$\overline{\Delta}_z(\tilde{J}_-) = e^{-(z/2)\tilde{J}_3} \otimes \tilde{J}_- - \tilde{J}_- \otimes e^{(z/2)\tilde{J}_3}.$$

These expressions are compatible with $sl_q(2)$ brackets [Eq. (2.4)] and define a non-cocommutative and non-coassociative homomorphism. From them, the $sl_q(2)$ generators can be expressed in terms of two phase-space realizations [Eq. (4.27)] with $c=0$:

$$\tilde{f}_3 = \overline{\Delta}_z(\tilde{J}_3) = p_1 q_1 + p_2 q_2,$$
$$\tilde{f}_+ = \overline{\Delta}_z(\tilde{J}_+) = e^{-(z/2) p_1 q_1} I_{(1/2)}[z, q_2 p_2]\, p_2^2 - I_{(1/2)}[z, q_1 p_1]\, p_1^2\, e^{(z/2) p_2 q_2}, \tag{5.9}$$
$$\tilde{f}_- = \overline{\Delta}_z(\tilde{J}_-) = -e^{-(z/2) p_1 q_1} I_{(1/2)}[z, q_2 p_2]\, q_2^2 + I_{(1/2)}[z, q_1 p_1]\, q_1^2\, e^{z/2 p_2 q_2}.$$

Now, if we apply the canonical transformation [Eq. (5.6)] onto the functions $\tilde{f}_i$, we shall obtain the appropriate standard deformation of the JS map [Eq. (5.1)], that can be recovered in the limit $z \to 0$.

Note that the q-deformation of the JS map has been treated in the previous literature[24] by making use of a deforming functional approach.[25,26] However, the discovery of its ''internal'' coalgebra structure makes it possible to give an answer in terms of the $su_q(2)$ properties. It is also worthy to stress that the non-standard deformation seems not to be compatible with such ''fermionic'' comultiplication.

Finally, we mention that the construction of a $2N$ dimensional standard deformation of the Gaudin-JS system [Eq. (5.3)] is straightforward by considering N copies of the deformed JS map [Eq. (5.9)] and by representing through them the N-th deformed coproduct of the standard $sl_q(2)$ Casimir [Eq. (2.6)]. The integrals of motion will be given by the M-th coproducts ($M = 2, \ldots, N-1$) of such deformed Casimir and by the N different functions C_i^z defined by the expressions of the $sl_q(2)$ Casimir on each copy of the JS realization.

VI. ON THE ROLE OF THE REPRESENTATION: BEYOND $sl(2)$

The aim of this Section is to emphasize that the coalgebra symmetry of the Hamiltonian can be used to obtain the full set of integrals of the motion provided that the initial phase space representation fulfills the sufficient conditions that have been stated in Sec. I. This has been the case for the examples presented so far, all of them based on $sl(2)$. As we shall see in the sequel, if we consider either non-simple algebras or higher rank ones, it could happen that the initial representation does not satisfy such requirements. In the cases presented here the integrals coming from the coproduct of the Casimirs turn out to be either trivial ones (Heisenberg-Weyl example) or

functionally dependent [$so(3,2)$ representation]. However, it is worth mentioning that certain deformations can help to overcome these restrictions, as we shall see in the Heisenberg-Weyl case.

A. Heisenberg-Weyl coalgebras

The Heisenberg-Weyl Poisson algebra h_3

$$\{A_-,A_+\}=M \quad \{A_-,M\}=0 \quad \{A_+,M\}=0 \tag{6.1}$$

is endowed with a Poisson coalgebra structure by means of the usual primitive coproduct

$$\Delta(M)=1\otimes M+M\otimes 1, \quad \Delta(A_\pm)=1\otimes A_\pm+A_\pm\otimes 1. \tag{6.2}$$

Note that the Casimir function for h_3 is just the central generator M. The natural phase-space realization for h_3 is given by

$$A_-=\omega_1 q_1, \quad A_+=p_1, \quad M=\omega_1. \tag{6.3}$$

If we consider the quadratic function

$$\mathcal{H}=A_+^2+A_-^2, \tag{6.4}$$

the associated one-particle Hamiltonian will be $H^{(1)}=p_1^2+\omega_1^2 q_1^2$, and the Casimir function is just the constant $C^{(1)}=M=\omega_1$. By following the coalgebra picture, the two-particle Hamiltonian $H^{(2)}=\Delta(\mathcal{H})$ reads:

$$H^{(2)}=p_1^2+p_2^2+\omega_1^2 q_1^2+\omega_2^2 q_2^2+2(p_1p_2+\omega_1\omega_2 q_1 q_2). \tag{6.5}$$

The constant of motion $C^{(2)}$ would be the coproduct of the Casimir $C^{(2)}=\Delta(C)=\omega_1+\omega_2$. Obviously, the generalization of this construction to N-particles will give the sum of the constants ω_i as the corresponding integrals. Therefore, the coalgebra symmetry is not able to provide a set of non-trivial constants of motion for this system (which is actually a completely integrable one).

However, this problem is surprisingly removed when we consider a certain quantum deformation of the Heisenberg-Weyl algebra. Let us introduce the quantum algebra $U_z(h_3)$ with deformed coproduct,[27]

$$\begin{aligned}
\Delta_z(A_-)&=1\otimes A_-+A_-\otimes 1\\
\Delta_z(A_+)&=e^{-zA_-}\otimes A_+ + A_+\otimes e^{zA_-}\\
\Delta_z(M)&=e^{-zA_-}\otimes M+M\otimes e^{zA_-}.
\end{aligned} \tag{6.6}$$

This coproduct is compatible with the non-deformed Poisson brakets [Eq. (6.1)]. As a consequence, the Casimir coincides again with M and the one-particle representation [Eq. (6.3)] also holds for the deformed case.

In fact, the deformation is restricted to the coproduct and, consequently, it will become apparent in the two-particle system. Although the phase-space realizations on each space are classical ones, their composition law [Eq. (6.6)] is not, and leads to the following two-particle functions

$$\begin{aligned}
\Delta_z(A_-)&=\omega_1 q_1+\omega_2 q_2\\
\Delta_z(A_+)&=p_2 e^{-z\omega_1 q_1}+p_1 e^{z\omega_2 q_2}\\
\Delta_z(M)&=\omega_2 e^{-z\omega_1 q_1}+\omega_1 e^{z\omega_2 q_2},
\end{aligned} \tag{6.7}$$

whose Poisson brackets will close again the h_3 Poisson algebra. If the function $\mathcal{H}$ given in Eq. (6.4) is considered, these expressions will lead to a deformed two-particle Hamiltonian

$$H_z^{(2)}=\Delta_z(\mathcal{H})=p_1^2\,e^{2z\omega_2 q_2}+p_2^2 e^{-2z\omega_1 q_1}+\omega_1^2 q_1^2+\omega_2^2 q_2^2+2\{p_1\,p_2 e^{-z(\omega_1 q_1-\omega_2 q_2)}+\omega_1\omega_2 q_1 q_2\}. \tag{6.8}$$

But now the deformed two-particle Casimir is no longer a constant:

$$C_z^{(2)}=\Delta_z(\mathcal{C})=\omega_1 e^{z\omega_2 q_2}+\omega_2 e^{-z\omega_1 q_1}. \tag{6.9}$$

Therefore, the non-primitive nature of the coproduct of the Casimir turns out to be an essential difference with respect to the non-deformed coalgebra and provides the non-trivial integral for the system (6.8).

B. A Poisson-$so(3,2)$ coalgebra

Finally, let us consider a representation of the Poisson $so(3,2)$ algebra with generators $\{E_0,E_\pm,F_0,F_\pm,C_\pm,D_\pm\}$ given by the two-particle functions

$$\begin{gathered} E_0=\tfrac{1}{2}p_1\,q_1,\quad E_+=\tfrac{1}{2}p_1^2,\quad E_-=\tfrac{1}{2}q_1^2,\\ F_0=\tfrac{1}{2}p_2\,q_2,\quad F_+=\tfrac{1}{2}p_2^2,\quad F_-=\tfrac{1}{2}q_2^2,\\ C_+=p_1\,q_2,\quad C_-=q_1\,p_2,\quad D_+=p_1\,p_2,\quad D_-=q_1\,q_2. \end{gathered} \tag{6.10}$$

The algebra $so(3,2)$ is of rank two (E_0 and F_0 are the generators of the Cartan sub-algebra) and, consequently, it has two independent Casimir functions,[28,29] that in this Poisson algebra context are given by

$$I_1=2\,(-E_0^2+E_+\,E_-)+2\,(-F_0^2+F_+\,F_-), \tag{6.11}$$

$$I_2=\{C_+,\Phi\}\,\{C_-,\Phi\}-\{D_+,\Phi\}\,\{D_-,\Phi\}-\Phi^2, \tag{6.12}$$

where $\Phi=(-E_0^2+E_+\,E_-)-(-F_0^2+F_+\,F_-)$ and $\{\cdot,\cdot\}$ is the Poisson bracket on $so(3,2)^*$. Note that in the representation [Eq. (6.10)] both Casimir functions vanish.

Obviously, the primitive coproduct $\Delta(X)=1\otimes X+X\otimes 1$ endows the $so(3,2)$ algebra with a coalgebra structure and the representation [Eq. (6.10)] has the same number of degrees of freedom as the rank of the algebra. A straightforward computation of the coproduct of the Casimir I_1 gives the four-particle integral

$$I_1^{(2)}=\Delta(I_1)=\tfrac{1}{2}(p_3\,q_1+p_4\,q_2-p_1\,q_3-p_2\,q_4)^2, \tag{6.13}$$

where the variables (p_3,q_3,p_4,q_4) come from to the second copy of the algebra. However, the coproduct of the second Casimir leads to a non-trivial second integral that is functionally dependent with respect to Eq. (6.13); namely $I_2^{(2)}=-(I_1^{(2)})^2/4$. As a consequence, the realization [Eq. (6.10)] of the $so(3,2)$ coalgebra can be used as the elementary block in order to construct N integrals of the motion in involution for a number of Hamiltonian systems with $2N$ degrees of freedom, but it does not account for the complete integrability of such systems. In this context, an interestingly open problem would be to determine whether some Poisson coalgebra deformation of $so(3,2)$ could break the functional dependence of the second set of corresponding (deformed) integrals.

(Received 21 August 2001; accepted for publication 1 November 2001)

A Hamiltonian with two degrees of freedom is said to be superintegrable if it admits three functionally independent integrals of the motion. This property has been extensively studied in the case of two-dimensional spaces of constant (possibly zero) curvature when all the independent integrals are either quadratic or linear in the canonical momenta. In this article the first steps are taken to solve the problem of superintegrability of this type on an arbitrary curved manifold in two dimensions. This is done by examining in detail one of the spaces of revolution found by G. Koenigs. We determine that there are essentially three distinct potentials which when added to the free Hamiltonian of this space have this type of superintegrability. Separation of variables for the associated Hamilton–Jacobi and Schrödinger equations is discussed. The classical and quantum quadratic algebras associated with each of these potentials are determined. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1429322]

I. INTRODUCTION

A Hamiltonian system in classical mechanics with n degrees of freedom is described by a Hamiltonian function $H(x_1,\ldots,x_n,p_1,\ldots,p_n)=H(x,p)$. The dynamics of such a system is described by Hamilton's equations

$$\dot{x}_i=\frac{\partial H}{\partial p_i},\quad \dot{p}_i=-\frac{\partial H}{\partial x_i}. \tag{1}$$

The time rate of change of a classical observable $\ell=\ell(x,p)$ is given by

$$\frac{d\ell}{dt}=\{\ell,H\}=\sum_{i=1}^{n}\left(\frac{\partial \ell}{\partial x_i}\frac{\partial H}{\partial p_i}-\frac{\partial \ell}{\partial p_i}\frac{\partial H}{\partial x_i}\right), \tag{2}$$

where $\{,\}$ is the Poisson bracket. A Hamiltonian system is called "Liouville integrable" if it admits n functionally independent integrals of motion $\{X_1,\ldots,X_n\}$ which are mutually in involution, i.e.,

$$\{X_i,X_j\}=0,\quad i,j=1,\ldots,n, \tag{3}$$

where one of these constants can be taken to be the Hamiltonian H.[1,2] The system is superintegrable if a further m integrals $\{Y_1,\ldots,Y_m,1\leqslant m\leqslant n-1\}$ exist such that the set of constants $\{X_1=H,X_2,\ldots,X_n,Y_1,\ldots,Y_m\}$ is functionally independent. The additional integrals have vanishing

[a]Electronic mail: e.kalnins@waikato.ac.nz
[b]Electronic mail: jonathan@math.waikato.ac.nz
[c]Electronic mail: wintern@crm.umontreal.ca

Poisson bracket with H, but not necessarily with each other or with the X_i's. A classical Hamiltonian system is maximally superintegrable if $m=n-1$. There are then $2n-1$ functionally independent integrals of motion. The concepts of complete integrability and superintegrability have their analog in quantum mechanics. In this case a superintegrable quantum mechanical system is described by $n+m$ quantum observables $\{\hat{X}_1=\hat{H},\hat{X}_2,\ldots,\hat{X}_n,\hat{Y}_1,\ldots,\hat{Y}_m\}$ which satisfy the commutation relations

$$[\hat{H},\hat{X}_i]=\hat{H}\hat{X}_i-\hat{X}_i\hat{H}=0,\quad [\hat{H},\hat{Y}_j]=0,\quad [\hat{X}_i,\hat{X}_k]=0, \tag{4}$$

where $i,k=1,...,n$, $j=1,...,m$. For superintegrable classical Hamiltonian systems it is often the case that the elements of our set of constants are polynomial in the canonical momenta. The best known maximally superintegrable systems in Euclidean space E_n are the Kepler problem and the harmonic oscillator. All finite (bounded) trajectories in these two systems are closed. Moreover, these are the only spherically symmetric potentials for which all finite trajectories are closed.[3]

Systematic studies of superintegrable systems have been conducted for spaces of constant curvature in two and three dimensions.[4–10] In particular, a complete classification of all superintegrable systems in the real Euclidean spaces E_2 and E_3 with at most second order integrals of motion was given.[4–8] More recently, a relation between superintegrable systems and generalized Lie symmetries has been established,[11] as well as their relation to exactly solvable problems in quantum mechanics.[12] Recently[13–15] it has been possible to classify all maximally superintegrable systems for spaces of constant curvature (possibly zero) in two dimensions for which all the extra constants of the motion are at most quadratic in the canonical momenta.

A natural question to ask is whether the concept of superintegrability is restricted to spaces of constant curvature. The purpose of this article is to show that this is not so and to start a study of superintegrable systems in more general Riemannian, pseudo-Riemannian and complex Riemannian spaces. More specifically, we consider real two-dimensional spaces and search for Hamiltonian systems allowing additional constants of the motion that are at most quadratic in the momenta.

To make initial progress on this problem we first need to know which Riemannian spaces in two dimensions have associated with them more than one classical quadratic constant of the motion. This is a problem that has been comprehensively solved by Koenigs[16] in a note written in Vol. IV of the treatise of Darboux.[17]

In addition to being of intrinsic interest, additional motivation for this problem comes from the observation that all two-dimensional Riemannian spaces can be embedded in the three-dimensional Euclidean or pseudo-Euclidean space. Consequently, any such two-dimensional classical motion is equivalent to a constrained motion in three dimensions. It is also possible to interpret the motion, via general relativity, as motion in a two-dimensional gravitational field.

Given that we have a Riemannian space in two dimensions with infinitesimal distance

$$ds^2=g_{ij}(u)du^i du^j,\quad i,j=1,2, \tag{5}$$

and $u=(u^1,u^2)$, the classical Hamiltonian has the form

$$H=\tfrac{1}{2}g^{ij}p_i p_j+V(u) \tag{6}$$

and the corresponding Schrödinger equation can be taken to have the form

$$\hat{H}\Psi=-\frac{1}{2\sqrt{g}}\partial_{u^i}(\sqrt{g}g^{ik}\partial_{u^k}\Psi)+V(u)\Psi=E\Psi, \tag{7}$$

where $g=\det(g_{ij})$. For the classical Hamiltonian H our problem is to look for potentials $V(u)$ and Riemannian spaces specified by the metric g_{ij} for which there are at least two extra functionally independent constants of the motion of the form

$$\lambda_1=a^{ij}(u)p_i p_j+b(u) \tag{8}$$

or

$$\lambda_2 = a^i(u)p_i + c(u), \tag{9}$$

other than H. One well known way of solving the corresponding classical problem is to use Hamilton–Jacobi theory. The crucial equation to solve is then the Hamilton–Jacobi equation obtained from the equation $H=E$ via the substitution $p_i = \partial S/\partial u^i$, that is,

$$H = \frac{1}{2} g^{ij} \frac{\partial S}{\partial u^i} \frac{\partial S}{\partial u^j} + V(u) = E. \tag{10}$$

This equation is sometimes solvable by the method of separation of variables using the additive separation ansatz

$$S = S_1(u^1, \alpha, E) + S_2(u^2, \alpha, E). \tag{11}$$

The corresponding Schrödinger equation can also be solved by separation of variables with the product ansatz

$$\Psi = \psi_1(u^1, \lambda, E)\psi_2(u^2, \lambda, E). \tag{12}$$

The quantities λ_i are constants of the motion if

$$\{\lambda_i, H\} = 0. \tag{13}$$

For λ_2 this implies that $a^i(u)$ is a Killing vector and $a^i(u)p_i$ is a symmetry of the free Hamiltonian [H without $V(u)$]. In the case of λ_1 this implies that $a^{ij}(u)$ is a Killing tensor. Such tensors are directly related to the notion of additive separation as described above. We note that for constants of the type λ_2, the condition implies $c(u)=0$. It is also clear that for every constant linear in the momenta, its square is a constant quadratic in the momenta, that is, of the form of λ_1.

As mentioned earlier, Darboux and Koenigs have given a comprehensive analysis of when a two-dimensional Riemannian space admits more than one quadratic constant. In Sec. II we summarize some of these results.[16,17] In the remaining sections we concentrate on a particular space with a Killing vector and two Killing tensors. Section III deals with the free Hamilton–Jacobi equation and we show that the Schrödinger equation allows separation of variables in three different coordinates systems which we determine explicitly. Potentials that allow separation of variables in these systems are then introduced. In Sec. IV we find all potentials with this superintegrability property. We then discuss in Sec. V the various surfaces that may be represented by the infinitesimal distances that we have and the consequent special functions that arise from the corresponding Schrödinger equation.

II. ON GEODESICS WITH QUADRATIC INTEGRALS

In 1889 G. Koenigs[16] wrote a note in the last volume of Darboux's treatise "Théorie générale de surfaces," the title of which coincides with the title of this section. This note contains a summary of results which are the solution of the problem outlined in the Introduction, viz. when does the free Hamiltonian of a two-dimensional Riemannian space admit more than one quadratic constant of the motion. The analysis was performed over the field of complex numbers and must be modified over the reals. What Koenigs did was to write the infinitesimal distance for a general two-dimensional Riemannian space in the form

$$ds^2 = 4f(x,y)dxdy. \tag{14}$$

This can always be done in two dimensions over $\mathbb{C}$. The corresponding free Hamiltonian then has the form

$$H=\frac{1}{2f(x,y)}p_x p_y. \tag{15}$$

By making the requirement that there is a second order Killing tensor of the form

$$\lambda=a^{ij}(u)p_i p_j, \tag{16}$$

Darboux and Koenigs establish the following propositions.

(1) Any two-dimensional Riemannian space that admits more than one Killing vector must be a space of constant curvature and admit three linearly independent Killing vectors.
(2) Any two-dimensional Riemannian space that admits more than three Killing tensors is a space of constant curvature. It then actually admits five linearly independent Killing tensors which are all bilinear expressions in the Killing vectors. The sixth bilinear combination is the Hamiltonian itself.
(3) Any two-dimensional Riemannian space that admits precisely three linearly independent Killing tensors will be a Riemannian space of revolution. In fact, there will be one Killing vector and two Killing tensors.

Two-dimensional Riemannian spaces of this latter type were distinguished to be of four types. The infinitesimal distances of these types are given by

(I) $ds^2=(x+y)dxdy$,
(II) $ds^2=(a/(x-y)^2+b)dxdy$,
(III) $ds^2=(ae^{-(x+y)/2}+be^{-x-y})dxdy$,
(IV) $ds^2=(a(e^{(x-y)/2}+e^{(y-x)/2})+b)/(e^{(x-y)/2}-e^{(y-x)/2})^2\,dxdy$.

It is the first of these infinitesimal distances that we analyze in some detail in the next section. We shall call the spaces ''Darboux spaces'' and denote them by D_1, D_2, D_3 and D_4, respectively.

III. THE FREE PARTICLE AND SEPARATION OF VARIABLES IN A DARBOUX SPACE OF TYPE ONE

If we consider the first space of Darboux's list and look at real forms of this space only, it is convenient to make the new choice of variables

$$x=u+iv, \quad y=u-iv. \tag{17}$$

The corresponding infinitesimal distance can then be taken as

$$ds^2=2u(du^2+dv^2), \tag{18}$$

and the corresponding Hamiltonian has the form

$$H=\frac{1}{4u}(p_u^2+p_v^2). \tag{19}$$

Associated with this Hamiltonian are three integrals of the free motion, two quadratic and one linear:

$$\begin{aligned} K&=p_v, \quad X_1=p_u p_v-\frac{v}{2u}(p_u^2+p_v^2),\\ X_2&=p_v(vp_u-up_v)-\frac{v^2}{4u}(p_u^2+p_v^2). \end{aligned} \tag{20}$$

These three integrals satisfy the polynomial Poisson algebra relations,

$$\{K,X_1\}=2H, \quad \{K,X_2\}=-X_1, \quad \{X_1,X_2\}=2K^3. \tag{21}$$

They cannot be functionally independent and, in fact, satisfy the relation

$$4HX_2+X_1^2+K^4=0. \tag{22}$$

For the analogous quantum problem it is sufficient to consider the operators

$$\hat{H}=-\frac{1}{4u}(\partial_u^2+\partial_v^2), \quad \hat{K}=-i\partial_v,$$
$$\hat{X}_1=-\partial_u\partial_v+\frac{v}{2u}(\partial_u^2+\partial_v^2), \quad \hat{X}_2=-\frac{1}{2}[\partial_v, v\partial_u-u\partial_v]_+ +\frac{v^2}{4u}(\partial_u^2+\partial_v^2), \tag{23}$$

where $[A,B]_+=AB+BA$. The quantum versions of the quadratic constants are obtained via the formula

$$\hat{\lambda}=-\frac{1}{\sqrt{g}}\partial_i(a^{ij}\sqrt{g}\partial_j). \tag{24}$$

These operators have the same commutation relations as for the classical constants with the Poisson bracket replaced by the commutator bracket:

$$[\hat{K},\hat{X}_1]=2i\hat{H}, \quad [\hat{K},\hat{X}_2]=-i\hat{X}_1, \quad [\hat{X}_1,\hat{X}_2]=-2i\hat{K}^3. \tag{25}$$

There is also the operator relation

$$4\hat{H}\hat{X}_2+\hat{X}_1^2+\hat{K}^4=0. \tag{26}$$

The question we address in this section relates to the various possible ways that separation of variables can be achieved in the case of free classical motion or its quantum analogue, the free Schrödinger equation. The criteria for this to occur is the same in either case. Classically, if we have a general quadratic first integral λ and free Hamiltonian

$$H=\tfrac{1}{2}g^{ij}(u)p_ip_j, \tag{27}$$

and if the characteristic equation,

$$|a^{ij}-\rho g^{ij}|=0, \tag{28}$$

has two distinct roots ρ_1 and ρ_2, the Hamiltonian will have Liouville form when written in terms of the new variables ρ_1, ρ_2. That is,

$$H=\frac{\sigma(\rho_1)p_{\rho_1}^2+\tau(\rho_2)p_{\rho_2}^2}{\rho_1+\rho_2}. \tag{29}$$

In this form, both classical and quantum systems can be solved by the separation of variables ansatz.

If we want to classify all different separable coordinate systems for a given Hamiltonian, we need to know how many essentially different quadratic first integrals are possible. To decide on the notion of equivalence we first observe that the variable v does not explicitly appear in the metric tensor, that is, it is an ignorable variable. This means that the transformations $v\to v+b$ form a

one-dimensional Lie group. Accordingly, we determine the notion of equivalence to mean that two quadratic integrals are equivalent if they are related by a motion of this group. Consequently, the most general quadratic constant can be written

$$\lambda = aX_1 + bX_2 + cK^2 \tag{30}$$

to within the addition of a multiple of H. The second order elements X_i transform under the adjoint action according to

$$X_i \to \exp(\alpha K) X_i \exp(-\alpha K) = \exp(\alpha Ad(K)) X_i = X_i + \alpha\{K, X_i\} + \tfrac{1}{2}\alpha^2\{K,\{K,X_i\}\} + \ldots, \tag{31}$$

or specifically

$$X_1 \to X_1 + 2\alpha H, \quad X_2 \to X_2 - \alpha X_1 - \alpha^2 H. \tag{32}$$

There are three classes of possible quadratic first integrals under this equivalence relation. Typical representatives are

$$X_1 + aK^2, \quad X_2 + aK^2, \quad K^2. \tag{33}$$

We can now explicitly demonstrate the separable coordinates in each of these cases.

(1) *Separating coordinates associated with* $X_1 + aK^2$. If we choose a representative to be

$$L = X_1 + \sinh c\, K^2, \tag{34}$$

the corresponding roots of the characteristic equation and hence new variables are

$$r = \rho_1 = -2(Cu + v), \quad s = \rho_2 = \frac{2}{C}(u - Cv), \quad C = e^{-c}. \tag{35}$$

In terms of these coordinates the Hamiltonian has the form

$$H = \frac{2(C^2+1)^2}{C(s-r)}\left(\frac{1}{C^2}p_s^2 + p_r^2\right), \tag{36}$$

and the corresponding quadratic constant in these coordinates is

$$L = 2\frac{(C^2+1)^2}{C(s-r)}\left(\frac{r}{C^2}p_s^2 + s p_r^2\right). \tag{37}$$

(2) *Separating coordinates associated with* $X_2 + aK^2$. Taking the second representative in the list (33), that is, $L = X_2 + aK^2$, a convenient choice of new variables ξ, η is related to the roots ρ_i by

$$\rho_1 = \eta^2(2a - \eta^2), \quad \rho_2 = -\xi^2(2a + \xi^2). \tag{38}$$

The corresponding classical Hamiltonian then has the form

$$H = \frac{p_\xi^2 + p_\eta^2}{2(\xi^2 + \eta^2)(\xi^2 - \eta^2 + 2a)}. \tag{39}$$

The associated constant of the motion in the new coordinates ξ and η is

$$L = \frac{\eta^2(2a - \eta^2)p_\xi^2 - \xi^2(\xi^2 + 2a)p_\eta^2}{2(\xi^2 + \eta^2)(\xi^2 - \eta^2 + 2a)}. \tag{40}$$

The defining coordinates u,v are written in terms of the new coordinates ξ,η via

$$u=\tfrac{1}{2}(\xi^2-\eta^2)+a, \quad v=\xi\eta, \tag{41}$$

which looks like displaced parabolic coordinates in the u,v plane.

(3) *Separating coordinates associated with* K^2. For the last representative, K^2, we need only the coordinates u,v and to recognize the fact that $K=p_v$.

We conclude this section by discussing the solutions to the free particle and free Schrödinger equation in these three cases.

In case 1 above it is more convenient to choose the variables according to

$$u=r\cos\theta+s\sin\theta, \quad v=-r\sin\theta+s\cos\theta. \tag{42}$$

The classical Hamilton–Jacobi equation then has the form

$$H=\frac{(\partial S/\partial r)^2+(\partial S/\partial s)^2}{4(r\cos\theta+s\sin\theta)}=E, \tag{43}$$

which has the general separable solution

$$S=S_1(r)+S_2(s)=\frac{(4Er\cos\theta-\lambda)^{3/2}}{6E\cos\theta}+\frac{(4Es\sin\theta+\lambda)^{3/2}}{6E\sin\theta}. \tag{44}$$

The corresponding free Schrödinger equation

$$\hat{H}\Psi=-\frac{1}{4(r\cos\theta+s\sin\theta)}(\partial_r^2+\partial_s^2)\Psi=E\Psi \tag{45}$$

has the typical product solutions

$$\Psi=\sqrt{\left(r-\frac{\mu}{4E\cos\theta}\right)\left(s+\frac{\mu}{4E\sin\theta}\right)}\,C_{1/3}\left(\frac{2}{3}\sqrt{4E\cos\theta}\left(r-\frac{\mu}{4E\cos\theta}\right)^{3/2}\right)$$
$$\times C_{1/3}\left(\frac{2}{3}\sqrt{4E\sin\theta}\left(s+\frac{\mu}{4E\sin\theta}\right)^{3/2}\right), \tag{46}$$

where $C_\nu(z)$ is a solution of Bessel's equation.

In the second case the classical Hamilton–Jacobi equation is

$$H=\frac{(\partial S/\partial\xi)^2+(\partial S/\partial\eta)^2}{2(\xi^2+\eta^2)(\xi^2-\eta^2+2c)}=E \tag{47}$$

and has a general solution of the form

$$S=\int\sqrt{2E\xi^4+2Ec\xi^2-\lambda}\,d\xi+\int\sqrt{-2E\eta^4+2Ec\eta^2+\lambda}\,d\eta, \tag{48}$$

which can be expressed in terms of elliptic integrals. The corresponding Schrödinger equation has a solution of the form $\Psi=\psi_1(\xi)\psi_2(\eta)$, where the ψ_i satisfy

$$(\partial_\xi^2+2E\xi^4+4Ec\xi^2+\lambda)\psi_1(\xi)=0,$$
$$(\partial_\eta^2-2E\eta^4+4Ec\eta^2-\lambda)\psi_2(\eta)=0. \tag{49}$$

These equations are readily identified as the equations for the anharmonic oscillator.

In the third case the classical Hamilton-Jacobi equation is

$$H=\frac{1}{4u}\left(\left(\frac{\partial S}{\partial u}\right)^2+\left(\frac{\partial S}{\partial v}\right)^2\right)=E, \tag{50}$$

which has separable solutions

$$S=\frac{1}{6E}(4Eu-k^2)^{3/2}+kv. \tag{51}$$

The separable solutions to the corresponding free Schrödinger equation

$$-\frac{1}{4u}(\partial_u^2+\partial_v^2)\Psi=E\Psi \tag{52}$$

have the form

$$\Psi=\sqrt{u-\frac{m^2}{4E}}C_{1/3}\left(\frac{2}{3}\sqrt{4E}\left(u-\frac{m^2}{4E}\right)^{3/2}\right)e^{imv}. \tag{53}$$

It is clear that the actual solutions to the classical motion or the corresponding Schrödinger equation depend on the range of values assumed by the various real variables, that is, on exactly which real manifold we are considering.

IV. INTEGRABLE AND SUPERINTEGRABLE SYSTEMS FOR THE DARBOUX SPACE OF TYPE ONE

In this section we address the problem of superintegrability for the Hamiltonian

$$H=\frac{1}{4u}(p_u^2+p_v^2), \tag{54}$$

that is, look for potentials $V(u,v)$ for which

$$\overline{H}=H+V(u,v) \tag{55}$$

admits at least two extra quadratic integrals. The way to solve this problem is as follows. First we consider that we already have one quadratic first integral

$$\overline{L}=a(u,v)p_u^2+b(u,v)p_up_v+c(u,v)p_v^2+d(u,v). \tag{56}$$

We know that the quadratic part of $\overline{L}$ [i.e., that part obtained by putting $d(u,v)=0$ in (56)] must correspond to one of the three possibilities outlined in the previous section. For each of these possibilities separation of variables is possible in coordinates α,β where $u=u(\alpha,\beta)$, $v=v(\alpha,\beta)$. The addition of a potential implies that separation is preserved. As a consequence of this, $\overline{H}$ can be written as

$$\overline{H}=\frac{p_\alpha^2+p_\beta^2+f(\alpha)+g(\beta)}{\sigma(\alpha)+\tau(\beta)} \tag{57}$$

and the corresponding first integral will be

$$\overline{L}=\frac{\sigma(\alpha)(p_\beta^2+g(\beta))-\tau(\beta)(p_\alpha^2+f(\alpha))}{\sigma(\alpha)+\tau(\beta)}. \tag{58}$$

The next step is to impose the condition that there is a further quadratic first integral and see what conditions this imposes on the functions $f(\alpha)$ and $g(\beta)$. If we do these calculations systematically, we arrive at the following three cases.

(1)

$$H=\frac{p_u^2+p_v^2}{4u}+\frac{b_1(4u^2+v^2)}{4u}+\frac{b_2}{u}+\frac{b_3}{uv^2}. \tag{59}$$

The additional constants of the motion have the form

$$R_1=X_2-\frac{b_1v^4}{4u}-\frac{b_2v^2}{u}-\frac{b_3(4u^2+v^2)}{v^2u},\quad R_2=K^2+b_1v^2+\frac{4b_3}{v^2} \tag{60}$$

and the corresponding quadratic algebra[18,19] relations are determined by

$$\begin{gathered}\{R,R_1\}=8HR_1+6R_2^2+16b_2R_2-32b_1b_3,\\ \{R,R_2\}=-8HR_2-16b_1R_1,\\ R^2=-16HR_1R_2-4R_2^3-16b_2R_2^2-64b_3H^2-16b_1R_1^2+64b_1b_3R_2+256b_1b_2b_3,\end{gathered} \tag{61}$$

where $R=\{R_1,R_2\}$. The Hamiltonian clearly separates in the coordinates u and v as well as the coordinates ξ,η given by $u=\frac{1}{2}(\xi^2-\eta^2)+a$, $v=\xi\eta$. This can be seen from the explicit form

$$H=\frac{p_\xi^2+p_\eta^2}{2(\xi^2+\eta^2)(\xi^2-\eta^2+2a)}+\frac{b_1((\xi^2-\eta^2+2a)^2+\xi^2\eta^2)+4b_2+(4b_3/\xi^2\eta^2)}{2(\xi^2-\eta^2+2a)}. \tag{62}$$

The corresponding quadratic quantum algebra relations are

$$\begin{gathered}[\hat R,\hat R_1]=-6\hat R_2^2-8\hat H\hat R_1+16b_2\hat R_2+2b_1(3+16b_3),\\ [\hat R,\hat R_2]=8\hat H\hat R_2-16b_1\hat R_1,\\ \hat R^2=+4\hat R_2^3-8\hat H[\hat R_1,\hat R_2]_+-16b_2\hat R_2^2-16b_1\hat R_1^2-4b_1(11+16b_3)\hat R_2\\ -4(3+16b_3)\hat H^2+16b_1b_2(3+16b_3),\end{gathered} \tag{63}$$

where $\hat R=[\hat R_1,\hat R_2]$.

(2)

$$H=\frac{p_u^2+p_v^2}{4u}+\frac{a_1}{u}+\frac{a_2v}{u}+\frac{a_3(u^2+v^2)}{u}. \tag{64}$$

The additional constants of the motion have the form

$$\begin{gathered}R_1=X_1-\frac{2a_1v}{u}+\frac{2a_2(u^2-v^2)}{u}+\frac{2a_3v(u^2-v^2)}{u},\\ R_2=K^2+4a_2v+4a_3v^2,\end{gathered} \tag{65}$$

and the corresponding quadratic algebra relations are determined by

$$\{R,R_1\}=-8H^2+16a_3R_2+8(a_2^2+4a_1a_3),$$

$$\{R,R_2\}=16a_2H-16a_3R_1, \tag{66}$$

$$R^2=16H^2R_2-16a_3R_2^2+32a_2HR_1-16a_3R_1^2-16(a_2^2+4a_1a_3)R_2-64a_1a_2^2.$$

If we change the coordinates according to $u=r\cos\theta+s\sin\theta$, $v=-r\sin\theta+s\cos\theta$, the Hamiltonian assumes the form

$$H=\frac{p_r^2+p_s^2+4a_1+4a_2(-r\sin\theta+s\cos\theta)+4a_3(r^2+s^2)}{4(r\cos\theta+s\sin\theta)}, \tag{67}$$

which clearly also separates in these coordinates.

The commutation relations of the corresponding quantum algebra are

$$[\hat{R},\hat{R}_1]=16a_3\hat{R}_2+8\hat{H}^2-8(a_2^2+4a_1a_3),$$

$$[\hat{R},\hat{R}_2]=-16a_3\hat{R}_1+16a_2\hat{H}, \tag{68}$$

$$\hat{R}^2=-16a_3\hat{R}_2^2-16a_3\hat{R}_1^2+16\hat{H}^2\hat{R}_2+32a_2\hat{H}\hat{R}_1-16(a_2^2+4a_1a_3)\hat{R}_2+64(a_3^2-a_1a_2^2).$$

(3) The third potential gives rise to a Hamiltonian of the form

$$H=\frac{p_u^2+p_v^2}{4u}+\frac{a}{u}. \tag{69}$$

There are three extra constants associated with this Hamilonian,

$$R_1=X_1-\frac{2av}{u},\quad R_2=X_2-\frac{av^2}{u}\quad\text{and}\quad K. \tag{70}$$

The associated Poisson bracket relations are

$$\{K,R_1\}=2H,\quad \{K,R_2\}=-R_1,\quad \{R_1,R_2\}=2K(K^2+2a), \tag{71}$$

and the corresponding functional relation among these constants is

$$4HR_2+R_1^2+K^4+4aK^2=0. \tag{72}$$

The commutation relations associated with the corresponding quantum problem have the form

$$[\hat{K},\hat{R}_1]=2i\hat{H},\quad [\hat{K},\hat{R}_2]=-i\hat{R}_1,\quad [\hat{R}_1,\hat{R}_2]=-2i\hat{K}(\hat{K}^2-2a), \tag{73}$$

and the identity amongst the defining operators is

$$4\hat{H}\hat{R}_2+\hat{R}_1^2+\hat{K}^4-4a\hat{K}^2=0. \tag{74}$$

Upon examination of the various superintegrable potentials we have constructed, we see that by multiplying the equation $H=E$ by a suitable factor we essentially recover a variant of one of the superintegrable systems already classified for spaces of constant (or zero) curvature. For the first potential above, the equation $H=E$ may be written

$$p_u^2+p_v^2+b_1(4u^2+v^2)+4b_2+\frac{4b_3}{v^2}-4Eu=0. \tag{75}$$

This equation is known to have separable solutions in coordinates u, v and associated parabolic coordinates ξ,η given by $u=\frac{1}{2}(\xi^2-\eta^2)$, $v=\xi\eta$. With the second potential, $H=E$ becomes

$$p_u^2+p_v^2+4a_3(u^2+v^2)+4a_1+4a_2v-4Eu=0, \tag{76}$$

and the third becomes

$$p_u^2+p_v^2-4Eu+4a=0. \tag{77}$$

This observation is crucial to the whole program that we will undertake which aims at finding all superintegrable systems associated with a curved space in two dimensions and having quadratic constants.

All three of the above systems are special cases of the superintegrable systems found in E_2.[4,11] They were shown to be exactly solvable in Ref. 12.

V. EMBEDDINGS OF A DARBOUX SPACE OF REVOLUTION OF TYPE ONE

It is clear that the infinitesimal distance

$$ds^2=2u(du^2+dv^2) \tag{78}$$

does not uniquely determine a manifold. This then gives rise to the question of just what sort of surfaces can this infinitesimal distance represent. A particular choice of such a surface would determine the range of variation of the parameters u, v which in turn enables the solution of the geodesic equations in the case of classical mechanics and the quantum mechanics of a point particle. It is known that any two-dimensional Riemannian space can be embedded in a three-dimensional Euclidean space of indefinite or definite signature. In this section we look at a number of natural embeddings and discuss their associated geodesics and quantum mechanics. The infinitesimal distance that we are dealing with can be embedded in three-dimensional Euclidean space E_3 via the formulas

$$X=\sqrt{2u}\cos v, \quad Y=\sqrt{2u}\sin v, \tag{79}$$

$$Z=\frac{\sqrt{2}}{3}\left(F\left(\varphi,\frac{1}{\sqrt{2}}\right)+\sqrt{4u^3-u}\right), \tag{80}$$

where $u\geqslant\frac{1}{2}$, $v_0\leqslant v\leqslant 2\pi+v_0$, $\sin\varphi=\sqrt{2u+1}$ and $F(\varphi,k)$ is an elliptic integral of the first kind. This embedding gives the infinitesimal distance

$$dX^2+dY^2+dZ^2=2u(du^2+dv^2). \tag{81}$$

To do quantum mechanics on this surface let us first look for separable solutions to the free Schrödinger equation. A typical solution has already been found in the previous section, viz.

$$\Psi=\sqrt{u-\frac{m^2}{4E}}\,C_{1/3}\left(\frac{2}{3}\sqrt{4E}\left(u-\frac{m^2}{4E}\right)^{3/2}\right)e^{imv}, \tag{82}$$

where m is an integer. As $u\geqslant\frac{1}{2}$ and we see that $u=\frac{1}{2}$ is not a singular point of the separable equation in u, we can impose a condition of the form

$$a\Psi(\tfrac{1}{2},v)+b\Psi_u(\tfrac{1}{2},v)=0 \tag{83}$$

together with the periodic boundary condition $\Psi(u,v)=\Psi(u,v+2\pi)$, which is already satisfied. If we take $a=1$, $b=0$, then $E\geqslant 0$, otherwise there is no solution satisfying the boundary condition at $u=\frac{1}{2}$. If $E\geqslant 0$, then we can find a suitably behaved solution that vanishes as $u\to\infty$ and satisfies the boundary condition at $u=\frac{1}{2}$, viz.

$$\Psi=(UU')^{1/2}(J_{1/3}(U)J_{-1/3}(U')-J_{1/3}(U')J_{-1/3}(U)), \tag{84}$$

where $U=\frac{2}{3}\sqrt{4E}(u-m^2/4E)^{3/2}$ and $U'=\frac{2}{3}\sqrt{4E}(\frac{1}{2}-m^2/4E)^{3/2}$. These solutions are the analog of the scattering states on this manifold subject to the boundary condition we have adopted.

An interesting embedding in pseudo-Euclidean space is given by

$$X=\sqrt{2u}v, \quad Y=\sqrt{u}(\tfrac{4}{5}u^2-v^2+\tfrac{1}{2}), \quad T=\sqrt{u}(\tfrac{4}{5}u^2-v^2-\tfrac{1}{2}), \tag{85}$$

for which $dX^2+dY^2-dT^2=2u(du^2+dv^2)$. In this case the variables vary over the ranges $-\infty<v<\infty$, $0\leqslant u<\infty$. We could indeed do an analysis of the free Schrödinger equation on this surface and come to a similar conclusion if we imposed the condition that the wave function is zero at $u=0$. However, if we consider the first potential (59) and choose $b_1=-\beta^2$, $b_3=\frac{1}{4}(\frac{1}{4}-\gamma^2)$ for real β and $\gamma\geqslant 0$, and if we write the solutions to Schrödinger's equation in the form $\Psi=U(u)V(v)$, then two independent solutions of the separation equation satisfied by V can be taken as

$$V_{\pm}=\exp\left(-\frac{1}{2}\beta v^2\right)v^{\pm\gamma+1/2}{}_1F_1\left(\frac{1}{2}(1\pm\gamma)-\frac{\mu}{\beta},1\pm\gamma,\beta v^2\right). \tag{86}$$

If we wish to interpret these solutions as being associated with an angle variable which varies in the range $0<v_0\leqslant v\leqslant v_0+2\pi$, then we would require the periodic boundary conditions

$$V(v_0)=V(v_0+2\pi), \quad V'(v_0)=V'(v_0+2\pi). \tag{87}$$

The possibility of imposing these boundary conditions depends on whether $v=0$ occurs inside the domain of v. If it does not, then the spectrum is determined from the condition

$$W[V_+(x)-V_+(x+2\pi),V_-(x)-V_-(x+2\pi)]\big|_{x=v_0}=0. \tag{88}$$

If $v=0$ is included, then the same conditions no longer work as this is a regular singular point of the equation. Indeed, if $v_0=0$ and we assume $\gamma>\frac{1}{2}$, then we choose the solution V_+ and impose the condition

$$V_+(2\pi)=0 \tag{89}$$

as $V_+(0)$ is already zero. The quantization condition is then determined by

$${}_1F_1\left(\frac{1}{2}(1+\gamma)-\frac{\mu}{\beta},1+\gamma,4\beta\pi^2\right)=0. \tag{90}$$

For the u separation equation the range of variation of the variable $u>\frac{1}{2}$ is clear and $u=\frac{1}{2}$ is not a singularity of the the separation equation. We can accordingly take typical solutions to be

$$U_{\pm}(u)=a_1D_\nu\left(2\sqrt{\beta}\left(u-\frac{E}{2\beta^2}\right)\right)+a_2D_\nu\left(-2\sqrt{\beta}\left(u-\frac{E}{2\beta^2}\right)\right), \tag{91}$$

where $\nu=(1/4\beta)(E^2/\beta^2+4b_2-\mu)-\frac{1}{2}$. To obtain a solution that vanishes as $u\to\infty$ requires that $a_2=0$. The remaining boundary condition becomes

$$D_\nu\left(2\sqrt{\beta}\left(\frac{1}{2}-\frac{E}{2\beta^2}\right)\right)=0. \tag{92}$$

This condition determines the nature of the discrete spectrum. For large eigenvalues the discrete spectrum is given by

$$E\cong-2\sqrt{\beta^3 n} \tag{93}$$

for suitable large integer n.

If we consider the second potential (64), then putting $a_3=-\alpha^2$ the equation for $V(v)$ has solutions of the form

$$V=d_1D_\nu\left(2\sqrt{\alpha}\left(v-\frac{a_2}{2\alpha^2}\right)\right)+d_2D_\nu\left(-2\sqrt{\alpha}\left(v-\frac{a_2}{2\alpha^2}\right)\right)=d_1V_+ + d_2V_-, \tag{94}$$

where

$$\nu=\frac{1}{4\alpha}\left(4\mu+\frac{a_2^2}{\alpha^2}\right)-\frac{1}{2}. \tag{95}$$

As there are no singularities in v in this equation and we can require that $w_0\leqslant v\leqslant w_0+2\pi$,

$$V(w_0)=V(w_0+2\pi), \quad V'(w_0)=V'(w_0+2\pi), \tag{96}$$

which is equivalent to

$$W[V_+(x)-V_+(x+2\pi),V_-(x)-V_-(x+2\pi)]|_{x=w_0}=0. \tag{97}$$

The solutions for the function $U(u)$ that are well behaved for large u are

$$U(u)=D_\rho\left(2\sqrt{\alpha}\left(u-\frac{E}{2\beta^2}\right)\right), \tag{98}$$

where $\rho=(1/4\beta)(4a_1-4\mu+E^2/\alpha^2)-\frac{1}{2}$.

VI. CONCLUSION

In this article we have examined one of the four spaces of revolution listed by Koenigs.[16] For the space that we have considered, it has been shown that there are three potentials that can be added to give superintegrable Hamiltonian systems of the type we seek. In each of these cases we have exhibited the various inequivalent ways in which a separation of variables can be achieved for both the classical and quantum equations that result. This is equivalent to determining the various inequivalent ways in which a Hamiltonian can be written in Liouville form (57) for suitable separable coordinates α, β. In particular, we note that each of the three superintegrable systems we have examined are such that when we write out the classical equation $H=E$ and factor out the denominator we recover a variant of a superintegrable system corresponding to flat space.[4] This is an example of what is called coupling-constant metamorphosis.[20] It has been proven in Ref. 12 that all of the superintegrable systems in the plane are such that the bound state energies can be calculated algebraically. In all cases the Hamiltonian lies in the enveloping algebra of $sl(3,\mathbb{R})$. We conclude that analogous statements apply to the superintegrable systems that we have found.

Dark soliton generation for the intermediate nonlinear Schrödinger equation

Yoshimasa Matsuno[a)]
Department of Applied Science, Faculty of Engineering, Yamaguchi University, Ube 755-8611, Japan

(Received 7 August 2001; accepted for publication 7 November 2001)

The generation of dark solitons due to a small change of the initial data is studied within the framework of the intermediate nonlinear Schrödinger (INLS) equation. In particular, we analyze the spectral problem associated with the INLS equation when the potential consists of a small perturbation imposed on a constant background. We derive a criterion for the perturbation to generate a pair of new discrete eigenvalues as well as their explicit expressions in terms of the perturbation. In addition, we demonstrate that the eigenvalues appear without a threshold on the magnitude of the perturbation. We also consider both the shallow- and deep-water limits of various results obtained for the INLS spectral problem. In the former case, the limiting procedure can be performed smoothly whereas in the latter case, the spectral equation exhibits a new feature of bound states, showing that the eigenvalue is exponentially small compared with the magnitude of the perturbation. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1430623]

I. INTRODUCTION

It is well known that the nonlinear Schrödinger (NLS) equation describes the long-term evolution of a quasiharmonic wave on the surface of a liquid layer.[1] Recently, a similar nonlinear evolution equation was derived in the context of internal (or interfacial) waves.[2,3] It can be written in an appropriate dimensionless form as follows:

$$iu_t = u_{xx} + u(i + \dot{T})(|u|^2)_x . \tag{1.1a}$$

Here, $u = u(x,t)$ is a complex function representing the envelope of the wave, T is an integral operator defined by

$$Tu(x,t) = \frac{1}{2\delta} P \int_{-\infty}^{\infty} \coth\left[\frac{\pi(y-x)}{2\delta}\right] u(y,t)\mathrm{d}y, \tag{1.1b}$$

where δ ia a parameter proportional to the depth of the fluid, the symbol P stands for the Cauchy principal value integral, and the subscripts t and x appended to u denote partial differentiation. It has been demonstrated that the constant state $u = \rho$ is modulationally stable against infinitesimal perturbation[2] and as a result, Eq. (1.1) has a dark soliton solution of the form[2]

$$u = \rho \frac{1 + \dfrac{V - i\kappa}{V + i\kappa} e^{-\kappa(\xi - i\delta)}}{1 + e^{-\kappa(\xi - i\delta)}}, \quad |u|^2 = \rho^2 - \frac{\kappa \sin(\kappa\delta)}{\cosh(\kappa\xi) + \cos(\kappa\delta)}, \tag{1.2}$$

a)Electronic mail: matsuno@po.cc.yamaguchi-u.ac.jp

where $\xi=x-Vt-x_0$ and V is determined by the algebraic equation $V^2+2\rho^2V+\kappa^2=2\rho^2\kappa\cot(\kappa\delta)$ (κ: positive constant, x_0: real constant). The profile of $|u|^2$ shows a dip on a constant background. It is noteworthy that the general N-soliton solution is now available which represents the interaction of N dark solitons.[2,4,5]

In the shallow-water limit $\delta\to 0$, Eq. (1.1) reduces to the defocusing NLS equation

$$iu_{\tilde{t}}=u_{\tilde{x}\tilde{x}}-\tilde{u}(|\tilde{u}|^2-\rho^2),\quad \tilde{u}=\tilde{u}(\tilde{x},\tilde{t}), \tag{1.3}$$

after rescaling the variables x, t, and u according to the relations $x=\sqrt{\delta}\tilde{x}$, $t=\delta\tilde{t}$, and $u(x,t)=\tilde{u}(\tilde{x},\tilde{t})$, respectively, where the expansion $Tf_x=-\delta^{-1}f+O(\delta)$ was used together with the boundary condition $|u|\to\rho,|x|\to\infty$. In the deep-water limit $\delta\to\infty$, on the other hand, Eq. (1.1) reduces simply to the nonlocal NLS equation

$$iu_t=u_{xx}+u(i+H)(|u|^2)_x, \tag{1.4a}$$

with the Hilbert transform operator H defined by

$$Hu(x,t)=\frac{1}{\pi}P\int_{-\infty}^{\infty}\frac{u(y,t)}{y-x}\mathrm{d}y. \tag{1.4b}$$

Thus, Eq. (1.1) is an intermediate version of Eqs. (1.3) and (1.4) and hence it is referred to as the intermediate nonlinear Schrödinger (INLS) equation.[2]

The initial value problem of Eq. (1.1) under the boundary condition $|u|\to\rho,|x|\to\infty$ has been solved by means of the inverse scattering transform (IST) method.[5] It turns out that Eq. (1.1) has common properties to completely integrable nonlinear evolution equation such as N-soliton solution, Bäcklund transformation, and infinite number of conservation laws. However, it should be remarked that its complete integrability is still an open problem. Although a number of works have been done for the defocusing NLS equation (1.3),[6,7] many open problems are left for the nonlocal NLS equation (1.4). In particular, the deep-water limit $\delta\to\infty$ of the IST scheme for the INLS equation would exhibit a novel feature to be resolved by a new method. Thus, the initial value problem of Eq. (1.4) is left for a future work. As for exact solutions, however, the multiperiodic and multisoliton solutions have recently been constructed[8] without recourse to the IST and the stability of the latter solution has been proved.[9]

The linear system (or the so-called Lax pair) associated with Eq. (1.1) is given by[5]

$$i\phi_x-\frac{\mu}{2}\phi+u\psi^+=0, \tag{1.5a}$$

$$\psi^+-\lambda\psi^-+u^*\phi=0, \tag{1.5b}$$

$$i\phi_t+i\mu\phi_x+\phi_{xx}-2iu_x\psi^++\nu\phi=0, \tag{1.5c}$$

$$i\psi_t^{\pm}+i\mu\psi_x^{\pm}+\psi_{xx}^{\pm}+[(\pm i+T)(|u|^2)_x+\nu]\psi^{\pm}=0. \tag{1.5d}$$

Here, $\phi=\phi(x,t)$ and $\psi^{\pm}=\psi^{\pm}(x,t)$ are Jost functions and λ, μ, and ν are constants related to a spectral parameter where $\psi^{\pm}(x,t)\equiv\psi(x\mp i\delta,t)$ represent the boundary values of functions analytic in the horizontal strip between $\mathrm{Im}\,x=0$ and $\mathrm{Im}\,x=\pm 2\delta$ and the asterisk appended to u denotes the complex conjugate.

In this paper, we shall deal with the problem of soliton generation within the framework of system (1.5). Our main concern here is as to whether a small initial data can support new eigenvalues. To be more specific, we consider the following initial data:

$$u(x,0)=\rho+\epsilon v(x), \tag{1.6}$$

where $\rho(>0)$ is the boundary value of u as $|x|\to\infty$, $v(x)$ is a complex function decreasing at infinity, and ϵ is a small positive parameter so that ϵv represents a perturbation imposed on a constant background. It is important that the above-noted initial data exhibit no phase change when x varies from $-\infty$ to $+\infty$. However, we can impose the more general boundary condition such that $u(x,0)\to\rho e^{-i\phi}(x\to-\infty)$ and $u(x,0)\to\rho(x\to\infty)$ where ϕ is a real constant. A simple example is given by the initial condition $u(x,0)=\rho e^{-i\phi}(x<0)$, $u(x,0)=\rho(x>0)$, which shows a phase step on a constant background. In this case, we can solve the eigenvalue problem (1.5) explicitly and obtain the equation $\tan(\phi/2)=\kappa/\mu$ that determines the eigenvalue κ where $\mu=\mu(i\kappa)$ satisfies the equation $\mu^2+2\rho^2\mu+\kappa^2=2\rho^2\kappa\cot(\kappa\delta)$. Comparing this equation with (1.2), one sees that $\mu=V=-\rho^2\pm\sqrt{\rho^4-\kappa^2+2\rho^2\kappa\cot(\kappa\delta)}\equiv\mu_{\pm}$. Thus, the above-noted initial data produce a single dark soliton whose amplitude and velocity are determined uniquely by the phase change ϕ. Note in particular that if the phase change is very small, i.e., $0<\phi\ll 1$, then $\kappa\simeq\mu\phi/2$ and $\mu=\mu_{+}\simeq-\rho^2+\sqrt{\rho^4+(2\rho^2/\delta)}$, implying the generation of a small dark soliton with a positive velocity. Another important example of the background field is provided by a single soliton solution (1.2). Obviously, this exhibits a finite phase change when x varies from $-\infty$ to ∞. It turns out that the generation of solitons due to small perturbation is a difficult problem to be handled by means of the Fourier transform method developed in this paper. One needs to solve the eigenvalue equation with variable coefficient. This issue is, however, beyond the scope of the present paper.

We now summarize the main result in this paper as follows: if the condition

$$\int_{-\infty}^{\infty}(v(x)+v^*(x))\mathrm{d}x<0 \tag{1.7}$$

is satisfied, then a small initial data generate a pair of new discrete eigenvalues (i.e., new solitons) in the linear spectral problem (1.5). These eigenvalues are found to emerge from the edge of the continuous spectrum without a *threshold* on the amplitude of the perturbation ϵv. We also show that the similar conclusion holds for both shallow- and deep-water limits. In connection with the problem under consideration, it is worth mentioning that the soliton generation by a small change of the initial date was studied recently in the context of the Benjamin–Ono (BO),[10] intermediate long wave (ILW),[11] and Kadomtsev–Petviashvili (KPI)[12] equations. It was demonstrated that the linear systems associated with the BO and ILW equations exhibit a thresholdless generation of a new eigenvalue whereas for the KPI equation, the corresponding linear system yields a threshold generation.

In Sec. II, we analyze the eigenvalue problem [(1.5a), (1.5b)] with the initial data (1.6). We first transform Eqs. (1.5a) and (1.5b) to an equivalent system of integral equations by using the Fourier transform and then employ a systematic perturbation method to obtain new eigenvalues. The criterion (1.7) is established for the generation of a pair of new eigenvalues. The explicit expressions of new eigenvalues as well as the corresponding eigenfunctions are obtained in terms of the initial disturbance v. In Sec. III, the shallow-water limit $\delta\to 0$ is taken straightforwardly for the expressions of the eigenvalues and eigenfunctions derived in Sec. II. We recover the first-order correction to the eigenvalues which has already been obtained by a different method.[13] We emphasize that the second-order correction is presented here for the first time. In Sec. IV, we consider the deep-water limit $\delta\to\infty$. We find that unlike the shallow-water limit, this limiting procedure yields no meaningful results. In particular, the eigenvalues are shown to vanish identically. This fact would imply that the order of the limits $\epsilon\to 0$ and $\delta\to\infty$ cannot be interchanged. Hence, we start from a system of integral equations equivalent to the eigenvalue problem associated with the nonlocal NLS equation (1.5). By developing the similar analysis to that used for finite δ, we obtain a criterion for a new eigenvalue to emerge from a small change of the initial data. The resulting eigenvalue is found to be exponentially small compared with ϵ. Section V is devoted to concluding remarks. In Appendix A, we describe some properties of a function as well as those of the spectral parameters μ and λ, which play important roles in developing the perturbation analysis. In Ap-

pendix B, we investigate the asymptotic behavior of the two-soliton solution of the INLS equation and show that the solution can be used to simulate a pair of dark solitons produced by a small perturbation.

II. EIGENVALUE PROBLEM ASSOCIATED WITH THE INLS EQUATION

A. Eigenvalue problem

We start our analysis with the system of eigenvalue equations (1.5a) and (1.5b) subjected to the initial data (1.6). It reads in the form

$$i\phi_x - \frac{\mu}{2}\phi + \rho\psi^+ = -\epsilon v\psi^+, \tag{2.1a}$$

$$\psi^+ - \lambda\psi^- + \rho\phi = -\epsilon v^*\phi. \tag{2.1b}$$

In the following, we focus our attention on the spatial part of the Lax pair since the temporal part is used only for determining the time dependence of the spectral parameters. We first specify the asymptotic forms of the Jost functions ϕ and ψ as $\phi \sim e^{\pm ikx/2}$, $\psi \sim e^{\pm ikx/2}$ where k is a spectral parameter. Then, the constants μ and λ are related to k by the following relations:[5]

$$\mu^2 + 2\rho^2\mu = 2\rho^2 k\coth(k\delta) + k^2, \tag{2.2a}$$

$$\lambda = \frac{k}{k\cosh(k\delta) - \mu\sinh(k\delta)}. \tag{2.2b}$$

It has been shown that the nth zero $k_n = i\kappa_n$, $0 < \kappa_n < \kappa_c$ of the scattering data corresponds to the nth soliton[5] where κ_c is a solution of the equation $\kappa_c \tan(\kappa_c\delta/2) = \rho^2$. Hence, we assume $\mu = \mu(i\kappa)$ and $\lambda = \lambda(i\kappa)$ $(0 < \kappa \ll 1)$ in (2.1) and solve it by using a perturbation method.

It is convenient to rewrite Eq. (2.1) into an equivalent system of integral equations. For this purpose, we decompose ϕ and $\psi^{\pm}$ in the form of the Fourier integral as

$$\phi(x) = \int_{-\infty}^{\infty} \alpha(k) e^{ikx/2}\,dk, \tag{2.3a}$$

$$\psi^{\pm}(x) = \int_{-\infty}^{\infty} \beta(k) e^{ik(x \mp i\delta)/2}\,dk. \tag{2.3b}$$

Substituting (2.3) into (2.1) and taking the inverse Fourier transform, we obtain the following system of integral equations for α and β:

$$-\frac{1}{2}\{k + \mu(i\kappa)\}\alpha(k) + \rho e^{k\delta/2}\beta(k) = -\frac{\epsilon}{4\pi}\int_{-\infty}^{\infty} K(k,k')e^{k'\delta/2}\beta(k')dk', \tag{2.4a}$$

$$\rho\alpha(k) + \{e^{k\delta/2} - \lambda(i\kappa)e^{-k\delta/2}\}\beta(k) = -\frac{\epsilon}{4\pi}\int_{-\infty}^{\infty} K^*(k',k)\alpha(k')dk', \tag{2.4b}$$

where we have put

$$K(k,k') = \int_{-\infty}^{\infty} v(x)e^{-i(k-k')x/2}\,dx, \tag{2.4c}$$

for simplicity. If we introduce the new variables A and B according to

$$A(k) = D(k,\kappa)\alpha(k), \tag{2.5a}$$

$$B(k)=D(k,\kappa)\beta(k)e^{k\delta/2}, \tag{2.5b}$$

with

$$D(k,\kappa)=-\tfrac{1}{2}\{k+\mu(i\kappa)\}\{1-\lambda(i\kappa)e^{-k\delta}\}-\rho^2, \tag{2.5c}$$

Eq. (2.4) can be put into the form

$$A(k)=\frac{\epsilon\rho}{4\pi}\int_{-\infty}^{\infty}\frac{K^*(k',k)}{D(k',\kappa)}A(k')\mathrm{d}k'-\frac{\epsilon}{4\pi}\{1-\lambda(i\kappa)e^{-k\delta}\}\int_{-\infty}^{\infty}\frac{K(k,k')}{D(k',\kappa)}B(k')\mathrm{d}k', \tag{2.6a}$$

$$B(k)=\frac{\epsilon}{8\pi}\{k+\mu(i\kappa)\}\int_{-\infty}^{\infty}\frac{K^*(k',k)}{D(k',\kappa)}A(k')\mathrm{d}k'+\frac{\epsilon\rho}{4\pi}\int_{-\infty}^{\infty}\frac{K(k,k')}{D(k',\kappa)}B(k')\mathrm{d}k'. \tag{2.6b}$$

The above-noted system of integral equations for $A(k)$ and $B(k)$ is the starting point of the following analysis. It is crucial to observe that the quantity $D(k',\kappa)$ in the integrand in (2.6) has zeros at $k'=\pm i\kappa$. To show this, we take the limit $|x|\to\infty$ in (2.1), use the asymptotic form ϕ, $\psi\sim e^{ikx/2}$ and obtain the relation

$$1-\lambda(k)e^{-k\delta}=-\frac{2\rho^2}{k+\mu(k)}. \tag{2.7}$$

Combining (2.7) with (2.5c) yields

$$D(k,\kappa)=-\frac{1}{2}\{k+\mu(i\kappa)\}\{\lambda(k)-\lambda(i\kappa)\}e^{-k\delta}-\rho^2\frac{\mu(k)-\mu(i\kappa)}{k+\mu(k)}. \tag{2.8}$$

Since $\mu(k)=\mu(-k)$, $\lambda(k)=\lambda(-k)$ by (2.2), one can see that $D(\pm i\kappa,\kappa)=0$. The function $D(k,\kappa)$ plays an important role in developing the perturbation analysis. Some properties of $D(k,\kappa)$ are summarized in Appendix A for later use. Thus, we see that the integrand in (2.6) exhibits singularities in the limit of $\kappa\to 0$. It turns out that these singularities become the origin of the generation of new eigenvalues, as will be demonstrated in the following. In order to regularize the singular behavior in each integrand, we modify the integral by subtracting the contribution from the two poles $k'=\pm i\kappa$ as

$$\int_{-\infty}^{\infty}\frac{K^*(k',k)}{D(k',\kappa)}A(k')\mathrm{d}k'=\int_{-\infty}^{\infty}\frac{1}{k'^2+\kappa^2}\left[\frac{k'^2+\kappa^2}{D(k',\kappa)}K^*(k',k)A(k')\right.$$
$$\left.-\{C_R(\kappa)k'+C_I(\kappa)\kappa\}K^*(0,k)A(0)\right]\mathrm{d}k'+\pi C_I(\kappa)K^*(0,k)A(0), \tag{2.9a}$$

where

$$C_R(\kappa)=\frac{1}{D_k(i\kappa,\kappa)}+\frac{1}{D_k(-i\kappa,\kappa)}, \tag{2.9b}$$

$$C_I(\kappa)=i\left[\frac{1}{D_k(i\kappa,\kappa)}-\frac{1}{D_k(-i\kappa,\kappa)}\right], \tag{2.9c}$$

$$D_k(\pm i\kappa,\kappa)=\left[\frac{\partial D(k,\kappa)}{\partial k}\right]_{k=\pm i\kappa}. \tag{2.9d}$$

Substituting (2.9) and an analogous expression for B into (2.6), we obtain the system of equations for A and B:

$$A(k)=\frac{\epsilon}{4}C_I(\kappa)[\rho K^*(0,k)A(0)-\{1-\lambda(i\kappa)e^{-k\delta}\}K(k,0)B(0)]$$
$$+\frac{\epsilon\rho}{4\pi}\left[\int_{-\infty}^{\infty}\frac{1}{k'^2+\kappa^2}\left\{\frac{k'^2+\kappa^2}{D(k',\kappa)}K^*(k',k)A(k')\right.\right.$$
$$\left.\left.-(C_R(\kappa)k'+C_I(\kappa)\kappa)K^*(0,k)A(0)\right\}dk'\right]-\frac{\epsilon}{4\pi}\{1-\lambda(i\kappa)e^{-k\delta}\}$$
$$\times\left[\int_{-\infty}^{\infty}\frac{1}{k'^2+\kappa^2}\left\{\frac{k'^2+\kappa^2}{D(k',\kappa)}K(k,k')B(k')\right.\right.$$
$$\left.\left.-(C_R(\kappa)k'+C_I(\kappa)\kappa)K(k,0)B(0)\right\}dk'\right], \tag{2.10a}$$

$$B(k)=\frac{\epsilon}{4}C_I(\kappa)\left[\frac{1}{2}\{k+\mu(i\kappa)\}K^*(0,k)A(0)+\rho K(k,0)B(0)\right]+\frac{\epsilon}{8\pi}\{k+\mu(i\kappa)\}$$
$$\times\left[\int_{-\infty}^{\infty}\frac{1}{k'^2+\kappa^2}\left\{\frac{k'^2+\kappa^2}{D(k',\kappa)}K^*(k',k)A(k')-(C_R(\kappa)k'+C_I(\kappa)\kappa)K^*(0,k)A(0)\right\}dk'\right]$$
$$+\frac{\epsilon\rho}{4\pi}\left[\int_{-\infty}^{\infty}\frac{1}{k'^2+\kappa^2}\left\{\frac{k'^2+\kappa^2}{D(k',\kappa)}K(k,k')B(k')-(C_R(\kappa)k'+C_I(\kappa)\kappa)K(k,0)B(0)\right\}dk'\right]. \tag{2.10b}$$

B. Perturbation analysis

1. Leading-order analysis

Now, we solve (2.10) by means of a perturbation method. We expand A, B, and κ in powers of ϵ as

$$A(k)=A_0(k)+\epsilon A_1(k)+\cdots, \tag{2.11a}$$

$$B(k)=B_0(k)+\epsilon B_1(k)+\cdots, \tag{2.11b}$$

$$\kappa=\epsilon\kappa_1+\epsilon^2\kappa_2+\cdots, \tag{2.11c}$$

substitute these expressions as well as (A1) and (A6) into (2.10), and compare the coefficient of ϵ^n $(n=0,1,\ldots)$ on both sides. At $O(\epsilon^0)$, one obtains

$$A_0(k)=-\frac{1}{2\kappa_1\lambda_0\delta(1-(\delta\mu_0/2))}[\rho K^*(0,k)A_0(0)-(1-\lambda_0e^{-k\delta})K(k,0)B_0(0)], \tag{2.12a}$$

$$B_0(k)=-\frac{1}{2\kappa_1\lambda_0\delta(1-(\delta\mu_0/2))}\left[\frac{1}{2}(k+\mu_0)K^*(0,k)A_0(0)+\rho K(k,0)B_0(0)\right]. \tag{2.12b}$$

The constants λ_0 and μ_0 are given explicitly by (A2a). If we put $k=0$ in (2.12), we have

$$(z+\rho K^*(0,0))A_0(0)-(1-\lambda_0)K(0,0)B_0(0)=0, \tag{2.13a}$$

$$\tfrac{1}{2}\mu_0K^*(0,0)A_0(0)+(z+\rho K(0,0))B_0(0)=0, \tag{2.13b}$$

where

$$z \equiv 2\kappa_1 \lambda_0 \delta (1 - \tfrac{1}{2}\delta\mu_0). \tag{2.13c}$$

The compatibility condition for (2.13) now yields the following algebraic equation for z:

$$(z+\rho K^*(0,0))(z+\rho K(0,0)) + \tfrac{1}{2}\mu_0(1-\lambda_0)K^*(0,0)K(0,0) = 0. \tag{2.14}$$

In view of relation (A3a) as well as the condition $z \neq 0$, we can find the solution of Eq. (2.14) that determines κ_1,

$$z = -\rho(K(0,0)+K^*(0,0)). \tag{2.15}$$

Using (2.13c), (A2a), and (A3b), this expression can be rewritten in an explicit form as

$$\kappa_1 = -\frac{\rho}{2\delta}\frac{1-\delta\mu_0}{1-(\delta\mu_0/2)}(K(0,0)+K^*(0,0)) = -\frac{\rho}{2\delta}\left(1 \mp \frac{1}{\sqrt{1+(2/\delta\rho^2)}}\right)(K(0,0)+K^*(0,0)). \tag{2.16}$$

The condition $\kappa > 0$ implies $\kappa_1 > 0$ when $\epsilon \to 0$ by virtue of (2.11c). Thus, the condition $\kappa_1 > 0$ is equivalent to

$$K(0,0)+K^*(0,0) \equiv \int_{-\infty}^{\infty} (v(x)+v^*(x))\mathrm{d}x < 0. \tag{2.17}$$

Under condition (2.17), the small perturbation on the constant background always generates two discrete eigenvalues whose explicit values are given by (2.16). These correspond to a pair of dark solitons of the form (1.2) with the amplitude parameters $\kappa \equiv \kappa_\pm$ and corresponding velocities $V \equiv V_\pm$ given, respectively, by

$$\kappa \sim \epsilon\kappa_1, \quad V = \mu(i\kappa) \sim \mu_0 + \mu_1(\epsilon\kappa_1)^2 = -\rho^2 \pm \sqrt{\rho^4 + \frac{2\rho^2}{\delta}} \mp \frac{2(1+\frac{2}{3}\rho^2\delta)}{\sqrt{\rho^4+(2\rho^2/\delta)}}(\epsilon\kappa_1)^2. \tag{2.18}$$

Note that the $\pm$ sign in κ and V is ordered vertically. The two solitons thus generated propagate to opposite directions with different amplitudes and velocities. This two-soliton state may be approximated by a two-soliton solution[2,4,5] of the INLS equation with the soliton parameters given by (2.18). See Appendix B for details. It should be stressed that the generation of solitons occurs without a threshold on the magnitude of the perturbation to a constant background. In Fig. 1, we display the three-dimensional plot of a two-soliton solution (B1). The soliton parameters are chosen in accordance with (2.18). Explicitly, $\rho = \delta = 1$, $\epsilon = 0.2$, $k_1 = \kappa_+ = 0.2$, $k_2 = \kappa_- = 0.746$, $v_1 = V_+ = 0.655$, $v_2 = V_- = -1.66$, $x_{10} = x_{20} = 0$. The amplitude of each soliton may be defined as $\kappa \tan(\kappa\delta/2)$, which is equal to the maximum value of the dip of $|u|^2$ [see (1.2)]. In the above-given example, the amplitude ratio is found to be 14.5. In the shallow-limit $\delta \to 0$, this ratio approaches 1 while in the deep-water limit $\delta \to \infty$, it increases indefinitely. As will be demonstrated in Sec. III, the former case represents the generation of two solitons with equal amplitude and opposite velocities.

It now follows from (2.13) and (2.15) that

$$A_0(0) = -\frac{1}{\rho}(1-\lambda_0)B_0(0). \tag{2.19}$$

Substituting (2.19) into (2.12), we obtain the leading terms for the coefficients $A(k)$ and $B(k)$,

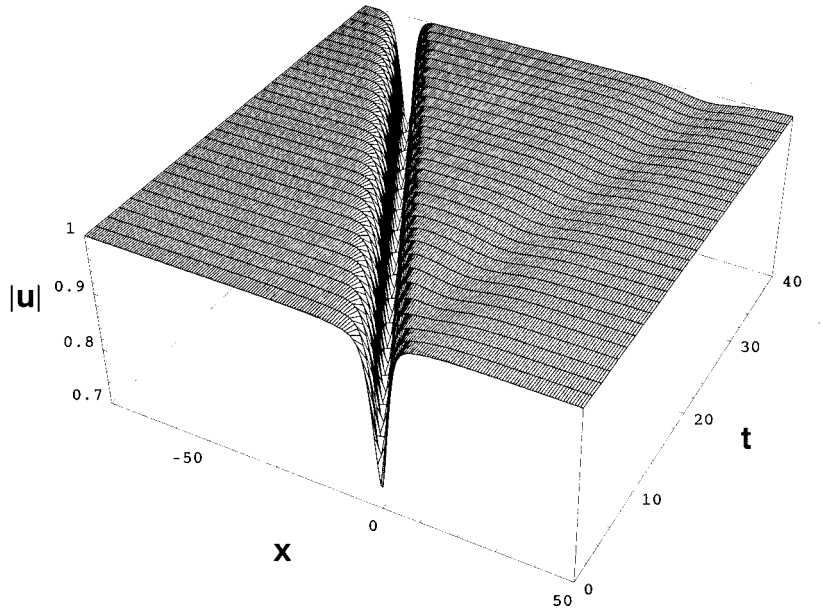

FIG. 1. Plot of a two-soliton solution of the INLS equation. The solution simulates a two-soliton state generated by a small perturbation.

$$A_0(k)=-\frac{1}{z}\left[\rho K^*(0,k)+\rho\frac{1-\lambda_0 e^{-k\delta}}{1-\lambda_0}K(k,0)\right]A_0(0), \tag{2.20a}$$

$$B_0(k)=-\frac{1}{z}\left[\rho K(k,0)-\frac{1}{2\rho}(1-\lambda_0)(k+\mu_0)K^*(0,k)\right]B_0(0). \tag{2.20b}$$

The eigenfunctions corresponding to the eigenvalue $\kappa\sim\epsilon\kappa_1$ are given from (2.3), (2.5), and (2.20) as

$$\phi(x)=-\frac{A_0(0)}{z}\int_{-\infty}^{\infty}\frac{\rho K^*(0,k)+\rho\dfrac{1-\lambda_0 e^{-k\delta}}{1-\lambda_0}K(k,0)}{D(k,\kappa)}e^{ikx/2}\,dk+O(\epsilon), \tag{2.21a}$$

$$\psi^{\pm}(x)=-\frac{B_0(0)}{z}\int_{-\infty}^{\infty}\frac{\rho K(k,0)-\dfrac{1}{2\rho}(1-\lambda_0)(k+\mu_0)K^*(0,k)}{D(k,\kappa)}e^{-k\delta/2}e^{ik(x\mp i\delta)/2}\,dk+O(\epsilon). \tag{2.21b}$$

The unknown constants $A_0(0)$ and $B_0(0)$ are fixed by specifying the asymptotic behavior of these eigenfunctions for large $|x|\sim O(1/\epsilon)$. We first observe that in view of (A4) the function $D(k,\kappa)$ behaves like

$$D(k,\kappa)=-\frac{1}{2}\lambda_0\delta\left(1-\frac{1}{2}\delta\mu_0\right)\left(k^2+\frac{(1-\lambda_0)\mu_1-\lambda_1\mu_0}{\lambda_0\delta(1-(\delta\mu_0/2))}\kappa^2\right)+O(\kappa^2 k), \tag{2.22}$$

for small k and κ. The coefficient of κ^2 in (2.22) is seen to be 1 by (A3c). Thus, we evaluate (2.21) with the aid of the Cauchy residue theorem to obtain

$$\phi(x)=\frac{2\pi A_0(0)}{\epsilon\kappa_1 z}\,\frac{\rho\{K(0,0)+K^*(0,0)\}}{\lambda_0\delta(1-(\delta\mu_0/2))}e^{-\epsilon\kappa_1|x|/2}+O(\epsilon), \tag{2.23a}$$

$$\psi^{\pm}(x)=\frac{2\pi B_0(0)}{\epsilon\kappa_1 z}\,\frac{\rho\{K(0,0)+K^*(0,0)\}}{\lambda_0\delta(1-(\delta\mu_0/2))}e^{-\epsilon\kappa_1|x|/2}+O(\epsilon). \tag{2.23b}$$

If we choose $A_0(0),B_0(0)\sim O(\epsilon)$, then (2.23) represent appropriate asymptotic forms for the bound states corresponding to the eigenvalues $\mu(i\kappa)$ given by (2.18).

2. Second-order analysis

We now proceed to the second-order analysis. The main purpose here is to derive the expression of the second-order correction κ_2 to the eigenvalue κ in terms of the initial data v. It follows from the $O(\epsilon)$ terms of (2.10) that

$$\begin{aligned}A_1(k)=&-\frac{1}{z}\Bigg[\rho K^*(0,k)A_1(0)-(1-\lambda_0e^{-k\delta})K(k,0)B_1(0)\\&-\frac{\kappa_2}{\kappa_1}\{\rho K^*(0,k)A_0(0)-(1-\lambda_0e^{-k\delta})K(k,0)B_0(0)\}\Bigg]\\&+\frac{\rho}{4\pi}\Bigg[P\int_{-\infty}^{\infty}\frac{1}{k'^2}\Bigg\{\frac{k'^2}{D(k',0)}K^*(k',k)A_0(k')\\&+\frac{2}{\lambda_0\delta(1-(\delta\mu_0/2))}K^*(0,k)A_0(0)\Bigg\}\mathrm{d}k'\Bigg]\\&-\frac{1}{4\pi}(1-\lambda_0e^{-k\delta})\Bigg[P\int_{-\infty}^{\infty}\frac{1}{k'^2}\Bigg\{\frac{k'^2}{D(k',0)}K^*(k,k')B_0(k')\\&+\frac{2}{\lambda_0\delta(1-(\delta\mu_0/2))}K^*(0,k)B_0(0)\Bigg\}\mathrm{d}k'\Bigg],\end{aligned} \tag{2.24a}$$

$$\begin{aligned}B_1(k)=&-\frac{1}{z}\Bigg[\frac{1}{2}(k+\mu_0)K^*(0,k)A_1(0)+\rho K(k,0)B_1(0)\\&-\frac{\kappa_2}{\kappa_1}\Bigg\{\frac{1}{2}(k+\mu_0)K^*(0,k)A_0(0)+\rho K(k,0)B_0(0)\Bigg\}\Bigg]+\frac{1}{8\pi}(k+\mu_0)\\&\times\Bigg[P\int_{-\infty}^{\infty}\frac{1}{k'^2}\Bigg\{\frac{k'^2}{D(k',0)}K^*(k',k)A_0(k')+\frac{2}{\lambda_0\delta(1-(\delta\mu_0/2))}K^*(0,k)A_0(0)\Bigg\}\mathrm{d}k'\Bigg]\\&+\frac{\rho}{4\pi}\Bigg[P\int_{-\infty}^{\infty}\frac{1}{k'^2}\Bigg\{\frac{k'^2}{D(k',0)}K(k,k')B_0(k')+\frac{2}{\lambda_0\delta(1-(\delta\mu_0/2))}K(0,k)B_0(0)\Bigg\}\mathrm{d}k'\Bigg],\end{aligned} \tag{2.24b}$$

where

$$D(k,0)=-\tfrac{1}{2}(k+\mu_0)(1-\lambda_0e^{-k\delta})-\rho^2, \tag{2.24c}$$

by (2.5c). We see from (A4) that for small k, $D(k,0)$ behaves like

$$D(k,0)=-\tfrac{1}{2}\lambda_0\delta(1-\tfrac{1}{2}\delta\mu_0)k^2+O(k^3). \tag{2.25}$$

Hence, the principal value should be taken for all the integrals in (2.24) since the integrands behave like k'^{-1} when $k'\to 0$. If we put $k=0$ in (2.24) and eliminate $A_1(0)$ and $B_1(0)$ with use of (2.15) and (A3a), we obtain

$$\frac{\kappa_2 z}{\kappa_1}[\rho K^*(0,0)A_0(0)-(1-\lambda_0)K(0,0)B_0(0)] + \frac{\rho z^2}{4\pi}P\int_{-\infty}^{\infty}\frac{1}{k^2}\left\{\frac{k^2}{D(k,0)}K^*(k,0)A_0(k)+\frac{4\kappa_1}{z}K^*(0,0)A_0(0)\right\}dk - \frac{1-\lambda_0}{4\pi}z^2P\int_{-\infty}^{\infty}\frac{1}{k^2}\left\{\frac{k^2}{D(k,0)}K(0,k)B_0(k)+\frac{4\kappa_1}{z}K(0,0)B_0(0)\right\}dk=0. \quad (2.26)$$

Last, introducing (2.19), (2.20), and (A2) into (2.26), we arrive at an explicit expression of κ_2 as follows:

$$\kappa_2=-\frac{\rho^2\kappa_1}{4\pi z}P\int_{-\infty}^{\infty}\frac{1}{k^2}\left[\frac{k^2}{D(k,0)}\left\{(K(0,k)+K^*(k,0))(K(k,0)+K^*(0,k)) - \frac{1}{\delta\mu_0}(1-e^{-k\delta})K(k,0)K^*(k,0)+\frac{1}{\mu_0}kK(0,k)K^*(0,k)\right\} + \frac{2(1-\delta\mu_0)}{\delta(1-(\delta\mu_0/2))}(K(0,0)+K^*(0,0))^2\right]dk. \quad (2.27)$$

Here, the ratio κ_1/z is obtained from (2.13c). We can express (2.27) in terms of v by substituting the definition (2.4c) of $K(k,k')$. However, the resulting integral with respect to k is too formidable to perform analytically. Thus, the expression (2.11c) with (2.16) and (2.27) gives the second-order approximation to the new eigenvalues generated by a small perturbation imposed on a constant background.

III. SHALLOW-WATER LIMIT

A. Eigenvalue problem

In this section, we consider the shallow-water limit of various formulas derived in Sec. II for the INLS spectral problem. It will be demonstrated that the limiting procedure can be performed smoothly by introducing appropriate scalings for the spectral parameters.

We first scale the variables x,t, and u according to the relations

$$x=\sqrt{\delta}\tilde{x},\quad t=\delta\tilde{t},\quad u=\tilde{u}(\tilde{x},\tilde{t}), \quad (3.1)$$

respectively. In this limit, the INLS equation reduces to the defocusing NLS equation (1.3) and the one-soliton solution (1.2) becomes

$$\tilde{u}=\rho\frac{1+\dfrac{\tilde{V}-i\tilde{\kappa}}{\tilde{V}+i\tilde{\kappa}}e^{-\tilde{\kappa}\tilde{\xi}}}{1+e^{-\tilde{\kappa}\tilde{\xi}}},\quad |\tilde{u}|^2=\rho^2-\frac{\tilde{\kappa}^2/2}{\cosh^2(\tilde{\kappa}\tilde{\xi}/2)}, \quad (3.2a)$$

with the scalings

$$\kappa=\frac{\tilde{\kappa}}{\sqrt{\delta}},\quad V=\frac{\tilde{V}}{\sqrt{\delta}},\quad x_0=\sqrt{\delta}\tilde{x}_0. \quad (3.2b)$$

Here, $\tilde{\xi}=\tilde{x}-\tilde{V}\tilde{t}-\tilde{x}_0$, and the soliton velocity $\tilde{V}$ is now given by $\tilde{V}=\pm\sqrt{2\rho^2-\tilde{\kappa}^2}$ $(0<\tilde{\kappa}<\sqrt{2}\rho)$.

To find the appropriate form of the IST equations corresponding to (2.1), we rescale the wave number k as $k=\tilde{k}/\sqrt{\delta}$. It then turns out that

$$\mu=-\rho^2\pm\sqrt{\frac{2\rho^2}{\delta}+\rho^4+k^2}\sim\pm\frac{1}{\sqrt{\delta}}\sqrt{\tilde{k}^2+2\rho^2}\equiv\frac{s\tilde{\mu}}{\sqrt{\delta}}, \tag{3.3a}$$

$$\lambda=1+\mu\delta+O(\delta^2)\sim1\pm\sqrt{\delta}\sqrt{\tilde{k}^2+2\rho^2}\equiv1+s\sqrt{\delta}\tilde{\mu}, \tag{3.3b}$$

where $s\equiv\pm1$.

Under these scalings, the Jost functions ϕ and $\psi^{\pm}$ take the form

$$\phi(x)\equiv\sqrt{\delta}\tilde{\phi}(\tilde{x}), \tag{3.4a}$$

$$\psi^{\pm}(x)=\psi(x\mp i\delta)=\psi(x)\mp i\delta\psi_x(x)+O(\delta^2)\equiv\tilde{\psi}(\tilde{x})\mp i\sqrt{\delta}\tilde{\psi}_{\tilde{x}}(\tilde{x})+O(\delta). \tag{3.4b}$$

Substituting (3.3) and (3.4) into (2.1) and taking the limit $\delta\to0$, we obtain

$$i\tilde{\phi}_{\tilde{x}}-\frac{\tilde{\mu}}{2}\tilde{\phi}+\tilde{u}\tilde{\psi}=0, \tag{3.5a}$$

$$-i\tilde{\psi}_{\tilde{x}}-\frac{\tilde{\mu}}{2}\tilde{\psi}+\frac{\tilde{u}^*}{2}\tilde{\phi}=0, \tag{3.5b}$$

which coincides with the spatial part of the IST equations[6] for the defocusing NLS equation.

A system of integral equations equivalent to (3.5) can be reduced from (2.6). For this purpose, we introduce the scalings

$$k=\tilde{k}/\sqrt{\delta},\quad k'=\tilde{k}'/\sqrt{\delta},\quad \alpha(k)=\delta\tilde{\alpha}(\tilde{k}),\quad \beta(k)=\sqrt{\delta}\tilde{\beta}(\tilde{k}),\quad A(k)=\delta\tilde{A}(\tilde{k}),\quad B(k)=\sqrt{\delta}\tilde{B}(\tilde{k}), \tag{3.6}$$

$$K(k,k')=\sqrt{\delta}\tilde{K}(\tilde{k},\tilde{k}')=\sqrt{\delta}\int_{-\infty}^{\infty}\tilde{v}(\tilde{x})e^{-i(\tilde{k}-\tilde{k}')\tilde{x}/2}\,d\tilde{x}.$$

At the leading order, (2.5) then become

$$A(k)\sim-\frac{\delta}{2}(\tilde{k}^2+\tilde{\kappa}^2)\tilde{\alpha}(\tilde{k})\equiv\delta\tilde{A}(\tilde{k}), \tag{3.7a}$$

$$B(k)\sim-\frac{\sqrt{\delta}}{2}(\tilde{k}^2+\tilde{\kappa}^2)\tilde{\beta}(\tilde{k})\equiv\sqrt{\delta}\tilde{B}(\tilde{k}), \tag{3.7b}$$

$$D(k,\kappa)\sim-\tfrac{1}{2}(\tilde{k}^2+\tilde{\kappa}^2). \tag{3.7c}$$

Substituting (3.3), (3.6), and (3.7) into (2.6), we obtain the system of integral equations for $\tilde{A}$ and $\tilde{B}$:

$$\tilde{A}(\tilde{k})=-\frac{\epsilon\rho}{2\pi}\int_{-\infty}^{\infty}\frac{\tilde{K}^*(\tilde{k}',\tilde{k})}{(\tilde{k}')^2+\tilde{\kappa}^2}\tilde{A}(\tilde{k}')d\tilde{k}'+\frac{\epsilon}{2\pi}(\tilde{k}-s\sqrt{2\rho^2-\tilde{\kappa}^2})\int_{-\infty}^{\infty}\frac{\tilde{K}(',\tilde{k})}{(\tilde{k}')^2+\tilde{\kappa}^2}\tilde{B}(\tilde{k}')d\tilde{k}', \tag{3.8a}$$

$$\tilde{B}(\tilde{k})=-\frac{\epsilon\rho}{4\pi}(\tilde{K}+s\sqrt{2\rho^2-\tilde{\kappa}^2})\int_{-\infty}^{\infty}\frac{\tilde{K}^*(\tilde{k}',\tilde{k})}{(\tilde{k}')^2+\tilde{\kappa}^2}\tilde{A}(\tilde{k}')\mathrm{d}\tilde{k}'-\frac{\epsilon\rho}{2\pi}\int_{-\infty}^{\infty}\frac{\tilde{K}(\tilde{k}',\tilde{k})}{(\tilde{k}')^2+\tilde{\kappa}^2}\tilde{B}(\tilde{k}')\mathrm{d}\tilde{k}'. \tag{3.8b}$$

B. Perturbation analysis

1. Leading-order analysis

We expand $\tilde{A}$, $\tilde{B}$, and $\tilde{\kappa}$ in powers of ϵ as

$$\tilde{A}(\tilde{k})=\tilde{A}_0(\tilde{k})+\epsilon\tilde{A}_1(\tilde{k})+\cdots, \tag{3.9a}$$

$$\tilde{B}(\tilde{k})=\tilde{B}_0(\tilde{k})+\epsilon\tilde{B}_1(\tilde{k})+\cdots, \tag{3.9b}$$

$$\tilde{\kappa}=\epsilon\tilde{\kappa}_1+\epsilon^2\tilde{\kappa}_2+\cdots. \tag{3.9c}$$

The expressions corresponding to (2.12), (2.16), and (2.19) become

$$2\tilde{\kappa}_1\tilde{A}_0(\tilde{k})=-\rho\tilde{K}^*(0,\tilde{k})\tilde{A}_0(0)+(\tilde{k}-s\sqrt{2}\rho)\tilde{K}(\tilde{k},0)\tilde{B}_0(0), \tag{3.10a}$$

$$2\tilde{\kappa}_1\tilde{B}_0(\tilde{k})=-\tfrac{1}{2}(\tilde{k}+s\sqrt{2}\rho)\tilde{K}^*(0,\tilde{k})\tilde{A}_0(0)-\rho\tilde{K}(\tilde{k},0)\tilde{B}_0(0), \tag{3.10b}$$

$$\tilde{\kappa}_1=-\frac{\rho}{2}\{\tilde{K}(0,0)+\tilde{K}^*(0,0)\}=-\frac{\rho}{2}\int_{-\infty}^{\infty}(\tilde{v}(\tilde{x})+\tilde{v}^*(\tilde{x})\mathrm{d}\tilde{x}, \tag{3.11}$$

$$\tilde{A}_0(0)=\sqrt{2}s\tilde{B}_0(0), \tag{3.12}$$

respectively. Thus, if $\tilde{\kappa}_1>0$, then the new eigenvalues

$$s\tilde{\mu}=\pm\sqrt{2\rho^2-(\epsilon\tilde{\kappa}_1)^2}\sim\pm(\sqrt{2\rho^2}-(\epsilon\tilde{\kappa}_1)^2/(2\sqrt{2\rho^2})), \tag{3.13}$$

with $\tilde{\kappa}_1$ given by (3.11) appear from the small initial data $\epsilon\tilde{v}$ without a threshold. Namely, any small perturbation generates a pair of dark solitons with an equal amplitude and opposite velocities $\pm\tilde{\mu}$. This result is in agreement with the corresponding one derived by a different method.[13] The expressions (2.20) now reduce to

$$\tilde{A}_0(\tilde{k})=-\frac{\rho}{2\tilde{\kappa}_1}\left\{\frac{s}{\sqrt{2}\rho}(-\tilde{k}+s\sqrt{2}\rho)\tilde{K}(\tilde{k},0)\mp K^*(0,\tilde{k})\right\}\tilde{A}_0(0), \tag{3.14a}$$

$$\tilde{B}_0(\tilde{k})=-\frac{\rho}{2\tilde{\kappa}_1}\left\{\tilde{K}(\tilde{k},0)+\frac{s}{\sqrt{2}\rho}(\tilde{k}+s\sqrt{2}\rho)\tilde{K}^*(0,\tilde{k})\right\}\tilde{B}_0(0). \tag{3.14b}$$

The eigenfunctions corresponding to the eigenvalue $\tilde{\kappa}\sim\epsilon\kappa_1$ follow from (2.21) as

$$\tilde{\phi}(\tilde{x})=\frac{2\rho\tilde{A}_0(0)}{\tilde{z}}\int_{-\infty}^{\infty}\frac{\frac{s}{\sqrt{2}\rho}(-\tilde{k}+s\sqrt{2}\rho)\tilde{K}(\tilde{k},0)+\tilde{K}^*(0,\tilde{k})}{\tilde{k}^2+\tilde{\kappa}^2}e^{i\tilde{k}\tilde{x}/2}\mathrm{d}\tilde{k}+O(\epsilon), \tag{3.15a}$$

$$\tilde{\psi}(\tilde{x})=\frac{2\rho\tilde{B}_0(0)}{\tilde{z}}\int_{-\infty}^{\infty}\frac{\tilde{K}(\tilde{k},0)+\frac{s}{\sqrt{2}\rho}(\tilde{k}+s\sqrt{2}\rho)\tilde{K}^*(0,\tilde{k})}{\tilde{k}^2+\tilde{\kappa}^2}e^{i\tilde{k}\tilde{x}/2}\mathrm{d}\tilde{k}+O(\epsilon), \tag{3.15b}$$

where

$$\tilde{z}=-\rho\{\tilde{K}(0,0)+\tilde{K}^*(0,0)\}. \tag{3.15c}$$

If we take $\tilde{A}_0(0),\tilde{B}_0(0)\sim O(\epsilon)$, then we can see that (3.14) represent the appropriate bound states for the eigenvalues $s\tilde{\mu}$ given by (3.13).

2. Second-order analysis

In the limit of $\delta\to 0$, $\lambda_0\sim 1$ and $\mu_0\sim s\sqrt{2\rho^2/\delta}$ $(s=\pm 1)$ as seen from (A7). Substituting these approximate values as well as (3.6) and (3.7c) into (2.27), we find the second-order correction to $\tilde{\kappa}$,

$$\tilde{\kappa}_2=\frac{\rho^2}{4\pi}P\int_{-\infty}^{\infty}\frac{1}{\tilde{k}^2}\Bigg[(\tilde{K}(0,\tilde{k})+\tilde{K}^*(\tilde{k},0))(\tilde{K}(\tilde{k},0)+\tilde{K}^*(0,\tilde{k}))-(\tilde{K}(0,0)+\tilde{K}^*(0,0))^2$$
$$-\frac{s}{\sqrt{2}\rho}\tilde{k}\tilde{K}(\tilde{k},0)\tilde{K}^*(\tilde{k},0)+\frac{s}{\sqrt{2}\rho}\tilde{k}\tilde{K}(0,\tilde{k})\tilde{K}^*(0,\tilde{k})\Bigg]\mathrm{d}\tilde{k}. \tag{3.16}$$

If we use (3.6) for $\tilde{K}(\tilde{k},\tilde{k}')$ and the formulas

$$\frac{1}{\pi}P\int_{-\infty}^{\infty}\frac{e^{ikx}-1}{k^2}\mathrm{d}k=-|x|, \tag{3.17a}$$

$$P\int_{-\infty}^{\infty}\frac{e^{ikx}}{k}\mathrm{d}k=\pi i\,\mathrm{sgn}\,x, \tag{3.17b}$$

(3.16) can be rewritten in terms of the perturbation $\tilde{v}$ as

$$\tilde{\kappa}_2=-\frac{\rho^2}{8}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\mathrm{d}\tilde{x}\,\mathrm{d}\tilde{y}|\tilde{x}-\tilde{y}|(\tilde{v}(\tilde{x})+\tilde{v}^*(\tilde{x}))(\tilde{v}(\tilde{y})+\tilde{v}^*(\tilde{y}))$$
$$+\frac{i\rho s}{2\sqrt{2}}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\mathrm{d}\tilde{x}\,\mathrm{d}\tilde{y}\,\mathrm{sgn}(\tilde{x}-\tilde{y})\{\tilde{v}(\tilde{x})\tilde{v}^*(\tilde{y})-\tilde{v}^*(\tilde{x})\tilde{v}(\tilde{y})\}. \tag{3.18}$$

This expression for the second-order correction to the new eigenvalue is obtained here for the first time.

IV. DEEP-WATER LIMIT

A. Eigenvalue problem

In the deep-water limit $\delta\to\infty$, we find it appropriate to scale the parameter κ as

$$\kappa=\frac{\pi}{\delta}\left(1-\frac{1}{a\delta}\right),\quad 0<a<\frac{\rho^2}{2}. \tag{4.1}$$

Then, the one-soliton solution (1.2) reduces to the algebraic soliton of the form

$$u=\rho\frac{a\xi+i\left(1+\dfrac{2a}{V}\right)}{a\xi+i},\quad |u|^2=\rho^2-\frac{2a}{(a\xi)^2+1}, \tag{4.2}$$

where $\xi=x-Vt-x_0$ and V is the velocity of the soliton determined by the algebraic equation $V^2+2\rho^2V+2\rho^2a=0$. In the deep-water limit, the eigenvalue derived in Sec. II for the INLS

equation does not yield a nonzero value. Indeed, we can see by using (A2) that both the first-order correction (2.16) and second-order one (2.27) vanish identically. This fact would imply that the limiting procedures $\epsilon \to 0$ and $\delta \to \infty$ cannot be interchanged. We should take the limit $\delta \to \infty$ first and then develop a perturbation expansion in ϵ. It turns out that the eigenvalue problem for the nonlocal NLS equation would exhibit a novel feature when compared with that of the INLS and defocusing NLS equations.

The linear system (2.1) remains the same form

$$i\phi_x - \frac{\mu}{2}\phi + \rho\psi^+ = -\epsilon v\psi^+, \tag{4.3a}$$

$$\psi^+ - \lambda\psi^- + \rho\phi = -\epsilon v^*\phi, \tag{4.3b}$$

but here $\psi^+(\psi^-)$ represents the boundary value of a function analytic in the upper-(lower-)half complex x plane. For the bound states, we impose the boundary conditions $\phi \sim \phi_0/x$, $\psi^\pm \sim \pm 1/x$, $|x| \to \infty$ where ϕ_0 is a constant. Using (2.2), the parameters μ and λ are expanded as

$$\mu(k) = -\rho^2 \pm (\rho^2 + |k|)\left\{1 + \frac{2\rho^2|k|}{(\rho^2+|k|)^2} e^{-2|k|\delta} + \cdots\right\}, \tag{4.4a}$$

$$\lambda(k) = \frac{2|k|}{(|k|-\mu)e^{|k|\delta} + (|k|+\mu)e^{-|k|\delta}}. \tag{4.4b}$$

By virtue of (4.1), the expressions of $\mu(i\kappa)$ and $\lambda(i\kappa)$ which follow from (2.2) become

$$\mu(i\kappa) \sim \rho^2\left(-1 \pm \sqrt{1 - \frac{2a}{\rho^2}}\right) \equiv \mu_\pm, \tag{4.5a}$$

$$\lambda(i\kappa) \sim -\frac{1}{1 + \dfrac{\mu(i\kappa)}{a}}. \tag{4.5b}$$

With $\mu(i\kappa)$ and $\lambda(i\kappa)$ given by (4.5), the function $D(k,\kappa)$ defined by (2.5c) has the following leading-order expression:

$$D(k,\kappa) \sim -\tfrac{1}{2}(k + \mu(i\kappa) + 2\rho^2) \quad (k>0), \tag{4.6a}$$

$$D(k,\kappa) \sim \tfrac{1}{2}(k + \mu(i\kappa))\lambda(i\kappa)e^{-k\delta} \quad (k<0). \tag{4.6b}$$

In order to find an appropriate form of the linear system corresponding to (2.6), we define the new variables $A_\pm$ and $B_\pm$ by the relations

$$A(k) = \theta(k)A_+(k) + \lambda(i\kappa)e^{-k\delta}\theta(-k)A_-(k), \tag{4.7a}$$

$$B(k) = \theta(k)B_+(k) + \theta(-k)\lambda(i\kappa)B_-(k), \tag{4.7b}$$

where $\theta(k)$ is the Heaviside function, i.e., $\theta(k)=1$ for $k>0$, and $\theta(k)=0$ for $k<0$. Substituting (4.6) and (4.7) into (2.6), we obtain, in the limit of $\delta \to \infty$, the following closed system of integral equations for $A_\pm$ and B_+:

$$A_+(k)=-\frac{\epsilon\rho}{2\pi}\int_0^\infty \frac{K^*(k',k)}{k'+\mu(i\kappa)+2\rho^2}A_+(k')\mathrm{d}k'+\frac{\epsilon\rho}{2\pi}\int_{-\infty}^0 \frac{K^*(k',k)}{k'+\mu(i\kappa)}A_-(k')\mathrm{d}k'$$
$$+\frac{\epsilon}{2\pi}\int_0^\infty \frac{K(k,k')}{k'+\mu(i\kappa)+2\rho^2}B_+(k')\mathrm{d}k' \quad (k>0), \tag{4.8a}$$

$$A_-(k)=-\frac{\epsilon}{2\pi}\int_0^\infty \frac{K(k,k')}{k'+\mu(i\kappa)+2\rho^2}B_+(k')\mathrm{d}k' \quad (k<0), \tag{4.8b}$$

$$B_+(k)=\frac{\epsilon}{4\pi}(k+\mu(i\kappa))\left[-\int_0^\infty \frac{K^*(k',k)}{k'+\mu(i\kappa)+2\rho^2}A_+(k')\mathrm{d}k'+\int_{-\infty}^0 \frac{K^*(k',k)}{k'+\mu(i\kappa)}A_-(k')\mathrm{d}k'\right]$$
$$-\frac{\epsilon\rho}{2\pi}\int_0^\infty \frac{K(k,k')}{k'+\mu(i\kappa)+2\rho^2}B_+(k')\mathrm{d}k' \quad (k>0). \tag{4.8c}$$

Note that the equation for $B_-(k)$ $(k<0)$ is obtained simply by replacing $B_+(k)$ by $\lambda(i\kappa)B_-(k)$ on the left-hand side of (4.8c).

The eigenfunctions corresponding to the eigenvalue $\mu(i\kappa)$ follow from (2.3), (2.5), (4.6), and (4.7). Explicitly, they take the form

$$\phi(x)=-2\int_0^\infty \frac{A_+(k)}{k+\mu(i\kappa)+2\rho^2}e^{ikx/2}\,\mathrm{d}k+2\int_{-\infty}^0 \frac{A_-(k)}{k+\mu(i\kappa)}e^{ikx/2}\,\mathrm{d}k, \tag{4.9a}$$

$$\psi^+(x)=-2\int_0^\infty \frac{B_+(k)}{k+\mu(i\kappa)+2\rho^2}e^{ikx/2}\,\mathrm{d}k, \tag{4.9b}$$

$$\psi^-(x)=2\int_{-\infty}^0 \frac{B_-(k)}{k+\mu(i\kappa)}e^{ikx/2}\,\mathrm{d}k. \tag{4.9c}$$

B. Perturbation analysis

1. Leading-order analysis

Now, we shall apply a perturbation method to Eq. (4.8) for two different values $\mu_\pm$ given by (4.5a). The constant a in $\mu_\pm$ should be a small quantity since it represents a dip on the constant background [see (4.2)] induced by a small initial data.

a. $\mu(i\kappa)=\mu_-$. We first consider the case $\mu(i\kappa)=\mu_-=\rho^2(-1-\sqrt{1-(2a/\rho^2)})$. Note that $\mu_-\sim-2\rho^2$, $\mu_+\sim-a$, $\lambda(i\kappa)\sim a/(2\rho^2)$ in the limit of $a\to0$. Hence, the integrand including a factor $(k'-\mu_+)^{-1}$ in Eq. (4.8) becomes singular when $k'\to0$. Indeed, it yields a logarithmic singularity upon integration. We remove this singularity by a similar procedure to that used in Sec. II [see (2.10)]. The resulting integral equations are written in the form

$$A_+(k)=\frac{\epsilon\rho}{2\pi}\left[-\int_0^1 \frac{K^*(0,k)}{k'-\mu_+}A_+(0)\mathrm{d}k'-\int_0^1 \frac{K^*(k',k)A_+(k')-K^*(0,k)A_+(0)}{k'-\mu_+}\mathrm{d}k'\right.$$
$$\left.-\int_1^\infty \frac{K^*(k',k)}{k'-\mu_+}A_+(k')\mathrm{d}k'+\int_{-\infty}^0 \frac{K^*(k',k)}{k'+\mu_-}A_-(k')\mathrm{d}k'\right]$$
$$+\frac{\epsilon}{2\pi}\left[\int_0^1 \frac{K(k,0)}{k'-\mu_+}B_+(0)\mathrm{d}k'+\int_0^1 \frac{K(k,k')B_+(k')-K(k,0)B_+(0)}{k'-\mu_+}\mathrm{d}k'\right.$$
$$\left.+\int_1^\infty \frac{K(k,k')}{k'-\mu_+}B_+(k')\mathrm{d}k'\right] \quad (k>0), \tag{4.10a}$$

$$A_-(k)=-\frac{\epsilon}{2\pi}\left[\int_0^1\frac{K(k,0)}{k'-\mu_+}B_+(0)\mathrm{d}k'+\int_0^1\frac{K(k,k')B_+(k')-K(k,0)B_+(0)}{k'-\mu_+}\mathrm{d}k'\right.$$
$$\left.+\int_1^\infty\frac{K(k,k')}{k'-\mu_+}B_+(k')\mathrm{d}k'\right]\quad(k<0),\tag{4.10b}$$

$$B_+(k)=\frac{\epsilon}{4\pi}(k+\mu_-)\left[-\int_0^1\frac{K^*(0,k)}{k'-\mu_+}A_+(0)\mathrm{d}k'-\int_0^1\frac{K^*(k',k)A_+(k')-K^*(0,k)A_+(0)}{k'-\mu_+}\mathrm{d}k'\right.$$
$$\left.-\int_1^\infty\frac{K^*(k',k)}{k'-\mu_+}A_+(k')\mathrm{d}k'+\int_{-\infty}^0\frac{K^*(k',k)}{k'+\mu_-}A_-(k')\mathrm{d}k'\right]-\frac{\epsilon\rho}{2\pi}\left[\int_0^1\frac{K(k,0)}{k'-\mu_+}B_+(0)\mathrm{d}k'\right.$$
$$\left.+\int_0^1\frac{K(k,k')B_+(k')-K(k,0)B_+(0)}{k'-\mu_+}\mathrm{d}k'+\int_1^\infty\frac{K(k,k')}{k'-\mu_+}B_+(k')\mathrm{d}k'\right]\quad(k>0).\tag{4.10c}$$

We now solve Eq. (4.10) in the form of an asymptotic series in ϵ. By inspecting the magnitude of each term in (4.10), it is legitimate to expand $A_\pm$, B_+, and μ_+ as

$$A_\pm(k)=A_\pm^{(0)}(k)+\epsilon A_\pm^{(1)}(k)+\cdots,\tag{4.11a}$$

$$B_+(k)=B_+^{(0)}(k)+\epsilon B_+^{(1)}(k)+\cdots,\tag{4.11b}$$

$$\ln(-\mu_+)=\frac{1}{\epsilon}\mu_+^{(-1)}+\mu_+^{(0)}+\cdots.\tag{4.11c}$$

Note that the expression of μ_- is simply derived by the relation $\mu_-=-\mu_+-2\rho^2$. At $O(\epsilon^0)$, one obtains

$$A_+^{(0)}(k)=\frac{1}{2\pi}\mu_+^{(-1)}[\rho K^*(0,k)A_+^{(0)}(0)-K(k,0)B_+^{(0)}(0)],\tag{4.12a}$$

$$A_-^{(0)}(k)=\frac{1}{2\pi}\mu_+^{(-1)}K(k,0)B_+^{(0)}(0),\tag{4.12b}$$

$$B_+^{(0)}(k)=\frac{1}{4\pi}\mu_+^{(-1)}[(k-2\rho^2)K^*(0,k)A_+^{(0)}(0)+2\rho K(k,0)B_+^{(0)}(0)].\tag{4.12c}$$

If we put $k=0$ in (4.12), we have

$$\left\{1-\frac{\rho}{2\pi}\mu_+^{(-1)}K^*(0,0)\right\}A_+^{(0)}(0)+\frac{1}{2\pi}\mu_+^{(-1)}K(0,0)B_+^{(0)}(0)=0.\tag{4.13a}$$

$$\frac{\rho^2}{2\pi}\mu_+^{(-1)}K^*(0,0)A_+^{(0)}(0)+\left\{1-\frac{\rho}{2\pi}\mu_+^{(-1)}K(0,0)\right\}B_+^{(0)}(0)=0,\tag{4.13b}$$

which gives the leading-order expression of μ_+,

$$\mu_+^{(-1)}=\frac{2\pi}{\rho}\frac{1}{K(0,0)+K^*(0,0)}.\tag{4.14}$$

This corresponds to the expression (2.16) for the INLS equation and the expression (3.11) for the defocusing NLS equation. To assure the convergence of the expansion (4.11c), one must impose the condition $\mu_+^{(-1)}<0$, which is equivalent to

$$K(0,0)+K^*(0,0)=\int_{-\infty}^{\infty}(v(x)+v^*(x))\mathrm{d}x<0. \tag{4.15}$$

Under this condition, a small eigenvalue would appear from the edge $k=0$ of the continuous spectrum. It is quite interesting to observe that the mechanism of the soliton generation is similar to that of the BO equation.[10] This result may be expected since Eq. (1.4) has been derived from the BO equation by means of an asymptotic multiscale expansion.[2]

It now follows from (4.13) and (4.14) that

$$B_+^{(0)}(0)=-\rho A_+^{(0)}(0). \tag{4.16}$$

Substituting (4.16) into (4.12), one obtains

$$A_+^{(0)}(k)=\frac{\rho}{2\pi}\mu_+^{(-1)}\{K(k,0)+K^*(0,k)\}A_+^{(0)}(0), \tag{4.17a}$$

$$A_-^{(0)}(k)=-\frac{\rho}{2\pi}\mu_+^{(-1)}K(k,0)A_+^{(0)}(0), \tag{4.17b}$$

$$B_+^{(0)}(k)=\frac{1}{4\pi}\mu_+^{(-1)}\{(k-2\rho^2)K(k,0)-2\rho^2K^*(0,k)\}A_+^{(0)}(0). \tag{4.17c}$$

The eigenfunctions corresponding to the eigenvalue $\mu(i\kappa)=\mu_-$ follow from (4.9), (4.17) and the relation $\mu_++\mu_-=-2\rho^2$. They read in the form

$$\phi(x)=-2\int_0^{\infty}\frac{A_+^{(0)}(k)}{k-\mu_+}e^{ikx/2}\,\mathrm{d}k+2\int_{-\infty}^{0}\frac{A_-^{(0)}(k)}{k+\mu_-}e^{ikx/2}\,\mathrm{d}k+O(\epsilon), \tag{4.18a}$$

$$\psi^+(x)=-2\int_0^{\infty}\frac{B_+^{(0)}(k)}{k-\mu_+}e^{ikx/2}\,\mathrm{d}k+O(\epsilon), \tag{4.18b}$$

$$\psi^-(x)=2\int_{-\infty}^{0}\frac{B_-^{(0)}(k)}{k+\mu_-}e^{ikx/2}\,\mathrm{d}k+O(\epsilon). \tag{4.18c}$$

The asymptotic forms of these eigenfunctions for $|x|\to\infty$ can be evaluated easily upon integration by parts and using (4.16) and the relation $\lambda(i\kappa)B_-^{(0)}(0)=B_+^{(0)}(0)$. The resulting expressions are given by

$$\phi(x)\sim\frac{4i}{\mu_+}\frac{A_+^{(0)}(0)}{x}, \tag{4.19a}$$

$$\psi^+(x)\sim-\frac{4i\rho}{\mu_+}\frac{A_+^{(0)}(0)}{x}, \tag{4.19b}$$

$$\psi^-(x)\sim\frac{4i\rho}{\mu_+}\frac{A_+^{(0)}(0)}{x}. \tag{4.19c}$$

The boundary conditions are satisfied if we put $A_+^{(0)}(0)=-\mu_+/(4i\rho)$.

b. $\mu(i\kappa)=\mu_+$. Next, we consider the generation of another eigenvalue $\mu(i\kappa)=\mu_+ =\rho^2(-1+\sqrt{1-(2a/\rho^2)})$. It then follows that $\mu_+\sim -a$, $\mu_-\sim -2\rho^2$, $\lambda(i\kappa)\sim 2\rho^2/a$ when $a\to 0$. This case can be treated following the same procedure as that developed for μ_-.

The linear system (4.8) now becomes

$$A_+(k)=-\frac{\epsilon\rho}{2\pi}\int_0^\infty \frac{K^*(k',k)}{k'-\mu_-}A_+(k')\mathrm{d}k'+\frac{\epsilon\rho}{2\pi}\int_{-\infty}^0 \frac{K^*(k',k)}{k'+\mu_+}A_-(k')\mathrm{d}k' + \frac{\epsilon}{2\pi}\int_0^\infty \frac{K(k,k')}{k'-\mu_-}B_+(k')\mathrm{d}k' \quad (k>0), \tag{4.20a}$$

$$A_-(k)=-\frac{\epsilon}{2\pi}\int_0^\infty \frac{K(k,k')}{k'-\mu_-}B_+(k')\mathrm{d}k' \quad (k<0), \tag{4.20b}$$

$$B_+(k)=\frac{\epsilon}{4\pi}(k+\mu_+)\left[-\int_0^\infty \frac{K^*(k',k)}{k'-\mu_-}A_+(k')\mathrm{d}k'+\int_{-\infty}^0 \frac{K^*(k',k)}{k'+\mu_+}A_-(k')\mathrm{d}k'\right] - \frac{\epsilon\rho}{2\pi}\int_0^\infty \frac{K(k,k')}{k'-\mu_-}B_+(k')\mathrm{d}k' \quad (k>0). \tag{4.20c}$$

The singularity arises from a factor $(k'+\mu_+)^{-1}$ when $k'\to 0$. The balance of the magnitude in ϵ would be satisfied if we assume the following expansions:

$$A_+(k)=A_+^{(0)}(k)+\epsilon A_+^{(1)}(k)+\cdots, \tag{4.21a}$$

$$A_-(k)=\epsilon A_-^{(1)}(k)+\epsilon^2 A_-^{(2)}(k)+\cdots, \tag{4.21b}$$

$$B_+(k)=B_+^{(0)}(k)+\epsilon B_+^{(1)}(k)+\cdots, \tag{4.21c}$$

$$\ln(-\mu_+)=\frac{1}{\epsilon^2}\mu_+^{(-2)}+\frac{1}{\epsilon}\mu_+^{(-1)}+\cdots. \tag{4.21d}$$

We substitute (4.21) into the linear system analogous to (4.10) and compare the coefficients of ϵ^n $(n=0,1,\ldots)$. At the lowest order, we obtain the relations

$$A_+^{(0)}(k)=\frac{\rho}{2\pi}\mu_+^{(-2)}K^*(0,k)A_-^{(0)}(0), \tag{4.22a}$$

$$A_-^{(1)}(k)=-\frac{1}{2\pi}\int_0^\infty \frac{K(k,k')}{k'+2\rho^2}B_+^{(0)}(k')\mathrm{d}k', \tag{4.22b}$$

$$B_+^{(0)}(k)=\frac{k}{4\pi}\mu_+^{(-2)}K^*(0,k)A_-^{(1)}(0). \tag{4.22c}$$

If we introduce (4.22) into (4.9) with $\mu(i\kappa)=\mu_+$, we obtain the lowest-order expressions of the Jost functions. The asymptotic evaluation of the Jost functions for $|x|\to\infty$ reveals that $\phi(x)\sim O(x^{-1})$ and $\psi^{\pm}\sim O(x^{-2})$. The latter expression comes from the fact $B_+^{(0)}(0)=0$ by (4.22c), which may be contrasted with the corresponding value $B_+^{(0)}(0)\neq 0$ derived from (4.17c). Obviously, these asymptotic forms are not consistent with the boundary conditions. Thus, we conclude that the perturbation does not produce a new eigenvalue in the eigenvalue problem (4.3) with $\mu(i\kappa)=\mu_+$.

2. Second-order analysis

We now evaluate the second-order correction to the eigenvalue in the case of $\mu(i\kappa)=\mu_-$. At $O(\epsilon)$, (4.10) and (4.11) yield the following linear system of integral equations for $A_+^{(1)}$, $A_-^{(1)}$ and $B_+^{(1)}$:

$$A_+^{(1)}(k)=\frac{\rho}{2\pi}[\{\mu_+^{(-1)}A_+^{(1)}(0)+\mu_+^{(0)}A_+^{(0)}(0)\}K^*(0,k)-F(k)]$$
$$+\frac{1}{2\pi}[-\{\mu_+^{(-1)}B_+^{(1)}(0)+\mu_+^{(0)}B_+^{(0)}(0)\}K(k,0)+G(k)], \tag{4.23a}$$

$$A_-^{(1)}(k)=\frac{1}{2\pi}[\{\mu_+^{(-1)}B_+^{(1)}(0)+\mu_+^{(0)}B_+^{(0)}(0)\}K(k,0)-F(k)], \tag{4.23b}$$

$$B_+^{(1)}(k)=\frac{1}{4\pi}(k-2\rho^2)[\{\mu_+^{(-1)}A_+^{(1)}(0)+\mu_+^{(0)}A_+^{(0)}(0)\}K^*(0,k)-F(k)]$$
$$-\frac{2\rho}{\pi}[-\{\mu_+^{(-1)}B_+^{(1)}(0)+\mu_+^{(0)}B_+^{(0)}(0)\}K(k,0)+G(k)], \tag{4.23c}$$

with

$$F(k)\equiv\int_0^1\frac{1}{k'}\{K^*(k',k)A_+^{(0)}(k')-K^*(0,k)A_+^{(0)}(0)\}dk'$$
$$+\int_1^\infty\frac{K^*(k',k)A_+^{(0)}(k')}{k'}dk'-\int_{-\infty}^0\frac{K^*(k',k)A_-^{(0)}(k')}{k'-2\rho^2}dk', \tag{4.24a}$$

$$G(k)\equiv\int_0^1\frac{1}{k'}\{K(k,k')B_+^{(0)}(k')-K(k,0)B_+^{(0)}(0)\}dk'+\int_1^\infty\frac{K^*(k,k')B_+^{(0)}(k')}{k'}dk'. \tag{4.24b}$$

If we put $k=0$ in (4.23a) and (4.23b) and eliminate $A_+^{(1)}(0)$ and $B_+^{(1)}(0)$ with use of (4.14), we obtain

$$\frac{1}{2\pi}\{\rho K^*(0,0)A_+^{(0)}(0)-K(0,0)B_+^{(0)}(0)\}\mu_+^{(0)}=\frac{\rho}{2\pi}F(0)-\frac{1}{2\pi}G(0). \tag{4.25a}$$

Substitution of (4.16) into (4.25a) gives

$$\frac{\rho}{2\pi}\{K(0,0)+K^*(0,0)\}A_+^{(0)}(0)\mu_+(0)=\frac{\rho}{2\pi}F(0)-\frac{1}{2\pi}G(0). \tag{4.25b}$$

The specific values $F(0)$ and $G(0)$ are expressed in terms of $K(k,k')$ and $K^*(k,k')$ by introducing (4.17) into (4.24). The resulting expressions are substituted into (4.25b) to obtain the second-order quantity $\mu_+^{(0)}$,

$$\frac{\mu_+^{(0)}}{\mu_+^{(-1)}}=\frac{\rho}{2\pi}\int_0^1\frac{1}{k}\left[\frac{\{K(0,k)+K^*(k,0)\}\{K(k,0)+K^*(0,k)\}}{K(0,0)+K^*(0,0)}-\{K(0,0)+K^*(0,0)\}\right]\mathrm{d}k$$
$$+\frac{\rho^2\mu_+^{(-1)}}{4\pi^2}\int_1^\infty\frac{1}{k}\{K(0,k)+K^*(k,0)\}\{K(k,0)+K^*(0,k)\}\mathrm{d}k$$
$$+\frac{\mu_+^{(-1)}}{8\pi^2}\left[-\int_0^\infty K(0,k)K^*(0,k)\mathrm{d}k+2\rho^2\int_{-\infty}^0\frac{K(k,0)K^*(k,0)}{k-2\rho^2}\mathrm{d}k\right]. \tag{4.26}$$

Lastly, we use the definition (2.4c) for $K(k,k')$ and the formula

$$\int_0^1\frac{e^{izs}-1}{s}\mathrm{d}s+\int_1^\infty\frac{e^{izs}}{s}\mathrm{d}s=-\gamma-\ln|z|+\frac{i\pi}{2}\mathrm{sgn}(z)\quad(\gamma:\text{Euler's constant}), \tag{4.27}$$

to express $\mu_+^{(0)}$ in terms of the initial data v. The result is

$$\mu_+^{(0)}=\left(\frac{\rho\mu_+^{(-1)}}{2\pi}\right)^2\left[-(\gamma-\ln 2)\left\{\int_{-\infty}^\infty(v(x)+v^*(x))\mathrm{d}x\right\}^2\right.$$
$$-\int_{-\infty}^\infty\int_{-\infty}^\infty\mathrm{d}x\,\mathrm{d}y(v(x)+v^*(x))(v(y)+v^*(y))\ln|x-y|$$
$$\left.-\int_{-\infty}^\infty\int_{-\infty}^\infty\mathrm{d}x\,\mathrm{d}yv(x)v^*(y)\int_0^\infty\frac{s+2}{s+1}e^{i\rho^2(x-y)s}\mathrm{d}s\right]. \tag{4.28}$$

Note that if $v(x)$ is an analytic function in the upper-half complex x plane, then the third-term on the right-hand side of (4.28) vanishes identically.

Up to the second-order approximation in ϵ, we thus obtain the expression of a new eigenvalue generated by a small initial data. Actually, it follows from (4.11c) that

$$\mu_+\sim-e^{\mu_+^{(0)}}e^{\mu_+^{(-1)}/\epsilon}, \tag{4.29}$$

where $\mu_+^{(-1)}$ and $\mu_+^{(0)}$ are given, respectively, by (4.14) and (4.28). This implies the generation of a new soliton of the form (4.2) whose amplitude parameter a and velocity V are given, respectively, by the relations $a=-\mu_+(\mu_++2\rho^2)/(2\rho^2)\sim-\mu_+$ and $V=\mu_-\sim-2\rho^2$. The magnitude of a is exponentially small compared with ϵ in contrast to the corresponding result for the INLS and defocusing NLS equations for which the magnitude is comparable to that of the perturbation.

V. CONCLUDING REMARKS

In this paper, we studied the problem of the soliton generation by a small perturbation on the basis of the INLS equation. In particular, we analyzed the spectral problem associated with it by means of the Fourier transform. An important generalization of our approach would be to investigate the mechanism of the soliton generation induced by a small perturbation on the general N-soliton state. This problem has been discussed in the case of the BO[10] and KPI[12] equations where the completeness relations for the Jost functions have played a central role in the perturbation analysis. For the spectral problem associated with the INLS equation, however, the corresponding completeness relation has not been established yet. We also remark that the soliton generation for the nonlocal NLS equation (1.4) has been considered quite recently in conjunction with the linear stability of the N-soliton solution.[9] We have found that any small perturbation on the N-soliton solution would produce a new soliton if the condition $\epsilon\int_{-\infty}^\infty(u_N(x)v^*(x)+u_N^*(x)v(x))\mathrm{d}x<0$ is satisfied where u_N is an N-soliton solution and $\epsilon v(x)$ is a perturbation. If we put $u_N=\rho$ ("0-soliton" state), then the above-given condition reduces to (4.15), which is just

a condition for the generation of a new soliton. One may extract a similar condition for the INLS equation through a full development of the associated spectral problem. Undoubtedly, this will become an important issue in the near future.

APPENDIX A: PROPERTIES OF THE FUNCTION $D(k,\kappa)$

In this Appendix, we describe some properties of the function $D(k,\kappa)$ introduced in (2.8) as well as those of the spectral parameters μ and λ.

By taking into account the fact that the parameters $\mu(i\kappa)$ and $\lambda(i\kappa)$ are even functions of κ, we expand $\mu(i\kappa)$ and $\lambda(i\kappa)$ in powers of κ^2,

$$\mu(i\kappa)=\mu_0+\mu_1\kappa^2+\cdots, \quad \lambda(i\kappa)=\lambda_0+\lambda_1\kappa^2+\cdots. \tag{A1}$$

Substituting these expressions into (2.2) and comparing the coefficient of κ^{2n} $(n=0,1,\ldots)$, one can determine μ_j and λ_j $(j=0,1,\ldots)$ successively. The first two terms of which read in the form

$$\mu_0^2+2\rho^2\mu_0-\frac{2\rho^2}{\delta}=0, \quad \lambda_0=\frac{1}{1-\delta\mu_0}, \tag{A2a}$$

$$\mu_1=-\frac{1+\frac{2}{3}\rho^2\delta}{2(\mu_0+\rho^2)}, \quad \lambda_1=\frac{\delta+\frac{1}{3}\rho^2\delta^2}{2(\mu_0+\rho^2)(\delta\mu_0-1)}. \tag{A2b}$$

Note that μ_0 has two real roots given by $\mu_0=-\rho^2+s\sqrt{\rho^4+(2\rho^2/\delta)}$ $(s\equiv\pm1)$ and the coefficients λ_0, μ_j and λ_j $(j\geqslant1)$ are expressed in terms of μ_0. Direct calculations using (A2) give the relations

$$\mu_0(1-\lambda_0)+2\rho^2=0, \tag{A3a}$$

$$\frac{1-\delta\mu_0}{1-(\delta\mu_0/2)}=1-s\frac{1}{\sqrt{1+(2/\delta\rho^2)}}, \tag{A3b}$$

$$\frac{(1-\lambda_0)\mu_1-\lambda_1\mu_0}{\lambda_0\delta(1-(\delta\mu_0/2))}=1. \tag{A3c}$$

If we introduce (A1)–(A3) into (2.5c), we obtain the Taylor series expansion of $D(k,\kappa)$,

$$\begin{aligned}D(k,\kappa)=&\frac{-1}{2}\{(1-\lambda_0)\mu_1-\lambda_1\mu_0\}\kappa^2-\frac{1}{2}\{\delta(\lambda_0\mu_1+\lambda_1\mu_0)-\lambda_1\}\kappa^2k\\&-\frac{1}{2}\left[\lambda_0\delta-\frac{\delta^2}{2}\lambda_0\mu_0+\left\{\lambda_1\delta-\frac{\delta^2}{2}(\lambda_0\mu_1+\lambda_1\mu_0)\right\}\kappa^2\right]k^2+O(\kappa^2k^3).\end{aligned} \tag{A4}$$

Differentiating (A4) by k and putting $k=\pm ik$, one has

$$D_k(i\kappa,\kappa)=-i\lambda_0\delta(1-\tfrac{1}{2}\delta\mu_0)\kappa-\tfrac{1}{2}\{\delta(\lambda_0\mu_1+\lambda_1\mu_0)-\lambda_1\}\kappa^2+O(\kappa^3), \tag{A5a}$$

$$D_k(-i\kappa,\kappa)=i\lambda_0\delta(1-\tfrac{1}{2}\delta\mu_0)\kappa-\tfrac{1}{2}\{\delta(\lambda_0\mu_1+\lambda_1\mu_0)-\lambda_1\}\kappa^2+O(\kappa^3). \tag{A5b}$$

It follows from (A5) that

$$C_R(\kappa)\equiv\frac{1}{D_k(i\kappa,\kappa)}+\frac{1}{D_k(-i\kappa,\kappa)}=-\frac{\delta(\lambda_0\mu_1+\lambda_1\mu_0)-\lambda_1}{\left(\lambda_0\delta-\frac{\delta^2}{2}\lambda_0\mu_0\right)^2}+O(\kappa^2), \tag{A6a}$$

$$C_I(\kappa)\equiv i\left[\frac{1}{D_k(i\kappa,\kappa)}-\frac{1}{D_k(-i\kappa,\kappa)}\right]=-\frac{2}{\lambda_0\delta(1-\frac{1}{2}\delta\mu_0)\kappa}+O(\kappa). \tag{A6b}$$

The following expansions in δ are useful in taking the shallow-water limit $\delta\to 0$:

$$\mu_0=s\sqrt{\frac{2\rho^2}{\delta}}-\rho^2+\frac{s\rho^3}{4}\sqrt{2\delta}+O(\delta^{3/2}), \tag{A7a}$$

$$\lambda_0=1+s\sqrt{2\rho^2\delta}+O(\delta), \tag{A7b}$$

$$\mu_1=-s\sqrt{\frac{\delta}{2\rho^2}}\left(1+\frac{5}{12}\delta\rho^2\right)+O(\delta^{5/2}), \tag{A7c}$$

$$\lambda_1=-\frac{\delta^{3/2}}{2\sqrt{2\rho^2}}(s+\sqrt{2\rho^2\delta})+O(\delta^{5/2}). \tag{A7d}$$

APPENDIX B: TWO-SOLITON SOLUTION OF THE INLS EQUATION

Here, we investigate the asymptotic properties of the two-soliton solution of the INLS equation. In particular, we show that the solution has a common asymptotic value under appropriate choice of the soliton parameters.

The two-soliton solution may be expressed in the form[2,4,5]

$$u=\rho\frac{G}{F},\quad |u|^2=\rho^2-i\frac{\partial}{\partial x}\ln\left(\frac{F}{F^*}\right), \tag{B1a}$$

where

$$F=1+e^{\eta_1+i\phi_1}+e^{\eta_2+i\phi_2}+e^{\eta_1+\eta_2+i(\phi_1+\phi_2)+A_{12}}, \tag{B1b}$$

$$G=1+e^{\eta_1+i\psi_1}+e^{\eta_2+i\psi_2}+e^{\eta_1+\eta_2+i(\psi_1+\psi_2)+A_{12}}, \tag{B1c}$$

$$\eta_j=k_j(x-v_jt-x_{j0}), \tag{B1d}$$

$$\phi_j=-\delta k_j,\quad \psi_j=-\delta k_j+i\ln\left(\frac{v_j-ik_j}{v_j+ik_j}\right), \tag{B1e}$$

$$e^{A_{ij}}=\frac{(k_i-k_j)^2+(v_i-v_j)^2}{(k_i+k_j)^2+(v_i-v_j)^2}\quad (i\neq j), \tag{B1f}$$

$$v_j^2+2\rho^2v_j+k_j^2=2\rho^2k_j\cot(k_j\delta). \tag{B1g}$$

Note that the soliton parameters k_j and v_j correspond, respectively, to κ and V in (2.18). It follows from (B1g) that the velocity of the jth soliton is determined by

$$\begin{aligned} v_j&=-\rho^2\pm\sqrt{\rho^4-k_j^2+2\rho^2k_j\cot(k_j\delta)}\\ &=-\rho^2\pm\sqrt{\{k_j+\rho^2\tan(k_j\delta/2)\}\{(\rho^2-k_j\tan(k_j\delta/2)\}/\tan(k_j\delta/2)}. \end{aligned} \tag{B2}$$

Hence, if $0<k_j<k_c$ with k_c being a positive solution of the equation $k_c\tan(k_c\delta/2)=\rho^2$, then v_j has two real roots. This inequality is assumed in the following analysis. The asymptotic form of u as $|x|\to\infty$ is easily obtained from (B1). It takes the form

$$u \to \rho, \quad x \to -\infty, \tag{B3a}$$

$$u \to \rho e^{i(\psi_1+\psi_2-\phi_1-\phi_2)} = \rho \frac{v_1+ik_1}{v_1-ik_1}\frac{v_2+ik_2}{v_2-ik_2}, x \to +\infty. \tag{B3b}$$

We can see that the solution exhibits a change of the phase given by (B3b). However, if the condition

$$v_1 k_2 + v_2 k_1 = 0, \tag{B4}$$

is satisfied, then the solution has the same asymptotic value ρ without the phase shift. We now show that (B4) holds for particular values of k_1 and k_2. Note that since both k_1 and k_2 are positive, v_1 and v_2 must have different signs. We may take them as

$$v_1 = -\rho^2 + \sqrt{\rho^4 - k_1^2 + 2\rho^2 k_1 \cot(k_1\delta)}, \tag{B5a}$$

$$v_2 = -\rho^2 - \sqrt{\rho^4 - k_2^2 + 2\rho^2 k_2 \cot(k_2\delta)}, \tag{B5b}$$

so that $v_2 < 0 < v_1$. The positivity of v_1 is assured by imposing the condition

$$k_1 < 2\rho^2 \cot(k_1\delta). \tag{B6}$$

If we substitute (B5) into (B4), condition (B4) is transformed into the form

$$(k_1+k_2)^2 - 2\rho^2(k_1+k_2)\{\cot(k_1\delta)+\cot(k_2\delta)\} + \{k_1\cot(k_2\delta) - k_2\cot(k_1\delta)\}^2 = 0. \tag{B7}$$

It can be verified that there exist pairs (k_1,k_2) $(0<k_1<k_2<k_c)$ that satisfy the conditions (B6) and (B7) simultaneously. We shall demonstrate this statement by a numerical calculation. We take $\rho=\delta=1$ as a typical example. Then, $k_c = 1.307$ and condition (B6) becomes $k_1 < 1.077$. In the following, we shall write down some numerical solutions (k_1,k_2) of (B7):

$$(k_1,k_2) = (0.05,0.186),\ (0.1,0.367),\ (0.2,0.695),\ (0.3,0.958),$$

$$(0.4,1.14),\ (0.5,1.25),\ (0.6,1.30),\ (0.65,1.306). \tag{B8}$$

When both k_1 and k_2 are sufficiently small, (B7) reduces to

$$(k_1-k_2)^2 = 2\rho^2\delta k_1 k_2. \tag{B9}$$

Solving this equation, the ratio k_1/k_2 is found to have a limiting value

$$\frac{k_1}{k_2} = 1 + \rho^2\delta - \sqrt{\rho^2\delta(2+\rho^2\delta)}. \tag{B10}$$

In the above-given example, this ratio is $2-\sqrt{3} \simeq 0.268$, which is in agreement with the numerical values (B8) for small k_j $(j=1,2)$.

It is quite interesting to observe that the two eigenvalues given by (2.16) exactly satisfy condition (B9). Hence, if we approximate a pair of dark solitons with the soliton parameters (2.18) by a two-soliton solution (B1), then we can see that the boundary condition $u \to \rho$, $|x| \to \infty$ is satisfied within the approximation up to order ϵ.

(Received 28 February 2001; accepted for publication 8 November 2001)

In this paper, five 2+1 dimensional lattices considered by several authors are revisited again. First of all we will show that two lattices proposed by Blaszak and Szum [J. Math. Phys. **42**, 225 (2001)] become the so-called differential-difference KP equation due to Date, Jimbo, and Miwa [J. Phys. Soc. Jpn. **51**, 4116 (1982); **51**, 4125 (1982); **52**, 388 (1983); **52**, 761 (1983); **52**, 766 (1983)] by simple variable transformations, while another lattice found by Blaszak and Szum can be viewed as a higher-dimensional generalization of a lattice given by Wu and Hu [J. Phys. A **32**, 1515 (1999)]. Some integrable properties on these three lattices are derived. Second, it is shown that a 2+1 dimensional Toda-like lattice studied by Cao, Geng, and Wu [J. Phys. A **32**, 8059 (1999)] can be transformed into the bilinear equation given by Hu, Clarkson, and Bullough [J. Phys. A **30**, L669 (1997)]. For this bilinear version we also present some rational solutions and Lie symmetries. Finally, a lattice due to Levi, Ragnisco, and Shabat [Can. J. Phys. **72**, 439 (1994)] is transformed into coupled bilinear equations. It is shown that these coupled bilinear equations do not have two-soliton solutions. This further confirms that the lattice under consideration is not completely integrable. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1430899]

I. INTRODUCTION

The subject of discrete systems described by differential-difference, difference, lattice equations and mappings has undergone remarkable development in recent years. With such development, there has also been an increasing interest in integrable discrete systems. Currently, much progress is being made in the understanding of the mathematical aspects of integrable discrete systems, including integrable dynamical mappings, ordinary and partial difference equations, lattice solitons, discrete versions of the Painlevé equations, and application to numerical analysis, computer science, physics, etc. Several powerful approaches, such as the inverse scattering method, singularity confinement criteria, symmetry approaches, etc., have been proposed to deal with discrete nonlinear systems toward their complete integrability, linearizability, and solvability.

[a)]Electronic mail: tam@comp.hkbu.edu.hk
[b)]Electronic mail: hxb@lsec.cc.ac.cn

(See, e.g., Refs. 1–3, and references therein.) Among these approaches, Hirota's bilinear formalism provides us with an efficient tool in the search for exact solutions of discrete systems, and also in the search for new integrable discrete equations.

Until now, much research has been conducted on many 1+1 dimensional lattices such as the Toda lattice

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}u(n)=e^{u(n-1)-u(n)}-e^{u(n)-u(n+1)}$$

and the Lotka–Volterra lattice

$$\frac{\mathrm{d}}{\mathrm{d}t}u(n)=u(n)(u(n+1)-u(n-1)).$$

Comparatively less research has been done on 2+1 dimensional lattices. Recently, the following five 2+1 dimensional lattices have been proposed by several authors:

$$u_t(n)=2u(n)u_y(n)+\mathcal{H}u_{yy}(n), \tag{1}$$

$$v_t(n)=\mathcal{H}v_{yy}(n)-(v(n)\mathcal{H}v(n))_y, \tag{2}$$

$$u_t(n)=u(n)\mathcal{H}^{-1}p(n-1), \tag{3}$$

$$v_t(n)=u(n+1)-u(n)+(E+1)^{-1}p_y(n), \tag{4}$$

$$p_t(n)=v(n+1)-v(n)-p(n)\mathcal{H}^{-1}p(n), \tag{5}$$

$$\frac{\partial^2 Q_n}{\partial x\partial y}=\exp(Q_{n+1}-Q_n)\frac{\partial}{\partial x}(Q_{n+1}+Q_n)-\exp(Q_n-Q_{n-1})\frac{\partial}{\partial x}(Q_n+Q_{n-1}), \tag{6}$$

and

$$\begin{aligned}\chi_{xy}(n)=&e^{\chi(n+2)+\chi(n+1)-2\chi(n)}+e^{2\chi(n+1)-\chi(n)-\chi(n-1)}\\&-e^{\chi(n+1)+\chi(n)-2\chi(n-1)}-e^{2\chi(n)-\chi(n-1)-\chi(n-2)},\end{aligned} \tag{7}$$

where E is a shift operator, i.e., $Eu(n)=u(n+1)$ and $\mathcal{H}=(E+1)/(E-1)$. The lattices (1), (2) and (3)–(5) are constructed by Blaszak and Szum as an application of the so-called ''central extension procedure and operand formalism'' in a very recent paper.[4] Lattice (6) was considered by Cao, Geng, and Wu in a remarkable paper,[5] and lattice (7) was proposed by Levi, Ragnisco, and Shabat in a short but interesting paper.[6] In view of the fact that there are not many integrable 2+1 dimensional lattices available in the literature, it would be of interest for us to revisit the above-mentioned five lattices again.

The purpose of this paper is to study these five 2+1 dimensional lattices in Hirota's bilinear formalism. Several new results, such as rational solutions, Lie symmetries, nonlinear superposition principles, etc., have been obtained on these lattices.

The organization of the paper is as follow. In Sec. II we show that lattices (1) and (2) become the so-called differential-difference KP equation considered in Refs. 7 and 8 by simple variable transformations. In Sec. III, it is shown that lattice (3)–(5) could be viewed as a higher dimensional generalization of a lattice derived in Ref. 9. By a dependent variable transformation, the lattice (3)–(5) is transformed into coupled bilinear equations. A bilinear Bäcklund transformation and its associated nonlinear superposition formula are presented. As a result, soliton solutions and lump solutions to (3)–(5) are obtained. In Sec. IV, we show that the lattice (6) can be transformed into a bilinear equation found by Hu, Clarkson, and Bullough in Ref. 10. Some particular solutions to the bilinear equation are derived by using the corresponding Bäcklund transformation. Finally,

in Sec. V, by a dependent variable transformation, the lattice (7) is transformed into coupled bilinear equations. For these coupled bilinear equations, we have obtained one-solition solution but failed to obtain two-soliton solutions. This further confirms that lattice (7) is not completely integrable.

II. LATTICES (1) AND (2)

It is noted that lattices (1) and (2) are related by the relation $v(n)=(1-E)u(n)$. Therefore in the following we only consider lattice (1). Lattice (1) can be rewritten as

$$u_t(n+1)-u_t(n)=2(u(n+1)u_y(n+1)-u(n)u_y(n))+u_{yy}(n+1)+u_{yy}(n). \tag{8}$$

Setting $u(n)=(\ln f(n+1)/f(n))_y$, Eq. (8) is transformed into the bilinear equation

$$(D_t-D_y^2)e^{(1/2)D_n}f(n)\cdot f(n)=0, \tag{9}$$

where Hirota's bilinear differential operator $D_y^m D_t^k$ and the bilinear difference operator $\exp(\delta D_n)$ are defined by[11]

$$D_y^m D_t^k a\cdot b\equiv\left(\frac{\partial}{\partial y}-\frac{\partial}{\partial y'}\right)^m\left(\frac{\partial}{\partial t}-\frac{\partial}{\partial t'}\right)^k a(y,t)b(y',t')|_{y'=y,t'=t},$$

$$\exp(\delta D_n)a(n)\cdot b(n)\equiv\exp\left[\delta\left(\frac{\partial}{\partial n}-\frac{\partial}{\partial n'}\right)\right]a(n)b(n')|_{n'=n}=a(n+\delta)b(n-\delta).$$

Equation (9) becomes the bilinear form

$$(D_t+2D_y-D_y^2)e^{(1/2)D_n}f(n)\cdot f(n)=0 \tag{10}$$

by the linear transformation $y\to y+2t, t\to t$. Equation (10) is just the bilinear form for the so-called differential-difference KP equation[7,8]

$$\Delta\left(\frac{\partial w}{\partial t}+2\frac{\partial w}{\partial y}-2w\frac{\partial w}{\partial y}\right)=(2+\Delta)\frac{\partial^2 w}{\partial y^2} \tag{11}$$

through the dependent variable transformation given by

$$w=\frac{\partial}{\partial y}\ln\frac{f(n+1)}{f(n)},$$

where $\Delta=E-1$, i.e., $\Delta w(n)=w(n+1)-w(n)$. Besides, it is obvious that (8) and (11) are linked by $u(n)=w(n)-1$. Concerning (9), we can easily obtain its bilinear BT

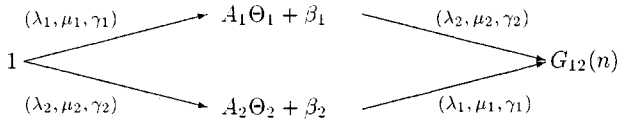
$$(D_y+\lambda^{-1}e^{-D_n}+\mu)f(n)\cdot g(n)=0, \tag{12}$$

$$(D_t-\lambda^{-1}D_y e^{-D_n}-\lambda^{-1}\mu e^{-D_n}-\gamma)f(n)\cdot g(n)=0, \tag{13}$$

and nonlinear superposition formula

$$\exp(-\tfrac{1}{2}D_n)f_0\cdot f_{12}=k[\lambda_1\exp(-\tfrac{1}{2}D_n)-\lambda_2\exp(\tfrac{1}{2}D_n)]f_1\cdot f_2, \tag{14}$$

where λ, μ, and γ are arbitrary constants and k is a nonzero constant. By using these results, we can easily rederive soliton solutions and rational solutions. For example, we have



where

$$G_{12}(n)=A_1A_2\Theta_1\Theta_2+\Theta_1\left(A_1\beta_2+\frac{A_1A_2}{\lambda_1-\lambda_2}\right)+\Theta_2\left(A_2\beta_1-\frac{A_1A_2}{\lambda_1-\lambda_2}\right)+\beta_1\beta_2+\frac{A_2\beta_1-A_1\beta_2}{\lambda_1-\lambda_2}, \tag{15}$$

with

$$\Theta_i\equiv\lambda_i^{-1}n+2\lambda_i^{-3}t+\lambda_i^{-2}y,\quad \mu_i=-\lambda_i^{-1},\quad \gamma_i=\lambda_i^{-2}.$$

Thus we have the following rational solution to (8) or (1):

$$u(n)=\frac{\partial}{\partial y}\ln\frac{G_{12}(n+1)}{G_{12}(n)}.$$

We can obtain a hierarchy of rational solutions for the lattice (9) using the above-mentioned process. In particular, if we choose

$$A_1=A_2,\quad \lambda_1=a+ib,\quad \lambda_2=\lambda_1^*=a-ib\quad (A_1,a,b\in\mathcal{R}),b\neq 0,$$

$$\beta_1=\frac{A_1}{\lambda_1-\lambda_2},\quad \beta_2=\frac{A_2}{\lambda_2-\lambda_1},$$

we have from (15) that

$$G_{12}(n)=A_1^2\Theta_1\Theta_1^*+\frac{A_1^2}{4b^2}-\frac{A_1}{2b^2}, \tag{16}$$

which becomes a one-lump solution when we choose $A_1<0$ or $A_1>2$. Correspondingly, we have the one-lump solution to (8) or (1):

$$u(n)=\frac{\partial}{\partial y}\ln\frac{G_{12}(n+1)}{G_{12}(n)},$$

where $G_{12}(n)$ is given by (16).

Since (9) is an integrable lattice, it would be interesting to derive some other integrable properties. In the following we write down five Lie symmetries for (9):

$$\sigma_0=h(t)f,\quad \sigma_1=yh(t)f,$$

$$\sigma_2=(h(t)n+\tfrac{1}{4}\dot{h}(t)y^2)f,\quad \sigma_3=h(t)f_y+(\tfrac{1}{2}ny\dot{h}+\tfrac{1}{24}y^3\ddot{h})f,$$

$$\sigma_4=h(t)f_t+\tfrac{1}{2}y\dot{h}f_y+(\tfrac{1}{8}ny^2\ddot{h}+\tfrac{1}{192}y^4h^{(3)}+\tfrac{1}{4}n^2\dot{h})f,$$

where $h(t)$ is an arbitrary function of t and $\dot{h}(t)\equiv \mathrm{d}h(t)/\mathrm{d}t$, $\ddot{h}(t)\equiv \mathrm{d}^2h(t)/\mathrm{d}t^2$, $h^{(3)}\equiv \mathrm{d}^3h(t)/\mathrm{d}t^3$.

III. LATTICES (3)–(5)

Setting $w(n)=(E+1)^{-1}p(n)$, lattices (3)–(5) can be rewritten as

$$u_t(n)=u(n)(w(n)-w(n-1)), \tag{17}$$

$$v_t(n)=u(n+1)-u(n)+w_y(n), \tag{18}$$

$$w_t(n+1)+w_t(n)=v(n+1)-v(n)-w^2(n+1)+w^2(n). \tag{19}$$

By the dependent variable transformation

$$u(n)=\frac{f(n+1)f(n-1)}{f^2(n)}, \quad v(n)=\frac{D_t^2 f(n)\cdot f(n+1)}{f(n)f(n+1)}, \quad w(n)=\left(\ln\frac{f(n+1)}{f(n)}\right)_t,$$

Eqs. (17)–(19) become

$$\begin{aligned} &D_t(D_t^2 f(n)\cdot f(n+1))\cdot f(n)f(n+1)\\ &\quad=f(n+2)f^3(n)-f(n-1)f^3(n+1)+D_y(D_t f(n+1)\cdot f(n))\cdot f(n+1)f(n). \end{aligned} \tag{20}$$

By introducing an auxiliary variable z, (20) can be decoupled into the bilinear form:

$$(D_z e^{(1/2)D_n}-D_t^2 e^{(1/2)D_n})f(n)\cdot f(n)=0, \tag{21}$$

$$(D_t D_z-D_t D_y)f(n)\cdot f(n)=4\sinh^2(\tfrac{1}{2}D_n)f(n)\cdot f(n). \tag{22}$$

In particular, if f is independent of y, then (21) and (22) become the bilinear form for a lattice proposed in Ref. 9. Therefore (21) and (22) may be viewed as a two-dimensioal generalization of the lattice in Ref. 9. Concerning (21) and (22), we have the following results:

Proposition 1: The system of bilinear equations (21) and (22) has the Bäcklund transformation

$$(D_t+\lambda^{-1}e^{-D_n}+\mu)f(n)\cdot g(n)=0, \tag{23}$$

$$(D_z e^{-(1/2)D_n}-D_y e^{-(1/2)D_n}-\lambda e^{(1/2)D_n}+\gamma e^{-(1/2)D_n})f(n)\cdot g(n)=0, \tag{24}$$

$$(D_z-\lambda^{-1}D_t e^{-D_n}-\lambda^{-1}\mu e^{-D_n}-\omega)f(n)\cdot g(n)=0, \tag{25}$$

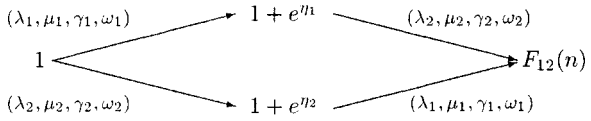
where λ, μ, γ, and ω are arbitrary constants.

Proposition 2: Let f_0 be a solution of (21) and (22). Suppose that $f_i(i=1,2)$ are solutions of (21) and (22), which are related to f_0 under the BT (23)–(25) with parameters $(\lambda_i,\mu_i,\gamma_i,\omega_i)$. Then f_{12} defined by

$$\exp(-\tfrac{1}{2}D_n)f_0\cdot f_{12}=c[\lambda_1\exp(-\tfrac{1}{2}D_n)-\lambda_2\exp(\tfrac{1}{2}D_n)]f_1\cdot f_2 \tag{26}$$

is a new solution related to f_1 and f_2 under the BT (23)–(25) with parameters $(\lambda_2,\mu_2,\gamma_2,\omega_2)$, $(\lambda_1,\mu_1,\gamma_1,\omega_1)$, respectively. Here c is a nonzero constant.

These results can be proved in a way similar to those of Ref. 9. We omit the details. Instead we are going to construct soliton solutions to (21) and (22) by using these results. Choose, for example, $f_0=1$, $c=1/(\lambda_1-\lambda_2)$. It can be easily verified that



where

$$F_{12}(n)=1+\frac{\lambda_1 e^{-p_1}-\lambda_2}{\lambda_1-\lambda_2}e^{\eta_1}+\frac{\lambda_1-\lambda_2 e^{-p_2}}{\lambda_1-\lambda_2}e^{\eta_2}+\frac{\lambda_1 e^{-p_1}-\lambda_2 e^{-p_2}}{\lambda_1-\lambda_2}e^{\eta_1+\eta_2}, \tag{27}$$

with

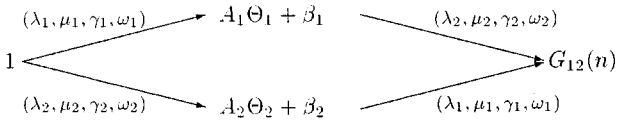
$$\eta_i=p_i n+\lambda_i^{-1}(e^{p_i}-1)t+\lambda_i^{-2}(e^{2p_i}-1)z+[\lambda_i^{-2}(e^{2p_i}-1)+\lambda_i(e^{-p_i}-1)]y+\eta_i^0,$$

$$\mu_i=-\lambda_i^{-1},\quad \gamma_i=\lambda_i,\quad \omega_i=\lambda_i^{-2}.$$

The corresponding two-soliton solution to (17)–(19) is given by

$$u(n)=\frac{F_{12}(n+1)F_{12}(n-1)}{F_{12}^2(n)},\quad v(n)=\frac{D_t^2F_{12}(n)\cdot F_{12}(n+1)}{F_{12}(n)F_{12}(n+1)},\quad w(n)=\left(\ln\frac{F_{12}(n+1)}{F_{12}(n)}\right)_t.$$

In general, along this line, we can obtain multisoliton solutions for the lattice (21) and (22) step by step. Besides, we have



where

$$G_{12}(n)=A_1A_2\Theta_1\Theta_2+\Theta_1\left(A_1\beta_2+\frac{A_1A_2}{\lambda_1-\lambda_2}\right)+\Theta_2\left(A_2\beta_1-\frac{A_1A_2}{\lambda_1-\lambda_2}\right)+\beta_1\beta_2+\frac{A_2\beta_1-A_1\beta_2}{\lambda_1-\lambda_2}, \tag{28}$$

with

$$\Theta_i\equiv\lambda_i^{-1}n+\lambda_i^{-2}t+(2\lambda_i^{-3}-1)y+2\lambda_i^{-3}z,\quad \mu_i=-\lambda_i^{-1},\quad \gamma_i=\lambda_i,\quad \omega_i=\lambda_i^{-2}.$$

The corresponding rational solution to (17)–(19) is given by

$$u(n)=\frac{G_{12}(n+1)G_{12}(n-1)}{G_{12}^2(n)},\quad v(n)=\frac{D_t^2G_{12}(n)\cdot G_{12}(n+1)}{G_{12}(n)G_{12}(n+1)},\quad w(n)=\left(\ln\frac{G_{12}(n+1)}{G_{12}(n)}\right)_t.$$

We can obtain a hierarchy of rational solutions for the lattice (21) and (22) using the above-mentioned process. In particular, if we choose

$$A_1=A_2,\quad \lambda_1=a+ib,\quad \lambda_2=\lambda_1^*=a-ib\quad (A_1,a,b\in\mathcal{R}),\quad b\neq 0,$$

$$\beta_1=\frac{A_1}{\lambda_1-\lambda_2},\quad \beta_2=\frac{A_2}{\lambda_2-\lambda_1},$$

we have from (28) that

$$G_{12}(n)=A_1^2\Theta_1\Theta_1^*+\frac{A_1^2}{4b^2}-\frac{A_1}{2b^2}, \tag{29}$$

which becomes a one-lump solution when we choose $A_1<0$ or $A_1>2$. In this case, the one-lump solution to (17)–(19) is given by

$$u(n)=\frac{G_{12}(n+1)G_{12}(n-1)}{G_{12}^2(n)},\quad v(n)=\frac{D_t^2G_{12}(n)\cdot G_{12}(n+1)}{G_{12}(n+1)},\quad w(n)=\left(\ln\frac{G_{12}(n+1)}{G_{12}(n)}\right)_t,$$

where $G_{12}(n)$ is given by (29). Furthermore, starting from $1 \xrightarrow{(\lambda_i,-\lambda_i^{-1},\lambda_i,\lambda_i^{-2})} A\Theta_i+\beta_i$ $(i=1,2,3,4)$, it is possible to construct two-lump solutions.

IV. THE SPECIAL 2+1 TODA LATTICE (6)

In Ref. 5, Cao *et al.* have considered the special 2+1 Toda lattice (6) and obtained the explicit theta-function solutions by resorting to separation techniques. Here we will show that there is some connection between this special 2+1 Toda lattice (6) and a bilinear equation found in Ref. 10. In fact, by the dependent variable transformation

$$Q_n=-\frac{x}{2}+h(y)+\ln\frac{f(n+1)}{f(n)}$$

with $h(y)$ being an arbitrary function of y, we can transform (6) into the bilinear equation

$$D_xD_yf(n)\cdot f(n)=2[D_xe^{D_n}+e^{D_n}-1]f(n)\cdot f(n), \tag{30}$$

which is a special case of the bilinear equation proposed in Ref. 10. Therefore we have the following bilinear BT for (30):

$$D_yf(n)\cdot g(n)=\left(\lambda e^{-D_n}-\frac{1}{\lambda}e^{D_n}+\mu\right)f(n)\cdot g(n), \tag{31}$$

$$(-4\lambda D_xe^{-(1/2)D_n}-4D_xe^{(1/2)D_n})f(n)\cdot g(n)=\left[\left(4+\frac{\gamma}{\lambda}\right)e^{(1/2)D_n}+\gamma e^{-(1/2)D_n}\right]f(n)\cdot g(n), \tag{32}$$

where λ, μ, and γ are arbitrary constants. Starting from BT (31) and (32), we have obtained explicit soliton solutions to (30).[10] Its Pfaffian solution was given in Ref. 12. Starting from BT (31) and (32), we can also obtain polynomial solutions to (30). For example, starting from the trivial solution $f(n)=1$ and using BT (31) and (32) with

$$\mu=\frac{1}{\lambda}-\lambda,\quad \gamma=-\frac{4\lambda}{1+\lambda},$$

we have

$$g(n)=n-\frac{\lambda}{(1+\lambda)^2}x-\frac{(\lambda^2+1)}{\lambda}y+\alpha.$$

Furthermore, starting from the solution

$$f(n)=n-\frac{\lambda_1}{(1+\lambda_1)^2}x-\frac{(\lambda_1^2+1)}{\lambda_1}y+\alpha$$

and using BT (31) and (32) with $\mu=1/\lambda-\lambda$, $\gamma=-4\lambda/(1+\lambda)$, we have

$$g(n)=n^2+n\left[-\left(\frac{\lambda}{(1+\lambda)^2}+\frac{\lambda_1}{(1+\lambda_1)^2}\right)x-\left(\frac{\lambda^2+1}{\lambda}+\frac{\lambda_1^2+1}{\lambda_1}\right)y+\beta\right]$$
$$+\left[\frac{(\lambda_1^2+1)\lambda}{\lambda_1(1+\lambda)^2}+\frac{(\lambda^2+1)\lambda_1}{\lambda(1+\lambda_1)^2}\right]xy+\frac{(\lambda^2+1)(\lambda_1^2+1)}{\lambda\lambda_1}y^2$$
$$+\frac{\lambda\lambda_1}{(\lambda_1+1)^2(\lambda+1)^2}x^2+y\left[\frac{\lambda^2-1}{\lambda}+\alpha\left(\frac{\lambda_1^2+1}{\lambda_1}-\frac{\lambda^2+1}{\lambda}\right)-\beta\frac{\lambda_1^2+1}{\lambda_1}\right]$$
$$+x\frac{-\alpha\lambda+[(1+\lambda)(-1+\beta+\lambda+\beta\lambda)+\alpha(1+\lambda^2)]\lambda_1-\alpha\lambda\lambda_1^2}{(1+\lambda)^2(1+\lambda_1)^2}$$
$$+\frac{\lambda\lambda_1}{\lambda_1(\lambda^2+1)-\lambda(\lambda_1^2+1)}\left[\frac{\lambda^2+1}{\lambda}(\alpha\beta-\alpha^2-1)+\frac{\lambda^2-1}{\lambda}(-\beta+2\alpha)+\frac{\lambda_1^2+1}{\lambda_1}(\alpha^2-\beta\alpha)\right],$$

where α, β, λ, and λ_1 are constants. The corresponding rational solution to (6) is given by

$$Q_n=-\frac{x}{2}+h(y)+\ln\frac{g(n+1)}{g(n)}.$$

In addition, concerning bilinear equation (30), we have found the following Lie symmetries:

$$\sigma_1=(h_1(x)+h_2(y))f,\quad \sigma_2=nh_2(y)f,$$

$$\sigma_3=h_1(x)f_x+(yh_1(x)+\tfrac{1}{2}nh_1(x))f,$$

$$\sigma_4=h_2(y)f_y+(xh_2(y)+\tfrac{1}{2}\dot{h}_2(y)n^2)f,$$

where $h_1(x)$ and $h_2(y)$ are arbitrary functions of x and y, respectively, and $\dot{h}_2(y)\equiv \mathrm{d}h_2(y)/\mathrm{d}y$.

V. THE LEVI–RAGNISCO–SHABAT LATTICE (7)

In this section, we will consider the Levi–Ragnisco–Shabat lattice (7). In Ref. 6, it was mentioned that (7) can be reduced to a nonintegrable equation under some reduction. This means that (7) is not completely integrable in such a sense. In what follows, we will show that (7) does not have multisoliton solution. To this end, we set $\chi(n)=\ln(f(n+1)/f(n))$. Then (7) can be transformed into the quadrilinear form

$$(D_xD_yf(n)\cdot f(n))f^2(n)=4\cosh(D_n)(e^{D_n}f(n)\cdot f(n))\cdot f^2(n)-4f^4(n). \tag{33}$$

By introducing an auxiliary variable z, (33) may be decoupled into the bilinear equations

$$(D_xD_y+4-4e^{2D_n}+D_ze^{2D_n})f(n)\cdot f(n)=0, \tag{34}$$

$$(D_ze^{D_n}+2-2e^{D_n})f(n)\cdot f(n)=0. \tag{35}$$

We can easily obtain one-soliton solution to (34) and (35):

$$f(n)=1+e^{\eta},\quad \eta=pn+qx+ry+sz+\eta^0,$$

$$s=\frac{2\cosh(p)-2}{\sinh(p)},\quad r=\frac{4\cosh(2p)-4-4\cosh^2(p)+4\cosh(p)}{q}.$$

Now it is natural to go on to seek the following two-soliton solution to (34) and (35):

$$f(n)=1+e^{\eta_1}+e^{\eta_2}+A_{12}e^{\eta_1+\eta_2}, \quad \eta_i=p_in+q_ix+r_iy+s_iz+\eta_i^0,$$

$$s_i=\frac{2\cosh(p_i)-2}{\sinh(p_i)}, \quad r_i=\frac{4\cosh(2p_i)-4-4\cosh^2(p_i)+4\cosh(p_i)}{q_i}.$$

From (34) and (35) we can determine A_{12}, respectively,

$$A_{12}=-\frac{(s_1-s_2)\sinh(p_1-p_2)+2-2\cosh(p_1-p_2)}{(s_1+s_2)\sinh(p_1+p_2)+2-2\cosh(p_1+p_2)}, \tag{36}$$

$$A_{12}=-\frac{(q_1-q_2)(r_1-r_2)+4+(s_1-s_2)\sinh(2(p_1-p_2))-4\cosh(2(p_1-p_2))}{(q_1+q_2)(r_1+r_2)+4+(s_1+s_2)\sinh(2(p_1+p_2))-4\cosh(2(p_1+p_2))}. \tag{37}$$

It is obvious to see that the system (34) and (35) has the above-mentioned two-soliton solution, provided that

$$\frac{(s_1-s_2)\sinh(p_1-p_2)+2-2\cosh(p_1-p_2)}{(s_1+s_2)\sinh(p_1+p_2)+2-2\cosh(p_1+p_2)} \equiv \frac{(q_1-q_2)(r_1-r_2)+4+(s_1-s_2)\sinh(2(p_1-p_2))-4\cosh(2(p_1-p_2))}{(q_1+q_2)(r_1+r_2)+4+(s_1+s_2)\sinh(2(p_1+p_2))-4\cosh(2(p_1+p_2))} \tag{38}$$

for arbitrary constants p_1, p_2, q_1 and q_2 and without any additional condition. But by using MATHEMATICA it turns out that (38) does not hold automatically. Therefore our computations give further evidence that (7) is not completely integrable.

VI. CONCLUSION

In this paper, five 2+1 dimensional lattices studied by several authors have been reviewed in Hirota's bilinear formalism. First, we have shown that two lattices proposed by Blaszak and Szum[4] share the same bilinear form with the so-called differential-difference KP equation due to Date, Jimbo, and Miwa.[7] This means that these two lattices are linked to the differential-difference KP equation by simple variable transformations. We have also transformed another lattice found by Blaszak and Szum[4] into a set of coupled bilinear equations, which is a higher-dimensional generalization of the bilinear form for a lattice given by Wu and Hu.[9] Several integrable properties on these three lattices given by Blaszak and Szum, such as lump solutions, Lie symmetries, etc., have been derived. Second, we have shown that a 2+1 dimensional Toda-like lattice considered by Cao, Geng, and Wu[5] can be transformed into a bilinear equation given by Hu, Clarkson, and Bullough.[10] For this bilinear version, some rational solutions and Lie symmetries have also been obtained. Finally, a lattice due to Levi, Ragnisco, and Shabat is transformed into coupled bilinear equations. Based on the fact that these coupled bilinear equations do not have two-soliton solutions, we further confirm that the lattice under consideration is not completely integrable.

Euclidean scalar Green function in a higher dimensional global monopole space–time

E. R. Bezerra de Mello[a)]
Departamento de Física-CCEN, Universidade Federal da Paraíba, 58.059-970, J. Pessoa, PB, C. Postal 5.008, Brazil

(Received 1 August 2001; accepted for publication 8 October 2001)

We construct the explicit Euclidean scalar Green function associated with a massless field in a higher dimensional global monopole space–time, i.e., a $(1+d)$-space–time with $d\geqslant 3$ which presents a solid angle deficit. Our result is expressed in terms of an infinite sum of products of Legendre functions with Gegenbauer polynomials. Although this Green function cannot be expressed in a closed form, for the specific case where the solid angle deficit is very small, it is possible to develop the sum and obtain the Green function in a more workable expression. Having this expression it is possible to calculate the vacuum expectation value of some relevant operators. As an application of this formalism, we calculate the renormalized vacuum expectation value of the square of the scalar field, $\langle \Phi^2(x)\rangle_{\mathrm{Ren}}$, and the energy-momentum tensor, $\langle T_{\mu\nu}(x)\rangle_{\mathrm{Ren}}$, for the global monopole space–time with spatial dimensions $d=4$ and $d=5$. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1421424]

I. INTRODUCTION

In this article we consider the Euclidean scalar Green function associated with a massless field in the higher dimensional global monopole space–time. We define this space–time as a generalization of the previous one given in Ref. 1 (the metric of cosmic string space–time, which is spatially flat, was considered in Ref. 2). The generalization of the Euclidean line element of Ref. 1 for a higher dimensional case is given by

$$ds^2=d\tau^2+\frac{dr^2}{\alpha^2}+r^2d\Omega_{d-1}^2=g_{\mu\nu}(x)dx^\mu dx^\nu, \tag{1}$$

where $\mu,\ \nu=0,1,2,\ldots,d$, with $d\geqslant 3$ and $x^\mu=(\tau,r,\theta_1,\theta_2,\ldots,\theta_{d-2},\phi)$. The coordinates are defined in the intervals $\tau\in(-\infty,\infty)$, $\theta_i\in[0,\pi]$ for $i=1,2,\ldots,d-2$, $\phi\in[0,2\pi]$ and $r\geqslant 0$. The parameter α, which codifies the presence of the global monopole, is smaller than unity. In this coordinate system the metric tensor is explicitly defined as shown:

$$\begin{gathered} g_{00}=1,\quad g_{11}=1/\alpha^2,\quad g_{22}=r^2,\\ g_{jj}=r^2\sin^2\theta_1\sin^2\theta_2\ldots\sin^2\theta_{j-2}, \end{gathered} \tag{2}$$

for $3\leqslant j\leqslant d$, and $g_{\mu\nu}=0$ for $\mu\neq\nu$.

This space–time corresponds to a pointlike global monopole. It is not flat: the scalar curvature $R=(d-1)(d-2)(1-\alpha^2)/r^2$, and the solid angle associated with a hypersphere with unity radius

a)Electronic mail: emello@fisica.ufpb.br

is $\Omega=2\pi^{d/2}\alpha^2/\Gamma(d/2)$, so it is smaller than an ordinary one. The energy-momentum tensor associated with this object has a diagonal form and its nonvanishing components read $T_0^0=T_1^1=(\alpha^2-1)(d-2)/r^2$.

The Euclidean scalar Green function associated with a massless field in the geometry defined by (2) should obey the nonhomogeneous second order differential equation

$$(\Box-\xi R)G_E(x,x')=-\delta^n(x,x')=-\frac{\delta^n(x-x')}{\sqrt{g}}, \tag{3}$$

where $n=d+1$, $\Box$ denotes the covariant d'Alembertian in the space–time defined by (2), ξ is an arbitrary coupling constant, $\delta^d(x,x')$ is the bidensity Dirac distribution and R is the scalar curvature.

The vacuum expectation value of the square of the scalar field, $\langle\Phi^2(x)\rangle$, is given by the evaluation of the Green function at the same point which provides a divergent result. So, in order to obtain a finite and well defined one, we should apply some renormalization procedure. The method which we shall adopt here is the point-splitting renormalization procedure. The basic idea of this method consists of subtracting from the Green function all the divergences which appears in the coincidence limit. (As it is well known, this procedure is ambiguous in even dimensions and the ambiguity is a consequence of mass scale parameter μ which is introduced after the renormalization procedure. In this way the final result contains a finite part which depends on the scale μ.)

In Ref. 3 Wald observed that the singular behavior of the Green function in the coincidence limit has the same structure as the Hadamard function, so his proposal was to subtract from the Green function the Hadamard one. In fact, the use of the Hadamard function to renormalize the vacuum expectation value of the energy-momentum tensor in a curved space–time was first introduced by Adler *et al.*[4] In Ref. 3 Wald added a modification to this technique in order to provide the correct result for the trace anomaly. In this way the renormalized vacuum expectation value of the square of the field operator is given by

$$\langle\Phi^2(x)\rangle_{\mathrm{Ren}}=\lim_{x'\to x}[G_E(x,x')-G_H(x,x')]. \tag{4}$$

The renormalized vacuum expectation value of the energy-momentum tensor can also be obtained in a similar way:

$$\langle T_{\mu\nu}(x)\rangle_{\mathrm{Ren}}=\lim_{x'\to x}\mathcal{D}_{\mu\nu'}(x,x')[G_E(x,x')-G_H(x,x')], \tag{5}$$

where $\mathcal{D}_{\mu\nu'}(x,x')$ is a bivector differential operator. Moreover, this vacuum expectation value should be conserved, i.e.,

$$\nabla_\mu\langle T^\mu_\nu(x)\rangle_{\mathrm{Ren}}=0, \tag{6}$$

and gives us the correct conformal trace anomaly,

$$\langle T^\mu_\mu(x)\rangle_{\mathrm{Ren}}=\frac{1}{(4\pi)^{n/2}}a_{n/2}(x) \tag{7}$$

for $n=1+d$ even and

$$\langle T^\mu_\mu(x)\rangle_{\mathrm{Ren}}=0 \tag{8}$$

for $n=1+d$ odd.[5]

In this article we study the quantum field theory associated with a massless scalar field in the background space–time defined by (2). More specifically, we shall specialize in the cases where

the spatial section of our space–time has dimensions $d=4$ and $d=5$. In Sec. II, we construct explicitly the Euclidean Green function for a massless scalar field in a higher dimensional global monopole space–time. We show that this Green function is expressed in terms of an infinite sum of product of the Legendre function with Gegenbauer polynomials. In Sec. III we calculate explicitly the renormalized vacuum expectation value of the square of the scalar field operator for $d=4$ and $d=5$ dimensions in the case where $\eta^2 \ll 1$, where $\eta^2=1-\alpha^2$. The parameter α is related to the energy scale where the global symmetry of the system is spontaneously broken (see Ref. 1). For a typical grand unified theory in a physical $(1+3)$-dimensional space–time, this scale is of order 10^{16} Gev. So, $1-\alpha^2=\eta^2 \sim 10^{-5}$. We show that for six dimensions the expression obtained presents an ambiguity given by the mass scale parameter and that this ambiguity vanishes if we assume for the nonminimal coupling constant its conformal value, $\xi=\frac{1}{5}$. In Sec. IV we present the formal expressions for the vacuum expectation values of the energy-momentum tensor for the cases $d=4$ and $d=5$. For the six dimensional case we present, after a long calculation, an explicit expression for the scale dependent term up to the first order in η^2. We explicitly show that this term is traceless for the conformal coupling. In Sec. V we present our conclusions and some important remarks about this article. Although the formalism developed here is applied only when the dimension of the space section is $d \geqslant 3$, in the Appendix we present an expression for the Green function in a limiting case $d \to 2$.

II. GREEN FUNCTION

In this section we calculate the Euclidean scalar Green function associated with a massless field in the space–time described by (2). This Green function must obey the nonhomogeneous second order differential equation

$$(\Box - \xi R) G_E(x,x') = -\delta^d(x,x') = -\frac{\delta^2(x-x')}{\sqrt{g}}, \tag{9}$$

where we have introduced the nonminimal coupling of the scalar field with the geometry. As we have already said, the scalar curvature for this space–time is $R=(d-1)(d-2)(1-\alpha^2)/r^2$.

The Euclidean Green function can also be obtained by the Schwinger–DeWitt formalism as follows:

$$G_E(x,x') = \int_0^\infty ds K(x,x';s), \tag{10}$$

where the heat kernel, $K(x,x';s)$, can be expressed in terms of eigenfunctions of the operator $\Box - \xi R$ as follows:

$$K(x,x';s) = \sum_\sigma \Phi_\sigma(x) \Phi_\sigma^*(x') \exp(-s\sigma^2), \tag{11}$$

σ^2 being the corresponding positively defined eigenvalue. Writing

$$(\Box - \xi R)\Phi_\sigma(x) = \sigma^2 \Phi_\sigma(x), \tag{12}$$

we obtain the complete set of normalized solutions of the above equation:

$$\Phi_\sigma(x) = \sqrt{\frac{\alpha p}{2\pi}} \frac{1}{r^{d/2-1}} e^{-i\omega\tau} J_{\nu_n}(pr) Y(n,m_j;\phi,\theta_j), \tag{13}$$

with

$$\sigma^2 = \omega^2 + \alpha^2 p^2, \tag{14}$$

$Y(n,m_j;\phi,\theta_j)$ being the hyperspherical harmonics of degree n,[6] J_ν the Bessel function of order

$$\nu_n=\alpha^{-1}\sqrt{(n+(d-2)/2)^2+(d-1)(d-2)(1-\alpha^2)(\xi-\overline{\xi})}, \tag{15}$$

with $\overline{\xi}=(d-2)/4(d-1)$. So according to (11) our heat kernel is given by

$$\begin{aligned}K(x,x';s)&=\int_{-\infty}^{\infty}d\omega\int_0^{\infty}dp\sum_{n,m_j}\Phi_\sigma(x)\Phi_\sigma^*(x')e^{-s\sigma^2}\\&=\frac{1}{8\alpha\pi^{(d+1)/2}s^{3/2}}\frac{1}{(rr')^{d/2-1}}\frac{\Gamma(d/2)}{d-2}e^{-(\Delta\tau^2\alpha^2+r^2+r'^2)/4\alpha^2 s}\\&\quad\times\sum_{n=0}^{\infty}[2(n-1)+d]I_{\nu_n}\left(\frac{rr'}{2\alpha^2 s}\right)C_n^{(d-2)/2}(\cos\gamma),\end{aligned} \tag{16}$$

I_ν being the modified Bessel function, $C_n^\mu(x)$ the Gegenbauer polynomial of degree n and order μ and γ is the angle between two arbitrary directions. Our final expression (16) was obtained using the addition theorem for the hyperspherical harmonics[6] and the integral table.[7]

Now we are in position to obtain the Euclidean Green function substituting (16) into (10). Our final result is

$$G_E^{(d)}(x,x')=\frac{1}{4\pi^{d/2+1}}\frac{1}{(rr')^{(d-1)/2}}\frac{\Gamma(d/2)}{d-2}\sum_{n=0}^{\infty}[2(n-1)+d]Q_{\nu_n-1/2}(u)C_n^{(d-2)/2}(\cos\gamma), \tag{17}$$

where

$$u=\frac{\alpha^2\Delta\tau^2+r^2+r'^2}{2rr'} \tag{18}$$

and Q_μ is the Legendre function. Unfortunately because the dependence of the order of the Legendre functions on the parameter α is not a simple one, it is not possible to develop the summation and to obtain a closed expression for the Green function even in the simpler case $d=3$.[8] However, for $\xi=\overline{\xi}$, ν_n becomes equal to $(n+(d-2)/2)/\alpha$ and for $\gamma=0$ it is possible to represent this Green function in an integral form using the integral representation for the Legendre function

$$Q_{\nu-1/2}(\cosh\rho)=\frac{1}{\sqrt{2}}\int_\rho^{\infty}dt\frac{e^{-\nu t}}{\sqrt{\cosh t-\cosh\rho}} \tag{19}$$

and

$$C_n^{(d-2)/2}(1)=\frac{(n+d-3)!}{n!(d-3)!}. \tag{20}$$

Now it is possible to develop the summation and after some intermediate steps we get

$$G_E^{(d)}(r,\tau;r',\tau')=\frac{1}{4\pi^{d/2+1}}\frac{1}{(rr')^{(d-1)/2}}\frac{\Gamma(d/2)}{2^{d-3/2}}\int_\rho^{\infty}dt\frac{1}{\sqrt{\cosh t-\cosh\rho}}\frac{\cosh(t/2\alpha)}{(\sinh(t/2\alpha))^{d-1}}. \tag{21}$$

For the case where $\alpha=\frac{1}{2}$, i.e., a large solid angle deficit, the above expression can be written in a simpler form by performing the integral. Making an appropriate transformation of variable, $t := \operatorname{arccosh}((u-1)/q+1)$, we get

$$G_E^{(d)}(r,\tau;r,\tau')=\frac{1}{4\sqrt{2}\,\pi^{d/2+1}}\,\frac{\Gamma(d/2)}{d-2}\,\frac{(rr')^{(d-3)/2}}{[(r-r')^2+\Delta\tau^2/4]^{d/2-1}}\,\frac{1}{[(r+r')^2+\Delta\tau^2/4]^{d/2-1}}. \tag{22}$$

The next section is devoted to the obtainment of the renormalized vacuum expectation value of the square of the field operator. As an explicit application we shall develop these quantities for the cases where $d=4$ and $d=5$.

III. CALCULATION OF $\langle\Phi^2(x)\rangle_{\mathrm{Ren}}$

The calculation of the vacuum expectation value of the square of the field operator is obtained computing the Green function in the coincidence limit:

$$\langle\Phi^2(x)\rangle=\lim_{x'\to x} G_E(x,x'). \tag{23}$$

However, this procedure provides a divergent result. In order to obtain a finite and well defined result, we must apply in this calculation some renormalization procedure. Here we shall adopt the point-splitting renormalization. This procedure is based upon a divergence subtraction scheme in the coincidence limit of the Green function. In Ref. 3, Wald examined the behavior of the Green function in this limit. He observed that its divergences have the same structure as given by the Hadamard function, which, on the other hand, can be explicitly written in terms of the square of the geodesic distance between the two points. So, we shall adopt the following prescription: we subtract from the Green function the Hadamard one before applying the coincidence limit as shown:

$$\langle\Phi^2(x)\rangle_{\mathrm{Ren}}=\lim_{x'\to x}[G_E(x,x')-G_H(x,x')]. \tag{24}$$

Now let us develop this calculation explicitly. As we have mentioned earlier, it is not possible to proceed exactly with the summation which appears in the Green function. By this reason the best that we can do is to obtain an approximate expression for it, developing a series expansion in powers of the parameter $\eta^2=1-\alpha^2$, which is much smaller than unity for the physical four-dimensional space–time. Moreover, because we want to take the coincidence limit in the Green function, let us take first $\gamma=0$ and $\Delta\tau=0$ in (17). The approximate expression for the order of the Legendre function, up to the first power in η^2, is

$$\nu_n\approx\left(n+\frac{d-2}{2}\right)(1+\eta^2/2)+\frac{(d-1)(d-2)(\xi-\overline{\xi})}{2n+d-2}\,\eta^2+O(\eta^4). \tag{25}$$

We also need to develop the summation

$$S=\sum_{n=0}^{\infty}[2n+d-2]\,\frac{(n+d-3)!}{n!}\,e^{-\nu_n t}. \tag{26}$$

Substituting the approximate expression for ν_n into the summation in (26), we get, after some intermediate steps,

$$S=\frac{(d-2)!}{2^{d-2}}\,\frac{\cosh(t/2)}{\sinh^{d-1}(t/2)}\left[1-\frac{t\,\eta^2(d-1)}{2\sinh(t)}(1+4\xi\sinh^2(t/2))\right]. \tag{27}$$

So the approximate Green function is given by

$$G_E^{(d)}(r,r')=\frac{1}{2^{d+1/2}\pi^{d/2+1}}\frac{\Gamma(d/2)}{(rr')^{(d-1)/2}}\int_\rho^\infty dt\,\frac{1}{\sqrt{\cosh t-\cosh\rho}}$$
$$\times\frac{\cosh(t/2)}{\sinh^{d-1}(t/2)}\left[1-\frac{t\eta^2(d-1)}{2\sinh(t)}(1+4\xi\sinh^2(t/2))\right]. \tag{28}$$

In his beautiful paper Christensen[5] has given a general expression for the Hadamard function for any dimensional space-time, which is expressed in terms of the square of the geodesic distance $2\sigma(x,x')$. Moreover, there he has called attention to the different behavior of this function when the dimension of the space–time is an even or odd number. In the latter case there is no logarithmic term in the expansion of the Hadamard function. So because of this fact we shall develop, separately, the calculation of the renormalized vacuum expectation value of the square of the field operator, for $n=1+d$ odd and even.

Following Ref. 5, next we write down the Hadamard function for the massless case when the dimension of the space–time is an odd number. This function is given by

$$G_H(x,x')=\frac{\Delta^{1/2}(x,x')}{2(2\pi)^{n/2}}\frac{1}{\sigma^{n/2-1}(x,x')}\sum_{k=0}^{(n-3)/2}a_k(x,x')\sigma^k(x,x')\frac{\Gamma(n/2-k-1)}{2^k}, \tag{29}$$

where $\Delta(x,x')$, the Van Vleck–Morette determinant, and the factor $a_k(x,x')$, for $k=0,1,2$, have been computed by many authors. See Refs. 9 and 10.

Now let us apply this formalism for the case $n=5$, i.e., $d=4$. The Euclidean Green function in this case is

$$G_E^{(4)}(r,r')=\frac{1}{16\sqrt{2}\pi^3}\frac{1}{(rr')^{3/2}}\int_\rho^\infty dt\,\frac{1}{\sqrt{\cosh t-\cos\rho}}$$
$$\times\frac{\cosh(t/2)}{\sinh^3(t/2)}\left[1-\frac{3t\eta^2}{2\sinh(t)}(1+4\xi\sinh^2(t/2))\right]. \tag{30}$$

Because we need to evaluate the Hadamard function in the coincidence limit we can write this function exhibiting only its divergent contributions as shown:

$$G_H(x,x')=\frac{1}{16\sqrt{2}\pi^2}\frac{1}{\sigma^{3/2}(x,x')}\left[1+\left(\frac{1}{6}-\xi\right)R(x)\sigma(x,x')\right], \tag{31}$$

where we have substituted the explicit expression for Δ, a_0 and a_1 in the coincidence limit. The scalar curvature in this five-dimensional space–time is $R=6\eta^2/r^2$. The radial one-half of the geodesic distance, $\sigma(x,x')=(1/2\alpha^2)(r-r')^2$, in our approximation is equal to $\sigma\approx(\frac{1}{2})(r-r')^2(1+\eta^2+\cdots)$. Now substituting (30) and (31) into (24) we get, after a long calculation,

$$\langle\Phi^2(x)\rangle_{\mathrm{Ren}}=\frac{3\eta^2}{64\pi r^3}\left(\xi-\frac{3}{16}\right). \tag{32}$$

We can see that for the conformal coupling in five dimensional space–time, $\xi=\frac{3}{16}$, the above expectation vanishes, i.e., the renormalized vacuum expectation value of the operator $\Phi^2(x)$ is zero up to the first order in η^2.

The six dimensional case will be analyzed now. This case, together with the four dimensional one studied in Ref. 8, exhibits explicitly the ambiguity in the renormalization procedure given by a mass subtraction point μ. (Moretti, in Ref. 11, has used the local ζ-function renormalization

technique to show, by a general argument, that the scale ambiguity is present in the calculation of vacuum expectation value of the square of scalar field operator in a curved space–time of dimension even.)

The Hadamard function in even dimensions is explicitly written in the paper by Christensen,[5] so we shall not reproduce it here. The singular behavior of the Hadamard function in the six dimensional space–time is

$$G_H(x,x')=\frac{\Delta^{1/2}(x,x')}{16\pi^3}\left[\frac{a_0(x,x')}{\sigma^2(x,x')}+\frac{a_1(x,x')}{2\sigma(x,x')}-\frac{a_2(x,x')}{4}\ln\left(\frac{\mu^2\sigma(x,x')}{2}\right)\right]. \tag{33}$$

Substituting the expressions for the factors a_k, we get, up to the first order in the parameter η^2, the following result:

$$G_H(r,r')=\frac{1}{2\pi^3}\left[\frac{(1-2\eta^2)}{(r-r')^4}+\frac{(1-6\xi)\eta^2}{2r^2(r-r')^2}-\frac{\eta^2}{4r^4}\left(\xi-\frac{1}{5}\right)\ln\left(\frac{\mu^2(r-r')^2}{4}\right)\right]. \tag{34}$$

Now taking $d=5$ in (28) and substituting the result, together with Eq. (34), into (24), we get, after some calculation, the following expression:

$$\langle\Phi^2(x)\rangle_{\mathrm{Ren}}=-\frac{\eta^2}{96\pi^3r^4}\left(\frac{47}{25}-10\xi\right)+\frac{\eta^2}{8\pi^3r^4}\left(\xi-\frac{1}{5}\right)\ln(\mu r). \tag{35}$$

We can see that for the conformal coupling in six dimensions, $\xi=\frac{1}{5}$, there is no ambiguity, the logarithmic contribution disappears and we get $\langle\Phi^2(x)\rangle_{\mathrm{Ren}}=\eta^2/800\pi^3r^4$. [In order to obtain the above result we expressed the logarithmic term which is present in (33) in terms of the $Q_0(\overline{u})$, $\overline{u}$ being $(r^2+r'^2)/2rr'$, and write this Legendre function in its integral representation (19).]

The next section is devoted to the analysis of the vacuum expectation value of the energy-momentum tensor in five and six dimensional space–time.

IV. VACUUM EXPECTATION VALUE OF THE ENERGY-MOMENTUM TENSOR

In this article we are working with a massless scalar quantum field theory in the metric space–time defined by (2), which does not present any dimensional parameter. Moreover, we are adopting the natural system units where $\hbar=c=1$, so because of these reasons the physical quantities calculated in this model can only depend on the radial coordinate r or on the renormalization mass scale μ. By dimensional point of view we could expect that $\langle\Phi^2(x)\rangle_{\mathrm{Ren}}$ be proportional to $1/r^{n-2}$ and $\langle T_{\mu,\nu}(x)\rangle_{\mathrm{Ren}}$ proportional to $1/r^n$. The factor of proportionality should be given in terms of the parameter η^2 and the nonminimal coupling ξ. As to the square of the scalar field, this calculation has been done in this article for the cases where the dimension of the space–time is 5 and 6 up to the first order in η^2. In this section we want to analyze the vacuum expectation value of the energy-momentum tensor. We start considering the five dimensional case.

The renormalized vacuum expectation value of the energy-momentum tensor in five dimensions does not depend on the subtraction mass parameter. So, there is no logarithmic term, and it can be written in a general form by

$$\langle T^{\nu}_{\mu}(x)\rangle_{\mathrm{Ren}}=\frac{A^{\nu}_{\mu}(\xi,\eta^2)}{r^5}. \tag{36}$$

Because there is no trace anomaly in odd dimension, for $\xi=\frac{3}{16}$, we can write

$$\langle T^{\mu}_{\mu}(x)\rangle_{\mathrm{Ren}}=0, \tag{37}$$

so $A^{\mu}_{\mu}=0$. On the other hand, by symmetry of this space–time, the above vacuum expectation value should be diagonal. Moreover, the conservation condition

$$\nabla_\nu \langle T^\nu_\mu(x)\rangle_{\rm Ren}=0 \tag{38}$$

imposes additional restrictions on the components of the tensor A^ν_μ. So, under these conditions we have

$$A^0_0=A^1_1, A^2_2=A^3_3=A^4_4. \tag{39}$$

Using these relations and the traceless condition we can express all nonzero components of A^ν_μ in terms of one of them. Let us choose A^0_0, so we can write

$$A^\nu_\mu=A^0_0\,\mathrm{diag}(1,\ 1,\ -\tfrac{2}{3},\ -\tfrac{2}{3},\ -\tfrac{2}{3}). \tag{40}$$

The explicit calculation of the component A^0_0 involves an extensive calculation which we shall not do here.

The vacuum expectation value of the energy-momentum tensor in six dimensions requires more details. By the expression obtained for the vacuum expectation value of the square of the field, it is possible to infer that there exists a logarithmic contribution to this tensor. Moreover, by the trace anomaly[5] we have

$$\langle T^\mu_\mu(x)\rangle_{\rm Ren}=\frac{1}{64\pi^3}a_3(x). \tag{41}$$

So, we can conclude that the general expression for this object is

$$\langle T^\nu_\mu(x)\rangle_{\rm Ren}=\frac{1}{64\pi^3 r^6}[A^\nu_\mu(\eta^2,\xi)+B^\nu_\mu(\eta^2,\xi)\ln(\mu r)], \tag{42}$$

where A^ν_μ, in principal, are arbitrary numbers. Because the cutoff factor μ is completely arbitrary, there is an ambiguity in the definition of this renormalized vacuum expectation value. Moreover, the change in this quantity under the change of the renormalization scale is given in terms of the tensor B^ν_μ as shown:

$$\langle T^\nu_\mu(x)\rangle_{\rm Ren}(\mu)-\langle T^\nu_\mu(x)\rangle_{\rm Ren}(\mu')=\frac{1}{64\pi^3 r^6}B^\nu_\mu(\eta^2,\xi)\ln(\mu/\mu'). \tag{43}$$

In Ref. 5, Christensen pointed out that the difference between them is given in terms of the effective action which depends on the logarithmic terms whose final expression, in arbitrary even dimension, is

$$\langle T^\nu_\mu(x)\rangle_{\rm Ren}(\mu)-\langle T^\nu_\mu(x)\rangle_{\rm Ren}(\mu')=\frac{1}{(4\pi)^{n/2}}\frac{1}{\sqrt{g}}\frac{\delta}{\delta g^{\mu\nu}}\int d^n x\sqrt{g}a_{n/2}(x)\ln(\mu/\mu'). \tag{44}$$

In our six dimensional case we need the factor $a_3(x)$. The explicit expression for this factor can be found in the paper by Gilkey[12] and in a more systematic form in the paper by Jack and Parker,[13] for a scalar second order differential operator D^2+X, D_μ being the covariant derivative including gauge field and X an arbitrary scalar function. This expression involves 46 terms and we shall not repeat it here in a complete form. The reason is that our calculation has been developed up to the first order in the parameter η^2 and only the quadratic terms in Riemann and Ricci tensors, and in the scalar curvature, are relevant for us. This reduces to 12 the number of terms which will be considered. Discarding the gauge fields and taking $X=-\xi R$ we get

$$\overline{a}_3(x)=\frac{1}{6}\left(\frac{1}{6}-\xi\right)\left(\frac{1}{5}-\xi\right)R\Box R+\frac{\xi^2}{12}R^{;\mu}R_{;\mu}+\frac{\xi}{90}R^{\mu\nu}R_{;\mu\nu}-\frac{\xi}{36}R^{;\mu}R_{;\mu}-\frac{1}{7!}[28R\Box R$$
$$+17R_{;\mu}R^{;\mu}-2R_{\mu\nu;\rho}R^{\mu\nu;\rho}-4R_{\mu\nu;\rho}R^{\mu\rho;\nu}+9R_{\mu\nu\rho\sigma;\gamma}R^{\mu\nu\rho\sigma;\gamma}-8R_{\mu\nu}\Box R^{\mu\nu}$$
$$+24R_{\mu\nu}R^{\mu\rho;\nu}{}_{\rho}+12R_{\mu\nu\rho\sigma}\Box R^{\mu\nu\rho\sigma}+O(R^3). \tag{45}$$

This expression is of sixth order derivative on the metric tensor. Our next step is to take the functional derivative of $\overline{a}_3(x)$. Using the expressions for the functional derivative of the Riemann and Ricci tensor, together with the scalar curvature,[14] we obtain after a long calculation the following expression for the tensor B_μ^ν:

$$B_\mu^\nu(\eta^2,\xi)=\frac{r^6}{6}\left[-\delta_\mu^\nu\Box^2R\left(\xi^2-\frac{\xi}{3}+\frac{23}{840}\right)+\frac{1}{40}\Box^2R_\mu^\nu+\nabla^\nu\nabla_\mu\Box R\left(\xi^2-\frac{\xi}{3}+\frac{1}{42}\right)\right]+O(R^2). \tag{46}$$

Moreover, developing all the terms which appear in Eq. (46) we obtain, after some calculations,

$$B_\mu^\nu(\eta^2,\xi)=\frac{\eta^2}{225}\,\mathrm{diag}(6,6,-3,-3,-3,-3)+16\eta^2(\xi-1/5)(\xi-2/15)\,\mathrm{diag}(1,-4,2,2,2,2). \tag{47}$$

As in the last case, it is possible to make some restrictions on the tensor A_μ^ν. Again because of the spherical symmetry of the problem, we can infer that this tensor should be diagonal. Moreover, the renormalized vacuum expectation value of the energy-momentum tensor must be conserved, i.e.,

$$\langle T_\mu^\nu(x)\rangle_{\mathrm{Ren};\nu}=0. \tag{48}$$

From these six equations and defining the variable $T=64\pi^3r^6\langle T_\mu^\mu(x)\rangle_{\mathrm{Ren}}$ we obtain

$$A_0^0=T+A_1^1-B_1^1+(B_1^1-B_0^0)\ln(\mu r) \tag{49}$$

and

$$A_2^2=A_3^3=A_4^4=A_5^5=\frac{B_1^1}{4}-\frac{A_1^1}{2}-\left(B_2^2+\frac{B_1^1}{2}\right)\ln(\mu r). \tag{50}$$

When the nonminimal coupling ξ coincides with the conformal one, $\frac{1}{5}$, we get

$$A_0^0=T+A_1^1-B_1^1, \tag{51}$$

$$A_2^2=A_3^3=A_4^4=A_5^5=\frac{B_1^1}{4}-\frac{A_1^1}{2}, \tag{52}$$

with

$$T=r^6a_3(x)=-\frac{1}{4200}\Box^2R+O(R^2)=\frac{8}{350}\frac{\eta^2}{r^6}+O(\eta^4). \tag{53}$$

Again the complete evaluation of $\langle T_\mu^\nu(x)\rangle_{\mathrm{Ren}}$ requires the knowledge of at least one component of the tensor A_μ^ν, say A_1^1. However, we do not attempt to do this straightforward and long calculation here.

V. CONCLUDING REMARKS

In this article we have found a formal expression for the Euclidean scalar Green function associated with a massless field in higher dimensional global monopole space–time defined by (2), i.e., space-time where the dimension is bigger than four and presents a solid angle deficit. The expression for this function is given in terms of an infinite sum of products of Legendre functions with Gegenbauer polynomials or hyperspherical harmonics. Having this Green function in our hands, we can use it to calculate the vacuum expectation value of some physically relevant operators, as the square of the field and the energy-momentum tensor. We have applied this formalism to calculate $\langle\Phi^2(x)\rangle$ and $\langle T_{\mu\nu}(x)\rangle$ in five and six dimensions. However, these calculations become effective only for the case when the parameter α, associated with the solid angle deficit, is close to unity. In this case we can expand the Green function in powers of the parameter $\eta^2=1-\alpha^2$, and obtain closed results for these two quantities.

As it was mentioned, the vacuum expectation values for these quantities are divergent and these divergences are a consequence of the evaluation of the two-point Green functions in the coincidence limit. In order to obtain finite and well defined results we adopted the point-splitting renormalization procedure and eliminated all divergences, subtracting from the Green function the Hadamard one. An interesting result of our calculation was that the renormalized vacuum expectation value of the square of the field in the five dimensional global monopole space–time vanishes when we take for the nonminimal coupling constant ξ the conformal value $\frac{3}{16}$. A similar calculation in the six dimensional case shows that a finite contribution remains for $\xi=\frac{1}{5}$, which is independent of the mass cutoff parameter.

Moreover, in the six dimensional case, there appears in the renormalized vacuum expectation value of the energy-momentum tensor, the function $a_3(x)$. This function, according to Ref. 15 on p. 159, is associated with a purely geometric (divergent) Lagrangian that should renormalize the modified classical Einstein one. When similar terms are inserted into the gravitational action, the field equation is modified by the presence of order six terms proportional to

$$c_1 g_{\mu\nu}\Box^2 R + c_2 \Box^2 R_{\mu\nu} + c_3 \nabla_\mu \nabla_\nu \Box R + O(R^2). \tag{54}$$

APPENDIX: THE (1+2)-DIMENSIONAL CASE LIMIT

In this appendix we present a nontrivial extension of our Green function (17) for the case where $d=2$. Although this Green function constructed for $d\geqslant 3$ presents a pole at $d=2$, the Gegenbauer polynomial is also not defined when its order is zero. However, it is possible to get such an expression if we admit that (17) is a function of a continuous parameter d. According to Ref. 16, it is possible to obtain a well defined limit for the ratio of the Gegenbauer polynomial by its order when it goes to zero. This limit is given by

$$\lim_{d\to 2}\frac{1}{d-2}C_n^{(d-2)/2}(x)=\frac{T_n(x)}{n}, \tag{A1}$$

where $T_n(x)$ is the Chebychev polynomials type I. Moreover, in the limit $d=2$, $\nu_n=|n|/\alpha$. However, we have to be careful when we try to substitute the above limit into (17). The definition of the Chebychev polynomial type I by its generating function reproduces explicitly the polynomials with order $n\geqslant 1$ in a recurrence equation separated from the $T_0(x)$ (see Ref. 16). Taking into account this fact we have to consider a multiplicity factor in the summation. Finally, we arrive at the following Green function:

$$G^{(2)}(x,x')=\frac{1}{2\pi^2}\frac{1}{\sqrt{rr'}}\sum_{n=0}^{\infty}Q_{n/\alpha-1/2}T_n(\cos\gamma)\epsilon(n), \tag{A2}$$

with $\epsilon(0)=1$ and $\epsilon(n>0)=2$. However, $T_n(\cos\gamma)=\cos(n\gamma)$ (see again Ref. 16, p. 631). Finally, substituting the integral representation for the Legendre function (19), we obtain

$$G^{(2)}(x,x')=\frac{1}{2\pi^2}\frac{1}{\sqrt{2rr'}}\int_{\rho}^{\infty}dt\,\frac{1}{\sqrt{\cosh t-\cosh\rho}}\,\frac{\sinh(t/\alpha)}{\cosh(t/\alpha)-\cos(\gamma)}. \tag{A3}$$

This equation is equivalent with the Euclidean Green function for the three dimensional conical space given in Eq. (2.19) of Ref. 17. We can see that by changing in a compatible way the coordinates r by r/α, γ by γ/α and τ by z.

Integrable cases of gravitating static isothermal fluid spheres

B. V. Ivanov[a)]
Institute for Nuclear Research and Nuclear Energy, Tzarigradsko Shausse 72, Sofia 1784, Bulgaria

(Received 24 July 2001; accepted for publication 7 November 2001)

It is shown that different approaches toward the solution of the Einstein equations for a static spherically symmetric perfect fluid with a γ-law equation of state lead to an Abel differential equation of the second kind. Its only integrable cases at present are flat space–time, de Sitter solution and its Buchdahl transform, Einstein static universe, and the Klein–Tolman solution. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1431259]

I. INTRODUCTION

The Einstein equations for static and spherically symmetric perfect fluids have been investigated by many authors.[1–3] The metric of a static spherically symmetric space–time reads:

$$ds^2 = e^{2\nu}dt^2 - e^{\lambda}dr^2 - R^2(d\theta^2 + \sin^2\theta\, d\varphi^2), \tag{1}$$

where ν,λ,R depend only on the radial coordinate r. We use units in which $8\pi G = c = 1$. Spherical symmetry requires that the energy–momentum tensor is diagonal, $T^{\nu}_{\mu} = \mathrm{diag}(\rho, -p_r, -p_0, -p_\varphi)$ where $\rho(r)$ is the fluid density, $p_r(r)$ is the radial pressure, and $p_\theta(r), p_\varphi(r)$ are the tangential pressures. It also requires that $p_\theta = p_\varphi$. Perfect fluids, in addition, have no pressure anisotropy, namely $p \equiv p_r = p_\theta = p_\varphi$.

An abundance of solutions has been found when no equation of state is prescribed, since then the unknown functions are more than the equations. The problem becomes very difficult when p is defined as a known function of ρ. A realistic equation of state is provided by the Newtonian polytropes $p = (1/n)\rho^{1+1/k}$, which have been studied for many years.[4,5] In the limit when $k \to \infty$ a softer isothermal equation of state emerges

$$\rho = np, \tag{2}$$

usually called the γ-law, because it is traditionally written as $p = (\gamma - 1)\rho$. Physically realistic perfect fluid solutions should have finite and positive density and pressure and $\rho \geqslant p$, i.e., we impose the weak and dominant energy conditions. The fluid should be causal; the speed of sound $(dp/d\rho)^{1/2}$ must be positive and less than 1, the speed of light. Stability against radial pulsations requires that p should decrease outwards and ρ should not increase outwards.[3] For the equation of state (2) these conditions demand that $n \geqslant 1$ and at least one of the fluid characteristics is finite, positive, and decreasing. Important special cases include dust ($n = \infty$), incoherent radiation ($n = 3$), and stiff fluid ($n = 1$) where the speed of sound equals the speed of light.

Even for such a simple relation, few analytic solutions have been found. When $n = \infty$ and $\rho \neq 0$ the pressure vanishes, giving the case of dust. In fact, the density also vanishes and what remains is trivial flat space–time. When $n = -1$ the pressure and the density are constant and the solution is equivalent to a vacuum solution with a cosmological constant found by de Sitter. We show in this paper that the case $n = -5$ is connected to it by the Buchdahl transformation $n \to -(n+6)$[6–8] and is also soluble. The case $n = -3$ leads to the Einstein static universe.[2] It is

a)Electronic mail: boyko@inrne.bas.bg

clear that the unphysical cases ($n<1$) should be studied too since they produce cosmological solutions or are connected to the physical ones by a general transformation, valid also when no equation of state is prescribed.

A simple solution for a general n was hidden among the solutions found by Tolman.[9] In fact, he studied the field equations under simplifying assumptions for the metric components, without imposing an equation of state. The pressure and the density in some of his solutions happen to satisfy Eq. (2) when certain constants are sent to zero or to infinity.[3] The first who systematically investigated relation (2) was Klein. He rediscovered the Tolman solution first for $n=3$ and later for arbitrary n.[10,11] His approach and results, published in a not-readily available journal, remained unnoticed for a long time. Even in Ref. 1 his second work is mentioned as referring to the polytropic equation of state, which is true only for its beginning. For a third time this Klein–Tolman (KT) solution was found by Misner and Zapolsky[12] where its relevance to neutron stars was studied. The radial dependence of the density, however, was omitted due to a misprint, causing additional confusion. Nevertheless, this paper became a standard reference toward which further rediscoveries[13,14] were directed.[15] This solution is singular at the center where ρ and p become infinite.

Klein also found numerically a regular solution for $n=3$, starting in phase space from Minkowski space–time and spiraling toward the KT solution. His work was based on a certain first-order differential equation. This solution was also rediscovered later by numeric studies of two-dimensional autonomous dynamical systems[5,16,17] and generalized for arbitrary realistic n. Its phase space is contaminated by grossly unrealistic solutions with density, vanishing in some finite interval $[0,r_c]$, and metric possessing curvature singularities. Only the exact KT solution and the numerical regular solution are acceptable. Unfortunately, solutions satisfying Eq. (2) are not asymptotically flat and the fluid sphere extends to infinity. Nevertheless they can describe the superdense core of a neutron star and have finite masses when a cutoff is done at some distance, despite the singularity in the KT solution.[12,18] They can be joined smoothly to the exterior Schwarzschild solution with the help of an intermediate layer of perfect fluid with boundary, like the degenerate nonrelativistic neutron gas[12] or the Schwarzschild interior solution.

Another way for the fluid to acquire a boundary is to add to the right-hand side of the scale-invariant Eq. (2) a positive constant ρ_0. The numerical study of a perfect fluid with such linear equation of state[19] stresses once more the importance of the solutions of Eq. (2) which appear as scale-invariant boundaries for all orbits in a three-dimensional compact phase space. All equilibrium points lie on these boundaries, including Minkowski space–time, which is a starting point for the regular subset of solutions. The high pressure limit which probes the relativistic effects lies there too. The KT and the regular scale-invariant solutions, together with some nonregular solution, play a crucial role in the understanding of the structure of solution space for the linear equation of state. Therefore it is desirable to have analytic expressions for these unique solutions. They will allow one to study in detail the qualitative changes in their behavior with respect to the parameter n such as the change of the KT equilibrium point from focus to node when $n=\sqrt{64/7}-3$, the bifurcation point at $n=1$ or the relation to the simple integrable cases for negative n.

The question whether the regular solution to Eq. (2) has an explicit expression has never been answered in a satisfactory way. The persistent closure of analytic methods on the irregular KT solution suggests that there are no more integrable cases except it and the few above-mentioned solutions. On the other hand, similar problems have been completely solved explicitly. For example, static dust solutions are not possible. The dust must be nonstatic or charged. In both cases the general solution has been found.[20–22] The cylindrically symmetric static case has been solved in simple functions, using two different gauges.[23,24] The relation between them was clarified in Ref. 25. The planar case follows easily from the cylindrical one[24] or from the spherical one.[17,26]

The purpose of this paper is to derive the integrable cases in a unified manner and to elucidate the mathematical difficulty of the problem. We show that in its heart stands the Abel equation of the second kind, whose normal form is

$$ww_{,z}-w=f(z). \tag{3}$$

Derivatives are denoted by a comma and subscript. Derivatives with respect to r are also denoted by a prime. The integrable cases of Eq. (3) depend on the shape of $f(z)$ and are tabulated in Ref. 27. The functions that emerge are in general transcendental, but simplify for special values of n. The integrable cases that we find are given by $n=-5,-3,-1,\infty$ and the KT solution with n outside the interval $(-5.83,-0.17)$.

In the following three sections three different approaches are discussed which invariably lead to Eq. (3) with functions $f(z)$ possessing the same general structure but with different coefficients. In Sec. II we start from the well-known Tolman–Oppenheimer–Volkoff (TOV) equation[9,28] written in a general spherical metric. In Sec. III the starting point is a differential equation derived by Klein in curvature coordinates. In Sec. IV we utilize the approach of Haggag and Hajj-Boutros (HH) described in Ref. 14 for a stiff perfect fluid in isotropic coordinates. Section V is dedicated to the Buchdahl transformation which supplies the integrable case $n=-5$. Finally, Sec. VI contains some discussion and conclusions.

II. ANALYSIS OF THE TOV EQUATION

The Einstein equations for the metric (1) and the energy–momentum tensor of a perfect fluid, discussed in Sec. I, are written as[29]

$$\rho=\frac{1}{R^2}-e^{-\lambda}\left(\frac{2R''}{R}+\frac{R'^2}{R^2}\right)-(e^{-\lambda})'\frac{R'}{R}, \tag{4}$$

$$p=-\frac{1}{R^2}+e^{-\lambda}\frac{R'}{R}\left(\frac{R'}{R}+2\nu'\right), \tag{5}$$

$$p=e^{-\lambda}\left[\frac{R''}{R}+\nu''+\left(\nu'-\frac{\lambda'}{2}\right)\left(\nu'+\frac{R'}{R}\right)\right]. \tag{6}$$

The contracted Bianchi identity

$$p'=-(\rho+p)\nu', \tag{7}$$

follows from Eqs. (4)–(6) and usually replaces Eq. (6). Thus Eqs. (4), (5), and (7) determine ν, λ, R, ρ and p. One of the metric functions is redundant and can be used to fix the gauge. Different coordinate systems have been introduced in the literature. Curvature coordinates (also called Schwarzschild coordinates) are obtained when $R=r$. Isotropic coordinates have $R=re^{\lambda/2}$ while polar Gaussian coordinates set $e^{\lambda}=1$. Other coordinates are known as well. Fixing the gauge and the equation of state equals the number of unknowns and equations. For the time being, we proceed in full generality to derive the TOV equation. Let us define the so-called mass function $m(r)$, which is obtained from the sectional curvature of the spherical two-surfaces:

$$m(r)\equiv\tfrac{1}{2}R(1-e^{-\lambda}R'^2). \tag{8}$$

Then Eq. (4) may be written as

$$\rho=\frac{2m'}{R^2R'}, \tag{9}$$

which integrates to

$$m(R)=\frac{1}{2}\int_0^R\rho R^2\,\mathrm{d}R. \tag{10}$$

Passing from r to R dependence, inserting $e^{-\lambda}$ from Eq. (8) and ν_R from Eq. (7) into Eq. (5) results in the general TOV equation

$$p_{,R}=-\frac{(\rho+p)(2m+pR^3)}{2R(R-2m)}. \tag{11}$$

In the case of dust $p=0$. Then Eq. (11) yields $\rho m=0$, which combined with Eqs. (9) and (10) gives $\rho=0$. There is no matter and the solution is trivial flat space–time. In the general case when $p=p(\rho)$, Eq. (9) shows that Eq. (11) is a differential equation for $m(R)$. Let us now introduce the variables $M=m/R$, $D=\frac{1}{2}\rho R^2$ and $P=\frac{1}{2}pR^2$. Then Eq. (11) becomes

$$RD_{,R}=2D-\frac{(D+P)(M+P)}{(1-2M)p_{,\rho}}. \tag{12}$$

Specializing to the γ-law equation of state and introducing $\tau=\ln R$ we obtain from Eqs. (12) and (9) the autonomous system[29]

$$(2M-1)D_{,\tau}=D\left[(n+5)M-2+\frac{n+1}{n}D\right], \tag{13}$$

$$D=M_{,\tau}+M. \tag{14}$$

The case $n=0$ is excluded because it gives vanishing density. This system was derived in polar Gaussian coordinates by Collins[5] and further analyzed by him in Refs. 17 and 30.

Now, let us insert Eq. (14) into Eq. (13) and define $x=M-1/2$. The result is

$$xx_{,\tau,\tau}=\frac{n+1}{2n}x_{,\tau}^2+\left[\frac{(n+1)(n+2)+2n}{2n}x+\frac{(n+1)(n+2)}{4n}\right]x_{,\tau}+A(x), \tag{15}$$

$$A(x)\equiv\left(x+\frac{1}{2}\right)\left[\frac{(n+1)^2+4n}{2n}\left(x+\frac{1}{2}\right)-1\right]. \tag{16}$$

Equation (8) indicates that $x<0$. The solution of Eq. (15) determines M and consequently m as functions of R. Then D is given by Eq. (14) which determines $\rho(R)$. The pressure is given by Eq. (2), while ν follows from Eq. (7) written as

$$(\rho+p)\nu_{,R}=-p_{,R}. \tag{17}$$

Finally, $e^{-\lambda}R'^2$ is found from Eq. (5), written as

$$e^{-\lambda}R'^2=\frac{1+pR^2}{1+2R\nu_{,R}}. \tag{18}$$

In order to determine $\lambda(r)$ one should specify $R(r)$, the most simple choice being $R=r$. In polar Gaussian coordinates Eq. (18) yields an equation for $R(r)$ with separated variables. The same is true in isotropic coordinates.

Equation (15) simplifies enormously when x is constant, becoming

$$M\left[\frac{(n+1)^2+4n}{2n}M-1\right]=0. \tag{19}$$

The choice $M_1=0$ leads to $m=p=\rho=0$, i.e., to flat space–time. The choice

$$M_2=\frac{2n}{(n+1)^2+4n} \tag{20}$$

gives via Eq. (14) $D=M=$const and $\lambda=$const, $\rho=2D/R^2$ which is exactly the KT solution. At the center the density and the pressure have poles and diverge. This solution does not exist when $-5.83=-3-2\sqrt{2}<n<-3+2\sqrt{2}=-0.17$ because then $x_2=M_2-1/2$ is positive or vanishes (when $n=-1$). In the intervals $-0.17<n<0$ and $n<-5.83$ the solution exists but ρ and p have different signs.

When $x_{,\tau}\neq 0$ we can decrease the order of Eq. (15) by the standard change of variables $x_{,\tau}\equiv -y(x)$:

$$xyy_{,x}=\frac{n+1}{2n}y^2-\left[\frac{(n+1)(n+2)+2n}{2n}x+\frac{(n+1)(n+2)}{4n}\right]y+A(x). \tag{21}$$

Equation (21) falls in the class

$$[g_1(x)y+g_0(x)]y_{,x}=f_2(x)y^2+f_1(x)y+f_0(x). \tag{22}$$

There is a standard procedure for the solution of such equations.[27] It consists of two changes of variables which bring them to the Abel equations of the second kind given by Eq. (2) or by

$$ww_{,\zeta}=g(\zeta)w+1. \tag{23}$$

This procedure is much easier when $g_0=0$ and $f_2=$const as in Eq. (21). Namely, we have $w=yE$, $f(z)=f_0E/f_1$, $g(\zeta)=f_1/f_0E$, and

$$E=\exp\left(-\int\frac{f_2}{g_1}\mathrm{d}x\right), \tag{24}$$

$$z(x)=\int\frac{f_1}{g_1}E\mathrm{d}x, \tag{25}$$

$$\zeta(x)=\int\frac{f_0}{g_1}E^2\mathrm{d}x. \tag{26}$$

Since f_1 is a simpler polynomial than f_0 we shall use Eqs. (3) and (25). The use of Eqs. (23) and (26) is more complicated, but does not bring additional integrable cases.

Applied to Eq. (21) the chosen alternative of the general method yields

$$w=yx^{-(n+1)/n}, \tag{27}$$

$$z=-\frac{1}{4n}\int[(n^2+5n+2)2x+(n+1)(n+2)]x^{-(n+1)/2n-1}\mathrm{d}x. \tag{28}$$

The case $n=1$ (stiff fluid) is special because a logarithmic term appears in z,

$$z=-4\ln|x|+\frac{3}{2x}, \tag{29}$$

$$f(z)=-\frac{(2x+1)(4x+1)}{x(8x+3)}. \tag{30}$$

The relation $z(x)$ is transcendental and throws $f(z)$ out of the tables with integrable cases present in Ref. 27. The case $n=-1$ also leads to a logarithmic term but its coefficient vanishes. This case

is integrable. In fact, we may go back directly to Eq. (13) which becomes $D_{,\tau}=2D$ if $M\neq 1/2$ and yields $\rho=-p=\text{const}$. This is the well-known de Sitter solution. When $M=1/2$, Eq. (13) is satisfied identically and we obtain formally the KT solution (20) with $n=-1$, but it has $e^{-\lambda}R'^2=0$ which is unacceptable.

In the generic case $n\neq\pm 1$ and Eq. (28) integrates to

$$z=-\frac{x^{-(n+1)/2n}}{2(n-1)}[(n^2+5n+2)2x-(n-1)(n+2)], \tag{31}$$

$$f(z)=\frac{(n-1)(2x+1)[(n^2+6n+1)2x+(n+1)^2]z}{[(n^2+5n+2)2x-(n-1)(n+2)][(n^2+5n+2)2x+(n+1)(n+2)]}. \tag{32}$$

The $z-x$ connection in Eq. (31) is transcendental, except for special values of n, and Eq. (3) is nonintegrable in general. Let us investigate the special cases.

When $n=-3$, f_1 divides f_0 and $f(z)=8z$, $z=-\frac{1}{2}(2x+1)x^{-1/3}$. This is an integrable case, corresponding to the Einstein static universe. It is discussed in more detail in Sec. III. There is also the formal $n=-3$ case of the KT solution (20). It does not exist since $x=1/4>0$.

One may try to simplify Eq. (31) by nullifying the coefficients on the right-hand side. The condition $n^2+5n+2=0$ gives $n=\frac{1}{2}(-5\pm\sqrt{17})$. This is of no good since the radical enters the power of x. The other possibility $n=-2$ looks more promising. Then Eq. (31) becomes $x^{3/4}=-3z/4$ and Eq. (32) reduces to

$$f(z)=\tfrac{21}{16}z-\tfrac{9}{16}(\tfrac{4}{3})^{4/3}z^{-1/3}+\tfrac{3}{64}(\tfrac{4}{3})^{8/3}z^{-5/3}. \tag{33}$$

This function leads to an integrable equation when the coefficient in front of z is $-3/16$, which is not true here.

There are several n which convert Eq. (31) into an algebraic equation for x of fourth order or lower. It can be solved explicitly for $x(z)$ and the answer replaced in Eq. (32). Third- and fourth-order equations appear when $n=\pm 1/5,\pm 1/7,-1/2,-3/5$. The radical structure of $f(z)$, however, is incompatible with the tables with integrable $f(z)$. Second-order equations appear when $n=\mp 1/3$, respectively,

$$4x=-5\pm\sqrt{25+48z}, \tag{34}$$

$$6zx=17\pm\sqrt{17+42z}. \tag{35}$$

Unfortunately, the only integrable functions with square roots include the term $\sqrt{z^2+z_0}$, which is not present in the above-given relations.

Comparison between Eqs. (31)–(32) and Eq. (20) shows how complex the numerical regular solution must be, which starts in x,y coordinates from flat space–time and focuses on the KT solution, following a spiral around it. The innocent parameter n, introduced in Eq. (2), proliferates like cancer in the process of solution, ending with the intricate coefficients in $z(x)$ and $f(z)$. It even determines the transcendental or algebraic nature of $z(x)$. In conclusion, the only integrable cases found within this approach are $n=\infty$ (trivial dust solution), $n=-1$ (de Sitter solution), $n=-3$ (Einstein static universe), and $M=\text{const}$ (the KT solution).

Finally, let us discuss for comparison the case of planar symmetry, which is solvable. Going to polar Gaussian coordinates, the metric element reads

$$\mathrm{d}s^2=e^{2\nu}\mathrm{d}t^2-\mathrm{d}r^2-R^2(\mathrm{d}x_2^2+F(x_2)^2\mathrm{d}x_3^2), \tag{36}$$

where $F(x_2)=\sin x_2$ for spherical symmetry and $F(x_2)=1$ for planar symmetry.[17,26] It is possible to generalize the TOV equation to encompass both cases. Instead of Eq. (13) one should write

$$(2M-K)D_{,\tau}=D\left[-2K+(n+5)M+\frac{n+1}{n}D\right], \tag{37}$$

where $K=1$ or 0, corresponding to spherical or planar symmetry, respectively. In the second case, Eq. (37) simplifies

$$2MM_{,\tau,\tau}=\frac{n+1}{n}M_{,\tau}^2+bMM_{,\tau}+aM^2, \tag{38}$$

where $a=n+1/n+6$, $b=n+2/n+5$. This is the analog of Eq. (15). Proceeding in the same way we again obtain the Abel equation (3) with $y=-M_{,\tau}$ and

$$w=yM^{-(n+1)/2n}, \tag{39}$$

$$z=\frac{bn}{1-n}M^{(n-1)/2n}, \tag{40}$$

$$f(z)=\frac{(n-1)a}{nb^2}z. \tag{41}$$

As mentioned before, Eq. (3) with $f(z)=\alpha z+\beta$, where α and β are constants, is integrable. The solution, in parametric form, reads

$$z=Ce^T-\frac{\beta}{\alpha}, \tag{42}$$

$$w=C\sigma e^T, \tag{43}$$

$$T=-\int\frac{\sigma \mathrm{d}\sigma}{\sigma^2-\sigma-\alpha}, \tag{44}$$

with C being an arbitrary constant. In Ref. 17 the problem was solved in a different way, by introducing the variable $\tilde{D}=D/M$. Then Eqs. (14) and (37) are equivalent to

$$2\tilde{D}_{,\tau}=\tilde{D}\left(n+7+\frac{1-n}{n}\tilde{D}\right). \tag{45}$$

This is a Bernoulli equation and is easily solved. Further details may be found in Ref. 17 where also a connection with earlier work[31,32] on the particular cases $n=1$ and $n=3$ is established.

III. THE APPROACH OF KLEIN

This approach was developed in curvature coordinates where Eqs. (4), (5), and (7) simplify to

$$p=\frac{2}{r}\nu' e^{-\lambda}-\frac{1}{r^2}(1-e^{-\lambda}), \tag{46}$$

$$\rho=\frac{1}{r}\lambda' e^{-\lambda}+\frac{1}{r^2}(1-e^{-\lambda}), \tag{47}$$

$$p'=-(\rho+p)\nu'. \tag{48}$$

Imposing the γ-law, we can integrate Eq. (48):

$$p = p_0 e^{-(n+1)\nu}. \tag{49}$$

Like before, the case of dust $n=\infty$, $p=0$ gives a trivial solution with constant ν and λ. Supposing that $p \neq 0$, let us introduce the variables $s = p_0 r^2$, $\xi = e^{(n+1)\nu}/s$ and

$$x = \xi e^{-\lambda} = \frac{e^{-\lambda}}{pr^2}. \tag{50}$$

Obviously x and ξ always have the same sign and are positive when the pressure is positive.

We shall derive an equation for x, similar to Eq. (15). In Secs. II–IV the main functions are denoted by x although they are different, in order to simplify notation and to stress the role of Eq. (22) in the whole problem. Let us multiply Eq. (46) by $(n+1)/4$, Eq. (47) by $-1/2$, and sum. The result is

$$4(sx)_{,s} - (n+3)(1-e^{-\lambda})\xi = 1-n. \tag{51}$$

Let us introduce $2\tau = \ln s$. It differs by a constant from the variable in Sec. II, but this is not important since the final equation will be autonomous. Laying temporarily aside the special case $n=-3$, we can express ξ from Eq. (51) as

$$\xi = \frac{1}{n+3}[2x_{,\tau} + (n+7)x + n - 1]. \tag{52}$$

Equation (46) may be written in the following way:

$$4(s\xi)_{,s} - (n+1)(e^{\lambda}-1)\xi = (n+1)e^{\lambda}. \tag{53}$$

The usage of Eqs. (50) and (52) transforms this relation into an autonomous second-order equation for x. The change of variables $x_{,\tau} = -y(x)$ applies again, leading to

$$\begin{aligned} 2(n+3)xyy_{,x} = {} & 2(n+1)y^2 + 2(n+11)xy - (n+1)(3n+1)y - 4(n+7)x^2 \\ & + (n^3+9n^2+11n+11)x + (n+1)^2(n-1). \end{aligned} \tag{54}$$

This is exactly the equation of Klein derived in Refs. 10 and 11, where the notation $n = 2n_{Kl} + 1$ and $x = (n_{Kl}+1)^2 x_{Kl}$ was used. He studied it by series expansion and numerically, and was the first to find its regular solution (see Fig. 1 from Ref. 10). When $x(\tau)$ is known Eq. (52) gives ξ, and Eq. (50) determines both λ and p. Then Eq. (49) becomes an expression for ν and finally ρ is given by Eq. (2). Modulo coefficients, Eq. (54) is the same as Eq. (21) and also falls in the class (22). Therefore, the procedure described in Sec. II can be applied to bring it to the form of Eq. (3) with

$$w = yx^{-(n+1)/(n+3)}, \tag{55}$$

$$z = \tfrac{1}{2}[(n+11)x + 3n + 1]x^{-(n+1)/(n+3)}, \tag{56}$$

$$f(z) = -\frac{2[4x-(n+1)^2][(n+7)x+n-1]z}{[2(n+11)x-(n+1)(3n+1)][(n+11)x+3n+1]}. \tag{57}$$

There are no logarithmic terms in z within this approach. As with Eq. (31), $x(z)$ is transcendental except in special cases.

Equation (54) shows that the KT solution is given here by

$$x_0 = \frac{(n+1)^2}{4}. \tag{58}$$

The other root $x=-(n-1)/(n+7)$ leads to $\xi=0$ and $e^{2\nu}=e^{\lambda}=0$, $\rho=np=\infty$, which is unacceptable. Now, since $x_0\geqslant 0$ for any n, we must ensure that $\xi_0>0$ in order to have positive $e^{-\lambda}$. Equation (52) gives $\xi_0=n^2+6n+1$ and we obtain the same conditions for the existence of the KT solution as Sec. II.

In the case $n=-1$, Eq. (48) yields $p=p_0$, $\rho=-p_0$, while the sum of Eqs. (46) and (47) provides the relation $2\nu=-\lambda$. Equation (47) is a linear equation for $e^{-\lambda}$, its solution being

$$e^{-\lambda}=1-\frac{2m_0}{r}+\frac{p_0}{3}r^2, \tag{59}$$

where m_0 is a constant of integration, identified as the gravitating mass. This is precisely the Kottler solution.[2] It can be used as a regular interior solution when $m_0=0$. Then it becomes the de Sitter solution. The KT solution for $n=-1$ has $x_0=0$ and does not exist.

When $n=-3$, Eq. (51) determines directly x: $x=1+x_1/s$, while Eq. (49) gives $p=p_0e^{2\nu}$. Then we have from Eq. (50) $e^{-2\nu-\lambda}=x_1+s$. Equation (46) becomes a linear equation for $e^{2\nu}$ when these results are taken into account. There are two possibilities. When the constant $x_1=0$, $x=1$, which is the formal KT solution (58) for $n=-3$. In fact, it does not exist. When $x_1\neq 0$ the solution is

$$x_1e^{2\nu}=1+C_1\left(1+\frac{x_1}{s}\right)^{1/2}, \tag{60}$$

where C_1 is another integration constant. A regular solution is obtained when $x_1=1$ and $C_1=0$. Then $\nu=0$ and

$$e^{\lambda}=\frac{1}{1+p_0r^2}. \tag{61}$$

The last two equations represent the metric of the Einstein static universe. The pressure and the density are constant, $p=p_0$, $\rho=-3p_0$.

There are two cases when the coefficients of $z(x)$ are simplified, namely $n=-11$ and $n=-1/3$. In the first case, Eq. (57) reads

$$-320f(z)=75z+16^{8/5}z^{-3/5}+22\times 16^{4/5}z^{1/5}. \tag{62}$$

The function

$$f(z)=c_1z+c_2z^{q_1}+c_3z^{q_2} \tag{63}$$

is integrable for a set of (q_1,q_2) but $(-3/5,1/5)$ is not among them. When $n=-1/3$ we have

$$f(z)=-\tfrac{15}{64}z+\tfrac{7}{96}\left(\tfrac{16}{3}\right)^{4/3}z^{-1/3}-\tfrac{1}{192}\left(\tfrac{16}{3}\right)^{8/3}z^{-5/3}. \tag{64}$$

The set $(-1/3,-5/3)$ is integrable, but only when $c_1=-3/16$, which is not the case here.

Finally, there are few n when Eq. (56) is an algebraic equation up to the fourth order. Only the cases $n=-5,-2,1$ are candidates for integrability because they lead to quadratic equations. Of these, $n=-5,-2$ yield radicals resembling those in Eqs. (34) and (35) and should be rejected. More interesting is the case of stiff fluid when

$$x=\tfrac{1}{72}(z^2-24\pm z\sqrt{z^2-48}), \tag{65}$$

$$f(z)=-\frac{2z[(z^2-60)x-4]}{9[(z^2-24)x-8]}. \tag{66}$$

The radicals in $f(z)$ are of the necessary type, but its structure is too complex to figure in the tables with integrable cases.

Like in Sec. II, the only integrable cases found are $n=-3,-1,\infty$ and $x=x_0$. The unsuccessful candidates for explicit solutions have in general different values of n in the two approaches. When they coincide, as is the case $n=1$, the reasons for rejection are different—a logarithmic term in the TOV–Collins approach and a complicated $f(z)$ in the Klein approach.

It is interesting to compare the main variable in this section $x\equiv x_K$ to the variables in the TOV approach, specialized to curvature coordinates. Equation (8) becomes

$$M=\frac{m}{r}=\frac{1}{2}(1-e^{-\lambda}), \tag{67}$$

and transforms Eq. (50) into

$$x_K=\frac{1-2M}{2nD}. \tag{68}$$

Thus, not only $x=M-1/2$, but also the above-mentioned combination satisfy Abel equations of the second kind. The function x_K resembles $\tilde{D}$, used in the planar case. It is well known that when $\tilde{D}$ satisfies the Bernoulli equation (45), $\tilde{D}^{-1}=M/D$ satisfies a linear equation. This fact stresses once more the conclusion that the spherical case is much more complicated than the planar one.

IV. APPROACH IN ISOTROPIC COORDINATES

One can pass from arbitrary to isotropic coordinates in Eqs. (4)–(6) by putting $R=re^{\lambda/2}$. Let us make also the change $s=\ln r$. Then

$$\rho r^2e^{\lambda}=-\lambda_{,s,s}-\tfrac{1}{4}\lambda_{,s}^2-\lambda_{,s}, \tag{69}$$

$$pr^2e^{\lambda}=\tfrac{1}{4}\lambda_{,s}^2+\lambda_{,s}\nu_{,s}+\lambda_{,s}+2\nu_{,s}, \tag{70}$$

$$pr^2e^{\lambda}=\tfrac{1}{2}\lambda_{,s,s}+\nu_{,s,s}+\nu_{,s}^2. \tag{71}$$

Let us introduce next the variable

$$\frac{1}{t}=\lambda_{,s}+2, \tag{72}$$

and impose the γ-law equation of state. An expression for $\nu_{,s}$ is obtained from Eqs. (69) and (70):

$$\nu_{,s}=\frac{t_{,s}}{nt}-\frac{n+1}{4n}\left(\frac{1}{t}-4t\right). \tag{73}$$

Next, let us combine Eqs. (70) and (71) and replace in them $\lambda_{,s}$ and $\nu_{,s}$ from Eqs. (73) and (74). A long, but straightforward computation produces an autonomous equation for t,

$$\begin{aligned}2ntt_{,s,s}=&-2(1-n)t_{,s}^2+\tfrac{1}{2}(n^2+5n+2)t_{,s}-2(n+1)(n+2)t^2t_{,s}-2(n+1)^2t^4\\&+[(n+1)^2+2n]t^2-\frac{n}{2}-\frac{(n+1)^2}{8}.\end{aligned} \tag{74}$$

A solution of this master equation determines all characteristics of the metric and the fluid.

When $n=1$, Eq. (74) is exactly Eq. (9) from Ref. 14. In this section we generalize the HH approach to arbitrary n and bring it to its logical end—the Abel equation (3). We first lower the order of the polynomial in Eq. (74) by setting $t^2=x/4$ and then perform the change of variables

$$(\sqrt{x})_{,s}=-\tfrac{1}{2}y. \tag{75}$$

The condition $x\geqslant 0$ should be maintained throughout the calculations. Equation (74) acquires its final form

$$2nxyy_{,x}=(n-1)y^2+[(n+1)(n+2)x-(n^2+5n+2)]y+(x-1)[4n+(n+1)^2-(n+1)^2x]. \tag{76}$$

It falls in the class (22) and resembles Eqs. (21) and (54), but its coefficients are different functions of n. Proceeding like before, we get

$$w=yx^{-(n-1)/2n}, \tag{77}$$

$$(n-1)z=[(n-1)(n+2)x+n^2+5n+2]x^{-(n-1)/2n}, \tag{78}$$

$$f(z)=\frac{(n-1)(x-1)[4n+(n+1)^2-(n+1)^2x]z}{[(n+1)(n+2)x-(n^2+5n+2)][(n-1)(n+2)x+n^2+5n+2]}, \tag{79}$$

in the generic case $n\neq\pm 1$.

The stiff fluid case leads to a logarithmic term in $z(x)$, which makes

$$f(z)=-\frac{2(x-1)(x-2)}{3x-4} \tag{80}$$

nonintegrable.

The case $n=-1$ is pseudologarithmic since the coefficient in front of $\ln x$ vanishes. We have $x=1/z$ and $f(z)=2z-2$. This case is integrable and the solution is given by Eqs. (42)–(44) with $\alpha=-\beta=2$.

The case $n=-3$ leads to a gross simplification of $f(z)$ and is also soluble. One obtains $f(z)=2z$, i.e., $\alpha=2$, $\beta=0$.

The other candidate cases may be investigated in the same manner as in Secs. II and III. The values $n=\pm 1/3$ lead to quadratic equations with radicals of the wrong type. The case $n=-2$ yields

$$f(z)=\tfrac{21}{16}z-\tfrac{18}{16}(\tfrac{4}{3})^{4/3}z^{-1/3}-\tfrac{3}{16}(\tfrac{4}{3})^{8/3}z^{-5/3}. \tag{81}$$

This equation belongs to the class (63) but again $c_1\neq -3/16$ and integrability is not gained.

Finally, let us discuss the KT solution in the HH approach. When $x=\text{const}$ Eq. (76) becomes purely algebraic and has two roots: $x_1=1$ and

$$x_2=1+\frac{4n}{(n+1)^2}. \tag{82}$$

When $n=-1$, x_2 does not exist. In fact, the requirement $x_2>0$ shows that n must satisfy the conditions derived in Sec. II. The first root leads to $t_1=\pm 1/2$. In the first subcase Eqs. (72) and (73) give flat space–time. In the second subcase the following line element is obtained

$$\mathrm{d}s^2=\mathrm{d}t^2-r^{-4}(\mathrm{d}r^2+r^2\,\mathrm{d}\Omega^2). \tag{83}$$

The transformation $\tilde{r}=1/r$ converts this element into the usual element for flat space–time.

The second root x_2 represents the KT solution in isotropic coordinates, namely $e^{\lambda}=r^{\alpha_1}$, $e^{2\nu}=r^{\alpha_2}$ where

$$\alpha_1=\pm\frac{2(n+1)}{\sqrt{4n+(n+1)^2}}-2, \tag{84}$$

$$\alpha_2=\pm\frac{4}{\sqrt{4n+(n+1)^2}}. \tag{85}$$

When $n=1$, $\alpha_1=\pm\sqrt{2}-2$ and $\alpha_2=\pm\sqrt{2}$. These values were found in Ref. 14, where the KT solution was discovered for a fifth time.

The integrable cases found in the HH approach coincide with those found in the Klein or the TOV–Collins approaches. In order to make connection with the last one, we must pass in Sec. II to isotropic coordinates. We have

$$R'=e^{\lambda/2}\left(1+\frac{\lambda_{,s}}{2}\right), \tag{86}$$

$$2x=2M-1=-R'^2e^{-\lambda}=-\frac{1}{4t^2}. \tag{87}$$

We cannot obtain Eq. (74) from Eq. (15) by replacing there just x from Eq. (87) because $s=\ln r$, while $\tau=\ln R=s+\lambda/2$. The necessary additional relations are

$$x_{,\tau}=\frac{t_{,s}}{2t^2}, \tag{88}$$

$$x_{,\tau,\tau}=\frac{t_{,s,s}}{t}-\frac{2t_{,s}^2}{t^2}. \tag{89}$$

Therefore, the HH approach combines the TOV equation in isotropic coordinates together with the linear equation (18) for λ.

V. BUCHDAHL TRANSFORMATION AND THE CASE $N=-5$

This transformation was found by Buchdahl[6] and rediscovered by Glass and Goldman.[7] Its general formulation refers to static perfect fluid solutions, not necessarily satisfying an equation of state. In the case of spherical symmetry it states that if

$$\mathrm{d}s^2=e^{2\nu}\,\mathrm{d}t^2-e^{\lambda}(\mathrm{d}r^2+r^2\,\mathrm{d}\Omega^2) \tag{90}$$

is the metric of a perfect fluid solution with pressure p and density ρ then there is a reciprocal solution which has $\nu_b=-\nu$, $\lambda_b=4\nu+\lambda$, and

$$p_b=e^{-4\nu}p, \tag{91}$$

$$\rho_b=-e^{-4\nu}(\rho+6p). \tag{92}$$

The transformation is simplest in isotropic coordinates and may be applied to the results obtained in Sec. IV. When p and ρ satisfy the γ-law, the same is true for p_b and ρ_b but with a different parameter:

$$\rho_b=-(n+6)p_b. \tag{93}$$

Thus, the transformation of the parameter is $n\to-(n+6)$. It is clear that when the starting solution is physically realistic ($n\geqslant 1$), the transformed one is unphysical, $-(n+6)\leqslant -7$. However, when the starting solution is unphysical and $n\leqslant -7$, then the reciprocal one is physical. When n is in the interval $-7<n<1$ both solutions are unphysical. The existence of this transformation teaches that unphysical solutions should not be neglected *a priori* and the whole spectrum of n must be investigated.

Let us apply the transformation to the integrable cases found in Sec. IV. The KT solution is self-reciprocal, i.e., transforms into itself. The reason is that $4n+(n+1)^2$ is invariant under the transformation. Taking α_{1-} and α_{2-} as the powers of r in the starting solution, it is easy to show that $\alpha_{2+}=-\alpha_{2-}$ and $\alpha_{1+}=\alpha_{1-}+2\alpha_{2-}$ when the plus solution is Buchdahl transformed. Solutions with n outside the interval $(-5.83,-0.17)$ transform between themselves.

The case $n=-3$ is also self-reciprocal, as was noticed already by Buchdahl. This explains why $\nu=0$ when the element of the Einstein static universe is written in isotropic coordinates.[33] This is necessary to ensure the equality between the starting and the transformed solution.

The interesting case is the de Sitter solution ($n=-1$) which transforms into an explicit solution with $n=-5$. In isotropic coordinates the de Sitter solution reads[33]

$$e^{2\nu}=\left(\frac{1+cr^2}{1-cr^2}\right)^2, \tag{94}$$

$$e^{\lambda}=(1-cr^2)^{-2}, \tag{95}$$

and $p=12/c$, $\rho=-12/c$, where c is some constant. The transformed solution has

$$e^{2\nu_b}=\left(\frac{1-cr^2}{1+cr^2}\right)^2, \tag{96}$$

$$e^{\lambda_b}=\frac{(1+cr^2)^4}{(1-cr^2)^6}, \tag{97}$$

$$p_b=\left(\frac{1-cr^2}{1+cr^2}\right)^4\frac{12}{c}, \tag{98}$$

and, of course, $\rho_b=-5p_b$. Equation (72) supplies the corresponding t:

$$t=\frac{1-cr^2}{2(1+cr^2)}, \tag{99}$$

$$t_b=\frac{1-c^2r^4}{2(1+10cr^2+c^2r^4)}. \tag{100}$$

From Eq. (75) we get $x=4t^2$ and $y=-4rt_{,r}$. When t_b is plugged in these relations we obtain the parametric solution $x(r)$, $y(r)$ of Eq. (76) for $n=-5$:

$$xyy_{,x}=\tfrac{3}{5}y^2-\tfrac{6}{5}xy+\tfrac{1}{5}y+\tfrac{2}{5}(4x^2-3x-1). \tag{101}$$

Equations (78) and (79) yield in this case

$$-3z=(9x+1)x^{-3/5}, \tag{102}$$

$$f(z)=\frac{6(x-1)(4x+1)}{(6x-1)(9x+1)}z. \tag{103}$$

Equation (102) is a fifth-order equation for x and seems to be transcendental. Obviously $f(z)$ is not among the tabulated integrable functions. Equation (101) does not coincide with any of the equations in Sec. 1.3.4. from Ref. 27 which belong to the class (22). If we use Eq. (23) instead, $g(\zeta)=1/f(z)$ and

$$3\zeta x^{6/5}=6x^2+18x+1. \tag{104}$$

This equation is even more complicated than Eq. (102) and $g(\zeta)$ is not among the few integrable cases listed in Sec. 1.3.2 from the same handbook. Unless some mistake has been made, Eq. (101) is integrable, but is not covered by Ref. 27. This situation is not unique. Recently, nonstatic charged perfect fluid distributions were discovered which, too, are missing in the handbooks with solutions of differential equations.[34]

VI. DISCUSSION AND CONCLUSIONS

In this paper we have discussed explicit solutions of the Einstein equations for a static spherically symmetric perfect fluid with the γ-law equation of state. Three approaches may be found in the literature which, at first sight, have nothing in common. The approach of Collins transforms the TOV equation in polar Gaussian coordinates into a two-dimensional autonomous system of differential equations. He studies it numerically.[5,17,30] This is a representative example of other similar dynamical systems.[16,19] In his approach Klein finds a second-order autonomous master equation, whose solution determines all characteristics of the metric and the fluid. He lowers its order and studies it by series expansion and numerically. Klein also discovers a simple exact but singular solution. This work is done in curvature coordinates.[10,11] Haggag and Hajj-Boutros perform a similar study but in isotropic coordinates and only for a stiff fluid.[14] They also obtain an autonomous second-order equation and transform it into another second-order equation [see Eqs. (9) and (14) in their paper]. Then they look for polynomial solutions and find either flat space–time or the KT solution.

We have generalized these three approaches and pursued them further, to their logical end—an equation, whose integrable cases are tabulated in the handbooks, like Ref. 27. Surprisingly, we invariably reach the Abel equation of the second kind (3). It behaves like a ''strange attractor'' and underlines the common features in the different approaches. The question of integrability is answered by the form of $f(z)$, the known integrable cases being tabulated. For this purpose we have generalized to an arbitrary coordinate system the dynamical system of Collins and to arbitrary n the HH approach. The functions $z(x)$ and $f(x)$ have the same general structure in all approaches but with different coefficients. The relations between the master variables x, x_K, and x_{HH} have been elucidated, the TOV–Collins approach serving as a basis.

The integrable cases found are one and the same and include $n=\infty$ (trivial dust solution), $n=-1$ (de Sitter solution), $n=-3$ (Einstein static universe) and $x=\mathrm{const}$, $n<-5.83$ or $n>-0.17$ (Klein–Tolman solution). They appear either as exceptional cases, when equations simpler than Eq. (3) are to be solved, or as Eq. (2) with $f(z)=\alpha z+\beta$, the simplest integrable case. Some candidate values of n lead to Eq. (63), but at least one of the constants there has the wrong value.

It has been shown that Eq. (3) stands in the center of the problem, independent from the approach or the coordinate system and the integrable cases may be derived in a unified manner. The problem is a very strange mixture of simple integrable cases and extremely difficult nonintegrable ones. Perhaps this gives some explanation why the de Sitter and the Einstein solutions were found in 1917, two years after the appearance of general relativity, and why the next years have brought only a fivefold discovery of the KT solution.

An important point is that the problem has been pushed to the mathematical realm of Abel differential equations and further progress depends on developments in this field. Using the Buchdahl transformation we have shown that the case $n=-5$ is integrable and have given its metric and fluid characteristics. However, its master equation in isotropic coordinates (101) does not seem to be present in the handbooks. This leaves this paper with an open end and one may hope that other integrable cases will be found in the future.

Finally, it is interesting to note that all discrete integrable cases $n=-1,-3,-5$ are regular and fall in the interval where the singular KT solution does not exist. One is tempted to speculate that in this interval there is a regular one-parameter solution, encompassing the discrete cases.

(Received 20 June 2001; accepted for publication 24 October 2001)

The inverse scattering theory of the heat equation is developed for a special subclass of potentials nondecaying at space infinity—perturbations of the one-soliton potential by means of decaying two-dimensional functions. Extended resolvent, Green's functions, and Jost solutions are introduced and their properties are investigated in detail. The singularity structure of the spectral data is given and then the inverse problem is formulated in an exact distributional sense. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1427410]

I. INTRODUCTION

The equation of the heat conduction, or heat equation for short,

$$\mathcal{L}\Phi(x)=0, \tag{1.1}$$

where the operator

$$\mathcal{L}(x,\partial_x)=-\partial_{x_2}+\partial_{x_1}^2-u(x), \quad x=(x_1,x_2), \tag{1.2}$$

for more than 25 years has been known[1,2] to be associated to the Kadomtsev–Petviashvili (more precisely, KPII) equation

$$(u_t-6uu_{x_1}+u_{x_1x_1x_1})_{x_1}=-3u_{x_2x_2}. \tag{1.3}$$

The scattering theory for the equation of heat conduction with a real potential $u(x)$ was developed in Refs. 3–5, but only the case of potentials rapidly decaying at large distances on the x-plane was considered. On the other side, it is well known that (1.3) is a $(2+1)$-dimensional generalization of the famous KdV equation: if the function $u_1(t,x_1)$ obeys KdV, then

$$u(t,x_1,x_2)=u_1(t,x_1+\mu x_2-3\mu^2 t) \tag{1.4}$$

solves (1.3) for an arbitrary constant $\mu\in\mathbb{R}$. Thus it is natural to consider solutions of (1.3) that are not decaying in all directions at space infinity but have one-dimensional rays with behavior of the type (1.4). The scattering theory for the operator (1.2) with such potentials is absent in the literature. Moreover, it is easy to observe that, like in the KPI case (see Ref. 6), the standard integral equation for the Jost solution[3] is meaningless for this situation and does not determine the solution itself. In trying to solve this problem for the nonstationary Schrödinger operator, associated to the KPI equation, a new general approach to the inverse scattering theory was introduced, which was called resolvent approach (see Refs. 6–10 and references therein). In Ref. 11 we

developed the scattering theory for the N-soliton solutions given in terms of Bäcklund transformations of the decaying background potential. These results for the simplest case $N=1$ are essentially used below.

Here we apply the resolvent approach to the heat equation (1.2) with a potential $u(x)$ that is a perturbation of a one-dimensional potential $u_1(x)$ of the kind (1.4) by means of a potential $u_2(x)$ rapidly decaying in all directions:

$$u(x)=u_1(x)+u_2(x). \tag{1.5}$$

We introduce and study properties of the resolvent, dressing operators, Jost solutions and scattering data, and formulate the inverse problem relevant to this case. In fact, we consider here the simplified version of (1.4) in which $\mu=0$. The generic case is reconstructed by means of the Galilean invariance of (1.3). Thus in what follows $u_1(x)\equiv u_1(x_1)$ and, moreover, we consider for simplicity the case where u_1 is the one-dimensional soliton potential [see (3.1)].

Thus here we apply the inverse scattering theory to a nonscattering situation since the "obstacle" is infinite. Such extension of the inverse scattering theory results in the new and unexpected properties of familiar objects, like the Jost solutions and the spectral data. We show that they get specific singularities in the complex domain of the spectral parameter. Derivation and description of these singularities are our main results here. The article is organized as follows. In Sec. II we sketch some general aspects of the resolvent approach that are necessary for our construction. In Sec. III we present results of embedding the theory of the one-dimensional one-soliton potential in two dimensions. Presentation here is based on work Ref. 11. We describe in detail properties of the extended resolvent and Green's functions of operator (1.2) with $u(x)=u_1(x_1)$. On this basis in Sec. IV the resolvent of the operator (1.2) now with the generic potential $u(x)$ given in (1.5) is introduced and its properties are described. The departure from analyticity of the resolvent leads us to definitions of the Jost solutions and spectral data and description of their properties (Sec. V). In this way we supply all terms of the inverse problem with proper meaning in terms of distributions. In the Conclusion some generalizations and future developments of these results are discussed. The main results of this article were announced in our earlier work, Ref. 12.

II. EXTENSION OF DIFFERENTIAL OPERATORS AND RESOLVENT

In the framework of the resolvent approach we work in the space $\mathcal{S}'$ of tempered distributions $A(x,x';q)$ of the six real variables $x=(x_1,x_2),x',q\in\mathbb{R}^2$. It is convenient to consider q as the imaginary part of a two-dimensional complex variable $\mathbf{q}=\mathbf{q}_{\Re}+i\mathbf{q}_{\Im}=(\mathbf{q}_1,\mathbf{q}_2)\in\mathbb{C}^2$ and to introduce the "shifted" Fourier transform

$$A(p;\mathbf{q})=\frac{1}{(2\pi)^2}\int dx\int dx'\, e^{i(p+\mathbf{q}_{\Re})x-i\mathbf{q}_{\Re}x'}A(x,x';\mathbf{q}_{\Im}), \tag{2.1}$$

where $p\in\mathbb{R}^2$, $px=p_1x_1+p_2x_2$ and $\mathbf{q}_{\Re}x=\mathbf{q}_{1\Re}x_1+\mathbf{q}_{2\Re}x_2$. We consider the distributions $A(x,x';q)$ and $A(p;\mathbf{q})$ as kernels in two different representations, the x- and p-representation, respectively, of the operator $A(q)$ (A for short). The composition law in the x-representation is defined in the standard way, that is,

$$(AB)(x,x';q)=\int dx''\,A(x,x'';q)\,B(x'',x';q). \tag{2.2}$$

Since the kernels are distributions, this composition is neither necessarily defined for all pairs of operators nor associative. In terms of the p-representation (2.1), this composition law is given by a sort of a "shifted" convolution, $(AB)(p;\mathbf{q})=\int dp'A(p-p';\mathbf{q}+p')B(p';\mathbf{q})$. On the space of these operators we define the conjugation A^*, which in the x-representations reads as

$$A^*(x,x';q)=\overline{A(x,x';q)}, \tag{2.3}$$

where bar denotes complex conjugation, or as $A^*(p;\mathbf{q})=\overline{A(-p;-\overline{\mathbf{q}})}$ in the p-representation. Below we say that the operator $A(q)$ is real if $A^*(q)=A(q)$, which in terms of p-representation means that $\overline{A(p;\mathbf{q})}=A(-p;-\overline{\mathbf{q}})$. The set of differential operators $\mathcal{D}(x,\partial_x)=\Sigma d_n(x)\partial_x^n$ is embedded in the introduced space of operators by considering the operators D with kernel $D(x,x')=\mathcal{D}(x,\partial_x)\delta(x-x')$, where $\delta(x)=\delta(x_1)\delta(x_2)$ is the two-dimensional δ-function and, then, by mapping them in the operators $D(q)$ with kernel

$$D(x,x';q)\equiv e^{-q(x-x')}D(x,x')=\mathcal{D}(x,\partial_x+q)\,\delta(x-x'), \tag{2.4}$$

to which we refer as the **extended** version of the differential operator $\mathcal{D}$. The notion of reality for a differential operator D is exactly the condition that its coefficients $d_n(x)$ are real.

For the operator (1.2) the extension $L(q)$ is given by

$$L=L_0-U, \tag{2.5}$$

where L_0 is the extension of $\mathcal{L}(x,\partial_x)$ in the case of zero potential, i.e., it has kernels

$$L_0(x,x';q)=[-(\partial_{x_2}+q_2)+(\partial_{x_1}+q_1)^2]\delta(x-x'),\quad L_0(p;\mathbf{q})=(i\mathbf{q}_2-\mathbf{q}_1^2)\delta(p), \tag{2.6}$$

and the multiplication operator U can be called the potential since it has kernel

$$U(x,x';q)=u(x)\,\delta(x-x'). \tag{2.7}$$

Below we always suppose that $u(x)$ is real, which by (2.3) means that the operator (1.2) is real also: $L^*=L$.

The main object of our approach is the **extended resolvent** $M(q)$ of the operator $L(q)$, which is defined as the inverse of the operator L, that is,

$$LM=ML=I, \tag{2.8}$$

in the space of operators. Here I is the unity operator, $I(x,x';q)=\delta(x-x')$, $I(p;\mathbf{q})=\delta(p)$. In order to make this inversion uniquely defined we impose the condition that the product

$$\int dp'M(p-p';\mathbf{q}+\mathbf{s}+p')M(p';\mathbf{q}) \tag{2.9}$$

exists as distribution in p and $\mathbf{q}$ and that it is a continuous function of $\mathbf{s}$ in a neighborhood of $\mathbf{s}=0$ when $\mathbf{s}\neq 0$.

Thanks to definitions (2.5), (2.6), and (2.8), M is real and, in particular, the resolvent M_0 of the bare operator L_0 has in the p-representation kernel

$$M_0(p;\mathbf{q})=\delta(p)\,\frac{1}{i\mathbf{q}_2-\mathbf{q}_1^2}. \tag{2.10}$$

As function of $\mathbf{q}$ it is singular when $\mathbf{q}=\not{\ell}(\mathbf{q}_1)$, where the special two-component vector

$$\not{\ell}(k)=(k,-ik^2) \tag{2.11}$$

was introduced. The kernel of M_0 in the x-representation

$$M_0(x,x';q)=\frac{1}{2\pi}\int d\alpha\,[\theta(q_1^2-\alpha^2-q_2)-\theta(x_2-x_2')]\,e^{-(i\not{\ell}(\alpha+iq_1)+q)(x-x')} \tag{2.12}$$

is obtained from (2.10) by using (2.1).

For a generic operator A with kernel $A(x,x';q)$ the operation inverse to the extension procedure, defined in (2.4) for a differential operator, is given by

$$\hat{A}(x,x';q)=e^{q(x-x')}A(x,x';q). \tag{2.13}$$

In contrast with the case of the extended differential operators for which $\hat{D}(x,x';q)=D(x,x')\equiv\mathcal{D}(x,\partial_x)\delta(x-x')$, in general $\hat{A}(x,x';q)$ does depend on q and, moreover, can have an exponential growth at space infinity. Therefore $\hat{A}(x,x';q)$ does not necessarily belong to the space $\mathcal{S}'$ of tempered distributions. The fact that $\hat{A}(x,x';q)$ can depend on q will play a crucial role in the following. For instance, also in the case of the simplest resolvent (2.12), we have that the function $\hat{M}_0(x,x';q)$ depends effectively on the variable q and is exponentially growing at space infinity. More generally from (2.8) we have

$$\mathcal{L}(x,\partial_x)\hat{M}(x,x';q)=\mathcal{L}^{\mathrm{d}}(x',\partial_{x'})\hat{M}(x,x';q)=\delta(x-x'), \tag{2.14}$$

where $\mathcal{L}^{\mathrm{d}}$ is the operator dual to $\mathcal{L}$. The function $\hat{M}(x,x';q)$ can be considered a parametric ($q\in\mathbb{R}^2$) family of Green's functions of the operator $\mathcal{L}$. In what follows we use special notations for the equalities of the type (2.14), writing them as

$$\vec{\mathcal{L}}\hat{M}(q)=\hat{M}(q)\tilde{\mathcal{L}}=I, \tag{2.15}$$

where $\vec{\mathcal{L}}$ denotes the operator $\mathcal{L}$ applied to the x-variable of the function $\hat{M}(x,x';q)$ and $\tilde{\mathcal{L}}$ denotes the operator dual to $\mathcal{L}$ applied to the x'-variable of the same function. Operation (2.13) has no analog in terms of the p-representation. Nevertheless, local properties of the kernels in the x-representation are preserved, and we use the kernels with the hat in what follows intensively.

Thanks to our definitions (2.1) and (2.4) it is easy to see that in terms of the p-representation the dependence on the $\mathbf{q}$-variables of the kernels of the extension of a differential operator is polynomial [like in the example (2.6)]. Correspondingly, the essential role in the study of the properties of the resolvent is played by the investigation of its departure from analyticity, in particular, by its d-bar derivatives with respect to the $\mathbf{q}$-variables. Thus to a generic operator A with kernel $A(p;\mathbf{q})$ in the p-representation we associate two operators $\overline{\partial}_j A$ with kernels

$$(\overline{\partial}_j A)(p;\mathbf{q})=\frac{\partial A(p;\mathbf{q})}{\partial\overline{\mathbf{q}}_j},\quad j=1,2, \tag{2.16}$$

where the derivatives are considered in the sense of distributions. In terms of the objects introduced in (2.13) we get by inversion of (2.1) that

$$\widehat{(\overline{\partial}_j A)}(q)=\frac{i}{2}\frac{\partial\hat{A}(q)}{\partial q_j}. \tag{2.17}$$

Multiplying equalities in (2.8) from the left and right, correspondingly, by M_0 we get, thanks to (2.5),

$$M=M_0+M_0UM,\quad M=M_0+MUM_0. \tag{2.18}$$

Since the resolvent M_0 is explicitly given, these are integral equations determining the solution M of (2.8). In the literature (see, say, Refs. 4 and 5) on the Jost solutions of the heat equation some small norm conditions on the potential u are known to guarantee the existence of the Jost solutions. So it is natural to assume that under such conditions the solution M of the above integral equations exists and is unique (the same for both integral equations). In this case the resolvent M can be considered as a small perturbation of the resolvent M_0 and this bare resolvent determines

the properties of M by means of (2.18). The main problem of construction of the inverse scattering transform for the operator (1.2) is that the potential $u(x)$ in (1.5) does not obey any small norm condition.

In order to overcome this difficulty we use a so-called inverse scattering transform on a nontrivial background.[10] Let us consider a kind of Hilbert identity, known in the standard spectral theory of operators. Precisely, if $M(q)$ is the extended resolvent of the operator $L(q)$ with potential u and $M'(q)$ the extended resolvent of the operator $L'(q)$ with a different potential u', then, by (2.8) we have

$$M'-M=-M'(L'-L)M. \tag{2.19}$$

Strictly speaking, this follows under the assumption that the product on the rhs is associative. This is a natural assumption since $L'(x,x';q)-L(x,x';q)=(u(x)-u(x'))\delta(x-x')$ and M satisfies condition (2.9). Let now $\mathcal{L}_1$ denote the operator (1.2) in the special case where the potential $u(x)$ in (1.5) is purely one-dimensional, i.e., $u_2(x)\equiv 0$. Let L_1 denote its extension and M_1 its resolvent, that is, let [cf. (2.5)]

$$L_1=L_0-U_1, \quad \mathcal{L}_1(x,\partial_x)=-\partial_{x_2}+\partial_{x_1}^2-u_1(x), \tag{2.20}$$

$$L=L_1-U_2, \quad L_1M_1=M_1L_1=I, \tag{2.21}$$

where as in (2.7) $U_j(x,x';q)=u_j(x)\delta(x-x')$. Choosing now in (2.19) $L'=L_1$ we get

$$M=M_1+M_1U_2M, \quad M=M_1+MU_2M_1, \tag{2.22}$$

where the second equality is derived in analogy. These equations generalize (2.18) for the case where M_1 is nontrivial and, if the resolvent M_1 is known, they also can be considered as defining the resolvent M. If we choose U_2 obeying the small norm condition mentioned above, we can assume that the solution M of both Eqs. (2.22) exists and is unique. Then, thanks to (2.21), M obeys (2.8). Contrary to (2.18), now M can be considered a perturbation of the resolvent M_1. So, in the next section, we study the properties of the resolvent M_1 in detail.

III. ONE-DIMENSIONAL POTENTIAL

We already mentioned in the Introduction that in this article we deal with the case where u_1 in (1.5) is the one-dimensional soliton potential

$$u_1(x)=\frac{-2a^2}{\cosh^2[a(x_1-x_0)]}, \tag{3.1}$$

with $a>0$ and x_0 real constants. In this section we consider the case where the perturbation is absent, $u_2\equiv 0$. We reformulate in the two-dimensional space the well known facts about Jost solutions of this one-soliton potential and introduce and study the properties of the resolvent and Green's functions in this case.

The differential equations $\mathcal{L}_1(x,\partial_x)\Phi_1(x,k)=0$, $\mathcal{L}_1^{\mathrm{d}}(x',\partial_{x'})\Psi_1(x',k)=0$ for the Jost solution $\Phi_1(x,k)$ and its dual $\Psi_1(x',k)$, by using the notation introduced in (2.15) and by considering $\Phi_1(x,k)$ and $\Psi_1(x',k)$ as kernel operators independent, respectively, of x' and x, can be rewritten in the operatorial form

$$\vec{\mathcal{L}}_1\Phi_1(k)=0, \quad \Psi_1(k)\vec{\mathcal{L}}_1=0, \tag{3.2}$$

which we will use frequently in the following. These solutions are given explicitly by

$$\Phi_1(x,k)=\frac{k-ia\tanh[a(x_1-x_0)]}{k-ia}e^{-i\not{\ell}(k)x}, \tag{3.3}$$

$$\Psi_1(x,k)=\frac{k+ia\tanh[a(x_1-x_0)]}{k+ia}e^{i\not{x}(k)x}, \tag{3.4}$$

where $k\in\mathbb{C}$ and the two-component vector $\not{x}(k)$ is defined in (2.11). They obey the conjugation properties

$$\overline{\Phi_1(x,k)}=\Phi_1(x,-\bar{k}),\quad \overline{\Psi_1(x,k)}=\Psi_1(x,-\bar{k}) \tag{3.5}$$

that are equivalent to the reality condition for the potential u_1, and are normalized at k-infinity as follows:

$$\lim_{k\to\infty}e^{i\not{x}(k)x}\Phi_1(x,k)=1,\quad \lim_{k\to\infty}e^{-i\not{x}(k)x}\Psi_1(x,k)=1. \tag{3.6}$$

The functions $\Phi_1(x,k)$ and $\Psi_1(x,k)$ are meromorphic in the complex domain of the spectral parameter k with poles at $k=ia$ and $k=-ia$, correspondingly. Thus, these functions obey the d-bar equations

$$\frac{\partial\Phi_1(x,k)}{\partial\bar{k}}=i\pi\Phi_{1,a}(x)\,\delta(k-ia),\quad \frac{\partial\Psi_1(x,k)}{\partial\bar{k}}=i\pi\Psi_{1,-a}(x)\,\delta(k+ia), \tag{3.7}$$

where we introduced the notations

$$\Phi_{1,a}(x)=-i\operatorname*{res}_{k=ia}\Phi_1(x,k),\quad \Psi_{1,-a}(x)=-i\operatorname*{res}_{k=-ia}\Psi_1(x,k). \tag{3.8}$$

Explicitly we have

$$\Phi_{1,a}(x)=\frac{ae^{ax_0+a^2x_2}}{\cosh[a(x_1-x_0)]},\quad \Psi_{1,-a}(x)=-\frac{ae^{ax_0-a^2x_2}}{\cosh[a(x_1-x_0)]}. \tag{3.9}$$

Let

$$c=2ae^{2ax_0} \tag{3.10}$$

and $\Phi_{1,-a}(x)$ and $\Psi_{1,a}(x)$ be the values of the Jost solutions in the conjugated points,

$$\Phi_{1,-a}(x)=\Phi_1(x,-ia),\quad \Psi_{1,a}(x)=\Psi_1(x,ia). \tag{3.11}$$

Then, thanks to (3.3), (3.4), and (3.9), the Jost solutions obey in the complex domain of the spectral parameter the following scalar products:

$$\int dx_1\Psi_1(x,k+p)\Phi_1(x,k)=2\pi\delta(p),\quad p\in\mathbb{R}, \tag{3.12}$$

$$c\int dx_1\,\Phi_{1,-a}(x)\Psi_{1,a}(x)=1, \tag{3.13}$$

$$\int dx_1\,\Psi_{1,a}(x)\Phi_1(x,k)=0,\quad k_\mathfrak{I}^2<a^2, \tag{3.14}$$

$$\int dx_1\,\Phi_{1,-a}(x)\Psi_1(x,k)=0,\quad k_\mathfrak{I}^2<a^2, \tag{3.15}$$

and the completeness relation

$$\frac{1}{2\pi}\int_{x_2=x_2'} dk_{\Re}\,\Phi_1(x,k)\Psi_1(x',k)+c\,\theta(a^2-k_{\Im}^2)\Phi_{1,-a}(x)\Psi_{1,a}(x')\Big|_{x_2=x_2'}=\delta(x_1-x_1'). \tag{3.16}$$

Equations (3.7) can be considered as two inverse problems defining the Jost solution and the dual Jost solution. The formulation of these problems is closed by giving the normalization conditions (3.6) and the following relations:

$$\Phi_{1,a}(x)=c\Phi_{1,-a}(x), \quad \Psi_{1,-a}(x)=-c\Psi_{1,a}(x), \tag{3.17}$$

where $\Phi_{1,-a}(x)$ and $\Psi_{1,a}(x)$ are defined in (3.11).

These formulas show that the embedding in two dimensions of the Jost solutions of the one-soliton potential is trivial and just mimics the one-dimensional construction up to the warning that, due to their exponential dependence on x_2, the functions $\Phi_{1,a}(x)$ and $\Psi_{1,-a}(x)$ are not square integrable with respect to the x-variables and, therefore, are not eigenfunctions of the operator $\mathcal{L}_1$.

On the contrary, the two-dimensional resolvent $M_1(q)$ as well as the Green's function G_1 of the two-dimensional operator $\mathcal{L}_1$ with the one-dimensional potential u_1 are not trivial extensions of the corresponding one-dimensional objects associated to the operator $(k^2+\partial_{x_1}^2-u_1(x_1))$. In terms of the Jost solutions introduced above, we can write the kernel of this resolvent obtained in Ref. 11 as

$$\begin{aligned}\hat{M}_1(x,x';q)=\frac{1}{2\pi}\int_{k_{\Im}=q_1} dk_{\Re}\,[\,\theta(q_1^2-q_2-k_{\Re}^2)-\theta(x_2-x_2')\,]\,\Phi_1(x,k)\Psi_1(x',k)\\ +c\,\theta(a^2-q_1^2)[\,\theta(a^2-q_2)-\theta(x_2-x_2')\,]\Phi_{1,-a}(x)\Psi_{1,a}(x'),\end{aligned} \tag{3.18}$$

where the hat over the kernel is used in the sense of notation (2.13).

Thanks to the equalities (3.2) and (3.16) it is easy to check directly that $\hat{M}_1(q)$ obeys the equations

$$\vec{\mathcal{L}}_1\hat{M}_1(q)=\hat{M}_1(q)\vec{\mathcal{L}}_1=I, \tag{3.19}$$

which means [cf. (2.15)] that $M_1(q)$ obeys (2.21) and is indeed the inverse of the operator $L_1(q)$. Moreover, using the explicit formulas (3.3), (3.4) and (3.9) we get that $M_1(x,x';q)\in\mathcal{S}'(R^6)$, i.e., it belongs to the space of operators under consideration. It can also be proved directly that M_1 obeys condition (2.9), so it is the extended resolvent according to our definition. By means of (3.5) we get also that M_1 is real, $M_1^*=M_1$ according to definition (2.3).

We emphasize that in order to prove these results it is not necessary to use the explicit formulas for Φ_1 and Ψ_1 but only their general properties. In fact, if one considers a one-dimensional potential u_1 which, in addition, has a nontrivial continuous spectrum, one gets the same formula for the resolvent M_1. If the discrete (one-dimensional) spectrum of u_1 contains N solitons with parameters a_j and c_j $(j=1,2,\ldots,N)$, then the last term in (3.18) must be substituted by the sum of similar terms each corresponding to a value of j.

Now we describe in detail the properties of $M_1(x,x';q)$. The first term on the rhs of (3.18) is a continuous function of $q=(q_1,q_2)$ on the q-plane with discontinuities on the lines $q_1=\pm a$ due to the pole singularities of $\Phi_1(k)$ and $\Psi_1(k)$. The second term, thanks to the θ functions, has discontinuities on the lines $q_1=\pm a$ and on the cut $q_2=a^2$, $|q_1|<a$. The singularities on the lines $q_1=\pm a$ are exactly compensated among the two terms. Thus the kernel $M_1(x,x';q)$ is a continuous function of q with a discontinuity on the cut $q_2=a^2$, $|q_1|<a$. This discontinuity is specific of the potential $u_1(x)$, or more generally of a potential with discrete spectrum and it gives the essential difference of M_1 with respect to the bare resolvent M_0 (2.12). Let us underline that, in spite of the fact that $\mathcal{L}_1$ applied to the term with $\theta(a^2-q_2)$ that causes this discontinuity gives

zero, this term cannot be omitted in (3.18), since, only thanks to the fact that $\theta(x_2-x_2')$ and $\theta(a^2-q_2)$ have opposite signs, the kernel $M_1(x,x';q)\equiv e^{-q(x-x')}\hat{M}_1(x,x';q)$ is a tempered distribution with respect to the x-variables.

The kernel $M_1(p;\mathbf{q})$ in the p-representation is not an analytic function of $\mathbf{q}$. By (2.17) the d-bar derivatives of M_1 with respect to $\mathbf{q}_j$ are proportional to $\partial\hat{M}_1/\partial q_j$ and for the latter we get from (3.18) equalities

$$\frac{\partial\hat{M}_1(q)}{\partial q_1}=\frac{i}{\pi}\int_{k_\Im=q_1} dk_\Re\,\overline{k}\,\delta(\mathscr{l}_{2\Im}(k)-q_2)\,\Phi_1(k)\otimes\Psi_1(k), \tag{3.20}$$

$$\frac{\partial\hat{M}_1(q)}{\partial q_2}=\frac{-1}{2\pi}\int_{k_\Im=q_1} dk_\Re\,\delta(\mathscr{l}_{2\Im}(k)-q_2)\,\Phi_1(k)\otimes\Psi_1(k), \tag{3.21}$$

where $(\Phi_1(k)\otimes\Psi_1(k))(x,x')\equiv\Phi_1(x,k)\Psi_1(x',k)$ is the standard direct product, $\mathscr{l}_{2\Im}(k)$ is the imaginary part of the second component of the vector $\mathscr{l}(k)$ defined in (2.11) and where by the above discussion we consider $q_2\neq a^2$. For the discontinuity along this line we get

$$\hat{M}_1(q)|_{q_2=a^2+0}-\hat{M}_1(q)|_{q_2=a^2-0}=-c\,\theta(a^2-q_1^2)\Phi_{1,-a}\otimes\Psi_{1,a}. \tag{3.22}$$

We have to study now the behavior of $M_1(q)$ at the end points of the cut, i.e., when $q\sim(\pm a,a^2)$. First, it is convenient to subtract from $M_1(q)$ its value, say, on the upper or lower edges of the cut:

$$g_1^{\pm}=\lim_{q_2=a^2\pm 0}\hat{M}_1(q)|_{|q_1|<a}. \tag{3.23}$$

Since $\Phi_1(k)$ and $\Psi_1(k)$ are analytic for $|k_\Im|<a$, we deduce from (3.18) that $g_1^{\pm}$ are independent also of q_1 and their kernels equal

$$g_1^{\pm}(x,x')=-\frac{\theta(x_2-x_2')}{2\pi}\int d\alpha\,\Phi_1(x,\alpha)\Psi_1(x',\alpha)\mp c\,\theta(\pm(x_2-x_2'))\Phi_{1,-a}(x)\Psi_{1,a}(x'), \tag{3.24}$$

where $\int d\alpha$ denotes integration along the whole real axis. Now extracting explicitly from the first term on the rhs of (3.18) the contribution coming from the poles of $\Phi_1(k)$ and $\Psi_1(k)$ we get that, say, difference $\hat{M}_1(q)-g_1^-$ behaves at points $q=(\pm a,a^2)$ as

$$\hat{M}_1(q)-g_1^-=-c\left(\frac{\theta(q_1^2-q_2)}{\pi}\operatorname{arccot}\frac{a-|q_1|}{\sqrt{q_1^2-q_2}}+\theta(q_2-q_1^2)\,\theta(q_2-a^2)\right)\Phi_{1,-a}\otimes\Psi_{1,a}+o(1),$$

$$q\sim(\pm a,a^2). \tag{3.25}$$

Thus $\hat{M}_1(q)$ is bounded but discontinuous at $q=(\pm a,a^2)$, while its regular part, g_1^-, is the same for both these points.

Now it is easy to see that the discontinuity of the resolvent along the cut $q_2=a^2$, $|q_1|<a$ and the ill definiteness at the points $q=(\pm a,a^2)$ are the result of embedding the one-dimensional potential in the two-dimensional space. Indeed, the resolvent of the Sturm–Liouville operator $\partial_{x_1}^2-u_1(x_1)-q_2$ is obtained from $M_1(q)$ by means of the operation $\int dx_2\,e^{-q_2(x_2-x_2')}\hat{M}_1(x,x';q)$. By (3.18) and (3.3), (3.4), and (3.9) we get the standard expression for the one-dimensional Green's function with a pole at $q_2=a^2$.

We already noted that $\hat{M}_1(x,x';q)$ defines a family of Green's functions. Among them that we expect should play a special role are those obtained considering the values of q belonging to the support of the defects of analyticity given in (3.20), (3.21) and (3.22). We consider, therefore, the Green's functions

$$G_1(x,x',k)=\hat{M}_1(x,x';q)|_{q=\ell_{\mathfrak{J}}(k)}, \tag{3.26}$$

$$G_1^{\pm}(x,x';k)=\hat{M}_1(x,x';q)|_{q_1=k_{\mathfrak{J}},\, q_2=a^2\pm 0}, \tag{3.27}$$

where $k\in\mathbb{C}$ is the spectral parameter and we denote $q_1=k_{\mathfrak{J}}$ [see (2.11)] in order to meet the standard notation. From these definitions it follows directly that

$$\vec{\mathcal{L}}_1 G_1(k)=G_1(k)\tilde{\mathcal{L}}_1=I, \quad \vec{\mathcal{L}}_1 G_1^{\pm}(k)=G_1^{\pm}(k)\tilde{\mathcal{L}}_1=I, \tag{3.28}$$

$$\overline{G_1(k)}\equiv G_1(-\bar{k})\equiv G_1(k), \tag{3.29}$$

$$G_1(k)|_{k_{\mathfrak{R}}=0}=G_1(0), \quad G_1^{\pm}(k)=G_1^{\pm}(ik_{\mathfrak{J}}), \tag{3.30}$$

i.e., $G_1^{\pm}(k)$ are independent on $k_{\mathfrak{R}}$ and then inside the strip they coincide with $g_1^{\pm}$ introduced in (3.23),

$$G_1^{\pm}(x,x';k)|_{|k_{\mathfrak{J}}|<a}=g_1^{\pm}(x,x'). \tag{3.31}$$

As well from (3.18) we get the representations

$$\begin{aligned} G_1(x,x',k)=\frac{1}{2\pi}\int_{k'_{\mathfrak{J}}=k_{\mathfrak{J}}} dk' \,[\,\theta(|k_{\mathfrak{R}}|-|k'_{\mathfrak{R}}|)-\theta(x_2-x'_2)]\Phi_1(x,k')\Psi_1(x',k') \\ +c\;\theta(a-|k_{\mathfrak{J}}|)\,\theta(x'_2-x_2)\Phi_{1,-a}(x)\Psi_{1,a}(x'), \end{aligned} \tag{3.32}$$

$$\begin{aligned} G_1^{\pm}(x,x',k)=\frac{1}{2\pi}\int_{k'_{\mathfrak{J}}=k_{\mathfrak{J}}} dk'_{\mathfrak{R}}\,[\,\theta((k_{\mathfrak{J}})^2-a^2-(k'_{\mathfrak{R}})^2)-\theta(x_2-x'_2)]\Phi_1(x,k')\Psi_1(x',k') \\ \mp c\;\theta(a^2-k_{\mathfrak{J}}^2)\,\theta(\pm(x_2-x'_2))\Phi_{1,-a}(x)\Psi_{1,a}(x'). \end{aligned} \tag{3.33}$$

The first of these equalities shows that the cut of the resolvent at $q_2=a^2$, $|q_1|<a$ is not inherited by $G_1(k)$ (in contrast to the case of the nonstationary Schrödinger equation, as mentioned in the Introduction) and that $G_1(k)$ is discontinuous only at the points $k=\pm ia$. Its behavior in the neighborhoods of these points follows from (3.25) and reads as

$$G_1(k)=g_1^{-}-\frac{c}{\pi}\left\{\operatorname{arccot}\frac{a-|k_{\mathfrak{J}}|}{|k_{\mathfrak{R}}|}\right\}\Phi_{1,-a}\otimes\Psi_{1,a}+o(1), \quad k\sim\pm ia. \tag{3.34}$$

Also the Green's functions $G_1^{\pm}(k)$ are discontinuous only at $k_{\mathfrak{J}}=\pm a$ and one gets, thanks to (3.25), that for $k\sim ia$ or $k\sim -ia$

$$G_1^{\pm}(k)=g_1^{-}-c\,\frac{1\pm\theta(a-|k_{\mathfrak{J}}|)}{2}\Phi_{1,-a}\otimes\Psi_{1,a}+o(1). \tag{3.35}$$

Notice that these functions $G_1^{\pm}(k)$ coincide when $|k_{\mathfrak{J}}|>a$ and are independent of $k_{\mathfrak{J}}$ [and then of k by (3.30)] when $|k_{\mathfrak{J}}|<a$. On the borders of these strips they have the discontinuity

$$G_1^{\pm}(k)\big|_{\text{outside}} - G_1^{\pm}(k)\big|_{\text{inside}} = \pm\frac{c}{2}\Phi_{1,-a}\otimes\Psi_{1,a}\,. \tag{3.36}$$

Taking into account the discontinuous behavior of the Green's functions we see that equalities of the type $G_1^{\pm}(ia)=G_1(ia)$ and $G_1^{\pm}(-ia)=G_1(-ia)$ have no meaning in our case. Thanks to (3.32) and (3.35) we have only that

$$\lim_{|k_{\Im}|\to a-0}\ \lim_{k_{\Re}\to 0} G_1(k) = g_1^{-}\,, \tag{3.37}$$

where the limiting procedure must be performed in such a way that $|k_{\Re}|/(a-|k_{\Im}|)\to+0$.

In order to complete the study of the Green's functions we mention that $G_1(k)$ obeys the standard equalities

$$\lim_{k\to\infty}(-2ik)\frac{\partial}{\partial x_1}e^{i\not<(k)(x-x')}G_1(x,x',k)=\delta(x-x'), \tag{3.38}$$

$$\frac{\partial G_1(x,x',k)}{\partial\overline{k}}=\frac{\operatorname{sgn}k_{\Re}}{2\pi}\Phi_1(x,-\overline{k})\Psi_1(x',-\overline{k}). \tag{3.39}$$

The first of them follows either from the differential equations (3.28), or from the integral representation (3.32) and properties (3.6). The second one also follows from (3.28), or it can be derived from (3.26) by means of (3.20) and (3.21). This equality must be understood in the sense of distributions and we see that the discontinuity of $G_1(k)$ at points $k=\pm ia$ leads [by (3.3) and (3.4)] to the pole singularities of the rhs at these points. In view of (3.39) in what follows we refer to $G_1(k)$ as the Green's function of the Jost solutions.

IV. RESOLVENT OF THE PERTURBED *L*-OPERATOR

Now we consider the general case of the operator (1.2) with potential given in (1.5), where $u_2(x)$ is a real function of two space variables, smooth and rapidly decaying at space infinity. The extended resolvent $M(q)$ is determined by (one of) Eqs. (2.22) and we need to study its analyticity properties first. The increment $M(p;\mathbf{q}+\mathbf{s})-M(p;\mathbf{q})$ of M can be obtained from the Hilbert identity (2.19) where prime means the increment $\mathbf{s}$ of $\mathbf{q}$. We have $M'-M=-M'(L_1'-L_1)M$ and, then, using (2.21),

$$M'-M=M'L_1'(M_1'-M_1)L_1M. \tag{4.1}$$

Thus for the d-bar derivatives with respect to $\mathbf{q}_j$ we get

$$\overline{\partial}_j M=(ML_1)(\overline{\partial}_j M_1)(L_1M),\quad j=1,2, \tag{4.2}$$

in the region where M_1 is continuous, i.e., for $q_2\neq a^2$. In terms of the objects introduced in (2.13), we obtain

$$\widehat{\overline{\partial}_j M}=\hat{M}\vec{\mathcal{L}}_1(\widehat{\overline{\partial}_j M_1})\vec{\mathcal{L}}_1\hat{M},\quad j=1,2, \tag{4.3}$$

where we used that $\hat{L}_1(x,x';q)=\mathcal{L}_1\delta(x-x')$ and took into account that when kernels with hats are considered, the multiplication by $\mathcal{L}_1$ is no longer associative and it is necessary to use the arrows to indicate the correct order of operations [cf. (2.15)]. Now, thanks to (2.17) and using (3.20) and (3.21) we get for $q_2\neq a^2$

$$\frac{\partial \hat{M}(q)}{\partial q_1} = \frac{i}{\pi} \int_{k_{\Im}=q_1} dk_{\Re}\, \overline{k}\, \delta(\not{\omega}_{2\Im}(k) - q_2)\, \Phi(k) \otimes \Psi(k), \tag{4.4}$$

$$\frac{\partial \hat{M}(q)}{\partial q_2} = \frac{-1}{2\pi} \int_{k_{\Im}=q_1} dk_{\Re}\, \delta(\not{\omega}_{2\Im}(k) - q_2)\, \Phi(k) \otimes \Psi(k), \tag{4.5}$$

where $\Phi(k)$ and $\Psi(k)$ are defined by

$$\Phi(k) = G(k)\vec{\mathcal{L}}_1 \Phi_1(k), \quad \Psi(k) = \Psi_1(k)\vec{\mathcal{L}}_1 G(k), \tag{4.6}$$

with

$$G(x,x',k) = \hat{M}(x,x';q)\big|_{q=\not{\omega}_{\Im}(k)}. \tag{4.7}$$

More explicitly, say, the first of Eqs. (4.6) stands for $\Phi(x,k) = \int dx' (\mathcal{L}_1^{\mathrm{d}}(x', \partial_{x'}) \times G_1(x,x',k)) \Phi_1(x',k)$. The function $G(k)$ with kernel $G(x,x',k)$ defined in (4.6) satisfies the differential equations

$$\vec{\mathcal{L}} G(k) = G(k)\tilde{\mathcal{L}} = I, \tag{4.8}$$

which can be obtained as a direct reduction of (2.15). Therefore, $G(k)$ is a Green's function. Since the reduction is the same used in (3.26) for getting $G_1(k)$ from $\hat{M}_1$ we derive from (2.22) that this Green's function obeys the integral equations

$$G(k) = G_1(k) + G_1(k) U_2 G(k), \quad G(k) = G_1(k) + G(k) U_2 G_1(k). \tag{4.9}$$

Again, as in Sec. III, thanks to (4.7) and (4.4) and (4.5) we get the d-bar derivative of the Green's function in the form

$$\frac{\partial G(k)}{\partial \overline{k}} = \frac{\operatorname{sgn} k_{\Re}}{2\pi} \Phi(-\overline{k}) \otimes \Psi(-\overline{k}), \tag{4.10}$$

where $\Phi(k)$ and $\Psi(k)$ are defined in (4.6). These objects, due to their definition and (4.9), obey the integral equations

$$\Phi(k) = \Phi_1(k) + G_1(k) U_2 \Phi(k), \quad \Psi(k) = \Psi_1(k) + \Psi(k)\, U_2 G_1(k), \tag{4.11}$$

where again the first equation more explicitly reads as $\Phi(x,k) = \Phi_1(x,k) + \int dx' G_1(x,x',k) \times u_2(x') \Phi(x',k)$. It is clear that the differential equations

$$\vec{\mathcal{L}} \Phi(k) = 0, \quad \Psi(k)\tilde{\mathcal{L}} = 0 \tag{4.12}$$

hold and, therefore, we can consider $\Phi(x,k)$ and $\Psi(x,k)$ as the generalization of the Jost solutions to the case where the perturbation $u_2(x)$ is different from zero. Let us mention that thanks to these definitions we succeeded in avoiding the indeterminacy in the definition of the Jost solutions discussed in the Introduction. Later we study the properties of the Green's function and the Jost solutions in more detail and discuss the singular structure of the terms involved in (4.10). Now let us mention the following standard properties

$$-2i \lim_{k\to\infty} k \partial_{x_1} (e^{i\not{\omega}(k)(x-x')} G(x,x',k)) = \delta(x-x'), \tag{4.13}$$

$$\overline{G(k)} = G(-\overline{k}) = G(k), \tag{4.14}$$

$$\overline{\Phi(x,k)}=\Phi(x,-\overline{k}),\quad \overline{\Psi(x,k)}=\Psi(x,-\overline{k}), \tag{4.15}$$

which can be obtained by means of the integral equations (4.9) and properties (3.5), (3.29), and (3.38) for the Green's function $G_1(k)$.

Till now we studied the departure from analyticity of the resolvent in the case $q_2\neq a^2$. Since the resolvent $M_1(q)$ is discontinuous along the line $q_2=a^2$ [see (3.22)], the integral equations (2.22) suggest that also $M(q)$ has a discontinuity. Let us denote the limiting values on the two edges of the line by

$$M^{\pm}(q)=M(q)|_{q_2=a^2\pm 0}. \tag{4.16}$$

Then from the Hilbert identity (4.1) we derive that

$$M^{+}(q)-M^{-}(q)=M^{\pm}(q)L_1(q)(M_1^{+}(q)-M_1^{-}(q))L_1(q)M^{\mp}(q),\quad q_2=a^2, \tag{4.17}$$

where the lhs is independent of the choice of the sign on the rhs. In analogy with (3.27) we introduce the two Green's functions

$$G^{\pm}(x,x';k)=\hat{M}(x,x';q)|_{q_1=k_{\Im},\ q_2=a^2\pm 0} \tag{4.18}$$

and rewrite (4.17) in these terms as $G^{+}(k)-G^{-}(k)=(G^{\pm}(k)\tilde{\mathcal{L}}_1)(G_1^{+}(k)-G_1^{-}(k))\times(\vec{\mathcal{L}}_1G^{\mp}(k))$. Then by (3.22) and (3.27) we get

$$G^{+}(k)-G^{-}(k)=-c\,\theta(a^2-k_{\Im}^2)\Phi^{\pm}(k)\otimes\Psi^{\mp}(k), \tag{4.19}$$

where the new solutions [cf. (4.6)] were introduced:

$$\Phi^{\pm}(k)=G^{\pm}(k)\tilde{\mathcal{L}}_1\Phi_{1,-a},\quad \Psi^{\pm}(k)=\Psi_{1,a}\vec{\mathcal{L}}_1G^{\pm}(k). \tag{4.20}$$

Following properties of $G_1^{\pm}(k)$ it is easy to show that these Green's functions obey the following differential and integral equations and reality condition:

$$\vec{\mathcal{L}}G^{\pm}(k)=G^{\pm}(k)\tilde{\mathcal{L}}=I, \tag{4.21}$$

$$G^{\pm}(k)=G_1^{\pm}(k)+G_1^{\pm}(k)U_2G^{\pm}(k),\quad G^{\pm}(k)=G_1^{\pm}(k)+G^{\pm}(k)U_2G_1^{\pm}(k), \tag{4.22}$$

$$\overline{G^{\pm}(k)}=G^{\pm}(k). \tag{4.23}$$

By definition they are independent of $k_{\Re}$ and by the corresponding properties of $G_1^{\pm}(k)$ we have that $G^{+}(k)=G^{-}(k)$ when $|k_{\Im}|>a$ and they are independent of $k_{\Im}$ when $|k_{\Im}|<a$. By (4.20) and (4.21) we get that $\Phi^{\pm}(k)$ and $\Psi^{\pm}(k)$ are solutions of the heat equation with potential (1.5),

$$\vec{\mathcal{L}}\Phi^{\pm}(k)=0,\quad \Psi^{\pm}(k)\tilde{\mathcal{L}}=0. \tag{4.24}$$

Integral equations for these solutions follow by applying operations (4.20) to the equations (4.22):

$$\Phi^{\pm}=\Phi_{1,-a}+G_1^{\pm}U_2\Phi^{\pm},\quad \Psi^{\pm}=\Psi_{1,a}+\Psi^{\pm}U_2G_1^{\pm}. \tag{4.25}$$

Let us also mention that, thanks to (4.23), these solutions are real and are independent of k inside the strip $|k_{\Im}|<a$, due to the corresponding property of $G^{\pm}(k)$ and (4.20). Since in the following we use intensively the Green's functions and these solutions inside the strip, it is convenient to introduce the following specific notations:

$$g^{\pm}(x,x')=G^{\pm}(x,x',k)|_{|k_{\Im}|<a}, \tag{4.26}$$

and also

$$\phi^{\pm}(x)=\Phi^{\pm}(x,k)\big|_{|k_{\jmath}|<a}, \quad \psi^{\pm}(x)=\Psi^{\pm}(x,k)\big|_{|k_{\jmath}|<a}. \tag{4.27}$$

Equality (4.19) enables us to find relations between solutions (4.20). Let $|k_{\jmath}|<a$. Then applying, say, $\tilde{\mathcal{L}}_1\Phi_{1,-a}$ to this equality from the right and using (4.20) we derive that

$$(1+\lambda)\phi^{+}=\phi^{-}, \tag{4.28}$$

where

$$\lambda=c(\Psi_{1,a}\vec{\mathcal{L}}_1 g^{-}\tilde{\mathcal{L}}_1\Phi_{1,-a}). \tag{4.29}$$

Explicitly $\lambda=c\int dx\int dx'\Psi_{1,a}(x)(\mathcal{L}_1(x,\partial_x)\mathcal{L}_1^{\mathrm{d}}(x',\partial_{x'})g^{-}(x,x')\Phi_{1,-a}(x'))$. By (4.23) this constant is real and, thanks to (4.20), it is also equal to $\lambda=c(\Psi_{1,a}\vec{\mathcal{L}}_1\phi^{-})=c(\psi^{-}\tilde{\mathcal{L}}_1\Phi_{1,-a})$. Inserting here $\mathcal{L}_1=\mathcal{L}+U_2$ we get by (4.21) and (4.24) that

$$\lambda=c\{(\Psi_{1,a}U_2\Phi_{1,-a})+(\Psi_{1,a}U_2 g^{-}U_2\Phi_{1,-a})\}, \tag{4.30}$$

or $\lambda=c(\Psi_{1,a}U_2\phi^{-})=c(\psi^{-}U_2\Phi_{1,-a})$, where we also used $\vec{\mathcal{L}}_1\Phi_{1,-a}=0$ and $\Psi_{1,a}\tilde{\mathcal{L}}_1=0$, which follow from (3.2) and (3.8). Next, applying to (4.28) $\Psi_{1,a}\vec{\mathcal{L}}_1$ from the left and again by (4.20) we get

$$(1+\lambda)[1-c(\Psi_{1,a}\vec{\mathcal{L}}_1 g^{+}\tilde{\mathcal{L}}_1\Phi_{1,-a})]=1, \tag{4.31}$$

where a new constant $(\Psi_{1,a}\vec{\mathcal{L}}_1 g^{+}\tilde{\mathcal{L}}_1\Phi_{1,-a})=(\Psi_{1,a}U_2\Phi_{1,-a})+(\Psi_{1,a}U_2 g^{+}U_2\Phi_{1,-a})$ [cf. (4.30)] appeared. Since we chose u_2 to be rapidly decaying at infinity, all terms must be finite. Then $1+\lambda\neq 0$ and, more precisely, taking into account that for $u_2\to 0$ also $\lambda\to 0$, we have that

$$1+\lambda>0. \tag{4.32}$$

Summarizing, we get the following relations:

$$c(\Psi_{1,a}\vec{\mathcal{L}}_1 g^{+}\tilde{\mathcal{L}}_1\Phi_{1,-a})=\frac{\lambda}{1+\lambda}, \tag{4.33}$$

$$\phi^{+}=\frac{\phi^{-}}{1+\lambda}, \quad \psi^{+}=\frac{\psi^{-}}{1+\lambda}, \tag{4.34}$$

$$G^{+}(k)=G^{-}(k)-\frac{c\,\theta(a-|k_{\jmath}|)}{1+\lambda}\phi^{-}\otimes\psi^{-}. \tag{4.35}$$

Here (4.33) is just (4.31), the first equality in (4.34) is (4.29) and the second equality is derived by analogy, and (4.35) follows from (4.19) thanks to (4.34). In their turn (4.33) and (4.34) follow from (4.35) thanks to (4.20) and (4.28).

We have shown in (3.36) that the Green's functions $G_1^{\pm}(k)$ are discontinuous at $k_{\jmath}=a$ and $k_{\jmath}=-a$. By (4.22) we deduce that $G^{\pm}(k)$ have the same behavior. In order to study this discontinuity we use, as above, the Hilbert identity (4.1) where $M=M(q)$, $M'=M(q')$, etc. We choose $q_2=q_2'=a^2\pm 0$, $q_1=a-\varepsilon$, $q_1'=a+\varepsilon$, and in the limit $\varepsilon\to+0$ we use the hat notation (2.13) and definitions (3.27) and (4.18) of the Green's functions. Then we get $G^{\pm}(i(a+0))-g^{\pm}=G^{\pm}(i(a+0))\tilde{\mathcal{L}}_1(G_1^{\pm}(i(a+0))-g_1^{\pm})\vec{\mathcal{L}}_1 g^{\pm}$, where again (3.31) and (4.26) were used. Now by (3.36) for the discontinuity of the unperturbed Green's functions we obtain

$$G^{\pm}(i(a+0))-g^{\pm}=\pm\frac{c}{2}\Phi^{\pm}(i(a+0))\otimes\psi^{\pm}, \tag{4.36}$$

where notations (4.20), (4.26) and (4.27) were used. Applying $\tilde{\mathcal{L}}_1\Phi_{1,-a}$ from the right and $\Psi_{1,a}\vec{\mathcal{L}}_1$ from the left in analogy with the derivation of (4.35) we get by (4.28) that $c(\Psi_{1,a}\vec{\mathcal{L}}_1G^{\pm}(i(a+0))\tilde{\mathcal{L}}_1\Phi_{1,-a})=2\lambda(2+\lambda)^{-1}$, which is finite due to (4.32). Then omitting details we derive the equalities $G^{\pm}(i(a+0))=G^{\pm}(-i(a+0))=g^{-}-c(2+\lambda)^{-1}\phi^{-}\otimes\psi^{-}$, that, say, for the bottom sign can also be rewritten in the form

$$G^{-}(k)=g^{-}-\frac{c\,\theta(|k_{\mathfrak{I}}|-a)}{2+\lambda}\phi^{-}\otimes\psi^{-}+o(1),\quad k\sim\pm ia, \tag{4.37}$$

where we took (4.26) into account.

V. PROPERTIES OF THE JOST SOLUTIONS AND INVERSE PROBLEM

In this section we complete the investigation of the properties of the Jost solutions by describing their behavior at the points $k=\pm ia$. Formulas (4.6) suggest to study first the behavior of the Green's function $G(k)$. We expect that it is ill defined at these points, so in order to describe this behavior we compare $G(k)$ with some well defined Green's function, say, g^{-}. For this aim, as we have already shown, relations of the type (4.19) can be very useful. In order to derive them we start again from the Hilbert identity (4.1) where $M'=M(q')$ and $M=M(q)$ and we choose $q'=\ell_{\mathfrak{I}}(k)$, $q_1=k_{\mathfrak{I}}$, $q_2=a^2-0$ [see (2.11), (4.7) and (4.16)]. Then, passing to the objects with hats by (2.13), recalling definitions (4.7) and (4.18) and keeping only the leading term in the neighborhood of $k\sim\pm ia$, we get

$$G(k)-G^{-}(k)=G(k)\tilde{\mathcal{L}}_1(G_1(k)-G_1^{-}(k))\vec{\mathcal{L}}_1G^{-}(k)+o(1),\quad k\sim\pm ia.$$

Inserting the explicit singular behaviors of $G_1(k)$, $G_1^{-}(k)$ and $G^{-}(k)$ at $k=\pm ia$ given in (3.34), (3.35) and (4.37), we have

$$G(k)-g^{-}=-\frac{c\,\theta(|k_{\mathfrak{I}}|-a)}{2+\lambda}\phi^{-}\otimes\psi^{-}+c\left(-\frac{1}{\pi}\operatorname{arccot}\frac{a-|k_{\mathfrak{I}}|}{|k_{\mathfrak{R}}|}+\frac{\theta(|k_{\mathfrak{I}}|-a)}{2}\right)G(k)\tilde{\mathcal{L}}_1\Phi_{1,-a}\otimes\Psi^{-}(k)+o(1),$$

where in the last multiplier the definition of $\Psi^{-}(k)$ in (4.20) was used. Again by (4.20) and (4.37) $\Psi^{-}(k)=\{[2+\lambda\,\theta(a-|k_{\mathfrak{I}}|)]/(2+\lambda)\}\psi^{-}$, where as always ψ^{-} denotes $\Psi^{-}(k)$ for $|k_{\mathfrak{I}}|<a$ by (4.27). Then

$$G(k)-g^{-}=\left\{-\frac{c\,\theta(|k_{\mathfrak{I}}|-a)}{2+\lambda}\phi^{-}+c\left(-\frac{1}{\pi}\operatorname{arccot}\frac{a-|k_{\mathfrak{I}}|}{|k_{\mathfrak{R}}|}+\frac{\theta(|k_{\mathfrak{I}}|-a)}{2}\right)\times\frac{2+\lambda\,\theta(a-|k_{\mathfrak{I}}|)}{2+\lambda}G(k)\tilde{\mathcal{L}}_1\Phi_{1,-a}\right\}\otimes\psi^{-}+o(1). \tag{5.1}$$

Thus in order to get the behavior of $G(k)$ we need to find that of $G(k)\tilde{\mathcal{L}}_1\Phi_{1,-a}$, which follows by applying to (5.1) operation $\tilde{\mathcal{L}}_1\Phi_{1,-a}$ from the right and using again (4.20), (4.27) and (4.29). Then

$$G(k)\tilde{\mathcal{L}}_1\Phi_{1,-a}=\frac{\pi\phi^{-}}{A(k)}+o(1),\quad k\sim\pm ia, \tag{5.2}$$

where we denoted for brevity

$$A(k)=\pi+\lambda\ \mathrm{arccot}\frac{a-|k_{\Im}|}{|k_{\Re}|}. \tag{5.3}$$

This function is real positive thanks to (4.32) and discontinuous at $k=\pm ia$. Now inserting (5.2) in (5.1) we derive finally that

$$G(k)=g^{-}-\frac{c}{A(k)}\left(\mathrm{arccot}\frac{a-|k_{\Im}|}{|k_{\Re}|}\right)\phi^{-}\otimes\psi^{-}+o(1),\quad k\sim\pm ia. \tag{5.4}$$

Applying to (5.4) from the left the operation $\Psi_{1,a}\vec{\mathcal{L}}_1$ and recalling the definitions (4.20) and (4.27) we derive

$$\Psi_{1,a}\vec{\mathcal{L}}_1G(k)=\frac{\pi\psi^{-}}{A(k)}+o(1),\quad k\sim\pm ia, \tag{5.5}$$

and by (4.29) also

$$c\Psi_{1,a}\vec{\mathcal{L}}_1G(k)\tilde{\mathcal{L}}_1\Phi_{1,-a}=\frac{\pi\lambda}{A(k)}+o(1),\quad k\sim\pm ia. \tag{5.6}$$

Correspondingly, we get for the behavior of the Jost solutions in the neighborhood of $k=\pm ia$, thanks to (3.3) and (5.2),

$$\Phi(k)=\frac{i\pi c\phi^{-}}{A(k)(k-ia)}+O(1),\quad k\sim ia, \tag{5.7}$$

$$\Phi(k)=\frac{\pi\phi^{-}}{A(k)}+o(1),\quad k\sim -ia \tag{5.8}$$

and analogous relations for $\Psi(k)$.

Now we are ready to consider the d-bar derivative in the sense of distributions of the Jost solution, say, $\Phi(k)$. Let first $k\neq\pm ia$. Then we use (3.3), (4.6), and (4.10) to derive

$$\frac{\partial\Phi(k)}{\partial\overline{k}}=\Phi(-\overline{k})r(k),\quad k\neq\pm ia, \tag{5.9}$$

where the spectral data are defined as follows:

$$r(k)=\frac{\mathrm{sgn}\,k_{\Re}}{2\pi}(\Psi_1(-\overline{k})\vec{\mathcal{L}}_1G(k)\tilde{\mathcal{L}}_1\Phi_1(k)). \tag{5.10}$$

Thanks to (3.3), (3.4) and (5.6) we get the singular behavior of these spectral data in the form

$$r(k)=\frac{i\lambda\ \mathrm{sgn}\,k_{\Re}}{2(k_{\Re}+i|k_{\Im}|-ia)A(k)}+o(1),\quad k\sim\pm ia, \tag{5.11}$$

i.e., in both points it has a pole singularity multiplied by the discontinuous function $A(k)$. Taking into account that the singular behavior of $\Phi(-\overline{k})$ is given by the denominator $\overline{(k-ia)}A(k)$ at point $k=ia$ and by $A(k)$ at point $k=-ia$ we see that the rhs in (5.9) is integrable at the latter point but it has a singularity $\mathrm{sgn}\,k_{\Re}|k-ia|^{-2}A(k)^{-2}$ at point $k=ia$, which is not integrable. On the other hand, $\Phi(k)$ is locally integrable for any k, so $\Phi(x,k)e^{i\not\subset(k)x}$ is a Schwartz distribution with respect to k. Thus its d-bar derivative in the sense of distributions exists and can be defined

in the standard way. Let $f(k)$ be a test function that properly decays at infinity (we are now not interested in the exponential growth due to the multiplier $e^{-i\ell(k)x}$). Then the d-bar derivative of $\Phi(k)$ is defined as

$$\int d^2k \frac{\partial\Phi(k)}{\partial\bar{k}} f(k) = -\int d^2k\, \Phi(k) \frac{\partial f(k)}{\partial\bar{k}} = -\lim_{\varepsilon\to 0}\int_{|k\pm ia|>\varepsilon} d^2k\, \Phi(k) \frac{\partial f(k)}{\partial\bar{k}},$$

where in the last equality we again used the property of local integrability of $\Phi(k)$. Integrating by parts for $\varepsilon>0$ we can use (5.9) and we have

$$-\lim_{\varepsilon\to 0}\int_{|k\pm ia|>\varepsilon} d^2k\, \Phi(k) \frac{\partial f(k)}{\partial\bar{k}} = \frac{f(ia)}{2i}\lim_{\varepsilon\to 0}\oint_{|k-ia|=\varepsilon} dk\, \Phi(k) + \lim_{\varepsilon\to 0}\int_{|k-ia|>\varepsilon} d^2k$$

$$\times\Phi(-\bar{k})r(k)f(k),$$

where we omitted the term $\oint_{|k+ia|>\varepsilon}$ since thanks to (5.8) it gives zero in the limit $\varepsilon\to 0$. Thanks to (5.7) and (5.8) both limits on the rhs exist. To be more precise, let us introduce the distribution

$$\text{p.v.}\int d^2k \frac{\operatorname{sgn} k_{\Re} f(k)}{|k-ia|^2 A(k)^2} = \lim_{\varepsilon\to 0}\int_{|k-ia|>\varepsilon} d^2k \frac{\operatorname{sgn} k_{\Re} f(k)}{|k-ia|^2 A(k)^2}. \tag{5.12}$$

Notice the presence in the numerator of $\operatorname{sgn} k_{\Re}$ that guaranties existence of the limit. We used the principal value (p.v.) notation in analogy with the one-dimensional case. It can be checked directly that

$$\text{p.v.}\int d^2k \frac{\operatorname{sgn} k_{\Re} f(k)}{|k-ia|^2 A(k)^2} = \int d^2k \frac{\operatorname{sgn} k_{\Re}}{|k-ia|^2 A(k)^2}[f(k)-\theta(\delta-|k-ia|)f(ia)]$$

$$= \frac{1}{2}\int d^2k \operatorname{sgn} k_{\Re} \frac{f(k)-f(-\bar{k})}{|k-ia|^2 A(k)^2}, \tag{5.13}$$

where δ is some real positive parameter and the second term in (5.13) is independent of the choice of δ. In the case where a distribution has singularities of this form at some finite number of points a_1, a_2, etc., we use the same notation for the integral assuming that either the cutoff procedure in (5.12) or the subtraction procedure in (5.13) is performed at each point. Of course, the parameters ε_j and δ_j must be chosen in such a way that corresponding discs do not overlap.

Let us denote

$$\Phi_a = -\frac{1}{2\pi}\lim_{\varepsilon\to 0}\oint_{|k-ia|=\varepsilon} dk\, \Phi(k), \tag{5.14}$$

so that $i\Phi_a$ can be considered as an extension of the definition of residuum to the case in which the pole singularity is multiplied by a function discontinuous at the same point. Thanks to (5.7) we get that this limit also exists and equals

$$\Phi_a = c\frac{\log(1+\lambda)}{\lambda}\phi^-. \tag{5.15}$$

Thus, summarizing all above definitions we get that

$$\frac{\partial\Phi(k)}{\partial\bar{k}} = \Phi(-\bar{k})r(k) + i\pi\Phi_a\delta(k-ia), \tag{5.16}$$

where $\Phi(x,-\overline{k})r(k)$ is now a distribution in k defined by the p.v. prescription given above. By (5.7), (5.8) and (5.11) it is integrable at $k=-ia$, but it behaves as $|k-ia|^{-2}A^{-2}(k)$ in the neighborhood of the point $k=ia$.

Equation (5.16) supplies us with the first equation of the inverse problem. In order to close it we need the analog of the first relation in (3.17), where it is stated that the residuum of the function is proportional to its value in the conjugated point. But in our case $\Phi(k)$ is discontinuous at point $k=-ia$, so again some modification of the notion of "value" at this point must be given. Following the procedure used in (5.14) we can define it as

$$\Phi_{-a}=\frac{1}{2\pi i}\lim_{\varepsilon\to 0}\oint_{|k+ia|=\varepsilon}\frac{dk}{k+ia}\Phi(k). \tag{5.17}$$

Thanks to (5.8) this limit also exists and equals

$$\Phi_{-a}=\frac{\log(1+\lambda)}{\lambda}\phi^{-}, \tag{5.18}$$

so that by (5.15) we have

$$\Phi_a=c\Phi_{-a}, \tag{5.19}$$

which shows that the parameter c is not modified by the perturbation. This equality closes the formulation of the inverse problem (5.16). Finally, taking into account the asymptotic behavior of $\Phi(x,k)$ and (5.17) and (5.19), we can formulate the inverse problem as the following system of integral equations:

$$\Phi(x,k)=e^{-i\not{\ell}(k)x}+\frac{1}{\pi}\text{p.v.}\int\frac{d^2k'}{k-k'}e^{i(\not{\ell}(k')-\not{\ell}(k))x}\Phi(x,-\overline{k'})r(k')+i\frac{e^{i(\not{\ell}(ia)-\not{\ell}(k))x}}{k-ia}\Phi_a(x), \tag{5.20}$$

$$\frac{1}{c}\Phi_a(x)=e^{-i\not{\ell}(-ia)x}-\frac{1}{\pi}\text{p.v.}\int d^2k\,\frac{\Phi(x,-\overline{k})r(k)}{k+ia}e^{i(\not{\ell}(k)-\not{\ell}(-ia))x}+\frac{e^{i(\not{\ell}(ia)-\not{\ell}(-ia))x}}{2a}\Phi_a(x). \tag{5.21}$$

The integrands on the rhs of these two equations are not locally integrable, respectively, the first at $k=ia$ and the second at $k=\pm ia$. Correspondingly, their integrals are regularized by means of the principal value prescription, as in (5.12) or (5.13), at $k=ia$ and at $k=\pm ia$.

The potential is reconstructed by means of

$$u(x)=-\frac{2i}{\pi}\text{p.v.}\int d^2k\,\frac{\partial}{\partial x_1}(\,e^{i\not{\ell}(k)x}\Phi(x,-\overline{k})r(k))+2\,\frac{\partial}{\partial x_1}(e^{i\not{\ell}(ia)x}\,\Phi_a(x)). \tag{5.22}$$

VI. CONCLUSION

In this article on the basis of the resolvent approach we gave a detailed presentation of an extension of the inverse scattering theory for the heat operator to the case where the potential (1.5) is a perturbation of the one-dimensional one-soliton potential $u_1(x_1)$ (3.1) by means of a smooth, decaying at infinity function $u_2(x)$ of two space variables. To our knowledge this is the first time that inverse scattering theory is applied to a nonscattering situation, i.e., a situation with an infinite obstacle. As a result of our investigation we proved that under such a perturbation the Jost solutions get specific singularities (5.7) and (5.8) on the complex plane of the spectral parameter k. We demonstrated that the d-bar problem (5.16) and (5.19), while looking familiar for a potential whose spectrum has a discrete and continuous part, needs a substantially modified approach due to the singularity structure of the spectral data given in (5.11). It was necessary to establish the

meaning in the sense of distributions of all terms involved in this problem, in order to be able to formulate the inverse problem as the system of integral equations (5.20) and (5.21). It is easy to check that the singular behavior of the spectral data and Jost solution as given in (5.11) and (5.7) and (5.8) is compatible with this inverse problem. On the other side, it is necessary to prove that the potential $u(x)$ reconstructed by means of (5.22) is of the type (1.5). We plan to address this problem in a forthcoming work.

Another open problem is the application of these results to the KPII equation (1.3) itself. In particular, investigation of the time asymptotics of solutions with initial data of the type (1.5) must be performed. Let us mention only that the singular behavior (5.11) of the spectral data is preserved under evolution (1.3). Indeed,[3] the time dependence of the spectral data is given as

$$r(k,t)=e^{4i(k^3+\bar{k}^3)}. \tag{6.1}$$

Thus we get that

$$a=\text{const}, \quad \lambda=\text{const}, \tag{6.2}$$

also with respect to time.

In Sec. III we mentioned that the above construction can be easily generalized to the case where the potential $u_1(x_1)$ is a pure N-soliton one-dimensional potential. At the same time our approach also admits straightforward generalization to the case where $u_1(x)$ is not a function of one space variable but the result of application of the Bäcklund transformation to a generic background two-dimensional potential $u_0(x)$ decaying on the x-plane. Then the inverse problem is again given by Eqs. (5.20) and (5.21), where the spectral data $r(k)$ are replaced with

$$r(k)+\frac{(k+ia)(\bar{k}+ia)}{(\bar{k}-ia)(k-ia)}r_0(k), \tag{6.3}$$

where $r(k)$ is of the type (5.11) and $r_0(k)$ are the spectral data of the potential $u_0(x)$ (see Ref. 11).

The theory of the heat equation with respect to the nonstationary Schrödinger equation is in some respects simpler and in some other respects unexpectedly more difficult. As we have shown, under perturbation the Jost solution get singularities more complicated than poles, but this solution has no additional cut in the complex domain, in contrast with the nonstationary Schrödinger case as discovered in Ref. 13. On the other hand, the generalization of this scheme to the case of multi-ray structure of the potential $u(x)$ meets with essential problems, first of all due to the fact that the resolvent (or Green's function) of the heat equation even of a two-soliton (generic) potential is unknown in the literature. This problem also needs future development.

(Received 4 April 2001; accepted for publication 10 October 2001)

Among the multiplication operators on weighted Bergman Hilbert spaces are those where the multiplying function (operator symbol) depends only on the angular polar coordinate in the unit disk: we call these ''angle operators.'' As these Hilbert spaces carry a CCR representation unitarily equivalent to the Schrödinger representation, angle operators are associated with quantum phase in the same way as are Toeplitz operators, for example. We determine the matrix elements of the angle operators with respect to the natural orthonormal basis on each of these spaces, and also with respect to the appropriate family of coherent states. By using a method of comparison with the corresponding results for Toeplitz operators, asymptotic expressions for the expectations and variances in these two families of states are obtained for the angle operators whose symbols are the polar angle function and its two complex exponentials. Notable is the fact that the asymptotic limit of the variance of the polar angle operator in the natural basis family is $\pi^2/3$, which many authors take to be a requirement for a quantum phase operator. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1423401]

I. INTRODUCTION

In order to understand the phenomena collectively known as ''quantum phase,'' a number of operators have been proposed as a quantum phase observable. These proposals have been described in a number of reviews and book,[1–5] highlighting different points of view, and particularly in a book by the authors together with Smith,[6] whose conventions we shall adopt here.

Among the proposals are the Toeplitz operator X of multiplication by the angle variable in the Hardy space $H^2(\mathbb{T})$, and the operator of multiplication by the angle variable in Bargmann–Segal space (Fock space over $\mathbb{C}$). In addition, functions of these operators (in the sense of spectral theory) have been considered as describing aspects of the quantum phase, and so we take it that there is a respectable pedigree to considering operators of multiplication by functions of an angle on Hilbert spaces of functions whose domain is a subset of the complex plane—notwithstanding that these operators are not diagonal (so that the angle is not the spectral variable which will be measured).

In this paper we add a one-parameter family to the catalog of such operators by considering angle operators on the weighted Bergman spaces (Hilbert spaces associated with the weighted Bergman kernels).

The paper is organized as follows. In Sec. II we set down our conventions for weighted Bergman spaces and general multiplication operators on them. In Sec. III we introduce those Toeplitz–Bergman operators we call angle operators, denoted $B_{\mathfrak{f}}^{(\alpha)}$. These are multiplication operators on the weighted Bergman Hilbert space by functions of the form $(r,\theta)\mapsto \mathfrak{f}(re^{i\theta})$, where $\mathfrak{f}$ is essentially bounded. We determine their matrix elements with respect to the natural basis $\{e_n^{(\alpha)}: n\geqslant 0\}$ on the Hilbert space in Sec. IV, in particular for the expectation and variance in the

a)Electronic mail: d.a.dubin@open.ac.uk
b)Electronic mail: mah30@cam.ac.uk

states $e_n^{(\alpha)}$. By interpolation from integer α, we are able to obtain an asymptotic expression (as $n\to\infty$) of the difference between the expectations and variances of the maps $B_{\mathfrak{f}}^{(\alpha)}$ and those of the Toeplitz operators whose symbols are $\mathfrak{f}$. We find this difference to be at least as fast as $O(1/n)$. Knowledge of the asymptotic properties of the variance of Toeplitz operator whose symbol is the angle function on the circle enables us to show that, in the limit $n\to\infty$, the variance of $B_{\varphi}^{(\alpha)}$ is $\pi^2/3$, where φ is the (suitably defined) argument function. This establishes $B_{\varphi}^{(\alpha)}$ as being as closely related to quantum phase as are the Toeplitz and Bargmann–Segal angle operators.

In Sec. V we introduce a family of coherent states on $\mathcal{H}_\alpha$, and consider the expectation of the angle operators with respect to them. Employing a comparison method, we then obtain an asymptotic form for the variance of $B_{\varphi}^{(\alpha)}$. In the final section we note some open mathematical problems.

II. WEIGHTED BERGMAN SPACES

Let $\mathbb{D}$ be the open unit disc and $dA(z)=dxdy/\pi$ the normalized Lebesgue area measure on $\mathbb{D}$. For all $\alpha\in(-1,\infty)$, define the measure

$$d\mu_\alpha(z)=(\alpha+1)(1-|z|^2)^\alpha dA(z). \tag{1}$$

We write $\mathcal{H}_\alpha$ for the Hilbert space of functions F which are both holomorphic in $\mathbb{D}$ and square integrable with respect to $d\mu_\alpha$. If $f, g\in\mathcal{H}_\alpha$, we write $\|f\|_\alpha$ for the norm of f and $\langle g,f\rangle_\alpha$ for the inner product of f and g: the inner product is antilinear in the first variable. The space $\mathcal{H}_\alpha$ is a weighted Bergman space in the terminology of Hendenmalm, Korenblum, and Zhu,[7] whose conventions we adopt (for the most part). The original Bergman space corresponds to $\alpha=0$, but we shall refer to all of the $\mathcal{H}_\alpha$ simply as Bergman spaces.

In several places we shall be using the Hilbert space $L^2(\mathbb{D},d\mu_\alpha)$ as a space in which $\mathcal{H}_\alpha$ is embedded. There will be no possibility of confusion if we use the same symbols for the norm and inner product on both spaces.

The functions,

$$e_n^{(\alpha)}(z)=i^{-n}\sqrt{\binom{n+\alpha+1}{n}}z^n,\quad n\in\mathbb{N}_0,\ z\in\mathbb{D}, \tag{2}$$

constitute an orthonormal basis for $\mathcal{H}_\alpha$. (The binomial coefficients are extended to nonintegral values by use of the Gamma function.) This choice differs from that of Hedenmalm *et al.*[7] and other authors through the appearance of the factor i^{-n}, which is necessary for consistency with the conventions of Dubin *et al.*[6]

The space $\mathcal{H}_\alpha$ is equipped with the reproducing kernel (see Neeb[8] for the general theory) which is the integral kernel of the projection operator,

$$P_\alpha f=\sum_{n=0}^{\infty}\langle e_n^{(\alpha)},P_\alpha f\rangle_\alpha\, e_n^{(\alpha)}, \tag{3a}$$

of $L^2(\mathbb{D},d\mu_\alpha)$ onto $\mathcal{H}_\alpha$. This series converges pointwise on $\mathbb{D}$, uniformly on compact subsets of $\mathbb{D}$, and is norm-convergent in $L^2(\mathbb{D},d\mu_\alpha)$. Its reproducing kernel is then the positive definite kernel,

$$\mathcal{K}_\alpha(z,w)=(1-z\bar{w})^{-(2+\alpha)}, \tag{3b}$$

so that

$$[P_\alpha f](z)=\int_{\mathbb{D}}\mathcal{K}_\alpha(z,w)f(w)d\mu_\alpha(w) \tag{3c}$$

belongs to $\mathcal{H}_\alpha$ for every $f \in L^2(\mathbb{D}, d\mu_\alpha)$. The $\mathcal{K}_\alpha$ are the weighted Bergman kernels; the original kernel of Bergman results from putting $\alpha = 0$.

We mention parenthetically that the Bergman metric is the Kähler metric,

$$ds^2 = \partial^2 \log \mathcal{K}_\alpha(z, \overline{z}) / \partial z \partial \overline{z} dz d\overline{z}.$$

If F is a function which is bounded except on a μ_α-null set (the usual convention of identifying functions which differ only on a null set is in force), pointwise multiplication by F will, in general, take a function f in $\mathcal{H}_\alpha$ to the function Ff in $L^2(\mathbb{D}, d\mu_\alpha)$. If we want an operator on $\mathcal{H}_\alpha$ we must act with the projection operator P_α on Ff. Now $f \mapsto Ff$ is bounded on $L^2(\mathbb{D}, d\mu_\alpha)$ with the bound not greater than the sup norm of F. As P_α is a projection operator, it can only reduce the bound, and so we come to the following result: a function $F \in L^\infty(\mathbb{D})$ determines a bounded operator $B_F^{(\alpha)}$ on $\mathcal{H}_\alpha$ by $B_F^{(\alpha)}(g) = P_\alpha(Fg)$. For the bound we have $\|B_F^{(\alpha)}\| \leqslant \|F\|_\infty$. In accordance with the standard practice in function theory, we shall refer to $B_F^{(\alpha)}$ as the Toeplitz–Bergman operator (on $\mathcal{H}_\alpha$) and F as the *symbol* of $B_F^{(\alpha)}$.

As a last topic in our cursory discussion of weighted Bergman spaces, we wish to note that each $\mathcal{H}_\alpha$ carries a representation of the canonical commutation relation for one degree of freedom which is equivalent to the Schrödinger representation on $L^2(\mathbb{R})$. As such, these representations are irreducible and gauge invariant and, if one has a quantum phase in mind, could be thought of as describing a single mode of the quantized electromagnetic field whose state is the coherent "laser" radiation. For a discussion of these points, see Dubin *et al.*[6]

This representation arises from the fact that the correspondence $h_n \mapsto W_\alpha(h_n) = e_n^{(\alpha)}$, $n \geqslant 0$, extends to a unitary transformation $L^2(\mathbb{R}) \to \mathcal{H}_\alpha$. (Here h_n is the nth Hermite–Gauss vector.) Since the raising operator of the Schrödinger representation is

$$A^+ h_n = \sqrt{n+1}\, h_{n+1}, \quad n \geqslant 0,$$

the raising operator on $\mathcal{H}_\alpha$ is

$$A_\alpha^+ = W_\alpha A^+ W_\alpha^*,$$

with action

$$A_\alpha^+ e_n^{(\alpha)} = \sqrt{n+1}\, e_{n+1}^{(\alpha)}, \quad n \geqslant 0:$$

similarly for the lowering operator. We have no explicit expression for these ladder operators, but we can describe the number operator N_α. From

$$N_\alpha\, e_n^{(\alpha)} = n e_n^{(\alpha)},$$

we obtain

$$N_\alpha = z d/dz.$$

Although every $f \in \mathcal{H}_\alpha$ is analytic, $zf'(z)$ need not belong to $\mathcal{H}_\alpha$, and so N_α is unbounded; similarly, the raising and lowering operators are unbounded. The appropriate domains for working with this representation can be transferred from those for the Schrödinger representation via the map W_α, but we shall have no need of this here. We note that, up to a phase factor, $e_0^{(\alpha)}$ is the only normalized function in $\mathcal{H}_\alpha$ which is invariant under the gauge group generated by N_α.

III. ANGULAR TOEPLITZ–BERGMAN OPERATORS

Our interest is in the class of Toeplitz–Bergman operators obtained by starting from a bounded function of the angle, $\mathfrak{f}: \mathbb{T} \to \mathbb{C}$, and using it to define a function $\mathfrak{f}_{\text{ang}} \in L^\infty(\mathbb{D})$ on $\mathbb{D}$ by the formula

$$\mathfrak{f}_{\mathrm{ang}}(re^{i\theta})=\mathfrak{f}(e^{i\theta}). \tag{4}$$

To avoid excessive notation, the multiplication operator determined by $\mathfrak{f}_{\mathrm{ang}}$ will be written as $B_{\mathfrak{f}}^{(\alpha)}$, but the distinction between $\mathfrak{f}$ and $\mathfrak{f}_{\mathrm{ang}}$ will be otherwise maintained.

We shall be considering the Fourier series for $\mathfrak{f}$, and our convention for the Fourier coefficients is

$$\hat{\mathfrak{f}}_n=\frac{1}{2\pi}\int_{\pi}^{\pi}\mathfrak{f}(e^{i\theta})e^{-in\theta}d\theta. \tag{5}$$

Since $L^{\infty}(\mathbb{T})\subset L^2(\mathbb{T})$, it is clear that the identity,

$$\mathfrak{f}(e^{i\theta})=\sum_{n\in\mathbb{Z}}\hat{\mathfrak{f}}_n e^{in\theta}, \tag{6a}$$

holds in $L^2(\mathbb{T})$. It is elementary to show that the functions

$$re^{i\theta}\mapsto e^{in\theta},\quad n\in\mathbb{Z},$$

form an orthonormal collection in $L^2(\mathbb{D},d\mu_\alpha)$ (but not an orthonormal basis), and so we deduce that $\mathfrak{f}_{\mathrm{ang}}\in L^2(\mathbb{D},d\mu_\alpha)$ for all $\mathfrak{f}\in L^{\infty}(\mathbb{T})$, and that

$$\mathfrak{f}_{\mathrm{ang}}(re^{i\theta})=\sum_{n\in\mathbb{Z}}\hat{\mathfrak{f}}_n e^{in\theta}, \tag{6b}$$

with this series converging in the norm topology on $L^2(\mathbb{D},d\mu_\alpha)$.

In order that our notation not cause any misunderstanding, we note that the function $\mathfrak{f}$ has a smooth harmonic extension $\mathfrak{f}_{\mathrm{ext}}:\mathbb{D}\to\mathbb{C}$ given by

$$\mathfrak{f}_{\mathrm{ext}}(re^{i\theta})=\sum_{n\in\mathbb{Z}}\hat{\mathfrak{f}}_n r^{|n|}e^{in\theta}, \tag{7}$$

but $\mathfrak{f}_{\mathrm{ext}}$ is *not* the same function as $\mathfrak{f}_{\mathrm{ang}}$—which has the unfortunate consequence of our not being able to use the known spectral theory for the harmonic case; cf. McDonald and Sundberg.[9]

In connection with the quantum phase, the exponential and angle function on $\mathbb{D}$ are particularly important. We reserve the symbol φ for the angle (argument) function $\varphi:\mathbb{D}\to\mathbb{C}$ given by

$$\varphi(re^{i\theta})=\begin{cases}\theta, & 0<r\leqslant 1,-\pi\leqslant\theta<\pi,\\ 0, & r=0.\end{cases} \tag{8}$$

If we identify $\mathbb{T}$ with the real interval $[-\pi,\pi)$, then $\varphi=\mathfrak{p}_{\mathrm{ang}}$ for $\mathfrak{p}(e^{i\theta})=\theta$. The function φ is bounded but discontinuous (across the cut).

Similarly, the complex exponential function on $\mathbb{D}$ will be taken to be given by

$$e^{\pm i\varphi}(re^{i\theta})=\begin{cases}e^{\pm i\theta}, & \text{if } 0<r<1,\\ 1, & \text{if } r=0.\end{cases} \tag{9}$$

These definitions are consistent with the complex exponentials of the values of φ.

We shall refer to an operator of the form $B_{\mathfrak{f}}^{(\alpha)}$ as a Toeplitz–Bergman angle operator—more simply, as an angle operator.

IV. MATRIX ELEMENTS FOR THE NATURAL BASIS

For the purposes of application we need the matrix elements of the angle operators: these will determine the quantum expectations and variances in the pure states we shall consider here.

When taking matrix elements $\langle g, B_{\mathfrak{f}}^{(\alpha)} f\rangle_\alpha$, because both f and g belong to $\mathcal{H}_\alpha$ and P_α is Hermitian and idempotent, the projection operator drops out of the integral, and so we have the following.

Lemma 1: For $f, g \in \mathcal{H}_\alpha$, $F \in L^\infty(\mathbb{D})$,

$$\langle g, B_F^{(\alpha)} f\rangle_\alpha = \int_{\mathbb{D}} \overline{g(w)} F(w) f(w) d\mu_\alpha(w), \tag{10}$$

and

$$\|B_F^{(\alpha)} g\|_\alpha^2 = \langle Fg, P_\alpha F g\rangle_\alpha = \int_{\mathbb{D}} \overline{F(z) g(z)} \left(\int_{\mathbb{D}} \mathcal{K}_\alpha(z,w) F(w) g(w) d\mu_\alpha(w) \right) d\mu_\alpha(w). \tag{11}$$

When we apply this lemma to the special case $f = e_n^{(\alpha)}$, $g = e_m^{(\alpha)}$ and $F = \mathfrak{f}_{\text{ang}}$, after a certain amount of calculation we can express the integral in terms of choose and beta functions. This result is basic to the application to quantum mechanics.

Proposition 2: Let $\mathfrak{f} \in L^\infty(\mathbb{T})$. The matrix elements of $B_{\mathfrak{f}}^{(\alpha)}$ with respect to the basis elements $e_n^{(\alpha)}$ and $e_m^{(\alpha)}$ on $\mathcal{H}_\alpha$ are

$$\langle e_m^{(\alpha)}, B_{\mathfrak{f}}^{(\alpha)} e_n^{(\alpha)}\rangle_\alpha = i^{m-n}(\alpha+1) \sqrt{\binom{m+\alpha+1}{m}\binom{n+\alpha+1}{n}} B\left(\frac{1}{2}(m+n)+1, \alpha+1\right) \hat{\mathfrak{f}}_{m-n}. \tag{12}$$

Proof: We have that

$$\begin{aligned}
&\langle e_m^{(\alpha)}, B_{\mathfrak{f}}^{(\alpha)}, e_n^{(\alpha)}\rangle_\alpha \\
&\quad = i^{m-n} \int \int_{\mathbb{D}} \sqrt{\binom{m+\alpha+1}{m}\binom{m+\alpha+1}{n}} \overline{z^m} \mathfrak{f}_{\text{ang}}(z) z^n d\mu_\alpha z \\
&\quad = i^{m-n} \frac{\alpha+1}{\pi} \sqrt{\binom{m+\alpha+1}{m}\binom{n+\alpha+1}{n}} \int_0^{2\pi} d\theta \int_0^1 r dr\, r^{m+n} e^{i(n-m)\theta} \mathfrak{f}(e^{i\theta}) (1-r^2)^\alpha \\
&\quad = i^{m-n} \frac{\alpha+1}{\pi} \sqrt{\binom{m+\alpha+1}{m}\binom{n+\alpha+1}{n}} \int_0^1 r^{m+n+1} (1-r^2)^\alpha dr \int_0^{2\pi} \mathfrak{f}(e^{i\theta}) e^{i(n-m)\theta} d\theta \\
&\quad = 2 i^{m-n} (\alpha+1) \sqrt{\binom{m+\alpha+1}{m}\binom{n+\alpha+1}{n}} \int_0^1 r^{m+n+1} (1-r^2)^\alpha dr \hat{\mathfrak{f}}_{m-n} \\
&\quad = i^{m-n} (\alpha+1) \sqrt{\binom{m+\alpha+1}{m}\binom{n+\alpha+1}{n}} \int_0^1 r^{(m+n)/2} (1-r)^\alpha dr \hat{\mathfrak{f}}_{m-n} \\
&\quad = i^{m-n} (\alpha+1) \sqrt{\binom{m+\alpha+1}{m}\binom{n+\alpha+1}{n}} B\left(\frac{1}{2}(m+n)+1, \alpha+1\right) \hat{\mathfrak{f}}_{m-n},
\end{aligned}$$

completing the proof. □

If we introduce the expression

$$X_{m,n}^{(\alpha)} = (\alpha+1) \sqrt{\binom{m+\alpha+1}{m}\binom{n+\alpha+1}{n}} B\left(\frac{1}{2}(m+n)+1, \alpha+1\right), \tag{13}$$

this last identity reads as

$$\langle e_m^{(\alpha)}, B_{\mathfrak{f}}^{(\alpha)} e_n^{(\alpha)}\rangle_\alpha = i^{m-n} X_{m,n}^{(\alpha)} \hat{\mathfrak{f}}_{m-n}. \tag{14}$$

Our further results depend on a close analysis of these positive real numbers $X_{m,n}^{(\alpha)}$.

We will now show that the limit $\alpha \to -1$ results in the matrix elements of the (usual) Toeplitz operator of multiplication by $\mathfrak{f}$ on $H^2(\mathbb{T})$. To this end we recall that, if P_+ is the projection operator from $L^2(\mathbb{T})$ to $H^2(\mathbb{T})$, the Toeplitz operator $\mathcal{M}(\mathfrak{f})$ with symbol $\mathfrak{f}$ is the bounded operator on $H^2(\mathbb{T})$ defined by

$$\mathcal{M}(\mathfrak{f})(F) = P_+(\mathfrak{f}F), \quad F \in H^2(\mathbb{T}). \tag{15a}$$

If χ_n is the function in $H^2(\mathbb{T})$ taking values $\chi_n(e^{i\theta}) = i^{-n}e^{in\theta}$, $\theta \in \mathbb{T}$, so that the set of vectors $\{\chi_n : n \geqslant 0\}$ forms an orthonormal basis for $H^2(\mathbb{T})$, we see that

$$\langle \chi_m, \mathcal{M}(\mathfrak{f})\chi_n \rangle = i^{m-n}\hat{\mathfrak{f}}_{m-n}. \tag{15b}$$

The precise connection is the following.

Proposition 3: For $\mathfrak{f} \in L^\infty(\mathbb{T})$ and all $m, n \geqslant 0$,

$$\lim_{\alpha \to -1} \langle e_m^{(\alpha)}, B_{\mathfrak{f}}^{(\alpha)} e_n^{(\alpha)} \rangle_\alpha = \langle \chi_m, \mathcal{M}(\mathfrak{f})\chi_n \rangle. \tag{16}$$

Proof: We rewrite $X_{m,n}^{(\alpha)}$ in a form in which the α-dependence is easier to work with; the expression we obtain will be used further on as well:

$$X_{m,n}^{(\alpha)2} = (\alpha+1)^2 \binom{m+\alpha+1}{m} \binom{n+\alpha+1}{n} B\left(\frac{1}{2}(m+n)+1, \alpha+1\right)^2$$

$$= \frac{\Gamma(m+\alpha+2)\Gamma(n+\alpha+2)\Gamma\left(\frac{1}{2}(m+n)+1\right)^2}{\Gamma(m+1)\Gamma(n+1)\Gamma\left(\frac{1}{2}(m+n)+\alpha+2\right)^2} = \frac{\Xi(m+1,n+1)}{\Xi(m+\alpha+2,n+\alpha+2)},$$

where the function $\Xi(r,s)$ is defined for $r, s \geqslant 1$ by the formula

$$\Xi(r,s) = \frac{\Gamma\left(\frac{1}{2}(r+s)^2\right)^2}{\Gamma(r)\Gamma(s)} = \prod_{k \geqslant 0} \left[1 - \left(\frac{r-s}{r+s+2k}\right)^2\right]$$

(see Gradshteyn and Ryzhik,[10] Sec. 8.325).

It follows from this that $X_{m,n}^{(\alpha)} = X_{n,m}^{(\alpha)}$ for all $m, n \geqslant 0$. Clearly, $X_{m,n}^{(\alpha)}$ is a continuous function of $\alpha \in (-1,\infty)$ for all $m, n \geqslant 0$, and $X_{m,n}^{(-1)} = 1$ for all $m, n \geqslant 0$. Consequently the limit $\alpha \to -1$ can be taken from above, and yields the indicated result. □

The expressions for the matrix elements evidently simplify when α is a positive integer. Further analysis of $X_{m,n}^{(\alpha)}$ allows us to interpolate from the integers. The precise estimate we need is the following.

Lemma 4: For all $m, n \geqslant 0$ and $\alpha \in [-1,\infty)$,

$$1 \geqslant X_{m,n}^{(\alpha)} \geqslant 1 - \frac{1}{2}(\lfloor \alpha \rfloor + 2)\left(\frac{m-n}{m+n+2}\right)^2. \tag{17}$$

Proof: We see that

$$\Xi(m+\alpha+2,n+\alpha+2) = \prod_{k \geqslant 0} \left[1 - \left(\frac{m-n}{m+n+2\alpha+4+2k}\right)^2\right],$$

from which it is clear that $\Xi(m+\alpha+2,n+\alpha+2)$ is an increasing function of $\alpha \in [-1,\infty)$, and hence it follows that $X^{(\alpha)}_{m,n}$ is a decreasing function of $\alpha \in [-1,\infty)$.

Restricting α to the non-negative integers, we obtain

$$X^{(\alpha)^2}_{m,n} = \frac{\Pi_{k\geqslant 0}\left[1-\left(\frac{m-n}{m+n+2+2k}\right)^2\right]}{\Pi_{k\geqslant 0}\left[1-\left(\frac{m-n}{m+n+2\alpha+4+2k}\right)^2\right]} = \frac{\Pi_{k\geqslant 0}\left[1-\left(\frac{m-n}{m+n+2+2k}\right)^2\right]}{\Pi_{k\geqslant \alpha+1}\left[1-\left(\frac{m-n}{m+n+2+2k}\right)^2\right]} = \prod_{k=0}^{\alpha}\left[1-\left(\frac{m-n}{m+n+2+2k}\right)^2\right],$$

and so

$$1\geqslant X^{(\alpha)^2}_{m,n}\geqslant \left[1-\left(\frac{m-n}{m+n+2}\right)^2\right]^{\alpha+1}.$$

As the quantity in braces is less than 1, we can sharpen this ''squeeze'' to

$$1\geqslant X^{(\alpha)}_{m,n}\geqslant 1-\frac{1}{2}(\alpha+1)\left(\frac{m-n}{m+n+2}\right)^2,$$

for all m, $n\geqslant 0$.

Since $X^{(\alpha)}_{m,n}$ is decreasing in α generally, extrapolation to $\alpha \in [-1,\infty)$ is immediate, and yields the estimate asserted in the lemma. □

Setting $m=n$ we see that $X^{(\alpha)}_{n,n}=1$, from which we obtain the expectation of the angle operator $B^{(\alpha)}_{\mathfrak{f}}$ in the state $e^{(\alpha)}_n$, and observe that it is identical to the expectation of the Toeplitz operator $\mathcal{M}(\mathfrak{f})$ in the state χ_n. That is, we have the following.

Proposition 5: For all $\mathfrak{f}\in L^\infty(\mathbb{T})$ and $n\geqslant 0$,

$$\mathfrak{Exp}[e^{(\alpha)}_n;B^{(\alpha)}_{\mathfrak{f}}]=\langle e^{(\alpha)}_n,B^{(\alpha)}_{\mathfrak{f}},e^{(\alpha)}_n\rangle=X^{(\alpha)}_{n,n}=\hat{\mathfrak{f}}_0=\mathfrak{Exp}[\chi_n;\mathcal{M}(\mathfrak{f})]. \tag{18}$$

The general form of the variance of $B^{(\alpha)}_{\mathfrak{f}}$ in the state $e^{(\alpha)}_n$ is as a series:

$$\mathfrak{Var}[e^{(\alpha)}_n;B^{(\alpha)}_{\mathfrak{f}}]=\mathfrak{Exp}[e^{(\alpha)}_n;B^{(\alpha)^2}_{\mathfrak{f}}]-\mathfrak{Exp}[e^{(\alpha)}_n;B^{(\alpha)}_{\mathfrak{f}}]^2 \tag{19a}$$

$$=\sum_{m\geqslant 0}|\hat{\mathfrak{f}}_{m-n}|^2X^{(\alpha)^2}_{m,n}-|\hat{\mathfrak{f}}_0|^2. \tag{19b}$$

Things become more tractable if we compare this with the variance for the corresponding Toeplitz operator. Indeed, the comparison allows us to obtain an asymptotic form for the difference.

Proposition 6: For all $\mathfrak{f}\in C^1[-\pi,\pi]$ and $n\geqslant 0$,

$$\mathfrak{Var}[\chi_n;\mathcal{M}(\mathfrak{f})]-\mathfrak{Var}[e^{(\alpha)}_n;B^{(\alpha)}_{\mathfrak{f}}]=O(1/n),\quad n\to\infty. \tag{20}$$

Proof: Starting from the known result, cf. Dubin *et al.*,[6]

$$\mathfrak{Var}[\chi_n;\mathcal{M}(\mathfrak{f})]=\sum_{m\geqslant 0}|\hat{\mathfrak{f}}_{m-n}|^2,$$

the expression

$$\begin{aligned}0&\geqslant\mathfrak{Var}[\chi_n;\mathcal{M}(\mathfrak{f})]-\mathfrak{Var}[e_n^{(\alpha)};B_{\mathfrak{f}}^{(\alpha)}]\\&=\sum_{m\geqslant 0}|\hat{\mathfrak{f}}_{m-n}|^2(1-X_{m,n}^{(\alpha)})^2\\&\geqslant\frac{1}{2}(\lfloor\alpha\rfloor+2)\sum_{m\geqslant 0}\left(\frac{(m-n)}{m+n+2}\right)^2|\hat{\mathfrak{f}}_{m-n}|^2.\end{aligned}$$

(for any $n\geqslant 0$) follows from our two-sided bound on $X_{m,n}^{(\alpha)}$.

At this point we use the assumption that $\mathfrak{f}\in C^1[-\pi,\pi]$, from which standard calculations then show the existence of a constant $K(\mathfrak{f})>0$ such that

$$|k\hat{\mathfrak{f}}_k|\geqslant K(\mathfrak{f}),\quad k\in\mathbb{Z}.$$

This implies that

$$0\leqslant\mathfrak{Var}[\chi_n;\mathcal{M}(\mathfrak{f})^2]-\mathfrak{Var}[e_n^{(\alpha)};B_{\mathfrak{f}}^{(\alpha)^2}]\geqslant\frac{1}{2}(\lfloor\alpha\rfloor+2)k(\mathfrak{f})^2\sum_{m\geqslant n+2}m^{-2}\leqslant\lfloor\alpha\rfloor+2K(\mathfrak{f})^2/2(n+1),$$

for all $n\geqslant 0$. As the right hand side is $O(1/n)$, the proof is complete.

Now we are in a position to use known results for the Toeplitz operators to obtain the asymptotic forms for $B_{\varphi}^{(\alpha)}$, $B_C^{(\alpha)}$ and $B_S^{(\alpha)}$, where $C(e^{i\theta})=\cos\theta$ and $S(e^{i\theta})=\sin\theta$. The latter two operators are preferred to the exponentials because they are (bounded) Hermitian. (Cf. Dubin *et al.*[6] for the relevant Toeplitz asymptotics.) □

Proposition 7: For the expectation and variance of $B_{\varphi}^{(\alpha)}$,

$$\mathfrak{Exp}[e_n^{(\alpha)};B_{\varphi}^{(\alpha)}]=0,\quad n\geqslant 0,\tag{21a}$$

$$\mathfrak{Var}[e_n^{(\alpha)};B_{\varphi}^{(\alpha)}]=\pi^2/3+O(1/n),\quad n\to\infty.\tag{21b}$$

For the trigonometric angle operators,

$$\mathfrak{Exp}[e_n^{(\alpha)};B_C^{(\alpha)}]=\mathfrak{Exp}[e_n^{(\alpha)};B_S^{(\alpha)}]=0,\quad n\geqslant 0,\tag{22a}$$

$$\mathfrak{Var}[e_n^{(\alpha)};B_C^{(\alpha)}]=\mathfrak{Var}[e_n^{(\alpha)};B_S^{(\alpha)}]=1/2+O(1/n^2),\tag{22b}$$

as $n\to\infty$. Taking the limit

$$\lim_{n\to\infty}\mathfrak{Var}[e_n^{(\alpha)};B_{\varphi}^{(\alpha)}]=\pi^2/3,\tag{23}$$

$$\lim_{n\to\infty}\mathfrak{Var}[e_n^{(\alpha)};B_C^{(\alpha)}]=\lim_{n\to\infty}\mathfrak{Var}[e_n^{(\alpha)};B_S^{(\alpha)}]=1/2.\tag{24}$$

The sharpening of the order from $O(1/n)$ to $O(1/n^2)$ results from the fact that C and S have only a finite number of nonzero Fourier coefficients—we omit the details.

These limiting results for $n\to\infty$ are in accord with the feeling of many physicists concerning the distribution law phase operators should obey in the ''classical'' limit, here represented by $n\to\infty$. For a discussion of this point, see Dubin *et al.*[6]

V. ANGLE OPERATORS AND BERGMAN COHERENT STATES

In all of the Hilbert spaces on which the various angle operators (of quantum phase) act, there are distinguished states known as *coherent*. These states characteristically act as classically as the laws of quantum mechanics permit. For example, the coherent states in the Schrödinger representation, they are states of minimal uncertainty (in position and momentum).

We will not need the general theory, and refer the reader to the excellent review of Ali, Antoine, Gazeau, and Mueller,[11] for a mathematical account. It suffices for our purposes simply to define the coherent states for $\mathcal{H}_\alpha$ as

$$\Psi_\zeta^{(\alpha)} = e^{-|\zeta|^2/2} \sum_{n\geqslant 0} \overline{\zeta^n} e_n^{(\alpha)} / \sqrt{n!}. \tag{25}$$

Here $\zeta \in \mathbb{C}$ is a parameter labelling the family of coherent states.

This family forms a weak overcomplete decomposition of the identity in the sense that, for all $f,g \in \mathcal{H}_\alpha$,

$$\int_{\mathbb{C}} \langle g, \Psi_\zeta^{(\alpha)} \rangle_\alpha \langle \Psi_\zeta^{(\alpha)}, f \rangle_\alpha dA(\zeta) = \langle g, f \rangle_\alpha . \tag{26}$$

The ''classical'' region for these coherent states is obtained from restricting ζ by $\zeta = -iR/\sqrt{2}$ and taking R large. For this choice of ζ we simplify the notation by writing $\Psi^{(\alpha,R)}$ for the vector in question, in which case

$$\Psi^{(\alpha,R)} = e^{-R^2/4} \sum_{n\geqslant 0} i^n R^n e_n^{(\alpha)} / \sqrt{2^n n!}. \tag{27}$$

By substituting our result for the matrix elements with respect to the $e_n^{(\alpha)}$, we obtain the expectation of Bergman angle operators with respect to these states.

Proposition 8: For $\mathfrak{f} \in L^\infty(\mathbb{T})$ and $R>0$,

$$\begin{aligned} \mathfrak{Expt}[\Psi^{(\alpha,R)}; B_\mathfrak{f}^{(\alpha)}] &= e^{-R^2/2} \sum_{m,n\geqslant 0} i^{n-m} R^{n+m} \langle e_m^{(\alpha)}, B_\mathfrak{f}^{(\alpha)} e_n^{(\alpha)} \rangle_\alpha / \sqrt{2^{m+n} m! n!} \\ &= e^{-R^2/2} \sum_{m,n\geqslant 0} R^{m+n} X_{m,n}^{(\alpha)} \hat{\mathfrak{f}}_{m-n} / \sqrt{2^{m+n} m! n!}. \end{aligned} \tag{28}$$

If $\mathfrak{f}$ is odd on $[-\pi, \pi]$, this expectation is zero, and so, in particular,

$$\mathfrak{Expt}[\Psi^{(\alpha,R)}; B_\varphi^{(\alpha)}] = 0. \tag{29}$$

Considering only $B_\varphi^{(\alpha)}$, its variance in these states reduces to

$$\mathfrak{Var}[\Psi^{(\alpha,R)}; B_\varphi^{(\alpha)}] = \| B_\varphi^{(\alpha)} \Psi^{(\alpha,R)} \|_\alpha^2. \tag{30}$$

This can be written as a series with terms containing the $X_{m,n}^{(\alpha)}$, but that is not very illuminating. More information is obtained from the large R asymptotic expression, but we will not attempt to compute this directly. Instead, we shall carry over a technique used in Dubin *et al.*[6] to obtain asymptotics for Toeplitz operators with respect to the coherent states on $H^2(\mathbb{T})$.

The first step is to note that the variance is smaller than the expression

$$\| \varphi \cdot \Psi^{(\alpha,R)} \|_\alpha^2 = \langle \Psi^{(\alpha,R)}, B_{|\varphi|^2}^{(\alpha)} \Psi^{(\alpha,R)} \rangle_\alpha = e^{-R^2/2} \sum_{m,n\geqslant 0} R^{m+n} X_{m,n}^{(\alpha)} (|\varphi|^2)\hat{}_{m-n} / \sqrt{2^{m+n} m! n!}.$$

This can be successfully compared to the quantity

$$\Phi(R)=e^{-R^2/2}\sum_{m,n\geqslant 0} R^{m+n}(|\Phi|^2)^{\wedge}_{m-n}/\sqrt{2^{m+n}m!n!}, \tag{31}$$

which is the expectation of the Toeplitz operator with symbol $\mathfrak{p}^2(e^{i\theta})=\theta^2$ with respect to a certain Hardy space coherent state, the details of which will not be needed here.

The asymptotic form for $\Phi(R)$ is[6]

$$\Phi(R)=1/(2R^2)+O(1/R^3). \tag{32}$$

The result is the following.

Proposition 9: The estimate

$$|\Phi(R)-\|\varphi\cdot\Psi^{(\alpha,R)}\|_\alpha^2|\leqslant C/R, \tag{33}$$

holds for some constant C. Hence

$$\mathfrak{Var}[\Psi^{(\alpha,R)};B_\varphi^{(\alpha)}]=O(1/R),\ \text{ as }\ R\to\infty. \tag{34}$$

From our work with Toeplitz operators, we expect that this result could be sharpened to the asymptotic order $O(R^{-2})$.

Proof: Using our estimate for $X_{m,n}^{(\alpha)}$,

$$\begin{aligned}|\Phi(R)-\|\varphi\cdot\Psi^{(\alpha,R)}\|_\alpha^2|&\leqslant e^{-R^2/2}\sum_{m,n\geqslant 0} R^{m+n}(1-X_{m,n}^{(\alpha)})|(|\varphi|^2)^{\wedge}_{m-n}|/\sqrt{2^{m+n}m!n!}\\ &\leqslant\frac{1}{2}(\lfloor\alpha\rfloor+2)e^{-R^2/2}\sum_{m,n\geqslant 0} R^{m+n}\left(\frac{m-n}{m+n+2}\right)^2|(|\varphi|^2)^{\wedge}_{m-n}|/\sqrt{2^{m+n}m!n!}.\end{aligned}$$

The Fourier coefficients of the function $\mathfrak{p}^2(e^{i\theta})=\theta^2$ are

$$(\mathfrak{p}^2)\hat{}_k=\begin{cases}2(-1)^k/k^2, & k\neq 0,\\ \pi^2/3, & k=0.\end{cases}$$

Substituting this back, then applying some manipulations to the result,

$$\begin{aligned}|\Phi(R)-\|\varphi\cdot\Psi^{(\alpha,R)}\|_\alpha^2&\leqslant(\lfloor\alpha\rfloor+2)e^{-R^2/2}\sum_{m\neq n}\frac{R^{m+n}}{\sqrt{2^{m+n}m!n!}}\frac{1}{(m+n+2)^2}\\ &\leqslant(\lfloor\alpha\rfloor+2)e^{-R^2/2}\sum_{m\neq n}\frac{R^{m+n}}{\sqrt{2^{m+n}m!(n+1)!}}\frac{1}{(m+n+2)^{3/2}}\\ &\leqslant(\lfloor\alpha\rfloor+2)e^{-R^2/2}\left(\sum_{m\neq n}\frac{R^{2(m+n)}}{2^{m+n}m!(n+1)!}\right)^{1/2}\left(\sum_{m\neq n}\frac{1}{(m+n+2)^3}\right)^{1/2}\leqslant C/R,\end{aligned}$$

for some constant C. With the asymptotic form for $\Phi(R)$ given above, the variance is seen to be as asserted. □

VI. SUMMARY

The angle operators $B_{\mathfrak{f}}^{(\alpha)}$, and in particular $B_\varphi^{(\alpha)}$, $B_{e^{\pm i\varphi}}^{(\alpha)}$, play the same role in relation to quantum phase theory for $\mathcal{H}_\alpha$ as do the Toeplitz and Bargmann–Segal operators do on their respective Hilbert spaces. The connection to physics relies on the fact that these Hilbert spaces carry (unitarily equivalent) irreducible and gauge invariant representations of the canonical commutation relation for one degree of freedom. The asymptotic variance of the operators with

symbol φ in the natural basis all have the limit $\pi^2/3$. Whether or not this is a convincing argument for the relevance of these operators for the quantum phase is left to the reader to decide: it is often taken so.

There are a number of mathematical questions left unanswered by this work. First, there is the technical question of sharpening the asymptotic order of the variance for $B_{\varphi}^{(\alpha)}$ for the coherent state family. Next, we have not considered all the families of states usually taken to be interesting for the quantum phase. Notably, we have omitted the family

$$\xi_{s;\beta}^{(\alpha)}=\frac{1}{\sqrt{s+1}}\sum_{n=0}^{s} e^{in\beta}e_n^{(\alpha)}, \tag{35}$$

which span the $s+1$-dimensional subspace of $\mathcal{H}_\alpha$ with the alternate basis $\{e^{(\alpha)},\ldots,e_s^{(\alpha)}\}$. Since

$$e^{-i\gamma N}\xi_{s;\beta}^{(\alpha)}=\xi_{s;\beta+\gamma}^{(\alpha)},$$

these states can be interpreted as being uniformly distributed over gauge—though some physicists identify gauge with quantum phase, which we do not believe to be justified. As all sums are finite, there is no particular difficulty in filling this gap in our asymptotic analysis.

There is the question of finding an explicit form for the raising and lowering operators acting on $\mathcal{H}_\alpha$. This is not essential for the quantum phase, but it would be useful to know nonetheless.

Most worrying is that we have no results at all for the spectrum of the $B_{\mathrm{f}}^{(\alpha)}$. This is a problem for Toeplitz–Bergman operators with symbols which do not happen to be special, e.g., harmonic, and any spectral results would be of interest to pure mathematicians as well.

(Received 17 January 2001; accepted for publication 15 October 2001)

This article introduces a concept of subharmonic projections for a quantum Markov semigroup, in view of characterizing the support projection of a stationary state in terms of the semigroup generator. These results, together with those of our previous article [J. Math. Phys. **42**, 1296 (2001)], lead to a method for proving the existence of *faithful stationary states*. This is often crucial in the analysis of ergodic properties of quantum Markov semigroups. The method is illustrated by applications to physical models. © *2002 American Institute of Physics.*

I. INTRODUCTION

This article continues the investigation on normal stationary states initiated in Ref. 1. Our main goal is to characterize the support projection of a stationary state under the action of a quantum Markov semigroup. This is an important problem in several respects, which is solved here for the first time, in terms of the semigroup generator.

The qualitative analysis of a quantum dynamics usually enquiries whether the evolution eventually goes in the steady state regime. This is information primarily carried by the support projection of a stationary state.

We recall that a normal state ω is called *faithful* if $\omega(a)=0$, for a positive a, implies that $a=0$. In this case its support projection coincides with the identity. The existence of a normal faithful stationary state is often assumed as a crucial hypothesis in the analysis of the ergodic behavior of a quantum Markov semigroup (see, e.g., Refs. 2–4).

The support of a normal stationary state here is characterized through subharmonic projections (see Definition II.1). This name is borrowed from potential and classical Markov processes theories (see Refs. 5 and 6). In the latter, the absence of nontrivial subharmonic projections is equivalent to the concept of *irreducibility*, which roughly means that the dynamics cannot end up eventually in a smaller subspace. In this article (see Corollary III.1 and the related discussion), we compare this notion with its operator-algebraic counterpart (see Refs. 7 and 8).

The article is organized as follows. The next section characterizes the support projection of a stationary state on a semi-finite von Neumann algebra. Then we analyze subharmonic projections for semigroups on the algebra of all linear bounded operators on a given Hilbert space. This is further specialized to a class of quantum Markov semigroups with unbounded infinitesimal generators of Lindblad type. The main result (Theorem III.1) shows that, in this case, the support projection of a stationary state determines an invariant subspace for the coefficient operators of the infinitesimal generator. A full description of invariant subspaces for a family of operators, on an infinite dimensional space, is usually a hard mathematical problem (see Ref. 9). However, this article also provides some useful tools (Theorems IV.1 and IV.2) for actually solving this problem. The last section is devoted to physical applications[10,11] illustrating our method.

II. THE SUPPORT OF A STATIONARY STATE

Let there be given a semifinite von Neumann algebra $\mathfrak{A}$ of operators over a complex separable Hilbert space $\mathfrak{h}$, endowed with a trace $\mathrm{tr}(\cdot)$ and a unit $\mathbf{1}$. A quantum Markov semigroup (QMS) $\mathcal{T}=(\mathcal{T}_t)_{t\geqslant 0}$ on $\mathfrak{A}$ is a w^*-continuous semigroup of normal, completely positive maps preserving $\mathbf{1}$. Its generator is the operator $\mathcal{L}$ whose domain $D(\mathcal{L})$ is the vector space of all elements $a\in\mathfrak{A}$ for which the w^*-limit of $t^{-1}(\mathcal{T}_t(a)-a)$ exists. For $a\in D(\mathcal{L})$, $\mathcal{L}(a)$ is defined as the limit above.

Throughout this article we will be concerned only with normal states; moreover, we will often identify such states with their density matrices. The *support projection* of a state ρ is the orthogonal projection over the closure of its range. An *invariant (or stationary) state* ρ is characterized through the equation $\mathrm{tr}(\rho\mathcal{T}_t(a))=\mathrm{tr}(\rho a)=\mathrm{tr}(\mathcal{T}_{*t}(\rho)a)$ for any $a\in\mathfrak{A}$, $t\geqslant 0$, where $\mathcal{T}_*$ denotes the predual semigroup.

Definition II.1: A positive operator $a\in\mathfrak{A}$ is subharmonic (resp. superharmonic, resp. harmonic*) for the semigroup if $\mathcal{T}_t(a)\geqslant a$* (resp. $\mathcal{T}_t(a)\leqslant a$, resp $\mathcal{T}_t(a)=a$), *for all $t\geqslant 0$.*

Subharmonic functions play a fundamental role in the potential theory of classical Markov semigroups (see, for instance, Ref. 5). They allow us to establish useful criteria for deciding whether the dynamics scatters or eventually remains in a bounded region. In our framework, we will start by showing a relation between invariant states and subharmonic projections.

Theorem II.1: *The support projection of a normal stationary state for a quantum Markov semigroup is subharmonic.*

This theorem has important consequences like the following proposition.

Proposition II.1: For any quantum Markov semigroup $\mathcal{T}$ the following are equivalent:

(a) *p is subharmonic for $\mathcal{T}_t(\cdot)$, for any $t\geqslant 0$,*
(b) *the subalgebra $p^\perp\mathfrak{A}p^\perp$ is invariant under $\mathcal{T}_t(\cdot)$, for all $t\geqslant 0$, and*
(c) *for any normal state ρ such that $p\rho p=\rho$, we have $\mathrm{tr}(\rho\mathcal{T}_t(p^\perp))=0$, for all $t\geqslant 0$.*

Postponing the proof, we introduce a definition motivated by this result.

Definition II.2: We say that a quantum Markov semigroup is irreducible if there is no nontrivial subharmonic projection.

This notion will be compared with that of *topological irreducibility* (see Ref. 7, Definition 2.3.7) in the next section.

We now proceed to the proofs, starting with a lemma of frequent use in this article.

Lemma II.1: Let p be a projection of the von Neumann algebra $\mathfrak{A}$, and $x\in\mathfrak{A}$ a positive element. If $pxp=0$, then $p^\perp xp=pxp^\perp=0$.

Proof: Suppose $\mathfrak{A}\subseteq\mathcal{B}(\mathfrak{h})$ and let $u,v\in\mathfrak{h}$ with $pu=u$, $pv=0$. Since x is positive, $\langle zu+v,x(zu+v)\rangle=2\Re(z\langle v,xu\rangle)+\langle v,xv\rangle$ is positive for every $z\in\mathbb{C}$. Therefore $\langle v,xu\rangle$ must vanish and the conclusion readily follows. □

Proof (of Theorem II.1): Let p be the support projection of a normal stationary state ρ of $(\mathcal{T}_t)_{t\geqslant 0}$. Thus $\rho p=p\rho=\rho$. Fix $t\geqslant 0$. We first notice that $p\mathcal{T}_t(p)p\leqslant p$, since $p\leqslant\mathbf{1}$. Therefore, $\mathrm{tr}(\rho(p-p\mathcal{T}_t(p)p))=\mathrm{tr}(\rho(p-\mathcal{T}_t(p)))=0$, and, since ρ is faithful on the subalgebra $p\mathfrak{A}p$, it follows

$$p\mathcal{T}_t(p)p=p. \tag{1}$$

On the other hand, $p\mathcal{T}_t(p^\perp)p=p\mathcal{T}_t(\mathbf{1})p-p\mathcal{T}_t(p)p=p-p=0$. Thus, since $\mathcal{T}_t(p^\perp)$ is positive and $\mathcal{T}_t(p)=\mathbf{1}-\mathcal{T}_t(p^\perp)$, Lemma II.1 yields $p\mathcal{T}_t(p^\perp)p^\perp=0=p^\perp\mathcal{T}_t(p^\perp)p$. This identity, together with (1), lead to $\mathcal{T}_t(p)=p+p^\perp\mathcal{T}_t(p)p^\perp$, showing that p is subharmonic. □

Proof (of Proposition II.1): Assume that condition (a) holds. Then (1) yields $p\mathcal{T}_t(p^\perp)p=p\mathcal{T}_t(\mathbf{1})p-p\mathcal{T}_t(p)p=0$. Therefore, for any positive $x\in p^\perp\mathfrak{A}p^\perp$ it follows $p\mathcal{T}_t(x)p=0$ since $0\leqslant p\mathcal{T}_t(x)p\leqslant\|x\|p\mathcal{T}_t(p^\perp)p=0$. From Lemma II.1, $p\mathcal{T}_t(x)p^\perp=p^\perp\mathcal{T}_t(x)p=0$, since $\mathcal{T}_t(x)$ is positive. Thus $\mathcal{T}_t(x)=p^\perp\mathcal{T}_t(x)p^\perp\in p^\perp\mathfrak{A}p^\perp$. The same conclusion holds for any arbitrary $x\in p^\perp\mathfrak{A}p^\perp$ since it is a linear combination of four positive elements of $p^\perp\mathfrak{A}p^\perp$.

We now prove that (b) implies (c). By hypothesis, for any $x\in p^\perp\mathfrak{A}p^\perp$, it holds $\mathcal{T}_t(x)=p^\perp yp^\perp$ for some $y\in\mathfrak{A}$. Clearly, the above equality yields $y=\mathcal{T}_t(x)$ since $\langle v,\mathcal{T}_t(x)u\rangle=\langle v,yu\rangle$

for all vectors u and v belonging to the range of $p^\perp$. Therefore, $\mathcal{T}_t(x)=p^\perp\mathcal{T}_t(x)p^\perp$. In particular, $\mathcal{T}_t(p^\perp)=p^\perp\mathcal{T}_t(p^\perp)p^\perp$. Hence, given a state ρ such that $p\rho=\rho p=\rho$, we have $p^\perp\rho=\rho p^\perp=0$ which yields $\mathrm{tr}(\rho\mathcal{T}_t(p^\perp))=0$.

Finally, (c) implies (a). From (c) we obtain $\mathrm{tr}(\rho p\mathcal{T}_t(p^\perp)p)=0$, thus $p\mathcal{T}_t(p^\perp)p=0$. As a result, by Lemma II.1, $\mathcal{T}_t(p^\perp)=p^\perp\mathcal{T}_t(p^\perp)p^\perp\leqslant p^\perp$, which gives $\mathcal{T}_t(p)=\mathcal{T}_t(\mathbf{1}-p^\perp)\geqslant p$. □

III. SUBHARMONIC PROJECTIONS. THE CASE $\mathfrak{A}=\mathcal{B}(\mathfrak{h})$

We now concentrate on the case $\mathfrak{A}=\mathcal{B}(\mathfrak{h})$. From now on, the QMS is the minimal obtained from an unbounded generator given as a quadratic form (generalizing the representations given by Gorini, Kossakowsky, and Sudharshan,[12] and Lindblad[13] and extended by Davies[14]):

$$\mathfrak{L}(x)[v,u]=\langle Gv,xu\rangle+\sum_{\ell\geqslant 1}\langle L_\ell v,xL_\ell u\rangle+\langle v,xGu\rangle,$$

$(x\in\mathcal{B}(\mathfrak{h}),v,u\in D(G))$, under the following hypotheses:

(1) **(H-min)** The operator G is the generator of a strongly continuous contraction semigroup $(P_t)_{t\geqslant 0}$ on $\mathfrak{h}$. The domain $D(L_\ell)$ of each operator L_ℓ contains the domain $D(G)$ of G and $\mathfrak{L}(\mathbf{1})[v,u]=0$, for all $u,v\in D(G)$.
(2) **(H-Markov)** $\mathcal{T}_t(\mathbf{1})=\mathbf{1}$, for all $t\geqslant 0$.

Thus, for all $x\in\mathcal{B}(\mathfrak{h})$, the quadratic form $\mathfrak{L}(x)$ is defined over the domain $D(G)\times D(G)$.

The main result of this section is the following characterization of subharmonic projections.

Theorem III.1: *Assume* **(H-min)** *and* **(H-Markov)**. *A projection p is subharmonic for $\mathcal{T}$ if and only if the range $R(p)$ of p is invariant for the operators P_t $(t\geqslant 0)$ and*

$$L_\ell u=pL_\ell u, \tag{2}$$

for all $u\in D(G)\cap R(p)$, $\ell\geqslant 1$.

If G and the L_ℓ's are bounded, Theorem III.1 says that a projection p is subharmonic if and only if its range $R(p)$ is an invariant subspace for these operators. In the general case, this needs to be handled more carefully as shows the following lemma.

Lemma III.1: Let $(P_t)_{t\geqslant 0}$ be the semigroup generated by G. A closed subspace $R(p)$ is invariant for the operators P_t $(t\geqslant 0)$ if and only if $D(G)\cap R(p)$ is dense in $R(p)$, $(\lambda-G)(D(G)\cap R(p))=R(p)$ for any $\lambda>0$ and $Gu=pGu$ for any $u\in D(G)\cap R(p)$.

Remark: In other words p is invariant for the operators $P_t(t\geqslant 0)$ if and only if the restriction of G to $R(p)$ is the infinitesimal generator of the semigroup $(P_{t|R(p)})_{t\geqslant 0}$ on $R(p)$.

Proof: Suppose first that $R(p)$ is invariant for the operators P_t $(t\geqslant 0)$. Then $R(p)$ is also invariant for the resolvent operators $R(\lambda;G)$ $(\lambda>0)$. Therefore, for each $u\in R(p)$, the vector $u_\lambda=\lambda R(\lambda;G)u$ belongs to $D(G)\cap R(p)$ and, by the well-known properties of the Yosida approximations, u_λ converges to u as λ goes to infinity. Thus $D(G)\cap R(p)$ is dense in $R(p)$. Moreover, for any $u\in D(G)\cap R(p)$ we have $t^{-1}(P_tu-u)=t^{-1}(P_tpu-pu)=pt^{-1}(P_tu-u)$. Therefore, letting $t\to 0$, we obtain $Gu=pGu$.

Finally, since $R(p)=(\lambda-G)R(\lambda;G)R(p)$ and $R(\lambda;G)(R(p))\subseteq D(G)\cap R(p)$,

$$R(p)\subseteq(\lambda-G)(D(G)\cap R(p))=p(\lambda-G)(D(G)\cap R(p))\subseteq R(p).$$

It follows that $(\lambda-G)(D(G)\cap R(p))=R(p)$.

Conversely, since $R(\lambda;G)R(p)=R(\lambda;G)(\lambda-G)(D(G)\cap R(p))=D(G)\cap R(p)$, the closed subspace $R(p)$ is invariant for $R(\lambda;G)$ for any $\lambda>0$. From the equality

$$P_t=\text{strong}-\lim_{n\to\infty}(nt^{-1}R(nt^{-1};G))^n, \tag{3}$$

(Ref. 15, Cor. 5.45, p. 92) it follows that $R(p)$ is P_t-invariant. □

To proceed with the proof of Theorem III.1 we recall some notations and well-known facts on the minimal QMS (see, e.g., Refs. 16, 1, and 17). Under **(H-min)** and **(H-Markov)**, for any $x \in \mathcal{B}(\mathfrak{h})$, $(\mathcal{T}_t(x))_{t\geqslant 0}$ is the unique w^*-continuous family of operators in $\mathfrak{h}$ such that, for all $u,v \in D(G)$, any of the equivalent equations below holds:

$$\langle v,\mathcal{T}_t(x)u\rangle=\langle P_tv,P_tu\rangle+\sum_{\ell\geqslant 1}\int_0^t\langle L_\ell P_{t-s}v,\mathcal{T}_t(x)L_\ell P_{t-s}u\rangle ds, \tag{4}$$

$$\langle v,\mathcal{T}_t(x)u\rangle=\langle v,xu\rangle+\int_0^t\langle v,\pounds(\mathcal{T}_s(x))u\rangle ds. \tag{5}$$

Moreover, the solution to (4) is obtained as the limit of an approximating sequence $(\mathcal{T}^{(n)})_{n\geqslant 0}$ defined recursively by $\mathcal{T}_t^{(0)}(x)=P_t^*xP_t$ and

$$\langle u,\mathcal{T}_t^{(n+1)}(x)u\rangle=\langle P_tu,xP_tu\rangle+\sum_{\ell\geqslant 1}\int_0^t\langle L_\ell P_{t-s}u,\mathcal{T}_t^{(n)}(x)L_\ell P_{t-s}u\rangle ds,$$

for any $x\in\mathcal{B}(\mathfrak{h})$ and $u\in D(G)$. Given a positive element $x\in\mathcal{B}(\mathfrak{h})$ the above sequence is increasing with n and this allows us to define $\mathcal{T}_t(x)=\sup_n\mathcal{T}_t^{(n)}(x)$, which is the well-known *minimal quantum Markov semigroup* (see, for instance, Ref. 16).

Proof (of Theorem III.1): We start assuming that p is subharmonic, thus $\mathcal{T}_t(p)\geqslant p$ for all $t\geqslant 0$. From Eq. (4) we obtain $p^\perp\geqslant\mathcal{T}_t(p^\perp)\geqslant P_t^*p^\perp P_t$. Therefore, for all $u\in R(p)$ it holds $\langle u,P_t^*p^\perp P_tu\rangle=\|p^\perp P_tu\|^2=0$, that is, $p^\perp P_tp=0$. Thus $P_tp=pP_tp$, for all $t\geqslant 0$, i.e., the range $R(p)$ of p is invariant for the operators P_t $(t\geqslant 0)$. In addition, Eq. (5) yields

$$\int_0^t\left(\langle Gu,\mathcal{T}_s(p^\perp)u\rangle+\sum_{\ell\geqslant 1}\langle L_\ell u,\mathcal{T}_s(p^\perp)L_\ell u\rangle+\langle u,\mathcal{T}_s(p^\perp)Gu\rangle\right)ds\leqslant 0,$$

for all $t\geqslant 0$ and all $u\in D(G)\cap R(p)$. As a result, computing the derivative at 0 of the above equation, we obtain $\langle Gu,p^\perp u\rangle+\Sigma_{\ell\geqslant 1}\langle L_\ell u,p^\perp L_\ell u\rangle+\langle u,p^\perp Gu\rangle\leqslant 0$. Now, $pu=u$ implies $p^\perp Gu=0$. The above inequality yields $\Sigma_{\ell\geqslant 1}\|p^\perp L_\ell pu\|^2\leqslant 0$, that is, $p^\perp L_\ell pu=0$ and (2) follows.

Conversely, we assume condition (2). We will prove that p is subharmonic by an induction argument which relays on the sequence $(\mathcal{T}^{(n)})_{n\geqslant 0}$ used in the construction of $\mathcal{T}$. First, p is subharmonic for $\mathcal{T}^{(0)}$ since $\mathcal{T}_t^{(0)}(p^\perp)=P_t^*p^\perp P_t=p^\perp P_t^*p^\perp P_tp^\perp\leqslant p^\perp$. Second, assume that p is subharmonic for $\mathcal{T}^{(n)}$. We prove that it is subharmonic for $\mathcal{T}^{(n+1)}$, too. Indeed, for all $u\in D(G)\cap R(p)$, the definition of $\mathcal{T}^{(n+1)}$ and the induction hypothesis yield

$$\langle u,\mathcal{T}_t^{(n+1)}(p^\perp)u\rangle\leqslant\langle u,P_t^*p^\perp P_tu\rangle+\sum_{\ell\geqslant 1}\int_0^t\langle L_\ell P_{t-s}u,p^\perp L_\ell P_{t-s}u\rangle ds=0,$$

for any $t\geqslant 0$. It follows that $p\mathcal{T}_t^{(n+1)}(p^\perp)p=0$ and Lemma II.1 implies $p^\perp\mathcal{T}_t^{(n+1)}(p^\perp)p=p\mathcal{T}_t^{(n+1)}(p^\perp)p^\perp=0$. Therefore, $\mathcal{T}_t^{(n+1)}(p^\perp)\leqslant p^\perp$, for all $t\geqslant 0$ and p is subharmonic for $\mathcal{T}^{(n)}$. Hence, p is subharmonic for the minimal semigroup $\mathcal{T}$ and the proof is complete. □

In what follows, given a set $\mathfrak{M}$ of bounded operators on $\mathfrak{h}$, we denote $\mathfrak{M}'$ the commutator algebra. We recall that $\mathfrak{M}$ is called *topologically irreducible* if $\mathfrak{M}'=\mathbb{C}\mathbf{1}$ (see Ref. 7, Definition 2.3.7). This is equivalent to saying that the only closed subspaces of $\mathfrak{h}$ which are invariant under the action of $\mathcal{M}$ are the trivial subspaces $\{0\}$ and $\mathfrak{h}$.

If G and the L_ℓ's are bounded operators, Theorem III.1 implies that *$\mathcal{T}$ is irreducible if and only if $\{G,L_\ell;\ell\geqslant 1\}$ is topologically irreducible.* If G and the L_ℓ's satisfy only **(H-min)**, we can prove the following:

Corollary III.1: Assume that **(H-min)** and **(H-Markov)** *hold and denote by $\mathcal{T}$ the related minimal quantum Markov semigroup. Let*

$$\mathfrak{M}=\{L_\ell\in\mathcal{B}(\mathfrak{h}):\ell\geqslant 1,\exists m\geqslant 1 s.t. L_m=L_\ell^*\}.$$

Then every subharmonic projection belongs to $\mathfrak{M}'$.

If $\mathfrak{M}$ *is topologically irreducible, then* $\mathcal{T}$ *is an irreducible semigroup.*

Moreover, if $\mathcal{T}$ *admits a normal stationary state* ρ*, then* ρ *is the unique normal faithful stationary state and* $\mathcal{T}_{*t}(\sigma)$ *converges in trace-norm to* ρ *as* t *goes to* ∞*, for any normal state* σ.

Proof: Let p be a subharmonic projection. Clearly, by (2) p satisfies $L_\ell p=pL_\ell p$, for all $L_\ell\in\mathfrak{M}$. In addition, if $L_{m*}=L_\ell$, then $pL_\ell=(L_\ell^* p^*)^*=(L_m p)^*=(pL_m p)^*=pL_\ell p=L_\ell p$. This shows that $p\in\mathfrak{M}'$. In particular, if $\mathfrak{M}'$ is trivial, then the semigroup is irreducible.

If $\mathcal{T}$ has a normal stationary state ρ, then Theorems III.1 and II.1 imply that its support projection coincides with the identity, so that this state is faithful.

Now, given any normal state σ, $\mathcal{T}_{*t}(\sigma)$ satisfies $\mathrm{tr}(\mathcal{T}_{*t}(\sigma)x)\to\mathrm{tr}(\rho x)$, by Theorem 2.1 in Ref. 4. Suppose that ρ_0 is another normal stationary state. Then $\mathrm{tr}(\rho_0 x)=\mathrm{tr}(\mathcal{T}_{*t}(\rho_0)x)\to\mathrm{tr}(\rho x)$, for all $x\in\mathcal{B}(\mathfrak{h})$. Then $\rho_0=\rho$.

Finally, notice that for each $t\geqslant 0$ both $\mathcal{T}_{*t}(\sigma)$ and ρ have unit trace norm. This fact, together with the weak convergence of the family $(\mathcal{T}_{*t}(\sigma))_{t\geqslant 0}$, finally implies its trace-norm convergence towards ρ. □

IV. INVARIANT SUBSPACES

The problem of finding *all* the invariant subspaces for a given bounded operator on an infinite dimensional Hilbert space is far from being simple (see, e.g., Ref. 9). Therefore, it is so far unclear how (2) will actually be useful for an unbounded L_ℓ. To overcome this difficulty, we start from the operators P_t and prove that any subharmonic projection is invariant also for semigroups generated by suitable perturbations of G by means of the L_ℓ's.

The first theorem is inspired by Theorem 3.2, on p. 81 of Ref. 15.

Theorem IV.1: *Let* G *be the generator of the strongly continuous contraction semigroup* P *and let* B *an operator on* $\mathfrak{h}$ *such that*

(i) $D(B)\supseteq D(G)$,
(ii) $\|Bu\|\leqslant\alpha\|Gu\|+\beta\|u\|$, *for* $u\in D(G)$, *with* $0\leqslant\alpha<1$ *and* $\beta\geqslant 0$, *and*
(iii) $G+rB$ *is dissipative for each* $r\in[0,1]$.

Then, $G+rB$ *generates a strongly continuous contraction semigroup* $P^{(r)}$.

Moreover, if the range $R(p)$ *of a projection* p *is invariant for the operators* P_t *and* $B(D(G)\cap R(p))\subseteq R(p)$*, then* $R(p)$ *is also invariant for the operators* $P_t^{(r)}$*, for each* $r\in[0,1]$.

Proof: We prove that there exists a $\delta>0$, depending only on α and β, such that if $G+r_0B$ is maximal dissipative (hence its generates a strongly continuous contraction semigroup by the Lumer–Phillips' theorem) and $R(p)$ is invariant for the operators $P_t^{(r_0)}$, then the same conclusion holds for $G+rB$ for $r\in[r_0-\delta,r_0+\delta]\cap[0,1]$. The result follows since every point of $[0,1]$ can be reached from 0 in a finite number of steps of length δ.

Since $G+r_0B$ is maximal dissipative, then $\lambda\mathbf{1}-(G+r_0B)$ is invertible for every $\lambda\geqslant 1$ and its inverse $I(\lambda,r_0)$ satisfies $\|I(\lambda,r_0)\|\leqslant\lambda^{-1}$. The inequality (ii) allows us to show that $BI(\lambda,r_0)$ is a bounded operator. Indeed, for $u\in D(G)$ we have

$$\|Bu\|\leqslant\alpha\|(G+r_0B)u\|+\alpha r_0\|Bu\|+\beta\|u\|\leqslant\alpha\|(G+r_0B)u\|+\alpha\|Bu\|+\beta\|u\|.$$

It follows that $\|Bu\|\leqslant\alpha(1-\alpha)^{-1}\|(G+r_0B)u\|+\beta(1-\alpha)^{-1}\|u\|$. Moreover, since $I(\lambda,r_0):\mathfrak{h}\to D(G)$ and satisfies $(G+r_0B)I(\lambda,r_0)=\lambda I(\lambda,r_0)-\mathbf{1}$, the above inequality implies

$$\|BI(\lambda,r_0)u\|\leqslant\frac{\alpha}{1-\alpha}\|(\lambda I(\lambda,r_0)-\mathbf{1})u\|+\frac{\beta}{1-\alpha}\|I(\lambda,r_0)u\|\leqslant\frac{2\alpha+\beta}{1-\alpha}\|u\|,$$

for all $u\in D(G)$. Therefore $BI(\lambda,r_0)$ $(\lambda\geqslant 1)$ is bounded.

Let $\delta=(1-\alpha)(4\alpha+2\beta)^{-1}$. We show now that, for every $r\in[r_0-\delta,r_0+\delta]\cap[0,1]$, $G+r_0B$ is maximal dissipative by proving that it is invertible so that its range is all of $\mathfrak{h}$. The identity $\lambda\mathbf{1}-(G+rB)=\lambda\mathbf{1}-(G+r_0B)+(r_0-r)B=(\mathbf{1}+(r_0-r)BI(\lambda,r_0))(\lambda\mathbf{1}-(G+r_0B))$ shows that $\lambda\mathbf{1}-(G+rB)$ is invertible if and only if $\mathbf{1}+(r_0-r)BI(\lambda,r_0)$ is invertible. But this operator is indeed invertible for all r such that $\|r-r_0\|<(1-\alpha)(2\alpha+\beta)^{-1}\leqslant\|BI(\lambda,r_0)\|^{-1}$ and its inverse is given by the von Neumann series

$$(\mathbf{1}+(r_0-r)BI(\lambda,r_0))^{-1}=\sum_{n\geqslant 0}(r-r_0)^nBI(\lambda,r_0)^n. \tag{6}$$

This shows that $G+rB$ is maximal dissipative and

$$(\lambda\mathbf{1}-(G+rB))^{-1}=(\lambda\mathbf{1}-(G+r_0B))^{-1}(\mathbf{1}+(r_0-r)BI(\lambda,r_0))^{-1}. \tag{7}$$

If $R(p)$ is invariant for the semigroup generated by $G+r_0B$ and $B(D(G)\cap R(p))\subseteq R(p)$, then $BI(\lambda,r_0)(R(p))\subseteq B(D(G)\cap R(p))\subseteq R(p)$. Therefore, by (6), $R(p)$ is invariant also for $(\mathbf{1}+(r_0-r)BI(\lambda,r_0))^{-1}$. It follows then from (7) that $R(p)$ is invariant also under the resolvent $(\lambda\mathbf{1}-(G+rB))^{-1}$. Finally, the approximation (3) shows that $R(p)$ is invariant also for the operators $P_t^{(r)}$. □

Invariant subspaces are also stable under appropriate multiplicative perturbations of G.

Theorem IV.2: *Let G be the generator of the strongly continuous contraction semigroup P and let $R(p)$ be an invariant subspace under the operators P_t. Let $B\in\mathcal{B}(\mathfrak{h})$ such that*

(i) *the domain of G is invariant under both B and B^*,*
(ii) *the closure of B^*GB generates a strongly continuous contraction semigroup P^B, and*
(iii) *$R(p)$ is an invariant subspace for both B and B^*.*

Then $R(p)$ is an invariant subspace for the operators P_t^B.

Remark: Notice that B^*GB is dissipative, hence it is closable (see, e.g., Ref. 7, Prop. 3.1.15). Moreover, its closure is dissipative, too, therefore the hypothesis (ii) is equivalent to require that B^*GB is maximal dissipative by the Lumer–Phillips theorem.

Proof: We first assume that G is bounded. In this case, for every $\lambda>\|B^*GB\|$, we have

$$(\lambda\mathbf{1}-B^*GB)^{-1}=\sum_{n\geqslant 0}\lambda^{-(n+1)}(B^*GB)^n.$$

It follows then from (iii) that $R(p)$ is invariant under $(\lambda\mathbf{1}-B^*GB)^{-1}$ and, by the approximation (3), we obtain that $R(p)$ is invariant under all the operators P_t^B.

In the general case, with G unbounded, for every $\lambda>0$, let $G^\lambda=\lambda G(\lambda\mathbf{1}-G)^{-1}$. The subspace $R(p)$ is invariant under G^λ, thus, by the first part of the proof, it is also invariant under the operators $P_t^{B,\lambda}$ of the semigroup generated by $B^*G^\lambda B$.

Clearly, for each $u\in D(B^*GB)$ we have $B^*GBu=\lim_{\lambda\to\infty}B^*G^\lambda Bu$, and $D(B^*GB)$ is a core for the closure of B^*GB, i.e., $(\eta\mathbf{1}-B^*GB)(D(B^*GB))$ is dense in $\mathfrak{h}$ for any $\eta>0$. Therefore, by Theorem 4.5 on p. 88 of Ref. 15, $P_t^{B,\lambda}$ converges strongly to P_t^B as $\lambda\to\infty$ uniformly for t in bounded intervals. The conclusion readily follows. □

V. APPLICATIONS

A. A quantum model of absorption and stimulated emission

This example corresponds to a family of models introduced by Gisin and Percival in Ref. 10. The framework is given by the Hilbert space $\mathfrak{h}=l^2(\mathbb{N})$ where, as usual, we call $(e_n)_{n\geqslant 0}$ the canonical orthonormal basis. The operators defining the form-generator $\mathfrak{L}(\cdot)$ are $L_1=\nu a^*a$, $L_2=\mu a$, $H=\xi(a^*+a)$, where $\mu,\nu>0$ and $\xi\in\mathbb{R}$. Thus, $G=-i\xi(a^*+a)-2^{-1}(\nu^2(a^*a)^2+\mu^2a^*a)$, whose domain is $D(G)=D(N^2)$, where $N=a^*a$ is the number operator. We skip the straightforward verification of **(H-min)**. **(H-Markov)** can be checked applying the main result of

Ref. 18. The existence of an invariant state has been proved in Ref. 17 as an application of the main result in Ref. 1. To continue the analysis, we prove its faithfulness and uniqueness.

Corollary V.1: If $\xi\neq 0$, the QMS which corresponds to the model of absorption and stimulated emission here before is Markovian and has a unique faithful stationary state ρ_∞.

Moreover, given any other state σ, $\lim_{t\to\infty}\mathrm{tr}(\mathcal{T}_{*t}(\sigma)x)=\mathrm{tr}(\rho_\infty x)$, for any $x\in\mathcal{B}(\mathfrak{h})$.

Proof: We must characterize *all* common invariant subspaces for P_t, which satisfy additionally (2) We will repeatedly use Theorem IV.1 to obtain the desired classification of invariant subspaces.

Note that, for $u\in D(N^2)$, $L_1^2u=(2G+\mu^2(a^*a)+2i\xi(a^*+a))u$. Hence, a standard computation, using Young's inequality ($2ts\leqslant\epsilon^2t^2+\epsilon^{-2}s^2$) and the canonical commutation relations, yields

$$\begin{aligned}\|L_1^2u\|&\leqslant 2\|Gu\|+\mu^2\nu^{-2}\|L_1u\|+4|\xi|\|a^*u\|\\&\leqslant 2\|Gu\|+\left(\frac{\mu^2}{\nu^2}+\frac{2|\xi|}{\nu^2}\right)\|L_1u\|+4|\xi|\|u\|\\&\leqslant 2\|Gu\|+\frac{\mu^2+2|\xi|}{\nu^2}\|L_1^2u\|^{1/2}\|u\|^{1/2}+4|\xi|\|u\|\\&\leqslant 2\|Gu\|+\epsilon\|L_1^2u\|+\left[\left(\frac{\mu^2+2|\xi|}{\nu^2\epsilon}\right)^2+4|\xi|\right]\|u\|.\end{aligned}$$

Therefore, $(1-\epsilon)\|L_1^2u\|\leqslant 2\|Gu\|+[(\mu^2+2|\xi|)^2\nu^{-4}\epsilon^{-2}+4|\xi|]\|u\|$, for any $u\in D(N^2)$, $0<\epsilon<1$. Thus, for all $0\leqslant\lambda<1$, there exists $0\leqslant\alpha<1$ and $\beta>0$ such that $\|(\lambda/2)L_1u\|\leqslant\alpha\|Gu\|+\beta\|u\|$. Clearly, $G_\lambda=G+(\lambda/2)L_1^2$ is dissipative and generates a semigroup $P^{(\lambda)}$, by Theorem IV.1. Moreover, the same theorem shows that all our invariant subspaces are also invariant under the operators $P_t^{(\lambda)}$.

We now let $\lambda\to 1$. Since $D(N^2)$ is a core for G_1 and $G_\lambda u\to G_1u$ as $\lambda\to 1$ for any $u\in D(N^2)$ it follows from Ref. 15, Theorem 4.5, p. 88, that $P_t^{(\lambda)}u\to P_t^{(1)}u$, uniformly in t for t in bounded intervals. As a result, all our invariant subspaces are $P_t^{(1)}$-invariant as well.

Repeating the above argument, it turns out that the sought invariant subspaces are invariant under the semigroup generated by $G_1+(\mu^2/2\nu)L_1$ too. This generator is a restriction of $-i\xi(a^*+a)$. It follows from Lemma III.1 that $(a^*+a)(D(N)\cap R(p))\subseteq R(p)$. At this point, we can apply again Theorem IV.1, adding $i\xi(a^*+a)$ to G_1, so that the desired invariant subspaces are also invariant under the operators e^{-tN}, for all t. These operators are compact and self-adjoint, therefore their invariant subspaces are generated by eigenvectors (see Ref. 19, Theorem 4), i.e., they are the subspaces $\mathfrak{I}_K$, spanned by $\{e_k:k\in K\}$ where $K\subseteq\mathbb{N}$.

In the above argument we obtained also that, if $\xi\neq 0$, $(a^*+a)(\mathfrak{I}_K\cap D(N))\subseteq\mathfrak{I}_K$. This, together with $a(\mathfrak{I}_K\cap D(N))\subseteq\mathfrak{I}_K$, yields $a^*(\mathfrak{I}_K\cap D(N))\subseteq\mathfrak{I}_K$, for all $K\subseteq\mathbb{N}$, if $\xi\neq 0$. As a result, if $\xi\neq 0$, the only invariant subspaces are $\{0\}$ and $\mathfrak{h}$. If $\xi=0$, it is easy to show that the full collection of invariant subspaces is $\{0\},\mathfrak{h},\mathfrak{I}_{\{0,\ldots,k\}}$, for all $k\in\mathbb{N}$.

To summarize, if $\xi\neq 0$, the QMS has a faithful normal stationary state ρ_∞, say.

Moreover, since the generalized commutator of $\{L_\ell,L_\ell^*,\ell\geqslant 1\}$ is trivial, the semigroup converges towards the equilibrium (cf. Refs. 2 and 4, Theorem 2.1, p. 567) and the set of normal stationary states is reduced to a single element. □

B. A multimode Dicke model in quantum optics

This model has been introduced by Alli and Sewell in Ref. 11. In our previous article,[1] we proved that a stationary state exists for this semigroup. We recall the corresponding notations briefly.

The system consists of N identical two-level atoms coupled with a radiation field corresponding to n modes. Therefore, one can choose $\mathfrak{h}=(\mathbb{C}^2)^{\otimes N}\otimes(l^2(\mathbb{N}))^{\otimes n}$.

Let σ_1, σ_2, σ_3 be the Pauli matrices and define the spin raising and lowering operators $\sigma_\pm=(\sigma_1\pm i\sigma_2)/2$. We denote by $\sigma_{\epsilon,r}$ ($\epsilon=1,2,3,+,-$) the spin component of the atom at the site r. The free evolution of the atoms is described by a generator $\mathcal{L}_{\text{mat}}$:

$$\mathcal{L}_{\text{mat}}(x)=i[H,x]-\frac{1}{2}\sum_{j=1}^{3N}(V_j^*V_jx-2V_j^*xV_j+xV_j^*V_j), \tag{8}$$

where $H=(\varepsilon/2)\Sigma_{r=1}^{N}\sigma_{3,r}$, and the V_j's are the operators $V_j=c_\pm\sigma_{\pm,r}$ if $j=3r\pm1$, and $V_j=c_3\sigma_{3,r}$ if $j=3r$, with $\varepsilon,c_+,c_->0$, $c_3\geqslant0$.

We denote by a_j^*, a_j, the creation and annihilation operators corresponding to the jth mode of the radiation ($j=1,\ldots,n$), which clearly satisfy the CCR: $[a_j,a_k^*]=\delta_{jk}\mathbf{1}$, $[a_j,a_k]=0$.

The free evolution of the radiation is given by the formal generator

$$\mathcal{L}_{\text{rad}}(x)=\sum_{\ell=1}^{n}(\kappa_\ell(-a_\ell^*a_\ell x+2a_\ell^*xa_\ell-xa_\ell^*a_\ell)+i\omega_\ell[a_\ell^*a_\ell,x]), \tag{9}$$

where $\kappa_\ell>0$ and ω_ℓ is real. The operator

$$H_{\text{int}}=\frac{i}{N^{1/2}}\sum_{r=1}^{N}\sum_{\ell=1}^{n}\lambda_\ell(\sigma_{-,r}a_\ell^*e^{-2\pi ik_\ell r}-\sigma_{+,r}a_\ell e^{2\pi ik_\ell r}) \tag{10}$$

(k_ℓ,λ_ℓ real) describes the coupling between radiation and matter.

With the above notations, the generator of the whole dynamics is given by

$$\mathcal{L}(x)=\mathcal{L}_{\text{mat}}(x)+\mathcal{L}_{\text{rad}}(x)+i[H_{\text{int}},x]. \tag{11}$$

Identifying L_ℓ and G in our notations, $L_\ell=\sqrt{\kappa_\ell}a_\ell$ ($\ell=1,\ldots,n$). All the remaining L_ℓ's are bounded. Among them a finite number ($3N$) coincide with some of the V_j's appearing in (8) and the others vanish. The operator G, with domain $D(\Sigma_{\ell=1}^{n}a_\ell^*a_\ell)$, becomes

$$G=-\frac{1}{2}\sum_\ell L_\ell^*L_\ell-i\sum_\ell\omega_\ell a_\ell^*a_\ell-iH-iH_{\text{int}}. \tag{12}$$

In Ref. 1 we checked both **(H-min)**, **(H-Markov)** and proved that a stationary state exists. As a further step we now show the following.

Corollary V.2: The Alli–Sewell QMS has a unique faithful normal stationary state.

Characterizing subharmonic projections p is not a trivial problem at all because the annihilation operators admit plenty of nontrivial invariant subspaces (e.g., the linear span of any finite family of exponential vectors).

Proof: Call $\mathfrak{M}$ the set $\{\sigma_{+,r},\sigma_{-,r}:r=1,\ldots,N\}$. $\mathfrak{M}$ is a self-adjoint set, and by Corollary III.1 any invariant projection is an element of $\mathfrak{M}'$, therefore it is of the form $\mathbf{1}\otimes p$, where p is a projection on $l^2(\mathbb{N})$. Now, $\mathbf{1}\otimes p$ must be invariant under the operators P_t of the semigroup generated by G. We apply Theorem IV.1 as in the previous example to remove $iH+(1/2)\Sigma_{\ell>n}L_\ell^*L_\ell$ from G, to end up with $G_1=-\frac{1}{2}\Sigma_{\ell=1}^{n}(\kappa_\ell+2i\omega_\ell)a_\ell^*a_\ell-iH_{\text{int}}$. Theorem IV.1 shows that $\mathbf{1}\otimes p$ is invariant under the operators $P_t^{(1)}$ of the semigroup generated by G_1, too.

Applying Theorem IV.2 with $B=\sigma_{+,1},\ldots,\sigma_{+,N}$, since $B^*H_{\text{int}}B=0$, the sought projections are also invariant under the operators P_t^B of the semigroup generated by $2B^*G_1B=-B^*B\Sigma_{\ell=1}^{n}(\kappa_\ell+2i\omega)a_\ell^*a_\ell$. Therefore, being of the form $\mathbf{1}\otimes p$, it follows that p is an invariant projection for $\exp(-t\Sigma_{\ell=1}^{n}(\kappa_\ell+2i\omega)a_\ell^*a_\ell)$, for all t. These are normal operators but normality alone does not guarantee that the eigenspaces are generated by eigenvectors (see Ref. 9). However, the above operators are compact, too. Thus, Theorem 4 on p. 272 in Ref. 19 applies, and shows that all the invariant subspaces are generated by eigenvectors.

At this point, since the eigenvectors are explicitly known and $L_\ell = \sqrt{\kappa_\ell} a_\ell$, with $\kappa_\ell > 0$, we can repeat the argument of the previous example to conclude that p must be trivial. □

C. A classical Markov semigroup

Let E be a metric space and let $\mathcal{E}$ its Borel σ-field. Given a positive measure μ on $(E,\mathcal{E})$ call $\mathfrak{A} = L^\infty(E,\mathcal{E},\boldsymbol{\mu})$. Let $M(x,A) = \int_A m(x,y)\mu(dy)$ be a transition function on $E \times \mathcal{E}$. Then (see, for instance, Ref. 6),

$$Lf(x) = \int_E (f(y) - f(x)) M(x,dy)$$

defines a bounded operator on $\mathfrak{A}$ which is the generator of a (classical) Markov semigroup.

In this case, the predual von Neumann algebra $\mathcal{A}_*$ is $L^1(E,\mathcal{E},\boldsymbol{\mu})$ and any normal state is represented by a probability measure ν absolutely continuous with respect to μ.

Proposition V.1: A projection 1_A $(A \in \mathcal{E})$ *is subharmonic for the given Markov semigroup if and only if* $M(x,A^c) = 0$ *for* μ *almost all* $x \in A$.

In particular, the semigroup is irreducible if and only if the support of $M(x,\cdot)$ *coincides with that of* μ *for* μ*-almost all* $x \in E$.

It is worth noticing that the Markov process, starting from a point $x \in A$, can only go inside the support of $M(x,\cdot)$. Then to say that 1_A is subharmonic means that A includes the support of any $M(x,\cdot)$ for $x \in A$, $\mu-$ almost surely. That is, for any $x \in A$, the process cannot jump outside of A.

Proof: Take a projection $p = 1_A \in \mathfrak{A}$. This projection is subharmonic if and only if $L1_A \geqslant 0$. However, for $x \in A$, $L1_A(x) = (M(x,A) - M(x,E)) \leqslant 0$, and for $x \in A^c$, $L1_A(x) = M(x,A)$. Therefore, 1_A is subharmonic if and only if, for μ, almost all $x \in A$, $M(x,A^c) = 0$.

The second assertion now follows easily. □

(Received 3 July 2001; accepted for publication 5 November 2001)

We consider the grading of $sl(n,\mathbb{C})$ by the group Π_n of generalized Pauli matrices. The grading decomposes the Lie algebra into n^2-1 one-dimensional subspaces. In the article we demonstrate that the normalizer of grading decomposition of $sl(n,\mathbb{C})$ in Π_n is the group $\mathrm{SL}(2,\mathbb{Z}_n)$, where $\mathbb{Z}_n$ is the cyclic group of order n. As an example we consider $sl(3,\mathbb{C})$ graded by Π_3 and all contractions preserving that grading. We show that the set of 48 quadratic equations for grading parameters splits into just two orbits of the normalizer of the grading in Π_3. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1430046]

I. INTRODUCTION

Among the gradings of reductive Lie algebras over the complex number field and the simultaneous gradings of their representation spaces, by far the most important ones are the gradings by maximal torus. In the case of the Lie algebra it is also called root or Cartan decomposition. Such a grading means a decomposition into eigenspaces of the maximal torus. For a greater part of the past century such gradings have been the workhorses of the theory and applications.

The typical role a Lie algebra plays in physics is the algebra of infinitesimal symmetries of a physical system, which themselves are described in terms of elements of representation spaces, eigenvectors of the maximal torus. The corresponding eigenvalues are then the quantum numbers.

The question about the existence of other gradings, like those by maximal torus (called fine gradings), has been raised systematically in Ref. 1 and solved for the simple Lie algebras of over $\mathbb{C}$ in Refs. 2–4 and recently also for the real number field in Refs. 5 and 6.

Gradings of Lie algebras are closely related to their automorphisms. In a seminal paper[1] in 1989, it was shown that the finest gradings (called fine) of finite-dimensional simple Lie algebras $\mathcal{L}$ can be classified (up to equivalence generated by elements of $\mathrm{Aut}\,\mathcal{L}$) by the maximal Abelian groups of diagonable automorphisms of $\mathcal{L}$, briefly the MAD groups. In general, the MAD groups

a)Electronic mail: havlicek@km1.fjfi.cvut.cz
b)Electronic mail: patera@crm.umontreal.ca
c)Electronic mail: pelantova@km1.fjfi.cvut.cz
d)Electronic mail: tolar@br.fjfi.cvut.cz

are composed, besides subgroups of the maximal torus, by well-known outer automorphisms,[7] and by elements of finite order (EFO) in the corresponding Lie groups. Since the conjugacy classes of EFO were systematically described in Ref. 8 (see also Ref. 7), it was not difficult to classify the fine gradings in the lowest cases like $sl(2,\mathbb{C})$ and $sl(3,\mathbb{C})$.[9–11]

A prominent role in the grading problem of simple Lie algebras is played by the finite group Π_n of n^3 matrices $\mathbb{C}^{n\times n}$. A subset of Π_n, consisting of n^2-1 traceless matrices, can be taken as a basis of $sl(n,\mathbb{C})$. Since these traceless matrices are used as a basis of a Lie algebra, they can be normalized in any convenient way. In particular, for $n=2$ the Pauli matrices of $sl(2,\mathbb{C})$ are obtained.

Most importantly, the adjoint action of Π_n, though non-Abelian in general, induces an Abelian action on $sl(n,\mathbb{C})$. The fine grading of $sl(n,\mathbb{C})$, which arises in this way, decomposes the algebra into one-dimensional subspaces generated by traceless elements of Π_n.[9]

In further prospect, the gradings are to be used, e.g., for constructing grading preserving contractions (*graded contractions*) of semisimple $\mathcal{L}$.[12,13] For gradings involving a decomposition into a small number of grading subspaces, this is a relatively easy task.[14–16] However for fine gradings of algebras with ranks $\geqslant 3$, the system of quadratic equations for contraction parameters one needs to solve often gets quite large. The task of solving of such a system would be simplified by knowledge of its symmetries. Symmetries that are available are provided by those elements of $\mathrm{Aut}\,\mathcal{L}$ which leave the given grading invariant.

The main goal of this paper is to demonstrate that the decomposition of $sl(n,\mathbb{C})$, as the fine grading by Π_n, is preserved by the finite group $\mathrm{SL}(2,\mathbb{Z}_n)$, acting through its n-dimensional representation on the labels (a,b) of the one-dimensional subspace of $sl(n,\mathbb{C})$. Thus the group $\mathrm{SL}(2,\mathbb{Z}_n)$ plays a role analogous to the Weyl group in the case of root decomposition/grading of $sl(n,\mathbb{C})$. Here $\mathbb{Z}_n$ is the cyclic group of order n. We also illustrate an application of this fact.

The special role of matrices Π_n has been recognized in the physical literature for a long time.[17] In more recent years there were a number of papers where the matrices were used as a basic part of the formalism in the development of quantum mechanics in discrete spaces $\mathbb{Z}_n$. Here, the finite group Π_n plays the role of the discrete Weyl group acting in an n-dimensional complex Hilbert space. See Refs. 18 and 19 and references therein.

The Π_n-grading of $sl(n,\mathbb{C})$ has other special properties. Let us name just two.

(1) All generators are in the same conjugacy class of $\mathrm{SL}(n,\mathbb{C})$. Considered as group elements, they are of order n, belonging to the Costant conjugacy class of finite order elements, specified as $[1,1,\ldots,1]$ in the notation introduced in Ref. 8.

(2) The Π_n-grading makes explicit the decomposition of $sl(n,\mathbb{C})$ into the sum of $n+1$ Cartan subalgebra. Indeed, if the element of $\mathcal{P}_n$ defined by a couple (a,b) (a,b considered $\bmod n$), belongs to one such Cartan subalgebra, that subalgebra is then generated by the $n-1$ elements carrying labels $(a,b),(2a,2b),\ldots,((n-1)a,(n-1)b)$. Clearly such elements commute and have a nonzero determinant.

In Sec. II, the role of automorphisms of the Lie algebra in its gradings is recalled. Grading groups of $sl(n,\mathbb{C})$ which do not involve outer automorphisms are described in Sec. III. Our main result is in Sec. IV, namely the normalizers of the grading groups. Sec. V contains an application to $sl(3,\mathbb{C})$: It is shown that the set of 48 quadratic equations for contraction parameters splits into just two orbits of the normalizer of the grading group Π_3.

II. GRADINGS AND AUTOMORPHISMS OF LIE ALGEBRAS

A grading of Lie algebra $\mathcal{L}$ is a decomposition of $\mathcal{L}$ into direct sum of subspaces

$$\Gamma: \quad \mathcal{L}=\bigoplus_{i\in I}\mathcal{L}_i \tag{1}$$

such that for any pair of indices $i,j\in I$ there exists an index $k\in I$ with the property

$$[\mathcal{L}_i,\mathcal{L}_j]:=\{[X,Y]\,|\,X\in\mathcal{L}_i, Y\in\mathcal{L}_j\}\subseteq\mathcal{L}_k.$$

A grading which cannot be further refined is called *fine*.

Gradings can be obtained by looking at $\mathrm{Aut}\,\mathcal{L}$, the group of all automorphisms of $\mathcal{L}$. It consists of all non-singular linear transformations ϕ of $\mathcal{L}$ as linear space $[\phi \in \mathrm{GL}(\mathcal{L})]$ which preserve the binary operation in $\mathcal{L}$:

$$\phi[X,Y]=[\phi X,\phi Y].$$

If ϕ is *diagonable* and X, Y are its eigenvectors with nonzero eigenvalues λ, μ,

$$\phi X=\lambda X, \quad \phi Y=\mu Y,$$

then clearly

$$\phi[X,Y]=[\phi X,\phi Y]=\lambda\mu[X,Y]. \tag{2}$$

This means that the element $[X,Y]$ is either an eigenvector of ϕ with eigenvalue $\lambda\mu$, or is the zero element. The given automorphism ϕ thus leads to a decomposition of the linear space $\mathcal{L}$ into eigenspaces of ϕ,

$$\mathcal{L}=\bigoplus_{i\in I}\mathrm{Ker}(\phi-\lambda_i\,\mathrm{id}),$$

which, according to (2), satisfies the definition of a grading.

Refinements of a given grading, i.e., further decompositions of the subspaces, can be obtained by adjoining further automorphisms commuting with ϕ. Hence, in general, sets $\phi_1,\ldots,\phi_m$ of mutually commuting automorphisms determine gradings.

Conversely, if a grading (1) of a simple Lie algebra $\mathcal{L}$ is given, it defines a particular Abelian subgroup $\mathrm{Diag}\,\Gamma\subset\mathrm{Aut}\,\mathcal{L}$ consisting of those automorphisms $\phi\in GL(\mathcal{L})$ which

(i) preserve Γ, $\phi(\mathcal{L}_i)=\mathcal{L}_i$,
(ii) are diagonal, $\phi X=\lambda_i X \quad \forall X\in\mathcal{L}_i$, $i\in I$, where $\lambda_i\neq 0$ depends only on ϕ and $i\in I$.

In Ref. 1 an important theorem was proved:

Theorem 1: *Let $\mathcal{L}$ be a finite-dimensional simple Lie algebra over an algebraically closed field of characteristic zero. Then the grading Γ is fine, if and only if the diagonal subgroup* $\mathrm{Diag}\,\Gamma$ *is a maximal Abelian group of diagonable automorphisms (MAD group).*

A general algorithm to construct all MAD groups for the class of simple classical Lie algebras over complex numbers was given in Refs. 2–4. (Further results concerning the real forms can be found in Refs. 5 and 6.) These Lie algebras are Lie subalgebras of $gl(n,\mathbb{C})$, hence their MAD groups can be determined from the MAD groups of $gl(n,\mathbb{C})$ by imposing certain conditions.

The automorphisms of $gl(n,\mathbb{C})$ can be easily written as combinations of inner and outer automorphisms. For all $X\in gl(n,\mathbb{C})$, *inner automorphisms* have the general form

$$\mathrm{Ad}_A X=A^{-1}XA \quad \text{for} \quad \text{any} \quad A\in GL(n,\mathbb{C});$$

outer automorphims have the general form

$$\mathrm{Out}_C X=-(C^{-1}XC)^T=\mathrm{Out}_I\,\mathrm{Ad}_C X, \quad \text{where} \quad C\in GL(n,\mathbb{C}).$$

Relevant properties of inner and outer automorphisms of $gl(n,\mathbb{C})$ are summarized in the following lemma (Ref. 2) which allows one to express MAD groups in $\mathrm{Aut}\,gl(n,\mathbb{C})$ in terms of special elements of $GL(n,\mathbb{C})$:

Lemma 2: Let $A,B,C\in GL(n,\mathbb{C})$.

(1) Ad_A *is diagonable automorphism if and only if the corresponding matrix A is diagonable.*

(2) *Inner automorphisms commute,* $\mathrm{Ad}_A\,\mathrm{Ad}_B=\mathrm{Ad}_B\,\mathrm{Ad}_A$, *if and only if there exists $q\in\mathbb{C}$ such that*

$$AB = qBA, \quad \textit{where } q \textit{ satisfies} \quad q^n = 1. \tag{3}$$

(3) Out_C *is diagonable if and only if* $C(C^T)^{-1}$ *is diagonable.*

(4) *Inner and outer automorphisms commute,* $\mathrm{Ad}_A \mathrm{Out}_C = \mathrm{Out}_C \mathrm{Ad}_A$, *if and only if* $ACA^T = rC$; *since* $\mathrm{Ad}_{\alpha A} = \mathrm{Ad}_A$ *for* $\alpha \neq 0$, *number* r *can be normalized to unity.*

Remark 3: The sets of complex $n \times n$ matrices satisfying (3) were to our knowledge first studied by Weyl.[17]

III. MAD GROUPS WITHOUT OUTER AUTOMORPHISMS

In this contribution we are going to look at the MAD groups in $\mathrm{Aut}\, gl(n,\mathbb{C})$ without outer automorphisms, i.e., generated by inner automorphisms [the Ad action in $GL(n,\mathbb{C})$ only]. It is shown in Ref. 2 that there exists a one-to-one correspondence between MAD groups without outer automorphisms and Ad groups (to be defined in the following) in $GL(n,\mathbb{C})$.

Definition 4: A subgroup of diagonable matrices $G \subset GL(n,\mathbb{C})$ *will be called an* **Ad group** *if*

(1) *for any pair* $A,B \in G$ *the commutator* $q(A,B) = ABA^{-1}B^{-1}$ *lies in the center* $Z = \{\alpha I_n | \alpha \in \mathbb{C}^*\} \subset GL(n,\mathbb{C})$;

(2) G *is maximal, i.e., for each* $M \notin G$ *there exists* $A \in G$ *such that* $q(A,M) \notin Z$.

In order to describe Ad groups we introduce the following notation. The subgroup of $GL(n,\mathbb{C})$ containing all regular diagonal matrices will be denoted by $D(n)$. We also define special $k \times k$ diagonal matrices (for $k=1$ we set $Q_1 = P_1 = 1$)

$$Q_k = \mathrm{diag}(1, \omega_k, \omega_k^2, \ldots, \omega_k^{k-1}),$$

where ω_k is the primitive kth root of unity, $\omega_k = \exp(2\pi i/k)$, and

$$P_k = \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 1 & \cdots & 0 & 0 \\ \vdots & & & \ddots & & \\ 0 & 0 & 0 & \cdots & 0 & 1 \\ 1 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix}.$$

The unitary matrices P_k, Q_k appear in the finite-dimensional quantum mechanics (FDQM),[17–20] where their integral powers play the role of exponentiated operators of position and momentum in the position representation. The matrices P_k, Q_k satisfy the identity (3) with $q = \omega_k$,

$$P_k Q_k = \omega_k Q_k P_k, \tag{4}$$

which in FDQM replaces the usual Heisenberg commutation relations. The discrete subgroup of $GL(k,\mathbb{C})$ generated by powers of P_k, Q_k is the *discrete Weyl (or Heisenberg) group* of FDQM in k-dimensional Hilbert space $\mathcal{H}_k$. In Ref. 9 this group was called the *Pauli group*; it consists of k^3 elements

$$\Pi_k = \{\omega_k^l Q_k^i P_k^j | i,j,l = 0,1,\ldots,k-1\}. \tag{5}$$

The classification of Ad groups in $GL(n,\mathbb{C})$ is given by the following theorem[3]

Theorem 5: $G \subset GL(n,\mathbb{C})$ *is an Ad group if and only if* G *is conjugated to one of the finite groups*

$$\Pi_{\pi_1} \otimes \cdots \otimes \Pi_{\pi_s} \otimes D(n/\pi_1 \ldots \pi_s),$$

where $\pi_1, \ldots, \pi_s$ *are powers of primes and their product* $\pi_1 \ldots \pi_s$ *divides* n, *with the exception of the case* $\Pi_2 \cdots \otimes \Pi_2 \otimes D(1)$. (In this case there is an outer automorphism in the MAD group.)

The simplest form of an Ad group is $G=D(n)$. The MAD group corresponding to this Ad group gives the Cartan decomposition of $gl(n,\mathbb{C})$.

In this article we shall focus on the other extremal case, namely on the Ad group

$$\Pi_n \otimes D(1) = \Pi_n .$$

The corresponding fine grading decomposes $gl(n,\mathbb{C})$ into a sum of n^2 one-dimensional subspaces[1,9]

$$\Gamma_\Pi : \quad gl(n,\mathbb{C}) = \bigoplus_{(r,s)\in \mathbb{Z}_n\times\mathbb{Z}_n} \mathcal{L}_{rs}, \tag{6}$$

where $\mathcal{L}_{rs}=\mathbb{C}X_{rs}$ with X_{rs} being the basis elements of $gl(n,\mathbb{C})$ representing n^2 cosets of Π_n with respect to its center $\{\omega^l | l\in\mathbb{Z}_n\}$:

$$X_{rs} = Q^r P^s .$$

Their commutators [henceforth the index k in ω_k, P_k, Q_k as well as explicit notation (mod n) will be omitted]

$$[X_{rs}, X_{r's'}] = Q^r P^s Q^{r'} P^{s'} - Q^{r'} P^{s'} Q^r P^s = (\omega^{sr'} - \omega^{rs'}) X_{r+r',s+s'} \tag{7}$$

clearly satisfy the grading property with the index set I being the Abelian group $\mathbb{Z}_n\times\mathbb{Z}_n$. The binary correspondence $((r,s),(r',s'))\mapsto(r+r',s+s')$, $0\neq[\mathcal{L}_{rs},\mathcal{L}_{r's'}]\subseteq\mathcal{L}_{r+r',s+s'}$ is the group multiplication in $\mathbb{Z}_n\times\mathbb{Z}_n$ written additively modulo n.

The corresponding grading of $sl(n,\mathbb{C})$ contains n^2-1 subspaces

$$sl(n,\mathbb{C}) = \bigoplus_{(r,s)\neq(0,0)} \mathcal{L}_{rs},$$

since $\mathrm{Tr}(X_{rs})=0$ except $r=s=0$.

IV. SYMMETRIES OF THE FINE GRADINGS Γ_Π

In this section we are going to study the symmetries of the fine gradings (6) of $gl(n,\mathbb{C})$. From Sec. III we know that they are induced by the Pauli group $\Pi_n\subset GL(n,\mathbb{C})$.

Generally, the symmetry group or the automorphism group $\mathrm{Aut}\,\Gamma\subset\mathrm{Aut}\,\mathcal{L}$ of the grading (1) consists of those automorphisms ϕ of $\mathcal{L}$ which permute the components of (1),

$$\phi\mathcal{L}_i = \mathcal{L}_{\overline{\phi}(i)} .$$

Here $\overline{\phi}: I\to I$ is a permutation of the elements of I, so we have a permutation representation Δ_Γ of $\mathrm{Aut}\,\Gamma$,

$$\overline{\phi} = \Delta_\Gamma(\phi), \quad \phi\in\mathrm{Aut}\,\Gamma .$$

The kernel of Δ_Γ is the stabilizer of Γ in $\mathrm{Aut}\,\Gamma$,

$$\mathrm{Stab}\,\Gamma = \ker\Gamma = \{\phi\in\mathrm{Aut}\,\mathcal{L} \,|\, \phi\mathcal{L}_i = \mathcal{L}_i \ \forall\, i\in I\}.$$

It is a normal subgroup of $\mathrm{Aut}\,\Gamma$ with quotient group isomorphic to the group of permutations of I,

$$\mathrm{Aut}\,\Gamma/\mathrm{Stab}\,\Gamma \simeq \Delta_\Gamma\,\mathrm{Aut}\,\Gamma .$$

For fine gradings $\mathrm{Stab}\,\Gamma=\mathcal{G}$. The *symmetry group* $\mathrm{Aut}\,\Gamma$ is by definition[1] the normalizer of $\mathcal{G}$ in $\mathrm{Aut}\,gl(n,\mathbb{C})$:

$$\mathcal{N}(\mathcal{G})=\mathrm{Aut}\,\Gamma=\{\phi\in \mathrm{Aut}\,gl(n,\mathbb{C})\,|\,\phi\mathcal{G}\phi^{-1}\subset\mathcal{G}\}.$$

Why do we look for the symmetry group $\mathrm{Aut}\,\Gamma$? We know that

(1) elements of $\mathrm{Aut}\,\Gamma/\mathrm{Stab}\,\Gamma$ permute the grading subspaces,
(2) given a grading subspace, the action of $\mathrm{Aut}\,\Gamma/\mathrm{Stab}\,\Gamma$ will yield some other grading subspaces.

So its knowledge may give us the way to construct the grading decomposition (1) from one or a small number of starting subspaces. $\mathrm{Aut}\,\Gamma/\mathrm{Stab}\,\Gamma$ may also be valuable as a symmetry of the contraction equations which enables one to lower their number and so simplify their solution.

Let us denote the MAD group Ad_{Π_n} by $\mathcal{P}_n$. It is an Abelian subgroup of $\mathrm{Aut}\,gl(n,\mathbb{C})=GL(n^2,\mathbb{C})$ with generators Ad_P, Ad_Q,

$$\mathcal{P}_n=\{\mathrm{Ad}_{Q^iP^j}|(i,j)\in\mathbb{Z}_n\times\mathbb{Z}_n\}.$$

It is obvious that n^2 elements of $\mathcal{P}_n$ stabilize the grading: namely, taking the generators Ad_P, Ad_Q, one has

$$\mathrm{Ad}_P X_{rs}=PQ^rP^sP^{-1}=\omega^r X_{rs},\quad \mathrm{Ad}_Q X_{rs}=QQ^rP^sQ^{-1}=\omega^{-s}X_{rs}$$

and $\mathcal{P}_n=\mathrm{Stab}\,\Gamma_\Pi$ since $\mathcal{P}_n$ is maximal.

In order to describe the quotient group $\mathcal{N}(\mathcal{P}_n)/\mathcal{P}_n$ we note that its elements are classes of equivalence in $\mathcal{N}(\mathcal{P}_n)$ given by

$$\phi\sim\psi \quad \text{if and only if} \quad \phi\psi^{-1}\in\mathcal{P}_n.$$

Let $\phi\sim\psi$, i.e., $\phi\psi^{-1}=\beta$ for some $\beta\in\mathcal{P}_n$. Using the commutativity of $\mathcal{P}_n$ we have

$$\phi^{-1}\alpha\phi=\psi^{-1}\beta^{-1}\alpha\beta\psi=\psi^{-1}\alpha\psi$$

for any $\alpha\in\mathcal{P}_n$. On the other hand, let $\phi^{-1}\alpha\phi=\psi^{-1}\alpha\psi$ for any $\alpha\in\mathcal{P}_n$. Then $\phi\psi^{-1}$ commutes with every element in $\mathcal{P}_n$ and therefore $\phi\psi^{-1}\in\mathcal{P}_n$. It means that

$$\phi\sim\psi \quad \text{if and only if} \quad \phi^{-1}\alpha\phi=\psi^{-1}\alpha\psi \quad \text{for any} \quad \alpha\in\mathcal{P}_n.$$

Since the group $\mathcal{P}_n$ has only two generators Ad_P and Ad_Q, the previous condition can be rewritten

$$\phi\sim\psi \quad \text{if and only if} \quad \phi^{-1}\,\mathrm{Ad}_P\,\phi=\psi^{-1}\,\mathrm{Ad}_P\,\psi \quad \text{and} \quad \phi^{-1}\,\mathrm{Ad}_Q\,\phi=\psi^{-1}\,\mathrm{Ad}_Q\,\psi. \tag{8}$$

If ϕ belongs to the normalizer $\mathcal{N}(\mathcal{P}_n)$, then there exist elements a,b,c,d in the cyclic group $\mathbb{Z}_n$ such that

$$\phi^{-1}\,\mathrm{Ad}_Q\,\phi=\mathrm{Ad}_{Q^aP^b} \quad \text{and} \quad \phi^{-1}\,\mathrm{Ad}_P\,\phi=\mathrm{Ad}_{Q^cP^d}.$$

Thus to any equivalence class a quadruple of indices is assigned. Denote this assignment by Φ. According to (8), quadruples assigned to distinct classes are different. We shall see that it is convenient to write the quadruple as a matrix

$$\Phi(\phi)=\begin{pmatrix} a & b \\ c & d \end{pmatrix} \quad \text{with entries from} \quad \mathbb{Z}_n.$$

Suppose that the equivalence classes containing the automorphisms ϕ_1 and ϕ_2 correspond to the quadruples a_1, b_1, c_1, d_1 and a_2, b_2, c_2, d_2, respectively. Computing the quadruple assigned to the composition $\phi_1\phi_2$,

$$(\phi_1\phi_2)^{-1}\,\mathrm{Ad}_Q(\phi_1\phi_2)=(\phi_2^{-1}\,\mathrm{Ad}_Q\phi_2)^{a_1}(\phi_2^{-1}\mathrm{Ad}_P\phi_2)^{b_1}$$
$$=(\mathrm{Ad}_{Q^{a_2}P^{b_2}})^{a_1}(\mathrm{Ad}_{Q^{c_2}P^{d_2}})^{b_1}$$
$$=\mathrm{Ad}_{Q^{a_2a_1}P^{b_2a_1}}\mathrm{Ad}_{Q^{c_2b_1}P^{d_2b_1}}$$
$$=\mathrm{Ad}_{Q^{a_1a_2+b_1c_2}P^{a_1b_2+b_1d_2}},$$

$$(\phi_1\phi_2)^{-1}\,\mathrm{Ad}_P(\phi_1\phi_2)=\mathrm{Ad}_{Q^{a_1a_2+b_1c_2}P^{a_1b_2+b_1d_2}}$$

we see that to the automorphism $\phi_1\phi_2$ the product matrix is assigned,

$$\Phi(\phi_1\phi_2)=\Phi(\phi_1)\Phi(\phi_2).$$

Thus Φ is an injective homomorphism of the quotient group $\mathcal{N}(\mathcal{P}_n)/\mathcal{P}_n$.

Let $\phi\in\mathcal{N}(\mathcal{P}_n)$ be an *inner* automorphism, say Ad_A with the corresponding matrix

$$\Phi(\phi)=\begin{pmatrix}a & b\\ c & d\end{pmatrix}\quad\text{with entries from } \mathbb{Z}_n.$$

Then

$$\mathrm{Ad}_A^{-1}\,\mathrm{Ad}_Q\,\mathrm{Ad}_A=\mathrm{Ad}_{A^{-1}QA}=\mathrm{Ad}_{Q^aP^b}\quad\text{implies}\quad A^{-1}QA=\mu Q^aP^b, \tag{9}$$

$$\mathrm{Ad}_A^{-1}\,\mathrm{Ad}_P\,\mathrm{Ad}_A=\mathrm{Ad}_{A^{-1}PA}=\mathrm{Ad}_{Q^cP^d}\quad\text{implies}\quad A^{-1}PA=\nu Q^cP^d \tag{10}$$

for some $\mu,\nu\in\mathbb{C}^*$. Multiplying Eqs. (9) and (10) by PA and QA from the right, respectively, and using the relation $PQ=\omega QP$, we obtain

$$PQA=\mu\nu AQ^cP^dQ^aP^b=\omega^{ad}\mu\nu Q^{a+c}P^{b+d}$$

and

$$QPA=\mu\nu AQ^aP^bQ^cP^d=\omega^{bc}\mu\nu Q^{a+c}P^{b+d}.$$

Since $PQA=\omega QPA$ we obtain the identity

$$\omega^{ad-1}=\omega^{bc},\quad\text{i.e.,}\quad ad-1=bc(\mathrm{mod}\,n),$$

hence

$$\det\Phi(\phi)=1.$$

A simple computation further shows that for this inner automorphism one has

$$A^{-1}X_{rs}A=\rho X_{r's'},$$

where $|\rho|=1$ and

$$(r',s')=(r,s)\begin{pmatrix}a & b\\ c & d\end{pmatrix}. \tag{11}$$

Consider now the outer automorphism $\mathrm{Out}_I X:=-X^T$. Because of

$$(\mathrm{Out}_I)^{-1}\mathrm{Ad}_Q\mathrm{Out}_I=\mathrm{Ad}_{(Q^{-1})^T}=\mathrm{Ad}_{Q^{-1}}\in\mathcal{P}_n,$$

$$(\mathrm{Out}_I)^{-1}\mathrm{Ad}_P\mathrm{Out}_I=\mathrm{Ad}_{(P^{-1})^T}=\mathrm{Ad}_P\in\mathcal{P}_n,$$

the automorphism Out_I belongs to the normalizer $\mathcal{N}(\mathcal{P}_n)$. The matrix corresponding to Out_I is

$$\Phi(\mathrm{Out}_I)=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix} \quad \text{and} \quad \det\Phi(\mathrm{Out}_I)=-1.$$

Note that

$$\mathrm{Out}_I X_{rs}=-\omega^{-rs}X_{r,-s}$$

corresponds to the permutation of indices

$$(r,s)\mapsto(r,-s).$$

Any other outer automorphism ϕ from $\mathcal{N}(\mathcal{P}_n)$ is the composition of Out_I and an inner automorphism from $\mathcal{N}(\mathcal{P}_n)$ and thus $\det\Phi(\phi)=-1$. We conclude with

Proposition 6: Φ is an injective homomorphism of $\mathcal{N}(\mathcal{P}_n)/\mathcal{P}_n$ into the group

$$H=\left\{\begin{pmatrix}a & b\\ c & d\end{pmatrix}\middle|\, a,b,c,d\in\mathbb{Z}_n, ad-bc=\pm 1 \bmod n,\right\}.$$

The group H contains as its subgroup the group of matrices with determinant $+1$. This group is usually denoted by $\mathrm{SL}(2,\mathbb{Z}_n)$. Note that $\mathbb{Z}_n$ is a field iff n is prime. Clearly

$$H=\mathrm{SL}(2,\mathbb{Z}_n)\cup\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\mathrm{SL}(2,\mathbb{Z}_n).$$

Let us briefly show that for any $n\in\mathbb{N}$, the group $\mathrm{SL}(2,\mathbb{Z}_n)$ is generated by two matrices

$$A=\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix} \quad \text{and} \quad B=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}.$$

In order to show it, we have to realize that in the ring $\mathbb{Z}_n$, the matrices A and B are of orders n and 4, respectively. The matrix $C=A^T$ is generated by A and B:

$$C=\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix}^{n-1}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}^3.$$

Moreover, any matrix of $\mathrm{SL}(2,\mathbb{Z}_n)$ satisfies

$$\begin{pmatrix}a & b\\ c & d\end{pmatrix}=\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix}\begin{pmatrix}a & b\\ c-a & d-b\end{pmatrix}=\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}\begin{pmatrix}a-c & b-d\\ c & d\end{pmatrix}. \tag{12}$$

Now recall that Euclid's algorithm for finding the greatest common divisor of integers is based on the trivial fact that $\gcd(x,y)=\gcd(x-y,y)$. By several repetitions of this rule, where we replace the pair of non-negative integers $\{x,y\}, x\geqslant y$, by another pair of non-negative integers $\{x-y,y\}$, the Euclid's algorithm gives finally a pair of integers, where one of them is 0 and the other is $\gcd(x,y)$.

Denote $\gcd(a,c)=s$. Then by suitable applications of (12) we obtain

$$\begin{pmatrix}a & b\\ c & d\end{pmatrix}=A^{k_1}C^{l_1}\ldots A^{k_p}C^{l_p}T,$$

where $k_1,l_1,\ldots,k_p,l_p\in\mathbb{N}_0$ and T is a matrix with $\det T=1$, of the form

$$T=\begin{pmatrix} s & t \\ 0 & u \end{pmatrix} \quad \text{or} \quad T=\begin{pmatrix} 0 & v \\ s & w \end{pmatrix}.$$

But any matrix T of such form is a product of several matrices A,B, and C, since

$$\begin{pmatrix} s & t \\ 0 & u \end{pmatrix}=\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}^{s(t-1)}\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}^{u}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}^{s}$$

$$\begin{pmatrix} 0 & v \\ s & w \end{pmatrix}=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}\begin{pmatrix} -s & -w \\ 0 & v \end{pmatrix}.$$

This proves that $\mathrm{SL}(2,\mathbb{Z}_n)$ has two generators, the matrices A and B.

Now we shall present two elements of the normalizer—special unitary $n\times n$ matrices inducing Ad actions which represent generating elements of $\mathrm{SL}(2,\mathbb{Z}_n)$.

Example 7: Since the matrices Q and P have the same spectra, they are similar with a similarity matrix S such that $S^{-1}PS=Q$. Such S is not determined uniquely. We choose for the matrix S the Sylvester matrix defined as follows:

$$S_{ij}=\omega^{-ij}, \quad \text{for } i,j\in\mathbb{Z}_n.$$

It is easy to verify that S^2 is a parity operator

$$S_{ij}^2=\delta_{i,-j} \quad \text{for} \quad i,j\in\mathbb{Z}_n \text{ such that } \quad S^4=I.$$

Note that the indices (and operations on them) are always considered to be elements of the ring $\mathbb{Z}_n$. Let us verify that Ad_S belongs to the normalizer. Note that S is a symmetric matrix and therefore $Q=Q^T=(S^{-1}PS)^T=SP^TS^{-1}=SP^{-1}S^{-1}$, which implies $S^{-1}QS=P^{-1}$. Now we can easily check the conditions on Ad_S to be in the normalizer:

$$(\mathrm{Ad}_S)^{-1}\mathrm{Ad}_Q\mathrm{Ad}_S=\mathrm{Ad}_{S^{-1}QS}=\mathrm{Ad}_{P^{-1}}\in\mathcal{P}_n$$

$$(\mathrm{Ad}_S)^{-1}\mathrm{Ad}_P\mathrm{Ad}_S=\mathrm{Ad}_{S^{-1}PS}=\mathrm{Ad}_Q\in\mathcal{P}_n.$$

By (9) and (10) the matrix corresponding to Ad_S is

$$\Phi(\mathrm{Ad}_S)=\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Example 8: For this example we shall use the similarity of matrices P and PQ. Put $\varepsilon=1$, if n is odd, and $\varepsilon=\sqrt{\omega}$, if n is even. Denote by

$$D=\mathrm{diag}(d_0,d_1,\ldots,d_{n-1}), \text{ where } d_j=\varepsilon^{-j}\omega^{-\binom{j}{2}}, \text{ for } j\in\mathbb{Z}_n.$$

It is easy to see that $Q=D^{-1}QD$ and $PQ=\varepsilon D^{-1}PD$; it implies

$$(\mathrm{Ad}_D)^{-1}\mathrm{Ad}_Q\mathrm{Ad}_D=\mathrm{Ad}_{D^{-1}QD}=\mathrm{Ad}_Q\in\mathcal{P}_n$$

and

$$(\mathrm{Ad}_D)^{-1}\mathrm{Ad}_P\mathrm{Ad}_D=\mathrm{Ad}_{D^{-1}PD}=\mathrm{Ad}_{PQ}\in\mathcal{P}_n,$$

which means that Ad_D belongs to the normalizer. By (9) and (10) the matrix assigned to Ad_D is therefore

$$\Phi(\mathrm{Ad}_D)=\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix}.$$

The homomorphism Φ maps three elements of the normalizer Out_I, Ad_S, and Ad_D into three matrices generating the whole group H. This observation together with Proposition 6 gives us

Theorem 10: *The quotient group $\mathcal{N}(\mathcal{P}_n)/\mathcal{P}_n$ is isomorphic to the group*

$$\left\{\begin{pmatrix}a & b\\ c & d\end{pmatrix}\middle| a,b,c,d\in\mathbb{Z}_n,\ ad-bc=\pm 1 \bmod n\right\}=\mathrm{SL}(2,\mathbb{Z}_n)\cup\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\mathrm{SL}(2,\mathbb{Z}_n).$$

The direct consequence of Theorem 10 is

Corollary 11: *The normalizer $\mathcal{N}(\mathcal{P}_n)$ of the group $\mathcal{P}_n$ is generated by*

$$\mathrm{Out}_I,\mathrm{Ad}_S,\mathrm{Ad}_D,\mathrm{Ad}_Q \quad \textit{and} \quad \mathrm{Ad}_P.$$

If n is prime, i.e., $\mathbb{Z}_n$ is a field, we can use the Bruhat decomposition of $\mathrm{SL}(2,\mathbb{Z}_n)$ and explicitly describe the normalizer. It enables us to count the number of its elements. The group $\mathrm{SL}(2,\mathbb{Z}_n)$ is the union of two disjoint sets

$$\left\{\begin{pmatrix}1 & 0\\ a & 1\end{pmatrix}\begin{pmatrix}b & 0\\ 0 & b^{-1}\end{pmatrix}\middle| a\in\mathbb{Z}_n, b\in\mathbb{Z}_n^*\right\}$$

and

$$\left\{\begin{pmatrix}1 & 0\\ a & 1\end{pmatrix}\begin{pmatrix}b & 0\\ 0 & b^{-1}\end{pmatrix}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}1 & 0\\ c & 1\end{pmatrix}\middle| a,c\in\mathbb{Z}_n, b\in\mathbb{Z}_n^*\right\}.$$

Corollary 12: *Let n be a prime. Any element of the normalizer $\mathcal{N}(\mathcal{P}_n)$ has the form Ad_A or $\mathrm{Out}_I\,\mathrm{Ad}_A$, where $A=D^iM^jQ^kP^l$ or $A=D^iM^jSD^sQ^kP^l$.*

The normalizer $\mathcal{N}(\mathcal{P}_n)$ has therefore $2(n^2-1)n^3$ elements for an odd prime n and 24 elements for $n=2$ (here the outer automorphism does not play any role).

Summarizing, for any natural number n we described the generators of the normalizer $\mathcal{N}(\mathcal{P}_n)/\mathcal{P}_n$. For n prime we moreover were able to determine the cardinality of normalizer, using the Bruhat decomposition of the group $\mathrm{SL}(2,\mathbb{Z}_n)$. For the explicit description of the special n-dimensional representation of $\mathrm{SL}(2,\mathbb{Z}_n)$, where n is prime of the form $n=4K\pm 1$, see Ref. 20.

V. GRADED CONTRACTIONS OF *sl*(3,$\mathbb{C}$)

In this section we want to illustrate how the explicit knowledge of the normalizer of a fine grading can simplify and, indeed, bring further insight into the structure of the problem of finding all graded contractions of $sl(3,\mathbb{C})$. Practically one needs to solve a system of 48 quadratic equations involving 28 contraction parameters. The normalizer is the symmetry group of that system. It turns out that there are only two orbits of the normalizer among the 48 quadratic equations. For more conventional approach to this problem see Refs. 11 and 21.

Let $\mathcal{L}=\oplus_{i\in I}\mathcal{L}_i$ be a grading decomposition of a Lie algebra with the commutator $[\,\cdot\,,\cdot\,]$. Definition of the contracted commutator of the algebra involves the contraction parameters ε_{ij} for $i,j\in I$ and the old commutator. The new bilinear mapping of the form

$$[x,y]_{new}:=\varepsilon_{ij}[x,y] \quad \text{for all } x\in\mathcal{L}_i,\ y\in\mathcal{L}_j$$

is a commutator on the same vector space $\mathcal{L}$.

To satisfy antisymmetry of the commutator we have to choose $\varepsilon_{ij}=\varepsilon_{ji}$. To satisfy the Jacobi identity one has to solve a system of quadratic equations for the unknown contraction parameters ε_{ij}.

Let us illustrate this problem on the graded algebra $sl(3,\mathbb{C})=\oplus_{(i,j)\neq(0,0)}\mathcal{L}_{ij}$, which has 8 one-dimensional graded subspaces $\mathcal{L}_{ij}=\mathbb{C}X_{ij}$, where $0\leqslant i,j\leqslant 2$. For example, for the triple of vectors $X_{(0,1)}$, $X_{(0,2)}$, and $X_{(1,0)}$ the Jacobi identity has the form

$$[X_{(0,1)},[X_{(0,2)},X_{(1,0)}]_{\text{new}}]_{\text{new}}+\text{cyclically}=0.$$

The commutation relations (7) give us

$$\varepsilon_{(02)(10)}\varepsilon_{(01)(12)}(\omega-1)(\omega^2-1)X_{(1,0)}+\varepsilon_{(10)(01)}\varepsilon_{(02)(11)}(1-\omega)(\omega^2-1)X_{(1,0)}=0$$

and therefore

$$\varepsilon_{(02)(10)}\varepsilon_{(01)(12)}-\varepsilon_{(10)(01)}\varepsilon_{(02)(11)}=0. \tag{13}$$

For all possible triples of basis elements $X_{(i,j)}$ we have to write similar equations. There are $\binom{8}{3}=56$ triples. Since triples of the form $X_{(a,b)}$, $X_{(c,d)}$, and $X_{(e,f)}$, with $a+c+e=0(\mathrm{mod}\,3)$ and $b+d+f=0(\mathrm{mod}\,3)$ satisfy $[X_{(a,b)},[X_{(c,d)},X_{(e,f)}]]=0$, we have in fact only 48 equations.

The Jacobi identity for the triple $X_{(0,1)}$, $X_{(1,0)}$, and $X_{(1,1)}$, is the equality

$$\varepsilon_{(10)(11)}\varepsilon_{(01)(21)}-\varepsilon_{(11)(01)}\varepsilon_{(10)(12)}=0. \tag{14}$$

The triple of indices (0,1), (1,0), and (1,1) is distinguished by the property that the indices of any epsilon appearing in (14) are linearly independent over the field $\mathbb{Z}_3$. Quite different are the indices in (13) There the pair of indices (0,1) and (0,2) is linearly dependent over the field $\mathbb{Z}_3$. These two cases exhaust all distinct possibilities for the choice of triples in the Jacobi identity.

Consider now the mappings on the index set I defined by (11)

$$(i,j)\mapsto(i,j)A \quad \text{where} \quad A\in \mathrm{SL}(2,\mathbb{Z}_3).$$

Applying such a mapping with a fixed matrix A to the indices occurring in Eq. (13) we obtain a new equation corresponding to the Jacobi identity for another triple of grading subspaces. If we gradually apply all 24 matrices from $\mathrm{SL}(2,\mathbb{Z}_3)$ to Eqs. (13) and (14), we obtain all 48 quadratic equations which should be satisfied. In this way the symmetries of the system of equations are directly seen.

We study Darboux and Laplace transformations of the solutions and potentials of the Goursat equation which is equivalent to one of the Lax pair equations for the 2D-MKdV hierarchy. The reduction restrictions for these transformations are considered. The derived reduction equations are generalizations of the Liouville and sinh-Gordon equation. The integrability of these equations by the ST method is proved. The binary Darboux transformation for the Goursat equation is suggested. We find exact rational nonsingular solutions of the 2D-MKdV equations via the Moutard transformation for the Goursat equation. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1427761]

I. INTRODUCTION

A covariance of general Lax pairs leads to abundant but generally useless integrable systems while reductions of them may have straight applications in mathematical physics.[1] In $2+1$ or higher dimensions there exists the problem of an elaboration of similar or another approach to classification or at least of a choice of invariant subsets by some key rule.[2] Such a rule is directly connected with discrete covariance of Lax equations[3] that appears in the classic Laplace scheme developed by Darboux, Moutard, and Le Roux[4] and investigated recently from different points of view (e.g., Refs. 5 and 6). We consider subclasses of Laplace (Darboux)-covariant ''potentials,'' i.e., introduce a notion of ''reduction equation'' that follows directly from the constraint form invariance. It means that Darboux (Laplace) transforms together with the appropriate partial solutions of a basic equation determine some discrete symmetry and chains of solutions. Let us demonstrate this by an example.

It is known that the Laplace transformation (LT) of the equation

$$\psi_{xy}+a\psi_y+b\psi=0 \tag{1}$$

has the form

$$a\to a_{-1}=a-\partial_x \ln(b-a_y), \quad b\to b_{-1}=b-a_y, \quad \psi\to\psi_{-1}=\psi_x+a\psi, \tag{2}$$

$$a\to a_1=a+\partial_x \ln b, \quad b\to b_1=b+\partial_y(a+\partial_x \ln b), \quad \psi\to\psi_1=\frac{\psi_y}{b}, \tag{3}$$

and plays a significant role in the theory of soliton equation development.

The Goursat equation (GE) has the form[7]

$$\zeta_{xy}=2\sqrt{\lambda\zeta_x\zeta_y},$$

a)Electronic mail: leble@mifgate.pg.gda.pl
b)Electronic mail: yurov@freemail.ru

where $\zeta=\zeta(x,y)$ and $\lambda=\lambda(x,y)$. We call λ a potential function. This equation can be linearized by the substitution $\psi=\sqrt{\zeta_x}$ and $\chi=\sqrt{\zeta_y}$. We get

$$\psi_y=\sqrt{\lambda}\chi, \quad \chi_x=\sqrt{\lambda}\psi$$

or

$$\psi_{xy}=\tfrac{1}{2}(\ln\lambda)_x\psi_y+\lambda\psi, \tag{4}$$

and the similar equation for the χ but we will not need one.

Equation (4) is the particular case of Eq. (1) with two potentials $a=a(x,y)$ and $b=b(x,y)$. This equation has two types of local discrete symmetries:

(1) Laplace transformations (2) and (3), mentioned above, and
(2) Darboux transformations (DT):

$$a\to a_1=a-\partial_x\ln(a+\tau), \quad b\to b_1=b+\tau_y, \quad \psi\to\psi_1=\psi_x-\tau\psi, \tag{5}$$

$$a\to{}_1a=-(\tau+b\rho), \quad b\to{}_1b=b-(b\rho)_y, \quad \psi\to{}_1\psi=\rho\psi_y-\psi, \tag{6}$$

where $\tau=\phi_x/\phi$, $\rho=\phi/\phi_y$, ψ and ϕ are particular solutions of (1) by preassigned a and b, and we call ϕ **the support function** of the DT.

The aim of this work is to study the validity of LT and DT for the GE. It is clear that after single DT or LT the reduction restriction

$$a=-\partial_x\ln b \tag{7}$$

will be true only for the special class of potentials and we will specify it in Sec. II.

Our interest in the GE is connected with the two applications of this equation in geometry and in the solitons theory, respectively.

(1) Let x be the complex coordinate, $y=-\overline{x}$, $\sqrt{\lambda}$ is the real-valued function, and ψ and χ from (1) are complex-valued functions. Then one defines three real-valued functions X_i, $i=1,2,3$, which are the coordinates of surface in R^3:[8]

$$X_1+iX_2=2i\int_\Gamma(\overline{\psi^2}dy'-\overline{\chi^2}dx'),$$

$$X_1-iX_2=-2i\int_\Gamma(\psi^2dy'-\chi^2dx'), \tag{8}$$

$$X_3=-2\int_\Gamma(\overline{\psi}\chi dy'+\overline{\chi}\psi dx'),$$

where Γ is an arbitrary path of integration in the complex plane. The corresponding first fundamental form, the Gaussian curvature K, and the mean curvature H yield

$$ds^2=4U^2dxdy, \quad K=\frac{1}{U^2}\partial_x\partial_y\ln U, \quad H=\frac{\sqrt{\lambda}}{U},$$

where

$$U=|\psi|^2+|\chi|^2,$$

and any analytic surface in R^3 can be globally represented by (8) (see Ref. 9).

(2) The system of the 2D-MKdV equations looks like:

$$4\lambda^2(\lambda_t - A\lambda_x + B\lambda_y - \lambda_{3x} - \lambda_{3y}) + 4\lambda^3[(2\lambda + B)_y + (2\lambda - A)_x]$$
$$+ 6\lambda(\lambda_y\lambda_{yy} + \lambda_x\lambda_{xx}) - 3(\lambda_x^3 + \lambda_y^3) = 0, \tag{9a}$$
$$B_x = 3\lambda_y - \lambda_x, \quad A_y = \lambda_y - 3\lambda_x.$$

Here $\lambda = \lambda(x,y,t)$, $A = A(x,y,t)$, $B = B(x,y,t)$. If we introduce the function $u = \sqrt{\lambda}$ then we can rewrite (9) in the more customary form (see Ref. 10):

$$u_t + 2u^2(u_x + u_y) + \tfrac{1}{2}(B_y - A_x)u + Bu_y - Au_x - u_{3y} - u_{3x} = 0$$
$$B_x = (3\partial_y - \partial_x)u^2, \quad A_y = (\partial_y - 3\partial_x)u^2. \tag{9b}$$

The reduction conditions

$$A = -B = -2u^2, \quad u_y = u_x,$$

lead us to the MKdV equation,

$$u_t + 12u^2u_x - 2u_{3x} = 0,$$

so we call (9a) the 2D-MKdV equations.

The 2D-MKdV equations (9) is the compatibility condition of the linear system (so-called [L, A] pair) which contains Eq. (4) and

$$\psi_t = \psi_{3x} + \psi_{3y} - \frac{3}{2}\frac{\lambda_y}{\lambda}\psi_{yy} + \left[\frac{3}{4}\left(\frac{\lambda_y}{\lambda}\right)^2 - \lambda - B\right]\psi_y + (A - \lambda)\psi_x + \frac{1}{2}(A_x - \lambda_x)\psi.$$

We will study (9a) in the last section (Sec. IV).

Remark 1: In Ref. 11 A. I. Zenchuk studied the discrete transformation (2), (3), (5), and (6) of solutions and potentials in the general case of the linear second order partial differential equation with two independent variables. The simplest ($k=2$) closed chains of these transformations are considered and the author obtain a novel **integrable** equation:

$$\tfrac{1}{2}S_{xy} - e^S - e^{-S}[C_1 - C_2\partial_x^{-1}(e^{-S})_y] = 0, \tag{10}$$

where $C_2 > 0$.

In the present work we use reduction restriction (7) as a (weak) condition of closing. In Sec. II we will obtain a new integrable equation [see (19)] which looks like (10) and it is a somewhat two-dimensional generalization of the sinh-Gordon equation. In Sec. III we suggest the binary DT for a construction of explicit solutions of the GE. These transformations allow one to obtain new solutions of the GE without solving some reduction equation. We also discuss the transformation for Laplace invariants.

II. THE REDUCTION EQUATIONS

The reduction restriction (7) is valid only for special types of potentials. These functions are solutions of the special equations which we call **reduction equations**. In this section we will obtain these equations for the LT and DT.

(I) Let us consider the Laplace transformations (2). The invariance of the reduction constraint means

$$\lambda_{-1} = \lambda - \frac{1}{2}\partial_x\partial_y \ln\lambda = \frac{C}{2\lambda}. \tag{11}$$

It is obvious that Eq. (11) is valid for the LT (3) because the one is inverse to the transformation (2).

It easy to show that the reduction equation for this transformation is the well-known sinh-Gordon equation:

$$\partial_x\partial_y \ln\lambda = 2\lambda - \frac{C}{\lambda}, \tag{12}$$

where $C=\text{const}$, and the new potential λ_{-1} is a solution of (12) too.

Let us remark that in the case of $C=0$ we obtain $\lambda_{-1}=0$ and the Liouville equation instead of (12). In this case the GE may be integrated and

$$\lambda = \frac{f'g'}{(f+g)^2}, \quad \zeta = -\frac{1}{C^2}\partial_y \ln(f+g) + V,$$

where $f=f(x)$ and $g=g(y)$ are arbitrary differentiable functions, $C=\text{const}$, $V=V(y)$ is the function such that

$$V' = \left[\frac{1}{2C}(\ln g')'\right]^2 = \frac{1}{4C^2}\left(\frac{g''}{g'}\right)^2,$$

and

$$\psi = \frac{\sqrt{f'g'}}{C(f+g)}, \quad \chi = \frac{1}{2C}\partial_y \ln\left(-\partial_y \frac{1}{f+g}\right).$$

Proposition 1: Let M and L be two Laplace invariants of Eq. (4). It means that

$$M = \tfrac{1}{2}\partial_x\partial_y \ln\lambda - \lambda, \quad L = -\lambda.$$

Using the reduction equation (11) we get

$$M = -\frac{C}{2\lambda}, \quad L = -\lambda$$

and

$$M_{-1} = M_1 = L, \quad L_{-1} = L_1 = M.$$

(II) Let us consider the DT (5). Inserting both transforms into the reduction condition (7) yields

$$\lambda_{-1} = \lambda - \tau_y = \lambda\left(\tau - \frac{\lambda_x}{2\lambda}\right). \tag{13}$$

Denote now $\alpha=\ln\phi$, $\Lambda=\ln\lambda$. Since

$$\lambda - \tau_y = (-\tfrac{1}{2}\Lambda_x + \alpha_x)\alpha_y,$$

and $\tau=\alpha_x$ one gets from the transform (13) the condition for Λ:

$$(\alpha_x - \tfrac{1}{2}\Lambda_x)[\alpha_y - \exp(\lambda)(\alpha_x - \tfrac{1}{2}\Lambda_x)] = 0. \tag{14}$$

The setting zero for the first parentheses yields

$$\Lambda_{xy} = 2\exp(\Lambda),$$

and $\alpha=\Lambda/2-c(y)$, where $c(y)$ is arbitrary function. But in this case we get $\lambda_1=0$, and the Liouville equation is in the realm of the reduction equation.

Setting equal to zero the square brackets in (14) one arrives at the relevant equation

$$(\exp(-2\alpha)\lambda)_x=(\exp(-2\alpha))_y, \tag{15}$$

therefore

$$\theta_x=\psi^2=\frac{1}{F_x+C_2}, \quad \lambda=\frac{F_y+C_1}{F_x+C_2},$$

where $F=F(x,y)$ is any differentiable function and $C_{1,2}=\text{const}$. Substituting (15) into (4) we get

$$2(C_2+F_x)C_1^2+[(F_{yxx}+4F_y)C_2+F_xF_{yxx}+4F_yF_x-F_{xx}F_{yx}]C_1+(F_{yxx}F_y-\tfrac{1}{2}F_{yx}^2+2F_y^2)C_2$$
$$+2F_y^2F_x-\tfrac{1}{2}F_{yx}^2F_x-F_yF_{xx}F_{yx}+F_xF_yF_{yxx}=0. \tag{16}$$

We define new fields:

$$F_x=P-C_2, \quad F_y=Q-C_1.$$

Then (16) can be split into the system

$$2Q_xQP_x-(2Q_{xx}Q-Q_x^2+4Q^2)P=0, \quad P_y=Q_x. \tag{17}$$

After integration of the first equation we get

$$P=\frac{CQ_x}{\sqrt{Q}}\exp(G), \quad G_x=2\frac{Q}{Q_x},$$

where C is the third constant of integration. It is necessary that the second equation in (17) will be true. Let

$$Q=n^2, \quad G=\ln m,$$

where $m=m(x,y)$ and $n=n(x,y)$. The reduction equation takes the simple form

$$(n^2)_x=2C(mn_x)_y, \quad m_xn_x=mn. \tag{18}$$

This system can be rewritten in more convenient form. Let

$$n_x=n\exp(S), \quad m_x=m\exp(-S),$$

$S=S(x,y)$. After substituting into (18) we get

$$S_y=\frac{1}{C}\frac{n}{m}-\partial_y\ln(mn),$$

therefore

$$S_{xy}=4\sinh S\partial_y\partial_x^{-1}\cosh S. \tag{19}$$

Equation (19) is the reduction equation for the DT (5). It looks like Eq. (10) and it is the generalization of $d=2$ sinh-Gordon equation. We will present the Lax pair analog for Eq. (19) by the following proposition:

Proposition 2: Let us introduce the $[L,A]$ pair for Eq. (19) in the form

$$K\psi=0, \quad K_1 D\psi=0$$

where

$$K=\partial_x\partial_y-\frac{1}{2}\frac{\lambda_x}{\lambda}\partial_y-\lambda, \quad K_1=\partial_x\partial_y-\frac{1}{2}\frac{\lambda_{1,x}}{\lambda_1}\partial_y-\lambda_1, \quad D=\partial_x-\tau,$$

the variables λ and λ_1 are defined by the equalities

$$\lambda=\frac{(S_x+2\cosh S)_y}{4\sinh S}\exp(-S), \quad \lambda_1=\frac{(S_x+2\cosh S)_y}{4\sinh S}\exp(S), \tag{20}$$

and

$$\tau_y\equiv\lambda-\lambda_1.$$

It is possible to check the statement by direct substitution. Thus the reduction equations for the DT (5) has either the form of Eq. (19) or the Liouville equation.

We can study the reduction equations for the DT (6) analogously. As a result we get

$$\lambda=C_1\phi_y\exp(F), \quad {}_1\lambda=-\frac{C_1C_2\phi^2}{\phi_y}\exp(F), \tag{21}$$

where ϕ is the support function of the DT (6) and the reduction equation can be written like the system:

$$\phi_{xy}=\phi_y[F_x+2C_1\phi\exp(F)], \quad F_y\phi_y-C_2\phi.$$

Proposition 3: By the construction (20) for the DT (5) we get

$$M=-\lambda_1, \quad L=-\lambda,$$

and

$$M_1=M\exp(-2S), \quad L_1=L\exp(2S).$$

Quite similar for the DT (6) the use of (21) gives

$$M=-\frac{C_2(-\phi_x+\phi F_x+C_1\phi^2\exp(F))}{\phi_y}, \quad L=-C_1\phi_y\exp(F),$$

and

$${}_1M=-\frac{\phi_y^2}{C_2\phi^2}M, \quad {}_1L=-\frac{C_2\phi^2}{\phi_y^2}L.$$

The multiple of the Laplace invariants ML is invariant in both cases.

III. BINARY DT

In Ref. 12 Ganzha studied the analog of the Moutard transformation for the Goursat equation. This transformation is valid without a reduction restriction and reduction equations. In this section we obtained binary Darboux transformation for the GE with the same property.

We introduce new variables ξ and η:

$$\partial_y=\partial_\eta-\partial_\xi, \quad \partial_x=\partial_\eta+\partial_\xi,$$

and rewrite (4) in the matrix form

$$\Psi_\eta = \sigma_3 \Psi_\xi + U\Psi, \tag{22}$$

where

$$\Psi = \begin{pmatrix} \psi_1 & \psi_2 \\ \chi_1 & \chi_2 \end{pmatrix}, \quad U = \sqrt{\lambda}\sigma_1, \tag{23}$$

$\psi_k = \psi_k(\xi, \eta)$, $\chi_k = \chi_k(\xi, \eta)$ with the $k = 1,2$ particular solutions of (1) with some $\lambda(\xi, \eta)$, and $\sigma_{1,3}$ are the Pauli matrices. Let Ψ_1 some solution of Eq. (22) and $\Psi \neq \Psi_1$. We define a matrix function $\tau \equiv \Psi_{1,\xi}\Psi_1^{-1}$. Equation (22) is covariant with respect to DT:

$$\Phi[1] = \Phi_\xi - \tau\Phi, \quad U[1] = U + [\sigma_3, \tau]. \tag{24}$$

Remark 2: It is not difficult to check that the DT (24) is the superposition formula for the two simpler Darboux transformations given by formulas (5) and (6).

Remark 3: Equation (22) is the spectral problem for the Davey–Stewartson (DS) equations.[13] The LTs produce an explicitly invertible Bäcklund autotransformation for the DS equations. In Ref. 14 we showed that these transformations allow one to construct solutions to the DS equations that fall off in all directions in the plane according to exponential and algebraic law.

Let us consider a closed one-form

$$d\Omega = d\xi \Phi\Psi + d\eta \Phi\sigma_3\Psi, \quad \Omega = \int d\Omega,$$

where a 2×2 matrix function Φ solves the equation

$$\Phi_\eta = \Phi_\xi \sigma_3 - \Phi U. \tag{25}$$

We shall apply the DT for (22). One can verify by immediate substitution that (25) is covariant with respect to the transform if

$$\Phi[+1] = \Omega(\Phi, \Psi_1)\Psi_1^{-1}.$$

Now we can alternatively affect U by the following transformation:

$$U[+1,-1] = U + [\sigma_3, \Psi_1\Omega^{-1}\Phi].$$

The particular solution of Eq. (25) has the form

$$\Phi_1 = \begin{pmatrix} s_1\psi_1 + s_2\psi_2 & -s_1\chi_1 - s_2\chi_2 \\ s_3\psi_1 + s_4\psi_2 & -s_3\chi_1 - s_4\chi_2 \end{pmatrix}, \tag{26}$$

where $s_k = \text{const}$ $(k = 1,...,4)$. It is convenient to choose one in the form

$$\Phi_1 = \Psi_1^T \sigma_3, \tag{27}$$

where Ψ_1^T is the transposed matrix Ψ_1 [(27) is the particular case of (26)].

In this case

$$U[+1,-1] = U - 2A_F, \tag{28}$$

where A_F is the off-diagonal part of the matrix A:

$$A = \Psi_1\Omega^{-1}\Psi_1^T,$$

$\Omega=\Omega(\Phi_1,\Psi_1)$, and

$$A_F^T=A_F=f\sigma_1, \tag{29}$$

where $f=f(\xi,\eta)$ is a some function.

Using (23), (28), and (29) we can see that $U[+1,-1]$ has the same form as the initial matrix U:

$$U[+1,-1]\equiv\begin{pmatrix} 0 & \sqrt{\lambda[+1,-1]} \\ \sqrt{\lambda[+1,-1]} & 0 \end{pmatrix}=\begin{pmatrix} 0 & \sqrt{\lambda}-2f \\ \sqrt{\lambda}-2f & 0 \end{pmatrix},$$

thus the reduction restriction is valid without the reduction equations.

The new function $\Phi[+1,-1]$ has the form

$$\Phi[+1,-1]=\Phi-\Omega(\Phi,\Psi_1)(\Omega(\Psi_1,\Psi_1))^{-1}\Phi_1, \tag{30}$$

where Φ is arbitrary solution of Eq. (25).

Using binary DT (28) and (30) we can construct a new solution of the GE from understanding particular solutions of one.

As a result we get the following theorem (in the old variables x and y):

Theorem: Let

$$\psi_{k,y}=\sqrt{\lambda}\chi_k, \quad \chi_{k,x}=\sqrt{\lambda}\psi_k, \quad \alpha_{k,y}=-\sqrt{\lambda}\beta_k, \quad \beta_{k,x}=-1\sqrt{\lambda}\alpha_k,$$

where $k=1,2$. Then new functions

$$\alpha_1'=\alpha_1-\frac{A_1\psi_1+A_2\psi_2}{D}, \quad \beta_1'=\beta_1+\frac{A_1\chi_1+A_2\chi_2}{D}$$

are solutions of the equations

$$\alpha_{1,y}'=\sqrt{\lambda'}\beta_1', \quad \beta_{1,x}'=\sqrt{\lambda'}\alpha_1',$$

where

$$\sqrt{\lambda'}=-\sqrt{\lambda}+\frac{\psi_1\chi_1\Omega_{22}+\psi_2\chi_2\Omega_{11}-(\psi_1\chi_2+\psi_2\chi_1)\Omega_{12}}{D},$$

and

$$\Omega_{11}=\int dx\psi_1^2+dy\chi_1^2, \quad \Omega_{12}=\Omega_{21}=\int dx\psi_1\psi_2+dy\chi_1\chi_2,$$

$$\Omega_{22}=\int dx\psi_2^2+dy\chi_2^2, \quad D=\Omega_{11}\Omega_{22}-\Omega_{12}^2,$$

$$\Lambda_{11}=\int dx\alpha_1\psi_1+dy\beta_1\chi_1, \quad \Lambda_{12}=\int dx\alpha_1\psi_2+dy\beta_1\chi_2,$$

$$\Lambda_{21}=\int dx\alpha_2\psi_1+dy\beta_2\chi_1, \quad \Lambda_{22}=\int dx\alpha_2\psi_2+\beta_2\chi_2,$$

$$A_1=\Lambda_{11}\Omega_{22}-\Lambda_{12}\Omega_{12}, \quad A_2=\Lambda_{12}\Omega_{11}-\Lambda_{11}\Omega_{12}.$$

Here $\int = \int_\Gamma$ where Γ is an arbitrary path of integration in the plane. It is easy to obtain the expressions for the functions α_2' and β_2', but we will not do it.

Thus the binary DT allows one to construct explicit solutions of the GE without the solving of some reduction equation.

IV. THE MOUTARD TRANSFORMATION FOR THE 2D-MKdV EQUATIONS

The Lax $([L,A])$ pair for the 2D-MKdV equations (9a) has the form

$$\psi_{xy} = \frac{u_x}{u}\psi_y + u^2\psi,$$
$$\psi_t = \psi_{3x} + \psi_{3y} - 3\frac{u_y}{u}\psi_{yy} + \left[3\left(\frac{u_y}{u}\right)^2 - u^2 - B\right]\psi_y + (A-u^2)\psi_x + \frac{1}{2}(A-u^2)_x\psi. \tag{31}$$

In Ref. 12 Ganzha studied the one of analog of the Moutard transformation for the Goursat equation. To use this transformation for obtaining exact solutions of (9a) we must complete a definition of the Moutard transformation. It is easy to do. Let ϕ be the second solution of (31) (the support function). Then we have a closed one-form,

$$d\theta = dx\,\theta_1 + dy\,\theta_2 + dt\,\theta_3, \quad \theta \equiv \int d\theta,$$

where

$$\theta_1 = \phi^2, \quad \theta_2 = \left(\frac{\phi_y}{u}\right)^2,$$

$$\theta_3 = (A-u^2)\phi^2 - \phi_y^2 - \phi_x^2 + 2\phi\phi_{xx} + \frac{(2\phi_{3y}\phi_y - \phi_{yy}^2 - B\phi_y^2)u^2 - 2u\phi_y(u_y\phi_y)_y + 3(u_y\phi_y)^2}{u^4}.$$

We define the **generalized** Moutard transformation in the following way:

$$u \to \tilde{u} = u - \sqrt{(\ln\theta)_x(\ln\theta)_y}, \quad A \to \tilde{A} = A - (\partial_x\partial_y - 3\partial_x^2)\ln\theta,$$
$$B \to \tilde{B} = B + (\partial_x\partial_y - 3\partial_y^2)\ln\theta, \quad \psi \to \tilde{\psi} = \frac{\phi Q}{\theta}, \tag{32}$$

where

$$Q \equiv \int dQ,$$

$$dQ = dx\,Q_1 + dy\,Q_2 + dt\,Q_3,$$

and $(w = \psi/\phi)$

$$Q_1 = \theta w_x, \quad Q_2 = -\frac{\theta^3(1/\theta)_{xy}w_y}{\theta_{xy}},$$

$$Q_3 = \theta w_{3x} + c_1 w_{3y} + c_2 w_{xx} + c_3 w_{yy} + c_4 w_x + c_5 w_y,$$

with

$$c_1=-\frac{\theta_{xy}}{2u^2}+\theta,\quad c_2=\frac{3}{2}\,\theta(\ln\theta_x)_x-\theta_x,\quad c_4=\left(\frac{3\phi_{xx}}{\phi}+A-u^2\right)\theta-\frac{\theta_{xx}}{2},$$

$$c_3=\frac{u_y\theta_{xy}}{2u^3}+\frac{\phi\phi_{yy}}{u^2}-\frac{3u_y\theta}{u}+3\left(\frac{\theta}{2}(\ln\theta_x)_y-\theta_y\right),$$

$$c_5=-\frac{3u_y^2\theta_{xy}}{2u^4}+\frac{1}{u^3}(\theta_{xy}u_{yy}+u_y\phi\phi_{yy})+\frac{1}{u^2}\left(3\theta u_y^2-\phi\phi_{3y}+\frac{1}{2}\left[B-\frac{\phi_{yy}}{\phi}\right]\theta_{xy}\right)$$
$$+\left(\frac{3\phi_{yy}}{\phi}-B\right)+\frac{u_y}{u}\left(2\theta_y-\frac{3\theta\theta_{xy}}{\theta_x}\right)+\frac{\theta_{xy}}{2}-u^2\theta.$$

The one-form dQ is closed,

$$Q_{1,y}=Q_{2,x},\quad Q_{1,t}=Q_{3,x},\quad Q_{2,t}=Q_{3,y}.$$

It is easy to verify that the $[L,A]$ pair (31) is covariant with respect to the generalized Moutard transformation (32).

Now we use these transformations to construct exact solutions of the 2D-MKdV equations (9a). First we would mention the known localized solutions from Ref. 10. Let us choose $u=\text{const}$, $A=B=0$. We will consider two examples.

(1) If we take the solution of (31) as $\phi=\sinh\xi$, where

$$\xi=ax+\frac{u^2}{a}y+\frac{(u^2-a^2)(u^4-a^4)}{a^3}t, \tag{33}$$

with the real $a=\text{const}$, then using (32) we get new solutions of the 2D-MKdV equations,

$$\tilde{u}=\frac{u[2\eta-a^3\sinh(2\xi)]}{2\eta+a^3\sinh(2\xi)},\quad \tilde{A}=\frac{16a^3\sinh\xi[3a^5\sinh\xi-(u^2-3a^2)\eta\cosh\xi]}{(2\eta+a^3\sinh(2\xi))^2},$$

$$\tilde{B}=\frac{16av^2\cosh\xi[3a^3u^2\cosh\xi-(3u^2-a^2)\eta\sinh\xi]}{(2\eta+a^3\sinh(2\xi))^2},$$

where

$$\eta=a^2(u^2y-a^2x)+(u^2-a^2)(3u^4+3a^4+2a^2u^2)t. \tag{34}$$

(2) To construct the algebraic solutions of (9a) we choose the solutions of (31) as

$$\phi=(-1)^n\int_\alpha^\beta dk\zeta(k)\exp(\xi(k))\frac{d^n}{dk^n}\delta(k-k_0),$$

with $\xi(k)$ from (33), $a=a(k)$, $\beta>k_0>\alpha>0$, and $\zeta(k)$ is some arbitrary differentiable function. For $n=1$, $\zeta=1$, we get

$$\tilde{u}=\frac{u(a^6-2\eta^2-2a^3\eta)}{2\eta^2+2a^3\eta+a^6},\quad \tilde{A}=-\frac{8a^6(u^2+3a^2)\eta(\eta+a^3)}{(2\eta^2+2a^3\eta+a^6)^2},$$
$$\tilde{B}=\frac{8u^2a^4(3u^2+a^2)\eta(\eta+a^3)}{(2\eta^2+2a^3\eta+a^6)^2}, \tag{35}$$

with the η from (34) and $a=a(k_0)$. Equation (35) is a simple nonsingular algebraic solution of the 2D-MKdV.

In the present paper, we investigate value distribution of the higher analogs of the second Painlevé equation $({}_vP_2)$. After getting the precise expression of the dominant term of $({}_vP_2)$, we obtain some value distribution properties for the transcendental meromorphic solutions of $({}_vP_2)$ in the general case which generalize the theorems in Gromak and He [Proc. Math. Inst. Belarus Natl. Acad. Sci. **4**, 37–48 (2000)]. We further get other results for the $({}_vP_2)$ and $({}_4P_2)$. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1420396]

I. INTRODUCTION

It is well known that the Painlevé equations (P_1)–(P_6) are the most important second-order algebraic ordinary differential equations. They were first derived by Painlevé (1897) and by his colleagues at the end of the 19th century from strictly mathematical considerations. In the last few years, there has been considerable interest in the Painlevé equations due to the fact that some of their affinities with mathematical and physical equations, such as (P_2) and the Korteweg–de Vries (KdV) equation, have been found. They arise as reduction of solutions of soliton equations solved by the inverse scattering method.

On the other hand, many works have focused on a variety of properties of Painlevé equations. Recently, Hinkkanen and Laine (1999) completely proved that every local solution of (P_1) and (P_2) admits unrestricted analytic continuation, and hence is a meromorphic function in the complex plane. Steinmets (2001) and Shimomura (2001) proved, by different methods, that the growth order of the solutions of (P_1) and (P_2) are finite. In addition, value distribution properties of the solutions of the Painlevé equations are studied in Baesch (1992), Schubart (1996), Shimomura (2000), Steinmetsz (1989), and Wittich (1968).

In this paper, we are concerned with value distribution of the higher analog of (P_2) which arises as an exact reduction of the higher analog of the KdV equation $({}_m\text{KdV})$. Let L_u be the operator

$$L_u := 2(u + \hat{D}u\hat{D}^{-1}) - \hat{D}^2, \tag{1.1}$$

where $\hat{D} = \partial/\partial x$, $\hat{D}^{-1}$ denotes the integral operator $\int \cdot \, dx$. Consider the higher analog of the KdV equation in the form

$$(2m-1)u_t = X_m u \quad ({}_m\text{KdV})$$

$$X_m u = L_u X_{m-1} u = \hat{D}\frac{\partial H_m}{\partial u}, \tag{1.2}$$

a)Electronic mail: yzhe@math03.math.ac.cn

where $X_1u=\hat{D}u=u_x=\hat{D}(\partial H_1/\partial u)$ and H_m is the Hamiltonian system. Let $z=xt^{-1/(2m-1)}$, $u(x,t)=t^{-2/(2m-1)}q(z)$, then $q(z)$ satisfies the differential equation

$$X_mq+2q+zq'=0,$$

where L_q and X_mq are defined by (1.1) and (1.2) with q and z instead of u and x. If $q(z)=y'(z)+y^2(z)$, and we define the operator $S_y=4y^2+4y'D^{-1}y-D^2$ as in Adler and Moser (1979), we have

$$(2y+D)S_y=L_q(2y+D)$$

and

$$X_mq=(2y+D)S_y^{m-1}(y'). \tag{1.3}$$

Airault (1979) proved that the system

$$y'+y^2=q, \quad y\left(2\frac{\partial H_{m-1}}{\partial q}+z\right)+\alpha=X_{m-1}q$$

is equivalent to the algebraic differential equation

$$({}_vP_2) \quad D^{-1}S_y^{m-1}(y')+zy+\alpha=0,$$

where α is an arbitrary parameter. The order of $({}_vP_2)$ is $v=2m-2$. We call $({}_vP_2)$ the higher analog of the second Painlevé equation. If $m=2$, equations $({}_m\mathrm{KdV})$ and $({}_vP_2)$ become

$$3u_t=6uu_x-u_{xxx}$$

and the second Painlevé equation

$$y''=2y^3+zy+\alpha,$$

respectively, with the connection between the solutions $u(x,t)=t^{-2/3}(y'(z)+y^2(z))$, $z=xt^{-1/3}$, which is the well-known Ablowitz's result. For $m=3$, 4, and 5 in $({}_vP_2)$, we have

$$({}_4P_2) \quad y^{(4)}=10y^2y''+10y(y')^2-6y^5-zy-\alpha,$$

$$({}_6P_2) \quad y^{(6)}=14y^2y^{(4)}+56yy'y^{(3)}+42y(y'')^2-70(y^4-(y')^2)y''-140y^3(y')^2+20y^7+zy+\alpha,$$

$$\begin{aligned}({}_8P_2) \quad y^{(8)}=&18y^2y^{(6)}+108yy'y^{(5)}-6(21y^4-35(y')^2-38yy'')y^{(4)}-138y(y^{(3)})^2\\&-252y'(4y^3-3y'')y^{(3)}+182(y'')^3-756y^3(y'')^2+84y^2(5y^4-37(y')^2)y''\\&-798y(y')^4+1260y^5(y')^2-70y^9-zy-\alpha.\end{aligned}$$

Throughout this paper, we use the standard notations and basic results of the Nevanlinna theory such as $m(r,f)$, $N(r,f)$, $T(r,f)$, $N_1(r,f)=N(r,f)-\overline{N}(r,f)$,

$$\delta(f,c)=\liminf_{r\to\infty}\frac{m\left(r,\frac{1}{f-c}\right)}{T(r,f)}=1-\limsup_{r\to\infty}\frac{N\left(r,\frac{1}{f-c}\right)}{T(r,f)} \quad (c\neq\infty),$$

$$\delta(f,\infty)=\liminf_{r\to\infty}\frac{m(r,f)}{T(r,f)}=1-\limsup_{r\to\infty}\frac{N(r,f)}{T(r,f)},$$

$$\vartheta(f,\infty)=\liminf_{r\to\infty}\frac{N_1(r,f)}{T(r,f)}.$$

And $T(r,1/(f-c))=N(r,1/(f-c))+m(r,1/(f-c))=T(r,f)+O(1)$, $(c\neq\infty)$ is called Nevanlinna's first fundamental theorem.

II. MAIN RESULTS

Theorem 2.1: Let $y(z)$ be a nonrational meromorphic solution of $({}_vP_2)$, then

(i) if $\alpha\neq 0$, then $y(z)$ assumes every complex number $c\in C$ an infinite number of times;

(ii) if $\alpha=0$, then $y(z)$ assumes every nonzero complex number $c\in C\backslash\{0\}$ an infinite number of times. In both of the cases, $y(z)$ has an infinite number of poles and

$$\delta(y,c)=\delta(y,\infty)=0,$$

(iii) if $\alpha=0$, then $\delta(y,\alpha)=\delta(y,0)\leqslant 1/2$,

(iv) $\vartheta(f,\infty)=0$.

Corollary 2.2: Suppose $y(z)$ is a nonrational meromorphic solution of $({}_vP_2)$, then there exists a set E in R with finite linear measure such that for all a, $b\in C$, $a\neq b$ and $(|\alpha|+|a|)(|\alpha|+|b|)\neq 0$, we have

$$\lim_{r\to\infty}\frac{N\left(r,\dfrac{1}{y-a}\right)}{N\left(r,\dfrac{1}{y-b}\right)}=1$$

for $r\notin E$.

Theorem 2.3: Let $y(z)$ be the nonrational meromorphic solution of $({}_vP_2)$, then for $\alpha\neq 0$,

$$\liminf_{r\to\infty}\frac{N\left(r,\dfrac{1}{y'}\right)}{T(r,y)}=2.$$

Theorem 2.4: Suppose $y(z)$ is a nonrational meromorphic solution of $({}_4P_2)$, for $\alpha=(\epsilon/2)$ $(\epsilon^2=1)$, then $y(z)$ has infinite number of poles with residue $-\epsilon$ or 2ϵ, and there is not any pole with residue -2ϵ.

III. PROOF OF THEOREMS

To prove Theorem 2.1, we need the following propositions and lemmas.

Proposition 3.1: The differential polynomial of the left-hand side of $({}_vP_2)$ has only one dominant term in the form $A_m y^{2m-1}$ where

$$A_m=\prod_{j=1}^{m-1}\frac{2(2j-1)}{j}.$$

The degree of other terms is no greater than $2m-3$ and the coefficients are constants except for y whose coefficient is z.

Proof: First, we assert that differentiating or integrating a differential polynomial will neither increase nor decrease the degree of its leading term. In fact, let $y^{l_o}(y')^{l_1}\cdots(y^{(n)})^{l_n}$ be a differential monomial with degree $n_l=l_o+l_1+\cdots+l_n$, then

$$(y^{l_o}(y')^{l_1}\cdots(y^{(n)})^{l_n})'=\sum_{i=0}^{n} l_i y^{l_o}(y')^{l_1}\cdots(y^{(i)})^{l_i-1}(y^{(i+1)})^{l_{i+1}+1}\cdots(y^{(n)})^{l_n}. \tag{3.1}$$

It is obvious that the highest degree of the differential polynomial of the right-hand side of (3.1) is also n_l. On the other hand, if $y^{l_o}(y')^{l_1}\cdots(y^{(n)})^{l_n}$ can be integrated into another differential

polynomial and the highest degree of $\int y^{l_o}(y')^{l_1}\cdots(y^{(n)})^{l_n}dz$ were greater or less than n_l, then the degree of $(\int y^{l_o}(y')^{l_1}\cdots(y^{(n)})^{l_n}dz)'$ is also greater or less than n_l. It is impossible, therefore, that the degree of $\int y^{l_o}(y')^{l_1}\cdots(y^{(n)})^{l_n}dz$ is n_l.

We are going to prove proposition 3.1 by inductive method. For $m=2$, we have

$$\begin{aligned}D^{-1}S_y^{m-1}(y')+zy+\alpha&=D^{-1}S_y(y')+zy+\alpha\\&=D^{-1}(4y^2+4y'D^{-1}y-D^2)(y')+zy+\alpha\\&=D^{-1}(4y^2y'+4y'D^{-1}yy'-y''')+zy+\alpha\\&=\int(6y^2y'-y''')dz+zy+\alpha\\&=2y^3+zy-y''+\alpha.\end{aligned}$$

The dominant term of $D^{-1}S_y(y')$ is $2y^3$ whose degree 3 is greater than the degree of the remaining terms of $D^{-1}S_y(y')$. Therefore, the result holds when $m=2$. For $m=3$, we have

$$\begin{aligned}D^{-1}S_y^2(y')+zy+\alpha&=D^{-1}S_y(6y^2y'-y''')+zy+\alpha\\&=D^{-1}[30y^4y'+y^{(5)}-D12y(y')^2-D6y^2y''-4y^2y^{(3)}-4yy'y''+2(y')^3]\\&\quad+zy+\alpha=6y^5-10y^2y''-10y(y')^2+y^{(4)}+zy+\alpha.\end{aligned}$$

Obviously, the conclusion also holds and $D^{-1}S_y^2(y')$ has only one dominant term $6y^5$. The degree of the remaining term of $D^{-1}S_y^2(y')$ is no greater than $3(=2m-3)$.

Now we may assume that the conclusion in proposition 3.1 holds for $m=k$, i.e., the dominant term of $T=D^{-1}S_y^{k-1}(y')$ is only A_ky^{2k-1} (A_k is a constant only depending on k) and the degree of the remaining monomials is no greater than $2k-3$. We wish to show the result also holds for $m=k+1$. In fact,

$$\begin{aligned}D^{-1}S_y^k(y')+zy+\alpha&=D^{-1}S_yD[D^{-1}S_y^{k-1}(y')]+zy+\alpha\\&=D^{-1}(4y^2+4y'D^{-1}y-D^2)D[T]+zy+\alpha\\&=D^{-1}4y^2D[T]+D^{-1}4y'D^{-1}yD[T]-D^2[T]+zy+\alpha\\&=4y^2(T)-D^{-1}8yy'[T]-D^2[T]+D^{-1}4y'(y[T]-D^{-1}[T]y')+zy+\alpha\\&=-4yD^{-1}[T]y'+4y^2[T]-D^2[T]+zy+\alpha\\&=-4yD^{-1}\left[A_ky^{2k-1}+\sum_{l_o+\cdots+l_{2k-2}\leqslant 2k-3}b_{kl}(y)^{l_o}\cdots(y^{(2k-2)})^{l_{2k-2}}\right]\\&\quad\times Dy+4y^2\left(A_ky^{2k-1}+\sum_{l_o+\cdots+l_{2k-2}\leqslant 2k-3}b_{kl}(y)^{l_o}\cdots(y^{(2k-2)})^{l_{2k-2}}\right)\\&\quad-D^2[T]+zy+\alpha\\&=\frac{4(2k-1)A_k}{2k}y^{2k+1}+4y^2(T-A_ky^{2k-1})\\&\quad-D^2[T]-4yD^{-1}[T-A_ky^{2k-1}]Dy\\&=\frac{4(2k-1)A_k}{2k}y^{2k+1}+\cdots+zy+\alpha+\sum_{l_o+\cdots+l_{2k}\leqslant 2k-1}b_{kl}(y)^{l_o}\cdots(y^{(2k)})^{l_{2k}}.\end{aligned}$$

So the result holds for $m=k+1$. In addition, noting $A_2=2$, from the above-mentioned computing process, we have

$$\begin{aligned}A_{k+1}&=\frac{4(2k-1)A_k}{2k}=\frac{4(2k-1)}{2k}\,\frac{4[2(k-1)-1]}{2(k-1)}A_{k-1}\\&=\frac{4(2k-1)}{2k}\,\frac{4[2(k-1)-1]}{2(k-1)}\cdots\frac{4(4-1)}{4}A_2\\&=A_2\prod_{j=2}^{k}\frac{4(2j-1)}{2j}=\prod_{j=1}^{k}\frac{2(2j-1)}{j}.\end{aligned}$$

Now we can rewrite $({}_vP_2)$ in the following form:

$$\begin{aligned}P(\alpha,z,y,y',\ldots,y^{(2m-2)})&=(A_m y^{2m-1}+\cdots+zy+\alpha)+y^{(2m-2)}\\&\quad+\sum_{l=l_o+\cdots+l_{2m-2}\leqslant 2m-3}B_l(y)^{l_o}\cdots(y^{(2m-2)})^{l_{2m-2}}=0,\end{aligned}\tag{3.2}$$

where $l_o+l_1+\cdots+l_{2m-2}\geqslant 2$, $l_1+\cdots+l_{2m-2}\geqslant 1$ and B_l is constant.

Lemma 3.2 (J. Clunie): Let f be a transcendental meromorphic solution of

$$f^nP(z,f)=Q(z,f),$$

where $P(z,f)$ and $Q(z,f)$ are polynomials in f and its derivatives with meromorphic coefficients, say $\{a_\lambda|\lambda\in I\}$, such that $m(r,a_\lambda)=S(r,f)$ for all $\lambda\in I$. If the total degree of $Q(z,f)$ as a polynomial in f and its derivatives is $\leqslant n$, then

$$m(r,P(z,f))=S(r,f).$$

Lemma 3.3 (A. Z. Mohon'ko and V. D. Mohon'ko): Let

$$P(z,f,f',\ldots,f^{(n)})=0\tag{3.3}$$

be an algebraic differential equation, i.e., $P(z,u_o,u_1,\ldots,u_n)$ is a polynomial in all of its arguments, and let f be a transcendental meromorphic solution of (3.3). If a constant $c\in\mathbf{C}$ does not solve (3.3), then

$$m\left(r,\frac{1}{f-c}\right)=S(r,f).$$

For proofs of the lemmas, see Lemma 2.4.2 and Proposition 9.2.3 in Laine (1993).

Proposition 3.4: Suppose $y(z)$ is a nonrational solution of $({}_vP_2)$. If $\alpha=c=0$, then $m(r,y)\leqslant\frac{1}{2}T(r,y)+S(r,y)$.

Proof: If $\alpha=0$, multiply $({}_vP_2)$ by $2y'$ and integrating, we get

$$\begin{aligned}&\int_{z_o}^{z}2D^{-1}S_y^{m-1}(y')y'\,\mathrm{d}z+\int_{z_o}^{z}2zyy'\,\mathrm{d}z\\&\quad=2yD^{-1}S_y^{m-1}(y')\\&\quad\quad-\int_{z_o}^{z}2yS_y^{m-1}(y')\mathrm{d}z+zy^2-\int_{z_o}^{z}y^2\,\mathrm{d}z=0\ .\end{aligned}\tag{3.4}$$

By (1.2) and (1.3), we have

$$2yS_y^{m-1}(y')=X_m(y'+y^2)-DS_y^{m-1}(y')=D\frac{\partial H_m(q)}{\partial q}-DS_y^{m-1}(y'),$$

where $q=y'+y^2$, H_m is the Hamiltonian system. Therefore

$$\int_{z_o}^{z}2yS_y^{m-1}(y')\mathrm{d}z=\frac{\partial H_m(q)}{\partial q}-S_y^{m-1}(y')$$

is a differential polynomial. Since differentiating or integrating a differential polynomial does not change its total degree, by (3.2), (3.4) can be written in the following form:

$$\int_{z_o}^{z}y^2\,\mathrm{d}z=zy^2+\sum_{l=l_o+\cdots+l_{2m-3}\leqslant 2m-3}C_l(y)^{l_o}\cdots(y^{(2m-3)})^{l_{2m-3}}+C_0$$

with $l_o+l_1+\cdots+l_{2m-3}\geqslant 2$ and C_l, C_0 are constants. Set

$$G(z)=zy^2+\sum_{l=l_o+\cdots+l_{2m-3}\leqslant 2m-3}C_l(y)^{l_o}\cdots(y^{(2m-3)})^{l_{2m-3}}$$

by proposition 3.1 and lemma 3.2, we have $m(r,G)=S(r,y)$.

From $G'(z)=y^2$, it is easy to know that $m(r,G/G')=S(r,y)$. Since $y(z)$ has only simple poles [Gromak and He (2000)], we have

$$N(r,G)=N(r,G')-\overline{N}(r,G')=N(r,y^2)-\overline{N}(r,y^2)=N(r,y)$$

hence $T(r,G)=T(r,y)+S(r,y)$ and $S(r,G)=S(r,y)$. From all the above, we have

$$2m\left(r,\frac{1}{y}\right)=m\left(r,\frac{1}{y^2}\right)=m\left(r,\frac{1}{G'}\right)\leqslant m\left(r,\frac{G}{G'}\right)+m\left(r,\frac{1}{G}\right)=m\left(r,\frac{1}{G}\right)+S(r,y)\leqslant T(r,y)+S(r,y)$$

so we can get the result of proposition 3.4.

Proof of Theorem 2.1: Suppose $y(z)$ is a nonrational solution of $({}_vP_2)$. By (3.2), $({}_vP_2)$ can be written as

$$A_m y y^{2m-2}=\sum_{l=l_o+\cdots+l_{2m-2}\leqslant 2m-3}B_l(y)^{l_o}\cdots(y^{(2m-2)})^{l_{2m-2}}+zy+\alpha$$

then by lemma 3.2 it follows

$$m(r,y)=S(r,y).$$

Therefore, $\delta(y,\infty)=0$ and so y has infinitely many poles. And through computation, it is not difficult to know c does not solve (3.2) in both cases of (i) and (ii). By lemma 4.3, we have $m(r,1/(y-c))=S(r,y)$ for both cases, hence $\delta(y,c)=0$ and y has infinitely many c points.

If $\alpha=0$, by proposition 3.4 and the definition of $\delta(y,0)$, we have $\delta(y,0)\leqslant\frac{1}{2}$.

Note: Especially, for $({}_4P_2)$, the multiplicity of zeros of $y(z)$ is no more than 3. In fact, by $({}_4P_2)$, we have

$$\frac{y^{(4)}}{y}=10yy''+10y(y')^2-6y^4-z. \tag{3.5}$$

If z_o is a zero of $y(z)$ with multiply $k(k\geqslant 4)$, then z_o must be a pole of the left-hand side of (3.5), this contradicts with the right-hand side of (3.5).

(iv) follows from the fact that $y(z)$ has only simple poles.

Proof of Corollary 2.2: If $|\alpha|+|a|\neq 0$, then by Theorem 2.1 and Nevanlinna's first fundamental theorem

$$N\left(r,\frac{1}{y-a}\right)=T(r,y)-m\left(r,\frac{1}{y-a}\right)+O(1)=T(r,y)+S(r,y)$$

and then

$$N\left(r,\frac{1}{y-a}\right)=T(r,y)(1+o(1)),\quad r\notin E_1,$$

where E_1 is a set with finite linear measure. Similarly for $|\alpha|+|b|\neq 0$,

$$N\left(r,\frac{1}{y-b}\right)=T(r,y)(1+o(1)),\quad r\notin E_2,$$

where E_2 is a set with finite linear measure. Set $E=E_1\cup E_2$, then

$$\lim_{r\to\infty}\frac{N\left(r,\frac{1}{y-a}\right)}{N\left(r,\frac{1}{y-b}\right)}=1$$

for $r\notin E$.

Proof of Theorem 2.3: Differentiating (3.2), we get

$$\begin{aligned}y=&-(2m-1)A_m y^{2m-2}y'-\cdots-zy'\\&-\sum_{l\leqslant 2m-3}B_l\sum_{i=0}^{2m-2}l_i y^{l_o}\cdots(y^{(i)})^{l_i-1}(y^{(i+1)})^{l_{i+1}+1}\cdots(y^{(2m-2)})^{l_{2m-2}}\end{aligned}\tag{3.5$'$}$$

dividing (3.5) by y' and rewriting it as the following form:

$$\begin{aligned}\frac{y}{y'}=&-(2m-1)A_m y^{2m-2}-\cdots-z\\&-\sum_{l\leqslant 2m-3}B_l\sum_{i=0}^{2m-2}l_i y^{l_o}(y')^{l_1-1}\cdots(y^{(i)})^{l_i-1}(y^{(i+1)})^{l_{i+1}+1}\cdots(y^{(2m-2)})^{l_2m-2}\\=&L_1(y)+L_2(y)+L_3(y)=L(y)\ ,\end{aligned}$$

where $L_1(y)=-(2m-1)A_m y^{2m-2}-\cdots-z$, $L_2(y)=-\Sigma_{l\leqslant 2m-3}B_l l_o y^{l_o-1}(y')^{l_1}\cdots(y^{(2m-2)})^{l_{2m-2}}$,

$$L_3(y)=-\sum_{l\leqslant 2m-3}B_l\sum_{i=1}^{2m-2}l_i y^{l_o}(y')^{l_1-1}\cdots(y^{(i)})^{l_i-1}(y^{(i+1)})^{l_{i+1}+1}\cdots(y^{(2m-2)})^{l_2m-2}$$

and $l_1+\cdots+l_{2m-2}\geqslant 1$ for $L_3(y)$. Noting $m(r,y)=S(r,y)$ and $m(r,y^{(i+k)}/y^{(i)})=S(r,y)$ outside a set of r with finite linear measure, from the above-mentioned expression, we have

$$m\left(r,\frac{y}{y'}\right)=m(r,L(y))\leqslant M_1 m(r,y)+M_2\sum_{i=1}^{2m-2}m\left(r,\frac{y^{(i)}}{y}\right)+M_3\sum_{i=2}^{2m-2}m\left(r,\frac{y^{(i)}}{y'}\right)=S(r,y),\tag{3.6}$$

where M_1, M_2, and M_3 are constants. Since $m(r,1/y)=S(r,y)$ for $\alpha\neq 0$, we get

$$m\left(r,\frac{1}{y'}\right)\leqslant m\left(r,\frac{y}{y'}\right)+m\left(r,\frac{1}{y}\right)=S(r,y)$$

we know that $y(z)$ just has simple poles, thus

$$T(r,y')=m(r,y')+N(r,y')=2N(r,y)+S(r,y).$$

By Nevanlinna's first fundamental theorem, we have

$$N\left(r,\frac{1}{y'}\right)=T(r,y)-m\left(r,\frac{1}{y'}\right)+O(1)=2T(r,y)+S(r,y)$$

therefore

$$\liminf_{r\to\infty}\frac{N\left(r,\frac{1}{y'}\right)}{T(r,y)}=2.$$

This proves Theorem 2.3.

To prove Theorem 2.4, we need the following proposition:

Proposition 3.5: Suppose $y(z)$ is a nonrational meromorphic solution of $({}_4P_2)$ and z_o is a pole of $y(z)$, then $y(z)$ just has its poles with residues ±1, ±2 and if the residues $a_{-1}=\pm1$, $y(z)$ have the following expression

$$y(z)=\pm(z-z_o)^{-1}+a_1(z-z_o)+a_2(z-z_o)^2+\cdots \tag{3.7}$$

if the residues $a_{-1}=\pm2$, then

$$y(z)=\pm2(z-z_o)^{-1}+a_3(z-z_o)^3+\cdots. \tag{3.8}$$

Proof: Suppose $y(z)=a_{-1}(z-z_o)^{-1}+\Sigma_{n=1}^{\infty}a_n(z-z_o)^n$, substituting it into $({}_4P_2)$, then we have

$$\begin{aligned}
&24a_{-1}(z-z_o)^{-5}+\sum n(n-1)(n-2)(n-3)a_n(z-z_o)^{n-4}\\
&\quad=10\left(a_{-1}(z-z_o)^{-1}+\sum_{n=1}^{\infty}a_n(z-z_o)^n\right)^2\left(2a_{-1}(z-z_o)^{-3}+\sum_{n=1}^{\infty}n(n-1)a_n(z-z_o)^{n-2}\right)\\
&\qquad+10\left(a_{-1}(z-z_o)^{-1}+\sum_{n=1}^{\infty}a_n(z-z_o)^n\right)\left(-a_{-1}(z-z_o)^{-2}+\sum_{n=1}^{\infty}na_n(z-z_o)^{n-1}\right)^2\\
&\qquad-6\left(a_{-1}(z-z_o)^{-1}+\sum_{n=1}^{\infty}a_n(z-z_o)^n\right)^5-z\left(a_{-1}(z-z_o)^{-1}+\sum_{n=1}^{\infty}a_n(z-z_o)^n\right)-\alpha.
\end{aligned}\tag{3.9}$$

Comparing the coefficients of $(z-z_o)^{-5}$, we have $24a_{-1}=20(a_{-1})^3+10(a_{-1})^3-6(a_{-1})^5$, since $a_{-1}\neq0$, we get $a_{-1}=\pm1$ or ±2; comparing the coefficients of $(z-z_o)^{-3}$ of both sides of Eq. (3.9), we get $40a_1(a_{-1})^2-10a_1(a_{-1})^2-30a_1(a_{-1})^4=0$, it follows that $a_1=0$ or $a_{-1}=\pm1$; Similarly from the coefficients of $(z-z_o)^{-2}$, we get $60a_2(a_{-1})^2-30a_2(a_{-1})^2-6C_5^4a_2(a_{-1})^4=0$ and then $a_2=0$ or $a_{-1}=\pm1$. So $y(z)$ has the property shown in the theorem.

Proof of Theorem 2.4: According to Airault (1979) and Gromak and Lukashevich (1990) for $\alpha=\epsilon/2$, $({}_4P_2)$ is equivalent to the system

$$y' = -\epsilon y^2 + w, \quad w'' = 3\epsilon w^2 + \frac{\epsilon z}{2}. \tag{3.10}$$

Let $(w(z),\epsilon) = w_\epsilon(z)$ denote the solution of (3.10) with parameter ϵ; Let z_{-1}, z_1, z_{-2}, and z_2 denote the poles of $y(z)$ with residue -1, 1, -2, and 2, respectively. If $\epsilon = 1$, then by (3.8), (3.9), and the first equation of (3.10), the Laurent expansions of $w(z)$ around z_{-1}, z_2 and z_1 are

$$w_1(z) = \frac{2}{(z-z_{-1})^2} - 2a_3(z-z_{-1})^2 + \cdots,$$

$$w_1(z) = \frac{2}{(z-z_2)^2} + 7a_3(z-z_2)^2 + \cdots,$$

$$w_1(z) = 3a_1 + 4a_2(z-z_1) + \cdots,$$

respectively. These expansions show that $w_1(z)$ has double poles at z_{-1} and z_2 and it is analytic at z_1. For $z = z_{-2}$, from (3.8) and the first equation of (3.10), we have

$$w_1(z) = \frac{6}{(z-z_2)^2} - a_3(z-z_2)^3 + \cdots.$$

It is obvious that $w_1(z)$ is not a solution of (3.10), because it does not satisfy the second equation of (3.10). So in the case $\epsilon = 1$, $y(z)$ has no poles with residue -2. If $\epsilon = -1$, by using the same reasoning, we get the following conclusions: $w_{-1}(z)$ has second-order poles at z_1, z_{-2} and is analytic at z_{-1}; $y(z)$ has no poles with residue 2.

Let E_ϵ denote the set of poles of $y(z)$ with residues $-\epsilon$ and 2ϵ, then E_ϵ is also the set of the poles of $w_\epsilon(z)$. We assert E_ϵ is an infinite set. In fact, from the second equation of (18), we have

$$2m(r,w_\epsilon) = m\left(r, w_\epsilon \frac{w_\epsilon''}{w_\epsilon}\right) + O(\log r) \leqslant m(r,w_\epsilon) + S(r,w_\epsilon)$$

hence, $m(r,w_\epsilon) = S(r,w_\epsilon)$. Then $N(r,w_\epsilon) = T(r,w_\epsilon) + S(r,w_\epsilon)$, and by definition $w_\epsilon(z)$ has an infinite number of poles. This proves Theorem 2.4.

Question: Related to Theorem 2.4, we are not sure whether y has infinitely many poles with residues $-\epsilon$ and infinitely many with $+2\epsilon$, but we believe this to be the case.

(Received 14 December 2000; accepted for publication 5 November 2001)

The L^p spectrum of the streaming operator in spherical geometry with detailed balancing wall is discussed. First, the L^p-independence of the spectrum is established. Second, the Browder essential spectrum is proved to be empty except for ∞ under the assumption that the wall is nonmultiplying. Finally, we give a simple example to show that the L^p spectral independence of the operator is not valid if the wall is not detailed balancing. © *2002 American Institute of Physics.*

I. INTRODUCTION

The systematic study of L^p spectral independence of differential operators in L^p spaces was initiated by Simon. He conjectured in Refs. 1 and 2 that the spectrum of the Schrödinger operator $-\Delta+V$ is of L^p independence when V belongs to Kato class. This problem was solved by Hempel and Voigt.[3,4] Since then, the L^p spectral independence for some general and higher order elliptic operators was established by many researchers (see, e.g., Refs. 5–7, and the references therein). On the other hand, Hempel and Voigt[4] gave an interesting example (a second-order singular differential operator on the half line) which shows that the spectrum is L^p dependent. So, generally speaking, the spectra of physical interesting operators are not always L^p independence. Nevertheless, we will show in this paper that the L^p spectral independence of the streaming operator, which is important in physics (especially in gas dynamics,[8] neutron transport,[9,10] and radiative transfer,[11] etc.), is valid if the material wall satisfies the detailed balancing principle.

Roughly speaking, the streaming operator is a first-order singular differential operator equipped with a half range boundary condition which is expressed by an integral operator.[8,12–14] So, we may regard the streaming operator as a differential-integral operator (rather than a differential operator) which is different from the Schrödinger operator in its physical background. Physics suggests that the natural space for Schrödinger operator is L^2 (Refs. 1, 2, and 15) whereas the natural space for streaming operator is L^1.[8,12–14] But the streaming operator is also treated in L^p spaces for some technical reasons (see, e.g., Refs. 8, 16, and 17). Generally speaking, we can calculate the spectrum of an operator more easily in L^2 than in L^1. Then a question arises: Is the L^2 spectrum just the L^1 one? This is the problem of L^p spectral independence. If the answer to the problem is negative, then the dynamics governed by the operator in L^2 may differ greatly from that in L^1 and results obtained in L^2 space do not tell the real story of the original physical problem. So just as in the theory of Schrödinger operators, the problem of L^p spectral independence is also important in the theory of streaming operators. Of course, this problem is also interesting from a pure mathematical point.

This paper is organized as follows: In Sec. II we describe the problem and the main results, and give the equivalent description of the problem. In Sec. III we prepare some auxiliary propositions which will be used in the proof of the main results. Section IV is devoted to the proof of Theorems 2.1 and 2.2, and we will finish the proof by several steps. In Sec. V, a counterexample is given to show that the spectrum is L^p dependent if the wall does not satisfy the detailed balancing principle [condition (2) of Sec. II].

II. DESCRIPTION OF THE PROBLEM AND MAIN RESULTS

For simplicity, we will restrict ourselves to the one-speed and spherical symmetric case. The spectrum of this operator was discussed in Refs. 12 and 13 in the L^1 setting. The multispeed case was thoroughly studied in Refs. 14 and 18, and we will follow the notations used there. Note that the results obtained in Ref. 14 are also valid for the one-speed case if we let $V_m=V_M=1$. It should be mentioned here that the spectra of the operator in slab geometry were discussed in Refs. 19 and 20 in L^1 space and in Refs. 16 and 17 (more general boundary conditions were considered) in L^p setting, and that more general cases (multidimensional and abstract boundary conditions) were discussed in Refs. 8 and 21 in the L^2 and L^1 spaces. Nevertheless, those authors did not investigate the L^p independent properties of the spectra.

Let $G=[0,R]\times[-1,1]$, $\Omega=[-1,1]$, the streaming operator B_p defined in the space $L^p(G,r^2 dr d\mu)$ for $1\leqslant p\leqslant\infty$ reads:

$$(B_p f)(r,\mu)=-\mu\frac{\partial}{\partial r}f(r,\mu)-\frac{1-\mu^2}{r}\frac{\partial}{\partial\mu}f(r,\mu)-\Sigma(r,\mu)f,\quad (r,\mu)\in[0,R]\times[-1,1]=G.$$

The domain $D(B_p)=\{f|f$ and $B_p f\in L^p(G,r^2\,\mathrm{d}r\,\mathrm{d}\mu)$ such that $f(r,\mu)$ satisfies the diffuse reflection boundary condition, i.e., $f(R,\mu)\in L^p(\Omega,|\mu|\mathrm{d}\mu)$, and $|\mu|f(R,\mu)=\int_0^1\alpha_0(\mu,\mu')\mu' f(R,\mu')\mathrm{d}\mu'$ for $\mu\in[-1,0)\}$. Where $\Sigma(r,\mu)$ is a bounded non-negative and measurable function, and $\alpha_0(\mu,\mu')$ is a non-negative and measurable function defined on $[-1,0)\times(0,1]$ which describes the interaction of particles with the boundary wall, we denote $\inf\{\Sigma(r,\mu)|(r,\mu)\in G\}$ by λ_0.

In the following, we suppose that the boundary wall is bounded multiplying (including conservative and nonmultiplying cases) and satisfies the detailed balancing principle, i.e., $\alpha_0(\mu,\mu')$ satisfies

$$\alpha=\sup\left\{\int_{-1}^{0}\alpha_0(\mu,\mu')\mathrm{d}\mu\,\middle|\,\mu'\in(0,1]\right\}<\infty,\tag{1}$$

$$|\mu'|\alpha_0(\mu,\mu')=|\mu|\alpha_0(-\mu',-\mu),\ (\mu,\mu')\in[-1,0)\times(0,1].\tag{2}$$

Furthermore, we also suppose that for every measurable subset $E\subset[-1,0)$ we have

$$\lim_{\mathrm{mes}\,E\to 0}\sup\left\{\int_E\alpha_0(\mu,\mu')\mathrm{d}\mu\,\middle|\,\mu'\in(0,1]\right\}=0.\tag{3}$$

Now we can write down our main results.

Theorem 2.1: *For every $p\in[1,\infty]$, we have, $\sigma(B_p)=\sigma(B_1)$.*

Theorem 2.2: *If $\alpha\leqslant 1$, then for every $p\in[1,\infty]$, $\sigma_{\mathrm{ess}}(B_p)=\{\infty\}$, where $\sigma_{\mathrm{ess}}(B_p)$ is the Browder essential spectrum of B_p.*

We remark that there exist several definitions of the essential spectrum and the Browder essential spectrum is the largest one among them (see, e.g., Ref. 22, p. 40). We also remark that the Browder essential spectrum is the complement of the discrete spectrum $\sigma_{\mathrm{dis}}(\cdot)$ relative to the spectrum $\sigma(\cdot)$ and the discrete spectrum $\sigma_{\mathrm{dis}}(\cdot)$ consists of all isolated eigenvalues with finite algebraic multiplicity (Ref. 23, pp. 242–243).

As in Refs. 12 and 14, we use the transformation $x=r\mu$, $y=r\sqrt{1-\mu^2}$, then B_p has the following equivalent form:

$$B_p:X_p\to X_p;(B_p\varphi)(x,y)=-\frac{\partial}{\partial x}\varphi(x,y)-\sigma(x,y)\varphi(x,y),$$

$$D(B_p)=\{\varphi|\varphi\ \text{ and }\ B_p\varphi\in X_p\ \text{ such that }\ \varphi(\pm\sqrt{R^2-y^2},y)\in Y_p,$$

and

$$\frac{y}{R^2}\varphi(-\sqrt{R^2-y^2},y)=\int_S \alpha(y,y')\frac{y'}{R^2}\varphi(\sqrt{R^2-y'^2},y')\mathrm{d}y'\},$$

where $X_p=L^p(D,y\,\mathrm{d}x\,\mathrm{d}y)$ and $Y_p=L^p(S,(y/R^2)\,\mathrm{d}y)$ with $D=\{(x,y)|x^2+y^2\leqslant R^2,y\geqslant 0\}$ and $S=[0,R]$. We denote the norms of X_p and Y_p by $\|\cdot\|_p$. Here for simplicity we introduced the following symbols:

$$\sigma(x,y)=\Sigma\left(\sqrt{x^2+y^2},\frac{x}{\sqrt{x^2+y^2}}\right),$$

$$\alpha(y,y')=\frac{y}{R\sqrt{R^2-y^2}}\alpha_0\left(-\frac{\sqrt{R^2-y^2}}{R},\frac{\sqrt{R^2-y'^2}}{R}\right).$$

With those in mind, we can rewrite Eqs. (1)–(3) as the following:

$$\alpha=\sup\left\{\int_S \alpha(y,y')\mathrm{d}y\,\middle|\,y'\in S\right\}<\infty, \tag{4}$$

$$y'\alpha(y,y')=y\alpha(y',y),(y,y')\in S\times S, \tag{5}$$

$$\lim_{\mathrm{mes}\,E\to 0}\sup\left\{\int_E \alpha(y,y')\mathrm{d}y\,\middle|\,y'\in S\right\}=0. \tag{6}$$

We will follow the notations of Ref. 14 and define the following operators:

$$M_{p,\lambda}:Y_p\to Y_p;(M_{p,\lambda}\psi)(y)=\int_S M(\lambda;y,y')\psi(y')\mathrm{d}y',$$

$$H_{p,\lambda}:X_p\to Y_p;(H_{p,\lambda}\varphi)(y)=\int_D H(\lambda;y,x',y')\varphi(x',y')\mathrm{d}x'\,\mathrm{d}y',$$

$$L_{p,\lambda}:Y_p\to X_p;(L_{p,\lambda}\psi)(x,y)=\exp\left(-\int_{-\sqrt{R^2-y^2}}^{x}\Delta(\lambda;z,y)\mathrm{d}z\right)\psi(y),$$

$$P_{p,\lambda}:X_p\to X_p;(P_{p,\lambda}\varphi)(x,y)=\int_{-\sqrt{R^2-y^2}}^{x}\exp\left(-\int_{x'}^{x}\Delta(\lambda;z,y)\mathrm{d}z\right)\varphi(x',y)\mathrm{d}x',$$

where

$$M(\lambda,y,y')=\frac{y'}{y}\alpha(y,y')\exp\left(-\int_{-\sqrt{R^2-y'^2}}^{\sqrt{R^2-y'^2}}\Delta(\lambda;z,y')\mathrm{d}z\right),$$

$$H(\lambda,y,x',y')=\frac{y'}{y}\alpha(y,y')\exp\left(-\int_{x'}^{\sqrt{R^2-y'^2}}\Delta(\lambda;z,y')\mathrm{d}z\right),$$

$$\Delta(\lambda;x,y)=\lambda+\sigma(x,y).$$

Remark 2.1: (i) If we denote the streaming operator defined in X_p with non-reentry boundary condition [i.e., $\alpha_0(\mu,\mu')=0$] by $B_{p,0}$, then $P_{p,\lambda}$ is nothing else but the resolvent of $B_{p,0}$ and the resolvent set $\rho(B_{p,0})=C$ (the whole complex plane).

(ii) The proof of the main theorems, which follows from several properties of the operators $M_{p,\lambda}$, $H_{p,\lambda}$, $L_{p,\lambda}$, and $P_{p,\lambda}$ established in Sec. III, will be given in Sec. IV, at present we want to describe the strategy used in the proof. We will show that (Proposition 4.3)

$$\sigma(B_p)=\{\lambda|1\in\sigma(M_{p,\lambda})\}\cup\{\infty\},p\in[1,\infty].$$

Then the problem reduces to prove the p independence of $\sigma(M_{p,\lambda})\backslash\{0\}$, which will be established in Proposition 4.2. It is worth notice that in proving Proposition 4.3 we also need to use Proposition 4.2. In general, spectra of integral operators (even with positively definite and symmetric kernels) may be dependent upon p.[3] In our situation, the kernel of $M_{p,\lambda}$ is unsymmetrical and very complicated. Nevertheless, we are able to show that it is of power compactness for $p=1,\infty$, which enables us to obtain the conclusions.

III. AUXILIARY THEOREMS

In this section, we prepare some auxiliary results which are useful in the proof of the main theorems. Especially, we will establish some compactness results and the analyticity of $M_{p,\lambda}$ and $H_{p,\lambda}$. In the L^1 setting, those results were obtained in Refs. 12–14, in order to derive those results in the L^p spaces, the detailed balancing principle is needed. In the following, we will denote the adjoint number of p by p'.

Proposition 3.1: The operators $M_{p,\lambda}$, $H_{p,\lambda}$, $L_{p,\lambda}$, and $P_{p,\lambda}$ have the following properties:

(i) *For every $\lambda\in C$ and every $p\in[1,\infty]$, $M_{p,\lambda}$, $H_{p,\lambda}$, $L_{p,\lambda}$, and $P_{p,\lambda}$ are bounded linear operators.*

(ii) *If* $\mathrm{Re}\,\lambda>-\lambda_0$, *then,*

$$r(M_{1,\lambda})<\alpha,\ \|M_{p,\lambda}\|<\alpha\quad\text{for } p\in(1,\infty],$$

where $r(M_{1,\lambda})$ is the spectral radius of $M_{1,\lambda}$.

(iii) *If* $\mathrm{Re}\,\lambda>-\lambda_0$, *then for every $p\in[1,\infty]$,*

$$\|H_{p,\lambda}\|\leqslant(\mathrm{Re}\,\lambda+\lambda_0)^{-1/p'}R^{-2/p}\alpha,\quad \|L_{p,\lambda}\|\leqslant R^{2/p}(p(\mathrm{Re}\,\lambda+\lambda_0))^{-1/p},\quad \|P_{p,\lambda}\|\leqslant\frac{1}{\mathrm{Re}\,\lambda+\lambda_0}.$$

Proof: The case of $p=1$ has been proved in Ref. 14, for $1<p<\infty$ and $\psi\in Y_p$ we have

$$\begin{aligned}\|M_{p,\lambda}\psi\|_p^p&=\int_S|(M_{p,\lambda}\psi)(y)|^p\frac{y}{R^2}\mathrm{d}y\\&=\int_S\left|\int_S M(\lambda;y,y')\psi(y')\mathrm{d}y'\right|^p\frac{y}{R^2}\mathrm{d}y\\&\leqslant\int_S\left(\int_S\frac{y'}{y}\alpha(y,y')\exp(-\sqrt{R^2-y'^2}(\mathrm{Re}\,\lambda+\lambda_0))|\psi(y')|dy'\right)^p\frac{y}{R^2}\mathrm{d}y.\end{aligned}$$

Using Hölder inequality and (5), we obtain,

$$\begin{aligned}\|M_{p,\lambda}\psi\|_p^p\leqslant&\int_S\left(\int_S\alpha(y',y)\exp(-\sqrt{R^2-y'^2}(\mathrm{Re}\,\lambda+\lambda_0))dy'\right)^{p/p'}\\&\times\left(\int_S y'\alpha(y,y')\exp(-\sqrt{R^2-y'^2}(\mathrm{Re}\,\lambda+\lambda_0))|\psi(y')|^p\,\mathrm{d}y'\right)\frac{1}{R^2}dy.\end{aligned}$$

If $\mathrm{Re}\,\lambda>-\lambda_0$, let

$$\alpha_1=\sup\left\{\int_S \alpha(y',y)\exp(-\sqrt{R^2-y'^2}(\mathrm{Re}\,\lambda+\lambda_0))\mathrm{d}y' \,\middle|\, y\in S\right\}$$

since

$$\alpha(y',y)\exp(-\sqrt{R^2-y'^2}(\mathrm{Re}\,\lambda+\lambda_0))<\alpha(y',y),\ (y,y')\in S\times S,$$

hence $\alpha_1<\alpha$, which implies that

$$\|M_{p,\lambda}\psi\|_p^p\leqslant\alpha_1^{p/p'}\alpha\int_S|\psi(y')|^p\frac{y'}{R^2}\mathrm{d}y',$$

i.e., $\|M_{p,\lambda}\|\leqslant\alpha_1^{1/p'}\alpha^{1/p}<\alpha$. Hence, $\|M_{p,\lambda}\|<\alpha$.

If $\mathrm{Re}\,\lambda\leqslant\lambda_0$, by a similar method we get

$$\|M_{p,\lambda}\psi\|_p^p\leqslant\alpha^{(p/p')+1}\exp\left(R|\mathrm{Re}\,\lambda+\lambda_0|\left(\frac{p}{p'}+1\right)\right)\int_S|\psi(y')|^p\frac{y'}{R^2}\mathrm{d}y'$$

so, $\|M_{p,\lambda}\psi\|_p\leqslant\alpha\exp(R|\mathrm{Re}\,\lambda+\lambda_0|)\|\psi\|_p$, which implies that $\|M_{p,\lambda}\|_p\leqslant\alpha\exp(R|\mathrm{Re}\,\lambda+\lambda_0|)$.

If $p=\infty$, then for $\psi\in Y_\infty$ we get from (4) and (5),

$$\begin{aligned}\|M_{\infty,\lambda}\psi\|_\infty&\leqslant\sup_{y\in S}\int_S M(\lambda;y,y')|\psi(y')|\mathrm{d}y',\\&\leqslant\sup_{y\in S}\int_S\frac{y'}{y}\alpha(y,y')\exp(-\sqrt{R^2-y'^2}(\mathrm{Re}\,\lambda+\lambda_0))|\psi(y')|\mathrm{d}y'\\&\leqslant\sup_{y\in S}\int_S\alpha(y',y)\exp(-\sqrt{R^2-y'^2}(\mathrm{Re}\,\lambda+\lambda_0))|\psi(y')|\mathrm{d}y'.\end{aligned}$$

Consequently, we obtain $\|M_{\infty,\lambda}\psi\|_\infty\leqslant\alpha_1\|\psi\|_\infty$ for $\mathrm{Re}\,\lambda>-\lambda_0$ and $\|M_{\infty,\lambda}\psi\|_\infty\leqslant\alpha\exp(R|\mathrm{Re}\,\lambda+\lambda_0|)\|\psi\|_\infty$ for $\mathrm{Re}\,\lambda\leqslant-\lambda_0$. That is to say, $\|M_{\infty,\lambda}\|_\infty\leqslant\alpha_1<\alpha$ for $\mathrm{Re}\,\lambda>-\lambda_0$ and $\|M_{\infty,\lambda}\|_\infty\leqslant\alpha\exp(R|\mathrm{Re}\,\lambda+\lambda_0|)$ for $\mathrm{Re}\,\lambda\leqslant-\lambda_0$.

Hence, (i) and (ii) of the theorem for $M_{p,\lambda}$ are proved. We can manage (i)–(iii) for the other three operators by similar procedures. Q.E.D.

Proposition 3.2: If $p=1$ or ∞, then for every $\lambda\in C$, $M_{p,\lambda}^2$ is compact. If furthermore $1\in\rho(M_{p,\lambda})$ and $\mu\in\rho(P_{p,\lambda})$, then $(L_{p,\lambda}(I-M_{p,\lambda})^{-1}H_{p,\lambda}(\mu I-P_{p,\lambda})^{-1})^2$ is compact.

Proof: It has been proved (see, Ref. 14, Lemma 2.3 and the proof of Theorem 3.2) that for $p=1$, $M_{p,\lambda}^2$ and $(L_{p,\lambda}(I-M_{p,\lambda})^{-1}H_{p,\lambda}(\mu I-P_{p,\lambda})^{-1})^2$ are compact operators for $\lambda\in C$ satisfying the conditions described previously. For $p=\infty$, we consider the following operators:

$$N_{1,\lambda}:Y_1\to Y_1;(N_{1,\lambda}\psi)(y)=\int_S\frac{y'}{y}M(\lambda;y',y)\psi(y')\mathrm{d}y',$$

$$J_{1,\lambda}:Y_1\to X_1;(J_{1,\lambda}\psi)(y)=\int_D\frac{1}{R^2}\frac{y'}{y}H(\lambda;y',x,y)\psi(y')\mathrm{d}y'.$$

Obviously, $M_{\infty,\lambda}=N_{1,\lambda}^\star$ and $H_{\infty,\lambda}=J_{1,\lambda}^\star$, where $\star$ means the adjoint operator. Define vector-valued functions $G_{1,\lambda}$ and $G_{2,\lambda}$ as

$$G_{1,\lambda}:S\to Y_1;G_{1,\lambda}(y')=\frac{y'}{y}M(\lambda;y',y),\quad y'\in S,$$

$$G_{2,\lambda}:S\to X_1;G_{2,\lambda}(y')=\frac{1}{R^2}\frac{y'}{y}H(\lambda;y',x,y),\quad y'\in S,$$

then we have

$$\begin{aligned}\|G_{1,\lambda}(y')\|_1&\leqslant\int_S\alpha(y',y)\exp(-2\sqrt{R^2-y^2}(\operatorname{Re}\lambda+\lambda_0))\frac{y}{R^2}\mathrm{d}y\\&\leqslant\int_S\alpha(y,y')\exp(-2\sqrt{R^2-y^2}(\operatorname{Re}\lambda+\lambda_0))\frac{y'}{R^2}\mathrm{d}y\\&\leqslant\alpha\exp(2R|\operatorname{Re}\lambda+\lambda_0|)\frac{1}{R},\end{aligned}\tag{7}$$

$$\begin{aligned}\|G_{2,\lambda}(y')\|_1&\leqslant\int_D\alpha(y',y)\exp(-(\sqrt{R^2-y^2}-x)(\operatorname{Re}\lambda+\lambda_0))\frac{y}{R^2}\mathrm{d}x\mathrm{d}y\\&\leqslant\int_D\alpha(y,y')\exp(-(\sqrt{R^2-y^2}-x)(\operatorname{Re}\lambda+\lambda_0))\frac{y'}{R^2}\mathrm{d}x\,\mathrm{d}y\\&\leqslant\alpha\exp(2R|\operatorname{Re}\lambda+\lambda_0|)\frac{1}{R}.\end{aligned}\tag{8}$$

Furthermore, for measurable subsets $E\in S$ and $F\in D$ we have

$$\int_E\frac{y'}{y}|M(\lambda;y',y)|\frac{y}{R^2}\mathrm{d}y\leqslant\int_E\alpha(y,y')\exp(2R|\operatorname{Re}\lambda+\lambda_0|)\frac{1}{R^2}\mathrm{d}y,$$

$$\int_F\frac{1}{R^2}\frac{y'}{y}|H(\lambda;y',x,y)|y\,\mathrm{d}x\,\mathrm{d}y\leqslant\int_F\frac{1}{R^2}\alpha(y,y')\exp(2R|\operatorname{Re}\lambda+\lambda_0|)\mathrm{d}x\,\mathrm{d}y.$$

By (6), we obtain that

$$\lim_{\text{mes }E\to0}\sup\left\{\int_E\frac{y'}{y}|M(\lambda;y',y)|\frac{y}{R^2}\mathrm{d}y\,\middle|\,y'\in S\right\}=0,\tag{9}$$

$$\lim_{\text{mes }F\to0}\sup\left\{\int_F\frac{1}{R^2}\frac{y'}{y}|H(\lambda;y',x,y)|y\,\mathrm{d}x\,\mathrm{d}y\,\middle|\,y'\in S\right\}=0.\tag{10}$$

It follows from (7)–(10) and Ref. 24 that $N_{1,\lambda}$ and $J_{1,\lambda}$ are weakly compact operators, consequently, $N_{1,\lambda}^2$ is compact. Hence, $M_{\infty,\lambda}^2=(N_{1,\lambda}^2)^\star$ is a compact operator. If $1\in\rho(M_{\infty,\lambda})$ and $\mu\in\rho(P_{\infty,\lambda})$, we consider the following operators:

$$T_{1,\lambda}:X_1\to Y_1;(T_{1,\lambda}\varphi)(y)=\int_{-\sqrt{R^2-y^2}}^{\sqrt{R^2-y^2}}R^2\exp\left(-\int_{-\sqrt{R^2-y^2}}^{x}\Delta(\lambda;z,y)\mathrm{d}z\right)\varphi(x',y)\mathrm{d}x',$$

$$Q_{1,\lambda}:X_1\to X_1;(Q_{1,\lambda}\varphi)(x,y)=\int_x^{\sqrt{R^2-y^2}}\exp\left(-\int_x^{x'}\Delta(\lambda;z,y)\mathrm{d}z\right)\varphi(x',y)\mathrm{d}x'.$$

Obviously, $T_{1,\lambda}^{\star}=L_{\infty,\lambda}$ and $Q_{1,\lambda}^{\star}=P_{\infty,\lambda}$. So, we have $1\in\rho(N_{1,\lambda})$ and $\mu\in\rho(Q_{1,\lambda})$, furthermore, $(L_{\infty,\lambda}(I-M_{\infty,\lambda})^{-1}H_{\infty,\lambda}(\mu I-P_{\infty,\lambda})^{-1})^2=\{((\mu I-Q_{1,\lambda})^{-1}J_{1,\lambda}(I-N_{1,\lambda})^{-1}T_{1,\lambda})^2\}^{\star}$. But $J_{1,\lambda}$ is weakly compact, so $((\mu I-Q_{1,\lambda})^{-1}J_{1,\lambda}(I-N_{1,\lambda})^{-1}T_{1,\lambda})^2$ is compact.[24] Hence, $(L_{\infty,\lambda}(I-M_{\infty,\lambda})^{-1}H_{\infty,\lambda}(\mu I-P_{\infty,\lambda})^{-1})^2$ is compact. Q.E.D.

Proposition 3.3: For every $p\in[1,\infty]$, the operator-valued functions $M_{p,\lambda}$, $H_{p,\lambda}$, $L_{p,\lambda}$ and $P_{p,\lambda}$ are analytic on the whole complex plane C.

Proof: Define bounded linear operators: $M'_{p,\lambda}:Y_p\to Y_p$, $H'_{p,\lambda}:X_p\to Y_p$, and $L'_{p,\lambda}:Y_p\to X_p$ as

$$(M'_{p,\lambda}\psi)(y)=\int_S -2\sqrt{R^2-y'^2}M(\lambda;y,y')\psi(y')\mathrm{d}y',$$

$$(H'_{p,\lambda}\varphi)(y)=\int_S (x'-\sqrt{R^2-y'^2})H(\lambda;y,x',y')\varphi(x',y')\mathrm{d}x'\,\mathrm{d}y',$$

$$(L'_{p,\lambda}\psi)(x,y)=-(x+\sqrt{R^2-y^2})(L_{p,\lambda}\psi)(x,y).$$

It follows from Ref. 25 that we only need to show that for $\psi\in Y_p$ and $\varphi\in X_p$,

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}M_{p,\lambda}\psi=M'_{p,\lambda}\psi,\quad \frac{\mathrm{d}}{\mathrm{d}\lambda}H_{p,\lambda}\varphi=H'_{p,\lambda}\varphi,\quad \frac{\mathrm{d}}{\mathrm{d}\lambda}L_{p,\lambda}\psi=L'_{p,\lambda}\psi.$$

Let $0<|\Delta\lambda|<1$ and denote $M(\lambda+\Delta\lambda;y,y')-M(\lambda;y,y')$ by $\Delta M(\lambda;y,y')$, then we have

$$|\Delta\lambda^{-1}\Delta M(\lambda;y,y')+2\sqrt{R^2-y'^2}M(\lambda;y,y')|\leqslant\exp(2R)|M(\lambda;y,y')|$$

and

$$\lim_{\Delta\lambda\to 0}(\Delta\lambda^{-1}\Delta M(\lambda;y,y')+2\sqrt{R^2-y'^2}M(\lambda;y,y'))=0.$$

On the other hand, by Hölder inequality we have

$$\begin{aligned}
&\|\Delta\lambda^{-1}(M_{p,\lambda+\Delta\lambda}\psi-M_{p,\lambda}\psi)-M'_{p,\lambda}\psi\|_p\\
&\quad\leqslant\int_S\frac{y}{R^2}\mathrm{d}y\left(\int_S\exp(2R)|M(\lambda;y,y')|\mathrm{d}y'\right)\\
&\qquad\times\left(\int_S|\Delta\lambda^{-1}\Delta M(\lambda;y,y')+2\sqrt{R^2-y'^2}M(\lambda;y,y')||\psi(y')|^p\,\mathrm{d}y'\right)\\
&\quad\leqslant C(\lambda)\int_S\frac{y}{R^2}\mathrm{d}y\int_S|\Delta\lambda^{-1}\Delta M(\lambda;y,y')+2\sqrt{R^2-y'^2}M(\lambda;y,y')||\psi(y')|^p\,\mathrm{d}y',
\end{aligned}$$

where $C(\lambda)=\alpha\exp(2R(1+|\mathrm{Re}\,\lambda+\lambda_0|))$. Using the above-given inequalities and the method used in the proof of Ref. 14, Lemma 2.3 (note that $|\psi|^p\in Y_1$ when $\psi\in Y_p$), we obtain

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}M_{p,\lambda}\psi=M'_{p,\lambda}\psi.$$

Similarly, we can verify $(\mathrm{d}/\mathrm{d}\lambda)H_{p,\lambda}\varphi=H'_{p,\lambda}\varphi$ and $(\mathrm{d}/\mathrm{d}\lambda)L_{p,\lambda}\psi=L'_{p,\lambda}\psi$. The analyticity of $P_{p,\lambda}$ follows from Remark 2.1(i). Q.E.D.

IV. PROOF OF THE MAIN THEOREMS

We will finish the proof of Theorems 2.1 and 2.2 by the following several propositions:
Proposition 4.1: For every $\lambda \in C$,

$$\sigma(M_{1,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{1,\lambda})\backslash\{0\}=\sigma(M_{\infty,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{\infty,\lambda})\backslash\{0\}.$$

Proof: We have by Proposition 3.2 and Riesz–Schauder theory that

$$\sigma(M_{1,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{1,\lambda})\backslash\{0\}, \tag{11}$$

$$\sigma(M_{\infty,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{\infty,\lambda})\backslash\{0\}. \tag{12}$$

On the other hand, it is easy to verify that the adjoint operator of $M_{1,\lambda}$ is

$$M_{1,\lambda}^{\star}: Y_\infty \to Y_\infty; (M_{1,\lambda}^{\star}\psi)(y)=\int_S \alpha(y',y)\exp\left(-\int_{-\sqrt{R^2-y^2}}^{\sqrt{R^2-y^2}}\Delta(\lambda,z,y)dz\right)\psi(y')\mathrm{d}y'.$$

Define bounded linear operators T_1 and T_2 as follows,

$$T_1: Y_\infty \to Y_\infty; (T_1\psi)(y)=\exp\left(-\int_{-\sqrt{R^2-y^2}}^{\sqrt{R^2-y^2}}\Delta(\lambda,z,y)\mathrm{d}z\right)\psi(y),$$

$$T_2: Y_\infty \to Y_\infty; (T_2\psi)(y)=\int_S \alpha(y',y)\,\psi(y')\mathrm{d}y'$$

obviously, $T_1T_2=M_{1,\lambda}^{\star}$ and $T_2T_1=M_{\infty,\lambda}$. It follows from Ref. 25 that

$$\sigma(M_{1,\lambda}^{\star})\backslash\{0\}=\sigma(M_{\infty,\lambda})\backslash\{0\}. \tag{13}$$

So, the result follows from (11)–(13) and $\sigma(M_{1,\lambda})=\sigma(M_{1,\lambda}^{\star})$. Q.E.D.

Proposition 4.2: For every $\lambda \in C$ *and* $p \in [1,\infty]$,

$$\sigma(M_{p,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{p,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{1,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{\infty,\lambda})\backslash\{0\}.$$

Proof: It follows from Proposition 4.1 that

$$\sigma(M_{1,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{1,\lambda})\backslash\{0\}=\sigma(M_{\infty,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{\infty,\lambda})\backslash\{0\}. \tag{14}$$

By the definition of $M_{p,\lambda}$, the above (14) and $Y_\infty \subset Y_p \subset Y_1$ for $p \in [1,\infty]$, we have

$$\sigma_{\mathrm{dis}}(M_{\infty,\lambda})\backslash\{0\}\subset\sigma_{\mathrm{p}}(M_{p,\lambda})\backslash\{0\}\subset\sigma_{\mathrm{dis}}(M_{1,\lambda})\backslash\{0\}, \tag{15}$$

where $\sigma_{\mathrm{p}}(\cdot)$ represents the point spectrum of an operator.

If $\mu \in \rho(M_{1,\lambda})\backslash\{0\}=\rho(M_{\infty,\lambda})\backslash\{0\}$, then $(\mu I-M_{1,\lambda})^{-1}$ and $(\mu I-M_{\infty,\lambda})^{-1}$ are bounded operators, further,

$$(\mu I-M_{1,\lambda})(\mu I-M_{1,\lambda})^{-1}=(\mu I-M_{1,\lambda})^{-1}(\mu I-M_{1,\lambda})=I,$$

$$(\mu I-M_{\infty,\lambda})(\mu I-M_{\infty,\lambda})^{-1}=(\mu I-M_{\infty,\lambda})^{-1}(\mu I-M_{\infty,\lambda})=I.$$

For every $\psi \in Y_1 \cap Y_\infty = Y_\infty$, we have

$$(\mu I-M_{1,\lambda})(\mu I-M_{1,\lambda})^{-1}\psi=(\mu I-M_{1,\lambda})^{-1}(\mu I-M_{1,\lambda})\psi=\psi,$$

$$(\mu I-M_{\infty,\lambda})(\mu I-M_{\infty,\lambda})^{-1}\psi=(\mu I-M_{\infty,\lambda})^{-1}(\mu I-M_{\infty,\lambda})\psi=\psi,$$

so $(\mu I-M_{1,\lambda})^{-1}|_{Y_\infty}=(\mu I-M_{\infty,\lambda})^{-1}$. By Riesz–Thorin interpolation theorem[15] $(\mu I-M_{\infty,\lambda})^{-1}$ can be extended to any Y_p for $p\in[1,\infty]$. Furthermore, for every $\psi\in Y_\infty$ we have

$$(\mu I-M_{p,\lambda})(\mu I-M_{\infty,\lambda})^{-1}\psi=(\mu I-M_{\infty,\lambda})^{-1}(\mu I-M_{p,\lambda})\psi=\psi.$$

Since Y_∞ is dense in Y_p, hence $\mu\in\rho(M_{p,\lambda})$. This shows that

$$\sigma(M_{p,\lambda})\backslash\{0\}\subset\sigma(M_{1,\lambda})\backslash\{0\}. \tag{16}$$

It follows from (14)–(16) and the trivial inclusion $\sigma_p(M_{p,\lambda})\backslash\{0\}\subset\sigma(M_{p,\lambda})\backslash\{0\}$ that

$$\sigma(M_{p,\lambda})\backslash\{0\}=\sigma_p(M_{p,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{1,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{\infty,\lambda})\backslash\{0\}.$$

The fact that $\sigma_p(M_{p,\lambda})\backslash\{0\}=\sigma_{\mathrm{dis}}(M_{p,\lambda})\backslash\{0\}$ is obvious since $N((\mu I-M_{\infty,\lambda})^k)\subset N((\mu I-M_{p,\lambda})^k)\subset N((\mu I-M_{1,\lambda})^k)$ for every $\mu\in\sigma_p(M_{p,\lambda})$ and every positive integer k, where $N(\cdot)$ is the null space of an operator. Q.E.D.

Proposition 4.3 (Theorem 2.1): For every $p\in[1,\infty]$, $\sigma(B_p)=\sigma(B_1)$. *Furthermore* $\sigma(B_p)=\{\lambda|1\in\sigma(M_{p,\lambda})\}\cup\{\infty\}$ *and* $(\lambda I-B_p)^{-1}=L_{p,\lambda}(I-M_{p,\lambda})^{-1}H_{p,\lambda}+P_{p,\lambda}$ *for* $\lambda\in\rho(B_p)$.

Proof: The proof of $\{\lambda|1\in\rho(M_{p,\lambda})\}\subset\rho(B_p)$ and $(\lambda I-B_p)^{-1}=L_{p,\lambda}(I-M_{p,\lambda})^{-1}H_{p,\lambda}+P_{p,\lambda}$ is the same as that of Ref. 14, Theorem 3.1(i). In the following, we show that $\{\lambda|1\in\sigma(M_{p,\lambda})\}\subset\sigma(B_p)$.

It follows from Propositions 4.1 and 4.2 that $\{\lambda|1\in\sigma(M_{p,\lambda})\}=\{\lambda|1\in\sigma_{\mathrm{dis}}(M_{p,\lambda})\}$. Hence, for every $\lambda\in\{\lambda|1\in\sigma(M_{p,\lambda})\}$ there exists an eigenvector $\psi\in Y_p$ and $\psi\neq0$ such that $M_{p,\lambda}\psi=\psi$. Let

$$f(x,y)=(L_{p,\lambda}\psi)(x,y)=(L_{p,\lambda}M_{p,\lambda}\psi)(x,y);$$

then $f\in X_p$ and $f\neq0$. On the one hand, we have

$$f(-\sqrt{R^2-y^2},y)=(M_{p,\lambda}\psi)(y)=\psi(y),$$

$$f(\sqrt{R^2-y^2},y)=\exp\left(-\int_{-\sqrt{R^2-y^2}}^{\sqrt{R^2-y^2}}\Delta(\lambda,z,y)\,dz\right)\psi(y),$$

so $f\in X_p$ is continuously differentiable with respect to x and satisfies the boundary condition, which shows that $f\in D(B_p)$. On the other hand, it is easy to verify that $(\lambda I-B_p)f=0$. Therefore, we have shown $\{\lambda|1\in\sigma(M_{p,\lambda})\}\subset\sigma(B_p)$. $\sigma(B_p)=\sigma(B_1)$ follows from the above-mentioned result and Propositions 4.1 and 4.2. Q.E.D.

Remark 4.1: It follows from the proof of Proposition 4.3 that $\sigma(B_p)\backslash\{\infty\}=\sigma_p(B_p)\backslash\{\infty\}$ and $L_{p,\lambda}N(I-M_{p,\lambda})\subset N(\lambda I-B_p)$ for $p\in[1,\infty],\lambda\in\sigma_p(B_p)\backslash\{\infty\}$. On the other hand, we can show that $L_{p,\lambda}N(I-M_{p,\lambda})\supset N(\lambda I-B_p)$ (see Ref. 14, Proof of Theorem 3.2). Hence we obtain that $L_{p,\lambda}N(I-M_{p,\lambda})=N(\lambda I-B_p)$.

Proposition 4.4 (Theorem 2.2): If the boundary wall is nonmultiplying or conservative, i.e., $\alpha\leqslant1$, *then for every* $p\in[1,\infty],\sigma_{\mathrm{ess}}(B_p)=\{\infty\}$.

Proof: If $p=1$, the result has been proved [see, Ref. 14, the proof of Theorem 3.2(i)], if $p=\infty$, with Remark 2.1(i) and Propositions 3.1–3.3, we can manage it by the same perturbation method as in Ref. 14 (note that Proposition 3.1 and Ref. 26 show that there exist at most countable $\lambda\in C$ such that $1\in\sigma_p(M_{\infty,\lambda})$). If $1<p<\infty$, let $\lambda\in\sigma(B_p)=\sigma_p(B_p)$ (see Remark 4.1), then for every positive integer n we have

$$N((\lambda I-B_\infty)^n)\subset N((\lambda I-B_p)^n)\subset N((\lambda I-B_1)^n)$$

since $B_\infty\subset B_p\subset B_1$. On the other hand, since $\sigma_{\mathrm{ess}}(B_\infty)=\sigma_{\mathrm{ess}}(B_1)=\{\infty\}$, the closure of $\cap_{n=1}^{\infty}N((\lambda I-B_1)^n)$ is finitely dimensional, so is $\cap_{n=1}^{\infty}N((\lambda I-B_p)^n)$. Hence, $\lambda\in\sigma_{\mathrm{dis}}(B_p)$, that is, $\sigma_{\mathrm{ess}}(B_p)=\{\infty\}$. Q.E.D.

V. DISCUSSION

In this section we shall give an example which shows that when the wall is not detailed balancing the spectrum of B_p is L^p dependent. Let $\Sigma(r,\mu)=\Sigma$ and $\alpha_0(\mu,\mu')=\alpha_0$ be constants, then the detailed balancing condition (2) is not valid: $|\mu'|\alpha_0(\mu,\mu')\neq|\mu|\alpha_0(-\mu',-\mu)$. In this case we have

$$\alpha(y,y')=\frac{\alpha_0 y}{R\sqrt{R^2-y^2}},$$

$$M(\lambda,y,y')=\frac{\alpha_0 y'}{R\sqrt{R^2-y^2}}\exp\left(-\int_{-\sqrt{R^2-y'^2}}^{\sqrt{R^2-y'^2}}\Delta(\lambda;z,y')\mathrm{d}z\right),$$

$$H(\lambda,y,x',y')=\frac{\alpha_0 y'}{R\sqrt{R^2-y^2}}\exp\left(-\int_{x'}^{\sqrt{R^2-y'^2}}\Delta(\lambda;z,y')\mathrm{d}z\right),$$

and it has been proved that

Proposition 5.1 (*Ref. 12, Theorems 1 and 2): If* $p=1$ *and* $\alpha_0\leqslant 1$, *then*

$$\sigma(B_1)=\sigma_{\mathrm{dis}}(\mathrm{B}_1)\cup\{\infty\}=\left\{\lambda\left|\frac{\alpha_0(1-\exp(-2(\lambda+\Sigma)R))}{2(\lambda+\Sigma)R}=1\right.\right\}\cup\{\infty\}$$

and each $\lambda\in\sigma_{\mathrm{dis}}(B_1)$ *is a simple eigenvalue of* B_1.

Remark 5.1: In fact, this result is also valid for every $\alpha_0>0$ (i.e., multiplying boundary wall is covered) and $p\in[1,2)$. The proof is similar to that of Ref. 12, Theorems 1 and 2.

If $p\geqslant 2$, there is a different result. In fact, we have,

Proposition 5.2: If $p\geqslant 2$, *then* $\sigma(B_p)=C\cup\{\infty\}$.

Proof: For every $\lambda\in C$, we shall show $R(\lambda I-B_p)\neq X_p$, i.e., the range of $\lambda I-B_p$ does not equal X_p. Consequently, every $\lambda\in C$ belongs to the spectrum of B_p. We know that Y_p is continuously embedded in X_p. Let $g\in Y_p$, if $\varphi\in D(B_p)$ satisfies $(\lambda I-B_p)\varphi=g$, then we obtain by integrating it,

$$\begin{aligned}\varphi(\sqrt{R^2-y^2},y)=&\exp(-2(\lambda+\Sigma)\sqrt{R^2-y^2})\varphi(-\sqrt{R^2-y^2},y)\\&+(\lambda+\Sigma)^{-1}(1-\exp(-2(\lambda+\Sigma)\sqrt{R^2-y^2}))g(y).\end{aligned}\tag{17}$$

On the other hand, $\varphi(\pm\sqrt{R^2-y^2},y)$ satisfy the boundary condition, i.e., $\varphi(\pm\sqrt{R^2-y^2},y)\in Y_p$ and

$$\frac{y}{R^2}\varphi(-\sqrt{R^2-y^2},y)=\int_S\alpha(y,y')\frac{y'}{R^2}\varphi(\sqrt{R^2-y'^2},y')\mathrm{d}y'.\tag{18}$$

It follows from (17) and (18) that $\varphi(-\sqrt{R^2-y^2},y)=c(R^2-y^2)^{-1/2}$, where c is a constant. So, we have $c=0$, otherwise $\varphi(-\sqrt{R^2-y^2},y)\notin Y_p$ (note that $p\geqslant 2$), i. e., $\varphi(-\sqrt{R^2-y^2},y)=0$. In consideration of (17) and (18), we obtain

$$\int_S(\lambda+\Sigma)^{-1}(1-\exp(-2(\lambda+\Sigma)\sqrt{R^2-y^2}))g(y)y\,\mathrm{d}y=0,$$

which is impossible for many $g\in Y_p$. The proof is complete. Q.E.D.

Remark 5.2: It follows from Propositions 5.1 and 5.2 and Remark 5.1 that the spectrum of B_p is possibly L^p dependent if the material wall is not detailed balancing.

On page 1151, Eq. (18) should be replaced by

$$\frac{e^{ab}b^{1-z}}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}t\,\frac{e^{ibt}}{(a+\mathrm{i}t)^{z}}=\begin{cases}\dfrac{1}{\Gamma(z)} & \text{for } b>0\\ 0 & \text{for } b<0\end{cases}.$$

Also on page 1151, in line 4 the equation for b should be replaced by

$$b=\left[1-(1-q)\beta\sum_{i=1}^{N}(P_i^2/2m)\Big/\left(1+(q-1)\beta\sum_{i\neq j}Gm^2\ln|\mathbf{x}_i-\mathbf{x}_j|\right)\right].$$

The relativistic *J*-matrix theory of scattering: An analytic solution

A. D. Alhaidari[a)]
Physics Department, King Fahd University of Petroleum & Minerals, Box 5047, Dhahran 31261, Saudi Arabia

(Received 21 March 2001; accepted for publication 3 December 2001)

The relativistic J-matrix is investigated in the case of Coulomb-free scattering for a general short-range spin-dependent perturbing potential and in two different L^2 bases. The resulting recursion relation of the reference problem, in this case, has an analytic solution. The nonrelativistic limit is obtained and shown to be identical to the familiar nonrelativistic J-matrix. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1445288]

The J-matrix[1–3] is an algebraic method of quantum scattering whose structure in function space parallels that of the R-matrix method in configuration space. The perturbing short range potential, $\tilde{V}(r)$, in the R-matrix method is confined to an "R-box" in configuration space [i.e., $\tilde{V}(r)=0$ for $r\geqslant R$], while in the J-matrix method it is confined to an "N- box" in function space. That is the matrix representation $\tilde{V}_{nm}=0$ for $n,m\geqslant N$. In the two methods, the unperturbed (reference) problem is solved analytically, enabling scattering calculation over a continuous range of energy despite the fact that confinement in both methods produce discrete energy spectra. The basis of the function space, in the J-matrix method, is chosen such that the matrix representation of the reference Hamiltonian, H_0, is tridiagonal. This has no parallel in the R-matrix method. It restricts the type of L^2 bases and limits reference Hamiltonians to those with this type of symmetry that admits such tridiagonal representations. It turns out that this restriction implies that the reference Hamiltonian must belong to the dynamical symmetry group SO(2,1).[4,5] Recently, a simple and robust numerical scheme was developed that lifts this restriction without compromising any of the advantages offered by the method.[6] The reference wave equation in the J-matrix method gives a symmetric three-term recursion relation for the expansion coefficients of the unperturbed wave function. The regularized analytic solutions of this recursion give the asymptotic scattering states that enable calculation of the phase shift after the introduction of the perturbing potential $\tilde{V}(r)$. The method together with its multi-channel extension[7,8] has been used successfully in a large number of scattering problems in atomic and nuclear physics.

P. Horodecki introduced a relativistic extension of the theory for the Coulomb free interaction.[9] This was followed by a systematic development of the theory for the Dirac–Coulomb problem that includes perturbing short-range potentials with spin-dependent coupling.[10] In this article, we investigate the case where $Z=0$ of the latter development and in two different L^2 bases: the Laguerre-type and oscillator-type functions. The motivation for this treatment comes from the fact that the resulting three-term recursion relation, in this case, has an analytic solution. This is in contrast to the general case, $Z\neq 0$, where the recursion relation was too difficult to solve analytically and a numerical solution is obtained.[10] It turns out that in the Coulomb-free case, the recursion relation is identical to the nonrelativistic one, whose analytic solution is well known,[3] except for a redefinition of the energy variable. The nonrelativistic limit is found and shown to coincide with the familiar nonrelativistic J-matrix. We carry out the detailed analysis of the problem in the two-component Laguerre-type L^2 basis. The extension to the oscillator-type basis,

a)Electronic mail: haidari@mailaps.org

which is straightforward, is summarized in Table I that lists all quantities needed for relativistic scattering calculations in this basis.

In atomic units ($m=e=\hbar=1$) and taking the speed of light $c=\alpha^{-1}$, the free radial Dirac equation for a two-component spinor is[10,11]

$$\begin{pmatrix} 1 & \alpha\left(\frac{\kappa}{r}-\frac{d}{dr}\right) \\ \alpha\left(\frac{\kappa}{r}+\frac{d}{dr}\right) & -1 \end{pmatrix}\begin{pmatrix} \phi(r) \\ \theta(r) \end{pmatrix}=\varepsilon\begin{pmatrix} \phi(r) \\ \theta(r) \end{pmatrix}, \tag{1}$$

where α is the fine structure parameter and ε is the relativistic energy. Here κ is the spin-orbit coupling parameter defined by $\kappa=\pm(j+\frac{1}{2})$ for $l=j\pm\frac{1}{2}$, where j is the total angular momentum quantum number. Equation (1) relates the two components of the spinor wave function as

$$\theta(r)=\frac{\alpha}{\varepsilon+1}\left(\frac{\kappa}{r}+\frac{d}{dr}\right)\phi(r). \tag{2}$$

Substituting this back into Eq. (1) gives the following second-order differential equation for the upper component,

$$\left[-\frac{d^2}{dr^2}+\frac{\kappa(\kappa+1)}{r^2}-\frac{\varepsilon^2-1}{\alpha^2}\right]\phi(r)=0, \tag{3}$$

which is analogous to the radial potential-free Schrödinger equation

$$\left[-\frac{d^2}{dr^2}+\frac{l(l+1)}{r^2}-2E\right]\chi(r)=0 \tag{4}$$

with the substitution $E=(\varepsilon^2-1)/2\alpha^2$ and $l=\kappa$ or $l=-\kappa-1$.

For building the relativistic J-matrix formalism, we need to construct an L^2 discrete representation in which the reference Hamiltonian,

$$H_0=\begin{pmatrix} 1 & \alpha\left(\frac{\kappa}{r}-\frac{d}{dr}\right) \\ \alpha\left(\frac{\kappa}{r}+\frac{d}{dr}\right) & -1 \end{pmatrix},$$

is tridiagonal so that the Dirac operator $J=H_0-\varepsilon$ gives a symmetric three-term recursion relation for the expansion coefficients of the spinor wave function. The solution of this recursion relation, subject to proper initial conditions, gives the two ''regularized'' solutions of the relativistic wave equation (1) that behave asymptotically as $\sin(kr)$ and $\cos(kr)$, where k is the energy-dependent wave number. Therefore, the J-matrix formalism can be applied giving the relativistic S-matrix for a scattering problem with perturbing short-range potential $\tilde{V}(r)$.[3,10] The L^2 space is spanned by the two-component radial spinor wave functions $\{\psi_n(r)\}_{n=0}^{\infty}$ whose upper component is $\phi_n(r)$ and lower component is $\theta_n(r)$. The conjugate space is spanned by $\{\overline{\psi}_n(r)\}_{n=0}^{\infty}$ such that

$$\langle\overline{\psi}_n|\psi_m\rangle=\int_0^{\infty}\overline{\phi}_n(r)\phi_m(r)dr+\int_0^{\infty}\overline{\theta}_n(r)\theta_m(r)dr=\delta_{nm}. \tag{5}$$

Now, the analogy of the second order differential equation (3) to the Schrödinger equation (4) suggests that the upper spinor component can be taken to be either of the Laguerre-type or oscillator-type basis functions of the nonrelativistic J-matrix[3] with $l=\kappa$. We shall work out the

TABLE I. The table gives the oscillator-type spinor basis $\{\phi_n,\theta_n\}_{n=0}^{\infty}$, its J-matrix coefficients $\{s_n,c_n\}$, the matrix elements of the reference Hamiltonian and that of the scattering short range potential. In the table ζ is an arbitrary real parameter, ${}_1F_1(a;c;z)$ is the confluent hypergeometric function, $\eta(\varepsilon)\equiv k(\varepsilon)/\lambda$ where $k(\varepsilon)$ is as defined in Eq. (15), and $G^{\nu}_{nm}\equiv\Sigma_{k=0}^{M-1}\Lambda^{\nu}_{nk}\Lambda^{\nu}_{mk}f[(\xi^{\nu}_k)^{1/2}/\lambda]$, $Q^{\nu}_{nm}\equiv\Sigma_{k=0}^{M-1}(\xi^{\nu}_k)^{-1/2}\Lambda^{\nu}_{nk}\Lambda^{\nu}_{mk}f[(\xi^{\nu}_k)^{1/2}/\lambda]$, where the eigenvalues $\{\xi^{\nu}_n\}_{n=0}^{M-1}$ and corresponding normalized eigenvectors $\{\Lambda^{\nu}_{mn}\}_{n,m=0}^{M-1}$ are associated with the same $M\times M$ tridiagonal matrix (17) but for a different value of the parameter ν.

$\phi_n(r)$	$a_n(\lambda r)^{\kappa+1}e^{-\lambda^2r^2/2}L_n^{\kappa+1/2}(\lambda^2r^2)$
$\theta_n(r)$	$\lambda C a_n(\lambda r)^{\kappa}e^{-\lambda^2r^2/2}[(n+\kappa+\frac{1}{2})L_n^{\kappa-1/2}(\lambda^2r^2)+(n+1)L_{n+1}^{\kappa-1/2}(\lambda^2r^2)]$
a_n	$\sqrt{2\lambda\Gamma(n+1)/\Gamma(n+\kappa+\frac{3}{2})}$

I_{nm}	$I_{nn}=1+\lambda^2C^2(2n+\kappa+\frac{3}{2})$ $I_{n,n-1}=\lambda^2C^2\sqrt{n(n+\kappa+\frac{1}{2})}$ $I_{n,n+1}=\lambda^2C^2\sqrt{(n+1)(n+\kappa+\frac{3}{2})}$
$\tilde{V}_{nm}$	$\tilde{V}_{nm}\cong\alpha^2\tilde{V}_+G^{\kappa+1/2}_{n,m}+\alpha^2\lambda^2C^2\tilde{V}_-[\sqrt{(n+\kappa+\frac{1}{2})(m+\kappa+\frac{1}{2})}G^{\kappa-1/2}_{n,m}+\sqrt{(n+1)(m+1)}G^{\kappa-1/2}_{n+1,m+1}$ $+\sqrt{(m+1)(n+\kappa+\frac{1}{2})}G^{\kappa-1/2}_{n,m+1}+\sqrt{(n+1)(m+\kappa+\frac{1}{2})}G^{\kappa-1/2}_{m,n+1}]$ $+2\alpha^2\lambda C\tilde{V}_0[\sqrt{(n+\kappa+\frac{1}{2})(m+\kappa+\frac{1}{2})}Q^{\kappa-1/2}_{n,m}-\sqrt{(n+1)(m+1)}Q^{\kappa-1/2}_{n+1,m+1}]$
$c_n(\varepsilon)$	$(-1)^n\dfrac{\Gamma(\kappa+\frac{1}{2})}{\sqrt{2\pi}}\dfrac{a_n}{\lambda}\eta^{-\kappa}e^{-\eta^2/2}\,{}_1F_1(-n-\frac{1}{2}-\kappa;\frac{1}{2}-\kappa;\eta^2)$
$s_n(\varepsilon)$	$\dfrac{(-1)^n}{\lambda}\sqrt{\dfrac{\pi}{2}}a_n\eta^{\kappa+1}e^{-\eta^2/2}L_n^{\kappa+1/2}(\eta^2)$

details in the first basis. The results for the second basis are obtainable the same way and in a straightforward manner. These results are summarized in Table I, which lists all quantities needed for relativistic scattering calculations in this basis.

In the Laguerre-type basis the stated analogy suggests that we can write

$$\phi_n(r)=a_n(\lambda r)^{\kappa+1}e^{-\lambda r/2}L_n^{2\kappa+1}(\lambda r), \tag{6}$$

where λ is the basis scale parameter and $L_n^{2\kappa+1}(x)$ is the generalized Laguerre polynomial. The normalization constant a_n will be determined from the normalization condition (5). Here $\phi_n(r)$ satisfies the following differential equation

$$\left[-\frac{d^2}{dr^2}+\frac{\kappa(\kappa+1)}{r^2}-\frac{\lambda(\kappa+n+1)}{r}+\frac{\lambda^2}{4}\right]\phi_n(r)=0.$$

The requirement that the matrix representation of the reference Hamiltonian and the basis-overlap matrix, $\langle \psi_n | \psi_m \rangle$, be at most tridiagonal is satisfied by the following expression for the lower component,

$$\theta_n(r) = C\left(\frac{\kappa}{r} + \frac{d}{dr}\right)\phi_n(r), \tag{7}$$

where the small component strength parameter, C, is nonzero and independent of n. This expression is also motivated by the solution of the wave equation in (2). Using the differential and recursion properties of the Laguerre polynomials,[12] we can write (7) explicitly as

$$\theta_n(r) = \frac{\lambda C}{2} a_n (\lambda r)^{\kappa} e^{-\lambda r/2}[(2\kappa + n + 1)L_n^{2\kappa}(\lambda r) + (n+1)L_{n+1}^{2\kappa}(\lambda r)]. \tag{8}$$

The orthogonal conjugate representation defined in (5) gives

$$\overline{\phi}_n(r) = \frac{(1-\zeta)/4}{\kappa + n + 1}\phi_n(r) + \frac{\zeta}{\lambda r}\phi_n(r), \quad \overline{\theta}_n(r) = \frac{(1-\zeta)/\lambda^2 C^2}{\kappa + n + 1}\theta_n(r),$$

where ζ is an arbitrary constant parameter. The normalization constant obtained is

$$a_n = \sqrt{\lambda \Gamma(n+1)/\Gamma(2\kappa + n + 2)}.$$

In this basis, which is defined by the set of functions in Eqs. (6) and (8), the matrix representation of the reference Hamiltonian H_0 is tridiagonal and has the following elements:

$$\begin{aligned}
(H_0)_{n,n} &= 2(\kappa + n + 1)[1 - (\lambda C/2)^2(1 - 2\alpha/C)], \\
(H_0)_{n,n+1} &= -\sqrt{(n+1)(2\kappa + n + 2)}[1 + (\lambda C/2)^2(1 - 2\alpha/C)], \\
(H_0)_{n,n-1} &= -\sqrt{n(2\kappa + n + 1)}[1 + (\lambda C/2)^2(1 - 2\alpha/C)].
\end{aligned} \tag{9}$$

The tridiagonal basis-overlap matrix elements, $I_{nm} = \langle \psi_n | \psi_m \rangle$, are

$$\begin{aligned}
I_{n,n} &= 2(\kappa + n + 1)[1 + (\lambda C/2)^2], \\
I_{n,n+1} &= -\sqrt{(n+1)(2\kappa + n + 2)}[1 - (\lambda C/2)^2], \\
I_{n,n-1} &= -\sqrt{n(2\kappa + n + 1)}[1 - (\lambda C/2)^2].
\end{aligned} \tag{10}$$

These will define the matrix elements of the tridiagonal Dirac operator $J_{nm}(\varepsilon) = (H_0)_{nm} - \varepsilon I_{nm}$ that gives the symmetric three-term recursion relation.

The expansion coefficients of the spinor wave function that solves the reference equation (1) satisfy this recursion relation, which reads

$$J_{n,n-1}h_{n-1} + J_{n,n}h_n + J_{n,n+1}h_{n+1} = 0, \quad n \geqslant 1, \tag{11}$$

where h_n stands for either s_n or c_n (the asymptotic sinelike and cosinelike solutions, respectively). The initial relations are[10]

$$J_{00}s_0 + J_{01}s_1 = 0, \quad J_{00}c_0 + J_{01}c_1 = -\alpha^2 W/2s_0,$$

where $W(\varepsilon)$ is the Wronskian of the regular and irregular solutions of the free Dirac problem:

$$W(\varepsilon)=W(\psi_{\rm reg},\psi_{\rm irreg})=\psi_{\rm reg}\frac{d\psi_{\rm irreg}}{dr}-\psi_{\rm irreg}\frac{d\psi_{\rm reg}}{dr}=-\frac{2}{\alpha}\sqrt{\frac{\varepsilon-1}{\varepsilon+1}}.$$

These coefficients also satisfy the Wronskian-like relation

$$J_{n,n-1}(c_n s_{n-1}-c_{n-1}s_n)=-\alpha^2 W/2,\quad n\geqslant 1.$$

Using the matrix elements given in (9) and (10), we can write the homogeneous recursion relation (11) as

$$2(n+\kappa+1)\left\{\frac{(\varepsilon-1)[1+(\lambda C/2)^2]-(\lambda^2C^2/2)(\alpha/C-1)}{(\varepsilon-1)[1-(\lambda C/2)^2]+(\lambda^2C^2/2)(\alpha/C-1)}\right\}h_n(\varepsilon)$$
$$+b_{n-1}h_{n-1}(\varepsilon)+b_n h_{n+1}(\varepsilon)=0, \tag{12}$$

where the recursion coefficient $b_n=\sqrt{(n+1)(2\kappa+n+2)}$. This is to be compared with the well-known analytically solved nonrelativistic J-matrix recursion relation in the Laguerre-type basis[3]

$$2(n+l+1)\left[\frac{E-\lambda^2/8}{E+\lambda^2/8}\right]h_n'(E)+b_{n-1}'h_{n-1}'(E)+b_n'h_{n+1}'(E)=0, \tag{13}$$

where $b_n'=\sqrt{(n+1)(2l+n+2)}$ and h_n' stands for either the sinelike or cosinelike solutions for the nonrelativistic problem. Therefore, by comparing relation (12) with (13) we conclude that

$$h_n(\varepsilon)=h_n'\left(\frac{-1}{2C^2}\frac{\varepsilon-1}{\varepsilon-1+2(1-\alpha/C)}\right)\Bigg|_{l=\kappa}$$

and that the range of the small component strength parameter is $\alpha>C>0$. Using the analytic solution of the nonrelativistic recursion, $h_n'(E)$, derived by Yamani and Fishman,[3] we can write

$$c_n(\varepsilon)=-\frac{2^\kappa}{\sqrt{\pi}}\frac{a_n}{\lambda}\frac{\Gamma(\kappa+1/2)}{(\sin\omega)^\kappa}{}_2F_1\left(-n-1-2\kappa,n+1;1/2-\kappa;\sin^2\frac{\omega}{2}\right),$$
$$s_n(\varepsilon)=\frac{2^\kappa}{\lambda}a_n\Gamma(\kappa+1)(\sin\omega)^{\kappa+1}C_n^{\kappa+1}(\cos\omega), \tag{14}$$

where ${}_2F_1(a,b;c;z)$ is the hypergeometric function and $C_n^\nu(x)$ is the Gegenbauer polynomial. The angle ω is defined by

$$\cos(\omega)=\frac{[k(\varepsilon)/\lambda]^2-\frac{1}{4}}{[k(\varepsilon)/\lambda]^2+\frac{1}{4}},$$

where

$$k(\varepsilon)=\sqrt{\frac{-1}{C^2}\frac{\varepsilon-1}{\varepsilon-1+2(1-\alpha/C)}}. \tag{15}$$

The nonrelativistic limit is achieved by letting $\alpha\to 0$ [i.e., $c(\text{speed of light})\to\infty$], which gives $\varepsilon\cong 1+\alpha^2E$ and $\kappa=l$. Moreover, in the same limit, the small component, $\theta_n(r)$, of the wave function will be negligible compared to the larger component $\phi_n(r)$. That is, the small component strength parameter C in Eq. (7) will be of the order of α. Taking this limit in the relativistic recursion relation (12) gives

$$2(n+l+1)\left[\frac{\alpha^2 E-(\lambda^2 C^2/2)(\alpha/C-1)}{\alpha^2 E+(\lambda^2 C^2/2)(\alpha/C-1)}\right]h_n(\varepsilon)+b_{n-1}h_{n-1}(\varepsilon)+b_n h_{n+1}(\varepsilon)=0.$$

This nonrelativistic limit can be identified with the nonrelativistic recursion relation (13) if we choose $C=+\alpha/2$. Therefore, the nonrelativistic J-matrix limit for the case $Z=0$ is achieved by making the following choice of parameters in the relativistic J-matrix formalism development above:

$$\alpha\to 0,\ \ \kappa=l,\ \ C=\alpha/2$$

with the nonrelativistic energy $E\cong(\varepsilon-1)/\alpha^2$.

The solution (14) gives the J-matrix kinematical coefficients $\{R_n^{\pm}\}_{n=1}^{\infty}$ and $\{T_n\}_{n=0}^{\infty}$ defined by

$$T_n=\frac{c_n-is_n}{c_n+is_n};\quad R_{n+1}^{\pm}=\frac{c_{n+1}\pm is_{n+1}}{c_n\pm is_n};\quad n\geqslant 0.$$

These will be the coefficients that enter in the calculation of the Nth order relativistic S-matrix,[10]

$$S^{(N)}(\varepsilon)=T_{N-1}(\varepsilon)\frac{1+g_{N-1,N-1}(\varepsilon)J_{N-1,N}(\varepsilon)R_N^{-}(\varepsilon)}{1+g_{N-1,N-1}(\varepsilon)J_{N-1,N}(\varepsilon)R_N^{+}(\varepsilon)},\tag{16}$$

where $g_{N-1,N-1}(\varepsilon)$ is the finite Green's function in the conjugate subspace[3,10] spanned by $\{\overline{\psi}_n(r)\}_{n=0}^{N-1}$ and carries the dynamical effects of the short range model potential $\tilde{V}(r)$:

$$g_{N-1,N-1}(\varepsilon)=\langle\overline{\psi}_{N-1}|(H_0+\tilde{V}-\varepsilon)^{-1}|\overline{\psi}_{N-1}\rangle.$$

Due to the fact that the basis of the L^2 space is nonorthogonal, care should be exercised in the calculation of the finite Green's function as outlined in Appendix B of Ref. 10.

Now, for scattering we consider a general short-range perturbing potential, which has spin-dependent coupling, that is, the potential is a 2×2 real symmetric matrix of the following form:

$$\tilde{V}(r)=\begin{pmatrix}\tilde{V}_+(r) & \tilde{V}_0(r)\\ \tilde{V}_0(r) & \tilde{V}_-(r)\end{pmatrix}.$$

Its matrix elements in the spinor basis are, therefore, written as

$$\tilde{V}_{nm}=\alpha^2\int_0^{\infty}\phi_n(r)\tilde{V}_+(r)\phi_m(r)dr+\alpha^2\int_0^{\infty}\theta_n(r)\tilde{V}_-(r)\theta_m(r)dr$$
$$+\alpha^2\int_0^{\infty}\phi_n(r)\tilde{V}_0(r)\theta_m(r)dr+\alpha^2\int_0^{\infty}\theta_n(r)\tilde{V}_0(r)\phi_m(r)dr.$$

We will consider the case where $\tilde{V}(r)=\tilde{A}_0 f(r)$ and $\tilde{A}_0$ is a constant 2×2 real symmetric matrix (i.e., the coupling parameters $\tilde{V}_{\pm},\tilde{V}_0$ are constants). To evaluate these integrals we utilize a scheme based on Gauss quadrature as outlined in Appendix A of Ref. 10 The result of this computation is

$$\tilde{V}_{nm} \cong \alpha^2 \tilde{V}_+ [\sqrt{(2\kappa+n+2)(2\kappa+m+2)}\, G^{2\kappa+2}_{n,m} + \sqrt{nm}\, G^{2\kappa+2}_{n-1,m-1} - \sqrt{m(2\kappa+n+2)}\, G^{2\kappa+2}_{n,m-1}$$
$$- \sqrt{n(2\kappa+m+2)}\, G^{2\kappa+2}_{m,n-1}] + \left(\frac{\alpha\lambda C}{2}\right)^2 \tilde{V}_- [\sqrt{(m+1)(2\kappa+n+1)}\, G^{2\kappa}_{n,m+1}$$
$$+ \sqrt{(n+1)(2\kappa+m+1)}\, G^{2\kappa}_{m,n+1}] + \alpha^2 \lambda C \left(\frac{\lambda C}{4}\tilde{V}_- + \tilde{V}_0\right) \sqrt{(2\kappa+n+1)(2\kappa+m+1)}\, G^{2\kappa}_{n,m}$$
$$+ \alpha^2 \lambda C \left(\frac{\lambda C}{4}\tilde{V}_- - \tilde{V}_0\right) \sqrt{(n+1)(m+1)}\, G^{2\kappa}_{n+1,m+1},$$

where G^{ν}_{nm} is the Gauss quadrature integral approximation

$$G^{\nu}_{nm} \cong \sum_{k=0}^{M-1} \Lambda^{\nu}_{nk} \Lambda^{\nu}_{mk} f(\xi^{\nu}_k/\lambda) = G^{\nu}_{mn}, \quad M > N.$$

The eigenvalues $\{\xi^{\nu}_n\}^{M-1}_{n=0}$ and corresponding normalized eigenvectors $\{\Lambda^{\nu}_{mn}\}^{M-1}_{n,m=0}$ are associated with the $M \times M$ tridiagonal matrix

$$\begin{pmatrix} \hat{a}_0 & \hat{b}_0 & & & & & \\ \hat{b}_0 & \hat{a}_1 & \hat{b}_1 & & 0 & & \\ & \hat{b}_1 & \hat{a}_2 & \hat{b}_2 & & & \\ & & \hat{b}_2 & \times & \times & & \\ & & & \times & \times & \times & \\ & 0 & & & \times & \times & \times \\ & & & & & \times & \times \end{pmatrix} \tag{17}$$

whose recursion coefficients are parametrized by ν and defined as $\hat{a}_n = 2n + \nu + 1$ and $\hat{b}_n = -\sqrt{(n+1)(n+\nu+1)}$.

Finally, with these potential matrix elements for the given problem, we have all the physical quantities that are needed for evaluating the relativistic scattering matrix in (16). Scattering examples have already been worked out where the accuracy of the nonrelativistic limit is verified and the relativistic effects in the phase shift were calculated. However, the present mathematical treatment of the problem may not be suitable for such presentation. These results will be reported shortly elsewhere.

Motion of Yang–Mills particles in Yang–Mills–Higgs fields are studied. By regarding the Higgs field contribution on the particle's motion, a complete set of equations is worked out for the particle and fields. The planar motions as well as three-dimensional bounded motions are studied. Stable orbits are allowed in this scenario. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1433942]

I. INTRODUCTION

In our last article[1] we described the motion of a colored test particle in which the color was coupled only to the Yang–Mills field, and the nonrelativistic real space motion at large distances was stated to be the same as for an electric point particle in a Dirac point monopole field. We introduced planar motion of a non-Abelian particle in field of a BPS monopole. There, a monopole exerts a force on the particle via its non-Abelian charge. We studied various characteristics of orbits and their stabilities. With some numerical analysis we stated that the planar bound motions are not stable, and three-dimensional bound orbits were not observed.

In this work, we introduce the Higgs field to exert a force on the particle in addition to the monopole force. We introduce Wong's equations in five dimensions, and modify the equations of motion for a particle in the Yang–Mills–Higgs fields. We have chosen the extra fifth dimension to have no contribution in the fields, leaving it as a dynamical variable. A close relation between the time evolution of the fifth dimension and the isospace vectors, the Higgs and non-Abelian charge, are observed. Motion of a test particle, now in the presence of a force from the Higgs field, is studied. Three-dimensional bounded orbits are observed, and stable planar orbits are allowed.

Fehér[2] has given a reinvestigation for a classical motion of a colored test particle in the Prasad–Sommerfield monopole field. He has considered coupling of the particle to both the Yang–Mills and the Higgs fields, and mentioned the existence of bounded orbits at nonrelativistic limit at large distances. He has used the Wong equations and regarded the Higgs field as the fifth component of a Yang–Mills vector field in five dimensions (Ref. 3, p. 46), interpreting the motion in the fifth direction as providing an effective mass of the particle. Fehér has supposed an affine parameter on the path of the particle in the five-dimensional manifold to write down the Wong's equations. Then he has reformulated the equations by using the proper time parameter as the projection of the affine parameter in the four-dimensional space–time path of the particle, and interpreted the mass as the derivative of the proper time by this affine parameter. We think this formalism is not a natural generalization of the four-dimensional Wong equations.[4] In addition, the limit of nonrelativistic motion is unclear, so the bounded orbits at far distances are questionable. We have searched the literature but we have not found any other work in this direction. So, we have reformulated the problem again.

II. GENERALIZING EQUATIONS OF MOTION TO FIVE DIMENSIONS

In this section we want to rebuild the equations of motion of a colored particle in a non-Abelian Yang–Mills–Higgs field in a five-dimensional space–time as Wong extracted his equations from a four-dimensional analysis. The Lagrangian regarding to the Kinetic part of the fields (with the usual definition) is

a)Electronic mail: azizi@physics.susc.ac.ir

$$-\tfrac{1}{4}F^{a\mu\nu}F^{a}_{\mu\nu}-\tfrac{1}{2}(\mathbf{D}^{\mu}\mathbf{\Phi})^{a}(\mathbf{D}_{\mu}\mathbf{\Phi})^{a}, \tag{2.1}$$

where $F^{a}_{\mu\nu}$ is the field strengths, $\mathbf{\Phi}^{a}$ is the Higgs's fields and $\mathbf{D}_{\mu}$ is covariant derivative. This field system can be regarded as a pure Yang–Mills system over a five-dimensional flat space–time $\mathcal{M}^{5}$, for which the corresponding connection is invariant with respect to translations of the fifth coordinate. We suggest the fifth coordinate, say x^{5} here, as an internal but dynamical coordinate so that no field variables depend on this internal coordinate. So the field Lagrangian (2.1) can formally be written in pure Yang–Mills fields in five dimensions in a compact form:

$$\mathcal{L}_{f}=-\tfrac{1}{4}F^{aAB}F^{a}_{AB}, \tag{2.2}$$

where $A,B,\ldots=0,1,2,3$ and 5 denote indices in the five-dimensional space–time, and

$$F^{a}_{AB}=\partial_{A}A^{a}_{B}-\partial_{B}A^{a}_{A}+e\,f^{abc}A^{b}_{A}A^{c}_{B} \tag{2.3}$$

is the gauge field strength where f^{abc} are the structure constants, and e is the coupling constant of the particle with the Yang–Mills–Higgs field. We have defined the Higgs field as the fifth component of the Yang–Mills field:

$$\Phi^{a}\equiv A^{a}_{5}, \tag{2.4}$$

$$F^{a}_{\mu 5}=\partial_{\mu}A^{a}_{5}-\partial_{5}A^{a}_{\mu}+e\,f^{abc}A^{b}_{\mu}A^{c}_{5}=(\mathbf{D}_{\mu}\mathbf{\Phi})^{a}, \tag{2.5}$$

where $\mu=0,1,2,3$ shows the usual four-dimensional space–time indices, and a, b, and c shows the isospace indices—that is $=1,2,3$ for SU(2) gauge group.

Now consider the interaction between the Yang–Mills field $\mathbf{A}_{A}(x)$ (x_{0} standing for time component and the rest for spatial components) and a spin-$\frac{1}{2}$ field $\Psi(x)$ which transforms under the fundamental representation of the gauge group with generators χ^{a} [for SU(2) gauge group, $\chi^{a}=\sigma^{a}/2i$ where σ^{a} with $a=1,2,3$ are Pauli matrices]. So we may add the particle-field interaction term to the Lagrangian (2.2) to get

$$\mathcal{L}=-\tfrac{1}{4}F^{aAB}F^{a}_{AB}-\bar{\Psi}(\gamma^{A}\partial_{A}+e\,\gamma^{A}A^{a}_{A}\chi^{a}+m)\Psi, \tag{2.6}$$

where e is the coupling constant, m is the mass of particle and γ^{A} are Dirac gamma matrices, with $\gamma^{5}=\gamma^{0}\gamma^{1}\gamma^{2}\gamma^{3}$. Comparing Lagrangian (2.6) with Wong analysis in four dimension, the extra term

$$-\bar{\Psi}(\gamma^{5}\partial_{5}+e\,\gamma^{5}\Phi^{a}\chi^{a})\Psi=-e\bar{\Psi}\gamma^{5}\Phi^{a}\chi^{a}\Psi$$

appears in five-dimensional generalization, which indicates the interaction between the particle and the Higgs field.[5–7]

The field equations are

$$(\mathbf{D}^{B}\mathbf{F}_{AB})^{a}=-e\bar{\Psi}\gamma_{A}\chi^{a}\Psi, \tag{2.7}$$

$$\gamma^{A}(\partial_{A}+e\chi^{a}A^{a}_{A})\Psi+m\Psi=0. \tag{2.8}$$

This is the usual Dirac-type treatment to find classical equations of motion from quantum recipe, by regarding Eq. (2.8) as a one-particle Dirac equation for a colored particle in a given external field $\mathbf{A}_{A}$. This has been done by Wong[4] in four dimensions. The equations of motion are essentially similar to the Wong equations in four dimensions. The five-dimensional motion of a particle in this pure Yang–Mills field is governed by the following Wong equations:

$$m\frac{d^2x^A}{d\tau^2}=e\frac{dx^B}{d\tau}F^{aA}{}_{B}I^a, \tag{2.9}$$

$$\frac{dI^a}{d\tau}+e\,f^{abc}\frac{dx^A}{d\tau}A^b_A I^c=0, \tag{2.10}$$

where I^a is the charge isovector and τ is proper time.

The fifth dimension is a dynamical variable, so the evolution of this internal coordinate (x^5) is governed by

$$m\frac{d^2x^5}{d\tau^2}=e\frac{dx^B}{d\tau}F^{a5}{}_{B}I^a=-e\frac{dx^\mu}{d\tau}(\mathbf{D}_\mu\mathbf{\Phi})^aI^a. \tag{2.11}$$

For the components of the real four-dimensional space–time, the equations of motion are

$$m\frac{d^2x^\mu}{d\tau^2}=e\frac{dx^B}{d\tau}F^{a\mu}{}_{B}I^a=e\frac{dx^5}{d\tau}F^{a\mu}{}_{5}I^a+e\frac{dx^\nu}{d\tau}F^{a\mu}{}_{\nu}I^a=e\frac{dx^\nu}{d\tau}F^{a\mu}{}_{\nu}I^a+e\frac{dx^5}{d\tau}(\mathbf{D}^\mu\mathbf{\Phi})^aI^a. \tag{2.12}$$

In Fehér's work an extra term appears on the right-hand side of Eq. (2.12) which comes from the difference between the affine parameter in the five dimensions and four dimensions. The Wong equation for non-Abelian charge **I** in five dimensions (2.10) can be expanded as

$$\frac{dI^a}{d\tau}+e\,f^{abc}\frac{dx^\mu}{d\tau}A^b_\mu I^c+e\,f^{abc}\frac{dx^5}{d\tau}\Phi^bI^c=0. \tag{2.13}$$

Multiplying both sides of Eq. (2.13) by I^a, we obtain the same result as in four-dimensional analysis:

$$\frac{d(I^aI^a)}{d\tau}=0,\ \text{ so }\ I^aI^a=\text{const}, \tag{2.14}$$

which indicates conservation of the length of charge isovector. It is in this sense that non-Abelian charge is conserved.

The field equations which arise from the Lagrangian (2.6) are

$$\mathbf{D}_B\mathbf{F}^{AB}=\mathbf{J}^A, \tag{2.15}$$

where $\mathbf{J}^A$ are current due to the colored particle(s). In the matrix representation

$$\mathbf{A}_B\equiv A^a_B\chi^a,\quad \mathbf{\Phi}\equiv\Phi^a\chi^a,\quad \mathbf{F}_{AB}\equiv F^a_{AB}\chi^a,\quad \mathbf{D}_B\equiv\mathbf{1}\partial_B+e[\mathbf{A}_B,\ ]. \tag{2.16}$$

One may simply show the identities

$$\mathbf{D}_A\mathbf{D}_B\mathbf{F}^{AB}=0, \tag{2.17}$$

$$\mathbf{D}_A\mathbf{F}_{BC}+\mathbf{D}_C\mathbf{F}_{AB}+\mathbf{D}_B\mathbf{F}_{CA}=0. \tag{2.18}$$

From Eqs. (2.17) and (2.15) the conservation of the colored (non-Abelian) current $\mathbf{J}^A$ is given by

$$\mathbf{D}_A\mathbf{J}^A=0. \tag{2.19}$$

Expanding Eq. (2.15), the fifth and the space–time components of the current are

$$\mathbf{J}^5=\mathbf{D}_B\mathbf{F}^{5B}=\mathbf{D}_\mu\mathbf{F}^{5\mu}=-\mathbf{D}_\mu\mathbf{D}^\mu\mathbf{\Phi}, \tag{2.20}$$

$$\mathbf{J}^{\mu}=\mathbf{D}_{B}\mathbf{F}^{\mu B}=\mathbf{D}_{\nu}\mathbf{F}^{\mu\nu}+\mathbf{D}_{5}\mathbf{F}^{\mu 5}. \tag{2.21}$$

When the potential $V(\mathbf{A}^5)\equiv V(\Phi^a\Phi^a)=(\lambda/4)\,(\Phi^b\Phi^b-a^2)^2$ is considered in the Lagrangian (2.6), the fifth component of current will be

$$\mathbf{J}^{5}=-\mathbf{D}_{\mu}\mathbf{D}^{\mu}\mathbf{\Phi}+\lambda\mathbf{\Phi}(\Phi^a\Phi^a-a^2).$$

The last term on the right-hand side of Eq. (2.21) is simplified by our initial principles:

$$\mathbf{D}_{5}\mathbf{F}^{\mu 5}=[\mathbf{A}_{5},\mathbf{F}^{\mu 5}]\quad(\partial_{5}\mathbf{F}^{\mu 5}=0).$$

Then

$$\mathbf{J}^{\mu}=\mathbf{D}_{\nu}\mathbf{F}^{\mu\nu}+[\mathbf{\Phi},\mathbf{D}^{\mu}\mathbf{\Phi}], \tag{2.22}$$

which shows the usual current in the four-dimensional space–time has a contribution from the Higgs field.

For a non-Abelian point particle with charge **I**, the current can be defined in five dimensions in the normal way as in Wong's work in four dimensions:

$$\mathbf{J}^{A}(y)=e\int d\tau\,\mathbf{I}(\tau)\,\frac{dx^{A}(\tau)}{d\tau}\,\delta^{5}(y-x(\tau)), \tag{2.23}$$

where $x(\tau)$ is the location (world-line) of the charged particle in the five-dimensional space–time, y is an arbitrary point in the space–time, and δ is the Dirac delta function. The consistency between the above definition and the equations of motion is valid, i.e., from Eqs. (2.19) and (2.23) and the definition of covariant derivative we may obtain Eq. (2.10).

Equations (2.11)–(2.13), (2.20) and (2.22) completely describe the motion of a colored particle in the non-Abelian Yang–Mills–Higgs field. It is possible to find a first integral of Eq. (2.11). The right-hand side of Eq. (2.11) can be expanded as

$$-e\,\frac{dx^{\mu}}{d\tau}\,\frac{d\Phi^{a}}{dx^{\mu}}I^{a}-e^{2}\frac{dx^{\mu}}{d\tau}f^{abc}A_{\mu}^{b}\Phi^{c}I^{a},$$

and then Eq. (2.11) can be written

$$m\,\frac{d^{2}x^{5}}{d\tau^{2}}=-e\,\frac{d\Phi^{a}}{d\tau}I^{a}-e^{2}\frac{dx^{\mu}}{d\tau}f^{abc}I^{a}A_{\mu}^{b}\Phi^{c}. \tag{2.24}$$

Multiplying both sides of Eq. (2.13) by Φ^a, one can show

$$\Phi^{a}\frac{dI^{a}}{d\tau}=e\,\frac{dx^{\mu}}{d\tau}f^{abc}I^{a}A_{\mu}^{b}\Phi^{c}, \tag{2.25}$$

which, if substituted in Eq. (2.24), we have

$$m\,\frac{d^{2}x^{5}}{d\tau^{2}}=-e\,\frac{d\Phi^{a}}{d\tau}I^{a}-e\,\Phi^{a}\frac{dI^{a}}{d\tau}=-e\,\frac{d}{d\tau}(\Phi^{a}I^{a}). \tag{2.26}$$

From this equation we obtain a first order differential equation for the internal coordinate

$$m\,\frac{dx^{5}}{d\tau}=-e\,\Phi^{a}I^{a}+h, \tag{2.27}$$

where h is the constant of integration, which is indeed a constant of motion. As the fields are independent of the fifth dimension x^5, in a Lagrangian approach[8–10] in five dimensions $\partial L/\partial x^5$ vanishes. Therefore $\partial L/\partial \dot{x}^5 = m\dot{x}^5 + e\Phi^a I^a$ is a constant, in agreement with Eq. (2.27). So the momentum conjugate to x^5, h, is a constant of motion. Equation (2.27) presents a relation for the internal component of the particle's momentum. In fact, this is an internal variable, i.e., this variable is only a function of isovectors, the Higgs field and charge isovectors. We called the extra dimension, x^5, an internal dimension, which is now sensible in the same way as the space of symmetry (isospace) is called an internal space. The time variation of the internal direction, x^5, is related to the field and particle internal (isospace) vectors. If we replace dx^5/dt in the equations of motion, it gives a completely four-dimensional equations, which contain terms corresponding to the Higgs interaction with the particle. The only remnant of the fifth dimension in the equations is the free parameter h, which depends on the initial value of dx^5/dt.

The constant, h, in Eq. (2.27) depends on the initial orientation of the two isovectors and the initial value of $dx^5/d\tau$. For example, in the field of the 'tHooft–Polyakov monopole, if the particle starts the motion from the rest, $dx^A/d\tau = 0$, in the Higgs vacuum ($\vec{\Phi} = a\hat{r}$), and if the particle's charge isovector lies in the radial direction, the constant will be eaI, where I is the norm of the charge isovector which is always constant. If the particle starts the motion while the charge isovector lies in a tangential direction, then the constant will be zero. Regardless of the constant, Eq. (2.27) shows the internal component of momentum is proportional to the projection of the Higgs field on the direction of the particle's charge isovector, and the proportionality factor is $-eI$, i.e., the particle's charge. One can replace $dx^5/d\tau$ from Eq. (2.27) in Eqs. (2.12) and (2.13) to obtain a complete set of equations independent of the internal coordinate.

The equations of motion become simpler with some interesting consequences if we use a BPS magnetic monopole as the source of the Yang–Mills–Higgs field.

III. PARTICLE IN THE FIELD OF A BPS MONOPOLE

One of the most important solutions of the Yang–Mills fields is monopoles. Although experimentally no monopole is found yet, but monopole solutions in the field theory are very rich phenomena in theoretical physics. The 'tHooft ansatz is a solution which gives the right behavior of a magnetic monopole at far distances. The BPS monopole is an exact solution which gives the answer everywhere. About the behavior of motion of a particle in a monopole at far distances we may find some results in literature. The goal of this section is to explain some solution not only at far distances, but everywhere. So we have used the BPS monopole to discuss solutions at far and close distances from the origin. In this section we use the procedure described in the previous section and apply the conditions of the BPS monopole for a test particle. With a test particle we mean, relative to the monopole, the particle is so small in mass and charge such that the resulting perturbation due to the particle can be ignored. Therefore, the particle has no contribution in the evolution of the fields, and we ignore the current **J** on the left-hand side of field equations (2.20) and (2.22). Thus the field equations satisfy the BPS monopole conditions,[11] and we can use BPS solution

$$A^{a0} = 0, \quad \partial_0 A^{ia} = \partial_0 \Phi^a = 0,$$

$$A^{ai} = \epsilon^{aij} \frac{x^j}{er^2}(1-K), \quad K = \frac{aer}{\sinh(aer)}, \tag{3.1}$$

$$\Phi^a = \frac{x^a}{er^2} H, \quad H = aer\coth(aer) - 1,$$

for the fields.

Equations (3.1) satisfy the field equations, and in a nonrelativistic framework the equations of motion (2.12) and (2.27) become

$$m\frac{d^2x^i}{dt^2}=e\frac{dx^j}{dt}F^a_{ij}I^a+e\,p\,(\mathbf{D}_i\mathbf{\Phi})^aI^a, \tag{3.2}$$

$$m\,p=-e\,\Phi^aI^a+h, \tag{3.3}$$

where we have substituted τ by $t=x^0$, dropped the equation for x^0 and defined

$$p=\frac{dx^5}{dt}. \tag{3.4}$$

The constant h depends on the initial conditions as we explained after its introduction in Eq. (2.27). A force due to the Higgs field has appeared in the equation of motion, Eq. (3.2), beyond the usual Lorentz force. The equation of evolution of the charge isovector (2.13) becomes

$$\frac{dI^a}{dt}+e\,\epsilon^{abc}\frac{dx^i}{dt}A^b_iI^c+e\,p\,\epsilon^{abc}\,\Phi^bI^c=0. \tag{3.5}$$

By replacing F^a_{ij}, $(\mathbf{D}_i\mathbf{\Phi})^a$, A^a_i and Φ^a from Eqs. (3.1) into Eqs. (3.2)–(3.5), the equations in a convenient form are

$$m\dot{\vec{v}}=e\vec{v}\times\vec{B}^aI^a-e\,p\vec{B}^aI^a=\frac{\vec{r}\cdot\vec{I}}{r^4}(K^2-rK'-1)[(\vec{v}\times\vec{r})-p\vec{r}]+\frac{K'}{r}[(\vec{v}\times\vec{I})-p\vec{I}], \tag{3.6}$$

$$m\,p=-\frac{H}{r^2}(\vec{r}\cdot\vec{I})+h, \tag{3.7}$$

$$\dot{\vec{I}}=\frac{1-K}{r^2}(\vec{r}\times\vec{v})\times\vec{I}-\frac{pH}{r^2}(\vec{r}\times\vec{I}), \tag{3.8}$$

where the magnetic field is

$$B^a_i=\frac{1}{2}\epsilon^{ijk}F^a_{jk}=-(\mathbf{D}_i\mathbf{\Phi})^a=\frac{1}{er^2}\left\{\frac{x^ax^i}{r^2}(K^2-rK'-1)+rK'\,\delta^{ai}\right\}. \tag{3.9}$$

The energy and the total angular momentum are constants of motion. Using the general equation in five dimensions (2.9), multiplying both sides by $dx^A/d\tau$, one can simply find

$$\frac{d}{d\tau}\left[\frac{1}{2}m\left(\frac{dx^A}{d\tau}\right)^2\right]=0,$$

which in a nonrelativistic framework implies

$$E\equiv\tfrac{1}{2}mv^2+\tfrac{1}{2}mp^2=\text{const.} \tag{3.10}$$

Here, $\vec{v}$ is velocity of the particle ($v=|\vec{v}|$), and p is defined in Eq. (3.4). The validity of relation (3.10) can be checked directly by using the equations of motion (3.3), (3.6), and (3.8) to show

$$m\dot{\vec{v}}\cdot\vec{v}+m\dot{p}\,p=0.$$

Another constant is $\vec{J}$, the total angular momentum of particle and fields,[12] which is

$$\vec{J}=m(\vec{r}\times\vec{v})+K\vec{I}+\frac{(1-K)(\vec{I}\cdot\vec{r})}{r^2}\vec{r}. \tag{3.11}$$

Replacing from Eqs. (3.6) and (3.8) in Eq. (3.11), after some algebra, one may easily show $\dot{\vec{J}}=0$ and so

$$\vec{J}=\text{const.} \tag{3.12}$$

In the first view, we find Eqs. (3.6) and (3.8) are too complicated to be solved. Therefore, we consider the asymptotic behavior of the equations at large distances. Because of the different behavior of K and K' with H at large distances we may consider two cases. At large distances $K(r)$ and $K'(r)$ vanish exponentially, and $\vec{B}^a=-(x^a/er^4)\vec{r}$. If r is not too much bigger than 1, $H(r)\to aer-1$, and if $r\gg 1$, then 1 might be ignored and so $H=aer$. So at large distances (but not too far) Eqs. (3.6) and (3.7) become

$$m\dot{\vec{v}}=\frac{\alpha}{r^3}[\vec{r}\times\vec{v}+p\vec{r}], \tag{3.13}$$

$$p=\left(-e\ a\ \alpha+h+\frac{\alpha}{r}\right)/m, \tag{3.14}$$

where we have defined the charge isovector as

$$\vec{I}=\alpha\hat{r}+\beta\hat{w}+\gamma\hat{z}, \tag{3.15}$$

in an orthogonal moving frame along the particle trajectory:

$$\vec{r},\vec{w}=\vec{r}\times\vec{v}\left(\vec{v}=\frac{d\vec{r}}{dt}\right),\vec{z}=\vec{r}\times\vec{w}, \tag{3.16}$$

where hatted letters denote the unit vectors along each axis. Evidently the coefficients α, β, and γ satisfy

$$I\equiv(I^aI^a)^{1/2}=(\alpha^2+\beta^2+\gamma^2)^{1/2}=\text{const.} \tag{3.17}$$

From Eq. (3.8), after a little algebra we find

$$\dot{\alpha}=-\frac{K|\vec{w}|}{r^2}\gamma, \tag{3.18}$$

$$\dot{\beta}=\left\{r\frac{\dot{\vec{v}}\cdot\vec{w}}{|\vec{w}|^2}+\frac{pH}{r}\right\}\gamma,\quad p=\frac{1}{m}\left(-\frac{\alpha H}{r}+h\right), \tag{3.19}$$

$$\dot{\gamma}=\left\{-r\frac{\dot{\vec{v}}\cdot\vec{w}}{|\vec{w}|^2}-\frac{pH}{r}\right\}\beta+\frac{K|\vec{w}|}{r^2}\alpha. \tag{3.20}$$

These equations, by using the asymptotic behaviors of K and H at large distances, and using the asymptotic equation (3.13), become

$$\dot{\alpha}=0, \tag{3.21}$$

$$\dot{\beta}=\left[\frac{\alpha}{mr^2}+p\frac{aer-1}{r}\right]\gamma, \tag{3.22}$$

$$\dot{\gamma}=-\left[\frac{\alpha}{mr^2}+p\frac{aer-1}{r}\right]\beta, \tag{3.23}$$

where p has the asymptotic value in Eq. (3.14). From Eq. (3.21), obviously $\alpha=\alpha_0$ is a constant.

For this asymptotic case, using Eqs. (3.13) and (3.21), the length of the angular momentum $l=|m(\vec{r}\times\vec{v})|$, the total angular momentum vector $\vec{j}=\vec{l}+\alpha_0\hat{r}$, and in addition, $\vec{j}\cdot\hat{r}=\alpha_0$ are constants of motion [in agreement with Eq. (3.11)]. From Eqs. (3.13) and (3.14) one may simply find $m(v^2+p^2)/2$ is also a constant of motion [see Eq. (3.10)]. If $j=|\vec{j}|=0$ so $l=\alpha_0=0$, then the particle moves uniformly in a radial direction (or stays at rest). For $j\neq 0$, the motion will take place on a cone with the axis $\vec{j}$ and the half-angle $\cos^{-1}(\alpha_0/j)$.

We may compare the forces on the right-hand side of the asymptotic equation (3.13) with forces due to certain point objects sitting at the origin. From the components of the isovector charge $\vec{I}$, only α (that is a constant) has appeared in the equation of motion, Eq. (3.13). Therefore, we may assume only the $e\alpha$ portion of the particle's charge, eI, participates in the motion at large distances

$$m\dot{\vec{v}}=-\frac{\alpha}{r^3}(\vec{v}\times\vec{r})+\frac{\alpha(h-e\,a\,\alpha)}{mr^3}\vec{r}+\frac{\alpha^2}{mr^4}\vec{r}. \tag{3.24}$$

The first term on the right-hand side of Eq. (3.24) is a force due to a point magnetic monopole. The second and the third terms are forces exerted from the scalar Higgs field on the colored test particle. The second term corresponds to the force due to an electric point charge on the test particle and the third term has the characteristic of a spherical charge distribution of total charge zero. At close distances the force from the fields on the particle are very complicated, and at far distances the dominant terms are those on the right-hand side of Eq. (3.24). For $r\gg 1$ the dominant forces are the first and second terms on the right-hand side of Eq. (3.24).

For too large distances, i.e., $r\gg 1$, where the Higgs field asymptotically becomes

$$\vec{\Phi}=a\hat{r}, \tag{3.25}$$

we may neglect 1 in the term $aer-1$, and rewrite the equations of motion (3.13), (3.14), and (3.21)–(3.23),

$$m\dot{\vec{v}}=\frac{\alpha}{r^3}[\vec{r}\times\vec{v}+p\,\vec{r}], \tag{3.26}$$

$$p=\frac{(-e\,a\,\alpha+h)}{m}, \tag{3.27}$$

$$\dot{\alpha}=0, \tag{3.28}$$

$$\dot{\beta}=eap\,\gamma, \tag{3.29}$$

$$\dot{\gamma}=-eap\,\beta, \tag{3.30}$$

where now p is a constant and $\dot{\beta}$ and $\dot{\gamma}$ have simpler forms. In this approximation (too large distances) l, α, and $\vec{j}$ (so $\hat{j}\cdot\hat{r}$) are constants of motion (the same as in the large distances approximation). Now p is a constant, so from Eq. (3.26) $mv^2/2+\alpha p/r=\text{const}$ [that can be obtained by expanding $E=m(v^2+p^2)/2=\text{const}$ at large distances using Eq. (3.14) and then dropping the order of $1/r^2$ and redefining p as in Eq. (3.27)].

Equations (3.29) and (3.30) provide a precession motion for the charge isovector $\vec{I}$, around the radial direction of the particle in the isospace

$$\beta(t)=\sqrt{I^2-\alpha^2}\sin(aep\,t+\Omega_0),\ \gamma(t)=\sqrt{I^2-\alpha^2}\cos(aep\,t+\Omega_0), \tag{3.31}$$

where Ω_0 is a constant. The charge isovector moves around a circle of radius $(I^2-\alpha^2)^{1/2}$ with a constant angular frequency $\omega=aep$. Therefore p measures how fast the charge isovector moves around in the isospace, when the particle travels its path in the real space. So p which was defined as the velocity in the fifth-spatial direction [Eq. (3.4)] appears as the velocity of the charge isovector in its precession around the particle's radial direction [note, ae has the dimension of $(\text{length})^{-1}$].

IV. SOLUTIONS OF THE EQUATIONS OF MOTION

In our previous work[1] we observed planar and bounded motions and we presented numerical works in two and three dimensions. There the only force on the particle was the force from the monopole and a force from the Higgs field on the particle was not considered. In the first part of this article we explained the equations of motion containing the Higgs and the particle interaction as well as the monopole force, and in this section we search for some solutions.

A. Planar motions

It is interesting to know if the planar motions occur here. In a planar motion $\vec{r}\times\vec{v}$ is always normal to the plane of motion, so in the equations of motion the coefficient of $\vec{w}=\vec{r}\times\vec{v}$ must be set to zero and we find some consistent solutions. Using the moving frame (3.16), the component of Eq. (3.6) in the $\hat{w}$-direction is

$$-\frac{\alpha(K^2-rK'-1)}{r^3}|\vec{w}|-\frac{K'}{r^2}(\alpha|\vec{w}|+\gamma(\vec{r}\cdot\vec{v}))-\frac{K'}{r}p\,\beta. \tag{4.1}$$

For a planar motion this coefficient must identically be equal to zero, so

$$(K^2-1)|\vec{w}|\alpha+r^2K'\,p\,\beta+rK'(\vec{r}\cdot\vec{v})\,\gamma=0. \tag{4.2}$$

Under these considerations the equations of motion (3.6) and (3.18)–(3.20) become

$$m\dot{\vec{v}}=\left[-\frac{K^2-rK'-1}{r^2}p\alpha+\frac{K'}{r^2}(|\vec{w}|\beta-rp\alpha)\right]\hat{r}+\frac{K'}{r^2}[(\vec{r}\cdot\vec{v})\beta-r\,p\,\gamma]\hat{z}, \tag{4.3}$$

$$\dot{\alpha}=-\frac{K\,w}{r^2}\gamma, \tag{4.4}$$

$$\dot{\beta}=\frac{p\,H}{r}\gamma, \tag{4.5}$$

$$\dot{\gamma}=\frac{K\,w}{r^2}\alpha-\frac{p\,H}{r}\beta, \tag{4.6}$$

and p is unchanged:

$$mp=-\frac{H}{r}\alpha+h. \tag{4.7}$$

Let us first examine the above equations at large distances. At large distances where K and K' vanish, Eq. (4.2) necessitates $\alpha=0$. Replacing this result in Eq. (4.3) shows the particle move on a straight line at large distances [see also Eq. (3.13)]. Also at large distances p is a constant and β and γ have a precessional motion (if $p\neq0$), which are compatible with the asymptotic behavior of equations we studied before.

In fact, Eq. (4.2) is an extra equation and might not be consistent with the equations of motion (4.3)–(4.6) in general. But it might be consistent with equations of motion under some circum-

stances. Finding the conditions where this extra equation might be consistent with the others does not seem to be easy. Looking at Eq. (4.2), one may choose $\alpha=\beta=\gamma=0$, which is, of course, a contradiction (while $\vec{I}$ is a nonzero vector). One acceptable possibility is $\alpha=\gamma=p=0$, which causes Eq. (4.2) to vanish identically. From Eq. (4.7) the condition $p=0$ is equivalent to $h=0$. So,

$$\alpha=\gamma=h=0 \tag{4.8}$$

are conditions for planar motion subject to the validity of equations of motion. Replacing from Eq. (4.8) in Eqs. (4.3)–(4.6) we obtain exactly the planar equations of Ref. 1. So the planar motion and indeed the bounded orbits are allowed in this regime as well. Because the equations of planar motion are the same as in Ref. 1 we skip their solutions in this article. The stability of planar motion must be studied independently. In the planar solutions of Ref. 1 we stated the planar motions were not stable, but in this case the Higgs field might play a role to keep the particle close to the plane and does not let it scatter to infinity. I have not checked this problem.

A proper question is, under what circumstances the force from the Higgs field on the particle fails and the particle feels only a force from the monopole (i.e., the generalized equations of motion we found in this article shrink to the equations of motion of Ref. 1). In fact, it is not possible to ignore the Higgs field interaction with the particle in general. Equating p to zero is an obvious way, but this equation exerts an extra constraint. Setting $p=0$ occasions $\alpha=hr/H$, then from Eq. (3.18) we find γ and from Eq. (3.20) β. So we may replace α, β, and γ in Eqs. (3.19) and (3.6) to find two parallel equations which are too complicated (and I think they are not consistent in general). A possible case (maybe the only one) is the mentioned planar motion, which means in the specified planar motions the Higgs interaction has no contribution.

B. Radial motions

A radial motion is possible if initially the charge isovector and the particle velocity are radial. In this case from Eq. (3.8) the charge isovector remains constant, $\alpha=I$ and $\beta=\gamma=0$, and from Eq. (3.6)

$$m\ddot{r}=\frac{I}{r^2}(K^2-1)p, \tag{4.9}$$

where $p=-IH/r+h$. In the previous case (the monopole interaction only), the right-hand side of Eq. (4.9) was vanishing ($p=0$) and the particle had a uniform radial motion, and could pass through the origin. Equation (4.9) shows a different situation.

Assume the particle is moving along a radial direction, say the z-axis. From Eq. (3.10) we may write

$$E=\tfrac{1}{2}m\dot{r}^2+V(r), \tag{4.10}$$

where

$$V(r)=\frac{1}{2}m\,p^2=\frac{1}{2}m\left(\frac{-IH(r)}{r}+h\right)^2 \tag{4.11}$$

is the one-dimensional potential, and r (is the variable along the z-axis and) takes both negative and positive values. The time derivative of Eq. (4.10) leads to Eq. (4.9). Regardless of mass, a, e, and I, the potential $V(r)$ depends on the constant h. Figure 1 shows the different shapes of $V(r)$ with respect to the different values of h. To see these results one may equate $V'(r)$ to zero and find the roots (that are indeed the roots of $p=0$). For a negative value of h, $V(r)$ is the mirror image of the the potential for $-h$, with respect to the vertical axis.

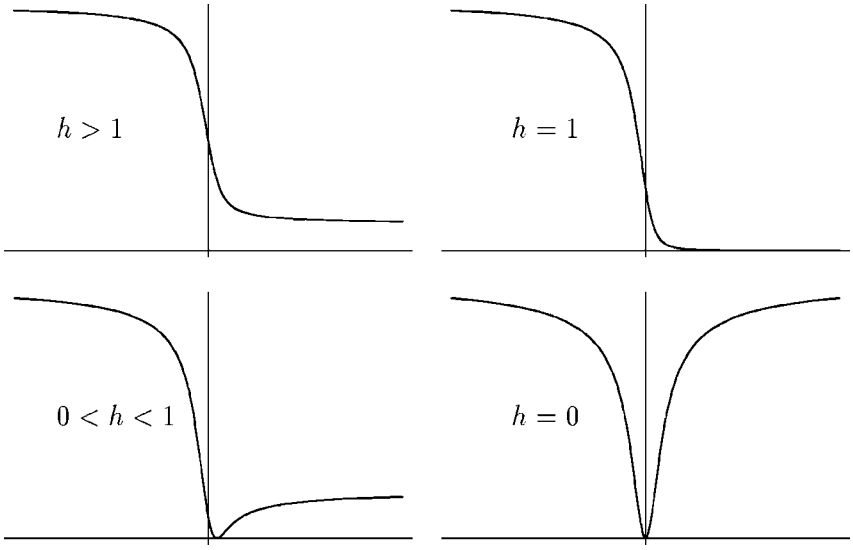

FIG. 1. One-dimensional potential $V(r)$ (vertical axis) vs r (horizontal axis). For a given h, the mirror image of $V(r)$ with respect to the vertical axis gives $V(r)$ for $-h$.

From Fig. 1, if $|h| \geqslant 1$, the particle may be repelled back (before reaching the origin, just at the origin or after passing the origin), or just passes through the origin depending on the energy E. For $0 < |h| < 1$, in addition to the mentioned possibilities for $|h| \leqslant 1$, bounded motions are also possible (in the $h = 0$ case, the particle just passes or is bound).

Referring to Fig. 2, for $E \geqslant E_1$ the particle passes through the origin and travels to infinity. For $E_1 < E \leqslant E_3$, such as E_2, the particle is repelled back (even before reaching the origin or after passing through the origin) in its trajectory and travels to infinity. For $0 < E < E_3$, the orbit is bounded and the particle oscillates along the z-axis. For $h = 0$ the oscillation is symmetric with respect to the origin (the origin is the equilibrium point). But in the other cases, the origin is not the equilibrium point (center of the oscillatory motion) and the amplitude of the motion on the two sides of the origin are not equal (even not equal on either side of the equilibrium point). And, on top of it all, for the energies less than E_4, the particle oscillates only on one side of the origin. At

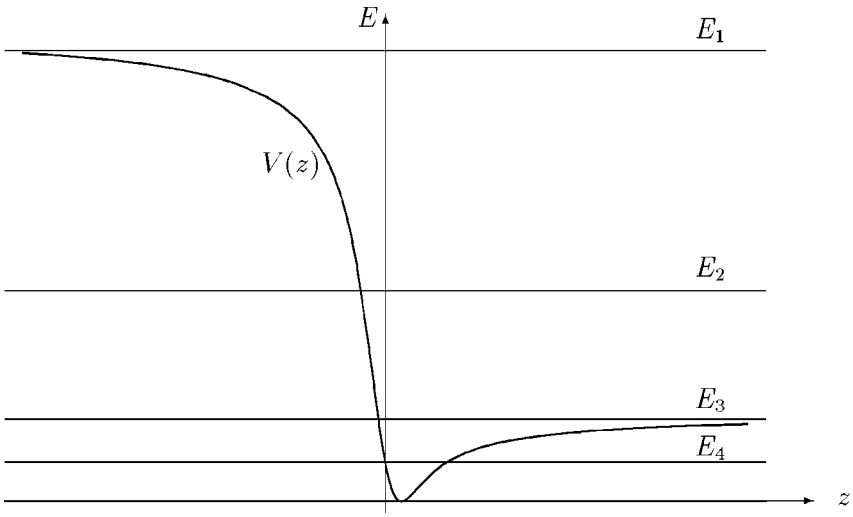

FIG. 2. Different possibilities of motion for $0 < h < 1$.

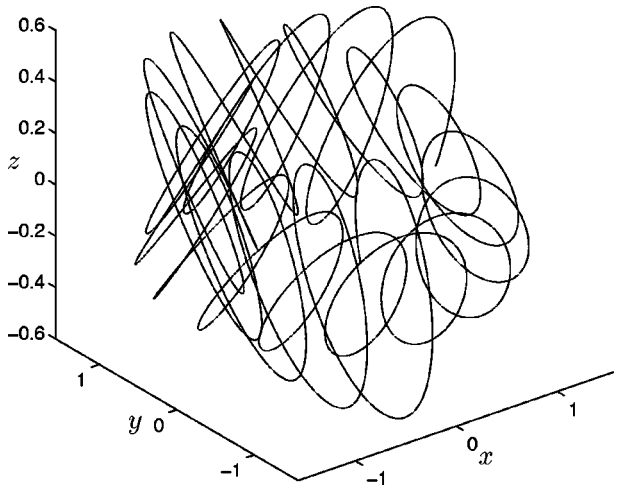

FIG. 3. Bounded orbit in three dimensions.

the equilibrium point $p=0$, the position of equilibrium (with respect to the origin) depends on the constant h. For larger $|h|$, the location of the equilibrium point is more distant.

The role of h in the radial motion is similar to the role of j in the planar motion. As the orientation of the charge isovector and the Higgs field are fixed in the radial motion, the constant h depends only on the initial starting point, r_0, and the initial value of p, p_0. The initial value of p, p_0, is a free parameter in the radial motion and it must be determined by the overall theory of motion. From Eq. (4.10) one may write an integral equation for t and r:

$$t=\pm\int_{r_0}^{r}\frac{dr}{\sqrt{2E/m-[-IH(r)/r+h]^2}}. \tag{4.12}$$

C. Three-dimensional bounded orbits

We studied the planar and radial motions in the previous subsections. In both cases, bounded orbits were allowed. Suppose a particle is moving in a bounded orbit in a plane, say the xy-plane, so that the charge isovector is normal to the plane of motion along the z-axis. Regardless of the motion in the plane, suppose the particle has also a motion in the z-direction such that the particle can oscillate in the z-direction. This is a motivation to believe, if we mix the initial condition of the both motions, we may get a bounded motion in three dimensions. Of course, we do not say that the resulting motion is the superposition of the two previously mentioned motions. It is clear that the equations governing the motion [i.e., Eqs. (3.6) and (3.8)] are not linear, therefore the superposition of the solutions is not necessarily a solution. The above motivation is correct only for the starting point, and for the other instants we must follow the equations of motion. Let us examine an example by numerical solution. Under these circumstances, the planar motion condition requires $h=0$. For example, with $h=0$, if the particle is launched into the fields with the initial values $[\vec{r}_0,\vec{v}_0,\vec{I}_0]=[[1,0,0],[0.1,0,0],[0,0,1]]$, the result is a bounded planar motion in the xy-plane (see plot on the bottom-left of Fig. (2). If the particle is launched in the field with the initial values [[0,0,0],[0,0,0.1],[0,0,1]], the result is a symmetric bounded oscillation along the z-axis around the origin. So we expect, if the particle is launched with the initial values [[1,0,0],[0.1,0,0.1],[0,0,1]], the result will be a bounded orbit in three dimensions. By chance it is right. Using the three-dimensional equations of motion (3.6) and (3.8), a numerical analysis confirms the claim as it is plotted in Fig. (3). We have tested the motion for a remarkable amount of time (10 000 units of time), and numerically a result is obtained.

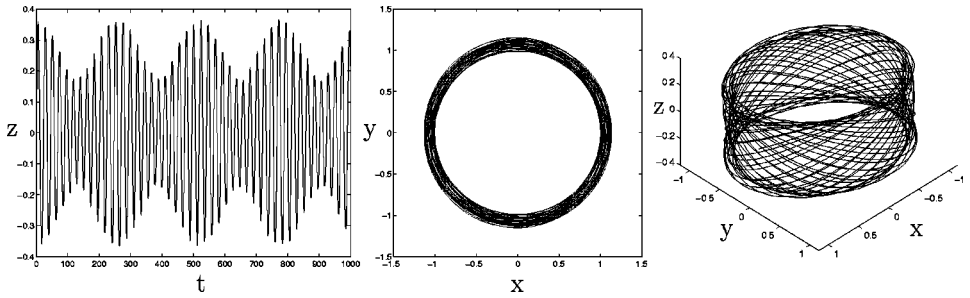

FIG. 4. The left plot shows the variation of z-direction vs time, the middle one shows the intersection of the motion in the xy-plane, and the right plot shows the three-dimensional orbit.

One result that we may get quickly from the above discussion is the stability of the planar motions. In fact, it is sensible to understand the stability of the planar motions in the new scenario. When small perturbations normal to the plane of motion disturb the motion, there is a vertical force to keep the motion oscillating close to the plane so that the pattern of the planar orbit stays unchanged. So, involving the Higgs field interaction makes a significant difference. In Ref. 1 the Higgs field interaction was ignored, so the planar motions were not stable (in the sense of vertical perturbations). We have checked the stability of the planar motions by considering small perturbations in any of the motion's parameters, numerically by using the general equations of motion.

In general the closed orbits are unknown in the nonplanar motions. For example, if we start the motion from the initial values [[1,0,0],[0,0.266,0],[0,0,1]] and $h=0$, we obtain a closed circular motion, and if we start the motion from [[0,0,0],[0,0,0.1],[0,0,1]] we obtain a symmetric radial oscillation. The motion with initial values [[1,0,0],[0,0.266,0.1],[0,0,1]] forms a bounded orbit such that the intersection of the orbits with the xy-axis is bounded between two circles, and the z-direction has an oscillatory motion along the z-axis with the domain changes between a minimum and a maximum periodically [see Fig. (4)]. If the equations of motions were linear, we might say the superposition of two closed orbits is closed if the ratio of periods of two motions is a rational number. But in our case the equations of motion are not linear, so we are not able to use this theorem. We might play with the parameters to gain a closed orbit in three dimensions. Studying the bounded and closed orbits needs an analytic description of the equations of motion, which is not available here.

With $h=0$ we may choose any combination of the initial values (not only a combination of the planar and radial motions initial values) and test the equations of motion by numerical computations. The bounded orbits are observed for different kinds of combinations of the initial values. Of course for many initial values we cannot expect a bounded orbit. For nonzero h's the combination of initial values is too sensitive and for most of them the orbit is unbounded. But still for some initial values bounded orbits are observed. An example is [[1,0,0],[0.1,0,0],[1,0,1]] with $h=0.5$. Now the initial values [[1,0,0],[0.1,0,0],[0,0,1]] with $h=0.5$ is neither a planar motion nor a nonplanar bounded motion, but when it mixes with an oscillatory motion in the x-direction, the resulting three-dimensional motion will be bounded.

At far distances a particle moves on a surface of a cone (see Sec. III). Figure 5 shows the orbit for an initial values [[10,10,0],[0,−0.1,0],[0,0,1]] with $h=1$ in 200 units of time. The variations on x and z are small and of the order 10^{-4} (the unusual ticks in the vertical axis are badly managed by MATLAB, and means the variations in this axis are of order 10^{-4}). The particle, which has started the motion with an initial velocity in the negative y-direction, moves along the y-direction almost uniformly.

V. THE FORCE LAW

In this section we consider further the force on a non-Abelian particle in a BPS monopole field configuration [$\mathbf{B}_i=\pm\mathbf{D}_i\Phi$, $\mathbf{A}_0=0$, $V(\Phi)=0$] which we studied in the previous section. We shall show the force has the form of a ''generalized'' Lorentz force.

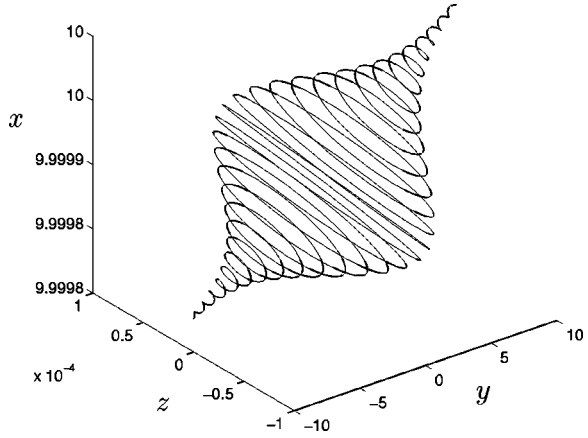

FIG. 5. Three-dimensional motion at large distance.

Looking at the first equality in Eq. (3.6), if we suppose eI^a is an electric charge of the particle (in a non-Abelian sense), then $eI^a\vec{v}\times\vec{B}^a$ is a magnetic force due to a magnetic field $\vec{B}^a$ on the particle, and $eI^a\,p\vec{B}^a$ may be interpreted as an electric force due to an electric field $p\vec{B}^a$ on the particle (regardless of the notation $\vec{B}^a$ that is used for magnetic field).

Let us explain more. In the usual electrodynamics, the force of an electric field $\vec{E}$ on an electric charged particle with the charge q is $q\vec{E}$, and the force of a magnetic field $\vec{B}$ on an electric charged particle with the charge q is $q\vec{v}\times\vec{B}$, where $\vec{v}$ is the velocity of particle. Let us switch to the non-Abelian fields and particles. Assume a field B_i^a in the space and a non-Abelian test particle with charge isovector Y^a in this field. The particle feels only the component of the magnetic field that is projected along its charge isovector. Let us choose a unit vector $\hat{n}$ along the charge isovector (remember in the isospace),

$$\vec{Y}=q\hat{n}, \tag{5.1}$$

where $q=|\vec{Y}|=\text{const}$ is the charge of the particle. Now the effective magnetic field the particle feels is

$$\mathcal{H}_i=\vec{B}_i\cdot\hat{n}, \tag{5.2}$$

or equivalently $\vec{\mathcal{H}}=\vec{B}^a\hat{n}^a$. Now we can write down the equation of motion of the particle, Eq. (3.6), in a familiar form (for positive magnetic charge):

$$m\dot{\vec{v}}=q\vec{v}\times\vec{\mathcal{H}}+p\,q\,\vec{\mathcal{H}}, \tag{5.3}$$

where here $q=eI$.

Equation (5.3) is a generalization of the Lorentz force. Comparing with the usual electrodynamics, two major differences show themselves in Eq. (5.3). The first difference is the following: In Eq. (5.3), rather than a term analogous to the usual Lorentz force (first term on the right-hand side), there is another term that is similar to the Coulomb force in the usual electrodynamics. We should remember that this new term is originally different from the Coulomb force. The Coulomb force is regarded as the zeroth component of the Yang–Mills fields, which in our discussions has been ignored (remember we are working in stationary fields with $\mathbf{A}_0=0$), but here the origin of the Coulomb-like force is the Higgs field. The coefficient p in front of the Coulomb-like force contains some information about the interaction of the Higgs field and the charge isovector. We will say how this generalized equation reduces to the normal Lorentz force when the field and particle can be regarded as a non-Abelian field and particle. The second difference is this:

In the usual Lorentz force, the force vanishes if and only if the nonvanishing magnetic field and the particle's velocity become parallel. But in the non-Abelian case it might happen that neither of the particle's velocity or the non-Abelian magnetic field vanish, nor the particle's velocity and the magnetic field (in any sense, either in the non-Abelian form B_i^a or in the Higgs gauge-invariant form $\mathcal{B}_i$ (Ref. 13) are parallel, but the force vanishes. This happens when the projection of the magnetic field along the charge isovector vanishes, i.e., $\vec{\mathcal{H}}=0$.

We can define a usual (say Abelian) particle in general as a non-Abelian particle whose charge isovector is fixed in the isospace, i.e.,

$$Y^a = q\,\delta^{a3}. \tag{5.4}$$

Now when the charge isovector $\vec{Y}$ takes a radial direction in the isospace, we can transform its direction to the three-direction by a proper gauge transformation.[14] This happens for both the charge isovector and the Higgs field simultaneously when both the isovectors take radial direction in a part of the space. A good example is the regions too far from the core of the fields, where we found the equations of motion asymptotically.

Suppose $\vec{Y}=q\hat{r}$ $(q=eI)$ and $\vec{\Phi}=a\hat{r}$ in the asymptotic case. So, the charge isovector has no components in the directions normal to the radial direction, and therefore $\beta=\gamma=0$. In this case our definitions of $\mathcal{B}$ and $\mathcal{H}$ overlap, and the equation of motion (5.3) transforms to Eq. (3.26) (for self-dual case):

$$m\dot{\vec{v}}=\frac{I}{r^3}[(\vec{v}\times\vec{r})+p\vec{r}], \quad p=(-eaI+h)/m. \tag{5.5}$$

Both of the isovectors can be rotated by a gauge transformation to lie in the three-direction by a gauge transformation, where we expect to have the usual Abelian electrodynamics laws. By the rotation, the particle will be the usual particle that is defined in Eq. (5.4), and the electromagnetic field becomes the usual one. In addition, in the usual space that we are talking about, there should be no trace of the free parameter p which is related to the extra dimension. So, we may have $p=0$, and set the constant h

$$h=eaI. \tag{5.6}$$

Now Eq. (5.5) is reverted to the proper usual Lorentz force. The differences between the generalized force and the usual Lorentz force we enumerated before automatically disappear, because the factor p vanishes and the extra term in the generalized force is gone. Also the Higgs field and the charge isovector have become parallel, therefore the second difference we mentioned can no longer happen.

In general we need 13 initial values $[x^A(t_0),\ \dot{x}^A(t_0),$ and $I^a(t_0)]$ to determine solutions of the equations of motion. In the nonrelativistic framework there are 11 values, 9 of which are position, velocity, and charge isovector that are indeed needed to solve the equations (3.2) and (3.5). The other two initial values are connected to the internal fifth dimension x^5. Because neither the fields nor the equations of motions depend on the internal direction, therefore the initial starting point in the x^5-direction is not important. But the time variation of internal direction dx^5/dt, which was called p, is very important.

(Received 4 April 2001; accepted for publication 12 November 2001)

We study spectral and scattering properties of a spinless quantum particle confined to an infinite planar layer with hard walls containing a finite number of point perturbations. A solvable character of the model follows from the explicit form of the Hamiltonian resolvent obtained by means of Krein's formula. We prove the existence of bound states, demonstrate their properties, and find the on-shell scattering operator. Furthermore, we analyze the situation when the system is put into a homogeneous magnetic field perpendicular to the layer; in that case the point interactions generate eigenvalues of a finite multiplicity in the gaps of the free Hamiltonian essential spectrum. © *2002 American Institute of Physics.*

I. INTRODUCTION

The object of our interest in this article is a spinless quantum particle living in a layer of a fixed width d with the Dirichlet boundary conditions and interacting with a finite number of point perturbations. An obvious motivation for this problem is to find a description for an electron in a semiconductor layer with impurities. However, such physical systems are in reality rather complicated objects which involve a crystal lattice with some alien atoms and an electron gas, so one has to ask first whether such a simple model can reproduce the basic features known from experiments.

It is well known that an electron in an ideally pure bulk semiconductor material can be modeled as a free particle with an effective mass m^* which characterizes the relation between the energy and quasi-momentum at the Fermi level. Properties of the crystalline structure are thus expressed through a single material constant, which may be very different from the ''bare'' mass—recall that for GaAs we have $m^* = 0.067 m_e$.

There are two other assumptions in the ''free'' part of the model. The first is its one-particle character which neglects the interactions between the electrons. There are situations where the repulsion plays an important role, such as the Coulomb blockade in quantum wires. On the other hand, the one-electron model is known to work when the electron-gas density is sufficiently low. Another assumption is the neglection of spin which is also not entirely trivial; recall that spin-dependent effects in nanostructures have been studied recently—see Ref. 1 and references therein. In most situations, however, spinless electrons are a reasonable approximation.

The next question concerns the way in which we model the impurities. Using again a certain idealization, we describe them by point interactions. This method proved rather useful in the last two decades and gave rise to numerous solvable models; our aim here is to add one more class to this family. Intuitively point interactions are understood as sharply localized potentials, but it is

[a)]Electronic mail: exner@ujf.cas.cz

known that a sophisticated coupling constant renormalization is required to give this concept meaning in terms of a limit of scaled potentials (Ref. 2, Secs. I.1 and I.5). Mathematically such operators can be handled since they differ from the free Hamiltonian H_0 just by a change of the boundary conditions at the interaction sites. However, the counterintuitive features of three-dimensional point interactions are reflected both in the slow way in which they found their place in the theory and in the fact that the parameters appearing in these conditions cannot be interpreted as δ potential coupling constants but rather as the inverse scattering lengths corresponding to the point ''obstacles'' (cf. Ref. 2, Chap. I.3).

Scores of papers discussing point-interaction models in the Euclidean space, both for particles otherwise free or with a background regular potential, are summarized in Ref. 2. Only in the last decade has the attention shifted to systems with point interactions restricted to a certain region of configuration space; the reason clearly was a wide collection of new physical phenomena observed in such spatially restricted systems, mostly mesoscopic objects, but also electromagnetic waveguides, photonic crystals, etc. (see Ref. 3). Here, too, point-interaction Hamiltonians proved a useful tool and yielded some unexpected results such as the existence of a chaotic behavior in systems whose classical counterparts are integrable.[4]

Today there are many papers treating point interaction in restricted areas; a bibliography is given in the introduction of Ref. 5. They typically put emphasis on the description of a specific model rather than a proper handling of the point interaction. Among the few existing rigorous treatments of the problem, it is Ref. 5 which motivates the present study analyzing point interactions in an infinite planar strip with Dirichlet boundary conditions, together with similar systems. There are two ways in which the results can be generalized to dimension three. One is a straight Dirichlet tube in $\mathbb{R}^3$ with a fixed compact cross section discussed in Ref. 6; it is a straightforward extension, a part of a different way of computing the regularized Green's function.

In the present article we are going to study a less trivial generalization, with point interactions situated in a flat layer with a Dirichlet boundary. The free system allows here again a separation of variables, so the free resolvent kernel and all the quantities derived from it such as eigenfunctions, etc., can be written by means of an explicitly given series (in this sense models considered here are little ''less solvable'' than those in the full space when such quantities can be written in terms of elementary or special functions).

Although the model description is simple, it covers many different situations. For the sake of brevity we restrict ourselves in this article to systems with a finite number of point perturbations in the absence of a background potential, leaving other cases to a sequel. We make an exception, however, by devoting a separate section to the case when the particle is under the influence of a homogeneous magnetic field perpendicular to the layer. The spectrum of the unperturbed system is then changed, completely consisting of infinitely degenerate eigenvalues which are sums of the Landau levels and the transverse eigenvalues; for ''rational'' combinations of parameters different Landau levels may lead to the same eigenvalue. A finite number of point perturbations then gives rise to a nontrivial discrete spectrum.

Let us describe briefly the contents. The next section is devoted to the case of a single perturbation. We start from the definition of the point-interaction Hamiltonian by means of boundary conditions coupling generalized boundary values. After that we use Krein's formula to derive the explicit expression for the resolvent; it involves the regularized Green's function which is given by a specific series as mentioned earlier [see (2.14)]. In Sec. II D we use this result to analyze spectral properties of such Hamiltonians. The bound state energies are given by the implicit equation (2.19), and it is just the limits of strong and weak coupling where we are able to write the explicit expressions for the leading term of the asymptotics. In both the extreme cases the eigenvalue behavior can be easily understood: in the strong-coupling situation it goes to $-\infty$ in the same way as if there were no boundaries because the corresponding eigenfunction is strongly localized, while in the weak-coupling case the eigenvalue approaches the threshold of the essential spectrum and the wavefunction is dominated transversally by the lowest mode. We also find that the eigenvalue decreases with the distance from the layer boundary. In the last part of Sec. II we shall discuss the scattering in the presence of a perturbation. If there is a single point interaction,

we can employ the symmetry of the problem with respect to rotation around the axis passing through the perturbation and perpendicular to the layer. The partial wave decomposition in the ''longitudinal'' coordinates shows that the only nontrivial contribution to the scattering comes from the s-wave, i.e., from states with the orbital momentum $m=0$. Within this subspace, the scattering problem is reduced to transitions between transverse modes; the final S-matrix then describes a coupling of the ''open'' channels, i.e., the transverse modes with the energies lower than that of the incoming spherical wave. We also derive the on-shell scattering operator which maps the incoming wave vector and transverse mode into the outgoing ones; the advantage of this approach is that it does employ the symmetry and allows for a generalization to the case with multiple perturbations.

Section III extends the described analysis to any finite number N of point perturbations. The technique remains the same, and since the difference between the two resolvents is of rank N, the essential and absolutely continuous spectra are again preserved. On the other hand, the analysis of the discrete spectrum becomes more complicated. There are n eigenvalues, where $1\leqslant n\leqslant N$, which are found by solving the implicit equation $\det\Lambda(z)=0$ with the $N\times N$ matrix Λ given by (3.8). The number n depends on the coupling strength. In the strong coupling limit there exist exactly N eigenvalues having the same asymptotic behavior as in the one-center case. On the other hand, for weak coupling we find only one eigenvalue approaching the threshold of the essential spectrum; in this sense our system exhibits a behavior typical for all weakly coupled Schrödinger operators.

A new feature for systems with $N\geqslant 2$ is that they can possess eigenvalues embedded in the essential spectrum. This is possible, e.g., when the point perturbations are placed symmetrically with respect to the layer axis and have the same (sufficiently strong) coupling: the corresponding eigenfunction cannot then contain contributions from transverse modes with the energy equal or smaller than this eigenvalue. We will show that this is true for embedded eigenvalues generally: their eigenvectors have to be orthogonal to the subspace spanned by the ''lower'' transverse modes. For $N\geqslant 2$ the system no longer exhibits a rotational symmetry, hence we cannot employ the partial-wave decomposition to describe the scattering. However, the second approach mentioned above is applicable here and we can derive again the on-shell scattering operator. It is similar to that of the one-center case differing just by replacement of a single regularized Green's function by a sum of the elements of the matrix Λ [see (3.34)].

Section IV deals with the situation when the layer is placed into a homogeneous magnetic field perpendicular to its boundary. The Krein's formula is applicable but the free resolvent is substantially different from the nonmagnetic case; this is reflected in the form of the essential spectrum which now consists the ''sum'' of the Landau levels and the transverse mode energies; it, of course, is preserved by a finite number of point perturbations. If there is a single perturbation, we get exactly one eigenvalue in each spectral gap, i.e., between any two neighboring levels. In the strong and weak coupling limits it approaches the upper and lower endpoint of corresponding ''free'' gap, respectively. Only for the lowest gap we find a different behavior in the strong-coupling limit case; the eigenvalue goes to $-\infty$ with the same asymptotics as in the nonmagnetic case. Finally, we present a generalization to the case of N point interactions analogous to the considerations of Sec. III.

II. A SINGLE PERTURBATION

A. The free system

Consider an infinite layer $\Sigma:=\mathbb{R}^2\times[0,d]$ with the coordinates denoted as $\vec{x}=(x,y)$, where $x=(x_1,x_2)\in\mathbb{R}^2$ and $y\in[0,d]$. We consider a single spinless nonrelativistic particle confined to Σ. Since the actual values of physical constants are not essential throughout the article, we put $\hbar=2m=1$ and suppose that the free motion of the particle is governed by the Dirichlet Laplacian $-\Delta_D^{\Sigma}$.

Recall that this operator can be defined for rather general domains in $\mathbb{R}^n$ as the Friedrichs extension of an appropriate quadratic form (Ref. 7, Sec. XIII.15). However, since the boundary of

Σ consists of two disjoint planes and has therefore the segment property, the operator acts simply as $H_0\psi=-\Delta\psi$ on the domain of all ψ of the local Sobolev space $W^{2,2}(\Sigma)$ which satisfy the boundary conditions

$$\psi(x,0)=\psi(x,d)=0 \tag{2.1}$$

for all $x\in\mathbb{R}^2$ (see again Ref. 7, Sec. XIII.15).

We will make use of the fact that the ''longitudinal'' and ''transverse'' variables decouple in the free system. The state Hilbert space of our problem can then be decomposed into traverse modes,

$$L^2(\Sigma)=\bigoplus_{n=1}^{\infty} L^2(\mathbb{R}^2)\otimes\{\chi_n\},\quad \chi_n(y):=\sqrt{\frac{2}{d}}\sin\left(\frac{\pi n y}{d}\right),$$

because the functions $\chi_n(y)$ form an orthonormal basis in $L^2([0,d])$. The free Hamiltonian can be correspondingly written in the form of a direct sum,

$$H_0=\bigoplus_{n=1}^{\infty} h_n\otimes I_n,\quad h_n:=-\frac{\partial^2}{\partial x_1^2}-\frac{\partial^2}{\partial x_2^2}+\left(\frac{\pi n}{d}\right)^2. \tag{2.2}$$

Since the resolvent $(H_0-z)^{-1}$ of the two-dimensional Laplacian is known explicitly, the above decomposition yields in turn the free resolvent kernel

$$G_0(x,y;x',y';z)=\frac{i}{4}\sum_{n=1}^{\infty} H_0^{(1)}(k_n|x-x'|)\chi_n(y)\,\chi_n(y'), \tag{2.3}$$

where $k_n\equiv k_n(z):=\sqrt{z-(\pi n/d)^2}$.

B. Definition of a point interaction

Our first goal is to construct a one-center perturbation supported by a point $\vec{a}:=(a,b)$ with $a\in\mathbb{R}^2$ and $b\in(0,d)$. This can be done in a standard way.[2] We restrict $-\Delta_D^{\Sigma}$ to functions which vanish in a neighborhood of $\vec{a}$; the operator obtained in this way is symmetric but not self-adjoint and we look for the perturbed one among its self-adjoint extensions. Since the restriction has deficiency indices (1,1), the family of extensions is by the standard von Neumann theory (Ref. 7, Sec. X.1) characterized by a single parameter.

What is equally important is that the perturbation is local, and therefore we can characterize the extensions by the usual boundary condition derived in Ref. 2, Chap. I.1, for point interactions in $\mathbb{R}^3$. We introduce the generalized boundary values,

$$L_0(\psi,\vec{a}):=\lim_{|\vec{x}-\vec{a}|\to 0}|\vec{x}-\vec{a}|\,\psi(\vec{x}),\quad L_1(\psi,\vec{a}):=\lim_{|\vec{x}-\vec{a}|\to 0}\left[\psi(\vec{x})-\frac{L_0(\psi,\vec{a})}{|\vec{x}-\vec{a}|}\right],$$

and require

$$L_1(\psi,\vec{a})-4\pi\alpha L_0(\psi,\vec{a})=0. \tag{2.4}$$

For a fixed $\alpha\in\mathbb{R}$ this leads to the self-adjoint operator $H(\alpha,\vec{a})$ acting as

$$(H(\alpha,\vec{a})\psi)(\vec{x})=-(\Delta\psi)(\vec{x}) \tag{2.5}$$

for $\vec{x}\neq\vec{a}$ on the domain

$$D(H(\alpha,\vec{a})):=\{\psi:-\Delta\psi\in L^2(\Sigma\backslash\{\vec{a}\})\ \text{and}\ (2.1)\ \text{and}\ (2.4)\ \text{are satisfied}\} \tag{2.6}$$

in $L^2(\Sigma)$, where $-\Delta\psi$ is, of course, understood in the sense of distributions. The family of self-adjoint extension also includes the case which is formally given by $\alpha=\infty$, which means $L_0(\psi,\vec{a})=0$. It is easy to see that the corresponding $H(\alpha,\vec{a})$ is nothing else than the free Hamiltonian H_0.

C. The resolvent

As usual the spectral properties of the operator $H(\alpha,\vec{a})$ can be studied using its resolvent. Since $H(\alpha,\vec{a})$ and H_0 have a common restriction with deficiency indices (1,1), the kernel of the full resolvent can be obtained by means of Krein's formula (Ref. 2, Appendix A)

$$(H(\alpha,\vec{a})-z)^{-1}(\vec{x}_1,\vec{x}_2)=G_0(\vec{x}_1,\vec{x}_2;z)+\frac{G_0(\vec{x}_1,\vec{a};z)\,G_0(\vec{a},\vec{x}_2;z)}{\alpha-\xi(\vec{a};z)}, \tag{2.7}$$

where

$$\xi(\vec{a};z):=\frac{1}{4\pi}\lim_{\vec{x}\to\vec{a}}\left\{\frac{2\pi i}{d}\sum_{n=1}^{\infty}H_0^{(1)}(k_n|x-a|)\sin\left(\frac{\pi n y}{d}\right)\sin\left(\frac{\pi n b}{d}\right)-\frac{1}{|x-a|}\right\} \tag{2.8}$$

is the regularized Green's function; we have employed here the fact that the resolvent singularity is the same as for the kernel of $-\Delta$ in $L^2(\mathbb{R}^3)$ (see Ref. 8, Sec. 13.5). The form of the denominator in expression (2.7) follows from the boundary condition (2.4) applied to $\psi=(H(\alpha,\vec{a})-z)^{-1}\varphi$, where φ is an arbitrary vector from $L^2(\Sigma)$. However, the above definition does not give a practical way to compute $\xi(\vec{a};z)$. To this end we use first $K_0(z)=(\pi i/2)\,H_0^{(1)}(iz)$ and introduce $\kappa_n:=\sqrt{(\pi n/d)^2-z}=-ik_n$. Then we have

$$\xi(\vec{a};z)=\lim_{\varrho\to 0}\left\{\frac{1}{\pi d}\sum_{n=1}^{\infty}K_0(\kappa_n\varrho)\sin^2\left(\frac{\pi n b}{d}\right)-\frac{1}{4\pi\varrho}\right\}, \tag{2.9}$$

where $\varrho:=|x-a|$ and we have already put $y=b$. We use the asymptotic behavior $\kappa_n\approx\pi n/d$ as $n\to\infty$ to write the identity

$$K_0(\kappa_n\varrho)=K_0\left(n\frac{\pi\varrho}{d}\right)+\left[K_0(\kappa_n\varrho)-K_0\left(n\frac{\pi\varrho}{d}\right)\right] \tag{2.10}$$

and to divide the function ξ into two parts, $\xi(\vec{a};z)=\xi_1+\xi_2$, where

$$\xi_1:=\lim_{\varrho\to 0}\frac{1}{\pi d}\sum_{n=1}^{\infty}\left[K_0(\kappa_n\varrho)-K_0\left(\frac{\pi n\varrho}{d}\right)\right]\sin^2\left(\frac{\pi n b}{d}\right),$$

$$\xi_2:=\lim_{\varrho\to 0}\left\{\frac{1}{2\pi d}\sum_{n=1}^{\infty}\left[K_0\left(\frac{\pi n\varrho}{d}\right)-K_0\left(\frac{\pi n\varrho}{d}\right)\cos\left(\frac{2\pi n b}{d}\right)\right]-\frac{1}{4\pi\varrho}\right\};$$

we have used $2\sin^2\alpha=1-\cos 2\alpha$. To deal with the first term we employ the asymptotic behavior of the Macdonald function (Ref. 9, Sec. 9.6.13) which yields

$$K_0(\kappa_n\varrho)-K_0\left(\frac{\pi n\varrho}{d}\right)=-\ln\sqrt{1-z\left(\frac{d}{\pi n}\right)^2}\,(1+\mathcal{O}(\varrho^2))$$

as $\varrho\to 0$. It shows that the sum converges uniformly wrt ϱ and the limit can be interchanged with the series thus giving

$$\xi_1 = -\frac{1}{\pi d}\sum_{n=1}^{\infty} \ln\sqrt{1-z\left(\frac{d}{\pi n}\right)^2}\,\sin^2\left(\frac{\pi n b}{d}\right). \tag{2.11}$$

The second part can be computed by means of the formula (Ref. 10, II, 5.9.1.4.),

$$\sum_{n=1}^{\infty} K_0(nx)\cos(na) = \frac{\pi}{2\sqrt{x^2+a^2}} + \frac{1}{2}\left(\gamma + \ln\frac{x}{4\pi}\right) + \frac{\pi}{2}\sum_{n=1}^{\infty}\left[\frac{1}{\sqrt{(2n\pi-a)^2+x^2}} - \frac{1}{2n\pi}\right] + \frac{\pi}{2}\sum_{n=1}^{\infty}\left[\frac{1}{\sqrt{(2n\pi+a)^2+x^2}} - \frac{1}{2n\pi}\right].$$

So, introducing $\beta := b/d$ and $\mu := \varrho/d$ and performing the limit $\mu \to 0$, we get

$$\xi_2 = \frac{1}{4\pi d}\left\{-\frac{1}{2\beta} - \sum_{n=1}^{\infty}\frac{\beta^2}{n(n^2-\beta^2)}\right\}. \tag{2.12}$$

The last sum equals Ref. 10, I, 5.1.15.2. expressed by means of the digamma function as $\psi(1) - 1/2\,(\psi(1+\beta)+\psi(1-\beta))$, and since $\psi(1) = -\gamma$, where $\gamma = 0.577\ldots$ is the Euler number, and $\psi(1-\beta) = \psi(\beta) + \pi\cot(\pi\beta)$, $\psi(1+\beta) = \psi(\beta) + 1/\beta$, we arrive at

$$\xi_2 = \frac{\gamma}{4\pi d} + \frac{1}{8\pi d}\,(2\psi(\beta) + \pi\cot(\pi\beta)). \tag{2.13}$$

Putting the results together, we get the sought formula

$$\xi(\vec{a};z) = -\frac{1}{\pi d}\sum_{n=1}^{\infty} \ln\sqrt{1-z\left(\frac{d}{\pi n}\right)^2}\,\sin^2\left(\frac{\pi n b}{d}\right) + \frac{1}{4\pi d}\left[\gamma + \psi\left(\frac{b}{d}\right) + \frac{\pi}{2}\cot\left(\frac{\pi b}{d}\right)\right], \tag{2.14}$$

expressing the regularized Green's function in the form of a series. It is certainly more complicated than an expression of the corresponding quantity for the whole space in terms of elementary functions (Ref. 2, Chap. I.1), but it allows us to derive the needed properties of the function ξ to compute the values of $\xi(\vec{a};z)$ numerically.

Remark 2.1: Notice the scaling behavior with respect to the change of the layer thickness, i.e., the formulas relating properties of the family $\Sigma^\sigma = \mathbb{R}^2 \times [0, d\sigma]$, $\sigma > 0$. Here the dimension of the configuration space is decisive. While for a two-dimensional system the scaling amounts to logarithmic shift of the function ξ as shown in Ref. 5, in three dimensions the transformation is multiplicative. We find easily that the situation is the same as for straight tubes in $\mathbb{R}^3$ studied in Ref. 6, i.e., we have $\xi(\vec{a}^\sigma; z\sigma^{-2}) = \sigma^{-1}\xi(\vec{a};z)$, where $\vec{a}^\sigma := (a\sigma, b\sigma)$. This means, in particular, that the singularities of the resolvent which we will discuss later using Eq. (2.19) are related as follows:

$$\epsilon^\sigma(\alpha^\sigma, \vec{a}^\sigma) = \sigma^{-2}\epsilon(\alpha,\vec{a}), \quad \alpha^\sigma := \sigma^{-1}\alpha. \tag{2.15}$$

Without loss of generality we put therefore $d = \pi$ in the rest of this and the next section.

D. Spectral properties

The explicit form of the resolvent (2.7) allows us to derive information about the spectrum. Since its difference from $(H_0 - z)^{-1}$ is a rank one operator, the essential spectrum remains by Weyl's theorem (Ref. 7, Thm. XIII.14) the same as for the free Hamiltonian H_0, i.e., we have $\sigma_{ess}(H(\alpha,\vec{a})) = [1,\infty)$. At the same time, also the absolutely continuous spectrum is preserved, $\sigma_{ac}(H(\alpha,\vec{a})) = [1,\infty)$, this time by Birman–Kuroda theorem (Ref. 7, Thm. XI.9).

Next we would like to prove the absence of the singularly continuous spectrum. To this aim we have to check that the expression $(\psi,(E_z-E_c)\psi)$ for all $\psi\in L^2(\Sigma)$ is an absolutely continuous function for z from any interval $(c,t)\subset(1,\infty)$; in other words, that it can be written as an integral of a locally integrable function. Since σ_{sc} cannot be supported by discrete points, we may choose the interval (c,t) in such a way that it contains none of the points m^2, $m\in\mathbb{N}$. We exclude these points because the free Green's function $G_0(z)$ diverges at them. For the spectral projection E_t-E_c to the interval (c,t) we employ Stone's formula,

$$(\psi,(E_t-E_c)\psi)=\frac{1}{\pi}\lim_{\varepsilon\to 0_+}\int_c^t(\psi,\mathrm{Im}\,G(u+i\varepsilon)\psi)\,du; \tag{2.16}$$

we have used here the fact which we will establish a little later, namely that $H(\alpha,\vec{a})$ has no eigenvalues in $(1,\infty)$, and therefore the spectral projections to (c,t) and $[c,t]$ are the same. The Green's function (2.7) is analytic for z with $\mathrm{Re}\,z\in(c,t)$ and $\pm\mathrm{Im}\,z\in(0,\varepsilon)$, and, furthermore, its limits when z approaches the real axis from above and from below exist and are continuous functions of z. Recall that by assumptions no thresholds are contained in (c,t) and ξ has nonzero imaginary part for $z\neq m^2$,

$$\mathrm{Im}\,\xi(\vec{a};z)=\frac{1}{2\pi}\sum_{n=1}^{[\sqrt{z}]}\sin^2(nb)>0, \tag{2.17}$$

where we have used $\sqrt{z-m^2}=i\sqrt{m^2-z}$; hence, the denominator of the second term in (2.7) cannot be singular. Consequently, the integrated function is bounded in $(c,t)\times[0,\varepsilon)$, and by the dominated convergence theorem the limits can be interchanged with the integral giving

$$(\psi,(E_t-E_c)\psi)=\frac{1}{\pi}\int_c^t(\psi,\mathrm{Im}\,G(u)\psi)\,du. \tag{2.18}$$

The function under the integral is again continuous in the interval (c,t), hence it is integrable and the statement is proved. If $t=t_0$ would be an isolated eigenvalue embedded in the continuous spectrum and ψ the corresponding eigenfunction, the above relation remains valid for $t\in(t_0-\eta,t_0)\cup(t_0,t_0+\eta)$ with some $\eta>0$, while at the point t_0 the lhs should have a jump, which is clearly impossible due to the continuity of the integrated function.

To determine the discrete spectrum, we have to find the poles of the resolvent. Recall that a perturbation which can be reduced to a self-adjoint extension of a common symmetric restriction with deficiency indices (1,1) can give rise to at most one simple eigenvalue in each gap of the spectrum (Ref. 11, Sec. 8.3, Cor. 1). In our case it means one simple eigenvalue in the interval $(-\infty,1)$. In view of the relation (2.7) one can find it by solving the implicit equation

$$\xi(\vec{a};z)=\alpha \tag{2.19}$$

for $z\in\mathbb{R}$. The series contained in the formula (2.14) converges for all $z\in\mathbb{R}\setminus\{n^2:n\in\mathbb{N}\}$, because its terms decay like n^{-2} as $n\to\infty$ as we can see using the Taylor expansion of $\ln(1-\zeta)$ to the first order. The remaining term ξ_2 is independent of z and finite for any $b\in(0,\pi)$.

The value of $\xi(\vec{a};z)$ is real for any $z\in(-\infty,1)$. In particular, it is easy to compute

$$\xi(\vec{a};z=0)=\frac{1}{4\pi^2}\left[\gamma+\psi\left(\frac{b}{\pi}\right)+\frac{\pi}{2}\cot(b)\right].$$

Differentiating $\xi(\vec{a},\cdot)$ we get

$$\frac{d\xi}{dz}=\frac{1}{2\pi^2}\sum_{n=1}^{\infty}\frac{1}{n^2-z}\sin^2(nb)>0, \tag{2.20}$$

so the function is monotonously increasing for $z<1$. Moreover, it diverges at both endpoints. At the continuum threshold we have

$$\xi(\vec{a};z)=-\frac{1}{\pi^2}\ln\sqrt{1-z}\,\sin^2(b)+\mathcal{O}(1)\quad\text{as}\quad z\to 1-, \tag{2.21}$$

while on the opposite side we may employ a simple estimate

$$\xi(\vec{a};z)<-\frac{1}{\pi^2}\ln\sqrt{1-z}\,\sin^2(b)+\xi_2\to-\infty\quad\text{as}\quad z\to-\infty.$$

We will need more precise asymptotics at large negative energies. Below we shall prove that

$$\xi(\vec{a};z)=-\frac{\sqrt{-z}}{4\pi}+\mathcal{O}(e^{-c\sqrt{-z}})\quad\text{as}\quad z\to-\infty \tag{2.22}$$

for any $c<\mathrm{dist}(\vec{a},\mathrm{bd}\,\Omega)=\pi/2-|b-\pi/2|$. In other words, the leading term corresponds to the analogous function for the point-interaction Laplacian in $\mathbb{R}^3$ computed in Ref. 2, Chap. I.1; it corresponds to the heuristic concept that strongly bound states are well localized, and therefore not much influenced by the presence of the boundary. Another property of $\xi(\vec{a},z)$ is its monotonicity across the half-layer,

$$\xi(\vec{a};z)>\xi(\vec{a}';z)\quad\text{if}\quad |b-\pi/2|<|b'-\pi/2|,\ \ a=a'. \tag{2.23}$$

To prove it we employ the relation (2.8) which yields

$$\xi(\vec{a};z)-\xi(\vec{a}';z)=\lim_{|x-a|\to 0}\frac{i}{2\pi}\sum_{n=1}^{\infty}H_0^{(1)}(k_n(z)|x-a|)[\sin^2(nb)-\sin^2(nb')].$$

Since $\sin^2(nb)-\sin^2(nb')=\sin(n(b+b'))\sin(n(b-b'))$ holds for $0<b'<b\leqslant\pi/2$ we arrive at

$$\xi(\vec{a};z)-\xi(\vec{a}';z)=G_0(a,b+b';a,b-b';z); \tag{2.24}$$

the monotonicity then follows from the fact that $z\in(-\infty,1]$ and from the positivity of free resolvent kernel (cf. Ref. 7, Appendix to Sec. XIII.12). This behavior is illustrated in Fig. 1.

This confirms the mentioned general conclusion: it follows from the stated properties of $\xi(\vec{a};\cdot)$ that Eq. (2.19) has for any $\alpha\in\mathbb{R}$ a unique eigenvalue $\varepsilon(\alpha,\vec{a})$ in $(-\infty,1]$ and that the function $\varepsilon(\cdot,\vec{a})$ is monotonously increasing,

$$\varepsilon(\alpha,\vec{a})>\varepsilon(\alpha',\vec{a})\quad\text{if}\quad\alpha>\alpha'.$$

Furthermore, $\xi(\vec{a},\cdot)$ is a real-analytic function because for a fixed $z_1<-1$ it is expressed on a complex neighborhood of $(-\infty,z_1)$ through a uniformly convergent series whose terms are analytic. It follows from the implicit-function theorem that $\varepsilon(\cdot,\vec{a})$ is a C^∞ function (see Ref. 12, Chap. XIV). The function $\varepsilon(\cdot,\vec{a})$ is also monotonous with b:

$$\varepsilon(\cdot,\vec{a})<\varepsilon(\cdot,\vec{a}')\quad\text{if}\quad|b-\pi/2|<|b'-\pi/2|. \tag{2.25}$$

The behavior of the eigenvalue is shown in Fig. 2.

We are also interested in the asymptotic behavior of the eigenvalue in the limits of weak and strong coupling. In the former case we have

$$\varepsilon(\alpha,\vec{a})\approx 1-\exp\left(-\frac{2\pi^2\alpha}{\sin^2(b)}\right)\quad\text{as}\quad\alpha\to\infty, \tag{2.26}$$

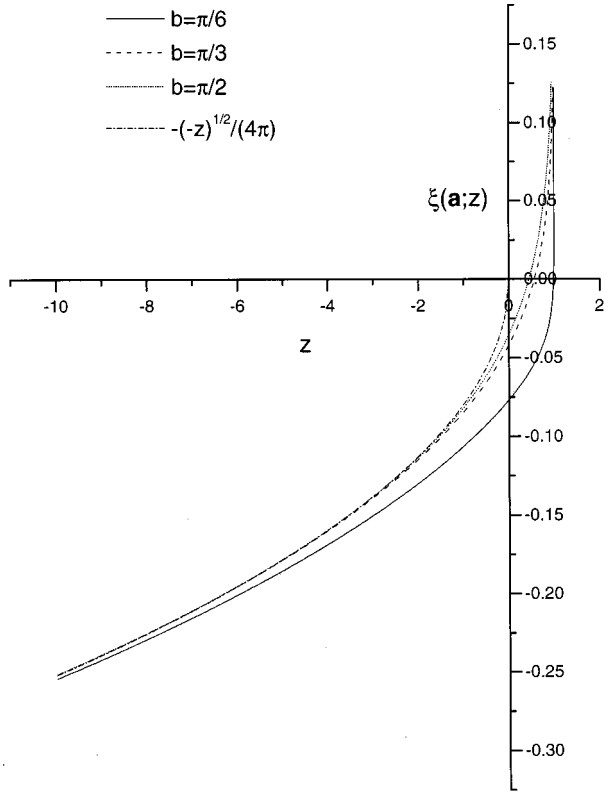

FIG. 1. The function $\xi(\vec{a};\cdot)$ for three different positions of the point interaction. The dash-dotted line is the leading term of the asymptotics (2.22).

where the symbol $\approx$ means that for any $\epsilon>0$ and α large enough the eigenvalue can be squeezed between a pair of expressions from the rhs in which $2\pi^2$ is replaced by $2\pi^2\pm\epsilon$. On the other hand, the strong coupling asymptotics can be proved directly. By Dirichlet bracketing (Ref. 7, Sec. XIII.15) $\varepsilon(\alpha,\vec{a})$ is for $\alpha<0$ bounded from below by $-(-4\pi\alpha)^2$, and from above by the ground state of the Dirichlet Laplacian in a ball of radius c with the point interaction in the center. The latter is easily found: writing $\varepsilon(\alpha,\vec{a})=-\kappa^2$ one has to solve the equation

$$(-4\pi\alpha)^2=\kappa^2(1+\sinh^{-2}\kappa c).$$

It yields the sought asymptotic behavior

$$\varepsilon(\alpha,\vec{a})=-16\pi^2\alpha^2+\mathcal{O}(e^{\alpha c}) \quad \text{as} \quad \alpha\to-\infty, \tag{2.27}$$

which justifies in view of (2.19) *a posteriori* the relation (2.22).

The formula (2.7) provides us with the (non-normalized) wavefunction of the bound state through the residue at the pole, $\psi(\vec{x};\alpha,\vec{a})=G_0(\vec{x},\vec{a};\varepsilon(\alpha,\vec{a}))$, so we have

$$\psi(\vec{x};\alpha,\vec{a})=\frac{i}{2\pi}\sum_{n=1}^{\infty} H_0^{(1)}(\sqrt{\varepsilon(\alpha,\vec{a})-n^2}\ |x-a|)\sin(nb)\sin(ny). \tag{2.28}$$

For $\alpha\to-\infty$ we can write $H_0^{(1)}(u)\approx\sqrt{2/\pi u}\ e^{i(u-\pi/4)}$ so we see that the wavefunction is well

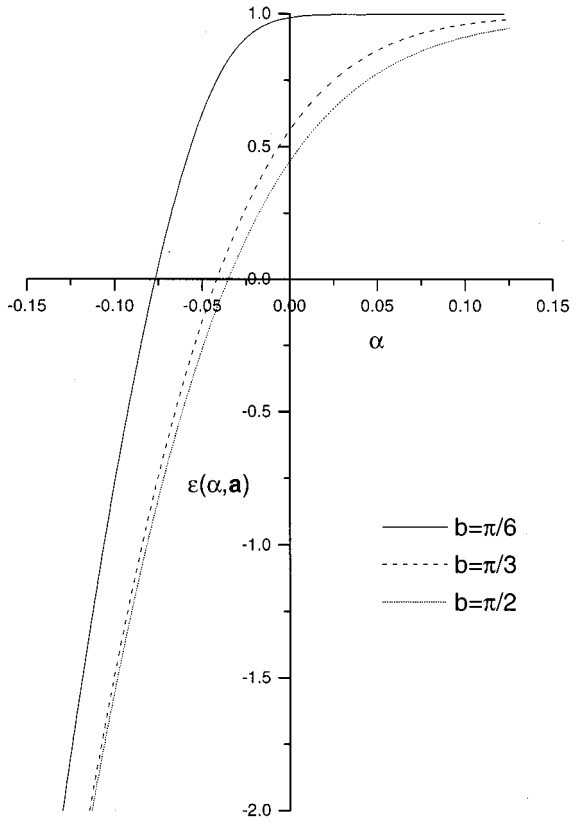

FIG. 2. The dependence of the eigenvalues $\varepsilon(\alpha,\vec{a})$ on the parameter α for three positions of the point interaction.

localized,

$$\psi(\vec{x};\alpha,\vec{a}) \approx \sum_{n=1}^{\infty} \sqrt{\frac{1}{\pi^3\sqrt{16\pi^2\alpha^2+n^2}|x-a|}}\, e^{-\sqrt{16\pi^2\alpha^2+n^2}|x-a|} \sin(nb)\sin(ny); \qquad (2.29)$$

this is illustrated in Fig. 3. On the other hand, in the limit $\alpha\to\infty$ the wavefunction for $|x-a|$ from a compact set behaves as

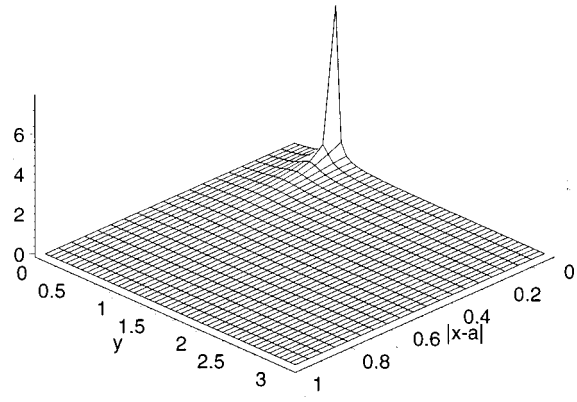

FIG. 3. The non-normalized eigenfunction for $b=\pi/6$ and $\alpha=-0.1$.

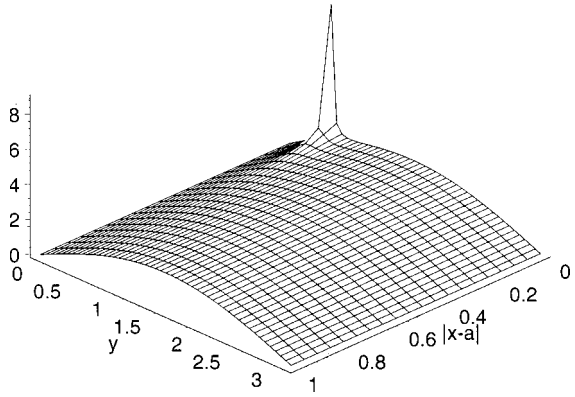

FIG. 4. The unnormalized eigenfunction for $b=\pi/6$ and $\alpha=1$.

$$\psi(\vec{x};\alpha,\vec{a})\approx\alpha\frac{\sin y}{\sin b}-\frac{1}{\pi^2}\ln|x-a|\sin b\sin y+\frac{i}{2\pi}\sum_{n=2}^{\infty}H_0^{(1)}(\sqrt{1-n^2}\ \ |x-a|)\sin(nb)\sin(ny). \tag{2.30}$$

The wavefunction is dominated by the first transverse mode as Fig. 4 shows.

Let us finally return to embedded eigenvalues. We have excluded their existence away from the thresholds. If $z=m^2$, we use Eq. (2.7) again to check that the singularities on the rhs cancel. In the vicinity of $z=m^2$ the free resolvent kernel and the denominator $\alpha-\xi(\vec{a};z)$ behave as

$$G_0(\vec{x}_1,\vec{x}_2;z)=-\frac{1}{\pi^2}\ln\sqrt{m^2-z}\,\sin(my_1)\sin(my_2)(1+\mathcal{O}(\sqrt{m^2-z})),$$

$$\alpha-\xi(\vec{a};z)=\tilde{\alpha}+\frac{1}{\pi^2}\ln\sqrt{m^2-z}\sin^2(mb),$$

where

$$\tilde{\alpha}:=\alpha-\xi_2+\frac{1}{\pi^2}\sum_{n\neq m}\ln\sqrt{1-\frac{m^2}{n^2}}\sin^2(nb)-\frac{1}{\pi^2}\ln\, m\,\sin^2(mb).$$

Then the full-resolvent kernel asymptotically behaves as

$$\left(\tilde{\alpha}+\frac{1}{\pi^2}\ln\sqrt{m^2-z}\,\sin^2(mb)\right)^{-1}\frac{\tilde{\alpha}}{\pi^2}\ln\sqrt{m^2-z}\,\sin(my_1)\sin(my_2)(1+\mathcal{O}(\sqrt{m^2-z}))$$

and cannot thus have a pole-type singularity at $z=m^2$.

Let us summarize the results obtained so far:

Theorem 2.2: *Let $H(\alpha,\vec{a})$ be defined by (2.5) and (2.6) for $d=\pi$. Then*

(a) $\sigma_{ess}(H(\alpha,\vec{a}))=\sigma_{ac}(H(\alpha,\vec{a}))=[1,\infty)$ *and* $\sigma_{sc}(H(\alpha,\vec{a}))=\varnothing$.

(b) *For any $\alpha\in\mathbb{R}$ there is a single eigenvalue $\varepsilon(\alpha,\vec{a})$ in $(-\infty,1)$ which is increasing and infinitely differentiable wrt α. The corresponding eigenfunction is given by (2.28).*

(c) *The eigenvalue is by (2.25) strictly monotonous across the half-layer, $\varepsilon(\alpha,\vec{a})<\varepsilon(\alpha,\vec{a}')$ if $|b-\pi/2|<|b'-\pi/2|$.*

(d) *In the limit $\alpha\to\infty$ the bound state behaves according to (2.26) and (2.30). In the strong coupling case the eigenvalue asymptotic is given by (2.27) and the eigenfunction is described by (2.29).*

(e) *There are no eigenvalues in* $[1,\infty)$.

E. Scattering

Since the Hamiltonian $H(\alpha,\vec{a})$ is invariant under rotations around the axis passing through the point $\vec{a}$ and perpendicular to Σ, we may simplify the treatment of stationary scattering using a partial-wave decomposition. We use the tensor-product representation

$$L^2(\Sigma)=L^2((0,\infty)\times[0,d];r\,dr\,dy)\otimes L^2(S^1), \tag{2.31}$$

where S^1 is the unit circle in $\mathbb{R}^2$ and $r:=|x|$. This can be written as

$$L^2(\Sigma)=\bigoplus_{m=-\infty}^{\infty}\tilde{U}^{-1}L^2((0,\infty)\times[0,d])\otimes\{Y_m\}, \tag{2.32}$$

where $\tilde{U}:L^2((0,\infty)\times[0,d];r\,dr\,dy)\to L^2((0,\infty)\times[0,d])$ is the unitary operator defined by $(\tilde{U}\psi)(r):=r^{1/2}\psi(r)$, the "spherical" functions $Y_m(\omega):=(2\pi)^{-1/2}e^{im\theta}$ with $\omega=(\cos\theta,\sin\theta)$ form a basis in $L^2(S^1)$, and the symbol $\{\cdot\}$ means, as above, the linear envelope. Shifting the point $\vec{a}$ to the origin of the polar coordinates by $T_a:(T_a\phi)(x,y)=\phi(x+a,y)$, we can decompose the corresponding free Hamiltonian $H_0=-\Delta_D^{\Sigma}$ as

$$H_0=T_a^{-1}\left\{\bigoplus_{m=-\infty}^{\infty}\tilde{U}^{-1}h_m^{(0)}\tilde{U}\otimes I\right\}T_a, \tag{2.33}$$

with the partial-wave operators

$$h_m^{(0)}=-\frac{\partial^2}{\partial r^2}-\frac{\partial^2}{\partial y^2}+\frac{4m^2-1}{4r^2},\quad m\in\mathbb{Z}. \tag{2.34}$$

Their domains are given in a standard way (Ref. 13, Sec. 5.7); the only nontrivial part is the radial boundary condition at the origin. As in Ref. 2, Chap. I.5, none are imposed in "higher" partial waves, $m\neq 0$, because the radial part of (2.34) is then limit-point at zero (Ref. 7, Appendix to Sec. X.1). Consequently, this part of the Hamiltonian is trivial from the point of view of the point interaction. On the other hand, for $m=0$ we introduce the generalized boundary values,

$$\ell_0(\phi)(y):=\lim_{r\to 0}\phi(r,y)\sqrt{r},\quad \ell_1(\phi)(y):=\lim_{r\to 0}r^{-1/2}[\phi(r,b)-\ell_0(\phi)(y)r^{-1/2}]. \tag{2.35}$$

The s-wave component of the free Hamiltonian is specified by the condition $\ell_0(\phi)(y)=0$ [for any $y\in(0,d)$], while the s-wave component h_0^{α} of $H(\alpha,\vec{a})$ is given by the same differential expression (2.34) with the boundary condition at $y=b$ changed to

$$\ell_1(\phi)(b)-4\pi\alpha\ell_0(\phi)(b)=0. \tag{2.36}$$

It is also clear from this discussion that the eigenfunction of $H(\alpha,\vec{a})$ analyzed in the previous section exhibits a symmetry, $\psi(R(\varphi)\vec{x};\alpha,\vec{a})=\psi(\vec{x};\alpha,\vec{a})$, where $R(\varphi)$ is the rotation of Σ on an angle φ around the axis passing through the point $\vec{a}$ and perpendicular to Σ.

Let us return to the scattering problem. As in Ref. 2, Chap. I.5, the rotational symmetry means that the S-matrix part corresponding to partial waves with $m\in\mathbb{Z}\setminus\{0\}$ is trivial, i.e., the unit operator. In distinction to Ref. 2, Chap. I.5, however, the s-wave part (we denote it as S again to keep the notation simple) is still in general a complicated operator because the point interaction can couple different transverse modes. Its dimension depends on the number of the "open channels," i.e., of the transverse modes in which the particle of energy z can propagate; for $d=\pi$ the latter is $[\sqrt{z}]$. Using the partial-wave operator (2.34) with $m=0$ it is easy to see that the function

$$\psi^{(0)}_{\alpha,n}(\vec{x};k)=J_0(k_n(z)r)\chi_n(y)+\frac{1}{\alpha-\xi(\vec{a};z)}\,\frac{i}{2\pi}\sum_{j=1}^{\infty}H_0^{(1)}(k_j(z)r)\sin(jb)\sin(nb)\chi_j(y)\,, \tag{2.37}$$

with $r=|x-a|$ satisfies the boundary condition (2.4) and $r^{1/2}\psi^{(0)}_{\alpha,n}(\vec{x};k)$ is a generalized eigenfunction of $h_0^{(0)}\otimes(-\partial^2/\partial y^2)$ with the eigenvalue $z=k^2$. In the limit $r\to\infty$ it behaves as

$$\begin{aligned}\psi^{(0)}_{\alpha,n}(\vec{x};k)\approx{}&\sqrt{\frac{2}{\pi k_n(z)r}}\cos(k_n(z)r-\pi/4)\chi_n(y)\\&+\frac{1}{\alpha-\xi(\alpha;z)}\,\frac{i}{2\pi}\sum_{j=1}^{[\sqrt{z}]}\sqrt{\frac{2}{\pi k_j(z)r}}\,e^{i(k_j(z)r-\pi/4)}\sin(nb)\sin(jb)\chi_j(y).\end{aligned} \tag{2.38}$$

To find the matrix elements S_{nj} one has to compare this with the asymptotics of the outgoing wave in the jth transverse mode expressed by means of the scattering phase shift. For the wave scattered back into the incident nth mode we have

$$\begin{aligned}&\sqrt{\frac{2}{\pi k_n(z)r}}\left[\cos(k_n(z)r-\pi/4)+\frac{1}{\alpha-\xi(\alpha;z)}\,\frac{i}{2\pi}\,e^{i(k_n(z)r-\pi/4)}\sin^2(nb)\right]\\&\quad=\sqrt{\frac{2}{\pi k_n(z)r}}\,e^{i\delta_{nn}}\cos(k_n(z)r-\pi/4+\delta_{nn}(k)),\end{aligned}$$

which yields

$$S_{nn}(k)=e^{2i\delta_{nn}(k)}=1+\frac{i}{\pi}\,\frac{\sin^2(nb)}{\alpha-\xi(\vec{a};z)}.$$

In a similar way scattering to the jth mode, $n\neq j$, requires the identification

$$\frac{1}{\alpha-\xi(\vec{a};z)}\,\frac{i}{2\pi}\,e^{i(k_j(z)r-\pi/4)}\sin(nb)\sin(jb)=e^{i\delta_{nj}(k)}\cos(k_n(z)r-\pi/4+\delta_{nj}(k));$$

together we get

$$S_{nj}(k)=e^{2i\delta_{nj}(k)}=\delta_{nj}+\frac{i}{\pi}\,\frac{\sin(nb)\sin(jb)}{\alpha-\xi(\vec{a};z)}. \tag{2.39}$$

We have to check that the obtained S-matrix is unitary, i.e.,

$$\sum_{j=1}^{[\sqrt{z}]}S_{nj}\overline{S}_{sj}=\delta_{ns}\,. \tag{2.40}$$

Using (2.39) we can write

$$\begin{aligned}\sum_{j=1}^{[\sqrt{z}]}S_{nj}\overline{S}_{sj}&=\sum_{j=1}^{[\sqrt{z}]}(S_{nj}-\delta_{nj})(\overline{S}_{sj}-\delta_{js})+2\,\mathrm{Re}(S_{ns}-\delta_{ns})+\delta_{ns}\\&=\frac{2}{\pi}\,\frac{\sin(nb)\sin(sb)}{|\alpha-\xi(\vec{a};z)|^2}\left(\frac{1}{2\pi}\sum_{j=1}^{[\sqrt{z}]}\sin^2(jb)-\mathrm{Im}\;\xi(\vec{a};z)\right)+\delta_{ns}\,,\end{aligned}$$

so the desired property follows from (2.17).

The scattering problem can be also described in another way—by means of a scattering operator in $L^2(S^1)\otimes L^2([0,d])$. Applying (2.7) to an arbitrary $\phi\in L^2(\Sigma)$ we see that to any $\psi\in D(H(\alpha,\vec{a}))$ and a nonreal z there is $\psi_z\in D(H_0)$ such that

$$\psi(\vec{x})=\psi_z(\vec{x})+\frac{1}{\alpha-\xi(\vec{a},z)}G_0(\vec{x},\vec{a};z)\psi_z(\vec{a}). \tag{2.41}$$

If we choose, in particular, $\psi_z^\varepsilon(\vec{x})=e^{ik_n(z)\omega x-\varepsilon|x|^2}\chi_n(y)$ with ω a unit vector in $\mathbb{R}^2$, then the corresponding $\psi^\varepsilon(\vec{x})\in D(H(\alpha,\vec{a}))$ satisfies the equation

$$((H(\alpha,\vec{a})-z)\psi^\varepsilon)(\vec{x})=4\varepsilon[1-\varepsilon|x|^2+ik_n\omega x]\,\psi_z^\varepsilon(\vec{x}). \tag{2.42}$$

The rhs converges in the L^2 sense as z approaches the real line and the resulting ψ^ε belongs to $D(H(\alpha,\vec{a}))$ for a fixed $z\in[1,\infty)$. Furthermore, the pointwise limit exists as $\varepsilon\to 0+$ and equals

$$\psi_{\alpha,n}(\vec{x};k_n(z)\omega)=e^{ik_n(z)\omega x}\chi_n(y)+\frac{e^{ik_n(z)\omega a}}{\alpha-\xi(\vec{a};z)}\frac{i}{2\pi}\sum_{j=1}^{\infty}H_0^{(1)}(k_j(z)|x-a|)\sin(jb)\sin(nb)\chi_j(y). \tag{2.43}$$

The function defined by the rhs is locally square integrable, solves the equation $(H(\alpha,\vec{a})-z)\psi=0$ and satisfies the appropriate boundary condition, i.e., it is a generalized eigenfunction of $H(\alpha,\vec{a})$. Let us expand it into partial waves. We know already the s-wave eigenfunction (2.37); the remaining ones are trivial, $\psi_n^{(m)}(\vec{x};k_n(z))=J_m(kr)\chi_n(y)$ if $m\neq 0$. Here again, this expression describes an eigenfunction of $h_m^{(0)}\otimes\partial^2/\partial y^2$ in the Hilbert space (2.31); multiplying it with $r^{1/2}$ one obtains an eigenfunction in the Hilbert space (2.32). Using the known identity

$$e^{ik\omega(x-a)}=2\pi\sum_{m=-\infty}^{\infty}i^m J_m(k|x-a|)\overline{Y_m(\omega)}Y_m(\omega_{x-a}), \tag{2.44}$$

where Y_m are the functions introduced above and $\omega_{x-a}:=(x-a)/|x-a|$, we get

$$e^{-ik_n(z)\omega a}\psi_{\alpha,n}(\vec{x};k_n(z)\omega)=\psi_{\alpha,n}^{(0)}(\vec{x};k_n(z))+2\pi\sum_{0\neq l\in\mathbb{Z}}i^l\psi_n^{(l)}(x-a,y;k_n(z))\overline{Y_l(\omega)}Y_l(\omega_{x-a}).$$

Components of the on-shell scattering amplitude $(f_\alpha(k_n(z),\omega_x,\omega))_{jn}$ are then given by $\lim_{|x|\to\infty,x/|x|=\omega_x}|x|^{1/2}e^{-ik_j|x|}[\psi_{\alpha,n}(\vec{x};k_n(z)\omega)-e^{ik_n\omega x}\chi_n(y)]$. Specifically, its part corresponding to the jth transverse mode is

$$(f_\alpha(k_n(z),\omega_x,\omega))_{jn}=\frac{e^{\pi i/4}}{\pi\sqrt{2\pi k_j(z)}}\frac{\sin(jb)\sin(nb)}{\alpha-\xi(\vec{a};z)}e^{ik_n(z)\omega a-ik_j(z)\omega_x a} \tag{2.45}$$

and the on-shell scattering operator $S_\alpha(z)$ on $L^2(S^1)\otimes L^2([0,d])$ has the form

$$S_\alpha(z)=I+\frac{i}{\pi}\sum_{n,j=1}^{[\sqrt{z}]}\frac{\sin(nb)\sin(jb)}{\alpha-\xi(\vec{a};z)}(e^{-ik_n(z)(\cdot)a}Y_0\chi_n,\cdot)e^{-ik_j(z)(\cdot)a}Y_0\chi_j. \tag{2.46}$$

It follows from (2.17) that the denominator is nonzero in $[1,\infty)$. However, we have argued above that $\xi(\vec{a};\cdot)$ can be continued analytically to the complex plane where zeros exist in general. In the weak coupling case there is one resonance pole of $S_\alpha(z)$ close to the threshold of each higher transverse mode similarly as in the two-dimensional case.[5]

III. A FINITE NUMBER OF POINT INTERACTIONS

A. Boundary conditions

Consider now a finite number N of point interactions and suppose that their positions are $\vec{a}_j = (a_j, b_j)$, where $a_j \in \mathbb{R}^2$ and $b_j \in (0,\pi)$. For the sake of brevity we denote $\vec{a} = (\vec{a}_1, \ldots, \vec{a}_N)$ and $\alpha = (\alpha_1, \ldots, \alpha_N)$. The way to define a point interaction is the same as above; now we have N independent boundary conditions

$$L_1(\psi, \vec{a}_j) - 4\pi\alpha_j L_0(\psi, \vec{a}_j) = 0, \quad j = 1, \ldots, N. \tag{3.1}$$

The Hamiltonian $H(\alpha, \vec{a})$ is given again by the formulas (2.5) and (2.6) with the boundary condition (2.4) replaced by (3.1) and $\vec{a}$ understood in the sense mentioned above. Any of the point interactions can be switched off when corresponding coupling constant α_j is formally put equal to infinity.

B. The resolvent

We again use the Krein formula to find the resolvent kernel. Since the deficiency indices of the operator obtained by restriction of the free Hamiltonian to the set of functions which vanish at the vicinity of the points $\vec{a}$ are equal to (N,N), the rhs is a rank N operator expressed in terms of vectors from the corresponding deficiency subspaces,

$$(H(\alpha,\vec{a}) - z)^{-1}(\vec{x}_1, \vec{x}_2) = G_0(\vec{x}_1, \vec{x}_2; z) + \sum_{j,k=1}^{N} \lambda_{jk}(\alpha, \vec{a}; z)\, G_0(\vec{x}_1, \vec{a}_j; z)\, G_0(\vec{a}_k, \vec{x}_2; z). \tag{3.2}$$

Applying this to an arbitrary vector of $L^2(\Sigma)$ we get

$$\psi(\vec{x}) = \psi_0(\vec{x}) + \sum_{j,k=1}^{N} \lambda_{jk}(\alpha, \vec{a}; z)\, G_0(\vec{x}, \vec{a}_j; z)\, \psi_0(\vec{a}_k), \tag{3.3}$$

with $\psi_0 \in D(H_0)$. The generalized boundary values are

$$L_0(\psi, \vec{a}_m) = \sum_{j,k=1}^{N} \frac{\lambda_{jk}}{4\pi}\, \delta_{jm}\, \psi_0(\vec{a}_k), \tag{3.4}$$

$$\begin{aligned} L_1(\psi, \vec{a}_m) = {} & \psi_0(\vec{a}_m) + \sum_{j,k=1}^{N} \lambda_{jk}(1 - \delta_{jm}) G_0(\vec{a}_m, \vec{a}_j; z)\, \psi_0(\vec{a}_k) \\ & + \sum_{j,k=1}^{N} \lambda_{jk}\, \delta_{jm}\, \psi_0(\vec{a}_k) \lim_{|\vec{x} - \vec{a}_m| \to 0} \left(G_0(\vec{x}, \vec{a}_j; z) - \frac{1}{4\pi|\vec{x} - \vec{a}_m|} \right). \end{aligned} \tag{3.5}$$

The limit contained in the expression of $L_1(\psi, \vec{a}_m)$ equals $\xi(\vec{a}_m; z)$. After substituting these boundary values into (3.1) we arrive at the conditions

$$\psi_0(\vec{a}_m) + \sum_{j,k=1}^{N} \lambda_{jk}[\, \delta_{jm}(\xi(\vec{a}_m; z) - \alpha_m) + (1 - \delta_{jm}) G_0(\vec{a}_m, \vec{a}_j; z)\,]\, \psi_0(\vec{a}_k) = 0, \tag{3.6}$$

which should be satisfied for an arbitrary vector ψ_0 belonging to $D(H_0)$, i.e., for any N-tuple $(\psi_0(\vec{a}_1), \ldots, \psi_0(\vec{a}_N))$. This is possible only if the expressions in the square brackets are up to the sign elements of the matrix inverse to $\lambda(\alpha, \vec{a}; z)$, in other words, if the coefficients are

$$\lambda(\alpha, \vec{a}; z) = \Lambda(\alpha, \vec{a}; z)^{-1}, \tag{3.7}$$

where

$$\Lambda_{jj} := \alpha_j - \xi(\vec{a}_j;z) = \alpha_j + \frac{1}{\pi^2}\sum_{n=1}^{\infty} \ln\sqrt{1-\frac{z}{n^2}}\sin^2(nb_j) - \frac{1}{4\pi^2}\left[\gamma + \psi\left(\frac{b_j}{\pi}\right) + \frac{\pi}{2}\cot(b_j)\right],$$
$$\Lambda_{jm} := -G_0(\vec{a}_j,\vec{a}_m;z) = -\frac{i}{2\pi}\sum_{n=1}^{\infty} H_0^{(1)}(\sqrt{z-n^2}|a_j-a_m|)\sin(nb_j)\sin(nb_m), \quad j\neq m. \tag{3.8}$$

The Green's function value $G_0(\vec{a}_j,\vec{a}_m;z)$ is finite for any pair of mutually different vectors $\vec{a}_j$ and $\vec{a}_m$. When the point interactions are arranged vertically, i.e., $a_j = a_m$, the expression through Hankel's functions is useless and the corresponding nondiagonal element Λ_{jm} can be alternatively written as

$$\Lambda_{jm} = \frac{1}{\pi^2}\sum_{n=1}^{\infty} \ln\sqrt{1-\frac{z}{n^2}}\sin(nb_j)\sin(nb_m) - \xi_2\left(\frac{b_j+b_m}{2}\right) + \xi_2\left(\frac{|b_j-b_m|}{2}\right). \tag{3.9}$$

To derive this expression we employ the argument analogous to that leading to the value of the function $\xi(\vec{a};z)$ in Sec. II C.

C. The discrete spectrum

Since a finite rank operator is both compact and trace class, the argument presented at the opening of Sec. II D remains valid. In other words, a finite number of point interaction changes neither the essential nor the absolutely continuous spectrum, $\sigma_{ess}(H(\alpha,\vec{a})) = \sigma_{ac}(H(\alpha,\vec{a})) = \sigma_{ess}(H_0) = [1,\infty)$. The singularly continuous spectrum is empty because the proof given in Sec. II D can be used here again.

The discrete spectrum is determined by poles of the resolvent, which occur if the coefficient matrix $(\lambda_{jk})^{-1}$ becomes singular. This leads to the condition

$$\det \Lambda(\alpha,\vec{a};z) = 0. \tag{3.10}$$

To find the eigenfunctions we use the procedure from Ref. 2, Sec. II.1. Suppose that $H := H(\alpha,\vec{a})$ satisfies the equation $H\varphi = z\varphi$ for some $z\in\mathbb{R}$ and pick an arbitrary $z'\in\varrho(H)$. Then in accordance with (3.3) there is a function $\psi_0 \in D(H_0)$ which makes it possible to write

$$\varphi(\vec{x}) = \psi_0(\vec{x}) + \sum_{j=1}^{N} d_j G_0(\vec{x},\vec{a}_j;z'), \tag{3.11}$$

with the coefficients $d_j := \Sigma_{k=1}^{N}(\Lambda(z')^{-1})_{jk}\psi_0(\vec{a}_k)$. We also see that

$$(H_0 - z')\psi_0 = (H-z')\varphi = (z-z')\varphi. \tag{3.12}$$

Applying the resolvent $(H_0-z')^{-1}$ to the last identity we arrive at the expression

$$\psi_0 = (z-z')\left[(H_0-z')^{-1}\psi_0 + \sum_{j=1}^{N} d_j (H_0-z')^{-1} G_0(\cdot,\vec{a}_j;z')\right], \tag{3.13}$$

which allows us to find the action of (H_0-z) at the vector ψ_0,

$$(H_0-z)\psi_0 = (H_0-z')\psi_0 - (z-z')\psi_0 = (z-z')\sum_{j=1}^{N} d_j G_0(\cdot,\vec{a}_j;z'). \tag{3.14}$$

If $z<1$, the resolvent $(H_0-z)^{-1}$ exists and may be applied to the last relation, giving by means of the first resolvent identity

$$\psi_0=\sum_{j=1}^{N} d_j[G_0(\cdot,\vec{a}_j;z)-G_0(\cdot,\vec{a}_j;z')]. \tag{3.15}$$

Substituting this into (3.11) we get an expression for the eigenfunction,

$$\varphi(\vec{x})=\sum_{j=1}^{N} d_j G_0(\vec{x},\vec{a}_j;z), \tag{3.16}$$

where it remains to determine the coefficients. Equation (3.15) taken at the point $\vec{x}=\vec{a}_j$ can be rewritten using the components of matrix Λ as

$$\psi_0(\vec{a}_j)=\sum_{m=1}^{N} d_m(\Lambda(\alpha,\vec{a};z')_{jm}-\Lambda(\alpha,\vec{a};z)_{jm}). \tag{3.17}$$

We already know that $d_m=\Sigma_{k=1}^{N}(\Lambda(z')^{-1})_{mk}\psi_0(\vec{a}_k)$; taking the inverse we get $\psi_0(\vec{a}_j)=\Sigma_{m=1}^{N}\Lambda(z')_{jm}d_m$. In combination with (3.17) this yields

$$\sum_{m=1}^{N} \Lambda(z)_{jm}d_m=0, \tag{3.18}$$

i.e., $d:=(d_1,\ldots,d_N)$ has to be an eigenvector of the matrix $\Lambda(\alpha,\vec{a};z)$ corresponding to zero eigenvalue. The corresponding system of linear equations is solvable under the condition (3.10), and the sought eigenfunctions of $H(\alpha,\vec{a})$ are given by the formula (3.11).

It remains to check that Eq. (3.10) can have a solution in $(-\infty,1)$. Let us start with the limiting situations of strong and weak coupling. We know from (2.22) how $\xi(\vec{a}_j;z)$ behaves as $-\sqrt{-z}/4\pi$ as $z\to-\infty$. At the same time, the nondiagonal part of matrix Λ vanishes in the limit in view of the asymptotics

$$H_0^{(1)}(\sqrt{z-n^2}|a_j-a_m|)=H_0^{(1)}(i\sqrt{n^2-z}|a_j-a_m|)\approx\sqrt{\frac{2}{i\pi\sqrt{n^2-z}\,|a_j-a_m|}}\,e^{-\sqrt{n^2-z}|a_j-a_m|-i\pi/4}$$

for $z\to-\infty$. This argument is not applicable if $a_j=a_m$ for $j\neq m$. Nevertheless, the nondiagonal matrix elements are up to the sign equal to Green's function values, and thus they are bounded. In this way we get

$$\Lambda(\alpha,\vec{a};z)=\frac{\sqrt{-z}}{4\pi}I+\mathcal{O}(1)\quad\text{as}\quad z\to-\infty \tag{3.19}$$

with the coefficient α_j included into the error term. On the other hand,

$$\Lambda(\alpha,\vec{a};z)=\frac{1}{\pi^2}\ln\sqrt{1-z}\;M+\mathcal{O}(1)\quad\text{as}\quad z\to1-, \tag{3.20}$$

where $M:=(\sin b_j \sin b_m)_{j,m=1}^{N}$. This matrix has zero eigenvalue of multiplicity $N-1$ and the positive eigenvalue $\Sigma_{j=1}^{N}\sin^2 b_j$ corresponding to the eigenvector $(\sin b_1,\ldots,\sin b_N)$. The latter is more important, because it means that one eigenvalue of $\Lambda(\alpha,\vec{a};z)$ tends to $-\infty$ as $z\to1-$. Furthermore, the eigenvalues of $\Lambda(\alpha,\vec{a};z)$ are continuous functions of z, so comparing the last claim with (3.19) we find that at least one of the eigenvalues crosses zero for some z, i.e., that $H(\alpha,\vec{a})$ has at least one isolated eigenvalue.

We may ask whether some of the eigenvalues may be degenerate. For the sake of brevity we rewrite the matrix $\Lambda(\alpha,\vec{a};z)$ as

$$\Lambda(\alpha,\vec{a};z)=\delta_{jm}(\alpha_j-\xi_j(z))+(1-\delta_{jm})g_{jm}(z), \tag{3.21}$$

where $\xi_j(z) := \xi(\vec{a}_j; z)$ and $g_{jm}(z) := -G_0(\vec{a}_j - \vec{a}_m; z)$. Since all g_{jm} are negative, the maximum possible degeneracy is $N-1$, which means that for a pair of point interactions the discrete spectrum is always simple. Let us consider the case $N=3$. Let $z<1$, $\vec{a}_{1,3}=(\pm a, b_1)$ and $\vec{a}_2 = (0, b_2)$. If $b_2 \to 0$, then the value $g_{12}=g_{23}$ approaches zero, thus being smaller than g_{13} for b_2 small enough. On the contrary, if $b_2 = b_1$ we obtain the opposite inequality; this follows from the expression (2.3) and from the monotonicity of the Macdonald function $K_0(u)$ with a positive argument (see Ref. 9, 9.6.24). Hence there exists a $b_2 \in (0, b_1)$ such that all the nondiagonal elements of the matrix are the same, $g_{13}=g_{12}=g_{23}$. Choosing α_j which satisfy $\alpha_j - \xi_j = g_{12}$ we obtain a matrix of rank one, i.e., z is an eigenvalue of multiplicity two.

D. Embedded eigenvalues

We have shown in the previous section, that a single point interaction cannot produce eigenvalues embedded in the continuous spectrum. This is no longer true if $N \geqslant 2$ as the following example shows.

Example 3.1: Consider a pair of perturbations with the same α placed at $\vec{a}_1=(0,0,b)$ and $\vec{a}_2=(0,0,\pi-b)$. We can divide the eigenvalue problem into symmetric and antisymmetric parts with respect to the plane $\{(x, \pi/2): x \in \mathbb{R}^2\}$. We obtain properties of the antisymmetric part by scaling the one-center problem: substituting $\sigma = 1/2$ into the relation (2.15) we see that the antisymmetric part has a single eigenvalue which tends to 4 as $\alpha \to \infty$, hence it is embedded in the continuous spectrum for α large enough.

Thus we cannot exclude existence of embedded eigenvalues in general. We can, however, prove a weaker result. In the example the symmetry was essential, which means in particular that the eigenfunction is dominated by the second transverse mode. We will show that in general *any eigenvalue $z>1$ cannot contain contributions from transverse modes with $n \leqslant [\sqrt{z}]$*. Suppose that $H(\alpha, \vec{a})\varphi = z\varphi$ for $z>1$. We employ the relation (3.11) and take ψ_0 in the form $\psi_0(\vec{x}) = \sum_{n=1}^{\infty} g_n(x)\chi_n(y)$, where $g_n \in L^2(\mathbb{R}^2)$. Substituting this ψ_0 into (3.11) and using the fact that $\{\chi_n\}$ is an orthonormal basis in $L^2((0,\pi))$ we get

$$\left[-\frac{\partial^2}{\partial x_1^2} - \frac{\partial^2}{\partial x_2^2} - z + n^2 \right] g_n(x) = (z - z') \sum_{j=1}^{N} d_j \, \frac{i}{4} H_0^{(1)}(k_n(z')|x - a_j|) \chi_n(b_j)$$

for $n = 1,2,\ldots$. The Fourier–Plancherel operator transforms this into

$$[|p|^2 - z + n^2] \hat{g}_n(p) = \frac{(z - z')}{2\pi} \sum_{j=1}^{N} d_j \, \chi_n(b_j) \frac{e^{-ipa_j}}{|p|^2 - z' + n^2}. \tag{3.22}$$

If $g_n \in L^2(\mathbb{R}^2)$, then $\hat{g}_n$ should also belong to $L^2(\mathbb{R}^2)$. It is not possible if $z > n^2$ and the rhs of (3.22) is nonzero at $p_n\omega$, where $p_n = \sqrt{z - n^2}$ and ω is a unit vector in $\mathbb{R}^2$. Recall that the factor $(|p|^2 - z' + n^2)^{-1}$ has no singularity, because $z' \in \rho(H)$ by assumption.

To avoid the singularity of $\hat{g}_n$ at $|p| = p_n$ we have to require

$$\sum_{j=1}^{N} d_j \chi_n(b_j) e^{-ip_n \omega a_j} = 0 \tag{3.23}$$

for an arbitrary unit vector ω from $\mathbb{R}^2$. If all the a_j's are different, it follows that $d_j \chi_n(b_j) = 0$ for each j. If some of them are the same, the condition changes to $\sum_j d_j \chi_n(b_j) = 0$ where j runs through the a_j's which coincide. In both cases $\hat{g}_n$ is identically zero for $n^2 < z$.

Consider now an arbitrary $g \in L^2(\mathbb{R}^2)$ and $n^2 < z$. Using (3.11) and (2.3) we arrive at

$$(g\chi_n, \varphi) = (\hat{g}, \hat{g}_n) + \sum_{j=1}^{N} d_j \, \chi_n(b_j) \left(g, \frac{i}{4} H_0^{(1)}(k_n(z')|x - a_j|) \right). \tag{3.24}$$

The first scalar product is equal to zero because $\hat{g}_n$ is zero. If all the a_j's are different, then $d_j\chi_n(b_j)=0$ for all j and the whole rhs is equal to zero. If some a_j's are the same, the condition $\Sigma_{j=1}^{N} d_j\chi_n(b_j)=0$ leads to $(g\chi_n,\varphi)=0$ again. The conclusion holds true for all $n=1,\ldots,[\sqrt{z}]$, what we have set out to prove.

E. The limits of strong and weak coupling

Of the two extreme situations, consider first the strong coupling. One can write the matrix $\Lambda(\alpha,\vec{a};z)$ in the form

$$\Lambda(z)=\left(\left(\alpha_j+\frac{\sqrt{-z}}{4\pi}\right)\delta_{jk}\right)\left[I+\left(\left(\alpha_j+\frac{\sqrt{-z}}{4\pi}\right)\delta_{jk}\right)^{-1}\tilde{\Lambda}(z)\right], \tag{3.25}$$

where $\tilde{\Lambda}(z)$ is the remainder matrix, which is independent of α_j and has a bounded norm as $z\to-\infty$. For an arbitrary finite interval $J\subset(-\infty,1)$ we can always choose α_j's large enough negative that no eigenvalues are contained in J and the two matrices in the above product are regular in J. It means that the roots of Eq. (2.19) come from the region where $\Lambda(z)$ is dominated by its diagonal part. Then there are exactly N eigenvalues (including a possible degeneracy), which behave asymptotically as

$$\varepsilon_j(\alpha,\vec{a})\approx-16\pi^2\alpha_j^2 \quad \text{as} \quad \max_{1\leqslant j\leqslant N}\alpha_j\to-\infty. \tag{3.26}$$

As we expect the eigenfunctions in the strong limit are strongly localized and only slightly influenced by the other perturbations. The eigenfunction localized at $\vec{a}_j$ has the same form as in Sec. II D where we put $\vec{a}=\vec{a}_j$.

Consider now on the contrary that all the point interactions are weak, i.e., that all the α_j's are large positive. Denoting $A:=\mathrm{diag}(\alpha_1,\ldots,\alpha_N)$ we can write

$$\Lambda(z)=A+\frac{1}{\pi^2}\ln\sqrt{1-z}M+\tilde{\Lambda}(z), \tag{3.27}$$

where $\tilde{\Lambda}(z)$ is a remainder matrix, which is again independent of α with its norm bounded, $\|\tilde{\Lambda}(z)\|\leqslant C_{\vec{a}}$ for $z\in(z_0,1)$. In Sec. III C we found that $\Lambda(z)$ was asymptotically a rank one operator on $\mathbb{C}^N$. Hence only one isolated eigenvalue of $H(\alpha,\vec{a})$ exists in this asymptotic situation.

To find the leading term of the asymptotic expansion, we have to solve the spectral problem for matrix $M-\eta A-\eta\tilde{\Lambda}(z)$, where $\eta:=-2\pi^2(\ln(1-z))^{-1}$. The largest eigenvalue of this matrix satisfies $\mu_N(\eta)\geqslant\mu_N(0)-(C_{\vec{a}}+\alpha_+)\eta$, where $\alpha_+:=\max\alpha_j$, while for $j=1,\ldots,N-1$ we have $\mu_j(\eta)\leqslant(C_{\vec{a}}-\alpha_-)\eta$, where $\alpha_-:=\min\alpha_j$. Since $\mu_N(0)>0$ we see that for α_- large enough the condition has just one solution for $\eta>0$. One can check directly that without $\tilde{\Lambda}(z)$ the condition is satisfied for $\eta=\Sigma_j\alpha_j^{-1}\sin^2 b_j$. Thus $\eta=\mathcal{O}(\alpha_-^{-1})$ and the eigenvalue expansion follows. Hence the bound-state energy in the weak-coupling case behaves as

$$\varepsilon(\alpha,\vec{a})\approx1-\exp\left\{-2\pi^2\left(\sum_{j=1}^{N}\frac{\sin^2 b_j}{\alpha_j}\right)^{-1}\right\} \tag{3.28}$$

as $\min_{1\leqslant j\leqslant N}\alpha_j\to\infty$. Since the eigenvector of matrix M corresponding to the nonzero eigenvalue is $(\sin b_1,\ldots,\sin b_N)$, the asymptotic expression of the eigenfunction for $\vec{x}$ from a restricted part of Σ is

$$\varphi(\vec{x}) \approx \sin y \left(\frac{\Sigma_{j=1}^{N} \sin^2 b_j}{\Sigma_{j=1}^{N} (\sin^2 b_j)/\alpha_j} - \frac{1}{\pi^2} \sum_{j=1}^{N} \sin^2 b_j \ln|x-a_j| \right) + \frac{1}{\pi^2} \sum_{n=2}^{\infty} \sin(ny) \sum_{j=1}^{N} \sin b_j \sin(nb_j)\, K_0(\sqrt{n^2-1}|x-a_j|). \tag{3.29}$$

Let us summarize the spectral properties of our Hamiltonian in the N-center case derived in the previous three paragraphs.

Theorem 3.2: *Let $H(\alpha,\vec{a})$ be defined by (2.5) and (2.6) for $d=\pi$, where $\vec{a}=(\vec{a}_1,\ldots,\vec{a}_N)$ and $\alpha=(\alpha_1,\ldots,\alpha_N)$ and the boundary condition (2.4) is replaced by (3.1). Then we have the following.*

(a) $\sigma_{ess}(H(\alpha,\vec{a}))=\sigma_{ac}(H(\alpha,\vec{a}))=[1,\infty)$ *and* $\sigma_{sc}(H(\alpha,\vec{a}))=\varnothing$.

(b) *For any $\alpha\in\mathbb{R}^N$ there is at least one eigenvalue $\varepsilon(\alpha,\vec{a})$ in $(-\infty,1)$. The maximum number of eigenvalues is N with the multiplicity taken into account; the maximum multiplicity is $N-1$. The corresponding eigenfunction is given by (3.16), where the coefficients d_m, $m=1,\ldots,N$, are components of a vector solving the equation $\Lambda d=0$ with the matrix Λ given by (3.8).*

(c) *In the limit $\min_{1\leqslant j\leqslant N}\alpha_j\to\infty$ the bound state wave function behaves according to (3.28) and (3.29). On the other hand, in the strong coupling case there are exactly N eigenvalues whose asymptotics is given by (3.26); the corresponding eigenfunctions are strongly localized around the points $\vec{x}=\vec{a}_j$ and given by (2.29) with $\vec{a}=\vec{a}_j$ and $\alpha=\alpha_j$.*

(d) *If an eigenvalue $z\in[1,\infty)$ exists, the corresponding eigenvector is orthogonal to the subspace $\oplus_{n=1}^{[\sqrt{z}]} L^2(\mathbb{R}^2)\otimes\{\chi_n\}$.*

F. Scattering

Comparing to the one-center case, the Hamiltonian $H(\alpha,\vec{a})$ with a finite number of perturbations loses in general the invariance with respect to rotations around an axis perpendicular to Σ. Hence we cannot employ here the partial wave decomposition and we turn directly to the "closed form" of the on-shell scattering amplitude and on-shell scattering operator. By (3.3), to any $\psi\in D(H(\vec{a},\alpha))$ and a nonreal z there exists $\psi_z\in D(H_0)$ such that

$$\psi(\vec{x}) = \psi_z(\vec{x}) + \sum_{j,k=1}^{N} \lambda_{jk}(\alpha,\vec{a};z)\, G_0(\vec{x},\vec{a}_j;z)\, \psi_z(\vec{a}_k). \tag{3.30}$$

We take again $\psi_0^\varepsilon(\vec{x})=e^{ik_n(z)\omega x-\varepsilon|x|^2}\chi_n(y)$ for ψ_z, where ω is a unit vector in $\mathbb{R}^2$. Denoting the lhs of (3.30) as ψ^ε we have $\psi^\varepsilon\in D(H(\alpha,\vec{a}))$ and

$$((H(\alpha,\vec{a})-z)\psi^\varepsilon)(\vec{x}) = 4\varepsilon[1-\varepsilon|x|^2+ik_n\omega x]\,\psi_z^\varepsilon(\vec{x}). \tag{3.31}$$

The rhs converges in $L^2(\mathbb{R}^2)$ as z approaches the real line and the ψ^ε belongs to $D(H(\alpha,\vec{a}))$. The pointwise limit $\varepsilon\to 0+$ exists and equals

$$\psi_{\alpha,n}(\vec{x};k_n(z)\omega) = e^{ik_n(z)\omega x}\chi_n(y) + \sum_{j,k=1}^{N} \lambda_{jk}(\alpha,\vec{a};z)\, G_0(\vec{x},\vec{a}_j;z)\, e^{ik_n(z)\omega a_k}\chi_n(b_k). \tag{3.32}$$

The limiting function is locally square integrable and it thus is a generalized eigenfunction of $H(\alpha,\vec{a})$.

The components $(f_\alpha(k_n(z),\omega_x,\omega))_{mn}$ of the on-shell scattering amplitude are then given by the part of the following expression corresponding to the outgoing mth transverse mode,

$$\lim_{|x|\to\infty, x/|x|=\omega_x} |x|^{1/2} e^{-ik_m|x|}[\psi_{\alpha,n}(\vec{x};k_n(z)\omega) - e^{ik_n\omega x}\chi_n(y)].$$

It yields

$$(f_\alpha(k_n(z),\omega_x,\omega))_{mn} = \frac{e^{i\pi/4}}{\pi\sqrt{2\pi k_m(z)}} \sum_{j,k=1}^{N} e^{-ik_m(z)\omega_x a_j} \lambda_{jk}(\alpha,\vec{a};z)\, e^{ik_n(z)\omega a_k} \sin(mb_j)\sin(nb_k), \tag{3.33}$$

and the on-shell scattering operator $S_\alpha(z)$ on $L^2(S^1)\otimes L^2([0,d])$ is

$$S_\alpha(z) = I + \frac{i}{2\pi^2} \sum_{k,j=1}^{N} \sum_{m,n=1}^{[\sqrt{z}]} \sin(mb_j)\sin(nb_k)\, \lambda_{jk}(\alpha,\vec{a};z)\, (e^{-ik_n(z)(\cdot)a_k}\chi_n, \cdot)\, e^{-ik_m(z)(\cdot)a_j}\chi_m . \tag{3.34}$$

As in the one-center case, resonances are determined by the poles in the meromorphic continuation of the matrix-valued function $(\lambda_{jk}(\alpha,\vec{a};\cdot))$.

IV. A LAYER IN MAGNETIC FIELD

A. The free Hamiltonian

In this section, the layer $\Sigma = \mathbb{R}^2\times(0,d)$ is placed into a homogeneous magnetic field $\vec{B} = (0,0,B)$. As usual the vector potential generating this field can be chosen in different ways, e.g., we can employ the symmetric gauge, $\vec{A} = 1/2\,(-Bx_2, Bx_1, 0)$. We again use the decomposition into transverse modes,

$$\begin{aligned} H_0^B &= \bigoplus_{n=1}^{\infty} h_n^B \otimes I_n , \\ h_n^B &= \left(-i\frac{\partial}{\partial x_1} + \frac{1}{2}Bx_2\right)^2 + \left(-i\frac{\partial}{\partial x_2} - \frac{1}{2}Bx_1\right)^2 + \left(\frac{\pi n}{d}\right)^2 . \end{aligned} \tag{4.1}$$

The first two terms on the rhs denoted as h^B describe a two-dimensional particle in the perpendicular homogeneous field. The resolvent kernel of such an operator is well known:[14]

$$\begin{aligned} (h^B - z)^{-1}(x,x') = \frac{1}{4\pi} \exp\left(\frac{iB}{2}(-x_1x_2' + x_2x_1') - \frac{|B|}{4}|x-x'|^2\right) \\ \times \Gamma\left(\frac{|B|-z}{2|B|}\right) U\left(\frac{|B|-z}{2|B|}, 1; \frac{|B|}{2}|x-x'|^2\right), \end{aligned}$$

where U is the irregular confluent hypergeometric function (Ref. 9, 13.1.33). For the sake of brevity we denote the exponential term in the above formula as $\Phi^B(x,x')$. The decomposition (4.1) then yields the sought resolvent kernel

$$\begin{aligned} G_0^B(\vec{x},\vec{x}';z) &\equiv (H_0^B - z)^{-1}(x,y;x',y') \\ &= \frac{1}{2\pi d} \exp\left(\frac{iB}{2}(-x_1x_2' + x_2x_1') - \frac{|B|}{4}|x-x'|^2\right) \\ &\quad \times \sum_{n=1}^{\infty} \Gamma\left(\frac{|B| - k_n^2(z)}{2|B|}\right) U\left(\frac{|B|-k_n^2(z)}{2|B|}, 1; \frac{|B|}{2}|x-x'|^2\right) \sin\left(\frac{n\pi y}{d}\right)\sin\left(\frac{n\pi y'}{d}\right). \end{aligned} \tag{4.2}$$

B. The perturbed resolvent

As in the nonmagnetic case we start from a single point interaction located at the point $\vec{a} \in \Sigma$ and modify to the present situation the argument of Sec. II C. We employ the fact that *locally* the magnetic field means a regular perturbation of the Schrödinger equation; motivated by this we *define* the one-center Hamiltonian in the same way as in Sec. II: it acts as free

$$(H^B(\alpha,\vec{a})\psi)(\vec{x}) = \left(\left[\left(-i\frac{\partial}{\partial x_1} + \frac{1}{2}Bx_2 \right)^2 + \left(-i\frac{\partial}{\partial x_2} - \frac{1}{2}Bx_1 \right)^2 - \frac{\partial^2}{\partial y^2} \right] \psi \right)(\vec{x}) \tag{4.3}$$

for $\vec{x} \neq \vec{a}$ with the domain changed to

$$\begin{aligned} D(H^B(\alpha,\vec{a})) = \{ \psi \in L^2(\Sigma \setminus \{\vec{a}\}) :\ & H^B(\alpha,\vec{a})\psi \in L^2(\Sigma \setminus \{\vec{a}\}), \\ & \psi(x,0) = \psi(x,d) = 0,\ L_1(\psi,\vec{a}) - 4\pi\alpha L_0(\psi,\vec{a}) = 0 \}, \end{aligned} \tag{4.4}$$

where L_0 and L_1 in the last relation are again the generalized boundary values from Ref. 2, Chap. I.1.

Remark 4.1: To justify such a definition we have to check that the resolvent kernel (4.2) has the same singularity as the nonmagnetic expression (2.3) for $\vec{x}' \to \vec{x}$. We have $G_0^B(\vec{x},\vec{x}';z) \approx c|\vec{x}' - \vec{x}|^{-1}$ by Ref. 15, Thm. III.5.1, with a nonzero c independent of z. To check that the constant has the needed value it is sufficient to find operators H_- and H_β with β from some interval $(\beta_0,1)$ whose resolvent kernels are $\sim(4\pi)^{-1}|\vec{x}' - \vec{x}|$ around the singularity and which satisfy the inequalities

$$H_- \leqslant H_0^B \leqslant \beta^{-1} H_\beta, \tag{4.5}$$

since the last named property implies easily

$$(H_- - z)^{-1} \geqslant (H_0^B - z)^{-1} \geqslant \beta(H_\beta - \beta z)^{-1}$$

for a fixed $z<0$ and $c=(4\pi)^{-1}$ follows by contradiction. For the lower bound we choose the projection to the layer of the magnetic Schrödinger operator $(-i\vec{\nabla} - \vec{A})^2$ in $L^2(\mathbb{R}^3)$ obtained by removing the Dirichlet boundaries of Σ, because the latter is of the form $h_B \otimes I + I \otimes (-\partial_y^2)$ and we may apply the bracketing argument (Ref. 7, Sec. XIII.15) to the nonmagnetic part in the y-direction. Its kernel is known[16,17] to be

$$\tilde{G}_0^B(\vec{x},\vec{x}';z) = \frac{1}{4\pi}\left(\frac{|B|}{2}\right)^{1/2} \Phi^B(x,x') \sum_{l=0}^{\infty} \frac{\exp[-(|B|(2l+1)-z)^{1/2}|y-y'|]}{(l+\frac{1}{2}-z/2|B|)^{1/2}} L_l\left(\frac{B}{2}|x-x'|^2\right), \tag{4.6}$$

where the factor Φ^B is the same as in the relation (4.2) and L_l are the Laguerre polynomials. We want to prove that $|\vec{x}-\vec{x}'|\tilde{G}_0^B(\vec{x},\vec{x}';z)$ tends to $(4\pi)^{-1}$ in the limit $|\vec{x}-\vec{x}'| \to 0$. Putting $|x-x'| = 0$, we can neglect the Laguerre polynomials and the factor Φ^B; it remains to compute the simplified sum. For a given z there exists an integer number l_0 such that $|B|(2l_0-1)-z>0$. Then one could split the series into two parts: the finite sum over $l=0,\ldots,l_0-1$ which is irrelevant for the singularity and the truncated series with $l=l_0,\ldots$. The latter can be estimated as follows,

$$I_- \leqslant \frac{|B|}{4\pi} \sum_{l=l_0}^{\infty} \frac{\exp[-(|B|(2l+1)-z)^{1/2}\varrho]}{(|B|(2l+1)-z)^{1/2}} \leqslant I_+, \tag{4.7}$$

where

$$I_{\pm} := \frac{|B|}{4\pi} \int_{l_0}^{\infty} \frac{\exp[-(|B|(2l\mp 1)-z)^{1/2}\varrho]}{(|B|(2l\mp 1)-z)^{1/2}}\, dl = \frac{1}{4\pi\varrho}\, e^{-(|B|(2l_0\mp 1)-z)^{1/2}\varrho}.$$

Hence the resolvent $\widetilde{G}_0^B$ has the needed singularity.

In the opposite direction we add a Dirichlet boundary at $|x|=R$, cutting thus a finite cylinder of Σ. It is clearly sufficient to find a bound of the type (4.5) for the ''planar'' part of the operator and this task is further reduced to finding bounds for its partial-wave components,

$$\widetilde{h}_m^B = -\frac{\partial^2}{\partial r^2} - \frac{1}{r}\frac{\partial}{\partial r} + \left(\frac{m}{r} - \frac{Br}{2}\right)^2 \tag{4.8}$$

on $L^2(0,R)$ with the boundary condition $\lim_{r\to 0}\phi(r)(r^{1/2}\ln r)^{-1}=0$ at the origin (Ref. 2, Sec. I.5) and Dirichlet at $r=R$. A comparison of the potential terms shows that $\widetilde{h}_m^B \leqslant \beta^{-1}\widetilde{h}_m^0$ holds if $R < ((2/|B|)(\beta^{-1/2}-1))^{1/2}$, so one can choose for H_β the nonmagnetic Dirichlet Laplacian in the cylinder of an arbitrarily small radius. This operator has again the resolvent kernel with the needed singularity.[8] Notice finally that alternative ways to prove this result can be found in Ref. 18 or derived by techniques from the classical theory of partial differential equations (Ref. 19, Thm. 20.6).

Remark 4.2: The previous remark still does not answer the question about the Green's function singularity fully. To explain why it is the case, recall that the requirement of symmetry of the magnetic Hamiltonian yields for any functions ψ_1, ψ_2 from the domain by means of the Gauss theorem the condition[18]

$$\lim_{r\to 0}\int_{S_{\vec{a}}}\left(-\overline{\psi}_1\frac{\partial\psi_2}{\partial r} + \psi_2\frac{\partial\overline{\psi}_1}{\partial r} + 2i\overline{\psi}_1\psi_2\frac{\vec{A}\vec{r}}{r}\right)dS = 0,$$

where $\vec{r}=\vec{x}-\vec{a}$, $r=|\vec{r}|$ and the integral is taken over the surface of the sphere $S_{\vec{a}}$ with center at $\vec{a}$ and radius r. It is satisfied if the functions have the following asymptotic behavior in the vicinity of the point interaction:

$$\psi(\vec{x}) = c_0\frac{1+\vec{A}(\vec{a})(\vec{x}-\vec{a})}{|\vec{x}-\vec{a}|} + c_1 + \mathcal{O}(|\vec{x}-\vec{a}|). \tag{4.9}$$

This motivates us to change the generalized boundary value L_1 to

$$L_1(\psi,\vec{a}) = \lim_{|\vec{x}-\vec{a}|\to 0}\left[\psi(\vec{x}) - L_0(\psi,\vec{a})\frac{1+i\vec{A}(\vec{a})(\vec{x}-\vec{a})}{|\vec{x}-\vec{a}|}\right]. \tag{4.10}$$

This suggests to use for $\xi(B,\vec{a};z)$ the following limit,

$$\xi(B,\vec{a};z) = \lim_{\vec{x}\to\vec{a}}\left[G_0^B(\vec{x},\vec{a};z) - \frac{1+i\vec{A}(\vec{a})(\vec{x}-\vec{a})}{4\pi|\vec{x}-\vec{a}|}\right], \tag{4.11}$$

which has the disadvantage that it is direction dependent and can be altered by a gauge change.

However, it is possible to employ the function $\xi(B,\vec{a};z)$ defined by means of the pole singularity alone. By (4.2) the Green's function $G_0^B(\vec{x},\vec{a};z)$ has the form $\exp(i\vec{A}(\vec{a})(\vec{x}-\vec{a}))F(|\vec{x}-\vec{a}|;z)$ in the symmetric gauge. In Remark 4.1 we have shown that $F(|\vec{x}-\vec{a}|;z)$ has the following asymptotic behavior for small $|\vec{x}-\vec{a}|$,

$$F(|\vec{x}-\vec{a}|;z) = \frac{1}{4\pi|\vec{x}-\vec{a}|} + c(z) + \mathcal{O}(|\vec{x}-\vec{a}|),$$

where $c(z) := \lim_{\varrho\to 0}[F(\varrho;z) - 1/4\pi\varrho]$. The function c defined in this way can be understood as $\xi(B,\vec{a};z)$ obtained for the Green's function without the exponential factor; the corresponding generalized boundary value L_1 does not contain the extra part $\vec{A}(\vec{a})(\vec{x}-\vec{a})$. In the respective asymptotic formula for complete Green's function one has to multiply the last expression by the two first terms of the Taylor series of the exponential factor,

$$G_0^B(\vec{x},\vec{a};z) = \frac{1+i\vec{A}(\vec{a})(\vec{x}-\vec{a})}{4\pi|\vec{x}-\vec{a}|} + c(z) + \mathcal{O}(|\vec{x}-\vec{a}|).$$

Using now the modified boundary value L_1 we find that $\xi(B,\vec{a};z) = c(z)$. This justifies the choice of the generalized boundary values made in the beginning of this section; one has to keep in mind to ignore the exponential term $\Phi^B(x,a)$ when computing $\xi(B,\vec{a};z)$. This argument also remains valid for a finite number of point interactions, hence the functions $\xi(B,\vec{a}_j;z)$ for $j=1,\ldots,N$ contained in matrix $\Lambda(B,\alpha,\vec{a};z)$ in Sec. IV D are computed in the way described here.

After this digression we can return to evaluation of the Green's function of the operator $H^B(\alpha,\vec{a})$. By construction it is given by Krein's formula,

$$G^B(\vec{x},\vec{x}';z) = G_0^B(\vec{x},\vec{x}';z) + \frac{G_0^B(\vec{x},\vec{a};z)G_0^B(\vec{a},\vec{x}';z)}{\alpha - \xi(B,\vec{a};z)}, \tag{4.12}$$

where the regularized Green's function $\xi(B,\vec{a};\cdot)$ is, as we have explained in the above remarks, now given by

$$\begin{aligned}\xi(B,\vec{a};z) &= \lim_{|\vec{x}-\vec{a}|\to 0}\left[G_0^B(\vec{x},\vec{a};z) - \frac{1}{4\pi|\vec{x}-\vec{a}|}\right] \\ &= \lim_{\varrho\to 0}\left[\frac{1}{2\pi d}\sum_{n=1}^{\infty}\Gamma\left(\frac{|B|-k_n^2(z)}{2|B|}\right)U\left(\frac{|B|-k_n^2(z)}{2|B|},1;\frac{|B|}{2}\varrho^2\right)\sin^2\left(\frac{n\pi b}{d}\right) - \frac{1}{4\pi\varrho}\right].\end{aligned} \tag{4.13}$$

One can check directly the consistency requirement

$$\lim_{B\to 0} G^B(\vec{x},\vec{x}';z) = G(\vec{x},\vec{x}';z) \tag{4.14}$$

for fixed α, $\vec{a}$ and $\vec{x}\neq\vec{x}'$, where $G(\cdot,\cdot;z)$ is the non-magnetic Green's function of Sec. II C. It follows easily from a known relation (Ref. 9, 13.3.3) for the confluent hypergeometric function,

$$\lim_{u\to\infty}\Gamma(u)U\left(u,1,\frac{s}{u}\right) = 2K_0(2\sqrt{s}).$$

To make use of the Green's function, we have to evaluate the rhs of (4.13). We employ again the same trick and split a part of the series which can be summed explicitly for a general ϱ while in the remaining series the limit $\varrho\to 0$ can be interchanged with the sum. Since $U(u,1;\cdot)$ and $K_0(\cdot)$ both have a logarithmic singularity at zero, we modify the ansatz of Sec. II C writing $\xi(B,\vec{a};z) = \xi_1 + \xi_2$ with

$$\xi_1 := \lim_{\varrho\to 0}\frac{1}{2\pi d}\sum_{n=1}^{\infty}\left[\Gamma\left(\frac{|B|-k_n^2(z)}{2|B|}\right)U\left(\frac{|B|-k_n^2(z)}{2|B|},1;\frac{|B|}{2}\varrho^2\right) - 2K_0\left(\varrho\frac{\pi n}{d}\right)\right]\sin^2\left(\frac{n\pi b}{d}\right),$$

$$\xi_2 := \lim_{\varrho\to 0}\left[\frac{1}{2\pi d}\sum_{n=1}^{\infty}2K_0\left(\varrho\frac{\pi n}{d}\right)\sin^2\left(\frac{n\pi b}{d}\right) - \frac{1}{4\pi\varrho}\right].$$

The function ξ_2 is evaluated as above: In analogy with (2.13) we have

$$\xi_2=\frac{\gamma}{4\pi d}+\frac{1}{8\pi d}\left(2\psi\left(\frac{b}{d}\right)+\pi\cot\left(\frac{\pi b}{d}\right)\right). \tag{4.15}$$

As for the first part, ξ_1, we employ the small ϱ asymptotics for the confluent hypergeometric and Macdonald functions,

$$U(u,1;s)=-\frac{1}{\Gamma(u)}[\ln s+\psi(u)-2\psi(1)]+\mathcal{O}(|s\ln s|) \quad \text{as} \quad s\to 0,$$

$$K_0(s)=-\left[\ln\frac{s}{2}-\psi(1)\right]+\mathcal{O}(s^2) \quad \text{as} \quad s\to 0$$

(see Ref. 20, 6.7.13 and Ref. 9, 9.6.13). Putting them together we see that the summand behaves for small ϱ as

$$\ln\left(\frac{(\pi n)^2}{2|B|d^2}\right)-\psi\left(\frac{|B|-z+(\pi n/d)^2}{2|B|}\right)+\mathcal{O}(|\varrho^2\ln\varrho|).$$

For large n the digamma function $\psi(s)=\ln(s)-2/s+\mathcal{O}(s^{-2})$, so the above expression can be written for large n as

$$-\ln\left(1+(|B|-z)\left(\frac{d}{\pi n}\right)^2\right)+\frac{1}{2}\,\frac{2|B|}{|B|-z+(\pi n/d)^2}+\mathcal{O}(n^{-4})=z\left(\frac{d}{\pi n}\right)^2+\mathcal{O}(n^{-4}).$$

Hence the series in the definition of ξ_1 converges uniformly and the limit can be interchanged with the sum giving the sought formula for the regularized Green's function,

$$\begin{aligned}\xi(B,\vec{a};z)=\xi_1+\xi_2=\frac{1}{2\pi d}\sum_{n=1}^{\infty}&\left[\ln\left(\frac{(\pi n)^2}{2|B|d^2}\right)-\psi\left(\frac{|B|-z+(\pi n/d)^2}{2|B|}\right)\right]\sin^2\left(\frac{\pi n b}{d}\right)\\&+\frac{1}{4\pi d}\left[\gamma+\psi\left(\frac{b}{d}\right)+\frac{\pi}{2}\cot\left(\frac{\pi b}{d}\right)\right].\end{aligned} \tag{4.16}$$

Remark 4.3: The scaling behavior for the family $\Sigma^\sigma=\mathbb{R}^2\times[0,d\sigma]$, $\sigma>0$, is similar to that of Remark 2.1; however, one has to scale simultaneously the magnetic field by

$$B^\sigma=\sigma^{-2}B. \tag{4.17}$$

In distinction to the previous sections we shall keep a general d in the following discussion.

C. Spectral properties

The essential spectrum of $H^B(\vec{a},\alpha)$ remains the same as that of the free Hamiltonian H_0^B which follows easily from Weyl's theorem (Ref. 7, Thm. XIII.14). The latter is in turn obtained from the essential spectrum of the two-dimensional Landau Hamiltonian, $\sigma(h^B)=\sigma_{ess}(h^B)=\{|B|(2m+1): m\in\mathbb{N}_0\}$ (see, e.g., Ref. 21, Thm. 1). Using the transverse-mode decomposition (4.1) we arrive at

$$\sigma_{ess}(H^B)=\sigma_{ess}(H_0^B)=\left\{|B|(2m+1)+\left(\frac{\pi n}{d}\right)^2:\ m,n-1\in\mathbb{N}_0\right\}. \tag{4.18}$$

Furthermore, the general properties of self-adjoint extensions mentioned in Sec. II D imply that there is at most one eigenvalue in each spectral gap of the unperturbed operator, i.e., between the two neighboring values from $\sigma_{ess}(H^B)$ and in the interval $(-\infty,|B|+(\pi/d)^2)$; to find these eigenvalues one has to solve the equation

$$\xi(B,\vec{a};z)=\alpha. \tag{4.19}$$

We have already checked that the terms of the series expressing $\xi(B,\vec{a};z)$ decay as n^{-2}, so the series converges with the exceptions of the points where the ψ function has a singularity, i.e., for any $z\in\mathbb{R}-\sigma_{ess}(H^B)$. It is also obvious that $\xi(B,\vec{a};z)$ is real for any such z. We have

$$\frac{d}{dz}\xi(B,\vec{a};z)=\frac{1}{4\pi d|B|}\sum_{n=1}^{\infty}\psi'\left(\frac{|B|-z+(\pi n/d)^2}{2|B|}\right)\sin^2\left(\frac{\pi nb}{d}\right), \tag{4.20}$$

where $\psi'(s)=(d/ds)\,\psi(s)$ is the trigamma function. For large n it behaves as

$$\psi'\left(\frac{|B|-z+(\pi n/d)^2}{2|B|}\right)=\frac{2|B|}{|B|-z+(\pi n/d)^2}+\mathcal{O}(n^{-4}),$$

so the series converges for $z\in\mathbb{R}\setminus\sigma_{ess}(H^B)$ and we are allowed to interchange the sum with the derivative. The explicit expression (Ref. 9, 6.4.10) for the digamma derivative,

$$\psi'(s)=\sum_{j=0}^{\infty}\frac{1}{(s+j)^2}\quad\text{for}\quad s\neq 0,-1,-2,\ldots,$$

shows that $\xi(B,\vec{a};z)$ is monotonously growing with respect to z in each gap. Using the relation (Ref. 9, 6.3.16)

$$\psi(1+s)=-\gamma+\sum_{j=1}^{\infty}\frac{s}{j(j+s)},\quad s\neq -1,-2,\ldots,$$

we find that ξ diverges as z approaches any point of the essential spectrum behaving in its vicinity as

$$\xi(B,\vec{a};z)=-\frac{|B|}{\pi d}\frac{\sin^2(\pi nb/d)}{z-|B|(2m+1)-(\pi n/d)^2}+\mathcal{O}(1), \tag{4.21}$$

provided the considered value from $\sigma_{ess}(H_0)$ is "nondegenerate" in the sense that it can be expressed by means of a single pair of indices m,n. This is the generical case since the last name property is valid always if the ratio of the coefficients $|B|$ and $(\pi/d)^2$ is irrational. If it is rational, then to a given $z_0\in\sigma_{ess}(H_0)$ there may exist different pairs m_j,n_j with the index belonging to a family $J(z_0)$ such that $|B|(2m_j+1)+(\pi n_j/d)^2=z_0$ for all $j\in J(z_0)$.

Taking this degeneracy into account we have

$$\xi(B,\vec{a};z)=-\frac{|B|}{\pi d}\frac{1}{z-z_0}\sum_{j\in J(z_0)}\sin^2\left(\frac{\pi n_j b}{d}\right)+\mathcal{O}(1). \tag{4.22}$$

When z approaches z_0 from below, ξ diverges to ∞, while if it approaches z_0 from above, ξ goes to $-\infty$. The formula (4.22) also shows that we can disregard those j for which $\sin(\pi n_j b/d)=0$: as above the system does not "feel" a point perturbation situated at a transverse eigenfunction node.

To find the behavior as $z\to-\infty$, recall that the argument leading to the expression (4.16) shows that the latter differs from the nonmagnetic formula (2.14) by the replacement $z\to z-|B|$ together with the addition of terms which remain bounded as $z\to-\infty$. Consequently, the asymptotics is independent of B and given by the formula

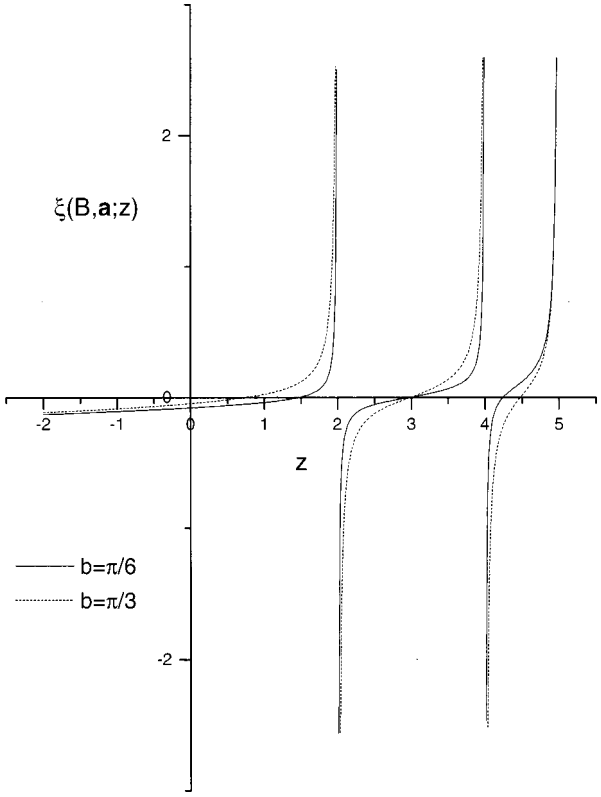

FIG. 5. The function $\xi(B,\vec{a};\cdot)$ for $B=1$, $d=\pi$ and $b=\pi/6,\pi/3$.

$$\xi(B,\vec{a};z)=-\frac{\sqrt{-z}}{4\pi}+\mathcal{O}(1) \quad \text{as} \quad z\to-\infty. \tag{4.23}$$

The behavior of the function $\xi(B,\vec{a};\cdot)$ is illustrated in Fig. 5.

Having discussed the properties of the function ξ, we can apply the conclusions on Eq. (4.19). Since ξ is strictly increasing between every pair of neighboring singularities, there is a unique eigenvalue $\varepsilon_r(B,\alpha,\vec{a})$ in each gap for any $\alpha\in\mathbb{R}$ and it satisfies the inequality

$$\varepsilon_r(B,\alpha,\vec{a})>\varepsilon_r(B,\alpha',\vec{a}) \quad \text{if} \quad \alpha>\alpha', \tag{4.24}$$

where the index r is labeling the gaps of H_0. The value $r=0$ corresponds to the interval $(-\infty,|B|+(\pi/d)^2)$, $r=1$ represents the first finite gap with the left endpoint $|B|+(\pi/d)^2$, etc.

Since we know the behavior of ξ around the singularities, we can write the explicit expression of $\varepsilon_r(B,\alpha,\vec{a})$ in the limits of strong and weak coupling. Suppose that the point $|B|(2m_j+1)+(\pi n_j/d)^2=z_0\in\sigma_{ess}(H_0)$ separates the rth and $(r+1)$th gap. Then, using the implicit-function theorem, we get

$$\begin{aligned}
\varepsilon_r(B,\alpha,\vec{a})&=z_0-\frac{1}{\alpha}\frac{|B|}{\pi d}\sum_{j\in J(z_0)}\sin^2\left(\frac{\pi n_j b}{d}\right)+\mathcal{O}(\alpha^{-2}) \quad \text{as} \quad \alpha\to\infty,\\
\varepsilon_{r+1}(B,\alpha,\vec{a})&=z_0-\frac{1}{\alpha}\frac{|B|}{\pi d}\sum_{j\in J(z_0)}\sin^2\left(\frac{\pi n_j b}{d}\right)+\mathcal{O}(\alpha^{-2}) \quad \text{as} \quad \alpha\to-\infty.
\end{aligned} \tag{4.25}$$

We see that the strong and weak limits are similar in the magnetic case. A different behavior we find only for the lowest eigenvalue for which the asymptotic formula (4.23) gives

$$\varepsilon_0(B,\alpha,\vec{a}) = -16\pi^2\alpha^2(1+\mathcal{O}(\alpha^{-1})) \quad \text{as} \quad \alpha\to-\infty. \tag{4.26}$$

A finer estimate with the error term replaced by $\mathcal{O}(\alpha^{-2})$ can be obtained when the ξ is expressed in terms of the Hurwitz ζ-function (see, e.g., Ref. 17). As in the nonmagnetic case, the residuum of the resolvent pole in the formula (4.12) yields a (non-normalized) eigenfunction

$$\psi(\vec{x};\alpha,\vec{a}) = G_0^B(\vec{x},\vec{a};\varepsilon_r(B,\alpha,\vec{a})) \tag{4.27}$$

corresponding to $\varepsilon_r(B,\alpha,\vec{a})$, where G_0^B is the free resolvent (4.2).

We are naturally interested in the behavior of the eigenfunction in the limit $|\alpha|\to\infty$ for eigenvalues satisfying the asymptotic relations (4.25). In both cases, by Ref. 20, 1.17.11 the gamma functions in the sum (4.2) corresponding to n_j, $j\in J(z_0)$, diverge as

$$\Gamma(-m_j+\epsilon) = \frac{(-1)^{m_j}}{m_j!}\frac{1}{\epsilon}+\mathcal{O}(1) \quad \text{as} \quad \epsilon\to 0.$$

This makes it possible to write the leading term of the asymptotics explicitly,

$$\begin{aligned}\psi(\vec{x};\alpha,\vec{a}) = {} & \frac{\alpha}{\sum_{j\in J(z_0)}\sin^2(\pi n_j b/d)}\Phi^B(x,x') \\ & \times\sum_{j\in J(z_0)} U\left(-m_j+\frac{1}{\alpha}\frac{1}{2\pi d}\sum_{j\in J(z_0)}\sin^2\left(\frac{\pi n_j b}{d}\right),1;\frac{|B|}{2}|x-a|^2\right) \\ & \times\frac{(-1)^{m_j}}{m_j!}\sin\left(\frac{\pi n_j b}{d}\right)\sin\left(\frac{\pi n_j y}{d}\right)+\mathcal{O}(1) \quad \text{as} \quad |\alpha|\to\infty.\end{aligned} \tag{4.28}$$

By Ref. 9, 13.6.27, the hypergeometric function is reduced to a Laguerre polynomial,

$$U(-n,1,u) = (-1)^n n! L_n(u),$$

at positive-integer values of the first index, so the wave function can be rewritten as

$$\psi(\vec{x};\alpha,\vec{a}) \approx \frac{\alpha}{\sum_{j\in J(z_0)}\sin^2(\pi n_j b/d)}\Phi^B(x,a)\sum_{j\in J(z_0)} L_{m_j}\left(\frac{|B|}{2}|x-a|^2\right)\sin\left(\frac{\pi n_j b}{d}\right)\sin\left(\frac{\pi n_j y}{d}\right). \tag{4.29}$$

In the last formula we have not specified the error term which has an extra part coming from the variation of the hypergeometric function $U(\cdot,1,u)$ around integer values.

We stated that the eigenvalue $\varepsilon_0(B,\alpha,\vec{a})$ in the strong coupling limit case has the same behavior as if there were no magnetic field. The same is true for the corresponding eigenfunction which is strongly localized,

$$\begin{aligned}\psi(\vec{x};\alpha,\vec{a}) = {} & \frac{1}{d}\Phi^B(x,a)\sum_{n=1}^{\infty}\left(2\pi\sqrt{|B|+16\pi^2\alpha^2+\left(\frac{\pi n}{d}\right)^2}|x-a|\right)^{-1/2} \\ & \times e^{-\sqrt{|B|+16\pi^2\alpha^2+(\pi n/d)^2}|x-a|}\sin\left(\frac{\pi n y}{d}\right)\sin\left(\frac{\pi n b}{d}\right)+\mathcal{O}(\alpha^{-1}).\end{aligned} \tag{4.30}$$

Let us summarize the results obtained for the layer in the magnetic field with one point interaction.

Theorem 4.4: *Let $H^B(\alpha,\vec{a})$ be defined by (4.3) and (4.4). Then*

(a) $\sigma_{ess}(H^B(\alpha,\vec{a})) = \{|B|(2m+1)+(\pi n/d)^2 : m,n-1\in\mathbb{N}_0\}$.

(b) *For any $\alpha\in\mathbb{R}$ there exists a single eigenvalue $\varepsilon_r(B,\alpha,\vec{a})$ between every two neighboring values from the essential spectrum, with the exception of the case when the leading term coefficient in (4.22) is zero and the eigenvalue coincides with the Landau in question for a particular value of α. Each of these eigenvalues is increasing and infinitely differentiable wrt α. The corresponding eigenfunction is given by (4.27).*

(c) *In both limits $\alpha\to\pm\infty$ the eigenvalue behaves similarly according to (4.25), except for the strong coupling limit for the lowest eigenvalue, where the formula (4.26) is valid. The eigenfunctions corresponding to the eigenvalues (4.25) and (4.26) are given by (4.28) and (4.30), respectively.*

D. Finite number of point interactions

Next we consider a finite number N of point interactions supported by points $\vec{a}_j$, $j=1,\dots,N$. We define the Hamiltonian in a way similar to that of Sec. III, i.e., it will be given by (4.3) and (4.4), where $\vec{a}$, α are again shorthands for $\vec{a}=(\vec{a}_1,\dots,\vec{a}_N)$ and $\alpha=(\alpha_1,\dots,\alpha_N)$, and instead of a single boundary condition there is an N-tuple of them,

$$L_1(\psi,\vec{a}_j)-4\pi\alpha_j L_0(\psi,\vec{a}_j)=0,\quad j=1,\dots,N. \tag{4.31}$$

Accordingly, Krein's formula reads

$$(H^B(\alpha,\vec{a})-z)^{-1}(\vec{x},\vec{x}')=G_0^B(\vec{x},\vec{x}';z)+\sum_{j,k=1}^{N}\lambda_{jk}(B,\alpha,\vec{a};z)\,G_0^B(\vec{x},\vec{a}_j;z)\,G_0^B(\vec{a}_k,\vec{x}';z). \tag{4.32}$$

Repeating the argument of Sec. III B, we find $\lambda(B,\alpha,\vec{a};z)^{-1}=\Lambda(B,\alpha,\vec{a};z)$ with

$$\Lambda_{mj}(B,\alpha,\vec{a};z):=\delta_{jm}(\alpha_m-\xi(B,\vec{a}_m;z))-(1-\delta_{jm})G_0^B(\vec{a}_m,\vec{a}_j;z), \tag{4.33}$$

or, more explicitly by means of (4.16) and (4.2),

$$\begin{aligned}\Lambda_{jj}=\alpha_j&-\frac{1}{2\pi d}\sum_{n=1}^{\infty}\left[\ln\left(\frac{(\pi n)^2}{2|B|d^2}\right)-\psi\left(\frac{|B|-k_n^2(z)}{2|B|}\right)\right]\sin^2\left(\frac{\pi n b_j}{d}\right)\\&-\frac{1}{4\pi d}\left[\gamma+\psi\left(\frac{b_j}{d}\right)+\frac{\pi}{2}\cot\left(\frac{\pi b_j}{d}\right)\right]\end{aligned} \tag{4.34}$$

and

$$\begin{aligned}\Lambda_{mj}=&-\frac{1}{2\pi d}\Phi^B(a_m,a_j)\sum_{n=1}^{\infty}\Gamma\left(\frac{|B|-k_n^2(z)}{2|B|}\right)\\&\times U\left(\frac{|B|-k_n^2(z)}{2|B|},1;\frac{|B|}{2}|a_m-a_j|^2\right)\sin\left(\frac{\pi n b_j}{d}\right)\sin\left(\frac{\pi n b_m}{d}\right)\end{aligned} \tag{4.35}$$

for $j\neq m$. If some perturbations are arranged vertically, $a_j=a_m$ for $j\neq m$, the last expression can be written as

$$\begin{aligned}\Lambda_{mj}=&-\frac{1}{2\pi d}\sum_{n=1}^{\infty}\left[\ln\left(\frac{(\pi n)^2}{2|B|d^2}\right)-\psi\left(\frac{|B|-z+(\pi n/d)^2}{2|B|}\right)\right]\sin\left(\frac{\pi n b_m}{d}\right)\sin\left(\frac{\pi n b_j}{d}\right)\\&-\xi_2\left(\frac{b_j+b_m}{2}\right)+\xi_2\left(\frac{|b_j-b_m|}{2}\right),\end{aligned} \tag{4.36}$$

as we find by a direct modification of the argument yielding $\xi(B,\vec{a};z)$.

Consider again a point $z_0 \in \sigma_{ess}(H_0)$. If z approaches this value, the appropriate contributions to the sums in (4.16) and (4.2) diverge and the matrix elements of Λ behave in the limit $z \to z_0$ as

$$\Lambda_{jj} = \alpha_j - \frac{|B|}{\pi d} \frac{1}{z_0 - z} \sum_{i \in J(z_0)} \sin^2\left(\frac{\pi n_i b_j}{d} \right) + \mathcal{O}(1),$$

$$\Lambda_{mj} = -\frac{|B|}{\pi d} \Phi^B(\vec{a}_m, \vec{a}_j) \frac{1}{z_0 - z} \sum_{i \in J(z_0)} \frac{(-1)^{m_i}}{m_i!} U\left(\frac{|B| + (\pi n_i/d)^2 - z}{2|B|}, 1; \frac{|B|}{2} |a_j - a_m|^2 \right)$$
$$\times \sin\left(\frac{\pi n_i b_j}{d} \right) \sin\left(\frac{\pi n_i b_m}{d} \right) + \mathcal{O}(1) \quad \text{if} \quad j \neq m, \tag{4.37}$$

$$\Lambda_{mj} = -\frac{|B|}{\pi d} \frac{1}{z_0 - z} \sum_{i \in J(z_0)} \sin\left(\frac{\pi n_i b_j}{d} \right) \sin\left(\frac{\pi n_i b_m}{d} \right) + \mathcal{O}(1) \quad \text{if} \quad j \neq m, \ \ a_j = a_m .$$

Moreover, the hypergeometric functions reduce to the Laguerre polynomials in the limit, so

$$\Lambda_{mj} \approx -\frac{|B|}{\pi d} \Phi^B(a_m, a_j) \frac{1}{z_0 - z} \sum_{i \in J(z_0)} L_{m_i}\left(\frac{|B|}{2} |a_m - a_j|^2 \right) \sin\left(\frac{\pi n_i b_j}{d} \right) \sin\left(\frac{\pi n_i b_m}{d} \right). \tag{4.38}$$

For large negative energies, $z \to -\infty$, we employ the asymptotic behavior of ξ given by (4.23), arriving thus at

$$\Lambda_{jj} = \alpha_j + \sqrt{\frac{-z}{4\pi}} + \mathcal{O}(1), \tag{4.39}$$

with B dependence being hidden in the error term. The nondiagonal part of the matrix Λ vanishes in the limit of large negative energy, because by Ref. 9, 13.3.3, one has

$$\Lambda_{mj} \approx -\frac{1}{2\pi d} \Phi^B(\vec{a}_m, \vec{a}_j) \sum_{n=1}^{\infty} K_0\left(\sqrt{|B| - k_n^2(z)} |a_m - a_j| \right) \sin\left(\frac{\pi n b_j}{d} \right) \sin\left(\frac{\pi n b_m}{d} \right),$$

which is exponentially decreasing, $K_0(s) \approx \sqrt{\pi/2s}\ e^{-s}$ as $s \to \infty$. In the case of a vertical arrangement, $a_j = a_m$ for $j \neq m$, we can again claim only that the matrix element Λ_{jm} is bounded.

Having obtained the coefficient matrix $\Lambda(B, \alpha, \vec{a}; z)$ given by (4.34) and (4.35) we proceed with finding the eigenvalues (the essential spectrum is preserved, of course). In the same way as in Sec. III C we check that an eigenvalue z is a solution of the implicit equation

$$\det \Lambda(B, \alpha, \vec{a}; z) = 0, \tag{4.40}$$

and the corresponding eigenfunction can be written as

$$\varphi(\vec{x}) = \sum_{j=1}^{N} d_j G_0^B(\vec{x}, \vec{a}_j; z), \tag{4.41}$$

where $d := (d_1, \ldots, d_N)$ is an eigenvector of the matrix $\Lambda(B, \alpha, \vec{a}; z)$.

As in the Sec. IV C we would like to say something about the number of eigenvalues in each gap. We already know that this number is limited from above by N. Denoting $\alpha_j = \tilde{\alpha}_j + \overline{\alpha}$ we can split the matrix $\Lambda(z, \alpha)$ into two parts,

$$\Lambda(z, \alpha) = \overline{\alpha} I - M(z, \tilde{\alpha}), \tag{4.42}$$

where $\tilde{\alpha}:=(\tilde{\alpha}_1,\ldots,\tilde{\alpha}_N)$. The explicit form of the matrix M can be obtained from the relations (4.34) and (4.35) by changing the signs and substituting α_j by $\tilde{\alpha}_j$. The same can be done for the formulas (4.37) which express the behavior around the singularity. In the limit $z\to z_0$ one can neglect the parameters $\tilde{\alpha}_j$'s. Then it is possible to write

$$M(z,\tilde{\alpha})=\frac{1}{z_0-z}\,\frac{|B|}{\pi d}\,\overline{M}(z_0)+\mathcal{O}(1),$$

where

$$\overline{M}_{jj}(z_0)=\sum_{i\in J(z_0)}\sin^2\left(\frac{\pi n_i b_j}{d}\right),$$

$$\overline{M}_{mj}(z_0)=\Phi_B(\vec{a}_m,\vec{a}_j)\sum_{i\in J(z_0)}L_{m_i}\left(\frac{|B|}{2}|a_m-a_j|^2\right)\sin\left(\frac{\pi n_i b_j}{d}\right)\sin\left(\frac{\pi n_i b_m}{d}\right).$$

Following Ref. 22 the eigenvalues of $\Lambda(z)$ monotonously increase between two neighboring singularities. Then all eigenvalues of $\overline{M}$ are non-negative numbers. For $\Sigma_{j=1}^{N}\Sigma_{i\in J(z_0)}\sin^2(\pi n_i b_j/d)\neq 0$ at least one is positive, hence at least one eigenvalue of the matrix $M(z,\tilde{\alpha})$ diverges to $-\infty$ or to ∞ as $z\to z_{0+}$, $z\to z_{0-}$, respectively. Let us summarize the results:

Theorem 4.5: *Let the operator $H^B(\alpha,\vec{a})$ be defined by (4.3) and (4.4), where $\vec{a}=(\vec{a}_1,\ldots,\vec{a}_N)$ and $\alpha=(\alpha_1,\ldots,\alpha_N)$ and the boundary condition is replaced by (4.31). Then*

(a) $\sigma_{ess}(H^B(\alpha,\vec{a}))=\{|B|(2m+1)+(\pi n/d)^2: m,n-1\in\mathbb{N}_0\}$.

(b) *For any $\alpha\in\mathbb{R}^N$ there exists at most N eigenvalues between every two neighboring values from the essential spectrum with the multiplicity taken into account. The corresponding eigenfunctions are given by (4.41).*

(c) *In the limits $\min_{1\leqslant j\leqslant N}\alpha_j\to\infty$ and $\max_{1\leqslant j\leqslant N}\alpha_j\to-\infty$ at least one eigenvalue converges to each value z_0 from the essential spectrum from below and from above, respectively, with the exception of the case when the leading term coefficients in (4.37) are zero. In the strong limit case there are also N eigenvalues given by (4.26) with corresponding eigenfunctions given by (4.30), where α and $\vec{a}$ is replaced by α_j and $\vec{a}_j$ for $j=1,\ldots,N$.*

Further results on the number of eigenvalues of the Hamiltonian H_0^B can be obtained in the same way as in Ref. 23.

Remark 4.6: If some of the point interactions are vertically arranged, we cannot exclude that eigenvalues are absent in a particular gap for some α.

Consider two point interactions placed at $(0,0,1/4d)$ and $(0,0,2/3d)$ with $\tilde{\alpha}_1=\tilde{\alpha}_2=0$. The numerical calculation for $B=1$ and $d=\pi$ shows that the eigenvalues of matrix $M(z,\tilde{\alpha})$ for $z\in(z_0(1,1),z_0(0,2))$ cover the whole $\mathbb{R}$ except one gap (see Fig. 6). The symbol $z_0(m,n)$ represents the Landau level $z_0=|B|(2m+1)+(\pi n/d)^2$. Hence for $\overline{\alpha}$ from this gap the matrix Λ has no eigenvalue in the interval $(z_0(1,1),z_0(0,2))=(4,5)$.

V. CONCLUSIONS

We have analyzed here spectral and scattering properties of a hard-wall layer with a finite number of point interactions. The results offer one more illustration of the efficiency of Krein's formula which allows us to reduce the task in fact to an algebraic problem. There are other interesting questions related to systems with finitely many perturbations such as relations between the perturbation configurations and the spectra including the nodal structure, etc., positions of resonances including those coming from perturbation of the embedded eigenvalues, and so on. To keep this article within reasonable limits, however, we postpone these questions to a sequel.

The same applies to systems with an infinite number of point obstacles which offer a wider variety of spectral types. Let us briefly mention several problems which we regard as worthy of

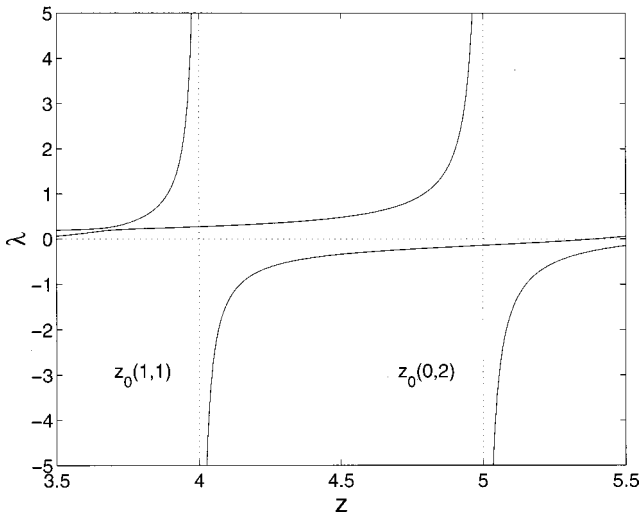

FIG. 6. The behavior of two eigenvalues of the matrix $M(z,\tilde{\alpha})$ for $z\in(4,5)$.

attention. One of them concerns the number of gaps in periodic systems. A periodic layer of point interactions in $\mathbb{R}^3$ has at most one gap (Ref. 2, Sec. III.1, or Ref. 24). On the other hand, it is known that the presence of boundaries can enhance the number of gaps in the two-dimensional case;[5] a similar effect is expected in dimension three: for a thin enough layer there will be many open gaps between the first and the second transverse threshold. A more difficult question concerns the validity of the Bohr–Sommerfeld conjecture in such systems.

Even more interesting are spectral properties of periodically perturbed layers in the presence of a magnetic field. It is well known that a combination of a square lattice of point interactions and a homogeneous magnetic field leads to a very rich spectrum whose properties depend substantially on the number-theoretical properties of the ratio between the lattice spacing and the field intensity (which determines the cyclotronic radius) (see Ref. 2, Sec. III.2.5, or Ref. 25). Putting such a system into a layer brings a third parameter (the layer width d) which will determine how ''thickly'' the transverse-mode component are overlayed in the spectrum.

The same applies to edge-type states. It was shown recently that an equidistant array of point interaction in combination with a homogeneous magnetic field can produce bands of absolutely continuous spectrum away from the Landau levels.[26] One is naturally interested in how the spectrum will change if the array is confined between a pair of hard walls. Other problems concern aperiodic perturbations, external electric field, spin effects, etc.

Semiclassics in the lowest Landau band

Christian Hainzl[a)]
Institut für Theoretische Physik, Universität Wien, Boltzmanngasse 5, A-1090 Vienna, Austria

(Received 21 June 2001; accepted for publication 15 November 2001)

This article deals with the comparison between the strong Thomas–Fermi theory and the quantum mechanical ground state energy of a large atom confined to lowest Landau band wave functions. Using the tools of microlocal semiclassical spectral asymptotics we derive precise error estimates. The approach presented in this article suggests the definition of a modified strong Thomas–Fermi functional, where the main modification consists in replacing the integration over the variables perpendicular to the magnetic field by an expansion in angular momentum eigenfunctions. The resulting DSTF theory is studied in detail in the second part of the article. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1432776]

I. INTRODUCTION

In this article we study semiclassical theories describing the ground state energies of heavy atoms in strong homogeneous magnetic fields, where additionally the electrons are confined to the lowest Landau band.

An atom with N electrons of charge $-e$ and mass m_e and nuclear charge Ze is described by the nonrelativistic Pauli Hamiltonian operator

$$H_N=\sum_{1\leqslant j\leqslant N}\left\{((-i\nabla^{(j)}+\mathbf{A}(x_j))\cdot\sigma^j)^2-\frac{Z}{|x_j|}\right\}+\sum_{1\leqslant i<j\leqslant N}\frac{1}{|x_i-x_j|}, \tag{I.1}$$

acting on the Hilbertspace $\wedge_{1\leqslant j\leqslant N}L^2(\mathbb{R}^3,\mathbb{C}^2)$ of electrons. The units are chosen such that $\hbar=2m_e=e=1$. The magnetic field is $\mathbf{B}=(0,0,B)$, with vector potential $\mathbf{A}=\frac{1}{2}B(-x_2,x_1,0)$, where B is the magnitude of the field in units of $B_0=m_e^2e^3c/\hbar^3=2.35\times10^9$ G, the field strength for which the cyclotron radius $l_B=(\hbar c/(eB))^{1/2}$ is equal to the Bohr radius $a_0=\hbar^2/(m_ee^2)$. The ground state energy is

$$E^{\mathrm{Q}}(N,Z,B)=\inf\{(\psi,H_N\psi):\psi\in\text{domain } H_N,(\psi,\psi)=1\}. \tag{I.2}$$

Recall that the spectrum of the free Pauli Hamiltonian on $\mathcal{L}^2(\mathbb{R}^3;\mathbb{C}^2)$ for one electron in the magnetic field $\mathbf{B}$,

$$H_{\mathbf{A}}=[\boldsymbol{\sigma}\cdot(-i\nabla+\mathbf{A}(\mathbf{x}))]^2, \tag{I.3}$$

is given by

$$p_z^2+2\nu B,\quad \nu=0,1,2,\ldots,\quad p_z\in\mathbb{R}. \tag{I.4}$$

The projector Π_0 onto the lowest Landau band, $\nu=0$, is represented by the kernel

$$\Pi_0(\mathbf{x},\mathbf{x}')=\frac{B}{2\pi}\exp\left\{\frac{i}{2}(\mathbf{x}_\perp\times\mathbf{x}'_\perp)\cdot\mathbf{B}-\frac{1}{4}(\mathbf{x}_\perp-\mathbf{x}'_\perp)^2B\right\}\delta(z-z')P_\downarrow, \tag{I.5}$$

a)Present address: Institut für Mathematik, LMU-München, Theresienstr. 39, D-80333 München; electronic mail: hainzl@rz.mathematik.uni-muenchen.de

where $\mathbf{x}_\perp$ and z are the components of $\mathbf{x}$ perpendicular and parallel to the magnetic field, and $P_\downarrow$ denotes the projection onto the spin-down component.

In this article we are especially interested in the ground state energy,

$$E^{\mathrm{Q}}_{\mathrm{conf}}(N,Z,B)=\inf_{\|\psi\|=1}(\psi,\Pi_0^N H_N \Pi_0^N \psi), \tag{I.6}$$

where Π_0^N denotes the Nth tensorial power of Π_0. Lieb, Solovej, and Yngvason pointed out that for $B\gg Z^{4/3}$ the electrons are to the leading order confined to the lowest Landau band, which is expressed by the following theorem.

Theorem I.1: *(Ref. 1, Theorem 1.2): For any fixed $\lambda=N/Z$ there is a $\delta(x)$ with $\delta(x)\to 0$ as $x\to\infty$ such that*

$$E^{\mathrm{Q}}_{\mathrm{conf}}\geqslant E^{\mathrm{Q}}\geqslant E^{\mathrm{Q}}_{\mathrm{conf}}(1+\delta(B/Z^{4/3})). \tag{I.7}$$

The energy (I.6) can be approximated by means of the STF-functional (strong Thomas–Fermi),

$$\mathcal{E}^{\mathrm{STF}}[\rho]=\frac{4\pi^4}{3B^2}\int \rho^3-\int V\rho+D(\rho,\rho), \tag{I.8}$$

$V(x)=Z/|x|$ and $D(\rho,\rho)=\frac{1}{2}(\rho,|x|^{-1}*\rho)$. In Ref. 2 it is shown that $E^{\mathrm{Q}}/E^{\mathrm{STF}}\to 1$ if $Z\to\infty$, $B/Z^3\to 0$ and $B/Z^{4/3}\to\infty$, where

$$E^{\mathrm{STF}}(N,Z,B)=\inf\left\{\mathcal{E}^{\mathrm{STF}}[\rho]\,\middle|\,\rho\geqslant 0,\rho\in D^{\mathrm{STF}},\int\rho\leqslant N\right\}, \tag{I.9}$$

with an appropriately chosen domain D^{STF}. Combined with Theorem I.1 this implies Theorem I.2

Theorem I.2: *(Ref. 2) If $Z\to\infty$ with N/Z fixed, $B/Z^3\to 0$ and $B/Z^{4/3}\to\infty$, then*

$$E^{\mathrm{Q}}_{\mathrm{conf}}(N,Z,B)/E^{\mathrm{STF}}(N,Z,B)\to 1. \tag{I.10}$$

This article contains an intensive study of the STF functional and of related functionals describing lowest Landau band particles. A justification for such studies is the fact that these functionals are of much simpler form than the original MTF (Magnetic Thomas-Fermi) functional (cf. Ref. 2), since the concerning kinetic energy density is the Legendre transform of the Fermi pressure P_B, i.e.

$$\tau_B(t)=\sup_{w\geqslant 0}[tw-P_B(w)], \tag{I.11}$$

with

$$P_B(w)=\frac{B}{3\pi^2}\left(w^{3/2}-2\sum_{i=1}^{\infty}\left|2iB-w\right|_-^{3/2}\right), \tag{I.12}$$

which is probably somewhat harder to deal with than (I.8).

A. Comparing the STF energy with the QM ground state energy in the lowest Landau band

In this article we not only want to give a direct proof of Theorem I, but we want to derive precise error estimates. In this respect our procedure is related to Refs. 3 and 4. Our main theorem is the following:

Theorem I.3: *Let $N\sim Z$ and $Z^{4/3}\leqslant B\leqslant Z^3$. Then*

$$|E^{\mathrm{Q}}_{\mathrm{conf}}(N,Z,B)-E^{\mathrm{STF}}(N,Z,B)|\leqslant CB^{4/5}Z^{3/5} \tag{I.13}$$

for an appropriate constant C.

Remark I.4: In Ref. 4 Ivrii estimated the difference between the full quantum mechanical energy E^{Q} and the MTF energy, which is given by minimizing the MTF functional (cf. Ref. 2), where all Landau levels are taken into account. The main theorem in Ref. 4 reads as follows.

Theorem I.5: *(Ref. 4, Theorem 0.2): Let $B \leqslant Z^3$ and $N \sim Z$. Then*

$$\left|E^{Q}(N,Z,B) - E^{\mathrm{MTF}}(N,Z,B) - \tfrac{1}{4}Z^2\right| \leqslant R_1 + R_2, \tag{I.14}$$

with

$$R_1 = CZ^{4/3}(N+B)^{1/3} \quad \textit{and} \quad R_2 = CZ^{3/5}B^{4/5}. \tag{I.15}$$

Remark I.6: Although true for all $B \leqslant Z^3$, it should be noted that only for $B < Z^{7/4}$ are the error terms R_1 and R_2 smaller than the Scott term $\frac{1}{4}Z^2$.

One of the main difficulties Ivrii has to cope with in the proof of Theorem I.5 is the fact that the self-consistent MTF potential is not smooth, because it includes all Landau levels. So he has to create an approximating C^{∞} potential in order to apply the tools of microlocal semiclassical spectral asymptotics. Fortunately, in our case of Theorem I.3 we need not care about such problems, since the STF potential [see (I.19)] has all required properties for semiclassical spectral asymptotics.

Moreover, in Theorem I.5 Ivrii already captures (I.13) on the region where only the lowest Landau band is occupied, i.e., on $\{\mathbf{x} \mid |\mathbf{x}| \geqslant C_0 Z/B\}$ with a large constant C_0.

Remark I.7: A good guess cencerning the magnitude of the difference between the physical ground state energy E^{Q} and the confined energy E^{Q}_{conf} is given by

$$\left|E^{Q} - E^{Q}_{\mathrm{conf}}\right| \sim \left|E^{\mathrm{MTF}} - E^{\mathrm{STF}}\right| \lesssim Z^3/B^{1/2}, \tag{I.16}$$

as presented in Ref. 5. Combined with (I.13) this leads to the estimate

$$\left|E^{Q} - E^{\mathrm{STF}}\right| \lesssim Z^3/B^{1/2} + B^{4/5}Z^{3/5}. \tag{I.17}$$

Therefore, the region, where from a physical point of view it is meaningful to use the STF functional intead of the MTF functional, is given by

$$Z^{24/13} \leqslant B \leqslant Z^3, \tag{I.18}$$

which is imposed by the condition $Z^3/B^{1/2} \leqslant B^{4/5}Z^{3/5}$. Nevertheless, E^{STF} produces the right leading order for $Z^{4/3} \ll B \ll Z^3$, which justifies, in some sense, the mathematical analysis of Theorem I.3 on the whole region $Z^{4/3} \leqslant B \leqslant Z^3$.

Next we mention some important steps of the proof of Theorem I.3. Let ϕ^{STF} denote the effective STF potential (for simplicity think of the neutral case $N = Z$)

$$\phi^{\mathrm{STF}}(x) = Z|x|^{-1} - \rho^{\mathrm{STF}} * |x|^{-1}, \tag{I.19}$$

where ρ^{STF} is the minimizer of the STF functional (I.8). We will see in Sec. II.A that the main contribution of (I.13) is given by

$$\left| \mathrm{Tr}[\Pi_0 (H_{\mathbf{A}} - \phi^{\mathrm{STF}}(\mathbf{x}))\Pi_0]_- - \frac{B}{2\pi}\int_{\mathbb{R}^3}\int_{\mathbb{R}} \frac{dp\,d\mathbf{x}}{2\pi}[p^2 - \phi^{\mathrm{STF}}(\mathbf{x})]_- \right|, \tag{I.20}$$

with $[t]_- = \min\{0,t\}$. Recall

$$E^{\mathrm{STF}} = \frac{B}{2\pi}\int_{\mathbb{R}^3}\int_{\mathbb{R}} \frac{dp\,dx}{2\pi}[p^2 - \phi^{\mathrm{STF}}(\mathbf{x})]_- - D(\rho^{\mathrm{STF}}, \rho^{\mathrm{STF}}). \tag{I.21}$$

With the decomposition $\mathcal{L}^2(\mathbb{R}^3,d\mathbf{x};\mathbb{C}^2)=\mathcal{L}^2(\mathbb{R}^2,d\mathbf{x}_\perp)\otimes\mathcal{L}^2(\mathbb{R},dz)\otimes\mathbb{C}^2$ the projector Π_0 can be written as

$$\Pi_0=\sum_{m\geqslant 0}|\phi_m\rangle\langle\phi_m|\otimes 1\otimes P_\downarrow, \tag{I.22}$$

where ϕ_m denotes the function in the lowest Landau band with angular momentum $-m\leqslant 0$, i.e., using polar coordinates (r,φ),

$$\phi_m(\mathbf{x}_\perp)=\sqrt{\frac{B}{2\pi}}\frac{1}{\sqrt{m!}}\left(\frac{Br^2}{2}\right)^{m/2}e^{-im\varphi}e^{-Br^2/4}. \tag{I.23}$$

Using this and $H_{\mathbf{A}}\Phi_m=0$, we can write

$$\Pi_0 H_{\mathbf{A}}\Pi_0=\sum_{m\geqslant 0}|\phi_m\rangle\langle\phi_m|\otimes(-\partial_z^2)\otimes P_\downarrow. \tag{I.24}$$

By means of the above decompositions one gets the relation (cf. Ref. 5, Theorem 3.13)

$$\mathrm{Tr}[\Pi_0(-\partial_z^2-\phi^{\mathrm{STF}}(\mathbf{x}))\Pi_0]_-=\sum_m \mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}[-\partial_z^2-\phi_m^{\mathrm{STF}}(z)]_-, \tag{I.25}$$

with

$$\phi_m^{\mathrm{STF}}(z)=\int d\mathbf{x}_\perp\,\phi^{\mathrm{STF}}(\mathbf{x})|\phi_m(\mathbf{x}_\perp)|^2. \tag{I.26}$$

Next we multiply the mth term of the right hand side of (I.25) with $(B/2\pi)\,\chi_m(\mathbf{x}_\perp)$, where

$$\chi_m(\mathbf{x}_\perp)=\begin{cases}1 & \text{for } \sqrt{2m/B}\leqslant|\mathbf{x}_\perp|\leqslant\sqrt{2(m+1)/B},\\ 0 & \text{otherwise,}\end{cases} \tag{I.27}$$

and integrate over $\mathbf{x}_\perp$, which is just an identity operation. Since we are allowed to put the sum into the trace as well into the $[\,]_-$ bracket we arrive at

$$\mathrm{Tr}[\Pi_0[-\partial_z^2-\phi^{\mathrm{STF}}(\mathbf{x})]\Pi_0]_-=\frac{B}{2\pi}\int d\mathbf{x}_\perp\,\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}[-\partial_z^2-\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})]_-, \tag{I.28}$$

with

$$\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})=\sum_m \chi_m(\mathbf{x}_\perp)\,\phi_m^{\mathrm{STF}}(z). \tag{I.29}$$

The equation (I.28) follows from the fact that the terms $\chi_m(\mathbf{x}_\perp)\phi_m^{\mathrm{STF}}(z)$ in (I.29) have disjoint supports.

Hence, (I.20) can be written as

$$\left|\frac{B}{2\pi}\int_{\mathbb{R}^2}d\mathbf{x}_\perp\left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}[-\partial_z^2-\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})]_- -\int_{\mathbb{R}^2}\frac{dzdp}{2\pi}[p^2-\phi^{\mathrm{STF}}(\mathbf{x})]_-\right)\right|. \tag{I.30}$$

We shall estimate (I.30) by splitting into the following two terms:

$$\left|\frac{B}{2\pi}\int_{\mathbb{R}^2}d\mathbf{x}_\perp\left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}[-\partial_z^2-\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})]_- -\int_{\mathbb{R}^2}\frac{dzdp}{2\pi}[p^2-\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})]_-\right)\right|. \tag{I.31}$$

and

$$\left| \frac{B}{2\pi} \int_{\mathbb{R}^2} d\mathbf{x}_\perp \left(\int_{\mathbb{R}} \frac{dzdp}{2\pi} [p^2 - \widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})]_- - \int_{\mathbb{R}^2} \frac{dzdp}{2\pi} [p^2 - \phi^{\mathrm{STF}}(\mathbf{x})]_- \right) \right|. \tag{I.32}$$

B. Modified STF functionals

From Eqs. (I.25) and (I.28) it is apparent that the STF energy (I.9) is not the most natural semiclassical approximation of $E^{\mathrm{Q}}_{\mathrm{conf}}$. As already argued in Ref. 5, (I.25) suggests the definition of a functional, where the integration over $\mathbf{x}_\perp$, the variables orthogonal to the magnetic field, is replaced by an expansion in angular momentum eigenfunctions in the lowest Landau band. This leads to a *discrete STF functional* (DSTF) depending on a sequence of one-dimensional densities $\rho = (\rho_n)_{n \in \mathbb{N}_0}$, i.e.,

$$\mathcal{E}^{\mathrm{DSTF}}[\rho] = \sum_{m \in \mathbb{N}_0} \left(\kappa \int \rho_m(z)^3 - Z \int V_m(z) \rho_m(z) dz \right) + \overline{D}(\rho, \rho), \tag{I.33}$$

where $\kappa = \pi^2/3$,

$$\overline{D}(\rho, \rho) = \frac{1}{2} \sum_{m,n} \int V_{m,n}(z - z') \rho_m(z) \rho_n(z') dz dz', \tag{I.34}$$

and the potentials V_m and $V_{m,n}$ are given by

$$\begin{aligned} V_m(z) &= \int \frac{1}{|\mathbf{x}|} |\phi_m(\mathbf{x}_\perp)|^2 d\mathbf{x}_\perp, \\ V_{m,n}(z - z') &= \int \frac{|\phi_m(\mathbf{x}_\perp)|^2 |\phi_n(\mathbf{x}_\perp')|^2}{|\mathbf{x} - \mathbf{x}'|} d\mathbf{x}_\perp d\mathbf{x}_\perp'. \end{aligned} \tag{I.35}$$

An equivalent functional, depending on a three-dimensional density ρ, can be obtained as in (I.28), if in STF theory the Coulomb potential is replaced by

$$\widetilde{|\mathbf{x}|^{-1}} = \sum_m \chi_m(\mathbf{x}_\perp) \int_{\mathbb{R}^2} d\mathbf{x}_\perp |\mathbf{x}|^{-1} \phi_m(\mathbf{x}_\perp). \tag{I.36}$$

The resulting *modified* STF functional is given by

$$\mathcal{E}^{\mathrm{MSTF}}[\rho] = \frac{4\pi^4}{3B^2} \int d\mathbf{x} \rho(\mathbf{x})^3 - \int d\mathbf{x} \widetilde{|\mathbf{x}|^{-1}} \rho(\mathbf{x}) + \tilde{D}(\rho, \rho), \tag{I.37}$$

with

$$\tilde{D}(\rho, \rho) = \frac{1}{2} \sum_{m,n} \int d\mathbf{x} d\mathbf{y} V_{m,n}(z - z') \chi_m(\mathbf{x}_\perp) \chi_n(\mathbf{y}_\perp) \rho(\mathbf{x}) \rho(\mathbf{y}). \tag{I.38}$$

Let $\rho^{\mathrm{DSTF}} = (\rho_m^{\mathrm{DSTF}}(z))_m$ and $\rho^{\mathrm{MSTF}} = \rho^{\mathrm{MSTF}}(\mathbf{x})$ be the ground state densities of (I.33) and (I.37), respectively, corresponding to a fixed particle number N. Then the relationship between the densities reads

$$\rho^{\mathrm{MSTF}}(\mathbf{x}) = \frac{B}{2\pi} \sum_m \rho_m^{\mathrm{DSTF}}(z) \chi_m(\mathbf{x}_\perp). \tag{I.39}$$

Furthermore, the energies are equal,

$$E^{\mathrm{MSTF}}(N,Z,B)=E^{\mathrm{DSTF}}(N,Z,B). \tag{I.40}$$

Since a short computation shows that for $B\geqslant Z^{4/3}$ the difference between the D(M)STF energy and the STF energy is smaller than $B^{4/5}Z^{3/5}$, the estimate (I.13) with STF replaced by D(M)STF immediately follows for this region ($B\geqslant Z^{4/3}$).

Theorem I.8: *Let $Z^{4/3}\leqslant B\leqslant Z^3$ and $N\sim Z$. Then*

$$\left|E^{\mathrm{Q}}_{\mathrm{conf}}(N,Z,B)-E^{\mathrm{D(M)STF}}(N,Z,B)\right|\leqslant CB^{4/5}Z^{3/5}. \tag{I.41}$$

II. PROOF OF THEOREM I.3

A. Derivation of lower and upper bounds to $E^{\mathrm{Q}}_{\mathrm{conf}}$

First of all, recall that the TF equation satisfied by the minimizer of (I.8) under the constraint $\int\rho=N$ is

$$\kappa(\rho^{\mathrm{STF}})^2/B^2=[Z|\mathbf{x}|^{-1}-\rho^{\mathrm{STF}}+\nu]_+=[\phi^{\mathrm{STF}}+\nu]_+, \tag{II.1}$$

where $\nu=\nu(N)$ is the chemical potential corresponding to the electron number N. Using (II.1) one sees that the STF energy (I.9) can be written as

$$E^{\mathrm{STF}}=\frac{B}{2\pi}\int_{\mathbb{R}^2}d\mathbf{x}_\perp\int_{\mathbb{R}}\frac{dzdp}{2\pi}[p^2-\phi^{\mathrm{STF}}(\mathbf{x})-\nu]_-+\nu N-D(\rho^{\mathrm{STF}},\rho^{\mathrm{STF}}). \tag{II.2}$$

This expression will be used for deriving upper and lower bounds to the quantum mechanical ground state energy $E^{\mathrm{Q}}_{\mathrm{conf}}$.

1. Lower bound

Let ψ denote a ground state wave function of H_N. Then we can write $E^{\mathrm{Q}}_{\mathrm{conf}}$ as

$$E^{\mathrm{Q}}_{\mathrm{conf}}=(\psi,\Pi_0^N H_N\Pi_0^N\psi)=\sum_{i=1}^N(\psi,\Pi_0^N[H_A(\mathbf{x}_i)-Z|\mathbf{x}_i|^{-1}+\rho^{\mathrm{STF}}*|\mathbf{x}_i|^{-1}-\nu]\Pi_0^N\psi)$$
$$+N\nu-2D(\rho_\psi,\rho^{\mathrm{STF}})+\sum_{i<j}(\psi,|\mathbf{x}_i-\mathbf{x}_j|^{-1}\psi), \tag{II.3}$$

where we have added and subtracted the term $\rho^{\mathrm{STF}}*|\mathbf{x}|^{-1}-\nu$ and used the definition

$$\rho_\psi(\mathbf{x})=N\sum_{s^i}\int|\psi(\mathbf{x},x_2,\ldots,x_N;s^1,\ldots,s^N)|^2dx_2\cdots dx_N. \tag{II.4}$$

By means of the Lieb–Oxford inequality[6]

$$\sum_{i<j}(\psi,|\mathbf{x}_i-\mathbf{x}_j|^{-1}\psi)\geqslant D(\rho_\psi,\rho_\psi)-1.68\int\rho_\psi^{4/3}, \tag{II.5}$$

(II.3) can be bounded from below by

$$E^{\mathrm{Q}}_{\mathrm{conf}}\geqslant\mathrm{Tr}[\Pi_0(H_{\mathbf{A}}-\phi^{\mathrm{STF}}-\nu)\Pi_0]_--D(\rho^{\mathrm{STF}},\rho^{\mathrm{STF}})+\nu N-1.68\int\rho_\psi^{4/3}, \tag{II.6}$$

where we have used that

$$D(\rho_\psi-\rho^{\mathrm{STF}},\rho_\psi-\rho^{\mathrm{STF}})\geqslant 0. \tag{II.7}$$

Furthermore, by (I.28) and (II.2) we get

$$E^{\mathrm{Q}}_{\mathrm{conf}} \geqslant E^{\mathrm{STF}} - \mathcal{R}_1 - 1.68 \int \rho_\psi^{4/3}, \tag{II.8}$$

with

$$\mathcal{R}_1 = \left| \frac{B}{2\pi} \int_{\mathbb{R}^2} d\mathbf{x}_\perp \left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})} [-\partial_z^2 - \widetilde{\phi^{\mathrm{STF}}}(\mathbf{x}) - \nu]_- - \int_{\mathbb{R}^2} \frac{dz dp}{2\pi} [p^2 - \phi^{\mathrm{STF}}(\mathbf{x}) - \nu]_- \right) \right|. \tag{II.9}$$

Since ψ is a ground state wave function, or at least an approximate ground state wave function, we can estimate [cf. Ref. 1, (8.5)]

$$\int \rho_\psi^{4/3} \leqslant \left(\int \rho_\psi^3 \right)^{1/6} \left(\int \rho_\psi \right)^{5/6} \leqslant \mathrm{const}(B^2 |E^{\mathrm{STF}}|)^{1/6} N^{5/6} \leqslant \mathrm{const}\, Z^{1/5} N^{14/15} B^{2/5} \leqslant C B^{4/5} Z^{3/5}, \tag{II.10}$$

using $N \sim Z$ and $B \geqslant Z^{4/3}$.

2. Upper bound

For every fixed integer N and a normalized N-particle wave function ψ we have

$$E^{\mathrm{Q}}_{\mathrm{conf}} \leqslant (\psi, \Pi_0^N H_N \Pi_0^N \psi) = \sum_{i=1}^N (\psi, \Pi_0^N [H_A(\mathbf{x}_i) - Z|\mathbf{x}_i|^{-1} + \rho^{\mathrm{STF}} * |\mathbf{x}_i|^{-1} - \nu] \Pi_0^N \psi)$$

$$+ N\nu - 2D(\rho_\psi, \rho^{\mathrm{STF}}) + \sum_{i<j} (\psi, |\mathbf{x}_i - \mathbf{x}_j|^{-1} \psi). \tag{II.11}$$

We set

$$\psi = \frac{1}{\sqrt{N!}} \phi_1 \wedge \cdots \wedge \phi_N, \tag{II.12}$$

where ϕ_i is the eigenvector corresponding to the ith lowest eigenvalue λ_i of the one-particle operator

$$\Pi_0 (H_A - Z|\mathbf{x}|^{-1} + \rho^{\mathrm{STF}} * |\mathbf{x}|^{-1}) \Pi_0. \tag{II.13}$$

By means of the decomposition,

$$\mathrm{Tr}[\Pi_0 (H_A(\mathbf{x}) - \phi^{\mathrm{STF}}(\mathbf{x}) - \nu) \Pi_0]_- = \sum_i [\lambda_i - \nu]_- = \sum_{i=1}^N (\lambda_i - \nu) + \sum_{\lambda_N < \lambda_i < \nu} (\lambda_i - \nu), \tag{II.14}$$

and the equation (II.7) we can estimate (II.11) as

$$E^{\mathrm{Q}}_{\mathrm{conf}} \leqslant \mathrm{Tr}[\Pi_0 (H_A - \phi^{\mathrm{STF}} - \nu) \Pi_0]_- + \nu N - D(\rho^{\mathrm{STF}}, \rho^{\mathrm{STF}})$$

$$+ D(\rho_\psi - \rho^{\mathrm{STF}}, \rho_\psi - \rho^{\mathrm{STF}}) - \sum_{\lambda_N < \lambda_i < \nu} (\lambda_i - \nu), \tag{II.15}$$

which implies

$$E^{\mathrm{Q}}_{\mathrm{conf}} \leqslant \mathcal{R}_1 + R_2 + R_3, \tag{II.16}$$

with

$$R_2 = -\sum_{\lambda_N < \lambda_i < \nu} (\lambda_i - \nu), \tag{II.17}$$

$$R_3 = D(\rho_\psi - \rho^{\mathrm{STF}}, \rho_\psi - \rho^{\mathrm{STF}}). \tag{II.18}$$

Since it is difficult to tackle directly the term R_2, we estimate R_2 by $|\lambda_N - \nu|$ multiplied by the number of eigenvalues of the operator (II.13) between λ_N and ν. We know

$$\frac{B}{2\pi}\int d\mathbf{x}_\perp \int \frac{dzdp}{2\pi}\Theta_-(p^2 - \phi^{\mathrm{STF}}(\mathbf{x}) - \nu) = \int \rho^{\mathrm{STF}} = N, \tag{II.19}$$

with

$$\Theta_-(t) = \begin{cases} 1 & \text{for } t \leqslant 0, \\ 0 & \text{otherwise.} \end{cases} \tag{II.20}$$

So the number of eigenvalues of (II.13) between λ_N and ν can be expressed by

$$\mathrm{Tr}\Theta_-(\Pi_0(-\partial_z^2 - \phi^{\mathrm{STF}}(\mathbf{x}) - \nu)\Pi_0) - \frac{B}{2\pi}\int d\mathbf{x}_\perp \int \frac{dzdp}{2\pi}\Theta_-(p^2 - \phi^{\mathrm{STF}}(\mathbf{x}) - \nu). \tag{II.21}$$

Mimicking the derivation of (I.28), with $[t]_-$ being replaced by $\Theta_-(t)$, leads to

$$(\text{II.21}) = \frac{B}{2\pi}\int_{\mathbb{R}^2} d\mathbf{x}_\perp \left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}\Theta_-(\tilde{H}_{\mathbf{x}_\perp} - \nu) - \int \frac{dzdp}{2\pi}\Theta_-(h_{\mathbf{x}_\perp} - \nu)\right), \tag{II.22}$$

where we have defined

$$\tilde{H}_{\mathbf{x}_\perp} = -\partial_z^2 - \widetilde{\phi^{\mathrm{STF}}}(\mathbf{x}) \quad \text{and} \quad h_{\mathbf{x}_\perp} = p^2 - \phi^{\mathrm{STF}}(\mathbf{x}). \tag{II.23}$$

Hence, instead of R_2 we estimate the error term

$$\mathcal{R}_2 = |\lambda_N - \nu|\frac{B}{2\pi}\int_{\mathbb{R}^2} d\mathbf{x}_\perp \left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}\Theta_-(\tilde{H}_{\mathbf{x}_\perp} - \nu) - \int \frac{dzdp}{2\pi}\Theta_-(h_{\mathbf{x}_\perp} - \nu)\right). \tag{II.24}$$

We introduce the notation

$$e(\tilde{H}_{\mathbf{x}_\perp}, \mu) = \Theta_-(\tilde{H}_{\mathbf{x}_\perp} - \mu), \tag{II.25}$$

the projector of the operator $\tilde{H}_{\mathbf{x}_\perp}$ onto the eigenspace corresponding to the eigenvalues smaller or equal to μ. Let ψ be given by (II.12). Then we have

$$\rho_\psi(\mathbf{x}) = \frac{B}{2\pi} e(z, z; \tilde{H}_{\mathbf{x}_\perp}, \lambda_N), \tag{II.26}$$

whereas the semiclassical density ρ^{STF} can be written as

$$\rho^{\mathrm{STF}}(\mathbf{x}) = \frac{B}{2\pi}\int_{\mathbb{R}} dp\,\Theta_-(h_{\mathbf{x}_\perp} - \nu) = \frac{B}{2\pi}[\phi^{\mathrm{STF}}(\mathbf{x}) + \nu]_+^{1/2}. \tag{II.27}$$

Furthermore, we introduce the auxiliary density

$$\overline{\rho}(\mathbf{x}) = \frac{B}{2\pi}[\phi^{\mathrm{STF}}(\mathbf{x}) + \lambda_N]_+^{1/2}. \tag{II.28}$$

In order to bound the error term R_3 from above, we combine the two terms

$$\mathcal{R}_3 = D(\rho_\psi - \overline{\rho}, \rho_\psi - \overline{\rho}), \tag{II.29}$$

$$\mathcal{R}_4 = D(\rho^{\mathrm{STF}} - \overline{\rho}, \rho^{\mathrm{STF}} - \overline{\rho}), \tag{II.30}$$

which are easier to handle than R_3 alone. Observe that by convexity one has $R_3 \leqslant 2\mathcal{R}_3 + 2\mathcal{R}_4$. In the next sections we will separately have to carry out the estimations

$$\mathcal{R}_i \leqslant C B^{4/5} Z^{3/5} \quad \forall i = 1,...,4. \tag{II.31}$$

B. Methods used in the proof

The methods used here in order to estimate the error terms $\mathcal{R}_{1-4}$, have been established in Refs. 3 and 7. For the sake of better understanding we will state here the most important theorem, which we use throughout this section.

Consider the Schrödinger operator

$$H = -\tfrac{1}{2}\Delta - \phi(\mathbf{x}) \text{ on } \mathbb{R}^d. \tag{II.32}$$

Its symbol is denoted by

$$\overline{h} = \tfrac{1}{2}p^2 - \phi(\mathbf{x}). \tag{II.33}$$

In addition there are the following conditions imposed on the real potential ϕ:

There are Lipschitz functions $l(\mathbf{x}) > 0$ and $f(\mathbf{x}) > 0$, such that

$$(i) \quad |\nabla l(\mathbf{x})| \leqslant M, \tag{II.34}$$

$$(ii) \quad c f(\mathbf{y}) \leqslant f(\mathbf{x}) \leqslant C f(\mathbf{y}), \tag{II.35}$$

$$(iii) \quad |\partial^\nu \phi(\mathbf{x})| \leqslant C_\nu f(\mathbf{x})^2 l(\mathbf{x})^{-|\nu|} \forall\, \nu \in \mathbb{N}^d. \tag{II.36}$$

Under these assumptions Ivrii and Sigal have proved the following theorem:

Theorem II.1: *(Ref. 3, Theorem 7.1.): Assume conditions (i)–(iii) are obeyed and let ψ be smooth and obey $|\partial^\nu \psi(\mathbf{x})| \leqslant C_\nu l(\mathbf{x})^{-|\nu|}$ for any ν. Let $g_s(\lambda) = [-\lambda]_+^s$ for some $s \in [0,1]$. Then*

$$\left| \mathrm{Tr}(\psi g_s(H)) - \int \frac{dx dp}{2\pi} \psi g_s(\overline{h}) \right| \tag{II.37}$$

$$\leqslant C \int_{\mathrm{supp}\psi} d\mathbf{x} \max\left[\left(\frac{1}{f(\mathbf{x}) l(\mathbf{x})} \right)^{\alpha - s - d}, 1 \right] l(\mathbf{x})^{-2s-d}. \tag{II.38}$$

Here $\alpha = 1$ if either $d \geqslant 2$ or $d = 1$ and ϕ obeys

$$|\phi(\mathbf{x})| + l(\mathbf{x}) |\nabla \phi(\mathbf{x})| \geqslant \varepsilon f(\mathbf{x})^2 \tag{II.39}$$

on $\{\mathbf{x} | l(\mathbf{x}) f(\mathbf{x}) \geqslant 1\}$, with some $\varepsilon > 0$, and $\alpha = 1/2$ otherwise.

The most important tools for the proof of Theorem II.1 are multiscale analysis and semiclassical spectral asymptotics. First of all, the domain, i.e., the support of ψ, is covered by a countable number of balls. Then on each of these balls $B(\mathbf{y}, l(\mathbf{y}))$, the operator H is transformed into

$$K_h = f^{-2} U(l) H U(l)^{-1} = -\frac{h^2}{2}\Delta - V(\mathbf{x}), \tag{II.40}$$

with $h=l(\mathbf{y})^{-1}f(\mathbf{y})^{-1}$, by means of a unitary scaling transformation $U(l)$, which maps the ball $B(\mathbf{y},l(\mathbf{y}))$ into $B(0,1)$. Next Theorem 6.1 from Ref. 3, which we state below, is applied to the sum of the negative eigenvalues of $g_s(K_h)$. After rescaling and summing over all balls one arrives at Theorem II.1.

The symbol of K_h is given by

$$k(\mathbf{x},p)=p^2/2-V(\mathbf{x}). \tag{II.41}$$

If, furthermore, all derivatives of V are bounded by a constant, i.e.,

$$|\partial^\nu V(\mathbf{x})|\leqslant C_\nu \text{ on } B(0,2)\forall i, \tag{II.42}$$

then the following theorem is valid:

Theorem II.2: *Let $\psi\in C_0^\infty(B(0,1))$ and let 0 be a regular value of the function k_0 restricted to* $\mathrm{supp}\psi\times\mathbb{R}^d$. *Then for $h\leqslant 1$*

$$\mathrm{Tr}(\psi g_s(K_h))=h^{-d}\int\frac{dxdp}{2\pi}\psi g_s(k(x,p))+O(h^{s+1-d}). \tag{II.43}$$

Assume next that the potential V can be written as

$$V(\mathbf{x})=V_0(\mathbf{x})+h\overline{V}(\mathbf{x},h), \tag{II.44}$$

such that the principal symbol of K_h reads $k_0(\mathbf{x},p)=p^2/2-V_0(\mathbf{x})$. Then, if additionally $\overline{V}$ fulfills (II.42) (uniformly in h), Theorem II.2 remains valid for $s=0$ with k replaced by the principal symbol k_0. (cf. Ref. 7, Theorem 4.5.3).

Theorem II.3: *Let $\psi\in C_0^\infty(B(0,1))$ and let 0 be a regular value of the function k_0 restricted to* $\mathrm{supp}\psi\times\mathbb{R}^d$. *Then for $h\leqslant 1$*

$$\mathrm{Tr}(\psi g_0(K_h))=h^{-d}\int\frac{dxdp}{2\pi}\psi g_0(k_0(x,p))+O(h^{1-d}). \tag{II.45}$$

C. Relationship between the potentials ϕ^{STF} and $\widetilde{\phi^{\mathrm{STF}}}$

Next we collect some information about the potentials ϕ^{STF} and $\widetilde{\phi^{\mathrm{STF}}}$.

The scaling functions, which we will use in order to apply Theorem II.1 to the operator $H_{\mathbf{x}_\perp}$, have to be chosen such that the conditions (II.34)–(II.36) hold for the potentials ϕ^{STF} and $\widetilde{\phi^{\mathrm{STF}}}$, at least away from the origin.

Since we will see that ϕ^{STF} behaves like $Z|\mathbf{x}|^{-1}$ for $|\mathbf{x}|\leqslant r_S$, the edge of the STF atom, it is thus natural to define

$$l(\mathbf{x})=(\mathrm{const})|\mathbf{x}| \quad\text{and}\quad f(\mathbf{x})^2=Z|\mathbf{x}|^{-1}. \tag{II.46}$$

If we denote the effective STF potential as

$$V_{\mathrm{eff}}^{\mathrm{STF}}(\mathbf{x})=\phi^{\mathrm{STF}}(\mathbf{x})+\nu, \tag{II.47}$$

then the following lemma is valid:

Lemma II.4: (i) (Ref. 2) The density $\rho^{\mathrm{STF}}(\mathbf{x})$ as well as $[V_{\mathrm{eff}}^{\mathrm{STF}}(\mathbf{x})]_+$ have compact support with radius $r_S\leqslant 3.3\pi^2Z^{1/5}B^{-2/5}$.

(ii) For fixed but arbitrary $\mathbf{x}_\perp$, $\phi^{\mathrm{STF}}(\mathbf{x})$ and $\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})$ are $\in C^\infty(\mathbb{R}-0)$ as a function of z and

$$|\partial_z^\nu\phi^{\mathrm{STF}}(\mathbf{x})|\leqslant C_\nu f(\mathbf{x})^2 l(\mathbf{x})^{-\nu},\quad |\partial_z^\nu\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})|\leqslant C'_\nu f(\mathbf{x})^2 l(\mathbf{x})^{-\nu}, \tag{II.48}$$

for all $\nu \in \mathbb{N}$ *and* $\mathbf{x} \in \mathbb{R}^3$.

Proof: (*ii*) The C^∞ property follows from the TF equation (II.1) and the definition (I.29). Equation (II.48) follows from (II.1) and (I.29) and the fact that

$$|\partial_z^\nu Z|\mathbf{x}|^{-1}| \leqslant f(\mathbf{x})^2 |\mathbf{x}|^{-\nu} \frac{Z}{|\mathbf{x}|} \leqslant f(\mathbf{x})^2 l(\mathbf{x})^{-\nu}. \tag{II.49}$$

The proof of (*i*) is given in Ref. 2, Theorem 4.11. □

Remark II.5: The estimates (II.48) seem to be very crude, especially in the vicinity of r_S, but nevertheless they are good enough to provide precise error estimates. Next let us try to get an idea of how $V_{\text{eff}}^{\text{STF}}$ behaves in the vicinity of the radius r_S. We consider the neutral case $N=Z$. Since $V_{\text{eff}}^{\text{STF}}$ is spherical symmetric, we can make the ansatz $V_{\text{eff}}^{\text{STF}}(\mathbf{x}) = \chi(r)/r$ ($|\mathbf{x}| = r$), which leads by (II.1) to

$$\chi''(r) = B r^{1/2} \chi(r) \quad \text{and} \quad \chi(0) = Z. \tag{II.50}$$

Around each point r_0, this equation has a solution χ that can be expanded in a series of terms $c_i[r_0 - r]^i$ with $i \geqslant 4$. In the vicinity of $r_0 = r_S$ we get the approximate solution

$$V_{\text{eff}}^{\text{STF}} \sim \frac{Z^{1/5} B^{8/5}}{r} [r_S - r]_+^4, \tag{II.51}$$

which shows that $V_{\text{eff}}^{\text{STF}}$ tends to 0 as $[r_S - r]_+^4$ as $r \to r_S$.

Next we fix a point $\mathbf{y} \in \mathbb{R}^3$ and we set $l = l(\mathbf{y})$ and $f = f(\mathbf{y}) = Z^{1/2}|\mathbf{y}|^{1/2}$. (We assume that (II.34)–(II.36) are fulfilled in $B(\mathbf{y}, l(\mathbf{y}))$. This in our case can be done by defining $l(\mathbf{y})$, e.g., as $|\mathbf{y}|/2$.) Furthermore, we define the unitary transformation

$$U(l): \psi(\mathbf{x}) \to l^{3/2} \psi(l\mathbf{x} + \mathbf{y}), \tag{II.52}$$

which maps the ball $B(\mathbf{y}, l(\mathbf{y}))$ to $B(0,1)$ and transforms the operator $-\partial_z^2 - \widetilde{\phi^{\text{STF}}}$ into

$$-l^{-2}\partial_z^2 - \widetilde{\phi^{\text{STF}}}(l\mathbf{x} + \mathbf{y}). \tag{II.53}$$

Introduce the new potential

$$\tilde{W}(\mathbf{x}) = f^{-2} \widetilde{\phi^{\text{STF}}}(l\mathbf{x} + \mathbf{y}). \tag{II.54}$$

The resulting operator is related to the original one (II.23) as

$$U(l) \tilde{H}_{\mathbf{x}_\perp} U(l)^{-1} = f^2 \tilde{K}_h, \tag{II.55}$$

with

$$\tilde{K}_h = -h^2 \partial_z^2 - \tilde{W}(\mathbf{x}) \quad \text{and} \quad h = (lf)^{-1}. \tag{II.56}$$

If we denote $W(\mathbf{x}) = f^{-2}\phi^{\text{STF}}(l\mathbf{x} + \mathbf{y})$, then one easily sees that $\tilde{W}$ can equivalently be defined by applying (I.29), i.e., the operation $\tilde{\cdot}$, to W, with B replaced by $B' = Bl^2$. In other words the unitary transformation $U(l)$ scales the magnetic field strength B to $B' = Bl^2$ and for the difference $\tilde{W} - W$ we get the following lemma.

Lemma II.6: There exists a function $a(\mathbf{x}, \alpha)$ *such that*

$$\tilde{W}(\mathbf{x}) - W(\mathbf{x}) = \alpha a(\mathbf{x}, \alpha), \tag{II.57}$$

where $\alpha = B^{-1/2} l^{-1}$ *and* $a(\mathbf{x}, \alpha)$ *fulfills (II.42) uniformly in* α *for* $\alpha \leqslant 1$.

Proof: Since the potential ϕ^{STF} is spherically symmetric and Eq. (II.48) is fulfilled for derivatives in all directions, we get for $\mathbf{x}\in B(0,2)$

$$|\partial^\nu W(\mathbf{x})| = |f^{-2}\partial^\nu \phi^{\mathrm{STF}}(l\mathbf{x}+\mathbf{y})| \leqslant C_\nu \text{ for all } \quad \nu \in \mathbb{N}^3. \tag{II.58}$$

Hence, $W(\mathbf{x})$, together with all derivatives, is bounded above by a constant on a ball around $\mathbf{x}=0$. Since the operation $\tilde{\cdot}$ smears the potential, for every $\mathbf{x}$, over a region $\sim\alpha$ in the $|\mathbf{x}_\perp|$-direction, the difference $\widetilde{W}-W$ can be expressed by α times a function $a(\mathbf{x},\alpha)$ which is bounded by a constant. Since $\widetilde{\partial_z^n W}(\mathbf{x}) = \partial_z^n \widetilde{W}(\mathbf{x})$ the same argument can be given for all derivatives. □

Let us rewrite the operator K_h in the form

$$K_h = -h^2\partial_z^2 - (W(\mathbf{x}) + \alpha a(\mathbf{x},\alpha)). \tag{II.59}$$

In order to be allowed to apply Theorem II.3 to (II.59), i.e., in order to guarantee that $p^2 - W(x)$ is the principal symbol of K_h, it is necessary, that

$$\alpha \leqslant h \Leftrightarrow B^{-1/2} l^{-1} \leqslant l^{-1} f^{-1}, \tag{II.60}$$

which leads to the condition

$$|\mathbf{y}| \geqslant Z/B. \tag{II.61}$$

Hence, in the sense of Theorem II.3, this implies that in the region $\{\mathbf{x}|\,|\mathbf{x}|\geqslant Z/B\}$ Theorem II.1, with $s=0$, can be applied to the error terms $\mathcal{R}_{2-4}$, with $\widetilde{\phi^{\mathrm{STF}}}$ replaced by ϕ^{STF}. Next we decompose $\mathbb{R}^3$ into $\Omega_1=\{\mathbf{x}||\mathbf{x}|\leqslant Z/B\}$ and $\Omega_2=\{\mathbf{x}|\,|\mathbf{x}|\geqslant Z/B\}$ and estimate the error terms $\mathcal{R}_{1-4}$ on each of these regions separately.

D. Analysis in the region Ω_1

We first assume that $B<Z^2$. This assumption is made in order to be sure that Ω_1 is not completely contained in the non-semiclassical region $\{\mathbf{x}||\mathbf{x}|\leqslant 1/Z\}$, where each term, the quantum mechanical as well as the semiclassical, has to be estimated separately. Furthermore, let $\psi^{(1)}(\mathbf{x})$ be supported in $\{\mathbf{x}|0\leqslant|\mathbf{x}|\leqslant Z/B(1+\epsilon)\}$ and fulfill $\psi^{(1)}(\mathbf{x})=1$ in $\{\mathbf{x}||\mathbf{x}|\leqslant(Z/B)(1-\epsilon)\}$, as well as $|\partial_z^n\psi^{(1)}|\leqslant C_n l(\mathbf{x})^{-n}$ for all $n\in\mathbb{N}$.

With respect to $\mathcal{R}_1$ and $\mathcal{R}_2$, we in particular have to estimate the term

$$\frac{B}{2\pi}\int d\mathbf{x}_\perp \left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi^{(1)} g_s(\widetilde{H}_{\mathbf{x}_\perp}-\nu)) - \int \frac{dzdp}{2\pi}\psi^{(1)} g_s(h_{\mathbf{x}_\perp}-\nu)\right), \tag{II.62}$$

with $\widetilde{H}_{\mathbf{x}_\perp}$ and $h_{\mathbf{x}_\perp}$ given by (II.23). Let $\widetilde{h}_{\mathbf{x}_\perp}$ be defined analogously, i.e., $\widetilde{h}_{\mathbf{x}_\perp}=p^2-\widetilde{\phi^{\mathrm{STF}}}$. Adding and subtracting $\int (dzdp/2\pi)\,\psi^{(1)} g_s(\widetilde{h}_{\mathbf{x}_\perp}-\nu)$ in (II.62), we split (II.62) into

$$R_1^s(\psi^{(1)}) = \frac{B}{2\pi}\int d\mathbf{x}_\perp \left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi^{(1)} g_s(\widetilde{H}_{\mathbf{x}_\perp}-\nu)) - \int \frac{dzdp}{2\pi}\psi^{(1)} g_s(\widetilde{h}_{\mathbf{x}_\perp}-\nu)\right) \tag{II.63}$$

and the fully semiclassical part

$$R_2^s(\psi^{(1)}) = \frac{B}{2\pi}\int d\mathbf{x}_\perp \left(\int \frac{dzdp}{2\pi}\psi^{(1)} g_s(\widetilde{h}_{\mathbf{x}_\perp}-\nu) - \int \frac{dzdp}{2\pi}\psi^{(1)} g_s(h_{\mathbf{x}_\perp}-\nu)\right). \tag{II.64}$$

Since $l(\mathbf{x})f(\mathbf{x})\geqslant 1$, which is equivalent to $|\mathbf{x}|\geqslant Z^{-1}$, is necessary for being able to apply Theorem II.1, we have to carry out a corresponding decomposition of Ω_1. Let $\psi_1^{(1)}+\psi_2^{(1)}=\psi^{(1)}$ be a partition of unity on Ω_1, with

$$\text{supp } \psi_1^{(1)}=\{\mathbf{x}||\mathbf{x}|\leqslant Z^{-1}(1+\epsilon)\},\ \ \text{supp } \psi_2^{(1)}=\{\mathbf{x}|Z^{-1}(1-\epsilon)\leqslant|\mathbf{x}|\leqslant Z/B(1+\epsilon)\},\quad \text{(II.65)}$$

and $|\partial_z^n\psi_i^{(1)}|\leqslant C_n l(\mathbf{x})^{-n}$ for $i=1,2$, with C_n independent of Z and B.

Lemma II.7: With the above definitions we have for (II.63)

$$R_1^s(\psi^{(1)})\leqslant CB^{(3/2)s-1}Z^{2-(1/2)s}. \quad \text{(II.66)}$$

Proof: On supp $\psi_2^{(1)}$ we apply Theorem II.1 to (II.62) with $\alpha=1$ and $d=1$, which implies for arbitrary but fixed $\mathbf{x}_\perp$ (we may set the chemical potential $\nu=0$ for simplicity; the computations for arbitrary ν are essentially the same)

$$\left|\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi_2^{(1)}g_s(\tilde{H}_{\mathbf{x}_\perp}))-\int\frac{dzdp}{2\pi}\psi_2^{(1)}g_s(\tilde{h}_{\mathbf{x}_\perp})\right|\leqslant C\int_{\mathrm{supp}\psi_2^{(1)}(\mathbf{x}_\perp,z)}dzl(\mathbf{x})^{-1-s}f(\mathbf{x})^s. \quad \text{(II.67)}$$

Hence, multiplying with $B/2\pi$ and integrating over $\mathbf{x}_\perp$ leads to

$$R_1^s(\psi^{(1)})\leqslant C\frac{B}{2\pi}\int d\mathbf{x}l(\mathbf{x})^{-1-s}f(\mathbf{x})^s\leqslant BZ^{(1/2)s}\int_{Z^{-1}}^{Z/B}r^{1-(3/2)s}dr\leqslant CB^{(3/2)s-1}Z^{2-(1/2)s}. \quad \text{(II.68)}$$

In the case of $r\leqslant Z^{-1}$ the terms of (II.63) have to be estimated separately. The semiclassical part reads

$$\frac{B}{2\pi}\int\frac{d\mathbf{x}dp}{2\pi}\psi_1^{(1)}[\tilde{h}_{\mathbf{x}_\perp}]_-^{1/2+s}\leqslant\frac{B}{2\pi}\int_{|\mathbf{x}|\leqslant Z^{-1}}d\mathbf{x}[\widetilde{\phi^{\mathrm{STF}}}]_+^{1/2+s}\leqslant CBZ^{2s-2}. \quad \text{(II.69)}$$

An analogous estimate is derived for $(B/2\pi)\int d\mathbf{x}_\perp\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi_1^{(1)}g_s(\tilde{H}_{\mathbf{x}_\perp}))$ by using Ref. 3, Lemma 7.9. □

Lemma II.8: For (II.64) we have

$$R_2^s(\psi^{(1)})\leqslant CZ^{s+1/2}B^{s/2-1/4}. \quad \text{(II.70)}$$

Proof: Obviously, the main contribution to the magnitude of the semiclassical term

$$R_2^s(\psi^{(1)})\leqslant\frac{B}{2\pi}\int_{\mathbb{R}^3}d\mathbf{x}\psi^{(1)}|[\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})]_+^{s+1/2}-[\phi^{\mathrm{STF}}(\mathbf{x})]_+^{s+1/2}| \quad \text{(II.71)}$$

is produced by the Coulomb singularity, i.e.,

$$R_2^s(\psi^{(1)})\leqslant\frac{B}{2\pi}\int_{|\mathbf{x}|\leqslant B^{-1/2}}d\mathbf{x}|\phi^{\mathrm{STF}}(\mathbf{x})|_+^{s+1/2} \quad \text{(II.72)}$$

$$\leqslant CB\int_{|\mathbf{x}|\leqslant B^{-1/2}}d\mathbf{x}\left(\frac{Z}{r}\right)^{s+1/2}$$

$$\leqslant CZ^{s+1/2}B^{s/2-1/4}. \quad \text{(II.73)}$$

□

Hence, we are ready to carry out the estimate of the error terms $\mathcal{R}_{1-4}$, restricted to Ω_1, which we denote as $\mathcal{R}_i(\Omega_1)$.

Proposition II.9: For $Z^{4/3}\leqslant B\leqslant Z^3$ one has

$$\mathcal{R}_1(\Omega_1)=\frac{B}{2\pi}\int_{\mathbb{R}^2}d\mathbf{x}_\perp\left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi^{(1)}[\tilde{H}_{\mathbf{x}_\perp}-\nu]_-)-\int\frac{dzdp}{2\pi}\psi^{(1)}[h_{\mathbf{x}_\perp}-\nu]_-\right)\leqslant CB^{4/5}Z^{3/5}. \quad \text{(II.74)}$$

Proof: This is done by putting together Lemmas II.7 and II.8 and setting $s=1$. □

Before turning to $\mathcal{R}_2(\Omega_1)$ we need a preparing lemma.

Lemma II.10: Let λ_N be the Nth eigenvalue of (II.13) and ν the chemical potential of (II.1) belonging to the electron number N. Then

$$|\lambda_N-\nu|\leqslant CB^{3/5}Z^{1/5}. \tag{II.75}$$

Proof: We assume now that we already have the estimate

$$\left|\mathrm{Tr}\Theta_-(\Pi_0(-\partial_z^2-\phi^{\mathrm{STF}})\Pi_0)-\frac{B}{2\pi}\int d\mathbf{x}_\perp\int\frac{dzdp}{2\pi}\Theta_-(p^2-\phi^{\mathrm{STF}})\right|\leqslant CB^{1/5}Z^{2/5}, \tag{II.76}$$

which until now we have only proven on Ω_1, by setting $s=0$ in Lemmas II.7 and II.8. The missing part will be proved in Lemma II.16. Since we know by definition

$$\frac{B}{2\pi}\int_{\mathbb{R}^2}d\mathbf{x}_\perp\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}\Theta_-(\tilde{H}_{\mathbf{x}_\perp}-\lambda_N)=N=\frac{B}{2\pi}\int d\mathbf{x}[\phi^{\mathrm{STF}}(\mathbf{x})+\nu]_+^{1/2}, \tag{II.77}$$

we get

$$B^{1/5}Z^{2/5}\geqslant\frac{B}{2\pi}\int d\mathbf{x}([\phi^{\mathrm{STF}}+\lambda_N]_+^{1/2}-[\phi^{\mathrm{STF}}+\nu]_+^{-1/2}) \tag{II.78}$$

$$\geqslant C|\lambda_N-\nu|B\int_0^{r_S}[\phi^{\mathrm{STF}}+\nu']_+^{-1/2}r^2dr$$

$$\geqslant C|\lambda_N-\nu|(BZ^{-1/2}r_S^{7/2}), \tag{II.79}$$

for some $\nu'\in[\nu,\lambda_N]$. This implies the statement of the lemma. □

Proposition II.11:

$$\mathcal{R}_2(\Omega_1)=\left|\lambda_N-\nu\left|\frac{B}{2\pi}\right|\int_{\mathbb{R}^2}d\mathbf{x}_\perp(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi^{(1)}\Theta_-(\tilde{H}_{\mathbf{x}_\perp}-\nu))\right| \tag{II.80}$$

$$-\int\frac{dzdp}{2\pi}\psi^{(1)}\Theta_-(h_{\mathbf{x}_\perp}-\nu))\Bigg|$$

$$\leqslant CB^{4/5}Z^{3/5}. \tag{II.81}$$

Proof: By Lemma II.10 and combining the estimations of Lemmas II.7 and II.8 with $s=0$.□

Remarki II.12: We remark here that if one has a partition of unity $\varphi_1+\varphi_2=1$, then the relation

$$D(f,f)\leqslant 2D(f\varphi_1,f\varphi_1)+2D(f\varphi_2,f\varphi_2) \tag{II.82}$$

is valid, which one gets by the simple inequality

$$D(f\varphi_1-f\varphi_2,f\varphi_1-f\varphi_2)\geqslant 0. \tag{II.83}$$

Remark II.12 justifies the notations $\mathcal{R}_3(\Omega_i),\mathcal{R}_4(\Omega_i)$, since (II.82) means that we can consider each region Ω_i separately.

Proposition II.13: For $Z^{4/3}\leqslant B\leqslant Z^3$ we get with (II.28)

$$\mathcal{R}_4(\Omega_1)=D(\psi^{(1)}(\rho^{\mathrm{STF}}-\overline{\rho}),\psi^{(1)}(\rho^{\mathrm{STF}}-\overline{\rho}))\leqslant CB^{4/5}Z^{3/5}. \tag{II.84}$$

Proof: Recall

$$\rho^{\mathrm{STF}}=\frac{B}{2\pi}[\phi^{\mathrm{STF}}+\nu]_+^{1/2} \text{ and } \overline{\rho}=[\phi^{\mathrm{STF}}+\lambda_N]_+^{1/2}. \tag{II.85}$$

By the Hardy–Littlewood–Sobolev inequality we derive

$$\begin{aligned}\mathcal{R}_4(\Omega_1)&=D(\psi^{(1)}(\rho^{\mathrm{STF}}-\overline{\rho}),\psi^{(1)}(\rho^{\mathrm{STF}}-\overline{\rho}))\\&\leqslant CB^2\|\psi^{(1)}(\rho^{\mathrm{STF}}-\overline{\rho})\|_{6/5}^2\\&\leqslant CB^2|\lambda_N-\nu|^2\|\psi^{(1)}(\phi^{\mathrm{STF}}+\nu')^{-1/2}\|_{6/5}^2\\&\leqslant Z^{27/5}B^{-14/5}.\end{aligned} \tag{II.86}$$

□

In the case of $\mathcal{R}_3(\Omega_1)$ we proceed as above, namely we introduce the auxiliary density $\tilde{\rho}(\mathbf{x})=(B/2\pi)[\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})+\lambda_N]_+^{1/2}$ and decompose $\mathcal{R}_3(\Omega_1)$ by using convexity.

Proposition II.14: For $Z^{4/3}\leqslant B\leqslant Z^3$ we have

$$\mathcal{R}_3(\Omega_1)=D(\psi^{(1)}(\rho^{\mathrm{STF}}-\rho_\psi),\psi^{(1)}(\rho^{\mathrm{STF}}-\rho_\psi))\leqslant CB^{4/5}Z^{3/5}. \tag{II.87}$$

Proof: By decomposition we have, on the one hand, the fully semiclassical and easier to handle part

$$\mathcal{R}_4(\Omega_1)=D(\psi^{(1)}(\rho^{\mathrm{STF}}-\tilde{\rho}),\psi^{(1)}(\rho^{\mathrm{STF}}-\tilde{\rho}))\leqslant B^2\|\psi^{(1)}(\rho^{\mathrm{STF}}-\tilde{\rho})\|_{6/5}^2\leqslant B^{4/5}Z^{3/5}. \tag{II.88}$$

On the other hand, there is the more interesting term

$$D(\psi^{(1)}(\rho_\psi-\tilde{\rho}),\psi^{(1)}(\rho_\psi-\tilde{\rho})). \tag{II.89}$$

For $r\leqslant Z^{-1}$ we separately calculate

$$\left(\frac{B}{2\pi}\right)^2 D(\psi_1^{(1)}e(z,z;\tilde{H}_{\mathbf{x}_\perp},\lambda_N),\psi_1^{(1)}e(z,z;\tilde{H}_{\mathbf{x}_\perp},\lambda_N))\leqslant CB^2\|\psi_1^{(1)}e(z,z;\tilde{H}_{\mathbf{x}_\perp},\lambda_N)\|_{6/5}^2 \tag{II.90}$$

and

$$\left(\frac{B}{2\pi}\right)^2 D(\psi_1^{(1)}[\widetilde{\phi^{\mathrm{STF}}}+\lambda_N]_+^{1/2},\psi_1^{(1)}[\widetilde{\phi^{\mathrm{STF}}}+\lambda_N]_+^{1/2})\leqslant CB^2\|\psi_1^{(1)}[\widetilde{\phi^{\mathrm{STF}}}+\lambda_N]_+^{1/2}\|_{6/5}^2. \tag{II.91}$$

Whereas (II.91) can be bounded by

$$CB^2\|\psi_1^{(1)}[Z/|\mathbf{x}|]^{1/2}\|_{6/5}^2\leqslant CB^2/Z^3, \tag{II.92}$$

(II.90) can analogously be estimated by Ref. 3, Lemma 10.7, or Ref. 4, Proposition 4.3.

The term

$$D(\psi_2^{(1)}(\rho_\psi-\tilde{\rho}),\psi_2^{(1)}(\rho_\psi-\tilde{\rho})) \tag{II.93}$$

is a bit more delicate. We can either use Ref. 4, Proposition 4.3, or Ref. 7, Theorem 4.5.4(i), which states that for K_h, given in (II.40), with V fulfilling (II.42) and $|V(\mathbf{x})+\tau|\geqslant\epsilon$,

$$\left|e(x,x;K_h,\tau)-h^{-d}\int\Theta_-(k(\mathbf{x},p)-\tau)\right|\leqslant h^{1-d}\quad\forall\mathbf{x}\in B\left(0,\frac{1}{2}\right). \tag{II.94}$$

Since $|\lambda_N|\leqslant B^{3/5}Z^{1/5}$, we get that $|\widetilde{\phi^{\mathrm{STF}}}+\lambda_N|\geqslant\epsilon f(\mathbf{x})^2$ in Ω_1. Hence, we can apply (II.94) to our case, with $d=1$, yielding

$$|e(z,z;\tilde{H}_{\mathbf{x}_\perp},\lambda_N)-[\widetilde{\phi^{\mathrm{STF}}}(\mathbf{x})+\lambda_N]_+^{1/2}|\leqslant l(\mathbf{x})^{-1}. \tag{II.95}$$

The term l^{-1} stems from rescaling $B(0,1)$ to $B(0,l)$. So,

$$D(\psi_2^{(1)}(\rho_\psi-\tilde{\rho}),\psi_2^{(1)}(\rho_\psi-\tilde{\rho}))\leqslant CB^2\|\psi_2^{(1)}l(\mathbf{x})^{-1}\|_{6/5}^2\leqslant CB^2[Z/B]^3. \tag{II.96}$$

□

In the case $B\geqslant Z^2$, Z/B is smaller than $1/Z$ and in the above calculations only the separate terms have to be taken into account, which yields analog estimates as above.

E. Analysis in the outer region Ω_2

This region has already been treated by Ivrii in Ref. 4, Sec. 4.

Recall first that r_S is the radius of the support of ϕ^{STF}, in the neutral case, and of $[\phi^{\mathrm{STF}}+\nu]_+$ otherwise. In order that Theorem II.1 can be applied ϕ^{STF} and $\widetilde{\phi^{\mathrm{STF}}}$ have to fulfill condition (II.39). We know that $\nabla\phi^{\mathrm{STF}}(r_S)=\phi^{\mathrm{STF}}(r_S)=0$. Hence, we look for a parameter $0<c<1$, and the concerning radius cr_S, such that the separate quantum mechanical as well as semiclassical parts of $\mathcal{R}_{1-4}$ in $\{\mathbf{x}||\mathbf{x}|\geqslant cr_S\}$ do not exceed $CB^{4/5}Z^{3/5}$ and that ϕ^{STF} fulfills (II.39). The existence of such a c is a consequence of the behavior of ϕ^{STF} in the vicinity of r_S [cf. (II.51)]. By means of such a parameter c we decompose the outer region Ω_2 into $\Omega_2^1\cup\Omega_2^2$ and define a concerning partition of unity, i.e.,

$$\mathrm{supp}\,\psi_1^{(2)}=\{\mathbf{x}|\,[Z/B](1+\epsilon)\leqslant|\mathbf{x}|\leqslant cr_S\},\quad \mathrm{supp}\,\psi_2^{(2)}=\{\mathbf{x}|\,|\mathbf{x}|\geqslant cr_S(1-\epsilon)\}, \tag{II.97}$$

with $\psi_1^{(2)}+\psi_2^{(2)}=1$ for $r\geqslant[Z/B](1+\epsilon)$. On Ω_2^2, by definition, all terms separately are bounded above by $CB^{4/5}Z^{3/5}$ and on Ω_2^1 condition (II.39) is fulfilled for ε small enough.

Throughout this section we assume $Z^{4/3}\leqslant B\leqslant Z^3$.

Proposition II.15:

$$\mathcal{R}_1(\Omega_2^1)\leqslant CB^{4/5}Z^{3/5}. \tag{II.98}$$

Proof: First we assume $B<Z^2$. Applying Theorem II.1 with $\alpha=1$ and $d=1$ we get for arbitrary but fixed $\mathbf{x}_\perp$ (we set $\nu=0$)

$$\left|\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi_1^{(2)}g_1(\tilde{H}_{\mathbf{x}_\perp}))-\int\frac{dzdp}{2\pi}\psi_1^{(2)}g_1(\tilde{h}_{\mathbf{x}_\perp})\right|\leqslant C\int_{\mathrm{supp}\psi_1^{(2)}(\mathbf{x}_\perp,z)}dzl(\mathbf{x})^{-2}f(\mathbf{x}). \tag{II.99}$$

After multiplying with B and integrating over $\mathbf{x}_\perp$ we get

$$(\mathrm{II.99})\leqslant C\frac{B}{2\pi}\int d\mathbf{x}l(\mathbf{x})^{-2}f(\mathbf{x})\leqslant CBZ^{1/2}\int_{Z/B}^{cr_S}r^{-1/2}dr\leqslant CBZ^{1/2}[r_S]^{1/2}. \tag{II.100}$$

In the case of $B>Z^2$ we again have to decompose Ω_2^1, since Z/B is smaller than $1/Z$. So for fixed but arbitrary B, Ω_2^1 is decomposed with respect to $r=1/Z$. For $r\leqslant 1/Z$ we proceed as in the previous section and estimate each term separately and for $r\geqslant 1/Z$ we immediately arrive at (II.100).

The pure semiclassical part

$$\frac{B}{2\pi}\int d\mathbf{x}_\perp\left(\int\frac{dzdp}{2\pi}\psi^{(2)}g_1(\tilde{h}_{\mathbf{x}_\perp}-\nu)-\int\frac{dzdp}{2\pi}\psi^{(2)}g_1(h_{\mathbf{x}_\perp}-\nu)\right) \tag{II.101}$$

can analogously be estimated as in Lemma II.8 □

Denote

$$R^0(\psi_1^{(2)}) = \frac{B}{2\pi}\int d\mathbf{x}_\perp \left(\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi_1^{(2)}\Theta_-(\tilde{H}_{\mathbf{x}_\perp}-\nu)) - \int \frac{dzdp}{2\pi}\psi_1^{(2)}\Theta_-(h_{\mathbf{x}_\perp}-\nu)\right). \tag{II.102}$$

Lemma II.16:

$$R^0(\psi_1^{(2)}) \leqslant CB^{1/5}Z^{2/5}. \tag{II.103}$$

Proof: As in Proposition II.15 we first assume $B<Z^2$. The other case, where the terms have to be computed separately, works as in Lemma II.7. Applying Theorem II.1 with $\alpha=1$ and $d=1$ we get for arbitrary but fixed $\mathbf{x}_\perp$ (we set $\nu=0$)

$$\left| \mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}(\psi_1^{(2)}\Theta_-(\tilde{H}_{\mathbf{x}_\perp})) - \int \frac{dzdp}{2\pi}\psi_1^{(2)}\Theta_-(h_{\mathbf{x}_\perp}) \right| \leqslant C\int_{\mathrm{supp}\psi_1^{(2)}(\mathbf{x}_\perp,z)} dz\, l(\mathbf{x})^{-1}. \tag{II.104}$$

This implies

$$R^0(\psi_1^{(2)}) \leqslant C\frac{B}{2\pi}\int d\mathbf{x} l(\mathbf{x})^{-1} \leqslant CB\int_{Z/B}^{cr_S} r\,dr \leqslant CB[r_S]^2. \tag{II.105}$$

□

Proposition II.17:

$$\mathcal{R}_2(\Omega_2^1) \leqslant CB^{4/5}Z^{3/5}. \tag{II.106}$$

Proof: Note that by the Lemmas II.7, II.8 and II.16 the estimate (II.76) is proved and the assumption of Lemmas II.10 justified. So by Lemmas II.10 and II.16 we arrive at (II.106). □

Proposition II.18:

$$\mathcal{R}_4(\Omega_2^1), \mathcal{R}_3(\Omega_2^1) \leqslant CB^{4/5}Z^{3/5}. \tag{II.107}$$

Proof: Let us start with

$$\mathcal{R}_4(\Omega_2^1) = D(\psi_1^{(2)}(\rho^{\mathrm{STF}}-\overline{\rho}), \psi_1^{(2)}(\rho^{\mathrm{STF}}-\overline{\rho})). \tag{II.108}$$

By the HLS inequality we get

$$\mathcal{R}_4(\Omega_2^1) \leqslant CB^2 \|\psi_1^{(2)}(\rho^{\mathrm{STF}}-\overline{\rho})\|_{6/5}^2 \leqslant CB^2|\lambda_N-\nu|^2\|\psi_1^{(2)}(\phi^{\mathrm{STF}}+\nu)^{-1/2}\|_{6/5}^2 \leqslant CB^{4/5}Z^{3/5}. \tag{II.109}$$

The term

$$\mathcal{R}_3(\Omega_2^1) = D(\psi_1^{(2)}(\rho^{\mathrm{STF}}-\rho_\psi), \psi_1^{(2)}(\rho^{\mathrm{STF}}-\rho_\psi)) \tag{II.110}$$

is a bit more delicate and we refer to Ref. 4 Propositions 4.2 and 4.3, for a proof of the estimate (II.107).

Note: Proposition 4.3 in Ref. 4 is proved for region $\chi_4=\{\mathbf{x}||\mathbf{x}|\geqslant C_0Z/B\}$ with possibly a very large parameter C_0. This parameter C_0 is chosen in a way such that only the lowest Landau band contributes to Ivrii's calculations. Since we only treat the lowest Landau band case, the assertion of Proposition 4.3 holds in our case on the whole region Ω_2^1.

Furthermore, we remark that if (II.95) would be valid on Ω_2^1, we could immediately conclude by the HLS inequality that $\mathcal{R}_4(\Omega_2^1) \leqslant CB^2[r_S]^3$. But since the validity of (II.95) cannot be guaranteed on Ω_2^1, we have to refer to Ivrii's method. □

Recall that we have made a partition of unity, $\Sigma_{i,j=1}^2 \psi_j^{(i)}(\mathbf{x})=1$. So, collecting all estimations of the Secs. II D and II E, we have finished the proof of Theorem I.3.

III. SEMICLASSICAL THEORIES APPROXIMATING E^{Q}_{conf}

As we have already argued throughout the introduction, the natural semiclassical approximation of E^{Q}_{conf} is given by the DSTF functional

$$\mathcal{E}^{\mathrm{DSTF}}[\rho]=\sum_{m\in\mathbb{N}_0}\left(\kappa\int\rho_m(z)^3-Z\int V_m(z)\rho_m(z)dz\right)+\overline{D}(\rho,\rho). \tag{III.1}$$

Here ρ is a sequence of one-dimensional densities $\rho=(\rho_m(z))_{m\in\mathbb{N}_0}$. Contrary to the usual STF theory, the integration over the variables orthogonal to the magnetic field is replaced by an expansion in angular momentum eigenfunctions in the lowest Landau band. The potentials V_m and $\overline{D}$ are defined in (I.35). The corresponding energy is given by

$$E^{\mathrm{DSTF}}(N,Z,B)=\inf\left\{\mathcal{E}^{\mathrm{DSTF}}[\rho]\,\middle|\,\rho\in\mathcal{D}\ \text{ and }\ \sum_m\int\rho_m\leqslant N\right\}, \tag{III.2}$$

with

$$\mathcal{D}=\left\{\rho\,\middle|\sum_m\int\rho_m^3<\infty,\sum_m\int V_m\rho_m<\infty,\widetilde{D}(\rho,\rho)<\infty\right\}. \tag{III.3}$$

Another semiclassical approximation, where the variables, as in the usual STF theory, are three dimensional densities, is realized by the MSTF functional

$$\mathcal{E}^{\mathrm{MSTF}}[\rho]=\frac{4\pi^4}{3B^2}\int d\mathbf{x}\rho^3(\mathbf{x})-\int d\mathbf{x}\widetilde{|\mathbf{x}|^{-1}}\rho(\mathbf{x})+\widetilde{D}(\rho,\rho), \tag{III.4}$$

with respective energy

$$E^{\mathrm{MSTF}}(N,Z,B)=\inf\left\{\mathcal{E}^{\mathrm{MSTF}}[\rho]\,\middle|\,\rho\in\widetilde{\mathcal{D}}\ \text{ and }\ \int\rho\leqslant N\right\}, \tag{III.5}$$

where

$$\widetilde{\mathcal{D}}=\left\{\rho\,\middle|\,\rho\in\mathcal{L}^3(\mathbb{R}^3),\int\widetilde{|x|^{-1}}\rho<\infty,\widetilde{D}(\rho,\rho)<\infty\right\}. \tag{III.6}$$

First of all, we will show that these two functionals are equivalent.

Lemma III.1: For all $\rho\in\widetilde{\mathcal{D}}$ let

$$\overline{\rho}(\mathbf{x})=\frac{B}{2\pi}\sum_m\chi_m(\mathbf{x}_\perp)\rho_m(z), \tag{III.7}$$

with $\rho_m(z)=\int\rho(\mathbf{x})\chi_m(\mathbf{x}_\perp)d\mathbf{x}_\perp$, and denote $\tilde{\rho}=(\rho_m)_m$. Then one gets

$$\mathcal{E}^{\mathrm{MSTF}}[\rho]\geqslant\mathcal{E}^{\mathrm{MSTF}}[\overline{\rho}]=\mathcal{E}^{\mathrm{DSTF}}[\tilde{\rho}]. \tag{III.8}$$

Proof: By the definition of the MSTF functional, it suffices to show that $\int\rho^3\geqslant\int\overline{\rho}^3$.

For this purpose we note that for every non-negative function f, on a general measure space, one derives from convexity that

$$\frac{1}{\mu(\Omega)}\int f^3d\mu\geqslant\left(\int\frac{1}{\mu(\Omega)}fd\mu\right)^3. \tag{III.9}$$

Hence for every $m\in\mathbb{N}$ and $z\in\mathbb{R}$, we have

$$\frac{1}{|\chi_m|}\int_{\mathrm{supp}\chi_m}\rho(\mathbf{x})^3\chi_m(\mathbf{x}_\perp)d\mathbf{x}_\perp \geqslant \left(\frac{1}{|\chi_m|}\int \rho(\mathbf{x})\chi_m(\mathbf{x}_\perp)d\mathbf{x}_\perp\right)^3. \tag{III.10}$$

Since $|\chi_m| = 2\pi/B$, we arrive at

$$\frac{4\pi^4}{3B^2}\int \rho(\mathbf{x})^3 d\mathbf{x} \geqslant \frac{\pi^2}{3}\sum_m \int \rho_m(z)^3 dz = \frac{4\pi^4}{3B^2}\int \overline{\rho}(\mathbf{x})^3 d\mathbf{x}. \tag{III.11}$$

□

Proposition III.2: For all N,Z,B

$$E^{\mathrm{MSTF}}(N,Z,B) = E^{\mathrm{DSTF}}(N,Z,B). \tag{III.12}$$

Proof: Lemma III.1 immediately implies

$$E^{\mathrm{MSTF}}(N,Z,B) = \inf\left\{\mathcal{E}^{\mathrm{MSTF}}[\rho]\,\middle|\,\rho = \frac{B}{2\pi}\sum_m \rho_m(z)\chi_m(\mathbf{x}_\perp), (\rho_m)_m \in \mathcal{D}\right\}. \tag{III.13}$$

□

For simplicity we first concentrate on the DSTF functional and then apply our results to the MSTF functional.

Lemma III.3: $\mathcal{E}^{\mathrm{DSTF}}[\rho]$ is uniformly bounded from below on $\mathcal{D}$. There exists even a positive constant α and a C, such that

$$\mathcal{E}^{\mathrm{DSTF}}[\rho] \geqslant \alpha\left(\sum_m \int \rho_m^3 + \overline{D}(\rho,\rho)\right) - C \tag{III.14}$$

for all $\rho \in \mathcal{D}$.

Proof: We set $\rho(\mathbf{x}) = \Sigma_m \rho_m(z)|\phi_m(\mathbf{x}_\perp)|^2$ for an arbitrary $(\rho_m)_m \in \mathcal{D}$. We get from Ref. 8, Lemma 2, that for every $\varepsilon > 0$ there exists a C_ε, such that

$$\int |\mathbf{x}|^{-1}\rho \leqslant \varepsilon\|\rho\|_3 + C_\varepsilon D(\rho,\rho)^{1/2}. \tag{III.15}$$

Hence, this implies

$$\sum_m \int V_m\rho_m \leqslant \varepsilon\left(\int d\mathbf{x}\left(\sum_m |\phi_m(\mathbf{x}_\perp)|^2\rho_m(z)\right)^3\right)^{1/3} + C_\varepsilon\overline{D}(\rho,\rho)^{1/2}. \tag{III.16}$$

By convexity of x^3, for $x \geqslant 0$, and by the equation $\Sigma_m|\phi_m|^2 = B/2\pi$, we get

$$\left(\frac{2\pi}{B}\sum_m |\phi_m|^2\rho_m\right)^3 \leqslant \frac{2\pi}{B}\sum_m |\phi_m|^2\rho_m^3. \tag{III.17}$$

Using (III.17) and integrating over the $\mathbf{x}_\perp$-variable, the inequality (III.16) can be written as

$$\sum_m \int V_m\rho_m \leqslant \varepsilon\left(\frac{B}{2\pi}\right)^{2/3}\left(\sum_m \int \rho_m^3\right)^{1/3} + C_\varepsilon\overline{D}(\rho,\rho)^{1/2}. \tag{III.18}$$

Consequently, the functional $\mathcal{E}^{\mathrm{DSTF}}[\rho]$ can be estimated from below by $[\epsilon = \varepsilon(B/2\pi)^{2/3}]$

$$\begin{aligned}\mathcal{E}^{\mathrm{DSTF}}[\rho] &\geq \kappa \sum_m \int \rho_m^3 - \epsilon \left(\sum_m \int \rho_m^3 \right)^{1/3} + \overline{D}(\rho,\rho) - C_\varepsilon \overline{D}(\rho,\rho)^{1/2} \\ &\geq \inf_{X,Y\geq 0} \{\kappa X^3 - \epsilon X + Y^2 - C_\varepsilon Y\} \\ &\geq \alpha(X^3+Y^2) - C, \end{aligned} \tag{III.19}$$

for α, C appropriately chosen, where we used the notations $X=(\Sigma_m \int \rho_m^3)^{1/3}$ and $Y=\overline{D}(\rho,\rho)^{1/2}$. □

Lemma III.4: There exists a $\rho^{(\infty)}$, *which minimizes* $\mathcal{E}^{\mathrm{DSTF}}[\rho]$ *uniquely in* $\mathcal{D}$, *i.e.*, $\inf\{\mathcal{E}^{\mathrm{DSTF}}[\rho] | \rho \in \mathcal{D}\} = \mathcal{E}^{\mathrm{DSTF}}[\rho^{(\infty)}]$.

Proof: Let $\rho^{(i)}$ be a minimizing sequence of $\mathcal{E}^{\mathrm{DSTF}}$. Lemma III.3 yields that there exists a constant C, such that

$$\sum_m \kappa \int (\rho_m^{(i)})^3 \leq C, \quad \overline{D}(\rho^{(i)},\rho^{(i)}) \leq C, \quad \sum_m \rho_m^{(i)} V_m \leq C \tag{III.20}$$

for all $m \in \mathbb{N}_0$. By the Banach–Alaoglu theorem there exists a subsequence, still denoted as $\rho^{(i)}$, and a $\rho^{(\infty)}$, with $\rho_m^{(i)} \in \mathcal{L}^3(\mathbb{R})$ $\forall m \in \mathbb{N}_0$, such that

$$\rho_m^{(i)} \rightharpoonup \rho_m^{(\infty)} \text{ weakly in } \mathcal{L}^3(\mathbb{R}) \quad \forall i \in \mathbb{N}_0. \tag{III.21}$$

Since $\mathcal{L}^p$-norms are weakly lower semicontinuous, we derive for all m

$$\liminf_{i\to\infty} \int (\rho_m^{(i)})^3 \geq \int (\rho_m^{(\infty)})^3, \tag{III.22}$$

and, using Fatou's lemma, we consequently arrive at

$$\liminf_{i\to\infty} \sum_m \int (\rho_m^{(i)})^3 \geq \sum_m \int (\rho_m^{(\infty)})^3. \tag{III.23}$$

Moreover, since $V_m \in \mathcal{L}^{3/2}(\mathbb{R})$ for all m, we conclude by weak convergence

$$\lim_{i\to\infty} \int dz V_m(z) \rho_m^{(i)}(z) \to \int dz V_m(z) \rho_m^{(\infty)}(z) \tag{III.24}$$

for each m. By (III.20) and the dominated convergence theorem we have

$$\lim_{i\to\infty} \sum_m \int dz V_m(z) \rho_m^{(i)}(z) \to \sum_m \int dz V_m(z) \rho_m^{(\infty)}(z). \tag{III.25}$$

In order to show

$$\liminf_{i\to\infty} \overline{D}(\rho^{(i)},\rho^{(i)}) \geq \overline{D}(\rho^{(\infty)},\rho^{(\infty)}), \tag{III.26}$$

we use the fact that for sequences of functions $f=(f_m(z))_m$, $g=(g_m(z))_m$,

$$\langle f,g\rangle_D = \overline{D}(f,g) \tag{III.27}$$

defines a real inner product and, consequently, a real Hilbert-space $\mathcal{H}_D$. Since (III.20) yields $\|\rho^{(i)}\|_D = \sqrt{\langle \rho^{(i)},\rho^{(i)}\rangle_D} \leq C$ for all i, we can extract another subsequence $\rho^{(i)}$, such that

$$\langle f,\rho^{(i)}\rangle \to \langle f,\rho^{(\infty)}\rangle \text{ for all } f \in \mathcal{H}_D. \tag{III.28}$$

Hence, we conclude

$$\overline{D}(\rho^{(\infty)},\rho^{(\infty)}) = \lim_{i\to\infty} \langle \rho^{(i)},\rho^{(\infty)}\rangle \leqslant \langle \rho^{(\infty)},\rho^{(\infty)}\rangle^{1/2} \liminf_{i\to\infty} \langle \rho^{(i)},\rho^{(i)}\rangle^{1/2}$$

$$= \overline{D}(\rho^{(\infty)},\rho^{(\infty)})^{1/2} \liminf_{i\to\infty} \overline{D}(\rho^{(i)},\rho^{(i)})^{1/2}, \tag{III.29}$$

and consequently get (III.26). Altogether we have shown

$$\liminf_{i\to\infty} \mathcal{E}^{\mathrm{DSTF}}[\rho^{(i)}] \geqslant \mathcal{E}^{\mathrm{DSTF}}[\rho^{(\infty)}]. \tag{III.30}$$

The uniqueness follows from the strict convexity of $\mathcal{E}^{\mathrm{DSTF}}$. □

Theorem III.5: Denote $N_c = \Sigma_m \int \rho_m^{(\infty)}$. Then (i) for each $N \leqslant N_c$ there exists a unique minimizer ρ^N for $\mathcal{E}^{\mathrm{DSTF}}$, under the restriction $\Sigma_m \int \rho_m \leqslant N$, i.e., $E^{\mathrm{DSTF}}(N,Z,B) = \mathcal{E}^{\mathrm{DSTF}}[\rho^N]$. Moreover, ρ^N satisfies $\Sigma_m \int \rho_m^N = N$.

(ii) $E^{\mathrm{DSTF}}(N,Z,B)$, as a function of N, is strictly decreasing and strictly convex up to N_c, and constant for $N > N_c$.

Proof: Let $N \leqslant N_c$. Then the same proof as in Lemma III.4 shows that there exists a $\rho^N \in \mathcal{D}$, with $\Sigma_m \int \rho_m^N \leqslant N$ and

$$\mathcal{E}^{\mathrm{DSTF}}[\rho^N] = E^{\mathrm{DSTF}}(N,Z,B). \tag{III.31}$$

Obviously $E^{\mathrm{DSTF}}(N,Z,B)$, as a function of N, is nonincreasing, and the convexity of $\mathcal{E}^{\mathrm{DSTF}}$ implies the convexity of E^{DSTF}. Hence, by definition of N_c and Lemma III.4 it is clear that E^{DSTF} is strictly decreasing up to N_c and constant for $N > N_c$. Furthermore, we get that $\Sigma_m \int \rho_m^N = N$ for $N \leqslant N_c$. (Note that $\Sigma_m \int \rho_m^N < N$ would be a contradiction to $N \leqslant N_c$.) □

Proposition III.6: Let $N \leqslant N_c$. Then for every minimizer ρ^N there exists a parameter $\mu(N)$, the chemical potential, such that ρ^N obeys the coupled TF equations

$$3\kappa(\rho_m^N(z))^2 = \left[ZV_m(z) - \sum_n \int V_{m,n}(z-z')\rho_n^N(z') + \mu(N) \right]_+ \quad \forall (m \in \mathbb{N}_0), \tag{III.32}$$

and $\mu(N)$ fulfills the relation

$$\frac{\partial}{\partial N} E^{\mathrm{DSTF}}(N,Z,B) = \mu(N). \tag{III.33}$$

Proof: The proof works analogously to Ref. 9, Theorem II.10, if the variable perpendicular to the field is replaced by the angular momentum quantum numbers. □

Theorem III.7: All statements of Theorem III.5 and Proposition III.6 are also valid for the MSTF theory, where the minimizing MSTF densities $\rho^N(\mathbf{x})$ and the minimizing DSTF densities $(\rho_m^N(z))_m$ are related as

$$\rho^N(\mathbf{x}) = \frac{B}{2\pi} \sum_m \chi_m(\mathbf{x}_\perp)\rho_m^N(z). \tag{III.34}$$

The corresponding TF equation reads

$$3\kappa(\rho^N(\mathbf{x}))^2 = \left[Z\widetilde{|\mathbf{x}|^{-1}} - \sum_{n,m} \int d\mathbf{x}' \chi_m(\mathbf{x}_\perp) V_{m,n}(z-z')\chi_n(\mathbf{x}'_\perp)\rho^N(\mathbf{x}') + \mu(N) \right]_+ . \tag{III.35}$$

Proof: The existence of a minimizing density $\rho^N(\mathbf{x})$ we get from Theorem III and Lemma III.1. The uniqueness follows from the strict convexity of ρ^3 in ρ. □

Next we try to collect some information about the ''critical'' particle number N_c, which measures the maximal particle number that can be bound to the nucleus in the D(M)STF theory.

Proposition III.8: $N_c \geqslant Z$.

Proof: By definition of N_c, we have $\mu(N_c)=0$, so the TF equation reads ($\rho^{N_c}=\rho$)

$$3\kappa\rho_m(z)=[\varphi_{\text{eff}}^{(m)}(z)]_+ \quad \forall m \in \mathbb{N}_0, \tag{III.36}$$

with

$$\varphi_{\text{eff}}^{(m)}(z)=ZV_m(z)-\sum_n \int V_{m,n}(z-z')\rho_n(z'). \tag{III.37}$$

We assume $N_c<Z$.

References 10 and 11 tell us that the potentials $V_m(z)$ and $V_{n,m}(z-z')$ behave like $1/|z|$ as $z\to\infty$. Hence, we get that for each m

$$\lim_{z\to\infty}|z|[ZV_m(z)]=Z, \tag{III.38}$$

as well as

$$\lim_{z\to\infty}|z|\left[\sum_n \int V_{m,n}(z-z')\rho_n(z')\right]=\sum_n \int \lim_{z\to\infty}|z|V_{m,n}(z-z')\rho_n(z')=\sum_n \int \rho_n=N_c. \tag{III.39}$$

Since we therefore get

$$\lim_{z\to\infty}|z|\varphi_{\text{eff}}^{(m)}(z)=Z-N_c>0, \tag{III.40}$$

we can conclude that there exists an $\varepsilon>0$ and a $\overline{z}>0$, such that

$$\varphi_{\text{eff}}^{(m)}(z)\geqslant\varepsilon|z| \quad \text{for } z\geqslant\overline{z}, \tag{III.41}$$

which by (III.36) is a contradiction to $\rho_m \in \mathcal{L}^1(\mathbb{R})$. □

In the usual STF theory the inequality $N_c\leqslant Z$ is a consequence of Newton's potential theory. Since we miss this powerful tool in our DSTF theory we cannot expect to get an analogous estimate. But if we use methods similar to those applied in Refs. 10, 12, and 13 we at least get the following B-independent upper bound for N_c.

Proposition III.9: $N_c\leqslant 4Z$.

Proof: If we multiply (III.36) with ρ_m/V_m and integrate over z, we get

$$3\kappa\int dz\frac{\rho_m(z)^3}{V_m(z)}=Z\int dz\rho_m(z)-\sum_n \int dzdz'\frac{1}{V_m(z)}\rho_n(z')V_{n,m}(z-z')\rho_m(z). \tag{III.42}$$

Note that by multiplication with ρ_m the $[\,]_+$-bracket can be dropped, since $\rho_m=0$ where $\varphi_{\text{eff}}^{(m)}(z)\leqslant 0$. Clearly $\int\rho_m^3/V_m\geqslant 0$, so after summing over m we arrive at

$$ZN_c\geqslant\sum_{n,m} \int dzdz'\frac{1}{V_m(z)}\rho_n(z')V_{n,m}(z-z')\rho_m(z). \tag{III.43}$$

Moreover, Ref. 13, Lemma 4.1, tells us

$$\left(\frac{1}{V_m(z)}+\frac{1}{V_n(z)}+\frac{1}{V_m(z')}+\frac{1}{V_n(z')}\right)V_{m,n}(z-z')\geqslant 1, \tag{III.44}$$

which we use, together with symmetry, in order to estimate the right side of (III.43):

$$\begin{aligned}\sum_{m,n}\int\frac{1}{V_m(z)}\rho_m(z)V_{m,n}(z-z')\rho_n(z')dzdz'&\\ =\frac{1}{4}\sum_{m,n}\int\left(\frac{1}{V_m(z)}+\frac{1}{V_n(z)}+\frac{1}{V_m(z')}+\frac{1}{V_n(z')}\right)\rho_m(z)V_{m,n}(z-z')\rho_n(z')dzdz'&\\ \geqslant\frac{1}{4}N_c^2.&\end{aligned}\tag{III.45}$$

Inserting into (III.43) finally leads to

$$N_c\leqslant 4Z.\tag{III.46}$$

□

Remark III.10 (The difference between E^{DSTF} and E^{STF}): Obviously, the magnitude of difference between the D(M)STF and the STF energy is given by

$$B\left[\int|\phi^{\mathrm{MSTF}}(\mathbf{x})|^{3/2}-\int|\phi^{\mathrm{STF}}(\mathbf{x})|^{3/2}\right].\tag{III.47}$$

Due to the singularity of the STF potential, (III.47) has to be split into

$$B\int_{|\mathbf{x}|\leqslant B^{-1/2}}\left[|\phi^{\mathrm{MSTF}}(\mathbf{x})|^{3/2}-\int|\phi^{\mathrm{STF}}(\mathbf{x})|^{3/2}\right]+B\int_{|\mathbf{x}|\geqslant B^{-1/2}}\left[|\phi^{\mathrm{MSTF}}(\mathbf{x})|^{3/2}-\int|\phi^{\mathrm{STF}}(\mathbf{x})|^{3/2}\right].\tag{III.48}$$

The magnitude of the first term is proportional to

$$Z^{3/2}B\int_{|\mathbf{x}|\leqslant B^{-1/2}}|\mathbf{x}|^{-3/2}=O(Z^{3/2}B^{1/4}).\tag{III.49}$$

The second term of (III.48) could be estimated by

$$B\int_{|\mathbf{x}|\geqslant B^{-1/2}}|\phi^{\mathrm{STF}}(\mathbf{x})|^{1/2}|\partial_\theta\phi^{\mathrm{STF}}(\mathbf{x})|B^{-1/2}\leqslant Z^{3/2}B^{1/2}[r_S]^{3/2},\tag{III.50}$$

with $\theta=|\mathbf{x}_\perp|$. So we see that the main contribution to (III.47) stems from the $B^{-1/2}$-vicinity of the nucleus, i.e.,

$$E^{\mathrm{DSTF}}-E^{\mathrm{STF}}=O(Z^{3/2}B^{1/4}).\tag{III.51}$$

A. Some notes about the one-dimensional case

If we reduce the DSTF functional to the angular momentum channel with $m=0$, one gets the functional

$$\mathcal{E}^{1\mathrm{DSTF}}[\rho]=\kappa\int dz\rho(z)^3-Z\int dzV_0(z)\rho(z)+\frac{1}{2}\int dzdz'V_{0,0}(z-z')\rho(z)\rho(z'),\tag{III.52}$$

which can be treated analogously to the three dimensional case, and Theorem III.5 and Proposition III.8 are also valid. Concerning the upper bound of N_c, it is not necessary to symmetrize over n and m, and in this case (III.45) reads

$$\int \frac{1}{V_0(z)}\rho(z)V_{0,0}(z-z')\rho(z')dzdz' = \frac{1}{2}\int \left(\frac{1}{V_0(z)}+\frac{1}{V_0(z')}\right)\rho(z)V_{0,0}(z-z')\rho(z')dzdz'$$
$$\geqslant \frac{1}{2}N_c^2.$$

Consequently, one gets $N_c \leqslant 2Z$ for the maximum particle number that can be bound to the nucleus in the one-dimensional theory.

Moreover, let us regard the absolute minimum $\overline{E}^{1\mathrm{DSTF}}(Z,B)$ of the functional $\mathcal{E}^{1\mathrm{DSTF}}[\rho] = \mathcal{E}_{Z,B}[\rho]$. If we use the scaling relations

$$V_0(z) = B^{1/2}V_0^1(B^{1/2}z), \quad V_{0,0}(z) = B^{1/2}V_{0,0}^1(B^{1/2}z), \tag{III.53}$$

and define

$$\overline{\rho}(z) = B^{1/4}Z^{1/2}\rho(B^{1/2}z), \tag{III.54}$$

we get

$$\mathcal{E}_{Z,B}[\overline{\rho}] = B^{1/4}Z^{3/2}\mathcal{E}_{1,1}^{\lambda}[\rho], \tag{III.55}$$

with

$$\mathcal{E}_{1,1}^{\lambda}[\rho] = \kappa\int dz\rho(z)^3 - \int dzV_0^1(z)\rho(z) + \frac{1}{\lambda}\int dzdz' V_{0,0}^1(z-z')\rho(z)\rho(z'), \tag{III.56}$$

and $\lambda = 2B^{1/4}Z^{1/2}$.

Let $E_w^{1D}(Z,B)$ be the minimum of the functional

$$\mathcal{E}_w^{1D}[\rho] = \kappa\int dz\rho(z)^3 - Z\int dzV_0(z)\rho(z), \tag{III.57}$$

where the repulsive energy term is omitted. Using the above scaling (III.54), one immediately gets $E_w^{1D}(Z,B) = Z^{3/2}B^{1/4}E_w^{1D}(1,1)$. So we can formulate the following theorem:

Theorem III.11: *If $Z,B \geqslant 1$ are fixed, then*

$$E_w^{1D}(Z,B) \leqslant \overline{E}^{1\mathrm{DSTF}}(Z,B) \leqslant E_w^{1D}(Z,B) + Z(1+2\ln[BZ^2]^2). \tag{III.58}$$

Proof: The lower bound is obvious.

For the upper bound we use the relation (III.55) and take the TF-solution of $\mathcal{E}_{1,1}^{\infty}$, i.e.,

$$\rho(z) = \frac{1}{\pi}\sqrt{V_0^1(z)}. \tag{III.59}$$

This density is neither in $\mathcal{L}^1$ nor in $\mathcal{L}^2$, so we define a cut-off density $\rho_R(z) = \pi\sqrt{V_0^1(z)}\Theta(R-|z|)$ and use this as comparison density in (III.55), which leads to

$$\mathcal{E}_{1,1}^{\lambda}[\rho_R] = E_w^{1D}(1,1) + \int_R^{\infty}(V_0^1(z))^{3/2} + \frac{1}{\lambda}\int \rho_R(z)V_{0,0}^1(z-z')\rho_R(z')dzdz'. \tag{III.60}$$

Since $V_{0,0}^1(z) \leqslant \min\{1/|x|, \sqrt{\pi/4}\}$ we get by Young's inequality

$$\int \rho_R(z)V_{0,0}^1(z-z')\rho_R(z')dzdz' \leqslant \left[\left(\int \rho_R\right)^2\frac{1}{\beta} + 2\ln(\beta)\int \rho_R^2\right] \quad \forall \beta \geqslant 1. \tag{III.61}$$

After estimating $\int \rho_R$ and $\int \rho_R^2$ we see that the minimum of (III.61) as a function of β is achieved for $\beta = R/\ln(R)$, which implies

$$\int \rho_R(z) V_{0,0}^1(z-z') \rho_R(z') dz dz' \leqslant [\ln(R) + \ln(R)^2]. \tag{III.62}$$

Next, optimizing the last two term on the right side of (III.60) with respect to R and multiplying with $B^{1/4}Z^{3/2}$ yields the statement of the theorem. □

By aid of this theorem we can also prove that $\overline{E}^{1\mathrm{DSTF}}(Z,B)$ is the semiclassical approximation of $\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}[-\partial_z^2 - ZV_0(z)]_-$, the sum of all negative eigenvalues of $-\partial_z^2 - ZV_0(z)$.

Corollary III.12: Let B,Z≥1 and B≤Z². Then there exists a constant C, such that

$$\left|\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}[-\partial_z^2 - ZV_0(z)]_- - \overline{E}^{1\mathrm{DSTF}}(Z,B)\right| \leqslant C \max\{Z \ln[BZ^2], B^{3/4}Z^{1/2}\}. \tag{III.63}$$

Proof: This is an immediate consequence of Theorem III.11 and Ref. 5, Theorem 3.19, which says that

$$\left|\mathrm{Tr}_{\mathcal{L}^2(\mathbb{R})}[-\partial_z^2 - ZV_0(z)]_- - E_w^{1D}(Z,B)\right| \leqslant CB^{3/4}Z^{1/2}. \tag{III.64}$$

□

We learn from Theorem 3.10 that in a model of a one dimensional semiclassical atom, where the electrons are forced to stay in the angular momentum channel $m=0$, the repulsive interaction energy does not contribute to the leading order of the energy $\overline{E}^{1\mathrm{DSTF}}(Z,B)$ for large Z and $B \geqslant 1$.

An analogous effect is obtained for the quantum mechanical interaction energy of N particles reduced to the angular momentum $m=0$, i.e.,

$$\Psi = \phi_0 \otimes \cdots \otimes \phi_0 \psi(z_1, \ldots, z_N). \tag{III.65}$$

For ψ a Slater determinant or at least for ψ close to the ground state of the corresponding N-particle Hamiltonian H_0, which is the projection onto the angular momentum eigenspace with angular momentum $m=0$, the interaction energy can be bounded from above by (for a precise lower bound see Ref. 14)

$$\frac{1}{2} \int_{\mathbb{R}^2} \rho_\psi(z) \rho_\psi(z') V_{0,0}(z-z') dz dz', \tag{III.66}$$

which can be estimated by an analogous method to (III.61). This leads to

$$\frac{1}{2} \int_{\mathbb{R}^2} \rho_\psi(z) \rho_\psi(z') V_{0,0}(z-z') dz dz' \leqslant C E_0^{1/2} N^{1/2} [1 + \ln(BN^3/E_0)], \tag{III.67}$$

where we have used that $\langle \Psi, H_N \Psi \rangle \leqslant 0$ and E_0 is the corresponding ground state energy [of wave functions of the form (III.65)], which is of the same order as $\overline{E}^{1\mathrm{DSTF}}$ as long as $B \leqslant Z^2$. Relation (III.67) yields that the quantum mechanical interaction energy in one dimension is $\ll E_0$ as long as $E_0 \gg N$.

(Received 21 September 2001; accepted for publication 7 December 2001)

We describe a family of coherent states and an associated resolution of the identity for a quantum particle whose classical configuration space is the d-dimensional sphere S^d. The coherent states are labeled by points in the associated phase space $T^*(S^d)$. These coherent states are *not* of Perelomov type but rather are constructed as the eigenvectors of suitably defined annihilation operators. We describe as well the Segal–Bargmann representation for the system, the associated unitary Segal–Bargmann transform, and a natural inversion formula. Although many of these results are in principle special cases of the results of Hall and Stenzel, we give here a substantially different description based on ideas of Thiemann and of Kowalski and Rembieliński. All of these results can be generalized to a system whose configuration space is an arbitrary compact symmetric space. We focus on the sphere case in order to carry out the calculations in a self-contained and explicit way. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1446664]

I. INTRODUCTION

In Ref. 1, Hall introduced a family of coherent states for a system whose classical configuration space is the group manifold of a compact Lie group G. These coherent states are labeled by points in the associated phase space, namely the cotangent bundle $T^*(G)$. The coherent states themselves were originally defined in terms of the *heat kernel* on G, although we will give a different perspective here. One may identify[2] $T^*(G)$ with the complexified group $G_{\mathbb{C}}$, where, for example, if $G=\mathrm{SU}(2)$ then $G_{\mathbb{C}}=\mathrm{SL}(2;\mathbb{C})$. The paper[1] establishes a resolution of the identity for these coherent states, and equivalently, a unitary Segal–Bargmann transform. The Segal–Bargmann representation of this system is a certain Hilbert space of holomorphic functions over the complex group $G_{\mathbb{C}}$. Additional results may be found in Refs. 2–4 and the survey paper.[5]

The coherent states for G (in the form of the associated Segal–Bargmann transform) have been applied to quantum gravity in Ref. 6, with proposed generalizations due to Thiemann.[7] More recently the coherent states themselves have been used by Thiemann and co-authors[8] in an attempt to determine the classical limit of the quantum gravity theory proposed by Thiemann in Ref. 9. In particular, the second entry in Ref. 8 establishes good phase space localization properties (in several different senses) for the coherent states associated to the configuration space $G=\mathrm{SU}(2)$.

In another direction, Wren,[10] using a method proposed by Landsman,[11] has shown that the coherent states for G arise naturally in the canonical quantization of $(1+1)$-dimensional Yang–Mills theory on a space–time cylinder. Here G is the structure group of the theory and plays the role of the reduced configuration space, that is, the space of connections modulo based gauge transformation over the spatial circle. Wren considers first the ordinary canonical coherent states for the unreduced (infinite-dimensional) system. He then shows that after ''projecting'' them into the gauge-invariant subspace (using a suitable regularization procedure) these become precisely the generalized coherent states for G, as originally defined in Ref. 1. Driver and Hall[12] elaborate

a)Electronic mail: bhall@nd.edu
b)Electronic mail: jeffrey_mitchell@baylor.edu

on the results of Wren, using a different regularization scheme. They show in particular how the resolution of the identity for the generalized coherent states can be obtained by projection from the resolution of the identity for the canonical coherent states. See also Ref. 13 for an appearance of the generalized Segal–Bargmann transform in the setting of two-dimensional Euclidean Yang–Mills theory.

Finally, the paper[14] shows that the generalized Segal–Bargmann transform for G can be obtained by means of geometric quantization (see also Ref. 5, Sec. 3.2). This means that the associated coherent states for G are of ''Rawnsley type'' [15] and are thus in the spirit of Berezin's approach to quantization.

We emphasize that the coherent states for G are *not of Perelomov type*.[16] Instead they are realized as the eigenvectors of certain non-self-adjoint ''annihilation operators,'' as will be described in detail in the present paper. (See Sec. X for further comments.)

The coherent states and the resolution of the identity for G ''descend'' in a straightforward way to the case of a system whose configuration space is a compact symmetric space X (Ref. 1, Sec. 11). Compact symmetric spaces are manifolds of the form G/K, where G is a compact Lie group and K is a special sort of subgroup, namely, the fixed-point subgroup of an involution. Examples include the spheres $S^d = \mathrm{SO}(d+1)/\mathrm{SO}(d)$ and the complex projective spaces $\mathbb{C}P^d = \mathrm{SU}(d+1)/\mathrm{SU}(d)$. Compact Lie groups themselves can be thought of as symmetric spaces by identifying G with $(G\times G)/\Delta(G)$ where $\Delta(G)$ is the ''diagonal'' copy of G inside $G\times G$.

We emphasize that in the case $X=S^2$ the 2-sphere is playing the role of the *configuration space* and thus the coherent states discussed here are completely different from the spin coherent states in which the 2-sphere plays the role of the phase space. Whereas the spin coherent states are labeled by points in S^2 itself, our coherent states are labeled by points in the cotangent bundle $T^*(S^2)$.

Although the case of compact symmetric spaces can be treated by descent from the group, it is preferable to give a direct treatment, and such a treatment was given by Stenzel.[17] In particular Stenzel gives a much better description, in the symmetric space case, of the measure that one uses to construct the resolution of the identity (see also Ref. 5, Sec. 3.4). Although Stenzel formulates things in terms of a unitary Segal–Bargmann transform and does not explicitly mention the coherent states, only a notational change is needed to re-express his results as a resolution of the identity for the associated coherent states.

More recently, the coherent states for the 2-sphere S^2 were independently discovered, from a substantially different point of view, by Kowalski and Rembieliński.[18] (Reference 18 builds on earlier work of Kowalski, Rembieliński, and Papaloucas[19] on the S^1 case.) These authors were unaware at the time of the work of Hall and Stenzel. Reference 20 then describes the resolution of the identity for the coherent states on the 2-sphere, showing in a different and more explicit way that the result of Ref. 17, Theorem 3 holds in this case. (See Sec. VII of Ref. 20 for comments on the relation of their work to that of Stenzel.)

The purpose of this paper is to describe the coherent states for a compact symmetric space using the points of view advocated by Thiemann and by Kowalski and Rembieliński. For the sake of concreteness we concentrate in this paper on the case $X=S^d$. In Refs. 1 and 17 the coherent states are defined in terms of the heat kernel on the configuration space, which takes the place of the Gaussian that enters into the description of the canonical coherent states. Here by contrast the coherent states are defined to be the eigenvectors of suitable annihilation operators, and only afterwards does one discover the role of the heat kernel, in the position wave function of the coherent states and in the reproducing kernel. The annihilation operators, meanwhile, are defined by (a special case of) the ''complexifier'' method proposed by Thiemann, which we will show is equivalent to (a generalization of) the polar decomposition method of Kowalski and Rembieliński. We emphasize, though, that the approach described in this paper gives ultimately the same results as the heat kernel approach of Hall and Stenzel.

II. MAIN RESULTS

In this section we briefly summarize the main results of the paper. All results are explained in greater detail in the subsequent sections. Briefly, our strategy is this. First, we construct complex-valued functions $a_1,\ldots,a_{d+1}$ on the classical phase space that serve to define a complex structure on phase space. Second, we construct the quantum counterparts of these functions, operators $A_1,\ldots,A_{d+1}$ that we regard as the annihilation operators. Third, we construct simultaneous eigenvectors for the annihilation operators, which we regard as the coherent states. Fourth, we construct a resolution of the identity for these coherent states.

We consider a system whose classical configuration space is the d-dimensional sphere S^d of radius r. We consider also the corresponding phase space, the cotangent bundle $T^*(S^d)$, which we describe as

$$T^*(S^d)=\{(\mathbf{x},\mathbf{p})\in\mathbb{R}^{d+1}\times\mathbb{R}^{d+1}|x^2=r^2,\mathbf{x}\cdot\mathbf{p}=0\},$$

where $\mathbf{p}$ is the *linear* momentum.

In Sec. III we consider the classical component of Thiemann's method. To apply this method we must choose a constant ω with units of frequency. The classical "complexifier" is then defined to be *kinetic energy function divided by* ω, which can be expressed as

$$\text{complexifier}=\frac{\text{kinetic energy}}{\omega}=\frac{j^2}{2m\omega r^2},$$

where j^2 is the total angular momentum. (Thiemann's method allows other complexifiers; see Sec. III.) We construct complex-valued functions $a_1,\ldots,a_{d+1}$ by taking the position functions $x_1,\ldots,x_{d+1}$ and applying repeated Poisson brackets with the complexifier. Specifically,

$$a_k=e^{i\{\cdot,\text{complexifier}\}}x_k=\sum_{n=0}^{\infty}\left(\frac{i}{2m\omega r^2}\right)^n\frac{1}{n!}\underbrace{\{\cdots\{\{x_k,j^2\},j^2\},\cdots,j^2\}}_{n}. \tag{1}$$

If we let $\mathbf{a}=(a_1,\ldots,a_{d+1})$ then the calculations in Sec. III will give the following explicit formula:

$$\mathbf{a}=\cosh\left(\frac{j}{m\omega r^2}\right)\mathbf{x}+i\frac{r^2}{j}\sinh\left(\frac{j}{m\omega r^2}\right)\mathbf{p}. \tag{2}$$

These complex-valued functions satisfy $a_1^2+\cdots+a_{d+1}^2=r^2$ and $\{a_k,a_l\}=0$. In the case $d=2$ this agrees with Eq. (6.1) of Ref. 18.

In Sec. IV we consider the quantum component of Thiemann's method. We consider the quantum counterpart of the classical complexifier, namely,

$$\text{complexifier}=\frac{\text{kinetic energy}}{\omega}=\frac{J^2}{2m\omega r^2},$$

where J^2 is the total angular momentum operator. Then if $X_1,\ldots,X_{d+1}$ denote the position operators we define, by analogy with (1),

$$A_k=e^{i[\cdot,\text{complexifier}]/i\hbar}X_k=\sum_{n=0}^{\infty}\left(\frac{1}{2m\omega r^2\hbar}\right)^n\frac{1}{n!}\underbrace{[\cdots[[X_k,J^2],J^2],\cdots,J^2]}_{n}. \tag{3}$$

This may also be written as

$$A_k=e^{-J^2/2m\omega r^2\hbar}X_k e^{J^2/2m\omega r^2\hbar}. \tag{4}$$

Equation (30) in Sec. IV gives the quantum counterpart of (2); it is slightly more complicated than (2) because of quantum corrections. The annihilation operators satisfy $A_1^2+\cdots+A_{d+1}^2=r^2$ and $[A_k,A_l]=0$. Applying the same procedure in the $\mathbb{R}^d$ case produces the usual complex coordinates on phase space and the usual annihilation operators (Sec. VIII).

One can easily deduce from (4) a "polar decomposition" for the annihilation operator, given in (33) in Sec. IV. In the case $d=2$ this is essentially the same as what Kowalski and Rembieliński take as the definition of the annihilation operators. This shows that Thiemann's complexifier approach is equivalent to the polar decomposition approach of Kowalski and Rembieliński. Similarly, the polar form of the annihilation operators in the $d=1$ case is essentially the same as what Kowalski, Rembieliński, and Papaloucas take as the definition of the annihilation operator in Ref. 19.

In Sec. V we consider the coherent states, defined to be the simultaneous eigenvectors of the annihilation operators. Using (4) we may immediately write down some eigenvectors for the A_k's, namely, the vectors of the form,

$$|\psi_{\mathbf{a}}\rangle = e^{-J^2/2m\omega r^2\hbar}|\delta_{\mathbf{a}}\rangle, \tag{5}$$

where $|\delta_{\mathbf{a}}\rangle$ is a simultaneous eigenvector for the position operators corresponding to a point $\mathbf{a}$ in S^d. A key result of Sec. V is that one can perform an analytic continuation with respect to the parameter $\mathbf{a}$, thereby obtaining coherent states $|\psi_{\mathbf{a}}\rangle$ corresponding to any point $\mathbf{a}$ in the *complexified* sphere, $S^d_{\mathbb{C}}=\{\mathbf{a}\in\mathbb{C}^{d+1}|\ a^2=r^2\}$. These vectors $|\psi_{\mathbf{a}}\rangle$ are normalizable and satisfy

$$A_k|\psi_{\mathbf{a}}\rangle = a_k|\psi_{\mathbf{a}}\rangle, \quad \mathbf{a}\in S^d_{\mathbb{C}}.$$

Equation (5) shows that the coherent states are expressible in terms of the heat kernel on the sphere, thus demonstrating that Thiemann's definition of the coherent states is equivalent to the definition in Refs. 1, 17 in terms of the heat kernel. The reproducing kernel for these coherent states is also expressed in terms of the heat kernel on the sphere.

In Sec. VI we describe a resolution of the identity for these coherent states. In a suitable coordinate system this takes the form

$$I=\int_{\mathbf{x}\in S^d}\int_{\mathbf{p}\cdot\mathbf{x}=0}|\psi_{\mathbf{a}}\rangle\langle\psi_{\mathbf{a}}|\,\nu(2\tau,2p)\left(\frac{\sinh 2p}{2p}\right)^{d-1}2^d d\mathbf{p}d\mathbf{x}, \tag{6}$$

where $\mathbf{a}$ is a function of $\mathbf{x}$ and $\mathbf{p}$ as in (2). Here ν is the heat kernel for d-dimensional hyperbolic space and τ is the dimensionless quantity given by $\tau=\hbar/m\omega r^2$. Explicit formulas for ν are found in Sec. VI. The resolution of the identity for the coherent states is obtained by a continuous deformation of the resolution of the identity for the position eigenvectors.

In Sec. VII we discuss the Segal–Bargmann representation for this system, namely, the space of holomorphic functions on the complexified sphere that are square-integrable with respect to the density in (6). We think of the Segal–Bargmann representation as giving a sort of *phase space wave function* for any state. There is an inversion formula stating the position wave function can be obtained from the phase space wave function by integrating out the momentum variables, specifically,

$$\langle\delta_{\mathbf{x}}|\phi\rangle=\int_{\mathbf{p}\cdot\mathbf{x}=0}\langle\psi_{\mathbf{a}(\mathbf{x},\mathbf{p})}|\phi\rangle\,\nu(\tau,p)\left(\frac{\sinh p}{p}\right)^{d-1}d\mathbf{p}$$

for any state $|\phi\rangle$. Note that whereas the resolution of the identity involves $\nu(2\tau,2p)$, the inversion formula involves $\nu(\tau,p)$.

In Sec. VIII we show that the complexifier method, when applied to the $\mathbb{R}^d$ case, yields the usual canonical coherent states and their resolution of the identity. In Sec. IX we summarize some of the relevant representation theory for the Euclidean group. Finally, in Sec. X we compare our construction to other constructions of coherent states on spheres.

Although all of the results here generalize to arbitrary compact symmetric spaces X, we concentrate for the sake of explicitness on the case $X=S^d$. We will describe the general case in a forthcoming paper.

III. COMPLEX COORDINATES ON PHASE SPACE

In this section we define Poisson-commuting complex-valued functions $a_1,\ldots,a_{d+1}$ on the classical phase space. In Sec. IV we will introduce the quantum counterparts of these functions, commuting non-self-adjoint operators $A_1,\ldots,A_{d+1}$ which we regard as the annihilation operators for this system. In Sec. V we will consider the coherent states, that is, the simultaneous eigenvectors of the annihilation operators.

Consider the d-dimensional sphere of radius r in $\mathbb{R}^{d+1}$, namely,

$$S^d=\{\mathbf{x}\in\mathbb{R}^{d+1}|x_1^2+\cdots+x_{d+1}^2=r^2\},$$

regarded as the *configuration space* for a classical system ($d\geqslant 1$). Then consider the associated phase space, the cotangent bundle $T^*(S^d)$, which we think of as

$$T^*(S^d)=\{(\mathbf{x},\mathbf{p})\in\mathbb{R}^{d+1}\times\mathbb{R}^{d+1}|x^2=r^2,\ \mathbf{x}\cdot\mathbf{p}=0\}.$$

Here p is the *linear* momentum, which must be tangent to S^d, i.e., perpendicular to $\mathbf{x}$.

We also have the **angular momentum** functions j_{kl}, $1\leqslant k,l\leqslant d+1$, given by

$$j_{kl}=p_kx_l-p_lx_k. \tag{7}$$

We may think of j as a function on $T^*(S^d)$ taking values in the space of $(d+1)\times(d+1)$ skew-symmetric matrices, that is, in the Lie algebra so$(d+1)$. Thinking of j as a matrix we may rewrite (7) as

$$\mathbf{j}(\mathbf{x},\mathbf{p})=\mathbf{p}\otimes\mathbf{x}-\mathbf{x}\otimes\mathbf{p},$$

where $\otimes$ denotes the outer product. [That is, $(\mathbf{a}\otimes\mathbf{b})_{kl}=a_kb_l$.]

For a particle constrained to the sphere it is possible and convenient to express everything in terms of $\mathbf{x}$ and $\mathbf{j}$ instead of $\mathbf{x}$ and $\mathbf{p}$. We may alternatively describe $T^*(S^d)$ as the set of pairs $(\mathbf{x},\mathbf{j})$ in which $\mathbf{x}$ is a vector in $\mathbb{R}^{d+1}$, $\mathbf{j}$ is a $(d+1)\times(d+1)$ skew-symmetric matrix, and $\mathbf{x}$ and $\mathbf{j}$ satisfy

$$x^2=r^2 \tag{8}$$

and

$$r^2j_{kl}=j_{km}x_mx_l-x_kj_{lm}x_m \tag{9}$$

(sum convention). This last condition says that if we *define* $\mathbf{p}$ to be $r^{-2}\mathbf{jx}$, then $\mathbf{j}=\mathbf{p}\otimes\mathbf{x}-\mathbf{x}\otimes\mathbf{p}$. Equation (9) reflects the constraint to the sphere and does not hold for a general particle in $\mathbb{R}^{d+1}$. On $T^*(S^d)$ we have the relations

$$\begin{aligned}\mathbf{jx}&=r^2\mathbf{p},\\ \mathbf{jp}&=-p^2\mathbf{x}.\end{aligned} \tag{10}$$

Recall that $\mathbf{j}$ is a matrix; thus $\mathbf{jx}$ is the vector obtained by applying the matrix $\mathbf{j}$ to the vector $\mathbf{x}$, and similarly for $\mathbf{jp}$.

In the case $d=2$ (S^2 sitting inside $\mathbb{R}^3$) a standard vector identity shows that for any vector $\mathbf{v}\in\mathbb{R}^3$, $\mathbf{jv}=(\mathbf{x}\times\mathbf{p})\times\mathbf{v}$, where $\times$ is the cross-product and $\mathbf{x}\times\mathbf{p}$ is the usual angular momentum vector $\mathbf{l}$. So in the $\mathbb{R}^3$ case $\mathbf{jv}=\mathbf{l}\times\mathbf{v}$.

The symplectic structure on $T^*(S^d)$ may be characterized by the Poisson bracket relations,

$$\{j_{kl},j_{mn}\}=\delta_{kn}j_{lm}+\delta_{lm}j_{kn}-\delta_{km}j_{ln}-\delta_{ln}j_{km},$$
$$\{x_k,j_{lm}\}=\delta_{kl}x_m-\delta_{km}x_l, \tag{11}$$
$$\{x_k,x_l\}=0.$$

These are the commutation relations for the Euclidean Lie algebra, which is the semidirect product $e(d+1)\cong \mathrm{so}(d+1)\ltimes \mathbb{R}^{d+1}$.

Poisson bracket relations involving $\mathbf{p}$ should be derived from (11) using the relation $\mathbf{p}=r^{-2}\mathbf{jx}$. Since the constraint to the sphere alters the dynamics and hence the Poisson bracket relations, we will not get the same formulas as in $\mathbb{R}^{d+1}$. For example, we have

$$\{x_k,p_l\}=\delta_{kl}-\frac{x_kx_l}{r^2}. \tag{12}$$

The complex coordinates on phase space will be constructed from the position functions x_k by means of repeated Poisson brackets with a multiple of the kinetic energy function. In the sphere case it is convenient to express the kinetic energy in terms of the total angular momentum j^2, given by

$$j^2=\sum_{k<l}(j_{kl})^2. \tag{13}$$

The total angular momentum satisfies $j^2=r^2p^2$, and the kinetic energy is $p^2/2m=j^2/2mr^2$.

We now choose a constant ω with units of a frequency. The significance of this constant is that $m\omega$ has the units of momentum divided by position. Thus ω (together with m) allows us to put position and momentum onto the same scale, which is necessary in order to define complex-valued functions that involve both x and p. Ultimately, $m\omega$ will control the ratio of the width in position space of the coherent states to the radius of the sphere.

Kowalski and Rembieliński do not have a parameter comparable to our ω; the only dimensional parameters in Ref. 18 are m, r, and $\hbar$. This affects the interpretation of their Eq. (6.1) for the complex coordinates on phase space (what we call **a**). Equation (6.1) involves $\cosh l$ and $\sinh l$, where l is the classical angular momentum. The argument of cosh and sinh should be dimensionless, and the only way to make l dimensionless using only m, r, and $\hbar$ is to divide l by $\hbar$. Thus in Eq. (6.1) of Ref. 18, l implicitly means $l/\hbar$. In our view it is unnatural in a *classical* formula to insist that the angular momentum be measured in units of Planck's constant. In our approach [see (18) below], angular momentum is measured in units of $m\omega r^2$. Although nothing prevents one from choosing ω so that $m\omega r^2=\hbar$, it seems artificial to us to insist on this. After all, Eq. (6.1) concerns a classical construction that ought to be independent of the value of Planck's constant.

We are now ready to apply the ''complexifier'' method of Thiemann.[7] We take as our classical complexifier the kinetic energy function divided by ω,

$$\text{complexifier}=\frac{\text{kinetic energy}}{\omega}=\frac{j^2}{2m\omega r^2}. \tag{14}$$

We then define complex-valued functions $a_1,\ldots,a_{d+1}$ on $T^*(S^d)$ by

$$a_k(\mathbf{x},\mathbf{p})=\exp\left(i\left\{\cdot,\frac{j^2}{2m\omega r^2}\right\}\right)x_k=\sum_{n=0}^{\infty}\left(\frac{i}{2m\omega r^2}\right)^n\frac{1}{n!}\underbrace{\{\cdots\{\{x_k,j^2\},j^2\},\cdots,j^2\}}_{n}. \tag{15}$$

Note that the a_k's are obtained from the x_k's by means of the classical time-evolution generated by the kinetic energy function, evaluated at the *imaginary* time i/ω. The calculations below will show that the series (15) converges for all $\mathbf{x}$ and $\mathbf{p}$.

In Ref. 7, Thiemann allows *any* function C on the phase space to be the complexifier, provided that $\exp(i\{\cdot,C\})x_k$ converges. (Thiemann also allows any cotangent bundle to be the phase space.) The condition of convergence, however, imposes severe restrictions on the choice of C, even when C is quadratic in the momenta. We consider in this paper only the complexifier (14).

To compute the functions a_k explicitly, we first compute using (11) and (13) that, in vector notation,

$$\left\{\mathbf{x},\frac{j^2}{2m\omega r^2}\right\}=\frac{1}{m\omega r^2}\mathbf{j}\mathbf{x}=\frac{1}{m\omega}\mathbf{p}. \tag{16}$$

On the other hand, it is easily verified that $\{j_{kl},j^2\}=0$, which means that if we compute further Poisson brackets with j^2, the matrix $\mathbf{j}$ gets ignored and we get

$$\left(\frac{1}{2m\omega r^2}\right)^n \underbrace{\{\cdots\{\{\mathbf{x},j^2\},j^2\},\cdots,j^2\}}_{n}=\left(\frac{1}{m\omega r^2}\right)^n \mathbf{j}^n\mathbf{x}.$$

Here $\mathbf{j}^n\mathbf{x}$ means the matrix $\mathbf{j}$ applied n times to the vector $\mathbf{x}$.

We obtain, then, the following "polar coordinates" expression for $\mathbf{a}=(a_1,\ldots,a_{d+1})$

$$\mathbf{a}(\mathbf{x},\mathbf{p})=e^{i\mathbf{j}(x,p)/m\omega r^2}\mathbf{x}. \tag{17}$$

[Compare Eq. (3.37) in the first entry of Ref. 8.] Using (10) we can compute this explicitly as

$$\mathbf{a}(\mathbf{x},\mathbf{p})=\cosh\left(\frac{p}{m\omega r}\right)\mathbf{x}+i\frac{r}{p}\sinh\left(\frac{p}{m\omega r}\right)\mathbf{p}=\cosh\left(\frac{j}{m\omega r^2}\right)\mathbf{x}+i\frac{r^2}{j}\sinh\left(\frac{j}{m\omega r^2}\right)\mathbf{p}. \tag{18}$$

We may at this point check the units: $p/m\omega r=j/m\omega r^2$ is dimensionless and the whole expression has units of position. Note also that $\mathbf{a}(\mathbf{x},-\mathbf{p})=\mathbf{a}(\mathbf{x},\mathbf{p})$.

With $d=2$ (and $r=m\omega=1$) (18) agrees with Eq. (6.1) of Ref. 18. [See also Eq. (3.6) in the second entry of Ref. 8.] In any dimension (18) agrees with the "adapted complex structure" on $T^*(S^d)$ as defined by Lempert and Szőke[21] and Guillemin and Stenzel,[22] which for the special case of rank one symmetric spaces was constructed earlier by Morimoto and Nagano.[23] See, for example, p. 410 of Ref. 24.

It is instructive to consider how this works out in the case of $S^1\subset\mathbb{R}^2$. In that case we have only a single component of angular momentum, $j_{12}=p_1x_2-p_2x_1$, so that $j=|j_{12}|$. Since both terms in (18) are even functions of j, we may replace j by j_{12} there. Then let θ be the usual angular coordinate and let $\rho=-j_{12}/m\omega r^2$, so that ρ is (up to a constant) the canonically conjugate momentum to θ. Our phase space is the set of points (x_1,x_2,p_1,p_2) with $x_1^2+x_2^2=r^2$ and $p_1x_1+p_2x_2=0$. On this set we have the easily verified identity $j_{12}(x_2,-x_1)=r^2(p_1,p_2)$. Upon using this identity and $\mathbf{x}=r(\cos\theta,\sin\theta)$, (18) becomes

$$\mathbf{a}=r(\cosh\rho\cos\theta-i\sinh\rho\sin\theta,\cosh\rho\sin\theta+i\sinh\rho\cos\theta)=r(\cos(\theta+i\rho),\sin(\theta+i\rho)). \tag{19}$$

This result facilitates comparison with the analysis of the S^1 case in Ref. 19 and should be thought of as the "complexification" of the identity $\mathbf{x}=r(\cos\theta,\sin\theta)$.

As is well known, the Poisson bracket satisfies a Leibniz-type product rule, $\{f_1,f_2f_3\}=\{f_1,f_2\}f_3+f_2\{f_1,f_3\}$, and the analogous formula for Poisson brackets, $\{f_1,\{f_2,f_3\}\}=\{\{f_1,f_2\},f_3\}+\{f_2,\{f_1,f_3\}\}$. (This last expression is equivalent to the Jacobi identity.) Suppose then that we define the "complexification" $f_{\mathbb{C}}$ of any function f to be

$$f_{\mathbb{C}}=e^{i\{\cdot,\text{complexifier}\}}f$$

whenever the power series for the exponential converges. Then by a standard power series argument we have

$$(f_1 f_2)_{\mathbb{C}} = (f_1)_{\mathbb{C}} (f_2)_{\mathbb{C}} \tag{20}$$

and

$$\{f_1, f_2\}_{\mathbb{C}} = \{(f_1)_{\mathbb{C}}, (f_2)_{\mathbb{C}}\}. \tag{21}$$

Equation (20) shows that if we "complexify" any polynomial in the variables $x_1, \ldots, x_{d+1}$ we will get simply the same polynomial in $a_1, \ldots, a_{d+1}$. Furthermore, since $\{x_k, x_l\} = 0$, (21) shows that

$$\{a_k, a_l\} = 0, \tag{22}$$

which implies that $\{\overline{a_k}, \overline{a_l}\} = 0$. The formula for $\{a_k, \overline{a_l}\}$, however, is complicated and we will not compute it here.

Equation (20) also shows that

$$a^2(\mathbf{x}, \mathbf{p}) = r^2 \tag{23}$$

for all $\mathbf{x}, \mathbf{p}$, which is also evident from (18). Thus the map $(\mathbf{x}, \mathbf{p}) \to \mathbf{a}(\mathbf{x}, \mathbf{p})$ defines a map of the cotangent bundle $T^*(S^d)$ to the *complexified sphere*,

$$S^d_{\mathbb{C}} = \{\mathbf{a} \in \mathbb{C}^{d+1} | a_1^2 + \cdots + a_{d+1}^2 = r^2\}. \tag{24}$$

It is not hard to see that this map is invertible, indeed a diffeomorphism of $T^*(S^d)$ with $S^d_{\mathbb{C}}$.

IV. THE ANNIHILATION OPERATORS

We now consider the quantum counterpart of the constructions in the previous section. This means that the functions j_{kl} and x_k should be replaced by self-adjoint operators J_{kl} and X_k acting on (suitable domains in) some separable complex Hilbert space. These should satisfy $J_{lk} = -J_{kl}$ and the quantum counterpart of the Poisson-bracket relations (11), namely,

$$\begin{aligned} \frac{1}{i\hbar}[J_{kl}, J_{mn}] &= \delta_{kn} J_{lm} + \delta_{lm} J_{kn} - \delta_{km} J_{ln} - \delta_{ln} J_{km}, \\ \frac{1}{i\hbar}[X_k, J_{lm}] &= \delta_{kl} X_m - \delta_{km} X_l, \\ \frac{1}{i\hbar}[X_k, X_l] &= 0. \end{aligned} \tag{25}$$

We recognize this as a representation of the Euclidean Lie algebra $e(d+1) = \mathrm{so}(d+1) \ltimes \mathbb{R}^{d+1}$. We assume that this representation of $e(d+1)$ comes from an irreducible unitary representation of the associated connected, simply connected Lie group $\tilde{E}(d+1)$. Here $\tilde{E}(d+1) \cong \mathrm{Spin}(d+1) \ltimes \mathbb{R}^{d+1}$ for $d \geq 2$ and $\tilde{E}(2) \cong \mathbb{R} \ltimes \mathbb{R}^2$, where $\ltimes$ denotes a semidirect product with the normal factor on the right.

The irreducible unitary representations of $\tilde{E}(d+1)$ may be classified by the Wigner–Mackey method. One first chooses an orbit of $\mathrm{Spin}(d+1)$ on $\mathbb{R}^{d+1}$, namely, a sphere of some radius $r \geq 0$. Since the case $r = 0$ is presumably unphysical (though mathematically permitted), we assume from now on that $r > 0$. Next one selects any one point in the sphere of radius r and considers the "little group," that is, the stabilizer in $\mathrm{Spin}(d+1)$ of the point. For $r > 0$ the little group is simply $\mathrm{Spin}(d)$. The irreducible representations of $\tilde{E}(d+1)$ are then labeled by the value of r and by an

irreducible unitary representation of the little group. In this paper we will consider only the case in which the representation of the little group is trivial. Nevertheless the definitions of the annihilation operators and of the coherent states make sense in general. Concretely, the representations in which the little group acts trivially may be realized in the Hilbert space $L^2(S^d)$, with the position operators acting as multiplication operators and the angular momentum operators acting as the differential operators given in (52) below.

Choosing a sphere of radius r amounts to requiring that the operators in (25) satisfy

$$X^2 = r^2. \tag{26}$$

We will shortly impose an additional condition among the X's and J's that forces the representation of the little group to be trivial. For now, however, we will assume only the $e(d+1)$ relations (25) and the condition (26).

We define the total angular momentum J^2 as in the classical case by

$$J^2 = \sum_{k<l} J_{kl}^2 . \tag{27}$$

As in the classical case we define

$$\text{complexifier} = \frac{\text{kinetic energy}}{\omega} = \frac{J^2}{2m\omega r^2}.$$

We then define the annihilation operators by replacing $\{\cdot, \text{complexifier}\}$ in (15) with its quantum counterpart, $(1/i\hbar)[\cdot, \text{complexifier}]$,

$$A_k = \exp\left(\frac{i}{i\hbar}\left[\cdot, \frac{J^2}{2m\omega r^2}\right]\right) X_k = \sum_{n=0}^{\infty} \frac{1}{(2m\omega r^2\hbar)^n} \frac{1}{n!} [\cdots[[X_k, J^2], J^2]\cdots, J^2]. \tag{28}$$

By a standard formula from Lie group theory this may be written as

$$A_k = e^{-J^2/2m\omega r^2\hbar} X_k e^{J^2/2m\omega r^2\hbar}. \tag{29}$$

In the general form of Thiemann's method, (29) would be $\exp(-\hat{C}/\hbar)X_k \exp(\hat{C}/\hbar)$, where $\hat{C}$ is the quantum operator corresponding to the classical complexifier C.

For determining the eigenvectors of the annihilation operators (i.e., the coherent states), (29) is the most useful expression for the A_k's. Nevertheless we will give two other formulas, a polar decomposition and an "explicit" formula in terms of the position and momentum operators. The A_k's are unbounded operators and so something must be said about their domains; see the discussion at the end of this section. The annihilation operators satisfy (in analogy to (22) and (23))

$$[A_k, A_l] = 0, \tag{30}$$

$$A^2 = r^2 \tag{31}$$

(since $[X_k, X_l] = 0$ and $X^2 = r^2$).

To compute $\mathbf{A}$ we first compute using (25) and (27) that

$$\frac{1}{i\hbar}[X_k, J^2] = J_{kl}X_l + X_l J_{kl} = 2J_{kl}X_l + i\hbar(\delta_{lk}X_l - \delta_{ll}X_k) = 2J_{kl}X_l - i\hbar d X_k .$$

Here we have chosen to order things with the J's to the left of the X's and we use the sum convention. Thus in vector notation we have

$$\frac{1}{i\hbar}\left[\mathbf{X}, \frac{J^2}{2m\omega r^2}\right] = \frac{1}{m\omega r^2}\left(\mathbf{J} - \frac{i\hbar d}{2}\right)\mathbf{X}. \tag{32}$$

Here the term involving $i\hbar d/2$ is a "quantum correction;" compare (16).

Since $[J_{kl}, J^2]=0$, further brackets will give just another factor of the matrix operator $\mathbf{J}-i\hbar d/2$. Thus the polar coordinates decomposition of $\mathbf{A}$ has just a single quantum correction, namely,

$$\mathbf{A}=\exp\left\{\frac{i\mathbf{J}+\hbar d/2}{m\omega r^2}\right\}\mathbf{X}. \tag{33}$$

In the case $d=2$, a formula very similar to this is taken in Ref. 18 as the definition of the annihilation operators. The only difference is that Kowalski and Rembieliński formulate things in terms of 2×2 matrix operators, whereas in the case $d=2$, (33) is in terms of 3×3 matrix operators. Nevertheless, our expression is equivalent to that of Kowalski and Rembieliński; see below and Eq. (5.9) of Ref. 20. The analog of (33) for the group case is given in Eq. (3.44) of the first entry in Ref. 8 and in Eq. (3.13) of the second entry in Ref. 8.

Note that the definition (28) makes sense in any irreducible representation of $\tilde{E}(d+1)$ (with $X^2=r^2>0$,) and that the formula (33) is valid in this generality. However, to compute $\mathbf{A}$ more explicitly than this we need to further specify the irreducible representation of $\tilde{E}(d+1)$. We limit ourselves to the case in which the representation of the little group Spin(d) is trivial. This corresponds to a quantum particle on the sphere with no internal degrees of freedom. In the case of S^2, this corresponds to taking the "twist" (in the notation of Kowalski and Rembieliński) to be zero. We show in Sec. IX that the little group acts trivially if and only if the following relation holds:

$$X^2 J_{kl}=J_{km}X_m X_l - J_{lm}X_m X_k\,. \tag{34}$$

This is the quantum counterpart of the classical constraint (9).

In computing $\mathbf{A}$ it is convenient to introduce "momentum" operators P_k given by

$$P_k := \frac{J_{kl}X_l}{r^2}.$$

These operators are *not* self-adjoint and we have chosen to put the J's to the left of the X's [because we have put $\mathbf{J}$ to the left of $\mathbf{X}$ in (32) and (33)]. We may rewrite (34) in terms of the P_k's as

$$J_{kl}=P_k X_l - P_l X_k\,. \tag{35}$$

The position and momentum operators satisfy

$$\frac{1}{i\hbar}[X_k, P_l]=\delta_{kl}I-\frac{X_k X_l}{r^2} \tag{36}$$

[compare (12)]. We may also compute using (25) the quantum counterpart of $\mathbf{x}\cdot\mathbf{p}=0$, which is really two relations on the quantum side,

$$\mathbf{P}\cdot\mathbf{X}=0,$$

$$\mathbf{X}\cdot\mathbf{P}=i\hbar d I.$$

We now write down the formulas that allow us to compute $\mathbf{A}$ in terms of $\mathbf{X}$ and $\mathbf{P}$,

$$\begin{aligned}\mathbf{J}\mathbf{X}&=r^2\mathbf{P},\\ \mathbf{J}\mathbf{P}&=-P^2\mathbf{X}+i\hbar(d-1)\mathbf{P}.\end{aligned} \tag{37}$$

The first line is simply the definition of **P**. The second line comes from (34) or (35) and is essential to the explicit calculation of the annihilation operators in terms of **X** and **P**. Note that there is an additional quantum correction here. To verify the second line of (37), write **J** in terms of **P** using (35) and then use (36).

We now treat **J** as a 2×2 matrix acting on the "basis" **X** and **P**, as given in (37). Since all the entries of this 2×2 matrix commute, we can just treat P^2 as a scalar and compute an ordinary 2×2 matrix exponential. So effectively we have

$$\mathbf{J}=\begin{pmatrix} 0 & -P^2 \\ r^2 & i\hbar(d-1) \end{pmatrix}.$$

One can then compute the exponential of this matrix either by hand or using a computer algebra program. A calculation shows that $P^2=r^{-2}J^2$ as in the classical case. It is convenient to express things in terms of the scalar operator,

$$J:=\sqrt{J^2+\hbar^2(d-1)^2/4}.$$

Then after exponentiating **J**, (33) becomes

$$\mathbf{A}=e^{\hbar/2m\omega r^2}\cosh\left(\frac{J}{m\omega r^2}\right)\mathbf{X}+e^{\hbar/2m\omega r^2}\frac{\hbar(d-1)}{2J}\sinh\left(\frac{J}{m\omega r^2}\right)\mathbf{X}+ie^{\hbar/2m\omega r^2}\frac{r^2}{J}\sinh\left(\frac{J}{m\omega r^2}\right)\mathbf{P}. \tag{38}$$

Equation (38) is similar to the corresponding classical expression (18), with only the following differences: (1) there is an overall factor of $\exp(\hbar/2m\omega r^2)$; (2) the quantity j in (18) is replaced by $(J^2+\hbar^2(d-1)^2/4)^{1/2}$; and (3) there is an extra sinh term in the coefficient of **X** that does not occur in the classical formula. Note that the above expression formally coincides with the classical one in the limit $\hbar\to 0$. In the case $d=2$ with $r=m\omega=\hbar=1$, (38) agrees with Eq. (4.16) in Ref. 18. In the case $d=3$ [identifying S^3 with SU(2) and adjusting for minor differences of normalization] (38) agrees with Eq. (3.132) in the last entry in Ref. 8. In the case $d=1$ we get an expression identical to the classical expression (19) except for an overall factor of $\exp(\hbar/m\omega r^2)$ [compare Eqs. (3.3) and (3.4) of Ref. 19].

It is clear from (38) that the A_k's are unbounded operators, as expected since the a_k's are unbounded functions. This means that the A_k's cannot be defined on the whole Hilbert space, but only on some dense subspace, which should be specified. We take the expression (29) as our definition of the annihilation operators. We first define the A_k's on what we will call the "minimal domain," namely, the space of finite linear combinations of spherical harmonics (that is, of eigenvectors for J^2). Expression (29) makes sense on the minimal domain, since each of the three factors making up A_k preserve this space. We consider also a "maximal domain" for the A_k's, defined as follows. Given any vector $|\phi\rangle$ in the Hilbert space, we expand $|\phi\rangle$ in a series expansion in terms of spherical harmonics. Then we apply A_k term-by-term, that is, by formally interchanging A_k with the sum. The result will then be a formal series of spherical harmonics. If this formal series converges in the Hilbert space then we say that $|\phi\rangle$ is in the maximal domain of A_k and that the value of $A_k|\phi\rangle$ is the sum of this series. (It can be shown that the product of x_k and a spherical harmonic of degree n is the sum of a spherical harmonic of degree $n+1$ and a spherical harmonic of degree $n-1$. It follows that the degree l term in the expansion of $A_k|\phi\rangle$ involves only the degree $n-1$ and degree $n+1$ terms of $|\phi\rangle$. So each term in the formal series for $A_k|\phi\rangle$ can be computed by means of a finite sum.)

It can be shown that if one starts with the operator A_k on its minimal domain and then takes its closure (in the functional analytic sense) the result is the operator A_k on its maximal domain. Thus if we want A_k to be a closed operator there is only one reasonable choice for its domain. The coherent states will not be finite linear combinations of spherical harmonics but will be in the maximal domain of all the A_k's.

V. THE COHERENT STATES

We are now ready to introduce the coherent states, which we define to be the simultaneous eigenvectors of the annihilation operators. These coherent states are *not of Perelomov type*. Although we have described the quantum Hilbert space as an irreducible representation of $\tilde{E}(d+1)$, the coherent states are not obtained from one fixed vector by the action of $\tilde{E}(d+1)$. Indeed the only elements of $\tilde{E}(d+1)$ that preserve the set of coherent states are the rotations. See Sec. X for a comparison of these coherent states to the generalized Perelomov-type coherent states for $\tilde{E}(d+1)$, as constructed either by De Bièvre or by Isham and Klauder.

The coherent states will be simultaneous eigenvectors of the annihilation operators A_k, and thus can be thought of as the quantum counterparts of a classical state with definite values for the complex coordinates a_k. On the quantum side, however, $A_k^\dagger$ does not commute with A_k, and thus although the coherent states satisfy $A_k|\psi\rangle = a_k|\psi\rangle$ they do *not* satisfy $A_k^\dagger|\psi\rangle = \overline{a_k}|\psi\rangle$.

We use formula (29) for the annihilation operators. If we introduce the dimensionless form of the total angular momentum,

$$\tilde{J}^2 = \frac{1}{\hbar^2} J^2,$$

then this may be expressed as

$$\mathbf{A} = e^{-\tau \tilde{J}^2/2} \mathbf{X} e^{\tau \tilde{J}^2/2}, \tag{39}$$

where τ is the dimensionless quantity given by

$$\tau = \frac{\hbar}{m\omega r^2}.$$

The parameter τ is a new feature of the sphere case; no such dimensionless quantity arises in the $\mathbb{R}^d$ case. The significance of τ for the coherent states is that it controls the ratio of the spatial width of the coherent states to the radius of the sphere. Specifically, we expect the approximate spatial width ΔX of a coherent state to be $\sqrt{\hbar/2m\omega}$, at least if this quantity is small compared to r. In that case

$$\frac{\Delta X}{r} \approx \frac{\sqrt{\hbar/2m\omega}}{r} = \sqrt{\frac{\tau}{2}}.$$

So if $\tau \ll 1$ we expect the coherent states to be concentrated in a small portion of the sphere, and to look, in appropriate coordinates, approximately Gaussian. This has been proven[8] for the case of $S^3 = \mathrm{SU}(2)$.

Kowalski and Rembieliński implicitly take $\tau = 1$ in their treatment of the $d = 2$ case, since they choose units with $m = r = \hbar = 1$, and since they do not have the parameter ω. (See our comments in Sec. III about the parameter ω.) To us this seems a needless loss of generality, even though it is easy to insert τ in the appropriate places in their formulas.

We now proceed with the construction of the coherent states. For each $\mathbf{a}$ in the *real* sphere S^d, let $|\delta_\mathbf{a}\rangle$ be the (generalized) position eigenfunction with $X_k|\delta_\mathbf{a}\rangle = a_k|\delta_\mathbf{a}\rangle$. Since we assume that the little group acts trivially these position eigenfunctions are (for each $\mathbf{a}$) unique up to a constant and we may normalize them so that the action of the rotation group takes $|\delta_\mathbf{a}\rangle$ to $|\delta_{R\mathbf{a}}\rangle$, $R \in \mathrm{SO}(d+1)$. If we let

$$|\psi_\mathbf{a}\rangle = e^{-\tau \tilde{J}^2/2}|\delta_\mathbf{a}\rangle, \tag{40}$$

then it follows immediately from (39) that $|\psi_\mathbf{a}\rangle$ is a simultaneous eigenvector for each A_k with eigenvalue a_k. Although $|\delta_\mathbf{a}\rangle$ is non-normalizable, the smoothing nature of the operator

$\exp(-\tau\tilde{J}^2/2)$ guarantees that $|\psi_{\mathbf{a}}\rangle$ is normalizable for all $\mathbf{a}\in S^d$. A key result of this section is the following proposition, which asserts that we can analytically continue the coherent states $|\psi_{\mathbf{a}}\rangle$ with respect to $\mathbf{a}$ so as to obtain states labeled by points $\mathbf{a}$ in the *complex* sphere $S^d_{\mathbb{C}}$.

Proposition 1: There exists a unique family of states $|\psi_{\mathbf{a}}\rangle$ *parameterized by* $\mathbf{a}\in S^d_{\mathbb{C}}$ *such that* (1) *the states depend holomorphically on* $\mathbf{a}$, *and* (2) *for* $\mathbf{a}\in S^d$, *they agree with the states in* (40). *These are normalizable states and satisfy*

$$A_k|\psi_{\mathbf{a}}\rangle = a_k|\psi_{\mathbf{a}}\rangle, \quad \mathbf{a}\in S^d_{\mathbb{C}}.$$

We call these states the *coherent states*. Note that we have then one coherent state for each point in $S^d_{\mathbb{C}}$, that is, one coherent state for each point in the classical phase space. It can be shown that these are (up to a constant) the *only* simultaneous eigenvectors of the annihilation operators. These coherent states are *not* normalized to be unit vectors. The proof of Proposition 1 is at the end of this section.

Note that since the operator $\tilde{J}^2$ commutes with rotations, the action of the rotation subgroup $\mathrm{SO}(d+1)$ of $E(d+1)$ will take $|\psi_{\mathbf{a}}\rangle$ to $|\psi_{R\mathbf{a}}\rangle$ for any $R\in\mathrm{SO}(d+1)$. On sufficiently regular states we can analytically continue the action of $\mathrm{SO}(d+1)$ to an action of $\mathrm{SO}(d+1;\mathbb{C})$, which will take $|\psi_{\mathbf{a}}\rangle$ to $|\psi_{R\mathbf{a}}\rangle$ for any $R\in\mathrm{SO}(d+1;\mathbb{C})$. Then any coherent state can be obtained from any other by the action of $\mathrm{SO}(d+1;\mathbb{C})$. Since, however, the action of $\mathrm{SO}(d+1;\mathbb{C})$ is neither unitary nor irreducible, this observation still does not bring the coherent states into the Perelomov framework.

We can give an explicit formula for the coherent states in the position representation in terms of the *heat kernel* on S^d. The heat kernel is the function on $S^d\times S^d$ given by $\rho_\tau(\mathbf{x},\mathbf{y}) = \langle\delta_{\mathbf{x}}|e^{-\tau\tilde{J}^2/2}|\delta_{\mathbf{y}}\rangle$. It can be shown (see Ref. 1 or the formulas below) that the ρ_τ extends (uniquely) to a holomorphic function on $S^d_{\mathbb{C}}\times S^d_{\mathbb{C}}$, also denoted ρ_τ. In terms of the analytically continued heat kernel the coherent states are given by

$$\langle\delta_{\mathbf{x}}|\psi_{\mathbf{a}}\rangle = \rho_\tau(\mathbf{a},\mathbf{x}), \quad \mathbf{a}\in S^d_{\mathbb{C}}, \mathbf{x}\in S^d. \tag{41}$$

Meanwhile, explicit formulas for the heat kernel may be found, for example, in Refs. 25 and 26. For $\mathbf{x}$ and $\mathbf{y}$ in the real sphere, $\rho_\tau(\mathbf{x},\mathbf{y})$ depends only on the angle θ between $\mathbf{x}$ and $\mathbf{y}$, where $\theta=\cos^{-1}(\mathbf{x}\cdot\mathbf{y}/r^2)$. This remains true for $\rho_\tau(\mathbf{a},\mathbf{x})$, with $\mathbf{a}\in S^d_{\mathbb{C}}$, except now $\theta=\cos^{-1}(\mathbf{a}\cdot\mathbf{x}/r^2)$ is complex-valued. Of course the inverse cosine function is multiple-valued, but because the heat kernel is an even, 2π-periodic function of θ, it does not matter which value of θ we use, provided that $\cos\theta=\mathbf{a}\cdot\mathbf{x}/r^2$.

We now record the formulas, writing ρ^d_τ to indicate the dependence on the dimension. For $d=1,2,3$ we have

$$\rho^1_\tau(\mathbf{a},\mathbf{x}) = (2\pi\tau)^{-1/2}\sum_{n=-\infty}^{\infty} e^{-(\theta-2\pi n)^2/2\tau},$$

$$\rho^2_\tau(\mathbf{a},\mathbf{x}) = (2\pi\tau)^{-1}e^{\tau/8}\frac{1}{\sqrt{\pi\tau}}\int_\theta^\pi \frac{1}{\sqrt{\cos\theta-\cos\phi}}\sum_{n=-\infty}^{\infty}(-1)^n(\phi-2\pi n)e^{-(\phi-2\pi n)^2/2\tau}\,d\phi,$$

$$\rho^3_\tau(\mathbf{a},\mathbf{x}) = (2\pi\tau)^{-3/2}e^{\tau/2}\frac{1}{\sin\theta}\sum_{n=-\infty}^{\infty}(\theta-2\pi n)e^{-(\theta-2\pi n)^2/2\tau}.$$

In the formula for ρ^2_τ we may without loss of generality take θ with $0\leqslant\mathrm{Re}\,\theta\leqslant\pi$, in which case the integral is to be interpreted as a contour integral in the strip $0\leqslant\mathrm{Re}\,\phi\leqslant\pi$. The relatively simple formula for the heat kernel on $S^3=\mathrm{SU}(2)$ allows for detailed calculations for the coherent states in this case, as carried out in Ref. 8. To find the formula in higher dimensions we use the inductive formula,

$$\rho_\tau^{d+2}(\mathbf{a},\mathbf{x}) = -e^{d\tau/2}\frac{1}{2\pi\sin\theta}\frac{d}{d\theta}\rho_\tau^d(\mathbf{a},\mathbf{x}).$$

There is also an expression for the heat kernel in terms of spherical harmonics. For example, when $d=2$ we have

$$\rho_\tau^2(\mathbf{a},\mathbf{x}) = \sum_{l=0}^{\infty} e^{-\tau l(l+1)/2}\sqrt{2l+1}P_l(\cos\theta), \tag{42}$$

where the P_l is the Legendre polynomial of degree l. [Compare Eq. (5.3) of Ref. 18.] The earlier expression for ρ_τ^2 is a sort of Poisson-summed version of (42) (see Ref. 26).

We also consider the reproducing kernel, defined by

$$R_\tau(\mathbf{a},\mathbf{b}) = \langle \psi_{\mathbf{b}} | \psi_{\mathbf{a}} \rangle, \quad \mathbf{a},\mathbf{b} \in S_{\mathbb{C}}^d. \tag{43}$$

In terms of the analytically continued heat kernel the reproducing kernel is given by

$$R_\tau(\mathbf{a},\mathbf{b}) = \rho_{2\tau}(\mathbf{a},\overline{\mathbf{b}}), \quad \mathbf{a},\mathbf{b} \in S_{\mathbb{C}}^d.$$

Note that $R_\tau(\mathbf{a},\mathbf{b})$ depends holomorphically on $\mathbf{a}$ and antiholomorphically on $\mathbf{b}$.

In the case of $S^1 = \mathrm{U}(1)$ and $S^3 = \mathrm{SU}(2)$, Thiemann and Winkler have proved in the second and third entries of Ref. 8 that the coherent states defined here satisfy good phase space localization properties and that the Ehrenfest theorem holds infinitesimally. We fully expect that these results hold for all d. This expectation is based on the idea that the heat kernel in (41) will behave for small τ like $c\exp(-\theta^2/2\tau)$, even for complex values of θ. Thiemann and Winkler have verified this in the cases $d=1,3$ and a similar analysis should be possible in general, using the explicit formulas for small d and the inductive formula for ρ^{d+2} in terms of ρ^d.

Proof of Proposition 1: There are two ways to prove this proposition. The simplest way is to use the expression for $\psi_{\mathbf{a}}$ in terms of the heat kernel ρ_τ and the explicit formulas above for ρ_τ. It is easily seen that ρ_τ extends to an entire holomorphic function of θ. Thus the expression $\langle \delta_{\mathbf{x}} | \psi_{\mathbf{a}} \rangle = \rho_\tau(\mathbf{a},\mathbf{x})$ makes sense for any $\mathbf{a}$ in $S_{\mathbb{C}}^d$, with $\cos\theta$ and thus also θ taking complex values. It is not hard to see that the $|\psi_{\mathbf{a}}\rangle$, so defined, is in the (maximal) domain of the annihilation operators and that it depends holomorphically on $\mathbf{a} \in S_{\mathbb{C}}^d$. Since $A_k|\psi_{\mathbf{a}}\rangle = a_k|\psi_{\mathbf{a}}\rangle$ for $\mathbf{a} \in S^d$, an analytic continuation argument will show that this equation remains true for all $\mathbf{a} \in S_{\mathbb{C}}^d$. Alternatively we may use the expansion of the coherent states in terms of spherical harmonics as in (42) and show that this expression can be analytically continued term-by-term in $\mathbf{a}$. (Compare Sec. IV of Ref. 1.) □

VI. THE RESOLUTION OF THE IDENTITY

We now choose a coordinate system in which $r=1$ and $m\omega=1$. This amounts to using the normalized position $\mathbf{x}/r$ and normalized momentum $\mathbf{p}/m\omega r$. Since these choices set our position and momentum scales we cannot also take $\hbar=1$. Note that the dimensionless parameter $\tau = \hbar/m\omega r^2$ equals $\hbar$ in such a coordinate system. We now write $|\psi_{\mathbf{x},\mathbf{p}}\rangle$ for $|\psi_{\mathbf{a}(\mathbf{x},\mathbf{p})}\rangle$.

Theorem 2: *The coherent states have a resolution of the identity of the form,*

$$I = \int_{\mathbf{x}\in S^d}\int_{\mathbf{p}\cdot\mathbf{x}=0} |\psi_{\mathbf{x},\mathbf{p}}\rangle\langle\psi_{\mathbf{x},\mathbf{p}}|\ \nu(2\tau,2p)\left(\frac{\sinh 2p}{2p}\right)^{d-1} 2^d d\mathbf{p}\, d\mathbf{x}, \tag{44}$$

where $\nu(s,R)$ is the solution to the differential equation,

$$\frac{d\nu(s,R)}{ds} = \frac{1}{2}\left[\frac{\partial^2\nu}{\partial R^2} - (d-1)\frac{\cosh R}{\sinh R}\frac{\partial\nu}{\partial R}\right],$$

subject to the initial condition,

$$\lim_{s\downarrow 0} c_d \int_0^\infty f(R)\,\nu(s,R)(\sinh R)^{d-1}\,dR = f(0)$$

for all continuous functions f on $[0,\infty)$ with at most exponential growth at infinity. Here $d\mathbf{x}$ is the surface area measure on S^d, τ is the dimensionless quantity $\tau=\hbar/m\omega r^2$, and c_d is the volume of the unit sphere in $\mathbb{R}^d$.

The operator on the right-hand side of the equation for ν is just the radial part of the Laplacian for d-dimensional hyperbolic space (Ref. 27, Sec. 5.7). This means that $\nu(s,R)$ is the heat kernel for hyperbolic space, that is, the fundamental solution of the heat equation. Hyperbolic space is the noncompact, negatively curved "dual" of the compact, positively curved symmetric space S^d. Note that the function ν is evaluated at "time" 2τ and radius $2p$. The inversion formula for the Segal–Bargmann transform, described in Sec. VII, involves the function ν evaluated at time τ and radius p.

The resolution of the identity for the coherent states will be obtained by continuously varying the dimensionless parameter τ. When $\tau=0$ the coherent states are simply the position eigenvectors, which have a resolution of the identity because the position operators are self-adjoint. We will show that the function ν satisfies the correct differential equation to make the resolution of the identity remain true as we move to nonzero τ.

Theorem 2 is a special case of Theorem 3 of Ref. 17, written out more explicitly and restated in terms of coherent states instead of the Segal–Bargmann transform. However we give below a self-contained and elementary proof. The case $d=2$ is also described (with a different proof) in Ref. 20. Since $S^3=\mathrm{SU}(2)$, the $d=3$ case belongs to the group case, which is found in Ref. 1. See also Sec. IV D of the second entry in Ref. 8 for another proof in the SU(2) case.

We report here the formulas for the function $\nu(s,R)$, which may be found, for example, in Ref. 27 Sec. 5.7 or Ref. 26 Eq. (8.73). Writing $\nu_d(s,R)$ to make explicit the dependence on the dimension we have

$$\nu_1(s,R)=(2\pi s)^{-1/2}e^{-R^2/2s},$$

$$\nu_2(s,R)=(2\pi s)^{-1}e^{-s/8}\frac{1}{\sqrt{\pi s}}\int_R^\infty \frac{\rho e^{-\rho^2/2s}}{(\cosh\rho-\cosh R)^{1/2}}\,d\rho,$$

$$\nu_3(s,R)=(2\pi s)^{-3/2}e^{-s/2}\frac{R}{\sinh R}e^{-R^2/2s},$$

and the recursion relation

$$\nu_{d+2}(s,R)=-\frac{e^{-ds/2}}{2\pi\sinh R}\frac{\partial}{\partial R}\nu_d(s,R).$$

Estimates on the behavior as $R\to\infty$ of ν may be found in Ref. 27, Sec. 5.7 and in Ref. 28. Note the similarities between the formulas for ν and the formulas for the heat kernel ρ_τ on the sphere.

Some care must be taken in the interpretation of the integral (44). Even in the $\mathbb{R}^d$ case this integral is not absolutely convergent in the operator norm sense. Rather the appropriate sense of convergence is the weak sense. This means that for all vectors ϕ_1,ϕ_2 in the Hilbert space we have

$$\langle\phi_1|\phi_2\rangle=\int_{\mathbf{x}\in S^d}\int_{\mathbf{p}\cdot\mathbf{x}=0}\langle\phi_1|\psi_{\mathbf{x},\mathbf{p}}\rangle\langle\psi_{\mathbf{x},\mathbf{p}}|\phi_2\rangle\;\nu(2\tau,2p)\left(\frac{\sinh 2p}{2p}\right)^{d-1}2^d d\mathbf{p}\,d\mathbf{x}, \tag{45}$$

where the integral (45) is an absolutely convergent complex-valued integral. This of course is formally equivalent to (44). We will prove Theorem 2 at first without worrying about convergence or other similar technicalities. Then at the end we will explain how such matters can be dealt with.

Proof of Theorem 2: We now write the coherent states as $|\psi_{\mathbf{a}}^{\tau}\rangle$ to emphasize the dependence on the dimensionless quantity $\tau=\hbar/m\omega r^2$. We regard the coherent states $|\psi_{\mathbf{a}}^{\tau}\rangle$ as living in some fixed (τ-independent) Hilbert space [for example, $L^2(S^d)$] and given heuristically by

$$|\psi_{\mathbf{a}}^{\tau}\rangle = e^{-\tau\tilde{J}^2/2}|\delta_{\mathbf{a}}\rangle, \quad \mathbf{a}\in S_{\mathbb{C}}^d, \tag{46}$$

where $|\delta_{\mathbf{a}}\rangle$ is a position eigenvector. Our strategy is essentially the one proposed by Thiemann in a more general setting in Ref. 7, Sec. 2.3. We begin with two lemmas that allow us to carry out this strategy explicitly in this situation. The proofs of these lemmas are given at the end of the proof of Theorem 2.

Lemma 3: The measure

$$\left(\frac{\sinh 2p}{2p}\right)^{d-1} 2^d d\mathbf{p}\, d\mathbf{x}$$

is invariant under the action of $\mathrm{SO}(d+1;\mathbb{C})$ *on* $S_{\mathbb{C}}^d \cong T^*(S^d)$.

Lemma 4: Let $J_{\mathbf{a}}^2$ *and* $J_{\overline{\mathbf{a}}}^2$ *denote the differential operators on* $S_{\mathbb{C}}^d$ *given by*

$$J_{\mathbf{a}}^2 = -\sum_{k<l}\left(a_l\frac{\partial}{\partial a_k} - a_k\frac{\partial}{\partial a_l}\right)^2,$$

$$J_{\overline{\mathbf{a}}}^2 = -\sum_{k<l}\left(\overline{a}_l\frac{\partial}{\partial \overline{a}_k} - \overline{a}_k\frac{\partial}{\partial \overline{a}_l}\right)^2.$$

Let ϕ *be a smooth, even, real-valued function on* $\mathbb{R}$ *and consider the function on* $S_{\mathbb{C}}^d$ *given by*

$$\phi(2p),$$

where p *is regarded as a function of* $\mathbf{a}$ *by means of (18). Then,*

$$J_{\mathbf{a}}^2\phi(2p) = J_{\overline{\mathbf{a}}}^2\phi(2p) = -\left[\frac{\partial^2\phi}{\partial R^2} + (d-1)\frac{\cosh R}{\sinh R}\frac{\partial\phi}{\partial R}\right]_{R=2p}.$$

Assuming for now the two lemmas, we proceed with the proof of the resolution of the identity. Because the coherent states depend holomorphically on $\mathbf{a}$ they satisfy

$$J_{\overline{\mathbf{a}}}^2|\psi_{\mathbf{a}}^{\tau}\rangle = 0.$$

Furthermore, it follows from the definition of the coherent states that

$$\frac{d}{d\tau}|\psi_{\mathbf{a}}^{\tau}\rangle = \frac{1}{2}J_{\mathbf{a}}^2|\psi_{\mathbf{a}}^{\tau}\rangle.$$

The proof of this is essentially the standard calculation of the action of $\tilde{J}^2$ in the position representation. It then follows that the projection operator $|\psi_{\mathbf{a}}^{\tau}\rangle\langle\psi_{\mathbf{a}}^{\tau}|$ satisfies the operator-valued differential equation,

$$\frac{\partial}{\partial\tau}|\psi_{\mathbf{a}}^{\tau}\rangle\langle\psi_{\mathbf{a}}^{\tau}| = \frac{1}{2}(J_{\mathbf{a}}^2 + J_{\overline{\mathbf{a}}}^2)|\psi_{\mathbf{a}}^{\tau}\rangle\langle\psi_{\mathbf{a}}^{\tau}|.$$

Now we let

$$\beta(p)=2^d\left(\frac{\sinh 2p}{2p}\right)^{d-1}. \tag{47}$$

Since by Lemma 3 the measure $\beta(p)\,d\mathbf{p}\,d\mathbf{x}$ is invariant under the action of $\mathrm{SO}(d+1;\mathbb{C})$ the operators $J_{\mathbf{a}}^2$ and $J_{\bar{\mathbf{a}}}^2$ are self-adjoint in $L^2(S_{\mathbb{C}}^d,\beta(p)\,d\mathbf{p}\,d\mathbf{x})$. Thus differentiating under the integral sign and using the self-adjointness gives

$$\frac{d}{d\tau}\int_{\mathbf{x}\in S^d}\int_{\mathbf{p}\cdot\mathbf{x}=0}|\psi_{\mathbf{a}}^\tau\rangle\langle\psi_{\mathbf{a}}^\tau|\;\nu(2\tau,2p)\beta(p)\,d\mathbf{p}\,d\mathbf{x}$$

$$=\int_{\mathbf{x}\in S^d}\int_{\mathbf{x}\cdot\mathbf{p}=0}|\psi_{\mathbf{a}}^\tau\rangle\langle\psi_{\mathbf{a}}^\tau|\left[\frac{\partial}{\partial\tau}+\frac{1}{2}(J_{\mathbf{a}}^2+J_{\bar{\mathbf{a}}}^2)\nu(2\tau,2p)\right]\beta(p)\,d\mathbf{p}\,d\mathbf{x}.$$

Lemma 4 and the differential equation satisfied by $\nu(s,R)$ tell us that the last integral is zero. Thus the operator on the right-hand side in (44) is independent of τ. On the other hand, the initial conditions for ν imply that as τ tends to zero the measure $\nu(2\tau,2p)\beta(p)\,d\mathbf{p}\,d\mathbf{x}$ "collapses" to the Lebesgue measure $d\mathbf{x}$ on the real sphere, i.e., the set where $\mathbf{p}=0$. Furthermore, if we consider coherent states $|\psi_{\mathbf{x},\mathbf{p}}^\tau\rangle$ with $\mathbf{p}=0$, these become simply $|\delta_{\mathbf{x}}\rangle$ in the $\tau\downarrow 0$ limit. Thus

$$\lim_{\tau\downarrow 0}\int_{\mathbf{x}\in S^d}\int_{\mathbf{p}\cdot\mathbf{x}=0}|\psi_{\mathbf{x},\mathbf{p}}^\tau\rangle\langle\psi_{\mathbf{x},\mathbf{p}}^\tau|\;\nu(2\tau,2p)\beta(p)\,d\mathbf{p}\,d\mathbf{x}=\int_{S^d}|\delta_{\mathbf{x}}\rangle\langle\delta_{\mathbf{x}}|\,d\mathbf{x}=I.$$

Since the value of the first integral is independent of τ this shows that the integral equals the identity for all τ. □

It remains now to prove Lemmas 3 and 4. We begin with the second lemma.

Proof of Lemma 4: Note that expressions such as $\partial/\partial a_k$ do not make sense when applied to a function that is defined only on the complex sphere $S_{\mathbb{C}}^d$. So the operator $a_l\partial/\partial a_k-a_k\partial/\partial a_l$ (and its complex conjugate) should be interpreted as follows. Given a smooth function f on $S_{\mathbb{C}}^d$, extend f smoothly to a neighborhood of $S_{\mathbb{C}}^d$, then apply $a_l\partial/\partial a_k-a_k\partial/\partial a_l$, and then restrict again to $S_{\mathbb{C}}^d$. Since $(a_l\partial/\partial a_k-a_k\partial/\partial a_l)a^2=0$ the derivatives are all in directions tangent to $S_{\mathbb{C}}^d$. This means that the value of the operator on $S_{\mathbb{C}}^d$ is independent of the choice of the extension. It is in this way that $J_{\mathbf{a}}^2$ and $J_{\bar{\mathbf{a}}}^2$ are to be interpreted as operators on $S_{\mathbb{C}}^d$.

Now let $R=2p$ and let $\alpha=|\mathbf{a}|^2=\Sigma|a_k|^2$. Then (18) (with $r=m\omega=1$) tells us that

$$\alpha:=|\mathbf{a}|^2=\cosh^2 p+\sinh^2 p=\cosh 2p.$$

So, $R=2p=\cosh^{-1}\alpha$. We now need to apply $J_{\mathbf{a}}^2$ to a function of the form $\phi(R)$, which we do by using the chain rule

$$\frac{\partial\phi}{\partial a_k}=\frac{d\phi}{dR}\frac{dR}{d\alpha}\frac{\partial\alpha}{\partial a_k}.$$

Calculation shows that (for $k\neq l$),

$$\left(a_l\frac{\partial}{\partial a_k}-a_k\frac{\partial}{\partial a_l}\right)^2\phi(R)=\frac{(a_k\overline{a_l}-a_l\overline{a_k})^2}{|\mathbf{a}|^4-1}\frac{\partial^2\phi}{\partial R^2}-\frac{(|a_k|^2+|a_l|^2)(|\mathbf{a}|^4-1)+|\mathbf{a}|^2(a_k\overline{a_l}-a_l\overline{a_k})^2}{(|\mathbf{a}|^4-1)^{3/2}}\frac{\partial\phi}{\partial R}. \tag{48}$$

We now note that

$$\sum_{k<l}(|a_k|^2+|a_l|^2)=\frac{1}{2}\sum_{k,l}(1-\delta_{kl})(|a_k|^2+|a_l|^2)=\frac{1}{2}[2(d+1)|\mathbf{a}|^2-2|\mathbf{a}|^2]=d\,|\mathbf{a}|^2. \tag{49}$$

We use also the easily verified identity

$$\sum_{k<l} (a_k \overline{a_l} - a_l \overline{a_k})^2 = -(|\mathbf{a}|^4 - |a^2|^2) = -(|\mathbf{a}|^4 - 1), \tag{50}$$

where the first equality is valid everywhere and the second equality is valid on the complex sphere $S^d_{\mathbb{C}} = \{a^2 = 1\}$.

Using (49) and (50) we get, upon summing (48) over $k<l$,

$$\sum_{k<l} \left(a_l \frac{\partial}{\partial a_k} - a_k \frac{\partial}{\partial a_l} \right)^2 \phi(R) = -\frac{\partial^2 \phi}{\partial R^2} - (d-1) \frac{|\mathbf{a}|^2}{\sqrt{|\mathbf{a}|^4 - 1}} \frac{\partial \phi}{\partial R}.$$

Recalling that $|\mathbf{a}|^2 = \cosh R$, so that $\sqrt{|\mathbf{a}|^4 - 1} = \sinh R$, we get the claimed formula. This completes the proof of the second lemma (with the same argument for the conjugated case). □

Proof of Lemma 3: Our proof is indirect and uses Lemma 4. We regard $S^d_{\mathbb{C}}$ as the quotient $\mathrm{SO}(d+1;\mathbb{C})/\mathrm{SO}(d;\mathbb{C})$. Since both $\mathrm{SO}(d+1;\mathbb{C})$ and $\mathrm{SO}(d;\mathbb{C})$ are unimodular, general principles (Ref. 29 Theorem. 8.36) tell us that there is a smooth $\mathrm{SO}(d+1;\mathbb{C})$-invariant measure on $S^d_{\mathbb{C}}$ and that it is unique up to a constant. This measure must be in particular $\mathrm{SO}(d+1)$-invariant, which means that it must be of the form $\gamma(p)\, d\mathbf{p}\, d\mathbf{x}$, since $d\mathbf{p}\, d\mathbf{x}$ is also $\mathrm{SO}(d+1)$-invariant. Now the operator $J^2_{\mathbf{a}}$ must be self-adjoint with respect to the $\mathrm{SO}(d+1;\mathbb{C})$-invariant measure. In particular, $J^2_{\mathbf{a}}$ must be self-adjoint when restricted to the space of $\mathrm{SO}(d+1)$-invariant functions, which can all be written in the form $f(\mathbf{a}) = \phi(2p)$, as in Lemma 4.

Meanwhile, according to Lemma 4, on $\mathrm{SO}(d+1)$-invariant functions $J^2_{\mathbf{a}}$ is just the hyperbolic Laplacian, rescaled by a factor of 2. This operator is therefore self-adjoint [on $\mathrm{SO}(d+1)$-invariant functions] with respect to the measure $\beta(p)\, d\mathbf{p}\, d\mathbf{x}$, which is just hyperbolic volume measure with the same rescaling.

We conclude, then, that on $\mathrm{SO}(d+1)$-invariant functions, $J^2_{\mathbf{a}}$ is self-adjoint with respect to both the measures $\gamma(p)\, d\mathbf{p}\, d\mathbf{x}$ and $\beta(p)\, d\mathbf{p}\, d\mathbf{x}$. From this it follows that

$$\left[\frac{\partial^2 g}{\partial R^2} + (d-1) \frac{\cosh R}{\sinh R} \frac{\partial g}{\partial R} \right]_{R=2p} = 0, \tag{51}$$

where $g(p) = \gamma(p)/\beta(p)$. But since both γ and β are smooth, $\mathrm{SO}(d+1)$-invariant functions on $S^d_{\mathbb{C}}$ we must have $\partial g/\partial R|_{R=0} = 0$. Solving (51) gives $\partial g/\partial R = c \exp[-(d-1)\int \coth S\, dS]$, so we have

$$\left. \frac{\partial g}{\partial R} \right|_{R=0} = c \lim_{\varepsilon \to 0} \exp\left[(d-1) \int_{\varepsilon}^{1} \coth S\, dS \right] = 0,$$

which can occur only if $c=0$, i.e., if g is constant. Thus γ is a constant multiple of β, which is what we want to show. □

We conclude this section with a few remarks about technicalities in the proof of the resolution of the identity. We have already said that the integral in Theorem 2 is to be interpreted in the weak sense, as in (45). We first establish (45) in the case where $|\phi_1\rangle$ and $|\phi_2\rangle$ are finite linear combinations of spherical harmonics. In that case it can be shown that the integrand $\langle \phi_1 | \psi^{\tau}_{\mathbf{x},\mathbf{p}} \rangle \times \langle \psi^{\tau}_{\mathbf{x},\mathbf{p}} | \phi_2 \rangle$ grows only exponentially with $\mathbf{p}$. Since ν has a faster-than-exponential decay (namely, Gaussian) the integral (45) is convergent. In this case there is not much difficulty in justifying the formal manipulations we have made, such as interchanging derivatives with the integral and integrating by parts. Then once (45) is established for such "nice" vectors, a simple passage to the limit will establish it for all $|\phi_1\rangle$ and $|\phi_2\rangle$ in the Hilbert space. See Refs. 1 or 17 for more details on these technicalities.

VII. THE SEGAL–BARGMANN REPRESENTATION

As shown in Sec. IX, any two irreducible unitary representations of $\tilde{E}(d+1)$ satisfying (26) and (34) are equivalent. The simplest concrete realization of such representations is the position

representation, in which the Hilbert space is $L^2(S^d)$, the position operators act by multiplication, and the angular momentum operators act as differential operators given by

$$J_{kl} = -i\hbar\left(x_l \frac{\partial}{\partial x_k} - x_k \frac{\partial}{\partial x_l} \right). \tag{52}$$

The resolution of the identity for the coherent states can be used to give another realization, the (generalized) Segal–Bargmann representation. In the Segal–Bargmann representation the Hilbert space is the space of holomorphic functions on $S^d_{\mathbb{C}}$ that are square-integrable with respect to the density occurring in the resolution of the identity. In this representation the action of the position operators X_k is somewhat complicated, but the action of the creation operators (the adjoints of the annihilation operators) becomes simply multiplication by a_k. The resolution of the identity can be reinterpreted as the unitary intertwining map between these two representations, that is, the generalized Segal–Bargmann transform.

Specifically, given any function f in $L^2(S^d)$ we define the Segal–Bargmann transform Cf of f by

$$Cf(\mathbf{a}) = \langle \overline{\psi_{\mathbf{a}}} | f \rangle. \tag{53}$$

Then for any f, $Cf(\mathbf{a})$ is a holomorphic function of $\mathbf{a} \in S^d_{\mathbb{C}}$. Note that in the interests of consistency with Refs. 1, 17 we have put a complex conjugate on the $\mathbf{a}$ in (53), so that the dependence of Cf on $\mathbf{a} \in S^d_{\mathbb{C}}$ is holomorphic rather than antiholomorphic. The Segal–Bargmann transform can be computed as

$$Cf(\mathbf{a}) = \int_{S^d} \rho_\tau(\mathbf{a},\mathbf{x}) f(\mathbf{x}) d\mathbf{x}, \quad \mathbf{a} \in S^d_{\mathbb{C}}. \tag{54}$$

Here $\rho_\tau(\mathbf{a},\mathbf{x})$ is the heat kernel on S^d, with the $\mathbf{a}$ variable extended by analytic continuation from S^d to $S^d_{\mathbb{C}}$.

Theorem 5 (Segal–Bargmann transform): *The map C defined by (53) or (54) is a unitary map of $L^2(S^d, d\mathbf{x})$ onto $\mathcal{H}L^2(S^d_{\mathbb{C}}, \nu)$, where $\mathcal{H}L^2(S^d_{\mathbb{C}}, \nu)$ denotes the space of holomorphic functions F on $S^d_{\mathbb{C}}$ for which*

$$\int_{\mathbf{x} \in S^d} \int_{\mathbf{p}\cdot\mathbf{x}=0} |F(\mathbf{a}(\mathbf{x},\mathbf{p}))|^2 \nu(2\tau, 2p) \left(\frac{\sinh 2p}{2p} \right)^{d-1} 2^d d\mathbf{p}\, d\mathbf{x} < \infty.$$

The isometricity of the map C as a map from $L^2(S^d)$ into $L^2(S^d_{\mathbb{C}}, \nu)$ is equivalent to the resolution of the identity [compare (45)]. That C maps into the holomorphic subspace of $L^2(S^d_{\mathbb{C}}, \nu)$ follows from the holomorphic dependence of the coherent states on $\mathbf{a}$. It remains only to show that the image of C is *all* of $\mathcal{H}L^2(S^d_{\mathbb{C}}, \nu)$. The proof of this is a fairly straightforward density argument using spherical harmonics, which we omit. (See Sec. IV of Ref. 17 and Sec. VIII of Ref. 1.)

In the Segal–Bargmann space $\mathcal{H}L^2(S^d_{\mathbb{C}}, \nu)$ the angular momentum operators act by the holomorphic analog of (52), namely,

$$J_{kl} = -i\hbar\left(a_l \frac{\partial}{\partial a_k} - a_k \frac{\partial}{\partial a_l} \right).$$

Meanwhile, the *creation* operators, defined as the adjoints of the annihilation operators, are given by

$$A_k^\dagger F(\mathbf{a}) = a_k F(\mathbf{a}).$$

The annihilation operators can be described as *Toeplitz operators*. This means that

$$A_k F = P(\overline{a_k} F),$$

where P is the orthogonal projection from the full L^2-space $L^2(S^d_{\mathbb{C}},\nu)$ onto the holomorphic subspace (see Ref. 33). In the Segal–Bargmann representation the action of the position operators is more complicated.

Another important feature of the Segal–Bargmann representation is the reproducing kernel identity. Recall from Sec. V that the reproducing kernel $R_\tau(\mathbf{a},\mathbf{b})=\langle \psi_{\mathbf{b}} | \psi_{\mathbf{a}} \rangle$ is holomorphic in $\mathbf{a}$ and antiholomorphic in $\mathbf{b}$. We then have the following result, which follows easily from general principles. (See, for example, Sec. IX of Ref. 1.)

Proposition 6 (Reproducing kernel identity): For any $F \in \mathcal{H}L^2(S^d_{\mathbb{C}},\nu)$ we have

$$F(\mathbf{a})=\int_{\mathbf{x}\in S^d}\int_{\mathbf{p}\cdot\mathbf{x}=0} R_\tau(\mathbf{a},\mathbf{b})F(\mathbf{b}(\mathbf{x},\mathbf{p}))\,\nu(2\tau,2p)\left(\frac{\sinh 2p}{2p}\right)^{d-1} 2^d d\mathbf{p}\; d\mathbf{x}.$$

Here $R_\tau(\mathbf{a},\mathbf{b})=\rho_{2\tau}(\mathbf{a},\overline{\mathbf{b}})$ is the reproducing kernel, and the integral is absolutely convergent.

The Segal–Bargmann representation can be thought of as defining a *phase space wave function* for a quantum particle on the sphere, which is related to the position wave function by the Segal–Bargmann transform. This phase space wave function can then be turned into a *phase space probability density* in the usual way: if f is a unit vector in $L^2(S^d)$ then the associated probability density is

$$|Cf(\mathbf{a}(\mathbf{x},\mathbf{p}))|^2\,\nu(2\tau,2p)\left(\frac{\sinh 2p}{2p}\right)^{d-1} 2^d. \tag{55}$$

This is a manifestly non-negative function on the phase space that integrates to one. In the $\mathbb{R}^d$ case,[33] the expression corresponds to the *Husimi function* of f.

If one takes the probability density (55) and integrates out the momentum variables one will *not* get the standard position probability density $|f(\mathbf{x})|^2$ (even in the $\mathbb{R}^d$ case). That is, with this definition, the position probability density cannot be obtained from the phase space probability density by integrating out the momentum variables. On the other hand, there is a nice inversion formula for the generalized Segal–Bargmann transform that can be stated roughly as follows: the position *wave function* can be obtained from the phase space *wave function* by integrating out the momentum variables.

Theorem 7 (Inversion Formula): *Given any function f in $L^2(S^d)$, let $F=Cf$ be the Segal–Bargmann transform of f. Then f may be recovered from F by the formula,*

$$f(\mathbf{x})=\int_{\mathbf{p}\cdot\mathbf{x}=0} F(\mathbf{a}(\mathbf{x},\mathbf{p}))\,\nu(\tau,p)\left(\frac{\sinh p}{p}\right)^{d-1} d\mathbf{p}. \tag{56}$$

This result is a special case of Ref. 17; the group analog of this inversion formula was given in Ref. 3. An analog of this formula holds also in the $\mathbb{R}^d$ case (Ref. 4, Sec. IV), but does not seem to be well known. Note that whereas the resolution of the identity involves $\nu(2\tau,2p)$, the inversion formula involves $\nu(\tau,p)$.

This statement of the inversion formula is a bit imprecise, because we have glossed over the question of the convergence of the integral in (56). The integral cannot always be convergent, since a general function f in $L^2(S^d)$ can have singularities. As shown in Theorems 1 and 2 of Ref. 17, we have the following two precise statements. First, if f is sufficiently smooth, then the integral in (56) is absolutely convergent for all $\mathbf{x}$ and is equal to $f(\mathbf{x})$. Second, for any $f \in L^2(S^d)$ we have

$$f(\mathbf{x})=\lim_{R\to\infty}\int_{\substack{\mathbf{p}\cdot\mathbf{x}=0\\ p\le R}} F(\mathbf{a}(\mathbf{x},\mathbf{p}))\,\nu(\tau,p)\left(\frac{\sinh p}{p}\right)^{d-1} d\mathbf{p},$$

where the limit is in the topology of $L^2(S^d)$.

We will describe the proof of Theorem 7 in greater detail in the setting of general compact symmetric spaces. Here we give only the barest outline. The Cauchy–Riemann equations on $S^d_{\mathbb{C}}$ imply that, when applied to holomorphic functions, the hyperbolic Laplacian in the momentum variables is the negative of the spherical Laplacian in the position variables, just as for holomorphic functions on $\mathbb{C}$ we have $\partial^2 F/\partial y^2 = -\partial^2 F/\partial x^2$. For this result to hold, we must omit the rescaling of the momentum variables that is present in the resolution of the identity; hence the inversion formula involves $\nu(\tau,p)$ rather than $\nu(2\tau,2p)$. The integration in (56) against the hyperbolic heat kernel is computing the forward heat equation in the momentum variables, which for holomorphic functions is then the same as the backward heat equation in the position variables. Since the Segal–Bargmann transform may be computed in terms of the forward heat equation in the position variables, (56) is inverting the Segal–Bargmann transform. Although this is the basic idea of the proof, the convergence questions are more subtle.

Note that there are, besides (56), many other inversion formulas for the Segal–Bargmann transform. The ''overcompleteness'' of the coherent states means that there is a lot of redundant information in the Segal–Bargmann transform, and therefore many different ways that one can recover f from Cf. To look at it another way, it is possible to have many different integrals that all give the same value when applied to holomorphic functions, as in the Cauchy integral formula. Of particular importance is the inversion formula,

$$f(\mathbf{x}') = \int_{S^d_{\mathbb{C}}} \overline{\rho_\tau(\mathbf{a},\mathbf{x}')} F(\mathbf{a}(\mathbf{x},\mathbf{p}))\, \nu(2\tau,2p) \left(\frac{\sinh 2p}{2p}\right)^{d-1} 2^d d\mathbf{p}\, d\mathbf{x},$$

where ρ_τ is the analytical continuation of the heat kernel for S^d. This formula is obtained by noting that C is isometric, and therefore its inverse is its adjoint. One can apply the above integral to any function F in $L^2(S^d_{\mathbb{C}},\nu)$ (not necessarily holomorphic), in which case we have $f = C^{-1}PF$, where PF is the orthogonal projection of F onto the holomorphic subspace of $L^2(S^d_{\mathbb{C}},\nu)$. See Ref. 1, Sec. IX and Ref. 20, Eq. (6.13).

VIII. THE $\mathbb{R}^d$ CASE

We verify in this section that the methods in this paper, when applied to the $\mathbb{R}^d$ case, do indeed reproduce the canonical coherent states. Our ''complexifier'' is $1/\omega$ times the kinetic energy function, namely, $p^2/2m\omega$. (In the $\mathbb{R}^d$ case the kinetic energy cannot be expressed in terms of the angular momentum.) Then we define

$$a_k = e^{i\{\cdot,\text{complexifier}\}} x_k = \sum_{n=0}^{\infty} \left(\frac{i}{2m\omega}\right)^n \frac{1}{n!} \underbrace{\{\ldots\{\{x_k,p^2\},p^2\},\ldots,p^2\}}_{n}.$$

Since $\{x_k,p^2\} = 2p_k$ and $\{\{x_k,p^2\},p^2\} = 0$ we obtain

$$a_k = x_k + i\frac{p_k}{m\omega}.$$

This is, up to an overall constant, the standard complex coordinate on phase space. More generally one can apply the same method to any function of the x_k's, and one will obtain the corresponding function of a_k. For example, it is easily verified by induction that

$$e^{i\{\cdot,\text{complexifier}\}}(x_k^n) = \left(x_k + i\frac{p_k}{m\omega}\right)^n$$

for all positive integers n.

Similarly on the quantum side if we define the complexifier to be $P^2/2m\omega$ and

$$A_k = e^{i[\,\cdot\,,\text{complexifier}]/i\hbar} X_k = \sum_{n=0}^{\infty} \frac{1}{(2m\omega\hbar)^n} \frac{1}{n!} [\cdots[[X_k, P^2], P^2]\cdots, P^2]$$

we get simply

$$A_k = X_k + i\frac{P_k}{m\omega}.$$

This is, up to an overall constant, the usual annihilation operator. Applying the same procedure to any function of the X_k's will give the corresponding function of the A_k's.

Following the same normalization procedure as in the sphere case we obtain coherent states given by

$$|\psi_{\mathbf{a}}\rangle = e^{-P^2/2m\omega\hbar}|\delta_{\mathbf{a}}\rangle,$$

at first for $\mathbf{a} \in \mathbb{R}^d$ and then by analytic continuation for any $\mathbf{a} \in \mathbb{C}^d$. In the $\mathbb{R}^d$ case we have the formula

$$|\psi_{\mathbf{a}}\rangle = e^{i\mathbf{a}\cdot\mathbf{P}/\hbar}|\psi_0\rangle.$$

This normalization coincides with what Hecht[30] calls type I coherent states. In the position representation we have

$$\langle \delta_{\mathbf{x}}|\psi_{\mathbf{a}}\rangle = (2\pi\hbar/m\omega)^{-d/2} \exp\left[-\frac{(\mathbf{x}-\mathbf{a})^2}{2\hbar/m\omega}\right].$$

With this normalization of the coherent states the resolution of the identity takes the form

$$I = \int_{\mathbb{C}^d} |\psi_{\mathbf{a}}\rangle\langle\psi_{\mathbf{a}}|\,\gamma(\mathbf{a})\,d\mathbf{a},$$

where $d\mathbf{a}$ is $2d$-dimensional Lebesgue measure and where γ is the density

$$\gamma(\mathbf{a}) = \left(\frac{\pi\hbar}{m\omega}\right)^{-d/2} \exp\left[-\frac{(\mathrm{Im}\,\mathbf{a})^2}{\hbar/m\omega}\right].$$

The associated Segal–Bargmann space is the space of holomorphic functions on $\mathbb{C}^d$ that are square-integrable with respect to the density γ. This normalization of the Segal–Bargmann space is different from that of Segal[31] and Bargmann,[32] because of the different normalization of the coherent states. See Ref. 33, Sec. VI for comparisons with the conventions of Segal and of Bargmann.

To compare this to what we have in the sphere case, let $\sigma = \hbar/m\omega$ and consider the Euclidean heat kernel in the imaginary directions, given by

$$\nu(\sigma, \mathbf{a}) = (2\pi\sigma)^{-d/2} \exp\left[-\frac{(\mathrm{Im}\,\mathbf{a})^2}{2\sigma}\right].$$

Then $\gamma(\mathbf{a}) = 2^d \nu(2\sigma, 2\mathbf{a})$, similar to what we have in the sphere case. Note that in the Euclidean case $\nu(2\sigma, 2\mathbf{a})$ is the same, up to an overall constant, as $\nu(\sigma/2, \mathbf{a})$. Thus it is hard to see the "correct" scaling of the space and time variables from the Euclidean case.

An inversion formula similar to Theorem 7 holds in the $\mathbb{R}^d$ case; see Ref. 4, Sec. IV.

IX. REPRESENTATION THEORY OF THE EUCLIDEAN GROUP

We consider representations by self-adjoint operators of the commutation relations (25) for the Lie algebra $e(d+1)$. We further assume that these operators are the Lie algebra representation associated to a representation of the corresponding connected, simply connected Lie group $\tilde{E}(d+1)$. It is known that all the irreducible unitary representations of $\tilde{E}(d+1)$ can be realized in spaces of sections of smooth vector bundles with the Lie algebra acting by smooth differential operators. The action of the Lie algebra then extends to an action on distributional sections, including the generalized eigenvectors of the position operators. With this discussion in mind we will make free use of position eigenvectors in what follows.

We apply the Wigner–Mackey method and consider an orbit of Spin$(d+1)$ in $\mathbb{R}^{d+1}$, namely, a sphere of radius r. We consider only the case $r>0$, in which case the little group is Spin(d). Fixing a value for r amounts to assuming that the operators X_k satisfy $\Sigma X_k^2 = r^2$.

The purpose of this section is to show that the little group acts trivially if and if the following relation holds for all k and l,

$$X^2 J_{kl} = J_{km} X_m X_l - J_{lm} X_m X_k \tag{57}$$

(sum convention). This is equivalent to the relation

$$J_{kl} = P_k X_l - P_l X_k , \tag{58}$$

where by definition $P_k = r^{-2} J_{kl} X_l$.

Note that (57) is the quantum counterpart of the constraint to the sphere (9) and therefore representations of $\tilde{E}(d+1)$ satisfying it are closest to the classical motion on a sphere. Nevertheless, other representations are of interest, and describe a quantum particle on a sphere with internal degrees of freedom. We will consider the general case in a future work.

Suppose now that (57) holds. We wish to show that this implies that the representation of the little group is trivial. So we consider the space of generalized eigenvectors for the operators X_k satisfying

$$X_k |\psi\rangle = 0, \quad k = 1,\ldots,d$$

$$X_{d+1} |\psi\rangle = r. \tag{59}$$

This is the space on which the little group acts, where the Lie algebra of the little group is given by the operators J_{kl} with $1 \leqslant k,l \leqslant d$. But now if (57) holds then for $k,l \leqslant d$ we have

$$r^2 J_{kl} |\psi\rangle = 0$$

since in that case $X_k |\psi\rangle = X_l |\psi\rangle = 0$. This shows (for $r>0$) that if (57) holds, then the little group acts trivially.

Consider now the quantity,

$$W_{kl} := X^2 J_{kl} - J_{km} X_m X_l + J_{lm} X_m X_k , \tag{60}$$

which satisfies $W_{lk} = -W_{kl}$. Condition (57) is equivalent to $W_{kl} = 0$. Consider also the quantity

$$C := \sum_{k<l} W_{kl}^2 . \tag{61}$$

As we will show below, C is a Casimir, that is, an element of the universal enveloping algebra of $e(d+1)$. This implies that C acts as cI in each irreducible representation. (The value of the constant c is r^4 times the value of the quadratic Casimir for the little group in each generalized eigenspace for the position operators.)

Let us now assume that the little group acts trivially and determine the value of c in this case. We may compute c by applying C to a position eigenvector as in (59). That the little group acts trivially means that $J_{kl}|\psi\rangle = 0$ for $k<l<d+1$. Since also $X_k|\psi\rangle = X_l|\psi\rangle = 0$ for $k<l<d+1$ we get

$$C|\psi\rangle = c|\psi\rangle = \sum_k \left(X^2 J_{k,d+1} - J_{km}X_m X_{d+1} + J_{d+1,m}X_m X_k\right)^2 |\psi\rangle.$$

But since $X_m|\psi\rangle = 0$ unless and $m = d+1$ (and since $J_{d+1,d+1} = 0$) we get that

$$\begin{aligned}\left(X^2 J_{k,d+1} - J_{km}X_m X_{d+1} + J_{d+1,m}X_m X_k\right)|\psi\rangle &= \left(X^2 J_{k,d+1} - J_{k,d+1}X_{d+1}^2 + 0\right)|\psi\rangle \\ &= \left(r^2 J_{k,d+1} - r^2 J_{k,d+1}\right)|\psi\rangle = 0.\end{aligned}$$

This means that if the representation of the little group is trivial then the constant c must be zero, which means the element C must be zero in that representation. A calculation shows that for each $k<l$, W_{kl} is self-adjoint. Thus C is a sum of squares of self-adjoint operators, and the only way the sum can be zero is if each term is zero, that is, if (57) holds. So if the little group acts trivially, (57) must hold, which is what we want to prove.

In the case $d=2$ (considered in Ref. 18) it is possible to verify that

$$C = X^2 (L \cdot X)^2, \tag{62}$$

where L is the angular momentum *vector*, related to our angular momentum *matrix* by $L = (J_{32}, J_{13}, J_{12})$. One can easily check that at least this relation holds in each irreducible representation (which is all that is really relevant) as follows. Both sides are Casimirs and so it suffices to check (62) on the generalized eigenspace in (59). But for $|\psi\rangle$ in this space we calculate that

$$C|\psi\rangle = X^2 (L \cdot X)^2 |\psi\rangle = X^4 J_{12}^2 |\psi\rangle,$$

and indeed (62) holds. From (62) we see that taking $C=0$ is equivalent in the $d=2$ case to taking $L \cdot X = 0$ as in Ref. 18.

It remains only to show that the element C in (61) is a Casimir. To do this we first compute the commutation relations of W_{kl} with the J's and the X's. These come out to be

$$\frac{1}{i\hbar}[X_k, W_{lm}] = 0, \tag{63}$$

$$\frac{1}{i\hbar}[J_{kl}, W_{mn}] = \delta_{kn} W_{lm} + \delta_{lm} W_{kn} - \delta_{km} W_{ln} - \delta_{ln} W_{km}. \tag{64}$$

Equation (64) is what we expect for a matrix operator—compare this to the formula for $[J_{kl}, J_{mn}]$. Equation (63) implies immediately that C commutes with each X_k, and Eq. (64) implies, after a short calculation, that C commutes with each J_{kl}.

X. CONCLUDING REMARKS

We end this paper by discussing how the coherent states described here compare to other coherent states that have been proposed for systems whose configuration space is a sphere (or homogeneous space). As we have explained in detail above, the coherent states introduced in Ref. 18 are equivalent to those in Refs. 1, 17, but were discovered independently and from a different point of view.

Meanwhile, there are several other generalized Segal–Bargmann transforms for spheres that have been considered. These are similar but not identical to each other and were introduced by Bargmann and Todorov,[34] Rawnsley,[35] Ii,[36] Wada,[37] Thomas and Wassell,[38] and Villegas-Blas.[39] In

most cases the transform is unitary, and this unitarity can be reformulated as a resolution of the identity for the associated coherent states. These constructions all have in common that the coherent states are labeled by points in the cotangent bundle *minus the zero section* (i.e., with the points of zero momentum removed). In these papers the cotangent bundle minus the zero section is identified with the null quadric $\{a \in \mathbb{C}^{d+1} | a^2 = 0\}$. This is to be contrasted with the present paper, in which the full cotangent bundle of the sphere is identified with the quadric $\{a^2 = r^2\}$ with $r > 0$. Thus these constructions are inequivalent to the one considered in this paper. Furthermore these constructions do not generalize to higher-rank symmetric spaces.[40]

Besides these, there have been to our knowledge two other proposed constructions of coherent states on spheres (and other homogeneous spaces). These constructions, inequivalent to Refs. 1, 17 and to each other, are those of De Bièvre[41] and of Isham and Klauder.[42] Both Refs. 41 and 42 are based on extensions of the Perelomov approach, in that their coherent states are all obtained from one fixed vector ψ_0 by the action of the Euclidean group. As explained in those papers, the ordinary Perelomov approach is not applicable in this case, because the irreducible representations of the Euclidean group are not square-integrable. Non-square-integrability means that the usual Perelomov-type integral, which should be a multiple of the identity operator, is in this case divergent.

De Bièvre's approach to this problem is to apply to the fiducial vector ψ_0 only a part of the Euclidean group. We describe just the simplest case of Ref. 41. (This special case was worked out independently in a more elementary way by Torresani.[43]) Specifically, if we work in $L^2(S^d)$ then start with a basic coherent state ψ_0 such that (a) ψ_0 is invariant under rotations about the north pole $\mathbf{n}$ and (b) ψ_0 is supported in the northern half-sphere with a certain rate of decay at the equator. One may think of ψ_0 being concentrated near the north pole and approximating a state whose position is at the north pole and whose momentum is zero. The other coherent states are then of the form,

$$\exp(i\mathbf{k}\cdot\mathbf{x})\psi_0(R^{-1}\mathbf{x}),$$

where we consider only pairs $(\mathbf{k}, R)$ satisfying $\mathbf{k}\cdot R\mathbf{n} = 0$. This last restriction is crucial. Since ψ_0 is invariant under rotations about the north pole, the coherent states are determined by the values of $\mathbf{k}$ and $R\mathbf{n}$ and are thus labeled by points in the cotangent bundle of S^d. The resolution of the identity for these coherent states follows from the general procedure in Ref. 41 but can also be proved in this case by an elementary application of the Plancherel formula. The condition that ψ_0 be supported in the northern half-sphere is crucial to the proof.

It is clear that the coherent states considered in this paper are quite different from those in Ref. 41. First, De Bièvre's coherent states do not depend holomorphically on the parameters. Second, each coherent state must be supported in a half-sphere, hence cannot be real-analytic in the space variable. Third, there does not seem to be any preferred choice for ψ_0 in Ref. 41, whereas for the coherent states considered here the only choice one has to make is the value of the parameter ω.

Meanwhile, Isham and Klauder use a different method of working around the nonsquare-integrability of the irreducible representations of $E(d+1)$. They use reducible representations, corresponding to integration over some small range $[r, r+\varepsilon]$ of radii. This allows for a family of coherent states invariant under the full Euclidean group and allows a more general basic coherent state ψ_0, without any support conditions. On the other hand it seems natural to get back to an irreducible representation by letting ε tend to zero, so that the particle is constrained to a sphere with one fixed radius. Unfortunately, although the representation itself does behave well under this limit (becoming irreducible) the coherent states themselves do not have a limit as ε tends to zero. (See the remarks at the bottom of the first column on p. 609 in Ref. 42.) This seems to be a drawback of this approach.

Finally, we mention that in the group case, the coherent states described in this paper can be obtained by means of geometric quantization, as shown in Ref. 14. This means that in the group case the coherent states are of "Rawnsley type."[15] However, this result does not carry over to the

case of general compact symmetric spaces. In particular the results of Ref. 14 apply only to those spheres that are also groups, namely, $S^1 = \mathrm{U}(1)$ and $S^3 = \mathrm{SU}(2)$.

(Received 13 August 2001; accepted for publication 6 December 2001)

We study the lowest energy E of a relativistic system of N identical bosons bound by harmonic-oscillator pair potentials in three spatial dimensions. In natural units $\hbar=c=1$ the system has the semirelativistic (or ''spinless-Salpeter'') Hamiltonian, $H=\Sigma_{i=1}^{N}\sqrt{m^2+\mathbf{p}_i^2}+\Sigma_{j>i=1}^{N}\gamma|\mathbf{r}_i-\mathbf{r}_j|^2$, $\gamma>0$. We derive the following energy bounds: $E(N)=\min_{r>0}[N(m^2+2(N-1)P^2/(Nr^2))^{1/2}+(N/2)(N-1)\gamma r^2]$, $N\geqslant 2$, where $P=1.376$ yields a lower bound and $P=\frac{3}{2}$ yields an upper bound for all $N\geqslant 2$. A sharper lower bound is given by the function $P=P(m)$ which makes the formula for $E(2)$ exact: with this choice of P, the bounds coincide for all $N\geqslant 2$ in the Schrödinger limit defined by $m\to\infty$. © *2002 American Institute of Physics.* [DOI: 10.1063/1.1446245]

I. INTRODUCTION AND MAIN RESULT

Many-body problems form essential links between quantum-theoretical models and real nuclear, atomic, or macroscopic systems. However, even for nonrelativistic quantum theory, there are very few many-body problems that have explicit analytic solutions; the harmonic oscillator and the attractive delta interaction are well-known exceptions. In relativistic quantum theories the situation is even worse, in spite of the fact that the phenomenon of particle creation allowed by quantum field theory would suggest that there is no such thing as a one-body problem in that theory. Therefore, it is of considerable interest to study model N-body systems within the framework of the semirelativistic ''spinless-Salpeter'' equation. For this problem there exists a well-defined nonrelativistic limit which yields a useful consistency check. Specifically, we investigate in this article the relative energy E of a system of N identical bosons represented by a semirelativistic ''spinless-Salpeter'' Hamiltonian[1,2] of the form

$$H=\sum_{i=1}^{N}\sqrt{m^2+\mathbf{p}_i^2}+\sum_{j>i=1}^{N}\gamma|\mathbf{r}_i-\mathbf{r}_j|^2, \tag{1.1}$$

where m is the boson mass, and $\gamma>0$ is a coupling parameter, and we have chosen units in which $\hbar=c=1$. The operators $\mathbf{p}_i$ are defined[3,4] in the momentum-space representation where they become multiplicative operators (c-variables). The present work is an extension to the case of N

bosons of our earlier study[5] in which we derived energy bounds for the corresponding one-body problem. We may compare H with the corresponding Schrödinger N-body problem with Hamiltonian

$$H_S=\sum_{i=1}^{N}\frac{\mathbf{p}_i^2}{2m}+\sum_{j>i=1}^{N}\gamma|\mathbf{r}_i-\mathbf{r}_j|^2. \tag{1.2}$$

Given our goal of investigating the *relative* (that is, binding) energies, both of these Hamiltonians have the unwelcome feature that they include the kinetic energy of the center-of-mass motion. This is easy to remedy for H_S, but a correct form is not so immediate in the relativistic case H. The exact solution to (1.2) is periodically ''rediscovered'' but has been known at least since 1935 when Houston solved the problem.[6,7] The ground-state energy E_S of the nonrelativistic problem is given for $N\geqslant 2$ (in three dimensions) by the simple formula

$$\varepsilon=3v^{1/2},\quad \varepsilon=\frac{mE_S}{N-1},\quad v=\frac{mN\gamma}{2}. \tag{1.3}$$

Thus ε is exactly the bottom of the spectrum of the one-body Hamiltonian $-\Delta+vr^2$. In this article we shall prove the following statement.

Theorem 1: *Bounds on the ground-state energy eigenvalue E of the semirelativistic Hamiltonian (1.1) are provided by the formula*

$$E=\min_{r>0}\left[N\left(m^2+\frac{2(N-1)P^2}{Nr^2}\right)^{1/2}+\frac{N}{2}(N-1)\gamma r^2\right],\quad N\geqslant 2, \tag{1.4}$$

which yields an upper bound on E when $P=\frac{3}{2}$, *and a lower bound on E when* $P=P(m)$, *a function that makes the approximation (1.4) exact in the case* $N=2$. *The function* $P(m)$ *is monotone increasing with m, has bounds*

$$1.376<P(m)<\tfrac{3}{2}, \tag{1.5}$$

and has the limit

$$\lim_{m\to\infty}P(m)=\tfrac{3}{2}. \tag{1.6}$$

In the large-m limit, the upper and lower bounds coalesce to the corresponding exact (nonrelativistic) Schrödinger energy $E_{NR}=E_S+Nm$.

The article is primarily concerned with proving Theorem 1. The main technical difficulties are twofold: to keep the fundamental symmetries of translation invariance and boson permutation symmetry, and to find ways of ''penetrating'' the square-root operator of the Salpeter kinetic energy. Our policy is to work with Jacobi relative coordinates to guarantee translation invariance of the wave functions, and to accept the concomitant complications of permutation symmetry. We discuss the relative coordinates and some of their properties in Sec. II. We shall exploit the necessary permutation symmetry to relate the N-body energy to that of a scaled and reduced two-body problem. The exact solution of the one-body problem is discussed in Sec. III. It is well known that the one-body Salpeter problem is equivalent to a Schrödinger problem with Hamiltonian $-\Delta+\sqrt{m^2+r^2}$.[8,9] We take the position in this article that the lowest eigenvalue $e(m)$ of this problem, which is easy to find numerically, is at our disposal. In Fig. 1 we exhibit graphs of the functions $\{e(m),P(m)\}$. The extension of these results to the two-body problem is treated in Sec. IV. The lower bound discussed in Sec. V is rendered possible by an operator property introduced in Sec. II that allows us, in a sense, to remove certain annihilation operators from inside the square-root operator. For the N-body upper bound discussed in Sec. VI we use a Gaussian wave function and minimize the energy expectation with respect to a scale variable. The

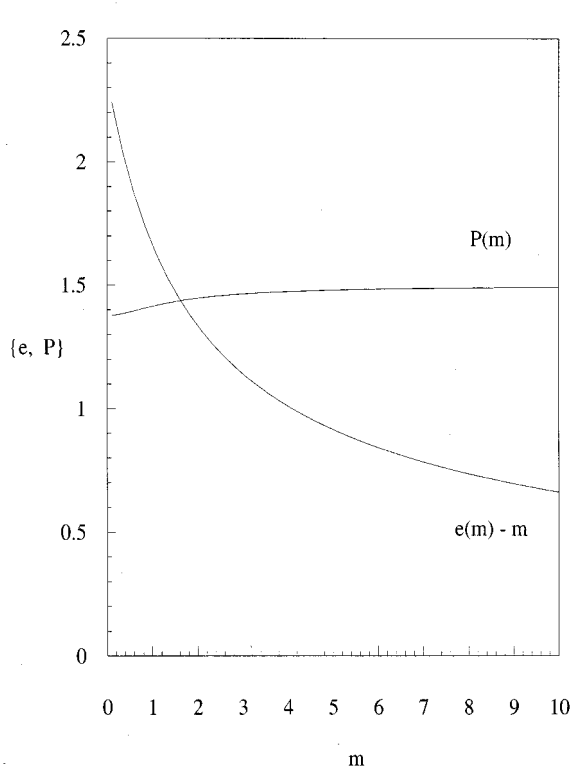

FIG. 1. The monotone energy function $e(m)$ of the one-body problem defined by (3.1), and the monotone function $P(m)$ used in our standard representation (3.8) for $e(m)$; the function $P(m)$ is bounded by $P(0)=1.376\leqslant P(m)\leqslant P(\infty)=\frac{3}{2}$.

calculation is helped by special factoring properties of the Gaussian and by the use of Jensen's inequality. The bounds corresponding to $P=\{1.376,1.5\}$ are depicted in Fig. 2, and the convergence of the bounds $P=\{P(m),\frac{3}{2}\}$ with increasing m is shown in Fig. 3, for $2\leqslant N\leqslant 8$.

II. RELATIVE COORDINATES

Jacobi relative coordinates may be defined with the aid of an orthogonal matrix B relating the column vectors of the new $[\rho_i]$ and old $[\mathbf{r}_i]$ coordinates according to

$$[\rho_i]=B[\mathbf{r}_i]. \tag{2.1}$$

The first row of B defines a center-of-mass variable with every entry $1/\sqrt{N}$, the second row defines a pair distance $\rho_2=(\mathbf{r}_1-\mathbf{r}_2)/\sqrt{2}$, and the kth row, $k\geqslant 2$, has the first $k-1$ entries $B_{ki}=1/\sqrt{k(k-1)}$, the kth entry $B_{kk}=-\sqrt{(k-1)/k}$, and the remaining entries zero. We define the corresponding momentum variables as

$$[\pi_i]=(B^{-1})^t[\mathbf{p}_i]=B[\mathbf{p}_i]. \tag{2.2}$$

These coordinates have some nice properties which we shall need. First, we have

$$k\sum_{i=2}^{k}\rho_i^2=\sum_{j>i=1}^{k}(\mathbf{r}_i-\mathbf{r}_j)^2,\quad k=2,3,...,N, \tag{2.3}$$

and similarly for the momenta

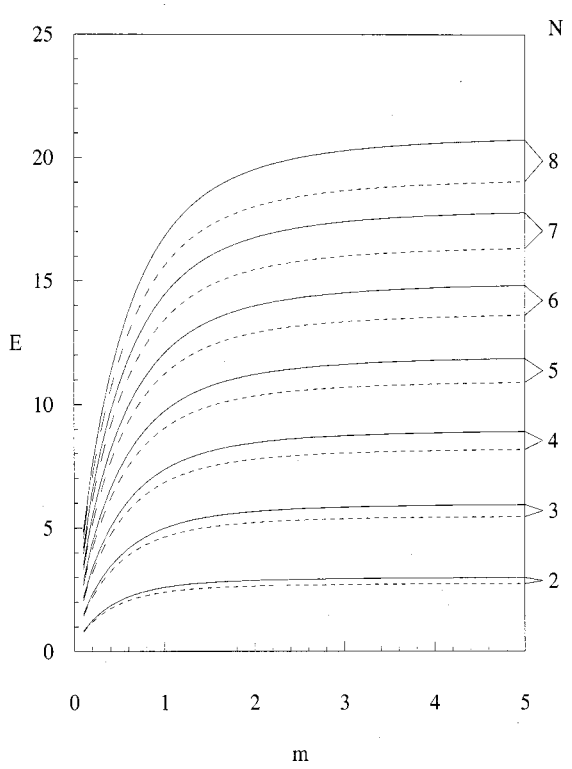

FIG. 2. Upper (full lines) and lower (dashed lines) bounds to the lowest energy $E(m)$ of the N-boson relativistic harmonic-oscillator problem for $N=2,3,...,8$ obtained by employing the constant values $P=1.376$ and $P=1.5$, respectively, in Eq. (1.4) of Theorem 1.

$$k\sum_{i=2}^{k}\pi_i^2=\sum_{j>i=1}^{k}(\mathbf{p}_i-\mathbf{p}_j)^2,\quad k=2,3,...,N. \tag{2.4}$$

It follows immediately that if Ψ is a translation-invariant wave function which is symmetric (or antisymmetric) under the permutation of the individual-particle indices, then it follows that

$$(\Psi,\rho_i^2\Psi)=(\Psi,\rho_2^2\Psi),\quad 2\leqslant i\leqslant N, \tag{2.5}$$

and

$$(\Psi,\pi_i^2\Psi)=(\Psi,\pi_2^2\Psi),\quad 2\leqslant i\leqslant N. \tag{2.6}$$

These expectation symmetries might suggest that the wave function Ψ is symmetric under permutation of the relative coordinates, but this stronger property is only true for Gaussian wave functions. Moreover, Gaussian boson wave functions of Jacobi relative coordinates uniquely[10,11] have the further factoring property that

$$\Phi(\rho_2,\rho_3,\ldots,\rho_N)=\phi(\rho_2)\,\theta(\rho_3,\ldots,\rho_N), \tag{2.7}$$

where ϕ and θ are also Gaussian.

III. THE ONE-BODY PROBLEM

We consider the one-body problem with Hamiltonian

$$H_1=\sqrt{m^2+\mathbf{p}^2}+r^2\rightarrow e(m), \tag{3.1}$$

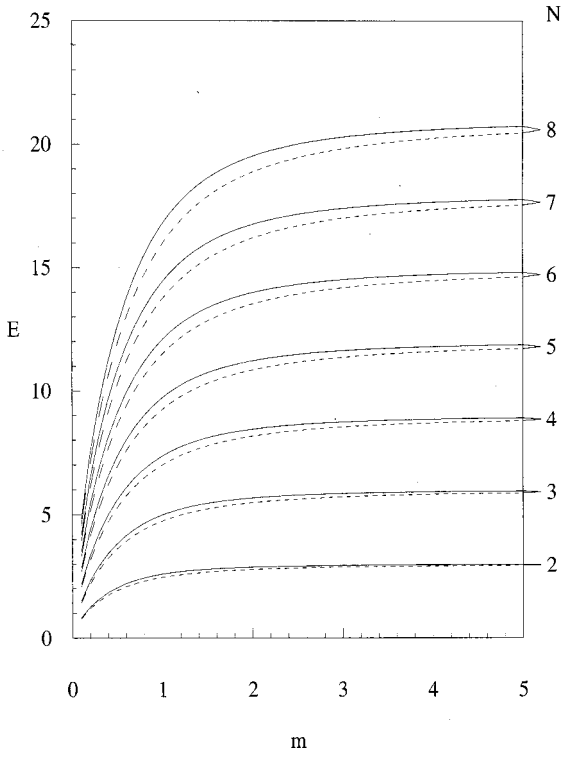

FIG. 3. Upper (full lines) and lower (dashed lines) bounds to the lowest energy $E(m)$ of the N-boson relativistic harmonic-oscillator problem for $N=2,3,...,8$ obtained by employing the values $P=P(m)$ and $P=1.5$, respectively, in Eq. (1.4) of Theorem 1. For $N=2$, the lower bound is exact.

where, for coupling $\gamma=1$, $e(m)$ is the lowest eigenvalue as a function of the mass m. By transforming this problem into momentum space we obtain the equivalent problem

$$\tilde{H}_1=-\Delta+\sqrt{m^2+r^2}\rightarrow e(m). \tag{3.2}$$

Since this Schrödinger problem is easy to solve numerically to arbitrary accuracy, we shall take the position that $e(m)$ is "known" and at our disposal. We note that in the large-m (nonrelativistic or Schrödinger) limit, we have

$$e(m)\simeq e_{\mathrm{NR}}(m)=m+\frac{3}{(2m)^{1/2}}. \tag{3.3}$$

We now define, for a given value of m, the (lowest) "kinetic potential" [12–14] $\overline{h}(s)$ associated with the relativistic-kinetic-energy square-root operator $\sqrt{m^2+\mathbf{p}^2}$ and the harmonic-oscillator potential r^2 by

$$\overline{h}(s)=\inf_{\substack{\psi\in\mathcal{D}(H_1)\\ \|\psi\|=1\\ (\psi,\sqrt{m^2+\mathbf{p}^2}\psi)=s}}(\psi,r^2\psi), \tag{3.4}$$

where $\psi(\mathbf{r})$ is a wave function in the domain $\mathcal{D}(H_1)$ of H_1. That is to say, we find the minimum mean-value of the potential, subject to the constraint that the mean kinetic energy is held constant at the value s. It follows that the eigenvalue may now be recovered from $\overline{h}(s)$ by a further minimization with respect to the kinetic energy s. Thus we have

$$e(m)=\min_{s>m}[s+\overline{h}(s)]. \tag{3.5}$$

An important and useful aspect of this representation for $e(m)$ is that the identical kinetic potential $\overline{h}(s)$ can be used for a more general one-body problem in which the kinetic-energy term is multiplied by the positive factor β, say, and the coupling $\gamma>0$ is returned. We have explicitly

$$\beta\sqrt{m^2+\mathbf{p}^2}+\gamma r^2\to\varepsilon(m,\beta,\gamma)=\min_{s>m}[\beta s+\gamma\overline{h}(s)]. \tag{3.6}$$

However, we still have to find the kinetic potential $\overline{h}(s)$. We do this by changing the minimization variable from $s>m$ to $r>0$ according to the following defining equation for $P(m)$:

$$\overline{h}(s)=r^2,\quad s=\sqrt{m^2+\left(\frac{P(m)}{r}\right)^2}. \tag{3.7}$$

Now, by rewriting (3.5) in terms of the function $P(m)$, we obtain

$$e(m)=\min_{r>0}\left[\sqrt{m^2+\left(\frac{P(m)}{r}\right)^2}+r^2\right], \tag{3.8}$$

and, by solving (3.8), we obtain the following expression for $P(m)$ in terms of the one-body energy $e(m)$:

$$P(m)=\left(\frac{2(e(m)+\sqrt{e^2(m)+3m^2})}{27}\right)^{1/2}(2e(m)-\sqrt{e^2(m)+3m^2}). \tag{3.9}$$

The graphs of $e(m)-m$ and $P(m)$ are shown in Fig. 1: both $e(m)$ and $P(m)$ are monotone increasing with m; $e(m)-m$, however, is monotone *decreasing*, in agreement, for large m, with the Feynman–Hellmann theorem for the corresponding nonrelativistic case. In the (ultrarelativistic) limit $m\to0$ we have $\tilde{H}_1\to-\Delta+r$, that is to say, the operator limit is the Schrödinger operator for the linear potential in three dimensions, with lowest energy $e(0)=2.338\,107\,41$. In the (nonrelativistic) large-m limit we have $H_1\to m-(1/2m)\Delta+r^2$, that is to say, the Schrödinger harmonic oscillator with energy $e(m)\simeq m+3/\sqrt{2m}$. By substituting these "outer" energies in (3.9), we obtain the bounds

$$1.376<P(m)<\tfrac{3}{2}. \tag{3.10}$$

It is clear from Eq. (3.8) that the expression for $e(m)$, as a function of *m and P*, is monotone increasing in P. Thus, by substituting, respectively, the constants $P=1.376$ and $P=1.5$, we obtain from this formula lower and upper bounds on the one-body energy $e(m)$. These bounds agree exactly with the bounds we obtained earlier[5,14] for this one-body harmonic-oscillator problem. In summary—and with the introduction of one more parameter $\lambda>0$, which we shall need later—we have

$$\beta\sqrt{m^2+\lambda\mathbf{p}^2}+\gamma r^2\to\varepsilon(m,\beta,\gamma\lambda)=\min_{r>0}\left[\beta\left(m^2+\lambda\left(\frac{P}{r}\right)^2\right)^{1/2}+\gamma r^2\right]. \tag{3.11}$$

For each $\beta>0$, $\gamma>0$, $\lambda>0$, this formula is exact when $P=P(m)$, is a lower bound when $P=1.376$, and is an upper bound when $P=1.5$. We have chosen to express this result in this form because of the extension to the N-body problem. By elementary scaling arguments we may also express $\varepsilon(m,\beta,\gamma\lambda)$ directly in terms of the energy function $e(m)$ by the explicit formula

$$\varepsilon(m,\beta,\gamma\lambda)=(\beta^2\gamma\lambda)^{1/3}e\left(m\left(\frac{\beta}{\gamma\lambda}\right)^{1/3}\right). \tag{3.12}$$

As we shall see in the next section, the two-body energy is obtained from (3.11) or (3.12) by simply setting $\lambda=1$, $\beta=2$. It is an extension of this reasoning that will allow us, in Sec. V, to obtain also the N-body, $N\geqslant 2$, lower energy bound by using suitable values for β, γ, and λ.

IV. THE TWO-BODY PROBLEM

For the case $N=2$ we have explicitly

$$H=\sqrt{m^2+\mathbf{p}_1^2}+\sqrt{m^2+\mathbf{p}_2^2}+\gamma|\mathbf{r}_1-\mathbf{r}_2|^2. \tag{4.1}$$

Let $\psi(\rho_2)$ be a normalized boson wave function. Then the lowest relative eigenvalue of the operator H is the infimum of expectation values of the form $(\psi,H\psi)$. But the boson symmetry of $\psi(\rho_2)$ means that the two kinetic-energy terms in $(\psi,H\psi)$ must have the same value. Moreover, in terms of relative coordinates, the operator $\mathbf{p}_2^2$ may be written

$$\mathbf{p}_2^2=\frac{(\pi_1-\pi_2)^2}{2}. \tag{4.2}$$

Now, the operator π_1 would immediately annihilate $\psi(\rho_2)$ if it were not contained in the square root. We claim that, inside the expectation value, the operator π_1 may simply be removed; this may be seen as an immediate generalization of the following observation.

Lemma 1: Suppose $\Psi(x,y)=\psi(x)$, *then*

$$\left[1-\left(\frac{\partial}{\partial x}-\frac{\partial}{\partial y}\right)^2\right]^{1/2}\Psi=\left(1-\frac{\partial^2}{\partial x^2}\right)^{1/2}\Psi. \tag{4.3}$$

Proof of Lemma 1: If $\mathcal{F}$ indicates the two-dimensional Fourier transform and our new variables are $\{p,q\}$, then we find $\mathcal{F}(\Psi)(p,q)=\tilde{\psi}(p)\,\delta(q)$, and, by definition, the Fourier transform of the left-hand side of (4.3) becomes

$$(1+(p-q)^2)^{1/2}\,\tilde{\psi}(p)\,\delta(q)=(1+p^2)^{1/2}\tilde{\psi}(p)\,\delta(q). \tag{4.4}$$

By transforming back to the variables $\{x,y\}$, we obtain the right-hand side of (4.3). □

Applying the generalization of this lemma to our problem in three dimensions, we find, for $\psi=\psi(\rho_2)$,

$$(\psi,H\psi)=(\psi,(2\sqrt{m^2+\tfrac{1}{2}\pi_2^2}+2\gamma\rho_2^2)\psi). \tag{4.5}$$

By defining the pair-distance variable $\mathbf{r}=\mathbf{r}_1-\mathbf{r}_2=\sqrt{2}\rho_2$, and the corresponding momentum as $\mathbf{p}=-i\nabla_{\mathbf{r}}=\pi_2/\sqrt{2}$, we may rewrite (4.5) as

$$(\psi,H\psi)=(\psi,(2\sqrt{m^2+\mathbf{p}^2}+\gamma r^2)\psi). \tag{4.6}$$

By using a formal relative coordinate $\mathbf{r}$, we have thus recovered the well-known[15] two-body result: the minimum of the right-hand side of (4.6) is the bottom of the spectrum of H which corresponds precisely to the energy of a one-body problem with the kinetic-energy parameter $\beta=2$. This result may also be expressed in terms of the one-body energy function $e(m)$ by means of Eq. (3.12). Thus we have explicitly for $N=2$

$$E=(4\gamma)^{1/3}e\left(m\left(\frac{2}{\gamma}\right)^{1/3}\right). \tag{4.7}$$

In the next section we shall apply a similar reasoning to the N-body problem; however, for $N>2$ we obtain, instead of the exact energy, a lower energy bound.

V. THE LOWER BOUND

Suppose that $\Psi(\rho_2,\rho_3,\ldots,\rho_N)$ is a normalized translation-invariant N-boson wave function. Boson symmetry and, in particular, formula (2.3) allow us to write

$$E\leqslant(\Psi,H\Psi)=N(\Psi,(m^2+\mathbf{p}_N^2)^{1/2}\Psi)+\binom{N}{2}\gamma(\Psi,2\rho_N^2\Psi). \tag{5.1}$$

Now, from the definition of the relative coordinates, we have

$$\mathbf{p}_N=\frac{1}{\sqrt{N}}\,\pi_1-\sqrt{\frac{N-1}{N}}\,\pi_N. \tag{5.2}$$

Consequently, an application of an immediate generalization of Lemma 1 allows us to ''remove'' the operator π_1 from the square root of the kinetic-energy term and write

$$E\leqslant N\left(\Psi,\left(m^2+\frac{N-1}{N}\,\pi_N^2\right)^{1/2}\Psi\right)+\binom{N}{2}\gamma(\Psi,2\rho_N^2\Psi). \tag{5.3}$$

Adapting the argument presented in Sec. IV for the two-body case $N=2$, we define a relative coordinate $\mathbf{r}=\sqrt{2}\rho_N$, and the corresponding momentum $\mathbf{p}=\pi_N/\sqrt{2}$. The expression for the upper bound to the lowest N-boson energy E then becomes

$$E\leqslant N\left(\Psi,\left(m^2+\frac{2(N-1)}{N}\,\mathbf{p}^2\right)^{1/2}\Psi\right)+\binom{N}{2}\gamma(\Psi,r^2\Psi). \tag{5.4}$$

The inequality (rather than an equality) in (5.4) comes only from the choice of wave function. If we find the infimum of such expressions over all normalized translation-invariant N-boson wave functions, we would obtain the exact energy E; if we find this minimum but without the constraint of boson symmetry, then the right-hand side of (5.4) will in general fall below E but will in any case be bounded from below by the bottom of the spectrum of the one-body semirelativistic Salpeter Hamiltonian

$$H=N\left(m^2+\frac{2(N-1)}{N}\,\mathbf{p}^2\right)^{1/2}+\binom{N}{2}\gamma r^2. \tag{5.5}$$

But this latter problem corresponds precisely to Eq. (3.11) if we make the parameter substitutions

$$\beta=N,\quad \lambda=\frac{2(N-1)}{N},\quad \gamma\to\binom{N}{2}\gamma=\frac{N(N-1)}{2}\,\gamma. \tag{5.6}$$

Thus, in view of the P representation (3.8), it is clear that we have established the lower bound (1.4) of Theorem 1.

It is interesting to note that we can substitute the N-body values (5.6) for the parameters β, γ, and λ into the result (3.12) for the one-body ground-state energy $\varepsilon(m,\beta,\gamma\lambda)$ in order to obtain the following explicit expression for the lower bound:

$$E\geqslant(N^2(N-1)^2\gamma)^{1/3}e\left(m\left(\frac{N}{(N-1)^2\gamma}\right)^{1/3}\right). \tag{5.7}$$

This expression—which is equivalent to the lower bound (1.4) of Theorem 1—gives the exact energy and agrees with Eq. (4.7) when $N=2$. Meanwhile, for all $N\geqslant 2$, in the nonrelativistic large-m (Schrödinger) limit it yields the exact N-body energy

$$E_{\mathrm{NR}}=Nm+3\left(\frac{\gamma}{2m}\right)^{1/2}N^{1/2}(N-1), \tag{5.8}$$

reproducing thus the old result of Houston recalled in Eq. (1.3).

VI. THE UPPER BOUND

For the upper bound we employ a Gaussian wave function of the form

$$\Phi(\rho_2,\rho_3,\ldots,\rho_N)=C\exp\left(-\alpha\sum_{i=2}^{N}\rho_i^2\right),\quad \alpha>0, \tag{6.1}$$

where C is a normalization constant. The factoring property (2.7) of this function and the boson-symmetry reduction leading to (5.4) allows us to write

$$E\leqslant N\left(\phi,\left(m^2+\frac{2(N-1)}{N}\mathbf{p}^2\right)^{1/2}\phi\right)+\binom{N}{2}\gamma(\phi,r^2\phi), \tag{6.2}$$

where the function $\phi(r)$ is given by

$$\phi(r)=\left(\frac{\alpha}{\pi}\right)^{3/4}\exp\left(-\frac{\alpha r^2}{2}\right). \tag{6.3}$$

Since the kinetic-energy operator is a *concave* function of the square $\mathbf{p}^2$ of the momentum, we can use Jensen's inequality[16] to move the expectation value $\langle\mathbf{p}^2\rangle$ inside the square root and thus estimate the mean value of this operator from above and write

$$E\leqslant N\left(m^2+\frac{2(N-1)}{N}(\phi,\mathbf{p}^2\phi)\right)^{1/2}+\binom{N}{2}\gamma(\phi,r^2\phi). \tag{6.4}$$

We shall minimize this upper bound with respect to the scale variable $\alpha>0$. We parametrize the basic kinetic-energy and potential-energy expectation values in terms of a variable $r>0$ by the following relations:

$$(\phi,r^2\phi)=\frac{3}{2\alpha}:=r^2,\quad (\phi,\mathbf{p}^2\,\phi)=\frac{3\alpha}{2}=\left(\frac{P}{r}\right)^2,\quad P:=\frac{3}{2}. \tag{6.5}$$

By substituting these expressions in Eq. (6.4) and minimizing over the variable r, we establish the upper bound (1.4) of Theorem 1.

VII. SUMMARY AND CONCLUSION

This article is devoted to the investigation of the ground-state eigenvalue of the semirelativistic ("spinless-Salpeter") Hamiltonian (1.1) which governs the dynamics of a system of N identical bosons that experience pair interactions described by a harmonic-oscillator potential with coupling strength γ. For a fixed coupling $\gamma=1$, we have represented the exact ground-state energy eigenvalue of the corresponding one-body problem, regarded as a function $e(m)$ of the boson mass m, by a monotone rising function $P(m)$, which is bounded by $1.376=P(0)\leqslant P(m)\leqslant P(\infty)=1.5$. Our bounds (1.4) on the energy of the N-body problem are expressed in terms of a formula which has this function P as a parameter.

In Fig. 2 we have plotted the energy bounds corresponding to fixed lower and upper limiting values of $P(m)$, namely, $P=\{1.376,1.5\}$. In Fig. 3 we have kept the same upper energy bound, obtained with the help of a Gaussian trial wave function and corresponding to $P=1.5$, but added the best lower energy bound of this type, using a ''running'' $P=P(m)$. The lower energy bound of Fig. 3 is identical to the exact energy for the case $N=2$. For higher $N>2$, Fig. 3 shows the approach of both upper and lower bounds to the well-known exact nonrelativistic solution (1.3) in the large-m limit.

A key ingredient in this analysis is the use of relative coordinates: only in such a framework could the upper and lower energy bounds be made to converge in the Schrödinger limit. This study of the semirelativistic harmonic-oscillator problem is a first step towards energy bounds valid for more general central pair interactions.

Maximization of capacity and l_p norms for some product channels

Christopher King[a)]
Department of Mathematics, Northeastern University, Boston, Massachusetts 02115

(Received 23 March 2001; accepted for publication 20 November 2001)

It is conjectured that the Holevo capacity of a product channel $\Omega\otimes\Phi$ is achieved when product states are used as input. Amosov, Holevo, and Werner have also conjectured that the maximal l_p norm of a product channel is achieved with product input states. In this article we establish both of these conjectures in the case that Ω is arbitrary and Φ is a CQ or QC channel (as defined by Holevo). We also establish the Amosov, Holevo and Werner conjecture when Ω is arbitrary and either Φ is a qubit channel and $p=2$, or Φ is a unital qubit channel and p is integer. Our proofs involve a new conjecture for the norm of an output state of the half-noisy channel $I\otimes\Phi$, when Φ is a qubit channel. We show that this conjecture in some cases also implies additivity of the Holevo capacity. © *2002 American Institute of Physics.*

I. INTRODUCTION

A quantum channel is the mathematical description of a device which stores and transmits quantum states. Much work has been devoted to the study of particular quantum channels with highly nonclassical properties, and also to general questions such as the information capacity of classes of channels. In this article we will consider some problems of the second type, concerning additivity and multiplicativity properties that are believed to hold for all product channels.

The basic components of a quantum channel are a Hilbert space $\mathcal{H}$ and a noise operator Φ. The quantum states are positive operators on $\mathcal{H}$, with trace equal to one. The noise operator Φ is a completely positive, trace-preserving map which acts on the set of states. Positivity means that Φ is a positive operator on $B(\mathcal{H})$ (the algebra of bounded operators on $\mathcal{H}$). Complete positivity means that the map $I\otimes\Phi$ is also a positive operator on $B(\mathbf{C}^K\otimes\mathcal{H})$ for every K.

When the channel $(\mathcal{H},\Phi)$ is used to store or transmit information, it is assumed that the information is encoded as a state on the product space $\mathcal{H}^{\otimes n}$ for some n, and that the noise acts on this state through the product operator $\Phi^{\otimes n}$, thereby mimicking the action of a memoryless channel in classical information theory. The basic properties of such quantum memoryless channels have been studied by many authors.[1–5] One outstanding problem is to determine the ultimate rate at which classical information can be transmitted through this channel, when no prior entanglement is available between sender and receiver. The protocol that achieves this capacity may require messages to be encoded using entangled states and/or decoded using collective measurements. It is conjectured that this ultimate capacity is given by the well-known Holevo bound[3]

$$C_{\mathrm{Holv}}(\Phi)=\sup_{\pi,\,\rho}\left[S\left(\sum\ \pi_i\Phi(\rho_i)\right)-\sum\ \pi_i S(\Phi(\rho_i))\right], \tag{1}$$

where $S(\rho)=-\mathrm{Tr}\rho\log\rho$ is the von Neumann entropy, and the sup runs over all probability distributions $\{\pi_i\}$ and collections of states $\{\rho_i\}$ on $\mathcal{H}$. This capacity conjecture is equivalent to the statement that there is no benefit gained when entangled states are used to encode messages for transmission through a quantum channel. As shown by Holevo[3] and Schumacher–Westmoreland,[5]

a)Electronic mail: king@neu.edu

the ultimate rate for information transmission using non-entangled coding states is exactly C_{Holv}. Thus the capacity conjecture is implied by the *additivity conjecture* for C_{Holv}, which states that for any channels Ω and Φ

$$C_{\mathrm{Holv}}(\Omega\otimes\Phi)=C_{\mathrm{Holv}}(\Omega)+C_{\mathrm{Holv}}(\Phi). \tag{2}$$

Although the equality (2) has been shown in some special cases,[4–8] it remains a challenging problem to prove this result for a general pair of channels (Ω,Φ). Amosov, Holevo, and Werner introduced a related conjecture, concerning the noncommutative l_p norm of output states from a product channel[6] (this norm is defined later in this work). In this article we report progress toward establishing these conjectures for some special product channels, namely the cases when Ω is arbitrary and either (i) Φ is a CQ or QC channel (these are defined later), or (ii) Φ is a qubit channel. In the first case we establish both conjectures. In the second case we establish the Amosov, Holevo, and Werner conjecture for integer values of p. A principal ingredient in our proof in the second case is a new bound concerning the l_p norm of the output from a ''half-noisy'' channel $I\otimes\Phi$, for integer values of p. We conjecture that this bound holds for all $p\geqslant 1$, and we show that in some cases this conjecture implies additivity of the Holevo bound (2).

The article is organized as follows. Section II contains a precise statement of the results, and the conjectured bound for half-noisy channels. In Sec. III we review the relation of relative entropy and the Holevo bound. In Secs. IV and V we prove the results for CQ and QC channels. Then in Sec. VI we prove the results for qubit channels, and in Sec. VII we prove the corollaries of our new conjecture. In Sec. VIII we give a summary and overview of the results in the paper. Finally, the Appendix contains a proof by Lieb and Ruskai of a special case of the conjecture.

II. STATEMENT OF RESULTS

The noncommutative l_p norm of a matrix A is defined by

$$\|A\|_p=(\mathrm{Tr}|A|^p)^{1/p}=[\mathrm{Tr}(A^*A)^{p/2}]^{1/p}. \tag{3}$$

The corresponding maximal l_p norm for a positive map Φ on $B(\mathcal{H})$ is

$$\nu_p(\Phi)=\sup_{\rho}\|\Phi(\rho)\|_p, \tag{4}$$

where the sup runs over states in $\mathcal{H}$ (this quantity was introduced in Ref. 6, where it was called the ''maximal output purity'' of the channel). It is always true that for any maps Ω and Φ, and any $p\geqslant 1$,

$$\nu_p(\Omega\otimes\Phi)\geqslant\nu_p(\Omega)\,\nu_p(\Phi). \tag{5}$$

The multiplicativity conjecture of Ref. 6 states that for any completely positive trace-preserving maps Ω and Φ, and for all $p\geqslant 1$,

$$\nu_p(\Omega\otimes\Phi)=\nu_p(\Omega)\,\nu_p(\Phi). \tag{6}$$

Equality always holds in (6) for $p=1$. It has been shown in several different ways that (6) holds for all $p\geqslant 1$ and all Ω when $\Phi=I$.[6,9,10] Recently, it has been shown that (6) holds when both Ω and Φ are depolarizing channels, and p is integer.[11] In this article we provide some further examples where it holds.

The first case we consider involves the CQ and QC channels introduced by Holevo,[4] so we recall their definitions now. Let $\{X_b\}$ be a POVM on $\mathcal{H}$ (so $X_b\geqslant 0$ and $\Sigma X_b=I$) and let $\{Q_b\}$ be any collection of states. Then we can define a channel Φ by the formula

$$\Phi(\rho)=\sum\ \mathrm{Tr}(\rho\,X_b)\,Q_b\,. \tag{7}$$

Holevo considered two special cases of (7). First, if $\{X_b=|e_b\rangle\langle e_b|\}$ are projections onto an orthonormal basis $\{|e_b\rangle\}$ in $\mathcal{H}$, then (7) is called a CQ channel. Second, if $\{Q_b=|e_b\rangle\langle e_b|\}$, then (7) is called a QC channel. Holevo proved the additivity result (2) when $\Omega=\Phi$ is either a CQ or QC channel. Our first result generalizes this by allowing one of the channels, Ω, to be arbitrary.

Theorem 1: *Let Φ be a CQ or QC channel. Then for any completely positive trace-preserving map Ω, l_p-multiplicativity* (6) *holds for all $p\geqslant 1$, and Holevo additivity* (2) *holds.*

For our second set of results we restrict to channels on a two-dimensional Hilbert space. For brevity of notation we will say that Φ is a *qubit channel* if it is a completely positive trace-preserving map on $\mathcal{B}(\mathbf{C}^2)$.

Theorem 2: *Let Φ be a qubit channel. Then the equality* (6) *holds for $p=2$, that is, $\nu_2(\Omega\otimes\Phi)=\nu_2(\Omega)\nu_2(\Phi)$ for all channels Ω.*

In order to state the next result we need to recall the classification of qubit maps. Any qubit map Φ can be represented by a real 4×4 matrix with respect to the basis $I,\sigma_1,\sigma_2,\sigma_3$, where σ_i are the Pauli matrices. In Ref. 8 it was explained that by using independent unitary transformations in its domain and range, this matrix can be put into the following form:

$$\Phi=\begin{pmatrix} 1 & 0 & 0 & 0 \\ t_1 & \lambda_1 & 0 & 0 \\ t_2 & 0 & \lambda_2 & 0 \\ t_3 & 0 & 0 & \lambda_3 \end{pmatrix}. \tag{8}$$

This form makes it easy to see how Φ acts on the Bloch sphere. The sphere is first compressed to an ellipsoid with semi-major axes $|\lambda_1|,|\lambda_2|,|\lambda_3|$, and is then translated by the vector $\mathbf{t}=(t_1,t_2,t_3)$. There are constraints on the allowed values of these six parameters (coming from the requirements that Φ be completely positive and trace-preserving), and these constraints have been fully worked out in Ref. 12. If $t_i=0$ for $i=1,2,3$, then $\Phi(I)=I$, in which case Φ is a *unital* qubit map.

Our next result requires a slightly stronger condition on the map Φ, which we now state in terms of these parameters:

$$\text{if } |\lambda_i|<|\lambda_j|<|\lambda_k|, \text{ then } t_it_j=0. \tag{9}$$

This condition can be stated in words as follows: the ellipsoid may be translated only in directions lying in the two planes that are perpendicular to its two smaller axes (if any two axes have equal length, there is no restriction).

Theorem 3: *Let Φ be a qubit channel satisfying the condition* (9). *Then l_p-multiplicativity* (6) *holds for all integer p, that is, $\nu_p(\Omega\otimes\Phi)=\nu_p(\Omega)\,\nu_p(\Phi)$ for all channels Ω and all integers p.*

The proofs of Theorems 2 and 3 make use of a bound for the l_p norm of the output state from the half-noisy channel $I\otimes\Phi$. We believe that this bound holds for all $p\geqslant 1$, however we can prove it only for the cases listed in the theorems. So, we state the general bound as a conjecture.

Conjecture 4: Let Φ be a qubit channel, and let $M\geqslant 0$ be a $2K\times 2K$ matrix. Write M in the form

$$M=\begin{pmatrix} X & Y \\ Y^* & Z \end{pmatrix}, \tag{10}$$

where X, Y and Z are $K\times K$ matrices. Then for all $p\geqslant 1$

$$\|(I\otimes\Phi)(M)\|_p\leqslant\nu_p(\Phi)\,(\|X\|_p+\|Z\|_p). \tag{11}$$

This conjecture has several important consequences, which we list in the next three corollaries. In particular, the first corollary shows that Conjecture 4 implies Theorems 2 and 3.

Corollary 5: Let Φ *be a qubit channel, and suppose that* (11) *holds for all positive* $2K \times 2K$ *matrices* M, *for some* $p \geqslant 1$. *Then for any completely positive map* Ω *on* $B(\mathbf{C}^K)$, l_p*-multiplicativity* (6) *holds for the same value of* p.

In Sec. V we will prove that (11) holds for all qubit maps Φ when $p=2$, and also for the cases listed in Theorem 3. Combining this with Corollary 5 will prove Theorems 2 and 3.

Our next result concerns the additivity of minimal entropy. The minimal entropy of a completely positive trace-preserving map Φ is defined by

$$S_{\min}(\Phi) = \inf_{\rho} S(\Phi(\rho)). \tag{12}$$

The additivity of minimal entropy is the statement that

$$S_{\min}(\Omega \otimes \Phi) = S_{\min}(\Omega) + S_{\min}(\Phi). \tag{13}$$

Corollary 6: Let Φ *be a qubit channel, and suppose that* (11) *holds for all positive* $2K \times 2K$ *matrices* M, *and for all* $p \in [1,s)$ *for some* $s>1$. *Then for any completely positive map* Ω *on* $B(\mathbf{C}^K)$, *additivity of minimal entropy* (13) *holds.*

For our last corollary, recall that a map Φ is unital if $\Phi(I)=I$, which means roughly that Φ leaves unchanged the "noisiest" state through the channel.

Corollary 7: Let Φ *be a unital qubit channel, and suppose that* (11) *holds for all positive* $2K \times 2K$ *matrices* M, *and for all* $p \in [1,s)$ *for some* $s>1$. *Then for any completely positive trace-preserving map* Ω *on* $B(\mathbf{C}^K)$, *Holevo additivity* (2) *holds.*

Remarks:

(1) There are two special cases where it is easy to verify Conjecture 4. First, if M is a one-dimensional projection, then the right side of (11) becomes $\nu_p(\Phi)\,\mathrm{Tr}(M)$, and then the result follows immediately from the definition (4). Second, suppose that Φ is the identity map, so $\nu_p(\Phi)=1$. Define the projections

$$P_0 = \begin{pmatrix} I & 0 \\ 0 & 0 \end{pmatrix}, \quad P_1 = \begin{pmatrix} 0 & 0 \\ 0 & I \end{pmatrix}. \tag{14}$$

Then convexity of the l_p norm for $p \geqslant 1$ implies that

$$\|M\|_p = \|M^{1/2}(P_0+P_1)M^{1/2}\|_p \leqslant \|M^{1/2}P_0M^{1/2}\|_p + \|M^{1/2}P_1M^{1/2}\|_p. \tag{15}$$

Furthermore, for any matrix A, the matrices AA^* and A^*A have the same spectrum, so we deduce that

$$\|M\|_p \leqslant \|P_0MP_0\|_p + \|P_1MP_1\|_p = \|X\|_p + \|Z\|_p \tag{16}$$

(this derivation is a special case of a more general result for POVMs which is described in Ref. 13).

(2) Lieb and Ruskai have recently established Conjecture 4, Eq. (11), for a depolarizing channel in the special case $X=Z$, for all $p \geqslant 1$. Recall that the depolarizing channel is described by the parameter values $\lambda_1=\lambda_2=\lambda_3=\lambda$, and $t_1=t_2=t_3=0$, so that in this case the bound (11) becomes

$$\left\| \begin{pmatrix} X & \lambda Y \\ \lambda Y^* & X \end{pmatrix} \right\|_p \leqslant \nu_p(\Phi)\,(2\|X\|_p), \tag{17}$$

where

$$\nu_p(\Phi) = \left[\left(\frac{1+\lambda}{2} \right)^p + \left(\frac{1-\lambda}{2} \right)^p \right]^{1/p}. \tag{18}$$

Their proof appears as an Appendix to this article.

(3) Theorem 3 was proved in Ref. 8 for unital maps in the case $p=\infty$, and our proof here extends this result to all integer values of p (and to a larger class of maps). The class of qubit maps which satisfy (9) includes all unital qubit maps and many nonunital maps. In particular, our proof applies to any extreme point in the set of qubit maps (this refers to recent work in Ref. 12, and we discuss it more fully in Sec. III).

(4) To prove Corollaries 6 and 7 we need only the derivative of (11) at $p=1$, which we now state as a separate bound. Assume that M has the form (10) with $\mathrm{Tr}(M)=1$, and define the states

$$\xi=\frac{1}{\mathrm{Tr}X}X, \quad \zeta=\frac{1}{\mathrm{Tr}Z}Z. \tag{19}$$

Then taking the derivative of (11) at $p=1$ gives

$$S((I\otimes\Phi)(M))\geqslant S_{\min}(\Phi)+\mathrm{Tr}(X)S(\xi)+\mathrm{Tr}(Z)S(\zeta). \tag{20}$$

(5) When Ω and Φ are both unital qubit maps, the additivity result (2) follows immediately from the additivity of minimal entropy (13), as was discussed in Ref. 8. This is also true if $\Omega=\Phi_1\otimes\cdots\otimes\Phi_n$ is a product of unital qubit maps. Additivity of Holevo capacity (2) for the ''half-noisy'' case $\Phi=I$ was proved by Schumacher and Westmoreland,[10] and their analysis underlies our proof of Corollary 7.

III. RELATIVE ENTROPY AND THE HOLEVO BOUND

The Holevo bound (1) can be reexpressed in terms of relative entropy in several ways (see, for example, the discussion in Ref. 14). Here we will follow the approach of Ohya, Petz, and Watanabe[15] and Schumacher and Westmoreland,[10] who express (1) as an optimization of relative entropy.

Let Φ be a channel, and let $\mathcal{E}=\{\pi_i,\rho_i\}$ be an ensemble of input states for the channel. Define

$$\chi(\Phi;\mathcal{E})=S\left(\sum\ \pi_i\Phi(\rho_i)\right)-\sum\ \pi_i S(\Phi(\rho_i)). \tag{21}$$

Following the notation of Ref. 10, the Holevo capacity of the channel is denoted

$$\chi^*(\Phi)=C_{\mathrm{Holv}}(\Phi)=\sup_{\mathcal{E}}\chi(\Phi;\mathcal{E}). \tag{22}$$

As shown in Ref. 10 there is an ensemble which achieves this supremum. The ensemble may not be unique, however its average input state is unique. We let $\rho^*=\Sigma\pi_i\rho_i$ denote this optimal average input state.

The relative entropy of a state ω with respect to a state ρ is defined by

$$S(\omega|\rho)=\mathrm{Tr}\omega(\log\omega-\log\rho). \tag{23}$$

Relative entropy is non-negative: $S(\omega|\rho)\geqslant 0$, with equality if and only if $\omega=\rho$. There is a useful characterization of the capacity $\chi^*(\Phi)$ in terms of relative entropy, namely

$$\chi^*(\Phi)=\inf_{\rho}\sup_{\omega}S(\Phi(\omega)|\Phi(\rho)). \tag{24}$$

This result was derived in Ref. 15 and also in Ref. 10. For our purposes it is convenient to restate it as follows: for any state ρ,

$$\chi^*(\Phi)\leqslant\sup_{\omega}S(\Phi(\omega)|\Phi(\rho)) \tag{25}$$

and equality holds in (25) if and only if $\rho=\rho^*$.

Our goal is the additivity result (2). By restricting to product states it is clear that

$$\chi^*(\Omega)+\chi^*(\Phi)\leqslant\chi^*(\Omega\otimes\Phi). \tag{26}$$

So, to establish (2) it is sufficient to prove the bound

$$\chi^*(\Omega\otimes\Phi)\leqslant\chi^*(\Omega)+\chi^*(\Phi). \tag{27}$$

For a channel Φ, denote the optimal average *output* state by

$$\rho_\Phi := \Phi(\rho^*). \tag{28}$$

Then (25) implies that

$$\chi^*(\Omega\otimes\Phi)\leqslant\sup_\tau S((\Omega\otimes\Phi)(\tau)|\rho_\Omega\otimes\rho_\Phi). \tag{29}$$

Therefore, in order to prove (27), and hence (2), it is sufficient to show that for any state τ,

$$S((\Omega\otimes\Phi)(\tau)|\rho_\Omega\otimes\rho_\Phi)\leqslant\chi^*(\Omega)+\chi^*(\Phi). \tag{30}$$

IV. PROOF FOR CQ CHANNEL

Let Φ be a CQ channel on $B(\mathbf{C}^N)$, so that

$$\Phi(\rho)=\sum \mathrm{Tr}(\rho X_b)Q_b, \tag{31}$$

where $\{X_b\}$ are one-dimensional orthogonal projections. It follows that for all $b=1,\ldots,N$,

$$Q_b=\Phi(X_b). \tag{32}$$

Let Ω be a completely positive map on $B(\mathbf{C}^K)$. Then for any state τ in $B(\mathbf{C}^K\otimes\mathbf{C}^N)$,

$$(\Omega\otimes\Phi)(\tau)=\sum_b \Omega(\mathrm{Tr}_2[(I\otimes X_b)\tau])\otimes Q_b, \tag{33}$$

where Tr_2 is the trace over the second factor. For each $b=1,\ldots,N$ let

$$n_b=\mathrm{Tr}((I\otimes X_b)\tau), \tag{34}$$

and define the state

$$\tau_b=\frac{1}{n_b}\mathrm{Tr}_2((I\otimes X_b)\tau). \tag{35}$$

Then (33) can be written

$$(\Omega\otimes\Phi)(\tau)=\sum_b n_b\Omega(\tau_b)\otimes Q_b=\sum_b n_b\Omega(\tau_b)\otimes\Phi(X_b), \tag{36}$$

where in the second equality we used (32).

Turning first to the l_p norm result, it follows from (36) and the definition (4) that

$$\|(\Omega\otimes\Phi)(\tau)\|_p\leqslant\sum n_b\,\nu_p(\Omega)\,\nu_p(\Phi)=\nu_p(\Omega)\,\nu_p(\Phi), \tag{37}$$

and this proves (6).

Turning next to the channel capacity result, we will prove that (30) holds. Indeed (36) implies that

$$S((\Omega\otimes\Phi)(\tau)|\rho_\Omega\otimes\rho_\Phi)\leqslant\sum\ n_b\,[S(\Omega(\tau_b)|\rho_\Omega)+S(\Phi(X_b)|\rho_\Phi)], \tag{38}$$

where we used the additivity of relative entropy for product states. Now (24) implies

$$S(\Omega(\tau_b)|\rho_\Omega)\leqslant\chi^*(\Omega),\quad S(\Phi(X_b)|\rho_\Phi)\leqslant\chi^*(\Phi), \tag{39}$$

which proves the result.

V. PROOF FOR QC CHANNEL

Let Φ be a QC channel, so that

$$\Phi(\rho)=\sum\ \mathrm{Tr}(\rho X_b)Q_b\,, \tag{40}$$

where now $\{Q_b\}$ are one-dimensional orthogonal projections. For any state τ,

$$(\Omega\otimes\Phi)(\tau)=\sum\ \Omega(\mathrm{Tr}_2(I\otimes X_b)\tau)\otimes Q_b=\sum\ n_b\Omega(\tau_b)\otimes Q_b\,, \tag{41}$$

where we use the definitions (34) and (35). Now define

$$\theta=\mathrm{Tr}_1(\tau). \tag{42}$$

Then it follows that

$$n_b=\mathrm{Tr}(\theta X_b) \tag{43}$$

and (41) can be written as

$$(\Omega\otimes\Phi)(\tau)=\sum\ \Omega(\tau_b)\otimes(\mathrm{Tr}(\theta X_b)Q_b). \tag{44}$$

First we prove the bound for the l_p norm. Using the fact that $\{Q_b\}$ are orthogonal projections, we get

$$\mathrm{Tr}|(\Omega\otimes\Phi)(\tau)|^p=\sum\ \mathrm{Tr}|\Omega(\tau_b)|^p\ (\mathrm{Tr}(\theta X_b))^p. \tag{45}$$

The definition of the l_p norm implies that for any positive matrix A,

$$\|\Omega(A)\|_p\leqslant\nu_p(\Omega)\ \mathrm{Tr}(A), \tag{46}$$

and hence (45) implies that

$$\mathrm{Tr}|(\Omega\otimes\Phi)(\tau)|^p\leqslant(\nu_p(\Omega))^p\sum\ (\mathrm{Tr}(\theta X_b))^p. \tag{47}$$

Furthermore, from (40) it follows that

$$\mathrm{Tr}|\Phi(\theta)|^p=\sum\ [\mathrm{Tr}(\theta X_b)]^p. \tag{48}$$

Combining (47) and (48) and taking the pth root gives

$$\|\Omega\otimes\Phi(\tau)\|_p \leqslant \nu_p(\Omega)\,\|\Phi(\theta)\|_p \leqslant \nu_p(\Omega)\,\nu_p(\Phi), \tag{49}$$

which then proves the result.

Turning now to the additivity of the channel capacity, we will again establish the bound (30). We claim that the following identity holds:

$$S((\Omega\otimes\Phi)(\tau)|\rho_\Omega\otimes\rho_\Phi) = \sum \mathrm{Tr}(\theta X_b) S(\Omega(\tau_b)|\rho_\Omega) + S(\Phi(\theta)|\rho_\Phi). \tag{50}$$

From the result (25) it follows that

$$S(\Phi(\theta)|\rho_\Phi) \leqslant \chi^*(\Phi), \quad S(\Omega(\tau_b)|\rho_\Omega) \leqslant \chi^*(\Omega). \tag{51}$$

Therefore (50) implies

$$S((\Omega\otimes\Phi)(\tau)|\rho_\Omega\otimes\rho_\Phi) \leqslant \sum \mathrm{Tr}(\theta X_b)\chi^*(\Omega) + \chi^*(\Phi) = \chi^*(\Omega) + \chi^*(\Phi), \tag{52}$$

and this proves the result.

So it remains to verify the identity (50). This follows easily from the definition of relative entropy, and the fact that $\{Q_b\}$ are orthogonal projections.

VI. PROOFS FOR QUBIT CHANNELS

In this section we prove Theorems 2 and 3. We do this by establishing the bound (11), and then using Corollary 5, which will be proved in the next section.

Let Φ be a qubit map, and assume that bases have been chosen in its domain and range so that it has the form (8). Clearly, the maximal l_p norm of Φ is invariant under permutations of the three coordinates. It is also invariant under the following symmetry operations.

Lemma 8: For every p, $\nu_p(\Phi)$ is invariant if the signs of any two of $(\lambda_1,\lambda_2,\lambda_3)$ are reversed, or if the signs of any two of (t_1,t_2,t_3) are reversed.

The proof is easy: first notice that conjugation by σ_1 in the domain of Φ switches the signs of λ_2,λ_3 without any other changes, and similarly for conjugation by σ_2 and σ_3. Then notice that simultaneous conjugation by σ_1 in both the domain and range of Φ switches the signs of t_2,t_3 without any other changes, and similarly for σ_2 and σ_3.

As a consequence, we will assume henceforth without loss of generality that

$$t_1 \geqslant 0, t_2 \geqslant 0 \quad \text{and} \quad \lambda_1 \geqslant \lambda_2 \geqslant 0. \tag{53}$$

Our first goal is to establish Conjecture 4 for $p=2$, for any map Φ. We rewrite (10) more fully as

$$M = \begin{pmatrix} X & Y_1 - iY_2 \\ Y_1 + iY_2 & Z \end{pmatrix}, \tag{54}$$

where $X>0$, $Z>0$ and Y_1, Y_2 are Hermitian. Let $W=(X+Z)/2$. Then using the special form (8) we get

$$(I\otimes\Phi)(M) = \begin{pmatrix} c_{++}X + c_{-+}Z & (t_1W + \lambda_1 Y_1) - i(t_2W + \lambda_2 Y_2) \\ (t_1W + \lambda_1 Y_1) + i(t_2W + \lambda_2 Y_2) & c_{--}X + c_{+-}Z \end{pmatrix}, \tag{55}$$

where

$$c_{++} = (1+\lambda_3+t_3)/2, \quad c_{-+} = (1-\lambda_3+t_3)/2, \tag{56}$$

$$c_{+-}=(1+\lambda_3-t_3)/2, \quad c_{--}=(1-\lambda_3-t_3)/2.$$

Note that since $M\geqslant 0$ and Φ is a qubit map, it follows that $(I\otimes\Phi)(M)\geqslant 0$ for all choices of X and Z. Hence the four coefficients in (56) are positive, for all allowed values of t_3 and λ_3.

Taking the trace of the square of (55) gives

$$\begin{aligned}\mathrm{Tr}|(I\otimes\Phi)(M)|^2=&\mathrm{Tr}(c_{++}X+c_{-+}Z)^2+\mathrm{Tr}(c_{+-}X+c_{--}Z)^2+2\,\mathrm{Tr}(t_1W+\lambda_1Y_1)^2\\&+2\,\mathrm{Tr}(t_2W+\lambda_2Y_2)^2.\end{aligned} \tag{57}$$

Define

$$x=\|X\|_2,\ \ z=\|Z\|_2,\ \ y_1=\|Y_1\|_2,\ \ y_2=\|Y_2\|_2. \tag{58}$$

Then using the Cauchy–Schwarz inequality for the Hilbert–Schmidt norm and our positivity condition (53) we get

$$\begin{aligned}\mathrm{Tr}|(I\otimes\Phi)(M)|^2\leqslant&(c_{++}x+c_{-+}z)^2+(c_{+-}x+c_{--}z)^2+2\left(t_1\frac{(x+z)}{2}+\lambda_1y_1\right)^2\\&+2\left(t_2\frac{(x+z)}{2}+\lambda_2y_1\right)^2.\end{aligned} \tag{59}$$

Define the 2×2 matrix

$$m=\begin{pmatrix}x & y_1-iy_2\\ y_1+iy_2 & z\end{pmatrix}. \tag{60}$$

Then (59) can be rewritten as

$$\|I\otimes\Phi(M)\|_2\leqslant\|\Phi(m)\|_2. \tag{61}$$

The positivity of M implies that

$$y_1^2+y_2^2=\mathrm{Tr}|Y_1-iY_2|^2\leqslant\|X\|_2\|Z\|_2=xz, \tag{62}$$

and hence that m is positive. Therefore

$$\|(I\otimes\Phi)(M)\|_2\leqslant\nu_2(\Phi)\mathrm{Tr}(m)=\nu_2(\Phi)(x+z)=\nu_2(\Phi)(\|X\|_2+\|Z\|_2), \tag{63}$$

which establishes (11) for $p=2$, and hence by Corollary 5 proves Theorem 2.

In order to prove Theorem 3 we will assume that the condition (9) is satisfied. Without loss of generality, this condition can be rewritten as follows:

$$t_1\geqslant 0 \quad \text{and} \quad t_2=0 \quad \text{and} \quad \lambda_1\geqslant\lambda_2\geqslant 0. \tag{64}$$

To see this, suppose first that $|\lambda_i|\neq|\lambda_j|$ for any i,j. Then the condition (9) implies that at least one of the t_i is zero, and also that the corresponding $|\lambda_i|$ is not the largest. Hence by permuting coordinates we can arrange that $t_2=0$ and that $|\lambda_1|>|\lambda_2|$. By switching signs of pairs of parameters we can then restate (9) as (64). Suppose now that $|\lambda_i|=|\lambda_j|$ for some i,j. By permuting coordinates we can assume that $|\lambda_1|=|\lambda_2|$, and by changing signs that $\lambda_1=\lambda_2\geqslant 0$. This allows a further symmetry transformation, namely we can conjugate by a unitary matrix $U=e^{i\theta\sigma_3}$ in the range of Φ without changing $\nu_p(\Phi)$. With such a conjugation we can set $t_2=0$, and then the condition (64) again holds.

The condition (64) is clearly satisfied for all unital maps, since in that case $t_i=0$ for all i. It is also satisfied by all maps in the closure of the set of extreme points of the (convex) set of qubit maps. This fact follows from Theorem 4 in Ref. 12, where it was shown that all such maps have only one of the parameters t_1,t_2,t_3 being nonzero.

In order to prove (11), we rewrite (55) as

$$(I\otimes\Phi)(M)=\begin{pmatrix} R_{11} & R_{12} \\ R_{21} & R_{22}\end{pmatrix}=R_{11}\otimes E_{11}+R_{12}\otimes E_{12}+R_{21}\otimes E_{21}+R_{22}\otimes E_{22}, \tag{65}$$

where E_{ij} is the 2×2 matrix with 1 in position (i,j) and 0 elsewhere, and where

$$\begin{aligned} R_{11}&=c_{++}X+c_{-+}Z,\\ R_{12}&=(t_1W+\lambda_1Y_1)-i\lambda_2Y_2,\\ R_{21}&=(t_1W+\lambda_1Y_1)+i\lambda_2Y_2,\\ R_{22}&=c_{--}X+c_{+-}Z \end{aligned} \tag{66}$$

[we have used the condition (64) to set $t_2=0$].

For integer p we can evaluate $\mathrm{Tr}|(I\otimes\Phi)(M)|^p$ by multiplying the right side of (65) with itself p times, and taking the trace with respect to a product basis $e_i\otimes f_j$ where $\{e_i\}$ span $\mathbf{C}^K$ and f_1,f_2 span $\mathbf{C}^2$. The result is

$$\mathrm{Tr}|(I\otimes\Phi)(M)|^p=\sum \mathrm{Tr}[E_{i_1j_1}E_{i_2j_2}\cdots E_{i_pj_p}]\mathrm{Tr}[R_{i_1j_1}R_{i_2j_2}\cdots R_{i_pj_p}], \tag{67}$$

where the sum runs over all indices $i_1,j_1,\ldots,i_p,j_p=1,2$. The coefficient $\mathrm{Tr}[E_{i_1j_1}E_{i_2j_2}\cdots E_{i_pj_p}]$ in each of these terms is non-negative, since the matrices $\{E_{ij}\}$ are all non-negative. Furthermore, repeated application of Hölder's inequality shows that

$$|\mathrm{Tr}A_1A_2\cdots A_p|\leqslant\|A_1\|_p\|A_2\|_p\cdots\|A_p\|_p \tag{68}$$

for any product of p matrices. Hence the sum in (67) is bounded above by

$$\mathrm{Tr}|(I\otimes\Phi)(M)|^p\leqslant\sum \mathrm{Tr}[E_{i_1j_1}E_{i_2j_2}\cdots E_{i_pj_p}]\|R_{i_1j_1}\|_p\|R_{i_2j_2}\|_p\cdots\|R_{i_pj_p}\|_p. \tag{69}$$

We define the 2×2 matrix

$$m'=\begin{pmatrix} x' & y' \\ y' & z'\end{pmatrix}, \tag{70}$$

where now

$$x'=\|X\|_p,\quad z'=\|Z\|_p,\quad y'=\|Y_1-iY_2\|_p. \tag{71}$$

The matrix m' is positive. This can be seen most easily by noting that the positivity of M implies that $Y_1-iY_2=\sqrt{X}\,T\,\sqrt{Z}$ where T is a contraction,[12] and hence by Hölder's inequality $y'\leqslant\sqrt{x'z'}$. Applying the map Φ gives

$$\begin{aligned}\Phi(m')=&[c_{++}x'+c_{-+}z']\otimes E_{11}+[t_1(x'+z')/2+\lambda_1y']\otimes E_{12}\\ &+[t_1(x'+z')/2+\lambda_1y']\otimes E_{21}+[c_{--}x'+c_{+-}z']\otimes E_{22}.\end{aligned} \tag{72}$$

Applying the same method to evaluate $\mathrm{Tr}|\Phi(m')|^p$ gives

$$\mathrm{Tr}|\Phi(m')|^p=\sum \mathrm{Tr}[E_{i_1j_1}E_{i_2j_2}\cdots E_{i_pj_p}]r_{i_1j_1}r_{i_2j_2}\cdots r_{i_pj_p}, \tag{73}$$

where

$$\begin{aligned} r_{11}&=c_{++}x'+c_{-+}z',\\ r_{12}=r_{21}&=t_1(x'+z')/2+\lambda_1 y',\\ r_{22}&=c_{--}x'+c_{+-}z'. \end{aligned} \tag{74}$$

We now claim that

$$\mathrm{Tr}|(I\otimes\Phi)(M)|^p\leqslant\mathrm{Tr}|\Phi(m')|^p. \tag{75}$$

If we assume for the moment that (75) is valid, then it implies

$$\|(I\otimes\Phi)(M)\|_p\leqslant\|\Phi(m')\|_p\leqslant\nu_p(\Phi)\mathrm{Tr}(m')\leqslant\nu_p(\Phi)(x'+z'). \tag{76}$$

This proves (11), which by Corollary 5 implies Theorem 3.

So, it is sufficient to demonstrate (75). From (69) and (73) it is sufficient to show that

$$\|R_{ij}\|_p\leqslant r_{ij} \tag{77}$$

for all $i,j=1,2$. First, using the positivity of c_{++}, etc., we have

$$\begin{aligned} \|R_{11}\|_p&=\|c_{++}X+c_{-+}Z\|_p\leqslant c_{++}x'+c_{-+}z'=r_{11},\\ \|R_{22}\|_p&=\|c_{+-}X+c_{--}Z\|_p\leqslant c_{+-}x'+c_{--}z'=r_{22}. \end{aligned}$$

The remaining bound also follows easily, since

$$\begin{aligned} \|R_{12}\|_p=\|t_1\frac{(X+Z)}{2}+\lambda_1Y_1-i\lambda_2Y_2\|_p&\leqslant\|t_1\frac{(X+Z)}{2}\|_p+\|(\lambda_1-\lambda_2)Y_1+\lambda_2(Y_1-iY_2)\|_p\\ &\leqslant t_1(x'+z')/2+(\lambda_1-\lambda_2)\|Y_1\|_p+\lambda_2\|Y_1-iY_2\|_p, \end{aligned} \tag{78}$$

where in the last line we used (53). Furthermore,

$$\|Y_1\|_p=\|(Y_1-iY_2)/2+(Y_1+iY_2)/2\leqslant\tfrac{1}{2}\|Y_1-iY_2\|_p+\tfrac{1}{2}\|Y_1+iY_2\|_p=y'.$$

Hence (78) becomes

$$\|R_{12}\|_p\leqslant t_1(x'+z')/2+(\lambda_1-\lambda_2)y'+\lambda_2y'=t_1(x'+z')/2+\lambda_1y'=r_{12}, \tag{79}$$

which establishes the result.

VII. PROOFS OF COROLLARIES

A. Corollary 5

Let Ω be any completely positive map on $\mathcal{B}(\mathbf{C}^K)$, and let τ be a state on $\mathcal{B}(\mathbf{C}^K\otimes\mathbf{C}^2)$ of the form

$$\tau=\begin{pmatrix} A & B\\ B^* & C\end{pmatrix}, \tag{80}$$

where A,B,C are $K\times K$ matrices, with $A\geqslant 0$, $C\geqslant 0$ and $\mathrm{Tr}(A+C)=1$. Then $M=(\Omega\otimes I)(\rho)$ has the form (10) with $X=\Omega(A)$, $Y=\Omega(B)$ and $Z=\Omega(C)$. Hence from the definition of the maximal l_p norm it follows that

$$\|X\|_p\leqslant \nu_p(\Omega)\mathrm{Tr}(A),\ \ \|Z\|_p\leqslant \nu_p(\Omega)\mathrm{Tr}(C). \tag{81}$$

Applying (11) and using the facts that $(I\otimes\Phi)(M)=(\Omega\otimes\Phi)(\rho)$ and $\mathrm{Tr}(A)+\mathrm{Tr}(C)=\mathrm{Tr}(\rho)=1$ we immediately deduce Corollary 5.

B. Corollary 6

Recall that the entropy of a state ρ is defined by

$$S(\rho)=-\mathrm{Tr}\rho\log\rho. \tag{82}$$

Using $\mathrm{Tr}\rho=1$ it follows that

$$\frac{d}{dp}(\|\rho\|_p)_{p=1}=-S(\rho), \tag{83}$$

and hence that

$$\frac{d}{dp}(\nu_p(\Phi))_{p=1}=-S_{\min}(\Phi). \tag{84}$$

Therefore taking the derivative of (6) at $p=1$ yields immediately (13).

C. Corollary 7

From the results of Sec. II, it is sufficient to establish the bound (30). For any states ω and ρ we have

$$\log(\omega\otimes\rho)=\log\omega\otimes I+I\otimes\log\rho. \tag{85}$$

Furthermore, since Φ is a unital qubit map it follows that its optimal average output state is

$$\rho_\Phi=\tfrac{1}{2}I. \tag{86}$$

Since $\log(1/2\,I)=-\log(2)I$ and $\mathrm{Tr}(\Omega\otimes\Phi)(\rho)=1$ it follows that the left side of (30) can be written as

$$-S((\Omega\otimes\Phi)(\tau))-\mathrm{Tr}((\Omega\otimes\Phi)(\tau)\log(\rho_\Omega)\otimes I)+\log(2). \tag{87}$$

Define

$$\omega=\mathrm{Tr}_2\tau. \tag{88}$$

Then the second term in (87) is equal to

$$-\mathrm{Tr}\Omega(\omega)\log(\rho_\Omega). \tag{89}$$

Also, the fact that Φ is unital implies that

$$\chi^*(\Phi)=\log(2)-S_{\min}(\Phi). \tag{90}$$

Hence to prove (30) it is sufficient to prove that

$$-S((\Omega\otimes\Phi)(\tau))-\mathrm{Tr}\Omega(\omega)\log(\rho_\Omega)\leqslant\chi^*(\Omega)-S_{\min}(\Phi). \tag{91}$$

Now we use the bound (20), which is implied by (11). Again let τ have the form (80), so that $M=(\Omega\otimes I)(\tau)$ has the form (10) with $X=\Omega(A)$ and $Z=\Omega(C)$. Let $a=\mathrm{Tr}A=\mathrm{Tr}X$, and define the states

$$\alpha=\frac{1}{\mathrm{Tr}A}A=\frac{1}{a}A, \quad \gamma=\frac{1}{\mathrm{Tr}C}C=\frac{1}{1-a}C. \tag{92}$$

Then using the notation of (19), $\xi=\Omega(\alpha)$ and $\zeta=\Omega(\gamma)$, and (20) can be written

$$S((\Omega\otimes\Phi)(\tau))\geqslant S_{\min}(\Phi)+aS(\Omega(\alpha))+(1-a)S(\Omega(\gamma)). \tag{93}$$

Comparing with (91), it is sufficient to prove that

$$-aS(\Omega(\alpha))-(1-a)S(\Omega(\gamma))-\mathrm{Tr}\,\Omega(\omega)\log(\rho_\Omega)\leqslant\chi^*(\Omega). \tag{94}$$

Since $\omega=a\alpha+(1-a)\gamma$, we can rewrite the left side of (94) as

$$aS(\Omega(\alpha)|\rho_\Omega)+(1-a)S(\Omega(\gamma)|\rho_\Omega). \tag{95}$$

Since ρ_Ω is the optimal output state for the channel Ω, it follows from (24) that

$$S(\Omega(\alpha)|\rho_\Omega)\leqslant\chi^*(\Omega), \tag{96}$$

$$S(\Omega(\gamma)|\rho_\Omega)\leqslant\chi^*(\Omega). \tag{97}$$

Combining (94)–(96) yields the result.

VIII. SUMMARY

The results in this article all concern product channels of the form $\Omega\otimes\Phi$, where in every case Ω is an arbitrary channel. For these product channels we prove a variety of results involving different measures of the purity of output states from the channel.

The first set of results apply when Φ is a CQ or QC channel. Recall that the CQ channel first maps an input state to a letter in a classical alphabet, and then maps this to a quantum state at the output. The QC channel measures the input state with some POVM, and assigns different results to orthogonal output states. In both cases we prove that the output state with maximal l_p norm is a product state, and also that the Holevo capacity is achieved on a product state. In other words, the maximal l_p norm of the product channel is multiplicative and the Holevo capacity is additive. These results were previously shown to be true in the case where Φ is the identity map (and the additivity of the Holevo capacity also when $\Omega=\Phi$).

The second set of results applies when Φ is a qubit map, that is, a map on states in $\mathbf{C}^2$. We prove multiplicativity for the $p=2$ norm, for any qubit map Φ. We also prove multiplicativity for the l_p norm when p is any integer, and with some restrictions on Φ. The class of maps Φ satisfying the restrictions includes all unital qubit maps.

The third set of results revolves around a conjectured bound (11) for the l_p norm of any output state from the half-noisy channel $I\otimes\Phi$, when Φ is a qubit channel. We show that this bound implies multiplicativity of the l_p norm for any product channel $\Omega\otimes\Phi$. We also show that when Φ is *unital* the bound implies additivity of the Holevo capacity of the product channel $\Omega\otimes\Phi$. Therefore we believe that this conjecture provides a new and useful approach to the conjecture that the Holevo capacity is universally additive. In a hopeful sign of future progress on this important problem, Lieb and Ruskai have established Conjecture 4 in one nontrivial case (their proof appears as the Appendix that follows).

ACKNOWLEDGMENTS

The author thanks M. B. Ruskai for useful discussions and comments. The author is also grateful to E. H. Lieb and M. B. Ruskai for allowing their proof of a special case of Conjecture 4, Eq. (11), which appears as an Appendix to this article. This research was supported in part by National Science Foundation Grant No. DMS-97-05779.

APPENDIX: THEOREM OF LIEB AND RUSKAI

Let $M=\left(\begin{smallmatrix} X & Y \\ Y^* & Z \end{smallmatrix}\right)$ and recall that M is positive semi-definite if and only $Y=\sqrt{X}R\sqrt{Z}$ with R a contraction. Moreover, any contraction can be written as a convex combination of unitary matrices. (See Ref. 16 or 12 for details and further references.) Hence, by the convexity of the p-norm, it suffices to prove (17) under the assumption that $Y=\sqrt{X}V\sqrt{Z}$ with V unitary.

We now consider the special case $X=Z$ and note that we can write

$$(I\otimes\Phi)(M)=\begin{pmatrix} X & \lambda Y \\ \lambda Y^* & X \end{pmatrix}=\sqrt{F}G\sqrt{F} \tag{A1}$$

with $F=\left(\begin{smallmatrix} X & 0 \\ 0 & X \end{smallmatrix}\right)$ and $G=\left(\begin{smallmatrix} I & \lambda V \\ \lambda V^* & I \end{smallmatrix}\right)$. We will use a result of Lieb and Thirring (Appendix B of Ref. 17) that, for $p\geqslant 1$ and $F,G\geqslant 0$,

$$\mathrm{Tr}(F^{1/2}GF^{1/2})^p\leqslant\mathrm{Tr}(F^pG^p). \tag{A2}$$

The critical feature is to note that G has eigenvalues $(1\pm\lambda)$. Moreover,

$$\begin{pmatrix} I & \lambda V \\ \lambda V^* & I \end{pmatrix}=\frac{1}{2}\begin{pmatrix} I & V \\ V^* & -I \end{pmatrix}\begin{pmatrix} (1+\lambda)I & 0 \\ 0 & (1-\lambda)I \end{pmatrix}\begin{pmatrix} I & V \\ V^* & -I \end{pmatrix}. \tag{A3}$$

Thus

$$\begin{aligned}\mathrm{Tr}[(I\otimes\Phi)(M)]^p&\leqslant\frac{1}{2}\mathrm{Tr}\begin{pmatrix} I & V \\ V^* & -I \end{pmatrix}\begin{pmatrix} X^p & 0 \\ 0 & X^p \end{pmatrix}\begin{pmatrix} I & V \\ V^* & -I \end{pmatrix}\begin{pmatrix} (1+\lambda)^pI & 0 \\ 0 & (1-\lambda)^pI \end{pmatrix}\\ &=(1+\lambda)^p\mathrm{Tr}\frac{1}{2}(X^p+VX^pV^*)+(1-\lambda)^p\,\mathrm{Tr}\frac{1}{2}(X^p+V^*X^pV)\\ &=[2\nu_p(\Phi)]^p\|X\|_p^p.\end{aligned}$$

Taking the pth root gives the desired result, $\|(I\otimes\Phi)(M)\|_p\leqslant\nu_p(\Phi)2\|X\|_p$.

(Received 8 August 2001; accepted for publication 14 December 2001)

In this paper, we prove that for fields close to the lower critical field, minimizers of the Ginzburg–Landau functional of an inhomogeneous superconductor have a number of vortices bounded independently from the Ginzburg–Landau parameter. We also locate the vortices. © *2002 American Institute of Physics.*
[DOI: 10.1063/1.1448681]

I. INTRODUCTION AND STATEMENT OF THE RESULTS

We are interested in describing the global minimizers of the Ginzburg–Landau functional

$$J(u,A)=\frac{1}{2}\int_{\Omega}|\nabla_A u|^2+|h-h_{\mathrm{ex}}|^2+\frac{\kappa^2}{2}(a(x)-|u|^2)^2 \tag{1.1}$$

that corresponds to the free energy of a superconductor[1,2] in a prescribed, constant magnetic field h_{ex}. Here $\Omega\subset\mathbb{R}^2$ is the smooth, bounded, simply connected section of the superconductor and $a(x):\Omega\to\mathbb{R}$ is a given function satisfying $0<\min_{\bar{\Omega}}a(x)\leqslant a(x)\leqslant 1$ in Ω. The unknowns in (1.1) are the complex-valued order parameter $u\in H^1(\Omega,\mathbb{C})$ and the $U(1)$ connection $A\in H^1(\Omega,\mathbb{R}^2)$. Here $h=\mathrm{curl}A=-\partial_2A_1+\partial_1A_2$ is the induced magnetic field and $\nabla_A u=\nabla u-iAu$. The order parameter u indicates the local state of the material: $|u|$ is the density of superconducting electron pairs, so that, when $|u|\simeq 1$, the material is in its superconducting state, whereas when $|u|\simeq 0$, it is in its normal state. $\kappa>0$ is the Ginzburg–Landau parameter depending on the material. The minima of $a(x)$ corresponds to the impurities in the material. It is expected that these minima will be the pinning sites for the vortices.

Minimizers of $J(u,A)$ in $H^1(\Omega,\mathbb{C})\times H^1(\Omega,\mathbb{R}^2)$ solve the Euler equations

$$\begin{cases}-\nabla_A^2 u=\kappa^2 u(a(x)-|u|^2) & \text{in } \Omega,\\ -\nabla^{\perp}h=(iu,\nabla_A u) & \text{in } \Omega,\end{cases} \tag{1.2}$$

with the boundary conditions

$$\begin{cases}h=h_{\mathrm{ex}} & \text{on } \partial\Omega,\\ (\nabla u-iAu)\cdot\nu=0 & \text{on } \partial\Omega.\end{cases} \tag{1.3}$$

Here $\nabla^{\perp}$ denotes $(-\partial_{x_2},\partial_{x_1})$, ν is the unit outer normal vector to $\partial\Omega$, and $(z,w)=\mathrm{Re}(z\bar{w})$ where z and w are in $\mathbb{C}$.

The functional $J(u,A)$ are invariant under $U(1)$ gauge transformations of the type

$$v=ue^{i\varphi},\quad B=A+\nabla\varphi \quad \text{for any } \varphi\in H^2(\Omega,\mathbb{R}). \tag{1.4}$$

It is well known that there are two critical fields H_{c_1} and H_{c_2} for which a phase transition occurs. Above H_{c_2}, superconductivity is destroyed and material is in the normal phase. Below

a)Electronic mail: zuhanl@yahoo.com

H_{c_1}, the material is superconducting everywhere. When $H_{c_1} \leqslant h_{\text{ex}} \leqslant H_{c_2}$, the material is in mixed state. In this state, the minimizers of (1.1) exhibit vortices, i.e., points where the order parameter vanishes. It is of interest to determine where these points are located. We refer to Refs. 3–13 for a discussion of this functional in the case $a(x)=1$.

In this paper, we want to address the question of how the term will modify the properties of the superconductor in the presence of an exterior magnetic field here. In particular, our interest is the pinning phenomena of vortices. First, we recall some results. In Ref. 14, we obtained the asymptotic expansion

$$H_{c_1} \sim \frac{|\log \kappa|}{\max_{\Omega} \left| \frac{\xi_0}{a} \right|} \quad \text{as} \quad \kappa \to \infty, \tag{1.5}$$

where h_0 is the solution of

$$\begin{cases} -\operatorname{div}\left(\frac{1}{a}\nabla h_0\right) + h_0 = 0 & \text{in } \Omega, \\ h_0 = 1 & \text{on } \partial\Omega, \end{cases} \tag{1.6}$$

and

$$\xi_0 = h_0 - 1 < 0. \tag{1.7}$$

In Ref. 15, we prove the following theorem.

Theorem A: *There exist constants $\kappa_0, C>0$ such that for any $\kappa > \kappa_0$ and $h_{\text{ex}} < H_{c_1} - C \log\log \kappa$, the minimizer (u,A) of (1.1) satisfies $|u| \geqslant \frac{1}{2}\min_{\Omega} a > 0$ in $\overline{\Omega}$, that is, the minimizer (u,A) has no vortex.*

In this paper, we are interested in the case $h_{\text{ex}} \leqslant H_{c_1} + C \log\log \kappa$. We prove that the minimizers have bounded vorticity and locate them. Before stating our main results, we recall the construction of vortex balls.

Proposition 1.1: Assume that $\Omega \subset \mathbb{R}^2$ is a smooth simply connected, bounded domain, $a(x):\Omega \to \mathbb{R}_+$ is a C^2--smooth function satisfying $0 < \min_{\Omega} a \leqslant a(x) \leqslant 1$. Then, for any $\kappa > \kappa_0, h_{\text{ex}} < K \log \kappa$, and critical point (u,A) of $J(u,A)$ satisfying the a priori bound $J(u,A) < K(\log \kappa)^2$ the following is true.

There exists a finite family of disjoint balls $\{B_i\}$, where $B_i = B_{r_i}(p_i)$ and

(1) $\{|u| < \sqrt{a} - 1/(\log \kappa)^2\} \subset \cup_i B_i$,
(2) $\Sigma_i r_i < (\log \kappa)^{-10}$.
(3) *Writing $u = \rho e^{i\varphi}$,*

$$\frac{1}{2}\int_{B_i} \rho^2 |\nabla \varphi - A|^2 + |h - h_{\text{ex}}|^2 \geqslant \pi a(p_i)|d_i|(\log \kappa - C \log\log \kappa), \tag{1.8}$$

where d_i is the degree of the map $u/|u|$ restricted to ∂B_i if $B_i \subset \Omega$ and $d_i = 0$ otherwise.

We say that $\{(p_i, d_i)\}$ is a family of vortices associated to (u,A), and we call $\{B_i\}$ the family of vortex balls. It is easily seen by testing J with the configuration $(u \equiv \sqrt{a}, A \equiv 0)$ that a minimizer (u,A) of (1.1) satisfies the *a priori* bound $J(u,A) < \frac{1}{2}(\int_{\Omega} |\nabla \sqrt{a}|^2) h_{\text{ex}}^2$, and therefore can be associated with a family of vortices by the above proposition whenever $h_{\text{ex}} < K \log \kappa$. We may now state our main theorem.

Theorem 1.2: *Let Ω be a smooth, bounded, simply connected domain in $\mathbb{R}^2$. Assume that $a(x):\Omega \to \mathbb{R}$ is an analytic function satisfying $0 < a_0 = \min_{\Omega} a(x) \leqslant a(x) \leqslant 1$ in Ω. For any $K>0$,*

there exist positive constants κ_0, C, α *such that for any* $\kappa>\kappa_0$ *and any* $h_{\text{ex}}<H_{c_1}+K\log\log\kappa$, *if* (u,A) *is a global minimizer of (1.1) and* $\{(p_i,d_i)\}$ *is an associated family of vortices then the following holds:*

(1) $\forall i,\ d_i\geqslant 0$,
(2) $\Sigma_i d_i\leqslant C$,
(3) $\text{dist}(p_i,\Lambda)\leqslant C(\log\kappa)^{-\alpha}$ *for any* i *such that* $d_i\neq 0$, *where*

$$\Lambda=\left\{x\in\Omega:\frac{\xi_0(x)}{a(x)}=\max_\Omega\left|\frac{\xi_0}{a}\right|\right\} \tag{1.9}$$

and $\xi_0=h_0-1$.

Remark: It follows from conclusion (3) of Theorem 1.2 that the distribution of the vortices location is governed both by the term $a(x)$ and by the function ξ_0. This is called the pinning phenomena in superconductor. This conclusion extends the results in Ref. 10.

This paper is organized as follows. In Sec. II, we shall prove Proposition 1.1. In Sec. III, we shall split the energy J. In Sec. IV, we shall prove Theorem 1.2.

II. CONSTRUCTION OF VORTEX BALLS

In this section we will give a proof of Proposition 1.1. We will divide the proof into three steps.

Step 1: Denoting $|u|$ by ρ, since $\int_\Omega|\nabla u|^2\geqslant\int_\Omega|\nabla\rho|^2$, we have from $J(u,A)<K(\log\kappa)^2$,

$$\int_\Omega|\nabla\rho|^2+\frac{\kappa^2}{2}(a-\rho^2)^2\leqslant 2K(\log\kappa)^2.$$

Hence,

$$\int_\Omega|\nabla(\rho-\sqrt{a})|^2+\frac{\kappa^2}{2}(a-\rho^2)^2\leqslant C(\log\kappa)^2.$$

Step 2: For any $t\in\mathbb{R}$, let $\Omega_t=\{x\in\Omega:|\rho-\sqrt{a}|>t\}$ and $\gamma_t=\partial\Omega_t$. Applying the Coarea formula and arguing as in Lemma 4.2 of Ref. 7,

$$C|\log\kappa|^2\geqslant\int_\Omega|\nabla(\rho-\sqrt{a})|^2+\frac{\kappa^2}{2}(a-\rho^2)^2\geqslant C\kappa\int_\Omega|\nabla(\rho-\sqrt{a})||a-\rho^2|\geqslant C\kappa\int_0^{+\infty}r(\gamma_t)\mathrm{d}t. \tag{2.1}$$

Here, as in Ref. 7, $r(\gamma_t)$ is defined as the infimum over all finite covering of γ_t by balls $B_i,\ldots,B_k$ of the sum $r_1+\cdots+r_k$, where r_i is the radius of B_i. Combining the previous inequality with the mean-value theorem, we find that there exists a $t\in[0,1/(\log\kappa)^2]$ such that $r(\gamma_t)<C(\log\kappa)^4/\kappa$.

Step 3: The next step to construct the vortex balls: starting from the chosen γ_t, covered by balls $B_1,\ldots,B_k$, we use the method of growing and merging of balls used in Refs. 16 and 7: one needs to grow these balls B_i, keeping a suitable lower bound on the energy they contain, until the desired size is reached, with the desired lower bound. When some balls happen to intersect during the growth process, they are merged into a large one.[7] Here we only need to apply the result of Proposition 4.1 of Ref. 7 to A and $v=u/|u|=e^{i\varphi}$ in $\Omega\backslash\Omega_t$, $\sigma=(\log\kappa)^{-10}$. We then obtain the existence of balls $B_i=B(p_i,r_i)$ such that conclusions (1), (2) of Proposition 1.1 hold,[17,18] and

$$\frac{1}{2}\int_{B_i\backslash\Omega_t}|\nabla\varphi-A|^2+\frac{1}{2}\int_{B_i}|h-h_{\text{ex}}|^2\geqslant\pi|d_i|\left(\log\frac{\sigma}{r(\gamma_t)}-C\right)\geqslant\pi|d_i|(\log\kappa-C\log\log\kappa), \tag{2.2}$$

with $d_i=(u,\partial B_i)$ if $\overline{B_i}\subset\Omega$, and 0 otherwise. But we also have, from the Ginzburg–Landau equation $-\nabla^\perp h=\rho^2(\nabla\varphi-A)$, and from $\rho\leqslant 1$ (Ref. 1),

$$\int_\Omega |\nabla h|^2=\int_\Omega \rho^4|\nabla\varphi-A|^2\leqslant\int_\Omega |\nabla_A u|^2\leqslant C(\log\kappa)^2, \tag{2.3}$$

hence

$$\int_{B_i}|h-h_{\rm ex}|^2\leqslant Cr_i\|h-h_{\rm ex}\|^2_{L^4(\Omega)}\leqslant Cr_i\|h-h_{ex}\|^2_{H^1(\Omega)}=o(1). \tag{2.4}$$

Thus, by (2.2), we have

$$\frac{1}{2}\int_{B_i\setminus\Omega_t}|\nabla\varphi-A|^2\geqslant\pi|d_i|(\log\kappa-C\log\log\kappa). \tag{2.5}$$

Now, by using conclusion (1) of this proposition,

$$\begin{aligned}\frac{1}{2}\int_{B_i\setminus\Omega_t}\rho^2|\nabla\varphi-A|^2&=\frac{1}{2}\int_{B_i\setminus\Omega_t}a|\nabla\varphi-A|^2+\frac{1}{2}\int_{B_i\setminus\Omega_t}(\rho^2-a)|\nabla\varphi-A|^2\\&\geqslant\frac{1}{2}(\min_{B_i}a)\int_{B_i\setminus\Omega_t}|\nabla\varphi-A|^2-\frac{C}{(\log\kappa)^2}\int_{B_i\setminus\Omega_t}|\nabla\varphi-A|^2.\end{aligned} \tag{2.6}$$

In view of (2.5), we have

$$\frac{1}{2}\int_{B_i\setminus\Omega_t}|\nabla\varphi-A|^2\geqslant\pi(\min_{B_i}a)|d_i|(\log\kappa-C\log\log\kappa). \tag{2.7}$$

Now, using mean-valued theorem and conclusion (2) of this proposition, we have the following lower bound:

$$\frac{1}{2}\int_{B_i\setminus\Omega_t}|\nabla\varphi-A|^2\geqslant\pi(a(p_i)|d_i|(\log\kappa-C\log\log\kappa). \tag{2.8}$$

This proves the conclusion (3) of Proposition 1.1. The proof of Proposition 1.1 is completed. □

III. SPLITTING OF THE ENERGY $J(u,A)$

The proof of Theorem 1.2 relies on an expansion of the energy of a minimizer in terms of the positions and degrees of its vortices. To get this expansion of the energy, we need the following lemma.

Lemma 3.1: (Ref. 1) *We have for any* $q<2$,

$$\left\|-\operatorname{div}\left(\frac{1}{a}\nabla h\right)+h-2\pi\sum_i d_i\delta_{p_i}\right\|_{W^{-1,q}(\Omega)}=o(1). \tag{3.1}$$

Proposition 3.2: For any $K>0$, *there exist positive* κ_0, C *such that for any* $\kappa>\kappa_0$ *and any* $h_{ex}<K\log\kappa$, *if* (u,A) *is a critical point of* $J(u,A)$ *satisfying* $J(u,A)<K(\log\kappa)^2$ and $\{(p_i,d_i)\}$ *is an associated family of vortices then*

$$J(u,A)\geqslant \frac{1}{2}\int_\Omega |\nabla\sqrt{a}|^2+h_{\rm ex}^2J_0+\pi\Big(\sum_i a(p_i)|d_i|\Big)(\log\kappa-C\log\log\kappa)+2\pi h_{\rm ex}\sum_i d_i\xi_0(p_i)$$
$$+\frac{1}{2}\int_{\Omega\setminus\cup_i B_i}\frac{1}{\rho^2}|\nabla(h-h_{\rm ex}h_0)|^2+\frac{1}{2}\int_\Omega |h-h_{\rm ex}h_0|^2-o(1), \tag{3.2}$$

where we have written $h=\mathrm{curl}A$ *and*

$$J_0=\frac{1}{2}\int_\Omega\frac{1}{a}|\nabla h_0|^2+|h_0-1|^2. \tag{3.3}$$

Proof: Since the quantities involved are gauge invariant we may assume we are working in a Coulomb gauge, i.e., that $\mathrm{div}\,A=0$ in Ω and $A\cdot\nu=0$ on $\partial\Omega$. In the Coulomb gauge, the following *a priori* bounds holds (see Refs. 1 and 14),

$$\|A\|_{H^1(\Omega)}\leqslant C\log\kappa,\quad \|A\|_{L^\infty(\Omega)}\leqslant C\log\kappa,\quad \|u\|_{H^1(\Omega)}\leqslant C\log\kappa. \tag{3.4}$$

Let $\tilde\Omega=\Omega\setminus\cup_i B_i$, where $\{B_i\}_{i\in I}$ is the family of vortex balls defined in Proposition 1.1. Writing $u=\rho e^{i\varphi}$, it follows from $-\nabla^\perp h=(iu,\nabla_A u)=\rho^2(\nabla\varphi-A)$ that

$$|\nabla_A u|^2=|\nabla\rho|^2+\rho^2|\nabla\varphi-A|^2=\frac{1}{\rho^2}|\nabla h|^2+|\nabla\rho|^2. \tag{3.5}$$

Thus,

$$J(u,A)\geqslant\frac{1}{2}\int_{\cup_i B_i}\rho^2|\nabla\varphi-A|^2+|h-h_{\rm ex}|^2+\frac{1}{2}\int_\Omega|\nabla\rho|^2+\frac{\kappa^2}{2}(a-\rho^2)^2$$
$$+\frac{1}{2}\int_{\tilde\Omega}\frac{1}{\rho^2}|\nabla h|^2+|h-h_{\rm ex}|^2. \tag{3.6}$$

Note that

$$\frac{1}{2}\int_\Omega|\nabla\rho|^2+\frac{\kappa^2}{2}(a-\rho^2)^2\geqslant\min_{v\in H^1(\Omega,\mathbb{R})}\frac{1}{2}\int_\Omega|\nabla v|^2+\frac{\kappa^2}{2}(a-v^2)^2. \tag{3.7}$$

Now let

$$\frac{1}{2}\int_\Omega|\nabla v_\kappa|^2+\frac{\kappa^2}{2}(a-v_\kappa^2)^2=\min_{v\in H^1(\Omega,\mathbb{R})}\frac{1}{2}\int_\Omega|\nabla v|^2+\frac{\kappa^2}{2}(a-v^2)^2, \tag{3.8}$$

we claim

$$\frac{1}{2}\int_\Omega|\nabla v_\kappa|^2=\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2+o(1)\quad\text{as}\quad\kappa\to\infty. \tag{3.9}$$

In fact, for any given sequence $\kappa_n\to\infty$, we have

$$\frac{1}{2}\int_\Omega|\nabla v_{\kappa_n}|^2+\frac{\kappa_n^2}{2}(a-v_{\kappa_n}^2)^2\leqslant\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2. \tag{3.10}$$

Hence, there exist a subsequence of $\{v_{\kappa_n}\}$ (still denote $\{v_{\kappa_n}\}$) and $v_0\in H^1(\Omega,\mathbb{R})$ such that $v_{\kappa_n}\rightharpoonup v_0$ weakly in $H^1(\Omega,\mathbb{R})$. From (3.10) we have

$$\int_\Omega (a-v_{\kappa_n}^2)^2 \leqslant \frac{C}{\kappa_n^2} \to 0,$$

which imply that $v_0 = \sqrt{a}$ a.e. in Ω. So, we have

$$\int_\Omega |\nabla \sqrt{a}|^2 = \int_\Omega |\nabla v_0|^2. \tag{3.11}$$

Hence, using (3.10) and (3.11),

$$\begin{aligned}\int_\Omega |\nabla (v_{\kappa_n} - v_0)|^2 &= \int_\Omega |\nabla v_{\kappa_n}|^2 + \int_\Omega |\nabla v_0|^2 - 2\int_\Omega \nabla v_{\kappa_n} \nabla v_0 \\ &\leqslant 2\int_\Omega |\nabla v_0|^2 - 2\int_\Omega \nabla v_{\kappa_n} \nabla v_0 \\ &= o(1). \end{aligned} \tag{3.12}$$

This proves (3.9). Combining (3.7) with (3.9), we have

$$\frac{1}{2}\int_\Omega |\nabla \rho|^2 + \frac{\kappa^2}{2}(a-\rho^2)^2 \geqslant \frac{1}{2}\int_\Omega |\nabla \sqrt{a}|^2 - o(1). \tag{3.13}$$

Also, from Proposition 1.1,

$$\frac{1}{2}\int_{\cup_i B_i} \rho^2 |\nabla \varphi - A| + |h - h_{\mathrm{ex}}^2| \geqslant \pi \sum_i \ (a(p_i)|d_i|)(\log \kappa - C \log\log \kappa)$$

and, letting $h = h_{\mathrm{ex}} h_0 + f$,

$$\begin{aligned}\frac{1}{2}\int_{\tilde{\Omega}} \frac{1}{\rho^2} |\nabla h|^2 + |h - h_{\mathrm{ex}}|^2 &= \frac{1}{2} h_{\mathrm{ex}}^2 \int_{\tilde{\Omega}} \frac{1}{\rho^2} |\nabla h_0|^2 + |h_0 - 1|^2 \\ &\quad + \frac{1}{2}\int_{\tilde{\Omega}} \frac{1}{\rho^2} |\nabla f|^2 + f^2 + h_{\mathrm{ex}} \int_{\tilde{\Omega}} \frac{1}{\rho^2} \nabla f \nabla h_0 + f(h_0 - 1). \end{aligned} \tag{3.14}$$

Note that $J(u,A) \leqslant C(\log \kappa)^2$ and conclusion (1) of Proposition 1.1, we have

$$\begin{aligned} h_{\mathrm{ex}}^2 \int_{\tilde{\Omega}} \frac{1}{\rho^2} |\nabla h_0|^2 &= h_{\mathrm{ex}}^2 \int_{\tilde{\Omega}} \frac{1}{a} |\nabla h_0|^2 + h_{\mathrm{ex}}^2 \int_{\tilde{\Omega}} \frac{a-\rho^2}{a\rho^2} |\nabla h_0|^2 \\ &\geqslant h_{\mathrm{ex}}^2 \int_{\tilde{\Omega}} \frac{1}{a} |\nabla h_0|^2 - \frac{C(\log \kappa)^3}{\kappa} \|\nabla h_0\|_{L^4(\Omega)}^2 \\ &\geqslant h_{\mathrm{ex}}^2 \int_{\tilde{\Omega}} \frac{1}{a} |\nabla h_0|^2 - o(1). \end{aligned} \tag{3.15}$$

From $-\nabla^\perp h = (iu, \nabla_A u)$ and $J(u,A) \leqslant C(\log \kappa)^2$, we have

$$\|\nabla h\|_{L^2(\Omega)} \leqslant C \log \kappa. \tag{3.16}$$

Hence, by $\|\nabla h_0\|_{L^\infty} \leqslant C$, (3.16), $J(u,A) \leqslant C(\log \kappa)^2$ and Holder inequality,

$$\begin{aligned} h_{\mathrm{ex}} \int_{\tilde{\Omega}} \frac{1}{\rho^2} \nabla f \nabla h_0 &= h_{\mathrm{ex}} \int_{\tilde{\Omega}} \frac{1}{a} \nabla f \nabla h_0 + h_{\mathrm{ex}} \int_{\tilde{\Omega}} \frac{a-\rho^2}{a\rho^2} \nabla f \nabla h_0 \\ &\geqslant h_{\mathrm{ex}} \int_{\tilde{\Omega}} \frac{1}{a} \nabla f \nabla h_0 - \frac{C(\log \kappa)^3}{\kappa} \\ &\geqslant h_{\mathrm{ex}} \int_{\tilde{\Omega}} \frac{1}{a} \nabla f \nabla h_0 - o(1). \end{aligned} \tag{3.17}$$

Note that $h_{\mathrm{ex}}^2\int_{\cup_i B_i}(1/a)\,|\nabla h_0|^2+|h_0-1|^2=o(1)$, combining the above relations, we have

$$J(u,A)\geqslant\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2+\pi\left(\sum_i\ a(p_i)|d_i|\right)(\log\kappa-C\log\log\kappa)+h_{\mathrm{ex}}^2\int_\Omega\frac{1}{a}|\nabla h_0|^2+|h_0-1|^2$$
$$+\frac{1}{2}\int_{\tilde\Omega}\frac{1}{\rho^2}|\nabla f|^2+f^2+h_{\mathrm{ex}}\int_{\tilde\Omega}\frac{1}{a}\nabla f\nabla h_0+f(h_0-1). \tag{3.18}$$

Since, $f=h_{\mathrm{ex}}h_0-h$ and both h and $h_{\mathrm{ex}}h_0$ are bounded in H^1 norm and therefore in L^4 norm for instance, by $C\log\kappa$. Then, by Holder inequality

$$\left(\int_{\cup_i B_i}f^2\right)^2\leqslant\left(\sum_i\ |B_i|\right)\int_{\cup_i}|f|^4=o(1).$$

Also,

$$h_{\mathrm{ex}}\int_{\cup_i B_i}\frac{1}{a}\nabla f\nabla h_0+f(h_0-1)\leqslant Ch_{\mathrm{ex}}\int_{\cup_i B_i}|\nabla f|+|f|=o(1).$$

Combining these relations with (3.17), we have

$$J(u,A)\geqslant\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2+h_{\mathrm{ex}}^2J_0+\pi\left(\sum_i\ a(p_i)|d_i|\right)(\log\kappa-C\log\log\kappa)$$
$$+\frac{1}{2}\int_{\tilde\Omega}\frac{1}{\rho^2}|\nabla f|^2+\frac{1}{2}\int_\Omega f^2+h_{\mathrm{ex}}\int_\Omega\frac{1}{a}\nabla f\nabla h_0+f(h_0-1). \tag{3.19}$$

Moreover,

$$-\mathrm{div}\left(\frac{1}{a}\nabla f\right)+f=-\mathrm{div}\left(\frac{1}{a}\nabla h\right)+h$$

and using Lemma 3.1,

$$\int_\Omega\frac{1}{a}\nabla f\nabla(h_0-1)+f(h_0-1)=2\pi\sum_i\ d_i(h_0-1)(p_i)+o(1),$$

which, together with (3.19), proves Proposition 3.2. □

IV. PROOF OF THEOREM 1.2

In this section, we will give a proof of Theorem 1.2. We need the following lemmas.

Lemma 4.1: For any $\kappa,h_{\mathrm{ex}}>0$, a minimizer (u,A) of (1.1) satisfies

$$J(u,A)\leqslant\frac{1}{2}\int_\Omega|\nabla\sqrt{a}|^2+h_{\mathrm{ex}}^2J_0. \tag{4.1}$$

Proof: Let $A_0=\nabla^\perp h_0$, then,

$$J(u,A)\leqslant J\left(\sqrt{a},\frac{1}{a}h_{\mathrm{ex}}A_0\right)=\frac{1}{a}\int_\Omega|\nabla\sqrt{a}|^2+\frac{1}{2}h_{\mathrm{ex}}^2\int_\Omega\frac{1}{a}|\nabla h_0|^2+|h_0-1|^2$$
$$=\frac{1}{a}\int_\Omega|\nabla\sqrt{a}|^2+h_{\mathrm{ex}}^2J_0. \tag{4.2}$$

This proves Lemma 4.1. □

Lemma 4.2: The set Λ where ξ_0/a attains its minimum is finite and there exist $\delta,N>0$ such that $\xi_0(p)/a(p)\geqslant\min_\Omega(\xi_0/a)+\delta\,\mathrm{dist}(p,\Lambda)^N$ for every $p\in\Omega$.

Proof: Since $a(x)$ is a real analytic function, we have the $\xi_0(x)$ is also a real analytic function. Also, Ω is a simply connected domain in $\mathbb{R}^2$. The standard analytic function theory implies directly the assertion of the lemma. □

Proof of Theorem 1.2: Let (u,A) be a minimizer of (1.1) and $\{(p_i,d_i)\}_{i\in I}$ are associated vortices. We assume that $h_{\text{ex}}<H_{c_1}+K\log\log\kappa$. Using Proposition 3.2 and Lemma 4.1 we have

$$\pi\left(\sum_i a(p_i)|d_i|\right)(\log\kappa - C\log\log\kappa)+2\pi h_{\text{ex}}\sum_i d_i\xi_0(p_i)$$
$$+\frac{1}{2}\int_{\Omega\setminus\cup_i B_i}\frac{1}{\rho^2}|\nabla(h-h_{\text{ex}}h_0)|^2+\frac{1}{2}\int_\Omega|h-h_{\text{ex}}h_0|^2\leqslant o(1). \tag{4.3}$$

We let

$$D=\sum_i a(p_i)|d_i|. \tag{4.4}$$

Step 1: Vortices have mostly positive degrees. Let

$$I_-=\{i\in I: d_i<0\},\quad I_+=I\setminus I_-,$$
$$D_-=\sum_{i\in I_-}a(p_i)|d_i|,\quad D_+=\sum_{i\in I_+}a(p_i)|d_i|, \tag{4.5}$$

so that $D=D_++D_-$. Since ξ_0 is negative in Ω, thus

$$\sum_i d_i\xi_i(p_i)=\sum_i a(p_i)d_i\frac{\xi_0(p_i)}{a(p_i)}\geqslant D_+\min_\Omega\frac{\xi_0}{a}=-D_+\max_\Omega\left|\frac{\xi_0}{a}\right|. \tag{4.6}$$

Since $h_{\text{ex}}\leqslant H_{c_1}+C\log\log\kappa$, using (4.3), we have

$$\pi D(\log\kappa - C\log\log\kappa)-D_+(\pi\log\kappa+C\log\log\kappa)\leqslant o(1),$$

which imply that

$$D_-\leqslant CD\frac{\log\log\kappa}{\log\kappa}+o(1).$$

Hence

$$D_-\leqslant CD_+\frac{\log\log\kappa}{\log\kappa}+o(1).$$

Note that $a(p_i\geqslant a_0)>0$, we have

$$\sum_{i\in I_-}|d_i|\leqslant C\left(\sum_{i\in I_+}|d_i|\right)\frac{\log\log\kappa}{\log\kappa}+o(1).$$

Hence,

$$\sum_{i\in I}|d_i|=\left(\sum_{i\in I_+}|d_i|\right)(1+o(1)). \tag{4.7}$$

Step 2: Vortices are mostly close to Λ. Let

$$I_0=\{i\in I:\mathrm{dist}(p_i,\Lambda)<(\log\kappa)^{-1/2N}\},\quad D_0=\sum_{i\in I_0}a(p_i)|d_i|, \tag{4.8}$$

where N is defined in Lemma 4.2. If $i\notin I_0$, Lemma 4.2 yields

$$\frac{\xi_0}{a}(p_i)\geqslant-\max_\Omega\left|\frac{\xi_o}{a}\right|+\frac{C}{\sqrt{\log\kappa}}, \tag{4.9}$$

while, if $i\in I_0$, we have the obvious inequality $(\xi_0/a)(p_i)\geqslant-\max_\Omega|(\xi_o/a)|$. Combining this relation with (4.3) we have

$$\pi D(\log\kappa-C\log\log\kappa)-2\pi(D-D_0)(H_{c_1}+C\log\log\kappa)\left(\max_\Omega\left|\frac{\xi_0}{a}\right|-\frac{C}{\sqrt{\log\kappa}}\right)$$

$$-2\pi d_0(H_{c_1}+C\log\log\kappa)\max_\Omega\left|\frac{\xi_0}{a}\right|\leqslant o(1). \tag{4.10}$$

From this we have

$$-CD\log\log\kappa+C(D-D_0)\sqrt{\log\kappa}\leqslant o(1)$$

and then

$$D-D_0\leqslant CD\frac{\log\log\kappa}{\sqrt{\log\kappa}}+o(1),$$

which imply that

$$\sum_{i\in I\setminus I_0}|d_i|\leqslant C\left(\sum_{i\in I}|d_i|\right)\frac{\log\log\kappa}{\sqrt{\log\kappa}}+o(1).$$

Hence,

$$\sum_{i\in I}|d_i|=\sum_{i\in I_0}|d_i|+\sum_{i\in I\setminus I_0}|d_i|=\sum_{i\in I_0}|d_i|+\left(\sum_{i\in I}|d_i|\right)o(1), \tag{4.11}$$

which implies

$$\sum_{i\in I_0}|d_i|=\left(\sum_{i\in I}|d_i|\right)(1+o(1)). \tag{4.12}$$

Step 3: To conclude the proof of Theorem 1.2, it suffices to prove that

$$D\leqslant C. \tag{4.13}$$

Let $f=h-h_{\mathrm{ex}}h_0$, $\tilde\Omega=\Omega\setminus\cup_i B_i$. Now we will deal with the term

$$\int_{\tilde\Omega}\frac{1}{\rho^2}|\nabla f|^2+\int_\Omega f^2. \tag{4.14}$$

Let C_t be a circle of radius t lying entirely in $\tilde\Omega$, i.e., not intersecting the vortex balls, and bounding a ball B_t. In $\tilde\Omega$ we write $u=\rho e^{i\varphi}$. Then,

$$-\nabla^{\perp}h=\rho^2(\nabla\varphi-A) \text{ in } \tilde{\Omega}.$$

Also, we have

$$-\operatorname{div}\left(\frac{1}{a}\nabla h_0\right)+h_0=0 \text{ in } \Omega.$$

Hence,

$$\int_{C_t}\frac{1}{a}\frac{\partial h_0}{\partial \nu}=-\int_{B_t}h_0, \quad \int_{C_t}\frac{1}{\rho^2}\frac{\partial h}{\partial \nu}=\int_{C_t}\frac{\partial \varphi}{\partial \tau}-A\cdot\tau=\int_{C_t}\frac{\partial \varphi}{\partial \tau}-\int_{B_t}h,$$

where ν is the inward unit normal vector to B_t and (τ,ν) is a direct frame. We deduce

$$\int_{C_t}\frac{1}{\rho^2}\frac{\partial f}{\partial \nu}+\int_{B_t}f+\int_{C_t}\frac{\rho^2-a}{a\rho^2}\frac{\partial h_0}{\partial \nu}=2\pi d_t, \tag{4.15}$$

where d_t is the winding number of $u:C_t\to S^1$. Equivalently, d_t is the sum of the degrees of vortices included in B_t. Using Holder inequality, we have

$$\frac{1}{2}\int_{C_t}\frac{1}{\rho^2}\left(\frac{\partial f}{\partial \nu}\right)^2+\frac{t}{4}\int_{B_t}f^2\geqslant 2\pi d_t^2-C\int_{C_t}(a-\rho^2)^2. \tag{4.16}$$

Now, Λ is a finite set, we have $\Lambda=\{b_1,\ldots,b_n\}$ where $b_i\in\Omega$. Let $1>\alpha>0$ be such that for all $1\leqslant i\neq j\leqslant n$,

$$\alpha<\frac{|b_i-b_j|}{2}, \quad \alpha<\operatorname{dist}(b_i,\partial\Omega).$$

We denote by $C_{i,t}$ the circle with center b_i and radius t and let E be the set of $0<\alpha<t$ such that for all $1\leqslant i\leqslant n$ we have $C_{i,t}\subset\tilde{\Omega}$. For $t\in E$, we let $d_{i,t}$ be the winding number of u restricted to $C_{i,t}$. From (4.16) we have

$$\frac{1}{2}\int_{C_{i,t}}\frac{1}{\rho^2}\left(\frac{\partial f}{\partial \nu}\right)^2+\frac{t}{4}\int_{B_{i,t}}f^2\geqslant 2\pi d_{i,t}^2-C\int_{C_{i,t}}(a-\rho^2)^2, \tag{4.17}$$

where $B_{i,t}$ is the ball bounded by $C_{i,t}$. Summing over $1\leqslant i\leqslant n$ we find

$$\frac{1}{2}\int_{\cup_i C_{i,t}}\frac{1}{\rho^2}\left(\frac{\partial f}{\partial \nu}\right)^2+\frac{t}{4}\int_{\cup_i B_{i,t}}f^2\geqslant 2\pi\sum_i d_{i,t}^2-C\int_{\cup_i C_{i,t}}(a-\rho^2)^2. \tag{4.18}$$

Now we know from step 2 that most of the vortices are close to Λ in a sense precise enough to imply that if $t\geqslant(\log\kappa)^{-1/2N}$ then

$$\sum_{i=1}^{n}|d_{i,t}|=\sum_{i\in I}|d_i|(1+o(1))+o(1). \tag{4.19}$$

But since step 1 the degrees of the vortices are mostly positive,

$$\sum_{i=1}^{n}d_{i,t}=\sum_{i=1}^{n}|d_{i,t}|(1+o(1))+o(1). \tag{4.20}$$

It follows that if $t\geqslant(\log\kappa)^{-1/2N}$ that

$$\sum_{i=1}^{n} d_{i,t} = \sum_{i \in I} |d_i|(1+o(1))+o(1). \tag{4.21}$$

Using Cauchy–Schawarz's inequality, we have

$$\frac{1}{2}\int_{\cup_i C_{i,t}} \frac{1}{\rho^2}|\nabla f|^2 + \frac{t}{4}\int_{\cup_i B_{i,t}} f^2 \geqslant \frac{C}{t}\left(\sum_{i\in I}|d_i|\right)^2 - C\int_{\cup_i C_{i,t}} (a-\rho^2)^2 \geqslant \frac{C}{t}D^2 - C\int_{\cup_i C_{i,t}} (a-\rho^2)^2 \tag{4.22}$$

for all $t \in E, t \geqslant (\log \kappa)^{-1/2N}$. We now wish to integrate this inequality with respect to t. Since the sum of the radius of the vortex ball is less than $(\log \kappa)^{-10}$ and the function $1/t$ is decreasing, we may bound from below the integral of the right-hand side of (4.22) over $t \in E$,

$$\int_{\{t\in E\}\cap\{t\geqslant(\log\kappa)^{-1/2N}\}} \frac{dt}{t} \geqslant \int_{(\log\kappa)^{-1/2N}+(\log\kappa)^{-10}}^{\alpha} \frac{dt}{t}.$$

This yields the lower bound

$$\begin{aligned}\frac{1}{2}\int_{\tilde{\Omega}} \frac{1}{\rho^2}|\nabla f|^2 + \frac{1}{2}\int_{\Omega} f^2 &\geqslant CD^2 \log\log\kappa - C\int_{\Omega}(a-\rho^2)^2 \\ &\geqslant CD^2\log\log\kappa - \frac{C(\log\kappa)^2}{\kappa^2} \\ &= CD^2\log\log\kappa - o(1).\end{aligned} \tag{4.23}$$

Using (4.23) in (4.3) together with the fact that $\xi_0(p_i)/a(p_i) \leqslant -\max_{\Omega}|\xi_0/a|$ we have

$$-CD\log\log\kappa - CD^2\log\log\kappa \leqslant o(1),$$

which yields

$$D \leqslant C.$$

This relation, step 1, step 2, and $a(x) \geqslant a_0 > 0$ prove the other assertions of Theorem 1.2. □

(Received 26 June 2001; accepted for publication 14 August 2001)

Singular perturbation theory for quantum mechanics is considered in a framework generalizing the spectral concentration theory. Under very general conditions, asymptotic estimations on the Rayleigh–Schrödinger expansions of the perturbed spectral projections are obtained. As a consequence almost invariant subspaces of exponential order are constructed. The results cover practically all singular perturbations considered in nonrelativistic quantum mechanics. In the magnetic field case, under the condition that the magnetic field does not increase at infinity, a gauge invariant perturbation theory leading to convergent series with field-dependent coefficients is developed. © *2002 American Institute of Physics.*

I. INTRODUCTION

While the regular perturbation theory achieved its final form in the papers of Sz-Nagy, Rellich and Kato [see Kato (1980), Reed and Simon (1978b), and references therein], in the case of singular perturbations (Stark and Zeeman effects in quantum mechanics are in this class) the progress has been much slower, at least for the degenerate eigenvalues case. In the general framework laid down in Kato's book a systematic theory of asymptotic Rayleigh–Schrödinger perturbation theory for degenerate eigenvalues has been developed fairly recently by Hunziker and co-workers: Vock and Hunziker (1982), Hunziker and Pillet (1983), Hunziker (1988) [see the beautiful review paper by Hunziker (1988) and also the recent book by Hislop and Sigal (1996) for detailed exposition and an extensive bibliography]. The key condition which selects the allowed class of perturbations is the so-called ''stability condition;'' in the cases where the considered eigenvalues are not stable one considers, in the spirit of Aguilar–Balslev–Combes theory [see Aguilar and Combes (1971), Balslev and Combes (1971)], a related (e.g., dilated) Hamiltonian for which the stability condition holds true. The main point of the theory is that the stability condition, together with the exponential decay of unperturbed eigenvectors given by Combes–Thomas (1973) theory [see also Hunziker (1988)], allows one to obtain powerful asymptotic estimates. The price to be paid are strong conditions (e.g., dilation analyticity) on the perturbation. Also, at the technical level the theory is far from being elementary since one has to deal with non-self-adjoint operators, analytic continuation, etc. In addition, as far as we understand, it does not seem easy to obtain information on the perturbed eigenvectors.

In this paper which, with the exception of the last section, is a continuation of Nenciu (1981) we follow a different route, closer in its spirit to the theory of spectral concentration, in which the main objects are the perturbed subspaces. The aim is twofold: First, using the results in Nenciu (1993) we push the estimations in Nenciu (1981), Nenciu and Nenciu (1981) up to exponential order; second, and more important, we extend the analysis to cases where the techniques in Nenciu (1981) and Nenciu (1993), based on adiabatic expansions, do not apply.

[a)]Electronic mail: nenciu@barutu.fizica.unibuc.ro

The content of the paper is as follows. In Sec. II we set up the framework. Almost invariant subspaces of families of self-adjoint operators are defined and it is shown that their existence gives (up to some errors) similar spectral and evolution information as the existence of invariant subspaces. In this context we give a very general form of the Hylleraas–Wigner "$2n+1$" theorem: "the knowledge of eigenfunction up to errors of order δ, gives the knowledge of the corresponding eigenvalue up to errors of order δ^2." Section III, again of general nature, is devoted to the construction of almost invariant subspaces out of asymptotic Rayleigh–Schrödinger series of the perturbed projection. Section IV contains one of the main results of the paper: For the Schrödinger operator in $\mathbb{R}^3$ (actually all the arguments work in an appropriate abstract setting), under very general conditions on the perturbing potential, we are able to construct formal Rayleigh–Schrödinger expansions for the perturbed projection [see also Howland (1991)] and to obtain good asymptotic estimates on the coefficients of this expansions. The results (or their easy extensions to $\mathbb{R}^n$) cover the perturbations by polynomially bounded potentials of bound states in atomic, molecular, and solid state physics. Also for perturbing potentials growing up at infinity at most linearly (as in the case of the Stark effect) one can treat the perturbations of the energy bands in solids (the Stark–Wannier problem). In all these cases one obtains that the perturbed subspaces are almost invariant up to exponentially long times, which in the present setting is the analog of the fact that the imaginary part of the corresponding resonances (in the cases when they can be defined) are exponentially small.

Section V concerns perturbations given by magnetic fields which do not grow at infinity (the most important particular case being the Zeeman effect, i.e., the case of constant magnetic field) and can be read independently of the rest of the paper. The main result is that this case is closer to regular perturbation theory. More exactly, one finds that *after factorizing* the so-called "nonintegrable gauge phase factor" on can write down a gauge invariant *convergent* perturbation series for the integral kernel of the perturbed resolvent, with coefficients depending themselves upon the perturbing magnetic field. This dependence comes from *phase factors* containing fluxes through some polygonal contours and the asymptotic nature of the usual expansions comes *solely* from expanding these phase factors. In particular this leads (for the first time to our best knowledge) to a convergent expansion for the usual Zeeman effect. The fact that the factorization of the nonintegrable gauge phase factor makes the perturbation given by magnetic fields less singular has been used many times in the physical literature [see, e.g., Luttinger (1951), Nenciu (1991), and references therein in connection with the Peierls–Onsager problem] and has been fully used recently by Cornean and Nenciu (1998) in connection with decay of eigenfunctions [see also Cornean (2000) for the use of the same idea to control the thermodynamic limit for quantum gases in constant magnetic field].

The results have been announced in Nenciu (2001).

II. ALMOST INVARIANT SUBSPACES: GENERAL THEORY

We start with the definition of almost invariant subspaces (a.i.s.).

Definition II.1: Let H_ϵ, P_ϵ, $\epsilon \in [0,\epsilon_0], \epsilon_0 > 0$ be families of self-adjoint operators and orthogonal projections, respectively, in a separable Hilbert space, $\mathcal{H}$, satisfying the following conditions:

(i)

$$\lim_{\epsilon\to 0} \|P_\epsilon - P_0\| = 0, \tag{2.1}$$

(ii) $P_\epsilon \mathcal{D}(H_\epsilon) \subset \mathcal{D}(H_\epsilon)$ where $\mathcal{D}(H_\epsilon)$ is the domain of H_ϵ and on $\mathcal{D}(H_\epsilon)$,

$$\|[H_\epsilon, P_\epsilon]\| \leq \delta(\epsilon), \quad 0 \leq \delta(\epsilon) < \infty, \quad \lim_{\epsilon\to 0} \delta(\epsilon) = 0. \tag{2.2}$$

Then we say that $P_\epsilon \mathcal{H}$ are almost invariant subspaces of order $\delta(\epsilon)$ for H_ϵ.

The definition implies that $P_0\mathcal{H}$ is an invariant subspace of H_0. In what follows we shall restrict ourselves to the case when P_0 is the spectral projection of H_0 corresponding to a bounded isolated part, σ_0, of $\sigma(H_0)$. That is,

(iii)

$$P_0=\frac{i}{2\pi}\oint_\Gamma (H_0-z)^{-1}\mathrm{d}z, \tag{2.3}$$

where Γ is a contour enclosing σ_0. In particular, we shall not consider the perturbation of embedded eigenvalues.

Remark 2.1: Condition (2.1) implies that for sufficiently small ϵ (for which $\|P_\epsilon-P_0\|<1$), P_ϵ and P_0 are unitarily equivalent; in particular $\dim P_\epsilon\mathcal{H}=\dim P_0\mathcal{H}$. Notice that (2.1) cannot be replaced by $s-\lim_{\epsilon\to 0}P_\epsilon=P_0$ even if $\dim P_0\mathcal{H}<\infty$ and $H_\epsilon\to H_0$ in the strong resolvent sense [see, e.g., Hunziker (1988)].

Remark 2.2: Condition (ii) is equivalent to the following one: $P_\epsilon\mathcal{D}_\epsilon\subset\mathcal{D}(H_\epsilon)$ where $\mathcal{D}_\epsilon$ is a core of H_ϵ and (2.2) holds true on $\mathcal{D}_\epsilon$.

If we write H_ϵ in a matrix form according to the decomposition $\mathcal{H}=P_\epsilon\mathcal{H}\oplus(1-P_\epsilon)\mathcal{H}$ then the off-diagonal part, B_ϵ,

$$B_\epsilon=P_\epsilon H(1-P_\epsilon)+(1-P_\epsilon)HP_\epsilon=(1-2P_\epsilon)[H_\epsilon,P_\epsilon], \tag{2.4}$$

is bounded on $\mathcal{D}(H_\epsilon)$,

$$\|B_\epsilon\|\leqslant\delta(\epsilon). \tag{2.5}$$

It follows that both $P_\epsilon H_\epsilon P_\epsilon$ and $(1-P_\epsilon)H_\epsilon(1-P_\epsilon)$ are self-adjoint on $P_\epsilon\mathcal{D}(H_\epsilon)$ and $(1-P_\epsilon)\mathcal{D}(H_\epsilon)$, respectively. Notice that $P_\epsilon H_\epsilon P_\epsilon$ need not be bounded.

In what follows we shall use the notations:

$$H_{\epsilon,D}\equiv H_\epsilon-B_\epsilon=P_\epsilon H_\epsilon P_\epsilon+(1-P_\epsilon)H_\epsilon(1-P_\epsilon), \tag{2.6}$$

$$h_\epsilon\equiv P_\epsilon H_\epsilon P_\epsilon:P_\epsilon\mathcal{D}(H_\epsilon)\to P_\epsilon\mathcal{H}. \tag{2.7}$$

Taking into account (2.4)–(2.7) the above-given definition of a.s.i. coincides with the definition of asymptotic invariant subspaces in Nenciu (1981).

One expects the existence of a.i.s. to give [up to some errors controlled by $\delta(\epsilon)$] similar spectral information on H_ϵ as the existence of invariant subspaces.

Proposition II.2: If $P_\epsilon\mathcal{H}$ are a.i.s. of order $\delta(\epsilon)$ for H_ϵ then

$$\|(1-P_\epsilon)\exp(-itH_\epsilon)P_\epsilon\|\leqslant|t|\,\delta(\epsilon). \tag{2.8}$$

If h_ϵ has an eigenvalue E_ϵ and

$$h_\epsilon\psi_\epsilon=E_\epsilon\psi_\epsilon \tag{2.9}$$

then

$$\exp(-itH_\epsilon)\psi_\epsilon=\exp(-itE_\epsilon)\psi_\epsilon+\chi_\epsilon(t) \tag{2.10}$$

with

$$\|\chi_\epsilon(t)\|\leqslant|t|\,\delta(\epsilon). \tag{2.11}$$

In particular,

$$|\langle\psi_\epsilon,\exp(-itH_\epsilon)\psi_\epsilon\rangle|\geqslant 1-|t|\,\delta(\epsilon), \tag{2.12}$$

i.e., in the physicists language ψ_ϵ describes a metastable state.

Proof: The direct consequence of the definition and of the formula:

$$\exp(-itH_\epsilon)=\exp(-itH_{\epsilon,D})-i\int_0^t \exp(-itH_{\epsilon,D}(t-s))B_\epsilon \exp(-isH_\epsilon)\mathrm{ds}. \tag{2.13}$$

Remark 2.3: Iterating once (2.13) and taking into account that B_ϵ is off-diagonal one can improve (2.12) to

$$|\langle \psi_\epsilon, \exp(-itH_\epsilon)\psi\epsilon\rangle| \geqslant 1-|t|^2\delta(\epsilon)^2/2. \tag{2.14}$$

Consider now the case when $H_\epsilon \to H_0$ in the strong resolvent sense and $\sigma_0=\{\lambda_0\}$ with λ_0 an isolated, m-degenerate eigenvalue so that

$$\dim P_0\mathcal{H}=m<\infty. \tag{2.15}$$

From (2.1) it follows that for sufficiently small ϵ,

$$\dim P_\epsilon\mathcal{H}=m<\infty. \tag{2.16}$$

In this case the existence of a.i.s. of order $\delta(\epsilon)$ is equivalent [see Nenciu (1981)] to the spectral concentration as defined in Riddell (1967) and Kato (1980). Indeed suppose $P_\epsilon\mathcal{H}$ are a.i.s. of order $\delta(\epsilon)$ for H_ϵ. Since $P_\epsilon\mathcal{H}$ are finite dimensional there exist

$$\phi_{\epsilon,j}\in P_\epsilon\mathcal{H}, \quad \langle \phi_{\epsilon,j},\phi_{\epsilon,k}\rangle=\delta_{j,k}, \quad \tilde{\lambda}_{\epsilon,j}\in\mathbf{R}, \quad j,k=1,2,\ldots,m$$

such that

$$h_\epsilon\phi_{\epsilon,j}=\tilde{\lambda}_{\epsilon,j}\phi_{\epsilon,j}. \tag{2.17}$$

From (2.1), (2.2), and (2.6) it follows that

$$\lim_{\epsilon\to 0}\|(1-P_0)\phi_{\epsilon,j}\|=0, \tag{2.18}$$

$$\|(H_\epsilon-\tilde{\lambda}_{\epsilon,j})\phi_{\epsilon,j}\|\leqslant\delta(\epsilon), \tag{2.19}$$

i.e., $\phi_{\epsilon,j},\tilde{\lambda}_{\epsilon,j}$ are pseudoeigenvectors and pseudoeigenvalues of all orders $p\in\mathbf{N}$ for which $\lim_{\epsilon\to 0}\epsilon^{-p}\delta(\epsilon)=0$ and this is equivalent to the spectral concentration according to Riddel's (1967) theorem. Conversely if $\tilde{\lambda}_{\epsilon,j}$ and $\phi_{\epsilon,j}$ satisfying (2.18) and (2.19) exist then $P_\epsilon\mathcal{H}$ with

$$P_\epsilon=\sum_{j=1}^m \langle \phi_{\epsilon,j},\cdot\rangle\phi_{\epsilon,j} \tag{2.20}$$

are a.i.s. of order $\delta(\epsilon)$ for H_ϵ.

Finally let us consider the case when, in addition, λ_0 is stable [see Hunziker (1988) and also Kato (1980), Hislop and Sigal (1996)]. From the definition of stability there exist $d>0,\epsilon_1>0$ such that for $\epsilon\in[0,\epsilon_1]$, $\Gamma=\{z\|z-\lambda_0|=d\}\subset\rho(H_\epsilon)$, and

$$\inf_{z\in\Gamma}\mathrm{dist}(z,\sigma(H_\epsilon))\geqslant d/2. \tag{2.21}$$

In addition, if

$$Q_\epsilon = \oint_\Gamma (H_\epsilon - z)^{-1} dz \tag{2.22}$$

then

$$\lim_{\epsilon \to 0} \| Q_\epsilon - P_0 \| = 0. \tag{2.23}$$

From (2.1), (2.2), and (2.23) there exist $\epsilon_2 > 0$ such that for all $\epsilon \in [0, \epsilon_2]$ one has

$$\| Q_\epsilon - P_0 \| < 1/6, \quad \| P_\epsilon - P_0 \| < 1/6, \quad \delta(\epsilon) \leqslant d/8. \tag{2.24}$$

As expected Q_ϵ and the spectrum of $Q_\epsilon H_\epsilon Q_\epsilon$ (as an operator in the m-dimensional space $Q_\epsilon \mathcal{H}$) are close to P_ϵ and $\sigma(h_\epsilon)$, respectively.

Proposition II.3: For $\epsilon \in [0, \min\{\epsilon_1, \epsilon_2\}]$,

$$\| P_\epsilon - Q_\epsilon \| \leqslant c_1(d)\, \delta(\epsilon), \tag{2.25}$$

$$\operatorname{dist}(\sigma(Q_\epsilon H_\epsilon Q_\epsilon), \sigma(h_\epsilon) \leqslant c_2(d)\, \delta(\epsilon)^2. \tag{2.26}$$

Remark 2.4: The proof gives the following (nonoptimal) values for $c_i(d)$: $c_1(d) = 16/3d$, $c_2(d) = 512/9d$.

Remark 2.5: The interesting part of Proposition II.3 is (2.26), which is a general form of the so called Hylleraas–Wigner "$2n+1$" theorem in perturbation theory [see Gonze (1995), and references therein]: Knowledge of the perturbed wave function to order $\delta(\epsilon)$ gives the perturbed eigenvalue with errors of order $\delta(\epsilon)^2$. To see the connection, consider the elementary case of regular perturbations of nondegenerate isolated eigenvalues. Let $H_\epsilon \psi_\epsilon = \lambda_\epsilon \psi_\epsilon$ and suppose that one knows an approximate *normalized* wave function $\tilde{\psi}_\epsilon$, $\| \tilde{\psi}_\epsilon \| = 1$ with $\| \tilde{\psi}_\epsilon - \psi_\epsilon \| \leqslant \delta(\epsilon)$, $\| H_\epsilon (\tilde{\psi}_\epsilon - \psi_\epsilon) \| \leqslant M\, \delta(\epsilon)$; M uniformly bounded as $\epsilon \to 0$. Then if

$$P_\epsilon = \langle \tilde{\psi}_\epsilon, \cdot \rangle \tilde{\psi}_\epsilon$$

one has

$$\| [P_\epsilon, H_\epsilon] \| \leqslant 2(M + |\lambda_\epsilon|)\, \delta(\epsilon),$$

which according to Proposition II.3 gives

$$|\lambda_\epsilon - \langle \tilde{\psi}_\epsilon, H_\epsilon \tilde{\psi}_\epsilon \rangle| \leqslant \text{const}\ \delta(\epsilon)^2. \tag{2.27}$$

Actually in this simple case one can obtain (2.27) at once from

$$\begin{aligned} |\lambda_\epsilon - \langle \tilde{\psi}_\epsilon, H_\epsilon \tilde{\psi}_\epsilon \rangle| &= |\langle \tilde{\psi}_\epsilon, (H_\epsilon - \lambda_\epsilon) \tilde{\psi}_\epsilon \rangle| \\ &= |\langle \tilde{\psi}_\epsilon, (H_\epsilon - \lambda_\epsilon)(\tilde{\psi}_\epsilon - \psi_\epsilon) \rangle| \\ &= |\langle (H_\epsilon - \lambda_\epsilon)(\tilde{\psi}_\epsilon - \psi_\epsilon), \tilde{\psi}_\epsilon - \psi_\epsilon \rangle|. \end{aligned}$$

Notice, however, that the above-presented argument cannot be generalized directly to the degenerate case and actually we do not know a reference for the Hylleraas–Wigner theorem in the degenerate case in spite of the fact that it is probably known to experts. The reason for the quadratic estimation in (2.26) is the fact that B_ϵ is an off-diagonal perturbation of $H_{\epsilon,D}$. Let us stress that the condition $P_\epsilon = P_\epsilon^2$ is essential for (2.26) to hold true; actually it replaces the condition that $\tilde{\psi}_\epsilon$, in the above-mentioned proof of Hylleraas–Wigner theorem, is normalized.

Remark 2.6: Proposition II.3 can be easily extended to the case when σ_0 is a stable, bounded isolated part of the spectrum oh H_0 but the constants in (2.25), (2.26) become more complicated and depend also upon the diameter of σ_0.

Proof of Proposition II.3: We apply regular perturbation theory to the pair $H_{\epsilon,D}, H_\epsilon = H_{\epsilon,D} + B_\epsilon$. From (2.5),(2.6), and (2.24),

$$\mathrm{dist}(\Gamma, \sigma(H_{\epsilon,D})) \geqslant 3d/8. \tag{2.28}$$

If

$$T_\epsilon = \frac{i}{2\pi} \oint_\Gamma (H_{\epsilon,D} - z)^{-1} \mathrm{d}z, \tag{2.29}$$

then

$$Q_\epsilon - T_\epsilon = -\frac{i}{2\pi} \oint_\Gamma (H_{\epsilon,D} - z)^{-1} B_\epsilon (H_\epsilon - z)^{-1} \mathrm{d}z, \tag{2.30}$$

which gives

$$\|Q_\epsilon - T_\epsilon\| \leqslant 16\delta(\epsilon)/3d < 2/3. \tag{2.31}$$

From (2.24) and (2.31) one has

$$\|P_\epsilon - T_\epsilon\| < 1. \tag{2.32}$$

Now (2.32) implies that

$$P_\epsilon = T_\epsilon, \tag{2.33}$$

which together with (2.31) gives (2.25). Indeed since P_ϵ, T_ϵ are orthogonal projections commuting with $H_{\epsilon,D}$, in a $L^2(M, d\mu)$ representation of $H_{\epsilon,D}$ they are multiplications with some characteristic functions so $P_\epsilon - T_\epsilon$ is the multiplication with a function taking only the values 0 and ± 1. As the values ± 1 are ruled out by (2.32) the equality (2.33) follows.

For the proof of (2.26) consider the Sz–Nagy transformation matrix [see Kato (1980)] corresponding to the pair P_ϵ, Q_ϵ,

$$U_\epsilon = (1 - (Q_\epsilon - P_\epsilon)^2)^{-1/2} [Q_\epsilon P_\epsilon + (1 - Q_\epsilon)(1 - P_\epsilon)]. \tag{2.34}$$

As is well known U_ϵ is unitary and intertwines Q_ϵ and P_ϵ,

$$Q_\epsilon = U_\epsilon P_\epsilon U_\epsilon^*. \tag{2.35}$$

As a consequence,

$$U_\epsilon^* Q_\epsilon H_\epsilon Q_\epsilon U_\epsilon = P_\epsilon U_\epsilon^* H_\epsilon U_\epsilon P_\epsilon, \tag{2.36}$$

i.e., $Q_\epsilon H_\epsilon Q_\epsilon$ is unitarily equivalent with the ''effective'' Hamiltonian $P_\epsilon U_\epsilon^* H_\epsilon U_\epsilon P_\epsilon$. On the other hand, the analytic perturbation theory [see Kato (1980)] applied to the pair $H_{\epsilon,D}$, $H_\epsilon = H_{\epsilon,D} + B_\epsilon$ gives for $P_\epsilon U_\epsilon^* H_\epsilon U_\epsilon P_\epsilon$:

$$P_\epsilon U_\epsilon^* H_\epsilon U_\epsilon P_\epsilon = h_\epsilon + P_\epsilon B_\epsilon P_\epsilon + \mathcal{O}(B_\epsilon^2) \tag{2.37}$$

so that (since the second terms on the right-hand side vanishes)

$$\|P_\epsilon U_\epsilon^* H_\epsilon U_\epsilon P_\epsilon - h_\epsilon\| \leqslant \mathcal{O}(B_\epsilon^2), \tag{2.38}$$

which in particular implies (2.26). The computation in the following gives a precise form of the error in terms of $\delta(\epsilon)$ and d. Without restricting the generality one can take $\lambda_0=0$. Using

$$Q_\epsilon H_\epsilon Q_\epsilon=\frac{i}{2\pi}\oint_\Gamma z(H_\epsilon-z)^{-1}\mathrm{d}z \tag{2.39}$$

and

$$\begin{aligned}(H_\epsilon-z)^{-1}=&(H_{\epsilon,D}-z)^{-1}-(H_{\epsilon,D}-z)^{-1}B_\epsilon(H_{\epsilon,D}-z)^{-1}\\&+(H_\epsilon-z)^{-1}B_\epsilon(H_{\epsilon,D}-z)^{-1}B_\epsilon(H_{\epsilon,D}-z)^{-1},\end{aligned} \tag{2.40}$$

one has

$$\begin{aligned}P_\epsilon Q_\epsilon H_\epsilon Q_\epsilon P_\epsilon=&P_\epsilon\frac{i}{2\pi}\oint_\Gamma z(H_{\epsilon,D}-z)^{-1}\mathrm{d}z\,P_\epsilon-P_\epsilon\frac{i}{2\pi}\oint_\Gamma z(H_{\epsilon,D}-z)^{-1}B_\epsilon(H_{\epsilon,D}-z)^{-1}\mathrm{d}z\,P_\epsilon\\&+P_\epsilon\frac{i}{2\pi}\oint_\Gamma z(H_\epsilon-z)^{-1}B_\epsilon(H_{\epsilon,D}-z)^{-1}B_\epsilon(H_{\epsilon,D}-z)^{-1}\mathrm{d}zP_\epsilon.\end{aligned} \tag{2.41}$$

Now from (2.39) written for $H_{\epsilon,D}$, the first terms on the right-hand side of (2.41) gives h_ϵ while the second vanishes due to the fact that B_ϵ is off-diagonal and P_ϵ commutes with $H_{\epsilon,D}$. Then estimating brutally the third terms on the right-hand side of (2.41) one obtains

$$\|P_\epsilon Q_\epsilon H_\epsilon Q_\epsilon P_\epsilon-h_\epsilon\|\leqslant 128\delta(\epsilon)^2/9d. \tag{2.42}$$

On the other hand,

$$P_\epsilon U_\epsilon^* H_\epsilon U_\epsilon P_\epsilon-P_\epsilon Q_\epsilon H_\epsilon Q_\epsilon P_\epsilon=(P_\epsilon U_\epsilon^*-P_\epsilon Q_\epsilon)Q_\epsilon H_\epsilon Q_\epsilon U_\epsilon P_\epsilon+P_\epsilon Q_\epsilon H_\epsilon Q_\epsilon(U_\epsilon P_\epsilon-Q_\epsilon P_\epsilon) \tag{2.43}$$

and then

$$\|U_\epsilon^* Q_\epsilon H_\epsilon Q_\epsilon U_\epsilon-P_\epsilon Q_\epsilon H_\epsilon Q_\epsilon P_\epsilon\|\leqslant 2\|U_\epsilon P\epsilon-Q_\epsilon P_\epsilon\|\cdot\|Q_\epsilon H_\epsilon Q_\epsilon\|. \tag{2.44}$$

Now from

$$U_\epsilon P_\epsilon-Q_\epsilon P_\epsilon=[(1-(Q_\epsilon-P_\epsilon)^2)^{-1/2})-1]Q_\epsilon P_\epsilon \tag{2.45}$$

one obtains [see (2.31) and (2.33)]

$$\|U_\epsilon P_\epsilon-Q_\epsilon P_\epsilon\|=\|P_\epsilon U_\epsilon^*-P_\epsilon Q_\epsilon\|\leqslant 128\delta(\epsilon)^2/3d^2. \tag{2.46}$$

Since (remember that we took $\lambda_0=0$)

$$\|Q_\epsilon H_\epsilon Q_\epsilon\|\leqslant d/2, \tag{2.47}$$

putting all together one obtains

$$\|P_\epsilon U_\epsilon^* H_\epsilon U_\epsilon P_\epsilon-h_\epsilon\|\leqslant\frac{512}{9d}\delta(\epsilon)^2, \tag{2.48}$$

which gives in particular (2.26) with the value of c_2 given in Remark 2.4.

III. PERTURBATIVE CONSTRUCTION OF ALMOST INVARIANT SUBSPACES

We turn now to the problem of constructing a.i.s. for families, H_ϵ, of self-adjoint operators. The setting we shall consider, which is sufficiently general to cover practically all physical situations in nonrelativistic quantum mechanics, is as follows: $\epsilon>0$ is a small parameter $\epsilon\in[0,\epsilon_0]$; H_0 and $V(\epsilon)$ are self-adjoint operators such that there exists a dense subspace, $\mathcal{D}$, $\mathcal{D}\subset\mathcal{D}(H_0)\cap\mathcal{D}(V(\epsilon))$ on which $H_0+\epsilon V(\epsilon)$ has self-adjoint extensions [in most examples $H_0+\epsilon V(\epsilon)$ is essentially self-adjoint on $\mathcal{D}$]; we shall denote by H_ϵ any of its self-adjoint extensions with the property $\mathcal{D}(H_\epsilon)\supset\mathcal{D}(H_0)\cap\mathcal{D}(V_\epsilon)$.

We shall consider explicitly only the particular case when $V(\epsilon)=V$ is independent of ϵ, and in this case $\mathcal{D}=\mathcal{D}(H_0)\cap\mathcal{D}(V)$, but all the results generalize as far as $V(\epsilon)$ obeys the needed technical conditions uniformly in ϵ. Indeed in this case one obtains results (uniformly in $\eta\in[0,\epsilon_0]$) for

$$H_{\epsilon,\eta}=H_0+\epsilon V(\eta)$$

and at the end one sets $\eta=\epsilon$.

At the heuristic level the problem of finding a.i.s. for H_ϵ can be viewed as the search for solutions of

$$[H_\epsilon,P_\epsilon]=[H_0,P_\epsilon]+\epsilon[V,P_\epsilon]\simeq 0, \tag{3.1}$$

$$P_\epsilon^2-P_\epsilon\simeq 0. \tag{3.2}$$

Making the ''perturbational'' ansatz

$$P_\epsilon\simeq\sum_j E_j\epsilon^j \tag{3.3}$$

one is led to the problem of solving the following equations for E_j, $j=1,2,...$:

$$P_0=E_0, \tag{3.4}$$

$$[H_0,E_j]=-[V,E_{j-1}], \tag{3.5}$$

$$\sum_{l=0}^{j}E_lE_{j-l}=E_j. \tag{3.6}$$

Equation (3.4) is nothing but (2.1) for $\epsilon=0$ while (3.5) and (3.6) follow from plugging (3.3) into (3.1) and (3.2), respectively.

In the rest of this section we shall outline how the existence of solutions, E_0, $E_1\ldots,E_N$; $N\leqslant\infty$ of (3.4)–(3.6) together with estimates on the norm of E_j and $[V,E_j]$ gives the existence of a.i.s. in the sense of (2.1) and (2.2) with control on the constant $\delta(\epsilon)$. Of course the technical core of the theory is the proof of existence of solutions of (3.4)–(3.6) with bounds on their norms and this question will be addressed in Sec. IV.

Suppose $E_j\mathcal{H}\subset\mathcal{D}(H_0)\cap\mathcal{D}(V)$, $j=0,1,...,N$ and there satisfy (3.4)–(3.6). In addition,

$$\|E_j\|\leqslant e_j, \tag{3.7}$$

$$\|[V,E_j]\|\leqslant f_j, \quad j=1,2...,N. \tag{3.8}$$

Consider

$$T_N(\epsilon)=\sum_{j=0}^{N}E_j\epsilon^j, \tag{3.9}$$

where N can depend upon ϵ. Unfortunately $T_N(\epsilon)$ is not a projection [in particular $T_N(\epsilon)^2 \neq T_N(\epsilon)$ and even if $T_N(\epsilon)$ is self-adjoint $i[(\mathrm{d}/\mathrm{d}\epsilon)\, T_N(\epsilon), T_N(\epsilon)]$ is not self-adjoint; this point has been overlooked in Howland (1991) but without consequences on the result there]. So the first step is to construct out of $T_N(\epsilon)$ a projection operator, $P_N(\epsilon)$, whose expansion in ϵ should coincide with $T_N(\epsilon)$ up to order N. Of course such a ''completion'' is far from being unique; we shall use the method employed in Nenciu (1993) since it gives an easy control on $\|[H_\epsilon, P_N(\epsilon)]\|$.

We need a few elementary facts about projections. Here we consider the self-adjoint case; for the non-self-adjoint case see the Appendix where a more elaborate version of (elementary) Proposition 3 in Nenciu (1993) is given. Let T be a bounded self-adjoint operator satisfying

$$\|T^2 - T\| \leqslant \delta < 1/4. \tag{3.10}$$

Then by the spectral theorem

$$\sigma(T) \subset \left[\frac{1-\sqrt{1+4\delta}}{2}, \frac{1-\sqrt{1-4\delta}}{2}\right] \cup \left[\frac{1+\sqrt{1-4\delta}}{2}, \frac{1+\sqrt{1+4\delta}}{2}\right].$$

In particular $1/2 \in \rho(T)$, $\|T\| \leqslant (1+\sqrt{1+4\delta})/2$, and

$$\sup_{|z-1|=1/2} \|(T-z)^{-1}\| \leqslant \frac{2}{\sqrt{1-4\delta}}. \tag{3.11}$$

Now, if P is the spectral projection of T corresponding to the part of the spectrum around 1:

$$P = \frac{i}{2\pi} \oint_{|z-1|=1/2} (T-z)^{-1} \mathrm{d}z. \tag{3.12}$$

Then again by the spectral theorem

$$\|T-P\| \leqslant \frac{1-\sqrt{1-4\delta}}{2} = \frac{2\delta}{1+\sqrt{1-4\delta}}. \tag{3.13}$$

Consider now $T_N(\epsilon)$. Due to (3.6) and (3.7) $\|T_N(\epsilon)^2 - T_N(\epsilon)\| \sim \mathcal{O}(\epsilon^{N+1})$, i.e., for sufficiently small ϵ,

$$\|T_N(\epsilon)^2 - T_N(\epsilon)\| < 1/4,$$

and one can define $P_N(\epsilon)$ by

$$P_N(\epsilon) = \frac{i}{2\pi} \oint_{|z-1|=1/2} (T_N(\epsilon) - z)^{-1} \mathrm{d}z. \tag{3.14}$$

$P_N(\epsilon)$ is a projection and according to (3.13)

$$\|P_N(\epsilon) - T_N(\epsilon)\| \sim \mathcal{O}(\epsilon^{N+1}). \tag{3.15}$$

We now compute $[H_\epsilon, P_N(\epsilon)]$. Notice first that due to the identity

$$(T-z)^{-1} = z^{-1}(T(T-z)^{-1} - 1),$$

$[H_\epsilon, P_N(\epsilon)]$ is well defined on a dense subspace and the following computation can be done. From (3.5)

$$[H_\epsilon, T_N(\epsilon)] = \epsilon^{N+1}[V, E_N]$$

and then

$$[H_\epsilon,P_N(\epsilon)]=-\frac{i}{2\pi}\oint_{|z-1|=1/2}(T_N(\epsilon)-z)^{-1}[H_\epsilon,T_N(\epsilon)](T_N(\epsilon)-z)^{-1}\mathrm{d}z$$

$$=-\epsilon^{N+1}\frac{i}{2\pi}\oint_{|z-1|=1/2}(T_N(\epsilon)-z)^{-1}[V,E_N](T_N(\epsilon)-z)^{-1}\mathrm{d}z. \tag{3.16}$$

We summarize the above-given discussion in the following lemma:

Lemma III.1: Suppose E_j satisfy (3.4)–(3.8), $T_N(\epsilon)$ is given by (3.9), and let ϵ_N be the positive solution of

$$\sum_{l=N+1}^{2N}\epsilon^l a_l=1/8, \tag{3.17}$$

where

$$a_l=\sum_{j+m=l,0\leqslant j,m\leqslant N}e_j e_m .$$

Then for $0\leqslant\epsilon\leqslant\epsilon_N$:

$$\|T_N(\epsilon)^2-T_N(\epsilon)\|\leqslant\sum_{l=N+1}^{2N}\epsilon^l a_l\equiv\delta_N(\epsilon)\leqslant 1/8 \tag{3.18}$$

and if $P_N(\epsilon)$ is given by (3.14)

$$\|P_N(\epsilon)-T_N(\epsilon)\|\leqslant 2\,\delta_N(\epsilon), \tag{3.19}$$

$$\|[H_\epsilon,P_N(\epsilon)]\|\leqslant 4\epsilon^{N+1}\|[V,E_N]\|. \tag{3.20}$$

Proof: For (3.18) notice that from (3.6)

$$T_N(\epsilon)^2-T_N(\epsilon)=\sum_{l=N+1}^{2N}\epsilon^l\left(\sum_{j+m=l,0\leqslant j,m\leqslant N}E_j E_m\right).$$

Then (3.19) follows from (3.18) and (3.14) while (3.20) follows from (3.16) and (3.19).

Remark 3.1: The main point of the lemma is the estimate (3.20).

Remark 3.2: Notice that in each particular case one has still to prove that $P_\epsilon\mathcal{D}_\epsilon\subset\mathcal{D}(H_\epsilon)$ [see Remark 2.2 and recall that $\mathcal{D}_\epsilon$ is a core of H_ϵ].

At a more elaborate level of perturbation theory the task is to obtain, under specific conditions on H_0, V, and P_0 the dependence on j of e_j, f_j; the rate of increase of these constants "measures" the singularity of the perturbation. The simplest case is when $e_j\leqslant e^j$ for some finite constant e; this corresponds to the well-known regular perturbations and there is no need for further discussion. The most interesting case is when $N=\infty$ and there exist constants $E,F'g<\infty$, $\alpha>0$ such that

$$e_j\leqslant Eg^j(j!)^\alpha,\quad f_j\leqslant Fg^{j+1}((j+1)!)^\alpha,\quad j=1,2,\ldots . \tag{3.21}$$

In this case the series in (3.3) is not convergent and the idea here is to use a best remainder estimate a la Necharosev, i.e., to take N depending on ϵ in (3.9) in order to have the right-hand side of (3.16) as small as possible. This requirement leads to N_ϵ given by

$$N_\epsilon + 1 = \left[\left(\frac{1}{g\epsilon} \right)^{1/\alpha} \right], \tag{3.22}$$

where [ ] means the integer part. Plugging (3.22) into (3.9) one obtains:

Lemma III.2: Let N_ϵ be given by (3.22). Then there exists $\epsilon_0 > 0$ such that for $\epsilon \in [0, \epsilon_0]$, (3.18) holds true and $P_\epsilon \equiv P_{N_\epsilon}$ satisfies (2.2) with

$$\delta(\epsilon) = 4FK^\alpha \frac{1}{(g\epsilon)^{1/2}} \exp\left(- \frac{\alpha}{(g\epsilon)^{1/\alpha}} \right), \tag{3.23}$$

where K is an absolute constant.

Proof: From (3.21)

$$a_l \leqslant \sum_{j=0}^{l} e_j e_{l-j} \leqslant E^2 g^l (l+1)(l!)^\alpha. \tag{3.24}$$

From the Stirling formula there exist $K > \infty$, $\tilde{K} > 0$ such that

$$\tilde{K} j^j e^{-j} \leqslant j! \leqslant K j^{j+1/2} e^{-j} \tag{3.25}$$

and from this and the fact that for all $N_\epsilon + 1 \leqslant k \leqslant 2N_\epsilon$:

$$\alpha \ln k \leqslant \alpha \ln 2N_\epsilon \leqslant \alpha \ln 2 - \ln(g\epsilon) \tag{3.26}$$

one obtains

$$\epsilon^j a_j \leqslant E^2 K^\alpha (j+1)^{1+\alpha/2} e^{-j\alpha(1-\ln 2)}, \tag{3.27}$$

so

$$\delta_N(\epsilon) \leqslant E^2 K^\alpha \sum_{j=N_\epsilon+1}^{\infty} (j+1)^{\alpha+1/2} e^{-\alpha(1-\ln 2)j}. \tag{3.28}$$

Since $N_\epsilon \to \infty$ as $\epsilon \to 0$ the first part of the lemma is proved. Then (3.23) follows from (3.8),(3.20),(3.21), (3.22), and (3.25).

Remark 3.3: If $g\epsilon < 1$, in the limit $\alpha \to 0$ one has $\delta(\epsilon) \to 0$, which fits with the fact that for $\alpha = 0$ the series in (3.3) is convergent for $\epsilon < g^{-1}$.

IV. ASYMPTOTIC ESTIMATIONS

In this section we consider the problem of finding solutions E_j of (3.4)–(3.6) satisfying estimations like (3.7) and (3.8) with e_j, f_j satisfying (3.21). In spite of the fact that all the following arguments work in an appropriate abstract setting (covering in particular N-body Stark and Zeeman effects in atoms and molecules), for definiteness we shall discuss a simple Schrödinger case in $\mathbb{R}^3$,

$$H_\epsilon = -\Delta + V_0(\mathbf{x}) + \epsilon V(\mathbf{x}) \equiv H_0 + \epsilon V(\mathbf{x}), \quad \epsilon > 0, \tag{4.1}$$

with

$$V_0 \in L^2_{\text{uloc}}, \text{ i.e., } \sup_{\mathbf{x} \in \mathbb{R}^3} \int_{|\mathbf{x}-\mathbf{y}| \leqslant 1} |V_0(\mathbf{y})|^2 d\mathbf{y} < \infty, \tag{4.2}$$

$$|V(\mathbf{x})| \leqslant \langle \mathbf{x} \rangle^\beta, \quad \langle \mathbf{x} \rangle = (1 + \mathbf{x}^2)^{1/2}, \quad \beta \in \mathbf{R}, \tag{4.3}$$

and $\epsilon>0$. In particular H_0 is essentially self-adjoint on $\mathcal{C}_0^\infty(\mathbb{R}^3)$ [see Reed and Simon (1978a)]. In what follows H_ϵ is *any* self-adjoint extension of $H_0+\epsilon V(\mathbf{x})$ defined on $\mathcal{D}(H_0)\cap\mathcal{D}(V)\supset\mathcal{C}_0^\infty(\mathbb{R}^3)$. As P_0 we shall take the spectral projection of H_0 corresponding to a bounded isolated part, σ_0, of its spectrum.

The main fact about H_0 we shall use is the following elementary result from Combes–Thomas theory [see Combes and Thomas (1973), Hunziker (1988), Nenciu (1991)]:

Proposition IV.1: Let $K\subset\rho(H_0)$ be compact, λ_0 an isolated finitely degenerate eigenvalue of H_0. Then there exist $\gamma_0>0, M<\infty$ such that for all $\gamma\in[0,\gamma_0]$:

$$\sup_{z\in K}\|R_{0,\gamma}(z)\|\leqslant M, \tag{4.4}$$

$$\|e^{\gamma\langle\cdot\rangle}P_0e^{\gamma\langle\cdot\rangle}\|\leqslant M, \tag{4.5}$$

where

$$R_{0,\gamma}(z)=e^{\gamma\langle\cdot\rangle}(H_0-z)^{-1}e^{-\gamma\langle\cdot\rangle} \tag{4.6}$$

and P_0 is the spectral projection of H_0 corresponding to λ_0.

If $\beta\in[-\infty,0]$ then $VR_0(z)$ $(R_0(z)=(H_0-z)^{-1})$ is bounded and E_j given by the well-known perturbation formula

$$E_j=(-1)^j\frac{i}{2\pi}\oint_\Gamma R_0(z)(VR_0(z))^j\mathrm{d}z, \tag{4.7}$$

where Γ is a contour enclosing σ_0, satisfying (3.4)–(3.6) and the estimations (3.7), (3.8), (3.21) with $\alpha=0$. Now, if $\beta>0$, $VR_0(z)$ is not bounded and one cannot decide at once from (4.7) whether or not E_j are bounded and the main idea in what follows is to find alternative formulas for E_j which coincide with (4.7) for $\beta\leqslant0$ but still make sense for $\beta>0$. Many such formulas, each of them making sense under various assumptions on β and $\dim P_0$, will appear in the following [see (4.12), (4.17), (4.31) and (4.41)]. The need for alternative formulas comes from the fact that a formula covering all interesting cases does not seem to exist; for example, if $\dim P_0<\infty$ one uses the exponential decay of the corresponding eigenvalues (see Proposition IV.1) while for $\dim P_0=\infty$ when (4.5) does not hold true one has to rely on the fact that $[V,R_0(z)]$ might be bounded even for potentials which are unbounded at infinity. Let us stress that although they look different, as far as they make sense, they give the same E_j: For example, if $\beta\leqslant1$ and $\dim P_0<\infty$ (4.12) gives the same E_j as the recurrence formula (4.31). This is due to the fact [see Nenciu (1993)] that as far as it exists and is bounded, the solution of (3.4)–(3.6) is unique.

We prove first that, for all β, E_j is well defined and bounded on $\mathcal{C}_0^\infty(\mathbb{R}^3)$.

Lemma IV.2: For all $\beta\in\mathbb{R}$, E_j given by (4.7) are well defined and satisfy (3.4)–(3.6) on $\mathcal{C}_0^\infty(\mathbb{R}^3)$.

Proof: The key observation [see Hunziker (1988)] is that due to (4.3) and (4.4) expressions like $R_0(z)(VR_0(z))^l$, $VR_0(z)(VR_0(z))^lV$ are well defined on $\mathcal{C}_0^\infty(\mathbb{R}^3)$. In particular from (4.7), for $u\in\mathcal{C}_0^\infty(\mathbb{R}^3)$, E_ju is well defined for all $\gamma\in[0,\gamma_0]$ since

$$E_ju=(-1)^j\frac{i}{2\pi}\oint_\Gamma R_0(z)(Ve^{-(\gamma/j)\langle\cdot\rangle})R_{0,\gamma/j}(z)\cdots R_{0,\gamma}(z)e^{\gamma\langle\cdot\rangle}u\,\mathrm{d}z. \tag{4.8}$$

For all $z\neq z'\in\rho(H_0)$, $j=1,\ldots,$ and $u\in\mathcal{C}_0^\infty(\mathbf{R}^3)$,

$$\frac{1}{z-z'}[R_0(z)(VR_0(z))^j-R_0(z')(VR_0(z'))^j]u=\sum_{l=0}^{j}[R_0(z)(VR_0(z))^l][R_0(z')(VR_0(z'))^{j-l}]u. \tag{4.9}$$

Indeed from the resolvent formula

$$(z-z')\sum_{l=0}^{j}[R_0(z)(VR_0(z))^l][R_0(z')(VR_0(z'))^{j-l}]u$$
$$=(R_0(z)-R_0(z'))VR_0(z')\cdots VR_0(z')u+R_0(z)V(R_0(z)-R_0(z'))VR_0(z')\ldots VR_0(z')u$$
$$+\cdots+R_0(z)VR_0(z)\cdots(R_0(z)-R_0(z'))u=R_0(z)(VR_0(z))^j-R_0(z')(VR_0(z'))^j u.$$

Integrating (4.9) on two contours $\Gamma,\Gamma'\subset\rho(H_0),\Gamma'\subset \mathrm{Int}\,\Gamma$ enclosing σ_0 one obtains

$$E_j u=\sum_{l=0}^{j}E_l E_{j-l}u. \tag{4.10}$$

From $H_0R_0(z)=1+zR_0(z)$, again on $u\in\mathcal{C}_0^\infty(\mathbb{R}^3)$,

$$H_0R_0(z)(VR_0(z))^jVR_0(z)u-R_0(z)(VR_0(z))^jVR_0(z)H_0u$$
$$=(VR_0(z))^jVR_0(z)u-R_0(z)(VR_0(z))^jVu,$$

which after the integration on Γ gives

$$[H_0,E_{j+1}]u=-[V,E_j]u$$

and the proof is finished.

Consider first the case when $\sigma_0=\{\lambda_0\}$ with λ_0 a finite degenerate, isolated eigenvalue of H_0:

$$\mathrm{dist}(\lambda_0,\sigma(H_0)\backslash\lambda_0)=d_0>0,\quad \dim P_0=m<\infty,\Gamma=\{z\|\lambda_0-z|=d_0/2\}. \tag{4.11}$$

By the residue theorem, for all β and $u\in\mathcal{C}_0^\infty(\mathbb{R}^3)$, from (4.7)

$$E_j u=(-1)^{j-1}\sum_{\nu_1,\nu_2\cdots\nu_{j+1};\nu_l\geqslant 0;\sum_{l=1}^{j+1}\nu_l=j}S^{\nu_1}VS^{\nu_2}V\cdots VS^{\nu_{j+1}}u, \tag{4.12}$$

where S is the reduced resolvent at λ_0:

$$S=S(\lambda_0),\quad S(z)=\frac{i}{2\pi}\oint_\Gamma R_0(\zeta)(z-\zeta)^{-1}\mathrm{d}\zeta,|z-\lambda_0|<\frac{d_0}{2} \tag{4.13}$$

and by convention

$$S^0=-P_0. \tag{4.14}$$

Taking $K=\Gamma$ in Proposition IV.1, one obtains from (4.13) that for $|z-\lambda_0|<d_0/4$:

$$\|e^{\gamma\langle\cdot\rangle}S(z)e^{-\gamma\langle\cdot\rangle}\|\leqslant\frac{d_0}{d_0-2|\lambda_0-z|}\leqslant 2M,\quad \text{all}\ \ \gamma\in[0,\gamma_0]. \tag{4.15}$$

The main point about (4.12) is that all terms on its right-hand side contain at *least* one P_0; this together with the decay property (4.5) of P_0 and (4.15), which allows to propagate this decay in order to control the unboundedness of V, implies that E_j defined initially on $\mathcal{C}_0^\infty(\mathbb{R}^3)$ are bounded and their extensions by continuity satisfy (3.5) and (3.6). Consider now the problem of estimating $\|E_j\|$. Estimating as in the proof of Lemma IV.2, one can see directly that each term in (4.12) is bounded by

$$M^{j+1}\|V^j e^{-\gamma_0\langle\cdot\rangle}\|$$

so that

$$\|E_j\| \leq N(j) M^{j+1} \| V^j e^{-\gamma_0 \langle \cdot \rangle} \|, \tag{4.16}$$

where $N(j)$ is the number of terms on the right-hand side of (4.12). Unfortunately, due to the fact that $N(j)$ is at least of order $j!$ (4.16) is much weaker than the expected estimation; for example if $\beta = 1$ one expects $\|E_j\| \leq \text{const}\, e^j j!$ while (4.16) gives at best $\text{const}\, e^j (j!)^2$. In order to overcome this difficulty we shall write down yet another formula for E_j:

Lemma IV.3: For all $\beta \in \mathbb{R}$ and $u \in \mathcal{C}_0^\infty(\mathbb{R}^3)$:

$$E_j u = (-1)^j \frac{i}{2\pi} \int_{|z-\lambda_0| = d_0/4} \frac{1}{\lambda_0 - z} \sum_{k=0}^{j} (S(z)V)^k P_0 (V R_0(z))^{j-k} \mathrm{d}z\, u. \tag{4.17}$$

Proof: Formula (4.17) follows from (4.7) by using repeatedly the decomposition [see Kato (1980)]:

$$R_0(z) = \frac{P_0}{\lambda_0 - z} + S(z)$$

and remarking that due to the analyticity of $S(z)$;

$$\int_{|z-\lambda_0| = d_0/4} (S(z)V)^j S(z) \mathrm{d}z\, u = 0.$$

The advantage of (4.17) over (4.12) is clear: on one hand all terms on the right-hand side of (4.17) still contain one P_0 and on the other hand the number of terms is only $j+1$.

We are now ready to state one of the main results of this section.

Theorem IV.4: *Let β, γ_0, M, d_0 as given by (4.3) and (4.4) with $K = \{z \mid d_0/4 \leq |z - \lambda_0| \leq d_0/2\}$ and (4.11). Then the operators E_j, $j = 0,1,2,\ldots$ defined as extensions by continuity starting from any of the formulas, (4.7), (4.12), (4.17) have the following properties:*

$$E_0 = P_0, \tag{4.18}$$

$$E_j L^2(\mathbb{R}^3) \subset \mathcal{D}(H_0) \cap \mathcal{D}(V), \tag{4.19}$$

$$E_j = \sum_{l=0}^{j} E_l E_{j-l}, \tag{4.20}$$

$$[H_0, E_j] u = -[V, E_j] u \quad all \quad u \in \mathcal{D}(H_0) \cap \mathcal{D}(V), \tag{4.21}$$

and for any $g > 2M(\beta/e\gamma_0)^\beta$ there exist $E < \infty$, $F < \infty$ such that for $j = 1,2,\ldots$:

$$\|E_j\| \leq E g^j j^{\beta j}, \tag{4.22}$$

$$\|[V, E_j]\| \leq F g^{j+1} j^{\beta(j+1)}. \tag{4.23}$$

Proof: The property (4.19) can be read from (4.12) and then (4.20), (4.21) follows from (4.19) and Lemma IV.2.

Writing $(S_\gamma(z) \equiv e^{\gamma \langle \cdot \rangle} S(z) e^{-\gamma \langle \cdot \rangle})$,

$$(S(z)V)^k P_0 (V R_0(z))^{j-k} = S(z) V e^{-\gamma_0 \langle \cdot \rangle / j} S_{\gamma_0/j}(z) \cdots S_{[(k-1)\gamma_0]/j}(z) V e^{-\gamma_0 \langle \cdot \rangle / j} e^{k \gamma_0 \langle \cdot \rangle / j} P_0$$
$$\times e^{(j-k)\gamma_0 \langle \cdot \rangle / j} V e^{-\gamma_0 \langle \cdot \rangle / j} \ldots R_{0,(j-k-1)\gamma_0/j}(z) V e^{-\gamma_0 \langle \cdot \rangle / j} R_0(z),$$

from

$$\|Ve^{-\gamma_0\langle\cdot\rangle/j}\|^j=\|V^je^{-\gamma_0\langle\cdot\rangle}\|\leqslant\sup_{a>0}a^{\beta j}e^{-\gamma_0 a}=(\beta j/e\gamma_0)^{\beta j}, \tag{4.24}$$

(4.17), (4.15) and IV.1 one obtains

$$\|E_j\|\leqslant M(j+1)(2M)^j\left(\frac{\beta}{e\gamma_0}\right)^{\beta j}j^{\beta j}. \tag{4.25}$$

In a similar way,

$$\|[V,E_j]\|\leqslant(j+1)(2M)^{j+1}\left(\frac{\beta}{e\gamma_0}\right)^{(j+1)\beta}(j+1)^{\beta(j+1)}, \tag{4.26}$$

which together with (4.25) gives the needed estimates.

Remark 4.1: One can also prove estimations of the form (4.22) and (4.23) by recurrence using the identity (4.20) in the form:

$$E_j=P_0E_j+E_jP_0+\sum_{l=1}^{j-1}E_lE_{j-l} \tag{4.27}$$

and taking advantage of the extra P_0 in P_0E_j and E_jP_0 which allows one to use (4.7) instead of (4.12).

Remark 4.2: By Stirling's formula $j^{\beta j}\leqslant e^{\beta j}(j!)^\beta$ so (4.22), (4.23) can be rewritten as

$$\|E_j\|\leqslant E\tilde{g}^j(j!)^\beta, \tag{4.28}$$

$$\|[V,E_j]\|\leqslant F\tilde{g}^{j+1}((j+1)!)^\beta \tag{4.29}$$

with

$$\tilde{g}=2M(\beta/\gamma_0)^\beta.$$

Remark 4.3: As already said the result in Theorem IV.4 can be extended in a variety of situations as for example for Zeeman effect

$$H_\epsilon=(\mathbf{P}-\epsilon\mathbf{a})^2+V_0,\quad \mathbf{P}=-i\nabla$$

with (4.3) replaced by

$$|\mathbf{a}|+|\nabla\cdot\mathbf{a}|\leqslant\langle\mathbf{x}\rangle^\beta.$$

Also if $V_0(\mathbf{x})\to\infty$ as $|\mathbf{x}|\to\infty$ one can replace the decay factor $e^{-\gamma_0\langle\cdot\rangle}$ by a better one, e.g., in the "harmonic oscillator" case $V_0(\mathbf{x})\sim|\mathbf{x}|^2$ as $|\mathbf{x}|\to\infty$ one can take [see Hunziker (1988)] $e^{-\gamma_0\langle\cdot\rangle^2}$ instead of $e^{-\gamma_0\langle\cdot\rangle}$ and in this case the asymptotic estimations are in terms of $\|V^je^{-\gamma_0\langle\cdot\rangle^2}\|$. Notice also that even in the case (4.3) one can allow $|V(\mathbf{x})|\leqslant e^{\eta\langle\cdot\rangle}$ with η sufficiently small, but in this case only a finite number of E_j can be controlled.

Remark 4.4: There is another way of proving that E_j given by (4.12) satisfy (4.20) and (4.21) namely starting with a cutoff perturbation, $V_\lambda(\mathbf{x})=V(\mathbf{x})$ if $|V(\mathbf{x})|\leqslant\lambda$ and zero otherwise, for which (4.20) and (4.21) are true (since the series $P_{\epsilon,\lambda}=\Sigma_{j=0}^\infty\epsilon^jE_{j,\lambda}$ is convergent and satisfies $-\epsilon[P_{\epsilon,\lambda},V_\lambda]=[P_{\epsilon,\lambda},H_0]$, $P_{\epsilon,\lambda}=P_{\epsilon,\lambda}^2$) and then taking the limit $\lambda\to\infty$. Yet another proof can be found in Howland (1991).

The proof of Theorem IV.4 rests heavily on exponential decay of eigenfunctions [see (4.5)], that is on the fact that $\dim P_0<\infty$. We consider now the case $\dim P_0=\infty$ when (4.5) does not hold true. Still, as far as $\beta\leqslant 1$ [see (4.3)] one can find solutions of (3.4)–(3.6). More exactly:

Theorem IV.5: *Suppose* $d_0=\mathrm{dist}(\sigma_0,\sigma(H_0)\backslash\sigma_0)>0$, $D_0=\sup_{\lambda,\mu\in\sigma_0}<\infty$ *and*

$$\sup_{\mathbf{x}\in\mathbb{R}^3}|\nabla V(\mathbf{x})|\leqslant 1. \tag{4.30}$$

Then:

(i) E_j *given recurrently by*

$$E_0=P_0,$$

$$E_{j+1}=\frac{i}{2\pi}\oint_\Gamma R_0(z)\{P_0[V,E_j]Q_0-Q_0[V,E_j]P_0\}R_0(z)\mathrm{d}z+S_j-2P_0S_jP_0, \tag{4.31}$$

where

$$Q_0=1-P_0, \tag{4.32}$$

$$S_j=\sum_{k=1}^{k=j}E_kE_{j+1-k} \tag{4.33}$$

have the properties:

$$E_j\mathcal{D}(V)\subset\mathcal{D}(H_0)\cap\mathcal{D}(V), \tag{4.34}$$

$$\|E_j\|\leqslant g^j j!, \tag{4.35}$$

$$\|[V,E_{j-1}]\|\leqslant g^j j! \tag{4.36}$$

for some $g<\infty$ *and satisfy (3.4)–(3.6).*

(ii) Let P_ϵ *as given by (3.14), (3.9), and (3.22) with* $\alpha=1$. *Let* H_ϵ *be the [unique by Faris–Lavine theorem: see Reed and Simon (1978a)] self-adjoint extension of* $H_0+\epsilon V$ *defined on* $\mathcal{D}(H_0)\cap\mathcal{D}(V)$. *Then for sufficiently small* ϵ*:*

$$P_\epsilon\mathcal{D}(H_0)\cap\mathcal{D}(V)\subset\mathcal{D}(H_0)\cap\mathcal{D}(V) \tag{4.37}$$

and on $\mathcal{D}(H_0)\cap\mathcal{D}(V)$

$$\|[H_\epsilon,P_\epsilon]\|\leqslant\frac{K}{(g\epsilon)^{1/2}}\exp\left(-\frac{1}{g\epsilon}\right), \tag{4.38}$$

where K is an absolute constant.

Remark 4.5: In order to see why bounded E_j should however exist consider E_1u with $u\in\mathcal{C}_0^\infty(\mathbb{R}^3)$ as given by (4.7). Then

$$\begin{aligned}E_1u&=-\frac{i}{2\pi}\left(\oint_\Gamma R_0(z)VR_0(z)\mathrm{d}z\right)u\\&=-\frac{i}{2\pi}\left(\oint_\Gamma R_0^2(z)V\mathrm{d}z\right)u-\frac{i}{2\pi}\left(\oint_\Gamma R_0(z)[V,R_0(z)]\mathrm{d}z\right)u.\end{aligned} \tag{4.39}$$

Now for $u\in\mathcal{C}_0^\infty(\mathbb{R}^3)$,

$$[V,R_0(z)]u=iR_0(z)(\mathbf{P}\cdot\nabla V+\nabla V\cdot\mathbf{P})R_0(z)u \tag{4.40}$$

so the operator in the last term on the right-hand side of (4.39) is bounded. On the other hand, by residue theorem, the first term on the right-hand side of (4.39) vanishes. It follows that E_1 as given by (4.39) is bounded on $\mathcal{C}_0^\infty(\mathbb{R}^3)$ and then it has a bounded extension by continuity. In addition it follows that $E_1L^2(\mathbb{R}^3)\subset\mathcal{D}(H_0)$ and one can argue that (see the proof of Lemma 4.2) that $E_1\mathcal{D}(V)\subset\mathcal{D}(V)$. Actually one can prove the existence of E_j "rewriting" (4.7) in a form in which V enters only in multiple commutators $[V,[V\cdots[V,R_0(z)]\cdots]$. This is achieved by the construction of the adiabatic projections based on the theory of pseudodifferential operators [see Sjostrand (1993), Martinez and Nenciu (1995)] which gives yet another recurrence formula for E_j:

$$E_j=\frac{i}{2\pi}\oint_\Gamma q_j(z)\mathrm{d}z, \tag{4.41}$$

where

$$q_0(z)=R_0(z),\quad q_j(z)=R_0(z)[q_{j-1}(z),V]. \tag{4.42}$$

Let us stress once again that various formulas for E_j must coincide since the solution of (3.4)–(3.6) (as far as it exists and is bounded) is unique [see Nenciu (1993)].

Remark 4.6: Actually, the result in Theorem IV.5 holds true for all potentials satisfying (4.3) with $\beta\leqslant 1$ since such a potential can be written as the sum of a potential satisfying (4.30) with a bounded one.

Proof of Theorem IV.5: As already said Theorem 4.4 follows from the treatment of the Stark effect in Nenciu (1981), Nenciu and Nenciu (1981) combined with the adiabatic exponential estimations in Nenciu (1993), so we shall only outline the main points.

Consider the family of self-adjoint operators

$$H(s)=e^{isV}H_0e^{-isV}=(\mathbf{P}-is\nabla V)^2+V_0. \tag{4.43}$$

Let $\Gamma\subset\rho(H_0)$ be a contour of finite length enclosing σ_0. By regular perturbation theory, $(H(s)-z)^{-1}$ is, for all $z\in\Gamma$, analytic in s, in a strip around real axis and uniformly bounded there so we can apply the methods in Nenciu (1993). In the following lemma we collect some results from Nenciu (1993) in an appropriate form.

Lemma IV.6: (*i*) *Let*

$$P_0(s)=e^{isV}P_0e^{-isV},\quad R(s;z)\equiv(H(s)-z)^{-1}=e^{isV}(H_0-z)^{-1}e^{-isV}. \tag{4.44}$$

Then $E_j(s)$ *given by the reccurence formula*

$$E_{j+1}(s)=\frac{1}{2\pi}\oint_\Gamma R(s;z)\left\{P_0(s)\frac{\mathrm{d}}{\mathrm{d}s}E_j(s)Q_0(s)-Q_0(s)\frac{\mathrm{d}}{\mathrm{d}s}E_j(s)P_0(s)\right\}$$
$$\times R(s;z)\mathrm{d}z+S_j(s)-2P_0(s)S_j(s)P_0(s) \tag{4.45}$$

where

$$Q_0(s)=1-P_0(s), \tag{4.46}$$

$$S_j(s)=\sum_{k=1}^{k=j}E_k(s)E_{j+1-k}(s) \tag{4.47}$$

are the unique solution of

$$E_0(s)=e^{isV}P_0e^{-isV}\equiv P_0(s), \tag{4.48}$$

$$i\frac{\mathrm{d}}{\mathrm{d}s}E_j(s)=[H(s),E_{j+1}(s)], \tag{4.49}$$

$$E_j(s)=\sum_{k=0}^{k=j}E_k(s)E_{j-k}(s), \tag{4.50}$$

are norm differentiable, and satisfy

$$E_j(s)L^2(\mathbb{R}^3)\subset\mathcal{D}(H(s)), \tag{4.51}$$

$$\|E_j(s)\|\leqslant g^j j!, \quad \left\|\frac{d}{ds}E_j(s)\right\|\leqslant g^{j+1}(j+1)!, \tag{4.52}$$

for some $g<\infty$.

(*ii*) *Let* $P_\epsilon(s)$ *as given by (3.14), (3.9), and (3.22) with* $\alpha=1$. *Then* $P_\epsilon(s)$ *is norm differentiable*

$$P_\epsilon(s)L^2(\mathbb{R}^3)\subset\mathcal{D}(H(s)) \tag{4.53}$$

and there exists $\epsilon_0>0$ *such that for* $\epsilon\in[0,\epsilon_0]$:

$$\left\|\epsilon\frac{\mathrm{d}}{\mathrm{d}s}P_\epsilon(s)-[H(s),P_\epsilon(s)]\right\|\leqslant\frac{K}{(g\epsilon)^{1/2}}\exp\left(-\frac{1}{g\epsilon}\right), \tag{4.54}$$

where K *is an absolute constant.*

Let A be a bounded operator, such that $A(s)=e^{isV}Ae^{-isV}$ is norm differentiable. Then from Stone's theorem for $f\in\mathcal{D}(V)$ one has $Af\in\mathcal{D}(V)$ and

$$i\frac{\mathrm{d}}{\mathrm{d}s}A(s)f=e^{isV}[A,V]e^{-isV}f. \tag{4.55}$$

Notice that $[A,V]$ is bounded on $\mathcal{D}(V)$. Since $E_0(s)=e^{isV}P_0e^{-isV}$, from (4.45) and (4.55) it follows that $E_j(s)$ are of the form

$$E_j(s)=e^{isV}E_je^{-isV}, \tag{4.56}$$

where E_j have all the properties stated in Theorem IV.5.i.

By the same argument [see (3.14)]

$$P_\epsilon(s)=e^{isV}P_\epsilon e^{-isV}, \quad P_\epsilon\mathcal{D}(V)\subset\mathcal{D}(V), \tag{4.57}$$

and

$$i\epsilon\frac{\mathrm{d}}{\mathrm{d}s}P_\epsilon(s)=\epsilon e^{isV}[P_\epsilon,V]e^{-isV}, \tag{4.58}$$

which together with $P_\epsilon L^2(\mathbb{R}^3)\subset\mathcal{D}(H_0)$ and (4.54) finishes the proof of Theorem IV.5.

V. MAGNETIC SCHRÖDINGER OPERATORS: GAUGE INVARIANT PERTURBATION THEORY

The aim of this section (which can be read independently of the rest of the paper) is to point out how the gauge covariance can be used to control the singularitiy of perturbations given by magnetic fields which do not vanish (or decay very slowly) as $|\mathbf{x}|\to\infty$. In order not to obscure the

main ideas we shall consider here a particular case: a particle in $\mathbb{R}^3$, subjected to a magnetic field $\mathbf{b}(\mathbf{x})$, and an electric potential $V_0(\mathbf{x})$. Also the proofs of some technical lemmas in the following will be given at the end of the section.

Concerning the magnetic field, $\mathbf{b}(\mathbf{x})$, we suppose that

$$|\mathbf{b}(\mathbf{x})|+\sum_{j=1}^{d}|\partial_j\mathbf{b}(\mathbf{x})|\leqslant\langle\mathbf{x}\rangle^{\beta},\quad \beta\leqslant 0 \tag{5.1}$$

and for $V_0(\mathbf{x})$ as before, we suppose to be uniformly L^2_{loc}, i.e.,

$$\sup_{\mathbf{x}\in\mathbb{R}^3}\int_{|\mathbf{x}-\mathbf{y}|\leqslant 1}|V_0(\mathbf{y})|^2\mathrm{d}\mathbf{y}<\infty. \tag{5.2}$$

As is well known [see, e.g., Cycon *et al.* (1986)], for a large class of vector potentials, $\mathbf{a}(\mathbf{x})$, corresponding to $\mathbf{b}(\mathbf{x})$ and $\epsilon\in[0,\infty)$ the Hamiltonian

$$H_{\epsilon,\mathbf{a}}=(\mathbf{P}-\epsilon\mathbf{a})^2+V_0 \tag{5.3}$$

is essentially self-adjoint on $\mathcal{C}_0^{\infty}(\mathbb{R}^3)$ and we shall denote by the same symbol its self-adjoint closure. As before, the unperturbed Hamiltonian (i.e., $\epsilon=0$) is denoted by H_0,

$$H_0=\mathbf{P}^2+V_0. \tag{5.4}$$

The results in the following can be extended in many directions: arbitrary dimensions; more (locally) singular $\mathbf{b}(\mathbf{x})$ and $V(\mathbf{x})$; many particle systems; the presence of a fixed magnetic field which amounts to replacing in (4.4) $\mathbf{P}$ by $(\mathbf{P}-\mathbf{A}_0)$ where $\mathbf{A}_0(\mathbf{x})$ corresponds to a *fixed* magnetic field, $\mathbf{B}_0(\mathbf{x})$; Dirac operators, etc.

Suppose that H_0 has an isolated and bounded part, σ_0, of the spectrum, i.e.,

$$\sigma(H_0)=\sigma_0\cup\sigma_1,\quad \mathrm{dist}(\sigma_0,\sigma_1)=d>0 \tag{5.5}$$

and let P_0 be the spectral projection of H_0 corresponding to σ_0. The problem is to study the "deformation" of σ_0 and P_0 when $\epsilon\neq 0$, $\epsilon\to 0$. If β in (5.1) is less than -1 then there exist magnetic potentials which are uniformly bounded (e.g., the transversal gauge, see the following) there is nothing new to say since in that case

$$H_{\epsilon,\mathbf{a}}=H_0-\epsilon(\mathbf{P}\cdot\mathbf{a}-\mathbf{a}\cdot\mathbf{P}+\epsilon^2|\mathbf{a}|^2)\equiv H_0-\epsilon W_{\epsilon,\mathbf{a}}, \tag{5.6}$$

where $W_{\epsilon,\mathbf{a}}$ is a regular perturbation of H_0 and the analytic perturbation theory works.

On the contrary, if in (5.1), $\beta\geqslant -1$ it is not possible in general to find $\mathbf{a}$ which is uniformly bounded and this implies that $W_{\epsilon,\mathbf{a}}(H_0-z)^{-1}$ is not bounded so one cannot obtain an expansion in ϵ of $(H_{\epsilon,\mathbf{a}}-z)^{-1}$ from

$$(H_{\epsilon,\mathbf{a}}-z)(H_0-z)^{-1}=1-\epsilon W_{\epsilon,\mathbf{a}}(H_0-z)^{-1}. \tag{5.7}$$

If $\sigma_0\subset\sigma_{\mathrm{discr}}(H_0)$ the asymptotic perturbation theory developed in previous sections works for all $\beta\in\mathbb{R}$ and gives asymptotic expansions for perturbed eigenvalues and corresponding eigenvectors. The situation is more involved when σ_0 is not contained in the discrete spectrum of H_0. On the one hand for $\beta\leqslant 0$, i.e., for magnetic fields which are uniformly bounded, it has been proved by Avron and Simon (1985) in a particular case and by Nenciu (1986) and Helffer and Sjostrand (1989) in the general case that the spectrum (as a set) is stable and then for sufficiently small ϵ one can still define the spectral projection $P_{\epsilon,\mathbf{a}}$ of $H_{\epsilon,\mathbf{a}}$ corresponding to the part of $\sigma(H_{\epsilon,\mathbf{a}})$ coinciding with σ_0 in the limit $\epsilon\to 0$. Now the singularity of the perturbation manifests itself in the "nonsmooth" behavior of $P_{\epsilon,\mathbf{a}}$ as $\epsilon\to 0$; There are examples [see Nenciu (1991)] in solid state theory (i.e., V periodic and $\mathbf{b}$ constant) where

$$\lim_{\epsilon\to 0}\|P_{\epsilon,\mathbf{a}}-P_0\|=1 \tag{5.8}$$

(of course one still has $s-\lim_{\epsilon\to 0}P_{\epsilon,\mathbf{a}}=P_0$) so there is no room for a (norm) asymptotic expansion of $P_{\epsilon,\mathbf{a}}$. Since, in contrast to $\sigma(H_{\epsilon,\mathbf{a}})$, $P_{\epsilon,\mathbf{a}}$ is not a gauge invariant quantity, the above-mentioned discussion suggests that, in general, the gauge invariant quantities behave much more smoothly in the limit $\epsilon\to 0$ than the nongauge invariant ones. In other words if one wants to develop a perturbation theory, one has to consider gauge invariant quantities. The problem is that, in almost all perturbation schemes, the basic object is the resolvent which is not a gauge invariant quantity.

Fortunately, one can ''factor'' out the nongauge invariant part. Let $G_{\epsilon,\mathbf{a}}(\mathbf{x},\mathbf{y};z)$, $z\in\rho(H_{\epsilon,\mathbf{a}})$ be the integral kernel (we shall prove in the following that it exists) of $(H_{\epsilon,\mathbf{a}}-z)^{-1}$ and $\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})$ be the famous nonintegrable phase factor corresponding to $\mathbf{a}$, i.e.,

$$\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})=\int_{\mathbf{y}}^{\mathbf{x}}\mathbf{a}(\mathbf{u})\cdot \mathrm{d}\mathbf{u}, \tag{5.9}$$

where the integral is along the straight line joining $\mathbf{x}$ and $\mathbf{y}$. Alternatively one can write (5.9) as

$$\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})=\left(\int_0^1\mathbf{a}(\mathbf{y}+t(\mathbf{x}-\mathbf{y}))\mathrm{d}t\right)\cdot(\mathbf{x}-\mathbf{y}). \tag{5.10}$$

Then as one can easily check

$$K_\epsilon(\mathbf{x},\mathbf{y};z)=e^{-i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})}G_{\epsilon,\mathbf{a}}(\mathbf{x},\mathbf{y};z) \tag{5.11}$$

is a gauge invariant quantity. In other words we have to make the ansatz

$$G_{\epsilon,\mathbf{a}}(\mathbf{x},\mathbf{y};z)=e^{i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})}K_\epsilon(\mathbf{x},\mathbf{y};z) \tag{5.12}$$

and seek a perturbation expansion for $K_\epsilon(\mathbf{x},\mathbf{y};z)$. The formula (5.12) is crucial for all that follows; it says that the whole gauge noninvariance of the integral kernel of the resolvent (and then for other related objects such as spectral projections, evolution, etc.) is contained in an exponential factor $e^{i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})}$. Coming back to perturbation theory, (5.12) suggests to take as the ''zeroth'' approximation for $(H_{\epsilon,\mathbf{a}}-z)^{-1}$ the operator $S_{\epsilon,\mathbf{a}}(z)$, given by the following integral kernel (''twisted'' unperturbed resolvent)

$$(S_{\epsilon,\mathbf{a}}(z)f)(\mathbf{x})=\int_{\mathbf{R}^3}e^{i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})}G_0(\mathbf{x},\mathbf{y};z)f(\mathbf{y})\mathrm{d}\mathbf{y}, \tag{5.13}$$

where $G_0(\mathbf{x},\mathbf{y};z)$ is the integral kernel of $(H_0-z)^{-1}$. Let us consider now (5.7) with $(H_0-z)^{-1}$ replaced by $S_{\epsilon,\mathbf{a}}(z)$ and define $T_{\epsilon,\mathbf{a}}(z)$ by

$$(H_{\epsilon,\mathbf{a}}-z)S_{\epsilon,\mathbf{a}}(z)=1-\epsilon T_{\epsilon,\mathbf{a}}(z). \tag{5.14}$$

Before computing $T_{\epsilon,\mathbf{a}}(z)$ let us give the following gauge covariance formula.

Lemma V.1: Let $\mathbf{a}(\mathbf{x})$ *be an arbitrary continuous vector potential corresponding to* $\mathbf{b}(\mathbf{x})$, $\mathbf{c}\in\mathbf{R}^3$ *and* $\phi_{\mathbf{a}}(\mathbf{x},\mathbf{c})$ *the corresponding nonintegrable phase factor. Then*

$$e^{-i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{c})}(\mathbf{P}_{\mathbf{x}}-\epsilon\mathbf{a}(\mathbf{x}))e^{i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{c})}=(\mathbf{P}_{\mathbf{x}}-\epsilon\mathbf{a}_{\mathbf{c}}(\mathbf{x})) \tag{5.15}$$

where $\mathbf{P}_{\mathbf{x}}=-i\nabla_{\mathbf{x}}$ *and* $\mathbf{a}_{\mathbf{c}}(\mathbf{x})$ *is the vector potential given by the transversal (Poincare) gauge relative to the point* $\mathbf{c}$*:*

$$\mathbf{a}_{\mathbf{c}}(\mathbf{x})=\left(\int_0^1 t\mathbf{b}(\mathbf{c}+t(\mathbf{x}-\mathbf{c}))\mathrm{d}t\right)\wedge(\mathbf{x}-\mathbf{c}). \tag{5.16}$$

Notice that $\mathbf{a_0}(\mathbf{x})$ is the usual transversal gauge [see Thaller (1992)]:

$$\mathbf{a_0}(\mathbf{x})=\left(\int_0^1 t\mathbf{b}(t\mathbf{x})\mathrm{d}t\right)\wedge\mathbf{x}. \tag{5.17}$$

The most interesting properties of $\mathbf{a_c}(\mathbf{x})$ and $\phi_{\mathbf{a_c}}(\mathbf{x},\mathbf{y})$ are given in the following:

Lemma V.2: (i)

$$\phi_{\mathbf{a_c}}(\mathbf{x},\mathbf{y})=-\left(\int_0^1 \mathrm{d}t\int_0^1 \mathrm{d}s\, s\mathbf{b}(st(\mathbf{x}-\mathbf{y})+s(\mathbf{y}-\mathbf{c}))\cdot((\mathbf{x}-\mathbf{c})\wedge(\mathbf{y}-\mathbf{c}))\right) \tag{5.18}$$

i.e., $\phi_{\mathbf{a_c}}(\mathbf{x},\mathbf{y})$ *is the flux through the triangle* **x c y**.

(ii)

$$|\mathbf{a_c}(\mathbf{x})|\leqslant|\mathbf{x}-\mathbf{c}|/2, \tag{5.19}$$

$$|\nabla\mathbf{a_c}(\mathbf{x})|\leqslant 2|\mathbf{x}-\mathbf{c}|. \tag{5.20}$$

(iii)

If $\mathbf{b}(\mathbf{x})=\mathbf{b}_0=\mathrm{const}$ *then*

$$\mathbf{a_c}(\mathbf{x})=\mathbf{b}_0\wedge(\mathbf{x}-\mathbf{c})/2, \tag{5.21}$$

$$\phi_{\mathbf{a_c}}(\mathbf{x},\mathbf{y})=-\mathbf{b}_0\cdot((\mathbf{x}-\mathbf{c})\wedge(\mathbf{y}-\mathbf{c}))/2. \tag{5.22}$$

Computing the right-hand side of (5.14) applied to $f\in\mathcal{C}_0^\infty(\mathbb{R}^3)$ by using Lemma V.1 one finds:

$$(T_{\epsilon,\mathbf{a}}(z)f)(\mathbf{x})=\int_{\mathbf{R}^3} e^{i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})}M_\epsilon(\mathbf{x},\mathbf{y};z)f(\mathbf{y})\mathrm{d}\mathbf{y}, \tag{5.23}$$

where

$$M_\epsilon(\mathbf{x},\mathbf{y};z)=(-2i\mathbf{a}_{\mathbf{y}}(\mathbf{x})\cdot\boldsymbol{\nabla}_{\mathbf{x}}-i(\nabla_{\mathbf{x}}\mathbf{a}_{\mathbf{y}}(\mathbf{x}))-\epsilon|\mathbf{a}_{\mathbf{y}}(\mathbf{x})|^2)G_0(\mathbf{x},\mathbf{y};z). \tag{5.24}$$

Notice that M_ϵ depends only upon **b**, i.e., is gauge invariant. Up to now the discussion was at the heuristic formal level. The main technical point of this section is contained in:

Theorem V.3: *Suppose: (5.1) and (5.2) hold true,* $z\in\rho(H_0)$, $\epsilon\in[0,\epsilon_0]$, $\epsilon_0<\infty$, $K\subset\rho(H_0)$ *compact. Then (5.23), (5.24) define a bounded operator in* $L^2(\mathbb{R}^3)$ *and there exist* $t(z)<\infty$ *(depending upon V,* **b***, and* ϵ_0 *but not upon* **a***) such that uniformly for* $\epsilon\in[0,\epsilon_0]$ *and* $z\in K$:

$$\|T_{\epsilon,\mathbf{a}}(z)\|\leqslant t(z). \tag{5.25}$$

As a direct consequence we obtain the following perturbation formula for $(H_{\epsilon,\mathbf{a}}-z)^{-1}$:

Lemma V.4: If $\epsilon\in[0,t(z)^{-1}]$ *then* $z\in\rho(H_{\epsilon,\mathbf{a}})$ *and*

$$(H_{\epsilon,\mathbf{a}}-z)^{-1}=S_{\epsilon,\mathbf{a}}(z)\sum_{j=0}^{\infty}\epsilon^j T_{\epsilon,\mathbf{a}}(z)^j \tag{5.26}$$

as a norm convergent series.

Combining (5.13), (5.23), and (5.26) one can write down the expansion for $K_\epsilon(\mathbf{x},\mathbf{y};z)$:

$$K_\epsilon(\mathbf{x},\mathbf{y};z)=G_0(\mathbf{x},\mathbf{y};z)+\sum_{j=1}^{\infty}\epsilon^j K_{\epsilon,j}(\mathbf{x},\mathbf{y};z), \tag{5.27}$$

where

$$K_{\epsilon,j}(\mathbf{x},\mathbf{y};z)=\int\cdots\int \mathrm{d}\mathbf{u}_1\mathrm{d}\mathbf{u}_2\cdots\mathrm{d}\mathbf{u}_j e^{i\epsilon\Phi(\mathbf{x},\mathbf{u}_1,\mathbf{u}_2\ldots\mathbf{u}_j,\mathbf{y})} \times G_0(\mathbf{x},\mathbf{u}_1;z)M_\epsilon(\mathbf{u}_1,\mathbf{u}_2;z)\cdots M_\epsilon(\mathbf{u}_j,\mathbf{y};z) \tag{5.28}$$

and

$$\Phi(\mathbf{x},\mathbf{u}_1,\mathbf{u}_2\ldots\mathbf{u}_j,\mathbf{y})=\phi_{\mathbf{a}}(\mathbf{y},\mathbf{u}_j)+\phi_{\mathbf{a}}(\mathbf{u}_j,\mathbf{u}_{j-1})+\cdots+\phi_{\mathbf{a}}(\mathbf{u}_1,\mathbf{x})+\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y}). \tag{5.29}$$

Notice that Φ is gauge invariant and is the flux through the polygonal contour $\mathbf{y}\mathbf{u}_j\mathbf{u}_{j-1}\ldots\mathbf{x}\mathbf{y}$. In terms of integral kernels, (5.26) rewrites as

$$G_{\epsilon,\mathbf{a}}(\mathbf{x},\mathbf{y};z)=e^{i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})}\left\{G_0(\mathbf{x},\mathbf{y};z)+\sum_{j=1}^{\infty}\epsilon^j K_{\epsilon,j}(\mathbf{x},\mathbf{y};z)\right\}. \tag{5.30}$$

Formulas (5.28) and (5.30) are the main result of this section.

Starting from (5.30), as in the analytic perturbations case, one can compute all physical quantities as convergent series in ϵ but with coefficients which depend themselves upon ϵ. For example, if $\sigma_0=\{\lambda_0\}$ where λ_0 is nondegenerate, then for sufficiently small ϵ the perturbed eigenvalue, $\lambda(\epsilon)$, has an expansion:

$$\lambda(\epsilon)=\sum_{j=0}^{\infty}\epsilon^j\lambda_{\epsilon,j},\quad |\lambda_{\epsilon,j}|\leqslant k^j \quad \text{for some } k<\infty. \tag{5.31}$$

The expressions for $\lambda_{\epsilon,j}$ can be obtained from

$$\lambda(\epsilon)=\mathrm{Tr}(H_{\epsilon,\mathbf{a}}P_{\epsilon,\mathbf{a}})=\mathrm{Tr}\frac{i}{2\pi}\oint_\Gamma z(H_{\epsilon,\mathbf{a}}-z)^{-1}\mathrm{d}z,$$

where Γ is a contour enclosing λ_0. Notice that [$\psi_0(\mathbf{x})$ is the eigenfunction of H_0 corresponding to λ_0]

$$\lambda_{\epsilon,0}=\frac{i}{2\pi}\int_{\mathbf{R}^3}\mathrm{d}\mathbf{x}\oint_\Gamma z\frac{|\psi_0(\mathbf{x})|^2}{\lambda_0-z}\mathrm{d}z=\lambda_0. \tag{5.32}$$

For $j\geqslant 1$, due to the fact that $K_{\epsilon,j}(\mathbf{x},\mathbf{x})$ is finite one can write

$$\lambda_{\epsilon,j}=\frac{i}{2\pi}\int_{\mathbf{R}^3}\mathrm{d}\mathbf{x}\oint_\Gamma zK_{\epsilon,j}(\mathbf{x},\mathbf{x};z)\mathrm{d}z. \tag{5.33}$$

In order to see that $\lambda_{\epsilon,j}$ as given by (5.33) are finite and satisfy (5.31) one has to plug the decomposition

$$R_0(z)=\frac{P_0}{\lambda_0-z}+S(z) \tag{5.34}$$

into (5.33), observe that the term containing no P_0 vanishes due to the contour integral and then use the exponential decay of the eigenfunction corresponding to λ_0. Further details and applications of Theorem V.3 will be given elsewhere.

The rest of this section is devoted to the proofs of Lemmas V.1 and V.2 and Theorem V.3.

Proof of Lemma V.1: By the usual computation

$$e^{-i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{c})}(\mathbf{P}_{\mathbf{x}}-\epsilon\mathbf{a}(\mathbf{x}))e^{i\epsilon\phi_{\mathbf{a}}(\mathbf{x},\mathbf{c})}=(\mathbf{P}_{\mathbf{x}}-\epsilon(\mathbf{a}(\mathbf{x})-\nabla\phi_{\mathbf{a}}(\mathbf{x},\mathbf{c})). \tag{5.35}$$

To compute $\nabla_{\mathbf{x}}\phi_{\mathbf{a}}$ one uses (5.10) and the vector analysis formula [see Spain (1965)]

$$\nabla(\mathbf{A}(\mathbf{x})\cdot\mathbf{B}(\mathbf{x}))=\mathbf{B}(\mathbf{x})\wedge(\nabla\wedge\mathbf{A}(\mathbf{x}))+\mathbf{A}(\mathbf{x})\wedge(\nabla\wedge\mathbf{B}(\mathbf{x}))+(\mathbf{B}(\mathbf{x})\cdot\nabla)\mathbf{A}(\mathbf{x})+(\mathbf{B}(\mathbf{x})\cdot\nabla)\mathbf{A}(\mathbf{x}) \tag{5.36}$$

with

$$\mathbf{A}(\mathbf{x})=\int_0^1\mathbf{a}(\mathbf{c}+t(\mathbf{x}-\mathbf{c}))\mathrm{d}t,$$

$$\mathbf{B}(\mathbf{x})=(\mathbf{x}-\mathbf{c}).$$

One obtains four terms; the first one gives $-\mathbf{a}_{\mathbf{c}}(\mathbf{x})$, the second vanishes, and the fourth gives $\int_0^1\mathbf{a}(\mathbf{c}+t(\mathbf{x}-\mathbf{c}))\mathrm{d}t$. Observing that

$$t\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{a}(\mathbf{c}+t(\mathbf{x}-\mathbf{c}))=((\mathbf{x}-\mathbf{c})\cdot\nabla_{\mathbf{x}})\mathbf{a}(\mathbf{c}+t(\mathbf{x}-\mathbf{c}))$$

the third term gives $\int_0^1 t\,(\mathrm{d}/\mathrm{d}t)\,\mathbf{a}(\mathbf{c}+t(\mathbf{x}-\mathbf{c}))\mathrm{d}t$ and then, after integration by parts $\mathbf{a}(\mathbf{x})-\int_0^1\mathbf{a}(\mathbf{c}+t(\mathbf{x}-\mathbf{c}))\mathrm{d}t$. Summing up all the terms one obtains (5.15).

Proof of Lemma V.2: The only thing to be proved is (5.18) since (5.19)–(5.22) can be read directly from (5.10),(5.16), and (5.1). Now (5.18) follows, either directly by direct computation from (5.10), and (5.16) or from Stokes's theorem by observing that

$$\int_{\mathbf{c}}^{\mathbf{x}}\mathbf{a}_{\mathbf{c}}(\mathbf{u})\cdot\mathrm{d}\mathbf{u}=\int_{\mathbf{c}}^{\mathbf{y}}\mathbf{a}_{\mathbf{c}}(\mathbf{u})\cdot\mathrm{d}\mathbf{u}=0.$$

Proof of Theorem V.3: We have to estimate $M_{\epsilon}(\mathbf{x},\mathbf{y};z)$. The key fact is that [see (5.19) and (5.20)] $\mathbf{a}_{\mathbf{y}}(\mathbf{x})$ and $\nabla_{\mathbf{x}}\cdot\mathbf{a}_{\mathbf{y}}(\mathbf{x})$ diverge only when $|\mathbf{x}-\mathbf{y}|\to\infty$ and this divergence is canceled by the decay of $G_0(\mathbf{x},\mathbf{y};z)$ and $\nabla_{\mathbf{x}}\cdot G_0(\mathbf{x},\mathbf{y};z)$ as given by the following proposition which is the pointwise analog of Proposition IV.1.

Proposition V.5: (i) For all $z\in\rho(H_0)$, $(H_0-z)^{-1}$ is a Carleman operator; in particular it has an integral kernel $G_0(\mathbf{x},\mathbf{y};z)$.

(ii) Let $K\subset\rho(H_0)$ be compact. Then there exist $C<\infty$, $\gamma>0$ such that uniformly in $z\in K$:

$$|G_0(\mathbf{x},\mathbf{y};z)|\leqslant\frac{C}{|\mathbf{x}-\mathbf{y}|}e^{-\gamma|\mathbf{x}-\mathbf{y}|}, \tag{5.37}$$

$$|\nabla_{\mathbf{x}}G_0(\mathbf{x},\mathbf{y};z)|\leqslant\frac{C}{|\mathbf{x}-\mathbf{y}|^2}e^{-\gamma|\mathbf{x}-\mathbf{y}|}. \tag{5.38}$$

From

$$\sup_{r>0}r^m e^{-\nu r}=M(m,\nu)<\infty,\quad m\geqslant 0,\nu>0, \tag{5.39}$$

(5.19), (5.20), (5.37), (5.38), and (5.24) one obtains that uniformly for $\epsilon\in[0,\epsilon_0]$, $z\in K$,

$$|M_{\epsilon}(\mathbf{x},\mathbf{y};z)|\leqslant\mathrm{const}\frac{1}{|\mathbf{x}-\mathbf{y}|}e^{-\gamma|\mathbf{x}-\mathbf{y}|/2} \tag{5.40}$$

and then by Young inequality

$$\|T_\epsilon f\| \leqslant \text{const}\left(\int_{\mathbb{R}^3} \frac{e^{-\gamma|\mathbf{x}|/2}}{|\mathbf{x}|} d\mathbf{x} \right) \|f\| \tag{5.41}$$

and the proof is finished.

Proof of Proposition V.5: The proposition follows from the results in Simon (1982), so we shall only outline the proof. The fact that $(H_0-z)^{-1}$ is a Carleman operator follows from the fact that V_0 is $-\Delta$ bounded and then $(H_0-z)^{-1} \in \mathcal{B}(L^2(\mathbb{R}^3), L^\infty(\mathbb{R}^3))$ [see Corollary A.1.2 in Simon (1982)]. The inequality (5.37) follows from Theorem B 7.2. in Simon (1982) [actually Theorem B 7.2. in Simon (1982) is stated for a fixed z but the proof covers the given case].

For $z=-a$, $a>0$ and sufficiently large

$$G_0(\mathbf{x},\mathbf{y};-a) = \frac{1}{4\pi|\mathbf{x}-\mathbf{y}|} e^{-a^{1/2}|\mathbf{x}-\mathbf{y}|} - \int_{\mathbb{R}^3} \frac{1}{4\pi|\mathbf{x}-\mathbf{u}|} e^{-a^{1/2}|\mathbf{x}-\mathbf{u}|} V(u) G_0(\mathbf{u},\mathbf{y};-a) \mathrm{d}\mathbf{u} \tag{5.42}$$

and then

$$\nabla_{\mathbf{x}} G_0(\mathbf{x},\mathbf{y};-a) = \nabla_{\mathbf{x}} \left(\frac{1}{4\pi|\mathbf{x}-\mathbf{y}|} e^{-a^{1/2}|\mathbf{x}-\mathbf{y}|} \right) - \int_{\mathbb{R}^3} \nabla_{\mathbf{x}} \left(\frac{1}{4\pi|\mathbf{x}-\mathbf{u}|} e^{-a^{1/2}|\mathbf{x}-\mathbf{u}|} \right) V(u) G_0(\mathbf{u},\mathbf{y};-a) \mathrm{d}\mathbf{u}, \tag{5.43}$$

which gives (5.38) for $z=-a$. Finally (5.38) is ''carried'' from $-a$ to $z \in K$ via the resolvent equation

$$\nabla_{\mathbf{x}} G_0(\mathbf{x},\mathbf{y};z) = \nabla_{\mathbf{x}} G_0(\mathbf{x},\mathbf{y};-a) \tag{5.44}$$

$$+ (z+a) \int_{\mathbb{R}^3} \nabla_{\mathbf{x}} G_0(\mathbf{x},\mathbf{u};-a) G_0(\mathbf{u},\mathbf{y};z) \mathrm{d}\mathbf{u}. \tag{5.45}$$

ACKNOWLEDGMENTS

The first draft of this paper was written during a one month participation to the program ''Magnetic Fields and Schrödinger Equation'' at E.S.I. Vienna. It is a pleasure to thank T. Hoffmann-Ostenhof for making the visit possible. Also the financial support from E.S.I. and from Romanian Ministry of Education (Grant No. CNCSU 13C) is acknowledged.

APPENDIX: ALMOST IDEMPOTENT OPERATORS

Although the Proposition 3 in Nenciu (1993) provides the needed construction we shall give below a more aesthetical form of it.

Let P be a bounded idempotent. Then [see, e.g., Kato (1980), Chap. III.4] $\mathcal{H}=\mathcal{M}+\mathcal{N}$ such that if $f=m+n$, $m \in \mathcal{M}$, $n \in \mathcal{N}$ then $Pf=m$, i.e., P is a projection. By direct computation

$$(P-z)(P+z-1) = z(z-1),$$

which in particular implies that $\sigma(P)=\{0,1\}$. Moreover it gives the following formula for the resolvent of P:

$$(P-z)^{-1} = \frac{(P+z-1)}{z(1-z)}.$$

Let T now be bounded and ''almost'' idempotent (but not necessarily self-adjoint). The problem is whether T is close to an idempotent.

Proposition VI.1: Let T be a bounded operator, $\Delta = T^2 - T$.

Then for $\|\Delta\| \equiv \delta \leqslant 1/4$ *one has* $\{|z-1|=1/2\} \subset \rho(T)$ *and*

$$\|T-P\| \leqslant \frac{4\delta(2\|T\|+1)}{1-4\delta},$$

where

$$P = \frac{i}{2\pi} \oint_{|z-1|=1/2} (T-z)^{-1}\, dz.$$

Proof: By direct computation,

$$(T-z)(T+z-1) = z(1-z)[1+\Delta/z(1-z)]$$

whereof for $\|\Delta\|/|z(z-1)| < 1$

$$(T-z)^{-1} = \frac{T+z-1}{z(1-z)}\left[1+\frac{\Delta}{z(1-z)}\right]^{-1} = \left(\frac{T}{z(1-z)} - \frac{1}{z}\right)\left[1 - \frac{\Delta}{z(1-z)}\left(1+\frac{\Delta}{z(1-z)}\right)^{-1}\right],$$

whereof for $\delta < 1/4$

$$P - T = -\Delta \frac{i}{2\pi} \oint_{|z-1|=1/2} \frac{1}{z(1-z)}\left(\frac{T}{z(1-z)} - \frac{1}{z}\right)\left(1+\frac{\Delta}{z(1-z)}\right)^{-1} dz, \tag{A1}$$

which gives the result.

Remark 6.1: If T is self-adjoint then P is also self-adjoint.

Remark 6.2: By performing the integral in the last equation by using the residue theorem one can show that

$$P - T = (T-1/2)[(1+4\Delta)^{-1/2} - 1],$$

which gives the estimation

$$\|P-T\| \leqslant \frac{2\delta(2\|T\|+1)}{1-4\delta}, \tag{A2}$$

which is better than the result in Proposition VI.1 by a factor of 2.

On the structure of covariant phase observables

Juha-Pekka Pellonpää[a)]
University of Turku, Department of Physics, 20014 Turku, Finland

(Received 24 August 2001; accepted for publication 7 December 2001)

We study the mathematical structure of covariant phase observables. Such observables can alternatively be expressed as phase matrices, as sequences of unit vectors, as sequences of phase states, or as equivalence classes of covariant trace-preserving operations. Covariant generalized operator measures are defined by structure matrices which form a W*-algebra with phase matrices as its subset. The properties of the Radon–Nikodým derivatives of phase probability measures are studied.
 [DOI: 10.1063/1.1446663]

I. INTRODUCTION

Covariant phase observables constitute a particular solution to the problem of quantum phase (see, e.g., Ref. 1, and 2). In this article, we study general mathematical properties of covariant phase observables and represent them as covariant trace-preserving operations (Sec. III). We also analyze the structure matrix W*-algebra of covariant generalized operator measures (Sec. IV) and the pointwise convergence of phase probability densities (Sec. V)

Let $\mathcal{H}$ be a complex Hilbert space with a fixed basis $\{|n\rangle \in \mathcal{H} \mid n \in \mathbb{N}\}$. Define the number operator $N := \Sigma_{n=0}^{\infty} n|n\rangle\langle n|$ with its usual domain $\mathcal{D}(N) := \{\psi \in \mathcal{H} \mid n^2 |\langle n|\psi\rangle|^2 < \infty\}$ and the phase shifter $R(\theta) := e^{i\theta N}$ for all $\theta \in \mathbb{R}$. Let $\mathcal{L}(\mathcal{H})$, $\mathcal{T}(\mathcal{H})$, and $\mathcal{T}(\mathcal{H})_1^+$ denote the sets of bounded operators, trace-class operators, and states (positive trace-one operators) on $\mathcal{H}$, respectively.

Let $\mathcal{B}([0,2\pi))$ denote the σ-algebra of the Borel subsets of $[0,2\pi)$, and consider an operator measure $E: \mathcal{B}([0,2\pi)) \to \mathcal{L}(\mathcal{H})$. The measure E is normalized if $E([0,2\pi)) = I$, positive if $E(X) \geqslant O$ for all $X \in \mathcal{B}([0,2\pi))$, and phase shift covariant if $R(\theta)E(X)R(\theta)^* = E(X \oplus \theta)$ for all $X \in \mathcal{B}([0,2\pi))$ and for all $\theta \in [0,2\pi)$, where $X \oplus \theta := \{x \in [0,2\pi) \mid (x-\theta) (\mathrm{mod}\ 2\pi) \in X\}$. A phase shift covariant normalized positive operator measure is called a *(covariant) phase observable*.

In the next section we collect some known properties of covariant phase observables. The new results are contained in Secs. III–V.

II. THE STRUCTURE OF PHASE OBSERVABLES

Any covariant phase observable is of the (weakly convergent) form

$$E(X) = \sum_{n,m=0}^{\infty} c_{n,m} i_{n-m}(X) |n\rangle\langle m|, \quad X \in \mathcal{B}([0,2\pi)), \tag{1}$$

where $i_k(X) := (2\pi)^{-1} \int_X e^{ik\theta} \mathrm{d}\theta$ for all $k \in \mathbb{Z}$, and where the phase matrix $(c_{n,m})_{n,m \in \mathbb{N}}$ is a positive semidefinite (complex) matrix with $c_{n,n} = 1$, $n \in \mathbb{N}$ (see, e.g., Phase Theorem 2.2 of Ref. 2). A complex matrix $(c_{n,m})$ is a phase matrix if and only if there exists a sequence $(\psi_n)_{n \in \mathbb{N}}$ of unit vectors such that $c_{n,m} = \langle \psi_n | \psi_m \rangle$, $n, m \in \mathbb{N}$.[3] A constant sequence, e.g., $\psi_n = |0\rangle$, $n \in \mathbb{N}$, defines the *canonical phase observable*

$$E_{\mathrm{can}}(X) := \sum_{n,m=0}^{\infty} i_{n-m}(X) |n\rangle\langle m|, \quad X \in \mathcal{B}([0,2\pi)),$$

a)Electronic mail: juhpello@utu.fi

whereas any orthonormal sequence, e.g., $\psi_n=|n\rangle$, $n\in\mathbb{N}$, gives the *trivial phase observable*

$$E_{\mathrm{triv}}(X):=i_0(X)\,I,\quad X\in\mathcal{B}([0,2\pi)).$$

Next we show how any phase observable can be constructed by using a sequence of phase states (Theorem 2).

Define $\mathcal{H}_1:=\{\psi\in\mathcal{H}\mid\Sigma_{n=0}^{\infty}|\langle n|\psi\rangle|<\infty\}$. A phase matrix $(c_{n,m})$ can be interpreted as a phase kernel, that is, a positive (possible unbounded in the norm of $\mathcal{H}$) sequilinear form $C:\mathcal{H}_1\times\mathcal{H}_1\to\mathbb{C}$ defined as

$$C(\varphi,\psi):=\sum_{n,m=0}^{\infty}c_{n,m}\langle\varphi|n\rangle\langle m|\psi\rangle,\quad\varphi,\psi\in\mathcal{H}_1,$$

where the sum converges absolutely. Keeping this in mind, we may formally write

$$C=\sum_{n,m=0}^{\infty}c_{n,m}|n\rangle\langle m|.$$

Since $R(\theta)\mathcal{H}_1=\mathcal{H}_1$ for all $\theta\in[0,2\pi)$ we can define a continuous integrable function $[0,2\pi]\to\mathbb{C}$,

$$\theta\mapsto C(R(-\theta)\varphi,R(-\theta)\psi)=\sum_{n,m=0}^{\infty}c_{n,m}e^{i(n-m)\theta}\langle\varphi|n\rangle\langle m|\psi\rangle,$$

for all $\varphi,\psi\in\mathcal{H}_1$, and thus a bounded positive sesquilinear form $\mathcal{H}_1\times\mathcal{H}_1\to\mathbb{C}$,

$$(\varphi,\psi)\mapsto E(X)_{\varphi,\psi}:=\frac{1}{2\pi}\int_X C(R(-\theta)\varphi,R(-\theta)\psi)\mathrm{d}\theta=\sum_{n,m=0}^{\infty}c_{n,m}i_{n-m}(X)\langle\varphi|n\rangle\langle m|\psi\rangle,$$

for all $X\in\mathcal{B}([0,2\pi))$.[4] The form $(\varphi,\psi)\mapsto E(X)_{\varphi,\psi}$ has a unique bounded positive extension to $\mathcal{H}\times\mathcal{H}$ which is determined by a unique bounded operator, say, $E(X)\in\mathcal{L}(\mathcal{H})$. Operators $E(X)$, $X\in\mathcal{B}([0,2\pi))$, constitute a covariant phase observable. The following route to define a phase observable is thus justified:

(1) Take a phase matrix $(c_{n,m})$ and define the phase kernel $\Sigma_{n,m=0}^{\infty}c_{n,m}|n\rangle\langle m|$.

(2) Act on it by $R(\theta)$ to get

$$R(\theta)\sum_{n,m=0}^{\infty}c_{n,m}|n\rangle\langle m|R(\theta)^*=\sum_{n,m=0}^{\infty}c_{n,m}e^{i(n-m)\theta}|n\rangle\langle m|.$$

(3) Integrate it over $X\in\mathcal{B}([0,2\pi))$ to get a bounded sesquilinear form $\mathcal{H}_1\times\mathcal{H}_1\to\mathbb{C}$,

$$\frac{1}{2\pi}\int_X R(\theta)\sum_{n,m=0}^{\infty}c_{n,m}|n\rangle\langle m|R(\theta)^*\mathrm{d}\theta=\sum_{n,m=0}^{\infty}c_{n,m}i_{n-m}(X)|n\rangle\langle m|.$$

(4) This has a unique bounded extension $\mathcal{H}\times\mathcal{H}\to\mathbb{C}$ which defines the phase observable

$$E(X):=\sum_{n,m=0}^{\infty}c_{n,m}i_{n-m}(X)|n\rangle\langle m|.$$

Let $\mathcal{H}_\infty$ be a complex Banach space of vectors $\Sigma_{n=0}^{\infty}g_n|n\rangle$ for which the norm $\|\Sigma_{n=0}^{\infty}g_n|n\rangle\|_\infty:=\sup\{|g_n|\mid n\in\mathbb{N}\}<\infty$.[5] Embedding $\mathcal{H}$ in $\mathcal{H}_\infty$ we get the following triplet:

$$\mathcal{H}_1\subset\mathcal{H}\subset\mathcal{H}_\infty.$$

We have the following theorem.[6]

Theorem 1: *For any phase matrix* $(c_{n,m})$,

$$\sum_{n,m=0}^{\infty} c_{n,m}\langle\varphi|n\rangle\langle m|\psi\rangle=\sum_{k=0}^{\infty}\langle\varphi|F_k)(F_k|\psi\rangle,$$

for all $\varphi,\ \psi\in\mathcal{H}_1$, *that is, briefly,*

$$\sum_{n,m=0}^{\infty} c_{n,m}|n\rangle\langle m|=\sum_{k=0}^{\infty}|F_k)(F_k|,$$

where $|F_k)\in\mathcal{H}_\infty$ *for all* $k\in\mathbb{N}$ *and* $\Sigma_{k=0}^{\infty}|\langle n|F_k)|^2=1$ *for all* $n\in\mathbb{N}$. *Conversely, if* $(|F_k))_{k\in\mathbb{N}}\subset\mathcal{H}_\infty$ *is such that* $\Sigma_{k=0}^{\infty}|\langle n|F_k)|^2=1$, *then* $\Sigma_{k=0}^{\infty}|F_k)(F_k|$ *is a phase kernel.*

Let $|F)\in\mathcal{H}_\infty$ and define $|F;\theta):=R(\theta)|F)$ and $(F;\theta|:=(F|R(\theta)^*$ for all $\theta\in\mathbb{R}$. Since $R(\theta')|F;\theta)=|F;\theta+\theta')$ we say that $|F;\theta)$ is a *phase state*. It is easy to see that the following sesquilinear form $\mathcal{H}_1\times\mathcal{H}_1\to\mathbb{C}$,

$$(\varphi,\psi)\mapsto\frac{1}{2\pi}\int_X\langle\varphi|F;\theta)(F;\theta|\psi\rangle\mathrm{d}\theta,$$

is positive and bounded for all $X\in\mathcal{B}([0,2\pi))$ and it defines a covariant positive operator measure

$$\mathcal{B}([0,2\pi))\ni X\mapsto E_F(X)=\sum_{n,m=0}^{\infty}\langle n|F)(F|m\rangle i_{n-m}(X)|n\rangle\langle m|\in\mathcal{L}(\mathcal{H}). \tag{2}$$

The operator measure E_F is normalized, that is, a phase observable, if and only if $|\langle n|F)|=1$ for all $n\in\mathbb{N}$, that is, when

$$|F)=\sum_{n=0}^{\infty}e^{i\upsilon_n}|n\rangle,$$

where $(\upsilon_n)_{n\in\mathbb{N}}\subset[0,2\pi)$. Let $U:=\Sigma_{n=0}^{\infty}e^{i\upsilon_n}|n\rangle\langle n|$. Then E_F is a phase observable if and only if

$$E_F(X)=UE_{\mathrm{can}}(X)U^*,\quad X\in\mathcal{B}([0,2\pi)).$$

If, for two phase observables E_1 and E_2, the condition $E_1(X)=UE_2(X)U^*$, $X\in\mathcal{B}([0,2\pi))$, holds, we say that E_1 is E_2 up to unitary equivalence, or, briefly, E_1 is E_2 (u.e.). Thus, using Theorem 1 we get a variant of Phase Theorem 2.2 of Ref. 2.

Theorem 2: *E is a phase observable if and only if for all* $X\in\mathcal{B}([0,2\pi))$

$$E(X)=\mathrm{w}\text{-}\lim_{n\to\infty}\sum_{k=0}^{n}E_{F_k}(X),$$

where $E_{F_k}(X)$ *is the bounded operator defined by a sesquilinear form*

$$\frac{1}{2\pi}\int_X|F_k;\theta)(F_k;\theta|\mathrm{d}\theta,$$

where $|F_k)\in\mathcal{H}_\infty$, $k\in\mathbb{N}$, *and* $\Sigma_{k=0}^{\infty}|\langle n|F_k)|^2=1$.

The phase observable E is defined by a single phase state if and only if E is E_{can} *(u.e.).*

Since the sequence $n\mapsto\Sigma_{k=0}^{n}E_{F_k}(X)$ is increasing, $E(X)=\text{s-}\lim_{n\to\infty}\Sigma_{k=0}^{n}E_{F_k}(X)$ also.

III. PHASE OBSERVABLES AS OPERATIONS

A linear mapping $\Phi:\mathcal{T}(\mathcal{H})\to\mathcal{T}(\mathcal{H})$ is a *covariant trace-preserving operation* if it is covariant $[R(\theta)\Phi(T)R(\theta)^*=\Phi(R(\theta)TR(\theta)^*),\quad \theta\in[0,2\pi),\quad T\in\mathcal{T}(\mathcal{H})]$, trace-preserving $[\mathrm{tr}(\Phi(T))=\mathrm{tr}(T),\ T\in\mathcal{T}(\mathcal{H})]$, and positive $[\Phi(\mathcal{T}(\mathcal{H})_1^+)\subseteq\mathcal{T}(\mathcal{H})_1^+]$ (for the theory of operations, see e.g., Refs. 7 and 8). We prove next a theorem essentially due to Hall and Fuss.[9,10]

Theorem 3: *A mapping* $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ *is a phase observable if and only if*

$$\mathrm{tr}(TE(X))=\mathrm{tr}(\Phi(T)E_{\mathrm{can}}(X)) \tag{3}$$

for all $X\in\mathcal{B}([0,2\pi))$ *and* $T\in\mathcal{T}(\mathcal{H})$ *where* $\Phi:\mathcal{T}(\mathcal{H})\to\mathcal{T}(\mathcal{H})$ *is a covariant trace-preserving operation.*

Proof: Let E be a phase observable with the phase matrix $(c_{n,m})$. For all $T\in\mathcal{T}(\mathcal{H})$ define

$$\Theta(T):=\sum_{n,m=0}^{\infty}c_{m,n}T_{n,m}|n\rangle\langle m|. \tag{4}$$

Since $T=\alpha T_\alpha-\beta T_\beta+i\gamma T_\gamma-i\delta T_\delta$ where T_α, T_β, T_γ, and T_δ are states, and α, β, γ, and δ are non-negative real numbers, it suffices to consider only states. Thus, assume that T is a state. Since $\sup\{|\langle\varphi|\Theta(T)\psi\rangle|\,|\,\|\varphi\|\leqslant1,\|\psi\|\leqslant1\}\leqslant\sup\{\Sigma_{n,m=0}^{\infty}|T_{n,m}|\,|\langle\varphi|n\rangle|\,|\langle m|\psi\rangle|\,|\,\|\varphi\|\leqslant1,\|\psi\|\leqslant1\}\leqslant1$ it follows that $\Theta(T)$ is a bounded operator. Using a decomposition $T=\Sigma_{j=0}^{\infty}|\phi_j\rangle\langle\phi_j|$, $\phi_j\in\mathcal{H}$, $j\in\mathbb{N}$, one sees that $\langle\psi|\Theta(T)\psi\rangle=\Sigma_{j=0}^{\infty}\Sigma_{n,m=0}^{\infty}\overline{\langle m|\phi_j\rangle\langle\psi|m\rangle}c_{m,n}\langle n|\phi_j\rangle\langle\psi|n\rangle\geqslant0$ for all $\psi\in\mathcal{H}_1$ and, thus, Θ is positive. Since $\Sigma_{n=0}^{\infty}\langle n|\Theta(T)|n\rangle=1$, $\Theta(T)$ is a trace-one operator. Moreover, $\mathrm{tr}(TE(X))=\mathrm{tr}(\Theta(T)E_{\mathrm{can}}(X))$, $X\in\mathcal{B}([0,2\pi))$, and Θ is covariant. Thus, Θ is a covariant trace-preserving operation. The converse part is trivial. □

There are many covariant trace-preserving operations Φ which satisfy Eq. (3) for a given E. One such operation Θ is defined in (4). It is the identity operation in the case of the canonical phase whereas for the trivial phase it is of the form $\Theta(T)=\Sigma_{n=0}^{\infty}T_{n,n}|n\rangle\langle n|$. We note also that, in the case of the trivial phase, $T\mapsto T_{0,0}|1\rangle\langle1|+T_{1,1}|0\rangle\langle0|+\Sigma_{n=2}^{\infty}T_{n,n}|n\rangle\langle n|$ is another operation fulfilling Theorem 3. Since the diagonal elements $T_{n,n}$ do not "contain" any phase information of the state T we see that the trivial phase "loses" all phase information. In the general case, if $c_{n,m}=0$ for some $n\neq m$, there are vector states (other than number states) $\psi:=d_n|n\rangle+d_m|m\rangle$, d_n, $d_m\in\mathbb{C}\backslash\{0\}$, $|d_n|^2+|d_m|^2=1$, for which the probability measure $X\mapsto\langle\psi|E(X)\psi\rangle$ is random. Next we study the properties of Θ.

Let E be a phase observable with the phase matrix $(c_{n,m})$, and let $\Theta(T)=\Sigma_{n,m=0}^{\infty}c_{m,n}T_{n,m}|n\rangle\langle m|$ for all $T\in\mathcal{T}(\mathcal{H})$. The dual mapping $\Theta^*:\mathcal{L}(\mathcal{H})\to\mathcal{L}(\mathcal{H})$ of an operation Θ defined by the relation $\mathrm{tr}(T\Theta^*(A))=\mathrm{tr}(\Theta(T)A)$, $A\in\mathcal{L}(\mathcal{H})$, $T\in\mathcal{T}(\mathcal{H})$, is a positive linear mapping, and

$$\Theta^*(A)=\sum_{n,m=0}^{\infty}c_{n,m}A_{n,m}|n\rangle\langle m|,\quad A\in\mathcal{L}(\mathcal{H}).$$

From Theorem 1 one gets (weakly)

$$\Theta(T)=\sum_{k=0}^{\infty}A_kTA_k^*,\quad T\in\mathcal{T}(\mathcal{H}),$$

where $A_k:=\Sigma_{n=0}^{\infty}(F_k|n\rangle)|n\rangle\langle n|$ for all $k\in\mathbb{N}$ showing that Θ is *completely positive* (see the First Representation Theorem of Ref. 8). Note that $\Sigma_{k=0}^{\infty}A_kA_k^*=I$ and $\Theta^*(A)=\Sigma_{k=0}^{\infty}A_k^*AA_k$, $A\in\mathcal{L}(\mathcal{H})$.

Let $\Theta_1^+:\mathcal{T}(\mathcal{H})_1^+\to\mathcal{T}(\mathcal{H})_1^+$ be the restriction of Θ to the set of states.

Theorem 4: (1) Θ *and* Θ_1^+ *are injections if and only if* $c_{n,m}\neq0$ *for all* $n,m\in\mathbb{N}$.

(2) Θ_1^+ *is surjection if and only if* E *is* E_{can} *(u.e.).*

(3) Θ_1^+ *is bijection if and only if* E *is* E_{can} *(u.e.).*

(4) Θ *preserves pure states* $[\Theta(|\psi\rangle\langle\psi|)^2=\Theta(|\psi\rangle\langle\psi|)$ *for all unit vectors* $\psi\in\mathcal{H}]$ *if and only if* E *is* E_{can} *(u.e.).*

Proof: It is easy to see that Θ and Θ_1^+ are injections if and only if $c_{m,n}T_{n,m}=0$ for all $n, m\in\mathbb{N}$ where $T\in\mathcal{T}(\mathcal{H})$ implies that $T=O$. Thus, Θ and Θ_1^+ are injections if and only if $c_{n,m}\neq 0$ for all n, m.

Suppose that Θ_1^+ is a surjection. If $c_{m,n}=0=c_{n,m}$ for some $n\neq m$, then $\Theta_1^+(T)\neq T':=(|n\rangle+|m\rangle)(\langle n|+\langle m|)/2$ for all $T\in\mathcal{T}(\mathcal{H})_1^+$ and, thus, $c_{n,m}\neq 0$ for all n, m and Θ_1^+ is an injection and bijection. If $|c_{n,m}|<1$ for some $n\neq m$, then there is no state T such that $\Theta_1^+(T)=T'$. Thus, $|c_{n,m}|=1$, $n, m\in\mathbb{N}$, and $E=E_{\mathrm{can}}$ (u.e.). This proves items (2) and (3).

Let $\psi:=\Sigma_{n=0}^{\infty}d_n|n\rangle$ where $d_n>0$ for all n and $\Sigma_{n=0}^{\infty}d_n^2=1$. Now $\Theta(|\psi\rangle\langle\psi|)^2=\Theta(|\psi\rangle\langle\psi|)$ implies that $\Sigma_{n=0}^{\infty}|c_{n,m}|^2d_n^2=1$ for all m which shows that $|c_{n,m}|=1$, $n, m\in\mathbb{N}$, and $E=E_{\mathrm{can}}$ (u.e.). This completes the proof. □

IV. COVARIANT GOMS AND PHASE MATRICES

The standard way to represent an observable in quantum mechanics is to find an appropriate self-adjoint operator, or an idempotent POM, which describes that observable. However, in many cases this representation is too narrow and it is convenient to give up the idempotency (see, e.g., Ref. 11). The strength of POMs is that they associate a probability measure to *all* states. If we restrict ourselves to a subset of (vector) states to be called physical states, we can give up the positivity of POM and require that the operator measure gives a probability measure (via trace formula) only for physical states. Actually, we do not have to assume that the observable can even be ''defined'' for other states than physical ones. Hence, define a set of physical states $\mathcal{V}$. It is a linear subspace of the Hilbert space of the physical system. The linearity is assumed because of the possibility to superpose the physical states. Let $\mathcal{SL}(\mathcal{V},\mathcal{V};\mathbb{C})$ be the set of sesquilinear forms from $\mathcal{V}\times\mathcal{V}$ to $\mathbb{C}$ (the first argument is antilinear). A *generalized operator measure*,[12] or a *GOM*, G is the mapping from the σ-algebra $\mathcal{A}$ of the set of measurement outcomes Ω to $\mathcal{SL}(\mathcal{V},\mathcal{V};\mathbb{C})$ such that $\mathcal{A}\ni X\to[G(X)](\varphi,\psi)\in\mathbb{C}$ is a complex measure for all $\varphi, \psi\in\mathcal{V}$. It is *normalized* if $[G(\Omega)](\varphi,\psi)=\langle\varphi|\psi\rangle$, $\varphi, \psi\in\mathcal{V}$.

In the case of phase, it is natural to assume that $\Omega=[0,2\pi)$, $\mathcal{A}=\mathcal{B}([0,2\pi))$, and $\mathcal{V}$ contains number states, coherent states, etc. Since they are elements of $\mathcal{H}_1$ we assume that $\mathcal{V}=\mathcal{H}_1$. If we study the coherent state phase measurements with the associated GOM $E:\mathcal{B}([0,2\pi))\to\mathcal{SL}(\mathcal{H}_1,\mathcal{H}_1;\mathbb{C})$, it is natural to assume the following phase shift covariance condition:

$$[E(X)](|ze^{-\alpha}\rangle,|ze^{-\alpha}\rangle)=[E(X\oplus\alpha)](|z\rangle,|z\rangle) \tag{5}$$

for all $X\in\mathcal{B}([0,2\pi))$, $z\in\mathbb{C}$, and $\alpha\in[0,2\pi)$. The following GOMs are solutions of (5):

$$[E(X)](\varphi,\psi)=\sum_{n,m=0}^{\infty}d_{n,m}i_{n-m}(X)\langle\varphi|n\rangle\langle m|\psi\rangle, \tag{6}$$

where $(d_{n,m})\in\mathbb{C}^{\mathbb{N}\times\mathbb{N}}$, $\sup\{|d_{n,m}|\,|\,n,m\in\mathbb{N}\}<\infty$, $X\in\mathcal{B}([0,2\pi))$, and $\varphi, \psi\in\mathcal{H}_1$. We use the following short notation for E:

$$E(X)=\sum_{n,m=0}^{\infty}d_{n,m}i_{n-m}(X)|n\rangle\langle m|,$$

and we say that E is a *covariant GOM* defined by the *structure matrix* $(d_{n,m})$. Note that $E([0,2\pi))=\Sigma_{n=0}^{\infty}d_{n,n}|n\rangle\langle n|$ can be extended to a unique bounded operator. If $d_{n,n}=1$, $n\in\mathbb{N}$, then E is normalized. If $(d_{n,m})$ is a phase matrix, then E is a phase observable. For all $\varphi, \psi\in\mathcal{H}_1$, the complex measure $X\to[E(X)](\varphi,\psi)$ has a continuous density which is

$$\theta \mapsto \sum_{n,m=0}^{\infty} d_{n,m} e^{i(n-m)\theta} \langle \varphi | n \rangle \langle m | \psi \rangle .$$

Let $\mathcal{M}_\infty$ be a set of structure matrices $(d_{n,m})_{n,m\in\mathbb{N}} \in \mathbb{C}^{\mathbb{N}\times\mathbb{N}}$, $\sup\{|d_{n,m}| \mid n,m \in \mathbb{N}\} < \infty$. Since for all $(d_{n,m}) \in \mathcal{M}_\infty$ we have a unique covariant genaralized operator measure E defined in (6), we can identify $(d_{n,m})$ with E. Now $\mathcal{M}_\infty$ is a W*-algebra (over $\mathbb{C}$) with the norm $\|(d_{n,m})\| := \sup\{|d_{n,m}| \mid n,m \in \mathbb{N}\} < \infty$. The summation, scalar product, and algebra product are defined pointwise. Let $\star$ be the algebra product operation, that is, $(d_{n,m}) \star (e_{n,m}) := (d_{n,m} e_{n,m})$. The identity of $\mathcal{M}_\infty$ is the canonical phase matrix $(c_{n,m})$ with $c_{n,m} = 1$, $n, m \in \mathbb{N}$. The algebra $\mathcal{M}_\infty$ is commutative and the involution is $(d_{n,m}) \mapsto (d_{n,m})^* := (\overline{d_{n,m}})$. The unique predual of $\mathcal{M}_\infty$ is the Banach space $\mathcal{M}_1$ of matrices $(d_{n,m})$ for which $\Sigma_{n,m=0}^{\infty} |d_{n,m}| < \infty$. A matrix $(d_{n,m}) \in \mathcal{M}_\infty$ has an inverse if and only if $d_{n,m} \neq 0$ for all $n, m \in \mathbb{N}$. The inverse is $(d_{n,m}^{-1})$. A matrix $(d_{n,m}) \in \mathcal{M}_\infty$ is positive if $d_{n,m} \geqslant 0$ for all $n, m \in \mathbb{N}$. However, we are not interested in this standard positivity; we rather study positive semidefinitess of matrices.

The positive semidefinite matrices of $\mathcal{M}_\infty$ form a convex cone. We denote it by $\mathcal{M}_\infty^+$. Any $(d_{n,m}) \in \mathcal{M}_\infty^+$ defines a covariant positive operator measure E via Eq. (6). The phase matrices are such matrices of $\mathcal{M}_\infty^+$ whose diagonal elements equal 1. Let $\mathcal{C}$ be the σ-convex set of phase matrices.[13] Phase matrices define phase observables. The phase matrices of phase observables unitarily equivalent to E_{can} are only phase matrices which have phase matrix inverses. Note that $\mathcal{C}^* = \mathcal{C}$, and for all $(c_{n,m}) \in \mathcal{C}$ the norm $\|(c_{n,m})\| = 1$, that is, all phase matrices lie on the unit ball.

We can embed the bounded operators, trace-class operators, and states in $\mathcal{M}_\infty$. We simply define

$$\mathcal{L} := \left\{ (A_{n,m}) \in \mathcal{M}_\infty \,\middle|\, \sum_{n,m=0}^{\infty} A_{n,m} |n\rangle\langle m| \in \mathcal{L}(\mathcal{H}) \right\},$$

$$\mathcal{T} := \left\{ (T_{n,m}) \in \mathcal{M}_\infty \,\middle|\, \sum_{n,m=0}^{\infty} T_{n,m} |n\rangle\langle m| \in \mathcal{T}(\mathcal{H}) \right\},$$

$$\mathcal{T}_1^+ := \left\{ (T_{n,m}) \in \mathcal{M}_\infty \,\middle|\, \sum_{n,m=0}^{\infty} T_{n,m} |n\rangle\langle m| \in \mathcal{T}(\mathcal{H})_1^+ \right\}.$$

Thus, $\mathcal{T}_1^+$ contains such $(T_{n,m}) \in \mathcal{M}_\infty^+$ for which $\Sigma_{n=0}^{\infty} T_{n,n} = 1$. Note that $\mathcal{T} \cap \mathcal{C} = \varnothing$ and $\mathcal{C} \nsubseteq \mathcal{L} \neq \mathcal{M}_\infty$.

As we saw in the previous section, for any phase matrix $(c_{n,m})$ and a state $(T_{n,m})$ the product $(c_{n,m}) \star (T_{n,m})$ is a state. Thus, $\mathcal{C} \star \mathcal{T}_1^+ = \mathcal{T}_1^+$. An operation Θ defined in (4) corresponds a mapping $\mathcal{T} \ni (T_{n,m}) \mapsto (c_{m,n}) \star (T_{n,m}) \in \mathcal{T}$, $(c_{n,m}) \in \mathcal{C}$, which is continuous with respect to the trace-norm. If Θ_1 and Θ_2 are the operations [defined in (4)] of phase observables E_1 and E_2 with $(c_{n,m}^1)$ and $(c_{n,m}^2)$, respectively, then the matrix $(c_{m,n}^1) \star (c_{m,n}^2)$ corresponds to the composition operation $\Theta_1 \circ \Theta_2$. Note that $\Theta_1 \circ \Theta_2 = \Theta_2 \circ \Theta_1$.

Let $(d_{n,m})$ and $(e_{n,m})$ be elements of $\mathcal{M}_\infty^+$. Now there exist vector sequences $(\varphi_n)_{n\in\mathbb{N}}$ and $(\psi_n)_{n\in\mathbb{N}}$ such that $d_{n,m} = \langle \varphi_n | \varphi_m \rangle$ and $e_{n,m} = \langle \psi_n | \psi_m \rangle$ for all $n, m \in \mathbb{N}$.[3] Now $d_{n,m} e_{n,m} = \langle \varphi_n \otimes \psi_n | \varphi_m \otimes \psi_m \rangle$, $n, m \in \mathbb{N}$, and $(d_{n,m}) \star (e_{n,m})$ is positive semidefinite.[14] Hence, $\mathcal{M}_\infty^+ \star \mathcal{M}_\infty^+ = \mathcal{M}_\infty^+$ and $\mathcal{C} \star \mathcal{C} = \mathcal{C}$.

Let $(d_{n,m}) \in \mathcal{M}_\infty^+$. Now we can write $d_{n,m} = \Sigma_{k=0}^{\infty} d_{n,m}^{(k)}$ where $d_{n,m}^{(k)} = \langle n | F_k \rangle \langle F_k | m \rangle$ for all $n, m \in \mathbb{N}$, and $|F_k) \in \mathcal{H}_\infty$, $k \in \mathbb{N}$. Hence, the finite sums of matrices $(\langle n|F)(F|m\rangle)_{n,m\in\mathbb{N}}$, $|F) \in \mathcal{H}_\infty$ form a dense subset of $\mathcal{M}_\infty^+$. Every $|F) \in \mathcal{H}_\infty$ defines a covariant positive operator measure E_F of Eq. (2).

Following Ref. 10, we can define a certain ordering relation on $\mathcal{M}_\infty$ as follows: $(d_{n,m}) \preccurlyeq (e_{n,m})$ if $(d_{n,m}) = (e_{n,m}) \star (f_{n,m})$ for some $(f_{n,m}) \in \mathcal{M}_\infty$. Let $(1)_{n,m\in\mathbb{N}}$ and $(\delta_{n,m})_{n,m\in\mathbb{N}}$ be the

phase matrices of the canonical and the trivial phase observables, respectively. Now $(d_{n,m})_{n,m\in\mathbb{N}} \preccurlyeq (1)_{n,m\in\mathbb{N}}$ for all $(d_{n,m})\in\mathcal{M}_\infty$ and $(\delta_{n,m}) \preccurlyeq (c_{n,m})$ for all $(c_{n,m})\in\mathcal{C}$. Note that $\preccurlyeq$ is not a partial ordering. It does not satisfy the antisymmetry condition.

Define the following equivalence relation in $\mathcal{C}$:

$$(c_{n,m}) \simeq (d_{n,m}) \quad \text{if } (c_{n,m}) = (d_{n,m}) \star (e^{i(v_n - v_m)}), \quad (v_n)_{n\in\mathbb{N}} \subset [0, 2\pi).$$

Denote the equivalence class of $(c_{n,m})\in\mathcal{C}$ by $[(c_{n,m})]$, and define a partial ordering $\preccurlyeq$ in the set of equivalence classes as follows: $[(c_{n,m})] \preccurlyeq [(d_{n,m})]$ if $(c_{n,m}) = (d_{n,m}) \star (e_{n,m})$ for some $(e_{n,m}) \in \mathcal{C}$. Now $[(\delta_{n,m})] \preccurlyeq [(c_{n,m})] \preccurlyeq [(1)]$ for all $(c_{n,m})\in\mathcal{C}$ and, thus, the equivalence class of the canonical phase matrix is the upper bound.

V. ON THE POINTWISE CONVERGENCE OF PHASE KERNELS

As we have seen, a phase observable E is determined uniquely by a phase matrix $(c_{n,m})$ via Eq. (1). For any trace-class operator T we can define a complex measure $X \mapsto p_T^E(X) := \mathrm{tr}(TE(X))$ which is absolutely continuous with respect to the normalized Lebesgue measure and, thus, has a Radon–Nikodým derivative g_T^E such that $p_T^E(X) = (2\pi)^{-1} \int_X g_T^E(\theta)\mathrm{d}\theta$, $X \in \mathcal{B}([0,2\pi))$. Following Eq. (1) it is tempting to write $g_T^E(\theta) = \sum_{n,m=0}^\infty T_{m,n} c_{n,m} e^{i(n-m)\theta}$ where the summation converges pointwise for $\mathrm{d}\theta$-almost all $\theta\in\mathbb{R}$. But is it possible? In this section we study this problem.

Let us start with the simplest case. Let E be the canonical phase, and let $T = |\varphi\rangle\langle\psi|$ where $\varphi, \psi \in \mathcal{H}$. From the Carleson theorem[15] we know that any L^2-Fourier series converges pointwise for almost all $\theta\in\mathbb{R}$. Thus, we get

$$g^{E_{\mathrm{can}}}_{|\varphi\rangle\langle\psi|}(\theta) = \sum_{n=0}^\infty \langle\psi|n\rangle e^{in\theta} \sum_{m=0}^\infty \langle m|\varphi\rangle e^{-im\theta} = \sum_{n,m=0}^\infty \langle m|\varphi\rangle\langle\psi|n\rangle e^{i(n-m)\theta}$$

for almost all $\theta\in\mathbb{R}$. Let then T be an arbitrary trace-class operator, and let E be any phase observable with the covariant trace-preserving operation Φ of Theorem 3. Now we can write $\Phi(T) = T_\alpha - T_\beta + iT_\gamma - iT_\delta$ where the operators T_u are positive trace-class operators with decompositions $T_u = \sum_{k=0}^\infty |\varphi_k^{(u)}\rangle\langle\varphi_k^{(u)}|$, $\varphi_k^{(u)} \in \mathcal{H}$, $k\in\mathbb{N}$, where $u = \alpha, \beta, \gamma, \delta$. Thus,

$$g_T^E(\theta) = g^{E_{\mathrm{can}}}_{T_\alpha}(\theta) - g^{E_{\mathrm{can}}}_{T_\beta}(\theta) + ig^{E_{\mathrm{can}}}_{T_\gamma}(\theta) - ig^{E_{\mathrm{can}}}_{T_\delta}(\theta)$$

and, by monotonic convergence,

$$g^{E_{\mathrm{can}}}_{T_u}(\theta) = \sum_{k=0}^\infty \sum_{n,m=0}^\infty \langle m|\varphi_k^{(u)}\rangle\langle\varphi_k^{(u)}|n\rangle e^{i(n-m)\theta} \tag{7}$$

for all $u = \alpha, \beta, \gamma, \delta$ and for almost all $\theta\in\mathbb{R}$. We will get a similar equation without using the operation Φ. Namely, by using Theorem 2 one gets for any $|\varphi\rangle\langle\varphi|$

$$g^E_{|\varphi\rangle\langle\varphi|}(\theta) = \sum_{k=0}^\infty \sum_{n,m=0}^\infty \langle\varphi|n\rangle\langle n|F_k)(F_k|m\rangle\langle m|\varphi\rangle e^{i(n-m)\theta} \tag{8}$$

for almost all $\theta\in\mathbb{R}$. A problem of Eqs. (7) and (8) is that it is not clear that we can change the order of k- and (n,m)-sums. So we have to consider other methods.

First we prove a simple proposition. Let B be a complex Banach space, and let $S: \mathcal{H}\times\mathcal{H} \to B$ be a bounded sesquilinear form (the first argument is antilinear), that is, $\|S\| := \sup\{\|S(\varphi,\psi)\| \mid \|\varphi\| \leq 1, \|\psi\| \leq 1\} < \infty$. Note that $\mathcal{T}(\mathcal{H})$ is equipped with the trace norm.

Proposition 1: Denote $S_{n,m} := S(|n\rangle, |m\rangle)$ for all $n, m \in \mathbb{N}$. Then for all $\varphi, \psi \in \mathcal{H}$

$$S(\varphi,\psi)=\lim_{s,t\to\infty}\sum_{n=0}^{s}\sum_{m=0}^{t}S_{n,m}\langle\varphi|n\rangle\langle m|\psi\rangle,$$

that is,

$$S=\sum_{n,m=0}^{\infty}S_{n,m}|n\rangle\langle m|$$

weakly, and S can be uniquely extended to a continuous linear mapping $\tilde{S}\colon\mathcal{T}(\mathcal{H})\to B$,

$$T\mapsto\tilde{S}(T):=\sum_{n,m=0}^{\infty}S_{n,m}T_{m,n}:=\lim_{s,t\to\infty}\sum_{n=0}^{s}\sum_{m=0}^{t}S_{n,m}T_{m,n},$$

where $T_{m,n}:=\langle m|T|n\rangle$, $n,m\in\mathbb{N}$. *Clearly,* $\tilde{S}(|\psi\rangle\langle\varphi|)=S(\varphi,\psi)$ *for all* $\varphi,\psi\in\mathcal{H}$.

Proof: For $\varphi,\psi\in\mathcal{H}$ one gets

$$\|S(\varphi,\psi)-S(P_s\varphi,P_t\psi)\|\leqslant\|S\|\,\|\varphi\|\,\|\psi-P_t\psi\|+\|S\|\,\|\varphi-P_s\varphi\|\,\|P_t\psi\|\to 0$$

when $s,t\to 0$, where $P_s:=\Sigma_{n=0}^{s}|n\rangle\langle n|$. Fix $T\in\mathcal{T}(\mathcal{H})_1^+$. One can write $T=\Sigma_{k=0}^{\infty}\lambda_k|\varphi_k\rangle\langle\varphi_k|$ where $\lambda_k\in[0,1]$, $\Sigma_{k=0}^{\infty}\lambda_k=1$, $\varphi_k\in\mathcal{H}$, and $\|\varphi_k\|=1$ for all $k\in\mathbb{N}$. Define $\alpha^T:=\Sigma_{k=0}^{\infty}\lambda_k S(\varphi_k,\varphi_k)$ and $\alpha_{s,t}^T:=\Sigma_{k=0}^{\infty}\lambda_k S(P_s\varphi_k,P_t\varphi_k)=\Sigma_{n=0}^{s}\Sigma_{m=0}^{t}S_{n,m}T_{m,n}$ which exist since $\Sigma_{k=0}^{\infty}\lambda_k=1$ and $\|S(\varphi,\psi)\|\leqslant\|S\|$ for all vectors φ,ψ with $\|\varphi\|\leqslant 1$, $\|\psi\|\leqslant 1$. Also we see that $\|\alpha^T\|\leqslant\|S\|$. By the dominated convergence theorem

$$\|\alpha^T-\alpha_{s,t}^T\|\leqslant\sum_{k=0}^{\infty}\lambda_k\|S(\varphi_k,\varphi_k)-S(P_s\varphi_k,P_t\varphi_k)\|\leqslant\|S\|\sum_{k=0}^{\infty}\lambda_k(\|\varphi_k-P_t\varphi_k\|+\|\varphi_k-P_s\varphi_k\|)\to 0$$

when $s,t\to\infty$. As we can easily see from the beginning of the proof, the matrix elements $T_{n,m}$ define the operator T uniquely and, thus, $\tilde{S}(T):=\alpha^T$ is well-defined. Since any $T\in\mathcal{T}(\mathcal{H})$ can be uniquely written in the form $T=\alpha T_\alpha-\beta T_\beta+i\gamma T_\gamma-i\delta T_\delta$ where T_α, T_β, T_γ, and T_δ are states, and α, β, γ, and δ are non-negative real numbers, we can define $\tilde{S}(T):=\alpha\tilde{S}(T_\alpha)-\beta\tilde{S}(T_\beta)+i\gamma\tilde{S}(T_\gamma)-i\delta\tilde{S}(T_\delta)$. The rest of the proof follows immediately. □

Note that it follows from Proposition 1 that any bounded operator A can be written in the form $A=\Sigma_{n,m=0}^{\infty}A_{n,m}|n\rangle\langle m|$ (weakly) and $\mathrm{tr}(AT)=\Sigma_{n,m=0}^{\infty}A_{n,m}T_{m,n}$ for any $T\in\mathcal{T}(\mathcal{H})$ where $A_{n,m}:=\langle n|A|m\rangle$, $n,m\in\mathbb{N}$.

Let E be a phase observable with $(c_{n,m})$, and let g_T^E be a Radon–Nikodým derivative of the complex measure p_T^E associated to $T\in\mathcal{T}(\mathcal{H})$. The sesquilinear mapping $\mathcal{H}\times\mathcal{H}\ni(\varphi,\psi)\mapsto g_{|\psi\rangle\langle\varphi|}^E\in L^1[0,2\pi)$ is bounded since by using the polarization identity and the parallelogram law $(2\pi)^{-1}\int_0^{2\pi}|g_{|\psi\rangle\langle\varphi|}^E(\theta)|\mathrm{d}\theta\leqslant\|\psi\|^2+\|\varphi\|^2$ for all $\psi,\varphi\in\mathcal{H}$. From Proposition 1 one gets

$$g_T^E=\sum_{n,m=0}^{\infty}T_{m,n}c_{n,m}e_n\overline{e_m},$$

where $e_n(\theta)=e^{in\theta}$ and the double series converges with respect to the L^1-norm. This implies (Ref. 16, Theorem 3.12, p. 68) the following theorem:

Theorem 5: *There exists a subsequence* $\mathbb{N}\ni k\mapsto n_k\in\mathbb{N}$, $n_1<n_2<n_3<\cdots$, *such that*

$$g_T^E(\theta)=\lim_{k\to\infty}\sum_{n,m=0}^{n_k}T_{m,n}c_{n,m}e^{i(n-m)\theta}$$

for almost all $\theta\in\mathbb{R}$.

It can be shown (Ref. 16, Theorem 7.8, p. 140) that

$$g_T^E(\theta)=2\pi\left.\frac{\mathrm{d}p_T^E[0,x)}{\mathrm{d}x}\right|_{x=\theta}$$

for almost all $\theta\in[0,2\pi)$. Thus, by direct calculation, one gets

$$g_T^E(\theta)=\lim_{\epsilon\to 0+}\sum_{n,m=0}^{\infty}T_{m,n}c_{n,m}e^{i(n-m)\theta}f_{n-m}^{(1)}(\epsilon)$$

for almost all $\theta\in\mathbb{R}$ where $f_k^{(1)}(\epsilon):=(e^{ik\epsilon}-1)/(ik\epsilon)$, $k\neq 0$, and $f_0^{(1)}(\epsilon)=1$. Thus, $\lim_{\epsilon\to 0+}f_k^{(1)}(\epsilon)=1$ for all $k\in\mathbb{Z}$. Also, by a theorem of Fatou (Ref. 17, p. 34), one can show that

$$g_T^E(\theta)=\lim_{\epsilon\to 0+}\sum_{n,m=0}^{\infty}T_{m,n}c_{n,m}e^{i(n-m)\theta}f_{n-m}^{(2)}(\epsilon)$$

for almost all $\theta\in\mathbb{R}$ where $f_k^{(2)}(\epsilon):=(1-\epsilon)^{|k|}$ for all $k\in\mathbb{Z}$ and the double series converges absolutely when $\epsilon\in(0,1]$. Also $\lim_{\epsilon\to 0+}f_k^{(2)}(\epsilon)=1$ for all $k\in\mathbb{Z}$.

Since the operators

$$C_\epsilon^{(j)}:=\sum_{n,m=0}^{\infty}c_{n,m}f_{n-m}^{(j)}(\epsilon)|n\rangle\langle m|,\quad j=1,2,$$

are bounded with $\|C_\epsilon^{(1)}\|\leqslant 2\pi/\epsilon$ and $\|C_\epsilon^{(2)}\|\leqslant 2/\epsilon-1$ for each $\epsilon\in(0,1]$ it follows that

$$g_T^E(\theta)=\lim_{\epsilon\to 0+}\mathrm{tr}[TR(\theta)C_\epsilon^{(j)}R(\theta)^*],\quad j=1,2,$$

for almost all $\theta\in\mathbb{R}$.

(Received 16 October 2001; accepted for publication 26 November 2001)

A family of maximally superintegrable systems containing the Coulomb atom as a special case is constructed in n-dimensional Euclidean space. Two different sets of n commuting second-order operators are found, overlapping in the Hamiltonian alone. The system is separable in several coordinate systems and is shown to be exactly solvable. It is solved in terms of classical orthogonal polynomials. The Hamiltonian and n further operators are shown to lie in the enveloping algebra of a hidden affine Lie algebra. © *2002 American Institute of Physics.*

I. INTRODUCTION

We shall consider the stationary Schrödinger equation

$$H\psi = E\psi, \quad H = -\frac{1}{2}\sum_{i=1}^{n}\frac{\partial^2}{\partial x_i^2} + V(x_1,\ldots,x_n) \tag{1}$$

in an n-dimensional Euclidean space E_n. By analogy with classical Hamiltonian mechanics, such a system is called integrable if there exist $n-1$ algebraically independent linear operators X_a satisfying

$$[H,X_a]=0, \quad [X_a,X_b]=0, \quad a,b=1,\ldots,n-1. \tag{2}$$

The system is called "superintegrable" if there exist further k operators $\{Y_1,\ldots,Y_k\}$ commuting with the Hamiltonian

$$[H,Y_j], \quad j=1,\ldots,k, \tag{3}$$

such that the set $\{H,X_1,\ldots,X_n,Y_1,\ldots,Y_k\}$ is algebraically independent. Note that the additional operators Y_i need not commute with the operators X_a nor amongst each other. The number of additional operators satisfies

$$1 \leqslant k \leqslant n-1. \tag{4}$$

For $k=1$ we call the system "minimally superintegrable," for $k=n-1$ it is "maximally superintegrable."

The best known superintegrable systems in E_3 (and also in E_n for any $n \geqslant 2$) are the harmonic oscillator and the hydrogen atom (or Kepler system in classical mechanics). The harmonic oscil-

a)Electronic mail: rodrigue@fis.ucm.es
b)Electronic mail: wintern@crm.umontreal.ca

lator is superintegrable because of the $su(n)$ algebra of first- and second-order operators commuting with the Hamiltonian.[1,2] The hydrogen atom in E_n is superintegrable, because of the $o(n+1)$ Lie algebra of linear operators commuting with the Hamiltonian.[3–7] In both cases it is possible to choose different subsets of n operators commuting with each other and overlapping only in the Hamiltonian. Each subset corresponds to the separation of variables in the Schrödinger equation in a different system of coordinates.[8]

Characteristic features of these two superintegrable systems are as follows.

(1) In classical mechanics all finite (bounded) trajectories are periodic. Moreover, Bertrand's theorem[9,10] tells us that γ/r and γr^2 are the only spherically symmetric potentials for which all finite trajectories are periodic.
(2) In quantum mechanics these two systems are exactly solvable: their energy levels can be calculated algebraically, as can the degeneracies of these levels. Their eigenfunctions are polynomials in the appropriate variables, multiplied by some overall factor.
(3) These systems are extremely important in physical applications, both in classical and quantum physics.

It makes sense to search systematically for superintegrable systems in classical and quantum mechanics, especially for maximally superintegrable ones. It can be safely assumed that they will all have the above-mentioned properties (1) and (2) and hoped that they will also, to some degree, share property (3).

In searches for superintegrable systems restrictions are imposed on the form of the commuting operators X_a and Y_i. A systematic search in E_2 and E_3 was conducted some time ago.[11–16] The restriction was that all operators involved should be at most of second order. All superintegrable systems satisfying this restriction in E_2 and E_3 were found.[11–16] Four classes of them exist in E_2, five maximally superintegrable ($2n-1=5$ operators commuting with H) and eight minimally superintegrable ones ($n+1=4$ operators) in E_3. These results have been recently extended to two- and three-dimensional spaces of constant curvature and to complex spaces[17–20] and also to certain two-dimensional spaces of nonconstant curvature.[21]

With the restriction to second-order operators all superintegrable systems turned out to be multiseparable, that is, separable in at least two different coordinate systems. In two-dimensional spaces they also turned out to be exactly solvable.[22] By this we mean that their energy spectra can be calculated algebraically (by solving algebraic equations only).[22–24] It was also shown that superintegrable systems are obtained by considering non-Abelian algebras of generalized Lie symmetries.[25]

The purpose of this article is to consider a family of integrable systems in n-dimensional Euclidean space for any n. The family, containing the n-dimensional hydrogen atom as a special case, is introduced in Sec. II, together with a set of $2n-1$ algebraically independent operators, commuting with the Hamiltonian. In Sec. III we solve the Schrödinger equation in parabolic and spherical coordinates and show that it is exactly solvable in a precise and well-defined sense.[22–24] Finally, in Sec. IV we introduce parabolic rotational coordinates in E_n and solve the Schrödinger equation in these coordinates and also in spherical ones. We also prove the exact solvability in this case. Some conclusions are drawn in Sec. 5.

II. A FAMILY OF MAXIMALLY SUPERINTEGRABLE SYSTEMS IN E_n CONTAINING THE HYDROGEN ATOM

Let us first consider the hydrogen atom in n-dimensional Euclidean space E_n,

$$H=-\frac{1}{2}\Delta-\frac{\gamma}{r},\quad \Delta=\sum_{i=1}^{n}\frac{\partial^2}{\partial x_i^2},\quad r=(x_1^2+\cdots+x_n^2)^{1/2}. \tag{5}$$

This Hamiltonian commutes with $n(n+1)/2$ linear operators, namely

$$L_{ik}=x_i\frac{\partial}{\partial x_k}-x_k\frac{\partial}{\partial x_i},\quad 1\leqslant i<k\leqslant n,$$
$$A_i=\frac{1}{2}\sum_{a=1}^{n}(p_aL_{ia}+L_{ia}p_a)+\gamma\frac{x_i}{r},\quad 1\leqslant i\leqslant n \tag{6}$$

with $p_i=\partial_{x_i}$. The operators L_{ik} correspond to angular momentum, A_i to the n-dimensional Laplace–Runge–Lenz vector, characterizing the Coulomb or Kepler problem.[6,10] Only $2n-1$ of the operators $\{H,L_{ik},A_i\}$ can be, and are, algebraically independent. They satisfy the commutation relations

$$[H,L_{ik}]=[H,A_i]=0,$$
$$[L_{ij},L_{ab}]=\delta_{ja}L_{ib}+\delta_{ib}L_{ja}-\delta_{ia}L_{jb}-\delta_{jb}L_{ia},$$
$$[L_{ij},A_k]=\delta_{jk}A_i-\delta_{ik}A_j, \tag{7}$$
$$[A_i,A_j]=-2HL_{ij}.$$

The commutation relations (7) in general correspond to a Kac–Moody algebra.[26,27] For a fixed energy, $H=E$ they correspond to the Lie algebra of the rotation group $O(n+1)$, the Lorentz group $O(n,1)$, and the Euclidean group $E(n)$ for $E<0$, $E>0$ and $E=0$, respectively. These symmetries for $n=3$ were discovered implicitly by Pauli[3] and explicitly by Fock[4] and Bargmann.[5]

According to the operator approach to the separation of variables,[28–33] separation of variables in the Schrödinger equation is achieved by looking for eigenfunctions of a complete set of n commuting second-order operators $\{H,X_1,\ldots,X_{n-1}\}$,

$$H\psi=E\psi,\quad X_a\psi=\lambda_a\psi,\quad a=1,\ldots,n-1. \tag{8}$$

The operators X_a will be at most linear in A_i and bilinear in L_{ik}. If more than one inequivalent set of commuting operators exists, the system is multiseparable, i.e., separable in more than one coordinate system.

In view of the commutation relations (7) any set of commuting operators $\{X_i\}$ can contain at most one operator involving A_i:

$$X=\sum_i a_iA_i+\sum_{i,k,j,m}b_{ik,jm}L_{ik}L_{jm},\quad \sum_{i=1}^{n}a_i^2\neq 0. \tag{9}$$

The complete sets of commuting operators can be classified under the action of $O(n)$; in particular we can rotate and normalize so as to have $a_n=1$, $a_k=0$ for $k=1,\ldots,n-1$. Here we just give the example of the case $n=3$. It is easy to verify by a direct calculation that in this case, precisely four inequivalent sets exist: $\{H,X_1,X_2\}$ with

$$X_1=A_3,\quad X_2=L_{12}^2, \tag{10}$$
$$X_1=A_3+a(L_{12}^2+L_{23}^2+L_{31}^2),\quad X_2=L_{12}^2, \tag{11}$$
$$X_1=L_{12}^2+L_{23}^2+L_{31}^2,\quad X_2=L_{12}^2, \tag{12}$$
$$X_1=L_{12}^2+L_{23}^2+L_{31}^2,\quad X_2=L_{23}^2+fL_{31}^2. \tag{13}$$

They correspond to the separation of variables in parabolic rotational coordinates, shifted spheroidal coordinates, spherical coordinates, and spheroconical coordinates, respectively.

In each coordinate system it is possible to add further terms to the potential $-\gamma/r$ in such a manner that the Schrödinger equation still separates. The system will remain integrable and the corresponding operators X_1 and X_2 will only be modified by the addition of a scalar function. It is also possible to preserve superintegrability and to require that the extended potentials should allow separation of variables in at least two coordinate systems.

Here we will be interested in the most general potential allowing separation of variables in the same four coordinate systems as the hydrogen atom itself. In E_3 there is, up to equivalence, only one such Hamiltonian, namely (see Refs. 13 and 14)

$$H=-\frac{1}{2}\Delta-\frac{\gamma}{r}+\frac{\beta_1}{x_1^2}+\frac{\beta_2}{x_2^2}. \tag{14}$$

One triplet of commuting operators for the Hamiltonian (14) consists of

$$\begin{aligned} X&=\frac{1}{2}(p_1L_{31}+L_{31}p_1+p_2L_{32}+L_{32}p_2)+2x_3\left(\frac{\gamma}{2r}-\frac{\beta_1}{x_1^2}-\frac{\beta_2}{x_2^2}\right),\\ Z&=L_{12}^2-2r^2\left(\frac{\beta_1}{x_1^2}+\frac{\beta_2}{x_2^2}\right). \end{aligned} \tag{15}$$

Another triplet can be chosen to be H and

$$\begin{aligned} Y_1&=L_{12}^2+L_{23}^2+L_{31}^2-2r^2\left(\frac{\beta_1}{x_1^2}+\frac{\beta_2}{x_2^2}\right),\\ Y_2&=L_{23}^2-2\beta_2\frac{x_2^2+x_3^2}{x_2^2}. \end{aligned} \tag{16}$$

It is the set of five algebraically independent operators $\{H,X_1,X_2,Y_1,Y_2\}$ which guarantees that the Hamiltonian (14) is maximally superintegrable.

The generalization to the n-dimensional Euclidean space E_n is immediate. Thus, the Hamiltonian will be

$$H=-\frac{1}{2}\Delta-\frac{\gamma}{r}+\sum_{i=1}^{n-1}\frac{\beta_i}{x_i^2} \tag{17}$$

with Δ and r as in Eq. (5). One of the two different complete sets of commuting operators can be chosen to be H and

$$\begin{aligned} X&=\frac{1}{2}\sum_{k=1}^{n-1}(L_{nk}p_k+p_kL_{nk})+2x_n\left(\frac{\gamma}{2r}-\sum_{i=1}^{n-1}\frac{\beta_i}{x_i^2}\right),\\ Z_l&=\sum_{1\leqslant i<k\leqslant l+1}L_{ik}^2-2\left(\sum_{i=1}^{l+1}x_i^2\right)\left(\sum_{k=1}^{l+1}\frac{\beta_k}{x_k^2}\right),\quad 1\leqslant l\leqslant n-2. \end{aligned} \tag{18}$$

Another complete set of commuting operators is again H and

$$Y_p=\sum_{p\leqslant i<k\leqslant n}L_{ik}^2-2\left(\sum_{i=p}^{n}x_i^2\right)\left(\sum_{k=p}^{n-1}\frac{\beta_k}{x_k^2}\right),\quad 1\leqslant p\leqslant n-1. \tag{19}$$

The two sets (18) and (19) are disjoint. If we set $\beta_i=0, 1\leqslant i\leqslant n-1$, then the operator Z_l will be a Casimir operator of the group $O(l+1)$ acting on the coordinates $\{x_1,\ldots,x_{l+1}\}$. The operator Y_p will be a Casimir operator of $O(n+1-p)$ acting on the coordinates $\{x_p,\ldots,x_n\}$.

It is the Hamiltonian (17) that we shall study in the following sections, first for $n=3$, then for arbitrary n.

III. EXACT SOLVABILITY OF THE SUPERINTEGRABLE SYSTEM FOR $n=3$

A. Solution by separation of variables

Let us first consider the Hamiltonian (14) and the complete set of commuting operators (15). We are looking for eigenvalues and common eigenfunctions of the systems:

$$H\psi=E\psi, \quad X\psi=\lambda\psi, \quad Z\psi=k\psi. \tag{20}$$

To do this we introduce parabolic rotational coordinates, putting

$$x_1=\mu\nu\cos\phi, \quad x_2=\mu\nu\sin\phi, \quad x_3=\tfrac{1}{2}(\mu^2-\nu^2). \tag{21}$$

In these coordinates the operators in (20) are

$$\begin{aligned} H&=-\frac{1}{2(\mu^2+\nu^2)}\left(\frac{\partial^2}{\partial\mu^2}+\frac{1}{\mu}\frac{\partial}{\partial\mu}+\frac{\partial^2}{\partial\nu^2}+\frac{1}{\nu}\frac{\partial}{\partial\nu}+4\gamma\right)-\frac{1}{2\mu^2\nu^2}\left(\frac{\partial^2}{\partial\phi^2}-\frac{2\beta_1}{\cos^2\phi}-\frac{2\beta_2}{\sin^2\phi}\right)\\ X&=\frac{1}{2(\mu^2+\nu^2)}\left(-\nu^2\left(\frac{\partial^2}{\partial\mu^2}+\frac{1}{\mu}\frac{\partial}{\partial\mu}\right)+\mu^2\left(\frac{\partial^2}{\partial\nu^2}+\frac{1}{\nu}\frac{\partial}{\partial\nu}\right)+2\gamma(\mu^2-\nu^2)\right)\\ &\quad+\frac{\mu^2-\nu^2}{2\mu^2\nu^2}\left(\frac{\partial^2}{\partial\phi^2}-\frac{2\beta_1}{\cos^2\phi}-\frac{2\beta_2}{\sin^2\phi}\right)\\ Z&=\frac{\partial^2}{\partial\phi^2}-\frac{2\beta_1}{\cos^2\phi}-\frac{2\beta_2}{\sin^2\phi}. \end{aligned} \tag{22}$$

We see immediately that the variables separate and we can solve the corresponding ordinary differential equations to obtain

$$\begin{aligned} \psi_{N_1,N_2,J}&=(\sin\phi)^{p_2}(\cos\phi)^{p_1}(\mu\nu)^m e^{-\sqrt{-E/2}(\mu^2+\nu^2)}\\ &\quad\times P_J^{(p_2-1/2,p_1-1/2)}(\cos 2\phi)L_{N_1}^m(\sqrt{-2E}\,\mu^2)L_{N_2}^m(\sqrt{-2E}\,\nu^2), \end{aligned} \tag{23}$$

where $P_J^{(\alpha,\beta)}(z)$ and $L_N^m(x)$ are Jacobi and Laguerre polynomials, respectively. We have put

$$\beta_i=\tfrac{1}{2}p_i(p_i-1), \quad m=2J+p_1+p_2$$

and the eigenvalues in Eq. (20) are equal to

$$\begin{aligned} E&=-\frac{\gamma^2}{2(N_1+N_2+2J+p_1+p_2+1)^2},\\ \lambda&=-\frac{\gamma(N_1-N_2)}{N_1+N_2+2J+p_1+p_2+1},\\ k&=-m^2=-(2J+p_1+p_2)^2. \end{aligned} \tag{24}$$

We see that the bound state energy is given by a shifted Balmer formula and the only effect of the β_i/x_i^2 terms in the potential is to add a constant p_1+p_2 to the principal quantum number. The

solutions (23) are square integrable and correspond to bound states when J, N_1, and N_2 are integers. They are polynomials multiplied by a factor which, however, is not "universal." It depends on the energy E and also on the angular quantum number J (since we have $m=2J+p_1+p_2$).

The second set of commuting operators, namely (16), also corresponds to the separation of variables, this time in spherical coordinates, chosen as

$$x_1=r\cos\theta, \quad x_2=r\sin\theta\cos\alpha, \quad x_3=r\sin\theta\sin\alpha. \tag{25}$$

In these coordinates we have

$$H\psi=-\frac{1}{2}\left[\frac{\partial^2}{\partial r^2}+\frac{2}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\left(\frac{\partial^2}{\partial\theta^2}+\cot\theta\frac{\partial}{\partial\theta}+\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\alpha^2}\right)+\frac{2\gamma}{r}-\frac{2}{r^2}\left(\frac{\beta_1}{\cos^2\theta}+\frac{\beta_2}{\sin^2\theta\cos^2\alpha}\right)\right]\psi$$
$$=E\psi,$$

$$Y_1\psi=\left(\frac{\partial^2}{\partial\theta^2}+\cot\theta\frac{\partial}{\partial\theta}-\frac{2\beta_1}{\cos^2\theta}+\frac{k_2}{\sin^2\theta}\right)\psi=k_1\psi, \tag{26}$$

$$Y_2\psi=\left(\frac{\partial^2}{\partial\alpha^2}-\frac{2\beta_2}{\cos^2\alpha}\right)\psi=k_2\psi.$$

The coordinates separate and we obtain $\psi=R(r)F(\theta)G(\alpha)$ where F and G can be expressed in terms of Jacobi polynomials and R in terms of Laguerre ones.

The explicit expression for the eigenfunctions in this type of spherical coordinates is

$$\psi_{N,J_1,J_2}(r,\theta,\alpha)=r^{m_1-1/2}e^{-\sqrt{-2E}\,r}L_N^{2m_1}(2\sqrt{-2E}\,r)(\sin\theta)^{m_1}(\cos\theta)^{p_1}(\cos\alpha)^{p_2}$$
$$\times P_{J_1}^{(m_2,p_1-1/2)}(\cos 2\theta)P_{J_2}^{(-1/2,p_2-1/2)}(\cos 2\alpha) \tag{27}$$

with eigenvalues equal to

$$E=-\frac{\gamma^2}{2(N+2J_1+2J_2+p_1+p_2+1)^2},$$
$$k_1=\tfrac{1}{4}-m_1^2, \quad k_2=-m_2^2, \quad m_1=2J_1+2J_2+p_1+p_2+\tfrac{1}{2}, \quad m_2=2J_2+p_2. \tag{28}$$

B. Exact solvability and underlying affine Lie algebra

We have established that the potential (14) provides a Hamiltonian that is maximally superintegrable and multiseparable. Let us now turn to the question of exact solvability. A Hamiltonian is exactly solvable if its spectrum can be calculated algebraically. This occurs if it can be explicitly transformed into block diagonal form where each block is finite dimensional. This in turn means that there exists an infinite flag of finite dimensional subspaces in the Hilbert space $\mathcal{H}$ of bound state solutions that is preserved by the Hamiltonian[22–24]

$$\mathcal{H}_1\subset\mathcal{H}_2\subset\cdots\subset\mathcal{H}, \quad H\mathcal{H}_i\subseteq\mathcal{H}_i. \tag{29}$$

Typically this occurs under the following circumstances.

(1) The bound state wave functions are polynomials in some variables, possible multiplied by some factor g, i.e., $\psi=gP$. We then have

$$h=g^{-1}Hg, \quad hP=EP, \tag{30}$$

that is, there exists a gauge transformation and a change of variables to a new Hamiltonian h that has polynomial eigenfunctions.

(2) The gauge transformed Hamiltonian h is an element of the enveloping algebra of some affine Lie algebra L, a basis of which can be realized by the operators

$$K_i=\frac{\partial}{\partial s_i},\quad M_{ik}=s_i\frac{\partial}{\partial s_k},\quad i,k\in\{1,\ldots,n\} \tag{31}$$

(in some coordinates s_i).

Let us now investigate the Hamiltonian (14) and the commuting set of operators (15) and (16) from this point of view.

Consider the wave function (23) in parabolic coordinates. They do have the required form

$$\psi_{N_1,N_2,J}=gP_{N_1,N_2,J}(s,t,z),\quad s=\sqrt{-2E}\,\mu^2,\quad t=\sqrt{-2E}\,\nu^2,\quad z=\cos 2\phi,$$
$$g=\left(\frac{1+z}{2}\right)^{p_1/2}\left(\frac{1-z}{2}\right)^{p_2/2}\left(\frac{s\,t}{-2E}\right)^{m/2}e^{-(s+t)/2}, \tag{32}$$

where P is a polynomial (a product of three polynomials in one variable each). To proceed further we must get rid of the conformal factor $(\mu^2+\nu^2)^{-1}$ figuring in Eq. (22) and replace the system (20) by

$$Q_0\psi=2\gamma\psi,\quad Q_1\psi=2\lambda\psi,\quad Z\psi=-m^2\psi \tag{33}$$

$$Q_0=(\mu^2+\nu^2)(H-E)+2\gamma=-\frac{1}{2}\left(\frac{\partial^2}{\partial\mu^2}+\frac{1}{\mu}\frac{\partial}{\partial\mu}+\frac{\partial^2}{\partial\nu^2}+\frac{1}{\nu}\frac{\partial}{\partial\nu}\right)+\frac{m^2}{2}\left(\frac{1}{\mu^2}+\frac{1}{\nu^2}\right)-E(\mu^2+\nu^2),$$

$$Q_1=2X+(\mu^2-\nu^2)(H-E)=-\frac{1}{2}\left(\frac{\partial^2}{\partial\mu^2}+\frac{1}{\mu}\frac{\partial}{\partial\mu}-\frac{\partial^2}{\partial\nu^2}-\frac{1}{\nu}\frac{\partial}{\partial\nu}\right)+\frac{m^2}{2}\left(\frac{1}{\mu^2}-\frac{1}{\nu^2}\right)-E(\mu^2-\nu^2),$$

$$Q_2=Z.$$

We see here a phenomenon which has been called ''metamorphosis'' [34] or ''migration'' [22] of the coupling constant. In Eq. (33) the energy E plays the role of the frequency of a harmonic oscillator whereas the Coulomb coupling constant γ plays the role of an eigenvalue of Q_0. The other eigenvalues, λ and m^2, remain eigenvalues (of Q_1 and Z, respectively).

Similarly as in the case of potentials containing the Coulomb atom as a special case in two dimensions, it is the system (33) [rather than the original system (20)] that is exactly solvable in the sense defined above. Indeed, let us gauge rotate the operators Q_0, Q_1, and Q_2 and transform to the variables s, t, and z. We obtain

$$\tilde{Q}_0=g^{-1}Q_0g=-2\sqrt{-2E}(s\partial_s^2+(m+1-s)\partial_s+t\partial_t^2+(m+1-t)\partial_t-m-1),$$

$$\tilde{Q}_1=g^{-1}Q_1g=-2\sqrt{-2E}(s\partial_s^2+(m+1-s)\partial_s-t\partial_t^2-(m+1-t)\partial_t), \tag{34}$$

$$\tilde{Q}_2=g^{-1}Q_2g=4(1-z^2)\partial z^2+4(p_1-p_2-(p_1+p_2+1)z)\partial_z-(p_1+p_2)^2.$$

We see that $\tilde{Q}_\mu$, $\mu=0,1,2$ lie in the enveloping algebra of the direct sum of three affine Lie algebras, $\mathrm{saff}(1,\mathbf{R})\oplus\mathrm{saff}(1,\mathbf{R})\oplus\mathrm{saff}(1,\mathbf{R})$, realized by

$$\{\partial_s,s\partial_s,\partial_t,t\partial_t,\partial_z,z\partial_z\}. \tag{35}$$

Now let us consider the two remaining operators Y_1 and Y_2 of (26). They are not diagonal in the basis that we use (where H,X,Z and equivalently Q_0,Q_1,Q_2 are diagonal). They do, however, commute with the Hamiltonian so they can only mix states of equal energy. We also have

$$[Y_1,Z]=0, \quad [Y_2,Z]\neq 0, \quad [Y_1,X]\neq 0. \tag{36}$$

It follows that Y_1 also preserves the quantum number $k=-m^2$ of Eq. (20), whereas Y_2 mixes all states of a given energy. The gauge factor g depends not only on the energy, but also on m, the eigenvalue of Z. Thus, $\tilde{Y}_1=g^{-1}Y_1g$ should transform polynomials into polynomials, whereas $\tilde{Y}_2=g^{-1}Y_2g$ is not obliged to. Performing the gauge transformation and change of variables we find

$$\tilde{Y}_1=g^{-1}Y_1g=s\,t(\partial_s-\partial_t)^2-(m+1)(s-t)(\partial_s-\partial_t)-m(m+1). \tag{37}$$

The algebra underlying this expression includes $t\partial_s$ and $s\partial_t$, in addition to the elements listed in (35). We recognize this to be the Lie algebra saff(2,**R**)$\oplus$saff(1,**R**)

Superintegrable systems, including the hydrogen atom as special case, in two dimensions were associated with the algebra saff(2,**R**). The extension to $n=3$ is seen to lead to saff(2,**R**) $\oplus$saff(1,**R**), not to saff(3,**R**) as one might have expected. It follows from expression (37) that $\tilde{Y}_1$ will take polynomials into polynomials and indeed we have

$$\begin{aligned}\tilde{Y}_1P_{N_1,N_2,J}=&-[2N_1N_2+(N_1+N_2+m)(m+1)]P_{N_1,N_2,J}+(N_1+m)(N_2+1)P_{N_1-1,N_2+1,J}\\&+(N_1+1)(N_2+m)P_{N_1+1,N_2-1,J}.\end{aligned} \tag{38}$$

The operator $\tilde{Y}_2$ does not take polynomials into polynomials and cannot be written as an element of the enveloping algebra of an affine Lie algebra.

The one-dimensional equations appearing above are easily shown to be related to the standard types in the classification of exact and quasiexact solvable one-dimensional systems.[35,36]

IV. EXACT SOLVABILITY OF THE SUPERINTEGRABLE SYSTEM IN E_n

A. Solution by separation of variables

We now consider the Hamiltonian (17) for arbitrary n. It allows separation of variables in many coordinate systems. We shall use parabolic rotational coordinates corresponding to the set of operators (18) and spherical ones corresponding to the set (19). The parabolic coordinates $(\mu,\nu,\theta_1,\ldots,\theta_{n-2})$ are defined by

$$\begin{aligned}x_1&=\mu\nu\cos\theta_1\cos\theta_2\cdots\cos\theta_{n-3}\cos\theta_{n-2},\\x_2&=\mu\nu\cos\theta_1\cos\theta_2\cdots\cos\theta_{n-3}\sin\theta_{n-2},\\x_3&=\mu\nu\cos\theta_1\cos\theta_2\cdots\sin\theta_{n-3},\\&\vdots\\x_{n-2}&=\mu\nu\cos\theta_1\sin\theta_2,\\x_{n-1}&=\mu\nu\sin\theta_1,\\x_n&=\tfrac{1}{2}(\mu^2-\nu^2).\end{aligned} \tag{39}$$

We put $\beta_i=p_i(p_i-1)/2$ in Eq. (17). The eigenvalue problem that we have to solve is

$$H\psi=E\psi, \quad X\psi=\lambda\psi, \quad Z_l\psi=k_l\psi, \quad 1\leqslant l\leqslant n-2. \tag{40}$$

In parabolic coordinates the operators H and X will involve all variables, the operators Z_l will involve the angles only. Indeed, we have

$$H=-\frac{1}{2(\mu^2+\nu^2)}\left(\frac{\partial^2}{\partial\mu^2}+\frac{n-2}{\mu}\frac{\partial}{\partial\mu}+\frac{\partial^2}{\partial\nu^2}+\frac{n-2}{\nu}\frac{\partial}{\partial\nu}\right)-\frac{2\gamma}{\mu^2+\nu^2}-\frac{1}{2\mu^2\nu^2}\left[\Delta(S_{n-2})\right.$$
$$\left.-\frac{p_1(p_1-1)}{\cos^2\theta_1\cdots\cos^2\theta_{n-2}}-\frac{p_2(p_2-1)}{\cos^2\theta_1\cdots\cos^2\theta_{n-3}\sin^2\theta_{n-2}}-\cdots-\frac{p_{n-1}(p_{n-1}-1)}{\sin^2\theta_1}\right] \tag{41}$$

$$X=\frac{1}{2(\mu^2+\nu^2)}\left[-\nu^2\left(\frac{\partial^2}{\partial\mu^2}+\frac{n-2}{\mu}\frac{\partial}{\partial\mu}\right)+\mu^2\left(\frac{\partial^2}{\partial\nu^2}+\frac{n-2}{\nu}\frac{\partial}{\partial\nu}\right)\right]+\gamma\frac{\mu^2-\nu^2}{\mu^2+\nu^2}+\frac{\mu^2-\nu^2}{2\mu^2\nu^2}$$
$$\times\left[\Delta(S_{n-2})-\frac{p_1(p_1-1)}{\cos^2\theta_1\cdots\cos^2\theta_{n-2}}-\frac{p_2(p_2-1)}{\cos^2\theta_1\cdots\cos^2\theta_{n-3}\sin^2\theta_{n-2}}-\cdots-\frac{p_{n-1}(p_{n-1}-1)}{\sin^2\theta_1}\right], \tag{42}$$

where $\Delta(S_{n-2})$ is the Laplace operator on an $n-2$ dimensional sphere.

The operators Z_l satisfy

$$Z_1\psi=\left(\frac{\partial^2}{\partial\theta_{n-2}^2}-\frac{p_1(p_1-1)}{\cos^2\theta_{n-2}}-\frac{p_2(p_2-1)}{\sin^2\theta_{n-2}}\right)\psi=k_1\psi,$$

$$Z_2\psi=\left(\frac{\partial^2}{\partial\theta_{n-3}^2}-\tan\theta_{n-3}\frac{\partial}{\partial\theta_{n-3}}+\frac{k_1}{\cos^2\theta_{n-3}}-\frac{p_3(p_3-1)}{\sin^2\theta_{n-3}}\right)\psi=k_2\psi,$$

and in general

$$Z_l\psi=\left(\frac{\partial^2}{\partial\theta_{n-l-1}^2}-(l-1)\tan\theta_{n-l-1}\frac{\partial}{\partial\theta_{n-l-1}}+\frac{k_{l-1}}{\cos^2\theta_{n-l-1}}-\frac{p_{l+1}(p_{l+1}-1)}{\sin^2\theta_{n-l-1}}\right)\psi=k_l\psi, \tag{43}$$

$$1\leqslant l\leqslant n-2,\quad k_0=-p_1(p_1-1).$$

We write

$$\psi=M(\mu)N(\nu)\prod_{l=1}^{n-2}F_l(\theta_{n-l-1}) \tag{44}$$

and solve (43) to obtain F_l in terms of Jacobi polynomials

$$F_l(\theta_{n-l-1})=(\sin\theta_{n-l-1})^{p_{l+1}}(\cos\theta_{n-l-1})^{m_{l-1}+1-l/2}P_{J_l}^{(p_{l+1}-1/2,m_{l-1})}(\cos 2\theta_{n-l-1}), \tag{45}$$

$$m_l=2\sum_{i=1}^{l}J_i+\sum_{i=1}^{l+1}p_i+\frac{l-1}{2},\quad k_l=\frac{(l-1)^2}{4}-m_l^2. \tag{46}$$

The equations for $M(\mu)$ and $N(\nu)$ are obtained from Eqs. (41) and (42) once the angular part is replaced by k_{n-2}. The final result is that the wave functions are

$$\psi_{N_1,N_2,J_1,J_2,\ldots,J_{n-2}}(\mu,\nu,\theta_1,\ldots,\theta_{n-2})$$
$$=(\mu\nu)^{\sigma}e^{-\sqrt{-E/2}(\mu^2+\nu^2)}\prod_{l=1}^{n-2}(\sin\theta_{n-l-1})^{p_{l+1}}(\cos\theta_{n-l-1})^{m_{l-1}+1-l/2}L_{N_1}^{m_{n-2}}(\sqrt{-2E}\,\mu^2)$$
$$\times L_{N_2}^{m_{n-2}}(\sqrt{-2E}\,\nu^2)\prod_{l=1}^{n-2}P_{J_l}^{(p_{l+1}-1/2,m_{l-1})}(\cos 2\theta_{n-l-1}),\quad \sigma=2\sum_{i=1}^{n-2}J_i+\sum_{i=1}^{n-1}p_i. \tag{47}$$

The energy is given by a shifted Balmer formula

$$E=-\frac{\gamma^2}{2\left(N_1+N_2+2\Sigma_{i=1}^{n-2}J_i+\Sigma_{i=1}^{n-1}p_i+\dfrac{n-1}{2}\right)^2} \tag{48}$$

and the remaining quantum number is

$$\lambda=-\frac{\gamma(N_1-N_2)}{N_1+N_2+2\Sigma_{i=1}^{n-2}J_i+\Sigma_{i=1}^{n-1}p_i+\dfrac{n-1}{2}}. \tag{49}$$

We see that the case of n arbitrary is a straightforward generalization of $n=3$ and involves the same functions, namely, Jacobi and Laguerre polynomials.

Obviously, one can also solve in spherical coordinates. In fact, formulas (39) can be written as

$$x_a=\mu\nu s_a,\quad x_n=\frac{1}{2}(\mu^2-\nu^2),\quad a=1,\ldots,n-1,\quad \sum_{a=1}^{n-1}s_a^2=1 \tag{50}$$

and we could introduce any coordinates on the S_{n-2} sphere that allow separation of variables in the Laplace–Beltrami equation. For a discussion of such coordinate systems see Refs. 33, 37–40.

We will write for the sake of completeness the explicit expression of the eigenfunctions in the following set of spherical coordinates on the S_{n-1} sphere [which are a generalization to dimension n of those we used in the case $n=3$, see Eq. (25)]:

$$\begin{aligned}
x_1&=r\cos\theta_1\\
x_1&=r\sin\theta_1\cos\theta_2\\
&\vdots\\
x_{n-1}&=r\sin\theta_1\cdots\sin\theta_{n-2}\cos\theta_{n-1}\\
x_n&=r\sin\theta_1\cdots\sin\theta_{n-2}\sin\theta_{n-1}
\end{aligned} \tag{51}$$

and the Hamiltonian can be written in these coordinates as

$$H=-\frac{1}{2}\left[\partial_r^2+\frac{n-1}{r}\partial_r+\frac{2\gamma}{r}\right]-\frac{1}{2r^2}\left\{\left[\partial_{\theta_1}^2+(n-2)\cot\theta_1\partial_{\theta_1}-\frac{p_1(p_1-1)}{\cos^2\theta_1}\right.\right.$$
$$+\frac{1}{\sin^2\theta_1}\left[\partial_{\theta_2}^2+(n-3)\cot\theta_2\partial_{\theta_2}-\frac{p_2(p_2-1)}{\cos^2\theta_2}+\cdots+\frac{1}{\sin^2\theta_{n-3}}\left[\partial_{\theta_{n-2}}^2+\cot\theta_{n-2}\partial_{\theta_{n-2}}\right.\right.$$
$$\left.\left.\left.-\frac{p_{n-2}(p_{n-2}-1)}{\cos^2\theta_{n-2}}+\frac{1}{\sin^2\theta_{n-2}}\left[\partial_{\theta_{n-1}}^2-\frac{p_{n-1}(p_{n-1}-1)}{\cos^2\theta_{n-1}}\right]\cdots\right]\right\}. \tag{52}$$

The set of Y_l, $l=1,\ldots,n-1$ operators are:

$$Y_l=\partial_{\theta_l}^2+(n-l-1)\cot\theta_l\partial_{\theta_l}-\frac{p_l(p_l-1)}{\cos^2\theta_l}+\frac{k_{l+1}}{\sin^2\theta_l},\quad l=1,\ldots,n-2,$$
$$Y_{n-1}=\partial_{\theta_{n-1}}^2-\frac{p_{n-1}(p_{n-1}-1)}{\cos^2\theta_{n-1}} \tag{53}$$

and the eigenvalue equations:

$$H\psi=E\psi,\quad Y_lG_l(\theta_l)=k_lG_l(\theta_l),\quad l=1,\ldots,n-1,\quad \psi=R(r)\prod_{l=1}^{n-1}G_l(\theta_l) \tag{54}$$

can be easily solved. The solution for the angular part is ($m_n=-1/2$):

$$\prod_{l=1}^{n-1}G_l(\theta_l)=\prod_{l=1}^{n-1}(\sin\theta_l)^{m_{l+1}+1-(n-l)/2}(\cos\theta_l)^{p_l}P_{J_l}^{(m_{l+1},p_l-1/2)}(\cos 2\theta_l) \tag{55}$$

and for the radial part:

$$R(r)=r^{m_1-(n-2)/2}e^{-\sqrt{-2E}r}L_{N_r}^{2m_1}(2\sqrt{-2E}r). \tag{56}$$

The energy is written as

$$E=-\frac{\gamma^2}{2\left(N_r+2\Sigma_{i=1}^{n-1}J_i+\Sigma_{i=1}^{n-1}p_{n-i}+\frac{1}{2}(n-1)\right)^2} \tag{57}$$

and the eigenvalues of the operators Y_l are

$$k_l=\frac{1}{4}(n-l-1)^2-m_l^2,\quad m_l=2\sum_{i=l}^{n-1}J_i+\sum_{i=l}^{n-1}p_i+\frac{1}{2}(n-l-1),\quad l=1,\ldots,n-1. \tag{58}$$

Finally, the eigenfunctions are

$$\psi_{N,J_1,\ldots,J_{n-1}}(r,\theta_1,\ldots,\theta_{n-1})=r^{m_1-(n-2)/2}e^{-\sqrt{-2E}r}L_{N_r}^{2m_1}(2\sqrt{-2E}r)$$
$$\times\prod_{l=1}^{n-1}\left[(\sin\theta_l)^{m_{l+1}+1-(n-l)/2}(\cos\theta_l)^{p_l}P_{J_l}^{(m_{l+1},p_l-1/2)}(\cos 2\theta_l)\right]. \tag{59}$$

B. Exact solvability

The exact solvability of the system (17) for general n can be treated in the same way as for $n=3$. We can gauge transform each of the operators in the set (18) separately and transform to the variables

$$s=\sqrt{-2E}\,\mu^2, \quad t=\sqrt{-2E}\,\nu^2, \quad z_{n-l+1}=\cos 2\theta_{n-l+1}, \quad l=1,\ldots,n-2. \tag{60}$$

Before doing this, we again introduce Q_0 and Q_1 as in Eq. (33).

The final result is

$$\begin{aligned}
&\tilde{Q}_0+\tilde{Q}_1=g^{-1}(Q_0+Q_1)g=-2\sqrt{-2E}(2s\partial_s^2+2(1+m_{n-2}-s)\partial_s-m_{n-2}-1),\\
&\tilde{Q}_0-\tilde{Q}_1=g^{-1}(Q_0-Q_1)g=-2\sqrt{-2E}(2t\partial_t^2+2(1+m_{n-2}-t)\partial_t-m_{n-2}-1),
\end{aligned} \tag{61}$$

$$\begin{aligned}
\tilde{Z}_l=g^{-1}Z_lg=4(1-z_{n-l-1}^2)\frac{\partial^2}{\partial z_{n-l-1}^2}+4\left(m_{l-1}-p_{l+1}+\frac{1}{2}-\left(p_{l+1}+m_{l-1}+\frac{3}{2}\right)z_{n-l-1}\right)\partial_{z_{n-l-1}}\\
+\frac{l(l-2)}{4}-(m_{l-1}+p_{l+1})(m_{l-1}+p_{l+1}+1).
\end{aligned}$$

We see that the entire set of operators $\{Q_0,Q_1,Z_1,\ldots,Z_{n-2}\}$ lies in the enveloping algebra of direct product of n special affine Lie algebras saff(1,**R**).

Finally let us turn to the other complete set of commuting operators (19), associated with the separation of variables in spherical coordinates. Among these operators there is just one, namely Y_1, that commutes with all the operators Z_l. We have

$$[Y_1,Z_l]=0, \quad [Y_1,X]\neq 0, \quad [Y_p,Z_l]\neq 0, \quad 1\leqslant l\leqslant n-2, \quad 2\leqslant p\leqslant n-1. \tag{62}$$

Thus, $\tilde{Y}_1$ will take polynomials into polynomials but $\{\tilde{Y}_2,\ldots,\tilde{Y}_{n-1}\}$ will not. We have

$$\tilde{Y}_1=g^{-1}\tilde{Y}_1g=s\,t(\partial_s-\partial_t)^2-(m_{n-2}+1)(s-t)(\partial_s-\partial_t)-m_{n-2}(m_{n-2}+1)+\frac{(n-3)(n-1)}{4}. \tag{63}$$

Finally we see that the ''hidden Lie algebra'' that is not a symmetry algebra of the problem, but underlies its exact solvability is saff(2,**R**)$\oplus$[saff(1,**R**)]$_1\oplus\cdots\oplus$[saff(1,**R**)]$_{n-2}$ generated by

$$\{\partial_s,\partial_t,s\partial_s,t\partial_t,s\partial_t,t\partial_s,\partial_{z_1},z_1\partial_{z_1},\ldots,\partial_{z_n-2},z_{n-2}\partial_{z_{n-2}}\}. \tag{64}$$

V. CONCLUSIONS

Superintegrability and exact solvability were defined in completely different ways, though both have a group theoretical underpinning. Superintegrability for a Hamiltonian system is defined by the requirement that there be more integrals of motion than degrees of freedom.[11] It can be characterized by the fact that the corresponding Schrödinger equation allows a non-Abelian algebra of generalized symmetries, containing an n-dimensional Abelian subalgebra.[25] Exact solvability is defined by the requirement that the energy spectrum can be calculated algebraically.[22–24] It can be characterized by the fact that the Hamiltonian lies in the enveloping algebra of a certain type of finite dimensional affine Lie algebra. It was conjectured[22] that all maximally superintegrable systems are exactly solvable. In this article we have confirmed the conjecture for the considered integrable system in E_n.

The exact connection between superintegrability and exact solvability remains an open problem.

(Received 27 August 2001; accepted for publication 11 December 2001)

The theory of fiber bundles provides a natural setting for the description of macroscopic quantum systems, wherein their classical and quantum features are represented by actions on the base manifolds and the fibers, respectively, of the relevant bundles. We provide realizations of this picture in the description of (a) quasiparticle excitations of many-body systems, especially those in superfluid helium, (b) the interplay between the microscopic and macroscopic dynamics in certain irreversible processes, such as that of a laser, and (c) local thermodynamic equilibrium. In particular, (b) involves the treatment of a dynamical system which is defined on a vector bundle. © *2002 American Institute of Physics.*

I. INTRODUCTION

As pointed out by Bohr, the description of a quantum system, Σ, must have a classical component: otherwise, we could not tell our friends what we have observed! A natural way of expressing this basic fact is to represent the classical and essentially quantum features of Σ by actions on the base space M and the fibers Y, respectively, of a fiber bundle B. In fact, this picture has already been employed in Refs. 1–3 for the description of quasiparticle excitations, such as phonons, magnons, etc., in many-particle systems. In the simplest cases, M was the space of Galilei boosts and Y the single particle Hilbert representation space. The natural action of the Galilei group on the bundle $M\times Y$ permitted a simple description of the quasiparticle spectrum and yielded the noteworthy result that the energy, E, and momentum, $\mathbf{p}$, of a phonon in superfluid helium transformed, under boosts of velocity $\mathbf{v}$, according to Landau's formula

$$\mathbf{p}\to\mathbf{p}, \quad E\to E+\mathbf{p}\cdot\mathbf{v}.$$

The object of this article is to enlarge the above-presented picture in two ways. First, we extend the actions on the bundle from groups to semigroups, in order to accommodate a description of the irreversible dynamics of open dissipative systems; and second we obtain a picture of the interplay between the macroscopic (classical) and microscopic (quantum) dynamics of many-particle systems in terms of these actions.

We shall organize our material as follows. In Sec. II, we present a simple sketch of the theory of fiber bundles. In Sec. III, we formulate the action thereon of both groups and semigroups, and in Sec. IV, we apply the resultant theory to the description of quasiparticle excitations in many-particle systems. Here, the key action is that of the Galilei semigroup, as given by the restriction of the Galilei group to non-negative time translations, and this serves to extend the results of Refs. 1–3 to quasiparticles with finite lifetimes.

The rest of the article is devoted to a demonstration that the interplay between the macroscopic and microscopic properties of many-particle quantum systems may naturally be expressed in terms of actions on fiber bundles. Since dynamics is perceived as a group or semigroup action but studied by infinitesimal (Hamiltonian) methods, we start in Sec. V by obtaining the infinitesimal form of the action of a one-parameter group or semigroup on a product bundle, provided that the action is fiber-preserving. We continue in Sec. VI with a brief sketch of the operator algebraic description of macroscopic quantum systems, including a formulation of local thermodynamic equilibrium conditions. We then turn, in Sec. VII, to a class of open systems, such as the laser model, in which the microscopic evolution is piloted by the macroscopic dynamics (Refs. 4 and 5). Here we show explicitly that the macroscopic-cum-microscopic dynamics of such a system corresponds to the action of a one-parameter semigroup of transformations of the bundle $B=M\times\mathfrak{A}$, where M, the base, is the space of its macroscopic (classical) variables and $\mathfrak{A}$, the fiber, is the $C^\star$-algebra of its microscopic (quantum) observables. Likewise, in Sec. VIII, we show that the local thermodynamic equilibrium conditions of Sec. VI can also be naturally expressed in terms of actions on a fiber bundle.

We conclude in Sec. IX with a brief discussion of the picture presented here and of its possible further ramifications.

Since some readers might not be conversant with both fiber bundles and operator-algebraic quantum theory, we have included brief sketches of these topics in Secs. II and V, respectively.

II. FIBER BUNDLES

A *fiber bundle* $\mathcal{B}=\{B,X,p,G,Y\}$ is, first and foremost, a topological space B which is locally, but not (necessarily) globally, a product. The notation and terminology are suggestive; one can visualize a fiber bundle as a bunch of fibers ''tied together'' by X, the base space. Y is the (abstract) fiber, and $p:B\to X$ a map called the *projection* and, for $x\in X$, the inverse image $Y_x=p^{-1}(x)$ is called the fiber over x. All fibers Y_x are homeomorphic to each other and to Y. G is a topological group, called the group of the bundle, which has an effective action on the fiber.

The space $B=X\times Y$ is a bundle with base X, fiber Y, and projection $p(x,y)=x$. It is called a *trivial bundle* because it is globally a product of the base and the fiber, and G consists only of the identity. The Euclidean plane is also a product, but one needs a coordinate system to display it as a product $X\times Y$. For this reason, it is said to be *equivalent to the product*, and is sometimes called *trivializable*. However, the mathematical literature is not consistent about the use of these terms.

A simple example of a nontrivial bundle is the *Möbius band*, which may be constructed as follows. Take the rectangular strip B_0 in $\mathbb{R}^2$ delimited by the points

$$(a,1),(a,-1),(-a,-1),\quad(-a,1).$$

It is the topological product $B_0=[-a,a]\times[-1,1]$. Now give this strip a twist and glue the short edges together; mathematically, identify the point $[a,-1]$ with $[-a,1]$, and $[a,1]$ with $[-a,-1]$. The twist flips the fibers, which destroys the global product structure. The Möbius band is a nontrivial bundle, with a circle S_1 as base and a real interval, here $[-1,1]$, as fiber. Observe that if glueing had been done without the twist, we would have obtained the cylinder $S_1\times[-1,1]$, which is again a trivial bundle.

The local product (or local triviality) condition in the bundle $\{B,X,p,G,Y\}$ is expressed as follows. There is an open cover $\{V_\alpha\}_{\alpha\in A}$ of X and, for each $\alpha\in A$, a fiber-preserving homeomorphism $\phi_a:p^{-1}(V_\alpha)\to V_\alpha\times Y$; a map $\psi:B_1\to B_2$ between two bundles or subbundles B_1,B_2 is called fiber-preserving if $b,b'\in B_1$, $p_1(b)=p_1(b')$ implies that $p_2(\psi(b))=p_2(\psi(b'))$. The maps ϕ_a are called local trivializations. The local trivializations are glued together to form the bundle, and this is where the group of the bundle G comes in. We shall omit the details, and refer the reader to the standard text of Steenrod (Ref. 6).

The fact that the Möbius band is locally trivial means that, for any open arc C in S_1, there is a fiber-preserving homeomorphism between $p^{-1}(C)$ and $C\times[-1,1]$. S_1 can be covered by two

such arcs C_1 and C_2. In this case the topological group G is the two-element group $\{e,g\}$, where e is the identity and g acts to flip the fibers on one of the two components of the intersection $C_1 \cap C_2$.

A bundle is equivalent to the product if either (1) the base X is paracompact and contractible, or if (2) the base is paracompact and the group G is contractible. Therefore any Banach bundle (a bundle of Banach spaces) on a paracompact and contractible base is equivalent to the product. A stronger result holds for Hilbert bundles,[7] because the group which preserves the inner product structure of an infinite-dimensional Hilbert space (called the ''big'' unitary group) is contractible (Ref. 8). Therefore any Hilbert bundle on a paracompact base is equivalent to the product. All Hilbert and Banach bundles that we shall consider will be equivalent to the product, and may be written as $X \times \mathfrak{K}$, where $\mathfrak{K}$ is a Hilbert space or a Banach space. Their interest would lie in the fact that they bring together two different structures, the differential or symplectic structure of the base space and the linear inner-product or normed space structure of the fiber.

III. ACTIONS OF GROUPS AND SEMIGROUPS ON PRODUCT BUNDLES

A. Principal and associated bundles; the bundle structure theorem

A bundle $\mathcal{B}=\{B,X,p,G,G\}$ is called a *principal bundle* if the fiber is the same as the group, and the group of the bundle acts upon the fiber by left-translations. A bundle $\mathcal{B}'=\{B',X,p,G,Y\}$ is said to be *associated* with the principal bundle $\mathcal{B}$ if the group G acts effectively upon the topological space Y. Note that changing the fiber changes the total space, and therefore the projection. However, we continue to use the same letter to denote the projection in all associated bundles as well. As the context will always be clear, there will be no confusion.

An important result in fiber bundle theory, known as the *bundle structure theorem*, has the following corollary (see Steenrod, Ref. 6, Secs. 7.4 and 7.5): If G is a Lie group and H a (topologically) closed subgroup of G, then G is a principal bundle over the space G/H of left-cosets with respect to the natural projection $p:G \to G/H$ which sends an element of $g \in G$ to its left-coset gH, with group and fiber H: $\mathcal{G}=\{G,G/H,p,H,H\}$.

B. Actions of groups

Any group acts upon itself by left-translations. Therefore any Lie group G has a natural action upon the principal bundle $\mathcal{G}=\{G,G/H,p,H,H\}$. An important special case is that of an associated Hilbert bundle $\mathcal{B}=\{B,G/H,p,H,\mathfrak{H}\}$, but since the group H will generally have many possible actions on the Hilbert space $\mathfrak{H}$, we shall have to choose a particular action, or representation $D(H)$ of H upon $\mathfrak{H}$, and write the associated bundle accordingly:

$$\mathcal{G}_D=\{B,G/H,p,D(H),\mathfrak{H}\}. \tag{1}$$

However, if G is a Lie group, then G/H is necessarily paracompact, and any Hilbert bundle over the base G/H is necessarily equivalent to the product,

$$\mathcal{G}_D \equiv G/H \times \mathfrak{H}. \tag{2}$$

The action of G upon $\mathcal{G}$ (i.e., upon G) by left-translations is known, and so therefore is its action upon $\mathcal{G}_D$, as given by Eq. (1). We have to derive an explicit formula for this action, and then to rework this formula when the total space of $\mathcal{G}_D$ is given in the product form.

It turns out to be simpler to do it directly. This has the further advantage that the resulting formulas are valid for the action of the group upon *any* product bundle, for example a bundle of Banach spaces or operator algebras. We shall therefore work with the generic product bundle

$$B=G/H \times \mathfrak{F}, \tag{3}$$

where the only demand on $\mathfrak{F}$ is that it be a complete normed linear space, and determine the actions of the group G on it.

Let $g \in G$, $x \in G/H$, $\phi \in \mathfrak{F}$, and $b=(x,\phi) \in B$. Write

$$gb = g(x,\phi) = (gx, u(g,x)\phi), \tag{4}$$

where $u(g,x)$ is an appropriate linear map upon $\mathfrak{F}$ which depends upon g and x. $u(g,x)$ has to satisfy the condition

$$u(g'g,x) = u(g',gx)u(g,x) \tag{5}$$

that arises from the associativity of multiplication in G:

$$(g'g)\cdot b = g'(g\cdot b). \tag{6}$$

Observe that Eq. (6) has to hold even if G is only a semigroup.

The action of G on G/H being known, it only remains to determine the quantity $u(g,x)$ which appears in Eq. (4). $u(g,x)$ must be a linear transformation of $\mathfrak{F}$, and it must satisfy Eq. (5). The method of solving Eq. (5) was devised by Wigner in 1939 (Ref. 9). It is as follows.

Let

$$\eta: G/H \to G \tag{7}$$

be an *algebraic cross section* of the bundle $\mathcal{G}$, i.e., a map which satisfies

$$p \circ \eta = \mathrm{id}, \tag{8}$$

where p is the projection in the bundle $\mathcal{G}$ and id is the identity map. An important theorem in fiber bundle theory states that a *continuous* cross section of a principal bundle $\mathcal{G}$ exists if and only if the bundle is equivalent to the product, $\mathcal{G} \equiv G/H \times H$, so that in general the map η cannot be continuous. We shall presently return to this point. Given η, define the map

$$k: G \times G/H \to G \tag{9}$$

by

$$k(g,x) = \eta(gx)^{-1} g\, \eta(x). \tag{10}$$

Then $k(g,x)$ obviously satisfies

$$k(g'g,x) = k(g',gx)k(g,x), \tag{11}$$

and it is easily seen that $k(g,x) \in H$, i.e., k is actually a map,

$$k: G \times G/H \to H. \tag{12}$$

Finally, choose a linear action $D(H)$ of H on $\mathfrak{F}$, and set

$$u(g,x) = D(k(g,x)). \tag{13}$$

The continuity of the action (4) remains to be established. It follows from the definition of the quotient topology that the action of G on G/H by left translations is continuous. According to a theorem of von Neumann, a unitary Hilbert-space representation of a locally compact group is strongly continuous if it is weakly measurable. If η is a measurable map, so is $k(g,x)$ defined by Eq. (10). Thus, for unitary representations, measurability of η suffices to ensure the continuity of $D(k(g,x))$, and therefore of the action (4). In practice, η can always be chosen to be piecewise-continuous. Finally, it is again a standard result in the theory of infinite-dimensional unitary group

representations that the passage from one section η to another is equivalent to a change of basis in $\mathfrak{H}$. (Detailed treatments of infinite-dimensional unitary group representations may be found in Refs. 9–11.)

The arguments of the previous paragraph do not apply if the fiber $\mathfrak{F}$ is not a Hilbert space and the group H does not act upon it as a unitary representation. In this case the problem of continuity has to be studied separately. In the examples we shall consider, the map η will always be continuous, so that the continuity of $D(H)$ would be a sufficient requirement.

The map k of Eq. (10) is sometimes called a $(G,G/H,H)$ cocycle in the mathematics literature, and sometimes a ''Wigner rotation'' of G into H in the physics literature. In Wigner's language, H is the ''little group.''

C. Actions of semigroups

The results of Sec. III B were based on the bundle structure theorem for Lie groups, and the theory of unitary representations on locally compact groups. Neither is available for an arbitrary semigroup G. However, for physical applications one is mainly interested in a very restricted class of semigroups, those that arise from symmetry groups like the Galilei or the Poincaré group by dropping the requirement of time reversibility. In these cases one may mimic the general theorems by *ad hoc* constructions. We shall illustrate the procedure for the ''Galilei semigroup.''

Let $g=(b,\mathbf{a},\mathbf{v},R)$ be an element of the inhomogeneous Galilei group G, where b is a time translation, $\mathbf{a}$ is a space translation, $\mathbf{v}$ is a (velocity) boost, and R is a rotation. The multiplication law in the group is

$$g'g=(b',\mathbf{a}',\mathbf{v}',R')(b,\mathbf{a},\mathbf{v},R)=(b'+b,\mathbf{a}'+R'\mathbf{a}+\mathbf{v}'b,\mathbf{v}'+R'\mathbf{v},R'R), \tag{14}$$

the identity element is $e=(0,0,0,1)$, and the inverse of g is

$$g^{-1}=(-b,-R^{-1}(\mathbf{a}-b\mathbf{v}),\quad R^{-1}\mathbf{v},R^{-1}). \tag{15}$$

We define the Galilei semigroup G^+ by the condition

$$b\geqslant 0. \tag{16}$$

Then the generic element g does not have an inverse, but group elements with $b=0$ are invertible,

$$(0,\mathbf{a},\mathbf{v},R)^{-1}=(0,-R^{-1}\mathbf{a},R^{-1}\mathbf{v},R^{-1}), \tag{17}$$

and G^+ has an identity which is the same as the identity of the group. Clearly, the one-parameter subsemigroup T^+ of time translations has an identity. Therefore, by the Hille–Yosida theorem (Ref. 12), $T^+(b)$ will be strongly differentiable and will have an infinitesimal generator in any bounded strongly continuous Hilbert space representation. We shall confine our search for representations to these cases.

Now T^+ is also topologically closed. The following facts are readily established:

(1) For any closed subsemigroup H^+ of G^+, the factor space $M=G^+/H^+$ is defined and is identical with G/H.
(2) If H^+ is a normal subsemigroup of G^+, then M is a group, and G^+ is equivalent to the product bundle $M\times H^+$.
(3) If the above-mentioned condition is satisfied, then there exists a self-evident cross section of M in G^+ which is continuous, and invertible in G^+.

In this case the action of the semigroup G^+ on the bundle $M\times\mathfrak{H}$ may be constructed exactly as in the case of the group.

We shall exhibit the above-mentioned procedures by the following simple example. Let G^+ be the Galilei semigroup, and H^+ the subsemigroup of time translations. Then $M=G^+/H^+$ is a group, the semidirect product of the group of boosts V and the Euclidean group E_3 in three dimensions. Write $x\in M$ explicitly as

$$x=(\mathbf{z};\mathbf{w};\rho), \tag{18}$$

where $\mathbf{z}$ is a space translation, $\mathbf{w}$ a boost, and ρ a rotation. The map $\eta: M\to G^+$ defined by

$$\eta(x)=(0,\mathbf{z},\mathbf{w},\rho), \tag{19}$$

is a continuous cross section which is invertible in G^+, and G^+ acts on M as follows:

$$gx= \ (b,\mathbf{a},\mathbf{v},R)\cdot(\mathbf{z};\mathbf{w};\rho)=(\mathbf{a}+R\mathbf{z}-(\mathbf{v}+R\mathbf{w})b;\mathbf{v}+R\mathbf{w};R\rho). \tag{20}$$

The cocycle k takes the simple form

$$k(g,x)=(b,0,0,1). \tag{21}$$

Finally, we choose a bounded representation, D, of H^+ on $\mathfrak{H}$:

$$D(b,0,0,1)\phi=D(k(g,x))\phi=e^{(i\alpha-\beta)b}\phi, \tag{22}$$

where $\phi\in\mathfrak{H}$, $\alpha,\beta\in\mathbb{R}$, and $\beta>0$. Hence, by Eq. (12),

$$u(k(g,x))\phi=e^{(i\alpha-\beta)b}\phi. \tag{23}$$

Equations (20) and (23) provide a representation of G^+ on the bundle $M\times\mathfrak{H}$. To see this representation in a more transparent form, we look at the fiber $(0;0;1)$, in a more familiar notation:

$$g(x_0,\phi)=(t,\mathbf{x},\mathbf{v},R)\cdot(0;0;1)=((\mathbf{x}-\mathbf{v}t;\mathbf{v};R), \ \ e^{(i\alpha-\beta)t}\phi). \tag{24}$$

The representation "decays" as t increases.

IV. ELEMENTARY EXCITATIONS AS BUNDLE REPRESENTATIONS

The description of elementary excitations by bundle representations of the Galilei and Poincaré groups has been discussed at length in earlier works (Refs. 2 and 3). Therefore we shall confine ourselves, in the following, to one particular representation of the Galilei group which seems to describe (stable) nonrelativistic zero-mass excitations, and consider how the representation changes if the Galilei group is replaced by the Galilei semigroup.

A. Case of the Galilei group

Here G is the Galilei group and $H=T\times E_3$, the direct product of the subgroup of time translations T and the Euclidean group E_3. In this case the base space M is just the space of the boosts, and there is a natural invertible cross section:

$$\begin{aligned} x&=\mathbf{w},\\ \eta(x)&=(0,0,\mathbf{w},1). \end{aligned} \tag{25}$$

Easy computations yield the formulas

$$\begin{aligned} gx&=\mathbf{v}+R\mathbf{w},\\ k(g,x)&=(b,\mathbf{a}-(\mathbf{v}+R\mathbf{w})b,0,R). \end{aligned} \tag{26}$$

To construct the bundle representation, we recall that irreducible unitary representations of E_3 are characterized by the invariants $\{\mathbf{p}^2,n\}$, where, loosely speaking, $\mathbf{p}^2$ is the square of the momentum and n is the helicity (a non-negative integer). The irreducible representation space is $L_2(S_2,dS)$, where S_2 is the two-sphere and dS is the rotation-invariant measure on it. For our purposes, it is convenient to use *not* the irreducible unitaries, but the following one, U, on $\mathfrak{H}=L_2(\mathbf{p},d^3p)$, which is the direct integral of copies of $L_2(S_2,dS)$ over two spheres of all radii.

$$U(\mathbf{a},R)\phi(\mathbf{p})=e^{in\sigma(R,\omega)}e^{-i\mathbf{a}\cdot\mathbf{p}}\phi\circ R^{-1}(\mathbf{p}). \tag{27}$$

In the above, $\sigma(R,\omega)$ is an (O_3,S_2,O_2)-cocycle or Wigner rotation, where O_3,O_2 are the orthogonal (rotation) groups in three and two dimensions, respectively, $S_2=O_3/O_2$ is the two sphere, and ω a point on S_2. All component irreducibles in Eq. (27) have the same helicity. Finally, we represent $T\times E_3$ on $\mathfrak{H}$ as follows:

$$U(b,\mathbf{a},R)\phi(\mathbf{p})=e^{iE(\mathbf{p}^2,n)b}U(\mathbf{a},R)\phi(\mathbf{p}). \tag{28}$$

In the previous text, E is a positive, but otherwise arbitrary function of $\mathbf{p}^2$, and n is fixed. By Eqs. (13) and (26), the bundle representations are obtained by taking $D(k(g,x))\phi=U(b,\mathbf{a}-(\mathbf{v}+R\mathbf{w})b),R)\phi$.

On the fiber $\mathbf{w}=0$, the bundle representation takes the explicit form

$$(b,\mathbf{a},\mathbf{v},R)(0,\phi)=(\mathbf{v},e^{i\Lambda}(\phi\circ R^{-1})\mathbf{p}), \tag{29}$$

where

$$\Lambda=-\mathbf{a}\cdot\mathbf{p}+b(E+\mathbf{v}\cdot\mathbf{p})+n\sigma(R,\omega). \tag{30}$$

In the previous text, we have suppressed the arguments in E. Formulas (29) and (30) show that under a boost,

$$\begin{aligned}\mathbf{p}&\to\mathbf{p},\\ E&\to E+\mathbf{p}\cdot\mathbf{v}.\end{aligned} \tag{31}$$

In their analysis of irreducible unitary representations of the Galilei group, Inönü and Wigner (Ref. 13) had concluded that these representations had no physical interpretation because they did not admit either localizable states (since $\mathbf{p}^2$ was constant in an irreducible, not enough momenta were available to form a delta function) or states that were—like the photon—localizable in velocity space. The first argument would not apply to a *reducible* representation which contains all values of $\mathbf{p}^2$ with the same weight. However, the invariance group imposes no relationship between E and $\mathbf{p}^2$, and, as the second equation of (31) shows, in any linear representation, for any value of $\mathbf{p}^2$, the quantity E takes—owing to the boosts—all values between $-\infty$ and $+\infty$. This alone would rule out the possibility of a physical interpretation for these representations.

In the above-constructed *bundle* representations, the boosts are represented not on the fibers but on the base space. Specializing formulas (29) and (30) to the case $\mathbf{a}=0$, $R=1$ and setting $\sigma(1,\omega)=0$ (which can be done without loss of generality), we find that

$$(b,0,\mathbf{v},1)(0,\phi)=(\mathbf{v},e^{ib(E+\mathbf{p}\cdot\mathbf{v})}\phi(\mathbf{p})), \tag{32}$$

i.e., on any given fiber, we are able to assign a value of E to a given $\mathbf{p}^2$, because this assignment will not be disturbed by the boosts. That is, we may choose, arbitrarily, a *dispersion law* $E=E(\mathbf{p}^2)$. Since all values of $\mathbf{p}$ occur with the same weight, it becomes possible to construct localizable states, which may be interpreted as excitations corresponding to the chosen dispersion law. Finally, Eq. (31) shows that these excitations have *zero nonrelativistic mass*.

Equation (31) constitutes the transformations laws, under boosts, of the excitations posited by Landau in his explanation of superfluidity (Refs. 14 and 15).

B. Case of the Galilei semigroup

For the Galilei semigroup G^+, we shall construct a representation that is as close as possible to that previously mentioned, above, without being identical to it. We shall take $H^+ = T^+ \times E_3$, so that G^+/H^+ will again be the space of the boosts. The natural cross section will again be given by the second equation in (25), and formula (26) for $g\mathbf{x}$ and $k(g,\mathbf{x})$ will remain valid, with the proviso that $b \geqslant 0$. We shall represent E_3 on $\mathfrak{H}$ as before, i.e., by formula (27). However, the subsemigroup of time translations will be represented, not by a character $\exp i\epsilon b$, but by a quantity $\exp(i\epsilon - \gamma)b$, where $\gamma \geqslant 0$. Equation (28) will [cf. Eqs. (22) and (23)] accordingly change to the following formula for the relevant representation, Δ, of H^+:

$$\Delta(b,\mathbf{a},R)\phi(\mathbf{p}) = e^{(iE(\mathbf{p}^2,n)-\Gamma(\mathbf{p}^2,n))b} U(\mathbf{a},R)\phi(\mathbf{p}), \tag{33}$$

where Γ is a positive function, n is a fixed positive integer, and $b \geqslant 0$. Formally, the passage from the group to the semigroup is equivalent to replacing E by $E + i\Gamma$ in the representation $U(b,\mathbf{a},R)$. Clearly, $\mathbf{p}, E,$ and Γ will transform under boosts as

$$\begin{aligned} \mathbf{p} &\to \mathbf{p}, \\ E &\to E + \mathbf{p}\cdot\mathbf{v}, \\ \Gamma &\to \Gamma. \end{aligned} \tag{34}$$

The quantity $\Gamma(\mathbf{p}^2)$ may be interpreted as the inverse lifetime of the excitation with momentum $\mathbf{p}$. For large values of $\Gamma(\mathbf{p}^2)$, the excitations become very unstable, and perhaps no longer experimentally detectable. As the last equation in (34) shows, properties of the excitations that depend on Γ are invariant under the boosts.

Since the representation Δ is bounded and continuous, and since the semigroup has an identity, the semigroup of time translations has an infinitesimal generator.

V. DYNAMICS ON BANACH BUNDLES

Symmetries are usually studied via group rather than Lie algebra actions, because they avoid the problems associated with unbounded operators. By contrast, dynamics is usually studied via the infinitesimal generator of the one-parameter group or semigroup of time translations—the Hamiltonian—because the Hamiltonian represents the total energy of the system. In quantum mechanics, the Hamiltonian is an operator on a Hilbert space. In classical mechanics, it is a complete vector field on a manifold of states. From physical considerations, one would expect a one-parameter group or semigroup of time translations of a Banach bundle to possess an infinitesimal generator, which would act like a linear transformation on the fibers and a vector field on the base space. To the best of the authors' knowledge, such mathematical objects have not yet been studied, and there is no generalized ''Stone–Whitney theorem'' which asserts their existence for dynamics on vector bundles. We therefore begin—assuming that time translations indeed act as a one-parameter group or semigroup of fiber-preserving maps on a vector bundle—by defining the two constituents of this generator, one acting on the base space and the other on the fibers. The dynamical systems these pairs define will be seen in Sec. VII to be realized by certain quantum mechanical models.

Let Γ be a dynamical system (B,T), where $B = X \times Y$ is a Banach bundle and $T = \{T_t | t \in \mathbb{R}$ or $\mathbb{R}^+\}$ is a one-parameter group or semigroup of fiber-preserving transformations of B. These maps define a one-parameter group or semigroup of base maps $\{S_t | t \in \mathbb{R}$ or $\mathbb{R}^+\}$, and the action of T on B is analogous to that of g in Eq. (4), i.e.,

$$T_t(x,y)=(S_tx,V(t,x)y)\equiv(x_t,y_t)\forall\ \ x\in X,\ \ y\in Y,\ \ t\in\mathbb{R}\ \text{ or }\ \mathbb{R}^+, \tag{35}$$

where $V(t,x)$ is a linear transformation of Y. Then it follows immediately from the semigroup properties of S and T that

$$\begin{aligned} S_{t+t'}x&=S_t(S_{t'}x),\\ V(t+t',x)&=V(t',S_tx)V(t,x). \end{aligned} \tag{36}$$

Furthermore, assuming that S_tx and $V(t,x)y$ are differentiable with respect to t in the natural topologies of X and Y, respectively, it follows from Eqs. (35) and (36) that the equations of motion for x_t and y_t are

$$\frac{\mathrm{d}x_t}{\mathrm{d}t}=F(x_t) \tag{37}$$

and

$$\frac{\mathrm{d}y_t}{\mathrm{d}t}=L(x_t)y_t, \tag{38}$$

where

$$F(x)=\lim_{h\to 0}h^{-1}(S_h-I)x\ \ \forall\ \ x\in X \tag{39}$$

and

$$L(x)y=\lim_{h\to 0}h^{-1}(V(h,x)-I)y\forall\ \ x\in X,\ \ y\in Y. \tag{40}$$

Thus, Eqs. (37) and (38) signify that the flow $x\to x_t$ in the base space X is not only autonomous but also serves to drive the flow $y\to y_t$ in the fibers.

VI. THE GENERIC OPERATOR ALGEBRAIC QUANTUM MODEL

A. Observables, states, dynamics

In a standard way (cf. Refs. 15–20), we idealize a macroscopic quantum system, Σ, as an infinitely extended assembly of interacting particles living in a space X, which may be either a Euclidean space $\mathbb{R}^d$ or a lattice $\mathbb{Z}^d$. The generic model of Σ is given[21] in the Schrödinger picture,[22] by an algebra of observables $\mathfrak{A}$, a state space Ω of expectation functionals on $\mathfrak{A}$, and a one-parameter group or semigroup τ of transformations of Ω representing the dynamics of the system. The model conforms to the following specifications.

(I) $\mathfrak{A}$ is the $C^\star$-algebra of observables. This has a local structure, which is as follows.

(a) Each bounded region Λ of X carries a $C^\star$-subalgebra $\mathfrak{A}_\Lambda$, comprising the bounded operators in a local Hilbert space $\mathfrak{H}_\Lambda$, whose self-adjoint elements are the observables in Λ.

(b) The algebras $\mathfrak{A}_\Lambda$ satisfy the conditions of isotony and local commutativity, namely

$$\mathfrak{A}_\Lambda\subset\mathfrak{A}_{\Lambda'}\qquad\text{if}\quad\Lambda\subset\Lambda'$$

and

$$[a,a']=0\qquad\text{if}\quad a\in\mathfrak{A}_\Lambda,\ \ a'\in\mathfrak{A}_{\Lambda'}\qquad\text{and}\ \ \Lambda\cap\Lambda'=\emptyset.$$

Furthermore, space translations correspond to a homomorphism, σ, of the additive group X into $\mathrm{Aut}(\mathfrak{A})$, and the local algebras $\mathfrak{A}_\Lambda$ transform covariantly under $\sigma(X)$, i.e.,

$$\sigma(x)\mathfrak{A}_\Lambda = \mathfrak{A}_{\Lambda+x}.$$

The unbounded observables for the region Λ are the unbounded self-adjoint operators in $\mathcal{H}_\Lambda$ (Ref. 23).

(c) $\mathfrak{A}$ is the norm-closure of the union of the local algebras $\mathfrak{A}_\Lambda$. We shall denote this union, which is a subalgebra of $\mathfrak{A}$, by $\mathfrak{A}_{\text{loc}}$.

(II) The state space Ω and the dynamical group or semigroup τ are defined as follows.[21] Ω is a folium[24] of positive, normalized, locally normal[25] linear functionals on $\mathfrak{A}$ that is stable under the dual of σ, while τ is a representation *either* of $\mathbb{R}$ *or* of $\mathbb{R}^+$ in the affine transformations of the state space Ω. The interpretation of the model is that the expectation value of an observable a at time t, subject to the condition that ω is the initial state of the system, is $\langle \tau(t)\omega;a\rangle$, where $\langle \omega;a\rangle \equiv \omega(a)$. We assume that τ and Ω satisfy the following conditions.

(a) τ is the infinite volume limit, in a sense we shall presently specify, of the one-parameter dynamical group or semigroup τ_Λ of the finite volume version, Σ_Λ, of Σ consisting of the particles of the given species confined to the bounded region Λ. Here τ_Λ is the predual of a one-parameter group of automorphisms or a semigroup of completely positive,[26–28] identity preserving transformations of $\mathfrak{A}_\Lambda$, depending on whether Σ_Λ is a conservative system or an open dissipative one. In either case, its form is obtained, by standard constructions, in terms of the interactions between the particles of the system. Denoting now by ω_Λ the restriction of a state ω of Σ to $\mathfrak{A}_\Lambda$, i.e., the state it induces in Σ_Λ, we express our condition that τ is an infinite volume limit of τ_Λ by

$$\langle \tau(t)\omega;a\rangle = \lim_{\Lambda\uparrow X}\langle \tau_\Lambda(t)\omega;a\rangle \forall \quad a\in\mathfrak{A}_{\text{loc}}, \quad \omega\in\Omega, t\in\mathbb{R} \text{ or } \mathbb{R}^+.$$

(b) Ω is the maximal locally normal folium of states that supports the dynamics given by this formula.

It follows from these specifications that Ω and τ, like τ_Λ, are determined by the interactions in the system. We note here that the norm-closed linear span $[\Omega]$ of Ω is a Banach space, whose dual is a $W^\star$-algebra $\hat{\mathfrak{A}}$ (Ref. 29) which in turn is just the weak closure of the representation, Π, of $\mathfrak{A}$ given by the direct sum of the GNS representations of this algebra for all states in the space Ω (Ref. 21). Correspondingly, the transformations $\tau^\star(t)$ of $\hat{\mathfrak{A}}$ dual to $\tau(t)$ form a one-parameter group of automormorphisms of $\hat{\mathfrak{A}}$ or a semigroup of completely positive, identity preserving linear transformations of $\hat{\mathfrak{A}}$, according to whether Σ is a conservative system or an open dissipative one.

B. Macroscopic observables

These are *classical* nonlocalized observables (such as the global space averages of the translates of local ones) that are attached, not to $\mathfrak{A}$, but to certain representations of $\mathfrak{A}$. We define them as follows (cf. Ref. 30). Let π be a representation of $\mathfrak{A}$ in a Hilbert space $\mathfrak{H}$, such that the set, Ω_π, of states on $\mathfrak{A}$ corresponding to the density matrices in $\mathfrak{H}$ is a subset of Ω. Then the macroscopic observables associated with the representation π are defined to be the strong limits, $\hat{F}$, of uniformly bounded sequences $\{\pi(F_n)|n\in\mathbb{N}\}$, where the F_n's are elements of $\mathfrak{A}$ such that

$$\text{norm}-\lim_{n\to\infty}[F_n,A]=0 \quad \forall \quad A\in\mathfrak{A}.$$

It follows easily from these specifications that the macroscopic observables $\hat{F}$ belong the center of the von Neumann algebra $\pi(\mathfrak{A})''$. They therefore form an Abelian $W^\star$-algebra, $\mathfrak{M}$, i.e., an algebra of functions on a classical phase space.[29] Evidently, they may be identified with functionals on the set of states Ω_π according to

$$\hat{F}(\omega) = \lim_{n\to\infty}\omega(F_n) \forall \quad \omega\in\Omega_\pi.$$

A prototype of a macroscopic observable is obtained by choosing

$$F_n = |\Lambda_n|^{-1} \int_{\Lambda_n} \mathrm{d}x\, \sigma(x) f,$$

where $f \in \mathfrak{A}$ and $\{\Lambda_n\}$ is a increasing sequence of bounded spatial regions, whose union is X. $\hat{F}$ is then the global space average of $\pi(\sigma(x)f)$, i.e.,

$$\hat{F} = s - \lim_{n\to\infty} |\Lambda_n|^{-1} \int_{\Lambda_n} \mathrm{d}x\, \pi(\sigma(x) f).$$

We shall now provide a sketch of how the above-mentioned general definition of $\hat{F}$ can be extended, for some representations π, to cases where the local observables F_n are unbounded, e.g., when they correspond to space averages over bounded regions of the locally conserved densities of standard thermodynamic observables (Refs. 14 and 20). Thus, we consider the case where $(\mathfrak{H}, \pi, \Phi)$ is the GNS representation of $\mathfrak{A}$ for a primary,[31] translationally invariant state ω. We assume that $\hat{\xi}$ is a Hermitian quantum field such that $\hat{\xi}(x)$ is a distribution-valued observable for the ball of center x and some x-independent radius a and that $\hat{\xi}$ is covariant with respect to space translations, i.e., $\sigma(x')\hat{\xi}(x) = \hat{\xi}(x+x')$. We define (formally) the derivation δ and the local observable F_n by

$$\delta = i \int_X \mathrm{d}x [\pi(\hat{\xi}(x)), .],$$

where the dot on the right refers to the argument of δ and

$$F_n = |\Lambda^n|^{-1} \int_{\Lambda_n} \mathrm{d}x\, \hat{\xi}(x).$$

We then make the following assumptions concerning $\hat{\xi}$.

(a) $\omega(F_n)$ converges to a limit, $\hat{F}(\omega)$, as $n \to \infty$. In view of the assumed translational invariance of ω, this is equivalent to the condition that $\omega(\hat{\xi}(x))$ is well-defined.

(b) There is a dense subset, $\mathfrak{B}$, of $\mathfrak{A}_{\mathrm{loc}}$ such that Φ lies in the domain of the (possibly unbounded) observable δB, for all $B \in \mathfrak{B}$. Here we note that it follows from the above-mentioned specifications that, in view of the local commutativity property of $\mathfrak{A}$, δB reduces here to $i\int_{\Lambda_n} \mathrm{d}x [\hat{\xi}(x), B]$ for n sufficiently large.

(c) For each $A \in \mathfrak{A}$, the correlation function $\omega(A\hat{\xi}(x)) - \omega(A)\omega(\hat{\xi}(x))$ is of class L_1, in keeping with the standard cluster properties of primary states (Ref. 32).

It follows easily from these specifications that, for all $B \in \mathfrak{B}$, the expectations of the observables F_n in the states $\omega_B(.) := \omega(B^\star(.)B)/\omega(B^\star B)$ satisfy the condition

$$\lim_{n\to\infty} \omega_B(F_n) = \hat{F}(\omega) \quad \forall B \in \mathfrak{B}.$$

This is equivalent to the statement that the sequence $\{\pi(F_n)\}$ converges to $\hat{F}(\omega)I$ as $n \to \infty$, and therefore signifies that the limit of the sequence is a macroscopic observable $\hat{F} := \hat{F}(\omega)I$.

Equilibrium states and thermodynamical variables. In the case where Σ is conservative, its equilibrium states at inverse temperature β comprise the convex set Ω_β of states that satisfy the Kubo–Martin–Schwinger condition, whose general significance was first exposed by Haag, Hugenholtz, and Winnink (Ref. 33). This takes the form

$$\omega(A_t B) = \omega(B A_{t+i\hbar\beta}) \quad \forall A, B \in \mathfrak{A},$$

where, in our Schrödinger picture (cf. Refs. 34 and 21), ω is the canonical extension of the state denoted by the same symbol, and A_t is the element $\tau^\star(t)\pi(A)$ of the von Neumann algebra generated by the corresponding GNS representation, π, of $\mathfrak{A}$. The extremal elements of Ω_β are precisely the primary ones and therefore may naturally be interpreted as the pure thermodynamic phases of the system (Refs. 35 and 36). Furthermore, it follows from their primary property that they may be indexed by an appropriate set of macroscopic observables (Ref. 30); and, in accordance with the demands of classical thermodynamics, we shall assume that the latter observables are the global space averages of locally conserved fields $\hat{q}(x) = (\hat{q}_1(x), .., \hat{q}_n(x))$, such as those representing densities of energy, mass, etc. We shall denote the pure equilibrium phase at inverse temperature β for which these macroscopic variables take the values $(q_1, \ldots, q_n)$ by $\omega_{\beta,q}$.

C. Local equilibrium

The concept of local equilibrium is natural for a hydrodynamic, i.e., large scale, description of Σ, in which a point corresponds to cell containing an enormous number of particles in the microscopic picture. We shall now formulate this concept for the case where Σ is a conservative system, whose algebra of observables, $\mathfrak{A}$, is generated by a quantum field, ψ, that satisfies the canonical commutation or anticommutation relations, according to whether Σ consists of bosons or fermions. Thus,

$$[\psi(x), \psi^\star(y)]_\pm = \delta(x-y); \quad [\psi(x), \psi(y)]_\pm = 0,$$

and the action of the space translational automorphisms is given by

$$\sigma(x)\psi(y) = \psi(x+y).$$

We define $\gamma(L)$ to be the automorphism of $\mathfrak{A}$ representing the distance rescaling $x \to Lx$, i.e.,

$$\gamma(L)\psi(y) = L^{d/2}\psi(Ly),$$

the factor $L^{d/2}$ ensuring that γ preserves the canonical commutation and anticommutation relations. It follows easily from these definitions that $\{\gamma(L) | L \in \mathbb{R}^+\}$ form a group, with $\gamma(L_1)\gamma(L_2) = \gamma(L_1 L_2)$, and that γ and σ satisfy the important equation

$$\gamma(L)\sigma(x) = \sigma(Lx)\gamma(L). \tag{41}$$

Now let $\{\omega^{(L)} | L \in \mathbb{R}^+\}$ be a family of states indexed by L, where the parameter L is a characteristic length governing the spatial variations of $\omega^{(L)}$ in the following sense. For any local observable a, $\omega^{(L)}(\sigma(Lx)a)$ reduces to an L-independent function of x, at least for sufficiently large L. We define $\tilde{\omega}^{(L)}$ to be the version of $\omega^{(L)}$ in the scaling for which the unit of length is L, i.e.,

$$\tilde{\omega}^{(L)}(a) = \omega^{(L)}(\gamma(L)a) \forall \quad a \in \mathfrak{A}. \tag{42}$$

Our hydrodynamic picture of Σ will be based on the structure of this state in the large scale limit where $L \to \infty$.

We now note that, by Eqs. (41) and (42),

$$\tilde{\omega}^{(L)}(\sigma(x)a) = \omega^{(L)}(\gamma(L)\sigma(x)a) = \omega^{(L)}(\sigma(Lx)\gamma(L)a).$$

Hence, replacing a by $\gamma(L^{-1})a$ and defining

$$\alpha(L,x) = \sigma(x)\gamma(L^{-1}), \tag{43}$$

it follows that

$$\tilde{\omega}^{(L)}(\alpha(L,x)a)=\omega^{(L)}(\sigma(Lx)a). \tag{44}$$

In order to see the significance of this equation, we note that it follows from our definitions of the automorphisms σ,γ, and α that

$$\alpha(L,x)\psi(y)=L^{-d/2}\psi(x+L^{-1}y). \tag{45}$$

Thus, for large L, the action of $\alpha(L,x)$ serves to localize the observables around the point x. Hence the left-hand side of our formula for $\tilde{\omega}^{(L)}$ yields the state in the vicinity of x, according to the large scale description.

Suppose now that D is a fixed, bounded spatial region that is sufficiently large to contain an enormous number of particles, in the microscopic description. Thus, the subsystem in D is mesoscopic, in that, on the one hand, it contains a huge number of particles, while, on the other hand, the ratio of its span to the distance, L, vanishes in the limit $L\to\infty$. In other words, D corresponds to a *hydrodynamic point*.

Our local equilibrium condition is that the restriction of $\omega^{(L)}$ to the space translate, $D+Lx$, of D reduces to an equilibrium state corresponding to some position-dependent values, $\beta(x)$ and $q(x)$, of the thermodynamic variables β and q, in the limit $L\to\infty$, i.e., that, if a is an arbitrary observable for the region D, then

$$\lim_{L\to\infty}\omega^{(L)}(\sigma(Lx)a)=\omega_{\beta(x),q(x)}(a), \tag{46}$$

which is consistent with our earlier assertion that $\omega^{(L)}(\sigma(x)a)$ is L independent for L sufficiently large. Evidently, $(\beta(x),q(x))$ is a classical field, representing the local thermodynamic variables in the hydrodynamic description. Further, since D is an arbitrary bounded region, the above-specified local equilibrium condition extends to all elements a of the algebra $\mathfrak{A}$. Moreover, by Eq. (44), it takes a particularly simple form when expressed in terms of the rescaled state, $\tilde{\omega}^{(L)}$, namely

$$\lim_{L\to\infty}\tilde{\omega}^{(L)}(\alpha(L,x)a)=\omega_{\beta(x),q(x)}(a)\quad\forall\quad a\in\mathfrak{A}. \tag{47}$$

In other words, the state as described in the large scale limit reduces, at any spatial point x, to the equilibrium state $\omega_{\beta(x),q(x)}$. In fact, this condition has been proved to be fulfilled by Gibbs states of nonrelativistic gravitational systems (Ref. 37).

Finally, this formulation of local equilibrium may easily be extended to the dynamical situation in the case where the macroscopic equations of motion for the evolutes, $(\beta_t(x),q_t(x))$, of $(\beta(x),q(x))$ are invariant under the transformation $x\to Lx, t\to L^k t$, for some positive constant k, as in the cases of both diffusion or Eulerian hydrodynamics. For then, the space–time generalization of the above-mentioned local equilibrium condition is simply

$$\lim_{L\to\infty}\langle\tau(L^k t)\omega^{(L)};(\sigma(Lx)a)\rangle=\omega_{\beta_t(x),q_t(x)}(a). \tag{48}$$

Equivalently, defining the time-dependent state, $\tilde{\omega}_t^{(L)}$, in the hydrodynamic description by

$$\tilde{\omega}_t^{(L)}(a)=\langle\tau(L^k t)\tilde{\omega}^{(L)};\gamma(L)a\rangle, \tag{49}$$

the local equilibrium condition takes the form

$$\lim_{L\to\infty}\tilde{\omega}_t^{(L)}(\alpha(L,x)a)=\omega_{\beta_t(x),q_t(x)}(a)\quad\forall\quad a\in\mathfrak{A}. \tag{50}$$

This condition has been proved to be satisfied by various classical stochastic models (Ref. 38).

VII. BUNDLE DYNAMICAL MODEL OF MACROSCOPIC-CUM-MICROSCOPIC EVOLUTION

In the generic model of a many-particle system, as formulated in Sec. VI, the microscopic observables are quantum mechanical variables, whereas the macroscopic ones are classical. This dichotomy is essential for the reconciliation of quantum microphysics with the empirical fact that the macroscopic dynamics of ''large'' systems generally conforms to classical laws, such as those of hydrodynamics or heat conduction. Furthermore, it has been established that, at least in particular models (cf. Refs. 39 and 5), the macroscopic dynamics is governed by self-contained deterministic laws and acts so as to ''pilot'' the microdynamics. We shall now show that the macroscopic-cum-microscopic evolution of such systems provides a concrete example of the bundle dynamical model of Sec. V.

We base our treatment on the model Σ of Sec. VI, and for simplicity, we restrict our consideration to the case where this is an open dissipative system, i.e., where τ is a one-parameter semigroup. The treatment of the conservative case can be carried out analogously.

We assume that, as in the laser model of Refs. 4 and 5, τ induces macroscopic and microscopic evolutions that may be described as follows.

(I) Σ has a set of macroscopic observables that are functions on a phase space M and evolve according to a deterministic law given by a one-parameter semigroup $\{S_t | t \in \mathbb{R}^+\}$ of transformations $m \to S_t m = m_t$ of M. Thus, assuming that $S_t m$ is differentiable with respect to t, the macroscopic equation of motion takes the form

$$\frac{\mathrm{d}m_t}{\mathrm{d}t} = F(m_t), \tag{51}$$

where F is a vector field on M.

(II) The microscopic evolution of the system is piloted by its macroscopic dynamics in such a way that the equation of motion for the evolute, a_t, of an observable a at time t has the form

$$\frac{\mathrm{d}a_t}{\mathrm{d}t} = L(m_t)a_t, \tag{52}$$

where $L(m_t)$ acts linearly on $\mathfrak{A}$. To be precise, the microscopic dynamics is given by a two-parameter family, $\{W(t,u;m) | t \geqslant u\}$, of completely positive, identity-preserving linear transformations of $\mathfrak{A}$, such that

$$a_t = W(t,u;m)a_u, \tag{53}$$

and

$$W(t,u;m)W(u,v;m) = W(t,v;m), \tag{54}$$

which is essentially a determinacy condition. Equations (51)–(54) then signify that $L(m_t)$ is the generator of the transformations W, i.e., that

$$L(m_t) = (\partial W(t,u;m)/\partial t)_{t=u} \tag{55}$$

and hence that

$$\frac{\partial}{\partial t} W(t,u;m) = L(m_t)W(t,u;m) \equiv L(S_t m)W(t,u;m), \quad \forall \quad m \in M, \quad t \geqslant u. \tag{56}$$

(III) $L(m_t)$ is indeed a true generator, in that Eq. (56) determines W uniquely, subject to the condition that $W(t,t;m) \equiv I$.

We shall now show that, under assumptions (I)–(III), the macroscopic-cum-microscopic dynamics of Σ reduces to that on a fiber bundle, as formulated in Sec. V. To this end, we start by defining B to be the bundle $M\times\mathfrak{A}$ and $V(t,m)$ and T_t to be the transformations of $\mathfrak{A}$ and B, respectively, given by

$$V(t,m)=W(t,0;m) \quad \forall \quad m\in M, \quad t\in\mathbb{R}^+ \tag{57}$$

and

$$T_t(m,a)=(S_t m, V(t,m)a) \quad \forall \quad m\in M, \quad a\in\mathfrak{A}, \quad t\in\mathbb{R}^+. \tag{58}$$

We then prove the following proposition, which establishes that the transformations T_t form a one-parameter semigroup that satisfies all the conditions of the bundle dynamical model of Sec. V.

Proposition 7.1: Under the above-given assumptions, V satisfies the bundle structure property (sometimes called the *cocycle condition*)

$$V(t+u,m)=V(u,S_t m)V(t,m) \quad \forall \quad m\in M, t,u\in\mathbb{R}^+ \tag{59}$$

and T possesses the semigroup properties

$$T_t T_u = T_{t+u} \qquad \text{and} \qquad T_0 = I \quad \forall t,u\in\mathbb{R}^+. \tag{60}$$

Comment: This proposition establishes that the transformations T_t form a one-parameter semigroup that satisfies all the conditions of the bundle dynamical model of Sec. V. In other words, the macroscopic-cum-microscopic dynamics of the system Σ are completely captured by that model.

Proof of Proposition 7.1: It follows from the replacement of m, t, u by $S_u m$, $t-u$,0, respectively, in Eq. (56) that

$$\frac{\partial}{\partial t}W(t-u,0;S_u m)=L(S_{t-u}S_u m)W(t-u,0;S_u m),$$

which, in view of the semigroup property of S, is equivalent to

$$\frac{\partial}{\partial t}W(t-u,0;S_u m)=L(S_t m)W(t-u,0;S_u m). \tag{61}$$

Hence, $W(t-u,0;S_u m)$, as well as $W(t,u;m)$, is a solution of Eq. (56), and therefore, in view of the uniqueness assumption (III),

$$W(t-u,0;S_u m)=W(t,u;m) \quad \forall \quad m\in M, \quad u,t(\geqslant u)\in\mathbb{R}^+.$$

On replacing t by $t+u$ in this equation, we see that

$$W(t,0;S_u m)=W(t+u,u;m) \quad \forall \quad m\in M, \quad t,u\in\mathbb{R}^+. \tag{62}$$

The bundle structure formula (59) for V now follows immediately from this formula, together with Eqs. (54) and (57). Furthermore, this result, together with the semigroup property of S, implies that the transformations T, defined by Eq. (58), form a one-parameter semigroup.

VIII. FIBER BUNDLE DESCRIPTION OF LOCAL EQUILIBRIUM

We shall now show that local thermodynamic equilibrium (LTE), as formulated in Sec. VI C, may be simply described in terms of actions on a fiber bundle. For notational simplicity, we denote by $\theta(x)$ the $(n+1)$-component hydrodynamic field $(\beta(x),q(x))\equiv(\beta(x),q_1(x),\ldots,q_n(x))$ specified in Sec. VI C. Thus, the LTE formula (47) takes the form

$$\lim_{L\to\infty} \tilde{\omega}^{(L)}(\alpha(L,x)a)) = \omega_{\theta(x)}(a). \tag{63}$$

Evidently, θ is a mapping from X into $\mathbb{R}^{n+1}$ whose range is the Cartesian product of those of the thermodynamic variables $(\beta, q_1, \ldots, q_n)$. We shall denote by Θ the space of kinematically possible forms of the field θ. For present purposes, it is not necessary to specify the topology of Θ. We shall assume that the dynamical group, τ, of Σ induces a phenomenological dynamics given by a semigroup $\{\phi(t) | t \in \mathbb{R}^+\}$ of transformations of Θ. Thus,

$$\phi(t)\theta = \theta_t \equiv (\beta_t, q_t), \tag{64}$$

where β_t, q_t are the time-dependent fields that appear in Eq. (50).

We now define the fiber bundle B, in the notation of Sec. V, to be $X \times \mathfrak{A}$. Its fiber at the spatial point x therefore consists of elements a_x of $\mathfrak{A}$. We then define P to be the mapping $\theta \to P_\theta$ of Θ into the complex-valued functions on B given by

$$P_\theta(x, a_x) = \omega_{\theta(x)}(a_x). \tag{65}$$

On comparing this equation with Eq. (63), we see immediately that P carries a full description of LTE in that, for each $\theta \in \Theta$, P_θ represents the local equilibrium corresponding to the hydrodynamic field θ at each spatial point x. Likewise, defining the evolute P^t of P to be the mapping $\theta \to {P^t}_\theta$ of Θ into the complex functions on B given by

$${P^t}_\theta = P_{\theta_t}, \tag{66}$$

we see from Eqs. (50) and (64) that P^t carries a full representation of the LTE at time t. Moreover, by Eqs. (64) and (66),

$${P^t}_\theta = P_{\phi(t)\theta}, \tag{67}$$

which signifies that the time dependence of the local equilibrium profile is completely determined by the phenomenological semigroup ϕ.

IX. CONCLUDING REMARKS

The purpose of this paper has been to combine the geometric picture of fiber bundles with the operator algebraic one of quantum theory for the purpose of describing macroscopic quantum systems. The combination of these mathematical structures is quite natural in this context, since it offers the means of representing the complementary classical and quantum aspects of complex systems by actions on the bases and the fibers, respectively, of the relevant bundles. Here, we have shown that it serves to provide simple pictures of quasiparticle excitations, of local thermodynamic equilibrium, and of the interplay between the macroscopic (classical) dynamics and microscopic (quantum) dynamics of certain systems, e.g., lasers. In view of its apparent generality, we envisage that the fusion of geometric and operator algebraic concepts presented here should have wider ramifications for the theory of complex systems.

Finally, in view of the results of this paper, it would appear that the mathematical problem of establishing the existence of infinitesimal generators of one-parameter groups of bundle maps of vector bundles is of physical interest as well. We have not addressed this problem in its abstract form, but have given an explicit construction in Sec. V which is of fairly wide applicability.

[7] That is, a fiber bundle in which the fiber is an infinite-dimensional complex Hilbert space. It should be noted that, in the mathematical literature, the term *Hilbert bundle* is often used to denote a somewhat larger class of spaces. See R. C. Fabec, *Fundamentals of Infinite-Dimensional Representation Theory*, (Chapman and Hall/CRC, Boca Raton, FL, 2000), and references cited therein.
